LEMMA 3.2. *If a square matrix $\mathbf{A}$ has a simple eigenvalue λ with corresponding left $\mathbf{v}^T$ and right $\mathbf{w}$ eigenvectors, $\mathbf{v}^T\mathbf{A} = \lambda\mathbf{v}^T$ and $\mathbf{A}\mathbf{w} = \mathbf{w}\lambda$, then $\nabla_{\mathbf{A}}\lambda = \mathbf{v}\mathbf{w}^T/\mathbf{v}^T\mathbf{w}$.*

Proof. See [14, p. 344] for the proof. □

Next Theorem 3.3 gives a sufficient condition for the numerical stability of root-finding based on a nonstandard companion matrix eigenvalue problem. It suffices for the computed eigenvalues to be the eigenvalues of $\mathbf{B}_n + \mathbf{E}_n$ nearby to $\mathbf{B}_n$ in a componentwise or relative sense. That is, there exists a tiny $\tau > 0$ such that $|\mathbf{E}_n| \leq \tau|\mathbf{B}_n|$. The result applies for any nonzero γ_n. The idea of the proof is that the factor of $1/\gamma_n$ in column n of $\mathbf{E}_n$ cancels with a factor of γ_n in row n of $\mathbf{w}$.

THEOREM 3.3. *Suppose that the degree n polynomial $p(x)$ has a simple root λ. Recall the notation of* (1.5), *in particular the definition of the column* $\mathbf{c}$ *in* (1.4), *and the definition of* $\mathbf{H}_n$ *in* (2.1). *The corresponding companion matrix* $\mathbf{B}_n$ *has left* *and right eigenvectors* $\mathbf{v}^T = \mathbf{f}_n(\lambda)^T$ *and* $\mathbf{w}$ *as in Lemma* 2.4 *so that* $\mathbf{v}^T\mathbf{w} = 1$. *A perturbation* $\mathbf{E}_n$ *of* $\mathbf{B}_n$ *such that* $|\mathbf{E}_n| \le \tau|\mathbf{B}_n|$ *perturbs* λ *by* $\delta\lambda$ *such that*

$$|\delta\lambda| \le \tau|\mathbf{v}|^T|\mathbf{H}_n|\ |\mathbf{w}| + \tau|\mathbf{v}|^T|\mathbf{c}|/|p'(\lambda)| + \mathcal{O}(\tau^2).$$

Proof. We start by establishing the following claim. For $h_{n,n-1}$ defined in (1.2) there holds

$$h_{n,n-1}\mathbf{e}_{n-1}^T\mathbf{w} = \gamma_n/p'(\lambda). \tag{3.1}$$

Substitute the expansion $l(x) = \mathbf{f}_n(x)\mathbf{w}$ below, and simplify to find that $\gamma_n = \langle p, \phi_n\rangle = \langle l(x)(x-\lambda)p'(\lambda), \phi_n\rangle = \langle l(x)xp'(\lambda), \phi_n\rangle = \langle \phi_{n-1}(x)xp'(\lambda), \phi_n\rangle\mathbf{e}_{n-1}^T\mathbf{w}$. Rewrite (1.2) in matrix form,

$$x\phi_{n-1}(x) = \mathbf{f}_n^T(x)\mathbf{H}_n e_{n-1} + \phi_n(x)h_{n,n-1}. \tag{3.2}$$

Equation (3.2) implies that $\gamma_n = h_{n,n-1}p'(\lambda)\mathbf{e}_{n-1}^T\mathbf{w}$. Divide by $p'(\lambda)$ to establish the claim.

By Lemma 3.2, to first order in τ there holds $|\delta\lambda| = |\mathbf{v}^T\mathbf{E}_n\mathbf{w}| \le |\mathbf{v}|^T|\mathbf{E}_n||\mathbf{w}| \le \tau|\mathbf{v}|^T|\mathbf{B}_n||\mathbf{w}|$. The proof is completed by substituting (1.6), applying the triangle inequality, and then the claim. □

Theorem 4.2 will show how for transcendental equations, QR iteration with balancing solves a nearby eigenvalue problem, $\mathbf{B}_n + \mathbf{E}_n$, such that only the last column of $\mathbf{E}_n$ is proportional to $1/\gamma_n$.

3.3. Classical orthogonal polynomials. In general, the term $\|\mathbf{f}_{n+1}(\xi)\|_2$ arising in polynomial roots sensitivity is associated with the "kernel polynomials." The kernel polynomials are defined by $\mathbf{K}_n(x_o, x) = \overline{\mathbf{f}}_{n+1}^T(x_o)\ \mathbf{f}_{n+1}(x)$. If x_o is a constant, then $\mathbf{K}_n(x_o, x)$ is a polynomial. The kernel polynomials maximize the ratio $|p(x_o)|/\|\|p(x)\|\|$ over all polynomials of exact degree n (see [22, Theorem 3.1.3]), and the maximum ratio is $\|\mathbf{f}_{n+1}(x_o)\|_2$. As we shall see, the asymptotic properties of the kernel polynomials indicates that the classical orthogonal polynomials over $[-1, 1]$, the Jacobi polynomials, are suitable for rootfinding. And conversely, for rootfinding over domains that are topologically different from intervals, none of the classical polynomials orthogonal over an interval is desirable, and a different inner product is needed [1, 9].

The Jacobi polynomials are orthogonal with respect to the inner product

$$\langle f, g\rangle_{\alpha,\beta} = \int_{-1}^{1} f(t)g(t)(1-t)^\alpha(1+t)^\beta dt$$

for $\alpha > -1, \beta > -1$ (see [22, section 2.4]). The case $\alpha = \beta = -1/2$ corresponds to the Chebyshev polynomials (of the first kind). The comparison of spectral methods for partial differential equations based on either Chebyshev polynomials or Legendre polynomials ($\alpha = \beta = 0$) in [3] demonstrates the advantages of Legendre polynomials. The Legendre orthonormal polynomials satisfy the three-term recurrence $\gamma_{n+1}\phi_{n+1}(x) = x\phi_n(x) - \gamma_n\phi_{n-1}(x)$ for $\gamma_n = n/\sqrt{4n^2-1}$. By rearranging the three-term recurrence into the form of (1.2), one may show that for $i \ge 0$, $h_{i+1,i} = h_{i,i+1} = \gamma_{i+1}$, and otherwise $h_{i,j} = 0$.

Theorem 7.71.2 in [22] states that $\max_{-1\le x_o\le 1}\|\mathbf{f}_{n+1}(x_o)\|_2 = \mathcal{O}(n^\kappa)$ for $\kappa = \max(\alpha+1, 1/2)$. The result is a consequence of the connection to Sturm–Liouville problems. The exponent is minimal for the Chebyshev polynomials, and for any admissible (α, β) the sensitivity bound grows like a polynomial. On the other hand, away from the interval $[-1, 1]$, the Jacobi polynomials grow exponentially with degree and are undesirable for rootfinding problems.

4. Solving transcendental equations.

We will discuss in depth a representative application of nonstandard companion matrices to rootfinding problems involving polynomial equations expressed with respect to Chebyshev polynomials. We discuss the solution of a transcendental equation $\psi(\xi) = 0$. Section 4.2 presents a complete description of the corresponding algorithm for a scalar transcendental equation. In numerical experiments, we find that the algorithm is numerically stable if matrix balancing is used (the default in MATLAB). However, it is crucial to use balancing with the QR algorithm in solving the eigenvalue problems that arise in the solution of transcendental equations.

4.1. Analysis of balancing.

Next some of the linear algebra issues associated with computing the eigenvalues of the B matrices are discussed in detail. Readers interested only in the solution of transcendental equations may choose to skip the section.

As a sequence of polynomials converge uniformly to $\psi(x)$ on some bounded domain, certain roots of the polynomials converge to $\{\xi : \psi(\xi) = 0\}$ [5]. The order of the approximation, n, is chosen to be sufficiently large such that the trailing γ_n is negligible [5]. For solving transcendental equations, balancing the generalized companion matrix (cf. [23]) usually employs an alarmingly ill-conditioned diagonal similarity transform, and extraordinarily reduces the condition number of the matrix of eigenvectors. Theorem 4.2 presents an explanation of the success of balancing for companion matrices arising in the solution of transcendental equations.

A transcendental equation $\psi(\zeta) = 0$ arises from $\psi(x)$ that is analytic in an open simply connected domain containing $[-1, 1]$. The orthogonal polynomials used are eigenfunctions of singular Sturm–Liouville problems in $[-1, 1]$, namely, the Jacobi polynomials (corresponding to one value of (α, β)) and here denoted $\{\phi_n(x)\}_{n\geq 0}$. The simplest case, $\{\phi_n(x)\}_{n\geq 0}$ orthonormal, is discussed. The convergence properties of Jacobi series expansion $\sum_{n\geq 0} \phi_n(x)\gamma_n$ with $\gamma_n = \langle \psi, \phi_n \rangle$ of $\psi(x)$ is described by Theorem 4.1.

Theorem 4.1. *Let $\psi(x)$ be an analytic function with an open domain containing $[-1, 1]$. The expansion of $\psi(x)$ in a Jacobi series is convergent in the interior of the greatest ellipse with foci at ± 1, in which $\psi(x)$ is regular. The expansion is divergent in the exterior of the ellipse. If $\psi(x) = \sum_{n\geq 0} \gamma_n \phi_n$, then we have the following representation of the sum R of the semiaxes of ellipse of convergence $R = \liminf_{n\to+\infty} |\gamma_n|^{-1/n}$.*

Proof. See [22, Theorem 9.1.1] for the proof. □

In Theorem 4.1, $R = A + B$ for an ellipse $(x/A)^2 + (y/B)^2 = 1$ in the (x, y)-plane with $A^2 = B^2 + 1$ and $A > B > 0$ (see [15, p. 37]). Roughly speaking, there holds $\sum_{j\geq n} |\gamma_j|^2 = \mathcal{O}(R^{-2n})$. The hypothesis that $\psi(x)$ is an analytic function on an open domain containing $[-1, 1]$ ensures that for the greatest ellipse $B > 0$ and $R > 1$.

An analytic function $\psi(x)$ with root ξ, $\psi(\xi) = 0$, has a Jacobi series. The Jacobi series has partial sums of the form $p_n(x) = \sum_{j=0}^{n} \phi_j(x)\gamma_j$. Each $p_n(x)$ has at least one root ξ_n nearest to ξ. In the case $R > 1$, Theorem 4.1 implies that in $[-1, 1]$, $\{p_n(x)\}_{n\geq 0}$ converges uniformly to $\psi(x)$. Furthermore, each derivative $p_n^{(m)}(x)$ converges uniformly to $\psi^{(m)}(x)$ in $[-1, 1]$.

If ξ is a simple root of $\psi(x)$ (i.e., $\psi'(\xi) \neq 0$), then $\xi_n \to \xi$. Moreover, for

n sufficiently large that $\psi'(\xi_n)\psi'(\xi) > (\psi'(\xi))^2/2$ the relationship between residual error and approximate solution error implies that $\xi_n - \xi = \mathcal{O}(R^{-n})$.

The algebraic eigenvalue problem $\mathbf{B}_n\mathbf{W}_n = \mathbf{W}_n\Lambda_n$ is solved by applying the QR algorithm to the balanced generalized companion matrix. In MATLAB, the default configuration of the QR algorithm applies balancing. Balancing refers to determining a diagonal matrix $\mathbf{\Sigma}_n$ such that the similar eigenvalue problem $\mathbf{\Sigma}_n^{-1}\mathbf{B}_n\mathbf{\Sigma}_n$ is (hopefully) much better conditioned. A nearly optimal diagonal similarity transformations $\mathbf{\Sigma}_n$ produces $\mathbf{\Sigma}_n^{-1}\mathbf{W}_n$ with equal row norms (see [16, section 12]), but $\mathbf{W}_n$ is not known a priori. Instead a diagonal similarity transformation $\mathbf{\Sigma}_n$ that nearly minimizes a norm of $\mathbf{\Sigma}_n^{-1}\mathbf{B}_n\mathbf{\Sigma}_n$ is determined.

To illustrate matrix balancing, consider $\mathbf{B}_4$ whose coefficients are chosen to reflect the asymptotic equation $\gamma_k = \mathcal{O}(R^{-k})$ for $R > 1$. A rootfinding algorithm based on Chebyshev polynomials is used. We use slightly more complicated coefficients, $\mathbf{c}^T = [2, 2R^{-1}, 2R^{-2} + \frac{1}{2}R^{-4}, 2R^{-3}]$ and $\gamma_4 = -R^4$, so that $\mathbf{B}_4$ takes the simple form in (4.1). We have included an extra nonzero element in the southwest term to illustrate the essential contribution of the upper Hessenberg structure of $\mathbf{B}_n$ to the success of the matrix balancing algorithm. We approximately balance this matrix using $\mathbf{\Sigma}_4 = \mathrm{diag}(R^3, R^2, R^1, 1)$,

$$\mathbf{\Sigma}_4^{-1}\begin{bmatrix} 0 & 1/2 & 0 & R^4 \\ 1 & 0 & 1/2 & R^3 \\ 0 & 1/2 & 0 & R^2 \\ S & 0 & 0 & R \end{bmatrix}, \quad \mathbf{\Sigma}_4 = \begin{bmatrix} 0 & \frac{1}{2R} & 0 & R \\ R & 0 & \frac{1}{2R} & R \\ 0 & R/2 & & R \\ SR^3 & 0 & 0 & R \end{bmatrix}. \tag{4.1}$$

Note that because $\mathbf{B}_4$ is upper Hessenberg, $S = 0$, so that balancing reduces $\mathbf{B}_4$ in norm from $\mathcal{O}(R^4)$ to $\mathcal{O}(R)$. In this example, as R increases, the diagonal matrix determined by the balancing algorithm converges to $\mathbf{\Sigma}_4$. For polynomials of degree n, the norm of $\mathbf{B}_n$ is proportional to R^k for k possibly as large as n.

Different normalizations of the orthogonal polynomials correspond to the different diagonal similarity transformations applied to $\mathbf{B}_n$. The product of (2.3) and $\mathbf{\Sigma}_n = \mathrm{diag}(\sigma_0, \ldots, \sigma_{n-1})$ has the form

$$x \;\; \mathbf{f}_n^T(x)\mathbf{\Sigma}_n = \mathbf{f}_n^T(x)\mathbf{\Sigma}_n \;\; \mathbf{\Sigma}_n^{-1}\mathbf{B}_n\mathbf{\Sigma}_n + \frac{p(x)}{\gamma_n} h_{n,n-1}\sigma_{n-1}\mathbf{e}_{n-1}^T. \tag{4.2}$$

In this sense, the balancing algorithm determines a suitable normalization of the orthogonal polynomials (cf. Definition 2.1). Bear in mind that $e_j^T\mathbf{B}_n e_{n-1}$ is proportional to γ_j/γ_n.

The next theorem will show that asymptotically the right eigenvectors all are graded in exactly the same way, decreasing from term to term by a ratio of approximately $1/R$. For such $\mathbf{B}_n$ for an optimal $\mathbf{\Sigma}_n$, which approximately equalizes the row norms of $\mathbf{\Sigma}_n^{-1}\mathbf{W}_n$, σ_i/σ_i is asymptotically R. In general, it is not necessarily the case that the diagonal $\mathbf{\Sigma}_n$ that approximately minimizes a norm of $\mathbf{\Sigma}_n^{-1}\mathbf{B}_n\mathbf{\Sigma}_n$ is nearly optimal for the eigenvalue problem. For transcendental equation solving, asymptotically the polynomial coefficients also decrease by a factor of $1/R$ from coefficient to coefficient. Equation (4.1) illustrates how in this case the balancing algorithm determines a nearly optimal scaling for eigenvalue problems.

By Theorem 4.1, $(\gamma_n)_{n\geq 0}$ decays exponentially. Not surprisingly, in practice the diagonal elements of $\mathbf{\Sigma}_n$ exhibits similar exponential decay. The resulting $\mathbf{\Sigma}_n$ has an alarmingly large condition number. Next Theorem 4.2 will show that the rows of $(\mathbf{e}_j^T\mathbf{W}_n\mathbf{e}_k)_{0\leq j<n}$ decay at the same exponential rate as $(\gamma_n)_{n\geq 0}$. The transformation

from $\mathbf{W}_n$ to $\mathbf{\Sigma}_n^{-1}\mathbf{W}_n$ reduces the variation in the norms of the rows of $\mathbf{W}_n$ and improves the condition number of the eigenvalue problem.

THEOREM 4.2. *Suppose that $\psi(x)$ is analytic in an ellipse with foci at ± 1 and that ξ is a simple root of $\psi(x)$ within the ellipse. Suppose in addition that for each partial sum of the Jacobi series expansion of $\psi(x)$, $p_n(x)$, all of the roots of $p_n(x)$ are within the ellipse. Choose a root ξ_n of $p_n(x)$ nearest to ξ. The generalized companion matrix corresponding to $p_n(x)$, $\mathbf{B}_n$, has an eigenvector $\mathbf{w}_n$ such that $\mathbf{B}_n\mathbf{w}_n = \mathbf{w}_n\xi_n$. Then $\mathbf{e}_j^T\mathbf{w}_n = \mathcal{O}(R^{-n})$.*

Proof The maximal ellipses for $l(t) = (\psi(t) - \psi(\xi))/(t - \xi)$ and $\psi(t)$ coincide. For $l(t) = \sum_{n\geq 0}\phi_n(t)\mu_n$, by Theorem 4.1, there holds $R = \liminf|\mu_n|^{-1/n}$. The partial sums are $l_n(x) = \sum_{0\leq j\leq n}\phi_j(x)\mu_j$. By careful accounting, one may show that for each fixed $\epsilon > 0$, and for $|x - \xi| > \epsilon$, there holds $l_n(x) - l(x) = \mathcal{O}(R^{-n})$. Furthermore, a similar argument shows that $l_n(\xi_n) - l(\xi_n) = \mathcal{O}(R^{-n})$, from which $|||l_n(x) - l(x)||| = \mathcal{O}(R^{-n})$ follows. By theorem

$$\begin{aligned}|\mathbf{e}_j^T\mathbf{w}_n| &= |\langle\phi_j, l_n\rangle| = |\langle\phi_j, l_n - l\rangle + \langle\phi_j, l\rangle| \\ &= |\langle\phi_j, l_n - l\rangle + \mu_j| \leq |||l_n - l||| + |\mu_j| = \mathcal{O}(R^{-n}). \qquad \square\end{aligned}$$

Note that if the Jacobi series converges superexponentially, or even if R is very large, our justification of the balancing algorithm breaks down. We performed many numerical experiments, in floating point arithmetic with machine precision 2^{-54}, attempting to cause the balancing algorithm to fail. The expansion coefficients in the Jacobi series of a transcendental function coefficients converge to zero. We assume that each expansion coefficient, γ_m, with the maximal absolute value, $\sup_k|\gamma_k| = |\gamma_m|$, arises for $m \ll n$. For an entire function, $\lim_{n\to+\infty}\gamma_n/\gamma_{n+1} = +\infty$. The values of $\{\gamma_n\}_{n\geq 0}$ computed in finite precision arithmetic do not share this asymptotic property. The absolute error in each nonzero γ_n is, very roughly, the product of the machine precision and $\sup_k|\gamma_k|$. In our numerical experiments, we never observed a huge value of γ_n/γ_{n+1} for the nonzero approximate values of $\{\gamma_n\}_{n\geq 0}$. In other words, although matrix balancing has always worked for us, one must check that balancing determines a B_n not much larger in norm than H_n.

4.2. An algorithm for transcendental equations. An algorithm is implemented as a MATLAB script that approximates the roots in an interval of a transcendental equation. Modified companion matrices are used to find the roots in or very near $[-1, 1]$. The case of a polynomial expressed as a sum of Chebyshev polynomials is considered. The algorithm to approximate a function by a polynomial is reviewed briefly. Many subtle numerical analysis issues are discussed that are crucial for readers who actually want to solve a transcendental equation, such as rules for when to discard some of the eigenvalues. Readers more interested in concrete information on how to find the roots of a given polynomial expressed as a sum of Chebyshev coefficients are directed to the paragraph directly following the algorithm.

A collocation method is used to determine the expansion coefficients with respect to the Chebyshev polynomials of a polynomial approximation of a scalar function $\psi(x)$ whose domain includes $[-1, 1]$ (see Appendix A in [6]). For completeness, we briefly review the popular method here. The Chebyshev–Gauss–Lobatto (CGL) points, $\cos(k\pi/n)_{k=0}^n$, are unisolvent. A unique nth degree polynomial interpolates $\psi(x)$ at the CGL points. The column vector of expansion coefficients $[\gamma_0, \ldots, \gamma_n]^T$ is the product of discrete Chebyshev transformation matrix, Π_n, and the column vector, $[\psi(\cos(0\pi/n)), \ldots, \psi(\cos(n\pi/n))]^T$, where $\Pi_n = [\cos(ij\pi/n)2/(q_iq_jn)]_{0\leq i,j\leq n}$, and $q_0 = q_n = 2$ and $q_i = 1$ otherwise. Other issues including spectral convergence, the adaptive selection of n, and the subdivision of the interval are discussed elsewhere [6].

Techniques for discarding some of the eigenvalues are discussed. There are two reasons to discard certain computed eigenvalues. First, equations with n_p roots in or near $[-1, 1]$ may be approximated by a polynomial of higher degree $n > n_p$. In finite precision arithmetic, the $n - n_p$ additional eigenvalues do not necessarily solve the polynomial equation. We would like to be able to reliably determine n_p. Second, in many applications the cost of evaluating the function is significant.

An important application of Chebyshev polynomials is solving transcendental equations in a way that minimizes the number of function evaluations [4]. For polynomials of high degree, some definitions of nearness to $[-1, 1]$ will classify a large percentage of the eigenvalues as potential polynomial roots, significantly increasing the number of function evaluations needed for equation residuals. The spurious eigenvalues are in a region in the complex plane in which Chebyshev polynomials of a given degree are wildly unstable. We select only eigenvalues within a domain of interest; here we discard eigenvalues outside of $(-2, 2) \times (-.2, .2)$. On the other hand, discarding roots may also be discarding part of the answer. Real roots may be approximated by complex eigenvalues near to $[-1, 1]$. For example, if the complex QR algorithm is applied to the real matrix $\mathbf{B}_n$ (for robustness), the set of computed roots is not closed under conjugation. The problem is addressed by using a partial condition number of the eigenvalues. The condition number of an eigenvalue, ξ, is the product of two terms, $\|\mathbf{f}_n(\xi)\|_2$ (defined in (1.3)) and a term that involves the Lagrange interpolation polynomial whose support contains the eigenvalue. Our solution is to add a test that discards ξ such that $\|\mathbf{f}_n(\xi)\|_2$ is enormous (compare the definition of `cond_max`). Chebyshev polynomials are wildly unstable in such regions in the complex plane. At multiple roots near $[-1, 1]$, the norm of the vector values of the orthogonal polynomial evaluated at the roots is of order one and is not discarded.

The parameters are chosen here to avoid large numbers of spurious roots. No attempt is made to find all of the roots of the polynomial.

```
n              = 2^4;                                     % polynomial degree
[CGLpoints, ChebTransMat] = setupChebyshev(n);
FunctValues    = problemRod(CGLpoints);                   % evaluate @ CGL pts
ExpansionCoeff = FunctValues * ChebTransMat;
if ExpansionCoeff(n+1) == 0,
   error(’leading expansion coefficient vanishes; try --n’);
end
ExpansionCoeff = ExpansionCoeff/(-2*ExpansionCoeff(n+1)); % normalize
H = diag(ones(n-1, 1)/2, 1) + diag(ones(n-1, 1)/2, -1); H(1, 2) = 1;
C = H; C(n, :) = C(n, :) + ExpansionCoeff(1:n);           % nonstandard
Eigenvalues    = eig( C );                                % ...companion matrix
Vandermonde    = evalCheb(n,Eigenvalues);                 % generalized...
Vcolsums       = sum( abs(Vandermonde’) );                % Vandermonde matrix
tube_index     = find((abs(imag(Eigenvalues))<.2) & ...
                     (abs(real(Eigenvalues))< 2));
Solutions      = Eigenvalues( tube_index );               % Spectrum in
Vcolsums       = Vcolsums( tube_index );                  % ...(-2,2)x(-.2,.2)
cond_max       = min( 2^(n/2), 10^6 );                    % Cluster threshold
condEigs_index = find ( Vcolsums < cond_max );            % Select
Solutions      = Solutions( condEigs_index );             % ...roots
```

Suppose we want to find the roots of the polynomial

$$p(x) = eT_0(x) + 2\pi T_1(x) + 2\gamma T_2(x) - 2T_3(x),$$

where $\gamma = 0.57721566\ldots$ is Euler's constant. The example corresponds to $n = 3$ at line 1. Lines 2 and 3 are replaced by ExpansionCoeff $= [e, 2\pi, 2\gamma, -2]$;. The roots are approximately 1.44, -1.02, and -0.13. The two roots outside of $[-1, 1]$ are due to their large condition numbers (estimated by Vcolsums).

In the algorithm, three user supplied external functions are called. The function setupChebyshev() determines the CGL points and the matrix that transforms function values to expansion coefficients.

```
function [cgl,CT] = setupChebyshev(n)
y = [0:n]*pi/n;
cgl = cos(y);
for i=0:n,
   CT(i+1,:) = cos(y*i);
end
pp = ones(n+1,1); pp(1) = 1/2; pp(n+1) = 1/2;
CT = diag(pp) * CT * diag(pp);
CT = CT * (2/n); %                     End of function setupChebyshev
```

The function problemRod evaluates user functions at specified points in the domain. Here a problem associated with the vibration of an elastic rod is solved.

```
function functValues = problemRod(cgl)
[one, ncol] = size(cgl);
n = ncol-1;
first = cgl*3 + ones(1,n+1)*(3+1);
functValues = cos(first*pi) - sech(first*pi);
%                                           End of function problemRod
```

The vector ExpansionCoeff is the vector of coefficients in the collocation approximation by Chebyshev polynomials of degree up to n. The function evalCheb evaluates the Chebyshev polynomials at a specified set of points.

```
function V = evalCheb(degree_max,z)
% Input: vector of points, z, and the polynomial degree, degree_max.
% Output: Vandermonde matrix, m by degree_max + 1, V(j+1,k)=T_j(z_k)
[m,one] = size(z);
if m*degree_max >= 0,
   V(:,1) = ones(m,1);
   if degree_max >= 1,
      V(:,2) = z;
      if degree_max >= 2,
          index = find( log(abs(z))  >= 100/degree_max ); %  avoid
          si = size(index,1);                              % overflow
          if si > 0
             z(index) = ones(si,1)*exp(100/degree_max);
          end
          for i=2:degree_max,
             V(:,i+1) = V(:,i).*(2*z)  - V(:,i-1);
          end
      end
   end
else
   V = [];
end %                                       End of function evalCheb
```

In practice, five figures are recommended for verification purposes. Graphs of the expansion coefficients of the function and its derivative versus the indices are useful for assessing convergence. The exponential decay of the expansion coefficients indicates the convergence of the series to the transcendental equation. A plot of the cubic spline interpolants at the CGL points to the function and its derivative over the interval $[-1, 1]$ is useful for detecting clusters of roots. Later the (real parts of the) roots and the (real parts of the) derivative values at the roots may be overlaid onto the respective graphs. In selecting the eigenvalues that approximate roots of the polynomial or transcendental equation, it is helpful to compare the distribution of the eigenvalues and the row sums of the generalized Vandermonde matrix. The roots in $[-1, 1]$ and the other roots appear as two sets that are easier to see than to quantify. Finally one must check the transcendental equation residuals at the selected eigenvalues.

5. Examples. We apply our rootfinding technique to Chebyshev expansions arising in the solution of some transcendental equations. Two representative applications of the algorithm are discussed, followed by two more challenging applications. For a transcendental equation $\psi(\xi) = 0$ with clustered or multiple roots, an added issue is that roots of $p_n(x)$ that are not near roots of $\psi(x)$ appear among the approximate solutions of $\psi(\xi) = 0$. Such problems demonstrate the importance of monitoring $\psi'(x)$. Examples 1 and 2 concern problems with well-separated simple roots. For polynomials with multiple roots, $p_n(x)$ may very accurately approximate $\psi(x)$ and still have spurious roots near roots of $\psi(x)$, as will be shown in Example 3. Last, numerical experiments on computing the eigenvalues of $\mathbf{B}_n$ are discussed.

The methodology of the experiments is as follows. The number of function evaluations is carefully minimized. The degree of the polynomial n is doubled. In fact n is a power of 2 in the examples, except Example 2. Although doubling the polynomial order with a spectral method is overkill, it is done here for two reasons. First, if the function is evaluated at n points, it is possible to reuse the previous $n/2$ function values [6], carefully minimizing the number of function evaluations. Second, we wish to illustrate the properties of the nonstandard companion matrices for all values of n, not just special values. We find that using excessively large values of n, up to 2^{10}, does not effect the accuracy of the approximate roots in $[-1, 1]$. For transcendental equations, we discuss at length the minimal values of n for which the series is (almost) converged.

Example 1 concerns the transverse vibrations (u) of a homogeneous rod of length π with both ends free (u'' and u''' vanish at endpoints). The first six flexible modes are found by solving the secular equation $\cos(\pi x) - \operatorname{sech}(\pi x)$ in the interval $1 \leq x \leq 7$ [8, p. 296]. For $n = 16$ or $n = 32$ all six roots are approximated to within 5 or 14 significant digits, respectively.

Example 2 reproduces results from [6]. The roots of Bessel's function of the first kind, $J_\nu(\xi) = 0$, are computed without doubling the polynomial degree. In the first numerical experiments $J_0(x) = 0$ is solved over three intervals, $[0, w]$, for $w = 20$, 60, and 180; $J_0(x)$ has 6, 19, and 57 roots in the respective intervals. The computed roots J_0 are compared to the roots computed by a stable algorithm. Here we can exactly reproduce the results of [6].

Example 3 originated in [20] and is the nonlinear eigenvalue problem for $T(\lambda) = \lambda^2 B^{(2)} + (e^\lambda - 1)B^{(1)} - B^{(0)}$. The transcendental equation here is $\det T(\lambda) = 0$. The determinant is evaluated by factoring $T(\lambda)$ (not by Cramer's rule). A large interval is chosen to test the numerical stability of the rootfinding algorithm.

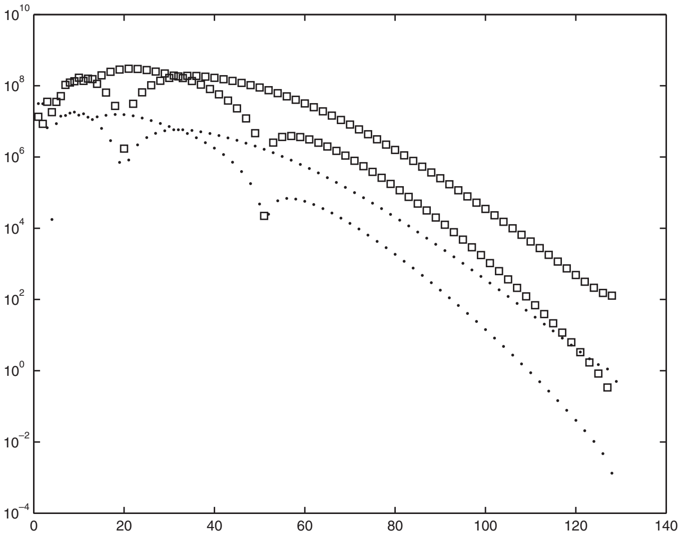

FIG. 5.1. *The function $\psi(x)$ of Example 3 is approximated by a Chebyshev series $p(x)$ of degree 128. The absolute values of the expansion coefficients of $p(x)$ (dots) and $p'(x)$ (squares) are plotted on a logarithmic scale.*

The problem is an example of an overdamped system. Each $B^{(i)}$ is symmetric positive definite. At $\lambda = -\infty$, $\lambda = 0$, and $\lambda = +\infty$ the normalized matrix $T(\lambda)/\|T(\lambda)\|$ is positive definite, negative definite, and positive definite. The matrices are 8 by 8 with $B^{(0)} = 100I_8$, and for $0 \le i, j < 8$,

$$B^{(1)}_{i,j} = (i+1)(j+1)(9 - \max(i+1, j+1)) \quad \text{and} \quad B^{(2)}_{i,j} = 8\delta_{i,j} - 1/(i+j+2).$$

Six roots are clustered near -3.7 with average absolute gap 0.1. As is carefully documented in [4], the the exponential growth of $\det T(\lambda)$ as $\lambda \to +\infty$ impedes resolution on certain intervals. The problem illustrates the rewards for choosing a suitable interval. On the interval $[-8, 8]$ in double precision arithmetic the roots of the polynomial approximation of $\det T(\lambda)$ poorly approximate the solutions, but in the interval $[-8, 4]$, the roots of the polynomial approximation converge rapidly to the solutions.

Another approach, pursued here, concerns the alternative scaled problem $\psi(\lambda) = \det(T(\Lambda)/\sigma(\lambda))$ for

$$\sigma(\lambda) = (\det B^{(0)})^{1/8} + (\det B^{(1)})^{1/8}(e^{\lambda} - 1) + (\det B^{(2)})^{1/8}\lambda^2.$$

The interval $[-10, 10]$ containing all 16 of the roots is used. We will discuss in detail the results obtained using a Chebyshev series expansions of degree 128 (see Figure 5.1). Of the 128 eigenvalues, 108 are discarded and 20 are potential solutions (see Figure 5.2).

Inspection of the graphs of the $\psi(x)$ and $\psi'(x)$, shown in Figures 5.3 and 5.4, respectively, is helpful. In a large neighborhood of the root cluster around -3.7, there holds $|\psi| < 10^{-9}$ and $|\psi'| < 10^{-5}$. A degree 128 polynomial is insufficient to resolve each root in the cluster. On the other hand, with a degree 256 polynomial, 240 eigenvalues are discarded. The remaining 16 eigenvalues approximate the 16 roots, each with residual norms below 10^{-13}.

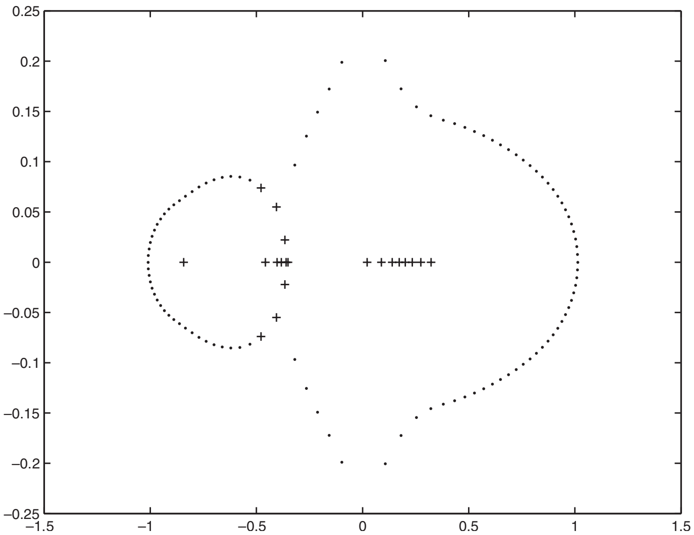

FIG. 5.2. *In Example* 3 *using a Chebyshev series of degree* 128 *results in a companion matrix* $\mathbf{B}_{128}$. *The figure displays the eigenvalues of* $\mathbf{B}_{128}$ *in the complex plane. A "$\cdot$" indicates each of the* 108 *discarded eigenvalues, and a "+" indicates each of the* 20 *potential roots.*

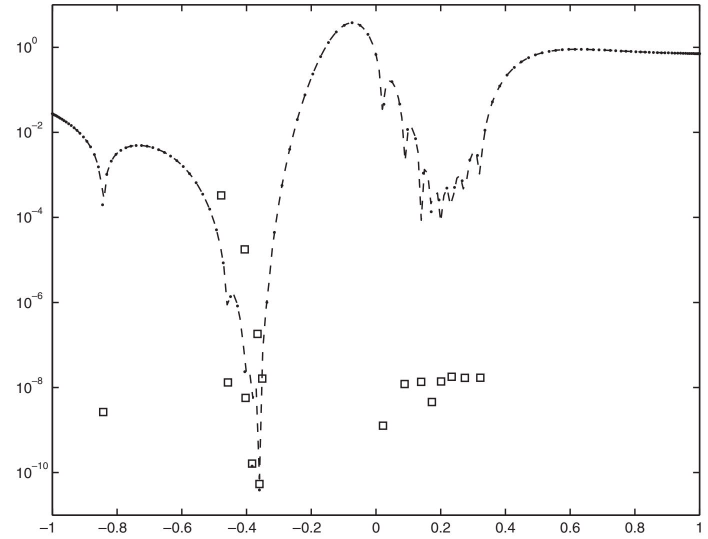

FIG. 5.3. *The value of* $|p(x)|$ *for* $-1 \le x \le 1$ *is shown on a logarithmic scale for the degree* 128 *Chebyshev series approximation of the function* $\psi(x)$ *of Example* 3. *The function values at CGL points (dots), a spline interpolant to the CGL points (dashed line), and the residuals at the* 20 *potential roots (squares) are each presented. A complex root* ξ *is displayed at* $x = \Re(\xi)$. *Because of this discrepancy, such function values appear above the spline interpolant in* $[-1, 1]$.

Before closing, we make an observation about accelerating the convergence of the QR algorithm for computing the eigenvalues of $\mathbf{B}_n$ arising from the solution of transcendental equations. Loosely speaking, a matrix is graded (by diagonal) if the norms of the diagonals increase geometrically. Note that $\mathbf{B}_n$ is graded by diagonal. We have

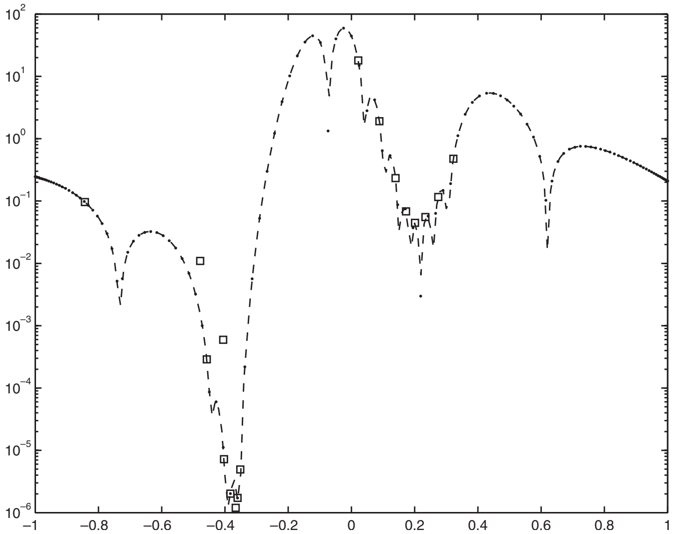

FIG. 5.4. *Example* 3*, the absolute value the derivative* $|p'(x)|$ *for* $-1 \le x \le 1$ *is shown on a logarithmic scale for the degree* 128 *Chebyshev series approximation of the function* $\psi(x)$ *of Example* 3*. The function values at CGL points (dots), a spline interpolant to the CGL points (dashed line), and the derivative values at the* 20 *potential roots (squares) are all shown. Complex roots are displayed at the real part of the root, and because of this discrepancy, such function values differ from the spline interpolant.*

observed that the computed Schur form of $\mathbf{B}_n$ is also graded. Careful examination of the QR iterates (say with zero shifts) from $\mathbf{B}_n$ (without balancing) indicates that along with the accuracy of the computed eigenvalues, the graded structure is also lost. Better results are obtained using the matrix $\mathbf{M}_n\mathbf{B}_n^T\mathbf{M}_n^T$ determined using the antidiagonal matrix $\mathbf{M}_n = [\mu_{i,j}]_{0\le i,j<n}$ with $\mu_{i,j} = \delta_{i,n-i-1}$. The matrix $\mathbf{M}_n\mathbf{B}_n^T\mathbf{M}_n^T$ is similar to $\mathbf{B}_n$ and inherits its unreduced upper Hessenberg and graded structure. We observe that the QR iteration applied to $\mathbf{M}_n\mathbf{B}_n^T\mathbf{M}_n^T$ (without balancing) preserves the graded structure of $\mathbf{B}_n$ and converges in many fewer iterations.

6. Conclusion.

We have shown how to find the roots of a degree n polynomial $p(x)$ expressed in terms of orthogonal polynomials. In particular, we have shown that these roots are the eigenvalues of a nonstandard companion matrix $\mathbf{B}_n$. This companion matrix gets infinitely large as the highest order coefficient γ_n in our orthogonal expansion goes to zero. However, we have analyzed the numerical stability of this algorithm for Jacobi polynomials and found that it has good numerical stability properties as long as we are interested only in roots in the interval $[-1, 1]$. This makes the algorithm particularly suited for finding the roots of transcendental equations.

We have presented an algorithm for finding the roots of a scalar transcendental equation by expressing it in terms of orthogonal polynomials, and using the companion matrix $\mathbf{B}_n$. We have given several numerical examples that illustrate the stability of this algorithm. For a more detailed summary, see section 1.1.

Acknowledgments. It is a pleasure to acknowledge the assistance of the referee Prof. L.N. Trefethen and the anonymous referee in the preparation of the document. We wish to thank Prof. Holly Dison for assistance in performing the numerical experiments and Prof. Ming Gu, who we heard had used the Chebyshev companion matrix, though he has not published anything on any nonstandard companion matrix.

A FINITE ELEMENT, MULTIRESOLUTION VISCOSITY METHOD FOR HYPERBOLIC CONSERVATION LAWS[*]

MARCUS CALHOUN-LOPEZ[†] AND MAX D. GUNZBURGER[‡]

Abstract. It is well known that the classic Galerkin finite element method is unstable when applied to hyperbolic conservation laws such as the Euler equations for compressible flow. It is also well known that naively adding artificial diffusion to the equations stabilizes the method but sacrifices too much accuracy to be of any practical use. An elegant approach, referred to as spectral viscosity methods, has been developed for spectral methods in which one adds diffusion only to the high-frequency modes of the solution, the result being that stabilization is effected without sacrificing accuracy. We extend this idea into the finite element framework by using hierarchical finite element functions as a multifrequency basis. The result is a new finite element method for solving hyperbolic conservation laws in which artificial diffusion can be applied selectively only to the high-frequency modes of the approximation. As for spectral viscosity methods, this results in stability without compromising accuracy. In the context of a one-dimensional scalar hyperbolic conservation law, we prove the convergence of approximate solutions, obtained using the new method, to the entropy solution of the conservation law. To illustrate the method, the results of a computational experiment for a one-dimensional hyperbolic conservation law are provided.

Key words. hyperbolic conservation laws, finite element methods, multiresolution viscosity, hierarchical basis functions

1. Introduction.

We consider a new finite element method, based on hierarchical basis functions and a scale-dependent artificial viscosity, for hyperbolic conservation laws. With respect to a given triangulation of a domain, standard nodal basis functions are all of the same scale; i.e., their support is roughly equal. In contrast, hierarchical basis functions can be clustered into groups such that basis functions within a particular group are of a different scale from those of the other groups. The multiscale nature of the hierarchical basis functions allows for the selective addition of viscosity only at the smallest scales, very much in the spirit of spectral viscosity methods. It is hoped that such flexibility will be sufficient for stabilizing discrete Galerkin finite element approximations while, at the same time, results in more accurate approximations with respect to both convergence rates in regions where the solution is smooth and the sharpness of the resolution of discontinuities in the solution.

This paper is a first step at verifying that finite element methods based on hierarchical basis functions and a scale-dependent artificial viscosity do indeed fulfill the promise mentioned in the previous paragraph. We provide some background

material and then describe the new method. We then analyze it for the case of a one-dimensional, periodic, scalar hyperbolic conservation law, showing that, under appropriate hypotheses, the approximate solution converges to the entropy solution of the conservation law. We then provide a simple example of the use of the method. Several issues concerning the efficient implementation of the new method as well as the results of more extensive computational testing are provided in [3,4].

1.1. Hyperbolic conservation laws. Let $\Omega \subseteq \mathbb{R}^d$ be a bounded domain. A general system of conservation laws has the form

$$\frac{\partial \mathbf{q}}{\partial t} + \sum_{j=1}^{d} \frac{\partial}{\partial x_j} \mathbf{f}_j (\mathbf{q}) = \mathbf{0} \quad \text{in } \Omega \times (0,\infty) \qquad \text{and} \qquad \mathbf{q}(\cdot, 0) = \mathbf{g} \quad \text{in } \Omega \tag{1.1}$$

along with appropriate boundary conditions. Here, $\mathbf{q} : \Omega \times [0,\infty) \to \mathbb{R}^p$ denotes the vector-valued conserved variable, $\mathbf{f}_j : \mathbb{R}^p \to \mathbb{R}^p$, $j = 1, \ldots, d$, denote the d flux functions, and $\mathbf{g} : \Omega \to \mathbb{R}^p$ denotes the given initial data. For $\widetilde{\mathbf{q}} \in \mathbb{R}^p$, let $\mathbf{A}_j(\widetilde{\mathbf{q}}) : \mathbb{R}^p \to \mathbb{R}^{p\times p}$ denote the $p \times p$ Jacobian matrix of $\mathbf{f}_j$, i.e., $\mathbf{A}_j(\widetilde{\mathbf{q}}) = \frac{\partial \mathbf{f}_j}{\partial \mathbf{q}}(\widetilde{\mathbf{q}})$. The system (1.1) is hyperbolic if, for all solutions $\mathbf{q}$, any linear combination of $\{\mathbf{A}_j(\mathbf{q})\}_{j=1}^{d}$ has real eigenvalues with eigenvectors that span $\mathbb{R}^p$. The system (1.1) is strictly hyperbolic if the eigenvalues are distinct. See, e.g., [8,10] for details.

The system (1.1) does not, in general, have a classical solution because of the spontaneous formation of discontinuities. Instead, one must look for a solution $\mathbf{q} \in L^\infty(\Omega \times (0,\infty); \mathbb{R}^p)$ which satisfies (1.1) in the distributional sense:

$$\int_0^\infty \int_\Omega \left[\mathbf{q} \cdot \frac{\partial \boldsymbol{\phi}}{\partial t} + \sum_{j=1}^{d} \mathbf{f}_j(\mathbf{q}) \cdot \frac{\partial \boldsymbol{\phi}}{\partial x_j} \right] d\Omega\, dt + \int_\Omega \mathbf{g} \cdot \boldsymbol{\phi}(\cdot, 0)\, d\Omega = 0 \tag{1.2}$$

for all test functions $\boldsymbol{\phi} \in C_0^\infty(\Omega \times [0,\infty); \mathbb{R}^p)$. It is clear that for a smooth enough solution, (1.1) and (1.2) are equivalent.

In the presence of discontinuities, solutions of the system (1.1) or of the weak formulation (1.2) are not uniquely determined. Additional conditions must be imposed to determine the unique, physically relevant solution. The second law of thermodynamics tells us that the entropy of the system should not decrease; satisfying this requirement suffices to allow one to obtain the unique, physically relevant entropy solution.

Let $\Phi, \{\Psi_j\}_{j=1}^{d} : \mathbb{R}^p \to \mathbb{R}$ be smooth functions; for (1.1), Φ is an entropy with entropy fluxes $\{\Psi_j\}_{j=1}^{d}$ if Φ is convex and $\boldsymbol{\nabla}_{\mathbf{q}} \Phi^T \frac{\partial \mathbf{f}_j}{\partial \mathbf{q}} = \boldsymbol{\nabla}_{\mathbf{q}} \Psi_j$ in $\mathbb{R}^p$ for $1 \leq j \leq d$. A simple calculation states that if $\mathbf{q}$ is a smooth solution to (1.1), then $\Phi(\mathbf{q})$ satisfies a scalar conservation law with flux $\Psi(\mathbf{q})$:

$$\frac{\partial}{\partial t} \Phi(\mathbf{q}) + \sum_{j=1}^{d} \frac{\partial}{\partial x_j} \Psi_j(\mathbf{q}) = 0 \text{ in } \mathbb{R}^d \times (0,\infty). \tag{1.3}$$

In some instances, Φ can be interpreted as the negative of the physical entropy, so (1.3) says that if $\mathbf{u}$ is a smooth solution, then $\Phi \circ \mathbf{q}$ satisfies a conservation law with flux functions $\{\Psi_j \circ \mathbf{q}\}_{j=1}^{d}$.

For solutions with discontinuities, we impose the *entropy condition* on $\mathbf{q}$ that requires the physical entropy to be nondecreasing:

$$\frac{\partial}{\partial t} \Phi(\mathbf{q}) + \sum_{j=1}^{d} \frac{\partial}{\partial x_j} \Psi_j(\mathbf{q}) \leq 0 \tag{1.4}$$

for every entropy function Φ with entropy fluxes $\{\Psi\}_{j=1}^{d}$; (1.4) is an inequality in the distributional sense:

$$\int_0^\infty \int_\Omega \left[\Phi\left(\mathbf{q}\right)\frac{\partial\phi}{\partial t}+\sum_{j=1}^{d}\Psi_j\left(\mathbf{q}\right)\frac{\partial\phi}{\partial x_j}\right]d\Omega\,dt \geq 0\ \forall\,\phi\in C_0^\infty\left(\Omega\times(0,\infty)\right),\ \phi\geq 0. \tag{1.5}$$

In (1.1), viscous effects are ignored. For the class of phenomena that are modeled with hyperbolic conservation laws, viscous effects are generally small, but they are present and play a role when sharp gradients (such as shocks) of the solution are present. An alternate and equivalent means of characterizing the unique, physically relevant solution of (1.1) is to let $\mathbf{q}=\lim_{\varepsilon\to 0}\mathbf{q}^\varepsilon$ a.e., where $\mathbf{q}^\varepsilon:\Omega\times[0,\infty)\to\mathbb{R}^p$ is the solution of the perturbed equation

$$\frac{\partial\mathbf{q}^\varepsilon}{\partial t}+\sum_{j=1}^{d}\frac{\partial}{\partial x_j}\mathbf{f}_j\left(\mathbf{q}^\varepsilon\right)-\varepsilon\,\Delta\mathbf{q}^\varepsilon=\mathbf{0}\ \text{ in } \Omega\times(0,\infty) \quad \text{and} \quad \mathbf{q}^\varepsilon\left(\cdot,0\right)=\mathbf{g}\ \text{ in } \Omega \tag{1.6}$$

along with boundary conditions. In other words, the entropy solution is the limit of the *viscous solution* as the viscosity goes to zero.

1.2. Numerical methods for hyperbolic conservation laws. Direct discretizations of (1.1) lead to unstable approximations. The most obvious stabilization approach is to instead discretize the perturbed system (1.6) but, as is well known, this leads to severe smearing of discontinuities and to low accuracy even in regions in which the solution is smooth. Of course, there have been many methods proposed for determining improved stabilized approximation solutions of hyperbolic conservation laws; see, e.g., [6,10,13,17,18,24,27].

Finite difference (FD) methods are the oldest of the numerical methods, so many variations have been developed. Many successful strategies for solving hyperbolic conservation laws were originally developed in the FD framework then adapted to other methods. However, FD schemes tend to have difficulties with complex geometries, satisfying prescribed boundary conditions, and rigorous analyses. In fluid dynamics, complex geometries are common, and, as shown in [6], poor approximation of boundary conditions can severely affect a numerical method.

Finite volume (FV) methods inherently capture many of the important aspects of conservation laws; FV methods are locally conservative. Information is propagated along the characteristic curves, at least approximately. FV methods use unstructured grids, so they can handle complex geometries. High-order schemes, however, are difficult to attain.

Finite element (FE) methods are well suited to handle complex geometries and prescribed boundary conditions. Formally high-order schemes can be defined by simply increasing the degree of the approximating polynomials used. The price paid is a large increase in the number of unknowns. In discontinuous Galerkin (DG) methods (see, e.g., [6]), no continuity restrictions are placed on the approximating solution, which results in several advantages. DG methods are easy to parallelize; adaptive strategies are relatively easy to implement; and the mass matrix is block diagonal, so explicit time-stepping schemes are possible. The lack of continuity of solutions, however, is also the cause of the biggest drawback of DG methods: The number of unknowns is drastically increased compared to, say, nodal finite element methods and other types of methods. The shock capturing streamline diffusion method adds a diffusion term to the conservation law, but unlike (1.6), diffusion is added in different amounts in the direction of the characteristic curves (streamline diffusion) and its normal direction (crosswind diffusion). Streamline diffusion is added everywhere, while crosswind diffusion is added only near discontinuities. To determine characteristic curves, space-time elements must be used, which increases the number of unknowns and results in an implicit time scheme. See [13, 14, 23].

Spectral methods, including the spectral viscosity (SV) method, provide another class of methods. Since incorporating the ideas from the SV method into the FE framework is the subject of this paper, we discuss SV methods in a little more detail in section 1.2.1.

The distinctions between the various methods are not always sharp. Some FV and FE schemes can be written into an equivalent FD formulation. As noted in [6], some FV methods can be considered to be special types of DG methods. Furthermore, there are other methods, e.g., kinetic methods [22], for hyperbolic conservation laws that do not fall within the classes just mentioned.

1.2.1. Spectral viscosity methods.

In [24], SV methods were introduced as a scheme to obtain approximate solutions of the periodic Burgers equation using Fourier spectral basis functions. The theory was further refined and extended in a series of papers [5, 9, 12, 19, 20, 25, 26]. Of particular importance to us are [12, 19], in which Legendre polynomials are used. The variational formulation of the Legendre SV method is closest to our FE formulation.

We present the most basic SV method, which uses Fourier spectral basis functions. Using standard notation from Fourier spectral methods, we define

$$u_N = P_N u\left(x,t\right), \quad P_N u = \sum_{|k|\le N} \widehat{u}_k\left(t\right) e^{ik\pi x}, \quad \widehat{u}_k\left(t\right) = \frac{1}{2}\int_{-1}^{+1} u\left(x,t\right) e^{-ik\pi x}\, d\Omega.$$

We seek u_N such that

$$\frac{\partial u_N}{\partial t} + \frac{\partial}{\partial x}\left(P_N \frac{{u_N}^2}{2}\right) = \varepsilon \frac{\partial}{\partial x}\left(Q_N \frac{\partial u_N}{\partial x}\right).$$

Q_N denotes the spectral viscosity operator defined as a convolution with the viscosity kernel, $Q_N\left(x\right)$, so that

$$Q_N \frac{\partial u_N}{\partial x} = Q_N\left(x\right) * \frac{\partial u_N\left(x,t\right)}{\partial x} \qquad \text{and} \qquad Q_N\left(x\right) = \sum_{|k|\le N} \widehat{Q}_k e^{ik\pi x}.$$

We choose $0 \le \widehat{Q}_k \le 1$ and $\widehat{Q}_k = 0$ for small $|k|$. It is easy to see the effect of Q_N if we write the diffusion term in Fourier space:

$$\varepsilon \frac{\partial}{\partial x}\left(Q_N \frac{\partial u_N}{\partial x}\right) = -\varepsilon \sum_{|k|\le N}\left(k^2\,\pi^2\,\widehat{Q}_k\,\widehat{u}_k\,e^{ik\pi x}\right).$$

Since $\widehat{Q}_k = 0$ for all but large $|k|$, Q_N dampens or eliminates the low frequency modes of u_N in the diffusion term. So, we see that the SV diffusion term is a compromise between not adding diffusion, which leads to instability, and adding full diffusion, which limits the convergence rate and smears out discontinuities in the solution. Ideally, one would like to add diffusion only in the vicinity of a discontinuity. However, the global nature of the basis functions does not allow for an adaptive viscosity kernel.

The SV solution u_N does not converge to the exact solution u at the optimal rate because of the poor convergence of $P_N u$. $P_N u$ is limited to first-order convergence in smooth regions and has $O(1)$ Gibbs oscillations near a discontinuity. Post-processing u_N recovers spectral convergence. The post-processing scheme can be enhanced by knowing the locations of discontinuities, as in [9]. Because of the global nature of spectral basis functions, this edge detection task is not trivial.

1.3. Hierarchical finite element basis functions. The usual (nodal) basis functions used in FE methods all have the same frequency. In order to have multi-frequency basis functions, we use hierarchical basis functions. In the elliptic partial differential equation setting, an early analysis of hierarchical basis functions, especially in one dimension, is given in [31]. For two dimensions, see [29]. A good overview of hierarchical basis functions can be found in [30].

First consider a polygonal domain Ω. Let $\mathcal{T}_0$ be a coarse grid approximation of Ω. The nth-level triangulation $\mathcal{T}_n$ is obtained by subdividing the elements of $\mathcal{T}_{n-1}$. Let S^N be the space of continuous functions which are polynomials of degree p on the elements of $\mathcal{T}_N$. Let $\mathcal{N}_N \subseteq \overline{\Omega}$ be the nodes of the elements of $\mathcal{T}_N$. The nodal basis functions of S^N are defined by $\phi_i \in S^N$ such that $\phi_i(x_j) = \delta_{ij}$ for all $x_j \in \mathcal{N}_N$. It is well known that $S^N = \operatorname{span}\{\phi_i\}_i$. The use of nodal bases leads to many nice numerical properties, such as sparse matrices and the local assembly of matrices. However, we cannot use the nodal bases for our purposes because, as we noted earlier, the elements of $\{\phi_i\}_i$ all have the same frequency.

Let $\mathcal{N}_n$ denote the nodes of the nth-level triangulation, $\mathcal{T}_n$, $\mathcal{S}^n$ denote the corresponding finite element space, and B^n denote the nodal basis of $\mathcal{S}^n$. The hierarchical basis functions are defined by

$$\psi_{n,i} \in B^n \quad \text{such that} \quad \psi_{n,i}(x_j) = 0 \quad \forall\, x_j \in \mathcal{N}_{n-1}.$$

For $0 \le n \le N$, $\{\psi_{n,i}\}_{n,i} \subseteq S^N$ is a linearly independent set with the same dimension as S^N, so $S^N = \operatorname{span}\{\psi_{n,i}\}_{n,i}$. See Figure 1 for a comparison of the nodal and hierarchical bases for linear elements in one dimension. As can be seen from the figure, $\psi_{n,i}$ is a low frequency function for small n and a high frequency function for large n.

The strategy just outlined works for polynomials of any degree. For example, the first column of Figure 2 consists of quadratic hierarchical basis functions. An alternate strategy is to use linear hierarchical basis functions for $n < N$, as in the second column of Figure 2.

In order to determine $\mathcal{T}_{n+1}$ from $\mathcal{T}_n$, we must decide, for a given $T \in \mathcal{T}_n$, how many subelements to divide T into. For linear and quadratic rectangular-type elements in $\mathbb{R}^d$, the natural choice is 2^d subelements. For cubic elements, the natural choice is 3^d since the vertices of an element will then be a subset of the vertices of its parent. Here, we limit our attention to linear and quadratic basis functions.

For domains with curved boundaries, the situation is more complicated. Let Ω be our potentially complicated domain. One strategy is to use the hierarchical decomposition of some polygonal domain Ω' such that $\Omega \subseteq \Omega'$, as in [15]. Another strategy is to try and impose a hierarchical structure on an unstructured mesh, as in [1]. The hierarchical structure could also be imposed on the mapping of Ω to a polygonal domain.

Several important properties of hierarchical finite element basis functions and several issues that arise in efficient implementations of finite element methods based on these kinds of bases are discussed in [3, 4].

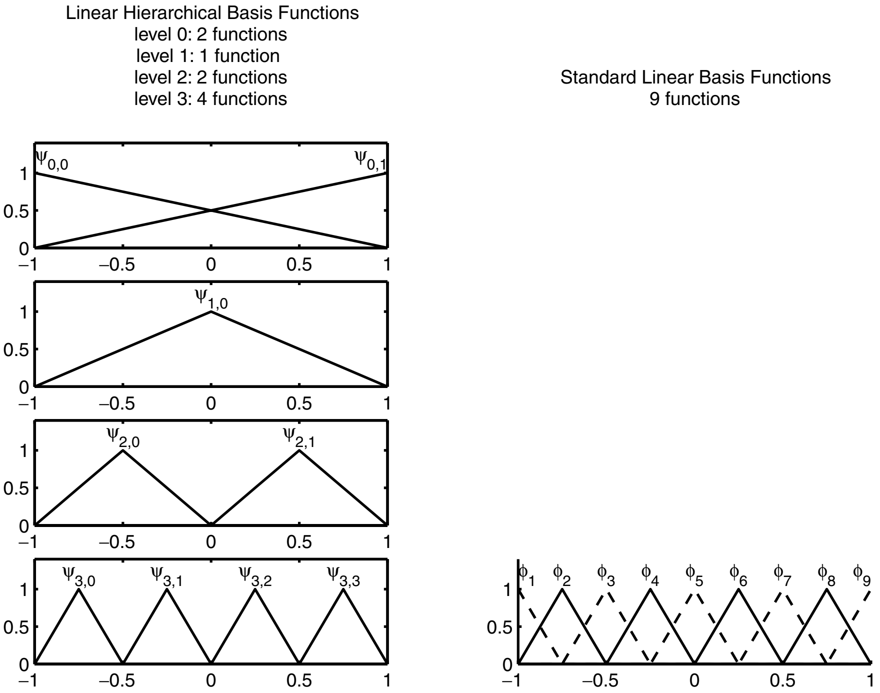

Fig. 1. *Hierarchical (left) and nodal (right) linear basis functions spanning the same nine-dimensional finite element space.*

2. Finite element multiresolution viscosity method. Assume we have a hierarchical sequence of partitions $\{\mathcal{T}_n\}_{n=0}^N$ of the open bounded set $\Omega \subseteq \mathbb{R}^d$. Let $\mathbf{S}^N$ be the space of continuous vector-valued functions whose components are in S^N. We seek an approximate solution to the hyperbolic conservation law (1.1). The finite element multiresolution viscosity method is defined as follows: seek $\mathbf{q}^N \in \mathbf{S}^N$ such that

$$\begin{aligned}(2.1)\qquad &\frac{d}{dt}\int_\Omega \mathbf{q}^N \cdot \mathbf{v}\, d\Omega + \sum_{j=1}^d \int_\Omega \frac{\partial}{\partial x_j}\mathbf{f}_j\left(\mathbf{q}^N\right)\cdot \mathbf{v}\, d\Omega \\ &\quad + \varepsilon_N \sum_{i=1}^p \sum_{j,k=1}^d \int_\Omega \frac{\partial}{\partial x_j}\left(Q_N^{j,k} q_i^N\right) \frac{\partial v_i}{\partial x_k}\, d\Omega \\ &\quad - \varepsilon_N \sum_{i=1}^p \sum_{j,k=1}^d \int_{\partial\Omega} \frac{\partial}{\partial x_j}\left(Q_N^{j,k} q_i^N\right) v_i\, \widehat{n}_k\, ds = 0 \qquad \forall\, \mathbf{v} \in \mathbf{S}^N,\end{aligned}$$

where $\widehat{\mathbf{n}}$ is the unit normal to the boundary $\partial\Omega$ of Ω. As in the SV method, $Q_N^{j,k}$ is chosen to dampen or eliminate the low frequency modes of a function:

$$(2.2)\qquad \begin{cases} Q_N^{j,k} : S^N \to S^N, \qquad \displaystyle\sum_{n=0}^N \sum_i \beta_{n,i}\, \psi_{n,i} \mapsto \sum_{n=0}^N \sum_i Q_{N;n,i}^{j,k}\, \beta_{n,i}\, \psi_{n,i}, \\ 0 \le Q_{N;n,i}^{j,k} \le 1, \qquad \text{and} \qquad Q_{N;n,i}^{j,k} = \begin{cases} 0 & \text{for small } n \ (n \text{ near } 0), \\ 1 & \text{for large } n \ (n \text{ near } N). \end{cases} \end{cases}$$

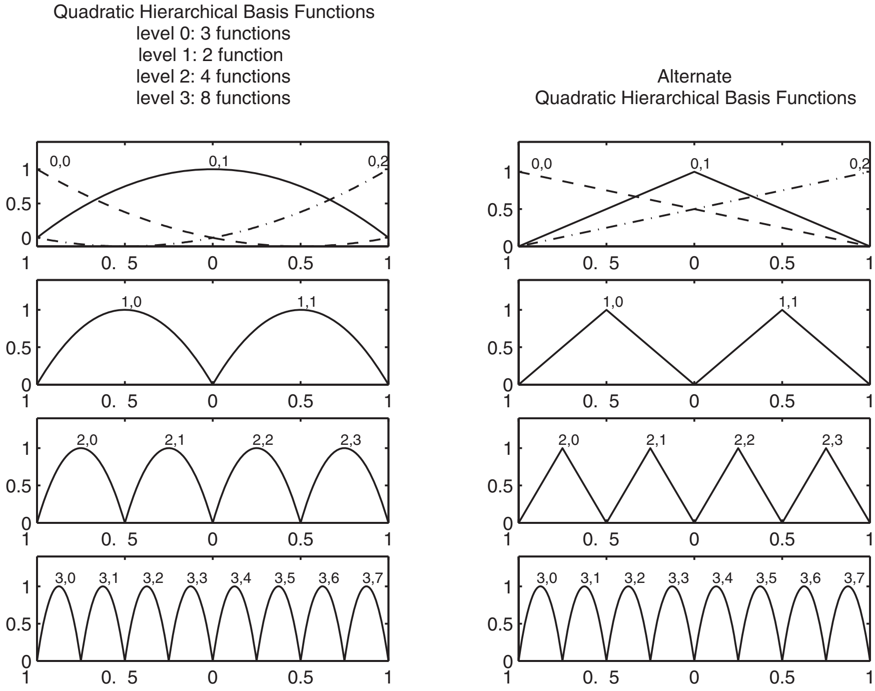

FIG. 2. *Two sets (left and right) of quadratic hierarchical basis functions spanning the same 17-dimensional, quadratic finite element space.*

To account for boundary conditions imposed along with (1.1), a subspace of S_N might need to be used (for essential boundary conditions) or the boundary integral in (2.1) might be reduced to one over part of $\partial\Omega$ (for natural boundary conditions).

Equation (2.1) is a weak formulation of the modified system

$$\frac{\partial \mathbf{q}}{\partial t} + \sum_{j=1}^{d} \frac{\partial}{\partial x_j} \mathbf{f}_j(\mathbf{q}) - \varepsilon_N \sum_{j,k=1}^{d} \frac{\partial^2}{\partial x_j \partial x_k} \left(Q_N^{j,k} \mathbf{q} \right) = \mathbf{0}, \tag{2.3}$$

where $[Q_N^{j,k}\mathbf{q}]_i = Q_N^{j,k} q_i$ for $1 \le i \le p$. The dependence of $Q_N^{j,k}$ on both j and k allows for the flexibility of introducing directional bias in the diffusion which can result in reduced crosswind diffusion. As in the streamline diffusion method, this would probably require the use of entropy variables. Here, we simplify our formulation by using an isotropic diffusion term, Q_N, such that

$$Q_{N;n,i}^{j,k} = Q_{N;n,i}\, \delta_{j,k}.$$

Then, (2.1) and (2.3), respectively, reduce to

$$\begin{aligned} &\frac{d}{dt} \int_\Omega \mathbf{q} \cdot \mathbf{v}\, d\Omega + \sum_{j=1}^{d} \int_\Omega \frac{\partial}{\partial x_j} \mathbf{f}_j(\mathbf{q}) \cdot \mathbf{v}\, d\Omega + \varepsilon_N \int_\Omega \boldsymbol{\nabla}(Q_N \mathbf{q}) : \boldsymbol{\nabla} \mathbf{v}\, d\Omega \\ &\qquad - \varepsilon_N \int_{\partial\Omega} \frac{\partial}{\partial n} (Q_N \mathbf{q}) \cdot \mathbf{v}\, ds = 0 \qquad \forall\, \mathbf{v} \in \mathbf{S}^N \end{aligned} \tag{2.4}$$

and

$$\frac{\partial \mathbf{q}}{\partial t} + \sum_{j=1}^{d} \frac{\partial}{\partial x_j} \mathbf{f}_j(\mathbf{q}) - \varepsilon_N \Delta (Q_N \mathbf{q}) = \mathbf{0}.$$

After choosing a time discretization technique, (2.4) is equivalent to a nonlinear system of equations that may be solved, e.g., by Newton's method. The relevant Jacobian matrix has the form $J^H = \widetilde{J}^H + K^H Q$, where $\widetilde{J}^H$ is the Jacobian of the time dependent and flux terms, K^H is the Laplacian stiffness matrix, and Q is a diagonal matrix whose nonzero elements are $\{Q_{N;n,i}\}$. For ease of presentation, we have ignored the boundary term. Note that for an explicit time integration method, the Jacobian matrix reduces to the mass matrix.

The solution of the discrete equations resulting from our hierarchical finite element discretization may be implemented using matrices arising from the corresponding nodal basis. See [3, 4] for details. Here, we merely observe that the Jacobian matrix J^H and residual vector $\vec{R}^H$ may be expressed, respectively, in terms of their nodal basis counterparts J^D and $\vec{R}^D$ through the relations $J^H = S^T(\widetilde{J}^D S + K^D S Q)$ and $\vec{R}^H = S^T \vec{R}^D$, where S is the change of basis matrix such that $\vec{X}^D = S\vec{X}^H$. The determination of $(J^H)^{-1}\vec{R}^H = (\widetilde{J}^D S + K^D S Q)^{-1}\vec{R}^D$ by an iterative solver then requires the calculation of the matrix-vector multiplication $(\widetilde{J}^D S + K^D S Q)\vec{X}$ and possibly $(\widetilde{J}^D S + K^D S Q)^T \vec{X}$ that only involve the nodal matrices $\widetilde{J}^D$ and K^D and the transfer matrix S. Compared to K^D and $\widetilde{J}^D$, S is not sparse, so one does not want to explicitly construct S. So, making the iterative linear solvers efficient requires being able to calculate $S\vec{X}$ and $S^T\vec{X}$ quickly. Algorithms for this purpose can be found in [3, 4].

2.1. Advantages of hierarchical bases. We use hierarchical bases (instead of nodal bases) because of their multifrequency property. Nodal bases, however, have important computational advantages such as producing matrices that are much more sparse and that can be locally assembled. However, as just discussed, one can retain most of the advantages of the nodal bases. One assembles and stores all of the system matrices as nodal basis matrices and uses the transfer matrix S in an iterative linear solver; S does not even have to be stored.

In the SV method, there is only one function, with global support, at a given frequency. In the hierarchical FE formulation, there are many functions, with local support, at a given frequency. Compared to SV methods, the hierarchical FE formulation offers two advantages: Diffusion can be added locally, and edge detection is trivial. For large values of n, the hierarchical basis function $\psi_{n,i}$ has local support, so $Q^{j,k}_{N;n,i}$ only has a local effect. One can therefore add more diffusion near a discontinuity and less or no diffusion in smooth regions. This should improve the accuracy of the method. As we are about to see, the size of $|\beta_{n,i}|$ (where $\beta_{n,i}$ is the coefficient of $\psi_{n,i}$ in the hierarchical basis expansion of a function; see (2.2)) can be used to determine if the support of $\psi_{n,i}$ resides in a smooth region or is near a discontinuity.

2.1.1. Edge detection. Using hierarchical bases, edge detection is a trivial task. Near a discontinuity, the high frequency hierarchical coefficients are of order one. In smooth regions, they shrink exponentially. Figure 3 illustrates a hierarchical decomposition of a piecewise smooth function containing a discontinuity. One can easily determine the location of discontinuities by looking at the magnitude of the coefficients of the high frequency basis functions.

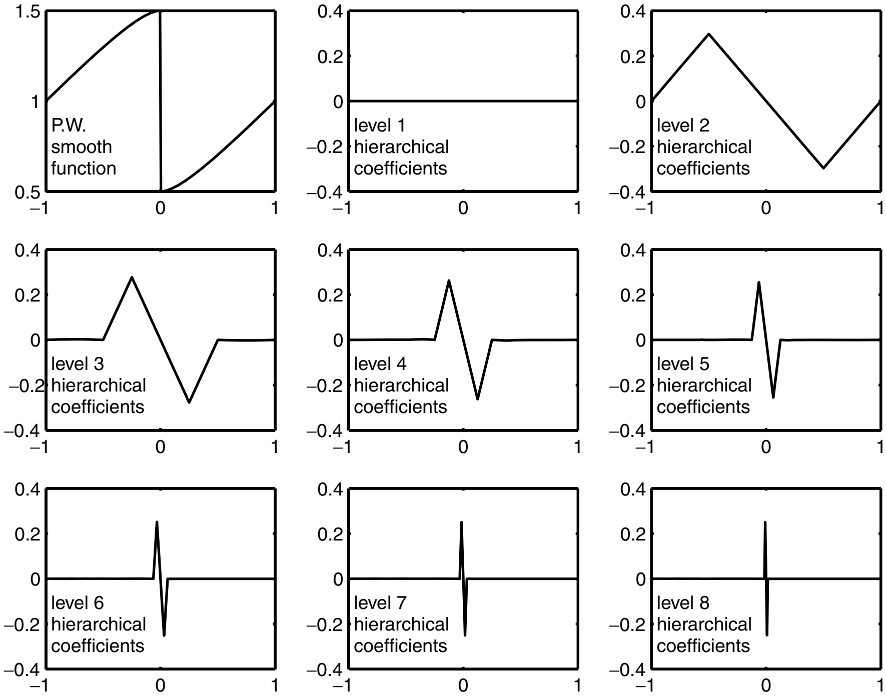

FIG. 3. *Hierarchical decomposition of a piecewise smooth function with a discontinuity.*

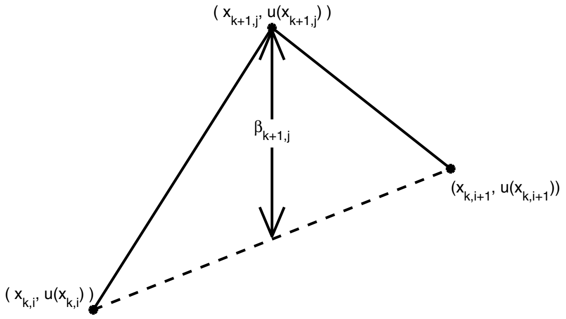

FIG. 4. *Determination of a linear hierarchical coefficient from function values.*

Edge detection for piecewise linear polynomials. Let us examine the behavior of the hierarchical coefficients for linear hierarchical basis functions. As one can see in Figure 4, $\beta_{k+1,j}$ can be calculated from the value of the function u at $x_{k+1,j}$ and at the node points of the parent cell. For a uniform partition, the cell size at level k is $\Delta x_k = |\Omega|\ 2^{-k}$. Thus, $x_{k+1,j} - x_{k,i} = x_{k,i+1} - x_{k+1,j} = \Delta x_{k+1}$ and

$$\beta_{k+1,j} = \frac{u\left(x_{k+1,j}\right) - u\left(x_{k,i}\right)}{2} - \frac{u\left(x_{k,i+1}\right) - u\left(x_{k+1,j}\right)}{2}. \tag{2.5}$$

Let $T_{k,i} = (x_{k,i}, x_{k,i+1})$.

Assume that u *is discontinuous* and has a discontinuity in $T_{k,i}$. Then, at least one of the two terms in (2.5) will have a relatively large value so that $|\beta_{k+1,j}|$ will be of the same order as the jump of u, independent of k.

Now, assume that u is *continuously differentiable*, i.e., $u \in C^1(\overline{T_{k,i}})$. Then, since (2.5) can be written as

$$\beta_{k+1,j} = \frac{|\Omega|}{4}\, 2^{-k} \left(\frac{u\,(x_{k+1,j}) - u\,(x_{k,i})}{x_{k+1,j} - x_{k,i}} - \frac{u\,(x_{k,i+1}) - u\,(x_{k+1,j})}{x_{k,i+1} - x_{k+1,j}} \right),$$

the mean value theorem yields that

$$\beta_{k+1,j} = \frac{|\Omega|}{4}\, 2^{-k}\, \left[u'\,(\widetilde{x}_1) - u'\,(\widetilde{x}_2)\right] \tag{2.6}$$

for some $\widetilde{x}_1, \widetilde{x}_2 \in T_{k,i}$. Therefore, $\beta_{k+1,j}$ is of order 2^{-k}, i.e.,

$$|\beta_{k+1,j}| \leq |\Omega|\ \|u'\|_{L^\infty(T_{k,i})}\ 2^{-k-1}$$

so that it decays exponentially with k.

If u is *twice continuously differentiable*, i.e., $u \in C^2(\overline{T_{k,i}})$, the mean value theorem applied to (2.6) yields that

$$\beta_{k+1,j} = -\frac{|\Omega|}{4}\, 2^{-k}\, (\widetilde{x}_2 - \widetilde{x}_1)\ u''\,(\widetilde{x})$$

for some $\widetilde{x} \in T_{k,i}$. Therefore, $\beta_{k+1,j}$ is of order 4^{-k}, i.e.,

$$|\beta_{k+1,j}| \leq \frac{|\Omega|}{4}\ |\widetilde{x}_2 - \widetilde{x}_1|\ |u''\,(\widetilde{x})|\ 2^{-k} \leq |\Omega|^2\ \|u''\|_{L^\infty(T_{k,i})}\ 4^{-k-1}$$

so that it again decays exponentially with k.

Similar results can be obtained for quadratic hierarchical basis function; see [3,4].

3. Convergence to entropy solutions for one-dimensional scalar conservation laws.

In this section, we prove that the solution of the hierarchical finite element discretization introduced in section 2 converges to the entropy solution of the one-dimensional, periodic Burgers equation. We will make use of the method of compensated compactness; in particular, we will use the div-curl lemma [7,21,28] and Murat's lemma [7,13,19,21,28]. The broad outlines of the proof follow that of [24].

3.1. The periodic, one-dimensional Burgers equation.

Let $\Omega = (a,b)$ be an open bounded interval and let $\Omega_T = (a,b) \times (0,T)$ for some finite time interval $(0,T)$. We seek a finite element (FE) approximation to $u\,(x,t)$, the entropy solution of the periodic hyperbolic conservation law:

$$\frac{\partial u}{\partial t} + \frac{\partial}{\partial x}\left(\frac{u^2}{2}\right) = 0 \quad \text{in } \Omega_T, \tag{3.1}$$

$$u\,(a,t) = u\,(b,t) \quad \text{in } (0,T), \qquad \text{and} \qquad u\,(x,0) = g \quad \text{in } (a,b), \tag{3.2}$$

along with the entropy condition

$$\frac{\partial}{\partial t}\left(\frac{u^2}{2}\right) + \frac{\partial}{\partial x}\left(\frac{u^3}{3}\right) \leq 0 \quad \text{in } \Omega_T, \tag{3.3}$$

where (3.1) and (3.3) hold in the distributional sense. We will assume the $g \in H^1\,(a,b)$ and that g is space-periodic. The entropy solution of Burgers' equation can be found using (3.3) instead of the more general entropy condition (1.4). This greatly simplifies our analysis since we now require an entropy-type inequality for one entropy/entropy flux pair, $(\frac{u^2}{2}, \frac{u^3}{3})$, instead of all of them. A weak form of the problem (3.1) is given by

$$\int_{\Omega_T} \left(\varphi \frac{\partial u}{\partial t} + \varphi \frac{\partial}{\partial x} \Big(\frac{u^2}{2} \Big) \right) dx\, dt = 0 \quad \forall \varphi \in C_0^\infty(\Omega_T). \tag{3.4}$$

Correspondingly, (3.3) can be expressed in the weak form

$$\int_{\Omega_T} \left(\varphi \frac{\partial}{\partial t} \Big(\frac{u^2}{2} \Big) + \varphi \frac{\partial}{\partial x} \Big(\frac{u^3}{3} \Big) \right) dx\, dt \le 0 \quad \forall \varphi \in C_0^\infty(\Omega_T),\ \varphi \ge 0. \tag{3.5}$$

3.1.1. The hierarchical finite element discretization. To formulate the FE approximation, we need some notation. Let $\mathcal{T}_0 = (a,b)$; $\mathcal{T}_N$ is obtained by subdividing the elements of $\mathcal{T}_{N-1}$ into M distinct elements. Let $|b-a|\, h_N$ be the maximal diameter of the elements of $\mathcal{T}_N$. Since we assume that the partition is quasi-uniform, there exists a positive constant ν such that $M^{-N} \le h_N \le \nu M^{-N}$ for all N.

Let $\{\psi_{k,i}\}_{k,i}$ be a hierarchical basis of S_p^N. Let us define $Q_N : S_p^N \to S_p^N$ as a damping operator $Q_N u_N = \sum_{k,i} (Q_{k,i}\, \beta_{k,i}\, \psi_{k,i})$ for $u = \sum_{k,i} (\beta_{k,i}\, \psi_{k,i}) \in S_p^N$, where $0 \le Q_{k,i} \le 1$ and $Q_{k,i} = 1$ for $k > m_H$. Thus, Q_N dampens (or eliminates) the low frequencies of a function while keeping the high frequencies above the level m_H. Occasionally, when the level of a basis function is unimportant, we will switch to the less cumbersome notation $\{\psi_i\}_i$ and $\{Q_i\}_i$ for the basis functions and damping coefficients, respectively.

We will also use the following convention: C will denote any positive constant which depends on known quantities and is independent of any indexing variables.

Let $g_N \in S_p^N$ be the interpolant of g. The hierarchical finite element approximation of (3.1)–(3.2) is given by the following: seek $u_N(x,t)$ with $u_N(\cdot,0) = g_N$ such that, for all $v \in S_p^N$,

$$\int_a^b \left[\frac{\partial u_N}{\partial t} + \frac{\partial}{\partial x} \left(\frac{{u_N}^2}{2} \right) \right] v\, dx + \varepsilon_N \int_a^b \left[\frac{\partial}{\partial x} (Q_N u_N) \frac{\partial v}{\partial x} \right] dx = 0. \tag{3.6}$$

3.2. Convergence theorem. We prove the following convergence results for hierarchical finite element approximations of the entropy solution of (3.1) and (3.2).

THEOREM 3.1. *Let $\{u_N\}_{N=0}^\infty$ denote a sequence of hierarchical finite element approximations determined by* (3.6). *Assume that $\|u_N\|_{L^\infty(\Omega_T)} \le C$ and assume that*

$$\varepsilon_N, h_N \to 0 \text{ as } N \to \infty, \tag{3.7}$$

$$\frac{\varepsilon_N}{h_N} \ge C, \tag{3.8}$$

$$\sqrt{\varepsilon_N} \left\| \frac{\partial}{\partial x} [(I - Q_N)\, v_N] \right\|_{L^2(a,b)} \le C\, \|v_N\|_{L^2(a,b)} \text{ for } v_N \in \left\{ u_N, \frac{\partial u_N}{\partial t} \right\}, \tag{3.9}$$

$$\left\| \frac{d}{dx} (Q_N g_N) \right\|_{L^2(U)} \le C \left\| \frac{d g_N}{dx} \right\|_{L^2(U)}. \tag{3.10}$$

Then, there exists a subsequence of $\{u_N\}_{N=0}^\infty$ that converges strongly in $L^2(\Omega_T)$ to a solution $u \in L^2(\Omega_T)$ of (3.1) *and* (3.2). *Further, assume that*

$$\frac{\varepsilon_N}{h_N} \to \infty \text{ as } N \to \infty \text{ and} \tag{3.11}$$

$$\sqrt{\varepsilon_N}\left\|\frac{\partial}{\partial x}\left[\left(I-Q_N\right)u_N\right]\right\|_{L^2(a,b)} \to 0 \ \textit{as } N\to\infty. \tag{3.12}$$

Then the subsequence of $\{u_N\}_N^\infty$ *converges strongly in* $L^2(\Omega_T)$ *to the entropy solution of* (3.1) *and* (3.2), *i.e., to the solution of* (3.1)–(3.3).

For the moment, we assume that (3.7)–(3.12) hold, and we prove, in sections 3.3 to 3.7, the theorem. Subsequently, in section 3.8, we will show that these conditions are satisfied in our context.

3.3. Existence of the finite element approximation.

The discrete FE equations (3.6) are equivalent to the following: seek $\vec{\alpha}:(0,T)\to\mathbb{R}^s$, where $s=\dim S_p^N$, such that

$$\dot{\vec{\alpha}}+M^{-1}\vec{F}\left(\vec{\alpha}\right)+M^{-1}\,K\,Q\,\vec{\alpha}=\vec{0}, \tag{3.13}$$

where M is the mass matrix, K is the stiffness matrix, Q is a diagonal matrix whose elements are $\{Q_i\}$, and $\vec{F}$ is the flux term: $[\vec{F}(\vec{\alpha})]_i=\int_a^b\psi_i\frac{1}{2}\frac{\partial}{\partial x}\left(\sum_j\alpha_j\,\psi_j\right)^2dx=\vec{\alpha}^TA_i\vec{\alpha}$, where A_i is the symmetric matrix $(A_i)_{j,k}=\frac{1}{2}\int_a^b\psi_i\frac{\partial}{\partial x}\left(\psi_j\,\psi_k\right)dx$. Evidently, the diffusion term is globally Lipschitz continuous. We now show that the flux term is locally Lipschitz continuous. For all $\vec{\alpha},\vec{\beta}\in\mathbb{R}^s$ and all i,

$$\begin{aligned}\left|\left[\vec{F}(\vec{\beta})-\vec{F}(\vec{\alpha})\right]_i\right| &= \left|\vec{\beta}^T A_i\,\vec{\beta}-\vec{\alpha}^T A_i\,\vec{\alpha}\right| = \left|(\vec{\beta}+\vec{\alpha})^T A_i\,(\vec{\beta}-\vec{\alpha})\right|\\ &\le \|\vec{\beta}+\vec{\alpha}\|_2\|A_i\|_2\|\vec{\beta}-\vec{\alpha}\|_2 \le \sqrt{s}\|\vec{\beta}+\vec{\alpha}\|_2\|A_i\|_2\|\vec{\beta}-\vec{\alpha}\|_\infty\end{aligned}$$

so that $\|\vec{F}(\vec{\beta})-\vec{F}(\vec{\alpha})\|_\infty\le\sqrt{s}\|\vec{\beta}+\vec{\alpha}\|_2\max_{1\le i\le s}\|A_i\|_2\|\vec{\beta}-\vec{\alpha}\|_\infty$. Since $\|A_i\|_2$ and s are independent of $\vec{\alpha}$ and $\vec{\beta}$, the flux term is locally Lipschitz continuous for any T.

Lipschitz continuity together with $|\vec{\alpha}\,(t)|<\infty$, by (3.15) and (3.17), yields that there exists a unique $\vec{C}^1\,[0,T]$ solution of (3.13) or, equivalently, of (3.6).

3.4. Estimates for u_N.

In (3.6), choose $v=u_N$; then

$$\int_a^b\left[\frac{\partial}{\partial t}\left(\frac{{u_N}^2}{2}\right)+\frac{\partial}{\partial x}\left(\frac{{u_N}^3}{3}\right)\right]dx+\varepsilon_N\int_a^b\frac{\partial}{\partial x}\left(Q_Nu_N\right)\frac{\partial u_N}{\partial x}\,dx=0.$$

Since u_N is periodic, $\int_a^b\frac{\partial}{\partial x}\left(\frac{{u_N}^3}{3}\right)dx=0$ so that

$$\frac{1}{2}\frac{d}{dt}\|u_N\|^2_{L^2(a,b)}+\varepsilon_N\int_a^b\frac{\partial}{\partial x}\left(Q_Nu_N\right)\frac{\partial u_N}{\partial x}\,dx=0. \tag{3.14}$$

3.4.1. $H^1\left(\Omega_T\right)$ estimates for u_N for linear polynomials.

The elements of the piecewise linear hierarchical basis are orthogonal with respect to the $H^1\left(a,b\right)$ seminorm. As a result,

$$\begin{aligned}\int_a^b\frac{\partial}{\partial x}\left(Q_Nu_N\right)\frac{\partial u_N}{\partial x}\,dx &= \sum_i\sum_j Q_i\beta_i\beta_j\int_a^b\psi_i'\psi_j'\,dx\\ &= \sum_i Q_i\beta_i^2\int_a^b\left(\psi_i'\right)^2\,dx \ge \sum_i Q_i^2\beta_i^2\int_a^b\left(\psi_i'\right)^2\,dx\\ &= \sum_i\sum_j Q_iQ_j\beta_i\beta_j\int_a^b\psi_i'\psi_j'\,dx = \left\|\frac{\partial}{\partial x}\left(Q_Nu_N\right)\right\|^2_{L^2(a,b)}.\end{aligned}$$

Integrating (3.14) over time, we obtain

$$\begin{aligned} C\left\|g\right\|^2_{L^2(a,b)} \geq \left\|g_N\right\|^2_{L^2(a,b)} &= \left\|u_N\left(\cdot,t\right)\right\|^2_{L^2(a,b)} + 2\varepsilon_N \int_0^t \int_a^b \frac{\partial}{\partial x}\left(Q_N u_N\right) \frac{\partial u_N}{\partial x}\, dx\, dt \\ &\geq \left\|u_N\left(\cdot,t\right)\right\|^2_{L^2(a,b)} + 2\varepsilon_N \int_0^t \left\|\frac{\partial}{\partial x}\left(Q_N u_N\right)\right\|^2_{L^2(a,b)} dt \end{aligned}$$

so that

$$\left\|u_N\right\|_{L^2(\Omega_T)} \leq C\sqrt{T}\, \left\|g\right\|_{L^2(a,b)}, \quad \sqrt{\varepsilon_N}\left\|\frac{\partial}{\partial x}\left(Q_N u_N\right)\right\|_{L^2(\Omega_T)} \leq C\left\|g\right\|_{L^2(a,b)}. \tag{3.15}$$

3.4.2. $H^1\left(\Omega_T\right)$ estimates for u_N for quadratic polynomials. The quadratic hierarchical basis functions are not orthogonal, but we can still obtain an estimate similar to (3.15). We now have that

$$\begin{aligned} \int_a^b \frac{\partial}{\partial x}\left(Q_N u_N\right) \frac{\partial u_N}{\partial x}\, dx &= \int_a^b \frac{\partial}{\partial x}\left(Q_N u_N\right) \frac{\partial}{\partial x}\left(Q_N u_N\right)\, dx \\ &\quad + \int_a^b \frac{\partial}{\partial x}\left(Q_N u_N\right) \frac{\partial}{\partial x}\left[\left(I-Q_N\right)u_N\right]\, dx \\ &\geq \int_a^b \left|\frac{\partial}{\partial x}\left(Q_N u_N\right)\right|^2 dx \\ &\quad -\frac{1}{2}\int_a^b \left|\frac{\partial}{\partial x}\left(Q_N u_N\right)\right|^2 dx - \frac{1}{2}\int_a^b \left|\frac{\partial}{\partial x}\left[\left(I-Q_N\right)u_N\right]\right|^2 dx \\ &= \frac{1}{2}\left\|\frac{\partial}{\partial x}\left(Q_N u_N\right)\right\|^2_{L^2(a,b)} - \frac{1}{2}\left\|\frac{\partial}{\partial x}\left[\left(I-Q_N\right)u_N\right]\right\|^2_{L^2(a,b)} \\ &\geq \frac{1}{2}\left\|\frac{\partial}{\partial x}\left(Q_N u_N\right)\right\|^2_{L^2(a,b)} - \frac{C}{2\,\varepsilon_N}\left\|u_N\right\|^2_{L^2(a,b)}. \end{aligned}$$

Substituting this result into (3.14), we obtain

$$\frac{d}{dt}\left\|u_N\right\|^2_{L^2(a,b)} \leq C\left\|u_N\right\|^2_{L^2(a,b)} - \varepsilon_N\left\|\frac{\partial}{\partial x}\left(Q_N u_N\right)\right\|^2_{L^2(a,b)}. \tag{3.16}$$

We require a nonstandard formulation of the differential form of Gronwall's inequality. A proof is given in [8].

LEMMA 3.2. *Let $\eta\left(t\right)$ be an absolutely continuous function on $[0,T]$ such that for a.e. $t \in [0,T]$, $\eta'\left(t\right) \leq \phi\left(t\right)\eta\left(t\right) + \psi\left(t\right)$, where $\phi\left(t\right)$ and $\psi\left(t\right)$ are summable functions on $[0,T]$. Then, $\eta\left(t\right) \leq e^{\int_0^t \phi(r)\, dr}[\eta\left(0\right) + \int_0^t e^{-\int_0^s \phi(r)\, dr}\psi\left(s\right)\, ds]\ \forall\ t \in [0,T]$.*

Let us now assume that $\phi = C$ is a positive constant, and $\psi \leq 0$ is never positive. We then have

$$\begin{aligned} \eta\left(t\right) &\leq e^{Ct}\left[\eta\left(0\right) + \int_0^t e^{-Cs}\psi\left(s\right)\, ds\right] \\ &\leq e^{Ct}\left[\eta\left(0\right) + \int_0^t e^{-Ct}\psi\left(s\right)\, ds\right] = e^{Ct}\,\eta\left(0\right) + \int_0^t \psi\left(s\right)\, ds. \end{aligned}$$

Using this result with (3.16), we obtain

$$\left\|u_N\right\|^2_{L^2(a,b)} \leq e^{Ct}\left\|g_N\right\|^2_{L^2(a,b)} - \varepsilon_N \int_0^t \left\|\frac{\partial}{\partial x}\left(Q_N u_N\right)\right\|^2_{L^2(a,b)} ds.$$

Since $\|g_N\|_{L^2(a,b)} \leq C\,\|g\|_{L^2(a,b)}$,

$$\|u_N\|^2_{L^2(a,b)} + \varepsilon_N \int_0^t \left\| \frac{\partial}{\partial x}\left(Q_N u_N\right)\right\|^2_{L^2(a,b)} ds \leq Ce^{Ct}\,\|g\|^2_{L^2(a,b)} .$$

Therefore, we have that

$$\text{(3.17)} \qquad \left\{ \begin{array}{l} \|u_N\|_{L^2(\Omega_T)} \leq C\sqrt{e^{CT}-1}\ \|g\|_{L^2(a,b)}, \\ \sqrt{\varepsilon_N}\Big\| \dfrac{\partial}{\partial x}\left(Q_N u_N\right)\Big\|_{L^2(\Omega_T)} \leq C\sqrt{e^{CT}}\ \|g\|_{L^2(a,b)} . \end{array} \right.$$

3.5. Strong convergence of $\{u_N\}$. Let $\mathbf{v}_N = (\frac{{u_N}^2}{2}, u_N)$ and $\mathbf{w}_N = (\frac{{u_N}^2}{2}, -\frac{{u_N}^3}{3})$ so that

$$\operatorname{div}\mathbf{v}_N = \frac{\partial u_N}{\partial t} + \frac{\partial}{\partial x}\left(\frac{{u_N}^2}{2}\right) \qquad \text{and} \qquad \operatorname{curl}\mathbf{w}_N = \frac{\partial}{\partial t}\left(\frac{{u_N}^2}{2}\right) + \frac{\partial}{\partial x}\left(\frac{{u_N}^3}{3}\right).$$

3.5.1. $L^2(\Omega_T)$ bound on $\{\operatorname{div}\mathbf{v}_N\}$. In (3.6), choose $v = \frac{\partial u_N}{\partial t}$; then

$$\begin{aligned}
&\int_a^b \left|\frac{\partial u_N}{\partial t}\right|^2 dx + \int_a^b \frac{\partial}{\partial x}\left(\frac{u_N^2}{2}\right)\frac{\partial u_N}{\partial t}\,dx = -\,\varepsilon_N \int_a^b \frac{\partial}{\partial x}\left(Q_N u_N\right)\frac{\partial^2 u_N}{\partial x \partial t}\,dx \\
&=-\,\varepsilon_N \int_a^b \frac{\partial}{\partial x}\left(Q_N u_N\right)\frac{\partial^2}{\partial x\partial t}\left(Q_N u_N\right)dx \\
&\quad -\varepsilon_N \int_a^b \frac{\partial}{\partial x}\left(Q_N u_N\right)\frac{\partial^2}{\partial x\partial t}\left[\left(I-Q_N\right)u_N\right]dx \\
&=-\,\frac{\varepsilon_N}{2}\int_a^b \frac{\partial}{\partial t}\Big\{\Big[\frac{\partial}{\partial x}\left(Q_N u_N\right)\Big]^2\Big\}dx - \varepsilon_N \int_a^b \frac{\partial}{\partial x}\left(Q_N u_N\right)\frac{\partial^2}{\partial x\partial t}\left[\left(I-Q_N\right)u_N\right]dx \\
&\leq-\,\frac{\varepsilon_N}{2}\int_a^b \frac{\partial}{\partial t}\Big\{\Big[\frac{\partial}{\partial x}\left(Q_N u_N\right)\Big]^2\Big\}dx \\
&\quad +\varepsilon_N\Big\|\frac{\partial}{\partial x}\left(Q_N u_N\right)\Big\|_{L^2(a,b)}\Big\|\frac{\partial^2}{\partial x\partial t}\left[\left(I-Q_N\right)u_N\right]\Big\|_{L^2(a,b)} \\
&\leq-\,\frac{\varepsilon_N}{2}\int_a^b \frac{\partial}{\partial t}\Big\{\Big[\frac{\partial}{\partial x}\left(Q_N u_N\right)\Big]^2\Big\}dx + C\sqrt{\varepsilon_N}\left\|\frac{\partial}{\partial x}\left(Q_N u_N\right)\right\|_{L^2(a,b)}\left\|\frac{\partial u_N}{\partial t}\right\|_{L^2(a,b)} \\
&\leq-\,\frac{\varepsilon_N}{2}\int_a^b \frac{\partial}{\partial t}\left\{\left[\frac{\partial}{\partial x}\left(Q_N u_N\right)\right]^2\right\}dx + C\Big\|\frac{\partial u_N}{\partial t}\Big\|_{L^2(a,b)} \\
&\leq-\,\frac{\varepsilon_N}{2}\int_a^b \frac{\partial}{\partial t}\Big\{\Big[\frac{\partial}{\partial x}\left(Q_N u_N\right)\Big]^2\Big\}dx + C^2 + \frac{1}{4}\Big\|\frac{\partial u_N}{\partial t}\Big\|^2_{L^2(a,b)}.
\end{aligned}$$

Rearranging terms in the last expression, we obtain

$$\begin{aligned}
\frac{3}{4}\left\|\frac{\partial u_N}{\partial t}\right\|^2_{L^2(a,b)} + \frac{\varepsilon_N}{2}\frac{d}{dt}\left\|\frac{\partial}{\partial x}\left(Q_N u_N\right)\right\|^2_{L^2(a,b)} - C &\leq -\int_a^b \frac{\partial}{\partial x}\left(\frac{u_N^2}{2}\right)\frac{\partial u_N}{\partial t}\,dx \\
&\leq \Big\|\frac{\partial}{\partial x}\left(\frac{u_N^2}{2}\right)\Big\|_{L^2(a,b)}\Big\|\frac{\partial u_N}{\partial t}\Big\|_{L^2(a,b)} \leq \Big\|\frac{\partial}{\partial x}\left(\frac{u_N^2}{2}\right)\Big\|^2_{L^2(a,b)} + \frac{1}{4}\Big\|\frac{\partial u_N}{\partial t}\Big\|^2_{L^2(a,b)}.
\end{aligned}$$

Rearranging terms again, we obtain

$$\left\|\frac{\partial u_N}{\partial t}\right\|^2_{L^2(a,b)} \leq C - \varepsilon_N\frac{d}{dt}\left\|\frac{\partial}{\partial x}\left(Q_N u_N\right)\right\|^2_{L^2(a,b)} + 2\left\|\frac{\partial}{\partial x}\left(\frac{u_N^2}{2}\right)\right\|^2_{L^2(a,b)} .$$

Integrating over time, we obtain

$$\begin{aligned}\left\|\frac{\partial u_N}{\partial t}\right\|^2_{L^2(\Omega_T)} &\le C + 2\int_{\Omega_T}\left|\frac{\partial}{\partial x}\left(\frac{u_N^2}{2}\right)\right|^2 dx\,dt \\ &\quad - \varepsilon_N\left\|\frac{\partial}{\partial x}\left(Q_N u_N(\cdot,T)\right)\right\|^2_{L^2(a,b)} + \varepsilon_N\left\|\frac{d}{dx}\left(Q_N g_N\right)\right\|^2_{L^2(a,b)} \qquad (3.18)\\ &\le C + 2\int_{U_T}\left|\frac{\partial}{\partial x}\left(\frac{u_N^2}{2}\right)\right|^2 dx\,dt + \varepsilon_N\left\|\frac{d}{dx}\left(Q_N g_N\right)\right\|^2_{L^2(a,b)} \qquad (3.19)\\ &\le C + 2\int_{U_T}\left|\frac{\partial}{\partial x}\left(\frac{u_N^2}{2}\right)\right|^2 dx\,dt + C\,\varepsilon_N\left\|\frac{dg_N}{dx}\right\|^2_{L^2(a,b)} \qquad (3.20)\\ &\le C + 2\int_{U_T}\left|\frac{\partial}{\partial x}\left(\frac{u_N^2}{2}\right)\right|^2 dx\,dt + C\,\varepsilon_N\left\|\frac{dg}{dx}\right\|^2_{L^2(a,b)}. \qquad (3.21)\end{aligned}$$

Now,

$$\begin{aligned}\int_{\Omega_T}\left|\frac{\partial}{\partial x}\left(\frac{u_N^2}{2}\right)\right|^2 dx\,dt &= \int_{\Omega_T}|u_N|^2\left|\frac{\partial u_N}{\partial x}\right|^2 dx\,dt \\ &\le \|u_N\|^2_{L^\infty(\Omega_T)}\left\|\frac{\partial u_N}{\partial x}\right\|^2_{L^2(\Omega_T)} \le \frac{C}{\varepsilon_N}.\end{aligned} \tag{3.22}$$

Combining the last two results, we obtain $\varepsilon_N\|\frac{\partial u_N}{\partial t}\|^2_{L^2(a,b)} \le C\left(1+\varepsilon_N+\varepsilon_N{}^2\right)$ so that

$$\sqrt{\varepsilon_N}\left\|\frac{\partial u_N}{\partial t}\right\|_{L^2(\Omega_T)} \le C. \tag{3.23}$$

Combining (3.22) and (3.23), we obtain

$$\begin{aligned}\sqrt{\varepsilon_N}\left\|\text{div }\mathbf{v}_N\right\|_{L^2(\Omega_T)} &= \sqrt{\varepsilon_N}\left\|\frac{\partial u_N}{\partial t} + \frac{\partial}{\partial x}\left(\frac{u_N{}^2}{2}\right)\right\|_{L^2(\Omega_T)} \\ &\le \sqrt{\varepsilon_N}\left\|\frac{\partial u_N}{\partial t}\right\|_{L^2(\Omega_T)} + \sqrt{\varepsilon_N}\left\|\frac{\partial}{\partial x}\left(\frac{u_N{}^2}{2}\right)\right\|_{L^2(\Omega_T)} \le C.\end{aligned}$$

3.5.2. $\{\mathbf{div\,v}_N\}$ lies in a compact subset of $H^{-1}(\Omega_T)$. Let $\widetilde{\varphi} \in H_0^1(\Omega_T)$. For all $t \in (0,T)$, let $\widetilde{\varphi}_N(\cdot,t) \in S_p^N \cap H_0^1(a,b)$ be the $H^1(a,b)$ projection of $\widetilde{\varphi}$ so that

$$\int_a^b \frac{\partial\widetilde{\varphi}_N(\cdot,t)}{\partial x}\frac{\partial v}{\partial x}\,dx = \int_a^b \frac{\partial\widetilde{\varphi}(\cdot,t)}{\partial x}\frac{\partial v}{\partial x}\,dx \qquad \forall\, v \in S_p^N \cap H_0^1(a,b).$$

We need the $H^1(a,b)$ projection into S_p^N of an arbitrary $\widetilde{\varphi} \in H_0^1(\Omega_T)$ in order to use our FE formulation:

$$\begin{aligned}&\int_{\Omega_T}(\text{div }\mathbf{v}_N)\,\widetilde{\varphi}\,dx\,dt = \int_{\Omega_T}(\text{div }\mathbf{v}_N)\,\widetilde{\varphi}_N\,dx\,dt + \int_{\Omega_T}(\text{div }\mathbf{v}_N)\left(\widetilde{\varphi}-\widetilde{\varphi}_N\right)dx\,dt \\ &= -\varepsilon_N\int_{\Omega_T}\frac{\partial}{\partial x}\left(Q_N u_N\right)\frac{\partial\widetilde{\varphi}_N}{\partial x}\,dx\,dt + \int_{\Omega_T}(\text{div }\mathbf{v}_N)\left(\widetilde{\varphi}-\widetilde{\varphi}_N\right)dx\,dt \\ &= -\varepsilon_N\int_{\Omega_T}\frac{\partial}{\partial x}\left(Q_N u_N\right)\frac{\partial\widetilde{\varphi}}{\partial x}\,dx\,dt + \int_{\Omega_T}(\text{div }\mathbf{v}_N)\left(\widetilde{\varphi}-\widetilde{\varphi}_N\right)dx\,dt\end{aligned}$$

$$\begin{aligned}
&\le \varepsilon_N \Big\| \frac{\partial}{\partial x}\left(Q_N u_N\right)\Big\|_{L^2(\Omega_T)} \Big\|\frac{\partial \widetilde{\varphi}}{\partial x}\Big\|_{L^2(\Omega_T)} + \|\text{div } v_N\|_{L^2(\Omega_T)} \|\widetilde{\varphi} - \widetilde{\varphi}_N\|_{L^2(\Omega_T)} \\
&\le \varepsilon_N \Big\| \frac{\partial}{\partial x}\left(Q_N u_N\right)\Big\|_{L^2(\Omega_T)} \Big\|\frac{\partial \widetilde{\varphi}}{\partial x}\Big\|_{L^2(\Omega_T)} + C\, h_N \,\|\text{div } v_N\|_{L^2(\Omega_T)} \Big\|\frac{\partial \widetilde{\varphi}}{\partial x}\Big\|_{L^2(\Omega_T)} \\
&\le C \left(\sqrt{\varepsilon_N} + \frac{h_N}{\sqrt{\varepsilon_N}}\right) \Big\|\frac{\partial \widetilde{\varphi}}{\partial x}\Big\|_{L^2(\Omega_T)} = C\sqrt{\varepsilon_N}\left(1 + \frac{h_N}{\varepsilon_N}\right)\Big\|\frac{\partial \widetilde{\varphi}}{\partial x}\Big\|_{L^2(\Omega_T)}.
\end{aligned}$$

From (3.8), we have that $\frac{h_N}{\varepsilon_N} \le C$ so that

$$\int_{\Omega_T} (\text{div}\, \mathbf{v}_N)\, \widetilde{\varphi}\, dx\, dt \le C\sqrt{\varepsilon_N}\,\Big\|\frac{\partial \widetilde{\varphi}}{\partial x}\Big\|_{L^2(\Omega_T)}. \tag{3.24}$$

Let $\widetilde{\varphi} \in H_0^1(\Omega_T)$ with $\|\widetilde{\varphi}\|_{H^1(\Omega_T)} \le 1$. Then, from (3.24), we have that

$$\|\text{div } \mathbf{v}_N\|_{H^{-1}(\Omega_T)} \le C\sqrt{\varepsilon_N} \to 0 \text{ as } N \to \infty$$

so that $\{\text{div}\, \mathbf{v}_N\}$ lies in a compact subset of $H^{-1}(\Omega_T)$.

3.5.3. $\{\text{curl}\, \mathbf{w}_N\}$ lies in a compact subset of $H^{-1}(\Omega_T)$. Let $\varphi \in C_0^\infty(\Omega_T)$ be a test function. Since $u_N\,\varphi \in H_0^1(\Omega_T)$, we can choose $\widetilde{\varphi} = u_N\varphi$ in (3.24). Then,

$$\begin{aligned}
&\int_{\Omega_T} (\text{curl } \mathbf{w}_N)\, \varphi\, dx\, dt = \int_{\Omega_T} (\text{div } \mathbf{v}_N)\, u_N\, \varphi\, dx\, dt \\
&\le C\sqrt{\varepsilon_N}\,\Big\|\frac{\partial}{\partial x}(u_N\varphi)\Big\|_{L^2(\Omega_T)} = C\sqrt{\varepsilon_N}\Big\|u_N\frac{\partial \varphi}{\partial x} + \varphi\frac{\partial u_N}{\partial x}\Big\|_{L^2(\Omega_T)} \\
&\le C\sqrt{\varepsilon_N}\Big(\Big\|u_N\frac{\partial \varphi}{\partial x}\Big\|_{L^2(\Omega_T)} + \Big\|\varphi\frac{\partial u_N}{\partial x}\Big\|_{L^2(\Omega_T)}\Big) \\
&\le C\sqrt{\varepsilon_N}\Big(\|u_N\|_{L^\infty(\Omega_T)}\,\Big\|\frac{\partial \varphi}{\partial x}\Big\|_{L^2(\Omega_T)} + \|\varphi\|_{L^\infty(\Omega_T)}\,\Big\|\frac{\partial u_N}{\partial x}\Big\|_{L^2(\Omega_T)}\Big) \\
&\le C\Big(\sqrt{\varepsilon_N}\Big\|\frac{\partial \varphi}{\partial x}\Big\|_{L^2(\Omega_T)} + \|\varphi\|_{L^\infty(\Omega_T)}\Big).
\end{aligned}$$

Using a variational form of Murat's lemma [13, 19] gives, from the last result, that $\{\text{curl}\, \mathbf{w}_N\}$ lies in a compact subset of $H^{-1}(\Omega_T)$.

3.5.4. Strong convergence in $L^2(\Omega_T)$ of a subsequence of $\{u_N\}$. Since $\|u_N\|_{L^\infty(\Omega_T)} \le C$, there exists a subsequence $\{u_{N_k}\}$ of $\{u_N\}$ such that for $1 \le p \le 4$, $\{u_{N_k}^p\}$ converges weakly in $L^2(\Omega_T)$. Let $\overline{u^{(p)}} \in L^2(\Omega_T)$ be the weak limit of $u_{N_k}^p$. Then, $\mathbf{v}_{N_k}$ and $\mathbf{w}_{N_k}$ converge weakly:

$$\mathbf{v}_{N_k} \rightharpoonup \left(\frac{\overline{u^{(2)}}}{2}, \overline{u^{(1)}}\right) =: \overline{\mathbf{v}} \qquad \text{and} \qquad \mathbf{w}_{N_k} \rightharpoonup \left(\frac{\overline{u^{(2)}}}{2}, -\frac{\overline{u^{(3)}}}{3}\right) =: \overline{\mathbf{w}}.$$

By the div-curl lemma [7, 21, 28], we have

$$\lim_{k\to\infty}\int_{\Omega_T} (\mathbf{v}_{N_k}\cdot \mathbf{w}_{N_k})\, \varphi\, dx\, dt = \int_{\Omega_T} (\overline{\mathbf{v}}\cdot\overline{\mathbf{w}})\, \varphi\, dx\, dt \quad \forall\, \varphi \in C_0^\infty(\Omega_T)\,. \tag{3.25}$$

For all $\varphi \in C_0^\infty(\Omega_T)$,

$$\begin{aligned}
\lim_{k\to\infty}\int_{\Omega_T} (\mathbf{v}_{N_k}\cdot \mathbf{w}_{N_k})\, \varphi\, dx\, dt &= \lim_{k\to\infty}\int_{\Omega_T}\left(\frac{{u_{N_k}}^4}{4} - \frac{{u_{N_k}}^4}{3}\right)\varphi\, dx\, dt \\
&= \lim_{k\to\infty}\int_{\Omega_T} -\frac{{u_{N_k}}^4}{12}\varphi\, dx\, dt = \int_{\Omega_T} -\frac{\overline{u^{(4)}}}{12}\varphi\, dx\, dt.
\end{aligned} \tag{3.26}$$

For the right-hand side of (3.25) we have

$$\int_{\Omega_T} (\overline{\mathbf{v}}\cdot\overline{\mathbf{w}})\,\varphi\,dx\,dt = \int_{\Omega_T} \left(\frac{1}{4}\left(\overline{u^{(2)}}\right)^2 - \frac{1}{3}\overline{u^{(1)}}\,\overline{u^{(3)}}\right)\varphi\,dx\,dt. \tag{3.27}$$

Combining (3.25)–(3.27) yields that

$$\overline{u^{(4)}} = 4\,\overline{u^{(1)}}\,\overline{u^{(3)}} - 3\,\left(\overline{u^{(2)}}\right)^2 \quad \text{a.e.,}$$

which can be used to show that u_{N_k} converges strongly to $\overline{u^{(1)}}$ in $L^2(\Omega_T)$. First, we have

$$\left(u_{N_k} - \overline{u^{(1)}}\right)^4 = {u_{N_k}}^4 - 4\,{u_{N_k}}^3\,\overline{u^{(1)}} + 6\,{u_{N_k}}^2\,\left(\overline{u^{(1)}}\right)^2 - 4\,u_{N_k}\,\left(\overline{u^{(1)}}\right)^3 + \left(\overline{u^{(1)}}\right)^4.$$

Taking the weak limit of both sides of the last equation, we have that

$$\begin{aligned} & w - \lim_{k\to\infty}\left(u_{N_k} - \overline{u^{(1)}}\right)^4 \\ &\quad = \overline{u^{(4)}} - 4\,\overline{u^{(3)}}\,\overline{u^{(1)}} + 6\,\overline{u^{(2)}}\,\left(\overline{u^{(1)}}\right)^2 - 4\,\left(\overline{u^{(1)}}\right)^4 + \left(\overline{u^{(1)}}\right)^4 \\ &\quad = 4\,\overline{u^{(1)}}\,\overline{u^{(3)}} - 3\,\left(\overline{u^{(2)}}\right)^2 - 4\,\overline{u^{(3)}}\,\overline{u^{(1)}} + 6\,\overline{u^{(2)}}\,\left(\overline{u^{(1)}}\right)^2 - 4\,\left(\overline{u^{(1)}}\right)^4 + \left(\overline{u^{(1)}}\right)^4 \\ &\quad = -3\,\left(\overline{u^{(2)}}\right)^2 + 6\,\overline{u^{(2)}}\,\left(\overline{u^{(1)}}\right)^2 - 3\,\left(\overline{u^{(1)}}\right)^4 = -3\,\left[\overline{u^{(2)}} - \left(\overline{u^{(1)}}\right)^2\right]^2 \le 0. \end{aligned}$$

Then

$$0 \le \lim_{k\to\infty}\int_{\Omega_T}\left(u_{N_k} - \overline{u^{(1)}}\right)^4 dx\,dt = \int_{\Omega_T} -3\,\left[\overline{u^{(2)}} - \left(\overline{u^{(1)}}\right)^2\right]^2 dx\,dt \le 0.$$

We now have $\overline{u^{(2)}} = \left(\overline{u^{(1)}}\right)^2$ a.e., which gives us

$$\left\|\overline{u^{(1)}}\right\|^2_{L^2(\Omega_T)} = \int_{\Omega_T}\overline{u^{(2)}}\,dx\,dt = \lim_{k\to\infty}\int_{\Omega_T}{u_{N_k}}^2\,dx\,dt = \lim_{k\to\infty}\|u_{N_k}\|^2_{L^2(\Omega_T)}.$$

Therefore, $\overline{u} := \overline{u^{(1)}}$ is the strong limit of u_{N_k} in $L^2(\Omega_T)$.

3.6. Convergence to a solution of the hyperbolic conservation law. We now show that $\overline{u}$ is a solution of the conservation law (3.4). For all test functions $\varphi \in C_0^\infty(\Omega_T)$,

$$\begin{aligned} &\int_{\Omega_T}\left[\frac{\partial\overline{u}}{\partial t}\varphi + \frac{\partial}{\partial x}\left(\frac{\overline{u}^2}{2}\right)\varphi\right]dx\,dt = -\int_{\Omega_T}\left[\overline{u}\frac{\partial\varphi}{\partial t} + \frac{\overline{u}^2}{2}\frac{\partial\varphi}{\partial x}\right]dx\,dt \\ &\quad = -\int_{\Omega_T}\left[\overline{u^{(1)}}\frac{\partial\varphi}{\partial t} + \frac{\overline{u^{(2)}}}{2}\frac{\partial\varphi}{\partial x}\right]dx\,dt = -\lim_{k\to\infty}\int_{\Omega_T}\left[u_{N_k}\frac{\partial\varphi}{\partial t} + \frac{u_{N_k}^2}{2}\frac{\partial\varphi}{\partial x}\right]dx\,dt \\ &\quad = \lim_{k\to\infty}\int_{\Omega_T}\left[\frac{\partial u_{N_k}}{\partial t}\varphi + \frac{\partial}{\partial x}\left(\frac{u_{N_k}^2}{2}\right)\varphi\right]dx\,dt = \lim_{k\to\infty}\int_{\Omega_T}(\operatorname{div}\mathbf{v}_{N_k})\,\varphi\,dx\,dt. \end{aligned}$$

The right-hand side of last expression vanishes since

$$\begin{aligned} 0 \le \left|\int_{\Omega_T}(\operatorname{div}\mathbf{v}_{N_k})\,\varphi\,dx\,dt\right| &\le \|\operatorname{div}\mathbf{v}_{N_k}\|_{H^{-1}(\Omega_T)}\,\|\varphi\|_{H^1(\Omega_T)} \\ &\le C\,\sqrt{\varepsilon_N}\,\|\varphi\|_{H^1(\Omega_T)} \to 0 \text{ as } k\to\infty \end{aligned}$$

so that $\overline{u}$ is a solution of (3.4).

3.7. Convergence to the entropy solution. We showed in sections 3.5 and 3.6 that $\{u_{N_k}\}$ converges strongly to a solution $\overline{u}$ of the conservation law. We now show that, if the strengthened requirements (3.11) and (3.12) are satisfied, then $\overline{u}$ is the physically relevant entropy solution.

Let $\varphi \in C_0^\infty(\Omega_T)$; then

$$\begin{aligned}\left|\int_{\Omega_T} \left(\overline{u}^3 - {u_{N_k}}^3\right)\varphi\,dx\,dt\right| &= \left|\int_{\Omega_T} \left(\overline{u} - u_{N_k}\right)\left(\overline{u}^2 + \overline{u}\,u_{N_k} + {u_{N_k}}^2\right)\varphi\,dx\,dt\right| \\ &\le \|\overline{u} - u_{N_k}\|_{L^2(\Omega_T)} \left\|\left(\overline{u}^2 + \overline{u}\,u_{N_k} + {u_{N_k}}^2\right)\varphi\right\|_{L^2(\Omega_T)} \\ &\le \|\varphi\|_{L^\infty(\Omega_T)} \|\overline{u} - u_{N_k}\|_{L^2(\Omega_T)} \left\|\overline{u}^2 + \overline{u}\,u_{N_k} + {u_{N_k}}^2\right\|_{L^2(\Omega_T)} \\ &\le \|\varphi\|_{L^\infty(\Omega_T)} \|\overline{u} - u_{N_k}\|_{L^2(\Omega_T)} \left(\left\|\overline{u}^2\right\|_{L^2(\Omega_T)} + \|\overline{u}\,u_{N_k}\|_{L^2(\Omega_T)} + \left\|{u_{N_k}}^2\right\|_{L^2(\Omega_T)}\right) \\ &\le \|\varphi\|_{L^\infty(\Omega_T)} \|\overline{u} - u_{N_k}\|_{L^2(\Omega_T)} \\ &\qquad \left(\|\overline{u}\|^2_{L^4(\Omega_T)} + \|u_{N_k}\|_{L^\infty(\Omega_T)} \|\overline{u}\|_{L^2(\Omega_T)} + \|u_{N_k}\|^2_{L^\infty(\Omega_T)} \sqrt{|\Omega_T|}\right).\end{aligned}$$

Since $\{u_N\}$ is uniformly bounded, we have that $\|u_{N_k}\|_{L^\infty(\Omega_T)} \le C$. Also, $\overline{u}$ is in $L^4(\Omega_T)$ since $\overline{u}^2 = \overline{u^{(2)}} \in L^2(\Omega_T)$. Then, since $\lim_{k\to\infty} \|\overline{u} - u_{N_k}\|_{L^2(\Omega_T)} = 0$, we have that

$$\lim_{k\to\infty} \int_{\Omega_T} (u_{N_k})^3\,\varphi\,dx\,dt = \int_{\Omega_T} \overline{u}^3 \varphi\,dx\,dt.$$

Now, let $\varphi \in C_0^\infty(\Omega_T)$ with $\varphi \ge 0$; then,

$$\begin{aligned}\int_{\Omega_T} \left[\frac{\partial}{\partial t}\left(\frac{\overline{u}^2}{2}\right) + \frac{\partial}{\partial x}\left(\frac{\overline{u}^3}{3}\right)\right]\varphi\,dx\,dt &= -\int_{\Omega_T} \left(\frac{\overline{u}^2}{2}\frac{\partial\varphi}{\partial t} + \frac{\overline{u}^3}{3}\frac{\partial\varphi}{\partial x}\right)dx\,dt \\ &= -\lim_{k\to\infty} \int_{\Omega_T} \left(\frac{{u_{N_k}}^2}{2}\frac{\partial\varphi}{\partial t} + \frac{{u_{N_k}}^3}{3}\frac{\partial\varphi}{\partial x}\right)dx\,dt \\ &= \lim_{k\to\infty} \int_{\Omega_T} \left[\frac{\partial}{\partial t}\left(\frac{{u_{N_k}}^2}{2}\right) + \frac{\partial}{\partial x}\left(\frac{{u_{N_k}}^3}{3}\right)\right]\varphi\,dx\,dt \\ &= \lim_{k\to\infty} \int_{\Omega_T} \left(\operatorname{curl} \mathbf{w}_{N_k}\right)\varphi\,dx\,dt = \lim_{k\to\infty} \int_{\Omega_T} \left(\operatorname{div} \mathbf{v}_{N_k}\right) u_{N_k}\,\varphi\,dx\,dt.\end{aligned} \tag{3.28}$$

Let $z_N = u_N\,\varphi$. For all $t \in (0,T)$, let $z_N^h(\cdot,t) \in S_p^N \cap H_0^1(a,b)$ be the $H^1(a,b)$ projection of z_N so that, for all $v \in S_p^N \cap H_0^1(a,b)$,

$$\int_a^b \frac{\partial z_N^h(\cdot,t)}{\partial x}\,\frac{\partial v}{\partial x}\,dx = \int_a^b \frac{\partial z_N(\cdot,t)}{\partial x}\,\frac{\partial v}{\partial x}\,dx.$$

We then show that, as $k \to \infty$, the right-hand side of (3.28) is nonpositive:

$$
\begin{aligned}
&\int_{\Omega_T} (\text{div } u_N)\; u_N\, \varphi\, dx\, dt = \int_{\Omega_T} (\text{div } u_N)\; z_N\, dx\, dt \\
&= \int_{\Omega_T} (\text{div } u_N)\; z_N^h\, dx\, dt + \int_{\Omega_T} (\text{div } u_{N_k})\; \left(z_N - z_N^h\right)\, dx\, dt \\
&= -\varepsilon_N \int_{\Omega_T} \frac{\partial z_N^h}{\partial x}\, \frac{\partial}{\partial x}\left(Q_N u_N\right)\, dx\, dt + \int_{\Omega_T} (\text{div } u_N)\; \left(z_N - z_N^h\right)\, dx\, dt \\
&= -\varepsilon_N \int_{\Omega_T} \frac{\partial z_N}{\partial x}\, \frac{\partial}{\partial x}\left(Q_N u_N\right)\, dx\, dt + \int_{\Omega_T} (\text{div } u_N)\; \left(z_N - z_N^h\right)\, dx\, dt \\
&= -\varepsilon_N \int_{\Omega_T} \frac{\partial z_N}{\partial x}\, \frac{\partial u_N}{\partial x}\, dx\, dt + \varepsilon_N \int_{\Omega_T} \frac{\partial z_N}{\partial x}\, \frac{\partial}{\partial x}\left[\left(I - Q_N\right) u_N\right]\, dx\, dt \\
&\quad + \int_{\Omega_T} (\text{div } u_N)\; \left(z_N - z_N^h\right)\, dx\, dt \\
&= -\varepsilon_N \int_{\Omega_T} \frac{\partial}{\partial x}\left(u_N\, \varphi\right)\, \frac{\partial u_N}{\partial x}\, dx\, dt \\
&\quad + \varepsilon_N \int_{\Omega_T} \frac{\partial z_N}{\partial x}\, \frac{\partial}{\partial x}\left[\left(I - Q_N\right) u_N\right]\, dx\, dt + \int_{\Omega_T} (\text{div } u_N)\; \left(z_N - z_N^h\right)\, dx\, dt \\
&= -\varepsilon_N \int_{\Omega_T} \varphi\, \left|\frac{\partial u_N}{\partial x}\right|^2\, dx\, dt - \varepsilon_N \int_{\Omega_T} u_N \frac{\partial \varphi}{\partial x}\, \frac{\partial u_N}{\partial x}\, dx\, dt \\
&\quad + \varepsilon_N \int_{\Omega_T} \frac{\partial z_N}{\partial x}\, \frac{\partial}{\partial x}\left[\left(I - Q_N\right) u_N\right]\, dx\, dt + \int_{\Omega_T} (\text{div } u_N)\; \left(z_N - z_N^h\right)\, dx\, dt.
\end{aligned}
\tag{3.29}
$$

For the second term on the right-hand side of (3.29), we have that

$$
\begin{aligned}
\left| -\varepsilon_N \int_{\Omega_T} u_N \frac{\partial \varphi}{\partial x}\, \frac{\partial u_N}{\partial x}\, dx\, dt \right| &\le \varepsilon_N\, \|u_N\|_{L^\infty(\Omega_T)} \left\| \frac{\partial u_N}{\partial x} \right\|_{L^2(\Omega_T)} \left\| \frac{\partial \varphi}{\partial x} \right\|_{L^2(\Omega_T)} \\
&\le C\, \sqrt{\varepsilon_N} \left\| \frac{\partial \varphi}{\partial x} \right\|_{L^2(\Omega_T)} \to 0 \text{ as } N \to \infty.
\end{aligned}
$$

For the third term on the right-hand side of (3.29), we have that

$$
\begin{aligned}
&\left| \varepsilon_N \int_{\Omega_T} \frac{\partial z_N}{\partial x}\, \frac{\partial}{\partial x}\left[\left(I - Q_N\right) u_N\right]\, dx\, dt \right| \le \varepsilon_N \left\| \frac{\partial z_N}{\partial x} \right\|_{L^2(\Omega_T)} \left\| \frac{\partial}{\partial x}\left[\left(I - Q_N\right) u_N\right] \right\|_{L^2(\Omega_T)} \\
&= \varepsilon_N \left\| \frac{\partial}{\partial x}\left(u_N\, \varphi\right) \right\|_{L^2(\Omega_T)} \left\| \frac{\partial}{\partial x}\left[\left(I - Q_N\right) u_N\right] \right\|_{L^2(\Omega_T)} \le \varepsilon_N \left\| \frac{\partial}{\partial x}\left[\left(I - Q_N\right) u_N\right] \right\|_{L^2(\Omega_T)} \\
&\qquad\qquad \left(\|\varphi\|_{L^\infty(\Omega_T)} \left\| \frac{\partial u_N}{\partial x} \right\|_{L^2(\Omega_T)} + \|u_N\|_{L^\infty(\Omega_T)} \left\| \frac{\partial \varphi}{\partial x} \right\|_{L^2(\Omega_T)} \right) \\
&\le C\, \sqrt{\varepsilon_N} \left\| \frac{\partial}{\partial x}\left[\left(I - Q_N\right) u_N\right] \right\|_{L^2(\Omega_T)} \left(\|\varphi\|_{L^\infty(\Omega_T)} + \sqrt{\varepsilon_N} \left\| \frac{\partial \varphi}{\partial x} \right\|_{L^2(\Omega_T)} \right) \to 0 \text{ as } N \to \infty.
\end{aligned}
$$

For the fourth term on the right-hand side of (3.29), we have that

$$
\begin{aligned}
&\left| \int_{\Omega_T} (\text{div } u_N)\; \left(z_N - z_N^h\right)\, dx\, dt \right| \le \|\text{div } u_N\|_{L^2(\Omega_T)}\, \left\|z_N - z_N^h\right\|_{L^2(\Omega_T)} \\
&\le C\, h_N\, \|\text{div } u_N\|_{L^2(\Omega_T)} \left\| \frac{\partial z_N}{\partial x} \right\|_{L^2(\Omega_T)} \le C\, \frac{h_N}{\sqrt{\varepsilon_N}} \left\| \frac{\partial z_N}{\partial x} \right\|_{L^2(\Omega_T)}
\end{aligned}
$$

$$= C\,\frac{h_N}{\sqrt{\varepsilon_N}}\left\|\frac{\partial}{\partial x}\left(u_N\,\varphi\right)\right\|_{L^2(\Omega_T)}$$
$$\leq C\,\frac{h_N}{\sqrt{\varepsilon_N}}\left(\|u_N\|_{L^\infty(\Omega_T)}\left\|\frac{\partial\varphi}{\partial x}\right\|_{L^2(\Omega_T)}+\|\varphi\|_{L^\infty(\Omega_T)}\left\|\frac{\partial u_N}{\partial x}\right\|_{L^2(\Omega_T)}\right)$$
$$\leq C\Big(\frac{h_N}{\sqrt{\varepsilon_N}}\left\|\frac{\partial\varphi}{\partial x}\right\|_{L^2(\Omega_T)}+\frac{h_N}{\varepsilon_N}\,\|\varphi\|_{L^\infty(\Omega_T)}\Big)\to 0 \text{ as } N\to\infty.$$

Thus, we have shown that the second, third, and fourth terms on the right-hand side of (3.29) vanish as $N\to\infty$. Since the first term is clearly nonpositive, we have that

$$\int_{\Omega_T}\left[\frac{\partial}{\partial t}\left(\frac{\overline{u}^2}{2}\right)+\frac{\partial}{\partial x}\left(\frac{\overline{u}^3}{3}\right)\right]\varphi\,dx\,dt=\liminf_{k\to\infty}\int_{\Omega_T}\left(\operatorname{div}\,u_{N_k}\right)\,u_{N_k}\,\varphi\,dx\,dt\leq 0$$

so that the $\overline{u}$ is the entropy solution of (3.4). This completes the proof of Theorem 3.1.

3.8. Verifying the hypotheses of Theorem 3.1. In the hierarchical finite element formulation (3.6), we have to choose ε_N, m, and the form of Q_N for $k\leq m$. Let $0<\delta\leq\theta\leq 1$. We then choose

$$\varepsilon_N=C\,{h_N}^{\theta},\qquad m_H\leq\frac{\delta\,N}{2},\qquad\text{and}\qquad Q_{k,i}=\begin{cases}0, & k\leq m_H,\\ 1, & k>m_H.\end{cases}$$

It is then evident that $\varepsilon_N, h_N\to 0$ as $N\to\infty$ so (3.7) holds. Since $0<\theta\leq 1$, $\frac{\varepsilon_N}{h_N}=C\,{h_N}^{\theta-1}\geq C$ so that (3.8) also holds.

Let $v\in S_p^N$; $(I-Q_N)$ is simply an interpolation operator on a coarse grid so that

$$\|(I-Q_N)\,v\|_{L^2(a,b)}\leq C\,\|v\|_{L^2(a,b)}\,.$$

Q_N retains the high frequencies of a function, so $(I-Q_N)$ eliminates them: $Q_{k,i}=1\Rightarrow 1-Q_{k,i}=0$ for $k>m_H$ so that $(I-Q_N)\,v\in S_p^{m_H}$. Using a standard inverse estimate,

$$\left\|\frac{\partial}{\partial x}\left[(I-Q_N)\,u_N\right]\right\|_{L^2(a,b)}\leq C\,\left(h_{m_H}\right)^{-1}\|(I-Q_N)\,v\|_{L^2(a,b)}$$
$$\leq C\,M^{m_H}\,\|(I-Q_N)\,v\|_{L^2(a,b)}\leq C\,M^{\frac{N\,\delta}{2}}\,\|(I-Q_N)\,v\|_{L^2(a,b)}$$
$$\leq C\,\left(\frac{\nu}{h_N}\right)^{\frac{\delta}{2}}\|(I-Q_N)\,v\|_{L^2(a,b)}\leq C\,\left(\frac{\nu}{h_N}\right)^{\frac{\delta}{2}}\|v\|_{L^2(a,b)}$$
$$=C\,\sqrt{\nu^\delta}\,{h_N}^{-\frac{\delta}{2}}\,\|v\|_{L^2(a,b)}$$

and

$$\begin{aligned}\sqrt{\varepsilon_N}\left\|\frac{\partial}{\partial x}\left[(I-Q_N)\,u_N\right]\right\|_{L^2(a,b)}&\leq C\,\sqrt{\nu^\delta}\,\sqrt{\frac{\varepsilon_N}{h_N^\delta}}\,\|v\|_{L^2(a,b)}\\&=C\,\sqrt{{h_N}^{\theta-\delta}}\,\|v\|_{L^2(a,b)}\,.\end{aligned}\tag{3.30}$$

Since $\delta\leq\theta$, we have that ${h_N}^{\theta-\delta}\leq C$; therefore, (3.9) is satisfied.

Since $(I-Q_N)$ is an interpolation operator on a coarse grid, for all $v\in S_p^N$,

$$\left\|\frac{d}{dx}\left(Q_N v\right)\right\|_{L^2(a,b)}=\left\|\frac{dv}{dx}-\frac{d}{dx}\left[(I-Q_N)\,v\right]\right\|_{L^2(a,b)}\leq C\left\|\frac{dv}{dx}\right\|_{L^2(a,b)}.$$

Therefore, (3.10) is satisfied. This completes the verification of the hypotheses (3.7)–(3.10) of Theorem 3.1 that are used to prove the convergence of the hierarchical finite element approximations.

To verify the hypotheses (3.11) and (3.12) of Theorem 3.1 that are used to prove the convergence of the hierarchical finite element approximations to the entropy solution, we must choose $0 < \theta < 1$. In this case, $\frac{\varepsilon_N}{h_N} = C\,{h_N}^{\theta-1} \to \infty$ as $N \to \infty$ so that (3.11) holds. Since now $\delta < \theta$ so that ${h_N}^{\theta-\delta} \to 0$ as $N \to \infty$, (3.30) implies that (3.12) holds.

4. A simple computational illustration. We consider the simple periodic problem for the Burgers equation in one dimension:

$$\begin{cases} \dfrac{\partial u}{\partial t} + \dfrac{\partial}{\partial x}\left(\dfrac{u^2}{2}\right) = 0 \text{ on } (-1,+1) \times (0,T) \\ u\,(-1,t) = u\,(+1,t) \text{ for all } t \in (0,T) \\ u\,(x,0) = 1 + \dfrac{1}{2}\sin\left(\pi x\right). \end{cases} \tag{4.1}$$

A means for establishing the exact solution of this problem is given in [8, 16]. All of our numerical results were generated using the finite element library `deal.II` [2]. More extensive computational experimentations are provided in [3, 4].

In (2.1), the values of several parameters must be chosen. We set $\varepsilon_N = h_N$ and add diffusion only to the finest level: $Q_{N;n,\imath} = 0$ for $n < N$. Neither of these choices satisfies the requirements of Theorem 3.1 for convergence to the entropy solution. Even with the smaller diffusion term, however, our numerical experiments indicate that the approximations still converge to the correct solution.

After spatial discretization is effected using linear hierarchical finite element functions, the resulting system of ordinary differential equations is integrated using a third-order, strong, stability-preserving Runge–Kutta method found in [11], with time step Δt that satisfies the CFL condition $\Delta t/h_N \sup u \le 0.2$.

The exact and discrete solutions of (4.1) are given in Figure 5. Because we are approximating a discontinuous solution with continuous piecewise polynomials, we see Gibbs oscillations near the discontinuity; see Figure 5. A simple post-processing strategy to remove the oscillations is to set the coefficients of the hierarchical expansion to zero around the discontinuity. The question then becomes how to determine the location of the discontinuity. Let $\beta_{n+1,\imath}$ be a high frequency hierarchical coefficient in the discrete solution. Let $\beta_{n,\jmath}$ be the parent hierarchical coefficient, so the support of $\psi_{n+1,\imath}$ is a subset of $\psi_{n,\jmath}$. If the solution is continuously differentiable in the region of the support of $\psi_{n,\jmath}$, then $\beta_{n,\jmath}/\beta_{n+1,\imath} \approx 2$. Thus, our simple post-processing strategy is as follows: For the highest four frequencies, if a hierarchical coefficient is larger than half the value of its parent, then it is set to zero. Our simple post-processing strategy only affects the region around a discontinuity, but it has the disadvantage of smoothing across the discontinuity. See Figure 6. We note that post-processing strategies must also be applied in the spectral viscosity method in order to reduce the size of the Gibbs oscillations.

In Table 1, we use the L^1 norm to measure errors in the approximate solution. Near a discontinuity, we are limited to how well a piecewise polynomial can approximate a solution. We are more interested in the convergence rates in the smooth regions. We therefore exclude a region of length 0.2 around the discontinuity in our error calculations. We see that away from the discontinuity, we achieve the optimal

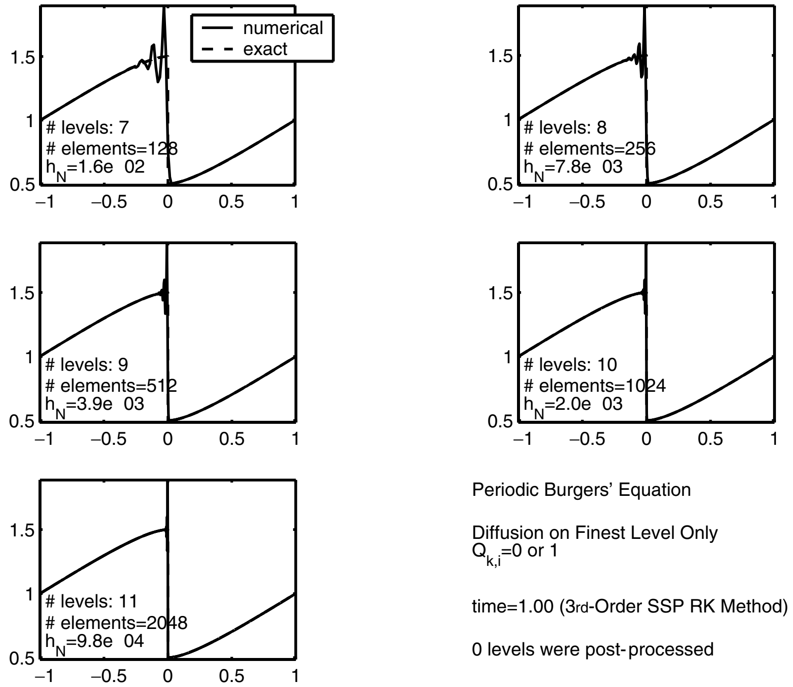

FIG. 5. *Solution of periodic Burgers equation with linear polynomials (without post-processing).*

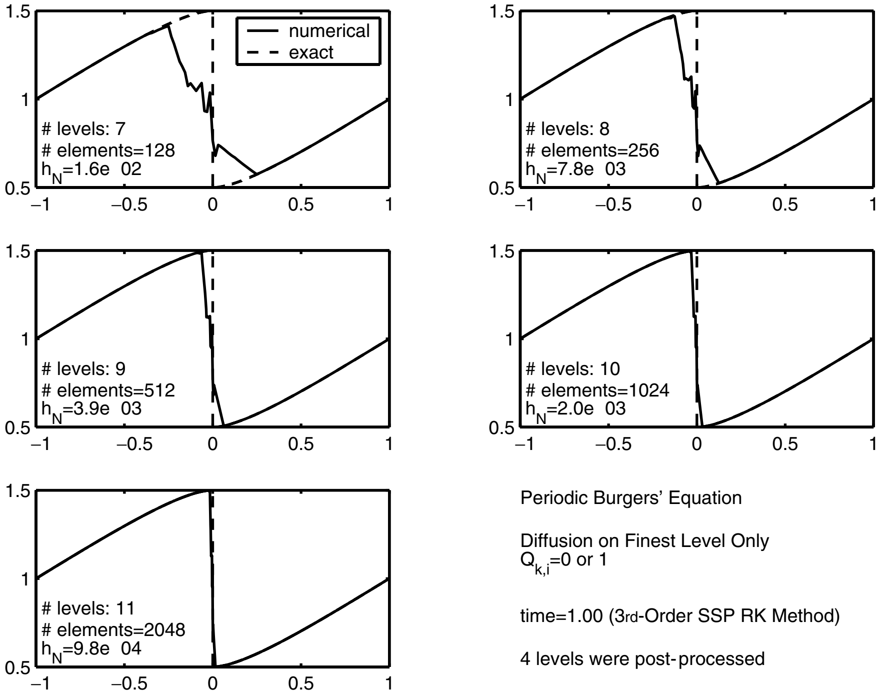

FIG. 6. *Solution of periodic Burgers equation with linear polynomials (with post-processing).*

Table 1
Convergence rate for the periodic Burgers equation using linear hierarchical basis functions.

	without post-processing		with post-processing

12	9.230e-07	2.00	9.230e-07	2.00
13	2.307e-07	2.00	2.307e-07	2.00
14	5.768e-08	2.00	5.768e-08	2.00

error rate with or without post-processing. We have no theoretical justification for these convergence rates, but this is a common failing for conservation laws.

5. Concluding remarks. Initial results for the new method seem promising. We have a stable finite element method which, in some cases, attains quasi-optimal convergence rates in smooth regions. We also have developed a theoretical foundation for understanding why the method works. These results, however, are preliminary. There are potential pitfalls awaiting in more complicated problems, but there is also untapped potential within the framework. Hierarchical bases, for example, should provide a suitable environment for implementing adaptive strategies, both for the grid and the diffusion term.

Acknowledgments. The authors wish to thank Professor Eitan Tadmor and Dr. Curtis Ober for many helpful discussions.

A UNIFIED ANALYSIS FOR CONFORMING AND NONCONFORMING STABILIZED FINITE ELEMENT METHODS USING INTERIOR PENALTY[*]

ERIK BURMAN[†]

Abstract. We discuss stabilized Galerkin approximations in a new framework, widening the scope from the usual dichotomy of the discontinuous Galerkin method on the one hand and Petrov–Galerkin methods such as the SUPG method on the other. The idea is to use interior penalty terms as a means of stabilizing the finite element method using conforming or nonconforming approximation, thus circumventing the need of a Petrov–Galerkin-type choice of spaces. This is made possible by adding a higher-order penalty term giving L^2-control of the jumps in the gradients between adjacent elements. We consider convection-diffusion-reaction problems using piecewise linear approximations and prove optimal order a priori error estimates for two different finite element spaces, the standard H^1-conforming space of piecewise linears and the nonconforming space of piecewise linear elements where the nodes are situated at the midpoint of the element sides (the Crouzeix–Raviart element). Moreover, we show how the formulation extends to discontinuous Galerkin interior penalty methods in a natural way by domain decomposition using Nitsche's method.

Key words. convection-diffusion problem, interior penalty, finite element approximation, Crouzeix–Raviart element

1. Introduction.

The solution of convection-diffusion problems with dominating convection using finite element methods has been the object of much research during the last 30 years. Essentially, the field has been separated into two main branches, Petrov–Galerkin methods in cases where conforming approximation is used [4, 16] and discontinuous Galerkin with interior penalty when nonconforming approximation is used [19, 17, 13]. Of course the discontinuous Galerkin method may also be supplied with an SUPG-type stabilization as in [25], and there is the SUPG method using the Crouzeix–Raviart element [15, 14, 20], which needs both interior penalty and Petrov–Galerkin-type approximation spaces to be stable in the limit of vanishing diffusion. So the current state of affairs seems to be that Petrov–Galerkin-type approximations are necessary for all approximations except the discontinuous Galerkin method. This is not satisfactory since the SUPG-method in practice suffers from several shortcomings:

- The mass matrix may not be lumped. This may severely reduce performance when solving large reactive systems using low-order elements.
- The consistency requirements practically impose the use of a space-time finite element approach for time-stepping, using discontinuous approximation in time. The practical implementation of such techniques is rather involved and requires additional unknowns.
- The stabilization parameter depends on the diffusion. This may lead to complications when computing the solution of large coupled systems with a

[†] Institut d'analyse et calcul scientifique, Ecole Polytechnique Federale de Lausanne, CH 1015 Lausanne, Switzerland (Erik.Burman@epfl.ch).

complex diffusion matrix or in cases when the diffusion/viscosity depends in a strongly nonlinear way on the solution.

The discontinuous Galerkin (DG) method, on the other hand, behaves well with respect to these above mentioned points but suffers from the fact that it involves a larger number of degrees of freedom due to the discontinuous approximation space. In fact, memory requirements of the DG method are typically a factor 7–10 larger than those of the SUPG method. Hence there is a strong motivation to find methods that use more economic spaces that do not suffer from the same disadvantages as the SUPG method.

In this paper we will go beyond this dichotomy between conforming finite element methods using Petrov–Galerkin-type stabilizations and discontinuous Galerkin methods using interior penalty-type stabilization and adopt a different point of view, where the interior penalty is the main stabilization. We also show that interior penalty stabilization is sufficient not only for the discontinuous Galerkin method but also for conforming piecewise linear finite element approximations, even in the case when the same trial and test spaces are used. The outline of the paper is as follows: In the next section we introduce the model problem and discuss in more detail this new framework; in section 3 we then consider the limiting case of conforming piecewise linear approximation stabilized by using only an interior penalty term; we prove stability and a priori error estimates. Then we use these results in the general framework and extend the method to the nonconforming case of Crouzeix–Raviart-type finite element approximation (continuity at the midpoints of the element sides) in section 4. In section 5 we discuss domain decomposition using Nitsche's method and how this naturally leads to discontinuous Galerkin-type interior penalty methods. The performance of the method is shown numerically in section 6. Finally, we draw some conclusions in section 7.

2. A new framework.

As a model problem we propose the convection-diffusion-reaction equation

$$\left\{ \begin{aligned} \beta\cdot\nabla u + \sigma u - \varepsilon\Delta u &= f \qquad \text{in } \Omega,\\ u &= 0 \qquad \text{on } \partial\Omega, \end{aligned}\right. \tag{2.1}$$

where Ω is a bounded open connected subset of $\mathbb{R}^d$ with a Lipschitz boundary $\partial\Omega$, $d = 2$ or 3 is the space dimension, $\beta \in [W^{1,\infty}(\Omega)]^d$ is a velocity field, $\varepsilon > 0$ is a diffusion coefficient (that may be zero if the boundary conditions are modified), and $\sigma > 0$ is the reaction coefficient, $f \in L^2(\Omega)$. We will use the notation $\partial\Omega_{in}$ ($\partial\Omega_{out}$) for the subset of $\partial\Omega$ such that $\beta\cdot n < 0$ ($\beta\cdot n > 0$). We assume that the following standard coercivity condition holds:

$$\sigma - \frac{1}{2}\nabla\cdot\beta \geq \sigma_0 > 0, \tag{2.2}$$

and we define the associated parameter σ_1 by

$$\sigma_1 = \text{ess sup}_{x\in\Omega}\frac{|\sigma - \nabla\cdot\beta|^2}{\sigma_0}.$$

Problem (2.1) is well-posed thanks to the Lax–Milgram lemma, and we will always assume that the solution is sufficiently smooth, i.e., $u \in H^2(\Omega)$.

Remark 2.1. An analysis including the case $\sigma_0 = 0$ could be undertaken using exponentially weighted test functions following [21] but is beyond the scope of the present paper.

For the finite element formulation of this problem, we introduce some additional notation. Let $\mathcal{T}_h$ be a triangulation of Ω, without hanging nodes, and let V_h be a space of (conforming or nonconforming) piecewise linear functions defined on $\mathcal{T}_h$. Let S_i be a vertex of $\mathcal{T}_h$, $\varphi_i \in V_h$ the associated nodal basis function, and denote by Ω_i the macro-element formed by the elements K in $\mathcal{T}_h$ sharing vertex S_i. Let $\mathcal{E}_i$ denote the set of faces connected to S_i. Let h_K denote the diameter of an element K and set $h = \max_{K\in\mathcal{T}_h} h_K$. Moreover, we shall assume that there exists a constant $\rho > 0$ such that for all vertices S_i in $\mathcal{T}_h$, we have

$$\max_{e\in\mathcal{E}_i} h_e \leq \rho \min_{e\in\mathcal{E}_i} h_e, \tag{2.3}$$

where $h_e = |e|$ is the length of edge e. Property (2.3) was introduced in [5] and is a local quasi-uniformity property of the mesh. It implies that for each node S_i there is a finite number, n_ρ, of elements in Ω_i. The jump $[x]_f$ of a quantity x over an interior face f will be defined by $[x(\xi)]_f = \lim_{\epsilon\to 0^+}(x(\xi - n_f\epsilon) - x(\xi + n_f\epsilon))$, where n_f denotes a normal vector to the face f having an arbitrary but fixed orientation and $\xi \in f$. The subscript is omitted when there is no ambiguity. For faces such that $f \subset \partial\Omega$, we define n_f as the outward pointing normal and set $[x]_f \equiv 0$. By $\{x\}_f$ we denote the average value of x over face f, $\{x(\xi)\}_f = \lim_{\epsilon\to 0^+}\frac{1}{2}(x(\xi - n_f\epsilon) + x(\xi + n_f\epsilon))$. Tangential vectors of a face f will be denoted τ_f ($\tau_f \cdot n_f = 0$). Furthermore, we will use the notation $(x,y)_X = \int_X x\cdot y \,\mathrm{dx}$, $\quad\langle x,y\rangle_{\partial X} = \int_{\partial X} x\cdot y \,\mathrm{ds}$ with the elementwise counterparts $(x,y)_{X,h} = \sum_{K\in X}\int_K x\cdot y\,\mathrm{dx}$ and $\quad\langle x,y\rangle_{\partial X,h} = \sum_{f\in\partial X}\int_f x\cdot y\,\mathrm{ds}$. Let $\|x\|_{\partial X} = (x,x)_X^{1/2}$ denote the L^2-norm over X and $|x|_X = \langle x,x\rangle_{\partial X}^{1/2}$ the L^2-norm over ∂X with the elementwise counterparts $\|x\|_{X,h} = (x,x)_{X,h}^{1/2}$ and $|x|_{\partial X,h} = \langle x,x\rangle_{\partial X,h}^{1/2}$, respectively. When the subscript X or ∂X is omitted, the norm is taken over the domain Ω or its boundary $\partial\Omega$. The norm of the space $H^i(X)$ will be denoted $\|x\|_{i,X}$ with $i = 1,2$. We will use c and C to denote generic positive constants independent of h_K but not necessarily of the local mesh geometry.

The general discretization for (2.1) typically takes the following form: Find $u_h \in V_h$ such that

$$A(u_h,v_h) + \sum_{i=0}^{1} J_i(u_h,v_h) = (f,v_h) \quad \forall v_h \in W_h, \tag{2.4}$$

where

$$\begin{aligned}(2.5)\qquad & \\ A(u_h,v_h) &= (\sigma u_h, v_h) + (\varepsilon\nabla u_h, \nabla v_h)_h + (\beta\cdot\nabla u_h, v_h)_h \\ -\tfrac{1}{2}\textstyle\sum_K\Big(\langle\beta\cdot n[u_h],\{v_h\}\rangle_{\partial K\setminus\partial\Omega} &+ \langle\{\varepsilon\nabla u_h\cdot n\},[v_h]\rangle_{\partial K\setminus\partial\Omega} + \langle\{\varepsilon\nabla v_h\cdot n\},[u_h]\rangle_{\partial K\setminus\partial\Omega}\Big)^* \\ &- \langle\varepsilon\nabla u_h\cdot n, v_h\rangle_h - \langle\varepsilon\nabla v_h\cdot n, u_h\rangle_h \\ &+ \left\langle\gamma_{bc}\tfrac{\varepsilon}{h}u_h, v_h\right\rangle + \langle|\beta\cdot n|u_h, v_h\rangle_{\partial\Omega_{in}},\end{aligned}$$

$$J_0(u_h,v_h) = \sum_K \langle\gamma_0(h)[u_h],[v_h]\ \rangle_{\partial K\setminus\partial\Omega},$$

and

$$J_1(u_h,v_h) = \sum_K \langle\gamma_1(h)[\nabla u_h],[\nabla v_h]\ \rangle_{\partial K\setminus\partial\Omega}, \tag{2.6}$$

with $\gamma_i(h) = \tilde{\gamma}_i h^{s_i}$ and s_i chosen so as to obtain optimal stability and approximation properties. W_h denote some test space, the choice of which will be discussed later. γ_{bc} denotes the penalization parameter for the weakly imposed boundary condition. Moreover, we have marked with an asterisk the terms that are present only when nonconforming approximation spaces are used. It should be noted that the term $J_1(u_h, v_h)$ can be decomposed in the streamline and the crosswind part. To this end, we assume that $|\beta| > 0$ and define the unit vector parallel to β as $e_\beta = \frac{\beta}{|\beta|}$ and the unit vector orthogonal to β such that $e_{\beta^\perp}$. Clearly we may decompose the gradient in the orthogonal basis formed by $\{e_\beta, e_{\beta^\perp}\}$ (in two space dimensions).

$$\nabla u_h = (e_\beta \cdot \nabla u_h) e_\beta + (e_{\beta^\perp} \cdot \nabla u_h) e_{\beta^\perp}.$$

Plugging this into (2.6) yields for the jumps

$$\begin{aligned}[\nabla u_h] \cdot [\nabla v_h] &= [(e_\beta \cdot \nabla u_h) e_\beta + (e_{\beta^\perp} \cdot \nabla u_h) e_{\beta^\perp}] \cdot [(e_\beta \cdot \nabla v_h) e_\beta + (e_{\beta^\perp} \cdot \nabla v_h) e_{\beta^\perp}] \\ &= [e_\beta \cdot \nabla u_h][e_\beta \cdot \nabla v_h] + [e_{\beta^\perp} \cdot \nabla u_h][e_{\beta^\perp} \cdot \nabla v_h].\end{aligned}$$

This implies that one may use the following form of the stabilization term:

$$\begin{aligned}J_1(u_h, v_h) &= \textstyle\sum_K \left\langle \gamma_{1,\beta}(h)[e_\beta \cdot \nabla u_h], [e_\beta \cdot \nabla v_h] \right\rangle_{\partial K \setminus \partial\Omega} \\ &\quad + \textstyle\sum_K \left\langle \gamma_{1,\beta^\perp}(h)[e_{\beta^\perp} \cdot \nabla u_h], [e_{\beta^\perp} \cdot \nabla v_h] \right\rangle_{\partial K \setminus \partial\Omega},\end{aligned}$$

which coincides with (2.6) when $\gamma_{1,\beta}(h) = \gamma_{1,\beta^\perp}(h)$. For stability, however, it is only essential that the parameter $\gamma_{1,\beta}(h)$ is large enough. The parameter $\gamma_{1,\beta^\perp}(h)$ may be set to zero. We note that in the case of piecewise linear continuous functions u_h, there holds $[\tau_f \cdot \nabla u_h]_f = 0$. Using this observation, we may introduce some further simplifications of the stabilization term. This time, consider the decomposition of the gradient in the directions normal and tangential to the element edge; for the jump in the streamline derivative we then obtain

$$\begin{aligned}[\beta \cdot \nabla u_h]_f &= [\beta \cdot ((n_f \cdot \nabla u_h) n_f + (\tau_f \cdot \nabla u_h) \tau_f)]_f \\ &= [\beta \cdot n_f (n_f \cdot \nabla u_h)]_f + [\beta \cdot \tau_f (\tau_f \cdot \nabla u_h)]_f.\end{aligned}$$

However, since the tangential jump is zero, the second term in the right-hand side vanishes and we may readily deduce that on each face we have $[\beta \cdot \nabla u_h]_f [\beta \cdot \nabla v_h]_f = |\beta \cdot n_f|^2 [n_f \cdot \nabla u_h]_f [n_f \cdot \nabla v_h]_f$. Using once again the fact that the tangential jump is zero, it follows that the product of the jumps in the normal component equals the scalar product of the jump in the full gradient; $[\beta \cdot \nabla u_h]_f [\beta \cdot \nabla v_h]_f = |\beta \cdot n_f|^2 [\nabla u_h]_f \cdot [\nabla v_h]_f$. Hence in this case the streamline diffusion character of the stabilization may be included in the parameter γ_1 in (2.6). We also recall that the addition of stabilization in the crosswind direction increases the accuracy of the approximation close to interior layers; see [18]. The first term on the second line of the expression for $A(u_h, v_h)$ is related to the consistency error of the convective term. This term can be chosen in a variety of different ways, related to what numerical flux one wishes to use in the nonconforming method. We will not pursue this further here, but only point out that the whole parenthesis marked * vanishes for conforming approximation. Note that in the above formulation we impose the boundary conditions weakly, see [22]; this is natural when considering the general framework, since the finite element solution may be nonconforming. It also has some advantages from the point of view of the analysis. For results using conforming piecewise linear approximation and strongly imposed boundary conditions, we refer to [6]. The SUPG method is typically obtained by choosing $\gamma_1 = 0$ and taking $W_h = \{w_h : w_h = v_h + \delta\beta \cdot \nabla v_h,\, v_h \in V_h\}$. Then γ_0 has to be chosen correctly in order to ensure the coercivity of $A(u_h, v_h)$ in the nonconforming case. However, our main concern in this paper is the case $W_h = V_h$. We will show that the use of approximation spaces that previously needed SUPG-type stabilization may, in fact, be stabilized using interior penalty only. The key observation is that the following inequality holds:

$$\inf_{\zeta_h \in V_h} \|h^{1/2}(\beta \cdot \nabla u_h - \zeta_h)\|^2 \leq J_1(u_h, u_h). \tag{2.7}$$

This means that we only stabilize the scales that are not already resolved by the finite element space; in this sense this is a minimal stabilizing procedure [3]. Other methods following similar ideas but using hierarchic meshes or projections have been proposed in [11, 9]. The inequality (2.7) was originally proved in [6] but only for constant velocities and uniform meshes. In this paper the essential restrictions that we impose are that β should belong to the space of piecewise linear continuous functions and that the computational mesh is locally quasi-uniform. Moreover, the general framework allows us to circumvent the *inf-sup* condition proved in [6]. The technique of proof introduced in this paper is flexible and may be used in the analysis of more complex problems. The low-order interior penalty term $J_0(u_h, v_h)$ should ensure coercivity and continuity of the bilinear form whereas the term $J_1(u_h, v_h)$ is what makes the method stable in the hyperbolic limit. Clearly for continuous approximations $J_0(u_h, v_h) = 0$, but in this case $A(u_h, v_h)$ is coercive without stabilization (if we discard the boundary conditions for the moment). For the discontinuous Galerkin method, on the other hand, $\beta \cdot \nabla u_h \in V_h$ so that (2.7) holds with $\gamma_1 \equiv 0$.

So it seems that the right dichotomy is between methods using Petrov–Galerkin-type stabilization and methods using interior penalty-type stabilization and not between conforming and nonconforming approximations. In this new framework the guideline is to add only the amount of stabilization needed to control the part of the streamline derivative that cannot be represented by the approximation space. This can be seen in the analysis leading to (2.7): a big space yields a small value of γ_1 and a small space yields a big value of γ_1. The Petrov–Galerkin approach, on the other hand, enforces stability in a much stronger sense when modifying the test space, and the stabilization will be the same regardless of the properties of the approximating space. We will first prove inequality (2.7) in the case where the space of piecewise linear H^1-conforming functions is a subspace of V_h. Let

$$P_c^1 = \{v_h : v_h \in H^1(\Omega); v_h|_K \in P_1(K)\}.$$

The crucial part is to prove that the jumps in the gradient can control some interpolation error of the streamline derivative, $\|h^{1/2}(\beta \cdot \nabla u_h - \pi_h^*(\beta \cdot \nabla u_h))\|$. For simplicity we will consider the case of two-space dimensions; the extension to three-space dimensions is straightforward.

THEOREM 2.2 (stability). *Assume that $P_c^1 \subset V_h$. Let $\beta \in [P_c^1]^2$ and let $u_h \in V_h$. Then there exists an interpolation operator $\pi_h^* : \beta \cdot \nabla V_h \to P_c^1$ and a constant $\tilde{\gamma}_1 \geq c_0 > 0$, depending only on the local mesh geometry, such that*

$$\|h^{1/2}(\beta \cdot \nabla u_h - \pi_h^*(\beta \cdot \nabla u_h))\|^2 \leq J_1(u_h, u_h)$$

with

$$J_1(u_h,u_h) = \sum_K \int_{\partial K\setminus\partial\Omega} \tilde{\gamma}_1 h_{\partial K}^2 [\beta\cdot\nabla u_h]^2 \; ds. \tag{2.8}$$

Proof. First we will define the operator π_h^*. To this end we recall a quasi-interpolant due to Oswald (see [23, 12]). Consider a node S_i and let $\nabla u_h(S_i)|_K$ denote the value of ∇u_h in the element K and in node S_i. Then let

$$\pi_h^*(\beta\cdot\nabla u_h)(S_i) = \frac{1}{n_i}\sum_{K\subset\Omega_i} \beta(S_i)\cdot\nabla u_h(S_i)|_K, \tag{2.9}$$

where n_i denotes the number of triangles in Ω_i. Let φ_j, $j=1,2,3$, be the basis functions on some arbitrary element K' in $\mathcal{T}_h$. Denoting the locally numbered nodes of K' by s_i, with associated macro-elements Ω_i, $i=1,2,3$, there holds $\varphi_j(s_i)=\delta_{ij}$, where δ_{ij} denotes the Kronecker delta. We now consider the projection error on the element K'.

$$\begin{aligned} &\|h_{K'}^{1/2}(\beta\cdot\nabla u_h - \pi_h^*(\beta\cdot\nabla u_h))\|_{K'}^2 \\ &\quad= \int_{K'} h_{K'}\left(\sum_{j=1}^3\left(\beta(s_j)\cdot\nabla u_h(s_j)|_{K'} - \frac{1}{n_j}\sum_{K\subset\Omega_j}\beta(s_j)\cdot\nabla u_h(s_j)|_K\right)\varphi_j\right)^2 \mathrm{d}x \\ &\quad= \int_{K'} h_{K'}\left(\sum_{j=1}^3\frac{1}{n_j}\sum_{K\subset\Omega_j}\Big(\beta(s_j)\cdot\nabla u_h(s_j)|_{K'} - \beta(s_j)\cdot\nabla u_h(s_j)|_K\Big)\varphi_j\right)^2 \mathrm{d}x. \end{aligned} \tag{2.10}$$

Clearly for any K and K', the difference of the streamline derivatives may be rewritten

$$\beta(s_j)\cdot(\nabla u_h(s_j)|_{K'} - \nabla u_h(s_j)|_K) = \sum_{e\in P(K,K')} [\beta(s_j)\cdot\nabla u_h(s_j)]_e,$$

where $P(K,K')$ is the set of edges between the elements connecting K and K' (the shortest path; see Figure 1) and we may write

$$\begin{aligned} &\|h_{K'}^{1/2}(\beta\cdot\nabla u_h - \pi_h^*(\beta\cdot\nabla u_h))\|_{K'}^2 \\ &\qquad= \int_{K'} h_{K'}\left(\sum_{j=1}^3\frac{1}{n_j}\left(\sum_{K\subset\Omega_j}\sum_{e\in P(K,K')}[\beta(s_j)\cdot\nabla u_h(s_j)]_e\right)\varphi_j\right)^2 \mathrm{d}x. \end{aligned} \tag{2.11}$$

Since V_h is a space of piecewise linears and $\beta\in[P_c^1]^2$, the integrand is a quadratic polynomial on K' and we may use the midpoints on the element sides to evaluate the integral. We let x_k denote the midpoints of the edges and write

$$\begin{aligned} &\|h_{K'}^{1/2}(\beta\cdot\nabla u_h - \pi_h^*(\beta\cdot\nabla u_h))\|_{K'}^2 \\ &\quad= \sum_{k=1}^3\frac{\mathrm{meas}(K')}{3}h_{K'}\left(\sum_{j=1}^3\frac{1}{n_j}\left(\sum_{K\subset\Omega_j}\sum_{e\in P(K,K')}[\beta(s_j)\cdot\nabla u_h(s_j)]_e\right)\varphi_j(x_k)\right)^2. \end{aligned}$$

We now consider $k=3$ and assume that this is the midpoint between s_1 and s_2 (see Figure 1). Using the inequality $(\sum_{i=1}^N a_i)^2 \le N\sum_{i=1}^N a_i^2$ and the inequality

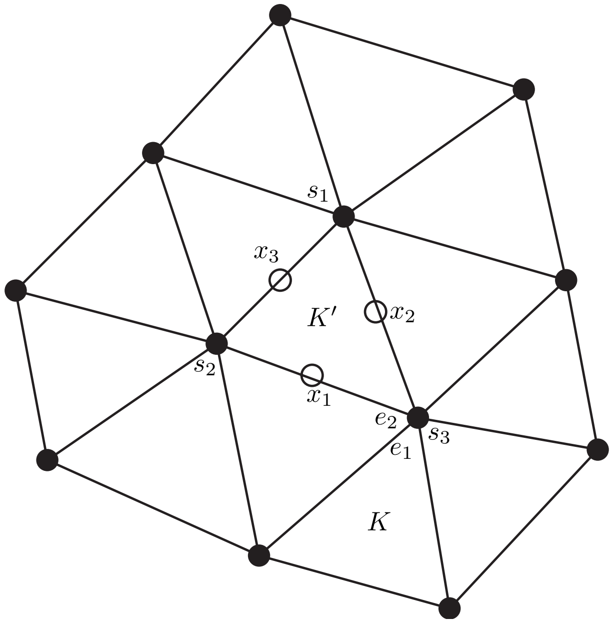

Fig. 1. *Example of element K' with nodes s_1, s_2, and s_3 and the three associated macro-elements Ω_1, Ω_2, and Ω_3. The edges e_1, e_2 separating K' and another triangle K are illustrated, $P(K,K') = \{e_1, e_2\}$, as well as the edge midpoint quadrature points x_1, x_2, and x_3.*

$|\sum_{e\in P(K,K')}[\beta(s_j)\cdot\nabla u_h(s_j)]_e| \le \frac{1}{2}\sum_{e\in\mathcal{E}_j}|[\beta(s_j)\cdot\nabla u_h(s_j)]_e|$, we obtain (recalling that we have $\varphi_1(x_3) = \varphi_2(x_3) = 1/2$ and $\varphi_3(x_3) = 0$ and that in two space dimensions card $\mathcal{E}_j = n_j$)

$$\begin{aligned}
&\frac{\mathrm{meas}(K')}{3} h_{K'} \left(\sum_{j=1}^{3} \frac{1}{n_j}\left(\sum_{K\subset\Omega_j}\sum_{e\in P(K,K')}[\beta(s_j)\cdot\nabla u_h(s_j)]_e\right)\varphi_j(x_3)\right)^2 \\
&\qquad\le \frac{\mathrm{meas}(K')}{3n_j^2} h_{K'} 2\sum_{j=1}^{2} n_j \sum_{K\subset\Omega_j}\frac{n_j}{4}\sum_{e\in\mathcal{E}_j}[\beta(s_j)\cdot\nabla u_h(s_j)]_e^2 \frac{1}{4} \\
&\qquad\qquad\le \frac{\mathrm{meas}(K')}{24} h_{K'} \sum_{j=1}^{2} n_j \sum_{e\in\mathcal{E}_j}[\beta(s_j)\cdot\nabla u_h(s_j)]_e^2.
\end{aligned}$$

It follows from the local quasi-uniformity of the mesh, using three-point quadrature for the edge integral (weights 1/6, 4/6, 1/6), that

$$\frac{\mathrm{meas}(K')}{24} h_{K'} \sum_{j=1}^{2} n_j \sum_{e\in\mathcal{E}_j}[\beta(s_j)\cdot\nabla u_h(s_j)]_e^2 \le \sum_{j=1}^{2}\sum_{e\in\mathcal{E}_j}\int_e \tilde{\gamma}_{1,j} h_e^2 [\beta\cdot\nabla u_h]_e^2 \,\mathrm{d}s,$$

where $\tilde{\gamma}_{1,j} \le \frac{\rho^3 n_j}{4}$. We complete the proof by summing over all Gauss points and all elements leading to a final upper bound on the parameter of $\gamma_1(h) = \tilde{\gamma}_1 h_{\partial K}^2$, with $\tilde{\gamma}_1 \le \frac{\rho^3 n_\rho^2}{4}$. ▯

Remark 2.3. Theorem 2.2 may be extended to finite element spaces using higher-order polynomial approximations. The dependence of the stabilization parameter on the polynomial order is, however, nontrivial and will be a subject for future work.

3. A crucial limit case: Piecewise linear H^1-conforming approximation.

The case of H^1-conforming piecewise linear approximation is important since it is the space for which Petrov–Galerkin-type approximations generally have been used. We will show that this approximation is stable for (2.1) and has (quasi-) optimal convergence properties. We consider H^1-conforming, piecewise-affine finite elements, $V_h = P_c^1$. In (2.4) we take $W_h = V_h$ and $\gamma_0 = 0$, $\gamma_1 = \tilde{\gamma}_1 h_{\partial K}^2$, where $\tilde{\gamma}_1$ scales as $\|\beta\|_\infty^{-1}$ and depends on the local mesh geometry (but not on the mesh size). This results in an interior penalty method originally proposed in [10] and analyzed in [6].

The finite element formulation now takes the following form: Find $u_h \in V_h$ such that

$$A(u_h, v_h) + J_1(u_h, v_h) = (f, v_h) \quad \forall v_h \in V_h, \tag{3.1}$$

where $A(u_h, v_h)$ is given by (2.5) with the terms marked (*) left out (being zero) and $J_1(u_h, v_h)$ is given by (2.8).

3.1. Analysis.

We will prove the three preliminary lemmas (Lemmas 3.1, 3.3, and 3.4) giving an approximation result, coercivity of the bilinear form, and Galerkin orthogonality. Using these preliminary results and the stability Theorem 2.2, we then prove the convergence in Theorem 3.5, which is the main result of this section. We first recall a trace inequality that we will use repeatedly:

$$\|v\|_{0,\partial K}^2 \le C\Big(h_K^{-1}\,\|v\|_{0,K}^2 + h_K\,\|v\|_{1,K}^2\Big) \quad \forall v \in H^1(K). \tag{3.2}$$

For a proof of this result, we refer to [26]. The triple norm takes the form

$$\begin{aligned} |||w_h|||^2 = \|\sigma_0^{1/2} w_h\|^2 + \|\varepsilon^{1/2}\nabla w_h\|_h^2 + |(h\varepsilon)^{1/2}\nabla w_h \cdot n|_h^2 \\ + J_1(w_h, w_h) + |\delta(\varepsilon,\beta) w_h|^2, \end{aligned} \tag{3.3}$$

where

$$\delta(\varepsilon,\beta)^2 = \Big(\gamma_{bc}\frac{\varepsilon}{h}\Big) + \frac{1}{2}|\beta \cdot n|.$$

For the continuity of the bilinear form, we will also use the modified norm

$$\begin{aligned} |]w_h[|^2 = \|\sigma_1^{1/2} w_h\|^2 + \|\beta\|_\infty \|h^{-1/2} w_h\|^2 + \|\varepsilon^{1/2}\nabla w_h\|_h^2 \\ + |(h\varepsilon)^{1/2}\nabla w_h \cdot n|_h^2 + J_1(w_h, w_h) + |\delta(\varepsilon,\beta) w_h|^2. \end{aligned}$$

Note that we have used the broken norm for the definition of the triple norms. This is not necessary in the conforming case, but it allows us to use the same triple norm also for the nonconforming approximation.

LEMMA 3.1 (approximation). *Assume that the mesh $\mathcal{T}_h$ is locally quasi-uniform. Let $u \in H^2(\Omega)$ and let $\pi_h u$ denote the standard L_2-projection of u onto V_h; then, if $\tilde{\gamma}_1 \le C\|\beta\|_\infty^{-1}$, we have that*

$$|||\pi_h u - u||| \le Ch(\sigma_0^{1/2} h + \varepsilon^{1/2} + \|\beta\|_\infty^{1/2} h^{1/2})\|u\|_{2,\Omega},$$

where C is independent of σ, ε, β, and h but depends on the mesh geometry.

Proof. It follows from standard interpolation results that $\|\sigma_0^{1/2}(\pi_h u - u)\| \leq \sigma_0^{1/2} h^2 \|u\|_{2,\Omega}$. We then write $\xi_h = \pi_h u - \pi_h^n u$, where π_h^n denotes the nodal interpolant, and note that $\xi_h = \pi_h(u - \pi_h^n u)$. By the H^1-stability of the L^2-projection on locally quasi-uniform meshes [2], we may write

$$\|\nabla \xi_h\| \leq \|\nabla(u - \pi_h^n u)\| \leq Ch\|u\|_{2,\Omega}. \tag{3.4}$$

It immediately follows that

$$\|\varepsilon^{1/2}\nabla(u - \pi_h u)\| \leq C\varepsilon^{1/2} h \|u\|_{2,\Omega},$$

and, using the trace inequality (3.2) and (3.4),

$$|(\varepsilon h)^{1/2}\nabla(\pi_h u - u)|_h^2 \leq \sum_{K \in \mathcal{T}_h} \left(\varepsilon\|\nabla(\pi_h u - u)\|_K^2 + \varepsilon h_K^2 |u|_{2,K}^2\right) \leq C\varepsilon h^2 \|u\|_{2,\Omega}^2.$$

Using once again (3.2) and (3.4) we get in a similar fashion

$$J_1(u - \pi_h u, u - \pi_h u) \leq c\tilde{\gamma}_1\Big(h^{-1}h^2\|\beta\|_\infty^2\|\nabla(u - \pi_h u)\|^2 + h^3\|\beta\|_\infty^2|u|_{2,\Omega}^2\Big)$$
$$\leq \|\beta\|_\infty h^3 \|u\|_{2,\Omega}^2.$$

Finally we note that for the boundary term we have, using (3.2),

$$\langle \pi_h u - u, \pi_h u - u\rangle_{\partial\Omega} \leq h^{-1}\|\pi_h u - u\|^2 + h\|\nabla(\pi_h u - u)\|^2 \leq Ch^3\|u\|_{2,\Omega}^2,$$

which concludes the proof. □

As an immediate consequence of the above result we have the following corollary.

COROLLARY 3.2. *Under the same assumptions as in Lemma* 3.1 *we have that*

$$|]\pi_h u - u[| \leq Ch(\sigma_1^{1/2} h + \varepsilon^{1/2} + \|\beta\|_\infty^{1/2} h^{1/2})\|u\|_{2,\Omega},$$

where C is independent of σ, ε, β, and h but depends on the mesh geometry.

LEMMA 3.3 (coercivity). *The bilinear form $A(u_h, v_h) + J(u_h, v_h)$ is coercive: There exists c, independent of $\varepsilon, \sigma, \beta$, and of h, such that*

$$c|||w_h|||^2 \leq A(w_h, w_h) + J_1(w_h, w_h) \quad \forall w_h \in V_h.$$

Proof. We essentially only need to show that the weakly imposed boundary conditions do not destroy coercivity. We have

$$\begin{aligned} A(w_h, w_h) &= \|\sigma^{1/2} w_h\|^2 + \|\varepsilon^{1/2}\nabla w_h\|^2 + (\beta \cdot \nabla w_h, w_h) \\ &\quad - 2\left\langle \varepsilon \nabla w_h \cdot n, w_h\right\rangle + \left\langle \gamma_{bc}\frac{\varepsilon}{h} w_h, w_h\right\rangle + \left\langle |\beta \cdot n| w_h, w_h\right\rangle_{\partial\Omega_{in}}. \end{aligned} \tag{3.5}$$

Consider the third term and the last term on the right-hand side. Integration by parts yields

$$\begin{aligned} &(\beta \cdot \nabla w_h, w_h) + \left\langle |\beta \cdot n| w_h, w_h\right\rangle_{\partial\Omega_{in}} \\ &\quad = -\frac{1}{2}(\nabla \cdot \beta\; w_h, w_h) + \frac{1}{2}\left\langle \beta \cdot n\, w_h, w_h\right\rangle + \left\langle |\beta \cdot n| w_h, w_h\right\rangle_{\partial\Omega_{in}} \\ &\quad = -\frac{1}{2}(\nabla \cdot \beta\; w_h, w_h) + \frac{1}{2}\left\langle |\beta \cdot n| w_h, w_h\right\rangle. \end{aligned} \tag{3.6}$$

We now consider the second, fourth, and fifth terms of (3.5). The nonsymmetric boundary integral is split using a Cauchy–Schwarz inequality followed by Young's inequality and controlled by the symmetric terms in the following fashion:

$$\begin{aligned}(3.7)\quad &\|\varepsilon^{1/2}\nabla w_h\|^2 - 2\left\langle \varepsilon\nabla w_h\cdot n, w_h\right\rangle + \left\langle \gamma_{bc}\frac{\varepsilon}{h}w_h, w_h\right\rangle\\ &\geq \|\varepsilon^{1/2}\nabla w_h\|^2 - \alpha|(h\varepsilon)^{1/2}\nabla w_h\cdot n|^2 + \left\langle \left(\gamma_{bc}-\frac{1}{\alpha}\right)\frac{\varepsilon}{h}w_h, w_h\right\rangle.\end{aligned}$$

As a consequence of the trace inequality (3.2) we have

$$(3.8)\qquad |(h\varepsilon)^{1/2}\nabla w_h\cdot n|^2 \leq C_t\|\varepsilon^{1/2}\nabla w_h\|^2,$$

and by choosing $\alpha = (2C_t)^{-1}$ and $\gamma_{bc} = 2C_t(\frac{2+2C_t}{1+2C_t})$ we conclude that

$$\begin{aligned}(3.9)\quad &\|\varepsilon^{1/2}\nabla w_h\|^2 - 2\left\langle \varepsilon\nabla w_h\cdot n, w_h\right\rangle + \left\langle \gamma_{bc}\frac{\varepsilon}{h}w_h, w_h\right\rangle\\ &\geq \frac{1}{2(1+C_t)}\left(\|\varepsilon^{1/2}\nabla w_h\|^2 + |(h\varepsilon)^{1/2}\nabla w_h\cdot n|^2 + \left\langle \gamma_{bc}\frac{\varepsilon}{h}w_h, w_h\right\rangle\right).\end{aligned}$$

Combining the results of (3.5), (3.6), (3.9), and the condition (2.2), the lemma follows with the coercivity constant $c = \frac{1}{2(1+C_t)}$. □

Lemma 3.4 (Galerkin orthogonality). *Let u be the solution of* (2.1) *and $u_h \in V_h$ the solution of* (3.1); *then we have that*

$$(3.10)\qquad A(u-u_h, w_h) + J_1(u-u_h, w_h) = 0 \quad \forall w_h \in V_h.$$

Proof. First note that since $u \in H^2(\Omega)$, the trace of ∇u is well-defined, and hence $J_1(u, w_h) = 0$. Since $u = 0$ on $\partial\Omega$, we have that

$$A(u, w_h) = (\sigma u + \beta\cdot\nabla u, w_h) + (\varepsilon\nabla u, \nabla w_h) - \left\langle \varepsilon\nabla u\cdot n, w_h\right\rangle.$$

By an integration by parts in the second term on the right-hand side, we conclude that

$$A(u, w_h) = (\sigma u + \beta\cdot\nabla u - \varepsilon\Delta u, w_h) = (f, w_h),$$

and the lemma is an immediate consequence of (3.1). □

Theorem 3.5. *Let $u \in H^2(\Omega)$ be the solution of* (2.1) *and let $u_h \in V_h$ be the solution of* (3.1); *then, the following a priori error estimate holds:*

$$|||u-u_h||| \leq Ch(\tilde{\sigma}^{1/2}h + \varepsilon^{1/2} + \|\beta\|_\infty^{1/2}h^{1/2})\|u\|_{2,\Omega},$$

where $\tilde{\sigma} = \max(\sigma_0, \sigma_1)$.

Proof. Let $\pi_h u$ be the L^2-projection of u onto V_h. Consider $\xi_h = u_h - \pi_h u$ and $\eta = u - \pi_h u$. By the triangle inequality we have

$$|||u-u_h||| \leq |||\eta||| + |||\xi_h|||$$

and hence by Lemma 3.1 we only need to control $|||\xi_h|||$. We now use the coercivity lemma, Lemma 3.3, followed by Galerkin orthogonality, Lemma 3.4, to obtain

$$(3.11)\qquad c|||\xi_h|||^2 \leq A(\xi_h, \xi_h) + J_1(\xi_h, \xi_h) = A(\eta, \xi_h) + J_1(\eta, \xi_h).$$

Note that after integration by parts in the convective term followed by the application of the Cauchy–Schwarz inequality in $A(\eta,\xi_h)+J_1(\eta,\xi_h)$ we have

$$\begin{aligned}A(\eta,\xi_h)+J_1(\eta,\xi_h) &\leq \|\sigma_1^{1/2}\eta\|\|\sigma_0^{1/2}\xi_h\| + \|\varepsilon^{1/2}\nabla\eta\|\|\varepsilon^{1/2}\nabla\xi_h\| \\ &\quad + J_1(\eta,\eta)^{1/2}J_1(\xi_h,\xi_h)^{1/2} + |(\eta,\beta\cdot\nabla\xi_h)| \\ &\quad + |\delta(\varepsilon,\beta)\xi_h||\delta(\varepsilon,\beta)\eta| \\ &\quad + C|(\varepsilon h)^{1/2}\nabla\eta\cdot n||\delta(\varepsilon,\beta)\xi_h| + C|(\varepsilon h)^{1/2}\nabla\xi_h\cdot n||\delta(\varepsilon,\beta)\eta| \\ &\leq C|]\eta[|\;|||\xi_h||| + |(\eta,\beta\cdot\nabla\xi_h)|.\end{aligned}$$

In the second term in the right-hand side of the last inequality, we now use the orthogonality of the L_2-projection to subtract the Oswald quasi-interpolant from the streamline derivative of ξ_h

$$\begin{aligned}|(\eta,\beta\cdot\nabla\xi_h)| &= |(\eta,\beta\cdot\nabla\xi_h-\pi_h^*(\beta\cdot\nabla\xi_h))| \\ &\leq \|\beta\|_\infty^{1/2}\|h^{-1/2}\eta\|\,\|\beta\|_\infty^{-1/2}\|h^{1/2}(\beta\cdot\nabla\xi_h-\pi_h^*(\beta\cdot\nabla\xi_h))\|.\end{aligned}$$

By Theorem 2.2 we then conclude that

$$\begin{aligned}c|||\xi_h|||^2 &\leq C|]\eta[|\;|||\xi_h||| + \|\beta\|_\infty^{1/2}\|h^{-1/2}\eta\|\,J_1(\xi_h,\xi_h)^{1/2} \\ &\leq C|]\eta[|\;|||\xi_h|||,\end{aligned}$$

and the claim follows by the approximation Corollary 3.2. □

4. An intermediate space: The nonconforming P_1-Crouzeix–Raviart element. Stabilized finite element methods using the Crouzeix–Raviart element have been considered in a number of articles [15, 14, 20], all from the Petrov–Galerkin standpoint. Here we will show how this discretization enters the interior penalty framework using only a penalization on the jump in the gradients, together with a (numerical flux) term involving the jump in the solution assuring coercivity of the convective term. The space of Crouzeix–Raviart finite elements is defined by

$$V_h^{CR} = \left\{ v : v|_K \subset P_1(K), \int_{\partial K\setminus\partial\Omega} [v]\,\mathrm{d}s = 0 \right\}.$$

It is well known that on triangular meshes $P_c^1 \subset V_h^{CR}$, and we will use this fact to simplify our analysis. We propose the following scheme, obtained by taking V_h^{CR} as test and trial space in (2.4): Find $u_h \in V_h^{CR}$ such that

$$A(u_h,v_h)+J_1(u_h,v_h)=(f,v_h) \quad \forall v_h \in V_h^{CR}, \tag{4.1}$$

where the bilinear form is given by

$$\begin{aligned}A(u_h,v_h) &= (\sigma u_h,v_h)+(\varepsilon\nabla u_h,\nabla v_h)_h+(\beta\cdot\nabla u_h,v_h)_h \\ &\quad -\frac{1}{2}\sum_K \langle \beta\cdot n[u_h],\{v_h\}\rangle_{\partial K\setminus\partial\Omega} - \langle\varepsilon\nabla u_h\cdot n,v_h\rangle_h - \langle\varepsilon\nabla v_h\cdot n,u_h\rangle_h \\ &\quad + \left\langle \gamma_{bc}\frac{\varepsilon}{h}u_h,v_h\right\rangle + \langle|\beta\cdot n|u_h,v_h\rangle_{\partial\Omega_{in}}.\end{aligned} \tag{4.2}$$

This time we choose the following form of the interior penalty term:

$$J_1(u_h, v_h) \;=\; \sum_K \Big(\langle \gamma_\tau(h)[\nabla u_h \cdot \tau], [\nabla v_h \cdot \tau]\rangle_{\partial K} \;+\; \langle \gamma_1(h)[\beta \cdot \nabla u_h], [\beta \cdot \nabla v_h]\rangle_{\partial K} \Big). \tag{4.3}$$

Note that we do not add any terms penalizing the jump in the solution; this is because for the Crouzeix–Raviart discretization the jump in the solution is bounded by the jump in the tangential derivative as shown in the following lemma.

Lemma 4.1. *The jump in the solution over element edges satisfies*

$$\int_e \alpha [u_h]^2 \ \mathrm{d}s = \frac{1}{12} \int_e \alpha h_e^2 [\nabla u_h \cdot \tau_e]^2 \ \mathrm{d}s.$$

Proof. Let x_e denote the midpoint on edge e. Clearly $[u_h(x)]^2 = [\nabla u_h \cdot \tau_e]^2 (x - x_e)^2$ for all $x \in e$ and the lemma follows by integration. □

The parameter $\gamma_1(h)$ may be chosen as in the previous section and $\gamma_\tau(h)|_{\partial K} = \tilde{\gamma}_\tau h^2 \|\beta \cdot n\|_{\infty, \partial K}$, $\tilde{\gamma}_\tau = 1/12$. For the analysis we also need the operator $\pi_h^0 : L^2(K) \to P_0(K)$ that denotes the L^2-projection onto the space $P_0(K)$ of piecewise constant functions on the element K. As an immediate consequence of (3.2) we have the estimate

$$\|v - \pi_h^0 v\|_{0,\partial K} \le C h_K^{1/2} \|\nabla v\|_K, \quad v \in H^1(K), \tag{4.4}$$

which we will use to prove that the consistency error is of optimal order. For the convergence proof we will use the same triple norm (3.3) (but with the slightly modified $J_1(u_h, v_h)$ given by (4.3) that has the same approximation properties) and the L_2-projection π_h onto the space P_c^1 so that Lemma 3.1 and Theorem 2.2 hold. We will now proceed to prove equivalents of Lemmas 3.3 and 3.4 for the formulation (4.1) using the Crouzeix–Raviart space. The convergence and, in particular, that the inconsistencies are of the correct order is then shown in Theorem 4.4.

Lemma 4.2. *The bilinear form of formulation* (4.1) *is coercive: There exists a constant c independent of ε, β, σ, and h such that*

$$c |||w_h|||^2 \le A(w_h, w_h) + J_1(w_h, w_h).$$

Proof. The boundary part is handled in the same way as in Lemma 3.3. The part that we need to show does not interfere with coercivity is, in this case, the convective term, but by partial integration we obtain, on using $[w_h^2] = 2[w_h]\{w_h\}$, that

$$\begin{aligned}(\beta \cdot \nabla w_h, w_h)_h = -(\nabla \cdot \beta \ w_h, w_h)_h - (w_h, \beta \cdot \nabla w_h)_h \\ + \sum_K \langle \beta \cdot n \ [w_h], \{w_h\} \rangle_{\partial K \setminus \partial\Omega} + \langle \beta \cdot n \ w_h, w_h \rangle .\end{aligned} \tag{4.5}$$

Using this in $A(w_h, w_h)$ gives

$$\begin{aligned}(\beta \cdot \nabla w_h, w_h)_h - \frac{1}{2} \sum_K \langle \beta \cdot n \ [w_h], \{w_h\} \rangle_{\partial K \setminus \partial\Omega} + \langle |\beta \cdot n| w_h, w_h \rangle_{\partial\Omega_{in}} \\ = -\frac{1}{2} (\nabla \cdot \beta \ w_h, w_h)_h + \frac{1}{2} \langle |\beta \cdot n| w_h, w_h \rangle\end{aligned} \tag{4.6}$$

and coercivity follows by the coercivity condition (2.2). □

Lemma 4.3 (Galerkin orthogonality). *Let u be the solution of* (2.1) *and let u_h be the solution of* (4.1)*; then, we have that*

$$A(u-u_h,w_h)+J_1(u-u_h,w_h)=\frac{1}{2}\sum_K\left\langle\varepsilon(\nabla u\cdot n-\pi_h^0(\nabla u\cdot n)),[w_h]\right\rangle_{\partial K\setminus\partial\Omega},$$

where π_h^0 denotes the projection onto piecewise constants on the element K.

Proof. We note that

$$\begin{aligned}A(u,w_h)&=(\sigma u+\beta\cdot\nabla u,w_h)+(\varepsilon\nabla u,\nabla w_h)_h-\langle\varepsilon\nabla u\cdot n,w_h\rangle\\&=(\sigma u+\beta\cdot\nabla u-\varepsilon\Delta u,w_h)+\frac{1}{2}\sum_{K\in\mathcal{T}_h}\langle\varepsilon\nabla u\cdot n,[w_h]\rangle_{\partial K\setminus\partial\Omega}.\end{aligned}$$

Using now (2.1), the zero mean value property of the jump $[w_h]$ and the fact that $J_1(u,w_h)=0$ for $u\in H^2(\Omega)$ we may write

$$A(u,w_h)=(f,w_h)+\frac{1}{2}\sum_{K\in\mathcal{T}_h}\left\langle\varepsilon(\nabla u\cdot n-\pi_h^0(\nabla u\cdot n)),[w_h]\right\rangle_{\partial K\setminus\partial\Omega},$$

which completes the proof. □

Theorem 4.4. *Let $u\in H^2(\Omega)$ be the solution of* (2.1) *and let $u_h\in V_h^{CR}$ be the solution of* (4.1)*; then, the following a priori error estimate holds:*

$$|||u-u_h|||\le Ch(\tilde\sigma^{1/2}h+\varepsilon^{1/2}+\|\beta\|_\infty^{1/2}h^{1/2})\|u\|_{2,\Omega},$$

where $\tilde\sigma=\max(\sigma_0,\sigma_1)$.

Proof. The proof is similar to the proof of Theorem 3.5. We only need to prove that the residual terms due to the inconsistency have the correct order of convergence. Consider $u-\pi_h u$ with π_h the L_2-projection onto P_c^1. Let $\xi_h=u_h-\pi_h u$ and $\eta=u-\pi_h u$. Following the previous convergence proof we obtain by Lemmas 4.2 and 4.3 and the continuity of the symmetric part that

$$\begin{aligned}|||\xi_h|||^2&\le A(\xi_h,\xi_h)+J_1(\xi_h,\xi_h)\\&=A(\eta,\xi_h)+J_1(\eta,\xi_h)+\frac{1}{2}\sum_K\left\langle\varepsilon(\nabla u\cdot n-\pi_h^0(\nabla u\cdot n)),[\xi_h]\right\rangle_{\partial K\setminus\partial\Omega}\\&\le C]|\eta[|\;|||\xi_h|||+\frac{1}{2}\sum_K\left\langle\varepsilon(\nabla u\cdot n-\pi_h^0(\nabla u\cdot n)),[\xi_h]\right\rangle_{\partial K\setminus\partial\Omega}\\&\qquad+\frac{1}{2}\sum_K\langle\beta\cdot n\eta,[\xi_h]\rangle_{\partial K\setminus\Omega}+|(\eta,\beta\cdot\nabla\xi_h)_h|.\end{aligned}$$

For the element boundary terms we readily obtain

$$\begin{aligned}&\sum_K\left\langle\varepsilon(\nabla u\cdot n-\pi_h^0(\nabla u\cdot n)),[\xi_h]\right\rangle_{\partial K\setminus\partial\Omega}\\&\le\left(\sum_K\|\varepsilon^{1/2}h^{1/2}(\nabla u\cdot n-\pi_h^0(\nabla u\cdot n))\|^2_{\partial K\setminus\partial\Omega}\right)^{1/2}\left(\sum_K\left\langle\varepsilon h^{-1}[\xi_h],[\xi_h]\right\rangle_{\partial K\setminus\partial\Omega}\right)^{1/2}\end{aligned}$$

and

$$\frac{1}{2}\sum_K \langle \beta\cdot n\eta, [\xi_h]\rangle_{\partial K\setminus\partial\Omega} \leq \frac{1}{2}\left(\sum_K \|\beta\|_\infty |\eta|^2_{\partial K}\right)^{1/2}\left(\sum_K \langle |\beta\cdot n|[\xi_h],[\xi_h]\rangle_{\partial K\setminus\partial\Omega}\right)^{1/2}.$$

Using now the projection estimate (4.4), approximation, and Lemma 4.1 we have

$$\left(\sum_K \|\varepsilon^{1/2}h^{1/2}(\nabla u\cdot n - \pi_h^0(\nabla u\cdot n))\|^2_{\partial K\setminus\partial\Omega}\right)^{1/2} \leq \varepsilon^{1/2}h\|u\|_{2,\Omega},$$

$$\frac{1}{2}\left(\sum_K \|\beta\|_\infty |\eta|^2_{\partial K}\right)^{1/2} \leq C\|\beta\|_\infty^{1/2}h^{3/2}\|u\|_{2,\Omega},$$

and

$$\left(\sum_K \big\langle(\varepsilon h^{-1}+|\beta\cdot n|)[\xi_h],[\xi_h]\big\rangle_{\partial K\setminus\partial\Omega}\right)^{1/2} \leq \Big(C\|\varepsilon^{1/2}\nabla\xi_h\|^2_h + J_1(\xi_h,\xi_h)\Big)^{1/2}.$$

Finally the convective term is handled exactly as in the proof of Theorem 3.5 using the orthogonality of the L^2-projection and Theorem 2.2, and we conclude the proof by an application of the approximation Corollary 3.2. □

Remark 4.5. The above analysis of the Crouzeix–Raviart discretization only shows that the method will converge with the same order as the conforming piecewise linear method. However, we expect a richer space to provide a better approximation of the streamline derivative and hence the upper bound on the parameter $\tilde{\gamma}_1$ to be smaller. A more precise analysis following the proof of Theorem 2.2 shows that this is indeed the case. For completeness below we add such a result, which is proven in [7]. What should be observed is that the richer space gives a sharper estimate: In this case the stabilization parameter is independent of the mesh geometry.

LEMMA 4.6. *Let $\beta\in[P_c^1]^d$ and $w_h\in V_h^{CR}$; then*

$$\|h^{1/2}(\beta\cdot\nabla w_h - \pi_h^{CR}(\beta\cdot\nabla w_h))\|^2_h \leq j_\beta(w_h,w_h),$$

where π_h^{CR} denotes the averaging interpolation operator of (2.9) *defined on the Crouzeix–Raviart space and $j_\beta(w_h,w_h)$ is given by*

$$j_\beta(w_h,w_h) = \sum_K \gamma_\beta \int_{\partial K\setminus\partial\Omega} h_K h_{\partial K^\perp}[\beta\cdot\nabla w_h]^2\ ds$$

with $h_{\partial K^\perp}$ denoting the triangle size perpendicular to the side on ∂K and γ_β depends only on the space dimension.

5. Domain decomposition and the relation to discontinuous Galerkin methods. In this section we will show how domain decomposition using Nitsche's method leads to discontinuous Galerkin-type penalty methods in a natural way. For the Poisson problem this method was analyzed in [1]. Below we will briefly sketch how the results of [1] may be extended to the case of convection-diffusion problems using the interior penalty framework. Consider a decomposition of the domain Ω into the disjoint subdomains ω_i, $i=1,\dots,N$, with corresponding triangulations $\mathcal{T}_{h,i}$ such that $\cup_{i=1}^N \mathcal{T}_{h,i} = \cup_{i=1}^N \bar\omega_i = \bar\Omega$. Note that we do not suppose that neighboring meshes are conforming over the intersubdomain boundary. On each triangulation we define a finite element space $V_{h,i}$ associated with the subdomain ω_i.

$$V_{h,i} = \{v_h : v_h \in H^1(\omega_i); v_h|_K \in P_1(K)\}$$

and we let $V_h = \sum_{i=1}^N V_{h,i}$. We now consider problem (2.1) on Ω and, by taking V_h as trial and test space in the formulation (2.4), we propose the finite element method: Find $u_h \in V_h$ such that

$$A(u_h, v_h) + J(u_h, v_h) = (f, v_h) \quad \forall v_h \in V_h, \tag{5.1}$$

where

$$\begin{aligned} A(u_h, v_h) = \textstyle\sum_{i=1}^N \left((\sigma u_h, v_h)_{\omega_i} + (\varepsilon \nabla u_h, \nabla v_h)_{\omega_i} + (\beta \cdot \nabla u_h, v_h)_{\omega_i}\right) \\ -\tfrac{1}{2} \textstyle\sum_{i=1}^N \left(\langle \beta \cdot n[u_h], \{v_h\}\rangle_{\partial\omega_i} + \langle \{\varepsilon \nabla u_h \cdot n\}, [v_h]\rangle_{\partial\omega_i} + \langle \{\varepsilon \nabla v_h \cdot n\}, [u_h]\rangle_{\partial\omega_i}\right) \\ - \langle \varepsilon \nabla u_h \cdot n, v_h\rangle - \langle \varepsilon \nabla v_h \cdot n, u_h\rangle \\ + \left\langle \gamma_{bc} \tfrac{\varepsilon}{h} u_h, v_h \right\rangle + \langle |\beta \cdot n| u_h, v_h\rangle_{\partial\Omega_{in}} \end{aligned}$$

and

$$\begin{aligned} J(u_h, v_h) = \sum_{i=1}^N \Bigg(\sum_{K \in \mathcal{T}_{h,i}} \langle \gamma_{1,i}(h) [\beta \cdot \nabla u_h], [\beta \cdot \nabla v_h]\ \rangle_{\partial K \setminus \partial\omega_j} \\ + \left\langle \delta(\varepsilon, \beta)^2 [u_h], [v_h] \right\rangle_{\partial\omega_i \setminus \partial\Omega} \Bigg). \end{aligned} \tag{5.2}$$

Note that the bilinear form A corresponds to a standard Galerkin formulation in each subdomain, supplemented with boundary terms on the inner and outer boundaries that appear naturally in the formulation to assure coercivity or consistency. The interior penalty term $J(u_h, v_h)$ has been decomposed into a term controlling the jumps in the gradient over *interior* edges of each subdomain ω_i and another term controlling the jump of the solution over interior boundaries of neighboring subdomains. The stabilization parameter $\gamma_{1,i}(h) = \tilde\gamma_{1,i} h_K^2$ is now dependent on the mesh geometry of the subdomain triangulation $\mathcal{T}_{h,i}$. We define the triple norm

$$\begin{aligned} |||w_h|||^2 = \sum_{i=1}^N \left(\|\sigma_0^{1/2} w_h\|_{\omega_i}^2 + \|\varepsilon^{1/2} \nabla w_h\|_{\omega_i}^2 + |(h\varepsilon)^{1/2} \nabla w_h \cdot n|_{\partial\omega_i}^2 \right) \\ + J(w_h, w_h) + |\delta(\varepsilon, \beta) w_h|_{\partial\Omega} \end{aligned} \tag{5.3}$$

and obtain the following a priori error estimate.

THEOREM 5.1. *Let $u \in H^2(\Omega)$ be the solution of* (2.1) *and let $u_h \in V_h$ be the solution of* (5.1); *then, the following a priori error estimate holds:*

$$|||u - u_h||| \leq Ch \left(\tilde\sigma^{1/2} h + \varepsilon^{1/2} + \|\beta\|_\infty^{1/2} h^{1/2} \right) \|u\|_{2,\Omega},$$

where $\tilde\sigma = \max(\sigma_0, \sigma_1)$.

Proof. We will not give the details of the proof here, but note that it follows by applying the techniques of Theorem 3.5 in each subdomain ω_i. The internal boundary terms are treated in the same fashion as the outer boundary terms. The added penalty terms on the jump of the solution over internal boundaries ensures the coercivity and continuity of the bilinear form. For a detailed analysis of the method in the case of the Poisson problem, we refer to [1]. □

COROLLARY 5.2. *If the triangulation of each subdomain consists of a single triangle, then the formulation* (5.1) *is equivalent to an interior penalty discontinuous Galerkin method for* (2.1).

Proof. This result is immediate by noting that the interior penalty term on the gradient jumps vanishes since there are no interior edges in the subdomains. ∎

Remark 5.3. The substructuring iterative method for parallel solution naturally associated to (5.1) will be analyzed in a forthcoming work [8].

6. Numerical examples.

In this section we illustrate the numerical performance of the interior penalty method on some academic test cases. We will only consider the case of conforming piecewise linear approximation. In these test cases we have used weakly imposed boundary conditions. For results using strongly imposed boundary conditions, or comparisons between stabilization using the jump in the streamline derivative versus the jump in the whole gradient, see [6]. For results on shock-capturing and discrete maximum principles, see [5], and for results using the Crouzeix–Raviart element, see [7]. First we consider three problems with known exact solution, the first two on structured meshes and the third on the so-called Peterson meshes. The reason we consider Peterson meshes is because we wish to verify that our a priori error estimate is sharp. Finally we will show qualitatively the effect of the weakly imposed boundary conditions. We have applied the finite element method (3.1) to (2.1) using the stabilizing term

$$J_{tot}(u_h, v_h) = \sum_K \int_{\partial K \setminus \partial \Omega} \gamma_1(h)[\nabla u_h] \cdot [\nabla v_h] \mathrm{d}s$$

with $\gamma_1(h) = 0.025\ h_K^2$. The a priori error estimate of Theorem 3.5 holds also for this choice, but some consistent crosswind diffusion is added, giving better control of the gradient. The parameter γ_{bc} is set to unity.

6.1. Convergence tests, smooth solutions.

Consider problem (2.1) with $\beta = (1, 0)$, $\sigma = 1$, and $\varepsilon = 1.\mathrm{E} - 5$ in a square with unit sidelength. To examine the convergence behavior of our method we propose two smooth test cases with known solution. The exact solutions are as follows (see Figure 2):

- test case 1: $u = \exp(-\frac{(x-0.5)^2}{a_w} - \frac{3(y-0.5)^2}{a_w})$, $a_w = 0.2$;
- test case 2: $u = \frac{1}{2}(1 - \tanh(\frac{x-0.5}{a_w}))$, $a_w = 0.05$.

These functions have then been inserted into the equations and the corresponding source terms have been computed. The solution has been computed on a series of structured meshes having 20, 40, 80, 160, and 320 elements, respectively, on each side. A typical mesh is presented in Figure 4. In Tables 6.1 and 6.2 we report the errors in the L^2-norm and the H^1-seminorm as well as the convergence of the jumps in the gradients over element edges given by $J_{tot}(u_h, u_h)$ (with $\gamma_1(h) = h_K^2$ for simplicity). Note that $J_{tot}(u_h, u_h)$ and $J_{tot}(u_h - \pi_h u, u_h - \pi_h u)$ have the same convergence order. The observed order of convergence is denoted by α indicating that the rate is of order $O(h^\alpha)$.

We observe second-order convergence of the error in the L_2-norm and first-order convergence in the H^1-norm. For the stabilization term we obtain the convergence order $h^{3/2}$. In Figure 3 we present a comparison between the numerical results obtained using the continuous interior penalty (CIP) method (for the corresponding theoretical result see Theorem 3.5) and those obtained by solving the problem using a standard SUPG approach. For these simple test cases, the numerical performance of the two methods is nearly identical.

6.2. Peterson meshes. Naively, one might hope that the consistently added crosswind diffusion in the jump term $J_1(u_h, v_h)$ obtained by taking the jump of the whole gradient and not only the streamline derivative would result in a numerical scheme for which the error in the L^2-norm never degenerates to $O(h^{3/2})$. However, as the following numerical example shows, this is not the case. We recall the test cases of [27, 24] on the so-called Peterson meshes. In Figure 4 we show an example of a Peterson mesh. In [27] it was shown that the convergence order of the streamline diffusion method on Peterson meshes depends on the number of vertical lines in the mesh. In fact, the streamline diffusion method can be made to converge with any rate $O(h^{3/2}) - O(h^2)$ depending on the distribution of the vertical edges. Here we only consider the worst case where the number of inserted lines is given by $m \approx h^{-3/4}$. Following [27] we chose $\beta = (0, 1)$, $\sigma = 1$, and $\varepsilon = 0$ in (2.1). Moreover we choose $f = x^2$ and the inflow boundary condition $u_{in} = x^2$. The exact solution is given by $u(x, y) = x^2$. In Table 6.3 we report the errors obtained in different norms and the corresponding convergence orders. We note that the convergence rate of the method degenerates to almost $O(h^{3/2})$ in the L^2-norm and to $O(h^{0.88})$ in the H^1-norm. The jump term has a slightly suboptimal convergence rate of $\alpha = 1.4$ but seems to be increasing toward the asymptotic value $\alpha = 1.5$ as the mesh is refined.

6.3. Nonsmooth solutions, weak boundary conditions. In this last numerical example we show the effect of the weakly imposed boundary condition and compare with the case when the boundary condition is imposed strongly. We consider a classical problem with an interior layer and an outflow layer. In this case we choose $\varepsilon = 2.\text{E} - 3$, $\sigma = 0$, $\beta = (-\cos 55°, -\sin 55°)$. The boundary conditions and the computational domain are specified in Figure 5. In Figure 6 we present solutions on three different meshes, having 20, 80, and 320 elements per side, respectively. On the coarsest mesh we show the carpet plot of the mesh and on the finer meshes we only show elevations of the contour plots. Note how the strongly imposed boundary conditions induce significant overshoots in the outflow layer. When the boundary conditions are imposed weakly there are hardly any overshoots, but the approximate solution will satisfy the boundary condition only when the layer is fully resolved. The parameter γ_{bc} can be tuned to impose the satisfaction of the boundary condition on a given scale. However, if the penalty parameter is chosen too large, the oscillations will reappear. The spurious oscillations on the interior layer are suppressed thanks to the added crosswind diffusion but disappear completely only when the mesh is sufficiently fine.

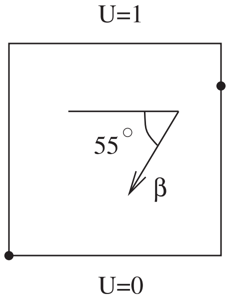

Fig. 5. *Problem data specification, outflow layer test case. At the points the boundary data changes linearly from $U = 1$ to $U = 0$ over an interval of size ε.*

7. Conclusion. We have proposed a new framework for stabilized methods based on interior penalty and conforming or nonconforming approximation. In order to avoid Petrov–Galerkin-type discretizations we added a term giving L^2-control of the jumps in the solution gradient over element boundaries when using spaces V_h that do not satisfy $\beta \cdot \nabla v_h \in V_h \; \forall v_h \in V_h$. We proved that this results in a method that is stable in the hyperbolic limit with optimal order convergence for continuous piecewise linear approximation. The stabilization is symmetric, uniform in the diffusion parameter ε and lumped mass may be used for efficient time stepping. The framework also allows for nonconforming approximations and we proved optimal order a priori error estimates for the first-order Crouzeix–Raviart element using the theory developed for the conforming case. Moreover we discussed domain decomposition using Nitsche's method and the relation to discontinuous Galerkin methods. Finally we considered some numerical examples for the continuous piecewise linear case. We showed that the method has optimal convergence order of $O(h^2)$ in the L^2 norm for smooth test problems on structured meshes, but degenerates to $O(h^{3/2})$ on the so-called Peterson meshes, indicating that our a priori error estimates are sharp. We believe that this form of stabilization offers an attractive compromise between the SUPG method and the discontinuous Galerkin method. Compared to SUPG we are more flexible with respect to time-stepping schemes and mass lumping; however, we pay a price in the size of the system matrix which increases in size by a factor of two in two space dimensions and a factor three in three space dimensions. The implementation also differs since one needs a data structure containing the elements neighboring to a given element in order to compute the gradient jumps. The method

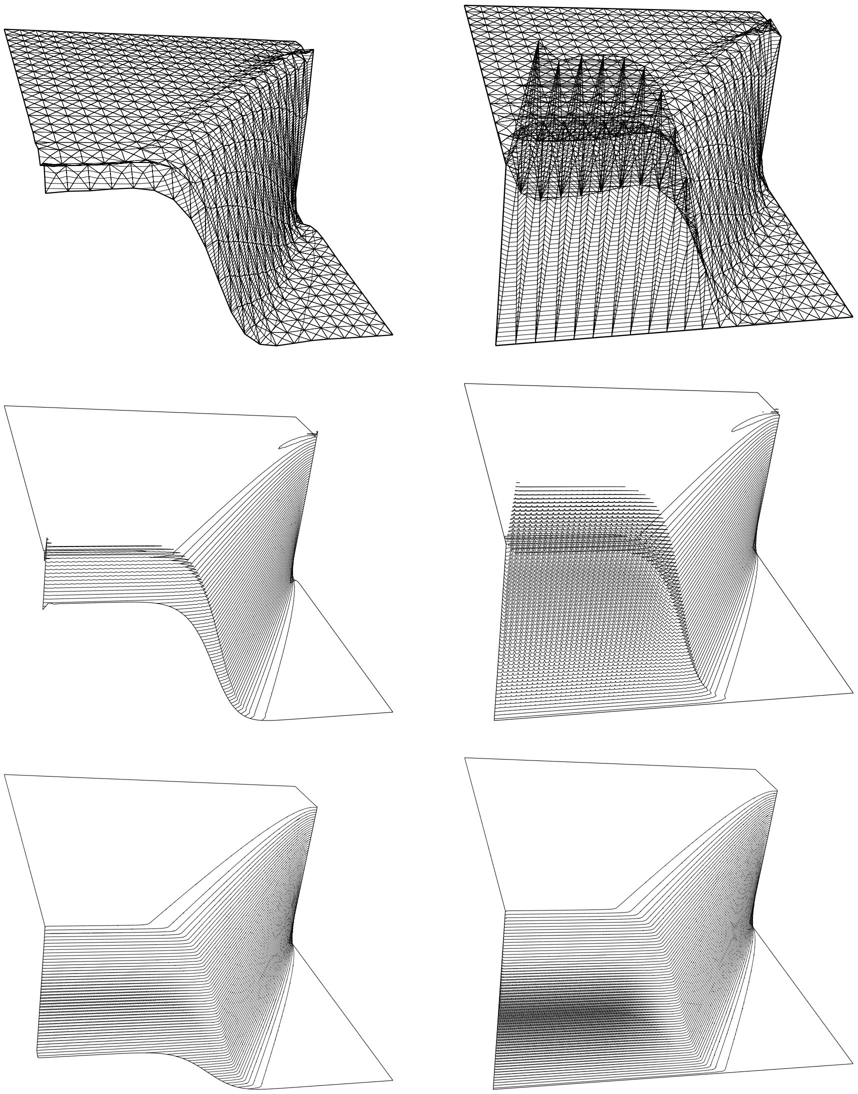

FIG. 6. *Outflow layer test case: weakly imposed boundary conditions (left); strongly imposed boundary conditions; resolutions from top down:* 20×20, 80×80, *and* 320×320 *(right).*

enjoys many of the advantages of the discontinuous Galerkin method. Two important exceptions, however, are the local conservation properties of the discontinuous Galerkin method and the ease by which one may couple finite elements with different polynomial degree. On the other hand, in the continuous interior penalty method we can control the number of degrees of freedom we use by choosing our approximation spaces judiciously. A particularly interesting feature of the method is the way in which it can be combined with discontinuous Galerkin approximations using a Nitsche-type coupling.

A LINEAR ALGEBRAIC ANALYSIS OF DIFFUSION SYNTHETIC ACCELERATION FOR THREE-DIMENSIONAL TRANSPORT EQUATIONS*

S. VAN CRIEKINGEN†

Abstract. The effectiveness of the three-dimensional (3-D) diffusion synthetic acceleration preconditioning procedure is proved in various asymptotic regimes for the discretized, mono-energetic, steady-state, linear Boltzmann transport equation with isotropic scattering. The discretizations consist of a discrete ordinate collocation in angle and a Petrov–Galerkin finite element method in space. Following the path initiated by Faber and Manteuffel, we pursue the 3-D development of Brown by providing a 3-D extension of the slab geometry convergence results of Ashby et al. Our theoretical results confirm the good numerical results of Brown in thin and thick limits and hold for problems with nonconstant coefficients and nonuniform spatial zoning posed on finite domains with an incident flux prescribed at the boundaries.

Key words. three-dimensional Boltzmann transport, diffusion limit, diffusion synthetic acceleration, linear algebra, asymptotic analysis

1. Introduction.

The integro-differential linear Boltzmann transport equation (BTE) models neutral and charged particle transport. In deterministic approaches, a spatio-angular discretization of the BTE yields a system of linear algebraic equations that is solved iteratively. Diffusion synthetic acceleration (DSA) is known to be effective in speeding up the iterative solution of the discretized BTE. A recent review paper by Adams and Larsen [2] gives an extensive survey of the DSA history together with other acceleration methods using discrete ordinate angular discretizations.

We follow here the path initiated by Faber and Manteuffel [7], who popularized the equivalence between DSA and preconditioning techniques. Their linear algebraic setting then allows benefiting from well-known linear system solution techniques such as conjugate gradients. Ashby et al. [4] extended the viewpoint of [7] by incorporating diamond-difference (or Petrov–Galerkin) spatial discretization and discrete ordinate angular discretization. Their matrix formulation of the resulting discretization enabled a linear algebraic derivation of the preconditioner and initial guess. They also showed the relationship between their work and the four-step method of Larsen [12].

While this was restricted to slab geometry (one-dimensional Cartesian), Brown [5] extended this viewpoint to three-dimensional (3-D) geometry. He derived the preconditioning matrix yielding the DSA procedure, and presented numerical experiments demonstrating the effectiveness of this 3-D DSA preconditioner on some example problems. Specifically, this preconditioner was shown to exhibit very good behavior

in the thin and thick limits, that is, for total cross-sections tending to zero or infinity, respectively.

Nevertheless, the 3-D DSA preconditioner derivation of Brown [5] lacks a detailed mathematical analysis of the thin and thick limits similar to that given by Ashby et al. [4] for the slab geometry. In this paper, we intend to remedy this lack so as to confirm the encouraging numerical results in [5]. Opposite to typical Fourier analyses, our results hold for problems posed on finite domains, with nonconstant coefficients and nonuniform spatial zoning.

We consider discretizations consisting of a standard discrete ordinate collocation of the angular variable and a Petrov–Galerkin finite element approximation of the spatial variable. This discretization scheme [5] is equivalent to the well-known discrete ordinate diamond-difference scheme in [13], here in a matrix formulation. As is well known [3, 12], a "consistent" discretization of a limiting diffusion approximation to the BTE leads to effective DSA algorithms. While for slab geometry the consistently-differenced diffusion problem is nonsingular, Brown [5] showed that the "consistently" differenced 3-D diffusion approximation is actually singular, although the DSA preconditioner itself remains nonsingular. This fact makes the 3-D convergence analysis challenging, forcing us to use pseudo-inverses while standard inverses could be used in slab geometry.

Similar to what was done to obtain slab geometry theoretical results [4], we will consider particular values of the cross-sections, namely the thick and thin limits. Within the thick limit, we more precisely investigate the asymptotic diffusion limit, where sources tend to zero and scattering ratios (fraction of "losses" due to scattering processes) tend to unity while total cross-sections tend to infinity. Besides, the effectiveness of the 3-D DSA preconditioner is proved in another thick limit, with scattering ratios bounded away from unity. Finally, we discuss the behavior of the system matrix and DSA preconditioner in the thin regime.

The paper is organized as follows. After some preliminaries in section 2, the 3-D BTE is introduced in section 3. Isotropic scattering is assumed, and Dirichlet boundary conditions are applied. Section 4 gives an integrated presentation of the BTE discretization, and section 5 displays the 3-D DSA preconditioner and related initial guess derived in [5]. Section 6 contains our 3-D convergence analysis results for the different problem regimes described above. Despite their importance, the proofs have been put in an appendix for ease of readability.

2. Preliminaries.

We review some notations and results used throughout the paper. For a linear operator A, $\mathcal{N}(A)$ denotes its null space and $\mathcal{R}(A)$ its range. For matrices $A = (a_{ij}) \in \mathbf{R}^{m\times n}$ and $B \in \mathbf{R}^{k\times l}$, the Kronecker (or tensor, or direct) product of A and B is the $mk \times nl$ matrix defined by

$$A \otimes B \equiv \begin{pmatrix} a_{11}B & \cdots & a_{1n}B \\ \vdots & \ddots & \vdots \\ a_{m1}B & \cdots & a_{mn}B \end{pmatrix}.$$

We recall the following Kronecker product properties [9]:

- If A and B are nonsingular, then $A \otimes B$ is nonsingular with $(A\otimes B)^{-1} = A^{-1} \otimes B^{-1}$,
- $(A \otimes B)^T = A^T \otimes B^T$,
- $(A \otimes B) \cdot (C \otimes D) = AC \otimes BD$ as long as both sides of the equation make sense,

- $(A+B)\otimes C = A\otimes C + B\otimes C$,
- $A\otimes(B+C) = A\otimes B + A\otimes C$, and
- for any two vectors u and v, $\|u\otimes v\|_2 = \|u\|_2 \cdot \|v\|_2$, where $\|\cdot\|_2$ denotes the usual Euclidean norm of a vector.

Finally, for diagonal matrices A and B, $A < (\leq)\ B$ means $a_{ii} < (\leq)\ b_{ii}$ for all i.

3. Problem definition. We begin with the mono-energetic, steady-state, linear BTE in a 3-D box geometry with isotropic scattering [13]. The spatial domain is the box $\mathcal{D} \equiv \{r = (x,y,z) | a_x \leq x \leq b_x, a_y \leq y \leq b_y, \text{ and } a_z \leq z \leq b_z\}$, the direction variable is $\Omega \in \mathcal{S}^2$ (the unit sphere in $\mathbf{R}^3$), and the equation in the flux ψ is given by

$$\Omega \cdot \nabla\psi(r,\Omega) + \sigma(r)\psi = \sigma_s(r) \int_{\mathcal{S}^2} \psi(r,\Omega')d\Omega' + q(r,\Omega), \tag{3.1}$$

where $\nabla\psi \equiv (\partial\psi/\partial x, \partial\psi/\partial y, \partial\psi/\partial z)$. The functions $\sigma(r)$, $\sigma_s(r)$ and $q(r,\Omega)$ are assumed known. The flux $\psi(r,\Omega)$ is expanded in surface harmonics $Y_n^m(\Omega)$ according to

$$\psi(r,\Omega) = \sum_{n=0}^{\infty} \sum_{m=-n}^{n} \phi_n^m(r) Y_n^m(\Omega),$$

where

$$\phi_n^m(r) \equiv \int_{\mathcal{S}^2} \psi(r,\Omega) Y_n^m(\Omega) d\Omega$$

is the (n,m)th moment of ψ. Similarly, the source q is expanded as

$$q(r,\Omega) = \sum_{n=0}^{\infty} \sum_{m=-n}^{n} q_n^m(r) Y_n^m(\Omega),$$

where

$$q_n^m(r) \equiv \int_{\mathcal{S}^2} q(r,\Omega) Y_n^m(\Omega) d\Omega.$$

For ease of exposition in what follows, we have elected to use real-valued surface harmonics, all scaled to have unit norm in $L^2(\mathcal{S}^2)$. See [5] for a detailed definition of these harmonics. To relate to notations in [5], we also define $\sigma_{s,0} = 4\pi\sigma_s$.

Given ψ in the above form, one is able to rewrite the scattering term in the form

$$\sigma_s(r) \int_{\mathcal{S}^2} \psi(r,\Omega')d\Omega' = \sigma_{s,0}(r)\phi_0^0(r) Y_0^0$$

with $Y_0^0 = \frac{1}{\sqrt{4\pi}}$. The total cross-section σ is given by

$$\sigma(r) = \sigma_a(r) + \sigma_{s,0}(r),$$

where σ_a is the absorption cross-section.

Boundary conditions must also be specified so as to make (3.1) well-posed. We consider Dirichlet boundary conditions in which the incident flux $g(r,\Omega)$ is specified on a face. That is,

$$\psi(r,\Omega) = g(r,\Omega) \quad \text{for all} \quad r \in \partial\mathcal{D} \quad \text{and} \quad \Omega \in \mathcal{S}^2 \quad \text{with } \vec{n}(r)\cdot\Omega < 0, \tag{3.2}$$

where $\vec{n}(r)$ is the outward pointing unit normal at $r \in \partial\mathcal{D}$. Another common choice of boundary conditions is a reflecting condition on a face. Note that a problem with a reflecting condition can be transformed into one with Dirichlet conditions by reflecting the problem data about the reflecting boundary.

4. Discretization of the 3-D problem.

We give here an integrated presentation of the discretization scheme developed in [5] for (3.1)–(3.2). This scheme is equivalent to the discrete ordinate diamond-difference scheme in [13]. On the other hand, the Petrov–Galerkin spatial discretization used here can also be related to the finite volume element method analyzed by Cai, Mandel, and McCormick [6].

4.1. Spatio-angular discretization of the BTE.

The angular variable is discretized using a discrete ordinate collocation method (see [13] for a complete overview of such methods). It consists simply of evaluating the BTE (3.1) in discrete angular directions $\Omega_\ell \in \mathcal{S}^2$ $(\ell = 1, \dots, L)$, each of them characterized by direction cosines $(\mu_\ell, \eta_\ell, \xi_\ell)$. The same set of (nonzero) direction cosines is used with respect to each of the three coordinate axes, i.e., $\{\mu_\ell\} = \{\eta_\ell\} = \{\xi_\ell\}$. Also, the direction cosines are assumed to be symmetrically placed (with respect to the origin) along each axis. Integrals over the unit sphere are approximated by a quadrature rule

$$\int_{\mathcal{S}^2} \psi(\Omega) d\Omega \approx \sum_{\ell=1}^{L} w_\ell \psi(\Omega_\ell). \tag{4.1}$$

As in [5], we consider either weights invariant under 90°-rotations about any coordinate axis, or weights that are all equal. In either case, we require all the weights to be positive and such that

$$\sum_{\ell=1}^{L} w_\ell \xi_\ell^{2n} = \frac{4\pi}{2n+1} \tag{4.2}$$

for $n = 0$ and 1. It follows from the symmetrical placement of the direction cosines that

$$\sum_{\ell=1}^{L} w_\ell \mu_\ell = 0, \quad \sum_{\ell=1}^{L} w_\ell \eta_\ell = 0, \quad \text{and} \quad \sum_{\ell=1}^{L} w_\ell \xi_\ell = 0. \tag{4.3}$$

For the spatial variable, we first discretize the box-shaped domain $\mathcal{D}$ into zones delimited by the coordinate lines $x = x_i$ $(i = 0, \dots, M)$, $y = y_j$ $(j = 0, \dots, J)$, and $z = z_k$ $(k = 0, \dots, K)$, and define $r_{ijk} = (x_i, y_j, z_k)$. Next, we define $\Delta x_i = x_i - x_{i-1}$ for $i = 1, \dots, M$, and similarly Δy_j and Δz_k. We also define $\Delta r_{ijk} \equiv \Delta x_i \Delta y_j \Delta z_k$. The $\{r_{ijk}\}$ are referred to as *nodes*, and function values at these points are called *nodal values*. Assume that σ, σ_s and q have constant values on each *zone*

$$\mathcal{Z}_{ijk} \equiv \{r | x_{i-1} < x < x_i, y_{j-1} < y < y_j, z_{k-1} < z < z_k\},$$

denoted by σ_{ijk}, $\sigma_{s,ijk}$, and q_{ijk}, respectively. In what follows, we assume $\sigma_{ijk} \neq 0$ for all i, j, k, even though we examine the thin limit (where total cross-sections tend to zero as described below) in section 6.2. Function values that are constant on zones will be referred to as *zone-centered* values. We use $\psi_{ijk,\ell}$ to denote the approximation to $\psi(r_{ijk}, \Omega_\ell)$, the true solution at r_{ijk} in the direction Ω_ℓ.

For the spatial expansions, we use the continuous piecewise-trilinear elements

$$P_{ijk}(r) \equiv p_i(x) p_j(y) p_k(z),$$

where $p_i(x)$, $p_j(y)$, and $p_k(z)$ are the standard continuous piecewise-linear one-dimensional basis functions. We then approximate $\psi(r, \Omega_\ell)$ by the piecewise-trilinear function ψ_a given by

$$\psi(r, \Omega_\ell) \approx \psi_a(r, \Omega_\ell) \equiv \sum_{i,j,k} \psi_{ijk,\ell} P_{ijk}(r). \tag{4.4}$$

Note that $\psi_a(r_{ijk}, \Omega_\ell) = \psi_{ijk,\ell}$.

The Petrov–Galerkin method consists of substituting ψ_a for ψ in the BTE (3.1) and then averaging over zone $\mathcal{Z}_{ijk}$. For each direction Ω_ℓ, this procedure yields a set of MJK zonal equations in the $(M+1)(J+1)(K+1)$ unknowns $\psi_{ijk,\ell}$. The boundary conditions provide the extra equations necessary to make the problem well-posed. In what follows, *nodes* and *zones* used as sub- or superscripts will respectively denote the number of nodes $(M+1)(J+1)(K+1)$ and zones MJK.

To obtain a compact notation, we define the vector of nodal values

$$\Psi \equiv \begin{pmatrix} \Psi_1 \\ \vdots \\ \Psi_L \end{pmatrix} \quad \text{with} \quad \Psi_\ell \equiv \begin{pmatrix} \Psi_{0,\ell} \\ \vdots \\ \Psi_{K,\ell} \end{pmatrix} \in \mathbf{R}^{nodes},$$

$$\Psi_{k,\ell} \equiv \begin{pmatrix} \Psi_{0k,\ell} \\ \vdots \\ \Psi_{Jk,\ell} \end{pmatrix} \in \mathbf{R}^{(M+1)(J+1)}, \quad \text{and} \quad \Psi_{jk,\ell} \equiv \begin{pmatrix} \psi_{0jk,\ell} \\ \vdots \\ \psi_{Mjk,\ell} \end{pmatrix} \in \mathbf{R}^{M+1}.$$

Next, we define

$$\begin{aligned} \Delta x &\equiv \operatorname{diag}(\Delta x_1, \dots, \Delta x_M), \\ \Delta y &\equiv \operatorname{diag}(\Delta y_1, \dots, \Delta y_J), \\ \Delta z &\equiv \operatorname{diag}(\Delta z_1, \dots, \Delta z_K), \\ \Delta r &= \Delta z \otimes \Delta y \otimes \Delta x, \end{aligned}$$

as well as the matrices

$$D_M \equiv \begin{pmatrix} -1 & 1 & & \\ & \ddots & \ddots & \\ & & -1 & 1 \end{pmatrix} \in \mathbf{R}^{M\times(M+1)}, \tag{4.5}$$

$$S_M \equiv \frac{1}{2}\begin{pmatrix} 1 & 1 & & \\ & \ddots & \ddots & \\ & & 1 & 1 \end{pmatrix} \in \mathbf{R}^{M\times(M+1)}, \tag{4.6}$$

and similarly the matrices D_J, S_J, D_K, and S_K for the other two directions. Furthermore, we introduce

$$\Sigma \equiv \operatorname{diag}(\sigma_{111}, \dots, \sigma_{zones}) \in \mathbf{R}^{zones},$$

and

$$\begin{aligned} S &\equiv S_K \otimes S_J \otimes S_M, \\ C_x &\equiv S_K \otimes S_J \otimes \Delta x^{-1} D_M, \\ C_y &\equiv S_K \otimes \Delta y^{-1} D_J \otimes S_M, \\ C_z &\equiv \Delta z^{-1} D_K \otimes S_J \otimes S_M. \end{aligned}$$

Note that S represents an averaging matrix taking nodal vectors into zone-centered vectors, while C_x, C_y, and C_z represent the discretized versions of the differentiation operators $\partial/\partial x$, $\partial/\partial y$, and $\partial/\partial z$, respectively. Then, for each ℓ,

$$C_\ell \equiv \mu_\ell C_x + \eta_\ell C_y + \xi_\ell C_z$$

is the discretized version of the $\Omega_\ell \cdot \nabla$ operator on the left-hand side of (3.1).

To represent the source term, we define the zone-centered vector

$$Q \equiv \begin{pmatrix} Q_1 \\ \vdots \\ Q_L \end{pmatrix} \quad \text{with} \quad Q_\ell \equiv \begin{pmatrix} Q_{1,\ell} \\ \vdots \\ Q_{K,\ell} \end{pmatrix} \in \mathbf{R}^{zones},$$

$$Q_{k,\ell} \equiv \begin{pmatrix} Q_{1k,\ell} \\ \vdots \\ Q_{Jk,\ell} \end{pmatrix} \in \mathbf{R}^{MJ}, \quad \text{and} \quad Q_{jk,\ell} \equiv \begin{pmatrix} q_{1jk,\ell} \\ \vdots \\ q_{Mjk,\ell} \end{pmatrix} \in \mathbf{R}^{M},$$

where $q_{ijk,\ell} \equiv q(r_{ijk}, \Omega_\ell)$ is given.

With I_{zones} the $MJK \times MJK$ identity matrix, we then define the $MJK \times LMJK$ matrices

$$L_{n,m} \equiv (w_1 Y_n^m(\Omega_1) I_{zones} \,|\, w_2 Y_n^m(\Omega_2) I_{zones} \,|\, \cdots \,|\, w_L Y_n^m(\Omega_L) I_{zones}) \tag{4.7}$$

and the $LMJK \times MJK$ matrices

$$L_{n,m}^{+} \equiv \begin{pmatrix} Y_n^m(\Omega_1) I_{zones} \\ \vdots \\ Y_n^m(\Omega_L) I_{zones} \end{pmatrix}. \tag{4.8}$$

Note that

$$L_{n,m} L_{n',m'}^{+} = \sum_{\ell=1}^{L} w_\ell Y_n^m(\Omega_\ell) Y_{n'}^{m'}(\Omega_\ell) I_{zones},$$

and it was proven in [5] that, for $n, n' = 0, 1$ and $|m| \le n, |m'| \le n'$, we have

$$L_{n,m} L_{n',m'}^{+} = \delta_{n,n'} \delta_{m,m'} I_{zones}. \tag{4.9}$$

We also define the grouped matrices L_n and L_n^+ as

$$L_n = \begin{pmatrix} L_{n,-n} \\ \vdots \\ L_{n,n} \end{pmatrix}$$

and

$$L_n^{+} = (L_{n,-n}^{+}, \dots, L_{n,n}^{+}).$$

Furthermore we need

$$\begin{aligned} &\Gamma_0 = \operatorname{diag}(\gamma_{0,111}, \dots, \gamma_{0,MJK}) \text{ with } \gamma_0 = \sigma_{s,0}/\sigma \le 1, \\ &\bar{\Sigma} \equiv I_L \otimes \Sigma, \text{ and} \\ &\bar{S} \equiv I_L \otimes S \end{aligned} \tag{4.10}$$

with I_L the $L \times L$ identity matrix. Then, with $D_\ell \equiv (\Sigma^{-1} C_\ell + S) \in \mathbf{R}^{zones \times nodes}$ and

$$D \equiv \operatorname{diag}(D_1, \dots, D_L),$$

the discretized version of the BTE equation (3.1) reads

$$D\Psi = L_0^{+} \Gamma_0 L_0 \bar{S} \Psi + \bar{\Sigma}^{-1} Q. \tag{4.11}$$

4.2. Discretized Dirichlet boundary conditions. For the boundary conditions (3.2), when $x = x_0$, the normal $\vec{n}(r_{0jk}) = (-1, 0, 0)$ for all j, k. Hence, $\vec{n}(r_{0jk}) \cdot \Omega_\ell = -\mu_\ell$, and for $\mu_\ell > 0$ we have

$$\psi_{0jk,\ell} = g_{0jk,\ell} (\equiv g(r_{0jk}, \Omega_\ell)). \tag{4.12}$$

The other cases are treated similarly. We let G be the nodal vector made out of the $g_{ijk,\ell}$ and built as the Ψ vector.

To isolate the boundary values, first note that for a direction vector Ω_ℓ with all its components positive, ψ satisfies a Dirichlet condition for all $r = r_{0jk}$, r_{i0k}, or r_{ij0}, i.e., for an r on any one of the three faces $x = x_0$, $y = y_0$, or $z = z_0$. In this case, after discretization, the boundary conditions (4.12) and their relevant $y-$ and $z-$ counterparts can be written in tensor notation as $E_{000}^T(\Psi - G) = 0$, where

$$E_{000}^T \equiv \begin{pmatrix} e_{0K}^T \otimes I_{J+1} \otimes I_{M+1} \\ (0, I_K) \otimes e_{0J}^T \otimes I_{M+1} \\ (0, I_K) \otimes (0, I_J) \otimes e_{0M}^T \end{pmatrix}$$

with $e_{0M} = (1, 0, \ldots, 0)^T \in \mathbf{R}^{M+1}$, and similarly for the vectors e_{0J} and e_{0K}. More generally, e_{IJ} designates a column vector of size $J + 1$, filled with zeros everywhere except for a 1 on the $(I + 1)$th row. There are different E matrices for the other possible cases. For example, for a direction Ω_ℓ with $\mu_\ell > 0$, $\eta_\ell > 0$ and $\xi_\ell < 0$, ψ satisfies a Dirichlet condition for r on any one of the three faces $x = x_0$, $y = y_0$, or $z = z_K$. We then have $E_{00K}(\Psi - G) = 0$, where

$$E_{00K}^T \equiv \begin{pmatrix} e_{KK}^T \otimes I_{J+1} \otimes I_{M+1} \\ (I_K, 0) \otimes e_{0J}^T \otimes I_{M+1} \\ (I_K, 0) \otimes (0, I_J) \otimes e_{0M}^T \end{pmatrix}.$$

In all, there are eight different E_{ijk} matrices, with $i = 0$ or M, $j = 0$ or J, and $k = 0$ or K. Defining

$$B_\ell = \begin{cases} E_{000}^T\,, \text{ if } \mu_l > 0, \eta_l > 0, \text{ and } \xi_l > 0, \\ E_{M00}^T\,, \text{ if } \mu_l < 0, \eta_l > 0, \text{ and } \xi_l > 0, \\ E_{0J0}^T\,, \text{ if } \mu_l > 0, \eta_l < 0, \text{ and } \xi_l > 0, \\ E_{00K}^T\,, \text{ if } \mu_l > 0, \eta_l > 0, \text{ and } \xi_l < 0, \\ E_{MJ0}^T\,, \text{ if } \mu_l < 0, \eta_l < 0, \text{ and } \xi_l > 0, \\ E_{M0K}^T\,, \text{ if } \mu_l < 0, \eta_l > 0, \text{ and } \xi_l < 0, \\ E_{0JK}^T\,, \text{ if } \mu_l > 0, \eta_l < 0, \text{ and } \xi_l < 0, \\ E_{MJK}^T\,, \text{ if } \mu_l < 0, \eta_l < 0, \text{ and } \xi_l < 0, \end{cases} \tag{4.13}$$

the discretized Dirichlet boundary conditions for each Ω_ℓ thus read

$$B_\ell \Psi_\ell = B_\ell G_\ell. \tag{4.14}$$

We have $B_l \in \mathbf{R}^{(nodes-zones)\times nodes}$.

4.3. The complete discretized system. We now combine (4.11) and the boundary conditions (4.14) into a single matrix notation. In this view we define

$$H \equiv \operatorname{diag}(H_1, \dots, H_L),$$

where

$$H_\ell \equiv \begin{pmatrix} D_\ell \\ B_\ell \end{pmatrix}.$$

Note that H_ℓ operates on nodal vectors. Let also

$$Z \equiv I_L \otimes Z_0, \quad \text{where } Z_0 \equiv \begin{pmatrix} I_{zones} \\ 0 \end{pmatrix} \in \mathbf{R}^{nodes \times zones}, \tag{4.15}$$

such that the matrix Z injects zone-centered vectors into the nodal vector space. For the boundary terms, define the block diagonal matrix $\bar{B}$ by

$$\bar{B} \equiv \operatorname{diag}(B_1^0, \dots, B_L^0), \quad \text{where } B_\ell^0 \equiv \begin{pmatrix} 0 \\ B_\ell \end{pmatrix}$$

for all ℓ, with each $B_\ell^0 \in \mathbf{R}^{nodes \times nodes}$, as well as $\beta \equiv \bar{B}G$.

The complete discretization of (3.1)–(3.2) can now be written in the compact form

$$H\Psi = ZL_0^+ \Gamma_0 L_0 \bar{S}\Psi + Z\bar{\Sigma}^{-1}Q + \beta. \tag{4.16}$$

Equivalently with $T = H - ZL_0^+\Gamma_0 L_0 \bar{S}$, we have

$$T\Psi = Z\bar{\Sigma}^{-1}Q + \beta. \tag{4.17}$$

It is shown in [5] that H is invertible. So, we can multiply (4.16) by $L_0\bar{S}H^{-1}$, to yield

$$L_0\bar{S}\Psi = L_0\bar{S}H^{-1}ZL_0^+\Gamma_0 L_0\bar{S}\Psi + L_0\bar{S}H^{-1}(Z\bar{\Sigma}^{-1}Q + \beta).$$

Defining $\Phi_0 \equiv L_0\bar{S}\Psi$, $R_0 \equiv L_0\bar{S}H^{-1}(Z\bar{\Sigma}^{-1}Q + \beta)$, and $K_{0,0} \equiv L_0\bar{S}H^{-1}ZL_0^+$, we obtain

$$\Phi_0 = K_{0,0}\Gamma_0\Phi_0 + R_0$$

or

$$A_0\Phi_0 = R_0 \tag{4.18}$$

with

$$A_0 \equiv I_{zones} - K_{0,0}\Gamma_0. \tag{4.19}$$

It is also shown in [5] that A_0 is nonsingular. Once Φ_0 is obtained by solving (4.18), Ψ is recovered by solving the equation

$$H\Psi = ZL_0^+\Gamma_0\Phi_0 + Z\bar{\Sigma}^{-1}Q + \beta.$$

5. Preconditioners and the initial guess. Due to the form of the matrix A_0 in equation (4.18), an iterative solution method is normally used, and a simple Richardson or source iteration is the most common choice. The selection of a preconditioner and an initial guess to speed up the iterative solving of (4.18) has been discussed in [5]. The preconditioner was derived through a "consistent" discretization of a limiting diffusion approximation to the BTE, and its use in Richardson's method is called DSA. We state the results of this discussion here, referring to [5] for the proofs, and restricting our attention to isotropic scattering.

5.1. Discrete DSA results. We first note that the definitions of the discrete moment matrices $L_{n,m}$ and $L^+_{n,m}$ can be easily modified to operate directly on the nodal vector Ψ. This is accomplished by replacing the I_{zones} identity matrix by the I_{nodes} identity in equations (4.7) and (4.8). We denote these nodal moment operators by $\tilde{L}_{n,m}$ and $\tilde{L}^+_{n,m}$, respectively, and analogously the operators $\tilde{L}_n$ and $\tilde{L}^+_n$. We can then define the nodal moments $\tilde{\Phi}_n$ of Ψ by

$$\tilde{\Phi}_n \equiv \tilde{L}_n \Psi.$$

To take discrete moments of the boundary conditions, we need to introduce the matrix operator $L_{\vec{n}}$ defined by

$$L_{\vec{n}} \equiv (v_1 w_1 Y_0^0 S_{\vec{n}} \,|\, v_2 w_2 Y_0^0 S_{\vec{n}} \,|\, \cdots \,|\, v_L w_L Y_0^0 S_{\vec{n}}),$$

with $v_\ell \equiv \vec{n} \cdot \Omega_\ell$ if $\vec{n} \cdot \Omega_\ell < 0$ and 0 otherwise and with $S_{\vec{n}}$ defined so that $S_{\vec{n}}\Psi$ gives a vector containing only two-dimensional zone-averaged entries of Ψ on the face of the box corresponding to $\vec{n}$. We have for

$$\vec{n} = \vec{n}_{x_0} \equiv (-1,0,0) : S_{\vec{n}_{x_0}} \equiv S_K \otimes S_J \otimes e^T_{0M}, \tag{5.1}$$

$$\vec{n} = \vec{n}_{x_M} \equiv (1,0,0) : S_{\vec{n}_{x_M}} \equiv S_K \otimes S_J \otimes e^T_{MM}, \tag{5.2}$$

and similarly for the other two directions.

The DSA preconditioner is obtained using a P_1 approximation to (4.17) that consists in approximating Ψ by $\tilde{L}^+_0\tilde{\Phi}_0 + \tilde{L}^+_1\tilde{\Phi}_1$. The following discrete P_1 system was derived in [5]:

$$T_1 \begin{pmatrix} \tilde{\Phi}_0 \\ \tilde{\Phi}_1 \end{pmatrix} \equiv \begin{pmatrix} L_{x_0,0} & L_{x_0,1} \\ L_{y_0,0} & L_{y_0,1} \\ L_{z_0,0} & L_{z_0,1} \\ T_{00} & T_{01} \\ T_{10} & T_{11} \\ L_{x_M,0} & L_{x_M,1} \\ L_{y_J,0} & L_{y_J,1} \\ L_{z_K,0} & L_{z_K,1} \end{pmatrix} \begin{pmatrix} \tilde{\Phi}_0 \\ \tilde{\Phi}_1 \end{pmatrix} = \begin{pmatrix} G_{x_0} \\ G_{y_0} \\ G_{z_0} \\ (\Sigma^0)^{-1}Q_0 \\ (\Sigma^1)^{-1}Q_1 \\ G_{x_M} \\ G_{y_J} \\ G_{z_K} \end{pmatrix}, \tag{5.3}$$

where

$$\begin{aligned} T_{00} &= (I_{zones} - \Gamma_0)S^0 \\ T_{01} &= \frac{1}{\sqrt{3}}[-\Sigma^{-1}C_y, \Sigma^{-1}C_z, -\Sigma^{-1}C_x] \\ T_{10} &= \frac{1}{\sqrt{3}}[-C_y^T\Sigma^{-1}, C_z^T\Sigma^{-1}, -C_x^T\Sigma^{-1}]^T \\ T_{11} &= S^1, \end{aligned}$$

with $S^n \equiv I_{2n+1} \otimes S$, $\Sigma^n \equiv I_{2n+1} \otimes \Sigma$, and $Q_n = L_n Q$ $(n = 0, 1)$. Also, $L_{x_0,0} \equiv L_{\vec{n}} \tilde{L}_0^+$, $L_{x_0,1} \equiv L_{\vec{n}} \tilde{L}_1^+$, and $G_{x_0} \equiv L_{\vec{n}} G$ for $\vec{n} = \vec{n}_{x_0} \equiv (-1, 0, 0)$, and similarly for the other directions. The T_1 matrix defined in (5.3) is the P_1 approximation to T. Its first and last lines correspond to the boundary conditions.

The system (5.3) can be reduced [5] to the solution of a diffusion problem involving only $\tilde{\Phi}_0$, namely

$$\begin{aligned} D_{co}\tilde{\Phi}_0 = {} & S^T \Delta r^0 Q_0 - T_{10}^T \Delta r^1 Q_1 \\ & + 2\frac{1}{\sqrt{4\pi}} \sum_{\ell=1}^{L} w_\ell S_K^T \Delta z S_K \otimes S_J^T \Delta y S_J \otimes (v_{x_0,\ell} e_{0M} e_{0M}^T + v_{x_M,\ell} e_{MM} e_{MM}^T) \cdot G_\ell \\ & + 2\frac{1}{\sqrt{4\pi}} \sum_{\ell=1}^{L} w_\ell S_K^T \Delta z S_K \otimes (v_{y_0,\ell} e_{0J} e_{0J}^T + v_{y_J,\ell} e_{JJ} e_{JJ}^T) \otimes S_M^T \Delta x S_M \cdot G_\ell \\ & + 2\frac{1}{\sqrt{4\pi}} \sum_{\ell=1}^{L} w_\ell (v_{z_0,\ell} e_{0K} e_{0K}^T + v_{z_K,\ell} e_{KK} e_{KK}^T) \otimes S_J^T \Delta y S_J \otimes S_M^T \Delta x S_M \cdot G_\ell, \end{aligned} \tag{5.4}$$

where $\Delta r^n \equiv I_{2n+1} \otimes \Delta r$ for $n = 0, 1$, $v_{x_0,\ell} = \vec{n}_{x_0} \cdot \Omega_\ell$ if $\vec{n}_{x_0} \cdot \Omega_\ell < 0$ and 0 otherwise, etc., $G_\ell \in \mathbf{R}^{nodes}$ are the elements of the boundary condition nodal vector G, and

$$\begin{aligned} D_{co} \equiv {} & S^T \Delta r \Sigma_{a,0} S + 2\alpha A \\ & + \frac{1}{3}\left(C_x^T \Delta r \Sigma^{-1} C_x + C_y^T \Delta r \Sigma^{-1} C_y + C_z^T \Delta r \Sigma^{-1} C_z\right), \end{aligned} \tag{5.5}$$

with $\alpha = \frac{1}{4\pi} \sum_{\mu_l > 0} w_l \mu_l$, $\Sigma_{a,0} \equiv \Sigma(I - \Gamma_0)$, and

$$A = (\hat{E}_{MM}\hat{E}_{MM}^T + \hat{E}_{0M}\hat{E}_{0M}^T) + (\hat{E}_{JJ}\hat{E}_{JJ}^T + \hat{E}_{0J}\hat{E}_{0J}^T) + (\hat{E}_{KK}\hat{E}_{KK}^T + \hat{E}_{0K}\hat{E}_{0K}^T), \tag{5.6}$$

where

$$\hat{E}_{0M} \equiv S_{\vec{n}_{x_0}}^T (\Delta z \otimes \Delta y \otimes I_M)^{1/2}, \quad \hat{E}_{MM} \equiv S_{\vec{n}_{x_M}}^T (\Delta z \otimes \Delta y \otimes I_M)^{1/2}, \tag{5.7}$$

and similarly for other directions.

It is shown in [5] that D_{co} is singular. Nevertheless, the system (5.4) has solutions and can be solved in a least-squares sense using the pseudo-inverse D_{co}^+ of D_{co} [9, 8]. Then, the DSA preconditioner for A_0 in (4.18) can be obtained from the P_1 approximation to the transport problem. This preconditioner reads [5]

$$C_0 = I_{zones} + S D_{co}^+ S^T \Sigma \Delta r \Gamma_0. \tag{5.8}$$

It is also shown in [5] that a good initial guess is given by

$$\Phi_0 = S D_{co}^+ \left\{ \begin{pmatrix} \Sigma^0 \Delta r S \\ \Delta r \Sigma^1 T_{10} \end{pmatrix}^T \begin{pmatrix} (\Sigma^0)^{-1} Q_0 \\ (\Sigma^1)^{-1} Q_1 \end{pmatrix} + 2\frac{1}{\sqrt{4\pi}} \sum_{\ell=1}^{L} W_\ell G_\ell \right\}, \tag{5.9}$$

where all the boundary terms are lumped into the sum over ℓ.

6. Limiting behavior of A_0 and C_0.

In this section, we demonstrate that the DSA preconditioner C_0 works well in different problem regimes. Our results are 3-D generalizations of the slab geometry results of Ashby et al. [4]. For ease of readability, the proofs were put in an appendix. Throughout the analysis, the number of quadrature points (L) and the number of spatial zones in each direction (M, J, and K) are assumed constant, as well as the mesh size.

Recall that the matrix A_0 is given by

$$A_0 = I_{zones} - K_{0,0}\Gamma_0,$$

where $K_{0,0} = L_0\bar{S}H^{-1}ZL_0^+$. For a fixed mesh size, H is a function only of Σ, hence A_0 is a function of the diagonal matrices Σ and Γ_0. We write $A_0 = A_0(\Sigma, \Gamma_0)$ to denote this dependence. Also, in what follows, I stands for I_{zones}.

6.1. The thick regime.

The thick regime refers to problems with large total cross sections, i.e., where $\|\Sigma^{-1}\|_2$ is small. We prove in section A.2 the following general result for the thick limit.

THEOREM 6.1. *Let A_0, Σ, and Γ_0 be defined as above. Then*

$$\|A_0(\Sigma,\Gamma_0) - (I - \Gamma_0)\|_2 \to 0 \quad \textit{as} \quad \|\Sigma^{-1}\|_2 \to 0, \tag{6.1}$$

uniformly for $0 \le \Gamma_0 \le I$.

6.1.1. The asymptotic diffusion limit.

A particular case of the thick regime is the asymptotic diffusion limit, which is defined by setting

$$\begin{aligned} \Sigma &= \epsilon^{-1}\hat{\Sigma}, \\ \Gamma_0 &= I - \epsilon^2\hat{\Gamma}_0, \\ Q &= \epsilon\hat{Q}, \end{aligned} \tag{6.2}$$

where $\hat{\Sigma}$ and $\hat{\Gamma}_0$ are fixed diagonal matrices, $\hat{Q}$ is a fixed zone-centered vector, and letting $\epsilon \to 0$. In view of Theorem 6.1, $\Gamma_0 \to I$ in a thick regime implies $A_0 \to 0$ so that C_0 has to converge to infinity to be a good preconditioner. The following theorem, proved in section A.2.1, shows the effectiveness of the DSA preconditioner in the asymptotic diffusion limit (even when $\hat{\Gamma}_0 = 0$).

THEOREM 6.2. *Assume that $\Sigma = \epsilon^{-1}\hat{\Sigma}$ and that $\Gamma_0 = I - \epsilon^2\hat{\Gamma}_0$, where $\hat{\Sigma} > 0$ and $\hat{\Gamma}_0 \ge 0$ are fixed diagonal matrices. Then*

$$\|C_0(\epsilon)A_0(\epsilon) - I\|_2 \to 0 \quad \textit{as} \quad \epsilon \to 0. \tag{6.3}$$

We also have (see section A.2.1) that in the asymptotic diffusion limit, $\bar{S}\Psi$ is well approximated (in L^2 norm) by $L_0^+\Phi_0$, where Ψ is the solution of (4.16) and Φ_0 is the solution of (4.18). This is formalized as follows.

THEOREM 6.3. *Assume that $\Sigma = \epsilon^{-1}\hat{\Sigma}$, $\Gamma_0 = I - \epsilon^2\hat{\Gamma}_0$, and $Q = \epsilon\hat{Q}$ for any fixed diagonal matrices $\hat{\Sigma} > 0$ and $\hat{\Gamma}_0 \ge 0$, and fixed vector $\hat{Q}$. Let Δr be fixed. Then*

$$\|\bar{S}\Psi_\epsilon - L_0^+\Phi_{0,\epsilon}\|_2 \to 0 \tag{6.4}$$

as $\epsilon \to 0$, where Ψ_ϵ and $\Phi_{0,\epsilon}$ are the respective solutions of (4.16) *and* (4.18). *If we additionally assume that $g \equiv 0$ in* (3.2) (*i.e., zero Dirichlet boundary conditions*), *then it also follows that*

$$\|\Phi_{0,\epsilon}^{init} - \Phi_{0,\epsilon}\|_2 \to 0, \tag{6.5}$$

where $\Phi_{0,\epsilon}^{init}$ is given by (5.9).

6.1.2. Another thick limit. We here consider the case of a thick regime where Γ_0 is bounded away from the identity. Then A_0 is bounded away from zero, and the analysis is somewhat simpler. Theorem 6.4 is proved in section A.2.2.

THEOREM 6.4. *Let C_0 be defined as above. Then for any $0 < \epsilon < 1$,*

$$\|C_0(\Sigma, \Gamma_0) - (I - \Gamma_0)^{-1}\|_2 \to 0 \quad \text{as} \quad \|\Sigma^{-1}\|_2 \to 0, \tag{6.6}$$

uniformly for $0 \leq \Gamma_0 \leq (1 - \epsilon)I$.

In view of Theorem 6.1, we have as an immediate corollary.

COROLLARY 6.5. *Under the assumptions of Theorem 6.1, given any $0 < \epsilon < 1$, we have*

$$\|C_0(\Sigma, \Gamma_0)A_0(\Sigma, \Gamma_0) - I\|_2 \to 0 \quad \text{as} \quad \|\Sigma^{-1}\|_2 \to 0,$$

uniformly for $0 \leq \Gamma_0 \leq (1 - \epsilon)I$.

6.2. The thin regime. The thin regime refers to problems with small total cross-sections, i.e., where $\|\Sigma\|_2$ is small. In this limit, the source iteration procedure is known to converge in one iteration [13]. It is therefore not surprising to have the following theorem.

THEOREM 6.6. *Let A_0 be defined as above. Then*

$$\|A_0(\Sigma, \Gamma_0) - I\|_2 \to 0$$

as $\|\Sigma\|_2 \to 0$, uniformly for $0 \leq \Gamma_0 \leq I$.

As in slab geometry [4], the proof involves the observation that H_ℓ^{-1} has a limiting value that is annihilated by Z_0 on the right so that $H^{-1}Z \to 0$, and so $\|A_0 - I\|_2 \to 0$ as $\|\Sigma\|_2 \to 0$.

Note that this theorem remains valid in pure absorbing media, i.e., for $\|\Gamma_0\|_2 \to 0$ and $K_1 < \|\Sigma\|_2 < K_2$ (with K_1, K_2 positive constants). This is also not surprising since the source iteration procedure is known to converge in one iteration in this limit as well [13].

Theorem 6.6 implies that the system (4.18) needs progressively less preconditioning as $\|\Sigma\|_2$ gets small. A preconditioner for (4.18) should thus converge to the identity as $\|\Sigma\|_2 \to 0$. The next result says that this indeed holds for C_0.

THEOREM 6.7. *Let C_0 be defined as above, and assume $\Sigma = \epsilon\hat{\Sigma}$. Then*

$$\|C_0(\epsilon, \Gamma_0) - I\|_2 \to 0$$

as $\epsilon \to 0$, uniformly for $0 \leq \Gamma_0 \leq I$.

The proof of this theorem is provided in section A.3. Again, this remains true in the pure absorbing case.

7. Discussion. Despite the singularity of the "consistently" differenced 3-D diffusion approximation required by the DSA, we could extend the slab geometry results of Ashby et al. [4] to 3-D geometry. We proved the efficiency of the 3-D DSA preconditioner in the asymptotic diffusion limit even though A_0 tends to zero. We also proved that in this limit, the discrete BTE solution is well-approximated (in the L^2 sense of Theorem 6.3) by its first discrete angular moment. Furthermore, the 3-D DSA preconditioner was proved efficient in another thick limit where A_0 is bounded away from zero. Our theoretical results thus confirm the good numerical results obtained by Brown [5]. Even if it does not pertain to the preconditioner performances, one should be aware that the discrete ordinate approximation does not necessarily provide accurate solutions in the thick limit. This was demonstrated by Larsen and Morel [10, 11] for the diamond-difference scheme, in case of unresolved boundary layers with anisotropic incoming fluxes. One should thus be careful in interpreting the output in this limit. In the thin limit, acceleration becomes unnecessary and the 3-D DSA preconditioner accordingly tends to the identity.

Possible theoretical extensions include the introduction of linear anisotropy [5] at the price of more cumbersome notations. Also, reflected boundary conditions could be introduced. This was done in slab geometry [4] using a mirror domain extension obtained by reflection about the boundary. Ashby et al. then obtained relationships between the A_0 and C_0 matrices and their reflected counterparts on the mirror domain. Kronecker product notations would certainly appear extremely useful in trying to generalize such results to 3-D geometry. Finally, the behavior of our DSA preconditioner for any value of the cross-sections still has to be theoretically investigated in slab geometry before possible 3-D generalizations can be addressed.

Another context where DSA can be found useful is the corner balance spatial discretization scheme [1, 2]. We started addressing the extension of the slab geometry DSA analysis to this scheme.

Appendix.

A.1. Additional notation. Before proving the theorems, we need to introduce some additional notation. Since

$$H_\ell \equiv \begin{pmatrix} S + \Sigma^{-1} C_\ell \\ B_\ell \end{pmatrix} \in \mathbf{R}^{nodes \times nodes}$$

for all $l = 1, \dots, L$, it can also be written as

$$H_\ell = H_{\ell,0} + Z_0(\Sigma^{-1} C_\ell),$$

with Z_0 defined in (4.15) and

$$H_{\ell,0} \equiv \begin{pmatrix} S \\ B_\ell \end{pmatrix}$$

independent of Σ. Note that H_ℓ and $H_{\ell,0}$ were shown to be nonsingular in [5]. Note also that what was defined as E_{000} in [5] is now defined as E_{000}^T, in order to resemble the one-dimensional case of [4] (where $e_{..}$ plays the role of $E_{...}$ here). Next, we define the matrices V_ℓ and W_ℓ so that

$$(V_\ell, W_\ell) = H_{\ell,0}^{-1},$$

where $V_\ell \in \mathbf{R}^{nodes \times zones}$ and $W_\ell \in \mathbf{R}^{nodes \times (nodes - zones)}$. Hence the following identities are true:

$$\begin{aligned} & V_\ell S + W_\ell B_\ell = I_{nodes}, \\ \text{(A.1)} \qquad & S V_\ell = I \qquad (i.e., I_{zones}), \\ & S W_\ell = 0\,(\in \mathbf{R}^{zones \times zones}), \\ \text{(A.2)} \qquad & B_\ell V_\ell = 0\,(\in \mathbf{R}^{[nodes-zones] \times [nodes-zones]}), \text{ and} \\ & B_\ell W_\ell = I_{[nodes-zones]}. \end{aligned}$$

Since B_ℓ defined in (4.13) can take eight different forms depending on the sign of μ_ℓ, η_ℓ and ξ_ℓ, V_ℓ and W_ℓ can each also take eight different forms and are constant in one octant. Further developments require a closed form for V_ℓ, which we derive in the following lemma.

LEMMA A.1. *We have*

$$V_\ell = \begin{cases} L_K \otimes L_J \otimes L_M, & \textit{if } \mu_\ell \geq 0, \eta_\ell \geq 0, \textit{ and } \xi_\ell \geq 0, \\ L_K \otimes L_J \otimes U_M, & \textit{if } \mu_\ell \leq 0, \eta_\ell \geq 0, \textit{ and } \xi_\ell \geq 0, \\ L_K \otimes U_J \otimes L_M, & \textit{if } \mu_\ell \geq 0, \eta_\ell \leq 0, \textit{ and } \xi_\ell \geq 0, \\ U_K \otimes L_J \otimes L_M, & \textit{if } \mu_\ell \geq 0, \eta_\ell \geq 0, \textit{ and } \xi_\ell \leq 0, \\ L_K \otimes U_J \otimes U_M, & \textit{if } \mu_\ell \leq 0, \eta_\ell \leq 0, \textit{ and } \xi_\ell \geq 0, \\ U_K \otimes L_J \otimes U_M, & \textit{if } \mu_\ell \leq 0, \eta_\ell \geq 0, \textit{ and } \xi_\ell \leq 0, \\ U_K \otimes U_J \otimes L_M, & \textit{if } \mu_\ell \geq 0, \eta_\ell \leq 0, \textit{ and } \xi_\ell \leq 0, \\ U_K \otimes U_J \otimes U_M, & \textit{if } \mu_\ell \leq 0, \eta_\ell \leq 0, \textit{ and } \xi_\ell \leq 0, \end{cases} \tag{A.3}$$

where

$$L_M \equiv 2 \begin{pmatrix} 0 & 0 & \cdots & 0 \\ (-1)^2 & 0 & \cdots & 0 \\ (-1)^3 & (-1)^2 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots \\ (-1)^M & (-1)^{M-1} & \cdots & 0 \\ (-1)^{M+1} & (-1)^M & \cdots & (-1)^2 \end{pmatrix} \in \mathbf{R}^{(M+1)\times M},$$

$$U_M \equiv 2 \begin{pmatrix} (-1)^2 & (-1)^3 & \cdots & (-1)^{M+1} \\ 0 & (-1)^2 & \cdots & (-1)^M \\ 0 & 0 & \cdots & (-1)^{M-1} \\ \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \cdots & (-1)^2 \\ 0 & 0 & \cdots & 0 \end{pmatrix} \in \mathbf{R}^{(M+1)\times M}.$$

Proof. First the V_ℓ in (A.3) verify $B_\ell V_\ell = 0$ for all ℓ. Indeed, for instance,

$$E_{00K}^T \cdot (U_K \otimes L_J \otimes L_M) = \begin{pmatrix} e_{KK}^T \otimes I_{J+1} \otimes I_{M+1} \\ (I_K, 0) \otimes e_{0J}^T \otimes I_{M+1} \\ (I_K, 0) \otimes (0, I_J) \otimes e_{0M}^T \end{pmatrix} (U_K \otimes L_J \otimes L_M) = 0$$

since $e_{KK}^T U_K = 0$, $e_{0J}^T L_J = 0$, and $e_{0M}^T L_M = 0$. Then the V_ℓ in (A.3) also verify $SV_\ell = I$ for all ℓ, because $S_K L_K = I_K = S_K U_K$, and similarly for the other two directions. The fact that $H_{\ell,0}$ is nonsingular assures that these V_ℓ are unique. □

Furthermore, we define

$$\begin{aligned} F_x &\equiv S^T \Delta r C_x + C_x^T \Delta r S, \\ F_y &\equiv S^T \Delta r C_y + C_y^T \Delta r S, \\ F_z &\equiv S^T \Delta r C_z + C_z^T \Delta r S, \end{aligned} \tag{A.4}$$

which can also be written in view of Lemma A.1 in [5] as

$$\begin{aligned} F_x &= S_K^T \Delta z S_K \otimes S_J^T \Delta y S_J \otimes (-e_{0M} e_{0M}^T + e_{MM} e_{MM}^T), \\ F_y &= S_K^T \Delta z S_K \otimes (-e_{0J} e_{0J}^T + e_{JJ} e_{JJ}^T) \otimes S_M^T \Delta x S_M, \\ F_z &= (-e_{0K} e_{0K}^T + e_{KK} e_{KK}^T) \otimes S_J^T \Delta y S_J \otimes S_M^T \Delta x S_M. \end{aligned}$$

Given (5.1) and (5.7), we have

$$S_K^T \Delta z S_K \otimes S_J^T \Delta y S_J \otimes e_{0M} e_{0M}^T = S_{\vec{n}_{x_0}}^T (\Delta z \otimes \Delta y \otimes I_M) S_{\vec{n}_{x_0}} = \hat{E}_{0M} \hat{E}_{0M}^T.$$

Thus, we end up with

$$\begin{aligned} F_x &= \hat{E}_{MM} \hat{E}_{MM}^T - \hat{E}_{0M} \hat{E}_{0M}^T, \\ F_y &= \hat{E}_{JJ} \hat{E}_{JJ}^T - \hat{E}_{0J} \hat{E}_{0J}^T, \\ F_z &= \hat{E}_{KK} \hat{E}_{KK}^T - \hat{E}_{0K} \hat{E}_{0K}^T. \end{aligned}$$

A.2. Proofs for the thick regime. We first prove Theorem 6.1. We need two technical lemmas.

LEMMA A.2. *Let $0 < \delta < 1$ be given. Then for any $\Sigma > 0$ such that*

$$\|\Sigma^{-1}\|_2 \leq \epsilon_1 \equiv \frac{\delta}{\max_\ell \{\|C_\ell \cdot (V_\ell, W_\ell)\|_2\}}, \tag{A.5}$$

we have

$$SH_\ell^{-1} Z_0 = \sum_{k=0}^{\infty} (-1)^k (\Sigma^{-1} C_\ell V_\ell)^k$$

for all $\ell = 1, \dots, L$. Furthermore, the convergence is uniform in Σ with $\|\Sigma^{-1}\|_2 \leq \epsilon_1$.

Proof. For $\|\Sigma^{-1}\|_2 \leq \epsilon_1$, we have

$$\begin{aligned} H_\ell^{-1} &= H_{\ell,0}^{-1} (I + Z_0 \Sigma^{-1} C_\ell H_{\ell,0}^{-1})^{-1} \\ &= (V_\ell, W_\ell) \sum_{k=0}^{\infty} (-1)^k \left(Z_0 \Sigma^{-1} C_\ell \cdot (V_\ell, W_\ell) \right)^k, \end{aligned}$$

where the Neumann series converges uniformly since

$$\|Z_0 \Sigma^{-1} C_\ell \cdot (V_\ell, W_\ell)\|_2 \leq \|Z_0\|_2 \cdot \|\Sigma^{-1}\|_2 \|C_\ell \cdot (V_\ell, W_\ell)\|_2 \leq \delta < 1,$$

using $\|Z_0\|_2 = 1$. Thus,

$$\begin{aligned} SH_\ell^{-1} Z_0 &= S \cdot (V_\ell, W_\ell) \cdot \sum_{k=0}^{\infty} (-1)^k \left(Z_0 \Sigma^{-1} C_\ell \cdot (V_\ell, W_\ell) \right)^k Z_0 \\ &= S \cdot (V_\ell, W_\ell) \cdot Z_0 \sum_{k=0}^{\infty} (-1)^k \left(\Sigma^{-1} C_\ell \cdot (V_\ell, W_\ell) \cdot Z_0 \right)^k \\ &= \sum_{k=0}^{\infty} (-1)^k \left(\Sigma^{-1} C_\ell V_\ell \right)^k \end{aligned}$$

from the fact that $S \cdot (V_\ell, W_\ell) \cdot Z_0 = I$ (A.1) and $C_\ell \cdot (V_\ell, W_\ell) \cdot Z_0 = C_\ell V_\ell$. □

LEMMA A.3. *Let $0 \leq \Gamma_0 \leq I$, and let ϵ_1 be defined by* (A.5). *Then*

$$A_0 = (I - \Gamma_0) - \frac{1}{4\pi} F(\Sigma^{-1}) \cdot \Gamma_0, \tag{A.6}$$

where

$$F(\Sigma^{-1}) \equiv \sum_{\ell=1}^{L} w_\ell \sum_{k=1}^{\infty} (-1)^k \left(\Sigma^{-1} C_\ell V_\ell\right)^k, \tag{A.7}$$

whenever $\|\Sigma^{-1}\|_2 \leq \epsilon_1$, *with the series converging uniformly.*

Proof. We first consider $K_{0,0}$ defined in section 4.3. We have

$$\begin{aligned} K_{0,0} &\equiv L_0 \bar{S} H^{-1} Z L_0^+ \\ &= \frac{1}{4\pi} \sum_{\ell=1}^{L} w_\ell S H_\ell^{-1} Z_0 \\ &= \frac{1}{4\pi} \sum_{\ell=1}^{L} w_\ell \sum_{k=0}^{\infty} (-1)^k \left(\Sigma^{-1} C_\ell V_\ell\right)^k \\ &= I + \frac{1}{4\pi} \sum_{\ell=1}^{L} w_\ell \sum_{k=1}^{\infty} (-1)^k \left(\Sigma^{-1} C_\ell V_\ell\right)^k \end{aligned}$$

where we used successively Lemma A.2 and the fact that $\sum_{\ell=1}^{L} w_\ell = 4\pi$. The lemma now follows easily using the definition (4.19) of A_0. □

Proof of Theorem 6.1. Using (A.6), $\|\Gamma_0\|_2 \leq 1$ and $\frac{w_\ell}{4\pi} \leq 1$, it now follows that

$$\begin{aligned} \|A_0 - (I - \Gamma_0)\|_2 &\leq \frac{1}{4\pi} \left\| \sum_{\ell=1}^{L} w_\ell \sum_{k=1}^{\infty} (-1)^k \left(\Sigma^{-1} C_\ell V_\ell\right)^k \right\|_2 \|\Gamma_0\|_2 \\ &\leq \sum_{\ell=1}^{L} \sum_{k=1}^{\infty} \| \left(\Sigma^{-1} C_\ell V_\ell\right)^k \|_2 \to 0 \end{aligned}$$

as $\|\Sigma^{-1}\|_2 \to 0$, and the convergence is uniform in $0 \leq \Gamma_0 \leq I$. □

A.2.1. Proofs for the asymptotic diffusion limit. Here, we prove Theorems 6.2 and 6.3 for the asymptotic diffusion limit. Recall from (5.8) that

$$C_0 = I + S D_{co}^{+} S^T \Sigma \Delta r \Gamma_0. \tag{A.8}$$

Using (A.6), we can write

$$C_0 A_0 - I = -\Gamma_0 - \frac{1}{4\pi} F(\Sigma^{-1}) \Gamma_0 + S D_{co}^{+} S^T \Sigma \Delta r \Gamma_0 A_0. \tag{A.9}$$

We will prove Proposition A.6, which establishes an extended form for $S^T \Sigma \Delta r \Gamma_0 A_0$. This proposition requires two preliminary lemmas, which we now establish.

Lemma A.4. *With the above notations, we have*

$$\sum_{\ell=1}^{L} w_\ell \mu_\ell F_x V_\ell = \pi \alpha (\hat{E}_{MM} \hat{E}_{MM}^T + \hat{E}_{0M} \hat{E}_{0M}^T) \sum_{i=1}^{8} V_{\mathcal{L}_i},$$

where $\alpha \equiv \frac{1}{4\pi} \sum_{\mu_\ell > 0} w_\ell \mu_\ell$, *and* $V_{\mathcal{L}_i}$ *is the (unique) value of* V_ℓ *for all* ℓ *corresponding to a direction* Ω_ℓ *in octant* i $(i = 1, 2, \ldots, 8)$. *We have similar results for the* y *and* z *directions.*

Proof. We have

$$\sum_{l=1}^{L} w_l \mu_l F_x V_l = \sum_{\mu_l > 0} w_l \mu_l F_x V_l + \sum_{\mu_l < 0} w_l \mu_l F_x V_l.$$

We showed in section A.1 that F_x can be expressed as

$$F_x = \hat{E}_{MM} \hat{E}_{MM}^T - \hat{E}_{0M} \hat{E}_{0M}^T. \tag{A.10}$$

Recall that $S_{\vec{n}_{x_0}} \equiv S_K \otimes S_J \otimes e_{0M}^T$ selects the $x = x_0$ face and then forms two-dimensional zone averages on this face. Meanwhile, E_{000}^T also selects (among others) the $x = x_0$ face. Thus, there exists a matrix $M_{000,\vec{n}_{x_0}}$ restricting E_{000}^T such that

$$S_{\vec{n}_{x_0}} = M_{000,\vec{n}_{x_0}} E_{000}^T. \tag{A.11}$$

Now, in view of (4.13) and (A.2), $E_{000}^T V_\ell = 0$ for any ℓ such that $\mu_\ell > 0$, $\eta_\ell > 0$, and $\xi_\ell > 0$. Thus, $S_{\vec{n}_{x_0}} V_\ell = 0$ and given (5.7), $\hat{E}_{0M} \hat{E}_{0M}^T V_\ell = 0$ for such ℓ. Moreover, $S_{\vec{n}_{x_0}}$ can be obtained as in (A.11) from any B_ℓ defined in (4.13) that selects the $x = x_0$ face, that is, from any B_ℓ with ℓ such that $\mu_l > 0$. Therefore, $\hat{E}_{0M} \hat{E}_{0M}^T V_\ell = 0$ for any ℓ such that $\mu_\ell > 0$. Similarly, $\hat{E}_{MM} \hat{E}_{MM} V_\ell = 0$ for any ℓ such that $\mu_\ell < 0$. Thus, flipping the sign of the vanishing terms, we can write

$$\begin{aligned} \sum_{\ell=1}^{L} w_\ell \mu_\ell F_x V_\ell = & \sum_{\mu_\ell > 0} w_\ell \mu_\ell (\hat{E}_{MM} \hat{E}_{MM}^T + \hat{E}_{0M} \hat{E}_{0M}^T) V_\ell \\ & - \sum_{\mu_l < 0} w_l \mu_\ell (\hat{E}_{MM} \hat{E}_{MM}^T + \hat{E}_{0M} \hat{E}_{0M}^T) V_\ell. \end{aligned} \tag{A.12}$$

We have

$$\sum_{\ell=1}^{L} = \sum_{i=1}^{8} \sum_{\ell \in \mathcal{L}_i}, \text{ where } \mathcal{L}_i \text{ includes all the } \ell \text{ corresponding to a } \Omega_\ell \text{ in one octant } i.$$

Let us take the convention that $i = 1, 2, 3$, and 4 correspond to the four octants where $\mu_\ell > 0$. We introduce α

$$\begin{aligned} \alpha &\equiv \frac{1}{4\pi} \sum_{\mu_\ell > 0} w_\ell \mu_\ell \\ &= \frac{1}{4\pi} \sum_{i=1}^{4} \sum_{\ell \in \mathcal{L}_i} w_\ell \mu_\ell \\ &= \frac{1}{\pi} \sum_{\ell \in \mathcal{L}_i} w_\ell \mu_\ell \quad (i = 1, 2, 3 \text{ or } 4) \end{aligned}$$

by symmetry over the four octants $i = 1, 2, 3$, and 4. Due to the symmetrical placement of the μ_ℓ along the x-axis, we have for the other four octants

$$\alpha = -\frac{1}{\pi} \sum_{\ell \in \mathcal{L}_i} w_\ell \mu_\ell \quad (i = 5, 6, 7 \text{ or } 8).$$

Since V_ℓ is constant in each octant, we introduce the notation $V_{\mathcal{L}_i}$ to denote its value for all $\ell \in \mathcal{L}_i$, i.e., for all ℓ corresponding to a direction Ω_ℓ in octant i. Then

$$\begin{aligned}\sum_{\mu_\ell>0} w_\ell \mu_\ell (\hat{E}_{MM}\hat{E}_{MM}^T + \hat{E}_{0M}\hat{E}_{0M}^T)V_\ell &= \sum_{i=1}^{4}\sum_{\ell\in\mathcal{L}_i} w_\ell \mu_\ell (\hat{E}_{MM}\hat{E}_{MM}^T + \hat{E}_{0M}\hat{E}_{0M}^T)V_{\mathcal{L}_i} \\ &= \pi\alpha(\hat{E}_{MM}\hat{E}_{MM}^T + \hat{E}_{0M}\hat{E}_{0M}^T)\sum_{i=1}^{4} V_{\mathcal{L}_i}.\end{aligned}$$

Similarly, for $\mu_\ell < 0$, we have

$$\sum_{\mu_\ell<0} w_\ell \mu_\ell (\hat{E}_{MM}\hat{E}_{MM}^T + \hat{E}_{0M}\hat{E}_{0M}^T)V_\ell = -\pi\alpha \sum_{i=5}^{8}(\hat{E}_{MM}\hat{E}_{MM}^T + \hat{E}_{0M}\hat{E}_{0M}^T)V_{\mathcal{L}_i}.$$

The conclusion now follows directly from (A.12). □

Lemma A.5.

$$\sum_{\ell=1}^{L} w_\ell C_\ell^T \Sigma^{-1}\Delta r C_\ell V_\ell = \frac{4\pi}{3}\frac{1}{8}\left[C_x^T\Sigma^{-1}\Delta r C_x + C_y^T\Sigma^{-1}\Delta r C_y + C_z^T\Sigma^{-1}\Delta r C_z\right]\sum_{i=1}^{8} V_{\mathcal{L}_i},$$

where $V_{\mathcal{L}_i}$ is defined as in Lemma A.4.

Proof. We have

$$\begin{aligned}\sum_{\ell=1}^{L} w_\ell C_\ell^T \Sigma^{-1}\Delta r C_\ell V_\ell = \sum_{\ell=1}^{L} w_\ell[&(\mu_\ell)^2 C_x^T\Sigma^{-1}\Delta r C_x + \mu_\ell\eta_\ell C_x^T\Sigma^{-1}\Delta r C_y \\ &+ \mu_\ell\xi_\ell C_x^T\Sigma^{-1}\Delta r C_z + \eta_\ell\mu_\ell C_y^T\Sigma^{-1}\Delta r C_x \\ &+ (\eta_\ell)^2 C_y^T\Sigma^{-1}\Delta r C_y + \eta_\ell\xi_\ell C_y^T\Sigma^{-1}\Delta r C_z \\ &+ \xi_\ell\mu_\ell C_z^T\Sigma^{-1}\Delta r C_x + \xi_\ell\eta_\ell C_z^T\Sigma^{-1}\Delta r C_y \\ &+ (\xi_l)^2 C_z^T\Sigma^{-1}\Delta r C_z]V_\ell.\end{aligned} \tag{A.13}$$

First we look at the "diagonal" terms in (A.13). We have for the x-direction

$$\begin{aligned}\sum_{\ell=1}^{L} w_\ell(\mu_\ell)^2 C_x^T\Sigma^{-1}\Delta r C_x V_\ell &= \sum_{i=1}^{8}\sum_{\ell\in\mathcal{L}_i} w_\ell(\mu_\ell)^2 C_x^T\Sigma^{-1}\Delta r C_x V_\ell \\ &= \frac{4\pi}{3}\frac{1}{8}\sum_{i=1}^{8} C_x^T\Sigma^{-1}\Delta r C_x V_{\mathcal{L}_i}\end{aligned}$$

using (4.2) and the symmetry over the eight octants. Combining the three directions, we obtain Lemma A.5 provided the "nondiagonal" terms in (A.13) vanish. Indeed, take for instance

$$\begin{aligned}&\sum_{\ell=1}^{L} w_\ell\eta_\ell\mu_\ell C_y^T\Sigma^{-1}\Delta r C_x V_\ell \\ &\quad = C_y^T\Sigma^{-1}\Delta r\left\{\sum_{i=1}^{4}\sum_{\ell\in\mathcal{L}_i} w_\ell\eta_\ell\mu_\ell C_x V_\ell + \sum_{i=5}^{8}\sum_{\ell\in\mathcal{L}_i} w_\ell\eta_\ell\mu_\ell C_x V_\ell\right\}.\end{aligned}$$

If the four octants $i = 1, 2, 3$ and 4 correspond to positive values of μ_ℓ, we have

$$\sum_{i=1}^{4}\sum_{\ell\in\mathcal{L}_i} w_\ell\eta_\ell\mu_\ell C_x V_\ell = (I_K \otimes I_J \otimes (\Delta x)^{-1} D_M L_M)\sum_{i=1}^{4}\sum_{\ell\in\mathcal{L}_i} w_\ell\eta_\ell\mu_\ell,$$

using (A.3) as well as $S_K L_K = I_K = S_K U_K$ and $S_J L_J = I_J = S_J U_J$. Since by symmetry $\sum_{i=1}^{4}\sum_{\ell\in\mathcal{L}_i} w_\ell\eta_\ell\mu_\ell = 0$, the "nondiagonal" terms vanish, and Lemma A.5 is proved. $\square$

We are now prepared to establish the following proposition.

PROPOSITION A.6. *For* $\|\Sigma^{-1}\|_2 \le \epsilon_1$*, with* ϵ_1 *defined in* (A.5)*, we have*

$$\begin{aligned}
&S^T\Sigma\Delta r\Gamma_0 A_0\\
&\quad = \left\{\frac{1}{8}D_{co}\sum_{i=1}^{8} V_{\mathcal{L}_i} + \frac{1}{4\pi}\sum_{k=2}^{\infty}\sum_{\ell=1}^{L} w_\ell\left\{C_\ell^T\Delta r\Sigma^{-1}C_\ell + |\mu_\ell| A\right\}V_\ell((-1)\Sigma^{-1}C_\ell V_\ell)^{k-1}\right.\\
&\qquad\left. + \frac{1}{4\pi}S^T\Sigma\Delta r(I-\Gamma_0)F(\Sigma^{-1})\right\}\cdot\Gamma_0,
\end{aligned}$$

where D_{co} *and* A *were defined in* (5.5) *and* (5.6)*, respectively.*

Proof. From (A.6), we have

$$\begin{aligned}
S^T\Sigma\Delta r\Gamma_0 A_0 &= \left\{S^T\Sigma\Delta r(I-\Gamma_0) - \frac{1}{4\pi}S^T\Sigma\Delta r\Gamma_0 F(\Sigma^{-1})\right\}\Gamma_0\\
&= \left\{S^T\Delta r\Sigma_{a,0} - \frac{1}{4\pi}S^T\Sigma\Delta r F(\Sigma^{-1}) + \frac{1}{4\pi}S^T\Sigma\Delta r(I-\Gamma_0)F(\Sigma^{-1})\right\}\Gamma_0, \qquad \text{(A.14)}
\end{aligned}$$

where $\Sigma_{a,0} = \Sigma(I-\Gamma_0)$.

Let us look now at the $S^T\Sigma\Delta r F(\Sigma^{-1})$ term

$$S^T\Sigma\Delta r F(\Sigma^{-1}) = \sum_{k=1}^{\infty}(-1)^k\sum_{\ell=1}^{L} w_\ell S^T\Sigma\Delta r\left(\Sigma^{-1}C_\ell V_\ell\right)^k.$$

We have

$$\begin{aligned}
S^T\Sigma\Delta r\left(\Sigma^{-1}C_\ell V_\ell\right)^k &= S^T\Delta r C_\ell V_\ell\left(\Sigma^{-1}C_\ell V_\ell\right)^{k-1}\\
&= S^T\Delta r(\mu_\ell C_x + \eta_\ell C_y + \xi_\ell C_z)V_\ell\left(\Sigma^{-1}C_\ell V_\ell\right)^{k-1}\\
&= [-C_\ell^T\Delta r S + \mu_\ell F_x + \eta_\ell F_y + \xi_\ell F_z]V_\ell\left(\Sigma^{-1}C_\ell V_\ell\right)^{k-1},
\end{aligned}$$

where F_x, F_y, and F_z were defined in (A.4). Recalling that $SV_\ell = I$ (A.1), we can write after some manipulations

$$\begin{aligned}
S^T\Sigma\Delta r F(\Sigma^{-1}) = &-\sum_{\ell=1}^{L} w_\ell[-C_\ell^T\Delta r + (\mu_\ell F_x + \eta_\ell F_y + \xi_\ell F_z)V_\ell]\\
&+\sum_{\ell=1}^{L} w_\ell[-C_\ell^T\Delta r\Sigma^{-1}C_\ell V_\ell] \qquad \text{(A.15)}\\
&+\sum_{k=2}^{\infty}\sum_{\ell=1}^{L}[-w_\ell C_\ell^T\Delta r(-1)^{k+1}(\Sigma^{-1}C_\ell V_\ell)^k\\
&+(-1)^k w_l(\mu_\ell F_x + \eta_l F_y + \xi_l F_z)V_l(\Sigma^{-1}C_l V_l)^{k-1}].
\end{aligned}$$

In the first sum of (A.15), the first term vanishes since

$$\sum_{l=1}^{L} w_l C_l^T = \sum_{l=1}^{L} w_l \mu_l C_x^T + \sum_{l=1}^{L} w_l \eta_l C_y^T + \sum_{l=1}^{L} w_l \xi_l C_z^T = 0,$$

where we have used (4.3). Lemma A.4 takes care of the second term in the first sum, while we can apply Lemma A.5 to the second sum. With A defined in (5.6), we obtain

$$\begin{aligned} S^T \Sigma \Delta r F(\Sigma^{-1}) = &-\pi\alpha A \sum_{i=1}^{8} V_{\mathcal{L}_i} \\ &- \frac{4\pi}{3}\frac{1}{8}\left[C_x^T \Sigma^{-1} \Delta r C_x + C_y^T \Sigma^{-1} \Delta r C_y + C_z^T \Sigma^{-1} \Delta r C_z\right] \sum_{i=1}^{8} V_{\mathcal{L}_i} \\ &+ \sum_{k=2}^{\infty} \sum_{\ell=1}^{L} \left[-w_\ell C_\ell^T \Delta r (-1)^{k+1} (\Sigma^{-1} C_\ell V_\ell)^k \right. \\ &\left. + (-1)^k w_\ell (\mu_\ell F_x + \eta_\ell F_y + \xi_\ell F_z) V_\ell (\Sigma^{-1} C_\ell V_\ell)^{k-1}\right]. \end{aligned}$$

Since $SV_\ell = I$ for all ℓ we have $I = \frac{1}{8} S \sum_{i=1}^{8} V_{\mathcal{L}_i}$. Then we have, using (A.14) and recalling definition (5.5) of D_{co},

$$\begin{aligned} S^T \Sigma \Delta r \Gamma_0 A_0 = &\left\{ \frac{1}{8} D_{co} \sum_{i=1}^{8} V_{\mathcal{L}_i} + \frac{1}{4\pi} \sum_{k=2}^{\infty} \sum_{\ell=1}^{L} w_\ell \{ C_\ell^T \Delta r (-1)^{k+1} (\Sigma^{-1} C_\ell V_\ell)^k \right. \\ &+ (\mu_\ell F_x + \eta_\ell F_y + \xi_\ell F_z) V_\ell ((-1) \Sigma^{-1} C_\ell V_\ell)^{k-1} \} \\ &\left. + \frac{1}{4\pi} S^T \Sigma \Delta r (I - \Gamma_0) F(\Sigma^{-1}) \right\} \cdot \Gamma_0. \end{aligned} \tag{A.16}$$

Now, proceeding as in (A.12) and using symmetry properties, the proposition follows. □

Before using Proposition A.6, we need to notice that

$$\frac{1}{8} S D_{co}^{+} D_{co} \sum_{i=1}^{8} V_{\mathcal{L}_i} = I. \tag{A.17}$$

Indeed, writing $V_{\mathcal{L}_i}$ as the direct sum $V_{\mathcal{L}_i} = R_1 \oplus R_2$, with $R_1 \in \mathcal{N}(D_{co})$ and $R_2 \in \mathcal{N}(D_{co})^\perp = \mathcal{R}(D_{co}^T)$, we have for $i = 1, \ldots, 8$ that $SD_{co}^{+} D_{co} V_{\mathcal{L}_i} = SR_2$ since $D_{co}^{+} D_{co}$ is the orthogonal projection on the range of $D_{co}^T = D_{co}$ [8]. Also, one can show [5] that $\mathcal{N}(D_{co}) \subset \mathcal{N}(S)$ which implies $SR_2 = SV_{\mathcal{L}_i} = I$ using (A.1). Thus (A.17) is verified, and we can write from (A.9) and Proposition A.6

$$\begin{aligned} C_0 A_0 - I = &-\frac{1}{4\pi} F(\Sigma^{-1}) \Gamma_0 \\ &+ S D_{co}^{+} \frac{1}{4\pi} \sum_{k=2}^{\infty} \sum_{\ell=1}^{L} w_\ell \left\{ C_\ell^T \Delta r \Sigma^{-1} C_\ell + |\mu_\ell| A \right\} V_\ell ((-1) \Sigma^{-1} C_\ell V_\ell)^{k-1} \Gamma_0 \\ &+ \frac{1}{4\pi} S D_{co}^{+} S^T \Sigma \Delta r (I - \Gamma_0)(SS^T)(SS^T)^{-1} F(\Sigma^{-1}) \Gamma_0. \end{aligned} \tag{A.18}$$

Given its definition in (A.7), $F(\Sigma^{-1}) \to 0$ when $\Sigma^{-1} \to 0$. Therefore, to prove our theorem, we will show that

$$\|D_{co}^{+} S^T \Sigma \Delta r (I - \Gamma_0) S\| \tag{A.19}$$

and

$$\|D_{co}^{+} w_\ell \left\{ C_\ell^T \Delta r \Sigma^{-1} C_\ell + |\mu_\ell| A \right\} \| \tag{A.20}$$

remain bounded as $\Sigma^{-1} \to 0$.

We need a few more intermediate results. Since D_{co} is symmetric and singular, its singular value decomposition [8] can be written

$$D_{co} = [U, V] \begin{pmatrix} \Theta & 0 \\ 0 & 0 \end{pmatrix} [U, V]^T, \tag{A.21}$$

where the vectors of V span the null space of D_{co} and those of U its range. The diagonal matrix Θ contains the nonzero singular values of D_{co}. Then, the pseudoinverse [8] reads

$$D_{co}^{+} = [U, V] \begin{pmatrix} \Theta^{-1} & 0 \\ 0 & 0 \end{pmatrix} [U, V]^T = U \Theta^{-1} U^T.$$

We have the following lemma.

LEMMA A.7. *With V defined as above, if R is such that $V^T R = 0$, then $D_{co}^{+} R = (D_{co} + \delta V V^T)^{-1} R$ for any $\delta > 0$.*

Proof.

$$(D_{co} + \delta V V^T)^{-1} = [U, V] \begin{pmatrix} \Theta^{-1} & 0 \\ 0 & \delta^{-1} I \end{pmatrix} [U, V]^T = U \Theta^{-1} U^T + \delta^{-1} V V^T,$$

thus

$$(D_{co} + \delta V V^T)^{-1} R = U \Theta^{-1} U^T R + \delta^{-1} V V^T R = D_{co}^{+} R,$$

which completes the proof. □

Plugging the asymptotic diffusion limit assumptions $\Sigma = \epsilon^{-1} \hat{\Sigma}$ and $\Gamma_0 = I - \epsilon^2 \hat{\Gamma}_0$ in the definition (5.5) of D_{co} yields

$$D_{co} + \epsilon V V^T = 2\alpha (A + \epsilon E) \tag{A.22}$$

with A defined in (5.6), and

$$E = \frac{1}{2\alpha} \left(\frac{1}{3} (C_x^T \hat{\Sigma}^{-1} \Delta r C_x + C_y^T \hat{\Sigma}^{-1} \Delta r C_y + C_z^T \hat{\Sigma}^{-1} \Delta r C_z) + S^T \hat{\Sigma} \hat{\Gamma}_0 \Delta r S + V V^T \right).$$

Arguments in [5] show that $\mathcal{N}(D_{co}) \subset \mathcal{N}(A)$. We define U_1, U_2 through the singular value decomposition of A:

$$A = [U_1, U_2] \begin{pmatrix} 0 & 0 \\ 0 & T_2 \end{pmatrix} [U_1, U_2]^T = U_2 T_2 U_2^T,$$

where the vectors of U_1 span the null space of A, and those of U_2 its range. The diagonal matrix T_2 contains the singular values of A. The next lemma then derives an expression for $(A + \epsilon E)^{-1}$ in terms of a power series in ϵ, for all ϵ sufficiently small.

Lemma A.8. *Let U_1, U_2, A, and E be defined as above. Define*

$$E_1 \equiv U_1^T E U_1,$$

and define the projections

$$P \equiv I - EU_1E_1^{-1}U_1^T \text{ and } Q \equiv I - U_1E_1^{-1}U_1^T E.$$

Also, introducing $\tilde{A} = U_2(T_2)^{-1}U_2^T$, define

$$X_{-1} \equiv U_1E_1^{-1}U_1^T \text{ and } X_k \equiv (-1)^k Q\tilde{A}P(E\tilde{A}P)^k.$$

Then

$$(A+\epsilon E)^{-1} = X \equiv \epsilon^{-1}X_{-1} + \sum_{k=0}^{\infty} \epsilon^k X_k, \tag{A.23}$$

and the convergence is uniform in ϵ for all ϵ sufficiently small.

Proof. First we show that the matrix E_1 is nonsingular. Suppose $E_1p = 0$ for some vector p. Then from the form of E_1, we must have that $U_1^T(C_x^T\hat{\Sigma}^{-1}\Delta r C_x + C_y^T\hat{\Sigma}^{-1}\Delta r C_y + C_z^T\hat{\Sigma}^{-1}\Delta r C_z)U_1p = 0$, and in turn that $C_xU_1p = 0$, $C_yU_1p = 0$, and $C_zU_1p = 0$. However, the description of $\mathcal{N}(A)$ in [5] show that the range of U_1 and the null space of the C_x, C_y, and C_z matrices intersect only trivially. Hence, $p = 0$ and E_1 is nonsingular.

Next, it is clear that the series in (A.23) converges uniformly in ϵ for any $\epsilon \leq \epsilon_{max} < 1/\|EAP\|_2$. To check that X in (A.23) is the inverse of $A + \epsilon E$, note that since the series converges in norm (i.e., absolutely), we can write

$$\begin{aligned}(A+\epsilon E)X - I &= \epsilon^{-1}AX_{-1} + (AX_0 + EX_{-1} - I)\\ &\quad + \sum_{k=0}^{\infty}\epsilon^{k+1}(AX_{k+1} + EX_k).\end{aligned} \tag{A.24}$$

From the definition of X_{-1}, it is immediate that $AX_{-1} = 0$. Moreover,

$$AX_0 + EX_{-1} - I = AQ\tilde{A}P + EU_1E_1^{-1}U_1^T - I = AQ\tilde{A}P - P.$$

Since $AQ = A$, we have $AQ\tilde{A}P - P = (A\tilde{A} - I)P$. But $U_1U_1^T + U_2U_2^T = I$ and $A\tilde{A} = U_2U_2^T$. Thus $(A\tilde{A} - I)P = -U_1U_1^TP = 0$ by definition of P, and the second term in (A.24) vanishes. For the remaining terms in (A.24),

$$\begin{aligned}AX_{k+1} + EX_k &= (-1)^{k+1}AQ\tilde{A}P(E\tilde{A}P)^{k+1} + (-1)^k EQ\tilde{A}P(E\tilde{A}P)^k\\ &= (-1)^k(-AQ\tilde{A}P + P)(E\tilde{A}P)^{k+1}\\ &= 0.\end{aligned}$$

using the fact that $EQ = PE$. Thus, all the terms in (A.24) vanish, and the lemma is proved. □

Using Lemma A.7, (A.22), and Lemma A.8, we obtain in the asymptotic diffusion limit, provided R verifies $V^TR = 0$ with V defined in (A.21),

$$D_{co}^{+}R = \left(\epsilon^{-1}\hat{X}_{-1} + \sum_{k=0}^{\infty}\epsilon^k\hat{X}_k\right)R, \tag{A.25}$$

where $\hat{X}_{-1} = (2\alpha)^{-1}X_{-1}$ and $\hat{X}_k = (2\alpha)^{-1}X_k$.

We now go back to (A.19) and (A.20).

LEMMA A.9. *Assume that* $\Sigma = \epsilon^{-1}\hat{\Sigma}$. *There exist positive constants* c_1 *and* c_2 *such that*

$$\|D_{co}^{+} S^T \Sigma \Delta r (I - \Gamma_0) S\| \leq c_1$$

and

$$\|D_{co}^{+} w_\ell \left\{ C_\ell^T \Delta r \Sigma^{-1} C_\ell + |\mu_\ell| A \right\}\| \leq c_2$$

for all $\hat{\Sigma} > 0$ *and* $\epsilon \to 0$.

Proof. It was shown in [5] that $\mathcal{N}(D_{co}) \subset \mathcal{N}(S)$, $\mathcal{N}(D_{co}) \subset \mathcal{N}(C_x)$, $\mathcal{N}(D_{co}) \subset \mathcal{N}(C_y)$, $\mathcal{N}(D_{co}) \subset \mathcal{N}(C_z)$, and $\mathcal{N}(D_{co}) \subset \mathcal{N}(A)$. Consequently, $V^T S^T = 0$, $V^T C_l^T = 0$, and $V^T A = 0$ so that we can apply (A.25). With the asymptotic diffusion limit assumptions, we obtain

$$\begin{aligned} D_{co}^{+} S^T \Sigma \Delta r (I - \Gamma_0) S &= \left(\epsilon^{-1} \hat{X}_{-1} + \sum_{k=0}^{\infty} \epsilon^k \hat{X}_k \right) \epsilon S^T \hat{\Sigma} \Delta r \hat{\Gamma}_0 S \\ &= \hat{X}_{-1} S^T \hat{\Sigma} \Delta r \hat{\Gamma}_0 S + O(\epsilon), \end{aligned}$$

and, using also (A.22),

$$\begin{aligned} & D_{co}^{+}(w_\ell \{ C_\ell^T \Delta r \Sigma^{-1} C_\ell + |\mu_\ell| A \}) \\ &\quad = \left(\epsilon^{-1} \hat{X}_{-1} + \sum_{k=0}^{\infty} \epsilon^k \hat{X}_k \right) (w_\ell \{ C_\ell^T \Delta r \epsilon \hat{\Sigma}^{-1} C_\ell + |\mu_\ell| A \}) \\ &\quad = \hat{X}_{-1} \left(w_\ell \left\{ C_\ell^T \Delta r \hat{\Sigma}^{-1} C_\ell + \frac{|\mu_\ell|}{2\alpha} V V^T - |\mu_\ell| E \right\} \right) + w_\ell \frac{|\mu_\ell|}{2\alpha} D_{co}^{+} D_{co} + O(\epsilon). \end{aligned}$$

Since $D_{co}^{+} D_{co}$ is a projection, its norm is bounded. Thus both terms remain bounded as $\epsilon \to 0$. ◻

We are now prepared to conclude the proof of Theorem 6.2.

Proof of Theorem 6.2. From (A.18) and Lemma A.9 we can write

$$\begin{aligned} \|C_0 A_0 - I\|_2 \leq & \frac{1}{4\pi} \|F(\Sigma^{-1}) \Gamma_0\|_2 + \frac{1}{4\pi} \|S\|_2 \sum_{k=2}^{\infty} \sum_{\ell=1}^{L} c_2 \|V_\ell\|_2 \, \|\Sigma^{-1} C_\ell V_\ell\|_2^{k-1} \, \|\Gamma_0\|_2 \\ & + \frac{1}{4\pi} \|S\|_2 \, c_1 \, \|S^T (S S^T)^{-1}\|_2 \, \|F(\Sigma^{-1})\|_2 \|\Gamma_0\|_2. \end{aligned}$$

Since $F(\Sigma^{-1}) \to 0$ when $\Sigma^{-1} \to 0$ (A.7), the conclusion follows. ◻

For Theorem 6.3, it follows from (A.25) that the preconditioner C_0 given by (5.8) can be written, in the asymptotic diffusion limit,

$$\begin{aligned} C_0 &= I + S D_{co}^{+} S^T \epsilon^{-1} \hat{\Sigma} \Delta r (I - \epsilon^2 \hat{\Gamma}_0) \\ &= \epsilon^{-2} C_{0,-2} + \epsilon^{-1} C_{0,-1} + C_{0,0} + O(\epsilon), \end{aligned}$$

where

$$\begin{aligned} C_{0,-2} &= S \hat{X}_{-1} S^T \hat{\Sigma} \Delta r, \\ C_{0,-1} &= S \hat{X}_0 S^T \hat{\Sigma} \Delta r, \text{ and} \\ C_{0,0} &= I - S \hat{X}_{-1} S^T \hat{\Sigma} \Delta r \hat{\Gamma}_0 + S \hat{X}_1 S^T \hat{\Sigma} \Delta r. \end{aligned}$$

Then, the proof of Theorem 6.3 parallels almost literally the one of Theorem 6.15 in [4]. We therefore do not repeat it here.

A.2.2. Proof for the other thick limit. To prove Theorem 6.4, we need to introduce the following lemma, proved in [14].

LEMMA A.10. *Given two matrices, A and B, a necessary and sufficient condition that*

$$\lim_{B\to A} B^+ = A^+ \tag{A.26}$$

is that $\operatorname{rank}(B) = \operatorname{rank}(A)$ *as B approaches A.*

Also, with T_1 defined in (5.3), we introduce $T_{1,0}$ as the limit of T_1 for $\|\Sigma^{-1}\|_2 \to 0$, i.e.,

$$T_{1,0} = \begin{pmatrix} L_{x_0,0} & L_{x_0,1} \\ L_{y_0,0} & L_{y_0,1} \\ L_{z_0,0} & L_{z_0,1} \\ \tilde{\Gamma}_0 S^0 & 0 \\ 0 & S^1 \\ L_{x_M,0} & L_{x_M,1} \\ L_{y_J,0} & L_{y_J,1} \\ L_{z_K,0} & L_{z_K,1} \end{pmatrix}, \tag{A.27}$$

where $\tilde{\Gamma}_0 = I - \Gamma_0 \geq \epsilon I$. From the developments in appendix A.2 of [5], one can show that T_1 and $T_{1,0}$ have full rank. Also, their pseudo-inverse T_1^+ and $T_{1,0}^+$ are such that $T_1 T_1^+ = I$ and $T_{1,0}T_{1,0}^+ = I$.

Proof of Theorem 6.4. We have that $T_1 - T_{1,0} \to 0$ uniformly as $\|\Sigma^{-1}\|_2 \to 0$. Developments in [5] show that C_0 defined in (5.8) can equivalently be written as

$$C_0 = I + \begin{pmatrix} S & 0_{LA} \end{pmatrix} T_1^+ \begin{pmatrix} 0_{BC} \\ I \\ 0_{LA} \\ 0_{BC} \end{pmatrix} \Gamma_0, \tag{A.28}$$

where the zero matrix $0_{LA} \in \mathbf{R}^{3MJK \times MJK}$ corresponds to the linear anisotropy terms (vanishing here since we assume isotropic scattering), and the zero matrix $0_{BC} \in \mathbf{R}^{KJ+MJ+MK\times MJK}$ corresponds to the boundary conditions. Then we look at the difference

$$E_0 \equiv C_0 - (I - \Gamma_0)^{-1} = C_0 - \tilde{\Gamma}_0^{-1}.$$

We have

$$\tilde{\Gamma}_0 E_0 = \tilde{\Gamma}_0 C_0 - I = \tilde{\Gamma}_0 \begin{pmatrix} S & 0_{LA} \end{pmatrix} T_1^+ \begin{pmatrix} 0_{BC} \\ I \\ 0_{LA} \\ 0_{BC} \end{pmatrix} \Gamma_0 + \tilde{\Gamma}_0 - I.$$

Thus

$$E_0 = \tilde{\Gamma}_0^{-1} \left[\tilde{\Gamma}_0 \begin{pmatrix} S & 0_{LA} \end{pmatrix} T_1^+ \begin{pmatrix} 0_{BC} \\ I \\ 0_{LA} \\ 0_{BC} \end{pmatrix} - I \right] \Gamma_0.$$

Using Lemma A.10 and the fact that T_1 and $T_{1,0}$ have the same (full) rank, the bracketed factor in the last expression tends to

$$\left[\tilde{\Gamma}_0 \begin{pmatrix} S & 0_{LA} \end{pmatrix} T_{1,0}^{+} \begin{pmatrix} 0_{BC} \\ I \\ 0_{LA} \\ 0_{BC} \end{pmatrix} - I \right] \equiv E_*,$$

as $\|\Sigma^{-1}\|_2 \to 0$, uniformly for $\tilde{\Gamma}_0 \geq \epsilon I$. But $E_* = 0$. Indeed, for any $w \in \mathbf{R}^{zones}$ define

$$v \equiv \begin{pmatrix} v_0 \\ v_1 \end{pmatrix} \equiv T_{1,0}^{+} \begin{pmatrix} 0_{BC} \\ I \\ 0_{LA} \\ 0_{BC} \end{pmatrix} w \qquad (v_0 \in \mathbf{R}^{zones}, v_1 \in \mathbf{R}^{3*zones}).$$

Then multiplying both sides by $T_{1,0}$ yields $\tilde{\Gamma}_0 S^0 v_0 = w$ (from (A.27) and $T_{1,0}T_{1,0}^{+} = I$) so that $E_* w = \tilde{\Gamma}_0 S^0 v_0 - w = 0$. Thus $E_0 \to 0$ as $\|\Sigma^{-1}\|_2 \to 0$, uniformly for $\tilde{\Gamma}_0 \geq \epsilon I$. □

A.3. Proof for the thin regime. We can here go straight to the proof.

Proof of Theorem 6.7. From (5.8) and Lemma A.7, we get

$$C_0 = I + S(D_{co} + \epsilon^{-1} V V^T)^{-1} S^T \Sigma \Delta r \Gamma_0.$$

From the definition (5.5) of D_{co}, we see that, for $\|\Sigma\|_2 \to 0$,

$$D_{co} \to \frac{1}{3}\left(C_x^T \Delta r \Sigma^{-1} C_x + C_y^T \Delta r \Sigma^{-1} C_y + C_z^T \Delta r \Sigma^{-1} C_z \right).$$

Thus, for $\Sigma = \epsilon \hat{\Sigma}$ and $\epsilon \to 0$,

$$C_0 - I \to \epsilon^2 S \left(\frac{1}{3} (C_x^T \Delta r \hat{\Sigma}^{-1} C_x + C_y^T \Delta r \hat{\Sigma}^{-1} C_y + C_z^T \Delta r \hat{\Sigma}^{-1} C_z) + V V^T \right)^{-1} S^T \hat{\Sigma} \Delta r \Gamma_0,$$

which leads to the conclusion for $0 \leq \Gamma_0 \leq I$. □

ON THE ADAPTIVE SELECTION OF THE PARAMETER IN REGULARIZATION OF ILL-POSED PROBLEMS*

SERGEI PEREVERZEV[†] AND EBERHARD SCHOCK[‡]

Abstract. We study the possibility of using the structure of the regularization error for a posteriori choice of the regularization parameter. As a result, a rather general form of a selection criterion is proposed, and its relation to the heuristical quasi-optimality principle of Tikhonov and Glasko [*Z. Vychisl. Mat. Mat. Fiz.*, 4 (1964), pp. 564–571] and to an adaptation scheme proposed in a statistical context by Lepskii [*Theory Probab. Appl.*, 36 (1990), pp. 454–466] is discussed. The advantages of the proposed criterion are illustrated by using such examples as self-regularization of the trapezoidal rule for noisy Abel-type integral equations, Lavrentiev regularization for nonlinear ill-posed problems, and an inverse problem of the two-dimensional profile reconstruction.

Key words. inverse problems in Banach spaces, parameter choice, Abel integral equations, Lavrentiev regularization for equations with monotone operators, scattering, profile reconstruction

1. Introduction.

How do we choose a posteriori a suitable value for the regularization parameter in ill-posed problems without knowledge about the solution's smoothness that may not be accessible? This question is discussed extensively in the regularization theory. A first a posteriori rule of choice is described in the paper by Phillips [21], which predates even Tikhonov's paper [26] recognized as a reference point of regularization theory.

We define an operator equation

$$Ax = y \tag{1.1}$$

with a linear operator $A \in \mathcal{L}(X, Y)$ between Banach spaces X and Y as essentially ill-posed if the range $R(A)$ of A is not closed in Y. If A is invertible, this nonclosed range is associated with the discontinuity of the inverse operator A^{-1}. In general, the best approximate solution $A^{+}y$, where A^{+} is the Moore–Penrose inverse of A, does not depend continuously on the right-hand side y. Since in practice data will almost never be available exactly, because of measurement error, one has to be aware of numerical instabilities when a noisy observation $y_\delta \in Y$ instead of y with

$$\|y - y_\delta\|_Y \le \delta \tag{1.2}$$

is known. Hence, in order to approximate $A^{+}y$ in a stable way, regularization methods should be applied. In general, regularization methods for the solution of (1.1) replace the generalized inverse A^{+} by a family of continuous operators R_α, which converge pointwise to A^{+}. The standard regularization methods have in common that the

approximation error $\|A^+y - R_\alpha y\|_X$ is monotonically decreasing for decreasing α-values. In general, it is natural to assume that there exists an increasing continuous function $\varphi(\alpha) = \varphi(\alpha; A, y)$ such that $0 = \varphi(0) \leq \varphi(\alpha) \leq 1$, and

$$\|A^+y - R_\alpha y\|_X \leq \varphi(\alpha). \tag{1.3}$$

This property is no longer true for the regularization error $\|A^+y - R_\alpha y_\delta\|_X$. The regularized solutions $R_\alpha y_\delta$ converge to A^+y as $\delta \to 0$ only if the regularization parameter α is properly chosen dependent upon the noise level and possibly upon the data, i.e., $\alpha = \alpha(\delta, y_\delta)$. There are several methods that have been proposed and used for the a posteriori choice of the regularization parameter α as a function of the noise level and the data. These include the discrepancy principle (DP) originally proposed by Phillips [21] and later reinvented by Morozov [20] and Marti [18], a method developed by Gferer [9], Engl and Gfrerer [8], and Raus [23], which is sometimes called the minimum-bound (MB) method [17], and the monotone error rule (ME) proposed recently by Tautenhahn and Hämarik [25]. The MB and ME methods have been designed for ill-posed problems in Hilbert spaces. The DP method is more universal, because Plato (see, e.g., [22]) demonstrated that the DP method can be successfully applied to problems in Banach spaces. However, the DP method does not provide the best order of approximation for all problems, which could be, in principle, treated by a fixed regularization method with optimal order of accuracy; see, e.g., [11]. The MB and ME methods are free from this drawback of the discrepancy principle, but a disadvantage of both methods is that they require the knowledge of an additional approximate solution obtained within the framework of the regularization method of higher qualification. For example, Tautenhahn and Hämarik [25] select the regularization parameter for the ordinary Tikhonov regularization by constructing an additional approximate solution using iterated Tikhonov regularization; i.e., another regularization method should be involved in the choice procedure, and that is not always reasonable.

At the same time the structure of regularization error is very similar to the loss function of statistical estimation, where some parameter always controls the trade-off between the bias and the variance of the risk. It gives a hint that the statistical art of bias-variance balancing can be used for choosing the regularization parameter.

Indeed, the regularization error can be estimated by

$$\|A^+y - R_\alpha y_\delta\|_X \leq \|A^+y - R_\alpha y\|_X + \|R_\alpha y - R_\alpha y_\delta\|_X, \tag{1.4}$$

where the first term on the right-hand side is an approximation error, whereas the second term is a stability bound on the regularizing operator R_α. If R_α possesses a locally uniformly bounded Fréchet derivative R'_α in a ball of radius δ around the exact free term y then

$$\|R_\alpha y - R_\alpha y_\delta\|_X \leq \delta \|R'_\alpha\|_{Y \to X} + o(\delta).$$

For linear problems (1.1) R_α is usually linear, and $R'_\alpha = R_\alpha$. Keeping in mind that $\{R_\alpha\}$ approximates the unbounded Moore–Penrose inverse A^+, it is easy to realize that $\|R_\alpha\|$ (or $\|R'_\alpha\|$) should increase for $\alpha \to 0$. Thus, there exists an increasing continuous function $\lambda(\alpha)$ such that $\lambda(0) = 0$, and

$$\|R_\alpha y - R_\alpha y_\delta\| \leq \frac{\delta}{\lambda(\alpha)}. \tag{1.5}$$

For each regularization method $\lambda(\alpha)$ is known, or at least it can be estimated effectively. For the standard regularization methods $\lambda(\alpha) = \gamma\sqrt{\alpha}$, where γ is a known constant. Another forms of $\lambda(\alpha)$ will be discussed later.

Thus, from (1.3)–(1.5) it follows that

$$\|A^+y - R_\alpha y_\delta\|_X \leq \varphi(\alpha) + \frac{\delta}{\lambda(\alpha)}. \tag{1.6}$$

Almost all existing results about the accuracy of regularization methods are asymptotic results in δ. These results indicate that a choice of

$$\alpha = \alpha_{\text{opt}} = (\varphi\lambda)^{-1}(\delta), \tag{1.7}$$

that balances $\varphi(\alpha)$ with $\frac{\delta}{\lambda(\alpha)}$, leads to the error estimate

$$\|A^+y - R_{\alpha_{\text{opt}}} y_\delta\|_X \leq 2\varphi((\varphi\lambda)^{-1}(\delta)), \tag{1.8}$$

which has at least optimal order with respect to δ. Unfortunately, an a priori parameter choice (1.7) can seldom be used in practice because the smoothness properties of the unknown solution A^+y reflected in function φ from (1.3) are generally unknown. On the other hand, an error estimate (1.8) can be considered as a benchmark for a posteriori parameter choice strategies, because it indicates the order of accuracy that cannot be beaten by any of them within the framework of assumptions (1.3), (1.5). The outline of the paper is as follows. In the next section our focus will be on the question of how to adapt the regularization parameter to the unknown smoothness in such a way that the optimal order of accuracy (1.8) would be reached automatically. We shall present two adaptive procedures solving this question. Then in section 3 the advantages of the proposed procedures will be illustrated by using several examples of linear and nonlinear ill-posed problems. We close this paper with a short conclusion.

2. General theorems.

In practical applications, different regularization parameters α_i are often selected from some finite set

$$\Delta_N = \{\alpha_i : 0 < \alpha_0 < \alpha_1 < \cdots < \alpha_N\}$$

and the corresponding regularization solutions

$$x^\delta_{\alpha_i} = R_{\alpha_i} y_\delta, \quad i = 1, 2, \ldots, N,$$

are studied online. In view of the representation

$$\alpha_{\text{opt}} = \max\left\{\alpha : \varphi(\alpha) \leq \frac{\delta}{\lambda(\alpha)}\right\}$$

the optimal choice of α_i from Δ_N is

$$\alpha_* = \alpha_\ell = \max\{\alpha_i : \alpha_i \in M(\Delta_N)\},$$

where

$$M(\Delta_N) := \left\{\alpha_i : \alpha_i \in \Delta_N,\ \varphi(\alpha_i) \leq \frac{\delta}{\lambda(\alpha_i)}\right\}.$$

But if φ is unknown, such a choice is also not feasible. At the same time, for any $\alpha_i, \alpha_j,\ \alpha_i \geq \alpha_j$, from the set $M(\Delta_N)$, containing α_* as an upper bound, the estimation of the norm $\|x^\delta_{\alpha_i} - x^\delta_{\alpha_j}\|$ does not require knowledge of φ. Indeed, due to the monotonicity of $\varphi(\alpha)$, $\lambda(\alpha)$ from (1.6), it follows that

$$\begin{aligned}\|x^\delta_{\alpha_i} - x^\delta_{\alpha_j}\| &\leq \|A^+y - R_{\alpha_i}y_\delta\| + \|A^+y - R_{\alpha_j}y_\delta\|\\ &\leq \varphi(\alpha_i) + \varphi(\alpha_j) + \frac{\delta}{\lambda(\alpha_i)} + \frac{\delta}{\lambda(\alpha_j)}\\ &\leq 2\varphi(\alpha_i) + \frac{\delta}{\lambda(\alpha_i)} + \frac{\delta}{\lambda(\alpha_j)}\\ &\leq \frac{4\delta}{\lambda(\alpha_j)}.\end{aligned}$$

This gives a hint that the upper bound of the subset

$$M^+(\Delta_N) := \left\{\alpha_i \in \Delta_N : \|x^\delta_{\alpha_i} - x^\delta_{\alpha_j}\| \leq \frac{4\delta}{\lambda(\alpha_j)},\ j = 0, 1, 2, \dots, i\right\} \tag{2.1}$$

should be sufficiently close to a desirable value α_*. The following proposition justifies this conjecture on α_i.

Theorem 2.1. *Let $\Delta_N = \Delta_N^{\lambda,q}$ be such that $M(\Delta_N) \neq \varnothing$, $\Delta_N \backslash M(\Delta_N) \neq \varnothing$, and for any $\alpha_i \in \Delta_N$, $i = 1, 2, \dots, N$,*

$$\lambda(\alpha_i) \leq q\lambda(\alpha_{i-1}), \tag{2.2}$$

where q is some fixed constant. Then under the assumptions (1.2), (1.3), (1.5) *for $\alpha_+ = \alpha_k \in \Delta_N$ chosen as*

$$\alpha_+ = \max\{\alpha_i : \alpha_i \in M^+(\Delta_N)\} \tag{2.3}$$

the following estimate holds:

$$\|A^+y - x^\delta_{\alpha_+}\| \leq 6q\varphi((\varphi\lambda)^{-1}(\delta)). \tag{2.4}$$

Proof. From the definition of $\alpha_* = \alpha_\ell$ we have that for $\alpha_{\ell+1} > \alpha_\ell$

$$\varphi(\alpha_{\ell+1})\lambda(\alpha_{\ell+1}) > \delta = \varphi(\alpha_{\text{opt}})\lambda(\alpha_{\text{opt}}),$$

and using the monotonicity of $\varphi(\alpha)$, $\lambda(\alpha)$ we deduce $\alpha_{\ell+1} > \alpha_{\text{opt}}$. Then under our hypothesis

$$\lambda(\alpha_{\text{opt}}) < \lambda(\alpha_{\ell+1}) \leq q\lambda(\alpha_\ell) = q\lambda(\alpha_*).$$

Hence

$$\frac{\delta}{\lambda(\alpha_*)} \leq q\frac{\delta}{\lambda(\alpha_{\text{opt}})}. \tag{2.5}$$

As already shown above, $M(\Delta_N) \subset M^+(\Delta_N)$, and therefore

$$\alpha_* = \alpha_\ell = \max\{\alpha_i \in M(\Delta_N)\} \leq \alpha_+ = \alpha_k = \max\{\alpha_i \in M^+(\Delta_N)\}.$$

From the definition of $M^+(\Delta_N)$ and (2.5) we conclude

$$\begin{aligned}\|A^+y - x^\delta_{\alpha_+}\| &= \|A^+y - x^\delta_{\alpha_k}\| \leq \|A^+y - x^\delta_{\alpha_\ell}\| + \|x^\delta_{\alpha_\ell} - x^\delta_{\alpha_k}\| \\ &\leq \varphi(\alpha_\ell) + \frac{\delta}{\lambda(\alpha_\ell)} + \frac{4\delta}{\lambda(\alpha_\ell)} \leq \frac{6\delta}{\lambda(\alpha_*)} \leq 6q\frac{\delta}{\lambda(\alpha_{\text{opt}})} \\ &= 6q\varphi((\varphi\lambda)^{-1}(\delta)),\end{aligned}$$

and the theorem is proved. □

If we would know in advance that the function $\varphi(\alpha)$ reflecting the smoothness properties of the unknown solution A^+y, then we may achieve the accuracy of the optimal order given in (1.8). Comparing (1.8) with (2.4) we can conclude that the choice of the regularization parameter $\alpha = \alpha_+$ is also order optimal in the sense of accuracy. We would like to stress, however, that the selection criterion (2.1), (2.3) producing α_+ is adaptive to the unknown smoothness, because φ is not involved in its construction. Observe, that α_+ depends only on the noisy data y_δ, on the noise level δ, and on the discrete set $\Delta_N = \Delta_N^{\lambda,q}$ which should meet the conditions of Theorem 2.1. The conditions $M(\Delta_N) \neq \varnothing$, $\Delta_N \backslash M(\Delta_N) \neq \varnothing$ are rather natural. It is satisfied if, for example, $\alpha_0 = \lambda^{-1}(\delta) \in \Delta_N$, $\alpha_N = \lambda^{-1}(1) \in \Delta_N$. The condition (2.2) is also not so restrictive. Recall that for the standard regularization methods $\lambda(\alpha) = \gamma\sqrt{\alpha}$. Then to meet (2.2) one can take Δ_N in the form of a geometric sequence

$$\Delta_N = \{\alpha_i : \alpha_i = \mu^i \alpha_0,\ i = 0, 1, \dots, N\} \tag{2.6}$$

with $\mu = q^2 > 1$.

We remark that the first time a geometric sequence was used as a set of regularization parameters in the papers by Tikhonov and Glasko [27, 28], where a method of choosing a paramter $\alpha_T = \alpha_m = \mu^m \alpha_0$ from such a sequence, termed quasi-optimality criterion, was suggested for which

$$\sigma(\alpha_i) := \|x^\delta_{\alpha_i} - x^\delta_{\alpha_{i-1}}\| \tag{2.7}$$

has the minimum value $\sigma(\alpha_m)$ in the chosen set (2.6). It is worth to mention that this quasi-optimality criterion is chronologically the first in the class of the heuristically motivated regularization parameter choice rules that seek to avoid any a priori knowledge of the noise level δ. There is, however, a negative result of Bakushinskii [1], which tells us that no convergence theory and error estimates as above can exist for noise level-free rules, and for the quasi-optimality criterion in particular.

At the same time the quasi-optimality criterion gives a hint that the quantities (2.7) can be used as indicators for the order optimal regularization parameter choice. Indeed, if α_{i-1}, $\alpha_i = \mu\alpha_{i-1}$ belong to the set $M(\Delta_N)$ containing the optimal parameter value $\alpha = \alpha_*$ then the quantity (2.7) can be estimated as

$$\|x^\delta_{\alpha_i} - x^\delta_{\alpha_{i-1}}\| \leq \frac{4\delta}{\lambda(\alpha_{i-1})}. \tag{2.8}$$

The right-hand side of (2.8) is a decreasing function of α. Therefore, the largest $\alpha_i \in \Delta_N$ satisfying (2.8) cannot be far from α_T minimizing (2.7). This observation leads to the following noise level-dependent analog of the quasi-optimality criterion:

$$\overline{\alpha} = \max\left\{\alpha_j \in \Delta_N : \|x^\delta_{\alpha_i} - x^\delta_{\alpha_{i-1}}\| \leq \frac{4\delta}{\lambda(\alpha_{i-1})},\ i = 0, 1, 2, \dots, j\right\}. \tag{2.9}$$

THEOREM 2.2. *Assume* (1.2), (1.3), (1.5) *to hold. Assume, furthermore, that* $\lambda(\alpha)$ *from* (1.5) *obeys a strong* Δ_2*-condition, i.e., there are* $\kappa_1 > \kappa > 1$ *such that for any* $\alpha > 0$, $\lambda(2\alpha)/\kappa_1 \leq \lambda(\alpha) \leq \lambda(2\alpha)/\kappa$. *If the geometric sequence* (2.6) *meets the condition of Theorem* 2.1, *then*

$$\|A^+y - x^\delta_{\overline{\alpha}}\| \leq c\varphi((\varphi\lambda)^{-1}(\delta)), \tag{2.10}$$

where the constant c depends only on q, κ, κ_1, μ.

Proof. Let $\overline{\alpha} = \alpha_m \in \Delta_N$. From (2.1), (2.3), and (2.9) it follows that $\overline{\alpha} \geq \alpha_+$. Then, as in the proof of Theorem 2.1, one can deduce $\overline{\alpha} = \alpha_m \geq \alpha_+ = \alpha_k \geq \alpha_* = \alpha_\ell$, and using the triangle inequality successively, we arrive at

$$\begin{aligned}\|A^+y - x^\delta_{\overline{\alpha}}\| &\leq \|A^+y - x^\delta_{\alpha_*}\| + \sum_{i=\ell+1}^{m} \|x^\delta_{\alpha_{i-1}} - x^\delta_{\alpha_i}\| \\ &\leq \|A^+y - x^\delta_{\alpha_*}\| + \sum_{i=\ell+1}^{m} \frac{4\delta}{\lambda(\alpha_{i-1})} \\ &\leq \|A^+y - x^\delta_{\alpha_*}\| + \sum_{\nu=0}^{m-\ell-1} \frac{4\delta}{\lambda(\alpha_*\mu^\nu)}.\end{aligned}$$

On the other hand, for any $\mu > 1$, $b > 1$ and integers n, j such that $2^n \leq \mu \leq 2^{n+1}$, $2^j \leq b \leq 2^{j+1}$ iterating the strong Δ_2-condition, if necessary, one obtains

$$\begin{aligned}&\frac{1}{\lambda(b\alpha_*)} \leq \frac{1}{\lambda(2^j\alpha_*)} \leq \frac{1}{\kappa^j\lambda(\alpha_*)} \leq \frac{\kappa}{\kappa^{\log_2 b}\lambda(\alpha_*)}; \\ &\lambda(\alpha_i) = \lambda(\alpha_{i-1}\mu) \leq \kappa_1^{n+1}\lambda(\alpha_{i-1}) \leq \kappa_1^{\log_2 2\mu}\lambda(\alpha_{i-1}).\end{aligned}$$

The last inequality means that (2.2) is satisfied with $q = \kappa_1^{\log_2 2\mu}$. Using these observations and (2.5) we conclude

$$\begin{aligned}\|A^+y - x^\delta_{\overline{\alpha}}\| &\leq \varphi(\alpha_*) + \frac{\delta}{\lambda(\alpha_*)} + \frac{4\kappa\delta}{\lambda(\alpha_*)} \sum_{\nu=0}^{m-\ell-1} \left(\frac{1}{\kappa^{\log_2 \mu}}\right)^\nu \\ &\leq \frac{\delta}{\lambda(\alpha_*)}\left[2 + \frac{4\kappa^{\log_2 2\mu}}{\kappa^{\log_2^{\mu}-1}}\right] = \frac{c_1\delta}{\lambda(\alpha_*)} \\ &\leq \frac{c_1\kappa_1^{\log_2 2\mu}}{\lambda(\alpha_{\mathrm{opt}})}\delta = c\varphi((\varphi\lambda)^{-1}(\delta)).\end{aligned}$$

The theorem is proved. □

At first glance the rule (2.9) looks like a simplified version of (2.1), (2.3), because it requires us to compare the regularized solutions $x^\delta_{\alpha_i}$ corresponding to parameters with adjacent numbers only. But as has been mentioned above, there are two different ideas behind these rules. The rule (2.9) is related to the heuristical quasi-optimality criterion. Up to a certain extent it supports heuristic theoretically. Moreover, numerical tests from [12] show that in some important particular cases both these criteria give the same value of regularization parameter. At the same time the rule (2.1), (2.3) has a statistical root. This rule was first studied in the paper [15] by Lepskii, devoted to statistical estimation from direct white noise observations that corresponds to (1.1) with identity operator A, but with random noisy data y_δ. Since then many authors have adopted this approach toward various statistical applications, we mention only [10, 5, 29], where the same idea has been realized in the context of ill-posed problems of the form (1.1) with compact operator A, but still with random noise. Deterministic noise model (1.2) allows to improve the order of accuracy of the regularized solution, as has been shown in [12, 4, 19] for the Hilbert space setting. Theorems 2.1 and 2.2 contain all these results as particular cases. Moreover, these theorems provide an uniform approach to order-optimal regularization parameter choice for linear ill-posed problems in Banach spaces.

3. Examples. This section applies Theorems 2.1 and 2.2 to several new examples such as self-regularization of the trapezoidal rule in the Banach space of continuous functions, Lavrentiev regularization for nonlinear problems, and an inverse problem of profile reconstruction.

3.1. Example 1: Self-regularization of the trapezoidal rule for noisy Abel-type integral equations. Consider an equation of the form (1.1) with the Abel-type integral operator

$$Ax(t) = A_\beta x(t) := \int_0^t \frac{a(t,\tau)}{(t-\tau)^\beta} x(\tau) d\tau, \quad t \in [0,1], \tag{3.1}$$

in Banach spaces $X = Y = C = C_{[0,1]}$, where $a(t,\tau)$ is at least Lipschitz-continuous on $0 \le \tau \le t \le 1$, and

$$|a(t,t)| \ge a_0 > 0. \tag{3.2}$$

The parameter β satisfies $0 < \beta < 1$.

The trapezoidal-discretization method for (1.1), (3.1) has been intensively studied in [2, 30, 7]. It consists of replacing (1.1), (3.1) by a set of linear equations

$$\int_0^{\frac{i}{n}} \frac{a\left(\frac{i}{n},\tau\right)}{\left(\frac{i}{n}-\tau\right)^\beta} x(\tau) d\tau = y\left(\frac{i}{n}\right), \quad i = 1, 2, \dots, n.$$

Then one replaces each of them by means of discretizing the integral on the left as follows:

$$n \sum_{j=1}^{i} \int_{\frac{j-1}{n}}^{\frac{j}{n}} \frac{\left(\tau - \frac{j-1}{n}\right) a_{ij}^n x_{n,j} + \left(\frac{j}{n} - \tau\right) a_{ij-1}^n x_{n,j-1}}{\left(\frac{i}{n}-\tau\right)^\beta} d\tau = y\left(\frac{i}{n}\right), \quad i = 1, 2, \dots, n, \tag{3.3}$$

where $a_{ij}^n = a(\frac{i}{n}, \frac{j}{n})$, and $x_{n,j}$ denotes the numerical approximation to $x(\frac{j}{n})$, $j = 0, 1, 2, \dots, n$. Thus, (3.3) is a system of n equations in $n+1$ unknown. For starting value $x_{n,0}$ one can take

$$x(0) = \lim_{t \to 0} \frac{(1-\beta)}{a(0,0)} \frac{y(t)}{t^{1-\beta}},$$

which exists, whenever (1.1), (3.1) has a continuous solution, or, as in [7],

$$x_{n,0} = \frac{(1-\beta)}{a(0,0)} \left\{ 3g\left(\frac{1}{n}\right) - 3g\left(\frac{2}{n}\right) + g\left(\frac{3}{n}\right) \right\}, \tag{3.4}$$

with $g(t) = t^{\beta-1}y(t)$. This yields the following triangular system for the approximations $\bar{x}_n = (x_{n,1}, x_{n,2}, \dots, x_{n,n})^T$

$$\frac{n^{\beta-1}}{(1-\beta)(2-\beta)}\,\bar{A}_n\bar{x}_n = \bar{y}_n - \frac{n^{\beta-1}}{(1-\beta)(2-\beta)}\,\bar{b}_n, \tag{3.5}$$

where $\bar{y}_n = (y(\frac{1}{n}), y(\frac{2}{n}), \dots, y(1))^T$, $\bar{b}_n = (b_{n,1}, b_{n,2}, \dots, b_{n,n})^T$,

$$\begin{aligned}
b_{n,i} &= a\left(\frac{i}{n}, 0\right) x_{n,0}, \quad i = 1, 2, \dots, n,\\
(\bar{A}_n)_{i,j} &= \begin{cases} a^n_{i,j}\kappa_{i-j}, & 1 \le j \le i \le n,\\ 0, & \text{otherwise},\end{cases}\\
\kappa_\ell &= (\ell+1)^{2-\beta} - 2\ell^{2-\beta} + (\ell-1)^{2-\beta}, \quad \ell \ge 1,\\
\kappa_0 &= 1.
\end{aligned}$$

The question of the existence and uniqueness of a solution (3.5) is summarized in the following proposition.

PROPOSITION 3.1 (see [7]). *If $a(t,\tau)$ is Lipschitz-continuous on $0 \le \tau \le t \le 1$, then there is a constant $\tilde{c}_{\beta,a}$ depending on β and such that $\|(\bar{A}_n)^{-1}\|_\infty \le \tilde{c}_{\beta,a}$, i.e., for any $\bar{f}_n = (f_1, f_2, \dots, f_n)^T$, $\|\bar{f}_n\|_\infty := \max_i |f_i|$,*

$$\|(\bar{A}_n)^{-1}\bar{f}_n\|_\infty \le \tilde{c}_{\beta,a}\|\bar{f}_n\|_\infty.$$

Moreover, in [2] (see also [31]) the convergence of the trapezoidal-discretization method has been shown to hold when the solution $x(t)$ of (1.1), (3.1) has only Lipschitz continuity and the same conditions on $a(t,\tau)$ apply. It means that there exists an increasing continuous function $\psi_{a,\beta}(x;t)$ such that $\psi_{a,\beta}(x;0) = 0$ and

$$\max_{0\le i\le n}\left|x\left(\frac{i}{n}\right) - x_{n,i}\right| \le \psi_{a,\beta}\left(x, \frac{1}{n}\right). \tag{3.6}$$

Let us turn to the case of the noisy equation

$$Ax(t) = y_\delta(t), \tag{3.7}$$

where A has the form (3.1), and y_δ can be only element from $Y = C_{[0,1]}$ such that (1.2) holds.

The trapezoidal-discretization method can be applied directly to (3.7) if in (3.4), (3.5) $y(\frac{i}{n})$ will be replaced by $y_\delta(\frac{i}{n})$, $i = 1, 2, \dots, n$. Then from Proposition 3.1 it follows that there is always a unique solution $\bar{x}^\delta_n$ of the system

$$\frac{n^{\beta-1}}{(1-\beta)(2-\beta)}\,\bar{A}_n\bar{x}^\delta_n = \bar{y}^\delta_n - \frac{n^{\beta-1}}{(1-\beta)(2-\beta)}\,\bar{b}^\delta_n.$$

It is easy to see that $\|\bar{y}_n - \bar{y}^\delta_n\|_\infty \le \delta$,

$$|x_{n,0} - x^\delta_{n,0}| \le \frac{(1-\beta)}{|a(0,0)|}n^{1-\beta}\delta(3 + 3\cdot 2^{\beta-1} + 3^{\beta-1}) = c_{\beta,a,1}n^{1-\beta}\delta, \tag{3.8}$$

and

$$\|\bar{b}_n - \bar{b}^\delta_n\|_\infty \le \|a(\cdot,0)\|_C|x_{n,0} - x^\delta_{n,0}| \le c_{\beta,a,2}n^{1-\beta}\delta.$$

Thus, under the condition of Proposition 3.1, the following bound holds:

$$\begin{aligned}\max_{0\le i\le n}|x_{n,i}-x^{\delta}_{n,i}| &\le n^{1-\beta}\|(\bar{A}_n)^{-1}\|_{\infty}((1-\beta)(2-\beta)+c_{\beta,a,2})\delta \\ &\le c_{\beta,a,3}n^{1-\beta}\delta.\end{aligned}\tag{3.9}$$

Within the framework of trapezoidal-discretization method the approximate solution of (1.1), (3.1) can be taken as piecewise linear interpolation spline $x_n(t)$ with uniform interpolation knots such that $x_n(\frac{i}{n})=x_{n,i}$, $i=0,1,2,\dots,n$. If only noisy right-hand side $y_\delta(t)$ is available then such a spline will interpolate $x^{\delta}_{n,i}$ and have the form

$$x^{\delta}_n(t)=\sum_{i=0}^{n}x^{\delta}_{n,i}\ell_{n,i}(t),$$

where $\ell_{n,i}(t)$ are so-called fundamental linear splines with knots $\{\frac{i}{n}\}_{i=0}^{n}$ such that $\ell_{n,i}(t)\ge 0$ for $t\in[0,1]$, and $\ell_{n,i}(\frac{j}{n})=\delta_{ij}$. From (3.8), (3.9) it follows that

$$\begin{aligned}|x_n(t)-x^{\delta}_n(t)| &\le \sum_{i=0}^{n}|x_{n,i}-x^{\delta}_{n,i}|\ell_{n,i}(t)\le \max_{0\le i\le n}|x_{n,i}-x^{\delta}_{n,i}| \\ &\le n^{1-\beta}\delta\max\{c_{\beta,a,1},c_{\beta,a,3}\}=c_{\beta,a}n^{1-\beta}\delta.\end{aligned}\tag{3.10}$$

Let now $s_n(x;t)$ be a piecewise linear spline with knots $\{\frac{i}{n}\}_{i=0}^{n}$ interpolating the values $x(\frac{i}{n})$, $i=0,1,\dots,n$, of the solution (1.1), (3.1). It is well-known that

$$|x(t)-s_n(x;t)|\le c\omega_2\left(x;\frac{1}{n}\right),$$

where $\omega_2(x;h)$ is the second-order modulus of smoothness, $\omega_2(x;h)\to 0$, and c is some absolute constant. Using (3.6) this yields

$$\begin{aligned}|x(t)-x_n(t)| &\le |x(t)-s_n(x;t)|+|s_n(x;t)-x_n(t)| \\ &\le c\omega_2\left(x;\frac{1}{n}\right)+\sum_{i=0}^{n}\left|x\left(\frac{i}{n}\right)-x_{n,i}\right|\ell_{n,i}(t) \\ &\le c\omega_2\left(x;\frac{1}{n}\right)+\psi_{a,\beta}\left(x;\frac{1}{n}\right)=\varphi\left(\frac{1}{n}\right).\end{aligned}$$

Combining it with (3.10), we obtain

$$|x(t)-x^{\delta}_n(t)|\le\varphi\left(\frac{1}{n}\right)+c_{\beta,a}n^{1-\beta}\delta.\tag{3.11}$$

Here the function φ depends on the smoothness of the solution (1.1), (3.1) and usually is unknown. But (3.11) has the same form as (1.6), where $\alpha=\frac{1}{n}$, $\lambda(\alpha)=c^{-1}_{\beta,a}\alpha^{1-\beta}$. For such α and $\lambda(\alpha)$ we have $\Delta_N=\{\alpha_i=\frac{1}{N-i+1}\}_{i=0}^{N}$ and

$$\begin{aligned}M^{+}(\Delta_N)=\Bigg\{\alpha_i=\frac{1}{N-i+1} &: \|x^{\delta}_{N-i+1}-x^{\delta}_{N-j+1}\|_C\le 4\delta c_{\beta,a}(N-j+1)^{1-\beta}, \\ &j=0,1,2,\dots,i\Bigg\} \\ =\{n:\|x^{\delta}_n-x^{\delta}_m\|_C &\le 4\delta c_{\beta,a}m^{1-\beta},\ m=N+1,N,\dots,n\}.\end{aligned}$$

Hence the selection criterion (2.1), (2.3) can be written as

$$n_+ := \min\{n : \|x_n^\delta - x_m^\delta\|_C \leq 4\delta c_{\beta,a} m^{1-\beta},\ m = N+1, N, \dots, n\} \tag{3.12}$$

and the conditions of Theorem 2.1 are satisfied with $q = 2^{1-\beta}$, $N > (c_{\beta,a}\delta)^{\frac{1}{\beta-1}}$. Thus, we have Theorem 3.2.

THEOREM 3.2. *If $a(t,\tau)$ and the solution $x(t)$ of* (1.1), (3.1) *are Lipschitz-continuous on $0 \leq \tau \leq t \leq 1$, then for $N > (c_{\beta,a}\delta)^{\frac{1}{\beta-1}}$ and n_+ chosen as* (3.12)

$$|x(t) - x_{n+}^\delta(t)| \leq 6 \cdot 2^{1-\beta}\varphi((\varphi\lambda)^{-1}(\delta)),$$

where $\lambda(\alpha) = c_{\beta,a}^{-1}\alpha^{1-\beta}$, $\varphi(\alpha) = c\omega_2(x;\alpha) + \psi_{a,\beta}(x;\alpha)$, and $\psi_{a,\beta}$ is the function from (3.6).

Remark 3.3. We can indicate only one case when the order of the function φ is known. Namely, in [7] it has been shown that $\psi_{a,\beta}(x, \frac{1}{n}) = c_1 n^{-2}$ for all $\beta \in (0,1)$, and for $x(t)$, $a(t,\tau)$ having Lipschitz-continuous second derivatives. For such $x(t)$ $\omega_2(x; \frac{1}{n})$ has the best possible order $\omega_2(x; \frac{1}{n}) = c_2 n^{-2}$. Thus, in the considered case $\varphi(\frac{1}{n}) = c_3 n^{-2}$ and to balance both terms in (3.11), one should take $n = n_{\text{opt}} \asymp \delta^{\frac{1}{\beta-3}}$ that gives an accuracy of order $O(\delta^{\frac{2}{3-\beta}})$. Note that Theorem 3.2 gives the same order of accuracy automatically without knowledge of φ.

Theorem 3.2 shows that the regularization of ill-posed problem (1.1), (3.1) with noisy right-hand side y_δ can be achieved by just choosing the number of knots in the trapezoidal rule properly. This is called self-regularization. Self-regularization adapted to unknown smoothness in a Hilbert space has been discussed recently in [13, 12, 4]. To the best of our knowledge, Theorem 3.2 is the first example of adaptive self-regularization in Banach space.

3.2. Example 2: Lavrentiev regularization for nonlinear ill-posed problems with monotone operators.

Throughout this section we assume that $A : D(A) \to X$ is a nonlinear monotone operator with domain $D(A)$ in a real Hilbert space X. Monotonicity means that for all $x_1, x_2 \in D(A)$

$$\langle A(x_1) - A(x_2),\ x_1 - x_2\rangle \geq 0,$$

where $\langle\cdot,\cdot\rangle$ is the inner product associated with norm $\|\cdot\| = \|\cdot\|_X$.

We further assume throughout that the nonlinear equation

$$A(x) = y$$

has a solution x^+, but only a noisy data y_δ with a known noise level δ is available, i.e., $\|y - y_\delta\| \leq \delta$. We do not assume that x^+ depends continuously on the data. It means that the stable reconstruction of x^+ from the noisy equation

$$A(x) = y_\delta \tag{3.13}$$

requires the application of special regularization methods. In the well-known Tikhonov regularization method a regularized approximation x_α^δ is obtained by minimizing the functional

$$J_\alpha(x) = \|A(x) - y_\delta\|^2 + \alpha\|x - \bar{x}\|^2,$$

with some initial guess $\bar{x} \in X$ and some properly chosen regularization parameter $\alpha > 0$. If A is Fréchet-differentiable in some ball $B_\rho(x^+)$ of radius ρ around x^+, and

x_α^δ is an interior point of $D(A)$ then it can be found from the (nonlinear) normal equation of Tikhonov's functional $J_\alpha(x)$

$$[A'(x)]^*[A(x) - y^\delta] + \alpha(x - \bar{x}) = 0,$$

where $[A'(x)]^*$ is the adjoint of the Fréchet derivative $A'(x)$. As has been indicated in [16, 24], for the problems with monotone operators the least squares minimization (and hence the use of the Fréchet derivatives) can be avoided and one can use the simpler regularized equation

$$A(x) + \alpha(x - \bar{x}) = y_\delta \tag{3.14}$$

known as Lavrentiev regularization.

If $D(A) = X$ and $A(x)$ is a continuous operator, then as has been shown in [6, pp. 97, 100], the monotonicity implies that for $\alpha > 0$ the operator $F(x) = \alpha x + A(x)$, $x \in X$, is strongly monotone, and $F^{-1}(x) = (\alpha I + A)^{-1}(x)$ is Lipschitz with constant $\frac{1}{\alpha}$; i.e., for any $u, v \in X$

$$\|(\alpha I + A)^{-1}(u - v)\| \le \frac{1}{\alpha}\|u - v\|. \tag{3.15}$$

Applying Lavrentiev regularization one usually assumes that for pure data $y = A(x^+)$ it produces an approximate solution $x_\alpha = (\alpha I + A)^{-1}(y + \alpha\bar{x})$ converging to x^+ as $\alpha \to 0$. It means that there exists an increasing continuous function $\varphi(\alpha) = \varphi(x^+; \alpha)$ such that $\varphi(0) = 0$ and

$$\|x^+ - x_\alpha\| \le \varphi(\alpha). \tag{3.16}$$

THEOREM 3.4. *Let $A(x)$ be a continuous monotone operator in a real Hilbert space X. Consider $\Delta_N = \{\alpha_i = q^i\delta,\ i = 0, 1, \dots, N\}$, $q > 1$, $\alpha_N \simeq 1$, and $\bar{\alpha} = \max\{\alpha_j \in \Delta_N : \|x_{\alpha_i}^\delta - x_{\alpha_{i-1}}^\delta\| \le 4q^{1-i},\ i = 1, 2, \dots, j\}$, where $x_{\alpha_i}^\delta$ is the unique solution of* (3.14) *for $\alpha = \alpha_i$. Then under the assumption* (3.16)

$$\|x^+ - x_{\bar{\alpha}}^\delta\| \le \frac{(6q - 2)q}{q - 1}\varphi(x^+; \theta_\varphi^{-1}(\delta)), \tag{3.17}$$

where $\theta_\varphi(t) = \varphi(t)t$.

Proof. From (3.15) and (3.16), it follows that for any $\alpha > 0$

$$\begin{aligned}\|x^+ - x_\alpha^\delta\| &\le \|x^+ - x_\alpha\| + \|x_\alpha - x_\alpha^\delta\| \\ &\le \varphi(\alpha) + \|(\alpha I + A)^{-1}(y - y_\delta)\| \\ &\le \varphi(\alpha) + \frac{\delta}{\alpha}.\end{aligned}$$

Hence, error bound has the form (1.6) with $\lambda(\alpha) = \alpha$. It is easy to see that for such $\lambda(\alpha)$, all conditions of Theorem 2.2 are satisfied. Moreover, for $\lambda(\alpha) = \alpha$ the arguments from the proof can be simplified, and it gives an explicit form of the constant c near the optimal order. □

Remark 3.5. Lavrentiev regularization is usually studied under the assumption (3.16) with $\varphi(\alpha) = c\alpha^p$, $p \in (0, 1]$. For example, the case of unknown p has been discussed recently in [24], where it has been shown that for α chosen as the solution of the nonlinear equation

$$\|\alpha(\alpha I + A'(x_\alpha^\delta))^{-1}(A(x_\alpha^\delta) - y_\delta)\| = c_1\delta, \quad c_1 > 1,$$

one has

$$\|x^+ - x_\alpha^\delta\| \le c_p \delta^{\frac{p}{p+1}}.$$

The disadvantage of this a posteriori rule is that its combination with the Lavrentiev regularization (3.14) does not allow to avoid the use of the Fréchet derivatives. At the same time, an a posteriori rule presented in Theorem 3.4 is free from the above mentioned drawback and gives the same order of accuracy $0(\delta^{\frac{p}{p+1}})$ for $\varphi(\alpha) = c\alpha^p$.

Moreover, to our knowledge, the rule from Theorem 3.4 is the only one that allows to reach the best possible order of accuracy of Lavrentiev regularization automatically, and does not involve another regularization methods.

3.3. Example 3: Inverse problem of profile reconstruction in diffractive optics. The statement of the problem discussed in this section is borrowed from [3]. Let the profile of two-dimensional diffraction grating be described by the curve

$$\Lambda_f := \{(x_1, f(x_1)) : x_1 \in \mathbb{R}\}$$

with 2π-periodic function f. Let

$$\Omega_f := \{x = (x_1, x_2) : x_2 > f(x_1),\ x_1 \in \mathbb{R}\}$$

be filled with a material whose index of refraction k is some positive constant. Suppose that a plane wave given by

$$u^{in}(x) = \exp(i\alpha x_1 - i\beta x_2)$$

is incident on Λ_f from the top, where $\alpha = k \sin\theta$, $\beta = k\cos\theta$, and $\theta \in (-\frac{\pi}{2}, \frac{\pi}{2})$ is the incident angle. Then the scattering of this wave by Λ_f is modelled by the Dirichlet problem for the Helmholz equation

$$\Delta u + k^2 u = 0 \quad \text{in } \Omega_f, \qquad u = -u^{in} \quad \text{on } \Lambda_f \tag{3.18}$$

where the scattered field u is assumed to satisfy a radiation condition, i.e., u is composed of bounded outgoing plane waves:

$$u(x_1, x_2) = \sum_{n\in\mathbb{Z}} A_n \exp[i(n+\alpha)x_1 + i\beta_n x_2], \tag{3.19}$$

with $\beta_n = \sqrt{k^2 - (n+\alpha)^2} \in \mathbb{C}$, and the Rayleigh coefficients $A_n \in \mathbb{C}$. To exclude resonances one assumes that $\beta_n \ne 0$, $n \in \mathbb{Z}$.

The inverse problem of profile reconstruction is to recover the profile function f from the trace $u_b(x) = u(x, b)$ of the scattered field $u(x_1, x_2)$ on the line $x_2 = b$ for a given incident wave u^{in}. Without loss of generality we can assume that the unknown profile Λ_f lies above the line $x_2 = b_0$ and below $x_2 = b$, i.e.,

$$b_0 < f(x_1) < b, \quad x_1 \in \mathbb{R}. \tag{3.20}$$

Representing the scattered field as a single layer potential

$$u(x_1, x_2) = \int_0^{2\pi} z(t) G(x_1, x_2, t, 0) dt$$

with an unknown density function $z \in L_2(0, 2\pi)$ and the free space quasi-periodic Green function

$$G(x_1, x_2, y_1, y_2) = \frac{i}{2\pi} \sum_{n \in \mathbb{Z}} \frac{1}{\beta_n} \exp[i(n + \alpha)(x_1 - y_1) + i\beta_n(x_2 - y_2)],$$

one can reduce the inverse problem of profile reconstruction to the following system of integral equations

$$\begin{aligned} Tz(x_1) &:= \int_0^{2\pi} z(t)G(x_1, b, t, 0)dt = u_b(x_1), \\ S_f z(x_1) &:= \int_0^{2\pi} z(t)G(x_1, f(x_1), t, 0)dt = -u^{in} \circ f(x_1), \end{aligned} \tag{3.21}$$

which is nonlinear with respect to f. Here $u^{in} \circ f(x_1) = \exp(i\alpha x_1 - i\beta f(x_1))$. Applying the arguments from the proof of [3, Lemma 4.1 and Theorem 4.2] one can obtain the following proposition.

PROPOSITION 3.6. *Let $u_b(x_1)$ be the exact pattern of the scattered field $u(x_1, x_2)$ on $x_2 = b$ that corresponds to some 2π-periodic profile functions $f \in C^2(\mathbb{R})$ meeting* (3.20). *Then there exists a solution (z_0, f_0) of the system* (3.21). *If in addition the inverse problem of profile reconstruction is uniquely solvable then $f = f_0$.*

Note that in problem (3.21) the knowledge of all Rayleigh coefficients A_n of the scattered waves is required. At the same time, the Fourier coefficients of $u_b(x_1) = u(x_1, b)$ with respect to orthonormal basis $\{\exp[i(n+\alpha)x_1]\}_{n\in\mathbb{Z}}$ of the complex Hilbert space $L_2(0, 2\pi)$ have the form $A_n e^{i\beta_n b}$, $n \in \mathbb{Z}$, and decay exponentially. Therefore, in practice one is able to measure only a finite number of $A_n, n \in U$, corresponding to outgoing plane waves (modes) of the scattered field (3.19) that can be observed on the line $x_2 = b$. Here U is some finite index set. Moreover, even these coefficients will not be given exactly but will be perturbed by measurement errors. To be more precise, we have only a vector $(A_n^\delta)_{n\in U}$ determining the "noisy trace"

$$u_b^\delta(x_1) = \sum_{n \in U} A_n^\delta \exp[i(n + \alpha)x_1 + i\beta_n b]$$

such that

$$\|u_b - u_b^\delta\| \le \delta, \tag{3.22}$$

where $\|\cdot\|$ denotes the norm in the complex Hilbert space $L_2(0, 2\pi)$.

Thus, replacing the scattered field u_b by u_b^δ one obtains the system (3.21) containing the noisy equation $Tz = u_b^\delta$, and for a stable profile reconstruction its regularized version should be considered. Such an approach was first proposed by Kirsch and Kress [14] for acoustic obstacle scattering. For the profile reconstruction problem it has been developed recently in [3]. These authors have observed that the structure of the system (3.21) allows the decomposition of the inverse problem of profile reconstruction into the severely ill-posed linear problem of estimating the scattered field potential density $z(t)$, and into the well-posed nonlinear problem of determining the unknown profile function as the location of the zeros of the total field; the later problem can then be replaced by the finite dimensional nonlinear least squares problem.

If $z(t)$ is given as a Fourier series

$$z(t) = \sum_{n\in\mathbb{Z}} z_n \exp[i(n+\alpha)t], \quad z_n \in \mathbb{C},$$

then the operators from the system (3.21) can be represented in the following form:

$$Tz(x_1) = i\sum_{n\in\mathbb{Z}} z_n\beta_n^{-1}\exp[i(n+\alpha)x_1 + i\beta_n b], \tag{3.23}$$

$$S_f z(x_1) = i\sum_{n\in\mathbb{Z}} z_n\beta_n^{-1}\exp[i(n+\alpha)x_1 + i\beta_n f(x_1)]. \tag{3.24}$$

Now it can be easily checked that T is an injective linear operator whose inverse T^{-1} acts continuously from $L_2 = L_2(0,2\pi)$ to the Hilbert space of generalized functions

$$L_{2,\exp}^{-b} := \left\{ z : \|z\|^2_{L^{-b}_{2,\exp}} := \sum_{n\in\mathbb{Z}} |z_n|^2 |e^{2i\beta_n b}||\beta_n|^{-2} < \infty \right\},$$

where z_n is the value of the functional $\langle z, e^{i(n+\alpha)}\rangle_{L_2(0,2\pi)}$, $n\in\mathbb{Z}$. Thus, if the problem was to find the solution of the equation $Tz = u_b^\delta$ in the space $L^{-b}_{2,\exp}$, it would be well-posed. But the second equation of (3.21) presumes $S_f z \in L_2(0,2\pi)$ for all admissible function meeting (3.20). One can guarantee it if $z \in L^{-b_0+h}_{2,\exp}$ for some $0 < h < b_0$. Indeed, $|\beta_m| \sim m$ and

$$\begin{aligned}\|S_f z\|^2 &= \int_0^{2\pi} \left| \sum_{n\in\mathbb{Z}} z_n \beta_n^{-1} e^{i(\alpha+n)x_1} e^{i\beta_n f(x_1)} \right|^2 dx_1 \\ &\le c\left(\sum_{n\in\mathbb{Z}} \frac{|z_n|^2}{|\beta_n|^2} |e^{2i\beta_n(b_0-h)}| \right) \int_0^{2\pi} \sum_{n\in\mathbb{Z}} e^{-2|\beta_n|(f(x_1)-b_0+h)} dx_1 \\ &\le \frac{c}{1-e^{-2h}} \|z\|^2_{L^{-b_0+h}_{2,\exp}} = c_h \|z\|^2_{L^{-b_0+h}_{2,\exp}},\end{aligned} \tag{3.25}$$

where the constant c_h depends only on h. Thus, it is reasonable to seek for solution of $Tz = u_b^\delta$ in the space $L^{-b_0+h}_{2,\exp}$.

Remark 3.7. In [3] it has been proposed to regularize the first equation of (3.21) in the space L_2. Keeping in mind that $L_2 \hookrightarrow L^{-b_0+h}_{2,\exp}$, it is easy to realize that for the pair (L_2, L_2) the problem $Tz = u_b^\delta$ is more ill-posed than for $(L^{-b_0+h}_{2,\exp}, L_2)$. Moreover, for any regularized solution z_δ of equation $Tz = u_b$ one has

$$\|z_0 - z_\delta\|_{L^{-b_0+h}_{2,\exp}} \le \|z_0 - z_\delta\|_{L_2},$$

where $z_0 = T^{-1}u_b$. At the same time, from (3.24) it follows that the perturbation of the left-hand side of the second equation of (3.21) caused by the replacement z_0 for z_δ can be estimated as

$$\|S_f z_0 - S_f z_\delta\| \le c_h \|z_0 - z_\delta\|_{L^{-b_0+h}_{2,\exp}}.$$

The equation supports the use of $L^{-b_0+h}_{2,\exp}$ as a more suitable space for the problem under consideration.

Singular value expansion (3.23) of the operator T allows us to apply the spectral cut-off scheme for the regularization of the equation $Tz = u_b^\delta$. It gives the following sequence of regularized solutions:

$$z_{m,\delta}(x_1) = -i \sum_{|n|<m} A_n^\delta \beta_n \exp[i(\alpha+n)x_1], \quad m = 1, 2, \ldots, M+1, \tag{3.26}$$

where $M = \max\{m : (-m, -m+1, \ldots, m-1, m) \subset U\}$. Replacing A_n^δ with A_n in (3.26), one obtains the partial sum $z_{m,0}$ of the Fourier series

$$z_0(x_1) = T^{-1}u_b(x_1) = -i \sum_{n \in \mathbb{Z}} A_n \beta_n \exp[i(\alpha+n)x_1].$$

Keeping in mind that $\|z_{m,0} - z_0\| \to 0$ as $m \to \infty$, and $\|z_{m,0} - z_0\|_{L_{2,\exp}^{-b_0+h}} \leq \|z_{m,0} - z_0\|$, we deduce that there exists an increasing continuous function $\varphi(\lambda)$ such that $\varphi(0) = 0$ and

$$\|z_0 - z_{m,0}\|_{L_{2,\exp}^{-b_0+h}} \leq \varphi\left(\frac{1}{m}\right). \tag{3.27}$$

Moreover, from (3.22) it follows that

$$\begin{aligned}
\|z_{m,0} - z_{m,\delta}\|^2_{L_{2,\exp}^{-b_0+h}} &= \sum_{|n|<m} |A_n - A_n^\delta|^2 |e^{2i\beta_n(b_0-h)}| \\
&= \sum_{|n|<m} |A_n - A_n^\delta|^2 |e^{2i\beta_n b}| |e^{2i\beta_n(b_0-h-b)}| \\
&\leq e^{2|\beta_m|(b+h-b_0)} \|u_b - u_b^\delta\|^2 \\
&\leq \delta^2 e^{2|\beta_m|(b+h-b_0)}.
\end{aligned}$$

Then

$$\|z_0 - z_{m,\delta}\|_{L_{2,\exp}^{-b_0+h}} \leq \varphi\left(\frac{1}{m}\right) + \delta e^{|\beta_m|(b+h-b_0)}.$$

This estimate has the form (1.6) with $\alpha = \frac{1}{m}$ and

$$\lambda(\alpha) = \exp\left[-\sqrt{|k^2 - (\alpha^{-1} + k\sin\theta)^2|}(b+h-b_0)\right]. \tag{3.28}$$

As in section 3.1 we consider $\Delta_M = \{\alpha_i = \frac{1}{M-i+1}\}_{i=0}^M$. Keeping in mind that

$$c_1 e^{-\frac{a}{\alpha}} \leq \lambda(\alpha) \leq c_1 e^{-\frac{a}{\alpha}}$$

with $a = (b+h-b_0)$ and some constants c_1, c_2 depending only on k and θ, it is easy to check that in considered case the condition (2.2) is satisfied with $q = \frac{c_2 e^a}{c_1}$. Then, as in section 3.1, the straightforward application of Theorem 2.1 gives the following theorem.

Theorem 3.8. *Assume that the inverse problem of profile reconstruction is uniquely solvable. If M is sufficiently large such that $M \sim (b+h-b_0)^{-1} \ln\frac{1}{\delta}$ then for m_+ chosen as*

$$m_+ = \min\left\{m : \|z_{m,\delta} - z_{n,\delta}\|^2_{L_{2,\exp}^{-b_0+h}} \leq 4\delta e^{|\beta_n|(b+h-b_0)},\ n = M+1, M, \ldots, m\right\}$$

one has

$$\|z_0 - z_{m_+,\delta}\|_{L_{2,\exp}^{-b_0+h}} \leq c\varphi((\varphi\lambda)^{-1}(\delta)),$$

where φ, λ are the functions from (3.27), (3.28), *and c depends only on b, b_0, h, k, θ.*

Remark 3.9. In the case under consideration, the spectral cut of scheme (3.26) can be combined with the discrepancy principle. Then the regularization parameter m would be chosen as

$$m_d = \min\{m : \|Tz_{m,\delta} - u_b^\delta\|_{L_2} \leq d\delta;\ m = 1, 2, \ldots, M+1\}. \tag{3.29}$$

It is easy to observe that the combination of (3.26) with (3.29) does not take into account our wish to regularize a problem in such an "exotic" space as $L_{2,\exp}^{-b_0+h}$. In this respect the parameter choice rule discussed above is much more flexible, and it is one more advantage of it.

4. Conclusion. As mentioned in the introduction, the a posteriori choice of the regularization parameter by several of the known principles may not yield the optimal order of accuracy for a given solution's smoothness. The principle proposed in the present paper is free from the above-mentioned drawback. Namely, for the first time one has a parameter choice rule that allows us to reach the best order of accuracy for all ill-posed problems that in principle can be treated in an optimal way by considered regularization methods.

We would like to emphasize that adaptive parameter choice strategy described in section 2 can be applied in a wide variety of situations where the goal is to find a balance between stability and approximation rate, and the latter one is unknown. Such a strategy may be of interest in other areas of numerical analysis. It seems that the problem of the weight choice in penalty finite element methods, for example, can be treated using the same idea.

Acknowledgments. The results of the paper were obtained while the first author was a DAAD guest professor at the University of Kaiserslautern. The support of the German Academic Exchange Service (DAAD) during the academic year 2002/2003 is gratefully acknowledged. The authors also thank Richard Lehoucq and two anonymous referees for careful reading and suggestions that have improved the presentation of the manuscript.

A PROLONGATION/RESTRICTION OPERATOR FOR WHITNEY ELEMENTS ON SIMPLICIAL MESHES[*]

ALAIN BOSSAVIT[†] AND FRANCESCA RAPETTI[‡]

Abstract. The paper is mainly focused on the construction of two transfer operators between nested grids in the case of Whitney finite elements (node-, edge-, face-, or volume-based). These transfer operators, instances of what is called "chain map" in homology, have duals acting on cochains, that is to say, arrays of degrees of freedom in the context of the finite-element discretization of variational problems. We show how these duals can act as restriction/prolongation operators in a multigrid approach to such problems, especially those involving vector fields (e.g., electromagnetism). The duality between the operation of mesh refinement of a simplicial complex and that of restriction/prolongation of degrees of freedom from one mesh to a nested one is thus analyzed and explained. We use the language of p-forms, with frequent explanatory references to the more traditional vector-fields formalism.

Key words. mesh refinement, p-chains, p-forms, Whitney elements, multigrid

1. Introduction.

In the approximation of a given differential problem by a finite element method, solving the final algebraic linear system is a delicate step. It is well-known that the associated matrix is sparse and can be of large size so that iterative solvers are preferable to direct ones. However, the convergence of iterative solvers strongly depends on the matrix condition number and slows down when the latter is large. Moreover, classical iterative methods fail to be effective whenever the spectral radius of the iteration matrix is close to one. A Fourier analysis shows that the reduction in the error depends on the spatial frequency. Errors with high frequency are rapidly damped whereas low frequency errors are slowly reduced and hold back convergence.

The multigrid algorithm [16] is an iterative technique well-adapted to solving linear systems arising from a finite element discretization of differential equations over a given grid. The basic idea of the method is to change the grid in such a way that low frequency (smooth) errors on a grid with elements of maximal diameter h can be singled out and cut down on a coarser grid, while high frequency errors that are not visible on the coarse grid with elements of maximal diameter $H > h$, for example, can be resolved on the fine grid. The exchange of information between the two meshes is done by means of two linear operators, one behaving as a prolongation and the other as a restriction. These operators are well known for nodal finite elements on nested or nonnested grids [19] but have still to be fully understood for edge or face finite elements.

It must be remarked that recovering the coarse grid from the fine one can be a very demanding operation. Therefore, in this paper we will address this problem the other

way around; i.e., we suppose that we have a coarse grid and we refine it repeatedly by means of a fixed procedure. This way, by using a suitable system of labels for the mesh nodes, we can know at which refinement level we are. Any other situation is not considered here since we wish to focus on the transfer of degrees of freedom from one mesh to the other, rather than on the coarsening process itself. However, the proposed analysis does not depend on the refinement or coarsening process. In short, we focus on a specific criterion to present the theory, but the theory is independent from the chosen criterion.

The paper is organized as follows. In section 2, suitable algebraic tools are introduced to lead the reader into the "world" of Whitney elements on simplicial meshes, including an appropriate formulation of the Stokes theorem. In section 3, we consider the problem of subdividing a simplicial mesh. The core of the paper is section 4, where we construct the information exchange operators between two "nested" meshes (by which we mean, two meshes m and $\tilde{m}$, the latter a conforming refinement of the former). Notions thus developed are applied in section 5, where we define the two transfer operators for Whitney elements on two nested simplicial meshes. The multigrid algorithm then comes as a straightforward application of these notions. Analyzing its performances is a difficult and technical issue, which we do not address. (Relevant references are given in section 5.)

2. Algebraic tools.

In this section, we recall some basic notions in algebraic topology (see, e.g., [1, 17]) and explain our notation. We restrict ourselves to a three-dimensional domain Ω (but the same notions can be defined in any dimension). For all integrals, we omit specifying the integration variable when this can be done without ambiguity. We shall denote by $\int_\gamma \mathbf{u}\cdot\mathbf{t}_\gamma$ and $\int_\sigma \mathbf{u}\cdot\mathbf{n}_\sigma$, respectively, the circulation and the flux of a vector field $\mathbf{u}$, where $\mathbf{t}_\gamma$ is the unit tangent to the smooth curve γ and $\mathbf{n}_\sigma$ the outward unit normal to the surface σ. Moreover, we shall emphasize the maps $\gamma \to \int_\gamma \mathbf{u}\cdot\mathbf{t}_\gamma$ and $\sigma \to \int_\sigma \mathbf{u}\cdot\mathbf{n}_\sigma$, that is to say, the differential forms of degree 1 and 2, respectively, which one can associate with a given vector field $\mathbf{u}$, and we occasionally use notations specific to exterior calculus, such as the exterior derivative d, as used in the Stokes theorem.

2.1. Triangulations and Whitney finite elements.

Given a domain $\Omega \subset \mathbb{R}^3$ with boundary Γ, a simplicial mesh m in Ω is a tessellation of $\overline{\Omega}$ by tetrahedra, under the condition that any two of them may intersect along a common face, edge, or node, but in no other way. We denote by $\mathcal{N}_m$, $\mathcal{E}_m$, $\mathcal{F}_m$, $\mathcal{T}_m$ (nodes, edges, faces, and tetrahedra, respectively) the sets of simplices of dimension 0 to 3 thus obtained (see Figure 1 for an example), each with its own orientation (more on this will follow), and by N_m, E_m, F_m, T_m their cardinalities. Alternatively, we may use $\mathcal{S}^p_m$ to denote the set of p-dimensional simplices in m and $\#\mathcal{S}^p_m$ for its cardinality. The importance of simplicial meshes lies in the fact that any triangulated domain is homeomorphic to one in which the triangles are flat and the edges straight. Note that the triangulation for Ω is not unique, but topological properties of a triangulated domain do not depend on the triangulation used to investigate them. (For such "homological" computations, using a definite triangulation but yielding mesh-independent results, which we believe are relevant to engineering practice, see [12, 15].)

For what follows, we need to underline some combinatorial properties of the simplicial mesh. Besides the list of nodes and their positions, the mesh data structure also contains incidence matrices, saying which node lies at an end of which edge, which edge bounds which face, etc. [4]. This encodes the orientation of each simplex, as we now explain. In short, an oriented edge is not only a two-node subset of $\mathcal{N}_m$,

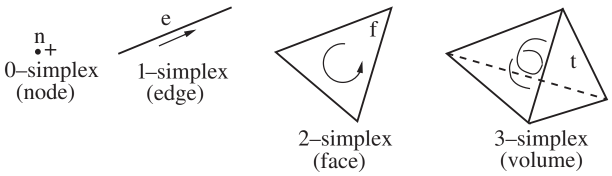

FIG. 1. *Examples of oriented p-simplex, $p = 0, \dots, 3$.*

but an ordered such set, where the order implies an orientation. Let $e = \{\ell, n\}$ be an edge of the mesh oriented from the node ℓ to n. We can define the incidence numbers $G_{e,n} = 1$, $G_{e,\ell} = -1$, and $G_{e,k} = 0$ for all nodes k other than ℓ and n. These numbers form a $(E_m \times N_m)$-matrix G, which describes how edges connect to nodes. A face $f = \{\ell, n, k\}$ has three vertices which are the nodes ℓ, n, k. Note that $\{n, k, l\}$ and $\{k, l, n\}$ denote the same face f, whereas $\{n, l, k\}$ denotes an oppositely oriented face, which is not supposed to belong to $\mathcal{F}_m$ if f does. An orientation of f induces an orientation of its boundary. So, with respect to the orientation of the face f, the one of the edge $\{l, n\}$ is positive and that of $\{k, n\}$ is negative. So we can define the incidence number $R_{f,e} = 1$ (resp., -1) if the orientation of e matches (resp., does not match) the one on the boundary of f and $R_{f,e} = 0$ if e is not an edge of f. These numbers form a $(F_m \times E_m)$-matrix R. Finally, let us consider the tetrahedron $t = \{k, l, m, n\}$, positively oriented if the three vectors $\{k, l\}$, $\{k, m\}$, and $\{k, n\}$ define a positive frame ($t' = \{l, m, n, k\}$ has a negative orientation and does not belong to $\mathcal{T}_m$ if t does). A $(V_m \times F_m)$-matrix D can be defined by setting $D_{t,f} = \pm 1$ if face f bounds the tetrahedron t, with the sign depending on whether the orientation of f and of the boundary of t match or not, and $D_{t,f} = 0$ in case f does not bound t. (For consistency, we may attribute an orientation to nodes as well—a sign, ± 1. Implicitly, we have been orienting all nodes the same way ($+1$) up to now. Note that a sign (-1) to node n changes the sign of all entries of column n in the above G.) It can easily be proved that $RG = 0$ and $DR = 0$ [4].

We now define the Whitney finite elements we use [4, 9, 10, 13]: They are scalar functions or vector fields associated to all the simplices of the mesh m. Given the node n, the edge $e = \{\ell, m\}$, the face $f = \{\ell, m, k\}$, and the tetrahedron $t = \{i, j, k, \ell\}$, we define the following scalar or vector functions (λ_n is the barycentric coordinate associated to node n):

$$\begin{aligned}
w^n &= \lambda_n,\\
w^e &= \lambda_\ell \,\mathbf{grad}\,\lambda_m - \lambda_m \mathbf{grad}\,\lambda_\ell,\\
w^f &= 2\,(\lambda_\ell \,\mathbf{grad}\,\lambda_m \times \mathbf{grad}\,\lambda_k + \lambda_m \,\mathbf{grad}\,\lambda_k \times \mathbf{grad}\,\lambda_\ell + \lambda_k \,\mathbf{grad}\,\lambda_\ell \times \mathbf{grad}\,\lambda_m),\\
w^t &= 6\,(\lambda_i \,\mathbf{grad}\,\lambda_j \times \mathbf{grad}\,\lambda_k \cdot \mathbf{grad}\,\lambda_\ell + \lambda_j \,\mathbf{grad}\,\lambda_k \times \mathbf{grad}\,\lambda_\ell \cdot \mathbf{grad}\,\lambda_i\\
&\qquad + \lambda_k \,\mathbf{grad}\,\lambda_\ell \times \mathbf{grad}\,\lambda_i \cdot \mathbf{grad}\,\lambda_j + \lambda_\ell \,\mathbf{grad}\,\lambda_i \times \mathbf{grad}\,\lambda_j \cdot \mathbf{grad}\,\lambda_k)
\end{aligned}$$

(w^t is just the constant $1/\mathrm{vol}(t)$). We define $W^p_m = \mathrm{span}\,\{w^s : s \in \mathcal{S}^p_m\}$, $p = 0, 1, 2, 3$ (the simplicial dimension, e.g., $p = 0$ for nodes). It can be verified that the value (resp., circulation, flux, integral) of w^n (resp., w^e, w^f, w^t) on its supporting simplex is 1, and 0 on other simplices of matching dimension, a fact we shall be able to state more compactly in a moment.

Given two adjacent tetrahedra t and t' sharing a face f, the function w^n and both the tangential component of w^e and the normal component of w^f are continuous across f, whereas the function w^t is not. Thanks to these continuity properties, $W^0_m \subset H^1(\Omega)$, $W^1_m \subset H(\mathbf{curl}, \Omega)$, $W^2_m \subset H(\mathrm{div}, \Omega)$, $W^3_m \subset L^2(\Omega)$. The spaces W^p_m, $p = 0, 1, 2, 3$, have finite dimension given by N_m, E_m, F_m, T_m, respectively, and they play the role of Galerkin approximation spaces for the functional spaces just mentioned. Therefore, a scalar field $k \in H^1(\Omega)$ can be represented in W^0_m by the approximation $\sum_{n\in\mathcal{N}_m} k_n\, w^n$ where $\{k_n : n \in \mathcal{N}_m\}$ are the values of k at the mesh nodes (i.e., the degrees of freedom of k on the mesh m). Similarly, a vector field $\mathbf{v} \in H(\mathbf{curl}, \Omega)$ can be represented in W^1_m by $\sum_{e\in\mathcal{E}_m} v_e\, w^e$, where $\{v_e : e \in \mathcal{E}_m\}$ are the circulations of $\mathbf{v}$ along the mesh edges. A vector field $\mathbf{v} \in H(\mathrm{div}, \Omega)$ can be represented in W^2_m by $\sum_{f\in\mathcal{F}_m} v_f\, w^f$, where $\{v_f : f \in \mathcal{F}_m\}$ are the fluxes of $\mathbf{v}$ across the mesh faces. Finally, a scalar field $k \in L^2(\Omega)$ can be represented in W^3_m by $\sum_{t\in\mathcal{T}_m} k_t\, w^t$, where $\{k_t : t \in \mathcal{T}_m\}$ are the integrals of k on the mesh tetrahedra.

Properties discussed so far concern the spaces W^p_m taken one by one. Properties of the structure made of the spaces W^p_m when taken together should also be mentioned. We know that the following inclusions hold:

$$\mathbf{grad}\, W^0_m \subset W^1_m, \qquad \mathbf{curl}\, W^1_m \subset W^2_m, \qquad \mathrm{div}\, W^2_m \subset W^3_m.$$

It is natural to ask whether the sequence

$$\{0\} \longrightarrow W^0_m \xrightarrow{\mathbf{grad}} W^1_m \xrightarrow{\mathbf{curl}} W^2_m \xrightarrow{\mathrm{div}} W^3_m \longrightarrow \{0\}$$

is *exact* at levels 1 and 2, i.e., when it happens that

$$\ker(\mathbf{curl}; W^1_m) = \mathbf{grad}\, W^0_m, \qquad \ker(\mathrm{div}; W^2_m) = \mathbf{curl}\, W^1_m,$$

where $\ker(\mathbf{curl}; W^1_m) := W^1_m \cap \ker(\mathbf{curl})$ and $\ker(\mathrm{div}; W^2_m) := W^2_m \cap \ker(\mathrm{div})$. (At level 0, the gradient operator is not injective. At level 3, the divergence operator is surjective.) The Poincaré lemma states that, when the domain Ω is contractible, the image fills the kernel in both cases. This may fail to happen: With Ω a solid torus, for example, $\mathbf{grad}\,(W^0_m)$ is a proper subset of $\ker(\mathbf{curl}; W^1_m)$. If so, it tells us something on the topology of Ω, namely the presence of b_1 "loops," where $b_1 = \dim[\ker(\mathbf{curl}; W^1_m)/\mathbf{grad}\,(W^0_m)]$ is the Betti number of dimension 1 of the domain. Solenoidal fields that are not **curl**s indicate the presence of b_2 "holes," where $b_2 = \dim[\ker(\mathrm{div}; W^2_m)/\mathbf{curl}\,(W^1_m)]$ is the Betti number of dimension 2 of the domain. (One may add that $b_0 = \dim[\ker(\mathbf{grad}; W^0_m)]$ is the number of connected components, here assumed to be 1, of Ω.) These are global topological properties of the meshed domain: They depend on Ω, but not on which mesh is used to compute them. The sequences are thus an algebraic tool by which the topology of Ω can be explored (which was the point of inventing Whitney forms [18]).

2.2. Chains and homology groups. We now introduce chains over the mesh m. A p-chain c is an assignment to each p-simplex s of a rational integer α_s. This can be denoted by $c = \sum_{s\in\mathcal{S}^p_m} \alpha_s\, s$. Let $C_p(m)$ be the set of all p-chains. This set has a structure of Abelian group with respect to the addition of p-chains: Two p-chains are added by adding the corresponding coefficients.

If s is an oriented simplex, the *elementary chain* corresponding to s is the assignment $\alpha_s = 1$ and $\alpha'_s = 0$ for all $s' \neq s$. In what follows, we will use the same symbol s (or n, e, etc., depending) to denote the oriented simplex and the associated elementary chain. Note how this is consistent with the above expansion of c as a formal weighted sum of simplices. Which meaning is implied will hopefully be clear from the context.

The *boundary* of an oriented p-simplex of m is a $(p-1)$-chain determined by the sum of its $(p-1)$-dimensional faces, each taken with the orientation induced from that of the whole simplex. So, the boundary ∂s of a single simplex s is

$$\partial e = \sum_{n \in \mathcal{N}_m} G_{e,n}\, n, \qquad \partial f = \sum_{e \in \mathcal{E}_m} R_{f,e}\, e, \qquad \partial t = \sum_{f \in \mathcal{F}_m} D_{t,f}\, f.$$

By linearity, the boundary operator ∂ defines a group homomorphism $C_p(m) \to C_{p-1}(m)$ as follows:

$$\partial c = \partial \left(\sum_{s \in \mathcal{S}_m^p} \alpha_s\, s \right) = \sum_{s \in \mathcal{S}_m^p} \alpha_s\, \partial s.$$

Note that ∂ is represented by a matrix, which is G^t, R^t, or D^t, depending on the dimension $p > 0$. We remark that $\partial \circ \partial = 0$, i.e., the boundary of a boundary is the null chain. When $p = 0$, we define the boundary of a single vertex to be zero and $C_{-1}(m) = \{0\}$.

The kernel of $\partial : C_p(m) \to C_{p-1}(m)$ is denoted by $Z_p(m)$ and is called the group of *p-cycles* of m. The image of $\partial : C_{p+1}(m) \to C_q(m)$ is denoted by $B_q(m)$ and is called the group of *p-boundaries* of m. The property $\partial \circ \partial = 0$ implies that $B_p(m)$ is a subgroup of $Z_p(m)$. The quotient $H_p(m) = Z_p(m)/B_p(m)$ is the *homology group* of order p of the mesh m and the Betti number b_p is equal to the rank of $H_p(m)$. Not all cycles bound, as a rule (think again of the solid torus, for $p = 1$), so b_p need not be zero.

By linearity, integration over simplices extends to chains as follows (let's deal with 2-chains for definiteness). If $c = \Sigma_{f \in \mathcal{F}_m} c_f f$, the integral of a vector field w over c is, by definition (and with some notational abuse for which we shall be rewarded later),

$$\int_c w = \sum_{f \in \mathcal{F}_m} c_f \int_f w \cdot \mathbf{n}_f. \tag{1}$$

Substituting the Whitney form w^f for w there, one sees that $\int_c w^f$ is just c_f. A similar definition can be stated for node-based, edge-based, or volume-based chains. So we now have $\int_{s'} w^s = 1$ if $s' = s$ and 0 if $s' \neq s$ for all p-simplices s' and Whitney elements w^s—the promised compact expression of their main property.

Remark 2.1. We note that (1) amounts to considering the vector field w as a differential form, as defined at the beginning of section 1. The functions and vector fields w^n, w^e, w^f, w^t of section 2.1 are thus differential forms, known as Whitney forms in the mathematical literature [18].

2.3. Cochains and cohomology groups. In this section, we introduce the dual concept of *p-cochain*. A *p-cochain* is a linear functional on the vector space of p-chains. For instance, given an array $\mathbf{b} = \{b^s : s \in \mathcal{S}_m^p\}$ of real numbers, we can define the p-cochain $c \to \sum_{s \in \mathcal{S}_m^p} b^s\, c_s$ acting on p-chains c with coefficients c_s. Also, as in (1), given a differential form w, the mapping $c \to \int_c w$ defines a p-cochain. More generally, the p-cochain coefficients are obtained by integrating the differential form w on the elements of the p-chain c; i.e., the map $c \to \sum_{s \in \mathcal{S}_m^p} c_s \int_s w$ is a cochain. We shall denote the latter value as $\langle w\ ;\ c \rangle$.

Once a metric is introduced on the ambient affine space, differential forms are in correspondence with scalar and vector fields (called "proxy fields"—metric dependent, of course). The coefficients of p-cochains become the degrees of freedom of scalar and vector fields (and this is exactly what occurs with Whitney finite elements in section 2.1). Let $W^p(m)$ denote the set of p-cochains (or p-forms) defined on Ω when triangulated by m. Then, $C_p(m)$ and $W^p(m)$ are *in duality* via the bilinear continuous map $\langle \cdot\ ;\ \cdot \rangle : W^p(m) \times C_p(m) \rightarrow \mathbb{R}$ defined as $\langle w\ ;\ c\rangle = \int_c w$ where the integral must be interpreted as in (1) in the example case $p = 2$. A duality product should be *nondegenerate*, i.e., $\langle w\ ;\ c\rangle = 0$ for all c implies $w = 0$, and $\langle w\ ;\ c\rangle = 0$ for all w implies $c = 0$. The former property holds true by definition, and the latter is satisfied because, if $c \neq 0$, one can construct an ad-hoc smooth vector field or function with nonzero integral and hence a nonzero form w such that $\langle w\ ;\ c\rangle \neq 0$.

For $p > 0$, the *exterior derivative* of the $(p-1)$-form w is the p-form $\mathrm{d}\, w$. The integral $\int_c w$ is treated in two ways: If $c = \partial\tau$ and w is smooth, one may go forward and integrate dw over τ. Alternatively, if the form $w = dv$, one may go backward and integrate v over ∂c. In particular, we have $\int_{\partial c} w = \int_c \mathrm{d}\, w$, which is the common form of Stokes' theorem [7], or equivalently,

$$\langle w\ ;\ \partial c\rangle = \langle \mathrm{d}\, w\ ;\ c\rangle \qquad \forall c \in C_p \quad \text{and} \quad \forall w \in W^{p-1}. \tag{2}$$

Equation (2) reveals that d is the *dual* of ∂ (in the sense of Yosida [20, p. 194]). As a corollary of the boundary operator property $\partial \circ \partial = 0$, we have that $\mathrm{d} \circ \mathrm{d} = 0$. A form w is *closed* if $\mathrm{d}\, w = 0$, *exact* if $w = \mathrm{d}\, v$ for some v (in the first case we have a *cocycle* and in the second case a *coboundary*). Denoting by $\mathcal{Z}^p(m)$ the vector space of all closed p-forms and by $\mathcal{B}^p(m)$ the subspace made of all exact p-forms, the property $\mathrm{d} \circ \mathrm{d} = 0$ implies that $\mathcal{B}^p(m) \subset \mathcal{Z}^p(m)$; i.e., the integral of a cocycle over a boundary vanishes. In domains Ω that are topologically trivial, all closed p-forms are exact (this is the Poincaré lemma). But closed forms need not be exact in general manifolds: This is the dual aspect of the above "not all cycles bound" (section 2.2). The quotient space $\mathcal{H}^p(m) = \mathcal{Z}^p(m)/\mathcal{B}^p(m)$ is (considered as an additive group) the *De Rham's* p*th cohomology group* of Ω or equivalently of m.

3. Refinement of a triangulation and simplicial maps.

A mesh refinement is a procedure to subdivide each simplex of a given mesh (referred to as the "coarse" one) m into a finite number of smaller ones, whose assembly is still a proper mesh (the "fine" one). We consider here conforming refinements, i.e., such that the set $\tilde{m}$ of all simplices of the fine mesh, is itself a cellular complex (no hanging nodes). Moreover, we are interested in subdividing a simplicial mesh in a way that will not deteriorate the aspect ratio of the new smaller and smaller tetrahedra that appear during the division process. In this framework, we speak of *uniform* refinement procedure if there is a *finite* catalog of "model cells" such that any cell in any $\tilde{m}$ is similar to one of them, for all meshes $\tilde{m}$ in the family $\mathcal{M}$ of meshes potentially created in the process of iterated refinement.

The *barycentric* (or *regular*) *refinement* is an example of conforming refinement procedure where the small cells are more and more stretched (see Figure 2 for a face) and hence not uniform in that sense. In three dimensions, each tetrahedron T is divided into 24 tetrahedra, and we can understand that after the first step of refinement, the new tetrahedra are more stretched toward the barycenter o: When their aspect ratio becomes too small, the classical a priori error estimates for finite elements do not apply and convergence is not warranted.

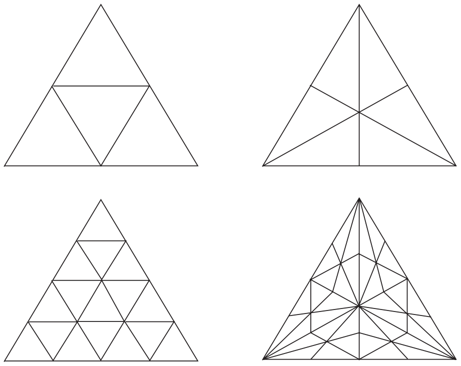

FIG. 2. *Two-level refinement of normal (left) and barycentric (right) type. A face is divided, respectively, into four faces (left) and six faces (right) at each refinement level.*

The *normal refinement*[1] presented in Figure 2 for a face, and in Figure 5 for a tetrahedron, is an example of conforming refinement procedure that enjoys uniformity. In three dimensions, let us consider a tetrahedron T built on four nodes k, l, m, n. Call o the center, lm, ln, etc., the midpoints. The big tetrahedron $T = \{k, l, m, n\}$ subdivides into four midsize ones, such as $\{kn, ln, mn, n\}$, and a midsize core octahedron (Figure 3), itself a half-size reduction of a big one O circumscribed to T. In turn, the core divides into six small octahedra and eight small tetrahedra, all similar to O and T, respectively, with a reduction factor of 4 (Figure 4). Hence there are two basic shapes, that of T and that of O, which are found again and again.

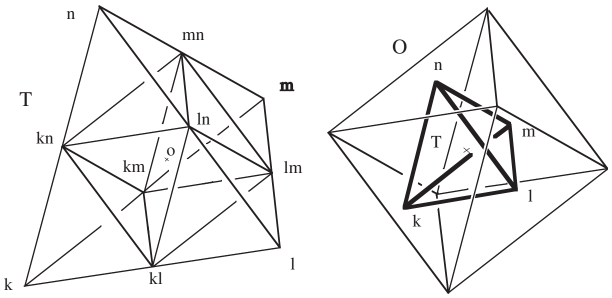

FIG. 3. *Cutting T into four midsize tetrahedra plus a core octahedron, similar to the circumscribed one, O. Note that the common center o of T and O is four times closer to face $\{k, l, m\}$ than node n was. Faces of O are similar to those of T, twice as big.*

All that is left to do, in order to get a series of nested simplicial meshes, is to cut the octahedra into tetrahedra, either eight (Figure 5) or just four. The latter solution simply consists of adding an edge joining two opposite nodes of the octahedron. As there are three nonequivalent ways to do that, one must be careful to draw all these

[1] Whitney defines in [18, pp. 358–360] a *standard subdivision* that guarantees uniformity but does not treat nodes symmetrically, the way ours does, hence the introduction of the adjective *normal* for definiteness. Normal subdivision can be done in dimensions $d > 3$, where it also involves, as can be inferred from Figure 3, convex hulls of barycenters of p-faces of the reference d-simplex. Denoting such convex polytopes by T_p (the reference simplex thus being T_0, and the O of Figure 5 a T_1), it can be shown that each T_p can be dissected into a finite number (bounded by a function of d only) of polytopes similar to one of the T_q, $1 \leq q \leq d$; hence there is uniformity.

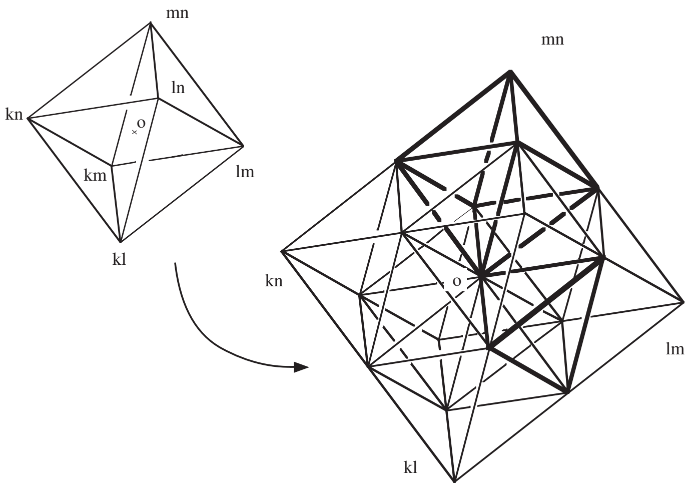

FIG. 4. *Cutting the octahedral core O into six small octahedra (one per node of the core, or edge of T) plus eight small tetrahedra (one per face of the core), all similar to T and O, respectively, and four times smaller.*

diagonals parallel to a same direction if one wants to minimize the number of different shapes of tetrahedra. Cutting in eight is a more symmetrical procedure. With both methods, the number of shapes is kept down to five. (That is the generic number, of course lower if T had some symmetry to start with.)

In any event, it is only at the latest stage of the subdivision that the final cut of octahedra should be involved. Conceptually, we have two cell shapes, T and O. Each T-cell breaks into four smaller T-cells and one O-cell. Each O-cell splits into six O-cells and eight T-cells. At the generic step $\kappa \geq 1$, we get

$$T \rightarrow \alpha \, \frac{T}{2^\kappa} + \beta \, \frac{O}{2^{\kappa-1}}, \tag{3}$$

where α, β are two positive integers. As a last step, O-cells are chopped.

If a tetrahedron t born from this last subdivision is earmarked for refinement by the error-estimator, one must look upward to its ancestry before dividing it. If t is a T-cell, apply normal subdivision. Otherwise, backtrack to its mother O-cell and subdivide the latter. Apart from those that are T-cells, tetrahedra of the subdivision are mules, not able to reproduce by division. The same strategy applies to the transition layer of tetrahedra that touch divided ones, and need division for conformity. They should be cut in two or more tetrahedra, depending on how many of their edges belong to divided tetrahedra. Here, for simplicity, we consider only two cases: a T-cell with a divided face results in four tetrahedra and the one with a divided edge results in two. Products of this subdivision can be mules as well as tetrahedra with divided edges or faces and the procedure goes on. All other T-cells presenting two or more divided faces are cut according to the normal subdivision (at worst, the normal subdivision applies to the whole set of tetrahedra). If one of the two or four tetrahedra t that compose a T-cell in the transition layer is pointed at for subdivision, one backtracks to its (mother) T-cell and applies normal subdivision. (Refining tetrahedra t the same way, by the normal subdivision that served for the T-cell, would make a mess.) The number of different tetrahedral shapes is thus kept small, whatever the depth of the subdivision procedure.

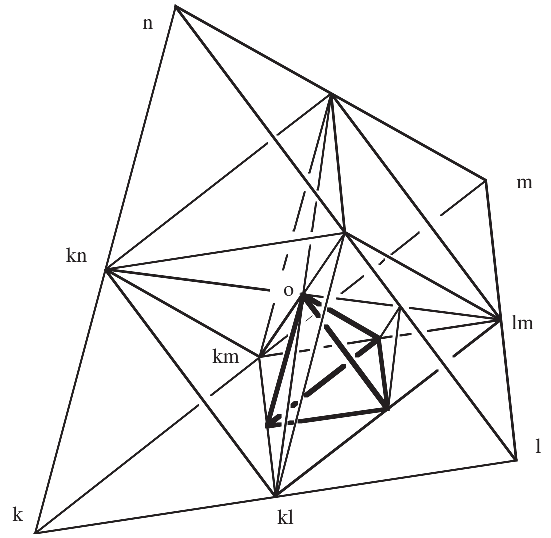

FIG. 5. *Normal refinement for the tetrahedron $T = \{k, l, m, n\}$. Mid-edges are denoted kl, lm, etc., and o is the barycenter. A first halving of edges generates four small tetrahedra and a core octahedron, which itself can be divided into eight "octants" such as $O = \{o, kl, lm, mk\}$, of at most four different shapes. At this point, we have twelve small tetrahedra, only eight in the octahedron. Now, octants like O should be subdivided as follows: Divide the face in front of o into four triangles and join to o; hence we have a tetrahedron similar to T, and three peripheral tetrahedra. These, in turn, are halved as shown for the one hanging from edge $\{o, lm\}$. Its two parts are similar to O and to the neighbor octant $\{o, kn, kl, mk\}$, respectively. At the end of the second step, we have* 56 *tetrahedra for the core octahedron.*

Note that, starting from a given mesh, the barycentric subdivision as well as the normal one do not change the homology group of a complex, since the triangulated domain is always the same. This is the very point of homology (see, for example, [1]).

4. Construction of a restriction/prolongation operator between two nested meshes. Recall that the collection of groups and homomorphisms

$$\{0\} \longrightarrow \ldots \xrightarrow{\partial} C_p(m) \xrightarrow{\partial} C_{p-1}(m) \xrightarrow{\partial} \ldots \longrightarrow \{0\}$$

is usually referred to as the *chain complex* of the mesh m and denoted by $C(m)$. Here, we shall consider *two* meshes, the coarse one m and the fine one $\tilde{m}$, as obtained from m by a given refinement technique; hence we have two complexes $C(m)$ and $C(\tilde{m})$. We use capital letters to denote nodes, edges, faces, and volumes in m and lowercase letters to denote analogous cells in $\tilde{m}$. Incidence matrices for $\tilde{m}$ are denoted g, r, d. Recall that the elementary chain associated with a simplex of m (or $\tilde{m}$) and the simplex itself are denoted by the same symbol. Last, we shall use the shorthand "$s \subset S$" when simplex s is, *as a subset of the three-dimensional space*, a part of S. (Thus, $N \subset E$ means N is an endpoint of E. In the case of nodes, $n \subset N$ just means that n and N sit at the same point.)

In what follows, we first introduce two maps, $\chi : C(m) \to C(\tilde{m})$ and $\pi : C(\tilde{m}) \to C(m)$; we next prove that χ and π are "chain maps," as defined below, and that $\pi\,\chi = 1$.

Definition 4.1. *Given a p-simplex S of the coarse complex m, set*

$$\chi(S) = \sum_{s\in\mathcal{S}^p_{\tilde{m}}} \chi^s_S\, s \quad \textit{with} \quad \chi^s_S = \begin{cases} 0 & \textit{if} \quad s \not\subset S, \\ +1 & \textit{if} \quad s \subset S \textit{ and same orientation}, \\ -1 & \textit{if} \quad s \subset S \textit{ and opposite orientation}. \end{cases} \tag{4}$$

Of course, the map χ is the natural way to embed m into $\tilde{m}$: Chop the large simplex into small ones, and build a chain from these, with weights ±1 according to respective orientations. For nodes, we assumed positive orientation for all of them, so χ^n_N is 1 if n coincides with N, 0 otherwise.

Next, let w^S denote the Whitney form associated with a p-simplex S of the coarse mesh so that $\langle w^S\ ;\ S'\rangle = \delta_{S,S'}$ for all p-simplices $S' \in m$. Then we have the following definition.

Definition 4.2. *Given a p-simplex s of the fine complex $\tilde{m}$, set*

$$\pi(s) = \sum_{S\in\mathcal{S}^p_m} \langle w^S\ ;\ s\rangle\, S \equiv \sum_{S\in\mathcal{S}^p_m} \pi^S_s\, S. \tag{5}$$

A small simplex is thus represented by a chain of big ones. (The use of Whitney forms for this is natural: As argued elsewhere [5], Whitney forms are best viewed as a device to represent manifolds by simplicial chains. Here, the manifold is the small simplex s.) We now prove three propositions.

Proposition 4.3. *One has $\pi\,\chi = 1$.*

Proof. We must show that $\pi(\chi(S)) = S$ for any coarse p-simplex S. Indeed,

$$\pi(\chi(S)) = \pi\left(\sum_{s\in\mathcal{S}^p_{\tilde{m}}} \chi^s_S\, s\right)$$

$$= \sum_{s\in\mathcal{S}^p_{\tilde{m}}} \chi^s_S \sum_{S'\in\mathcal{S}^p_m} \langle w^{S'}\ ;\ s\rangle\, S'$$

$$= \sum_{S'\in\mathcal{S}^p_m} \left\langle w^{S'}\ ;\ \sum_{s\in\mathcal{S}^p_{\tilde{m}}} \chi^s_S s \right\rangle S' \tag{6}$$

$$= \sum_{S'\in\mathcal{S}^p_m} \langle w^{S'}\ ;\ S\rangle\, S' \tag{7}$$

$$= S,$$

thanks to the fundamental property of Whitney forms, $\langle w^{S'}\ ;\ S\rangle = \delta_{S,S'}$. To pass from (6) to (7), use the equality $\langle w\ ;\ S\rangle = \langle w\ ;\ \chi(S)\rangle$, for any given p-form w, which stems from additivity of the integral. □

It is important to remark that Proposition 4.3 and its proof do not depend on the refinement *technique*, but just on the fact that coarse cells are tessellations of small ones.

Proposition 4.4. *The map χ defined in* (4) *is a chain map, i.e., $\partial\,\chi = \chi\,\partial$.*

Proof. Although both statement and proof are independent of the refinement procedure, we suppose here that the normal subdivision is considered at the first step (where each tetrahedron gives 12 small tetrahedra) to build up the fine complex $\tilde{m}$

from the coarse one m. We also treat separately the cases $p = 1, 2, 3$, where p is the dimension of the chain on which $\partial\chi$ and $\chi\partial$ act, though as will be apparent a generic proof (much shorter, but perhaps less informative) could be given. Our purpose is to help understand, on concrete examples, what is going on.

For $p = 1$, we have

$$\begin{aligned}\chi\,\partial\,E &= \chi\,(\textstyle\sum_{N\in\mathcal{N}_m} G_{E,N}\,N)\\ &= \textstyle\sum_{N\in\mathcal{N}_m} G_{E,N}\sum_{n\in\mathcal{N}_{\tilde m}} \chi_N^n\,n\\ &= \textstyle\sum_{n\in\mathcal{N}_{\tilde m}} [\sum_{N\in\mathcal{N}_m} G_{E,N}\,\chi_N^n\,]\,n = \sum_{n\in\mathcal{N}_{\tilde m}} [\sum_{N\subset E} G_{E,N}\,\chi_N^n\,]\,n,\end{aligned}$$

since only those nodes N that are, as sets, part of E, make $G_{E,N} \neq 0$, and thus contribute to the sum. On the other hand, we obtain:

$$\begin{aligned}\partial\,\chi\,E &= \partial\,(\textstyle\sum_{e\in\mathcal{E}_{\tilde m}}\ \chi_E^e\ e)\\ &= \textstyle\sum_{e\in\mathcal{E}_{\tilde m}}\ \chi_E^e\ \sum_{n\in\mathcal{N}_{\tilde m}}\ g_{e,n}\ n\\ &= \textstyle\sum_{n\in\mathcal{N}_{\tilde m}} [\sum_{e\in\mathcal{E}_{\tilde m}} \chi_E^e\ g_{e,n}]\,n = \sum_{n\in\mathcal{N}_{\tilde m}} [\sum_{e\subset E} \chi_E^e\ g_{e,n}]\,n,\end{aligned}$$

since only those e that are, as sets, part of E, make $\chi_E^e \neq 0$, and thus contribute to the sum. The conclusion comes from the equality between bracketed terms above, which stems from the interplay between incidence numbers on both meshes, as we now show in detail.

If $n \not\subset E$, there is no N such that $n \subset N \subset E$, so the first bracket vanishes. There is no e either such that $n \subset e \subset E$, so the second bracket vanishes too. Assuming therefore $n \subset E$, we have two cases to examine, illustrated by the center part and the right-hand part of Figure 6, where E is supposed to be E_2: either $n \subset N$ for N one of the endpoints of E_2 (say N_1 or N_2), or not (see Figure 6, center and right-hand part, respectively).

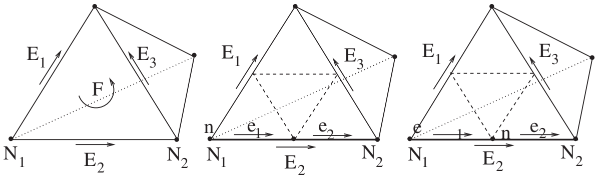

FIG. 6. *For node $n \in \mathcal{N}_{\tilde m}$ belonging to edge E_2, either there exists $N \subset E_2$ such that $n \subset N$ (center) or not (right).*

According to the situation at the center of Figure 6 ($n \subset N_1$), we have

$$\sum_{N\subset E_2} G_{E_2,N}\,\chi_N^n = G_{E_2,N_1}\,\chi_{N_1}^n + G_{E_2,N_2}\,\chi_{N_2}^n = (-1)(1) + (1)(0) = -1.$$

For the situation at the right-hand side of Figure 6, since $n \not\subset N_i$, for $i = 1$ or 2, we have

$$\chi_{N_i}^n = 0 \quad \forall\, i \quad \text{so that} \quad \sum_{N\subset E} G_{E,N}\,\chi_N^n = 0.$$

Let us do the same reasoning for the other quantity, looking at Figure 6. For the situation at the center of Figure 6, we have (recalling that g is the “fine” incidence matrix)

$$\sum_{e\subset E_2} g_{e,n}\, \chi^{e}_{E_2} = g_{e_1,n}\, \chi^{e_1}_{E_2} + g_{e_2,n}\, \chi^{e_2}_{E_2} = (-1)(1) + (0)(1) = -1.$$

For the situation at the right-hand side of Figure 6, we have

$$\sum_{e\subset E_2} g_{e,n}\, \chi^{e}_{E_2} = g_{e_1,n}\, \chi^{e_1}_{E_2} + g_{e_2,n}\, \chi^{e_2}_{E_2} = (1)(1) + (-1)(1) = 0.$$

Summing up, for a given $n \in \mathcal{N}_{\tilde{m}}$, the two quantities in brackets take the same value (-1, 1 or 0), due to the definition of the incidence matrices G and g and coefficients χ^n_N and χ^e_E.

For $p = 2$, we can write that

$$\begin{aligned}\chi\,\partial\, F &= \chi\,(\textstyle\sum_{E\in\mathcal{E}_m} R_{F,E}\, E)\\ &= \textstyle\sum_{E\in\mathcal{E}_m} R_{F,E} \sum_{e\in\mathcal{E}_{\tilde{m}}} \chi^e_E\, e\\ &= \textstyle\sum_{e\in\mathcal{E}_{\tilde{m}}} [\sum_{E\in\mathcal{E}_m} R_{F,E}\, \chi^e_E\,]\, e = \sum_{e\in\mathcal{E}_{\tilde{m}}} [\sum_{E\subset F} R_{F,E}\, \chi^e_E\,]\, e.\end{aligned}$$

On the other hand, we have

$$\begin{aligned}\partial\,\chi\, F &= \partial\,(\textstyle\sum_{f\in\mathcal{F}_{\tilde{m}}} \chi^f_F\, f)\\ &= \textstyle\sum_{f\in\mathcal{F}_{\tilde{m}}} \chi^f_F \sum_{e\in\mathcal{E}_{\tilde{m}}} r_{f,e}\, e\\ &= \textstyle\sum_{e\in\mathcal{E}_{\tilde{m}}} [\sum_{f\in\mathcal{F}_{\tilde{m}}} \chi^f_F\, r_{f,e}]\, e = \sum_{e\in\mathcal{E}_{\tilde{m}}} [\sum_{f\subset F} \chi^f_F\, r_{f,e}]\, e.\end{aligned}$$

We compare again the two quantities in brackets, noting again that both brackets vanish for each $e \in \mathcal{E}_{\tilde{m}}$ such that $e \not\subset F$. Assuming therefore $e \subset F$ (Figure 7), we have two cases: Either there exists $E \in \mathcal{E}_m$ such that $e \subset E$ and $E \subset F$, or not (see Figures 7 and 8, center and right-hand part, respectively).

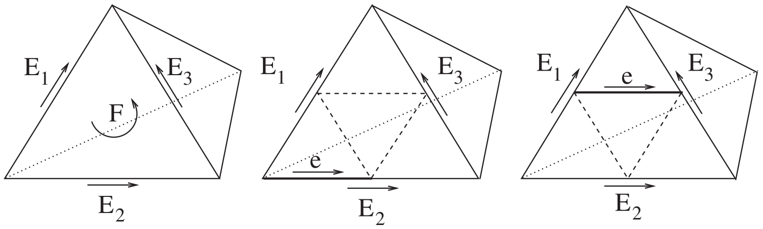

FIG. 7. *For edge $e \in \mathcal{E}_{\tilde{m}}$ belonging to face F, either there exists $E \subset F$ such that $e \subset E$ (center) or not (right).*

According to the situation at the center of Figure 7, we have

$$\begin{aligned}\textstyle\sum_{E\subset F} R_{F,E}\, \chi^e_E &= R_{F,E_1}\, \chi^e_{E_1} + R_{F,E_2}\, \chi^e_{E_2} + R_{F,E_3}\, \chi^e_{E_3}\\ &= (-1)(0) + (1)(1) + (1)(0) = 1.\end{aligned}$$

For the situation at the right-hand side of Figure 7, since $e \not\subset E_i$, $i = 1, 2, 3$, we have

$$\chi^e_{E_i} = 0 \quad \forall\, i \quad \text{so that} \quad \sum_{E\subset F} R_{F,E}\, \chi^e_E = 0.$$

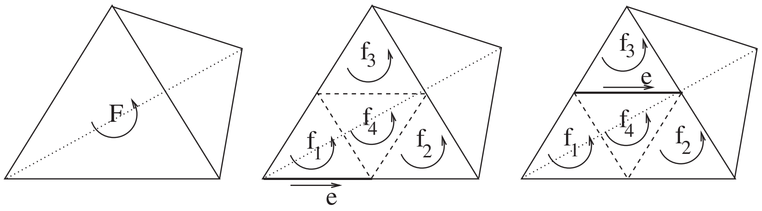

FIG. 8. *For edge $e \in \mathcal{E}_{\tilde{m}}$ belonging to face F, either there exists only one face $f \in \mathcal{E}_{\tilde{m}}$ such that $e \subset f$ (center) or two (right).*

Let us do the same reasoning for the other quantity, looking at Figure 8. For the situation at the center of Figure 8, we have

$$\begin{aligned}\textstyle\sum_{f\subset F} \chi_F^f\, r_{f,e} &= \chi_F^{f_1}\, r_{f_1,e} + \chi_F^{f_2}\, r_{f_2,e} + \chi_F^{f_3}\, r_{f_3,e} + \chi_F^{f_4}\, r_{f_4,e}\\ &= (1)(1) + (0)(1) + (0)(1) + (0)(1) = 1.\end{aligned}$$

For the situation at the right-hand side of Figure 8, we have

$$\begin{aligned}\textstyle\sum_{f\subset F} r_{f,e}\, \chi_F^f &= \chi_F^{f_1}\, r_{f_1,e} + \chi_F^{f_2}\, r_{f_2,e} + \chi_F^{f_3}\, r_{f_3,e} + \chi_F^{f_4}\, r_{f_4,e}\\ &= (0)(1) + (0)(1) + (1)(1) + (-1)(1) = 0.\end{aligned}$$

Summing up, for a given $e \in \mathcal{E}_{\tilde{m}}$, the two quantities in brackets take the same value (1 or 0), due to the definition of the incidence matrices R and r and coefficients χ_E^e and χ_F^f.

Finally, for $p = 3$, we have

$$\begin{aligned}\chi\,\partial T &= \chi\,(\textstyle\sum_{F\in\mathcal{F}_m} D_{T,F}\, F)\\ &= \textstyle\sum_{F\in\mathcal{F}_m} D_{T,F} \sum_{f\in\mathcal{F}_{\tilde{m}}} \chi_F^f\, f\\ &= \textstyle\sum_{f\in\mathcal{F}_{\tilde{m}}} (\sum_{F\in\mathcal{F}_m} D_{T,F}\, \chi_F^f)\, f = \sum_{f\in\mathcal{F}_{\tilde{m}}} [\sum_{F\subset T} D_{T,F}\, \chi_F^f]\, f.\end{aligned}$$

On the other hand,

$$\begin{aligned}\partial\,\chi\, T &= \partial\,(\textstyle\sum_{t\in\mathcal{T}_{\tilde{m}}} \chi_T^t\, t)\\ &= \textstyle\sum_{t\in\mathcal{T}_{\tilde{m}}} \chi_T^t \sum_{f\in\mathcal{F}_{\tilde{m}}} d_{t,f}\, f\\ &= \textstyle\sum_{f\in\mathcal{F}_{\tilde{m}}} (\sum_{t\in\mathcal{T}_{\tilde{m}}} \chi_T^t\, d_{t,f})\, f = \sum_{f\in\mathcal{F}_{\tilde{m}}} [\sum_{t\subset T} \chi_T^t\, d_{t,f}]\, f.\end{aligned}$$

We compare again the two quantities in brackets, assuming $f \subset T$. We have two cases: either there exists $F \in \mathcal{F}_m$ such that $f \subset F$ or not (see Figure 9's left-hand and right-hand part, respectively). If f is part of, say, F_1, then

$$\begin{aligned}\textstyle\sum_{F\subset T} D_{T,F}\, \chi_F^f &= D_{T,F_1}\, \chi_{F_1}^f + D_{T,F_2}\, \chi_{F_2}^f + D_{T,F_3}\, \chi_{F_3}^f + D_{T,F_4}\, \chi_{F_4}^f\\ &= (1)(1) + (1)(0) + (1)(0) + (1)(0) = 1.\end{aligned}$$

If $f \not\subset F_i$, whatever $F_i \subset T$, then

$$\chi_{F_i}^f = 0 \quad \forall\, i; \qquad \text{hence} \quad \sum_{F\subset T} D_{T,F}\, \chi_F^f = 0.$$

For the other bracketed term, either f is part of some F_1, and there exists only one $t \in \mathcal{T}_{\tilde{m}}$ containing f, namely t^*, so that

$$\sum_{t\subset T} d_{t,f}\, \chi_T^t = d_{t^*,f}\, \chi_T^{t^*} = (1)(1) = 1,$$

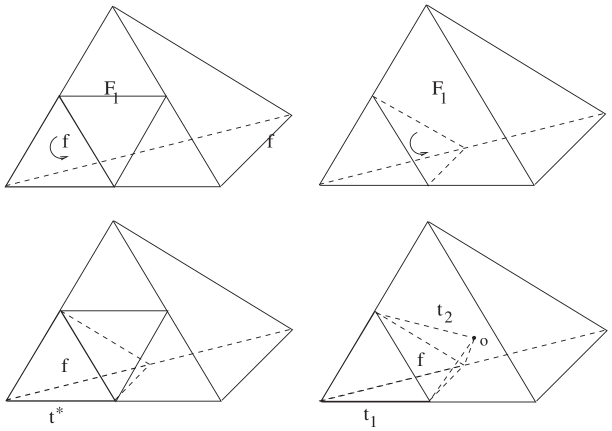

FIG. 9. *For face $f \in \mathcal{F}_{\tilde{m}}$ belonging to tetrahedron $T \in \mathcal{T}_m$, either there exists $F \subset T$ such that $f \subset F$ (left) or not (right). In the first case, there exists a unique tetrahedron $t^* \in \mathcal{T}_{\tilde{m}}$ containing f, and in the second case, two tetrahedra $t_1, t_2 \in \mathcal{T}_{\tilde{m}}$. The normal subdivision of T is not completely shown to make the figure clearer (o is the barycenter of T).*

or $f \not\subset F_i$ whatever $F_i \subset T$. Then, f is inside T and is thus shared by two tetrahedra of $\tilde{m}$, say t_1 and t_2. So,

$$\sum_{t \subset T} d_{t,f}\, \chi_{T}^{t} = d_{t_1,f}\, \chi_{T}^{t_1} + d_{t_2,f}\, \chi_{T}^{t_2} = (1)(1) + (-1)(1) = 0.$$

Summing up, for a given $f \in \mathcal{F}_{\tilde{m}}$, the two quantities in brackets take the same value (1 or 0), owing to the definition of the incidence matrices D and d and coefficients χ_{F}^{f} and χ_{T}^{t}.

This completes the proof, which has been detailed for all cases, much beyond logical necessity, to show how the incidence matrices and the two maps interact. Later on, we will consider only one case, the others being on the same pattern. ∎

PROPOSITION 4.5. *The map π defined in* (5) *is a chain map, i.e., $\partial \pi = \pi \partial$.*

Proof. We consider the case $p = 2$ to detail the proof. Then

$$\begin{aligned} \pi\, \partial\, f &= \pi\, \big(\textstyle\sum_{e \in \mathcal{E}_{\tilde{m}}} r_{f,e}\, e\big) \\ &= \textstyle\sum_{e \in \mathcal{E}_{\tilde{m}}} r_{f,e} \sum_{E \in \mathcal{E}_m} \langle w^{E}\ ;\ e \rangle\, E \\ &= \textstyle\sum_{E \in \mathcal{E}_m} \big[\sum_{e \in \mathcal{E}_{\tilde{m}}} r_{f,e}\, \langle w^{E}\ ;\ e \rangle\big]\, E. \end{aligned}$$

On the other hand, we can write

$$\begin{aligned} \partial\, \pi\, f &= \partial\, \big(\textstyle\sum_{F \in \mathcal{F}_m} \langle w^{F}\ ;\ f \rangle\, F\big) \\ &= \textstyle\sum_{F \in \mathcal{F}_m} \langle w^{F}\ ;\ f \rangle \sum_{E \in \mathcal{E}_m} R_{F,E}\, E \\ &= \textstyle\sum_{E \in \mathcal{E}_m} \big[\sum_{F \in \mathcal{F}_m} R_{F,E}\, \langle w^{F}\ ;\ f \rangle\big]\, E. \end{aligned}$$

We now recall that, when $p = 2$,

$$\mathrm{d}\, w^{E} = \sum_{F \in \mathcal{F}_m} R_{F,E}\, w^{F} \tag{8}$$

so that

$$\begin{aligned}\partial\,\pi\, f &= \textstyle\sum_{E\in\mathcal{E}_m} [\,\sum_{F\in\mathcal{F}_m} R_{F,E}\,\langle w^{F}\ ;\ f\rangle\,]\,E\\ &= \textstyle\sum_{E\in\mathcal{E}_m} [\,\langle \mathrm{d}\, w^{E}\ ;\ f\rangle\,]\,E\\ &= \textstyle\sum_{E\in\mathcal{E}_m} [\,\langle w^{E}\ ;\ \partial f\rangle\,]\,E\\ &= \textstyle\sum_{E\in\mathcal{E}_m} [\,\sum_{e\in\mathcal{E}_{\tilde m}} r_{f,e}\,\langle w^{E}\ ;\ e\rangle\,]\,E\\ &= \pi\,\partial\, f.\end{aligned}$$

Note the two ingredients of the proof: the Stokes theorem and the structural property, (8), of the Whitney complex. For other dimensions, the proof is similar: Just change R and r into G and g if $p = 1$, into D and d if $p = 3$. ∎

Remark 4.6. The chain map $\chi : C(m) \to C(\tilde m)$ can be defined, similarly to π, as follows: Given a p-simplex S of the coarse complex m, set

$$\chi(S) = \sum_{s\in\mathcal{S}^p_{\tilde m}} \langle w^s\ ;\ S\rangle\, s = \sum_{s\in\mathcal{S}^p_{\tilde m}} \chi^s_{S}\, s. \tag{9}$$

In the nested case, definitions (9) and (4) coincide. In the nonnested case, (9) is a generalization of (4); the property $\pi\,\chi = 1$ is lost, and the coefficients π^S_s and χ^s_S cannot be computed "by hands" as we shall see in the next section for nested grids.

5. Application.

We explain how the map π can be used to design a multigrid algorithm for the solution of linear systems arising from the use of Whitney elements on tetrahedra to discretize a given differential (e.g., electromagnetic) problem. The detailed analysis of the mesh-independent convergence and performances of the multigrid algorithm based on π is not considered here. We refer to [3, 8, 14] for rigorous theoretical and numerical results in the edge element framework, and to [6] for a formulation and application of the multigrid algorithm on hexahedral meshes.

As already pointed out in the introduction, the motivation for this approach comes from the analysis of the error on the numerical solution in the frequency domain. We recall the basic multigrid algorithm, assuming a two-grid method for simplicity. Let h and H denote, respectively, the maximal diameter of tetrahedra in the fine $\tilde m$ and coarse m grids. Let $\mathcal{V}_h$ and $\mathcal{V}_{H}$ be the underlying finite dimensional spaces of cochains, with $\dim(\mathcal{V}_h) > \dim(\mathcal{V}_{H})$, consistent with $h < H$. One wishes to solve the linear system $A_h\mathbf{u}_h = \mathbf{b}_h$ in $\mathcal{V}_h$, assuming that the matrix A_h is symmetric and positive definite (as is usually the case for matrices resulting from finite element discretizations of a variational problem). Denoted by $(\mathbf{u},\mathbf{v})$ the scalar product of $\mathbf{u},\mathbf{v} \in \mathcal{V}_h$, solving $A_h\mathbf{u}_h = \mathbf{b}_h$ in $\mathcal{V}_h$ is then equivalent to finding the minimizer $\mathbf{u}_h \in \mathcal{V}_h$ of the quadratic functional $\Phi(\mathbf{u}) = \frac{1}{2}(A_h\mathbf{u},\mathbf{u}) - (\mathbf{b}_h,\mathbf{u})$. In what follows, M_h represents a suitable preconditioner for A_h. The maps $R^{H}_h : \mathcal{V}_h \to \mathcal{V}_{H}$, usually called *restriction operator*, and $P^h_{H} : \mathcal{V}_{H} \to \mathcal{V}_h$, called *prolongation operator*, are full-rank linear cochain-to-cochain operators. The so-called *two-level V-cycle* of the multigrid procedure reads as follows:

1. *Fine grid presmoothing*: from $\mathbf{u}_h^0 \in \mathcal{V}_h$ and for $k = 1, \ldots, n_1$, do

$$\mathbf{u}_h^k = \mathbf{u}_h^{k-1} + M_h\,(\mathbf{b}_h - A_h \mathbf{u}_h^{k-1}). \tag{10}$$

2. *Coarse grid correction*: given $\mathbf{r}_h^{n_1} = \mathbf{b}_h - A_h \mathbf{u}_h^{n_1}$ in $\mathcal{V}_h$, do

   restict the residual on the coarse grid: $\mathbf{r}_H \leftarrow R_h^H \mathbf{r}_h^{n_1}$.
   solve the residual problem: $A_H \mathbf{z}_H = \mathbf{r}_H$.
   correct the solution in $\mathcal{V}_h$: $\mathbf{u}_h^{n_1} \leftarrow \mathbf{u}_h^{n_1} + P_H^h\, \mathbf{z}_H$.

3. *Fine grid postsmoothing*: from $\mathbf{u}_h^{n_1} \in \mathcal{V}_h$ and for $k = 1, \ldots n_2$, do (10).

In the *fine grid presmoothing* step, one iteratively solves $A_h \mathbf{u}_h = \mathbf{b}_h$ in $\mathcal{V}_h$ by a basic iterative method. High frequency errors are thus well eliminated, and once this is achieved in, e.g., n_1 iterations, further fine grid iterations would not improve significantly the convergence rate. In the *coarse grid correction*, one tries to correct $\mathbf{u}_h^{n_1}$ on the coarse space $\mathcal{V}_H$. The coarse correction $\mathbf{z}_H$ minimizes $\Phi(\mathbf{u}_h^{n_1} + P_H^h \mathbf{z}_H)$ over $\mathcal{V}_H$. This is equivalent to solving $(P_H^h)^t A_h P_H^h \mathbf{z}_H = (P_H^h)^t \mathbf{r}_h^{n_1}$ on $\mathcal{V}_H$. Thus, $A_H = (P_H^h)^t A_h P_H^h$ and the R_h^H of step 2 is the transpose $(P_H^h)^t$ [16]. On m, the low frequency errors of $\tilde{m}$ manifest themselves as relatively high frequency errors and are thus eliminated efficiently using again simple iterative smoothing methods. If the coarsest grid has been reached, the coarse system has to be solved exactly, by a direct solver, which can be done with little computational effort due to the small number of unknowns. Otherwise, the three-step multigrid procedure can be repeated recursively to solve the residual problem, as many times as the number of coarsening levels m one considers, starting from the fine one $\tilde{m}$. Each grid level is responsible for eliminating a particular frequency bandwidth of the error. Finally, in the *fine grid postsmoothing* step, one solves iteratively n_2 times in $\mathcal{V}_h$ the system $A_h \mathbf{u}_h = \mathbf{b}_h$, starting from $\mathbf{u}_h^{n_1} + P_H^h \mathbf{z}_H$, to eliminate high frequency errors on the term $P_H^h \mathbf{z}_H$.

Our proposal is now to define the operator P_H^h as the dual of the chain map π. Indeed, recall that $\mathcal{V}_h$ and $\mathcal{V}_H$ are spaces of p-cochains, while π is defined on p-chains (see Definition 4.2). There is therefore a natural prolongation operator P_H^h, defined as the dual of π, i.e., by $\langle \mathbf{u}\,;\, \pi(s) \rangle = \langle P_H^h \mathbf{u}\,;\, s \rangle$ for all p-chains s and p-cochains $\mathbf{u} \in \mathcal{V}_H$, as suggested by the diagram below.

$$\begin{tikzcd}
\mathcal{V}_h \arrow[r, phantom, ""] & C(\tilde{m}) \arrow[d, "\pi"] \\
\mathcal{V}_H \arrow[u, "P_H^h"] \arrow[r, phantom, "\langle \cdot\,;\,\cdot \rangle"] & C(m)
\end{tikzcd}$$

Taking dual bases on both $\mathcal{V}_h$ and $\mathcal{V}_H$ as explained in section 2.3, the matrix representation of P_H^h has entries $(P_H^h)_S^s = \pi_s^S$ (cf. (5)). Recall that S and s here are two simplices of same dimension p in m and $\tilde{m}$, respectively, so that there are distinct prolongation operators for each p, i.e., for degrees of freedom based on nodes, edges, faces, and volumes.

We now detail the calculation of π in the case where a number of coarse tetrahedra have undergone one normal subdivision, i.e., by using (3) with $\kappa = 1$ (see Figure 5), thus being divided into twelve small ones, while tetrahedra in the transition layer are split into four or two small ones; hence we have the three cases considered below. It is important to remark that the chain-map coefficients π_s^S we search, defined as $\langle w^S\,;\, s \rangle$ in (5), do not depend on the shape of S and s but on their relative position and orientation. Their computation relies on the following two obvious lemmas.

LEMMA 5.1. *Let s be a p-simplex and w a linear p-differential form, linear with respect to position x. Then $\int_s w = \int_s w(\mathbf{x}_s)$, where $\mathbf{x}_s$ denotes the barycenter of s.*

This replaces a linear differential form by a constant one. For these, one has:

LEMMA 5.2. *Let s be a p-simplex and w a constant p-differential form, L a linear map which sends simplex s to simplex s'. Then $\int_{s'} w = \det(L) \int_s w$.*

Case I. Tetrahedron T has been divided into twelve small tetrahedra t.

For $p = 3$, let w^T be the scalar function associated to T (section 2.1), that is the constant such that $\langle w^T \; ; \; T\rangle = 1$. Computing $\langle w^T \; ; \; t\rangle$ thus amounts to finding the relative volume of t (an affine notion, not a metric one) with respect to T. This is $\frac{1}{8}$ for the four tetrahedra t sharing a vertex with T (scaling factor $\frac{1}{2}$, to the cube), which leaves $\frac{1}{2}$ to be shared equally between the 8 tetrahedra with a vertex at the barycenter o of T. So one has

$\langle w^T \; ; \; t\rangle = \pm\frac{1}{8}$ for all t not contained in the core octahedron;

$\langle w^T \; ; \; t\rangle = \pm\frac{1}{16}$ for all t contained in the core octahedron.

The sign ± 1 depends on the relative orientation between t and T.

Note that the Lebesgue measure of t or of T played no role here: Considerations of *scaling* and *symmetry* suffice to do the job, as will also be the case for other values of p. We give only the results without further comments. Only the nonzero coefficients are displayed.

For $p = 2$, there are four different situations, depending on where the small face f is located with respect to the big one F and we refer again to Figure 5, $\kappa = 1$. The coefficients $\langle w^F \; ; \; f\rangle$ are the fluxes of the vector function w^F across the small faces f. Let F be $\{k, l, n\}$ for definiteness. Using $\langle w^F \; ; \; F\rangle = 1$, scaling, and symmetry, then

$\langle w^F \; ; \; f\rangle = \pm\frac{1}{4}$ for all $f \subset F$ such as $f = \{k, kl, kn\}$;

$\langle w^F \; ; \; f\rangle = \pm\frac{1}{8}$ for all $f \not\subset F$ and with three vertices at mid-points not in F, such as $f = \{mk, lm, mn\}$;

$\langle w^F \; ; \; f\rangle = \pm\frac{1}{8}$ for all $f \not\subset F$ and with three vertices at mid-points and one edge on F, such as $f = \{kl, kn, km\}$;

$\langle w^F \; ; \; f\rangle = \pm\frac{1}{16}$ for all $f \not\subset F$ and with two vertices at mid-points and the third one at o, such as $f = \{kl, kn, o\}$.

For $p = 1$, the coefficients $\langle w^E \; ; \; e\rangle$ are the circulations of the vector function w^E along the small edges e. Consider $E = \{k, n\}$. Again, $\langle w^E \; ; \; E\rangle = 1$, scaling and symmetry yield

$\langle w^E \; ; \; e\rangle = \pm\frac{1}{2}$ for all $e \subset E$, such as $e = \{k, kn\}$;

$\langle w^E \; ; \; e\rangle = \pm\frac{1}{4}$ for all $e \not\subset E$ with vertices at mid-points, one of which belongs to E, such as $e = \{kn, kl\}$;

$\langle w^E \; ; \; e\rangle = \pm\frac{1}{4}$ for all $e \not\subset E$ with vertices at mid-points and parallel to E, such as $e = \{kl, ln\}$;

$\langle w^E \; ; \; e\rangle = \pm\frac{1}{8}$ for all $e \not\subset E$ with one vertex at o and one at a mid-point not in E, such as $e = \{ln, o\}$ or $e = \{mn, o\}$.

For $p = 0$, the coefficient $\langle w^N \; ; \; n\rangle$ is the value of the scalar function w^N at node

n. Take for example $N = k$. Using $\langle w^{N} \; ; \; N\rangle = 1$ and linearity, one gets

$\langle w^{N} \; ; \; n\rangle = 1$ for $n \subset N$;

$\langle w^{N} \; ; \; n\rangle = \frac{1}{2}$ for n at the middle of an edge
incident on N, such as kn or km;

$\langle w^{N} \; ; \; n\rangle = \frac{1}{4}$ for n at o.

Case II. Here, T is a tetrahedron of the transition layer, divided into four small tetrahedra t, as shown in Figure 10 (left and right).

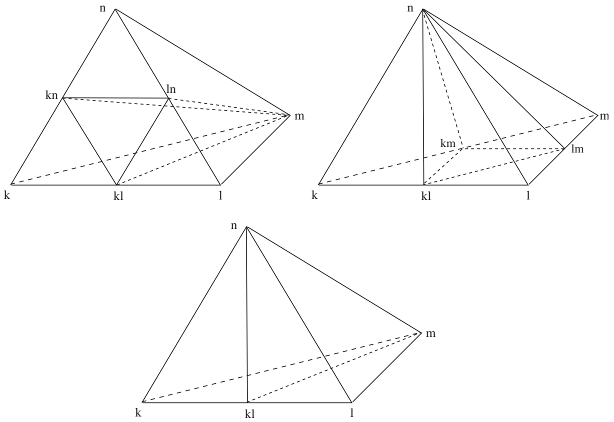

FIG. 10. *Tetrahedron T in the transition layer and division in four and two tetrahedra t.*

For $p = 3$, by symmetry, $\langle w^{T} \; ; \; t\rangle = \pm\frac{1}{4}$ for all t contained in T.

For $p = 2$, two cases. If F (taken here as $\{k, l, n\}$ for the sake of the example) is divided in four as in Figure 10 (left), then

$\langle w^{F} \; ; \; f\rangle = \pm\frac{1}{4}$ for all $f \subset F$, such as $f = \{k, kl, kn\}$,

while F is divided in two, as in Figure 10 (right), then

$\langle w^{F} \; ; \; f\rangle = \pm\frac{1}{2}$ for all $f \subset F$, such as $f = \{k, kl, n\}$;

$\langle w^{F} \; ; \; f\rangle = \pm\frac{1}{4}$ for all f neither in F nor in $F' \neq F$, such as $f = \{kl, km, n\}$.

For $p = 1$, two cases again. If $E \subset F$ and F is divided in four, then (with $E = \{k, n\}$ for illustration)

$\langle w^{E} \; ; \; e\rangle = \pm\frac{1}{2}$ for all $e \subset E$, such as $e = \{k, kn\}$;

$\langle w^{E} \; ; \; e\rangle = \pm\frac{1}{4}$ for all $e \not\subset E$ with vertices at mid-points,
one of which belongs to E, such as $e = \{kn, kl\}$;

$\langle w^{E} \; ; \; e\rangle = \pm\frac{1}{4}$ for all $e \not\subset E$ parallel to E with
vertices at mid-points, such as $e = \{kl, ln\}$,

while if F is divided in two, then

$\langle w^{E} \; ; \; e\rangle = 1$ for $e = E$;
$\langle w^{E} \; ; \; e\rangle = \pm\frac{1}{2}$ for $e = \{kl, n\}$ and $\{km, n\}$.

For $p = 0$, by linearity,

$\langle w^{N} \; ; \; n\rangle = 1$ for n at N ;
$\langle w^{N} \; ; \; n\rangle = \frac{1}{2}$ for all n mid-points of edges with one extremity at N, such as kn or kl.

Case III. Now T, is halved, as shown in Figure 10 (bottom).

For $p = 3$, $\langle w^{T} \; ; \; t\rangle = \pm\frac{1}{2}$ for all t contained in T.

For $p=2$ and F halved (as in Figure 10, bottom, take $F = \{k, l, n\}$ for illustration),

$\langle w^{F} \; ; \; f\rangle = \pm\frac{1}{2}$ for all $f \subset F$, such as $f = \{k, kl, n\}$.

If $F' \neq F$ is halved, then

$\langle w^{F} \; ; \; f\rangle = 1$ for $f \equiv F$;
$\langle w^{F} \; ; \; f\rangle = \pm\frac{1}{2}$ for $f = \{k, lm, n\}$.

For $p = 1$, if $E \subset F$ and F is divided in two but not E, then (consider $E = \{k, n\}$)

$\langle w^{E} \; ; \; e\rangle = 1$ for $e = E$;
$\langle w^{E} \; ; \; e\rangle = \pm\frac{1}{2}$ for $e = \{kl, n\}$.

If $E \subset F$ and F is not divided in two, then

$\langle w^{E} \; ; \; e\rangle = 1$ for $e = E$

and last, if $E \subset F$ and F is divided in two along E, then

$\langle w^{E} \; ; \; e\rangle = \pm\frac{1}{2}$ for $e \subset E$, such as $e = \{k, kn\}$.

For $p = 0$, finally

$\langle w^{N} \; ; \; n\rangle = 1$ for n at N;
$\langle w^{N} \; ; \; n\rangle = \frac{1}{2}$ for all n mid-points of edges with one extremity at N, such as kn, kl or km.

Remark 5.3. The strategy adopted to compute the coefficients π_s^S, $S \in \mathcal{S}_m^p$ and $s \in \mathcal{S}_{\tilde{m}}^p$, can be used when dealing with quadratic, cubic, etc., differential forms, provided that the integration rule is modified accordingly. Therefore, the main problem with Whitney elements of order $r > 1$ (see, e.g., [9]) is the definition on a p-simplex, $p = 2, 3$, of an integration rule which is exact for all polynomials of degree r (on 1-simplices we can use Gaussian quadratures). This problem is far from being trivial and is linked to another one, namely, the location in a p-simplex of the degrees of freedom associated with Whitney elements of order $r > 1$. Both problems will be addressed in future work.

As we have stressed, computing the coefficients of the chain-map π is a metric-independent process. Implementation, however, may have to be done in a code conceived in terms of proxy vector fields, with an underlying metric, instead of differential forms. Hence we have the following description of the procedure, where $|t|$ denotes the volume of tetrahedron t, $|f|$ the area of face f, and $|e|$ the length of edge e. We use $\mathbf{x}_e, \mathbf{x}_f, \mathbf{x}_t$ to denote the barycenters of edge e, face f, and tetrahedron t, respectively. Points $\mathbf{x}_k, \mathbf{x}_\ell, \mathbf{x}_m, \mathbf{x}_n$ are the vertices of t or T. Moreover, $\mathbf{t}_e$ denotes the unit vector along the mesh side e, and $\mathbf{n}_f$ stands for the unit vector normal to the mesh face f. For completeness, we throw in the computation of the other chain map, χ. Thanks to Lemmas 5.1 and 5.2, the following algorithm, though relying on metric elements such as dot product, etc., does implement in the nested case (up to floating-point errors, and barring clerical mistakes of ours . . .) the metric-free computation of the prolongation/restriction operator we have detailed.

FIRST-ORDER SYSTEM $\mathcal{LL}^*$ (FOSLL*) FOR GENERAL SCALAR ELLIPTIC PROBLEMS IN THE PLANE*

T. A. MANTEUFFEL[†], S. F. MCCORMICK[†], J. RUGE[†], AND J. G. SCHMIDT[‡]

Abstract. This paper develops new first-order system $\mathcal{LL}^*$ (FOSLL*) formulations for scalar elliptic partial differential equations. It extends the work of [Z. Cal et al., *SIAM J. Numer. Anal.*, 39 (2001), pp. 1418–1445], where the FOSLL* methodology was first introduced. One focus of that paper was to develop FOSLL* formulations that allow the use of H^1-conforming finite element spaces and optimal multigrid solution techniques to construct L^2 approximations of the dependent variables in the presence of discontinuous coefficients. The problems for which this goal was achieved were limited to those with no reaction term and with Dirichlet and Neumann boundaries that were individually connected; that is, each had at most one component. Here, new FOSLL* formulations are developed to achieve the same goals on a wider class of problems, including problems with reaction terms, Dirichlet and Neumann boundaries with multiple components, reentrant corners, and points at which Dirichlet and Neumann boundaries meet with an inner angle greater than $\pi/2$. The efficiency of the improved FOSLL* formulations is illustrated by a series of numerical examples.

Key words. first-order systems, least-squares methods, finite element methods, discontinuous coefficients, reduced regularity, nonsmooth solutions

1. Introduction.

First-order system $\mathcal{LL}^*$ (FOSLL*) was developed in an earlier paper [12] as a numerical method for solving partial differential equations (PDEs) that do not exhibit the regularity required by standard first-order system least squares (FOSLS [10, 11]). The purpose here is to extend the class of problems to which the FOSLL* approach can be efficiently applied. While we include a brief discussion of the context of this development below, the interested reader should consult [12] for more background and historical perspective.

Standard FOSLS recasts the original problem as an expanded first-order system, $Lu = f$, to which a least-squares principle is then applied. The usual goal is to reformulate the original problem as the minimization of a functional, $\|Lu - f\|^2$, whose bilinear part is equivalent to the product H^1 norm (i.e., the square root of the bilinear part is continuous and coercive in the norm formed by summing the H^1 norms applied to each dependent variable). This product H^1-equivalence means that the minimization process amounts to solving a weakly coupled system of scalar elliptic equations, which, in turn, implies that H^1-conforming finite element spaces and multigrid solvers can be used to full efficiency. Unfortunately, standard FOSLS is product H^1-equivalent only under sufficient smoothness assumptions on the original problem (e.g., the domain, coefficients, and data). Inverse-norm versions of FOSLS could be used when the problem lacks sufficient smoothness, but these methods tend to lose

efficiency, especially for problems with widely varying coefficients.

Our purpose here is to continue the development of a potentially more efficient alternative, FOSLL*. As with FOSLS, the FOSLL* approach begins by recasting the original problem as an expanded first-order system, $Lu = f$. Now, however, instead of applying a least-squares principle to this *primal* problem, we introduce the *dual normal equations*, $LL^*w = f$, defined in terms of dual variable w and adjoint L^*. Note that $f = Lu$, so that $LL^*w = Lu$, which are the normal equations for the dual problem, $L^*w = u$. The original problem can now be recast as one of minimizing the functional, $\|L^*w - u\|^2$, which has the same minimizer as the functional $\|L^*w\|^2 - 2\,\langle w\,, f\rangle$.

If H^1-conforming finite element spaces are used in a standard FOSLS formulation, then it must fail when u is not in H^1. For this choice of finite element spaces, the discrete approximation produced by FOSLS cannot converge to the solution, u. It will, instead, converge optimally to the minimizer of $\|Lv - f\|^2$, that is, to $v \in H^1$ that minimizes $\|L(u-v)\|$. FOSLL* attempts to overcome this limitation by recasting the primal problem in terms of a dual variable, w such that $L^*w = u$. The aim is to use L^* to lift the smoothness of u so that w is in H^1.

Consider the following scalar elliptic problem:

$$\begin{aligned} \nabla\cdot(A\nabla p) - \mathbf{b}\cdot\nabla p - cp &= f \text{ in } \Omega,\\ p &= 0 \text{ on } \Gamma_D,\\ \mathbf{n}\cdot A\nabla p &= 0 \text{ on } \Gamma_N, \end{aligned}$$

and define the flux variable $\mathbf{u} = \nabla p$ (for a complete list of assumptions, see (2.1)–(2.3)). One focus of the earlier paper [12] was to develop the FOSLL* methodology for problems of this type with the reduced regularity that arises by allowing discontinuous A. In that paper, the goal of using H^1-conforming finite element spaces to approximate the flux variable, $\mathbf{u}$, in the L^2 norm and the primal variable, p, in the H^1 norm was achieved through a two-stage procedure. The two-stage procedure described there is applicable only when $c = 0$ and when Γ_D and Γ_N each have at most one component.

The aim of this paper is to expand the class of problems for which H^1-conforming finite element spaces and optimal multigrid solvers can be efficiently used. In section 2, we show that when $c \neq 0$, the original FOSLL* formulation can be modified to achieve this goal, provided that the domain, Ω, is sufficiently smooth. By this we mean that the boundary of Ω contains no reentrant corners or corners at which $\overline{\Gamma}_D$ and $\overline{\Gamma}_N$ meet with an inner angle bigger than $\pi/2$. Such points are referred to as irregular boundary points. These are precisely the conditions under which $H(\nabla\cdot) \cap H(\nabla\times) \subset (H^1)^2$.

In section 3, we develop a new FOSLL* formulation that achieves the goal of allowing accurate approximation using H^1-conforming finite element spaces in the presence of irregular boundary points. The key idea behind this new approach is to first expand the domain of the primal problem in such a manner that the domain of the dual problem remains in a subspace of H^1. Generally, at this point the primal operator, L, is not bijective and the dual operator, L^*, is not surjective. The next step is to apply additional boundary conditions to the slack variables in the primal equations so that fewer boundary conditions are needed for the dual problem. The aim is that the primal operator, L, becomes bijective and the dual operator becomes surjective. This process generally means that the dual equations are not uniquely solvable. However, this is not an issue for the FOSLL* formulation, since any one solution of the dual problem, say, w, yields the primal solution, $L^*w = u$. This approach is limited to problems for which $\Gamma_D \neq \emptyset$. The pure Neumann case remains an open question. In section 3.2, we show that, in the case $\mathbf{b} = \mathbf{0}$ and either $c > 0$ or $c = 0$, the FOSLL*approximation is equivalent to a Galerkin formulation of the original boundary value problem (2.1)–(2.3).

The numerical results presented in section 4 confirm the optimality of H^1-conforming finite element spaces and multigrid solvers for the new FOSLL*formulation. The loss of unique solution for the dual problem is not an issue for the FOSLL* approximation in that we seek any dual solution for which $L^*w = u$. However, the loss of uniqueness does affect the multigrid solution algorithm. In section 4.2, we develop an additional modification that mitigates this effect. Section 5 contains conclusions.

Alternatives to the approach we develop here are described in detail in [1] and include adding H^1 singular basis functions in standard Galerkin methods to enhance the rate of convergence (cf. [23], [14], [8], and [9]) the use of $H(\text{div})$-conforming finite element spaces with mixed formulations (see [7]) or with FOSLS functionals that are based on $H(\text{div})$ (see [10], [20], and [21]) and including $H(\nabla\cdot) \cap H(\nabla\times)$ singular functions in a FOSLS formulation (see [1], [2]). Standard finite element spaces can be used with FOSLS functionals that are weighted to eliminate the overall impact on accuracy of the singular behavior of the flux [14], [19], [24]. Alternatives similar to the FOSLL* formulation use FOSLS based on inverse norms [3], [5], [6], [13].

We begin in the next section with a brief overview of the current theory underlying FOSLS and FOSLL* as a way of exposing the need for modifications of the original FOSLL* approach.

2. General FOSLS and FOSLL* theory.

This section summarizes the principles and theory underlying the FOSLS and FOSLL* methods. For more detail and historical perspective, see [10], [11], [12], [4]. The main goal of this section is to clarify the need for modifying the FOSLL* method introduced in [12].

2.1. Model problem.

Let Ω be a bounded, open, simply connected domain in $\mathbb{R}^2$ with Lipschitz boundary, $\partial\Omega$. Let $\bigcup_{i=1}^{M}(\overline{\Gamma}_{D,i} \cup \overline{\Gamma}_{N,i}) = \partial\Omega$ be a partition of the boundary, interlaced so that every pair $(\Gamma_{D,i}, \Gamma_{D,i+1})$ is separated by a Neumann boundary segment $\Gamma_{N,i}$ and every Neumann pair is similarly separated by a Dirichlet segment. The Neumann and Dirichlet boundaries of the problem are defined by $\Gamma_N := \bigcup_{i=1}^{M} \Gamma_{N,i}$ and $\Gamma_D := \bigcup_{i=1}^{M} \Gamma_{D,i}$, respectively. Let $\mathbf{n}$ be the outward unit normal vector and $\mathbf{t}$ the counterclockwise-oriented tangent vector on $\partial\Omega$. We do not consider the pure Neumann case here, so Γ_D is assumed to have positive measure.

The FOSLL* methodology has application in many contexts, including elliptic systems of PDEs. However, in this paper, we restrict our considerations to the following reaction–convection–diffusion boundary value problem (BVP):

$$\nabla\cdot(A\nabla p) - \mathbf{b}\cdot\nabla p - cp = f \text{ in } \Omega, \tag{2.1}$$

$$p = 0 \text{ on } \Gamma_D, \tag{2.2}$$

$$\mathbf{n}\cdot A\nabla p = 0 \text{ on } \Gamma_N, \tag{2.3}$$

where $f \in L^2(\Omega)$, $0 \le c \in L^\infty(\Omega)$, $\mathbf{b} \in L^\infty(\Omega) \cap H(\nabla\cdot)$, and $A(\mathbf{x})$ is a 2×2 matrix of $L^\infty(\Omega)$-functions that is uniformly symmetric positive definite; i.e., there exists $\lambda_1 \ge \lambda_0 > 0$ such that

$$\lambda_0 \boldsymbol{\xi}\cdot\boldsymbol{\xi} \le \boldsymbol{\xi}\cdot A(\mathbf{x})\boldsymbol{\xi} \le \lambda_1 \boldsymbol{\xi}\cdot\boldsymbol{\xi}$$

for all $\boldsymbol{\xi} \in \mathbb{R}^2$ and $\mathbf{x} \in \Omega$. We also assume that both (2.1)–(2.3) and the adjoint problem,

$$\nabla\cdot(A\nabla p) + \nabla\cdot(\mathbf{b}p) - cp = f \text{ in } \Omega, \tag{2.4}$$

$$p = 0 \text{ on } \Gamma_D, \tag{2.5}$$

$$\mathbf{n}\cdot(A\nabla p + \mathbf{b}p) = 0 \text{ on } \Gamma_N, \tag{2.6}$$

have unique solutions in $H^1(\Omega)$.

We make use of the following standard differential operators:

$$\nabla s = \operatorname{grad} s = \begin{pmatrix}\partial_x s\\ \partial_y s\end{pmatrix}, \qquad \nabla\cdot\mathbf{v} = \operatorname{div}\begin{pmatrix}v_1\\ v_2\end{pmatrix} = \partial_x v_1 + \partial_y v_2,$$

$$\nabla^\perp s = \operatorname{rot} s = \begin{pmatrix}\partial_y s\\ -\partial_x s\end{pmatrix}, \qquad \nabla\times\mathbf{v} = \operatorname{curl}\begin{pmatrix}v_1\\ v_2\end{pmatrix} = -\partial_y v_1 + \partial_x v_2.$$

We use $\langle\cdot,\cdot\rangle$ and $\|\cdot\|$ to denote the respective L^2 inner product and norm and $\mathcal{D}$, $\mathcal{R}$, and $\mathcal{N}$ for the respective domain, range, and null space of an operator. We also use $\|\cdot\|_1$ to denote the $H^1(\Omega)$ norm: $\|s\|_1^2 = \|s\|^2 + \|\nabla s\|^2$. As usual, norms of vectors are meant to be taken componentwise, so that $\|\nabla s\| = (\|\frac{\partial s}{\partial x}\|^2 + \|\frac{\partial s}{\partial y}\|^2)^{1/2}$, for example.

2.2. FOSLS. We begin with a brief introduction to the main ideas of FOSLS as a way of providing a foundation for the FOSLL* methodology. We describe how it works for domains without irregular boundary points and show why it may fail for domains with irregular boundary points.

Standard FOSLS transforms BVP (2.1)–(2.3) into a first-order system to which an L^2 norm minimization principle is applied. This transformation can be done by introducing the gradient, $\mathbf{u} = \nabla p$, as a dependent variable and adding the curl constraint, $\nabla\times\mathbf{u} = 0$ on Ω, and tangential boundary condition, $\mathbf{t}\cdot\mathbf{u} = 0$ on Γ_D. The resulting first-order system, then has the form

$$L_0(\mathbf{u},p) = (\mathbf{0}, f, 0)^t \text{ in } \Omega, \tag{2.7}$$

$$\mathbf{t}\cdot\mathbf{u} = 0 \text{ on } \Gamma_D, \tag{2.8}$$

$$\mathbf{n}\cdot A\mathbf{u} = 0 \text{ on } \Gamma_N, \tag{2.9}$$

$$p = 0 \text{ on } \Gamma_D, \tag{2.10}$$

where

$$L_0(\mathbf{u},p) := \begin{bmatrix} I & -\nabla\\ \nabla\cdot A - \mathbf{b}\cdot & -c\\ -\nabla\times & 0\end{bmatrix}\begin{pmatrix}\mathbf{u}\\ p\end{pmatrix} = \begin{pmatrix}\mathbf{u} - \nabla p\\ \nabla\cdot A\mathbf{u} - \mathbf{b}\cdot\mathbf{u} - cp\\ -\nabla\times\mathbf{u}\end{pmatrix}. \tag{2.11}$$

The least-squares functional to be minimized is

$$\mathcal{F}_0(\mathbf{v},t) = \left\|L_0(\mathbf{v},t) - (\mathbf{0},f,0)^t\right\|^2.$$

Since we want this functional to exist for all $(\mathbf{v},t) \in \mathcal{D}(L_0)$, we need

$$\mathcal{R}(L_0) \subseteq \left(L^2(\Omega)\right)^4. \tag{2.12}$$

We are, thus, lead to choose

$$\mathcal{D}(L_0) = (H_N(\nabla\cdot A;\Omega) \cap H_D(\nabla\times;\Omega)) \times H_D^1(\Omega),$$

where, for a general 2×2 matrix B, we define

$$\begin{aligned} H^1_J(\Omega) &:= \left\{ s \in H^1(\Omega) : s = 0 \text{ on } \Gamma_J \right\}, \\ H_J(\nabla\cdot B; \Omega) &:= \left\{ \mathbf{w} \in (L^2(\Omega))^2 : \nabla\cdot(B\mathbf{w}) \in L^2(\Omega), \mathbf{n}\cdot B\mathbf{w} = 0 \text{ on } \Gamma_J \right\}, \\ H_J(\nabla\times B; \Omega) &:= \left\{ \mathbf{w} \in (L^2(\Omega))^2 : \nabla\times(B\mathbf{w}) \in L^2(\Omega), \mathbf{t}\cdot B\mathbf{n} = 0 \text{ on } \Gamma_J \right\} \end{aligned}$$

for $J \in \{N, D\}$. Moreover, $H_J(\nabla\cdot; \Omega) := H_J(\nabla\cdot I; \Omega)$ and $H_J(\nabla\times; \Omega) := H_J(\nabla\times I; \Omega)$, where I is the 2×2 identity matrix. Clearly, $\mathcal{D}(L_0)$ is a Hilbert space under the norm

$$\|(\mathbf{v}, t)\|^2_{L_0} := \|\mathbf{v}\|^2 + \|\nabla\cdot A\mathbf{v}\|^2 + \|\nabla\times\mathbf{v}\|^2 + \|t\|^2_1.$$

Since BVP (2.1)–(2.3) is well posed by assumption, we know that (2.7)–(2.10) has a unique solution in $\mathcal{D}_0$. Thus, $\mathcal{F}_0$ has a unique minimizer in $\mathcal{D}_0$ with minimum value zero. We minimize functional $\mathcal{F}_0$ in the weak sense; i.e., we look for solutions of the corresponding variational problem:

Find $(\mathbf{u}, p) \in \mathcal{D}_0$ *such that*

$$\left\langle L_0(\mathbf{u}, p) - (\mathbf{0}, f, 0)^t, L_0(\mathbf{v}, t) \right\rangle = 0 \tag{2.13}$$

for all $(\mathbf{v}, t) \in \mathcal{D}_0$.

A convenient choice for this FOSLS formulation is to discretize variational problem (2.13), using H^1-conforming finite element spaces, such as bilinears on quadrilaterals or linears on triangles. As the mesh size of the discretization tends to zero, the use of H^1-conforming finite element spaces yields converging approximations of the solution provided that solution is in H^1. This approach requires

$$(\mathbf{u}, p) \in \left(H^1(\Omega)\right)^3 \tag{2.14}$$

for FOSLL* approximations using H^1-conforming finite elements to converge to the solution of primal problem (2.7)–(2.10). The requirement (2.14) is more restrictive than (2.12) and is, in general, not fulfilled for problems with irregular boundary points or discontinuous coefficient matrix A. In such cases, the FOSLS approximations, $(\mathbf{u}^h, p^h)$, do not converge to the solution of (2.7)–(2.10), as the following example illustrates.

Example 2.1. *Define the following L-shaped domain:*

$$\Omega = \left\{ \mathbf{x} \in \mathbb{R}^2 : \|\mathbf{x}\|_\infty < 1 \text{ and } \theta(\mathbf{x}) \in (0, 3\pi/2) \right\}, \tag{2.15}$$

where $\theta = \arcsin(y/x)$. *Let* $A = I$, $c = 1$, *and* $\mathbf{b} = (-y/10, 10x)^t$. *The Neumann boundary consists of three parts,*

$$\begin{aligned} &\Gamma_{N,1} = \{(x, y) \in \partial\Omega : x \in (0, 1), y = 1\}, \quad \Gamma_{N,2} = \{(x, y) \in \partial\Omega : y = -1\}, \\ &\Gamma_{N,3} = \{(x, y) \in \partial\Omega : x = -1, y \in (0, 1)\}. \end{aligned}$$

The three remaining parts of $\partial\Omega$ *form* Γ_D. *This domain contains irregular boundary points at* $(0, 0)$, $(-1, 0)$, *and* $(0, 1)$.

Let (r, θ) *denote standard polar coordinates on* $\mathbb{R}^2$ *and let*

$$p = \delta(r) r^{2/3} \sin(2\theta/3). \tag{2.16}$$

Then, p *is a solution of BVP* (2.1)–(2.3) *when* $f = \sin(2\theta/3) r^{2/3}(\delta''(r) + \frac{7}{3r}\delta'(r)) - \mathbf{b}\cdot\nabla p - cp$. *Here,* $\delta(r) \in C^2(\Omega)$ *is a cut-off function that satisfies* $\delta(r) = 1$ *for* $r < 1/4$

TABLE 2.1
Error norms for Example 2.1 *on a sequence of uniform meshes with mesh sizes* h.

h	1/4	1/8	1/16	1/32	1/64	1/128	1/256
$\|\|p - p^h\|\|_0$	0.1461	0.1521	0.1543	0.1550	0.1551	0.1550	0.1549
$\|\|\nabla p - \mathbf{u}^h\|\|_0$	0.8433	0.8267	0.8199	0.8173	0.8152	0.8137	0.8127

and $\delta(r) = 0$ *for* $r > 3/4$. *Clearly,* $f \in L^2(\Omega)$, *but* $\mathbf{u} = \nabla p$ *is not in* $(H^\alpha(\Omega))^2$ *for any* $\alpha \geq 2/3$. *Table* 2.1 *shows the results of numerical experiments for this problem with error norms* $||p - p^h||_0$ *and* $||\nabla p - \mathbf{u}^h||_0$ *for a sequence of uniform meshes with decreasing mesh sizes* h *and standard bilinear* H^1*-conforming finite element spaces. Standard FOSLS clearly fails for this example. A closer look at* $\mathbf{u}^h$ *shows that the FOSLS approximation is completely unaware of the singularities in the gradient at the reentrant corner of* Ω.

2.3. FOSLL*. The FOSLL* method was developed to overcome this difficulty with standard FOSLS, while continuing to use standard H^1-conforming finite element spaces in the discretization process. Clearly, H^1-conforming spaces cannot be used to approximate the nonsmooth primal solution, $(\mathbf{u}, p)$, so FOSLL* instead attempts to introduce a dual first-order system whose solution is in H^1.

The main idea can be motivated by looking at the simplest discrete analog, that is, a linear system of equations, $Ax = b$. Solving the corresponding least-squares problem of minimizing $\|Ax - b\|^2_{\ell^2}$ leads to the normal equations, $A^tAx = A^tb$, and the weak form, $\langle Ax, Az\rangle = \langle b, Az\rangle$ *for all* z. This is analogous to what FOSLS does at the PDE level. But another way to recast $Ax = b$ as a minimization problem is to recognize that if $Ax = b$ has a solution, then so does $AA^ty = b$. Note that this system for dual variable y is the normal equations for dual problem $A^ty = x$, and that it can be recast as the minimization of $\|A^ty - x\|^2_{\ell^2}$, which has the same minimizer as the functional $\langle A^ty, A^ty\rangle - 2\langle y, b\rangle$. This leads to the weak form, $\langle A^ty, A^tz\rangle = \langle b, z\rangle$ *for all* z. Note that $x = A^ty$ yields the minimal norm solution of the original problem, $Ax = b$. This idea is formally applicable at the PDE level since our primal problem surely has a solution.

While simpler approaches are possible in some cases, a fairly general methodology for applying FOSLL* is to attempt to reformulate the original BVP as a first-order primal problem whose associated operator, L_1, and adjoint, L_1^*, are bijective. This guarantees the existence of a unique solution for the dual normal equations, $L_1L_1^*w = f$.

This bijectivity is achieved for BVP (2.1)–(2.3) by incorporating a scalar slack variable, q, into the system and using the scaled gradient, $\tilde{\mathbf{u}} = A^{1/2}\nabla p$. (Here, we incorporate a slightly different scaling than in (2.11) because it has computational advantages.) This is done in such a way that $(\tilde{\mathbf{u}}, p, 0)$ solves the primal problem, which for BVP (2.1)–(2.3) is given by

$$L_1(\tilde{\mathbf{u}}, p, q) = (\mathbf{0}, f, 0)^t \text{ in } \Omega, \tag{2.17}$$

$$\mathbf{t} \cdot A^{-1/2}\tilde{\mathbf{u}} = 0 \text{ on } \Gamma_D, \tag{2.18}$$

$$\mathbf{n} \cdot A^{1/2}\tilde{\mathbf{u}} = 0 \text{ on } \Gamma_N, \tag{2.19}$$

$$p = 0 \text{ on } \Gamma_D, \tag{2.20}$$

$$q = 0 \text{ on } \Gamma_N, \tag{2.21}$$

where

$$L_1(\tilde{\mathbf{u}}, p, q) := \begin{bmatrix} A^{-1/2} & -\nabla & -\nabla^\perp \\ \nabla\cdot A^{1/2} - \mathbf{b}\cdot A^{-1/2} & -c & 0 \\ -\nabla\times A^{-1/2} & 0 & 0 \end{bmatrix} \begin{pmatrix} \tilde{\mathbf{u}} \\ p \\ q \end{pmatrix} = \begin{pmatrix} A^{-1/2}\tilde{\mathbf{u}} - \nabla p - \nabla^\perp q \\ \nabla\cdot(A^{1/2}\tilde{\mathbf{u}}) - \mathbf{b}\cdot A^{-1/2}\tilde{\mathbf{u}} - cp \\ -\nabla\times(A^{-1/2}\tilde{\mathbf{u}}) \end{pmatrix}. \tag{2.22}$$

The domain of L_1 is

$$\mathcal{D}(L_1) = \Big(H_N(\nabla\cdot A^{1/2};\Omega) \cap H_D(\nabla\times A^{-1/2};\Omega)\Big) \times H^1_D(\Omega) \times H^1_N(\Omega),$$

which is a Hilbert space under the norm

$$\|(\mathbf{v}, t, z)\|^2_{L_1} := \|\mathbf{v}\|^2 + \left\|\nabla\cdot(A^{1/2}\mathbf{v})\right\|^2 + \left\|\nabla\times(A^{-1/2}\mathbf{v})\right\|^2 + \|t\|_1^2 + \|z\|_1^2. \tag{2.23}$$

The FOSLL* approach is to approximate the solution, $(\mathbf{w}, r, s)$, of the corresponding dual problem,

$$L_1^*(\mathbf{w}, r, s) = (\tilde{\mathbf{u}}, p, q)^t = (A^{1/2}\nabla p, p, 0)^t \text{ in } \Omega, \tag{2.24}$$

$$\mathbf{t}\cdot A^{-1/2}\mathbf{w} = 0 \text{ on } \Gamma_D, \tag{2.25}$$

$$\mathbf{n}\cdot A^{1/2}\mathbf{w} = 0 \text{ on } \Gamma_N, \tag{2.26}$$

$$r = 0 \text{ on } \Gamma_D, \tag{2.27}$$

$$s = 0 \text{ on } \Gamma_N, \tag{2.28}$$

where the adjoint operator is defined by

$$L_1^*(\mathbf{w}, r, s) = \begin{bmatrix} A^{-1/2} & -A^{1/2}\nabla - A^{-1/2}\mathbf{b} & -A^{-1/2}\nabla^\perp \\ \nabla\cdot & -c & 0 \\ -\nabla\times & 0 & 0 \end{bmatrix} \begin{pmatrix} \mathbf{w} \\ r \\ s \end{pmatrix}. \tag{2.29}$$

The domain of L_1^* is

$$\mathcal{D}(L_1^*) = (H_N(\nabla\cdot;\Omega) \cap H_D(\nabla\times;\Omega)) \times H^1_D(\Omega) \times H^1_N(\Omega).$$

which is a Hilbert space under the norm

$$\|(\mathbf{v}, t, z)\|^2_{L_1^*} := \|\mathbf{v}\|^2 + \|\nabla\cdot(\mathbf{v})\|^2 + \|\nabla\times(\mathbf{v})\|^2 + \|t\|_1^2 + \|z\|_1^2. \tag{2.30}$$

This formulation is similar to the FOSLL$^*_e$ formulation described in [12]. The difference is that in (2.29), the coefficient matrix, A, only appears outside of the differential operators. Note, also, that this scaling yields $A^{1/2}\nabla r$ orthogonal to $A^{-1/2}\nabla^\perp s$, which produces better performance for the multigrid solvers. A minor modification of the proof of Theorem 4.1 in [12] yields the following result.

THEOREM 2.2. *Operators L_1 and L_1^* are bijective from $\mathcal{D}(L_1)$ and $\mathcal{D}(L_1^*)$, respectively, onto $(L^2(\Omega))^4$. Further, L_1 and L_1^* are coercive and continuous in the norms defined in* (2.23) *and* (2.30), *respectively.*

Proof. The proof requires the assumption that the adjoint problem (2.4)–(2.6) is well posed and follows with minor modifications from the proof of Theorem 4.1 in [12], together with an application of Lemma 2.1 in [12]. □

Solving the dual problem is equivalent to minimizing the dual functional,

$$\mathcal{F}_1^*(\mathbf{v}, t, z) = \left\| L_1^*(\mathbf{v}, t, z) - (\tilde{\mathbf{u}}, p, q)^t \right\|^2, \tag{2.31}$$

on $\mathcal{D}(L_1^*)$. The associated weak form is as follows:

Find $(\mathbf{w}, r, s) \in \mathcal{D}(L_1^*)$ *such that*

$$\langle L_1^*(\mathbf{w}, r, s), L_1^*(\mathbf{v}, t, z)\rangle = \left\langle (\tilde{\mathbf{u}}, p, q)^t, L_1^*(\mathbf{v}, t, z)\right\rangle \tag{2.32}$$

for all $(\mathbf{v}, t, z) \in \mathcal{D}(L_1^*)$.

The unknown solution, $(\tilde{\mathbf{u}}, p, q)$, is eliminated from the right side of (2.32) by rewriting the right side as follows:

$$\left\langle (\tilde{\mathbf{u}}, p, q)^t, L_1^*(\mathbf{v}, t, z)\right\rangle = \left\langle L_1(\tilde{\mathbf{u}}, p, q), (\mathbf{v}, t, z)^t\right\rangle = \left\langle (\mathbf{0}, f, 0)^t, (\mathbf{v}, t, z)^t\right\rangle.$$

After discretizing this variational form and computing an approximation, $(\mathbf{w}^h, r^h, s^h)$, for the dual unknowns, an L^2 approximation, $(\tilde{\mathbf{u}}^h, p^h, q^h)$, for the primal unknowns is computed easily by applying the adjoint: $(\tilde{\mathbf{u}}^h, p^h, q^h)^t = L_1^*(\mathbf{w}^h, r^h, s^h)$.

This formulation of FOSLL* works well with H^1-conforming finite element spaces if the violation of the crucial regularity condition, (2.14), is due only to the discontinuities in A. This can be most easily seen by noting that in (2.29) the coefficients are never differentiated. However, in the presence of irregular boundary points, we may be left with the difficulty that

$$H_N(\nabla\cdot; \Omega) \cap H_D(\nabla\times; \Omega) \not\subset \left(H^1(\Omega)\right)^2. \tag{2.33}$$

For example, (2.33) holds if the boundary of Ω contains re-entrant corners or points in $\overline{\Gamma_D} \cap \overline{\Gamma_N}$ with an inner angle bigger than $\pi/2$ (cf. [17]). If H^1-conforming finite element spaces are used to approximate the solution to (2.32), then the approximation will not, in general, converge to the solution, but rather to the closest element in $(H^1)^4$ to the solution. In general, this error will not have local support. In the next section, we introduce a modification to FOSLL* that overcomes this difficulty.

We close this section by demonstrating numerically how the FOSLL* formulation described above fails in the presence of irregular boundary points.

EXAMPLE 2.3. *We apply the FOSLL* method* (2.32), *using H^1-conforming finite elements, to the BVP from Example* 2.1. *Table* 2.2 *shows that the L^2 norm of the errors of the approximations for p and $\tilde{\mathbf{u}}$ stagnate as h decreases.*

TABLE 2.2
Error norms for the standard FOSLL* approximations for Example 2.3 *on a sequence of uniform meshes with mesh sizes h.*

h	1/4	1/8	1/16	1/32	1/64	1/128	1/256
$\|\|p - p^h\|\|_0$	0.0482	0.0259	0.0231	0.0230	0.0229	0.0228	0.0228
$\|\|\tilde{\mathbf{u}} - \tilde{\mathbf{u}}^h\|\|_0$	0.6767	0.3202	0.1825	0.1220	0.1001	0.0933	0.0914

3. Improved FOSLL*.

We begin here by introducing modifications to the standard FOSLL* formulation that overcome the shortcomings for problems with irregular boundary points. We then describe how the method can be made more efficient for the special cases $\mathbf{b} = \mathbf{0}$ and $c = 0$.

As a starting point of our improvements, we revert to the scaling used in (2.11). While the scaling in (2.22) is preferable in practice, we use this simpler scaling for ease of exposition. All results in this section can be easily generalized to the scaling in (2.22).

Thus, we define the unscaled gradient, $\mathbf{u} = \nabla p$, as a dependent variable. The primal problem has the form $\mathcal{L}_0(\mathbf{u}, p, q) = (\mathbf{0}, f, 0)^t$, where q is a slack variable as introduced in the previous subsection,

$$\mathcal{L}_0 = \begin{bmatrix} I & -\nabla & -\nabla^{\perp} \\ (\nabla \cdot A - \mathbf{b}\cdot) & -c & 0 \\ -\nabla\times & 0 & -d \end{bmatrix}, \tag{3.1}$$

and d is a nonnegative analytic function on Ω.

Following the development for standard FOSLL*, the domain of $\mathcal{L}_0$ is given by

$$\mathcal{D}(\mathcal{L}_0) = (H_N(\nabla\cdot A; \Omega) \cap H_D(\nabla\times; \Omega)) \times H^1_D(\Omega) \times H^1_N(\Omega).$$

Clearly, $(\nabla p, p, 0)$ solves this problem when p is the solution of the BVP (2.1)–(2.3). The corresponding dual problem is

$$\mathcal{L}_0^*(\mathbf{w}, r, s) := \begin{bmatrix} I & -(A\nabla + \mathbf{b}) & -\nabla^{\perp} \\ \nabla\cdot & -c & 0 \\ -\nabla\times & 0 & -d \end{bmatrix} \begin{pmatrix} \mathbf{w} \\ r \\ s \end{pmatrix} = \begin{pmatrix} \mathbf{u} \\ p \\ q \end{pmatrix} \tag{3.2}$$

on the adjoint domain

$$\mathcal{D}(\mathcal{L}_0^*) = (H_N(\nabla\cdot; \Omega) \cap H_D(\nabla\times; \Omega)) \times H^1_D(\Omega) \times H^1_N(\Omega).$$

Formulating the FOSLL* method using $\mathcal{L}_0^*$ reveals exactly the same difficulty as the formulation using L_1^* in the last subsection. While discontinuous coefficients do not cause difficulties, irregular boundary points do, because they imply $H_N(\nabla\cdot; \Omega) \cap H_D (\nabla\times; \Omega) \not\subset \left(H^1(\Omega)\right)^2$, which in turn implies $\mathcal{D}(\mathcal{L}_1^*) \not\subset \left(H^1(\Omega)\right)^4$.

The next step is to introduce a modified operator, $\mathcal{L}_1$, that is formally identical to $\mathcal{L}_0$ in (3.1) but has a different domain. The aim is to expand the domain of $\mathcal{L}_1$ so that the domain of its adjoint shrinks to a subspace of $\left(H^1(\Omega)\right)^4$. To see how this is done, note that the second and third entries in the first row of $\mathcal{L}_0$ in (3.1) can be rewritten as follows:

$$\begin{bmatrix} -\nabla & -\nabla^{\perp} \end{bmatrix} = \begin{bmatrix} -\partial_x & -\partial_y \\ -\partial_y & \partial_x \end{bmatrix} = \begin{bmatrix} -\nabla\cdot \\ \nabla\times \end{bmatrix}.$$

Thus, instead of asking the gradients of p and q to be in $L^2(\Omega)$ individually, we may impose the more general condition that the div and curl of the pair (p, q) be in $L^2(\Omega)$. We are thus lead to rewrite $\mathcal{L}_0$ as

$$\mathcal{L}_1 = \begin{bmatrix} I & \begin{matrix} -\nabla\cdot \\ \nabla\times \end{matrix} \\ \begin{matrix} (\nabla\cdot A - \mathbf{b}\cdot) \\ -\nabla\times \end{matrix} & -B \end{bmatrix}, \qquad \text{where } B = \begin{pmatrix} c & 0 \\ 0 & d \end{pmatrix},$$

so that

$$\mathcal{D}(\mathcal{L}_1) = (H_N(\nabla\cdot A; \Omega) \cap H_D(\nabla\times; \Omega)) \times \mathcal{H}_{DN}(\Omega),$$

where

$$\mathcal{H}_{DN}(\Omega) := \{(v_1, v_2) \in H(\nabla\cdot; \Omega) \cap H(\nabla\times; \Omega) : v_1 = 0 \text{ on } \Gamma_D, v_2 = 0 \text{ on } \Gamma_N\}.$$

Integration by parts then shows that the domain of $\mathcal{L}_1^*$ is in $\left(H^1(\Omega)\right)^4$:

$$\mathcal{D}(\mathcal{L}_1^*) = (H_N(\nabla\cdot;\Omega) \cap H_D(\nabla\times;\Omega) \cap \left(H^1(\Omega)\right)^2) \times H_D^1(\Omega) \times H_N^1(\Omega).$$

Unfortunately, this approach is not yet viable because the adjoint, $\mathcal{L}_1^*$, is in general no longer surjective and we can no longer guarantee that $(\mathbf{u}, p, q) \in \mathcal{R}(\mathcal{L}_1^*)$, as the following example shows.

EXAMPLE 3.1. *Let Ω be the L-shaped domain from* (2.15) *and set $A = I$ and $\mathbf{b} = \mathbf{0}$. Let d be any positive analytic function and $c \in L^\infty$ with $0 < c < 1$ a.e. We choose homogeneous Dirichlet boundary conditions: $\Gamma_D = \partial\Omega$. Let Γ_H be the union of the three horizontal edges and Γ_V be the union of the three vertical edges of Ω. Thus, imposing $v_1 = 0$ on Γ_D is equivalent to imposing $\mathbf{n} \cdot (v_1, v_2) = 0$ on Γ_H and $\mathbf{t} \cdot (v_1, v_2) = 0$ on Γ_V, so*

$$\mathcal{H}_{DN}(\Omega) = H_H(\nabla\cdot;\Omega) \cap H_V(\nabla\times;\Omega)$$

holds for this example. The analysis of the div-curl *operator in* [11] *shows that $\left[\begin{smallmatrix}-\nabla\cdot\\ \nabla\times\end{smallmatrix}\right]$ has a nontrivial null space on $\mathcal{H}_{DN}(\Omega)$. (For example, let $\mathbf{z} = \nabla\phi$, where $\Delta\phi = 0$, $\mathbf{n} \cdot \nabla\phi = 0$ on Γ_H, $\phi = 0$ on $\Gamma_{V_1} \cup \Gamma_{V_2}$, and $\phi = 1$ on Γ_{V_3}.) Let $\mathbf{z} \neq \mathbf{0}$ be such a null space element. Note that $\mathcal{L}_1(\mathbf{0}, \mathbf{z}) = (\mathbf{0}, -cz_1, -dz_2)^t$ is in $\left(L^2(\Omega)\right)^4$. Since $\mathcal{L}_1 = \mathcal{L}_1^*$ formally holds, Lemma* 3.6 *in* [11] *implies the existence of a more regular preimage, $(\mathbf{v}, \mathbf{w}) \in \mathcal{D}(\mathcal{L}_1) \cap \left(H^1(\Omega)\right)^4$ with $\mathcal{L}_1(\mathbf{v}, \mathbf{w}) = (\mathbf{0}, -cz_1, -dz_2)^t$. Therefore, $(\mathbf{v}, \mathbf{w} - \mathbf{z})$ is a nontrivial element of null space $\mathcal{N}(\mathcal{L}_1)$. Since $(\mathcal{L}_1^*)^* = \mathcal{L}_1$, the closed range theorem implies that $\mathcal{R}(\mathcal{L}_1^*) = \mathcal{N}(\mathcal{L}_1)^\perp$, so $\mathcal{R}(\mathcal{L}_1^*)$ is not all of $\left(L^2(\Omega)\right)^4$ and $\mathcal{L}_1^*$ is not surjective.*

To prove that, in general, $U = (\nabla p, p, 0) \notin \mathcal{R}(\mathcal{L}_1^*)$ so that the dual problem is not solvable, assume otherwise: $U \in \mathcal{R}(\mathcal{L}_1^*)$ or, equivalently, $U \perp \mathcal{N}(\mathcal{L}_1)$ for all admissible p. Let $(\mathbf{v}, \mathbf{w})$ be an element of $\mathcal{N}(\mathcal{L}_1)$, i.e.,

$$\mathbf{v} + \begin{bmatrix}-\nabla\cdot\\ \nabla\times\end{bmatrix}\mathbf{w} = \mathbf{0} \tag{3.3}$$

$$\begin{bmatrix}\nabla\cdot\\ -\nabla\times\end{bmatrix}\mathbf{v} - \begin{pmatrix}cw_1\\ dw_2\end{pmatrix} = \mathbf{0}. \tag{3.4}$$

Now, $U \perp (\mathbf{v}, \mathbf{w})$ means $\langle\nabla p, \mathbf{v}\rangle + \langle p, w_1\rangle = 0$. Using the divergence theorem and (3.4), *we thus have $(c-1)\,\langle p, w_1\rangle = 0$. Since $\langle p, w_1\rangle$ must vanish for all admissible p, we must have $w_1 = 0$. From* (3.3) *and* (3.4), *we conclude that $w_2 \in H^1(\Omega)$ and*

$$\Delta w_2 - dw_2 = 0.$$

The definition of $\mathcal{D}(\mathcal{L}_1)$ and (3.3) *supply the boundary condition*

$$\mathbf{n} \cdot \nabla w_2 = -\mathbf{t} \cdot \nabla^\perp w_2 = -\mathbf{t} \cdot \mathbf{v} = 0 \text{ on } \Gamma_D = \partial\Omega.$$

Therefore, w_2 is a constant on Ω and (3.3)–(3.4) *yield $\mathbf{v} = \mathbf{w} = \mathbf{0}$. Since $\mathcal{N}(\mathcal{L}_1)$ is nontrivial, our assumption is wrong, and the dual problem is not, in general, solvable in $\mathcal{D}(\mathcal{L}_1^*)$.*

Our numerical experience supports the difficulty expressed in this example: it seems that $(\nabla p, p, 0)$ is in $\mathcal{R}(\mathcal{L}_1^*)$ only for very special choice of $A, \mathbf{b}, c, d$, and Ω, whenever $\partial\Omega$ contains irregular boundary points.

Nevertheless, the modifications that lead from $\mathcal{L}_0$ to $\mathcal{L}_1$ take a step in the right direction because we now have $\mathcal{D}(\mathcal{L}_1^*) \subset \left(H^1(\Omega)\right)^4$. This H^1-inclusion property guarantees that a dual solution, when it exists, can be easily approximated by standard H^1 finite element spaces. As the final step, we now modify the domain of the operators again to ensure solvability. The aim is to increase the domain of the new dual operator, $\mathcal{L}^*$, in order to make it surjective. This is done indirectly by reducing the number of boundary conditions on the dual domain. We do this by enforcing more boundary conditions on the domain of the primal operator, $\mathcal{L}$. Of course, we are only allowed to enforce additional boundary conditions on the primal problem that are fulfilled by the primal solution, $(\mathbf{u}, p, q)$. The key is to identify these allowable conditions and choose those that induce the appropriate $\mathcal{D}(\mathcal{L}^*)$.

First, we introduce the new modified operator, $\mathcal{L}$, then prove some useful lemmas, and finally we present our main results, the surjectivity of the dual operator, $\mathcal{L}^*$.

The two additional boundary conditions we enforce on the primal problem are

$$\int_{\Gamma_{N,i}} \mathbf{t} \cdot \mathbf{u}\, ds = 0, \quad i = 1, \dots, M, \tag{3.5}$$

$$q = 0 \text{ on } \Gamma_Q \subset \Gamma_D. \tag{3.6}$$

These additional conditions are allowable because the primal solution, $(\mathbf{u}, p, q)$, satisfies them:

$$\int_{\Gamma_{N,i}} \mathbf{t} \cdot \mathbf{u}\, ds = \int_{\Gamma_{N,i}} \mathbf{t} \cdot \nabla p\, ds = \int_{\Gamma_{N,i}} \frac{dp}{ds}\, ds = 0, \qquad i = 1, \dots, M,$$

and $q = 0$ on $\partial\Omega$. For theoretical purposes, we impose condition (3.6) only on a subset, $\Gamma_Q \subset \Gamma_D$, that does not contain any irregular boundary points in its closure but has positive measure. See Remark 3.2 for motivation.

The new operator, $\mathcal{L}$, has the same form as $\mathcal{L}_1$, but differs again by its domain. We define the form of $\mathcal{L}$ blockwise:

$$T = \begin{bmatrix} \nabla\cdot A - \mathbf{b}\cdot \\ -\nabla\times \end{bmatrix}, \qquad B = \begin{bmatrix} c & 0 \\ 0 & d \end{bmatrix}, \tag{3.7}$$

$$S = \begin{bmatrix} -\partial_x & -\partial_y \\ -\partial_y & \partial_x \end{bmatrix} = \begin{bmatrix} -\nabla\cdot \\ \nabla\times \end{bmatrix}, \tag{3.8}$$

$$\mathcal{L} = \begin{bmatrix} I & S \\ T & -B \end{bmatrix}. \tag{3.9}$$

The corresponding domains include the following additional boundary conditions:

$$\mathcal{D}(T) = \left\{ \mathbf{v} \in H_N(\nabla\cdot A; \Omega) \cap H_D(\nabla\times; \Omega) \ : \ \int_{\Gamma_{N,i}} \mathbf{t} \cdot \mathbf{v}\, ds = 0,\ 1 \le i \le M \right\}, \tag{3.10}$$

$$\mathcal{D}(S) = \left\{ (t, z) \in \mathcal{H}_{DN}(\Omega) \ : \ z = 0 \text{ on } \Gamma_Q \right\}, \tag{3.11}$$

$$\mathcal{D}(\mathcal{L}) = \mathcal{D}(T) \times \mathcal{D}(S). \tag{3.12}$$

These domains are Hilbert spaces under the div-curl norms,

$$\|\mathbf{v}\|_S^2 := \|\mathbf{v}\|^2 + \|\nabla\cdot\mathbf{v}\|^2 + \|\nabla\times\mathbf{v}\|^2, \tag{3.13}$$

$$\|\mathbf{v}\|_T^2 := \|\mathbf{v}\|^2 + \|\nabla\cdot(A\mathbf{v})\|^2 + \|\nabla\times\mathbf{v}\|^2, \tag{3.14}$$

$$\|(\mathbf{v}, \mathbf{w})\|_{\mathcal{L}}^2 := \|\mathbf{v}\|_T^2 + \|\mathbf{w}\|_S^2. \tag{3.15}$$

Integration by parts leads to the adjoint operators,

$$T^* = \begin{bmatrix} -(A\nabla + \mathbf{b}) & -\nabla^\perp \end{bmatrix}, \tag{3.16}$$

$$S^* = \begin{bmatrix} \partial_x & \partial_y \\ \partial_y & -\partial_x \end{bmatrix} = \begin{bmatrix} \nabla & \nabla^\perp \end{bmatrix}, \tag{3.17}$$

$$\mathcal{L}^* = \begin{bmatrix} I & T^* \\ S^* & -B \end{bmatrix}, \tag{3.18}$$

and the domains,

$$\mathcal{D}(S^*) = \left\{ \mathbf{v} \in \left(H^1(\Omega)\right)^2 \ : \ \mathbf{n}\cdot\mathbf{v} = 0 \text{ on } \Gamma_N \text{ and } \mathbf{t}\cdot\mathbf{v} = 0 \text{ on } \Gamma_D \backslash \Gamma_Q \right\}, \tag{3.19}$$

$$\mathcal{D}(T^*) = \left\{ (t, z) \in \left(H^1(\Omega)\right)^2 \ : \ t = 0 \text{ on } \Gamma_D \text{ and } z \equiv c_i \text{ on } \Gamma_{N,i} \right\}, \tag{3.20}$$

where $1 \leq i \leq M$, and c_i are arbitrary constants, and

$$\mathcal{D}(\mathcal{L}^*) = \mathcal{D}(S^*) \times \mathcal{D}(T^*). \tag{3.21}$$

Remark 3.2. We do not allow the closure of $\Gamma_Q \subset \Gamma_D$ to contain irregular boundary points because we would expect singular functions in $H(\nabla\times;\Omega) \cap H(\nabla\cdot;\Omega)$ to arise at these points. These singular functions would no longer be in $\mathcal{D}(S)$, but they would be in $\mathcal{D}(S^*)$. In practice, there seems to be no difficulty with allowing Γ_Q to touch irregular boundary points.

For the remainder of this section, we adopt the assumptions on BVP (2.1)–(2.3) made in subsection 2.1 and let d be any nonnegative analytic function. We now prove coercivity of the primal operator, $\mathcal{L}$. To this end, we need two auxiliary results.

LEMMA 3.3. *$\mathcal{L}$ is injective.*

Proof. Assume that there exists a $(\mathbf{v}, \mathbf{w}) \in \mathcal{D}(\mathcal{L})$ such that

$$\mathcal{L}(\mathbf{v}, \mathbf{w}) = \begin{bmatrix} I & S \\ T & -B \end{bmatrix} \begin{pmatrix} \mathbf{v} \\ \mathbf{w} \end{pmatrix} = \begin{pmatrix} \mathbf{0} \\ \mathbf{0} \end{pmatrix}.$$

Then, $S\mathbf{w} \in \mathcal{D}(T)$, which, together with $\mathbf{w} \in \mathcal{D}(S)$, implies that

$$\mathbf{t} \cdot S\mathbf{w} = -\mathbf{n} \cdot \nabla w_2 = 0 \text{ on } \Gamma_Q, \tag{3.22}$$

$$\mathbf{n} \cdot AS\mathbf{w} = -\mathbf{n} \cdot A(\nabla w_1 + \nabla^\perp w_2) = 0 \text{ on } \Gamma_N. \tag{3.23}$$

Now, choose any open set, $\mathcal{O} \subset \Omega$ such that $\overline{\mathcal{O}} \cap \Gamma_Q$ has positive measure and $\partial\mathcal{O}$ contains no irregular points of $\partial\Omega$. On $\mathcal{O}$ we have $\mathbf{w} \in (H^1)^2$. If we only look at the set $\mathcal{O}$, eliminating $\mathbf{v}$ yields the following equation for $\mathbf{w}$:

$$\begin{aligned} -TS\mathbf{w} - B\mathbf{w} &= -\begin{bmatrix} \nabla\cdot A - \mathbf{b}\cdot \\ -\nabla\times \end{bmatrix} \begin{bmatrix} -\nabla & -\nabla^\perp \end{bmatrix} \mathbf{w} - \begin{bmatrix} c & 0 \\ 0 & d \end{bmatrix} \mathbf{w} \\ &= \begin{bmatrix} (\nabla\cdot A\nabla - \mathbf{b}\cdot\nabla - c) & (\nabla\cdot A\nabla^\perp - \mathbf{b}\cdot\nabla^\perp) \\ 0 & \Delta - d \end{bmatrix} \mathbf{w} = \mathbf{0}. \end{aligned} \tag{3.24}$$

Consider the second equation together with the boundary conditions to get

$$\begin{aligned} \Delta w_2 - d w_2 &= 0 \text{ in } \mathcal{O}, \\ w_2 &= 0 \text{ on } \partial\mathcal{O} \cap \Gamma_Q, \\ \mathbf{n} \cdot \nabla w_2 &= 0 \text{ on } \partial\mathcal{O} \cap \Gamma_Q. \end{aligned}$$

According to the unique continuation theorem (cf. Hörmander [18]), we must have $w_2 = 0$ in $\mathcal{O}$. Since every point of Ω is in some $\mathcal{O}$ of this type, we conclude that $w_2 = 0$ in Ω. Since $S\mathbf{w} \in (L^2)^2$, then $w_2 = 0$ implies that $w_1 \in H^1(\Omega)$. Equations (3.23) and (3.24) now yield

$$\begin{aligned}(\nabla\cdot A\nabla - \mathbf{b}\cdot\nabla - c)w_1 &= 0 \text{ in } \Omega,\\ w_1 &= 0 \text{ on } \Gamma_D,\\ \mathbf{n}\cdot A\nabla w_1 &= 0 \text{ on } \Gamma_N.\end{aligned}$$

The well-posedness of BVP (2.1)–(2.3) implies that $w_1 = 0$ and, therefore, $\mathbf{v} = \mathbf{0}$. Hence, $\mathcal{N}(\mathcal{L}) = \{\mathbf{0}\}$ and the lemma follows. □

Lemma 3.4. *S is injective.*

Proof. Assume that there is a $\mathbf{w} \in \mathcal{D}(S)$ such that

$$S\mathbf{w} = \begin{bmatrix} -\nabla\cdot \\ \nabla\times \end{bmatrix} \mathbf{w} = \mathbf{0}.$$

Since Ω is simply connected, the curl-free condition here implies that $\mathbf{w} = \nabla\phi$ for some $\phi \in H^1(\Omega)$, with ϕ determined uniquely up to a constant (cf. [16]). The div-free condition implies that ϕ is harmonic. The boundary conditions on $\mathcal{D}(S)$ imply that $\nabla\phi = \mathbf{0}$ on Γ_Q, so

$$\mathbf{n}\cdot\nabla\phi = 0 \text{ on } \Gamma_Q.$$

But $\mathbf{t}\cdot\nabla\phi = 0$ is also true on Γ_Q. Thus, ϕ is constant on Γ_Q and, without loss of generality, we may assume

$$\phi = 0 \text{ on } \Gamma_Q.$$

Applying the unique continuation theorem (cf. Hörmander [18]) yields $\phi = 0$, which completes the proof. □

We are now able to establish coercivity of $\mathcal{L}$.

Theorem 3.5. *Operators S, T, and $\mathcal{L}$ are coercive in the norms* (3.13), (3.14), *and* (3.15)*, respectively.*

Proof. We begin by proving coercivity of S and T. For S, it suffices to prove a Poincaré inequality of the following form:

There exists constant $C > 0$ such that

$$\|\mathbf{w}\|^2 \le C\left(\|\nabla\cdot\mathbf{w}\|^2 + \|\nabla\times\mathbf{w}\|^2\right) \tag{3.25}$$

for all $\mathbf{w} \in \mathcal{D}(S)$.

To establish (3.25), we assume that no such inequality exists, that is, that there exists $\{\mathbf{w}^{(i)}\}_{i=1,\infty} \in \mathcal{D}(S)$ such that, for all $i > 0$,

$$\|\nabla\cdot\mathbf{w}^{(i)}\|^2 + \|\nabla\times\mathbf{w}^{(i)}\|^2 = 1, \tag{3.26}$$

$$\|\mathbf{w}^{(i)}\|^2 \ge i. \tag{3.27}$$

Now, every $\mathbf{w}^{(i)} \in \mathcal{D}(S)$ can be written as

$$\mathbf{w}^{(i)} = \mathbf{z}^{(i)} + \sum_{j=1}^{K} \beta_{ij}\boldsymbol{\phi}^{(j)},$$

where $\mathbf{z}^{(i)} \in \mathcal{D}(S) \cap \left(H^1(\Omega)\right)^2$ and $\{\boldsymbol{\phi}^{(j)}\}_{j=1,K}$ is a basis of the finite-dimensional orthogonal complement of $\mathcal{D}(S) \cap \left(H^1(\Omega)\right)^2$ in $\mathcal{D}(S)$. Here, we take orthogonality in the $\mathcal{H}_{DN}(\Omega)$ sense, which is an inner product because S is injective. That is, we require

$$\left\langle \nabla\cdot\boldsymbol{\phi}^{(j)}, \nabla\cdot\mathbf{z} \right\rangle + \left\langle \nabla\times\boldsymbol{\phi}^{(j)}, \nabla\times\mathbf{z} \right\rangle = 0$$

for every $\mathbf{z} \in \mathcal{D}(S) \cap \left(H^1(\Omega)\right)^2$. Then, (3.26) becomes

$$\|\nabla\cdot\mathbf{z}^{(i)}\|^2 + \|\nabla\times\mathbf{z}^{(i)}\|^2 + \left\|\nabla\cdot\sum_{j=1}^{K}\beta_{ij}\boldsymbol{\phi}^{(j)}\right\|^2 + \left\|\nabla\times\sum_{j=1}^{K}\beta_{ij}\boldsymbol{\phi}^{(j)}\right\|^2 = 1. \tag{3.28}$$

Since $\mathbf{z}^{(i)} \in \left(H^1(\Omega)\right)^2$, we know that there exist constants $C_0, C_1 > 0$ such that, for all $i > 0$,

$$\|\mathbf{z}^{(i)}\|^2 \le C_0 \left(\|\nabla\mathbf{z}^{(i)}\|^2\right) \le C_1 \left(\|\nabla\cdot\mathbf{z}^{(i)}\|^2 + \|\nabla\times\mathbf{z}^{(i)}\|^2\right) \le C_1, \tag{3.29}$$

where the second inequality can be found in [17] and the last inequality follows from (3.28). In several places in this proof, we make use of the general inequality

$$\|\alpha + \beta\|^2 \le 2(\|\alpha\|^2 + \|\beta\|^2). \tag{3.30}$$

Now, to satisfy (3.27), we combine it with (3.28) and (3.29), using inequality (3.30), to see that we must have

$$\left\|\sum_{j=1}^{K}\beta_{ij}\boldsymbol{\phi}^{(j)}\right\|^2 \ge \frac{i}{2} - C_1 \tag{3.31}$$

for all $i > 0$. We now define $P, N \in \mathbb{R}^{(K\times K)}$ as

$$\begin{aligned} P &:= (p_{kl}) = \left\langle \boldsymbol{\phi}^{(k)},\, \boldsymbol{\phi}^{(l)} \right\rangle, \\ N &:= (n_{kl}) = \left\langle \nabla\cdot\boldsymbol{\phi}^{(k)}, \nabla\cdot\boldsymbol{\phi}^{(l)} \right\rangle + \left\langle \nabla\times\boldsymbol{\phi}^{(k)}, \nabla\times\boldsymbol{\phi}^{(l)} \right\rangle. \end{aligned}$$

Because the $\{\boldsymbol{\phi}^{(j)}\}_{j=1,K}$ are linearly independent and S has no null space (see Lemma 3.4), P and N must be symmetric positive definite matrices. Now, define the vectors

$$\mathbf{b}^{(i)} := (\beta_{i1}, \beta_{i2}, \ldots, \beta_{iK})^t.$$

Equations (3.28) and (3.31) imply

$$\frac{\mathbf{b}^{(i)} \cdot P\mathbf{b}^{(i)}}{\mathbf{b}^{(i)} \cdot N\mathbf{b}^{(i)}} \ge \frac{i}{2} - C_1,$$

which contradicts positive definiteness of N. Therefore, (3.25) holds and S is coercive in the norm defined by (3.13).

To prove coercivity of T, note that, by inequality (3.30), there exists a constant $C_2 > 0$ (dependent only on $\|\mathbf{b}\|$) such that

$$\begin{aligned} \|\mathbf{v}\|_T^2 &\le \|\mathbf{v}\|^2 + 2\|\nabla\cdot(A\mathbf{v}) - \mathbf{b}\cdot\mathbf{v}\|^2 + \|\nabla\times\mathbf{v}\|^2 + 2\|\mathbf{b}\cdot\mathbf{v}\|^2 \\ &\le C_2 \left(\|T\mathbf{v}\|^2 + \|\mathbf{v}\|^2\right) \end{aligned}$$

for all $\mathbf{v} \in \mathcal{D}(T)$. Since T is injective (cf. [11]) and $\mathcal{D}(T)$ is compactly embedded in $\left(L^2(\Omega)\right)^2$, a standard compactness argument establishes coercivity of T.

By coercivity of T and S and the inequality (3.30), there exist constants $C_3, C_4 > 0$ (depending only on $\|\mathbf{b}\|$, $\|c\|$, and $\|d\|$) such that for all $(\mathbf{v}, \mathbf{w}) \in \mathcal{D}(\mathcal{L})$,

$$\begin{aligned} \|(\mathbf{v},\mathbf{w})\|_{\mathcal{L}}^2 = \|\mathbf{v}\|_T^2 + \|\mathbf{w}\|_S^2 &\leq C_3\left(\|T\mathbf{v}\|^2 + \|S\mathbf{w}\|^2\right) \\ &\leq C_4\left(\|T\mathbf{v} - B\mathbf{w}\|^2 + \|\mathbf{v} + S\mathbf{w}\|^2 + \|\mathbf{v}\|^2 + \|\mathbf{w}\|^2\right). \end{aligned}$$

Since $\mathcal{L}$ is injective (see Lemma 3.3) and $\mathcal{D}(\mathcal{L})$ is compactly embedded in $\left(L^2(\Omega)\right)^4$, again we appeal to a standard compactness argument and establish the coercivity of $\mathcal{L}$. □

The main result of this section is the following theorem, which confirms the existence of a dual solution. It is a simple consequence of Theorem 3.5.

THEOREM 3.6. *$\mathcal{L}^* : \mathcal{D}(\mathcal{L}^*) \to \left(L^2(\Omega)\right)^4$ is surjective.*

Proof. It is clear that $(\mathcal{L}^*)^* = \mathcal{L}$. Thus, both $\mathcal{L}$ and $\mathcal{L}^*$ are closed and we may use the closed range theorem. Since $\mathcal{L}$ is coercive (see Theorem 3.5), then $\mathcal{R}(\mathcal{L})$ is closed. The closed range theorem implies that $\mathcal{R}(\mathcal{L}^*)$ is closed. Thus, we know that $\mathcal{R}(\mathcal{L}^*) = \mathcal{N}(\mathcal{L})^\perp$. Since $\mathcal{N}(\mathcal{L})$ is empty, then $\mathcal{L}^*$ is surjective. □

3.1. The case $c = 0$. This is the case that was examined in [12]. In this paper we remove the requirement that Γ_D and Γ_N have at most one component. When $c = 0$, it is useful to choose $d = 0$ because the second and third rows of $\mathcal{L}_0$ in (3.1) only involve $\mathbf{u}$. This allows us to write the primal problem, $\mathcal{L}U = F$, in two stages:

$$T\mathbf{u} = \begin{pmatrix} f \\ 0 \end{pmatrix}, \tag{3.32}$$

$$\nabla p = \mathbf{u}. \tag{3.33}$$

Since T is injective by itself (see the proof of Theorem 3.5), problem (3.32) alone is sufficient to determine $\mathbf{u}$. We can, thus, begin by solving this so-called first-stage equation. The second stage, (3.33), can be then solved for p if needed.

Discontinuous coefficients in A and irregular boundary points on $\partial\Omega$ imply $\mathbf{u} \notin \left(H^1(\Omega)\right)^2$, so we use a FOSLL* formulation to solve (3.32). To accommodate the possibility of multiply connected boundary components, (3.32) is posed on domain $\mathcal{D}(T)$ defined in (3.10). Note, then, that the dual problem for the first stage reads $T^*\mathbf{w} = \mathbf{u}$ and takes the variational form

$$\langle T^*\mathbf{w}, T^*\mathbf{v}\rangle = \left\langle (f,0)^t, \mathbf{v}\right\rangle \text{ for all } \mathbf{v} \in \mathcal{D}(T^*). \tag{3.34}$$

THEOREM 3.7. *Operator $T^* : \mathcal{D}(T^*) \to \left(L^2(\Omega)\right)^2$ is surjective.*

Proof. Coercivity of T was proved for Theorem 3.5 and, by arguments similar to those in Theorem 3.6, we can then prove surjectivity of T^*. □

This theorem establishes existence of a solution for the first stage (3.32). Note that recovery of the solution, p, of the original BVP, (2.1)–(2.3), can then be done by applying a standard FOSLS scheme for the second stage equation, (3.33), i.e., by minimizing $\|\nabla p - \mathbf{u}\|$, where $\mathbf{u} = T^*\mathbf{w}$ is the approximation obtained in the first stage. This minimization is done in an appropriate subspace of $H_D^1(\Omega)$ and leads to an H^1 approximation of p, which is clearly more desirable than the L^2 approximations for p obtained by the general FOSLL* approach for $c \neq 0$.

Remark 3.8. A closer look at the dual problem for the first stage, $T^*\mathbf{w} = \mathbf{u}$, shows that the second component of the dual variable, w_2, is only determined up to a constant. Therefore, without loss of generality, we can restrict the space in which we are looking for $\mathbf{w}$ to

$$\begin{aligned}\bigl\{\mathbf{w} \in \bigl(H^1(\Omega)\bigr)^2 \ :\ & w_1 = 0 \text{ on } \Gamma_D,\\ & w_2 = 0 \text{ on } \Gamma_{N,1}, w_2 \equiv c_i \text{ on } \Gamma_{N,i},\ 2 \le i \le M\bigr\}.\end{aligned}$$

Thus, for the case $c = 0$, standard FOSLL*, as proposed in [12], works well enough, unless Γ_D or Γ_N is not simply connected.

Remark 3.9. A scaled version of the first stage (3.32) that solves for the scaled flux, $\tilde{\mathbf{u}} = A^{1/2}\nabla p$ (see (3.36)), yields a dual problem with better computational performance when used in conjunction with multigrid solvers.

3.2. The case $\mathbf{b} = \mathbf{0}$. For $\mathbf{b} = \mathbf{0}$, we consider two cases: $c > 0$ and $c = 0$. (We exclude the case that c is neither 0 nor strictly positive.) We show in both cases that a scaled form of FOSLL* reduces to the standard Galerkin formulation of (2.1)–(2.3).

Consider, first the case $c > 0$. We can rescale the primal problem by using the scaled primal unknowns, $(\tilde{\mathbf{u}}, \tilde{p}, \tilde{q}) = (A^{1/2}\nabla p, c^{1/2}p, c^{1/2}q)$. The primal operator is then simply a scaled version of L_1 used in standard FOSLL*. The primal problem takes the form

$$\begin{aligned}\tilde{L}_1(\tilde{\mathbf{u}}, \tilde{p}, \tilde{q}) &= (\mathbf{0}, f, 0)^t \text{ in } \Omega,\\ \mathbf{t}\cdot A^{-1/2}\tilde{\mathbf{u}} &= 0 \text{ on } \Gamma_D,\\ \mathbf{n}\cdot A^{1/2}\tilde{\mathbf{u}} &= 0 \text{ on } \Gamma_N,\\ \tilde{p} &= 0 \text{ on } \Gamma_D,\\ \tilde{q} &= 0 \text{ on } \Gamma_N,\end{aligned}$$

where

$$\begin{aligned}\tilde{L}_1(\tilde{\mathbf{u}}, \tilde{p}, \tilde{q}) &:= \begin{bmatrix} A^{-1/2} & -\nabla c^{-1/2} & -\nabla^{\perp} c^{-1/2} \\ \nabla\cdot A^{1/2} & -c^{1/2} & 0 \\ -\nabla\times A^{-1/2} & 0 & 0 \end{bmatrix} \begin{pmatrix} \tilde{\mathbf{u}} \\ \tilde{p} \\ \tilde{q} \end{pmatrix}\\ &= \begin{pmatrix} A^{-1/2}\tilde{\mathbf{u}} - \nabla c^{-1/2}\tilde{p} - \nabla^{\perp} c^{-1/2}\tilde{q} \\ \nabla\cdot(A^{1/2}\tilde{\mathbf{u}}) - c^{1/2}\tilde{p} \\ -\nabla\times(A^{-1/2}\tilde{\mathbf{u}}) \end{pmatrix}.\end{aligned}$$

The domain of this operator is

$$\mathcal{D}(\tilde{L}_1) = \Bigl(H_N(\nabla\cdot A^{1/2};\Omega) \cap H_D(\nabla\times A^{-1/2};\Omega)\Bigr) \times H^1_D(c^{-1/2};\Omega) \times H^1_N(c^{-1/2};\Omega),$$

where $\phi \in H^1_J(c^{-1/2};\Omega)$ if and only if $c^{-1/2}\phi \in H^1_J(\Omega)$. Thus, the dual problem takes the form

$$\tilde{L}_1^*(\mathbf{w}, r, s) = (\tilde{\mathbf{u}}, \tilde{p}, \tilde{q})^t = (A^{1/2}\nabla p, c^{1/2}p, 0)^t \text{ in } \Omega \tag{3.35}$$

on

$$\mathcal{D}(\tilde{L}_1^*) = (H_N(\nabla\cdot;\Omega) \cap H_D(\nabla\times;\Omega)) \times H^1_D(\Omega) \times H^1_N(\Omega),$$

where the adjoint operator has the form

$$\tilde{L}_1^*(\mathbf{w}, r, s) = \begin{bmatrix} A^{-1/2} & -A^{1/2}\nabla & -A^{-1/2}\nabla^{\perp} \\ c^{-1/2}\nabla\cdot & -c^{1/2} & 0 \\ -c^{-1/2}\nabla\times & 0 & 0 \end{bmatrix} \begin{pmatrix} \mathbf{w} \\ r \\ s \end{pmatrix}.$$

Remarkably, this specially scaled problem has a dual solution in $\left(H^1(\Omega)\right)^4$, namely,

$$(\mathbf{w}, r, s) = (\mathbf{0}, -p, 0).$$

Knowing that $\mathbf{w}$ and s vanish in this special case, dual problem (3.35) takes the following variational form:

Find $p \in H^1_D(\Omega)$ such that

$$\langle A\nabla p, \nabla t\rangle + \langle cp, t\rangle = -\langle f, t\rangle$$

for all $t \in H^1_D(\Omega)$.

This is precisely the variational form of the Galerkin approach for BVP (2.1)–(2.3) with $\mathbf{b} = \mathbf{0}$. In other words, FOSLL* yields the same H^1 approximation, p^h, as the Galerkin approach.

Next, consider the case $\mathbf{b} = \mathbf{0}$ and $c = 0$. A scaled two-stage approach leads to the following first stage primal problem:

$$\begin{bmatrix} \nabla\cdot A^{1/2} \\ -\nabla\times A^{-1/2} \end{bmatrix} \tilde{\mathbf{u}} = \begin{pmatrix} f \\ 0 \end{pmatrix} \tag{3.36}$$

on $H_N(\nabla\cdot A^{1/2}; \Omega) \cap H_D(\nabla\times A^{-1/2}; \Omega)$. The corresponding dual problem is

$$-A^{1/2}\nabla w_1 - A^{-1/2}\nabla^{\perp} w_2 = \tilde{\mathbf{u}} = A^{1/2}\nabla p$$

on $H^1_D(\Omega) \times H^1_N(\Omega)$, which obviously has the solution $\mathbf{w} = (-p, 0)$. Knowing that w_2 vanishes leads to the following variational form:

Find $p \in H^1_D(\Omega)$ such that

$$\langle A\nabla p, \nabla t\rangle = -\langle f, t\rangle$$

for all $t \in H^1_D(\Omega)$.

This, again, is precisely the variational form of the Galerkin approach for BVP (2.1)–(2.3) when $\mathbf{b} = \mathbf{0}$ and $c = 0$. Thus, FOSLL* and Galerkin again yield the same H^1 approximation, p^h.

4. Numerical results. Here we report on various numerical results and discuss some implementation issues for the methods proposed in the previous section. All problems in this section were computed with FOSPACK [22]. The linear solver used for the discretized equations was a conjugate gradient iteration (PCG), preconditioned by algebraic multigrid (AMG) using one standard W(1,1)-cycle based on point Gauss–Seidel relaxation. In all cases, the PCG/AMG iterations were applied until the residual norm of the linear system was reduced by a factor of at least 10^{-10}. While this criterion is unnecessarily strong, and is not recommended in practice, it was used to eliminate algebraic error from the analysis of the convergence of the finite element approximations.

First, we show how the improved FOSLL* method performs on the problem proposed in Examples 2.1 and 2.3. One of our improvements was the introduction of

Table 4.1

Error norms, approximate order of discretization convergence, β, and asymptotic AMG convergence factors, ρ, for the improved FOSLL approximations for Example* 4.1 *on a sequence of uniform meshes with mesh sizes h.*

h	1/4	1/8	1/16	1/32	1/64	1/128	1/256

β		1.129	0.956	0.958	0.946	0.923	0.892
ρ	0.20	0.31	0.46	0.65	0.77	0.83	0.87

$\Gamma_Q \subset \Gamma_D$, an additional Dirichlet boundary for the slack variable. For our numerical tests, we chose the domain described in Example 2.1 and

$$\Gamma_Q = \{(x, y) \in \Gamma_D : x \in (0.5, 1) \text{ and } y = 0\}. \tag{4.1}$$

Example 4.1. *We apply the improved FOSLL* method to the BVP from Examples* 2.1 *and* 2.3. *We, thus, use the constructs defined in* (3.7)–(3.21), *with Γ_Q as in* (4.1) *and $d = 1$. The L^2 norms of the errors are shown in Table* 4.1. *Since the primal solution is in $(H^\alpha(\Omega))^4$ only for $\alpha < 2/3$, the optimal asymptotic bounds on these errors is in general proportional to $h^{2/3}$. We compute the approximate order of convergence by computing β such that $(1/2)^\beta$ is equal to the ratio of errors on consecutive grids. The table suggests that the improved FOSLL* approach does indeed achieve these optimal bounds, while the FOSLS and standard FOSLL* methods do not converge at all* (*cf. Tables* 2.1 *and* 2.2).

For the improved FOSLL* method, the four components of the dual solution, $(\mathbf{w}^h, r^h, s^h)$, on the $h = 1/32$ mesh are shown in Figure 4.1. By simply computing $(\mathbf{u}^h, p^h, q^h)^t = \mathcal{L}^*(\mathbf{w}^h, r^h, s^h)$, we obtained L^2 approximations for the primal variables, as shown in Figure 4.2. As these figures and tables show, the improved FOSLL* method yields converging L^2 approximations for the primal variables, $\mathbf{u}$ and p.

Unfortunately, convergence of $\|p-p^h\|_0$ tends to drop to a suboptimal rate if Γ_Q is chosen to be too small, especially when there are irregular points inside the Neumann boundary. Therefore, one has to take care in choosing Γ_Q sufficiently large. On the other hand, choosing such a large Γ_Q with a fixed length seems to inhibit optimal AMG performance: the average per-step residual error reduction factor, which we call ρ, seems to depend on the mesh size h. In fact, $1 - \rho$ seems to be proportional to h^α for some positive α. For Example 4.1, the multigrid reduction factor given in Table 4.1 suggests that $1 - \rho$ is proportional to $h^{3/4}$. This difficulty seems to come from the null space of $\mathcal{L}^*$ as defined in (3.7)–(3.21). This null space is nontrivial since there are no boundary conditions for the first two components of $\mathcal{D}(\mathcal{L}^*)$ on Γ_Q. One remedy could be to use linear solvers that can deal with nontrivial null spaces, such as the MINRES algorithm (cf. [15]). Another remedy is discussed in the next subsection.

Remark 4.2. For $c = 0$, the primal problem can be decomposed as shown in (3.32)–(3.33). Problem (3.32) can be solved by a FOSLL* method. Since this problem only involves the operator T, no Γ_Q is needed. Furthermore, the dual problem of this first stage has a full set of boundary conditions, namely, $w_1 = 0$ on Γ_D, $w_2 = 0$ on $\Gamma_{N,1}$, and $w_2 \equiv$ const. on $\Gamma_{N,i}$, $2 \leq i \leq M$. This full set of boundary conditions leads to optimal multigrid convergence for $c = 0$. To demonstrate this, we tested this approach on Example 4.1 with $c = 0$. Table 4.2 shows the approximation errors and

the multigrid convergence factors for both stages. Here, second-stage equation (3.33) is solved by FOSLS, since we know $p \in H^1(\Omega)$ and can, therefore, obtain H^1 approximations for p. Both finite element and multigrid convergence show optimal behavior.

4.1. Restoring optimal multigrid convergence. A heuristic approach for restoring optimal multigrid convergence (i.e., $\rho \ll 1$) is to choose different boundaries Γ_Q^h on different meshes so that $|\Gamma_Q^h| = O(h)$. The motivation for this is that such a choice for Γ_Q^h should control the dimension of the null space of the discrete operator since only a bounded number of elements could then intersect Γ_Q^h. These null space components that AMG cannot seem to eliminate by itself would then hopefully be attenuated by a fixed number of conjugate gradient steps.

The new difficulty that this choice introduces is that operators S^* and $\mathcal{L}^*$ lose surjectivity in the limit $h \to 0$. This, in turn, impairs finite element convergence as h decreases. Fortunately, this difficulty does not affect coercivity of T nor, as our observations show, convergence of $\|\mathbf{u}^h - \mathbf{u}\|$. Convergence of $\|p^h - p\|$ does degrade,

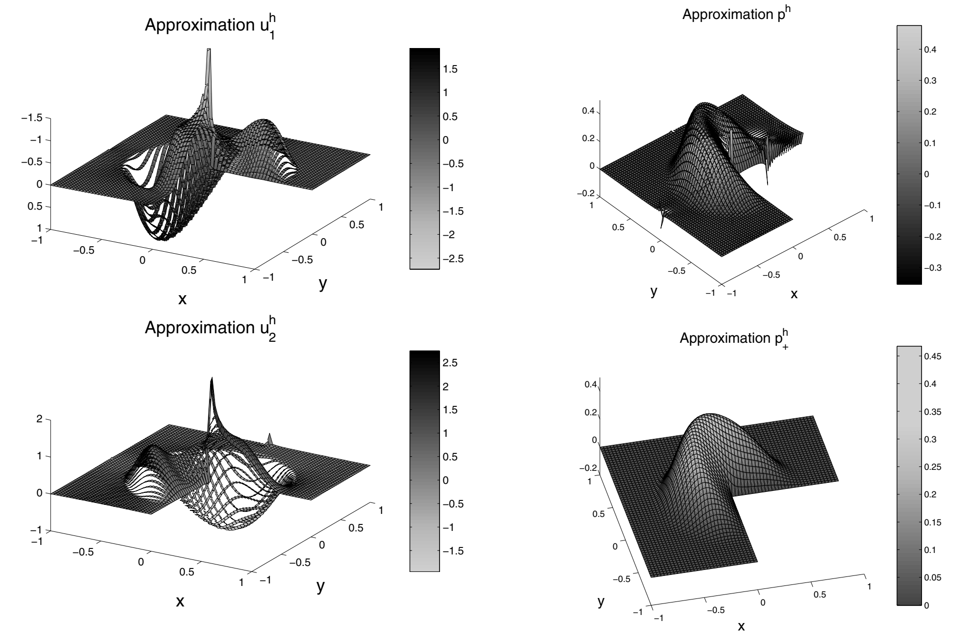

FIG. 4.2. *Approximations p^h and $\mathbf{u}^h$ of primal variables p and $\mathbf{u} = \nabla p$ as well as second-stage approximation p_+^h of p on a uniform mesh with $h = 1/32$ for Example* 4.1.

however, but this can be remedied by appealing to the relation $\nabla p = \mathbf{u}$. That is, we can simply replace p^h by a new approximation, denoted p_+^h, that approximately solves $\nabla p_+^h = \mathbf{u}^h$, where $\mathbf{u}^h$ is the approximation for $\mathbf{u}$ obtained by the improved FOSLL* method with variable Γ_Q^h. This postprocessing step is exactly the same as in (3.33), so we refer to it as the second stage. Since convergence of $\|\mathbf{u}^h - \mathbf{u}\|$ is still optimal for Γ_Q^h, then convergence of $\|p_+^h - p\|$ should be optimal as well. Our implementation solves this second stage by the FOSLS approach of finding $p_+^h = \arg\min \|\nabla z - \mathbf{u}^h\|_0$, where z is chosen from the same H^1-conforming finite element space that was used to approximate the dual solution.

EXAMPLE 4.3. *Using the same problem as in Example* 4.1*, we make a different choice for Γ_Q:*

$$\Gamma_Q^h = \{(x, y) \in \Gamma_D : x \in (1 - 4h, 1), y = 0\},$$

for which $|\Gamma_Q^h| = 4h$. In Table 4.3*, we list the L^2 errors associated with $\mathbf{u}^h$, p^h, and p_+^h. We also include the multigrid convergence factors, ρ, for the solution of the discretized dual problem and the computational cost of the second stage as a percentage of the computational cost of the solution of the discretized dual problem. The results show that our approach leads to optimal multigrid convergence and a very accurate approximation for p at very small additional cost. Approximations p_+^h and p^h for this problem on a mesh with $h = 1/32$ are shown in Figure* 4.2.

Remark 4.4. The second stage yields an H^1 approximation to p, while p^h is in general in $L^2 \backslash H^1$. This desirable feature of this new approach utilizes the higher regularity of p in an efficient way. The approximation is not only in a smoother space, but also more accurate. Thus, the second stage is generally an effective tool to improve convergence of FOSLL*, not only just for the case of variable Γ_Q^h.

improvement of the AMG convergence rates.

5. Conclusions.

In this paper we have developed new FOSLL* formulations that allow the use of H^1-conforming finite element spaces and optimal multigrid solvers for constructing L^2 approximations of the primal variables on an extended class of scalar elliptic equations. This class includes problems with reaction terms, domains with Dirichlet and Neumann boundaries with multiple components, and irregular boundary points. The extension was accomplished by redefining the boundary conditions associated with the slack variables in the primal problem. Specifically, for domains with $\Gamma_D \neq \emptyset$, the slack variable, q, was given additional boundary conditions on $\Gamma_Q \subset \Gamma_D$. Our theory establishes the surjectivity of the adjoint operator, $\mathcal{L}^*$, as long as Γ_Q contains no irregular points. However, numerical results show that the multilevel solution techniques work better, and the finite element approximations are no worse, if Γ_Q is chosen to touch irregular boundary points and to shrink along with the mesh spacing, h. The case of pure Neumann boundary conditions remains an open problem.

The improved FOSLL* approach yields an L^2 approximation to the primal flux variable that achieves the optimal theoretical convergence rate. A postprocessing step was shown to yield optimal H^1 approximation to the original scalar variable, p, at a small additional cost.

We also showed that the FOSLL* formulation produces the same approximation as a Galerkin formulation of the original second-order boundary value problem, (2.1)–(2.3), in the absence of first order terms ($\mathbf{b} = \mathbf{0}$) and either no reaction term ($c = 0$) or strictly positive reaction term ($c > 0$).

The efficiency of the improved FOSLL* formulations was illustrated by a series of numerical examples.

CONVERGENCE ANALYSIS OF THE PERFECTLY MATCHED LAYER PROBLEMS FOR TIME-HARMONIC MAXWELL'S EQUATIONS*

GANG BAO† AND HAIJUN WU‡

Abstract. This paper is concerned with convergence analysis of the perfectly matched layer (PML) problem in spherical coordinates for the three-dimensional electromagnetic scattering. Under some simple assumptions on the PML medium parameter, it is shown that the truncated PML problem attains a unique solution. The main result of the paper is to establish an explicit error estimate between the solution of the scattering problem and that of the truncated PML problem. The error estimate implies, in particular, that the PML solution converges exponentially to the scattering solution by increasing either the PML medium parameter or the PML layer thickness. The convergence result is expected to be useful for determining the PML medium parameter in the computational electromagnetic scattering problems.

Key words. Maxwell's equations, electromagnetic scattering, perfectly matched layer, convergence

DOI. 10.1137/040604315

1. Introduction. Since the pioneering work of Bérenger [3, 4], the perfectly matched layer (PML) has become an increasingly important mesh termination technique in computational wave propagation due to its effectiveness, simplicity, and flexibility [5, 6, 7, 9, 10, 12, 13, 17, 18, 19]. The idea is to surround the computational domain by a nonphysical PML medium which has the remarkable property of being reflectionless for incident waves of any frequency or any incident direction, and the waves decay exponentially in magnitude into the PML medium. In practical computation, the PML medium must be truncated and the truncation boundary generates reflected waves which can pollute the solution in the computational domain. Therefore, it is imperative to study the error estimate in the computational domain between the solution of the wave propagation problem and that of the truncated PML problem.

For a simple two-dimensional model of the electromagnetic scattering by periodic structures, Chen and Wu have recently proved in [5] the exponential convergence with respect to a definite integral of the PML medium parameter. The exponential convergence can be achieved by increasing either the medium parameter or the PML layer thickness. Moreover, the error estimate given in [5] is explicit and can be used to determine the PML medium parameter according to the error tolerance in practical computation. Other convergence results of the PML problems for the Helmholtz scattering may be found in [9, 12, 13, 18]. To the best of our knowledge, there is no convergence result of the truncated PML problem for the three-dimensional

electromagnetic scattering, though the PML technique has been the subject of a substantial engineering literature.

Our goal in this paper is to analyze the convergence of PML solutions for the three-dimensional electromagnetic scattering. Attempts are made to generalize the results of [5] to the PML in spherical coordinates for Maxwell's equations. However, the techniques completely differ due to the more complicated model in the three-dimensional case. Under the assumption that there is a unique solution of the original scattering problem and a proper assumption on the PML medium parameter, we prove in this paper that the truncated PML problem attains a unique solution in $H(\mathrm{curl})$ and obtain an explicit error estimate between the solution of the scattering problem and the solution of the truncated PML problem in the computational domain. The error estimate implies particularly that the PML solution converges exponentially to the scattering solution when either the PML medium parameter or the layer thickness is increased. The significance of our main result is twofold:

- new error estimates for a fixed PML layer thickness;
- explicit constants in the estimates which may be used to determine the PML constants in the computational electromagnetic scattering.

Our proof is based on a variational approach. A crucial step is to conduct a careful analysis of special functions, for example, the Bessel functions and the spherical Hankel functions.

2. PML formulation in spherical coordinates.

We first introduce the scattering problem. Suppose that a bounded medium characterized by permittivity ε and permeability μ is illuminated by a time-harmonic electromagnetic wave (E^{in}, H^{in}), where E^{in} is the electric field and H^{in} is the magnetic field. The incoming wave (E^{in}, H^{in}) is assumed to be a classical solution of the Maxwell system

$$\operatorname{curl} E^{in} = \mathbf{i}\omega\mu_0 H^{in} \quad \text{and} \quad \operatorname{curl} H^{in} = -\mathbf{i}\omega\varepsilon_0 E^{in} \quad \text{in } \mathbb{R}^3. \tag{2.1}$$

Here ε_0 and μ_0 are two positive constants. The interaction of the incident field and the medium gives rise to the scattered field (E^{sc}, H^{sc}). Let ε, μ be two functions of the spatial variable $x = (x_1, x_2, x_3)^T$, and $r = |x|$. Then the scattered field satisfies the time-harmonic Maxwell system

$$\begin{cases} \operatorname{curl} E^{sc} = \mathbf{i}\omega\mu H^{sc} + \mathbf{i}\omega(\mu H^{in} - \mu_0 H^{in}) & \text{in } \mathbb{R}^3, \\ \operatorname{curl} H^{sc} = -\mathbf{i}\omega\varepsilon E^{sc} - \mathbf{i}\omega(\varepsilon E^{in} - \varepsilon_0 E^{in}) & \text{in } \mathbb{R}^3, \\ \lim_{r\to+\infty}(\sqrt{\mu_0} H^{sc} \wedge x - r\sqrt{\varepsilon_0} E^{sc}) = 0. \end{cases} \tag{2.2}$$

Assume that ε and μ, respectively, are in $(L^\infty(\mathbb{R}^3))^{3\times 3}$, and so are ε^{-1} and μ^{-1}. Assume also that the inhomogeneity is bounded so that there is a constant $R > 0$ such that $\varepsilon(x) = \varepsilon_0 I$ and $\mu(x) = \mu_0 I$ if $r = |x| \geq R$, where I is the 3×3 identity matrix. Denote the ball of radius by R and its surface by $\Omega = \{x \in \mathbb{R}^3, |x| < R\}$, respectively, and $S = \{x \in \mathbb{R}^3, |x| = R\}$.

Next, introduce the PML medium in spherical coordinates (r, θ, φ), where θ and φ are the Euler angles: $x_1 = r \sin\theta\cos\varphi,\ x_2 = r\sin\theta\sin\varphi,\ x_3 = r\cos\theta$.

For any point x, let $\vec{e_r}, \vec{e_\theta}$, and $\vec{e_\varphi}$ be the local orthonormal basis, i.e.,

$$\begin{cases} \vec{e_r} = (\sin\theta\cos\varphi, \sin\theta\sin\varphi, \cos\theta)^T = x/r, \\ \vec{e_\theta} = (\cos\theta\cos\varphi, \cos\theta\sin\varphi, -\sin\theta)^T, \\ \vec{e_\varphi} = (-\sin\varphi, \cos\varphi, 0)^T. \end{cases} \tag{2.3}$$

For any vector field $v = (v_1, v_2, v_3)^T$, denote by v_r, v_θ, and v_φ the projections of v onto $\vec{e_r}$, $\vec{e_\theta}$, and $\vec{e_\varphi}$, respectively,

$$v_r = v \cdot \vec{e_r}, \quad v_\theta = v \cdot \vec{e_\theta}, \quad v_\varphi = v \cdot \vec{e_\varphi}. \tag{2.4}$$

Let $Q = \begin{pmatrix} \vec{e_r} & \vec{e_\theta} & \vec{e_\varphi} \end{pmatrix}$ be a 3×3 matrix composed of $\vec{e_r}, \vec{e_\theta}$, and $\vec{e_\varphi}$. It is clear that

$$\begin{pmatrix} v_r & v_\theta & v_\varphi \end{pmatrix}^T = Q^T \begin{pmatrix} v_1 & v_2 & v_3 \end{pmatrix}^T, \quad \begin{pmatrix} v_1 & v_2 & v_3 \end{pmatrix}^T = Q \begin{pmatrix} v_r & v_\theta & v_\varphi \end{pmatrix}^T. \tag{2.5}$$

Furthermore,

$$\begin{aligned} \operatorname{curl} v = {} & \frac{1}{r \sin\theta} \left(\frac{\partial(\sin\theta v_\varphi)}{\partial\theta} - \frac{\partial v_\theta}{\partial\varphi} \right) \vec{e_r} + \left(\frac{1}{r\sin\theta} \frac{\partial v_r}{\partial\varphi} - \frac{1}{r} \frac{\partial(r v_\varphi)}{\partial r} \right) \vec{e_\theta} \\ & + \frac{1}{r} \left(\frac{\partial(r v_\theta)}{\partial r} - \frac{\partial v_r}{\partial\theta} \right) \vec{e_\varphi}. \end{aligned} \tag{2.6}$$

Obviously, the scattered field (E^{sc}, H^{sc}) outside the ball Ω satisfies the following Faraday equation and Ampere equation (Maxwell's equations):

$$\operatorname{curl} E^{sc} = \mathbf{i}\omega\mu_0 H^{sc} \quad \text{and} \quad \operatorname{curl} H^{sc} = -\mathbf{i}\omega\varepsilon_0 E^{sc} \quad \text{in } \mathbb{R}^3 \setminus \overline{\Omega}. \tag{2.7}$$

In the spherical coordinates, Faraday's equation becomes

$$\begin{cases} \dfrac{1}{r\sin\theta} \left(\dfrac{\partial(\sin\theta E^{sc}_\varphi)}{\partial\theta} - \dfrac{\partial E^{sc}_\theta}{\partial\varphi} \right) = \mathbf{i}\omega\mu_0 H^{sc}_r & \text{in } \mathbb{R}^3 \setminus \overline{\Omega}, \\ \dfrac{1}{r\sin\theta} \dfrac{\partial E^{sc}_r}{\partial\varphi} - \dfrac{1}{r} \dfrac{\partial(r E^{sc}_\varphi)}{\partial r} = \mathbf{i}\omega\mu_0 H^{sc}_\theta & \text{in } \mathbb{R}^3 \setminus \overline{\Omega}, \\ \dfrac{1}{r} \left(\dfrac{\partial(r E^{sc}_\theta)}{\partial r} - \dfrac{\partial E^{sc}_r}{\partial\theta} \right) = \mathbf{i}\omega\mu_0 H^{sc}_\varphi & \text{in } \mathbb{R}^3 \setminus \overline{\Omega}. \end{cases} \tag{2.8}$$

Following Teixeira and Chew [17], we introduce the PML problem by a change of variables,

$$r \to \int_0^{\hat r} s(\tau)\, d\tau, \tag{2.9}$$

where $s(\tau) = 1 + \mathbf{i}s_I(\tau)$ is continuous, $s_I(\tau) \geq 0$ and $s_I(\tau) = 0$ for $0 \leq \tau \leq R$. In the Cartesian coordinates, the change of variables is equivalent to

$$x \to \hat{x} = (\hat r \sin\theta\cos\varphi, \hat r \sin\theta\sin\varphi, \hat r\cos\theta). \tag{2.10}$$

It is clear that $s(\tau) = 1$ and $r = \hat r$, $x = \hat x$ for $0 \leq \hat r \leq R$.

Noting that $\partial/\partial r = (1/s(\hat r))\partial/\partial \hat r$ and $E^{sc}_r = E^{sc}_{\hat r}$, $H^{sc}_r = H^{sc}_{\hat r}$, we have from (2.8) that

$$\begin{cases} \dfrac{1}{r\sin\theta} \left(\dfrac{\partial(\sin\theta E^{sc}_\varphi)}{\partial\theta} - \dfrac{\partial E^{sc}_\theta}{\partial\varphi} \right) = \mathbf{i}\omega\mu_0 H^{sc}_{\hat r} & \text{in } \mathbb{R}^3 \setminus \overline{\Omega}, \\ \dfrac{1}{r\sin\theta} \dfrac{\partial E^{sc}_{\hat r}}{\partial\varphi} - \dfrac{1}{r s(\hat r)} \dfrac{\partial(r E^{sc}_\varphi)}{\partial \hat r} = \mathbf{i}\omega\mu_0 H^{sc}_\theta & \text{in } \mathbb{R}^3 \setminus \overline{\Omega}, \\ \dfrac{1}{r} \left(\dfrac{1}{s(\hat r)} \dfrac{\partial(r E^{sc}_\theta)}{\partial \hat r} - \dfrac{\partial E^{sc}_{\hat r}}{\partial\theta} \right) = \mathbf{i}\omega\mu_0 H^{sc}_\varphi & \text{in } \mathbb{R}^3 \setminus \overline{\Omega}. \end{cases}$$

Multiplying the first equation by $(r/\hat{r})^2$, the second and the third equations by $s(\hat{r})(r/\hat{r})$, and denoting by

$$\begin{aligned} E_{\hat{r}}^{sc,\mathrm{PML}} &= s(\hat{r})E_{\hat{r}}^{sc}, \quad E_{\theta}^{sc,\mathrm{PML}} = \frac{r}{\hat{r}}E_{\theta}^{sc}, \quad E_{\varphi}^{sc,\mathrm{PML}} = \frac{r}{\hat{r}}E_{\varphi}^{sc}, \\ H_{\hat{r}}^{sc,\mathrm{PML}} &= s(\hat{r})H_{\hat{r}}^{sc}, \quad H_{\theta}^{sc,\mathrm{PML}} = \frac{r}{\hat{r}}H_{\theta}^{sc}, \quad H_{\varphi}^{sc,\mathrm{PML}} = \frac{r}{\hat{r}}H_{\varphi}^{sc}, \end{aligned} \tag{2.11}$$

we obtain the Faraday equation for the PML medium in $\{\hat{x} \in \mathbb{R}^3 \setminus \overline{\Omega}\}$:

$$\begin{cases} \dfrac{1}{\hat{r}\sin\theta}\left(\dfrac{\partial(\sin\theta E_{\varphi}^{sc,\mathrm{PML}})}{\partial\theta} - \dfrac{\partial E_{\theta}^{sc,\mathrm{PML}}}{\partial\varphi}\right) = \mathbf{i}\omega\mu_0\left(\left(\dfrac{r}{\hat{r}}\right)^2\dfrac{1}{s(\hat{r})}\right)H_{\hat{r}}^{sc,\mathrm{PML}}, \\ \dfrac{1}{\hat{r}\sin\theta}\dfrac{\partial E_{\hat{r}}^{sc,\mathrm{PML}}}{\partial\varphi} - \dfrac{1}{\hat{r}}\dfrac{\partial(\hat{r}E_{\varphi}^{sc,\mathrm{PML}})}{\partial\hat{r}} = \mathbf{i}\omega\mu_0 s(\hat{r})H_{\theta}^{sc,\mathrm{PML}}, \\ \dfrac{1}{\hat{r}}\left(\dfrac{\partial(\hat{r}E_{\theta}^{sc,\mathrm{PML}})}{\partial\hat{r}} - \dfrac{\partial E_{\hat{r}}^{sc,\mathrm{PML}}}{\partial\theta}\right) = \mathbf{i}\omega\mu_0 s(\hat{r})H_{\varphi}^{sc,\mathrm{PML}}. \end{cases} \tag{2.12}$$

The Ampere equation for the PML medium may be derived similarly.

Furthermore, from (2.5) and (2.6), we rewrite Maxwell's equations for the PML medium in the Cartesian coordinates as

$$\mathrm{curl}_{\hat{x}}\, E^{sc,\mathrm{PML}} = \mathbf{i}\omega\hat{\mu}H^{sc,\mathrm{PML}} \quad \text{and} \quad \mathrm{curl}_{\hat{x}}\, H^{sc,\mathrm{PML}} = -\mathbf{i}\omega\hat{\varepsilon}E^{sc,\mathrm{PML}},$$

where

$$\hat{\varepsilon} = \widehat{Q}\varepsilon, \quad \hat{\mu} = \widehat{Q}\mu, \quad \widehat{Q} = Q\,\mathrm{diag}((r/\hat{r})^2/s(\hat{r}),\ s(\hat{r}),\ s(\hat{r}))Q^T, \tag{2.13}$$

and $Q = \begin{pmatrix}\vec{e_r} & \vec{e_\theta} & \vec{e_\varphi}\end{pmatrix}$. Note that $\hat{\varepsilon} = \varepsilon$ and $\hat{\mu} = \mu$ for $x \in \Omega$.

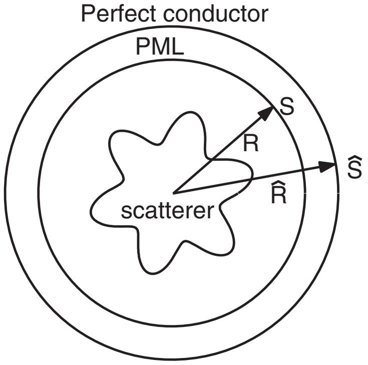

FIG. 2.1. *Geometry of the scattering with truncated PML.*

In practical computation, the PML medium is truncated by a perfect conductor boundary condition on $\widehat{S} = \{\hat{x} \in \mathbb{R}^3, |\hat{x}| = \widehat{R}\}$ for some $\widehat{R} > R$ (see Figure 2.1). Denote by $\widehat{\Omega} = \{\hat{x} \in \mathbb{R}^3, |\hat{x}| < \widehat{R}\}$. Then the scattering problem with a truncated PML takes the following form: find $(\widehat{E}^{sc,\mathrm{PML}}, \widehat{H}^{sc,\mathrm{PML}})$ such that

$$\begin{cases} \mathrm{curl}_{\hat{x}}\, \widehat{E}^{sc,\mathrm{PML}} = \mathbf{i}\omega\hat{\mu}\widehat{H}^{sc,\mathrm{PML}} + \mathbf{i}\omega(\mu H^{in} - \mu_0 H^{in}) & \text{in } \widehat{\Omega}, \\ \mathrm{curl}_{\hat{x}}\, \widehat{H}^{sc,\mathrm{PML}} = -\mathbf{i}\omega\hat{\varepsilon}\widehat{E}^{sc,\mathrm{PML}} - \mathbf{i}\omega(\varepsilon E^{in} - \varepsilon_0 E^{in}) & \text{in } \widehat{\Omega}, \\ \widehat{E}^{sc,\mathrm{PML}} \wedge n = 0 & \text{on } \widehat{S}. \end{cases} \tag{2.14}$$

The goal of the paper is to estimate the error between $(\widehat{E}^{sc,\mathrm{PML}}, \widehat{H}^{sc,\mathrm{PML}})$ and (E^{sc}, H^{sc}).

3. The main result. We begin with the variational form of the scattering problem (2.2). For any smooth vector field v, denote by v_S its tangential component on the surface S:

$$v_S = -(v \wedge n) \wedge n \quad \text{on } S, \tag{3.1}$$

where $n = \vec{e_r}$ is the unit outer normal vector to S. Introduce the following usual functional spaces:

$$\begin{aligned}
&H(\mathrm{curl}, \Omega) = \{u \in (L^2(\Omega))^3,\ \mathrm{curl}\, u \in (L^2(\Omega))^3\},\\
&TL^2(S) = \{u \in (L^2(S))^3,\ u \cdot n = 0\},\\
&TH^{-1/2}(\mathrm{curl}, S) = \{u \in (H^{-1/2}(S))^3,\ u \cdot n = 0,\ \mathrm{curl}_S\, u \in H^{-1/2}(S)\},\\
&TH^{-1/2}(\mathrm{div}, S) = \{u \in (H^{-1/2}(S))^3,\ u \cdot n = 0,\ \mathrm{div_S}\, u \in H^{-1/2}(S)\}.
\end{aligned}$$

For the definitions of the surface divergence $\mathrm{div_S}$ and the scalar rotational curl_S, we refer to [14]. Recall the following Paquet duality result [16]: $TH^{-1/2}(\mathrm{curl}, S) = TH^{-1/2}(\mathrm{div}, S)'$.

Following Ammari and Nédélec [1], define the capacity operator $\mathcal{T}_S$ from $TH^{-1/2}$ (curl, S) to $TH^{-1/2}(\mathrm{div}, S)$:

$$\mathcal{T}_S u = \mathcal{H} \wedge n, \tag{3.2}$$

where

$$\begin{cases}
\mathrm{curl}\, \mathcal{E} = \mathbf{i}\omega\mu_0 \mathcal{H} \quad \text{and} \quad \mathrm{curl}\, \mathcal{H} = -\mathbf{i}\omega\varepsilon_0 \mathcal{E} & \text{in } \mathbb{R}^3 \setminus \overline{\Omega},\\
\mathcal{E}_S = u & \text{on } S,\\
\lim_{r\to+\infty} \left(\sqrt{\mu_0}\mathcal{H} \wedge x - r\sqrt{\varepsilon_0}\mathcal{E}\right) = 0.
\end{cases} \tag{3.3}$$

From (2.2), it is easily seen that

$$H^{sc} \wedge n = \mathcal{T}_S E^{sc}_S \quad \text{on } S. \tag{3.4}$$

By eliminating the magnetic field H^{sc} from (2.2), we obtain

$$\mathrm{curl}(\mu^{-1}\, \mathrm{curl}\, E^{sc}) - \omega^2 \varepsilon E^{sc} = f^{in} \quad \text{in } \Omega, \tag{3.5}$$

where

$$f^{in} = -\mathbf{i}\omega\mu_0\, \mathrm{curl}(\mu^{-1} H^{in}) + \omega^2 \varepsilon E^{in}. \tag{3.6}$$

Multiplying (3.5) by a test function $\phi \in H(\mathrm{curl}, \Omega)$, integrating over Ω, and using integration by parts, we arrive at the variational form for the scattering problem (2.2): find $E^{sc} \in H(\mathrm{curl}, \Omega)$ such that

$$A(E^{sc}, \phi) = \langle f^{in}, \phi\rangle \quad \forall \phi \in H(\mathrm{curl}, \Omega), \tag{3.7}$$

where the bilinear form

$$A(v, \phi) = \int_\Omega \mu^{-1}\, \mathrm{curl}\, v \cdot \mathrm{curl}\, \phi - \omega^2 \int_\Omega \varepsilon v \cdot \phi - \mathbf{i}\omega \int_S \mathcal{T}_S v_S \cdot \phi_S \tag{3.8}$$

and

$$\langle f^{in}, \phi\rangle = -\mathbf{i}\omega\mu_0 \int_\Omega \mu^{-1} H^{in}\cdot \operatorname{curl}\phi + \mathbf{i}\omega \int_S H^{in}\wedge n\cdot \phi_S + \omega^2 \int_\Omega \varepsilon E^{in}\cdot\phi. \tag{3.9}$$

Assume in the following that the variational problem (3.7) attains a unique solution. Then the general theory in Babuška and Aziz [2, Chapter 5] implies that there exists a constant $\gamma_1 > 0$ such that the following inf-sup condition holds:

$$\sup_{0\neq\phi\in H(\operatorname{curl},\Omega)} \frac{|A(v,\phi)|}{\|\phi\|_{H(\operatorname{curl},\Omega)}} \geq \gamma_1 \|v\|_{H(\operatorname{curl},\Omega)} \quad \forall v\in H(\operatorname{curl},\Omega). \tag{3.10}$$

See also Kirsch and Monk [11] for additional discussions on the variational problem.

Similarly, we introduce a variational form for the truncated PML scattering problem (2.14) by defining a capacity operator $\mathcal{T}_S^{\mathrm{PML}}$ from $TH^{-1/2}(\operatorname{curl}, S)$ to $TH^{-1/2}(\operatorname{div}, S)$:

$$\mathcal{T}_S^{\mathrm{PML}} u = \mathcal{H}^{\mathrm{PML}}\wedge n, \tag{3.11}$$

where

$$\begin{cases} \operatorname{curl}_{\hat{x}} \mathcal{E}^{\mathrm{PML}} = \mathbf{i}\omega\hat{\mu}\mathcal{H}^{\mathrm{PML}} \quad \text{and} \quad \operatorname{curl}_{\hat{x}} \mathcal{H}^{\mathrm{PML}} = -\mathbf{i}\omega\hat{\varepsilon}\mathcal{E}^{\mathrm{PML}} & \text{in } \mathbb{R}^3\setminus\overline{\Omega}, \\ \mathcal{E}_S^{\mathrm{PML}} = u & \text{on } S, \\ \mathcal{E}^{\mathrm{PML}}\wedge n = 0 & \text{on } \widehat{S}. \end{cases} \tag{3.12}$$

It follows from (2.14) that

$$\widehat{H}^{sc,\mathrm{PML}}\wedge n = \mathcal{T}_S^{\mathrm{PML}} \widehat{E}_S^{sc,\mathrm{PML}} \quad \text{on } S. \tag{3.13}$$

For $x\in\Omega$, since $\hat{\varepsilon} = \varepsilon$ and $\hat{\mu} = \mu$, the fields $(\widehat{E}^{sc,\mathrm{PML}}, \widehat{H}^{sc,\mathrm{PML}})$ and (E^{sc}, H^{sc}) satisfy the same equation. Therefore, we have the variational form of (2.14): find $\widehat{E}^{sc,\mathrm{PML}}\in H(\operatorname{curl},\Omega)$ such that

$$A^{\mathrm{PML}}(\widehat{E}^{sc,\mathrm{PML}}, \phi) = \langle f^{in}, \phi\rangle \quad \forall\phi\in H(\operatorname{curl},\Omega), \tag{3.14}$$

where the bilinear form

$$A^{\mathrm{PML}}(v,\phi) = \int_\Omega \mu^{-1}\operatorname{curl} v\cdot\operatorname{curl}\phi - \omega^2\int_\Omega \varepsilon v\cdot\phi - \mathbf{i}\omega\int_S \mathcal{T}_S^{\mathrm{PML}} v_S\cdot\phi_S. \tag{3.15}$$

In order to estimate the error between $\widehat{E}^{sc,\mathrm{PML}}$ and E^{sc}, it is sufficient to estimate the error between the two capacity operators $\mathcal{T}_S^{\mathrm{PML}}$ and $\mathcal{T}_S$. We have the following important lemma that will be proved in section 6.

Lemma 3.1. *Let*

$$\widetilde{R}_I = \int_R^{\widehat{R}} s_I(\tau)\,d\tau \quad \textit{and} \quad a = \min\left\{\frac{1}{2}, \frac{kR}{5}\right\}. \tag{3.16}$$

Suppose

$$\widetilde{R}_I \geq \max\{7R/5,\ \widehat{R},\ 17/k\}. \tag{3.17}$$

Then for any $v_S, \phi_S \in TH^{-1/2}(\mathrm{curl}, S)$,

$$\left|\omega \int_S (\mathcal{T}_S^{\mathrm{PML}} - \mathcal{T}_S) v_S \cdot \phi_S\right| \leq \mathcal{M} \, \|v_S\|_{TH^{-1/2}(\mathrm{curl},S)} \, \|\phi_S\|_{TH^{-1/2}(\mathrm{curl},S)} \,,$$

where

$$\mathcal{M} = \frac{4k(a\mu_0)^{-1} \max\{(kR)^2(3kR+3/2)^2, 1\}}{e^{k\widetilde{R}_I[2-(a\widetilde{R}_I/R)^{-2}+(a\widetilde{R}_I/R)^{-4}/19]} - 10}. \tag{3.18}$$

Remark 3.1. The constant $\widetilde{R}_I$ is known as the PML parameter. Here, we examine the structure of the constant $\mathcal{M}$ which controls the modeling error between the PML equation and the original scattering problem (see Theorem 3.2). Obviously, the constant $\mathcal{M}$ approaches zero exponentially as the PML parameters $\widetilde{R}_I$ goes to infinity. From definition (3.16), $\widetilde{R}_I$ may be calculated by the medium property $s_I(\tau)$, which is usually taken as a power function

$$s_I(\tau) = \delta_m[(\tau - R)/(\widehat{R} - R)]^m \quad \text{for } \tau \geq R, \quad m \geq 1.$$

Thus,

$$\widetilde{R}_I = \delta_m(\widehat{R} - R)/(m+1). \tag{3.19}$$

It is obvious that the PML approximation error is reduced by either enlarging the medium parameter δ_m or increasing the layer thickness $\widehat{R} - R$.

Recall the trace regularity result for $H(\mathrm{curl}, \Omega)$ (cf. [14]):

$$\|v_S\|_{TH^{-1/2}(\mathrm{curl},S)} \leq \gamma_0 \, \|v\|_{H(\mathrm{curl},\Omega)} \quad \forall v \in H(\mathrm{curl}, \Omega), \tag{3.20}$$

where γ_0 is a positive constant. We are now ready to present the main result of this paper.

Theorem 3.2. *Assume that* (3.10) *and* (3.17) *hold.*

(i) *If* $\mathcal{M}\gamma_0^2 < \gamma_1$, *then the PML variational problem* (3.14) *attains a unique solution. Furthermore, the following a priori estimate (dependent on the original scattering solution) holds:*

$$\begin{aligned} |||\widehat{E}^{sc,\mathrm{PML}} - E^{sc}||| &:= \sup_{0 \neq \phi \in H(\mathrm{curl},\Omega)} \frac{|A(\widehat{E}^{sc,\mathrm{PML}} - E^{sc}, \phi)|}{\|\phi\|_{H(\mathrm{curl},\Omega)}} \\ &\leq \frac{\mathcal{M}\gamma_0^2}{1 - \mathcal{M}\gamma_0^2/\gamma_1} \|E^{sc}\|_{H(\mathrm{curl},\Omega)}. \end{aligned} \tag{3.21}$$

(ii) *If the PML variational problem* (3.14) *has a solution* $\widehat{E}^{sc,\mathrm{PML}} \in H(\mathrm{curl}, \Omega)$, *then the following a posteriori estimate (dependent on the PML solution) holds:*

$$|||\widehat{E}^{sc,\mathrm{PML}} - E^{sc}||| \leq \mathcal{M}\gamma_0^2 \|\widehat{E}^{sc,\mathrm{PML}}\|_{H(\mathrm{curl},\Omega)}, \tag{3.22}$$

where γ_0 *is defined in* (3.20), γ_1 *and* $\mathcal{M}$ *are defined in* (3.10) *and* (3.18), *respectively.*

Proof. We first prove (ii). By the definitions (3.8) and (3.15) of A and A^{PML}, Lemma 3.1, and the trace regularity (3.20), we have

$$\begin{aligned} |A^{\mathrm{PML}}(v, \phi) - A(v, \phi)| &= \left|\omega \int_S (\mathcal{T}_S^{\mathrm{PML}} - \mathcal{T}_S) v_S \cdot \phi_S\right| \\ &\leq \mathcal{M}\gamma_0^2 \, \|v\|_{H(\mathrm{curl},\Omega)} \, \|\phi\|_{H(\mathrm{curl},\Omega)}. \end{aligned} \tag{3.23}$$

Hence from (3.7) and (3.14), we conclude that

$$\begin{aligned}|A(\widehat{E}^{sc,\mathrm{PML}} - E^{sc}, \phi)| &= |A(\widehat{E}^{sc,\mathrm{PML}}, \phi) - A^{\mathrm{PML}}(\widehat{E}^{sc,\mathrm{PML}}, \phi)| \\ &\le \mathcal{M}\gamma_0^2 \|\widehat{E}^{sc,\mathrm{PML}}\|_{H(\mathrm{curl},\Omega)} \|\phi\|_{H(\mathrm{curl},\Omega)},\end{aligned}$$

which implies (3.22).

Next we prove (i). From (3.10), the assumption $\mathcal{M}\gamma_0^2 < \gamma_1$, and (3.23), we conclude that the bilinear form, $A^{\mathrm{PML}} : H(\mathrm{curl},\Omega) \times H(\mathrm{curl},\Omega) \to \mathbf{C}$, defined in (3.15) satisfies the inf-sup condition. Therefore, the PML variational problem (3.14) attains a unique solution. Finally, the error estimate (3.21) follows from (3.22) and (3.10). □

Remark 3.2. Since the norm $|||\cdot|||$ is equivalent to the norm $\|\cdot\|_{H(\mathrm{curl},\Omega)}$ with $|||\cdot||| \ge \gamma_1 \|\cdot\|_{H(\mathrm{curl},\Omega)}$ (cf. (3.10)), the error estimate between E^{sc} and $\widehat{E}^{sc,\mathrm{PML}}$ in $H(\mathrm{curl},\Omega)$ is easily obtained from Theorem 3.2. Having established the error estimate for the electric field, the error estimate between the magnetic fields H^{sc} and $\widehat{H}^{sc,\mathrm{PML}}$ in $H(\mathrm{curl},\Omega)$ may be obtained by examining the following system:

$$\begin{cases}\widehat{H}^{sc,\mathrm{PML}} - H^{sc} = (\mathbf{i}\omega\mu)^{-1}\,\mathrm{curl}(\widehat{E}^{sc,\mathrm{PML}} - E^{sc}) & \text{in } \Omega,\\ \mathrm{curl}(\widehat{H}^{sc,\mathrm{PML}} - H^{sc}) = -\mathbf{i}\omega\varepsilon(\widehat{E}^{sc,\mathrm{PML}} - E^{sc}) & \text{in } \Omega,\end{cases}$$

which is derived from (2.2), (2.14), and the fact that $\hat{x} = x$, $\hat{\varepsilon} = \varepsilon$, and $\hat{\mu} = \mu$ for $x \in \Omega$.

4. Capacity operators. This section is devoted to the derivation of explicit representations of the capacity operators $\mathcal{T}_S$ and $\mathcal{T}_S^{\mathrm{PML}}$. We first present series solutions for (3.3) and (3.12). We also give explicit representations of the capacity operators $\mathcal{T}_S$ and $\mathcal{T}_S^{\mathrm{PML}}$.

We start by representing the boundary data in terms of suitable vector basis functions on S. Following [8], let $Y_l^m(\theta,\varphi)$ be an orthonormal sequence of spherical harmonics on the unit sphere that satisfies (cf. [8])

$$\Delta_S Y_l^m + l(l+1)Y_l^m = 0, \tag{4.1}$$

where $\Delta_S = \frac{1}{\sin\theta}\frac{\partial}{\partial\theta}(\sin\theta\frac{\partial}{\partial\theta}) + \frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\varphi^2}$ is the Laplace–Beltrami operator on S. Let $\nabla_S = \vec{e_\theta}\frac{\partial}{\partial\theta} + \vec{e_\varphi}\frac{1}{\sin\theta}\frac{\partial}{\partial\varphi}$ be the tangential gradient on S. Then an orthonormal basis for $TL^2(S)$ (the tangential fields on S) consists of functions of the form

$$V_l^m = \frac{1}{R\sqrt{l(l+1)}}\nabla_S Y_l^m \quad \text{and} \quad U_l^m = V_l^m \wedge n. \tag{4.2}$$

It follows that any tangential vector field $u \in TL^2(S)$ may be represented as

$$u = \sum_{l=1}^{\infty}\sum_{m=-l}^{l}\left[c_l^m U_l^m + d_l^m V_l^m\right].$$

Using the series coefficients (see [14] or [1]), the norm on the space $TH^{-1/2}(\mathrm{curl},S)$ may be characterized by

$$\|u\|_{TH^{-1/2}(\mathrm{curl},S)}^2 = \sum_{l=1}^{\infty}\sum_{m=-l}^{l}\left[\sqrt{1+l(l+1)}\,|c_l^m|^2 + \frac{1}{\sqrt{1+l(l+1)}}\,|d_l^m|^2\right]. \tag{4.3}$$

To represent the solutions, we need the first kind and second kind of spherical Hankel functions,

$$h_l^{(1)}(z) = (-\mathbf{i})^l \frac{e^{\mathbf{i}z}}{z} \sum_{m=0}^{l} \mathbf{i}^m \frac{(m+l)!}{m!(l-m)!2^m z^m}, \quad h_l^{(2)}(z) = \overline{h_l^{(1)}(\bar{z})}. \tag{4.4}$$

Define

$$\mathsf{z}_l^{(1)}(z) = z\frac{\frac{d}{dz}h_l^{(1)}(z)}{h_l^{(1)}(z)}, \quad \mathsf{z}_l^{(2)}(z) = \overline{\mathsf{z}_l^{(1)}(\bar{z})} = z\frac{\frac{d}{dz}h_l^{(2)}(z)}{h_l^{(2)}(z)}. \tag{4.5}$$

From the spherical harmonic expansion (cf. [8, Theorems 6.24 and 6.25]) of the radiating solution of (3.3), (2.6), (4.1), the definitions of ∇_S, Δ_S, and a simple calculation, we get

$$\begin{aligned} \mathcal{E} = &\sum_{l=1}^{\infty}\sum_{m=-l}^{l} \sqrt{\mu_0} h_l^{(1)}(kr) \\ &\times \left\{ u_l^m \nabla_S Y_l^m \wedge n + \frac{v_l^m}{\mathbf{i}kr}\left[\left(1+\mathsf{z}_l^{(1)}(kr)\right)\nabla_S Y_l^m + l(l+1)Y_l^m n\right]\right\}, \end{aligned} \tag{4.6}$$

$$\begin{aligned} \mathcal{H} = &\sum_{l=1}^{\infty}\sum_{m=-l}^{l} \sqrt{\varepsilon_0} h_l^{(1)}(kr) \\ &\times \left\{ -v_l^m \nabla_S Y_l^m \wedge n + \frac{u_l^m}{\mathbf{i}kr}\left[\left(1+\mathsf{z}_l^{(1)}(kr)\right)\nabla_S Y_l^m + l(l+1)Y_l^m n\right]\right\}. \end{aligned} \tag{4.7}$$

By using the definition of ∇_S, and noting that $n = \vec{e_r}$ and $\vec{e_\theta} \wedge \vec{e_r} = -\vec{e_\varphi}$, $\vec{e_\varphi} \wedge \vec{e_r} = \vec{e_\theta}$ (see (2.3)), we have on S,

$$\mathcal{E}_S = \sum_{l=1}^{\infty}\sum_{m=-l}^{l} \sqrt{\mu_0} h_l^{(1)}(kR) \left\{ u_l^m \nabla_S Y_l^m \wedge n + \frac{v_l^m}{\mathbf{i}kR}\left(1+\mathsf{z}_l^{(1)}(kR)\right)\nabla_S Y_l^m \right\}, \tag{4.8}$$

$$\mathcal{H}\wedge n = \sum_{l=1}^{\infty}\sum_{m=-l}^{l} \sqrt{\varepsilon_0} h_l^{(1)}(kR) \left\{ \frac{u_l^m}{\mathbf{i}kR}\left(1+\mathsf{z}_l^{(1)}(kR)\right)\nabla_S Y_l^m \wedge n + v_l^m \nabla_S Y_l^m \right\}. \tag{4.9}$$

Therefore, from definition (3.2) of $\mathcal{T}_S$ and definitions (4.2) of U_l^m, V_l^m, we obtain an explicit representation for the map $\mathcal{T}_S$: for any

$$u = \mathcal{E}_S = \sum_{l=1}^{\infty}\sum_{m=-l}^{l} \left[c_l^m U_l^m + d_l^m V_l^m\right],$$

$$\mathcal{T}_S u = \mathcal{H}\wedge n = \sum_{l=1}^{\infty}\sum_{m=-l}^{l} \left[\frac{c_l^m}{\mathbf{i}\omega\mu_0 R}\left(1+\mathsf{z}_l^{(1)}(kR)\right)U_l^m + \frac{\mathbf{i}\omega\varepsilon_0 R d_l^m}{1+\mathsf{z}_l^{(1)}(kR)} V_l^m\right]. \tag{4.10}$$

Next we derive an explicit representation of $\mathcal{T}_S^{\mathrm{PML}}$. Introduce a field $(\mathcal{E}^{sc}, \mathcal{H}^{sc})$:

$$\mathcal{E}^{sc}_{\hat r} = \frac{1}{s(\hat r)}\mathcal{E}^{\rm PML}_{\hat r}, \quad \mathcal{E}^{sc}_{\theta} = \frac{\hat r}{r}\mathcal{E}^{\rm PML}_{\theta}, \quad \mathcal{E}^{sc}_{\varphi} = \frac{\hat r}{r}\mathcal{E}^{\rm PML}_{\varphi},$$
$$\mathcal{H}^{sc}_{\hat r} = \frac{1}{s(\hat r)}\mathcal{H}^{\rm PML}_{\hat r}, \quad \mathcal{H}^{sc}_{\theta} = \frac{\hat r}{r}\mathcal{H}^{\rm PML}_{\theta}, \quad \mathcal{H}^{sc}_{\varphi} = \frac{\hat r}{r}\mathcal{H}^{\rm PML}_{\varphi},$$

where $(\mathcal{E}^{\rm PML}, \mathcal{H}^{\rm PML})$ is defined in (3.12). From the boundary condition in (3.12), it is obvious that

$$\mathcal{E}^{sc} \wedge n = 0 \quad \text{on } \widehat{S}. \tag{4.11}$$

It is easily verified, from the derivation of the PML formulation in section 2, that the field $(\mathcal{E}^{sc}, \mathcal{H}^{sc})$ satisfies Maxwell's equations (2.7), that is, the first two equations of (3.3). Note that the expressions of (4.6) and (4.7) form a class of solutions for (2.7), and if we replace the first kind of spherical Hankel functions in (4.6) and (4.7) with the second kind of spherical Hankel functions, then we get another class of solutions for Maxwell's equations (2.7). Let

$$\widetilde{R} = \int_0^{\widehat{R}} s(\tau)\, d\tau. \tag{4.12}$$

By choosing properly a linear combination of the two classes of solutions, we get the following solution satisfying the boundary condition (4.11):

$$\begin{aligned}
\mathcal{E}^{sc} = \sum_{l=1}^{\infty}\sum_{m=-l}^{l}\sqrt{\mu_0}\Bigg\{ & u_l^m\left(\frac{h_l^{(1)}(kr)}{h_l^{(1)}(k\widetilde{R})} - \frac{h_l^{(2)}(kr)}{h_l^{(2)}(k\widetilde{R})}\right)\nabla_S Y_l^m \wedge n \\
&+ \frac{v_l^m}{\mathbf{i}kr}\Bigg[\left(\frac{h_l^{(1)}(kr)\big(1+\mathsf{z}_l^{(1)}(kr)\big)}{h_l^{(1)}(k\widetilde{R})\big(1+\mathsf{z}_l^{(1)}(k\widetilde{R})\big)} - \frac{h_l^{(2)}(kr)\big(1+\mathsf{z}_l^{(2)}(kr)\big)}{h_l^{(2)}(k\widetilde{R})\big(1+\mathsf{z}_l^{(2)}(k\widetilde{R})\big)}\right)\nabla_S Y_l^m \\
&+ \left(\frac{l(l+1)h_l^{(1)}(kr)}{h_l^{(1)}(k\widetilde{R})\big(1+\mathsf{z}_l^{(1)}(k\widetilde{R})\big)} - \frac{l(l+1)h_l^{(2)}(kr)}{h_l^{(2)}(k\widetilde{R})\big(1+\mathsf{z}_l^{(2)}(k\widetilde{R})\big)}\right)Y_l^m n\Bigg]\Bigg\},
\end{aligned}$$

$$\begin{aligned}
\mathcal{H}^{sc} = \sum_{l=1}^{\infty}\sum_{m=-l}^{l}\sqrt{\varepsilon_0} & \\
\times\Bigg\{ & -v_l^m\left(\frac{h_l^{(1)}(kr)}{h_l^{(1)}(k\widetilde{R})\big(1+\mathsf{z}_l^{(1)}(k\widetilde{R})\big)} - \frac{h_l^{(2)}(kr)}{h_l^{(2)}(k\widetilde{R})\big(1+\mathsf{z}_l^{(2)}(k\widetilde{R})\big)}\right)\nabla_S Y_l^m \wedge n \\
&+ \frac{u_l^m}{\mathbf{i}kr}\Bigg[\left(\frac{h_l^{(1)}(kr)\big(1+\mathsf{z}_l^{(1)}(kr)\big)}{h_l^{(1)}(k\widetilde{R})} - \frac{h_l^{(2)}(kr)\big(1+\mathsf{z}_l^{(2)}(kr)\big)}{h_l^{(2)}(k\widetilde{R})}\right)\nabla_S Y_l^m \\
&+ \left(\frac{l(l+1)h_l^{(1)}(kr)}{h_l^{(1)}(k\widetilde{R})} - \frac{l(l+1)h_l^{(2)}(kr)}{h_l^{(2)}(k\widetilde{R})}\right)Y_l^m n\Bigg]\Bigg\}.
\end{aligned}$$

Similar to (4.8) and (4.9), since $\mathcal{E}^{\rm PML} = \mathcal{E}^{sc}$ and $\mathcal{H}^{\rm PML} = \mathcal{H}^{sc}$ on S, we have on S

$$
\begin{aligned}
\mathcal{E}_S^{\mathrm{PML}} = \mathcal{E}_S^{sc} = \sum_{l=1}^{\infty}\sum_{m=-l}^{l}\sqrt{\mu_0}\Bigg\{ & u_l^m\left(\frac{h_l^{(1)}(kR)}{h_l^{(1)}(k\widetilde{R})}-\frac{h_l^{(2)}(kR)}{h_l^{(2)}(k\widetilde{R})}\right)\nabla_S Y_l^m\wedge n\\
&+\frac{v_l^m}{\mathbf{i}kR}\left(\frac{h_l^{(1)}(kR)\big(1+\mathsf{z}_l^{(1)}(kR)\big)}{h_l^{(1)}(k\widetilde{R})\big(1+\mathsf{z}_l^{(1)}(k\widetilde{R})\big)}-\frac{h_l^{(2)}(kR)\big(1+\mathsf{z}_l^{(2)}(kR)\big)}{h_l^{(2)}(k\widetilde{R})\big(1+\mathsf{z}_l^{(2)}(k\widetilde{R})\big)}\right)\nabla_S Y_l^m\Bigg\},\\
\mathcal{H}^{\mathrm{PML}}\wedge n = \mathcal{H}^{sc}\wedge n = \sum_{l=1}^{\infty}\sum_{m=-l}^{l}\sqrt{\varepsilon_0}&\\
\times\Bigg\{&\frac{u_l^m}{\mathbf{i}kR}\left(\frac{h_l^{(1)}(kR)\big(1+\mathsf{z}_l^{(1)}(kR)\big)}{h_l^{(1)}(k\widetilde{R})}-\frac{h_l^{(2)}(kR)\big(1+\mathsf{z}_l^{(2)}(kR)\big)}{h_l^{(2)}(k\widetilde{R})}\right)\nabla_S Y_l^m\wedge n\\
&+v_l^m\left(\frac{h_l^{(1)}(kR)}{h_l^{(1)}(k\widetilde{R})\big(1+\mathsf{z}_l^{(1)}(k\widetilde{R})\big)}-\frac{h_l^{(2)}(kR)}{h_l^{(2)}(k\widetilde{R})\big(1+\mathsf{z}_l^{(2)}(k\widetilde{R})\big)}\right)\nabla_S Y_l^m\Bigg\}.
\end{aligned}
$$

Then from definition (3.11) of $\mathcal{T}_S^{\mathrm{PML}}$ and definitions (4.2) of U_l^m, V_l^m, we obtain an explicit representation for the map $\mathcal{T}_S^{\mathrm{PML}}$: for any

$$
u=\sum_{l=1}^{\infty}\sum_{m=-l}^{l}\big[c_l^m U_l^m + d_l^m V_l^m\big],
$$

$$
\begin{aligned}
\mathcal{T}_S^{\mathrm{PML}}u = \sum_{l=1}^{\infty}\sum_{m=-l}^{l}\Bigg[&\frac{c_l^m}{\mathbf{i}\omega\mu_0 R}\frac{h_l^{(1)}(kR)h_l^{(2)}(k\widetilde{R})\big(1+\mathsf{z}_l^{(1)}(kR)\big)-h_l^{(1)}(k\widetilde{R})h_l^{(2)}(kR)\big(1+\mathsf{z}_l^{(2)}(kR)\big)}{h_l^{(1)}(kR)h_l^{(2)}(k\widetilde{R})-h_l^{(1)}(k\widetilde{R})h_l^{(2)}(kR)}U_l^m\\
&+\mathbf{i}\omega\varepsilon_0 R d_l^m\\
&\times\frac{h_l^{(1)}(kR)h_l^{(2)}(k\widetilde{R})\big(1+\mathsf{z}_l^{(2)}(k\widetilde{R})\big)-h_l^{(2)}(kR)h_l^{(1)}(k\widetilde{R})\big(1+\mathsf{z}_l^{(1)}(k\widetilde{R})\big)}{h_l^{(1)}(kR)\big(1+\mathsf{z}_l^{(1)}(kR)\big)h_l^{(2)}(k\widetilde{R})\big(1+\mathsf{z}_l^{(2)}(k\widetilde{R})\big)-h_l^{(1)}(k\widetilde{R})\big(1+\mathsf{z}_l^{(1)}(k\widetilde{R})\big)h_l^{(2)}(kR)\big(1+\mathsf{z}_l^{(2)}(kR)\big)}V_l^m\Bigg].
\end{aligned}
$$

By using the representations of $\mathcal{T}_S$ (4.10) and the above $\mathcal{T}_S^{\mathrm{PML}}$, we have

$$
\big(\mathcal{T}_S^{\mathrm{PML}}-\mathcal{T}_S\big)u=\sum_{l=1}^{\infty}\sum_{m=-l}^{l}\big(\rho_l c_l^m U_l^m+\sigma_l d_l^m V_l^m\big) \tag{4.13}
$$

with

$$
\rho_l=\frac{(\mathbf{i}\omega\mu_0 R)^{-1}\big[\mathsf{z}_l^{(1)}(kR)-\mathsf{z}_l^{(2)}(kR)\big]\cdot h_l^{(2)}(kR)\big[h_l^{(1)}(kR)\big]^{-1}}{h_l^{(2)}(k\widetilde{R})\big[h_l^{(1)}(k\widetilde{R})\big]^{-1}-h_l^{(2)}(kR)\big[h_l^{(1)}(kR)\big]^{-1}}, \tag{4.14}
$$

$$
\sigma_l=\frac{\mathbf{i}\omega\varepsilon_0 R\big[\mathsf{z}_l^{(2)}(kR)-\mathsf{z}_l^{(1)}(kR)\big]\big[1+\mathsf{z}_l^{(1)}(kR)\big]^{-2}h_l^{(2)}(kR)\big[h_l^{(1)}(kR)\big]^{-1}}{\frac{h_l^{(2)}(k\widetilde{R})\left(1+\mathsf{z}_l^{(2)}(k\widetilde{R})\right)}{h_l^{(1)}(k\widetilde{R})\left(1+\mathsf{z}_l^{(1)}(k\widetilde{R})\right)}-\frac{h_l^{(2)}(kR)\left(1+\mathsf{z}_l^{(2)}(kR)\right)}{h_l^{(1)}(kR)\left(1+\mathsf{z}_l^{(1)}(kR)\right)}}. \tag{4.15}
$$

Therefore, in order to estimate the error between $\mathcal{T}_S$ and $\mathcal{T}_S^{\mathrm{PML}}$, it is essential to derive upper bounds for ρ_l and σ_l. To do so, we need asymptotic results for the spherical Hankel functions.

Remark 4.1. In practice, it is important to have explicit error estimates between $\mathcal{T}_S$ and $\mathcal{T}_S^{\mathrm{PML}}$. For this reason, we choose not to use the usual uniform Airy-type asymptotic expansions of the spherical Hankel functions $h_l^{(1)}(z)$ and $h_l^{(2)}(z)$, which are efficient for $l \approx z$, because the Airy functions are implicit. Instead, we employ the explicit exponential-type expansions of the modified Bessel functions and derive explicit approximations for the spherical Hankel functions. It should be pointed out that the spherical Hankel functions and the modified Bessel functions are related by the connection formula given in section 5.2.

Remark 4.2. We comment on the validity of the exponential-type expansions of the spherical Hankel functions. Unlike the Airy-type expansions, the exponential-type expansions may be invalid for $l \leq z$ with real z. In this case, some special treatment must be used. A detailed discussion is given in subsequent sections.

5. Estimates on the spherical Hankel functions. Our goal in this section is to derive explicit estimates for the spherical Hankel functions. We first derive and estimate the asymptotic expansions of the modified Bessel functions in section 5.1. The connection formula between the spherical Hankel functions and the modified Bessel functions in section 5.2 can then be employed to establish the desirable estimates.

5.1. First approximations of the modified Bessel functions. Consider the asymptotic behavior of the modified Bessel functions $I_\nu(\nu z)$ and $K_\nu(\nu z)$ of large order ν. The order ν is always assumed to be real and positive throughout.

Introduce new variables

$$\xi = (1+z^2)^{1/2} + \ln \frac{z}{1+(1+z^2)^{1/2}}, \tag{5.1}$$

$$p = (1+z^2)^{-1/2}. \tag{5.2}$$

Define

$$U_1 = (3p - 5p^3)/24. \tag{5.3}$$

The following lemma was proved in sections 10.7–10.8 of [15].

LEMMA 5.1. *Denote by $b_1 = 0$ and $b_2 = +\infty$. Assume that z satisfies $|\arg z| < \pi/2$ or $|\arg z| = \pi/2$ but $|z| < 1$. Then*

$$I_\nu(\nu z) = \left(\frac{1}{2\pi\nu}\right)^{1/2} \frac{e^{\nu\xi}}{(1+z^2)^{1/4}} \frac{1+\eta_1(\nu,z)}{1+\eta_1(\nu,\infty)}, \tag{5.4}$$

$$K_\nu(\nu z) = \left(\frac{\pi}{2\nu}\right)^{1/2} \frac{e^{-\nu\xi}}{(1+z^2)^{1/4}} \big(1+\eta_2(\nu,z)\big), \tag{5.5}$$

$$I_\nu'(\nu z) = \left(\frac{1}{2\pi\nu}\right)^{1/2} \frac{e^{\nu\xi}(1+z^2)^{1/4}}{z} \frac{1+\eta_3(\nu,z)}{1+\eta_1(\nu,\infty)}, \tag{5.6}$$

$$K_\nu'(\nu z) = -\left(\frac{\pi}{2\nu}\right)^{1/2} \frac{e^{-\nu\xi}(1+z^2)^{1/4}}{z} (1+\eta_4(\nu,z)), \tag{5.7}$$

where

$$\eta_3(\nu,z) = \kappa_1(\nu,z) - \frac{z^2p^3}{2\nu}(1+\eta_1(\nu,z)), \tag{5.8}$$

$$\eta_4(\nu,z) = -\kappa_2(\nu,z) + \frac{z^2p^3}{2\nu}(1+\eta_2(\nu,z)). \tag{5.9}$$

Moreover, the error terms $\eta_j, \kappa_j, j = 1, 2$, are bounded by

$$|\eta_1(\nu, z)|, |\kappa_1(\nu, z)| \le \exp\left(\frac{2\,\mathcal{V}_{b_1,z}(U_1)}{\nu}\right)\frac{2\,\mathcal{V}_{b_1,z}(U_1)}{\nu}, \tag{5.10}$$

$$|\eta_2(\nu, z)|, |\kappa_2(\nu, z)| \le \exp\left(\frac{2\,\mathcal{V}_{b_2,z}(U_1)}{\nu}\right)\frac{2\,\mathcal{V}_{b_2,z}(U_1)}{\nu}, \tag{5.11}$$

where $\mathcal{V}_{b_j,z}(U_1)$ is the bounded variation from b_j to z, and the variational paths being taken by traveling in the ξ plane from $\xi(z)$ parallel to the imaginary axis until the real axis is reached, then proceeding along the real axis to $\xi(b_1)$ or $\xi(b_2)$.

Let

$$D_1 = \{z;\ |\arg z| \le \pi/4\}, \qquad D_2 = \{z;\ |\arg z| = \pi/2 \text{ and } |z| < 1\}. \tag{5.12}$$

Note that estimates (5.10) and (5.11) are not yet explicit in the sense that the right-hand sides remain to be estimated. This problem is resolved by our next lemma whose proof is given in the appendix.

LEMMA 5.2. *For $m = 1, 2, z \in D_m$,*

$$|\eta_1(\nu, z)|, |\eta_2(\nu, z)| \le \widehat{M}_m(\nu, z) := \exp\left(\frac{2M_m(z)}{\nu}\right)\frac{2M_m(z)}{\nu},$$
$$|\eta_1(\nu, \infty)| \le \widehat{M}_1(\nu, +\infty),$$
$$|\eta_3(\nu, z)|, |\eta_4(\nu, z)| \le \widehat{N}_m(\nu, z) := \frac{N_m(z)}{2\nu} + \left(1 + \frac{N_m(z)}{2\nu}\right)\widehat{M}_m(\nu, z),$$

where

$$M_1(z) = \frac{1}{12} + \frac{1}{6\sqrt{5}} + \frac{|\Im(z)|}{\Re(z)}\min\left\{\left(\frac{4}{27}\right)^{1/4}, \frac{1}{\Re(z)}\right\}, \tag{5.13}$$

$$N_1(z) = \min\left\{\left(\frac{4}{27}\right)^{1/4}, \frac{1}{|z|}\right\}, \tag{5.14}$$

$$M_2(z) = \frac{1}{12} + \frac{1}{6\sqrt{5}} + \frac{\pi\,|z|^2\,(4 + |z|^2)}{16(1 - |z|^2)^3}, \tag{5.15}$$

$$N_2(z) = \frac{|z|^2}{(1 - |z|^2)^{3/2}}. \tag{5.16}$$

Equipped with the estimates of the modified Bessel functions I_ν and K_ν, we are now ready to establish estimates of the spherical Hankel functions. The results are useful for the estimates of ρ_l and σ_l that are essential for the proof of Lemma 3.1.

5.2. Spherical Hankel functions. The spherical Hankel functions $h_l^{(j)}(z)$ ($j = 1, 2, l \ge 0$ integers) can also be defined by the Hankel functions of half-odd-integer order $H_{l+\frac{1}{2}}^{(j)}(z)$ (cf. (4.4) and [15, p. 238]):

$$h_l^{(1)}(z) = \mathbf{i}\sqrt{\frac{\pi}{2z}}H_{l+\frac{1}{2}}^{(1)}(z), \quad h_l^{(2)}(z) = -\mathbf{i}\sqrt{\frac{\pi}{2z}}H_{l+\frac{1}{2}}^{(2)}(z). \tag{5.17}$$

The Hankel functions and the modified Bessel functions satisfy the following connection formulas (see, e.g., [15, pp. 250–251]):

$$K_\nu(z) = \frac{\pi\mathbf{i}}{2}e^{\nu\pi\mathbf{i}/2}H_\nu^{(1)}\big(ze^{\pi\mathbf{i}/2}\big), \quad I_\nu(z) = \frac{1}{2}e^{-\nu\pi\mathbf{i}/2}\big[H_\nu^{(1)}\big(ze^{\pi\mathbf{i}/2}\big) + H_\nu^{(2)}\big(ze^{\pi\mathbf{i}/2}\big)\big],$$

hence

$$h_l^{(1)}(z) = \sqrt{\frac{2}{\pi z}}e^{-(l+\frac{1}{2})\pi\mathbf{i}/2}K_{l+\frac{1}{2}}\big(ze^{-\pi\mathbf{i}/2}\big), \tag{5.18}$$

$$h_l^{(2)}(z) = -\mathbf{i}\sqrt{\frac{2\pi}{z}}e^{(l+\frac{1}{2})\pi\mathbf{i}/2}I_{l+\frac{1}{2}}\big(ze^{-\pi\mathbf{i}/2}\big) + h_l^{(1)}(z). \tag{5.19}$$

It follows from the definition of $\mathsf{z}_l^{(j)}(z)$ that

$$\begin{aligned} h_l^{(1)}(z)\big[1+\mathsf{z}_l^{(1)}(z)\big] &= h_l^{(1)}(z) + zh_l^{(1)'}(z) \\ &= \sqrt{\frac{2}{\pi z}}e^{-(l+\frac{1}{2})\pi\mathbf{i}/2}\bigg(\frac{1}{2}K_{l+\frac{1}{2}}\big(ze^{-\pi\mathbf{i}/2}\big) - \mathbf{i}zK'_{l+\frac{1}{2}}\big(ze^{-\pi\mathbf{i}/2}\big)\bigg), \end{aligned} \tag{5.20}$$

$$\begin{aligned} h_l^{(2)}(z)\big[1+\mathsf{z}_l^{(2)}(z)\big] &= h_l^{(2)}(z) + zh_l^{(2)'}(z) \\ &= h_l^{(1)}(z)\big(1+\mathsf{z}_l^{(1)}(z)\big) - \mathbf{i}\sqrt{\frac{2\pi}{z}}e^{(l+\frac{1}{2})\pi\mathbf{i}/2}\bigg(\frac{1}{2}I_{l+\frac{1}{2}}\big(ze^{-\pi\mathbf{i}/2}\big) - \mathbf{i}zI'_{l+\frac{1}{2}}\big(ze^{-\pi\mathbf{i}/2}\big)\bigg). \end{aligned} \tag{5.21}$$

The following three lemmas present estimates that are crucial for estimating ρ_l and σ_l in (4.14) and (4.15), respectively.

Lemma 5.3. *Denote $\nu = l + 1/2$ and $\hat{z} = ze^{-\pi\mathbf{i}/2}$. For $m = 1, 2$, $\hat{z} \in D_m$, and $\nu \geq 3/2$, the following estimates hold:*

$$e^{2\nu\Re(\xi(\hat{z}))}\cdot C_m^-(\nu,\hat{z}) \leq \left|\frac{h_l^{(2)}(\nu z)}{h_l^{(1)}(\nu z)} - 1\right| \leq e^{2\nu\Re(\xi(\hat{z}))}\cdot C_m^+(\nu,\hat{z}), \tag{5.22}$$

$$e^{2\nu\Re(\xi(\hat{z}))}\cdot \widehat{C}_m^-(\nu,\hat{z}) \leq \left|\frac{h_l^{(2)}(\nu z)\big[1+\mathsf{z}_l^{(2)}(\nu z)\big]}{h_l^{(1)}(\nu z)\big[1+\mathsf{z}_l^{(1)}(\nu z)\big]} - 1\right| \leq e^{2\nu\Re(\xi(\hat{z}))}\cdot \widehat{C}_m^+(\nu,\hat{z}) \tag{5.23}$$

if $C_m^-(\nu,\hat{z})$ and $\widehat{C}_m^-(\nu,\hat{z})$ are positive. Here

$$C_m^{\pm}(\nu,\hat{z}) = \frac{1}{1\mp\widehat{M}_1(\nu,+\infty)}\cdot\frac{1\pm\widehat{M}_m(\nu,\hat{z})}{1\mp\widehat{M}_m(\nu,\hat{z})}, \tag{5.24}$$

$$\widehat{C}_m^{\pm}(\nu,\hat{z}) = \frac{1}{1\mp\widehat{M}_1(\nu,+\infty)}\cdot\frac{1\pm\Big\{\widehat{N}_m(\nu,\hat{z}) + \frac{|(1+\hat{z}^2)^{-1/2}|}{2\nu}\big[1+\widehat{M}_m(\nu,\hat{z})\big]\Big\}}{1\mp\Big\{\widehat{N}_m(\nu,\hat{z}) + \frac{|(1+\hat{z}^2)^{-1/2}|}{2\nu}\big[1+\widehat{M}_m(\nu,\hat{z})\big]\Big\}}. \tag{5.25}$$

Here ξ is defined by (5.1)*, D_m is defined by* (5.12)*, and $\widehat{M}_m, \widehat{N}_m$ are defined in Lemma* 5.2.

Proof. From (5.18) to (5.21) and (5.4) to (5.7), we obtain, after some simple calculations, that

$$\frac{h_l^{(2)}(\nu z)}{h_l^{(1)}(\nu z)} = 1 + \frac{(-1)^l e^{2\nu\xi(\hat{z})}}{1+\eta_1(\nu,\infty)}\cdot\frac{1+\eta_1(\nu,\hat{z})}{1+\eta_2(\nu,\hat{z})},$$

$$\frac{h_l^{(2)}(\nu z)\big[1+\mathsf{z}_l^{(2)}(\nu z)\big]}{h_l^{(1)}(\nu z)\big[1+\mathsf{z}_l^{(1)}(\nu z)\big]} = 1 + \frac{(-1)^l e^{2\nu\xi(\hat{z})}}{1+\eta_1(\nu,\infty)}\cdot\frac{\frac{(1+\hat{z}^2)^{-1/2}}{2\nu}\left[1+\eta_1(\nu,\hat{z})\right] + \left[1+\eta_3(\nu,\hat{z})\right]}{\frac{(1+\hat{z}^2)^{-1/2}}{2\nu}\left[1+\eta_2(\nu,\hat{z})\right] - \left[1+\eta_4(\nu,\hat{z})\right]}.$$

Estimates (5.22)–(5.23) then follow directly from Lemma 5.2 by noting that $\widehat{M}_1(\nu, +\infty) < 1$ for $v \geq 3/2$. □

Once again, for the representations ρ_l and σ_l of (4.14) and (4.15), an important term is $\mathsf{z}_l^{(1)} - \mathsf{z}_l^{(2)}$. The following result provides an estimate of the term.

LEMMA 5.4. *Denote $\nu = l + \frac{1}{2}$ and $\hat{z} = z e^{-\pi \mathbf{i}/2}$. Assume that z is real and $0 < z < 1$ and that $\widehat{M}_2(\nu, \hat{z}) < 1$. Then*

$$\left|\mathsf{z}_l^{(1)}(\nu z) - \mathsf{z}_l^{(2)}(\nu z)\right| \leq 2\nu e^{2\nu \Re(\xi(\hat{z}))}\left|(1+\hat{z}^2)^{1/2}\right|\left[1 - \widehat{M}_2(\nu, \hat{z})\right]^{-2}. \tag{5.26}$$

Proof. We need the following expression of $\mathsf{z}_l^{(1)}(z)$ for $z > 0$ [14, Theorem 2.6.1]:

$$\mathsf{z}_l^{(1)}(z) = -\frac{p_l}{q_l} + \mathbf{i}\frac{z}{q_l}, \tag{5.27}$$

where

$$\begin{aligned} q_l &= 1 + \alpha_1^l \frac{1}{z^2} + \cdots + \alpha_l^l \frac{1}{z^{2l}} = z^2 \left|h_l^{(1)}(z)\right|^2, \\ p_l &= 1 + 2\alpha_1^l \frac{1}{z^2} + \cdots + (l+1)\alpha_l^l \frac{1}{z^{2l}}, \quad \alpha_m^l = \frac{(m+l)!(2m)!}{m!^2(l-m)!4^m}. \end{aligned} \tag{5.28}$$

Hence,

$$\left|\mathsf{z}_l^{(1)}(z) - \mathsf{z}_l^{(2)}(z)\right| = \left|\mathsf{z}_l^{(1)}(z) - \overline{\mathsf{z}_l^{(1)}(z)}\right| = 2z/q_l = 2z^{-1}\left|h_l^{(1)}(z)\right|^{-2}. \tag{5.29}$$

Therefore, by (5.18), (5.5), and (5.29), we have

$$\left|\mathsf{z}_l^{(1)}(\nu z) - \mathsf{z}_l^{(2)}(\nu z)\right| = 2\nu\left|e^{2\nu\xi(\hat{z})}(1+\hat{z}^2)^{1/2}\right|\left|1 + \eta_2(\nu, \hat{z})\right|^{-2},$$

which implies (5.26). □

The result below presents additional estimates of the terms in the representations ρ_l and σ_l of (4.14) and (4.15).

LEMMA 5.5. *If z is real and positive, then*

$$\left|\frac{h_l^{(1)}(z)}{h_l^{(2)}(z)}\right| = 1, \qquad \left|\frac{h_l^{(1)}(z)\left[1 + \mathsf{z}_l^{(1)}(z)\right]}{h_l^{(2)}(z)\left[1 + \mathsf{z}_l^{(2)}(z)\right]}\right| = 1, \tag{5.30}$$

$$\left|\mathsf{z}_l^{(1)}(z) - \mathsf{z}_l^{(2)}(z)\right| \leq 2z\,, \tag{5.31}$$

$$\left|1 + \mathsf{z}_l^{(j)}(z)\right| \geq \frac{\sqrt{1 + l(l+1)}}{3z + 3/2}, \quad j = 1, 2, \;\; l \geq 2. \tag{5.32}$$

Proof. From (4.4) and (4.5), we know that (5.30) holds. By using (5.29) and $q_l \geq 1$, we get (5.31). Hence, it remains to prove (5.32). From (4.5) and (5.27), we have

$$\left|1 + \mathsf{z}_l^{(2)}(z)\right| = \left|1 + \mathsf{z}_l^{(1)}(z)\right| \geq \max\left\{\frac{p_l}{q_l} - 1, \; \frac{z}{q_l}\right\}.$$

From expressions (5.28) of p_l and q_l, some simple calculations yield

$$\frac{p_l}{q_l} - 1 \geq \frac{l(l+1)}{2z^2 + l + 1} \quad \text{and} \quad \frac{z}{q_l} \geq z - \frac{l(l+1)}{z},$$

which implies that $\frac{p_l}{q_l} - 1 > \frac{l+1}{3z+3/2}$ if $z < l+1$ and $\frac{z}{q_l} \geq 1 \geq \frac{l+1}{z}$ if $z \geq l+1$. The proof is now complete. □

6. Proof of the key lemma. Lemma 3.1 may be proved by estimating ρ_l and σ_l. For simplicity, we introduce the following notation:

$$\nu = l + 1/2, \quad z_\nu = kR/\nu, \quad \tilde{z}_\nu = k\widetilde{R}/\nu, \quad \hat{z}_\nu = z_\nu e^{-\pi \mathbf{i}/2}, \quad \text{and} \quad \hat{\tilde{z}}_\nu = \tilde{z}_\nu e^{-\pi \mathbf{i}/2}. \tag{6.1}$$

It follows from (4.12), (3.16), and $s(\tau) = 1 + \mathbf{i} s_I(\tau)$ that

$$\widetilde{R} = \widehat{R} + \mathbf{i}\widetilde{R}_I \quad \text{and} \quad \hat{\tilde{z}}_\nu = k\widetilde{R}_I/\nu - \mathbf{i}k\widehat{R}/\nu. \tag{6.2}$$

Note that the estimates in Lemmas 5.3 and 5.4 are no longer valid for $z = z_\nu$ if $z_\nu \geq 1$, that is, if $\nu = l + 1/2 \leq kR$. We estimate ρ_l and σ_l in (4.14) and (4.15) by considering two separate cases: $\nu \geq \nu_a$ and $\nu < \nu_a$, where

$$\nu_a = kR/a. \tag{6.3}$$

Here, recall from (3.16) that $a = \min\{1/2,\, kR/5\}$ is a positive number less than 1.

The following lemma gives uniform lower bounds for the exponential terms that appear in Lemmas 5.3 and 5.4.

LEMMA 6.1. *The following estimate holds:*

$$e^{2\nu \Re(\xi(\hat{\tilde{z}}_\nu))} \geq e^{\xi(a\widetilde{R}_I/R)\cdot 2kR/a} \quad \textit{for } 0 < \nu < \nu_a. \tag{6.4}$$

If, in addition,

$$2\frac{kR}{a} \ln \frac{(1 + \sqrt{1 - a^2}) \cdot \widetilde{R}_I/R}{1 + \sqrt{1 + a^2 \widetilde{R}_I^2/R^2}} \geq 1, \tag{6.5}$$

then

$$\frac{1}{2\nu} e^{2\nu[\Re(\xi(\hat{\tilde{z}}_\nu)) - \Re(\xi(\hat{z}_\nu))]} \geq \frac{a}{2kR} e^{\xi(a\widetilde{R}_I/R)\cdot 2kR/a} \quad \textit{for } \nu \geq \nu_a. \tag{6.6}$$

Proof. First from Lemma A.1(ii) and (6.2), we have

$$\Re(\xi(\hat{\tilde{z}}_\nu)) \geq \xi(k\widetilde{R}_I/\nu).$$

Let

$$g_1(\nu) = \nu \xi(k\widetilde{R}_I/\nu) = \sqrt{\nu^2 + k^2 \widetilde{R}_I^2} + \nu \ln \frac{k\widetilde{R}_I}{\nu + \sqrt{\nu^2 + k^2 \widetilde{R}_I^2}}.$$

Then

$$g_1'(\nu) = \ln \frac{k\widetilde{R}_I}{\nu + \sqrt{\nu^2 + k^2 \widetilde{R}_I^2}} < 0 \quad \text{for } \nu > 0,$$

which implies that $g_1(\nu) \geq g_1(\nu_a)$ for $0 < \nu < \nu_a$, and hence (6.4) holds.

Now we turn to prove (6.6). For $\nu \geq \nu_a$, define $g(\nu) = \nu[\xi(k\widetilde{R}_I/\nu) - \Re(\xi(\hat{z}_\nu))]$. Since $|\hat{z}_\nu| \leq kR/\nu_a = a < 1$, it follows from the definition (5.1) of ξ that

$$g(\nu) = g_1(\nu) - \left(\sqrt{\nu^2 - k^2 R^2} + \nu \ln \frac{kR}{\nu + \sqrt{\nu^2 - k^2 R^2}} \right),$$

$$g'(\nu) = g_1'(\nu) - \ln \frac{kR}{\nu + \sqrt{\nu^2 - k^2 R^2}}, \quad g''(\nu) = -\frac{1}{\sqrt{\nu^2 + k^2 \widetilde{R}_I^2}} + \frac{1}{\sqrt{\nu^2 - k^2 R^2}}.$$

By $g''(\nu) \geq 0$ and (6.5), we have, for $\nu \geq \nu_a$,

$$g'(\nu) \geq g'(\nu_a) = \ln \frac{(1+\sqrt{1-a^2}) \cdot \widetilde{R}_I/R}{1+\sqrt{1+a^2\widetilde{R}_I^2/R^2}} > 0,$$

which implies

$$\frac{d\left(\frac{1}{2\nu}e^{2g(\nu)}\right)}{d\nu} = \frac{e^{2g(\nu)}}{2\nu^2}(2\nu g'(\nu)-1) \geq \frac{e^{2g(\nu)}}{2\nu^2}(2\nu_a g'(\nu_a)-1) \geq 0.$$

Hence $\frac{1}{2\nu}e^{2g(\nu)} \geq \frac{1}{2\nu_a}e^{2g(\nu_a)}$ for $\nu \geq \nu_a$. Inequality (6.6) follows from the definition of $g(\nu)$ and the fact $g(\nu_a) \geq g_1(\nu_a)$. □

In addition, the next lemma gives estimates for the constants in Lemmas 5.3–5.4.

Lemma 6.2. *Under assumption* (3.17),

$$C_1^-(\nu, \hat{\tilde{z}}_\nu) > 1/5, \quad \widehat{C}_1^-(\nu, \hat{\tilde{z}}_\nu) > 1/5 \quad \textit{for } \nu \geq 5/2 \tag{6.7}$$

and

$$\begin{aligned} &C_1^-(\nu, \hat{\tilde{z}}_\nu) > 17/40, \quad \widehat{C}_1^-(\nu, \hat{\tilde{z}}_\nu) > 17/40, \quad \widehat{M}_2(\nu, \hat{z}_\nu) < 17/50, \\ &C_2^+(\nu, \hat{z}_\nu) < 91/25, \quad \widehat{C}_2^+(\nu, \hat{z}_\nu) < 91/25 \quad \textit{for } \nu \geq \nu_a. \end{aligned} \tag{6.8}$$

Furthermore inequality (6.5) *in the statement of Lemma* 6.1 *holds.*

Proof. Obviously, assumption (3.17) implies that

$$a \leq 1/2, \quad \nu_a \geq 5, \quad k\widetilde{R}_I \geq 17, \quad \text{and} \quad |\Im(\hat{\tilde{z}}_\nu)|/\Re(\hat{\tilde{z}}_\nu) = \widehat{R}/\widetilde{R}_I \leq 1. \tag{6.9}$$

Then by $\hat{\tilde{z}}_\nu = k\widetilde{R}_I/\nu - \mathbf{i}k\widehat{R}/\nu$, $\hat{z}_\nu = -\mathbf{i}kR/\nu$ (cf. (6.1) and (6.2)), and (5.13)–(5.16), we get

$$\begin{aligned} &M_1(\hat{\tilde{z}}_\nu) \leq \frac{1}{12} + \frac{1}{6\sqrt{5}} + 1 \cdot \frac{\nu}{k\widetilde{R}_I} \leq \frac{1}{12} + \frac{1}{6\sqrt{5}} + \frac{\nu}{17}, \\ &N_1(\hat{\tilde{z}}_\nu) \leq \frac{\nu}{k\widetilde{R}_I} \leq \frac{\nu}{17} \quad \text{for } \nu \geq \frac{5}{2} \end{aligned}$$

and

$$\begin{aligned} &M_2(\hat{z}_\nu) \leq \frac{1}{12} + \frac{1}{6\sqrt{5}} + \frac{\pi\,|a|^2\,(4+|a|^2)}{16(1-|a|^2)^3} \leq \frac{1}{12} + \frac{1}{6\sqrt{5}} + \frac{17\pi}{108}, \\ &N_2(\hat{z}_\nu) \leq \frac{|a|^2}{(1-|a|^2)^{3/2}} \leq \frac{2\sqrt{3}}{9} \quad \text{for } \nu \geq \nu_a. \end{aligned}$$

In addition

$$M_1(+\infty) = \frac{1}{12} + \frac{1}{6\sqrt{5}}, \quad (1+\hat{\tilde{z}}_\nu^2)^{-1/2} \leq 1, \quad (1+\hat{z}_\nu^2)^{-1/2} = (1-z_\nu^2)^{-1/2}.$$

By combining the above estimates and definitions (5.24)–(5.25), (6.1), and some direct calculations, it is straightforward to complete the proof of (6.7)–(6.8).

From (3.16) and (3.17), it follows that $kR/a \geq 5, \widetilde{R}_I/R \geq 7/5, a \leq 1/2$. Hence,

$$\text{the left-hand side of (6.5)} \geq 2 \times 5 \ln \frac{\left(1+\sqrt{1-(1/2)^2}\right) \cdot 7/5}{1+\sqrt{1+(1/2)^2(7/5)^2}} > 1,$$

which completes the proof of Lemma 6.2. □

By combining the above estimates, we can now estimate ρ_l and σ_l in (4.14) and (4.15), respectively.

LEMMA 6.3. *Under assumption* (3.17), *the following estimates hold for* $l = 1, 2, \dots$*:*

$$\omega\,|\rho_l| \le \mathcal{M}\sqrt{1+l(l+1)} \quad \textit{and} \quad \omega\,|\sigma_l| \le \frac{\mathcal{M}}{\sqrt{1+l(l+1)}}, \tag{6.10}$$

where

$$\mathcal{M} = \frac{4k(a\mu_0)^{-1}\max\left\{(kR)^2(3kR+3/2)^2, 1\right\}}{e^{k\widetilde{R}_I\left[2-\left(a\widetilde{R}_I/R\right)^{-2}+\left(a\widetilde{R}_I/R\right)^{-4}/19\right]}-10},$$

and the constant $\widetilde{R}_I$ *is defined in* (3.16).

Proof. Due to the validity consideration of the exponential-type estimates for the spherical Hankel functions, we divide the proof into three cases: $\nu = l + 1/2 \ge \nu_a$, $5/2 \le \nu < \nu_a$, and $\nu = 3/2$. These cases are proved by using different approaches. For the first case, we employ the exponential-type estimates for estimating ρ_l and σ_l. For the second case, we combine the exponential-type estimates and the estimates in Lemma 5.5. The definitions of the spherical Hankel functions are used to treat the third case.

Case I. $\nu = l + 1/2 \ge \nu_a$.

By using (4.14)–(4.15) and Lemmas 5.3–5.5, we get

$$\begin{aligned}|\rho_l| &= \frac{(\omega\mu_0 R)^{-1}|\mathsf{z}_l^{(1)}(\nu z_\nu) - \mathsf{z}_l^{(2)}(\nu z_\nu)|}{|h_l^{(2)}(\nu\tilde{z}_\nu)\left[h_l^{(1)}(\nu\tilde{z}_\nu)\right]^{-1} - 1 - \left(h_l^{(2)}(\nu z_\nu)\left[h_l^{(1)}(\nu z_\nu)\right]^{-1} - 1\right)|}\\ &\le \frac{(\omega\mu_0 R)^{-1}|1 - \widehat{M}_2(\nu, \hat{z}_\nu)|^{-2}}{\frac{1}{2\nu}e^{2\nu[\Re(\xi(\hat{\tilde{z}}_\nu)) - \Re(\xi(\hat{z}_\nu))]}C_1^-(\nu, \hat{\tilde{z}}_\nu) - \frac{1}{2\nu}C_2^+(\nu, \hat{z}_\nu)}\end{aligned}$$

and

$$\begin{aligned}|\sigma_l| &= \frac{\omega\varepsilon_0 R\cdot|\mathsf{z}_l^{(2)}(\nu z_\nu) - \mathsf{z}_l^{(1)}(\nu z_\nu)||1+\mathsf{z}_l^{(1)}(kR)|^{-2}}{\left|\frac{h_l^{(2)}(\nu\tilde{z}_\nu)\left(1+\mathsf{z}_l^{(2)}(\nu\tilde{z}_\nu)\right)}{h_l^{(1)}(\nu\tilde{z}_\nu)\left(1+\mathsf{z}_l^{(1)}(\nu\tilde{z}_\nu)\right)} - 1 - \left(\frac{h_l^{(2)}(\nu z_\nu)\left(1+\mathsf{z}_l^{(2)}(\nu z_\nu)\right)}{h_l^{(1)}(\nu z_\nu)\left(1+\mathsf{z}_l^{(1)}(\nu z_\nu)\right)} - 1\right)\right|}\\ &\le \frac{\omega\varepsilon_0 R|1 - \widehat{M}_2(\nu, \hat{z}_\nu)|^{-2}[1+l(l+1)]^{-1}(3kR+3/2)^2}{\frac{1}{2\nu}e^{2\nu[\Re(\xi(\hat{\tilde{z}}_\nu)) - \Re(\xi(\hat{z}_\nu))]}\widehat{C}_1^-(\nu, \hat{\tilde{z}}_\nu) - \frac{1}{2\nu}\widehat{C}_2^+(\nu, \hat{z}_\nu)}\ .\end{aligned}$$

Then by using Lemmas 6.1 and 6.2, we obtain

$$|\rho_l| \le \frac{11k(a\omega\mu_0)^{-1}[1+l(l+1)]^{-1/2}[1+l(l+1)]^{1/2}}{e^{\xi(a\widetilde{R}_I/R)\cdot 2kR/a} - 10}, \tag{6.11}$$

$$|\sigma_l| \le \frac{11k(a\omega\mu_0)^{-1}[1+l(l+1)]^{-1/2}[1+l(l+1)]^{-1/2}(kR)^2(3kR+3/2)^2}{e^{\xi(a\widetilde{R}_I/R)\cdot 2kR/a} - 10}. \tag{6.12}$$

Since $\nu_a \ge 5$ (cf. (6.9)) and the integer $l \ge \nu_a - \frac{1}{2}$, we have $l \ge 5$ and hence $11[1 + l(l+1)]^{-1/2} < 4$. Hence, estimate (6.10) follows from the inequality

$$\xi(a\widetilde{R}_I/R)\cdot 2kR/a > k\widetilde{R}_I\left[2 - \left(a\widetilde{R}_I/R\right)^{-2} + \left(a\widetilde{R}_I/R\right)^{-4}/19\right], \tag{6.13}$$

which can be derived by Lemma A.1(v) and $a\widetilde{R}_I/R = \min\{\widetilde{R}_I/(2R), k\widetilde{R}_I/5\} \geq 7/10$.

Case II. $5/2 \leq \nu = l + 1/2 < \nu_a$.

By using (4.14)–(4.15) and Lemmas 5.3–5.5, we have

$$|\rho_l| \leq \frac{(\omega\mu_0 R)^{-1}\left|\mathsf{z}_l^{(1)}(kR) - \mathsf{z}_l^{(2)}(kR)\right|}{\left|h_l^{(2)}(\nu\tilde{z}_\nu)/h_l^{(1)}(\nu\tilde{z}_\nu)\right| - 1} \leq \frac{(\omega\mu_0 R)^{-1} 2kR}{e^{2\nu\Re(\xi(\hat{\tilde{z}}_\nu))}C_1^-(\nu, \hat{\tilde{z}}_\nu) - 2},$$

$$|\sigma_l| \leq \frac{\omega\varepsilon_0 R\left|\mathsf{z}_l^{(2)}(kR) - \mathsf{z}_l^{(1)}(kR)\right|\left|1 + \mathsf{z}_l^{(1)}(kR)\right|^{-2}}{\left|\frac{h_l^{(2)}(\nu\tilde{z}_\nu)\left(1+\mathsf{z}_l^{(2)}(\nu\tilde{z}_\nu)\right)}{h_l^{(1)}(\nu\tilde{z}_\nu)\left(1+\mathsf{z}_l^{(1)}(\nu\tilde{z}_\nu)\right)}\right| - 1} \leq \frac{\omega\varepsilon_0 R \cdot 2kR\frac{(3kR+3/2)^2}{1+l(l+1)}}{e^{2\nu\Re(\xi(\hat{\tilde{z}}_\nu))}\widehat{C}_1^-(\nu, \hat{\tilde{z}}_\nu) - 2}.$$

From Lemmas 6.1 and 6.2, we further obtain that

$$|\rho_l| \leq \frac{10k(\omega\mu_0)^{-1}[1 + l(l+1)]^{-1/2}[1 + l(l+1)]^{1/2}}{e^{\xi(a\widetilde{R}_I/R)\cdot 2kR/a} - 10}, \tag{6.14}$$

$$|\sigma_l| \leq \frac{10k(\omega\mu_0)^{-1}[1 + l(l+1)]^{-1/2}[1 + l(l+1)]^{-1/2}(kR)^2(3kR + 3/2)^2}{e^{\xi(a\widetilde{R}_I/R)\cdot 2kR/a} - 10}. \tag{6.15}$$

Now estimate (6.10) follows from $10[1 + l(l+1)]^{-1/2} < 4$ and inequality (6.13).

Case III. $\nu = l + \frac{1}{2} = \frac{3}{2}$.

From (4.4)–(4.5), we have

$$h_1^{(1)}(z) = -\frac{\mathbf{i}e^{\mathbf{i}z}}{z}\left(1 + \frac{\mathbf{i}}{z}\right), \quad h_1^{(2)}(z) = \frac{\mathbf{i}e^{-\mathbf{i}z}}{z}\left(1 - \frac{\mathbf{i}}{z}\right),$$

$$\mathsf{z}_1^{(1)}(z) = \frac{-(z^2+2) + \mathbf{i}z^3}{z^2+1}, \quad \mathsf{z}_1^{(2)}(z) = \frac{-(z^2+2) - \mathbf{i}z^3}{z^2+1}.$$

It follows from definitions (4.14) and (4.15) of ρ_l and σ_l that

$$|\rho_1| \leq \frac{(\omega\mu_0 R)^{-1}\left|2\mathbf{i}(kR)^3[(kR)^2+1]^{-1}\right|}{\left|e^{-2\mathbf{i}k\widetilde{R}}(\mathbf{i} - k\widetilde{R})(\mathbf{i} + k\widetilde{R})^{-1}\right| - 1} \leq \frac{2k(\omega\mu_0)^{-1}}{e^{2k\widetilde{R}_I}(k\widetilde{R}_I - 1)(k\widetilde{R}_I + 1)^{-1} - 1},$$

$$|\sigma_1| \leq \frac{\left|\mathbf{i}\omega\varepsilon_0 R \cdot 2\mathbf{i}(kR)^3[(kR)^2+1][(kR)^6+1]^{-1}\right|}{\left|e^{-2\mathbf{i}k\widetilde{R}}\frac{\mathbf{i}-k\widetilde{R}}{\mathbf{i}+k\widetilde{R}}\frac{1+\mathbf{i}(k\widetilde{R})^3}{1-\mathbf{i}(k\widetilde{R})^3}\right| - 1} \leq \frac{2k(\omega\mu_0)^{-1}\cdot 4/3}{e^{2k\widetilde{R}_I}\frac{k\widetilde{R}_I-1}{k\widetilde{R}_I+1}\frac{(k\widetilde{R}_I)^3-1}{(k\widetilde{R}_I)^3+1} - 1}.$$

Since $k\widetilde{R}_I \geq 17$ (cf. (6.9)), it is easily seen that (6.10) holds for $l = 1$. The proof of Lemma 6.3 is complete. □

Now we return to the proof of Lemma 3.1. Let

$$v_S = \sum_{l=1}^{\infty}\sum_{m=-l}^{l}[c_l^m U_l^m + d_l^m V_l^m] \quad \text{and} \quad \overline{\phi_S} = \sum_{l=1}^{\infty}\sum_{m=-l}^{l}[\tilde{c}_l^m U_l^m + \tilde{d}_l^m V_l^m].$$

From (4.13), we have from the orthogonality of the basis functions that

$$\left|\omega\int_S(\mathcal{T}_S^{\mathrm{PML}} - \mathcal{T}_S)v_S\cdot\phi_S\right| = \left|\omega\sum_{l=1}^{\infty}\sum_{m=-l}^{l}[\rho_l c_l^m\overline{\tilde{c}_l^m} + \sigma_l d_l^m\overline{\tilde{d}_l^m}]\right|$$
$$\leq \mathcal{M}\sum_{l=1}^{\infty}\sum_{m=-l}^{l}\left[\sqrt{1 + l(l+1)}\,|c_l^m|\,|\tilde{c}_l^m| + \frac{1}{\sqrt{1 + l(l+1)}}\,|d_l^m|\,|\tilde{d}_l^m|\right].$$

The proof of Lemma 3.1 may be completed by the Cauchy–Schwarz inequality, Lemma 6.3, and the definition (4.3) of the norm of $TH^{-1/2}(\mathrm{curl}, S)$.

7. Conclusion.

Under the assumption that there is a unique solution of the original three-dimensional electromagnetic problem and some proper assumptions on the PML medium parameter, it is shown that the truncated PML problem attains a unique solution in $H(\mathrm{curl})$. An explicit error estimate between the solution of the scattering problem and that of the truncated PML problem in the computational domain is obtained. The error decays exponentially as the product of the wave number and the integrated absorption across the layer goes to infinity. The error estimate implies particularly that the PML solution converges exponentially to the scattering solution by increasing either the PML medium parameter or the PML layer thickness.

Appendix. Proof of Lemma 5.2.

A.1. Properties of $\boldsymbol{\xi}$.

Let

$$z = x + \mathbf{i}y = re^{\mathbf{i}\theta}, \qquad r > 0 \text{ and } |\theta| < \pi/2 \quad \text{or} \quad 0 < r < 1 \text{ and } |\theta| = \pi/2,$$

$$1/p = (1+z^2)^{1/2} = r_1 e^{\mathbf{i}\theta_1}, \quad |\theta_1| \le \pi/2,$$

where

$$r_1 = (1 + 2r^2\cos 2\theta + r^4)^{1/4}, \quad r_1^2 \cos 2\theta_1 = 1 + r^2 \cos 2\theta, \quad r_1^2 \sin 2\theta_1 = r^2 \sin 2\theta.$$

Denote

$$1 + (1+z^2)^{1/2} = r_2 e^{\mathbf{i}\theta_2}, \quad |\theta_2| \le \pi/2,$$

where

$$r_2 = (1 + 2r_1\cos\theta_1 + r_1^2)^{1/2}, \quad r_2\cos\theta_2 = 1 + r_1\cos\theta_1, \quad r_2 \sin\theta_2 = r_1\sin\theta_1.$$

Then, by the definition (5.1) of ξ, we have

$$\Re(\xi) = r_1\cos\theta_1 + \ln\frac{r}{r_2}, \quad \Im(\xi) = r_1\sin\theta_1 + \theta - \theta_2. \tag{A.1}$$

LEMMA A.1.
(i) $\Re(\xi)$ *is decreasing in* $|\theta|$.
(ii) $\Re(\xi)$ *is increasing in* $|y|$ *and hence* $\Re(\xi) \ge \xi(x)$.
(iii) $\Re(\xi)$ *is increasing in* r.
(iv) $|\Im(\xi)| \le r_1 \sin|\theta| + |\theta|$.
(v) $x - \frac{1}{2x} + \frac{1}{24x^3} > \xi(x) > x - \frac{1}{2x} + \frac{1}{38x^3}$ *for* $x \ge \frac{7}{10}$.

Proof. From

$$r_1\cos\theta_1 = \sqrt{(r_1^2 + 1 + r^2\cos 2\theta)/2} \tag{A.2}$$

and a direct calculation, we deduce that

$$\frac{\partial\Re(\xi)}{\partial\theta} = -\frac{r^2\cos\theta\sin\theta}{r_1\cos\theta_1}, \tag{A.3}$$

which yields (i).

Let $u =: r^2 \cos 2\theta = x^2 - y^2$. From (A.1) and (A.2), we have

$$\frac{\partial \Re(\xi)}{\partial y} = \frac{y f(r,u)}{2r^2 r_1 \cos\theta_1 r_2^2}, \text{ where } f(r,u) =: r^4 - r^2 r_2^2 + 2r_1 \cos\theta_1 r_2^2. \tag{A.4}$$

Noting that $r_1^4 \geq (1-r^2)^2$, we conclude that

$$\frac{\partial f}{\partial u} = \frac{r_2^2}{2r_1^3 \cos\theta_1}\left(2r_1\cos\theta_1 + r_1^2 + 1 - r^2\right) > 0.$$

Consequently, statement (ii) may be proved by observing

$$f(r,u) \begin{cases} \geq f(r,-r^2) = 2(1-r^2)(1+\sqrt{1-r^2})^2 > 0 & \text{if } r < 1, \\ > f(r,-r^2) = 0 & \text{if } r \geq 1. \end{cases}$$

By

$$\frac{\partial \Re(\xi)}{\partial y} = \frac{\partial \Re(\xi)}{\partial r}\frac{\partial r}{\partial y} + \frac{\partial \Re(\xi)}{\partial \theta}\frac{\partial \theta}{\partial y} = \frac{\partial \Re(\xi)}{\partial r}\frac{y}{r} + \frac{\partial \Re(\xi)}{\partial \theta}\frac{\cos\theta}{r},$$

(A.3), and (A.4), we get

$$\frac{\partial \Re(\xi)}{\partial r} = \frac{f(r,u)}{2rr_1\cos\theta_1 r_2^2} + \frac{r\cos^2\theta}{r_1\cos\theta_1} > 0,$$

which implies that (iii) holds.

By $r_1^2 \leq 1 + r^2$, we have

$$1 + r^2\cos 2\theta \leq (1+r^2)\cos 2\theta_1 \leq 1 + r^2 \cos 2\theta_1,$$

which is $\cos 2\theta \leq \cos 2\theta_1$, and hence $|\theta_1| \leq |\theta|$. Furthermore, by $r_1^2 \sin 2\theta_1 = r^2 \sin 2\theta$, we know that $\theta\theta_1 \geq 0$. Similarly, we can prove that $|\theta_2| \leq |\theta_1|$ and $\theta_2\theta_1 \geq 0$. Then (iv) follows from (A.1).

By $\frac{d\xi(x)}{dx} = \frac{\sqrt{1+x^2}}{x}$, we know that $\xi(x) - (x - \frac{1}{2x} + \frac{1}{24x^3})$ increases for $x \geq \frac{7}{10}$ and $\xi(x) - (x - \frac{1}{2x} + \frac{1}{38x^3})$ first increases and then decreases for $x \geq \frac{7}{10}$. The estimate (v) follows then from the facts that $\xi(x) - (x - \frac{1}{2x} + \frac{1}{24x^3})$ and $\xi(x) - (x - \frac{1}{2x} + \frac{1}{38x^3})$ both approach 0 as x approaches infinity, and $\xi(x) - (x - \frac{1}{2x} + \frac{1}{38x^3}) > 0$ at $x = \frac{7}{10}$. The proof of Lemma A.1 is complete. □

A.2. Variations of U_1. In the ξ plane, the variations $\mathcal{V}_{b_j,z}(U_1)$ in (5.10) and (5.11) can be written as $\mathcal{V}_{\xi(b_j),\xi}(U_1)$. We denote by $\mathcal{P}(\xi)$ the first segment of the variational paths, i.e., $\tilde{\xi} = \Re(\xi) + \mathbf{i}\Im(\xi)(1-t)$, $0 \leq t \leq 1$. Denote by $\tilde{\xi} = \xi(\tilde{z})$ $(\tilde{z} = \tilde{r}e^{\mathbf{i}\tilde{\theta}})$ a point on $\mathcal{P}(\xi)$, and let $\tilde{p} = p(\tilde{z}) = (1+\tilde{z}^2)^{-1/2}$ (cf. (5.1) and (5.2)). It is clear that

$$\begin{aligned} \mathcal{V}_{b_j,z}(U_1) = \mathcal{V}_{\xi(b_j),\xi}(U_1) &= \mathcal{V}_{\xi(b_j),\Re(\xi)}(U_1) + \mathcal{V}_{\Re(\xi),\xi}(U_1) \\ &\leq \int_0^1 |U_1'(\tilde{p})|\, d\tilde{p} + \int_0^1 |U_1'(\tilde{p})\tilde{p}'_{\tilde{\xi}}\Im(\xi)|\, dt, \end{aligned} \tag{A.5}$$

where $U_1'(\tilde{p}) = \frac{1-5\tilde{p}^2}{8}$ and $\tilde{p}'_{\tilde{\xi}} = \tilde{p}^4 - \tilde{p}^2$ (cf. (5.1)–(5.3)).

It is obvious that

$$\int_0^1 |U_1'(\tilde{p})| \, d\tilde{p} = \frac{1}{12} + \frac{1}{6\sqrt{5}} \,. \tag{A.6}$$

Lemma A.2. *Suppose* $|\arg z| = |\theta| \le \pi/4$. *Then*

$$\mathcal{V}_{b_j,z}(U_1) \le \frac{1}{12} + \frac{1}{6\sqrt{5}} + \frac{|\Im(z)|}{\Re(z)} \min\left\{ \left(\frac{4}{27}\right)^{1/4}, \frac{1}{\Re(z)} \right\}, \quad j = 1, 2.$$

Proof. First by Lemma A.1, we have

$$r\cos\theta \le \tilde{r} = |\tilde{z}| \le r \quad \text{and} \quad |\tilde{\theta}| \le |\theta| \le \pi/4 \ \text{ for } \ \tilde{\xi} \ \text{ on } \ \mathcal{P}(\xi).$$

Thus,

$$|U_1'(\tilde{p})| = \frac{1}{8}\left|\frac{(\tilde{z}^2-4)}{1+\tilde{z}^2}\right| = \frac{1}{8}\Big(\frac{16-8\tilde{r}^2\cos 2\tilde{\theta}+\tilde{r}^4}{1+2\tilde{r}^2\cos 2\tilde{\theta}+\tilde{r}^4}\Big)^{1/2} \le \frac{1}{8}\Big(\frac{16+\tilde{r}^4}{1+\tilde{r}^4}\Big)^{1/2} \le \frac{1}{2}$$

and

$$\begin{aligned} \left|\tilde{p}^3 - \tilde{p}\right| = \left|\tilde{z}^2\tilde{p}^3\right| &= \tilde{r}^2(1+2\tilde{r}^2\cos 2\tilde{\theta}+\tilde{r}^4)^{-3/4} \\ &\le \tilde{r}^2(1+\tilde{r}^4)^{-3/4} \le \min\left\{(4/27)^{1/4}, 1/\tilde{r}\right\}. \end{aligned} \tag{A.7}$$

We also have from the definition of $\tilde{p}$ that

$$|\tilde{p}| = (1+2\tilde{r}^2\cos 2\tilde{\theta}+\tilde{r}^4)^{-1/4} \le (1+2r^2\cos^2\theta\cos 2\theta + r^4\cos^4\theta)^{-1/4} \le 1.$$

Hence, form Lemma A.1(iv), we get

$$|\tilde{p}|\,|\Im\xi| \le \Big(\frac{1+2r^2\cos 2\theta + r^4}{1+2r^2\cos^2\theta\cos 2\theta + r^4\cos^4\theta}\Big)^{1/4} \sin|\theta| + |\theta| \le \tan|\theta| + |\theta| \le 2\tan|\theta|.$$

Finally, the proof is complete by combining (A.5) and (A.6),

$$|U_1'(\tilde{p})\tilde{p}_{\tilde{\xi}}'\Im(\xi)| = |U_1'(\tilde{p})|\left|\tilde{p}^3 - \tilde{p}\right||\tilde{p}|\,|\Im\xi|$$

along with the above estimates. □

Lemma A.3. *Suppose* $|\arg z| = \pi/2$ *and* $|z| < 1$. *Then*

$$\mathcal{V}_{b_j,z}(U_1) \le \frac{1}{12} + \frac{1}{6\sqrt{5}} + \frac{\pi|z|^2(4+|z|^2)}{16(1-|z|^2)^3}, \quad j = 1, 2.$$

Proof. By Lemma A.1(i) and (iii), we have, for $\tilde{\xi}$ on $\mathcal{P}(\xi)$, $\tilde{r} = |\tilde{z}| \le |z|$. Hence

$$\begin{aligned} |U_1'(\tilde{p})\tilde{p}_{\tilde{\xi}}'| = \left|\frac{\tilde{z}^2(\tilde{z}^2-4)}{8(1+\tilde{z}^2)^3}\right| &= \frac{\tilde{r}^2(16-8\tilde{r}^2\cos 2\tilde{\theta}+\tilde{r}^4)^{1/2}}{8(1+2\tilde{r}^2\cos 2\tilde{\theta}+\tilde{r}^4)^{3/2}} \\ &\le \frac{\tilde{r}^2(4+\tilde{r}^2)}{8(1-\tilde{r}^2)^3} \le \frac{|z|^2(4+|z|^2)}{8(1-|z|^2)^3}. \end{aligned}$$

Then the proof follows from (A.5), (A.6) and the fact that $\Im(\xi) = \pi/2$. □

A.3. The proof of Lemma 5.2. From (A.7), we have the following lemma.

LEMMA A.4.

$$\left|z^2p^3\right| \leq \begin{cases} \min\left\{\left(4/27\right)^{1/4}, 1/|z|\right\} & \textit{if } z \in D_1, \\ |z|^2/(1-|z|^2)^{3/2} & \textit{if } z \in D_2, \end{cases}$$

where D_1 *and* D_2 *are defined in* (5.12).

By applying Lemmas A.2–A.4 and (5.8)–(5.11), Lemma 5.2 may be proved easily.

EXPONENTIALLY CONVERGENT ALGORITHMS FOR THE OPERATOR EXPONENTIAL WITH APPLICATIONS TO INHOMOGENEOUS PROBLEMS IN BANACH SPACES*

I. P. GAVRILYUK† AND V. L. MAKAROV‡

Abstract. New exponentially convergent algorithms for the operator exponential generated by a strongly positive operator A in a Banach space X are proposed. These algorithms are based on representations by a Dunford–Cauchy integral along paths enveloping the spectrum of A combined with a proper quadrature involving a short sum of resolvents where the choice of the integration path dramatically affects desired features of the algorithms. A parabola and a hyperbola are analyzed as the integration paths, and scales of estimates of dependence on the smoothness of initial data, i.e., of the initial vector and of the inhomogeneous right-hand side, are obtained. One of the algorithms possesses an exponential convergence rate for the operator exponential e^{-At} for all $t \geq 0$ including the initial point. This allows one to construct an exponentially convergent algorithm for inhomogeneous initial value problems. The algorithm is parallelizable. It turns out that the resolvent must be modified in order to get numerically stable algorithms near the initial point. The efficiency of the proposed method is demonstrated by numerical examples.

1. Introduction.

We consider the problem

$$\frac{du(t)}{dt} + Au(t) = f(t), \quad u(0) = u_0, \tag{1.1}$$

where A is a strongly positive operator in a Banach space X, $u_0 \in X$ is a given vector, and $f(t)$ is a given and $u(t)$ is the unknown vector-valued function. A simple example of a partial differential equation covered by the abstract setting (1.1) is the classical inhomogeneous heat equation

$$\frac{\partial u(t,x)}{\partial t} - \frac{\partial^2 u(t,x)}{\partial x^2} = f(t,x)$$

with corresponding boundary and initial conditions, where the operator A is defined by

$$\begin{aligned} D(A) &= \{v \in H^2(0,1) : \ v(0) = 0, v(1) = 0\}, \\ Av &= -\frac{d^2 v}{dx^2} \qquad \forall v \in D(A). \end{aligned}$$

The homogeneous equation

$$\frac{dT(t)}{dt} + AT(t) = 0, \quad T(0) = I, \tag{1.2}$$

where I is the identity operator and $T(t)$ is an operator valued function, defines the semigroup of bounded operators $T(t) = e^{-At}$ generated by A (also called the operator exponential or the solution operator of the homogeneous equation (1.1)). Given the solution operator, the initial vector u_0, and the right-hand side $f(t)$, the solution of the homogeneous initial value problem (1.1) can be represented by

$$u(t) = u_o(t) = T(t)u_0 = e^{-At}u_0, \tag{1.3}$$

and the solution of the inhomogeneous problem can be represented by

$$u(t) = e^{-At}u_0 + u_p(t) \tag{1.4}$$

with

$$u_p(t) = \int_0^t e^{-A(t-\xi)} f(\xi)d\xi. \tag{1.5}$$

We can see that an efficient approximation of the operator exponential is needed in order to get an efficient discretization of both (1.3) and (1.4). Further, having in mind a discretization of the second summand in (1.4) by a quadrature sum, we need an efficient approximation of the operator exponential for all $t \geq 0$ including the point $t = 0$.

A convenient representation of the operator exponential is the one provided by the improper Dunford–Cauchy integral

$$e^{-At} = \frac{1}{2\pi i}\int_{\Gamma_I} e^{-tz}(zI - A)^{-1}dz, \tag{1.6}$$

where Γ_I is an integration path enveloping the spectrum of A. After parametrizing Γ we get an improper integral of the type

$$e^{-At} = \frac{1}{2\pi i}\int_{\Gamma_I} e^{-tz}(zI - A)^{-1}dz = \frac{1}{2\pi i}\int_{-\infty}^{\infty} \mathcal{F}(t,\xi)d\xi. \tag{1.7}$$

The last integral can be discretized by a quadrature rule (desirable exponentially convergent) involving a short sum of resolvents. Such an algorithm inherits a two-level parallelism with respect to both the computation of resolvents and the treatment of different time values.

Two efficient methods for solving linear homogeneous parabolic problems based on the improper Dunford–Cauchy integrals along a path enveloping the spectrum of A were recently proposed in [12,14,18,33,34] where the boundary of a sector containing the spectrum of A or a parabola was used as the integration path. The method from [33] possesses a polynomial convergence rate. The method from [12,18,23] uses sinc quadratures [1,36,37] and possesses an exponential convergence rate for $t > 0$ and a polynomial convergence rate for $t = 0$ depending on the smoothness of the initial vector u_0 from a Hilbert space. An exponential convergence rate for all $t \geq 0$ was proved in [13,42] under assumptions that the initial function u_0 belongs to the domain of $D(A^\sigma)$ for some $\sigma > 1$, where the preliminary computation of $A^\sigma u_0$ is needed. Note that all these algorithms cannot be directly applied to inhomogeneous problems due to the inefficiency of computation of the operator exponential at $t = 0$. In [20] a hyperbola was used as the integration path which allows one to get the uniform exponential convergence rate with respect to $t \geq 0$ without preliminary computation of $A^\sigma u_0$. An exponentially convergent algorithm for the case of an operator family $A(t)$ depending on the parameter t was proposed in [21]. This algorithm uses an exponentially convergent algorithm for the operator exponential generated by a constant operator.

In contrast to various other approximation methods with a polynomial convergence rate for the problem (1.1) using finite differences [4, 5, 6, 7, 9, 24, 25, 26, 28, 30, 39, 40, 41] or the Padé fractions [3, 9, 30] (both discrete in time), the Cayley transform [2,16,17,21] (continuous in time), and other ideas (see, for example, [19,22,32,38] and the references therein), the present paper introduces and analyzes new efficient *exponentially convergent* algorithms for the operator exponential including $t = 0$ which are also applied to inhomogeneous problems with certain holomorphic right-hand sides. The algorithms under consideration are parallelizable in an evident way.

The paper is organized as follows. In section 2 we derive some preliminary results concerning estimates of the resolvent of strongly positive operators by fractional powers of these operators. In this section we also discuss the question of selecting an integration parabola enveloping the spectrum of strongly P-positive operators avoiding intersection with the spectral parabola. In section 3 we analyze a parabola different from that of [12, 18] as the integration path in the Dunford–Cauchy representation of the operator exponential generated by a strongly P-positive operator A in a Banach space [11]. Then we construct a sinc approximation of this representation and give a new unified estimate for all $t \geq 0$ which shows the exponential convergence for $t > 0$ and presents a scale of estimates with respect to σ for $t = 0$ provided that $u_o \in D(A^\sigma), \quad \sigma > 1/2$. Using a hyperbola as the integration path, in section 4 we justify a new algorithm (a quadrature sum with with a step-size h including $2N$ resolvents) for the operator exponential e^{-At} which is of the order $\mathcal{O}(e^{-c\sqrt{N}})$ uniformly in $t \geq 0$ provided that $h = \mathcal{O}(1/\sqrt{N})$ and of the order $\mathcal{O}\left(\max\left\{e^{-\pi dN/(c_1 \ln N)},\ e^{-c_1 a_I tN/2 - c_1 \alpha \ln N}\right\}\right)$ for each fixed $t \geq 0$ provided that $h = c_1 \ln N/N$. Note that this algorithm supposes $u_0 \in D(A^\sigma),\ \sigma > 0$, but does not need the computation of $A^\sigma u_0$. The algorithms of section 4 based on the integration along a hyperbola have much better convergence properties than the algorithms of section 3 based on the integration along a parabola. Nevertheless we consider it necessary to also include these results as an example of the application of estimates from section 2 and in order to complete the theory developed in [12, 15, 18, 23] which was not extended for the case $t \geq 0$.

Let A be a densely defined strongly positive operator and $u_0 \in D(A^\alpha),\ \alpha \in (0, 1)$. Then sinc quadrature (4.22) represents an approximate solution of the homogeneous initial value problem (1.1) (i.e., $u(t) = e^{-At}u_0$) and possesses a uniform, with respect to $t \geq 0$, exponential convergence rate with estimate (4.23) which is of the order $\mathcal{O}(e^{-c\sqrt{N}})$ uniformly in $t \geq 0$ provided that $h = \mathcal{O}(1/\sqrt{N})$ and of the order $\mathcal{O}\left(\max\left\{e^{-\pi dN/(c_1 \ln N)},\ e^{-c_1 a_I tN/2 - c_1 \alpha \ln N}\right\}\right)$ for each fixed $t \geq 0$ provided that $h = c_1 \ln N/N$.

Since the integrand in (1.7) is mainly concentrated on a finite interval and decreases very rapidly outside the interval, we truncate the integral to the one over the finite interval and implement a sinc quadrature to approximate it. Estimating the remainders and equalizing all estimates leads to another exponentially convergent approximation. A comparative analysis of both approximations is given in section 5 and shows that despite of lower asymptotic convergence rate this approach can be better for N not very large. Section 6 deals with the inhomogeneous problem (1.1). In order to approximate the inhomogeneous problem, we represent the second summand in

(1.4) in the following way:

$$
\begin{aligned}
u_p(t) &= \int_0^t e^{-A(t-\xi)} f(\xi) d\xi = \frac{1}{2\pi i} \int_{\Gamma_I} \int_0^t e^{-z(t-\xi)} f(\xi) d\xi dz \\
&= \int_{-\infty}^{\infty} \mathcal{F}_1(t,\eta) d\eta.
\end{aligned} \tag{1.8}
$$

We then replace this integral by a new quadrature. The latter uses our first algorithm to compute the integrand $\mathcal{F}_1(t,\eta)$ at each quadrature node. Note that one of the crucial points in our approach disinguishing the new algorithms from other ones cited above is the use of a modified resolvent which allows one to also get a numerical stable algorithm for small t. The theoretical results of this paper are confirmed by numerical examples. We establish the conditions on $f(t)$ under which this algorithm possesses an exponential convergence rate when solving the problem (1.2) on the infinite interval $[0,\infty)$. It turns out that the function $f(t)$ has to possess the analytical extension in a sector $\Sigma_f = \{z = \rho e^{i\psi} : \ \rho \in (0,\infty), \ \psi \in (-\phi_1, \phi_1), 0 < \phi_1 < \pi/2\}$ and has to possess the estimate $\|f(z)\| \le ce^{-c_1 \Re z}$ for all $z \in \Sigma_f$, where ϕ_1, c_1 are consistent with the spectral characteristics of the operator A.

2. Preliminaries.

2.1. Estimates of the resolvent through fractional powers of strongly positive operators.

Let A be a densely defined strongly positive (sectorial) operator in a Banach space X with the domain $D(A)$; i.e., its spectrum $\Sigma(A)$ lies in the sector

$$
\Sigma = \left\{ z = a_0 + re^{i\theta} : \ r \in [0,\infty), \ |\theta| < \varphi < \frac{\pi}{2} \right\} \tag{2.1}
$$

and on its boundary Γ_Σ, and outside the sector the following estimate for the resolvent holds true:

$$
\|(zI - A)^{-1}\| \le \frac{M}{1+|z|} \tag{2.2}
$$

with some positive constant M (compare with [17,27,29,35]). The angle φ is called the spectral angle of the operator A. A practically important example of strongly positive operators in $X = L_p(\Omega), \ 0 < p < \infty$, represents a strongly elliptic partial differential operator [10,11,12,17,21,29,31] where the parameters a_0, φ of the sector Σ are defined by its coefficients.

For an initial vector $u_0 \in D(A^{m+1})$ it holds

$$
\sum_{k=1}^{m+1} \frac{A^{k-1} u_0}{z^k} + \frac{1}{z^{m+1}} (zI - A)^{-1} A^{m+1} u_0 = (zI - A)^{-1} u_0. \tag{2.3}
$$

This equality together with

$$
A^{-(m+1)} v = \frac{1}{2\pi i} \int_{\Gamma_I} z^{-(m+1)} (zI - A)^{-1} v dz, \tag{2.4}
$$

by setting $v = A^{m+1} u_0$, yields the following representation:

$$
\begin{aligned}
u_0 &= A^{-(m+1)} A^{m+1} u_0 = \frac{1}{2\pi i} \int_{\Gamma_I} z^{-(m+1)} (zI - A)^{-1} A^{m+1} u_0 dz \\
&= \int_{\Gamma_I} \left[(zI - A)^{-1} - \sum_{k=1}^{m+1} \frac{A^{k-1}}{z^k} \right] u_0 dz
\end{aligned} \tag{2.5}
$$

with an integration path Γ_I situated in the right half-plane and enveloping Γ_Σ. Let us estimate the norm of the first integrand in (2.5) as a function of $|z|$ under the assumption $u_0 \in D(A^{m+\alpha})$, $m \in \mathbb{N}$, $\alpha \in [0,1]$. Since the operator A is strongly positive it holds on and outside the integration path:

$$\begin{aligned} &\|(zI-A)^{-1}w\| \le \frac{M}{1+|z|}\|w\|, \\ &\|A(zI-A)^{-1}w\| \le (1+M)\|w\|. \end{aligned} \tag{2.6}$$

These estimates yield (see, e.g., Theorem 4 of [27])

$$\|A^{1-\alpha}(zI-A)^{-1}w\| \le K\|A(zI-A)^{-1}w\|^{1-\alpha}\|(zI-A)^{-1}w\|^{\alpha}, \tag{2.7}$$

where the constant K depends on α and M only. This inequality while taking into account (2.6) implies

$$\|A^{1-\alpha}(zI-A)^{-1}\| \le \frac{K(1+M)}{(1+|z|)^{\alpha}}, \quad \alpha \in [0,1], \tag{2.8}$$

which leads to the estimate

$$\begin{aligned} &\left\| \left[(zI-A)^{-1} - \frac{1}{z}I\right]u_0 \right\| = \frac{1}{|z|}\|A^{1-\alpha}(zI-A)^{-1}A^{\alpha}u_0\| \\ &\le \frac{(1+M)K}{|z|(1+|z|)^{\alpha}}\|A^{\alpha}u_0\| \qquad \forall \alpha \in [0,1],\ u_0 \in D(A^{\alpha}). \end{aligned} \tag{2.9}$$

This estimate can be easily generalized to

$$\begin{aligned} &\left\| \left[(zI-A)^{-1} - \sum_{k=1}^{m+1}\frac{A^{k-1}}{z^k}\right]u_0 \right\| = \left\| \frac{1}{z^{m+1}}(zI-A)^{-1}A^{m+1}u_0 \right\| \\ &= \frac{1}{|z|^{m+1}}\|A^{1-\alpha}(zI-A)^{-1}A^{m+\alpha}u_0\| \le \frac{1}{|z|^{m+1}}\frac{(1+M)K}{(1+|z|)^{\alpha}}\|A^{m+\alpha}u_0\| \\ &\forall \alpha \in [0,1],\ u_0 \in D(A^{m+\alpha}). \end{aligned} \tag{2.10}$$

Thus, we get the following result, which we will need below.

THEOREM 2.1. *Let $u_0 \in D(A^{m+\alpha})$ for some $m \in \mathbb{N}$, and let $\alpha \in [0,1]$. Then the estimate* (2.10) *holds true.*

2.2. The integration parabola. There are many possibilities to define and to approximate functions of an operator A. Let Γ be the boundary of a domain Σ in the complex plane containing the spectrum of A, and let $\tilde{f}(z)$ be an analytical function in Σ. Then the Dunford–Cauchy integral

$$\tilde{f}(A) = \frac{1}{2\pi i}\int_{\Gamma}\tilde{f}(z)(zI-A)^{-1}dz \tag{2.11}$$

defines a function of A provided that the integral converges.

By a parametrizing of $\Gamma = \{z = \xi(s) + i\eta(s) :\ s \in (-\infty,\infty)\}$, one can translate the integral (2.11) into the integral

$$\tilde{f}(A) = \int_{-\infty}^{\infty}F(s)ds \tag{2.12}$$

with

$$F(s) = \frac{1}{2\pi i}\tilde{f}(z)(zI - A)^{-1}z'(s). \tag{2.13}$$

Choosing various integration paths and using various quadrature formulas, one can obtain approximations of $\tilde{f}(A)$ with desired properties (see, for example, [12, 13, 15, 17, 21, 23] where various functions of operators were investigated).

It was shown in [8, 11, 12, 18, 31] that the spectrum of a strongly elliptic operator in a Hilbert space lies in a domain enveloped by a parabola defined by the coefficients of the operator and that the resolvent on and outside of the parabola possesses the estimate

$$\|(zI - A)^{-1}\| \leq \frac{M}{1 + \sqrt{|z|}} \tag{2.14}$$

with some positive constant M. Such operators are called strongly P-positive operators. The paper [31] also contains examples of differential operators which are strongly P-positive in such genuine Banach spaces as $L_1(0,1)$ or $L_\infty(0,1)$. One of the natural choices of the integration path for these operators is a parabola which does not intersect the spectral parabola containing the spectrum of the operator.

Let

$$\Gamma_0 = \{z = \xi - i\eta :\ \xi = a_0\eta^2 + b_0,\ a_0 > 0,\ b_0 > 0,\ \eta \in (-\infty, \infty)\} \tag{2.15}$$

be the spectral parabola enveloping the spectrum of the operator A. [12, 18] showed how one can define the coefficients of an integration parabola by the coefficients of the spectral parabola so that the integrand in (2.12) can be analytically extended into a symmetric strip D_d of a width $2d$ around the real axes, but this choice was rather complicated.

Below we propose another (simpler) method to define the integration parabola through the spectral one.

We have to choose an integration parabola

$$\Gamma_I = \{z = \xi - i\eta :\ \xi = a_I\eta^2 + b_I,\ a_I > 0,\ b_I > 0,\ \eta \in (-\infty, \infty)\} \tag{2.16}$$

so that its top lies in $(0, b_0)$ and its opening is greater than the one of the spectral parabola, i.e., $a_I < a_0$. Moreover, by changing η to $\eta + i\nu$ the set of parabolas

$$\begin{aligned} &\Gamma(\nu) = \{z = \xi - i\eta : \xi = a_I\eta^2 + b_I - a_I\nu^2 + \nu - i\eta(1 - 2a_I\nu), \eta \in (-\infty, \infty)\} \\ &\quad = \left\{z = \xi - i\tilde{\eta} :\ \xi = \frac{a_I}{(1 - 2a_I\nu)^2}\tilde{\eta}^2 + b_I - a_I\nu^2 + \nu, \tilde{\eta} = (1 - 2a_I\nu)\eta \in (-\infty, \infty)\right\}, \end{aligned} \tag{2.17}$$

for $|\nu| < d$ must lie outside of the spectral parabola (only in this case can one guarantee that the resolvent of A remains bounded). Note that the substitution $\tilde{\eta} = (1 - 2a_I\nu)\eta$ must be nonsingular for all $|\nu| < d$, which yields $a_I < 1/(2d)$. We choose d so that the top of the integration parabola coincides with top of the spectral one and the opening of the integration parabola is greater than the opening of the spectral parabola for $\nu = d$. For $\nu = -d$ we demand that the integration parabola lies outside of the spectral parabola and that its top lies at the origin. Thus, it must be

$$\begin{cases} \frac{a_I}{(1-2a_Id)^2} = a_0, \\ b_I - a_Id^2 + d = b_0, \\ b_I - a_Id^2 - d = 0. \end{cases} \tag{2.18}$$

It follows immediately from the last two equations that $2d = b_0$. From the first equation

$$4d^2 a_0 a_I^2 - a_I(1 + 4a_0 d) + a_0 = 0. \tag{2.19}$$

After the substitution $d = b_0/2$ we get

$$a_I = \frac{1 + 2a_0 b_0 \pm \sqrt{1 + 4a_0 b_0}}{2a_0 b_0}, \tag{2.20}$$

but only the root

$$a_I = \frac{1 + 2a_0 b_0 - \sqrt{1 + 4a_0 b_0}}{2a_0 b_0} = \frac{2a_0}{1 + 2a_0 b_0 + \sqrt{1 + 4a_0 b_0}} \tag{2.21}$$

satisfies the condition $a_I < 1/(2d) = 1/b_0$. Thus, the parameters of the integration parabola from which the integrand can be analytically extended into the strip D_d of the width

$$d = b_0/2 \tag{2.22}$$

are

$$\begin{aligned} a_I &= \frac{1 + 2a_0 b_0 - \sqrt{1 + 4a_0 b_0}}{2a_0 b_0} = \frac{2a_0}{1 + 2a_0 b_0 + \sqrt{1 + 4a_0 b_0}}, \\ b_I &= \frac{a_I b_0^2}{4} + \frac{b_0}{2}. \end{aligned} \tag{2.23}$$

3. New algorithm with integration along a parabola and a scale of estimates. Let A be a strongly P-positive operator, and let

$$u_0 \in D(A^\alpha),\ \alpha > 0. \tag{3.1}$$

In this case due to (2.10) with $m = 0$ we have

$$\begin{aligned} &\left\| \left[(zI - A)^{-1} - \frac{1}{z} I \right] u_0 \right\| = \left\| \frac{1}{z} (zI - A)^{-1} A u_0 \right\| \\ &= \frac{1}{|z|} \| A^{1-\alpha} (zI - A)^{-1} A^\alpha u_0 \| \le \frac{1}{|z|} \| A^{1-\alpha} (zI - A)^{-1} \| \| A^\alpha u_0 \|. \end{aligned} \tag{3.2}$$

The resolvent of the strongly P-positive operator is bounded on and outside the spectral parabola; more precisely, we have

$$\begin{aligned} &\|(zI - A)^{-1} w\| \le \frac{M}{1 + \sqrt{|z|}} \|w\|, \\ &\|A(zI - A)^{-1} w\| \le \left(1 + \frac{M|z|}{1 + \sqrt{|z|}} \right) \|w\| \le (1 + M\sqrt{|z|}) \|w\|. \end{aligned} \tag{3.3}$$

We suppose that our operator A is at the same time strongly positive (note that a strongly elliptic operator is both strongly P-positive [11] and strongly positive). We can use Theorem 4 of [27] and get

$$\begin{aligned} &\|A^{1-\alpha} (zI - A)^{-1} w\| \le K(\alpha) (1 + M\sqrt{|z|})^{1-\alpha} \left(\frac{M}{1 + \sqrt{|z|}} \right)^\alpha \|w\| \\ &\le \max(1, M) K(\alpha) \frac{\|w\|}{(1 + \sqrt{|z|})^{2\alpha - 1}} \end{aligned} \tag{3.4}$$

with a constant $K(\alpha)$ independent of α where $K(1) = K(0) = 1$. The last inequality and (3.1) imply that

$$\left\| \left[(zI - A)^{-1} - \frac{1}{z} I \right] u_0 \right\| \le \max(1, M) K(\alpha) \frac{\|A^\alpha u_0\|}{|z|^{\alpha + \frac{1}{2}}} \tag{3.5}$$

which justifies for the integration path above the following representation of the solution of the homogeneous problem (1.1)

$$\begin{aligned} u(t) = e^{-At} u_0 &= \frac{1}{2\pi i} \int_{\Gamma_I} e^{-tz} (zI - A)^{-1} u_0 dz \\ &= \frac{1}{2\pi i} \int_{\Gamma_I} e^{-tz} \left[(zI - A)^{-1} - \frac{1}{z} I \right] u_0 dz, \end{aligned} \tag{3.6}$$

provided that $\alpha > 0$. After parametrizing the integral we get

$$u(t) = \int_{-\infty}^{\infty} F(t, \eta) d\eta \tag{3.7}$$

with

$$\begin{aligned} F(t, \eta) &= -\frac{1}{2\pi i} (2 a_I \eta - i) e^{-t(a_I \eta^2 + b_I - i\eta)} \\ &\times \left\{ [(a_I \eta^2 + b_I - i\eta) I - A]^{-1} - \frac{1}{a_I \eta^2 + b_I - i\eta} I \right\} u_0. \end{aligned} \tag{3.8}$$

Following to [36], we construct a quadrature rule for the integral in (2.12) by using the sinc approximation on $(-\infty, \infty)$. For $1 \le p \le \infty$, introduce the family $\mathbf{H}^p(D_d)$ of all vector-valued functions, which are analytic in the infinite strip D_d,

$$D_d = \{ z \in \mathbb{C} : -\infty < \Re z < \infty, |\Im z| < d \}, \tag{3.9}$$

such that if $D_d(\epsilon)$ is defined for $0 < \epsilon < 1$ by

$$D_d(\epsilon) = \{ z \in \mathbb{C} : |\Re z| < 1/\epsilon, |\Im z| < d(1 - \epsilon) \}, \tag{3.10}$$

then for each $\mathcal{F} \in \mathbf{H}^p(D_d)$ there holds $\|\mathcal{F}\|_{\mathbf{H}^p(D_d)} < \infty$ with

$$\|\mathcal{F}\|_{\mathbf{H}^p(D_d)} = \begin{cases} \lim\limits_{\epsilon \to 0} \left(\int_{\partial D_d(\epsilon)} \|\mathcal{F}(z)\|^p |dz| \right)^{1/p} & \text{if } 1 \le p < \infty, \\ \lim\limits_{\epsilon \to 0} \sup\limits_{z \in \partial D_d(\epsilon)} \|\mathcal{F}(z)\| & \text{if } p = \infty. \end{cases} \tag{3.11}$$

Let

$$S(k, h)(x) = \frac{\sin[\pi(x - kh)/h]}{\pi(x - kh)/h} \tag{3.12}$$

be the kth sinc function with step-size h, evaluated in x. Given $\mathcal{F} \in \mathbf{H}^p(D_d), h > 0,$

and positive integer N, let us use the notations

$$\begin{aligned}
&I(\mathcal{F}) = \int_{\mathbb{R}} \mathcal{F}(x)dx, \qquad T_N(\mathcal{F},h) = h\sum_{k=-N}^{N}\mathcal{F}(kh),\\
&T(\mathcal{F},h) = h\sum_{k=-\infty}^{\infty}\mathcal{F}(kh),\\
&C(\mathcal{F},h) = \sum_{k=-\infty}^{\infty}\mathcal{F}(kh)S(k,h),\\
&\eta_N(\mathcal{F},h) = I(\mathcal{F}) - T_N(\mathcal{F},h), \qquad \eta(\mathcal{F},h) = I(\mathcal{F}) - T(\mathcal{F},h).
\end{aligned}$$

Applying the quadrature rule T_N with the vector-valued function (3.8), we obtain for integral (3.7)

$$u(t) = \exp(-tA)u_0 \approx u_N(t) = \exp_N(-tA)u_0 = h\left(\sum_{k=-N}^{N}F(kh,t)\right)u_0. \tag{3.13}$$

Below we show that this Sinc-quadrature approximation with a proper choice of h converges exponentially provided that the integrand can be analytically extended into a strip D_d. This property of the integrand depends on the choice of the integration path.

Taking into account (3.5) we get

$$\|F(t,\eta)\| \le c\frac{e^{-t(a_I\eta^2+b_I)}}{(1+|\eta|)^{2\alpha}}\|A^\alpha u_0\| \qquad \forall t\ge 0,\ \alpha > 1/2 \tag{3.14}$$

(the inequality $\alpha > 1/2$ guarantees the convergence of the integral (3.7)). The analysis of the integration parabola above implies that the vector-valued function $F(\eta,t)$ can be analytically extended into the strip D_d and belongs to the class $\mathbf{H}^1(D_d)$ with respect to η with the estimate

$$\|F(t,z)\|_{\mathbf{H}^1(D_d)} \le c\frac{e^{-b_It}}{2\alpha-1}\|A^\alpha u_0\| \qquad \forall t\ge 0,\ \alpha > 1/2. \tag{3.15}$$

For our further analysis of the error $\eta_N(\mathcal{F},h) = \exp(-tA)u_0 - \exp_N(-tA)u_0$ of the quadrature rule (3.13), we use the following lemma from [23].

LEMMA 3.1. *For any vector-valued function $f \in \mathbf{H}^1(D_d)$, there holds*

$$\eta(\tilde{f},h) = \frac{i}{2}\int_{\mathbb{R}}\left\{\frac{\tilde{f}(\xi - id^-)e^{-\pi(d+i\xi)/h}}{\sin[\pi(\xi-id)/h]} - \frac{\tilde{f}(\xi + id^-)e^{-\pi(d-i\xi)/h}}{\sin[\pi(\xi+id)/h]}\right\}d\xi, \tag{3.16}$$

which yields the estimate

$$\|\eta(\tilde{f},h)\| \le \frac{e^{-\pi d/h}}{2\sinh(\pi d/h)}\|\tilde{f}\|_{\mathbf{H}^1(D_d)}. \tag{3.17}$$

If, in addition, $\tilde{f}$ satisfies on $\mathbb{R}$ the condition

$$\begin{aligned}&\|\tilde{f}(x)\| \le \frac{ce^{-\beta x^2}}{(1+x^2)^\sigma}, \qquad 1/2 < \sigma \le 1\\ &c,\beta > 0,\end{aligned} \tag{3.18}$$

then

$$\|\eta_N(\tilde{f},h)\| \le \frac{2c}{2\sigma-1}\left\{2\sigma\frac{\exp(-\pi d/h)}{\sinh(\pi d/h)}+\frac{\exp\left(-\beta(Nh)^2\right)}{(Nh)^{2\sigma-1}}\right\}. \tag{3.19}$$

Taking into account the estimates (3.14) and (3.15) and setting F for $\tilde{f}$, α for σ, and ta_I for β, we get the estimate

$$\begin{aligned}\|\eta_N(F,h)\| &= \|\exp(-tA)u_0-\exp_N(-tA)u_0\|\\ &\le c\frac{e^{-b_It}}{2\alpha-1}\left\{2\alpha\frac{\exp(-\pi d/h)}{\sinh(\pi d/h)}+\frac{\exp\left(-a_It(Nh)^2\right)}{(Nh)^{2\alpha-1}}\right\}\|A^\alpha u_0\|.\end{aligned} \tag{3.20}$$

Equalizing the exponents here by setting $\pi d/h = a_I(Nh)^2$, we get for the step-size of the quadrature

$$h=\sqrt[3]{\pi d/(a_IN^2)}. \tag{3.21}$$

Since $\sinh(\pi d/h)\ge e^{\pi d/h}/2$, $\pi d/h=(\sqrt{a_I}\pi dN)^{2/3}$, $Nh=\sqrt[3]{\pi dN/a_I}$, $(Nh)^{2\alpha-1}=(\pi dN/a_I)^{(2\alpha-1)/3}$, and $d=b_0$, we get with this step-size the following scale of estimates for the algorithm (3.13):

(3.22)
$$\begin{aligned}&\|\eta_N(\mathcal{F},h)\| = \|\exp(-tA)u_0-\exp_N(-tA)u_0\|\\ &\le c\frac{e^{-b_It}}{2\alpha-1}\left\{4\alpha\exp(-2(\sqrt{a_I}\pi b_0)^{2/3}N^{2/3})+\frac{\exp\left(-a_It(\pi b_0N/a_I)^{2/3}\right)}{(\pi b_0N/a_I)^{(2\alpha-1)/3}}\right\}\|A^\alpha u_0\|.\end{aligned}$$

Thus, we have proven the following statement.

THEOREM 3.2. *Let A be a strongly P-positive operator in a Banach space X with the resolvent satisfying* (2.14) *and with the spectral parabola given by* (2.15). *Then for the sinc approximation* (3.13) *we have the estimate* (3.22), *i.e.,*

$$\|\exp(-tA)u_0-\exp_N(-tA)u_0\| = \begin{cases}\mathcal{O}(e^{-c_1N^{2/3}}) & \text{if } t>0,\\ \mathcal{O}(N^{(2\alpha-1)/3}) & \text{if } t=0,\end{cases} \tag{3.23}$$

provided that $u_0\in D(A^\alpha)$, $\alpha>1/2$.

Remark 3.1. The above algorithm possesses two sequential levels of parallelism: First, one can compute all $\hat{u}(z_p)$ at step 2 in parallel, and second, the solution $u(t)=e^{-At}u_0$ at different time values $(t_1,t_2,\dots,t_M)$.

4. New algorithm for the operator exponential with an exponential convergence estimate including $t=0$. We consider the following representation of the operator exponential:

$$u(t)=\frac{1}{2\pi i}\int_{\Gamma_I}e^{-zt}(zI-A)^{-1}u_0dz. \tag{4.1}$$

Our aim is to approximate this integral by a quadrature with exponential convergence rate including $t=0$. It is of great importance to have in mind the representation of the solution of the nonhomogeneous initial value problem (1.1) by

$$u(t)=e^{-At}u_0+\int_0^t e^{-A(t-\xi)}\tilde{f}(\xi)d\xi, \tag{4.2}$$

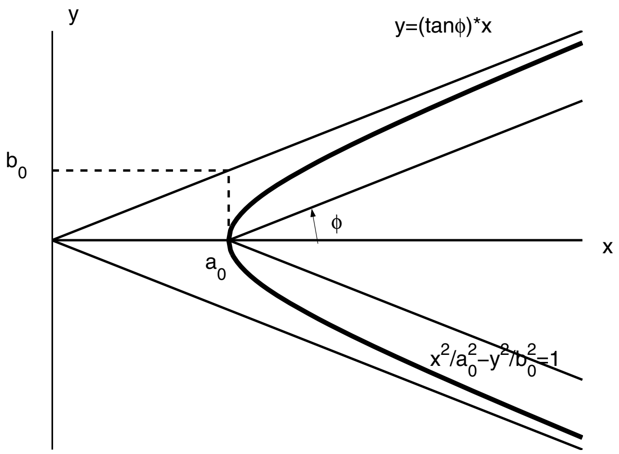

FIG. 4.1. *Spectral characteristics of the operator A.*

where the argument of the operator exponential under the integral becomes zero for $\xi = t$. Taking into account (2.5) for $m = 0$, one can see that we can represent

$$u(t) = \frac{1}{2\pi i}\int_{\Gamma_I} e^{-zt}\left[(zI - A)^{-1} - \frac{1}{z}I\right]u_0 dz \tag{4.3}$$

instead of (4.1) (for $t > 0$, the integral from the second summand is equal to zero due to the analyticity of the integrand inside of the integration path), and this integral represents the solution of the problem (1.1) for $u_0 \in D(A^\alpha),\ \alpha > 0$. We call the hyperbola

$$\Gamma_0 = \{z(\xi) = a_0\cosh\xi - ib_0\sinh\xi :\ \xi \in (-\infty,\infty),\ b_0 = a_0\tan\varphi\} \tag{4.4}$$

the spectral hyperbola, which has paths through the vertex $(a_0, 0)$ of the spectral angle and possesses asymptotes which are parallel to the rays of the spectral angle Σ (see Figure 4.1). We choose the following hyperbola as an integration path:

$$\Gamma_I = \{z(\xi) = a_I\cosh\xi - ib_I\sinh\xi :\ \xi \in (-\infty,\infty)\}. \tag{4.5}$$

After parametrizing the integral (4.3) by (4.5), we get

$$u(t) = \frac{1}{2\pi i}\int_{-\infty}^{\infty}\mathcal{F}(t,\xi)d\xi \tag{4.6}$$

with

$$\begin{aligned} &\mathcal{F}(t,\xi) = F_A(t,\xi)u_0,\\ &F_A(t,\xi) = e^{-z(\xi)t}(a_I\sinh\xi - ib_I\cosh\xi)\left[(z(\xi)I - A)^{-1} - \frac{1}{z(\xi)}I\right]. \end{aligned} \tag{4.7}$$

In order to estimate $\|\mathcal{F}(t,\xi)\|$ we need an estimate for $|z'(\xi)/z(\xi)| = \overline{(a_I\sinh\xi - ib_I\cosh\xi)/(a_I\cosh\xi - ib_I\sinh\xi)} = \sqrt{(a_I^2\tanh^2\xi + b_I^2)/(b_I^2\tanh^2\xi + a_I^2)}$. The quotient under the square root as a function of $v = \tanh^2\xi \in [0,1]$ takes its maximum at $v = 0$ since the sign of the first derivative coincides with the sign of

$a_I^4 - b_I^4 = -a_0^4 \sin\varphi/\cos^4\varphi$, i.e., we have

$$|z'(\xi)/z(\xi)| \le b_I/a_I. \tag{4.8}$$

Supposing $u_0 \in D(A^\alpha)$, $0 < \alpha < 1$, using (4.8) and Theorem 2.1, we can estimate the integrand on the real axis $\xi \in \mathbb{R}$ for each $t \ge 0$ by

$$\begin{aligned} \|\mathcal{F}(t,\xi)\| &\le e^{-a_I t\cosh\xi}\frac{(1+M)K\sqrt{a_I^2\sinh^2\xi + b_I^2\cosh^2\xi}}{(a_I^2\cosh^2\xi + b_I^2\sinh^2\xi)^{(1+\alpha)/2}}\|A^\alpha u_0\| \\ &\le (1+M)K\frac{b_I}{a_I}\frac{e^{-a_I t\cosh\xi}}{(a_I^2\cosh^2\xi + b_I^2\sinh^2\xi)^{\alpha/2}}\|A^\alpha u_0\| \\ &\le (1+M)K\frac{b_I}{a_I}\left(\frac{2}{a_I}\right)^\alpha e^{-a_I t\cosh\xi - \alpha|\xi|}\|A^\alpha u_0\|, \qquad \xi \in \mathbb{R},\ t \ge 0. \end{aligned} \tag{4.9}$$

Let us show that the function $\mathcal{F}(t,\xi)$ can be analytically extended with respect to ξ into a strip of a width d_1. After changing ξ to $\xi + i\nu$ the integration hyperbola Γ_I will be translated into the curve

$$\begin{aligned} \Gamma(\nu) &= \{z(w) = a_I\cosh(\xi+i\nu) - ib_I\sinh(\xi+i\nu) :\ \xi \in (-\infty,\infty)\} \\ &= \{z(w) = a(\nu)\cosh\xi - ib(\nu)\sinh\xi :\ \xi \in (-\infty,\infty)\} \end{aligned} \tag{4.10}$$

with

$$\begin{aligned} a(\nu) &= a_I\cos\nu + b_I\sin\nu = \sqrt{a_I^2+b_I^2}\sin(\nu+\phi/2), \\ b(\nu) &= b_I\cos\nu - a_I\sin\nu = \sqrt{a_I^2+b_I^2}\cos(\nu+\phi/2), \\ \cos\frac{\phi}{2} &= \frac{b_I}{\sqrt{a_I^2+b_I^2}}, \qquad \sin\frac{\phi}{2} = \frac{a_I}{\sqrt{a_I^2+b_I^2}}. \end{aligned} \tag{4.11}$$

The analyticity of the function $\mathcal{F}(t,\xi+i\nu)$, $|\nu| < d_1/2$, can be violated if the resolvent becomes unbounded. Thus, we must choose d_1 so that the hyperbola $\Gamma(\nu)$ for $\nu \in (-d_1/2, d_1/2)$ remains in the right half-plane of the complex plane, for $\nu = -d_1/2$ coincides with the imaginary axis, for $\nu = d_1/2$ coincides with the spectral hyperbola, and for all $\nu \in (-d_1/2, d_1/2)$ does not intersect the spectral sector. Then we choose the hyperbola $\Gamma(0)$ as the integration hyperbola.

This implies the following system of equations

$$\begin{cases} a_I\cos(d_1/2) + b_I\sin(d_1/2) = a_0, \\ b_I\cos(d_1/2) - a_I\sin(d_1/2) = a_0\tan\varphi, \\ a_I\cos(-d_1/2) + b_I\sin(-d_1/2) = 0, \end{cases} \tag{4.12}$$

from which we get

$$\begin{cases} 2a_I\cos(d_1/2) = a_0, \\ b_I = a_0\sin(d_1/2) + b_0\cos(d_1/2), \\ a_I = a_0\cos(d_1/2) - b_0\sin(d_1/2). \end{cases} \tag{4.13}$$

Eliminating a_I from the first and the third equations, we get $a_0\cos d_1 = b_0\sin d_1$, i.e., $d_1 = \pi/2 - \varphi$ with $\cos\varphi = \frac{a_0}{\sqrt{a_0^2+b_0^2}}$, $\sin\varphi = \frac{b_0}{\sqrt{a_0^2+b_0^2}}$. Thus, if we choose the parameters of the integration hyperbola by

$$\begin{aligned} a_I &= a_0\cos\left(\frac{\pi}{4}-\frac{\varphi}{2}\right) - b_0\sin\left(\frac{\pi}{4}-\frac{\varphi}{2}\right) \\ &= \sqrt{a_0^2+b_0^2}\cos\left(\frac{\pi}{4}+\frac{\varphi}{2}\right) = a_0\frac{\cos\left(\frac{\pi}{4}+\frac{\varphi}{2}\right)}{\cos\varphi}, \\ b_I &= a_0\sin\left(\frac{\pi}{4}-\frac{\varphi}{2}\right) + b_0\cos\left(\frac{\pi}{4}-\frac{\varphi}{2}\right) \\ &= \sqrt{a_0^2+b_0^2}\sin\left(\frac{\pi}{4}+\frac{\varphi}{2}\right) = a_0\frac{\sin\left(\frac{\pi}{4}+\frac{\varphi}{2}\right)}{\cos\varphi}, \end{aligned} \tag{4.14}$$

then the vector-valued function $\mathcal{F}(t,w)$ is for all $t \geq 0$ analytic with respect to $w = \xi + i\nu$ in the strip

$$D_{d_1} = \{w = \xi + i\nu : \ \xi \in (-\infty,\infty), \ |\nu| < d_1/2\}. \tag{4.15}$$

Now, estimate (4.9) takes the form

$$\begin{aligned} \|\mathcal{F}(t,\xi)\| &\leq C(\varphi,\alpha)e^{-a_I t\cosh\xi - \alpha|\xi|}\|A^\alpha u_0\| \\ &\leq C(\varphi,\alpha)e^{-\alpha|\xi|}\|A^\alpha u_0\|, \qquad \xi\in\mathbb{R},\ t\geq 0, \end{aligned} \tag{4.16}$$

with

$$C(\varphi,\alpha) = (1+M)K\tan\left(\frac{\pi}{4}+\frac{\varphi}{2}\right)\left(\frac{2\cos\varphi}{a_0\cos\left(\frac{\pi}{4}+\frac{\varphi}{2}\right)}\right)^\alpha. \tag{4.17}$$

Comparing (4.14) with (4.11) we get $\phi = \pi/2 - \varphi$ and

$$\begin{aligned} &a(\nu) = a_I\cos\nu + b_I\sin\nu = \frac{a_0\sin(\nu+\pi/4-\varphi/2)}{\cos\varphi} = \frac{a_0\cos(\pi/4+\varphi/2-\nu)}{\cos\varphi}, \\ &b(\nu) = b_I\cos\nu - a_I\sin\nu = \frac{a_0\sin(\pi/4+\varphi/2-\nu)}{\cos\varphi}, \\ &0 < a(\nu) < a_0, \quad a_0\tan\varphi < b(\nu) < \frac{a_0}{\cos\varphi}. \end{aligned} \tag{4.18}$$

We choose $d = d_1 - \delta$ for an arbitrarily small positive δ, and for $w \in D_d$ we get the estimate (compare with (4.9))

$$\begin{aligned} \|\mathcal{F}(t,w)\| &\leq e^{-a(\nu)t\cosh\xi}\frac{(1+M)K\sqrt{a^2(\nu)\sinh^2\xi + b^2(\nu)\cosh^2\xi}}{(a^2(\nu)\cosh^2\xi + b^2(\nu)\sinh^2\xi)^{(1+\alpha)/2}}\|A^\alpha u_0\| \\ &\leq (1+M)K\frac{b(\nu)}{a(\nu)}\frac{e^{-a(\nu)t\cosh\xi}}{(a^2(\nu)\cosh^2\xi + b^2(\nu)\sinh^2\xi)^{(\alpha/2)}}\|A^\alpha u_0\| \\ &\leq (1+M)K\frac{b(\nu)}{a(\nu)}\left(\frac{2}{a(\nu)}\right)^\alpha e^{-a(\nu)t\cosh\xi-\alpha|\xi|}\|A^\alpha u_0\| \\ &\leq (1+M)K\tan\left(\frac{\pi}{4}+\frac{\varphi}{2}-\nu\right)\left(\frac{2\cos\varphi}{a_0\cos(\pi/4+\varphi/2-\nu)}\right)^\alpha e^{-\alpha|\xi|}\|A^\alpha u_0\| \\ &\forall w \in D_d. \end{aligned} \tag{4.19}$$

Taking into account that the integrals over the vertical sides of the rectangle $D_d(\epsilon)$ vanish as $\epsilon \to 0$, this estimate implies

$$\|\mathcal{F}(t,\cdot)\|_{\mathbf{H}^1(D_d)} \le \|A^\alpha u_0\| [C_-(\varphi,\alpha,\delta) + C_+(\varphi,\alpha,\delta)] \int_{-\infty}^{\infty} e^{-\alpha|\xi|} d\xi = C(\varphi,\alpha,\delta)\|A^\alpha u_0\| \tag{4.20}$$

with

$$\begin{aligned} &C(\varphi,\alpha,\delta) = \frac{2}{\alpha}[C_+(\varphi,\alpha,\delta) + C_-(\varphi,\alpha,\delta)], \\ &C_\pm(\varphi,\alpha,\delta) = (1+M)K(\cos\varphi)^\alpha \tan\left(\frac{\pi}{4} + \frac{\varphi}{2} \pm \frac{d}{2}\right)\left(\frac{2}{a_0\cos\left(\frac{\pi}{4}+\frac{\varphi}{2}\pm\frac{d}{2}\right)}\right)^\alpha. \end{aligned} \tag{4.21}$$

Note that the constant $C(\varphi,\alpha,\delta)$ tends to ∞ if $\alpha \to 0$ or $\delta \to 0,\ \varphi \to \pi/2$.

We approximate integral (4.6) by the sinc quadrature

$$u_N(t) = \frac{h}{2\pi i}\sum_{k=-N}^{N} \mathcal{F}(t, z(kh)) \tag{4.22}$$

with the error

$$\begin{aligned} &\|\eta_N(\mathcal{F},h)\| = \|u(t) - u_N(t)\| \\ &\le \left\| u(t) - \frac{h}{2\pi i}\sum_{k=-\infty}^{\infty}\mathcal{F}(t,z(kh))\right\| + \left\|\frac{h}{2\pi i}\sum_{|k|>N}\mathcal{F}(t,z(kh))\right\| \\ &\le \frac{1}{2\pi}\frac{e^{-\pi d/h}}{2\sinh(\pi d/h)}\|\mathcal{F}\|_{\mathbf{H}^1(D_d)} + \frac{C(\varphi,\alpha)h\|A^\alpha u_0\|}{2\pi}\sum_{k=N+1}^{\infty}\exp[-a_I t\cosh(kh) - \alpha kh] \\ &\le \frac{c\|A^\alpha u_0\|}{\alpha}\left\{\frac{e^{-\pi d/h}}{\sinh(\pi d/h)} + \exp[-a_I t\cosh((N+1)h) - \alpha(N+1)h]\right\}, \end{aligned} \tag{4.23}$$

where the constant c does not depend on h, N, t. Equalizing both exponentials for $t = 0$ by

$$\frac{2\pi d}{h} = \alpha(N+1)h, \tag{4.24}$$

we get for the step-size

$$h = \sqrt{\frac{2\pi d}{\alpha(N+1)}}. \tag{4.25}$$

With this step-size the following error estimate holds true:

$$\|\eta_N(\mathcal{F},h)\| \le \frac{c}{\alpha}\exp\left(-\sqrt{\frac{\pi d\alpha}{2}(N+1)}\right)\|A^\alpha u_0\| \tag{4.26}$$

with a constant c independent of t, N. In the case $t > 0$ the first summand in the exponent of $\exp[-a_I t\cosh((N+1)h) - \alpha(N+1)h]$ in (4.23) contributes mainly to the error order. Setting in this case $h = c_1 \ln N/N$ with some positive constant c_1, we remain asymptotic for a fixed t with an error

$$\|\eta_N(\mathcal{F}, h)\| \le c \left[e^{-\pi d N/(c_1 \ln N)} + e^{-c_1 a_I t N/2 - c_1 \alpha \ln N} \right] \|A^\alpha u_0\|, \tag{4.27}$$

where c is a positive constant. Thus, we have proved the following result.

THEOREM 4.1. *Let A be a densely defined strongly positive operator, and let $u_0 \in D(A^\alpha)$, $\alpha \in (0,1)$. Then sinc quadrature (4.22) represents an approximate solution of the homogeneous initial value problem (1.1) (i.e., $u(t) = e^{-At}u_0$) and possesses a uniform, with respect to $t \ge 0$, exponential convergence rate with estimate (4.23) which is of the order $\mathcal{O}(e^{-c\sqrt{N}})$ uniformly in $t \ge 0$ provided that $h = \mathcal{O}(1/\sqrt{N})$ and of the order $\mathcal{O}\left(\max\left\{e^{-\pi d N/(c_1 \ln N)},\ e^{-c_1 a_I t N/2 - c_1 \alpha \ln N}\right\}\right)$ for each fixed $t \ge 0$ provided that $h = c_1 \ln N/N$.*

Remark 4.1. Two other algorithms of the convergence order $\mathcal{O}(e^{-c\sqrt{N}})$ uniformly in $t \ge 0$ were proposed in [15, Remark 4.3 and (2.41)]. One of them used a sum of resolvents applied to u_0 provided that the operator coefficient is bounded. Another one was based on the representation

$$u(t) = \int_\Gamma z^{-\sigma} e^{-zt} (zI - A)^{-1} A^\sigma u_0 \tag{4.28}$$

valid for $u_0 \in D(A^\sigma), \sigma > 1$. Approximating the integral (after parametrizing Γ) by a sinc quadrature, one gets a short sum of resolvents applied to $A^\sigma u_0$ (see [15, (2.41)] and [42]). The last vector must be computed as a preliminary where in practice $\sigma = 2$ is the first choice. It is easy to see that for $u_0 \in D(A^\sigma)$ both representations (4.28) and (4.3) are, in fact, equivalent although the orders of computational stages (i.e., the algorithms) are different depending on the integral representation in use. But in the case $\sigma < 1$ the convergence theory for (4.28) was not presented in [15, 42]. Our representation (4.3) produces a new approximation through a short sum of modified resolvents $(zI - A)^{-1} - z^{-1}I$ applied to u_0 with the convergence properties given by Theorem 4.1. An approximation of the accuracy order $\mathcal{O}(e^{-cN/\ln N})$ for each fixed $t > 0$ to the operator exponential generated by a strongly P-positive operator and using a short sum of the usual resolvents was recently proposed in [14].

Remark 4.2. Note that taking $(zI - A)^{-1}$ instead of $(zI - A)^{-1} - \frac{1}{z}I$ in (4.3) results in a difference given by

$$D_I(t) = -\frac{1}{2\pi i} \int_{\Gamma_I} e^{-zt} \frac{1}{z} u_0 dz. \tag{4.29}$$

For the integration path Γ_I and $t = 0$ this difference can be calculated analytically. Actually, taking into account that the real part is an odd function and the integral of it in the sense of Cauchy is equal to zero, we further get for the integral of the imaginary part

$$\begin{aligned} D_I(0) &= -\frac{1}{2\pi i} P.V. \int_{\Gamma_I} \frac{1}{z} u_0 dz \\ &= -\frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{a_I b_I d\xi}{a_I^2 \cosh^2 \xi + b_I \sinh^2 \xi} u_0 \\ &= \frac{a_I b_I}{2\pi} \int_{-\infty}^{\infty} \frac{d(\tanh \xi)}{a_I^2 + b_I^2 \tanh^2 \xi} u_0 \\ &= \frac{1}{\pi} \arctan \frac{b_I}{a_I} u_0 = \frac{1}{\pi} \left(\frac{\pi}{4} + \frac{\varphi}{2} \right) u_0, \end{aligned} \tag{4.30}$$

where the factor in the front of u_0 is less than 1/2. It means that one can expect a large error for t small enough when using $(zI-A)^{-1}$ instead of $(zI-A)^{-1}-\frac{1}{z}I$ in (4.3). This phenomena can be observed in the next example. Note that for $t > 0$ integral (4.29) is equal to 0 due to the analyticity of the integrand inside of the integration path.

Example 4.1. Let us choose $a_0 = \pi^2$, $\varphi = 0.8\pi/2$. Then Table 1 gives the values of $\|D_I(t)\|/\|u_0\|$ for various t.

TABLE 1

The unremovable error when using the resolvent instead of $(zI - A)^{-1} - \frac{1}{z}I$.

t	$\|D_I(t)\|/\|u_0\|$
0	0.45
$0.1 \cdot 10^{-8}$	0.404552
$0.1 \cdot 10^{-7}$	0.081008
$0.1 \cdot 10^{-6}$	0.000257
$0.1 \cdot 10^{-5}$	$0.147153 \cdot 10^{-6}$

5. Exponentially convergent algorithm II.

Figure 5.1 shows the behavior of the integrand $\mathcal{F}(t,\xi)$ in (4.6) with the operator A defined by $D(A) = \{v(x):\ v \in H^2(0,1),\ v(0) = v(1) = 0\},\ Au = -\frac{d^2u}{dx^2}$. One can observe that the integrand is concentrated on a small finite interval and decays very rapidly outside of this interval. This fact can be a reason for slow convergence of the above algorithm for N not large enough. In this section we construct another exponentially convergent quadrature which takes into account the behavior of the integrand.

Due to the fact that the integrand exponentially decays on the infinite interval, it is reasonable to use an exponentially convergent quadrature rule on a finite interval where the integrand is mostly concentrated and to estimate the residual part. We represent integral (4.6) in the form

$$u(t) = \frac{1}{2\pi i}\int_{-\infty}^{\infty} \mathcal{F}(t,\xi)d\xi = I_1(t) + I_2(t) \tag{5.1}$$

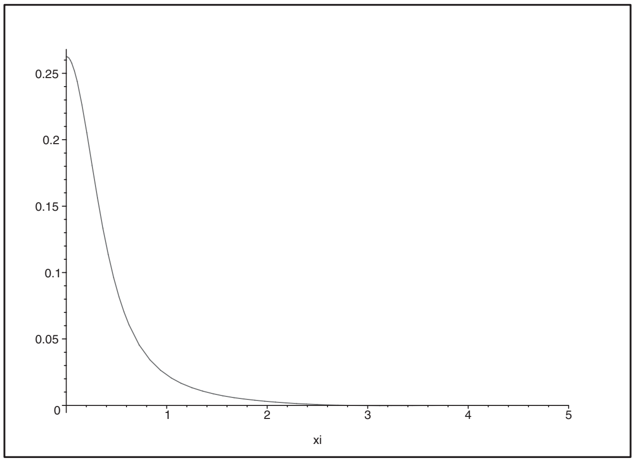

FIG. 5.1. *The behavior of the integrand* $\mathcal{F}(t,\xi)$ *in* (4.6).

with

$$
\begin{aligned}
I_1(t) &= \frac{1}{2\pi i}\int_{-\beta}^{\beta}\mathcal{F}(t,\xi)d\xi,\\
I_2(t) &= \frac{1}{2\pi i}\int_{-\infty}^{-\beta}\mathcal{F}(t,\xi)d\xi + \frac{1}{2\pi i}\int_{\beta}^{\infty}\mathcal{F}(t,\xi)d\xi.
\end{aligned} \tag{5.2}
$$

Using estimate (4.17) we get

(5.3)

$$
\begin{aligned}
&\left\|\frac{\|A^\alpha u_0\|}{2\pi i}\int_{\beta}^{\infty}\mathcal{F}(t,\xi)\right\| \le \frac{\|A^\alpha u_0\|}{2\pi}(1+M)K\tan\left(\frac{\pi}{4}+\frac{\varphi}{2}\right)\left(\frac{2}{\sqrt{a_0^2+b_0^2}\cos\left(\frac{\pi}{4}+\frac{\varphi}{2}\right)}\right)^\alpha\\
&\times\int_{\beta}^{\infty}e^{-\sqrt{a_0^2+b_0^2}\cos\left(\frac{\pi}{4}+\frac{\varphi}{2}\right)t\cosh\xi-\alpha|\xi|}d\xi\\
&\le C_1(\varphi,\alpha)\|A^\alpha u_0\|e^{-\sqrt{a_0^2+b_0^2}\cos\left(\frac{\pi}{4}+\frac{\varphi}{2}\right)t\cosh\beta}\int_{\beta}^{\infty}e^{-\alpha|\xi|}d\xi\\
&\le C_1(\varphi,\alpha)\|A^\alpha u_0\|e^{-\sqrt{a_0^2+b_0^2}\cos\left(\frac{\pi}{4}+\frac{\varphi}{2}\right)t\cosh\beta}e^{-\alpha|\beta|}
\end{aligned}
$$

with the constant

$$
C_1(\varphi,\alpha) = \frac{(1+M)K}{2\pi\alpha}\tan\left(\frac{\pi}{4}+\frac{\varphi}{2}\right)\left(\frac{2}{\sqrt{a_0^2+b_0^2}\cos\left(\frac{\pi}{4}+\frac{\varphi}{2}\right)}\right)^\alpha
$$

independent of β. This constant tends to ∞ if $\alpha \to 0$ or $\varphi \to \pi/2$. Analogously one gets

$$
\left\|\frac{1}{2\pi i}\int_{-\infty}^{-\beta}\mathcal{F}(t,\xi)\right\| \le C_1(\varphi,\alpha)\|A^\alpha u_0\|e^{-\sqrt{a_0^2+b_0^2}\cos\left(\frac{\pi}{4}+\frac{\varphi}{2}\right)t\cosh\beta}e^{-\alpha|\beta|}, \tag{5.4}
$$

which yields the estimate

$$
\|I_2\| \le 2C_1(\varphi,\alpha)\|A^\alpha u_0\|e^{-\sqrt{a_0^2+b_0^2}\cos\left(\frac{\pi}{4}+\frac{\varphi}{2}\right)t\cosh\beta}e^{-\alpha|\beta|}. \tag{5.5}
$$

Following [36] let us define for $d \in (0,\pi)$ the eye-shaped region

$$
\mathcal{D} = D_d^2 = \left\{z \in \mathbb{C} : \left|\arg\left(\frac{z+\beta}{z-\beta}\right)\right| < d\right\} \tag{5.6}
$$

(see Figure 5.2) and the class $\mathbf{L}_{\kappa,\mu}(\mathcal{D})$ of all holomorphic in $\mathcal{D}$ vector-valued functions satisfying

$$
\|F(z)\| \le c|z+\beta|^{\kappa-1}|z-\beta|^{\mu-1} \tag{5.7}
$$

with some positive constants c, κ, μ.

In the previous section we have shown that $\mathcal{F}(t,\xi)$ can be analytically extended into the symmetric with respect to the real axis strip D_d of the width $2d$. The equation of the boundary of the eye-shaped region in cartesian coordinates is $\frac{2\beta y}{x^2+y^2-\beta^2} = \pm\tan d_1$. For $x = 0$ the maximal value of y, which still lies in the analyticity region, is $y = d$, and we get for the maximal d_1 the equation $\frac{2\beta d}{d^2-\beta^2} = \pm\tan d_1$, from which

$$
d_1 \asymp d/\beta \tag{5.8}
$$

for β large enough.

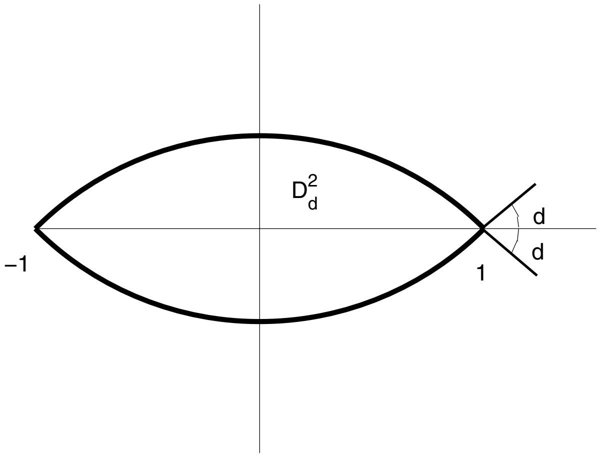

Fig. 5.2. *The eye-shaped region.*

Given N and a function $F(\xi) \in \mathbf{L}_{\kappa,\mu}$, which can be analytically extended into an eye-shaped domain $D^2_{d_1}$, let us define (see [36])

$$\begin{aligned} &\epsilon = \min(\kappa, \mu), \qquad \delta = \max(\kappa, \mu),\\ &h = \left(\frac{2\pi d}{\epsilon n}\right)^{1/2},\\ &M_l = \begin{cases} N & \text{if } \epsilon = \kappa,\\ [\mu N/\kappa] & \text{otherwise,}\end{cases} \qquad M_u = \begin{cases} [\kappa N/\mu] & \text{if } \epsilon = \kappa,\\ N & \text{otherwise.}\end{cases} \end{aligned} \tag{5.9}$$

Then

$$\left\| \int_{-\beta}^{\beta} F(\xi)d\xi - 2\beta h \sum_{-M_l}^{M_u} \frac{e^{kh}}{(1+e^{kh})^2} F(z_k) \right\| \le c e^{-\sqrt{2\pi d_1 \epsilon N}}, \tag{5.10}$$

where the nodes are $z_k = \frac{-\beta+\beta e^{kh}}{1+e^{kh}}$.

Using this quadrature and taking into account that $\mathcal{F}(t,\xi) \in \mathbf{L}_{1,1}(\mathcal{D})$ (with respect to ξ), we get the following sinc quadrature approximation for I_1:

$$\begin{aligned} &I_1(t) \approx I_{1,N}(t) = \frac{2\beta h}{2\pi i} \sum_{-N}^{N} \frac{e^{kh}}{(1+e^{kh})^2} \mathcal{F}(t, z_k),\\ &h = \left(\frac{2\pi d_1}{N}\right)^{1/2} \end{aligned} \tag{5.11}$$

with the approximation error

$$\|\eta_{N,1}(t)\| \le c\|A^\alpha u_0\| e^{-\sqrt{2\pi d_1 N}}. \tag{5.12}$$

Setting

$$u(t) = e^{-At}u_0 \approx I_1(t) \tag{5.13}$$

results in the full approximation error

$$\begin{aligned}\|u(t)-I_{1,N}\| &= \|e^{-At}u_0 - I_{1,N}\| \le \|\eta_{N,1}\| + \|I_2(t)\| \\ &\le c\|A^\alpha u_0\|(e^{-\sqrt{2\pi d_1 N}} + e^{-\sqrt{a_0^2+b_0^2}\cos\left(\frac{\pi}{4}+\frac{\varphi}{2}\right)t\cosh\beta}e^{-\alpha|\beta|}).\end{aligned} \tag{5.14}$$

Equalizing the exponents and taking into account (5.8), we get that $h = \left(\frac{2\pi d}{N^{4/3}}\right)^{1/2}$ and

$$\|e^{-At}u_0 - I_{1,N}(t)\| \le c\|A^\alpha u_0\| e^{-c_1 N^{1/3}} \tag{5.15}$$

provided that

$$\beta \asymp N^{1/3}. \tag{5.16}$$

Example 5.1. We consider problem (1.1) with $u_0 = (1-x)x^2$ and the operator A defined by $D(A) = \{v(x): \ v \in H^2(0,1), \ v(0) = v(1) = 0\}$, $Au = -\frac{d^2u}{dx^2}$. It is easy to see that $u_0 \in D(A^1)$, and the exact solution is given by $u(t,x) = -\frac{4}{\pi^3}\sum_1^\infty \frac{2(-1)^k+1}{k^3}e^{-\pi^2k^2t}\sin(\pi k x)$. One can show that

$$\begin{aligned}(zI-A)^{-1}u_0 - u_0/z &= \frac{1}{z}(zI-A)^{-1}Au_0 \\ &= \frac{6x-2}{z^2} - \frac{\cos[\sqrt{z}(1/2-x)]}{z^2\cos(\sqrt{z}/2)} + 3\frac{\sin[\sqrt{z}(1/2-x)]}{z^2\sin(\sqrt{z}/2)}.\end{aligned} \tag{5.17}$$

Table 2 gives the solutions computed by the algorithm (4.22) with $h = \sqrt{2\pi/N}$ (the first column) and by algorithm (5.13) with $h = \sqrt{2\pi/N^{4/3}}$ (the second column). The exact solution is $u(0,1/2) = u_0(1/2) = 1/8$. This example shows that although algorithm (4.22) is better for N large enough, algorithm (5.13) can be better for relatively small N. Besides the table confirms the exponential convergence of both algorithms.

TABLE 2
The solution for $t = 0$, $x = 1/2$ by the algorithms (4.22) (A1) *and* (5.13) (A2).

6. Inhomogeneous differential equation. In this section we consider the inhomogeneous problem (1.1) with the solution

$$u(t) = u_o(t) + u_p(t), \tag{6.1}$$

where

$$u_o(t) = e^{-At}u_0, \quad u_p(t) = \int_0^t e^{-A(t-s)}f(s)ds. \tag{6.2}$$

Note that there exist algorithms for convolution integrals of the same type as the ones from previous sections and also based on sinc quadratures [36]. Since these algorithms use the inverse Laplace transformation combined with Tikhonov's regularization, their justification is rather complicated and the convergence order is $\mathcal{O}(\sqrt{N}e^{-c\sqrt{N}})$. In order to shake off the factor $\sqrt{N}$ in the front of the exponential, we propose in this section a discretization different from [36].

Using representation (4.3) of the operator exponential we get

$$\begin{aligned} u_p(t) &= \int_0^t \frac{1}{2\pi i}\int_{\Gamma_I} e^{-z(t-s)}\left[(zI-A)^{-1}-\frac{1}{z}I\right]f(s)dzds \\ &= \frac{1}{2\pi i}\int_{\Gamma_I}\left[(z(\xi)I-A)^{-1}-\frac{1}{z(\xi)}I\right]\int_0^t e^{-z(\xi)(t-s)}f(s)dsz'(\xi)d\xi, \\ z(\xi) &= a_I\cosh\xi - ib_I\sinh\xi. \end{aligned} \tag{6.3}$$

Replacing here the first integral by quadrature (4.22) we get

$$u_p(t) \approx u_{ap}(t) = \frac{h}{2\pi i}\sum_{k=-N}^{N} z'(kh)\left[(z(kh)I-A)^{-1}-\frac{1}{z(kh)}I\right]f_k(t) \tag{6.4}$$

with

$$f_k(t) = \int_0^t e^{-z(kh)(t-s)}f(s)ds, \qquad k=-N,\dots,N. \tag{6.5}$$

In order to construct an exponentially convergent quadrature for these integrals, we change the variables by

$$\frac{t}{2}-s=\frac{t}{2}\tanh\xi \tag{6.6}$$

and get instead of (6.5)

$$f_k(t) = \int_{-\infty}^{\infty}\mathcal{F}_k(t,\xi)d\xi, \tag{6.7}$$

where

$$\mathcal{F}_k(t,\xi) = \frac{t}{2\cosh^2\xi}\exp[-z(kh)t(1+\tanh\xi)/2]f(t(1-\tanh\xi)/2). \tag{6.8}$$

Note that with the complex variables $z=\xi+i\nu$ and $w=u+iv$, equation (6.6) represents the conformal mapping $w=\psi(z)=t[1-\tanh z]/2$, $z=\phi(w)=\frac{1}{2}\ln\frac{t-w}{w}$, of the strip D_ν onto the domain $\mathcal{A}_\nu$ (compare with the domain D_ν^2 in [36]; also see Figure 6.1). The integrand can be estimated on the real axis by

$$\begin{aligned} \|\mathcal{F}_k(t,\xi)\| &\le \frac{t}{2\cosh^2\xi}\exp[-a_I\cosh(kh)t(1+\tanh\xi)/2]\|f(t(1-\tanh\xi)/2)\| \\ &\le 2te^{-2|\xi|}\|f(t(1-\tanh\xi)/2)\|. \end{aligned} \tag{6.9}$$

Lemma 6.1. *Let the right-hand side $f(t)$ in (1.1) for $t\in[0,\infty]$ be analytically extended into the sector $\Sigma_f=\{\rho e^{i\theta_1}:\ \rho\in[0,\infty],\ |\theta_1|<\varphi\}$, and for all complex $w\in\Sigma_f$ we have*

$$\|f(w)\| \le ce^{-\delta|\Re w|} \tag{6.10}$$

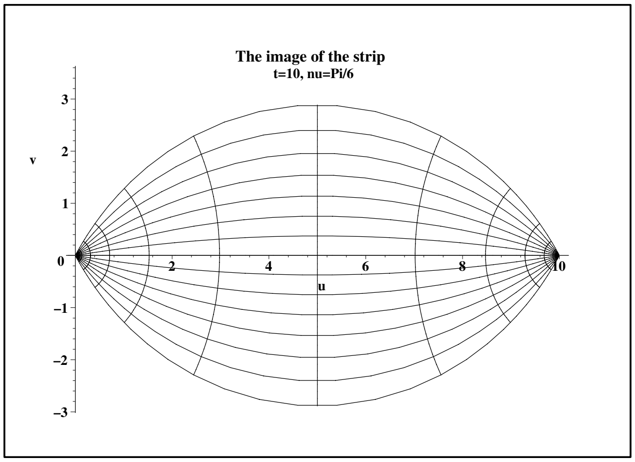

FIG. 6.1. *The image of the strip for* $t = 10,\ \nu = \pi/6$.

with $\delta \in (0, \sqrt{2}a_0]$*. Then the integrand* $\mathcal{F}_k(t,\xi)$ *can be analytically extended into the strip* D_{d_1}, $0 < d_1 < \varphi/2$, *and belongs to the class* $H^1(D_{d_1})$ *with respect to* ξ, *where* a_0, φ *are the spectral characterizations* (2.1) *of* A.

Proof. Let us investigate the domain in the complex plane to which the function $\mathcal{F}(t,\xi)$ can be analytically extended from the real axis $\xi \in \mathbb{R}$. Replacing in the integrand ξ to $\xi + i\nu$, $\xi \in (-\infty,\infty)$, $|\nu| < d_1$, we get in particularly for the argument of f

$$\begin{aligned} \tanh(\xi + i\nu) &= \frac{\sinh\xi\cos\nu + i\cosh\xi\sin\nu}{\cosh\xi\cos\nu + i\sinh\xi\sin\nu} \\ &= \frac{\sinh(2\xi) + i\sin(2\nu)}{2(\cosh^2\xi - \sin^2\nu)}, \\ 1 \pm \tanh(\xi + i\nu) &= q_r^{\pm} + iq_i^{\pm}, \end{aligned} \tag{6.11}$$

where

$$\begin{aligned} q_r^{\pm}(\xi,\nu) &= 1 \pm \frac{\sinh 2\xi}{2(\cosh^2\xi - \sin^2\nu)} = \frac{e^{\pm 2\xi} + \cos(2\nu)}{2(\cosh^2\xi - \sin^2\nu)}, \\ q_i^{\pm}(\xi,\nu) &= \pm\frac{\sin 2\nu}{2(\cosh^2\xi - \sin^2\nu)}. \end{aligned} \tag{6.12}$$

The denominator in (6.11) is not equal to zero for all $\xi \in (-\infty,\infty)$ provided that $\nu \in (-\pi/2, \pi/2)$. It is easy to see that for $\xi \in (-\infty,\infty)$ we have

$$\begin{aligned} 0 \le q_r^{\pm}(\xi,\nu) &\le 2, \\ |q_i^{\pm}(\xi,\nu)| &\le |\tan\nu|, \end{aligned} \tag{6.13}$$

i.e., for each fixed t, ν and for $\xi \in (-\infty,\infty)$ the parametric curve $\Gamma_{\mathcal{A}}(t)$ given by (in the coordinates μ, η)

$$\begin{aligned} \mu &= \frac{t}{2}q_r^{-}(\xi,\nu), \\ \eta &= \frac{t}{2}q_i^{-}(\xi,\nu) \end{aligned} \tag{6.14}$$

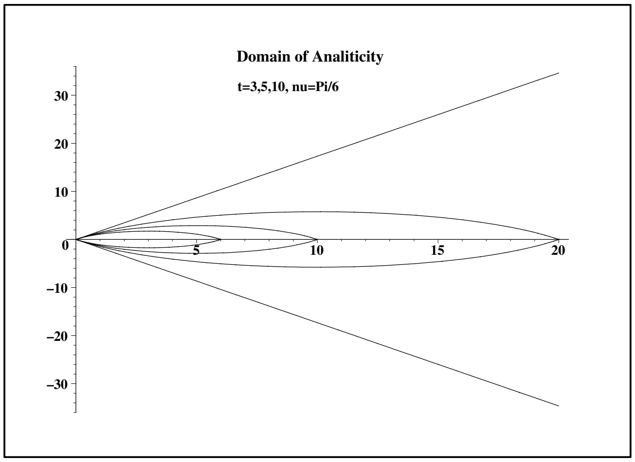

FIG. 6.2. *The domains of the analyticity of the integrand for* $t = 3, 5, 10,\ \nu = \pi/6$.

from (6.11) is closed and builds with the real axis at the origin the angle

$$\theta = \theta(\nu) = \arctan \left| \lim_{\xi \to \infty} q_i^-(\xi, \nu)/q_r^-(\xi, \nu) \right| = \arctan(\tan(2\nu)) = 2\nu. \tag{6.15}$$

For $\nu \in (-\pi/4, \pi/4)$ the domain $\mathcal{A}(t)$ inside of $\Gamma_{\mathcal{A}}(t)$ lies in the right half-plane, and for $t \to \infty$ fills the sector $\Sigma_f(\nu) = \{z = \rho e^{i\psi} :\ \rho \in (0, \infty),\ \psi \in (-\nu, \nu),\ \nu \in (0, \pi/4)\}$ (see Figure 6.2). Taking into account (4.14) we have

$$\begin{aligned} \|\mathcal{F}(t, \xi + i\nu)\| &\le \frac{t}{2(\cosh^2 \xi - \sin^2 \nu)} \\ &\times \left| \exp\left\{ -\frac{t[a_I \cosh(kh) - i b_I \sinh(kh)]}{2} \left[q_r^+ + i q_i^+\right] \right\} \right| \\ &\times \|f(t(1 - \tanh(\xi + i\nu))/2)\| \\ &\le \frac{t}{2(\cosh^2 \xi - \sin^2 \nu)} \\ &\times \exp\left\{ -\frac{t a_0 [\cosh(kh) \cos(\pi/4 + \varphi/2)(\cos(2\nu) + e^{2\xi})]}{2(\cosh^2 \xi - \sin^2 \nu)} \right. \\ &\left. -\frac{t a_0 [\sinh(kh) \cos(\pi/4 + \varphi/2) \sin(2\nu)]}{2(\cosh^2 \xi - \sin^2 \nu)} \right\} \\ &\times \|f(t(1 - \tanh(\xi + i\nu))/2)\| \end{aligned} \tag{6.16}$$

(note that $\nu \in (-\pi/2, \pi/2)$ provides that $\cosh^2 \xi - \sin^2 \nu > 0$ for all $\xi \in (-\infty, \infty)$). Since we suppose that

$$\|f(w)\| \le c e^{-\delta |\Re w|}, \qquad \delta > 0, \tag{6.17}$$

then by omitting the second summand in the argument of the exponential and replacing $\cosh(kh)$ by 1, we arrive at the inequality

$$\begin{aligned} \|\mathcal{F}(t, \xi + i\nu)\| &\le \frac{ct}{2(\cosh^2 \xi - \sin^2 \nu)} \\ &\times \exp\left\{ \frac{t[-\Delta e^{2\xi} - \delta e^{-2\xi}/2]}{2(\cosh^2 \xi - \sin^2 \nu)} \right\}, \end{aligned} \tag{6.18}$$

where

$$\frac{a_0}{2} \le \Delta = a_0 \frac{\cos(\varphi/2 + \pi/4)}{\cos\varphi} = \frac{a_0}{\sqrt{2}\sqrt{1+\sin\varphi}} \le \frac{a_0}{\sqrt{2}}. \tag{6.19}$$

Due to assumption $\delta \le \sqrt{2}a_0$ we have $\delta/2 \le \Delta$, and the last estimate yields

$$\|\mathcal{F}(t, \xi + i\nu)\| \le \frac{ct}{2(\cosh^2\xi - \sin^2\nu)} \exp\left\{ -\frac{t\delta\cosh(2\xi)}{2(\cosh^2\xi - \sin^2\nu)} \right\}. \tag{6.20}$$

Denoting $w = t\Delta\cosh(2\xi)/[2(\cosh^2\xi - \sin^2\nu)]$ and using (6.19) and the inequality $we^{-w} \le e^{-1}\ \forall\, w \ge 0$, we get

(6.21)
$$\begin{aligned}
&\int_{-\infty}^{\infty} \|\mathcal{F}(t, \xi + i\nu)\| d\xi \le \int_{-\infty}^{\infty} \frac{ct}{2(\cosh^2\xi - \sin^2\nu)} \exp\left\{ -\frac{t\delta\cosh(2\xi)}{2(\cosh^2\xi - \sin^2\nu)} \right\} d\xi \\
&= \int_{-\infty}^{\infty} \frac{1}{\Delta\cosh(2\xi)} we^{-w} d\xi \le \frac{c}{e\Delta} \int_{-\infty}^{\infty} \frac{1}{\cosh(2\xi)} d\xi \\
&\le \frac{2c}{e\Delta} \int_{-\infty}^{\infty} e^{-2|\xi|} d\xi = \frac{2c}{e\Delta} \le \frac{4c}{a_0 e}.
\end{aligned}$$

This estimate yields $\mathcal{F}_k(t,\xi) \in H^1(D_{d_1})$ with respect to ξ. □

The assumptions of Lemma 6.1 can be weakened if we consider problem (1.1) on some finite interval $(0, T]$.

LEMMA 6.2. *Let the right-hand side $f(t)$ in* (1.1) *for $t \in [0, T]$ be analytically extended into the domain $\mathcal{A}(T)$. Then the integrand $\mathcal{F}_k(t,\xi)$ can be analytically extended into the strip D_{d_1}, $0 < d_1 < \varphi/2$, and belongs to the class $H^1(D_{d_1})$ with respect to ξ.*

Proof. The proof is analogous to the proof of Lemma 6.1 but with constants depending on T. □

Let the assumptions of Lemma 6.1 hold. Then we can use the following quadrature rule to compute the integrals (6.7) (see [36], p. 144):

$$f_k(t) \approx f_{k,N}(t) = h \sum_{p=-N}^{N} \mu_{k,p}(t) f(\omega_p(t)), \tag{6.22}$$

where

$$\begin{aligned}
\mu_{k,p}(t) &= \frac{t}{2}\exp\{-\frac{t}{2}z(kh)[1 + \tanh(ph)]\}/\cosh^2(ph), \\
\omega_p(t) &= \frac{t}{2}[1 - \tanh(ph)], \qquad h = \mathcal{O}(1/\sqrt{N}), \\
z(\xi) &= a_I\cosh\xi - ib_I\sinh\xi.
\end{aligned} \tag{6.23}$$

Substituting (6.22) into (6.4) we get the following algorithm to compute an approach $u_{ap,N}(t)$ to $u_{ap}(t)$:

$$\begin{aligned}
u_{ap,N}(t) &= \frac{h}{2\pi i} \sum_{k=-N}^{N} z'(kh) \left[(z(kh)I - A)^{-1} - \frac{1}{z(kh)} I \right] \\
&\times h \sum_{p=-N}^{N} \mu_{k,p}(t) f(\omega_p(t)).
\end{aligned} \tag{6.24}$$

The next theorem characterizes the error of this algorithm.

THEOREM 6.3. *Let A be a densely defined strongly positive operator with the spectral characterization a_0, φ, and let the right-hand side $f(t) \in D(A^\alpha)$, $\alpha > 0$ for $t \in [0,\infty]$ be analytically extended into the sector $\Sigma_f = \{\rho e^{i\theta_1} : \rho \in [0,\infty], |\theta_1| < \varphi\}$ where the estimate*

$$\|A^\alpha f(w)\| \le c_\alpha e^{-\delta_\alpha |\Re w|}, \qquad w \in \Sigma_f \tag{6.25}$$

with $\delta_\alpha \in (0, \sqrt{2}a_0]$ holds. Then algorithm (6.24) converges with the error estimate

$$\|\mathcal{E}_N(t)\| = \|u_p(t) - u_{ap,N}(t)\| \le c e^{-c_1\sqrt{N}} \tag{6.26}$$

uniformly in t with positive constants c, c_1 depending on α, φ, a_0 and independent of N.

Proof. Let us denote

$$R_k(t) = f_k(t) - f_{k,N}(t). \tag{6.27}$$

Then we get for the error

$$\mathcal{E}_N(t) = u_p(t) - u_{ap,N}(t) = r_{1,N}(t) + r_{2,N}(t), \tag{6.28}$$

where

$$\begin{aligned} r_{1,N}(t) &= u_p(t) - u_{ap}(t), \\ r_{2,N}(t) &= u_{ap}(t) - u_{ap,N}(t). \end{aligned} \tag{6.29}$$

Using estimate (4.26) (see also Theorem 4.1) we get for $r_{1,N}(t)$ the estimate

$$\begin{aligned} &\|r_{1,N}(t)\| = \left\| \int_0^t \left\{ \frac{1}{2\pi i} \int_{-\infty}^{\infty} F_A(t-s,\xi)d\xi - \frac{h}{2\pi i} \sum_{k=-N}^{N} F_A(t-s,kh) \right\} f(s)ds \right\| \\ &\le \frac{c}{\alpha} \exp\left(-\sqrt{\frac{\pi d \alpha}{2}(N+1)} \right) \int_0^t \|A^\alpha f(s)\| ds, \end{aligned} \tag{6.30}$$

where $F_A(t,\xi)$ is the operator defined in (4.7). Due to (2.9) we have for the error $r_{2,N}(t)$

$$\begin{aligned} \|r_{2,N}(t)\| &= \left\| \frac{h}{2\pi i} \sum_{k=-N}^{N} z'(kh) \left[(z(kh)I - A)^{-1} - \frac{1}{z(kh)} I \right] R_k(t) \right\| \\ &\le \frac{h(1+M)K}{2\pi} \sum_{k=-N}^{N} \frac{|z'(kh)|}{|z(kh)|^{1+\alpha}} \|A^\alpha R_k(t)\|. \end{aligned} \tag{6.31}$$

The estimate (6.9) yields

$$\|A^\alpha \mathcal{F}(t,\xi)\| \le 2te^{-2|\xi|} \left\| A^\alpha f\left(\frac{t}{2}(1-\tanh \xi) \right) \right\|. \tag{6.32}$$

Due to Lemma 6.1 the assumption $\|A^{\alpha}f(w)\| \le c_{\alpha}e^{-\delta_{\alpha}|\Re w|}$ for all $w \in \Sigma_f$ guarantees that $A^{\alpha}f(w) \in H^1(D_{d_1})$ and $A^{\alpha}\mathcal{F}_k(t,w) \in H^1(D_{d_1})$. Then we are in the situation analogous to that of Theorem 3.2.1, p. 144, of [36] with $A^{\alpha}f(w)$ instead of f which implies

$$\begin{aligned}
&\|A^{\alpha}R_k(t)\| = \|A^{\alpha}(f_k(t) - f_{k,N}(t))\| \\
&= \left\| \int_{-\infty}^{\infty} A^{\alpha}\mathcal{F}_k(t,\xi)d\xi - h\sum_{k=-\infty}^{\infty} A^{\alpha}\mathcal{F}_k(t,kh)\right\| + \left\| h\sum_{|k|>N} A^{\alpha}\mathcal{F}_k(t,kh)\right\| \\
&\le \frac{e^{-\pi d_1/h}}{2\sinh(\pi d_1/h)} \|\mathcal{F}_k(t,w)\|_{H^1(D_{d_1})} \\
&+ h\sum_{|k|>N} 2te^{-2|kh|} \left\| A^{\alpha}f\left(\frac{t}{2}(1-\tanh kh)\right)\right\| \\
&\le ce^{-2\pi d_1/h}\|A^{\alpha}f(t,w)\|_{H^1(D_{d_1})} \\
&+ h\sum_{|k|>N} 2te^{-2|kh|}c_{\alpha}\mathrm{exp}\left\{-\delta_{\alpha}\frac{t}{2}(1-\tanh kh)\right\} \\
&\le ce^{-c_1\sqrt{N}},
\end{aligned} \tag{6.33}$$

where positive constants $c_{\alpha}, \delta_{\alpha}, c, c_1$ do not depend on $t,\ N,\ k$. Now, (6.31) takes the form

$$\begin{aligned}
\|r_{2,N}(t)\| &= \frac{h}{2\pi i}\sum_{k=-N}^{N} z'(kh)\left[(z(kh)I - A)^{-1} - \frac{1}{z(kh)}I\right] R_k(t) \\
&\le ce^{-c_1\sqrt{N}} S_N
\end{aligned} \tag{6.34}$$

with $S_N = \sum_{k=-N}^{N} h\frac{|z'(kh)|}{|z(kh)|^{1+\alpha}}$. Using the estimate (4.8) and

$$\begin{aligned}
|z(kh)| &= \sqrt{a_I^2\cosh^2(kh) + b_I^2\sinh^2(kh)} \\
&\ge a_I\cosh(kh) \ge a_I e^{|kh|}/2,
\end{aligned} \tag{6.35}$$

the last sum can be estimated by

$$|S_N| \le \frac{c}{\sqrt{N}}\sum_{k=-N}^{N} e^{-\alpha|k/\sqrt{N}|} \le c\int_{-\sqrt{N}}^{\sqrt{N}} e^{-\alpha t}dt \le c/\alpha. \tag{6.36}$$

Taking into account (6.33) and (6.36) we get from (6.34)

$$\|r_{2,N}(t)\| \le ce^{-c_1\sqrt{N}}. \tag{6.37}$$

The assertion of the theorem follows now from (6.28) and (6.30). □

Example 6.1. We consider the inhomogeneous problem (1.1) with the operator A defined by

$$\begin{aligned}
&D(A) = \{u(x) \in H^2(0,1):\ u(0) = u(1) = 0\}, \\
&Au = -u''(x) \qquad \forall u \in D(A).
\end{aligned} \tag{6.38}$$

The initial function is $u_0 = u(0,x) = 0$, and the right-hand side $f(t)$ is given by

$$f(t,x) = x^3(1-x)^3\frac{1-t^2}{(1+t^2)^2} - \frac{6t}{1+t^2}x(1-x)(5x^2-5x+1). \tag{6.39}$$

It is easy to see that the exact solution is $u(t,x) = x^3(1-x)^3\frac{t}{1+t^2}$. The algorithm (6.24) was implemented for $t = 1,\ x = 1/2$ in Maple 8 with Digits=16. Table 3 shows an exponential decay of the error $\varepsilon_N = |u(1,1/2) - u_{ap,N}(1)|$ with growing N.

TABLE 3
The error of algorithm (6.24) *for* $t = 0,\ x = 1/2$.

A SECOND-ORDER MAXIMUM PRINCIPLE PRESERVING FINITE VOLUME METHOD FOR STEADY CONVECTION-DIFFUSION PROBLEMS*

ENRICO BERTOLAZZI† AND GIANMARCO MANZINI‡

Abstract. A cell-centered finite volume method is proposed to approximate numerically the solution to the steady convection-diffusion equation on unstructured meshes of d-simplexes, where $d \geq 2$ is the spatial dimension. The method is formally second-order accurate by means of a piecewise linear reconstruction within each cell and at mesh vertices. An algorithm is provided to calculate nonnegative and bounded weights. Face gradients, required to discretize the diffusive fluxes, are defined by a nonlinear strategy that allows us to demonstrate the existence of a maximum principle. Finally, a set of numerical results documents the performance of the method in treating problems with internal layers and solutions with strong gradients.

Key words. unstructured grids, finite volume methods, maximum principles, M-matrices

1. Introduction.

We are concerned with the finite volume approximation of the steady convection-diffusion boundary value problem:

Find a function $\mathtt{u}$ *satisfying*

$$\operatorname{div}(\boldsymbol{v}\mathtt{u} - \nu\nabla\mathtt{u}) = \mathtt{s} \qquad \text{in } \Omega, \tag{1a}$$

$$\mathtt{u} = \mathtt{g} \qquad \text{on } \Gamma, \tag{1b}$$

where $\Omega \in \mathbb{R}^d$, $d \geq 2$, is a polyhedral domain with boundary Γ. We assume that the unit vector almost everywhere orthogonal to Γ, denoted by $\boldsymbol{n}$, is always oriented outward of Ω. The model problem of (1a)–(1b) describes the advective transport of the scalar quantity $\mathtt{u}(\boldsymbol{x})$ by the velocity field $\boldsymbol{v}(\boldsymbol{x})$ and the diffusion process driven by the scalar viscosity field $\nu(\boldsymbol{x})$. A forcing term can be present on the right-hand side of (1a), namely, $\mathtt{s}(\boldsymbol{x})$. Dirichlet boundary conditions are set on Γ by using the scalar field $\mathtt{g}(\boldsymbol{x})$. Let the fields $\boldsymbol{v}(\boldsymbol{x})$, $\nu(\boldsymbol{x})$, $\mathtt{s}(\boldsymbol{x})$, and $\mathtt{g}(\boldsymbol{x})$ satisfy the constraints listed below:

$$\begin{array}{llll} & \text{(i)} & \nu(\boldsymbol{x}) \geq \beta > 0, & \nu \in \mathtt{C}^1(\overline{\Omega}); \\ & \text{(ii)} & \operatorname{div} \boldsymbol{v} \geq 0, & \boldsymbol{v} \in \mathtt{C}^1(\overline{\Omega})^d; \\ (2) & \text{(iii)} & \mathtt{s} \in \mathtt{L}^2(\Omega); & \\ & \text{(iv)} & \mathtt{g} \in \mathtt{H}^{1/2}(\Gamma) \bigcap \mathtt{C}(\Gamma) & \end{array}$$

for a suitable real constant β, and where

$$\mathtt{H}^m(\Omega) = \left\{\mathtt{u} \in \mathtt{L}^2(\Omega) \,:\, D^\alpha\mathtt{u} \in \mathtt{L}^2(\Omega),\, |\alpha| \leq m\right\},$$

for $m \geq 0$, is the standard notation of a Sobolev space [1]. Under conditions (2) a weak reformulation of problem (1a)–(1b) is possible in terms of the $\mathtt{H}^1$-coercive bilinear form:

$$a(\mathsf{u}, \mathsf{v}) = \int_\Omega (\nu \nabla \mathsf{u} - \mathsf{u}\boldsymbol{v}) \cdot \nabla \mathsf{v}\, dV.$$

In view of the Lax–Milgram lemma, the weak problem has a unique solution in $\mathtt{H}^1(\Omega)$ [1].

Following Stampacchia [29], a function $\mathsf{u} \in \mathtt{H}^1(\Omega)$ is said to be *superelliptic* if $a(\mathsf{u}, \mathsf{v}) \leq 0$ for any $\mathsf{v} \in \mathtt{C}_0^\infty(\Omega)$ and $\mathsf{v} \geq 0$, where $\mathtt{C}_0^\infty(\Omega)$ is the space of infinitely differentiable functions with compact support in Ω. Under the above-stated regularity assumptions, a *maximum principle* for superelliptic weak solutions exists. If u is a superelliptic solution and is such that $\operatorname{ess\,sup}_{\boldsymbol{x} \in \Gamma} \mathsf{u}(\boldsymbol{x}) \leq k$, then $\operatorname{ess\,sup}_{\boldsymbol{x} \in \Omega} \mathsf{u}(\boldsymbol{x}) \leq \max\{0, k\}$; see [15]. A *minimum principle* can be stated as well by introducing the notion of *subelliptic* solution, which is a function $\mathsf{u} \in \mathtt{H}^1(\Omega)$ that satisfies the condition $a(\mathsf{u}, \mathsf{v}) \geq 0$ for any $\mathsf{v} \in \mathtt{C}_0^\infty(\Omega)$ and $\mathsf{v} \geq 0$. Then if u is a subelliptic weak solution and is such that $\operatorname{ess\,inf}_{\boldsymbol{x} \in \Gamma} \mathsf{u}(\boldsymbol{x}) \geq k$, then $\operatorname{ess\,inf}_{\boldsymbol{x} \in \Omega} \mathsf{u}(\boldsymbol{x}) \geq \min(0, k)$; see again [15].

From the analytical viewpoint, maximum and minimum principles are quite general but very significant due to their physical implications. For example, if u attains physically meaningful values in a specific range of real numbers, and is suitably bounded on Γ, then u must attain values in the same range (almost) everywhere in the interior of Ω. From the numerical viewpoint, it is widely recognized that maximum and minimum principles provide a valuable tool in proving solvability results (existence and uniqueness of discrete solutions), enforcing numerical stability, and deriving convergence results (a priori error estimates) for the sequence of approximate solutions; see [26]. Recent papers investigating the existence of maximum principles in discretization schemes for partial differential equations are cited in [9]. Other papers pertinent to the issue of discrete maximum principle preserving methods are found in [21, 22, 32].

A literature review of the many finite volume methods that ensure a maximum principle is beyond the scope of this paper. For this purpose, we refer the reader to the general introductions found, for example, in [13, 26] and to the references therein. However, we wish to emphasize a rather important fact that we realized after a careful and systematic inspection of the cell-centered finite volume methods that are available in the literature and capable of preserving a discrete maximum principle. Most of these methods are designed to show that the method gives rise to a *monotone matrix* or an *M-matrix* on uniform (or quasi-uniform) grids and their accuracy in approximating cell averages degenerates to first order on general unstructured grids. Let us recall that a monotone matrix is a nonsingular matrix with nonnegative inverse; a nonsingular M-matrix is a monotone matrix having nonpositive off-diagonal entries [2]. If a difference scheme is described by a monotone matrix or an M-matrix operator, a stability condition which is equivalent to a discrete maximum principle can be easily derived for the approximate solution. For example, we mention the schemes in [14, 18] for the steady model, and the ones proposed in [23, 31] to discretize the spatial terms of the time-dependent model.

As a matter of fact and against intuition, the major difficulty in obtaining second-order accurate schemes based on monotone or M-matrices is related to the discretization of the diffusive term and not of the advective term, the latter being properly controlled by limiters; see [6, 7, 19]. Owing to the negative result of [20], it is possible to show by appropriate counterexamples that *no finite difference approximation* *of second-order partial derivatives on general unstructured grids that is both linear and second- or higher-order accurate can be based on an M-matrix.* For instance, it is an enlightening fact that the second-order accurate cell-centered approximations developed in [31] satisfy a discrete maximum principle but only on uniform (or quasi-uniform) grids.

It is worth mentioning that the difficulty of obtaining M-matrices has also been related to the one of controlling the positivity and boundedness of the coefficients in the scheme required to ensure monotonicity [17]. A technique that surely suffers from this major fault is the *diamond scheme*; see [13] for a recent literature review. This approach defines the face gradients that are needed to discretize the numerical diffusive flux from the approximate cell averages. The solution gradient is provided at each internal face by a piecewise constant reconstruction of Gauss–Green type. This reconstruction takes place on the convex hull of the face vertices and the centers of the cells adjacent to the face. It is well known that this technique cannot ensure the correct sign of the coefficients in the scheme on general unstructured grids [11].

In this work, we propose the design of a finite volume approximation to the solution of (1a)–(1b) that is based on a *nonlinear extension* of the diamond scheme and that simultaneously satisfies these three conditions:

- it is based on a *conservative cell-centered formulation*;
- it provides *second order of accuracy in approximating cell averages of the solution on general unstructured grids*;
- it ensures a *maximum principle in some discrete form for the approximate solution.*

We emphasize that the nonlinearity is the crucial issue of the design of the scheme; this makes it possible to bypass the negative result of [20] and prove the existence of a discrete maximum principle for the numerical solution. Throughout the paper, we will refer to the standard technique as the *diamond scheme* and to this new method as the *nonlinear diamond scheme.*

The key steps of the derivation of the method are the following. First, (1a) is reformulated in the integral-conservative way on an unstructured mesh of d-dimensional simplices (triangles for $d = 2$ and tetrahedra for $d = 3$). As usual in finite volume methods, we relate the approximation of the solution-average on any mesh control volume to the discrete balance of the numerical advective and diffusive flux on the control volume boundary. The definition of the numerical flux uses the approximate cell averages, the values recovered at the mesh vertices by a piecewise linear reconstruction process, and the boundary data of (1b). The existence of a suitable set of nonnegative and bounded coefficients for the recovery of the vertex value is theoretically demonstrated by a constructive proof that provides an algorithm to compute them.

The numerical advective flux implements the usual first-order upstream formula, and second order of accuracy is formally achieved by the cellwise linear reconstruction from cell averages proposed and analyzed in [5].

The design of the numerical diffusive flux deserves much more attention. As pointed out in [5, 24], the face gradient provided by the diamond scheme can be written as the weighted average of two independent one-sided face gradients. Each one-sided gradient is calculated by linearly interpolating the values at the face vertices and the cell averages on the adjacent cells. The weights of the diamond scheme are constant and taken to be proportional to the measure of the portion of diamond cell shared by the corresponding adjacent cell.

In the nonlinear diamond scheme, the face gradient at any internal face is reformulated as a *nonlinear average* of the one-sided gradients *by suitably designing* *solution-dependent weights.* Under very general assumptions on the regularity of the mesh, we demonstrate that there always exists a solution to the discrete nonlinear problem and that all the numerical solutions (if more than one exist) satisfy a discrete maximum (or minimum) principle.

A similar nonlinear design was originally considered in [3] to build nonlinear M-matrix operators by relaxing conservation in difference approximations. These difference methods were also shown to possess second-order accurate solutions that preserve a discrete maximum principle.

The preservation of the maximum principle of the nonlinear diamond scheme solution has been experimentally verified by a comparative assessment with the behavior of the diamond scheme solution in the same critical situations. Numerical experiments also show the expected second-order convergence rate and a nonoscillatory behavior when the analytical solution has strong gradient regions such as internal layers.

The outline of the paper is as follows. In section 2, we introduce the notation adopted in this paper and other technical details. In section 3, we discuss the regularity assumption on the family of grids considered in the approximation process when the mesh size tends to zero. We also present the algorithm that recovers the vertex values from the cell averages. Then the derivation of the method is presented in section 4. In section 5, we investigate the theoretical properties concerning the solvability of the scheme and demonstrate the existence of a discrete maximum principle for the numerical solutions provided by the method. In section 6, a set of numerical results illustrates the performance of the method in treating problems with internal layers and solutions with strong gradients. Final remarks and conclusions are offered in section 7.

2. General setup and notation.

In this section, we introduce the notation adopted in this paper. For ease of reference, we also collect herein the definitions of the topological and geometrical entities and of the discrete function spaces, scalar product, and norms that are in use throughout the paper.

The polyhedral domain $\Omega \in \mathbb{R}^d$ is covered by a finite collection of nonoverlapping and nonempty d-dimensional simplices, namely, the *mesh*. These simplices are denoted by the letter "T" and labeled by a Latin index like i (j, k, ...); i.e., T_i is the ith control volume (cell) of the mesh. The set of all mesh control volumes is denoted by $\mathcal{T}_h = \{\mathsf{T}_i\}$; the control volumes are such that $\overline{\Omega} = \cup_{\mathsf{T}_i \in \mathcal{T}_h} \mathsf{T}_i$.

The mesh faces are denoted by the letter "f" and labeled by a couple of Latin indices, i.e., f_{ij}. It is useful to distinguish between *internal* and *boundary* faces. When f_{ij} is an internal face, there must exist two control volumes T_i and T_j such that $\mathsf{f}_{ij} = \mathsf{T}_i \cap \mathsf{T}_j$. When f_{ij} is a boundary face, i.e., $\mathsf{f}_{ij} \subseteq \Gamma$, the first index always refers to the unique control volume T_i to which the face belongs, while the second index is defined in accordance with a suitable boundary numbering system (such as a sort of fictitious *ghost cell*). The symbols $\mathcal{F}_h$, $\mathcal{F}_h^{\text{int}}$, and $\mathcal{F}_h^{\text{bnd}}$ denote, respectively, the set of all mesh faces, the set of the *internal faces*, and the set of the *boundary faces*. When dealing with internal faces, f_{ij} and f_{ji} are equivalent symbols that denote the same face; in expressions like $\mathsf{f}_{ij} \in \mathcal{F}_h$ (or $\mathcal{F}_h^{\text{int}}$) we assume that the face labeled by i and j is considered only once (for example, by taking the representative with $i < j$). Clearly, $\mathcal{F}_h = \mathcal{F}_h^{\text{int}} \cup \mathcal{F}_h^{\text{bnd}}$ and $\mathcal{F}_h^{\text{int}} \cap \mathcal{F}_h^{\text{bnd}} = \emptyset$.

The mesh vertices are denoted by the symbol "v" and labeled by Greek letters like α (β, γ, ...). The symbols $\mathcal{V}_h$, $\mathcal{V}_h^{\text{int}}$, and $\mathcal{V}_h^{\text{bnd}}$ denote, respectively, the set of all mesh vertices, the set of the *internal* vertices, and the set of the *boundary* vertices. We have that $\mathcal{V}_h = \mathcal{V}_h^{\text{int}} \cup \mathcal{V}_h^{\text{bnd}}$ and $\mathcal{V}_h^{\text{int}} \cap \mathcal{V}_h^{\text{bnd}} = \emptyset$.

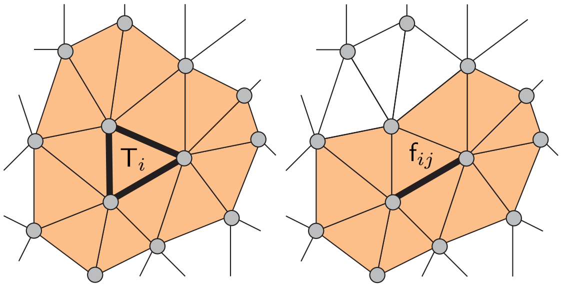

FIG. 1. *The stencils $\sigma\nu_i$ (left) and $\sigma\nu_{ij}$ (right) for the two-dimensional case.*

2.1. Topological quantities. Summations are taken over the index sets:

- σ_i, cells sharing a face with T_i;
- σ_α, cells surrounding the vertex v_α;
- σ'_i, "ghost" cells sharing a face with T_i;
- ν_i, vertices of the cell T_i;
- ν_α, vertices connected to the vertex v_α;
- ν_{ij}, vertices of the face f_{ij}; we also distinguish between $\nu_{ij}^{\rm int} = \{\alpha \in \nu_{ij} | \mathsf{v}_\alpha \in \mathcal{V}_h^{\rm int}\}$ and $\nu_{ij}^{\rm bnd} = \{\alpha \in \nu_{ij} | \mathsf{v}_\alpha \in \mathcal{V}_h^{\rm bnd}\}$;
- $\sigma\nu_i$, cells having a vertex in common with T_i;
- $\sigma\nu_{ij}$, cells having a vertex in common with f_{ij}.

We anticipate that the last two sets listed above, i.e., $\sigma\nu_i$ and $\sigma\nu_{ij}$, are the stencils of the discrete gradient $\boldsymbol{G}_i(\mathsf{u}_h)$ and of the numerical diffusive flux $\mathcal{G}_{ij}(\mathsf{u}_h)$ at $\mathsf{f}_{ij} \in \mathcal{F}_h$; see the definitions in section 4.2. Figure 1 illustrates the two-dimensional case.

Coherently with face notation, f_{ij} is a boundary face of T_i for every $j \in \sigma'_i$ and the internal face shared by T_i and T_j for $j \in \sigma_i$. Thus, the index $j \in \sigma_i \cup \sigma'_i$ labels all the faces forming the boundary of T_i.

2.2. Geometric quantities. The quantities related to T_i are consistently labeled by the same index i:

- $|\mathsf{T}_i|$, the d-dimensional Lebesgue measure of T_i (area in two dimensions, volume in three);
- $\partial\mathsf{T}_i$, the boundary of T_i;
- $\boldsymbol{x}_i$, the barycenter of T_i.

The quantities related to the mesh vertex v_α are consistently labeled by the same index α:

- $\boldsymbol{x}_\alpha$, the position vector of v_α;
- $\mathcal{B}_{\boldsymbol{x}_\alpha,r}$, the (closed) ball of center v_α and radius r; $\partial\mathcal{B}_{\boldsymbol{x}_\alpha,r}$ denotes the boundary of the ball.

The quantities related to the face f_{ij} are consistently labeled by the same couple of indices ij:

- $|\mathsf{f}_{ij}|$, the $(d-1)$-dimensional Lebesgue measure of $\mathsf{f}_{ij} \in \mathcal{F}_h$ (length in two dimensions, surface area in three);
- $\boldsymbol{x}_{ij}$, the position vector of the center of $\mathsf{f}_{ij} \in \mathcal{F}_h$;
- $\boldsymbol{n}_{ij}$, the unit vector orthogonal to $\mathsf{f}_{ij} \in \mathcal{F}_h$ and oriented from T_i to T_j if $\mathsf{f}_{ij} \in \mathcal{F}_h^{\rm int}$, outward of Ω if $\mathsf{f}_{ij} \in \mathcal{F}_h^{\rm bnd}$;
- $\tilde{\boldsymbol{x}}_{ij}$, the position vector of the orthogonal projection of $\boldsymbol{x}_i$ on the hyperplane containing the face $\mathsf{f}_{ij} \in \mathcal{F}_h$;

- $\tilde{\lambda}^{ij}_{\alpha}$, the barycentric coordinate of $\tilde{\boldsymbol{x}}_{ij}$ with respect to $\mathsf{v}_{\alpha} \in \mathsf{f}_{ij}$; hence,

$$\sum_{\alpha \in \nu_{ij}} \tilde{\lambda}^{ij}_{\alpha} = 1 \quad \text{and} \quad \sum_{\alpha \in \nu_{ij}} \tilde{\lambda}^{ij}_{\alpha} \boldsymbol{x}_{\alpha} = \tilde{\boldsymbol{x}}_{ij};$$

- $h_{ij} = (\tilde{\boldsymbol{x}}_{ij} - \boldsymbol{x}_i) \cdot \boldsymbol{n}_{ij}$, the distance between the center of T_i and the face $\mathsf{f}_{ij} \in \mathcal{F}_h$;
- $H_{ij} = (\boldsymbol{x}_j - \boldsymbol{x}_i) \cdot \boldsymbol{n}_{ij} = h_{ij} + h_{ji}$, the *effective distance* between the centers of T_i and T_j when $\mathsf{f}_{ij} \in \mathcal{F}^{\text{int}}_h$.

2.3. Discrete function spaces and norms. Let us introduce the set of piecewise constant functions,

$$\mathtt{T}_h = \Big\{ \mathsf{w}_h \in \mathtt{L}^2(\Omega), \text{ such that } \mathsf{w}_h|_{\mathsf{T}_i} = w_i \text{ for } \mathsf{T}_i \in \mathcal{T}_h \Big\},$$

that are defined on a given triangulation $\mathcal{T}_h$. The set $\mathtt{T}_h$ is clearly isomorphic to $\mathbb{R}^{\mathsf{card}\{\mathcal{T}_h\}}$. In this paper, we use the $\mathtt{L}^2$ mesh-dependent scalar product, its derived norm, and the $\mathtt{H}^1$-norm defined on $\mathtt{T}_h$ by the formulae

$$\begin{aligned}
(\mathsf{u}_h, \mathsf{w}_h)_{\mathcal{T}_h} &= \sum_{\mathsf{T}_i \in \mathcal{T}_h} |\mathsf{T}_i|\, u_i w_i, \\
\|\mathsf{w}_h\|_{\mathcal{T}_h} &= \sqrt{(\mathsf{w}_h, \mathsf{w}_h)_{\mathcal{T}_h}}, \\
\|\mathsf{w}_h\|_{\mathcal{T}_h,1} &= \Bigg(\sum_{\mathsf{f}_{ij} \in \mathcal{F}^{\text{int}}_h} \frac{|\mathsf{f}_{ij}|}{H_{ij}} (w_j - w_i)^2 + \sum_{\mathsf{f}_{ij} \in \mathcal{F}^{\text{bnd}}_h} \frac{|\mathsf{f}_{ij}|}{h_{ij}} w_i^2 \Bigg)^{1/2}.
\end{aligned}$$

3. Mesh regularity assumption and vertex reconstruction. In this section, we discuss the sense in which the mesh used to formulate the finite volume scheme is regular. We also describe the algorithm to recover the approximate vertex values.

3.1. Mesh regularity assumption. In accordance with the definition of [10], the parameter h that labels the mesh $\mathcal{T}_h$ is called the *mesh size*, and is formally given by the supremum of the mesh control volume diameters; i.e., $h = \max_{\mathsf{T}_i \in \mathcal{T}_h} h_i$ with $h_i = \mathsf{diam}\{\mathsf{T}_i\}$. Let us denote the maximum radius of the balls contained in the cell T_i and centered at $\boldsymbol{x}_i$ by ρ_i, and consider $\rho = \min_{\mathsf{T}_i \in \mathcal{T}_h} \rho_i$. The approximation method described in this paper is formulated on a family of d-dimensional conforming grids $\mathcal{T}_h$ that are *regular* in the following sense.

Assumption 1 (mesh regularity).

(i) There exists a *mesh regularity constant* $C_{\text{reg}} > 0$ that is independent of h and such that $(h/\rho)^d \leq C_{\text{reg}}$ for any $h \leq h_0$.

(ii) Let $\pi_{ij}\mathsf{v}_{\alpha}$ denote the orthogonal projection of the vertex v_{α} on the hyperplane containing the face f_{ij}. Then $\pi_{ij}\mathsf{v}_{\alpha} \in \mathsf{f}_{ij}$ for any $\alpha \in \nu_i$ and $j \in \sigma_i \cup \sigma'_i$.

(iii) The face f_{ij} is internal, i.e., $\mathsf{f}_{ij} \in \mathcal{F}^{\text{int}}_h$ iff $\mathsf{card}\big\{\nu^{\text{int}}_{ij}\big\} > 0$.

Note that the first condition is similar to but slightly stronger than the one that is normally met in the analysis of finite element methods; see [10]. The present formulation of item (i) is particularly useful to demonstrate the existence of the positive weights of the vertex reconstruction in the next subsection. A weaker assumption could be considered as well by imposing a local regularity constraint on h_j/ρ_j and taking the supremum on the set of cells surrounding any mesh vertex. Nonetheless, this would complicate the analysis that follows. The second condition is trivial when $\mathsf{v}_\alpha \in \mathsf{f}_{ij}$ because in this case $\pi_{ij}\mathsf{v}_\alpha = \mathsf{v}_\alpha$, and is satisfied by a wide family of grids, such as, for example, the ones based on regular acute and weakly acute two-dimensional triangulations and their suitable extensions to higher dimensions [10].

For the sake of reference, in the following proposition we list some properties of regular grids that will be useful in the paper.

Proposition 2.

(i) $\max\{h_{ij}/h_{ji},\, h_{ji}/h_{ij}\} \leq C_{\mathrm{reg}}$ *for any internal face* $\mathsf{f}_{ij} \in \mathcal{F}_h^{\mathrm{int}}$.

(ii) $\mathsf{card}\{\sigma_\alpha\} \leq C_{\mathrm{reg}}$ *for any vertex* $\mathsf{v}_\alpha \in \mathcal{V}_h$.

(iii) $\tilde{\lambda}_\alpha^{ij} \geq 1/(d+1)$ *for any face* $\mathsf{f}_{ij} \in \mathcal{F}_h$ *and any vertex* $\mathsf{v}_\alpha \in \nu_{ij}$.

The proof is omitted because these relations readily follow from Assumption 1.

3.2. Reconstruction of vertex values. The value at the mesh vertex v_α is reconstructed by

$$u_\alpha = \begin{cases} \sum_{k\in\sigma_\alpha} \mathrm{w}_k^\alpha u_k, & \mathsf{v}_\alpha \in \mathcal{V}_h^{\mathrm{int}}, \\ \mathsf{g}(\boldsymbol{x}_\alpha), & \mathsf{v}_\alpha \in \mathcal{V}_h^{\mathrm{bnd}}, \end{cases} \tag{3}$$

where $\{\mathrm{w}_k^\alpha,\ k \in \sigma_\alpha\}$ is the set of coefficients associated to $\mathsf{v}_\alpha \in \mathcal{V}_h^{\mathrm{int}}$, and $\mathsf{g}(\boldsymbol{x}_\alpha)$ is the Dirichlet boundary condition of the vertex $\mathsf{v}_\alpha \in \mathcal{V}_h^{\mathrm{bnd}}$. In Theorem 5 we demonstrate the existence of a special set of coefficients $\{\mathrm{w}_k^\alpha\}$ that are strictly positive, bounded from above by 1, and such that (3) is exact for linear polynomials defined on $\cup_{k\in\sigma_\alpha}\mathsf{T}_k \subseteq \overline{\Omega}$. The proof of Theorem 5 is based on the technical result of Lemma 4 that exploits the possibility of separating convex sets in $\mathbb{R}^n$. As this latter one is a standard result from convex analysis, it is given in Lemma 3 without proof for the sake of reference.

Lemma 3. *There exists a closed hyperplane that strictly separates any two nonempty and disjoint closed convex subsets of* $\mathbb{R}^n$*, provided that one of the two sets is also compact.*

Proof. See, e.g., Rockafellar [28, section 11]. □

Lemma 4. *Under the mesh regularity Assumption* 1*, for every* $\mathsf{v}_\alpha \in \mathcal{V}_h^{\mathrm{int}}$ *we have that* $\mathcal{B}_{\boldsymbol{x}_\alpha,\rho} \subseteq \mathcal{C}$*, where* $\mathcal{C} = \mathsf{conv}\{\boldsymbol{x}_k,\ k \in \sigma_\alpha\}$.

Proof. Let v_α be an internal vertex of the triangulation $\mathcal{T}_h$. We will demonstrate by contradiction that neither does $\mathcal{B}_{\boldsymbol{x}_\alpha,\rho}$ lie completely outside of the convex hull $\mathcal{C}$ nor is $\mathcal{B}_{\boldsymbol{x}_\alpha,\rho}$ partially (but not entirely) included in $\mathcal{C}$. Both contradiction arguments rely on the two following basic observations that are consequences of Assumption 1(ii): (a) any hyperplane for v_α divides the space $\mathbb{R}^d$ in two (closed) half-spaces that must entirely contain at least one d-simplex with index in σ_α; (b) the distance between each one of the barycenters of the two simplices of item (a) and the given hyperplane for v_α must be greater than or equal to ρ. This situation is illustrated by Figure 2(a).

Let us first consider the case in which the two closed and convex sets $\mathcal{B}_{\boldsymbol{x}_\alpha,\rho}$ and $\mathcal{C}$ are disjoint; a strictly separating hyperplane exists by Lemma 3, as shown by Figure 2(b). Thus, the barycenters of all the d-simplices surrounding v_α, which of course belong to $\mathcal{C}$, must lie in the same half-space of the two half-spaces defined by the hyperplane for v_α and parallel to the separating hyperplane. This fact contradicts the initial observation (a).

When $\mathcal{B}_{\boldsymbol{x}_\alpha,\rho}$ is partially but not fully included in $\mathcal{C}$, a point $\mathbf{y}$ exists in the interior of $\mathcal{B}_{\boldsymbol{x}_\alpha,\rho}\backslash\mathcal{C}$. Lemma 3 again provides a hyperplane separating $\mathbf{y}$ and $\mathcal{C}$, as shown by Figure 2(c). The distance between the separating hyperplane and v_α must be strictly less than ρ because $\mathbf{y}$ is an interior point of $\mathcal{B}_{\boldsymbol{x}_\alpha,\rho}$. Let us now consider the hyperplane

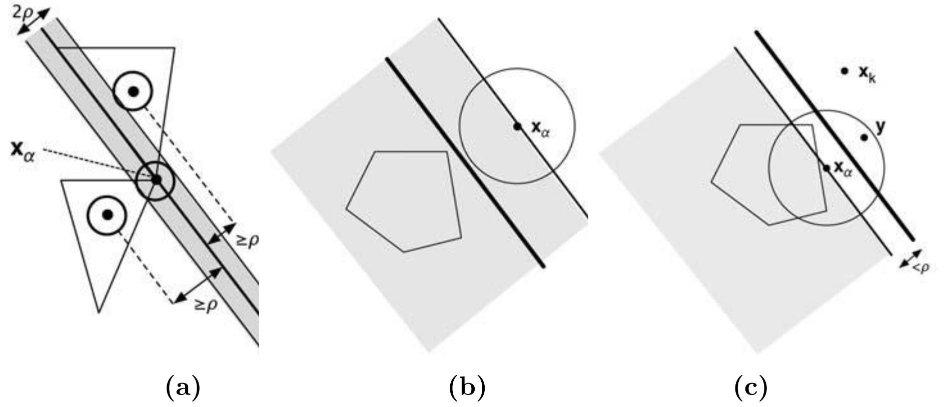

FIG. 2. *Proof of Lemma* 4*: the thicker lines in* (b) *and* (c) *are the separating hyperplane provided by Lemma* 3*; the polygonal body is the convex hull of the cell centers.*

for v_α, which is parallel to the separating hyperplane provided by Lemma 3, and the two half-spaces defined by it. Observation (a) implies that at least one d-simplex T_k exists in the same half-space containing $\mathbf{y}$, and observation (b) that its barycenter $\boldsymbol{x}_k$ has a distance greater than ρ from the hyperplane for v_α. As shown by Figure 2(c), the barycenter $\boldsymbol{x}_k$ must be located on the same side of $\mathbf{y}$ and beyond the separating hyperplane because the distance between the hyperplane for v_α and the separating hyperplane is strictly less than ρ. This last statement contradicts the fact that all the barycenters are in the half-space defined by the separating hyperplane and not containing $\mathbf{y}$. ▯

The following regularity constant is used in Theorem 5:

$$C_{\text{grid}} = \frac{1}{2} C_{\text{reg}}{}^{\frac{d-1}{d}}.$$

THEOREM 5. *Under the mesh regularity Assumption* 1*, for any internal vertex* $\mathsf{v}_\alpha \in \mathcal{V}_h^{\text{int}}$ *there exists a set of coefficients* $\{\mathrm{w}_k^\alpha\}$ *such that*

(i) $C_{\text{grid}} \leq \mathrm{w}_k^\alpha < 1$ *for* $k \in \sigma_\alpha$*;*

(ii) $\sum_{k\in\sigma_\alpha} \mathrm{w}_k^\alpha = 1$*;*

(iii) $\sum_{k\in\sigma_\alpha} \mathrm{w}_k^\alpha(\boldsymbol{x}_k - \boldsymbol{x}_\alpha) = 0$.

Proof. For any $k \in \sigma_\alpha$, let us define the two vectors

$$\sum_{j\in\sigma_\alpha} a_{kj}\boldsymbol{x}_j = \{\boldsymbol{x}_\alpha + t(\boldsymbol{x}_k - \boldsymbol{x}_\alpha),\ t \leq 0\} \cap \partial\mathcal{B}_{\boldsymbol{x}_\alpha,\rho}, \tag{4a}$$

$$\boldsymbol{x}_\alpha + b_k(\boldsymbol{x}_k - \boldsymbol{x}_\alpha) = \{\boldsymbol{x}_\alpha + t(\boldsymbol{x}_k - \boldsymbol{x}_\alpha),\ t \geq 0\} \cap \partial\mathcal{B}_{\boldsymbol{x}_\alpha,h} \tag{4b}$$

that are expressed by a suitable choice of the scalar coefficients a_{kj} and b_k. In view of Lemma 4, the right-hand side of (4a) defines a *convex* linear combination of the vectors $\boldsymbol{x}_j$ for $j \in \sigma_\alpha$. Thus, the coefficients $\{a_{kj}\}$ at the left-hand side of (4a) can be chosen nonnegative and such that $\sum_{j\in\sigma_\alpha} a_{kj} = 1$. Relation (4b) is valid with $b_k \geq 1$. By construction we have that

$$\rho b_k(\boldsymbol{x}_k - \boldsymbol{x}_\alpha) + h \sum_{j\in\sigma_\alpha} a_{kj}(\boldsymbol{x}_j - \boldsymbol{x}_\alpha) = 0 \qquad \text{for every } k \in \sigma_\alpha. \tag{5}$$

The proof terminates by verifying that the coefficients

$$\mathrm{w}_k^\alpha = \frac{1}{\mathsf{card}\{\sigma_\alpha\}\,(\rho b + h)}\Big[\rho b_k + h\sum_{j\in\sigma_\alpha} a_{jk}\Big], \qquad \text{with } b = \frac{1}{\mathsf{card}\{\sigma_\alpha\}}\sum_{k\in\sigma_\alpha} b_k, \tag{6}$$

actually satisfy the statements of the theorem. The left inequality of item (i) follows from

$$\mathrm{w}_k^\alpha \geq \frac{\rho b_k}{\mathsf{card}\{\sigma_\alpha\}\,(\rho b + h)} \geq \frac{\rho}{2\mathsf{card}\{\sigma_\alpha\}\,h} \geq \frac{\rho}{2hC_{\mathrm{reg}}} \geq C_{\mathrm{grid}}$$

because $b_k \geq 1$ and $b \leq h/\rho$. Items (ii) and (iii) are a straightforward consequence of the construction property (5) and definition (6). The proof of item (i) is finally completed by observing that none of the strictly positive coefficients w_k^α for $k \in \sigma_\alpha$ can be greater than or equal to 1 if item (ii) is true. □

Let us emphasize the constructive nature of the above proof that provides a practical method of computing the set of coefficients $\{\mathrm{w}_k^\alpha\}$. In view of the mesh regularity Assumption 1 and Lemma 4, for any cell center $\boldsymbol{x}_k$, $k \in \sigma_\alpha$, there always exists a subset of d indices $\{k_1, \ldots, k_d\} \in \sigma_\alpha$ such that $\mathsf{conv}\{\boldsymbol{x}_{k_1}, \ldots, \boldsymbol{x}_{k_d}\}$ has a nonempty intersection with the half-line starting from $\boldsymbol{x}_\alpha$ and having direction $\boldsymbol{x}_\alpha - \boldsymbol{x}_k$. As more than one choice of indices $\{k_1, \ldots, k_d\}$ may exist, we select the one that maximizes the distance between the intersection point and the vertex v_α. Let $\mathsf{p}_{\alpha k}$ denote the position vector of this intersection point. Replacing the ball $\mathcal{B}_{\boldsymbol{x}_\alpha,\rho}$ in the proof of Theorem 5 by the convex hull of this suitably chosen subset of cell centers surrounding v_α yields the following algorithm:

```
**foreach** $k \in \sigma_\alpha$ **do** let $\mathrm{w}_k^\alpha = 0$;
**foreach** $k \in \sigma_\alpha$ **do**
    choose the $d$ indices $\{\boldsymbol{x}_{k_1}, \ldots, \boldsymbol{x}_{k_d}\}$ maximizing $|\mathsf{p}_{\alpha k} - \boldsymbol{x}_\alpha|$;
    compute $0 \leq \beta \leq 1$ such that $\boldsymbol{x}_\alpha = (1-\beta)\mathsf{p}_{\alpha k} + \beta \boldsymbol{x}_k$;
    compute $\{\lambda_l\}$ such that $\mathsf{p}_{\alpha k} = \sum_{l=1}^d \lambda_l \boldsymbol{x}_{k_l}$;
    accumulate $\mathrm{w}_k^\alpha \leftarrow \mathrm{w}_k^\alpha + \beta$;
    **foreach** $l = 1, \ldots, d$ **do** accumulate $\mathrm{w}_{k_l}^\alpha \leftarrow \mathrm{w}_{k_l}^\alpha + (1-\beta)\lambda_l$;
**end**
**foreach** $k \in \sigma_\alpha$ **do** let $\mathrm{w}_k^\alpha \leftarrow \mathrm{w}_k^\alpha / \sum_{k\in\sigma_\alpha} \mathrm{w}_k^\alpha$.
```

4. Finite volume formulation.

The model problem (1a)–(1b) is reformulated by integrating on the generic control volume $\mathsf{T}_i \in \mathcal{T}_h$ and applying the Gauss–Green theorem as follows:

$$\frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma_i\,\cup\,\sigma_i'} \int_{\mathsf{f}_{ij}} \big(\mathsf{u}\boldsymbol{v} - \nu\nabla\mathsf{u}\big)\cdot \boldsymbol{n}_{ij}\, dS = \frac{1}{|\mathsf{T}_i|}\int_{\mathsf{T}_i} \mathsf{s}\, dV \quad \text{for } \mathsf{T}_i \in \mathcal{T}_h.$$

The finite volume approximation of the cell average of u on T_i is denoted by u_i. The vector that collects all the approximate cell averages is denoted by u_h; i.e., $\mathsf{u}_h|_i = u_i$. The finite volume scheme correlates the approximate cell-average vector u_h to the balance of the numerical fluxes across the bounding faces in $\partial\mathsf{T}_i$ by the set of relations

$$\frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma_i} |\mathsf{f}_{ij}|\,\Big[\mathcal{F}_{ij}(\mathsf{u}_h) + \mathcal{G}_{ij}(\mathsf{u}_h)\Big] + \frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma_i'} |\mathsf{f}_{ij}|\,\mathcal{B}_{ij}(\mathsf{u}_h) = \mathsf{s}_i \text{ for } \mathsf{T}_i \in \mathcal{T}_h. \tag{7}$$

The terms $\mathcal{F}_{ij}(\mathsf{u}_h)$ and $\mathcal{G}_{ij}(\mathsf{u}_h)$ are the face integrals of the numerical advective and diffusive fluxes on $\mathsf{f}_{ij} \in \mathcal{F}_h^{\mathrm{int}}$; $\mathcal{B}_{ij}(\mathsf{u}_h)$ is the face integral of the numerical flux on $\mathsf{f}_{ij} \in \mathcal{F}_h^{\mathrm{bnd}}$ and collects boundary contributions from both advective and diffusive terms; s_i is the volume integral of the source term over T_i approximated by an appropriate quadrature formula.

4.1. Cell-centered gradient, slope limiter, and numerical advective flux. The piecewise constant approximation of the solution gradient within the control volume T_i is derived by applying the Gauss–Green theorem to the volume integral of $\nabla \mathsf{u}$ and by linearly approximating the boundary integrals on $\partial \mathsf{T}_i$.

Let f_α denote the face opposite to the vertex v_α and $\boldsymbol{n}_\alpha$ its unit normal vector. We thus obtain the formula

$$\boldsymbol{G}_i(\mathsf{u}_h) = -\frac{l_i(\mathsf{u}_h)}{d\,|\mathsf{T}_i|} \sum_{\alpha \in \nu_i} u_\alpha\, |\mathsf{f}_\alpha|\, \boldsymbol{n}_\alpha, \tag{8}$$

where $l_i(\mathsf{u}_h)$ is the limiter factor defined as follows. In view of (8), we first introduce the linear reconstruction of the solution approximation:

$$\mathcal{R}_i(\mathsf{u}_h)(\boldsymbol{x}) = \begin{cases} u_i + \boldsymbol{G}_i(\mathsf{u}_h) \cdot (\boldsymbol{x} - \boldsymbol{x}_i) & \text{if } \boldsymbol{x} \in \mathsf{T}_i, \\ 0 & \text{otherwise.} \end{cases}$$

The slope limiter factor $l_i(\mathsf{u}_h)$ in (8) is the largest real number in $[0, 1]$ such that

$$\min\{u_i, \min_{\alpha \in \nu_i} u_\alpha\} \leq \mathcal{R}_i(\mathsf{u}_h)(\boldsymbol{x}_{ij}) \leq \max\{u_i, \max_{\alpha \in \nu_i} u_\alpha\} \quad \text{for } j \in \sigma_i \cup \sigma_i', \tag{9}$$

and

$$\|\boldsymbol{G}(\mathsf{u}_h)\|_{\mathcal{T}_h} \leq C_{\mathrm{lim}}, \tag{10}$$

where C_{lim} is a suitable bound from above of the $\mathtt{T}_h$-norm of the finite volume approximation of the solution gradient $\nabla \mathsf{u}$. Note that condition (10) makes it possible to control a discrete counterpart of the total variation of u_h.

LEMMA 6. *If u_i is a local maximum (minimum), i.e., $u_i \geq \max_{\alpha \in \nu_i} u_\alpha$ ($u_i \leq \min_{\alpha \in \nu_i} u_\alpha$), then $\boldsymbol{G}_i(\mathsf{u}_h) = 0$.*

Proof. In view of the definition of the limiter and the assumption of the lemma, we have that $\mathcal{R}_i(\mathsf{u}_h)(\boldsymbol{x}_{ij}) \leq \max\{u_i, \max_{\alpha \in \nu_i} u_\alpha\} = u_i$; i.e., $\boldsymbol{G}_i(\mathsf{u}_h) \cdot (\boldsymbol{x}_{ij} - \boldsymbol{x}_i) \leq 0$ for $j \in \sigma_i \cup \sigma_i'$. Since $\boldsymbol{x}_i$ is the barycenter of T_i, we have that $(d+1)\boldsymbol{x}_i = \sum_{j \in \sigma_i \cup \sigma_i'} \boldsymbol{x}_{ij}$, and then $\sum_{j \in \sigma_i \cup \sigma_i'} \boldsymbol{G}_i(\mathsf{u}_h) \cdot (\boldsymbol{x}_{ij} - \boldsymbol{x}_i) = 0$. Consequently, d linearly independent directions $\boldsymbol{x}_{ij} - \boldsymbol{x}_i$ exist among the $(d+1)$-ones for $j \in \sigma_i \cup \sigma_i'$ such that the orthogonal projection of $\boldsymbol{G}_i(\mathsf{u}_h)$ onto them is the zero vector. □

The numerical advective flux at the internal face f_{ij} is derived from the standard upwind formula

$$\mathcal{F}_{ij}(\mathsf{u}_h) = v_{ij}^+ \mathcal{R}_i(\mathsf{u}_h)(\boldsymbol{x}_{ij}) + v_{ij}^- \mathcal{R}_j(\mathsf{u}_h)(\boldsymbol{x}_{ij}), \qquad j \in \sigma_i,$$

where

$$v_{ij} = \frac{1}{|\mathsf{f}_{ij}|} \int_{\mathsf{f}_{ij}} \boldsymbol{v}(\boldsymbol{x}) \cdot \boldsymbol{n}_{ij}\, dS, \qquad v_{ij}^\pm = \frac{v_{ij} \pm |v_{ij}|}{2}.$$

Since $v^-_{ij} + v^+_{ji} = 0$, the balance of the numerical advective flux of the internal face $\mathsf{f}_{ij} \in \mathcal{F}^{\rm int}_h$ of the cell T_i can be compactly written as

$$\frac{1}{|\mathsf{T}_i|} \sum_{j\in\sigma_i} |\mathsf{f}_{ij}|\, \mathcal{F}_{ij}(\mathsf{u}_h) = \big(\mathbf{F}\mathsf{u}_h - \mathbf{r}^{\rm int}(\mathsf{u}_h)\big)\Big|_i \tag{11}$$

by introducing the advective flux matrix

$$\mathsf{F}_{ij} = \frac{1}{|\mathsf{T}_i|} \begin{cases} \sum_{k\in\sigma_i} |\mathsf{f}_{ik}|\, v^+_{ik}, & j = i, \\ -\,|\mathsf{f}_{ij}|\, v^+_{ji}, & j \in \sigma_i, \\ 0 & \text{otherwise} \end{cases} \tag{12}$$

and the advective flux vector

$$\mathsf{r}^{\rm int}_i(\mathsf{u}_h) = \frac{1}{|\mathsf{T}_i|} \sum_{j\in\sigma_i} |\mathsf{f}_{ij}| \big(v^+_{ij} \boldsymbol{G}_i(\mathsf{u}_h)\cdot(\boldsymbol{x}_i - \boldsymbol{x}_{ij}) - v^+_{ji} \boldsymbol{G}_j(\mathsf{u}_h)\cdot(\boldsymbol{x}_j - \boldsymbol{x}_{ji}) \big). \tag{13}$$

Note that the term $\mathbf{F}\mathsf{u}_h|_i$ in (11) is a first-order accurate discretization of the flux integral $\int_{\partial\mathsf{T}_i\setminus\partial\Omega} \mathsf{u}(\boldsymbol{x})\boldsymbol{v}(\boldsymbol{x})\cdot\boldsymbol{n}\, dS/\,|\mathsf{T}_i|$, while second-order accuracy is provided by the term $\mathsf{r}^{\rm int}_i(\mathsf{u}_h)$.

4.2. Face gradient and numerical diffusive flux. To define the numerical diffusive flux at the internal face $\mathsf{f}_{ij} \in \mathcal{F}^{\rm int}_h$, we introduce the face gradient by a special nonlinear average of two *one-sided* face gradients $\widetilde{\boldsymbol{G}}_{ij}(\mathsf{u}_h)$ and $\widetilde{\boldsymbol{G}}_{ji}(\mathsf{u}_h)$. The *one-sided* face gradient $\widetilde{\boldsymbol{G}}_{ij}(\mathsf{u}_h)$ is recovered from cell averages by applying the Gauss–Green theorem to the integral of $\nabla\mathsf{u}$ on the *half-diamond* delimited by the center of T_i and the face vertices v_α, $\alpha \in \nu_{ij}$. The linear approximation of the resulting boundary integrals gives the one-sided formula

$$\widetilde{\boldsymbol{G}}_{ij}(\mathsf{u}_h) = \frac{\tilde{u}_{ij} - u_i}{h_{ij}} \boldsymbol{n}_{ij} + \{\text{TANGENTIAL TERM}\}, \tag{14}$$

where $\tilde{u}_{ij}$ is the approximate solution at $\tilde{\boldsymbol{x}}_{ij} \in \mathsf{f}_{ij}$, and the tangential term is left unspecified because it does not contribute to the integral of the normal flux. The value $\tilde{u}_{ij}$ is approximated by linear interpolation of the values at the vertices of the face f_{ij} given by (3); we have the formula

$$\tilde{u}_{ij} = \sum_{\alpha\in\nu_{ij}} \tilde{\lambda}^{ij}_\alpha u_\alpha. \tag{15}$$

The other one-sided face gradient $\widetilde{\boldsymbol{G}}_{ji}(\mathsf{u}_h)$ is similarly defined on the opposite half-diamond (related formulae are readily available by simply interchanging i and j in the previous derivation).

Note that a *unique* definition of the face gradient is required to have a *conservative* formulation of the diffusive flux. The two one-sided face gradients previously built cannot be taken as possible candidates because selecting one of them would imply a loss of information from the discarded one. Thus, we define the face gradient at $\mathsf{f}_{ij} \in \mathcal{F}^{\rm int}_h$ by the nonlinear average

$$\boldsymbol{G}_{ij}(\mathsf{u}_h) = \omega_{ij}(\mathsf{u}_h)\widetilde{\boldsymbol{G}}_{ij}(\mathsf{u}_h) + \omega_{ji}(\mathsf{u}_h)\widetilde{\boldsymbol{G}}_{ji}(\mathsf{u}_h), \tag{16}$$

where $\omega_{ij}(\mathsf{u}_h)$ and $\omega_{ji}(\mathsf{u}_h)$ are two nonnegative solution-dependent weights satisfying $\omega_{ij}(\mathsf{u}_h)+\omega_{ji}(\mathsf{u}_h)=1$ for any vector $\mathsf{u}_h \in \mathtt{T}_h$.

As pointed out in [5], the usual face gradient of the diamond scheme is readily obtained by choosing the constant weights

$$\omega_{ij}(\mathsf{u}_h)=|\mathsf{T}_i|/(|\mathsf{T}_i|+|\mathsf{T}_j|). \tag{17}$$

When $d=2$, this choice leads to the numerical diffusive flux considered in [11].

It is well known that the diamond scheme cannot ensure a maximum principle on general grids; see, for instance, [11, 20]. Thus, a different design of the weights $\omega_{ij}(\mathsf{u}_h)$ and $\omega_{ji}(\mathsf{u}_h)$ must be envisaged that generalizes (17) in a nonlinear sense. To do that, we proceed as follows. We substitute the vertex-reconstructed values provided by (3) in (15) and use the summation rule

$$\sum_{\alpha\in\nu_{ij}^{\text{int}}}\sum_{k\in\sigma_\alpha}=\sum_{k\in\sigma\nu_{ij}}\sum_{\alpha\in\nu_k\cap\nu_{ij}^{\text{int}}} \tag{18}$$

to get

$$\tilde{u}_{ij}=\sum_{k\in\sigma\nu_{ij}}p_k^{ij}u_k+p^{ij}g_{ij}^{\text{bnd}},\qquad g_{ij}^{\text{bnd}}=\frac{1}{p^{ij}}\sum_{\alpha\in\nu_{ij}^{\text{bnd}}}\tilde{\lambda}_\alpha^{ij}\,\mathsf{g}(\boldsymbol{x}_\alpha),$$

where

$$p_k^{ij}=\sum_{\alpha\in\nu_k\cap\nu_{ij}^{\text{int}}}\tilde{\lambda}_\alpha^{ij}\mathrm{w}_k^\alpha\quad\text{for } k\in\sigma_\alpha,\qquad\text{and}\qquad p^{ij}=\sum_{\alpha\in\nu_{ij}^{\text{bnd}}}\tilde{\lambda}_\alpha^{ij}. \tag{19}$$

Note that the term g_{ij}^{bnd} collects the contributions to $\tilde{u}_{ij}$ from the boundary vertices that may belong to the internal face $\mathsf{f}_{ij}\in\mathcal{F}_h^{\text{int}}$. Next, we rewrite the orthogonal term in (14) as

$$\boldsymbol{n}_{ij}\cdot\widetilde{\boldsymbol{G}}_{ij}(\mathsf{u}_h)=D_{ij}\frac{u_j-u_i}{H_{ij}}+g_{ij}(\mathsf{u}_h) \tag{20}$$

by introducing the scalar quantity

$$D_{ij}=H_{ij}\min\{p_j^{ij}/h_{ij},\,p_i^{ji}/h_{ji}\} \tag{21}$$

and the remainder term

$$g_{ij}(\mathsf{u}_h)=\sum_{k\in\sigma\nu_{ij}}\left(\frac{p_k^{ij}}{h_{ij}}-\delta_{jk}\frac{D_{ij}}{H_{ij}}\right)(u_k-u_i)+\frac{p^{ij}}{h_{ij}}(g_{ij}^{\text{bnd}}-u_i), \tag{22}$$

with $\delta_{jk}=1$ if $j=k$, $\delta_{jk}=0$ otherwise.

The orthogonal component of $\widetilde{\boldsymbol{G}}_{ji}(\mathsf{u}_h)$ is similarly defined. The corresponding formulae are easily obtained by interchanging i and j in (20)–(22).

Finally, we define the nonlinear weights to be used in (16) by the formula

$$\omega_{ij}(\mathsf{u}_h)=\begin{cases}\frac{|g_{ji}(\mathsf{u}_h)|}{|g_{ij}(\mathsf{u}_h)|+|g_{ji}(\mathsf{u}_h)|} & \text{if } |g_{ij}(\mathsf{u}_h)|+|g_{ji}(\mathsf{u}_h)|>0,\\ 1/2 & \text{otherwise.}\end{cases} \tag{23}$$

Let $s_{ij}(\mathsf{u}_h)$ indicate the sign of $g_{ij}(\mathsf{u}_h)$; i.e., $|g_{ij}(\mathsf{u}_h)| = g_{ij}(\mathsf{u}_h)s_{ij}(\mathsf{u}_h)$. A direct calculation shows that

$$\omega_{ij}(\mathsf{u}_h)g_{ij}(\mathsf{u}_h) - \omega_{ji}(\mathsf{u}_h)g_{ji}(\mathsf{u}_h) = g_{ij}(\mathsf{u}_h)g_{ji}(\mathsf{u}_h)\frac{s_{ji}(\mathsf{u}_h) - s_{ij}(\mathsf{u}_h)}{|g_{ij}(\mathsf{u}_h)| + |g_{ji}(\mathsf{u}_h)|}.$$

Thus, the nonlinear coefficients introduced in (23) satisfy the relation

$$\omega_{ij}(\mathsf{u}_h)g_{ij}(\mathsf{u}_h) - \omega_{ji}(\mathsf{u}_h)g_{ji}(\mathsf{u}_h) = 2\,\omega^0_{ij}(\mathsf{u}_h)g_{ij}(\mathsf{u}_h), \tag{24}$$

where

$$\omega^0_{ij}(\mathsf{u}_h) = \begin{cases} \omega_{ij}(\mathsf{u}_h) & \text{if } g_{ij}(\mathsf{u}_h)g_{ji}(\mathsf{u}_h) < 0, \\ 0 & \text{otherwise.} \end{cases} \tag{25}$$

This remark has a very important consequence: using (24)–(25) we can reformulate the orthogonal component of the nonlinearly weighted face gradient (16) in a one-sided form. To prove this fact, we first substitute into (16) the expression for $\boldsymbol{n}_{ij} \cdot \widetilde{\boldsymbol{G}}_{ij}(\mathsf{u}_h)$ given by (20)–(22) and the similar one for $\boldsymbol{n}_{ji} \cdot \widetilde{\boldsymbol{G}}_{ji}(\mathsf{u}_h)$ obtained by interchanging i and j. Then we consider the nonlinear weights (23) and use the property expressed by (24) together with (25). Finally, we introduce the nonlinear mapping $\boldsymbol{\psi}(\mathsf{u}_h) = \{w^{ij}_k(\mathsf{u}_h)\}$ whose components are

$$w^{ij}_k(\mathsf{u}_h) \;=\; 2\,\omega^0_{ij}(\mathsf{u}_h)\begin{cases} p^{ij}H_{ij}/h_{ij}, & k = i, \\ p^{ij}_j H_{ij}/h_{ij} - D_{ij}, & k = j, \\ p^{ij}_k H_{ij}/h_{ij}, & k \in \sigma\nu_{ij}\backslash\{i,\, j\}, \\ 0 & \text{otherwise.} \end{cases} \tag{26}$$

This straightforward calculation shows that (16) becomes

$$\begin{aligned} \boldsymbol{n}_{ij} \cdot \boldsymbol{G}_{ij}(\mathsf{u}_h) \;&=\; \frac{D_{ij}}{H_{ij}}(u_j - u_i) + 2\,\omega^0_{ij}(\mathsf{u}_h)g_{ij}(\mathsf{u}_h) \\ &=\; \frac{1}{H_{ij}}\Big(D_{ij}(u_j - u_i) + \sum_{k\in\sigma\nu_{ij}} w^{ij}_k(\mathsf{u}_h)(u_k - u_i) + w^{ij}_i(\mathsf{u}_h)(g^{\text{bnd}}_{ij} - u_i)\Big). \end{aligned} \tag{27}$$

Replacing $\boldsymbol{n} \cdot \nabla \mathsf{u}$ by $\boldsymbol{n}_{ij} \cdot \boldsymbol{G}_{ij}(\mathsf{u}_h)$ in the flux integral $\int_{\mathsf{f}_{ij}} \boldsymbol{n} \cdot \nabla \mathsf{u}\, dS / |\mathsf{f}_{ij}|$ and using the final expression of $\boldsymbol{G}_{ij}(\mathsf{u}_h)$ in (27) yield the average value of the numerical diffusive flux on $\mathsf{f}_{ij} \in \mathcal{F}^{\text{int}}_h$. Thus,

$$\mathcal{G}_{ij}(\mathsf{u}_h) = -\nu_{ij}\boldsymbol{G}_{ij}(\mathsf{u}_h) \cdot \boldsymbol{n}_{ij},$$

where $\nu_{ij} = \int_{\mathsf{f}_{ij}} \nu(\boldsymbol{x})\, dS / |\mathsf{f}_{ij}|$ is the average of the viscosity field $\nu(\boldsymbol{x})$ over f_{ij}.

Let us denote by $\mathbf{w}$ the generic instance of $\boldsymbol{\psi}(\mathsf{u}_h)$. The flux balance of the diffusive terms at the internal faces of T_i can be compactly written as

$$\frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma_i} |\mathsf{f}_{ij}|\, \mathcal{G}_{ij}(\mathsf{u}_h) = \big(\mathbf{G}(\mathbf{w})\mathsf{u}_h - \mathbf{g}(\mathbf{w})\big)\Big|_i \tag{28}$$

by taking into account the summation rule

$$\sum_{l\in\sigma_i}\;\sum_{k\in\sigma\nu_{il}} = \sum_{k\in\sigma\nu_i}\;\sum_{l\in\sigma_i\,\cap\,\sigma\nu_k}$$

and introducing the diffusive flux matrix and vector

$$
\begin{aligned}
\mathsf{G}_{ij}(\mathbf{w}) &= \frac{1}{|\mathsf{T}_i|}\begin{cases} \sum_{l\in\sigma_i} \frac{|\mathsf{f}_{il}|\nu_{il}}{H_{il}}(D_{il}+\sum_{k\in\sigma\nu_{il}} w_k^{il}) & \text{for } j=i,\\ -\sum_{l\in\sigma_i\cap\sigma\nu_j} \frac{|\mathsf{f}_{il}|\nu_{il}}{H_{il}}(w_j^{il}+\delta_{lj}D_{il}) & \text{for } j\in\sigma\nu_i\backslash\{i\},\\ 0 & \text{otherwise,}\end{cases} \\
\mathsf{g}_i(\mathbf{w}) &= \frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma_i}\frac{|\mathsf{f}_{ij}|\,\nu_{ij}w_i^{ij}}{H_{ij}}g_{ij}^{\mathrm{bnd}}.
\end{aligned}
\tag{29}
$$

4.3. Treatment of boundary terms. The contribution to the flux balance of the cell T_i from the boundary faces $\mathsf{f}_{ij}\in\mathcal{F}_h^{\mathrm{bnd}}$ takes the vector form

$$
\frac{1}{\mathsf{T}_i}\sum_{j\in\sigma_i'}|\mathsf{f}_{ij}|\,\mathcal{B}_{ij}(\mathsf{u}_h) = \big(\mathbf{B}\mathsf{u}_h-\mathbf{b}-\mathsf{r}^{\mathrm{bnd}}(\mathsf{u}_h)\big)\Big|_i,
$$

where

$$
\begin{aligned}
\mathsf{B}_{ij} &= \frac{1}{|\mathsf{T}_i|}\begin{cases}\sum_{k\in\sigma_i'}|\mathsf{f}_{ij}|\,[v_{ij}^{+}+\frac{\nu_{ik}}{h_{ik}}], & j=i,\\ 0 & \text{otherwise,}\end{cases}\\
\mathsf{b}_i &= \frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma_i'}|\mathsf{f}_{ij}|\left(v_{ij}^{+}g_{ij}^{D}+\nu_{ij}\frac{\widetilde{g}_{ij}^{D}}{h_{ij}}\right),\\
\mathsf{r}_i^{\mathrm{bnd}}(\mathsf{u}_h) &= \frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma_i'}|\mathsf{f}_{ij}|\,v_{ij}^{+}\boldsymbol{G}_i(\mathsf{u}_h)\cdot(\boldsymbol{x}_i-\boldsymbol{x}_{ij}),
\end{aligned}
\tag{30}
$$

and the terms

$$
g_{ij}^{D}=\sum_{\alpha\in\nu_{ij}^{\mathrm{bnd}}}\mathsf{g}(\boldsymbol{x}_\alpha)/d \qquad \text{and} \qquad \widetilde{g}_{ij}^{D}=\sum_{\alpha\in\nu_{ij}^{\mathrm{bnd}}}\tilde{\lambda}_{\alpha}^{ij}\mathsf{g}(\boldsymbol{x}_\alpha)
\tag{31}
$$

are the linear interpolations at the face points $\boldsymbol{x}_{ij}$ and $\tilde{\boldsymbol{x}}_{ij}$, respectively, of the Dirichlet boundary data $\mathsf{g}(\boldsymbol{x}_\alpha)$ for $\mathsf{v}_\alpha\in\mathsf{f}_{ij}\in\mathcal{F}_h^{\mathrm{bnd}}$.

4.4. The finite volume approximation problem: Vector formulation. Let us collect all the numerical flux matrices and vectors in the terms

$$
\boldsymbol{\mathcal{A}}(\mathbf{w}) = \mathbf{F}+\mathbf{G}(\mathbf{w})+\mathbf{B}, \tag{32a}
$$

$$
\boldsymbol{b}(\mathsf{u}_h;\mathbf{w}) = \mathbf{s}+\mathbf{r}(\mathsf{u}_h)+\mathbf{g}(\mathbf{w})+\mathbf{b}. \tag{32b}
$$

The symbol $\mathbf{w}$—already introduced in (28)—will be considered in the rest of the paper as an independent variable to indicate the generic instance of the coefficients $\{w_k^{ij}\}$. The approximation problem in flux balance formulation (7) can be compactly reformulated as

$$
\boldsymbol{\mathcal{A}}(\mathbf{w})\mathsf{u}_h = \boldsymbol{b}(\mathsf{u}_h;\mathbf{w}), \tag{33a}
$$

$$
\mathbf{w} = \boldsymbol{\psi}(\mathsf{u}_h), \tag{33b}
$$

where $\mathsf{u}_h\in\mathtt{T}_h$ is the finite volume approximation of the solution cell averages, and $\mathbf{w}$ the vector collecting the solution-dependent weights for the face gradient definition.

5. Theoretical issues. In this section, we investigate the solvability of the nonlinear finite volume approximation problem (33a)–(33b) and we demonstrate the existence of at least one numerical solution. Furthermore, we prove that all the numerical solutions to (33a)–(33b) (if more than one exist) must satisfy a discrete maximum principle. Finally, we remark that a discrete minimum principle can be proved as well by suitably adapting the same arguments.

5.1. Technical lemmas. The following lemma formalizes the properties of the face gradient coefficients p^{ij} and $\{p^{ij}_k\}$ defined in (19), of D_{ij} defined in (21), and of the components of the nonlinear mapping $\boldsymbol{\psi}(\mathsf{u}_h) = \{w^{ij}_k(\mathsf{u}_h)\}$ in (26) used in the definition of the numerical diffusive flux (27)–(29).

LEMMA 7. *The coefficients p^{ij} and $\{p^{ij}_k,\, k \in \sigma\nu_{ij}\}$ are nonnegative and such that for any $\mathsf{f}_{ij} \in \mathcal{F}^{\rm int}_h$*

(i) $p^{ij} + \sum_{k\in\sigma\nu_{ij}} p^{ij}_k = 1$*;*

(ii) $C_{\rm grid}/(d+1) \le p^{ij}_j$*;*

(iii) $C_{\rm grid}/(d+1) \le D_{ij} \le 1 + C_{\rm reg}$*;*

(iv) $0 \le w^{ij}_k(\mathsf{u}_h) \le 2(1+C_{\rm reg})$ *for any* $\mathsf{u}_h \in \mathtt{T}_h$.

Proof. The nonnegativity of the coefficients p^{ij} and p^{ij}_k for $k \in \sigma\nu_{ij}$ follows from their definition in (19) by noting that both the vertex reconstruction weights $\{\mathrm{w}^{\alpha}_k\}$ (see Theorem 5(i)) and the coefficients $\{\tilde{\lambda}^{ij}_{\alpha}\}$ (see Proposition 2(iii)) are nonnegative real numbers.

Item (i) follows by reversing the summation rule (18) and using Theorem 5(ii) to get

$$\sum_{k\in\sigma\nu_{ij}} p^{ij}_k = \sum_{k\in\sigma\nu_{ij}} \sum_{\alpha\in\nu_k \cap \nu^{\rm int}_{ij}} \tilde{\lambda}^{ij}_{\alpha} \mathrm{w}^{\alpha}_k = \sum_{\alpha\in\nu^{\rm int}_{ij}} \tilde{\lambda}^{ij}_{\alpha} \sum_{k\in\sigma_\alpha} \mathrm{w}^{\alpha}_k = 1 - \sum_{\alpha\in\nu^{\rm bnd}_{ij}} \tilde{\lambda}^{ij}_{\alpha} = 1 - p^{ij}.$$

Item (ii) follows because $p^{ij}_j = \sum_{\alpha\in\nu^{\rm int}_{ij}} \tilde{\lambda}^{ij}_{\alpha} \mathrm{w}^{\alpha}_j$ from (19), $\tilde{\lambda}^{ij}_{\alpha} \ge 1/(d+1)$ from Proposition 2, $\mathrm{w}^{\alpha}_j \ge C_{\rm grid}$ from Theorem 5(i), and $\mathsf{card}\{\nu^{\rm int}_{ij}\} \ge 1$ from Assumption 1(iii).

Item (iii) and the left inequality of item (iv) readily follow by taking into account item (ii) in (21) and (26), respectively.

The right inequality of item (iv) follows by noting that

$$w^{ij}_k(\mathsf{u}_h) \;\le\; 2\,\omega^0_{ij}(\mathsf{u}_h)\frac{p^{ij}_k H_{ij}}{h_{ij}} \;\le\; 2(1+C_{\rm reg}),$$

by recalling that $H_{ij} = h_{ij} + h_{ji}$ (see the definition in section 2), and by applying Proposition 2(i). ▯

After Lemma 7(iv), it is natural to consider the coefficient vectors $\mathbf{w}$ for face gradient calculations that are ranging in the following compact convex set.

DEFINITION 8 (the set of coefficient vectors for face gradients). *Let*

$$\boldsymbol{\mathcal{K}} = \Big\{\mathbf{w} \textit{ such that } 0 \le w^{ij}_k \le 2(1+C_{\rm reg})\Big\}.$$

Similarly, it is possible to restrict the set of admissible solutions u_h of the nonlinear finite volume approximation problem (33a)–(33b). We proceed by demonstrating these two technical lemmas, the result of the first one being useful in proving the second one.

Lemma 9. *There exists a real constant $C_R > 0$, independent of h, and such that $\|\mathbf{r}(\mathsf{u}_h)\|_{\mathcal{T}_h} \leq C_R$.*

Proof. The proof of this lemma uses the same arguments of the proof of Lemma 6.2 in [5]. For this reason and for the sake of completeness, we shortly sketch the proof herein and refer the reader to that paper for a detailed discussion.

Let us first introduce the quantities

$$\Delta u_{ij} = (\boldsymbol{x}_{ij} - \boldsymbol{x}_i) \cdot \boldsymbol{G}_i(\mathsf{u}_h) \quad \text{and} \quad \Delta u_{ji} = (\boldsymbol{x}_{ji} - \boldsymbol{x}_j) \cdot \boldsymbol{G}_j(\mathsf{u}_h).$$

In view of (13), by applying the Cauchy–Schwarz inequality and by rewriting the summations over $\mathsf{f}_{ij} \in \mathcal{F}_h$ we get

$$\begin{aligned} \|\mathbf{r}(\mathsf{u}_h)\|^2_{\mathcal{T}_h} &= \sum_{\mathsf{T}_i \in \mathcal{T}_h} |\mathsf{T}_i| \left(\frac{1}{|\mathsf{T}_i|} \Big[\sum_{j \in \sigma_i} |\mathsf{f}_{ij}| \left(v^+_{ij} \Delta u_{ij} + v^-_{ij} \Delta u_{ji} \right) + \sum_{j \in \sigma'_i} |\mathsf{f}_{ij}| \, v^+_{ij} \Delta u_{ij} \Big] \right)^2 \\ &\leq 2(d+1) \, \|\boldsymbol{v}\|^2_{\mathrm{L}^\infty(\Omega)} \times (\star), \end{aligned}$$

where

$$(\star) = \sum_{\mathsf{f}_{ij} \in \mathcal{F}^{\mathrm{int}}_h} \left(\frac{|\mathsf{f}_{ij}|^2}{|\mathsf{T}_i|} + \frac{|\mathsf{f}_{ij}|^2}{|\mathsf{T}_j|} \right) \left(|\Delta u_{ij}|^2 + |\Delta u_{ji}|^2 \right) + \sum_{\mathsf{f}_{ij} \in \mathcal{F}^{\mathrm{bnd}}_h} \frac{|\mathsf{f}_{ij}|^2}{|\mathsf{T}_i|} \, |\Delta u_{ij}|^2 .$$

Then, taking into account that $|\mathsf{T}_i| = (d+1) h_{ij} \, |\mathsf{f}_{ij}| / d$, multiplying and dividing this expression by H_{ij}, and exploiting the fact that $H_{ij}/h_{ij} = 1 + h_{ji}/h_{ij} \leq 1 + C_{\mathrm{reg}}$ from Proposition 2(i) yield

$$(\star) \leq \frac{d(1 + C_{\mathrm{reg}})}{d+1} \Bigg(\sum_{\mathsf{f}_{ij} \in \mathcal{F}^{\mathrm{int}}_h} |\mathsf{f}_{ij}| \, H_{ij} \frac{|\Delta u_{ij}|^2 + |\Delta u_{ji}|^2}{H^2_{ij}} + \sum_{\mathsf{f}_{ij} \in \mathcal{F}^{\mathrm{bnd}}_h} |\mathsf{f}_{ij}| \, h_{ij} \frac{|\Delta u_{ij}|^2}{h^2_{ij}} \Bigg).$$

By using $|\Delta u_{ij}| \leq h \, |\boldsymbol{G}_i(\mathsf{u}_h)|$, we have

$$\begin{aligned} (\star) &\leq \frac{d(1 + C_{\mathrm{reg}})}{d+1} \Big(\sup_{\mathsf{f}_{ij} \in \mathcal{F}_h} \frac{h}{H_{ij}} \Big)^2 \Big(\sum_{\mathsf{T}_i \in \mathcal{T}_h} |\boldsymbol{G}_i(\mathsf{u}_h)|^2 \sum_{j \in \sigma_i} |\mathsf{f}_{ij}| \, H_{ij} \Big), \\ &\leq \left(2d^2 (1 + C_{\mathrm{reg}})^2 C^2 \right) / (d+1) \sum_{\mathsf{T}_i \in \mathcal{T}_h} |\mathsf{T}_i| \, |\boldsymbol{G}_i(\mathsf{u}_h)|^2 , \end{aligned}$$

where $h/H_{ij} \leq C$ is true from the mesh regularity; see Assumption 1. In view of (10), the lemma follows by setting $C_R = 2d \, \|\boldsymbol{v}\|_{\mathrm{L}^\infty(\Omega)} \, C_{\mathrm{lim}} C (1 + C_{\mathrm{reg}})$. ☐

Lemma 10. *The matrix $\boldsymbol{\mathcal{A}}(\mathbf{w}) = \mathbf{F} + \mathbf{G}(\mathbf{w}) + \mathbf{B}$ introduced in* (32a) *is a nonsingular M-matrix for any vector $\mathbf{w} \geq \mathbf{0}$. Moreover, there exists a nonnegative constant C_M independent of u_h and $\mathbf{w}$ such that*

$$\left\| \boldsymbol{\mathcal{A}}(\mathbf{w})^{-1} \boldsymbol{b}(\mathsf{u}_h; \mathbf{w}) \right\|_{\mathcal{T}_h} \leq C_M \qquad \textit{for any } \mathsf{u}_h \in \mathsf{T}_h \textit{ and } \mathbf{w} \in \boldsymbol{\mathcal{K}},$$

where $\boldsymbol{b}(\mathsf{u}_h; \mathbf{w})$ has been introduced in (32b).

Proof. In this proof, we use the symbol $\| \cdot \|_{\mathcal{T}_h}$ to denote both the vector norm and its induced matrix norm.

If $\mathbf{w} \geq \mathbf{0}$, the matrices $\mathbf{F}$ and $\mathbf{G}(\mathbf{w})$ are irreducible Z-matrices, all of whose rows have sum equal to zero by construction (see (12) and (29)), and the matrix $\mathbf{B}$ is a nonnegative diagonal matrix with some strictly positive diagonal elements (see (30)). Thus, $\boldsymbol{\mathcal{A}}(\mathbf{w})$ is a diagonally dominant Z-matrix.

The ijth entry of $\boldsymbol{\mathcal{A}}(\mathbf{w})$, namely, $\boldsymbol{\mathcal{A}}_{ij}(\mathbf{w})$, is strictly positive if the index pair ij refers to an internal face, i.e., $\mathsf{f}_{ij} \in \mathcal{F}_h^{\text{int}}$, because in such a case $\boldsymbol{\mathcal{A}}_{ij}(\mathbf{w}) \geq C_{\text{grid}}/(d+1)$ from Lemma 7(iii). Hence, the matrix $\boldsymbol{\mathcal{A}}(\mathbf{w})$ is irreducible and, consequently, a nonsingular M-matrix.

To demonstrate the inequality of the lemma, let us consider the inequality

$$\left\|\boldsymbol{\mathcal{A}}(\mathbf{w})^{-1}\boldsymbol{b}(\mathsf{u}_h;\mathbf{w})\right\|_{\mathcal{T}_h} \leq \left\|\boldsymbol{\mathcal{A}}(\mathbf{w})^{-1}\right\|_{\mathcal{T}_h}\left(\|\mathbf{s}+\mathbf{b}\|_{\mathcal{T}_h} + \|\mathbf{r}(\mathsf{u}_h)\|_{\mathcal{T}_h} + \|\mathbf{g}(\mathbf{w})\|_{\mathcal{T}_h}\right).$$

As $\boldsymbol{\mathcal{A}}(\mathbf{w})$ and $\mathbf{g}(\mathbf{w})$ are continuous functions of $\mathbf{w}$, the scalar quantities $\left\|\,\boldsymbol{\mathcal{A}}(\mathbf{w})^{-1}\,\right\|_{\mathcal{T}_h}$ and $\|\mathbf{g}(\mathbf{w})\|_{\mathcal{T}_h}$ are also continuous functions of this argument. Since $\mathbf{w}$ ranges over the compact set $\boldsymbol{\mathcal{K}}$, $\left\|\,\boldsymbol{\mathcal{A}}(\mathbf{w})^{-1}\,\right\|_{\mathcal{T}_h}$ and $\|\mathbf{g}(\mathbf{w})\|_{\mathcal{T}_h}$ must be uniformly bounded in view of the Weierstrass theorem. Thus,

$$\left\|\boldsymbol{\mathcal{A}}(\mathbf{w})^{-1}\boldsymbol{b}(\mathsf{u}_h;\mathbf{w})\right\|_{\mathcal{T}_h} \leq \sup_{\mathbf{w}\in\boldsymbol{\mathcal{K}}}\left\|\boldsymbol{\mathcal{A}}(\mathbf{w})^{-1}\right\|_{\mathcal{T}_h}\left(\|\mathbf{s}+\mathbf{b}\|_{\mathcal{T}_h}+C_R+\sup_{\mathbf{w}\in\boldsymbol{\mathcal{K}}}\|\mathbf{g}(\mathbf{w})\|_{\mathcal{T}_h}\right), \tag{34}$$

where we also used Lemma 9 and where C_R is the constant introduced therein. The inequality of the lemma follows by setting C_M equal to the right-hand side of (34). □

After Lemma 10, we can introduce the set $\boldsymbol{\mathcal{M}} \in \mathbb{R}^{\mathsf{card}\{\mathtt{T}_h\}}$ of the admissible finite volume solutions.

Definition 11 (the set of admissible finite volume solutions). *Let*

$$\boldsymbol{\mathcal{M}} = \Big\{\mathsf{u}_h \in \mathtt{T}_h \text{ such that } \|\mathsf{u}_h\|_{\mathcal{T}_h} \leq C_M\Big\},$$

where C_M is the constant of Lemma 10.

5.2. Existence of the finite volume approximation. The finite volume approximation problem whose vector formulation has been derived in section 4.4 can be formally restated by taking into consideration Definitions 8 and 11.

Definition 12 (the finite volume approximation problem).

$$\textit{Find } \mathsf{u}_h \in \boldsymbol{\mathcal{M}} \textit{ and } \mathbf{w} \in \boldsymbol{\mathcal{K}} \textit{ satisfying } \text{(33a)–(33b)}. \tag{35}$$

This problem can also be reformulated in the fixed-point form

$$\textit{find } (\mathsf{u}_h,\,\mathbf{w}) \in \boldsymbol{\mathcal{M}}\times\boldsymbol{\mathcal{K}} \textit{ such that } \begin{bmatrix} \mathsf{u}_h \\ \mathbf{w} \end{bmatrix} = \mathfrak{F}\begin{bmatrix} \mathsf{u}_h \\ \mathbf{w} \end{bmatrix}, \tag{36}$$

where the nonlinear mapping $\mathfrak{F} : \boldsymbol{\mathcal{M}}\times\boldsymbol{\mathcal{K}} \to \boldsymbol{\mathcal{M}}\times\boldsymbol{\mathcal{K}}$ is given by

$$\mathfrak{F}\begin{bmatrix} \mathsf{u}_h \\ \mathbf{w} \end{bmatrix} = \begin{bmatrix} \boldsymbol{\Phi}(\mathsf{u}_h;\mathbf{w}) \\ \boldsymbol{\psi}(\mathsf{u}_h) \end{bmatrix},$$

and

$$\boldsymbol{\Phi}(\mathsf{u}_h;\mathbf{w}) = \boldsymbol{\mathcal{A}}(\mathbf{w})^{-1}\boldsymbol{b}(\mathsf{u}_h;\mathbf{w}).$$

Unfortunately, $\mathfrak{F}(\mathsf{u}_h,\,\mathbf{w})$ is not guaranteed to be a continuous function of its arguments because the mapping $\boldsymbol{\psi}(\mathsf{u}_h) = \{w_k^{ij}(\mathsf{u}_h)\}$ may be discontinuous at some internal face

$\mathsf{f}_{ij} \in \mathcal{F}_h^{\text{int}}$. For this reason, Brouwer's fixed-point theorem cannot be directly applied to demonstrate the existence of a solution to (36) and hence to (35).

We thus proceed in a different way. First, we define a special "regularization" mapping $\boldsymbol{\psi}^{\varepsilon}(\cdot)$ that is continuous in its argument and depends on the positive parameter ε. Replacing $\boldsymbol{\psi}(\mathsf{u}_h) = \{w_k^{ij}(\mathsf{u}_h)\}$ by $\boldsymbol{\psi}^{\varepsilon}(\mathsf{u}_h^{\varepsilon}) = \{w_k^{\varepsilon ij}(\mathsf{u}_h^{\varepsilon})\}$ in (27) regularizes both the face gradient formula and the numerical diffusive flux. Brouwer's fixed-point theorem is applicable to the regularized approximation problems that are defined for any $\varepsilon \geq 0$. Then we take the limit of $\varepsilon \to 0$, and a compactness argument proves that a converging subsequence can be extracted from the solutions of these regularized problems. Finally, we demonstrate that the limit of this subsequence of regularized solutions solves the finite volume approximation problem stated in (35).

Let us introduce, for any control volume T_i and any face $\mathsf{f}_{ij} \in \mathcal{F}_h$, $j \in \sigma_i \cup \sigma_i'$, the regularized continuous weights

$$\omega_{ij}^{\varepsilon}(\mathsf{u}_h) = \frac{|g_{ij}(\mathsf{u}_h)|}{|g_{ij}(\mathsf{u}_h)| + \varepsilon} \, \frac{|g_{ji}(\mathsf{u}_h)|}{|g_{ji}(\mathsf{u}_h)| + \varepsilon} \, \omega_{ij}^{0}(\mathsf{u}_h). \tag{37}$$

These weights are designed to satisfy the following important property.

LEMMA 13. *If* $\mathsf{u}_h^{\varepsilon} \to \mathsf{u}_h$ *for* $\varepsilon \to 0$*, then at each internal face* $\mathsf{f}_{ij} \in \mathcal{F}_h^{\text{int}}$ *we have*

$$\lim_{\varepsilon \to 0} \omega_{ij}^{\varepsilon}(\mathsf{u}_h^{\varepsilon}) g_{ij}(\mathsf{u}_h^{\varepsilon}) = \omega_{ij}^{0}(\mathsf{u}_h) g_{ij}(\mathsf{u}_h).$$

Proof. As $g_{ij}(\cdot)$ and $g_{ji}(\cdot)$ are continuous functions of their argument, $\mathsf{u}_h^{\varepsilon} \to \mathsf{u}_h$ for $\varepsilon \to 0$ implies $g_{ij}(\mathsf{u}_h^{\varepsilon}) \to g_{ij}(\mathsf{u}_h)$ and $g_{ji}(\mathsf{u}_h^{\varepsilon}) \to g_{ji}(\mathsf{u}_h)$. Furthermore, when $g_{ij}(\mathsf{u}_h) g_{ji}(\mathsf{u}_h) \neq 0$ a real number $\varepsilon' > 0$ must exist such that the signs of $g_{ij}(\mathsf{u}_h^{\varepsilon}) g_{ji}(\mathsf{u}_h^{\varepsilon})$ and $g_{ij}(\mathsf{u}_h) g_{ji}(\mathsf{u}_h)$ coincide for any $\varepsilon \leq \varepsilon'$. Let us distinguish among the following three cases.

(i) $g_{ij}(\mathsf{u}_h) g_{ji}(\mathsf{u}_h) < 0$.

Then $g_{ij}(\mathsf{u}_h^{\varepsilon}) g_{ji}(\mathsf{u}_h^{\varepsilon})$ is also negative for any $\varepsilon \leq \varepsilon'$, and from the definitions in (26) and (23)–(25) it follows that

$$\begin{aligned} \lim_{\varepsilon \to 0} \omega_{ij}^{\varepsilon}(\mathsf{u}_h^{\varepsilon}) g_{ij}(\mathsf{u}_h^{\varepsilon}) &= \lim_{\varepsilon \to 0} \frac{|g_{ji}(\mathsf{u}_h^{\varepsilon})|}{|g_{ij}(\mathsf{u}_h^{\varepsilon})| + \varepsilon} \, \frac{|g_{ji}(\mathsf{u}_h^{\varepsilon})|}{|g_{ji}(\mathsf{u}_h^{\varepsilon})| + \varepsilon} \, \frac{|g_{ji}(\mathsf{u}_h^{\varepsilon})|}{|g_{ij}(\mathsf{u}_h^{\varepsilon})| + |g_{ji}(\mathsf{u}_h^{\varepsilon})|} g_{ij}(\mathsf{u}_h^{\varepsilon}) \\ &= \frac{|g_{ji}(\mathsf{u}_h)|}{|g_{ij}(\mathsf{u}_h)| + |g_{ji}(\mathsf{u}_h)|} g_{ij}(\mathsf{u}_h) = \omega_{ij}^{0}(\mathsf{u}_h) g_{ij}(\mathsf{u}_h) \end{aligned}$$

due to the continuity of $g_{ij}(\cdot)$, $g_{ji}(\cdot)$ and because $\mathsf{u}_h^{\varepsilon} \to \mathsf{u}_h$.

(ii) $g_{ij}(\mathsf{u}_h) g_{ji}(\mathsf{u}_h) = 0$.

Definitions (23)–(25) yield $\omega_{ij}^{0}(\mathsf{u}_h) = 0$. As $g_{ij}(\cdot)$ and $g_{ji}(\cdot)$ are continuous functions, at least one of them approaches zero as $\mathsf{u}_h^{\varepsilon} \to \mathsf{u}_h$ for $\varepsilon \to 0$. The statement of the lemma follows by noting that whenever $g_{ij}(\mathsf{u}_h^{\varepsilon}) \neq 0$ we have

$$\left| \omega_{ij}^{\varepsilon}(\mathsf{u}_h^{\varepsilon}) g_{ij}(\mathsf{u}_h^{\varepsilon}) \right| \leq \left| \omega_{ij}^{0}(\mathsf{u}_h^{\varepsilon}) g_{ij}(\mathsf{u}_h^{\varepsilon}) \right| \leq \frac{|g_{ji}(\mathsf{u}_h^{\varepsilon})| \, |g_{ij}(\mathsf{u}_h^{\varepsilon})|}{|g_{ij}(\mathsf{u}_h^{\varepsilon})| + |g_{ji}(\mathsf{u}_h^{\varepsilon})|},$$

and taking the limit for $\varepsilon \to 0$.

(iii) $g_{ij}(\mathsf{u}_h) g_{ji}(\mathsf{u}_h) > 0$.

The statement of the lemma is trivially true because from definitions (23)–(25) and (37) it follows that $\omega_{ij}^{0}(\mathsf{u}_h) = 0$ and $\omega_{ij}^{\varepsilon}(\mathsf{u}_h^{\varepsilon}) = 0$ for $\varepsilon \leq \varepsilon'$. □

Let $\boldsymbol{\psi}^{\varepsilon}(\mathsf{u}_h)$ be the *regularized mapping* obtained by using $\omega_{ij}^{\varepsilon}(\mathsf{u}_h)$ in place of $\omega_{ij}(\mathsf{u}_h)$ in (26).

Theorem 14. *The regularized problem*

$$\begin{aligned}&\textit{find } \mathsf{u}_h^\varepsilon \in \boldsymbol{\mathcal{M}} \textit{ and } \mathbf{w}^\varepsilon \in \boldsymbol{\mathcal{K}} \textit{ such that}\\ &\boldsymbol{\mathcal{A}}(\mathbf{w}^\varepsilon)\mathsf{u}_h^\varepsilon = \boldsymbol{b}(\mathsf{u}_h^\varepsilon;\mathbf{w}^\varepsilon),\\ &\mathbf{w}^\varepsilon = \boldsymbol{\psi}^\varepsilon(\mathsf{u}_h^\varepsilon)\end{aligned} \tag{38}$$

admits at least one solution for any $\varepsilon > 0$.

Proof. Let us consider the mapping $\mathfrak{F}^\varepsilon : \boldsymbol{\mathcal{M}} \times \boldsymbol{\mathcal{K}} \to \boldsymbol{\mathcal{M}} \times \boldsymbol{\mathcal{K}}$ defined by

$$\mathfrak{F}^\varepsilon \begin{bmatrix} \mathsf{u}_h^\varepsilon \\ \mathbf{w}^\varepsilon \end{bmatrix} = \begin{bmatrix} \boldsymbol{\Phi}(\mathsf{u}_h^\varepsilon;\mathbf{w}^\varepsilon) \\ \boldsymbol{\psi}^\varepsilon(\mathsf{u}_h^\varepsilon) \end{bmatrix}.$$

Problem (38) can be reformulated as the fixed-point problem

$$\textit{find } (\mathsf{u}_h^\varepsilon,\, \mathbf{w}^\varepsilon) \in \boldsymbol{\mathcal{M}} \times \boldsymbol{\mathcal{K}} \textit{ such that } \begin{bmatrix} \mathsf{u}_h^\varepsilon \\ \mathbf{w}^\varepsilon \end{bmatrix} = \mathfrak{F}^\varepsilon \begin{bmatrix} \mathsf{u}_h^\varepsilon \\ \mathbf{w}^\varepsilon \end{bmatrix}.$$

As $\mathfrak{F}^\varepsilon$ is a continuous mapping from the compact convex set $\boldsymbol{\mathcal{M}} \times \boldsymbol{\mathcal{K}}$ into itself, this fixed-point problem admits at least one solution in view of Brouwer's fixed-point theorem. □

Theorem 15. *The finite volume approximation problem* (35) *admits at least one solution.*

Proof. Let us consider the set of regularized solutions of (38) for $\varepsilon > 0$. This set is a subset of the compact set $\boldsymbol{\mathcal{M}} \times \boldsymbol{\mathcal{K}}$, and thus a subsequence exists that converges to a limit solution $(\mathsf{u}_h,\, \mathbf{w}) \in \boldsymbol{\mathcal{M}} \times \boldsymbol{\mathcal{K}}$. Thus,

$$\begin{bmatrix} \mathsf{u}_h^{\varepsilon_k} \\ \mathbf{w}^{\varepsilon_k} \end{bmatrix} \to \begin{bmatrix} \mathsf{u}_h \\ \mathbf{w} \end{bmatrix} \in \boldsymbol{\mathcal{M}} \times \boldsymbol{\mathcal{K}} \quad \text{for } k \to \infty, \tag{39}$$

where $\{\varepsilon_k\}$ is a suitable sequence of nonnegative "epsilons" converging to zero for $k \to \infty$.

The crucial fact to be proved is that the limit solution $(\mathsf{u}_h,\, \mathbf{w})$ in (39) actually solves (35). To achieve this task, we show that $\|\boldsymbol{\mathcal{A}}(\mathbf{w})\mathsf{u}_h - \boldsymbol{b}(\mathsf{u}_h;\mathbf{w})\|_{\mathcal{T}_h}$ is an infinitesimal quantity. First, we subtract the quantity $\boldsymbol{\mathcal{A}}(\mathbf{w}^{\varepsilon_k})\mathsf{u}_h^{\varepsilon_k} - \boldsymbol{b}(\mathsf{u}_h^{\varepsilon_k};\mathbf{w}^{\varepsilon_k}) = 0$ for $\varepsilon_k > 0$ to $\boldsymbol{\mathcal{A}}(\mathbf{w})\mathsf{u}_h - \boldsymbol{b}(\mathsf{u}_h;\mathbf{w})$, rearrange the terms, take the $\|\cdot\|_{\mathcal{T}_h}$-norm, and apply the triangle inequality to get

$$\begin{aligned}\|\boldsymbol{\mathcal{A}}(\mathbf{w})\mathsf{u}_h - \boldsymbol{b}(\mathsf{u}_h;\mathbf{w})\|_{\mathcal{T}_h} &\le \|\mathbf{F}(\mathsf{u}_h - \mathsf{u}_h^{\varepsilon_k})\|_{\mathcal{T}_h}\\ &+ \|\mathbf{G}(\boldsymbol{\psi}(\mathsf{u}_h))\mathsf{u}_h + \mathbf{g}(\boldsymbol{\psi}(\mathsf{u}_h)) - \mathbf{G}(\boldsymbol{\psi}^{\varepsilon_k}(\mathsf{u}_h^{\varepsilon_k}))\mathsf{u}_h^{\varepsilon_k} - \mathbf{g}(\boldsymbol{\psi}^{\varepsilon_k}(\mathsf{u}_h^{\varepsilon_k}))\|_{\mathcal{T}_h}\\ &+ \|\mathbf{B}(\mathsf{u}_h - \mathsf{u}_h^{\varepsilon_k})\|_{\mathcal{T}_h} + \|\mathbf{r}(\mathsf{u}_h) - \mathbf{r}(\mathsf{u}_h^{\varepsilon})\|_{\mathcal{T}_h}.\end{aligned}$$

Then we note that all of the terms in this inequality except the second one can be readily shown to be infinitesimal for $k \to \infty$ by a simple continuity argument. Instead, the second term has to be more carefully treated due to its nonlinear dependence on u_h and $\mathsf{u}_h^{\varepsilon_k}$ throughout the mappings $\boldsymbol{\psi}(\cdot)$ and $\boldsymbol{\psi}^{\varepsilon_k}(\cdot)$, respectively. Let us observe that this second term describes the difference between the numerical diffusive flux at any internal face calculated using the regularized solution $\mathsf{u}_h^{\varepsilon_k}$ and the one using the limit solution u_h. The ith component satisfies the inequality

$$\begin{aligned}
&\left| \mathbf{G}(\boldsymbol{\psi}(\mathsf{u}_h))\mathsf{u}_h\Big|_i - \mathbf{G}(\boldsymbol{\psi}^{\varepsilon_k}(\mathsf{u}_h^{\varepsilon_k}))\mathsf{u}_h^{\varepsilon_k}\Big|_i + \mathsf{g}_i(\boldsymbol{\psi}(\mathsf{u}_h)) - \mathsf{g}_i(\boldsymbol{\psi}^{\varepsilon_k}(\mathsf{u}_h^{\varepsilon_k})) \right| \\
&\qquad \leq \frac{1}{|\mathsf{T}_i|} \sum_{j\in\sigma_i} |\mathsf{f}_{ij}|\, \nu_{ij} D_{ij} \left| \frac{\tilde{u}_j^{\varepsilon_k} - u_i^{\varepsilon_k}}{H_{ij}} - \frac{\tilde{u}_j - u_i}{H_{ij}} \right| \\
&\qquad + 2\frac{1}{|\mathsf{T}_i|} \sum_{j\in\sigma_i} |\mathsf{f}_{ij}|\, \nu_{ij} \left| w_{ij}(\mathsf{u}_h) g_{ij}(\mathsf{u}_h) - w_{ij}^{\varepsilon_k}(\mathsf{u}_h^{\varepsilon_k}) g_{ij}(\mathsf{u}_h^{\varepsilon_k}) \right|.
\end{aligned}$$

The right-hand side of this inequality approaches zero when $k \to \infty$ because $u_i^{\varepsilon_k} \to u_i$, $\tilde{u}_{ij}^{\varepsilon_k} \to \tilde{u}_{ij}$ due to the continuity of the reconstruction process, and

$$\left| w_{ij}(\mathsf{u}_h) g_{ij}(\mathsf{u}_h) - w_{ij}^{\varepsilon_k}(\mathsf{u}_h^{\varepsilon_k}) g_{ij}(\mathsf{u}_h^{\varepsilon_k}) \right| \to 0$$

thanks to Lemma 13. □

5.3. The maximum principle for the finite volume approximation. In this section, we demonstrate the existence of a maximum principle for the solution of the finite volume approximation problem formulated in (35).

To achieve this task, we proceed as follows. We restrict the finite volume approximation problem (35) to $\boldsymbol{\mathcal{M}}$ by taking a constant weight vector $\mathbf{w} \in \boldsymbol{\mathcal{K}}$ in (33a), thus relaxing the dependence on the solution u_h through (33b). This restricted problem will be shown to admit at least one discrete solution in Theorem 16, and all of its solutions will be proved to satisfy a discrete maximum principle in Theorem 17. Finally, the solution of (35) will be shown to satisfy a discrete maximum principle as a consequence of Theorem 17 in Corollary 18.

THEOREM 16. *The nonlinear fixed-point problem that involves the mapping* $\boldsymbol{\Phi}(\cdot, \mathbf{w})$ *restricted to a constant* $\mathbf{w} \in \boldsymbol{\mathcal{K}}$,

$$\textit{find } \mathsf{u}_h \in \boldsymbol{\mathcal{M}} \textit{ such that } \mathsf{u}_h = \boldsymbol{\Phi}(\mathsf{u}_h; \mathbf{w}),$$

admits at least one solution.

Proof. The restriction $\boldsymbol{\Phi}(\cdot; \mathbf{w})$ to $\boldsymbol{\mathcal{M}}$ provided by any specific choice of the weight vector $\mathbf{w} \in \boldsymbol{\mathcal{K}}$ is a continuous mapping from the convex compact set $\boldsymbol{\mathcal{M}}$ into itself. The statement of the theorem follows by the application of Brouwer's fixed-point theorem. □

The following theorem states that the solution of this restricted problem satisfies a discrete maximum principle. The proof extends to unstructured finite volumes some standard arguments used for proving similar results for finite differences. Nonetheless, we report this proof in some detail to illustrate the role played by the positivity of the factors D_{ij} and the nonnegativity of the weights $\{w_k^{ij}(\mathsf{u}_h)\}$ in the definition of the face gradient.

THEOREM 17 (maximum principle for the solution of the nonlinear restricted problem). *Let us consider problem* (33a)–(33b) *with definitions* (32a)–(32b)*. Let* $\mathbf{s} \leq 0$ *in* (32b)*, and assume that* $\mathbf{w} \geq \mathbf{0}$ *be taken constant and that* $\mathsf{u}_h \in \boldsymbol{\mathcal{M}}$ *satisfies*

$$\boldsymbol{\mathcal{A}}(\mathbf{w})\mathsf{u}_h - \boldsymbol{b}(\mathsf{u}_h; \mathbf{w}) \leq \mathbf{0}. \tag{40}$$

Then u_h *satisfies the* discrete maximum principle *expressed in the inequality form*

$$\max_{\mathsf{T}_k\in\mathcal{T}_h} u_k \leq \max\Big[0, \max_{\mathsf{v}_\alpha\in\mathcal{V}_h^{\mathrm{bnd}}} \mathsf{g}(\boldsymbol{x}_\alpha)\Big].$$

Proof. Let us assume that there is a cell T_i such that

$$u_i = \max_{\mathsf{T}_k \in \mathcal{T}_h} u_k > \max\Big[0, \max_{\mathsf{v}_\alpha \in \mathcal{V}_h^{\mathrm{bnd}}} \mathsf{g}(\boldsymbol{x}_\alpha)\Big]. \tag{41}$$

We will demonstrate that this assumption contradicts the hypothesis of the theorem.

By rearranging (7) in order to collect the contribution from both internal and boundary faces, and using the definitions introduced in section 4, we reformulate the numerical flux balance for the cell T_i as the sum of the advective terms, labeled $\{\text{Adv. Terms}\}$, and the diffusive terms, labeled $\{\text{Diff. Terms}\}$:

$$\begin{aligned}\{\text{Adv. Terms}\} = {}& \frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma_i} |\mathsf{f}_{ij}| \Big[v_{ij}^{+}\mathcal{R}_i(\mathsf{u}_h)(\boldsymbol{x}_{ij}) + v_{ij}^{-}\mathcal{R}_j(\mathsf{u}_h)(\boldsymbol{x}_{ij}) \Big] \\ &+ \frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma_i'} |\mathsf{f}_{ij}| \Big[v_{ij}^{+}\mathcal{R}_i(\mathsf{u}_h)(\boldsymbol{x}_{ij}) + v_{ij}^{-} g_{ij}^{D} \Big]\end{aligned}$$

and

$$\begin{aligned}\{\text{Diff. Terms}\} = {}& \frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma_i} \frac{|\mathsf{f}_{ij}|\,\nu_{ij} D_{ij}}{H_{ij}}(u_i - u_j) \\ &+ \frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma_i} \frac{|\mathsf{f}_{ij}|\,\nu_{ij}}{H_{ij}} \Bigg(\sum_{k\in\sigma\nu_j} w_k^{ij}(u_i-u_k) + w_i^{ij}(u_i - g_{ij}^{\mathrm{bnd}}) \Bigg) \\ &+ \frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma_i'} |\mathsf{f}_{ij}|\,\nu_{ij} \frac{u_i - \widetilde{g}_{ij}^{D}}{h_{ij}}.\end{aligned}$$

Both $\{\text{Adv. Terms}\}$ and $\{\text{Diff. Terms}\}$ are nonnegative quantities. Since from Lemma 6 $\mathcal{R}_i(\mathsf{u}_h)(\boldsymbol{x}) = u_i$ for $\boldsymbol{x} \in \mathsf{T}_i$, we can rewrite $\{\text{Adv. Terms}\}$ as

$$\begin{aligned}\{\text{Adv. Terms}\} = {}& \frac{u_i}{|\mathsf{T}_i|}\sum_{j\in\sigma_i\,\cup\,\sigma_i'} |\mathsf{f}_{ij}|\, v_{ij} + \frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma_i} |\mathsf{f}_{ij}|\, v_{ij}^{-}\big(\mathcal{R}_j(\mathsf{u}_h)(\boldsymbol{x}_{ij}) - u_i\big) \\ &+ \frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma_i'} |\mathsf{f}_{ij}|\, v_{ij}^{-}(g_{ij}^{D} - u_i),\end{aligned} \tag{42}$$

and note that the three terms on the right-hand side of (42) are nonnegative. The first term in the sum can be transformed as

$$\sum_{j\in\sigma_i\,\cup\,\sigma_i'} |\mathsf{f}_{ij}|\, v_{ij} = \sum_{j\in\sigma_i\,\cup\,\sigma_i'} \int_{\mathsf{f}_{ij}} \boldsymbol{n}_{ij}\cdot\boldsymbol{v}\, dS = \int_{\partial\mathsf{T}_i} \boldsymbol{n}\cdot\boldsymbol{v}\, dS = \int_{\mathsf{T}_i} \mathrm{div}\boldsymbol{v}\, dV \geq 0,$$

and is nonnegative because $\mathrm{div}\,\boldsymbol{v} \geq 0$ by the initial assumption (2)(ii) and $u_i > 0$ from the proof assumption in (41). The second term in the sum is nonnegative because $v_{ij}^{-} \leq 0$ by definition and $\mathcal{R}_j(\mathsf{u}_h)(\boldsymbol{x}_{ij}) \leq u_i$ in view of the limiter constraints (9). The third term in the sum is nonnegative because $v_{ij}^{-} \leq 0$ as before, and $g_{ij}^{D} < u_i$ by (31) and the assumption stated in (41).

Similarly, the entries in the sum comprising $\{\text{Diff. Terms}\}$ are all nonnegative quantities. Indeed, they contain scalar coefficients that are nonnegative by construction, such as ν_{ij}, H_{ij}, D_{ij}, and $\{w_k^{ij}\}$, which multiply difference terms like $(u_i - u_k)$

for $k \in \sigma\nu_i$ or $(u_i - g^{\rm bnd}_{ij})$ and $(u_i - \widetilde{g}^D_{ij})$ for $j \in \sigma_i \cap \sigma'_i$. All of these difference terms are nonnegative as a consequence of the assumption stated in (41).

Since $\{\textsc{Adv. Terms}\} + \{\textsc{Diff. Terms}\} - \mathsf{s}_i = (\boldsymbol{\mathcal{A}}(\mathbf{w})\mathsf{u}_h - \boldsymbol{b}(\mathsf{u}_h;\mathbf{w}))\big|_i \leq 0$, it follows that

$$\begin{aligned} \mathsf{s}_i &\geq \{\textsc{Adv. Terms}\} + \{\textsc{Diff. Terms}\} \\ &\geq \frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma_i} |\mathsf{f}_{ij}|\,\nu_{ij}D_{ij}\frac{u_i-u_j}{H_{ij}} + \frac{1}{|\mathsf{T}_i|}\sum_{j\in\sigma'_i} |\mathsf{f}_{ij}|\,\nu_{ij}\frac{u_i-\widetilde{g}^D_{ij}}{h_{ij}} \geq 0, \end{aligned} \tag{43}$$

where the second inequality is obtained by canceling $\{\textsc{Adv. Terms}\} \geq 0$ and some other nonnegative terms in $\{\textsc{Diff. Terms}\}$. As $\mathbf{s} \leq \mathbf{0}$ by the hypothesis of the theorem, relation (43) implies that $u_j = u_i$ for *any* $j \in \sigma_i$ because the coefficients D_{ij} of the scheme are *all strictly positive* and $\widetilde{g}^D_{ij} = u_i$ for any $j \in \sigma'_i$. By repeating this argument on the control volumes adjacent to the cell T_i and exploiting also the connectivity of the mesh and the fact that $D_{ij} > 0$ for any $\mathsf{f}_{ij} \in \mathcal{F}^{\rm int}_h$, we eventually obtain that u_h must be constant over all the mesh cells and equal to the boundary data $\widetilde{g}^D_{ij}$.

We emphasize that any solution u_h consistent with the hypothesis (40) of the theorem and the assumption (41) must satisfy the condition proved above. Nonetheless, this result then contradicts (41) because $\widetilde{g}^D_{ij}$ is the convex linear combination of the vertex boundary values $\mathsf{g}(\boldsymbol{x}_\alpha)$ for $\mathsf{v}_\alpha \in \mathcal{V}^{\rm bnd}_h$ (see (31)), and this should imply $u_i \leq \max_{\mathsf{v}_\alpha\in\mathcal{V}^{\rm bnd}_h} \mathsf{g}(\boldsymbol{x}_\alpha)$. ∎

Corollary 18. *Let* $\mathbf{s}(\boldsymbol{x}) \leq 0$*, and let* $(\mathsf{u}_h, \mathbf{w}) \in \boldsymbol{\mathcal{M}} \times \boldsymbol{\mathcal{K}}$ *be a solution to the finite volume approximation problem* (35)*. Then* u_h *satisfies the maximum principle in the same discrete form as in Theorem* 17*; that is,*

$$\max_{\mathsf{T}_k\in\mathcal{T}_h} u_k \leq \max\left\{0,\ \max_{\mathsf{v}_\alpha\in\mathcal{V}^{\rm bnd}_h} \mathsf{g}(\boldsymbol{x}_\alpha)\right\}.$$

Proof. In view of the corollary's hypothesis, $\mathsf{u}_h \in \boldsymbol{\mathcal{M}}$ satisfies the fixed-point relation $\mathsf{u}_h = \boldsymbol{\Phi}(\mathsf{u}_h;\mathbf{w})$ with $\mathbf{w} = \boldsymbol{\psi}(\mathsf{u}_h) \in \boldsymbol{\mathcal{K}}$. Thus, u_h solves the restricted problem defined by taking these weights $\mathbf{w}$ constant, and the statement of the corollary is a straightforward consequence of Theorem 17. ∎

Remark 19. A minimum principle can be proved when $\mathbf{s}(\boldsymbol{x}) \geq 0$ and can be expressed in the form

$$\min_{\mathsf{T}_k\in\mathcal{T}_h} u_k \geq \min\left\{0,\ \min_{\mathsf{v}_\alpha\in\mathcal{V}^{\rm bnd}_h} \mathsf{g}(\boldsymbol{x}_\alpha)\right\}.$$

The proof essentially repeats the same arguments as in the proofs of Theorem 17 and Corollary 18, but the symbols max, min and "$\geq$", "$\leq$" must be consistently interchanged.

6. Numerical experiments. In this section we present the performance of the method on two different test cases that are taken from the recent literature. Both test cases require the resolution of an advection-diffusion problem that is strongly dominated by the convection term.

The first test case is taken from section 7.2 of [8]. A thorough comparison of the behavior of the diamond scheme of [5] and the nonlinear diamond scheme of this paper is carried out. In particular, we focus on the violation of the discrete maximum principle and the additional computational cost for solving the nonlinear diamond scheme. Our investigation reveals that the second-order accurate solution provided by the nonlinear diamond scheme exhibits a violation of the discrete maximum principle by an error less than 10^{-12} against about 10^{-6}–10^{-5} of the diamond scheme. The additional cost for ensuring the satisfaction of the discrete maximum principle is about 10–15% of the cost for solving the same problem by using the diamond scheme.

The second test case is taken from Examples 5.1 and 5.2 of [27] to investigate the order of accuracy of the nonlinear diamond scheme when numerically approximating strong gradient solutions. The strength of the gradients of the solution is controlled by varying the ratio between the viscosity coefficient and the absolute value of the velocity field; note that this ratio is proportional to the Péclet number [27]. As theoretically expected, second order of convergence is observed over a wide range of this parameter. However, deterioration may occur for the most difficult case, and second-order convergence is then lost. This behavior is similar to the behavior of the scheme presented in [27].

Both the diamond scheme and the nonlinear diamond scheme require the resolution of a nonlinear algebraic problem. To achieve this task, we consider the quasi-Newton iterative scheme GIANT described in [12]. This scheme is very efficient in solving general nonlinear problems and seems to be particularly suitable in linearizing the Jacobian matrix of the nonlinear functional (36). The nonlinear iterations are stopped when the residual is smaller than 10^{-10}; this threshold value is the same one that ensures the violation of the maximum principle of the order 10^{-12} in the test case of section 6.1. The linear algebraic problems arising from the Jacobian linearization at the quasi-Newton iterative steps are solved by applying the Bi-CGSTAB algorithm [30] preconditioned by an incomplete LU (ILU) factorization [16]. The mesh data structures are managed by P2MESH [4], which is a C^{++} public domain library designed for fast and efficient implementation of partial differential equation solvers.

6.1. Test case 1. We investigate a pure convection-diffusion problem with dominant convection. The problem is posed on the computational domain $\Omega = [0,\, 1]\times[0,\, 1]$ by using the constant velocity field $\boldsymbol{v} = -(\cos\theta, \sin\theta)$ with $\theta = 55°$, and the scalar viscosity coefficient $\nu = 10^{-5}$.

Dirichlet boundary conditions are set as follows: $\mathsf{u} = 0$ on the bottom edge; $\mathsf{u} = 1$ on the left and top edges; u steps from 0 to 1 at $y = 4/5$ on the right edge. The solution exhibits an internal layer across the domain and a boundary layer along a part of the bottom edge. As the discrete maximum principle is theoretically demonstrated by assuming that the mesh is weakly acute, we consider, as in [8], the mesh obtained by splitting into two triangles the square cells of a tensor product uniform mesh with 40 partitions per side of the computational domain. For this mesh, we solve the advection-diffusion problem by using the diamond scheme and the nonlinear diamond scheme. The two solutions are shown in Figure 3, where constant level curves are depicted for discrete values from 0.01 to 0.99. A comparison of the two pictures in Figure 3 shows that no additional smearing of the internal layer takes place in the solution approximated by the nonlinear diamond scheme. The width of the internal layer is approximately the same for both schemes because the satisfaction of the discrete maximum principle is not based on the addition of some form of artificial or cross-wind diffusion to the standard second-order version of the diamond scheme.

Similar results (not shown) were also obtained by repeating these calculations on a truly unstructured mesh with a comparable number of triangles and all angles smaller than 90°. The performance of the two schemes for the two different kinds of

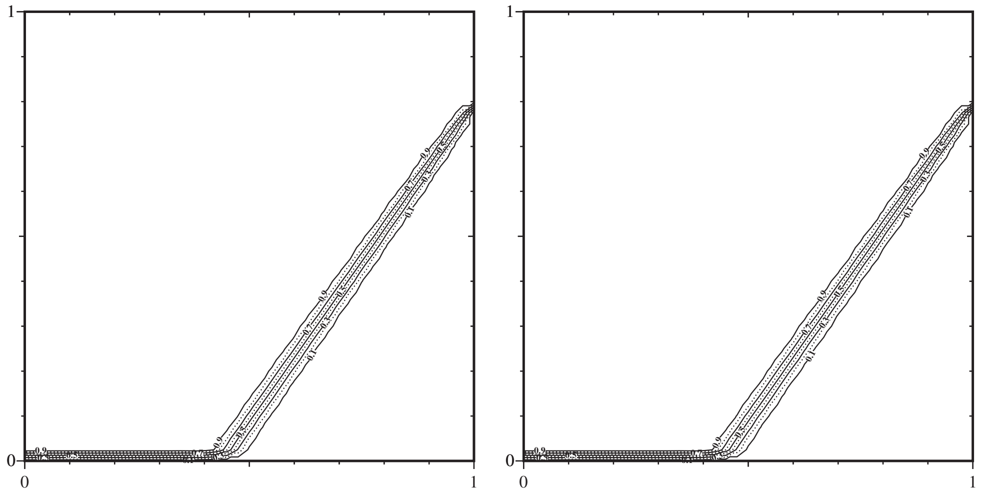

Fig. 3. *Test case* 1: *Linearly reconstructed vertex solution provided by the diamond scheme (left) and the nonlinear diamond scheme (right).*

Table 1

Test case 1: *Performance in terms of quality and computational cost for the calculation with a regular mesh violating the strictly acute mesh condition (top) and an unstructured mesh satisfying the strictly acute mesh condition (bottom).*

Regular mesh ($40 \times 40 \times 2$ triangles)				
Scheme	Overshoot	Undershoot	Layer width	Normalized cost
Diamond	2.42×10^{-4}	1.03×10^{-6}	0.1	1
NL diamond	5.65×10^{-12}	3.01×10^{-12}	0.1	1.12

Unstructured mesh (4352 triangles)				
Scheme	Overshoot	Undershoot	Layer width	Normalized cost
Diamond	8.87×10^{-5}	2.34×10^{-6}	0.1	1
NL diamond	9.48×10^{-11}	6.46×10^{-11}	0.1	1.13

meshes, i.e., the regular one and the unstructured one, is summarized by Table 1. The measure of the absolute values of the maximum overshoot and undershoot, which is a measure of the violation of the maximum and minimum principle, reveals that the nonlinear diamond scheme actually provides a better approximation on both meshes. Table 1 also gives the relative cost for the calculation using the two methods on the two grids and the layer width approximately taken at $y = 0.5$ on the two pictures. It is clear from this table that the nonlinear diamond scheme makes it possible to achieve a higher quality approximation at a very small additional cost, this latter one being no more than 15% of the cost of the diamond scheme for solving the same problem. An explanation of this fact is possible by comparing the convergence curves for the calculations that use the two schemes. The two convergence curves are illustrated in Figure 4. From this figure, we note that the number of quasi-Newton iterations does not significantly change when the nonlinear discretization is considered for the diffusive term. We observe that the maximum number of quasi-Newton iterations that

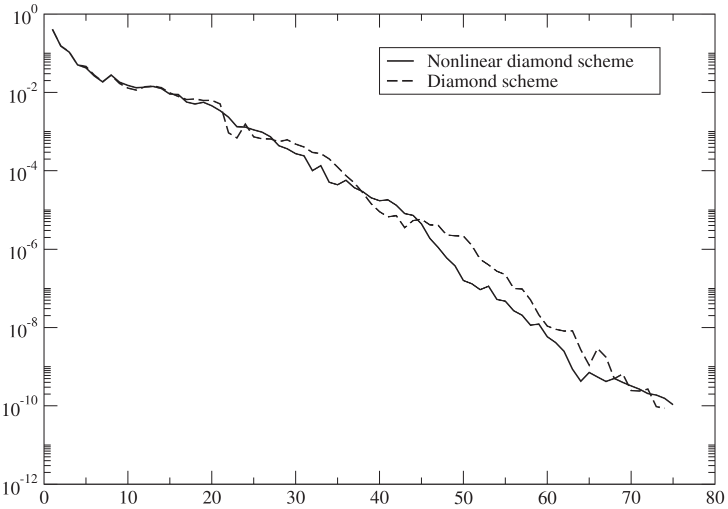

FIG. 4. *Test case* 1: *Comparison of the convergence curves for the quasi-Newton iterations.*

are necessary to attain a residual error under 10^{-10} is about the same: 75 iterations for the nonlinear diamond scheme and 74 iterations for the diamond scheme. The difference between the costs of the two calculations is mainly due to the different number of "internal" Bi-CGSTAB iterations that are required to solve the linearized problem at each step of the quasi-Newton "external" loop. The total number of internal Bi-CGSTAB iterations is 1970 for the diamond scheme and 2198 for the nonlinear diamond scheme.

From this numerical experiment we conclude that the nonlinear discretization of the diffusive term that is proposed in this paper effectively ensures the preservation of a discrete maximum principle. This linearity does not dramatically affect the computational cost compared to the cost of solving the same problem by the standard second-order version of the diamond scheme.

6.2. Test case 2. In this section, we investigate the performance of the nonlinear diamond scheme when numerically solving the two steady convection-diffusion problems of Examples 5.1 and 5.2 of [27], which will be respectively denoted "Problem A" and "Problem B." Both problems are defined on the computational domain $\Omega = [0,\,1] \times [0,\,1]$. The domain Ω is covered by a regular triangulation of 40×40 square-shaped cells, each one of these being divided into two triangles by using the same main diagonal. We run three different calculations by using $\nu \in \{1, 10^{-1}, 10^{-5}\}$. The source function s appearing on the right-hand side of the equation and the boundary data g are chosen so that the exact solution u is the one indicated in the following problem specifications. The velocity field $\boldsymbol{v}$ is also indicated below.

Problem A:

$$\boldsymbol{v} = (-1,-1)^T, \qquad \mathsf{u}(x,y) = x\cos(\pi y).$$

Problem B:

$$\boldsymbol{v} = (2,3)^T,$$
$$\mathsf{u}(x,y) = xy^2 - y^2\exp\Big(2\frac{x-1}{\nu}\Big) - x\exp\Big(3\frac{y-1}{\nu}\Big) + \exp\Big(\frac{2(x-1)+3(y-1)}{\nu}\Big).$$

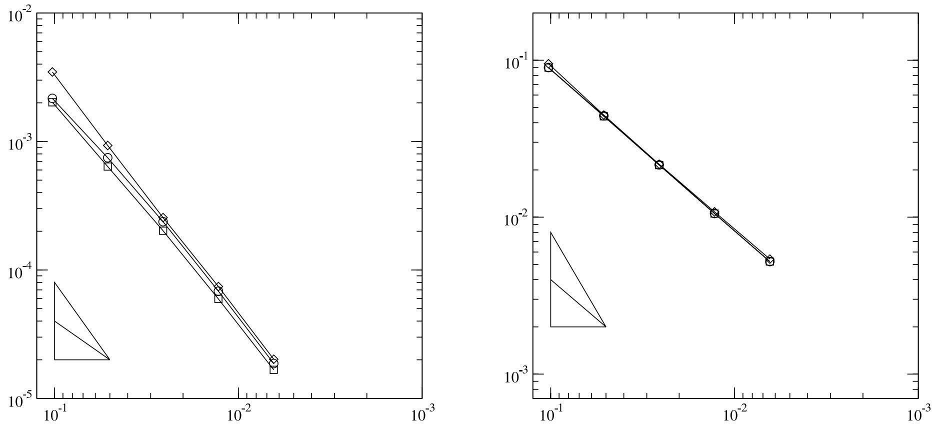

FIG. 5. *Test case 2, Problem* A: *Error convergence rates measured by using the* $\mathtt{L}^2(\Omega)$*-norm (left) and the* $\mathtt{H}^1(\Omega)$*-norm (right); the results concern the approximation of the solution for* $\nu = 1$ *(circles),* $\nu = 10^{-1}$ *(squares), and* $\nu = 10^{-5}$ *(diamonds); second-order and first-order convergence slopes are indicated in the bottom-left corner of both pictures.*

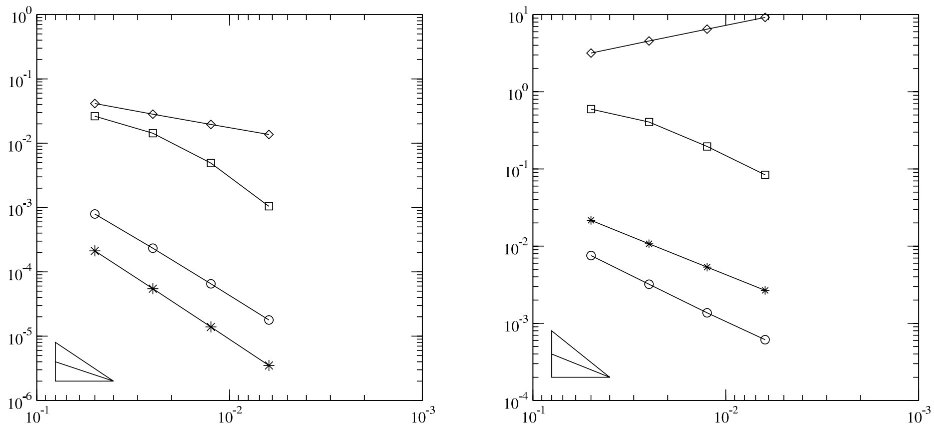

FIG. 6. *Test case 2, Problem* B: *Error convergence rates measured by using the* $\mathtt{L}^2(\Omega)$*-norm (left) and the* $\mathtt{H}^1(\Omega)$*-norm (right); the results concern the approximation of the solution on* $\Omega = [0,1]\times[0,1]$ *for* $\nu = 1$ *(circles),* $\nu = 10^{-1}$ *(squares),* $\nu = 10^{-5}$ *(diamonds) and on* $\Omega = [0,0.8]\times[0,0.8]$ *for* $\nu = 10^{-5}$ *(stars); second- and first-order convergence slopes are indicated in the bottom-left corner of both pictures.*

Problem A allows us to verify the convergence rate when approximating smooth solutions. Instead, the solution of Problem B is characterized by a boundary layer at the outflow near the edges defined by the equations $x = 1$ and $y = 1$. We mention, for comparison's sake, that this last test case is also solved in [27] by using a stabilized Lagrange multiplier method and in [25] by using a nonconforming finite element discretization. The results of this section are shown in Figures 5 and 6, both reporting the $\mathtt{H}^1(\Omega)$- and $\mathtt{L}^2(\Omega)$-norm error of the solution provided by the nonlinear diamond scheme for the above-mentioned values of ν. As shown by both figures, the formal second order of convergence is achieved when we approximate a smooth solution, as in Problem A, and a boundary layer on a mesh that is sufficiently fine to resolve it, as in Problem B, for $\nu = 1$ and $\nu = 10^{-1}$. In both cases, the convergence rate that is experimentally measured is 1 for the $\mathtt{H}^1(\Omega)$-norm error and 2 for the $\mathtt{L}^2(\Omega)$-norm error. When the layer is not resolved in Problem B, e.g., for the strongest advective case corresponding to $\nu = 10^{-5}$, the convergence rate of the $\mathtt{L}^2(\Omega)$-norm of the approximation error is only of order 1/2, while the $\mathtt{H}^1(\Omega)$-norm of the approximation error is not converging to zero on the sequence of meshes considered. Nonetheless, we still observe the expected convergence rate for both error norms away from the boundary layers, e.g., by restricting the error measurement to the domain $\Omega = [0, 0.8] \times [0, 0.8]$ as proposed in [27]. This local convergence behavior is perfectly in agreement with the one observed by the authors of [27], who used a completely different approximation method for this same problem.

7. Conclusions. A new finite volume method has been developed to numerically solve the steady multidimensional convection-diffusion equation. The method is designed on the conservative form of the equation and approximates the cell averages of the analytical solution on unstructured meshes of d-simplices, $d \geq 2$ being the spatial dimension. The formulation of the numerical advective fluxes requires a limiter on the reconstructed slope within each mesh cell in order to ensure monotonicity. Instead, the diffusive numerical fluxes are based on a nonlinear extension of the face gradients used in the standard version of the diamond scheme. Second-order accuracy has been achieved by using a piecewise linear reconstruction within each cell and at mesh vertices. The linear reconstruction relies on the weighted average of the cell averages of the solution. An algorithm was proposed to calculate nonnegative and bounded weights for the mesh vertex values. The nonlinear face gradients have some significant theoretical properties which allowed us to prove the solvability of the resulting scheme and the existence of a discrete maximum and minimum principle. The numerical results illustrate these features and the performance of the method in treating problems with both smooth solutions and solutions with internal and boundary layers. It turns out that second order of convergence of the sequence of approximate solutions is achievable with negligible violation of the discrete maximum and minimum principles. The discrete maximum and minimum principles are obtained at a relatively small additional cost with respect to the computational cost required for solving the same problem by the version of the method not preserving the discrete maximum and minimum principle. The relative additional cost is about 10–15%. Finally, we remark that the stencils of the diamond scheme and the nonlinear diamond scheme are identical; hence, the new method does not require additional memory storage.

CONVERGENCE OF TIME-STEPPING METHOD FOR INITIAL AND BOUNDARY-VALUE FRICTIONAL COMPLIANT CONTACT PROBLEMS*

JONG-SHI PANG†, VIJAY KUMAR‡, AND PENG SONG§

Abstract. Beginning with a proof of the existence of a discrete-time trajectory, this paper establishes the convergence of a time-stepping method for solving continuous-time, boundary-value problems for dynamic systems with frictional contacts characterized by local compliance in the normal and tangential directions. Our investigation complements the analysis of the initial-value rigid-body model with one frictional contact encountering inelastic impacts by Stewart [Arch. Ration. Mech. Anal., 145 (1998), pp. 215–260] and the recent analysis by Anitescu [*Optimization-Based Simulation for Nonsmooth Rigid Multibody Dynamics*, Argonne National Laboratory, Argonne, IL, 2004] using the framework of measure differential inclusions. In contrast to the measure-theoretic approach of these authors, we follow a differential variational approach and address a broader class of problems with multiple elastic or inelastic impacts. Applicable to both initial and affine boundary-value problems, our main convergence result pertains to the case where the compliance in the normal direction is decoupled from the compliance in the tangential directions and where the friction coefficients are sufficiently small.

Key words. time-stepping methods, frictional contact problems, compliance models, differenctial complementarity problems, boundary-value problems

1. Introduction.

This paper investigates the limiting properties of time-stepping methods for rigid-body dynamics problems with multiple contacts characterized by friction and local compliance. Comprehensive reviews on rigid-body models and their applications can be found in the monographs [5, 13] and the excellent survey [20]. The benefits of introducing contact compliance for analysis and numerical simulation have been discussed in previous work [23]. In particular, a compliant model eliminates the static indeterminacy that is inherent in a rigid body dynamic model with multiple contacts and the need to make assumptions about linear independence of the columns of the Jacobian matrix [3, 10, 19]. Most important, even when one makes the requisite assumptions for uniqueness and existence, it is not possible to analyze the boundary-value problem in a fully rigid-body model because of the presence of discontinuities in velocities during impacts.

The present paper is closest in spirit to the work of Stewart [19], who analyzed the convergence of a time-stepping method [21] for initial-value rigid-body problems

with frictional contact. Stewart's analysis is the first of its kind in the rigid-body dynamics literature. However, his analysis is somewhat limiting in several respects. In particular, the main result of the paper [19], Theorem 1, pertains essentially to the case of one inelastic contact. Even for such a simplified case, the analysis relies on a Radon–Nikodym derivative with several technical restrictions. It is difficult to fully extend Stewart's analysis because of the intrinsic analytical difficulties associated with the rigid-body paradigm. This difficulty is acknowledged in the recent paper by Anitescu [1], who established the convergence of a sequential quadratic programming method to a solution of a measure differential inclusion for nonsmooth rigid multibody dynamics.

Our previous work was concerned with several analytical aspects of dynamic models with compliant frictional contacts. Comparisons between results obtained with and without local compliance with a singular perturbation analysis are included in [15]. Uniqueness and existence results for the discrete-time problem are presented in [17] under a semi-implicit discretization that permits the use of linear complementarity theory [6]. In this paper, we analyze the convergence of a broad scheme of time-stepping methods for solving frictional compliant contact problems. In contrast to [17], the discretization scheme employed here is more general, allowing in particular for nonlinearities in the state variables, thus going well beyond the previous analysis of existence and uniqueness that is based on a linear theory. Unlike the analysis in [19, 1], our main convergence result is not in terms of measure differential inclusions. Most importantly, our analysis is carried out in a broad setting that includes both initial-value and boundary-value problems with affine constraints on the initial and final state (see (13)). It should be noted that although boundary-value problems arise naturally in the design of mechanical systems governed by dynamics, previous literature on this subject addresses only initial-value problems and ours is the first attempt to study contact problems subject to boundary conditions.

This paper addresses neither the numerical implementation nor the order of convergence of the time-stepping methods. For details on practical implementation and computational results, see [16, 18]; see also [4] for a part-insertion application of a boundary-value planar rigid-body problem. The order of convergence analysis for frictional contact problems is a very difficult topic, even for initial-value problems. The discontinuity of the friction forces as a function of the system states is a main cause for such difficulty.

The organization of the rest of the paper is as follows. In the next section, we summarize the formulation of the continuous-time frictional compliant contact problem and formally define a concept of a weak solution to the problem. A numerical time-stepping scheme for computing such a solution is described in section 3. The convergence analysis of the numerical scheme begins in section 4, where we first investigate in detail the normal and tangential frictional conditions in the discrete-time subproblems, establishing in particular the existence of a discrete-time trajectory of the normal and tangential contact forces that are continuous functions of the state. We also establish the uniqueness of such a trajectory under a "small coefficient of friction" assumption; see Propositions 6 and 7. With the aid of the machinery of differential variational inequalities [11], and under the small-friction-coefficient assumption, we complete the convergence analysis of the time-stepping method for a compliant-body frictional contact problem in section 5. There, an existence result, Theorem 8, for the discrete-time boundary-value problem is first proved, which is followed by the main convergence theorem of the paper, Theorem 9. The small-friction assumption is the artifact of the nonlinear friction law that is in turn a characteristic of the discretization scheme that we employ. Such a nonlinear analysis is in contrast to previous analysis by Stewart and Anitescu, which is based on a polygonal approximation of the quadratic Coulomb cone.

2. Model formulation.

The mathematical formulation of the frictional compliant contact problem has several components: (a) equations of motion, (b) compliance constitutive law, (c) contact and friction, and (d) boundary conditions. In what follows, we present only the essentials of the formulation and refer the reader to [14, 17] for the detailed explanation of the overall model.

Equations of motion. The dynamics equation of motion for a multibody system with frictional contacts can be written as

$$M(q)\dot{\nu} \;=\; f(t,q,\nu) + \boldsymbol{\Gamma}(q)^T \boldsymbol{\lambda}, \tag{1}$$

where q is the n_q-dimensional vector of generalized coordinates, ν is the n_ν-dimensional vector of the system velocities, $\dot{\nu}$ denotes the time derivative of ν (i.e., $\dot{\nu} = d\nu/dt$), $M(q)$ is the $n_\nu \times n_\nu$ symmetric positive definite mass-inertia matrix, $f(t,q,\nu)$ is the n_ν-dimensional external force vector (excluding contact forces),

$$\boldsymbol{\Gamma}(q)^T \;\equiv\; \left[\; \Gamma_{\rm n}(q)^T \;\; \Gamma_{\rm t}(q)^T \;\; \Gamma_{\rm o}(q)^T \;\right] \;\equiv\; G(q)^T \left[\; J\Psi_{\rm n}(q)^T \;\; J\Psi_{\rm t}(q)^T \;\; J\Psi_{\rm o}(q)^T \;\right]$$

is the transpose of the system Jacobian matrix, with $\Psi_{\rm n,t,o}(q)$ and $J\Psi_{\rm n,t,o}(q)$ being the constraint functions and their Jacobians for all possible contacts in the normal direction (labeled n) and the two tangential directions (labeled t and o), respectively, and $\boldsymbol{\lambda} \equiv (\lambda_{\rm n}, \lambda_{\rm t}, \lambda_{\rm o}) = \lambda_{\rm n,t,o}$ is the vector of contact forces in these directions. For compliant contact models, the dimensions of the contact forces and, accordingly, the orders of the associated Jacobian matrices, are related to the compliance constitutive model being used. The matrix $G(q)$ is a $n_q \times n_\nu$ parametrization matrix that allows us to use different parameterizations for the motion group via the the following kinematics equation:

$$\dot{q} \;=\; G(q)\nu, \tag{2}$$

where $\dot{q} \equiv dq/dt$ is the time-derivative of the system configuration. Together, (1) and (2) constitute the equations of motion governing the dynamics of the mechanical system.

Letting $T > 0$ be the terminal time of the problem, we postulate the following assumptions (A)–(C) on the above model functions. Notice that no rank assumption is imposed on $\boldsymbol{\Gamma}(q)$; this is a distinct advantage of a compliant model in that the number of contact points need not be restricted by the degrees of freedom of the bodies in contact.

(A) The function $f(t,q,\nu)$ is Lipschitz continuous on $[0,T] \times \Re^{n_q+n_\nu}$ with constant $L_f > 0$; thus,

$$\begin{gathered}\| f(t,q,\nu) - f(t',q',\nu') \| \leq L_f \left[|t-t'| + \|q-q'\| + \|\nu-\nu'\| \right] \\ \forall\,(t,q,\nu), (t',q',\nu') \in [0,T] \times \Re^{n_q+n_\nu}.\end{gathered}$$

(B) The functions $G(q)$ and $\boldsymbol{\Gamma}(q)$ are Lipschitz continuous and bounded on $\Re^{n_q}$; thus there exist positive constants L_G, L_W, η_G, and η_W such that for all q and q' in $\Re^{n_q}$,

$$\begin{aligned} &\|\, G(q) - G(q') \,\| \;\leq\; L_G \,\|\, q - q' \,\|, && \|\, \boldsymbol{\Gamma}(q) - \boldsymbol{\Gamma}(q') \,\| \;\leq\; L_W \,\|\, q - q' \,\|, \\ &\sup_{q \in \Re^{n_q}} \|\, G(q) \,\| \;\leq\; \eta_G, && \sup_{q \in \Re^{n_q}} \|\, \boldsymbol{\Gamma}(q) \,\| \;\leq\; \eta_W; \end{aligned}$$

moreover, the function $\Psi_{\rm n}(q)$ satisfies the limit condition

$$\lim_{\| q - q' \| \to 0} \frac{\| \Psi_{\rm n}(q) - \Psi_{\rm n}(q') - J\Psi_{\rm n}(q')(q - q') \|}{\| q - q' \|} = 0, \tag{3}$$

or, equivalently, for every scalar $\varepsilon > 0$, a scalar $\varsigma > 0$ exists such that

$$\| q - q' \| \leq \varsigma \Rightarrow \| \Psi_{\rm n}(q) - \Psi_{\rm n}(q') - J\Psi_{\rm n}(q')(q - q') \| \leq \varepsilon \| q - q' \|. \tag{4}$$

(C) The mass-inertia matrix $M(q)$ is Lipschitz continuous on $\Re^{n_q}$ with Lipschitz constant $L_M > 0$; moreover, positive constants σ_M and σ'_M exist such that

$$\inf_{q \in \Re^{n_q}} \min_{\| \nu \| = 1} \nu^T M(q) \nu \geq \sigma_M \quad \text{and} \quad \sup_{q \in \Re^{n_q}} \max_{\| \nu \| = 1} \nu^T M(q) \nu \leq 1/\sigma'_M.$$

Condition (3) is clearly satisfied if $J\Psi_{\rm n}(q)$ is Lipschitz continuous. Unlike the treatment in [1], $\Psi_{\rm n}(q)$ is not assumed to be twice differentiable. (The squared distance function to a closed convex set—the obstacle set—is an example of a (scalar) function that is continuously differentiable with a Lipschitz gradient but is not twice differentiable.) Conditions (A), (B), and (C) have several immediate consequences, which will be used freely throughout the paper where appropriate.

A constitutive model for compliance. While there are many compliance models, we employ the distributed model described in [14, 17], to which we refer the reader for details and references. Specifically, this model postulates that the contact forces are linearly dependent on the body deformations and on the deformation rates:

$$\boldsymbol{\lambda} = \mathbf{K}(q)\boldsymbol{\delta} + \mathbf{C}(q)\dot{\boldsymbol{\delta}} \tag{5}$$

where $\boldsymbol{\delta} \equiv (\delta_{\rm n}, \delta_{\rm t}, \delta_{\rm o}) = \delta_{\rm n,t,o}$ is the vector of body deformations in the normal (n) and the two tangential directions (t and o), $\dot{\boldsymbol{\delta}}$ denotes the vector of velocities of the deformations (i.e., $\dot{\boldsymbol{\delta}} = d\boldsymbol{\delta}/dt$); the stiffness matrix $\mathbf{K}(q)$ and the damping matrix $\mathbf{C}(q)$, which are partitioned as

$$\mathbf{K}(q) \equiv \begin{bmatrix} K_{\rm nn}(q) & K_{\rm nt}(q) & K_{\rm no}(q) \\ K_{\rm tn}(q) & K_{\rm tt}(q) & K_{\rm to}(q) \\ K_{\rm on}(q) & K_{\rm ot}(q) & K_{\rm oo}(q) \end{bmatrix} \text{ and } \mathbf{C}(q) \equiv \begin{bmatrix} C_{\rm nn}(q) & C_{\rm nt}(q) & C_{\rm no}(q) \\ C_{\rm tn}(q) & C_{\rm tt}(q) & C_{\rm to}(q) \\ C_{\rm on}(q) & C_{\rm ot}(q) & C_{\rm oo}(q) \end{bmatrix},$$

are each of order $3n_s^2 n_c$, with n_s^2 being the number of elements with lumped stiffness and damping properties that comprise a contact patch; each of the 18 block matrices (such as $K_{\rm nt}(q)$, etc.) in $\mathbf{K}(q)$ and $\mathbf{C}(q)$ is an $n_s^2 n_c$ block diagonal matrix with n_c diagonal blocks, one for each contact patch, and each such diagonal block is in turn a square matrix of order n_s^2. With $n_\delta \equiv n_s^2 n_c$, it follows that the vectors $\lambda_{\rm n}$, $\lambda_{\rm t}$, $\lambda_{\rm o}$, $\delta_{\rm n}$, $\delta_{\rm t}$, and $\delta_{\rm o}$ are each of dimension n_δ. We postulate the following condition:

(D) $\mathbf{K}(q)$ and $\mathbf{C}(q)$ are Lipschitz continuous symmetric positive definite matrix-valued functions of q; moreover, positive constants $\eta_K > 0$, σ_{KC} and η_{KC} exist such that $\sup_{q \in \Re^{n_q}} \| \mathbf{K}(q) \| \leq \eta_K$, and, for all scalars $h > 0$ sufficiently small,

$$\inf_{q \in \Re^{n_q}} \min_{\| \boldsymbol{\delta} \| = 1} \boldsymbol{\delta}^T [\, h\,\mathbf{K}(q) + \mathbf{C}(q)\,]^{-1} \boldsymbol{\delta} \geq \sigma_{KC} \text{ and } \sup_{q \in \Re^{n_q}} \left\| [\, h\,\mathbf{K}(q) + \mathbf{C}(q)\,]^{-1} \right\| \leq \eta_{KC}.$$

Notice that the above implies $\sup_{q \in \Re^{n_q}} \| \mathbf{C}(q) \| \leq 1/\sigma_{KC}$.

Contact and friction. Stated as a complementarity condition, the normal contact condition is

$$0 \leq \lambda_{\mathrm{n}} \perp \Psi_{\mathrm{n}}(q) + \delta_{\mathrm{n}} \geq 0, \tag{6}$$

where the notation $u \perp v$ means that the two vectors u and v are perpendicular. The tangential friction condition is expressed by a minimization principle over the cone of frictional forces: for each $i = 1, \ldots, n_\delta$,

$$(\lambda_{i\mathrm{t}}, \lambda_{i\mathrm{o}}) \in \operatorname{argmin} \left\{ s_{i\mathrm{t}}\tilde{\lambda}_{i\mathrm{t}} + s_{i\mathrm{o}}\tilde{\lambda}_{i\mathrm{o}} : (\tilde{\lambda}_{i\mathrm{t}}, \tilde{\lambda}_{i\mathrm{o}}) \in \mathcal{F}(\mu_i \lambda_{i\mathrm{n}}) \right\}, \tag{7}$$

where

$$\begin{aligned} s_{i\mathrm{t}} &\equiv \frac{d(\delta_{it} + \Psi_{it}(q))}{dt} = \dot{\delta}_{it} + \nabla\Psi_{it}(q)^T \dot{q}, \\ s_{i\mathrm{o}} &\equiv \frac{d(\delta_{i\mathrm{o}} + \Psi_{i\mathrm{o}}(q))}{dt} = \dot{\delta}_{i\mathrm{o}} + \nabla\Psi_{i\mathrm{o}}(q)\dot{q} \end{aligned} \tag{8}$$

are the tangential slip velocities at contact patch i, which depend on both the deformations of the compliant elements and the rigid body motions, and where $\mu_i \geq 0$ is the friction coefficient and

$$\mathcal{F}(\tau) \equiv \{ (a, b) \in \Re^2 : \sqrt{a^2 + b^2} \leq \tau \}, \quad \tau \geq 0,$$

is the standard Coulomb friction cone. From (7), it follows that

$$s_{it}\lambda_{it} + s_{i\mathrm{o}}\lambda_{i\mathrm{o}} = -\mu_i \lambda_{i\mathrm{n}} \sqrt{s_{i\mathrm{t}}^2 + s_{i\mathrm{o}}^2}. \tag{9}$$

Moreover, provided that $\mu_i\lambda_{i\mathrm{n}} > 0$, we have, with $r_i \equiv \sqrt{s_{i\mathrm{t}}^2 + s_{i\mathrm{o}}^2}$,

$$s_{i\mathrm{t}} + \frac{r_i \lambda_{i\mathrm{t}}}{\sqrt{\lambda_{i\mathrm{t}}^2 + \lambda_{i\mathrm{o}}^2}} = 0, \quad s_{\mathrm{o}} + \frac{r_i \lambda_{i\mathrm{o}}}{\sqrt{\lambda_{i\mathrm{t}}^2 + \lambda_{i\mathrm{o}}^2}} = 0,$$

$$0 \leq r_i \perp \mu_i \lambda_{i\mathrm{n}} - \sqrt{\lambda_{i\mathrm{t}}^2 + \lambda_{i\mathrm{o}}^2} \geq 0,$$

where we define 0/0 to be 1. If we use polar coordinates to represent the pair $(s_{i\mathrm{t}}, s_{i\mathrm{o}})$, say,

$$s_{i\mathrm{t}} = r_i \cos\psi_i \quad \text{and} \quad s_{i\mathrm{o}} = r_i \sin\psi_i,$$

then there exists a scalar $\phi_i \in [-1, 1]$ satisfying $r_i > 0 \Rightarrow \phi_i = 1$ such that

$$\lambda_{i\mathrm{t}} = -\mu_i \lambda_{i\mathrm{n}} \phi_i \cos\psi_i \quad \text{and} \quad \lambda_{i\mathrm{o}} = -\mu_i \lambda_{i\mathrm{n}} \phi_i \sin\psi_i.$$

The latter representation of $(\lambda_{it}, \lambda_{io})$ remains valid when $\mu_i\lambda_{in} = 0$, by letting $\phi_i = 0$.

More on the compliance model. The constitutive law (5) can be used to eliminate the slip velocities (s_{it}, s_{io}) in the friction law (7), resulting in an expression of the latter in terms of the state variables $(q, \nu, \delta_{\mathrm{n,t,o}})$ and the normal force λ_{n}. This reformulation of the friction law is significant because the slip velocities may behave discontinuously and lead to technical difficulties in the convergence analysis of a numerical method. From (5), we have $\dot{\boldsymbol{\delta}} = \mathbf{C}(q)^{-1}(\boldsymbol{\lambda} - \mathbf{K}(q)\boldsymbol{\delta})$. Writing

$$\mathbf{C}(q)^{-1} \equiv \begin{bmatrix} \widehat{C}_{\mathrm{nn}}(q) & \widehat{C}_{\mathrm{nt}}(q) & \widehat{C}_{\mathrm{no}}(q) \\ \widehat{C}_{\mathrm{tn}}(q) & \widehat{C}_{\mathrm{tt}}(q) & \widehat{C}_{\mathrm{to}}(q) \\ \widehat{C}_{\mathrm{on}}(q) & \widehat{C}_{\mathrm{ot}}(q) & \widehat{C}_{\mathrm{oo}}(q) \end{bmatrix},$$

we obtain

$$\begin{pmatrix} \dot{\delta}_{i\mathrm{t}} \\ \dot{\delta}_{i\mathrm{o}} \end{pmatrix} = \begin{bmatrix} \widehat{C}_{i\mathrm{tn}}(q) & \widehat{C}_{i\mathrm{tt}}(q) & \widehat{C}_{i\mathrm{to}}(q) \\ \widehat{C}_{i\mathrm{on}}(q) & \widehat{C}_{i\mathrm{ot}}(q) & \widehat{C}_{i\mathrm{oo}}(q) \end{bmatrix} (\boldsymbol{\lambda} - \mathbf{K}(q)\boldsymbol{\delta}),$$

where $\widehat{C}_{i\mathrm{tn}}(q)$ denotes the ith row of the (sub)matrix $\widehat{C}_{\mathrm{tn}}(q)$, and similarly for the other notation. Clearly, the friction condition (7) at contact i is equivalent to: for all $(\widetilde{\lambda}_{i\mathrm{t}}, \widetilde{\lambda}_{i\mathrm{o}}) \in \mathcal{F}(\mu_i \lambda_{i\mathrm{n}})$,

(10)
$$0 \leq \begin{pmatrix} \widetilde{\lambda}_{i\mathrm{t}} - \lambda_{i\mathrm{t}} \\ \widetilde{\lambda}_{i\mathrm{o}} - \lambda_{i\mathrm{o}} \end{pmatrix}^T \begin{pmatrix} s_{i\mathrm{t}} \\ s_{i\mathrm{o}} \end{pmatrix} = \begin{pmatrix} \widetilde{\lambda}_{i\mathrm{t}} - \lambda_{i\mathrm{t}} \\ \widetilde{\lambda}_{i\mathrm{o}} - \lambda_{i\mathrm{o}} \end{pmatrix}^T \left[\begin{pmatrix} \dot{\delta}_{i\mathrm{t}} \\ \dot{\delta}_{i\mathrm{o}} \end{pmatrix} + \begin{pmatrix} \Gamma_{i\mathrm{t}}(q) \\ \Gamma_{i\mathrm{o}}(q) \end{pmatrix} \nu \right]$$
$$= \begin{pmatrix} \widetilde{\lambda}_{i\mathrm{t}} - \lambda_{i\mathrm{t}} \\ \widetilde{\lambda}_{i\mathrm{o}} - \lambda_{i\mathrm{o}} \end{pmatrix}^T \left\{ \begin{bmatrix} \widehat{C}_{i\mathrm{tn}}(q) \; \widehat{C}_{i\mathrm{tt}}(q) \; \widehat{C}_{i\mathrm{to}}(q) \\ \widehat{C}_{i\mathrm{on}}(q) \; \widehat{C}_{i\mathrm{ot}}(q) \; \widehat{C}_{i\mathrm{oo}}(q) \end{bmatrix} (\boldsymbol{\lambda} - \mathbf{K}(q)\boldsymbol{\delta}) + \begin{pmatrix} \Gamma_{i\mathrm{t}}(q) \\ \Gamma_{i\mathrm{o}}(q) \end{pmatrix} \nu \right\}.$$

Proposition 1 shows that under the constitutive compliance law (5), the tangential friction forces in a frictional compliant model can be characterized by the solution to a convex quadratic program.

PROPOSITION 1. *Given q, ν, λ_{n}, and $\boldsymbol{\delta}$, under* (5)*, the tangential forces $(\lambda_{\mathrm{t}}, \lambda_{\mathrm{o}})$ satisfy the minimum principle* (7) *if and only if $(\lambda_{\mathrm{t}}, \lambda_{\mathrm{o}})$ is the optimal solution, which must necessarily be unique, of the convex quadratic program:*

(11)
$$\textit{minimize} \quad \frac{1}{2} \begin{pmatrix} \tilde{\lambda}_{\mathrm{t}} \\ \tilde{\lambda}_{\mathrm{o}} \end{pmatrix} \begin{bmatrix} \widehat{C}_{\mathrm{tt}}(q) & \widehat{C}_{\mathrm{to}}(q) \\ \widehat{C}_{\mathrm{ot}}(q) & \widehat{C}_{\mathrm{oo}}(q) \end{bmatrix} \begin{pmatrix} \tilde{\lambda}_{\mathrm{t}} \\ \tilde{\lambda}_{\mathrm{o}} \end{pmatrix}$$
$$+ \begin{pmatrix} \tilde{\lambda}_{\mathrm{t}} \\ \tilde{\lambda}_{\mathrm{o}} \end{pmatrix}^T \left\{ \begin{bmatrix} \widehat{C}_{\mathrm{tn}}(q) \\ \widehat{C}_{\mathrm{on}}(q) \end{bmatrix} \lambda_{\mathrm{n}} + \begin{bmatrix} \Gamma_{\mathrm{t}}(q) \\ \Gamma_{\mathrm{o}}(q) \end{bmatrix} \nu - \begin{bmatrix} \widehat{C}_{\mathrm{tn}}(q) & \widehat{C}_{\mathrm{tt}}(q) & \widehat{C}_{\mathrm{to}}(q) \\ \widehat{C}_{\mathrm{on}}(q) & \widehat{C}_{\mathrm{ot}}(q) & \widehat{C}_{\mathrm{oo}}(q) \end{bmatrix} \mathbf{K}(q)\boldsymbol{\delta} \right\}$$
$$\textit{subject to} \quad (\tilde{\lambda}_{\mathrm{t}}, \tilde{\lambda}_{\mathrm{o}}) \in \prod_{i=1}^{n_\delta} \mathcal{F}(\mu_i \, \lambda_{i\mathrm{n}}).$$

Proof. It suffices to note that the first-order optimality conditions of (11) are equivalent to the variational conditions (10). □

Boundary conditions. To complete the description of the model, we postulate a set of boundary conditions that connect the state variable $\mathbf{x} \equiv (q, \nu, \boldsymbol{\delta}) \in \Re^n$, where $n \equiv n_q + n_\nu + 3n_\delta$, at the initial and terminal times: $t = 0$ and $t = T$, respectively. The most general such conditions would be expressed by a nonlinear functional relation of the form $F(\mathbf{x}(0), \mathbf{x}(T)) = 0$. Nevertheless, such generality would make the analysis extremely difficult, if not impossible. In general, the boundary conditions should be consistent with the constraints; such consistency would require the initial pair $(q^0, \delta_{\mathrm{n}}^0)$ to satisfy the feasibility condition:

(12) $$\Psi_{\mathrm{n}}(q^0) + \delta_{\mathrm{n}}^0 \geq 0.$$

Therefore, to both accommodate realistic applications and facilitate the mathematical analysis, we consider a class of boundary conditions where the initial configuration $q(0) = q^0$ and deformation $\boldsymbol{\delta}(0) = \boldsymbol{\delta}^0$ are known and satisfy (12); but the initial velocity $\nu(0)$ and terminal state $\mathbf{x}(T)$ are subject to a system of linear equations,

$$\mathbf{b} \,=\, \mathbf{M}_\nu \nu(0) + \mathbf{N}\mathbf{x}(T), \tag{13}$$

for some given vector $\mathbf{b} \in \Re^{n_\nu}$ and matrices $\mathbf{M}_\nu \in \Re^{n_\nu \times n_\nu}$ and $\mathbf{N} \in \Re^{n_\nu \times n}$. When $\mathbf{M}_\nu$ is the identity matrix and $\mathbf{N}$ is the zero matrix, we recover an initial-value problem with a known initial state $\mathbf{x}(0)$.

Weak solutions. The frictional compliant contact problem under study is to find a state trajectory $\mathbf{x} : [0,T] \to \Re^n$ and a force trajectory $\boldsymbol{\lambda} : [0,T] \to \Re^{3n_\delta}$ such that $q(0) = q^0$, $\boldsymbol{\delta}(0) = \boldsymbol{\delta}^0$, and the conditions (1), (2)–(8), (12), and (13) are satisfied. Ideally, we want these conditions to be satisfied at all times $t \in [0,T]$, but due to the possible discontinuity of the force trajectory $\boldsymbol{\lambda}$, this ideal goal is generally not attainable, especially when it pertains to the numerical solutions obtained by a time-stepping scheme, such as the one described in the next section; see [19, 20]. Therefore, we have to settle for a kind of weak solution that satisfies the dynamics equations and the contact and friction conditions in a weak sense. This is an inherent limitation of the model, particularly (5). It may be possible to get a strong solution by using a more sophisticated, nonlinear constitutive model. (See [15] for an example of such a model.) However, we refrain from pursuing such an extended consideration and restrict ourselves to the law (5), whose analysis is already fairly involved.

DEFINITION 2. *The pair of trajectories* $\mathbf{x} : [0,T] \to \Re^n$ *and* $\boldsymbol{\lambda} : [0,T] \to \Re^{3n_\delta}$ *is said to be a weak solution of the frictional compliant contact problem if*

(a) *(the state equations)* $\mathbf{x}(t)$ *is absolutely continuous on* $[0,T]$ *and satisfy for all* $\tau \leq \tau\,'$ *in* $[0,T]$,

$$\begin{aligned}
\nu(\tau\,') - \nu(\tau) &= \int_\tau^{\tau\,'} M(q(t))^{-1}[\, f(t,q(t),\nu(t)) + \boldsymbol{\Gamma}(q(t))^T\boldsymbol{\lambda}(t)\,]\, dt, \\
q(\tau\,') - q(\tau) &= \int_\tau^{\tau\,'} G(q(t))\nu(t)\, dt, \\
\boldsymbol{\delta}(\tau\,') - \boldsymbol{\delta}(\tau) &= \int_\tau^{\tau\,'} C(q(t))^{-1}[\,\boldsymbol{\lambda}(t) - \mathbf{K}(q(t))\boldsymbol{\delta}(t)\,]\, dt;
\end{aligned}$$

(b) *(the normal contact condition)* $\Psi_{\rm n}(q(t)) + \delta_{\rm n}(t) \geq 0$ *for all* $t \in [0,T]$, $\lambda_{\rm n}(t) \geq 0$ *for almost all* $t \in [0,T]$, *and*

$$\int_0^T \lambda_{\rm n}(t)^T[\,\Psi_{\rm n}(q(t)) + \delta_{\rm n}(t)\,]\, dt \,=\, 0;$$

(c) *(the friction condition) for every* $i = 1, \ldots, n_\delta$, $(\lambda_{it}(t), \lambda_{io}(t)) \in \mathcal{F}(\mu_i\lambda_{in}(t))$ *for almost all* $t \in [0,T]$ *and for every continuous function* $(\widetilde{\lambda}_{\rm t}, \widetilde{\lambda}_{\rm o}) : [0,T] \to \Re^{2n_\delta}$ *such that for every* $i = 1, \ldots, n_\delta$, $(\widetilde{\lambda}_{i\rm t}(t), \widetilde{\lambda}_{i\rm o}(t))$ *belongs to* $\mathcal{F}(\mu_i\lambda_{in}(t))$ *for almost all* $t \in [0,T]$, *it holds that*

$$\int_0^T \begin{pmatrix} \widetilde{\lambda}_{\rm t}(t) - \lambda_{\rm t}(t) \\ \widetilde{\lambda}_{\rm o}(t) - \lambda_{\rm o}(t) \end{pmatrix}^T \left\{ \begin{bmatrix} \widehat{C}_{\rm tt}(q(t)) & \widehat{C}_{\rm to}(q(t)) \\ \widehat{C}_{\rm ot}(q(t)) & \widehat{C}_{\rm oo}(q(t)) \end{bmatrix} \left[\begin{pmatrix} \lambda_{\rm t}(t) \\ \lambda_{\rm o}(t) \end{pmatrix} \right.\right.$$
$$\left.\left. - \begin{bmatrix} K_{\rm tt}(q(t)) & K_{\rm to}(q(t)) \\ K_{\rm ot}(q(t)) & K_{\rm oo}(q(t)) \end{bmatrix} \begin{pmatrix} \delta_{\rm t}(t) \\ \delta_{\rm o}(t) \end{pmatrix} \right] + \begin{pmatrix} \Gamma_{\rm t}(q(t)) \\ \Gamma_{\rm o}(q(t)) \end{pmatrix} \nu(t) \right\} dt \geq 0,$$

(d) *(initial and boundary conditions)* $q(0) = q^0$, $\boldsymbol{\delta}(0) = \boldsymbol{\delta}^0$, *and* (13) *hold.*

We make a couple remarks about the above definition. First, the slip velocities do not enter in the above definition; second, the tangential friction condition is stipulated to hold in an integral form that is an aggregation over all contacts. This is in contrast to requiring the condition to hold at every contact. In the special case where compliance is decoupled among the contacts, then the aggregated condition indeed decouples into separate conditions at each individual contact.

3. A time-stepping scheme.

The kind of "semi-implicit" discretization methods described herein for computing a weak solution to the frictional compliant contact problems has been used extensively for solving initial-value rigid-body problems and, to a lesser extent, for compliant-body problems; see, e.g., [2, 3, 11, 21, 17, 18, 19]. Specifically, we divide the time interval $[0, T]$ into $N_h + 1$ subintervals each of equal length $h > 0$; thus $(N_h + 1)h = T$. The variables of the discrete-time system are

$$\begin{gathered}\{\, q^{h,0}, q^{h,1}, \ldots, q^{h,N_h+1} \,\},\ \{\, \nu^{h,0}, \nu^{h,1}, \ldots, \nu^{h,N_h+1} \,\},\ \{\, \delta^{h,0}_{\mathrm{n,t,o}}, \delta^{h,1}_{\mathrm{n,t,o}}, \ldots, \delta^{h,N_h+1}_{\mathrm{n,t,o}} \,\}, \\ \{\, \lambda^{h,1}_{\mathrm{n,t,o}}, \lambda^{h,2}_{\mathrm{n,t,o}}, \ldots, \lambda^{h,N_h+1}_{\mathrm{n,t,o}} \,\},\ \text{and}\ \{\, s^{h,1}_{\mathrm{t,o}}, \ldots, s^{h,N_h+1}_{\mathrm{t,o}} \,\}. \end{gathered} \tag{14}$$

We write $\mathbf{x}^{h,j} \equiv (q^{h,j}, \nu^{h,j}, \boldsymbol{\delta}^{h,j})$, $\boldsymbol{\delta}^{h,j} \equiv \delta^{h,j}_{\mathrm{n,t,o}}$, and $\boldsymbol{\lambda}^{h,j} \equiv \lambda^{h,j}_{\mathrm{n,t,o}}$. To derive the discrete-time system, we replace the time derivatives of the state variable $\mathbf{x} \equiv (q, \nu, \boldsymbol{\delta})$ by standard finite-difference quotients such as:

$$\dot{\mathbf{x}}(t) \approx \frac{\mathbf{x}(t+h) - \mathbf{x}(t)}{h}.$$

The right-hand expressions in the equation of motion (1) and in the kinematic equation (2) are approximated by a semi-implicit scheme that employs a θ-rule, whereby the differential variables q and ν are evaluated at some intermediate values in the respective subintervals determined by the scalar $\theta \in [0, 1]$. Specifically, with

$$q^{h,\theta_j} \equiv \theta\, q^{h,j} + (1-\theta)\, q^{h,j+1} \quad \text{and} \quad \nu^{h,\theta_j} \equiv \theta\, \nu^{h,j} + (1-\theta)\, \nu^{h,j+1},$$

the discrete-time dynamics and kinematics equations at time $t_{h,j+1}$ are

$$\begin{aligned} M(q^{h,j})(\nu^{h,j+1} - \nu^{h,j}) &= h\,[\, f(t_{h,j+1}, q^{h,\theta_j}, \nu^{h,\theta_j}) + \boldsymbol{\Gamma}(q^{h,j})^T \boldsymbol{\lambda}^{h,j+1}], \\ q^{h,j+1} - q^{h,j} &= h\, G(q^{h,j}) \nu^{h,\theta_j}. \end{aligned} \tag{15}$$

(More generally, we could use different θ-values in these two equations. For simplicity, we avoid this minor variation and use (15).) Since $s_{\mathrm{t,o}} = \dot{\delta}_{\mathrm{t,o}} + J\Psi_{\mathrm{t,o}}(q)\dot{q}$ by (8), we employ the following discrete-time approximation for the vector of tangential slip velocities $s_{\mathrm{t,o}}$:

$$s^{h,j+1}_{\mathrm{t,o}} = \frac{\delta^{h,j+1}_{\mathrm{t,o}} - \delta^{h,j}_{\mathrm{t,o}}}{h} + J\Psi_{\mathrm{t,o}}(q^{h,j}) \frac{q^{h,j+1} - q^{h,j}}{h} = \frac{\delta^{h,j+1}_{\mathrm{t,o}} - \delta^{h,j}_{\mathrm{t,o}}}{h} + \Gamma_{\mathrm{t,o}}(q^{h,j}) \nu^{h,\theta_j},$$

where we have used the discrete-time kinematics equation $q^{h,j+1} - q^{h,j} = hG(q^{h,j})\nu^{h,\theta_j}$ and the definition of $\Gamma_{\mathrm{t,o}}(q^{h,j}) \equiv J\Psi_{\mathrm{t,o}}(q^{h,j}) G(q^{h,j})$ to obtain the second equality. In deriving the discrete-time normal contact condition, we employ the first-order approximation

$$\Psi_{\mathrm{n}}(q(t+h)) \approx \Psi_{\mathrm{n}}(q(t)) + h\, J\Psi_{\mathrm{n}}(q(t))\, \dot{q}(t),$$

which holds for all $h > 0$ sufficiently small, and approximate $\dot{q}(t)$ similarly.

Putting together all the above approximations, we arrive at the following discrete-time frictional compliant contact problem: given $(q^0, \boldsymbol{\delta}^0)$ satisfying (12), compute (14) such that the conditions below are satisfied for all $j = 0, 1, \ldots, N_h$,

$$\begin{aligned}
&M(q^{h,j})(\,\nu^{h,j+1} - \nu^{h,j}\,) \,=\, h\,[\,f(t_{h,j+1}, q^{h,\theta_j}, \nu^{h,\theta_j}) + \boldsymbol{\Gamma}(q^{h,j})^T \boldsymbol{\lambda}^{h,j+1}],\\
&q^{h,j+1} - q^{h,j} \,=\, h\,G(q^{h,j})\nu^{h,\theta_j},\\
&\delta_{\rm t}^{h,j+1} - \delta_{\rm t}^{h,j} \,=\, h\,[s_{\rm t}^{h,j+1} - \Gamma_{\rm t}(q^{h,j})\nu^{h,\theta_j}\,],\\
&\delta_{\rm o}^{h,j+1} - \delta_{\rm o}^{h,j} \,=\, h\,[s_{\rm o}^{h,j+1} - \Gamma_{\rm o}(q^{h,j})\nu^{h,\theta_j}\,],\\
&0 \,\leq\, \lambda_{\rm n}^{h,j+1} \,\perp\, \Psi_{\rm n}(q^{h,j}) + h\,\Gamma_{\rm n}(q^{h,j})\nu^{h,\theta_j} + \delta_{\rm n}^{h,j+1} \,\geq\, 0,\\
&\boldsymbol{\lambda}^{h,j+1} \,=\, \mathbf{K}(q^{h,j})\boldsymbol{\delta}^{h,j+1} + \frac{\mathbf{C}(q^{h,j})}{h}\,(\,\boldsymbol{\delta}^{h,j+1} - \boldsymbol{\delta}^{h,j}\,),\\
&\begin{pmatrix} \lambda_{i\rm t}^{h,j+1} \\ \lambda_{i\rm o}^{h,j+1} \end{pmatrix} \in \underset{(\tilde{\lambda}_{i\rm t}, \tilde{\lambda}_{i\rm o}) \in \mathcal{F}(\mu_i\,\lambda_{i\rm n}^{h,j+1})}{\arg\min} \left\{ \begin{pmatrix} s_{i\rm t}^{h,j+1} \\ s_{i\rm o}^{h,j+1} \end{pmatrix}^T \begin{pmatrix} \tilde{\lambda}_{i\rm t} \\ \tilde{\lambda}_{i\rm o} \end{pmatrix} \right\},\\
&\\
&\mathbf{b} \,=\, \mathbf{M}_\nu \nu^{h,0} + \mathbf{N}\mathbf{x}^{h,N_h+1}, \quad \text{and} \quad (\,q^{h,0}, \boldsymbol{\delta}^{h,0}\,) \,=\, (\,q^0, \boldsymbol{\delta}^0\,).
\end{aligned} \tag{16}$$

The inclusion of the parameter θ in selected terms raises the question of why it is not used consistently throughout the constraints. An answer to this question can be traced to the paper [21], where the intention was to use a linear complementarity solver to solve the subproblems. As seen from the subsequent paper [19], excluding θ from the matrices $M(q^{h,j})$, $\boldsymbol{\Gamma}(q^{h,j})$, and $G(q^{h,j})$ simplifies the analysis significantly. The Ph.D. thesis [24] contains an analysis of a fully implicit time-stepping method for an initial-value rigid-body model, which leads to subproblems that are nonlinear complementarity problems. A computational comparison between a fully implicit scheme versus a semi-implicit scheme can be found in [25]. Presumably, the use of the parameter θ is to induce a higher order of convergence; yet such a goal is hard to substantiate formally. The analysis below does not address this issue of order of convergence.

Beginning in the next section, we will analyze two fundamental issues associated with the above discrete-time system: (a) the existence of a solution to each discrete-time boundary-value subproblem, and (b) the convergence of such a discrete-time trajectory to a weak solution of the frictional compliant contact problem. Part of the challenge in the convergence analysis lies in the coupled nature of the individual time-step subproblems, which are linked by the boundary equation $\mathbf{b} = \mathbf{M}_\nu \nu^{h,0} + \mathbf{N}\mathbf{x}^{h,N_h+1}$. Briefly, the analysis consists of two major tasks. First, we show that for an arbitrary triple $\mathbf{x}^{h,j}$, a unique friction triple $\boldsymbol{\lambda}^{h,j+1}$ exists that has some desirable continuity and boundedness properties, provided that the friction coefficients μ_i are sufficiently small. These properties of the friction forces allow us to apply an argument used in [11] for a class of boundary-value differential variational inequalities to complete the convergence analysis of the discrete-time trajectory as the time step tends to zero.

Naturally, there is an important computational issue associated with the above numerical scheme; namely, how can the discrete-time system (16) be efficiently solved in practice? The proof of Theorem 8 suggests a fixed-point method. Yet, specialized complementarity methods [8] may prove to be more effective. Nevertheless, there is presently no formal study on the applicability of the latter methods. The numerical experiments in [17] employed the complementarity solver PATH [7], which produced satisfactory results. Despite such practical experience, which is somewhat limited, there is an urgent need for the development of some robust algorithms for solving (16) along with a rigorous proof of applicability.

4. Preliminary analysis: Initial-value problems. The analysis in this section is best considered as one for an initial-value problem, where $\nu^{h,0}$, in addition to $(q^{h,0}, \boldsymbol{\delta}^{h,0})$, is assumed to be fixed but arbitrary. (This is the case where $\mathbf{M}_\nu$ is the identity matrix and $\mathbf{N}$ is the zero matrix.) This analysis will be the basis for extension to the boundary-value problem where $\nu^{h,0}$ has to be determined to satisfy the boundary equation defined by a more general pair of boundary matrices $(\mathbf{M}_\nu, \mathbf{N})$. As the first step in the convergence analysis, we show that the discrete-time dynamics and kinematics equations (15) have a unique solution $(q^{h,j+1}, \nu^{h,j+1})$ for any $(q^{h,j}, \nu^{h,j})$ and $\boldsymbol{\lambda}^{h,j+1}$; moreover, such a solution, for fixed $(q^{h,j}, \nu^{h,j})$, has several desirable properties in $\boldsymbol{\lambda}^{h,j+1}$.

PROPOSITION 3. *Under conditions* (A)–(C), *for any* $\theta \in [0,1]$, *positive constants* h_0, η_q, L_q, *and* σ_ν *exist such that for every tuple* $y \equiv (t, q^{\rm ref}, \nu^{\rm ref}) \in [0,T] \times \Re^{n_q+n_\nu}$ *and every* h *in* $(0, h_0]$, *a bounded continuous function* $(q^h(\cdot\,; y), \nu^h(\cdot\,; y)) : \Re^{n_\nu} \to \Re^{n_q+n_\nu}$ *exists satisfying the following properties:*

(a) *for every vector* $e \in \Re^{n_\nu}$, $(q^h(e;y), \nu^h(e;y))$ *is the unique pair* (q^h, ν^h) *satisfying*

$$M(q^{\rm ref})(\nu^h - \nu^{\rm ref}) = h[f(t, q^{\rm ref} + (1-\theta)(q^h - q^{\rm ref}), \nu^{\rm ref} + (1-\theta)(\nu^h - \nu^{\rm ref})) + e],$$
$$q^h - q^{\rm ref} = h\, G(q^{\rm ref})[\,\nu^{\rm ref} + (\,1-\theta\,)\,(\,\nu^h - \nu^{\rm ref}\,)\,];$$

moreover,

$$\|\, q^h - q^{\rm ref} \,\| + \|\, \nu^h - \nu^{\rm ref} \,\| \;\leq\; h\, \eta_q \,\left[\, 1 + \|\, q^{\rm ref} \,\| + \|\, \nu^{\rm ref} \,\| + \|\, e \,\| \,\right];$$

(b) $(q^h(\cdot\,; y), \nu^h(\cdot\,; y))$ *is Lipschitz continuous with constant* hL_q; *thus*

$$\|\, q^h(e^1; y) - q^h(e^2; y) \,\| + \|\, \nu^h(e^1; y) - \nu^h(e^2; y) \,\| \;\leq\; h\, L_q \,\|\, e^1 - e^2 \,\| \quad \forall\, e^1, e^2 \,\in\, \Re^{n_\nu};$$

(c) *the function* $\nu^h(\cdot\,; y) : \Re^{n_\nu} \to \Re^{n_\nu}$ *is strongly monotone with constant* $h\sigma_\nu$; *thus,*

$$(\, \nu^h(e^1; y) - \nu^h(e^2; y) \,)^T (\, e^1 - e^2 \,) \;\geq\; h\, \sigma_\nu \,\|\, e^1 - e^2 \,\|^2 \quad \forall\, e^1, e^2 \,\in\, \Re^{n_\nu}.$$

Proof. For a given vector $e \in \Re^{n_\nu}$, it is easily seen that the map

$$\begin{pmatrix} \nu \\ q \end{pmatrix} \mapsto \begin{pmatrix} \nu^{\rm ref} + hM(q^{\rm ref})^{-1}\,[f(t,\, q^{\rm ref} + (1-\theta)(q - q^{\rm ref}),\, \nu^{\rm ref} + (1-\theta)(\nu - \nu^{\rm ref})) + e] \\ q^{\rm ref} + hG(q^{\rm ref})[\nu^{\rm ref} + (1-\theta)(\nu - \nu^{\rm ref})] \end{pmatrix}$$

is a contraction with a modulus that can be made as small as we want by choosing $h > 0$ sufficiently small. Moreover, the constant h_0 depends only on the constants L_f, θ, η_G, and σ_M. Therefore, the above map has a unique fixed point, which yields the existence and uniqueness of the pair $(q^h(e;y), \nu^h(e;y))$. The proof of the bound on $\|q^h - q^{\rm ref}\| + \|\, \nu^h - \nu^{\rm ref}\|$ is similar to that of (b); for this reason, we prove only the latter. For any two vectors e^1 and e^2, we have

$$\begin{aligned} &\|\, \nu^h(e^1; y) - \nu^h(e^2; y) \,\| \\ &\leq \frac{h}{\sigma_M}\,[\, L_f\,(\,1-\theta\,)\,(\, \|q^h(e^1; y) - q^h(e^2; y)\| + \|\nu^h(e^1; y) - \nu^h(e^2; y)\| \,) + \|e^1 - e^2\| \,] \\ &\leq \frac{h}{\sigma_M}\,[\, L_f\,(\,1-\theta\,)\,(\,1 + h\,(\,1-\theta\,)\,\eta_G\,)\,\|\, \nu^h(e^1; y) - \nu^h(e^2; y) \,\|\,) + \|e^1 - e^2\| \,], \end{aligned}$$

which implies

$$\| \, \nu^h(e^1;y) - \nu^h(e^2;y) \, \| \; \leq \; \frac{h \, \sigma_{_M}^{-1} \, \| \, e^1 - e^2 \, \|}{1 - h \, \sigma_{_M}^{-1} \, [\, L_f \, (\, 1 - \theta \,) \, (\, 1 + h \, (\, 1 - \theta \,) \, \eta_{_G} \,) \,]}.$$

Hence,

$$\| \, q^h(e^1;y) - q^h(e^2;y) \, \| \; \leq \; \frac{h^2 \, (\, 1 - \theta \,) \, \eta_{_G} \, \sigma_{_M}^{-1} \, \| \, e^1 - e^2 \, \|}{1 - h \, \sigma_{_M}^{-1} \, [\, L_f \, (\, 1 - \theta \,) \, (\, 1 + h \, (\, 1 - \theta \,) \, \eta_{_G} \,) \,]},$$

establishing the desired Lipschitz continuity of $(q^h(\cdot;y), \nu^h(\cdot;y))$. To prove (c), note that

$$\begin{aligned} &\sigma_{_M} \, \| \, \nu^h(e^1;y) - \nu^h(e^2;y) \, \|^2 \; \leq \; h \, (\, \nu^h(e^1;y) - \nu^h(e^2;y) \,)^T (\, e^1 - e^2 \,) \\ &+ h L_f (1-\theta) \, \| \nu^h(e^1;y) - \nu^h(e^2;y) \| (\| q^h(e^1;y) - q^h(e^2;y) \| + \| \nu^h(e^1;y) - \nu^h(e^2;y) \|), \end{aligned}$$

which yields

$$\begin{aligned} &(\, \nu^h(e^1;y) - \nu^h(e^2;y) \,)^T (\, e^1 - e^2 \,) \\ &\qquad \geq \; \frac{[\, \sigma_{_M} - h \, L_f \, (\, 1 - \theta \,) \, (\, 1 + h \, (\, 1 - \theta \,) \, \eta_{_G} \,) \,]}{h} \, \| \, \nu^h(e^1;y) - \nu^h(e^2;y) \, \|^2. \end{aligned}$$

Furthermore,

$$\begin{aligned} h \, \| \, e^1 - e^2 \, \| \quad &\leq \quad \eta_{_M} \, \| \, \nu^h(e^1;y) - \nu^h(e^2;y) \, \| \\ &\qquad + h \, L_f \, (\, 1 - \theta \,) \, (\| q^h(e^1;y) - q^h(e^2;y) \| + \| \nu^h(e^1;y) - \nu^h(e^2;y) \|) \\ &\leq \quad [\, \eta_{_M} + h \, L_f \, (\, 1 - \theta \,) \, (\, 1 + h \, (\, 1 - \theta \,) \, \eta_{_G} \,) \,] \, \| \, \nu^h(e^1;y) - \nu^h(e^2;y) \|, \end{aligned}$$

which implies

$$\| \, \nu^h(e^1;y) - \nu^h(e^2;y) \| \; \geq \; \frac{h \, \| \, e^1 - e^2 \, \|}{\eta_{_M} + h \, L_f \, (\, 1 - \theta \,) \, (\, 1 + h \, (\, 1 - \theta \,) \, \eta_{_G} \,)}.$$

Consequently,

$$(\nu^h(e^1;y) - \nu^h(e^2;y))^T (e^1 - e^2) \geq \frac{h \, [\, \sigma_{_M} - h L_f (1-\theta) \, (1 + h(1-\theta)\eta_{_G}) \,] \, \| e^1 - e^2 \|^2}{\eta_{_M} + h L_f (1-\theta) \, (1 + h(1-\theta)\eta_{_G})},$$

which establishes the desired strong monotonicity of $\nu^h(\cdot;y)$. □

From the discrete-time compliance equation

$$\boldsymbol{\lambda}^{h,j+1} \; = \; \mathbf{K}(q^{h,j}) \boldsymbol{\delta}^{h,j+1} + \frac{\mathbf{C}(q^{h,j})}{h} \, (\, \boldsymbol{\delta}^{h,j+1} - \boldsymbol{\delta}^{h,j} \,),$$

we deduce

$$(17) \qquad \boldsymbol{\delta}^{h,j+1} - \boldsymbol{\delta}^{h,j} \; = \; h \, [\, h \, \mathbf{K}(q^{h,j}) + \mathbf{C}(q^{h,j}) \,]^{-1} \, [\, \boldsymbol{\lambda}^{h,j+1} - \mathbf{K}(q^{h,j}) \boldsymbol{\delta}^{h,j} \,].$$

Considering the expression in the normal direction,

$$\Psi_{\rm n}(q^{h,j}) + h \Gamma_{\rm n}(q^{h,j}) \nu^{h,\theta_j} + \delta_{\rm n}^{h,j+1} = \Psi_{\rm n}(q^{h,j}) + h \Gamma_{\rm n}(q^{h,j}) \nu^{h,\theta_j} + \delta_{\rm n}^{h,j} + \delta_{\rm n}^{h,j+1} - \delta_{\rm n}^{h,j},$$

we define the discrete-time normal slip velocity,

$$s_{\mathrm{n}}^{h,j+1} \equiv \frac{\delta_{\mathrm{n}}^{h,j+1} - \delta_{\mathrm{n}}^{h,j}}{h} + \Gamma_{\mathrm{n}}(q^{h,j})\,\nu^{h,\theta_j},$$

which is consistent with the corresponding expressions for the discrete-time tangential velocities $s_{\mathrm{t,o}}^{h,j+1}$. Writing $\mathbf{s} \equiv s_{\mathrm{n,t,o}}$, we have

$$\begin{aligned}\mathbf{s}^{h,j+1} &= \frac{\boldsymbol{\delta}^{h,j+1} - \boldsymbol{\delta}^{h,j}}{h} + \boldsymbol{\Gamma}(q^{h,j})\,[\,\theta\,\nu^{h,j} + (\,1-\theta\,)\,\nu^{h,j+1}\,] \\ &= [\,h\mathbf{K}(q^{h,j}) + \mathbf{C}(q^{h,j})\,]^{-1}[\,\boldsymbol{\lambda}^{h,j+1} - \mathbf{K}(q^{h,j})\boldsymbol{\delta}^{h,j}\,] \\ &\quad + \boldsymbol{\Gamma}(q^{h,j})\nu^{h,j} + (1-\theta)\boldsymbol{\Gamma}(q^{h,j})(\nu^{h,j+1} - \nu^{h,j}).\end{aligned}$$

In view of the latter expression, we define, for fixed $\mathbf{y}^{\mathrm{ref}} = (t, q^{\mathrm{ref}}, \nu^{\mathrm{ref}}, \boldsymbol{\delta}^{\mathrm{ref}})$, the following function in $\boldsymbol{\lambda}$:

$$\begin{aligned}\mathbf{s}(\boldsymbol{\lambda};\mathbf{y}^{\mathrm{ref}}) \equiv{}& [\,h\,\mathbf{K}(q^{\mathrm{ref}}) + \mathbf{C}(q^{\mathrm{ref}})\,]^{-1}[\boldsymbol{\lambda} - \mathbf{K}(q^{\mathrm{ref}})\boldsymbol{\delta}^{\mathrm{ref}}\,] + \boldsymbol{\Gamma}(q^{\mathrm{ref}})\nu^{\mathrm{ref}} \\ &+ (\,1-\theta\,)\,\boldsymbol{\Gamma}(q^{\mathrm{ref}})\,[\,\nu^{h,\mathrm{ref}}(\boldsymbol{\Gamma}(q^{\mathrm{ref}})^T\boldsymbol{\lambda}) - \nu^{\mathrm{ref}}\,],\end{aligned}$$

where $\nu^{h,\mathrm{ref}}(r) \equiv \nu^h(r;(t,q^{\mathrm{ref}},\nu^{\mathrm{ref}}))$. Since $\nu^{h,\mathrm{ref}}$ is strongly monotone (albeit nonlinear), it follows that the map $\boldsymbol{\lambda} \mapsto \boldsymbol{\Gamma}(q^{\mathrm{ref}})\,\nu^{h,\mathrm{ref}}(\boldsymbol{\Gamma}(q^{\mathrm{ref}})^T\boldsymbol{\lambda})$ is monotone. Consequently, by assumption (D), we deduce

$$(\,\boldsymbol{\lambda} - \boldsymbol{\lambda}'\,)^T(\,\mathbf{s}(\boldsymbol{\lambda};\mathbf{y}^{\mathrm{ref}}) - \mathbf{s}(\boldsymbol{\lambda}';\mathbf{y}^{\mathrm{ref}})\,) \ge \sigma_{KC}\,\|\,\boldsymbol{\lambda} - \boldsymbol{\lambda}'\,\|^2, \quad \forall\,\boldsymbol{\lambda},\boldsymbol{\lambda}' \in \Re^{3n_\delta};$$

that is, the function $\mathbf{s}(\cdot;\mathbf{y}^{\mathrm{ref}})$ is strongly monotone with a modulus that is independent of $\mathbf{y}^{\mathrm{ref}}$. Moreover, $\mathbf{s}(\cdot;\mathbf{y}^{\mathrm{ref}})$ is Lipschitz continuous with a modulus that is also independent of $\mathbf{y}^{\mathrm{ref}}$; indeed, by assumption (D) and part (b) of Proposition 3, we have

$$\|\,\mathbf{s}(\boldsymbol{\lambda};\mathbf{y}^{\mathrm{ref}}) - \mathbf{s}(\boldsymbol{\lambda}';\mathbf{y}^{\mathrm{ref}})\,\| \le [\,\eta_{KC} + h\,L_q\,(\,1-\theta\,)\,\eta_W^2\,]\,\|\,\boldsymbol{\lambda} - \boldsymbol{\lambda}'\,\| \quad \forall\,\boldsymbol{\lambda},\boldsymbol{\lambda}' \in \Re^{3n_\delta}.$$

Furthermore,

$$\mathbf{s}(0;\mathbf{y}^{\mathrm{ref}}) = -[\,h\mathbf{K}(q^{\mathrm{ref}}) + \mathbf{C}(q^{\mathrm{ref}})\,]^{-1}\mathbf{K}(q^{\mathrm{ref}})\boldsymbol{\delta}^{\mathrm{ref}} + \theta\,\boldsymbol{\Gamma}(q^{\mathrm{ref}})\nu^{\mathrm{ref}} + (1-\theta)\,\boldsymbol{\Gamma}(q^{\mathrm{ref}})\,\nu^{h,\mathrm{ref}}(0).$$

From part (a) of Proposition 3, we obtain

$$\|\,\nu^{h,\mathrm{ref}}(0)\,\| \le \|\,\nu^{\mathrm{ref}}\,\| + h\,\eta_q\,[\,1 + \|\,q^{\mathrm{ref}}\,\| + \|\,\nu^{\mathrm{ref}}\,\|\,].$$

Consequently, we deduce that a constant $c_s > 0$ exists such that

$$\|\,\mathbf{s}(0;\mathbf{y}^{\mathrm{ref}})\,\| \le c_s\,[\,1 + \|\,q^{\mathrm{ref}}\,\| + \|\,\nu^{\mathrm{ref}}\,\| + \|\,\boldsymbol{\delta}^{\mathrm{ref}}\,\|\,] \quad \forall\,\mathbf{y}^{\mathrm{ref}} \equiv (\,t, q^{\mathrm{ref}}, \nu^{\mathrm{ref}}, \boldsymbol{\delta}^{\mathrm{ref}}\,). \tag{18}$$

This inequality will be used later; see Lemma 4. It is important to remark that the above constant c_s and the strong modulus and the Lipschitz constant of the function $\mathbf{s}(\cdot;\mathbf{y}^{\mathrm{ref}})$ are all independent of $\mathbf{y}^{\mathrm{ref}}$ and of $h > 0$, provided that the latter is sufficiently small.

In terms of the function $\mathbf{s}(\cdot;\mathbf{y}^{h,j})$, where $\mathbf{y}^{h,j} \equiv (t_{h,j+1}, \mathbf{x}^{h,j})$, the discrete frictional compliant contact problem at time step $t_{h,j+1}$, without the boundary condition, can be stated simply as the quasi-variational inequality of finding a triple $\boldsymbol{\lambda} \equiv \lambda_{\mathrm{n,t,o}} \in \Re^{3n_\delta}$ such that

$$0 \le \lambda_{\mathrm{n}} \perp \frac{\Psi_{\mathrm{n}}(q^{h,j}) + \delta_{\mathrm{n}}^{h,j}}{h} + s_{\mathrm{n}}(\boldsymbol{\lambda};\mathbf{y}^{h,j}) \ge 0$$

and for all $i = 1, \ldots, n_\delta$,

$$(\,\lambda_{it}, \lambda_{io}\,) \,\in\, \operatorname{argmin}\,\left\{\, s_{it}(\boldsymbol{\lambda}; \mathbf{y}^{h,j})\tilde{\lambda}_{it} + s_{io}(\boldsymbol{\lambda}; \mathbf{y}^{h,j})\tilde{\lambda}_{io} \,:\, (\,\tilde{\lambda}_{it}, \tilde{\lambda}_{io}\,) \,\in\, \mathcal{F}(\mu_i\,\lambda_{in})\,\right\}.$$

We state and prove a lemma pertaining to the above contact and friction conditions. This lemma is the key to the entire convergence analysis of the time-stepping method.

LEMMA 4. *Let $\mathbf{s}(\boldsymbol{\lambda}; \mathbf{y})$ be a continuous function that is Lipschitz continuous and strongly monotone in $\boldsymbol{\lambda} \in \Re^{3n_\delta}$ uniformly in $\mathbf{y} \in \Re^m$; i.e., positive constants η_s and σ_s exist such that for all $\boldsymbol{\lambda}$ and $\boldsymbol{\lambda}'$ and $\mathbf{y}$,*

$$(\boldsymbol{\lambda} - \boldsymbol{\lambda}')^T(\,\mathbf{s}(\boldsymbol{\lambda}; \mathbf{y}) - \mathbf{s}(\boldsymbol{\lambda}'; \mathbf{y})\,) \geq \sigma_s\,\|\boldsymbol{\lambda} - \boldsymbol{\lambda}'\|^2 \;\; \textit{and} \;\; \|\mathbf{s}(\boldsymbol{\lambda}; \mathbf{y}) - \mathbf{s}(\boldsymbol{\lambda}'; \mathbf{y})\| \leq \eta_s\,\|\boldsymbol{\lambda} - \boldsymbol{\lambda}'\|.$$

Suppose further that a constant $c_s > 0$ exists such that $\|\mathbf{s}(0; \mathbf{y})\| \leq c_s\|\mathbf{y}\|$ for all $\mathbf{y} \in \Re^m$. There exists a positive scalar $\bar{\mu} > 0$ such that for every vector $\mu > 0$ satisfying $\max_{1 \leq i \leq n_\delta} \mu_i \leq \bar{\mu}$, a continuous function $\boldsymbol{\lambda}^\mu : \Re^m \to \Re^{3n_\delta}$ exists such that for every parameter $\mathbf{y}$, $\boldsymbol{\lambda}^\mu(\mathbf{y})$ is the unique triple $\lambda_{\mathrm{n,t,o}}$ satisfying

$$0 \,\leq\, \lambda_{\mathrm{n}} \,\perp\, s_{\mathrm{n}}(\lambda_{\mathrm{n,t,o}}; \mathbf{y}) \,\geq\, 0,$$

and, for every $i = 1, \ldots, n_\delta$,

$$\begin{pmatrix} \lambda_{it} \\ \lambda_{io} \end{pmatrix} \in \underset{(\tilde{\lambda}_{it}, \tilde{\lambda}_{io}) \in \mathcal{F}(\mu_i\,\lambda_{i\mathrm{n}})}{\arg\min} \left\{ \begin{pmatrix} \tilde{\lambda}_{it} \\ \tilde{\lambda}_{io} \end{pmatrix}^T \begin{pmatrix} s_{it}(\lambda_{\mathrm{n,t,o}}; \mathbf{y}) \\ s_{io}(\lambda_{\mathrm{n,t,o}}; \mathbf{y}) \end{pmatrix} \right\}.$$

Proof. There are several things to be proved: the existence of the scalar $\bar{\mu}$ and the existence, uniqueness, and continuity of $\lambda^\mu_{\mathrm{n,t,o}}(\mathbf{y})$ for all $\mu > 0$ as specified. Indeed, the existence of a triple $\boldsymbol{\lambda}$ satisfying the above friction conditions for every $\mu > 0$ is proved by invoking a general result from the theory of quasi-variational inequalities [8, Corollary 2.8.4], as done in several previous references, such as [12]. In what follows, we show the uniqueness of such a solution for all $\mu > 0$ sufficiently small.

Suppose that $\lambda^1_{\mathrm{n,t,o}}$ and $\lambda^2_{\mathrm{n,t,o}}$ are two solutions corresponding to a given $\mathbf{y}$. Write, for $j = 1, 2$, $s^j_{\mathrm{n,t,o}} \equiv s_{\mathrm{n,t,o}}(\lambda^j_{\mathrm{n,t,o}}; \mathbf{y})$. We may write, for every i,

$$s^j_{i\mathrm{t}} \,\equiv\, r^j_i\,\cos\psi^j_i \quad \text{and} \quad s^j_{i\mathrm{o}} \,\equiv\, r^j_i\,\sin\psi^j_i,$$

where $r^j_i \equiv \sqrt{(s^j_{i\mathrm{t}})^2 + (s^j_{i\mathrm{o}})^2}$. It then follows that $\phi^j_i \in [-1, 1]$ exist satisfying

$$r^j_i \,>\, 0 \,\Rightarrow\, \phi^j_i \,=\, 1 \tag{19}$$

(ϕ^j_i is not necessarily equal to 1 when $r^j_i = 0$) and

$$\lambda^j_{i\mathrm{t}} \,=\, -\mu_i\,\lambda^j_{i\mathrm{n}}\,\phi^j_i\,\cos\psi^j_i \quad \text{and} \quad \lambda^j_{i\mathrm{o}} \,=\, -\mu_i\,\lambda^j_{i\mathrm{n}}\,\phi^j_i\,\sin\psi^j_i.$$

We have

$$\begin{aligned} \lambda^1_{i\mathrm{t}} - \lambda^2_{i\mathrm{t}} &= -\mu_i\,\lambda^1_{i\mathrm{n}}\,\phi^1_i\,\cos\psi^1_i + \mu_i\,\lambda^2_{i\mathrm{n}}\,\phi^2_i\,\cos\psi^2_i \\ &= -(\,\mu_i\,\phi^1_i\,\cos\psi^1_i\,)\,(\,\lambda^1_{i\mathrm{n}} - \lambda^2_{i\mathrm{n}}\,) + \mu_i\,\lambda^2_{i\mathrm{n}}\,(\,\phi^2_i\,\cos\psi^2_i - \phi^1_i\,\cos\psi^1_i\,). \end{aligned}$$

Similarly,

$$\lambda^1_{i\mathrm{o}} - \lambda^2_{i\mathrm{o}} \;=\; -(\,\mu_i\,\phi^1_i\,\sin\psi^1_i\,)\,(\,\lambda^1_{i\mathrm{n}} - \lambda^2_{i\mathrm{n}}\,) + \mu_i\,\lambda^2_{i\mathrm{n}}\,(\,\phi^2_i\,\sin\psi^2_i - \phi^1_i\,\sin\psi^1_i\,).$$

Therefore, letting D_t and D_o be the diagonal matrices whose diagonal entries are $-\mu_i\phi^1_i\cos\psi^1_i$ and $-\mu_i\phi^1_i\sin\psi^1_i$, respectively, we can write

$$\begin{aligned}\lambda^1_\mathrm{t} - \lambda^2_\mathrm{t} &= D_t(\,\lambda^1_\mathrm{n} - \lambda^2_\mathrm{n}\,) + \mu\,\lambda^2_\mathrm{n}\,(\,\phi^2\cos\psi^2 - \phi^1\cos\psi^1\,),\\ \lambda^1_\mathrm{o} - \lambda^2_\mathrm{o} &= D_o(\,\lambda^1_\mathrm{n} - \lambda^2_\mathrm{n}\,) + \mu\,\lambda^2_\mathrm{n}\,(\,\phi^2\sin\psi^2 - \phi^1\sin\psi^1\,),\end{aligned}$$

where the notation in the second terms in the right-hand side of the above equations has an obvious componentwise meaning. Consequently,

$$\begin{pmatrix}\lambda^1_\mathrm{n} - \lambda^2_\mathrm{n}\\ \lambda^1_\mathrm{t} - \lambda^2_\mathrm{t}\\ \lambda^1_\mathrm{o} - \lambda^2_\mathrm{o}\end{pmatrix} = \begin{bmatrix} I & 0 & 0\\ D_t & I & 0\\ D_o & 0 & I\end{bmatrix}\begin{pmatrix}\lambda^1_\mathrm{n} - \lambda^2_\mathrm{n}\\ \mu\,\lambda^2_\mathrm{n}\,(\phi^2\cos\psi^2 - \phi^1\cos\psi^1)\\ \mu\,\lambda^2_\mathrm{n}\,(\phi^2\sin\psi^2 - \phi^1\sin\psi^1)\end{pmatrix}$$

or, equivalently,

$$\begin{aligned}\begin{pmatrix}\lambda^1_\mathrm{n} - \lambda^2_\mathrm{n}\\ \mu\lambda^2_\mathrm{n}(\phi^2\cos\psi^2 - \phi^1\cos\psi^1)\\ \mu\lambda^2_\mathrm{n}(\phi^2\sin\psi^2 - \phi^1\sin\psi^1)\end{pmatrix} &= \begin{bmatrix} I & 0 & 0\\ D_t & I & 0\\ D_o & 0 & I\end{bmatrix}^{-1}\begin{pmatrix}\lambda^1_\mathrm{n} - \lambda^2_\mathrm{n}\\ \lambda^1_\mathrm{t} - \lambda^2_\mathrm{t}\\ \lambda^1_\mathrm{o} - \lambda^2_\mathrm{o}\end{pmatrix}\\ &= \begin{bmatrix} I & 0 & 0\\ -D_t & I & 0\\ -D_o & 0 & I\end{bmatrix}\begin{pmatrix}\lambda^1_\mathrm{n} - \lambda^2_\mathrm{n}\\ \lambda^1_\mathrm{t} - \lambda^2_\mathrm{t}\\ \lambda^1_\mathrm{o} - \lambda^2_\mathrm{o}\end{pmatrix}.\end{aligned}$$

Writing

$$\mathbf{D}(\mu) \;\equiv\; \begin{bmatrix} I & 0 & 0\\ -D_t & I & 0\\ -D_o & 0 & I\end{bmatrix},$$

we claim that positive constants σ'_s and $\bar\mu$ exist such that for all $\mu > 0$ satisfying $\max\limits_{1\le i\le n_\delta}\mu_i \le \bar\mu$,

$$(\,\mathbf{D}(\mu)\boldsymbol{\lambda} - \mathbf{D}(\mu)\boldsymbol{\lambda}'\,)^T(\,\mathbf{s}(\boldsymbol{\lambda};\mathbf{y}) - \mathbf{s}(\boldsymbol{\lambda}';\mathbf{y})\,) \;\ge\; \sigma'_s\,\|\,\boldsymbol{\lambda} - \boldsymbol{\lambda}'\,\|^2$$

for all $\boldsymbol{\lambda}$ and $\boldsymbol{\lambda}'$. To establish the claim, we write

$$\begin{aligned}&(\,\mathbf{D}(\mu)\boldsymbol{\lambda} - \mathbf{D}(\mu)\boldsymbol{\lambda}'\,)^T(\,\mathbf{s}(\boldsymbol{\lambda};\mathbf{y}) - \mathbf{s}(\boldsymbol{\lambda}';\mathbf{y})\,)\\ &\quad= (\,\boldsymbol{\lambda} - \boldsymbol{\lambda}'\,)^T(\,\mathbf{s}(\boldsymbol{\lambda};\mathbf{y}) - \mathbf{s}(\boldsymbol{\lambda}';\mathbf{y})\,) - [\,(\,I - \mathbf{D}(\mu)\,)\,(\,\boldsymbol{\lambda} - \boldsymbol{\lambda}'\,)\,]^T(\,\mathbf{s}(\boldsymbol{\lambda};\mathbf{y}) - \mathbf{s}(\boldsymbol{\lambda}';\mathbf{y})\,)\\ &\quad\ge [\,\sigma_s - \eta_s\,\|\,I - \mathbf{D}(\mu)\,\|\,]\,\|\,\boldsymbol{\lambda} - \boldsymbol{\lambda}'\,\|^2;\end{aligned}$$

clearly, we can choose $\bar\mu > 0$ sufficiently small such that for all $\mu > 0$ satisfying $\max\limits_{1\le i\le n_\delta}\mu_i \le \bar\mu$, we have $\sigma_s - \eta_s\|I - \mathbf{D}(\mu)\| \ge \frac{1}{2}\sigma_s \equiv \sigma'_s$. This establishes the claim. Next, we show that

$$0 \;\ge\; (\,\mathbf{D}(\mu)\boldsymbol{\lambda}^1 - \mathbf{D}(\mu)\boldsymbol{\lambda}^2\,)^T(\,\mathbf{s}(\boldsymbol{\lambda}^1;\mathbf{y}) - \mathbf{s}(\boldsymbol{\lambda}^2;\mathbf{y})\,). \tag{20}$$

The right-hand side of the above inequality is equal to

$$\left(\begin{array}{c} \lambda_{\rm n}^1 - \lambda_{\rm n}^2 \\ \mu\,\lambda_{\rm n}^2\,(\phi^2\cos\psi^2 - \phi^1\cos\psi^1) \\ \mu\,\lambda_{\rm n}^2\,(\phi^2\sin\psi^2 - \phi^1\sin\psi^1) \end{array} \right)^T \left(\begin{array}{c} s_{\rm n}^1 - s_{\rm n}^2 \\ s_{\rm t}^1 - s_{\rm t}^2 \\ s_{\rm o}^1 - s_{\rm o}^2 \end{array} \right).$$

By complementarity, we have $(\lambda_{\rm n}^1 - \lambda_{\rm n}^2)^T(s_{\rm n}^1 - s_{\rm n}^2) \leq 0$. Furthermore,

$$\begin{aligned} & (\,\phi_i^2\cos\psi_i^2 - \phi_i^1\cos\psi_i^1\,)\,(\,s_{i\rm t}^1 - s_{i\rm t}^2\,) + (\,\phi_i^2\sin\psi_i^2 - \phi_i^1\sin\psi_i^1\,)\,(\,s_{i\rm o}^1 - s_{i\rm o}^2\,) \\ =\ & (\,\phi_i^2\cos\psi_i^2 - \phi_i^1\cos\psi_i^1\,)\,(\,r_i^1\,\cos\psi_i^1 - r_i^2\,\cos\psi_i^2\,) \\ & \quad + (\,\phi_i^2\sin\psi_i^2 - \phi_i^1\sin\psi_i^1\,)\,(\,r_i^1\,\sin\psi_i^1 - r_i^2\,\sin\psi_i^2\,) \\ =\ & -r_i^1\,\phi_i^1 - r_i^2\,\phi_i^2 + (\,r_i^1\,\phi_i^2 + r_i^2\,\phi_i^1\,)\cos(\psi_i^1 - \psi_i^2\,) \\ =\ & -r_i^1 - r_i^2 + (\,r_i^1\,\phi_i^2 + r_i^2\,\phi_i^1\,)\cos(\psi_i^1 - \psi_i^2\,)\ \leq\ 0, \end{aligned}$$

where the last equality follows from (19) and the last inequality holds because $|\phi_j^{1,2}| \leq 1$. Consequently, the inequality (20) holds. In turn, this implies that $\lambda_{\rm n,t,o}^1 = \lambda_{\rm n,t,o}^2$. This establishes the uniqueness of $\boldsymbol{\lambda}^\mu(x)$ for all $\mu > 0$ sufficiently small.

In the rest of the proof, we fix an arbitrary $\mu > 0$ sufficiently small and drop the superscript μ in $\boldsymbol{\lambda}^\mu$. To show the continuity of $\lambda_{\rm n,t,o}(\mathbf{y})$, we first derive a bound for $\|\lambda_{\rm n,t,o}(\mathbf{y})\|$. We have

$$\begin{aligned} 0 \quad & \geq \quad \boldsymbol{\lambda}(\mathbf{y})^T\mathbf{s}(\boldsymbol{\lambda}(\mathbf{y});\mathbf{y})\ =\ \boldsymbol{\lambda}(\mathbf{y})^T(\,\mathbf{s}(\boldsymbol{\lambda}(\mathbf{y});\mathbf{y}) - \mathbf{s}(0;\mathbf{y})\,) + \boldsymbol{\lambda}(\mathbf{y})^T\mathbf{s}(0;\mathbf{y}) \\ & \geq \quad \sigma_s\,\|\,\boldsymbol{\lambda}(\mathbf{y})\,\|^2 - c_s\,\|\,\boldsymbol{\lambda}(\mathbf{y})\,\|\,\|\,\mathbf{y}\,\|, \end{aligned}$$

which implies $\|\boldsymbol{\lambda}(\mathbf{y})\| \leq c_s\|\mathbf{y}\|$. Let $\{\mathbf{y}^k\}$ be a sequence of parameters converging to $\mathbf{y}^\infty$. Write $\lambda_{\rm n,t,o}^k \equiv \lambda_{\rm n,t,o}(\mathbf{y}^k)$. Since the sequence $\{\lambda_{\rm n,t,o}^k\}$ is bounded, by what has just been shown, let $\lambda_{\rm n,t,o}^\infty$ be the limit of a convergent subsequence $\{\lambda_{\rm n,t,o}^k : k \in \kappa\}$, where κ is an infinite subset of $\{1, 2, \dots\}$. It suffices to show that $\lambda_{\rm n,t,o}^\infty$ is a solution to the limiting system

$$0\ \leq\ \lambda_{\rm n}^\infty\ \perp\ s_{\rm n}(\lambda_{\rm n,t,o}^\infty;\mathbf{y}^\infty)\ \geq\ 0 \tag{21}$$

and

$$\left(\begin{array}{c} \lambda_{i\rm t}^\infty \\ \lambda_{i\rm o}^\infty \end{array} \right) \in \underset{(\tilde{\lambda}_{it},\tilde{\lambda}_{io})\in\mathcal{F}(\mu_i\,\lambda_{i\rm n}^\infty)}{\arg\min} \left\{ \left(\begin{array}{c} \tilde{\lambda}_{it} \\ \tilde{\lambda}_{io} \end{array} \right)^T \left(\begin{array}{c} s_{it}(\lambda_{\rm n,t,o}^\infty;\mathbf{y}^\infty) \\ s_{io}(\lambda_{\rm n,t,o}^\infty;\mathbf{y}^\infty) \end{array} \right) \right\}.$$

Since $0 \leq \lambda_{\rm n}^k \perp s_{\rm n}(\boldsymbol{\lambda}^k;\mathbf{y}^k) \geq 0$ for all k, passing to the limit $k(\in\kappa) \to \infty$ yields (21). Similarly, since $(\lambda_{i\rm t}^k)^2 + (\lambda_{i\rm o}^k)^2 \leq \mu_i^2(\lambda_{i\rm n}^k)^2$ for all k, we deduce $(\lambda_{i\rm t}^\infty, \lambda_{i\rm o}^\infty) \in \mathcal{F}(\mu_i\lambda_{i\rm n}^\infty)$. Moreover, since

$$\lambda_{i\rm t}^k\,s_{i\rm t}(\boldsymbol{\lambda}^k;\mathbf{y}^k) + \lambda_{i\rm o}^k\,s_{i\rm o}(\boldsymbol{\lambda}^k;\mathbf{y}^k)\ =\ -\mu_i\,\lambda_{i\rm n}^k\,\sqrt{s_{i\rm t}(\boldsymbol{\lambda}^k;\mathbf{y}^k)^2 + s_{i\rm o}(\boldsymbol{\lambda}^k;\mathbf{y}^k)^2},$$

passing to the limit $k(\in\kappa) \to \infty$ easily completes the proof. □

Applying Lemma 4 to the friction and contact conditions, we conclude that for all $h > 0$ and sufficiently small and for all $\mu > 0$ not exceeding a certain upper bound $\bar{\mu}$, for a given triple $\mathbf{x}^{h,j} \equiv (q^{h,j}, \nu^{h,j}, \boldsymbol{\delta}^{h,j})$, a unique friction force triple $\lambda_{\rm n,t,o}^{h,j+1}$ exists at time step $t_{h,j+1}$ that is a continuous function of $\mathbf{x}^{h,j}$. In what follows, we derive a bound on $\|\boldsymbol{\lambda}^{h,j+1}\|$ that takes advantage of the normal contact condition at time step j. This improved bound is important for the subsequent analysis. (A straightforward application of the previous lemma would yield a bound of the order $1/h$, which tends to infinity as $h \downarrow 0$, and thus is not effective for small h. The bound obtained below stays finite as h tends to zero, as shown subsequently.)

LEMMA 5. *Let $\boldsymbol{\lambda}^{h,j+1}$ satisfy*

$$0 \,\le\, \lambda_{\rm n}^{h,j+1} \,\perp\, \frac{\Psi_{\rm n}(q^{h,j}) + \delta_{\rm n}^{h,j}}{h} + s_{\rm n}(\boldsymbol{\lambda}^{h,j+1};\mathbf{y}^{h,j}) \,\ge\, 0$$

and for all $i = 1, \dots, n_\delta$,

$$(\lambda_{it}^{h,j+1}, \lambda_{io}^{h,j+1}) \in \underset{(\tilde\lambda_{it},\tilde\lambda_{io})\in\mathcal{F}(\mu_i\lambda_{in}^{h,j+1})}{\arg\min} \left\{ s_{it}(\boldsymbol{\lambda}^{h,j+1};\mathbf{y}^{h,j})\tilde\lambda_{it} + s_{io}(\boldsymbol{\lambda}^{h,j+1};\mathbf{y}^{h,j})\tilde\lambda_{io} \right\}.$$

A constant $\eta_\lambda > 0$, which depends only the model functions, exists such that

$$\|\boldsymbol{\lambda}^{h,j+1}\| \,\le\, \eta_\lambda \left[\frac{\|\min(\,0, \Psi_{\rm n}(q^{h,j}) + \delta_{\rm n}^{h,j}\,)\,\|}{h} + 1 + \|\mathbf{x}^{h,j}\| \right].$$

Proof. As in the proof of Lemma 4, we have

$$\begin{aligned} 0 \,&\ge\, (\,\lambda_{\rm n}^{h,j+1}\,)^T \frac{\Psi_{\rm n}(q^{h,j}) + \delta_{\rm n}^{h,j}}{h} + (\,\boldsymbol{\lambda}^{h,j+1}\,)^T \mathbf{s}(\boldsymbol{\lambda}^{h,j+1};\mathbf{y}^{h,j}) \\ &\ge\, (\,\lambda_{\rm n}^{h,j+1}\,)^T \frac{\Psi_{\rm n}(q^{h,j}) + \delta_{\rm n}^{h,j}}{h} + \|\,\boldsymbol{\lambda}^{h,j+1}\,\|^2 - c_s\,\|\,\boldsymbol{\lambda}^{h,j+1}\,\|\,[\,1 + \|\,\mathbf{x}^{h,j}\,\|\,] \\ &\ge\, (\,\lambda_{\rm n}^{h,j+1}\,)^T \min\left(0,\, \frac{\Psi_{\rm n}(q^{h,j}) + \delta_{\rm n}^{h,j}}{h}\right) + \|\,\boldsymbol{\lambda}^{h,j+1}\,\|^2 - c_s\,\|\,\boldsymbol{\lambda}^{h,j+1}\,\|\,[\,1 + \|\,\mathbf{x}^{h,j}\,\|\,], \end{aligned}$$

where the last inequality holds because $\lambda_{\rm n}^{h,j+1} \ge 0$. Consequently, the desired bound on $\|\boldsymbol{\lambda}^{h,j+1}\|$ follows easily by rearranging terms and then applying the Cauchy–Schwartz inequality. □

Combining Proposition 3 and Lemmas 4 and 5, we obtain the following result, which brings us one step closer to the main existence and uniqueness for the discrete-time boundary value problem.

PROPOSITION 6. *Under conditions* (A)–(D)*, positive scalars $\bar\mu$, h_0, and η_x exist such that for every vector $\mu > 0$ satisfying $\max\limits_{1\le i\le n_\delta} \mu_i \le \bar\mu$, every scalar $h \in (0, h_0]$, and every tuple $(q^{h,0}, \nu^{h,0}, \boldsymbol{\delta}^{h,0})$, a unique discrete-time trajectory* (14) *exists satisfying* (16) *for every $j = 0, 1, \dots, N_h$ but not necessarily* (13)*; moreover,*

$$\|\,\mathbf{x}^{h,j+1} - \mathbf{x}^{h,j}\,\| \,\le\, h\,\eta_x\,[\,1 + \|\,\mathbf{x}^{h,j}\,\| + \|\,\boldsymbol{\lambda}^{h,j+1}\,\|\,]. \tag{22}$$

Finally, if $\Psi_{\rm n}(q^{h,0}) + \delta_{\rm n}^{h,0} \ge 0$, then, for any scalar $c_q > 0$, the implication below holds for all $j = 0, 1, \dots, N_h$, where $q^{h,-1} \equiv q^{h,0}$:

$$\begin{aligned} &\|\min(0, \Psi_{\rm n}(q^{h,j}) - \Psi_{\rm n}(q^{h,j-1}) - J\Psi_{\rm n}(q^{h,j-1})(q^{h,j} - q^{h,j-1}))\| \,\le\, c_q\,h \\ &\quad\Rightarrow\; \|\boldsymbol{\lambda}^{h,j+1}\| \,\le\, \eta_\lambda\,(\,1 + c_q + \|\mathbf{x}^{h,j}\|\,). \end{aligned} \tag{23}$$

Proof. The bound for $\|\boldsymbol{\delta}^{h,j+1} - \boldsymbol{\delta}^{h,j}\|$, which is part of (22), follows from (17). Since

$$\Psi_{\rm n}(q^{h,j}) + \Gamma_{\rm n}(q^{h,j-1})(q^{h,j} - q^{h,j-1}) + \delta_{\rm n}^{h,j} \,\geq\, 0,$$

we have

$$\begin{array}{rcl} 0 & \geq & \min(\,0, \Psi_{\rm n}(q^{h,j}) + \delta_{\rm n}^{h,j}\,) \\ & \geq & \min(\,0, \Psi_{\rm n}(q^{h,j}) - \Psi_{\rm n}(q^{h,j-1}) - \Gamma_{\rm n}(q^{h,j-1})(q^{h,j} - q^{h,j-1})\,) \\ & & \quad + \min(\,0, \Psi_{\rm n}(q^{h,j-1}) + \Gamma_{\rm n}(q^{h,j-1})(q^{h,j} - q^{h,j-1}) + \delta_{\rm n}^{h,j}\,) \\ & = & \min(\,0, \Psi_{\rm n}(q^{h,j}) - \Psi_{\rm n}(q^{h,j-1}) - \Gamma_{\rm n}(q^{h,j-1})(q^{h,j} - q^{h,j-1})\,). \end{array}$$

Taking norms, we obtain

$$\|\min(0, \Psi_{\rm n}(q^{h,j}) + \delta_{\rm n}^{h,j})\| \leq \|\min(\,0, \Psi_{\rm n}(q^{h,j}) - \Psi_{\rm n}(q^{h,j-1}) - \Gamma_{\rm n}(q^{h,j-1})(q^{h,j} - q^{h,j-1}))\|.$$

The bound (23) on $\|\boldsymbol{\lambda}^{h,j+1}\|$ follows readily from Lemma 5. ∎

So far, we have not used the limit condition (3) in proving the above results. This condition allows us to establish the boundedness of the state variables $\{\mathbf{x}^{h,j}\}$ and thus of the force variables $\{\boldsymbol{\lambda}^{h,j+1}\}$ also. We first state a technical fact, which can be proved by induction; see also [11, Lemma 7]. Namely, for every nonnegative integer $k \leq N_h$, if

$$(24) \qquad \|\,\mathbf{x}^{h,j+1} - \mathbf{x}^{h,j}\,\| \,\leq\, h\,\psi_x\,(\,1 + \|\,\mathbf{x}^{h,j}\|\,) \quad \forall\, j \,=\, 0, 1, \ldots, k,$$

then (recalling that $T = (N_h + 1)h$),

$$(25) \qquad \|\,\mathbf{x}^{h,j+1}\,\| \,\leq\, e^{T\,\psi_x}\,(\,1 + \|\,\mathbf{x}^{h,0}\,\|\,) - 1 \quad \forall\, j \,=\, 0, 1, \ldots, k.$$

PROPOSITION 7. *For any positive scalar c_q, let $\psi_x \equiv \eta_x(1 + \eta_\lambda(1 + c_q))$. For any scalar $R_0 > 0$, the scalar h_0 in Proposition 6 can be chosen such that (25) holds for $k = N_h$ for all $h \in (0, h_0]$ and for all $\mathbf{x}^{h,0}$ satisfying $\|\mathbf{x}^{h,0}\| \leq R_0$; moreover, for all $j = 0, 1, \ldots, N_h$,*

$$(26) \qquad \|\,\boldsymbol{\lambda}^{h,j+1}\,\| \,\leq\, \eta_\lambda\,[\,c_q + e^{T\,\psi_x}\,(\,1 + \|\,\mathbf{x}^{h,0}\,\|\,)].$$

Proof. Choose $\varepsilon > 0$ such that $\varepsilon\psi_x e^{T\psi_x}(1 + R_0) < c_q$. Corresponding to the chosen ε, let $\varsigma > 0$ be such that (3) holds. Let $h_0 > 0$ be sufficiently small such that $h_0\psi_x e^{T\psi_x}(1 + R_0) < \varsigma$. Let $\mathbf{x}^{h,0}$ be an arbitrary vector satisfying $\|\mathbf{x}^{h,0}\| \leq R_0$ and let $h \in (0, h_0]$ be arbitrary. It suffices to prove (24) for $k = N_h$. Clearly, (24) is valid for $k = 0$ because $\|\mathbf{x}^{h,1} - \mathbf{x}^{h,0}\| \leq h\eta_x(1 + \|\mathbf{x}^{h,0}\|) \leq h\psi_x(1 + \|\mathbf{x}^{h,0}\|)$. Assume that (24), and thus (25), holds for some $k \geq 0$. To complete the induction, we need to show

$$\|\,\mathbf{x}^{h,k+2} - \mathbf{x}^{h,k+1}\,\| \,\leq\, h\,\psi_x\,(\,1 + \|\,\mathbf{x}^{h,k+1}\,\|\,).$$

By the choice of h and $\|\mathbf{x}^{h,0}\|$, (24) with $j = k$ and (25) with $j = k - 1$ imply

$$\|\,\mathbf{x}^{h,k+1} - \mathbf{x}^{h,k}\,\| \,\leq\, h\,\psi_x\,e^{T\,\psi_x}\,(\,1 + \|\,\mathbf{x}^{h,0}\,\|\,) \,<\, \varsigma.$$

By (3) and the choice of c_q, it follows that

$$\begin{array}{l} \|\,\min(\,0, \Psi_{\rm n}(q^{h,k+1}) - \Psi_{\rm n}(q^{h,k}) - J\Psi_{\rm n}(q^{h,k})(q^{h,k+1} - q^{h,k})\,)\,\| \\ \quad \leq\, \varepsilon\,\|\,q^{h,k+1} - q^{h,k}\,\| \,\leq\, \varepsilon\,h\,\psi_x\,e^{T\,\psi_x}\,(\,1 + \|\,\mathbf{x}^{h,0}\,\|\,) \,\leq\, h\,c_q. \end{array}$$

Consequently, by the implication (23), we obtain

$$\|\boldsymbol{\lambda}^{h,k+2}\| \leq \eta_{\lambda}\,(1 + c_q + \|\mathbf{x}^{h,k+1}\|) \leq \eta_{\lambda}\,(1 + c_q)\,(1 + \|\mathbf{x}^{h,k+1}\|).$$

Substituting this into (22) with $j = k+1$ yields

$$\begin{aligned}\|\mathbf{x}^{h,k+2} - \mathbf{x}^{h,k+1}\| &\leq h\,\eta_x\,[\,1 + \|\mathbf{x}^{h,k+1}\| + \eta_{\lambda}\,(1+c_q)\,(1+\|\mathbf{x}^{h,k+1}\|)\,] \\ &= h\,\psi_x\,(1 + \|\mathbf{x}^{h,k+1}\|),\end{aligned}$$

completing the induction. The bound on $\|\boldsymbol{\lambda}^{h,j+1}\|$ holds by (23) and the bound on $\|\mathbf{x}^{h,j}\|$. □

Based on Proposition 7, we can establish the convergence of the time-stepping method for an initial-value frictional compliant contact problem where $\mathbf{x}(0)$ is completely known. Since our treatment of the boundary-value problem will cover this case, we proceed directly to the latter.

5. Boundary-value analysis.

Proposition 7 allows us to employ the line of proof in [11] to complete the convergence analysis of the time-stepping method. Needless to say, the boundary equation (13) will play a key role in this analysis. For this reason, we partition the boundary matrix $\mathbf{N}$ as

$$\mathbf{N} \equiv \left[\begin{array}{ccc} \mathbf{N}_q & \mathbf{N}_{\nu} & \mathbf{N}_{\delta} \end{array}\right],$$

where $\mathbf{N}_q \in \Re^{n_\nu \times n_q}$, $\mathbf{N}_\nu \in \Re^{n_\nu \times n_\nu}$, and $\mathbf{N}_\delta \in \Re^{n_\nu \times n_\delta}$, and we write the discrete-time boundary equation as

$$(27)\qquad (\mathbf{M}_\nu + \mathbf{N}_\nu)\nu^{h,0} = \mathbf{b} + \mathbf{N}_\nu \nu^{h,0} - \mathbf{N}\mathbf{x}^{h,N_h+1} = \widehat{\mathbf{b}} - \mathbf{N}\,(\mathbf{x}^{h,N_h+1} - \mathbf{x}^{h,0}),$$

where $\widehat{\mathbf{b}} \equiv \mathbf{b} - \mathbf{N}_q q^0 - \mathbf{N}_\delta \boldsymbol{\delta}^0$. We are now ready to formally state and prove the two main results of this paper: Theorems 8 and 9. While the former establishes the existence of a solution to the discrete-time boundary system (16), including the boundary condition, the latter proves the convergence to a continuous-time trajectory.

THEOREM 8. *Assume conditions* (A)–(D) *and that* $\mathbf{M}_\nu + \mathbf{N}_\nu$ *is nonsingular. Let* ψ_x *be the constant obtained in Proposition* 7. *If*

$$(28)\qquad e^{T\psi_x} < 1 + \frac{1}{\|(\mathbf{M}_\nu + \mathbf{N}_\nu)^{-1}\mathbf{N}\|},$$

positive scalars $\bar{\mu}$, h_0, *and* ψ_x *exist such that for every vector* $\mu > 0$ *satisfying* $\max_{1\leq i\leq n_\delta} \mu_i \leq \bar{\mu}$, *every scalar* $h \in (0, h_0]$, *and every pair* $(q^{h,0}, \boldsymbol{\delta}^{h,0})$ *satisfying* (12), *a discrete-time trajectory* (14) *exists satisfying* (16) *for every* $j = 0, 1, \ldots, N_h$. *Moreover,* (24) *holds for* $k = N_h$ *and* (26) *holds for all* $j = 0, 1, \ldots, N_h$.

Proof. Throughout the proof below, the scalars h and μ_i are taken to be sufficiently small so that the previous results can all be applied. More specifically, with the constant r_0 chosen at the end of the proof (cf. (31)), the upper limits h_0 and $\bar{\mu}$ are then guaranteed by Proposition 7. The derivation below emphasizes the process of how the constant r_0 is obtained.

For $\mathbf{x}^{\text{ref}} \equiv (q^{\text{ref}}, \nu^{\text{ref}}, \boldsymbol{\delta}^{\text{ref}})$ in $\Re^n$, let $\nu^h(\mathbf{x}^{\text{ref}})$ be the unique tuple $(q^h, \nu^h, \boldsymbol{\delta}^h)$, which, along with a (unique) triple of friction forces $\boldsymbol{\lambda}^h$, satisfies the following conditions:

$$
\begin{aligned}
& M(q^{\rm ref})(\,\nu^h - \nu^{\rm ref}\,) \,=\, h\,[\,f(t_{h,j+1}, q^{h,\theta_{\rm ref}}, \nu^{h,\theta_{\rm ref}}) + \boldsymbol{\Gamma}(q^{\rm ref})^T \boldsymbol{\lambda}^h\,],\\
& q^h - q^{\rm ref} \,=\, h\,G(q^{\rm ref})\nu^{h,\theta_{\rm ref}},\\
& \delta^h_{\rm t} - \delta^{\rm ref}_{\rm t} \,=\, h\,[s^h_{\rm t} - \Gamma_{\rm t}(q^{\rm ref})\nu^{h,\theta_{\rm ref}}\,],\\
& \delta^h_{\rm o} - \delta^{\rm ref}_{\rm o} \,=\, h\,[s^h_{\rm o} - \Gamma_{\rm o}(q^{\rm ref})\nu^{h,\theta_{\rm ref}}\,],\\
& 0 \,\le\, \lambda^h_{\rm n} \,\perp\, \Psi_{\rm n}(q^{\rm ref}) + h\,\Gamma_{\rm n}(q^{\rm ref})\nu^{h,\theta_{\rm ref}} + \delta^h_{\rm n} \,\ge\, 0,\\
& \boldsymbol{\lambda}^h \,=\, \mathbf{K}(q^{\rm ref})\boldsymbol{\delta}^h + \frac{\mathbf{C}(q^{\rm ref})}{h}\,(\,\boldsymbol{\delta}^h - \boldsymbol{\delta}^{\rm ref}\,),\\
& \begin{pmatrix} \lambda^h_{i{\rm t}} \\ \lambda^h_{i{\rm o}} \end{pmatrix} \in \underset{(\tilde\lambda_{it},\tilde\lambda_{io})\in\mathcal{F}(\mu_i\,\lambda^h_{i{\rm n}})}{\arg\min} \left\{ \begin{pmatrix} s^h_{i{\rm t}} \\ s^h_{i{\rm o}} \end{pmatrix}^T \begin{pmatrix} \tilde\lambda_{it} \\ \tilde\lambda_{io} \end{pmatrix} \right\},
\end{aligned}
$$

where

$$q^{h,\theta_{\rm ref}} \,\equiv\, \theta\,q^{\rm ref} + (\,1-\theta\,)\,q^h \quad \text{and} \quad \nu^{h,\theta_{\rm ref}} \,\equiv\, \theta\,\nu^{\rm ref} + (\,1-\theta\,)\,\nu^h.$$

The well-definedness of $\nu^h(\mathbf{x}^{\rm ref})$ is ensured by Proposition 3 and Lemma 4; moreover, this map is continuous. For $j = 0, 1, \ldots, N_h$, define the maps $\Lambda^{h,j} : \Re^n \to \Re^n$ recursively by $\Lambda^{h,j+1}(\mathbf{x}) \equiv \nu^h(\Lambda^{h,j}(\mathbf{x}))$, where $\Lambda^{h,0}$ is the identity map. Define the auxiliary map $\Phi : \Re^{n_\nu} \to \Re^n$ by $\Phi(\nu) \equiv (q^{h,0}, \nu, \boldsymbol{\delta}^{h,0})$. In terms of these maps we can write the boundary equation (27) as a fixed-point equation: $\nu^{h,0} = \Upsilon(\nu^{h,0})$, where $\Upsilon : \Re^{n_\nu} \to \Re^{n_\nu}$ is the map defined by

$$\Upsilon(\nu) \,=\, (\,\mathbf{M}_\nu + \mathbf{N}_\nu\,)^{-1}[\,\widehat{\mathbf{b}} - \mathbf{N} \circ (\,\Lambda^{h,N_h+1} - I\,) \circ \Phi(\nu)\,],$$

which is continuous. We claim that a constant $r_0 > 0$ exists such that Υ maps the closed Euclidean ball with center at the origin and radius r_0 into itself. Once this claim is established, Brouwer's fixed-point theorem then shows that the discrete-time boundary system (16) has a solution.

By Proposition 7, we have, for $j = 0, 1, \ldots, N_h$,

$$\| \Lambda^{h,j+1}(\mathbf{x}^{\rm ref}) \| \le R_{h,j+1} \quad \text{and} \quad \| \Lambda^{h,j+1}(\mathbf{x}^{\rm ref}) - \Lambda^{h,j}(\mathbf{x}^{\rm ref}) \| \le R_{h,j+1} - R_{h,j}, \tag{29}$$

where $R_{h,j+1}$ satisfies the recursion

$$R_{h,j+1} \,\equiv\, (\,1 + h\,\psi_x\,)\,R_{h,j} + h\,\psi_x, \quad j \,=\, 0, 1, \ldots, N_h, \tag{30}$$

with $R_{h,0} \ge \|\mathbf{x}^{\rm ref}\|$. Consequently, for any vector $\nu \in \Re^{n_\nu}$, letting $r_0 \ge \|\nu\|$ and $R_{h,0} \equiv r_0 + \|q^0\| + \|\boldsymbol{\delta}^0\|$, we have

$$
\begin{aligned}
\|\Upsilon(\nu)\| &\le \|\,(\,\mathbf{M}_\nu + \mathbf{N}_\nu\,)^{-1}\widehat{\mathbf{b}}\,\| + \|\,(\,\mathbf{M}_\nu + \mathbf{N}_\nu\,)^{-1}\mathbf{N}\,\|\,\|\Lambda^{h,N_h+1}(\Phi(\nu)) - \Lambda^{h,0}(\Phi(\nu))\|\\
&\le \|\,(\,\mathbf{M}_\nu + \mathbf{N}_\nu\,)^{-1}\widehat{\mathbf{b}}\,\| + \|\,(\,\mathbf{M}_\nu + \mathbf{N}_\nu\,)^{-1}\mathbf{N}\,\|\,(\,R_{h,N_h+1} - R_{h,0}\,)\\
&\le \|\,(\,\mathbf{M}_\nu + \mathbf{N}_\nu\,)^{-1}\widehat{\mathbf{b}}\,\| + \|\,(\,\mathbf{M}_\nu + \mathbf{N}_\nu\,)^{-1}\mathbf{N}\,\|\,(\,e^{T\psi_x} - 1\,)(\,1 + R_{h,0}\,),
\end{aligned}
$$

where the last inequality follows from (25), which gives $R_{h,N_h+1} \le e^{T\psi_x}(1 + R_{h,0}) - 1$. Consequently for any $r_0 \ge \|\nu\|$, we have

$$\|\Upsilon(\nu)\| \,\le\, \|\,(\,\mathbf{M}_\nu + \mathbf{N}_\nu\,)^{-1}\widehat{\mathbf{b}}\,\| + \|\,(\,\mathbf{M}_\nu + \mathbf{N}_\nu\,)^{-1}\mathbf{N}\,\|\,(\,e^{T\psi_x} - 1\,)(\,1 + \|\,q^0\,\| + r_0 + \|\,\boldsymbol{\delta}^0\,\|\,).$$

By (28), it follows that $1 > \|(\mathbf{M}_\nu + \mathbf{N}_\nu)^{-1}\mathbf{N}\|(e^{T\psi_x} - 1)$; hence if

$$r_0 > \frac{\|(\mathbf{M}_\nu + \mathbf{N}_\nu)^{-1}\widehat{\mathbf{b}}\| + \|(\mathbf{M}_\nu + \mathbf{N}_\nu)^{-1}\mathbf{N}\|(e^{T\psi_x} - 1)(1 + \|q^0\| + \|\boldsymbol{\delta}^0\|)}{1 - \|(\mathbf{M}_\nu + \mathbf{N}_\nu)^{-1}\mathbf{N}\|(e^{T\psi_x} - 1)} \tag{31}$$

then $\|\Upsilon(\nu)\| < r_0$. □

5.1. Final convergence. The remaining issue to be dealt with is the convergence of the discrete-time trajectory to a weak solution of the continuous-time frictional compliant contact problem. To deal with this issue, we use the discrete-time iterates $\{\mathbf{x}^{h,0}, \mathbf{x}^{h,1}, \ldots, \mathbf{x}^{h,N_h+1}\}$ to construct a continuous-time state trajectory by linear interpolation. Specifically, define the affine function $\widehat{\mathbf{x}}^h : [0,T] \to \Re^n$ as follows:

$$\widehat{\mathbf{x}}^h(t) \equiv \mathbf{x}^{h,j} + \frac{t - t_{h,j}}{h}(\mathbf{x}^{h,j+1} - \mathbf{x}^{h,j}) \quad \forall t \in [t_{h,j}, t_{h,j+1}].$$

Let $\widehat{\boldsymbol{\lambda}}^h(t)$ be the (possibly discontinuous) piecewise constant interpolants of the families $\{\boldsymbol{\lambda}^{h,j+1}\}$, i.e., $\widehat{\boldsymbol{\lambda}}^h(t) \equiv \boldsymbol{\lambda}^{h,j+1}$ for $t \in (t_{h,j}, t_{h,j+1}]$.

The following theorem is the main convergence result of this paper. Part (c) of the theorem assumes that the constitutive law of compliance for the normal forces is decoupled from that for the tangential forces. In this case, the submatrices $K_{\text{tn}}(q)$, $K_{\text{on}}(q)$, $\widehat{C}_{\text{tn}}(q)$ and $\widehat{C}_{\text{on}}(q)$ are zero, and the tangential friction QP becomes

$$\begin{aligned}
&\text{minimize} \quad \begin{pmatrix} \lambda_{\text{t}} \\ \lambda_{\text{o}} \end{pmatrix} \left\{ \frac{1}{2} \begin{bmatrix} \widehat{C}_{\text{tt}}(q) & \widehat{C}_{\text{to}}(q) \\ \widehat{C}_{\text{ot}}(q) & \widehat{C}_{\text{oo}}(q) \end{bmatrix} \begin{pmatrix} \lambda_{\text{t}} \\ \lambda_{\text{o}} \end{pmatrix} + \begin{bmatrix} \Gamma_{\text{t}}(q) \\ \Gamma_{\text{o}}(q) \end{bmatrix} \nu \right. \\
&\qquad \left. - \begin{bmatrix} \widehat{C}_{\text{tt}}(q) & \widehat{C}_{\text{to}}(q) \\ \widehat{C}_{\text{ot}}(q) & \widehat{C}_{\text{oo}}(q) \end{bmatrix} \begin{bmatrix} K_{\text{tt}}(q) & K_{\text{to}}(q) \\ K_{\text{ot}}(q) & K_{\text{oo}}(q) \end{bmatrix} \begin{pmatrix} \delta_{\text{t}} \\ \delta_{\text{o}} \end{pmatrix} \right\} \\
&\text{subject to} \quad (\lambda_{\text{t}}, \lambda_{\text{o}}) \in \prod_{i=1}^{n_\delta} \mathcal{F}(\mu_i \lambda_{i\text{n}}).
\end{aligned} \tag{32}$$

Theorem 9. *Under the setting of Theorem* 8, *the following statements hold:*

(a) *There is a sequence $\{h_\ell\} \downarrow 0$ such that $\widehat{\mathbf{x}}^{h_\ell}$ converges uniformly on $[0,T]$ to a Lipschitz function $\widehat{\mathbf{x}}$, and $\widehat{\boldsymbol{\lambda}}^{h_\nu}$ converge weakly to a function $\widehat{\boldsymbol{\lambda}}$ in $L^2(0,T)$; i.e.,*

$$\lim_{\ell\to\infty} \sup_{t\in[0,T]} \|\widehat{\mathbf{x}}(t) - \widehat{\mathbf{x}}^{h_\ell}(t)\| = 0$$

and, for any function $\varphi \in L^2(0,T)$,

$$\lim_{\ell\to\infty} \int_0^T \varphi(t)^T \lambda^{h_\ell}_{\text{n,t,o}}(t)\, dt = \int_0^T \varphi(t)^T \widehat{\lambda}_{\text{n,t,o}}(t)\, dt.$$

(b) *All such limits $(\widehat{\mathbf{x}}, \widehat{\boldsymbol{\lambda}})$ satisfy properties* (a), (b), *and* (d) *in Definition* 2 *of a weak solution of the frictional compliant contact problem.*

(c) *If $K_{\text{tn}}(q)$, $K_{\text{on}}(q)$, $C_{\text{tn}}(q)$, and $C_{\text{on}}(q)$ are equal to zero for all q, then $(\widehat{\mathbf{x}}, \widehat{\boldsymbol{\lambda}})$ also satisfies property* (c) *in Definition* 2 *and hence is a weak solution of the frictional compliant contact problem.*

Proof. Combining (24) and (25), we deduce

$$\| \widehat{\mathbf{x}}^h(t) - \mathbf{x}^{h,j} \| \le \| \mathbf{x}^{h,j+1} - \mathbf{x}^{h,j} \| \le h\, \psi_x\, e^{T\psi_x}\, (1 + r_0), \tag{33}$$

where r_0 satisfies (31). By the limit condition (3), we obtain

$$\lim_{h \downarrow 0} \max_{0 \le j \le N_h} \sup_{t \in [t_{h,j}, t_{h,j+1}]} \| \Psi_{\rm n}(\widehat{q}^h(t)) - \Psi_{\rm n}(q^{h,j}) - h\, \Gamma_{\rm n}(q^{h,j}) \nu^{h,\theta_j} \| = 0. \tag{34}$$

Moreover, the former inequalities show that the piecewise interpolants $\widehat{\mathbf{x}}^h$ are not only Lipschitz continuous on $[0,T]$, but the Lipschitz constant is independent of h. Hence there is a positive scalar h_0', which depends only on the model functions such that the family of functions $\{\widehat{\mathbf{x}}^h\}$ for h in $(0, h_0']$ is an equicontinuous family of functions. As in the proof of [11, Theorem 7.1], it follows from the Arzelá–Ascoli theorem (see, e.g., [22, p. 167] or [9, pp. 57–59]) that there is a sequence $\{h_\ell\} \downarrow 0$ such that $\{\widehat{\mathbf{x}}^{h_\ell}\}$ converges in the supremum (i.e., L^∞) norm to a Lipschitz function $\widehat{\mathbf{x}}$ on $[0,T]$. Since

$$\sup_{h \in (0,h_0']} \sup_{t \in [0,T]} \| \widehat{\mathbf{x}}^h(t) \| < \infty,$$

by (26), we deduce that

$$\sup_{h \in (0,h_0']} \sup_{t \in [0,T]} \| \widehat{\boldsymbol{\lambda}}^h(t) \| < \infty. \tag{35}$$

Moreover, by the same proof, it follows that, by working with an appropriate subsequence of $\{h_\ell\}$ if necessary and by invoking Alaoglu's theorem [9, pp. 71–72] and Mazur's theorem [9, p. 88], the sequence $\{\widehat{\boldsymbol{\lambda}}^{h_\ell}\}$ is weakly convergent with a weak* limit $\widehat{\boldsymbol{\lambda}}$, which satisfies $\widehat{\lambda}_{\rm n}(t) \ge 0$ and $(\widehat{\lambda}_{i{\rm t}}(t), \widehat{\lambda}_{i{\rm o}}(t)) \in \mathcal{F}(\mu_i \widehat{\lambda}_{i{\rm n}}(t))$ for almost all t. The proof of the latter frictional inclusion is based on the observation that a pair $(a,b) \in \mathcal{F}(\tau)$ if and only if the triple (a,b,τ) belongs to the closed convex graph of the friction map $\mathcal{F}$.

We need to verify the four properties (a)–(d) of a weak solution to the contact problem. The boundary equation (d) requires no verification, as it is a simple matter of passing to the limit in the discrete-time boundary equation (27). Hence we focus on the verification of (a)–(c). We first deal with the dynamics equations. We have

$$\begin{aligned} \nu^{h,j+1} - \nu^{h,j} &= h\, M(q^{h,j})^{-1} [f(t_{h,j+1}, q^{h,\theta_j}, \nu^{h,\theta_j}) + \boldsymbol{\Gamma}(q^{h,j})^T \boldsymbol{\lambda}^{h,j+1}] \\ &= \int_{t_{h,j}}^{t_{h,j+1}} M(\widehat{q}^h(t))^{-1} [\, f(t, \widehat{q}^h(t), \widehat{\nu}^h(t)) + \boldsymbol{\Gamma}(\widehat{q}^h(t))^T \widehat{\boldsymbol{\lambda}}^h(t) \,]\, dt + O(h^2). \end{aligned}$$

Hence for $0 \le \tau \le \tau' \le T$, we obtain

$$\widehat{\nu}^h(\tau') - \widehat{\nu}^h(\tau) = \int_\tau^{\tau'} M(\widehat{q}^h(t))^{-1} [\, f(t, \widehat{q}^h(t), \widehat{\nu}^h(t)) + \boldsymbol{\Gamma}(\widehat{q}^h(t))^T \widehat{\boldsymbol{\lambda}}^h(t) \,]\, dt + O(h).$$

Restricted to the subsequence $\{h_\ell\}$, we have

$$\lim_{\ell \to \infty} \int_\tau^{\tau'} M(\widehat{q}^{h_\ell}(t))^{-1} f(t, \widehat{q}^{h_\ell}(t), \widehat{\nu}^{h_\ell}(t))\, dt = \int_\tau^{\tau'} M(\widehat{q}(t))^{-1} f(t, \widehat{q}(t), \widehat{\nu}(t))\, dt$$

by the uniform convergence of $(\widehat{q}^{h_\ell}, \widehat{\nu}^{h_\ell}) \to (\widehat{q}, \widehat{\nu})$. We also have

$$\begin{aligned}
&\left\| \int_\tau^{\tau'} \left[M(\widehat{q}^{h_\ell}(t))^{-1}\mathbf{\Gamma}(\widehat{q}^{h_\ell}(t))^T \boldsymbol{\lambda}^{h_\ell}(t) - M(\widehat{q}(t))^{-1}\mathbf{\Gamma}(\widehat{q}(t))^T \widehat{\boldsymbol{\lambda}}(t) \right] \right\| \\
&\quad \le \int_\tau^{\tau'} \left\| M(\widehat{q}^{h_\ell}(t))^{-1}\mathbf{\Gamma}(\widehat{q}^{h_\ell}(t))^T - M(\widehat{q}(t))^{-1}\mathbf{\Gamma}(\widehat{q}(t))^T \right\| \| \widehat{\boldsymbol{\lambda}}^{h_\ell}(t) \| \, dt \\
&\qquad + \left\| \int_\tau^{\tau'} M(\widehat{q}(t))^{-1}\mathbf{\Gamma}(\widehat{q}(t))^T (\widehat{\boldsymbol{\lambda}}^{h_\ell}(t) - \widehat{\boldsymbol{\lambda}}(t)) \, dt \right\|
\end{aligned}$$

The first summand on the right-hand side converges to zero because $\{\widehat{q}^{h_\ell}\} \to \widehat{q}$ uniformly and $\widehat{\boldsymbol{\lambda}}^{h_\ell}$ is bounded; the second summand converges to zero because $\{\widehat{\boldsymbol{\lambda}}^{h_\nu}\}$ converges weakly in $L^2(0,T)$ to $\widehat{\boldsymbol{\lambda}}$. Consequently, we deduce

$$\widehat{\nu}(\tau') - \widehat{\nu}(\tau) = \lim_{\ell\to\infty} [\widehat{\nu}^{h_\ell}(\tau') - \widehat{\nu}^{h_\ell}(\tau)] = \int_\tau^{\tau'} M(\widehat{q}(t))^{-1}[f(t, \widehat{q}(t), \widehat{\nu}(t)) + \mathbf{\Gamma}(\widehat{q}(t))^T \widehat{\boldsymbol{\lambda}}(t)] dt.$$

Similarly, we can establish

$$\begin{aligned}
\widehat{q}(\tau') - \widehat{q}(\tau) &= \int_\tau^{\tau'} G(\widehat{q}(t))\widehat{\nu}(t)\, dt \quad \text{and} \\
\widehat{\boldsymbol{\delta}}(\tau') - \widehat{\boldsymbol{\delta}}(\tau) &= \int_\tau^{\tau'} \mathbf{C}(\widehat{q}(t))^{-1}[\, \widehat{\boldsymbol{\lambda}}(t) - \mathbf{K}(\widehat{q}(t))\widehat{\boldsymbol{\delta}}(t)\,]\, dt,
\end{aligned}$$

completing the proof of property (a) of a weak solution. We next address property (b). For t in $[t_{h,j}, t_{h,j+1}]$, we can write

$$\begin{aligned}
\Psi_{\mathrm{n}}(\widehat{q}^h(t)) + \widehat{\delta}^h_{\mathrm{n}}(t) = {}& \Psi_{\mathrm{n}}(\widehat{q}^h(t)) - \Psi_{\mathrm{n}}(q^{h,j}) + \widehat{\delta}^h_{\mathrm{n}}(t) - \delta^{h,j+1}_{\mathrm{n}} \\
&+ \Psi_{\mathrm{n}}(q^{h,j}) + h\,\Gamma_{\mathrm{n}}(q^{h,j})\nu^{h,\theta_j} + \delta^{h,j+1}_{\mathrm{n}} - h\Gamma_{\mathrm{n}}(q^{h,j})\nu^{h,\theta_j};
\end{aligned}$$

since $\Psi_{\mathrm{n}}(q^{h,j}) + h\,\Gamma_{\mathrm{n}}(q^{h,j})\nu^{h,\theta_j} + \delta^{h,j+1}_{\mathrm{n}} \ge 0$, we deduce

$$\Psi_{\mathrm{n}}(\widehat{q}^h(t)) + \widehat{\delta}^h_{\mathrm{n}}(t) \;\ge\; \Psi_{\mathrm{n}}(\widehat{q}^h(t)) - \Psi_{\mathrm{n}}(q^{h,j}) + \widehat{\delta}^h_{\mathrm{n}}(t) - \delta^{h,j+1}_{\mathrm{n}} - h\,\Gamma_{\mathrm{n}}(q^{h,j})\nu^{h,\theta_j}.$$

Letting $\Phi^h_{\mathrm{n}}(t)$ be the right-hand expression, we deduce from (34) and (33) that $\|\Phi^h_{\mathrm{n}}(t)\|$ is bounded by a constant for all $h > 0$ sufficiently small and all t and $\Phi^h_{\mathrm{n}}(t) \to 0$ for all t as $h \downarrow 0$. Restricted to the subsequence $\{h_\ell\}$, the left-hand side converges uniformly to $\Psi_{\mathrm{n}}(\widehat{q}(t)) + \widehat{\delta}_{\mathrm{n}}(t)$; therefore, $\Psi_{\mathrm{n}}(\widehat{q}(t)) + \widehat{\delta}_{\mathrm{n}}(t) \ge 0$ for all $t \in [0,T]$. Next we show that

$$\int_0^T \widehat{\lambda}_{\mathrm{n}}(t)^T[\, \Psi_{\mathrm{n}}(\widehat{q}(t)) + \widehat{\delta}_{\mathrm{n}}(t)\,]\, dt \;=\; 0. \tag{36}$$

The left-hand side is equal to the limit

$$\lim_{\ell\to\infty} \int_0^T \widehat{\lambda}^{h_\ell}_{\mathrm{n}}(t)^T[\, \Psi_{\mathrm{n}}(\widehat{q}(t)) + \widehat{\delta}_{\mathrm{n}}(t)\,]\, dt \;=\; \lim_{\ell\to\infty} \int_0^T \widehat{\lambda}^{h_\ell}_{\mathrm{n}}(t)^T[\, \Psi_{\mathrm{n}}(\widehat{q}^{h_\ell}(t)) + \widehat{\delta}^{h_\ell}_{\mathrm{n}}(t)\,]\, dt.$$

For each $h > 0$, we have

$$\begin{aligned}\int_0^T \widehat{\lambda}_{\rm n}^h(t)^T[\,\Psi_{\rm n}(\widehat{q}^{\,h}(t)) + \widehat{\delta}_{\rm n}^h(t)\,]\,dt &= \sum_{j=0}^{N_h}\int_{t_{h,j}}^{t_{h,j+1}} \widehat{\lambda}_{\rm n}^h(t)^T[\,\Psi_{\rm n}(\widehat{q}^{\,h}(t)) + \widehat{\delta}_{\rm n}^h(t)\,]\,dt \\ &= \sum_{j=0}^{N_h}\int_{t_{h,j}}^{t_{h,j+1}} (\,\lambda^{h,j+1}\,)^T\Phi_{\rm n}^h(t)\,dt. \end{aligned} \tag{37}$$

Since $\{\lambda^{h,j+1}\}$ is bounded, by letting $h \downarrow 0$ in (37) along the subsequence $\{h_\ell\}$, (36) follows readily from the dominated convergence theorem, thereby completing the proof of property (b) of weak solution.

Finally, to prove property (c), let $(\widetilde{\lambda}_{\rm t}, \widetilde{\lambda}_{\rm o}) : [0,T] \to \Re^{2n_\delta}$ be continuous functions such that $(\widetilde{\lambda}_{i{\rm t}}(t), \widetilde{\lambda}_{i{\rm o}}(t)) \in \mathcal{F}(\mu_i\widehat{\lambda}_{i{\rm n}}(t))$ for almost all $t \in [0,T]$ and all $i = 1,\dots,n_\delta$. We need to verify

$$\int_0^T \begin{pmatrix} \widetilde{\lambda}_{\rm t}(t) - \widehat{\lambda}_{\rm t}(t) \\ \widetilde{\lambda}_{\rm o}(t) - \widehat{\lambda}_{\rm o}(t) \end{pmatrix}^T \left\{ \begin{bmatrix} \widehat{C}_{\rm tt}(\widehat{q}(t)) & \widehat{C}_{\rm to}(\widehat{q}(t)) \\ \widehat{C}_{\rm ot}(\widehat{q}(t)) & \widehat{C}_{\rm oo}(\widehat{q}(t)) \end{bmatrix} \left[\begin{pmatrix} \widehat{\lambda}_{\rm t}(t) \\ \widehat{\lambda}_{\rm o}(t) \end{pmatrix} \right.\right.$$
$$\left.\left. - \begin{bmatrix} K_{\rm tt}(\widehat{q}(t)) & K_{\rm to}(\widehat{q}(t)) \\ K_{\rm ot}(\widehat{q}(t)) & K_{\rm oo}(\widehat{q}(t)) \end{bmatrix} \begin{pmatrix} \widehat{\delta}_{\rm t}(t) \\ \widehat{\delta}_{\rm o}(t) \end{pmatrix} \right] + \begin{pmatrix} \Gamma_{\rm t}(\widehat{q}(t)) \\ \Gamma_{\rm o}(\widehat{q}(t)) \end{pmatrix} \widehat{\nu}(t) \right\} dt \,\geq\, 0.$$

Since

$$\int_0^T \begin{pmatrix} \widehat{\lambda}_{\rm t}^{h_\ell}(t) \\ \widehat{\lambda}_{\rm o}^{h_\ell}(t) \end{pmatrix}^T \begin{bmatrix} \widehat{C}_{\rm tt}(\widehat{q}(t)) & \widehat{C}_{\rm to}(\widehat{q}(t)) \\ \widehat{C}_{\rm ot}(\widehat{q}(t)) & \widehat{C}_{\rm oo}(\widehat{q}(t)) \end{bmatrix} \begin{pmatrix} \widehat{\lambda}_{\rm t}^{h_\ell}(t) \\ \widehat{\lambda}_{\rm o}^{h_\ell}(t) \end{pmatrix} dt$$
$$= \int_0^T \begin{pmatrix} \widehat{\lambda}_{\rm t}^{h_\ell}(t) - \widehat{\lambda}_{\rm t}(t) \\ \widehat{\lambda}_{\rm o}^{h_\ell}(t) - \widehat{\lambda}_{\rm o}(t) \end{pmatrix}^T \begin{bmatrix} \widehat{C}_{\rm tt}(\widehat{q}(t)) & \widehat{C}_{\rm to}(\widehat{q}(t)) \\ \widehat{C}_{\rm ot}(\widehat{q}(t)) & \widehat{C}_{\rm oo}(\widehat{q}(t)) \end{bmatrix} \begin{pmatrix} \widehat{\lambda}_{\rm t}^{h_\ell}(t) - \widehat{\lambda}_{\rm t}(t) \\ \widehat{\lambda}_{\rm o}^{h_\ell}(t) - \widehat{\lambda}_{\rm o}(t) \end{pmatrix} dt$$
$$-2\int_0^T \begin{pmatrix} \widehat{\lambda}_{\rm t}^{h_\ell}(t) - \widehat{\lambda}_{\rm t}(t) \\ \widehat{\lambda}_{\rm o}^{h_\ell}(t) - \widehat{\lambda}_{\rm o}(t) \end{pmatrix}^T \begin{bmatrix} \widehat{C}_{\rm tt}(\widehat{q}(t)) & \widehat{C}_{\rm to}(\widehat{q}(t)) \\ \widehat{C}_{\rm ot}(\widehat{q}(t)) & \widehat{C}_{\rm oo}(\widehat{q}(t)) \end{bmatrix} \begin{pmatrix} \widehat{\lambda}_{\rm t}(t) \\ \widehat{\lambda}_{\rm o}(t) \end{pmatrix} dt$$
$$+\int_0^T \begin{pmatrix} \widehat{\lambda}_{\rm t}(t) \\ \widehat{\lambda}_{\rm o}(t) \end{pmatrix}^T \begin{bmatrix} \widehat{C}_{\rm tt}(\widehat{q}(t)) & \widehat{C}_{\rm to}(\widehat{q}(t)) \\ \widehat{C}_{\rm ot}(\widehat{q}(t)) & \widehat{C}_{\rm oo}(\widehat{q}(t)) \end{bmatrix} \begin{pmatrix} \widehat{\lambda}_{\rm t}(t) \\ \widehat{\lambda}_{\rm o}(t) \end{pmatrix} dt,$$

and since the first integral on the right-hand side is nonnegative (by the positive semidefiniteness of the quadratic form), the second integral converges to zero because $\widehat{\lambda}_{\rm t,o}^{h_\ell}$ converge to $\widehat{\lambda}_{\rm t,o}$ in $L^2(0,T)$, we deduce

$$\begin{aligned} \infty \;&>\; \liminf_{\ell\to\infty} \int_0^T \begin{pmatrix} \widehat{\lambda}_{\rm t}^{h_\ell}(t) \\ \widehat{\lambda}_{\rm o}^{h_\ell}(t) \end{pmatrix}^T \begin{bmatrix} \widehat{C}_{\rm tt}(\widehat{q}(t)) & \widehat{C}_{\rm to}(\widehat{q}(t)) \\ \widehat{C}_{\rm ot}(\widehat{q}(t)) & \widehat{C}_{\rm oo}(\widehat{q}(t)) \end{bmatrix} \begin{pmatrix} \widehat{\lambda}_{\rm t}^{h_\ell}(t) \\ \widehat{\lambda}_{\rm o}^{h_\ell}(t) \end{pmatrix} dt \\ &\geq\; \int_0^T \begin{pmatrix} \widehat{\lambda}_{\rm t}(t) \\ \widehat{\lambda}_{\rm o}(t) \end{pmatrix}^T \begin{bmatrix} \widehat{C}_{\rm tt}(\widehat{q}(t)) & \widehat{C}_{\rm to}(\widehat{q}(t)) \\ \widehat{C}_{\rm ot}(\widehat{q}(t)) & \widehat{C}_{\rm oo}(\widehat{q}(t)) \end{bmatrix} \begin{pmatrix} \widehat{\lambda}_{\rm t}(t) \\ \widehat{\lambda}_{\rm o}(t) \end{pmatrix} dt, \end{aligned} \tag{38}$$

where the left-hand limit is finite by (35). Consequently, it follows that

$$\begin{aligned}
&\int_0^T \begin{pmatrix} \widetilde{\lambda}_{\rm t}(t) - \widehat{\lambda}_{\rm t}(t) \\ \widetilde{\lambda}_{\rm o}(t) - \widehat{\lambda}_{\rm o}(t) \end{pmatrix}^T \left\{ \begin{bmatrix} \widehat{C}_{\rm tt}(\widehat{q}(t)) & \widehat{C}_{\rm to}(\widehat{q}(t)) \\ \widehat{C}_{\rm ot}(\widehat{q}(t)) & \widehat{C}_{\rm oo}(\widehat{q}(t)) \end{bmatrix} \left[\begin{pmatrix} \widehat{\lambda}_{\rm t}(t) \\ \widehat{\lambda}_{\rm o}(t) \end{pmatrix} \right.\right. \\
&\qquad \left.\left. - \begin{bmatrix} K_{\rm tt}(\widehat{q}(t)) & K_{\rm to}(\widehat{q}(t)) \\ K_{\rm ot}(\widehat{q}(t)) & K_{\rm oo}(\widehat{q}(t)) \end{bmatrix} \begin{pmatrix} \widehat{\delta}_{\rm t}(t) \\ \widehat{\delta}_{\rm o}(t) \end{pmatrix} \right] + \begin{pmatrix} \Gamma_{\rm t}(\widehat{q}(t)) \\ \Gamma_{\rm o}(\widehat{q}(t)) \end{pmatrix} \widehat{\nu}(t) \right\} dt \\
&\geq \limsup_{\ell\to\infty} \int_0^T \begin{pmatrix} \widetilde{\lambda}_{\rm t}(t) - \widehat{\lambda}^{h_\ell}_{\rm t}(t) \\ \widetilde{\lambda}_{\rm o}(t) - \widehat{\lambda}^{h_\ell}_{\rm o}(t) \end{pmatrix}^T \left\{ \begin{bmatrix} \widehat{C}_{\rm tt}(\widehat{q}(t)) & \widehat{C}_{\rm to}(\widehat{q}(t)) \\ \widehat{C}_{\rm ot}(\widehat{q}(t)) & \widehat{C}_{\rm oo}(\widehat{q}(t)) \end{bmatrix} \left[\begin{pmatrix} \widehat{\lambda}^{h_\ell}_{\rm t}(t) \\ \widehat{\lambda}^{h_\ell}_{\rm o}(t) \end{pmatrix} \right.\right. \\
&\qquad \left.\left. - \begin{bmatrix} K_{\rm tt}(\widehat{q}(t)) & K_{\rm to}(\widehat{q}(t)) \\ K_{\rm ot}(\widehat{q}(t)) & K_{\rm oo}(\widehat{q}(t)) \end{bmatrix} \begin{pmatrix} \widehat{\delta}_{\rm t}(t) \\ \widehat{\delta}_{\rm o}(t) \end{pmatrix} \right] + \begin{pmatrix} \Gamma_{\rm t}(\widehat{q}(t)) \\ \Gamma_{\rm o}(\widehat{q}(t)) \end{pmatrix} \widehat{\nu}(t) \right\} dt \quad \text{by (38)} \\
&\geq \limsup_{\ell\to\infty} \int_0^T \begin{pmatrix} \widetilde{\lambda}_{\rm t}(t) - \widehat{\lambda}^{h_\ell}_{\rm t}(t) \\ \widetilde{\lambda}_{\rm o}(t) - \widehat{\lambda}^{h_\ell}_{\rm o}(t) \end{pmatrix}^T \left\{ \begin{bmatrix} \widehat{C}_{\rm tt}(\widehat{q}^{h_\ell}(t)) & \widehat{C}_{\rm to}(\widehat{q}^{h_\ell}(t)) \\ \widehat{C}_{\rm ot}(\widehat{q}^{h_\ell}(t)) & \widehat{C}_{\rm oo}(\widehat{q}^{h_\ell}(t)) \end{bmatrix} \left[\begin{pmatrix} \widehat{\lambda}^{h_\ell}_{\rm t}(t) \\ \widehat{\lambda}^{h_\ell}_{\rm o}(t) \end{pmatrix} \right.\right. \\
&\qquad \left.\left. - \begin{bmatrix} K_{\rm tt}(\widehat{q}^{h_\ell}(t)) & K_{\rm to}(\widehat{q}^{h_\ell}(t)) \\ K_{\rm ot}(\widehat{q}^{h_\ell}(t)) & K_{\rm oo}(\widehat{q}^{h_\ell}(t)) \end{bmatrix} \begin{pmatrix} \widehat{\delta}^{h_\ell}_{\rm t}(t) \\ \widehat{\delta}^{h_\ell}_{\rm o}(t) \end{pmatrix} \right] + \begin{pmatrix} \Gamma_{\rm t}(\widehat{q}^{h_\ell}(t)) \\ \Gamma_{\rm o}(\widehat{q}^{h_\ell}(t)) \end{pmatrix} \widehat{\nu}^{h_\ell}(t) \right\} dt,
\end{aligned}$$

where the second inequality holds because $\{(\widehat{q}^{h_\ell}, \widehat{\nu}^{h_\ell}, \widehat{\delta}^{h_\ell}_{\rm t,o})\}$ converges to $(\widehat{q}, \widehat{\nu}, \widehat{\delta}_{\rm t,o})$ uniformly. For each $h > 0$, we have

$$\begin{aligned}
&\int_0^T \begin{pmatrix} \widetilde{\lambda}_{\rm t}(t) - \widehat{\lambda}^{h}_{\rm t}(t) \\ \widetilde{\lambda}_{\rm o}(t) - \widehat{\lambda}^{h}_{\rm o}(t) \end{pmatrix}^T \left\{ \begin{bmatrix} \widehat{C}_{\rm tt}(\widehat{q}^{h}(t)) & \widehat{C}_{\rm to}(\widehat{q}^{h}(t)) \\ \widehat{C}_{\rm ot}(\widehat{q}^{h}(t)) & \widehat{C}_{\rm oo}(\widehat{q}^{h}(t)) \end{bmatrix} \left[\begin{pmatrix} \widehat{\lambda}^{h}_{\rm t}(t) \\ \widehat{\lambda}^{h}_{\rm o}(t) \end{pmatrix} \right.\right. \\
&\qquad \left.\left. - \begin{bmatrix} K_{\rm tt}(\widehat{q}^{h}(t)) & K_{\rm to}(\widehat{q}^{h}(t)) \\ K_{\rm ot}(\widehat{q}^{h}(t)) & K_{\rm oo}(\widehat{q}^{h}(t)) \end{bmatrix} \begin{pmatrix} \widehat{\delta}^{h}_{\rm t}(t) \\ \widehat{\delta}^{h}_{\rm o}(t) \end{pmatrix} \right] + \begin{pmatrix} \Gamma_{\rm t}(\widehat{q}^{h}(t)) \\ \Gamma_{\rm o}(\widehat{q}^{h}(t)) \end{pmatrix} \widehat{\nu}^{h}(t) \right\} dt \\
&= \sum_{j=1}^{N_h} \int_{t_{h,j}}^{t_{h,j+1}} \begin{pmatrix} \widetilde{\lambda}_{\rm t}(t) - \lambda^{h,j+1}_{\rm t} \\ \widetilde{\lambda}_{\rm o}(t) - \lambda^{h,j+1}_{\rm o} \end{pmatrix}^T \left\{ \begin{bmatrix} \widehat{C}_{\rm tt}(\widehat{q}^{h}(t)) & \widehat{C}_{\rm to}(\widehat{q}^{h}(t)) \\ \widehat{C}_{\rm ot}(\widehat{q}^{h}(t)) & \widehat{C}_{\rm oo}(\widehat{q}^{h}(t)) \end{bmatrix} \left[\begin{pmatrix} \lambda^{h,j+1}_{\rm t} \\ \lambda^{h,j+1}_{\rm o} \end{pmatrix} \right.\right. \\
&\qquad \left.\left. - \begin{bmatrix} K_{\rm tt}(\widehat{q}^{h}(t)) & K_{\rm to}(\widehat{q}^{h}(t)) \\ K_{\rm ot}(\widehat{q}^{h}(t)) & K_{\rm oo}(\widehat{q}^{h}(t)) \end{bmatrix} \begin{pmatrix} \widehat{\delta}^{h}_{\rm t}(t) \\ \widehat{\delta}^{h}_{\rm o}(t) \end{pmatrix} \right] + \begin{pmatrix} \Gamma_{\rm t}(\widehat{q}^{h}(t)) \\ \Gamma_{\rm o}(\widehat{q}^{h}(t)) \end{pmatrix} \widehat{\nu}^{h}(t) \right\} dt.
\end{aligned}$$

Since for almost all $t \in (t_{h,j}, t_{h,j+1}]$, we have $(\widetilde{\lambda}_{it}(t), \widetilde{\lambda}_{io}(t)) \in \mathcal{F}(\mu_i \lambda^{h,j+1}_{\rm in})$, it follows that

$$\begin{pmatrix} \widetilde{\lambda}_{\rm t}(t) - \lambda_{\rm t}^{h,j+1} \\ \widetilde{\lambda}_{\rm o}(t) - \lambda_{\rm o}^{h,j+1} \end{pmatrix}^T \left\{ \begin{bmatrix} \widehat{C}_{\rm tt}(q^{h,j}) & \widehat{C}_{\rm to}(q^{h,j}) \\ \widehat{C}_{\rm ot}(q^{h,j}) & \widehat{C}_{\rm oo}(q^{h,j}) \end{bmatrix} \left[\begin{pmatrix} \lambda_{\rm t}^{h,j+1} \\ \lambda_{\rm o}^{h,j+1} \end{pmatrix} \right.\right.$$

$$\left.\left. - \begin{bmatrix} K_{\rm tt}(q^{h,j}) & K_{\rm to}(q^{h,j}) \\ K_{\rm ot}(q^{h,j}) & K_{\rm oo}(q^{h,j}) \end{bmatrix} \begin{pmatrix} \delta_{\rm t}^{h,j} \\ \delta_{\rm o}^{h,j} \end{pmatrix} \right] + \begin{pmatrix} \Gamma_{\rm t}(q^{h,j}) \\ \Gamma_{\rm o}(q^{h,j}) \end{pmatrix} \nu^{h,\theta_j} \right\} \geq 0$$

for almost all $t \in (t_{h,j}, t_{h,j+1}]$. Since the state variables satisfy

$$\lim_{\substack{\ell \to \infty \\ t \in (t_{h_\ell,j}, t_{h_\ell,j+1}]}} (\widehat{\mathbf{x}}^{h_\ell}(t) - \mathbf{x}^{h_\ell,j}) = 0$$

uniformly on $[0,T]$, we easily derive the desired limiting friction property (c). □

6. Conclusion and discussion.

This paper provided an in-depth investigation of time-stepping methods for rigid body dynamics problems with multiple contacts characterized by friction and local compliance. The main results are (a) the existence of a discrete-time solution trajectory the boundary-value problem (Theorem 8), and (b) the convergence of such a solution to a weak solution of the corresponding continuous-time problem (Theorem 9). Whereas the convergence results obtained are in a sense stronger than those in [19, 1], it is worth noting that this is because of our choice of a phenomenologically correct model that explicitly characterizes the compliance at each contact. Even so, there are limitations in our investigation. First, the friction coefficients are required to be sufficiently small in the main results (this is the result of our discretization which respects the nonlinear friction conditions at all iterates $\boldsymbol{\lambda}^{h,\nu+1}$). Second, we are not able to establish convergence to a strong solution. This limitation begs the question of whether such a solution can be proved to exist in a continuous-time model under an appropriate compliance constitutive law. The key difficulty lies in the fact that the friction forces are not continuous functions of the system states with the model (5). This issue remains unresolved to date. Third, in our convergence analysis, the parameters of the compliance model (i.e., the stiffness and damping) are fixed. It would be very interesting to extend the analysis to allow these parameters to tend to infinity, with the goal of recovering a solution of some kind to a fully rigid-body model. Such an extended analysis is beyond the scope of this paper. In the previous paper [17], we considered, in a discrete-time framework with a fixed discretization step, the issue of convergence when the stiffness and damping both tend to infinity and obtained some positive results; nevertheless, such a convergence issue in a continuous-time model seems difficult and has not been studied.

In view of the unresolved issues associated with strong solutions, which are seemingly very difficult, our results are significant and provide a first step for a deeper analysis. Needless to say, we are interested in extending the analysis to models with nonlinear constitutive laws for which the existence of strong solutions to the continuous-time model could be shown and for which the convergence of a numerical time-stepping method to such a solution could be established. Our future work will address such extensions and the application of numerical methods for solving boundary value problems to the optimal design of manufacturing processes with frictional contacts.

Acknowledgements. This paper has benefitted from the constructive comments of two referees and the associate editor. The authors are also grateful to David Stewart who has offered some valuable insights on the properties of the compliant contact model relative to the rigid body model.

A POSTERIORI ERROR ANALYSIS OF THE LINKED INTERPOLATION TECHNIQUE FOR PLATE BENDING PROBLEMS*

CARLO LOVADINA† AND ROLF STENBERG‡

Abstract. We develop a posteriori error estimates for the so-called linked interpolation technique to approximate the solution of plate bending problems. We show that the proposed (residual-based) estimator is both reliable and efficient.

Key words. Reissner–Mindlin plates, finite element methods, a posteriori error analysis.

1. Introduction.

In this paper we present an a posteriori error analysis for the so-called linked interpolation technique (cf. [2], [3], and [21], for instance) to approximate the solution of the Reissner–Mindlin plate problem.

It is worth noticing that the main effort concerning the finite element discretization of the plate bending problems has been focused on proposing and analyzing locking-free schemes. As a consequence, most of the mathematical literature on the subject is addressed to establish a priori error estimates. We mention here the works [1], [4], [6], [12], [13], [15], [18], [20], and the references therein, for example. On the contrary, when considering the a posteriori error analysis for plates, only very few results are available (see [7], [8], and [14]).

In this work we consider the so-called linked interpolation technique focusing on two triangular elements: the low-order element proposed in [21] (see also [22]), and the quadratic scheme proposed in [3]. An a priori error analysis has been developed for both the methods in [16], [17] and [3], respectively. We also remark that our a posteriori error analysis may be straightforwardly extended to other schemes taking advantage of the linked interpolation technique, such as the quadrilateral elements considered in [2] and [3], for example.

An outline of the paper is as follows. In section 2 we briefly recall the Reissner–Mindlin problem, together with a mixed variational formulation and some useful regularity results. The linked interpolation technique is described in section 3, where we develop an a priori analysis for the sake of completeness (see also [16] or [17]). Section 4 is devoted to the a posteriori error estimates. In particular we introduce our estimator, and we prove its reliability (section 4.1) and efficiency (section 4.2). We consider the case of a clamped plate only for simplicity. Indeed, both the a priori and the a posteriori error analysis can be easily adapted to cover other relevant boundary conditions.

Throughout the paper we use standard notations for Sobolev norms and seminorms (see [5], for example). Moreover, we denote with C a generic constant

independent of the mesh parameter h and the plate thickness t, which may take different values in different occurrences.

2. The Reissner–Mindlin problem. The Reissner–Mindlin equations for a clamped plate with polygonal midplane Ω require one to find $(\boldsymbol{\theta}, w, \boldsymbol{\gamma})$ such that

$$\begin{cases} -\operatorname{div} \mathbf{C}\,\varepsilon(\boldsymbol{\theta}) - \boldsymbol{\gamma} = 0 & \text{in } \Omega, \\ -\operatorname{div} \boldsymbol{\gamma} = g & \text{in } \Omega, \\ \boldsymbol{\gamma} = \mu t^{-2}(\boldsymbol{\nabla} w - \boldsymbol{\theta}) & \text{in } \Omega, \\ \boldsymbol{\theta} = 0, \ w = 0 & \text{on } \partial\Omega. \end{cases} \tag{2.1}$$

Here, $\mathbf{C}$ is the tensor of bending moduli, $\boldsymbol{\theta}$ represents the rotations, w the transversal displacement, $\boldsymbol{\gamma}$ the scaled shear stresses, and g a given transversal load. Moreover, ε is the usual symmetric gradient operator, μ is the shear modulus, and t is the thickness. The classical variational formulation of problem (2.1) is

$$\begin{cases} \text{Find } (\boldsymbol{\theta}, w, \boldsymbol{\gamma}) \in \boldsymbol{\Theta} \times W \times (L^2(\Omega))^2 : \\ a(\boldsymbol{\theta}, \boldsymbol{\eta}) + (\boldsymbol{\nabla} v - \boldsymbol{\eta}, \boldsymbol{\gamma}) = (g, v), & (\boldsymbol{\eta}, v) \in \boldsymbol{\Theta} \times W, \\ (\boldsymbol{\nabla} w - \boldsymbol{\theta}, \boldsymbol{\tau}) - \mu^{-1} t^2 (\boldsymbol{\gamma}, \boldsymbol{\tau}) = 0, & \boldsymbol{\tau} \in (L^2(\Omega))^2, \end{cases} \tag{2.2}$$

where $\boldsymbol{\Theta} = (H_0^1(\Omega))^2$, $W = H_0^1(\Omega)$, $(\cdot, \cdot)$ is the inner product in $L^2(\Omega)$ and

$$a(\boldsymbol{\theta}, \boldsymbol{\eta}) := \int_\Omega \mathbf{C}\,\varepsilon(\boldsymbol{\theta}) : \varepsilon(\boldsymbol{\eta}).$$

Following [9], we write the pair $(\boldsymbol{\theta}, w)$ as

$$(\boldsymbol{\theta}, w) = (\boldsymbol{\theta}_0 + \boldsymbol{\theta}_r, w_0 + w_r), \tag{2.3}$$

where the pair $(\boldsymbol{\theta}_0, , w_0)$ is the solution of the limit problem,

$$\begin{cases} \text{Find } (\boldsymbol{\theta}_0, w_0, \boldsymbol{\gamma}_0) \in \boldsymbol{\Theta} \times W \times \boldsymbol{\Gamma} : \\ a(\boldsymbol{\theta}_0, \boldsymbol{\eta}) + < \boldsymbol{\nabla} v - \boldsymbol{\eta}, \boldsymbol{\gamma}_0 >= (g, v), & (\boldsymbol{\eta}, v) \in \boldsymbol{\Theta} \times W, \\ < \boldsymbol{\nabla} w_0 - \boldsymbol{\theta}_0, \boldsymbol{\tau} >= 0, & \boldsymbol{\tau} \in \boldsymbol{\Gamma}, \end{cases} \tag{2.4}$$

and $(\boldsymbol{\theta}_r, w_r)$ can be thought of as a remainder. Furthermore, $\boldsymbol{\Gamma} = H^{-1}(\operatorname{div}, \Omega)$ and $< \cdot, \cdot >$ is the duality pairing between $H_0(\operatorname{rot}, \Omega)$ and $H^{-1}(\operatorname{div}, \Omega)$. One has the following proposition (cf. [9]).

PROPOSITION 2.1. *Suppose that Ω is convex and $g \in L^2(\Omega)$. Then it holds*

$$||w_0||_3 + ||\boldsymbol{\theta}||_2 + ||\boldsymbol{\gamma}||_0 + t\,||\boldsymbol{\gamma}||_1 \leq C(||g||_{-1} + t\,||g||_0), \tag{2.5}$$

$$||\boldsymbol{\theta}_r||_1 \leq Ct\,||g||_{-1}, \tag{2.6}$$

$$||w_r||_2 \leq Ct(||g||_{-1} + t\,||g||_0). \qquad \square \tag{2.7}$$

3. The linked interpolation scheme and an a priori analysis.

In this section we present the general idea of the linked interpolation technique (see [3] and [21], for instance), together with two examples of triangular elements. Furthermore, for the sake of completeness, we develop an a priori error analysis, focusing on the lowest-order element (see [16] and [17]).

3.1. The linked interpolation scheme.

Let $\{\mathcal{T}_h\}_{h>0}$ be a sequence of decompositions of Ω into triangular elements T, satisfying the usual compatibility conditions (see [11]). We also assume that the family $\{\mathcal{T}_h\}_{h>0}$ is regular, i.e., there exists a constant $\sigma > 0$ such that

$$h_T \leq \sigma \rho_T \qquad \forall T \in \mathcal{T}_h, \tag{3.1}$$

where h_T is the diameter of the element T and ρ_T is the maximum diameter of the circles contained in T. We recall (see [11], for instance) that regularity implies the minimum angle condition: there exists a constant $\alpha > 0$ such that

$$\alpha_T \geq \alpha \qquad \forall T \in \mathcal{T}_h, \tag{3.2}$$

where α_T denotes the smallest inner angle of T. Moreover, given the decomposition $\mathcal{T}_h$ we will denote with $\mathcal{E}_h$ the set of the edges e of the triangles $T \in \mathcal{T}_h$. We now select the finite element spaces $\boldsymbol{\Theta}_h \subset \boldsymbol{\Theta}$, $W_h \subset W$, $\boldsymbol{\Gamma}_h \subset L^2(\Omega)^2$, together with a suitable linear operator (the so-called linking operator)

$$L : \boldsymbol{\Theta}_h \longrightarrow H^1_0(\Omega). \tag{3.3}$$

We then form the finite dimensional subspace of $\boldsymbol{X} := \boldsymbol{\Theta} \times W$

$$\boldsymbol{X}_h = \big\{(\boldsymbol{\eta}_h, v_h^*) = (\boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h) : \boldsymbol{\eta}_h \in \boldsymbol{\Theta}_h\,,\ v_h \in W_h\big\}, \tag{3.4}$$

and we finally consider the discrete problem

$$\begin{cases} \text{Find } (\boldsymbol{\theta}_h, w_h^*; \boldsymbol{\gamma}_h) \in \boldsymbol{X}_h \times \boldsymbol{\Gamma}_h : \\ a(\boldsymbol{\theta}_h, \boldsymbol{\eta}_h) + (\boldsymbol{\gamma}_h, \boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h) = (g, v_h^*), \qquad (\boldsymbol{\eta}_h, v_h^*) \in \boldsymbol{X}_h, \\ (\boldsymbol{\nabla} w_h^* - \boldsymbol{\theta}_h, \boldsymbol{\tau}_h) - \mu^{-1} t^2 (\boldsymbol{\gamma}_h, \boldsymbol{\tau}_h) = 0, \qquad \boldsymbol{\tau}_h \in \boldsymbol{\Gamma}_h. \end{cases} \tag{3.5}$$

Remark 3.1. We point out that eliminating $\boldsymbol{\gamma}_h$ from system (3.5), our scheme is equivalent to the following problem involving only the rotations and the vertical displacements:

$$\begin{cases} \text{Find } (\boldsymbol{\theta}_h, w_h^*) \in \boldsymbol{X}_h : \\ a(\boldsymbol{\theta}_h, \boldsymbol{\eta}_h) + \mu t^{-2} \big(P_h(\boldsymbol{\nabla} w_h^* - \boldsymbol{\theta}_h), P_h(\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h)\big) = (g, v_h) \quad \forall (\boldsymbol{\eta}_h, v_h^*) \in \boldsymbol{X}_h, \end{cases} \tag{3.6}$$

where P_h denotes the L^2-projection operator onto $\boldsymbol{\Gamma}_h$.

We are now ready to present the following two elements. (For other methods based on the same strategy, see, e.g., [2], [3].)

3.1.1. The linear element. This element (see [21]) is described by the finite element spaces

$$\boldsymbol{\Theta}_h = \big\{\boldsymbol{\eta} \in \boldsymbol{\Theta} : \boldsymbol{\eta}_{|T} \in (P_1(T) \oplus B_3(T))^2\big\}, \tag{3.7}$$

$$W_h = \big\{v \in W : v_{|T} \in P_1(T)\big\}, \tag{3.8}$$

$$\boldsymbol{\Gamma}_h = \big\{\boldsymbol{\tau} \in L^2(\Omega)^2 : \boldsymbol{\tau}_{|T} \in P_0(T)^2\big\}, \tag{3.9}$$

where $P_k(T)$ is the space of polynomials of degree at most k defined on T and $B_3(T) = P_3(T) \cap H_0^1(T)$ is the space of cubic bubbles on T. The linking operator $L : \boldsymbol{\Theta}_h \longrightarrow H_0^1(\Omega)$ is defined as follows. For each $T \in \mathcal{T}_h$, we set

$$\varphi_i = \lambda_j \lambda_k \qquad \text{and} \qquad EB_2(T) = \operatorname{Span}\{\varphi_i\}_{1\le i\le 3}\,, \tag{3.10}$$

where $\{\lambda_i\}_{1\le i\le 3}$ are the barycentric coordinates of the triangle T and the indices (i, j, k) form a permutation of the set $(1, 2, 3)$. Then, the operator L is locally defined as

$$L\boldsymbol{\eta}_{h|T} = \sum_{i=1}^{3} \alpha_i \varphi_i \in EB_2(T), \tag{3.11}$$

where the coefficients α_i are determined by requiring that

$$(\boldsymbol{\nabla} L\boldsymbol{\eta}_h - \boldsymbol{\eta}_h) \cdot \mathbf{t} \quad \text{is constant on each } e. \tag{3.12}$$

Above, $\mathbf{t}$ denotes the tangential vector to the edge e. We recall that for the linking operator it holds (see [16] and [17])

$$||L\boldsymbol{\eta}_h||_{0,T} \le Ch_T||\boldsymbol{\nabla} L\boldsymbol{\eta}_h||_{0,T}, \qquad ||\boldsymbol{\nabla} L\boldsymbol{\eta}_h||_{0,T} \le Ch_T|\boldsymbol{\eta}_h|_{1,T}. \tag{3.13}$$

3.1.2. The quadratic element. This element (see [3]) is described by the finite element spaces

$$\boldsymbol{\Theta}_h = \big\{\boldsymbol{\eta} \in \boldsymbol{\Theta} : \boldsymbol{\eta}_{|T} \in P_2(T)^2 \oplus (P_1(T)^2 \oplus \boldsymbol{\nabla} B_3(T))b_T\big\}, \tag{3.14}$$

$$W_h = \big\{v \in W : v_{|T} \in P_2(T) \oplus B_3(T)\big\}, \tag{3.15}$$

$$\boldsymbol{\Gamma}_h = \big\{\boldsymbol{\tau} \in L^2(\Omega)^2 : \boldsymbol{\tau}_{|T} \in P_1(T)^2 \oplus \boldsymbol{\nabla} B_3(T)\big\}, \tag{3.16}$$

where $b_T = 27\lambda_1\lambda_2\lambda_3$. The linking operator $L : \boldsymbol{\Theta}_h \longrightarrow H_0^1(\Omega)$ is defined as follows. For each $T \in \mathcal{T}_h$, we set

$$\varphi_i = \lambda_j \lambda_k(\lambda_k - \lambda_j) \qquad \text{and} \qquad EB_3(T) = \operatorname{Span}\{\varphi_i\}_{1\le i\le 3}\,, \tag{3.17}$$

where the indices (i, j, k) form a permutation of the set $(1, 2, 3)$. Then, the operator L is locally defined as

$$L\boldsymbol{\eta}_{h|T} = \sum_{i=1}^{3} \alpha_i \varphi_i \in EB_3(T), \tag{3.18}$$

where the coefficients α_i are determined by requiring that

$$(\boldsymbol{\nabla} L\boldsymbol{\eta}_h - \boldsymbol{\eta}_h) \cdot \mathbf{t} \quad \text{is linear on each } e. \tag{3.19}$$

For this linking operator it holds (see [3])

$$||L\boldsymbol{\eta}_h||_{0,T} \le Ch_T||\boldsymbol{\nabla} L\boldsymbol{\eta}_h||_{0,T}, \qquad ||\boldsymbol{\nabla} L\boldsymbol{\eta}_h||_{0,T} \le Ch_T^2|\boldsymbol{\eta}_h|_{2,T} \le Ch_T|\boldsymbol{\eta}_h|_{1,T}. \tag{3.20}$$

3.2. A priori error estimates. Following the lines of [9], [10], [16], [18], [20], we prove a priori error estimates with respect to the norms

$$\|\!|(\boldsymbol{\eta}, v)\|\!|_h^2 := ||\boldsymbol{\eta}||_1^2 + ||v||_1^2 + \sum_{T\in\mathcal{T}_h} \frac{1}{h_T^2+t^2}||\boldsymbol{\nabla} v - \boldsymbol{\eta}||_{0,T}^2 \qquad \forall(\boldsymbol{\eta}, v) \in \boldsymbol{\Theta}\times W \tag{3.21}$$

and

$$||\boldsymbol{\tau}||_{-1} + t\,||\boldsymbol{\tau}||_0 \qquad \forall\boldsymbol{\tau}\in L^2(\Omega)^2. \tag{3.22}$$

We will also use the following discrete norm:

$$||\boldsymbol{\tau}||_h^2 := \sum_{T\in\mathcal{T}_h} h_T^2||\boldsymbol{\tau}||_{0,T}^2 + t^2||\boldsymbol{\tau}||_0^2 \qquad \forall\boldsymbol{\tau}\in L^2(\Omega)^2. \tag{3.23}$$

Before proceeding, we need the following lemma, which establishes a suitable norm equivalence in the used finite element spaces.

Lemma 3.1. *Consider the finite element spaces and the linking operator detailed in section* 3.1.1 *(or in section* 3.1.2*), and let P_h denote the L^2-projection operator on $\boldsymbol{\Gamma}_h$. Then for each $(\boldsymbol{\eta}_h, v_h^*) \in \boldsymbol{X}_h$ it holds*

$$\left(||\boldsymbol{\eta}_h||_1^2 + \sum_{T\in\mathcal{T}_h} \frac{1}{h_T^2+t^2}||P_h(\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h)||_{0,T}^2\right)^{1/2} \leq \|\!|(\boldsymbol{\eta}_h, v_h^*)\|\!|_h \tag{3.24}$$

and

$$\|\!|(\boldsymbol{\eta}_h, v_h^*)\|\!|_h \leq C\left(||\boldsymbol{\eta}_h||_1^2 + \sum_{T\in\mathcal{T}_h} \frac{1}{h_T^2+t^2}||P_h(\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h)||_{0,T}^2\right)^{1/2}. \tag{3.25}$$

Proof. Since (3.24) is trivial, we consider only (3.25). Therefore, take $\boldsymbol{\eta}_h \in \boldsymbol{\Theta}_h$, $v_h \in W_h$ and form $(\boldsymbol{\eta}_h, v_h^*) = (\boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h) \in \boldsymbol{X}_h$. We first notice that

$$\begin{aligned} ||\boldsymbol{\nabla} v_h^*||_0^2 &\leq 2\left(||\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h||_0^2 + ||\boldsymbol{\eta}_h||_0^2\right) \\ &\leq C\left(\sum_{T\in\mathcal{T}_h} \frac{1}{h_T^2+t^2}||\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h||_{0,T}^2 + ||\boldsymbol{\eta}_h||_1^2\right), \end{aligned} \tag{3.26}$$

so that, by Poincaré's inequality, we have

$$||v_h^*||_1^2 \leq C\left(\sum_{T\in\mathcal{T}_h} \frac{1}{h_T^2+t^2}||\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h||_{0,T}^2 + ||\boldsymbol{\eta}_h||_1^2\right), \tag{3.27}$$

Next, we write $\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h$ as

$$\begin{aligned} \boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h &= \boldsymbol{\nabla} v_h + \boldsymbol{\nabla} L\boldsymbol{\eta}_h - \boldsymbol{\eta}_h = P_h\boldsymbol{\nabla} v_h + \boldsymbol{\nabla} L\boldsymbol{\eta}_h - \boldsymbol{\eta}_h \\ &= P_h\boldsymbol{\nabla} v_h^* - (P_h\boldsymbol{\nabla} L\boldsymbol{\eta}_h - \boldsymbol{\nabla} L\boldsymbol{\eta}_h) - \boldsymbol{\eta}_h \\ &= P_h(\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h) - (P_h\boldsymbol{\nabla} L\boldsymbol{\eta}_h - \boldsymbol{\nabla} L\boldsymbol{\eta}_h) + (P_h\boldsymbol{\eta}_h - \boldsymbol{\eta}_h). \end{aligned} \tag{3.28}$$

Therefore, we have

$$\begin{aligned}||\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h||_{0,T} \leq ||P_h(\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h)||_{0,T} \\ + ||P_h \boldsymbol{\nabla} L\boldsymbol{\eta}_h - \boldsymbol{\nabla} L\boldsymbol{\eta}_h||_{0,T} + ||P_h\boldsymbol{\eta}_h - \boldsymbol{\eta}_h||_{0,T}.\end{aligned} \tag{3.29}$$

Since (see also (3.13) and (3.20))

$$||P_h \boldsymbol{\nabla} L\boldsymbol{\eta}_h - \boldsymbol{\nabla} L\boldsymbol{\eta}_h||_{0,T} \leq 2||\boldsymbol{\nabla} L\boldsymbol{\eta}_h||_{0,T} \leq Ch_T|\boldsymbol{\eta}_h|_{1,T} \tag{3.30}$$

and

$$||P_h\boldsymbol{\eta}_h - \boldsymbol{\eta}_h||_{0,T} \leq Ch_T|\boldsymbol{\eta}_h|_{1,T}, \tag{3.31}$$

from (3.29) we obtain

$$\begin{aligned}\frac{1}{h_T^2+t^2}||\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h||_{0,T}^2 &\leq C\left(\frac{1}{h_T^2+t^2}||P_h(\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h)||_{0,T}^2 + \frac{h_T^2}{h_T^2+t^2}|\boldsymbol{\eta}_h|_{1,T}^2\right) \\ &\leq C\left(\frac{1}{h_T^2+t^2}||P_h(\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h)||_{0,T}^2 + |\boldsymbol{\eta}_h|_{1,T}^2\right).\end{aligned} \tag{3.32}$$

Therefore, we get

$$\sum_{T\in\mathcal{T}_h}\frac{1}{h_T^2+t^2}||\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h||_{0,T}^2 \leq C\left(\sum_{T\in\mathcal{T}_h}\frac{1}{h_T^2+t^2}||P_h(\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h)||_{0,T}^2 + ||\boldsymbol{\eta}_h||_1^2\right). \tag{3.33}$$

Using (3.27) and (3.31) we deduce estimate (3.25). □

It is now useful to set

$$\begin{aligned}\mathcal{A}(\boldsymbol{\theta}, w, \boldsymbol{\gamma}; \boldsymbol{\eta}, v, \boldsymbol{\tau}) := a(\boldsymbol{\theta}, \boldsymbol{\eta}) + (\boldsymbol{\nabla} v - \boldsymbol{\eta}, \boldsymbol{\gamma}) \\ - (\boldsymbol{\nabla} w - \boldsymbol{\theta}, \boldsymbol{\tau}) + \mu^{-1}t^2(\boldsymbol{\gamma}, \boldsymbol{\tau}).\end{aligned} \tag{3.34}$$

Therefore, the continuous problem (2.2) reads

$$\begin{cases}\text{Find } (\boldsymbol{\theta}, w; \boldsymbol{\gamma}) \in \boldsymbol{X} \times L^2(\Omega)^2 \text{ such that} \\ \mathcal{A}(\boldsymbol{\theta}, w, \boldsymbol{\gamma}; \boldsymbol{\eta}, v, \boldsymbol{\tau}) = (g, v) \qquad \forall(\boldsymbol{\eta}, v; \boldsymbol{\tau}) \in \boldsymbol{X} \times L^2(\Omega)^2,\end{cases} \tag{3.35}$$

while the discrete problem (3.5) is

$$\begin{cases}\text{Find } (\boldsymbol{\theta}_h, w_h^*; \boldsymbol{\gamma}_h) \in \boldsymbol{X}_h \times \boldsymbol{\Gamma}_h \text{ such that} \\ \mathcal{A}(\boldsymbol{\theta}_h, w_h^*, \boldsymbol{\gamma}_h; \boldsymbol{\eta}_h, v_h^*, \boldsymbol{\tau}_h) = (g, v_h^*) \qquad \forall(\boldsymbol{\eta}_h, v_h^*; \boldsymbol{\tau}_h) \in \boldsymbol{X}_h \times \boldsymbol{\Gamma}_h.\end{cases} \tag{3.36}$$

We have the following stability result, for which we only sketch the proof, since it takes advantage of the same techniques detailed in [9] and [16].

PROPOSITION 3.2. *Given $(\boldsymbol{\beta}_h, z_h^*; \boldsymbol{\rho}_h) \in \boldsymbol{X}_h \times \boldsymbol{\Gamma}_h$ there exists $(\boldsymbol{\eta}_h, v_h^*; \boldsymbol{\tau}_h) \in \boldsymbol{X}_h \times \boldsymbol{\Gamma}_h$ such that*

$$\mathcal{A}(\boldsymbol{\beta}_h, z_h^*, \boldsymbol{\rho}_h; \boldsymbol{\eta}_h, v_h^*, \boldsymbol{\tau}_h) \geq C\left(|||(\boldsymbol{\beta}_h, z_h^*)|||_h^2 + ||\boldsymbol{\rho}_h||_h^2\right), \tag{3.37}$$

$$\|\!|(\boldsymbol{\eta}_h, v_h^*)|\!\|_h + ||\boldsymbol{\tau}_h||_h \leq C\left(\|\!|(\boldsymbol{\beta}_h, z_h^*)|\!\|_h + ||\boldsymbol{\rho}_h||_h\right). \tag{3.38}$$

Proof. Let us $(\boldsymbol{\beta}_h, z_h^*; \boldsymbol{\rho}_h)$ be given in $\boldsymbol{X}_h \times \boldsymbol{\Gamma}_h$. Using exactly the same arguments of [9] and [16] we get that there exists $(\boldsymbol{\eta}_h, v_h^*; \boldsymbol{\tau}_h)$ in $\boldsymbol{X}_h \times \boldsymbol{\Gamma}_h$ such that

$$\mathcal{A}(\boldsymbol{\beta}_h, z_h^*, \boldsymbol{\rho}_h; \boldsymbol{\eta}_h, v_h^*, \boldsymbol{\tau}_h) \geq C\left(||\boldsymbol{\beta}_h||_1^2 + \sum_{T\in\mathcal{T}_h} \frac{1}{h_T^2 + t^2}||P_h(\boldsymbol{\nabla} z_h^* - \boldsymbol{\beta}_h)||_{0,T}^2 + ||\boldsymbol{\rho}_h||_h^2\right) \tag{3.39}$$

and

$$\begin{aligned}||\boldsymbol{\eta}_h||_1 &+ \left(\sum_{T\in\mathcal{T}_h} \frac{1}{h_T^2 + t^2}||P_h(\boldsymbol{\nabla} v_h^* - \boldsymbol{\eta}_h)||_{0,T}^2\right)^{1/2} + ||\boldsymbol{\tau}_h||_h \\ &\leq C\left(||\boldsymbol{\beta}_h||_1 + \left(\sum_{T\in\mathcal{T}_h} \frac{1}{h_T^2 + t^2}||P_h(\boldsymbol{\nabla} z_h^* - \boldsymbol{\beta}_h)||_{0,T}^2\right)^{1/2} + ||\boldsymbol{\rho}_h||_h\right).\end{aligned} \tag{3.40}$$

We now use Lemma 3.1 to infer that given $(\boldsymbol{\beta}_h, z_h^*; \boldsymbol{\rho}_h) \in \boldsymbol{X}_h \times \boldsymbol{\Gamma}_h$, there exists $(\boldsymbol{\eta}_h, v_h^*; \boldsymbol{\tau}_h) \in \boldsymbol{X}_h \times \boldsymbol{\Gamma}_h$ such that

$$\mathcal{A}(\boldsymbol{\beta}_h, z_h^*, \boldsymbol{\rho}_h; \boldsymbol{\eta}_h, v_h^*, \boldsymbol{\tau}_h) \geq C\left(\|\!|(\boldsymbol{\beta}_h, z_h^*)|\!\|_h^2 + ||\boldsymbol{\rho}_h||_h^2\right) \tag{3.41}$$

and

$$\|\!|(\boldsymbol{\eta}_h, v_h^*)|\!\|_h + ||\boldsymbol{\tau}_h||_h \leq C\left(\|\!|(\boldsymbol{\beta}_h, z_h^*)|\!\|_h + ||\boldsymbol{\rho}_h||_h\right). \qquad \square \tag{3.42}$$

We are now ready to prove our error estimate (see also [17] and [16]). We focus on the lowest-order element detailed in section 3.1.1, but a similar technique (together with the ideas developed in [18]) may be applied to appropriately treat the higher-order case of section 3.1.2.

PROPOSITION 3.3. *Suppose that Ω is a convex polygon and $g \in L^2(\Omega)$ and consider the element detailed in section* 3.1.1. *Let $(\boldsymbol{\theta}, w; \boldsymbol{\gamma}) \in \boldsymbol{X} \times L^2(\Omega)^2$ and $(\boldsymbol{\theta}_h, w_h^*; \boldsymbol{\gamma}_h) \in \boldsymbol{X}_h \times \boldsymbol{\Gamma}_h$ be the solutions of problem* (3.35) *and* (3.36), *respectively. Then the following a priori estimates holds:*

$$\|\!|(\boldsymbol{\theta} - \boldsymbol{\theta}_h, w - w_h^*)|\!\|_h + ||\boldsymbol{\gamma} - \boldsymbol{\gamma}_h||_{-1} + ||\boldsymbol{\gamma} - \boldsymbol{\gamma}_h||_h \leq C\, h(||g||_{-1} + t\,||g||_0). \tag{3.43}$$

Proof. Since our method is consistent (cf. (3.35) and (3.36)) and stable (see Proposition 3.2), error estimates with respect to the norms in question can be established in the standard way. Hence, let

$$(\boldsymbol{\theta}_I, w_I^*; \boldsymbol{\gamma}_I) = (\boldsymbol{\theta}_I, w_I + L\boldsymbol{\theta}_I; \boldsymbol{\gamma}_I) \in \boldsymbol{X}_h \times \boldsymbol{\Gamma}_h \tag{3.44}$$

be a suitable interpolant (to be specified later) of the continuous solution $(\boldsymbol{\theta}, w^*; \boldsymbol{\gamma})$. Corresponding to $(\boldsymbol{\theta}_h - \boldsymbol{\theta}_I, w_h^* - w_I^*; \boldsymbol{\gamma}_h - \boldsymbol{\gamma}_I) \in \boldsymbol{X}_h \times \boldsymbol{\Gamma}_h$ there exists (see Proposition 3.2) $(\boldsymbol{\eta}_h, v_h^*; \boldsymbol{\tau}_h) \in \boldsymbol{X}_h \times \boldsymbol{\Gamma}_h$ such that

$$\mathcal{A}(\boldsymbol{\theta}_h - \boldsymbol{\theta}_I, w_h^* - w_I^*, \boldsymbol{\gamma}_h - \boldsymbol{\gamma}_I; \boldsymbol{\eta}_h, v_h^*, \boldsymbol{\tau}_h) \geq C\big(\|\!|(\boldsymbol{\theta}_h - \boldsymbol{\theta}_I, w_h^* - w_I^*)|\!\|_h^2 + ||\boldsymbol{\gamma}_h - \boldsymbol{\gamma}_I||_h^2\big), \tag{3.45}$$

and

$$\|\!|(\boldsymbol{\eta}_h, v_h^*)|\!\|_h + ||\boldsymbol{\tau}_h||_h \leq C\left(\|\!|(\boldsymbol{\theta}_h - \boldsymbol{\theta}_I, w_h^* - w_I^*)|\!\|_h + ||\boldsymbol{\gamma}_h - \boldsymbol{\gamma}_I||_h\right). \tag{3.46}$$

By consistency it holds

$$\begin{aligned}\mathcal{A}(\boldsymbol{\theta}_h-\boldsymbol{\theta}_I, w_h^*-w_I^*,\boldsymbol{\gamma}_h-\boldsymbol{\gamma}_I;\boldsymbol{\eta}_h,v_h^*,\boldsymbol{\tau}_h) &= \mathcal{A}(\boldsymbol{\theta}-\boldsymbol{\theta}_I, w-w_I^*,\boldsymbol{\gamma}-\boldsymbol{\gamma}_I;\boldsymbol{\eta}_h,v_h^*,\boldsymbol{\tau}_h)\\ &= a(\boldsymbol{\theta}-\boldsymbol{\theta}_I,\boldsymbol{\eta}_h)+(\boldsymbol{\nabla} v_h^*-\boldsymbol{\eta}_h,\boldsymbol{\gamma}-\boldsymbol{\gamma}_I)\\ &-\big(\boldsymbol{\nabla}(w-w_I^*)-(\boldsymbol{\theta}-\boldsymbol{\theta}_I),\boldsymbol{\tau}_h\big)+\mu^{-1}t^2(\boldsymbol{\gamma}-\boldsymbol{\gamma}_I,\boldsymbol{\tau}_h)\\ &= \text{(I)}+\text{(II)}+\text{(III)}+\text{(IV)}.\end{aligned} \tag{3.47}$$

To bound the four terms above, we first choose the interpolants $\boldsymbol{\theta}_I$, w_I^* and $\boldsymbol{\gamma}_I$ as follows. According to the splitting (2.3), $\boldsymbol{\theta}_I$ is given by

$$\boldsymbol{\theta}_I := \mathcal{I}\boldsymbol{\theta} = \mathcal{I}\boldsymbol{\theta}_0 + \mathcal{I}\boldsymbol{\theta}_r, \tag{3.48}$$

where $\mathcal{I}$ is the Lagrange interpolating operator. To define w_I^*, we need to specify w_I (cf. (3.44)). Again, the splitting (2.3) suggests to set

$$w_I := \mathcal{I}w = \mathcal{I}w_0 + \mathcal{I}w_r. \tag{3.49}$$

Therefore, w_I^* turns out to be $w_I^* = w_I + L\boldsymbol{\theta}_I = \mathcal{I}w + L(\mathcal{I}\boldsymbol{\theta})$. Finally, $\boldsymbol{\gamma}_I$ is simply the L^2-projection of $\boldsymbol{\gamma}$ onto $\boldsymbol{\Gamma}_h$.

Estimate for (I). Using the H^1-continuity of the bilinear form $a(\cdot,\cdot)$, standard approximation results, and estimate (2.5) we have

$$\text{(I)} = a(\boldsymbol{\theta}-\boldsymbol{\theta}_I,\boldsymbol{\eta}_h) \le Ch||\boldsymbol{\theta}||_2||\boldsymbol{\eta}_h||_1 \le Ch(||g||_{-1}+t\,||g||_0)||\boldsymbol{\eta}_h||_1. \tag{3.50}$$

Estimate for (II). We notice that

$$\begin{aligned}\text{(II)} &= (\boldsymbol{\nabla} v_h^*-\boldsymbol{\eta}_h,\boldsymbol{\gamma}-\boldsymbol{\gamma}_I)\\ &\le \left(\sum_{T\in\mathcal{T}_h}\frac{1}{h_T^2+t^2}||\boldsymbol{\nabla} v_h^*-\boldsymbol{\eta}_h||_{0,T}^2\right)^{1/2}\left(\sum_{T\in\mathcal{T}_h}(h_T^2+t^2)||\boldsymbol{\gamma}-\boldsymbol{\gamma}_I||_{0,T}^2\right)^{1/2},\end{aligned} \tag{3.51}$$

by which, using again (2.5) and standard approximation estimates, we get

$$\text{(II)} \le Ch(||g||_{-1}+t\,||g||_0)\left(\sum_{T\in\mathcal{T}_h}\frac{1}{h_T^2+t^2}||\boldsymbol{\nabla} v_h^*-\boldsymbol{\eta}_h||_{0,T}^2\right)^{1/2}. \tag{3.52}$$

Estimate for (III).

$$\begin{aligned}\text{(III)} &= -\big(\boldsymbol{\nabla}(w-w_I^*)-(\boldsymbol{\theta}-\boldsymbol{\theta}_I),\boldsymbol{\tau}_h\big)\\ &\le \left(\sum_{T\in\mathcal{T}_h}\frac{1}{h_T^2+t^2}||\boldsymbol{\nabla}(w-w_I^*)-(\boldsymbol{\theta}-\boldsymbol{\theta}_I)||_{0,T}^2\right)^{1/2}\left(\sum_{T\in\mathcal{T}_h}(h_T^2+t^2)||\boldsymbol{\tau}_h||_{0,T}^2\right)^{1/2}.\end{aligned} \tag{3.53}$$

We now notice that we have (see (2.3), (3.44) and (3.48)–(3.49))

$$\begin{aligned}\boldsymbol{\nabla}(w-w_I^*)-(\boldsymbol{\theta}-\boldsymbol{\theta}_I) &= \Big\{\boldsymbol{\nabla}\big(w_0-\mathcal{I}w_0-L(\mathcal{I}\boldsymbol{\theta}_0)\big)-(\boldsymbol{\theta}_0-\mathcal{I}\boldsymbol{\theta}_0)\Big\}\\ &+\Big\{\boldsymbol{\nabla}\big(w_r-\mathcal{I}w_r-L(\mathcal{I}\boldsymbol{\theta}_r)\big)-(\boldsymbol{\theta}_r-\mathcal{I}\boldsymbol{\theta}_r)\Big\}.\end{aligned} \tag{3.54}$$

In [16] it has been proved that

$$\big|\boldsymbol{\nabla}\big(w_0 - \mathcal{I}w_0 - L(\mathcal{I}\boldsymbol{\theta}_0)\big)\big|_{0,T} \le Ch_T^2|w_0|_{3,T}, \tag{3.55}$$

while standard approximation results give

$$|\boldsymbol{\theta}_0 - \mathcal{I}\boldsymbol{\theta}_0|_{0,T} \le Ch_T^2|\boldsymbol{\theta}_0|_{2,T}, \tag{3.56}$$

$$|\boldsymbol{\theta}_r - \mathcal{I}\boldsymbol{\theta}_r|_{0,T} \le Ch_T^2|\boldsymbol{\theta}_r|_{2,T}. \tag{3.57}$$

Furthermore, using also (3.13) it holds

$$\begin{aligned}\big|\boldsymbol{\nabla}\big(w_r - \mathcal{I}w_r - L(\mathcal{I}\boldsymbol{\theta}_r)\big)\big|_{0,T} &\le |\boldsymbol{\nabla}(w_r - \mathcal{I}w_r)|_{0,T} + |\boldsymbol{\nabla}L(\mathcal{I}\boldsymbol{\theta}_r)|_{0,T} \\ &\le |\boldsymbol{\nabla}(w_r - \mathcal{I}w_r)|_{0,T} + |\boldsymbol{\nabla}L(\mathcal{I}\boldsymbol{\theta}_r - \boldsymbol{\theta}_r)|_{0,T} + |\boldsymbol{\nabla}L(\boldsymbol{\theta}_r)|_{0,T} \\ &\le C\big(h_T|w_r|_{2,T} + h_T|\mathcal{I}\boldsymbol{\theta}_r - \boldsymbol{\theta}_r|_{1,T} + h_T|\boldsymbol{\theta}_r|_{1,T}\big) \\ &\le C\big(h_T|w_r|_{2,T} + h_T^2|\boldsymbol{\theta}_r|_{2,T} + h_T|\boldsymbol{\theta}_r|_{1,T}\big).\end{aligned} \tag{3.58}$$

From (3.54)–(3.58) we obtain

$$\begin{aligned}&\sum_{T\in\mathcal{T}_h} \frac{1}{h_T^2+t^2}||\boldsymbol{\nabla}(w - w_I^*) - (\boldsymbol{\theta} - \boldsymbol{\theta}_I)||_{0,T}^2 \\ &\qquad \le C\sum_{T\in\mathcal{T}_h} \frac{1}{h_T^2+t^2}\left(h_T^4|w_0|_{3,T}^2 + h_T^4|\boldsymbol{\theta}|_{2,T}^2 + h_T^2|w_r|_{2,T}^2 + h_T^2|\boldsymbol{\theta}_r|_{1,T}^2\right) \\ &\qquad \le Ch^2\big(|w_0|_3^2 + |\boldsymbol{\theta}|_2^2\big) + \sum_{T\in\mathcal{T}_h}\frac{h_T^2}{h_T^2+t^2}\big(|w_r|_{2,T}^2 + |\boldsymbol{\theta}_r|_{1,T}^2\big) \\ &\qquad \le Ch^2\big(|w_0|_3^2 + |\boldsymbol{\theta}|_2^2\big) + \sum_{T\in\mathcal{T}_h} h_T^2\left(\frac{|w_r|_{2,T}^2}{t^2} + \frac{|\boldsymbol{\theta}_r|_{1,T}^2}{t^2}\right) \\ &\qquad \le Ch^2\left(|w_0|_3^2 + |\boldsymbol{\theta}|_2^2 + \frac{|w_r|_2^2}{t^2} + \frac{|\boldsymbol{\theta}_r|_1^2}{t^2}\right).\end{aligned} \tag{3.59}$$

Using (2.5)–(2.7), from (3.59) it follows that

$$\begin{aligned}&\left(\sum_{T\in\mathcal{T}_h} \frac{1}{h_T^2+t^2}||\boldsymbol{\nabla}(w - w_I^*) - (\boldsymbol{\theta} - \boldsymbol{\theta}_I)||_{0,T}^2\right)^{1/2} \\ &\qquad \le Ch\left(||w_0||_3 + ||\boldsymbol{\theta}||_2 + \frac{||w_r||_2}{t} + \frac{||\boldsymbol{\theta}_r||_1}{t}\right) \\ &\qquad \le Ch(||g||_{-1} + t\,||g||_0).\end{aligned} \tag{3.60}$$

Therefore, we obtain (see (3.53))

$$\text{(III)} \le Ch(||g||_{-1} + t\,||g||_0)\left(\sum_{T\in\mathcal{T}_h}(h_T^2+t^2)||\boldsymbol{\tau}_h||_{0,T}^2\right)^{1/2}. \tag{3.61}$$

Estimate for (IV). We simply notice that

$$(\mathrm{IV}) = \mu^{-1}t^2(\boldsymbol{\gamma} - \boldsymbol{\gamma}_I, \boldsymbol{\tau}_h) \leq Ct\,||\boldsymbol{\gamma} - \boldsymbol{\gamma}_I||_0 t\,||\boldsymbol{\tau}_h||_0 \leq Ch(||g||_{-1} + t\,||g||_0)t\,||\boldsymbol{\tau}_h||_0. \tag{3.62}$$

Collecting (3.50), (3.52), (3.61), and (3.62), from (3.47) we get

$$\begin{aligned}\mathcal{A}(\boldsymbol{\theta}_h - \boldsymbol{\theta}_I, w_h^* - w_I^*, &\boldsymbol{\gamma}_h - \boldsymbol{\gamma}_I; \boldsymbol{\eta}_h, v_h^*, \boldsymbol{\tau}_h)\\ &\leq Ch(||g||_{-1} + t\,||g||_0)\left(|||(\boldsymbol{\eta}_h, v_h^*)|||_h + ||\boldsymbol{\tau}_h||_h\right).\end{aligned} \tag{3.63}$$

From (3.45), (3.46), (3.63), and the triangle inequality, we infer

$$|||(\boldsymbol{\theta} - \boldsymbol{\theta}_h, w - w_h^*)|||_h + ||\boldsymbol{\gamma} - \boldsymbol{\gamma}_h||_h \leq C\,h(||g||_{-1} + t\,||g||_0). \tag{3.64}$$

To obtain the error in the H^{-1}-norm for the shears, we use the Pitkäranta–Verfürth trick (cf. [19], [23], and [20]). Hence, we recall that

$$||\boldsymbol{\gamma} - \boldsymbol{\gamma}_h||_{-1} = \sup_{\boldsymbol{\eta} \in \boldsymbol{\Theta}} \frac{(\boldsymbol{\gamma} - \boldsymbol{\gamma}_h, \boldsymbol{\eta})}{||\boldsymbol{\eta}||_1}. \tag{3.65}$$

For a generic $\boldsymbol{\eta} \in \boldsymbol{\Theta}$ we consider its Clemént's interpolant $\boldsymbol{\eta}^c \in \boldsymbol{\Theta}_h$ (see [11], for instance), and we write

$$(\boldsymbol{\gamma} - \boldsymbol{\gamma}_h, \boldsymbol{\eta}) = (\boldsymbol{\gamma} - \boldsymbol{\gamma}_h, \boldsymbol{\eta} - \boldsymbol{\eta}^c) + (\boldsymbol{\gamma} - \boldsymbol{\gamma}_h, \boldsymbol{\eta}^c). \tag{3.66}$$

On the one hand, we have

$$\begin{aligned}(\boldsymbol{\gamma} - \boldsymbol{\gamma}_h, \boldsymbol{\eta} - \boldsymbol{\eta}^c) &\leq \left(\sum_{T \in \mathcal{T}_h} h_T^2 ||\boldsymbol{\gamma} - \boldsymbol{\gamma}_h||_{0,T}^2\right)^{1/2} \left(\sum_{T \in \mathcal{T}_h} h_T^{-2} ||\boldsymbol{\eta} - \boldsymbol{\eta}^c||_{0,T}^2\right)^{1/2}\\ &\leq C||\boldsymbol{\gamma} - \boldsymbol{\gamma}_h||_h ||\boldsymbol{\eta}||_1.\end{aligned} \tag{3.67}$$

On the other hand, recalling (2.2) and (3.5), we get

$$(\boldsymbol{\gamma} - \boldsymbol{\gamma}_h, \boldsymbol{\eta}^c) = a(\boldsymbol{\theta} - \boldsymbol{\theta}_h, \boldsymbol{\eta}^c) \leq C||\boldsymbol{\theta} - \boldsymbol{\theta}_h||_1 ||\boldsymbol{\eta}^c||_1 \leq C||\boldsymbol{\theta} - \boldsymbol{\theta}_h||_1 ||\boldsymbol{\eta}||_1. \tag{3.68}$$

From (3.65)–(3.68), we obtain

$$||\boldsymbol{\gamma} - \boldsymbol{\gamma}_h||_{-1} \leq C\left(||\boldsymbol{\gamma} - \boldsymbol{\gamma}_h||_h + ||\boldsymbol{\theta} - \boldsymbol{\theta}_h||_1\right). \tag{3.69}$$

Estimate (3.43) now follows from (3.64) and (3.69). □

Using the technique in [9], one may also get the following improved estimates.

PROPOSITION 3.4. *Suppose that* Ω *is a convex polygon and* $g \in L^2(\Omega)$. *Then the following a priori estimates hold:*

$$||\boldsymbol{\theta} - \boldsymbol{\theta}_h||_0 \leq Ch^2(||g||_{-1} + t\,||g||_0), \tag{3.70}$$

$$||w - w_h^*||_1 \leq Ch(h + t)(||g||_{-1} + t\,||g||_0). \quad \square \tag{3.71}$$

4. A posteriori error estimates. The aim of this section is to introduce suitable error estimator for the elements based on the linked interpolation technique and to prove its reliability and efficiency. To begin, for each $T \in \mathcal{T}_h$ and $e \in \mathcal{E}_h$ we introduce the following quantities:

$$\begin{aligned}\widetilde{\eta}_T^2 := h_T^2 || \operatorname{div} \mathbf{C}\, \varepsilon(\boldsymbol{\theta}_h) + \boldsymbol{\gamma}_h ||_{0,T}^2 + h_T^2(h_T^2 + t^2) || \operatorname{div} \boldsymbol{\gamma}_h + g_h ||_{0,T}^2 \\ + \frac{\mu^2}{h_T^2 + t^2} || \mu^{-1} t^2\, \boldsymbol{\gamma}_h - (\boldsymbol{\nabla} w_h^* - \boldsymbol{\theta}_h) ||_{0,T}^2,\end{aligned} \tag{4.1}$$

$$\eta_e^2 := h_e || \left[\!\left[\mathbf{C}\, \varepsilon(\boldsymbol{\theta}_h) \mathbf{n} \right]\!\right] ||_{0,e}^2 + h_e(h_e^2 + t^2) || \left[\!\left[\boldsymbol{\gamma}_h \cdot \mathbf{n} \right]\!\right] ||_{0,e}^2, \tag{4.2}$$

where g_h is some approximation of the load g. Moreover, h_e is the length of the side e and $[\![\cdot]\!]$ denotes the jump operator. We then define a local indicator η_T as

$$\eta_T := \left(\widetilde{\eta}_T^2 + \sum_{e \subset \partial T} \eta_e^2 \right)^{1/2} \tag{4.3}$$

and a global indicator η as

$$\eta := \left(\sum_{T \in \mathcal{T}_h} \widetilde{\eta}_T^2 + \sum_{e \in \mathcal{E}_h} \eta_e^2 \right)^{1/2}. \tag{4.4}$$

Remark 4.1. When considering the element described in section 3.1.1, the expression in (4.1) becomes simpler, since we locally have $\operatorname{div} \boldsymbol{\gamma}_h = 0$ (see (3.9)).

We now introduce some useful notation. Given a generic $e \in \mathcal{E}_h$, we denote with ω_e the union of the triangles in $\mathcal{T}_h$ having e as a side. Furthermore, for $T \in \mathcal{T}_h$ we set ω_T as the union of the ω_e, with $e \subset \partial T$. We proceed with the following result.

LEMMA 4.1. *Given $e \in \mathcal{E}_h$, let $P_k(e)$ be the space of polynomials of degree at most k defined on e. There exists a linear operator*

$$\Pi_e \,:\, P_k(e) \longrightarrow H_0^2(\omega_e) \tag{4.5}$$

such that for all $p_k \in P_k(e)$ it holds

$$C_1 ||p_k||_{0,e}^2 \leq \int_e p_k \big(\Pi_e p_k\big) \leq ||p_k||_{0,e}^2, \tag{4.6}$$

$$||\Pi_e p_k||_{0,\omega_e} \leq C_2 h_e^{1/2} ||p_k||_{0,e}, \tag{4.7}$$

$$|\boldsymbol{\nabla}(\Pi_e p_k)|_{0,\omega_e} \leq C_3 h_e^{-1/2} ||p_k||_{0,e}, \tag{4.8}$$

$$|\boldsymbol{\nabla}(\Pi_e p_k)|_{1,\omega_e} \leq C_4 h_e^{-3/2} ||p_k||_{0,e}. \tag{4.9}$$

Above, the constants C_i depend only on k and on the minimum angle of the triangles in the meshes $\mathcal{T}_h$.

Proof. We consider only the case of an interior edge e: if e is a boundary edge (i.e., $e \subset \partial\Omega$), the required modifications are obvious. Due to the minimum angle condition, there exists a fixed reference rhomb $\widehat{D}$, as depicted in Figure 4.1, where, e.g., $\delta = \alpha/2$ (see (3.2)), with the following property: for each $e \in \mathcal{E}_h$ it is possible to determine a rhomb $D_e \subseteq \omega_e$ similar to $\widehat{D}$ (see Figure 4.2). According to Figure 4.2,

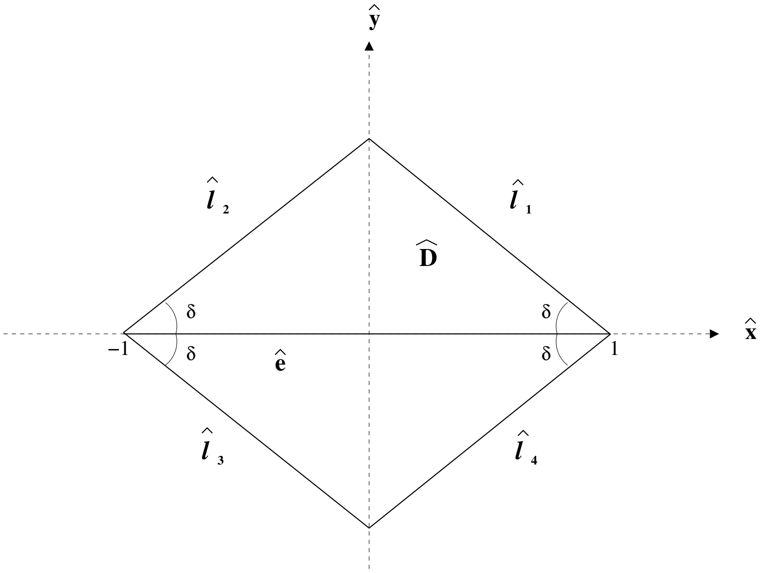

FIG. 4.1. *The reference rhomb $\widehat{D}$.*

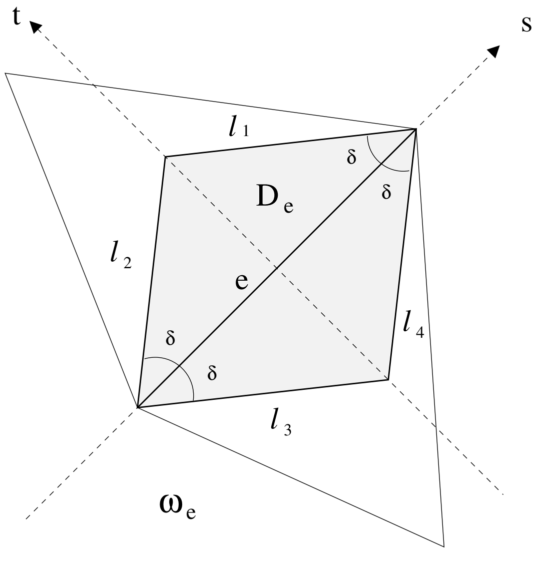

FIG. 4.2. *Relevant objects associated with the edge e.*

on ω_e we now introduce local Cartesian coordinates (s, t), as well as the functions

(4.10) $d_i(s, t) =$ "distance of (s, t) from the edge l_i", $i = 1, \dots, 4$ (see Figure 4.2).

Next, we define $\psi_e(s, t) : \omega_e \longrightarrow \mathbf{R}$ as

$$\psi_e(s, t) := \alpha_e\, \chi_{D_e}(s, t) \prod_{i=1}^{4} d_i(s, t)^2, \tag{4.11}$$

where $\chi_{D_e}(s, t)$ is the characteristic function of the set D_e, while α_e is a normalization constant in order to have $||\psi_e||_\infty = 1$. We also notice that in the coordinates (s,t) a generic polynomial $p_k \in P_k(e)$ can be simply written as $p_k(s)$. We are ready to define $\Pi_e : P_k(e) \longrightarrow H^2_0(\omega_e)$ by setting

$$(\Pi_e p_k)(s,t) := \psi_e(s,t)p_k(s), \qquad (s,t) \in \omega_e. \tag{4.12}$$

Estimates (4.6)–(4.9) easily follows from standard scaling arguments, using the fixed reference rhomb $\widehat{D}$. □

4.1. Upper bounds. We now prove that the indicator just introduced can be used as a reliable error estimator. We will prove our upper bounds for the linear element of section 3.1.1 by means of a saturation assumption involving its quadratic version. Therefore, to avoid confusion, we will denote all the quantities relative to the quadratic element described in section 3.1.2 by a tilde. For example, the approximation spaces and linking operator in (3.14)–(3.19) will be renamed as $\widetilde{\boldsymbol{\Theta}}_h$, $\widetilde{W}_h$, $\widetilde{\boldsymbol{\Gamma}}_h$, and $\widetilde{L}$, respectively. Accordingly, we define

$$\widetilde{\boldsymbol{X}}_h = \big\{(\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}^*_h) = (\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}_h + \widetilde{L}\widetilde{\boldsymbol{\eta}}_h) : \widetilde{\boldsymbol{\eta}}_h \in \widetilde{\boldsymbol{\Theta}}_h\,,\ \widetilde{v}_h \in \widetilde{W}_h\big\}. \tag{4.13}$$

We need to make the following assumption.

Saturation assumption. Let $(\boldsymbol{\theta}_h, w^*_h, \boldsymbol{\gamma}_h) \in \boldsymbol{X}_h \times \boldsymbol{\Gamma}_h$ (resp., $(\widetilde{\boldsymbol{\theta}}_h, \widetilde{w}^*_h, \widetilde{\boldsymbol{\gamma}}_h) \in \widetilde{\boldsymbol{X}}_h \times \widetilde{\boldsymbol{\Gamma}}_h$) be the discrete solution using the linear (resp., quadratic) element. We assume that there exists $0 < \rho < 1$ such that

$$\begin{aligned} &|||(\boldsymbol{\theta} - \widetilde{\boldsymbol{\theta}}_h, w - \widetilde{w}^*_h)|||_h + ||\boldsymbol{\gamma} - \widetilde{\boldsymbol{\gamma}}_h||_{-1} + t\,||\boldsymbol{\gamma} - \widetilde{\boldsymbol{\gamma}}_h||_0 \\ &\qquad \le \rho\Big(|||(\boldsymbol{\theta} - \boldsymbol{\theta}_h, w - w^*_h)|||_h + ||\boldsymbol{\gamma} - \boldsymbol{\gamma}_h||_{-1} + t\,||\boldsymbol{\gamma} - \boldsymbol{\gamma}_h||_0\Big). \end{aligned} \tag{4.14} \quad \square$$

By using the saturation assumption (4.14), it is easily seen that one gets the reliability estimate

$$\begin{aligned} &|||(\boldsymbol{\theta} - \boldsymbol{\theta}_h, w - w^*_h)|||_h + ||\boldsymbol{\gamma} - \boldsymbol{\gamma}_h||_{-1} + t\,||\boldsymbol{\gamma} - \boldsymbol{\gamma}_h||_0 \\ &\qquad \le C\left(\sum_{T\in\mathcal{T}_h}\Big(\eta_T^2 + h_T^2(h_T^2 + t^2)||g - g_h||^2_{0,T}\Big)\right)^{1/2}, \end{aligned} \tag{4.15}$$

provided one is able to bound

$$|||(\widetilde{\boldsymbol{\theta}}_h - \boldsymbol{\theta}_h, \widetilde{w}^*_h - w^*_h)|||_h + ||\widetilde{\boldsymbol{\gamma}}_h - \boldsymbol{\gamma}_h||_{-1} + t\,||\widetilde{\boldsymbol{\gamma}}_h - \boldsymbol{\gamma}_h||_0. \tag{4.16}$$

To this aim, we need the next result, which states that $\boldsymbol{X}_h \subseteq \widetilde{\boldsymbol{X}}_h$, and that functions in $\widetilde{\boldsymbol{X}}_h$ can be approximated by functions in $\boldsymbol{X}_h$.

LEMMA 4.2. *It holds $\boldsymbol{X}_h \subseteq \widetilde{\boldsymbol{X}}_h$; moreover, given $(\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}^*_h) \in \widetilde{\boldsymbol{X}}_h$, there exists $(\boldsymbol{\eta}_h, v^*_h) \in \boldsymbol{X}_h$ such that*

$$\begin{aligned} &\sum_{T\in\mathcal{T}_h} h_T^{-2}\left(||\widetilde{\boldsymbol{\eta}}_h - \boldsymbol{\eta}_h||^2_{0,T} + \frac{1}{h_T^2 + t^2}||\widetilde{v}^*_h - v^*_h||^2_{0,T}\right) \\ &\quad + \sum_{e\in\mathcal{E}_h} h_e^{-1}\left(||\widetilde{\boldsymbol{\eta}}_h - \boldsymbol{\eta}_h||^2_{0,e} + \frac{1}{h_e^2 + t^2}||\widetilde{v}^*_h - v^*_h||^2_{0,e}\right) \le C|||(\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}^*_h)|||^2_h. \end{aligned} \tag{4.17}$$

Proof. First, we need to show that a generic $(\boldsymbol{\eta}_h, v_h^*) = (\boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h) \in \boldsymbol{X}_h$ can be written as $(\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}_h^*) = (\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}_h + \widetilde{L}\widetilde{\boldsymbol{\eta}}_h) \in \widetilde{\boldsymbol{X}}_h$ for suitable $\widetilde{\boldsymbol{\eta}}_h \in \widetilde{\boldsymbol{\Theta}}_h$ and $\widetilde{v}_h \in \widetilde{W}_h$. This forces $\widetilde{\boldsymbol{\eta}}_h = \boldsymbol{\eta}_h$, which is an admissible choice, since obviously $\boldsymbol{\Theta}_h \subseteq \widetilde{\boldsymbol{\Theta}}_h$. Noting that $v_h + L\boldsymbol{\eta}_h \in \widetilde{W}_h$, we set $\widetilde{v}_h = v_h + L\boldsymbol{\eta}_h$. We now observe (see (3.18)–(3.19)) that $\widetilde{L}\widetilde{\boldsymbol{\eta}}_h = \widetilde{L}\boldsymbol{\eta}_h = 0$. Indeed, given $\boldsymbol{\eta}_h \in \boldsymbol{\Theta}_h$, the equation

$$(\boldsymbol{\nabla}\widetilde{L}\boldsymbol{\eta}_h - \boldsymbol{\eta}_h) \cdot \mathbf{t} \quad \text{is linear on each } e \tag{4.18}$$

has unique solution $\widetilde{L}\boldsymbol{\eta}_h = 0$, since $\boldsymbol{\eta}_h$ is already linear on each edge e. Therefore we have

$$(\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}_h^*) = (\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}_h + \widetilde{L}\widetilde{\boldsymbol{\eta}}_h) = (\boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h + \widetilde{L}\boldsymbol{\eta}_h) = (\boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h) = (\boldsymbol{\eta}_h, v_h^*),$$

which proves $\boldsymbol{X}_h \subseteq \widetilde{\boldsymbol{X}}_h$.

To prove estimate (4.17), let $(\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}_h^*) = (\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}_h + \widetilde{\boldsymbol{\eta}}_h) \in \widetilde{\boldsymbol{X}}_h$ be given. We define (recalling that $\mathcal{I}$ denotes the Lagrange interpolating operator):

$$\boldsymbol{\eta}_h = \mathcal{I}\widetilde{\boldsymbol{\eta}}_h \in \boldsymbol{\Theta}_h, \qquad\qquad v_h = \mathcal{I}\widetilde{v}_h \in W_h. \tag{4.19}$$

Accordingly, we set

$$(\boldsymbol{\eta}_h, v_h^*) = \big(\mathcal{I}\widetilde{\boldsymbol{\eta}}_h, \mathcal{I}\widetilde{v}_h + L(\mathcal{I}\widetilde{\boldsymbol{\eta}}_h)\big) \in \boldsymbol{X}_h. \tag{4.20}$$

By standard approximation results and scaling arguments, we have

$$\sum_{T\in\mathcal{T}_h} h_T^{-2}||\widetilde{\boldsymbol{\eta}}_h - \boldsymbol{\eta}_h||_{0,T}^2 + \sum_{e\in\mathcal{E}_h} h_e^{-1}||\widetilde{\boldsymbol{\eta}}_h - \boldsymbol{\eta}_h||_{0,e}^2 \leq C||\widetilde{\boldsymbol{\eta}}_h||_1^2. \tag{4.21}$$

To continue, let us note that

$$\begin{aligned}\sum_{T\in\mathcal{T}_h} \frac{h_T^{-2}}{h_T^2+t^2}||\widetilde{v}_h^* - v_h^*||_{0,T}^2 &\leq 2\sum_{T\in\mathcal{T}_h} \frac{h_T^{-2}}{h_T^2+t^2}||\widetilde{v}_h - v_h||_{0,T}^2 \\ &\quad + 2\sum_{T\in\mathcal{T}_h} \frac{h_T^{-2}}{h_T^2+t^2}||\widetilde{L}\widetilde{\boldsymbol{\eta}}_h - L\boldsymbol{\eta}_h||_{0,T}^2.\end{aligned} \tag{4.22}$$

From standard approximation theory we have

$$\begin{aligned}||\widetilde{v}_h - v_h||_{0,T}^2 &\leq Ch_T^4|\widetilde{v}_h|_{2,T}^2 = Ch_T^4|\boldsymbol{\nabla}\widetilde{v}_h|_{1,T}^2 \\ &\leq Ch_T^4\left(|\boldsymbol{\nabla}\widetilde{v}_h^* - \widetilde{\boldsymbol{\eta}}_h|_{1,T}^2 + |\widetilde{\boldsymbol{\eta}}_h - \boldsymbol{\nabla}\widetilde{L}\widetilde{\boldsymbol{\eta}}_h|_{1,T}^2\right).\end{aligned} \tag{4.23}$$

Using an inverse inequality and (3.20) we get

$$||\widetilde{v}_h - v_h||_{0,T}^2 \leq Ch_T^2||\boldsymbol{\nabla}\widetilde{v}_h^* - \widetilde{\boldsymbol{\eta}}_h||_{0,T}^2 + Ch_T^4|\widetilde{\boldsymbol{\eta}}_h|_{1,T}^2. \tag{4.24}$$

Therefore, we obtain

$$\begin{aligned}\sum_{T\in\mathcal{T}_h} \frac{h_T^{-2}}{h_T^2+t^2}||\widetilde{v}_h - v_h||_{0,T}^2 &\leq C\sum_{T\in\mathcal{T}_h} \frac{1}{h_T^2+t^2}||\boldsymbol{\nabla}\widetilde{v}_h^* - \widetilde{\boldsymbol{\eta}}_h||_{0,T}^2 \\ &\quad + C\sum_{T\in\mathcal{T}_h} \frac{h_T^2}{h_T^2+t^2}|\widetilde{\boldsymbol{\eta}}_h|_{1,T}^2 \\ &\leq C\left(\sum_{T\in\mathcal{T}_h} \frac{1}{h_T^2+t^2}||\boldsymbol{\nabla}\widetilde{v}_h^* - \widetilde{\boldsymbol{\eta}}_h||_{0,T}^2 + ||\widetilde{\boldsymbol{\eta}}_h||_1^2\right).\end{aligned} \tag{4.25}$$

Furthermore, from (3.13), (3.20), and (4.19), we have

$$\begin{aligned}||\widetilde{L}\widetilde{\boldsymbol{\eta}}_h - L\boldsymbol{\eta}_h||^2_{0,T} &\le 2\left(||\widetilde{L}\widetilde{\boldsymbol{\eta}}_h||^2_{0,T} + ||L\boldsymbol{\eta}_h||^2_{0,T}\right)\\ &\le Ch_T^4\left(|\widetilde{\boldsymbol{\eta}}_h|^2_{1,T} + |\boldsymbol{\eta}_h|^2_{1,T}\right) \le Ch_T^4|\widetilde{\boldsymbol{\eta}}_h|^2_{1,T}.\end{aligned} \tag{4.26}$$

As a consequence, we get

$$\sum_{T\in\mathcal{T}_h}\frac{h_T^{-2}}{h_T^2+t^2}||\widetilde{L}\widetilde{\boldsymbol{\eta}}_h - L\boldsymbol{\eta}_h||^2_{0,T} \le C\sum_{T\in\mathcal{T}_h}\frac{h_T^2}{h_T^2+t^2}|\widetilde{\boldsymbol{\eta}}_h|^2_{1,T} \le C||\widetilde{\boldsymbol{\eta}}_h||^2_{1,T}. \tag{4.27}$$

Using (4.25) and (4.27), from (4.22) we have

$$\sum_{T\in\mathcal{T}_h}\frac{h_T^{-2}}{h_T^2+t^2}||\widetilde{v}_h^* - v_h^*||^2_{0,T} \le C|||(\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}_h^*)|||^2_h. \tag{4.28}$$

The shape regularity of $\mathcal{T}_h$, scaling arguments, and estimate (4.28) show that

$$\sum_{e\in\mathcal{E}_h}\frac{h_e^{-1}}{h_e^2+t^2}||\widetilde{v}_h^* - v_h^*||^2_{0,e} \le C\sum_{T\in\mathcal{T}_h}\frac{h_T^{-2}}{h_T^2+t^2}||\widetilde{v}_h^* - v_h^*||^2_{0,T} \le C|||(\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}_h^*)|||^2_h. \tag{4.29}$$

Collecting (4.21), (4.28) and (4.29), we infer estimate (4.17). □

We are now ready to prove the following proposition.

PROPOSITION 4.3. *We have*

$$\begin{aligned}&|||(\widetilde{\boldsymbol{\theta}}_h - \boldsymbol{\theta}_h, \widetilde{w}_h^* - w_h^*)|||_h + ||\widetilde{\boldsymbol{\gamma}}_h - \boldsymbol{\gamma}_h||_{-1} + t\,||\widetilde{\boldsymbol{\gamma}}_h - \boldsymbol{\gamma}_h||_0\\ &\qquad\le C\left(\sum_{T\in\mathcal{T}_h}\left(\eta_T^2 + h_T^2(h_T^2+t^2)||g-g_h||^2_{0,T}\right)\right)^{1/2}.\end{aligned} \tag{4.30}$$

Proof. Consider $(\widetilde{\boldsymbol{\theta}}_h - \boldsymbol{\theta}_h, \widetilde{w}_h^* - w_h^*; \widetilde{\boldsymbol{\gamma}}_h - \boldsymbol{\gamma}_h) \in \widetilde{\boldsymbol{X}}_h \times \widetilde{\boldsymbol{\Gamma}}_h$. Discrete stability for the quadratic element (see Proposition 3.2) implies that there exists $(\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}_h^*; \widetilde{\boldsymbol{\tau}}_h)$ in $\widetilde{\boldsymbol{X}}_h \times \widetilde{\boldsymbol{\Gamma}}_h$ such that

$$|||(\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}_h^*)|||_h + ||\widetilde{\boldsymbol{\tau}}_h||_h \le 1 \tag{4.31}$$

and

$$\begin{aligned}&C\Big(|||(\widetilde{\boldsymbol{\theta}}_h - \boldsymbol{\theta}_h, \widetilde{w}_h^* - w_h^*)|||_h + ||\widetilde{\boldsymbol{\gamma}}_h - \boldsymbol{\gamma}_h||_h\Big)\\ &\qquad\le \Big\{a(\widetilde{\boldsymbol{\theta}}_h - \boldsymbol{\theta}_h, \widetilde{\boldsymbol{\eta}}_h) + (\widetilde{\boldsymbol{\gamma}}_h - \boldsymbol{\gamma}_h, \boldsymbol{\nabla}\widetilde{v}_h^* - \widetilde{\boldsymbol{\eta}}_h)\Big\}\\ &\qquad\quad + \Big\{-\big(\boldsymbol{\nabla}(\widetilde{w}_h^* - w_h^*) - (\widetilde{\boldsymbol{\theta}}_h - \boldsymbol{\theta}_h), \widetilde{\boldsymbol{\tau}}_h\big) + \mu^{-1}t^2(\widetilde{\boldsymbol{\gamma}}_h - \boldsymbol{\gamma}_h, \widetilde{\boldsymbol{\tau}}_h)\Big\}\\ &\qquad = \text{(I)} + \text{(II)}.\end{aligned} \tag{4.32}$$

On one hand, since $(\widetilde{\boldsymbol{\theta}}_h, \widetilde{w}_h^*; \widetilde{\boldsymbol{\gamma}}_h)$ (resp., $(\boldsymbol{\theta}_h, w_h^*; \boldsymbol{\gamma}_h)$) solves the higher-order (resp., low-order) discrete problem, we have

$$\begin{aligned}\text{(I)} &= a(\widetilde{\boldsymbol{\theta}}_h - \boldsymbol{\theta}_h, \widetilde{\boldsymbol{\eta}}_h) + (\widetilde{\boldsymbol{\gamma}}_h - \boldsymbol{\gamma}_h, \boldsymbol{\nabla}\widetilde{v}_h^* - \widetilde{\boldsymbol{\eta}}_h)\\ &= (g, \widetilde{v}_h^*) - a(\boldsymbol{\theta}_h, \widetilde{\boldsymbol{\eta}}_h) - (\boldsymbol{\gamma}_h, \boldsymbol{\nabla}\widetilde{v}_h^* - \widetilde{\boldsymbol{\eta}}_h)\\ &= (g, \widetilde{v}_h^* - v_h^*) - a(\boldsymbol{\theta}_h, \widetilde{\boldsymbol{\eta}}_h - \boldsymbol{\eta}_h) - \big(\boldsymbol{\gamma}_h, \boldsymbol{\nabla}(\widetilde{v}_h^* - v_h^*) - (\widetilde{\boldsymbol{\eta}}_h - \boldsymbol{\eta}_h)\big),\end{aligned} \tag{4.33}$$

where we choose $(\boldsymbol{\eta}_h, v_h^*) \in \boldsymbol{X}_h$ satisfying estimate (4.17). An elementwise integration by parts gives

$$\text{(I)} = \sum_{T\in\mathcal{T}_h} \left\{ \int_T \big(\operatorname{div} \mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h) + \boldsymbol{\gamma}_h\big)\cdot(\widetilde{\boldsymbol{\eta}}_h - \boldsymbol{\eta}_h) - \int_{\partial T} \mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h)\mathbf{n}\cdot(\widetilde{\boldsymbol{\eta}}_h - \boldsymbol{\eta}_h) \right\}$$
$$+ \sum_{T\in\mathcal{T}_h} \left\{ \int_T \big(\operatorname{div}\boldsymbol{\gamma}_h + g\big)\,(\widetilde{v}_h^* - v_h^*) - \int_{\partial T} \boldsymbol{\gamma}_h\cdot\mathbf{n}\,(\widetilde{v}_h^* - v_h^*) \right\}, \tag{4.34}$$

by which

$$\text{(I)} = \sum_{T\in\mathcal{T}_h} \int_T \big(\operatorname{div} \mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h) + \boldsymbol{\gamma}_h\big)\cdot(\widetilde{\boldsymbol{\eta}}_h - \boldsymbol{\eta}_h) - \sum_{e\in\mathcal{E}_h} \int_e [\![\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h)\mathbf{n}]\!]\cdot(\widetilde{\boldsymbol{\eta}}_h - \boldsymbol{\eta}_h)$$
$$+ \sum_{T\in\mathcal{T}_h} \int_T \big(\operatorname{div}\boldsymbol{\gamma}_h + g\big)\,(\widetilde{v}_h^* - v_h^*) - \sum_{e\in\mathcal{E}_h} \int_e [\![\boldsymbol{\gamma}_h\cdot\mathbf{n}]\!]\,(\widetilde{v}_h^* - v_h^*). \tag{4.35}$$

Hence, it holds

$$\text{(I)} \le C \Bigg(\Big(\sum_{T\in\mathcal{T}_h} h_T^2 || \operatorname{div} \mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h) + \boldsymbol{\gamma}_h ||_{0,T}^2 \Big)^{1/2} \Big(\sum_{T\in\mathcal{T}_h} h_T^{-2} || \widetilde{\boldsymbol{\eta}}_h - \boldsymbol{\eta}_h ||_{0,T}^2 \Big)^{1/2}$$
$$+ \Big(\sum_{e\in\mathcal{E}_h} h_e || [\![\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h)\mathbf{n}]\!] ||_{0,e}^2 \Big)^{1/2} \Big(\sum_{e\in\mathcal{E}_h} h_e^{-1} || \widetilde{\boldsymbol{\eta}}_h - \boldsymbol{\eta}_h ||_{0,e}^2 \Big)^{1/2}$$
$$+ \Big(\sum_{T\in\mathcal{T}_h} h_T^2 (h_T^2 + t^2) || \operatorname{div}\boldsymbol{\gamma}_h + g ||_{0,T}^2 \Big)^{1/2} \Big(\sum_{T\in\mathcal{T}_h} \frac{1}{h_T^2 (h_T^2 + t^2)} || \widetilde{v}_h^* - v_h^* ||_{0,T}^2 \Big)^{1/2}$$
$$+ \Big(\sum_{e\in\mathcal{E}_h} h_e (h_e^2 + t^2) || [\![\boldsymbol{\gamma}_h\cdot\mathbf{n}]\!] ||_{0,e}^2 \Big)^{1/2} \Big(\sum_{e\in\mathcal{E}_h} \frac{1}{h_e (h_e^2 + t^2)} || \widetilde{v}_h^* - v_h^* ||_{0,e}^2 \Big)^{1/2} \Bigg). \tag{4.36}$$

Using Lemma 4.2, we get

$$\text{(I)} \le C \Bigg(\Big(\sum_{T\in\mathcal{T}_h} h_T^2 || \operatorname{div} \mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h) + \boldsymbol{\gamma}_h ||_{0,T}^2 \Big)^{1/2} + \Big(\sum_{e\in\mathcal{E}_h} h_e || [\![\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h)\mathbf{n}]\!] ||_{0,e}^2 \Big)^{1/2}$$
$$+ \Big(\sum_{T\in\mathcal{T}_h} h_T^2 (h_T^2 + t^2) || \operatorname{div}\boldsymbol{\gamma}_h + g ||_{0,T}^2 \Big)^{1/2} + \Big(\sum_{e\in\mathcal{E}_h} h_e (h_e^2 + t^2) || [\![\boldsymbol{\gamma}_h\cdot\mathbf{n}]\!] ||_{0,e}^2 \Big)^{1/2} \Bigg)$$
$$\times |\!|\!| (\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}_h^*) |\!|\!|_h. \tag{4.37}$$

Therefore, one has

(4.38)

$$\begin{aligned}(\mathrm{I}) \leq C \Bigg(&\left(\sum_{T\in\mathcal{T}_h} h_T^2 || \operatorname{div} \mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h) + \boldsymbol{\gamma}_h ||_{0,T}^2 \right)^{1/2} + \left(\sum_{e\in\mathcal{E}_h} h_e || [\![\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h)\mathbf{n}]\!] ||_{0,e}^2 \right)^{1/2} \\ &+ \left(\sum_{T\in\mathcal{T}_h} h_T^2(h_T^2+t^2) || \operatorname{div} \boldsymbol{\gamma}_h + g_h ||_{0,T}^2 \right)^{1/2} + \left(\sum_{T\in\mathcal{T}_h} h_T^2(h_T^2+t^2) || g - g_h ||_{0,T}^2 \right)^{1/2} \\ &+ \left(\sum_{e\in\mathcal{E}_h} h_e(h_e^2+t^2) || [\![\boldsymbol{\gamma}_h \cdot \mathbf{n}]\!] ||_{0,e}^2 \right)^{1/2} \Bigg) |\!|\!| (\widetilde{\boldsymbol{\eta}}_h, \widetilde{v}_h^*) |\!|\!|_h.\end{aligned}$$

On the other hand, since $(\widetilde{\boldsymbol{\theta}}_h, \widetilde{w}_h^*; \widetilde{\boldsymbol{\gamma}}_h)$ solves the higher-order discrete problem, we have

(4.39)

$$\begin{aligned}(\mathrm{II}) &= -\big(\boldsymbol{\nabla}(\widetilde{w}_h^* - w_h^*) - (\widetilde{\boldsymbol{\theta}}_h - \boldsymbol{\theta}_h), \widetilde{\boldsymbol{\tau}}_h\big) + \mu^{-1}t^2(\widetilde{\boldsymbol{\gamma}}_h - \boldsymbol{\gamma}_h, \widetilde{\boldsymbol{\tau}}_h) \\ &= -\big(\mu^{-1}t^2\,\boldsymbol{\gamma}_h - (\boldsymbol{\nabla} w_h^* - \boldsymbol{\theta}_h), \widetilde{\boldsymbol{\tau}}_h\big) \\ &\leq \left(\sum_{T\in\mathcal{T}_h} \frac{1}{h_T^2+t^2} ||\mu^{-1}t^2\,\boldsymbol{\gamma}_h - (\boldsymbol{\nabla} w_h^* - \boldsymbol{\theta}_h)||_{0,T}^2 \right)^{1/2} \left(\sum_{T\in\mathcal{T}_h} (h_T^2+t^2) ||\widetilde{\boldsymbol{\tau}}_h||_{0,T}^2 \right)^{1/2}.\end{aligned}$$

As a consequence, from (4.32), (4.38), (4.39), using (4.31) and recalling definitions (4.1)–(4.3), we have

(4.40)

$$|\!|\!|(\widetilde{\boldsymbol{\theta}}_h - \boldsymbol{\theta}_h, \widetilde{w}_h^* - w_h^*)|\!|\!|_h + ||\widetilde{\boldsymbol{\gamma}}_h - \boldsymbol{\gamma}_h||_h \leq C \left(\sum_{T\in\mathcal{T}_h} \Big(\eta_T^2 + h_T^2(h_T^2+t^2)||g-g_h||_{0,T}^2 \Big) \right)^{1/2}.$$

The same arguments as in (3.65)–(3.69), applied to $\widetilde{\boldsymbol{\gamma}}_h - \boldsymbol{\gamma}_h$, give

$$||\widetilde{\boldsymbol{\gamma}}_h - \boldsymbol{\gamma}_h||_{-1} \leq C \left(||\widetilde{\boldsymbol{\gamma}}_h - \boldsymbol{\gamma}_h||_h + ||\widetilde{\boldsymbol{\theta}}_h - \boldsymbol{\theta}_h||_1 \right). \tag{4.41}$$

Combining (4.40) and (4.41) we infer estimate (4.30). The proof is complete. □

4.2. Lower bounds. We now prove the efficiency of our error estimator by establishing the following proposition.

PROPOSITION 4.4. *Let* $(\boldsymbol{\theta}, w; \boldsymbol{\gamma})$ *(resp.,* $(\boldsymbol{\theta}_h, w_h^*; \boldsymbol{\gamma}_h)$*) be the solution of the continuous (resp., discrete) problem. Given* $T \in \mathcal{T}_h$*, it holds*

(4.42)

$$\begin{aligned}\eta_T \leq C \Bigg(&\frac{1}{(h_T^2+t^2)^{1/2}} \big|\big| \boldsymbol{\nabla}(w_h^* - w) - (\boldsymbol{\theta}_h - \boldsymbol{\theta}) \big|\big|_{0,T} + ||\boldsymbol{\theta}_h - \boldsymbol{\theta}||_{1,\omega_T} \\ &+ ||\boldsymbol{\gamma}_h - \boldsymbol{\gamma}||_{-1,\omega_T} + t\,||\boldsymbol{\gamma}_h - \boldsymbol{\gamma}||_{0,\omega_T} + \left(\sum_{T'\subset\omega_T} h_{T'}^2(h_{T'}^2+t^2)||g-g_h||_{0,T'}^2 \right)^{1/2} \Bigg),\end{aligned}$$

where η_T *is defined by* (4.1)*–*(4.3)*.*

Proof. Fix $T \in \mathcal{T}_h$ and a generic edge $e \subset \partial T$. We proceed in three steps.

First step. Since

$$\mu^{-1}t^2\boldsymbol{\gamma} = \boldsymbol{\nabla} w - \boldsymbol{\theta}, \tag{4.43}$$

we get

$$\begin{aligned}
&\frac{1}{(h_T^2+t^2)^{1/2}}||\mu^{-1}t^2\,\boldsymbol{\gamma}_h - (\boldsymbol{\nabla} w_h^* - \boldsymbol{\theta}_h)||_{0,T}\\
&= \frac{1}{(h_T^2+t^2)^{1/2}}\big|\big|\mu^{-1}t^2\,(\boldsymbol{\gamma}_h-\boldsymbol{\gamma}) - \big(\boldsymbol{\nabla}(w_h^*-w) - (\boldsymbol{\theta}_h-\boldsymbol{\theta})\big)\big|\big|_{0,T}\\
&\le C\left(t\,||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{0,T} + \frac{1}{(h_T^2+t^2)^{1/2}}\big|\big|\boldsymbol{\nabla}(w_h^*-w) - (\boldsymbol{\theta}_h-\boldsymbol{\theta})\big|\big|_{0,T}\right).
\end{aligned} \tag{4.44}$$

Second step. We choose

$$\boldsymbol{\eta}_T = h_T^2(\operatorname{div}\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h) + \boldsymbol{\gamma}_h)\,b_T, \tag{4.45}$$

where b_T is the standard cubic bubble on T. We observe that

$$|\boldsymbol{\eta}_T|_{1,T} \le Ch_T||\operatorname{div}\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h) + \boldsymbol{\gamma}_h||_{0,T}. \tag{4.46}$$

Taking advantage of the equilibrium equation

$$-\operatorname{div}\mathbf{C}\,\varepsilon(\boldsymbol{\theta}) - \boldsymbol{\gamma} = \mathbf{0}, \tag{4.47}$$

we get

$$\begin{aligned}
&h_T^2||\operatorname{div}\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h) + \boldsymbol{\gamma}_h||_{0,T}^2\\
&\quad\le C\big(\operatorname{div}\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h) + \boldsymbol{\gamma}_h, \boldsymbol{\eta}_T\big) = C\big(\operatorname{div}\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h-\boldsymbol{\theta}) + (\boldsymbol{\gamma}_h-\boldsymbol{\gamma}), \boldsymbol{\eta}_T\big)\\
&\quad= C\,(-a(\boldsymbol{\theta}_h-\boldsymbol{\theta},\boldsymbol{\eta}_T) + (\boldsymbol{\gamma}_h-\boldsymbol{\gamma},\boldsymbol{\eta}_T))\\
&\quad\le C\,(||\boldsymbol{\theta}_h-\boldsymbol{\theta}||_{1,T} + ||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{-1,T})\;|\boldsymbol{\eta}_T|_{1,T}.
\end{aligned} \tag{4.48}$$

Using (4.46), from (4.48) we thus obtain

$$h_T||\operatorname{div}\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h) + \boldsymbol{\gamma}_h||_{0,T} \le C\,(||\boldsymbol{\theta}_h-\boldsymbol{\theta}||_{1,T} + ||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{-1,T})\,. \tag{4.49}$$

Next, we choose

$$\boldsymbol{\eta}_e = h_e P([\![\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h)\mathbf{n}]\!])\,b_e, \tag{4.50}$$

where P is the prolongation operator introduced in [24] and b_e is the usual edge bubble on e. We observe that it holds

$$\left(\sum_{T\subset\omega_e} h_T^{-2}||\boldsymbol{\eta}_e||_{0,T}^2\right)^{1/2} \le C|\boldsymbol{\eta}_e|_{1,\omega_e} \le Ch_e^{1/2}||\,[\![\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h)\mathbf{n}]\!]\,||_{0,e}. \tag{4.51}$$

Integrating by parts and using again the equilibrium equation (4.47), we have

$$
\begin{aligned}
&h_e|| \,[\![\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h)\mathbf{n}]\!]\, ||_{0,e}^2 \\
&\quad \le C\int_e [\![\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h)\mathbf{n}]\!]\,\cdot\boldsymbol{\eta}_e = C\left(\int_{\omega_e}\operatorname{div}\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h)\cdot\boldsymbol{\eta}_e + \int_{\omega_e}\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h):\varepsilon(\boldsymbol{\eta}_e)\right) \\
&\quad = C\Big(\big(\operatorname{div}\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h)+\boldsymbol{\gamma}_h,\boldsymbol{\eta}_e\big) + a(\boldsymbol{\theta}_h-\boldsymbol{\theta},\boldsymbol{\eta}_e) - (\boldsymbol{\gamma}_h-\boldsymbol{\gamma},\boldsymbol{\eta}_e)\Big) \\
&\quad \le C\left(\left(\sum_{T\subset\omega_e} h_T^2||\operatorname{div}\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h)+\boldsymbol{\gamma}_h||_{0,T}^2\right)^{1/2}\left(\sum_{T\subset\omega_e} h_T^{-2}||\boldsymbol{\eta}_e||_{0,T}^2\right)^{1/2}\right. \\
&\qquad \left. +\Big(||\boldsymbol{\theta}_h-\boldsymbol{\theta}||_{1,\omega_e} + ||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{-1,\omega_e}\Big)\,|\boldsymbol{\eta}_e|_{1,\omega_e}\right).
\end{aligned}
\tag{4.52}
$$

Therefore, using (4.51) and (4.49), from (4.52) we get

$$
h_e^{1/2}||\,[\![\mathbf{C}\,\varepsilon(\boldsymbol{\theta}_h)\mathbf{n}]\!]\,||_{0,e} \le C\,(||\boldsymbol{\theta}_h-\boldsymbol{\theta}||_{1,\omega_e} + ||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{-1,\omega_e})\,. \tag{4.53}
$$

Third step. We first define

$$
\varphi_T = (\operatorname{div}\boldsymbol{\gamma}_h + g_h)\,b_T^2. \tag{4.54}
$$

We observe that $\varphi_T \in H_0^2(T)$ and one has

$$
\begin{aligned}
|\varphi_T|_{1,T} &\le Ch_T^{-1}||\operatorname{div}\boldsymbol{\gamma}_h + g_h||_{0,T}, \\
|\boldsymbol{\nabla}\varphi_T|_{1,T} &\le Ch_T^{-2}||\operatorname{div}\boldsymbol{\gamma}_h + g_h||_{0,T}.
\end{aligned}
\tag{4.55}
$$

We then set

$$
v_T = h_T^2(h_T^2+t^2)\,\varphi_T. \tag{4.56}
$$

Using the equilibrium equation

$$
-\operatorname{div}\boldsymbol{\gamma} = g, \tag{4.57}
$$

we get

$$
\begin{aligned}
h_T^2(h_T^2+t^2)||\operatorname{div}\boldsymbol{\gamma}_h + g_h||_{0,T}^2 &\le C\big(\operatorname{div}\boldsymbol{\gamma}_h + g_h, v_T\big) \\
&= C\Big(\big(\operatorname{div}(\boldsymbol{\gamma}_h-\boldsymbol{\gamma}), v_T\big) + (g_h - g, v_T)\Big).
\end{aligned}
\tag{4.58}
$$

We now separately treat the two terms at the right-hand side of (4.58). Integrating by parts, recalling (4.54) and (4.56), and using (4.55), we have

$$
\begin{aligned}
&\big(\operatorname{div}(\boldsymbol{\gamma}_h-\boldsymbol{\gamma}), v_T\big) = -(\boldsymbol{\gamma}_h-\boldsymbol{\gamma}, \boldsymbol{\nabla}v_T) \\
&= -h_T^4(\boldsymbol{\gamma}_h-\boldsymbol{\gamma},\boldsymbol{\nabla}\varphi_T) - t^2h_T^2(\boldsymbol{\gamma}_h-\boldsymbol{\gamma},\boldsymbol{\nabla}\varphi_T) \\
&\le ||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{-1,T}h_T^4|\boldsymbol{\nabla}\varphi_T|_{1,T} + t\,||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{0,T}h_T^2t\,||\boldsymbol{\nabla}\varphi_T||_{0,T} \\
&\le C\Big(||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{-1,T}h_T^2||\operatorname{div}\boldsymbol{\gamma}_h+g_h||_{0,T} + t\,||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{0,T}h_Tt\,||\operatorname{div}\boldsymbol{\gamma}_h+g_h||_{0,T}\Big) \\
&\le C\Big(||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{-1,T} + t\,||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{0,T}\Big)\,h_T(h_T^2+t^2)^{1/2}||\operatorname{div}\boldsymbol{\gamma}_h+g_h||_{0,T}.
\end{aligned}
\tag{4.59}
$$

Furthermore, it holds

$$
\begin{aligned}
(g_h - g, v_T) &\le h_T(h_T^2 + t^2)^{1/2}||g_h - g||_{0,T}\, h_T(h_T^2 + t^2)^{1/2}||\varphi_T||_{0,T} \\
&\le C h_T(h_T^2 + t^2)^{1/2}||g_h - g||_{0,T}\, h_T(h_T^2 + t^2)^{1/2}||\operatorname{div}\boldsymbol{\gamma}_h + g_h||_{0,T}.
\end{aligned} \tag{4.60}
$$

Therefore, using (4.59) and (4.60), from (4.58) we infer

$$
\begin{aligned}
h_T(h_T^2 + t^2)^{1/2}||\operatorname{div}\boldsymbol{\gamma}_h + g_h||_{0,T} \le C\Big(&||\boldsymbol{\gamma}_h - \boldsymbol{\gamma}||_{-1,T} \\
&+ t\,||\boldsymbol{\gamma}_h - \boldsymbol{\gamma}||_{0,T} + h_T(h_T^2 + t^2)^{1/2}||g_h - g||_{0,T}\Big).
\end{aligned} \tag{4.61}
$$

Next, we define

$$
\varphi_e = \Pi_e([\![\boldsymbol{\gamma}_h \cdot \mathbf{n}]\!]), \tag{4.62}
$$

where Π_e is the linear operator of Lemma 4.1. Therefore, we have

$$
||\,[\![\boldsymbol{\gamma}_h \cdot \mathbf{n}]\!]\,||_{0,e}^2 \le C\int_e [\![\boldsymbol{\gamma}_h \cdot \mathbf{n}]\!]\,\varphi_e, \tag{4.63}
$$

$$
||\varphi_e||_{0,\omega_e} \le C h_e^{1/2}||\,[\![\boldsymbol{\gamma}_h \cdot \mathbf{n}]\!]\,||_{0,e}, \tag{4.64}
$$

$$
||\boldsymbol{\nabla}\varphi_e||_{0,\omega_e} \le C h_e^{-1/2}||\,[\![\boldsymbol{\gamma}_h \cdot \mathbf{n}]\!]\,||_{0,e}, \tag{4.65}
$$

$$
|\boldsymbol{\nabla}\varphi_e|_{1,\omega_e} \le C h_e^{-3/2}||\,[\![\boldsymbol{\gamma}_h \cdot \mathbf{n}]\!]\,||_{0,e}. \tag{4.66}
$$

We then set

$$
v_e = h_e(h_e^2 + t^2)\,\varphi_e. \tag{4.67}
$$

Integrating by parts using (4.63) and the equilibrium equation (4.57), we get

$$
\begin{aligned}
h_e(h_e^2 + t^2)||\,[\![\boldsymbol{\gamma}_h \cdot \mathbf{n}]\!]\,||_{0,e}^2 &\le C\int_e [\![\boldsymbol{\gamma}_h \cdot \mathbf{n}]\!]\,v_e \\
&\le C\left(\int_{\omega_e} v_e \operatorname{div}\boldsymbol{\gamma}_h + \int_{\omega_e}\boldsymbol{\gamma}_h \cdot \boldsymbol{\nabla} v_e\right) \\
&= C\Big((\operatorname{div}\boldsymbol{\gamma}_h + g, v_e) + (\boldsymbol{\gamma}_h - \boldsymbol{\gamma}, \boldsymbol{\nabla} v_e)\Big) \\
&= C\Big((\operatorname{div}\boldsymbol{\gamma}_h + g_h, v_e) + (g - g_h, v_e) + (\boldsymbol{\gamma}_h - \boldsymbol{\gamma}, \boldsymbol{\nabla} v_e)\Big).
\end{aligned} \tag{4.68}
$$

We now estimate the three terms above. Recalling (4.67) and using (4.64), we obtain

(4.69)

$$\begin{aligned}(\operatorname{div}\boldsymbol{\gamma}_h + g_h, v_e) &= h_e(h_e^2+t^2)\big(\operatorname{div}\boldsymbol{\gamma}_h + g_h, \varphi_e\big)\\
&= \sum_{T\subset\omega_e}\int_T \left(h_e(h_e^2+t^2)^{1/2}(\operatorname{div}\boldsymbol{\gamma}_h + g_h)\right)\left((h_e^2+t^2)^{1/2}\varphi_e\right)\\
&\le \left(\sum_{T\subset\omega_e} h_e^2(h_e^2+t^2)||\operatorname{div}\boldsymbol{\gamma}_h + g_h||_{0,T}^2\right)^{1/2}\left(\sum_{T\subset\omega_e}(h_e^2+t^2)||\varphi_e||_{0,T}^2\right)^{1/2}\\
&\le \left(\sum_{T\subset\omega_e} h_T^2(h_T^2+t^2)||\operatorname{div}\boldsymbol{\gamma}_h + g_h||_{0,T}^2\right)^{1/2}\left(\sum_{T\subset\omega_e}(h_e^2+t^2)||\varphi_e||_{0,T}^2\right)^{1/2}\\
&\le C\left(\sum_{T\subset\omega_e} h_T^2(h_T^2+t^2)||\operatorname{div}\boldsymbol{\gamma}_h + g_h||_{0,T}^2\right)^{1/2} h_e^{1/2}(h_e^2+t^2)^{1/2}||\,[\![\boldsymbol{\gamma}_h\cdot\mathbf{n}]\!]\,||_{0,e}.\end{aligned}$$

The same argument shows that it holds

(4.70)

$$(g-g_h, v_e) \le C\left(\sum_{T\subset\omega_e} h_T^2(h_T^2+t^2)||g-g_h||_{0,T}^2\right)^{1/2} h_e^{1/2}(h_e^2+t^2)^{1/2}||\,[\![\boldsymbol{\gamma}_h\cdot\mathbf{n}]\!]\,||_{0,e}.$$

We now notice that

$$(\boldsymbol{\gamma}_h-\boldsymbol{\gamma}, \boldsymbol{\nabla} v_e) = h_e^3(\boldsymbol{\gamma}_h-\boldsymbol{\gamma}, \boldsymbol{\nabla}\varphi_e) + h_e t^2(\boldsymbol{\gamma}_h-\boldsymbol{\gamma}, \boldsymbol{\nabla}\varphi_e). \tag{4.71}$$

On one hand, using (4.66), we have

$$\begin{aligned}h_e^3(\boldsymbol{\gamma}_h-\boldsymbol{\gamma}, \boldsymbol{\nabla}\varphi_e) &\le ||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{-1,\omega_e} h_e^3|\boldsymbol{\nabla}\varphi_e|_{1,\omega_e}\\
&\le C||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{-1,\omega_e} h_e^{3/2}||\,[\![\boldsymbol{\gamma}_h\cdot\mathbf{n}]\!]\,||_{0,e}.\end{aligned} \tag{4.72}$$

On the other hand, from (4.65) we get

$$\begin{aligned}h_e t^2(\boldsymbol{\gamma}_h-\boldsymbol{\gamma}, \boldsymbol{\nabla}\varphi_e) &\le t\,||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{0,\omega_e} h_e t\,||\boldsymbol{\nabla}\varphi_e||_{0,\omega_e}\\
&\le Ct\,||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{0,\omega_e} h_e^{1/2} t\,||\,[\![\boldsymbol{\gamma}_h\cdot\mathbf{n}]\!]\,||_{0,e}.\end{aligned} \tag{4.73}$$

Therefore, using (4.72) and (4.73) from (4.71) we obtain

$$(\boldsymbol{\gamma}_h-\boldsymbol{\gamma}, \boldsymbol{\nabla} v_e) \le C\big(||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{-1,\omega_e} + t\,||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{0,\omega_e}\big) h_e^{1/2}(h_e^2+t^2)^{1/2}||\,[\![\boldsymbol{\gamma}_h\cdot\mathbf{n}]\!]\,||_{0,e}. \tag{4.74}$$

Collecting (4.69), (4.70) and (4.74), we infer from (4.68) that

(4.75)

$$\begin{aligned}h_e^{1/2}(h_e^2+t^2)^{1/2}||\,[\![\boldsymbol{\gamma}_h\cdot\mathbf{n}]\!]\,||_{0,e} \le C\Bigg(&\left(\sum_{T\subset\omega_e} h_T^2(h_T^2+t^2)||\operatorname{div}\boldsymbol{\gamma}_h + g_h||_{0,T}^2\right)^{1/2}\\
&+ ||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{-1,\omega_e} + t\,||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{0,\omega_e}\\
&+\left(\sum_{T\subset\omega_e} h_T^2(h_T^2+t^2)||g-g_h||_{0,T}^2\right)^{1/2}\Bigg).\end{aligned}$$

Hence, from (4.61) we get

(4.76)

$$h_e^{1/2}(h_e^2+t^2)^{1/2}||\,[\![\boldsymbol{\gamma}_h\cdot\mathbf{n}]\!]\,||_{0,e} \leq C\Bigg(||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{-1,\omega_e}+t\,||\boldsymbol{\gamma}_h-\boldsymbol{\gamma}||_{0,\omega_e} + \Bigg(\sum_{T\subset\omega_e} h_T^2(h_T^2+t^2)||g-g_h||_{0,T}^2\Bigg)^{1/2}\Bigg).$$

Estimate (4.42) now follows from (4.44), (4.49), (4.53), (4.61), and (4.76). □

Acknowledgments. The authors are grateful to L. Beirão da Veiga (University of Milan) for several suggestions about the manuscript and to G. Sangalli (IMATI–CNR, Pavia) for the useful discussions regarding Lemma 4.1.

COMPRESSION TECHNIQUES FOR BOUNDARY INTEGRAL EQUATIONS—ASYMPTOTICALLY OPTIMAL COMPLEXITY ESTIMATES[*]

WOLFGANG DAHMEN[†], HELMUT HARBRECHT[‡], AND REINHOLD SCHNEIDER[‡]

Abstract. Matrix compression techniques in the context of wavelet Galerkin schemes for boundary integral equations are developed and analyzed that exhibit optimal complexity in the following sense. The fully discrete scheme produces approximate solutions within discretization error accuracy offered by the underlying Galerkin method at a computational expense that is proven to stay proportional to the number of unknowns. Key issues are the second compression, which reduces the near field complexity significantly, and an additional a posteriori compression. The latter is based on a general result concerning an optimal work balance that applies, in particular, to the quadrature used to compute the compressed stiffness matrix with sufficient accuracy in linear time.

Key words. wavelets, norm equivalences, multilevel preconditioning, first and second compression, a posteriori compression, asymptotic complexity estimates

1. Introduction.

Many mathematical models concerning, e.g., field calculations, flow simulation, elasticity, or visualization are based on operator equations with *global operators*, especially *boundary integral* operators. Discretizing such problems will then lead in general to possibly very large linear systems with *densely populated* matrices. Moreover, the involved operator may have an order different from zero, which means that it acts on different length scales in a different way. This is well known to entail the linear systems to become more and more ill-conditioned when the level of resolution increases. Both features pose serious obstructions to the efficient numerical treatment of such problems to an extent that desirable realistic simulations are still beyond the current computing capacities.

This fact has stimulated enormous efforts to overcome these obstructions. The resulting significant progress made over the past 10 or 15 years manifests itself in several different approaches such as panel clustering (PC) [18], multipole expansions (FMM) [16], and wavelet compression (WC) [2]. Each of these methodologies has its recognized advantages and drawbacks whose balance may depend on the problem at hand. The first two (PC, FMM) are quite similar in spirit and exploit perhaps in the best way the (typical) smoothness of the potential kernel in the space rather than the integral kernel on the boundary manifold. As a consequence, they are fairly robust with regard to the shape and complexity of the boundary manifold. This is also the case for further developments like hierarchical matrices ($\mathcal{H}$-matrices) [17] and adaptive cross approximation (ACA) [1] based on a low rank approximation in the far

field; see also [30]. Common experience seems to indicate that the third option (WC) depends in a more sensitive way on the underlying geometry, and its performance may suffer from strong domain anisotropies. On the other hand, WC allows one in a natural way to incorporate preconditioning techniques, which very much supports the fast solution of the resulting sparsified systems. Moreover, recent developments suggest a natural combination with adaptive discretizations to keep from the start, for a given target accuracy, the size of the linear systems as small as possible. Perhaps the main difference between PC, FMM on the one hand and WC on the other is that the former are essentially *agglomeration* techniques, while WC is more apt for refining a given coarse discretization. Since these methodologies are, in that sense, somewhat complementary in spirit, it is in our opinion less appropriate to contrapose them, but one should rather try to extract the best from each option.

As indicated before, a preference for any of the above-mentioned solution strategies will, in general, depend on the concrete application at hand. The objective of this paper is therefore to provide a complete analysis of the wavelet approach (WC) from the following perspectives. Recall that WC has been essentially initiated by the pioneering paper [2], where it was observed that certain operators have an almost sparse representation in wavelet coordinates. Discarding all entries below a certain threshold in a given principal section of the wavelet representation will then give rise to a sparse matrix that can be further processed by efficient linear algebra tools. This idea has since then initiated many subsequent studies. The diversity as well as the partly deceiving nature of the by now existing rich body of literature is one reason for us to take up this subject here again. Our attempt to provide a unified analysis is certainly based, to some extent, on previously used techniques. However, on the one hand we have extended these concepts essentially by several new analytical tools, to be detailed later below. On the other hand, the numerical implementation has been brought now to a state that makes the method applicable to practically relevant problems. The main objective of this paper is to present these new theoretical and practical developments centering on the following issues.

When dealing with large-scale problems, a sharp *asymptotic analysis* of the complexity is in our opinion ultimately essential for assessing its potential. It is important to clarify the meaning of “complexity” in this context. It is always understood as the *work/accuracy* rate of the method under consideration when the level of resolution increases, i.e., the overall accuracy of the computed approximate solution is to be tied to the computational work required to obtain it. There is no point in increasing the number of degrees of freedom, i.e., the size of the linear systems, without improving the accuracy of the resulting solutions. On the other hand, since one is ultimately interested in the “exact solution of the infinite-dimensional problem” it makes no sense to determine the solution to the discrete finite-dimensional problem with much more accuracy than that offered by the discretization. Thus, a reasonable target accuracy for the solutions of the discrete systems is *discretization error accuracy* which will guide all our subsequent considerations. A method will therefore be said to exhibit *asymptotically optimal complexity* if the discrete solution can be computed, for any discretization level, within discretization error accuracy at a computational expense that stays *proportional* to the number N of unknowns, i.e., when not even logarithmic factors are permitted. Obviously, computational optimality refers here to the given discretization framework based on the chosen hierarchy of trial spaces.

In the present context, this means that the solutions of the compressed systems should exhibit the same asymptotic convergence rates as the solutions to unperturbed discretizations. In connection with WC, this in turn means that any threshold parameters and truncation strategies have to be adapted to the current number N of degrees of freedom. Such an asymptotic analysis is missing in [2] and in many subsequent investigations. The program carried out in [11, 12, 24, 25, 27] aimed at determining exactly such work/accuracy rates for various types of boundary integral equations. Roughly speaking, it could be shown that discretization error accuracy can be realized for appropriately chosen wavelet bases at a computational work that stays bounded by $C\,N(\log N)^a$ for some constants C, a independent of the size N of the linear systems. Moreover, in [27] it was shown for the first time that, by incorporating a second compression, an overall optimal compression strategy can be devised that even avoids additional logarithmic factors, while the complexity estimates for a corresponding adaptive quadrature scheme were confined to collocation methods.

The purpose of the present paper can now be summarized as follows.

We present a complete, in several respects new and improved analysis of wavelet compression schemes for boundary integral equations based on Galerkin discretizations that exhibit overall asymptotically optimal complexity. This means that discretization error accuracy is obtained at a computational expense that stays proportional to the size N of the arising linear systems, uniformly in N. In contrast to the earlier treatments of the authors it is based on bilinear forms and Strang's lemma; see also [25].

The analysis significantly simplifies previous studies including the effect of the second compression. In fact, the analysis of the second compression is completely new, resulting in slightly different conclusions; see section 6. The complete work balance synchronizing quadrature and compression accuracy is based on new *balance estimates* given in section 11; see Theorem 11.1. In particular, it reveals the right work balance for the compression and the quadrature needed to compute the compressed matrices with sufficient accuracy, so as to realize asymptotically optimal computational complexity of the fully discretized scheme. Specifically, the computational work for computing and assembling the compressed stiffness matrix remains proportional to the number N of degrees of freedom.

This also lays the foundation for an additional new *a posteriori compression* whose analysis is again based on the above-mentioned balance estimate. This improves the quantitative performance of the scheme significantly as shown in [20, 22].

Our analysis concerns what is called the *standard* wavelet representation. A preference for using the so-called *nonstandard* form is frequently reported in the literature. The reason is that the entries in this latter form only involve scaling functions and wavelets on the *same* level. This indeed simplifies assembling the matrices and offers essential advantages when dealing with shift-invariant problems. However, aside from the problem of preconditioning in connection with operators of nonzero order, to our knowledge it has so far *not* been shown that, for a fixed order of vanishing moments, optimal computational complexity in the above sense can be obtained with the nonstandard form. In fact, for regular solutions approximate solutions with prescribed accuracy can be obtained at (asymptotically) a lower computational cost with the aid of the standard form when compared with the nonstandard form. This is backed by theory and confirmed by numerical experience; see [20, 22].

As mentioned before, it is important to employ the "right" wavelet bases. This question has been discussed extensively in previous work [3, 6, 13, 14]. The theory tells us that, depending on the order of the operator, a proper relation between the approximation order of the underlying multiresolution spaces and the order of vanishing moments matters, which often rules out orthonormal wavelets. Given the validity of this relation it is important to keep supports as small as possible; see Remark 7.1 in section 7. Moreover, our present analysis of the second compression refers exclusively to biorthogonal spline wavelets whose singular supports are well defined; see [21] for examples and graphical illustrations.

We shall frequently write $a \lesssim b$ to express that a is bounded by a constant multiple of b, uniformly with respect to all parameters on which a and b may depend. Then $a \sim b$ means $a \lesssim b$ and $b \lesssim a$.

2. Problem formulation and preliminaries. We consider boundary integral equations on a closed boundary surface Γ of an $(n+1)$-dimensional domain $\Omega \subset \mathbb{R}^{n+1}$

$$Au(\widehat{x}) = \int_\Gamma k(\widehat{x},\widehat{y})u(\widehat{y})d\Gamma_{\widehat{y}} = f(\widehat{x}), \quad \widehat{x} \in \Gamma, \tag{2.1}$$

where the boundary integral operator is assumed to be an operator of order $2q$, that is, $A : H^q(\Gamma) \to H^{-q}(\Gamma)$. The kernel functions under consideration are supposed to be smooth as functions in the variables $\widehat{x}, \widehat{y}$, apart from the diagonal $\{(\widehat{x},\widehat{y}) \in \Gamma\times\Gamma : \widehat{x} = \widehat{y}\}$ and may have a singularity on the diagonal. Such kernel functions arise, for instance, by applying a boundary integral formulation to a second-order elliptic problem. In general, they decay like a negative power of the distance of the arguments which depends on the spatial dimension n and the order $2q$ of the operator.

Throughout the remainder of this paper we shall assume that the boundary manifold Γ is given as a parametric surface consisting of smooth patches. More precisely, let $\square := [0,1]^n$ denote the unit n cube. The manifold $\Gamma \subset \mathbb{R}^{n+1}$ is partitioned into a finite number of *patches*,

$$\Gamma = \bigcup_{i=1}^{M} \Gamma_i, \qquad \Gamma_i = \gamma_i(\square), \qquad i = 1, 2, \ldots, M, \tag{2.2}$$

where each $\gamma_i : \square \to \Gamma_i$ defines a diffeomorphism of $\square$ onto Γ_i. We also assume that there exist smooth extensions $\Gamma_i \subset\subset \widetilde{\Gamma}_i$ and $\widetilde{\gamma}_i : \widetilde{\square} := [-1,2]^n \to \widetilde{\Gamma}_i$. The intersection $\Gamma_i \cap \Gamma_{i'}$, $i \neq i'$, of the patches Γ_i and $\Gamma_{i'}$ is supposed to be either $\emptyset$ or a lower-dimensional face.

A mesh of level j on Γ is induced by dyadic subdivisions of depth j of the unit cube into 2^{nj} cubes $C_{j,k} \subseteq \square$, where $k = (k_1, \ldots, k_n)$ with $0 \le k_m < 2^j$. This generates $2^{nj}M$ *elements* (or elementary domains) $\Gamma_{i,j,k} := \gamma_i(C_{j,k}) \subseteq \Gamma_i$, $i = 1, \ldots, M$.

In order to ensure that the collection of elements $\{\Gamma_{i,j,k}\}$ on the level j forms a regular mesh on Γ, the parametric representation is subjected to the following *matching condition*: for all $\widehat{x} \in \Gamma_i \cap \Gamma_{i'}$ there exists a bijective, affine mapping $\Xi : \square \to \square$ such that $\gamma_i(x) = (\gamma_{i'} \circ \Xi)(x) = \widehat{x}$ for $x = (x_1, \ldots, x_n) \in \square$ with $\gamma_i(x) = \widehat{x}$.

The first fundamental tensor of differential geometry is given by the matrix $K_i(x) \in \mathbb{R}^{n\times n}$ defined by

$$K_i(x) := \left[\left(\frac{\partial\gamma_i(x)}{\partial x_j}, \frac{\partial\gamma_i(x)}{\partial x_{j'}}\right)_{l^2(\mathbb{R}^{n+1})}\right]_{j,j'=1}^{n}. \tag{2.3}$$

Since γ_i is supposed to be a diffeomorphism, the matrix $K_i(x)$ is symmetric and positive definite. The canonical inner product in $L^2(\Gamma)$ is then given by

$$\langle u, v\rangle = \int_\Gamma u(x)v(x)d\Gamma_x = \sum_{i=1}^{M} \int_\square u\big(\gamma_i(x)\big)v\big(\gamma_i(x)\big)\sqrt{\det K_i(x)}dx. \tag{2.4}$$

The corresponding Sobolev spaces are denoted by $H^s(\Gamma)$, endowed with the norms $\|\cdot\|_s$, where for $s<0$ it is understood that $H^s(\Gamma)=(H^{-s}(\Gamma))'$. Of course, depending on the global smoothness of the surface, the range of permitted $s\in\mathbb{R}$ is limited to $s\in(-s_\Gamma,s_\Gamma)$. In the case of general Lipschitz domains we have at least $s_\Gamma=1$ since for all $0\le s\le 1$ the spaces $H^s(\Gamma)$ consist of traces of functions $\in H^{s+1/2}(\Omega)$; cf. [7].

We can now specify the kernel functions. To this end, we denote by $\alpha=(\alpha_1,\dots,\alpha_n)$ and $\beta=(\beta_1,\dots,\beta_n)$ multi-indices of dimension n and define $|\alpha|:=\alpha_1+\cdots+\alpha_n$. Recall that $\widehat{x}$ and $\widehat{y}$ are points on the surface, i.e., $\widehat{x}:=\gamma_i(x)$ and $\widehat{y}:=\gamma_{i'}(y)$ for some $1\le i,i'\le M$.

Definition 2.1. *A kernel $k(\widehat{x},\widehat{y})$ is called standard kernel of order $2q$ if the partial derivatives of the transported kernel function*

$$\widetilde{k}(x,y):=k\big(\gamma_i(x),\gamma_{i'}(y)\big)\sqrt{\det K_i(x)}\sqrt{\det K_{i'}(y)} \tag{2.5}$$

are bounded by

$$|\partial_x^\alpha\partial_y^\beta\widetilde{k}(x,y)|\le c_{\alpha,\beta}\ \operatorname{dist}(\widehat{x},\widehat{y})^{-(n+2q+|\alpha|+|\beta|)}, \tag{2.6}$$

provided that $n+2q+|\alpha|+|\beta|>0$.

We emphasize that this definition requires patchwise smoothness but *not* global smoothness of the geometry. The surface itself needs to be only Lipschitz. Generally, under this assumption, the kernel of a boundary integral operator A of order $2q$ is a standard kernel of order $2q$. Hence, we may assume this property in the following. We shall encounter further specifications below in connection with discretizations.

3. Galerkin scheme. We shall be concerned with the Galerkin method with respect to a hierarchy of conforming trial spaces $V_J\subset V_{J+1}\subset H^q(\Gamma)$: find $u_J\in V_J$ solving the variational problem

$$\langle Au_J,v_J\rangle=\langle f,v_J\rangle\quad\text{for all}\quad v_J\in V_J. \tag{3.1}$$

Here the index J reflects a meshwidth of the order 2^{-J}. Moreover, we say that the trial spaces have *(approximation) order* $d\in\mathbb{N}$ and *regularity* $\gamma>0$ if

$$\begin{aligned}\gamma&=\sup\{s\in\mathbb{R}:V_J\subset H^s(\Gamma)\},\\ d&=\sup\{s\in\mathbb{R}:\inf_{v_J\in V_J}\|v-v_J\|_0\lesssim 2^{-Js}\|v\|_s\ \text{ for all } v\in H^s(\Gamma)\}.\end{aligned} \tag{3.2}$$

Thus conformity requires, of course, that $\gamma>\max\{0,q\}$.

In order to ensure that (3.1) is well posed we shall make the following assumptions on the operator A throughout the remainder of the paper.

Assumptions:

1. A is strongly elliptic, i.e., there exists a symmetric compact operator $C: H^q(\Gamma)\to H^{-q}(\Gamma)$ such that $\langle(A+A^\star+C)u,u\rangle\gtrsim\|u\|_q^2$.
2. The operator $A:H^q(\Gamma)\to H^{-q}(\Gamma)$ is injective, i.e., $\operatorname{Ker}A=\{0\}$.

Remark. 1. Most boundary integral equations of the first kind, resulting from a direct approach, are known to be strongly elliptic, even if Γ is supposed to be the boundary of a Lipschitz domain [7]. In particular, this is the case for boundary integral equations of the first kind for the Laplacian, the system of Navier–Lamé equations, and the Stokes system. For integral equations of the second kind the condition is obvious if the double layer potential operator is compact, or in the case of smooth boundaries, since the principal symbol satisfies a Gårding inequality.

2. For several boundary integral operators like the single layer operator of the Stokes system, for operators associated with Neumann problems or multiply connected domains, the second assumption is not valid. But in these cases the kernel of the operator A is finite-dimensional and known a priori. The kernels can be factored out, i.e., $A : H^q(\Gamma)/\operatorname{Ker}(A) \to (H^q(\Gamma)/\operatorname{Ker}(A))'$. A standard approach uses constrained conditions and Lagrange multipliers. With a minor modification our method can be applied also to these cases. Therefore, the second assumption is only for the sake of simplicity and not a restriction of generality.

LEMMA 3.1 (see, e.g., [31]). *Under the above assumptions the Galerkin discretization is stable, i.e.,*

$$\langle (A + A^\star)v_J, v_J\rangle \gtrsim \|v_J\|_q^2, \quad v_J \in V_J, \tag{3.3}$$

for J sufficiently large, and

$$|\langle Av_J, w_J\rangle| \lesssim \|v_J\|_q \|w_J\|_q, \quad v_J, w_J \in V_J. \tag{3.4}$$

Furthermore, let u, u_J denote the solution of the original equation $Au = f$, respectively, of (3.1). *Then one has*

$$\|u - u_J\|_t \lesssim 2^{J(t-t')}\|u\|_{t'} \tag{3.5}$$

provided that $2q - d \le t < \gamma$, $t \le t'$, $q \le t' \le d$ and Γ is sufficiently regular.

Note that the best possible convergence rate is given by

$$\|u - u_J\|_{2q-d} \lesssim 2^{-2J(d-q)}\|u\|_d \tag{3.6}$$

provided that $u \in H^d(\Gamma)$, which is only possible when Γ is sufficiently regular. Since this case gives rise to the highest convergence rate, it will be seen later to impose the most stringent demands on the matrix compression.

4. Wavelets and multiresolution analysis.

The nested trial spaces $V_j \subset V_{j+1}$ that we shall employ in (3.1) are spanned by so-called *single-scale bases* $\Phi_j = \{\phi_{j,k} : k \in \Delta_j\}$, where Δ_j denote suitable index sets of cardinality $\dim V_j$. The elements of Φ_j are normalized in $L^2(\Gamma)$ and their compact supports scale like $\operatorname{diam}\operatorname{supp}\phi_{j,k} \sim 2^{-j}$. Associated with these collections are always *dual* bases $\widetilde{\Phi}_j = \{\widetilde{\phi}_{j,k} : k \in \Delta_j\}$, i.e., one has $\langle \phi_{j,k}, \widetilde{\phi}_{j,k'}\rangle = \delta_{k,k'}$, $k, k' \in \Delta_j$. For the current type of boundary surfaces Γ the $\Phi_j, \widetilde{\Phi}_j$ are generated by constructing first dual pairs of single-scale bases on the interval $[0, 1]$, using B-splines for the primal bases and the dual components from [5] adapted to the interval [10]. Tensor products yield corresponding dual pairs on $\square$. Using the parametric liftings γ_i and gluing across patch boundaries leads to globally continuous single-scale bases $\Phi_j, \widetilde{\Phi}_j$ on Γ [3, 6, 14, 19]. For B-splines of order d and duals of order $\widetilde{d} \ge d$ such that $d + \widetilde{d}$ is even, the $\Phi_j, \widetilde{\Phi}_j$ have approximation orders $d, \widetilde{d}$, respectively. It is known that the respective regularity indices $\gamma, \widetilde{\gamma}$ (inside each patch) satisfy $\gamma = d - 1/2$, while $\widetilde{\gamma} > 0$ is known to increase proportionally to $\widetilde{d}$. We refer the reader to [21] for a detailed description of the construction of wavelets on manifolds, including examples and figures.

In view of the biorthogonality of $\Phi_j, \widetilde{\Phi}_j$, it will be convenient to employ the canonical projectors

$$Q_j v := \sum_{k\in\Delta_j} \langle v, \widetilde{\phi}_{j,k}\rangle \phi_{j,k}, \qquad Q_j^\star v := \sum_{k\in\Delta_j} \langle v, \phi_{j,k}\rangle \widetilde{\phi}_{j,k}, \tag{4.1}$$

associated with the *multiresolution sequences* $\{V_j\}_{j>j_0}$, $\{\widetilde{V}_j\}_{j>j_0}$. Here and below j_0+1 always stands for some fixed coarsest level of resolution that may depend on Γ.

It follows from the L^2-boundedness of the Q_j that one has the following *Jackson-* and *Bernstein*-type estimates uniformly in j, namely,

$$\|v - Q_j v_j\|_s \lesssim 2^{-j(t-s)}\|v\|_t, \quad v \in H^t(\Gamma), \tag{4.2}$$

for all $-\widetilde{d} \leq s \leq t \leq d$, $s < \gamma$, $-\widetilde{\gamma} < t$ and

$$\|Q_j v\|_s \lesssim 2^{j(s-t)}\|Q_j v\|_t, \quad v \in H^t(\Gamma), \tag{4.3}$$

for all $t \leq s \leq \gamma$.

We introduce the index sets $\nabla_j := \Delta_{j+1} \setminus \Delta_j$. Given the single-scale bases $\Phi_j, \widetilde{\Phi}_j$, one can construct now biorthogonal *complement bases* $\Psi_j = \{\psi_{j,k} : k \in \nabla_j\}$, $\widetilde{\Psi}_j = \{\widetilde{\psi}_{j,k} : k \in \nabla_j\}$, i.e., $\langle \psi_{j,k}, \widetilde{\psi}_{j',k'}\rangle = \delta_{(j,k),(j',k')}$, such that

$$\operatorname{diam}\operatorname{supp}\psi_{j,k} \sim 2^{-j}, \quad j > j_0; \tag{4.4}$$

see, e.g., [3, 6, 13, 14] and [19] for particularly useful local representations of important construction ingredients. In fact, for these types of bases, the dual wavelets scale in the same way, but this will not be needed and does not hold for alternative constructions based on finite elements [15].

Denoting by $W_j, \widetilde{W}_j$ the span of Ψ_j, respectively, $\widetilde{\Psi}_j$, biorthogonality implies that

$$V_{j+1} = W_j \oplus V_j, \qquad \widetilde{V}_{j+1} = \widetilde{W}_j \oplus \widetilde{V}_j, \qquad \widetilde{V}_j \perp W_j, \qquad V_j \perp \widetilde{W}_j.$$

Hence V_J and $\widetilde{V}_J$ can be written as a direct sum of the complement spaces W_j, respectively, $\widetilde{W}_j$, $j_0 \leq j < J$ (using the convention $W_{j_0} := V_{j_0+1}$, $\widetilde{W}_{j_0} := \widetilde{V}_{j_0+1}$, $Q_{j_0} = Q^\star_{j_0} := 0$). In fact, one has for $v_J \in V_J$, $\widetilde{v}_J \in \widetilde{V}_J$

$$v_J = \sum_{j=j_0}^{J-1}(Q_{j+1} - Q_j)v_J, \qquad \widetilde{v}_J = \sum_{j=j_0}^{J-1}(Q^\star_{j+1} - Q^\star_j)\widetilde{v}_J,$$

where

$$(Q_{j+1} - Q_j)v = \sum_{k\in\nabla_j}\langle v, \widetilde{\psi}_{j,k}\rangle\psi_{j,k}, \qquad (Q^\star_{j+1} - Q^\star_j)v = \sum_{k\in\nabla_j}\langle v, \psi_{j,k}\rangle\widetilde{\psi}_{j,k}.$$

A biorthogonal or *dual* pair of wavelet bases is now obtained by taking the coarse single-scale basis and the union of the complement bases $\Psi = \bigcup_{j\geq j_0}\Psi_j$, $\widetilde{\Psi} = \bigcup_{j\geq j_0}\widetilde{\Psi}_j$, where we have set for convenience $\Psi_{j_0} := \Phi_{j_0+1}$, $\widetilde{\Psi}_{j_0} := \widetilde{\Phi}_{j_0+1}$. We will refer to Ψ and $\widetilde{\Psi}$ as the *primal*, respectively, *dual*, basis. Throughout the paper, all basis functions (scaling functions and wavelets) are normalized in $L^2(\Gamma)$.

From biorthogonality and the fact that the dual single-scale bases on $\square$ represent all polynomials of order $\widetilde{d}$ exactly, one infers vanishing polynomial moments of the primal wavelets on $\square$, which, on account of the locality (4.4), entails the first key feature of the primal wavelets, namely, *vanishing moments* or the *cancellation property*

$$|\langle v, \psi_{j,k}\rangle| \lesssim 2^{-j(\widetilde{d}+n/2)}|v|_{W^{\widetilde{d},\infty}(\operatorname{supp}\psi_{j,k})}. \tag{4.5}$$

Here $|v|_{W^{\tilde{d},\infty}(\Omega)} := \sup_{|\alpha|=\widetilde{d},\, x\in\Omega} |\partial^\alpha v(x)|$ denotes the seminorm in $W^{\widetilde{d},\infty}(\Omega)$. The fact that the concept of biorthogonality allows us to choose the order $\widetilde{d}$ of vanishing moments higher than the approximation order d will be essential for deriving optimal compression strategies that could not be realized by orthonormal bases.

Of course, in the infinite-dimensional case the notion of basis has to be made more specific. The second key feature of the basis Ψ is the fact that (properly scaled versions of) Ψ, $\widetilde{\Psi}$ are actually *Riesz bases* for a *whole range* of Sobolev spaces, i.e.,

$$\begin{aligned} \|v\|_t^2 &\sim \sum_{j\ge j_0}\sum_{k\in\nabla_j} 2^{2jt}|\langle v,\widetilde{\psi}_{j,k}\rangle|^2, \qquad t\in(-\widetilde{\gamma},\gamma), \\ \|v\|_t^2 &\sim \sum_{j\ge j_0}\sum_{k\in\nabla_j} 2^{2jt}|\langle v,\psi_{j,k}\rangle|^2, \qquad t\in(-\gamma,\widetilde{\gamma}). \end{aligned} \tag{4.6}$$

The validity of these norm equivalences hinges on the estimates (4.2) and (4.3) for *both* the primal and dual multiresolution sequences. The equivalences (4.6) will be essential for preconditioning.

5. Wavelet Galerkin schemes—preconditioning. As before let $A : H^q(\Gamma) \to H^{-q}(\Gamma)$ be a boundary integral operator of order $2q$. Since the wavelet basis Ψ is, in particular, a Riesz basis for $L^2(\Gamma)$, the associated system matrices

$$\mathbf{A}_J = [\langle A\psi_{j',k'},\psi_{j,k}\rangle]_{j_0\le j,j'<J,\, k\in\nabla_j,\, k'\in\nabla_{j'}}$$

become more and more ill-conditioned when J increases. In fact, one has $\operatorname{cond}_{l^2}\mathbf{A}_J \sim 2^{2J|q|}$. However, as a consequence of the stability of the Galerkin discretization under the given circumstances and the norm equivalences (4.6), the following simple *diagonal preconditioner* gives rise to uniformly bounded spectral condition numbers [8, 9, 11].

THEOREM 5.1. *Let the diagonal matrix* $\mathbf{D}_J^r$ *be defined by*

$$\left[\mathbf{D}_J^r\right]_{(j,k),(j',k')} = 2^{rj}\delta_{(j,k),(j',k')}, \quad k\in\nabla_j, \quad k'\in\nabla_{j'}, \quad j_0\le j,j'<J.$$

If $A : H^q(\Gamma)\to H^{-q}(\Gamma)$ *is a boundary integral operator of order* $2q$*, satisfying the assumptions* (1), (2) *from section* 3*, and if* $\widetilde{\gamma} > -q$*, the diagonal matrix* $\mathbf{D}_J^{2q}$ *defines an asymptotically optimal preconditioner for* $\mathbf{A}_J$*, i.e.,* $\operatorname{cond}_{l^2}(\mathbf{D}_J^{-q}\mathbf{A}_J\mathbf{D}_J^{-q}) \sim 1$.

Although the above scaling is asymptotically optimal, it should be stressed that the quantitative performance may vary significantly among different scalings with the same asymptotic behavior. In particular, since Ψ is, on account of the mapping properties of A and the norm equivalences (4.6), also a Riesz basis with respect to the energy norm, it would be natural to normalize the wavelets in the energy norm which would suggest the specific scaling $\langle A\psi_{j,k},\psi_{j,k}\rangle \sim 2^{2qj}$. In fact, this latter diagonal scaling improves and simplifies the wavelet preconditioning.

In view of the above simple preconditioning, the iterative solution of the Galerkin systems is feasible and its overall efficiency relies now on the cost of matrix/vector multiplications, which brings us to the central issue, namely, *matrix compression.*

6. Basic estimates. The basic ingredients in the analysis of the compression procedure are estimates for the matrix entries $\langle A\psi_{j',k'},\psi_{j,k}\rangle$ with $k\in\nabla_j$, $k'\in\nabla_{j'}$ and $j,j'\ge j_0$. The convex hulls of the supports of the wavelets will be denoted by

$$\Omega_{j,k} := \operatorname{conv\,hull}(\operatorname{supp}\psi_{j,k}). \tag{6.1}$$

A complete proof of the following estimates can be found, e.g., in [15, 27].

THEOREM 6.1. *Suppose $n + 2\widetilde{d} + 2q > 0$ and $j, j' > j_0$. Then one has*

$$|\langle A\psi_{j',k'}, \psi_{j,k}\rangle| \lesssim 2^{-(j+j')(\widetilde{d}+n/2)} \operatorname{dist}(\Omega_{j,k}, \Omega_{j',k'})^{-(n+2q+2\widetilde{d})}$$

uniformly with respect to J.

However, in order to arrive ultimately at solution schemes with linear complexity, the number of nonzero entries in the compressed matrices should remain proportional to their size while preserving discretization error accuracy. To achieve this, it is not sufficient to consider only coefficients where the supports of the involved wavelets do not overlap. There are still $\mathcal{O}(N_J \log N_J) = \mathcal{O}(2^{Jn}J)$ coefficients that would remain. To avoid the logarithmic term we propose an additional, so-called *second compression.* For this purpose, we require that our primal basis functions be piecewise polynomial, in the sense that $\psi_{j,k}\big|_{\Gamma_{i,j+1,l}} = p \circ \gamma_i^{-1}$, where p is a polynomial. By

$$\Omega'_{j,k} := \operatorname{sing\,supp} \psi_{j,k} \tag{6.2}$$

we denote the *singular support* of $\psi_{j,k}$, which is that subset of Γ where the function $\psi_{j,k}$ is not smooth. Thus the singular support of the wavelet $\psi_{j,k}$ consists of the boundaries of some of the elements $\Gamma_{i,j+1,l}$. The goal of the subsequent investigation is to estimate those matrix entries for which $\operatorname{dist}(\Omega_{j,k}, \Omega'_{j',k'})$, $j \geq j'$, is sufficiently large.

To this end, we require the following extension lemma which follows, e.g., immediately from the well-known extension theorem of Calderón [28].

LEMMA 6.2. *The function $f_{i,j,k,l}$, defined by*

$$f_{i,j,k,l} := \psi_{j,k}\big|_{\Gamma_{i,j+1,l}} \circ \gamma_i = (\psi_{j,k} \circ \gamma_i)\big|_{C_{j+1,l}} \in C^\infty(C_{j+1,l}),$$

can be extended to a function $\widetilde{f}_{i,j,k,l} \in C_0^\infty(\mathbb{R}^n)$ in such a way that $\operatorname{diam} \operatorname{supp} \widetilde{f}_{i,j,k,l} \lesssim 2^{-j}$*, $\widetilde{f}_{i,j,k,l} \equiv \psi_{j,k} \circ \gamma_i$ on $C_{j+1,l}$, and that for all $s \geq 0$ there holds $\big\|\widetilde{f}_{i,j,k,l}\big\|_{H^s(\mathbb{R}^n)} \lesssim 2^{js}$, independently of i, j, k, l.*

Proof. Suppose that $f_\square \in C^\infty(\square)$ with $\|f_\square\|_{H^s(\square)} \lesssim 1$. By virtue of Calderón's extension theorem, there exists an extension $f \in C_0^\infty(\mathbb{R}^n)$, i.e., $f(x) \equiv f_\square(x)$ on $\square$, satisfying $\|f\|_{H^s(\mathbb{R}^n)} \lesssim \|f_\square\|_{H^s(\square)}$. Let us consider an affine map κ with $\kappa(C_{j+1,l}) = \square$ and choose $f_{i,j,k,l}(x) := f_\square\big(\kappa(x)\big)$. The claim follows now from $|\partial_{x_i}\kappa| = 2^{j+1}$, $i = 1, \ldots, n$. $\square$

It is well known that boundary integral operators A of order $2q$, acting on smooth surfaces, are classical *pseudodifferential operators* [28]. Since the patches Γ_i are smooth and have smooth extensions $\widetilde{\Gamma}_i$, there exists for each i a pseudodifferential operator $A^\sharp : H^q(\mathbb{R}^n) \to H^{-q}(\mathbb{R}^n)$ such that

$$A^\sharp f(x) = \int_{\mathbb{R}^n} \chi(x)\chi(y) k\big(\widetilde{\gamma}_i(x), \widetilde{\gamma}_i(y)\big) f(y) \sqrt{\det \widetilde{K}_i(y)}dy, \tag{6.3}$$

where χ is a C^∞-cut-off function with respect to $\square$, i.e., $\chi(x) = 1$ on $\square$ and $\chi(x) = 0$ outside $[-1, 2]^n$. Therefore $A^\sharp f(x) = A(f \circ \gamma_i)(\gamma_i(x))$ for all $f \in C_0^\infty(\square)$, $x \in \square$, and $A^\sharp$ is compactly supported [29]. Moreover, it is well known [28] that the Schwartz kernel of pseudodifferential operators satisfies the standard estimate (2.6).

A compactly supported pseudodifferential operator $A^\sharp : H^s(\mathbb{R}^n) \to H^{s-2q}(\mathbb{R}^n)$ of order $2q$ acts continuously on Sobolev spaces [28, 29]. Therefore, for any function

$\widetilde{f}_{i,j,k,l} \in C_0^\infty(\mathbb{R}^n)$, satisfying $\operatorname{diam}\operatorname{supp}\widetilde{f}_{i,j,k,l} \sim 2^{-j}$ and $\|\widetilde{f}_{i,j,k,l}\|_{H^s(\mathbb{R}^n)} \lesssim 2^{js}$ for all $s \geq 0$, one has $A^\sharp \widetilde{f}_{i,j,k,l} \in C_0^\infty(\mathbb{R}^n)$ with

$$\|A^\sharp \widetilde{f}_{i,j,k,l}\|_{H^{s-2q}(\mathbb{R}^n)} \lesssim 2^{js}. \tag{6.4}$$

With these preparations at hand, we are able to formulate the following result.

THEOREM 6.3. *Suppose that $n + 2\widetilde{d} + 2q > 0$ and $j' > j \geq j_0$. Then, the coefficients $\langle A\psi_{j',k'}, \psi_{j,k}\rangle$ and $\langle A\psi_{j,k}, \psi_{j',k'}\rangle$ satisfy*

$$|\langle A\psi_{j',k'}, \psi_{j,k}\rangle|,\ |\langle A\psi_{j,k}, \psi_{j',k'}\rangle| \lesssim 2^{jn/2} 2^{-j'(\widetilde{d}+n/2)} \operatorname{dist}(\Omega'_{j,k}, \Omega_{j',k'})^{-(2q+\widetilde{d})},$$

uniformly with respect to j, provided that

$$\operatorname{dist}(\Omega'_{j,k}, \Omega_{j',k'}) \gtrsim 2^{-j'}. \tag{6.5}$$

Proof. We shall consider three cases.

(i) The first observation concerns an estimate for disjoint supports that will be applied several times.

LEMMA 6.4. *Suppose that $\Omega_{j,k} \cap \Omega_{j',k'} = \emptyset$ and that f is any function supported on $\Omega_{j,k}$ satisfying $|f(x)| \lesssim 2^{jn/2}$, $x \in \Omega_{j,k}$. Then one has*

$$|\langle A\psi_{j',k'}, f\rangle| \lesssim 2^{jn/2} 2^{-j'(\widetilde{d}+n/2)} \operatorname{dist}(\Omega_{j,k}, \Omega_{j',k'})^{-(2q+\widetilde{d})}. \tag{6.6}$$

To prove (6.6) note that our assumption implies $\operatorname{dist}(\Omega'_{j,k}, \Omega_{j',k'}) = \operatorname{dist}(\Omega_{j,k}, \Omega_{j',k'})$. On account of the cancellation property (4.5) of the wavelet bases and the decay property (2.6) of the kernel, we obtain

$$\begin{aligned}|A\psi_{j',k'}(x)| = |\langle k(x,\cdot), \psi_{j',k'}\rangle| &\lesssim 2^{-j'(\widetilde{d}+n/2)} |k(x,\cdot)|_{W^{\infty,\widetilde{d}}(\Omega_{j',k'})}\\ &\lesssim 2^{-j'(\widetilde{d}+n/2)} \operatorname{dist}(x, \Omega_{j',k'})^{-(n+2q+\widetilde{d})}\end{aligned}$$

for all $x \in \operatorname{supp}\psi_{j,k}$. Therefore, we conclude that

$$\begin{aligned}|\langle A\psi_{j',k'}, f\rangle| &\lesssim \|f\|_{L^\infty(\Gamma)} \int_{\Omega_{j,k}} |A\psi_{j',k'}(x)| d\Gamma_x\\ &\lesssim 2^{jn/2} 2^{-j'(\widetilde{d}+n/2)} \int_{\Omega_{j,k}} \operatorname{dist}(x, \Omega_{j',k'})^{-(n+2q+\widetilde{d})} d\Gamma_x\\ &\leq 2^{jn/2} 2^{-j'(\widetilde{d}+n/2)} \operatorname{dist}(\Omega_{j,k}, \Omega_{j',k'})^{-(2q+\widetilde{d})},\end{aligned}$$

which proves the lemma. Of course, the same reasoning applies to the adjoint boundary integral operator $A^\star$.

(ii) Next, we treat the case $\Omega_{j,k} \cap \Omega_{j',k'} \neq \emptyset$ and $\Omega_{j,k} \subset \Gamma_i$. By (6.5) we have $\Omega_{j',k'} \subset \Omega_{j,k}$ i.e., both wavelets are supported on the same patch. We infer from (6.5) that there exists an element $\Omega_{j',k'} \subset \Gamma_{i,j+1,l} \subset \Omega_{j,k}$ such that

$$f_{i,j,k,l} := \psi_{j,k}\big|_{\Gamma_{i,j+1,l}} \circ \gamma_i = (\psi_{j,k} \circ \gamma_i)\big|_{C_{j+1,l}}$$

is a $C^\infty(C_{j+1,l})$ function. On account of Lemma 6.2, we can choose an extension of $f_{i,j,k,l}$, denoted by $\widetilde{f}_{i,j,k,l}$. Decomposing $\psi_{j,k}\circ\gamma_i = \widetilde{f}_{i,j,k,l} + \widetilde{f}^C_{i,j,k,l}$, we obtain

$$\begin{aligned}|\langle A\psi_{j,k},\psi_{j',k'}\rangle| &= \left|\int_{\mathbb{R}^n} A^\sharp(\widetilde{f}_{i,j,k,l}+\widetilde{f}^C_{i,j,k,l})(x)(\psi_{j',k'}\circ\gamma_i)(x)dx\right| \\ &\le \left|\int_{\mathbb{R}^n} A^\sharp\widetilde{f}_{i,j,k,l}(x)(\psi_{j',k'}\circ\gamma_i)(x)dx\right| \\ &\quad + \left|\int_{\mathbb{R}^n} A^\sharp\widetilde{f}^C_{i,j,k,l}(x)(\psi_{j',k'}\circ\gamma_i)(x)dx\right|.\end{aligned}$$

The second term on the right-hand side can be treated analogously to (6.6), i.e.,

$$\left|\int_{\mathbb{R}^n} A^\sharp\widetilde{f}^C_{i,j,k,l}(x)(\psi_{j',k'}\circ\gamma_i)(x)dx\right| \lesssim 2^{jn/2}2^{-j'(\tilde{d}+n/2)}\operatorname{dist}(\Omega'_{j,k},\Omega_{j',k'})^{-(2q+\tilde{d})},$$

because $\operatorname{dist}\big(\operatorname{supp}\widetilde{f}^C_{i,j,k,l},\operatorname{supp}(\psi_{j',k'}\circ\gamma_i)\big)\sim\operatorname{dist}(\Omega'_{j,k},\Omega_{j',k'})$. Invoking (4.5) and (6.4), the first term can be estimated by

$$\left|\int_{\mathbb{R}^n} A^\sharp\widetilde{f}_{i,j,k,l}(x)(\psi_{j',k'}\circ\gamma_i)(x)dx\right| \lesssim 2^{-j'(\tilde{d}+n/2)}\|A^\sharp\widetilde{f}_{i,j,k,l}(x)\|_{W^{\infty,\tilde{d}}(\operatorname{supp}(\psi_{j',k'}\circ\gamma_i))}.$$

By virtue of Sobolev's embedding theorem, this implies, in view of (6.4),

$$\begin{aligned}\left|\int_{\mathbb{R}^n} A^\sharp\widetilde{f}_{i,j,k,l}(x)(\psi_{j',k'}\circ\gamma_i)(x)dx\right| &\lesssim 2^{-j'(\tilde{d}+n/2)}\|A^\sharp\widetilde{f}_{i,j,k,l}(x)\|_{H^{\tilde{d}+n/2}(\mathbb{R}^n)} \\ &\lesssim 2^{-j'(\tilde{d}+n/2)}2^{j(\tilde{d}+2q+n/2)}.\end{aligned}$$

Since $\Omega_{j,k}\cap\Omega_{j',k'}\neq\emptyset$, one has, in view of (6.5) and $j'\ge j$, that $\operatorname{dist}(\Omega'_{j,k},\Omega_{j',k'})\lesssim 2^{-j}$, so that we arrive at the desired estimate

$$\left|\int_{\mathbb{R}^n} A^\sharp\widetilde{f}_{i,j,k,l}(x)(\psi_{j',k'}\circ\gamma_i)(x)dx\right| \lesssim 2^{jn/2}2^{-j'(\tilde{d}+n/2)}\operatorname{dist}(\Omega'_{j,k},\Omega_{j',k'})^{-(2q+\tilde{d})}.$$

(iii) It remains to consider the case $\Omega_{j,k}\cap\Omega_{j',k'}\neq\emptyset$, where, however, $\psi_{j,k}$ is not supported completely in the patch Γ_i. In this case, we decompose $\psi_{j,k} = (\psi_{j,k} - \psi_{j,k}\big|_{\Gamma_i}) + \psi_{j,k}\big|_{\Gamma_i}$. Invoking (6.6), we derive

$$\big|\langle A(\psi_{j,k}-\psi_{j,k}\big|_{\Gamma_i}),\psi_{j',k'}\rangle\big| \lesssim 2^{jn/2}2^{-j'(\tilde{d}+n/2)}\operatorname{dist}(\Omega'_{j,k},\Omega_{j',k'})^{-(2q+\tilde{d})}$$

because we have again $\operatorname{dist}\big(\operatorname{supp}(\psi_{j,k}-\psi_{j,k}\big|_{\Gamma_i}),\Omega_{j',k'}\big)\ge\operatorname{dist}(\Omega'_{j,k},\Omega_{j',k'})$. Finally, estimating $\big|\langle A(\psi_{j,k}\big|_{\Gamma_i}),\psi_{j',k'}\rangle\big|$ as in step (ii) finishes the proof. □

Remark. We recall from [8, 27] that there is a general estimate which states that the matrix entries for wavelets with overlapping supports decay with increasing difference of scales. In fact, for each $0\le\delta<\gamma-q$ we have $|\langle A\psi_{j',k'},\psi_{j,k}\rangle|\lesssim 2^{-\delta|j-j'|}$. Since $\gamma<d$ this estimate is, however, not sufficient to achieve the optimal order of convergence within the desired linear complexity.

7. Matrix compression. The discretization of a boundary integral operator $A: H^q(\Gamma)\to H^{-q}(\Gamma)$ by wavelets with a sufficiently strong cancellation property (4.5) yields, in view of the above estimates, quasi-sparse matrices. In the first compression step all matrix entries, for which the distance of the supports of the corresponding trial and test functions is larger than a level depending cut-off parameter $\mathcal{B}_{j,j'}$, are set to zero. In the second compression step also some of those matrix entries are neglected, for which the corresponding trial and test functions have overlapping supports.

A priori compression. Let $\Omega_{j,k}$ and $\Omega'_{j,k}$ be given as in (6.1) and (6.2). Then, the compressed system matrix $\mathbf{A}_J^\epsilon$, corresponding to the boundary integral operator A, is defined by

$$[\mathbf{A}_J^\epsilon]_{(j,k),(j',k')} := \begin{cases} 0, & \operatorname{dist}(\Omega_{j,k},\Omega_{j',k'}) > \mathcal{B}_{j,j'} \text{ and } j,j' > j_0, \\ 0, & \operatorname{dist}(\Omega_{j,k},\Omega_{j',k'}) \lesssim 2^{-\min\{j,j'\}} \text{ and} \\ & \operatorname{dist}(\Omega'_{j,k},\Omega_{j',k'}) > \mathcal{B}'_{j,j'} \text{ if } j' > j \geq j_0, \\ & \operatorname{dist}(\Omega_{j,k},\Omega'_{j',k'}) > \mathcal{B}'_{j,j'} \text{ if } j > j' \geq j_0, \\ \langle A\psi_{j',k'},\psi_{j,k}\rangle, & \text{otherwise.} \end{cases} \tag{7.1}$$

Fixing

$$a, a' > 1, \qquad d < d' < \widetilde{d} + 2q, \tag{7.2}$$

the cut-off parameters $\mathcal{B}_{j,j'}$ and $\mathcal{B}'_{j,j'}$ are set as follows:

$$\begin{aligned} \mathcal{B}_{j,j'} &= a\ \max\left\{2^{-\min\{j,j'\}}, 2^{\frac{2J(d'-q)-(j+j')(d'+\widetilde{d})}{2(\widetilde{d}+q)}}\right\}, \\ \mathcal{B}'_{j,j'} &= a' \max\left\{2^{-\max\{j,j'\}}, 2^{\frac{2J(d'-q)-(j+j')d'-\max\{j,j'\}\widetilde{d}}{\widetilde{d}+2q}}\right\}. \end{aligned} \tag{7.3}$$

Remark 7.1. Relation (7.2) requires the order of vanishing moments, viz. the order of exactness of the dual basis, to exceed the order of the primal basis by an amount determined by the order of the operator $d < \widetilde{d} + 2q$. In the case of equality the matrices are still compressible, but additional log terms arise in the complexity estimates. One can find many pairs of biorthogonal wavelets from the family in [14, 21] satisfying this relation. To obtain quantitatively best performance we employ those with possibly small support, i.e., with possibly small $\widetilde{d}$ satisfying $d < \widetilde{d} + 2q$. This choice is confirmed by numerical experience.

The parameter a is a fixed constant which determines the bandwidth in the block matrices $\mathbf{A}_{j,j'}^\epsilon := [\mathbf{A}_J^\epsilon]_{(j,\nabla_j),(j',\nabla_{j'})}$, $j_0 \leq j, j' < J$. We emphasize that the parameters a and a' are independent of J.

When the entries of the compressed system matrix $\mathbf{A}_J^\epsilon$ have been computed, we apply an *a posteriori compression* by setting all entries to zero, which are smaller than a level-depending threshold. In this way, a matrix $\widetilde{\mathbf{A}}_J^\epsilon$ is obtained which has even less nonzero entries than the matrix $\mathbf{A}_J^\epsilon$. Although this does not accelerate the computation of the matrix coefficients, the amount of necessary memory for storing the system matrix is reduced considerably.

A posteriori compression. We define the a posteriori compression by

$$\left[\widetilde{\mathbf{A}}_J^\epsilon\right]_{(j,k),(j',k')} = \begin{cases} 0 & \text{if } \left|[\mathbf{A}_J^\epsilon]_{(j,k),(j',k')}\right| \leq \varepsilon_{j,j'}, \\ [\mathbf{A}_J^\epsilon]_{(j,k),(j',k')} & \text{if } \left|[\mathbf{A}_J^\epsilon]_{(j,k),(j',k')}\right| > \varepsilon_{j,j'}. \end{cases} \tag{7.4}$$

Here the level-dependent threshold $\varepsilon_{j,j'}$ is chosen as

$$\varepsilon_{j,j'} = a'' \min\left\{2^{-\frac{|j-j'|n}{2}}, 2^{-n(J-\frac{j+j'}{2})\frac{d'-q}{\widetilde{d}+q}}\right\} 2^{2Jq} 2^{-2d'(J-\frac{j+j'}{2})} \tag{7.5}$$

with $a'' < 1$ and $d' \in (d, \widetilde{d} + 2q)$ from (7.2).

8. Matrix estimates. In order to study the accuracy of the solutions to the compressed systems, we investigate the perturbation introduced by discarding specific matrix elements. The perturbation matrices are of scalewise blocks of the type $\mathbf{R}_{j,j'} := \mathbf{A}_{j,j'} - \mathbf{A}^{\epsilon}_{j,j'}$. By $\|\mathbf{R}_{j,j'}\|_p$ we denote the operator norm of the matrix $\mathbf{R}_{j,j'}$ with respect to the norm l^p.

In order to analyze the error introduced by our compression strategy, we decompose the complete compression into three subsequent steps.

THEOREM 8.1 (first compression). *We define the matrix* $\mathbf{A}^{\epsilon_1}_J$ *by*

$$[\mathbf{A}^{\epsilon_1}_J]_{(j,k),(j',k')} := \begin{cases} 0, & \operatorname{dist}(\Omega_{j,k}, \Omega_{j',k'}) > \mathcal{B}_{j,j'} \textit{ and } j, j' > j_0, \\ \langle A\psi_{j',k'}, \psi_{j,k}\rangle, & \textit{otherwise.} \end{cases}$$

Here the parameter $\mathcal{B}_{j,j'}$ *is given by* (7.2) *and* (7.3). *Then, one has for the perturbation matrix* $\mathbf{R}_{j,j'} := \mathbf{A}_{j,j'} - \mathbf{A}^{\epsilon_1}_{j,j'}$

$$\|\mathbf{R}_{j,j'}\|_2 \lesssim a^{-2(\tilde{d}+q)} 2^{2Jq} 2^{-2d'(J-\frac{j+j'}{2})}.$$

Proof. We proceed in two steps.

(i) We abbreviate $\mathbf{R}_{j,j'} := \left[r_{(j,k),(j',k')}\right]_{k\in\nabla_j, k'\in\nabla_{j'}}$. Invoking Theorem 6.1, we find for the column sum

$$\begin{aligned}\sum_{k\in\nabla_j} |r_{(j,k),(j',k')}| &= \sum_{\{k\in\nabla_j :\, \operatorname{dist}(\Omega_{j,k},\Omega_{j',k'})>\mathcal{B}_{j,j'}\}} |\langle A\psi_{j',k'}, \psi_{j,k}\rangle| \\ &\lesssim \sum_{\{k\in\nabla_j :\, \operatorname{dist}(\Omega_{j,k},\Omega_{j',k'})>\mathcal{B}_{j,j'}\}} \\ &\quad \times 2^{-(j+j')(\tilde{d}+n/2)} \operatorname{dist}\left(\Omega_{j,k}, \Omega_{j',k'}\right)^{-(n+2\tilde{d}+2q)}.\end{aligned}$$

Since $\mathcal{B}_{j,j'} \geq a \max\{2^{-j}, 2^{-j'}\}$, we can estimate this sum by an integral which yields

$$\begin{aligned}\sum_{k\in\nabla_j} |r_{(j,k),(j',k')}| &\lesssim 2^{-(j+j')(\tilde{d}+n/2)} 2^{jn} \int_{\|x\|>\mathcal{B}_{j,j'}} \|x\|^{-(n+2\tilde{d}+2q)} dx \\ &\lesssim 2^{-(j+j')(\tilde{d}+n/2)} 2^{jn} \mathcal{B}_{j,j'}^{-2(\tilde{d}+q)}.\end{aligned}$$

On the other hand, inserting the estimate $\mathcal{B}_{j,j'} \geq a 2^{\frac{2J(d'-q)-(j+j')(\tilde{d}+d')}{2(\tilde{d}+q)}}$ (see (7.3)), we arrive at

$$\sum_{k\in\nabla_j} |r_{(j,k),(j',k')}| \lesssim a^{-2(\tilde{d}+q)} 2^{\frac{(j-j')n}{2}} 2^{2Jq} 2^{-2d'(J-\frac{j+j'}{2})}.$$

In complete analogy, one proves an analogous estimate for the row sums,

$$\sum_{k'\in\nabla_{j'}} |r_{(j,k),(j',k')}| \lesssim a^{-2(\tilde{d}+q)} 2^{\frac{(j'-j)n}{2}} 2^{2Jq} 2^{-2d'(J-\frac{j+j'}{2})}.$$

(ii) From the estimate for the operator norms of matrices $\|\mathbf{R}_{j,j'}\|_2^2 \leq \|\mathbf{R}_{j,j'}\|_1 \|\mathbf{R}_{j,j'}\|_\infty$, it is easy to conclude the following version of the Schur lemma (see, e.g., [23, 27]):

$$\begin{aligned}\|\mathbf{R}_{j,j'}\|_2 &\leq \left[\max_{k\in\nabla_j} \sum_{k'\in\nabla_{j'}} 2^{\frac{(j-j')n}{2}} |r_{(j,k),(j',k')}|\right]^{1/2} \left[\max_{k'\in\nabla_{j'}} \sum_{k\in\nabla_j} 2^{\frac{(j'-j)n}{2}} |r_{(j,k),(j',k')}|\right]^{1/2} \\ &\lesssim a^{-2(\tilde{d}+q)} 2^{2Jq} 2^{-2d'(J-\frac{j+j'}{2})},\end{aligned}$$

which proves the assertion. □

The following so-called second compression concerns entries involving basis functions with overlapping supports. It is important that here the coarse scale basis function may be a scaling function which greatly affects the near field compression.

THEOREM 8.2 (second compression). *In addition to the first compression we apply the following second compression:*

$$[\mathbf{A}_J^{\epsilon_2}]_{(j,k),(j',k')} := \begin{cases} 0, & \operatorname{dist}(\Omega_{j,k},\Omega_{j',k'}) \lesssim 2^{-\min\{j,j'\}} \text{ and} \\ & \operatorname{dist}(\Omega'_{j,k},\Omega_{j',k'}) > \mathcal{B}'_{j,j'} \text{ if } j' > j \geq j_0, \\ & \operatorname{dist}(\Omega_{j,k},\Omega'_{j',k'}) > \mathcal{B}'_{j,j'} \text{ if } j > j' \geq j_0, \\ [\mathbf{A}_J^{\epsilon_1}]_{(j,k),(j',k')}, & \text{otherwise,} \end{cases}$$

where the parameter $\mathcal{B}'_{j,j'}$ is set in accordance with (7.2) *and* (7.3). *Then, the corresponding perturbation matrix $\mathbf{S}_{j,j'} := \mathbf{A}^{\epsilon_1}_{j,j'} - \mathbf{A}^{\epsilon_2}_{j,j'}$ satisfies*

$$\|\mathbf{S}_{j,j'}\|_2 \lesssim (a')^{-(\tilde{d}+2q)} 2^{2Jq} 2^{-2d'(J-\frac{j+j'}{2})}.$$

Proof. Abbreviating $\mathbf{S}_{j,j'} := [s_{(j,k),(j',k')}]_{k\in\nabla_j,k'\in\nabla_{j'}}$ and assuming without loss of generality that $j' > j$, we infer from Theorem 6.3 that

$$\begin{aligned} |s_{(j,k),(j',k')}| &\lesssim 2^{jn/2} 2^{-j'(\tilde{d}+n/2)} \mathcal{B}_{j,j'}^{-(2q+\tilde{d})} \\ &\lesssim (a')^{-(\tilde{d}+2q)} 2^{jn/2} 2^{-j'(\tilde{d}+n/2)} 2^{-2J(d'-q)+(j+j')d'+j'\tilde{d}} \\ &= (a')^{-(\tilde{d}+2q)} 2^{(j-j')n/2} 2^{2Jq} 2^{-2d'(J-\frac{j+j'}{2})}. \end{aligned}$$

The condition $\operatorname{dist}(\Omega_{j,k},\Omega_{j',k'}) \lesssim 2^{-\min\{j,j'\}}$ guarantees that in each row and column of $\mathbf{S}_{j,j'}$ we have set at most $\mathcal{O}(2^{(j'-j)n})$, respectively, $\mathcal{O}(1)$ entries to zero. Therefore, we obtain for the weighted row sums

$$\begin{aligned} \sum_{k\in\nabla_j} 2^{\frac{(j-j')n}{2}} |s_{(j,k),(j',k')}| &\lesssim \sum_{k'\in\nabla_{j'}} (a')^{-(\tilde{d}+2q)} 2^{j'n} 2^{(j-j')n} 2^{2Jq} 2^{-2d'(J-\frac{j+j'}{2})} \\ &\lesssim (a')^{-(\tilde{d}+2q)} 2^{2Jq} 2^{-2d'(J-\frac{j+j'}{2})}, \end{aligned}$$

and likewise for the weighted column sums

$$\sum_{k'\in\nabla_{j'}} 2^{\frac{(j'-j)n}{2}} |s_{(j,k),(j',k')}| \lesssim (a')^{-(\tilde{d}+2q)} 2^{2Jq} 2^{-2d'(J-\frac{j+j'}{2})}$$

for all $j_0 \leq j < j' < J$. In complete analogy to the proof of Theorem 8.1 we conclude the assertion. □

THEOREM 8.3 (a posteriori compression). *Let the matrix $\mathbf{A}_J^{\epsilon}$ be compressed according to Theorems* 8.1 *and* 8.2. *Then the a posteriori compression defined by* (7.4) *with the level-dependent threshold $\varepsilon_{j,j'}$ from* (7.5) *causes a block perturbation $\mathbf{T}_{j,j'} := \widetilde{\mathbf{A}}^{\epsilon}_{j,j'} - \mathbf{A}^{\epsilon}_{j,j'}$ satisfying*

$$\|\mathbf{T}_{j,j'}\|_2 \lesssim a'' 2^{2Jq} 2^{-2d'(J-\frac{j+j'}{2})}.$$

Proof. We organize the proof in four steps.

(i) Abbreviating $\mathbf{T}_{j,j'} := [t_{(j,k),(j',k')}]_{k\in\nabla_j,k'\in\nabla_{j'}}$, one obviously has

$$\left|t_{(j,k),(j',k')}\right| \leq a'' \min\left\{2^{-\frac{|j-j'|n}{2}}, 2^{-n(J-\frac{j+j'}{2})\frac{d'-q}{\tilde{d}+q}}\right\} 2^{2Jq}2^{-2d'(J-\frac{j+j'}{2})}. \tag{8.1}$$

We shall use the first compression in order to derive from this inequality the desired. To this end, we find in each row and column of $\mathbf{T}_{j,j'}$ only $\mathcal{O}([\mathcal{B}_{j,j'}2^{j'}]^n)$, respectively, $\mathcal{O}([\mathcal{B}_{j,j'}2^{j}]^n)$ nonzero entries. Setting $M := \frac{d'+\tilde{d}}{2(\tilde{d}+q)}$, one has

$$2^{\frac{2J(d'-q)-(j+j')(d'+\tilde{d})}{2(\tilde{d}+q)}} = 2^{-J}2^{\frac{(J-j)(d'+\tilde{d})}{2(\tilde{d}+q)}}2^{\frac{(J-j')(d'+\tilde{d})}{2(\tilde{d}+q)}} = 2^{-J}2^{(J-j)M}2^{(J-j')M}.$$

Hence, by (7.3), the cut-off parameter for the first compression takes the form

$$\mathcal{B}_{j,j'} \sim \max\left\{2^{-\min\{j,j,'\}}, 2^{-J}2^{(J-j)M}2^{(J-j')M}\right\}. \tag{8.2}$$

From (7.2) and $q < d - \frac{1}{2}$, one concludes $\frac{1}{2} < M < 1$. Moreover, we shall make use of the identity

$$2^{-n(J-\frac{j+j'}{2})\frac{d'-q}{\tilde{d}+q}} = 2^{-2n(J-\frac{j+j'}{2})(M-\frac{1}{2})}. \tag{8.3}$$

Without loss of generality, we assume in the following that $j' \geq j$.

(ii) With these preparations at hand we shall first estimate the block matrices $\mathbf{T}_{j,j'}$ with $2^{-\frac{(j'-j)n}{2}} \leq 2^{-2n(J-\frac{j+j'}{2})(M-\frac{1}{2})}$. One readily verifies that this relation is equivalent to $2^{-j} \geq 2^{-J}2^{(J-j)M}2^{(J-j')M}$, which, by (8.2), implies that the cut-off parameter satisfies $\mathcal{B}_{j,j'} \sim 2^{-j}$. Thus, from (8.1) one infers the estimate

$$\begin{aligned}\sum_{k'\in\nabla_{j'}} 2^{\frac{(j-j')n}{2}}|t_{(j,k),(j',k')}| &\lesssim a''2^{\frac{(j+j')n}{2}}2^{-jn}2^{-\frac{(j'-j)n}{2}}2^{2Jq}2^{-2d'(J-\frac{j+j'}{2})}\\ &= a''2^{2Jq}2^{-2d'(J-\frac{j+j'}{2})}\end{aligned}$$

for the weighted row sums of $\mathbf{T}_{j,j'}$. Analogously, one derives

$$\sum_{k\in\nabla_{j}} 2^{\frac{(j'-j)n}{2}}|t_{(j,k),(j',k')}| \lesssim a''2^{2Jq}2^{-2d'(J-\frac{j+j'}{2})}$$

for the weighted column sums.

(iii) We still have to estimate the errors in the remaining blocks, where $2^{-\frac{(j'-j)n}{2}} > 2^{-2n(J-\frac{j+j'}{2})(M-\frac{1}{2})}$. Then, by (8.3), the cut-off parameter is given by $B_{j,j'} \sim 2^{-J}2^{(J-j)M}2^{(J-j')M}$. Therefore, we obtain for the weighted row sums

$$\begin{aligned}&\sum_{k'\in\nabla_{j'}} 2^{\frac{(j-j')n}{2}}|t_{(j,k),(j',k')}|\\ &\quad\lesssim a''2^{\frac{(j+j')n}{2}}2^{-Jn}2^{(J-j)Mn}2^{(J-j')Mn}2^{-2n(J-\frac{j+j'}{2})(M-\frac{1}{2})}2^{2Jq}2^{-2d'(J-\frac{j+j'}{2})}\\ &\quad= a''2^{2Jq}2^{-2d'(J-\frac{j+j'}{2})},\end{aligned}$$

and a similar estimate for the weighted column sums.

(iv) Combining the estimates in steps (ii) and (iii), we conclude that

$$\sum_{k'\in\nabla_{j'}} 2^{\frac{(j-j')n}{2}}|t_{(j,k),(j',k')}|, \sum_{k\in\nabla_{j}} 2^{\frac{(j'-j)n}{2}}|t_{(j,k),(j',k')}| \lesssim a''2^{2Jq}2^{-2d'(J-\frac{j+j'}{2})}$$

for all $j_0 \leq j, j' < J$. The proof can now be completed in complete analogy to the proof of Theorem 8.1. □

9. Consistency. We shall establish next the consistency of the compressed scheme with the original operator equation in the corresponding Sobolev norms. To this end, note that the operator $\widetilde{A}_J^\epsilon : H^s(\Gamma) \to H^{s-2q}(\Gamma)$, $-\widetilde{\gamma} < s < \widetilde{\gamma} + 2q$, defined by

$$A_J^\epsilon u = \sum_{j,j'=j_0}^{J-1} \sum_{k,k'} \widetilde{\psi}_{j,k} [\widetilde{\mathbf{A}}_J^\epsilon]_{(j,k),(j',k')} \langle \widetilde{\psi}_{j,k}, u \rangle,$$

is represented by the compressed system matrix, since apparently $\langle \widetilde{A}_J^\epsilon \psi_{j',k'}, \psi_{j,k} \rangle = [\widetilde{\mathbf{A}}_J^\epsilon]_{(j,k),(j',k')}$.

THEOREM 9.1. *Let $d < \widetilde{d}+2q$ and $\widetilde{\mathbf{A}}_J^\epsilon$ be the compressed matrix, defined according to section* 7. *Then, for $q \le t, t' \le d$ the estimate*

$$|\langle (A - \widetilde{A}_J^\epsilon) Q_J u, Q_J v \rangle| \lesssim \epsilon 2^{J(2q-t-t')} \|u\|_t \|v\|_{t'} \tag{9.1}$$

holds uniformly with respect to J, where

$$\epsilon := a^{-2(\widetilde{d}+q)} + (a')^{-(\widetilde{d}+2q)} + a'', \tag{9.2}$$

and a, a', a'' are the constants from (7.2) *and* (7.5).

Proof. By definition of the block perturbation matrices $\mathbf{R}_{j,j'}$, $\mathbf{S}_{j,j'}$, $\mathbf{T}_{j,j'}$, one has

$$|\langle (A - \widetilde{A}_J^\epsilon) \psi_{j',k'}, \psi_{j,k} \rangle| \le \big| [\mathbf{R}_{j,j'} + \mathbf{S}_{j,j'} + \mathbf{T}_{j,j'}]_{k,k'} \big|.$$

Hence, we can estimate

$$\begin{aligned} (9.3) \quad & |\langle (A - \widetilde{A}_J^\epsilon) Q_J u, Q_J v \rangle| \\ &= \left| \sum_{j,j'=j_0}^{J-1} \langle (A - \widetilde{A}_J^\epsilon)(Q_{j'+1} - Q_{j'}) u, (Q_{j+1} - Q_j) v \rangle \right| \\ &\le \sum_{j,j'=j_0}^{J-1} |\langle (A - \widetilde{A}_J^\epsilon)(Q_{j'+1} - Q_{j'}) u, (Q_{j+1} - Q_j) v \rangle| \\ &= \sum_{j,j'=j_0}^{J-1} \left| \sum_{k \in \nabla_j} \sum_{k \in \nabla_{j'}} \langle (A - \widetilde{A}_J^\epsilon) \psi_{j',k'}, \psi_{j,k} \rangle \langle u, \widetilde{\psi}_{j',k'} \rangle \langle v, \widetilde{\psi}_{j,k} \rangle \right| \\ &\le \sum_{j,j'=j_0}^{J-1} \big\| \mathbf{R}_{j,j'} + \mathbf{S}_{j,j'} + \mathbf{T}_{j,j'} \big\|_2 \big\| [\langle u, \widetilde{\psi}_{j',k'} \rangle]_{k' \in \nabla_{j'}} \big\|_2 \big\| [\langle v, \widetilde{\psi}_{j,k} \rangle]_{k \in \nabla_j} \big\|_2. \end{aligned}$$

Invoking the inverse estimate (4.3) and the approximation property (4.2) yields

$$\begin{aligned} \big\| [\langle u, \widetilde{\psi}_{j',k'} \rangle]_{k' \in \nabla_{j'}} \big\|_2 &\sim \|(Q_{j'+1} - Q_{j'}) u\|_0 \lesssim 2^{-j't} \|u\|_t, \\ \big\| [\langle v, \widetilde{\psi}_{j,k} \rangle]_{k \in \nabla_j} \big\|_2 &\sim \|(Q_{j+1} - Q_j) v\|_0 \lesssim 2^{-jt'} \|v\|_{t'}. \end{aligned}$$

Further, from Theorems 8.1, 8.2, and 8.3, we conclude

$$\|\mathbf{R}_{j,j'} + \mathbf{S}_{j,j'} + \mathbf{T}_{j,j'}\|_2 \lesssim \epsilon 2^{2Jq} 2^{-2d'(J - \frac{j+j'}{2})}.$$

Inserting these estimates in (9.3) provides

$$\begin{aligned}|\langle(A-\widetilde{A}_J^\epsilon)Q_J u, Q_J v\rangle| &\lesssim \epsilon 2^{J(2q-t-t')}\|u\|_t\|v\|_{t'}\sum_{j,j'=j_0}^{J-1}2^{-j'(d'-t)}2^{-j(d'-t')}\\ &\lesssim \epsilon 2^{J(2q-t-t')}\|u\|_t\|v\|_{t'}\end{aligned}$$

since $t,t'\le d<d'$. □

10. Convergence. With the estimates of section 8 at hand we can prove that the proposed compression strategy retains the optimal order of convergence of the underlying Galerkin scheme. In this context, we shall encounter conditions on the parameters a,a',a'' defining ϵ in (9.2). From Theorem 9.1 we deduce

$$|\langle(A-\widetilde{A}_J^\epsilon)u_J,u_J\rangle|\le\varepsilon\|u_J\|_q^2,$$

which implies the V_J ellipticity. Indeed, inserting this result into (3.3), we get for $J>J_0$ that

$$|\langle(\widetilde{A}_J^\epsilon+\widetilde{A}_J^{\epsilon\star})u_J,u_J\rangle|\ge(c-2\varepsilon)\|u_J\|_q^2\gtrsim\|u_J\|_q^2,$$

with $c>0$, if ϵ from (9.2) is sufficiently small.

THEOREM 10.1 (stability). *Let ϵ from* (9.2) *be sufficiently small. Then, the matrix $\widetilde{\mathbf{A}}_J^\epsilon$, which arises by the compression according to* (7.1) *and* (7.4), *defines a stable scheme, i.e., $\|\widetilde{A}_J^\epsilon u_J\|_{-q}\sim\|u_J\|_q$, uniformly in $J>J_0$.*

This theorem is an immediate consequence of Lemma 3.1 and the norm equivalences, which already requires that $\widetilde{\gamma}>-q$. In the limit case $\widetilde{\gamma}=-q$ a more sophisticated proof presented in [26] shows that Theorem 10.1 remains valid.

THEOREM 10.2 (convergence). *Let ϵ from* (9.2) *be sufficiently small to ensure uniform stability of $\widetilde{A}_J^\epsilon$. Then, the solution $u_J=\sum_{j=j_0}^{J-1}\sum_{k\in\nabla_j}u_{j,k}\psi_{j,k}$ of the compressed scheme $\widetilde{\mathbf{A}}_J^\epsilon\mathbf{u}_J=\mathbf{f}_J$, where $\mathbf{u}_J=[u_{j,k}]_{j_0\le j<J,\,k\in\nabla_j}$, differs from the exact solution u, satisfying $Au=f$, in the energy norm only by*

$$\|u-u_J\|_q\lesssim 2^{J(q-d)}\|u\|_d$$

uniformly in J.

Proof. Strang's first lemma [4] provides

$$\|u-u_J\|_q\lesssim\inf_{v_J\in V_J}\left\{\|u-v_J\|_q+\sup_{w_J\in V_J}\frac{|\langle(A-\widetilde{A}_J^\epsilon)v_J,w_J\rangle|}{\|w_J\|_q}\right\}.$$

The consistency (Theorem 9.1) implies that

$$|\langle(A-\widetilde{A}_J^\epsilon)Q_Ju,w_J\rangle|=|\langle(A-\widetilde{A}_J^\epsilon)Q_Ju,Q_Jw_J\rangle\lesssim 2^{J(q-d)}\|u\|_d\|w_J\|_q$$

for all $u\in H^d(\Gamma)$ and $w_J\in V_J$. Hence, choosing $v_J:=Q_Ju$, we arrive at

$$\begin{aligned}\|u-u_J\|_q&\lesssim\|u-Q_Ju\|_q+\sup_{w_J\in V_J}\frac{|\langle(A-\widetilde{A}_J^\epsilon)Q_Ju,Q_Jw_J\rangle|}{\|w_J\|_q}\\&\lesssim 2^{J(q-d)}\|u\|_d.\end{aligned}$$ □

Theorem 10.3 (Aubin–Nitsche). *In addition to the assumptions of Theorem* 10.2 *suppose that* $\|A^\star v\|_{t-q} \sim \|v\|_{t+q}$ *for all* $0 \le t \le d-q$, *i.e.,* $A^\star : H^{t+q}(\Gamma) \to H^{t-q}(\Gamma)$ *is an isomorphism. Then the error estimate*

$$\|u - u_J\|_{q-t} \lesssim 2^{J(q-d-t)}\|u\|_d$$

holds for all $0 \le t \le d-q$.

Proof. Recalling that

$$\|u - u_J\|_{q-t} = \sup_{g \in H^{t-q}(\Gamma)} \frac{\langle u - u_J, g\rangle}{\|g\|_{t-q}}.$$

we obtain for $v \in H^{t+q}(\Gamma)$ with $A^\star v = g$

$$\|u - u_J\|_{q-t} = \sup_{v \in H^{t+q}(\Gamma)} \frac{|\langle A(u - u_J), v\rangle|}{\|v\|_{t+q}}.$$

Utilizing the Galerkin orthogonality $\langle \widetilde{A}_J^\epsilon u_J, Q_J v\rangle = \langle Au, Q_J v\rangle$, we can decompose

$$\begin{aligned}\langle A(u - u_J), v\rangle &= \langle A(u - u_J), v - Q_J v\rangle + \langle A(u - u_J), Q_J v\rangle \\ &= \langle A(u - u_J), v - Q_J v\rangle - \langle (A - \widetilde{A}_J^\epsilon)u_J, Q_J v\rangle.\end{aligned}$$

The first term on the right-hand side is estimated by Theorem 10.2 in combination with the approximation property (4.2),

$$|\langle A(u - u_J), v - Q_J v\rangle| \lesssim \|u - u_J\|_q \|v - Q_J v\|_q \lesssim 2^{J(q-d-t)}\|u\|_d\|v\|_{t+q}.$$

For the second term we obtain, on account of Theorem 9.1,

$$\begin{aligned}|\langle (A - \widetilde{A}_J^\epsilon)u_J, Q_J v\rangle| &\le |\langle (A - \widetilde{A}_J^\epsilon)(u_J - Q_J u), Q_J v\rangle| + |\langle (A - \widetilde{A}_J^\epsilon)Q_J u, Q_J v\rangle| \\ &\lesssim 2^{-Jt}\|u_J - Q_J u\|_q \|v\|_{t+q} + 2^{J(q-d-t)}\|u\|_d\|v\|_{t+q}.\end{aligned}$$

Inserting $\|u_J - Q_J u\|_q \le \|u - u_J\|_q + \|u - Q_J u\|_q \lesssim 2^{J(q-d)}\|u\|_d$ yields

$$|\langle (A - \widetilde{A}_J^\epsilon)u_J, Q_J v\rangle| \lesssim 2^{J(q-d-t)}\|u\|_d\|v\|_{t+q}.$$

Therefore, we conclude

$$\|u - u_J\|_{q-t} = \sup_{v \in H^{t+q}(\Gamma)} \frac{\langle A(u - u_J), v\rangle}{\|v\|_{t+q}} \lesssim 2^{J(q-d-t)}\|u\|_d,$$

which finishes the proof. ▯

Note that in the extreme case $t = d - q$ we obtain the best possible convergence rate of the Galerkin scheme (3.6).

11. Complexity.

In this section, we present a general theorem which shows that the overall complexity of assembling the compressed system matrix with sufficient accuracy can be kept of the order $\mathcal{O}(N_J)$, even when a computational cost of logarithmic order is allowed for each entry. This theorem is used in [19, 22] as the essential ingredient to provide a quadrature strategy which scales linearly.

Theorem 11.1. *Assume that* $\mathbf{A}_J^\epsilon$ *is obtained by compressing the system matrix* $\mathbf{A}_J = [\langle A\psi_{j',k'}, \psi_{j,k}\rangle]_{j_0 \le j,j' < J,\ k \in \nabla_j,\ k' \in \nabla_{j'}}$ *according to* (7.1). *The complexity of* *computing this compressed matrix is* $\mathcal{O}(N_J)$ *provided that for some* $\alpha \geq 0$ *at most* $\mathcal{O}\big(\big[J - \frac{j+j'}{2}\big]^{\alpha}\big)$ *operations are spent on the approximate calculation of the nonvanishing entries* $\langle A\psi_{j',k'}, \psi_{j,k}\rangle$.

Proof. (i) We begin with some technical preparations. Recall from the proof of Theorem 8.3 that the cut-off parameter of the first compression is given by

$$\mathcal{B}_{j,j'} \sim \max\big\{2^{-\min\{j,j,'\}}, 2^{-J}2^{(J-j)M}2^{(J-j')M}\big\},$$

where, as in the proof of Theorem 8.3, $M = \frac{d'+\widetilde{d}}{2(\widetilde{d}+q)} < 1$. Moreover, we set $M' := \frac{2d'-2q}{\widetilde{d}+d'}$ and $N' := \frac{\widetilde{d}+d'}{\widetilde{d}+2q}$ with d' given by (7.2). Note that M' and N' satisfy the relations $0 < M' < 1$ and $0 < N'$. As one readily verifies, the cut-off parameter with respect to the second compression may now be rewritten as

$$\mathcal{B}'_{j,j'} \sim \max\big\{2^{-j}, 2^{-j'}2^{[JM'+(1-M')j'-j]N'}\big\}, \qquad j \geq j'. \tag{11.1}$$

Further, we make use of the inequality $x^{\alpha} \lesssim 2^{2\delta x}$ which holds for all $x > 0$ and any fixed $\alpha, \delta > 0$. Thus, it suffices to prove the claim for $\mathcal{O}\big(\big[J - \frac{j+j'}{2}\big]^{\alpha}\big)$ replaced by $\mathcal{O}\big(2^{\delta(J-j)}2^{\delta(J-j')}\big)$ where δ is chosen sufficiently small.

(ii) First, we determine now the complexity $\mathcal{C}^{(1)}$ of computing, within the above cost allowance, all matrix entries found in the block matrices $\mathbf{A}^{\epsilon}_{j,j'} = [\mathbf{A}^{\epsilon}_{J}]_{(j,\nabla_j),(j',\nabla_{j'})}$ with $\mathcal{B}_{j,j'} \sim 2^{-J}2^{(J-j)M}2^{(J-j')M}$. In such blocks, we have to process all coefficients $\langle A\psi_{j',k'}, \psi_{j,k}\rangle$ with

$$\operatorname{dist}(\Omega_{j,k}, \Omega_{j',k'}) \lesssim \operatorname{dist}^{(1)}_{j,j'} := 2^{-J}2^{(J-j)M}2^{(J-j')M}. \tag{11.2}$$

In each block, we find only $\mathcal{O}\big(\big[2^{j'}\operatorname{dist}^{(1)}_{j,j'}\big]^{n}\big)$ entries satisfying (11.2) per row, and hence a total of $\mathcal{O}\big(\big[2^{j+j'}\operatorname{dist}^{(1)}_{j,j'}\big]^{n}\big)$. Summing over all blocks yields

$$\begin{aligned}\mathcal{C}^{(1)} &\lesssim \sum_{j,j'=0}^{J} 2^{(j+j')n}2^{-Jn}2^{(J-j)(M+\delta)n}2^{(J-j')(M+\delta)n}\\ &= 2^{Jn}\sum_{j,j'=0}^{J} 2^{(J-j)(M+\delta-1)n}2^{(J-j')(M+\delta-1)n} \lesssim 2^{Jn},\end{aligned}$$

provided that δ is chosen so as to ensure $M + \delta < 1$.

(iii) It remains to show that the complexity for computing the omitted blocks is likewise $\mathcal{O}(N_J)$. Without loss of generality, we assume $j \geq j'$ in the remainder of this proof, since the roles of j and j' can be reversed. Observing that, because of $0 < M' < 1$, one has $0 < JM' + (1-M')j' \leq J$, we consider first the blocks $\mathbf{A}^{\epsilon}_{j,j'}$ with $(j,j') \in S$, where the index set S is given by

$$S := \{(j,j') : 0 \leq j' \leq J,\ JM' + (1-M')j' \leq j \leq J\}. \tag{11.3}$$

In these blocks, we estimate the complexity $\mathcal{C}^{(2)}$ required for the approximate computation of the matrix entries $\langle A\psi_{j',k'}, \psi_{j,k}\rangle$ satisfying the relation

$$\operatorname{dist}(\Omega'_{j,k}, \Omega_{j',k'}) \lesssim \operatorname{dist}^{(2)}_{j,j'} := 2^{-j'}2^{[JM'+(1-M')j'-j]N'}, \tag{11.4}$$

where we refer to expression (11.1) for $\mathcal{B}'_{j,j'}$. Since $\operatorname{dist}^{(2)}_{j,j'} \leq 2^{-j'}$ for all $(j,j') \in S$, in each block one finds only $\mathcal{O}([2^{jn}2^{-j'(n-1)}\operatorname{dist}^{(2)}_{j,j'}])$ nontrivial matrix entries per column with (11.4), and thus a total of $\mathcal{O}([2^{jn}2^{j'}\operatorname{dist}^{(2)}_{j,j'}])$. Therefore, noting that the set S is equivalent to $S = \{(j,j') : JM' \le j \le J,\ 0 \le j' \le \frac{j-JM'}{1-M'}\}$, the complexity is bounded by

$$\begin{aligned}\mathcal{C}^{(2)} &\lesssim \sum_{j=JM'}^{J} \sum_{j'=0}^{\frac{j-JM'}{1-M'}} 2^{jn} 2^{[JM'+(1-M')j'-j]N'} 2^{\delta(J-j)} 2^{\delta(J-j')} \\ &= \sum_{j=JM'}^{J} 2^{jn} 2^{[JM'-j]N'} 2^{\delta(J-j)} 2^{\delta J} \sum_{j'=0}^{\frac{j-JM'}{1-M'}} 2^{j'[(1-M')N'-\delta]} \\ &\lesssim 2^{\delta J \frac{2-M'}{1-M'}} \sum_{j=0}^{J} 2^{j(n-\delta\frac{2-M'}{1-M'})} \lesssim 2^{Jn}.\end{aligned}$$

$\mathcal{C}^{(2)}$ estimates the complexity for those blocks with $(j,j') \in S$ when $\mathcal{B}'_{j,j'} \sim \operatorname{dist}^{(2)}_{j,j'}$. But according to (11.1), the cut-off parameter $\mathcal{B}'_{j,j'}$ is bounded from below by 2^{-j}. In the case of $\mathcal{B}'_{j,j'} \sim 2^{-j}$ we find $\mathcal{O}\big(\big[2^{jn}2^{j'}\operatorname{dist}^{(3)}_{j,j'}\big]\big)$ matrix entries $\langle A\psi_{j',k'}, \psi_{j,k}\rangle$ with $\operatorname{dist}(\Omega'_{j,k}, \Omega_{j',k'}) \lesssim \operatorname{dist}^{(3)}_{j,j'} := 2^{-j}$. Arguing analogously as above, summing over all blocks with $(j,j') \in S$, one obtains

$$\begin{aligned}\mathcal{C}^{(3)} &\lesssim \sum_{j=JM'}^{J} \sum_{j'=0}^{\frac{j-JM'}{1-M'}} 2^{j(n-1)} 2^{j'} 2^{\delta(J-j)} 2^{\delta(J-j')} = \sum_{j=JM'}^{J} 2^{j(n-1)} 2^{\delta(2J-j)} \sum_{j'=0}^{\frac{j-JM'}{1-M'}} 2^{j'(1-\delta)} \\ &\lesssim 2^{\delta J \frac{2-M'}{1-M'}} \sum_{j=0}^{J} 2^{j(n-\delta\frac{2-M'}{1-M'})} \lesssim 2^{Jn}.\end{aligned}$$

(iv) Finally, we consider the blocks $\mathbf{A}^{\epsilon}_{j,j'}$ with $j \ge j'$ and $(j,j') \notin S$. In view of step (ii), it suffices to consider all entries $\langle A\psi_{j',k'}, \psi_{j,k}\rangle$ which fulfill

$$\operatorname{dist}(\Omega_{j,k}, \Omega_{j',k'}) \lesssim \operatorname{dist}^{(4)} := 2^{-\min\{j',j\}} = 2^{-j'}. \tag{11.5}$$

Each block $\mathbf{A}^{\epsilon}_{j,j'}$ consists of only $\mathcal{O}\big(\big[2^{j}2^{j'}\operatorname{dist}^{(4)}\big]^{n}\big)$ entries with (11.5). Hence, according to (11.3), the complexity $\mathcal{C}^{(4)}$ for the computation of these entries is

$$\begin{aligned}\mathcal{C}^{(4)} &\lesssim \sum_{j'=0}^{J} \sum_{j=j'}^{JM'+(1-M')j'} 2^{jn} 2^{\delta(J-j)} 2^{\delta(J-j')} \lesssim \sum_{j'=0}^{J} 2^{2\delta(J-j')} 2^{j'n} \sum_{j=0}^{(J-j')M'} 2^{j(n-\delta)} \\ &\lesssim 2^{Jn} \sum_{j'=0}^{J} 2^{(J-j')((M'-1)(n-\delta)+\delta)} \lesssim 2^{Jn},\end{aligned}$$

since $(M'-1)(n-\delta)+\delta < 0$. This completes this proof. □

ARTIFICIAL BOUNDARY CONDITIONS FOR ONE-DIMENSIONAL CUBIC NONLINEAR SCHRÖDINGER EQUATIONS[*]

XAVIER ANTOINE[†], CHRISTOPHE BESSE[†], AND STÉPHANE DESCOMBES[‡]

Abstract. This paper addresses the construction of nonlinear integro-differential artificial boundary conditions for one-dimensional nonlinear cubic Schrödinger equations. Several ways of designing such conditions are provided and a theoretical classification of their accuracy is given. Semidiscrete time schemes based on the method developed by Durán and Sanz-Serna [*IMA J. Numer. Anal.* 20 (2000), pp. 235–261] are derived for these unusual boundary conditions. Stability results are stated and several numerical tests are performed to analyze the capacity of the proposed approach.

Key words. nonlinear cubic Schrödinger equation, artificial boundary conditions, pseudodifferential operators, stable semidiscrete schemes, solitons interaction

1. Introduction.

In many physical and technological domains of interest, the numerical solution to a one-dimensional cubic nonlinear Schrödinger (NLS) equation of the form

$$
\begin{aligned}
i\partial_t u + \partial_x^2 u + q|u|^2 u = 0,\ x \in \mathbb{R},\ t > 0, \\
u(x,0) = u_0(x),\ x \in \mathbb{R},
\end{aligned}
\tag{1.1}
$$

is required. The real parameter q corresponds to a focusing ($q > 0$) or defocusing ($q < 0$) effect of the cubic nonlinearity. One example of such an equation is given in nonlinear optic for laser beam propagation where the polarization of the material has a cubic nonlinearity according to the electric field. Using the slowly varying envelope assumption of the electric field and several approximations, it can be shown that the problem reduces to (1.1). The solution is then the unknown amplitude of the electric field. Other applications come from plasma physics or quantum mechanics [11].

The numerical treatment of (1.1) is often realized by restricting the computational domain to a finite one. More precisely, let us assume that the initial datum u_0 is compactly supported in a finite domain $\Omega_i =]x_l, x_r[\subset \mathbb{R}$, with $x_r > x_l$. The Dirichlet boundary condition is usually imposed on the boundary $\Sigma = \{x_l, x_r\}$ of Ω_i. However, the wave reflects back into the computational domain when u strikes Σ. If the Neumann boundary condition is preferred, then reflection still occurs. The problem of the choice of a suitable boundary condition is linked to the construction of a nonreflecting (also called transparent) boundary condition which models the propagation of the solution into the complementary unbounded domain $\mathbb{R}/\overline{\Omega_i}$.

Such conditions have been widely studied in the linear case ($q = 0$) where the exact boundary condition is given through the Dirichlet–Neumann (DN) operator [8]

$$\partial_{\mathbf{n}} u + e^{-i\frac{\pi}{4}} \partial_t^{1/2} u = 0 \quad \text{on } \Sigma \times \mathbb{R}^{*+}. \tag{1.2}$$

The operator $\partial_t^{1/2}$ designates the fractional time derivative operator of half-order given by the Riemann–Liouville nonlocal integral representation

$$\partial_t^{1/2} f(t) = \frac{1}{\sqrt{\pi}} \partial_t \int_0^t \frac{f(s)}{\sqrt{t-s}} ds. \tag{1.3}$$

Another equivalent continuous representation is given by the Neumann–Dirichlet (ND) operator

$$u + e^{i\frac{\pi}{4}} I_t^{1/2} \partial_{\mathbf{n}} u = 0 \quad \text{on } \Sigma \times \mathbb{R}^{*+},$$

where the fractional integral operator of half-order is given by the convolution operator

$$I_t^{1/2} f(t) = \frac{1}{\sqrt{\pi}} \int_0^t \frac{f(s)}{\sqrt{t-s}} ds.$$

Even if the above two boundary conditions are transparent in the linear case, it appears that they still generate a lot of reflection at the boundary when the nonlinear perturbation is added [20]. This is finally quite natural since the nonlinear term generally compensates the dispersion due to the linear part of the NLS equation. Therefore, we cannot expect that a linear boundary condition simulates the nonlinear phenomenon. To the best of the authors' knowledge, no nonlinear artificial boundary conditions (NLABCs) have been derived and studied until now for a nonlocal NLS equation. The goal of this paper is to propose some efficient NLABCs for the model problem (1.1) (section 2), to construct some suitable and (if possible) stable schemes for their discretization (sections 3 and 4), and finally to numerically test them (section 4) in some interesting situations (e.g., interaction of two solitons).

2. A first construction of NLABCs for the cubic NLS equation.

This section is devoted to the construction of NLABCs for the one-dimensional cubic NLS equation. Two ways of designing such conditions are proposed and energy bounds are derived.

2.1. Construction of NLABCs.

The adopted strategy for constructing some artificial boundary conditions for the NLS equation is issued from linear analysis. It consists first in designing some suitable artificial boundary conditions for the linear Schrödinger equation being given a potential V

$$i\partial_t u + \partial_x^2 u + Vu = 0, \tag{2.1}$$

and next in making the formal substitution $V(x,t) = q|u(x,t)|^2$ to deduce some NLABCs.

Let us assume that V is a sufficiently smooth potential. First, we consider a time-dependent potential, V: $V(x,t) = V(t)$. Then, considering the new unknown $v(x,t) = e^{-i\mathcal{V}(t)} u(x,t)$ in (2.1), where the phase function $\mathcal{V}$ is given by

$$\mathcal{V}(t) = \int_0^t V(s) ds,$$

we reduce the initial equation to a linear Schrödinger equation without potential,

$$i\partial_t v + \partial_x^2 v = 0, \tag{2.2}$$

where $v(x,0) = u_0(x)$. Now, we assume that the initial datum u_0 is compactly supported in an open bounded computational domain $\Omega_i =]x_l, x_r[$ of boundary $\Sigma = \{x_l, x_r\}$. We can therefore directly show that the DN transparent boundary condition for this latter equation is [3, 6, 16]

$$\partial_{\mathbf{n}} v(x,t) + e^{-i\frac{\pi}{4}} \partial_t^{1/2} v(x,t) = 0 \qquad \text{on } \Sigma \times \mathbb{R}^+,$$

which can be rewritten according to the initial unknown u as the *exact* boundary condition

$$\partial_{\mathbf{n}} u(x,t) + e^{-i\frac{\pi}{4}} e^{i\mathcal{V}(t)} \partial_t^{1/2} (e^{-i\mathcal{V}(t)} u(x,t)) = 0 \qquad \text{on } \Sigma \times \mathbb{R}^+. \tag{2.3}$$

The operator $\partial_t^{1/2}$ stands for the Riemann–Liouville fractional derivative operator of order 1/2 defined by (1.3). Following the proposed approach, we consider the formal NLABC

$$\partial_{\mathbf{n}} u(x,t) + e^{-i\frac{\pi}{4}} e^{i\mathbb{U}(x,t)} \partial_t^{1/2} (e^{-i\mathbb{U}(x,t)} u(x,t)) = 0 \qquad \text{on } \Sigma \times \mathbb{R}^+, \tag{2.4}$$

with

$$\mathbb{U}(x,t) = q \int_0^t |u(x,s)|^2 ds. \tag{2.5}$$

The boundary condition (2.4)–(2.5) is denoted by NLABC_1^1 in the rest of the paper.

We have seen that we can explicitly write the transparent boundary condition for a potential which depends only on the time variable. Now a question is: How can we extend this approach to the case of a potential which also depends on the spatial variable x? To give a possible answer to this problem, let us denote by u the solution to (2.1) and by v the new unknown defined by the relation $v(x,t) = e^{-i\mathcal{V}(x,t)} u(x,t)$. We straightforwardly remark that $v_0(x) = u_0(x)$ and then the initial solutions coincide. Moreover, the time and spatial derivatives of u are given in terms of derivatives of v by

$$i\partial_t u = e^{i\mathcal{V}} (i\partial_t - V) v$$

and

$$\partial_x^2 u = ie^{i\mathcal{V}} (\partial_x^2 v + 2i\partial_x \mathcal{V} \partial_x v + i\partial_x^2 \mathcal{V} v - (\partial_x \mathcal{V})^2 v).$$

As a consequence, the function v satisfies the Schrödinger equation

$$L(x,t,\partial_x,\partial_t) v = i\partial_t v + \partial_x^2 v + A\partial_x v + Bv = 0, \tag{2.6}$$

where we have defined the two functions A and B by the relations $A = 2i\partial_x \mathcal{V}$ and $B = (i\partial_x^2 \mathcal{V} - (\partial_x \mathcal{V})^2)$. For a potential which depends only on the time variable t, the operators A and B vanish and the approach coincides with the previous case. However, in the general situation, (2.6) is a variable coefficients Schrödinger equation. For this reason, we propose to develop a constructive approach of the artificial boundary conditions based on the theory of pseudodifferential operators as proposed by Engquist and Majda [14, 15] in the seventies. Many authors have extended and improved this technique to various equations and systems. In the particular case of the Schrödinger equation, a fractional pseudodifferential operators calculus [2] is required to include the inhomogeneity appearing between the time and space derivatives. Using a Nirenberg-like factorization theorem [2, 18] for the Schrödinger operator L, we can compute an asymptotic expansion in inhomogeneous symbols of the transparent operator for (2.6).

The inhomogeneous pseudodifferential operator calculus used here has been introduced by Lascar [17]. We just give the main results adapted to our situation and refer to [17] for further details. Let us consider a real number α and Ω an open subset of the space $\mathbb{R}^n$. Then (see, e.g., [18]), $S^\alpha(\Omega\times\Omega)$ denotes the linear space of $\mathcal{C}^\infty$ functions $a(x,t,\tau)$ in $\Omega\times\Omega\times\mathbb{R}^n$ such that for each $K\subseteq\Omega\times\Omega$ and for any multiindices β, δ, γ there exists a constant $C_{\beta,\delta,\gamma}(K)$ such that we get

$$|\partial_\tau^\beta\partial_t^\delta\partial_x^\gamma a(x,t,\tau)| \leq C_{\beta,\delta,\gamma}(K)(1+|\tau|^2)^{\alpha-|\beta|}$$

for all $(x,t)\in K$ and $\tau\in\mathbb{R}^n$. Here, $|\beta|$ denotes the length of a multi-index β and τ is the time Fourier symbol. Let us introduce now some specific notation and definitions for our problem (setting $n=1$). A function f is said to be inhomogeneous of degree m if it fulfills $f(x,t,\mu^2\tau)=\mu^m f(x,t,\tau)$ for any $\mu>0$. Then, a pseudodifferential operator $P=P(x,t,\partial_t)$ is called inhomogeneous and classical of order M, $M\in\mathbb{Z}/2$, if its total symbol, denoted by $p=\sigma(P)$, admits an asymptotic expansion in inhomogeneous symbols $\{p_{M-j/2}\}_{j=0}^{+\infty}$ under the form

$$p(x,t,\tau)\sim\sum_{j=0}^{+\infty}p_{M-j/2}(x,t,\tau),$$

where functions $p_{M-j/2}$ are inhomogeneous of degree $2M-j$ for $j\in\mathbb{N}$. The sense to give to this last approximation is that

$$\forall\widetilde{m}\in\mathbb{N},\quad p-\sum_{j=0}^{\widetilde{m}}p_{M-j/2}\in S^{M-(\widetilde{m}+1)/2}.$$

A symbol p satisfying the above property is quoted by $p\in S_S^M$ and the associated operator $P=Op(p)$ by inverse Fourier transform by $P\in OPS_S^M$. For instance, if we consider the fractional derivative operator $P=e^{-i\frac{\pi}{4}}\partial_t^{1/2}$, a direct calculation shows that its symbol is equal to $\sqrt{\tau}$, where τ is the time covariable. Notation $\sqrt{z}$ designates the standard principal determination of the complex square root of a complex number z for a branch-cut along the negative real axis. Function $\sqrt{\tau}$ is inhomogeneous of degree 1 and is an element of $S_S^{1/2}$. So, P is a pseudodifferential operator of $OPS_S^{1/2}$. Similarly, the fractional integration operators $i^{-\alpha/2}I_t^{\alpha/2}$ defined by the relations

$$I_t^{\alpha/2}f(t)=\frac{1}{\Gamma(\alpha/2)}\int_0^t(t-s)^{\alpha/2-1}f(s)ds\quad\text{for }\alpha\in\mathbb{N}$$

have $\tau^{-\alpha/2}$ as symbol, where Γ stands for the Gamma function. This symbol is inhomogeneous of degree $-\alpha$ and is an element of $S_S^{-\alpha/2}$. Therefore, $i^{-\alpha/2}I_t^{\alpha/2}$ defines a pseudodifferential operator of $OPS_S^{-\alpha/2}$.

Under the previous notation, the following proposition holds.

PROPOSITION 2.1. *Let L be the variable coefficients Schrödinger operator defined by* (2.6). *There exist two inhomogeneous and classical pseudodifferential operators $\Lambda^{\pm} = \Lambda^{\pm}(x, t, \partial_t) \in OPS_S^{1/2}$, regular with respect to the spatial variable x and such that*

$$L = (\partial_x + i\Lambda^-)(\partial_x + i\Lambda^+) + R, \tag{2.7}$$

where R is a smoothing operator of $OPS_S^{-\infty}$ and the principal symbols $\lambda^{\pm}_{1/2}$ of the operators $\Lambda^{\pm}$ are given by $\lambda^{\pm}_{1/2} = \mp\sqrt{-\tau}$. Furthermore, the total symbol $\lambda^{\pm} = \sigma(\Lambda^{\pm})$ of $\Lambda^{\pm}$ admits an asymptotic expansion in inhomogeneous symbols as

$$\lambda^{\pm} = \sigma(\Lambda^{\pm}) \sim \sum_{j=0}^{+\infty} \lambda^{\pm}_{1/2-j/2}. \tag{2.8}$$

Proof. Expanding the factorization (2.7) (of Nirenberg-type [18]) and using similar calculations to those in [1, 2], we get

$$(\partial_x + i\Lambda^-)(\partial_x + i\Lambda^+) = \partial_x^2 + i(\Lambda^+ + \Lambda^-)\partial_x + iOp(\partial_x\lambda^+) - \Lambda^-\Lambda^+.$$

By identification with the terms appearing in front of the spatial derivatives ∂_x in the expression (2.6) of L, we deduce the system of operators

$$\begin{aligned} i(\Lambda^+ + \Lambda^-) &= A, \\ iOp(\partial_x\lambda^+) - \Lambda^-\Lambda^+ &= i\partial_t + B, \end{aligned} \tag{2.9}$$

which yields the symbolic system of equations

$$\begin{aligned} li(\lambda^+ + \lambda^-) &= a, \\ i\partial_x\lambda^+ - \sum_{\alpha=0}^{+\infty} \frac{(-i)^\alpha}{\alpha!}\partial_\tau^\alpha\lambda^-\partial_t^\alpha\lambda^+ &= -\tau + b, \end{aligned} \tag{2.10}$$

setting $a = A$ and $b = B$. These two functions correspond to zero order operators. If we identify the terms of order 1/2 in the first relation of system (2.10), we obtain $\lambda^-_{1/2} = -\lambda^+_{1/2}$. Using now the second equation, we deduce that

$$\lambda^+_{1/2} = \pm\sqrt{-\tau}.$$

For a potential which depends only on the time variable, the DN operator corresponds to the choice $\lambda^+_{1/2} = -\sqrt{-\tau}$ which can be extended to the space-dependent case. If we consider now the next order of identification, the first equation of the symbolic system gives the zero order term $\lambda^-_0 = -\lambda^+_0 - ia$. Substituting this expression into the second equation of system (2.10), we get

$$i\partial_x\lambda^+_{1/2} - (\lambda^-_0\lambda^+_{1/2} + \lambda^+_0\lambda^-_{1/2}) = 0.$$

But since $\partial_x\lambda^+_{1/2} = 0$, the previous relation yields

$$\lambda^+_0 = -i\frac{a}{2}.$$

Let us now consider the next term. Developing the computations and using the fact that $\lambda^+_{-1/2} = -\lambda^-_{-1/2}$, the zero order identification gives

$$i\partial_x\lambda_0^+ - (\lambda^-_{-1/2}\lambda^+_{1/2} + \lambda_0^-\lambda_0^+ + \lambda^+_{-1/2}\lambda^-_{1/2}) = b$$

since $\partial_t^\alpha\lambda^\pm_{-1/2} = 0$ and $\partial_\tau^\alpha\lambda_0^\pm = 0$ for any $\alpha \in \mathbb{N}$. After some simplifications, we conclude that

$$\lambda^+_{-1/2} = \frac{1}{2\lambda^+_{1/2}}(b - i\partial_x\lambda_0^+ + (\lambda_0^+)^2 + ia\lambda_0^+),$$

with $b = i\partial_x^2\mathcal{V} - (\partial_x\mathcal{V})^2$. An explicit computation yields $\lambda^+_{-1/2} = 0$. Following the process initialized above, we obtain that the next symbol is given by

$$\lambda^+_{-1} = i\frac{\partial_x V}{4\tau}.$$

The computation of the four first symbols shows how to construct the symbolic asymptotic expansion. Using the same inductive arguments as in [2], we end the proof of the proposition. □

The factorization (2.7) yields a splitting of the Schrödinger operator into two parts: one corresponding to an outgoing wave to the computational domain and another one yielding the reflected part of the wave. Then we can show that a condition for having a vanishing reflected wave is given by the DN transparent boundary condition applied to the unknown field v

$$(\partial_{\mathbf{n}} + i\Lambda^+)v = 0 \quad \text{on } \Sigma \times \mathbb{R}^*.$$

Since the operator Λ^+ has an infinite expansion in inhomogeneous symbols, we choose to approximate the above condition by retaining the M first terms yielding the following definition.

DEFINITION 2.2. *Let M be a nonnegative integer. We consider the operator $\Lambda^+_{M/2}$ approximating $i\Lambda^+$ in $OPS_S^{1/2-M/2}$ and given by*

$$\Lambda^+_{M/2} = iOp\left(\sum_{j=0}^{M-1}\lambda^+_{1/2-j/2}\right).$$

Then, the artificial boundary condition of order $M/2$ (acting on u) is defined by

$$\partial_{\mathbf{n}}u + e^{i\mathcal{V}}\Lambda^+_{M/2}(e^{-i\mathcal{V}}u) = 0 \quad \text{on } \Sigma \times \mathbb{R}^*,$$

where we have set

$$\mathcal{V}(x,t) = \int_0^t V(x,s)ds.$$

Using the computation of the symbols obtained during the proof of Proposition 2.1, we show that the first order boundary condition is given by

$$\partial_{\mathbf{n}}u + e^{-i\frac{\pi}{4}}e^{i\mathcal{V}}\partial_t^{1/2}(e^{-i\mathcal{V}}u) = 0 \ \text{ on } \Sigma \times \mathbb{R}^*, \tag{2.11}$$

and the second order one by

$$\partial_{\mathbf{n}} u + e^{-i\frac{\pi}{4}} e^{i\mathcal{V}} \partial_t^{1/2}(e^{-i\mathcal{V}} u) + i\frac{\partial_x V}{4} e^{i\mathcal{V}} I_t(e^{-i\mathcal{V}} u) = 0 \text{ on } \Sigma \times \mathbb{R}^*. \tag{2.12}$$

In the case of an x-independent potential, we straightforwardly observe that all these conditions coincide with the transparent boundary condition (2.3). Moreover, the conditions of order 1 and 3/2 are exactly the same. This indicates that, even for a space varying potential, the first order artificial boundary condition should be quite efficient.

Before writing the formal transposition to the nonlinear operator, we emphasize the fact that, in the linear situation, the function $\partial_x V$ is seen as an operator of order zero since it just multiplies u. In the nonlinear case, the situation is completely different if we make the substitution $V \to q|u|^2$ since we have $\partial_x V \to \partial_x(q|u|^2)$. For this reason, we must specify this aspect in the deduced boundary conditions by adding the dependence of the nonlinear operators according to ∂_x. Following the proposed strategy, we formally deduce the two NLABCs of order $M/2$ ($\text{NLABC}_1^{M/2}$)

$$\partial_{\mathbf{n}} u + \Lambda_{M/2}^{NLS}(x, t, \partial_x, \partial_t, |u|)u = 0 \text{ on } \Sigma \times \mathbb{R}^*, \tag{2.13}$$

where the nonlinear operators are defined by

$$\begin{aligned} &\Lambda_1^{NLS}(x, t, \partial_x, \partial_t, |u|) = e^{-i\frac{\pi}{4}} e^{i\mathbb{U}} \partial_t^{1/2}(e^{-i\mathbb{U}} u), \\ &\Lambda_2^{NLS}(x, t, \partial_x, \partial_t, |u|) = \Lambda_1^{NLS}(x, t, \partial_x, \partial_t, |u|) + i\frac{q}{4}\partial_{\mathbf{n}}(|u|^2) e^{i\mathbb{U}} I_t(e^{-i\mathbb{U}} u). \end{aligned} \tag{2.14}$$

The function $\mathbb{U}$ is defined by the relation (2.5).

Remark 2.3. The particular form of the asymptotic expansion (2.8) for the operators $\Lambda^{\pm}$ suggests that we use a high-frequency assumption on the solution to the linear Schrödinger equation. This should also be the case for the formal extension to the nonlinear case. We will see during the numerical experiments that these NLABCs are particularly accurate for a "fast" soliton.

2.2. An energy bound on the solution to the approximate initial boundary value problems. In the case of the linear Schrodinger equation sets in the whole space with a smooth real-valued time-dependent potential V, the conservation of the L^2-norm of the solution can be proved. When the infinite domain is truncated by the transparent boundary condition (2.3), the conservation of the L^2-norm becomes an energy bound; the $L^2(\Omega_i)$-norm, denoted by $\|u\|_{0,\Omega_i}$, of the solution u at a given time is bounded by $\|u_0\|_{0,\Omega_i}$. This implies the uniqueness of the solution to the bounded initial boundary value problem. In the case of the cubic NLS equation defined on the whole space, both the L^2-norm of the solution and its Hamiltonian defined by

$$\mathcal{H}(t) = \|\partial_x u\|_0^2(t) - \frac{1}{2}\left\||u|^2\right\|_0^2(t)$$

are conserved. The question which naturally arises is to know if the $L^2(\Omega_i)$-norm of the solution to the truncated NLS is bounded by $\|u_0\|_{0,\Omega_i}$. In the case of the first-order condition, the following results hold.

PROPOSITION 2.4. *Let $u_0 \in L^2(\Omega_i)$ be a compactly supported initial datum such that* $\text{Supp}(u_0) \subset \Omega_i$ *and u is a solution to the initial boundary value problem*

$$\begin{aligned} &i\partial_t u + \partial_x^2 u + q|u|^2 u = 0 \quad \text{in } \Omega_i \times \mathbb{R}^+, \\ &\partial_{\mathbf{n}} u + \Lambda_1^{NLS}(x, t, \partial_x, \partial_t, |u|)u = 0 \quad \text{on } \Sigma \times \mathbb{R}^+, \\ &u(x, 0) = u_0(x) \quad \forall x \in \Omega_i, \end{aligned} \tag{2.15}$$

with the function $\mathbb{U}$ *given by* (2.5)*. Then, u fulfills the energy bound*

$$\forall t > 0, \forall u_0 \in L^2(\Omega_i),\ \ \|u(t)\|_{0,\Omega_i} \leq \|u_0\|_{0,\Omega_i}\,. \tag{2.16}$$

Proof. Let us multiply the NLS equation, given by the first equation of system (2.15), by $-i\overline{u}$, where $\overline{u}$ designates the conjugate complex value of u. Integrating by parts on Ω_i and next taking the real part of the resulting equation, we obtain the following expression after integration on an arbitrary time interval $[0, T]$, with $T > 0$:

$$\frac{1}{2}(\|u\|^2_{0,\Omega_i}(T) - \|u_0\|^2_{0,\Omega_i}) = \Re\left(i\int_0^T [\overline{u}\partial_x u]_{x_l}^{x_r}\,dt\right). \tag{2.17}$$

To get the result of the proposition, let us prove the positiveness of the term involved in the right-hand side of (2.17). To simplify the presentation, we consider only the term at point x_r; the other one at x_l can be treated in a similar way. Using the expression of the first order artificial boundary condition and considering the extension $\widetilde{u}$ of u by zero for any time $t > T$, we have

$$\Re\left(i\int_0^T \overline{u}(x_r,t)\partial_{\mathbf{n}}u(x_r,t)dt\right) = -\Re\left(e^{i\frac{\pi}{4}}\int_0^\infty \partial_t^{1/2}(e^{-i\widetilde{\mathbb{U}}(x_r,t)}\widetilde{u})\overline{(e^{-i\widetilde{\mathbb{U}}(x_r,t)}\widetilde{u})}dt\right). \tag{2.18}$$

The control of the sign of the term on the right-hand side is a consequence of the property that the operator $e^{i\frac{\pi}{4}}\partial_t^{1/2}$ is a positive memory-type operator [5, 7]. The proof is based on the Plancherel theorem of the Laplace transform.

LEMMA 2.5. *Let* $\varphi \in H^{1/4}(0,T)$ *be a function extended by zero for any time* $s > t$*. Then, we have the inequality*

$$\Re\left(e^{i\frac{\pi}{4}}\int_0^\infty \partial_s^{1/2}\varphi(s)\overline{\varphi(s)}ds\right) \geq 0.$$

Moreover, the following estimate holds for the imaginary part:

$$\Im\left(e^{i\frac{\pi}{4}}\int_0^\infty \partial_s^{1/2}\varphi(s)\overline{\varphi(s)}ds\right) \geq 0.$$

Applying this lemma to (2.18) and using (2.17), we prove the needed inequality. ☐

If we develop the same approach for the second order artificial boundary condition, it does not seem possible to control the sign of the corrective term. This is essentially due to the quantity $\partial_{\mathbf{n}}(|u|^2)$ which does not have a well-defined sign. Another point is that the Hamiltonian $\mathcal{H}$ of the nonlinear cubic Schrodinger equation defined on $\mathbb{R}_x \times \mathbb{R}_t^+$ is conserved. A similar bound as (2.16) for the Hamiltonian of the solution to (2.15) cannot be obtained by direct arguments.

2.3. Other asymptotic NLABCs. We consider now the artificial boundary conditions (2.11) and (2.12) derived for a potential V. These boundary conditions involve some time fractional derivative and integration operators applied to the product of two functions. To expand these quantities, we can use the Leibnitz derivation rule for fractional operators. To this end, let us recall that if f and g are two functions, where f is $\mathcal{C}^\infty$ on $[0,t]$ and g is continuous, then the fractional derivative of fg is given by

$$\partial_t^p(fg) = \sum_{k=0}^{\infty} \frac{\Gamma(p+1)}{k!\Gamma(p-k+1)} f^{(k)} \partial_t^{p-k} g. \tag{2.19}$$

(A similar formula with a finite number of terms and an integral rest also holds [22].) Using formula (2.19), we can expand the fractional derivative operator as

$$\partial_t^{1/2}(e^{-i\mathcal{V}}u) = \sum_{k=0}^{\infty} \frac{\Gamma(3/2)}{k!\Gamma(3/2-k)} \partial_t^k(e^{-i\mathcal{V}})\partial_t^{1/2-k}u.$$

Considering the relation $\Gamma(z+1) = z\Gamma(z)$ for the Gamma function, we have $\Gamma(z) = \Gamma(z-k)\prod_{j=1}^{k}(z-j)$ for any $k \geq 1$. We then deduce the expression

$$\partial_t^{1/2}(e^{-i\mathcal{V}}u) = e^{-i\mathcal{V}}\partial_t^{1/2}u + \sum_{k=1}^{\infty} \frac{\prod_{j=1}^{k}(3/2-j)}{k!} \partial_t^k(e^{-i\mathcal{V}}) I_t^{k-1/2}u.$$

Truncating this series to a finite number M of terms, we get some new approximations of the artificial boundary conditions (2.11) and (2.12). For instance, keeping three terms in the above expression yields the approximation of (2.11)

$$\partial_{\mathbf{n}}u + e^{-i\pi/4}\partial_t^{1/2}u - \frac{e^{i\pi/4}}{2}VI_t^{1/2}u + \frac{e^{i\pi/4}}{8}\partial_t V I_t^{3/2}u + e^{-i\pi/4}\frac{V^2}{8}I_t^{3/2}u = 0. \tag{2.20}$$

Let us notice that the condition (2.11) has been constructed modulo some operators of OPS^{-1} for the modified Schrödinger equation defined by the operator (2.6). As a consequence, we should keep only the first two time operators of the previous expression. However, if we try to prove an energy bound for the $L^2(\Omega_i)$-norm of the solution to the truncated nonlinear initial boundary value problem, it appears that we cannot derive an a priori estimate to control the operator of order $-1/2$. There is a lack of symmetry of this latter term. To circumvent this drawback, we propose a modification of the conditions. To this end, let us recall that we have from the Leibnitz derivation rule for any strictly positive real number ν and real analytic functions v and u on $[0;+\infty[$

$$I_t^\nu(vu) = \sum_{k=0}^{\infty} \frac{\Gamma(-\nu+1)}{k!\Gamma(-\nu-k+1)} \partial_t^k v I_t^{\nu+k}u.$$

In particular, the first two coefficients are 1 and $-1/2$ for $\nu = 1/2$. If we now consider $v = \sqrt{V}$, the following approximation holds:

$$\sqrt{V}I_t^{1/2}(\sqrt{V}u) = VI_t^{1/2}u - \frac{\sqrt{V}}{2}\partial_t\sqrt{V}I_t^{3/2}u \mod(OPS^{-5/2}).$$

Moreover, we also have the symmetrization

$$\frac{e^{-i\pi/4}}{8}V^2 I_t^{3/2}u = \frac{e^{-i\pi/4}}{8}VI_t^{3/2}(Vu) \mod(OPS^{-5/2}). \tag{2.21}$$

Since the artificial boundary condition (2.11) is designed modulo an operator of OPS^{-1}, we can modify it by using the above relation and considering the new boundary condition

$$\partial_{\mathbf{n}}u + e^{-i\pi/4}\partial_t^{1/2}u - \frac{e^{i\pi/4}}{2}\sqrt{V}I_t^{1/2}(\sqrt{V}u) + \frac{e^{-i\pi/4}}{8}VI_t^{3/2}(Vu) = 0 \quad \text{on } \Sigma \times \mathbb{R}^+. \tag{2.22}$$

If we now come back to the NLS, we can deduce some symmetric NLABCs by using the formal substitution: $Vu = q|u|^2u$. Following this process, one gets different alternative boundary conditions of order $M \in \mathbb{N}$. For instance, the modification of the NLABC$_1^2$ artificial boundary condition (2.13)–(2.14) leads to

$$\partial_{\mathbf{n}}u + e^{-i\pi/4}\partial_t^{1/2}u - q\frac{e^{i\pi/4}}{2}|u|I_t^{1/2}(|u|u) + q^2\frac{e^{-i\pi/4}}{8}|u|^2I_t^{3/2}(|u|^2u) + i\frac{q}{4}\partial_{\mathbf{n}}(|u|^2)I_tu = 0. \tag{2.23}$$

More generally, one gets the following definition.

Definition 2.6. *The symmetric approximate NLABC of order $M/2$ (denoted by NLABC$_2^{M/2}$) for $M \in \mathbb{N}^*$ is given by*

$$\partial_{\mathbf{n}}u + T_{M/2}^{NLS}(x, t, \partial_x, \partial_t, |u|)u = 0 \quad \textit{on } \Sigma \times \mathbb{R}^{*+}, \tag{2.24}$$

defining the different nonlinear fractional artificial boundary operators $T_{M/2}$ as

$$\begin{aligned} T_1^{NLS}u &= e^{-i\pi/4}\partial_t^{1/2}u, \\ T_2^{NLS}u &= T_1^{NLS}u - q\frac{e^{i\pi/4}}{2}|u|I_t^{1/2}(|u|u) + i\frac{q}{4}\partial_{\mathbf{n}}(|u|^2)I_tu, \\ T_{5/2}^{NLS}u &= T_2^{NLS}u + q^2\frac{e^{-i\pi/4}}{8}|u|^2I_t^{3/2}(|u|^2u). \end{aligned} \tag{2.25}$$

Once again and similarly to the artificial boundary conditions (2.11) and (2.12), it seems impossible to control the sign of $\partial_{\mathbf{n}}(|u|^2)I_tu$. However, if we do not consider this term in the definition of the above boundary conditions, we can prove that the $L^2(\Omega_i)$-norm of the solution to the truncated nonlinear initial boundary value problem is bounded by the norm of the initial datum. The proof (not detailed here) uses some lemmas similar to Lemma 2.5 to treat the quantities issued from the integral operators $I_t^{1/2}$ [3] and $I_t^{3/2}$. Moreover, in the particular case of the first order condition where only the time fractional operator of order 1/2 appears, one can show that the Hamiltonian of the solution at a given instant t is bounded by the Hamiltonian at $t = 0$.

3. Semidiscrete approximation of the cubic NLS equation and the NLABC.

We investigate the construction of stable time discretization schemes of the NLABC associated to the NLS equation. The developments are based on the method of Dúran and Sanz-Serna [13] and on works for treating the linear transparent boundary condition [3].

3.1. Preliminary results.

Several time discretization schemes can be developed for solving the cubic NLS equation. The most widely used approach is based on the second order Strang splitting formula for the time discretization and on the application of the FFT for the spatial part [10, 19]. This method requires the application of some periodic boundary conditions to bound the computational domain.

Since these conditions do not reproduce the real physical propagation phenomenon at the boundary, this limits the applicability of this method (for instance, to simulate the evolution of the interaction of two solitons). Furthermore, this technique does not take into account more complicated boundary conditions such as the one that we propose here. Another possibility consists in using an interior Crank–Nicolson scheme. The Schrödinger equation is then discretized at time $t_{n+1/2} = (t_{n+1} + t_n)/2$ by a second order approximation. In what follows, if δt designates the time step, then $t_n = n\delta t$ stands for the nth time step, where $n \in \mathbb{N}$. The first approximation introduced by Delfour, Fortin, and Payne [12] consists in approximating both u and $|u|^2$ by the midpoint formula. More recently, Durán and Sanz-Serna [13] proposed another second order scheme based on the only discretization of u by the midpoint rule. The usual Crank–Nicolson scheme is given by

$$i\frac{u^{n+1}-u^n}{\delta t} + \partial_x^2 \frac{u^{n+1}+u^n}{2} + q\left(\frac{|u^{n+1}|^2+|u^n|^2}{2}\right)\frac{u^{n+1}+u^n}{2} = 0 \tag{3.1}$$

and the Durán–Sanz-Serna scheme by

$$i\frac{u^{n+1}-u^n}{\delta t} + \partial_x^2 \frac{u^{n+1}+u^n}{2} + q\left|\frac{u^{n+1}+u^n}{2}\right|^2\frac{u^{n+1}+u^n}{2} = 0. \tag{3.2}$$

We recall, following [13], that this scheme is very well adapted for computing soliton-like solutions. We denote here by u^n the approximate value of u at time t_n. Let us notice that the scheme (3.2) has a lower computational cost than (3.1). Indeed, if we set $2v^{n+1} = u^{n+1} + u^n$, the scheme reads for $n \geq 0$

$$2i\frac{v^{n+1}-u^n}{\delta t} + \partial_x^2 v^{n+1} + q|v^{n+1}|^2 v^{n+1} = 0, \tag{3.3}$$

imposing $v^0 = 0$. Moreover, the simple form of the scheme (3.2) leads to an easier implementation of the NLABCs. In the developments below, we focus our attention on the presentation of this latter scheme.

Remark 3.1. The approximation of the artificial boundary conditions for the Crank–Nicolson scheme (3.1) is however possible. We do not present the results here since this approach has proved to be less accurate than for the Durán–Sanz-Serna scheme.

In the linear case, the fractional operators defining the boundary conditions need to be discretized by the trapezoidal rule to yield the stability of the Crank–Nicolson scheme coupled to a discrete transparent artificial boundary condition. This is still the case for the NLS equation. To prove it, we begin by recalling the main results stated in [3].

PROPOSITION 3.2. *If $\{f_n\}_{n\in\mathbb{N}}$ is a sequence of complex values approximating $\{f(t_n)\}_{n\in\mathbb{N}}$, then the approximations of $\partial_t^{1/2} f(t_n)$ and $I_t^{1/2} f(t_n)$ are given by the numerical quadrature formulas*

$$I_t^{1/2} f(t_n) \approx \frac{\sqrt{2\delta t}}{2}\sum_{k=0}^{n} \alpha_k f^{n-k} \tag{3.4}$$

and

$$\partial_t^{1/2} f(t_n) \approx \frac{2}{\sqrt{2\delta t}}\sum_{k=0}^{n} \beta_k f^{n-k}, \tag{3.5}$$

where $(\alpha_k)_{k\in\mathbb{N}}$ *and* $(\beta_k)_{k\in\mathbb{N}}$ *designate the sequences defined by*

$$\begin{cases} (\alpha_0,\alpha_1,\alpha_2,\alpha_3,\alpha_4,\alpha_5,\dots) = \left(1,1,\frac{1}{2},\frac{1}{2},\frac{1\cdot 3}{2\cdot 4},\frac{1\cdot 3}{2\cdot 4},\dots\right), \\ \beta_k = (-1)^k\alpha_k \ \forall k\geq 0. \end{cases}$$

3.2. Approximation and stability result for the Dúran–Sanz-Serna-type scheme and the boundary conditions NLABC$_1^j$, $j = 1, 2$. Let us recall that the initial boundary value problem in the truncated domain with a NLABC$_1^j$-type condition is

$$\text{(3.6)} \qquad \begin{cases} i\partial_t u + \partial_x^2 u + q|u|^2 u = 0,\ (x,t)\in\Omega_i\times\mathbb{R}^{*+}, \\ \partial_{\mathbf{n}} u + \Lambda_j^{NLS}(x,t,\partial_x,\partial_t,|u|)u = 0 \ \text{ on } \Sigma\times\mathbb{R}^{*+} \text{ for } j = 1/2,\ 1, \text{ or } 2, \\ u(x,0) = u_0(x),\ x\in\Omega_i, \end{cases}$$

where the artificial boundary operators are given by the expressions (2.14).

To define the semidiscretization in the time of the boundary conditions, we introduce the approximation $\mathbb{U}^p$ of

$$\mathbb{U}(x,t) = q\int_0^t |u(x,s)|^2 ds$$

by the trapezoidal formula for $p\geq 2$

$$\text{(3.7)} \qquad \mathbb{U}^p = q\delta t\left(\sum_{l=1}^{p-1}\left|u^l\right|^2 + \frac{1}{2}\left|u^p\right|^2\right),$$

with $\mathbb{U}^0 = 0$ and $\mathbb{U}^1 = q\delta t\left|u^1\right|^2/2$. Let $\mathbb{E}^p$ and $\widetilde{\mathbb{E}^{p-1}}$ be the quantities defined by

$$\text{(3.8)}\quad \mathbb{E}^p = \exp(i\mathbb{U}^p) = \exp\left(iq\delta t\sum_{l=1}^{p-1}\left|u^l\right|^2\right)\exp\left(iq\frac{\delta t}{2}\left|u^p\right|^2\right) = \widetilde{\mathbb{E}^{p-1}}\exp\left(iq\frac{\delta t}{2}\left|u^p\right|^2\right),$$

setting $\mathbb{E}^0 = 1$ and $\mathbb{E}^1 = \exp(i\mathbb{U}^1)$. Using relations (3.5), we can define the semidiscrete approximations, denoted by $\Lambda_{j,n+1}^{NLS}$, of the continuous artificial operators Λ_j^{NLS} by

$$\text{(3.9)} \qquad \Lambda_{1,n+1}^{NLS}(x,\partial_x,|u^{n+1}|)u^{n+1} = e^{-i\frac{\pi}{4}}\sqrt{\frac{2}{\delta t}}\mathbb{E}^{n+1}\sum_{k=0}^{n+1}\beta_k\overline{\mathbb{E}^{n+1-k}}u^{n+1-k}$$

and

$$\begin{aligned} \Lambda_{2,n+1}^{NLS}(x,\partial_x,|u^{n+1}|)u^{n+1} &= \Lambda_{1,n+1}^{NLS}(x,|u^{n+1}|)u^{n+1} \\ \text{(3.10)} \qquad &\quad + i\frac{q}{4}\partial_{\mathbf{n}}\left(|u^{n+1}|^2\right)\mathbb{E}^{n+1}\delta t\sum_{k=0}^{n+1}\gamma_k\overline{\mathbb{E}^{n+1-k}}u^{n+1-k}, \end{aligned}$$

where $(\gamma_k)_{k\in\mathbb{N}}$ is the sequence defined by $(\gamma_0,\gamma_1,\gamma_2,\gamma_3,\dots) = \left(\frac{1}{2},1,1,1,\dots\right)$.

Proposition 3.3. *The Durán–Sanz-Serna semidiscrete scheme for the initial boundary value problem* (3.6) *is given by*

$$\begin{aligned} &2i\frac{v^{n+1}-u^n}{\delta t}+\partial_x^2 v^{n+1}+q|v^{n+1}|^2v^{n+1}=0,\ x\in\Omega_i,\\ &\partial_{\mathbf{n}}v^{n+1}+\Lambda^{NLS}_{j,n+1}(x,\partial_x,|v^{n+1}|)v^{n+1}=0 \quad \text{on } \Sigma \text{ for } j=1 \text{ or } 2,\\ &u^0=u_0,\ x\in\Omega_i, \end{aligned} \tag{3.11}$$

where $v^{n+1}=\frac{u^{n+1}+u^n}{2}$. *Furthermore, the following energy inequality holds for* $j=1$*:*

$$\|u^{N+1}\|_{L^2(\Omega_i)}\le\|u_0\|_{L^2(\Omega_i)}\ \forall N\ge 0, \tag{3.12}$$

implying the stability of the scheme.

Proof. The construction of the Durán–Sanz-Serna semidiscrete scheme is immediate in view of the preliminary results. We just sketch the proof of the stability result. Essentially, the arguments are adapted from the analysis developed in [3] for the one-dimensional linear Schrödinger equation (the techniques are mainly based on the $\mathcal{Z}$-transform). The particular symmetrical form of the continuous NLABCs and the property of dissipation of the fractional operators used in Proposition 2.4 extend in a certain way at the semidiscrete level. This is finally quite natural since the semidiscretization of the boundary conditions has been written a priori to be consistent with the interior scheme. □

Remark 3.4. Like in the continuous case, we cannot prove the estimate (3.12) for the second order condition. This is due to a lack of control of the sign of the corrective term.

3.3. Approximation and stability result for the Dúran–Sanz-Serna-type scheme and the boundary conditions NLABC$_2^j$, $j=1,2$. The initial boundary value problem in the bounded computational domain for an NLABC$_2^j$ condition is given by

$$\left\{\begin{array}{l} i\partial_t u+\partial_x^2u+q|u|^2u=0,\ (x,t)\in\Omega_i\times\mathbb{R}^+,\\ \partial_{\mathbf{n}}u+T_j^{NLS}(x,t,\partial_x,\partial_t,|u|)u=0 \quad \text{on } \Sigma\times\mathbb{R}^{*+} \text{ for } j=1 \text{ or } 2,\\ u(x,0)=u_0(x)\ x\in\Omega_i. \end{array}\right. \tag{3.13}$$

Using the semidiscrete versions (3.4) and (3.5) of the half-order integral and derivative operators, we introduce the following semidiscretizations of the artificial operators T_1^{NLS} and T_2^{NLS}, respectively, given by

$$T^{NLS}_{1,n+1}(x,\partial_x,|v^{n+1}|)v^{n+1}=e^{-i\frac{\pi}{4}}\sqrt{\frac{2}{\delta t}}\sum_{k=0}^{n+1}\beta_k v^{n+1-k} \tag{3.14}$$

and

$$\begin{aligned} T^{NLS}_{2,n+1}(x,\partial_x,|v^{n+1}|)v^{n+1}&=T^{NLS}_{1,n+1}(x,\partial_x,|v^{n+1}|)v^{n+1}\\ &\quad-q\frac{e^{i\frac{\pi}{4}}}{2}|v^{n+1}|\frac{\sqrt{2\delta t}}{2}\sum_{k=0}^{n+1}\alpha_k|v^{n+1-k}|v^{n+1-k}\\ &\quad+i\frac{q}{4}\partial_{\mathbf{n}}(|v^{n+1}|^2)\delta t\left(\sum_{k=1}^{n}v^k+\frac{v^{n+1}}{2}\right). \end{aligned} \tag{3.15}$$

As for the NLABCs of the first type, the following proposition holds.

Proposition 3.5. *Let us define* $v^{n+1} = \frac{u^{n+1}+u^n}{2}$*. Then, the Durán–Sanz-Serna semidiscrete scheme for the initial boundary value problem* (3.13) *reads*

$$\begin{aligned} &2i\frac{v^{n+1}-u^n}{\delta t} + \partial_x^2 v^{n+1} + q|v^{n+1}|^2 v^{n+1} = 0, \;\; x \in \Omega_i, \\ &\partial_{\mathbf{n}} v^{n+1} + T_{j,n+1}^{NLS}(x, \partial_x, |v^{n+1}|)v^{n+1} = 0 \quad \text{on } \Sigma \text{ for } j = 1 \text{ or } 2, \\ &u^0 = u_0, \quad x \in \Omega_i. \end{aligned} \tag{3.16}$$

Moreover, we have the inequality

$$\|u^{N+1}\|_{L^2(\Omega_i)} \leq \|u_0\|_{L^2(\Omega_i)} \; \forall N \geq 0,$$

for $j = 1$ *or for* $j = 2$ *by neglecting the last term of the expression* (3.15)*. In this case, this implies the stability of the scheme* (3.16)*.*

Proof. Once again, we do not detail the proof of Proposition 3.5 which is obtained by some arguments close to the ones used in the linear case [3]. □

4. Numerical implementation and simulations.

4.1. Some aspects of the numerical implementation. Since the Jacobian of the map associated to the nonlinear problems (3.11) and (3.16) is complicated to obtain, we propose to rather use a classical fixed point method. To this end, let us begin by writing the artificial boundary conditions as some nonlinear Fourier–Robin-type boundary conditions. We choose to develop only the calculations for the conditions $\Lambda_{j,n+1}^{NLS}$. We get the relation

$$\partial_{\mathbf{n}} v^{n+1} + e^{-i\frac{\pi}{4}}\sqrt{\frac{2}{\delta t}}\left(v^{n+1} + \widetilde{\mathbb{E}^n}\exp\left(iq\delta t\frac{\left|v^{n+1}\right|^2}{2}\right)\sum_{k=1}^{n}\beta_{n+1-k}\overline{\mathbb{E}^k}v^k\right) = 0 \tag{4.1}$$

for the operator $\Lambda_{1,n+1}^{NLS}$. The corrective term involved in the definition of $\Lambda_{2,n+1}^{NLS}$ can be rewritten as

$$i\frac{q}{4}\partial_{\mathbf{n}}(|v^{n+1}|^2)\left(\frac{\delta t}{2}v^{n+1} + \delta t\widetilde{\mathbb{E}^n}\exp\left(iq\delta t\frac{\left|v^{n+1}\right|^2}{2}\right)\sum_{k=1}^{n}\overline{\mathbb{E}^k}v^k\right). \tag{4.2}$$

The fixed point algorithm is applied for treating the nonlinearities appearing both in the Schrödinger equation and in the artificial boundary conditions. The resulting scheme is summarized in Table 4.1.

At each iteration of the algorithm, we incorporate the linear Fourier–Robin boundary condition by using the weak formulation

$$\begin{aligned} \int_{\Omega_i}\frac{2i}{\delta t}w^{s+1}\psi dx - \int_{\Omega_i}\partial_x w^{s+1}\partial_x\psi dx - \int_{\Sigma}e^{-i\frac{\pi}{4}}\sqrt{\frac{2}{\delta t}}w^{s+1}\psi d\Sigma \\ = -\int_{\Omega_i}q|w^s|^2 w^s\psi dx + \int_{\Omega_i}\frac{2i}{\delta t}u^n\psi dx - \int_{\Sigma}g^s\psi d\Sigma, \end{aligned}$$

where ψ designates a sufficiently smooth function. The spatial discretization is performed by a conform linear Galerkin finite element method for u, $|u|^2$, and ψ providing hence the stability of the whole scheme. This variational approach leads to a tridiagonal banded matrix. The solution to the associated linear system is therefore simple and realized by a direct LU solver. The involvement of the other NLABCs follows the same approach.

Table 4.1

$v^{n+1} = w^{s+1}$
$u^{n+1} = 2v^{n+1} - u^n$
```

4.2. Numerical results. The one-dimensional cubic NLS equation is integrable by using the inverse scattering theory [21]. This approach yields the so-called exact *soliton* solution given by

$$u_{\text{ex}}(x,t) = \sqrt{\frac{2a}{q}} \operatorname{sech}(\sqrt{a}(x-ct)) \exp\left(i\frac{c}{2}(x-ct) \right) \exp\left(i\left(a + \frac{c^2}{4} \right) t \right). \tag{4.3}$$

From now on, we fix the focusing parameter q to 1. The real parameter a gives the amplitude of the wavefield. Finally, c is the velocity of the soliton. Since the derivation of the NLABCs has been constructed under a high-frequency assumption (see Remark 2.3), we can expect that our approach will be more efficient for a high-speed soliton. Throughout the computations, we have taken $\varepsilon = 10^{-6}$ in the fixed point algorithm (4.1).

To perform an exhaustive study of the proposed artificial boundary conditions, we compare the nonlinear conditions NLABC$_i^j$ for $1 \leq i,j \leq 2$ to the linear artificial boundary condition (LABC) (1.2) for the soliton defined by $a = 2$ and $c = 15$. The numerical parameters are $\delta t = 10^{-3}$ for a final time $T_f = 2$. The finite computational spatial domain is $\Omega_i = [-10, 10]$ discretized by 4000 equally spaced points. To focus on the spurious reflections link to the different methods, we plot the contour of $\log_{10}(|u|)$ in Figures 1–5. The curves are presented with respect to the increasing accuracy of the artificial boundary conditions. We see in Figure 1 that the maximal reflection is approximately equal to 10^{-2} for an initial amplitude of 2 and the LABC. For Figures 2–5, the reflection attains a maximal value around 5×10^{-3}. The reflection occurring at the right boundary decreases according to the order of the different conditions NLABC$_1^j$ or NLABC$_2^j$. Moreover, the most accurate results are obtained for the condition NLABC$_1^2$ with a minimal region of maximal reflection. Unlike the LABC, the reflection at the left boundary has an amplitude inferior to 10^{-4}.

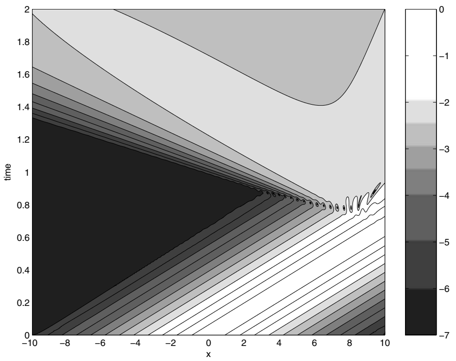

FIG. 1. *Contour plot of* $\log_{10}(|u|)$ *for the linear artificial boundary condition (LABC).*

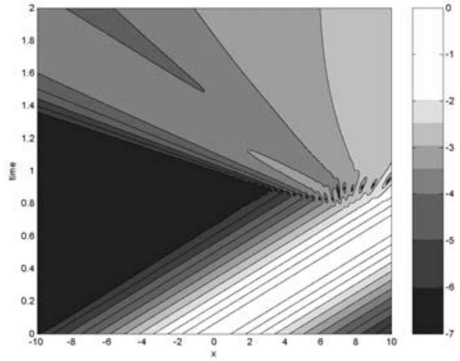

FIG. 2. *Contour plot for the nonlinear artificial boundary condition* $NLABC_2^1$.

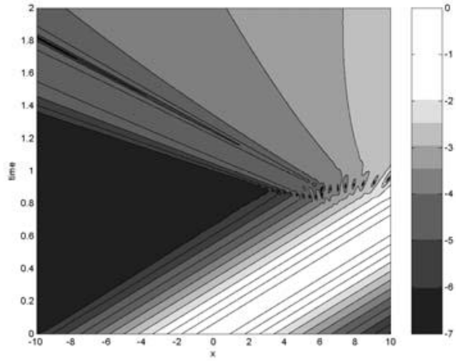

FIG. 3. *Contour plot for the nonlinear artificial boundary condition* $NLABC_2^2$.

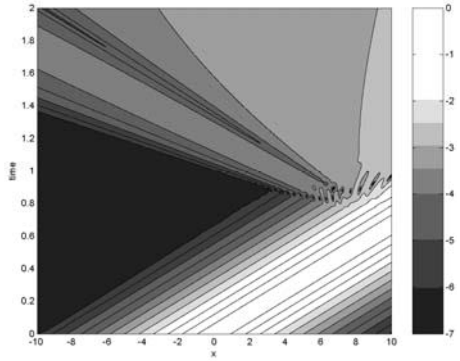

FIG. 4. *Contour plot for the nonlinear artificial boundary condition* $NLABC_1^1$.

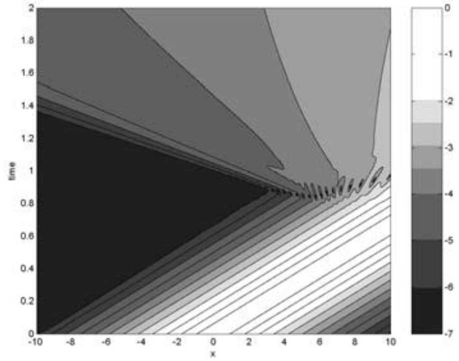

FIG. 5. *Contour plot for the nonlinear artificial boundary condition* $NLABC_1^2$.

To specify these results, we plot in Figure 6 the relative error for the $L^2(\Omega_i)$-norm

$$\frac{\|u_{\mathrm{ex}} - u_{\mathrm{num}}\|_{0,\Omega_i}}{\|u_{\mathrm{num}}\|_{0,\Omega_i}},$$

where u_{num} denotes the numerical solution. For the linear case, the error is about 2%,

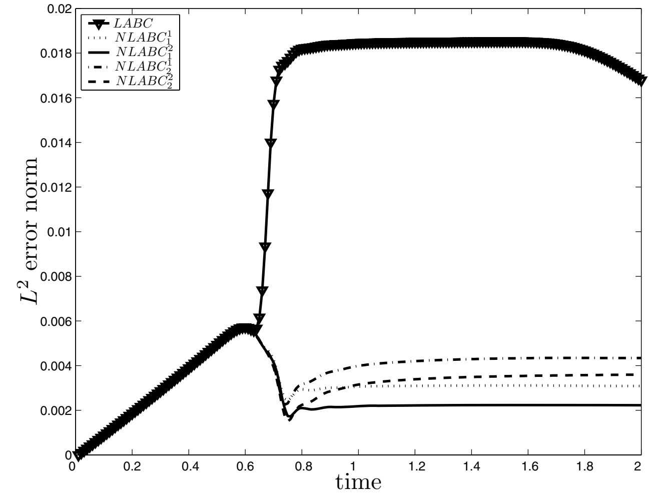

Fig. 6. *Relative error for the different linear and nonlinear artificial boundary conditions.*

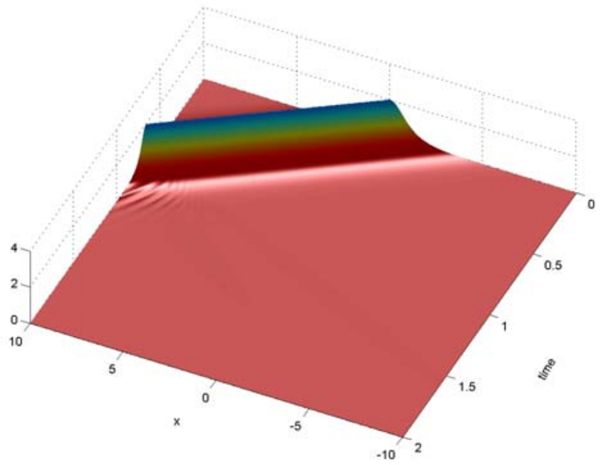

Fig. 7. *Representation of the amplitude of the computed "fast" soliton.*

whereas the best result is obtained for the NLABC_1^2 for a final error of 0.2%. This last error is less than the intrinsic phase error of the Sanz-Serna scheme generally linked to the Crank–Nicolson-type schemes (see, for instance, [9]). The most accurate NLABC does not require any additional cost. The numerical classification of the artificial boundary conditions coincides with the theoretical one. To end with this test case, we depict in Figure 7 the evolution of this "fast" soliton. We emphasize the very small spurious reflections by adding a light to the figure. This allows to visualize it by showing the associated shadow zones. Without this brightness, the reflections are too small to be seen in the representation.

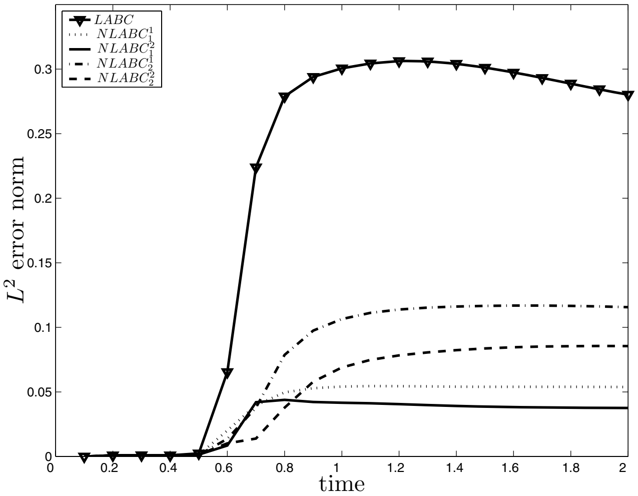

Fig. 8. *Relative error for the different linear and nonlinear artificial boundary conditions.*

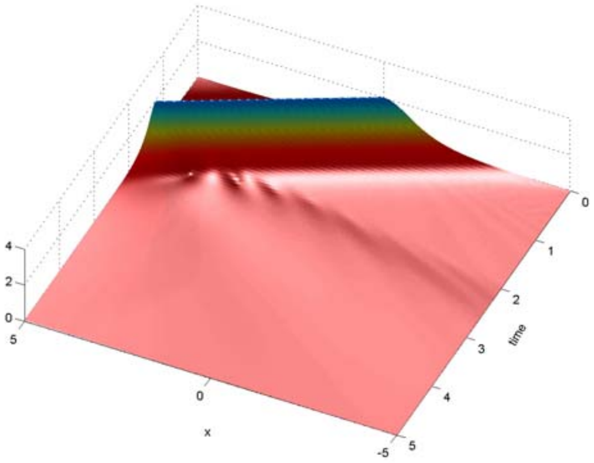

Fig. 9. *Representation of the amplitude of the computed "slow" soliton.*

The next experiment concerns a "slow" propagative soliton defined by a velocity $c = 4$ and an amplitude $a = 2$. The finite domain of computation is reduced to $\Omega_i = [-5, 5]$ and discretized with 4000 points. The time step is now $\delta t = 5 \times 10^{-3}$ and the final time is fixed to $T_f = 5$. Let us recall that all the conditions have been derived under an assumption of high frequency. Since we consider a slower soliton, the reflection should be larger. We get an acceptable error of 5% (see Figure 8) for the NLABC_1^2. This is not the case of the LABC which yields a large error of 30%. Even if the error occurring in this situation for the NLABC_1^1 and NLABC_1^2 is larger than for the "fast" soliton, this always allows us to reproduce the behavior of the solution as can be seen in Figure 9. Once again, an artificial light has been added to show the numerical reflection involving in the approximation. Finally, from all the above tests,

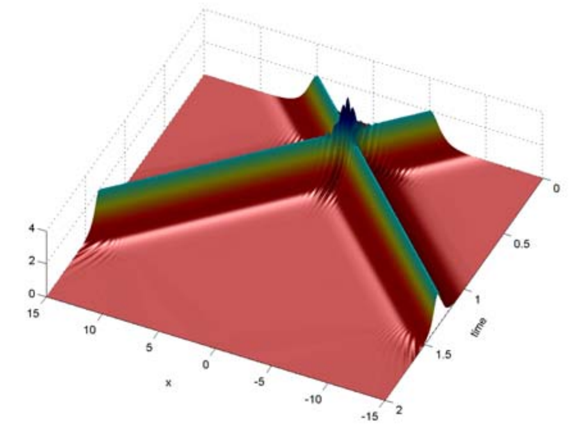

Fig. 10. *Interaction of two fast solitons with opposite directions.*

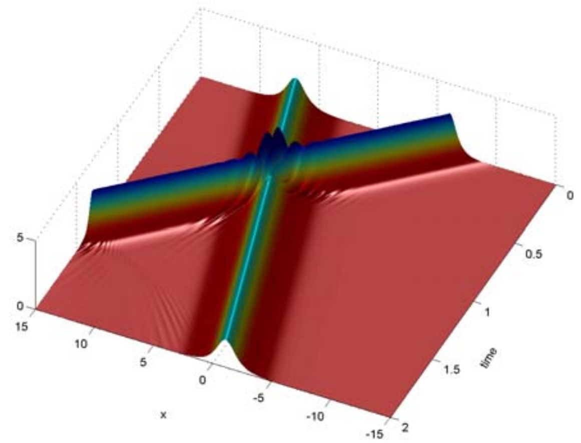

Fig. 11. *Interaction of slow and fast solitons with opposite directions.*

we conclude that the most accurate results are obtained with the NLABC_1^2, which is from now on taken as the reference.

We consider now the problem of simulating the interaction of two solitons. The domain of computation $\Omega_i = [-15, 15]$ is discretized with 6000 points. The final time is $T_f = 2$ for a time step $\delta t = 10^{-3}$. We consider in Figure 10 two fast solitons evolving in two opposite directions and centered at $x = -5$ and $x = 5$ at the initial time. The two velocities are $c = 12$ and $c = -12$. As for one soliton, we observe a small reflection which is made visible by the added artificial light.

We now consider in Figure 11 the interaction of a slow soliton centered at $x = 7$ for a velocity $c = -4$ and a fast soliton of velocity $c = 16$ and centered at a point $x = -6$. We see that some small reflections can be visualized with the help of the light. The last example, presented in Figure 12, consists in the same interaction as in

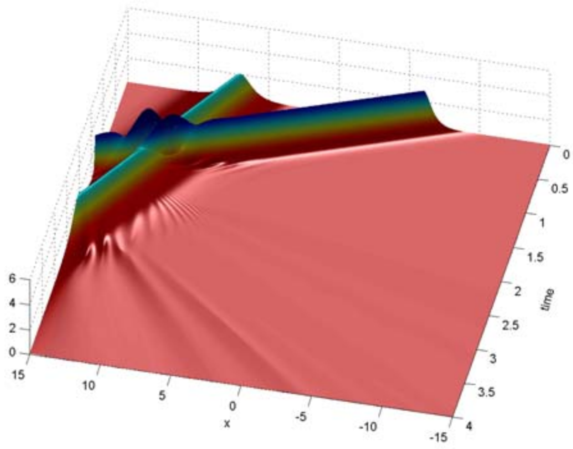

FIG. 12. *Interaction of slow and fast solitons with same directions.*

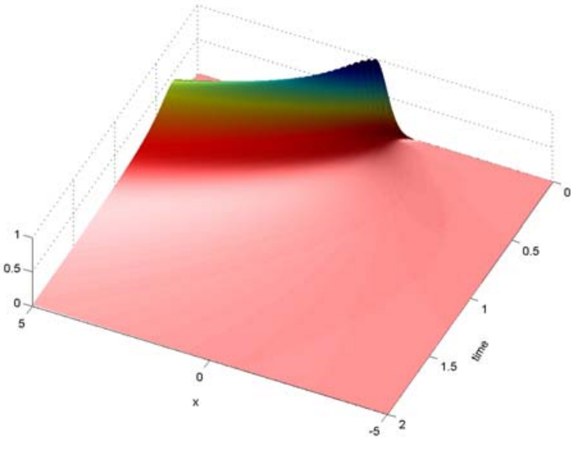

FIG. 13. *Propagation of the solution for the gaussian initial datum.*

the previous case but with the velocity $c = 4$ for the slowest soliton. In this situation, the two solitons interact near the right boundary. Once again, the artificial boundary condition reveals a satisfactory behavior and generates some relatively low-amplitude reflections (however more important than in the previous case).

To end the numerical experiments, we consider a gaussian initial datum

$$u(x, 0) = \exp(icx/2) \exp(-5x^2)$$

to observe the pure dispersion phenomenons involved in the NLS equation. The velocity is taken to $c = 15$. The finite spatial domain $\Omega_i = [-5, 5]$ is discretized with 4000 points, the time discretization being unchanged. As can be noticed in Figures 13 and 14, no reflection occurs and the dispersion is not affected by any wave reflected back into the computational domain.

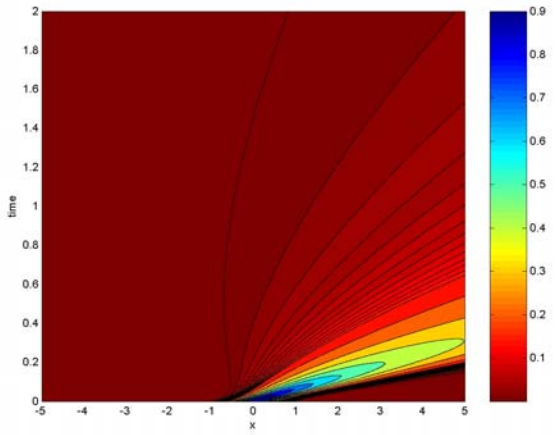

FIG. 14. *Contour plot of the solution for the gaussian initial datum.*

5. Conclusion. We have introduced different kinds of NLABCs for the one-dimensional nonlinear cubic Schrödinger equation. They are constructed with the help of some general pseudodifferential techniques usually involved in the derivation of artificial boundary conditions associated to linear operators. Stable and accurate semidiscretizations in time have been proposed. These conditions appear to be efficient for simulating the propagation of sufficiently fast solitons (simple soliton, interaction of two solitons). A loss of accuracy occurs for slower solutions but the artificial reflection is always much lower than for the LABC without any additional cost. These results are currently being extended for two-dimensional problems using the approach analyzed in [4].

A POSTERIORI ERROR ESTIMATES FOR FINITE ELEMENT APPROXIMATION OF PARABOLIC p-LAPLACIAN*

CARSTEN CARSTENSEN†, WENBIN LIU‡, AND NINGNING YAN§

Abstract. In this paper, we derive a posteriori error estimates in the quasi-norm for the finite element approximation of the parabolic p-Laplacian. We obtain a posteriori error bounds for the semidiscrete scheme and the fully backward Euler discretization. We show that the new a posteriori error estimators provide both upper and lower bounds on the discretization error.

Key words. finite element approximation, backward Euler discretization, parabolic p-Laplacian, a posteriori error estimators, quasi-norm error bounds

1. Introduction.

In this paper, we derive a posteriori error estimates for the finite element approximation of the parabolic p-Laplacian with homogeneous Dirichlet data

$$
\begin{aligned}
u_t(x,t) - \operatorname{div}(|\nabla u(x,t)|^{p-2}\nabla u(x,t)) &= f(x,t), && x \in \Omega,\ t \in [0,T],\\
u(x,t) &= 0, && x \in \partial\Omega,\ t \in [0,T],\\
u(x,0) &= u_0(x), && x \in \Omega,
\end{aligned}
\tag{1.1}
$$

where $1 < p < \infty$ and Ω is a bounded open subset of R^2 with a Lipschitz boundary $\partial\Omega$. Assumptions on the data f and u_0 will be specified later. This equation is viewed as one of the typical examples of a large class of nonlinear problems—parabolic degenerate nonlinear systems, where many existing techniques (such as the linearization or deformation procedure) in the finite element method do not seem to work well.

Finite element approximations of the p-Laplacian have been extensively studied in the literature; see [Ci, GM, Ch] for some previous work. Sharp a priori error bounds were obtained in [BL1] and [LB] via the quasi-norm techniques; see [BL2] for an overview of some recent work. The quasi-norm approach, which has proved successful in deriving sharper a priori error bounds for the conforming finite element approximation of the degenerate systems, was summarized in [LY1, LY2] with a review of relevant recent work. Furthermore, sharp a priori error bounds in the space variable approximation were derived in [BL4] for the parabolic p-Laplacian, although the error bounds in time variable approximation are only suboptimal there. In [BB],

sharp a priori error bounds were obtained for both space and time approximation of the parabolic p-Laplacian. Another important area is a posteriori error estimation of the p-Laplacian. The work in this area seems to date back to [ODSD], and some of the recent work can be found in [BA, BL2, P, GS, V1], where among other things, a posteriori error estimates on the conforming and nonconforming discretization errors were derived with both upper and lower bounds. In these contributions, however, there are *gaps* in the power between the established upper and lower estimates. Recently in [LY1, LY2], the quasi-norm techniques were further developed, and improved a posteriori error estimates of residual type were derived for the p-Laplacian. Initial analysis and numerical tests indicate that the new estimators are sharper than the existing ones and, indeed, lead to more efficient computational meshes [CK, LY1].

It is the purpose of this work to extend our a posteriori error estimates to the finite element approximation of the parabolic p-Laplacian by combining the quasi-norm techniques developed in [LY1, LY2] and the weighted Clement-type interpolation introduced in [Ca, CF2, CF3, CF4] and further modified in [CLY].

The plan of this paper is as follows. In section 2 we state some important inequalities. In section 3 we give the parabolic p-Laplacian a variational formulation. We then set up the finite element approximation for the equation. We also introduce some quasi-norms and related results. In section 4, we derive a posteriori upper and lower error estimates in quasi-norm for the semidiscrete finite element approximation. In section 5, we derive quasi-norm a posteriori error estimates for the fully discrete scheme-backward Euler discretization. In the appendix, we introduce the weighted Clement-type interpolator and prove interpolation error estimates in the quasi-norm.

Let Ω be a bounded open set in R^2 with a Lipschitz boundary $\partial\Omega$. In this paper we adopt the standard notation $W^{m,q}(\Omega)$ for Sobolev spaces on Ω with norm $\|\cdot\|_{W^{m,q}(\Omega)}$ (or $\|\cdot\|_{m,q,\Omega}$ as a simplification) and seminorm $|\cdot|_{W^{m,q}(\Omega)}$ (or $|\cdot|_{(m,q,\Omega)}$). We set $W_0^{m,q}(\Omega) \equiv \{w \in W^{m,q}(\Omega) : w|_{\partial\Omega} = 0\}$. We denote $W^{m,2}(\Omega)$ by $H^m(\Omega)$ with norm $\|\cdot\|_{m,\Omega}$ and seminorm $|\cdot|_{m,\Omega}$. We also denote by $L^s(0,T;W^{m,q}(\Omega))$ the Banach space of L^s functions from $(0,T)$ into $W^{m,q}(\Omega)$ with norm $\|v\|_{L^s(0,T;W^{m,q}(\Omega))} = (\int_0^T \|v\|^s_{W^{m,q}(\Omega)} dt)^{\frac{1}{s}}$ for $s \in [1,\infty)$ with the standard modification for $s = \infty$. Similarly, one can define $H^1(0,T;W^{m,q}(\Omega))$ and $C^k(0,T;W^{m,q}(\Omega))$. In addition, c or C denotes a general positive constant independent of h, and $A \le CB$ is abbreviated as $A \lesssim B$. The generic constant C is allowed to depend only on p, Ω, and the aspect ratio of the finite elements.

2. Preliminaries.

The following inequalities play an essential role in our error analysis. Therein, the generic positive constant C in $A \le CB$ (abbreviated $A \lesssim B$) depends only on p. The first two lemmas have been used in our work on a priori quasi-norm error bounds for the finite element approximation of degenerate nonlinear PDEs [BL1, LB, BL3].

LEMMA 2.1 (see [BL3]). *For all $p > 1$, ξ, $\eta \in \mathbb{R}^n$, there holds*

$$||\xi|^{p-2}\xi - |\eta|^{p-2}\eta\,| \lesssim |\xi - \eta|(|\xi| + |\eta|)^{p-2}, \tag{2.1}$$

$$|\xi - \eta|^2(|\xi| + |\eta|)^{p-2} \lesssim (|\xi|^{p-2}\xi - |\eta|^{p-2}\eta, \xi - \eta). \tag{2.2}$$

LEMMA 2.2 (see [BL3, LY1, LY2]). *For all a, σ_1, $\sigma_2 \ge 0$, $p > 1$, $\theta > 0$, there holds*

$$(a + \sigma_1)^{p-2}\sigma_1\sigma_2 \le \theta^{-\gamma}(a + \sigma_1)^{p-2}\sigma_1^2 + \theta(a + \sigma_2)^{p-2}\sigma_2^2,$$

where

$$\gamma = \begin{cases} 1 & 1 < p \le 2,\ \theta \in [1, \infty) \quad \textit{or} \quad 2 < p < \infty,\ \theta \in (0, 1), \\ \dfrac{1}{p-1} & 1 < p \le 2,\ \theta \in (0, 1) \quad \textit{or} \quad 2 < p < \infty,\ \theta \in [1, \infty). \end{cases}$$

The following generalization of the Young inequality (for $a = 0$) is essential for estimating a bilinear form via the quasi-norms.

LEMMA 2.3 (see [LY1, LY2]). *For all $a, \sigma_1, \sigma_2 \ge 0$, $p > 1$, and $\delta > 0$, there holds*

$$\sigma_1 \sigma_2 \le \delta^{-\beta}(a^{p-1} + \sigma_1)^{p'-2}\sigma_1^2 + \delta(a + \sigma_2)^{p-2}\sigma_2^2,$$

where β is such that $\delta^{-\beta} = \max\{\delta^{-1}, \delta^{-\frac{1}{p-1}}\}$, and p' is such that $\frac{1}{p} + \frac{1}{p'} = 1$.

The following two lemmas will be used to prove some triangle-inequality like results for a power of the quasi-norms.

LEMMA 2.4 (see [LY1, LY2]). *For all $1 < p < \infty$, $\sigma_1, \sigma_2 \in \mathbb{R}^n$, and $a \ge 0$, there holds*

$$(a + |\sigma_1 + \sigma_2|)^{p-2}|\sigma_1 + \sigma_2|^2 \lesssim (a + |\sigma_1|)^{p-2}|\sigma_1|^2 + (a + |\sigma_2|)^{p-2}|\sigma_2|^2.$$

LEMMA 2.5 (see [LY1, LY2]). *For all $1 < p < \infty$ and $\sigma, \sigma_1, \sigma_2 \in \mathbb{R}^n$, there holds*

$$(|\sigma_1| + |\sigma_2|)^{p-2}|\sigma_1 - \sigma_2|^2 \lesssim (|\sigma| + |\sigma - \sigma_1|)^{p-2}|\sigma - \sigma_1|^2 + (|\sigma| + |\sigma - \sigma_2|)^{p-2}|\sigma - \sigma_2|^2.$$

3. Discretization of the parabolic p-Laplacian. In this section we consider the weak formulation of the parabolic p-Laplacian and its semidiscrete and full-discrete finite element approximation. We also introduce some quasi-norms which naturally arise in degenerate problems of this type.

The weak form (WP) of the p-Laplacian reads as follows: Given $f \in C(0, T; L^2(\Omega))$ and $u_0 \in W_0^{1,p}(\Omega)$, find $u \in L^\infty(0, T; W_0^{1,p}(\Omega)) \cap H^1(0, T; L^2(\Omega))$ such that

$$(u_t, v) + a(u, v) = (f, v) \qquad \forall v \in W_0^{1,p}(\Omega), \tag{3.1}$$

$$u(x, 0) = u_0(x),$$

where

$$a(u, v) = \int_\Omega |\nabla u|^{p-2}\nabla u \cdot \nabla v \quad \text{and} \quad (w, v) = \int_\Omega wv.$$

It can be shown that WP has a unique solution $u \in C([0, T], L^2(\Omega))$; see [BL4], for instance. There has been a great deal of work on the regularity of the solution u to WP. For sufficiently regular data, global $C^{1,\alpha}$ regularity was established in [DeB].

Let Ω^h be a polygonal approximation to Ω with boundary $\partial\Omega^h$. Let T^h be a partitioning of Ω^h into disjoint open regular triangles K, so that $\bar{\Omega}^h = \bigcup_{K \in T^h} \bar{K}$. Each element has at most one edge on $\partial\Omega^h$, and $\bar{K}$ and $\bar{K}'$ have either only one common vertex or a whole edge if K and $K' \in T^h$. We further require that $P_i \in \partial\Omega^h \Rightarrow P_i \in \partial\Omega$, where $\{P_i\}(i = 1, \dots, J)$ is the vertex set associated with the partitioning T^h. Let h_K denote the maximum diameter of the element K in T^h and let ρ_K denote the diameter of the largest ball contained in K. We assume that there is a regularity constant R of T^h, independent of h, such that $1 \le \max_{K \in T^h}(h_K/\rho_K) \le R$. Let $h = \max_{K \in T^h} h_K$.

Because of limited regularity for the solution of the p-Laplacian, we shall discuss only the conforming piecewise linear elements in this paper.

Associated with T^h is a finite-dimensional subspace V^h of $H_0^1(\Omega^h)$ such that $\chi|_K$ are linear functions for all $\chi \in V^h$ and $K \in T^h$. For ease of exposition we will assume that $\Omega^h = \Omega \subset R^2$, though all the results can be extended to the more general case, where $\Omega^h \subset \Omega$. Let

$$u_0^h \in V_0^h = \{v \in V^h : v = 0 \text{ on } \partial\Omega\}$$

be an approximation to u_0 and let $W^h = L^\infty(0,T;V^h) \cap H^1(0,T;V^h)$, $W_0^h = L^\infty(0,T;V_0^h) \cap H^1(0,T;V_0^h)$.

The weak form of the semidiscrete finite element approximation (WP^h) for (3.1) reads as follows: Find $u_h \in W_0^h$ such that

$$\left(\frac{\partial u_h}{\partial t}, v_h\right) + a(u_h, v_h) = (f, v_h) \quad \forall v_h \in V_0^h, \tag{3.2}$$

$$u_h(x,0) = u_0^h(x).$$

Furthermore, we can consider fully discrete approximation of WP. In this paper we consider the following the backward Euler discretization applied to (WP^h): (WP^{hk}).

Let $0 = t_0 < t_1 < t_2 < \cdots < t_{N-1} < t_N = T$, $k_n = t_n - t_{n-1}$, $I_n = (t_{n-1}, t_n]$, $n = 1, 2, \ldots, N$, $k = \max_n\{k_n\}$. Then for $n = 1, 2, \ldots, N$, find $U^n \in V^h$ such that

$$\left(\frac{U^n - U^{n-1}}{k_n}, v_h\right) + a(U^n, v_h) = (f(x,t_n), v_h) \qquad \forall v_h \in V_0^h, \tag{3.3}$$

$$U^0(x) = u_0^h(x).$$

For the purposes of the error analysis it is convenient to introduce the fact that for $t \in (t_{n-1}, t_n]$, $n = 1, 2, \ldots, N$,

$$U(x,t) = \frac{t - t_{n-1}}{k_n} U^n(x) + \frac{t_n - t}{k_n} U^{n-1}(x),$$

$$\hat{U}(x,t) = U(x,t_n), \quad \hat{f}(x,t) = f(x,t_n).$$

Then (WP^{hk}) can be restated as follow: For almost every $t \in (0,T]$ there holds

$$\left(\frac{\partial U}{\partial t}, v_h\right) + a(\hat{U}, v_h) = (\hat{f}, v_h) \quad \forall v_h \in V_0^h, \tag{3.4}$$

$$U(x,0) = u_0^h(x).$$

One of the key ideas in our approach is to introduce some quasi-norms to handle the degeneracy of the p-Laplacian in order to obtain sharp error bounds. We briefly introduce a quasi-norm and some relations between it and the standard Sobolev norms. Given $v, w \in W^{1,p}(\Omega)$, set

$$|v|_{(w,p)}^2 \equiv \int_\Omega |\nabla v|^2 (|\nabla w| + |\nabla v|)^{(p-2)}. \tag{3.5}$$

We shall simply write $|\cdot|_{(u,p)}$ as $|\cdot|_{(p)}$ when doing so causes no confusion.

PROPOSITION 3.1. (i) *There holds* $|v|_{(w,p)} \geq 0$ *and, when* $v \in W_0^{1,p}(\Omega)$, $|v|_{(w,p)} = 0$ *if and only if* $v = 0$.

(ii) *There holds* $|v_1 + v_2|_{(w,p)} \lesssim |v_1|_{(w,p)} + |v_2|_{(w,p)}$ *for any* $v_1, v_2 \in W^{1,p}(\Omega)$.

(iii) *Furthermore, for* $1 < p \leq 2$*, there holds*

$$|v|_{W^{1,p}(\Omega)} \lesssim (|w|_{W^{1,p}(\Omega)}, |v|_{W^{1,p}(\Omega)})|v|_{(w,p)} \quad \textit{and} \quad |v|^2_{(w,p)} \leq |v|^p_{W^{1,p}(\Omega)}. \tag{3.6}$$

(iv) *For* $2 \leq p < \infty$*,* $s \in [2, p]$*,* $r = s(2-p)/(2-s)$*, there holds*

$$|v|^p_{W^{1,p}(\Omega)} \leq |v|^2_{(w,p)} \leq C(|w|_{W^{1,r}(\Omega)}, |v|_{W^{1,r}(\Omega)})|v|^2_{W^{1,s}(\Omega)}. \tag{3.7}$$

Proof. Conclusion (ii) can be proved with Lemma 2.4. The rest of the proposition can be shown as in [BL3]. We, therefore, omit the details. □

The essential relations between the quasi-norm and the equation are reflected in the following inequalities. If u solves WP and $v \in W^{1,p}(\Omega)$, then it follows from Lemma 2.1 that

$$|u - v|^2_{(u,p)} \lesssim a(u, u - v) - a(v, u - v). \tag{3.8}$$

For any $\theta > 0$, $v, w \in W^{1,p}(\Omega)$, it follows from Lemmas 2.1 and 2.2 that there exists a $\gamma > 0$ such that

$$|a(u, w) - a(v, w)| \lesssim \theta^\gamma |u - v|^{\tilde{2}}{}_{(u,p)} + \theta |w|^2_{(u,p)}. \tag{3.9}$$

Then it follows from (3.8)–(3.9) that for any $u, v \in W^{1,p}(\Omega)$,

$$a(u, u - v) - a(v, u - v) \lesssim |u - v|^2_{(u,p)} \lesssim a(u, u - v) - a(v, u - v).$$

Thus the quasi-norm is naturally related to the total energy difference.

The relations (3.8)–(3.9) are important in proving the following optimal a priori error bound in the quasi-norm [BL1, LB] for the finite element approximation of the p-Laplacian:

$$|u - u_h|^2_{(p)} \lesssim \min_{v_h \in V_0^h} |u - v_h|^2_{(p)}.$$

Explicit error bounds can then be obtained. For example, if $1 < p \leq 2$, one has the optimal a priori error bound in $W^{1,p}$ ([BL1]),

$$\|u - u_h\|_{W^{1,p}} \lesssim h,$$

provided u is smooth enough. Furthermore, (3.8) and (3.9) are among the keys to the proof of the optimal a priori error bound for the parabolic p-Laplacian in [BL4]. For the semidiscrete finite element approximation of the parabolic p-Laplacian, for example, one can show that for sufficiently smooth u and almost all $s \in (0, T]$

$$\|(u - u_h)(s)\|^2_{L^2(\Omega)} + \int_0^s |u - u_h|^2_{(p)}\, dt \leq Ch^2.$$

Remark 3.1. *In the a priori error analysis, the error* $|u - u_h|_{(w,p)}$ *is considered with* $w = u$*. To make this norm computable within an a posteriori error analysis, one considers* $w = u_h$*. The triangle inequality shows equivalence of the two error terms, that is,*

$$|u - u_h|_{(u,p)} \lesssim |u - u_h|_{(u_h,p)} \lesssim |u - u_h|_{(u,p)}.$$

Recently, the quasi-norm techniques have been further developed towards a posteriori error estimates for the p-Laplacian [LY1, LY2]. For instance, let u_h be the finite element approximation of the p-Laplacian and let $1/p + 1/p' = 1$. Then

$$\eta_1^2 + \eta_2^2 - \epsilon_1 \lesssim |u - u_h|_{(p)}^2 \lesssim (\eta_1^2 + \eta_2^2) + \epsilon_2,$$

where ε_1 and ε_2 are higher order terms and

$$\begin{aligned} |u - u_h|_{(p)}^2 &= \int_\Omega (|\nabla u| + |\nabla(u - u_h)|)^{p-2} |\nabla(u - u_h)|^2, \\ \eta_1^2 &= \sum_K \int_K (|\nabla u_h|^{p-1} + h_K|f|)^{p'-2} h_K^2 |f|^2, \\ \eta_2^2 &= \sum_l \int_{K_l} (|\nabla u_h|^{p-1} + |A_l|)^{p'-2} A_l^2, \end{aligned}$$

where A_l is the jump of the A-normal derivative of $u_h \in V^h$ on the edge $l = \bar{K}_l^1 \cap \bar{K}_l^2$,

$$A_l = ((|\nabla u_h|^{p-2} \nabla u_h)_{K_l^1} - (|\nabla u_h|^{p-2} \nabla u_h)_{K_l^2})n$$

with n being the unit normal vector on $l = \bar{K}_l^1 \cap \bar{K}_l^2$ outwards K_l^1.

In the next section, we shall derive such a posteriori error estimates for the finite element approximation of the parabolic p-Laplacian. To this end let us introduce a weighted Clement-type interpolator in the finite element space V_0^h introduced in [Ca].

DEFINITION 3.1. *Let D be the set of nodes,*

$$\Lambda = \{z \in D : z \in \partial\Omega\}.$$

Given the nodal basis function φ_z of z in V^h, set $\omega_z = \{x \subset \Omega : \varphi_z(x) > 0\}$,

$$\psi_z = \varphi_z / \psi \quad \textit{and} \quad \psi = \sum_{z \in \Lambda} \varphi_z.$$

Then, for all $v \in W_0^{1,p}(\Omega)$, define the interpolation of v by

$$\pi v = \sum_{z \in \Lambda} v_z \varphi_z \in V_0^h, \quad v_z = \left(\int_\Omega \psi_z v \right) \Big/ \left(\int_\Omega \varphi_z \right).$$

Some interpolation error estimates for the interpolator in the quasi-norm will be given in the appendix.

4. A posteriori error estimates for the semidiscrete scheme.

In the following sections we derive a posteriori error estimates for the semidiscrete finite element approximation of WP. First we need some further notation. Let l be an edge of an element $K \in T^h$. If l is on the boundary of Ω^h, then we define the element $K_{max}^l = K_{min}^l = K$. Otherwise let $l = \bar{K}_l^1 \cap \bar{K}_l^2$, where K_l^1, K_l^2 are the two elements sharing the common edge l. Then we define the element $K_{max}^l(K_{min}^l) = K_l^i$ (i = 1 or 2) be such that

$$|\nabla u_h|_{K_{max}^l}^{p-2} = \max_{i=1,2} \{|\nabla u_h|_{K_l^i}^{p-2}\} \quad \text{and} \quad |\nabla u_h|_{K_{min}^l}^{p-2} = \min_{i=1,2} \{|\nabla u_h|_{K_l^i}^{p-2}\}.$$

We will take $K_{max}^l = K_{min}^l = K_l^1$ just for fixing the idea if $|\nabla u_h|_{K_l^1}^{p-2} = |\nabla u_h|_{K_l^2}^{p-2}$. Let $[w]_l = w|_{K_l^1} - w|_{K_l^2}$. The purpose of introducing K_{min} and K_{max} is to make the estimators η and η_2 below sharper. The necessity of introducing them will be discussed after Lemmas 4.1 and 4.2.

THEOREM 4.1. *Let u and u_h be solutions of (3.1) and (3.2), respectively. Let $p > 1$ and $p' > 1$ be such that $\frac{1}{p} + \frac{1}{p'} = 1$. Assume that $f \in L^1(0,T; W^{1,p'}(\Omega))$. Then there exists a $\delta_0 > 0$ such that for all $s \in [0,T]$, $0 < \delta \le \delta_0$, there exist C, C_1 (where only C_1 depends on δ) such that*

$$\|(u-u_h)(s)\|_{0,\Omega}^2 + \int_0^s |u-u_h|_{(p)}^2 \, dt \le C_1\eta^2 + C\eta_0^2 + C_1\eta_1^2 + C\delta\eta_2^2, \tag{4.1}$$

with

$$\begin{aligned}
\eta^2 &= \int_0^s \sum_{l\cap\partial\Omega=\emptyset} \int_{K^l_{max}} (|\nabla u_h|^{p-1} + |A_l|)^{p'-2}|A_l|^2 \, dx\, dt,\\
\eta_0^2 &= \|u_0 - u_0^h\|_{0,\Omega}^2,\\
\eta_1^2 &= \int_0^s \sum_K \int_K \Big(|\nabla u_h|^{p-1} + h_K^2\Big|\nabla\Big(f - \frac{\partial u_h}{\partial t}\Big)\Big|\Big)^{p'-2} h_K^4 \Big|\nabla\Big(f-\frac{\partial u_h}{\partial t}\Big)\Big|^2 \, dx\, dt,\\
\eta_2^2 &= \int_0^s \sum_{l\cap\partial\Omega=\emptyset} \int_{K^l_{min}} \Big(|\nabla u_h| + \Big|\Big[\frac{\partial u_h}{\partial n}\Big]_l\Big|\Big)^{p-2}\Big|\Big[\frac{\partial u_h}{\partial n}\Big]_l\Big|^2,
\end{aligned}$$

where $[\frac{\partial u_h}{\partial n}]_l$ is the jump of the normal derivative of u_h on the edge l and A_l is the jump of the A-normal derivative of $u_h \in V^h$ on the edge $l = \bar{K}_l^1 \cap \bar{K}_l^2$,

$$A_l = \big((|\nabla u_h|^{p-2}\nabla u_h)_{K_l^1} - (|\nabla u_h|^{p-2}\nabla u_h)_{K_l^2}\big)n,$$

with n being the unit normal vector on $l = \bar{K}_l^1 \cap \bar{K}_l^2$ outwards K_l^1.

Proof. Let $e = u - u_h$, $e_I(x,t) = \pi e(x,t) \in V_0^h$ be the weighted Clement-type interpolation of $e(x,t)$ defined in Definition 3.1 for almost all $t \in [0,T]$. It follows from Lemma 2.1 and (3.1), (3.2) that

$$\begin{aligned}
&\frac{1}{2}\|(u-u_h)(s)\|_{0,\Omega}^2 + c\int_0^s |u-u_h|_{(p)}^2 dt\\
&\le \frac{1}{2}\|(u-u_h)(0)\|_{0,\Omega}^2 + \int_0^s\int_\Omega \frac{\partial}{\partial t}(u-u_h)e + \int_0^s\int_\Omega (|\nabla u|^{p-2}\nabla u - |\nabla u_h|^{p-2}\nabla u_h)\nabla e\\
&= \frac{1}{2}\eta_0^2 + \int_0^s\int_\Omega \frac{\partial}{\partial t}(u-u_h)(e-e_I) + \int_0^s\int_\Omega (|\nabla u|^{p-2}\nabla u - |\nabla u_h|^{p-2}\nabla u_h)\nabla(e-e_I)\\
&= \frac{1}{2}\eta_0^2 + \int_0^s\int_\Omega \Big(f - \frac{\partial u_h}{\partial t}\Big)(e-e_I) - \int_0^s \sum_K \int_{\partial K} |\nabla u_h|^{p-2}\frac{\partial u_h}{\partial n}(e-e_I)\\
&= \frac{1}{2}\eta_0^2 + I_1 + I_2,
\end{aligned}$$

where the constant c results from that in Lemma 2.1. It follows from Lemma 6.4 that for any $\delta_1 > 0$ there exist constants C and C_1 (where only C_1 depends on δ_1) such that

$$\begin{aligned}
I_1 &= \int_0^s \int_\Omega \Big(f - \frac{\partial u_h}{\partial t}\Big)(e - e_I) \\
&\leq C_1 \int_0^s \sum_K \int_K \Big(|\nabla u_h|^{p-1} + h_K^2 \Big|\nabla \Big(f - \frac{\partial u_h}{\partial t}\Big)\Big|\Big)^{p'-2} h_K^4 \Big|\nabla\Big(f - \frac{\partial u_h}{\partial t}\Big)\Big|^2 \\
&\quad + C\delta_1 \int_0^s \sum_K \int_K (|\nabla u_h| + |\nabla e|)^{p-2} |\nabla e|^2 \\
&\quad + C\delta_1 \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_{K^l_{min}} \Big(|\nabla u_h| + \Big|\Big[\frac{\partial u_h}{\partial n}\Big]_l\Big|\Big)^{p-2} \Big|\Big[\frac{\partial u_h}{\partial n}\Big]_l\Big|^2 \\
&\leq C_1 \eta_1^2 + C\delta_1 \bigg(\int_0^s |u - u_h|^2_{(p)} + \eta_2^2 \bigg).
\end{aligned}$$

Similarly, by Lemmas 2.3, 6.3, and 6.5, for any $\delta_2 > 0$

$$\begin{aligned}
I_2 &= -\int_0^s \sum_K \int_{\partial K} |\nabla u_h|^{p-2} \frac{\partial u_h}{\partial n}(e - e_I) = -\int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_l A_l (e - e_I) \\
&\lesssim \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_{K^l_{max}} |A_l| (h^{-1}_{K^l_{max}} |e - e_I| + |\nabla(e - e_I)|) \\
&\lesssim \delta_2^{-\beta} \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_{K^l_{max}} (|\nabla u_h|^{p-1} + |A_l|)^{p'-2} A_l^2 \\
&\quad + \delta_2 \int_0^s \sum_K \int_K (|\nabla u_h| + h_K^{-1} |e - e_I|)^{p-2} h_K^{-2} |e - e_I|^2 \\
&\quad + \delta_2 \int_0^s \sum_K \int_K (|\nabla u_h| + |\nabla(e - e_I)|)^{p-2} |\nabla(e - e_I)|^2 \\
&\lesssim \delta_2^{-\beta} \eta^2 + \delta_2 \bigg(\int_0^s |u - u_h|^2_{(p)} + \eta_2^2 \bigg).
\end{aligned}$$

Hence, by letting $\delta_0 = \frac{c}{4C}$, we have that for all $0 < \delta \leq \delta_0$, there exist C, C_1 (where only C_1 depends on δ) such that

$$\|(u - u_h)(s)\|^2_{2,\Omega} + \int_0^s |u - u_h|^2_{(p)}\, dt \leq C\eta_0^2 + C_1(\eta_1^2 + \eta^2) + C\delta\eta_2^2\ .$$

This proves (4.1). □

Remark 4.1. *Let P_k denote the space of k-degree polynomials and set*

$$V_h^k = \{v \in C^1(\bar{\Omega}) \cap H_0^1(\Omega) : v|_K \in P_k\, \forall K \in T^h\}.$$

Lemmas 2.5 *and* 6.6 *imply, for all $v_h^k \in V_h^k$, that*

$$\begin{aligned}
\eta_2^2 &= \sum_{l \cap \partial\Omega = \emptyset} \int_{K^l_{min}} \Big(|\nabla u_h| + \Big|\Big[\frac{\partial u_h}{\partial n}\Big]_l\Big|\Big)^{p-2} \Big|\Big[\frac{\partial u_h}{\partial n}\Big]_l\Big|^2 \\
&\lesssim \sum_{l \cap \partial\Omega = \emptyset} h_{K^l_{min}} \int_l \Big(|\nabla u_h|_{K^l_{min}} + \Big|\Big[\frac{\partial u_h}{\partial n}\Big]_l\Big|\Big)^{p-2} \Big|\Big[\frac{\partial u_h}{\partial n}\Big]_l\Big|^2
\end{aligned}$$

$$
\begin{aligned}
&\lesssim \sum_{l\cap\partial\Omega=\emptyset} h_{K^l_{min}} \int_l \Big(|\nabla u_h|_{K^l_{min}} + \Big|\Big[\frac{\partial u_h}{\partial n} - \frac{\partial v_h^k}{\partial n}\Big]_l\Big|\Big)^{p-2} \Big|\Big[\frac{\partial u_h}{\partial n} - \frac{\partial v_h^k}{\partial n}\Big]_l\Big|^2 \\
&\lesssim \sum_{l\cap\partial\Omega=\emptyset} \int_{K_l^1\cup K_l^2} \big(|\nabla u_h|_{K^l_{min}} + |\nabla(u_h - v_h^k)|\big)^{p-2} |\nabla(u_h - v_h^k)|^2 \\
&\lesssim \sum_K \int_K \big(|\nabla u_h| + |\nabla(u_h - v_h^k)|\big)^{p-2} |\nabla(u_h - v_h^k)|^2 \\
&\lesssim |u-u_h|^2_{(p)} + |u - v_h^k|^2_{(p)}.
\end{aligned}
$$

Let v_h^k be the Hermite interpolation of u in V_h^k. Then, if u is smooth enough, say $u \in W^{1+\frac{2}{p},p}(\Omega)$ when $1 < p \leq 2$ or $u \in W^{2,p}(\Omega)$ when $p > 2$, $|u - v_h^k|^2_{(p)} = o(h^2)$. Moreover, note that $\eta_0^2 = \|u_0 - u_0^h\|^2_{0,\Omega} = O(h^4)$, $\eta_1^2 \leq Ch^{2s}$, $s = \min\{p', 2\}$ if $f, \frac{\partial u}{\partial t} \in L^1(0,T; W^{1,p'}(\Omega))$.

REMARK 4.2. *It follows from the proofs of Theorem 4.1 and Lemma 6.4 that for the case where f is not so smooth, we still have the a posteriori error estimates if we replace η_1^2 by*

$$\bar{\eta}_1^2 = \int_0^s \sum_K \int_K \Big(|\nabla u_h|^{p-1} + \Big|f - \frac{\partial u_h}{\partial t}\Big|\Big)^{p'-2} h_K^2 \Big|f - \frac{\partial u_h}{\partial t}\Big|^2 \, dx\, dt.$$

To derive a lower bound we need two lemmas.

LEMMA 4.1. *Let l be an edge shared by two elements $K_l^1, K_l^2 \in T^h$: $l = \bar{K}_l^1 \cap \bar{K}_l^2$. Let K^l_{max} be defined as in the beginning of this section. Then for any constant A, there exists a function $w_l \in H_0^1(\Omega)$ such that there holds $w_l|_{\Omega\setminus(\bar{K}_l^1\cup\bar{K}_l^2)} = 0$,*

$$\int_l A w_l = \int_{K^l_{max}} (|\nabla u_h|^{p-1} + |A|)^{p'-2} A^2, \tag{4.2}$$

$$\|w_l\|_{0,\infty} \lesssim h_{K^l_{max}} \Big(|\nabla u_h|^{p-1}_{K^l_{max}} + |A|\Big)^{p'-2} |A|, \tag{4.3}$$

$$\int_{K_l^1\cup K_l^2} (|\nabla u_h| + |\nabla w_l|)^{p-2} |\nabla w_l|^2 \lesssim \int_{K^l_{max}} (|\nabla u_h|^{p-1} + |A|)^{p'-2} A^2. \tag{4.4}$$

LEMMA 4.2. *For any element $K \in T^h$ and any constant f, there exists a polynomial w_K on K such that there holds $w_K|_{\partial K} = 0$,*

$$\int_K f w_K = \int_K (|\nabla u_h|^{p-1} + h_K|f|)^{p'-2} h_K^2 |f|^2,$$

$$\|w_K\|_{0,\infty} \lesssim (|\nabla u_h|^{p-1} + h_K|f|)^{p'-2} h_K^2 |f|,$$

$$\int_K (|\nabla u_h| + |\nabla w_K|)^{p-2} |\nabla w_K|^2 \lesssim \int_K \big(|\nabla u_h|^{p-1} + h_K|f|\big)^{p'-2} h_K^2 |f|^2.$$

Lemmas 4.1 and 4.2 have been proved in [LY1, LY2]. In the fact, let w_l in Lemma 4.1 be such that $w_l = \alpha_l \lambda_1 \lambda_2$, where λ_1, λ_2 are the base functions of linear triangular elements (barycentric co-ordinates) for the two vertices on l, and

$$\alpha_l = \int_{K^l_{max}} (|\nabla u_h|^{p-1} + |A|)^{p'-2} |A|^2 \Big/ \int_l A \lambda_1 \lambda_2.$$

Let w_K in Lemma 4.2 be such that $w_K = \alpha_K \lambda_1 \lambda_2 \lambda_3$, where λ_1, λ_2, and λ_3 are the base functions of linear triangular elements on three vertices of K,

$$\alpha_K = \frac{\int_K (|\nabla u_h|^{p-1} + h_K |f|)^{p'-2} h_K^2 |f|^2}{\int_K f \lambda_1 \lambda_2 \lambda_3}.$$

Then one can check that all the conclusions in the Lemmas 4.1 and 4.2 hold. It can be shown that the first two inequalities in Lemma 4.1 still hold without using K_{max}. However, there are counterexamples for the third inequality. Thus it is necessary to introduce K_{max} (K_{min}) in this sense.

THEOREM 4.2. *Let u and u_h be the solutions of* (3.1) *and* (3.2)*, respectively. Let $p > 1$ and $p' > 1$ be such that $\frac{1}{p} + \frac{1}{p'} = 1$. Assume that $f, \frac{\partial u}{\partial t} \in L^1(0,T; L^{p'}(\Omega))$. Then*

$$\eta^2 \lesssim \int_0^s |u - u_h|_{(p)}^2 \, dt + \epsilon,$$

with $\bar{f}|_K = \int_K f/|K|$, $\overline{\frac{\partial u}{\partial t}}|_K = \int_K \frac{\partial u}{\partial t}/|K|$, and

$$\begin{aligned}\epsilon = &\int_0^s \sum_K \int_K \left(|\nabla u_h|^{p-1} + h_K |f - \bar{f}|\right)^{p'-2} h_K^2 |f - \bar{f}|^2 \\ &+ \int_0^s \sum_K \int_K \left(|\nabla u_h|^{p-1} + h_K \left|\frac{\partial u}{\partial t} - \overline{\frac{\partial u}{\partial t}}\right|\right)^{p'-2} h_K^2 \left|\frac{\partial u}{\partial t} - \overline{\frac{\partial u}{\partial t}}\right|^2,\end{aligned}$$

Proof. It follows from Lemmas 2.1, 2.2, and 4.1 that, for any $\theta_1, \theta_2 > 0$,

$$\begin{aligned}\eta^2 &= \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_{K^l_{max}} (|\nabla u_h|^{p-1} + |A_l|)^{p'-2} A_l^2 = \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_l A_l w_l \\ &= \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_l \left[|\nabla u_h|^{p-2} \frac{\partial u_h}{\partial n} - |\nabla u|^{p-2} \frac{\partial u}{\partial n}\right]_l w_l \\ &= \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_{\partial K_l^1 \cup \partial K_l^2} \left(|\nabla u_h|^{p-2} \frac{\partial u_h}{\partial n} - |\nabla u|^{p-2} \frac{\partial u}{\partial n}\right) w_l \\ &= \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \left(\int_{K_l^1 \cup K_l^2} (|\nabla u_h|^{p-2} \nabla u_h - |\nabla u|^{p-2} \nabla u) \nabla w_l + \int_{K_l^1 \cup K_l^2} \left(f - \frac{\partial u}{\partial t}\right) w_l\right) \\ &\lesssim \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_{K_l^1 \cup K_l^2} (|\nabla u_h| + |\nabla (u - u_h)|)^{p-2} |\nabla (u_h - u)| \, |\nabla w_l| \\ &\quad + \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_{K_l^1 \cup K_l^2} \left|f - \frac{\partial u}{\partial t}\right| h_{K^l_{max}} \left(|\nabla u_h|^{p-1}_{K^l_{max}} + |A_l|\right)^{p'-2} |A_l| \\ &\lesssim \theta_1^{-\gamma} \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_{K_l^1 \cup K_l^2} (|\nabla u_h| + |\nabla (u_h - u)|)^{p-2} |\nabla (u_h - u)|^2 \\ &\quad + \theta_1 \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_{K_l^1 \cup K_l^2} (|\nabla u_h| + |\nabla w_l|)^{p-2} |\nabla w_l|^2 \\ &\quad + \theta_2^{-\gamma} \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_{K_l^1 \cup K_l^2} \left(|\nabla u_h|^{p-1}_{K^l_{max}} + |A_l|\right)^{p'-2} A_l^2\end{aligned}$$

$$+\theta_2\int_0^s \sum_{l\cap\partial\Omega=\emptyset}\int_{K_l^1\cup K_l^2}\Big(|\nabla u_h|^{p-1}_{K^l_{max}}+h_{K^l_{max}}\Big|f-\frac{\partial u}{\partial t}\Big|\Big)^{p'-2}h^2_{K^l_{max}}\Big|f-\frac{\partial u}{\partial t}\Big|^2$$
$$\lesssim \theta_1^{-\gamma}\int_0^s |u-u_h|^2_{(p)}+\theta_2 L+C(\theta_1+\theta_2^{-\gamma})\eta^2,$$

where γ is defined in Lemma 2.2, and

$$L=\int_0^s\sum_K\int_K\Big(|\nabla u_h|^{p-1}+h_K\Big|f-\frac{\partial u}{\partial t}\Big|\Big)^{p'-2}h_K^2\Big|f-\frac{\partial u}{\partial t}\Big|^2.$$

Let $\theta_1=\frac{1}{4C}$, $\theta_2=(4C)^{\frac{1}{\gamma}}$. Then we have

$$\eta^2\lesssim\int_0^s|u-u_h|^2_{(p)}\,dt+L. \tag{4.5}$$

Let $F=f-\frac{\partial u}{\partial t}$. It follows from Lemma 2.4 that

$$\begin{aligned}L&=\int_0^s\sum_K\int_K(|\nabla u_h|^{p-1}+h_K|F|)^{p'-2}h_K^2|F|^2\\&\lesssim\int_0^s\sum_K\int_K(|\nabla u_h|^{p-1}+h_K|\bar F|)^{p'-2}h_K^2|\bar F|^2\\&\quad+\int_0^s\sum_K\int_K(|\nabla u_h|^{p-1}+h_K|f-\bar f|)^{p'-2}h_K^2|f-\bar f|^2\\&\quad+\int_0^s\sum_K\int_K\Big(|\nabla u_h|^{p-1}+h_K\Big|\frac{\partial u}{\partial t}-\overline{\frac{\partial u}{\partial t}}\Big|\Big)^{p'-2}h_K^2\Big|\frac{\partial u}{\partial t}-\overline{\frac{\partial u}{\partial t}}\Big|^2\\&\lesssim I+\epsilon,\end{aligned} \tag{4.6}$$

where we have simply written $\bar f|_K$ as $\bar f$ and $\overline{\frac{\partial u}{\partial t}}|_K$ as $\overline{\frac{\partial u}{\partial t}}$. It follows from Lemma 4.2 that

$$\begin{aligned}I&=\int_0^s\sum_K\int_K(|\nabla u_h|^{p-1}+h_K|\bar F|)^{p'-2}h_K^2|\bar F|^2\\&=\int_0^s\sum_K\int_K\bar F w_K=\int_0^s\sum_K\int_K F w_K+\int_0^s\sum_K\int_K(\bar F-F)w_K\\&=I_1+I_2.\end{aligned} \tag{4.7}$$

It follows from Lemmas 2.1, 2.2, and 4.2 that, for any $\theta>0$,

$$\begin{aligned}I_1&=\int_0^s\sum_K\int_K F w_K=-\int_0^s\sum_K\int_K div\big(|\nabla u|^{p-2}\nabla u-|\nabla u_h|^{p-2}\nabla u_h\big)w_K\\&=\int_0^s\sum_K\int_K(|\nabla u|^{p-2}\nabla u-|\nabla u_h|^{p-2}\nabla u_h)\nabla w_K\\&\le C\int_0^s\sum_K\int_K\big(|\nabla u_h|+|\nabla(u-u_h)|\big)^{p-2}|\nabla(u-u_h)|\,|\nabla w_K|\\&\lesssim\theta_1^{-\gamma}\int_0^s\sum_K\int_K(|\nabla u_h|+|\nabla(u-u_h)|)^{p-2}|\nabla(u-u_h)|^2\end{aligned} \tag{4.8}$$

$$\begin{aligned}
&+\theta_1 \int_0^s \sum_K \int_K (|\nabla u_h| + |\nabla w_K|)^{p-2} |\nabla w_K|^2 \\
&\lesssim \theta_1^{-\gamma} \int_0^s |u-u_h|_{(p)}^2 + \theta_1 \int_0^s \sum_K \int_K (|\nabla u_h|^{p-1} + h_K |\bar{F}|)^{p'-2} h_K^2 |\bar{F}|^2 \\
&\approx \theta_1^{-\gamma} \int_0^s |u-u_h|_{(p)}^2 + \theta_1 I.
\end{aligned}$$

It follows from Lemmas 4.2 and 2.2 that, for any $\theta_2 > 0$,

$$\begin{aligned}
I_2 &= \int_0^s \sum_K \int_K (\bar{F} - F) w_K \leq \sum_K \int_K |F - \bar{F}| \, \|w_K\|_{0,\infty} \\
&\lesssim \int_0^s \sum_K \int_K |F - \bar{F}| (|\nabla u_h|^{p-1} + h_K |\bar{F}|)^{p'-2} h_K^2 |\bar{F}| \\
&\lesssim \theta_2^{-\gamma} \int_0^s \sum_K \int_K (|\nabla u_h|^{p-1} + h_K |\bar{F}|)^{p'-2} h_K^2 |\bar{F}|^2 \qquad (4.9) \\
&\quad + \theta_2 \int_0^s \sum_K \int_K (|\nabla u_h|^{p-1} + h_K |F - \bar{F}|)^{p'-2} h_K^2 |F - \bar{F}|^2 \\
&\lesssim \theta_2^{-\gamma} I + \theta_2 \epsilon.
\end{aligned}$$

From (4.7)–(4.9),

$$I \lesssim \theta_1^{-\gamma} \int_0^s |u-u_h|_{(p)}^2 + (\theta_1 + \theta_2^{-\gamma}) I + \theta_2 \epsilon.$$

Let $\theta_1 + \theta_2^{-\gamma} = \frac{1}{2C}$. Then

$$I \lesssim \int_0^s |u-u_h|_{(p)}^2 + \epsilon. \qquad (4.10)$$

It follows from (4.6) and (4.10) that

$$L \lesssim \int_0^s |u-u_h|_{(p)}^2 dt + \epsilon. \qquad (4.11)$$

Therefore, Theorem 4.2 follows from (4.5) and (4.11). □

REMARK 4.3. *Note that when* $f, \frac{\partial u}{\partial t} \in L^1(0,T;W^{1,p'}(\Omega))$, $\epsilon \lesssim h^{2s}$, $s = \min\{2, p'\}$. *Then, combined with the results of Remark* 4.1, *we have that when the solution is smooth enough,*

$$\int_0^s |u-u_h|_{(p)}^2 \, dt - \epsilon^* \lesssim \eta^2 \lesssim \int_0^s |u-u_h|_{(p)}^2 \, dt + \epsilon \quad \textit{with} \quad \epsilon^*, \epsilon = o(h^2).$$

5. A posteriori error estimates for the full discrete scheme.

THEOREM 5.1. *Let* u *and* U *be solutions of* (3.1) *and* (3.4), *respectively. Let* $p > 1$ *and* $p' > 1$ *be such that* $\frac{1}{p} + \frac{1}{p'} = 1$. *Assume that* $f \in L^1(0,T;W^{1,p'}(\Omega))$. *Then there exists a* $\delta_0 > 0$ *such that for all* $s \in [0,T]$, $0 < \delta \leq \delta_0$,

$$\|(u-U)(s)\|_{0,\Omega}^2 + \int_0^s |u - \hat{U}|_{(p)}^2 \, dt \lesssim \eta_0^2 + C(\delta)\big(\hat{\eta}_1^2 + \hat{\eta}_2^2\big) + \hat{\eta}_3^2 + \hat{\eta}_4^2 + \delta \hat{\eta}_5^2 \qquad (5.1)$$

with $\hat{A}_l = ((|\nabla\hat{U}|^{p-2}\nabla\hat{U})_{K_l^1} - (|\nabla\hat{U}|^{p-2}\nabla\hat{U})_{K_l^2})n$ *and* $\eta_0 = \|u_0 - u_0^h\|_{0,\Omega}$,

$$\hat{\eta}_1^2 = \int_0^s \sum_K \int_K \left(|\nabla\hat{U}|^{p-1} + h_K^2 \left|\nabla\left(\hat{f} - \frac{\partial U}{\partial t}\right)\right|\right)^{p'-2} h_K^4 \left|\nabla\left(\hat{f} - \frac{\partial U}{\partial t}\right)\right|^2 dx\,dt,$$

$$\hat{\eta}_2^2 = \int_0^s \sum_{l\cap\partial\Omega=\emptyset} \int_{K^l_{max}} (|\nabla\hat{U}|^{p-1} + |\hat{A}_l|)^{p'-2}|\hat{A}_l|^2,$$

$$\hat{\eta}_3^2 = \int_0^s \|f - \hat{f}\|^2_{L^2(\Omega)}\,dt, \qquad \hat{\eta}_4^2 = \int_0^s |U - \hat{U}|^2_{(\hat{U},p)}\,dt,$$

$$\hat{\eta}_5^2 = \int_0^s \sum_{l\cap\partial\Omega=\emptyset} \int_{K^l_{min}} \left(|\nabla\hat{U}| + \left|\left[\frac{\partial\hat{U}}{\partial n}\right]_l\right|\right)^{p-2} \left|\left[\frac{\partial\hat{U}}{\partial n}\right]_l\right|^2.$$

Proof. Let $\hat{e} = u - U$, $\hat{e}_I(x,t) = \pi_h\hat{e}(x,t) \in V_0^h$ be the interpolation of $\hat{e}(x,t)$ defined in Definition 3.1 for almost all $t \in [0,T]$. It follows from Lemma 2.1 and (3.1), (3.4) that

$$\begin{aligned}
&\frac{1}{2}\|(u-U)(s)\|^2_{0,\Omega} + \alpha\int_0^s |u - \hat{U}|^2_{(p)}\,dt \\
&\le \frac{1}{2}\|(u-U)(0)\|^2_{0,\Omega} + \int_0^s\int_\Omega \frac{\partial}{\partial t}(u-U)(u-U) \\
&\quad + \int_0^s\int_\Omega (|\nabla u|^{p-2}\nabla u - |\nabla\hat{U}|^{p-2}\nabla\hat{U})\nabla(u-\hat{U}) \\
&= \frac{1}{2}\hat{\eta}_0^2 + \int_0^s\int_\Omega \frac{\partial}{\partial t}(u-U)(\hat{e}-\hat{e}_I) + \int_0^s\int_\Omega (|\nabla u|^{p-2}\nabla u - |\nabla\hat{U}|^{p-2}\nabla\hat{U})\nabla(\hat{e}-\hat{e}_I) \\
&\quad + \int_0^s\int_\Omega \frac{\partial}{\partial t}(u-U)\hat{e}_I + \int_0^s\int_\Omega (|\nabla u|^{p-2}\nabla u - |\nabla\hat{U}|^{p-2}\nabla\hat{U})\nabla\hat{e}_I \\
&\quad + \int_0^s\int_\Omega (|\nabla u|^{p-2}\nabla u - |\nabla\hat{U}|^{p-2}\nabla\hat{U})\nabla(U-\hat{U}) \\
&= \frac{1}{2}\hat{\eta}_0^2 + \int_0^s\int_\Omega \left(f - \frac{\partial U}{\partial t}\right)(\hat{e}-\hat{e}_I) - \int_0^s\sum_K\int_{\partial K} |\nabla\hat{U}|^{p-2}\frac{\partial\hat{U}}{\partial n}(\hat{e}-\hat{e}_I) \\
&\quad + \int_0^s (f-\hat{f})\hat{e}_I + \int_0^s\int_\Omega (|\nabla u|^{p-2}\nabla u - |\nabla\hat{U}|^{p-2}\nabla\hat{U})\nabla(U-\hat{U}) \\
&= \frac{1}{2}\hat{\eta}_0^2 + \int_0^s\int_\Omega \left(\hat{f} - \frac{\partial U}{\partial t}\right)(\hat{e}-\hat{e}_I) - \int_0^s\sum_K\int_{\partial K} |\nabla\hat{U}|^{p-2}\frac{\partial\hat{U}}{\partial n}(\hat{e}-\hat{e}_I) \\
&\quad + \int_0^s (f-\hat{f})\hat{e} + \int_0^s\int_\Omega (|\nabla u|^{p-2}\nabla u - |\nabla\hat{U}|^{p-2}\nabla\hat{U})\nabla(U-\hat{U}) \\
&= \frac{1}{2}\eta_0^2 + I_1 + I_2 + I_3 + I_4.
\end{aligned}$$

Similarly, as in Theorem 4.1, it follows from Lemma 6.4 that

$$\begin{aligned}
I_1 &= \int_0^s \int_\Omega \Big(\hat{f} - \frac{\partial U}{\partial t}\Big)(\hat{e} - \hat{e}_I) \\
&\lesssim C(\delta_1) \int_0^s \sum_K \int_K \Big(|\nabla \hat{U}|^{p-1} + h_K^2 \Big|\nabla\Big(\hat{f} - \frac{\partial U}{\partial t}\Big)\Big|\Big)^{p'-2} h_K^4 \Big|\nabla\Big(\hat{f} - \frac{\partial U}{\partial t}\Big)\Big|^2 \\
&\quad + \delta_1 \int_0^s \sum_K \int_K (|\nabla \hat{U}| + |\nabla \hat{e}|)^{p-2} |\nabla \hat{e}|^2 \\
&\quad + \delta_1 \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_{K^l_{min}} \Big(|\nabla \hat{U}| + \Big|\Big[\frac{\partial \hat{U}}{\partial n}\Big]_l\Big|\Big)^{p-2} \Big|\Big[\frac{\partial \hat{U}}{\partial n}\Big]_l\Big|^2 \\
&\lesssim C(\delta_1)\hat{\eta}_1^2 + \delta_1 \Big(\int_0^s |u - U|^2_{(\hat{U},p)} + \hat{\eta}_5^2\Big).
\end{aligned}$$

By Lemmas 2.3, 6.3, and 6.5, we similarly have

$$\begin{aligned}
I_2 &= -\int_0^s \sum_K \int_{\partial K} |\nabla \hat{U}|^{p-2} \frac{\partial \hat{U}}{\partial n}(\hat{e} - \hat{e}_I) = -\int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_l \hat{A}_l (\hat{e} - \hat{e}_I) \\
&\lesssim \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_{K^l_{max}} |A_l| \Big(h^{-1}_{K^l_{max}} |\hat{e} - \hat{e}_I| + |\nabla(\hat{e} - \hat{e}_I)|\Big) \\
&\lesssim \delta_2^{-\beta} \int_0^s \sum_{l \cap \partial\Omega = \emptyset} \int_{K^l_{max}} (|\nabla \hat{U}|^{p-1} + |\hat{A}_l|)^{p'-2} \hat{A}_l^2 \\
&\quad + \delta_2 \int_0^s \sum_K \int_K (|\nabla \hat{U}| + h_K^{-1} |\hat{e} - \hat{e}_I|)^{p-2} h_K^{-2} |\hat{e} - \hat{e}_I|^2 \\
&\quad + \delta_2 \int_0^s \sum_K \int_K (|\nabla \hat{U}| + |\nabla(\hat{e} - \hat{e}_I)|)^{p-2} |\nabla(\hat{e} - \hat{e}_I)|^2 \\
&\lesssim \delta_2^{-\beta} \hat{\eta}_2^2 + \delta_2 \Big(\int_0^s |u - U|^2_{(\hat{U},p)} + \hat{\eta}_5^2\Big).
\end{aligned}$$

Then, by Lemma 2.4,

$$\begin{aligned}
I_1 + I_2 &\lesssim C(\delta_1, \delta_2)(\hat{\eta}_1^2 + \hat{\eta}_2^2) + (\delta_1 + \delta_2)\Big(\int_0^s |u - U|^2_{(\hat{U},p)} + \hat{\eta}_5^2\Big) \\
&\lesssim C(\delta_1, \delta_2)(\hat{\eta}_1^2 + \hat{\eta}_2^2) + (\delta_1 + \delta_2)\Big(\int_0^s |u - \hat{U}|^2_{(p)} + \hat{\eta}_4^2 + \hat{\eta}_5^2\Big).
\end{aligned}$$

It follows from the Schwarz inequality that

$$I_3 = \int_0^s \int_\Omega (f - \hat{f})\hat{e} \lesssim \int_0^s \|f - \hat{f}\|^2_{0,\Omega}\, dt + \int_0^s \|\hat{e}\|^2_{0,\Omega}\, dt \approx \hat{\eta}_3^2 + \int_0^s \|u - U\|^2_{0,\Omega}\, dt.$$

It follows from Lemmas 2.1 and 2.2 that

$$\begin{aligned}
I_4 &= \int_0^s \int_\Omega (|\nabla u|^{p-2}\nabla u - |\nabla \hat{U}|^{p-2}\nabla \hat{U})\nabla(U - \hat{U}) \\
&\lesssim \theta^{-\gamma} \int_0^s (|\nabla \hat{U}| + |\nabla(u - \hat{U})|)^{p-2} |\nabla(u - \hat{U})|^2 \\
&\quad + \theta \int_0^s (|\nabla \hat{U}| + |\nabla(U - \hat{U})|)^{p-2} |\nabla(U - \hat{U})|^2 \\
&\approx \theta^{-\gamma} \int_0^s |u - \hat{U}|^2_{(p)} + \theta \hat{\eta}_4^2.
\end{aligned}$$

Hence, letting $2\delta_0 + \theta^{-\gamma} = \frac{\alpha}{2C}$, we have that

$$\|(u-U)(s)\|_{0,\Omega}^2 + \int_0^s |u-\hat{U}|_{(p)}^2\,dt \lesssim \hat{\eta}_0^2 + C(\delta)(\hat{\eta}_1^2 + \hat{\eta}_2^2) + \hat{\eta}_3^2 + \hat{\eta}_4^2 + \delta\hat{\eta}_5^2 + \int_0^s \|u-U\|_{0,\Omega}^2 dt.$$

Then the estimate (5.1) follows from a Gronwall-type inequality. □

Theorem 5.2. *Let u and U be the solutions of* (3.1) *and* (3.4), *respectively. Let $p>1$ and $p'>1$ be such that $\frac{1}{p}+\frac{1}{p'}=1$. Assume that $f, \frac{\partial u}{\partial t} \in L^1(0,T;L^{p'}(\Omega))$, and that $c \le k_j/k_{j-1} \le C$. Then*

$$\hat{\eta}_2^2 \lesssim \int_0^s |u-\hat{U}|_{(p)}^2 dt + \hat{\epsilon}, \tag{5.2}$$

with

$$\hat{\epsilon} = \int_0^s \sum_K \int_K (|\nabla\hat{U}|^{p-1} + h_K|f-\bar{f}|)^{p'-2} h_K^2 |f-\bar{f}|^2$$
$$+ \int_0^s \sum_K \int_K \left(|\nabla\hat{U}|^{p-1} + h_K\left|\frac{\partial u}{\partial t} - \overline{\frac{\partial u}{\partial t}}\right|\right)^{p'-2} h_K^2 \left|\frac{\partial u}{\partial t} - \overline{\frac{\partial u}{\partial t}}\right|^2,$$

where $\bar{f}|_K = \int_K f/|K|$, $\overline{\frac{\partial u}{\partial t}}|_K = \int_K \frac{\partial u}{\partial t}/|K|$. Furthermore, for each $V \in C\,(0,T;W^{1,2}(\Omega))$ which is affine in time on each time interval $(t_{j-1},t_j]$, $j=1,\dots,N$, there holds

$$\hat{\eta}_4^2 \lesssim \int_0^s |u-\hat{U}|_{(p)}^2\,dt + \int_0^s |u-V|_{(p)}^2\,dt. \tag{5.3}$$

Proof. Similarly as in Theorem 4.2, it can be proved that

$$\hat{\eta}_2^2 \lesssim \int_0^s |u-\hat{U}|_{(p)}^2\,dt + L,$$

where

$$L = \int_0^s \sum_K \int_K \left(|\nabla\hat{U}|^{p-1} + h_K|f - \frac{\partial u}{\partial t}|\right)^{p'-2} h_K^2 \left|f - \frac{\partial u}{\partial t}\right|^2.$$

Similarly, as in Theorem 4.2, it also can be proved that

$$L \lesssim \int_0^s |u-\hat{U}|_{(p)}^2\,dt + \hat{\epsilon}.$$

Then (5.2) follows. For $x,y\ge 0$ and $1<p<\infty$, let

$$G(x,y) := \begin{cases} y^2(x+y)^{p-2} & \text{if } x+y>0, \\ 0 & \text{if } x=y=0. \end{cases} \tag{5.4}$$

Then

$$\hat{\eta}_4^2 := \int_0^s |U-\hat{U}|_{(\hat{U},p)}^2\,dt = \int_0^s \int_\Omega G(|\nabla\hat{U}|, |\nabla U - \nabla\hat{U}|)\,dx\,dt$$
$$= \sum_K \sum_{j=1}^n \int_K \int_{t_{j-1}}^{t_j} G(|\nabla\hat{U}|, |\nabla U - \nabla\hat{U}|)\,dt\,dx.$$

We consider one contribution

$$\int_K \int_{t_{j-1}}^{t_j} G(|\nabla \hat{U}|, |\nabla U - \nabla \hat{U}|)\, dt\, dx \le k_j \int_K G(|\nabla U_j|, |\nabla U_j - \nabla U_{j-1}|)\, dx. \tag{5.5}$$

The inequality follows from $(U - \hat{U})(t) = -(t_j - t)(U_j - U_{j-1})/k_j$ for $t \in I_j := (t_{j-1}, t_j)$ and $|(U - \hat{U})(t)| \le |U_j - U_{j-1}|$ combined with the monotonicity of $G(x, y)$ in y. It follows from Lemma 2.5 that for all $a, b, c \in R^n$,

$$\begin{aligned} G(|a|, |a-b|) &\lesssim (|a| + |b|)^{p-2}|b-a|^2 \lesssim G(|c|, |a-c|) + G(|c|, |b-c|) \\ &\lesssim G(|a|, |a-c|) + G(|b|, |b-c|). \end{aligned}$$

Given $V \in C(I_{j-1} \cup I_j; W^{1,2}(K))$, let $a := \nabla U_j$, $b := \nabla U_{j-1}$, and $c := \nabla V(t_{j-1}) = \nabla V_{j-1}$. Then

$$\begin{aligned} &\int_K G(|\nabla U_j|, |\nabla U_j - \nabla U_{j-1}|)\, dx \\ &\lesssim \int_K G(|\nabla U_{j-1}|, |\nabla U_{j-1} - \nabla V_{j-1}|)\, dx + \int_K G(|\nabla U_j|, |\nabla U_j - \nabla V_{j-1}|)\, dx. \end{aligned}$$

A direct calculation shows the estimate

$$\frac{k}{2} = \min_{m \in R} \int_0^k |1 + mt|\, dt$$

for all $k > 0$. Therefore, for any $b \in R$ and $k > 0$,

$$\frac{k}{2}\, |b| = \min_{m \in R} \int_0^k |b + mt|\, dt.$$

From this and a decomposition of $b \in R^n$ and $m \in R^n$ in the direction b and its orthogonal complement, one infers for all $b \in R^n$ and $k > 0$

$$\frac{k}{2}\, |b| = \min_{m \in R^n} \int_0^k |b + mt|\, dt = \min_{m \in R^n} \int_{-k}^0 |b + mt|\, dt.$$

Therefore, for all $b, m \in R^n$,

$$|b| \le \frac{2}{k_j} \int_{t_{j-1}}^{t_j} |b + m(t_j - s)|\, ds, \quad |b| \le \frac{2}{k_j} \int_{t_{j-1}}^{t_j} |b + m(t_{j-1} - s)|\, ds.$$

Since $G(|a|, \cdot)$ is monotone increasing and convex in $|\cdot|$,

$$G(|a|, |b|) \le G\left(|a|, \frac{2}{k_j} \int_{t_{j-1}}^{t_j} |b + m(t_{j-1} - s)|\, ds\right) \le \frac{1}{k_j} \int_{t_{j-1}}^{t_j} G(|a|, 2|b + m(t_{j-1} - s)|)\, ds.$$

The latter inequality follows Jensen's inequality for $G(|a|, |\cdot|)$ convex and so the value $G(|a|, 2\overline{b})$ for the mean value $\overline{b} = \frac{1}{k_j} \int_{t_{j-1}}^{t_j} |b + m(t_{j-1} - s)|\, ds$ of $|b + m(t_{j-1} - s)|$ is smaller than or equal to the mean value of $G(|a|, 2|b + m(t_{j-1} - s)|)$. Note that

$$\hat{U} - V = U_j - V_{j-1} + \frac{V_j - V_{j-1}}{k_j}(t_{j-1} - t).$$

The last inequality is employed to bound

$$\text{(5.6)}\quad k_j\int_K G(|\nabla U_j|,|\nabla U_j-\nabla V_{j-1}|)\,dx \le \int_{t_{j-1}}^{t_j}\int_K G(|\nabla U_j|,2|\nabla(\hat U-V)|)\,dxdt$$
$$\lesssim \int_K\int_{t_{j-1}}^{t_j} G(|\nabla U_j|,|\nabla\hat U-\nabla V)|\,dt\,dx.$$

Similarly (with another interval but the same argument), we have

(5.7)
$$k_j\int_K G(|\nabla U_{j-1}|,|\nabla U_{j-1}-\nabla V_{j-1}|)\,dx \lesssim \int_K\int_{t_{j-2}}^{t_{j-1}} G(|\nabla U_{j-1}|,|\nabla\hat U-\nabla V|)\,dtdx,$$

using the condition $c\le k_j/k_{j-1}\le C$ and

$$\hat U - V = U_{j-1}-V_{j-1}+\frac{V_{j-1}-V_{j-2}}{k_{j-1}}(t_{j-1}-t).$$

The combination of (5.5)–(5.7) proves that for each $V\in C(0,T;W^{1,2}(\Omega))$ which is affine in time on each time interval $(t_{j-1},t_j]$, $j=1,\dots,N$, there holds

$$\hat\eta_4^2\lesssim\int_0^s|\hat U-V|^2_{(\hat U,p)}\,dt.$$

From this estimate and the aforementioned estimate

$$G(|a|,|b-a|)\lesssim G(|c|,|a-c|)+G(|c|,|b-c|)\quad\forall\,a,b,c\in R^n,$$

we deduce

$$\hat\eta_4^2\lesssim\int_0^s\int_\Omega G(|\nabla\hat U|,|\nabla\hat U-\nabla V|)\,dt\,dx$$
$$\lesssim\int_0^s\int_\Omega G(|\nabla u|,|\nabla u-\nabla V|)\,dt\,dx+\int_0^s\int_\Omega G(|\nabla u|,|\nabla u-\nabla\hat U|)\,dt\,dx.$$

Then the estimate (5.3) follows. □

6. Appendix. In this section, we state some results on the interpolation error in the quasi-norm from [CLY]. For the readers' convenience, we include the proofs here. First, we prove a lemma which is a quasi-norm version of quotient theorem. We take a general approach here so that the results obtained can be applied to a class of degenerate systems.

Recall the definition of $G(x,y)$ from (5.4). Without further (explicit) notice, we shall use the fact that $G(x,y)$ is monotone increasing and convex with respect to the variable y.

First, we prove a quasi-norm version of the quotient theorem.

LEMMA 6.1. *Let Ω be a bounded connected open set in R^2. Let $1<p<\infty$ and $f\in(W^{1,p}(\Omega))^*$ with $P_0(\Omega)\cap\mathrm{Ker}(f)=\{0\}$. Then there exists a constant $c_1=c(f,p,\Omega)$ such that, for all $a\in R$, $a\ge0$, and $v\in W^{1,p}(\Omega)$,*

$$\int_\Omega G(a,|v|)\,dx\le c_1\,G(a,|f(v)|)+c_1\int_\Omega G(a,|\nabla v|)\,dx.$$

Proof. We argue by contradiction and suppose the lemma is false. Then there would exist a sequence v_j in $W^{1,p}(\Omega)$ with $\delta_j := \|v_j\|_{1,q} > 0$, $q = \min\{2,p\}$, and a sequence a_j of nonnegative real numbers such that

$$G(a_j, |f(v_j)|) + \int_\Omega G(a_j, |\nabla v_j|)\,dx \le 1/j \int_\Omega G(a_j, |v_j|)\,dx \tag{6.1}$$

for all $j \in N$. We observe in any case there exists a $u \in W^{1,q}(\Omega)$ with

$$u_j := v_j/\delta_j \text{ satisfies } \|u_j\|_{1,q} = 1, \quad u_j \rightharpoonup u \text{ in } W^{1,q}(\Omega). \tag{6.2}$$

Here we have chosen a weak convergent subsequence with Banach Alaoglu's theorem. In the first case we suppose that there exists a constant γ, $0 < \gamma < \infty$, with

$$a_j \le \gamma\,\delta_j \quad \text{for} \quad j = 1, 2, 3, \dots . \tag{6.3}$$

At least we suppose (6.3) for a subsequence we have not relabeled. If $1 < p \le 2$, then $G(a, x) \le x^p$ for all $x \ge 0$. Therefore, even without (6.3),

$$\int_\Omega G(a_j/\delta_j, |u_j|)\,dx \le \|u_j\|_p^p \le 1.$$

If $2 \le p$, then $G(\cdot, |u_j|)$ is monotone increasing. Hence, (6.2)–(6.3) yields

$$\int_\Omega G(a_j/\delta_j, |u_j|)\,dx \le \int_\Omega (\gamma + |u_j|)^{p-2}|u_j|^2\,dx \le \|\gamma + |u_j|\|_p^p \le (1 + \gamma|\Omega|^{1/p})^p.$$

Hence, for all $1 < p < \infty$, $\int_\Omega G(a_j/\delta_j, |u_j|)\,dx$ is bounded. A scaling of (6.1) then shows

$$\lim_{j\to\infty} \int_\Omega G(a_j/\delta_j, |\nabla u_j|)\,dx = \lim_{j\to\infty} G(a_j/\delta_j, |f(u_j)|) = 0. \tag{6.4}$$

If $1 < p \le 2$, a Hölder inequality with exponents $2/p$ and $2/(2-p)$ leads to

$$\begin{aligned} \|\nabla u_j\|_p^p &= \int_\Omega |\nabla u_j|^p (a_j/\delta_j + |\nabla u_j|)^{p(p-2)/2} (a_j/\delta_j + |\nabla u_j|)^{p(2-p)/2}\,dx \\ &\le \left(\int_\Omega G(a_j/\delta_j, |\nabla u_j|)\,dx\right)^{p/2} \left(\int_\Omega (a_j/\delta_j + |\nabla u_j|)^p\,dx\right)^{1-p/2}. \end{aligned} \tag{6.5}$$

The last factor is bounded as $j \to \infty$ by (6.2)–(6.3) and the second last tends to zero by (6.4). Again, for $1 < p \le 2$ (when $G(\cdot, |f(u_j)|)$ is monotone decreasing), (6.4) shows that $G(\gamma, |f(u_j)|)$ tends to zero and, hence, so does $|f(u_j)|$. Consequently,

$$\lim_{j\to\infty} \|\nabla u_j\|_q = \lim_{j\to\infty} |f(u_j)| = 0. \tag{6.6}$$

So far we have established (6.6) for $1 < p \le 2$. For $2 < p < \infty$, $|\nabla u_j|^p \le G(a_j/\delta_j, |\nabla u_j|)$ and $|f(u_j)|^p \le G(a_j/\delta_j, |f(u_j)|)$ and so (6.4) implies (6.6) directly. From (6.6) we deduce a contradiction to (6.2): Since $W^{1,q}(\Omega)$ is compactly embedded in $L^q(\Omega)$ we have $u_j \to u$ in $L^q(\Omega)$. With (6.6), $u_j \to u$ in $W^{1,q}(\Omega)$ and so $\|u\|_{1,q} = 1$. Conversely, u is constant (as $\nabla u_j \to 0$ in $L^q(\Omega)$). Since f is a bounded linear form, $f(u_j) \to f(u)$ and $f(u) = 0$. Since $u \in P_0(\Omega) \cap \operatorname{Ker}(f)$, we have $u = 0$. This contradiction with $\|u\|_{1,q} = 1$ concludes the proof in case (6.3).

In the remaining second case we suppose that a_j/δ_j is not bounded (not even for a subsequence). Hence, $\lim_{j\to\infty} a_j/\delta_j = +\infty$. One can assume that

$$\delta_j \le \gamma\, a_j \quad \text{for } q = \min\{2,p\} \quad \text{and} \quad \text{for } j = 1,2,3,\dots \tag{6.7}$$

for a constant γ (and at least for sufficiently large j which we have not relabeled). If $1 < p \le 2$, we use $(1+\delta_j/a_j|u_j|)^{p-2} \le 1$. If $2 \le p < \infty$, we use $\delta_j/a_j \le \gamma$. This leads to

$$\frac{1}{j}\int_\Omega (1+\delta_j/a_j|u_j|)^{p-2}|u_j|^2\,dx \le \begin{cases} \|u_j\|_2^2/j & \text{if } 1 < p \le 2, \\ \|u_j\|_p^2(\gamma\|u_j\|_p + |\Omega|^{1/p})^{p-2}/j & \text{if } 2 \le p < \infty. \end{cases} \tag{6.8}$$

Since $q = \min\{2,p\}$ and $\|u_j\|_{1,q} = 1$, we conclude that (6.8) tends to zero as $j \to \infty$ from embedding. A scaling of (6.1) therefore yields

$$\lim_{j\to\infty}\int_\Omega (1+\delta_j/a_j\,|\nabla u_j|)^{p-2}|\nabla u_j|^2\,dx = 0 \tag{6.9}$$

and

$$\lim_{j\to\infty}(1+\delta_j/a_j\,|f(u_j)|)^{p-2}|f(u_j)|^2 = 0. \tag{6.10}$$

If $2 \le p < \infty$, we directly deduce (6.6) for $q = 2$ and finish the proof as in the first case since $\|u_j\|_{1,2} = 1$. If $1 < p \le 2$, we argue with a Hölder inequality analogy to (6.5) and infer

$$\|\nabla u_j\|_p^2 \le \int_\Omega (1+\delta_j/a_j|\nabla u_j|)^{p-2}|\nabla u_j|^2\,dx \left(\int_\Omega (1+\delta_j/a_j|\nabla u_j|)^p\,dx\right)^{\frac{2-p}{p}}.$$

The last factor is bounded according to (6.7) and $\|u_j\|_{1,p} = 1$. This and (6.9) show (6.6) with $p = q \le 2$. The proof is then finished as in the first case. □

REMARK 6.1. *Lemma* 6.1 *is employed in connection with a scaling argument. If we scale the domain* Ω *from a reference size* 1 *to a patch-size* h*, the first term obtains the factor* h^2 *from a change of variables while the last term in values* $h\,|\nabla v|$ *instead of* $|\nabla v|$. *With a different* $a > 0$*, this yields*

$$\int_\Omega G(a,|v|)\,dx \lesssim \int_\Omega G(a,h|\nabla v|)\,dx$$

for all $v \in W^{1,p}(\Omega) \cap \mathrm{Ker(f)}$ *and* $h = \mathrm{diam}(\Omega)$*; the generic constant depends on the shape of* Ω *but is h-independent.*

Now, let us recall a weighted Clement-type interpolation on the finite element space V_0^h defined in Definition 3.1. It is essential for later analysis to establish approximation error estimates in the quasi-norm for the operator π.

LEMMA 6.2. *For any* $1 < p < \infty$ *and positive integers* d *and* n *there exists a constant* $c_2 = c(p,d,n)$ *such that, for all* $a_1, a_2, \dots, a_n \in R^d$*, there holds*

$$\sum_{j=1}^{n}\sum_{k=1}^{j-1} G(|a_j|,|a_j-a_k|) \le c_2 \sum_{\ell=1}^{n-1}\min_{m=1,\dots,n} G(|a_m|,|a_{\ell+1}-a_\ell|).$$

Proof. Let $\alpha := (a_1+\cdots+a_n)/n \in R^d$ and $b_j := a_j - \alpha \in R^d$ so that $b_1+\cdots+b_n = 0$. Define

$$f(\alpha; b_1, \ldots, b_n) := \sum_{j=1}^{n} \sum_{k=1}^{j-1} G(|\alpha + b_j|, |b_j - b_k|),$$
$$g(\alpha; b_1, \ldots, b_n) := \sum_{\ell=1}^{n-1} \min_{m=1,\ldots,n} G(|\alpha + b_m|, |b_{\ell+1} - b_\ell|).$$

Observe that $g(\alpha, \cdot)$ is positive for nonzero arguments on

$$X := \{(b_1, \ldots, b_n) \in R^{d\times n} : \, b_1 + \cdots + b_n = 0\},$$

since $g(\alpha; b_1, \ldots, b_n) = 0$ implies $b_1 = b_2 = \cdots = b_n$. Let

$$B := \{(b_1, \ldots, b_n) \in X : \, |b_1|^2 + \cdots + |b_n|^2 = 1\}$$

denote the unit ball surface in X. Then, for any $\beta \in R^d$,

$$c(\beta) := \max_{(b_1,\ldots,b_n)\in B} f(\beta; b_1, \ldots, b_n)/g(\beta; b_1, \ldots, b_n) < \infty,$$

since the denominator is positive and $f(\alpha; \cdot), g(\alpha; \cdot)$ are continuous on the compact set B. The same argument shows

$$c_\infty := \max_{(b_1,\ldots,b_n)\in X\setminus\{0\}} \sum_{j=1}^{n} \sum_{k=1}^{j-1} |b_j - b_k|^2 \Big/ \sum_{\ell=1}^{n-1} |b_{\ell+1} - b_\ell|^2 < \infty.$$

Note that

$$\limsup_{|\beta|\to\infty} c(\beta) \le c_\infty < \infty,$$

and so $c(\beta)$ is a bounded continuous function in $\beta \in R^d$. For all $a_1, \ldots, a_n \in R^d$, we have $\alpha \in R^d$ and $(b_1, \ldots, b_n) \in X$ as above. Since f and g are positively homogeneous functions we have, for $\lambda := (|b_1|^2 + \cdots + |b_n|^2)^{1/2} > 0$,

$$\begin{aligned} f(\alpha; b_1, \ldots, b_n) &= \lambda^p f(\alpha/\lambda; b_1/\lambda, \ldots, b_n/\lambda) \\ &\lesssim \lambda^p g(\alpha/\lambda, b_1/\lambda, \ldots, b_n/\lambda) \lesssim g(\alpha; b_1, \ldots, b_n). \qquad \Box \end{aligned}$$

Then we have following interpolation error estimates for the interpolator π in the quasi-norm.

LEMMA 6.3. *Let π be the operator of Definition* 3.1. *For any $1 < p < \infty$, $u_h \in V_h$, $v \in W_0^{1,p}(\Omega)$, and $K \in T^h$, there holds*

$$\begin{aligned} &\int_K G(|\nabla u_h|, |v - \pi v|/h_K)\, dx + \int_K G(|\nabla u_h|, |\nabla(v - \pi v)|)\, dx \\ &\quad \lesssim \sum_{z\in\Lambda\cap K} \left(\int_{\omega_z} G(|\nabla u_h|, |\nabla v|)\, dx + \min_{K'\in T_K} \int_{\cup E_K} G(|\nabla u_h|_{K'}|, |[\partial u_h/\partial n_\varepsilon]|)\, ds \right). \end{aligned} \tag{6.11}$$

Here, $T_K := \{K' \in T^h : \, \bar{K}' \cap \bar{K} \ne \emptyset\}$, $\cup E_K := \cup\{l \subset \partial K' : \, K' \in T_K, \, l \cap \partial\Omega = \emptyset\}$, and $[\partial u_h/\partial n_\varepsilon]$ denotes the jump of the discrete normal fluxes across inner element *boundaries. Consequently,*

$$\begin{aligned}&\sum_K\Big(\int_K G(|\nabla u_h|,|v-\pi v|/h_K)\,dx+\int_K G(|\nabla u_h|,|\nabla(v-\pi v)|)\,dx\Big)\\ &\qquad\lesssim\sum_K\int_K G(|\nabla u_h|,|\nabla v|)\,dx+\tilde\eta^2,\end{aligned}\tag{6.12}$$

where

$$\tilde\eta^2=\sum_{l\cap\partial\Omega=\emptyset}\int_{K^l_{min}}\left(|\nabla u_h|+\left|\left[\frac{\partial u_h}{\partial n}\right]_l\right|\right)^{p-2}\left|\left[\frac{\partial u_h}{\partial n}\right]_l\right|^2.$$

Proof. In the first step, we show that the first term of the left-hand side of (6.11) is bounded by the right-hand side. Fix $a:=\nabla u_h|_K$ and set $v_z:=(\pi v)(z)$ for all $z\in D$. Since $(\psi_z)_{z\in\Lambda\cap K}$ is a partition of unity on K, and G satisfies a triangle inequality in the sense of Lemma 2.4, we have

$$\begin{aligned}\int_K G(|\nabla u_h|,|v-\pi v|/h_K)\,dx&=\int_K G(|a|,|\sum_{z\in\Lambda\cap K}(v\psi_z-v_z\varphi_z)|/h_K)dx\\ &\lesssim\sum_{z\in\Lambda\cap K}\int_K G(|a|,|v\psi_z-v_z\varphi_z|/h_K)\,dx.\end{aligned}\tag{6.13}$$

Let ω_z be the support of ϕ_z. Since $K\subseteq\overline{\omega}_z$, we have for any fixed $z\in\Lambda\cap\bar K$,

$$\int_K G(|a|,|v\psi_z-v_z\varphi_z|/h_K)\,dx\le\int_{\omega_z}G(|a|,|v\psi_z-v_z\varphi_z|/h_K)\,dx.\tag{6.14}$$

In the first case, we suppose $\psi_z=\varphi_z$, i.e., all nodes in $\overline{\omega}_z$ are free nodes. A scaled version of Lemma 6.1 with $w:=(v-v_z)/h_K$, $f(w)=\int_{\omega_z}\varphi_z w\,dx$, and $\psi_z=\varphi_z$ and $|\varphi_z|\le 1$ yield

$$\begin{aligned}\int_{\omega_z}G(|a|,|v\psi_z-v_z\varphi_z|/h_K)\,dx&\le\int_{\omega_z}G(|a|,|v-v_z|/h_K)\,dx\\ &\lesssim\int_{\omega_z}G(|a|,|\nabla v|)\,dx.\end{aligned}\tag{6.15}$$

In the remaining second case, $\psi\not\equiv 1$ on ω_z and so $\partial\omega_z\cap\partial\Omega$ includes at least one outer age E. With $f(w)=\int_E w\,dx$, we deduce from Lemma 6.1 that

$$\int_{\omega_z}G(|a|,|v\psi_z|/h_K)dx\le\int_{\omega_z}G(|a|,|v|/h_K)dx\lesssim\int_{\omega_z}G(|a|,|\nabla v|)dx.\tag{6.16}$$

Since $|v_z|\lesssim|⨍_{\omega_z}\psi_z v\,dx|$ and $G(|a|,\cdot/h_K)$ is convex, Jensen's inequality shows

$$\begin{aligned}\int_{\omega_z}G(|a|,|v_z|/h_K)\,dx&\lesssim\int_{\omega_z}G(|a|,\Big|⨍_{\omega_z}\psi_z v\,dx\Big|/h_K)\,dy\\ &\le\int_{\omega_z}⨍_{\omega_z}G(|a|,|\psi_z v|/h_K)\,dx\,dy=\int_{\omega_z}G(|a|,|\psi_z v|/h_K)\,dx,\end{aligned}\tag{6.17}$$

where the sign $\fint_{\omega_z}$ represents the integral average over ω_z. It follows from the triangle-like inequality of Lemma 2.4, (6.16)–(6.17), monotonicity in the second argument of G, and the inequalities $0 \le \varphi_z \le 1, 0 \le \psi \le 1$ that

$$\begin{aligned}(6.18)\qquad \int_{\omega_z} G(|a|, |v\psi_z - v_z\varphi_z|/h_K)\,dx &\lesssim \int_{\omega_z} G(|a|, |v\psi_z|/h_K)\,dx \\ + \int_{\omega_z} G(|a|, |v_z\varphi_z|/h_K)\,dx &\lesssim \int_{\omega_z} G(|a|, |\nabla v|)\,dx.\end{aligned}$$

Notice that $a + |\nabla u_h - a| \approx a + |\nabla u_h| \approx |\nabla u_h| + |a - \nabla u_h|$ and so

$$\begin{aligned}G(|a|, |\nabla v|) &\le G(|a|, |\nabla v| + |a - \nabla u_h|) \\ &= (|a| + |a - \nabla u_h| + |\nabla v|)^{p-2}(|\nabla v| + |a - \nabla u_h|)^2 \\ (6.19)\qquad &\lesssim (|\nabla u_h| + |\nabla v| + |a - \nabla u_h|)^{p-2}(|\nabla v| + |a - \nabla u_h|)^2 \\ &= G(|\nabla u_h|, |\nabla v| + |a - \nabla u_h|).\end{aligned}$$

Then, the triangle inequality of Lemma 2.4 shows

$$(6.20)\qquad G(|a|, |\nabla v|) \lesssim G(|\nabla u_h|, |\nabla v|) + G(|\nabla u_h|, |a - \nabla u_h|).$$

This, (6.15), and (6.18) result in

$$\begin{aligned}(6.21)\qquad &\int_{\omega_z} G(|a|, |v\psi_z - v_z\varphi_z|/h_K)\,dx \\ &\lesssim \int_{\omega_z} G(|\nabla u_h|, |\nabla v|)\,dx + \int_{\omega_z} G(|\nabla u_h|, |a - \nabla u_h|)\,dx.\end{aligned}$$

This and Lemma 6.2 with $a_j = \nabla u_h|_{K_j}$ for $K_1, \dots, K_n \in T^h$ with $K_1 \cup \dots \cup K_n = \overline{\omega}_z$ and $\{K_1 \cap K_2, \dots, K_{n-1} \cap K_n\} \subset \omega_z$ proves that (6.13) is bounded by the right-hand side of (6.11). The second step is to show that the second term on the left-hand side of (6.11) is bounded in this way as well. To this end, we let c be the integral mean of v on K. The triangle like inequality of Lemma 2.4 shows

$$\begin{aligned}(6.22)\qquad &\int_K G(|\nabla u_h|, |\nabla(v - \pi v)|)\,dx \\ &\lesssim \int_K G(|\nabla u_h|, |\nabla v|)\,dx + \int_K G(|\nabla u_h|, |\nabla(\pi v - c)|\,dx.\end{aligned}$$

The first term on the right-hand side of (6.22) is already bounded as asserted. To estimate the second term, note that $\pi v - c$ is an affine function on K. Then an inverse estimate shows

$$(6.23)\qquad |\nabla(\pi v - c)| \lesssim \fint_K |\pi v - c|\,dx/h_K.$$

It follows from the Jensen's inequality that

$$\begin{aligned}\int_K G(|\nabla u_h|, |\nabla(\pi v - c)|)\,dx &\lesssim \int_K \fint_K G(\nabla u_h|, |\pi v - c|/h_K)\,dxdy \\ &= \int_K G(|\nabla u_h|, |\pi v - c|/h_K)\,dx.\end{aligned}$$

The triangle like inequality of Lemma 2.4 yields

$$\int_K G(|\nabla u_h|, |\pi v - c|/h_K)\,dx \lesssim \int_K G(|\nabla u_h|, |v - \pi v|/h_K)\,dx + \int_K G(|\nabla u_h|, |v - c|/h_K)\,dx. \tag{6.24}$$

The first term on the right-hand side of (6.24) is already shown to be bounded by the right side of (6.11). The same conclusion for the second term follows from Lemma 6.1 with $f(w) = \int_K w\,dx$ and $\Omega = K$ as in (6.15):

$$\int_K G(|\nabla u_h|, |v - c|/h_K)\,dx \lesssim \int_K G(|\nabla u_h|, |\nabla v|)\,dx. \tag{6.25}$$

Then it follows from (6.22)–(6.25) that

$$\int_K G(|\nabla u_h|, |\nabla(v - \pi v)|)\,dx \lesssim \int_K G(|\nabla u_h|, |\nabla v|)\,dx + \int_K G(|\nabla u_h|, |v - \pi v|/h_K)\,dx. \tag{6.26}$$

Hence the desired estimate of the second term on the left-hand side of (6.11) follows from (6.26) and the first step of the proof. □

The next lemma establishes a quasi-norm estimate for the inner produce of a function and an interpolation error.

Lemma 6.4. *For any $\delta > 0, 1 < p < \infty$, $u_h \in V_h$, $v \in W_0^{1,p}(\Omega)$, and $f \in W^{1,p'}(\Omega)$, where $1/p + 1/p' = 1$, there exist constants C and C_1 (where only C_1 depends on δ) such that*

$$\begin{aligned}\int_\Omega f(v - \pi v)\,dx \le C\delta \int_\Omega G(|\nabla u_h|, |\nabla v|)\,dx \\ + C_1 \int_\Omega \left(|\nabla u_h|^{p-1} + h_z^2 |\nabla f|\right)^{p'-2} h_z^4 |\nabla f|^2\,dx \\ + C\delta \sum_K \min_{K' \in T_K} \int_{\cup E_K} G(|\nabla u_h|_{K'}|, |[\partial u_h/\partial n_\varepsilon]|)\,ds,\end{aligned} \tag{6.27}$$

where $G(\cdot,\cdot)$ is defined by (5.4). Therefore, with $\tilde\eta$ defined in Lemma 6.3, there holds

$$\begin{aligned}\int_\Omega f(v - \pi v) \le C_1 \sum_K \int_K (|\nabla u_h|^{p-1} + h_K^2 |\nabla f|)^{p'-2} h_K^4 |\nabla f|^2 \\ + C\delta \sum_K \int_K (|\nabla u| + |\nabla v|)^{p-2} |\nabla v|^2 + C\delta \tilde\eta^2.\end{aligned} \tag{6.28}$$

Proof. First note that $\int (v\psi_z - v_z\varphi_z)\,dx = 0$. Thus, with $f_z := ⨍_{\omega_z} f(x)\,dx$,

$$\begin{aligned}\int_\Omega f(v - \pi v)\,dx &= \sum_{z\in\Lambda} \int_\Omega f(v\psi_z - v_z\varphi_z)\,dx \\ &= \sum_{z\in\Lambda} \int_{\omega_z} (f - f_z) h_z\,(v\psi_z - v_z\varphi_z)/h_z\,dx.\end{aligned} \tag{6.29}$$

We use Lemma 2.3 to estimate the product inside the integral. This yields

$$\begin{aligned}&\int_{\omega_z}(f-f_z)h_z\,(v\psi_z-v_z\varphi_z)/h_z\,dx\\ &\le \delta^{-\beta}\int_{\omega_z}(|a|^{p-1}+|f-f_z|h_z)^{p'-2}h_z^2|f-f_z|^2\,dx\\ &+\delta\int_{\omega_z}G(|a|,|v\psi_z-v_z\varphi_z)|/h_z)\,dx.\end{aligned}\tag{6.30}$$

Here a is one of the discrete gradients $|\nabla u_h|$ on ω_z. Lemma 6.1 will be employed for $f-f_z$ and the functional $g(w)=\int_{\omega_z}w$ (so it vanishes for $w:=f-f_z$). Notice that a is replaced by $|a|^{p-1}$ and p is replaced by p'. Then we obtain

$$\begin{aligned}&\int_{\omega_z}(|a|^{p-1}+|f-f_z|h_z)^{p'-2}h_z^2|f-f_z|^2\,dx\\ &\quad\lesssim\int_{\omega_z}(|a|^{p-1}+h_z^2|\nabla f|)^{p'-2}h_z^4|\nabla f|^2\,dx.\end{aligned}\tag{6.31}$$

Arguing as we had done in proving (6.14)–(6.18), we deduce from (6.30)–(6.31) that

$$\begin{aligned}\int_{\omega_z}(f-f_z)h_z\,(v\psi_z-v_z\varphi_z)/h_z\,dx&\lesssim\delta\int_{\omega_z}G(|a|,|\nabla v|)\,dx\\ +\delta^{-\beta}\int_{\omega_z}&(|a|^{p-1}+h_z^2|\nabla f|)^{p'-2}h_z^4|\nabla f|^2\,dx.\end{aligned}\tag{6.32}$$

So far, a is a constant vector on ω_z. Depending on p', we choose a so that $|a|$ is minimal or maximal among $(|\nabla u_h|_{K'}:K'\in T_K)$, and thus

$$\int_{\omega_z}(|a|^{p-1}+h_z^2|\nabla f|)^{p'-2}h_z^4|\nabla f|^2\,dx\le\int_{\omega_z}(|\nabla u_h|^{p-1}+h_z^2|\nabla f|)^{p'-2}h_z^4|\nabla f|^2\,dx.$$

Arguing as in the first step of the proof of Lemma 6.3, we have

$$\begin{aligned}\int_{\omega_z}G(|a|,|\nabla v|)\,dx&\lesssim\int_{\omega_z}G(|\nabla u_h|,|\nabla v|)\,dx\\ &\quad+\sum_{K\in\omega_z}\min_{K'\in T_K}\int_{\cup E_K}G(|\nabla u_h|_{K'}|,|[\partial u_h/\partial n_\varepsilon]|)\,ds.\end{aligned}$$

Thus the desired estimate follows from (6.32) and the above two inequalities. □

REMARK 6.2. *It follows from the above proofs that Lemmas* 6.1–6.4 *hold for any continuous function* $G(\cdot,\cdot)$ *such that it is increasing* (*decreasing*) *as* $p\ge 2$ ($p\le 2$) *in the first argument, and is convex and increasing in the second argument.*

Next is a well-known trace theorem [KJF].

LEMMA 6.5. *For all* $v\in W^{1,q}(K)$, $1\le q<\infty$,

$$\|v\|_{0,q,\partial K}\lesssim h_K^{-\frac{1}{q}}\|v\|_{0,q,K}+h_K^{1-\frac{1}{q}}|v|_{1,q,K}.\tag{6.33}$$

We need a quasi-norm version of the trace theorem for polynomials.

LEMMA 6.6. *Let* $K\in T^h$ *and* v *be a polynomial of degree* $s\le k$. *Then*

$$h_K\int_{\partial K}(|\nabla u_h|+|\nabla v|)^{p-2}|\nabla v|^2\lesssim\int_K(|\nabla u_h|+|\nabla v|)^{p-2}|\nabla v|^2.\tag{6.34}$$

The generic constant depends only on k and the aspect ratio of the finite elements.

Proof. Because v is a polynomial in K, by an inverse inequality, we have that, for any $x \in K$,

$$|\nabla v(x)| \leq |v|_{1,\infty,K} \lesssim h_K^{-2} \int_K |\nabla v| \, .$$

Therefore, it follows from Jensen's inequality that

$$\begin{aligned} h_K \int_{\partial K} (|\nabla u_h| + |\nabla v|)^{p-2} |\nabla v|^2 &\lesssim h_K^2 \left(|\nabla u_h| + \int_K h_K^{-2} |\nabla v| \right)^{p-2} \left(\int_K h_K^{-2} |\nabla v| \right)^2 \\ &\leq \int_K (|\nabla u_h| + |\nabla v|)^{p-2} |\nabla v|^2. \qquad \square \end{aligned}$$

SOME NEW ERROR ESTIMATES OF A SEMIDISCRETE FINITE VOLUME ELEMENT METHOD FOR A PARABOLIC INTEGRO-DIFFERENTIAL EQUATION WITH NONSMOOTH INITIAL DATA*

RAJEN K. SINHA[†], RICHARD E. EWING[‡], AND RAYTCHO D. LAZAROV[§]

Abstract. A semidiscrete finite volume element (FVE) approximation to a parabolic integro-differential equation (PIDE) is analyzed in a two-dimensional convex polygonal domain. An optimal-order L^2-error estimate for smooth initial data and nearly the same optimal-order L^2-error estimate for nonsmooth initial data are obtained. More precisely, for homogeneous equations, an elementary energy technique and a duality argument are used to derive an error estimate of order $O\left(t^{-1}h^2 \ln h\right)$ in the L^2-norm for positive time when the given initial function is only in L^2.

Key words. parabolic equation, integro-differential equation, optimal-order error estimate, smooth and nonsmooth initial data

DOI. 10.1137/040612099

1. Introduction.

The aim of this paper is to analyze a semidiscrete finite volume element (FVE) method for solving initial-boundary value problems for an integro-differential equation of the form

$$\begin{aligned} (1.1) \qquad u_t - \nabla\cdot(\mathcal{A}\nabla u) &= -\int_0^t \nabla\cdot(\mathcal{B}\nabla u(s))ds + f(x,t) \ \text{ in } \ \Omega\times J,\\ u &= 0 \ \text{ on } \ \partial\Omega\times J,\\ u(\cdot,0) &= u_0 \ \text{ in } \ \Omega. \end{aligned}$$

Here, $\Omega \subset \mathbb{R}^2$ is a bounded convex polygonal domain with boundary $\partial\Omega$, $J=(0,T]$ with $T<\infty$, and $u_t = \partial u/\partial t$. Further, $\mathcal{A}=\{a_{i,j}(x)\}$ is a symmetric and uniformly positive definite matrix of size 2×2 in Ω and $\mathcal{B}=\{b_{i,j}(x,t,s)\}$ is a 2×2 matrix. The nonhomogeneous term $f=f(x,t)$ and the coefficients $a_{ij}(x)$, $b_{ij}(x;t,s)$ are assumed to be smooth for our purpose. For the sake of simplicity, we shall denote $Au = -\nabla\cdot(\mathcal{A}\nabla u)$ and $B(t,s)u(s) = -\nabla\cdot(\mathcal{B}\nabla u(s))$. For references to studies regarding existence, uniqueness, and regularity of such problems, one may refer to [33].

Parabolic integro-differential equations (PIDEs) of the above type arise naturally in many applications, such as, for instance, heat conduction in materials with memory [27], nonlocal reactive flows in porous media [10, 11], and non-Fickian flow of fluid in porous media [15]. One very important characteristic of these models is that they all

express the conservation of a certain quantity (mass, momentum, heat, etc.) in any moment for any subdomain. This in many applications is the most desirable feature of the approximation method when it comes to numerical solution of the corresponding initial-boundary value problem. For references to studies of existence, uniqueness, and regularity of such problems, one may refer to [33].

To put our work into proper perspective, we first give a brief account of the development of the finite element methods for such problems. Over the last decade, various numerical methods based on finite element approximations in space and special quadrature in time have been developed and studied for this type of problem [20, 24, 25, 29, 31, 32, 34]. The crucial tools used in the analysis are the Ritz and Ritz–Volterra projections which are instrumental in deriving optimal-order error estimates in various Sobolev norms [5, 6, 20]. In [31], the authors studied this type of problem for both smooth and nonsmooth initial data cases. In particular, for a homogeneous equation with nonsmooth initial data, an optimal-order L^2-error estimate is proved via a semigroup theoretic approach. Subsequently, using the energy method, the authors of [25] derived convergence of order $O\big(\frac{h^2}{t}\big)$ for the L^2-norm and $O\big(\frac{h^2}{t}\log(\frac{1}{h})\big)$ for the L^∞-norm for the homogeneous equation when the initial function is in $H_0^1(\Omega)\cap H^2(\Omega)$. Recently, in [26], the analysis from [21] of the case $B(t,s)=0$ was carried over to a time dependent PIDE. An optimal-order error estimate by energy techniques and a duality argument for the homogeneous equation with both smooth and nonsmooth initial data were carried over. In both [21] and [26], negative norm estimates are used in a crucial way in their analyses. In the absence of the memory term, i.e., when $B(t,s)\equiv 0$, the error estimates for finite element methods for both smooth and nonsmooth data cases are described in [2, 18, 28, 30] and the references cited therein.

In recent years, the numerical methods for problem (1.1) by means of FVE discretizations were considered in [13] and [14]. The interest in such methods is due to certain conservation features of FVE methods that are desirable in many applications. In [13] and [14], the authors studied FVE approximation of such a problem in the framework of the standard Petrov–Galerkin formulation and obtained L^2-error estimate of the form (cf. [14, p. 305])

$$\begin{aligned}\|u(t)-u_h(t)\| \le{}& Ch^2(\|u_0\|_{3,p}+\|u(t)\|_{3,p}\\ &+\int_0^t(\|u(s)\|_{3,p}+\|u_t(s)\|_{3,p})ds), \quad p>1,\end{aligned} \tag{1.2}$$

where u and u_h represent the solution of (1.1) and its FVE approximation, respectively. Note that the estimate (1.2) is optimal with respect to the approximation property, but its regularity requirement on the exact solution seems to be too high when compared with that for finite element methods. This is primarily due to the fact that the bounds in the L^2-norm of a new variant of the Ritz–Volterra projection (the so-called Petrov–Volterra projection introduced in [13, 14]) are not optimal with respect to the regularity of the solution.

In this paper, we analyze the FVE method for the problem (1.1) and derive optimal-order L^2-error estimates for both smooth and nonsmooth initial data. For the homogeneous problem with smooth initial data, we are able to show an L^2-error estimate which is optimal with respect to the order of convergence as well as the regularity of the solution. This is exactly the result known for finite element methods (cf. [25]). More precisely, we prove an optimal-order L^2-error estimate for $f=0$ and initial data $u_0\in H^2(\Omega)\cap H_0^1(\Omega)$. This technique, quite new and promising, is based on improved estimates for a new variant of the Ritz–Volterra projection (see

Theorems 3.1 and 3.2).

The main concern of this paper is to prove an L^2-error estimate for the homogeneous equation ($f = 0$) with nonsmooth initial data. This is motivated by the fact that the solutions of a homogeneous linear parabolic equation have the so-called *smoothing property.* That is, the solution is smooth for positive time t, even when the initial data are not. In quantitative form, this may be expressed by the inequality

$$\|u(t)\|_\alpha \leq Ct^{-\alpha/2}\|u_0\|, \quad t \in J, \tag{1.3}$$

which is valid for any $\alpha \geq 0$. Here $\|\cdot\|_\alpha$ is a Sobolev norm. However, this is not the case with PIDEs as they have a limited smoothing property. This fact is proved in [31], where the inequality (1.3) is shown to be valid only for $\alpha \leq 2$. Since the smoothing property plays a significant role in the error analysis in the semidiscrete solution, an attempt has been made in this paper to derive an L^2-error estimate for the FVE method when the initial data u_0 is only in $L^2(\Omega)$. More importantly, our analysis uses only energy techniques and a duality argument.

The proposed techniques have several attractive features. Unlike the analyses of [21] and [26], we do not require error estimates in negative-indexed Sobolev norms while dealing with L^2-error estimates with nonsmooth initial data. Thus, these results hold for convex polygonal domains with corners, unlike [21] and [26]. Since the FVE method is thought of as a perturbation of the Galerkin finite element method, the proposed technique can easily be adopted to the finite element method as well. However, to the best of our knowledge the error estimates for nonsmooth initial data using the FVE method were not established earlier.

The previous work on the theoretical framework and the basic tools for the analysis of the FVE methods for elliptic and parabolic problems are described in [3, 4, 9, 7, 8, 12, 16, 17, 19, 22, 23] and references therein.

The outline of this paper is as follows. In section 2, we introduce some notation, formulate FVE approximations for piecewise linear finite element spaces defined on a triangulation, and recall some basic estimates from the literature. Further, the Ritz–Volterra projection is introduced and related estimates are obtained in section 3. Section 4 is devoted to the error estimates for smooth initial data. Finally, error estimates with nonsmooth initial data are carried out in section 5.

Throughout this paper C denotes a generic positive constant which does not depend on the mesh parameter h but may depend on T.

2. Notation and preliminaries.

Let $H_0^1(\Omega) = \{\phi \in H^1(\Omega) \mid \phi = 0 \text{ on } \partial\Omega\}$. Further, let $A(\cdot,\cdot)$ and $B(t,s;\cdot,\cdot)$ be the bilinear forms on $H_0^1(\Omega) \times H_0^1(\Omega)$ given by

$$A(u,v) = \int_\Omega \mathcal{A}(x)\nabla u \cdot \nabla v dx; \quad B(t,s;u(s),v) = \int_\Omega \mathcal{B}(x,t,s)\nabla u(s) \cdot \nabla v dx. \tag{2.1}$$

For the purpose of FVE approximations we now consider the following weak formulation: Find $u : \bar{J} \to H_0^1(\Omega)$ such that

$$(u_t, v) + A(u,v) = \int_0^t B(t,s;u(s),v)ds + (f,v) \quad \forall v \in H_0^1(\Omega), \quad t \in J, \tag{2.2}$$

with $u(0) = u_0$.

Here and below, $(\cdot,\cdot)$ and $\|\cdot\|$ denote the L^2 inner product and the induced norm on $L^2(\Omega)$. Further, we shall use the standard notation for Sobolev spaces $W^{m,p}(\Omega)$

with $1 \leq p \leq \infty$. The norm on $W^{m,p}(\Omega)$ is defined by

$$\|u\|_{m,p,\Omega} = \|u\|_{m,p} = \left(\int_{\Omega} \sum_{|\alpha| \leq m} |D^{\alpha} u|^p dx \right), \quad 1 \leq p < \infty,$$

with the standard modification for $p = \infty$. When $p = 2$, we write $W^{m,2}(\Omega)$ by $H^m(\Omega)$ and denote the norm by $\| \cdot \|_m$. Further, $H^{-1}(\Omega)$ denotes the space of all bounded linear functionals on $H_0^1(\Omega)$. For a functional $f \in H^{-1}(\Omega)$, its action on a function $u \in H_0^1(\Omega)$ is denoted by (f, u), which represents the duality pairing between $H^{-1}(\Omega)$ and $H_0^1(\Omega)$. To simplify notation, we use $(\cdot, \cdot)$ to denote both the $L^2(\Omega)$ inner product and the duality pairing between $H^{-1}(\Omega)$ and $H_0^1(\Omega)$.

2.1. A priori estimates. In the following lemmas, we state some a priori bounds for the solution u satisfying (1.1) under appropriate regularity assumptions on the initial function u_0. For a proof, one may refer to [25, 26, 21].

LEMMA 2.1. *Let u satisfy* (1.1). *If $u_0 \in L^2(\Omega)$ and $f \in L^2(\Omega)$, then*

$$\|u(t)\|^2 + \int_0^t \|u(s)\|_1^2 ds \leq C \left(\|u_0\|^2 + \int_0^t \|f(s)\|^2 ds \right).$$

Moreover, when $u_0 \in H_0^1(\Omega)$ and $f \in L^2(\Omega)$, we have

$$\|u(t)\|_1^2 + \int_0^t \{\|u_s(s)\|^2 + \|u(s)\|_2^2\} ds \leq C \left(\|u_0\|_1^2 + \int_0^t \|f(s)\|^2 ds \right).$$

LEMMA 2.2. *Let u satisfy* (1.1). *If $u_0 \in H^2(\Omega) \cap H_0^1(\Omega)$ and $f \in L^2(\Omega)$, then*

$$\|u_t(t)\|^2 + \int_0^t \|u_s(s)\|_1^2 ds \leq C \left(\|u_t(0)\|^2 + \int_0^t \|f(s)\|^2 ds \right).$$

LEMMA 2.3. *Let u satisfy* (1.1) *with $f = 0$, and let $0 \leq i, j, k \leq 2$. If $0 \leq k + 2j - i \leq 2$, then*

$$t^i \left\| \frac{\partial^j u}{\partial t^j}(t) \right\|_k^2 \leq C \|u_0\|_{k+2j-i}^2.$$

Further, if $0 \leq k + 2j - i - 1 \leq 2$, then

$$\int_0^t s^i \left\| \frac{\partial^j u}{\partial s^j}(s) \right\|_k^2 ds \leq C \|u_0\|_{k+2j-i-1}^2.$$

2.2. FVE approximation. Let T_h be a quasi-uniform family of triangulations of Ω such that $\bar{\Omega} = \cup_{K \in T_h} K$, where K is a closed triangle element. Let N_h be the set of all nodes or vertices of T_h, i.e.,

$$N_h = \{p \ : \ p \text{ is a vertex of element } K \in T_h \text{ and } p \in \bar{\Omega}\}.$$

Further, we denote $N_h^0 = N_h \cap \Omega$. For a vertex $x_i \in N_h$, let $\Pi(i)$ be the index set of those vertices that, along with x_i, are in some element of T_h.

For a given triangulation T_h, we now introduce a dual mesh T_h^* as follows: In each element $K \in T_h$ with vertices x_i, x_j, and x_k, select a point $q \in K$, select a point

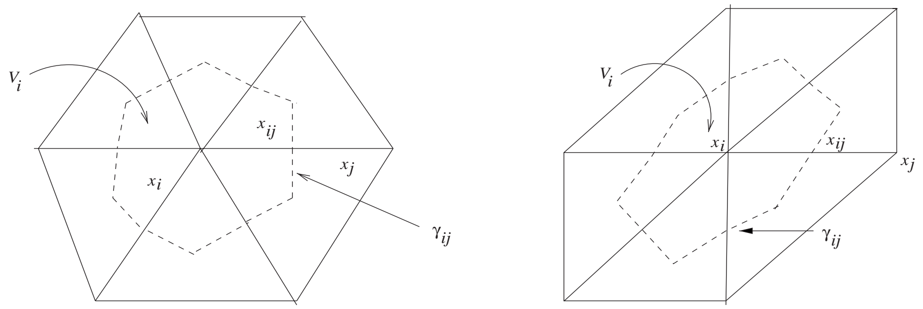

FIG. 2.1. *Control volumes with barycenter as internal point and interface γ_{ij} of V_i and V_j.*

x_{ij} on the edge connecting x_i and x_j, and connect q with x_{ij} by straight lines $\gamma_{ij,K}$. Then for a vertex x_i we let V_i be the polygon whose edges are $\gamma_{ij,K}$ in which x_i is a vertex of the element K. We call this V_i a *control volume* centered at x_i. Further, we note that $\cup_{x_i \in N_h} V_i = \bar{\Omega}$. Thus, the dual mesh T_h^* is then defined as the collection of these *control volumes.* A *control volume* centered at a vertex x_i is given in Figure 2.1.

We call the control volume mesh T_h^* regular or quasi-uniform if there exists a positive constant $C > 0$ such that

$$C^{-1}h^2 \leq \text{meas}(V_i) \leq Ch^2 \quad \forall\, V_i \in T_h^*,$$

where h is the maximum diameter of all elements $K \in T_h$.

There are various ways to introduce a regular dual mesh T_h^* depending on the choices of the point q in an element $K \in T_h$ and the points x_{ij} on its edges. In this paper, we choose q to be the barycenter of an element $K \in T_h$, and the points x_{ij} are chosen to be the midpoints of the edges of K. Obviously, if T_h is regular, i.e., there is a constant C such that

$$Ch_K^2 \leq \text{meas}(K) \leq h_K^2,$$

where $h_K = \text{diam}(K)$ for all elements $K \in T_h$, then the dual mesh T_h^* is also regular. For the purpose of FVE approximation, let S_h be the standard linear finite element space defined on the triangulation T_h,

$$S_h = \{v \in C(\Omega) \;:\; v|_K \text{ is linear } \forall\ K \in T_h \text{ and } v|_{\partial\Omega} = 0\},$$

and its dual volume element space S_h^*,

$$S_h^* = \{v \in L^2(\Omega) \;:\; v|_V \text{ is constant } \forall\ V \in T_h^* \text{ and } v|_{\partial\Omega} = 0\}.$$

Obviously, $S_h = \text{span}\{\phi_i(x) \;:\; x_i \in N_h^0\}$ and $S_h^* = \text{span}\{\psi_i(x) \;:\; x_i \in N_h^0\}$, where ϕ_i are the standard nodal basis functions associated with the node x_i, and ψ_i are the characteristic functions of the volume V_i. Let $I_h \;:\; C(\Omega) \to S_h$ and $I_h^* \;:\; C(\Omega) \to S_h^*$ be the usual interpolation operators, i.e.,

$$I_h u(x) = \sum_{x_i \in N_h} u_i \phi_i(x) \quad \text{and} \quad I_h^* u(x) = \sum_{x_i \in N_h} u_i \psi_i(x),$$

where $u_i = u(x_i)$.

The FVE approximation is then defined to be the function $u_h : \bar{J} \to S_h$ such that

$$(u_{ht}, I_h^*\chi) + A(u_h, I_h^*\chi) = \int_0^t B(t, s; u_h(s), I_h^*\chi)ds + (f, I_h^*\chi) \quad \forall \chi \in S_h. \tag{2.3}$$

Here $u_h(0) = \tilde{P}_h u_0$, where $\tilde{P}_h u_0$ is the L^2-projection of u_0 onto S_h defined by

$$(\tilde{P}_h u_0, I_h^*\chi) = (u_0, I_h^*\chi) \quad \forall \chi \in S_h, \tag{2.4}$$

the bilinear forms $A(\cdot,\cdot)$ and $B(t, s; \cdot, \cdot)$ in (2.3) are defined by

$$A(u, v) = -\sum_{x_i \in N_h} v_i \int_{\partial V_i} \mathcal{A}(x)\nabla u \cdot \mathbf{n} dS_x,$$

$$B(t, s; u, v) = -\sum_{x_i \in N_h} v_i \int_{\partial V_i} \mathcal{B}(x, t, s)\nabla u \cdot \mathbf{n} dS_x$$

for $(u, v) \in ((H_0^1 \cap H^2) \cup S_h) \times S_h^*$, and $\mathbf{n}$ is the outer-normal vector of the involved integration domain. Note that when $(u, v) \in H_0^1(\Omega) \times H_0^1(\Omega)$, the bilinear forms $A(\cdot,\cdot)$ and $B(t, s; \cdot, \cdot)$ are given by (2.1).

In order to describe features of the bilinear forms defined in (2.2) and (2.3), we use some discrete norms on S_h and S_h^*,

$$|u_h|_{0,h}^2 = (u_h, u_h)_{0,h}, \quad |u_h|_{1,h}^2 = \sum_{x_i \in N_h} \sum_{x_j \in \Pi(i)} \text{meas}(V_i)((u_{hi} - u_{hj})/d_{ij}^2,$$

$$\|u_h\|_{1,h}^2 = |u_h|_{0,h}^2 + |u_h|_{1,h}^2, \qquad |||u_h|||^2 = (u_h, I_h^* u_h),$$

where $(u_h, v_h)_{0,h} = \sum_{x_i \in N_h} \text{meas}(V_i) u_{hi} v_{hi} = (I_h^* u_h, I_h^* v_h)$ and $d_{ij} = d(x_i, x_j)$ is the Euclidean distance between x_i and x_j.

The discrete norms $|\cdot|_{0,h}$ and $\|\cdot\|_{1,h}$ are equivalent to the usual norms $\|\cdot\|$ and $\|\cdot\|_1$, respectively, on S_h. Some properties of the bilinear forms are stated below without proof. For a proof, see, e.g., [1, 12, 14].

Lemma 2.4. *There exist positive constants C_1 and C_2 such that for all $v_h \in S_h$, we have*

$$C_1 |v_h|_{0,h} \le \|v_h\| \le C_2 |v_h|_{0,h},$$

$$C_1 |||v_h||| \le \|v_h\| \le C_2 |||v_h|||,$$

$$C_1 \|v_h\|_{1,h} \le \|v_h\|_1 \le C_2 \|v_h\|_{1,h}.$$

Lemma 2.5. *There exist positive constants C and c such that for all $\phi_h, \psi_h \in S_h$, we have*

$$|A(\phi_h, I_h^* \psi_h)| \le C\|\phi_h\|_1 \|\psi_h\|_1,$$

$$|B(t, s; \phi_h, \psi_h)| \le C\|\phi_h\|_1 \|\psi_h\|_1,$$

and

$$A(\phi_h, I_h^* \phi_h) \ge c\|\phi_h\|_1^2.$$

Lemma 2.6. *If the matrix $\mathcal{A}(x)$ is constant over each element $K \in T_h$, then we have*

$$A(u_h, \chi) = A(u_h, I_h^*\chi) \quad \forall u_h, \chi \in S_h.$$

Following the arguments of Lemma 2.3 on the discrete level, it is easy to derive the following stability estimates for the FVE solution u_h satisfying (2.3).

LEMMA 2.7. *Let u_h satisfy (2.3) with $f = 0$. Then we have*

$$\|u_h(t)\|^2 + \int_0^t \|u_h(s)\|_1^2 ds \le C\|u_h(0)\|^2,$$
$$\int_0^t s\|u_{hs}(s)\|^2 + t\|u_h(t)\|_1^2 ds \le C\|u_h(0)\|^2,$$
$$t^2\|u_{ht}(t)\|^2 + \int_0^t s^2\|u_{hs}(s)\|_1^2 ds \le C\|u_h(0)\|^2.$$

The following lemma gives the key feature of the bilinear forms in the FVE method. For a proof, see [12] or [7].

LEMMA 2.8. *Let $\phi \in H_0^1(\Omega)$. Then we have*

$$\begin{aligned} A(\phi,\chi) = A(\phi, I_h^*\chi) &+ \sum_{K\in T_h}\int_{\partial K}(A\nabla\phi\cdot\mathbf{n})(\chi - I_h^*\chi)dS \\ &- \sum_{K\in T_h}\int_K(\nabla\cdot A\nabla\phi)(\chi - I_h^*\chi)dx \quad \forall\chi\in S_h. \end{aligned}$$

The above identity holds true when $A(\cdot,\cdot)$ is replaced by $B(t,s;\cdot,\cdot)$.

Remark 2.9. We note that the above identity is proved in [12, 7] for $\phi, \chi \in S_h$. In fact, identities in Lemma 2.8 holds true even if $\phi \in H_0^1(\Omega)$.

3. Ritz–Volterra projection and related estimates. Following Lin et al. [20], we define the Ritz–Volterra projection $W_h u$ of a function $u(x,t)$ defined on $\Omega \times \bar{J}$ in the context of the FVE method and obtain bounds for the error in H^1 and L^2 norms. The Ritz–Volterra projection $W_h : L^\infty(H_0^1 \cap H^2) \to L^\infty(S_h)$ is defined by

$$A((u - W_h u)(t), I_h^*\chi) = \int_0^t B(t,s;(u - W_h u)(s), I_h^*\chi)ds \;\; \forall\,\chi\in S_h,\; t\in\bar{J}. \tag{3.1}$$

Below, we shall prove a lemma which is frequently used in our subsequent analysis.

LEMMA 3.1. *For any function $\phi \in H^r(\Omega)(r = 0, 1)$, we have*

$$|(\phi, \chi - I_h^*\chi)| \le Ch^{1+r}\|\phi\|_r\|\chi\|_1 \;\; \forall\,\chi\in S_h. \tag{3.2}$$

Further, for $\phi \in H_0^1(\Omega)$, we have

$$|A(\phi, \chi - I_h^*\chi)| \le Ch\|\phi\|_1\|\chi\|_1 \quad \forall\,\chi\in S_h. \tag{3.3}$$

The second inequality also holds true when $A(\cdot,\cdot)$ is replaced by $B(t,s;\cdot,\cdot)$.

Proof. We borrow the proof of (3.2) from [8]. To show (3.3), we have [7]

$$\begin{aligned} A(\phi, \chi - I_h^*\chi) = &- \sum_{K\in T_h}\int_K(\nabla\cdot\mathcal{A}\nabla\phi)(\chi - I_h^*\chi)dx \\ &+ \sum_{K\in T_h}\int_{\partial K}((\mathcal{A} - \bar{\mathcal{A}}_K)\nabla\phi\cdot\mathbf{n})(\chi - I_h^*\chi)dS. \end{aligned} \tag{3.4}$$

Here, $\bar{\mathcal{A}}_K$ is a function designed in a piecewise manner such that for any edge E of a triangle $K \in T_h$ and $x \in E$, $\bar{\mathcal{A}}_K(x) = \mathcal{A}(x_c)$, where x_c is the midpoint of E. Applying the Cauchy–Schwarz inequality and using the fact that $\|\chi - I_h^*\chi\| \le Ch\|\chi\|_1$ and $|\mathcal{A}(x) - \bar{\mathcal{A}}_K| \le h\|\mathcal{A}\|_{1,\infty}$, we obtain

$$|A(\phi, \chi - I_h^*\chi)| \le Ch\|\phi\|_1\|\chi\|_1,$$

and this completes the proof. □

Set $\rho = u - W_h u$. We now establish the H^1-error estimate for ρ and its temporal derivative.

THEOREM 3.1. *Let $W_h u$ be defined by* (3.1). *Then we have*

$$\|\rho(t)\|_1 \le Ch\left(\|u(t)\|_2 + \int_0^t \|u(s)\|_2 ds\right),$$
$$\|\rho_t(t)\|_1 \le Ch\left(\|u(t)\|_2 + \|u_t(t)\|_2 + \int_0^t \|u(s)\|_2 ds\right).$$

Proof. With $\phi_h = I_h u - W_h u$, we have

$$\begin{aligned} c\|\rho\|_1^2 \le A(\rho,\rho) &= A(\rho, u - I_h u) + A(\rho, I_h u - W_h u) \\ &= A(\rho, u - I_h u) + A(\rho, \phi_h - I_h^*\phi_h) + \int_0^t B(t,s;\rho(s), I_h^*\phi_h)ds. \end{aligned}$$

An application of (3.3) yields

$$c\|\rho\|_1^2 \le Ch(\|u\|_2 + \|u\|_1)\|\rho\|_1 + C\left(\int_0^t \|\rho\|_1 ds\right)(\|\rho\|_1 + h\|u\|_2),$$

where for the last term on the right we have used the fact that $\|\phi_h\|_1 \le C(\|\rho\|_1 + h\|u\|_2)$. Kicking back $\|\rho\|_1$, we get

$$\|\rho\|_1^2 \le C\left(h^2\|u\|_2^2 + \int_0^t \|\rho\|_1^2 ds\right).$$

Now applying Gronwall's lemma, we obtain the first inequality. To estimate $\|\rho_t\|_1$, we differentiate (3.1) with respect to time t to get

$$A(\rho_t, I_h^*\chi) = B(t,t,\rho(t), I_h^*\chi) + \int_0^t B_t(t,s;\rho(s), I_h^*\chi)ds. \tag{3.5}$$

As before, with $\phi_h = I_h u_t - W_h u_t$ we obtain

$$\begin{aligned} c\|\rho_t\|_1^2 \le A(\rho_t,\rho_t) = A(\rho_t, u_t - I_h u_t) + A(\rho_t, \phi_h - I_h^*\phi_h) + B(t,t,\rho(t), I_h^*\phi_h) \\ + \int_0^t B_t(t,s;\rho(s), I_h^*\phi_h)ds. \end{aligned}$$

Now apply (3.3), the estimate of $\|\rho\|_1$, and the standard kickback argument to obtain the second inequality. □

Next, we derive L^2 estimates for $\rho = u - W_h u$ and its temporal derivative in the following theorem.

Theorem 3.2. *Let $W_h u$ be defined by* (3.1). *Then we have*

$$\|\rho(t)\| \le Ch^2 \left(\|u(t)\|_2 + \int_0^t \|u(s)\|_2 ds \right),$$
$$\|\rho_t(t)\| \le Ch^2 \left(\|u(t)\|_2 + \|u_t(t)\|_2 + \int_0^t \|u(s)\|_2 ds \right).$$

Proof. The proof will proceed by the duality argument. For $t \in (0,T)$ let $\psi(t) \in H^2(\Omega) \cap H_0^1(\Omega)$ be the solution of

$$\begin{aligned} A\psi &= \rho \quad \text{in } \Omega, \\ \psi &= 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{3.6}$$

satisfying the following regularity estimate (recall that Ω is convex):

$$\|\psi\|_2 \le C\|\rho\|. \tag{3.7}$$

Multiplying (3.6) by ρ and then integrating over Ω, we obtain

$$\begin{aligned} \|\rho\|^2 &= A(\rho, \psi - I_h\psi) + A(\rho, I_h\psi - I_h^*(I_h\psi)) \\ &\quad + \int_0^t B(t,s;\rho(s), I_h^*(I_h\psi) - I_h\psi) ds + \int_0^t B(t,s;\rho(s), I_h\psi - \psi) ds \\ &\quad + \int_0^t B(t,s;\rho(s),\psi) ds = I_1 + I_2 + I_3 + I_4 + I_5. \end{aligned}$$

In view of Theorem 3.1, I_1 and I_4 are bounded as

$$|I_1| + |I_4| \le Ch^2 \left(\|u\|_2 + \int_0^t \|u\|_2 ds \right) \|\psi\|_2.$$

For I_2 and I_3, an application of Lemma 3.3 and Theorem 3.1 yields

$$|I_2| + |I_3| \le Ch \left(\|\rho\|_1 + \int_0^t \|\rho\|_1 ds \right) \|\psi\|_1 \le Ch^2 \left(\|u\|_2 + \int_0^t \|u\|_2 ds \right) \|\psi\|_1.$$

Finally, I_5 is estimated as

$$|I_5| \le \left| \int_0^t (\rho(s), B^*(t,s)\psi) \right| ds \le C \left(\int_0^t \|\rho\| ds \right) \|\psi\|_2,$$

where $B^*(t,s)$ is the adjoint of $B(t,s)$. Now putting these estimates together and with an aid of (3.7) we obtain

$$\|\rho\| = Ch^2 \left(\|u\|_2 + \int_0^t \|u\|_2 ds \right) + C \int_0^t \|\rho\| ds.$$

Finally, an application of Gronwall's lemma yields the first estimate. To estimate $\|\rho_t\|$, we again use the duality argument, (3.5), and the estimate of $\|\rho\|$ to complete the proof. □

Remark 3.2. (i) The estimates in Theorem 3.2 are optimal with respect to the order of convergence as well as the regularity requirement on the solution. This improves upon the earlier result of [13] and [14] by requiring less regularity on the solution.

(ii) In the absence of an integral term (when $B(t,s)=0$), as a consequence of Theorems 3.1 and 3.2, error estimates associated with the Petrov–Ritz projection $R_h : H_0^1 \to S_h$ defined by

$$A(R_h u - u, I_h^* \chi) = 0 \ \ \forall \, \chi \in S_h, \ \ t \in \bar{J},$$

can easily be obtained. Thus, we immediately have

$$\|R_h u - u\| + h\|R_h u - u\|_1 \le Ch^j \|u\|_j, \ \ u \in H_0^1(\Omega) \cap H^j(\Omega), \ \ j = 1, 2. \tag{3.8}$$

Below, we shall prove a lemma which is crucial for the error estimate in the case of nonsmooth initial data to be discussed in section 5.

Define $\hat{\rho}(t) = \int_0^t \rho(\tau) d\tau$. Then, integrating by parts we rewrite (3.1) as

$$\begin{aligned} A(\hat{\rho}_t(t), I_h^* \chi) &= \int_0^t B(t,s;\hat{\rho}_s(s), I_h^* \chi) ds \\ &= B(t,t,\hat{\rho}, I_h^* \chi) - \int_0^t B_s(t,s;\hat{\rho}(s), I_h^* \chi) ds. \end{aligned}$$

Integrate from 0 to t to obtain

$$A(\hat{\rho}(t), I_h^* \chi) = \int_0^t B(s,s,\hat{\rho}(s), I_h^* \chi) ds - \int_0^t \int_0^s B_s(s,\tau;\hat{\rho}(\tau), I_h^* \chi) d\tau ds. \tag{3.9}$$

LEMMA 3.2. *Let u be the solution of the initial value problem* (1.1) *with* $f = 0$ *and* $\hat{\rho}(t) = \int_0^t (u - W_h u)(s) ds$. *Then we have*

$$\|\hat{\rho}\| + h\|\hat{\rho}\|_1 \le Ch^2 \|u_0\|.$$

Proof. With $\phi_h = I_h \hat{u} - W_h \hat{u}$, we have

$$\begin{aligned} c\|\hat{\rho}\|_1^2 &\le A(\hat{\rho},\hat{\rho}) = A(\hat{\rho}, \hat{u} - I_h \hat{u}) + A(\hat{\rho}, I_h \hat{u} - W_h \hat{u}) \\ &\le A(\rho, \hat{u} - I_h \hat{u}) + A(\hat{\rho}, \phi_h - I_h^* \phi_h) + \int_0^t B(s,s;\hat{\rho}(s), I_h^* \phi_h) ds \\ &\quad - \int_0^t \int_0^s B_s(s,\tau;\hat{\rho}(\tau), I_h^* \phi_h) d\tau ds, \end{aligned}$$

where $\hat{u}(t) = \int_0^t u(s) ds$. Then proceeding as in the estimate of $\|\rho\|_1$ in Theorem 3.1 we obtain

$$\|\hat{\rho}\|_1 \le Ch \left(\|\hat{u}\|_2 + \int_0^t \|\hat{u}\|_2 ds \right). \tag{3.10}$$

Now it remains to estimate $\|\hat{u}\|_2$. From (1.1) with $f = 0$, we have

$$Au = -u_t + \int_0^t B(t,s)\hat{u}_s(s) ds = -u_t + B(t,t)\hat{u}(t) - \int_0^t B_s(t,s)\hat{u}(s) ds.$$

Integrating from 0 to t and then using elliptic regularity and Lemma 2.1, we obtain

$$\|\hat{u}\|_2 \le \|u_0\| + \|u(t)\| + C\int_0^t \|\hat{u}\|_2 ds \le C\|u_0\| + C\int_0^t \|\hat{u}\|_2 ds.$$

Now an application of Gronwall's lemma yields

$$\|\hat{u}\|_2 \le C\|u_0\|. \tag{3.11}$$

Combine (3.10) and (3.11) to obtain $\|\hat{\rho}\|_1$. Next, using (3.9), the proof technique of $\|\rho\|$ in Theorem 3.2, and (3.11), the estimate of $\|\hat{\rho}\|$ can be easily obtained. This completes the rest of the proof. □

4. Error estimates for problems with smooth initial data. In this section, we estimate the error of the semidiscrete FVE method for problems with smooth initial data. In particular, an optimal-order L^2-error estimate is obtained when $u_0 \in H_0^1(\Omega) \cap H^2(\Omega)$.

As usual we write the error $e(t) = u(t) - u_h(t)$ as a sum of two terms $e(t) = (u - W_h u) + (W_h u - u_h) = \rho + \theta$. The estimate of $\|\rho\|$ is already established, so it is enough to estimate $\|\theta\|$. Using (2.3), an equation of the form (2.3) with u_h replaced by u, and (3.1), it is easy to verify that θ satisfies an error equation of the form

$$(\theta_t, I_h^*\chi) + A(\theta, I_h^*\chi) = \int_0^t B(t,s;\theta(s), I_h^*\chi)ds - (\rho_t, I_h^*\chi) \ \ \forall \chi \in S_h. \tag{4.1}$$

Analogously, integrating (2.3) from 0 to t and then using the resulting equation with u_h replaced by u, (3.9), and $u_h(0) = \tilde{P}_h u_0$, we obtain an error equation in $\hat{\theta}$ as

$$\begin{aligned}(\hat{\theta}_t, I_h^*\chi) + A(\hat{\theta}, I_h^*\chi) = &\int_0^t B(s,s;\hat{\theta}(s), I_h^*\chi)ds \\ &- \int_0^t \int_0^s B_\tau(s,\tau;\hat{\theta}(\tau), I_h^*\chi)d\tau ds - (\rho, I_h^*\chi), \ \ \chi \in S_h,\end{aligned} \tag{4.2}$$

where $\hat{\theta}(t) = \int_0^t \theta(s)ds$. Below, we shall prove a sequence of lemmas that will lead us to the desired result.

LEMMA 4.1. *There is a positive constant C such that*

$$\|\hat{\theta}(t)\|^2 + \int_0^t \|\hat{\theta}(s)\|_1^2 ds \le C \int_0^t \|\rho(s)\|^2 ds.$$

Proof. Choose $\chi = \hat{\theta}$ in (4.2) to have

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}(\hat{\theta}, I_h^*\hat{\theta}) + A(\hat{\theta}, I_h^*\hat{\theta}) = &\int_0^t B(s,s;\hat{\theta}(s), I_h^*\hat{\theta}(t))ds \\ &- \int_0^t \int_0^s B_\tau(s,\tau;\hat{\theta}(\tau), I_h^*\hat{\theta})d\tau ds - (\rho, I_h^*\hat{\theta}).\end{aligned}$$

Integrating from 0 to t and using the standard kickback argument yield

$$\|\hat{\theta}(t)\|^2 + \int_0^t \|\hat{\theta}(s)\|_1^2 ds \le C \int_0^t \|\rho(s)\|^2 ds + C \int_0^t \int_0^s \|\hat{\theta}(\tau)\|_1^2 d\tau ds.$$

Finally, apply Gronwall's lemma to complete the rest of the proof. □

LEMMA 4.2. *There is a positive constant C such that*

$$\int_0^t \|\theta(s)\|^2 ds + \|\hat{\theta}(t)\|_1^2 \le C \int_0^t \|\rho(s)\|^2 ds.$$

Proof. Take $\chi = \theta$ in (4.2) and integrate from 0 to t to have

$$\begin{aligned}\int_0^t (\theta, I_h^*\theta)ds + \frac{1}{2}A(\hat{\theta}, I_h^*\hat{\theta}) &= \int_0^t \int_0^s B(\tau,\tau;\hat{\theta}(\tau), I_h^*\theta(s))d\tau ds \\ &\quad - \int_0^t \int_0^s \int_0^\tau B_{\tau'}(\tau,\tau';\hat{\theta}(\tau'), I_h^*\theta(s))d\tau' d\tau ds - (\rho, I_h^*\theta) \\ &= I_1 + I_2 + I_3.\end{aligned}$$

For I_1, we note that

$$\begin{aligned}I_1 &= \int_0^t \int_\tau^t B(\tau,\tau;\hat{\theta}(\tau), I_h^*\hat{\theta}_s(s))dsd\tau \\ &= \int_0^t B(\tau,\tau;\hat{\theta}(\tau), I_h^*\hat{\theta}(t))d\tau ds - \int_0^t B(\tau,\tau;\hat{\theta}(\tau), I_h^*\hat{\theta}(\tau))d\tau.\end{aligned}$$

Similarly, we rewrite the term I_2. Now use the standard kickback argument to obtain

$$\int_0^t \|\theta(s)\|^2 ds + \|\hat{\theta}\|_1^2 \le C\int_0^t \|\hat{\theta}\|_1^2 ds + C\int_0^t \|\rho\|^2 ds.$$

Finally, an application of Lemma 4.1 completes the rest of the proof. □

LEMMA 4.3. *There is a positive constant C such that*

$$t\|\theta(t)\|^2 + \int_0^t s\|\theta(s)\|_1^2 ds \le C\int_0^t \{\|\rho(s)\|^2 + s^2\|\rho_s(s)\|^2\}ds.$$

Proof. Take $\chi = t\theta$ in (4.1) and integrate by parts to have

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\{t(\theta, I_h^*\theta)\} + tA(\theta, I_h^*\theta) &= \frac{1}{2}(\theta, I_h^*\theta) + tB(t,t;\hat{\theta}(t), I_h^*\theta(t)) \\ &\quad - \int_0^t tB_s(t,s;\hat{\theta}(s), I_h^*\theta(t))ds - t(\rho_t, I_h^*\theta).\end{aligned}$$

Integrating from 0 to t and applying the standard kickback argument, we obtain

$$\begin{aligned}t\|\theta(t)\|^2 + c\int_0^t s\|\theta(s)\|_1^2 ds &\le C\int_0^t \|\hat{\theta}(s)\|_1^2 ds + C\int_0^t \int_0^s \|\hat{\theta}(\tau)\|_1^2 d\tau ds \\ &\quad + C\int_0^t \{\|\theta\|^2 + s^2\|\rho_s\|^2\}ds.\end{aligned}$$

Then use Lemmas 4.1 and 4.2 to complete the proof. □

The main result of this section is given in the following theorem.

THEOREM 4.1. *Let u and u_h, respectively, satisfy* (1.1) *and* (2.3) *with* $f = 0$. *Then for $u_0 \in H^2(\Omega) \cap H_0^1(\Omega)$ and $u_h(0) = \tilde{P}_h u_0$, we have*

$$\|e(t)\| \le Ch^2\|u_0\|_2.$$

Proof. By the triangle inequality, we write

$$t^{1/2}\|e(t)\| \le t^{1/2}\|\rho(t)\| + t^{1/2}\|\theta(t)\|.$$

By Theorem 3.2 and a priori estimates in Lemma 2.3, the first term on the right is bounded by

$$t^{1/2}\|\rho(t)\| \le Ch^2 t^{1/2}\|u_0\|_2.$$

For the second term, we use Lemma 4.3, Theorem 3.2, and a priori estimates in Lemma 2.3 to have

$$t^{1/2}\|\theta\| \le C\left(\int_0^t \{\|\rho(s)\|^2 + s^2\|\rho_s(s)\|^2\}ds\right)^{1/2} \le Ch^2 t^{1/2}\|u_0\|_2.$$

Altogether these estimates yield the desired result and this completes the proof. □

Remark 4.4. Note that the result presented in Theorem 4.1 is optimal with respect to the approximation property as well as the regularity of the solution. Similar result for finite element methods is established in [31, 25, 26].

5. Error estimates for nonsmooth initial data. In this section we establish one of the main results of the paper, namely, an error estimate for problems with nonsmooth initial data. More precisely, an almost optimal-order L^2-error estimate is obtained when $u_0 \in L^2(\Omega)$.

The following lemma is useful in our subsequent analysis.

LEMMA 5.1. *For all $\chi_1, \chi_2 \in S_h$, we have*

$$A(\chi_1, \chi_2 - I_h^*\chi_2)| \le Ch^2(\|\chi_1\|_1 + h^{-1/2}\|\hat{u} - \chi_1\|_1)\|\chi_2\|_1,$$

where $\hat{u}(t) = \int_0^t u(s)ds$. The above estimate also holds true when $A(\cdot,\cdot)$ is replaced by $B(t,s;\cdot,\cdot)$.

Proof. From (3.4), we have

$$\begin{aligned} A(\chi_1, \chi_2 - I_h^*\chi_2) = &- \sum_{K\in T_h}\int_K (\nabla\cdot\mathcal{A}\nabla\chi_1)(\chi_2 - I_h^*\chi_2)dx \\ &+ \sum_{K\in T_h}\int_{\partial K}((\mathcal{A} - \bar{\mathcal{A}}_K)\nabla\chi_1\cdot\mathbf{n})(\chi_2 - I_h^*\chi_2)dS = I_1 + I_2. \end{aligned}$$

Since the dual mesh is formed by the barycenters, we have

$$\int_K (\chi - I_h^*\chi)dx = 0 \quad \forall\chi \in T_h,$$

and hence, we apply the Cauchy–Schwarz inequality to have

$$|I_1| = \left|\sum_{K\in T_h}\int_K \left(\nabla\cdot\mathcal{A}\nabla\chi_1 - (\overline{\nabla\cdot\mathcal{A}\nabla\chi_1})_K\right)(\chi_2 - I_h^*\chi_2)\,dx\right| \le Ch^2\|\chi_1\|_1\|\chi_2\|_1,$$

where $(\overline{\nabla\cdot\mathcal{A}\nabla\chi_1})_K = \frac{1}{\text{area}(K)}\int_K \nabla\cdot A\nabla\chi_1\,dx$. Since $\nabla\hat{u}\cdot\mathbf{n}$ is continuous across any edge $E \in T_h$, we may rewrite I_2 as

$$I_2 = \sum_{K\in T_h}\int_{\partial K}\left((\mathcal{A} - \bar{\mathcal{A}}_K)\nabla(\hat{u} - \chi_1)\cdot\mathbf{n}\right)(\chi_2 - I_h^*\chi_2)dS,$$

and hence using the fact that $|\mathcal{A}(x) - \bar{\mathcal{A}}_K| \le h\|\mathcal{A}\|_{1,\infty}$, the Cauchy–Schwarz inequality, and trace results, we obtain

$$|I_2| \le Ch\sum_{K\in T_h}\|\nabla(\hat{u} - \chi_1)\|_{L^2(\partial K)}\|\chi_2 - I_h^*\chi_2\|_{L^2(\partial K)} \le Ch^{3/2}\|\hat{u} - \chi_1\|_1\|\chi_2\|_1.$$

Combining these estimates we complete the proof. □

Below, we shall prove several lemmas which will be used to derive error estimates for problems with nonsmooth initial data.

LEMMA 5.2. *Let u and u_h be the solution of* (1.1) *and* (2.3)*, respectively. Then for $u_0 = 0$, we have*

$$\int_0^t \|u(s) - u_h(s)\|_1^2 ds \leq Ch^2 \left(\|f(0)\|^2 + \int_0^t \|f\|^2 ds \right).$$

Proof. Set $\chi = R_h e$ in the error equation

$$(e_t, I_h^* \chi) + A(e, I_h^* \chi) = \int_0^t B(t, s; e(s), I_h^* \chi) ds \tag{5.1}$$

to get

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}|||e|||^2 + A(e,e) &= (e_t, u - I_h^*(R_h u)) + A(e, u - I_h^*(R_h u)) \\ &\quad - \int_0^t B(t, s; e(s), I_h^*(R_h u) - I_h^* u_h) ds + (e_t, I_h^* u_h - u_h) \\ &\quad + A(e, I_h^* u_h - u_h) = I_1 + I_2 + I_3 + I_4 + I_5. \end{aligned}$$

By (3.8), (3.2), and (3.3), we have

$$\begin{aligned} |I_1| + |I_2| &\leq |(e_t, u - R_h u)| + |(e_t, R_h u - I_h^*(R_h u))| \\ &\quad + |A(e, u - R_h u)| + |A(e, R_h u - I_h^*(R_h u))| \\ &\leq Ch^2(\|e_t\|\|u\|_2 + \|e_t\|_1\|u\|_1) + Ch\|e\|_1(\|u\|_2 + \|u\|_1). \end{aligned}$$

Again, in view of (3.2) and (3.3), I_4 and I_5 can be estimated as

$$|I_4| + |I_5| \leq C(h^2\|e_t\|_1 + h\|e\|_1)\|u_h\|_1.$$

To estimate I_3, we first rewrite it as

$$\begin{aligned} I_3 = &\int_0^t B(t, s; e(s), I_h^*(R_h u) - R_h u) ds + \int_0^t B(t, s; e(s), R_h u - u) ds \\ &+ \int_0^t B(t, s; e(s), e) ds + \int_0^t B(t, s; e(s), u_h - I_h^* u_h) ds. \end{aligned}$$

Apply (3.3) and (3.8) to obtain

$$|I_3| \leq Ch \left(\int_0^t \|e(s)\|_1 ds \right) (\|u\|_1 + \|u\|_2 + \|u_h\|_1) + C \left(\int_0^t \|e(s)\|_1 ds \right) \|e\|_1.$$

Combining these estimates now leads to

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}\|e\|^2 + A(e,e) &\leq Ch^2\|e_t\|\|u\|_2 + Ch^2\|e_t\|_1(\|u\|_1 + \|u_h\|_1) + Ch\|e\|_1\|u\|_1 \\ &\quad + h\left(\int_0^t \|e\|_1 ds \right)(\|u_1\| + \|u\|_2 + \|u_h\|_1) + C\left(\int_0^t \|e(s)\|_1 ds \right)\|e\|_1. \end{aligned}$$

Integrate from 0 to t, use the fact that $e(0) = 0$, and then apply the standard kickback argument to obtain

$$\int_0^t \|e(s)\|_1^2 ds \le Ch^2 \left[\int_0^t (\|u_h\|_1^2 + \|u\|_2^2 + \|e_t\|^2 + \|e_t\|_1^2) ds\right] + C\int_0^t \int_0^s \|e(\tau)\|_1^2 d\tau ds.$$

The desired estimate now easily follows from Lemmas 2.1 and 2.2, its discrete analogue, and Gronwall's lemma. □

Define $\hat{e}(t) = \int_0^t e(s)ds$. Then, as a consequence of Lemmas 4.2 and 3.2 and a priori estimates we have the following lemma.

LEMMA 5.3. *Assume that $u_0 \in L^2(\Omega)$ and $f = 0$. Then there is a positive constant C independent of h such that*

$$\|\hat{e}(t)\|_1 \le Ch\|u_0\|.$$

In order to obtain optimal L^2-error estimate for problems with nonsmooth data, it is convenient to prove an estimate of $\|\hat{e}\|$. For this purpose, we now consider the following backward problems. For fixed time $t > 0$ and given any $\bar{f} \in L^2(\Omega)$, let $v(s) \in H^2(\Omega) \cap H_0^1(\Omega)$ be the solution of the backward problem

$$v_s - Av = -\int_s^t B^*(\tau, s)v(\tau)d\tau + \bar{f}, \quad s \le t, \tag{5.2}$$

with $v(t) = g$, where $B^*(\tau, s)$ is the adjoint of $B(\tau, s)$.

The associated weak solution is then defined to be the function $v : [0, t) \to H_0^1(\Omega)$ such that

$$(\phi, v_s) - A(\phi, v) = -\int_s^t B(\tau, s; \phi, v(\tau))d\tau + (\phi, \bar{f}) \quad \forall \phi \in H_0^1(\Omega), \ s \le t, \tag{5.3}$$

with $v(t) = g$. Analogous to (2.3), the FVE approximation is then defined to be the function $v_h : [0, t) \to S_h$ such that

$$(I_h^*\chi, v_{hs}) - A(I_h^*\chi, v_h) = -\int_s^t B(\tau, s; I_h^*\chi, v_h(\tau))d\tau + (I_h^*\chi, \bar{f}) \tag{5.4}$$

for all $\chi \in S_h$, $s \le t$, with $v_h(t) = g_h$, where g_h is a suitable approximation of g in S_h to be defined later.

Remark 5.4. With a simple change of variables in the proofs of Lemmas 2.1–2.3 and using the backward Gronwall lemma, it is easy to obtain a priori bounds for the backward solutions v and v_h.

LEMMA 5.4. *Assume that $u_0 \in L^2(\Omega)$ and $f = 0$. Then there is a generic constant C such that*

$$\|\hat{e}(t)\| \le Ch^2\|u_0\| \quad \forall t > 0. \tag{5.5}$$

Proof. Let $w(s) \in H^2(\Omega) \cap H_0^1(\Omega)$ be the solution of the backward problem (5.2) with $\bar{f} = \hat{e}$ and $g = 0$. Then, with a change of variables in the proofs of Lemmas 2.1–2.3 and its discrete analogue, Lemma 5.2 and using the backward Gronwall lemma, it is an easy exercise to check that the solution $w(s)$ and its FVE solution $w_h(s)$, which may be stated in a manner similar to (5.3)–(5.4), satisfy the following estimate:

$$\int_0^t \{\|w_s - w_{hs}\|^2 + \|w_s - w_{hs}\|_1^2 + h^{-2}\|w - w_h\|_1^2 + \|w\|_2^2\}ds \le C\int_0^t \|\hat{e}\|^2 ds. \tag{5.6}$$

We take an L^2 inner product of (5.2) with e and use (5.1) to obtain

$$\begin{aligned}\frac{1}{2}\frac{d}{ds}\|\hat{e}(s)\|^2 = &\frac{d}{ds}(e, I_h^* w_h) + (e, w_s - w_{hs}) - (e, w_{hs} - I_h^* w_{hs}) - A(e, w - w_h)\\ &-A(e, w_h - I_h^* w_h) + \int_s^t B(\tau, s; e(s), (w - w_h)(\tau))d\tau\\ &+\int_s^t B(\tau, s; e(s), (w_h - I_h^* w_h)(\tau))d\tau + \int_s^t B(\tau, s; e(s), I_h^* w_h(\tau))d\tau\\ &-\int_0^s B(s, \tau; e(\tau), I_h^* w_h(s))d\tau.\end{aligned}$$

With $\eta = u - I_h^*(R_h u)$ and $\zeta = I_h^* u_h - u_h$, we rewrite the above equation as

$$\begin{aligned}\frac{1}{2}\frac{d}{ds}\|\hat{e}(s)\|^2 = &\frac{d}{ds}(e, I_h^* w_h) + (\eta, w_s - w_{hs}) - A(\eta, w - w_h)\\ &+\int_s^t B(\tau, s; \eta(s), (w - w_h)(\tau))d\tau + (e, w_{hs} - I_h^* w_{hs}) - A(e, w_h - I_h^* w_h)\\ &+\int_s^t B(\tau, s; e(s), w_h(\tau) - I_h^* w_h(\tau))d\tau + (\zeta, w_s - w_{hs}) - A(\zeta, w - w_h)\\ &+\int_s^t B(\tau, s; \zeta(s), (w - w_h)(\tau))d\tau.\end{aligned}$$

Multiply both sides by s and integrate from 0 to t to have

$$\begin{aligned}\frac{1}{2}t\|\hat{e}(t)\|^2 = &\frac{1}{2}\int_0^t \|\hat{e}(s)\|^2 ds + \int_0^t (e, I_h^* w_h) ds + \int_0^t s(\eta, w_s - w_{hs}) ds\\ &-\int_0^t sA(\eta, w - w_h) ds + \int_0^t \int_s^t sB(\tau, s; \eta, (w - w_h))(\tau) d\tau ds\\ &+\int_0^t s(e, w_{hs} - I_h^* w_{hs}) ds - \int_0^t sA(e, w_h - I_h^* w_h) ds\\ &-\int_0^t \int_0^s sB(s, \tau; e(\tau), I_h^* w_h(s) - w_h(s)) d\tau ds + \int_0^t s(\zeta, w_s - w_{hs}) ds\\ &-\int_0^t sA(\zeta, w - w_h) ds + \int_0^t \int_s^t sB(\tau, s; \zeta(s), (w - w_h)(\tau)) d\tau ds\\ = &\frac{1}{2}\int_0^t \|\hat{e}(s)\|^2 ds + \sum_{i=1}^{10} I_i.\end{aligned}$$

Since $\hat{e}(0) = 0 = I_h^* w(t)$, we obtain using (5.6)

$$\begin{aligned}|I_1| = &\left|-\int_0^t (\hat{e}, I_h^* w_{hs}) ds\right| \le C\int_0^t \|\hat{e}\|\|w_{hs}\| ds\\ \le &\left(\int_0^t \|\hat{e}\|^2 ds\right)^{1/2}\left(\int_0^t \|w_{hs}\|^2 ds\right)^{1/2} \le C\int_0^t \|\hat{e}(s)\|^2 ds.\end{aligned}$$

For I_2, an application of (3.2), (3.8), (5.6), and a priori estimates yield

$$\begin{aligned}|I_2| &= \left| \int_0^t s(u - R_h u, w_s - w_{hs})ds + \int_0^t s(R_h u - I_h^*(R_h u), w_s - w_{hs})ds \right| \\ &\le Ch^4 \int_0^t (s^2\|u\|_2^2 + s\|u\|_1^2)ds + C\int_0^t \|w_s - w_{hs}\|_1^2 ds \\ &\le Ch^4 t\|u_0\|^2 + C\int_0^t \|\hat{e}\|^2 ds.\end{aligned}$$

Similarly, for I_3 and I_4, using (3.8), (3.3), and (5.6), we obtain

$$\begin{aligned}|I_3| + |I_4| &\le C\int_0^t s\|u - R_h u\|_1 \|w - w_h\|_1 ds + h\int_0^t s\|R_h u - I_h^*(R_h u)\|_1 \|w - w_h\|_1 ds \\ &\le Ch^4 \int_0^t (s^2\|u\|_2^2 + s^2\|u\|_1^2)ds + Ch^{-2}\int_0^t \|w - w_h\|_1^2 ds \\ &\le Ch^4 t\|u_0\|^2 + C\int_0^t \|\hat{e}\|^2 ds.\end{aligned}$$

Apply (3.2), (5.6), and a priori estimates to have

$$|I_5| = Ch^4 \int_0^t s\|e\|_1^2 ds + C\int_0^t \|w_{hs}\|_1^2 ds \le Ch^4 t\|u_0\|^2 + C\int_0^t \|\hat{e}\|^2 ds.$$

For I_7, with a change of variables and integration by parts, we note that

$$\begin{aligned}\int_0^t \int_s^t sB(\tau, s; e(s), (w_h - I_h^* w_h)(\tau))d\tau ds &= \int_0^t \int_0^s \tau B(s, \tau; \hat{e}_\tau(\tau), (w_h - I_h^* w_h)(s))d\tau ds \\ &= \int_0^t sB(s, s; \hat{e}(s), (w_h - I_h^* w_h)(s))ds \\ &\quad - \int_0^t \int_0^s \tau B_\tau(s, \tau; \hat{e}(\tau), (w_h - I_h^* w_h)(s))d\tau ds \\ &\quad - \int_0^t \int_0^s B(s, \tau; \hat{e}(\tau), (w_h - I_h^* w_h)(s))d\tau ds.\end{aligned}$$

Similarly, we rewrite the term I_6 as

$$I_6 = \int_0^t sA(\hat{e}, w_{hs} - I_h^* w_{hs})ds + \int_0^t A(\hat{e}, w_h - I_h^* w_h)ds,$$

where we have used the fact that $w_h(t) = 0 = \hat{e}(0)$. Thus, applying (3.3), Lemma 5.3, and (5.6), I_6 and I_7 are bounded by

$$|I_6| + |I_7| \le Cth^4\|u_0\|^2 + C\int_0^t (\|w_h\|_1^2 + \|w_{hs}\|_1^2)ds \le Cth^4\|u_0\|^2 + C\int_0^t \|\hat{e}\|^2 ds.$$

Finally, using (3.2), (3.3), and (5.6), we obtain

$$\begin{aligned}|I_8| + |I_9| + |I_{10}| &\le Ch^4 \int_0^t s\|u_h\|_1^2 ds + C\int_0^t (\|w_s - w_{hs}\|_1^2 + h^{-2}\|w - w_h\|_1^2)ds \\ &\le Ch^4 t\|u_0\|^2 + C\int_0^t \|\hat{e}\|^2 ds.\end{aligned}$$

Altogether this now leads to

$$t\|\hat{e}(t)\| \le Ch^4 t\|u_0\|^2 + C\int_0^t \|\hat{e}(s)\|^2 ds. \tag{5.7}$$

It now remains to estimate $\int_0^t \|\hat{e}\|^2 ds$. Multiply (5.2) by $\hat{e}$ and integrate by parts with respect to x to have

$$\begin{aligned}\|\hat{e}(s)\|^2 &= \frac{d}{ds}(\hat{e}, I_h^* w_h) + (\hat{e}, w_s - w_{hs}) - A(\hat{e}, w - w_h)\\ &\quad + \int_s^t B(\tau, s; \hat{e}(s), w(\tau) - w_h(\tau))d\tau + (\hat{e}, w_{hs} - I_h^* w_{hs}) - A(\hat{e}, w_h - I_h^* w_h)\\ &\quad - \int_0^s B(\tau, \tau; \hat{e}(\tau), I_h^* w_h(s))d\tau + \int_0^s \int_0^\tau B_{\tau'}(\tau, \tau'; \hat{e}(\tau'), I_h^* w_h(s))d\tau' d\tau\\ &\quad + \int_s^t B(\tau, s; \hat{e}(s), w_h(\tau))d\tau. \end{aligned} \tag{5.8}$$

Here, we have used the relation

$$(e, I_h^*\chi) + A(\hat{e}, I_h^*\chi) = \int_0^t B(s, s; \hat{e}(s), I_h^*\chi)ds - \int_0^t \int_0^s B_\tau(s, \tau; \hat{e}(\tau), I_h^*\chi)d\tau ds,$$

which is obtained by integrating (5.1) from 0 to t and using (2.4). Now integrate (5.8) from 0 to t and use the fact that $\hat{e}(0) = 0 = I_h^* w_h(t)$ to have

$$\begin{aligned}\int_0^t \|\hat{e}(s)\|^2 ds &= \int_0^t (\hat{\eta}, w_s - w_{hs})ds - \int_0^t A(\hat{\eta}, w - w_h)ds\\ &\quad - \int_0^t \int_s^t B(\tau, s; \hat{\eta}(s), (w - w_h)(\tau))d\tau ds\\ &\quad - \int_0^t \int_0^s B(\tau, \tau; \hat{e}(\tau), I_h^* w_h(s))d\tau ds\\ &\quad + \int_0^t \int_0^s \int_0^\tau B_{\tau'}(\tau, \tau'; \hat{e}(\tau'), I_h^* w_h(s))d\tau' d\tau ds\\ &\quad + \int_0^t (\hat{e}(s), w_{hs} - I_h^* w_{hs})ds - \int_0^t A(\hat{e}, w_h - I_h^* w_h)ds\\ &\quad + \int_0^t \int_s^t B(\tau, s; \hat{e}(s), w_h(\tau))d\tau ds + \int_0^t (\hat{\zeta}, w_s - w_{hs})ds\\ &\quad - \int_0^t A(\hat{\zeta}, w - w_h)ds - \int_0^t \int_s^t B(\tau, s; \hat{\zeta}(s), (w - w_h)(\tau))d\tau ds\\ &= \sum_{i=1}^{11} J_i,\end{aligned}$$

where $\hat{\eta} = \hat{u} - I_h^*(R_h\hat{u})$ and $\hat{\zeta} = I_h^*\hat{u}_h - \hat{u}_h$. Let us estimate each term separately. For J_1, use of (3.8), (3.11), (5.1), and (5.6) yields

$$\begin{aligned}|J_1| &\le \int_0^t \{|(\hat{u} - R_h\hat{u}, w_s - w_{hs})| + |(R_h\hat{u} - I_h^*(R_h\hat{u}), w_s - w_{hs})|\}ds\\ &\le C(\epsilon)h^4 \int_0^t \|\hat{u}\|_2^2 ds + \epsilon \int_0^t \|w_s - w_{hs}\|^2 ds \le C(\epsilon)th^4\|u_0\|^2 + \epsilon C\int_0^t \|\hat{e}\|^2 ds.\end{aligned}$$

Similarly,

$$|J_2| + |J_3| \le C(\epsilon) t h^4 \|u_0\|^2 + \epsilon h^{-2} \int_0^t \|w - w_h\|_1^2 ds \le C(\epsilon) t h^4 \|u_0\|^2 + \epsilon C \int_0^t \|\hat{e}\|^2 ds.$$

For J_4, we note that

$$\begin{aligned} J_4 = &- \int_0^t \int_0^s B(\tau, \tau; \hat{e}(\tau), I_h^* w_h(s) - w_h(s)) d\tau ds \\ &- \int_0^t \int_0^s B(\tau, \tau; \hat{e}(\tau), w_h(s) - w(s)) d\tau ds - \int_0^t \int_0^s B(\tau, \tau; \hat{e}(\tau), w(s)) d\tau ds, \end{aligned}$$

and hence, using (3.3), Lemma 5.3, and (5.6), we obtain

$$\begin{aligned} |J_4| &\le C \int_0^t \int_0^s \{h \|\hat{e}(\tau)\|_1 (\|w_h(s)\|_1 + h^{-1} \|w(s) - w_h(s)\|_1) + \|\hat{e}(\tau)\| \|w(s)\|_2\} d\tau ds \\ &\le C t h^4 \|u_0\|^2 + C \int_0^t \int_0^s \|\hat{e}(\tau)\|^2 d\tau ds. \end{aligned}$$

Similarly,

$$|J_5| \le C t h^4 \|u_0\|^2 + C \int_0^t \int_0^s \|\hat{e}(\tau)\|^2 d\tau ds.$$

Using (3.1)–(3.3), Lemma 5.3, and (5.6), we obtain

$$\begin{aligned} |J_6| + |J_7| &\le C(\epsilon) h^2 \int_0^t \|\hat{e}\|_1^2 ds + \epsilon \int_0^t \{\|w_{hs}\|_1^2 + \|w_h\|_1^2\} ds \\ &\le C t h^4 \|u_0\|^2 + \epsilon C \int_0^t \|\hat{e}\|^2 ds. \end{aligned}$$

By changing the order of integration, rewrite the term J_8 as

$$J_8 = \int_0^t \int_0^s B(\tau, s; \hat{e}(s), (w_h - w)(\tau)) ds d\tau + \int_0^t \int_0^s B(\tau, s; \hat{e}(s), w(\tau)) ds d\tau.$$

In view of Lemma 5.3 and (5.6), we obtain

$$|J_8| \le C t h^4 \|u_0\|^2 + C \int_0^t \int_0^s \|\hat{e}(\tau)\|^2 d\tau ds.$$

Finally, using (3.2), (3.3), and (5.6), we have

$$\begin{aligned} |J_9| + |J_{10}| + |J_{11}| &\le C(\epsilon) t h^4 \|u_0\|^2 + \epsilon \int_0^t (\|w_s - w_{hs}\|_1^2 + h^{-2} \|w - w_h\|_1^2) ds \\ &\le C(\epsilon) t h^4 \|u_0\|^2 + \epsilon C \int_0^t \|\hat{e}(s)\|^2 ds. \end{aligned}$$

Putting these estimates together and choosing ϵ appropriately, we arrive at

$$\int_0^t \|\hat{e}(s)\|^2 ds \le C t h^4 \|u_0\|^2 + C \int_0^t \int_0^s \|\hat{e}(\tau)\|^2 d\tau ds.$$

An application of Gronwall's lemma yields

$$\int_0^t \|\hat{e}\|^2 ds \le C t h^4 \|u_0\|^2,$$

and this combined with (5.7) completes the rest of the proof. □

Remark 5.5. Defining the error $\bar{e} = v - v_h$ associated with the backward problem (5.3) and its FVE approximation (5.4), set $\tilde{\bar{e}}(s) = -\int_s^t \bar{e}(\tau)d\tau,\ s \le t$. Then, for $g \in L^2(\Omega)$ and $\bar{f} = 0$, analogous to Lemmas 5.3 and 5.4, it is easy to show that

$$\|\tilde{\bar{e}}\|_j \le Ch^{2-j}\|g\|, \ \ j = 0, 1. \tag{5.9}$$

We conclude this section by showing our main result in the following theorem.

THEOREM 5.1. *Let u and u_h be solutions of* (1.1) *and* (1.4), *respectively, with $f = 0$. Assume that $u_0 \in L^2(\Omega)$ and the matrix $\mathcal{A}$ is constant over each element $K \in T_h$. Then there is a generic positive constant C independent of h such that*

$$\|e(t)\| \le Ct^{-1}h^2 \ln h \|u_0\|, \quad t \in J.$$

Proof. Using (5.3) and (5.4) with $\bar{f} = 0$ and Lemma 2.6, we first note that

$$\begin{aligned}
&\frac{d}{ds}\left\{s^2[(u,v) - (I_h^* u_h, v_h)]\right\} \\
&\quad = 2s\left\{(u,v) - (I_h^* u_h, v_h)\right\} + \int_0^s s^2 B(s,\tau; u(\tau), v(s))d\tau \\
&\qquad - \int_s^t s^2 B(\tau, s; u(s), v(\tau))d\tau - \int_0^s s^2 B(s,\tau; u_h(\tau), I_h^* v_h(s) - v_h(s))d\tau \\
&\qquad + \int_s^t s^2 B(\tau, s; I_h^* u_h(s) - u_h(s), v_h(\tau))d\tau - \int_0^s s^2 B(s,\tau; u_h(\tau), v_h(s))d\tau \\
&\qquad + \int_s^t s^2 B(\tau, s; u_h(s), v_h(\tau))d\tau - s^2(u_{hs}, v_h - I_h^* v_h) - s^2(I_h^* u_{hs} - u_{hs}, v_h).
\end{aligned}$$

Integrate the above equation from 0 to t. Then, with $g_h = L_h g$, where $L_h : L^2(\Omega) \to S_h$ defined by $(L_h g, I_h^* \chi) = (g, \chi),\ \chi \in S_h$, we have

$$\begin{aligned}
t^2(e(t), g) = {} & 2\int_0^t s\left\{(u(s), v(s)) - (u_h(s), v_h(s))\right\}ds \\
& - \int_0^t \int_0^s s^2 B(s,\tau; u_h(\tau), I_h^* v_h(s) - v_h(s))d\tau \\
& + \int_0^t \int_s^t s^2 B(\tau, s; I_h^* u_h(s) - u_h(s), v_h(\tau))d\tau - \int_0^t s^2(u_{hs}, v_h - I_h^* v_h)ds \\
& - \int_0^t s^2(u_{hs} - I_h^* u_{hs}, v_h)ds = 2I_1 + I_2 + I_3 + I_4 + I_5.
\end{aligned} \tag{5.10}$$

For the term I_2, with $\hat{u}_h(t) = \int_0^t u_h(s)ds$, we integrate by parts to have

$$\begin{aligned}
I_2 &= -\int_0^t \int_0^s s^2 B(s,\tau; \hat{u}_{h\tau}(\tau), (I_h^* v_h - v_h)(s))d\tau ds \\
&= -\int_0^t s^2 B(s,s; \hat{u}_h(s), (I_h^* v_h - v_h)(s))ds \\
&\quad + \int_0^t \int_0^s s^2 B_\tau(s,\tau; \hat{u}_h(\tau), (I_h^* v_h - v_h)(s))d\tau ds \\
&= I_2^1 + I_2^2.
\end{aligned}$$

For I_2^1, apply Lemma 5.1 with $\chi_1 = \hat{u}_h$ and $\chi_2 = v_h$, Lemma 5.3, and a priori estimates to obtain

$$|I_2^1| \leq Ch^2 \int_0^t s^2(\|\hat{u}_h\|_1 + h^{-1/2}\|\hat{e}\|_1)\|v_h(s)\|_1 ds \leq Cth^2\|u_0\|\|g\|.$$

The term I_2^2 is treated in a similar manner and hence

$$|I_2| \leq Cth^2\|u_0\|\|g\|.$$

Similarly, defining $\tilde{v}_h(s) = -\int_s^t v_h(\tau)d\tau,\ s \leq t$, we rewrite the term I_3 as

$$\begin{aligned} I_3 &= \int_0^t \int_s^t s^2 B(\tau, s; I_h^* u_h(s) - u_h(s), \tilde{v}_{h,\tau}(\tau))d\tau ds \\ &= -\int_0^t s^2 B(s, s; I_h^* u_h(s) - u_h(s), \tilde{v}_h(s))ds \\ &\quad - \int_0^t \int_s^t s^2 B_\tau(\tau, s; I_h^* u_h(s) - u_h(s), \tilde{v}_h(\tau))d\tau ds \\ &= I_3^1 + I_3^2. \end{aligned}$$

As before, again an application of Lemma 5.1 (analogous result for the backward problem), (5.9), and a priori bounds for the discrete solution yield

$$|I_3^1| \leq Ch^2 \int_0^t s^2(\|v_h\|_1 + h^{-1/2}\|\tilde{\bar{e}}\|_1)\|u_h(s)\|_1 ds \leq Cth^2\|u_0\|\|g\|.$$

The term I_3^2 is treated in a similar fashion and hence

$$|I_3| \leq Cth^2\|u_0\|\|g\|.$$

For I_4 and I_5, apply (3.2) and a priori estimates to have

$$|I_4| + |I_5| \leq Cth^2 \left(\int_0^t \|v_h\|_1^2 ds\right)^{1/2} \left(\int_0^t s^2\|u_{hs}\|_1^2 ds\right)^{1/2} \leq Cth^2\|u_0\|\|g\|.$$

It now remains to estimate the term I_1. We first rewrite I_1 as

$$\begin{aligned} I_1 &= \int_0^t s(e(s), v)ds - \int_0^t s(e(s), \bar{e}(s))ds + \int_0^t s(u, \bar{e}(s))ds - \int_0^t s(I_h^* u_h - u_h, v_h)ds \\ &= I_1^1 + I_1^2 + I_1^3 + I_1^4. \end{aligned}$$

To estimate I_1^1, we note that

$$I_1^1 = \int_0^{t-h^2} s(e(s), v(s))ds + \int_{t-h^2}^t s(e(s), v(s))ds = II_1 + II_2.$$

For II_1, we integrate by parts and use the fact that $\hat{e}(0) = 0$ to have

$$\begin{aligned} II_1 = \int_0^{t-h^2} s(\hat{e}_s, v)ds &= (t - h^2)(\hat{e}(t - h^2), v(t - h^2)) \\ &\quad - \int_0^{t-h^2} (\hat{e}, v)ds - \int_0^{t-h^2} s(\hat{e}, v_s)ds, \end{aligned}$$

and hence, by the Cauchy–Schwarz inequality, Lemma 5.4, and Lemma 2.3 (with time reversed), we obtain

$$\begin{aligned} |II_1| &\leq t\|\hat{e}(t-h^2)\|\|v(t-h^2)\| + \int_0^{t-h^2} \|\hat{e}(s)\|\|v(s)\|ds + \int_0^{t-h^2} s\|\hat{e}(s)\|\|v_s(s)\|ds \\ &\leq Cth^2\|u_0\|\|g\| + Cth^2\|u_0\|\|g\| \int_0^{t-h^2} \frac{1}{(t-s)}ds \\ &\leq \left(Cth^2\|u_0\|\|g\| + Cth^2 \ln h\|u_0\|\|g\|\right) \leq Cth^2 \ln h\|u_0\|\|g\|. \end{aligned} \tag{5.11}$$

By Lemma 2.3, its semidiscrete analogue, and further using a priori estimates for the backward solution v, we obtain

$$|II_2| \leq Ct\int_{t-h^2}^{t} \|e(s)\|\|v(s)\|ds \leq Cth^2\|u_0\|\|g\|,$$

which together with (5.11) yields

$$|I_1^1| \leq Cth^2 \ln h\|u_0\|\|g\|.$$

Since $\tilde{\tilde{e}}(t) = 0$, integrate I_1^2 by parts to have

$$I_1^2 = -\int_0^t s(e, \tilde{\tilde{e}}_s)ds = \int_0^t (e, \tilde{\tilde{e}})ds + \int_0^t s(e_s, \tilde{\tilde{e}}(s))ds.$$

Apply the Cauchy–Schwarz inequality, (5.9), and a priori estimates in Lemma 2.3 to obtain

$$|I_1^2| \leq \int_0^t \|e\|\|\tilde{\tilde{e}}(s)\|ds + \int_0^t s\|e_s\|\|\tilde{\tilde{e}}\|ds \leq Cth^2\|u_0\|\|g\|.$$

Similarly, using (5.9) and Lemma 2.3 we estimate I_1^3 as

$$|I_1^3| \leq \int_0^t \|\tilde{\tilde{e}}\|\|u\|ds + \int_0^t s\|\tilde{\tilde{e}}\|\|u_s\|ds \leq Cth^2\|u_0\|\|g\|.$$

Finally, for I_1^4, apply (3.2) and a priori estimates to have

$$|I_1^4| \leq Cth^2 \left(\int_0^t \|u_h\|_1^2\right)^{1/2} \left(\int_0^t \|v_h\|_1^2 ds\right)^{1/2} \leq Cth^2\|u_0\|\|g\|.$$

Altogether these estimates yield the desired result and this completes the proof. □

Acknowledgments. The authors wish to thank the referees for their valuable comments and suggestions which led to the improvement of the presentation of this paper. This first author thanks the Institute for Scientific Computation and the Department of Mathematics, at Texas A&M University for providing necessary facilities for carrying out the research.

ANALYTICAL AND NUMERICAL STUDY OF A MODEL OF EROSION AND SEDIMENTATION*

ROBERT EYMARD† AND THIERRY GALLOUËT‡

Abstract. We consider the following problem, arising within a geological model of sedimentation-erosion: For a given vector field g and a given nonnegative function F defined on a one- or two-dimensional domain Ω, find a vector field under the form $\tilde{g} = ug$, with $0 \leq u(x) \leq 1$ for a.e. $x \in \Omega$, such that $\text{div}\tilde{g} + F \geq 0$ and $(u-1)(\text{div}\tilde{g} + F) = 0$ in Ω. We first give a weak formulation of this problem, and we prove a comparison principle on a weak solution of the problem. Thanks to this property, we get the proof of the uniqueness of the weak solution. The existence of a solution results from the proof of the convergence of an original scheme. Numerical examples show the efficiency of this scheme and illustrate its convergence properties.

Key words. hyperbolic inequalities, doubling variable technique, process solutions, finite volume methods, erosion and sedimentation models

1. Introduction.

In the framework of the petroleum industry, geological simulations are used more and more in order to get a better knowledge of the history of the sedimentary basins. Among them, the computation of the sedimentation and erosion processes leads to a better knowledge of the geometry of the layers and of their lithological nature (see, for example, [15], [11], or [5]). An unknown of such models is the thickness $H(x,t)$ of the sediments at a point $(x,t) \in \Omega \times (0,T)$, where Ω describes the horizontal extension of the basin (the magnitude of the diameter of Ω can be about several hundreds of kilometers) and T is the age of the basin (between 0 and 10^7 years for example). The simplest model is a diffusion equation

$$H_t(x,t) - \text{div}[\Lambda(x)\nabla H(x,t)] = 0 \text{ for a.e. } (x,t) \in \Omega \times (0,T), \tag{1}$$

where $\Lambda(x)$ is a matrix in the general case, reducing in most of the cases to a scalar function. But the model (1) is not sufficient for actual applications, in particular, because it does not account for the assymetry between the erosion process (due to the action of the weather) and the sedimentation process. Indeed, more realistic models (see [1] or [6] and references therein) are based on the introduction in (1) of a multiplier $\overline{u}(x,t)$ on the fluxes of sediments:

$$H_t(x,t) - \text{div}[\Lambda(x)\overline{u}(x,t)\nabla H(x,t)] = 0 \text{ for a.e. } (x,t) \in \Omega \times (0,T), \tag{2}$$

in order to satisfy the following constraints on $(\overline{u}, H)$,

$$H_t(x,t) \geq -F(x) \text{ for a.e. } (x,t) \in \Omega \times (0,T), \tag{3}$$

$$0 \leq \overline{u}(x,t) \leq 1 \text{ for a.e. } (x,t) \in \Omega \times (0,T), \tag{4}$$

and

$$(\overline{u}(x,t)-1)\ (H_t(x,t)+F(x))=0 \text{ for a.e. } (x,t)\in\Omega\times(0,T). \tag{5}$$

In (3) and (5), we denote by $F(x)\geq 0$ the maximum erosion rate at point x.

In practical situations, F is estimated by the geological study of the sedimental history, and may be improved by solving an inverse problem (which is quite complicated, by the way), using (2)–(5) as the direct problem. In large parts of the simulation domain, the transport of sediments is due mainly to gravity effects, taken into account by a scalar value for the matrix $\Lambda(x)$. In a same way as above, this scalar value can be estimated by some geological studies or by solving an inverse problem. However, the main mechanism for the transport of sediments is the action of surface water flows. These flows, located in river basins, can be represented by introducing anisotropic values for this matrix $\Lambda(x)$. The determination of realistic values for these parameters is not an easy task and is still a challenging subject of research for the simulation of the sedimentary basins. The function $\overline{u}$ is a complete unknown factor, reducing the flux of sediments in order to respect the constraint (3). Despite these difficulties of data identification, this model is considered interesting enough to be actually implemented in an industrial simulator (see [11], [6]).

Existence and uniqueness for the full problem (2)–(5) is an open problem (some partial results can be found in [10] or [2]). Thus we consider a semidiscretization in time of this system of equations. We define a time step $\delta t>0$, and for an integer n such that $n\delta t<T$, we assume that the function $H^{(n)}$ is an approximation of $H(\cdot,n\delta t)$. We then look for the functions $H^{(n+1)}$ and $\overline{u}^{(n+1)}$, respective approximations of $H(\cdot,(n+1)\delta t)$ and $\overline{u}(\cdot,(n+1)\delta t)$, which are solutions of the system of equations

$$\frac{1}{\delta t}(H^{(n+1)}(x)-H^{(n)}(x))-\operatorname{div}[\Lambda(x)\overline{u}^{(n+1)}(x)\nabla H^{(n)}(x)]=0 \text{ for a.e. } x\in\Omega, \tag{6}$$

under the constraints

$$\frac{1}{\delta t}(H^{(n+1)}(x)-H^{(n)}(x))\geq -F(x) \text{ for a.e. } x\in\Omega, \tag{7}$$

$$0\leq \overline{u}^{(n+1)}(x)\leq 1 \text{ for a.e. } x\in\Omega, \tag{8}$$

and

$$(\overline{u}^{(n+1)}(x)-1)\ \left(\frac{1}{\delta t}(H^{(n+1)}(x)-H^{(n)}(x))+F(x)\right)=0 \text{ for a.e. } x\in\Omega. \tag{9}$$

Denoting by $g(x)=\Lambda(x)\nabla H^{(n)}(x)$ and reporting in (7)–(9) the expression of $\frac{1}{\delta t}(H^{(n+1)}-H^{(n)})$ taken from (6), the unknown function $\overline{u}^{(n+1)}$ is then a solution u of the following system of equations:

$$\begin{aligned}&\operatorname{div}[u(x)g(x)]+F(x)\geq 0 \text{ for a.e. } x\in\Omega,\\ &0\leq u(x)\leq 1 \text{ for a.e. } x\in\Omega,\end{aligned} \tag{10}$$

and

$$(u(x)-1)\ (\operatorname{div}[u(x)g(x)]+F(x))=0 \text{ for a.e. } x\in\Omega. \tag{11}$$

Hence, if we are able to prove that problem (10)–(11) has one and only one solution $\tilde{g} = u(\cdot)g(\cdot)$, the function $H^{(n+1)}$ is then given by the relation $H^{(n+1)}(x) = H^{(n)}(x) + \delta t\, \mathrm{div}\tilde{g}(x)$ for a.e. $x \in \Omega$.

Remark 1.1. If there exist some regions where $g = 0$ and $F = 0$ simultaneously, it is clear that any value in $[0, 1]$ is possible for u. Nevertheless, $\tilde{g}$ is uniquely defined by the value 0 in such a region.

A fully implicit version of this method (namely $\nabla H^{(n)}(x)$ is replaced by $\nabla H^{(n+1)}(x)$ in (6)) in addition to a finite volume space discretization are used in an industrial simulator (see [11], [6]).

The aim of this paper is to focus on both the analytical and the numerical aspects of the subproblem (10)–(11). Although it is not clear that the resolution of this subproblem yields the complete theoretical resolution of the fully coupled problem (2)–(5), we emphasize that it leads to the key points of a correct numerical implementation.

In this paper, the following hypotheses, denoted Hypotheses (H), are assumed.

Hypotheses (H).

1. Ω is a bounded open subset of $\mathbb{R}^d$, $d \in \mathbb{N}^\star = \mathbb{N} \setminus \{0\}$ (in applications, $d = 2$), with a Lipschitz continuous boundary $\partial\Omega$ (this gives the existence, for a.e. $x \in \partial\Omega$, of the unit outward vector $\mathbf{n}(x)$ normal to the boundary).
2. There exist two functions, $h \in C^1(\overline{\Omega})$ and $\Lambda\ : \Omega \longrightarrow \mathcal{M}_d$ (the set of bounded, symmetric, definite positive, $d \times d$ matrices) such that the function $g\ : \Omega \to \mathbb{R}^d$, defined by $g(x) = \Lambda(x)\nabla h(x)$ for all $x \in \Omega$, is Lipschitz continuous on $\overline{\Omega}$ and satisfies $g(x) \cdot \mathbf{n}(x) = 0$ for a.e. $x \in \partial\Omega$.
3. $F \in L^\infty(\Omega)$ is such that $F(x) \geq 0$ for a.e. $x \in \Omega$.

As we see below in section 2, there does not always exist a continuous function $u\ : \Omega \to \mathbb{R}$ such that (10)–(11) are satisfied, and the regularity of $\tilde{g} = ug$ in the general case is an open problem. Therefore we first look for a weak formulation of problem (10)–(11). For this purpose, let $\varphi \in C^1(\overline{\Omega}, \mathbb{R}_+)$, and let $\xi \in C^1(\mathbb{R})$ be such that $\xi'(1) \geq 0$. We multiply the first inequality of (10) by $\xi'(u(x))\varphi(x)$, and we integrate on Ω. We get

(12)
$$\int_\Omega \xi'(u(x))\varphi(x)(\mathrm{div}[u(x)g(x)] + F(x))\mathrm{d}x = \int_\Omega \xi'(1)\varphi(x)(\mathrm{div}[u(x)g(x)] + F(x))\mathrm{d}x$$
$$+ \int_\Omega (\xi'(u(x)) - \xi'(1))\varphi(x)(\mathrm{div}[u(x)g(x)] + F(x))\mathrm{d}x.$$

The second term of the right-hand side vanishes, using (11), and the first one is nonnegative. This leads to

$$\int_\Omega \xi'(u(x))\varphi(x)(\mathrm{div}[u(x)g(x)] + F(x))\mathrm{d}x \geq 0. \tag{13}$$

We remark that, for any function ξ which is such that $\xi'(1) \geq 0$ and ξ' is decreasing, we can get (13) from (12) for any function u which only verifies (10). For this reason, we now assume that ξ is convex (in the sense that ξ' is nondecreasing, this terminology is used in the sequel of this paper), and we develop equation (13), integrating by parts. We then derive the following weak sense for a solution to problem (10)–(11).

Definition 1.1 (weak solution to problem (10)–(11)). *Under Hypotheses* (H), *we say that a function $\tilde{g} \in L^\infty(\Omega)^d$ is a weak solution to problem* (10)–(11) *if there* *exists $u \in L^\infty(\Omega)$ such that $\tilde{g}(x) = u(x)g(x)$ for a.e. $x \in \Omega$, and u satisfies the following inequalities: $0 \le u(x) \le 1$ for a.e. $x \in \Omega$ and*

$$\begin{aligned}(14)\qquad \int_\Omega \big(\xi(u(x))(-g(x)\cdot\nabla\varphi(x)) + [\xi'(u(x))u(x) - \xi(u(x))]\varphi(x)\mathrm{div}g(x)\\ + \xi'(u(x))\varphi(x)F(x)\big)\mathrm{d}x \ge 0\\ \forall \xi \in C^1(\mathbb{R}) \textit{ convex such that } \xi'(1) \ge 0 \qquad \forall\varphi \in C^1(\overline{\Omega}, \mathbb{R}_+).\end{aligned}$$

The following proposition expresses that any weak solution in the above sense satisfies (10) in a weak sense, and the next one shows that any regular weak solution satisfies (10)–(11), thus completing the justification of Definition 1.1.

PROPOSITION 1.2. *Under Hypotheses* (H), *let $\tilde{g} : \Omega \to \mathbb{R}^d$ be a weak solution to problem* (10)–(11) *in the sense of Definition* 1.1. *Then*

$$(15)\qquad \int_\Omega (-\tilde{g}(x)\cdot\nabla\varphi(x)\mathrm{d}x + F(x)\varphi(x))\mathrm{d}x \ge 0 \qquad \forall\varphi \in C^1(\overline{\Omega}, \mathbb{R}_+).$$

Proof. Let us assume that $u \in L^\infty(\Omega)$ is such that $\tilde{g}(x) = u(x)g(x)$ and $0 \le u(x) \le 1$ for a.e. $x \in \Omega$, and (14) is satisfied. Let us take $\xi : s \mapsto s$ in (14). We then obtain (15). □

PROPOSITION 1.3. *Under Hypotheses* (H), *let $\tilde{g} : \Omega \to \mathbb{R}^d$ be a Lipschitz continuous function. Then $\tilde{g}$ is a weak solution to problem* (10)–(11) *in the sense of Definition* 1.1 *if and only if there exists a function $u \in L^\infty(\Omega)$ with $\tilde{g}(x) = u(x)g(x)$ and $0 \le u(x) \le 1$ for a.e. $x \in \Omega$ such that* (10) *and* (11) *are satisfied by the function u.*

Proof. Let us assume that $\tilde{g}$ is a weak solution to problem (10)–(11) in the sense of Definition 1.1. Then there exists $u \in L^\infty(\Omega)$ such that $\tilde{g}(x) = u(x)g(x)$ and $0 \le u(x) \le 1$ for a.e. $x \in \Omega$, and (14) is satisfied. Proposition 1.2 shows that (10) is satisfied by the function u for a.e. $x \in \Omega$. In order to prove that (11) is satisfied for a.e. $x \in \Omega$ by the function u, we shall separate the cases $x \in \Omega_0 := \{x \in \Omega, g(x) = 0\}$ and $x \in \Omega \setminus \Omega_0$. Let us take in (14) a test function φ whose support is included in the open set $\Omega \setminus \Omega_0$. Since the function u verifies $u(x) = |\tilde{g}(x)|/|g(x)|$ for a.e. $x \in \Omega \setminus \Omega_0$, u is Lipschitz continuous on the support of φ; we can thus integrate by parts, which produces, from (14), that (13) is satisfied by u. Let us now prove that u verifies (11).

Choosing $\xi : s \mapsto (s-1)^2$, we get that $\int_\Omega (u(x)-1)\varphi(x)(\mathrm{div}[u(x)g(x)] + F(x))\mathrm{d}x \ge 0$ holds. This implies that $(u(x) - 1)(\mathrm{div}[u(x)g(x)] + F(x)) \ge 0$ for a.e. $x \in \Omega$ such that $g(x) \ne 0$. But on one hand, $u(x) \le 1$ for a.e. $x \in \Omega$, and on the other hand, (10) is satisfied for a.e. $x \in \Omega$. Therefore, u verifies (11) for a.e. $x \in \Omega \setminus \Omega_0$.

Let us now obtain the same conclusion for a.e. $x \in \Omega_0$. Let $\eta \in C^1(\mathbb{R})$ be a function such that $0 \le \eta(x) \le 1$ for all $x \in \mathbb{R}$, $\eta(0) = 1$ and support$(\eta) \subset [-1, 1]$. For all $n \in \mathbb{N}^\star$, let us define the Lipschitz continuous function $\varphi_n : x \mapsto \eta(n|g(x)|)$. On one hand, we have that for a.e. $x \in \Omega_0$, $g(x)\cdot\nabla\varphi_n(x) = 0$ holds. On the other hand, for all $x \in \Omega \setminus \Omega_0$, we get that $g(x)\cdot\nabla\varphi_n(x)$ tends to 0 as $n \to \infty$ and remains bounded (indeed, it suffices to consider the cases $|g(x)| \le 1/n$ and $|g(x)| \ge 1/n$ and to use the property $\nabla g_i \in L^\infty(\Omega)^d$, where g_i, $i = 1, \dots, d$ are the components of g).

We then introduce $\xi : s \to (s-1)^2$ and $\varphi = \varphi_n$ in (14) (this is possible, taking regularizations in $C^1(\overline{\Omega}, \mathbb{R}_+)$ of φ_n). We then get

$$(16)\qquad T_1^{(n)} + T_2^{(n)} + T_3^{(n)} \ge 0,$$

with $T_1^{(n)} = \int_\Omega (u(x)-1)^2(-g(x)\cdot\nabla\varphi_n(x))\mathrm{d}x$, $T_2^{(n)} = \int_\Omega (u(x)^2-1)\varphi_n(x)\mathrm{div}g(x)\mathrm{d}x$, and $T_3^{(n)} = 2\int_\Omega (u(x)-1)F(x)\varphi_n(x)\mathrm{d}x$. Thus, thanks to the convergence properties of $g\cdot\nabla\varphi_n$ and to the dominated convergence theorem, we get that $T_1^{(n)}$ tends to 0 as $n\to\infty$.

Since $\varphi_n(x)$ tends to 0 for all $x\in\Omega\setminus\Omega_0$ and to 1 for all $x\in\Omega_0$, we get that $T_2^{(n)}$ tends to $\int_{\Omega_0}(u(x)^2-1)\mathrm{div}g(x)\mathrm{d}x$. Since $g(x)=0$ for all $x\in\Omega_0$, then $\partial_i g(x)=0$ for a.e. $x\in\Omega_0$ and all $i=1,\dots,d$ (this classical property has been shown, for example, in [17]), which produces $\int_{\Omega_0}(u(x)^2-1)\mathrm{div}g(x)\mathrm{d}x=0$.

We finally get that $T_3^{(n)}$ tends to $2\int_{\Omega_0}(u(x)-1)F(x)\mathrm{d}x$ as $n\to\infty$.

We thus get, passing to the limit $n\to\infty$ in (16), $\int_{\Omega_0}(u(x)-1)F(x)\mathrm{d}x\ge 0$, which proves that $u(x)=1$ for a.e. $x\in\Omega_0$ such that $F(x)>0$.

Therefore, for a.e. $x\in\Omega_0$, either $F(x)>0$ and $u(x)=1$, or $F(x)=0$ and $\mathrm{div}(\tilde g(x))+F(x)=0$, since $\tilde g(x)=0$ for a.e. $x\in\Omega_0$. Thus (11) is satisfied for a.e. $x\in\Omega_0$.

Reciprocally, let us assume that (10) and (11) are satisfied a.e. by the function u. We then get that (13) is satisfied, and therefore equation (14) is satisfied. This proves that $\tilde g$ is a weak solution to problem (10)–(11) in the sense of Definition 1.1. □

This paper is organized as follows. We first give, in section 2, the analytical expression of the weak solution in the one-dimensional case (the uniqueness result, proved in section 3, indeed holds in this case). In section 3, we first give a characterization of the set $\mathcal{C}(g,F)$ of functions which weakly satisfy (10). We prove a comparison result between a weak process solution to problem (10)–(11) (defined in Definition 3.3) and any element of $\mathcal{C}(g,F)$. This result suffices to prove the uniqueness of the weak solution to problem (10)–(11) in the sense of Definition 1.1. We then present a numerical scheme in section 4. The existence and uniqueness of a discrete solution is itself a nontrivial problem, which we solve by proving the convergence of an iterative method. This scheme is then proven to converge to a weak process solution to problem (10)–(11) in the sense of Definition 3.3. Thanks to the uniqueness result of the weak solution, we deduce the strong convergence result of the numerical scheme to this weak solution. We then give some numerical results in section 5 and conclude with some open problems.

2. Weak solutions in the one-dimensional case.

We have the following result.

PROPOSITION 2.1 (expression of the weak solution in the one-dimensional case). *Let $(a,b)\in\mathbb{R}^2$ be such that $a<b$, let $F\in L^\infty((a,b))$ be a nonnegative function, and let $g\in C^0([a,b])$ be a Lipschitz continuous function with $g(a)=g(b)=0$.*

Then, the function $\tilde g\ :[a,b]\to\mathbb{R}$ defined by

$$\tilde g(x) = \min_{y\in[x,b]}\left(g^+(y)+\int_x^y F(t)\mathrm{d}t\right) - \min_{y\in[a,x]}\left(g^-(y)+\int_y^x F(t)\mathrm{d}t\right) \quad \forall x\in[a,b], \tag{17}$$

where for all $s\in\mathbb{R}$ we denote $s^+=\max(s,0)$ and $s^-=\max(-s,0)$, is the unique weak solution to problem (10)–(11) *in the sense of Definition* 1.1.

Proof. Let us first remark that $\tilde g$ defined as such verifies that for all $x\in[a,b]$, $\tilde g^+(x)=\min_{y\in[x,b]}\left(g^+(y)+\int_x^y F(t)\mathrm{d}t\right)$ and $\tilde g^-(x)=\min_{y\in[a,x]}(g^-(y)+\int_y^x F(t)\mathrm{d}t)$ with $0\le\tilde g^+(x)\le g^+(x)$ and $0\le\tilde g^-(x)\le g^-(x)$. Then the function $\tilde g^+$ satisfies

$\tilde{g}^+(x) = \min_{y\in[a,b]} G_p(x,y)$ for all $x \in [a,b]$ with

$$G_p(x,y) = g^+(\max(x,y)) + \int_x^{\max(x,y)} F(t)\mathrm{d}t \qquad \forall (x,y) \in [a,b]^2.$$

Similarly, we have $\tilde{g}^-(x) = \min_{y\in[a,b]} G_m(x,y)$ for all $x \in [a,b]$ with

$$G_m(x,y) = g^-(\min(x,y)) + \int_{\min(x,y)}^{x} F(t)\mathrm{d}t \qquad \forall (x,y) \in [a,b]^2.$$

It is then clear that the functions G_p and G_m are Lipschitz continuous on $[a,b]^2$ with any Lipschitz constant M such that M is a bound of $F + |g'|$ in $L^\infty((a,b))$. Let $(x,\bar{x}) \in [a,b]^2$ be given, and let $(Y,\bar{Y}) \in [a,b]^2$ be such that $\tilde{g}^+(x) = G_p(x,Y)$ and $\tilde{g}^+(\bar{x}) = G_p(\bar{x},\bar{Y})$. Since we have

$$\tilde{g}^+(x) - \tilde{g}^+(\bar{x}) \le G_p(x,\bar{Y}) - G_p(\bar{x},\bar{Y}) \le M|x-\bar{x}|,$$

and, inverting the roles of x and $\bar{x}$,

$$\tilde{g}^+(\bar{x}) - \tilde{g}^+(x) \le G_p(x,Y) - G_p(\bar{x},Y) \le M|x-\bar{x}|,$$

we thus get that $\tilde{g}^+$ is Lipschitz continuous. Since the same proof holds for $\tilde{g}^-$, we thus get that $\tilde{g} = \tilde{g}^+ - \tilde{g}^-$ is Lipschitz continuous as well. We thus define the function $u\ :\ [a,b] \to [0,1]$ by $u(x) = 1$ for all $x \in \Omega$ such that $g(x) = 0$ and $u(x) = \tilde{g}(x)/g(x)$ for all $x \in [a,b]$ such that $g(x) \neq 0$. Let us prove that u satisfies (10)–(11) (from Proposition 1.3, since Hypotheses (H) are satisfied, this is sufficient to conclude). Since for all $x \in [a,b]$ such that $g(x) = 0$, $\tilde{g}(x) = 0$ holds, $\tilde{g}'(x) + F(x) \ge 0$ for a.e. $x \in [a,b]$ such that $g(x) = 0$ [17]. Let $x \in [a,b]$ be such that $g(x) > 0$. Then there exists $\alpha > 0$ such that $x+\alpha \le b$ and $g(y) > 0$ for all $y \in (x, x+\alpha)$. For $\bar{x} \in (x, x+\alpha)$, let $\bar{Y} \in [\bar{x}, b]$ be such that $\tilde{g}(\bar{x}) = G_p(\bar{x},\bar{Y})$. We have

$$\tilde{g}(x) - \tilde{g}(\bar{x}) \le G_p(x,\bar{Y}) - G_p(\bar{x},\bar{Y}) = \int_x^{\bar{x}} F(t)\mathrm{d}t. \tag{18}$$

The above inequality proves that $\tilde{g}'(x)+F(x) \ge 0$ for a.e. $x \in [a,b]$ such that $g(x) > 0$. Similarly, we obtain that $\tilde{g}'(x) + F(x) \ge 0$ for a.e. $x \in [a,b]$ such that $g(x) < 0$. This proves that (10) is satisfied. Let $x \in (a,b)$ such that $u(x) < 1$. Let us assume that $g(x) > 0$. Again, there exists $\alpha > 0$ such that $x + \alpha \le b$ and $g(y) > 0$ for all $y \in (x, x+\alpha)$, and again, for all $\bar{x} \in (x, x+\alpha)$, (18) holds. Since we have $0 \le \tilde{g}(x) < g(x)$, there exists $Y \in (x,b)$ such that $\tilde{g}(x) = G_p(x,Y)$. Therefore, for all $\bar{x} \in (x,Y)$, since $Y > \bar{x}$, we get

$$\tilde{g}(x) - \tilde{g}(\bar{x}) \ge G_p(x,Y) - G_p(\bar{x},Y) = \int_x^{\bar{x}} F(t)\mathrm{d}t.$$

Thus, for all $\bar{x} \in (x, \min(Y, x+\alpha))$, we get $\tilde{g}(x) - \tilde{g}(\bar{x}) = \int_x^{\bar{x}} F(t)\mathrm{d}t$, which implies that $\tilde{g}'(x) = -F(x)$ for a.e. $x \in \Omega$ such that $u(x) < 1$ and $g(x) > 0$. The case $u(x) < 1$ and $g(x) < 0$ can be similarly handled. Therefore $\tilde{g}$ is Lipschitz continuous and (10)–(11) are satisfied. Thanks to Proposition 1.3, this completes the proof that $\tilde{g}$ is a weak solution to problem (10)–(11) in the sense of Definition 1.1.

Since, within the hypotheses of the above proposition, Hypotheses (H) are satisfied (in particular, $g = h'$ with $h\ :\ x \mapsto \int_a^x g(t)\mathrm{d}t$), we can apply Proposition 3.5, which implies the uniqueness of the weak solution to problem (10)–(11) in the sense of Definition 1.1. □

Let us take two simple examples (one can find some examples inspired by geological problems in [6]). We consider a one-dimensional case (see Figure 1 below), with $\Omega = (-1, 1)$, $g : x \mapsto x^3 - x$, and $F : x \mapsto 1/2$. In this case, it is easy to verify that the function $\tilde{g}$ defined by (17) is such that $\tilde{g} = ug$, where the function u is such that $u : x \mapsto 1$ for all $x \in (-1, -\sqrt{1/2}) \cup (\sqrt{1/2}, 1)$ and $u : x \mapsto 1/(2(1 - x^2))$ for all $x \in (-\sqrt{1/2}, \sqrt{1/2})$. We thus obtain that the function u is continuous over Ω, but this is not always the case.

Indeed, let us consider the case $\Omega = (-1, 1)$, $g : x \mapsto x^3 - x$ for all $x \in [-1, 0]$, $g : x \mapsto \frac{1}{2}(x^3 - x)$ for all $x \in [0, 1]$, and $F : x \mapsto 1/2$. In such a case, g is only Lipschitz continuous, and the function $\tilde{g} = ug$ given by (17) is such that $u : x \mapsto 1$ for all $x \in (-1, -\sqrt{1/2}) \cup (0, 1)$ and $u : x \mapsto 1/(2(1 - x^2))$ for all $x \in (-\sqrt{1/2}, 0)$. This function u is therefore discontinuous in 0, although the function $\tilde{g} = ug$ remains Lipschitz continuous.

3. Uniqueness results.

3.1. Properties of the set of functions which satisfy (10). We consider in this section the set $\mathcal{C}(g, F)$ of functions which satisfy (10) in the sense of distributions. We shall prove below that the weak solution $\tilde{g}$ to problem (10)–(11) in the sense of Definition 1.1 is the projection of g in $L^2(\Omega)^d$ on $\mathcal{C}(g, F)$, and it is an extremal point of $\mathcal{C}(g, F)$ in the sense that $|\tilde{g}| \geq |\gamma|$ for all $\gamma \in \mathcal{C}(g, F)$ (see Proposition 3.5). The proof of this property is obtained thanks to the characterization of $\mathcal{C}(g, F)$ given by Proposition 3.2.

Definition 3.1 (the set $\mathcal{C}(g, F)$). *Under Hypotheses* (H), *we define the set $\mathcal{C}(g, F)$ of functions $\gamma \in L^2(\Omega)^d$ such that there exists $v \in L^\infty(\Omega)$, with $\gamma(x) = v(x)g(x)$ and $0 \leq v(x) \leq 1$, for a.e. $x \in \Omega$ and*

$$\int_{\mathbb{R}_+} \int_\Omega ([-\gamma(x) \cdot \nabla\varphi(x)] + \varphi(x)F(x))\,\mathrm{d}x \geq 0 \qquad \forall\varphi \in C^1(\overline{\Omega}, \mathbb{R}_+). \tag{19}$$

Remark 3.1 (some properties of $\mathcal{C}(g, F)$). The set $\mathcal{C}(g, F)$ is nonempty (because $0 \in \mathcal{C}(g, F)$), convex (since the left-hand side of (19) is linear with respect to γ), and closed (in $L^2(\Omega)^d$).

Remark 3.2 (weak solutions and $\mathcal{C}(g, F)$). Thanks to Proposition 1.2, any weak solution to problem (10)–(11) in the sense of Definition 1.1 belongs to $\mathcal{C}(g, F)$.

We have the following proposition, which gives a characterization of the functions of $\mathcal{C}(g, F)$.

Proposition 3.2 (characterization of $\mathcal{C}(g, F)$). *Under Hypotheses* (H), *let $v \in L^\infty(\Omega)$, such that $0 \leq v(x) \leq 1$ for a.e. $x \in \Omega$, and let $\gamma(x) = v(x)g(x)$. Then $\gamma \in \mathcal{C}(g, F)$ (defined in Definition* 3.1*) holds if and only if the following property holds:*

$$\begin{aligned} &\int_\Omega \big(\xi(v(x))[-g(x) \cdot \nabla\varphi(x)] + [\xi'(v(x))v(x) - \xi(v(x))]\,\varphi(x)\ \mathrm{div} g(x) \\ &\qquad\qquad + \xi'(v(x))\varphi(x)F(x)\big)\mathrm{d}x \geq 0 \\ &\qquad \forall\varphi \in C^1(\overline{\Omega}, \mathbb{R}_+),\ \forall\xi \in C^1(\mathbb{R}) \textit{ s.t. } \forall\kappa \in [0, 1],\ \xi'(\kappa) \geq 0. \end{aligned} \tag{20}$$

Proof. Under the hypotheses of the above proposition, let us assume that $\gamma \in \mathcal{C}(g, F)$. We introduce a sequence of mollifiers in $\mathbb{R}^d$. Let $\rho \in C_c^\infty(\mathbb{R}^d, \mathbb{R}_+)$ (the set of smooth functions with a compact support) be such that

$$\{x \in \mathbb{R}^d;\ \rho(x) \neq 0\} \subset \{x \in \mathbb{R}^d;\ |x| \leq 1\} \tag{21}$$

and

$$\int_{\mathbb{R}^d} \rho(x)\mathrm{d}x = 1. \tag{22}$$

For $n \in \mathbb{N}^\star$, we define

$$\rho_n(x) = n^d \rho(nx) \qquad \forall x \in \mathbb{R}^d. \tag{23}$$

We then define the functions $v_n(y) = \int_\Omega v(x)\rho_n(x-y)\mathrm{d}x$. Let $\psi \in C^1(\overline{\Omega}, \mathbb{R}_+)$ be given. For a given $y \in \Omega$, we introduce the function $\varphi \ :\ x \to \xi'(v_n(y))\psi(y)\rho_n(y-x) \in C^1(\overline{\Omega}, \mathbb{R}_+)$ in (19), and we integrate with respect to y. We thus get $T_4^{(n)} + T_5^{(n)} \geq 0$ with

$$T_4^{(n)} = -\int_\Omega \int_\Omega \xi'(v_n(y))\psi(y)v(x)g(x) \cdot \nabla\rho_n(y-x)\mathrm{d}x\mathrm{d}y \tag{24}$$

and

$$T_5^{(n)} = \int_\Omega \int_\Omega \xi'(v_n(y))\psi(y)F(x)\rho_n(y-x)\mathrm{d}x\mathrm{d}y. \tag{25}$$

The limit of the last term, as $n \to \infty$, satisfies

$$\lim_{n\to\infty} T_5^{(n)} = \int_\Omega \left(\xi'(v(y))\psi(y)F(y)\right)\mathrm{d}y.$$

We then turn to the study of $T_4^{(n)}$ as $n \to \infty$. We have $T_4^{(n)} = T_6^{(n)} + T_7^{(n)} + T_8^{(n)}$ with

$$T_6^{(n)} = \int_\Omega \int_\Omega \xi'(v_n(y))\psi(y)v(x)g(y) \cdot \nabla\rho_n(y-x)\mathrm{d}x\mathrm{d}y,$$

$$T_7^{(n)} = \int_\Omega \int_\Omega \xi'(v_n(y))\psi(y)v(y)(g(x)-g(y)) \cdot \nabla\rho_n(y-x)\mathrm{d}x\mathrm{d}y,$$

and

$$T_8^{(n)} = \int_\Omega \int_\Omega \xi'(v_n(y))\psi(y)(v(x)-v(y))(g(x)-g(y)) \cdot \nabla\rho_n(y-x)\mathrm{d}x\mathrm{d}y.$$

We then have

$$T_6^{(n)} = \int_\Omega \xi'(v_n(y))\psi(y)g(y) \cdot \nabla v_n(y)\mathrm{d}y = \int_\Omega \psi(y)g(y) \cdot \nabla\xi(v_n)(y)\mathrm{d}y,$$

which delivers, thanks to an integration by parts with respect to y,

$$T_6^{(n)} = -\textstyle\int_\Omega \xi(v_n(y))\mathrm{div}[\psi(y)g(y)]\mathrm{d}y.$$

This leads to

$$\lim_{n\to\infty} T_6^{(n)} = \int_\Omega \xi(v(y))\mathrm{div}[\psi(y)g(y)]\mathrm{d}y.$$

We also have, thanks to an integration by parts with respect to x,

$$T_7^{(n)} = -\int_\Omega \int_\Omega \xi'(v_n(y))\psi(y)v(y)\rho_n(y-x)\mathrm{div}g(x)\mathrm{d}x\mathrm{d}y,$$

which produces

$$\lim_{n\to\infty} T_7^{(n)} = \int_\Omega \xi'(v(y))v(y)\psi(y)\mathrm{div}g(y)\mathrm{d}y.$$

Finally, we get

$$\lim_{n\to\infty} T_8^{(n)} = 0$$

thanks to the continuity in means of v and to the fact that $x \mapsto (g(x)-g(y))\cdot\nabla\rho_n(y-x)$ belongs to $L^1(\Omega)$. Then (20) is obtained by gathering all the results obtained above by passing to the limit $n \to \infty$.

Conversely, it suffices to choose the function $\xi \; : \; s \mapsto s$ in (20), for obtaining (19). □

3.2. Weak process solutions. Since we consider below the convergence of numerical schemes, on which the only estimate that we obtain in this case is an $L^\infty(\Omega)$ estimate, we must therefore consider weaker solutions than that defined in Definition 1.1, namely, weak process solutions. This notion of a weak process solution, introduced in [7], is related to the notion of Young measure first used by [3] in the nonlinear scalar hyperbolic framework. Young measures are extensively used in optimal control, nonconvex variational problems, phase transitions, microstructure problems, ... (see, e.g., [14], [16]).

The uniqueness result proven below leads to the uniqueness of such a weak process solution and to the fact that any weak process solution is indeed a weak solution. We then obtain the uniqueness of the weak solution to problem (10)–(11) in the sense of Definition 1.1. Moreover, this result is mainly used in the study of the numerical scheme in order to prove its strong convergence.

Definition 3.3 (weak process solutions to problem (10)–(11)). *Under Hypotheses* (H), *we say that a function $\hat{g}$ is a weak process solution to problem* (10)–(11) *if there exists $u \in L^\infty(\Omega\times(0,1))$ such that $\hat{g} \; : \; (x,\alpha) \mapsto u(x,\alpha)g(x)$ for a.e. $(x,\alpha) \in \Omega\times(0,1)$. And u satisfies the following inequalities: $0 \le u(x,\alpha) \le 1$ for a.e. $(x,\alpha) \in \Omega\times(0,1)$ and*

(26)
$$\int_\Omega\int_0^1 \big(\xi(u(x,\alpha))(-g(x)\cdot\nabla\varphi(x)) + [\xi'(u(x,\alpha))u(x,\alpha) - \xi(u(x,\alpha))]\varphi(x)\mathrm{div}g(x) \\ + \xi'(u(x,\alpha))\varphi(x)F(x)\big)\mathrm{d}\alpha\mathrm{d}x \ge 0 \\ \forall\xi\in C^1(\mathbb{R}),\ \text{convex s.t. } \xi'(1)\ge 0,\ \forall\varphi\in C^1(\overline{\Omega},\mathbb{R}_+).$$

We first prove the following property, which at the same time, gives some elements to conclude to the uniqueness of the weak process solution but also helps to prove that this solution is an extremal point of $\mathcal{C}(g,F)$.

Proposition 3.4 (comparison of a weak process solution and an element of $\mathcal{C}(g,F)$). *Under Hypotheses* (H), *let $\gamma \in \mathcal{C}(g,F)$ be given, where $\mathcal{C}(g,F)$ is defined* *in Definition* 3.1, *and let* $v \in L^\infty(\Omega)$, *such that* $\gamma(x) = v(x)g(x)$ *and* $0 \le v(x) \le 1$ *for a.e.* $x \in \Omega$. *Let* $\hat{g}$ *be a weak process solution to problem* (10)–(11) *in the sense of Definition* (3.3). *Let* $u \in L^\infty(\Omega\times(0,1))$ *be such that* $0 \le u(x,\alpha) \le 1$ *and* $\hat{g} \; : \; (x,\alpha) \mapsto u(x,\alpha)g(x)$ *for a.e.* $(x,\alpha) \in \Omega\times(0,1)$ *and such that* u *satisfies* (27). *Then the following inequality holds:*

$$\int_\Omega \int_0^1 (v(x) - u(x,\alpha))^+ \left[-g(x) \cdot \nabla\varphi(x)\right] \mathrm{d}\alpha \mathrm{d}x \ge 0 \qquad \forall \varphi \in C^1(\overline{\Omega}, \mathbb{R}_+). \tag{27}$$

Proof. This proof uses the method of doubling variables (first introduced by Krushkov [12]) adapted to weak process solutions [8].

Let us assume the hypotheses of the proposition. Let $\eta \in C^1(\mathbb{R}^2, \mathbb{R})$ be given such that $\eta(\cdot, b)$ is convex for all $b \in (-\infty, 1]$. We also assume that $\partial_1\eta$, the derivative of η with respect to its first argument, is such that $\partial_1\eta(1,b) \ge 0$ for all $b \in [0,1]$, and that $\partial_2\eta$, the derivative of η with respect to its second argument, is such that $\partial_2\eta(a,b) \ge 0$ for all $a, b \in [0,1]$. Let $\psi \in C^1(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{R}_+)$ be given.

Then, for all $x \in \Omega$, we have $\psi(x,\cdot) \in C^1(\overline{\Omega}, \mathbb{R}_+)$ and for all $y \in \Omega$, $\psi(\cdot, y) \in C^1(\overline{\Omega}, \mathbb{R}_+)$. We introduce $\xi(\cdot) = \eta(\cdot, v(y))$ and $\varphi = \psi(\cdot, y)$ in (27) for $y \in \Omega$, and we integrate the result on Ω. This produces

$$\begin{aligned} &\int_\Omega\int_\Omega \int_0^1 \Big(\eta(u(x,\alpha), v(y)) \left[-g(x) \cdot \nabla_x\psi(x,y)\right] \\ &+ \left[\partial_1\eta(u(x,\alpha), v(y))u(x,\alpha) - \eta(u(x,\alpha), v(y))\right] \psi(x,y) \mathrm{div} g(x) \\ &\qquad + \partial_1\eta(u(x,\alpha), v(y))\psi(x,y)F(x)\Big) \mathrm{d}\alpha \mathrm{d}x \mathrm{d}y \ge 0. \end{aligned} \tag{28}$$

We now consider (20) for v, with $\xi(\cdot) = \eta(u(x,\alpha), \cdot)$ and $\varphi = \psi(x, \cdot)$, and we integrate the result on $\Omega \times (0,1)$. We thus get

$$\begin{aligned} &\int_\Omega\int_\Omega \int_0^1 \Big(\eta(u(x,\alpha), v(y)) \left[-g(y) \cdot \nabla_y\psi(x,y)\right] \\ &+ \left[\partial_2\eta(u(x,\alpha), v(y))v(y) - \eta(u(x,\alpha), v(y))\right] \psi(x,y) \mathrm{div} g(y) \\ &\qquad + \partial_2\eta(u(x,\alpha), v(y))\psi(x,y)F(y)\Big) \mathrm{d}\alpha \mathrm{d}x \mathrm{d}y \ge 0. \end{aligned} \tag{29}$$

We now add (28) and (29). This delivers

$$T_9 + T_{10} + T_{11} \ge 0, \tag{30}$$

where

$$\begin{aligned} T_9 = -\int_\Omega\int_\Omega \int_0^1 \quad &\eta(u(x,\alpha), v(y)) \\ &\times \big(g(x) \cdot \nabla_x\psi(x,y) + g(y) \cdot \nabla_y\psi(x,y)\big) \mathrm{d}\alpha \mathrm{d}x \mathrm{d}y, \end{aligned} \tag{31}$$

$$\begin{aligned} T_{10} = \int_\Omega\int_\Omega \int_0^1 &\Big(\big(\partial_1\eta(u(x,\alpha), v(y))u(x,\alpha) - \eta(u(x,\alpha), v(y))\big)\psi(x,y) \mathrm{div} g(x) \\ &+ \big(\partial_2\eta(u(x,\alpha), v(y))v(y,\beta) - \eta(u(x,\alpha), v(y))\big)\psi(x,y) \mathrm{div} g(y)\Big) \mathrm{d}\alpha \mathrm{d}x \mathrm{d}y, \end{aligned} \tag{32}$$

and

$$T_{11} = \int_\Omega\int_\Omega\int_0^1 \big(\partial_1\eta(u(x,\alpha),v(y))F(x) + \partial_2\eta(u(x,\alpha),v(y))F(y)\big)\psi(x,y)\mathrm{d}\alpha\mathrm{d}x\mathrm{d}y. \tag{33}$$

We again use the sequence of mollifiers in $\mathbb{R}$ and $\mathbb{R}^d$, defined by (21)–(23). Let $\phi \in C^1(\mathbb{R}^d,\mathbb{R}_+)$ and $n \in \mathbb{N}^\star$ be given. We then take $\psi(x,y) = \phi(x)\rho_n(x-y)$ in (28) and (29), which gives $\psi \in C^1(\mathbb{R}^d\times\mathbb{R}^d,\mathbb{R}_+)$. We thus get, from (30),

$$T_9^{(n)} + T_{10}^{(n)} + T_{11}^{(n)} \geq 0, \tag{34}$$

with

$$\begin{aligned} T_9^{(n)} &= -\int_\Omega\int_\Omega\int_0^1 \eta(u(x,\alpha),v(y)) \\ &\quad\times\Big(\rho_n(x-y)g(x)\cdot\nabla\phi(x) + \phi(x)(g(x)-g(y))\cdot\nabla\rho_n(x-y)\Big)\mathrm{d}\alpha\mathrm{d}x\mathrm{d}y, \end{aligned} \tag{35}$$

$$\begin{aligned} T_{10}^{(n)} = \int_\Omega\int_\Omega\int_0^1 \Big(&[\partial_1\eta(u(x,\alpha),v(y))u(x,\alpha) - \eta(u(x,\alpha),v(y))]\,\mathrm{div}g(x) \\ &+ [\partial_2\eta(u(x,\alpha),v(y))v(y) - \eta(u(x,\alpha),v(y))]\,\mathrm{div}g(y)\Big)\phi(x)\rho_n(x-y)\mathrm{d}\alpha\mathrm{d}x\mathrm{d}y, \end{aligned} \tag{36}$$

$$\begin{aligned} T_{11}^{(n)} = \int_\Omega\int_\Omega\int_0^1 \quad &\big(\partial_1\eta(u(x,\alpha),v(y))F(x) + \partial_2\eta(u(x,\alpha),v(y))F(y)\big) \\ &\times\phi(x)\rho_n(x-y)\mathrm{d}\alpha\mathrm{d}x\mathrm{d}y. \end{aligned} \tag{37}$$

We have $T_9^{(n)} = T_{12}^{(n)} + T_{13}^{(n)} + T_{14}^{(n)}$, with

$$T_{12}^{(n)} = -\int_\Omega\int_\Omega\int_0^1 \eta(u(x,\alpha),v(y))\rho_n(x-y)g(x)\cdot\nabla\phi(x)\mathrm{d}\alpha\mathrm{d}x\mathrm{d}y, \tag{38}$$

$$\begin{aligned} T_{13}^{(n)} = -\int_\Omega\int_\Omega\int_0^1 \quad &\eta(u(x,\alpha),v(x)) \\ &\times\phi(x)(g(x)-g(y))\cdot\nabla\rho_n(x-y)\mathrm{d}\alpha\mathrm{d}x\mathrm{d}y, \end{aligned} \tag{39}$$

$$\begin{aligned} T_{14}^{(n)} = -\int_\Omega\int_\Omega\int_0^1 \quad &\Big(\eta(u(x,\alpha),v(y)) - \eta(u(x,\alpha),v(x))\Big) \\ &\times\phi(x)(g(x)-g(y))\cdot\nabla\rho_n(x-y)\mathrm{d}\alpha\mathrm{d}x\mathrm{d}y. \end{aligned} \tag{40}$$

The limit of $T_{12}^{(n)}$ as $n \longrightarrow \infty$ is given by

$$\lim_{n\to\infty} T_{12}^{(n)} = -\int_\Omega\int_0^1 \eta(u(x,\alpha),v(x))g(x)\cdot\nabla\phi(x)\mathrm{d}\alpha\mathrm{d}x.$$

Thanks to an integration by parts with respect to y and to Hypotheses (H), we get $T_{13}^{(n)} = T_{15}^{(n)} + T_{16}^{(n)}$, where

$$T_{15}^{(n)} = \int_\Omega\int_{\partial\Omega}\int_0^1 \eta(u(x,\alpha),v(x))\phi(x)\rho_n(x-y)g(x)\cdot\mathbf{n}(y)\mathrm{d}\alpha\mathrm{d}y\mathrm{d}x \tag{41}$$

and

$$T_{16}^{(n)} = \int_\Omega \int_\Omega \int_0^1 \eta(u(x,\alpha), v(x))\phi(x)\rho_n(x-y)\mathrm{div}g(y)\mathrm{d}\alpha\mathrm{d}x\mathrm{d}y. \tag{42}$$

We have, for a.e. $y \in \partial\Omega$,

$$\lim_{n\to\infty} \int_\Omega \int_0^1 \eta(u(x,\alpha), v(x))\phi(x)\rho_n(x-y)g(x)\cdot\mathbf{n}(y)\mathrm{d}\alpha\mathrm{d}x = 0,$$

which produces

$$\lim_{n\to\infty} T_{15}^{(n)} = 0,$$

and therefore

$$\lim_{n\to\infty} T_{13}^{(n)} = \lim_{n\to\infty} T_{16}^{(n)} = \int_\Omega \int_0^1 \eta(u(x,\alpha), v(x))\phi(x)\mathrm{div}g(x)\mathrm{d}\alpha\mathrm{d}x.$$

Thanks to the theorem of continuity in means applied to the function v and thanks to the fact that $(x,y) \mapsto (g(x) - g(y)) \cdot \nabla\rho_n(x-y)$ vanishes for $|x-y| > 1/n$ and belongs to $L^1(\Omega)$ since g is regular, we get

$$\lim_{n\to\infty} T_{14}^{(n)} = 0.$$

We have, again using the Lebesgue dominated convergence theorem,

$$\lim_{n\to\infty} T_{10}^{(n)} = \int_\Omega \int_0^1 \big(\partial_1\eta(u(x,\alpha), v(x))u(x,\alpha) + \partial_2\eta(u(x,\alpha), v(x))v(x) \\ - 2\eta(u(x,\alpha), v(x))\big)\phi(x)\mathrm{div}g(x)\mathrm{d}\alpha\mathrm{d}x$$

and

$$\lim_{n\to\infty} T_{11}^{(n)} = \int_\Omega \int_0^1 \left(\partial_1\eta(u(x,\alpha), v(x)) + \partial_2\eta(u(x,\alpha), v(x))\right) F(x)\phi(x)\mathrm{d}\alpha\mathrm{d}x.$$

We thus get, passing to the limit $n \to \infty$ in (34),

(43)

$$\int_\Omega \int_0^1 \Big(\eta(u(x,\alpha), v(x))\left[-g(x)\cdot\nabla\phi(x)\right] \\ + \big(\partial_1\eta(u(x,\alpha), v(x))u(x,\alpha) + \partial_2\eta(u(x,\alpha), v(y))v(x) - \eta(u(x,\alpha), v(x))\big)\phi(x)\mathrm{div}g(x) \\ + \big(\partial_1\eta(u(x,\alpha), v(x)) + \partial_2\eta(u(x,\alpha), v(x))\big)F(x)\phi(x)\Big)\mathrm{d}\alpha\mathrm{d}x \geq 0.$$

We now consider, for a given $\varepsilon > 0$, the function $S_\varepsilon \in C^1(\mathbb{R})$ defined by

$$\begin{array}{ll} S_\varepsilon(s) = 0 & \forall s \in (-\infty, 0], \\ S_\varepsilon(s) = s^2(3\varepsilon - 2s)/\varepsilon^3 & \forall s \in [0,\varepsilon], \\ S_\varepsilon(s) = 1 & \forall s \in [\varepsilon, +\infty). \end{array} \tag{44}$$

We define $\xi_\varepsilon(s) = \int_0^s S_\varepsilon(\tau)d\tau$, and we set, for all $(a,b) \in \mathbb{R}^2$, $\eta_\varepsilon(a,b) = \xi_\varepsilon(b-a)$. We then easily get that this function η_ε satisfies $\partial_1\eta_\varepsilon(1,b) = -S_\varepsilon(b-1) = 0 \geq 0$ for all

$b \le 1$, $\eta_\varepsilon(\cdot,b)$ is convex for all $b \le 1$, and $\partial_2\eta_\varepsilon(a,b) = S_\varepsilon(b-a) \ge 0$ for all $(a,b) \in \mathbb{R}^2$. We can then use this function in (44). We remark that, for all $(a,b) \in \mathbb{R}^2$,

$$a\partial_1\eta_\varepsilon(a,b) + b\partial_2\eta_\varepsilon(a,b) - \eta_\varepsilon(a,b) = (b-a)S_\varepsilon(b-a) - \eta_\varepsilon(a,b)$$

leads to

$$\lim_{\varepsilon\to 0}(a\partial_1\eta_\varepsilon(a,b) + b\partial_2\eta_\varepsilon(a,b) - \eta_\varepsilon(a,b)) = 0,$$

and we also remark that

$$\partial_1\eta_\varepsilon(a,b) + \partial_2\eta_\varepsilon(a,b) = 0.$$

Thus, using the Lebesgue dominated convergence theorem, we can let $\varepsilon \to 0$ in (44) which produces

$$\int_\Omega \int_0^1 (v(x) - u(x,\alpha))^+ \left[-g(x)\cdot\nabla\phi(x)\right] \mathrm{d}\alpha \mathrm{d}x \ge 0, \tag{45}$$

which is (27) and thus concludes the proof of the proposition. □

The above result is now used to yield the uniqueness of the weak process solution, and thus to obtain that this weak process solution is in fact a weak solution. Note that, in the proof of all the above propositions, the hypothesis that g can be written under the form $g(x) = \Lambda(x)\nabla h(x)$ for all $x \in \Omega$ is not used (g being Lipschitz continuous is sufficient). A uniqueness result for the weak solution could then be obtained assuming that $F > 0$ a.e. in addition to g being Lipschitz continuous, but the uniqueness result for the weak process solution remains an open problem under such hypotheses. The proof of the uniqueness result given below explicitly uses the hypothesis $g(x) = \Lambda(x)\nabla h(x)$ for all $x \in \Omega$, which fortunately holds in the physical problem.

Proposition 3.5 (uniqueness of the weak process solution). *Under Hypotheses* (H), *there exists at most one weak process solution $\hat g$ to problem* (10)–(11) *in the sense of Definition* 3.3. *Moreover, if $\hat u \in L^\infty(\Omega\times(0,1))$ is such that* $0 \le u(x,\alpha) \le 1$ *and $\hat g : (x,\alpha) \mapsto u(x,\alpha)g(x)$ for a.e. $(x,\alpha) \in \Omega\times(0,1)$ and if u satisfies* (27), *then $u(x,\alpha)$ does not depend on α on a.e. $x \in \Omega$ such that $g(x) \ne 0$ ($g(x) = 0$ and $F(x) > 0$). Then the function $\tilde g$ defined by $\tilde g(x) = u(x,\alpha)g(x)$ for a.e. $x \in \Omega$ and $\alpha \in (0,1)$ is the unique weak solution to problem* (10)–(11) *in the sense of Definition* 1.1. *Moreover, this function $\tilde g$ is an extremal point of $\mathcal{C}(g,F)$ in the sense that $|\tilde g| \ge |\gamma|$ for all $\gamma \in \mathcal{C}(g,F)$ (the set $\mathcal{C}(g,F)$ is defined in Definition* 3.1*), and it is also the projection in $L^2(\Omega)^d$ of g on the convex set $\mathcal{C}(g,F)$.*

Proof. Let us assume that $\hat g$ is a weak process solution to problem (10)–(11) in the sense of Definition 3.3. Let $u \in L^\infty(\Omega\times(0,1))$ correspond to $\hat g$ in Definition 3.3. We again denote $\Omega_0 = \{x \in \Omega,\ g(x) = 0\}$ and we remark that (27), proven in Proposition 3.4, gives for all $\gamma \in \mathcal{C}(g,F)$, letting $v \in L^\infty(\Omega)$ be such that $\gamma(x) = v(x)g(x)$ and $0 \le v(x) \le 1$ for a.e. $x \in \Omega$, that

$$\int_{\Omega\setminus\Omega_0} \int_0^1 (v(x) - u(x,\alpha))^+ \left[-g(x)\cdot\nabla\varphi(x)\right] \mathrm{d}\alpha \mathrm{d}x \ge 0.$$

Thanks to Hypotheses (H), we can define the nonnegative function φ by $\varphi(x) = h(x) - \min_{y\in\Omega} h(y)$ for all $x \in \Omega$, where $h \in C^1(\overline{\Omega})$ is such that $g(x) = \Lambda(x)\nabla h(x)$ for all

$x \in \Omega$. We then get that, for all $x \in \Omega \setminus \Omega_0$, $-g(x) \cdot \nabla\varphi(x) = -\Lambda(x)\nabla h(x).\nabla h(x) < 0$. This produces

$$(v(x) - u(x,\alpha))^+ = 0 \text{ for a.e. } (x,\alpha) \in \Omega \setminus \Omega_0 \times (0,1). \tag{46}$$

We then remark that the function $\gamma \ : \ x \mapsto \int_0^1 u(x,\alpha)\mathrm{d}\alpha g(x)$ belongs to the convex set $\mathcal{C}(g,F)$. Therefore, setting $v = \int_0^1 u(\cdot,\alpha)\mathrm{d}\alpha$ in (46), we get that for a.e. $x \in \Omega \setminus \Omega_0$, $\int_0^1 (\int_0^1 u(x,\beta)d\beta - u(x,\alpha))^+\mathrm{d}\alpha = 0$, which proves that $u(x,\alpha)$ does not depend on α for a.e. $x \in \Omega \setminus \Omega_0$. We define $T(u) \in L^\infty(\Omega)$ by $T(u)(x) = u(x,\alpha)$ for a.e. $x \in \Omega \setminus \Omega_0$ and $\alpha \in (0,1)$ and by $T(u)(x) = 1$ for a.e. $x \in \Omega_0$. We then get that the function $\tilde{g} \ : \ \Omega \to \mathbb{R}^d$ such that $\tilde{g} = T(u)g$ is such that $\tilde{g}(x) = \hat{g}(x,\alpha)$ for a.e. $x \in \Omega$ and $\alpha \in (0,1)$.

Let us assume that $\hat{g}$ and $\hat{\hat{g}}$ are two weak process solutions to problem (10)–(11) in the sense of Definition 3.3. Let u and $\hat{u}$ be some elements of $L^\infty(\Omega \times (0,1))$ which correspond to $\hat{g}$ and $\hat{\hat{g}}$, respectively, in Definition 3.3. We then get, setting $v = T(\hat{u})$ in (46), that $(T(\hat{u})(x) - T(u)(x))^+ = 0$ for a.e. $x \in \Omega \setminus \Omega_0$ and, inverting the roles of u and $\hat{u}$, $(T(u)(x) - T(\hat{u})(x))^+ = 0$. This suffices to prove that $T(\hat{u})(x) = T(u)(x)$ for a.e. $x \in \Omega \setminus \Omega_0$, which completes the proof of uniqueness of the weak process solution.

Let us prove that the function $\tilde{g} = T(u)g$ is a weak solution to problem (10)-(11) in the sense of Definition 1.1. We introduce in (27) the functions $\xi \ : \ s \to (s-1)^2$ and, for all $n \in \mathbb{N}^\star$, $\varphi = \varphi_n$, as defined in the proof of Proposition 1.3. The same analysis as that which is done in the proof of Proposition 1.3 delivers that, passing to the limit $n \to \infty$, $\int_{\Omega_0} \int_0^1 (u(x,\alpha) - 1)\mathrm{d}\alpha F(x)\mathrm{d}x \geq 0$. This proves that $u(x,\alpha) = 1 = u(x)$ for a.e. $\alpha \in (0,1)$ and a.e. $x \in \Omega_0$ such that $F(x) > 0$. Since all the terms of (27) under the symbols $\int$ vanish a.e. on $\{x \in \Omega,\ g(x) = 0 \text{ and } F(x) = 0\}$, we get that (27) with u implies (14) with $T(u)$. Thus the function $\tilde{g}$ is a weak solution to problem (10)–(11) in the sense of Definition 1.1. Since it is obvious that any weak solution is a weak process solution, we thus deduce, from the uniqueness of the weak process solution, that of this weak solution.

Let us now show that $\tilde{g}$ is an extremal point of $\mathcal{C}(g,F)$. Let $\gamma \in \mathcal{C}(g,F)$, and let $v \in L^\infty(\Omega)$ such that $\gamma(x) = v(x)g(x)$ and $0 \leq v(x) \leq 1$ for a.e. $x \in \Omega$. Thanks to (46), we get that, for a.e. $x \in \Omega \setminus \Omega_0$, $v(x) \leq T(u)(x)$. This proves that, for a.e. $x \in \Omega$, $|\gamma(x)| \leq |\tilde{g}(x)|$. This property implies that $\int_\Omega (g(x) - \tilde{g}(x)) \cdot (\tilde{g}(x) - \gamma(x))\mathrm{d}x = \int_\Omega |g(x)|^2 (1 - T(u)(x))(T(u)(x) - v(x))\mathrm{d}x \geq 0$ for all $\gamma \in \mathcal{C}(g,F)$, which shows that $\tilde{g}$ is the projection of g on $\mathcal{C}(g,F)$ in $L^2(\Omega)^d$. □

4. Passing to the limit in numerical schemes. We now start the study of the convergence of a numerical scheme, which is based on finite volume methods. Such methods proved their efficiency for various nonlinear problems such as, for instance, nonlinear degenerate problems (see, e.g., [9], [13] and references therein) and nonlinear hyperbolic problems (see [8], but there exists a huge literature on this subject). The main additional difficulty of the present problem is due to the introduction of the limiter $\overline{u}$ in (2) in order to satisfy the constraints (3)–(5) (recall that (2)–(5) lead to (10) and (11) using a time discretization). The "equation" on this unknown $\overline{u}$ seems to lead to a new type of problem which is unexpectedly not really related to variational inequalities but has some similarity with a scalar conservation law, leading to a nonlinear hyperbolic equation. From the numerical point of view, this similarity may be viewed in the upwinding choice for u in (50) (more precisely, the choice of u_K or u_L, on the interface between the control volumes K and L, depends on the sign of $g_{K,L}$). This upwinding is crucial, for instance, in order to have a solution

u taking values in $[0,1]$ (which is a constraint given by (10)). Numerical simulations using a centered choice of u often lead to troubles (such as oscillations) and the simulation has to stop (this is also true in the industrial framework). Another similarity with scalar conservation laws appears in the choice of the convex function ξ in Definition 1.1.

Let us first define the notion of admissible mesh of $\mathbb{R}^d$ (this definition is inspired by [8]).

DEFINITION 4.1 (admissible meshes). *An admissible finite volume mesh of Ω, denoted by $\mathcal{T}$, is given by a finite family of disjoint polygonal (one uses here the two space dimensions terms for the setting of the general space dimension) connected subsets of $\mathbb{R}^d$ such that Ω is the union of the closure of the elements of $\mathcal{T}$ (which are called control volumes in the following) and such that the common interface of any pair of neighboring control volumes is included in a hyperplane of $\mathbb{R}^d$ (this is not necessary but is introduced in order to simplify the formulation). We denote by* $\text{size}(\mathcal{T}) := \sup\{\text{diam}(K), K \in \mathcal{T}\}$*, by m_K the measure of K for all $K \in \mathcal{T}$, and by $\mathcal{N}_K$ the subset of $\mathcal{T}$ of all the control volumes having a common interface with K. We then denote by $\mathcal{E}$ one set of pairs of neighbors $(K,L) \in \mathcal{T}^2$ such that, if $(K,L) \in \mathcal{E}$, $(L,K) \notin \mathcal{E}$, and for all $K \in \mathcal{T}$ and $L \in \mathcal{N}_K$, $(K,L) \in \mathcal{E}$ or $(L,K) \in \mathcal{E}$. For $K \in \mathcal{T}$ and $L \in \mathcal{N}_K$, we denote by m_{KL} the measure of the common interface between K and L. We measure the regularity of the mesh by means of the following expression:*

$$\text{regul}(\mathcal{T}) := \max\left\{\sum_{L \in \mathcal{N}_K} m_{KL}\text{diam}(K)/m_K,\ K \in \mathcal{T}\right\}.$$

Let $\mathcal{T}$ be an admissible mesh of Ω. Let $g_{\mathcal{T}} := (g_{K,L})_{K\in\mathcal{T},L\in\mathcal{N}_K}$ be a family of real numbers such that

$$g_{K,L} = -g_{L,K} \qquad \forall K \in \mathcal{T},\ \forall L \in \mathcal{N}_K \tag{47}$$

and

$$\sum_{L\in\mathcal{N}_K} g_{K,L} = \int_K \text{div}g(x)\text{d}x := G_K \qquad \forall K \in \mathcal{T}. \tag{48}$$

Denoting

$$F_K = \int_K F(x)\text{d}x, \tag{49}$$

the finite volume scheme, in order to approximate problem (10)–(11), is given by

$$\begin{aligned} &\sum_{L\in\mathcal{N}_K} (g^+_{K,L}u_L - g^-_{K,L}u_K) + F_K = 0 \text{ and } u_K \le 1 \text{ or} \\ &\sum_{L\in\mathcal{N}_K} (g^+_{K,L}u_L - g^-_{K,L}u_K) + F_K \ge 0 \text{ and } u_K = 1. \end{aligned} \tag{50}$$

We define the function $u_{\mathcal{T}}$ by

$$u_{\mathcal{T}}(x) = u_K \qquad \forall x \in K,\ \forall K \in \mathcal{T}. \tag{51}$$

We then define the following value, which measures the consistency of the approximation $g_{\mathcal{T}}$ of the fluxes by means of a discrete $L^2(\Omega)^d$ norm and which is expected to tend to 0 with size($\mathcal{T}$):

$$\text{cons}(g_{\mathcal{T}}) := \sum_{K\in\mathcal{T}} \sum_{L\in\mathcal{N}_K} \frac{\text{diam}(K)}{m_{KL}} \left(g_{K,L} - \bar{g}_{K,L}\right)^2, \tag{52}$$

where

$$\bar{g}_{K,L} = \int_{K|L} g(x)\cdot \mathbf{n}_{K,L} \mathrm{d}s(x) \qquad \forall K \in \mathcal{T},\ \forall L \in \mathcal{N}_K. \tag{53}$$

Different choices are possible for $g_{\mathcal{T}}$. We can propose the following, for example.

- The choice $g_{K,L} = \bar{g}_{K,L}$ for all $K \in \mathcal{T}$ and $L \in \mathcal{N}_K$ is the simplest one which satisfies that cons($g_{\mathcal{T}}$) tends to 0 as size($\mathcal{T}$) tends to 0. Unfortunately, it demands in the general case the knowledge of g.
- In the framework of the coupled problem given in the introduction to this paper, the field $g = \Lambda\nabla h$ is not analytically known, and it must be approximated. This can be achieved, assuming that Λ is scalar (this is the case in some of the geological applications), using for example the finite volume method (see [8]). The notion of admissible meshes must then be restricted to the case where there exists, for all $K \in \mathcal{T}$, a point x_K in the control volume K such that, for a pair of two neighboring grid blocks K and L, the line (x_K, x_L) is orthogonal to the interface $\bar{K}\cap\bar{L}$ between these grid blocks. One then defines $\tau_{KL} = \int_{\bar{K}\cap\bar{L}} \Lambda(x)\mathrm{d}s(x)/d(x_K, x_L)$, where we denote by $\mathrm{d}s(x)$ the $d-1$ Lebesgue measure at point $x \in \bar{K}\cap\bar{L}$. One can then compute the family $(h_K)_{K\in\mathcal{T}}$ of reals such that (48) holds under the condition

  $$g_{K,L} = \tau_{KL}(h_L - h_K) \qquad \forall K \in \mathcal{T},\ \forall L \in \mathcal{N}_K \tag{54}$$

  in addition to such a relation as $\sum_{K\in\mathcal{T}} m_K h_K = 0$ (this corresponds to the discrete solution of a homogeneous Neumann problem). One can then prove that, under Hypotheses (H), cons($g_{\mathcal{T}}$) tends to 0 as size($\mathcal{T}$) tends to 0 (see [8] and [18]).
- In the same way, one can compute a mixed finite element approximate for $g_{K,L}$ which also satisfies that cons($g_{\mathcal{T}}$) tends to 0 as size($\mathcal{T}$) tends to 0 (see [4]).

In order to compute a solution of (47)–(50), we shall now describe an algorithm, denoted by Algorithm (A) below.

Algorithm (A).

Initialization: $u_K^{(0)} = 1$ and $p_K^{(0)} = 1$ for all $K \in \mathcal{T}$.

Iterations: Let $n \in \mathbb{N}^\star$. Assume that $u_K^{(n-1)}$ and $p_K^{(n-1)}$ are known for all $K \in \mathcal{T}$.

1. Computation of $\{p_K^{(n)},\ K \in \mathcal{T}\}$:

$$\begin{aligned} &\text{If } \sum_{L\in\mathcal{N}_K} (g_{K,L}^{+} u_L^{(n-1)} - g_{K,L}^{-} u_K^{(n-1)}) + F_K < 0, \text{ then } p_K^{(n)} = 0.\\ &\text{If } \sum_{L\in\mathcal{N}_K} (g_{K,L}^{+} u_L^{(n-1)} - g_{K,L}^{-} u_K^{(n-1)}) + F_K \geq 0, \text{ then } p_K^{(n)} = p_K^{(n-1)}. \end{aligned} \tag{55}$$

2. Computation of $\{u_K^{(n)},\ K \in \mathcal{T}\}$, solution to the following linear system:

$$\begin{aligned} \sum_{L\in\mathcal{N}_K} (g_{K,L}^{+} u_L^{(n)} - g_{K,L}^{-} u_K^{(n)}) &= -F_K \qquad \forall K \in \mathcal{T} \text{ s.t. } p_K^{(n)} = 0,\\ u_K^{(n)} &= 1 \qquad \forall K \in \mathcal{T} \text{ s.t. } p_K^{(n)} = 1. \end{aligned} \tag{56}$$

The following proposition gives a monotonicity property of Algorithm (A).

PROPOSITION 4.2 (a monotonicity property of Algorithm (A)). *Under Hypotheses* (H), *let $\mathcal{T}$ be an admissible mesh of Ω, and let $(g_{K,L})_{K\in\mathcal{T},L\in\mathcal{N}_K}$ be a family of real numbers such that* (47) *and* (48) *are satisfied. Let $n \in \mathbb{N}^\star$ be given such that there exists a family $\{(p_K^{(k)}, u_K^{(k)})$, $K \in \mathcal{T}$, $k = 0, \dots, n-1\}$ such that* (55) *and* (56) *hold in addition to $u_K^{(k)} \geq 0$ for all $K \in \mathcal{T}$, $k = 0, \dots, n-1$. Let $(p_K^{(n)})_{K\in\mathcal{T}}$ be given by* (55).

Then, for all family of reals $(w_K, s_K)_{K\in\mathcal{T}}$ such that $s_K \geq 0$ for all $K \in \mathcal{T}$ and such that

$$(57)\qquad \begin{aligned} \sum_{L\in\mathcal{N}_K} (g_{K,L}^{+} w_L - g_{K,L}^{-} w_K) &= -s_K \qquad \forall K \in \mathcal{T} \text{ s.t. } p_K^{(n)} = 0,\\ w_K &= s_K \qquad \forall K \in \mathcal{T} \text{ s.t. } p_K^{(n)} = 1, \end{aligned}$$

the property $w_K \geq 0$ for all $K \in \mathcal{T}$ holds.

Let us first remark that Proposition 4.2 suffices to prove that the matrix of the linear system (57) is invertible. Since in the case $s_K = 0$ for all $K \in \mathcal{T}$, for any family $(w_K)_{K\in\mathcal{T}}$ satisfying (57), then $(-w_K)_{K\in\mathcal{T}}$ also satisfies (57), which proves that $w_K = 0$ for all $K \in \mathcal{T}$. We therefore state the following corollary.

COROLLARY 4.3. *Under the hypotheses of Proposition* 4.2, *for all families $(s_K)_{K\in\mathcal{T}}$ of reals, there exists one and only one family of reals $(w_K)_{K\in\mathcal{T}}$ such that* (57) *holds.*

Proof of Proposition 4.2. Let us assume the hypotheses of Proposition 4.2, and let $(w_K, s_K)_{K\in\mathcal{T}}$ be a family of reals such that $s_K \geq 0$ for all $K \in \mathcal{T}$ and such that (57) holds. Let us assume that the set $\mathcal{T}_- = \{K \in \mathcal{T};\, w_K < 0\}$ is not empty. Then, if $K \in \mathcal{T}_-$, one has $p_K^{(n)} = 0$, since $w_K = s_K \geq 0$ for $K \in \mathcal{T}$ such that $p_K^{(n)} = 1$. We therefore have

$$(58)\qquad \sum_{L\in\mathcal{N}_K} (g_{K,L}^{+} w_L - g_{K,L}^{-} w_K) + s_K = 0 \qquad \forall K \in \mathcal{T}_-.$$

Summing (58) for $K \in \mathcal{T}_-$ leads to

$$(59)\qquad \sum_{K\in\mathcal{T}_-} \sum_{L\in\mathcal{N}_K\setminus\mathcal{T}_-} (g_{K,L}^{+} w_L - g_{K,L}^{-} w_K) + \sum_{K\in\mathcal{T}_-} s_K = 0.$$

Since $w_K < 0$ for $K \in \mathcal{T}_-$ and $w_L \geq 0$ for $L \notin \mathcal{T}_-$, (59) gives $s_K = 0$ for all $K \in \mathcal{T}_-$ and $g_{K,L} \geq 0$ for all (K, L) such that $K \in \mathcal{T}_-$ and $L \in \mathcal{N}_K \setminus \mathcal{T}_-$. Let $k < n$ be the greatest integer such that there exists $K \in \mathcal{T}_-$ with $p_K^{(k)} = 1$ and $p_K^{(k+1)} = 0$ (such a k exists since $p_K^{(0)} = 1$ for all $K \in \mathcal{T}$). We then have, for all $K \in \mathcal{T}_-$, $p_K^{(k+1)} = 0$ (otherwise this would be in contradiction with the choice of k), and therefore one has $\sum_{L\in\mathcal{N}_K} (g_{K,L}^{+} u_L^{(k)} - g_{K,L}^{-} u_K^{(k)}) + F_K \leq 0$.

For $K \in \mathcal{T}_-$ such that $p_K^{(k)} = 1$ and $p_K^{(k+1)} = 0$, one has $\sum_{L\in\mathcal{N}_K} (g_{K,L}^{+} u_L^{(k)} - g_{K,L}^{-} u_K^{(k)}) + F_K < 0$. We thus get

$$\sum_{K\in\mathcal{T}_-} \sum_{L\in\mathcal{N}_K,\, L\notin\mathcal{T}_-} (g_{K,L}^{+} u_L^{(k)} - g_{K,L}^{-} u_K^{(k)}) + \sum_{K\in\mathcal{T}_-} F_K < 0.$$

On the other hand, since $u_L^{(k)} \geq 0$ and since $g_{K,L} \geq 0$ for all (K, L) such that $K \in \mathcal{T}_-$

and $L \in \mathcal{N}_K \setminus \mathcal{T}_-$ and $F_K \geq 0$, we can write

$$\begin{aligned} 0 &\leq \sum_{K\in\mathcal{T}_-} \sum_{L\in\mathcal{N}_K,\, L\notin\mathcal{T}_-} g^+_{K,L} u^{(k)}_L \\ &\leq \sum_{K\in\mathcal{T}_-} \sum_{L\in\mathcal{N}_K,\, L\notin\mathcal{T}_-} (g^+_{K,L} u^{(k)}_L - g^-_{K,L} u^{(k)}_K) + \sum_{K\in\mathcal{T}_-} F_K < 0, \end{aligned}$$

which is impossible. This contradiction proves that $\mathcal{T}_-$ is empty, which concludes the proof of the proposition. □

We can now prove the following proposition, which states that Algorithm (A) is well defined and leads to a solution of (50) for some $n \leq \operatorname{card}(\mathcal{T})$.

Proposition 4.4 (convergence of an algorithm and existence of a discrete solution). *Under Hypotheses* (H), *let $\mathcal{T}$ be an admissible mesh of Ω, and let $(g_{K,L})_{K\in\mathcal{T},L\in\mathcal{N}_K}$ be a family of real numbers such that* (47) *and* (48) *are satisfied. Then the following hold.*

1. *There exists a unique family $\{(p^{(n)}_K, u^{(n)}_K),\ K \in \mathcal{T},\ n \in \mathbb{N}\}$ solution of Algorithm* (A).
2. *For all $K \in \mathcal{T}$ and all $n \in \mathbb{N}$, one has $u^{(n)}_K \geq 0$.*
3. *For all $K \in \mathcal{T}$, the sequence $(u^{(n)}_K)_{n\in\mathbb{N}}$ is nonincreasing.*
4. *There exists $n \leq$ card($\mathcal{T}$) such that, setting $u_K = u^{(n)}_K$ for all $K \in \mathcal{T}$, the family $\{u_K,\ K \in \mathcal{T}\}$ is such that $u^{(p)}_K = u_K$ for all $K \in \mathcal{T}$ and $p \geq n$. This family is therefore a solution of* (49) *and* (50) *such that*

$$0 \leq u_K \leq 1 \qquad \forall K \in \mathcal{T}. \tag{60}$$

Proof. The family $\{(p^{(0)}_K, u^{(0)}_K),\ K \in \mathcal{T}\}$ is uniquely defined and satisfies $u^{(0)}_K \geq 0$ for all $K \in \mathcal{T}$.

Let us prove the first two items of the above proposition by induction. Let $n \in \mathbb{N}^\star$; we assume that there exists a family $\{(p^{(k)}_K, u^{(k)}_K),\ K \in \mathcal{T},\ k = 0, \ldots, n-1\}$ such that (55) and (56) hold in addition to $u^{(k)}_K \geq 0$ for all $K \in \mathcal{T}$, $k = 0, \ldots, n-1$. Let $(p^{(n)}_K)_{K\in\mathcal{T}}$ be given by (55). We can then apply Proposition 4.2 and Corollary 4.3, setting $s_K = 1$ for all $K \in \mathcal{T}$ such that $p^{(n)}_K = 1$ and $s_K = F_K \geq 0$ for all $K \in \mathcal{T}$ such that $p^{(n)}_K = 0$. We thus immediately get the existence and the uniqueness of $u^{(n)}_K \geq 0$ for all $K \in \mathcal{T}$ such that (56) holds. This suffices to prove the first two items at the level n.

We can now prove that $u^{(n)}_K \leq u^{(n-1)}_K$ for all $K \in \mathcal{T}$. Indeed let us consider $w_K = u^{(n-1)}_K - u^{(n)}_K$ for all $K \in \mathcal{T}$. We have, for all $K \in \mathcal{T}$ such that $p^{(n)}_K = 0$, $\sum_{L\in\mathcal{N}_K}(g^+_{K,L}u^{(n)}_L - g^-_{K,L}u^{(n)}_K) + F_K = 0$ and $\sum_{L\in\mathcal{N}_K}(g^+_{K,L}u^{(n-1)}_L - g^-_{K,L}u^{(n-1)}_K) + F_K \leq 0$, which gives, by subtraction

$$\sum_{L\in\mathcal{N}_K} (g^+_{K,L} w_L - g^-_{K,L} w_K) := -s_K,$$

with $s_K \geq 0$. For all $K \in \mathcal{T}$ such that $p^{(n)}_K = 1$, we have

$$w_K = s_K := 0.$$

We can then apply Proposition 4.2, and we get that $0 \leq w_K$ for all $K \in \mathcal{T}$, which is the third item of the proposition. Let us prove the last item.

The definition of the algorithm gives $p_K^{(n)} = p_K^{(n-1)}$ or $p_K^{(n)} = 0$ for all K and all $n \in \mathbb{N}^\star$. Then, setting $A_n = \{K \in \mathcal{T};\, p_K^{(n)} = 0\}$, one has $\mathrm{card}(A_n) \geq \mathrm{card}(A_{n-1})$ for all $n \in \mathbb{N}^\star$. Since $\mathrm{card}(A_0)$ =0, there exists $n \leq \mathrm{card}(\mathcal{T}) + 1$ such that $\mathrm{card}(A_n)$ $= \mathrm{card}(A_{n-1})$. For this value of n one has $p_K^{(n)} = p_K^{(n-1)}$ for all $K \in \mathcal{T}$. If $p_K^{(n-1)} = 1$, one has $u_K^{(n-1)} = 1$ and $\sum_{L\in\mathcal{N}_K}(g^+_{K,L}u_L^{(n-1)} - g^-_{K,L}u_K^{(n-1)}) + F_K \geq 0$ (since $\sum_{L\in\mathcal{N}_K}(g^+_{K,L}u_L^{(n-1)} - g^-_{K,L}u_K^{(n-1)}) + F_K < 0$ gives $p_K^{(n)} = 0$).

If $p_K^{(n-1)} = 0$, one has $\sum_{L\in\mathcal{N}_K}(g^+_{K,L}u_L^{(n-1)} - g^-_{K,L}u_K^{(n-1)}) + F_K = 0$ and $u_K^{(n-1)} \leq 1$ thanks to the fact that the sequence $(u_K^{(n)})_{n\in\mathbb{N}}$ is nonincreasing and $u_K^{(0)} = 1$.

Therefore, setting $u_K = u_K^{(n-1)}$ for all $K \in \mathcal{T}$, the family $\{u_K,\ K \in \mathcal{T}\}$ is a solution of (49) and (50). It is also obvious to see that $u_K^{(p)} = u_K$ for all $K \in \mathcal{T}$ and for all $p \geq n - 1$.

This concludes the proof of Proposition 4.4. □

Remark 4.1. Under Hypotheses (H), assuming that Λ is a scalar function and following a method similar to the proof of uniqueness of Proposition 3.5, it is possible to prove that there exists a unique solution to (49) and (50), with the choice (54) for the discrete fluxes.

We then have the following proposition.

Proposition 4.5 (weak bounded variation inequality). *Under Hypotheses* (H), *let $\mathcal{T}$ be an admissible mesh of Ω in the sense of Definition* 4.1, *and let $g_\mathcal{T}$ be a family of reals which satisfies* (47) and (48). *Let $(u_K)_{K\in\mathcal{T}}$ be a solution of scheme* (49) and (50) *such that* (60) *holds. Then there exists $C > 0$, which only depends on d, Ω, g, F and not on $\mathcal{T}$, such that*

$$\sum_{(K,L)\in\mathcal{E}} |g_{K,L}|(u_K - u_L)^2 \leq C. \tag{61}$$

Proof. We multiply (50) by $(1 - u_K)$; we sum on K. We get $T_{17} + T_{18} = 0$ with

$$T_{17} = \sum_{K\in\mathcal{T}} (1 - u_K) \sum_{L\in\mathcal{N}_K} (g^+_{K,L}u_L - g^-_{K,L}u_K)$$

and

$$T_{18} = \sum_{K\in\mathcal{T}} (1 - u_K)F_K.$$

We have $T_{17} = T_{19} + T_{20}$, with

$$T_{19} = \sum_{K\in\mathcal{T}} (1 - u_K) \sum_{L\in\mathcal{N}_K} g^+_{K,L}(u_L - u_K)$$

and, using (48),

$$T_{20} = \sum_{K\in\mathcal{T}} (1 - u_K)u_K G_K.$$

We develop T_{19}: we get

$$\begin{aligned} T_{19} = \ & \frac{1}{2}\sum_{K\in\mathcal{T}} (1 - u_K)^2 \sum_{L\in\mathcal{N}_K} g^+_{K,L} + \frac{1}{2}\sum_{K\in\mathcal{T}}\sum_{L\in\mathcal{N}_K} g^+_{K,L}(u_L - u_K)^2 \\ & -\frac{1}{2}\sum_{K\in\mathcal{T}} (1 - u_L)^2 \sum_{L\in\mathcal{N}_K} g^+_{K,L}. \end{aligned}$$

Since $g^+_{K,L} = g^-_{L,K}$, we get

$$T_{19} = \frac{1}{2} \sum_{K \in \mathcal{T}} (1 - u_K)^2 G_K + \frac{1}{2} \sum_{(K,L) \in \mathcal{E}} |g_{K,L}| (u_L - u_K)^2.$$

Gathering the previous results, we get the conclusion. □

We can now state the convergence of the scheme to a weak process solution. This convergence result is obtained in the sense of the nonlinear weak-$\star$ convergence, defined in [7], which is a convenient way to understand the convergence towards a Young measure. Indeed, a bounded sequence $(u_n)_{n\in\mathbb{N}}$ of $L^\infty(\Omega)$ converges in the nonlinear weak-$\star$ sense to some function $u \in L^\infty(\Omega \times (0,1))$ if, for all $\xi \in C^0(\mathbb{R})$, the sequence $(\xi(u_n))_{n\in\mathbb{N}}$ converges for the weak-$\star$ topology of $L^\infty(\Omega)$ to the function $x \mapsto \int_0^1 \xi(u(x,\alpha))\mathrm{d}\alpha$ (the notation $\mathrm{d}\alpha$ stands here for the Lebesgue measure on $(0,1)$). A main compactness result is that from a bounded sequence of $L^\infty(\Omega)$, it is possible to extract a subsequence converging in the nonlinear weak-$\star$ sense (see [7] or [8] for more details).

PROPOSITION 4.6 (convergence of the scheme to a weak process solution). *Under Hypotheses* (H), *let* $(\mathcal{T}^{(m)}, g_{\mathcal{T}^{(m)}})_{m\in\mathbb{N}}$ *be a sequence such that, for all* $m \in \mathbb{N}$, $\mathcal{T}^{(m)}$ *is an admissible mesh of* Ω *in the sense of Definition* 4.1 *and* $g_{\mathcal{T}^{(m)}}$ *is a family of reals such that* (47) and (48) *are satisfied. We assume that* $\lim_{m\to\infty} \mathrm{size}(\mathcal{T}^{(m)}) = 0$, *that there exists* $R > 0$ *s.t* $\mathrm{regul}(\mathcal{T}^{(m)}) \le R$ *for all* $m \in \mathbb{N}$ *(see Definition* 4.1 *for the definitions of* size *and* regul*), and that* $\lim_{m\to\infty} \mathrm{cons}(g_{\mathcal{T}^{(m)}}) = 0$. *For all* $m \in \mathbb{N}$, *we denote by* $u_{\mathcal{T}^{(m)}}$ *a solution of scheme* (49)–(50) *such that* (60) *holds. Then, from the sequence* $(\mathcal{T}^{(m)})_{m\in\mathbb{N}}$, *one can extract a subsequence, again denoted* $(\mathcal{T}^{(m)})_{m\in\mathbb{N}}$, *such that the corresponding sequence* $(u_{\mathcal{T}^{(m)}} g)_{m\in\mathbb{N}}$ *converges in the nonlinear weak-*$\star$ *sense (see above for the sense of this convergence) to a weak process solution of problem* (10)–(11) *in the sense of Definition* 1.1.

Proof. Using the property (60) satisfied by $u_{\mathcal{T}^{(m)}}$, we can deduce the existence of a subsequence, again denoted $(\mathcal{T}^{(m)})_{m\in\mathbb{N}}$, such that the corresponding sequence $(u_{\mathcal{T}^{(m)}})_{m\in\mathbb{N}}$ converges in the nonlinear weak-$\star$ sense to some function $u \in L^\infty(\Omega \times (0,1))$. We shall now prove that u is the weak process solution of problem (10)–(11) in the sense of Definition 1.1. Let $\varphi \in C^1(\overline{\Omega}, \mathbb{R}_+)$, and let $\xi \in C^1(\mathbb{R})$ be a convex function with $\xi'(1) \ge 0$. Let $m \in \mathbb{N}$, and let $(\mathcal{T}^{(m)})$ be the corresponding admissible mesh of the subsequence. For simplicity, we do not mention the index m until we consider some convergence properties as $m \to \infty$. We get from (50), using $\xi'(u_K) = \xi'(1) + \xi'(u_K) - \xi'(1)$, that

$$\xi'(u_K) \left(\sum_{L \in \mathcal{N}_K} (g^+_{K,L} u_L - g^-_{K,L} u_K) + F_K \right) \ge 0 \qquad \forall K \in \mathcal{T}. \tag{62}$$

We can then multiply (62) by φ_K, where we denote $\varphi_K = \frac{1}{m_K} \int_K \varphi(x)\mathrm{d}x$, and we sum on $K \in \mathcal{T}$. We get $T_{21} + T_{22} \ge 0$, with

$$T_{21} = \sum_{K \in \mathcal{T}} \xi'(u_K)\varphi_K \sum_{L \in \mathcal{N}_K} (g^+_{K,L} u_L - g^-_{K,L} u_K)$$

and

$$T_{22} = \sum_{K \in \mathcal{T}} \xi'(u_K)\varphi_K F_K.$$

We have $T_{21} = T_{23} + T_{24}$ with

$$T_{23} = \sum_{K\in\mathcal{T}} \xi'(u_K)u_K\varphi_K \sum_{L\in\mathcal{N}_K} g_{K,L}$$

and

$$T_{24} = \sum_{K\in\mathcal{T}} \xi'(u_K)\varphi_K \sum_{L\in\mathcal{N}_K} g^+_{K,L}(u_L - u_K).$$

Since $\sum_{L\in\mathcal{N}_K} g_{K,L} = \int_K \mathrm{div} g(x)\mathrm{d}x$, we thus get that

$$\lim_{m\to\infty} T^{(m)}_{23} = \int_\Omega \int_0^1 \xi'(u(x,\alpha))u(x,\alpha)\varphi(x)\mathrm{div} g(x)\mathrm{d}\alpha\mathrm{d}x.$$

On the other hand, we have

$$T_{24} \le T_{25} := \sum_{K\in\mathcal{T}} \varphi_K \sum_{L\in\mathcal{N}_K} g^+_{K,L}(\xi(u_L) - \xi(u_K)).$$

Gathering by edges, we get

$$T_{25} = \sum_{(K,L)\in\mathcal{E}} (\xi(u_L) - \xi(u_K))(\varphi_K g^+_{K,L} - \varphi_L g^-_{K,L}).$$

Let us compare T_{25} with T_{26} defined by

$$T_{26} = -\sum_{K\in\mathcal{T}} \xi(u_K) \int_K \mathrm{div}(\varphi(x)g(x))\mathrm{d}x.$$

We have, on one hand, that

$$\lim_{m\to\infty} T^{(m)}_{26} = -\int_\Omega \int_0^1 \xi(u(x,\alpha))\mathrm{div}(\varphi(x)g(x))\mathrm{d}\alpha\mathrm{d}x,$$

and on the other hand, we have

$$T_{26} = \sum_{(K,L)\in\mathcal{E}} (\xi(u_L) - \xi(u_K)) \int_{K|L} \varphi(x)g(x)\cdot \mathbf{n}_{K,L}\mathrm{d}s(x).$$

Thus we get that

$$T_{25} - T_{26} = T_{27} + T_{28} + T_{29},$$

with

$$T_{27} = \sum_{(K,L)\in\mathcal{E}} (\xi(u_L) - \xi(u_K)) \left(\varphi_K g^+_{K,L} - \varphi_L g^-_{K,L} - \frac{g_{K,L}}{m_{KL}} \int_{K|L} \varphi(x)\mathrm{d}s(x)\right),$$

$$T_{28} = \sum_{(K,L)\in\mathcal{E}} (\xi(u_L) - \xi(u_K)) \left(g_{K,L} - \bar{g}_{K,L}\right) \left(\frac{1}{m_{KL}} \int_{K|L} \varphi(x)\mathrm{d}s(x)\right),$$

$$T_{29} = \sum_{(K,L)\in\mathcal{E}} (\xi(u_L) - \xi(u_K)) \left(\int_{K|L} (\frac{\bar{g}_{K,L}}{m_{KL}} - g(x)\cdot \mathbf{n}_{K,L})\varphi(x)\mathrm{d}s(x)\right)$$

(recall that $\bar{g}_{K,L}$ is defined by (53)). In the following, we designate by C_i various real numbers which can depend on $d, \Omega, g, F, \varphi, \xi$ but not on $\mathcal{T}$. Using $|\xi(u_K) - \xi(u_L)| \le$

$C_1\,|u_K - u_L|$ and the Cauchy–Schwarz inequality,

$$\left|\varphi_K - \frac{1}{m_{KL}}\int_{K|L}\varphi(x)\mathrm{d}s(x)\right| \le \mathrm{diam}(K)C_2\,,$$

and

$$\left|\varphi_L - \frac{1}{m_{KL}}\int_{K|L}\varphi(x)\mathrm{d}s(x)\right| \le \mathrm{diam}(L)C_2\,,$$

we get

$$|T_{27}|^2 \le C_3\left(\sum_{(K,L)\in\mathcal{E}}|g_{K,L}|(u_K-u_L)^2\right)\left(\sum_{(K,L)\in\mathcal{E}}|g_{K,L}|(\mathrm{diam}(K)^2+\mathrm{diam}(L)^2)\right).$$

Using (61) and

$$\sum_{(K,L)\in\mathcal{E}}|g_{K,L}|(\mathrm{diam}(K)^2+\mathrm{diam}(L)^2) \le C_4\,\mathrm{size}(\mathcal{T}),$$

we thus get that

$$\lim_{m\to\infty}|T_{27}^{(m)}| = 0.$$

We now turn to the study of T_{28}. Since we have

$$T_{28} = -\sum_{K\in\mathcal{T}}\xi(u_K)\sum_{L\in\mathcal{N}_K}(g_{K,L}-\bar{g}_{K,L})\left(\frac{1}{m_{KL}}\int_{K|L}\varphi(x)\mathrm{d}s(x)\right),$$

we get, using the property (48),

$$T_{28} = -\sum_{K\in\mathcal{T}}\xi(u_K)\sum_{L\in\mathcal{N}_K}(g_{K,L}-\bar{g}_{K,L})\left(\frac{1}{m_{KL}}\int_{K|L}\varphi(x)\mathrm{d}s(x)-\varphi_K\right).$$

Thus, thanks to the Cauchy–Schwarz inequality and using (52), we get

$$T_{28}^2 \le C_5\,\mathrm{cons}(g_{\mathcal{T}}).$$

Thus

$$\lim_{m\to\infty}|T_{28}^{(m)}| = 0.$$

We conclude with the study of T_{29}. Since

$$T_{29} = -\sum_{K\in\mathcal{T}}\xi(u_K)\sum_{L\in\mathcal{N}_K}\left(\int_{K|L}\left(\frac{\bar{g}_{K,L}}{m_{KL}} - g(x)\cdot\mathbf{n}_{K,L}\right)(\varphi(x)-\varphi_K)\mathrm{d}s(x)\right)$$

and since $\int_{K|L}(\frac{\bar{g}_{K,L}}{m_{KL}} - g(x)\cdot\mathbf{n}_{K,L})(\varphi(x)-\varphi_K)\mathrm{d}s(x) \le C_6\,m_{KL}\mathrm{diam}(K)^2$, we easily get

$$\lim_{m\to\infty}|T_{29}^{(m)}| = 0.$$

Gathering these results gives

$$\lim_{m\to\infty} T_{25}^{(m)} = -\int_\Omega \int_0^1 \xi(u(x,\alpha))\mathrm{div}(\varphi(x)g(x))\mathrm{d}\alpha\mathrm{d}x.$$

Finally, we easily get

$$\lim_{m\to\infty} T_{22}^{(m)} = \int_\Omega \int_0^1 \xi'(u(x,\alpha))\varphi(x)F(x)\mathrm{d}\alpha\mathrm{d}x.$$

Gathering the previous results, we get $T_{23} + T_{25} + T_{22} \le 0$. Passing to the limit $m \to \infty$ in this inequality, we get

$$\begin{aligned}&+\int_\Omega \int_0^1 u(x,\alpha)\xi'(u(x,\alpha))\varphi(x)\mathrm{div}g(x)\mathrm{d}\alpha\mathrm{d}x\\ &-\int_\Omega \int_0^1 \xi(u(x,\alpha))\mathrm{div}(\varphi(x)g(x))\mathrm{d}\alpha\mathrm{d}x\\ &+\int_\Omega \int_0^1 \xi'(u(x,\alpha))\varphi(x)F(x)\mathrm{d}\alpha\mathrm{d}x \ge 0,\end{aligned}$$

which is exactly Definition 3.3. □

Thanks to the uniqueness result, we now classically conclude with the following convergence theorem (similar proofs can be found in [8]).

THEOREM 4.7 (strong convergence of the scheme to a weak solution). *Under Hypotheses* (H), *let $\mathcal{T}$ be an admissible mesh of Ω in the sense of Definition* 4.1*, and let $g_\mathcal{T}$ be a family of reals such that* (47) *and* (48) *are satisfied. Then the function $u_\mathcal{T} g$, where $u_\mathcal{T}$ is a solution of scheme* (49)–(50) *such that* (60) *holds, converges in $L^p(\Omega)^d$ for all $p \in [1,\infty)$ to $\tilde{g}$, the unique weak solution to problem* (10)–(11) *in the sense of Definition* 1.1*, as* size$(\mathcal{T})$ *tends to* 0*,* cons$(g_\mathcal{T})$ *tends to* 0*, and* regul$(\mathcal{T})$ *remains bounded (see Definition* 4.1 *for the definitions of* size$(\mathcal{T})$ *and* regul$(\mathcal{T})$*, and see* (52) *for the definition of* cons$(g_\mathcal{T})$*).*

Proof. Under Hypotheses (H), let $(\mathcal{T}^{(m)})_{m\in\mathbb{N}}$ be a sequence of admissible meshes of Ω in the sense of Definition 4.1 such that $\lim_{m\to\infty} \mathrm{size}(\mathcal{T}^{(m)}) = 0$. For all $m \in \mathbb{N}$, we denote by $u_{\mathcal{T}^{(m)}}$ a solution of scheme (47)–(50) such that (60) holds. Using Proposition 4.6, from the sequence $(\mathcal{T}^{(m)})_{m\in\mathbb{N}}$, one can extract a subsequence, again denoted $(\mathcal{T}^{(m)})_{m\in\mathbb{N}}$, such that the corresponding sequence $(u_{\mathcal{T}^{(m)}})_{m\in\mathbb{N}}$ converges in the nonlinear weak-$\star$ sense to a weak process solution u of problem (10)–(11) in the sense of Definition 1.1. We then get that the limit of $\int_\Omega g(x)^2(u_{\mathcal{T}^{(m)}}(x) - \int_0^1 u(x,\alpha)\mathrm{d}\alpha)^2\mathrm{d}x$ as $m \to \infty$ is equal to $\int_\Omega g(x)^2(\int_0^1 u(x,\alpha)^2\mathrm{d}\alpha - 2(\int_0^1 u(x,\alpha)\mathrm{d}\alpha)^2 + (\int_0^1 u(x,\alpha)\mathrm{d}\alpha)^2)\mathrm{d}x = 0$, using Proposition 3.5 which stands that $\tilde{g}(x) = u(x,\alpha)g(x)$, for a.e. $x \in \Omega$ and $\alpha \in (0,1)$. This proves that $(u_{\mathcal{T}^{(m)}}g)_{m\in\mathbb{N}}$ converges to $\tilde{g}$ in $L^2(\Omega)^d$. The uniqueness of $\tilde{g}$ gives the conclusion of the theorem. □

5. Numerical results.

5.1. One-dimensional example. We again consider the following data, studied in section 2: $\Omega = (-1,1)$, $g : x \mapsto x^3 - x$, and $F : x \mapsto 1/2$. We recall that the weak solution is the function $\tilde{g}$ given by $\tilde{g} = ug$, where the function u is such that $u : x \mapsto 1$ for all $x \in (-1, -\sqrt{1/2}) \cup (\sqrt{1/2}, 1)$ and $u : x \mapsto 1/(2(1-x^2))$ for all $x \in (-\sqrt{1/2}, \sqrt{1/2})$. We use Algorithm (A) to solve the nonlinear system (49)–(50)

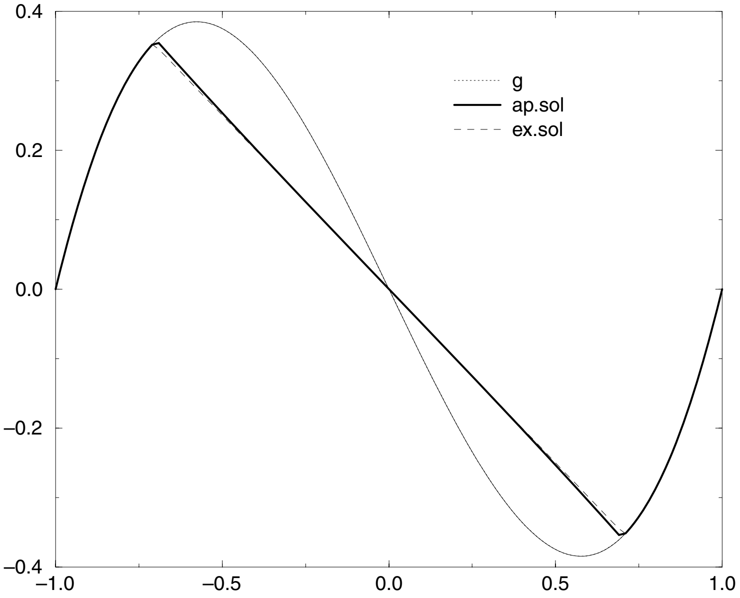

FIG. 1. *Approximate solution (ap.sol) and exact solution (ex.sol) with* 100 *control volumes.*

with $g_{K,L} = \bar{g}_{K,L}$ ($\bar{g}_{K,L}$ is defined in (53)). We get, with 100 uniform control volumes, the results given in Figure 1. The exact solution $\tilde{g}$ is represented by the dashed line (and denoted by "ex.sol." in the legend). The approximate solution of (49)–(50) is $u_{\mathcal{T}}$. Figure 1 gives, with the solid line, the product of $u_{\mathcal{T}}$ with the exact function g (and this product is denoted by "ap.sol." in the legend). The dashed line and the solid line are very close to one another. The last line, namely the grey dotted one, represents the exact function g.

It is interesting to remark that Algorithm (A) converges for a significantly smaller number of iterations than card($\mathcal{T}$). The table below gives, for different numbers of control volumes, the number of iterations until $p_K^{(n)} = p_K^{(n+1)}$ for all $K \in \mathcal{T}$.

Number of control volumes	Number of iterations	$\|\tilde{g} - u_{\mathcal{T}} g\|_{L^1(\Omega)}$
10	3	0.031757
50	9	0.006969
100	17	0.003488
500	76	0.000699
1000	151	0.000348
5000	748	0.000070
10000	1496	0.000035
50000	7473	0.000007

We observe that this number behaves as 1/size($\mathcal{T}$), whereas the error in $L^1(\Omega)$ behaves as size($\mathcal{T}$).

5.2. Two-dimensional examples. We use the coupled finite volume scheme (48)–(54) in order to compute $g_{\mathcal{T}}$. We consider the following data: $\Omega = (0,1)^2$, $\Lambda(x) = \mathrm{I}_d$, and $F(x) = 1/100$ for a.e. $x \in \Omega$, $g = \nabla h$, where h is a solution of

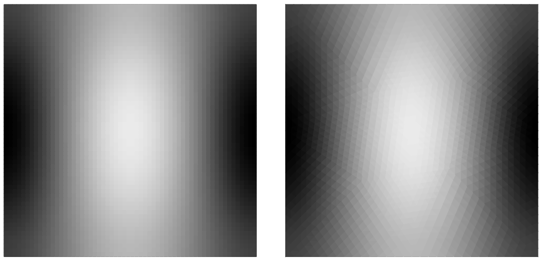

FIG. 2. *Value of h from* 0 *(black) to* 0.00111 *(white): rectangular* 60×60 *mesh (left) and triangular mesh with* 3650 *triangles (right).*

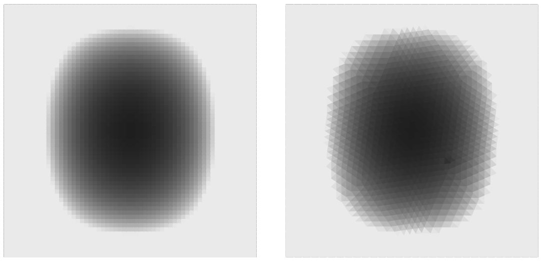

FIG. 3. *Value of u from* 0.48 *(black) to* 1 *(white): rectangular* 60×60 *mesh (left) and triangular mesh with* 3650 *triangles (right).*

the homogeneous Neumann problem

$$-\Delta h(x,y) = y(1-y)(-x^2+x-1/6) \qquad \forall (x,y) \in (0,1)^2,$$

$$\nabla h \cdot \mathbf{n} = 0 \text{ on } \partial\Omega.$$

These data have been chosen since they represent a kind of generalization in two dimensions of the one-dimensional case presented above. Two meshes have been tested. With a rectangular 60×60 mesh, the convergence of Algorithm (A) is obtained after 10 iterations; with a triangular mesh with 3650 triangles, 14 iterations are necessary to converge. The results obtained after the resolution of h by the finite volume method are presented in Figure 2. The corresponding values of the function u such that ug is the weak solution are given in Figure 3, and the values of g_x, g_y, $\tilde{g}_x$, $\tilde{g}_y$ which are the components of g and $\tilde{g}$ are given in Figures 4 and 5 for the rectangular mesh.

These results show the efficiency of the numerical method. In particular, we can remark that the approximate solution obtained with the rectangular mesh is very close to the approximate solution obtained with the triangular mesh.

The following table gives, for rectangular meshes, the number of iterations needed by Algorithm (A) for convergence.

Number of control volumes	Number of iterations
10×10	3
50×50	9
100×100	16
150×150	23
200×200	30

We again observe that this number behaves as $1/\text{size}(\mathcal{T})$.

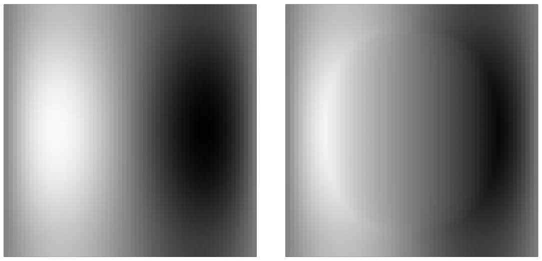

Fig. 4. *Value of g_x (left) and of $\tilde{g}_x$ (right) from* -0.00342 *(black) to* 0.00342 *(white).*

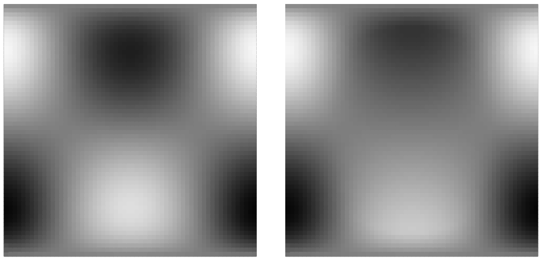

Fig. 5. *Value of g_y (left) and of $\tilde{g}_y$ (right) from* -0.00094 *(black) to* 0.00094 *(white).*

6. Conclusions.

We have been able to prove the existence and the uniqueness of the weak solution to problem (10)–(11) in the sense of Definition 1.1, and we have proved the convergence of a numerical scheme, under Hypotheses (H). At this time, we have not yet derived an error estimate although we can guess that it will be possible to follow the same steps as that of a scalar nonlinear hyperbolic problem, since the basis of proof of the uniqueness theorem is the doubling variable technique of Krushkov. It is, however, probable that the error estimate that we shall obtain will be not sharp. Moreover, the mathematical problem is not directly formulated as a function of h but on g. We have only briefly mentioned in remarks that some of the results of this paper can be obtained without the assumption $g = \Lambda\nabla h$. However, this is not the case for all of them. Finally, much work remains to be done in order to handle the complete problem (2)–(5).

APPROXIMATIONS FOR VISCOSITY SOLUTIONS OF HAMILTON–JACOBI EQUATIONS WITH LOCALLY VARYING TIME AND SPACE GRIDS*

JIANLIANG QIAN†

Abstract. A new monotone finite difference scheme is introduced that approximates viscosity solutions of first-order nonlinear Hamilton–Jacobi equations. The main feature of the scheme is that it allows for locally varying time and space grids, making it ideal for use with adaptive algorithms. Explicit a priori error estimates are given to establish convergence. Numerical examples, including adaptive mesh refinement examples, demonstrate the effectiveness of the proposed scheme.

Key words. local time-stepping, error estimates, monotone schemes, Hamilton–Jacobi

1. Introduction.

We consider Hamilton–Jacobi equations

$$u_t + H(t, x, u, \nabla u) = 0 \qquad \text{in } \mathbb{R}^d \times (0, T),$$

where H is a nondecreasing function of u. These equations arise in many areas of applied mathematics, like optimal control, differential games, seismic wave propagation, terrain navigation of robotic navigation, and financial mathematics [16], among many others. They also appear when modeling evolving interfaces in geometry, fluid mechanics, computer vision [34, 28, 21, 42], and materials science [36]; they are essential when dealing with level set methods [30], numerical methods that have reached widespread popularity. Therefore, there is general interest in designing efficient numerical methods for such equations; see [26, 24, 27, 41, 6, 7] and references therein.

Osher and Sanders [29] designed a class of monotone schemes for scalar conservation laws with locally varying time and space grids. Inspired by this work, we design a new class of monotone schemes for Hamilton–Jacobi equations. In this paper, we shall obtain an upper bound of the L^∞-norm of the difference between the approximate solution v_h and the viscosity solution of the model Hamilton–Jacobi equation

$$u_t + H(\nabla u) = 0 \qquad \text{in } \mathbb{R}^d \times (0, T).$$

The class of monotone schemes we consider here includes the classical Lax–Friedrichs scheme, the monotone schemes considered by Crandall and Lions [15], the intrinsic monotone scheme of Abgrall [1], and the monotone schemes devised by Kossioris, Makridakis, and Souganidis [22]; it consists of numerical schemes that can be characterized in terms of the so-called numerical Hamiltonian $\widehat{H}$ which approximates the exact Hamiltonian H. Therefore, all the schemes proposed in [15, 1, 22] can be formulated under this new framework.

Our error estimate is of the form

$$\| u - v_h \|_{L^\infty(Q_h)} \le C_1 \, h^{\frac{1}{2}},$$

*Received by the editors April 15, 2004; accepted for publication (in revised form) June 14, 2005; published electronically January 6, 2006. This research was supported by ONR Grant N00014-02-1-0720.

†Department of Mathematics, UCLA, Los Angeles, CA 90095-1555 (qian@math.ucla.edu).

where Q_h denotes the set of space-time points at which v_h is defined, h denotes the so-called mesh-size, and C_1 depends on the $W^{1,\infty}$-norm of u. The order of convergence in h, $\frac{1}{2}$, is the now classical order of convergence already obtained in the previously mentioned papers. However, if the solution is smooth, then we can also prove that

$$\| u - v_h \|_{L^\infty(Q_h)} \leq C_2 \, h,$$

where C_2 depends on the $W^{2,\infty}$-norm of u; this seems to be a new result.

Just as was done in [15], the error estimate we present is obtained by using the *structure* of the numerical scheme and three key properties of its numerical Hamiltonian $\widehat{H}$, namely, consistency, monotonicity, and local smoothness. In this respect, our result is similar to the error estimates for monotone schemes for nonlinear scalar hyperbolic conservation laws obtained by Cockburn and Gremaud [9, 10] and by Cockburn, Gremaud, and Yang [11].

The technique we use to prove our result is a variation of the technique used by Albert et al. [2] to prove a posteriori error estimates for steady-state Hamilton–Jacobi equations. Those estimates are of the form

$$\| u - v_h \|_{L^\infty(\mathbb{R}^d)} \leq \Phi(v_h)$$

and are obtained by using a modification of the elegant technique that Crandall, Evans, and Lions [14] devised to study viscosity solutions of Hamilton–Jacobi equations, where Φ is a nonlinear functional depending only on the computed solution v_h. Our technique is also related to the one used by Cockburn and Qian [12] to prove continuous dependence results for steady-state Hamilton–Jacobi equations, but in that work we dealt only with steady Hamilton–Jacobi equations and no time variable is involved in the error estimates. In this work we apply this doubling variable technique to deal with time-dependent Hamilton–Jacobi equations with locally varying time and space grids.

The devising of such schemes with locally varying time and space grids is fundamental to the development of efficient adaptive methods for Hamilton–Jacobi equations. As is well known, the viscosity solution for Hamilton–Jacobi equations is continuous but may develop kinks in finite time; namely, its gradient might be discontinuous although the initial data is smooth. To resolve such sharp kinks with high resolution, one might use higher-order schemes [30, 31, 26, 20, 41, 6]. On the other hand, one might also use an adaptive strategy to resolve the kinks with lower-order methods.

In general there are two distinct starting points for devising adaptive methods for PDEs. One is getting the most accurate solution for a fixed cost, and the other is attaining a fixed accuracy for a minimum cost.

The so-called adaptive mesh redistribution method is based on the former starting point: getting the most accurate solution with a fixed number of mesh points; see [19, 33, 35, 25, 8, 38, 39, 37] and references therein. In such methods, one dynamically maps the physical domain to a computational domain via an invertible mesh generator. The mesh generator is derived from a variational principle so that the dynamic behavior of the solution can be taken into account. However, the resulting mesh typically concentrates a high number of mesh points around a localized region where the solution is singular or nearly singular [19, 8, 39]; therefore, globally chosen time steps need to be small to be proportional to the smallest mesh size in space, according to the Courant-Friedrichs-Lewy (CFL) stability condition. Nevertheless, for Hamilton–Jacobi equations viscosity solutions are usually Lipschitz continuous and thus are differentiable almost everywhere, and the resulting kinks are expected to develop in quite localized regions. Hence, the small time steps are really needed only in those localized regions, and it is meaningful to develop schemes with locally varying time and space grids. In [37], Tan et al. successfully tested a class of adaptive mesh redistribution methods with locally varying time steps for nonlinear hyperbolic conservation laws. Although an adaptive mesh redistribution method was proposed for Hamilton–Jacobi equations in [39], the method can be made more efficient based on a monotone scheme with locally varying time and space grids. For a nice review on mesh redistribution methods for computational fluid dynamics, see [40].

The so-called adaptive mesh refinement method is based on the following starting point: attaining a prespecified accuracy with a minimum cost; see [3, 5, 23, 17] for such methods for nonlinear hyperbolic conservation laws and see [32, 13] for such methods for Hamilton–Jacobi equations. The local adaptive mesh refinement methods in [3, 5] are based on ad hoc local truncation error estimation procedures and thus are not optimal. The adaptive methods in [23, 17] are based on a posteriori error estimates for hyperbolic conservation laws and thus are optimal to some extent. In particular, the adaptive algorithm proposed by Gosse and Makridakis [17] enforces a strict error control mechanism on each mesh cell by refining and coarsening computational grids according to their local a posteriori error estimates so that a given error tolerance is satisfied for each cell at every time step. Interestingly, a similar error control mechanism was used for solving a class of Hamilton–Jacobi equations in [32], where an adaptive mesh refinement method for eikonal equations is designed based on asymptotic truncation error estimates and some numerical ODE techniques. However, an optimal approach for triggering mesh refinement and coarsening should be based on a posteriori error estimates. The adaptive mesh refinement method proposed by Cockburn and Yenikaya [13] is based on such an a posteriori error estimate [2] and thus has a rigorous error control for steady Hamilton–Jacobi equations; the study of the effectivity index carried out in that paper indicates that the adaptive method has optimal complexity. However, for the time-dependent Hamilton–Jacobi equations the adaptive mesh refinement method must allow time space meshes to vary locally. In this work, we construct a class of monotone finite difference methods for Hamilton–Jacobi equations with locally varying time and space grids and obtain convergence rates. As mentioned above, this class of methods can be used for both adaptive mesh redistribution and adaptive mesh refinement methods.

The results obtained for the model time-dependent Hamilton–Jacobi equation can be extended to the more general case,

$$H(x, t, u, u_t, \nabla u) = 0,$$

without major difficulty, provided that the mapping $u \mapsto H(x, t, u, p_t, p_x)$ is nondecreasing and the mapping $p_t \mapsto H(x, t, u, p_t, p_x)$ is strictly increasing.

We are currently incorporating the proposed scheme with a posteriori error estimates to design optimal adaptive methods for Hamilton–Jacobi equations. This constitutes the subject of an ongoing work. However, to demonstrate the effectiveness of the new scheme we will present some numerical examples for one- and two-dimensional Hamilton–Jacobi equations; in particular, we present adaptive mesh refinement (AMR) examples for two-dimensional Hamilton–Jacobi equations using the monotone scheme presented here as the driving method and a local truncation error estimator in [3] as the indicator for the mesh refinement.

The paper is organized as follows. In section 2, we define the viscosity solution and describe the new monotone schemes. In section 3, we state, discuss, and prove our main results. Section 4 presents some examples of monotone schemes for which our results hold. In section 5 we present some numerical experiments to demonstrate the effectiveness of the scheme.

2. New monotone schemes for Hamilton–Jacobi equations. We consider the following model time-dependent Hamilton–Jacobi equation:

$$u_t + H(\nabla u) = 0 \qquad \text{in } \mathbb{R}^d \times (0,T), \tag{2.2.1}$$

$$u(t=0) = u_0 \qquad \text{in } \mathbb{R}^d, \tag{2.2.2}$$

where u and u_0 are periodic in each coordinate with period 1, and $H \in C(\mathbb{R}^d)$. We begin by defining the notion of viscosity solution and describing the monotone schemes of interest. Then, we state, discuss, and prove the main results.

2.1. Viscosity solutions. We begin by defining the viscosity solutions of the initial value problem (2.2.1) and (2.2.2). To do this, we need the notions of *semidifferentials* of a function on $\mathbb{R}^d \times (0,T)$. The *superdifferential* of a function u at a point $(x,t) \in \mathbb{R}^d \times (0,T)$, $D^+u(x,t)$, is the set of all vectors $p = (p_x, p_t)$ in $\mathbb{R}^d \times \mathbb{R}$ such that

$$\limsup_{(y,s)\in\mathbb{R}^d\times(0,T)\to(x,t)} \left(\frac{u(y,s) - \{u(x,t) + (s-t)\,p_t + (y-x)\cdot p_x\}}{\|(y,s)-(x,t)\|} \right) \le 0,$$

and the *subdifferential* of u at a point (x,t), $D^-u(x,t)$, is the set of all vectors p in $\mathbb{R}^{d+1}$ such that

$$\liminf_{(y,s)\in\mathbb{R}^d\times(0,T)\to(x,t)} \left(\frac{u(y,s) - \{u(x,t) + (s-t)\,p_t + (y-x)\cdot p_x\}}{\|(y,s)-(x,t)\|} \right) \ge 0.$$

We are now ready to define the viscosity solution of (2.2.1).

Definition 2.1 (see [14]). *A viscosity solution u of the initial-value problem for the Hamilton–Jacobi equation* (2.2.1) *is a periodic, continuous function on* $\mathbb{R}^d \times [0,T]$ *satisfying $u(t=0) = u_0$ such that for all (x,t) in $\mathbb{R}^d \times (0,T]$,*

$$\sigma\,(\,p_t + H(p_x)\,) \le 0 \qquad \forall\, p = (p_x, p_t) \in D^\sigma u(x,t), \qquad \sigma \in \{+,-\}.$$

2.2. The monotone schemes. The numerical schemes we consider determine the values of a function v_h on a standard grid $Q_h = G_h \times \{t^n\}_{n=0}^{N_T}$ of $\mathbb{R}^d \times [0,T]$; the spatial grid G_h is periodic with period 1 in each of the canonical directions of $\mathbb{R}^d$. To avoid cluttered notation, we use v instead of v_h to denote the numerical solution in the following derivation. These schemes take the form

$$v(y,0) = u_0(y) \qquad \forall\, y \in G_h, \tag{2.2.3}$$

$$v(y,t^{n+1}) = v(y,t^n) - \Delta t^n \widehat{H}_y(\partial_{\delta_y} v(y,t^n)) \quad \forall\, y \in G_h, \quad n = 0, \dots, N_T - 1, \tag{2.2.4}$$

where $\widehat{H}_y(\partial_{\delta_y} v(y,t^n))$ is an approximation to $H(\nabla v(y,t^n))$,

$$\partial_{\delta_y} v(y,t^n) = (\partial_{\delta_{y,1}} v(y,t^n), \dots, \partial_{\delta_{y,N_y}} v(y,t^n)),$$

and

$$\partial_{\delta_{y,i}} v(y,t^n) = \frac{v(y,t^n) - v(y-\delta_{y,i},t^n)}{|\,\delta_{y,i}\,|}, \text{ where } y - \delta_{y,i} \in G_h, \qquad i = 1, \dots, N_y.$$

Here N_y denotes the number of edges at node y and $\delta_{y,i}$ denotes the position vector of the ith edge at node y. We shall show later that many important numerical Hamiltonians found in current literature have such a structure.

We denote bounded functions on G_h by $l^\infty(G_h)$ equipped with the norm

$$\|v\|_\infty = \sup_{y\in G_h} |v(y)|,$$

where $v \in l^\infty(G_h)$. Such functions can be identified with piecewise linear functions, still denoted by v.

In addition, we assume that the numerical Hamiltonian $\widehat{H}$ has the following properties:

(i) consistency: $\widehat{H}_y(\partial_{\delta_y} v(y)) = H(p)$ if $\nabla v = p \in \mathbb{R}^d$;

(ii) monotonicity: $\widehat{H}_y$ is nondecreasing in each of its arguments;

(iii) smoothness: $\widehat{H}_y$ is locally Lipschitz, that is,

$$|\, \widehat{H}_y(z_1) - \widehat{H}_y(z_2)\,| \le L(M)\, \|\, z_1 - z_2\,\|_\infty, \quad \text{where } \|\, z_i\,\|_\infty \le M, \quad i = 1, 2.$$

As is well known, the first property ensures that $\widehat{H}_y$ is exact for v with constant gradients on the whole domain so that we are approximating the viscosity solution with the correct Hamiltonian. The second property is *precisely* the one on the numerical Hamiltonian that is required to obtain the a priori error estimates. The third property, unlike the previous two, is not really essential and can be relaxed; however, we do not know of any numerical scheme used in practice that does not satisfy it.

It is not difficult to verify that the function

$$\mathbb{G}_y(v(y,t); v(y-\delta_{y,1},t), \ldots, v(y-\delta_{y,N_y},t)) = v(y,t) - \Delta t \widehat{H}_y(\partial_{\delta_y} v(y,t)) \tag{2.2.5}$$

is nondecreasing in each of its arguments for all $y \in G_h$ for a small enough $\Delta t \ge 0$. As is well known, when this is the case, the scheme is said to be a monotone scheme. In what follows, we assume that the above schemes are monotone.

Next, we show that the well-known Lax–Friedrichs scheme satisfies the above conditions.

Example 2.2. *The Lax–Friedrichs scheme.* The Lax–Friedrichs scheme [15, 31] on the uniform Cartesian grid

$$G_h = \{(i,j) = (x_0 + (i-1)\Delta x, y_0 + (j-1)\Delta y)\}$$

reads as follows:

$$\begin{aligned} v_{i,j}^{n+1} = v_{i,j}^n &- \Delta t^n H\left(\frac{v_{i+1,j}^n - v_{i-1,j}^n}{2\Delta x}, \frac{v_{i,j+1}^n - v_{i,j-1}^n}{2\Delta y}\right) \\ &+ \Delta t^n \omega_x \frac{v_{i+1,j}^n - 2v_{i,j}^n + v_{i-1,j}^n}{\Delta x^2} + \Delta t^n \omega_y \frac{v_{i,j+1}^n - 2v_{i,j}^n + v_{i,j-1}^n}{\Delta y^2}, \end{aligned}$$

where

$$\omega_x = \sup_{(x,y)\in\mathbb{R}^d} \frac{1}{2}\, |H_1(\cdot,\cdot)|\, \Delta x,$$

$$\omega_y = \sup_{(x,y)\in\mathbb{R}^d} \frac{1}{2}\, |H_2(\cdot,\cdot)|\, \Delta y,$$

and $H_i(p_1,p_2) = \frac{\partial H}{\partial p_i}(p_1,p_2)$ for $i = 1, 2$.

Since the grid G_h is Cartesian, for each $y = (i, j) \in G_h$ we have $N_y = 4$; the quantities $\partial_{\delta_{y,i}} v(y)$ are thus the following:

$$\partial_{-\Delta x} v_{i,j} = \frac{v_{i,j} - v_{i+1,j}}{\Delta x}, \qquad \partial_{\Delta x} v_{i,j} = \frac{v_{i,j} - v_{i-1,j}}{\Delta x},$$
$$\partial_{-\Delta y} v_{i,j} = \frac{v_{i,j} - v_{i,j+1}}{\Delta y}, \qquad \partial_{\Delta y} v_{i,j} = \frac{v_{i,j} - v_{i,j-1}}{\Delta y};$$

therefore,

$$\begin{aligned}\widehat{H}_y = {} & H\left(\frac{1}{2}(\partial_{\Delta x} v_{i,j} - \partial_{-\Delta x} v_{i,j}), \frac{1}{2}(\partial_{\Delta y} v_{i,j} - \partial_{-\Delta y} v_{i,j})\right) \\ & + \frac{\omega_x}{\Delta x}(\partial_{-\Delta x} v_{i,j} + \partial_{\Delta x} v_{i,j}) + \frac{\omega_y}{\Delta y}(\partial_{-\Delta y} v_{i,j} + \partial_{\Delta y} v_{i,j}).\end{aligned}$$

It is easy to verify that the above $\widehat{H}_y$ satisfies properties (i), (ii), and (iii).

In section 4, we give more examples of schemes satisfying these three properties.

2.3. A new class of monotone schemes. Consider a regular triangulation $\mathcal{T}_h$ of $\mathbb{R}^d$ and define the grid G_h to be the collection of vertices y_j of simplexes in $\mathcal{T}_h$. In the two-dimensional case, these simplexes are triangles. Consider a function v on the standard grid Q_h. Here we enumerate the points y_j of the grid G_h and identify the function v defined on G_h with the point $(v_1, \ldots, v_N)$, where $v_j = v(y_j)$; similar considerations lead to $v_j^n = v(y_j, t^n)$ on Q_h.

Next we denote by Ω_j a control-volume centered at y_j used to define the average of the solution $u(x, t)$ and its numerical gradients at y_j and time t. The control-volume can be taken as Abgrall's intrinsic control-volume [1], the covolume introduced in [22], or the nonconforming dual-volume in [22]. Denote the collection of control-volumes Ω_j as Ω_h.

At each time level t^n, decompose Ω_h into two sets, $\bigcup_{j\in\mathcal{C}^n} \Omega_j$ and $\bigcup_{j\notin\mathcal{C}^n} \Omega_j$, where $\mathcal{C}^n$ is any subset of integers. Let $\Delta t^n = t^{n+1} - t^n$ be the time increment associated to $j \in \mathcal{C}^n$. For $j \notin \mathcal{C}^n$, define the following fractional time increment: $[t^n, t^{n+1}) = \bigcup_{l=0}^{M-1} [t^{n+\eta_l}, t^{n+\eta_{l+1}})$, where $t^{n+\eta_l}$ is defined below. Let $\{\sigma_k\}_{k=1}^M$ satisfy $\sigma_k > 0$ for $k = 1, \ldots, M$ and $\sum_{k=1}^M \sigma_k = 1$. Define η_l to be the partial sum: $\eta_l = \sum_{k=1}^l \sigma_k$ with $\eta_0 = 0$. Then define $t^{n+\eta_{l+1}} = t^{n+\eta_l} + \sigma_{l+1}\Delta t^n$. See Figure 1 for an illustration of such a decomposition in the one-dimensional case.

In the adaptive computation, the set $\mathcal{C}^n$ can be constructed through a posteriori error estimates so that it identifies where the solution is smooth and the complement of the set $\mathcal{C}^n$ identifies where the solution has higher or discontinuous gradients. Therefore, for $j \in \mathcal{C}^n$ we may use large time steps; for $j \notin \mathcal{C}^n$ we may use small time steps according to the local CFL condition shown below; see [13] for such identification mechanisms for the one-dimensional steady case of Hamilton–Jacobi equations.

We shall consider the piecewise linear continuous approximation of the solution on Q_h; namely, the gradient of the numerical solution is piecewise constant. We propose to advance from time level t^n to time level t^{n+1} via a predictor-corrector type scheme. Next we give a formal derivation of the scheme.

Integrating (2.2.1) over Ω_j from $t^{'}$ to $t^{''}$, we have

$$\text{(2.2.6)} \quad \frac{1}{|\Omega_j|}\int_{\Omega_j} u(x, t^{''})dx = \frac{1}{|\Omega_j|}\int_{\Omega_j} u(x, t^{'})dx - \frac{1}{|\Omega_j|}\int_{t'}^{t^{''}}\int_{\Omega_j} H(\nabla u(x, t))dxdt;$$

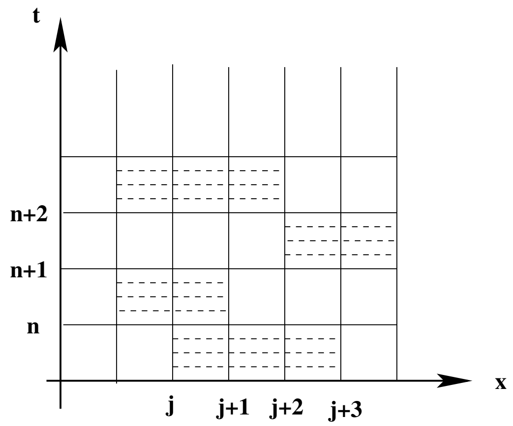

FIG. 1. *An illustration of decomposing nodes into two different sets and substepping in time.*

denote

$$v_j(t) = \frac{1}{|\Omega_j|}\int_{\Omega_j} u(x,t)dx. \tag{2.2.7}$$

For $j \in \mathcal{C}^n$, define

$$v_j(t) = \frac{(t^{n+1}-t)}{\Delta t^n} v_j(t^n) + \frac{(t-t^n)}{\Delta t^n} v_j(t^{n+1}) \quad \text{when } t \in [t^n, t^{n+1});$$

for $j \notin \mathcal{C}^n$, define

$$v_j(t) = \frac{(t^{n+\eta_{k+1}}-t)}{\sigma_{k+1}\Delta t^n} v_j(t^{n+\eta_k}) + \frac{(t-t^{n+\eta_k})}{\sigma_{k+1}\Delta t^n} v_j(t^{n+\eta_{k+1}})$$

when $t \in [t^{n+\eta_k}, t^{n+\eta_{k+1}})$ for $k = 0, \dots, M-1$.

In (2.2.6), for $j \in \mathcal{C}^n$, we take $t^{'} = t^n$ and $t^{''} = t^{n+1}$; for $j \notin \mathcal{C}^n$, we take $t^{'} = t^{n+\eta_k}$ and $t^{''} = t^{n+\eta_{k+1}}$ for $k = 0, \dots, M-1$. Formally substitute the numerical Hamiltonian $\widehat{H}$ for H in (2.2.6). For $j \in \mathcal{C}^n$, we obtain

$$v_j^{n+1} = v_j^n - \Delta t^n \frac{1}{|\Omega_j|}\int_{\Omega_j} \widehat{H}_j(\partial_{\delta_j} v_j^n)dx;$$

for $j \notin \mathcal{C}^n$, we obtain

$$v_j^{n+\eta_{k+1}} = v_j^{n+\eta_k} - \sigma_{k+1}\Delta t^n \frac{1}{|\Omega_j|}\int_{\Omega_j} \widehat{H}_j(\partial_{\delta_j} v_j^{n+\eta_k})dx$$

for $k = 0, \dots, M-1$. Here j corresponds to node y,

$$\partial_{\delta_j} v_j^n = (\partial_{\delta_{j,1}} v(y,t^n), \dots, \partial_{\delta_{j,N_y}} v(y,t^n))$$

and

$$\partial_{\delta_{j,i}} v_j^n = \frac{v(y,t^n) - v(y-\delta_{j,i},t^n)}{|\,\delta_{j,i}\,|}, \text{ where } y - \delta_{j,i} \in G_h, \qquad i = 1, \dots, N_j;$$

N_j denotes the number of edges at node y indexed by j, $\delta_{j,i}$ denotes the position vector of the ith edge at node y, and $|\delta_{j,i}|$ is the length of the ith edge associated to node j.

Because the approximation is piecewise linear on G_h, we can simplify the above formulation to the following: for $j \in \mathcal{C}^n$,

$$v_j^{n+1} = v_j^n - \Delta t^n \widehat{H}_j(\partial_{\delta_j} v_j^n);$$

for $j \notin \mathcal{C}^n$,

$$v_j^{n+\eta_{k+1}} = v_j^n - \sum_{l=0}^{k} \sigma_{l+1} \Delta t^n \widehat{H}_j(\partial_{\delta_j} v_j^{n+\eta_l})$$

for $k = 0, \dots, M-1$.

Therefore we have the predictor scheme

$$v_j^{n+\eta_k} = \begin{cases} v_j^n - \eta_k \Delta t^n \widehat{H}_j(\partial_{\delta_j} v_j^n), & j \in \mathcal{C}^n, \\ v_j^n - \sum_{l=0}^{k-1} \sigma_{l+1} \Delta t^n \widehat{H}_j(\partial_{\delta_j} v_j^{n+\eta_l}), & j \notin \mathcal{C}^n \end{cases} \tag{2.2.8}$$

for $k = 1, \dots, M-1$; the corrector is

$$v_j^{n+1} = \begin{cases} v_j^n - \Delta t^n \widehat{H}_j(\partial_{\delta_j} v_j^n), & j \in \mathcal{C}^n, \\ v_j^n - \sum_{l=0}^{M-1} \sigma_{l+1} \Delta t^n \widehat{H}_j(\partial_{\delta_j} v_j^{n+\eta_l}), & j \notin \mathcal{C}^n. \end{cases} \tag{2.2.9}$$

The above predictor-corrector type scheme is monotone under the following local CFL condition:

$$\sum_{i=1}^{N_j} \frac{\Delta t^n}{|\delta_{j,i}|} \frac{\partial \widehat{H}_j}{\partial p_{j,i}} \le 1 \qquad \text{for } j \in \mathcal{C}^n, \tag{2.2.10}$$

$$\sum_{i=1}^{N_j} \frac{\sigma_{l+1} \Delta t^n}{|\delta_{j,i}|} \frac{\partial \widehat{H}_j}{\partial p_{j,i}} \le 1 \qquad \text{for } j \notin \mathcal{C}^n, \tag{2.2.11}$$

where

$$\widehat{H}_j = \widehat{H}_j(\partial_{\delta_j} v_j) = \widehat{H}_j(p_{j,1}, \dots, p_{j,N_j}).$$

The above CFL condition is obtained by using the definition of monotone schemes defined through the operator (2.2.5). The condition (2.2.10) is the usual CFL restriction to make the scheme stable. The condition (2.2.11) is to enforce smaller time steps when local directional derivatives vary significantly.

Notice that in practice we do not need to compute all the solutions at the intermediate steps for $i \in \mathcal{C}^n$; only at those is involved in the computation for $j \notin \mathcal{C}^n$ is there a need for computation and storage; this, in turn, can be dealt with by using ghost points around those $j \notin \mathcal{C}^n$ as illustrated in the numerical examples.

2.4. Stability properties of the new monotone scheme. Let $\vec{G}_{\Delta t^n}$ be the self-map of $l^\infty(G_h)$ defined by (2.2.9), i.e.,

$$v^{n+1} = \vec{G}_{\Delta t^n}(v^n) \tag{2.2.12}$$

at each time step t^n.

We identify $\lambda \in \mathbb{R}$ with the constant function on G_h. From the form of $\vec{G}_{\Delta t^n}$, it is clear that

$$\vec{G}_{\Delta t^n}(v+\lambda) = \vec{G}_{\Delta t^n}(v) + \lambda$$

for all $v \in l^\infty(G_h)$ and $\lambda \in \mathbb{R}$. Since $\vec{G}_{\Delta t^n}$ is monotone by the CFL condition (2.2.10) and (2.2.11), $\vec{G}_{\Delta t^n}$ is a nonexpansive operator on $l^\infty(G_h)$ [15]. Namely,

$$\|\vec{G}_{\Delta t^n}(w) - \vec{G}_{\Delta t^n}(v)\|_\infty \le \|w - v\|_\infty$$

for all $w, v \in l^\infty(G_h)$.

Next we assume that the Lipschitz constant of v is preserved by the operator $\vec{G}_{\Delta t^n}$ at each time step t^n if v is Lipschitz continuous; this assumption can be verified for individual schemes, for example, the monotone finite difference schemes in [15] and the intrinsic monotone scheme [1]. Therefore, if the given initial data v^0 is Lipschitz continuous with L_0 as a Lipschitz constant, then L_0 will be the Lipschitz constant for each v^n $(n = 1, 2, \dots)$.

Because the numerical Hamiltonian $\hat{H}$ is locally Lipschitz continuous, we have

$$K = \sup\{|\widehat{H}_j(p_{j,1}, \dots, p_{j,N_j})| : |p_{j,i}| \le L_0, 1 \le i \le N_j, j \in G_h, 0 \le n \le N_T\} < \infty. \tag{2.2.13}$$

Furthermore, we can estimate, for any $j \in G_h$,

$$\begin{aligned} |v_j^{n+m} - v_j^n| &\le |v_j^{n+m} - v_j^{n+m-1}| + \cdots + |v_j^{n+1} - v_j^n| \\ &\le K\Delta t^{n+m-1} + \cdots + K\Delta t^n \\ &= K(t^{n+m} - t^n); \end{aligned} \tag{2.2.14}$$

thus

$$\|v^{n+m} - v^n\|_\infty \le K(t^{n+m} - t^n).$$

We can summarize the above properties in the following.

Proposition 2.3. *Let the scheme be monotone and $\vec{G}_{\Delta t^n}$ be the self-map of $l^\infty(G_h)$ as given in* (2.2.12). *Then we have*

(1) $\vec{G}_{\Delta t^n}(u) \le \vec{G}_{\Delta t^n}(v)$ *for* $u, v \in l^\infty(G_h)$, $u \le v$;

(2) $\vec{G}_{\Delta t^n}(v+\lambda) = \vec{G}_{\Delta t^n}(v) + \lambda$ *for* $u \in l^\infty(G_h)$, $\lambda \in \mathbb{R}$;

(3) $\|\vec{G}_{\Delta t^n}(u) - \vec{G}_{\Delta t^n}(v)\|_\infty \le \|u - v\|_\infty$ *for all* $u, v \in l^\infty(G_h)$;

(4) $\|v^{n+m} - v^n\|_\infty \le K(t^{n+m} - t^n)$ *for* $m, n \ge 0$, *where K is defined as* (2.2.13), *for a given initial Lipschitz continuous function v^0 with L_0 as a Lipschitz constant, provided that the Lipschitz constant of v^n is preserved by the operator $\vec{G}_{\Delta t^n}$ at each time step t^n if v^n is Lipschitz continuous.*

3. The error estimate for the scheme.

3.1. The main result. The main result of this section gives an upper bound for the following seminorms:

$$\begin{aligned} |\, w - v \,|_{-,Q_h} &= \sup_{(x,t)\in Q_h} (\, w(x,t) - v(x,t)\,)^+, \\ |\, w - v \,|_{+,Q_h} &= \sup_{(x,t)\in Q_h} (\, v(x,t) - w(x,t)\,)^+, \end{aligned}$$

where $w^+ \equiv \max\{0, w\}$.

In addition, we need to introduce the quantity

$$\omega_\epsilon(w; y, t, p_x) = w(y + \epsilon_x\, p_x, t) - w(y, 0) - \frac{t^2}{2\,\epsilon_t} - \frac{\epsilon_x}{2}\,|\, p_x\,|^2, \tag{3.3.1}$$

which can be bounded in terms of the moduli of continuity of w. For example, if $w(t=0) \in W^{1,\infty}(\mathbb{R}^d)$ and $w_t \in L^\infty(0, T; \mathbb{R}^d)$ we easily get

$$|\,\omega_\epsilon(w; y, t, p_x)\,| \le \frac{|\,w_t\,|^2_{L^\infty(0,T;\mathbb{R}^d)}}{2}\epsilon_t + \frac{|\,w(0)\,|_{W^{1,\infty}(\mathbb{R}^d)}}{2}\epsilon_x. \tag{3.3.2}$$

With the notation introduced above, we have the following result.

THEOREM 3.1 (a priori error estimate). *Assume that H is continuous in $\mathbb{R}^d$ and u_0 is Lipschitz continuous with L_0 as a Lipschitz constant. Let u be the viscosity solution of the equation* (2.2.1), (2.2.2) *and let v be the approximate solution given by the scheme* (2.2.3), (2.2.8), *and* (2.2.9) *under the local CFL condition* (2.2.10) *and* (2.2.11). *In addition, the assumption for Proposition* 2.3(4) *holds. Define $h = \max_{y\in G_h} \max_{i=1,\dots,N_y} |\,\delta_i\,|$ and $\Delta t = \max_{0\le i\le N_T} \Delta t^i$. Let $\frac{h}{\Delta t}$ be fixed. Then we have*

$$\|\,u - v\,\|_{L^\infty(Q_h)} \le C_3\sqrt{\Delta t},$$

where C_3 is a constant depending only on u_0, L_0, T, and $\widehat{H}_y$ as well as the solution u.

Note that the above L$^\infty$-norm is implied by

$$\|\,u - v\,\|_{L^\infty(Q_h)} = \max\{|\,u - v\,|_{+,Q_h}, |\,u - v\,|_{-,Q_h}\}.$$

THEOREM 3.2 (a priori error estimate for smooth solutions). *Assume that H is smooth in $\mathbb{R}^d$ and u_0 is Lipschitz continuous with L_0 as a Lipschitz constant. Let u be the smooth viscosity solution of the equation* (2.2.1), (2.2.2) *and let v be the approximate solution given by the scheme* (2.2.3), (2.2.8), *and* (2.2.9) *with the CFL condition* (2.2.10) *and* (2.2.11). *Define $h = \max_{y\in G_h} \max_{i=1,\dots,N_y} |\,\delta_i\,|$ and $\Delta t = \max_{0\le i\le N_T} \Delta t^i$. Let $\frac{h}{\Delta t}$ be fixed. Then we have*

$$\|\,u - v\,\|_{L^\infty(Q_h)} \le C_4\Delta t,$$

where C_4 is a constant depending only on u_0, L_0, T, and $\widehat{H}_y$ as well as the second-order derivatives of the solution u.

Remark. The technique used to prove Theorem 3.1 and Theorem 3.2 is related to the one used to prove a posteriori error estimates [2, 12]. One may also use such a technique to establish local a posterior error estimates for Hamilton–Jacobi equations. Analogous ideas can be used in the context of hyperbolic conservation laws. For example, borrowing some continuous dependence results from nonlinear conservation laws, Gosse and Makridakis [17] have established such local a posterior error estimates in the context of one-dimensional scalar hyperbolic conservation laws.

3.2. Proof of Theorem 3.1.

We prove the above result for $\sigma = -$; the proof for $\sigma = +$ is entirely analogous.

We attempt to obtain an estimate of the quantity

$$\Delta = |\,u - v\,|_{-,Q_h},$$

which we assume to be strictly positive since otherwise there is nothing to prove. We introduce the auxiliary function

$$\psi(x,y,t,s) = u(x,t) - v(y,s) - (1-\theta)\frac{(t+s)}{2T}\Delta - \frac{(t-s)^2}{2\epsilon_t} - \frac{|x-y|^2}{2\epsilon_x},$$

where the parameter θ belongs to $(0,1)$ and ϵ_x, ϵ_t to $(0,\infty)$; there is a point $(\hat{x},\hat{y},\hat{t},\hat{s})$: $(\hat{x},\hat{t}) \in \mathbb{R}^d \times [0,T]$ and $(\hat{y},\hat{s}) \in Q_h$ such that

$$\psi(\hat{x},\hat{y},\hat{t},\hat{s}) \geq \psi(x,y,t,s) \qquad \forall\,(x,t) \in \mathbb{R}^d \times [0,T] \text{ and } \forall\,(y,s) \in Q_h.$$

The existence of such a point easily follows from the fact that both u and v are continuous and periodic in space with the same period.

To obtain the desired estimate, we proceed in four steps.

Step 1. The case $\hat{s} > 0$ and $\hat{t} > 0$. By the construction of the function ψ, we have that $(\hat{x},\hat{t})$ is a maximum point on $\mathbb{R}^d \times (0,T]$ for

$$(x,t) \to u(x,t) - v(\hat{y},\hat{s}) - (1-\theta)\frac{(t+\hat{s})}{2T}\Delta - \frac{(t-\hat{s})^2}{2\epsilon_t} - \frac{|x-\hat{y}|^2}{2\epsilon_x};$$

thus $(\hat{p_t}, \hat{p_x}) \in D^+u(\hat{x},\hat{t})$, where

$$\hat{p}_t = \frac{\hat{t}-\hat{s}}{\epsilon_t} + \frac{1-\theta}{2T}\Delta \quad \text{ and } \quad \hat{p}_x = \frac{\hat{x}-\hat{y}}{\epsilon_x}.$$

By the assumption, u being the viscosity solution gives us that

$$\hat{p}_t + H(\hat{p}_x) \leq 0. \tag{3.3.3}$$

On the other hand, we note that $(\hat{y},\hat{s})$ is a maximum point on Q_h for

$$(y,s) \to u(\hat{x},\hat{t}) - v(y,s) - (1-\theta)\frac{(\hat{t}+s)}{2T}\Delta - \frac{(\hat{t}-s)^2}{2\epsilon_t} - \frac{|\hat{x}-y|^2}{2\epsilon_x};$$

therefore, it follows that

$$\begin{aligned} v(y,s) &\geq v(\hat{y},\hat{s}) + \left(\frac{(\hat{t}-\hat{s})}{\epsilon_t} - \frac{(1-\theta)\Delta}{2T}\right)(s-\hat{s}) - \frac{(s-\hat{s})^2}{2\,\epsilon_t} \\ &\quad + (y-\hat{y})\cdot\frac{(\hat{x}-\hat{y})}{\epsilon_x} - \frac{|y-\hat{y}|^2}{2\,\epsilon_x} \\ &=: V(y,s) \qquad \forall\,(y,s) \in Q_h; \end{aligned}$$

furthermore, the above inequality can be rewritten as

$$\begin{aligned} v(y,s) &\geq v(\hat{y},\hat{s}) - \frac{(1-\theta)\Delta}{T}(s-\hat{s}) + \hat{p}_t(s-\hat{s}) - \frac{(s-\hat{s})^2}{2\,\epsilon_t} \\ &\quad + (y-\hat{y})\cdot\hat{p}_x - \frac{|y-\hat{y}|^2}{2\,\epsilon_x} \\ &= V(y,s) \qquad \forall\,(y,s) \in Q_h. \end{aligned}$$

In the current case, for some $n_0 \geq 0$ and j_0, we have $\hat{s} = t^{n_0+1}$ and $\hat{y} = y_{j_0}$; thus, taking $s = t^{n_0}$ and $y = y_j$ in the above inequality leads to

$$\begin{aligned} v_j^{n_0} &\geq v_{j_0}^{n_0+1} + \frac{(1-\theta)\Delta}{T}\Delta t^{n_0} - \hat{p}_t \Delta t^{n_0} - \frac{(\Delta t^{n_0})^2}{2\,\epsilon_t} \\ &\quad + (y_j - \hat{y}) \cdot \hat{p}_x - \frac{|y_j - \hat{y}|^2}{2\,\epsilon_x} \\ &= V_j^{n_0} \qquad \forall\, y_j \in G_h. \end{aligned}$$

Next we use the scheme (2.2.8) and (2.2.9) to propagate the above relation from level $s = t^{n_0}$ to level $s = t^{n_0+1}$. To do this, we shall make use of the boundedness of the stencil size of the scheme.

Let $\mathcal{D}_{j_0}^{n_0+\eta_l}$ denote at time level $t^{n_0+\eta_l}$ the set of points $y_j \in Q_h$ involved in computing $v_{j_0}^{n_0+1}$ from time level t^{n_0} to t^{n_0+1} by the predictor-corrector scheme (2.2.8), (2.2.9). Therefore,

$$\mathcal{D}_{j_0}^{n_0+\eta_M} = \{y_{j_0}\} \quad \text{ and } \quad \mathcal{D}_{j_0}^{n_0+\eta_{M-1}} = \{y_{j_0}, y_{j_0,1}, \ldots, y_{j_0,N_{j_0}}\};$$

then $\mathcal{D}_{j_0}^{n_0+\eta_{M-2}}$ consists of all the points needed in evaluating $v_{j_0}^{n_0+\eta_{M-1}}$ and $v_{j_0,i}^{n_0+\eta_{M-1}}$ for $i = 1, \ldots, N_{j_0}$, and so on. Because M is finite, every $\mathcal{D}_{j_0}^{n_0+\eta_l}$ for $l = 0, \ldots, M$ is a finite set and

$$\mathcal{D}_{j_0}^{n_0+\eta_M} \subset \mathcal{D}_{j_0}^{n_0+\eta_{M-1}} \subset \cdots \subset \mathcal{D}_{j_0}^{n_0}.$$

Now define

$$C_{j_0} h = \max\{|y_j - \hat{y}| = |y_j - y_{j_0}| : y_j \in \mathcal{D}_{j_0}^{n_0+\eta_1}\}, \tag{3.3.4}$$

where C_{j_0} is a fixed positive constant and h is the mesh size.

Next we estimate $v_j^{n_0+\eta_1}$ for all $y_j \in Q_h$. By the predictor (2.2.8), it follows for all $y_j \in Q_h$,

$$\begin{aligned} v_j^{n_0+\eta_1} &= v_j^{n_0} - \eta_1 \Delta t^{n_0} \widehat{H}_j(\partial_{\delta_j} v_j^{n_0}) \\ &\geq V_j^{n_0} - \eta_1 \Delta t^{n_0} \widehat{H}_j(\partial_{\delta_j} V_j^{n_0}) \\ &= V_j^{n_0} - \eta_1 \Delta t^{n_0} \widehat{H}_j\left(\frac{V_j^{n_0} - V_{j,1}^{n_0}}{|\,\delta_{j,1}\,|}, \ldots, \frac{V_j^{n_0} - V_{j,N_j}^{n_0}}{|\,\delta_{j,N_j}\,|}\right) \end{aligned}$$

by the monotonicity of the scheme which is guaranteed by the local CFL condition (2.2.10), (2.2.11) and the relation that $v_j^{n_0} \geq V_j^{n_0}$, for all $y_j \in G_h$, shown above. Since for $i = 1, \ldots, N_j$,

$$\frac{V_j^{n_0} - V_{j,i}^{n_0}}{|\,\delta_{j,i}\,|} = \frac{\delta_{j,i}}{|\,\delta_{j,i}\,|} \cdot \hat{p}_x + \frac{\delta_{j,i}}{|\,\delta_{j,i}\,|} \cdot \frac{\delta_{j,i} - 2(y_j - \hat{y})}{2\,\epsilon_x},$$

we obtain by using the Lipschitz continuity of the Hamiltonian $\widehat{H}_j$ that

$$\begin{aligned}
v_j^{n_0+\eta_1} &\geq V_j^{n_0} - \eta_1 \Delta t^{n_0} \widehat{H}_j \left(\frac{\delta_{j,1}}{|\,\delta_{j,1}\,|} \cdot \hat{p}_x, \dots, \frac{\delta_{j,N_j}}{|\,\delta_{j,N_j}\,|} \cdot \hat{p}_x \right) \\
&\quad - \frac{L\eta_1 \Delta t^{n_0}}{2\,\epsilon_x} \max_{1\leq i\leq N_j} \left| \frac{\delta_{j,i}}{|\,\delta_{j,i}\,|} \cdot (\delta_{j,i} - 2(y_j - \hat{y})) \right| \\
&\geq V_j^{n_0} - \eta_1 \Delta t^{n_0} H(\hat{p}_x) - \frac{L\eta_1 \Delta t^{n_0}}{2\,\epsilon_x} \max_{1\leq i\leq N_j} |\delta_{j,i} - 2(y_j - \hat{y})| \\
&\geq V_j^{n_0} - \eta_1 \Delta t^{n_0} H(\hat{p}_x) - \frac{L\eta_1 \Delta t^{n_0}}{2\,\epsilon_x} \max_{1\leq i\leq N_j} |\delta_{j,i}\,| - \frac{L\eta_1 \Delta t^{n_0}}{\epsilon_x} |y_j - \hat{y}| \\
&\geq V_j^{n_0} - \eta_1 \Delta t^{n_0} H(\hat{p}_x) - \frac{L\,h\eta_1 \Delta t^{n_0}}{2\,\epsilon_x} - \frac{L\eta_1 \Delta t^{n_0}}{\epsilon_x} |y_j - \hat{y}|.
\end{aligned} \tag{3.3.5}$$

In the above derivation, we used the consistency of numerical Hamiltonian in the following way: setting $\mathcal{L}u(x,t) = u(y_j, t^{n_0}) + \hat{p}_x \cdot (x - y_j) + p_t(t - t^{n_0})$, we have

$$H(\hat{p}_x) = \widehat{H}_j(\partial_{\delta_j} \mathcal{L}u(y_j, t^{n_0})) \qquad \text{and} \qquad \partial_{\delta_{j,i}} \mathcal{L}u(y_j, t^{n_0})) = \hat{p}_x \cdot \frac{\delta_{j,i}}{|\,\delta_{j,i}\,|}.$$

Hence, for $j \in \mathcal{D}_{j_0}^{n_0+\eta_1}$, invoking (3.3.4) we find from (3.3.5) that

$$\begin{aligned}
v_j^{n_0+\eta_1} &\geq V_j^{n_0} - \eta_1 \Delta t^{n_0} H(\hat{p}_x) - \frac{\eta_1\, L\, h \Delta t^{n_0}}{2\,\epsilon_x} - \frac{\eta_1\, L \Delta t^{n_0}}{\epsilon_x} |y_j - \hat{y}| \\
&\geq V_j^{n_0} - \eta_1 \Delta t^{n_0} H(\hat{p}_x) - \frac{\eta_1\, L\, h \Delta t^{n_0}}{2\,\epsilon_x} - \frac{\eta_1\, L\, C_{j_0}\, h \Delta t^{n_0}}{\epsilon_x} \\
&= V_j^{n_0} - \eta_1 \Delta t^{n_0} H(\hat{p}_x) - \frac{\eta_1\, L\, h \Delta t^{n_0}(1 + 2\,C_{j_0})}{2\,\epsilon_x} \\
&=: V_j^{n_0+\eta_1}.
\end{aligned} \tag{3.3.6}$$

Next we estimate $v_j^{n_0+\eta_2}$. Apparently, for $j \in \mathcal{C}^{n_0}$ and $j \in \mathcal{D}_{j_0}^{n_0+\eta_2}$, by the predictor (2.2.8), we have that

$$\begin{aligned}
v_j^{n_0+\eta_2} &= v_j^{n_0} - \eta_2 \Delta t^{n_0} \widehat{H}_j(\partial_{\delta_j} v_j^{n_0}) \\
&\geq V_j^{n_0} - \eta_2 \Delta t^{n_0} \widehat{H}_j(\partial_{\delta_j} V_j^{n_0}) \\
&\geq V_j^{n_0} - \eta_2 \Delta t^{n_0} H(\hat{p}_x) - \frac{L\,h\eta_2 \Delta t^{n_0}}{2\,\epsilon_x} - \frac{L\eta_2 \Delta t^{n_0}}{\epsilon_x} |y_j - \hat{y}| \\
&\geq V_j^{n_0} - \eta_2 \Delta t^{n_0} H(\hat{p}_x) - \frac{\eta_2\, L\, h \Delta t^{n_0}(1 + 2\,C_{j_0})}{2\,\epsilon_x} \\
&=: V_j^{n_0+\eta_2}.
\end{aligned}$$

For $j \notin \mathcal{C}^{n_0}$ and $j \in \mathcal{D}_{j_0}^{n_0+\eta_2}$, still by the predictor (2.2.8) the inequality (3.3.6), and the monotonicity of the scheme, we get

$$\begin{aligned}
v_j^{n_0+\eta_2} &= v_j^{n_0+\eta_1} - \sigma_2 \Delta t^{n_0} \widehat{H}_j(\partial_{\delta_j} v_j^{n_0+\eta_1}) \\
&\geq V_j^{n_0+\eta_1} - \sigma_2 \Delta t^{n_0} \widehat{H}_j(\partial_{\delta_j} V_j^{n_0+\eta_1}) \\
&= V_j^{n_0+\eta_1} - \sigma_2 \Delta t^{n_0} \widehat{H}_j \left(\frac{V_j^{n_0+\eta_1} - V_{j,1}^{n_0+\eta_1}}{|\,\delta_{j,1}\,|}, \dots, \frac{V_j^{n_0+\eta_1} - V_{j,N_j}^{n_0+\eta_1}}{|\,\delta_{j,N_j}\,|} \right).
\end{aligned}$$

Since for $i = 1, \ldots, N_j$,

$$\frac{V_j^{n_0+\eta_1} - V_{j,i}^{n_0+\eta_1}}{|\,\delta_{j,i}\,|} = \frac{V_j^{n_0} - V_{j,i}^{n_0}}{|\,\delta_{j,i}\,|};$$

moreover, by the smoothness and consistency of the numerical Hamiltonian, we get

$$\begin{aligned} v_j^{n_0+\eta_2} &\geq V_j^{n_0+\eta_1} - \sigma_2 \Delta t^{n_0} \widehat{H}_j \left(\tfrac{V_j^{n_0} - V_{j,1}^{n_0}}{|\,\delta_{j,1}\,|}, \ldots, \tfrac{V_j^{n_0} - V_{j,N_j}^{n_0}}{|\,\delta_{j,N_j}\,|} \right) \\ &\geq V_j^{n_0+\eta_1} - \sigma_2 \Delta t^{n_0} \left(H(\hat{p}_x) + \tfrac{L\,h}{2\,\epsilon_x} + \tfrac{L}{\epsilon_x} |y_j - \hat{y}| \right) \\ &= V_j^{n_0} - \eta_2 \Delta t^{n_0} H\,(\hat{p}_x) - \tfrac{\eta_1\,L\,h \Delta t^{n_0}(1+2\,C_{j_0})}{2\,\epsilon_x} \\ &\quad - \tfrac{\sigma_2\,L\,h\Delta t^{n_0}}{2\,\epsilon_x} - \tfrac{\sigma_2\,L \Delta t^{n_0}}{\epsilon_x} |y_j - \hat{y}| \\ &\geq V_j^{n_0} - \eta_2 \Delta t^{n_0} H\,(\hat{p}_x) - \tfrac{\eta_1\,L\,h \Delta t^{n_0}(1+2\,C_{j_0})}{2\,\epsilon_x} \\ &\quad - \tfrac{\sigma_2\,L\,h\Delta t^{n_0}}{2\,\epsilon_x} - \tfrac{\sigma_2\,L \Delta t^{n_0} C_{j_0}\,h}{\epsilon_x} \\ &= V_j^{n_0} - \eta_2 \Delta t^{n_0} H\,(\hat{p}_x) - \tfrac{\eta_2\,L\,h \Delta t^{n_0}(1+2\,C_{j_0})}{2\,\epsilon_x} \\ &=: V_j^{n_0+\eta_2}, \qquad j \in \mathcal{D}_{j_0}^{n_0+\eta_2}. \end{aligned}$$

Inductively, we get for $j \in \mathcal{D}_{j_0}^{n_0+\eta_k}$, whether $j \in \mathcal{C}^n$ or not,

$$\begin{aligned} v_j^{n_0+\eta_k} &\geq V_j^{n_0} - \eta_k \Delta t^{n_0} H\,(\hat{p}_x) - \frac{\eta_k\,L\,h \Delta t^{n_0}(1+2\,C_{j_0})}{2\,\epsilon_x} \\ &=: V_j^{n_0+\eta_k}, \qquad k = 1, \ldots, M. \end{aligned}$$

Therefore, taking $k = M$ in the above: for $j \in \mathcal{D}_{j_0}^{n_0+1}$,

$$v_j^{n_0+1} \geq V_j^{n_0} - \Delta t^{n_0} H\,(\hat{p}_x) - \frac{L\,h \Delta t^{n_0}(1+2\,C_{j_0})}{2\,\epsilon_x}; \tag{3.3.7}$$

that is, for $j = j_0$ in the inequality (3.3.7), we have

$$\begin{aligned} v_{j_0}^{n_0+1} &\geq V_{j_0}^{n_0} - \Delta t^{n_0} H\,(\hat{p}_x) - \frac{L\,h \Delta t^{n_0}(1+2\,C_{j_0})}{2\,\epsilon_x} \\ &= v_{j_0}^{n_0+1} + \frac{(1-\theta)\Delta}{T} \Delta t^{n_0} - \hat{p}_t \Delta t^{n_0} - \frac{(\Delta t^{n_0})^2}{2\,\epsilon_t} - \Delta t^{n_0} H\,(\hat{p}_x) \\ &\quad - \frac{L\,h \Delta t^{n_0}(1+2\,C_{j_0})}{2\,\epsilon_x}; \end{aligned}$$

hence

$$\begin{aligned} \frac{(1-\theta)\Delta}{T} &\leq \hat{p}_t + H\,(\hat{p}_x) + \frac{\Delta t^{n_0}}{2\,\epsilon_t} + \frac{L\,h(1+2\,C_{j_0})}{2\,\epsilon_x} \\ &\leq \frac{\Delta t^{n_0}}{2\,\epsilon_t} + \frac{L\,h(1+2\,C_{j_0})}{2\,\epsilon_x}, \end{aligned} \tag{3.3.8}$$

where we have used the relation (3.3.3).

Step 2. The case $\hat{s} = 0$ and $\hat{t} \geq 0$. In this case, we no longer can use the definition of the approximate solution, so we rely instead on simple algebraic manipulations. We proceed as follows. Let $(\underline{y}, \underline{t}) \in Q_h$ be such that $|\,u - v\,|_{-,Q_h} = u(\underline{y}, \underline{t}) - v(\underline{y}, \underline{t})$. Then

$$\psi(\underline{y}, \underline{y}, \underline{t}, \underline{t}) = |\,u - v\,|_{-,Q_h} - (1-\theta)\frac{\underline{t}}{T}\Delta.$$

On the other hand,

$$\begin{aligned}\psi(\underline{y},\underline{y},\underline{t},\underline{t}) &\le \psi(\hat{x},\hat{y},\hat{t},\hat{s}) = \psi(\hat{x},\hat{y},\hat{t},0)\\ &= u(\hat{x},\hat{t}) - v(\hat{y},0) - \frac{\hat{t}^2}{2\epsilon_t} - \frac{|\hat{x}-\hat{y}|^2}{2\epsilon_x} - (1-\theta)\frac{\hat{t}}{2T}\Delta\\ &\le u(\hat{x},\hat{t}) - u(\hat{y},0) - \frac{\hat{t}^2}{2\epsilon_t} - \frac{|\hat{x}-\hat{y}|^2}{2\epsilon_x} - (1-\theta)\frac{\hat{t}}{2T}\Delta\\ &= \omega_\epsilon(u;\hat{y},\hat{t},\hat{p}_x) - (1-\theta)\frac{\hat{t}}{2T}\Delta\end{aligned}$$

since $\hat{x} = \hat{y} + \epsilon_x\,\hat{p}_x$; see (3.3.1) for definition of ω_ϵ. This implies that

$$\left(1 - (1-\theta)\frac{2\underline{t}-\hat{t}}{2T}\right)\Delta \le \omega_\epsilon(u;\hat{y},\hat{t},\hat{p}_x);$$

therefore by (3.3.2)

$$\Delta \le \frac{1}{\theta}\left(\frac{|\,u_t\,|^2_{L^\infty(0,T;\mathbb{R}^d)}}{2}\epsilon_t + \frac{|\,u(0)\,|_{W^{1,\infty}(\mathbb{R}^d)}}{2}\epsilon_x\right)$$

since

$$(1-\theta)\frac{2\underline{t}-\hat{t}}{2T} \le (1-\theta).$$

Step 3. The case $\hat{s} > 0$ and $\hat{t} = 0$. In this case, we also rely on simple algebraic manipulations. We proceed as follows. Let $(\underline{y},\underline{t}) \in Q_h$ be such that $|\,u - v\,|_{-,Q_h} = u(\underline{y},\underline{t}) - v(\underline{y},\underline{t})$. Then

$$\psi(\underline{y},\underline{y},\underline{t},\underline{t}) = |\,u - v\,|_{-,Q_h} - (1-\theta)\frac{\underline{t}}{T}\Delta.$$

On the other hand,

$$\begin{aligned}\psi(\underline{y},\underline{y},\underline{t},\underline{t}) &\le \psi(\hat{x},\hat{y},\hat{t},\hat{s}) = \psi(\hat{x},\hat{y},0,\hat{s})\\ &= u(\hat{x},0) - v(\hat{y},\hat{s}) - \frac{\hat{s}^2}{2\epsilon_t} - \frac{|\hat{x}-\hat{y}|^2}{2\epsilon_x} - (1-\theta)\frac{\hat{s}}{2T}\Delta\\ &\le u(\hat{x},0) - u(\hat{y},0) + v(\hat{y},0) - v(\hat{y},\hat{s}) - \frac{\hat{s}^2}{2\epsilon_t} - \frac{|\hat{x}-\hat{y}|^2}{2\epsilon_x} - (1-\theta)\frac{\hat{s}}{2T}\Delta\\ &\le \omega_\epsilon(u;\hat{y},0,\hat{p}_x) + K\hat{s} - \frac{\hat{s}^2}{2\epsilon_t} - (1-\theta)\frac{\hat{s}}{2T}\Delta\end{aligned}$$

by $\hat{x} = \hat{y} + \epsilon_x\,\hat{p}_x$ and Proposition 2.3(4).

Now we have to estimate $\hat{s}$ carefully. Since

$$\psi(\hat{x},\hat{y},\hat{t},\hat{s}) = \psi(\hat{x},\hat{y},0,\hat{s}) \ge \psi(\hat{x},\hat{y},0,0),$$

we get

$$v(\hat{y},0) - v(\hat{y},\hat{s}) \ge (1-\theta)\frac{\hat{s}}{2T}\Delta + \frac{\hat{s}^2}{2\epsilon_t}.$$

By Proposition 2.3(4), we get

$$\hat{s} \leq 2K\epsilon_t.$$

This implies that

$$\left(1-(1-\theta)\frac{t}{T}\right)\Delta \leq \omega_\epsilon(u;\hat{y},0,\hat{p}_x)+2K^2\epsilon_t;$$

therefore by (3.3.2)

$$\Delta \leq \frac{1}{\theta}\left(\frac{|\,u(0)\,|_{W^{1,\infty}(\mathbb{R}^d)}}{2}\epsilon_x+2K^2\epsilon_t\right),$$

since

$$(1-\theta)\frac{t}{T} \leq (1-\theta).$$

Step 4. Conclusion. Putting together the above inequalities and the bound (3.3.8), we get

$$\Delta \leq \max\left\{\frac{A+C}{\theta},\frac{B}{1-\theta}\right\},$$

where

$$A=\frac{|\,u_t\,|^2_{L^\infty(0,T;\mathbb{R}^d)}}{2}\epsilon_t+\frac{|\,u(0)\,|_{W^{1,\infty}(\mathbb{R}^d)}}{2}\epsilon_x,$$

$$B=T\left(\frac{\Delta t^{n_0}}{2\,\epsilon_t}+\frac{L\,h(1+2\,C_{j_0})}{2\,\epsilon_x}\right),$$

$$C=\frac{|\,u(0)\,|_{W^{1,\infty}(\mathbb{R}^d)}}{2}\epsilon_x+2K^2\epsilon_t.$$

Hence, we obtain that

$$\Delta \leq A+C+B$$

by taking the limit when θ tends to $\frac{A+C}{A+B+C}\in[0,1]$.

Note that according to classical results on the viscosity solution, L_0 is also a Lipschitz constant for u; see [15]. The result now follows from the above inequality by minimizing the right-hand side with respect to ϵ. This completes the proof of Theorem 3.1. □

3.3. Proof of Theorem 3.2 when *u* is the smooth solution. Consider $\sigma=-$ only; the proof for $\sigma=+$ is similar.

Let $(\underline{y},\underline{t})\in Q_h$ be such that $|\,u-v\,|_{-,Q_h}=u(\underline{y},\underline{t})-v(\underline{y},\underline{t})$. To estimate $u(\underline{y},\underline{t})-v(\underline{y},\underline{t})$ directly, we compute the local truncation error of the scheme (2.2.3), (2.2.8), (2.2.9). To simplify the presentation, we concentrate on the scheme (2.2.3), (2.2.4) only, since a similar analysis applies to (2.2.3), (2.2.8), (2.2.9).

If u is the smooth solution of (2.2.2), (2.2.1), then

$$\begin{aligned}u(y,t^n+\Delta t^n) &= u(y,t^n)+\Delta t^n u_t+\frac{1}{2}(\Delta t^n)^2 u_{tt}+o((\Delta t)^3)\\ &= u(y,t^n)-\Delta t^n H(\nabla u)+\frac{1}{2}(\Delta t^n)^2(\nabla_p H)^T(\partial^2_{i,j}\, u)(\nabla_p H)+o((\Delta t)^3),\end{aligned}$$

where $\partial^2_{i,j}\, u$ is the Hessian matrix of u.

Substituting the true solution into the scheme (2.2.4) and using the Taylor series expansion of the numerical scheme, we obtain

$$\begin{aligned}\mathbb{G}_y &= \mathbb{G}_y(u(y,t^n);u(y-\delta_{y,1},t^n),\ldots,u(y-\delta_{y,N_y},t^n))\\ &= u(y,t^n)-\Delta t^n\widehat{H}_y(\partial_{\delta_y}u(y,t^n))\\ &= u(y,t^n)-\Delta t^n\widehat{H}_y\left(\nabla u\cdot\frac{\delta_{y,1}}{|\delta_{y,1}|},\ldots,\nabla u\cdot\frac{\delta_{y,N_y}}{|\delta_{y,N_y}|}\right)\\ &\quad-\frac{1}{2}(\Delta t^n)^2\sum_{i=1}^{i=N_y}\frac{|\delta_{y,i}|}{\Delta t^n}\frac{\partial\widehat{H}_y}{\partial p_i}\left(\frac{\delta_{y,i}}{|\delta_{y,i}|}\right)^T(\partial^2_{l,m}\, u)\left(\frac{\delta_{y,i}}{|\delta_{y,i}|}\right)+o((\Delta t)^3)\\ &= u(y,t^n)-\Delta t^n H(\nabla u)\\ &\quad-\frac{1}{2}(\Delta t^n)^2\sum_{i=1}^{i=N_y}\frac{|\delta_{y,i}|}{\Delta t^n}\frac{\partial\widehat{H}_y}{\partial p_i}\left(\frac{\delta_{y,i}}{|\delta_{y,i}|}\right)^T(\partial^2_{l,m}\, u)\left(\frac{\delta_{y,i}}{|\delta_{y,i}|}\right)+o((\Delta t)^3),\end{aligned}$$

where we have used the consistency of the numerical Hamiltonian.

Consequently, the local truncation error is

$$\begin{aligned}&u(y,t^n+\Delta t^n)-\mathbb{G}_y(u(y,t^n);u(y-\delta_{y,1},t^n),\ldots,u(y-\delta_{y,N_y},t^n))\\ &=\ \frac{1}{2}(\Delta t^n)^2(\nabla_p H)^T(\partial^2_{i,j}\, u)(\nabla_p H)\\ &\quad+\frac{1}{2}(\Delta t^n)^2\sum_{i=1}^{i=N_y}\frac{|\delta_{y,i}|}{\Delta t^n}\frac{\partial\widehat{H}_y}{\partial p_i}\left(\frac{\delta_{y,i}}{|\delta_{y,i}|}\right)^T(\partial^2_{l,m}\, u)\left(\frac{\delta_{y,i}}{|\delta_{y,i}|}\right)+o((\Delta t)^3).\end{aligned}$$

Since $\frac{\partial\widehat{H}_y}{\partial p_i}\geq 0$ by the monotonicity of the numerical Hamiltonian, we have that the first two terms on the right-hand side have the same sign, and they cannot be identical to zero unless the solution is a linear function. This essentially shows that the monotone finite-difference schemes for Hamilton–Jacobi equations have only first-order accuracy; see [18] for similar results for hyperbolic conservation laws.

Next we estimate $|\, u-v\,|_{-,Q_h}=u(\underline{y},\underline{t})-v(\underline{y},\underline{t})$.

If $\underline{t}=0$, then we are done. So assume $\underline{y}=y_{j_0}$ for some j_0 and $\underline{t}=t^{n_0+1}$ for some integer $n_0\geq 0$. Define $\mathcal{D}^n_{j_0}$ to be the set of points $y_j\in Q_h$ at the time level $t=t^n$ involved in computing $v(y_{j_0},t^{n_0+1})$ by marching the scheme (2.2.4) from $t=0$ to $t=t^{n_0+1}$. Apparently,

$$\mathcal{D}^{n_0}_{j_0}\subset\mathcal{D}^{n_0-1}_{j_0}\subset\cdots\subset\mathcal{D}^0_{j_0};$$

$\mathcal{D}^0_{j_0}$ is a finite set according to the boundedness of the stencil size of the scheme. Therefore, using the above local truncation error analysis, we have the following

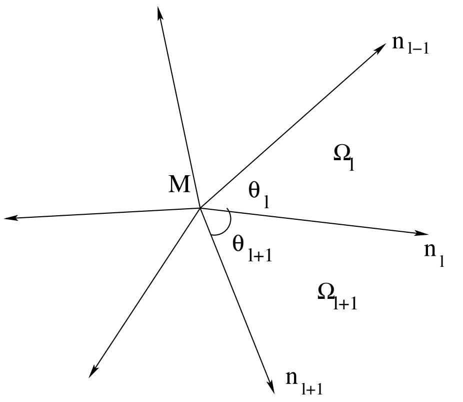

Fig. 2. *Triangulation for the intrinsic monotone scheme.*

estimates for computed solutions:

$$\begin{aligned}
&v(y_j,0)=u(y_j,0) \qquad \text{for } j\in\mathcal{D}^0_{j_0},\\
&v(y_j,t^1)=u(y_j,t^1)+o((\Delta t)^2) \qquad \text{for } j\in\mathcal{D}^1_{j_0},\\
&\dots\\
&v(y_j,t^{n_0})=u(y_j,t^{n_0})+o(n_0(\Delta t)^2) \qquad \text{for } j\in\mathcal{D}^{n_0}_{j_0}.
\end{aligned}$$

Finally, we obtain that

$$|\,u-v\,|_{-,Q_h}=v(y_{j_0},t^{n_0+1})-u(y_{j_0},t^{n_0+1})\le C_4\Delta t,$$

where C_4 depends on the initial condition u_0, T, H, and $\widehat{H}_y$ as well as second-order derivatives of the solution u.

This completes the proof. □

4. Examples of monotone schemes. In this section, we display several examples of monotone schemes for which our results hold.

Example 4.1 (The monotone schemes of [15, 31]). In a way similar to that used to deal with the Lax–Friedrich scheme, the monotone schemes considered in [15, 31] can be recast in our framework and proven to have the desired properties.

Example 4.2 (Abgrall's intrinsic monotone scheme [1]). To describe this scheme, we need to introduce some notation. Let $\mathcal{T}$ be a triangulation of $\mathbb{R}^2$. We denote the triangles by T and their vertices by M_i; the grid G_h is the collection of the vertices M_i. To each vertex M_i we associate a family of angular sectors $\{\Omega^i_l\}_{l=1}^{N_i}$, defined as the inner angles at M_i of all the triangles, T^i_l, having M_i as a vertex. Denote by θ^i_l the angle of Ω^i_l and by n^i_l the unit vector of the half-line $D^i_l=\Omega^i_l\cap\Omega^i_{l+1}$ pointing outward; see Figure 2.

For any set $\{v_i\}$, we denote by v the piecewise-linear function on $\mathcal{T}$ such that $v(M_i)=v_i$; note that $\nabla v|_{T^i_l}=\nabla v_{T^i_l}$ is constant in the triangle T^i_l. The intrinsic monotone scheme for (2.2.1) at a generic point M_i reads

$$v_i^{n+1} = v_i^n - \Delta t^n \left(H\left(\frac{1}{2\pi} \sum_{l=1}^{N_i} \theta_l^i \nabla v_{T_l^i} \right) - \omega \sum_{l=1}^{N_i} \beta_l^i \nabla v_{T_l^i} \cdot n_l^i \right),$$

where

$$\omega = \frac{\eta C(L)}{\pi}, \qquad \beta_l^i = \tan\left(\frac{\theta_l^i}{2}\right) + \tan\left(\frac{\theta_{l+1}^i}{2}\right).$$

Here η is a suitably chosen positive parameter, and $C(L)$ is the Lipschitz constant for H in the ball $B_L = \{p : \|p\| \le L\}$; we denote by $\|\cdot\|$ the usual Euclidean norm.

We have N_i directional derivatives at M_i:

$$p_l^i = -\nabla v_{T_l^i} \cdot n_l^i = -\nabla v_{T_{l+1}^i} \cdot n_l^i, \qquad l = 1, \dots, N_i.$$

Furthermore,

$$\nabla v_{T_l^i} = \frac{1}{\sin^2 \theta_l^i} \left((p_l^i \cos\theta_l^i - p_{l-1}^i) n_{l-1}^i + (p_{l-1}^i \cos\theta_l^i - p_l^i) n_l^i \right);$$

thus the numerical Hamiltonian can be expressed as

$$\widehat{H}_i \left(p_1^i, \dots, p_{N_i}^i\right) = H\left(\frac{1}{2\pi} \sum_{l=1}^{N_i} \theta_l^i \nabla v_{T_l^i} \right) + \omega \sum_{l=1}^{N_i} \beta_l^i p_l^i.$$

The consistency of $\widehat{H}_i$ holds since

$$\sum_{l=1}^{N_i} \beta_l^i p \cdot n_l^i = 0$$

for all $\nabla v = p \in \mathbb{R}^2$ [1].

Differentiating the above $\widehat{H}$ with respect to p_j^i, we have that

$$\begin{aligned} \frac{\partial \widehat{H}_i}{\partial p_j^i} &= \frac{1}{2\pi} \frac{\theta_j^i}{\sin^2 \theta_j^i} \nabla H \cdot (\cos\theta_j^i n_{j-1}^i - n_j^i) \\ &\quad + \frac{1}{2\pi} \frac{\theta_{j+1}^i}{\sin^2 \theta_{j+1}^i} \nabla H \cdot (\cos\theta_{j+1}^i n_{j+1}^i - n_j^i) + \omega\beta_j \ge 0 \end{aligned}$$

if η is chosen as follows:

$$\eta = \frac{1}{4\sin^2 \frac{\alpha}{2}} \max(\alpha, \sin\alpha + (\pi - \alpha)\cos\alpha),$$

where α denotes the smallest angle of the triangles T of the triangulation $\mathcal{T}$. Therefore, $\widehat{H}_i$ is nondecreasing in each of its arguments.

The smoothness of $\widehat{H}_i$ follows by the local smoothness of H.

Example 4.3 (The covolume scheme of [22]). Following [22], we consider a regular triangulation $\mathcal{T}_h$ of $\mathbb{R}^2$ and define the grid G_h to be the collection of vertices M_i of triangles in $\mathcal{T}_h$. Next, we construct a dual mesh by joining the circumcenters of

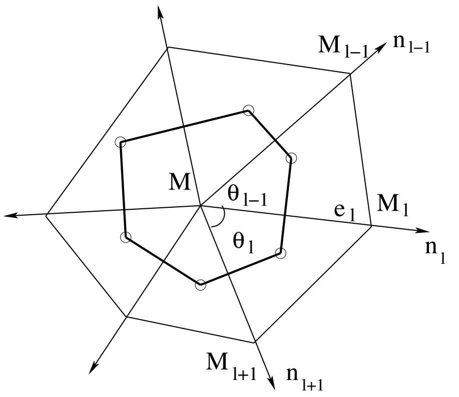

FIG. 3. *Triangulation for the co-volume scheme.*

the triangles in $\mathcal{T}_h$ and denote by V_i the covolume bounded by all the edges of the dual mesh that are perpendicular to edges containing the vertex M_i. Denote by M_l^i, $1 \le l \le N_i$, the vertices linked to M_i by an edge; we enumerate them in the clockwise direction. Denote by e_l^i the line segment joining M_i and M_l^i and by $e_{l,\perp}^i$ the edge of V_i that intersects perpendicularly e_l^i. Moreover, the triangle with vertices M_i, M_l^i, and M_{l+1}^i is denoted by T_l^i, the angle between e_l^i and e_{l+1}^i by θ_l^i, and the unit vector along e_l^i directed towards M_l^i by n_l^i. Finally, let $m(V_i)$ and $m(e_l^i)$ denote the area and length of V_i and e_l^i, respectively; see Figure 3.

Just like in the case of Abgrall's intrinsic monotone scheme, given the set of values $\{v_i\}$, we define a piecewise-linear interpolant v on $\mathcal{T}_h$ by $v(M_i) = v_i$. The covolume scheme for (2.2.1) is

$$v_i^{n+1} = v_i^n - \Delta t^n \left(\widehat{H}_i(\nabla v^n_{T_1^i}, \dots, \nabla v^n_{T^i_{N_i}}) \right),$$

where

$$\widehat{H}_i = \frac{1}{m(V_i)} \sum_{l:T_l^i \cap V_i \neq \emptyset} m(V_i \cap T_l^i) H(\nabla v_{T_l^i}) - \frac{\epsilon_{h,i}}{m(V_i)} \sum_l (\nabla v_{T_l^i}, n_l^i) m(e_{l,\perp}^i).$$

We have N_i directional derivatives at M_i:

$$p_l^i = -\nabla v_{T_{l-1}^i} \cdot n_l^i = -\nabla v_{T_l^i} \cdot n_l^i,$$
$$l = 1, \dots, N_i.$$

Furthermore, we can express $\nabla v_{T_l^i}$ in terms of p_l^i,

$$\nabla v_{T_l^i} = \frac{1}{\sin^2 \theta_l^i} \left((p_{l+1}^i \cos \theta_l^i - p_l^i) n_l^i + (p_l^i \cos \theta_l^i - p_{l+1}^i) n_{l+1}^i \right).$$

$\widehat{H}_i$ is consistent by the fact that

$$\sum_l (p, n_l^i) m(e_{l,\perp}^i) = 0$$

for all $p \in \mathbb{R}^2$ [22].

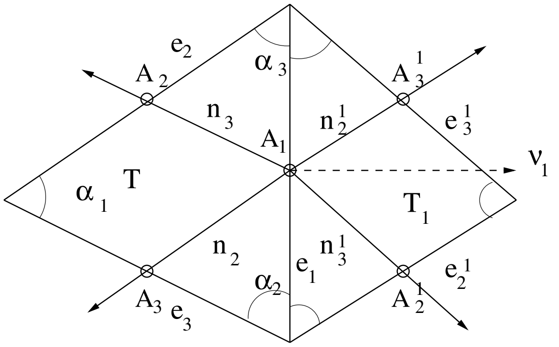

FIG. 4. *Triangulation for the edge-centered scheme.*

Differentiating the above $\widehat{H}_i$ with respect to p^i_j, we have that

$$\begin{aligned}\frac{\partial \widehat{H}_i}{\partial p^i_j} &= \frac{m(V_i \cap T^i_j)}{m(V_i)} \frac{1}{\sin^2 \theta^i_j} \nabla H \cdot (\cos \theta^i_j n^i_{j+1} - n^i_j) \\ &+ \frac{m(V_i \cap T^i_{j-1})}{m(V_i)} \frac{1}{\sin^2 \theta^i_{j-1}} \nabla H \cdot (\cos \theta^i_{j-1} n^i_{j-1} - n^i_j) \\ &+ \frac{\epsilon_{h,i}}{m(V_i)} m(e^i_{l,\perp}) \geq 0\end{aligned}$$

provided that $\epsilon_{h,i}$ is chosen such that

$$\epsilon_{h,i} \geq C^{'} C(L) \max_l (h_{T^i_l}),$$

where $h_{T^i_l}$ is the diameter of the triangle T^i_l and $C^{'}$ is a constant independent of the triangulation. To estimate the constant $C^{'}$, we have used the regularity of the triangulation [22]. The monotonicity of $\widehat{H}_i$ follows.

The smoothness of $\widehat{H}_i$ is implied by the local smoothness of H.

Example 4.4 (The edge-centered schemes of [22]). To describe these schemes, we need to introduce more notation. Consider a regular triangulation $\mathcal{T}_h$ of $\mathbb{R}^2$ with the property that all the inner angles α of the triangles in $\mathcal{T}_h$ satisfy that $\alpha \leq \omega_0 < \frac{\pi}{2}$. Given a triangle T of $\mathcal{T}_h$, we denote by $e_\ell, \ell = 1, 2, 3$ the edges of the triangle and by T_1 the triangle that shares the edge e_1 with T. The midpoints of the edges of T, T_ℓ are denoted by A_ℓ and A^1_ℓ, respectively; $\ell = 1, 2, 3$, are named in the counterclockwise direction. The common midpoints are A_1, A^1_1. The unit normal vector ν_1 to the common edge is directed toward T_1. Denote the inner angles facing e_ℓ by α_ℓ. At the common midpoint A_1, we introduce four outward unit direction vectors n_ℓ, n^1_ℓ such that $n_\ell \parallel e_\ell, n^1_\ell \parallel e^1_\ell, \ell = 2, 3$. See Figure 4.

Define the grid G_h to be the collection of the midpoints of the edges of all the triangles in $\mathcal{T}_h$. The approximating function v_h will lie in the space X_h of nonconforming piecewise linear functions defined on $\mathcal{T}_h$ [22]; namely, v_h is continuous at every $A \in G_h$ and piecewise linear in every triangle $T \in \mathcal{T}_h$.

The edge-centered scheme for (2.2.1) at a generic point A_1 is

$$v^{n+1}_{A_1} = v^n_{A_1} - \Delta t^n \left(\widehat{H}_{A_1}(\nabla v^n_T, \nabla v^n_{T_1}) \right),$$

where

$$\widehat{H}_{A_1} = H\left(\frac{1}{m(T)+m(T_1)}\left(m(T)\nabla v_T + m(T_1)\nabla v_{T_1}\right)\right) - \theta_h^{A_1}(\nabla v_{T_1} - \nabla v_T)\cdot \nu_1.$$

At A_1, we have four possible directions $n_\ell, n_\ell^1, \ell = 2, 3$; thus $N_{A_1} = 4$. Accordingly, we define four quantities:

$$\begin{aligned}
p_1 &= \frac{v_{A_1} - v_{A_2}}{m(\overline{A_1A_2})} = -\nabla v_T \cdot n_3,\\
p_2 &= \frac{v_{A_1} - v_{A_3}}{m(\overline{A_1A_3})} = -\nabla v_T \cdot n_2,\\
p_3 &= \frac{v_{A_1} - v_{A_2^1}}{m(\overline{A_1A_2^1})} = -\nabla v_{T_1} \cdot n_3^1,\\
p_4 &= \frac{v_{A_1} - v_{A_3^1}}{m(\overline{A_1A_3^1})} = -\nabla v_{T_1} \cdot n_2^1.
\end{aligned}$$

Furthermore, we have that

$$\begin{aligned}
\nu_1 &= -\frac{\cos\alpha_3}{\sin\alpha_1}n_3 - \frac{\cos\alpha_2}{\sin\alpha_1}n_2,\\
-\nu_1 = \nu_1^1 &= -\frac{\cos\alpha_3^1}{\sin\alpha_1^1}n_3^1 - \frac{\cos\alpha_2^1}{\sin\alpha_1^1}n_2^1,\\
\nabla v_T &= \frac{1}{\sin^2\alpha_1}\left((p_1\cos\alpha_1 - p_2)n_2 + (p_2\cos\alpha_1 - p_1)n_3\right),\\
\nabla v_{T_1} &= \frac{1}{\sin^2\alpha_1^1}\left((p_3\cos\alpha_1^1 - p_4)n_2^1 + (p_4\cos\alpha_1^1 - p_3)n_3^1\right).
\end{aligned}$$

Therefore, we can express $\widehat{H}_{A_1}$ as

$$\begin{aligned}
\widehat{H}_{A_1}(p_1, p_2, p_3, p_4) = H&\left(\frac{1}{m(T)+m(T_1)}\left(m(T)\nabla v_T + m(T_1)\nabla v_{T_1}\right)\right)\\
&+ \theta_h^{A_1}\left(\frac{\cos\alpha_3}{\sin\alpha_1}p_1 + \frac{\cos\alpha_2}{\sin\alpha_1}p_2 + \frac{\cos\alpha_3^1}{\sin\alpha_1^1}p_3 + \frac{\cos\alpha_2^1}{\sin\alpha_1^1}p_4\right).
\end{aligned}$$

Differentiating the above Hamiltonian with respect to, say, p_1, we have that

$$\frac{\partial\widehat{H}_{A_1}}{\partial p_1} = \frac{m(T)}{m(T)+m(T_1)}\frac{1}{\sin^2\alpha_1}\nabla H\cdot(\cos\alpha_1 n_2 - n_3) + \theta_h\frac{\cos\alpha_3}{\sin\alpha_1} \geq 0$$

if

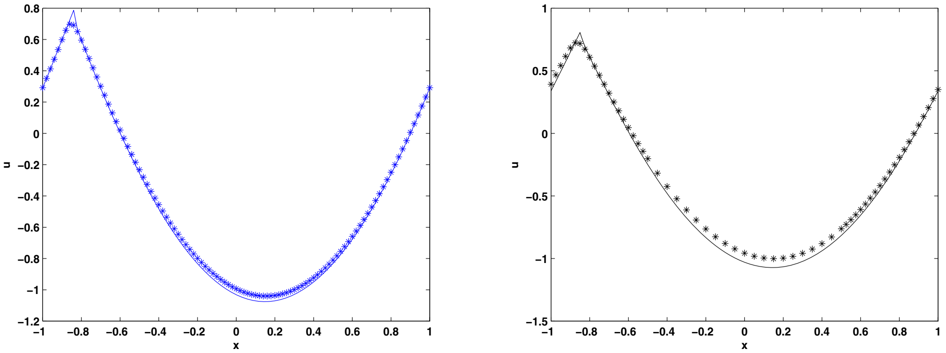
$$\theta_h^{A_1} \geq \frac{m(T)}{m(T)+m(T_1)}\frac{\|\nabla H\|}{\cos\omega_0}.$$

By similar considerations for $p_i, i = 2, 3, 4$, we have that

$$\frac{\partial\widehat{H}_{A_1}}{\partial p_i} \geq 0,\ i = 1, 2, 3, 4,$$

provided that

$$\theta_h^{A_1} = \frac{\max(m(T), m(T_1))}{m(T)+m(T_1)}\frac{\|\nabla H\|}{\cos\omega_0}.$$



(a) (b)

FIG. 5. *Local time stepping for the convex Hamiltonian. Numerical solution (in dots) and exact solution (in solid lines).* (a): *a uniform mesh;* (b): *a nonuniform mesh.*

Hence the monotonicity of $\widehat{H}_{A_1}$ follows.

The consistency of $\widehat{H}_{A_1}$ is obvious and the smoothness follows by the local smoothness of H.

5. Numerical experiments. We show some numerical examples to demonstrate the effectiveness of the new scheme.

Example 5.1 (A one-dimensional Hamilton–Jacobi equation). We solve

$$u_t + H(u_x) = 0, \qquad -1 \le x \le 1, \tag{5.5.1}$$

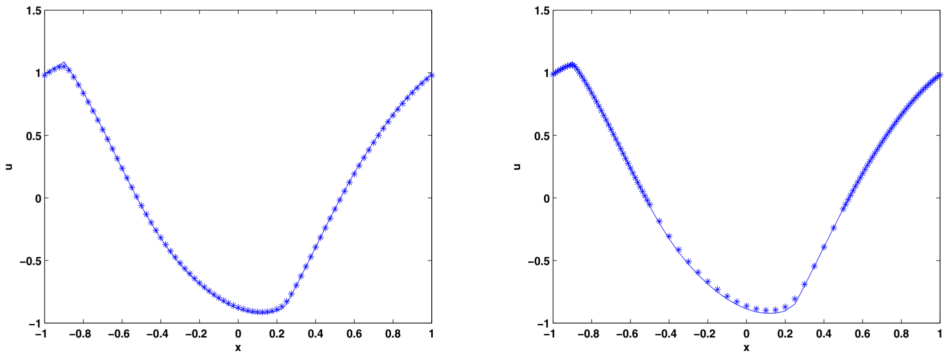
$$u(x,0) = -\cos\ \pi x, \tag{5.5.2}$$

with a convex $H(p) = \frac{(p+\alpha)^2}{2}$ and a nonconvex $H(p) = -\cos(p+\alpha)$.

We take $\alpha = 1$ and use the first order monotone scheme based on the Lax–Friedrichs numerical Hamiltonian to compute the viscosity solution. We use both uniform meshes and locally varying time and space grids to compute the solution up to $t = \frac{1.5}{\pi^2}$ when the solution has a discontinuous derivative.

Figure 5 shows solutions for the case of the convex Hamiltonian. Figure 5(a) shows the exact solution (in solid lines) and the solution computed with a uniform mesh of $dx = 0.02$ (in stars). Figure 5(b) shows the exact solution (in solid lines) and the solution computed with a nonuniform mesh (in stars). In the nonuniform mesh case, we have predetermined to use a mesh size of $dx = 0.025$ on the intervals $[-1,-0.5]$ and $[0.5,1]$ and a mesh size of $dx = 0.05$ on the interval $[-0.5,0.5]$; correspondingly we have used time steps on these different intervals according to the local CFL conditions. Although we did not use an optimal strategy to indicate where the solution is smooth or has kinks, the results show that the scheme based on locally varying space and time grids is convergent.

Figure 6 shows solutions for the case of the nonconvex Hamiltonian. Figure 6(a) shows the exact solution (in solid lines) and the solution computed with a uniform mesh of $dx = 0.025$ (in stars). Figure 6(b) shows the exact solution (in solid lines) and the solution computed with a nonuniform mesh (in stars). In the nonuniform mesh case, we have predetermined to use a mesh size of $dx = 0.0125$ on the intervals $[-1,-0.5]$ and $[0.5,1]$ and a mesh size of $dx = 0.05$ on the interval $[-0.5,0.5]$; correspondingly we have used time steps on these different intervals according to the local



(a) (b)

FIG. 6. *Local time stepping for the nonconvex Hamiltonian. Numerical solution (in dots) and exact solution (in solid lines).* (a): *a uniform mesh;* (b): *a nonuniform mesh.*

CFL conditions. Although we did not use an optimal strategy to indicate where the solution is smooth or has kinks, the results show that the scheme based on locally varying space and time grids is convergent.

Example 5.2 (A two-dimensional non-convex Hamilton–Jacobi equation: a Riemann problem). We use the proposed scheme in the AMR method [3, 5] to solve a two-dimensional nonconvex Riemann problem [31],

$$u_t + \sin(u_x + u_y) = 0, \qquad -2 \leq x, y \leq 2, \tag{5.5.3}$$

$$u(x, y, 0) = \pi(|y| - |x|), \tag{5.5.4}$$

to investigate the behavior of the AMR method and the convergence to the viscosity solution. In the following we assume that the reader is familiar with the version of AMR presented in [3].

We use the first-order Lax–Friedrichs monotone scheme [31] as the driving method in the AMR method to compute the viscosity solution. To simplify the implementation, we use the local truncation error estimator [3, 5] to flag where the computational mesh should be refined or coarsened; then a grid generation procedure dynamically creates or removes rectangular fine patches. On different patches, the time step-size is set according to the local CFL condition (2.2.10) and (2.2.11) so that efficient time stepping can be achieved on different levels of computational grids (or patches). Different from the AMR method for hyperbolic conservation laws where conservation has to be ensured across interfaces between coarse and fine grid patches [3, 5], the AMR method for Hamilton–Jacobi equations only needs to update the solution on a coarse patch by using the solution on a fine patch if available. To further simplify the implementation, we only allow the mesh refinement ratio to be two.

In the computation shown here, we have taken the coarsest mesh to be 40 × 40, the CFL number to be 0.85, the tolerance for the Richardson error estimator [3] to be 0.002528, the maximum mesh refinement to be 2, and the number of ghost points to be 4.

We compute the solution up to $t = 1.0$ by the AMR method. Figure 7 shows the solution in pseudocolor and its computational mesh; the AMR method has refined the mesh in the neighborhood of the two axes where the solution has rapid changes according to the local truncation error estimator; see the solution shown in Figure

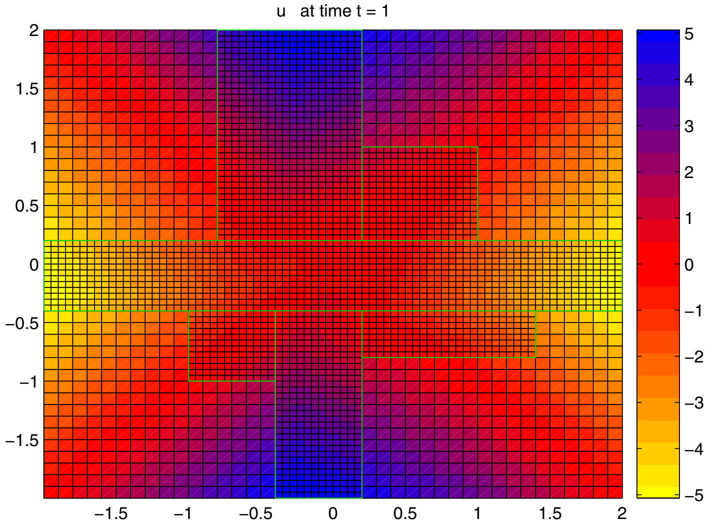


Fig. 7. *The solution at $t = 1$ by the AMR method and its computational mesh.*

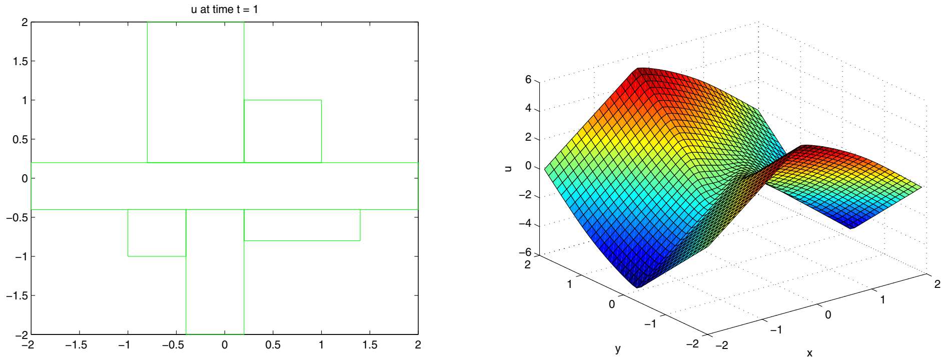

(a)

(b)

Fig. 8. *The two-dimensional Hamilton–Jacobi equation by the AMR method.* (a): *$t = 1$ with seven grids, including the underlying coarsest mesh;* (b): *the solution at $t = 1$. Notice that the refined meshes are along the two axes, where the solution changes rapidly.*

8(b). Figure 8(a) shows the computational mesh at $t = 1$ consisting of seven patches (or grids) including the underlying coarsest mesh; Figure 8(b) shows the solution obtained by the AMR method at $t = 1$.

Figure 9 shows the calibration results at $t = 1$, where we have compared three solutions: the one computed by the AMR method, and the two solutions computed on the uniform 40×40 mesh by the first-order monotone Lax–Friedrichs scheme [31] and the third-order weighted essentially nonoscillatory (WENO) Lax–Friedrichs scheme [20]; as we can see, the solution by the AMR method based on the first-order monotone Lax–Friedrichs scheme is much more accurate than the one by the first-order monotone Lax–Friedrichs scheme on the uniform mesh if the solution by the third WENO scheme is accepted as the “true” solution.

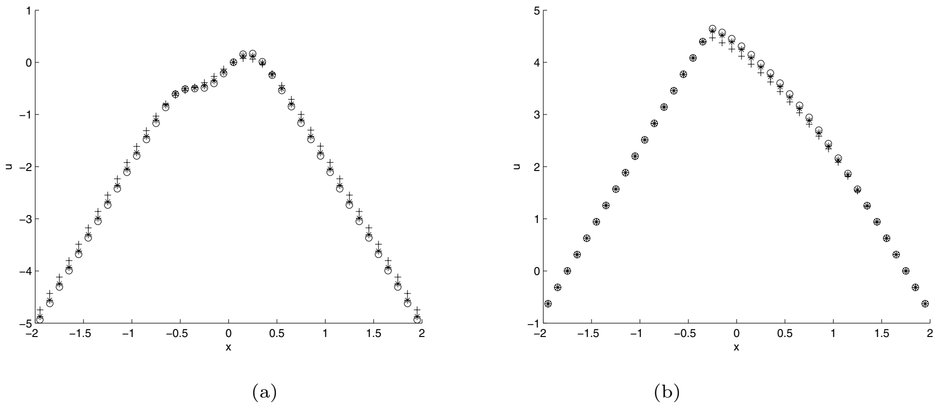

FIG. 9. *Calibration for the solution at $t = 1$ by the AMR method. WENO third-order: o; AMR: *; first-order Lax–Friedrichs scheme: +.* (a): $y = 0.05$*;* (b): $y = -1.75$.

We also point out that since in this example the coarsest mesh size is $h = 0.1$, the finest mesh size in the AMR method is $\frac{h}{2} = 0.05$, and $h^3 = 0.001$, the AMR solution based on the first-order scheme is not as accurate as the one by the third-order WENO scheme on the coarsest mesh. Therefore, the advantage of the AMR method will be more significant if a third-order WENO scheme is incorporated into the AMR method; this is an ongoing work.

Example 5.3 (A two-dimensional convex Hamilton–Jacobi equation). Now we use the proposed scheme in the AMR method [3, 5] to solve a two-dimensional convex periodic problem [31],

$$u_t + \frac{(u_x + u_y + 1)^2}{2} = 0, \qquad -2 \le x, y \le 2, \tag{5.5.5}$$

$$u(x, y, 0) = -\cos \pi \left(\frac{x + y}{2} \right), \tag{5.5.6}$$

to further investigate the behavior of the AMR method and the convergence to the viscosity solution.

We still use the first-order Lax–Friedrichs monotone scheme [31] as the driving method in the AMR method to compute the viscosity solution. Other implementation details are the same as those for the nonconvex Riemann problem.

In the computation shown here, we have taken the coarsest mesh to be 40 × 40, the CFL number to be 0.85, the tolerance for the Richardson error estimator [3] to be 0.0004525, the maximum mesh refinement to be 3, the mesh refinement ratio to be 2, and the number of ghost points to be 4.

We compute the solution up to $t = 0.152$ by the AMR method, when the solution has developed discontinuous gradients. Figure 10 shows the solution in pseudocolor and its computational mesh; the AMR method has refined the mesh where the solution has rapid changes according to the local truncation error estimator; see the solution shown in Figure 11(b). Figure 11(a) shows the computational mesh at $t = 0.152$ consisting of six patches (or grids) including the underlying coarsest mesh, the refined mesh in all the domain at the second level, and four local patches at the third level; Figure 11(b) shows the solution obtained by the AMR method at $t = 0.152$. Because the rapid changes in the solution are not aligned with horizontal or vertical direc-

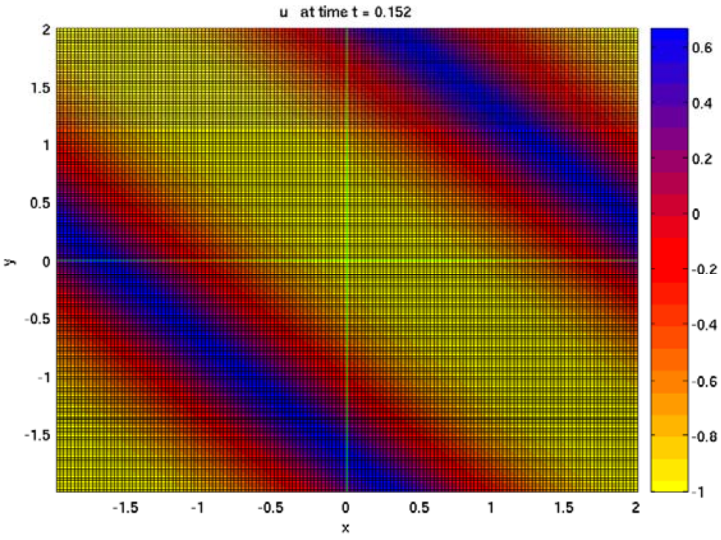

FIG. 10. *The solution at $t = 0.152$ by the AMR method and its computational mesh.*

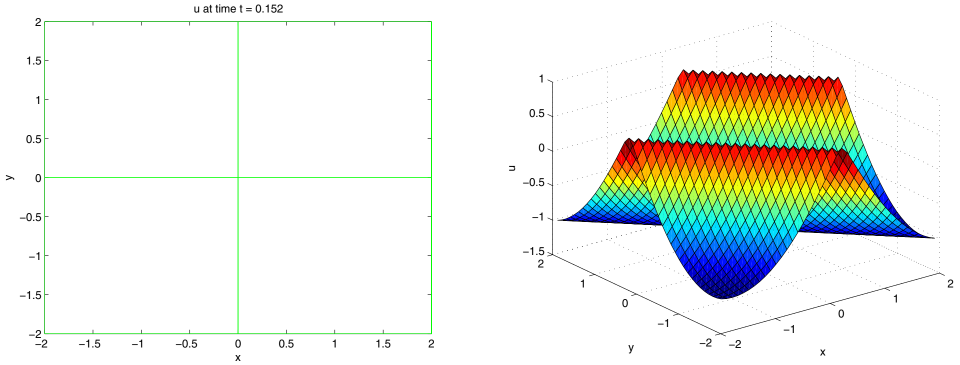
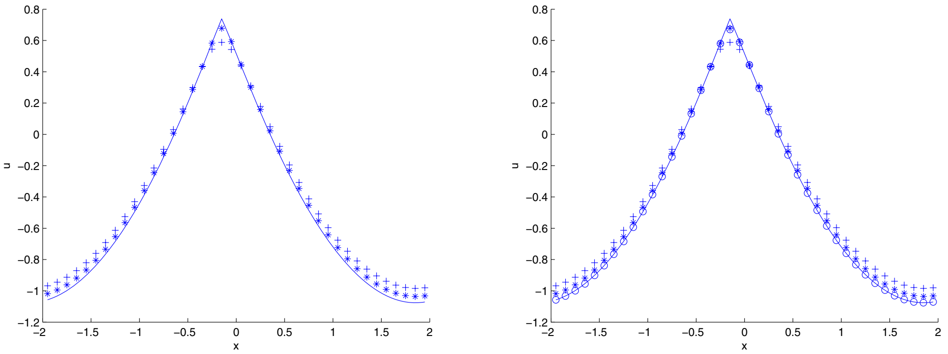


(a) (b)

FIG. 11. *The two-dimensional Hamilton–Jacobi equation by the AMR method.* (a): $t = 0.152$ *with six grids, including the underlying coarsest mesh, the refined mesh in all the domain at the second level and four local patches at the third level;* (b): *the solution at* $t = 0.152$.

tions, the AMR method based on rectangular meshes without rotation has refined the mesh everywhere so as to capture those sharp features; therefore, to have a more efficient AMR method for such features, one may use a version of the AMR method with rotations [4] or use a posteriori error estimators rather than local truncation error estimators to indicate more accurately where the computational mesh should be refined.

Figure 12 shows the calibration results at $t = 0.152$, where we have compared four solutions: the exact solution, the one computed by the AMR method presented here and the two solutions computed on the uniform 40×40 mesh by the first-order monotone Lax–Friedrichs scheme [31] and the third-order WENO Lax–Friedrichs scheme [20]; as we can see, the solution by the AMR method based on the first-order mono-



(a) (b)

FIG. 12. *Calibration for the solution at $t = 0.152$ for $y = -1.75$.* (a) *exact: -; AMR: *; first-order Lax–Friedrichs scheme: +.* (b) *exact: -; AMR: *; WENO third-order: o; first-order Lax–Friedrichs scheme: +.*

tone Lax–Friedrichs scheme is much more accurate than the one by the first-order monotone Lax–Friedrichs scheme on the uniform mesh; moreover, the AMR method provides very sharp resolution at the kink which is as good as the one by the third-order WENO scheme.

Example 5.4 (A two-dimensional Hamilton–Jacobi equation from geometrical optics). Now we use the proposed scheme in the AMR method [3, 5] to solve a two-dimensional periodic problem from geometrical optics [30, 26, 39],

$$u_t + \sqrt{u_x^2 + u_y^2 + 1} = 0, \qquad 0 \le x, y \le 1, \tag{5.5.7}$$

$$u(x, y, 0) = 0.25(\cos(2\pi x) - 1)(\cos(2\pi y) - 1) - 1. \tag{5.5.8}$$

We still use the first-order Lax–Friedrichs monotone scheme [31] as the driving method in the AMR method to compute the viscosity solution. Other implementation details are the same as those for the nonconvex Riemann problem.

In the computation shown here, we have taken the coarsest mesh to be 40 × 40, the CFL number to be 0.85, the tolerance for the Richardson error estimator [3] to be 0.0008250, the maximum mesh refinement to be 3, the mesh refinement ratio to be 2, and the number of ghost points to be 4.

We compute the solution up to $t = 0.60562$ by the AMR method, when the solution has developed discontinuous gradients. Figure 13 shows the solution in pseudocolor and its computational mesh; the AMR method has refined the mesh where the solution has rapid changes according to the local truncation error estimator; see the solution shown in Figure 14(b). Figure 14(a) shows the computational mesh at $t = 0.60562$ consisting of two grids including the underlying coarsest mesh and a refined patch in a neighborhood of (0.5, 0.5) at the second level; Figure 14(b) shows the solution obtained by the AMR method at $t = 0.60562$. Because the rapid changes in the solution are near the point (0.5, 0.5), the AMR method has refined the mesh in a neighborhood of that point so as to capture those sharp features. The results shown here can be compared with those in [39], in which a mesh redistribution method was used to cluster more mesh points in a neighborhood of (0.5, 0.5); see [39] for more details.

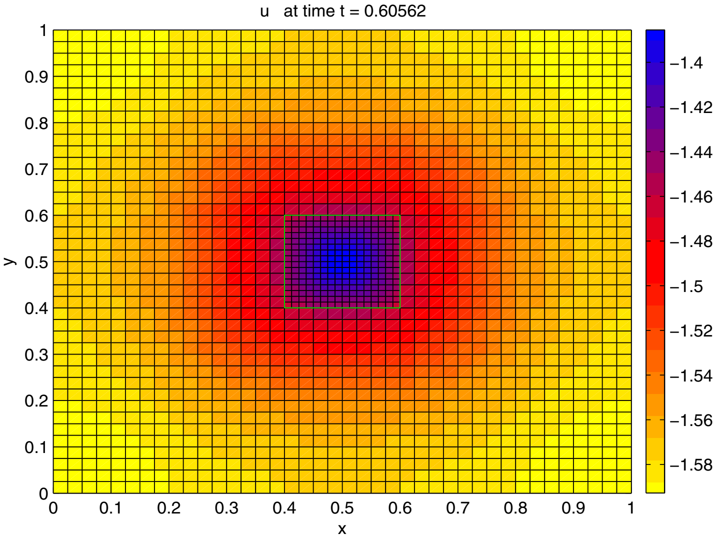


FIG. 13. *The solution at* $t = 0.60562$ *by the AMR method and its computational mesh.*

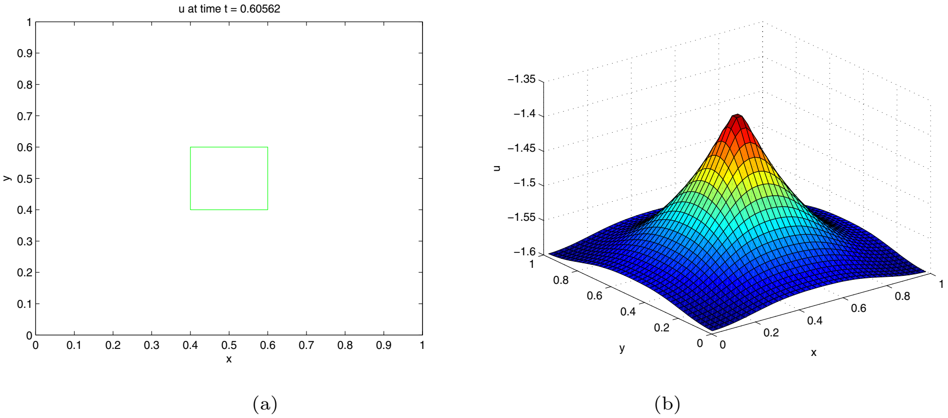

FIG. 14. *The two-dimensional Hamilton–Jacobi equation by the AMR method.* (a): $t = 0.60562$ *with two grids, including the underlying coarsest mesh and a refined patch in a neighborhood of* $(0.5, 0.5)$ *at the second level;* (b): *the solution at* $t = 0.60562$.

The above AMR examples based on the first-order Lax–Friedrichs scheme show that the proposed scheme fares well in comparison with existing methods. Currently we are incorporating a posteriori error estimators and WENO schemes into the AMR method so that we can have optimal mesh refinement and higher-order accuracy during the computation; a fully numerical assessment of such AMR methods and their performance as well as various conditions on the spatial and temporal meshes is an ongoing work.

Acknowledgment. The author thanks Prof. B. Cockburn, S. Osher and E. Tadmor for discussions and their generosity of sharing ideas with him. The author also would like to thank referees for many helpful suggestions. The author also would like to thank Prof. Marsha Berger for the AMR code that facilitates the implementation of examples used in the paper.

NUMERICAL APPROXIMATION OF A TWO-PHASE FLOW PROBLEM IN A POROUS MEDIUM WITH DISCONTINUOUS CAPILLARY FORCES[*]

GUILLAUME ENCHÉRY[†], R. EYMARD[‡], AND A. MICHEL[§]

Abstract. We consider a simplified model of a two-phase flow through a heterogeneous porous medium. Focusing on the capillary forces motion, a nonlinear degenerate parabolic problem is approximated in a domain shared in two homogeneous parts, each of them being characterized by its relative permeability and capillary curves functions of the phase saturations. We first give a weak form of the conservation equations on the whole domain, with a new general expression of the conditions at the interface between the two regions. We then propose a finite volume scheme for the approximation of the solution, which is shown to converge to a weak solution in one-, two-, or three-dimensional domains. We conclude with some numerical tests.

Key words. flows in porous media, capillarity, nonlinear PDE of parabolic type, finite volume methods

1. Introduction.

Simulations of two-phase flows through heterogeneous porous media are widely used in petroleum engineering. For example, for exploration purposes, the basin modeling aims to reconstruct the geological history of a sedimentary basin and in particular the migration of hydrocarbon components at geological time scale. The reservoir simulation is devoted to the understanding and the prediction of fluid flows occurring during production processes.

One of the most important consequences of the presence of heterogeneities in a porous medium is the phenomenon of capillary entrapment. This phenomenon occurs at the interface between two geological layers where discontinuous capillary thresholds appear. Indeed, if the mean pore radius in one layer is smaller than in the other, the oil phase must reach an access pressure so that the oil phase can enter the least permeable layer. In a sedimentary basin, this mechanism can induce the formation of oilfields. On the other hand, in reservoir engineering, the capillary trapping can reduce the recovery factor since large quantities of oil can remain trapped. Therefore, for this kind of application, one needs a precise understanding of this phenomenon on the physical plane as on the mathematical plane.

The physical principles which govern these flows and the mathematical models can be found in [2], [3], [4], [7]. However, the phenomenon of capillary trapping and its mathematical modelization have been completed only in some simplified cases [5], [9], [14].

The aim of this paper is to propose a general model for this phenomenon and to give the mathematical study of the convergence of a scheme which can be used in the industrial context.

We thus consider an incompressible and immiscible oil-water flow through a one-, two-, or three-dimensional heterogeneous and isotropic porous medium Ω. Using Darcy's law, the conservation of oil and water phases is given for all $(x,t) \in \Omega \times (0,T)$ by

$$(1.1) \qquad \begin{cases} -\phi(x)\dfrac{\partial u(x,t)}{\partial t} - \operatorname{div}\Big(\mu_w(x,u(x,t))(\nabla p_w(x,t) - \rho_w g)\Big) = 0, \\ \phi(x)\dfrac{\partial u(x,t)}{\partial t} - \operatorname{div}\Big(\mu_o(x,u(x,t))(\nabla p_o(x,t) - \rho_o g)\Big) = 0, \\ p_o(x,t) - p_w(x,t) = \pi(x,u(x,t)), \end{cases}$$

where the function ϕ is the porosity of the medium, $u \in [0,1]$ is the oil saturation (and therefore $1-u$ is the water saturation), $\pi(x,u)$ is the capillary pressure, and g is the gravity acceleration. The indices o and w, respectively, stand for the oil and the water phase. Thus, for $\beta = o, w$, p_β is the pressure of the phase β, $\mu_\beta(x,u)$ is the mobility of the phase β, and ρ_β is the density of the phase β. The unknowns of the problem are the functions u, p_w, and p_o.

Focusing on the modeling of flow at the interface between two different porous materials, we make the following assumptions.

Assumption 1.1.

H1-1. *The domain Ω is such that $\Omega = \Omega_1 \bigcup \Omega_2$. The subdomains Ω_1 and Ω_2 are disjoint open segments (if $d=1$), polygonal (if $d=2$), or polyhedral (if $d=3$) bounded connected subsets of $\mathbb{R}^d$. We assume that the common boundary between Ω_1 and Ω_2, $\Gamma = \partial\overline{\Omega}_1 \bigcap \partial\overline{\Omega}_2$, has a strictly positive and finite $d-1$-measure. The real $T > 0$ is the length of the considered time period.*

H1-2. *The function ϕ takes the strictly positive constant value $0 < \phi_i < 1$ in Ω_i for $i = 1,2$.*

H1-3. *For $\beta \in \{o,w\}$, $i = 1,2$, and for all $x \in \Omega_i$ $\mu_\beta(x,.) = \mu_{\beta,i}$. $\mu_{o,i}$ is a strictly increasing continuous function satisfying $\mu_{o,i}(u) = \mu_{o,i}(0) = 0$ for all $u \le 0$ and $\mu_{o,i}(u) = \mu_{o,i}(1)$ for all $u \ge 1$. $\mu_{w,i}$ is a strictly decreasing continuous function satisfying $\mu_{w,i}(u) = \mu_{w,i}(1) = 0$ for all $u \ge 1$ and $\mu_{w,i}(u) = \mu_{w,i}(0)$ for all $u \le 0$.*

H1-4. *For all $x \in \Omega_i$, $\pi(x,.) = \pi_i \in C^0(\mathbb{R},\mathbb{R})$ and π_i is such that its restriction $\pi_{i|[0,1]}$ to $[0,1]$ is strictly increasing, belongs to $C^1([0,1],\mathbb{R})$, and satisfies $\pi_i(u) = \pi_i(0)$ for all $u \le 0$ and $\pi_i(u) = \pi_i(1)$ for all $u \ge 1$. We assume that $\pi_1(0) \le \pi_2(0) \le \pi_1(1) \le \pi_2(1)$. We denote by $u_1^\star$ the unique real in $[0,1]$ satisfying $\pi_1(u_1^\star) = \pi_2(0)$. Thus, for all $u \in [0,u_1^\star)$, we have $\pi_1(u) < \pi_2(u)$. We denote by $u_2^\star$ the unique real in $[0,1]$ satisfying $\pi_2(u_2^\star) = \pi_1(1)$. Thus, for all $u \in (u_2^\star,1]$, we have $\pi_1(u) < \pi_2(u)$. (See Figure 1.1.)*

H1-5. *The initial condition in saturation $u_{\text{ini}} \in L^\infty(\Omega)$ and $0 \le u_{\text{ini}}(x) \le 1$ for almost everywhere (a.e.) $x \in \Omega$.*

The following conditions must be satisfied on the traces of u_i, $p_{\beta,i}$, and $\nabla p_{\beta,i}$ on $\Gamma \times (0,T)$, respectively, denoted by $u_{i,\Gamma}$, $p_{\beta,i,\Gamma}$, and $(\nabla p)_{\beta,i,\Gamma}$ (see [3]):

1. For any $\beta = o,w$, the flux of the phase β must be continuous:

$$(1.2)\ \mu_{\beta,1}(u_{1,\Gamma})((\nabla p)_{\beta,1,\Gamma} - \rho_\beta g).\overrightarrow{n}_{1,\Gamma} = -\mu_{\beta,2}(u_{2,\Gamma})((\nabla p)_{\beta,2,\Gamma} - \rho_\beta g).\overrightarrow{n}_{2,\Gamma},$$

where $\overrightarrow{n}_{i,\Gamma}$ is the unit normal of Γ outward to Ω_i.

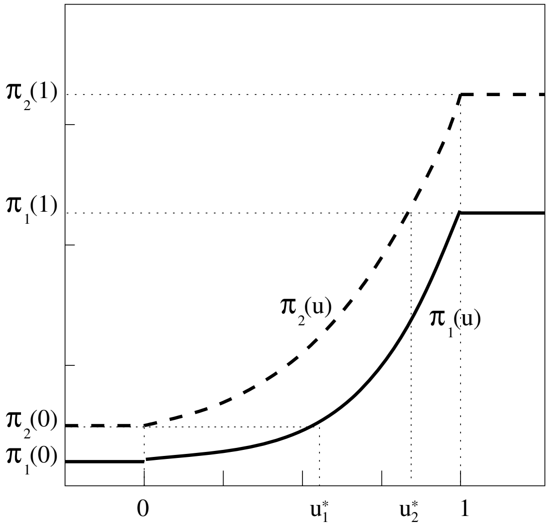

FIG. 1.1. *Functions* π_i, $i = 1, 2$.

2. For any $\beta = o, w$, either (p_β is continuous) or (p_β is discontinuous and $\mu_\beta = 0$); since the saturation is itself discontinuous across Γ, one must express the mobility at the upstream side of the interface. This gives

$$\mu_{\beta,1}(u_{1,\Gamma})(p_{\beta,1,\Gamma} - p_{\beta,2,\Gamma})^+ - \mu_{\beta,2}(u_{2,\Gamma})(p_{\beta,2,\Gamma} - p_{\beta,1,\Gamma})^+ = 0 \tag{1.3}$$

along with $p_{o,i,\Gamma} - p_{w,i,\Gamma} = \pi_i(u_{i,\Gamma})$, for $i = 1, 2$, where we denote, for all $a \in \mathbb{R}$, $a^+ = \max(a, 0)$.

The relations (1.3) can be directly expressed in terms of relations between $u_{i,\Gamma}$ and $p_{\beta,i,\Gamma}$, $\beta = o, w$, $i = 1, 2$:

1. If $0 \le u_{1,\Gamma} < u_1^\star$, then $\mu_{w,1}(u_{1,\Gamma}) > 0$; this implies $p_{w,1,\Gamma} \le p_{w,2,\Gamma}$. Since $\pi_1(u_{1,\Gamma}) < \pi_2(0) \le \pi_2(u_{2,\Gamma})$, we get $p_{o,1,\Gamma} < p_{o,2,\Gamma}$, which in turn implies $\mu_{o,2}(u_{2,\Gamma}) = 0$, and thus $u_{2,\Gamma} = 0$. Therefore $\mu_{w,2}(u_{2,\Gamma}) > 0$ and $p_{w,2,\Gamma} \le p_{w,1,\Gamma}$. Thus $p_{w,2,\Gamma} = p_{w,1,\Gamma}$. In this case, the oil phase is trapped in Ω_1, and the water flows across Γ.
2. If $u_1^\star \le u_{1,\Gamma}$ and $u_{2,\Gamma} \le u_2^\star$, then $\pi_2(0) \le \pi_1(u_{1,\Gamma})$, and $\pi_2(u_{2,\Gamma}) \le \pi_1(1)$. Since $\mu_{o,1}(u_{1,\Gamma}) > 0$, then $p_{o,1,\Gamma} \le p_{o,2,\Gamma}$ and $\mu_{o,2}(u_{2,\Gamma}) = 0$ or $p_{o,1,\Gamma} = p_{o,2,\Gamma}$. Similarly, since $\mu_{w,2}(u_{2,\Gamma}) > 0$, then $p_{w,1,\Gamma} \ge p_{w,2,\Gamma}$ and $\mu_{w,1}(u_{1,\Gamma}) = 0$ or $p_{w,1,\Gamma} = p_{w,2,\Gamma}$. Therefore, we get $p_{o,1,\Gamma} - p_{w,1,\Gamma} \le p_{o,2,\Gamma} - p_{w,2,\Gamma}$, which gives $\pi_1(u_{1,\Gamma}) \le \pi_2(u_{2,\Gamma})$. If we consider the case $\mu_{o,2}(u_{2,\Gamma}) = 0$, we get $u_{2,\Gamma} = 0$ and thus $\pi_2(0) = \pi_1(u_{1,\Gamma})$. Similarly, if we consider the case $\mu_{w,1}(u_{1,\Gamma}) = 0$, we get $\pi_2(u_{2,\Gamma}) = \pi_1(1)$. If we have at the same time $\mu_{o,2}(u_{2,\Gamma}) > 0$ and $\mu_{w,1}(u_{1,\Gamma}) > 0$, then $p_{o,1,\Gamma} = p_{o,2,\Gamma}$ and $p_{w,1,\Gamma} = p_{w,2,\Gamma}$, which implies $\pi_1(u_{1,\Gamma}) = \pi_2(u_{2,\Gamma})$. Therefore, in all cases, we get $\pi_1(u_{1,\Gamma}) = \pi_2(u_{2,\Gamma})$, and consequently $p_{o,1,\Gamma} = p_{o,2,\Gamma}$ and $p_{w,1,\Gamma} = p_{w,2,\Gamma}$. In this case, both phases flow across Γ.
3. If $u_2^\star < u_{2,\Gamma} \le 1$, a similar discussion yields $u_{1,\Gamma} = 1$ and $p_{o,1,\Gamma} = p_{o,2,\Gamma}$. In this case, the water phase is trapped in Ω_1, and the oil flows across Γ.

A consequence of this discussion is that in all cases, the resulting condition on the oil saturations at the boundary Γ is given by $\hat{\pi}_1(u_{1,\Gamma}) = \hat{\pi}_2(u_{2,\Gamma})$, defining the functions $\hat{\pi}_1$ and $\hat{\pi}_2$ by $\hat{\pi}_1 \;:\; u \mapsto \max(\pi_1(u), \pi_2(0))$ and $\hat{\pi}_2 \;:\; u \mapsto \min(\pi_2(u), \pi_1(1))$.

Now let us introduce the global pressure

$$\tilde{p}_i(x,t) = p_{w,i}(x,t) + \int_0^{u_i(x,t)} \frac{\mu_{o,i}(a)}{\mu_{o,i}(a) + \mu_{w,i}(a)} \pi_i'(a) da$$

(first introduced by Chavent; see, for example, [7]) and the functions $\eta_i \;:\; u \mapsto \frac{\mu_{o,i}(u)\mu_{w,i}(u)}{\mu_{o,i}(u)+\mu_{w,i}(u)}$ and $\varphi_i \;:\; u \mapsto \int_0^u \eta_i(a)\pi_i'(a)da$. We denote by L_{φ_i} the Lipschitz constant of φ_i and by C_η an upper bound of $\eta_i(u)$, $u \in \mathbb{R}$, $i = 1$ and 2. Using these notations we have for $(x,t) \in \Omega_i \times (0,T)$, $i = 1, 2$,

$$(1.4) \quad \begin{cases} \phi_i \dfrac{\partial u_i(x,t)}{\partial t} - \operatorname{div}\Big(\mu_{o,i}(u_i(x,t))(\nabla \tilde{p}_i(x,t) - \rho_o g)\Big) - \Delta\varphi_i(u_i(x,t)) = 0, \\ -\operatorname{div}\left(\displaystyle\sum_{\beta=o,w} \mu_{\beta,i}(u_i(x,t))\nabla\tilde{p}_i(x,t) - \sum_{\beta=o,w} \mu_{\beta,i}(u_i(x,t))\rho_\beta g\right) = 0. \end{cases}$$

We neglect in the first equation of (1.4) the term div $[\mu_{o,i}(u_i(x,t))(\nabla\tilde{p}_i(x,t) - \rho_o g)]$ in front of $\Delta\varphi_i(u_i(x,t))$, since this is sufficient to get the mathematical properties which are involved in the oil trapping phenomenon, as shown in the numerical examples at the end of this paper. Equations (1.2), (1.3), and (1.4) then produce within this simplified case the following equations, the solution of which are the functions $u_i(x,t)$, $(x,t) \in \Omega_i \times (0,T)$:

$$(1.5) \qquad \phi_i \frac{\partial u_i}{\partial t} - \Delta\varphi_i(u_i) = 0, \text{in } \Omega_i \times (0,T) \text{ for all } i \in \{1,2\},$$

$$(1.6) \qquad \nabla\varphi_1(u_{1,\Gamma}).\overrightarrow{n}_{1,\Gamma} = -\nabla\varphi_2(u_{2,\Gamma}).\overrightarrow{n}_{2,\Gamma} \text{ on } \Gamma \times (0,T),$$

and

$$(1.7) \qquad \hat{\pi}_1(u_{1,\Gamma}) = \hat{\pi}_2(u_{2,\Gamma}),$$

which summarizes the discussion induced by (1.3). Considering the problem of the migration of oil, we prescribe a homogeneous Neumann condition, which is expressed by

$$(1.8) \qquad \eta(.,u)\nabla\pi(.,u).\overrightarrow{n} = 0 \text{ on } \partial\Omega \times (0,T).$$

For $t = 0$, we have

$$(1.9) \qquad u(x,0) = u_{\text{ini}} \text{ in } \Omega.$$

Before giving the weak formulation of the problem we prove the following lemma.

LEMMA 1.2. *Under Assumption* 1.1*, let* $\Psi \;:\; [\pi_2(0), \pi_1(1)] \to \mathbb{R}$ *be the strictly increasing function defined by* $p \mapsto \Psi(p) = \int_{\pi_2(0)}^p \min(\eta_1(\pi_1^{(-1)}(a)), \eta_2(\pi_2^{(-1)}(a)))da$. *For all* $i \in \{1,2\}$*, the function* $\Psi \circ \hat{\pi}_i \circ \varphi_i^{(-1)}$ *is Lipschitz continuous with a constant lower than* 1.

Proof. For $i = 1$ or 2, let a be real such that $\varphi_1(u_1^\star) < a < \varphi_1(1)$ if $i = 1$, $0 < a < \varphi_2(u_2^\star)$ if $i = 2$. Within such a condition, we have $\hat{\pi}_i(\varphi_i^{(-1)}(a)) = \pi_i(\varphi_i^{(-1)}(a))$.

Let us calculate the derivative of the function $\pi_i \circ \varphi_i^{(-1)}$. Let $b \neq a$ be a real such that $\varphi_1(u_1^\star) < b < \varphi_1(1)$ if $i = 1$, $0 < b < \varphi_2(u_2^\star)$ if $i = 2$; setting $A = \varphi_i^{(-1)}(a)$ and $B = \varphi_i^{(-1)}(b)$, we have

$$\frac{\pi_i(\varphi_i^{(-1)}(b)) - \pi_i(\varphi_i^{(-1)}(a))}{b - a} = \frac{\pi_i(B) - \pi_i(A)}{\varphi_i(B) - \varphi_i(A)}.$$

Let us denote by $I(A, B)$ the interval $[A, B]$ if $B \geq A$, $[B, A]$ otherwise. Using the definition of φ_i, we have

$$\begin{aligned}\left(\min_{C \in I(A,B)} \eta_i(C)\right)(\pi_i(B) - \pi_i(A)) &\leq \varphi_i(B) - \varphi_i(A) \\ \leq \left(\max_{C \in I(A,B)} \eta_i(C)\right)(\pi_i(B) - \pi_i(A)),&\end{aligned}$$

and therefore there exists $C \in I(A, B)$ such that $\varphi_i(B) - \varphi_i(A) = \eta_i(C)(\pi_i(B) - \pi_i(A))$. Thus

$$\frac{\pi_i(\varphi_i^{(-1)}(b)) - \pi_i(\varphi_i^{(-1)}(a))}{b - a} = \frac{1}{\eta_i(C)},$$

which gives, letting $b \to a$, $(\pi_i \circ \varphi_i^{(-1)})'(a) = \frac{1}{\eta_i(\varphi_i^{(-1)}(a))}$. We thus get that the function $\Psi \circ \hat{\pi}_i \circ \varphi_i^{(-1)}$ has a derivative in a which is

$$(\Psi \circ \hat{\pi}_i \circ \varphi_i^{(-1)})'(a) = \Psi'(\pi_i(\varphi_i^{(-1)}(a)))(\pi_i \circ \varphi_i^{(-1)})'(a) = \frac{\Psi'(\pi_i(\varphi_i^{(-1)}(a)))}{\eta_i(\varphi_i^{(-1)}(a))}.$$

Using the definition of Ψ, we get $\Psi'(\pi_i(y)) \leq \eta_i(y)$ for $y = \varphi_i^{(-1)}(a)$. Gathering these results, we get that

$$(\Psi \circ \hat{\pi}_i \circ \varphi_i^{(-1)})'(a) \leq 1.$$

If $i = 1$ and $0 < a < \varphi_1(u_1^\star)$, or if $i = 2$ and $\varphi_2(u_2^\star) < a < 1$, then the function $\Psi \circ \hat{\pi}_i \circ \varphi_i^{(-1)}$ is constant, which implies a zero derivative. This completes the proof of the lemma. □

The system (1.5)–(1.9) is a nonlinear parabolic problem defined on a heterogeneous domain. Since in the general case, such a problem does not have any strong solution, we now give the definition of a weak solution to this problem.

Definition 1.3. *Under Assumption* 1.1*, a weak solution u of the problem* (1.5)–(1.9) *is defined by*

1. *for all $i \in \{1, 2\}$, $u = u_i$ in $\Omega_i \times (0, T)$ with*

$$u_i \in L^\infty(\Omega_i \times (0, T)),\ 0 \leq u_i \leq 1 \text{ a.e. and } \varphi_i(u_i) \in L^2(0, T; H^1(\Omega_i));$$

2. *for all $\psi \in C_{test} = \{h \in H^1(\Omega \times (0, T)),\ \ h(., T) = 0\}$,*

$$\sum_{i=1}^{2} \left[\begin{array}{l} \displaystyle\int_0^T \int_{\Omega_i} [\phi_i u_i(x,t)\psi_t(x,t) - \nabla\varphi_i(u_i(x,t)).\nabla\psi(x,t)]\, dxdt + \\ \displaystyle\int_{\Omega_i} \phi_i u_{\text{ini}}(x,0)\psi(x,0)dx \end{array} \right] = 0,$$

3. *the function $w : \Omega \times (0,T) \to \mathbb{R}$ defined by $(x,t) \mapsto \Psi(\hat{\pi}_i(u_i(x,t)))$ for a.e. $(x,t) \in \Omega_i \times (0,T)$, $i = 1,2$, belongs to $L^2(0,T;H^1(\Omega))$.*

Remark 1.4. This weak formulation is sufficient to impose (1.5), (1.6), (1.8), (1.9) on regular solutions. The last condition given in Definition 1.3 is a functional method to impose the condition (1.7).

In the homogeneous case, i.e., $\phi_1 = \phi_2$, $\pi_1 = \pi_2$, and $\eta_1 = \eta_2$, classical results of existence and uniqueness of a solution are available (see, for instance, [1] and [6] for a uniqueness result in more general cases). A simplified case of (1.5)–(1.9) has been handled in the heterogeneous case in [5], where the authors handle the case $d = 1$, $\Omega_1 = (-\infty,0)$, $\Omega_2 = (0,+\infty)$, and for $i = 1,2$, $\phi_i = 1$, $\eta_i(u) = k_i u$, and $\pi_i(u) = (1+u)/\sqrt{k_i}$, where $0 < k_2 < k_1$. (Note that only the problem of the oil trapping is considered here, since the physical conditions $\eta_i(1) = 0$ is not ensured.) Under additional hypotheses of regularity on the initial data, the authors get the existence and the uniqueness of the solution to the problem (1.5)–(1.9). We focus in this paper on the convergence of a numerical scheme for the approximation of u, in the general framework of Assumption 1.1. Up to a subsequence, we prove (see Theorem 2.15) the convergence of the finite volume scheme given by (2.2)–(2.4) to a weak solution in the sense of Definition 1.3. As an immediate consequence, the convergence of the scheme gives the existence of a solution to the problem (1.5)–(1.9) (see Corollary 2.17). Similar works have already been done, for example, in [12], [13] in the case of a homogeneous domain. Therefore, in the following proofs, we only insist on the new elements which appear in our study, mainly related to the presence of two domains linked by (1.6)–(1.7) (or (2.4) for the discrete problem). We end this study with numerical results (see section 3) and concluding remarks on ongoing works and future prospects (see section 4).

2. Study of a finite volume scheme.

In this section, we study a finite volume scheme discretizing (1.5)–(1.9). First we define an admissible discretization of $\Omega \times (0,T)$.

2.1. Admissible discretization of $\Omega \times (0,T)$.

Definition 2.1 (admissible mesh). *We denote by $\mathcal{M}$ an admissible finite volume discretization on a domain Ω; $\mathcal{M}$ is composed of a triplet $(\mathcal{T},\mathcal{E},\mathcal{P})$ with $\mathcal{T} = \mathcal{T}_1 \bigcup \mathcal{T}_2$, $\mathcal{E} = \mathcal{E}_1 \bigcup \mathcal{E}_2$, and $\mathcal{P} = \mathcal{P}_1 \bigcup \mathcal{P}_2$, which satisfy the following properties:*

- *For $i \in \{1,2\}$, $\mathcal{T}_i$ is a family of control volumes which are nonempty open polygonal convex disjoint subsets of Ω_i. These elements satisfy $\cup_{K\in\mathcal{T}_i}\overline{K} = \overline{\Omega}_i$. We denote by $\partial K = \overline{K} \setminus K$ the boundary of volume K and by $m(K)$ its measure (its length for $d = 1$, its area for $d = 2$, its volume for $d = 3$).*
- *For $i \in \{1,2\}$, $\mathcal{E}_i$ stands for the set of the edges of the control volumes in $\mathcal{T}_i$. For all $\sigma \in \mathcal{E}_i$, there exist a hyperplane E of $\mathbb{R}^d$ and a control volume $K \in \mathcal{T}_i$ such that $\overline{\sigma} = E \bigcap \partial K$ and σ is a nonempty open subset of E. We denote by $\mathcal{E}_K$ the subset of $\mathcal{E}$ composed of the edges of the volume K. Then we have $\partial K = \cup_{\sigma\in\mathcal{E}_K}\overline{\sigma}$. For any $\sigma \in \mathcal{E}_i$, we have*
  - *either $\sigma \in \mathcal{E}_{int,i} = \{\sigma \in \mathcal{E}_i,\ \exists\ (K,L) \in \mathcal{T}_i^2,\ K \neq L,$ such that $\overline{\sigma} = \overline{K} \cap \overline{L} \neq \emptyset\}$ (in that case σ is also denoted by $K|L$),*
  - *or $\sigma \in \mathcal{E}_\Gamma = \{\sigma \in \mathcal{E}_i,\ \exists\,(K,L) \in \mathcal{T}_1 \times \mathcal{T}_2,\ K \neq L,$ such that $\overline{\sigma} = \overline{K} \bigcap \overline{L} \neq \emptyset\}$,*
  - *or $\sigma \in \mathcal{E}_{ext,i} = \{\sigma \in \mathcal{E}_i,\ \exists\ K\ \in \mathcal{T}_i$ such that $\bar{\sigma} = \partial K \bigcap (\partial\Omega_i \setminus \Gamma) \neq \emptyset\}$.*
- *For $i \in \{1,2\}$, $\mathcal{P}_i$ refers to a family of points $(x_K)_{K\in\mathcal{T}}$ satisfying the following properties:*
  - *$x_K \in K$,*

- *for all $L \in \mathcal{T}_j$, $j \in \{1, 2\}$, the straight line (x_K, x_L) going through x_K and x_L is orthogonal to $K|L$.*

We also set

- $\mathcal{T}_\Gamma = \{(K, L),\ K \in \mathcal{T}_1,\ L \in \mathcal{T}_2,\ K|L \in \mathcal{E}_\Gamma\}$,
- $\mathcal{E}_{int} = \mathcal{E}_{int,1} \bigcup \mathcal{E}_{int,2} \bigcup \mathcal{E}_\Gamma$,
- $\mathcal{E}_{ext} = \mathcal{E}_{ext,1} \bigcup \mathcal{E}_{ext,2}$.

For $i = 1, 2$, the set of the neighboring volumes of a volume $K \in \mathcal{T}_i$ within Ω_i is represented by $N(K) = \{L \in \mathcal{T}_i,\ K|L \in \mathcal{E}_K\}$. The unit normal of an edge $K|L \in \mathcal{E}_{int}$ outward to K is denoted by $\overrightarrow{n}_{K,L}$. The area of an edge σ is denoted by $m(\sigma)$. For all $K \in \mathcal{T}$, $\sigma \in \mathcal{E}_K$, $d_{K,\sigma}$ stands for the euclidean distance between x_K and the edge σ and for $K|L \in \mathcal{E}_{int}$, $d_{K|L}$ is the euclidean distance between x_K and x_L. Using these notations the transmissivity $\tau_{K|L}$ through $K|L$ is equal to $m(K|L)/d_{K|L}$ and, for $\sigma \in \mathcal{E}_{ext}$ with $\sigma \in \mathcal{E}_K$, the transmissivity $\tau_{K,\sigma}$ through σ is equal to $m(\sigma)/d_{K,\sigma}$. For $i \in \{1, 2\}$ and $K|L \in \mathcal{E}_{int,i}$, we denote by $D_{K|L}$ the union of the two cones with the respective vertices x_K and x_L and the basis $K|L$. For $\sigma \in \mathcal{E}_{ext}$ such that $\sigma \in \mathcal{E}_K$, D_σ is the cone with vertex x_K and basis σ.

We set $\mathrm{size}(\mathcal{M}) = \sup\{\mathrm{diam(K)}, \mathrm{K} \in \mathcal{T}\}$. *The regularity of the mesh is defined by*

$$\mathrm{regul}(\mathcal{M}) = \frac{\mathrm{size}(\mathcal{M})}{\min_{K \in \mathcal{T}, \sigma \in \mathcal{E}_K} d_{K,\sigma}}. \tag{2.1}$$

In this paper, for the sake of simplicity, we restrict our study to constant time steps. But all results stated in the following can be adjusted to variable time steps.

DEFINITION 2.2 (admissible time discretization of $(0, T)$). *A discretization of $(0, T)$ is given by an integer $M \in \mathbb{N}$ such that $\delta t = \frac{T}{M+1}$. The increasing sequence of times $(t_n)_{n \in \{0 \dots M+1\}}$ which discretizes $(0, T)$ is then given by $t_n = n\delta t$.*

DEFINITION 2.3 (admissible discretization of $\Omega \times (0, T)$). *An admissible discretization $\mathcal{D}$ of $\Omega \times (0, T)$ is composed of a pair $(\mathcal{M}, M)$, where $\mathcal{M}$ is an admissible discretization of Ω and $M \in \mathbb{N}$ (see Definitions* 2.1 *and* 2.2*). We then denote* $\mathrm{size}(\mathcal{D}) = \max(\mathrm{size}(\mathcal{M}), \delta t)$.

2.2. Discrete functional properties. Let $\mathcal{D}$ be an admissible discretization of the domain $\Omega \times (0, T)$ (see Definition 2.3), $K \in \mathcal{T}$, and $n \in \{0 \dots M\}$. For a variable u, we denote by u_K^{n+1} its approximation over the volume K and over the time interval $]n\delta t, (n+1)\delta t]$ and by $(u_K^0)_{K \in \mathcal{T}}$ a piecewise constant approximation of the initial condition. We denote by

- $\mathcal{X}(\mathcal{T})$ the set of piecewise constant functions over the mesh $\mathcal{T}$: $u_\mathcal{T} \in \mathcal{X}(\mathcal{T})$ is defined for all $x \in \Omega$ by $u_\mathcal{T}(x) = u_K$ for $x \in K$,
- $\mathcal{X}(\mathcal{D})$ the set of piecewise constant functions over the discretization $\mathcal{D}$: $u_\mathcal{D} \in \mathcal{X}(\mathcal{D})$ is defined for all $n \in \{0 \dots M\}$ by $u_\mathcal{D}(., t) = u_\mathcal{T}^{n+1} \in \mathcal{X}(\mathcal{T})$ for $t \in]n\delta t, (n+1)\delta t]$.

We introduce the notation $\delta u_{K,L} = u_L - u_K$.

For $i \in \{1, 2\}$, the discrete $L^2(0, T; H^1(\Omega_i))$-seminorm is defined as follows.

DEFINITION 2.4. *Let $\Omega \times (0, T)$ be a domain satisfying* H1-1 *and $\mathcal{D}$ be an admissible discretization of this domain in the sense of Definition* 2.3. *For $i \in \{1, 2\}$, the $L^2(0, T; H^1(\Omega_i))$-seminorm of a function $u_\mathcal{D} \in \mathcal{X}(\mathcal{D})$ is defined by*

$$|u_\mathcal{D}|_{1,\mathcal{D},i}^2 = \sum_{n=0}^{M} \delta t \sum_{K|L \in \mathcal{E}_{int,i}} \tau_{K|L} (\delta u_{K,L}^{n+1})^2.$$

2.3. An implicit scheme. The initial condition u_K^0 is given by

$$u_K^0 = \frac{1}{m(K)} \int_K u_{\mathrm{ini}}(x)\, dx,\ \forall K \in \mathcal{T}. \tag{2.2}$$

For the following time steps, $n \in \{0, \dots, M\}$, we compute a discrete solution in saturation $(u_K^{n+1})_{K\in\mathcal{T}}$ thanks to the scheme

$$\begin{aligned} &m(K)\phi_i \frac{u_K^{n+1} - u_K^n}{\delta t} \sum_{L\in N(K)} \tau_{K|L} \left(\varphi_i(u_K^{n+1}) - \varphi_i(u_L^{n+1})\right) \\ &+ \sum_{\sigma\in\mathcal{E}_\Gamma \bigcap \mathcal{E}_K} \tau_{K,\sigma} \left(\varphi_i(u_K^{n+1}) - \varphi_i(u_{K,\sigma}^{n+1})\right) = 0,\ K \in \mathcal{T}_i,\ i \in \{1, 2\}, \end{aligned} \tag{2.3}$$

where for all $(K, L) \in \mathcal{T}_\Gamma$ and for given values of u_K^{n+1} and u_L^{n+1}, the values $u_{K,K|L}^{n+1}$, $u_{L,K|L}^{n+1} \in [0, 1]$ are the unique solutions (according to Lemma 2.5 below) of the system

$$\left\{ \begin{array}{rcl} \tau_{K,K|L}(\varphi_1(u_K^{n+1}) - \varphi_1(u_{K,\sigma}^{n+1})) & = & \tau_{L,K|L}(\varphi_2(u_{L,\sigma}^{n+1}) - \varphi_2(u_L^{n+1})), \\ \hat{\pi}_1(u_{K,\sigma}^{n+1}) & = & \hat{\pi}_2(u_{L,\sigma}^{n+1}). \end{array} \right. \tag{2.4}$$

Lemma 2.5. *Under Assumption* 1.1, *let* $\alpha_i > 0$ *be given for* $i = 1, 2$. *Let* $(a, b) \in \mathbb{R}^2$. *Then there exists one and only one pair* $(c, d) \in [0, 1]^2$ *such that*

$$\alpha_1(\varphi_1(a) - \varphi_1(c)) = \alpha_2(\varphi_2(d) - \varphi_2(b))$$

and

$$\hat{\pi}_1(c) = \hat{\pi}_2(d).$$

We then denote $c = U_1(a, b, \alpha_1, \alpha_2)$ *and* $d = U_2(a, b, \alpha_1, \alpha_2)$. *Then the functions* U_1 *and* U_2 *are continuous and nondecreasing with respect to* a *and* b. *Moreover, the following inequalities hold:*

$$\begin{aligned} &0 \le (\varphi_1(a) - \varphi_1(c))(\pi_1(a) - \pi_1(c)) \le (\varphi_1(a) - \varphi_1(c))(\pi_1(a) - \pi_2(b)), \\ &0 \le (\varphi_2(d) - \varphi_2(b))(\pi_2(d) - \pi_2(b)) \le (\varphi_2(d) - \varphi_2(c))(\pi_1(a) - \pi_2(b)). \end{aligned} \tag{2.5}$$

Proof. Let us take as unknowns the values $C = \varphi_1(c)$ and $D = \varphi_2(d)$ and let us denote $A = \varphi_1(a)$ and $B = \varphi_2(b)$. Then (C, D) is solution of

$$\alpha_1 C + \alpha_2 D = \alpha_1 A + \alpha_2 B, \tag{2.6}$$

$$\hat{\pi}_1(\varphi_1^{(-1)}(C)) = \hat{\pi}_2(\varphi_2^{(-1)}(D)). \tag{2.7}$$

Let us first consider the case where $\alpha_1 A + \alpha_2 B \le \alpha_1\varphi_1(u_1^\star)$. Since this implies $C \le \varphi_1(u_1^\star)$, we have necessarily $D = 0$ according to (2.7). Thus the solution is obtained, taking $D = 0$ and $C = (\alpha_1 A + \alpha_2 B)/\alpha_1$. In this case, since $D \le B$, we have $C \ge A$, and since $\pi_2(b) \ge \pi_2(0) \ge \pi_1(c) \ge \pi_1(a)$, we get (2.5).

We now consider the case where $\alpha_1\varphi_1(u_1^\star) < \alpha_1 A + \alpha_2 B < \alpha_1\varphi_1(1) + \alpha_2\varphi_2(u_2^\star)$. Since in this case we necessarily have $\varphi_1(u_1^\star) < C$ and $D < \varphi_2(u_2^\star)$ (see (2.7)), the relation $C = \varphi_1(\pi_1^{(-1)}(\pi_2(\varphi_2^{(-1)}(D))))$ holds, and since the function $D \mapsto \alpha_1\varphi_1 (\pi_1^{(-1)}(\pi_2(\varphi_2^{(-1)}(D)))) + \alpha_2 D$ is continuous and strictly increasing, the system has one and only one solution (C, D). We then get in this case that $\pi_1(c) = \pi_2(d)$, and since $\pi_1(a) - \pi_1(c)$ has the same sign as $\pi_2(d) - \pi_2(b)$, we get (2.5).

Finally, the case $\alpha_1\varphi_1(1) + \alpha_2\varphi_2(u_2^\star) \leq \alpha_1 A + \alpha_2 B$ is symmetric with the first case, and we get $C = \varphi_1(1)$ and $D = (\alpha_1(A - \varphi_1(1)) + \alpha_2 B)/\alpha_2$. We then have in this case $C \geq A$ and thus $D \leq B$, and since $\pi_2(b) \geq \pi_2(d) \geq \pi_1(1) \geq \pi_1(a)$, we again get (2.5).

In all these cases, C and D have been expressed as continuous nondecreasing functions of A and B, so the same conclusion holds for c and d as functions of a and b. □

Remark 2.6. It is possible to show that C and D, seen as functions of $A = \varphi_1(a)$ and $B = \varphi_2(b)$, verify, for a.e. $(a, b) \in \mathbb{R}^2$,

$$0 \leq \frac{\partial C}{\partial A} \leq 1,\ 0 \leq \frac{\partial D}{\partial A} \leq \frac{\alpha_1}{\alpha_2},\ 0 \leq \frac{\partial C}{\partial B} \leq \frac{\alpha_2}{\alpha_1},\ \text{and } 0 \leq \frac{\partial D}{\partial B} \leq 1.$$

Now we can state the L^∞-stability of the scheme and then the existence of a solution to (2.2)–(2.4).

2.4. L^∞-stability of the scheme.

If Ω were a homogeneous porous medium we could prove that the discrete solution in saturation satisfies a maximum principle depending on the initial condition [12]. Here, in presence of a heterogeneity, this result no longer holds.

PROPOSITION 2.7. *Under Assumption* 1.1*, let $\mathcal{D}$ be an admissible discretization of the domain $\Omega \times (0, T)$ (see Definition* 2.3*) and $u_\mathcal{T}^{n+1} \in \mathcal{X}(\mathcal{T})$, $n \in \{0 \ldots M\}$, the solution to the system* (2.2)–(2.4)*. (The existence and uniqueness of such a solution is shown in Proposition* 2.8*.) Then $u_\mathcal{T}^{n+1}$ satisfies*

$$\textit{for all } K \in \mathcal{T},\ 0 \leq u_K^{n+1} \leq 1. \tag{2.8}$$

Proof. For all $K \in \mathcal{T}_i$, $i \in \{1, 2\}$, (2.2)–(2.4) imply

$$u_K^{n+1} = H_K(u_K^n, (u_L^{n+1})_{L\in\mathcal{T}})$$

with

$$H_K(a, (a_L)_{L\in\mathcal{T}}) = \frac{1}{1+\lambda_K}\left(a + \lambda_K a_K + \frac{\delta t}{m(K)\phi_i}\left(\begin{array}{l} \displaystyle\sum_{L\in N(K)} \tau_{K|L}\left(\varphi_i(a_L) - \varphi_i(a_K)\right) \\ \displaystyle + \sum_{\sigma\in\mathcal{E}_\Gamma \bigcap \mathcal{E}_K} \tau_{K,\sigma}\left(\varphi_i(a_{K,\sigma}) - \varphi_i(a_K)\right) \end{array} \right)\right)$$

and

$$\lambda_K = \frac{\delta t L_\varphi}{m(K)\phi_i}\left(\sum_{L\in N(K)} \tau_{K|L} + \sum_{\sigma\in\mathcal{E}_\Gamma \bigcap \mathcal{E}_K} \tau_{K,\sigma} \right)$$

and where for all $(K, L) \in \mathcal{T}_\Gamma$, $a_{K,K|L}$ is defined by $a_{K,K|L} = U_1(a_K, a_L, \tau_{K,K|L}, \tau_{L,K|L})$ and $a_{L,K|L} = U_2(a_K, a_L, \tau_{K,K|L}, \tau_{L,K|L})$. (The functions U_1 and U_2 are defined in Lemma 2.5.)

Lemma 2.5 implies that the function $H_K(a,(a_L)_{L\in\mathcal{T}})$ is nondecreasing with respect to a and to a_L for all $L \in \mathcal{T}$ (including the case $L = K$).

Let us prove the above proposition by induction on n. It is true for $n = 0$. We assume that is true for n, and that there is $K_{\max} \in \mathcal{T}$ such that $K_{\max} = \max_{K\in\mathcal{T}}(u_K^{n+1})$ and $u_{K_{\max}}^{n+1} > 1$. Using the monotony of the function $H_{K_{\max}}$, we have

$$1 < u_{K_{\max}}^{n+1} \le H_{K_{\max}}(1,(u_{K_{\max}}^{n+1})_{L\in\mathcal{T}}) = \frac{1+\lambda_{K_{\max}}u_{K_{\max}}^{n+1}}{1+\lambda_{K_{\max}}}.$$

We then get a contradiction with the existence of such a $K_{\max}$. In the same way, we prove that there is no $K_{\min} \in \mathcal{T}_i$ such that $K_{\min} = \min_{K\in\mathcal{T}}(u_K^{n+1})$ and $u_{K_{\min}}^{n+1} < 0$. □

2.5. Existence and uniqueness of a discrete solution.

Proposition 2.8. *Under Assumption* 1.1*, let $\mathcal{D}$ be an admissible discretization of the domain $\Omega \times (0,T)$ (see Definition* 2.3*). Then for all $n \in \{0\dots M\}$, there exists one and only one solution $u_{\mathcal{T}}^{n+1} \in \mathcal{X}(\mathcal{T})$ to the system* (2.2)–(2.4).

Proof. The system composed of (2.2)–(2.4) can be seen as a system with unknowns $(u_K^{n+1})_{K\in\mathcal{T}}$ thanks to Lemma 2.5.

We set $N = \mathrm{card}(\mathcal{T})$ and we consider the application $\psi : \mathbb{R}^N \times [0,1] \to \mathbb{R}^N$ defined by $((u_K)_{K\in\mathcal{T}},\lambda) \mapsto (v_K)_{K\in\mathcal{T}}$ with for all $K \in \mathcal{T}$

$$v_K = m(K)\phi_i\frac{u_K - u_K^n}{\delta t} + \lambda\sum_{L\in N(K)}\tau_{K|L}\left(\varphi_i(u_K) - \varphi_i(u_L)\right) + \lambda\sum_{\sigma\in\mathcal{E}_\Gamma\bigcap\mathcal{E}_K}\tau_{K,\sigma}\left(\varphi_i(u_K) - \varphi_i(u_{K,\sigma})\right),$$

where for all $(K,L) \in \mathcal{T}_\Gamma$ we take $u_{K,K|L} = U_1(u_K,u_L,\tau_{K,K|L},\tau_{L,K|L})$ and $u_{L,K|L} = U_2(u_K,u_L,\tau_{K,K|L},\tau_{L,K|L})$. (The functions U_1 and U_2 are defined in Lemma 2.5.)

The function ψ is continuous with respect to each one of its arguments. Moreover, reproducing the proof of the Proposition 2.7 we can prove that for all $\lambda \in [0,1]$, $\psi((u_K)_{K\in\mathcal{T}},\lambda) = (0)_{K\in\mathcal{T}}$ implies $u_K \in [0,1]$ for all $K \in \mathcal{T}$. Since $\psi((u_K)_{K\in\mathcal{T}},0)$ is linear, an argument based on the topological degree (see [11] and references therein) implies that $\psi((u_K)_{K\in\mathcal{T}},1) = (0)_{K\in\mathcal{T}}$ admits at least one solution.

Turning now to the proof of uniqueness, we assume that for a given $n \in \{0\dots M\}$, $(u_K)_{K\in\mathcal{T}}$ and $(\tilde{u}_K)_{K\in\mathcal{T}}$ are two solutions of (2.2)–(2.4). Using for all $K \in \mathcal{T}$, the functions H_K defined in the proof of Proposition 2.7, we get that

$$\max(u_K,\tilde{u}_K) \le H_K(u_K^n,(\max(u_L,\tilde{u}_L))_{L\in\mathcal{T}})$$

and

$$\min(u_K,\tilde{u}_K) \ge H_K(u_K^n,(\min(u_L,\tilde{u}_L))_{L\in\mathcal{T}}).$$

If we multiply the above inequalities by $(1+\lambda_K)m(K)\phi_i$, if we substract the second inequality from the first one, and if we sum the result over $K \in \mathcal{T}$, the exchange terms between all the pairs of neighboring grid blocks and in particular the terms including λ_K vanish, and we obtain

$$\sum_{i=1,2}\sum_{K\in\mathcal{T}_i} m(K)\phi_i|u_K - \tilde{u}_K| \le 0,$$

which proves the uniqueness of the solution. □

2.6. Convergence. The remaining part of this section is devoted to the convergence proof of the scheme (2.2)–(2.4). The first step consists in obtaining some compactness properties for the sequence of approximated solutions. This will be done thanks to Kolmogorov's theorem. In particular this theorem requires that the space and time translates of the approximated solutions remain bounded.

2.6.1. Upper bound on the space translates.

PROPOSITION 2.9. *Under Assumption* 1.1, *let $\mathcal{D}$ be an admissible discretization of the domain $\Omega \times (0,T)$ in the sense of Definition* 2.3. *Let $u_{\mathcal{D}} \in \mathcal{X}(\mathcal{D})$ be the solution of* (2.2)–(2.4). *Then, there is $C_1 > 0$ only depending on η_j, π_j, Ω_j, $j \in \{1,2\}$ such that*

$$
\begin{aligned}
0 &\le \sum_{n=0}^{M} \& \sum_{(K,L)\in\mathcal{E}_\Gamma} \tau_{K,K|L} \left(\varphi_1(u_K^{n+1}) - \varphi_1(u_{K,K|L}^{n+1})\right) \left(\pi_1(u_K^{n+1}) - \pi_2(u_L^{n+1})\right) \\
&= \sum_{n=0}^{M} \& \sum_{(K,L)\in\mathcal{E}_\Gamma} \tau_{L,K|L} \left(\varphi_2(u_{L,K|L}^{n+1}) - \varphi_2(u_L^{n+1})\right) \left(\pi_1(u_K^{n+1}) - \pi_2(u_L^{n+1})\right) \le C_1
\end{aligned}
\tag{2.9}
$$

and for $i \in \{1,2\}$ there exists $C_2 > 0$ depending on C_1 and on C_η such that

$$
|\varphi_i(u_{\mathcal{D}})|^2_{1,\mathcal{D},i} \le C_2\,. \tag{2.10}
$$

Proof. For $n \in \{0\dots M\}$ and $K \in \mathcal{T}_i$, we multiply the equation (2.3) by $\pi_i(u_K^{n+1})$ and we sum over the discretization $\mathcal{D}$. This leads to

$$
\sum_{\substack{i=1\dots 2,\\ n=0\dots M,\\ K\in\mathcal{T}_i}} \left(\begin{array}{l} \Bigg(m(K)\phi_i(u_K^{n+1} - u_K^n) + \& \Bigg(\displaystyle\sum_{L\in N(K)} \tau_{K|L} \left(\varphi_i(u_K^{n+1}) - \varphi_i(u_L^{n+1})\right) \\ \quad + \displaystyle\sum_{\sigma\in\mathcal{E}_\Gamma \bigcap \mathcal{E}_K} \tau_{K,\sigma} \left(\varphi_i(u_K^{n+1}) - \varphi_i(u_{K,\sigma}^{n+1})\right) \Bigg) \Bigg) \pi_i(u_K^{n+1}) \end{array} \right) = 0.
$$

Accumulation term. Since the function $\pi_i(.)$ is nondecreasing, the function g_i defined by $g_i(u) = \int_0^u \pi_i(a)\,da$ is therefore convex. So we have

$$
(u_K^{n+1} - u_K^n)\pi_i(u_K^{n+1}) \ge g_i(u_K^{n+1}) - g_i(u_K^n).
$$

Thus we get

$$
\sum_{n=0}^{M} \sum_{K\in\mathcal{T}_i} m(K)\phi_i(u_K^{n+1} - u_K^n)\pi_i(u_K^{n+1}) \ge \sum_{K\in\mathcal{T}_i} m(K)\phi_i(g_i(u_K^{M+1}) - g_i(u_K^0)).
$$

Moreover, we notice that

$$
\left| \sum_{K\in\mathcal{T}_i} m(K)\phi_i(g_i(u_K^{M+1}) - g_i(u_K^0)) \right| \le m(\Omega_i)\Big(\int_0^1 |\pi_i(a)|\,da \Big).
$$

Diffusion term. As $\varphi_i(b) - \varphi_i(a) \le C_\eta \int_a^b \pi_i^{'}(u)\,du$, we have

$$
\begin{aligned}
&\sum_{n=0}^{M} \& \sum_{K|L\in\mathcal{E}_{int,i}} \tau_{K|L} \left(\varphi_i(u_K^{n+1}) - \varphi_i(u_L^{n+1})\right) \left(\pi_i(u_K^{n+1}) - \pi_i(u_L^{n+1})\right) \\
&\ge \frac{1}{C_\eta} \sum_{n=0}^{M} \& \sum_{K|L\in\mathcal{E}_{int,i}} \tau_{K|L} \Big(\varphi_i(u_K^{n+1}) - \varphi_i(u_L^{n+1})\Big)^2.
\end{aligned}
$$

For $(K,L) \in \mathcal{T}_\Gamma$, we apply (2.5). This leads to

$$\tau_{K,\sigma}(\varphi_1(u_K^{n+1}) - \varphi_1(u_{K,\sigma}^{n+1}))(\pi_1(u_K^{n+1}) - \pi_2(u_L^{n+1})) \geq 0.$$

Finally, gathering the lower and upper bounds we obtained, we get

$$\sum_{i=1}^{2} |\varphi_i(u_\mathcal{D})|^2_{1,\mathcal{D},i} \leq C_\eta \sum_{i=1}^{2} m(\Omega_i)\Big(\int_0^1 |\pi_i(a)|\, da\Big) = C_2$$

and

$$\begin{aligned}0 &\leq \sum_{n=0}^{M} \delta t \sum_{\sigma=K|L\in\mathcal{E}_\Gamma} \tau_{K,\sigma}\left(\varphi_1(u_K^{n+1}) - \varphi_1(u_{K,\sigma}^{n+1})\right)\left(\pi_1(u_K^{n+1}) - \pi_2(u_L^{n+1})\right) \\ &\leq \sum_{i=1}^{2} m(\Omega_i)\Big(\int_0^1 |\pi_i(a)|\, da\Big) = C_1\,,\end{aligned}$$

which concludes the proof. □

We recall the following result, given in [11].

LEMMA 2.10. *Under Assumption* 1.1*, let $\mathcal{D}$ be an admissible discretization of the domain $\Omega \times (0,T)$ in the sense of Definition* 2.3*. Let $u_\mathcal{D} \in \mathcal{X}(\mathcal{D})$ be given by* (2.2)–(2.4)*. Let $i = 1,2$ and $\xi \in \mathbb{R}^d$. We define the domain $\Omega_{i,\xi}$ by*

$$\Omega_{i,\xi} = \{x \in \Omega_i \ / \ [x, x+\xi] \subset \Omega_i\}.$$

Then the function $\varphi_i(u_\mathcal{D})$ satisfies

$$\int_0^T\!\!\int_{\Omega_{i,\xi}} |\varphi_i(u_\mathcal{D}(x+\xi,t) - \varphi_i(u_\mathcal{D}(x,t)|^2 dxdt \leq |\xi|\Big(|\xi| + 2\text{size}(\mathcal{M})\Big)|\varphi_i(u_\mathcal{D})|^2_{1,\mathcal{D},i}. \tag{2.11}$$

This result produces the following proposition.

PROPOSITION 2.11. *Under Assumption* 1.1*, let $\mathcal{D}$ be an admissible discretization of the domain $\Omega \times (0,T)$ in the sense of Definition* 2.3*. Let $u_\mathcal{D} \in \mathcal{X}(\mathcal{D})$ be given by* (2.2)–(2.4)*. Let $i = 1,2$ and ω_i be an open bounded subset of Ω_i with a regular boundary. We define the function $\varphi_{\mathcal{D},\omega_i}$ by $\varphi_{\mathcal{D},\omega_i}(x,t) = \varphi_i(u_\mathcal{D}(x,t))$ for a.e. $(x,t) \in \omega_i \times (0,T)$, $\varphi_{\mathcal{D},\omega_i}(x,t) = 0$ if $(x,t) \notin \omega_i \times (0,T)$. Then there exists $C_3 > 0$, only depending on T, η_j, π_j, Ω_j, $j \in \{1,2\}$ and of ω_i, such that*

$$\|\varphi_{\mathcal{D},\omega_i}(.+\xi,.) - \varphi_{\mathcal{D},\omega_i}\|^2_{L^2(\mathbb{R}^{d+1})} \leq C_3\,|\xi|\Big(|\xi|+1\Big) \textit{ for all } \xi \in \mathbb{R}^d. \tag{2.12}$$

Proof. This result is a direct consequence of Proposition 2.9 and of Lemma 2.10 and of the fact that the measure of $\{x \in \omega_i,\ [x,x+\xi] \not\subset \omega_i\}$ is bounded by $C_{\omega_i}|\xi|$. □

2.6.2. Upper bound on the time translates.

PROPOSITION 2.12. *Under Assumption* 1.1*, let $\mathcal{D}$ be an admissible discretization of the domain $\Omega \times (0,T)$ in the sense of Definition* 2.3*. Let $u_\mathcal{D} \in \mathcal{X}(\mathcal{D})$ be given by* (2.2)–(2.4)*. Let $i = 1,2$ and ω_i be an open bounded subset of Ω_i with a regular boundary. We define the function $\varphi_{\mathcal{D},\omega_i}$ by $\varphi_{\mathcal{D},\omega_i}(x,t) = \varphi_i(u_\mathcal{D}(x,t))$ for a.e. $(x,t) \in \omega_i \times (0,T)$, $\varphi_{\mathcal{D},\omega_i}(x,t) = 0$ if $(x,t) \notin \omega_i \times (0,T)$. Then there exists $C_4 > 0$, only* *depending on* T*,* η_j*,* π_j*,* ϕ_j*,* Ω_j*,* $j \in \{1,2\}$ *and of* ω_i*, such that, for* $\mathrm{size}(\mathcal{M})$ *small enough,*

$$\text{(2.13)} \qquad \int_{\mathbb{R}} \int_{\Omega} \Big(\varphi_{\mathcal{D},\omega_i}(x,t+\tau) - \varphi_{\mathcal{D},\omega_i}(x,t) \Big)^2 dxdt \leq C_4 \, |\tau| \textit{ for all } \tau \in \mathbb{R}.$$

Proof. We suppose that $\tau \in (0,T)$ (the case $\tau < 0$ is deduced from $\tau > 0$ and the case $\tau > T$ is a consequence of an easy bound of $\int_{\mathbb{R}} \int_{\Omega} (\varphi_{\mathcal{D},\omega_i}(x,t+\tau) - \varphi_{\mathcal{D},\omega_i}(x,t))^2) dxdt$). Let $i = 1,2$ and let $\Theta_i \in C_c^\infty(\Omega_i,[0,1])$ be such that for all $x \in \omega_i$, $\Theta_i(x) = 1$. We suppose that $\mathrm{size}(\mathcal{M})$ is small enough so that Θ_i vanishes on all $K \in \mathcal{T}_i$ having edges on the boundary of Ω_i. For all $K \in \mathcal{T}_i$, we set $\Theta_{i,K} = \frac{1}{m(K)} \int_K \Theta_i(x) \, dx$.

Since the function φ_i is Lipschitz continuous, we have

$$\int_0^{T-\tau} \int_{\Omega} \Theta_i(x) \phi_i \Big(\varphi_i(u_{\mathcal{D}}(x,t+\tau)) - \varphi_i(u_{\mathcal{D}}(x,t)) \Big)^2 dxdt \leq L_\varphi \int_0^{T-\tau} A(t) \, dt$$

with

$$A(t) = \int_{\Omega} \Theta_i(x) \phi_i \Big(\varphi_i(u(x,t+\tau)) - \varphi_i(u(x,t)) \Big) \Big(u(x,t+\tau) - u(x,t) \Big) \, dx.$$

Following the method used in [11], we first write $A(t)$ as

$$A(t) = \sum_{K \in \mathcal{T}_i} \left(m(K) \Theta_{i,K} \phi_i \Big(\varphi_i(u_K^{n_1(t)+1}) - \varphi_i(u_K^{n_0(t)+1}) \Big) \sum_{n=0}^{M} \mathcal{X}_n(t,t+\tau)(u_K^{n+1} - u_K^n) \right),$$

where the indices $n_0(t)$ and $n_1(t)$ satisfy $n_0(t)\delta t < t \leq (n_0(t)+1)\delta t$, $n_1(t)\delta t < t + \tau \leq (n_1(t)+1)\delta t$ and the function $\mathcal{X}_n(a,b)$ is such that $\mathcal{X}_n(a,b) = 1$ if $a < b$ and $n\delta t \in [a,b[$, and $\mathcal{X}_n(a,b) = 0$ otherwise.

Using the definition of the scheme, we get

$$\begin{aligned} A(t) = \quad & \sum_{K \in \mathcal{T}_i} \left(\Theta_{i,K} \Big(\varphi_i(u_K^{n_1(t)+1}) - \varphi_i(u_K^{n_0(t)+1}) \Big) \right. \\ & \left. \qquad \sum_{n=0}^{M} \mathcal{X}_n(t,t+\tau) \sum_{L \in N(K)} \delta t \tau_{K|L} \Big(\varphi_i(u_K^{n+1}) - \varphi_i(u_L^{n+1}) \Big) \right). \end{aligned}$$

Gathering the terms by edges leads to

$$\begin{aligned} A(t) = \quad & \sum_{n=0}^{M} \delta t \mathcal{X}_n(t,t+\tau) \sum_{K|L \in \mathcal{E}_{int,i}} \tau_{K|L} \left[\begin{array}{c} \Theta_{i,K} \Big(\varphi_i(u_K^{n_1(t)+1}) - \varphi_i(u_K^{n_0(t)+1}) \Big) \\ -\Theta_{i,L} \Big(\varphi_i(u_L^{n_1(t)+1}) - \varphi_i(u_L^{n_0(t)+1}) \Big) \end{array} \right] \\ & \times \Big(\varphi_i(u_K^{n+1}) - \varphi_i(u_L^{n+1}) \Big). \end{aligned}$$

Applying the equality $2(\Theta_{i,K} a - \Theta_{i,L} b) = (\Theta_{i,K} + \Theta_{i,L})(a-b) + (\Theta_{i,K} - \Theta_{i,L})(a+b)$ we get that

$$A(t) \leq A_0(t) + A_1(t) + A_2(t)$$

with

$$\begin{aligned} A_0(t) = \quad & \sum_{n=0}^{M} \delta t \mathcal{X}_n(t,t+\tau) \sum_{K|L \in \mathcal{E}_{int,i}} \tau_{K|L} \left| \varphi_i(u_K^{n_1(t)+1}) - \varphi_i(u_L^{n_1(t)+1}) \right| \\ & \times \left| \varphi_i(u_K^{n+1}) - \varphi_i(u_L^{n+1}) \right|, \end{aligned}$$

$$\begin{aligned} A_1(t) = \; & \sum_{n=0}^{M} \delta t \mathcal{X}_n(t, t+\tau) \sum_{K|L \in \mathcal{E}_{int,i}} \tau_{K|L} \left| \varphi_i(u_K^{n_0(t)+1}) - \varphi_i(u_L^{n_0(t)+1}) \right| \\ & \times \left| \varphi_i(u_K^{n+1}) - \varphi_i(u_L^{n+1}) \right| \end{aligned}$$

and

$$A_2(t) = \sum_{n=0}^{M} \delta t \mathcal{X}_n(t, t+\tau) \sum_{K|L \in \mathcal{E}_{int,i}} \tau_{K|L} L_\varphi \left| \Theta_{i,K} - \Theta_{i,L} \right| \; \left| \varphi_i(u_K^{n+1}) - \varphi_i(u_L^{n+1}) \right|.$$

We then use Young's inequality, Proposition 2.9, and the regularity of the function Θ to bound $A_0(t)$, $A_1(t)$, and $A_2(t)$ by a sum of terms under the form $\sum_{n=0}^{M} \delta t \mathcal{X}_n(t, t+\tau) a^n$, $\sum_{n=0}^{M} \delta t \mathcal{X}_n(t, t+\tau) a^{n_0(t)}$, and $\sum_{n=0}^{M} \delta t \mathcal{X}_n(t, t+\tau) a^{n_1(t)}$ such that $0 \leq a^n$ for all $n = 0 \ldots, M$ and such that $\delta t \sum_{n=0}^{M} a^n$ is bounded independently on the discretization. We then use the properties

$\int_0^{T-\tau} \sum_{n=0}^{M} \delta t \mathcal{X}_n(t, t+\tau) a^n dt \leq \tau \delta t \sum_{n=0}^{M} a^n$,
$\int_0^{T-\tau} \sum_{n=0}^{M} \delta t \mathcal{X}_n(t, t+\tau) a^{n_0(t)} dt \leq \tau \delta t \sum_{n=0}^{M} a^n$, and
$\int_0^{T-\tau} \sum_{n=0}^{M} \delta t \mathcal{X}_n(t, t+\tau) a^{n_1(t)} dt \leq \tau \delta t \sum_{n=0}^{M} a^n$, proven in [11]. □

2.6.3. Upper bound on the discrete $L^2(0,T;H^1(\Omega))$-seminorm of the function $w_{\mathcal{D}}$.

Let $u_{\mathcal{D}}$ be given by (2.2)–(2.4). We consider $w_{\mathcal{D}}$ defined by $w_K^{n+1} = \Psi(\hat{\pi}_i(u_K^{n+1}))$ for all $i = 1, 2$ and $K \in \mathcal{T}_i$. The following proposition states that the discrete $L^2(0,T;H^1(\Omega))$-seminorm of the function $w_{\mathcal{D}}$ remains bounded. We first recall the definition of this seminorm defined on the whole domain Ω.

Definition 2.13. *Let $\Omega \times (0,T)$ be a domain satisfying* H1-1 *and $\mathcal{D}$ be an admissible discretization of this domain in the sense of Definition* 2.3. *The $L^2(0,T;H^1(\Omega))$-seminorm of a function $u_{\mathcal{D}} \in \mathcal{X}(\mathcal{D})$ is defined by*

$$|u_{\mathcal{D}}|_{1,\mathcal{D}}^2 = \sum_{n=0}^{M} \delta t \sum_{K|L \in \mathcal{E}_{int}} \tau_{K|L} (\delta u_{K,L}^{n+1})^2 = \sum_{i=1,2} |u_{\mathcal{D}}|_{1,\mathcal{D},i}^2 + \sum_{n=0}^{M} \delta t \sum_{(K,L) \in \mathcal{T}_\Gamma} \tau_{K|L} (\delta u_{K,L}^{n+1})^2.$$

Proposition 2.14. *Under Assumption* 1.1, *let $\mathcal{D}$ be an admissible discretization in the sense of Definition* 2.3. *Let $u_{\mathcal{D}} \in \mathcal{X}(\mathcal{D})$ be the solution of* (2.2)–(2.4). *Then, there exists $C_5 > 0$ only depending on η_j, π_j, Ω_j, $j \in \{1, 2\}$ such that*

$$|w_{\mathcal{D}}|_{1,\mathcal{D}}^2 \leq C_5 \,. \tag{2.14}$$

Proof. For $K \in \mathcal{T}_i$ and $L \in N(K)$, using the property of Lipschitz continuity of $\Psi \circ \hat{\pi}_i \circ \varphi_i^{(-1)}$ (see Lemma 1.2), we get

$$(w_K^{n+1} - w_L^{n+1})^2 \leq (\varphi_i(u_K^{n+1}) - \varphi_i(u_L^{n+1}))^2$$

and therefore we deduce from (2.10)

$$|w_{\mathcal{D}}|_{1,\mathcal{D},i}^2 \leq C_2 \,.$$

We now consider the case $(K, L) \in \mathcal{T}_\Gamma$. We have, since $\hat{\pi}_1(u_{K,K|L}^{n+1}) = \hat{\pi}_2(u_{L,K|L}^{n+1})$,

$$\begin{aligned} \tau_{K|L} (\Psi(\hat{\pi}_1(u_K^{n+1})) - \Psi(\hat{\pi}_2(u_L^{n+1})))^2 \leq \; & \tau_{K,K|L} (\Psi(\hat{\pi}_1(u_K^{n+1})) - \Psi(\hat{\pi}_1(u_{K,K|L}^{n+1})))^2 \\ & + \tau_{L,K|L} (\Psi(\hat{\pi}_2(u_{L,K|L}^{n+1})) - \Psi(\hat{\pi}_2(u_L^{n+1})))^2, \end{aligned}$$

thanks to the convexity of the function $x \mapsto x^2$ and to $1/\tau_{K|L} = 1/\tau_{K,K|L} + 1/\tau_{L,K|L}$. We again use the properties of $\Psi \circ \hat{\pi}_i \circ \varphi_i^{(-1)}$ (see Lemma 1.2):

$$(\Psi(\hat{\pi}_1(u_K^{n+1})) - \Psi(\hat{\pi}_1(u_{K,K|L}^{n+1})))^2 \le (\varphi_1(u_K^{n+1}) - \varphi_1(u_{K,K|L}^{n+1}))^2$$

and

$$(\Psi(\hat{\pi}_2(u_{L,K|L}^{n+1})) - \Psi(\hat{\pi}_2(u_L^{n+1})))^2 \le (\varphi_2(u_L^{n+1}) - \varphi_2(u_{L,K|L}^{n+1}))^2.$$

Now, using (2.5), we have, for all $(K, L) \in \mathcal{T}_\Gamma$,

$$\begin{aligned} &\Big(\varphi_1(u_K^{n+1}) - \varphi_1(u_{K,K|L}^{n+1})\Big)^2 \\ &\le \Big(\varphi_1(u_K^{n+1}) - \varphi_1(u_{K,K|L}^{n+1})\Big) C_\eta \Big(\pi_1(u_K^{n+1}) - \pi_1(u_{K,K|L}^{n+1})\Big) \\ &\le \Big(\varphi_1(u_K^{n+1}) - \varphi_1(u_{K,K|L}^{n+1})\Big) C_\eta \Big(\pi_1(u_K^{n+1}) - \pi_2(u_L^{n+1})\Big). \end{aligned} \tag{2.15}$$

Then, from (2.9) and (2.15), we get

$$\sum_{n=0}^{M} \& \sum_{(K,L)\in\mathcal{T}_\Gamma} \tau_{K,K|L} \Big(\Psi(\hat{\pi}_1(u_K^{n+1})) - \Psi(\hat{\pi}_1(u_{K,K|L}^{n+1}))\Big)^2 \le C_\eta C_1\,,$$

and in the same way

$$\sum_{n=0}^{M} \& \sum_{(K,L)\in\mathcal{T}_\Gamma} \tau_{L,K|L} \Big(\Psi(\hat{\pi}_2(u_{L,K|L}^{n+1})) - \Psi(\hat{\pi}_2(u_L^{n+1}))\Big)^2 \le C_\eta C_1\,.$$

Thus we get

$$\sum_{n=0}^{M} \& \sum_{(K,L)\in\mathcal{T}_\Gamma} \tau_{K|L} (w_K^{n+1} - w_L^{n+1})^2 \le 2C_1\, C_\eta.$$

Gathering the above results proves that there exists $C_6 > 0$, only depending on η_j, π_j, Ω_j, $j \in \{1, 2\}$ such that

$$|w_{\mathcal{D}}|_{1,\mathcal{D}}^2 \le C_6 \qquad \square$$

2.6.4. Convergence of the scheme toward the weak problem. Thanks to the previous propositions, we are now able to prove the following theorem, which states the convergence of the scheme (2.2)–(2.4) toward a solution to the weak problem introduced in Definition 1.3.

THEOREM 2.15. *Under Assumption* 1.1*, let us consider a sequence* $(\mathcal{D}_m)_{m\in\mathbb{N}}$*, of admissible discretizations in the sense of Definition* 2.3*, such that there exists* $\alpha > 0$ *with* $\mathrm{regul}(\mathcal{M}_\mathrm{m}) \le \alpha$ *for all* $m \in \mathbb{N}$ *and such that* $\mathrm{size}(\mathcal{D}_m) \to 0$ *as* $m \to +\infty$*. Let* $u_{\mathcal{D}_m} = u_m \in \mathcal{X}(\mathcal{D}_m)$ *be the solution of* (2.2)–(2.4) *for* $\mathcal{D} = \mathcal{D}_m$*. Then there exists a subsequence of* $(\mathcal{D}_m, u_m)_{m\in\mathbb{N}}$*, again denoted by* $(\mathcal{D}_m, u_m)_{m\in\mathbb{N}}$*, and a weak solution* u *of problem* (1.5)–(1.9) *in the sense of Definition* 1.3*, such that* $u_m \to u$ *in* $L^p(\Omega \times (0, T))$ *for all* $p < \infty$*.*

Remark 2.16. A proof that the problem (1.5)–(1.9) admits at most one regular solution can be obtained following the method of [5]. A uniqueness result on the solution of the weak problem given in Definition 1.3 implies that the whole sequence of discrete solutions converges.

Proof.

Step 1: Existence of a convergent subsequence of $(\mathcal{D}_m, u_m)_{m\in\mathbb{N}}$. For any open subset ω_i of Ω_i, $i = 1, 2$, Propositions 2.7, 2.11, and 2.12 ensure that the hypotheses of Kolmogorov's theorem are satisfied. We thus get the existence of a subsequence of $(\varphi_{\mathcal{D}_m,\omega_i})_{m\in\mathbb{N}}$, converging in $L^2(\omega_i \times (0,T))$ to some function $\varphi_{\omega_i} \in L^2(\omega_i \times (0,T))$. Using an increasing sequence of domains $\omega_{i,k}$ which converges toward Ω_i, we can extract, thanks to a diagonal process, a subsequence again denoted by $(\mathcal{D}_m, u_m)_{m\in\mathbb{N}}$ such that $(\varphi_{\mathcal{D}_m,\omega_{i,m}})_{m\in\mathbb{N}}$ converges in $L^2(\omega_{i,k} \times (0,T))$ for all $k \in \mathbb{N}$, to some bounded function $\tilde{\varphi}_i \in L^2(\omega_{i,k} \times (0,T))$ for all $k \in \mathbb{N}$. We then obtain that $(\varphi_i(u_m))_{m\in\mathbb{N}}$ converges in $L^2(\Omega_i \times (0,T))$ to $\tilde{\varphi}_i$. Since φ_i is continuous and strictly increasing, this implies that, up to a subsequence, $(u_m)_{m\in\mathbb{N}}$ converges toward a function $u_i \in L^2(\Omega_i \times (0,T)) \bigcap L^\infty(\Omega_i \times (0,T))$ for all $i \in \{1, 2\}$.

To prove that $\varphi_i(u_i) \in L^2(0,T; H^1(\Omega_i))$ for all $i \in \{1, 2\}$, it is sufficient to show that $\frac{\partial\varphi_i(u_i)}{\partial x} \in L^2(\Omega_i \times (0,T))$. Let $m \in \{0 \dots M\}$, $\psi_i \in C_c^\infty(\Omega_i \times (0,T))$ and $\epsilon > 0$ be such that $\mathrm{supp}(\psi_i) = \{(x,t) \in \Omega_i \times (0,T) \ / \ \mathrm{dist(x, \mathbb{R}^d \setminus \Omega_i)} \leq \epsilon\}$. Using the Cauchy–Schwarz inequality and Lemma 2.10, we have for all $|\xi| \leq \epsilon$

$$\int_{\Omega_{i,\xi}\times(0,T)} \Big(\varphi_i(u_m(x+\xi,t)) - \varphi_i(u_m(x,t))\Big)\psi_i(x,t)dxdt$$
$$\leq \Big(|\xi|(|\xi| + 2\mathrm{size}(\mathcal{M}_\mathrm{m}))\mathrm{C}_2\Big)^{\frac{1}{2}} \|\psi_\mathrm{i}\|_{\mathrm{L}^2(\Omega_\mathrm{i}\times(0,\mathrm{T}))}.$$

Passing to the limit and after a change of variable we obtain

$$\int_{\Omega_{i,\xi}\times(0,T)} \Big(\psi_i(x-\xi,t) - \psi_i(x,t)\Big)\varphi_i(u_i(x,t))dxdt \tag{2.16}$$
$$\leq |\xi|(C_2\,)^{\frac{1}{2}}||\psi_i||_{L^2(\Omega_i\times(0,T))}.$$

Now if we denote by $\{e_i, i = 1 \dots d\}$ the canonical basis of $\mathbb{R}^d$ and if we take $\xi = \lambda e_i$, $i \in \{1 \dots d\}$ with $|\lambda| < \epsilon$ in (2.16), we then have as $\epsilon \to 0$

$$-\int_{\Omega_{i,\xi}\times(0,T)} \frac{\partial\psi_i(x,t)}{\partial x_i}\varphi_i(u_i(x,t))dxdt \leq (C_2\,)^{\frac{1}{2}}\|\psi_i\|_{L^2(\Omega_i\times(0,T))}$$
$$\text{for all } \psi_i \in C_c^\infty(\Omega_i \times (0,T)),$$

which implies that $\frac{\partial\varphi_i(u_i)}{\partial x} \in L^2(\Omega_i \times (0,T))$.

Step 2: u is a weak solution to the problem (1.5)–(1.9). Let us consider $\tilde{C}_{test} = \{h \in C^2(\overline{\Omega} \times [0,T]) \ / \ h(.,T) = 0\}$ which is dense in C_{test}. Let $\psi \in \tilde{C}_{test}$ and, for $m \in \mathbb{N}$, let u_m be given by (2.2)–(2.4) for $\mathcal{D} = \mathcal{D}_m$. For all $n \in \{0 \dots M\}$ and for all $K \in \mathcal{T}$, we multiply the equation (2.3) by $\psi_K^n = \psi(x_K, n\delta t)$, and we sum these equalities over the volume control set and $n = 0, \dots, M$. We get $\sum_{i=1}^2(E_{i,1,m} +$

$E_{i,2,m}) + E_{1|2,m} = 0$ with

$$E_{i,1,m} = \sum_{n=0}^{M} \sum_{K\in\mathcal{T}_i} m(K)\phi_i(u_K^{n+1} - u_K^n)\psi_K^n,$$
$$E_{i,2,m} = -\sum_{n=0}^{M} \delta t \sum_{K\in\mathcal{T}_i} \sum_{L\in N(K)} \tau_{K|L}\Big(\varphi_i(u_L^{n+1}) - \varphi_i(u_K^{n+1})\Big)\psi_K^n,$$
$$E_{1|2,m} = \sum_{n=0}^{M} \delta t \sum_{(K,L)\in\mathcal{T}_\Gamma} \tau_{K,K|L}\left(\varphi_1(u_K^{n+1}) - \varphi_1(u_{K,K|L}^{n+1})\right)\left(\psi_K^n - \psi_L^n\right).$$

Following some classical proofs (see [11]), we get that

$$\lim_{m\to+\infty} E_{i,1,m} = -\int_0^T \int_{\Omega_i} \phi_i u_i(x,t)\psi_t(x,t)dxdt - \int_{\Omega_i} \phi_i u_{\mathrm{ini}}(x)\psi(x,0)dx.$$

Convergence of $\boldsymbol{E_{i,2,m}}$. Gathering the terms by edges in $E_{i,2,m}$ leads to

$$E_{i,2,m} = \sum_{n=0}^{M} \delta t \sum_{\sigma=K|L\in\mathcal{E}_{int,i}} \tau_{K|L}\Big(\varphi_i(u_K^{n+1}) - \varphi_i(u_L^{n+1})\Big)\Big(\psi_K^n - \psi_L^n\Big).$$

We apply the method presented, for example, in [10] (which is a discrete version of a strong-weak convergence) to conclude that

$$\lim_{m\to+\infty} E_{i,2,m} = \int_0^T \int_{\Omega_i} \nabla\varphi_i(u_i)(x,t).\nabla\psi(x,t)\,dx\,dt. \tag{2.17}$$

Convergence of $\boldsymbol{E_{1|2,m}}$. We have

$$E_{1|2,m}^2 \le \left(\sum_{n=0}^{M} \delta t \sum_{(K,L)\in\mathcal{T}_\Gamma} \tau_{K,K|L}\Big(\varphi_1(u_K^{n+1}) - \varphi_1(u_{K,K|L}^{n+1})\Big)^2\right)$$
$$\times \left(\sum_{n=0}^{M} \delta t \sum_{(K,L)\in\mathcal{T}_\Gamma} m(K|L)\frac{(\psi_K^n - \psi_L^n)^2}{d_{K,K|L}}\right).$$

But we notice that, thanks to the regularity of the function ψ, there exists $C_\psi > 0$ such that $|\psi_K^n - \psi_L^n| \le C_\psi d_{K|L}$, which implies with (2.1)

$$\sum_{n=0}^{M} \delta t \sum_{(K,L)\in\mathcal{T}_\Gamma} m(K|L)\frac{(\psi_K^n - \psi_L^n)^2}{d_{K,K|L}} \le 4Tm(\Gamma)C_\psi^2\alpha\mathrm{size}(\mathcal{M}).$$

Thus, using (2.9) and (2.15), we get

$$\sum_{n=0}^{M} \delta t \sum_{(K,L)\in\mathcal{T}_\Gamma} \tau_{K,K|L}\Big(\varphi_i(u_K^{n+1}) - \varphi_i(u_{K,K|L}^{n+1})\Big)^2 \le C_\eta C_1\,.$$

Gathering the above results produces

$$\lim_{m\to+\infty} E_{1|2,m} = 0.$$

Step 3: Let us prove that $\boldsymbol{w \in L^2(0,T;H^1(\Omega))}$. Following the proofs of Lemma 2.10 and of $\varphi(u_i) \in L^2(0,T;H^1(\Omega_i))$ (see Step 1), we obtain that $w \in L^2(0,T;H^1(\Omega))$ using inequality (2.14). $\square$

As an immediate consequence of Theorem 2.15 we get the following corollary.

COROLLARY 2.17. *Under Assumption* 1.1, *problem* (1.5)–(1.9) *admits at least one weak solution in the sense of Definition* 1.3.

As an illustration of the previous results we now give numerical results.

3. Numerical results. Let us consider a domain Ω such that $\Omega_1 = (0,1)$ and $\Omega_2 = (1,2)$. The mobilities are given by

$$\eta_o(u) = \begin{cases} u & \text{if } 0 \le u \le 1, \\ 0 & \text{if } u < 0, \\ 1 & \text{otherwise,} \end{cases} \qquad \eta_w(u) = \begin{cases} 1-u & \text{if } 0 \le u \le 1, \\ 1 & \text{if } u < 0, \\ 0 & \text{otherwise,} \end{cases}$$

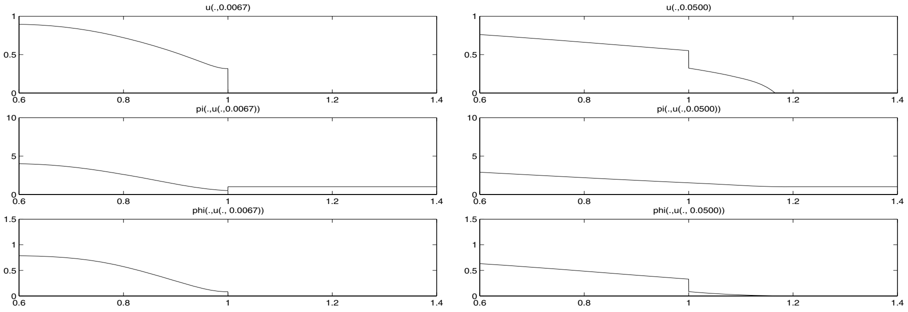
and the capillary pressure is given by

$$\pi_1(u) = \begin{cases} 5u^2 & \text{if } 0 \le u \le 1, \\ 0 & \text{if } u < 0, \\ 5 & \text{otherwise,} \end{cases} \qquad \pi_2(u) = \begin{cases} 5u^2+1 & \text{if } 0 \le u \le 1, \\ 1 & \text{if } u < 0, \\ 6 & \text{otherwise.} \end{cases}$$

In that case, $u_1^\star = \frac{1}{\sqrt{5}}$, $u_2^\star = \frac{2}{\sqrt{5}}$. For the initial condition we take

$$u_{\text{ini}}(x) = \begin{cases} 0.9 & \text{if} \qquad x < 0.9, \\ 0 & \text{otherwise.} \end{cases}$$

To discretize the domains Ω_i, we use a regular mesh such that $\text{dx} = \text{size}(\mathcal{M}) = 10^{-2}$ for all $i \in \{1,2\}$ and we use a constant time step $\delta t = \frac{1}{6}.10^{-3}$. Figure 3.1 represents functions $u(.,t)$, $\pi(.,u(.,t))$, $\varphi(.,u(.,t))$ for $t = 0.007$ and $t = 0.05$. In the first case



(a) (b)

FIG. 3.1. $u(.,t)$, $\pi(.,u(.,t))$, $\varphi(.,u(.,t))$ *for* $t = 0.007$ (a) *and* $t = 0.05$ (b).

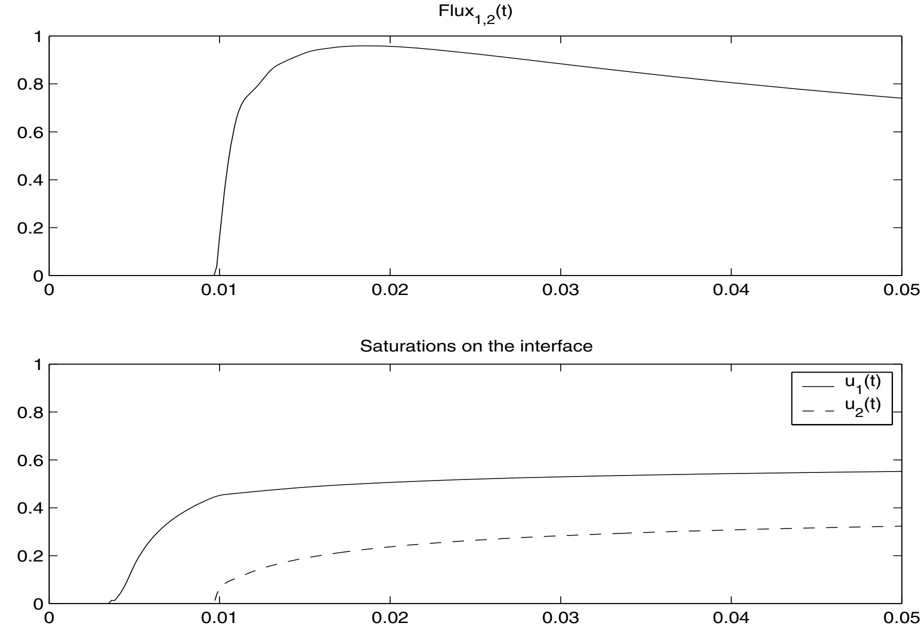


FIG. 3.2. *Evolution of the flux and of the saturations on the interface.*

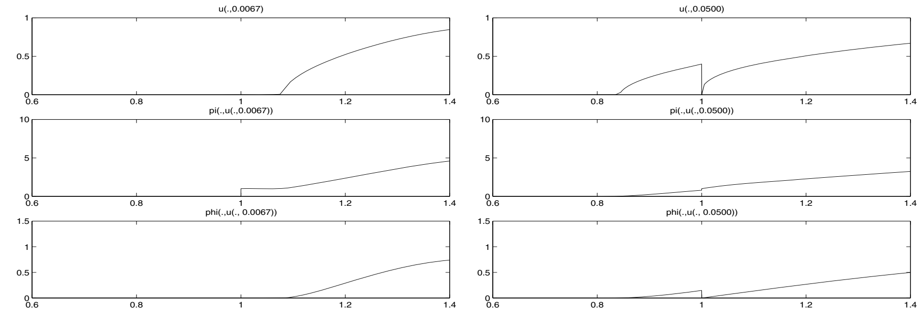

(a) (b)

FIG. 3.3. $u(.,t)$, $\pi(.,u(.,t))$, $\varphi(.,u(.,t))$ *for* $t = 0.007$ (a) *and* $t = 0.05$ (b).

oil is trapped under the interface Γ located in $x = 1$ and the capillary pressure is discontinuous, whereas in the second case oil can flow through Γ and the continuity of the capillary pressure is ensured. Figure 3.2 represents the evolution of the flux and of the saturations on the interface Γ according to the time variable. We have also done tests with the initial condition

$$u_{\text{ini}}(x) = \begin{cases} 0.9 & \text{if} \qquad\qquad x > 1.2, \\ 0 & \text{otherwise,} \end{cases}$$

where oil already lies in the capillary barrier. Figures 3.3 and 3.4 show the results we obtained. We notice that although the capillary pressure is discontinuous, oil can flow

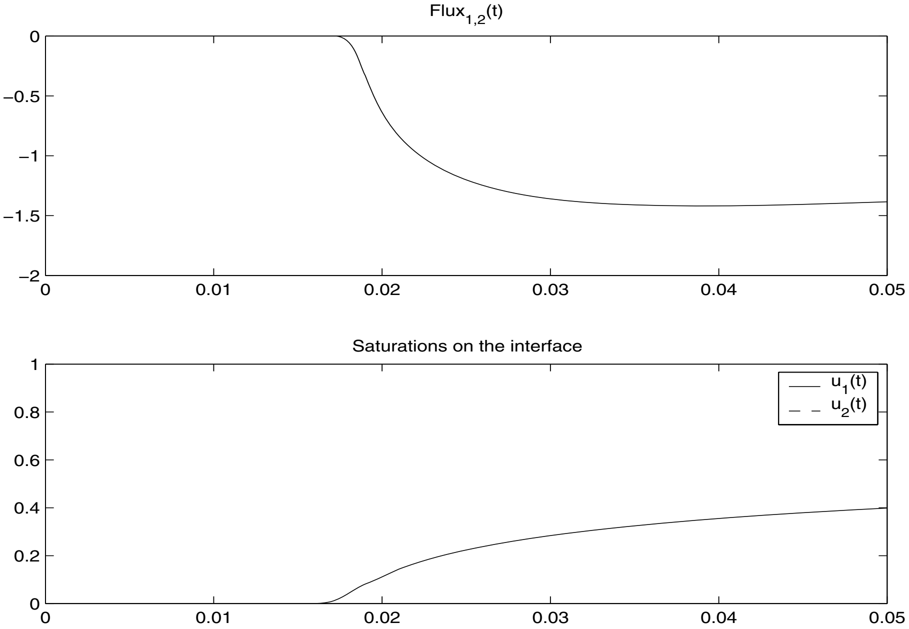

FIG. 3.4. *Evolution of the flux and of the saturations on the interface.*

through Γ from Ω_2 to Ω_1 while satisfying the conditions (2.4) since for all $t \in [0, 0.05]$, $u_2(t) = 0$.

4. Concluding remarks. In this paper we have established a convergence property for the scheme (2.2)–(2.4) toward a weak solution of the problem (1.5)–(1.9) in the sense of Definition 1.3. It remains to prove the uniqueness of such a weak solution. Further work will be done taking into account a total flux and the gravity gradient (see [8]).

ERROR ESTIMATES FOR FINITE VOLUME APPROXIMATIONS OF CLASSICAL SOLUTIONS FOR NONLINEAR SYSTEMS OF HYPERBOLIC BALANCE LAWS*

VLADIMIR JOVANOVIĆ[†] AND CHRISTIAN ROHDE[‡]

Abstract. We consider a general class of finite volume schemes on unstructured but quasi-uniform meshes for first-order *systems* of hyperbolic balance laws on unstructured meshes. Provided the system is equipped with at least one entropy-entropy flux tuple and the associated Cauchy problem allows for a classical solution u we give conditions such that the finite volume approximation u_h converges to u if the mesh parameter h tends to zero. In fact we prove an error estimate of the form $\|u - u_h\|_{L^2} \leq C\sqrt{h}$, where C is independent of h. The proof relies on a stability result for classical solutions in the class of entropy solutions due to Dafermos [*Arch. Rational Mech. Anal.*, 94 (1979), pp. 373–389] and DiPerna [*Indiana Univ. Math. J.*, 28 (1979), pp. 137–188].

Finally, we present examples such that the conditions to apply the general convergence estimate can be satisfied (at least in part). The examples cover general scalar equations, weakly coupled systems, and the system of elastodynamics in one dimension. Moreover, we generalize the concept of entropy conservative methods due to Tadmor [*Math. Comp.*, 49 (1987), pp. 91–103] and show how this can be used to establish the convergence of finite volume methods for the system's case.

Key words. hyperbolic conservation laws, entropy-entropy flux tuples, classical solutions, finite volume schemes on unstructured meshes, entropy conservative schemes

1. Introduction.

Let us consider a nonlinear convection process for a vector valued state variable $u = u(x,t) \in \mathcal{U}$ of $m \in \mathbb{N}$ components, where the state space $\mathcal{U}$ is an open subset of $\mathbb{R}^m$, $x = (x_1, \ldots, x_d)^T$ denotes the vector of spatial coordinates and $t \geq 0$ stands for time. Assume that the dynamics for u in the time interval $[0,T)$, $T > 0$, are given by the solution of the Cauchy problem

$$\partial_t u + \sum_{i=1}^{d} \partial_i G_i(u) = B(u) \text{ in } \mathbb{R}^d \times (0,T), \tag{1.1}$$

$$u(.,0) = u_0 \text{ in } \mathbb{R}^d. \tag{1.2}$$

Here $G_i \in [C^2(\mathcal{U})]^m$, $i = 1, \ldots, m$, is the flux in x_i-direction and $B \in [C^1(\mathcal{U})]^m$ some source. We suppose that there exists a vector $\bar{u} \in \mathcal{U}$ with $B(\bar{u}) = 0$ and for the initial function we have $u_0 - \bar{u} \in [L^\infty(\mathbb{R}^d)]^m \cap [H^1(\mathbb{R}^d)]^m \cap [C^1(\mathbb{R}^d)]^m$.

As a structural prerequisite we suppose that (1.1) is equipped with an entropy-entropy flux tuple $(\eta, q_1, \ldots, q_d)^T \in C^3(\mathcal{U}) \times [C^2(\mathcal{U})]^d$, i.e., η is a function that is uniformly convex on compact sets and the consistency relation

$$(\nabla q_i(w))^T = (\nabla \eta(w))^T DG_i(w) \tag{1.3}$$

holds for $i = 1, \ldots, d$ and all $w \in \mathcal{U}$.

This work is devoted to classical solutions of (1.1). A function $u \in [C^1(\mathbb{R}^d \times [0,T])]^m$ is called a *classical solution* of (1.1), (1.2) if (1.1), (1.2) are satisfied pointwise everywhere. Throughout the paper we suppose that the following assumption is true.

Assumption 1.1. *There is classical solution u of the Cauchy problem* (1.1)*,* (1.2)*. In addition we have $\int_0^T \int_{\mathbb{R}^d} |Du|^2\,dxdt < \infty$, $\sup_{\mathbb{R}^d\times[0,T]} |Du| < \infty$ and there exists a convex compact set $S \subset\subset \mathcal{U}$ such that*

$$u(x,t),\ \bar{u} \in S \quad \textit{for all } (x,t) \in \mathbb{R}^d \times [0,T)]. \tag{1.4}$$

It is well known that in general classical solutions for the Cauchy problem (1.1), (1.2) can exist only for short times [23]. For important exceptions due to the presence and structure of the source term B we refer to the last paragraph of the introduction. As a not-so-strong notion of solutions, entropy solutions are considered. A function $v \in [L^\infty_{loc}(\mathbb{R}^d \times [0,T))]^m$ is called an *entropy solution* of (1.1), (1.2) if it is a weak solution of (1.1), (1.2) and if

(1.5)
$$\int_0^T \int_{\mathbb{R}^d} \eta(u)\partial_t\omega + \sum_{i=1}^d q_i(u)\partial_i\omega + \nabla\eta(u)\cdot B(u)\omega\,dxdt \geq -\int_{\mathbb{R}^d} \eta(u_0)\omega(.,0)\,dxdt$$

holds for all nonnegative functions $\omega \in C_0^{0,1}(\mathbb{R}^d \times [0,T))$. Here $C_0^{0,1}(\mathbb{R}^d \times [0,T))$ is the space of Lipschitz-continuous functions with compact support on $\mathbb{R}^d \times [0,T)$. There is no general multidimensional well-posedness theory for globally-in-time defined entropy solutions. The only result in this direction is the following stability result for classical solutions in the class of entropy solutions. We cite it from the book [5] (where it is proven for the case $B \equiv 0$).

Theorem 1.2 (see [5, Theorem 5.2.1]). *Let u from Assumption* 1.1 *be given. Suppose furthermore that $v \in [L^\infty(\mathbb{R}^d \times [0,T))]^m$ is an entropy solution of* (1.1) *with $v(.,0) = v_0$ for some $v_0 \in [L^\infty(\mathbb{R}^d)]^m$.*

If also v takes values in S there is a constant $\lambda > 0$ and a positive function $\mathcal{C} \in C^0([0,T])$ depending on S such that we have for all $t \in [0,T)$ and $R > 0$

$$\int_{\{|x|\leq R\}} |u(x,t) - v(x,t)|^2\,dx \leq \mathcal{C}(t)\int_{\{|x|\leq R+\lambda t\}} |u_0 - v_0|^2\,dx. \tag{1.6}$$

In particular we observe for $u_0 = v_0$ that classical solutions of (1.1)*,* (1.2) *are unique in the class of entropy solutions.*

We shall use this stability theory for classical solutions due to Dafermos [4] and DiPerna [6] to set up a convergence theory for finite volume schemes applied to the Cauchy problem (1.1), (1.2). We point out that our results hold only if (1.1), (1.2) is classically solvable.

In section 2 we present the precise setting of our problem and introduce an extension of Theorem 1.2: in Theorem 2.2, we estimate the L^2-difference between u and an *arbitrary discontinuous function* v in terms of some error measures. This theorem generalizes Theorem 1.2 to the inhomogeneous case. In section 3 we describe a class of standard finite volume schemes in d space dimensions on an unstructured but quasi-uniform mesh. Denote the mesh parameter by h which is the diameter of the largest volume. We assume that the numerical approximation $u_h : \mathbb{R}^d \times [0,T] \to \mathbb{R}^m$ is uniformly bounded in $[L^\infty(\mathbb{R}^d \times [0,T])]^m$ and satisfies a cell entropy inequality (Assumption 3.1).

These strong but realistic assumptions are then used in section 4 to establish the error bound. With our main result, Theorem 4.4, we prove an estimate of the form

$$\|u - u_h\|_{L^2(\mathbb{R}^d \times [0,T])} \leq C\sqrt{h}, \tag{1.7}$$

where C is some constant independent of h. The proof relies on the generalized stability estimate in Theorem 2.2. We point out that the estimate is given in terms of the L^2-norm (in space) rather than in the L^1-norm, as in the results of Kruzkov [19] and Kuznetsov [20] for scalar equations such that we cannot follow these more usual convergence proofs for finite volume schemes.

In the final part of the paper (section 5) we consider several applications of the convergence theorem. First we consider the example of weakly coupled hyperbolic systems and apply monotone numerical fluxes for each component. Then it is possible to satisfy all assumptions required in Theorem 4.4. The result improves the known estimates which give an estimate of order $h^{1/4}$ in the L^1-norm [3, 8, 34]. These estimates are probably not optimal (see the sharpness results in [32, 26] in the scalar convex case and [31] in the nonconvex case). However, the $h^{1/4}$ results are proven for less regular discontinuous solutions! We stress that our result holds in particular in the scalar case $m = 1$. It gives then a new improved estimate.

As an example for a (strongly coupled) system for which all assumptions on the discrete solution can be verified we consider the one-dimensional system of elastodynamics in section 5.2.

For the final application we return to the general Cauchy problem (1.1), (1.2). Tadmor has introduced in one space dimension a class of semidiscrete second-order entropy conservative schemes [29], (see also [30]). Fully discrete and high-order entropy conservative schemes were established later in [21, 22]. Here we generalize this concept to the multidimensional case on unstructured meshes. To our knowledge, entropy conservative schemes in multiple space dimensions have not been introduced before. Adding artificial viscosity terms, we obtain a new class of finite volume schemes such that the numerical approximation satisfies a cell entropy inequality and an entropy dissipation bound. If the numerical approximation is uniformly bounded we can apply Theorem 4.4 without further restrictions on the system (1.1).

We conclude the introduction with a number of remarks.

The use of Dafermos' approach to derive estimates for approximations of classical solutions goes back to [1]. Another recent application in nonlinear electrodynamics can be found in [2]. Let us note that in one space dimension a result similar to (1.7) has been communicated by Vila [35]. Convergence rates for numerical methods in one space dimension for smooth parts of a weak solution (which might contain singularities!) were established in [28].

In the general case, (1.1), (1.2) has no global smooth solution but there are many physically relevant situations where a classical solution pertains for all times, among these of course problems for linear systems. In the context of hydromechanics we mention the results for special initial data obtained in [10, 27]. If one takes into account a source term B, much more interesting scenarios exist where dissipative effects lead to smooth solutions close to equilibrium states. We mention just a few, like relaxation effects, damping effects through radiation or through gravitational forces, frictional damping, or memory effects [11, 16, 15, 36, 37]. Surveys on general systems with classical solutions and the rôle of the so-called null condition are [17, 33].

Notation. By $C, C_0, C_1, \dots$ we shall denote nonnegative constants depending on a given classical solution but not on the mesh parameter h.

2. Preliminaries and an L^2-stability theorem.

Throughout this section we consider the general problem (1.1), (1.2) and suppose that Assumption 1.1 holds.

We mention that the existence of an entropy-entropy flux tuple implies that the symmetry relation

$$(\nabla^2\eta(w)DG_i(w))^T = \nabla^2\eta(w)DG_i(w) \tag{2.1}$$

holds for $i = 1, \dots, d$ and $w \in \mathcal{U}$.

Without loss of generality, we can assume that we have for $\bar{u}$ with $B(\bar{u}) = 0$ the relations

$$\eta(\bar{u}) = 0, \;\; \nabla\eta(\bar{u}) = 0, \tag{2.2}$$

$$q_i(\bar{u}) = 0, \;\; \nabla q_i(\bar{u}) = 0 \;\; (i = 1, \dots, d). \tag{2.3}$$

We define

$$a := \min_{v \in S} \|\nabla^2\eta(v)\|, \quad b := \max_{v \in S} \|\nabla^2\eta(v)\|. \tag{2.4}$$

Note that $a, b > 0$. Thanks to (2.2), (2.3) we see that we have for all $v \in S$ the inequalities

$$\begin{gathered} a|v-\bar{u}|^2 \le \eta(v) \le b|v-\bar{u}|^2, \;\; |\nabla\eta(v)| \le c|v-\bar{u}|, \\ |q_i(v)| \le c|v-\bar{u}|^2, \;\; |\nabla q_i(v)| \le c|v-\bar{u}| \;\; (i = 1, \dots, d), \end{gathered} \tag{2.5}$$

where the constant c depends only on the set S.

Our aim now is to derive an L^2-stability result similar to but more general than Theorem 1.2. For that purpose, we introduce Dafermos' relative entropy h and entropy fluxes f_i, $i = 1, \dots, d$, by

$$h(v, w) = \eta(w) - \eta(v) - \nabla\eta(v) \cdot (w - v),$$

$$f_i(v, w) = q_i(w) - q_i(v) - \nabla\eta(v) \cdot [G_i(w) - G_i(v)].$$

Note that the function h has locally quadratic growth in $w - v$. This is also true for f_i thanks to (1.3). We conclude that

$$a|v-w|^2 \le h(v, w) \le b|v-w|^2 \qquad (v, w \in S) \tag{2.6}$$

holds and that there is a constant $\lambda = \lambda(S) > 0$, such that

$$\left\{\sum_{i=1}^{d} [f_i(v, w)]^2\right\}^{1/2} \le \lambda h(v, w) \qquad (v, w \in S). \tag{2.7}$$

Similarly, there exists a constant $\alpha = \alpha(S, \|Du\|_{L^\infty}) \geq 0$, such that we have for all $v \in S$

$$\begin{aligned}
&\sum_{i=1}^{d} \big|\nabla^2\eta(u)\partial_i u \cdot \big[G_i(v) - G_i(u) - DG_i(u)(v-u)\big]\big| \leq \frac{\alpha}{3} h(u,v),\\
&\big|B(u) \cdot \big[\nabla\eta(v) - \nabla\eta(u) - \nabla^2\eta(u)(v-u)\big]\big| \leq \frac{\alpha}{3} h(u,v),\\
&\big|[B(u) - B(v)] \cdot [\nabla\eta(u) - \nabla\eta(v)]\big| \leq \frac{\alpha}{3} h(u,v)
\end{aligned} \tag{2.8}$$

on $\mathbb{R}^d \times [0,T]$ for a solution u of (1.1) that satisfies Assumption 1.1. For $R, \lambda > 0$ define the cone

$$\mathcal{C}_R = \{(x,t) \,|\, |x| \leq R + \lambda(T-t),\ x \in \mathbb{R}^d,\ t \in [0,T]\}.$$

We introduce the following measures.

Definition 2.1. *Let $v \in [L^\infty_{loc}(\mathbb{R}^d \times (0,T))]^m$ be an arbitrary function with values in $\mathcal{U}$. The* weak consistency measure *$\mu_v : [C_0^{0,1}(\mathbb{R}^d \times [0,T])]^m \to \mathbb{R}$ and the* dissipation measure *$\nu_v : C_0^{0,1}(\mathbb{R}^d \times [0,T]) \to \mathbb{R}$ are defined by*

$$\langle \mu_v, \pi \rangle = -\int_0^T \int_{\mathbb{R}^d} v \cdot \partial_t \pi + \sum_{i=1}^{d} G_i(v) \cdot \partial_i \pi + B(v) \cdot \pi \; dxdt - \int_{\mathbb{R}^d} u_0 \cdot \pi(.,0)\, dx,$$

$$\begin{aligned}
\langle \nu_v, \omega \rangle = -\int_0^T \int_{\mathbb{R}^d} &\eta(v)\, \partial_t \omega + \sum_{i=1}^{d} q_i(v)\, \partial_i \omega\\
&+ \nabla\eta(v) \cdot B(v)\, \omega \; dxdt - \int_{\mathbb{R}^d} \eta(u_0)\, \omega(.,0)\, dx.
\end{aligned}$$

These measures are important since one can estimate the L^2-distance between the solution u and an *arbitrary function* v in terms of the measures.

Theorem 2.2. *Suppose that Assumption* 1.1 *for the solution u of* (1.1), (1.2) *holds. Let $v \in [L^\infty_{loc}(\mathbb{R}^d \times (0,T))]^m$ be a function with values in the set S (from Assumption* 1.1*). Then, for α given by* (2.8)*, the following estimate holds:*

$$\int_0^T \int_{\mathbb{R}^d} e^{-\alpha t} \xi_R\, h(u,v)\, dxdt \leq \langle \nu_v, \varphi_R \rangle - \langle \mu_v, \psi_R \rangle. \tag{2.9}$$

Here we have $\varphi_R(x,t) = e^{-\alpha t}(T-t)\xi_R(x,t)$, $\psi_R = \varphi_R \nabla\eta(u)$, and

$$\xi_R(x,t) = \gamma(|x| - R - \lambda(T-t)), \quad \gamma(s) = \begin{cases} 1 & : s \leq 0,\\ 1-s & : s \in (0,1),\\ 0 & : s \geq 1. \end{cases}$$

$R > 0$ is an arbitrary number and the parameter λ is given by (2.7).

Proof. Let $\omega \in C_0^{0,1}(\mathbb{R}^d \times [0,T])$ be any function with $\omega(.,T) = 0$ and let $\pi = \omega\nabla\eta(u)$. Note that the classical solution u satisfies (1.5) with equality. Partial integration and application of (1.1) yield

$$\begin{aligned}
&-\int_0^T\int_{\mathbb{R}^d} h(u,v)\,\partial_t\omega+\sum_{i=1}^d f_i(u,v)\,\partial_i\omega\ \ dxdt\\
&=\ \langle\nu_v,\omega\rangle+\int_0^T\int_{\mathbb{R}^d}\omega\,B(v)\cdot\nabla\eta(v)-\omega\,B(u)\cdot\nabla\eta(u)\,dxdt\\
&\qquad+\int_0^T\int_{\mathbb{R}^d}\left[\partial_t\omega\,\nabla\eta(u)\cdot(v-u)+\sum_{i=1}^d\partial_i\omega\,\nabla\eta(u)\cdot[G_i(v)-G_i(u)]\right]dxdt\\
&=\langle\nu_v,\omega\rangle+\int_0^T\int_{\mathbb{R}^d}\omega\,B(v)\cdot\nabla\eta(v)-\omega\,B(u)\cdot\nabla\eta(u)\,dxdt\\
&\qquad+\int_0^T\int_{\mathbb{R}^d}\big[\partial_t[\omega\,\nabla\eta(u)]-\omega\,\nabla^2\eta(u)\partial_t u\big]\cdot\big[v-u\big]\,dxdt\\
&\qquad+\int_0^T\int_{\mathbb{R}^d}\sum_{i=1}^d\big[\partial_i[\omega\,\nabla\eta(u)]-\omega\,\nabla^2\eta(u)\partial_i u\big]\cdot\big[G_i(v)-G_i(u)\big]\,dxdt\\
&=\langle\nu_v,\omega\rangle-\langle\mu_v,\pi\rangle+\int_0^T\int_{\mathbb{R}^d}\omega\,B(v)\cdot\nabla\eta(v)-B(v)\cdot\pi-\omega\,\nabla^2\eta(u)B(u)\cdot(v-u)\,dxdt\\
&\qquad+\int_0^T\int_{\mathbb{R}^d}\sum_{i=1}^d\omega\big[\nabla^2\eta(u)DG_i(u)\partial_i u\cdot(v-u)-\nabla^2\eta(u)\partial_i u\cdot[G_i(v)-G_i(u)]\big]\,dxdt.
\end{aligned}$$

The symmetry of the operators $\nabla^2\eta(u)$ and $\nabla^2\eta(u)DG_i(u)$ (see (2.1)) implies

$$\begin{aligned}
-\int_0^T\int_{\mathbb{R}^d} &h(u,v)\,\partial_t\omega+\sum_{i=1}^d f_i(u,v)\,\partial_i\omega\ dxdt\\
=\quad&\langle\nu_v,\omega\rangle-\langle\mu_v,\pi\rangle+\int_0^T\int_{\mathbb{R}^d}\omega\,B(u)\cdot\big[\nabla\eta(v)-\nabla\eta(u)-\nabla^2\eta(u)(v-u)\big]\,dxdt\\
&+\int_0^T\int_{\mathbb{R}^d}\omega\,[B(u)-B(v)]\cdot[\nabla\eta(u)-\nabla\eta(v)]\,dxdt\\
&-\int_0^T\int_{\mathbb{R}^d}\sum_{i=1}^d\omega\,\nabla^2\eta(u)\partial_i u\cdot\big[G_i(v)-G_i(u)-DG_i(u)(v-u)\big]\,dxdt.
\end{aligned}$$

Using the definition (2.8) of the constant α, one obtains

(2.10)
$$-\int_0^T\int_{\mathbb{R}^d} h(u,v)\,\partial_t\omega+\sum_{i=1}^d f_i(u,v)\,\partial_i\omega\ dxdt\le\langle\nu_v,\omega\rangle-\langle\mu_v,\pi\rangle+\alpha\int_0^T\int_{\mathbb{R}^d}\omega\,h(u,v)\,dxdt.$$

Since

$$\begin{aligned}
&\partial_t\varphi_R(x,t)=-\alpha\varphi_R(x,t)-e^{-\alpha t}\xi_R(x,t)+\lambda e^{-\alpha t}(T-t)\gamma'\big(|x|-R-\lambda(T-t)\big),\\
&\partial_i\varphi_R(x,t)=\gamma'\big(|x|-R-\lambda(T-t)\big)\frac{x_i}{|x|}e^{-\alpha t}(T-t),
\end{aligned}$$

for $i = 1, \dots, d$, we have

$$\begin{aligned}
&-\int_0^T \int_{\mathbb{R}^d} h(u,v)\,\partial_t\varphi_R + \sum_{i=1}^d f_i(u,v)\,\partial_i\varphi_R \;dxdt\\
&= \alpha\int_0^T \int_{\mathbb{R}^d} h(u,v)\,\varphi_R\,dxdt + \int_0^T \int_{\mathbb{R}^d} e^{-\alpha t}\xi_R\,h(u,v)\,dxdt\\
&\quad + \int_0^T \int_{\mathbb{R}^d} e^{-\alpha t}(T-t)\Big[-\gamma'(|x| - R - \lambda(T-t))\Big]\\
&\quad \cdot\Big[\sum_{i=1}^d f_i(u,v)\frac{x_i}{|x|} + \lambda h(u,v)\Big]\,dxdt\\
&\geq \alpha\int_0^T \int_{\mathbb{R}^d} h(u,v)\,\varphi_R\,dxdt + \int_0^T \int_{\mathbb{R}^d} e^{-\alpha t}\xi_R\,h(u,v)\,dxdt.
\end{aligned}$$

The last estimate follows from $\gamma' \leq 0$ almost everywhere (a.e.) on $\mathbb{R}$ and

$$\sum_{i=1}^d f_i(u,v)\frac{x_i}{|x|} + \lambda h(u,v) \geq 0 \quad \text{for } (x,t) \in \mathbb{R}^d \times [0,T],\ x \neq 0,$$

due to (2.7). Finally, if we plug $\omega = \varphi_R$ in (2.10) we get (2.9). □

Theorem 2.2 gives an estimate in terms of Dafermos' relative entropy. Due to the properties of the entropy and our assumptions we can pass to the more convenient L^2-norm.

Corollary 2.3. *Under the conditions stated in Theorem* 2.2 *we have*

$$a\int_0^T \int_{\{|x|\leq R\}} e^{-\alpha t}|u-v|^2 dxdt \leq \langle \nu_v, \varphi_R\rangle - \langle \mu_v, \psi_R\rangle.$$

Here $a > 0$ is the constant from (2.4).

Proof. The statement is a direct consequence of (2.6), Theorem 2.2, and the fact that $\xi_R = 1$ on $\{x \in \mathbb{R}^d \,|\, |x| \leq R\} \times [0,T]$. □

Remark 2.4.

(i) To recover the statement of Theorem 1.2 from Theorem 2.2 let v be an entropy solution as in Theorem 1.2. Then we compute from (2.9)

$$\begin{aligned}
a\int_0^T \int_{\mathbb{R}^d} e^{-\alpha t}\xi_R|u-v|^2\,dxdt &\leq T\int_{\mathbb{R}^d} h(v_0,u_0)\xi_R(x,0)\,dx\\
&\leq b\,T\int_{\{|x|\leq R+\lambda T\}} |u_0 - v_0|^2\,dx.
\end{aligned}$$

The pointwise estimate in time as in Theorem 1.2 can be obtained by a slightly different choice of test functions in Theorem 2.2.

(ii) Due to $B(\bar{u}) = 0$ the function $u = \bar{u}$ is a classical solution of (1.1) and initial condition $u_0 = \bar{u}$. If we choose $v \equiv u$, $v_0 \equiv u_0$ in (i) and let $R \to \infty$, we obtain

$$\int_0^T \int_{\mathbb{R}^d} |u-\bar{u}|^2\,dxdt \leq d_1\int_{\mathbb{R}^d} |u_0 - \bar{u}|^2\,dx \tag{2.11}$$

with a constant d_1 depending on the set S, since $\xi_R \to 1$ and $\alpha = 0$.

(iii) From (1.1), Assumption 1.1, and (ii) we conclude that there is a constant $d_2 > 0$ such that

$$\int_0^T \int_{\mathbb{R}^d} |\partial_t u|^2 \, dxdt \leq d_2. \tag{2.12}$$

3. Discretization. We introduce a class of finite volume schemes to solve (1.1), (1.2) numerically. Beside that we make some assumptions on the corresponding numerical approximation.

3.1. The unstructured mesh. We consider a quasiuniform triangulation $\mathcal{T}_h$ of $\mathbb{R}^d$: this is a set of convex polyhedra, with the property

$$\operatorname{diam}(K) \leq h, \;\; |K| \geq c_0 h^d \quad (K \in \mathcal{T}_h), \tag{3.1}$$

and

$$|e| \geq c_0 h^{d-1} \;\; (e \in \mathcal{E}(K)), \tag{3.2}$$

for some constants $h, \; c_0 > 0$, where $|K|$ is the Lebesgue measure of K on $\mathbb{R}^d$ and $|e|$ the $\mathbb{R}^{d-1}$-Lebesgue measure of the edge e. For a given $K \in \mathcal{T}_h$ the set $\mathcal{E}(K)$ contains all edges of K. Note that for simplices (triangles, tetrahedra) (3.2) is a consequence of (3.1).

We assume that for each $K \in \mathcal{T}_h$ and each edge e of K, there exists exactly one neighboring cell $K_e \in \mathcal{T}_h$. Let furthermore $F = \bigcup_{K \in \mathcal{T}_h} \mathcal{E}(K)$ be the set of all edges.

The mesh with respect to t is uniform: $t^n = n\Delta t$ $(n \in \mathbb{N} \cup \{0\})$. Here $\Delta t > 0$ is such that there is a $N \in \mathbb{N}$ with $N\Delta t = T$. With this number we define the set $\mathcal{N} = \{0, 1, \ldots, N-1\}$.

We will impose on Δt and h the following condition: there exists a constant $c_1 > 0$ independent on $\Delta t, \; h$, such that

$$\frac{\Delta t}{h} \geq c_1. \tag{3.3}$$

Denote by $h_{K,e}$ the height of K that corresponds to $e \in \mathcal{E}(K)$. Then, we have $|e|\,|h_{K,e}| = c(d)|K|$ for a constant $c(d)$ that depends only on the dimension d. For later use we note that the mesh condition (3.3) yields

$$\Delta t|e| = \frac{(\Delta t|e|)^2}{|K|} \frac{|K| h_{K,e}}{\Delta t|e| h_{K,e}} \leq \frac{1}{c(d)} \frac{h}{\Delta t} \frac{(\Delta t|e|)^2}{|K|} \leq \frac{1}{c(d)c_1} \frac{(\Delta t|e|)^2}{|K|} \tag{3.4}$$

and

$$\frac{(\Delta t|e|)^2}{|K|} = \frac{c^2(d)(\Delta t)^2|K|}{h_{K,e}^2} \geq c^2(d) \frac{\Delta t|K|}{h} \frac{\Delta t}{h} \geq c^2(d)c_1 \frac{\Delta t|K|}{h}. \tag{3.5}$$

By Bramble–Hilbert-like techniques one can deduce that for $K \in \mathcal{T}_h, \; e \in \mathcal{E}(K)$, and $z \in [C^1(\overline{K})]^m$

$$\int_K \left| z - \frac{1}{|K|} \int_K z \, dx \right|^2 dx \leq C_0 h^2 \int_K |Dz|^2 dx, \tag{3.6}$$

$$\left| \frac{1}{|K|} \int_K z \, dx - \frac{1}{|e|} \int_e z \, d\sigma \right| \leq C_0 \frac{h^{1/2}}{|e|^{1/2}} \Big(\int_K |Dz|^2 dx \Big)^{1/2} \tag{3.7}$$

holds for some constant $C_0 = C_0(d, c_0)$, under the mesh conditions (3.1), (3.2).

3.2. The finite volume method. To solve the Cauchy problem (1.1), (1.2) numerically we use the finite volume scheme

$$\begin{aligned} u_K^{n+1} &= u_K^n - \frac{\Delta t}{|K|} \sum_{e \in \mathcal{E}(K)} |e| \, g_{K,e}^n(u_K^n, u_{K_e}^n) + \Delta t \, B(u_K^n), \\ u_K^0 &= \frac{1}{|K|} \int_K u_0(x) \, dx. \end{aligned} \tag{3.8}$$

From the iteratives u_K^n we define the piecewise constant approximation $u_h : \mathbb{R}^d \times [0,T] \to \mathbb{R}^m$ of u by

$$u_h(x,t) = u_K^n \quad \text{for } \; x \in K, \; t \in [t^n, t^{n+1}), \tag{3.9}$$

where $K \in \mathcal{T}_h$ and $n \in \mathcal{N}$.

For the numerical flux $g_{K,e}^n$ in (3.8) we suppose the usual consistency and conservation properties.

- For all $n \in \mathcal{N}, \; K \in \mathcal{T}_h, \; e \in \mathcal{E}(K)$ we have

$$g_{K,e}^n(v,v) = \sum_{i=1}^d n_{K,e}^i G_i(v) \quad (v \in \mathcal{U}), \tag{3.10}$$

where $n_{K,e} = (n_{K,e}^1, \dots, n_{K,e}^d)^T$ is the unit outward normal to $e \in \mathcal{E}(K)$.

- For all $n \in \mathcal{N}, \; K \in \mathcal{T}_h, \; e \in \mathcal{E}(K)$, it holds

$$g_{K,e}^n(v,w) = -g_{K_e,e}^n(w,v) \quad (v,w \in \mathcal{U}). \tag{3.11}$$

A special consequence of (3.10) is

$$\sum_{e \in \mathcal{E}(K)} |e| \, g_{K,e}^n(u_K^n, u_K^n) = 0 \quad (n \in \mathcal{N}, \; K \in \mathcal{T}_h). \tag{3.12}$$

We introduce now the numerical entropy flux $q_{K,e}^n$, having the following properties.

- For all $M > 0$ there exists a constant $c(M) > 0$, such that for all $n \in \mathcal{N}$, $K \in \mathcal{T}_h, \; e \in \mathcal{E}(K)$,

$$|q_{K,e}^n(v,w)| \leq c(M)\big(|v - \bar{u}|^2 + |w - \bar{u}|^2\big) \quad (|v - \bar{u}|, |w - \bar{u}| \leq M). \tag{3.13}$$

- For all $n \in \mathcal{N}, \; K \in \mathcal{T}_h, \; e \in \mathcal{E}(K)$, we have

$$q_{K,e}^n(v,v) = \sum_{i=1}^d n_{K,e}^i q_i(v) \quad (v \in \mathcal{U}). \tag{3.14}$$

- For all $n \in \mathcal{N}, \; K \in \mathcal{T}_h, \; e \in \mathcal{E}(K)$, it is

$$q_{K,e}^n(v,w) = -q_{K_e,e}^n(w,v) \quad (v,w \in \mathcal{U}). \tag{3.15}$$

The conditions on the numerical flux functions can be satisfied by standard choices. In particular this is true for the Lax–Friedrichs flux (cf. [18]).

Before we proceed with the convergence proof we make the following strong assumption on u_h.

ASSUMPTION 3.1. *Let u_h be the finite volume approximation defined by* (3.8), (3.9). *Suppose that*

(H.1) u_h *takes values in the set* S *(from Assumption* 1.1*).*

(H.2) *For each* $n \in \mathcal{N}$, $K \in \mathcal{T}_h$, *the following relation holds:*

$$\begin{aligned}\eta(u_K^{n+1}) - \eta(u_K^n) &+ \frac{\Delta t}{|K|} \sum_{e \in \mathcal{E}(K)} |e|\, q_{K,e}^n(u_K^n, u_{K_e}^n) \\ &+ \left(\frac{\Delta t}{|K|}\right)^2 \sum_{e \in \mathcal{E}(K)} |e|^2 \big|g_{K,e}^n(u_K^n, u_{K_e}^n) - g_{K,e}^n(u_K^n, u_K^n)\big|^2 \\ &\qquad \le \Delta t \nabla \eta(u_K^n) \cdot B(u_K^n) + C(\Delta t)^2 |u_K^n - \bar{u}|^2.\end{aligned}$$

The assumption (H.2) expresses that we are supposed to have a cell entropy inequality for the approximate solution u_h. Moreover, the scheme should provide some entropy dissipation to get the weak derivative bound on the fluxes. Together with the L^∞-bound in (H.1) this will restrict the choice of possible flux functions and moreover introduce a CFL-like restriction on the time step. In section 5 we shall consider examples where (H.1) and (H.2) are met.

We conclude this section with several important a priori estimates for u_h, which are essential for our further considerations and are induced by Assumption 3.1. We present them in the next proposition and in the corollary following it. They can be proven in the linear case [13, 34]. Therefore we omit the proofs.

Proposition 3.2. *Let* u_h *be given by* (3.8), (3.9) *and suppose that it obeys Assumption* 3.1. *For the numerical flux* $g_{K,e}^n$ *and the numerical entropy flux* $q_{K,e}^n$ *assume* (3.10), (3.11) *and* (3.13), (3.15), *respectively. Under the mesh condition* (3.1), *we have*

$$\text{(a)} \quad \sum_{K \in \mathcal{T}_h} \sum_{e \in \mathcal{E}(K)} |e|\, q_{K,e}^n(u_K^n, u_{K_e}^n) = 0 \quad (n \in \mathcal{N}),$$

$$\text{(b)} \quad \int_0^T \int_{\mathbb{R}^d} |u_h - \bar{u}|^2 \, dx dt \le C,$$

$$\text{(c)} \quad \sum_{n \in \mathcal{N}} \sum_{K \in \mathcal{T}} \sum_{e \in \mathcal{E}(K)} \frac{(\Delta t |e|)^2}{|K|} \big|g_{K,e}^n(u_K^n, u_{K_e}^n) - g_{K,e}^n(u_K^n, u_K^n)\big|^2 \le C.$$

The a priori estimate (c) in Proposition 3.2 is not optimal with respect to h (and therefore doesn't lead to the optimal error estimate scaling with h instead of $\sqrt{h}$ later). It can be improved a posteriori. For that purpose we introduce the term

$$Q_h = \sum_{n \in \mathcal{N}} \sum_{K \in \mathcal{T}} \sum_{e \in \mathcal{E}(K)} \theta^n \frac{(\Delta t\, |e|)^2}{|K|} \big|g_{K,e}^n(u_K^n, u_{K_e}^n) - g_{K,e}^n(u_K^n, u_K^n)\big|^2 \tag{3.16}$$

with

$$\theta^n = \frac{1}{\Delta t} \int_{t^n}^{t^{n+1}} \theta(t)\, dt$$

and $\theta(t) = e^{-\alpha t}(T - t)$.

Corollary 3.3. *Under the assumptions in the previous proposition, we have*

$$\int_0^T \int_{\mathbb{R}^d} |u - u_h|^2 \, dxdt \leq C, \tag{3.17}$$

$$\sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}_h} |K| \, |u_K^{n+1} - u_K^n|^2 \leq C, \tag{3.18}$$

$$\sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}_h} \theta^n |K| \, |u_K^{n+1} - u_K^n|^2 \leq CQ_h + C\Delta t. \tag{3.19}$$

4. The error estimate for classical solutions.

By the L^2-stability result from section 2 we can now tackle the convergence proof. Throughout this section we consider the general problem (1.1), (1.2) and suppose that Assumption 1.1 holds. Moreover we take Assumption 3.1 for the numerical approximation u_h to be valid.

4.1. Identification of the error measure and estimates.

We are now in a position to replace the function v in Corollary 2.3 by u_h. Furthermore, it turns out that one can pass to limits for $R \to \infty$. This is the subject of the next proposition. In addition, since $\varphi_R \to \theta$, the limit function becomes independent of x. This is essential for the derivation of error estimates.

Proposition 4.1. *Suppose that u is the solution of* (1.1), (1.2) *which satisfies Assumption* 1.1. *For the numerical fluxes $g_{K,e}^n$ and $q_{K,e}^n$ we assume the properties* (3.10), (3.11) *and* (3.13), (3.15), *respectively. Assume further that for u_h defined by* (3.9) *Assumption* 3.1 *holds. Then, under the mesh condition* (3.1), *it holds that*

$$a \int_0^T \int_{\mathbb{R}^d} e^{-\alpha t} |u - u_h|^2 dxdt \leq \langle \nu_h, \theta \rangle - \langle \mu_h, \psi \rangle,$$

for α given by (2.8), $\theta(t) = e^{-\alpha t}(T - t)$, $\psi = \theta \nabla \eta(u)$, *and*

$$\begin{aligned}\langle \mu_h, \psi \rangle = &- \int_0^T \int_{\mathbb{R}^d} (u_h - \bar{u}) \cdot \partial_t \psi + \sum_{i=1}^d [G_i(u_h) - G_i(\bar{u})] \cdot \partial_i \psi + B(u_h) \cdot \psi \; dxdt \\ &- \int_{\mathbb{R}^d} (u_0 - \bar{u}) \cdot \psi(.,0) \, dx, \\ \langle \nu_h, \theta \rangle = &- \int_0^T \int_{\mathbb{R}^d} \eta(u_h) \, \theta' + \nabla \eta(u_h) \cdot B(u_h) \, \theta \; dxdt - \int_{\mathbb{R}^d} \eta(u_0) \, \theta(0) \, dx.\end{aligned}$$

Proof. From Definition 2.1 we deduce

$$\begin{aligned}\langle \mu_{u_h}, \psi_R \rangle = &- \int_0^T \int_{\mathbb{R}^d} (u_h - \bar{u}) \cdot \partial_t \psi_R + \sum_{i=1}^d [G_i(u_h) - G_i(\bar{u})] \cdot \partial_i \psi_R + B(u_h) \cdot \psi_R \; dxdt \\ &- \int_{\mathbb{R}^d} (u_0 - \bar{u}) \cdot \psi_R(.,0) \, dx\end{aligned}$$

because ψ_R has a compact support. According to (b) in Proposition 3.2, we have $u_h - \bar{u} \in [L^2(\mathbb{R}^d \times (0,T))]^m$. Due to (2.11), (2.12), and (2.5) one infers ψ, $\partial_t \psi$, $\partial_i \psi$,

$B(u_h)$, $\nabla\eta(u_h) \in [L^2(\mathbb{R}^d \times (0,T))]^m$, and $\eta(u_h), q_i(u_h) \in [L_1(\mathbb{R}^d \times (0,T))]^m$. On the other side $\xi_R \to 1$, $\partial_t \xi_R \to 0$, $\partial_i \xi_R \to 0$ a.e. on $\mathbb{R}^d \times [0,T]$, $i = 1,\dots,d$, for $R \to \infty$, and all these terms remain bounded. Therefore one can pass to limits in Corollary 2.3. ▯

To obtain error estimates, it remains to estimate the expression $\langle \nu_h, \theta\rangle - \langle \mu_h, \psi\rangle$. This is done in the next two lemmas. We need the following inequality:

$$\max_{[t^n,t^{n+1}]} \theta(t) \le 2e^{\alpha\Delta t}\theta^n \quad (n \in \mathcal{N}). \tag{4.1}$$

Lemma 4.2. *Under the assumptions in Proposition* 4.1 *we have*

$$\langle \nu_h, \theta\rangle - \langle \mu_h, \psi\rangle \le L + R + \int_0^T \int_{\mathbb{R}^d} \theta(t) B(u_h) \cdot [\nabla\eta(u) - \nabla\eta(u_h)]\, dxdt + Ch^2,$$

where

$$L = \sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}_h} \int_K \theta(t^{n+1}) \big[\eta(u_K^{n+1}) - \eta(u_K^n) - \nabla\eta(u(x,t^{n+1}))\cdot(u_K^{n+1} - u_K^n)\big]\, dx,$$

$$R = \frac{1}{2} \sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}} \sum_{e\in\mathcal{E}(K)} \left[\sum_{i=1}^d n_{K,e}^i \big(G_i(u_K^n) - G_i(u_{K_e}^n)\big)\right] \cdot \int_{t^n}^{t^{n+1}} \int_e \psi\, d\sigma dt.$$

Proof. For the sake of simplicity assume that $\bar{u} = 0$ and $G_i(\bar{u}) = 0$ for $i = 1,\dots,d$. Partial integration with respect to t yields

$$\begin{aligned} &\int_0^T \int_{\mathbb{R}^d} u_h \cdot \psi_t\, dxdt + \int_{\mathbb{R}^d} u_0(x)\cdot\psi(x,0)\, dx \\ &= \sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}_h} \int_K \psi(x,t^{n+1})\cdot(u_K^n - u_K^{n+1})\, dx + \sum_{K\in\mathcal{T}_h} \int_K \psi(x,0)\cdot(u_0(x) - u_K^0)\, dx \end{aligned}$$

and

$$\begin{aligned} &-\int_0^T \int_{\mathbb{R}^d} \eta(u_h)\theta'(t)\, dxdt - \int_{\mathbb{R}^d} \eta(u_0(x))\theta(0)\, dx \\ &= \sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}_h} \int_K \theta(t^{n+1}) \big[\eta(u_K^{n+1}) - \eta(u_K^n)\big]\, dx + \sum_{K\in\mathcal{T}_h} \int_K \varphi(x,0) \big[\eta(u_K^0) - \eta(u_0(x))\big]\, dx. \end{aligned}$$

After applying the Gauss theorem, one obtains

$$\sum_{i=1}^d \int_{t^n}^{t^{n+1}} \int_K G_i(u_K^n)\cdot\partial_i\psi\, dxdt = \sum_{e\in\mathcal{E}(K)} \left[\sum_{i=1}^d n_{K,e}^i G_i(u_K^n)\right] \cdot \int_{t^n}^{t^{n+1}} \int_e \psi\, d\sigma dt.$$

Therefore, taking into account that

$$n_{K,e}^i\big(G_i(u_K^n) - G_i(u_{K_e}^n)\big) = \frac{1}{2}\big[n_{K,e}^i\big(G_i(u_K^n) - G_i(u_{K_e}^n)\big) + n_{K_e,e}^i\big(G_i(u_{K_e}^n) - G_i(u_K^n)\big)\big],$$

we have

$$\begin{aligned}
&\int_0^T \int_{\mathbb{R}^d} \sum_{i=1}^d G_i(u_h)\cdot \partial_i\psi \, dxdt\\
&\qquad = \sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}} \sum_{e\in\mathcal{E}(K)} \left[\sum_{i=1}^d n_{K,e}^i G_i(u_K^n)\right]\cdot \int_{t^n}^{t^{n+1}} \int_e \psi \, d\sigma dt\\
&\qquad = \sum_{n\in\mathcal{N}} \sum_{e\in F} \left[\sum_{i=1}^d n_{K,e}^i \big(G_i(u_K^n) - G_i(u_{K_e}^n)\big)\right]\cdot \int_{t^n}^{t^{n+1}} \int_e \psi \, d\sigma dt\\
&\qquad = \frac{1}{2}\sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}} \sum_{e\in\mathcal{E}(K)} \left[\sum_{i=1}^d n_{K,e}^i \big(G_i(u_K^n) - G_i(u_{K_e}^n)\big)\right]\cdot \int_{t^n}^{t^{n+1}} \int_e \psi \, d\sigma dt.
\end{aligned}$$

From the equation

$$\begin{aligned}
\langle \nu_h, \varphi\rangle - \langle \mu_h, \psi\rangle = \int_0^T \int_{\mathbb{R}^d} u_h\cdot\psi_t \ + \sum_{i=1}^d G_i(u_h)\cdot\partial_i\psi \ \ dxdt + \int_{\mathbb{R}^d} u_0(x)\cdot\psi(x,0)\, dx\\
+ \int_0^T \int_{\mathbb{R}^d} \theta B(u_h)\cdot[\nabla\eta(u) - \nabla\eta(u_h)] - \eta(u_h)\theta' \, dxdt - \int_{\mathbb{R}^d} \eta(u_0(x))\theta(0)\, dx,
\end{aligned}$$

the relations derived above, and the fact that $\psi = \theta\nabla\eta(u)$, one concludes that

$$\langle \nu_h, \varphi\rangle - \langle \mu_h, \psi\rangle = L + R + J + \int_0^T \int_{\mathbb{R}^d} \theta(t) B(u_h)\cdot[\nabla\eta(u) - \nabla\eta(u_h)]\, dxdt, \tag{4.2}$$

where

$$J = \sum_{K\in\mathcal{T}_h} \int_K \theta(0)\big[\eta(u_K^0) - \eta(u_0(x)) - \nabla\eta(u_0(x))\cdot(u_K^0 - u_0(x))\big]\, dx.$$

The inequality (3.6) implies $\left\|u_K^0 - u_0\right\|_{L^2(K)} \le Ch\|Du_0\|_{L^2(K)}$, which leads to

$$\begin{aligned}
J &= \sum_{K\in\mathcal{T}_h} \int_K \theta(0) h(u_0(x), u_K^0)\, dx\\
&\le bT \sum_{K\in\mathcal{T}_h} \int_K |u_K^0 - u_0(x)|^2 dx \le Ch^2 \int_{\mathbb{R}^d} |Du_0|^2 dx. \qquad \square
\end{aligned}$$

In the next step we estimate L from Lemma 4.2.

LEMMA 4.3. *Let the assumptions in Proposition* 4.1 *hold. Assume additionally the mesh conditions* (3.2), (3.3). *Then for the term L from Lemma* 4.2, *we have*

$$\begin{aligned}
L \le P - \frac{1}{2} Q_h + \frac{a}{2}\int_0^T \int_{\mathbb{R}^d} e^{-\alpha t} |u - u_h|^2 \, dxdt\\
+ \int_0^T \int_{\mathbb{R}^d} \theta\, B(u_h)\cdot[\nabla\eta(u_h) - \nabla\eta(u)]\, dxdt + C(\Delta t + h),
\end{aligned}$$

where

$$P = \sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}} \sum_{e\in\mathcal{E}(K)} \big[g_{K,e}^n(u_K^n, u_{K_e}^n) - g_{K,e}^n(u_K^n, u_K^n)\big]\cdot \int_{t^n}^{t^{n+1}} \int_e \psi \, d\sigma dt.$$

Proof. Assume again that $\bar{u} = 0$. The term L can be rewritten as

$$L = E + I, \tag{4.3}$$

where

$$E = \frac{1}{\Delta t} \sum_{n \in \mathcal{N}} \sum_{K \in \mathcal{T}_h} \int_{t^n}^{t^{n+1}} \int_K \theta(t) \big[\eta(u_K^{n+1}) - \eta(u_K^n) - \nabla\eta(u(x,t^{n+1})) \\ \cdot (u_K^{n+1} - u_K^n) \big] \, dxdt,$$

$$I = \frac{1}{\Delta t} \sum_{n \in \mathcal{N}} \sum_{K \in \mathcal{T}_h} \int_{t^n}^{t^{n+1}} \int_K \Big[[\theta(t^{n+1}) - \theta(t)] \\ \big[\eta(u_K^{n+1}) - \eta(u_K^n) - \nabla\eta(u(x,t^{n+1})) \cdot (u_K^{n+1} - u_K^n) \big] \Big] \, dxdt.$$

We split up $I = I_1 + I_2 + I_3$ according to

$$I_1 = \frac{1}{\Delta t} \sum_{n \in \mathcal{N}} \sum_{K \in \mathcal{T}_h} \int_{t^n}^{t^{n+1}} \int_K \Big[[\theta(t^{n+1}) - \theta(t)] \\ \big[\eta(u_K^{n+1}) - \eta(u_K^n) - \nabla\eta(u_K^n) \cdot \big(u_K^{n+1} - u_K^n\big) \big] \Big] \, dxdt,$$

$$I_2 = \frac{1}{\Delta t} \sum_{n \in \mathcal{N}} \sum_{K \in \mathcal{T}_h} \int_{t^n}^{t^{n+1}} \int_K [\theta(t^{n+1}) - \theta(t)] \\ \big[\nabla\eta(u(x,t)) - \nabla\eta(u(x,t^{n+1})) \big] \cdot \big[u_K^{n+1} - u_K^n \big] \, dxdt,$$

$$I_3 = \frac{1}{\Delta t} \sum_{n \in \mathcal{N}} \sum_{K \in \mathcal{T}_h} \int_{t^n}^{t^{n+1}} \int_K [\theta(t^{n+1}) - \theta(t)] \\ \big[\nabla\eta(u_K^n) - \nabla\eta(u(x,t)) \big] \cdot \big[u_K^{n+1} - u_K^n \big] \, dxdt.$$

Because of $|\theta(t^{n+1}) - \theta(t)| \le C\Delta t$ for $t \in [t^n, t^{n+1}]$ and

$$|\eta(u_K^{n+1}) - \eta(u_K^n) - \nabla\eta(u_K^n) \cdot (u_K^{n+1} - u_K^n)| \le b|u_K^{n+1} - u_K^n|^2,$$

we obtain by applying the a priori estimate (3.18)

$$I_1 \le C \sum_{n \in \mathcal{N}} \sum_{K \in \mathcal{T}_h} \Delta t \, |K| \, |u_K^{n+1} - u_K^n|^2 \le C\Delta t.$$

For $t \in [t^n, t^{n+1}]$ one obtains

$$\big| \nabla\eta(u(x,t)) - \nabla\eta(u(x,t^{n+1})) \big| = \Big| \int_{t^{n+1}}^{t} \nabla^2\eta(u(x,s)) \partial_t u(x,s) \, ds \Big| \le C \int_{t^n}^{t^{n+1}} |\partial_t u| \, ds.$$

The integral Cauchy–Schwarz inequality implies

$$I_2 \le C\Delta t \sum_{n \in \mathcal{N}} \sum_{K \in \mathcal{T}_h} \int_{t^n}^{t^{n+1}} \int_K |\partial_t u| \, |u_K^{n+1} - u_K^n| \, dxdt \\ \le C\Delta t \sum_{n \in \mathcal{N}} \sum_{K \in \mathcal{T}_h} \left(\int_{t^n}^{t^{n+1}} \int_K |\partial_t u|^2 \, dxdt \right)^{1/2} (\Delta t \, |K|)^{1/2} |u_K^{n+1} - u_K^n|.$$

Finally, the Cauchy–Schwarz inequality applied to the last sum together with (2.12), (3.18) gives

$$I_2 \le C\Delta t \left(\int_0^T \int_{\mathbb{R}^d} |\partial_t u|^2 \, dxdt\right)^{1/2} \left(\sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}_h} \Delta t \, |K| \, |u_K^{n+1} - u_K^n|^2\right)^{1/2} \le C(\Delta t)^{3/2}.$$

For the term I_3, we have

$$\begin{aligned} I_3 &\le C \sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}_h} \int_{t^n}^{t^{n+1}} \int_K |u - u_K^n| \, |u_K^{n+1} - u_K^n| \, dxdt \\ &\le C \left(\int_0^T \int_{\mathbb{R}^d} e^{-\alpha t} |u - u_h|^2 \, dxdt\right)^{1/2} \left(\sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}_h} \Delta t \, |K| \, |u_K^{n+1} - u_K^n|^2\right)^{1/2} \\ &\le C(\Delta t)^{1/2} \left(\int_0^T \int_{\mathbb{R}^d} e^{-\alpha t} |u - u_h|^2 \, dxdt\right)^{1/2} \\ &\le \frac{a}{2} \int_0^T \int_{\mathbb{R}^d} e^{-\alpha t} |u - u_h|^2 \, dxdt + C\Delta t. \end{aligned}$$

Note that we needed here the fact, that $\int_0^T \int_{\mathbb{R}^d} e^{-\alpha t} |u - u_h|^2 \, dxdt < \infty$ (see (3.17)). Decompose E as $E = E_1 + E_2 + E_3$ with

$$\begin{aligned} E_1 &= \frac{1}{\Delta t} \sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}_h} \int_{t^n}^{t^{n+1}} \int_K \theta(t) \left[\eta(u_K^{n+1}) - \eta(u_K^n)\right] dxdt, \\ E_2 &= \frac{1}{\Delta t} \sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}_h} \int_{t^n}^{t^{n+1}} \int_K \theta(t) \left[\nabla\eta(u(x,t)) - \nabla\eta(u(x,t^{n+1}))\right] \cdot \left[u_K^{n+1} - u_K^n\right] dxdt, \\ E_3 &= -\frac{1}{\Delta t} \sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}_h} \int_{t^n}^{t^{n+1}} \int_K \theta(t) \nabla\eta(u(x,t)) \cdot (u_K^{n+1} - u_K^n) \, dxdt. \end{aligned}$$

If we apply (H.2) in Assumption 3.1, we infer using (a) in Proposition 3.2 that

$$\begin{aligned} E_1 &\le -Q_h + \int_0^T \int_{\mathbb{R}^d} \theta \nabla\eta(u_h) \cdot B(u_h) \, dxdt + C\Delta t \int_0^T \int_{\mathbb{R}^d} |u_h - \bar{u}|^2 \, dxdt \\ &\le -Q_h + \int_0^T \int_{\mathbb{R}^d} \theta \nabla\eta(u_h) \cdot B(u_h) \, dxdt + C\Delta t \\ &\qquad \text{(here we used (b) in Proposition 3.2).} \end{aligned}$$

Proceeding similarly as for the term I_2, one obtains, with the help of (4.1) and (3.19),

$$\begin{aligned} E_2 &\le C \left(\int_0^T \int_{\mathbb{R}^d} |\partial_t u|^2 \, dxdt\right)^{1/2} \left(\sum_{n\in\mathcal{N}} \sum_{K\in\mathcal{T}_h} \theta^n \, \Delta t \, |K| \, |u_K^{n+1} - u_K^n|^2\right)^{1/2} \\ &\le C(\Delta t)^{1/2} (Q_h)^{1/2} + C\Delta t \\ &\le \frac{Q_h}{4} + C\Delta t. \end{aligned}$$

From (3.8) and (3.12) follows

$$
\begin{aligned}
E_3 = \quad & \sum_{n\in\mathcal{N}}\sum_{K\in\mathcal{T}}\sum_{e\in\mathcal{E}(K)} |e|\left[g^n_{K,e}(u^n_K,u^n_{K_e}) - g^n_{K,e}(u^n_K,u^n_K)\right] \\
& \cdot \int_{t^n}^{t^{n+1}} \theta(t) \int_K \frac{1}{|K|}\nabla\eta(u)\,dxdt \\
& - \int_0^T \int_{\mathbb{R}^d} \theta\nabla\eta(u)\cdot B(u_h)\,dxdt.
\end{aligned}
$$

Define a new term

$$
\begin{aligned}
\overline{E}_3 = & \sum_{n\in\mathcal{N}}\sum_{K\in\mathcal{T}}\sum_{e\in\mathcal{E}(K)} |e|\big[g^n_{K,e}(u^n_K,u^n_{K_e}) - g^n_{K,e}(u^n_K,u^n_K)\big] \\
& \cdot \int_{t^n}^{t^{n+1}} \theta\left\{\frac{1}{|K|}\int_K \nabla\eta(u)\,dx - \frac{1}{|e|}\int_e \nabla\eta(u)\,d\sigma\right\}dt.
\end{aligned}
$$

Then, we have

$$
E_3 = P + \overline{E}_3 - \int_0^T \int_{\mathbb{R}^d} \theta\nabla\eta(u)\cdot B(u_h)\,dxdt. \tag{4.4}
$$

The term $\overline{E}_3$ can be estimated, using (3.7), as follows:

$$
\begin{aligned}
\overline{E}_3 \le\ & Ch^{1/2}\sum_{n\in\mathcal{N}}\sum_{K\in\mathcal{T}}\sum_{e\in\mathcal{E}(K)} |e|^{1/2}\big|g^n_{K,e}(u^n_K,u^n_{K_e}) - g^n_{K,e}(u^n_K,u^n_K)\big| \\
& \int_{t^n}^{t^{n+1}} \theta(t)\left(\int_K |Du|^2\,dx\right)^{1/2} dt \\
\le\ & Ch^{1/2}\sum_{n\in\mathcal{N}}\sum_{K\in\mathcal{T}}\sum_{e\in\mathcal{E}(K)} (\Delta t\,|e|)^{1/2}\big|g^n_{K,e}(u^n_K,u^n_{K_e}) - g^n_{K,e}(u^n_K,u^n_K)\big| \\
& \cdot\left(\max_{[t^n,t^{n+1}]}\theta(t)\right)\left(\int_{t^n}^{t^{n+1}}\int_K |Du|^2\,dxdt\right)^{1/2} \\
\le\ & Ch^{1/2}(Q_h)^{1/2}\left(\int_0^T\int_{\mathbb{R}^d} |Du|^2\,dxdt\right)^{1/2} \quad \text{(here we used (3.4))} \\
\le\ & \frac{Q_h}{4} + Ch.
\end{aligned}
$$

Finally, the conclusion follows from (4.3), the estimates for $I_1, I_2, I_3, E_1, E_2, \overline{E}_3$, and (4.4). □

4.2. ‘. The main theorem The assertions of Proposition 4.1, Lemma 4.2, and Lemma 4.3 are summarized in the error estimate given in the next theorem.

THEOREM 4.4. *Let u be the classical solution of the Cauchy problem* (1.1), (1.2), *satisfying Assumption* 1.1. *Let further the numerical fluxes $g^n_{K,e}$ and $q^n_{K,e}$ have the properties* (3.10), (3.11) *and* (3.13), (3.15), *respectively. Then, for the finite volume approximation u_h defined by* (3.8), (3.9) *that obeys Assumption* 3.1 *and the mesh which satisfies* (3.1), (3.2), (3.3), *the a priori error estimate*

$$
a\int_0^T\int_{\mathbb{R}^d} e^{-\alpha t}|u-u_h|^2\,dxdt + Q_h \le C(\Delta t + h)
$$

holds for a constant C which doesn't depend on the mesh. The constant α is given by (2.8)*, the constant a by* (2.4)*, and the term Q_h by* (3.16)*.*

Proof. From Lemma 4.2 and Lemma 4.3 we get

(4.5)
$$\langle \nu_h, \theta\rangle - \langle \mu_h, \psi\rangle \leq P + R - \frac{1}{2}Q_h + \frac{a}{2}\int_0^T \int_{\mathbb{R}^d} e^{-\alpha t}|u-u_h|^2\,dxdt + C(\Delta t + h).$$

Taking into account the consistency (3.10) and conservation (3.11) properties of the flux $g^n_{K,e}$, one obtains

$$\begin{aligned}
&\frac{1}{2}\sum_{i=1}^{d} n^i_{K,e}\big(G(u^n_K) - G(u^n_{K_e})\big) + g^n_{K,e}(u^n_K, u^n_{K_e}) - g^n_{K,e}(u^n_K, u^n_K)\\
&= \frac{1}{2}\big[g^n_{K,e}(u^n_K, u^n_K) - g^n_{K,e}(u^n_{K_e}, u^n_{K_e})\big] + g^n_{K,e}(u^n_K, u^n_{K_e}) - g^n_{K,e}(u^n_K, u^n_K)\\
&= \frac{1}{2}\big[g^n_{K,e}(u^n_K, u^n_{K_e}) - g^n_{K,e}(u^n_K, u^n_K)\big] - \frac{1}{2}\big[g^n_{K_e,e}(u^n_{K_e}, u^n_K) - g^n_{K_e,e}(u^n_{K_e}, u^n_{K_e})\big].
\end{aligned}$$

After rearranging the sums in P and R, we obtain that $P+R=0$. Now, the conclusion follows from (4.5) and Proposition 4.1. □

As discussed in section 3.2 after Proposition 3.2 one can improve the weak derivative estimate in the cell entropy inequality in (H.2). This is done in the concluding corollary.

COROLLARY 4.5. *Under the assumptions of Theorem* 4.4*, it is*

$$\sum_{t^{n+1}\leq T/2}\ \sum_{K\in\mathcal{T}_h}\ \sum_{e\in\mathcal{E}(K)} \Delta t\,|K| \left|\frac{g^n_{K,e}(u^n_K, u^n_{K_e}) - g^n_{K,e}(u^n_K, u^n_K)}{h}\right|^2 \leq C.$$

Proof. From $Q_h \leq Ch$ and (3.5) we deduce

$$\sum_{n\in\mathcal{N}}\ \sum_{K\in\mathcal{T}}\ \sum_{e\in\mathcal{E}(K)} \theta^n\,\Delta t\,|K| \left|\frac{g^n_{K,e}(u^n_K, u^n_{K_e}) - g^n_{K,e}(u^n_K, u^n_K)}{h}\right|^2 \leq C.$$

Because of

$$\theta^n \geq \frac{1}{\Delta t}\int_{t^n}^{t^{n+1}} e^{-\alpha t^{n+1}}T/2\,dt \geq \frac{T}{2}e^{-\alpha T/2},$$

for $t^{n+1}\leq T/2$, we get the statement. □

5. Applications. To apply Theorem 4.4 the Assumptions 1.1, 3.1 have to established. Although the latter assumption for the numerical scheme is reasonable, it is hard to verify it for general systems of type (1.1). In the concluding section we discuss subclasses of (1.1) and corresponding finite-volume discretizations such that both assumptions can be satisfied at least in part.

5.1. Monotone schemes for weakly coupled systems. We shall now apply the theory previously developed in this paper to the class of weakly coupled systems with bounded source terms. The system (1.1) is called weakly coupled if the flux functions $G_i = (G_{i1}(u), \ldots, G_{im}(u))^T$, $i = 1, \ldots, d$, satisfy

(5.1)
$$G_{ik}(u) = G_{ik}(u_k) \quad (k = 1, \ldots, m).$$

The coupling is only due to the source term vector B. For simplicity assume $\mathcal{U} = \mathbb{R}^m$. As before let $\bar{u} \in \mathbb{R}^m$ with $B(\bar{u}) = 0$ and assume that there is a constant $\beta > 0$ such that

$$|\nabla B_k(w)| \le \beta \quad (w \in \mathbb{R}^m,\ k = 1, \dots, m). \tag{5.2}$$

In this case the growth of the solution can be controlled and there is for each $T > 0$ a unique Kruzkov solution $u \in L^\infty(0, T; [L^\infty(\mathbb{R}^d) \cap BV(\mathbb{R}^d)]^m)$ of the Cauchy problem provided that we have $u_0 \in [L^\infty(\mathbb{R}^d) \cap BV(\mathbb{R}^d)]^m$ [24]. Moreover, due to (5.1), entropy tuples can be constructed by

$$\eta(w) = \sum_{k=1}^{m} \eta_k(w_k),\ q_i(w) = \sum_{k=1}^{m} q_{ik}(w_k) \quad (w \in \mathbb{R}^m,\ i = 1, \dots, d) \tag{5.3}$$

such that $\eta_k \in C^3(\mathbb{R})$ are uniformly convex functions and

$$q_{ik} = q_{ik}(w_k) = \int_{\bar{u}}^{w_k} \eta_k'(z) G_{ik}'(z)\, dz \quad (k = 1, \dots, m,\ i = 1, \dots, d).$$

Of course a scalar inhomogeneous conservation law can be written in terms of a weakly coupled system, but moreover there are physically relevant examples of weakly coupled systems with $m > 1$ that admit global-in-time classical solutions for initial data close to a constant state $\bar{u}$ [37].

To discretize the initial value problem for a weakly coupled system we use the finite volume scheme (3.8) such that the numerical flux function $g_{K,e}^n : \mathbb{R}^{2m} \to \mathbb{R}^m$ satisfies (3.10), (3.11) for all $n \in \mathcal{N}$, $K \in \mathcal{T}_h$, $e \in \mathcal{E}(K)$. Moreover we suppose that we have

$$g_{K,e}^n(w, \tilde{w}) = (h_{K,e}^n(w_1, \tilde{w}_1), \dots, h_{K,e}^n(w_m, \tilde{w}_m))^T \quad (w, \tilde{w} \in \mathbb{R}^m), \tag{5.4}$$

where $h_{K,e}^n$ is a scalar locally Lipschitz continuous numerical flux function, i.e., for all $M > 0$, there exists a constant $L_G(M) > 0$, such that we have for all $z_1, z_2, \tilde{z}_1, \tilde{z}_2 \in [-M, M]$

$$|h_{K,e}^n(z_1, z_2) - h_{K,e}^n(\tilde{z}_1, \tilde{z}_2)| \le L_G(M)\big(|z_1 - \tilde{z}_1| + |z_2 - \tilde{z}_2|\big). \tag{5.5}$$

We suppose that $h_{K,e}^n$ is a monotone flux, i.e., we have for all $n \in \mathcal{N}$, $K \in \mathcal{T}_h$, $e \in \mathcal{E}(K)$, $z_1, z_2 \in \mathbb{R}$

$$\frac{\partial}{\partial z_2} h_{K,e}^n(z_1, z_2) \le 0. \tag{5.6}$$

Finally, let there be a numerical entropy flux function $q_{K,e}^n$ for $g_{K,e}^n$ such that

$$\text{(3.13), (3.14), and (3.15) hold.} \tag{5.7}$$

Taking the Lax–Friedrichs flux or the Engquist–Osher flux for $h_{K,e}^n$ provides us with examples of fluxes that can satisfy all above conditions [18].

The property (5.6) is fundamental to ensure the L^∞-stability of a finite volume scheme, and the following statement can be found in any textbook on the subject (e.g., [18]). Let $M > 0$ and $K \in \mathcal{T}_h$. Assume that $z \in \mathbb{R}$ and $z_e \in \mathbb{R}$, $e \in \mathcal{E}(K)$, are from $[\bar{z}-M,\bar{z}+M]$ for $\bar{z}\in\mathbb{R}$. Then there exists a constant c_0 depending only on the mesh such that under the CFL-like time restriction

$$\Delta t \leq \frac{c_0}{L_G(M)}h \tag{5.8}$$

we have

$$z - \frac{\Delta t}{|K|}\sum_{e\in\mathcal{E}(K)} |e| h^n_{K,e}(z,z_e) \in [\bar{z}-M,\bar{z}+M]. \tag{5.9}$$

Monotone finite volume schemes for weakly coupled systems has been analyzed in [14, 25] by variants of Diperna's theory of measure-valued solutions and Kruzkov's L^1-stability estimate for scalar equations. For the Kruzkov solution it is shown that the approximation u_h obtained by the monotone finite volume scheme converges and satisfies the estimate

$$\|u-u_h\|_{L^1(Q\times[0,T])} \leq Ch^{1/4}$$

on each compact subset $Q\subset\mathbb{R}^d$. Theorem 4.4 allows us to prove a better estimate with respect to the order if u is a classical solution.

Theorem 5.1. *Consider the Cauchy problem* (1.1), (1.2) *for fluxes G_i, $i=1,\ldots,d$, and source B such that* (5.1) *and* (5.2) *hold. Assume that this Cauchy problem has a classical solution u such that Assumption* 1.1 *for u (and u_0) is satisfied with some $\bar{u}\in\mathbb{R}^m$.*

Let for $M=\exp(\beta T)\|u_0-\bar{u}\|_{L^\infty(\mathbb{R}^d)}$ the time step restriction (5.8) *hold and assume the mesh conditions* (3.1), (3.2), (3.3).

Let a finite volume approximation u_h obtained by a finite volume scheme (3.8) *with numerical fluxes satisfying* (3.10), (3.11), (5.4), (5.5), (5.6), *and* (5.7) *be given. Then there exists constants $C_1, C_2>0$ such that we have*

$$\|u_h(.,t)-\bar{u}\|_{L^\infty(\mathbb{R}^d)} \leq M \quad (t\in[0,T]), \tag{5.10}$$

$$\|u_h(.,t)-\bar{u}\|_{L^2(\mathbb{R}^d)} \leq \exp(C_1\beta T)\|u_0-\bar{u}\|_{L^2(\mathbb{R}^d)} \quad (t\in[0,T]), \tag{5.11}$$

and

$$\|u-u_h\|_{L^2(\mathbb{R}^d\times[0,T])} \leq C_2 h^{1/2}. \tag{5.12}$$

The constant C_1 depends on B and the constant C_2 depends on T, G_i, β, and u_0 but not on h.

Proof. Assume that we have have proven for some $n\in\mathcal{N}$

$$\|u_h(.,t)-\bar{u}\|_{L^\infty(\mathbb{R}^d)} \leq \exp\left(\beta t^n\right)\|u_0-\bar{u}\|_{L^\infty(\mathbb{R}^d)}. \tag{5.13}$$

Since Δt satisfies the condition (5.8) we deduce from (5.2) and (5.9) for $k=1,\ldots,m$ with $\bar{z}=\bar{u}_k$

$$\begin{aligned}|u^{n+1}_{K,k}-\bar{u}_k| &\leq \left| u^n_{K,k}-\bar{u}_k - \frac{\Delta t}{|K|}\sum_{e\in\mathcal{E}(K)}|e|h^n_{K,e}(u^n_{K,k},u^n_{K_e,k})\right| + \Delta t\beta\|u_h(.,t^n)-\bar{u}\|_{L^\infty(\mathbb{R}^d)}\\ &\leq (1+\Delta t\beta)\|u_h(.,t^n)-\bar{u}\|_{L^\infty(\mathbb{R}^d)}\\ &\leq \exp\left(\beta t^{n+1}\right)\|u_0-\bar{u}\|_{L^\infty(\mathbb{R}^d)}.\end{aligned}$$

The statement (5.10) follows now by induction.

Finite volume schemes for weakly coupled systems are analyzed in [25]. In Lemma 4.4 of [25] it has been proven under the assumptions of the theorem that (H.2) in Assumption 3.1 holds provided u_h is bounded in L^∞ and we choose our entropy tuple $(\eta, q_1, \dots, q_d)$ according to $\eta_k(w_k) = (w_k - \bar{u})^2/2$, $k = 1, \dots, m)$, in (5.3). This implies in particular (5.11) if we proceed iteratively like for the L^∞-bound. Since Assumption 1.1 and 3.1 hold we can apply Theorem 4.4 and get (5.12). □

5.2. System of elastodynamics. The next application is the system of elastodynamics in one dimension. For the unknown vector $u = (w, v)^T$ with strain $w : \mathbb{R} \times [0, T) \to [-1, \infty)$ and velocity $v : \mathbb{R} \times [0, T) \to \mathbb{R}$ the system is given by

$$\partial_t w - \partial_x v = 0, \quad \partial_t v - \partial_x \sigma(w) = 0 \text{ in } \mathbb{R} \times (0, T), \tag{5.14}$$

$$w(x, 0) = w_0(x), \qquad v(x, 0) = v_0(x) \text{ in } \mathbb{R}. \tag{5.15}$$

The stress-strain relation $\sigma \in C^2(\mathbb{R})$ is supposed to satisfy $\sigma'(w) > 0$, $w\,\sigma''(w) > 0$ for all $w \in \mathbb{R}$. Then the system has the strictly convex entropy pair $\eta(w, v) = \frac{1}{2}v^2 + \int^w \sigma(s)\,ds$, $q(w, v) = -v\sigma(w)$. It is known (see [7]) for $N > 0$ that the compact set

$$S_N = \{(w, v) \subset [-1, \infty) \times \mathbb{R} : |y(w, v)| \le N, \ |z(w, v)| \le N\} \tag{5.16}$$

is convex and invariant for the underlying system, where $y(w, v) = -\int_{w_0}^{w} \sqrt{\sigma'(s)}\,ds + v$, $z(w, v) = -\int_{w_0}^{w} \sqrt{\sigma'(s)}\,ds - v$ are the Riemann invariants.

Moreover S_N is invariant for the discrete solution operator defined through the Lax–Friedrichs scheme

$$u_i^{n+1} = u_i^n - \frac{\alpha}{2}\big(f(u_{i+1}^n) - f(u_{i-1}^n)\big) + \frac{1}{2}\big(u_{i-1}^n - 2u_i^n + u_{i+1}^n\big),$$

provided $\alpha \sup_{(w,v)\in S_N} \sqrt{\sigma'(w)} \le 1$. Here we used $f(u) = (-v, -\sigma(w))^T$. This can be shown in the analogous way as it was done in [12] for the appropriate invariant regions of the p-system.

As the numerical scheme for (5.14), (5.15) we consider now

$$u_i^{n+1} = u_i^n - \lambda\big[g(u_i^n, u_{i+1}^n) - g(u_{i-1}^n, u_i^n)\big], \tag{5.17}$$

$$u_i^0 = \frac{1}{\Delta x}\int_{x_i}^{x_{i+1}} u_0(x)\,dx \tag{5.18}$$

with the uniform mesh parameters Δx, $\Delta t > 0, \lambda = \frac{\Delta t}{\Delta x}$. The numerical flux is given by $g(u_1, u_2) = \frac{1}{2}[f(u_1) + f(u_2)] + \frac{1}{2\mu}(u_1 - u_2)$, where μ is a positive parameter. For the mesh we assume only that (3.3) holds. Since (5.17) may be rewritten as

$$\begin{aligned} u_i^{n+1} &= u_i^n - \frac{\lambda}{2}\big[f(u_{i+1}^n) - f(u_{i-1}^n)\big] + \frac{\lambda}{2\mu}\big(u_{i-1}^n - 2u_i^n + u_{i+1}^n\big) \\ &= \Big(1 - \frac{\lambda}{\mu}\Big)u_i^n + \frac{\lambda}{\mu}\Big[u_i^n - \frac{\mu}{2}\big(f(u_{i+1}^n) - f(u_{i-1}^n)\big) + \frac{1}{2}\big(u_{i-1}^n - 2u_i^n + u_{i+1}^n\big)\Big], \end{aligned}$$

one infers that S_N is an invariant region for (5.17) as well, if $\lambda/\mu \le 1$ and $\mu \sup_{(w,v)\in S_N} \sqrt{\sigma'(w)} \le 1$.

LEMMA 5.2. *Let S_N be an arbitrary invariant region of the form* (5.16) *and suppose that the parameters λ, μ satisfy $0 < \mu \leq \mu_0,\ \ \lambda/\mu \leq 1,\ \ \mu \sup_{(w,v)\in S_N} \sqrt{\sigma'(w)} \leq 1$,*

$$\frac{2\lambda(1+\gamma)L^2}{\mu l} \leq 1, \tag{5.19}$$

for some positive constants μ_0, L, l, γ (defined below in the proof) depending only on S_N and σ. Thereby L/μ is the Lipschitz constant for g on S_N. If $u_0 \in L^\infty(\mathbb{R})$ takes values in S_N, then we have for the scheme (5.17), (5.18)

$$\begin{aligned}
&(A1) \quad u_i^n \in S_N,\\
&(A2) \quad \eta(u_i^{n+1}) - \eta(u_i^n) + \lambda[q_h(u_i^n, u_{i+1}^n) - q_h(u_{i-1}^n, u_i^n)]\\
&\qquad\qquad + L^2\Big(\frac{\lambda}{\mu}\Big)^2\big(|u_{i+1}^n - u_i^n|^2 + |u_i^n - u_{i-1}^n|^2\big) \leq 0
\end{aligned}$$

for all $i \in \mathbb{Z},\ n \in \mathcal{N}$.

The numerical entropy flux in this case is $q_h(u_1,u_2) := \frac{1}{2}[q(u_1)+q(u_2)] + \frac{1}{2\mu}[\eta(u_1) - \eta(u_2)]$.

Proof. (A1) has already been proved above. By the Taylor expansion, we get

$$\begin{aligned}
E_{in} &:= \eta(u_i^{n+1}) - \eta(u_i^n) + \lambda\big[q_h(u_i^n, u_{i+1}^n) - q_h(u_{i-1}^n, u_i^n)\big]\\
&= \nabla\eta(u_i^n)\cdot\big[-\lambda\big(g(u_i^n,u_{i+1}^n) - g(u_{i-1}^n,u_i^n)\big)\big] + \lambda\big[q_h(u_i^n, u_{i+1}^n) - q_h(u_{i-1}^n, u_i^n)\big]\\
&\quad + \frac{1}{2}\lambda^2\big[g(u_i^n,u_{i+1}^n) - g(u_{i-1}^n,u_i^n)\big]^T \nabla^2\eta(\xi)\,\big[g(u_i^n,u_{i+1}^n) - g(u_{i-1}^n,u_i^n)\big]\\
&= E_{in}^{(1)} + E_{in}^{(2)} + \frac{1}{2}\lambda^2\big[g(u_i^n,u_{i+1}^n) - g(u_{i-1}^n,u_i^n)\big]^T \nabla^2\eta(\xi)\,\big[g(u_i^n,u_{i+1}^n) - g(u_{i-1}^n,u_i^n)\big],
\end{aligned}$$

where

$$\begin{aligned}
E_{in}^{(1)} &= \lambda\nabla\eta(u_i^n)\cdot\big[g(u_i^n,u_i^n) - g(u_i^n,u_{i+1}^n)\big] + \lambda\big[q_h(u_i^n,u_{i+1}^n) - q_h(u_i^n,u_i^n)\big],\\
E_{in}^{(2)} &= \lambda\nabla\eta(u_i^n)\cdot\big[g(u_{i-1}^n,u_i^n) - g(u_i^n,u_i^n)\big] + \lambda\big[q_h(u_i^n,u_i^n) - q_h(u_{i-1}^n,u_i^n)\big].
\end{aligned}$$

Define $H(a,b) := \lambda\nabla\eta(a)\cdot[g(a,a) - g(a,b)] + \lambda[q_h(a,b) - q_h(a,a)]$. In our particular case, one easily verifies that for $a = (a_1,a_2),\ b = (b_1,b_2)$,

$$\begin{aligned}
H(a,b) = \frac{\lambda}{2}\Big[&\sigma(a_1)(b_2 - a_2) + a_2\big(\sigma(b_1) - \sigma(a_1)\big) + \frac{1}{\mu}\sigma(a_1)(b_1 - a_1) + \frac{1}{\mu}a_2(b_2 - a_2)\\
&+ a_2\sigma(a_1) - b_2\sigma(b_1) + \frac{1}{2\mu}a_2^2 + \frac{1}{\mu}\int^{a_1}\sigma(s)\,ds - \frac{1}{2\mu}b_2^2 - \frac{1}{\mu}\int^{b_1}\sigma(s)\,ds\Big],
\end{aligned}$$

$$\nabla_b^2 H(a,b) = -\frac{\lambda}{\mu}\begin{bmatrix} \frac{1}{2}\sigma'(b_1) - \frac{\mu}{2}(a_2 - b_2)\sigma''(b_1) & \frac{\mu}{2}\sigma'(b_1)\\ \frac{\mu}{2}\sigma'(b_1) & \frac{1}{2}\end{bmatrix} =: -\frac{\lambda}{\mu}A(a,b).$$

Moreover, $H(a,a) = 0,\ \ \nabla_b H(a,a) = 0$. Since $A(a,b)$ is positive definite for $\mu = 0$ and $\inf_{S_N}\sigma' > 0$, we conclude that there exist positive constants $\mu_0,\ l$ with the property $\lambda_2 \geq l$ for all $0 \leq \mu \leq \mu_0$ and $a,b \in S$, where λ_2 is the lower eigenvalue of $A(a,b)$. Summarizing the considerations presented above, one obtains $H(a,b) \leq -\frac{\lambda}{\mu}\cdot\frac{l}{2}|a-b|^2$ for all $a,b \in S_N$. From $E_{in}^{(1)} = H(u_i^n, u_{i+1}^n)$ we conclude $E_{in}^{(1)} \leq -\frac{\lambda}{\mu}\cdot\frac{l}{2}|u_{i+1}^n - u_i^n|^2$.

Considering $\bar{H}(a,b) := \lambda\nabla\eta(a)\cdot[g(b,a)-g(a,a)]+\lambda[q_h(a,a)-q_h(b,a)]$ in the similar way, we have $E_{in}^{(2)} \le -\frac{\lambda}{\mu}\cdot\frac{l}{2}|u_i^n-u_{i-1}^n|^2$. Let $L>0$ be a constant which depends on S_N, such that L/μ is a Lipschitz constant for g on S_N. Finally, by (5.19), with $\gamma = \max\{\sup_{a\in S}\sigma'(a_1),1\}$, it is

$$\begin{aligned} E_{in} &\le \left(-\frac{\lambda l}{2\mu}+\left(\frac{\lambda}{\mu}\right)^2\gamma L^2\right)\left(|u_{i+1}^n-u_i^n|^2+|u_i^n-u_{i-1}^n|^2\right)\\ &\le -L^2\left(\frac{\lambda}{\mu}\right)^2\left(|u_{i+1}^n-u_i^n|^2+|u_i^n-u_{i-1}^n|^2\right). \qquad \square \end{aligned}$$

Taking into account (A1), (A2) we see that Assumption (3.1) can be satisfied for $d=1$. Note that the scheme (5.17), (5.18) matches with the multidimensional scheme (3.8), if one takes $K=(e_-,\,e_+)$, $\mathcal{E}(K)=\{e_-,e_+\}, |e_\pm|=1$, and $n_{K_{e_\pm}}=\pm1$.

Thus Theorem (4.4) applies and we have an error estimate for the Lax–Friedrichs finite volume approximation for (5.14), (5.15) if the latter has a classical solution (which for general smooth initial data can only be guaranteed for T small).

THEOREM 5.3. *Suppose that the Cauchy problem* (5.14), (5.15) *has a classical solution u that satisfies Assumption* 1.1 *for $d=1$ with S having the form* (5.16). *Furthermore let λ, μ satisfy the conditions stated in the Lemma* 5.2.

Then for the numerical solution u_h defined from the scheme (5.17), (5.18) *and the uniform mesh satisfying* (3.3), *the error estimate from Theorem* 4.4 *holds with the constant C depending only on u, c_1, σ, and S.*

5.3. Entropy conservative and entropy dissipative schemes for arbitrary sytems. We consider finally general systems (1.1) of balance laws and suppose that the initial value problem (1.1), (1.2) has a classical solution u that obeys Assumption 1.1.

We shall construct a finite volume scheme that satisfies the cell entropy inequality (H.2) together with the weak H^1-bound. The technique relies on the auxiliary construction of a scheme that satisfies a cell entropy equation, i.e., provides no entropy dissipation. Adding of artificial viscosity then leads to an entropy dissipative scheme. The scheme will be constructed in three steps starting from two semidiscrete versions to exemplify the idea behind the construction and a final step in section 5.3.3. The final finite volume scheme will be given as an implicit-in-time scheme. Throughout the section we assume $d=3$.

5.3.1. Entropy variables and entropy conservative schemes. As the first step to derive the entropy conservative schemes we introduce entropy variables [9]. Since the entropy η is supposed to be uniformly convex function the relation

$$\tilde{u}(u) = \nabla\eta(u) \qquad (u\in\mathcal{U})$$

defines a change of variables on $\mathcal{U}$. The function $\tilde{u}=\tilde{u}(u)$ is called entropy variable. We define furthermore the entropy variable state space $\tilde{\mathcal{U}}=\tilde{u}(\mathcal{U})$ and denote for $i=1,2,3$

$$\tilde{G}_i=\tilde{G}_i(\tilde{u}) := G_i(u), \quad \tilde{q}_i=\tilde{q}_i(\tilde{u}) := q_i(u).$$

Thus we can in particular rewrite the system (1.1) in the equivalent form (neglecting the source term B for simplicity)

$$\partial_t u+\sum_{i=1}^{3}\partial_i\tilde{G}_i(\tilde{u}) = 0 \text{ in } \mathbb{R}^3\times(0,T).$$

It turns out to be convenient to work with the function

$$\psi(\tilde{u}) = \begin{pmatrix} \psi_1(\tilde{u}) \\ \psi_2(\tilde{u}) \\ \psi_3(\tilde{u}) \end{pmatrix} := \begin{pmatrix} \tilde{u} \cdot \tilde{G}_1(\tilde{u}) - \tilde{q}_1(\tilde{u}) \\ \tilde{u} \cdot \tilde{G}_2(\tilde{u}) - \tilde{q}_2(\tilde{u}) \\ \tilde{u} \cdot \tilde{G}_3(\tilde{u}) - \tilde{q}_3(\tilde{u}) \end{pmatrix} \quad (\tilde{u} \in \tilde{\mathcal{U}}). \tag{5.20}$$

We observe that ψ satisfies

$$\tilde{G}_i(\tilde{u}) = \nabla\psi_i(\tilde{u}) \quad (i = 1, 2, 3,\ \tilde{u} \in \tilde{\mathcal{U}}). \tag{5.21}$$

Let us consider for $t \in [0, T]$ the following semidiscrete finite volume scheme

$$u'_K(t) = -\frac{1}{|K|} \sum_{e \in \mathcal{E}(K)} |e| \tilde{g}_{K,e}(\tilde{u}_K(t), \tilde{u}_{K_e}(t)), \qquad u_K(0) = \frac{1}{|K|} \int_K u_0(x)\, dx. \tag{5.22}$$

The numerical flux function $\tilde{g}_{K,e} : \mathbb{R}^{2m} \to \mathbb{R}^m$ is given for $\tilde{u}_1, \tilde{u}_2 \in \tilde{\mathcal{U}}$ by

$$\tilde{g}_{K,e}(\tilde{u}_1, \tilde{u}_2) = \sum_{i=1}^{3} n^i_{K,e} \tilde{g}^*_i(\tilde{u}_1, \tilde{u}_2), \tag{5.23}$$

where $n_{K,e} = (n^1_{K,e}, n^2_{K,e} n^3_{K,e})^T$ is as before the unit outward normal of the edge e of K and $\tilde{g}^*_i$, $i = 1, 2, 3$ is given by the three-dimensionally generalized *Tadmor flux*

$$\tilde{g}^*_i(\tilde{u}_1, \tilde{u}_2) = \int_0^1 \tilde{G}_i(\tilde{u}_1 + s(\tilde{u}_1 - \tilde{u}_2))\, ds. \tag{5.24}$$

The vector $\tilde{u}_K(t)$ in (5.22) is given for $t \in [0, T]$ by

$$\tilde{u}_K(t) = \tilde{u}(u_K(t)).$$

The flux function $\tilde{g}^*_i$ has been introduced in [29] to construct entropy conservative schemes in one space dimension. An overview on this type of scheme can be found in [30].

THEOREM 5.4. *Let there be a solution $u_K : [0, T] \to \mathbb{R}^m$ of* (5.22). *Then for $K \in \mathcal{T}$ and $t \in [0, T]$ the function u_K satisfies the cell entropy equation*

$$\frac{d}{dt}\eta(u_K(t)) + \frac{1}{|K|} \sum_{e \in \mathcal{E}(K)} |e| \tilde{q}_{K,e}(\tilde{u}_K(t), \tilde{u}_{K_e}(t)) = 0. \tag{5.25}$$

The numerical entropy flux $\tilde{q}_{K,e} : \mathbb{R}^{2m} \to \mathbb{R}$ is given for $\tilde{u}_1, \tilde{u}_2 \in \tilde{\mathcal{U}}$ by

$$\tilde{q}_{K,e}(\tilde{u}_1, \tilde{u}_2) = \frac{1}{2}(\tilde{u}_1 + \tilde{u}_2) \cdot \tilde{g}_{K,e}(\tilde{u}_1, \tilde{u}_2) - \frac{1}{2} n_{K,e} \cdot (\psi(\tilde{u}_2) + \psi(\tilde{u}_1)). \tag{5.26}$$

$\tilde{q}_{K,e}$ is consistent with the entropy flux, i.e.,

$$\tilde{q}_{K,e}(\tilde{u}, \tilde{u}) = \sum_{i=1}^{3} n^i_{K,e} \tilde{q}_i(\tilde{u}) \quad (\tilde{u} \in \tilde{\mathcal{U}}).$$

Proof. From (5.21) and the definition (5.24) of the Tadmor flux we observe for $i = 1, 2, 3$ and $t \in [0, T]$

$$\begin{aligned} \psi_i(\tilde{u}_{K_e}(t)) - \psi_i(\tilde{u}_K(t)) &= \int_0^1 \nabla\psi_i(\tilde{u}_K(t) + s(\tilde{u}_{K_e}(t) - \tilde{u}_K(t))) \cdot (\tilde{u}_{K,e}(t) - \tilde{u}_K(t))\, ds \\ &= \left(\int_0^1 \tilde{G}_i(\tilde{u}_K(t) + s(\tilde{u}_{K_e}(t) - \tilde{u}_K(t)))\, ds \right) \cdot (\tilde{u}_{K_e}(t) - \tilde{u}_K(t)) \\ &= \tilde{g}^*_i(\tilde{u}_K(t), \tilde{u}_{K_e}(t)) \cdot (\tilde{u}_{K_e}(t) - \tilde{u}_K(t)). \end{aligned}$$

Thus we compute with the definition of the numerical entropy flux $\tilde{q}_{K,e}$

$$\begin{aligned}
&\sum_{e\in\mathcal{E}(K)} |e|\tilde{q}_{K_e}(\tilde{u}_K(t),\tilde{u}_{K_e}(t))\\
&= \frac{1}{2}\sum_{e\in\mathcal{E}(K)} |e|(\tilde{u}_K(t)+\tilde{u}_{K_e}(t))\cdot\tilde{g}_{K,e}(\tilde{u}_K(t),\tilde{u}_{K_e}(t))\\
&\quad -\frac{1}{2}\sum_{e\in\mathcal{E}(K)} |e|n_{K,e}\cdot(\psi(\tilde{u}_K(t))+\psi(\tilde{u}_{K_e}(t)))\\
&= \frac{1}{2}\sum_{e\in\mathcal{E}(K)} |e|(\tilde{u}_K(t)+\tilde{u}_{K_e}(t))\cdot\tilde{g}_{K,e}(\tilde{u}_K(t),\tilde{u}_{K_e}(t))\\
&\quad -\frac{1}{2}\sum_{e\in\mathcal{E}(K)} |e|n_{K,e}\cdot(\psi(\tilde{u}_{K_e}(t))-\psi(\tilde{u}_K(t)))\\
&= \frac{1}{2}\sum_{e\in\mathcal{E}(K)} |e|(\tilde{u}_K(t)+\tilde{u}_{K_e}(t))\cdot\tilde{g}_{K,e}(\tilde{u}_K(t),\tilde{u}_{K_e}(t))\\
&\quad -\frac{1}{2}\sum_{e\in\mathcal{E}(K)} |e|n_{K,e}\cdot\begin{pmatrix}\tilde{g}_1^*(\tilde{u}_K(t),\tilde{u}_{K_e}(t))\cdot(\tilde{u}_{K_e}(t)-\tilde{u}_K(t))\\ \tilde{g}_2^*(\tilde{u}_K(t),\tilde{u}_{K_e}(t))\cdot(\tilde{u}_{K_e}(t)-\tilde{u}_K(t))\\ \tilde{g}_3^*(\tilde{u}_K(t),\tilde{u}_{K_e}(t))\cdot(\tilde{u}_{K_e}(t)-\tilde{u}_K(t))\end{pmatrix}\\
&= \frac{1}{2}\sum_{e\in\mathcal{E}(K)} |e|(\tilde{u}_K(t)+\tilde{u}_{K_e}(t))\cdot\tilde{g}_{K,e}(\tilde{u}_K(t),\tilde{u}_{K_e}(t))\\
&\quad -\frac{1}{2}\sum_{e\in\mathcal{E}(K)} |e|\tilde{g}_{K,e}(\tilde{u}_K(t),\tilde{u}_{K_e}(t))\cdot(\tilde{u}_{K_e}(t)-\tilde{u}_K(t))\\
&= \sum_{e\in\mathcal{E}(K)} |e|\tilde{g}_{K,e}(\tilde{u}_K(t),\tilde{u}_{K_e}(t))\cdot\tilde{u}_K(t).
\end{aligned}$$

From the last equation we conclude that multiplication of (5.22) with $\tilde{u}_K(t) = \nabla\eta(u_K(t))$ implies (5.25). The consistency of $\tilde{q}_{K,e}$ can be checked in a straightforward manner. □

5.3.2. Entropy dissipative schemes. Based on the results of section 5.3 we shall now propose a class of schemes that satisfies condition (H.2) from Assumption 3.1 written in the semidiscrete case.

For $K \in \mathcal{T}$ and $e \in \mathcal{E}(K)$ let the numbers $\lambda_{K,e} \in \mathbb{R}_{>0}$ be given such that we have for all $K \in \mathcal{T}$ and $e \in \mathcal{E}(K)$ the relation $\lambda_{K_e,e} = \lambda_{K,e}$. Here K_e denotes the volume that shares the edge e with K. We define the entropy dissipative flux $\tilde{g}^{\triangle}_{K,e} : \mathbb{R}^{2m} \to \mathbb{R}^m$ by

$$\tilde{g}^{\triangle}_{K,e}(\tilde{u}_1,\tilde{u}_2) = \tilde{g}_{K,e}(\tilde{u}_1,\tilde{u}_2) + \frac{1}{\lambda_{K,e}}(\tilde{u}_1-\tilde{u}_2) \quad (\tilde{u}_1,\tilde{u}_2 \in \tilde{\mathcal{U}}).$$

Using this (consistent) numerical flux we get for $t \in [0, T]$ the following semidiscrete finite volume scheme to approximate solutions of (1.1), (1.2).

$$u_K'(t) = -\frac{1}{|K|} \sum_{e \in \mathcal{E}(K)} |e| \tilde{g}^{\triangle}_{K,e}(\tilde{u}_K(t), \tilde{u}_{K_e}(t)), \quad u_K(0) = \frac{1}{|K|} \int_K u_0(x)\, dx. \tag{5.27}$$

The construction is based on artificial viscosity and therefore it is possible to get a cell entropy inequality as stated below.

THEOREM 5.5. *Let there be a solution $u_K : [0, T] \to \mathbb{R}^m$ of* (5.27). *Then for $K \in \mathcal{T}$ and $t \in [0, T]$ the function u_K satisfies*

$$\begin{aligned} &\frac{d}{dt}\eta(u_K(t)) + \frac{1}{|K|} \sum_{e \in \mathcal{E}(K)} |e| \tilde{q}^{\triangle}_{K,e}(\tilde{u}_K(t), \tilde{u}_{K_e}(t)) \\ &\qquad = -\frac{1}{2|K|} \sum_{e \in \mathcal{E}(K)} \frac{|e|}{\lambda_{K,e}} |\tilde{u}_{K_e}(t) - \tilde{u}_K(t)|^2 \leq 0. \end{aligned} \tag{5.28}$$

The numerical entropy flux $\tilde{q}^{\triangle}_{K,e} : \mathbb{R}^{2m} \to \mathbb{R}$ is given for $\tilde{u}_1, \tilde{u}_2 \in \mathbb{R}^m$ by

$$\tilde{q}^{\triangle}_{K,e}(\tilde{u}_1, \tilde{u}_2) = \tilde{q}_{K,e}(\tilde{u}_1, \tilde{u}_2) + \frac{1}{2\lambda_{K,e}}(\tilde{u}_1 - \tilde{u}_2) \cdot (\tilde{u}_1 + \tilde{u}_2). \tag{5.29}$$

$\tilde{q}^{\triangle}_{K,e}$ is consistent with the entropy flux, i.e.,

$$\tilde{q}^{\triangle}_{K,e}(\tilde{u}, \tilde{u}) = \sum_{i=1}^{3} n^i_{K,e} \tilde{q}_i(\tilde{u}) \quad (\tilde{u} \in \mathcal{U}).$$

Proof. For $K \in \mathcal{T}$ and $t \in [0, T]$ we consider the term

$$\begin{aligned} &\sum_{e \in \mathcal{E}(K)} \frac{|e|}{\lambda_{K,e}} (\tilde{u}_K(t) - \tilde{u}_{K_e}(t)) \cdot \tilde{u}_K(t) \\ &\qquad = \sum_{e \in \mathcal{E}(K)} \frac{|e|}{2\lambda_{K,e}} |\tilde{u}_K(t) - \tilde{u}_{K_e}(t)|^2 \\ &\qquad + \sum_{e \in \mathcal{E}(K)} \frac{|e|}{2\lambda_{K,e}} (\tilde{u}_K(t) - \tilde{u}_{K_e}(t)) \cdot (\tilde{u}_K(t) + \tilde{u}_{K_e}(t)). \end{aligned}$$

The inequality (5.28) follows as in (the proof of) Theorem 5.4 and using the definition (5.29). □

5.3.3. Fully discrete entropy dissipative schemes. In this final step we propose a class of schemes that satisfies condition (H.2) from Assumption 3.1 in the fully discrete case. Relying on entropy conservative schemes and artificial dissipation these seem to be possible only in an implicit manner. Theorem 4.4 does not apply directly to implicit schemes (5.30) since the theorem is formulated and proven for the explicit case. However, the implicit version can be proven along the same lines.

We rely on the notations from section 5.3.2.

Consider the following fully discrete finite volume scheme for (1.1), (1.2) neglecting the source term for simplicity:

$$\begin{aligned} u_K^{n+1} &= u_K^n - \frac{\Delta t}{|K|} \sum_{e\in\mathcal{E}(K)} |e| \tilde{g}^{\triangle}_{K,e}(\tilde{u}_K^{n,n+1}, \tilde{u}_{K_e}^{n,n+1}), \\ \tilde{u}_K^{n,n+1} &= \int_0^1 \tilde{u}\big(s u_K^{n+1} + (1-s) u_K^n\big)\, ds, \qquad (5.30) \\ u_K^0 &= \frac{1}{|K|} \int_K u_0(x)\, dx. \end{aligned}$$

For this implicit version we get the following theorem.

THEOREM 5.6. *For $\Delta t/h$ sufficiently small there is a solution $u_K^n \in \mathbb{R}^m$ of* (5.30) *for each $n \in \mathcal{N}$ and $K \in \mathcal{T}$.*

The function $u_h : \mathbb{R}^3 \times [0,T] \to \mathbb{R}^m$ defined as in (3.9) *satisfies*

$$\begin{aligned} &\eta(u_K^{n+1}) - \eta(u_K^n) + \frac{\Delta t}{|K|} \sum_{e\in\mathcal{E}(K)} |e| \tilde{q}^{\triangle}_{K,e}(\tilde{u}_K^{n,n+1}, \tilde{u}_{K_e}^{n,n+1}) \qquad (5.31) \\ &\quad + \frac{\Delta t}{2|K|} \sum_{e\in\mathcal{E}(K)} \frac{|e|}{\lambda_{K,e}} \big|\tilde{u}_K^{n,n+1} - \tilde{u}_{K_e}^{n,n+1}\big|^2 \leq 0. \end{aligned}$$

Proof. The proof of existence follows easily with the implicit function theorem.

To prove the cell entropy inequality we multiply (5.30) with $\tilde{u}_K^{n,n+1}$. Then we obtain the numerical entropy flux term and the dissipation term in (5.31) exactly as in the proof of Theorem 5.5 if we interchange $\tilde{u}_K(t)$ with $\tilde{u}_K^{n,n+1}$ (and $\tilde{u}_{K_e}(t)$ with $\tilde{u}_{K_e}^{n,n+1}$). It remains to consider the product

$$\big(u_K^{n+1} - u_K^n\big) \cdot \tilde{u}_K^{n,n+1} = \int_0^1 \nabla\eta\big(s u_K^{n+1} + (1-s) u_K^n\big) \cdot \big(u_K^{n+1} - u_K^n\big)\, ds = \eta(u_K^{n+1}) - \eta(u_K^n).$$

This concludes the proof. □

A WAVENUMBER INDEPENDENT BOUNDARY ELEMENT METHOD FOR AN ACOUSTIC SCATTERING PROBLEM*

S. LANGDON[†] AND S. N. CHANDLER-WILDE[†]

Abstract. In this paper we consider the impedance boundary value problem for the Helmholtz equation in a half-plane with piecewise constant boundary data, a problem which models, for example, outdoor sound propagation over inhomogeneous flat terrain. To achieve good approximation at high frequencies with a relatively low number of degrees of freedom, we propose a novel Galerkin boundary element method, using a graded mesh with smaller elements adjacent to discontinuities in impedance and a special set of basis functions so that, on each element, the approximation space contains polynomials (of degree ν) multiplied by traces of plane waves on the boundary. We prove stability and convergence and show that the error in computing the total acoustic field is $\mathcal{O}(N^{-(\nu+1)}\log^{1/2} N)$, where the number of degrees of freedom is proportional to $N \log N$. This error estimate is independent of the wavenumber, and thus the number of degrees of freedom required to achieve a prescribed level of accuracy does not increase as the wavenumber tends to infinity.

1. Introduction.

High-frequency scattering problems are of enormous interest to the mathematics, physics, and engineering communities, with applications to electromagnetic scattering, radar problems, high frequency acoustics, and geophysical waves. Although these problems have a long pedigree, their numerical solution continues to pose considerable difficulties. Many problems of scattering of time-harmonic acoustic or electromagnetic waves can be formulated as the Helmholtz equation

$$\Delta u + k^2 u = 0, \tag{1.1}$$

in $\mathbb{R}^d \backslash \Omega$, $d = 2, 3$, supplemented with appropriate boundary conditions. Here Ω is the scattering object and $k > 0$ (the wavenumber) is an arbitrary positive constant, proportional to the frequency of the incident wave.

Standard schemes for solving (1.1) become prohibitively expensive as $k \to \infty$. For standard boundary element or finite element schemes, where the approximation space typically consists of piecewise polynomials, the number of degrees of freedom per wavelength must remain fixed in order to maintain accuracy, with the rule of thumb in the engineering literature a requirement for 6 to 10 elements per wavelength. Often in applications this results in excessively large systems when the wavelength is small compared to the size of the obstacle. These difficulties have been well documented; see, for example, [44, 45]. For the finite element method the situation is arguably worse in that additional pollution effects are known to be important [5, 33], these being phase errors in wave propagation across the domain, so that the degrees of freedom per wavelength need to increase somewhat to retain accuracy as k increases.

The development of more efficient numerical schemes for high frequency scattering problems has attracted much recent attention in the literature. In the case of

boundary element methods, a great deal of effort has focused on the fast solution of the large systems which arise, using preconditioned iterative methods (e.g., [22]) combined with fast multipole (e.g., [24, 25]) or fast Fourier transform based methods (e.g., [9, 21]) to carry out the matrix-vector multiplications efficiently. The reduction in the computing cost achieved by the use of these schemes increases the upper limit on the frequency for which accurate results can be obtained in a reasonable time. However, as the size of the system still grows at least linearly with k in two dimensions (2D), quadratically in three dimensions (3D), this upper limit is not removed altogether.

An increasingly popular approach in the literature for higher frequencies is to use either a finite element or a boundary element method in which the approximation space is enriched with plane wave or Bessel function solutions of (1.1), in order to represent efficiently the highly oscillatory solution when k is large. This idea has been applied to both finite element (e.g., [4, 13, 41, 29, 14, 43]) and boundary element schemes [26, 1, 24, 44, 45, 20, 43, 27, 10, 46, 28]. Promising numerical results are reported, but most of the papers are lacking in mathematical analysis, especially with regard to how any error estimates depend on the wavenumber k. As the present paper follows the same general approach of enriching the approximation space, we survey this body of work in a little more detail.

The methods in this category fall approximately into three groups, distinguished by how the enrichment is carried out. In one group the distinguishing feature is that a large number of solutions of the Helmholtz equation are used to form the approximation space. Most commonly the approximation space consists of standard finite element basis functions multiplied by plane waves traveling in a large number of directions, approximately uniformly distributed on the unit circle (in 2D) or sphere (in 3D). This is the approach in the generalized finite element method of Babuška and Melenk [4], the ultra weak variational formulation of Cessenat and Després [13, 14], and the least squares method of Monk and Wang [41]; see also [43, 32, 37]. In the boundary element context this approach is used in the microlocal discretization method of de La Bourdonnaye et al. [26, 27] and in the work of Perrey-Debain et al. [44, 45, 43, 46]. The theoretical analysis carried out (e.g., [4]) and computational results (e.g., [43]) confirm that these methods converge very rapidly as the number of plane wave directions used increases. Moreover, the computational results suggest that to achieve a required accuracy, the number of degrees of freedom needed is reduced by a large factor compared with conventional h-version finite or boundary element methods. However, in the case of boundary element methods, while constants of proportionality are reduced very significantly [44, 45, 43, 46], it is not clear that, asymptotically, the number of degrees of freedom increases any less fast than linearly with k for 2D problems, the same rate of increase as for conventional boundary element methods.

At the other extreme, the second group of papers, using direct integral equation methods, are distinguished by using only one solution of the Helmholtz equation to enrich the approximation space, namely, the known incident field. This approach amounts to applying conventional boundary element methods to the ratio of the total field to the incident field, rather than to the total field directly. This simple idea, employed for the impedance boundary value problem we consider in this paper in [15], seems particularly appropriate in the case of smooth convex obstacles, as physical optics predicts that this ratio is approximately constant on the illuminated side and approximately zero on the shadow side at high frequencies. This approach is used for smooth convex obstacles in 2D in [1], where a standard Galerkin boundary element method with uniform mesh is applied to the ratio of the scattered field to the incident field. In fact, this paper appears to be the first in which the dependence of the error estimates on the wavenumber k is indicated. The error estimate stated in [1] is that the relative error in the best approximation from a boundary element space of piecewise polynomials of degree $\leq \nu$ is $\mathcal{O}(h^{\nu}) + \mathcal{O}((hk^{1/3})^{\nu+1})$. While clearly better than the (at least) linear dependence on k of conventional boundary element methods, the number of degrees of freedom needed to maintain accuracy is still predicted to grow like $k^{1/3}$ as k increases, and moreover the analysis does not guarantee that the Galerkin method solution is close to this best approximation in the limit as $k \to \infty$.

The method of [1] is applied in [24], where results for realistic 3D scatterers are shown. This approach has also recently been applied in [10]. In this latter paper, which focuses on 2D scattering by a sound-soft circular obstacle, the numerical scheme is not completely defined. However, one of the main features of the numerical scheme is that a coordinate stretching is carried out in a k-dependent neighborhood of the shadow boundary (of length $O(k^{-1/3})$). The numerical results in [10, 11] for scattering by a circle suggest that after this transformation, the slowly varying normal derivative of the ratio of scattered to incident field can be approximated using Fourier series basis functions in the L^2 norm with a number of degrees of freedom which remains fixed as the wavenumber k tends to infinity. The authors do not attempt to establish this wavenumber independence theoretically by a rigorous error analysis.

The third group of papers is intermediate in approach between the first and second groups, attempting to identify, by geometrical optics or geometrical theory of diffraction considerations or otherwise, the important wave propagation directions at high frequency. They then incorporate the oscillatory part of this high-frequency asymptotics into the approximation space for the numerical solution. This is the approach in the finite element method of Giladi and Keller [29] and in the boundary integral equation method of Bruno, Geuzaine, and Reitich [12], our own recent work [20], and the present paper. The paper [12], generalizing [10], considers specifically the case of multiple scattering between two 2D convex obstacles and employs a Neumann series approach, solving for each of the multiple scatters in turn, and factoring out a geometric optics estimate of the main oscillatory behavior at each step. We remark that the distinction between the second and third groups of papers is somewhat blurred in that, arguably, for a smooth convex obstacle the only important wave direction to include in the ansatz for the scattered field and its normal derivative on the boundary is the incident wave direction.

The last two groups of papers have in common that, while the number of degrees of freedom may be reduced, very significantly, by incorporating the oscillatory behavior of the solution, the work required to compute a typical matrix entry of the linear system to be solved increases significantly. In particular, in boundary integral equation based methods, a typical entry of the full system matrix corresponds to an integration over a part of the boundary which is large in diameter compared to the wavelength so that the integrand is highly oscillatory. The problem of efficient evaluation of these integrals is tackled by the fast multipole method in [24]. In [10], ideas from the method of stationary phase are used to reduce the support of the integrand, and quadrature rules based on the trapezoidal rule, exponentially accurate for smooth periodic functions, are employed. Numerical results using this approach for 2D scattering by a circle are encouraging and appear to indicate a fixed computational cost as

k tends to infinity. A somewhat similar approach for evaluating the integrals to that of Bruno et al. [10] is employed for scattering by smooth 3D convex scatterers in [28]. We note that there has been considerable recent interest in the efficient evaluation of highly oscillatory integrals for a variety of applications; see [34, 35] and the references therein.

As an instance of the third group of papers, the authors and Ritter recently proposed [20] a new high-frequency boundary element method for the specific problem of 2D acoustic scattering by an inhomogeneous impedance plane. For this new scheme it was shown [20] that the number of degrees of freedom needed to maintain accuracy as $k \to \infty$ grows only logarithmically with k. This appears to be the best theoretical estimate to date for a numerical method for a scattering problem in terms of the dependence on the wavenumber.

In this paper we will be concerned with the numerical solution of the same problem, proposing modifications of the numerical scheme of [20]. For our modified scheme we are able to show, employing somewhat more elaborate arguments than those of [20], that for a fixed number of degrees of freedom the error is bounded independently of the wavenumber k. To our knowledge, this is the first such numerical analysis result for any scattering problem.

The problem we will consider is one of acoustic scattering of an incident wave by a planar surface with spatially varying acoustical surface impedance. This problem has attracted much attention in the literature (see, for example, [17, 30, 31, 16, 21, 6, 48]), both in its own right and also as a model of the scattering of an incident acoustic or electromagnetic wave by an infinite rough surface [8, 47, 36, 7]. In the case in which there is no variation in the acoustical properties of the surface or the incident field in some fixed direction parallel to the surface, the problem is effectively two-dimensional. Adopting Cartesian coordinates $0x_1x_2x_3$, let this direction be that of the x_3-axis and the surface be the plane $x_2 = 0$. Assuming further that the incident wave and scattered fields are time harmonic, the total acoustic field $u^t \in \mathcal{C}(\overline{U}) \cap \mathcal{C}^2(U)$ then satisfies (1.1) in $U := \{(x_1, x_2) \in \mathbb{R}^2 : x_2 > 0\}$, supplemented with the impedance boundary condition

$$\frac{\partial u^t}{\partial x_2} + \mathrm{i}k\beta u^t = f \quad \text{on } \Gamma := \{(x_1, 0) : x_1 \in \mathbb{R}\} \tag{1.2}$$

with $f \equiv 0$, where $k = \omega/c > 0$. Here $\omega = 2\pi\mu$, μ is the frequency of the incident wave and c is the speed of sound in U. The acoustic pressure at time t, position (x_1, x_2, x_3), is then given by $\mathrm{Re}(\mathrm{e}^{-\mathrm{i}\omega t} u^t(x))$ for $x = (x_1, x_2) \in \overline{U}$.

In outdoor sound propagation, the relative surface admittance β depends on the frequency and the ground properties and is often assumed in modeling to be piecewise constant and constant outside some finite interval $[a, b]$ (see, for example, [17, 30, 31]), with β taking a different value for each ground surface type (grassland, forest floor, road pavement, etc. [3]). Thus, for some real numbers $a = t_0 < t_1 < \cdots < t_n = b$, the relative surface admittance at $(x_1, 0)$ on Γ is given by

$$\beta(x_1) = \begin{cases} \beta_j, & x_1 \in (t_{j-1}, t_j], \\ \beta_c, & x_1 \in \mathbb{R} \backslash (t_0, t_n]. \end{cases} \tag{1.3}$$

If the ground surface is to absorb rather than emit energy, the condition $\mathrm{Re}\beta \geq 0$ must be satisfied. We assume throughout that, for some $\epsilon > 0$,

$$\mathrm{Re}\beta_c \geq \epsilon, \quad \mathrm{Re}\beta_j \geq \epsilon, \quad |\beta_c| \leq \epsilon^{-1}, \quad |\beta_j| \leq \epsilon^{-1}, \quad j = 1, \ldots, n. \tag{1.4}$$

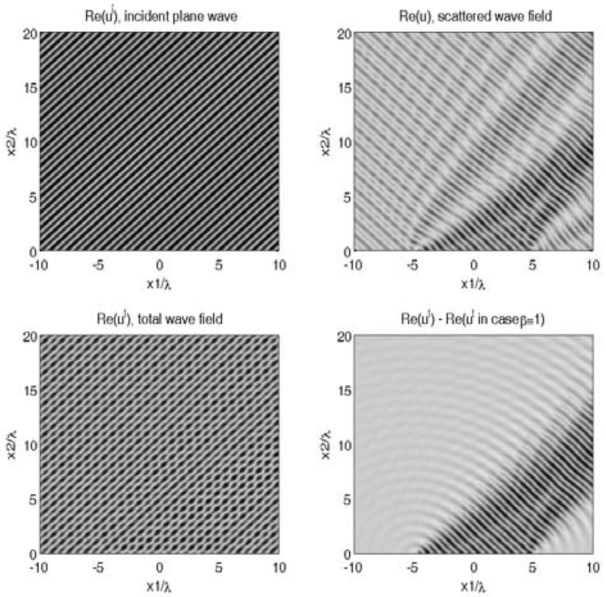

FIG. 1.1. *Acoustic scattering by an impedance boundary.*

For simplicity of exposition, we restrict our attention to the case of plane wave incidence, so that the incident field u^i is given by $u^i(x) = \exp[\mathrm{i}k(x_1 \sin\theta - x_2 \cos\theta)]$, where $\theta \in (-\pi/2, \pi/2)$ is the angle of incidence. The reflected or scattered part of the wave field is $u := u^t - u^i \in C(\overline{U}) \cap C^2(U)$, and this also satisfies (1.1) and (1.2) with

$$f(x_1) := \mathrm{i}k\mathrm{e}^{\mathrm{i}kx_1 \sin\theta}(\cos\theta - \beta(x_1)), \quad x_1 \in \mathbb{R}. \tag{1.5}$$

In Figure 1.1 we show scattering by a typical impedance plane. In this particular example, the surface admittance β is given by

$$\beta(x_1) = \begin{cases} 0.505 - 0.3\mathrm{i}, & x_1 \in (-5\lambda, 5\lambda], \\ 1, & x_1 \in \mathbb{R}\backslash(-5\lambda, 5\lambda], \end{cases}$$

where $\lambda = c/\mu = 2\pi/k$ is the wavelength. There are discontinuities in impedance at $x_1 = -5\lambda$ and at $x_1 = 5\lambda$. The incident plane wave ($\theta = \pi/4$ in this example) can be seen in the top left and the scattered wave in the top right of Figure 1.1. This scattered wave is a combination of reflected and diffracted rays. The diffracted rays, propagating radially from the points $(-5\lambda, 0)$ and $(5\lambda, 0)$, can be seen more clearly in the bottom right of Figure 1.1, where we have subtracted from the total field u^t the (known) total field in the case that $\beta \equiv 1$.

To achieve good approximations with a relatively low number of degrees of freedom, a boundary element method approach was used in [20] with ideas in the spirit of the geometrical theory of diffraction (GTD) being used to identify and subtract off the leading order behavior (namely, the incident and reflected rays) as $k \to \infty$. The remaining scattered wave (consisting of the rays diffracted at impedance discontinuities as visible in the lower right corner of Figure 1.1) can then be expressed (on the boundary Γ) as the product of the known oscillatory functions $\mathrm{e}^{\pm\mathrm{i}kx_1}$ and unknown nonoscillatory functions denoted as $f_j^{\pm}$. Rigorous bounds were established in [20] on the derivatives of the nonoscillatory functions $f_j^\pm$ both adjacent to and away from discontinuities in impedance. Using these bounds a Galerkin method was developed, using a graded mesh with elements very large compared to the wavelength away from discontinuities in β, in order to take advantage of the smooth behavior of $f_j^\pm$ away from these points, and a special set of basis functions so that on each element the approximation space consists of polynomials (of degree ν) multiplied by $\mathrm{e}^{\pm \mathrm{i}kx_1}$, so as to obtain a piecewise polynomial representation of the nonoscillatory functions $f_j^\pm$. Using this approach, it was shown in [20] that the error in computing an approximation to $u^t|_\Gamma$ on $[a,b]$ in the L_2 norm is $\mathcal{O}(\log^{\nu+3/2}(k(b-a))M^{-(\nu+1)})$, where M is the number of degrees of freedom.

In this paper we consider the same problem as in [20] and use a similar approach. We again subtract off the leading order behavior as $k \to \infty$ on each interval and express the scattered wave as a product of oscillatory and nonoscillatory functions. However, here (in section 2) we prove sharper bounds on the nonoscillatory functions $f_j^\pm$ away from impedance discontinuities. Based on these bounds, in section 3 we propose a Galerkin method similar to that in [20], but with a different approximation space. As in [20] this consists of polynomials (of degree ν) multiplied by $\mathrm{e}^{\pm \mathrm{i}kx_1}$, but unlike in [20] the choice of whether to use $\mathrm{e}^{+\mathrm{i}kx_1}$ or $\mathrm{e}^{-\mathrm{i}kx_1}$ on each element is dictated by how close the element is to each impedance discontinuity, and the graded mesh is chosen differently so that when k is large compared to N we do not discretize the entire domain. This is key to achieving a convergence rate independent of the wavenumber.

In section 3 we present an error analysis for this new approach, and we show that the error in computing an approximation to $u^t|_\Gamma$ on $[a,b]$ is $\mathcal{O}(N^{-(\nu+1)}\log^{1/2}\min(N,k(b-a)))$, in the L_2 norm, using a number of degrees of freedom proportional to $N\log\min(N,k(b-a))$. As $\min(N,k(b-a)) \le N$, this error estimate shows that the error is bounded independently of k for a fixed number of degrees of freedom. We believe this to be the first proof for any scattering problem that, for a fixed discretization, the error does not grow as the size (in terms of number of wavelengths) of the scattering object to be discretized tends to infinity. Moreover, for fixed k, as $N \to \infty$ the extra logarithmic dependence on N of the error estimate and the number of degrees of freedom disappears, and we retain the same asymptotic convergence rate as in [20].

Whereas in [20] results were proved regarding only the approximation of $u^t|_\Gamma$, here we also show, in Theorem 3.6, that the total acoustic field at any point $x \in U$ can be computed to a similar order of accuracy. In section 4 we discuss the practical implementation of our approach, and we present some numerical results demonstrating that the theoretically predicted behavior is achieved. Finally in section 5 we present some conclusions and discuss possible future extensions of the ideas presented here.

2. Integral equation formulation and regularity of the solution. In the rest of this paper, ν is the degree of the polynomial approximations used in the Galerkin method described in section 3, and ϵ, in the range $0<\epsilon<1$, is the constant in the bound (1.4). Throughout C_ϵ, C_ν, and $C_{\epsilon,\nu}$ denote constants depending only on ϵ, ν, and both ϵ and ν, respectively, each not necessarily the same at each occurence.

We begin by stating the problem we wish to solve precisely and reformulating it as an integral equation. For $H \ge 0$, let $U_H := \{(x_1,x_2) : x_2 > H\}$ and $\Gamma_H := \{(x_1,H) : x_1 \in \mathbb{R}\}$. To determine the scattered field u uniquely we impose the radiation condition proposed in [16] that, for some $H>0$, u can be written in the half plane U_H as the double layer potential

$$u(x) = \int_{\Gamma_H} \frac{\partial H_0^{(1)}(k|x-y|)}{\partial y_2} \phi(y)\,\mathrm{d}s(y), \quad x \in U_H, \tag{2.1}$$

for some density $\phi \in L_\infty(\Gamma_H)$, where $H_0^{(1)}$ is the Hankel function of the first kind of order zero. The boundary value problem that we wish to solve for u is thus as follows.

Boundary value problem. *Given $k > 0$ (the wavenumber), $\theta \in (-\pi/2, \pi/2)$ (the angle of incidence) and β given by* (1.3)*, find $u \in \mathcal{C}(\overline{U}) \cap \mathcal{C}^2(U)$ such that*

(i) *u is bounded in the horizontal strip $U \backslash U_H$ for every $H > 0$;*
(ii) *u satisfies the Helmholtz equation* (1.1) *in U;*
(iii) *u satisfies the impedance boundary condition* (1.2) *on Γ (in the weak sense explained in* [16]*), with $f \in L_\infty(\Gamma)$ given by* (1.5)*;*
(iv) *u satisfies the radiation condition* (2.1)*, for some $H > 0$ and $\phi \in L_\infty(\Gamma_H)$.*

For $\beta^* \in \mathbb{C}$ with $\mathrm{Re}\beta^* > 0$ let $G_{\beta^*}(x, y)$ denote the Green's function for the above problem in the case of constant relative surface impedance, which satisfies (1.2), with $\beta \equiv \beta^*$ and $f \equiv 0$, and the standard Sommerfeld radiation and boundedness conditions. Explicit representations and efficient calculation methods for G_{β^*} are discussed in [18]. We shall require later the following bounds on G_{β^*} [20, (2.9), (2.10)], which hold provided $\mathrm{Re}\beta^* \geq \epsilon$ and $|\beta^*| \leq \epsilon^{-1}$:

$$|G_{\beta^*}(x, y)| \leq \frac{C_\epsilon(1 + kx_2)}{(k|x-y|)^{3/2}}, \quad x \in \overline{U},\ y \in \Gamma,\ x \neq y, \tag{2.2}$$

$$|G_{\beta^*}(x, y)| \leq C_\epsilon(1 - \log(k|x-y|)), \quad x \in \overline{U},\ y \in \Gamma,\ 0 < k|x-y| \leq 1. \tag{2.3}$$

The following result is shown in [20].

THEOREM 2.1. *If u satisfies the above boundary value problem, then*

$$u(x) = \int_\Gamma G_{\beta^*}(x, y)(\mathrm{i}k(\beta(y) - \beta^*)u(y) - f(y))\,\mathrm{d}s(y), \quad x \in \overline{U}. \tag{2.4}$$

Conversely, if $u|_\Gamma \in BC(\Gamma)$ (the space of bounded and continuous functions on Γ) and u satisfies (2.4)*, for some β^* with $\mathrm{Re}\beta^* > 0$, then u satisfies the above boundary value problem. Moreover,* (2.4) *has exactly one solution with $u|_\Gamma \in BC(\Gamma)$, and hence the boundary value problem has exactly one solution.*

We denote the (known) solution of the above boundary value problem in the special case $\beta \equiv \beta^*$ by u_{β^*} and the corresponding total field by $u^t_{\beta^*} := u^i + u_{\beta^*}$. Then it is easily seen [20] that u_{β^*} is the plane wave $u_{\beta^*}(x) = R_{\beta^*}(\theta)\exp[\mathrm{i}k(x_1 \sin\theta + x_2 \cos\theta)]$, where $R_{\beta^*}(\theta) := (\cos\theta - \beta^*)/(\cos\theta + \beta^*)$ is a reflection coefficient. Moreover, it is shown rigorously in [20] that u^t satisfies

$$u^t(x) = u^t_{\beta^*}(x) + \mathrm{i}k \int_\Gamma G_{\beta^*}(x, y)(\beta(y) - \beta^*)u^t(y)\,\mathrm{d}s(y), \quad x \in \overline{U}. \tag{2.5}$$

We note that the approximate and numerical solution of this integral equation has been extensively studied; see, for example, [42, 30, 17, 21, 20].

To make explicit the dependence on the wavenumber k in the results we obtain, it is useful to introduce new, dimensionless variables. Thus, define $\phi(s) := u^t((s/k, 0))$, $\psi_{\beta^*}(s) := u^t_{\beta^*}((s/k, 0))$, and $\kappa_{\beta^*}(s) := G_{\beta^*}((s/k, 0), (0, 0))$, $s \in \mathbb{R}$. Then (2.5) restricted to Γ is the following second kind boundary integral equation for ϕ:

$$\phi(s) = \psi_{\beta^*}(s) + \mathrm{i}\int_{-\infty}^{\infty} \kappa_{\beta^*}(s - t)(\beta(t/k) - \beta^*)\phi(t)\,\mathrm{d}t, \quad s \in \mathbb{R}. \tag{2.6}$$

It is the main concern in the remainder of the paper to solve this equation numerically in the case when $\beta^* = \beta_c$. Clearly,

$$\psi_{\beta^*}(s) = (1 + R_{\beta^*}(\theta))\mathrm{e}^{\mathrm{i}s\sin\theta}, \tag{2.7}$$

and it is shown in [20], using the representation for G_{β^*} in [18], that

$$\kappa_{\beta^*}(s) = \frac{\mathrm{i}}{2}H_0^{(1)}(|s|) + \frac{\beta^{*2}\mathrm{e}^{\mathrm{i}|s|}}{\pi}\int_0^\infty \frac{t^{-1/2}e^{-|s|t}}{(t-2\mathrm{i})^{1/2}(t^2-2\mathrm{i}t-\beta^{*2})}\,\mathrm{d}t + C_{\beta^*}e^{\mathrm{i}|s|(1-\hat{a}_+)} \tag{2.8}$$

$$= \mathrm{e}^{\mathrm{i}|s|}\breve{\kappa}_{\beta^*}(s), \quad s \in \mathbb{R}\backslash\{0\}, \tag{2.9}$$

where $\hat{a}_\pm := 1 \mp (1-\beta^{*2})^{\frac{1}{2}}$, with $\mathrm{Re}\{(1-\beta^{*2})^{1/2}\} \geq 0$,

$$C_{\beta^*} := \begin{cases} \frac{\beta^*}{(1-\beta^{*2})^{1/2}}, & \mathrm{Im}\beta^* < 0, \mathrm{Re}(\hat{a}_+) < 0, \\ \frac{\beta^*}{2(1-\beta^{*2})^{1/2}}, & \mathrm{Im}\beta^* < 0, \mathrm{Re}(\hat{a}_+) = 0, \\ 0, & \text{otherwise}, \end{cases}$$

and

$$\breve{\kappa}_{\beta^*}(s) := \frac{1}{\pi}\int_0^\infty \frac{r^{\frac{1}{2}}(r-2\mathrm{i})^{\frac{1}{2}}}{r^2-2\mathrm{i}r-\beta^{*2}}\mathrm{e}^{-r|s|}\,\mathrm{d}r + C_{\beta^*}e^{-\mathrm{i}|s|\hat{a}_+}, \quad s \in \mathbb{R}\backslash\{0\}. \tag{2.10}$$

Clearly the only dependence on k in the known terms in (2.6) is in the impedance function $\beta(t/k)$. We shall see shortly that the oscillating part of $\kappa_{\beta^*}(s)$ is contained in the factor $\mathrm{e}^{\mathrm{i}|s|}$ in (2.9), $\breve{\kappa}_{\beta^*}(s)$ becoming increasingly smooth as $s \to \pm\infty$.

In view of (1.3), if we set $\beta^* = \beta_c$ in (2.6), the interval of integration reduces to the finite interval $[\tilde{a}, \tilde{b}]$, where $\tilde{a} := ka = kt_0$, $\tilde{b} := kb = kt_n$. Explicitly, (2.6) becomes

$$\phi(s) = \psi_{\beta_c}(s) + \mathrm{i}\int_{\tilde{a}}^{\tilde{b}} \kappa_{\beta_c}(s-t)(\beta(t/k)-\beta_c)\phi(t)\,\mathrm{d}t, \quad s \in \mathbb{R}, \tag{2.11}$$

with ψ_{β_c} and κ_{β_c} given by (2.7) and (2.8), respectively, with $\beta^* = \beta_c$. This integral equation is studied, in the case $\beta_c = 1$, in [16]. From [16, Theorem 4.17] it follows that

$$\|\phi\|_\infty \leq C_\epsilon\|\psi_1\|_\infty = C_\epsilon|1 + R_1(\theta)| \leq C_\epsilon\cos\theta. \tag{2.12}$$

As in [20], and as discussed in the introduction, our numerical scheme for solving (2.11) is based on a consideration of the contribution of the reflected and diffracted ray paths in the spirit of the GTD. In particular, to leading order as $k \to \infty$, on the interval (t_{j-1}, t_j) it seems reasonable to suppose that the total field $\phi \approx \psi_{\beta_j}$, the total field there would be if the whole boundary had the admittance β_j of the interval (t_{j-1}, t_j), given explicitly by (2.7) with $\beta^* = \beta_j$. In fact, for $s \neq \tilde{t}_j := kt_j$, $j = 0, \ldots, n$, it follows from theorem 2.3 below that $\phi(s) \to \Psi(s)$ as $k \to \infty$, where

$$\Psi(s) := \begin{cases} \psi_{\beta_j}(s), & s \in (\tilde{t}_{j-1}, \tilde{t}_j], \quad j = 1, \ldots, n, \\ \psi_{\beta_c}(s), & s \in \mathbb{R}\backslash(\tilde{t}_0, \tilde{t}_n]. \end{cases} \tag{2.13}$$

In our numerical scheme we compute the difference between ϕ and Ψ, i.e.,

$$\Phi(s) := \phi(s) - \Psi(s), \quad s \in \mathbb{R}, \tag{2.14}$$

which may be thought of as the correction to the leading order field due to scattering from impedance discontinuities. Clearly, from (2.11) we have that

$$\Phi = \Psi_\beta^{\beta_c} + K_\beta^{\beta_c}\Phi, \tag{2.15}$$

where $\Psi_\beta^{\beta_c} \in L_\infty(\mathbb{R})$ is given by $\Psi_\beta^{\beta_c} := \psi_{\beta_c} - \Psi + K_\beta^{\beta_c}\Psi$, and

$$K_\beta^{\beta_c}\chi(s) := \mathrm{i}\int_{\tilde{a}}^{\tilde{b}} \kappa_{\beta_c}(s-t)(\beta(t/k)-\beta_c)\chi(t)\,\mathrm{d}t.$$

Equation (2.15) will be the integral equation that we solve numerically. By setting $\beta^* = \beta_j$ in (2.6) we obtain explicit expressions for Φ on each subinterval, namely,

$$\Phi(s) = \mathrm{e}^{\mathrm{i}s} f_j^+(s-\tilde{t}_{j-1}) + \mathrm{e}^{-\mathrm{i}s} f_j^-(\tilde{t}_j - s), \quad s \in (\tilde{t}_{j-1}, \tilde{t}_j],\ j = 1, \dots, n, \tag{2.16}$$

where for $j = 1, \dots, n$, $f_j^+, f_j^- \in \mathcal{C}[0,\infty)$ are defined by

$$f_j^+(r) := \int_{-\infty}^{\tilde{t}_{j-1}} \check{\kappa}_{\beta_j}(r + \tilde{t}_{j-1} - t)\mathrm{e}^{-\mathrm{i}t}\mathrm{i}(\beta(t/k)-\beta_j)\phi(t)\,\mathrm{d}t, \tag{2.17}$$

$$f_j^-(r) := \int_{\tilde{t}_j}^{\infty} \check{\kappa}_{\beta_j}(t - \tilde{t}_j + r)\mathrm{e}^{\mathrm{i}t}\mathrm{i}(\beta(t/k)-\beta_j)\phi(t)\,\mathrm{d}t \tag{2.18}$$

with $\check{\kappa}_{\beta_j}$ given by (2.10) with $\beta^* = \beta_j$. Similarly, from (2.11),

$$\Phi(s) = \begin{cases} \mathrm{e}^{\mathrm{i}s} f_{n+1}^+(s - \tilde{t}_n), & s > \tilde{t}_n, \\ \mathrm{e}^{-\mathrm{i}s} f_0^-(\tilde{t}_0 - s), & s < \tilde{t}_0, \end{cases} \tag{2.19}$$

where f_{n+1}^+, f_0^- are given by (2.17), (2.18), respectively, with $\beta_0 := \beta_c$ and $\beta_{n+1} := \beta_c$.

The first term in (2.16) can be viewed as an explicit summation of all the diffracted rays scattered at the discontinuity in impedance at t_{j-1} which travel from left to right along (t_{j-1}, t_j). Similarly, the other term in (2.16) is the contribution to the diffracted field diffracted by the discontinuity at t_j. In the remainder of this section, so as to design an efficient discretisation for Φ, we investigate in detail the behavior of the integrals $f_j^{\pm}$. As a first step, we prove the following bounds on $|\check{\kappa}_{\beta^*}^{(m)}(s)|$, for $m = 0, 1, \dots$, $s \in (0, \infty)$, which were stated without proof in [20].

LEMMA 2.2. *Suppose that* $\mathrm{Re}\beta^* \geq \epsilon$, $|\beta^*| \leq \epsilon^{-1}$ *hold for some* $\epsilon > 0$. *Then, for* $m = 0, 1, \dots,$ *there exist constants* c_m, *dependent only on* m *and* ϵ, *such that*

$$|\check{\kappa}_{\beta^*}^{(m)}(s)| \leq \begin{cases} c_m(1 + |\log s|), & m = 0, \\ c_m s^{-m}, & m \geq 1, \end{cases} \qquad \textit{for } 0 < s \leq 1,$$

$$|\check{\kappa}_{\beta^*}^{(m)}(s)| \leq c_m s^{-\frac{3}{2}-m} \qquad \textit{for } s > 1.$$

Proof. Throughout the proof, c_m is a constant dependent only on m and ϵ, not necessarily the same at each occurrence. Let

$$F(z) := \frac{z^{1/2}(z-2\mathrm{i})^{1/2}}{z^2 - 2\mathrm{i}z - \beta^{*2}} = \frac{z^{1/2}(z-2\mathrm{i})^{1/2}}{(z - \mathrm{i}\hat{a}_+)(z - \mathrm{i}\hat{a}_-)}, \quad z \in \mathbb{C}, \tag{2.20}$$

where $\mathrm{Re}\, z^{1/2}, \mathrm{Re}\,(z-2\mathrm{i})^{1/2} \geq 0$, and $\hat{a}_\pm = 1 \mp \sqrt{1-\beta^{*2}}$, as before, with $\mathrm{Re}\sqrt{1-\beta^{*2}} \geq 0$. Then $F(z)$ has simple poles at $z = \mathrm{i}\hat{a}_+$ (which may lie near the real axis if $\mathrm{Re}\hat{a}_+$ is small) and $z = \mathrm{i}\hat{a}_-$ (which cannot lie near the real axis as $\mathrm{Re}\hat{a}_- \geq 1$). Recalling (2.10) we then have, at least provided $\mathrm{Re}\hat{a}_+ \neq 0$ or $\mathrm{Im}\hat{a}_+ > 0$, so that the pole at $\mathrm{i}\hat{a}_+$ does not lie on the positive real axis,

$$|\check{\kappa}^{(m)}_{\beta^*}(s)| \leq \frac{1}{\pi}\left|\int_0^\infty F(r) r^m \mathrm{e}^{-rs}\,\mathrm{d}r\right| + \left|C_{\beta^*}\hat{a}_+^m \mathrm{e}^{\mathrm{Im}\hat{a}_+ s}\right|, \quad s > 0. \tag{2.21}$$

Now, since $\mathrm{Re}\beta^* \geq \epsilon$, it is easy to see that $\mathrm{Im}\hat{a}_+ = 0$ if and only if $\beta^* \in [\epsilon, 1]$, and in this case $\mathrm{Re}\hat{a}_+ \geq 1 - \sqrt{1-\epsilon^2} = \epsilon^2/(1+\sqrt{1-\epsilon^2}) > \epsilon^2/2$. We thus define $S_\epsilon := \{\beta^* : \mathrm{Re}\beta^* \geq \epsilon, |\beta^*| \leq \epsilon^{-1}, \mathrm{Re}\hat{a}_+ \leq \epsilon^2/4\}$. Then S_ϵ is closed and bounded, and $|\mathrm{Im}\hat{a}_+|$ and $|\sqrt{1-\beta^{*2}}|$ are both continuous and nonzero on S_ϵ. Thus, for some $\eta > 0$,

$$|\mathrm{Im}\hat{a}_+| \geq \eta \quad \text{and} \quad \left|\sqrt{1-\beta^{*2}}\right| \geq \eta \tag{2.22}$$

for all $\beta^* \in S_\epsilon$.

Next, we note that if $\mathrm{Re}\hat{a}_+ > 0$, then $C_{\beta^*} = 0$, while if $\mathrm{Re}\hat{a}_+ \leq 0$, then $\beta^* \in S_\epsilon$, so that (2.22) holds. Moreover, if $C_{\beta^*} \neq 0$, then $\mathrm{Im}\beta^* < 0$, and so $\mathrm{Im}\hat{a}_+ < 0$. Since also $|\hat{a}_\pm| \leq 1 + \sqrt{1+\epsilon^{-2}}$, we see that

$$\left|C_{\beta^*}\hat{a}_+^m \mathrm{e}^{\mathrm{Im}\hat{a}_+ s}\right| \leq c_m \mathrm{e}^{-\eta s}, \quad s > 0.$$

We turn to bounding the first term on the right-hand side of (2.21). To do this we consider the two cases $|\mathrm{Re}\hat{a}_+| > \epsilon^2/4$ and $|\mathrm{Re}\hat{a}_+| \leq \epsilon^2/4$ separately.

First, suppose $|\mathrm{Re}\hat{a}_+| > \epsilon^2/4$. Then

$$|F(r)| \leq C_\epsilon r^{1/2}, \quad r > 0, \tag{2.23}$$

and thus

$$\left|\int_0^\infty F(r) r^m \mathrm{e}^{-rs}\,\mathrm{d}r\right| \leq C_\epsilon \int_0^\infty r^{m+1/2}\mathrm{e}^{-rs}\,\mathrm{d}r \leq c_m s^{-m-3/2}, \;\; s > 0. \tag{2.24}$$

This bound suffices when $s > 1$, but for $0 < s \leq 1$ we need a sharper bound.

We proceed by establishing bounds on the mth derivatives of the first two terms on the right-hand side of (2.8) for $0 < s \leq 1$. It can easily be deduced from the power series representations defining the Bessel functions that there exist constants C_j, $j = 0, \ldots$, such that, for $0 < z \leq 1$,

$$|H_0^{(1)}(z)| \leq C_0(1 + |\log z|), \tag{2.25}$$

$$\left|\frac{d^m}{dz^m} H_0^{(1)}(z)\right| \leq C_m z^{-m}, \quad m = 1, 2, \ldots. \tag{2.26}$$

Next note that, for $0 < s \leq 1$, the mth derivative of the second term in (2.8) has absolute value not more than

$$\left|\frac{\beta^{*2}}{\pi}\int_0^\infty \frac{(\mathrm{i}-t)^m \mathrm{e}^{-st} t^{-1/2}\,\mathrm{d}t}{(t-2\mathrm{i})^{1/2}(t^2 - 2\mathrm{i}t - \beta^{*2})}\right| \leq \frac{\epsilon^{-2}}{\pi}\int_0^\infty \frac{(1+t^2)^{m/2}\mathrm{e}^{-st}t^{-1/2}\,\mathrm{d}t}{(t^2+4)^{1/4}\,|(t-\mathrm{i}\hat{a}_+)(t-\mathrm{i}\hat{a}_-)|} \tag{2.27}$$

$$\leq C_\epsilon\left[\int_0^1 t^{-1/2}\,\mathrm{d}t + \int_1^\infty t^{m-1}\mathrm{e}^{-st}\,\mathrm{d}t\right] \tag{2.28}$$

$$\leq \begin{cases} C_\epsilon(1 - \log s), & m = 0, \\ c_m s^{-m}, & m = 1, 2, \ldots. \end{cases} \tag{2.29}$$

Combining (2.25), (2.26), and (2.29) and recalling (2.9) the result follows.

Now we consider the case $0 \leq \mathrm{Re}\hat{a}_+ \leq \epsilon^2/4$. (The proof for the case $-\epsilon^2/4 \leq \mathrm{Re}\hat{a}_+ < 0$ is similar.) As $\beta \in S_\epsilon$, (2.22) holds. If $\mathrm{Im}\hat{a}_+ > 0$, then the bounds (2.23) and (2.28) hold and we proceed as above. If $\mathrm{Im}\hat{a}_+ < 0$, however, $F(z)$ has a pole at $z = \mathrm{i}\hat{a}_+$ with $\mathrm{Re}(\mathrm{i}\hat{a}_+) > \eta$, $0 \leq \mathrm{Im}(\mathrm{i}\hat{a}_+) \leq \epsilon^2/4$. To bound the integrals on the left-hand side of (2.24) and (2.27) in this case, uniformly in β^*, we first deform the path of integration. Define Γ_ϵ to be the semicircle, center $(-\mathrm{Im}\hat{a}_+, 0)$, radius $\tilde{\eta} := \min(1/2, \eta)$, lying in the lower half plane. (Note that by (2.22), $\mathrm{Re}z > \eta/2$ for $z \in \Gamma_\epsilon$.) Let $\gamma_\epsilon = [0, -\mathrm{Im}\hat{a}_+ - \eta/2] \cup [-\mathrm{Im}\hat{a}_+ + \eta/2, \infty)$. Then, by Cauchy's theorem, it follows from (2.21) that, for $\mathrm{Re}\hat{a}_+ > 0$,

$$|\check{\kappa}_{\beta^*}^{(m)}(s)| \leq \frac{1}{\pi}\left|\int_{\gamma_\epsilon} F(r) r^m \mathrm{e}^{-rs}\,\mathrm{d}r + \int_{\Gamma_\epsilon} F(r) r^m \mathrm{e}^{-rs}\,\mathrm{d}r\right|, \quad s > 0. \tag{2.30}$$

By continuity arguments, taking the limit $\mathrm{Re}\hat{a}_+ \to 0^+$ in (2.30), equation (2.30) holds also for $\mathrm{Re}\hat{a}_+ = 0$. For $r \in \gamma_\epsilon$ the bound (2.23) holds, and so the integral over γ_ϵ is bounded by the right-hand side of (2.24). Further,

$$\left|\int_{\Gamma_\epsilon} F(r) r^m \mathrm{e}^{-rs}\,\mathrm{d}r\right| \leq \frac{\pi\eta}{2}\max_{r\in\Gamma_\epsilon}|F(r) r^m \mathrm{e}^{-rs}| \leq c_m \mathrm{e}^{-\eta s/2},$$

so we obtain the required bound for $s \geq 1$. To obtain the desired bound for $0 < s \leq 1$ we proceed as in the case $|\mathrm{Re}\hat{a}_+| > \epsilon^2/4$, but deforming the path of integration as above to bound the left-hand side of (2.27). □

The following result is a slight sharpening of [20, Theorem 2.6], obtained by combining the bounds in Lemma 2.2 and (2.12) with the representations (2.17) and (2.18).

THEOREM 2.3. *Suppose* (1.4) *holds for some* $\epsilon > 0$. *Then, for* $r > 0$, $j = 1, \ldots, n$, $m = 0, 1, \ldots$, *there exist constants* c_m, *dependent only on* m *and* ϵ, *such that*

$$\left|f_j^{\pm(m)}(r)\right| \leq c_m \cos\theta E_m(r),$$

where

$$E_m(r) = \begin{cases} 1, & m = 0, \\ 1 - \log r, & m = 1, \\ r^{1-m}, & m \geq 2, \end{cases} \qquad \text{for } 0 < r \leq 1,$$
$$E_m(r) = r^{-\frac{1}{2}-m} \qquad \text{for } r > 1.$$

Remark. Using the identical argument it can easily be shown that $|{f_{n+1}^{+}}^{(m)}(r)|$, $|{f_0^{-}}^{(m)}(r)| \leq c_m \cos\theta E_m(r)$, $r > 0$, for $m = 0, 1, \ldots$, where c_m is the same constant as in Theorem 2.3.

To prove the main result of this section, a sharper bound on $|f_j^{\pm}(r)|$ when $r > 1$ (Theorem 2.6), we require the bounds in the following two lemmas.

LEMMA 2.4. *Suppose* $p < -1$ *and* $q \leq 0$. *Then there exists a constant* C, *independent of* r, *such that, for* $r \geq 1$,

$$\int_0^\infty (t + r)^p (1 + t)^q\,\mathrm{d}t \leq \begin{cases} C r^{p+q+1}, & q \neq -1, \\ C r^p \log(1 + r), & q = -1. \end{cases}$$

Proof.

$$\int_0^\infty (t+r)^p(1+t)^q\,\mathrm{d}t \le r^p\int_0^r (1+t)^q\,\mathrm{d}t + r^q\int_r^\infty (t+r)^p\,\mathrm{d}t,$$

and the result follows. □

LEMMA 2.5. *Suppose $q \le 0$. Then there exists a constant C, independent of r and D, such that, for $r \ge 1$ and $D > 0$,*

$$\int_0^{2D} (s+r)^{-3/2}(1+2D-s)^q\,\mathrm{d}s \le \begin{cases} Cr^{-3/2}, & q < -1,\\ Cr^{-3/2}\log(1+r), & q = -1,\\ Cr^{-1/2+q}, & -1 < q \le 0. \end{cases}$$

Proof. Splitting the integration range as $[0, 2D] = [0, D] \cup [D, 2D]$, and making the change of variable $t := 2D - s$, we see that

$$\int_0^{2D} (s+r)^{-3/2}(1+2D-s)^q\,\mathrm{d}s \le I_A + I_B,$$

where

$$I_A := (1+D)^q\int_0^D (s+r)^{-3/2}\,\mathrm{d}s, \quad I_B := (D+r)^{-3/2}\int_0^D (1+t)^q\,\mathrm{d}t.$$

Further,

$$\begin{aligned} I_A &= \frac{2D(1+D)^q}{r^{1/2}(D+r)^{1/2}((D+r)^{1/2}+r^{1/2})}\\ &\le \frac{2(1+D)^{q+1}}{r^{1/2}(D+r)} \le \begin{cases} 2r^{-3/2}, & q \le -1,\\ 2r^{-1/2+q}, & -1 < q \le 0. \end{cases} \end{aligned} \tag{2.31}$$

For $q \ne -1$, $I_B = (1+q)^{-1}(D+r)^{-3/2}((1+D)^{q+1} - 1)$. Thus

$$|1+q|I_B \le \begin{cases} r^{-3/2}, & q < -1,\\ r^{-1/2+q}, & -1 < q \le 0. \end{cases}$$

To bound I_B in the case that $q = -1$ we need to consider the cases $r \ge D$ and $r < D$ separately. For $r \ge D$,

$$I_B = (D+r)^{-3/2}\log(1+D) \le r^{-3/2}\log(1+r).$$

For $r < D$ we split the range of integration as $[0, D] = [0, r] \cup [r, D]$ and note that

$$(D+r)^{-3/2}\int_0^r (1+t)^{-1}\,\mathrm{d}t \le r^{-3/2}\log(1+r),$$

$$(D+r)^{-3/2}\int_r^D (1+t)^{-1}\,\mathrm{d}t \le \frac{(D-r)}{(D+r)^{3/2}(1+r)} \le r^{-3/2}.$$

This completes the proof. □

We are now ready to prove the main result of this section, the following sharper bound on $|f_j^\pm(r)|$ when $r > 1$, on which the design of our numerical scheme is based.

THEOREM 2.6. *Suppose* (1.4) *holds for some $\epsilon > 0$. Then for $r > 1$, $j = 0, \dots, n$,*

$$\left|f_{j+1}^+(r)\right|, \left|f_j^-(r)\right| \le C_\epsilon \frac{r^{-3/2}n^3}{\cos\theta}.$$

Proof. First we consider $f_j^-(r)$. Recalling (2.14), for $j = 0,\dots,n$, $f_j^-(r) = I_1(r) + I_2(r)$, where

$$I_1(r) := \int_{\tilde{t}_j}^{\infty} \breve{\kappa}_{\beta_j}(t - \tilde{t}_j + r)\mathrm{e}^{\mathrm{i}t}\mathrm{i}(\beta(t/k) - \beta_j)\Psi(t)\,\mathrm{d}t,$$

$$I_2(r) := \int_{\tilde{t}_j}^{\infty} \breve{\kappa}_{\beta_j}(t - \tilde{t}_j + r)\mathrm{e}^{\mathrm{i}t}\mathrm{i}(\beta(t/k) - \beta_j)\Phi(t)\,\mathrm{d}t.$$

We begin by establishing a bound on I_1. Recalling (2.13) and (2.7),

$$I_1(r) = \sum_{m=j+1}^{n} \mathrm{i}(\beta_m - \beta_j) \int_{\tilde{t}_{m-1}}^{\tilde{t}_m} \breve{\kappa}_{\beta_j}(t - \tilde{t}_j + r)(1 + R_{\beta_m}(\theta))\mathrm{e}^{\mathrm{i}t(\sin\theta+1)}\,\mathrm{d}t$$
$$+ \mathrm{i}(\beta_c - \beta_j) \int_{\tilde{t}_n}^{\infty} \breve{\kappa}_{\beta_j}(t - \tilde{t}_j + r)(1 + R_{\beta_c}(\theta))\mathrm{e}^{\mathrm{i}t(\sin\theta+1)}\,\mathrm{d}t.$$

Integrating by parts,

$$I_1(r) = \sum_{m=j+1}^{n} \frac{(\beta_m - \beta_j)(1 + R_{\beta_m}(\theta))}{\sin\theta + 1} \left(\left[\breve{\kappa}_{\beta_j}(t - \tilde{t}_j + r)\mathrm{e}^{\mathrm{i}t(\sin\theta+1)}\right]_{\tilde{t}_{m-1}}^{\tilde{t}_m} \right.$$
$$\left. - \int_{\tilde{t}_{m-1}}^{\tilde{t}_m} \breve{\kappa}'_{\beta_j}(t - \tilde{t}_j + r)\mathrm{e}^{\mathrm{i}t(\sin\theta+1)}\,\mathrm{d}t \right)$$
$$+ \frac{(\beta_c - \beta_j)(1 + R_{\beta_c}(\theta))}{\sin\theta + 1} \left(\left[\breve{\kappa}_{\beta_j}(t - \tilde{t}_j + r)\mathrm{e}^{\mathrm{i}t(\sin\theta+1)}\right]_{\tilde{t}_n}^{\infty} \right.$$
$$\left. - \int_{\tilde{t}_n}^{\infty} \breve{\kappa}'_{\beta_j}(t - \tilde{t}_j + r)\mathrm{e}^{\mathrm{i}t(\sin\theta+1)}\,\mathrm{d}t \right).$$

Now from Lemma 2.2, for $r > 1$,

$$\left|\breve{\kappa}_{\beta_j}(\tilde{t}_m - \tilde{t}_j + r)\right| \le C_\epsilon(\tilde{t}_m - \tilde{t}_j + r)^{-3/2} \le C_\epsilon r^{-3/2}, \quad m = j,\dots,n.$$

Thus, noting that $|1 + R_{\beta_m}(\theta)| = |2\cos\theta/(\cos\theta + \beta_m)| \le 2\cos\theta/\epsilon$ and $|\beta_m - \beta_j| \le 2/\epsilon$, and using Lemma 2.2 again to bound $\breve{\kappa}'_{\beta_j}$, we have, for $r > 1$,

$$|I_1(r)| \le C_\epsilon \frac{(n+1-j)\cos\theta}{\sin\theta + 1} \left[r^{-3/2} + \int_{\tilde{t}_j}^{\infty} \left|\breve{\kappa}'_{\beta_j}(t - \tilde{t}_j + r)\right| \mathrm{d}t \right]$$

$$\le C_\epsilon \frac{r^{-3/2} n \cos\theta}{\sin\theta + 1}. \tag{2.32}$$

We next bound I_2. Recalling (2.16) and (2.19),

$$|I_2(r)| \le \frac{2}{\epsilon} \left(J_\infty^+ + \sum_{m=j+1}^{n} (J_m^+ + J_m^-) \right), \tag{2.33}$$

where

$$J_m^+ := \int_{\tilde{t}_{m-1}}^{\tilde{t}_m} |\breve{\kappa}_{\beta_j}(t - \tilde{t}_j + r)||f_m^+(t - \tilde{t}_{m-1})|\,\mathrm{d}t, \tag{2.34}$$

$$J_m^- := \int_{\tilde{t}_{m-1}}^{\tilde{t}_m} |\breve{\kappa}_{\beta_j}(t - \tilde{t}_j + r)||f_m^-(\tilde{t}_m - t)|\,\mathrm{d}t, \tag{2.35}$$

$$J_\infty^+ := \int_{\tilde{t}_n}^{\infty} |\breve{\kappa}_{\beta_j}(t - \tilde{t}_j + r)||f_{n+1}^+(t - \tilde{t}_n)|\,\mathrm{d}t. \tag{2.36}$$

First we bound J_∞^+. Applying Lemma 2.2 and Theorem 2.3, and noting the remark after Theorem 2.3, for $r > 1$,

$$J_\infty^+ \leq C_\epsilon \cos\theta \int_{\tilde{t}_n}^{\infty} (t - \tilde{t}_n + r)^{-3/2}(1 + t - \tilde{t}_n)^{-1/2}\, \mathrm{d}t \leq C_\epsilon r^{-1}\cos\theta,$$

making the change of variables $s = t - \tilde{t}_n$ and using Lemma 2.4 with $p = -3/2$ and $q = -1/2$. Arguing similarly, $J_m^+ \leq C_\epsilon r^{-1}\cos\theta$. To bound J_m^-, again using Lemma 2.2 and Theorem 2.3 we have

$$J_m^- \leq C_\epsilon \cos\theta \int_{\tilde{t}_{m-1}}^{\tilde{t}_m} (t - \tilde{t}_{m-1} + r)^{-3/2}(1 + \tilde{t}_m - t)^{-1/2}\, \mathrm{d}t \leq C_\epsilon r^{-1}\cos\theta,$$

making the change of variables $s = t - \tilde{t}_{m-1}$ and using Lemma 2.5 with $D = (\tilde{t}_m - \tilde{t}_{m-1})/2$ and $q = -1/2$. Thus, recalling (2.33), $|I_2(r)| \leq C_\epsilon r^{-1} n\cos\theta$.

So far in the argument we have shown that, for $r > 1$, $j = 0, \ldots, n$,

$$|f_j^-(r)| \leq |I_1(r)| + |I_2(r)| \leq C_\epsilon r^{-1} n\cos\theta\left(\frac{r^{-1/2}}{1+\sin\theta} + 1\right). \tag{2.37}$$

Proceeding in a similar way, we can show that, for $r > 1$, $j = 1, \ldots, n+1$,

$$|f_j^+(r)| \leq C_\epsilon r^{-1} n\cos\theta\left(\frac{r^{-1/2}}{1-\sin\theta} + 1\right). \tag{2.38}$$

Next, starting from (2.33)–(2.36), we can use (2.37) and (2.38) to establish sharper bounds on I_2 and hence a sharper bound on f_j^-. Using (2.38) in (2.36), we have for $r > 1$ that

$$\begin{aligned} J_\infty^+ &\leq C_\epsilon n\cos\theta \int_{\tilde{t}_n}^{\infty} (t - \tilde{t}_n + r)^{-3/2}(1 + t - \tilde{t}_n)^{-1}\left(1 + \frac{(1 + t - \tilde{t}_n)^{-1/2}}{1 - \sin\theta}\right) \mathrm{d}t \\ &\leq C_\epsilon r^{-3/2} n\cos\theta(\log(1+r) + (1-\sin\theta)^{-1}), \end{aligned} \tag{2.39}$$

making the change of variable $s = t - \tilde{t}_n$ and using Lemma 2.4 with $p = -3/2$ and $q = -1, -3/2$. Arguing similarly, we can show that

$$J_m^+ \leq C_\epsilon r^{-3/2} n\cos\theta(\log(1+r) + (1-\sin\theta)^{-1}), \quad m = j+1, \ldots, n, \tag{2.40}$$

and, using (2.37) and Lemma 2.2,

$$\begin{aligned} J_m^- &\leq C_\epsilon n\cos\theta \int_{\tilde{t}_{m-1}}^{\tilde{t}_m} (t - \tilde{t}_{m-1} + r)^{-3/2}(1 + \tilde{t}_m - t)^{-1}\left(1 + \frac{(1 + \tilde{t}_m - t)^{-1/2}}{1 + \sin\theta}\right) \mathrm{d}t \\ &\leq C_\epsilon r^{-3/2} n\cos\theta(\log(1+r) + (1+\sin\theta)^{-1}), \end{aligned}$$

where again we make the change of variable $s = t - \tilde{t}_{m-1}$ and use Lemma 2.5 with $D := (\tilde{t}_m - \tilde{t}_{m-1})/2$ and $q = -1, -3/2$. Combining this with (2.39) and (2.40),

$$|I_2(r)| \leq C_\epsilon r^{-3/2} n^2 \cos\theta(\log(1+r) + (1-\sin^2\theta)^{-1}) \leq C_\epsilon \frac{r^{-3/2}\log(1+r)n^2}{\cos\theta}.$$

Thus

$$|f_j^-(r)| \leq |I_1| + |I_2| \leq C_\epsilon \frac{r^{-3/2}\log(1+r)n^2}{\cos\theta}. \tag{2.41}$$

In a similar way it can be proved that

$$|f_j^+(r)| \leq C_\epsilon \frac{r^{-3/2}\log(1+r)n^2}{\cos\theta}. \tag{2.42}$$

To obtain sharper bounds still on $f_j^\pm$, removing the dependence on $\log r$ in (2.41), (2.42), we note that it follows from (2.41) and (2.42) that

$$\int_0^\infty |f_j^\pm(r)|\,\mathrm{d}r \leq C_\epsilon \frac{n^2}{\cos\theta}.$$

Using this bound and the bounds in Lemma 2.2 in (2.34)–(2.36), we see that

$$J_m^\pm \leq C_\epsilon r^{-3/2}\int_0^\infty |f_m^\pm(s)|\,\mathrm{d}s \leq C_\epsilon \frac{r^{-3/2}n^2}{\cos\theta},$$

and an identical bound holds on J_∞^+. Hence, recalling (2.33),

$$|I_2(r)| \leq C_\epsilon \frac{r^{-3/2}n^3}{\cos\theta},$$

and combining this with (2.32) the desired bound on $f_j^-(r)$ follows. The desired bound on $f_j^+(r)$ follows similarly. □

3. Galerkin method and error analysis. Our aim now is to design a numerical method for the solution of (2.15), supported by a full error analysis, for which the error bounds are independent of the parameter $k(b-a)$. To achieve this we will work in $L_2(\mathbb{R})$, and to that end we introduce the operator $Q : L_\infty(\mathbb{R}) \to L_2(\mathbb{R})$ defined by

$$Q\chi(s) := \begin{cases} \chi(s), & s \in [\tilde{a},\tilde{b}] = [\tilde{t}_0,\tilde{t}_n], \\ 0, & s \in \mathbb{R}\backslash[\tilde{a},\tilde{b}]. \end{cases}$$

Writing $\Phi^* := Q\Phi$, and noting that $K_\beta^{\beta_c}\Phi = K_\beta^{\beta_c}\Phi^*$, it follows from (2.15) that

$$\Phi^* - QK_\beta^{\beta_c}\Phi^* = Q\Psi_\beta^{\beta_c}, \tag{3.1}$$

where Φ^* and $Q\Psi_\beta^{\beta_c}$ are both in $L_2(\mathbb{R})$.

Existence and boundedness of $(I - QK_\beta^{\beta_c})^{-1} : L_2(\mathbb{R}) \to L_2(\mathbb{R})$ are shown in [20], where it is also shown that the unique solution $\Phi^* = (I - QK_\beta^{\beta_c})^{-1}Q\Psi_\beta^{\beta_c}$ of (3.1) satisfies $\|\Phi^*\|_2 \leq C_1\|Q\Psi_\beta^{\beta_c}\|_2$ with $C_1 = \mathrm{Re}\beta_c/(\mathrm{Re}\beta_c - \|\beta-\beta_c\|_\infty)$ if

$$|\beta_j - \beta_c| < \mathrm{Re}\beta_c, \quad j = 1,\ldots,n, \tag{3.2}$$

and C_1 unspecified but dependent only on ϵ and β_c if (3.2) does not hold.

To approximate the solution $\Phi^* = Q\Phi$ of (3.1) we use a Galerkin method, similar to that in [20], but with the approximation space chosen in a different way so as to take advantage of our stronger bound on Φ (Theorem 2.6), in order to remove the dependence of the error estimates on $k(b-a)$. As in [20], on each interval $(\tilde{t}_{j-1},\tilde{t}_j)$, we approximate $f_j^+(s-\tilde{t}_{j-1})$ and $f_j^-(\tilde{t}_j - s)$ in (2.16) by conventional piecewise polynomial approximations, rather than approximating Φ itself. This makes sense since, as quantified by Theorems 2.3 and 2.6, the functions $f_j^+(s-\tilde{t}_{j-1})$ and $f_j^-(\tilde{t}_j - s)$ are smooth (their higher order derivatives are small) away from $\tilde{t}_{j-1}$ and $\tilde{t}_j$, respectively. To approximate $f_j^+(s-\tilde{t}_{j-1})$ and $f_j^-(\tilde{t}_j - s)$ we use piecewise polynomials of a fixed degree $\nu \geq 0$ on a graded mesh, the mesh grading adapted in an optimal way to the bounds on $f_j^{\pm(m)}$ in Theorems 2.3 and 2.6.

To begin, we define a graded mesh on a general interval $[0, A]$, for $A > 1$, with more mesh points near 0 and less near A. This mesh is identical to that defined in [20, Definition 3.1]; the difference here is in how we choose the value of A when we apply this mesh to the discretization of each interval $[\tilde{t}_{j-1}, \tilde{t}_j]$. Whereas in [20], A was chosen as a function of $\tilde{t}_j - \tilde{t}_{j-1}$ and the functions $f_j^\pm$ were approximated over the whole interval $[\tilde{t}_{j-1}, \tilde{t}_j]$, here we choose A as a function of N, a positive integer, where the size of N also determines the density of the mesh on $[0, A]$. A judicious choice of $A = A(N)$, as described below, allows us to discretize only a subsection of the interval $[\tilde{t}_{j-1}, \tilde{t}_j]$, near to $\tilde{t}_{j-1}$ and $\tilde{t}_j$, and to approximate $f_j^\pm$ by zero away from these points without harming the overall accuracy of our scheme. This is the key to achieving error estimates independent of $k(b-a)$.

The mesh we use also has similarities to that used in [40] for solving (1.1) in the case $k = \mathrm{i}\tau$, $\tau > 0$, τ large, where a similar idea of only discretizing a subsection of the boundary as $k \to \infty$ was used to establish error bounds independent of τ.

Definition 3.1. *For $A > 1$ and $N = 2, 3, \ldots$, the mesh $\Lambda_{N,A} = \{y_0, \ldots, y_{N+N_A}\}$ consists of the points $y_i = (i/N)^q$, $i = 0, \ldots, N$, where $q = 1 + 2\nu/3$, together with the points $y_{N+j} = A^{j/N_A}$, $j = 1, \ldots, N_A$, where $N_A = \lceil N^* \rceil$, the smallest integer $\geq N^*$, and $N^* := -\log A/[q \log(1 - 1/N)]$.*

The mesh $\Lambda_{N,A}$ is a composite mesh with a polynomial grading on $[0, 1]$ and a geometric grading on $[1, A]$. The definition of N_A ensures a smooth transition between the two parts of the mesh. Precisely, the definition of N^* is such that, in the case $N_A = N^*$, it holds that $y_{N+1}/y_N = y_N/y_{N-1}$, so that y_{N-1} and y_N are points in both the polynomial and the geometric parts of the mesh. It is shown in [20] that the total number of subintervals $N + N_A$ of the mesh on $[0, A]$ satisfies

$$N + N_A < \left(\frac{3}{2} + \frac{\log A}{q}\right) N. \tag{3.3}$$

Let $\Pi_{A,N,\nu} := \{\sigma : \sigma|_{[y_{j-1}, y_j]}$ is a polynomial of degree $\leq \nu$, $j = 1, \ldots, N + N_A\}$, and let P_N^* be the orthogonal projection operator from $L_2(0, A)$ to $\Pi_{A,N,\nu}$, so that setting $p = P_N^* f$ minimizes $\|f - p\|_{2,(0,A)} = \{\int_0^A |f(t) - p(t)|^2 \,\mathrm{d}t\}^{1/2}$ over all $p \in \Pi_{A,N,\nu}$. The mesh $\Lambda_{N,A}$ is designed to approximately minimize $\|f - P_N^* f\|_{2,(0,A)}$, over all meshes with the same number of points, when $f \in \mathcal{C}^\infty(0, \infty)$ with $|f^{(\nu+1)}(s)| = E_{\nu+1}(s)$, $s > 0$, where $E_{\nu+1}$ is defined as in Theorem 2.3. It achieves this by ensuring that $\|f - P_N^* f\|_{2,(y_{j-1}, y_j)}$ is approximately constant for $j = 1, \ldots, N + N_A$, i.e., by equidistributing the approximation error over the intervals of the mesh, as shown in the proof of the following result in [20].

Theorem 3.2. *Suppose that $f \in \mathcal{C}^\infty(0, \infty)$ and $|f'(s)| \leq E_1(s)$, $|f^{(\nu+1)}(s)| \leq E_{\nu+1}(s)$, $s > 0$. Then*

$$\|f - P_N^* f\|_{2,(0,A)} \leq C_\nu \frac{1 + \log^{1/2} A}{N^{\nu+1}}.$$

To form our approximation space on $[\tilde{a}, \tilde{b}] = [\tilde{t}_0, \tilde{t}_n]$, we begin by defining

$$A_j := \min \left\{ \alpha \frac{n^3 N^{\nu+1}}{\cos\theta}, \tilde{t}_j - \tilde{t}_{j-1} \right\}, \tag{3.4}$$

where $\alpha \geq 1$ is an absolute constant which will be determined experimentally and whose value will not effect the asymptotic convergence rates. The reason for our choice of A_j will become apparent shortly, in the proof of Theorem 3.3. Clearly A_j is bounded independently of $k(b-a)$. As we are primarily concerned with the high-frequency problem, we assume for simplicity that $A_j \geq 1$, $j = 1, \ldots, n$, but remark that in the case $A_j < 1$ for any value of j then we can define Λ_{N,A_j} to be an appropriate subset of the points y_i, and this will give similar approximation properties to those achieved using Λ_{N,A_j} when $A_j \geq 1$. For $j = 1, \ldots, n$ we define the two meshes $\Omega_j^+ := \tilde{t}_{j-1} + \Lambda_{N,A_j}$, $\Omega_j^- := \tilde{t}_j - \Lambda_{N,A_j}$. Letting $e_\pm(s) := \mathrm{e}^{\pm \mathrm{i}s}$, $s \in \mathbb{R}$, we then define $V_{\Omega_j^+,\nu} := \{\sigma e_+ : \sigma \in \Pi_{\Omega_j^+,\nu}\}$, $V_{\Omega_j^-,\nu} := \{\sigma e_- : \sigma \in \Pi_{\Omega_j^-,\nu}\}$, for $j = 1, \ldots, n$, where

$$\begin{aligned}
\Pi_{\Omega_j^+,\nu} := \{\sigma \in L_2(\mathbb{R}) : \sigma|_{(\tilde{t}_{j-1}+y_{m-1}, \tilde{t}_{j-1}+y_m)} &\text{ is a polynomial of degree} \leq \nu, \text{ for} \\
m = 1, \ldots, N + N_{A_j}, \text{ and } \sigma|_{\mathbb{R}\setminus[\tilde{t}_{j-1}, \tilde{t}_{j-1}+A_j]} &= 0\}, \\
\Pi_{\Omega_j^-,\nu} := \{\sigma \in L_2(\mathbb{R}) : \sigma|_{(\tilde{t}_j - y_m, \tilde{t}_j - y_{m-1})} &\text{ is a polynomial of degree} \leq \nu, \text{ for} \\
m = 1, \ldots, N + N_{A_j}, \text{ and } \sigma|_{\mathbb{R}\setminus[\tilde{t}_j - A_j, \tilde{t}_j]} &= 0\},
\end{aligned}$$

and $y_0, \ldots, y_{N_{A_j}}$ are the points of the mesh Λ_{N,A_j}. Our approximation space is then $V_{\Omega,\nu}$, the linear span of $\bigcup_{j=1,\ldots,n}\{V_{\Omega_j^+,\nu} \cup V_{\Omega_j^-,\nu}\}$.

Let $(\cdot,\cdot)$ denote the usual inner product on $L_2(\mathbb{R})$, $(\chi_1, \chi_2) := \int_{-\infty}^{\infty} \chi_1(s)\overline{\chi_2}(s)\,\mathrm{d}s$, $\chi_1, \chi_2 \in L_2(\mathbb{R})$. Then our Galerkin method approximation, $\Phi_N \in V_{\Omega,\nu}$, is defined by

$$(\Phi_N, \rho) = (\Psi_\beta^{\beta_c}, \rho) + (K_\beta^{\beta_c}\Phi_N, \rho) \quad \text{for all } \rho \in V_{\Omega,\nu}; \tag{3.5}$$

equivalently,

$$\Phi_N - P_N K_\beta^{\beta_c}\Phi_N = P_N Q \Psi_\beta^{\beta_c}, \tag{3.6}$$

where $P_N : L_2(\mathbb{R}) \to V_{\Omega,\nu}$ is the operator of orthogonal projection onto $V_{\Omega,\nu}$. Equation (3.5) can be written explicitly as a system of M_N linear algebraic equations, where M_N, the dimension of $V_{\Omega,\nu}$, i.e., the number of degrees of freedom, is given by

$$M_N = 2(\nu+1)\sum_{j=1}^{n}(N + N_{A_j}). \tag{3.7}$$

By (3.3) and (3.4), where $\bar{A} := (A_1 \ldots A_n)^{1/n} \leq (A_1 + \cdots + A_n)/n$,

$$M_N < (\nu+1)Nn\left[3 + \frac{2\log\bar{A}}{q}\right] \leq (\nu+1)Nn\left[3 + \frac{2}{q}\log\min\left(\frac{\alpha n^3 N^{\nu+1}}{\cos\theta}, \frac{k(b-a)}{n}\right)\right].$$

Using an argument similar to that for the Galerkin method in [20], it can be shown that, provided (3.2) holds, (3.6) is uniquely solvable and

$$\|(I - P_N K_\beta^{\beta_c})^{-1}\| \leq \frac{\mathrm{Re}\beta_c}{\mathrm{Re}\beta_c - \|\beta - \beta_c\|_\infty}, \tag{3.8}$$

and thus

$$\|\Phi^* - \Phi_N\|_2 \leq \frac{\mathrm{Re}\beta_c}{\mathrm{Re}\beta_c - \|\beta - \beta_c\|_\infty}\|\Phi^* - P_N\Phi^*\|_2. \tag{3.9}$$

There is also a description in [20] of how one can perturb the original problem in such a way that the condition (3.2) on β is forced to hold, and the solution of the perturbed problem is arbitrarily close in an arbitrarily large bounded region to the solution of the original problem. In any case, numerical results in [38] suggest that the Galerkin scheme we propose is stable and convergent even when (3.2) does not hold. In this case the bound (3.9) does not apply, however.

It remains to bound $\|\Phi^* - P_N\Phi^*\|_2$, showing that our approximation space is well adapted to approximate Φ^*. We introduce P_N^+ and P_N^-, the orthogonal projection operators from $L_2(\mathbb{R})$ onto $\Pi_{\Omega^+,\nu}$ and $\Pi_{\Omega^-,\nu}$, respectively, where $\Pi_{\Omega^\pm,\nu}$ denotes the linear span of $\bigcup_{j=1,\dots,n}\Pi_{\Omega_j^\pm,\nu}$. We also define

$$f_+(s) := \begin{cases} f_j^+(s-\tilde{t}_{j-1}), & s\in(\tilde{t}_{j-1},\tilde{t}_j],\ j=1,\dots,n,\\ 0, & s\in\mathbb{R}\backslash(\tilde{t}_0,\tilde{t}_n],\end{cases}$$
$$f_-(s) := \begin{cases} f_j^-(\tilde{t}_j - s), & s\in(\tilde{t}_{j-1},\tilde{t}_j],\ j=1,\dots,n,\\ 0, & s\in\mathbb{R}\backslash(\tilde{t}_0,\tilde{t}_n].\end{cases}$$

Then we have the following error estimate.

THEOREM 3.3. *If* (1.4) *holds for some* $\epsilon > 0$, *then*

$$\|f_+ - P_N^+ f_+\|_2 \le C_{\epsilon,\nu}\frac{n^{1/2}}{N^{\nu+1}}\left(1+\log^{1/2}\left(\min\left(\alpha\frac{n^3N^{\nu+1}}{\cos\theta}, k(b-a)\right)\right)\right),$$

where α *is the constant in* (3.4), *and the identical bound holds on* $\|f_- - P_N^- f_-\|_2$.

Proof. We prove the result for $\|f_+ - P_N^+ f_+\|_2$, the bound on $\|f_- - P_N^- f_-\|_2$ can be proved in a similar way. Recalling (3.4),

$$\begin{aligned}\|f_+ - P_N^+ f_+\|_2^2 &= \|f_+ - P_N^+ f_+\|_{2,(\tilde{a},\tilde{b})}^2\\ &= \sum_{j=1}^n\left[\|f_+ - P_N^+ f_+\|_{2,(\tilde{t}_{j-1},\tilde{t}_{j-1}+A_j)}^2 + \|f_+ - P_N^+ f_+\|_{2,(\tilde{t}_{j-1}+A_j,\tilde{t}_j)}^2\right].\end{aligned}$$

Now, by Theorems 2.3 and 3.2,

$$\|f_+ - P_N^+ f_+\|_{2,(\tilde{t}_{j-1},\tilde{t}_{j-1}+A_j)} \le C_{\epsilon,\nu}\cos\theta\frac{1+\log^{1/2}A_j}{N^{\nu+1}}.$$

If $\alpha n^3N^{\nu+1}/\cos\theta \ge \tilde{t}_j - \tilde{t}_{j-1}$, then $A_j = \tilde{t}_j - \tilde{t}_{j-1}$, in which case

$$\|f_+ - P_N^+ f_+\|_{2,(\tilde{t}_{j-1}+A_j,\tilde{t}_j)} = 0.$$

If $\alpha n^3N^{\nu+1}/\cos\theta < \tilde{t}_j - \tilde{t}_{j-1}$, then $A_j = \alpha n^3N^{\nu+1}/\cos\theta$, and then, recalling the definition of $\Pi_{\Omega^+,\nu}$ and Theorem 2.6,

$$\begin{aligned}\|f_+ - P_N^+ f_+\|_{2,(\tilde{t}_{j-1}+A_j,\tilde{t}_j)}^2 = \|f_+\|_{2,(\tilde{t}_{j-1}+A_j,\tilde{t}_j)}^2 &\le C_\epsilon\frac{n^6}{\cos^2\theta}\int_{A_j}^\infty s^{-3}\,\mathrm{d}s\\ &= C_\epsilon\frac{n^6}{2\cos^2\theta}A_j^{-2} = \frac{C_\epsilon}{2\alpha^2}N^{-2(\nu+1)},\end{aligned}$$

and recalling that $\alpha \ge 1$ the result follows. □

To use the above error estimate, note from (2.16) that $\Phi^* = e_+ f_+ + e_- f_-$. But $e_+ P_N^+ f_+ + e_- P_N^- f_- \in V_{\Omega,\nu}$, and $P_N \Phi^*$ is the best approximation to Φ^* in $V_{\Omega,\nu}$. So

$$\begin{aligned}\|\Phi^* - P_N\Phi^*\|_2 &\le \|\Phi^* - (e_+ P_N^+ f_+ + e_- P_N^- f_-)\|_2 \\ &= \|e_+(f_+ - P_N^+ f_+) + e_-(f_- - P_N^- f_-)\|_2 \\ &\le \|e_+\|_\infty \|f_+ - P_N^+ f_+\|_2 + \|e_-\|_\infty \|f_- - P_N^- f_-\|_2.\end{aligned}$$

Applying Theorem 3.3 we obtain the following result.

Theorem 3.4. *If* (1.4) *holds for some* $\epsilon > 0$*, then*

$$\|\Phi^* - P_N\Phi^*\|_2 \le C_{\epsilon,\nu} \frac{n^{1/2}}{N^{\nu+1}} \left(1 + \log^{1/2}\left(\min\left(\alpha \frac{n^3 N^{\nu+1}}{\cos\theta}, k(b-a)\right)\right)\right),$$

where α *is the constant in* (3.4).

Combining this result with the stability bound (3.9) we obtain our final error estimate for the approximation of Φ by Φ_N.

Theorem 3.5. *If* (1.4) *holds for some* $\epsilon > 0$*, and* (3.2) *is satisfied, then*

$$\|\Phi - \Phi_N\|_{2,(\tilde{a},\tilde{b})} = \|\Phi^* - \Phi_N\|_2 \le \frac{C_{\epsilon,\nu} n^{1/2}(1 + \log^{1/2}(\min(\alpha n^3 N^{\nu+1}/\cos\theta, k(b-a))))}{(\mathrm{Re}\beta_c - \|\beta - \beta_c\|_\infty) N^{\nu+1}},$$

where α *is the constant in* (3.4)*. Further, the number of degrees of freedom* M_N *satisfies*

$$M_N \le C_\nu N n \left[1 + \log\min\left(\frac{\alpha n^3 N^{\nu+1}}{\cos\theta}, \frac{k(b-a)}{n}\right)\right].$$

We finish by considering the computation of an approximation to u^t throughout the upper half plane U, once the Galerkin solution Φ_N has been computed. Recalling (2.13) and (2.14) we define $\phi_N \in L_2(\tilde{a}, \tilde{b})$, an approximation to ϕ on $(\tilde{a}, \tilde{b})$, by

$$\phi_N(s) := \Phi_N(s) + \psi_{\beta_j}(s), \quad s \in (\tilde{t}_{j-1}, \tilde{t}_j],\ j = 1, \dots, n,$$

where ψ_{β_j} is given explicitly by (2.7). Then, recalling that $u^t((y_1, 0)) = \phi(ky_1)$, we define an approximation to u^t by replacing $u^t(y)$ by its approximation $\phi_N(ky_1)$ in (2.5), to give the approximation u_N^t defined by

$$u_N^t(x) := u_{\beta_c}^t(x) + \mathrm{i}k \int_a^b G_{\beta_c}(x, (y_1, 0))(\beta(y_1) - \beta_c)\phi_N(ky_1)\,\mathrm{d}y_1. \tag{3.10}$$

From (2.2) and (2.3), and using properties of standard single-layer potentials [23], it follows that $u_N^t \in C^2(U) \cap C(\overline{U})$ and satisfies the Helmholtz equation (1.1) in U. Further, from Theorem 3.5 we deduce the following error estimate.

Theorem 3.6. *If* (1.4) *holds for some* $\epsilon > 0$*, and* (3.2) *is satisfied, then*

$$|u^t(x) - u_N^t(x)| \le \frac{C_{\epsilon,\nu} n^{1/2}(1 + \log^{1/2}(\min(\alpha n^3 N^{\nu+1}/\cos\theta, k(b-a))))}{(\mathrm{Re}\beta_c - \|\beta - \beta_c\|_\infty) N^{\nu+1}}$$

for $x \in \overline{U}$*, where* α *is the constant in* (3.4).

Proof. Subtracting (3.10) from (2.5) and using the Cauchy–Schwarz inequality and the definitions of Φ^* and ϕ_N, we see that

$$\begin{aligned}|u^t(x) - u^t_N(x)| &= \left| \int_{\tilde{a}}^{\tilde{b}} G_{\beta_c}(x, (t/k, 0))(\beta(t/k) - \beta_c)(\Phi(t) - \Phi_N(t))\,\mathrm{d}t \right| \\ &\le \|\beta - \beta_c\|_\infty \left\{ \int_{-\infty}^{\infty} |G_{\beta_c}(x, (t/k, 0))|^2 \,\mathrm{d}t \right\}^{1/2} \|\Phi - \Phi_N\|_{2,(\tilde{a},\tilde{b})}.\end{aligned}$$

Now, defining $H = kx_2$ and using (2.2) we see that for $H \ge 1/2$ it holds that

$$\begin{aligned}\int_{-\infty}^{\infty} |G_{\beta_c}(x, (t/k, 0))|^2 \,\mathrm{d}t &\le C_\epsilon (1 + H)^2 \int_{-\infty}^{\infty} \frac{\mathrm{d}t}{(t^2 + H^2)^{3/2}} \\ &= 2C_\epsilon \frac{(1 + H)^2}{H^2} \int_0^\infty \frac{\mathrm{d}s}{(1 + s^2)^{3/2}} \le C_\epsilon \int_0^\infty \frac{\mathrm{d}s}{(1 + s^2)^{3/2}}.\end{aligned}$$

Using (2.2) and (2.3) we see that, for $0 \le H < 1/2$,

$$\begin{aligned}\int_{-\infty}^{\infty} |G_{\beta_c}(x, (t/k, 0))|^2 \,\mathrm{d}t &\le C_\epsilon \left(\int_{\sqrt{1-H^2}}^{\infty} \frac{(1 + H)^2 \mathrm{d}t}{(t^2 + H^2)^{3/2}} + \int_0^{\sqrt{1-H^2}} \left(1 - \frac{1}{2}\log(t^2 + H^2)\right) \mathrm{d}t \right) \\ &\le C_\epsilon \left(\frac{9}{4} \int_{\sqrt{3}/2}^{\infty} \frac{\mathrm{d}t}{t^3} + \int_0^1 (1 - \log t)\,\mathrm{d}t \right).\end{aligned}$$

Thus $|u^t(x) - u^t_N(x)| \le C_\epsilon \|\Phi - \Phi_N\|_{2,(\tilde{a},\tilde{b})}$, and the result follows from Theorem 3.5. □

4. Implementation and numerical results.

We restrict our attention in this section to the case $\nu = 0$. The implementation of the scheme is similar for higher values of ν. Recalling (3.5), the equation we wish to solve is

$$(\Phi_N, \rho) - (K^{\beta_c}_\beta \Phi_N, \rho) = (\Psi^{\beta_c}_\beta, \rho) \quad \text{for all } \rho \in V_{\Omega,0}. \tag{4.1}$$

Writing Φ_N as a linear combination of basis functions of $V_{\Omega,0}$, we have $\Phi_N(s) = \sum_{j=1}^{M_N} v_j \rho_j(s)$, where M_N is given by (3.7) and ρ_j is the jth basis function, defined by

$$\begin{aligned}\rho_j(s) &:= \frac{\mathrm{e}^{\mathrm{i}s}\chi_{[s^+_{\tilde{j}}, s^+_{\tilde{j}-1})}(s)}{(s^+_{\tilde{j}} - s^+_{\tilde{j}-1})^{1/2}}, \quad j = \tilde{j} + 2\sum_{m=1}^{p-1}(N + N_{A_m}),\ \tilde{j} = 1, \dots, N + N_{A_p}, \\ \rho_j(s) &:= \frac{\mathrm{e}^{-\mathrm{i}s}\chi_{[s^-_{\tilde{j}}, s^-_{\tilde{j}-1})}(s)}{(s^-_{\tilde{j}} - s^-_{\tilde{j}-1})^{1/2}}, \quad j = \tilde{j} + N + N_{A_p} + 2\sum_{m=1}^{p-1}(N + N_{A_m}),\ \tilde{j} = 1, \dots, N + N_{A_p},\end{aligned}$$

for $p = 1, \dots, n$, where $s^+_l \in \Omega^+_p$, $s^-_l \in \Omega^-_p$ for $l = 0, \dots, N + N_{A_p}$, and $\chi_{[s_1,s_2)}$ denotes the characteristic function of the interval $[s_1, s_2)$. Equation (4.1) then becomes the linear system

$$\sum_{j=1}^{M_N} v_j((\rho_j, \rho_m) - (K^{\beta_c}_\beta \rho_j, \rho_m)) = (\Psi^{\beta_c}_\beta, \rho_m), \quad m = 1, \dots, M_N. \tag{4.2}$$

If k is large compared to N, then, from the definition of A_j in (3.4), it is clear that the two meshes Ω^+_j and Ω^-_j will not overlap. In this case the basis functions ρ_j,

$j = 1, \dots, M_N$, form an orthonormal basis for $V_{\Omega,\nu}$ (this is not true for the Galerkin method described in [20]), and hence the condition number of our linear system (4.2) will be bounded by (see, e.g., [2, section 3.6.3])

$$\begin{aligned}\|(I - P_N K_\beta^{\beta_c})\|_2 \|(I - P_N K_\beta^{\beta_c})^{-1}\|_2 &\leq (1 + \|K_\beta^{\beta_c}\|_2) \left(\frac{\mathrm{Re}\beta_c}{\mathrm{Re}\beta_c - \|\beta - \beta_c\|_\infty} \right) \\ &\leq \left(1 + \frac{\|\beta - \beta_c\|_\infty}{\mathrm{Re}\beta_c}\right) \left(\frac{\mathrm{Re}\beta_c}{\mathrm{Re}\beta_c - \|\beta - \beta_c\|_\infty} \right) \\ &= \frac{\mathrm{Re}\beta_c + \|\beta - \beta_c\|_\infty}{\mathrm{Re}\beta_c - \|\beta - \beta_c\|_\infty}, \qquad (4.3)\end{aligned}$$

where we have used (3.8) (under the assumption that (3.2) holds) and the facts that $\|K_\beta^{\beta_c}\|_2 \leq \|\beta - \beta_c\|_\infty / \mathrm{Re}\beta_c$ (see, e.g., [20, (3.2)]) and $\|P_N\|_2 = 1$. The fact that we can establish such a bound on the condition number of our linear system is in direct contrast to some other schemes in the literature where the approximation space consists of plane wave basis functions, e.g., [41, 44, 45], where serious difficulties due to ill-conditioning have been reported.

To evaluate the coefficients $(K_\beta^{\beta_c} \rho_j, \rho_m)$ and $(\Psi_\beta^{\beta_c}, \rho_m)$ of (4.2) we must compute some integrals numerically. The exact formulas are given in [38], but note that after some integrations are carried out analytically, the most difficult of these take the forms

$$\int_0^\infty \frac{(\mathrm{i} - r)F(r)}{r(r - 2\mathrm{i})}\,\mathrm{d}r, \int_0^\infty \frac{(1 - \mathrm{e}^{rs})F(r)}{r^2}\,\mathrm{d}r, \int_0^\infty \frac{(1 - \mathrm{e}^{rs})F(r)}{r(r - 2\mathrm{i})}\,\mathrm{d}r,$$

where $s < 0$ and $F(r)$ is given by (2.20). These integrals are similar in difficulty to integral representations for the Green's function G_{β^*}, for which very efficient numerical schemes are proposed in [18]. The integrands are not oscillatory and the coefficients do not become more difficult to evaluate as $k \to \infty$.

As a numerical example, we take $\theta = \pi/4$, $n = 1$, and

$$\beta(s) = \begin{cases} 0.505 - 0.3\mathrm{i}, & s \in [-m\lambda, m\lambda], \\ 1, & s \notin [-m\lambda, m\lambda], \end{cases}$$

for $m = 5$, 10, 20, 40, 80, 160, 320, 640, 1280, 2560, and 5120, where $k = 1$ and $\lambda = 2\pi$ is the wavelength. This experiment is equivalent to fixing the interval $[a, b] = [t_0, t_1]$ and decreasing the wavelength. The assumption (3.2) is satisfied, so that Theorem 3.5 holds. For each value of m, we compute Φ_N with $\nu = 0$, $\alpha = 25\sqrt{2}$ (so that $\alpha n^3/\cos\theta = \sqrt{2}\alpha = 50$, this value chosen experimentally) and $N = 2$, 4, 8, 16, 32, 64. For the purpose of computing errors, we take the "exact" solution (Φ^*) to be the solution computed with $\sqrt{2}\alpha = 1000$ and $N = 128$. Whereas for the scheme of [20] the number of degrees of freedom needed to maintain accuracy increases logarithmically with respect to $k(b - a)$ as $k(b - a) \to \infty$, here the number needed to maintain accuracy remains bounded as $k(b - a) \to \infty$, as we shall see below.

In Figure 4.1 we plot $|\Phi^*|$ and $|\Phi_2|$ for $m = 10$. Noting the logarithmic scales on the plots, it is clear that $|\Phi^*|$ is highly peaked near the discontinuities in impedance. Recalling that Φ is a correction term, namely, the difference between the true solution and the solution that there would be if the impedance were constant everywhere, the reason for this is clear. On the plot of $|\Phi_2|$ we also show the two grids Ω_1^+ and Ω_1^-. For

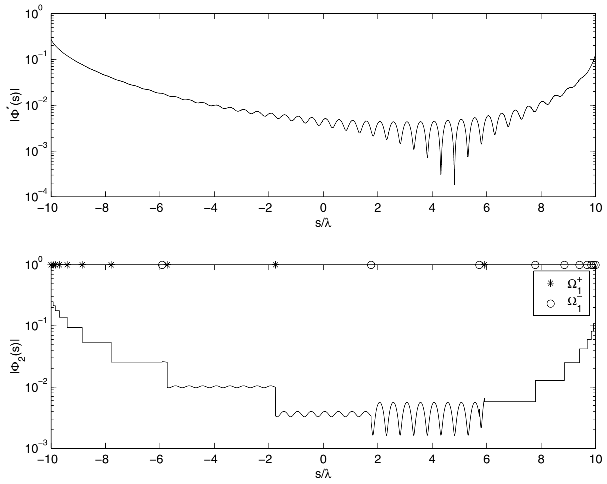

FIG. 4.1. *Plot of* $|\Phi^*|$ *and* $|\Phi_2|$*,* $m = 10$*, so that* $b - a = 20\lambda$*.*

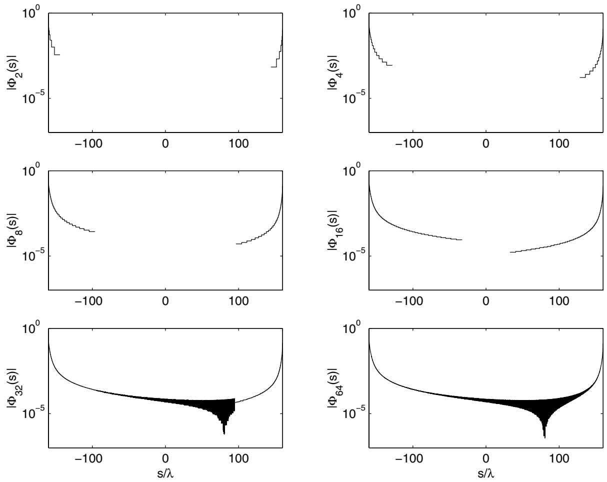

FIG. 4.2. *Plot of* $|\Phi_N|$*,* $N = 2$*, 4, 8, 16, 32, 64 for* $m = 160$*, so that* $b - a = 320\lambda$*.*

s/λ less than about -6 and for s/λ greater than about 6 the grids do not overlap, and on these regions $\Phi_2(s) = e^{\mathrm{i}s}\times$ (piecewise constants) and $\Phi_2(s) = e^{-\mathrm{i}s}\times$ (piecewise constants), respectively. Thus $|\Phi_2(s)|$ is piecewise constant where the grids do not overlap, and this can be clearly seen in Figure 4.1. Where the grids overlap, (roughly between $s/\lambda = -6$ and $s/\lambda = 6$) the oscillatory nature of $\Phi_2(s)$ is more apparent.

In Figure 4.2 we plot $|\Phi_N|$ for $m = 160$ and for $N = 2, 4, 8, 16, 32, 64$. Again noting the logarithmic scales on each plot, $|\Phi_N|$ is highly peaked near the impedance discontinuities, much more so than for $m = 10$. As N increases so we discretize a larger part of the domain $[-m\lambda, m\lambda]$, as well as having a finer mesh near the discontinuities in impedance at $-m\lambda$, $m\lambda$. For $N = 2, 4, 8, 16$ the piecewise constant approximation can be clearly seen, as the grids Ω_1^+ and Ω_1^- do not overlap. For $N = 32$ the grids overlap between about $s\lambda = -100$ and $s\lambda = 100$. For $N = 64$, each grid covers the whole domain $[-m\lambda, m\lambda]$.

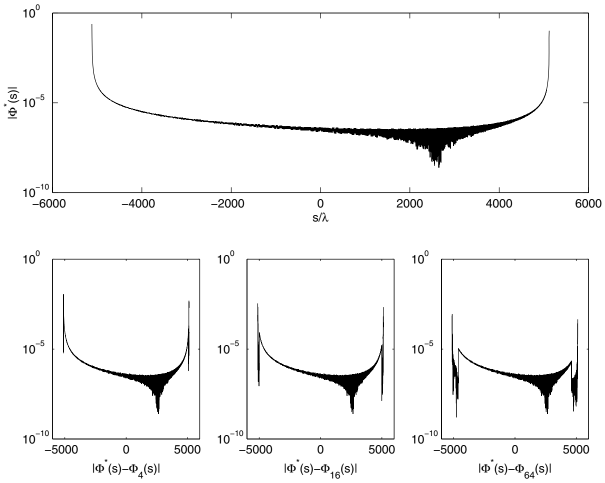

FIG. 4.3. *Plot of* $|\Phi^*|$ *and* $|\Phi^* - \Phi_N|$, $N = 4$, 16, 64 *for* $m = 5120$, *so that* $b - a = 10240\lambda$.

	64	1154	4.579×10^{-3}		2.1

In Figure 4.3 we plot $|\Phi^*|$ and $|\Phi^* - \Phi_N|$ for $m = 5120$ and for $N = 4$, 16 and 64. In this case the interval $[-m\lambda, m\lambda]$ is over 10,000 wavelengths long, and so even for $N = 64$ the grids Ω_1^+ and Ω_1^- do not overlap. As m increases, so $|\Phi^*|$ becomes even more peaked, and the benefit of clustering the grid points around the impedance discontinuities becomes even more apparent.

For $m = 10$, 160, and 5120 the relative L_2 errors $\|\Phi^* - \Phi_N\|_2/\|\Phi^*\|_2$ are shown in Table 4.1. (All L_2 norms are computed by approximating by discrete L_2 norms, sampling at 100,000 evenly spaced points in the relevant interval for the function whose norm is to be evaluated.) The estimated order of convergence is given by

$$\mathrm{EOC} := \log_2\left(\frac{\|\Phi^* - \Phi_N\|_2}{\|\Phi^* - \Phi_{2N}\|_2}\right).$$

Table 4.2
$\|\Phi^* - \Phi_{16}\|_2/\|\Phi^*\|_2$ *for increasing interval length.*

$(b-a)/\lambda$	M_N	$\|\Phi^* - \Phi_{16}\|_2/\|\Phi^*\|_2$	$\|\Phi^* - \Phi_{16}\|_2$	COND
10	162	1.746×10^{-2}	7.936×10^{-3}	181.5
20	182	1.773×10^{-2}	8.059×10^{-3}	94.0
40	204	1.775×10^{-2}	8.068×10^{-3}	24.7

640	240	1.749×10^{-2}	7.916×10^{-3}	2.1
1280	240	1.650×10^{-2}	7.435×10^{-3}	2.1
2560	240	1.616×10^{-2}	7.216×10^{-3}	2.1
5120	240	1.556×10^{-2}	6.831×10^{-3}	2.1
10240	240	1.751×10^{-2}	7.433×10^{-3}	2.1

For this example, Theorem 3.5 predicts that

$$\|\Phi^* - \Phi_N\|_2 \le \frac{C}{N}(1 + \log^{1/2}(\min(\sqrt{2}\alpha N, 2m\lambda))),$$

so that we expect EOC ≈ 1, and this is what we see. For each value of m, the number of degrees of freedom M_N increases approximately in proportion to $N \log N$ as N increases until the two grids Ω_1^+ and Ω_1^- each cover the whole domain $[-m\lambda, m\lambda]$ (i.e., until $\sqrt{2}\alpha N \ge 2m\lambda$), after which M_N increases only proportionally to N as N increases further. For $m = 10$, the whole domain is covered by the grids for $N = 4$; for $m = 160$ this occurs for $N = 64$ but for $m = 5120$ the two grids do not overlap even for $N = 64$. The condition numbers for the matrix of the linear system (4.2) (denoted by COND) satisfy the bound (4.3), which predicts that COND ≤ 3.75 if the grids do not overlap, i.e., if $N \le 16$ for $m = 160$, for all values of N when $m = 5120$. For $N \le 32$ the number of degrees of freedom is the same for $m = 160$ and $m = 5120$, and yet the relative L_2 error is almost the same for the two cases $b - a = 320\lambda$ and $b - a = 10240\lambda$.

In Table 4.2 we fix $N = 16$ and show $\|\Phi^* - \Phi_{16}\|_2/\|\Phi^*\|_2$ and also $\|\Phi^* - \Phi_{16}\|_2$ for increasing values of $m = (b - a)/2\lambda$. As m increases, the number of degrees of freedom increases logarithmically for those values of m for which $\sqrt{2}\alpha N \ge 2m\lambda$, i.e., for $m \le 40$, but as m increases further for $m \ge 80$ the number of degrees of freedom remains constant, and yet both the relative and the actual L_2 error also remain roughly constant as m grows. For $m = 5120$ the interval is of length greater than 10,000 wavelengths, and yet we achieve almost 1% relative error with only 240 degrees of freedom. As in Table 4.1, the condition number of the linear system (4.2) is bounded by (4.3), so that COND ≤ 3.75, when m is sufficiently large that the grids Ω_1^+ and Ω_1^- do not overlap, i.e., for $m \ge 160$.

In the last figure and table we show numerical computations of the total field above the boundary, i.e., $u_N^t(x)$ given by (3.10). We note that computing $u_N^t(x)$ requires, for each point x, the computation of the highly oscillatory integral (3.10), which is evaluated here using accurate but slow "black box" techniques. In the future it is hoped that more efficient quadrature schemes can be developed, taking advantage of the fact that the oscillatory parts of both G_{β_c} and ϕ_N are known explicitly. We note that Iserles [34, 35] has recently proposed and analyzed Filon-type quadrature methods appropriate for the efficient evaluation of highly oscillatory integrals, which we expect may be appropriate.

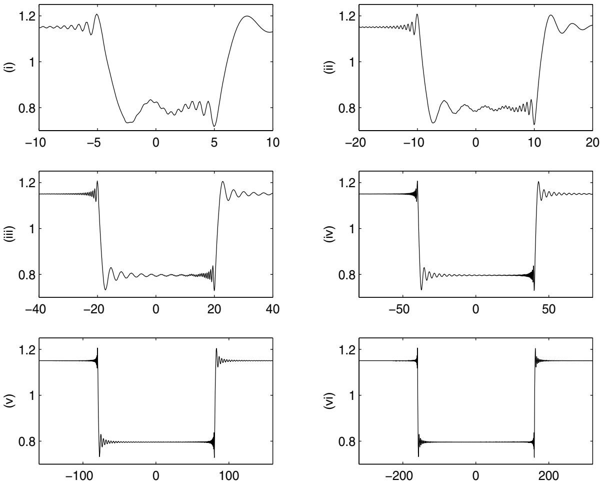

FIG. 4.4. $|u^t(x)|$ *(on the y-axis) against* x_1/λ *(on the x-axis) for* $x = (x_1, \lambda)$, $x_1 \in [-2m\lambda, 2m\lambda]$, *plotted for* $m = 5$ *(plot* (i)*),* $m = 10$ *(plot* (ii)*),* $m = 20$ *(plot* (iii)*),* $m = 40$ *(plot* (iv)*),* $m = 80$ *(plot* (v)*), and* $m = 160$ *(plot* (vi)*).*

	16	1.981×10^{-5}	2.1	1.060×10^{-5}	0.8
	32	4.474×10^{-6}	0.9	6.029×10^{-6}	3.4
	64	2.431×10^{-6}		5.634×10^{-7}	

In Figure 4.4 we plot $|u^t_{128}(x)|$ for $x = (x_1, \lambda)$, $x_1 \in [-2m\lambda, 2m\lambda]$, i.e., the absolute value of the total acoustic field one wavelength above the plane, as computed with $\sqrt{2}\alpha = 1000$ and $N = 128$, for $m = 5$ (plot (i)), $m = 10$ (plot (ii)), $m = 20$ (plot (iii)), $m = 40$ (plot (iv)), $m = 80$ (plot (v)), and $m = 160$ (plot (vi)). In each plot the x-axis represents x_1/λ and the y-axis represents $|u^t(x)|$. One can clearly see that the wave diffracted from the impedance discontinuities at $x = (-m\lambda, 0)$ and $x = (m\lambda, 0)$ is a significant component of the total field only within a small number of wavelengths of the impedance discontinuities. Figure 1.1 shows a surface plot of the incident, scattered and total wave fields up to 10 wavelengths above the plane for this same example with $m = 5$.

We also computed $u^t_N(x)$ for $x = (m\lambda/2, \lambda)$ and $x = (m\lambda, \lambda)$ for $m = 10$ and $m = 160$ and for $\sqrt{2}\alpha = 50$, $N = 2$, 4, 8, 16, 32, and 64. Taking the values for $\alpha = 500\sqrt{2}$, $N = 128$ to be the "exact" values, the errors are shown in Table 4.3. The estimated order of convergence is calculated as

$$\mathrm{EOC} := \log_2 \left(\frac{|u^t(x) - u^t_N|}{|u^t(x) - u^t_{2N}|} \right),$$

and from Theorem 3.6 we would expect EOC ≈ 1. The convergence rate is rather irregular, but broadly speaking it is at least as good as expected, and the actual and relative errors are both very small. At every point x it holds that $0.7 < |u^t(x)| < 0.9$.

Further numerical results for $\theta \approx \pi/2$, i.e., grazing incidence, can be found in [39].

5. Conclusions and discussion. In this paper we have presented a Galerkin boundary element method for an acoustic scattering problem, and we have demonstrated, via both an a priori error analysis and numerical examples, that the number of degrees of freedom required for an accurate solution is bounded independently of the wavenumber. Our numerical method and analysis are for a specific scattering problem, namely the 2D problem of scattering by an unbounded flat surface with piecewise constant surface impedance, this problem being important in the theory of outdoor noise propagation and in an electromagnetic context.

As we discussed in our review of the literature, our method is an instance of the general idea of expressing the solution of the scattering problem as a finite sum of known oscillatory terms (given by the leading order behavior of the solution as $k \to \infty$) multiplied by unknown more slowly oscillating terms, these smoother components much more suitable for approximation by standard finite element functions than the original solution. Our results add to the evidence of the theory and numerical experiments of other authors [1, 29, 24, 10, 12] that this general methodology has promise for a range of scattering problems.

Specifically, we anticipate that many of the details of our numerical scheme and analysis will be applicable to other interesting scattering problems. This is clearest in the case of 2D acoustic scattering by a convex polygon, in the case that a homogeneous Dirichlet condition or an impedance boundary condition with constant impedance holds on each side. For this problem we expect that the behavior of the total field on each side of the polygon (after subtraction of the leading order high frequency asymptotics given by physical optics) will be very similar to the behavior quantified in Theorems 2.3 and 2.6. Thus the same mesh may be applicable and much of the same analysis. For more discussion of scattering by a 2D polygon see [20, section 6], [19].

Moreover, we expect that our mesh design will be relevant more generally, at least for representing certain components of the total field. In the case of three-dimensional scattering by convex polyhedra it seems to us likely that the mesh we propose will be useful in representing the variation of edge scattered waves in the direction perpendicular to the edge. In the case of 2D convex curvilinear polygons something close to the mesh we use on each interval $[t_{j-1}, t_j]$ may be appropriate on each side of the polygon, especially at higher frequencies when our mesh becomes more localized near the ends of the intervals just as the waves diffracted by the corners become more localized near the corners.

ERROR ESTIMATES FOR DISCONTINUOUS GALERKIN APPROXIMATIONS OF IMPLICIT PARABOLIC EQUATIONS*

K. CHRYSAFINOS[†] AND NOEL J. WALKINGTON[‡]

Abstract. We analyze the classical discontinuous Galerkin method for "implicit" parabolic equations. Symmetric error estimates for schemes of arbitrary order are presented. The ideas developed allow certain assumptions frequently required in previous work to be relaxed. For example, different discrete spaces are allowed at each time step, and the spatial operator is not required to be self-adjoint or independent of time. Error estimates are posed in terms of projections of the exact solution onto the discrete spaces and are valid under the minimal regularity guaranteed by the natural energy estimate. These projections are local and enjoy optimal approximation properties when the solution is sufficiently regular.

Key words. error estimates, discontinuous Galerkin, implicit parabolic equations

AMS subject classification. 65M60

DOI. 10.1137/040602948

1. Introduction.

We consider implicit parabolic partial differential equations of the form

$$(M(t)u)_t + A(t)u = F(t), \qquad u(0) = u_0. \tag{1.1}$$

The operators act on Hilbert spaces related through the standard pivot construction, $U \hookrightarrow H \simeq H' \hookrightarrow U'$, where each embedding is continuous and dense. Then, $A(.) : U \to U'$ is a linear map and $F(.) \in U'$. It is assumed that $M(.) : H \to H$ is a self-adjoint positive definite operator.

Conservation laws for systems undergoing diffusion may take the form of (1.1) when the capacity changes with time; for example, in a porous medium the porosity could change as the medium collapses due to oil being extracted from the reservoir. Classical parabolic equations (i.e., equations with M the identity) also take the form of (1.1) under a time-dependent change of coordinates, common examples being diffusion on surfaces (more generally manifolds) which are in motion and the Lagrange (or characteristic) Galerkin formulation of the convection diffusion equation [10, 19].

Here the classical discontinuous Galerkin (DG) scheme for approximating solutions of (1.1) is analyzed, and fully discrete error estimates are derived under minimal regularity assumptions. The class of DG schemes considered is classical in the sense that the discrete solutions may be discontinuous in time but are conforming in space, i.e., are in (a subspace of) U at each time. Our analysis extends the ideas introduced in [6] and addresses the following issues which have not yet been adequately considered in the literature.

- A systematic treatment of DG approximations of implicit parabolic equations of the form (1.1) has not been considered in the past.
- The natural setting for (1.1) involves time dependent norms (Hilbert scales); this gives rise to technical problems not encountered in the analysis of classical parabolic equations.
- The operator $A(.)$ may depend upon time and is not required to be self-adjoint.
- The subspaces of U used for the DG approximations may be different on each time interval $(t^{n-1}, t^n]$. This adds a significant complication to the analysis which is present even when $A = 0$. Indeed, the first step in our analysis is to consider the DG scheme for an auxiliary equation which reduces to an implicit ODE when the coercivity constant vanishes. This limiting case plays an important role in the error analysis.

  Different subspaces are an essential ingredient of adaptive strategies used in conjunction with a posteriori error estimates to give guaranteed error bounds. Retriangulation is also necessary for many algorithms based upon a Lagrangian coordinate system; below we present an example.
- The operator $A(.)$ is not required to be strictly coercive; semicoercivity of the form $\langle A(.)u, u\rangle \geq c|u|^2_{U(.)} - C\|u\|^2_{H(.)}$ is assumed. Here $|.|_{U(.)}$ is a seminorm such that $\|.\|^2_{U(.)} = |.|^2_{U(.)} + \|.\|^2_{H(.)}$. This causes significant problems in the analysis of DG schemes since the classical Gronwall argument, used for the continuous problem, fails in the discrete setting. This failure is due to the elementary observation that functions of the form $\chi_{[0,\hat{t})}u_h$ are not polynomial in time unless $\hat{t}$ is a partition point, so these functions are not available as test functions in the discrete setting.[1] Below these issues are circumvented by constructing polynomial approximations to the characteristic functions $\chi_{[0,\hat{t})}$.

As stated above, our analysis does not require any regularity above and beyond the natural bounds that follow from the usual energy estimate. This is essential for control problems where solutions of the dual problem typically will not exhibit any additional regularity. Care is taken to keep track of how the various constants depend upon the coercivity constant of $A(.)$. This is important for the analysis of problems like the convection diffusion equation where the coercivity constant is small.

We present an example which can be analyzed within the general framework developed here but falls outside of the theory developed, for example, in Thomée's text [28].

Example: Diffusion on manifolds. As an illustrative example, consider diffusion on a cell membrane, $\mathcal{S}(t) \subset \mathbb{R}^3$, which is being transported in an ambient fluid with velocity $\mathbf{V} = \mathbf{V}(t, x)$. In order to avoid triangulating the manifold at each step, a numerical scheme may compute the triangulation of a reference configuration, $\mathcal{S}_r$, and at each time t construct a mapping $x(t, .) : \mathcal{S}_r \to \mathcal{S}(t) \subset \mathbb{R}^3$. The reference configuration is typically $\mathcal{S}(0)$ or possibly the unit sphere S^2. If $\mathcal{S}_r$ is locally parameterized by coordinates $X \in U \subset \mathbb{R}^2$, the diffusion equation with diffusion constant $\sigma > 0$ takes the form

$$u_t - (1/J)\mathrm{div}_X \left(\sigma J (F^T F)^{-1} \nabla_X u\right) = 0, \tag{1.2}$$

where F is the 3×2 matrix with components $F_{i\alpha} = \partial x_i / \partial X_\alpha$ and $J = \sqrt{\det(F^T F)}$

[1] Here $\chi_{[0,\hat{t})}$ is the characteristic function equal to 1 on $[0, \hat{t})$ and equal to zero otherwise.

is the determinant of the first fundamental form. The determinant J satisfies

$$J_t = J\,(I - \mathbf{n}\otimes\mathbf{n})\cdot(\nabla_x \mathbf{V}) = J\sum_{ij}(\delta_{ij} - n_i n_j)(\partial V_i/\partial x_j),$$

where $\mathbf{n} = \mathbf{n}(t, X)$ is the normal to $\mathcal{S}(.)$. It follows that the diffusion equation is of the form (1.1) with $M(.)u = Ju$ and

$$A(.)u = -(I - \mathbf{n}\otimes\mathbf{n})\cdot(\nabla_x \mathbf{V})uJ - \operatorname{div}_X\left(\sigma J(F^T F)^{-1}\nabla_X u\right).$$

As $\mathcal{S}(.)$ and the solution $u(.)$ evolve, adaptive error control may modify the triangulation of $\mathcal{S}_r$ giving rise to different discrete subspaces on different intervals $(t^{n-1}, t^n]$ of $[0, T]$. It is also possible that $\mathcal{S}(t)$ will undergo large shears in which case matrix $F^T F$ will become ill conditioned; in this situation the geometry of $\mathcal{S}_r$ no longer resembles that of $\mathcal{S}(t)$, so the reference configuration needs to be updated and retriangulated. This example is considered in more detail in section 6 below.

1.1. Related results. The DG method was first introduced by Lasaint and Raviart [17] to simulate neutron transport. There is an abundant literature concerning applications of the DG scheme in hyperbolic problems; see, e.g., [5, 15, 29] and references within. The DG method for ordinary differential equations was considered by Delfour, Hager, and Trochu in [7]. They showed that the DG scheme was super convergent at the partition points (order $2k+2$ for polynomials of degree k).

In the context of parabolic equations DG schemes were first analyzed for linear parabolic problems by Jamet in [14] where $\mathcal{O}(\tau^k)$ results were proved and then by Eriksson, Johnson, and Thomée [13] where $\mathcal{O}(\tau^{2k-1})$ estimates are established at the partition points for smooth solutions. An excellent exposition of their results and, more generally, the DG method for parabolic equations can be found in Thomée's book [28]. In [28] nodal and interior estimates are presented in various norms. One may also consult [20] for the analysis of a related formulation based on the backward Euler scheme. The relation between the DG scheme and adaptive techniques was studied in [11] and [12]. Finally, some results concerning the analysis of parabolic integro-differential equations by discontinuous Galerkin method are presented in [18] (see also references therein).

In [10] DuPont and Liu introduce the concept of "symmetric error estimates" for parabolic problems. They define such an error estimate to be one of the form

$$|||u - u_h||| \le C \inf_{w_h\in\mathcal{U}_h} |||u - w_h|||,$$

where u and u_h are the exact and approximate solutions respectively, $|||.|||$ is an appropriate norm, and $\mathcal{U}_h$ is the discrete subspace in which approximation solutions are sought. While estimates of this form are standard for elliptic problems, this is not the case for evolution problems. For example, error estimates for evolution problems approximated by the implicit Euler scheme frequently involve terms of the form $\|u_{tt}\|_{L^2(\Omega)}$. Symmetric error estimates are useful for problems where the solution u may not be very regular, such as control problems, and are used to develop a posteriori error estimates for adaptive schemes. Symmetric error estimates for moving mesh finite element methods were studied in [10, 19] (see also references therein). Mesh modification techniques for finite elements have also been introduced in [21] and [22]. For some earlier work on convection-dominated problems based on the methods of characteristics and mesh modification, one may consult [8] and [9], respectively.

An alternative to the symmetric error estimates are estimates of the form

$$|||u - u_h||| \leq C|||u - \mathbb{P}_h u|||, \tag{1.3}$$

where $\mathbb{P}_h : \mathcal{U} \to \mathcal{U}_h$ is a projection which exhibits optimal interpolation properties if u is sufficiently smooth. Estimates of this form enjoy the same advantages of those proposed by DuPont and Liu. Theorem 5.1 below provides an estimate of the form (1.3) for implicit parabolic equations of the form (1.1), where the projection $\mathbb{P}_h u$ is the numerical approximation of an auxiliary equation using the DG scheme and is not local. However,

$$|||u - \mathbb{P}_h u||| \leq |||u - \mathbb{P}_h^{loc} u||| + |||\mathbb{P}_h u - \mathbb{P}_h^{loc} u|||,$$

where $\mathbb{P}_h^{loc}$ is a local projection, so the first term can be estimated using classical interpolation theory. The second term, $|||\mathbb{P}_h u - \mathbb{P}_h^{loc} u|||$, vanishes if the same subspace of U is used in each partition (t^{n-1}, t^n); otherwise, it depends solely upon the jump in the interpolant of the exact solution at the partition points $\{t^n\}_{n=0}^N$. The size of the constant C in (1.3) and its dependence on various constants play an important role; below we are careful to state the dependence of the constant upon the various coercivity constants and bounds assumed for the operator A.

Error estimates for Lagrange–Galerkin approximations of convection dominated problems for divergence-free velocity fields vanishing on the boundary are presented in [4]. Issues related to the stability of Lagrange–Galerkin approximations are also discussed in [23]. Recently there has been a lot of work on the development and analysis of discontinuous (in space) Galerkin methods for elliptic problems. A comprehensive survey and comparison of this work can be found in [3], which contains many references related to this approach.

1.2. Outline. In section 2 we introduce spaces and structural assumptions on the operators which guarantee that (1.1) is a well-posed implicit parabolic equation. Discrete spaces used for the DG approximation of (1.1) are introduced in section 3, and "discrete characteristic functions" are constructed on these spaces. These were introduced in [6] and are modified here to accommodate the time-dependent spaces.

We formulate and analyze the DG scheme for an auxiliary equation in section 4. This section focuses on the difficulties that arise in the presence of time-dependent norms and when different subspaces of U are used at every time step. Finally in section 5 error estimates are developed for the DG approximation of (1.1). The approximate solution of (1.1) is first compared with that of the auxiliary equation in Theorem 5.1. The results of section 4 are then used to obtain error estimates which take the form of the sum of (i) the "local truncation error," (ii) projection errors between different subspaces, and (iii) errors in the initial data.

One technical distinction between the error estimate developed for the classical parabolic problem in [6, Theorem 3.1] and Theorem 5.1 of section 5 is that the latter assumes the existence of an inverse hypothesis of the form $\|u_h\|_{U(t)} \leq C_{inv}(h)\|u_h\|_{H(t)}$ for u_h in the discrete subspaces of U. In Theorem 5.1 the product $\tau C_{inv}(h)$ enters into the error estimate where τ is the time step size. For classical second order parabolic problems, this term will be of order $\mathcal{O}(1)$ if $\tau \sim h$ and quasi-uniform finite element meshes with no small angles are used.

1.3. Notation. Spaces $H(t) = (H, \|.\|_{H(t)})$ and $U(t) = (U, \|.\|_{U(t)})$ with time dependent norms are used. The pivot spaces $H(t)$ have inner product $(u, v)_{H(t)} = (M(t)u, v)_H$, and the norms on the these spaces are often denoted by $|.|_{H(t)} \equiv \|.\|_{H(t)}$.

Each norm and inner product will be explicitly subscripted; while this is rather cumbersome, it helps to minimize confusion due the plethora of spaces and projections. Notation of the form $L^2[0,T;U(.)]$, $H^1[0,T;U'(.)]$, etc., is used to indicate the temporal regularity of functions with values in $U(.)$, $U'(.)$, etc.

Approximations of (1.1) will be constructed on a partition $0 = t^0 < t^1 < \cdots < t^N = T$ of $[0,T]$ with time step size denoted by $\tau^n = t^n - t^{n-1}$. On each interval of the form $(t^{n-1}, t^n]$ a subspace U_h^n of U is specified, and the approximate solutions will lie in the space

$$\mathcal{U}_h = \{u_h \in L^2[0,T;U(.)] \mid u_h|_{(t^{n-1},t^n]} \in \mathcal{P}_k(t^{n-1}, t^n; U_h^n)\}.$$

Here $\mathcal{P}_k(t^{n-1}, t^n; U_h^n)$ is the space of polynomials of degree k or less having values in U_h^n. Notice that, by convention, functions in $\mathcal{U}_h$ have been chosen to be left continuous with right limits. We will write u^n for $u_h(t^n) = u_h(t_-^n)$ and let u_+^n denote $u(t_+^n)$. This notation is also used with functions like the error $e = u - u_h$. The exact solution, u, is assumed to be in $C[0,T;H(.)]$ so that the jump in the error at t^n, denoted by $[e^n]$, is equal to $[u^n] = u_+^n - u^n$.

2. Implicit parabolic equations.

In this section structural assumptions required for the analysis of the implicit parabolic problem

$$(M(t)u)_t + A(t)u = F(t), \qquad u(0) = u_0, \tag{2.1}$$

are introduced. To characterize the time dependence of $A(.)$, equivalent norms on U of the form $\|u\|_{U(t)}^2 = |u|_{H(t)}^2 + |u|_{U(t)}^2$ are considered where $|.|_{U(t)}$ is a seminorm on U (the principle part) and $|.|_{H(t)} = (M(t).,.)_H$ is a norm on H with Riesz map (the symmetric positive operator) $M(t)$. Let $a(.;u,v)$ denote the natural bilinear form associated with $A(.)$, and assume that the spaces $(U(t), H(t))$ satisfy $U(t) \hookrightarrow H(t) \hookrightarrow U'(t)$, where each embedding is dense and continuous and the embedding constant is independent of time.

2.1. Structural assumptions.

The existence theory for implicit evolution equations of the form (2.1) almost always requires the operators $M(.)$ to be Riesz maps for a Hilbert space [26, 27], and this assumption is used in the analysis below.

Assumption 1. The operators $M(\cdot)$ are nonnegative and self-adjoint, and there exist constants $c(t) > 0$ such that

$$(M(t)u, u)_H \geq c(t)|u|_H^2.$$

It follows for each $t \geq 0$ that $(M(t)u, v)$ is an inner product on H, which is denoted by $(.,.)_{H(t)}$.

Definition 2.1. *$H(t)$ is the Hilbert space with underlying set H and inner product $(u,v)_{H(t)} = (M(t)u, v)_H$.*

With this notation it is possible to state the structural hypotheses which guarantee that (2.1) is parabolic in nature and facilitate the development of error estimates.

Assumption 2.

1. Smoothness of $M(t)$: For each $t > 0$ there exists a symmetric bilinear form, $\mu(t,.,.)$, satisfying

$$\frac{d}{dt}(u,v)_{H(t)} = (u_t, v)_{H(t)} + (u, v_t)_{H(t)} + \mu(t; u, v)$$

for u, $v \in H^1[0,T;H]$, and there exists $C_\mu > 0$ independent of time such that

$$|\mu(t,u,v)| \le C_\mu |u|_{H(t)} |v|_{H(t)}.$$

2. Equivalence of norms on $U(t)$: For each $0 < \tau \le T$ there exists $C_u > 0$ such that for all s, $t \ge 0$ with $|t-s| < \tau$

$$1/C_u \le \|v\|_{U(t)}/\|v\|_{U(s)} \le C_u \qquad \forall\, v \in U.$$

3. Continuity of the bilinear form and data: There exist nonnegative constants $0 \le c_a \le C_a$ such that

$$|a(t;u,v)| \le \Big(c_a|u|^2_{U(t)} + C_a|u|^2_{H(t)}\Big)^{1/2}\Big(c_a|v|^2_{U(t)} + C_a|v|^2_{H(t)}\Big)^{1/2},$$

and there exists a (weighted dual) norm $\|.\|_*$ equivalent to $\|.\|_{U'}$ such that

$$|\langle F(t),u\rangle| \le \|F(t)\|_* \Big(c_a|u|^2_{U(t)} + C_a|u|^2_{H(t)}\Big)^{1/2}.$$

4. Coercivity of the bilinear form: There exist constants $C_\alpha \in \mathbb{R}$ and $c_\alpha > 0$ such that

$$a(t;u,u) \ge c_\alpha |u|^2_{U(t)} - C_\alpha |u|^2_{H(t)}.$$

In this context the natural weak statement of (2.1) is to find $u \in \mathcal{U} \equiv L^2[0,T;U(.)] \cap H^1[0,T;U'(.)]$ such that

$$\begin{aligned}(u(T),v(T))_{H(T)} &+ \int_0^T \Big(-(u,v_t)_{H(t)} + a(.;u,v)\Big)\\ &= (u_0,v(0))_{H(0)} + \int_0^T \langle F,v\rangle \qquad \forall\, v \in \mathcal{U}.\end{aligned} \tag{2.2}$$

2.2. Properties of $H(t)$. The smoothness assumption 2.1 guarantees that the norms on the pivot spaces $H(t)$ vary continuously with t. The following lemma quantifies this and will be used ubiquitously below.

LEMMA 2.2. *Let w, $z \in H$ and $s \le t$. Then* $\mathrm{e}^{C_\mu(s-t)} \le |z|^2_{H(t)}/|z|^2_{H(s)} \le \mathrm{e}^{C_\mu(t-s)}$ *and*

$$|(w,z)_{H(t)} - (w,z)_{H(s)}| \le (t-s)C_\mu \mathrm{e}^{C_\mu(t-s)} |w|_{H(\xi_1)} |z|_{H(\xi_2)}, \qquad \xi_1,\ \xi_2 \in [s,t].$$

Proof. The differentiability of $(.,.)_{H(.)}$ implies

$$(w,z)_{H(t)} - (w,z)_{H(s)} = \int_s^t \frac{d}{d\xi}(w,z)_{H(\xi)}\, d\xi = \int_s^t \mu(\xi,w,z).$$

Putting $w = z$ gives

$$|z|^2_{H(t)} = |z|^2_{H(s)} + \int_s^t \mu(\xi,z,z)\, d\xi \le |z|^2_{H(s)} + C_\mu \int_s^t |z|^2_{H(\xi)}\, d\xi.$$

Gronwall's inequality then shows $|z|^2_{H(t)} \le |z|^2_{H(s)} \mathrm{e}^{C_\mu(t-s)}$. Since this argument is symmetric in s and t, the first inequality follows.

The second inequality now follows from the intermediate value theorem:

$$|(w,z)_{H(t)} - (w,z)_{H(s)}| \le C_\mu \int_s^t |w|_{H(\xi)} |z|_{H(\xi)}\, d\xi = C_\mu(t-s)|w|_{H(\hat\xi)}|z|_{H(\hat\xi)}$$

for some $\hat\xi \in [s,t]$. Upon introducing a factor of $\mathrm{e}^{C_\mu(t-s)}$ each instance of $\hat\xi$ on the right may be replaced by any $\xi \in [s,t]$. □

3. Discrete spaces.

Discrete subspaces $\mathcal{U}_h$ of $L^2[0,T;U(.)]$ are constructed from a partition $0=t^0<t^1<\cdots<t^N=T$ and a sequence of subspaces $\{U_h^n\}_{n=1}^N$ of U as

$$\mathcal{U}_h=\{u_h\in L^2[0,T;U(.)]\ \mid\ u_h|_{(t^{n-1},t^n]}\in\mathcal{P}_k(t^{n-1},t^n;U_h^n)\}.$$

Projections of H onto the subspaces U_h^n with respect to the norms $H(t)$ appear in the analysis below; the following notation is used to denote these.

Notation 1. *$P_n(t)$ is the projection $P_n(t):H(t)\to U_h^n$ characterized by $P_n(t)u\in U_h^n$, $(P_n(t)u,v_h)_{H(t)}=(u,v_h)_{H(t)}$ for all $v_h\in U_h^n$.*

3.1. Discrete characteristic functions.

Estimates for the solution $u(t)$ of an evolution equation are frequently obtained by multiplying the equation by $\chi_{[0,t)}u$. This choice of test functions is not available in the discrete context unless the terminal time is one of the partition points. To estimate the solution at times $t\in[t^{n-1},t^n)$ we first recall the discrete characteristic functions introduced in [6, section 2.3].

The discrete characteristic functions on each interval are invariant under translation, so it is convenient to work on the interval $[0,\tau)$ with $\tau=t^n-t^{n-1}$. The first step is to consider polynomials $p\in\mathcal{P}_k(0,\tau)$. A discrete approximation of $\chi_{[0,t)}p$ is the polynomial $\hat p\in\{\hat p\in\mathcal{P}_k(0,\tau)|\hat p(0)=p(0)\}$ satisfying

$$\int_0^\tau\hat pq=\int_0^t pq\qquad\forall\,q\in\mathcal{P}_{k-1}(0,\tau).$$

The above construction is motivated by the fact that it is possible to select $q=p'$ to obtain $\int_0^\tau\hat pp'=\int_0^t pp'=(1/2)(p^2(t)-p^2(0))$.

This elementary construction extends to approximate functions of the form $\chi_{[0,t)}v$ for $v_h\in\mathcal{P}_k(0,\tau;V)$, where V is any semi-inner product space. If $v\in\mathcal{P}_k(0,\tau;V)$, it may be written as $v=\sum_{i=0}^k p_i(t)v_i$, where $\{p_i\}\subset\mathcal{P}_k(0,\tau)$ and $\{v_i\}\subset V$. Defining $\hat v=\sum_{i=0}^k\hat p_i(t)v_i$ it is clear that $\hat v\in\mathcal{P}_k(0,\tau;V)$ satisfies

$$\hat v(0)=v(0)\text{ and }\int_0^\tau(\hat v,w)_V=\int_0^t(v,w)_V\qquad\forall\,w\in\mathcal{P}_{k-1}(0,\tau;V).\tag{3.1}$$

We recall the following elementary lemma from [6, Lemma 2.7] which shows that the mapping $v\mapsto\hat v$ is continuous on $\mathcal{P}_k(0,\tau,V)$.

Lemma 3.1. *Let V be a semi-inner product space. Then the mapping*

$$v=\sum_{i=0}^k p_i(t)v_i\mapsto\hat v=\sum_{i=0}^k\hat p_i(t)v_i$$

on $\mathcal{P}_k(0,\tau;V)$ is continuous in $\|\cdot\|_{L^2[0,\tau;V]}$. In particular, there exists $C_k>0$ depending upon only k such that

$$\|\hat v\|_{L^2[0,\tau;V]}\le C_k\|v\|_{L^2[0,\tau;V]}\quad\textit{and}\quad\|\hat v-\chi_{[0,t)}v\|_{L^2[0,\tau;V]}\le C_k\|v\|_{L^2[0,\tau;V]}.$$

Notice that the above construction is purely algebraic in the sense that (3.1) holds for any choice of inner product on V. A major complication encountered with the time-dependent spaces is that the analogous construction with V replaced by $H(t)$ is no longer algebraic; the time dependence of $H(t)$ enters into the definition. In this situation estimates in other spaces, such as $U(t)$, are no longer automatic.

For the implicit evolution problem it is necessary to modify the above construction. If $u \in \mathcal{P}_k(0,\tau;U_h)$, define a discrete approximation $\tilde{u}$ of $\chi_{[0,\tau)}u$ by the following: $\tilde{u} \in \mathcal{P}_k(0,\tau;U_h)$ is the function satisfying

$$\tilde{u}(0) = u(0) \quad \text{and} \quad \int_0^\tau (\tilde{u}, w)_{H(.)} = \int_0^t (u, w)_{H(.)} \qquad \forall\, w \in \mathcal{P}_{k-1}(0,\tau;U_h). \tag{3.2}$$

A slight modification of Lemma 2.4 from [6] can be used to establish bounds for $\tilde{u}$ in $L^2[0,\tau;H(.)]$.

Lemma 3.2. *The mapping $u \mapsto \tilde{u}$ in $\mathcal{P}_k[0,\tau;H(.)]$ is linear and continuous, and there exists a constant C_k depending only upon k such that*

$$\|\tilde{u} - u\|_{L^2[0,\tau;H(.)]} \le C_k \mathrm{e}^{C_\mu \tau} \|u\|_{L^2[t,\tau;H(.)]}.$$

Moreover

$$\|\tilde{u} - \chi_{[0,t)}u\|_{L^2[0,\tau;H(.)]} \le (1 + C_k \mathrm{e}^{C_\mu \tau}) \|u\|_{L^2[t,\tau;H(.)]},$$

and $\|\tilde{u}\|_{L^2[0,\tau;H(.)]} \le (1 + C_k \mathrm{e}^{C_\mu \tau}) \|u\|_{L^2[0,\tau;H(.)]}$

The proof is essentially the same as in [6, Lemma 2.4]; the only difference concerns the scaling argument required to show that C_k can be chosen to be independent of time. To do this Lemma 2.2 is used to bound $\|u - \tilde{u}\|_{L^2[0,\tau,H(.)]}$ by $\|u - \tilde{u}\|_{L^2[0,\tau,H(\tau/2)]}$ to remove the implicit time dependence through $H(t)$.

To bound $\tilde{u}$ in $L^2[0,\tau;U(.)]$, the difference, $\tilde{u} - \hat{u}$, with the algebraic projection $\hat{u}$ is first estimated in the weaker norm $L^2[0,\tau;H(.)]$.

Lemma 3.3. *Let $u \in \mathcal{P}_k(0,\tau,U_h^n)$ and $\tilde{u}$ be the projections defined in* (3.2). *If $\hat{u}$ is the* algebraic *projection characterized by* (3.1), *then*

$$\|\hat{u} - \tilde{u}\|_{L^2[0,\tau;H(.)]} \le C_\mu^{1/2} C(k,\mu) \tau \|u\|_{L^2[0,\tau;H(.)]},$$

where $C(\mu,k)$ is a constant depending on k and μ through C_μ and C_k, the constant in Lemma 3.2.

Proof. In this proof $C(k,\mu)$ denotes a constant depending only on C_k and C_μ which may change from step to step. Recall that $\hat{u} \in \mathcal{P}_k(0,\tau;U_h)$ satisfies $\hat{u}(0) = u(0) = \tilde{u}(0)$,

$$\int_0^\tau (\hat{u}, w)_{H(0)} = \int_0^t (u, w)_{H(0)}, \qquad w \in \mathcal{P}_{k-1}(0,\tau;U_h),$$

and $\|\hat{u}\|_{L^2[0,\tau,H(0)]} \le C_k \|u\|_{L^2[0,\tau;H(0)]}$. If $w \in \mathcal{P}_{k-1}(0,\tau;U_h)$, then

$$\begin{aligned} \int_0^\tau (\tilde{u} - \hat{u}, w)_{H(.)} &= \int_0^t (u, w)_{H(.)} - \int_0^\tau (\hat{u}, w)_{H(.)} \\ &= \int_0^t \Big((u, w)_{H(.)} - (u, w)_{H(0)} \Big) - \int_0^\tau \Big((\hat{u}, w)_{H(.)} - (\hat{u}, w)_{H(0)} \Big). \end{aligned}$$

Since $(\hat{u} - \tilde{u})(0) = 0$ it follows that $(\hat{u} - \tilde{u})(s) = s\bar{u}(s)$, where $\bar{u} \in \mathcal{P}_{k-1}(0,\tau;U_h)$. Putting $w = \bar{u}$ and using Lemma 2.2 to estimate the right-hand side gives

$$\int_0^\tau s|\bar{u}|^2_{H(s)}\, ds \le \int_0^\tau s C_\mu e^{C_\mu s} \big(|u(s)|_{H(0)} + |\hat{u}(s)|_{H(0)} \big) |\bar{u}(s)|_{H(s)}\, ds.$$

An application of the Cauchy–Schwarz inequality then shows

$$\int_0^\tau s|\bar{u}(s)|^2_{H(s)}\,ds \le C_\mu e^{C_\mu \tau}\int_0^\tau s\big(|u(s)|^2_{H(0)} + |\hat{u}(s)|^2_{H(0)}\big)\,ds \le C_\mu C(k,\mu)\tau \int_0^\tau |u|^2_{H(0)}.$$

Lemma 2.2 is used to compare $|.|_{H(s)}$ with the fixed norm $|.|_{H(0)}$ to obtain

$$\int_0^\tau s|\bar{u}|^2_{H(0)}\,ds \le C_\mu C(k,\mu)\tau \int_0^\tau |u|^2_{H(0)} \le C_\mu C(k,\mu)\tau \int_0^\tau |u|^2_{H(.)}.$$

Using the equivalence of norms on $\mathcal{P}_{k-1}(0,\tau)$ and Lemma 2.2 once again to compare $|.|_{H(0)}$ with $|.|_{H(.)}$ gives

$$\int_0^\tau |\tilde{u}-\hat{u}|^2_{H(.)} = \int_0^\tau s^2|\bar{u}|^2_{H(s)}\,ds \le C_\mu C(k,\mu)\tau^2 \int_0^\tau |u|^2_{H(.)}. \qquad \square$$

To estimate $\|\tilde{u}\|_{L^2[0,\tau;U(.)]}$ an inverse hypothesis is used to bound $\|u_h\|_{U(.)}$ by the weaker norm $|u_h|_{H(.)}$ for $u_h \in U_h$. Recall that in the usual finite element context, the constant depends upon the minimum angle in the mesh.

Corollary 3.4. *Define the "inverse hypothesis constant" $C_{inv}(h)$ by*

$$C_{inv}(h) = \max_{0\le n\le N}\ \sup_{u_h\in U_h^n}\ \sup_{t\in(t^{n-1},t^n]} \frac{|u_h|_{U(t)}}{|u_h|_{H(t)}}.$$

Then there exists a constant $C(k,\mu)$ depending only on C_k, and C_μ such that

$$|\tilde{u}|_{L^2[0,\tau;U(.)]} \le C(k,\mu)\Big(C_u^2|u|_{L^2[0,\tau;U(.)]} + C_\mu^{1/2}\tau C_{inv}(h)\|u\|_{L^2[0,\tau;H(.)]}\Big),$$

where C_u and c_u are the constants in Assumption 2 *and $\tau = \max_{1\le n\le N}(t^n - t^{n-1})$.*

Remark 1. When $U \subset H^1(\Omega)$ and $H = L^2(\Omega)$ the inverse inequality states $C_{inv}(h) \le C/h$ for the classical finite element subspaces constructed over quasi-uniform meshes.

Proof. As in the proof of the lemma, let $\hat{u}$ be the algebraic projection. Then

$$\begin{aligned}
|\tilde{u}|_{L^2[0,\tau;U(.)]} &\le |\hat{u}|_{L^2[0,\tau;U(.)]} + |\hat{u}-\tilde{u}|_{L^2[0,\tau;U(.)]}\\
&\le C_u|\hat{u}|_{L^2[0,\tau;U(0)]} + C_{inv}(h)\|\hat{u}-\tilde{u}\|_{L^2[0,\tau;H(.)]}\\
&\le C_kC_u|u|_{L^2[0,\tau;U(0)]} + C_\mu^{1/2}C(k,\mu)\tau C_{inv}(h)\|u\|_{L^2[0,\tau;H(.)]}\\
&\le C(\mu,k)\Big(C_u^2|u|_{L^2[0,\tau;U(.)]} + C_\mu^{1/2}\tau C_{inv}(h)\|u\|_{L^2[0,\tau;H(.)]}\Big). \qquad \square
\end{aligned}$$

4. DG scheme for an auxiliary PDE. We consider approximating implicit parabolic equations of the form

$$(Mu)_t + Bu = f, \qquad u(0) = u_0, \tag{4.1}$$

where $B(.) : U(.) \to U'(.)$ is the operator corresponding to the bilinear form $b(.) : U(.) \times U(.) \to \mathbb{R}$ defined by

$$b(t;u,v) = \eta(u,v)_{U(t)} + C_\mu(u,v)_{H(t)}$$

and the coefficient $\eta \ge 0$ is constant. Since $b(.)$ is symmetric and positive definite it induces a norm on $U(.)$ which is denoted as $\|u\|^2_{B(.)} = b(.;u,u)$. The situation where

η is small is important, and the estimates obtained below are valid when $\eta = 0$, which corresponds to the situation where (4.1) is an ODE in H.

It is assumed that there exists a unique solution $u \in L^2[0,T;U(.)] \cap H^1[0,T;U'(.)] \hookrightarrow C[0,T;H(.)]$ satisfying the associated weak problem

$$\begin{aligned}(4.2)\quad &(u(T),v(T))_{H(T)} + \int_0^T -\langle u, v_t\rangle_{H(.)} + b(.;u,v) \\ &\quad = (u_0, v(0))_{H(0)} + \int_0^T \langle f, v\rangle \qquad \forall\, v \in L^2[0,T;U(.)] \cap H^1[0,T;U'(.)].\end{aligned}$$

Given a partition $0 = t^0 < t^1 < \cdots < t^N = T$ of $[0,T]$ and a collection $\{U_h^n\}_{n=0}^N$ of subspaces of U, the DG method constructs an approximate solution $u_h|_{(t_{n-1},t_n]} \in \mathcal{P}_k(t^{n-1},t^n;U_h^n)$ satisfying

$$\begin{aligned}&(u^n, v^n)_{H(t^n)} + \int_{t^{n-1}}^{t^n} \big(-(u_h, v_{ht})_{H(.)} + b(.;u_h,v_h)\big) - (u^{n-1}, v_+^{n-1})_{H(t^{n-1})} \\ (4.3)\qquad &\qquad = \int_{t^{n-1}}^{t^n} \langle f, v_h\rangle \quad \forall\, v_h \in \mathcal{P}_k(t^{n-1},t^n;U_h^n).\end{aligned}$$

The next definition characterizes the local truncation error in the present context.

Definition 4.1. (1) *The projection* $\mathbb{P}_n^{loc} : C[t^{n-1},t^n;H(.)] \to \mathcal{P}_k(t^{n-1},t^n;U_h^n)$ *satisfies* $(\mathbb{P}_n^{loc}u)^n = P_n(t^n)u(t^n)$, *and*

$$\int_{t^{n-1}}^{t^n} (u - \mathbb{P}_n^{loc}u, v_h)_{H(.)} = 0 \qquad \forall\, v_h \in \mathcal{P}_{k-1}(t^{n-1},t^n;U_h^n).$$

Here we have used the convention $(\mathbb{P}_n^{loc}u)^n \equiv (\mathbb{P}_n^{loc}u)(t^n)$.

(2) *The projection* $\mathbb{P}_h^{loc} : C[0,T;H(.)] \to \mathcal{U}_h$ *satisfies*

$$\mathbb{P}_h^{loc}u \in \mathcal{U}_h \qquad \text{and} \qquad (\mathbb{P}_h^{loc}u)|_{(t^{n-1},t^n]} = \mathbb{P}_n^{loc}(u|_{[t^{n-1},t^n]}).$$

(3) $\mathbb{P}_h : \{u \in C[0,T;H(.)] \mid (Mu) \in H^1[0,T;U'(.)]\} \to \mathcal{U}_h$ *is the discontinuous Galerkin solution of* (4.1) *with* $f = u_t + Bu$ *and initial data* u_0 *specified.*

Remark 2. Notice that $\mathbb{P}_n^{loc}u$ is the solution of the DG approximation of $(M(.)u)' = f$ on $(t^{n-1},t^n]$ with $u(t^{n-1})$ specified as the initial data. It follows that $\sup_{t^{n-1}\le t\le t^n} |u - \mathbb{P}_n^{loc}u|_{H(.)}$ (or related norms) measures the local truncation error of the scheme with $\eta = 0$.

The following theorem estimates the error at the partition points and is the analogue of [6, Theorem 2.2]. We remind the reader that $P_n(t) : H(t) \to U_h^n$ is the projection from $H(t)$ onto the discrete space U_h^n.

Theorem 4.2. *Let Assumptions* 1 *and* 2 *hold, and let* u *and* u_h *satisfy* (4.1) *and* (4.3), *respectively. Then the error* $\hat{e}^n = P_n(t^n)u(t^n) - u^n$ *at the partition points satisfies*

$$\begin{aligned}&(1/2)|\hat{e}^n|_{H(t^n)}^2 + (1/4)\int_0^{t^n} \|\hat{e}\|_{B(.)}^2 + (1/4)\sum_{i=0}^{n-1} |\hat{e}^i - \hat{e}_+^i|_{H(t^{n-1})}^2 \le (1/2)|\hat{e}^0|_{H(0)}^2 \\ &+ \sum_{i=0}^{n-1} \min\Big((C(k,C_u)/\tau^{i+1}\eta)\|P_{i+1}\big(I-P_i\big)u(t^i)\|_{U'(t^i)}^2, |(I-P_i)u(t^i)|_{H(t^i)}^2\Big) \\ &+ \int_0^{t^n} \|(I - \mathbb{P}_h^{loc})u\|_{B(.)}^2,\end{aligned}$$

where the projections in the sum are evaluated at t^i *(*$P_i = P_i(t^i)$ *and* $P_{i+1} = P_{i+1}(t^i)$*).*

Proof. Let $e = u - u_h$ be the total error and note that the Galerkin orthogonality gives

$$(e^n, v^n)_{H(t^n)} + \int_{t^{n-1}}^{t^n} \big(-(e, v_{ht})_{H(.)} + b(.; e, v_h)\big) - (e^{n-1}, v_+^{n-1})_{H(t^{n-1})} = 0.$$

Letting $\hat{e} = \mathbb{P}_n^{loc} u - u_h = e - (I - \mathbb{P}_n^{loc})u$ and using the properties of $\mathbb{P}_n^{loc}$ gives

$$\begin{aligned}(\hat{e}^n, v^n)_{H(t^n)} &+ \int_{t^{n-1}}^{t^n} \Big(-(\hat{e}, v_{ht})_{H(.)} + b(.; \hat{e}, v_h)\Big) - (\hat{e}^{n-1}, v_+^{n-1})_{H(t^{n-1})} \\ &= ((I - P_{n-1})u(t^{n-1}), v_+^{n-1})_{H(t^{n-1})} - \int_{t^{n-1}}^{t^n} b(.; (I - \mathbb{P}_n^{loc})u, v_h).\end{aligned} \tag{4.4}$$

Setting $v_h = \hat{e}$ and using Assumption 2, (4.4) becomes

$$\begin{aligned}(1/2)|\hat{e}^n|_{H(t^n)}^2 &+ \int_{t^{n-1}}^{t^n} \|\hat{e}\|_{B(.)}^2 + (1/2)|\hat{e}^{n-1} - \hat{e}_+^{n-1}|_{H(t^{n-1})}^2 \\ &= (1/2)|\hat{e}^{n-1}|_{H(t^{n-1})}^2 + ((I - P_{n-1})u(t^{n-1}), \hat{e}_+^{n-1})_{H(t^{n-1})} \\ &\quad - \int_{t^{n-1}}^{t^n} (1/2)\mu(.; \hat{e}, \hat{e}) + b(.; (I - \mathbb{P}_n^{loc})u, \hat{e}).\end{aligned} \tag{4.5}$$

The last two terms on the right are bounded using Assumption 2 and the Cauchy–Schwarz inequality; specifically,

$$\begin{aligned}\int_{t^{n-1}}^{t^n} (1/2)\mu(.; \hat{e}, \hat{e}) + b(.; (I - \mathbb{P}_n^{loc})u, \hat{e}) &\le \int_{t^{n-1}}^{t^n} (C_\mu/2)\|\hat{e}\|_{H(.)}^2 + \|(I - \mathbb{P}_n^{loc})u\|_{B(.)}\|\hat{e}\|_{B(.)} \\ &\le \int_{t^{n-1}}^{t^n} (C_\mu/2)\|\hat{e}\|_{H(.)}^2 + \|(I - \mathbb{P}_n^{loc})u\|_{B(.)}^2 \\ &\quad + (1/4)\|\hat{e}\|_{B(.)}^2.\end{aligned}$$

The jump term on the right or (4.5) is bounded two different ways. Since $\hat{e}^{n-1} \in U^{n-1}$ an estimate independent of η is computed as

$$\begin{aligned}((I - P_{n-1})u(t^{n-1}), \hat{e}_+^{n-1})_{H(t^{n-1})} &= ((I - P_{n-1})u(t^{n-1}), \hat{e}_+^{n-1} - \hat{e}^{n-1})_{H(t^{n-1})} \\ &\le |(I - P_{n-1})u(t^{n-1})|_{H(t^{n-1})}^2 \\ &\quad + (1/4)|\hat{e}_+^{n-1} - \hat{e}^{n-1}|_{H(t^{n-1})}^2\end{aligned}$$

(we write $P_{n-1} = P_{n-1}(t^{n-1})$ and similarly $P_n = P_n(t^{n-1})$ below). An alternative estimate is obtained upon writing

$$\begin{aligned}((I - P_{n-1})u(t^{n-1}), \hat{e}_+^{n-1})_{H(t^{n-1})} &= (P_n(I - P_{n-1})u(t^{n-1}), \hat{e}_+^{n-1})_{H(t^{n-1})} \\ &\le \|P_n(I - P_{n-1})u(t^{n-1})\|_{U'(t^{n-1})}\|\hat{e}_+^{n-1}\|_{U(t^{n-1})}.\end{aligned}$$

The following "inverse" estimate for functions in $\mathcal{P}_k(t^{n-1}, t^n, U^n)$ is used to bound the $\|\hat{e}_+^{n-1}\|_{U(t^{n-1})}$:

$$\|\hat{e}_+^{n-1}\|_{U(t^{n-1})}^2 \le (C_k/\tau^n) \int_{t^{n-1}}^{t^n} \|\hat{e}\|_{U(t^{n-1})}^2 \le (C_k C_u^2/\tau^n) \int_{t^{n-1}}^{t^n} \|\hat{e}\|_{U(.)}^2.$$

The finite dimensionality of $\mathcal{P}_k(t^{n-1}, t^n)$ and a scaling argument shows that the constant C_k appearing in the first inequality depends only upon k. It follows that

$$((I - P_{n-1})u(t^{n-1}), \hat{e}_+^{n-1})_{H(t^{n-1})} \leq (C(C_k, C_u)/\tau^n \eta) \|P_n(I - P_{n-1})u(t^{n-1})\|^2_{U'(t^{n-1})} + (\eta/2) \int_{t^{n-1}}^{t^n} \|\hat{e}\|^2_{U(.)}.$$

Substituting these estimates into (4.5), recalling the definition of $b(.;.,.)$, and summing completes the proof. □

The following theorem compares the (global) solution, $\mathbb{P}_h u$, of the DG scheme with the local projections, $\mathbb{P}_n^{loc} u$, at arbitrary times.

Theorem 4.3. *Let Assumptions* 1 *and* 2 *hold, and let u and u_h satisfy* (4.1) *and* (4.3), *respectively. Let $\hat{e} = \mathbb{P}_h^{loc} u - u_h$. Then there exists a constant*

$$C = C(C_k, C_\mu, C_u, \sqrt{\eta} \tau C_{inv}(h))$$

such that

$$\begin{aligned} &|\hat{e}(t)|^2_{H(t)} + \int_0^{t^n} \Big(\eta \|\hat{e}\|^2_{U(.)} + C_\mu |\hat{e}|^2_{H(.)} \Big) + \sum_{i=0}^{n-1} |[\hat{e}^i]|^2_{H(t^i)} \\ &\leq C \Big(|\hat{e}^0|^2_{H(0)} + \int_0^{t^n} \Big(\eta \|(I - \mathbb{P}_h^{loc})u\|^2_{U(.)} + C_\mu |(I - \mathbb{P}_h^{loc})u|^2_{H(.)} \Big) \\ &\quad + \sum_{i=0}^{n-1} \min \Big(1/(\tau^{i+1}\eta) \|P_{i+1}(I - P_i)u(t^i)\|^2_{U'(t^i)}, |(I - P_i)u(t^i)|^2_{H(t^i)} \Big) \end{aligned}$$

for any time $t \in (t^{n-1}, t^n]$. Here $[\hat{e}^i] = \hat{e}_+^i - \hat{e}^i$ is the jump in $\hat{e}$ at t^i, $\tau = \max_{1<i\leq n}(t^i - t^{i-1})$, and the projections in the sum are evaluated at t^i.

Proof. Given Theorem 4.2 it suffices to bound $|\hat{e}(t)|_{H(t)}$ for $t \in (t^{n-1}, t^n]$. Recall inequality (4.4)

$$\begin{aligned} &(\hat{e}^n, v^n)_{H(t^n)} + \int_{t^{n-1}}^{t^n} \Big(-(\hat{e}, v_{ht})_{H(.)} + b(.; \hat{e}, v_h) \Big) - (\hat{e}^{n-1}, v_+^{n-1})_{H(t^{n-1})} \\ &\quad = ((I - P_{n-1})u(t^{n-1}), v_+^{n-1})_{H(t^{n-1})} - \int_{t^{n-1}}^{t^n} b(.; (I - \mathbb{P}_n^{loc})u, v_h), \end{aligned}$$

and rewrite it as

$$\begin{aligned} &\int_{t^{n-1}}^{t^n} \Big((\hat{e}_{ht}, v_h)_{H(.)} + \mu(.; \hat{e}, v_h) + b(., \hat{e}, v_h) \Big) + (\hat{e}_+^{n-1} - \hat{e}^{n-1}, v_+^{n-1})_{H(t^{n-1})} \\ &\quad = ((I - P_{n-1})u(t^{n-1}), v_+^{n-1})_{H(t^{n-1})} - \int_{t^{n-1}}^{t^n} b(.; (I - \mathbb{P}_n^{loc})u, v_h). \end{aligned}$$

Next let $v_h = \tilde{e}$ be the discrete approximation of $\chi_{[t^{n-1},t)}\hat{e}$ characterized by equation (3.2) to get

$$\begin{aligned} &\int_{t^{n-1}}^{t} (\hat{e}_t, \hat{e})_{H(.)} + \int_{t^{n-1}}^{t^n} \mu(.; \hat{e}, \tilde{e}) + (\hat{e}_+^{n-1} - \hat{e}^{n-1}, \hat{e}_+^{n-1})_{H(t^{n-1})} \\ &= ((I - P_{n-1})u(t^{n-1}), \hat{e}_+^{n-1})_{H(t^{n-1})} - \int_{t^{n-1}}^{t^n} b(.; (I - \mathbb{P}_n^{loc})u, \tilde{e}) + b(.; \hat{e}, \tilde{e}). \end{aligned}$$

The differentiability properties of $(.,.)_{H(.)}$ allow the first term integrated so that

$$\begin{aligned}(1/2)|\hat{e}(t)|^2_{H(t)} &- (1/2)\int_{t^{n-1}}^{t} \mu(.;\hat{e},\hat{e}) + \int_{t^{n-1}}^{t^n} \mu(.;\hat{e},\tilde{e})\\ &+ (1/2)|\hat{e}^{n-1}_{+} - \hat{e}^{n-1}|^2_{H(t^{n-1})} - (1/2)|\hat{e}^{n-1}|^2_{H(t^{n-1})}\\ &= ((I-P_{n-1})u(t^{n-1}), \hat{e}^{n-1}_{+})_{H(t^{n-1})}\\ &\quad - \int_{t^{n-1}}^{t^n} b(.;(I-\mathbb{P}^{loc}_n)u,\tilde{e}) + b(.;\hat{e},\tilde{e}).\end{aligned}$$

Use Lemma 3.2 and Corollary 3.4 to bound $\tilde{e}$ in terms of $\hat{e}$; specifically,

- Using Lemma 3.2 shows

$$\begin{aligned}\int_{t^{n-1}}^{t^n} \mu(.;\hat{e},\tilde{e}) &\le C_\mu \|\hat{e}\|_{L^2[t^{n-1},t^n;H(.)]} \|\tilde{e}\|_{L^2[t^{n-1},t^n;H(.)]}\\ &\le C_\mu(1 + C_k e^{C_\mu \tau^n}) \|\hat{e}\|^2_{L^2[t^{n-1},t^n;H(.)]}\end{aligned}$$

so that

$$(1/2)\int_{t^{n-1}}^{t} \mu(.;\hat{e},\hat{e}) - \int_{t^{n-1}}^{t^n} \mu(.;\hat{e},\tilde{e}) \le C_\mu C(k,\mu) \int_{t^{n-1}}^{t^n} |\hat{e}|^2_{H(.)}.$$

- Expanding the definition of $b(.;.,.)$ and recalling Corollary 3.4 shows

$$\begin{aligned}&\int_{t^{n-1}}^{t^n} b(.;\hat{e},\tilde{e}) \le (1/2)\int_{t^{n-1}}^{t^n} \|\hat{e}\|^2_{B(.)} + \Big(\eta\|\tilde{e}\|^2_{U(.)} + C_\mu|\tilde{e}|^2_{H(.)}\Big)\\ &\le (1/2)\int_{t^{n-1}}^{t^n} \|\hat{e}\|^2_{B(.)}\\ &\quad + C(k,\mu)\Big(\eta\big(C_u^4\|\tilde{e}\|^2_{U(.)} + C_\mu \tau^2 C_{inv}(h)^2 \|\hat{e}\|^2_{H(.)}\big) + C_\mu\|\hat{e}\|^2_{H(.)}\Big)\\ &\le (1/2)C(k,\mu,u,\sqrt{\eta}\tau C_{inv}(h)) \int_{t^{n-1}}^{t^n} \|\hat{e}\|^2_{B(.)}.\end{aligned}$$

- Similarly

$$\begin{aligned}\int_{t^{n-1}}^{t^n} b(.;(I-\mathbb{P}^{loc}_n)u,\tilde{e}) \le (1/2)\int_{t^{n-1}}^{t^n} &\|(I-\mathbb{P}^{loc}_n)u\|^2_{B(.)}\\ &+ C(k,\mu,u,\sqrt{\eta}\tau C_{inv}(h))\|\hat{e}\|^2_{B(.)}.\end{aligned}$$

It follows that

$$\begin{aligned}(1/2)|\hat{e}(t)|^2_{H(t)} &+ (1/2)|\hat{e}^{n-1}_{+} - \hat{e}^{n-1}|^2_{H(t^{n-1})} - (1/2)|\hat{e}^{n-1}|^2_{H(t^{n-1})}\\ &\le ((I-P_{n-1})u(t^{n-1}), \hat{e}^{n-1}_{+})_{H(t^{n-1})}\\ &\quad + \int_{t^{n-1}}^{t^n} \|(I-\mathbb{P}^{loc}_n)u\|^2_{B(.)} + C(k,\mu,u,\sqrt{\eta}\tau C_{inv}(h))\|\hat{e}\|^2_{B(.)}.\end{aligned} \tag{4.6}$$

As in the proof of Theorem 4.2 the first term on the right can be bounded by

$$|(I-P_{n-1})u(t^{n-1})|^2_{H(t^{n-1})} + (1/4)|\hat{e}^{n-1}_{+} - \hat{e}^{n-1}|^2_{H(t^{n-1})}$$

or

$$C(k,u)/(\tau^n\eta)\|P_n(I-P_{n-1})u(t^{n-1})\|^2_{U'(t^{n-1})}+(\eta/2)\int_{t^{n-1}}^{t^n}\|\hat{e}\|^2_{U(.)},$$

so

$$|\hat{e}(t)|^2_{H(t)}\leq|\hat{e}^{n-1}|^2_{H(t^{n-1})}+\int_{t^{n-1}}^{t^n}C(k,\mu,u,\sqrt{\eta}\tau C_{inv}(h))\|\hat{e}\|^2_{B(.)}+\|(I-\mathbb{P}_n^{loc})u\|^2_{B(.)}$$
$$+2\max\Big(C(k,u)/(\tau^n\eta)\|P_n(I-P_{n-1})u(t^{n-1})\|^2_{U'(t^{n-1})},\,|(I-P_{n-1})u(t^{n-1})|^2_{H(t^{n-1})}\Big).$$

The theorem then follows upon using Theorem 4.2 to bound the first two terms on the right. ☐

5. DG scheme for implicit parabolic equations.

In this section DG approximations of (2.2) are considered. It is shown that the error for the parabolic PDE can be bounded by the error of the DG approximation of the auxiliary equation introduced in the previous section.

5.1. DG scheme.

To approximate the solution of the weak formulation (2.2), let $0=t^0<t^1<\cdots<t^N=T$ be a partition of $[0,T]$, and on each partition construct a closed subspace $U_h^n\subset U$. The discontinuous Galerkin approximates the solution of (2.2) on $(t^{n-1},t^n]$ by $u_h\in\mathcal{P}_k(t^{n-1},t^n;U_h^n)$ satisfying

$$(u^n,v^n)_{H(t^n)}+\int_{t^{n-1}}^{t^n}\Big(-(u_h,v_{ht})_{H(t)}+a(.;u_h,v_h)\Big)$$
$$-(u^{n-1},v_+^{n-1})_{H(t^{n-1})}=\int_{t^{n-1}}^{t^n}\langle F,v_h\rangle\quad\forall v_h\in\mathcal{P}_k(t^{n-1},t^n;U_h^n).\tag{5.1}$$

The stability and error estimates are established using very similar arguments; for this reason we will just focus on the error estimate. The Galerkin orthogonality condition shows that the error $e=u-u_h$ satisfies

$$(e^n,v^n)_{H(t^n)}+\int_{t^{n-1}}^{t^n}\Big(-(e,v_{ht})_{H(t)}+a(.;e,v_h)\Big)-(e^{n-1},v_+^{n-1})_{H(t^{n-1})}=0\tag{5.2}$$

for all $v_h\in\mathcal{P}_k(t^{n-1},t^n;U_h^n)$. Decompose the error as $e=e_p+e_h\equiv(u-\mathbb{P}_hu)+(\mathbb{P}_hu-u_h)$, where $\mathbb{P}_h:\{u\in C[0,T;H(.)]\mid M(.)u\in H^1[0,T;U'(.)]\}\to\mathcal{U}_h$ is the projection introduced in Definition 4.1. The orthogonality condition (5.2) becomes

$$(e_h^n,v^n)_{H(t^n)}+\int_{t^{n-1}}^{t^n}\Big(-(e_h,v_{ht})_{H(.)}+a(.;e_h,v_h)\Big)-(e_h^{n-1},v_+^{n-1})_{H(t^{n-1})}$$
$$=-(e_p^n,v^n)_{H(t^n)}+\int_{t^{n-1}}^{t^n}(e_p,v_{ht})_{H(.)}+(e_p^{n-1},v_+^{n-1})_{H(t^{n-1})}$$
$$-\int_{t^{n-1}}^{t^n}a(.;e_p,v_h).$$

By construction, $\mathbb{P}_hu$ is the discontinuous Galerkin approximation of (4.1), so e_p satisfies the orthogonality condition (4.4). It follows that the first three terms of the right-hand side simplify to $-\int_{t^{n-1}}^{t^n} \eta(e_p, v_h)_{U(.)} + C_\mu(e_p, v_h)_{H(.)}$ so that (with $\eta = c_a$)

$$(e_h^n, v^n)_{H(t^n)} + \int_{t^{n-1}}^{t^n} (-(e_h, v_{ht})_{H(.)} + a(.; e_h, v_h)) - (e_h^{n-1}, v_+^{n-1})_{H(t^{n-1})}$$

$$= -\int_{t^{n-1}}^{t^n} \big(a(\cdot; e_p, v_h) + c_a(e_p, v_h)_{U(.)} + C_\mu(e_p, v_h)_{H(.)}\big). \tag{5.3}$$

A preliminary estimate satisfied by the error at the partition points is obtained by setting $v_h = e_h$ and using the coercivity of $a(.; ., .)$:

$$\begin{aligned}\frac{1}{2}|e_h^n|^2_{H(t^n)} &+ c_\alpha \int_{t^{n-1}}^{t^n} |e_h|^2_{U(.)} + \frac{1}{2}|e_{h+}^{n-1} - e_h^{n-1}|^2_{H(t^{n-1})} \\ &\le \frac{1}{2}|e_h^{n-1}|^2_{H(t^{n-1})} - \int_{t^{n-1}}^{t^n} \Big((1/2)\mu(\cdot; e_h, e_h) + a(.; e_p, e_h) + c_a(e_p, e_h)_{U(.)} \\ &\quad + C_\mu(e_p, e_h)_{H(.)} - C_\alpha |e_h|^2_{H(.)}\Big).\end{aligned} \tag{5.4}$$

Using Assumption 2 on the continuity of $a(.; ., .)$ and $\mu(.; ., .)$ shows

$$\begin{aligned}&|e_h^n|^2_{H(t^n)} + c_\alpha \int_{t^{n-1}}^{t^n} |e_h|^2_{U(.)} + |e_h^{n-1} - e_{h+}^{n-1}|^2_{H(t^{n-1})} \le |e_h^{n-1}|^2_{H(t^{n-1})} \\ &+ \int_{t^{n-1}}^{t^n} \Big((1 + 2c_a/c_\alpha)\big(2c_a|e_p|^2_{U(.)} + (2C_a + C_\mu)|e_p|^2_{H(.)}\big) + 2(C_\alpha + C_\mu + C_a)|e_h|^2_{H(.)}\Big).\end{aligned} \tag{5.5}$$

The inequalities $c_\alpha \le c_a \le C_a$ were used to derive expressions on the right that are independent of the coercivity constant.

Notice that the last term on the right-hand side involves $|e_h(s)|_{H(s)}$ at times $s \in (t^{n-1}, t^n)$, so the discrete Gronwall inequality is not applicable. Below the discrete characteristic functions developed in section 3.1 are used to obtain an expression similar to the above with $\sup_{t^{n-1} \le s \le t^n} |e_h(s)|_{H(s)}$ on the left-hand side.

Remark 3. One way to circumvent this problem is to bound temporal derivatives of the solution [7, 28] so that $e_h(s)$, $s \in (t^{n-1}, t^n)$, can be controlled by the values at the partition points. Bounds on the temporal derivatives of the discrete solution are frequently obtained by assuming A to be self-adjoint. Clearly this line of argument fails for solutions having minimal regularity.

An alternative approach developed in [16] and [2] is to construct a discrete approximation of $(e_h(t) - e_h^{n-1})/(t - t^{n-1})$ in $\mathcal{P}_k(t^{n-1}, t^n; U_h)$. A formal calculation with $v(t) = (e_h(t) - e_h^{n-1})/(t - t^{n-1} + \epsilon)$ shows

$$\begin{aligned}\int_{t^{n-1}}^{t^n} (e_h', v)_H + (e_{h+}^{n-1} - e_h^{n-1}, v_+^{n-1})_H &= \int_{t^{n-1}}^{t^n} (e_h', v)_H + \epsilon|v_+^{n-1}|^2_H \\ &= (1/2)\int_{t^{n-1}}^{t^n} (e_h - e_h^{n-1})^2/(t - t^{n-1} + \epsilon)^2 \\ &\quad + (1/2)|e_h^n - e_h^{n-1}|^2_H/(t^n - t^{n-1} + \epsilon) + (1/2)\epsilon|v_+^{n-1}|^2_H,\end{aligned}$$

which was used to bound $\|e_h\|_{L^2(t^{n-1}, t^n)}$.

5.2. Error estimate. We are now ready to state and prove our main error estimate for the DG approximation of (1.1).

THEOREM 5.1. *Let $U(.) \hookrightarrow H \hookrightarrow U'(.)$ be a dense embedding of Hilbert spaces satisfying Assumption* 1. *Assume each norm $\|.\|_{U(.)}$ is equivalent to $\|.\|_U$, and let $\mathcal{U}_h$ be the subspace of $L^2[0,T;U]$ defined in section* 3. *Let the bilinear form $a : U(.) \times U(.) \to \mathbb{R}$ and the linear form $F : U(.) \to \mathbb{R}$ satisfy Assumption* 2. *Let $u \in \{u \in C[0,T;H(.)] \mid M(.)u \in H^1[0,T;U'(.)]\}$ be the solution of* (2.1) *and $u_h \in \mathcal{U}_h$ be the approximate solution computed using the discontinuous Galerkin scheme* (5.1) *on the partition $0 = t^0 < t^1 < \cdots < t^N = T$, and set $\tau \equiv \max_n t^n - t^{n-1}$.*

Then there exist constants $C > 0$ and $0 < \lambda < 1$ depending only on k (through the constant C_k of Lemma 3.2*), the constants C_a, C_α, C_μ, C_u, c_u, the ratio c_a/c_α, and the product $\sqrt{c_a}\tau C_{inv}(h)$ (defined in Corollary* 3.4*) such that*

$$\begin{aligned}(1-\lambda)|e_h^n|^2_{H(t^n)} + \lambda \sup_{0\le s\le t^n} |e_h(s)|^2_{H(s)} + \sum_{i=0}^{n-1} \mathrm{e}^{C(t^{n-1}-t^i)} |e_h^i - e_{h+}^i|^2_{H(t^i)} \\ + (1-\lambda)\frac{c_\alpha}{2}\int_0^{t^n} \mathrm{e}^{C(t-s)} |e_h(s)|^2_{U(s)}\, ds \\ \le \big(1 + T\mathcal{O}(\tau)\big)\Big(\mathrm{e}^{Ct^n}|e_h^0|^2_{H(0)} \\ + C\lambda \int_0^{t^n} \mathrm{e}^{C(t-s)}\big(c_a |e_p(s)|^2_{U(s)} + (C_a + C_\mu)|e_p(s)|^2_{H(s)}\big)\, ds\Big),\end{aligned}$$

provided $C\tau < 1$. Here $e_h = \mathbb{P}_h u - u_h$ and $e_p = u - \mathbb{P}_h u$, where $\mathbb{P}_h$ is the projection defined in Definition 4.1.

Proof. Rewrite (5.3) as

$$\begin{aligned}\int_{t^{n-1}}^{t^n} \Big((e_{ht}, v_h)_{H(.)} + \mu(.;e_h,v_h) + a(.;e_h,v_h)\Big) + \big(e_{h+}^{n-1} - e_h^{n-1}, v_+^{n-1}\big)_{H(t^{n-1})} \\ = -\int_{t^{n-1}}^{t^n} a(.;e_p,v_h) + b(.;e_p,v_h),\end{aligned}$$

where $b(t;u,v) = c_a(u,v)_{U(t)} + C_\mu(u,v)_{H(t)}$. Set $v_h = \tilde{e}_h$, where $\tilde{e}_h$ is the discrete approximation of $\chi_{[t^{n-1},t)} e_h$ constructed in section 3.1, to obtain

$$\begin{aligned}\int_{t^{n-1}}^{t} (e_{ht}, e_h)_{H(.)} + \big(e_{h+}^{n-1} - e_h^{n-1}, e_{h+}^{n-1}\big)_{H(t^{n-1})} \\ = -\int_{t^{n-1}}^{t^n} \Big(\mu(.;e_h,\tilde{e}_h) + a(.;e_h,\tilde{e}_h) + a(.;e_p,\tilde{e}_h) + b(.;e_p,\tilde{e}_h)\Big).\end{aligned}$$

Recalling that $(e_{ht}, e_h)_{H(.)} = (1/2)(d/dt)|e_h|^2_{H(.)} - (1/2)\mu(.;e_h,e_h)$ shows

$$\begin{aligned}\frac{1}{2}|e_h(t)|^2_{H(t)} + \frac{1}{2}|e_h^{n-1} - e_{h+}^{n-1}|^2_{H(t^{n-1})} - \frac{1}{2}|e_h^{n-1}|^2_{H(t^{n-1})} = \int_{t^{n-1}}^{t} \frac{1}{2}\mu(.;e_h,e_h) \\ - \int_{t^{n-1}}^{t^n} \Big(a(.;e_p,\tilde{e}_h) + a(.;e_h,\tilde{e}_h) + b(.;e_p,\tilde{e}_h)_{U(.)} + \mu(.,e_h,\tilde{e}_h)\Big).\end{aligned}$$

Estimating the right-hand side using Lemma 3.2 and Corollary 3.4, as in the derivation of (4.6), gives

$$\begin{aligned} |e_h(t)|^2_{H(t^n)} + |e_h^{n-1} - e_{h+}^{n-1}|^2_{H(t^{n-1})} &\leq |e_h^{n-1}|^2_{H(t^{n-1})} \\ &+ \int_{t^{n-1}}^{t^n} \Big(c_a |e_p|^2_{U(.)} + (C_a + C_\mu)|e_p|^2_{H(.)} \\ &+ c_\alpha C\big(C_k, C_\mu, C_u, c_a/c_\alpha\big)|e_h|^2_{U(.)} + C(...)|e_h|^2_{H(.)}\Big). \end{aligned} \tag{5.6}$$

Here $C(...)$ is a constant depending upon $C_a, C_k, C_\mu, \sqrt{c_a}\tau C_{inv(h)}$, and c_a/c_α. The remainder of the proof parallels the proof of [6, Theorem 3.1]. Specifically, construct the convex combination of $(1-\lambda)$ from (5.5) and λ from (5.6), and choose the coefficient, λ, so that the term involving $|e_h(t)|^2_{U(.)}$ on the right-hand side of (5.6) is dominated by the corresponding term on the left-hand side of (5.6). Setting

$$\lambda C\big(C_k, C_\mu, C_u, c_a/c_\alpha\big) = (1/2)(1-\lambda) \qquad \text{or} \qquad \lambda = \frac{1}{1 + 2C\big(C_k, C_\mu, C_u, c_a/c_\alpha\big)}$$

leads to an estimate of the form

$$\begin{aligned} &(1-\lambda)|e_h^n|^2_{H(t^n)} + \lambda|e_h(t)|^2_{H(.)} + (1-\lambda)\frac{c_\alpha}{2}\int_{t^{n-1}}^{t^n} |e_h|^2_{U(.)} + |e_h^{n-1} - e_{h+}^{n-1}|^2_{H(t^{n-1})} \\ &\leq |e_h^{n-1}|^2_{H(t^{n-1})} + C(...)\lambda \int_{t^{n-1}}^{t^n} \Big(c_a|e_p|^2_{U(.)} + (C_a + C_\mu)|e_p|^2_{H(.)} + |e_h|^2_{H(.)}\Big), \end{aligned}$$

where $C(...)$ may now depend additionally upon C_α. Bound the first and last terms on the right by

$$|e_h^{n-1}|^2_{H(t^n)} \leq (1-\lambda)|e_h^{n-1}|^2_{H(t^{n-1})} + \lambda \sup_{t^{n-2} < s \leq t^{n-1}} |e_h(s)|^2_{H(s)}$$

and

$$\int_{t^{n-1}}^{t^n} |e_h|^2_{H(.)} \leq \tau^n \sup_{t^{n-1} < s \leq t^n} |e_h(s)|^2_{H(s)}, \qquad \tau^n \equiv t^n - t^{n-1},$$

respectively, and select the time t on the left so that $|e_h(t)|_{H(s)} = \sup_{t^{n-1} < s \leq t^n} |e_h(s)|_{H(s)}$ to get

$$\begin{aligned} (1-\lambda)|e_h^n|^2_{H(t^n)} &+ \lambda(1 - C(...)\tau^n) \sup_{t^{n-1} < s \leq t^n} |e_h(t)|^2_{H(s)} \\ &\qquad + (1-\lambda)\frac{c_\alpha}{2}\int_{t^{n-1}}^{t^n} |e_h|^2_{U(.)} + |e_h^{n-1} - e_{h+}^{n-1}|^2_{H(t^{n-1})} \\ &\leq (1-\lambda)|e_h^{n-1}|^2_{H(t^{n-1})} + \lambda \sup_{t^{n-2} < s \leq t^{n-1}} |e_h(s)|^2_{H(s)} \\ &\qquad + C(...)\lambda \int_{t^{n-1}}^{t^n} (c_a|e_p|^2_{U(.)} + (C_a + C_\mu)|e_p|^2_{H(.)}). \end{aligned}$$

Upon introducing a factor $(1 - C(...)\tau^n)$ in front of the first term, this inequality takes the form

$$(1 - C(...)\tau^n)\alpha^n + \beta^n \leq \alpha^{n-1} + f^n,$$

and the theorem follows from the discrete Gronwall inequality. □

This theorem enables error estimates to be established in various norms. Defining

$$|||e|||_\infty^2 = \sup_{0\le s\le T} |e(s)|_{H(s)}^2 + c_\alpha \int_0^T \mathrm{e}^{C(T-s)} |e(s)|_{U(s)}^2 \, ds$$

and

$$|||e|||_2^2 = \int_0^T \mathrm{e}^{C(T-s)} |e(s)|_{H(s)}^2 \, ds + c_a \int_0^T \mathrm{e}^{C(T-s)} |e(s)|_{U(s)}^2 \, ds,$$

Theorem 4.3 shows that

$$\begin{aligned} |||\mathbb{P}_h u - \mathbb{P}_h^{loc} u|||_\infty^2 \le C \Bigg(& |||u - \mathbb{P}_h^{loc}|||_2^2 \\ & + \sum_{i=0}^{n-1} \min\left(|(I-P_i)u(t^i)|_{H(t^i)}^2, 1/(\tau^{i+1} c_a) \|P_{i+1}(I-P_i)u(t^i)\|_{U'(t^i)}^2 \right) \Bigg). \end{aligned}$$

Here the initial data and constant $\eta \ge 0$ have been selected as $\mathbb{P}_h(0) = P_0(u_0)$ and $\eta = c_a$. Similarly, Theorem 5.1 states

$$\begin{aligned} |||\mathbb{P}_h u - u_h|||_\infty^2 &\le C\Big(|P_0(u_0) - u_h^0|_{H(0)} + |||u - \mathbb{P}_h u|||_2^2 \Big) \\ &\le C\Big(|P_0(u_0) - u_h^0|_{H(0)} + |||u - \mathbb{P}_h^{loc} u|||_2^2 + |||\mathbb{P}_h u - \mathbb{P}_h^{loc}|||_2^2 \Big). \end{aligned}$$

Combining these estimates gives an estimate for the (total) error of the solution.

Theorem 5.2. *Under the assumptions of Theorem* 5.1, *there exists a positive constant $C > 0$ depending only on T, k (through the constant C_k of Lemma* 3.2*), the constants C_a, C_α, C_μ, C_u, c_u, the ratio c_a/c_α, and the product $\sqrt{c_a}\tau C_{inv}(h)$ (defined in Corollary* 3.4*) such that the following estimate holds:*

$$\begin{aligned} |||u - u_h|||_\infty^2 \le C \Bigg(& |P_0(u_0) - u_h^0|_{H(0)} + |||u - \mathbb{P}_h^{loc} u|||_\infty^2 \\ & + \sum_{i=0}^{N-1} \min\left(|(I-P_i)u(t^i)|_{H(t^i)}^2, 1/(\tau^{i+1} c_a) \|P_{i+1}(I-P_i)u(t^i)\|_{U'(t^i)}^2 \right) \Bigg), \end{aligned}$$

where $\mathbb{P}_h^{loc} u$ is the local projection defined in Definition 4.1 *and $P_n(t) : H(t) \to U_h^n$ is the orthogonal projection. A similar estimate also holds with $|||.|||_2$ in place of $|||.|||_\infty$.*

Proof. Using the triangle inequality compute

$$|||u - u_h|||_\infty \le |||u - \mathbb{P}_h^{loc} u|||_\infty + |||\mathbb{P}_h u - \mathbb{P}_h^{loc} u|||_\infty + |||\mathbb{P}_h u - u_h|||_\infty.$$

The estimate now follows from the estimates stated prior to the theorem and the inequality $|||.|||_2 \le C(T) |||.|||_\infty$. □

6. Example: Diffusion on a manifold. This section illustrates how our results apply to the example presented in the introduction. The bilinear forms associated with this problem are

$$(u, v)_{H(.)} = (M(.)u, v)_{L^2(\mathcal{S}_r)} = \int_{\mathcal{S}_r} uv \, J$$

and

$$a(.;u,v) = \int_{\mathcal{S}_r} \Big(\sigma(\nabla v)^T (F^T F)^{-1} \nabla u - (I - \mathbf{n} \otimes \mathbf{n}) \cdot (\nabla_x \mathbf{V}) uv \Big) J.$$

Here $\mathcal{S}_r \subset \mathbb{R}^3$ is homeomorphic to the sphere, and $\mathcal{S}(t) = x(t, \mathcal{S}_r)$, where $x : [0,T] \times \mathcal{S}_r \to \mathbb{R}^3$, determines the present position of a membrane. If $X = (X_1, X_2)$ locally parameterizes the $\mathcal{S}_r$, then $F_{i\alpha} = \partial x_i / \partial X_\alpha$, $J = \sqrt{\det(F^T F)}$, and we write ∇u for $\nabla_X u$. The matrix $F = F(t,X)$ is related to the velocity by $F_t = (\nabla_x \mathbf{V}) F$.

Notice that $(.,.)_{H(.)}$ and the principle part of $a(.;.,.)$ are intrinsic in the sense that

$$\int_{\mathcal{S}_r} uv\, J = \int_{\mathcal{S}(t)} \tilde{u}\tilde{v}, \qquad \text{and} \qquad \int_{\mathcal{S}_r} \sigma(\nabla v)^T . (F^T F)^{-1} \nabla u\, J = \int_{\mathcal{S}(t)} \sigma \operatorname{grad}(\tilde{u}).\operatorname{grad}(\tilde{v}),$$

where $\tilde{u} : \mathcal{S}(t) \to \mathbb{R}$ is related to $u : \mathcal{S}_r \to \mathbb{R}$ by the change of variables $u(t,X) = \tilde{u}(t, x(t,X))$. As indicated above, geometric properties of $\mathcal{S}(t)$, such as the first fundamental form $F^T F$, are determined by the ambient velocity field $\mathbf{V}$; for example, the unit normal $\mathbf{n}$ to $\mathcal{S}(t)$ satisfies

$$\mathbf{n}_t = \left(\mathbf{n}^T (\nabla_x \mathbf{V}) \mathbf{n}\, I - (\nabla_x \mathbf{V})^T\right) \mathbf{n}.$$

The columns of F form a basis for the tangent space of $\mathcal{S}(t)$, and if they become parallel at time $\tilde{t}$, the first fundamental form becomes singular and the hypotheses in Assumption 2 fail. In this situation it is necessary to redefine and triangulate a new reference configuration. The natural choice for the new reference configuration is $\tilde{\mathcal{S}}_r = \mathcal{S}(\tilde{t})$. Since the bilinear forms are intrinsic to the manifold, such a redefinition is covered by our theory in the sense that if $\mathcal{T}_r$ is the triangulation of $\mathcal{S}_r$ at time $\tilde{t}$, then $\{x(\tilde{t}, K) \mid K \in \mathcal{T}_r\}$ becomes the triangulation of $\tilde{\mathcal{S}}_r$ at $\tilde{t}_-$ and the (new) triangulation $\tilde{\mathcal{T}}_r$ of $\tilde{\mathcal{S}}_r$ is the triangulation at $\tilde{t}_+$. The coefficients J, etc., are continuous in the sense that

$$(u,v)_{H(\tilde{t}_-)} = \int_{\mathcal{S}_r} uv\, J = \int_{\tilde{\mathcal{S}}_r} \tilde{u}\tilde{v}\, \tilde{J} = (\tilde{u}, \tilde{v})_{H(\tilde{t}_+)},$$

where $\tilde{J}(\tilde{t}, .) = 1$ and $u(\tilde{t}, X) = \tilde{u}(\tilde{t}, x(\tilde{t}, X))$. Of course the mesh $\tilde{\mathcal{T}}_r$ should be adapted so that the interpolant $\tilde{u}(\tilde{t}_+, .)$ of $\tilde{u}(\tilde{t}_-, .)$ gives a good approximation.

To verify that $M(.)$ satisfies the hypothesis of Assumption 1, recall that

$$J_t = J(I - \mathbf{n} \otimes \mathbf{n}) \cdot (\nabla_x \mathbf{V}) \qquad \text{or} \qquad \ln(J)_t = (I - \mathbf{n} \otimes \mathbf{n}) \cdot (\nabla_x \mathbf{V}).$$

It follows that $\ln(J)_t \leq 2\|\nabla_x \mathbf{V}\|$, where $\|.\|$ is the Frobenius norm, so if $0 < c_0 \leq J(0,.) \leq C_0$, then

$$c_0 e^{-Ct} \leq J(t,.) \leq C_0 e^{Ct}, \qquad \text{where} \qquad C = 2\|\nabla_x \mathbf{V}\|_{L^\infty}. \tag{6.1}$$

We verify that this problem satisfies the hypotheses of Assumption 2 when the seminorm $|.|_{U(t)}$ is defined by

$$|u|^2_{U(.)} = \int_{\mathcal{S}_r} \sigma(\nabla u)^T (F^T F)^{-1} \nabla u\, J.$$

1. Smoothness of $M(t)$: For this example
$$\mu(.;u,v) = \int_{\mathcal{S}_r} uvJ_t = \int_{\mathcal{S}_r} uv(I - \mathbf{n}\otimes\mathbf{n})\cdot(\nabla_x\mathbf{V})$$
so $C_\mu = 2\|\nabla_x\mathbf{V}\|_{L^\infty}$.
2. Equivalence of norms on $U(t)$: If F_1 and F_2 are the columns of F, $F = [F_1, F_2]$, then
$$|u|_{U(.)} = \int_{\mathcal{S}_r} \sigma(\nabla u)^T (F^T F)^{-1} \nabla u\, J = \int_{\mathcal{S}_r} \sigma(\nabla u)^T \frac{1}{J}\begin{bmatrix} |F_2|^2 & -F_1.F_2 \\ -F_1.F_2 & |F_1|^2 \end{bmatrix} \nabla u.$$
Letting $\cos(\theta) = F_1.F_2/|F_1||F_2|$ and $x \in \mathbb{R}^2$, then
$$\begin{aligned}(1-\cos(\theta))\Big((x_1|F_2|)^2 + (x_2|F_2|)^2\Big) &\le x^T \begin{bmatrix} |F_2|^2 & -F_1.F_2 \\ -F_1.F_2 & |F_1|^2 \end{bmatrix} x \\ &\le (1+\cos(\theta))\Big((x_1|F_2|)^2 + (x_2|F_2|)^2\Big).\end{aligned}$$
Since $F_{it} = (\nabla_x\mathbf{V})F_i$ it follows that $\ln(|F_i|)_t \le \|\nabla_x\mathbf{V}\|_{\ell^2}$, so if $0 \le c_0 \le |F_i(0,.)| \le C_0$, a calculation shows that for $s < t$
$$\frac{1-\|\cos(\theta)\|_{L^\infty}}{1+\|\cos(\theta)\|_{L^\infty}} c_0 e^{-C(t-s)} \le \frac{|u|_{U(t)}}{|u|_{U(s)}} \le \frac{1+\|\cos(\theta)\|_{L^\infty}}{1-\|\cos(\theta)\|_{L^\infty}} C_0 e^{C(t-s)}, \tag{6.2}$$
where C is a small multiple of $\|\nabla_x\mathbf{V}\|$ and it is assumed that $\|\cos(\theta)\|_{L^\infty} < 1$. Notice that $\cos(\theta)$ measures the amount of shear the membrane $\mathcal{S}(t)$ experiences when deformed from the reference configuration $\mathcal{S}_r$ and that $|(\cos(\theta))_t| \le C\|\nabla_x\mathbf{V}\|_{L^\infty}$. If the membrane is elastic, it will resist shear, so $|\cos(\theta)|$ will typically be bounded away from one. Examples of flow computations with elastic membranes can be found in [25].
3. Continuity of the bilinear form and data:
$$\begin{aligned}|a(t;u,v)| &\le \sigma\|u\|_{U(t)}\|v\|_{U(t)} + 2\|\nabla_x\mathbf{V}\|_{L^\infty}\|u\|_{H(t)}\|v\|_{H(t)} \\ &\le \Big(c_a|u|^2_{U(t)} + C_a|u|^2_{H(t)}\Big)^{1/2}\Big(c_a|v|^2_{U(t)} + C_a|v|^2_{H(t)}\Big)^{1/2},\end{aligned}$$
where $c_a = \sigma$ and $C_a = 2\|\nabla_x\mathbf{V}\|_{L^\infty}$.
Since the equation is homogeneous ($f = 0$), the continuity hypothesis on f is trivially satisfied.
4. Coercivity of the bilinear form: If $c_\alpha = c_a = \sigma$ and $C_\alpha = C_a = 2\|\nabla_x\mathbf{V}\|_{L^\infty}$, then the bilinear form satisfies
$$a(t;u,u) \ge c_\alpha|u|^2_{U(t)} - C_\alpha|u|^2_{H(t)}.$$

Assuming the existence of constants $0 < c_0 < C_0$ introduced above and assuming that $\|\cos(\theta)\|_{L^\infty} < C_1 < 1$, the approximate solutions of (1.2) computed using the discontinuous Galerkin scheme (4.3) will satisfy the error estimates stated in Theorems 5.1 and 5.2. The estimates in (6.1) and (6.2) show that the norms $\|.\|_{H(.)}$ and $|.|_{U(.)}$ are equivalent to unweighted L^2 and H^1 norms scaled appropriately. If classical Lagrange finite elements with polynomials of degree $\ell > 0$ are used to construct subspaces of $U \sim H^1(\mathcal{S}_r)$ over a quasi-regular triangulation of $\mathcal{S}_r$, then classical interpolation theory shows that the initial error is bounded by
$$\|e_h^0\|_{L^2(\Omega)} \le C\|D_x^\ell u_0\|_{L^2(\mathcal{S}_r)} h^\ell.$$

Similarly, for $1 \leq p \leq \infty$,

$$\|u - \mathbb{P}_h^{loc} u\|_{L^p[0,T;L^2(S_r)]} \leq C \left(\|D_x^{\ell+1} u\|_{L^p[0,T;L^2(S_r)]} h^{\ell+1} + \|D_t^{k+1} u\|_{L^p[0,T;L^2(S_r)]} \tau^{k+1} \right),$$

where $h > 0$ is the usual mesh parameter. The inverse inequality shows

$$\|u - \mathbb{P}_h^{loc} u\|_{L^2[0,T;H^1(S_r)]} \leq C \left(\|D_x^{\ell+1} u\|_{L^2[0,T;L^2(S_r)]} h^{\ell} + \|D_t^{k+1} u\|_{L^2[0,T;L^2(S_r)]} (\tau^{k+1}/h) \right),$$

so

$$|||u - \mathbb{P}_h^{loc} u|||_\infty \leq C \left(\sqrt{\sigma} \left(h^\ell + \tau^{k+1}/h \right) + h^\ell + \tau^k \right),$$

where the constant C depends upon T, k, ℓ, and the norms

$$\|D_x^{\ell+1} u\|_{L^2[0,T;L^2(S_r)]}, \quad \|D_x^{\ell} u\|_{L^\infty[0,T;L^2(S_r)]},$$
$$\|D_t^{k+1} u\|_{L^2[0,T;L^2(S_r)]}, \quad \|D_t^{k} u\|_{L^\infty[0,T;L^2(S_r)]}.$$

When $\sigma << h$ the minimum of the expressions in the jump term is $\|(I - P_i)u(t^i)\|_{L^2(\Omega)}$ and

$$\sum_{i=0}^{N-1} \|(I - P_i)u(t^i)\|^2_{L^2(\Omega)} \leq C \|D_x^\ell u\|^2_{L^\infty[0,T;L^2(S_r)]} N h^{2\ell} \leq CT \|D_x^\ell u\|^2_{L^\infty[0,T;L^2(S_r)]} h^{2\ell}/\tau.$$

This gives an error of size $h^\ell/\sqrt{\tau}$, which is typical of the discontinuous Galerkin method for hyperbolic equations [24]. If σ is $O(1)$, the second term in the minimum can be bounded as $\|P_{i+1}(I - P_i)u(t^i)\|^2_{U'(t^i)} \leq C \|D_x^\ell u\|_{L^\infty[0,T;L^2(S_r)]} h^{\ell+1}$, and

$$\sum_{i=0}^{N-1} 1/(\sigma\tau) \|P_{i+1}(I - P_i)u(t^i)\|^2_{U'(t^i)} \leq (CT/\sigma) \|D_x^\ell u\|^2_{L^\infty[0,T;L^2(S_r)]} h^{2\ell+2}/\tau^2,$$

which gives the optimal $O(h^{\ell+1}/\tau)$ bound (assuming $\tau \sim h$).

Remark 4. (1) The above estimates assume that $\mathcal{S}_r$ is been triangulated exactly using a curvilinear coordinate system.

(2) The geometry of $\mathcal{S}(t)$ doesn't explicitly appear in the error estimates. However, if $\mathcal{S}_r$ has narrow regions of high curvature, the quasi-uniform assumption on the mesh will force a fine triangulation in such regions.

(3) If the exact solution is more regular in time, $u \in L^\infty[0,T;H^{\ell+1}(\Omega)]$, then the jump terms will be one order of h smaller. In this situation the jump terms will be asymptotically negligible compared with $|||u - \mathbb{P}_h^{loc} u|||_\infty$ when $\sigma = O(1)$.

LOCALIZATION OF THE GENERALIZED SAMPLING SERIES AND ITS NUMERICAL APPLICATION*

LIWEN QIAN† AND DENNIS B. CREAMER‡

Abstract. We study the localization of the sampling series with general kernel and obtain its error estimates. To achieve exponentially decaying accuracy for the series to approximate a band-limited function and its derivatives, a sufficient condition is given and a rigorous criterion is provided for the sampling to obtain any desired accuracy. The result includes several known results as special cases and gives new results about wavelet sampling series.

1. Introduction.

Let $\mathbb{R}$ be the set of all real numbers, $\mathbb{Z}$ the set of all integers, $\mathbb{Z}_+$ the set of all nonnegative integers, and $\mathbb{N}$ the set of all positive integers. For any interval $\mathbb{I} \subseteq \mathbb{R}$ and $1 \leq p \leq \infty$, we let $L^p(\mathbb{I})$ be the space of complex-valued Lebesgue measurable functions f on $\mathbb{I}$ for which the norm

$$\|f\|_{p,\mathbb{I}} := \begin{cases} \left\{\int_{\mathbb{I}} |f(x)|^p \mathrm{d}x\right\}^{1/p}, & 1 \leq p < \infty, \\ \operatorname{ess\,sup}\{|f(x)| : x \in \mathbb{I}\}, & p = \infty, \end{cases}$$

is finite. When $\mathbb{I} = \mathbb{R}$ we denote this norm as $\|f\|_p$.

Every function $f \in L^2(\mathbb{R})$ has a *Fourier transform* in $L^2(\mathbb{R})$ which we denote by $\widehat{f}$:

$$\widehat{f}(\omega) := \int_{\mathbb{R}} f(x) \exp(\mathrm{i}x\omega)\mathrm{d}x, \quad w \in \mathbb{R}.$$

A *signal*, that is, a function f in $L^2(\mathbb{R})$, is said to be band-limited with bandwidth σ provided we have for $|w| > \sigma$ that $\widehat{f}(w) = 0$. We denote the totality of such functions by

$$B_\sigma := \{f \in L^2(\mathbb{R}) : \widehat{f}(w) = 0, |w| > \sigma\}.$$

We let $C(\mathbb{R})$ be the space of complex-valued continuous functions on $\mathbb{R}$ with the maximum norm $\|\cdot\|_\infty$. For $h > 0$ we define $\mathcal{S}_h : C(\mathbb{R}) \to C(\mathbb{R})$ for $f \in C(\mathbb{R})$ by the equation

$$(\mathcal{S}_h f)(x) := \sum_{k\in\mathbb{Z}} f(kh)\phi(h^{-1}x - k), \quad x \in \mathbb{R}. \tag{1}$$

We refer to $\mathcal{S}_h$ as a *sampling operator* because it uses the values f on $h\mathbb{Z}$. By $C_c(\mathbb{R})$ we denote the subspace of $C(\mathbb{R})$ consisting of all functions which vanish outside of

some finite subinterval of $\mathbb{R}$. When $\phi \in C_c(\mathbb{R})$, we call (1) the *Schoenberg operator* because of the work of I. J. Schoenberg [1] on spline functions. This hypothesis on ϕ naturally arises in his work on spline functions. When $\phi = \text{sinc}$, we call (1) the *cardinal operator* and denote it by $\mathcal{C}_h$:

$$(\mathcal{C}_h f)(x) := \sum_{k\in\mathbb{Z}} f(kh)\text{sinc}(h^{-1}x-k), \quad x \in \mathbb{R}. \tag{2}$$

A fundamental result in information theory is the Whittaker–Kotel'nikov–Shannon (WKS) sampling theorem [2, 3, 4]. It states that any $f \in B_\sigma$ can be reconstructed from its sampled values $f(x_k)$, where $x_k := k\pi/\sigma$ and $k \in \mathbb{Z}$, by the formula

$$f(x) = \sum_{k\in\mathbb{Z}} f(x_k)\text{sinc}(\sigma x/\pi - k), \quad x \in \mathbb{R},$$

where

$$\text{sinc}(x) := \begin{cases} \frac{\sin \pi x}{\pi x}, & x \in \mathbb{R}\setminus\{0\}, \\ 1, & x = 0, \end{cases}$$

and the series converges absolutely and uniformly on any finite closed interval of $\mathbb{R}$.

The applications of the WKS the sampling theorem have been widely studied [5, 6, 7, 8]. However, the sinc function in the WKS sampling series is not very convenient for practical applications, due largely to the fact that it has a very slow rate of decay at infinity.

An effort has been made to find replacements for the sinc kernel that have better decay properties and are more convenient for numerical computation. It is expected that a modification of the sinc function will yield a better convergence rate of the WKS sampling formula. Many particular convergence factors have been considered; see, for example, [8, 9, 10, 11, 12, 13, 14, 15, 16, 17] and references therein. Another approach is to replace the sinc function with a sampling atom with rapid decay; see, for example, [18, 19] and references therein.

In [20], the *localization operator* $\mathcal{G}_h : B_\sigma \to L^2(\mathbb{R})$, where $h \in (0, \pi/\sigma]$, defined by

$$(\mathcal{G}_h f)(x) := \sum_{k\in\mathbb{Z}} f(kh)\text{sinc}(h^{-1}x-k)\phi_r(h^{-1}x-k), \quad x \in \mathbb{R}, \tag{3}$$

is considered where $\phi_r := \phi(r^{-1}\cdot)$. The function ϕ is even on $\mathbb{R}$ satisfying $\phi(0) = 1$ and that ϕ is continuous at 0. We require $\phi \in L^\infty(\mathbb{R}) \cap L^1(\mathbb{R})$, so that the sampling series in (3) is uniformly convergent on $\mathbb{R}$ when $f \in B_\sigma$ for any $\sigma > 0$. Such a function ϕ can be a band-limited function or a duration-limited function.

For practical application, we consider its truncation version defined by

$$(\mathcal{T}_h f)(x) := \sum_{k\in\mathbb{Z}_m(x)} f(kh)\text{sinc}(h^{-1}x-k)\phi_r(h^{-1}x-k), \quad x \in \mathbb{R}, \tag{4}$$

where $\mathbb{Z}_m(x) := \{k \in \mathbb{Z} : |[h^{-1}x]-k| \le m\}$ for $m \in \mathbb{N}$ and $[x]$ denotes the integer part of $x \in \mathbb{R}$. Note that the truncation terms chosen here coincide with what is applied in [17], and it is different from what is considered in, for example, [10, 11, 12, 21], where the truncation is made from $-m$ to m for a given m.

For $h > 0$ and $s \in \mathbb{Z}_+$, we define the sth order derivative of the localization operator by $\mathcal{G}_h^{(s)} f := \mathcal{D}^{(s)}\mathcal{G}_h$, and correspondingly for the truncated form $\mathcal{T}_h^{(s)} f := \mathcal{D}^{(s)}\mathcal{T}_h$, where $\mathcal{D}^{(s)}$ denotes the sth order derivative operator.

We will study how well the operator $\mathcal{G}_h^{(s)}$ or $\mathcal{T}_h^{(s)}$ approximates $\mathcal{D}^{(s)}$. This problem is valuable for numerical application. To this end, we recall for $p \in [1, \infty]$ and $s \in \mathbb{Z}^+$ that the *Sobolev space* is defined as

$$W^{s,p}(\mathbb{R}) := \{f \in L^1(\mathbb{R}), f^{(k)} \in L^p(\mathbb{R}), 1 \leq k \leq s\},$$

where for $f \in W^{s,p}(\mathbb{R})$ and an interval $\mathbb{I} \subseteq \mathbb{R}$, we let

$$\|f\|_{s,p,\mathbb{I}} := \sum_{k=1}^{s} \|f^{(s)}\|_{p,\mathbb{I}}.$$

Typically, for given $m \in \mathbb{N}$ and $\mathbb{I} := \mathbb{R} \setminus [-m, m]$, we denote $\|f\|_{s,p,\mathbb{I}}$ by $\|f\|_{s,p,m}$.

For $h > 0$ and $s \in \mathbb{Z}_+$, error estimations for $\mathcal{T}_h^{(s)} f$ to approximate the sth order derivative of a band-limited function f have been obtained in [20]. When ϕ is the Gaussian function $G(x) := \exp(-x^2/2)$ for $x \in \mathbb{R}$, which is proposed in [16], the explicit error bound is given in [22]. If the sinc kernel in (4) is replaced by $r_1 \mathrm{sinc}(r_1 x)$ for $x \in \mathbb{R}$ and certain $r_1 > 0$, the error estimates are given in [23] and its numerical application for solving Burgers's equation is discussed in [24]. When the sinc kernel in (4) is replaced by a modified version, which is defined for $x \in \mathbb{R}$ and $\lambda \in [0, \pi)$ by the formula $S(x) := \mathrm{sinc}(x) \cos(\lambda x)$, the L^∞ error estimates are given in [25], which shows that the approximation accuracy is comparable with that achieved by using the sinc kernel.

Since different kernels have been efficiently applied and analyzed, we were motivated to replace the sinc kernel in (4) by a general kernel K, that is, to consider

$$(\mathcal{G}_h f)(x) := \sum_{k \in \mathbb{Z}} f(kh) K(h^{-1}x - k) G_r(h^{-1}x - k), \quad x \in \mathbb{R}. \tag{5}$$

Furthermore, we consider its truncated version defined by

$$(\mathcal{T}_h f)(x) := \sum_{k \in \mathbb{Z}_m(x)} f(kh) K(h^{-1}x - k) G_r(h^{-1}x - k), \quad x \in \mathbb{R}. \tag{6}$$

We will give a sufficient condition for the kernel function K so that (6) can approximate a band-limited function f with exponentially decaying accuracy.

In the next section, we review some known results for later comparison and introduce some preliminaries. Error estimates are derived in section 3. Rigorous and practical means for obtaining any desired accuracy for the sampling will be provided in section 4, where we also give a new result of sampling series which is based on Meyer wavelets. Section 5 provides a few numerical experiments to demonstrate the high efficiency of the approximation. The conclusion will be given in the last section.

2. Preliminaries.

We first review a basic result about approximation by the Schoenberg operator (1). For this purpose, we let π_n be the space of polynomials of degree not exceeding n, and we denote for any $h > 0$ the *modulus of continuity* of a function f defined on $\mathbb{R}$ by $w(f; h) := \sup\{|f(x) - f(y)| : |x - y| \leq h\}$. The following result is standard; see, for example, [20, pp. 13–14].

THEOREM 2.1. *If $\phi \in C_c(\mathbb{R})$ and $n \in \mathbb{Z}_+$, then there exists a positive constant c such that for all f with $f^{(n)} \in C(\mathbb{R})$ and $h > 0$ there holds the inequality*

$$\|\mathcal{S}_h f - f\|_\infty \leq c h^n w(f^{(n)}, h)$$

if and only if for every $p \in \pi_n$,

$$p(x) = \sum_{j \in \mathbb{Z}} p(j)\phi(x-j), \quad x \in \mathbb{R}.$$

For later comparison, we introduce the following result [22] for (6) with a sinc kernel to approximate a band-limited function f.

THEOREM 2.2. *If* $f \in B_\sigma$, $h \in (0, \pi/\sigma]$, $K := \operatorname{sinc}$ *in* (6), $r > 0$, $m \in \mathbb{N}$, $m \geq sr/\sqrt{2}$, $\alpha_0 := \min\{m/r, r(\pi - h\sigma)\}$, *and* $s \in \mathbb{Z}_+$, *then*

$$\|f^{(s)} - \mathcal{T}_h^{(s)} f\|_\infty \leq \beta_0 \exp(-\alpha_0^2/2),$$

where $\beta_0 := \frac{e^\pi r(s+1)!}{h^s \pi \alpha_0}(\sqrt{2\sigma}\|f\|_2 + 2r\|f\|_\infty)$.

The following inequality about the *Mills' ratio*, which is defined for $x \in \mathbb{R}$ as

$$M(x) := \exp\left(\frac{x^2}{2}\right)\int_x^{+\infty} \exp\left(-\frac{t^2}{2}\right)\mathrm{d}t,$$

will be essential for our later use.

LEMMA 2.1. *If* $x \geq 0$, *then*

$$\frac{\pi}{\sqrt{x^2 + 2\pi} + (\pi - 1)x} \leq M(x) \leq \frac{\pi}{\sqrt{(\pi-2)^2 x^2 + 2\pi} + 2x}.$$

Both bounds tend to $\sqrt{\pi/2}$ when $x \to 0$. See, for example, [28, pp. 177–181]. Based on Lemma 2.1, we have the following result [25].

LEMMA 2.2. *If* $x_0 \geq 0$, $s \in \mathbb{Z}_+$, *and* $x \geq \max\{1, \sqrt{s}\}$, *then*

$$\int_x^\infty (t + x_0)^s \exp(-t^2/2)\mathrm{d}t \leq (1+s)(x+x_0)^s \frac{\exp(-x^2/2)}{x}.$$

3. Error estimates. For a kernel function K used in (5), we suppose that K satisfies the following:

(1) for certain $0 \leq a \leq b \leq 2\pi$ that

$$\widehat{K}(w) = 1, \quad |w| \leq a; \widehat{K}(w) = 0, \quad |w| \geq b; \widehat{K}(w) \in [0,1], \quad \text{otherwise}, \tag{7}$$

(2) for given $s \in \mathbb{Z}_+$ and $m \in \mathbb{N}$ that

$$\|K\|_{s,\infty,m} < \infty. \tag{8}$$

For simplicity of notation, we denote

$$c := \min\{2\pi - b, a\},$$

which will be used throughout the rest of the paper. Note that from (7) we have $c \leq \pi$. We will derive the error bounds for (6) to approximate a band-limited function f. We carry out the estimates in three steps.

3.1. Without truncation. The first step is to consider the operator $\mathcal{G}_h$ defined in (5) and to derive for any $s \in \mathbb{Z}_+$ the estimate of the *localization error* $f^{(s)} - \mathcal{G}_h^{(s)} f$. To this end, for a given function $K \in L^1(\mathbb{R})$ and $h, r > 0$, we associate functions μ

and ν defined for $\omega \in \mathbb{R}$ by setting

$$\mu(\omega) := \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} \widehat{K}(h\omega - t/r) \exp(-t^2/2) \mathrm{d}t \tag{9}$$

and

$$\nu(\omega) := 1 - \mu(\omega) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} [1 - \widehat{K}(h\omega - t/r)] \exp(-t^2/2) \mathrm{d}t.$$

We need the following result.

Lemma 3.1. *If K satisfies* (7), $h \in (0, c/\sigma]$, $r(c - h\sigma) \geq \max\{1, \sqrt{s}\}$, *and* $\omega \in [-\sigma, \sigma]$, *then*

$$\begin{aligned} &\sqrt{|\omega^s \nu(\omega)|^2 + \sum_{k \in \mathbb{Z} \setminus \{0\}} |(\omega + 2k\pi/h)^s \mu(\omega + 2k\pi/h)|^2} \\ &\quad \leq (1 + 2^{s+1})(1 + s) \sqrt{\frac{2}{\pi}} \Big(\frac{\pi}{h}\Big)^s \frac{\mathrm{e}^{-r^2(c-h\sigma)^2/2}}{r(c - h\sigma)} \end{aligned}$$

and

$$|\omega^s \nu(\omega)| + \sum_{k \in \mathbb{Z} \setminus \{0\}} |(\omega + 2k\pi/h)^s \mu(\omega + 2k\pi/h)| \leq (1 + 2^{s+1})(1 + s) \sqrt{\frac{2}{\pi}} \Big(\frac{\pi}{h}\Big)^s \frac{\mathrm{e}^{-r^2(c-h\sigma)^2/2}}{r(c - h\sigma)}.$$

Proof. From (7) and (9) we observe for $\omega \in [-\sigma, \sigma]$ that

$$|\mu(\omega)| \leq \frac{1}{\sqrt{2\pi}} \int_{|h\omega - t/r| \leq b} \exp(-t^2/2) \mathrm{d}t,$$

which leads to

$$\begin{aligned} S_1(\omega) : &= \sum_{k \in \mathbb{N}} |(\omega + 2k\pi/h)^s \mu(\omega + 2k\pi/h)| \\ &= \frac{1}{\sqrt{2\pi}} \sum_{k \in \mathbb{N}} (\omega + 2k\pi/h)^s \int_{r(2k\pi + h\omega - b)}^{r(2k\pi + h\omega + b)} \exp(-t^2/2) \mathrm{d}t \\ &\leq \frac{1}{\sqrt{2\pi}(rh)^s} \sum_{k \in \mathbb{N}} \int_{r(h\omega + 2k\pi - b)}^{r(h\omega + 2k\pi + b)} (t + rb)^s \exp(-t^2/2) \mathrm{d}t. \end{aligned}$$

Since $b \leq 2\pi$, we have $h\omega + 2(k+2)\pi - b \geq h\omega + 2k\pi + b$ for $k \in \mathbb{N}$ and that

$$\begin{aligned} S_1(\omega) &\leq \frac{1}{\sqrt{2\pi}(rh)^s} \sum_{k \in 2\mathbb{N} - 1} \int_{r(h\omega + 2k\pi - b)}^{r(h\omega + 2k\pi + b)} (t + rb)^s \exp(-t^2/2) \mathrm{d}t \\ &\quad + \frac{1}{\sqrt{2\pi}(rh)^s} \sum_{k \in 2\mathbb{N}} \int_{r(h\omega + 2k\pi - b)}^{r(h\omega + 2k\pi + b)} (t + rb)^s \exp(-t^2/2) \mathrm{d}t \\ &\leq \frac{2}{\sqrt{2\pi}(rh)^s} \int_{r(h\omega + 2\pi - b)}^{\infty} (t + rb)^s \exp(-t^2/2) \mathrm{d}t \\ &\leq \frac{2}{\sqrt{2\pi}(rh)^s} \int_{r(c - h\sigma)}^{\infty} (t + rb)^s \exp(-t^2/2) \mathrm{d}t \\ &\leq \frac{2(1 + s)}{\sqrt{2\pi}} \Big(\frac{2\pi}{h} - \sigma\Big)^s \frac{\exp(-r^2(c - h\sigma)^2/2)}{r(c - h\sigma)}, \end{aligned} \tag{10}$$

where the last step follows from Lemma 2.2. Furthermore, we have

$$\begin{aligned}S_2(\omega) :&= \sum_{-k\in\mathbb{N}} |(\omega+2k\pi/h)^s\mu(\omega+2k\pi/h)|\\ &= \frac{1}{\sqrt{2\pi}}\sum_{-k\in\mathbb{N}}|\omega+2k\pi/h|^s\int_{r(h\omega+2k\pi-b)}^{r(h\omega+2k\pi+b)}\exp(-t^2/2)\mathrm{d}t\\ &= \frac{1}{\sqrt{2\pi}}\sum_{k\in\mathbb{N}}(2k\pi/h-\omega)^s\int_{r(2k\pi-b-h\omega)}^{r(2k\pi+b-h\omega)}\exp(-t^2/2)\mathrm{d}t = S_1(-\omega).\end{aligned}\tag{11}$$

On the other hand, since

$$\nu(\omega)\le 1-\frac{1}{\sqrt{2\pi}}\int_{|h\omega-t/r|\le a}\exp(-t^2/2)\mathrm{d}t = \frac{1}{\sqrt{2\pi}}\int_{|h\omega-t/r|\ge a}\exp(-t^2/2)\mathrm{d}t,$$

from Lemma 2.1 we have

$$\begin{aligned}|\omega^s\nu(\omega)| &\le \frac{|\omega|^s}{\sqrt{2\pi}}\int_{r(h\omega+a)}^{\infty}\mathrm{e}^{-t^2/2}\mathrm{d}t+\frac{|\omega|^s}{\sqrt{2\pi}}\int_{-\infty}^{r(h\omega-a)}\mathrm{e}^{-t^2/2}\mathrm{d}t\\ &\le \sqrt{\frac{2}{\pi}}\sigma^s\frac{\exp(-r^2(c-h\sigma)^2/2)}{r(c-h\sigma)} \le \sqrt{\frac{2}{\pi}}\Big(\frac{\pi}{h}\Big)^s\frac{\exp(-r^2(c-h\sigma)^2/2)}{r(c-h\sigma)},\end{aligned}\tag{12}$$

where the last step follows from $\sigma\le c/h$ and $c\le\pi$. Thus, combining (10), (11), and (12) gives

$$\begin{aligned}&|\omega^s\nu(\omega)|+\sum_{k\in\mathbb{Z}\setminus\{0\}}|(\omega+2k\pi/h)^s\mu(\omega+2k\pi/h)|\\ &\quad\le(1+2^{s+1})(1+s)\sqrt{\frac{2}{\pi}}\Big(\frac{\pi}{h}\Big)^s\frac{\exp(-r^2(c-h\sigma)^2/2)}{r(c-h\sigma)}.\end{aligned}$$

From

$$\begin{aligned}&\sqrt{|\omega^{2s}\nu(\omega)^2|+\sum_{k\in\mathbb{Z}\setminus\{0\}}|(\omega+2k\pi/h)^{2s}\mu(\omega+2k\pi/h)^2|}\\ &\le|\omega^s\nu(\omega)|+\sum_{k\in\mathbb{Z}\setminus\{0\}}|(\omega+2k\pi/h)^s\mu(\omega+2k\pi/h)|,\end{aligned}$$

we finish the proof. □

Now, we are ready to obtain for given $f\in B_\sigma$ the error estimates of $\mathcal{G}_hf-f$ and its derivatives.

THEOREM 3.1. *If $f\in B_\sigma$, K satisfies (7), $h\in(0,c/\sigma]$, $r>0$, $s\in\mathbb{Z}_+$, and $r(c-h\sigma)\ge\max\{1,\sqrt{s}\}$, then*

$$\|f^{(s)}-\mathcal{G}_h^{(s)}f\|_2\le(1+2^{s+1})(1+s)\sqrt{\frac{2}{\pi}}\Big(\frac{\pi}{h}\Big)^s\frac{\mathrm{e}^{-r^2(c-h\sigma)^2/2}}{r(c-h\sigma)}\|f\|_2$$

and

$$\|f^{(s)}-\mathcal{G}_h^{(s)}f\|_\infty\le(1+2^{s+1})(1+s)\frac{\sqrt{2\sigma}}{\pi}\Big(\frac{\pi}{h}\Big)^s\frac{\mathrm{e}^{-r^2(c-h\sigma)^2/2}}{r(c-h\sigma)}\|f\|_2.$$

Proof. Since for $\omega \in \mathbb{R}$ we have

$$K(h^{-1}\cdot -k)\widehat{(\omega)} = h\exp(\mathrm{i}kh\omega)\widehat{K}(h\omega)$$

and

$$G_r(h^{-1}\cdot -k)\widehat{(\omega)} = hr\exp(\mathrm{i}kh\omega)\sqrt{2\pi}\exp(-r^2h^2\omega^2/2),$$

we obtain

$$\begin{aligned} &K(h^{-1}\cdot -k)\widehat{(\omega)} * G_r(h^{-1}\cdot -k)\widehat{(\omega)} \\ &\quad = \sqrt{2\pi}h^2 r\exp(\mathrm{i}kh\omega)\int_{\mathbb{R}}\widehat{K}(h(\omega-\theta))\exp(-r^2h^2\theta^2/2)\mathrm{d}\theta, \end{aligned}$$

which provides for

$$\mathcal{G}_h f := \sum_{k\in\mathbb{Z}} f(kh)K(h^{-1}\cdot -k)G_r(h^{-1}\cdot -k)$$

that

$$\begin{aligned} (\mathcal{G}_h f)\widehat{(\omega)} &= \frac{1}{2\pi}\sum_{k\in\mathbb{Z}} f(kh)K(h^{-1}\cdot -k)\widehat{(\omega)} * G_r(h^{-1}\cdot -k)\widehat{(\omega)} \\ &= \sum_{k\in\mathbb{Z}} f(kh)h\exp(\mathrm{i}kh\omega)\mu(\omega), \end{aligned} \tag{13}$$

where μ is defined in (9). On the other hand, since $c \le \pi$, function f satisfies

$$\widehat{f} \in L^2[-\sigma,\sigma] \subseteq L^2[-c/h, c/h] \subseteq L^2[-\pi/h,\pi/h],$$

and from its Fourier series expansion, we have

$$\widehat{f}(\omega) = \widehat{f}(\omega)\chi_{[-\sigma,\sigma]}(\omega) = \sum_{k\in\mathbb{Z}} hf(kh)\exp(\mathrm{i}kh\omega)\chi_{[-\sigma,\sigma]}(\omega), \quad \omega\in\mathbb{R}. \tag{14}$$

Applying (13) and (14) to $E_1 := f^{(s)} - \mathcal{G}_h^{(s)}f$ gives for all $\omega \in \mathbb{R}$ that

$$\widehat{E_1}(\omega) = (\mathrm{i}\omega)^s\sum_{k\in\mathbb{Z}} hf(kh)\exp(\mathrm{i}kh\omega)(\chi_{[-\sigma,\sigma]}(\omega) - \mu(\omega)).$$

Since f is band-limited to σ, we restrict $\widehat{f}$ to the interval $[-\pi/h, \pi/h]$, extend this function to a $2\pi/h$-periodic function and denote the resulting function as g. Then

$$\widehat{E_1}(\omega) = \begin{cases} (\mathrm{i}\omega)^s\widehat{f}(\omega)\nu(\omega), & |\omega| \le \sigma, \\ -(\mathrm{i}\omega)^s g(\omega)\mu(\omega), & |\omega - 2k\pi/h| \le \sigma, k\in\mathbb{Z}\setminus\{0\}, \\ 0 & \text{otherwise.} \end{cases}$$

We observe that if $\omega \in \mathbb{R}$ such that $|\omega - 2k\pi/h| \le \sigma$, where $k \in \mathbb{Z}\setminus\{0\}$, then

$$g(\omega) = g(\omega - 2k\pi/h) = \widehat{f}(\omega - 2k\pi/h),$$

which provides that

$$\widehat{E_1}(\omega) = \begin{cases} (\mathrm{i}\omega)^s\widehat{f}(\omega)\nu(\omega), & |\omega| \le \sigma, \\ -(\mathrm{i}\omega)^s\widehat{f}(\omega - 2k\pi/h)\mu(\omega), & |\omega - 2k\pi/h| \le \sigma, k\in\mathbb{Z}\setminus\{0\}, \\ 0 & \text{otherwise.} \end{cases}$$

Therefore, we have that

$$\|\widehat{E}_1\|_2^2 = \int_{-\sigma}^{\sigma} |\omega^s \widehat{f}(\omega)\nu(\omega)|^2 \mathrm{d}\omega + \sum_{k\in\mathbb{Z}\setminus\{0\}} \int_{-\sigma}^{\sigma} |(\omega + 2k\pi/h)^s \widehat{f}(\omega)\mu(\omega + 2k\pi/h)|^2 \mathrm{d}\omega$$
$$= \int_{-\sigma}^{\sigma} |\widehat{f}(\omega)|^2 \left(|\omega^s \nu(\omega)|^2 + \sum_{k\in\mathbb{Z}\setminus\{0\}} |(\omega + 2k\pi/h)^s \mu(\omega + 2k\pi/h)|^2 \right) \mathrm{d}\omega.$$

Lemma 3.1 implies the L^2 estimates. Since

$$\int_{\mathbb{R}} |\widehat{E_1}(\omega)| \mathrm{d}\omega = \int_{-\sigma}^{\sigma} |\omega^s \widehat{f}(\omega)\nu(\omega)| \mathrm{d}\omega + \sum_{k\in\mathbb{Z}\setminus\{0\}} \int_{-\sigma}^{\sigma} |(\omega + 2k\pi/h)^s \widehat{f}(\omega)\mu(\omega + 2k\pi/h)| \mathrm{d}\omega$$
$$= \int_{-\sigma}^{\sigma} |\widehat{f}(\omega)| \left(|\omega^s \nu(\omega)| + \sum_{k\in\mathbb{Z}\setminus\{0\}} |(\omega + 2k\pi/h)^s \mu(\omega + 2k\pi/h)| \right) \mathrm{d}\omega,$$

applying Lemma 3.1 and the Cauchy–Schwarz inequality to the above gives the L^∞ estimates. □

Note that if $r \to +\infty$, then $\exp(-r^2(-h\sigma + c)^2/2) \to 0$. Thus, from Theorem 3.1 we have the following result.

COROLLARY 3.1. *If $f \in B_\sigma$, K satisfies* (7), *and $h \in (0, c/\sigma]$, then*

$$f(x) = \sum_{k\in\mathbb{Z}} f(kh)K(h^{-1}x - k), \quad x \in \mathbb{R},$$

and the series converges in the L^2 norm and in the L^∞ norm on $\mathbb{R}$. It also converges uniformly on any finite closed interval of $\mathbb{R}$.

If $K :=$ sinc, then the above result reduces to the WKS sampling theorem. Therefore, both Theorem 3.1 and Corollary 3.1 can be viewed as generalizations of the WKS sampling theorem.

3.2. Truncated series. The next step is to estimate for $h > 0$ and $s \in \mathbb{Z}_+$ the *truncation error* $\mathcal{G}_h^{(s)} f - \mathcal{T}_h^{(s)} f$, where $\mathcal{G}_h$ and $\mathcal{T}_h$ are defined in (5) and (6), respectively.

THEOREM 3.2. *If $f \in L^\infty(\mathbb{R}) \cap L^2(\mathbb{R})$, $h, r > 0$, $s \in \mathbb{Z}_+$, $m \in \mathbb{N}$, $m \geq sr/\sqrt{2}$, and K satisfies* (8), *then*

$$\|\mathcal{G}_h^{(s)} f - \mathcal{T}_h^{(s)} f\|_\infty \leq \frac{2\sqrt{\sigma/\pi}\, r^2 s! \|K\|_{s,\infty,m}}{(m-2)h^s} \exp(-(m-2)^2/2r^2)\|f\|_2.$$

Proof. We denote $E_2 := \mathcal{G}_h^{(s)} f - \mathcal{T}_h^{(s)} f$. For $x \in \mathbb{R}$ and $s \in \mathbb{Z}_+$ we have

$$E_2(x) := \sum_{|[x/h]-k|>m} f(kh) \frac{\mathrm{d}^s}{\mathrm{d}x^s} \psi(x/h - k),$$

where

$$\psi(x) := K(x) \exp(-x^2/2r^2).$$

We denote the fractional part of $x \in \mathbb{R}$ by $\{x\}$ and let $l := [x/h] - k$; then we have

$$E_2(x) = \sum_{|l|>m} f(x - lh - \{x/h\}h) \frac{1}{h^s} \psi^{(s)}(l + \{x/h\}),$$

which leads to

$$|E_2(x)| \le \frac{\|f\|_\infty}{h^s} \sum_{|l|>m} |\psi^{(s)}(l + \{x/h\})|. \tag{15}$$

On the other hand, since for $k \in \mathbb{N}$ we have

$$\frac{\mathrm{d}^k}{\mathrm{d}x^k} \exp(-x^2/2r^2) = \frac{(-1)^k}{(\sqrt{2}r)^k} H_k(x/\sqrt{2}r) \exp(-x^2/2r^2),$$

where $H_k(x)$ is the kth order Hermite polynomial

$$\exp(-x^2) H_k(x) = (-1)^k \frac{\mathrm{d}^k}{\mathrm{d}x^k} \exp(-x^2),$$

we obtain

$$\psi^{(s)}(x) = \sum_{j_1+j_2=s} \frac{s!}{j_1! j_2!} K^{(j_1)}(x) \frac{(-1)^{j_2}}{(\sqrt{2}r)^{j_2}} H_{j_2}(x/\sqrt{2}r) \exp(-x^2/2r^2).$$

From [29, p. 187] we have

$$H_k(x) = \sum_{j=0}^{[k/2]} \frac{(-1)^j k! (2x)^{k-2j}}{j!(k-2j)!}.$$

For $x \in \mathbb{R}$, $k \in \mathbb{N}$, and $j \in \mathbb{Z}_+$ we denote $a_j := \frac{k!(2x)^{k-2j}}{j!(k-2j)!}$. Then we have $H_k(x) = \sum_{j=0}^{[k/2]} (-1)^j a_j$. It is easily shown that $\{a_j : j \in \mathbb{Z}_+\}$ decrease for $|x| \ge k/2$. This leads to $|H_k(x)| \le |a_0|$. Therefore, for $|x| \ge sr/\sqrt{2}$, we have

$$|H_k(x/\sqrt{2}r)| \le (\sqrt{2}|x|/r)^k,$$

which provides the estimation

$$|\psi^{(s)}(x)| \le \sum_{j_1+j_2=s} \frac{s!}{j_1! j_2!} K^{(j_1)}(x) \frac{|x|^{j_2}}{r^{2j_2}} \exp(-x^2/2r^2).$$

For $x \ge sr\sqrt{2}$ we have $\sum_{n=0}^{s} |x|^n/n! < e^{|x|}$. Thus, for $|x| > m$ we have

$$\begin{aligned} |\psi^{(s)}(x)| &\le s! \|K\|_{s,\infty,m} \exp(|x|/r^2) \exp(-x^2/2r^2) \\ &\le s! \|K\|_{s,\infty,m} \exp(-(|x|-1)^2/2r^2). \end{aligned} \tag{16}$$

Since $m \ge sr/\sqrt{2}$, applying (16) to (15) gives

$$\begin{aligned} |E_2(x)| \le \frac{s! \|K\|_{s,\infty,m} \|f\|_\infty}{h^s} \Bigg\{ &\sum_{l \ge m} \exp(-(l + \{x/h\})^2/2r^2) \\ &+ \sum_{l \ge m} \exp(-(l - \{x/h\})^2/2r^2) \Bigg\}. \end{aligned}$$

From Lemma 2.1,

$$\sum_{l\geq m} \exp(-(l+\{x/h\})^2/2r^2) < \int_{m-1}^{\infty} \exp(-x^2/2r^2)\mathrm{d}x$$
$$\leq \frac{r^2}{m-1}\exp(-(m-1)^2/2r^2).$$

Likewise,

$$\sum_{l\geq m} \exp(-(l-\{x/h\})^2/2r^2) < \int_{m-2}^{\infty} \exp(-x^2/2r^2)\mathrm{d}x$$
$$\leq \frac{r^2}{m-2}\exp(-(m-2)^2/2r^2).$$

Therefore, we obtain

$$|E_2(x)| \leq \frac{2r^2 s!\|K\|_{s,\infty,m}\|f\|_\infty}{(m-2)h^s}\exp(-(m-2)^2/2r^2).$$

By applying the Cauchy–Schwarz inequality and the Parseval identity, we have

$$\|f\|_\infty \leq \frac{1}{2\pi}\int_{-\sigma}^{\sigma}|\widehat{f}(\omega)|\mathrm{d}\omega \leq \frac{\sqrt{2\sigma}}{2\pi}\|\widehat{f}\|_2 = \sqrt{\sigma/\pi}\|f\|_2,$$

from which we obtain the estimate. □

3.3. Main result. For practical applications, only the *truncated* sampling series can be used. Therefore, we will now turn our attention to error estimates for $\mathcal{T}_h$ defined in (6) to approximate a band-limited function and its derivatives.

THEOREM 3.3. *If $f \in B_\sigma$, $h \in (0, c/\sigma]$, $r > 0$, $s \in \mathbb{Z}_+$, $r(c-h\sigma) \geq \max\{1, \sqrt{s}\}$, $m \in \mathbb{N}$, $m \geq sr/\sqrt{2}$, K satisfies* (7) *and* (8), *and* $\alpha := \min\{r(c-h\sigma), (m-2)/r\}$, *then*

$$\|f^{(s)} - \mathcal{T}_h^{(s)}f\|_\infty \leq \beta\exp(-\alpha^2/2)\|f\|_2,$$

where

$$\beta := ((1+2^{s+1})(1+s)\pi^{s-1} + \sqrt{2/\pi}rs!\|K\|_{s,\infty,m})\frac{\sqrt{2\sigma}}{\alpha h^s}.$$

Proof. Since

$$\|f^{(s)} - \mathcal{T}_h^{(s)}f\|_\infty \leq \|f^{(s)} - \mathcal{G}_h^{(s)}f\|_\infty + \|\mathcal{G}_h^{(s)}f - \mathcal{T}_h^{(s)}f\|_\infty,$$

combining the error bounds in Theorems 3.1 and 3.2 gives the estimate with

$$\alpha := \min\{r(c-h\sigma), (m-2)/r\}$$

and

$$\beta := (1+2^{s+1})(1+s)\frac{\sqrt{2\sigma}}{\pi}\left(\frac{\pi}{h}\right)^s\frac{1}{r(c-h\sigma)} + \frac{2\sqrt{\sigma/\pi}r^2 s!\|K\|_{s,\infty,m}}{(m-2)h^s}$$
$$\leq ((1+2^{s+1})(1+s)\pi^{s-1} + \sqrt{2/\pi}rs!\|K\|_{s,\infty,m})\frac{\sqrt{2\sigma}}{\alpha h^s}. \tag{17}$$

Thus, we finish the proof. □

Theorem 3.3 tells us that the approximation can achieve *exponentially decaying* accuracy provided $\alpha > 0$. Note that here the convergence is measured by a balance of various parameters, which include the variance r of the Gaussian, the bandwidth σ of f, the sampling rate h, and the truncation level m. This point of view is different from that found in the literature, where convergence is measured by the sample rate for functions.

In fact, if we specialize error bounds available in the literature to the class of functions we considered, our error estimates are far superior. For example, Theorem 2.1 tells us that if the kernel function is B-splines, the error estimate is of polynomial order. The convergence in Theorem 3.3 could be much faster for given h.

Theorem 3.3 provides great flexibility in approximation by involving many parameters that can be chosen appropriately. For application, simplified error bounds depending only on the truncation level m for a given grid spacing h are desirable. Since the maximal α takes when $r(c - h\sigma) = (m - 2)/r$, we can choose the optimal scaling factor $r = \sqrt{\frac{m-2}{c-h\sigma}}$ in the error bounds of Theorem 3.3. For this and the effects of different parameters on the error estimate, see, for example, [25]. Since the approaches and results there are basically similar to our general cases, we omit the details for simplicity of presentation.

As the proof of the above result mainly requires an application of the Fourier transform, it is possible to use the distributional theory of the Fourier transform to prove analogous results for a function that is bounded by a polynomial at infinity. This case is valuable for the study of radial basis approximation; see, for example, [26]. We will not require such improvements here, although they are important.

We remark that extensive numerical experiments have shown that high accuracy of approximation still holds for not necessarily band-limited functions and their derivatives. However, the explicit error estimates for the aliasing error are not available yet, though some preliminary results have been obtained.

4. Applications. For applications in computation, we deal with finite domain. Let $\mathbb{I}$ be a finite interval on $\mathbb{R}$ and $|\mathbb{I}|$ be its Lebesgue measure. For $p \in [1, \infty]$, the following result gives the estimates in L^p norms for approximation on the interval $\mathbb{I}$.

THEOREM 4.1. *If the hypotheses of Theorem* 3.3 *hold,* α, β *are given in Theorem* 3.3*,* $\mathbb{I} \subset \mathbb{R}$*, and* $p \in [1, \infty]$*, then*

$$\|f^{(s)} - \mathcal{T}_h^{(s)} f\|_{p,\mathbb{I}} \leq \beta_p \exp(-\alpha^2/2)\|f\|_2,$$

where

$$\beta_p := \begin{cases} |\mathbb{I}|^{1/p}\beta, & p \in [1, \infty), \\ \beta, & p = \infty. \end{cases}$$

Proof. It is obvious for $p \in [1, \infty)$ that

$$\left\{ \int_{\mathbb{I}} |f^{(s)}(x) - (\mathcal{T}_h^{(s)} f)(x)|^p \mathrm{d}x \right\}^{1/p} \leq |\mathbb{I}|^{1/p} \|f^{(s)} - \mathcal{T}_h^{(s)} f\|_\infty,$$

and for $p = \infty$ that

$$\|f^{(s)} - \mathcal{T}_h^{(s)} f\|_{\infty,\mathbb{I}} \leq \|f^{(s)} - \mathcal{T}_h^{(s)} f\|_\infty.$$

Thus, from Theorem 3.3 we obtain the conclusion. □

We remark that the L^2 estimate in Theorem 3.2, and thereafter in Theorem 3.3, has not been obtained yet. It is not clear whether or not the L^2 estimate is similar to the L^∞ estimate.

The error estimates in Theorem 4.1 are a useful guide for use in numerical computations. For this purpose, we obtain the following fact, which provides rigorous means for obtaining the desired accuracy of sampling.

THEOREM 4.2. *Given any $\rho > 0$, if the hypotheses of Theorem* 4.1 *hold, $\gamma_p := \ln \beta_p$, and the parameters m, r, and h are chosen such that*

$$\min\{r(c - h\sigma), (m-2)/r\} \geq \sqrt{2(\gamma_p + \rho \ln 10)}, \tag{18}$$

then

$$\|f^{(s)} - \mathcal{T}_h^{(s)} f\|_{p,\mathbb{I}} \leq 10^{-\rho}.$$

Proof. From Theorem 4.1 the result follows directly. □

By using (18), we can choose m, r, and h appropriately to attain any desired accuracy. Roughly speaking, suppose $c = \pi$, $\beta_p = 1$, and h and σ are small enough; then we can choose $r \in [3, 4]$ and $m \sim 30$ to ensure the highest accuracy in a double precision computation, that is, $\rho = 16$.

There are a few examples of kernel function K that satisfy the hypotheses (7) and (8).

Example 1:

$$K(x) := \operatorname{sinc}(x), \quad x \in \mathbb{R}.$$

This is the Shannon kernel discussed in [22]. Here $a = b = c = \pi$.

Example 2:

$$K(x) := r_1 \operatorname{sinc}(r_1 x), \quad x \in \mathbb{R},$$

for $r_1 > 0$. This is the oversampled Shannon kernel discussed in [24]. Here $a = b = r_1\pi$ and $c = \min\{2\pi - r_1\pi, r_1\pi\}$. When $r_1 := 1$ it reduces to the case of Example 1.

Example 3:

$$K(x) := \operatorname{sinc}(x)\cos(\lambda x), \quad x \in \mathbb{R},$$

for $\lambda \in [0, \pi)$. This is the modified sinc kernel studied in [25]. Here $a = \pi - \lambda$, $b = \pi + \lambda$, and $c = \pi - \lambda$. When $\lambda := 0$ it reduces to the case of Example 1.

Example 4:

$$K(x) := \operatorname{sinc}(x)\operatorname{sinc}(x/3), \quad x \in \mathbb{R}.$$

This is the de la Vallée Poussin kernel discussed in [27]. Here $a = c = 2\pi/3$ and $b = 4\pi/3$.

Example 5: The scaling function ϕ of the Meyer wavelet [30] is given by its Fourier transform

$$\widehat{\phi}(w) = \begin{cases} 1, & |w| \leq 2\pi/3, \\ \cos[\frac{\pi}{2}\theta(3|w|/2\pi - 1)], & 2\pi/2 < |w| < 4\pi/3, \\ 0, & |w| \geq 4\pi/3, \end{cases} \tag{19}$$

where θ is a real-valued function satisfying $\theta + \theta(1-\cdot) = 1$. Let $d \in (1/2, 1]$ and

$$\theta(w) = \begin{cases} \frac{2}{\pi}\operatorname{arccot}\left(\frac{w-d}{1-w-d}\right), & 1/2 \le w \le d, \\ 1, & w > d. \end{cases} \tag{20}$$

Using $\theta + \theta(1-\cdot) = 1$, we extend θ on $[0,1]$. Then the sampling function for the wavelet subspace [31] is

$$W(x) = \frac{3\sin(\pi x)\sin(2\pi(d-0.5)x/3)}{2\pi^2(d-0.5)x^2}, \quad x \in \mathbb{R}. \tag{21}$$

See [32, 21]. We have the following estimates, which provide much faster convergence than that given in [32, 21].

COROLLARY 4.1. *If $f \in B_\sigma$, $K := W$ defined in (21), $d \in (1/2,1]$, $h \in (0, (4-2d)\pi/3\sigma]$, $r > 0$, $s \in \mathbb{Z}_+$, $r[(4-2d)\pi/3 - h\sigma] \ge \max\{1, \sqrt{s}\}$, $m \in \mathbb{N}$, $m \ge sr/\sqrt{2}$, and $\alpha_1 := \min\{r[(4-2d)\pi/3 - h\sigma], (m-2)/r\}$, then*

$$\|f^{(s)} - \mathcal{T}_h^{(s)} f\|_\infty \le \beta_1 \exp(-\alpha_1^2/2)\|f\|_2,$$

where $\beta_1 := \left((1+2^{s+1})(1+s)\pi^{s-1} + \sqrt{2/\pi}rs!\frac{s(1+\lambda)^s}{\lambda m^2}\right)\frac{\sqrt{2\sigma}}{\alpha h^s}$.

Proof. Direct computing shows that W satisfies hypotheses (7) with $a = c = (4-2d)\pi/3$. So we need only to estimate for $s \in \mathbb{Z}_+$ and $m \in \mathbb{N}$ the quantity $\|W\|_{s,\infty,m}$. We observe for $\lambda := 2(d-0.5)/3 \in (0, 1/3]$ and $x \in \mathbb{R}$ that

$$W(x) = \frac{\cos(1-\lambda)x - \cos(1+\lambda)x}{2\lambda x^2}$$

and

$$W^{(s)}(x) = \sum_{j+k=s} \frac{s!}{j!k!}\{(1-\lambda)^j \cos[(1-\lambda)x + j\pi/2] \\ -(1+\lambda)^j\cos[(1+\lambda)x + j\pi/2]\}\frac{(-1)^k(k+1)!}{2\lambda x^{k+2}},$$

which provides

$$|W^{(s)}(x)| \le \frac{s!}{2\lambda}\sum_{j+k=s}\frac{(1-\lambda)^j + (1+\lambda)^j}{j!}\frac{k+1}{x^{k+2}}.$$

Since for $j \in \mathbb{Z}_+$ the function $x^j/j!$ increases on $x > 0$, we have

$$|W^{(s)}(x)| \le \frac{(1-\lambda)^s + (1+\lambda)^s}{2\lambda}\sum_{k=0}^{s}\frac{k+1}{x^{k+2}} \le \frac{(1+\lambda)^s}{\lambda}\sum_{k=0}^{s}\frac{k+1}{x^{k+2}} \le \frac{s(1+\lambda)^s}{\lambda x^2}.$$

So, we conclude that

$$\|W\|_{s,\infty,m} \le \frac{s(1+\lambda)^s}{\lambda m^2},$$

and W satisfies (8). Thus, from Theorem 3.3 we finish our proof. □

There are many examples of wavelet sampling series (see, for example, [33, pp. 160–162]) that Theorem 3.3 can be applied to obtain much faster convergence. We omit the details. For the relation between the localized sampling and the Meyer wavelets, we will investigate it further at another occasion.

5. Numerical experiments. We may illustrate the approximation with numerical experiments. We consider the function $f := \operatorname{sinc}^7 \in B_{7\pi}$ and denote the computation domain by $\mathbb{I} \subset \mathbb{R}$. First, we describe the numerical scheme based on applying the operator (6). We start by specifying the spatial grids. Let $h := |\mathbb{I}|/n$ and $x_j := jh$ for $0 \leq j \leq n-1$. Here n is the number of the grid points and we choose $n > 2m$, where m is the truncation level. From (6) we have

$$(\mathcal{T}_h f)(x_j) = \sum_{k \in \mathbb{Z}_m(x_j)} f(x_k) K(x_j - x_k) G_r(x_j - x_k). \tag{22}$$

For $s \in \mathbb{Z}^+$, we use $\mathcal{T}_h^{(s)} f$ to approximate $f^{(s)}$.

Note that the values $\{f(x_k) : -m \leq k \leq n+m-1\}$ are required to implement (22). So, we need to extend the values $\{f(x_k) : 0 \leq k \leq n-1\}$ to $\{f(x_k) : -m \leq k \leq n+m-1\}$. Since the function f decays fast, we will make an antisymmetric extension of the function f and therefore set $f(x_k) := -f(x_{-k})$ for $-m \leq k \leq -1$ and $f(x_k) := -f(x_{2n-k-2})$ for $n \leq k \leq n+m-1$.

All the computations were done on a UNIX workstation with a Fortran 90 compiler. It is simple to measure the errors of the solutions in the discrete p-norms for $p \in [1, \infty]$.

$$|f|_{p,\mathbb{I}} := \begin{cases} \left\{ h \sum_{j=0}^{n-1} |f^{(s)}(x_j) - (\mathcal{T}_h^{(s)} f)(x_j)|^p \right\}^{1/p}, & 1 \leq p < \infty, \\ \max\{|f^{(s)}(x_j) - (\mathcal{T}_h^{(s)} f)(x_j)| : 0 \leq j \leq n-1\}, & p = \infty. \end{cases}$$

Similar to Theorem 4.1, we have the following estimates for the above errors.

COROLLARY 5.1. *If the hypotheses of Theorem* 3.3 *hold,* α *and* β_p *are given in Theorem* 3.3*,* $\mathbb{I} \subset \mathbb{R}$*, and* $p \in [1, \infty]$*, then*

$$|f^{(s)} - \mathcal{T}_h^{(s)} f|_{p,\mathbb{I}} \leq \beta_p \exp(-\alpha^2/2) \|f\|_2.$$

Proof. It is obvious for $p \in [1, \infty)$ that

$$\left\{ h \sum_{j=0}^{n-1} |f^{(s)}(x_j) - (\mathcal{T}_h^{(s)} f)(x_j)|^p \right\}^{1/p} \leq (nh)^{1/p} \|f^{(s)} - \mathcal{T}_h^{(s)} f\|_\infty = |\mathbb{I}|^{1/p} \|f^{(s)} - \mathcal{T}_h^{(s)} f\|_\infty,$$

and for $p = \infty$ that

$$|f^{(s)} - \mathcal{T}_h^{(s)} f|_{\infty,\mathbb{I}} \leq \|f^{(s)} - \mathcal{T}_h^{(s)} f\|_\infty.$$

Therefore, the conclusion follows from Theorem 3.3. □

First, we compare the localized sampling with the WKS sampling series. The accuracy of approximation achieved by the localized sampling in Example 1 is denoted by LS, and the corresponding approximation accuracy obtained by using the truncated version of the cardinal series (2),

$$(\mathcal{C}_{h,m} f)(x) := \sum_{k \in \mathbb{Z}_m(x)} f(kh) \operatorname{sinc}(h^{-1}x - k), \quad x \in \mathbb{R},$$

is denoted by CS. The numerical results of LS and CS approximating f' are reported and compared in Table 1, from which the advantage of the localization with Gaussian multiplier is obvious.

Table 1
Approximation for $f'(x)$ on $x \in [-5,5]$, Example 1.

			LS		CS	
Nodes	m	r	L^2 error	L^∞ error	L^2 error	L^∞ error
100	30	3.0	2.07(−7)	2.34(−7)	1.41(−1)	1.67(−1)
		3.3	3.20(−8)	3.65(−8)		
		3.6	4.92(−9)	5.50(−9)		
		3.9	7.47(−10)	8.02(−10)		
200	35	3.0	1.77(−13)	2.69(−13)	2.40(−1)	2.82(−1)
		3.3	2.98(−14)	5.84(−14)		
		3.6	2.86(−14)	5.41(−14)		
		3.9	2.74(−14)	5.11(−14)		

Table 2
Approximation for $f(x) := \operatorname{sinc}^7(x)$ on $x \in [-5,5]$, Example 2.

				$f'(x)$		$f''(x)$	
Nodes	m	r	r_1	L^2 error	L^∞ error	L^2 error	L^∞ error
100	30	2	1	2.15(−6)	3.57(−6)	1.72(−4)	3.09(−4)
			1.1	1.50(−5)	2.55(−5)	3.73(−5)	6.06(−5)
			1.2	1.10(−4)	1.90(−4)	3.31(−4)	5.56(−4)
		3	1	9.39(−12)	1.60(−11)	3.30(−10)	4.19(−10)
			1.1	4.07(−10)	6.09(−10)	2.31(−9)	2.99(−9)
			1.2	1.96(−8)	3.018(−8)	1.12(−7)	1.52(−7)
200	30	2	1	1.42(−7)	2.39(−7)	2.86(−5)	6.00(−5)
			1.1	1.66(−6)	2.74(−6)	7.86(−7)	1.25(−6)
			1.2	1.81(−5)	2.93(−5)	1.55(−5)	2.93(−5)
		3	1	4.43(−14)	8.90(−14)	3.53(−12)	1.54(−11)
			1.1	1.20(−13)	2.12(−13)	3.26(−12)	1.24(−11)
			1.2	1.72(−11)	3.00(−11)	3.25(−11)	5.89(−11)

Table 3
Approximation for $f'(x)$ on $x \in [-3,3]$, Example 4.

			LMS		MS	
Nodes	m	r	L^2 error	L^∞ error	L^2 error	L^∞ error
100	30	3	2.82(−9)	4.32(−9)	4.05(−3)	4.75(−3)
		3.3	1.63(−10)	2.37(−10)		
		3.6	1.37(−11)	2.17(−11)		
		3.9	9.87(−12)	2.00(−11)		
200	32	3	1.89(−12)	3.30(−12)	2.57(−2)	3.01(−2)
		3.3	6.04(−14)	1.49(−13)		
		3.6	5.71(−14)	1.52(−13)		
		3.9	5.60(−14)	1.55(−13)		

Table 2 reports the numerical results obtained by using the kernel in Example 2. It is observed for $K := r_1 \operatorname{sinc}(r_1 \cdot)$ that if $r_1 \sim 1$ and h decreases, then the error bounds decrease to the double precision accuracy. The computational results confirm the theoretical conclusions of Theorem 4.2.

Finally, we choose $d := 3/4$ in Example 4. The accuracy of approximation achieved by using the localized sampling series with kernel (21) is denoted by LMS, and the corresponding approximation accuracy obtained by using the sampling without localization is denoted by MS. The numerical results of LMS and MS are reported and compared in Table 3. It demonstrates the superior efficiency of the localized sampling in approximation.

For any fixed parameters in Tables 1, 2, and 3, the corresponding L^2 error and L^∞ error are basically of the same order. This is in good agreement with the theoretical conclusions given in Corollary 5.1.

6. Conclusion.

We give a sufficient condition for the kernel K used in (6), so that the localized sampling series can achieve exponentially decaying accuracy for approximating band-limited functions and their derivatives.

For application, our result provides for $p \in [1, \infty]$ the L^p estimates for approximation on finite domain. Numerical experiments demonstrate the high accuracy achieved by using the localized sampling series.

The general kernel obtained here includes some known kernel functions, such as the Shannon kernel, the oversampled Shannon kernel, the modified sinc kernel, and the de la Vallée Poussin kernel, as special cases.

Furthermore, the general kernel sampling gives new results on the interpolating Meyer wavelets. Note that by the localization with Gaussian function, the sampling series achieves much faster convergence for approximation.

Acknowledgments. The first author is very thankful to Professor Say Song Goh, Professor Charles A Micchelli, and Professor Hidemitsu Ogawa for their helpful discussion, which was invaluable to the investigation and presentation of the results.

LEAST-SQUARES FINITE ELEMENT METHODS FOR OPTIMALITY SYSTEMS ARISING IN OPTIMIZATION AND CONTROL PROBLEMS[*]

PAVEL BOCHEV[†] AND MAX D. GUNZBURGER[‡]

Abstract. The approximate solution of optimization and optimal control problems for systems governed by linear, elliptic partial differential equations is considered. Such problems are most often solved using methods based on applying the Lagrange multiplier rule to obtain an optimality system consisting of the state system, an adjoint-state system, and optimality conditions. Galerkin methods applied to this system result in indefinite matrix problems. Here, we consider using modern least-squares finite element methods for the solution of the optimality systems. The matrix equations resulting from this approach are symmetric and positive definite and are readily amenable to uncoupling strategies. This is an important advantage of least-squares principles as they allow for a more efficient computational solution of the optimization problem. We develop an abstract theory that includes optimal error estimates for least-squares finite element methods applied to optimality systems. We then provide an application of the theory to optimization problems for the Stokes equations.

Key words. optimal control, optimization, least-squares finite element methods, optimality systems, Lagrange multipliers

1. Introduction.

Optimization and control problems for systems governed by partial differential equations arise in many applications. Experimental studies of such problems go back 100 years [22], and computational approaches have been applied since the advent of the computer age. Most of the efforts in the latter direction have employed elementary optimization strategies, but more recently, there has been considerable practical and theoretical interest in the application of sophisticated local and global optimization strategies, e.g., Lagrange multiplier methods, sensitivity or adjoint-based gradient methods, quasi-Newton methods, evolutionary algorithms, etc.

The optimal control or optimization problems we consider consist of

- *state variables*, i.e., variables that describe the system being modeled;
- *control variables* or *design parameters*, i.e., variables at our disposal that can be used to affect the state variables;
- a *state system*, i.e., partial differential equations relating the state and control variables; and
- a *functional* of the state and control variables whose minimization is the goal.

Then, the problems we consider consist of finding state and control variables that minimize the given functional subject to the state system being satisfied. Here, we restrict attention to linear, elliptic state systems and to quadratic functionals.

The Lagrange multiplier rule is a standard approach for solving finite-dimensional, constrained optimization problems. It is not surprising then that several popular approaches to solving optimization and control problems constrained by partial differential equations are also based on solving optimality systems deduced from the application of the Lagrange multiplier rule. The optimality system consists of

- the *state system*, i.e., the given partial differential equations that relate the unknown state and control variables;
- an *adjoint* or *costate system* which is also partial differential equations involving the adjoint operator of the state system; and
- an *optimality condition* that reflects the fact that the gradient of the functional vanishes for optimal values of the state and control variables.

The three components of the optimality system are coupled. In the linear constraints/quadratic functional context we consider in this paper, the optimality system, viewed as a coupled system, is a symmetric and weakly coercive linear system in the state, adjoint-state, and control variables.

In the context of finite element methods, optimality systems are usually discretized using Galerkin methods, resulting in typical saddle-point-type matrix problems that are symmetric and indefinite. In many if not most practical situations, the coupled optimality system is a formidable system to solve; compared to solving direct problems involving the state system alone, discrete optimality systems typically involve at least double the number of unknowns. For this reason, many approaches have been proposed for decoupling, through iterative processes, the different components of the optimality system. An extensive discussion of several such strategies in both an abstract setting and for fluid flow problems can be found in [18].

In this paper, we discuss the use of modern least-squares finite element methods for finding approximate solutions of the optimality system. The resulting matrix problems are symmetric and *positive definite*. Moreover, their diagonal blocks are also symmetric and positive definite, thus opening up better possibilities for devising efficient uncoupling methods than is the case for Galerkin discretizations. In order to develop a basic theory for least-squares finite element methods for optimization and control problems, we focus on treating the optimality system as a fully coupled system and only briefly discuss the application of decoupling strategies. Nevertheless, the reader should keep in mind that amenability to efficient uncoupling strategies is, perhaps, the chief reason to consider the application of least-squares principles to optimization problems. The application of least-squares principles to optimality systems was previously discussed, in a concrete setting, in [19].

The approach we have described for finding approximate solutions of optimal control and optimization problems for partial differential equations is of the *differentiate-then-discretize* or *optimize-then-discretize* type. One first applies, at the continuous partial differential equations level, the first-order necessary conditions for finding saddle points of a Lagrangian functional, and then one uses a finite element method, be it of Galerkin or of least-square type, to discretize the resulting optimality system. For the alternative *discretize-then-differentiate* or *discretize-then-optimize* type approach, one reverses the steps: One first discretizes the optimization or control problem by some means and then applies the Lagrange multiplier rule to the resulting discrete optimization problem. The two steps do not, in general, commute so that the discrete systems determined by the two approaches are not the same. A discussion of the relative merits of the two approaches can be found, e.g., in [18]. Here, we focus on the differentiate-then-discretize approach.

Instead of using the Lagrange multiplier rule for solving constrained optimization problems, one may use a penalty method. Penalty/least-squares finite element methods are the subject of the companion paper [9]; see also [20]. Other applications of least-squares finite element methods to optimization problems may be found in [2,3,5,8].

The paper is organized as follows. In section 3, we study, in an abstract setting, Lagrange multiplier methods for quadratic optimization and control problems constrained by linear, elliptic partial differential equations. In section 4, we study least-squares finite element methods for the approximate solution of the optimality system resulting from the application of the Lagrange multiplier rule. In section 5, we provide concrete examples that illustrate the theory of sections 3 and 4. In passing, we briefly remark on several related topics, including decoupling strategies for the solution of the discretized optimality system. Before we embark, however, in section 2, we present mostly well-known results about general constrained optimization problems and their solution via Lagrange multiplier methods. These results serve as the foundation for the considerations of sections 3 and 4. We remark that in several inequalities appearing in the paper, C denotes a positive constant whose value changes with context but that is independent of any of the data or solution functions appearing in the inequalities.

2. Linearly constrained quadratic minimization problems in Hilbert spaces.

In this section, we review the now classical theory (see [12] and also [13,16]) for finite element methods for constrained quadratic minimization problems. The optimization and control problems that are the subject of this paper can be profitably viewed as special cases of the types of problems treated by the classical theory.

Given Hilbert spaces V and S along with their dual spaces V^* and S^*, respectively, the symmetric bilinear form $a(\cdot,\cdot)$ on $V \times V$, the bilinear form $b(\cdot,\cdot)$ on $V \times S$, the functions $f \in V^*$ and $g \in S^*$, and the real number t, we define the *quadratic functional*[1]

$$\mathcal{J}(u) = \frac{1}{2}a(u,u) - \langle f,u\rangle_{V^*,V} + t \qquad \forall\, u \in V, \tag{2.1}$$

the *linear constraint equation*

$$b(u,q) = \langle g,q\rangle_{S^*,S} \qquad \forall\, q \in S, \tag{2.2}$$

where $\langle\cdot,\cdot\rangle$ denotes an appropriate duality pairing, and the *constrained minimization problem*[2]

$$\min_{u\in V} \mathcal{J}(u) \quad \text{subject to (2.2)}. \tag{2.3}$$

[1] The value of t does not affect the minimizer of $\mathcal{J}(\cdot)$. We include it in the definition of $\mathcal{J}(u)$ only to facilitate, in later sections, the identification of concrete functionals with the abstract functional (2.1).

[2] Such problems arise in many applications. A classical example is provided by the functional $\mathcal{J}(\mathbf{v}) = \frac{1}{2}\int_\Omega |\mathbf{v}|^2\, d\Omega$, the linear constraint $\nabla\cdot\mathbf{v} = f$, and the minimization problem $\min J(\mathbf{v})$ subject to $\nabla\cdot\mathbf{v} = f$ in Ω, where the minimization is effected over a suitable function space. For example, in fluid mechanics, this problem is known as the *Kelvin principle* and, in structural mechanics (where $\mathbf{v}$ is a tensor), as the *complimentary energy principle.* For the Kelvin principle, S is the space $L^2(\Omega)$ of all square integrable functions, and V is the space $H(\mathrm{div},\Omega)$ of all square integrable vector fields whose divergencies are also square integrable, $a(\mathbf{u},\mathbf{v}) = \int_\Omega \mathbf{u}\cdot\mathbf{u}\, d\Omega$, $b(\mathbf{v},q) = \int_\Omega q\nabla\cdot\mathbf{v}\, d\Omega$. Also, the operators A and B defined below are the identity and divergence operators, respectively.

The bilinear forms serve to define the associated operators

$$A : V \to V^*, \qquad B : V \to S^*, \qquad \text{and} \qquad B^* : S \to V^* \tag{2.4}$$

through the relations

$$\begin{cases} a(u,v) = \langle Au, v\rangle_{V^*,V} & \forall\, u,v \in V, \\ b(v,q) = \langle Bv, q\rangle_{S^*,S} = \langle B^*q, v\rangle_{V^*,V} & \forall\, v \in V,\, q \in S. \end{cases}$$

The minimization problem (2.3) can then be given the form

$$\min_{u\in V} \mathcal{J}(u) \quad \text{subject to} \quad Bu = g,$$

where the constraint equation $Bu = g$ holds in S^*. We define the subspace

$$Z = \{v \in V \ : \ b(v,q) = 0 \ \forall\, q \in S\} \tag{2.5}$$

and make the following assumptions about the bilinear forms:

$$\begin{cases} a(u,v) \le C_a \|u\|_V \|v\|_V & \forall\, u,v \in V, \\ b(u,q) \le C_b \|u\|_V \|q\|_S & \forall\, u \in V,\ q \in S, \\ a(u,u) \ge 0 & \forall\, u \in V, \\ a(u,u) \ge K_a \|u\|_V^2 & \forall\, u \in Z, \\ \displaystyle\sup_{v\in V, v\neq 0} \frac{b(v,q)}{\|v\|_V} \ge K_b \|q\|_S & \forall\, q \in S, \end{cases} \tag{2.6}$$

where C_a, C_b, K_a, and K_b are all positive constants.

2.1. Existence of solutions. The following result is well known; see, e.g. [21].

Proposition 2.1. *Let the assumptions* (2.6) *hold. Then, the constrained minimization problem* (2.3) *has a unique solution* $u \in V$. □

2.2. Solution via Lagrange multipliers. For all $v \in V$ and $q \in S$, we introduce the Lagrangian functional

$$\mathcal{L}(v,q) = \mathcal{J}(v) + b(v,q) - \langle g, q\rangle_{S^*,S} = \frac{1}{2} a(v,v) + b(v,q) - \langle f, v\rangle_{V^*,V} - \langle g, q\rangle_{S^*,S} + t.$$

Then, the constrained minimization problem (2.3) is equivalent to the unconstrained optimization problem of finding saddle points $(u,p) \in V \times S$ of the Lagrangian functional. These saddle points may be found by solving the optimality system

$$\begin{cases} a(u,v) + b(v,p) &= \langle f, v\rangle_{V^*,V} & \forall\, v \in V, \\ b(u,q) &= \langle g, q\rangle_{S^*,S} & \forall\, q \in S. \end{cases} \tag{2.7}$$

The following result is also well known; see, e.g., [12].

Proposition 2.2. *Let the assumptions* (2.6) *hold. Then, the system* (2.7) *has a unique solution* $(u,p) \in V \times S$. *Moreover,*

$$\|u\|_V + \|p\|_S \le C\big(\|f\|_{V^*} + \|g\|_{S^*}\big), \tag{2.8}$$

and $u \in V$ *is the unique solution of the constrained minimization problem* (2.3). □

In terms of the operators introduced in (2.4), the system (2.7) takes the form

$$\begin{cases} Au + B^*p &= f \quad \text{in } V^*, \\ Bu &= g \quad \text{in } S^*. \end{cases}$$

Remark 2.3. The unique solvability of (2.7) and the estimate (2.8) do not require that the bilinear form $a(\cdot,\cdot)$ be symmetric or that it satisfy the third condition in (2.6). Also, the fourth condition in (2.6) may be weakened to a weak coercivity condition. However, these conditions are required to make the connection between (2.7) and the constrained minimization problem (2.3). So, throughout, we will assume that all the conditions in (2.6) hold.

2.3. Galerkin approximations of the optimality system. We choose (conforming) finite-dimensional subspaces $V^h \subset V$ and $S^h \subset S$, and we then restrict (2.7) to these subspaces, i.e., we seek $u^h \in V^h$ and $p^h \in S^h$ that satisfy

$$\begin{cases} a(u^h,v^h) + b(v^h,p^h) &= \langle f, v^h\rangle_{V^*,V} \qquad \forall\, v^h \in V^h, \\ b(u^h,q^h) &= \langle g, q^h\rangle_{S^*,S} \qquad \forall\, q^h \in S^h. \end{cases} \tag{2.9}$$

This is also the optimality system for the minimization of the functional $\mathcal{J}(\cdot)$ over V^h subject to $b(u^h,q^h) = \langle g,q^h\rangle_{S^*,S}$ for all $q^h \in S^h$. Let

$$Z^h = \{v^h \in V^h \;:\; b(v^h,q^h) = 0 \;\forall\, q^h \in S^h\}.$$

In general, $Z^h \not\subset Z$ even though $V^h \subset V$ and $S^h \subset S$, and so the last two assumptions in (2.6) may not be satisfied with respect to the subspaces. If V^h and S^h are such that the last two assumptions hold, then one obtains the following well-known result; see, e.g., [12].

PROPOSITION 2.4. *Let the hypotheses of Proposition* 2.1 *hold and assume that*

$$a(u^h,u^h) \geq K_a^h \|u^h\|_V^2 \quad \forall\, u^h \in Z^h \tag{2.10}$$

and

$$\sup_{v^h \in V^h, v^h \neq 0} \frac{b(v^h,q^h)}{\|v^h\|_V} \geq K_b^h \|q^h\|_S \quad \forall\, q^h \in S^h, \tag{2.11}$$

where K_a^h and K_b^h are positive constants independent of h. Then, the discrete system (2.9) *has a unique solution $(u^h,p^h) \in V^h \times S^h$, and moreover*

$$\|u^h\|_V + \|p^h\|_S \leq C\big(\|f\|_{V^*} + \|g\|_{S^*}\big).$$

Furthermore, if $(u,p) \in V \times S$ denotes the unique solution of (2.7), *then*

$$\|u-u^h\|_V + \|p-p^h\|_S \leq C\Big(\inf_{v^h \in V^h} \|u-v^h\|_V + \inf_{q^h \in S^h} \|p-q^h\|_S\Big). \tag{2.12}$$

The discrete problem (2.9) is equivalent to a linear system. Indeed, let $\{U_i\}_{i=1}^n$ and $\{P_i\}_{i=1}^m$, where $n = \dim(V^h)$ and $m = \dim(S^h)$, denote bases for V^h and S^h, respectively, and let $\vec{\mathbf{u}} = (u_1,\dots,u_n)^T$ and $\vec{\mathbf{p}} = (p_1,\dots,p_m)^T$ denote the vectors of coefficients in the expansions of u^h and p^h in terms of the respective bases. Furthermore, let $f_i = \langle f, U_i\rangle_{V^*,V}$ for $i = 1,\dots,n$, $g_i = \langle g, P_i\rangle_{S^*,S}$ for $i = 1,\dots,m$,

$\vec{\mathbf{f}} = (f_1, \dots, f_n)^T$, and $\vec{\mathbf{g}} = (g_1, \dots, g_m)^T$, and define the elements of the $n \times n$ matrix $\mathbb{A}$ and the $m \times n$ matrix $\mathbb{B}$ by $\mathbb{A}_{ij} = a(U_i, U_j)$ for $i, j = 1, \dots, n$ and $\mathbb{B}_{ij} = b(U_j, P_i)$ for $i = 1, \dots, m$, $j = 1, \dots, n$, respectively. Then, (2.9) is equivalent to the linear system

$$\begin{pmatrix} \mathbb{A} & \mathbb{B}^T \\ \mathbb{B} & 0 \end{pmatrix} \begin{pmatrix} \vec{\mathbf{u}} \\ \vec{\mathbf{p}} \end{pmatrix} = \begin{pmatrix} \vec{\mathbf{f}} \\ \vec{\mathbf{g}} \end{pmatrix}. \tag{2.13}$$

Remark 2.5. The coefficient matrix in (2.13) is symmetric and indefinite. This is universal for discretizations of saddle-point problems arising from the use of the Lagrange multiplier rule for constrained optimization problems.

Remark 2.6. The assumptions (2.10) and (2.11) guarantee that the $(m+n) \times (m+n)$ coefficient matrix in (2.13) is invertible and that the norms of its inverse are bounded from above independently of m and n, i.e., independently of the grid size h.

Remark 2.7. The observations made in Remark 2.3 about the bilinear form $a(\cdot, \cdot)$ and (2.7) also apply to (2.9).

3. Quadratic optimization and control problems in Hilbert spaces with linear constraints.

In this section, we specialize the results of section 2 to the type of optimization and control problems described in section 1. We identify the variable u of section 2 with the pair (ϕ, θ), where ϕ and θ are the state and control variables, respectively, of the control problem.

We begin with four given Hilbert spaces Θ, Φ, $\widehat{\Phi}$, and $\widetilde{\Phi}$ along with their dual spaces denoted by $(\cdot)^*$. We assume that $\Phi \subseteq \widehat{\Phi} \subseteq \widetilde{\Phi}$ with continuous embeddings and that $\widetilde{\Phi}$ acts as the pivot space for both the pair $\{\Phi^*, \Phi\}$ and the pair $\{\widehat{\Phi}^*, \widehat{\Phi}\}$ so that we have not only that $\Phi \subseteq \widehat{\Phi} \subseteq \widetilde{\Phi} \subseteq \widehat{\Phi}^* \subseteq \Phi^*$ but also that

$$\langle \psi, \phi \rangle_{\Phi^*, \Phi} = \langle \psi, \phi \rangle_{\widehat{\Phi}^*, \widehat{\Phi}} = (\psi, \phi)_{\widetilde{\Phi}} \quad \forall\, \psi \in \widehat{\Phi}^* \subseteq \Phi^* \quad \text{and} \quad \forall\, \phi \in \Phi \subseteq \widehat{\Phi}, \tag{3.1}$$

where $(\cdot, \cdot)_{\widetilde{\Phi}}$ denotes the inner product on $\widetilde{\Phi}$.

Next, we define the *quadratic functional*

$$\mathcal{J}(\phi, \theta) = \frac{1}{2} a_1(\phi - \widehat{\phi}, \phi - \widehat{\phi}) + \frac{1}{2} a_2(\theta, \theta) \qquad \forall\, \phi \in \Phi,\ \theta \in \Theta, \tag{3.2}$$

where $a_1(\cdot, \cdot)$ and $a_2(\cdot, \cdot)$ are symmetric bilinear forms on $\widehat{\Phi} \times \widehat{\Phi}$ and $\Theta \times \Theta$, respectively, and $\widehat{\phi} \in \widehat{\Phi}$ is a given function. In the language of control theory, Φ is called the *state space,* ϕ the *state variable,* Θ the *control space,* and θ the *control variable.* In many applications, the control space is finite dimensional in which case θ is often referred to as the vector of *design variables.* We note that often Θ is chosen to be a bounded set in a Hilbert space, but for our purposes, we consider the less general situation of Θ itself being a Hilbert space. We make the following assumptions about the bilinear forms $a_1(\cdot, \cdot)$ and $a_2(\cdot, \cdot)$:

$$\begin{cases} a_1(\phi, \mu) \le C_1 \|\phi\|_{\widehat{\Phi}} \|\mu\|_{\widehat{\Phi}} & \forall\, \phi, \mu \in \widehat{\Phi}, \\ a_2(\theta, \nu) \le C_2 \|\theta\|_{\Theta} \|\nu\|_{\Theta} & \forall\, \theta, \nu \in \Theta, \\ a_1(\phi, \phi) \ge 0 & \forall\, \phi \in \widehat{\Phi}, \\ a_2(\theta, \theta) \ge K_2 \|\theta\|_{\Theta}^2 & \forall\, \theta \in \Theta, \end{cases} \tag{3.3}$$

where C_1, C_2, and K_2 are all positive constants. The second term in the functional (3.2) can be interpreted as a penalty term which limits the size of the control θ.

Given another Hilbert space Λ, the additional bilinear forms $b_1(\cdot,\cdot)$ on $\Phi\times\Lambda$ and $b_2(\cdot,\cdot)$ on $\Theta\times\Lambda$, and the function $g\in\Lambda^*$, we define the *linear constraint equation*

$$b_1(\phi,\psi)+b_2(\theta,\psi)=\langle g,\psi\rangle_{\Lambda^*,\Lambda}\quad\forall\,\psi\in\Lambda. \tag{3.4}$$

We make the following assumptions about the bilinear forms $b_1(\cdot,\cdot)$ and $b_2(\cdot,\cdot)$:

$$\begin{cases} b_1(\phi,\psi)\le c_1\|\phi\|_\Phi\|\psi\|_\Lambda & \forall\,\phi\in\Phi,\ \ \psi\in\Lambda,\\[2mm] b_2(\theta,\psi)\le c_2\|\psi\|_\Phi\|\theta\|_\Theta & \forall\,\theta\in\Theta,\ \ \psi\in\Lambda,\\[2mm] \displaystyle\sup_{\psi\in\Lambda,\psi\neq0}\frac{b_1(\phi,\psi)}{\|\psi\|_\Lambda}\ge k_1\|\phi\|_\Phi & \forall\,\phi\in\Phi,\\[2mm] \displaystyle\sup_{\phi\in\Phi,\phi\neq0}\frac{b_1(\phi,\psi)}{\|\phi\|_\Phi}>0 & \forall\,\psi\in\Lambda, \end{cases} \tag{3.5}$$

where c_1, c_2, and k_1 are all positive constants. These assumptions suffice to guarantee that, given any $\theta\in\Theta$, the constraint equation (3.4) is uniquely solvable for $\phi\in\Phi$; this observation easily follows from [1] and (3.5).

We consider the *optimal control problem*[3]

$$\min_{(\phi,\theta)\in\Phi\times\Theta}\mathcal{J}(\phi,\theta)\quad\text{subject to}\quad b_1(\phi,\psi)+b_2(\theta,\psi)=\langle g,\psi\rangle_{\Lambda^*,\Lambda}\quad\forall\,\psi\in\Lambda. \tag{3.6}$$

It is easy to verify that the problem (3.6) falls into the framework of section 2. To this end, we let $V\equiv\Phi\times\Theta$, $S\equiv\Lambda$, $\|\{\phi,\theta\}\|_V=\sqrt{\|\phi\|_\Phi^2+\|\theta\|_\Theta^2}$ for all $\{\phi,\theta\}\in V$,

$$\begin{cases} a\big(\{\phi,\theta\},\{\mu,\nu\}\big)\equiv a_1(\phi,\mu)+a_2(\theta,\nu) & \forall\,\phi,\mu\in\Phi,\ \ \theta,\nu\in\Theta,\\ b\big(\{\phi,\theta\},\{\psi\}\big)\equiv b_1(\phi,\psi)+b_2(\theta,\psi) & \forall\,\phi\in\Phi,\ \ \theta\in\Theta,\ \ \psi\in\Lambda,\\ \big\langle f,\{\mu,\nu\}\big\rangle_{V^*,V}\equiv a_1(\mu,\widehat{\phi}) & \forall\,\mu\in\Phi,\ \ \nu\in\Theta,\\ t=\dfrac{1}{2}a_1(\widehat{\phi},\widehat{\phi}). \end{cases} \tag{3.7}$$

From (3.3), it follows that $t\le(C_1/2)\|\widehat{\phi}\|_{\widehat{\Phi}}^2$ and, also using the continuous embedding $\Phi\subseteq\widehat{\Phi}$,

$$\frac{\langle f,\{\mu,\nu\}\rangle_{V^*,V}}{\|\{\mu,\nu\}\|_V}\le\frac{\langle f,\{\mu,\nu\}\rangle_{V^*,V}}{\|\mu\|_\Phi}=\frac{a_1(\mu,\widehat{\phi})}{\|\mu\|_\Phi}\le C_1\|\widehat{\phi}\|_{\widehat{\Phi}}\quad\forall\,\{\mu,\nu\}\in\Phi\times\Theta=V$$

so that $\|f\|_{V^*}\le C_1\|\widehat{\phi}\|_{\widehat{\Phi}}$, i.e., f does indeed belong to V^*. Then, with the obvious identifications $u=\{\phi,\theta\}$, $v=\{\mu,\nu\}$, and $q=\{\psi\}$, the functionals (2.1) and (3.2) are equivalent as are the constraint equations (2.2) and (3.4). The constrained optimization problem (2.3) and the optimal control problem (3.6) are also equivalent.

We will use the framework and results established in section 2 to study the optimal control problem (3.6). Many of the results we discuss are well known, but we repeat them here to establish a context for later discussions.

[3] In section 5 we will consider an example where the linear constraint will be the weak form of the Stokes equations of incompressible viscous flows. We draw attention to the fact that these equations themselves are another example of a problem that fits the abstract setting of section 2 with $\mathcal{J}(\mathbf{v};\mathbf{f})=\frac{1}{2}\int_\Omega|\nabla\mathbf{v}|^2\,d\Omega-\int_\Omega\mathbf{f}\cdot\mathbf{v}\,d\Omega$, $b(\mathbf{v},q)=\int_\Omega q\nabla\cdot\mathbf{v}\,d\Omega$, and $g=0$.

3.1. Existence of optimal states and controls. We begin with the following preliminary result.

LEMMA 3.1. *Let the assumptions* (3.3) *and* (3.5) *hold. Then the spaces* $V \equiv \Phi \times \Theta$ *and* $S \equiv \Lambda$ *and the bilinear forms* $a(\cdot,\cdot)$ *and* $b(\cdot,\cdot)$ *defined in* (3.7) *satisfy the assumptions* (2.6).

Proof. Using (3.3) and the continuous embedding $\Phi \subset \widehat{\Phi}$, we have that

$$\begin{aligned} a(\{\phi,\theta\},\{\mu,\nu\}) &= a_1(\phi,\mu) + a_2(\theta,\nu) \le C_1\|\phi\|_{\widehat{\Phi}}\|\mu\|_{\widehat{\Phi}} + C_2\|\theta\|_\Theta\|\nu\|_\Theta \\ &\le C_1\|\phi\|_\Phi\|\mu\|_\Phi + C_2\|\theta\|_\Theta\|\nu\|_\Theta \le \max\{C_1,C_2\}\sqrt{\|\phi\|_\Phi^2+\|\theta\|_\Theta^2}\sqrt{\|\mu\|_\Phi^2+\|\nu\|_\Theta^2}\end{aligned}$$

for all $\phi,\mu \in \Phi$, $\theta,\nu \in \Theta$ so that $a(u,v) \le C_a\|u\|_V\|v\|_V$ for all $u,v \in V$ with $C_a = \max\{C_1,C_2\}$. Similarly, we have using (3.5) that $b(u,q) \le C_b\|u\|_V\|q\|_S$ for all $u \in V$, $q \in S$ with $C_b = \max\{c_1,c_2\}$. Next, from (3.3) we have that

$$a(\{\phi,\theta\},\{\phi,\theta\}) = a_1(\phi,\phi) + a_2(\theta,\theta) \ge a_2(\theta,\theta) \ge K_2\|\theta\|_\Theta^2 \qquad \forall \phi \in \Phi,\ \ \theta \in \Theta$$

so that $a(u,u) \ge 0$ for all $u \in V$. We next define the subspace $Z \subset \Phi \times \Theta$ by

$$Z = \Big\{\{\phi,\theta\} \in \Phi \times \Theta \ :\ b_1(\phi,\psi) + b_2(\theta,\psi) = 0 \quad \forall\,\psi \in \Lambda\Big\}. \tag{3.8}$$

The assumptions (3.5) imply that, given any $\theta \in \Theta$, the problem

$$b_1(\phi,\psi) = -b_2(\theta,\psi) \quad \forall\,\psi \in \Lambda \tag{3.9}$$

has a unique solution ϕ_θ and, moreover,

$$\|\phi_\theta\|_\Phi \le \frac{c_2}{k_1}\|\theta\|_\Theta; \tag{3.10}$$

see, e.g., [1]. Thus, Z can be completely characterized by $(\phi_\theta,\theta) \in \Phi \times \Theta$, where for arbitrary $\theta \in \Theta$, ϕ_θ is the solution of (3.9). Then, (3.10) and (3.3) imply that

$$\begin{aligned} a(\{\phi_\theta,\theta\},\{\phi_\theta,\theta\}) &= a_1(\phi_\theta,\phi_\theta) + a_2(\theta,\theta) \ge a_2(\theta,\theta) \ge K_2\|\theta\|^2 \\ &\ge \frac{K_2}{2}\min\left\{1,\frac{k_1^2}{c_2^2}\right\}\|\{\phi_\theta,\theta\}\|_V \qquad \forall\,\{\phi_\theta,\theta\} \in Z.\end{aligned}$$

As a result, $a(u,u) \ge K_a\|u\|_V^2$ for all $u \in Z$ with $K_a = \frac{1}{2}K_2\min\{1,\frac{k_1^2}{c_2^2}\}$ so that the third assumption in (2.6) is also satisfied.

To verify the last assumption in (2.6), note that

$$\sup_{\phi\in\Phi,\phi\neq 0}\frac{b_1(\phi,\psi)}{\|\phi\|_\Phi} \ge k_1\|\psi\|_\Lambda \qquad \forall\,\psi \in \Lambda. \tag{3.11}$$

Indeed, assumptions (3.5) imply that (see [1]), for any $\psi \in \Lambda$, the problem

$$b_1(\phi,\mu) = (\psi,\mu)_\Lambda \qquad \forall\,\mu \in \Lambda \tag{3.12}$$

has a unique solution ϕ_ψ and, moreover,

$$\|\phi_\psi\|_\Phi \le \frac{1}{k_1}\|\psi\|_\Lambda. \tag{3.13}$$

Using (3.12) and (3.13), it is easy to see that

$$\frac{b_1(\phi_\psi, \psi)}{\|\phi_\psi\|_\Phi} = \frac{\|\psi\|_\Lambda^2}{\|\phi_\psi\|_\Phi} \geq k_1 \|\psi\|_\Lambda \qquad \forall\, \psi \in \Lambda$$

which immediately implies (3.11). Finally, using (3.11),

$$\sup_{(\phi,\theta)\in\Phi\times\Theta,\, (\phi,\theta)\neq(0,0)} \frac{b(\{\phi,\theta\},\{\psi\})}{\sqrt{\|\phi\|_\Phi^2 + \|\theta\|_\Theta^2}} \geq \sup_{\phi\in\Phi,\, \phi\neq 0} \frac{b_1(\phi,\psi)}{\|\phi\|_\Phi} \geq k_1 \|\psi\|_\Lambda \qquad \forall\, \psi \in \Lambda$$

so that

$$\sup_{u\in V,\, u\neq 0} \frac{b(u,q)}{\|u\|_V} \geq K_b \|q\|_S \quad \forall\, q \in S$$

with $K_b = k_1$. □

Having verified the assumptions (2.6) for the optimal control problem (3.6), we immediately have the following result.

THEOREM 3.2. *Let the assumptions* (3.3) *and* (3.5) *hold. Then, the optimal control problem* (3.6) *has a unique solution* $(\phi, \theta) \in \Phi \times \Theta$.

Proof. The result immediately follows from Proposition 2.1 and Lemma 3.1. □

It is instructive to rewrite the functional (3.2), the constraint (3.4), and the optimal control problem (3.6) in operator notation. To this end, we note that the bilinear forms serve to define operators

$$\begin{array}{lll} A_1 : \widehat{\Phi} \to \widehat{\Phi}^*, & A_2 : \Theta \to \Theta^*, & B_1 : \Phi \to \Lambda^*, \\ B_1^* : \Lambda \to \Phi^*, & B_2 : \Theta \to \Lambda^*, & B_2^* : \Lambda \to \Theta^* \end{array}$$

through the following relations:

$$(3.14) \qquad \begin{cases} a_1(\phi,\mu) = \langle A_1\phi, \mu\rangle_{\widehat{\Phi}^*,\widehat{\Phi}} & \forall\, \phi,\mu \in \widehat{\Phi}, \\ a_2(\theta,\nu) = \langle A_2\theta, \nu\rangle_{\Theta^*,\Theta} & \forall\, \theta,\nu \in \Theta, \\ b_1(\phi,\psi) = \langle B_1\phi, \psi\rangle_{\Lambda^*,\Lambda} = \langle B_1^*\psi, \phi\rangle_{\Phi^*,\Phi} & \forall\, \phi \in \Phi,\;\; \psi \in \Lambda, \\ b_2(\psi,\theta) = \langle B_2\theta, \psi\rangle_{\Lambda^*,\Lambda} = \langle B_2^*\psi, \theta\rangle_{\Theta^*,\Theta} & \forall\, \theta \in \Theta,\;\; \psi \in \Lambda. \end{cases}$$

Then, the functional (3.2) and the constraint (3.4) take the forms

$$(3.15) \qquad \mathcal{J}(\phi,\theta) = \frac{1}{2}\big\langle A_1(\phi-\widehat{\phi}), (\phi-\widehat{\phi})\big\rangle_{\widehat{\Phi}^*,\widehat{\Phi}} + \frac{1}{2}\langle A_2\theta, \theta\rangle_{\Theta^*,\Theta} \qquad \forall\, \phi\in\Phi,\, \theta\in\Theta$$

and

$$(3.16) \qquad B_1\phi + B_2\theta = g \qquad \text{in } \Lambda^*,$$

respectively, and the optimal control problem (3.6) takes the form

$$(3.17) \qquad \min_{(\phi,\theta)\in\Phi\times\Theta} \mathcal{J}(\phi,\theta) \quad \text{subject to (3.16).}$$

Assumptions (3.3) and (3.5) imply that A_1, A_2, B_1, B_2, B_1^*, and B_2^* are bounded with

$$\begin{array}{lll} \|A_1\|_{\widehat{\Phi}\to\widehat{\Phi}^*} \leq C_1, & \|A_2\|_{\Theta\to\Theta^*} \leq C_2, & \|B_1\|_{\Phi\to\Phi^*} \leq c_1, \\ \|B_1^*\|_{\Phi\to\Phi^*} \leq c_1, & \|B_2\|_{\Phi\to\Theta^*} \leq c_2, & \|B_2^*\|_{\Theta\to\Phi^*} \leq c_2 \end{array}$$

and that the operator B_1 is invertible with $\|B_1^{-1}\|_{\Lambda^*\to\Phi} \leq 1/k_1$. Note also that the subspace $Z \subset V = \Phi \times \Theta$ can be defined by

$$Z = \Big\{ \{\phi,\theta\} \in \Phi\times\Theta \;:\; \phi = -B_1^{-1}B_2\theta \quad \forall\, \theta \in \Theta \Big\}.$$

3.2. Solution via Lagrange multipliers and the optimality system. For all $\{\mu, \nu\} \in V = \Phi \times \Theta$ and $\psi \in S = \Lambda$, we introduce the Lagrangian functional

$$\begin{aligned}\mathcal{L}(\{\mu,\nu\},\{\psi\}) &= \mathcal{J}(\{\mu,\nu\}) + b(\{\mu,\nu\},\{\psi\}) - \langle g,\psi\rangle_{\Lambda^*,\Lambda}\\ &= \frac{1}{2}a_1(\mu-\widehat{\phi},\mu-\widehat{\phi}) + \frac{1}{2}a_2(\nu,\nu) + b_1(\mu,\psi) + b_2(\nu,\psi) - \langle g,\psi\rangle_{\Lambda^*,\Lambda}.\end{aligned}$$

Then, (3.6) is equivalent to the unconstrained optimization problem of finding saddle points $(\{\phi,\theta\},\{\lambda\})$ in $V \times S$ of the Lagrangian functional. These saddle points may be found by solving the *optimality system*

$$\left\{\begin{array}{lllllll} a_1(\phi,\mu) & & & + & b_1(\mu,\lambda) & = & a_1(\widehat{\phi},\mu) \quad \forall\,\mu\in\Phi,\\ & & a_2(\theta,\nu) & + & b_2(\nu,\lambda) & = & 0 \quad \forall\,\nu\in\Theta,\\ b_1(\phi,\psi) & + & b_2(\theta,\psi) & & & = & \langle g,\psi\rangle_{\Lambda^*,\Lambda} \quad \forall\,\psi\in\Lambda.\end{array}\right. \tag{3.18}$$

The third equation in the optimality system (3.18) is simply the constraint equation. The first equation is commonly referred to as the *adjoint* or *costate equation* and the Lagrange multiplier λ is referred as the *adjoint* or *costate* variable. The second equation in (3.18) is referred to as the *optimality condition* since it is merely a statement that the gradient of the functional $\mathcal{J}(\cdot,\cdot)$ defined in (3.2) vanishes at the optimum.

Using the framework of section 2.2, the following result is immediate.

THEOREM 3.3. *Let the assumptions* (3.3) *and* (3.5) *hold. Then, the optimality system* (3.18) *has a unique solution* $(\phi,\theta,\lambda) \in \Phi\times\Theta\times\Lambda$. *Moreover*

$$\|\phi\|_\Phi + \|\theta\|_\Theta + \|\lambda\|_\Lambda \le C\big(\|g\|_{\Lambda^*} + \|\widehat{\phi}\|_{\widehat{\Phi}}\big),$$

and $(\phi,\theta)\in\Phi\times\Theta$ *is the unique solution of the optimal control problem* (3.6).

Proof. With the associations $V=\Phi\times\Theta$, $S=\Lambda$, $u=\{\phi,\theta\}$, and $p=\{\lambda\}$, the results immediately follow from Lemma 3.1 and Proposition 2.2. ∎

Using the operators introduced in (3.14) and (3.1), the optimality system (3.18) takes the form

$$\left\{\begin{array}{lllllll} A_1\phi & & & + & B_1^*\lambda & = & A_1\widehat{\phi} \quad \text{in } \Phi^*,\\ & & A_2\theta & + & B_2^*\lambda & = & 0 \quad \text{in } \Theta^*,\\ B_1\phi & + & B_2\theta & & & = & g \quad \text{in } \Lambda^*.\end{array}\right. \tag{3.19}$$

3.3. Galerkin approximation of the optimality system. We choose (conforming) finite dimensional subspaces $\Phi^h\subset\Phi$, $\Theta^h\subset\Theta$, and $\Lambda^h\subset\Lambda$ and then restrict (3.18) to the subspaces, i.e., we seek $(\phi^h,\theta^h,\lambda^h)\in\Phi^h\times\Theta^h\times\Lambda^h$ that satisfies

$$\left\{\begin{array}{llll} a_1(\phi^h,\mu^h) & & +b_1(\mu^h,\lambda^h) & = a_1(\widehat{\phi},\mu^h) \quad \forall\,\mu^h\in\Phi^h,\\ & a_2(\theta^h,\nu^h) & +b_2(\nu^h,\lambda^h) & = 0 \quad \forall\,\nu^h\in\Theta^h,\\ b_1(\phi^h,\psi^h) & +b_2(\theta^h,\psi^h) & & = \langle g,\psi^h\rangle_{\Lambda^*,\Lambda} \quad \forall\,\psi^h\in\Lambda^h.\end{array}\right. \tag{3.20}$$

This is also the optimality system for the minimization of (3.2) over $\Phi^h\times\Theta^h$ subject to the constraint $b_1(\phi^h,\psi^h)+b_2(\psi^h,\theta^h)=\langle g,\psi^h\rangle_{\Lambda^*,\Lambda}$ for all $\psi^h\in\Lambda^h$.

We next define the subspace $Z^h\subset\Phi^h\times\Theta^h$ by

$$Z^h = \Big\{\{\phi^h,\theta^h\}\in\Phi^h\times\Theta^h \ :\ b_1(\phi^h,\psi^h)+b_2(\theta^h,\psi^h)=0 \quad \forall\,\psi^h\in\Lambda^h\Big\}. \tag{3.21}$$

Note that, in general, $Z^h \not\subset Z$ even though $\Phi^h \subset \Phi$, $\Theta^h \subset \Theta$, and $\Lambda^h \subset \Lambda$. Thus, we make the following additional assumptions about $b_1(\cdot,\cdot)$ and Φ^h:

$$(3.22) \qquad \begin{cases} \displaystyle\sup_{\psi^h \in \Lambda^h, \psi^h \neq 0} \frac{b_1(\phi^h, \psi^h)}{\|\psi^h\|_\Lambda} \geq k_1^h \|\phi^h\|_\Phi & \forall\, \phi^h \in \Phi^h, \\ \displaystyle\sup_{\phi^h \in \Phi^h, \phi^h \neq 0} \frac{b_1(\phi^h, \psi^h)}{\|\phi^h\|_V} > 0 & \forall\, \psi^h \in \Lambda^h, \end{cases}$$

where k_1^h is a positive constant whose value is independent of h. Analogous to Lemma 3.1, we have the following result.

LEMMA 3.4. *Let the assumptions* (3.3), (3.5), *and* (3.22) *hold. Then, the spaces* $V^h = \Phi^h \times \Theta^h$ *and* $S^h = \Phi^h$ *and the bilinear forms* $a(\cdot,\cdot)$ *and* $b(\cdot,\cdot)$ *defined in* (3.7) *satisfy the assumptions* (2.10) *and* (2.11).

Proof. The proof proceeds exactly as that for Lemma 3.1; the constants in (2.10) are given by $K_a^h = \frac{1}{2} K_2 \min\{1, \frac{(k_1^h)^2}{c_2^2}\}$ and $K_b^h = k_1^h$. □

We then easily obtain the following results.

THEOREM 3.5. *Let the assumptions* (3.3), (3.5), *and* (3.22) *hold. Then, the discrete optimality system* (3.20) *has a unique solution* $(\phi^h, \theta^h, \lambda^h) \in \Phi^h \times \Theta^h \times \Lambda^h$, *and moreover*

$$\|\phi^h\|_\Phi + \|\theta^h\|_\Theta + \|\lambda^h\|_\Lambda \leq C\big(\|g\|_{\Lambda^*} + \|\widehat{\phi}\|_{\widehat{\Phi}}\big).$$

Furthermore, let $(\phi, \theta, \lambda) \in \Phi \times \Theta \times \Lambda$ *denote the unique solution of the optimality system* (3.18) *or, equivalently, of the optimal control problem* (3.6). *Then,*

$$(3.23) \qquad \begin{aligned} &\|\phi - \phi^h\|_\Phi + \|\theta - \theta^h\|_\Theta + \|\lambda - \lambda^h\|_\Lambda \\ &\qquad \leq C\Big(\inf_{\mu^h \in \Phi^h} \|\phi - \mu^h\|_\Phi + \inf_{\xi^h \in \Theta^h} \|\theta - \xi^h\|_\Theta + \inf_{\psi^h \in \Lambda^h} \|\lambda - \psi^h\|_\Lambda\Big). \end{aligned}$$

Proof. The results immediately follow from Proposition 2.4 and Lemma 3.4. □

The discrete optimality system (3.20) is equivalent to the linear system

$$(3.24) \qquad \begin{pmatrix} \mathbb{A}_1 & 0 & \mathbb{B}_1^T \\ 0 & \mathbb{A}_2 & \mathbb{B}_2^T \\ \mathbb{B}_1 & \mathbb{B}_2 & 0 \end{pmatrix} \begin{pmatrix} \vec{\boldsymbol{\phi}} \\ \vec{\boldsymbol{\theta}} \\ \vec{\boldsymbol{\lambda}} \end{pmatrix} = \begin{pmatrix} \vec{\mathbf{f}} \\ \vec{\mathbf{0}} \\ \vec{\mathbf{g}} \end{pmatrix},$$

where $\vec{\mathbf{f}}$ and $\vec{\mathbf{g}}$ are defined using $a_1(\widehat{\phi}, \mu^h)$ and $\langle g, \psi^h \rangle_{\Lambda^*,\Lambda}$, respectively, and $\mathbb{A}_k$ and $\mathbb{B}_k$ are defined in the standard manner from the bilinear forms $a_k(\cdot,\cdot)$ and $b_k(\cdot,\cdot)$, $k = 1, 2$, respectively.

Remark 3.6. There are two sets of inf-sup conditions associated with the problems (3.18) and (3.20). First, we have the "inner" conditions (3.5) and (3.22) that involve only the state variable and that guarantee the unique solvability of the state equation and the discrete state equation, respectively, i.e., of the third equations in (3.18) and (3.20). Second, we have the "outer" conditions (2.6) and (2.11) involving the bilinear form $b(\cdot,\cdot)$ defined in (3.7) and that involve both the state and control variables. These latter conditions help guarantee the unique solvability of the optimality system (3.18) and the discrete optimality system (3.20), respectively. Note that the outer conditions and the related saddle-point nature of the optimality systems occur regardless of the nature of the inner problem, i.e., the state equations. For example, even if the state equations involve a strongly coercive bilinear form $b_1(\cdot,\cdot)$ so that the last two inequalities in (3.5) can be replaced by $b_1(\phi,\phi) \geq k_1\|\phi\|_\Phi^2$ for all $\phi \in \Phi$, we would still have the inf-sup condition in the form of the last equation in (2.6).

Remark 3.7. As mentioned in Remark 3.6, the assumptions in (3.22) guarantee the unique solvability of the discrete state equation (the third equation in (3.20)) for the discrete state variable $\phi^h \in \Phi^h$. Thus, if the constraint equation (3.4) is a partial differential equation problem, then the assumptions in (3.22) are the general assumptions on the associated bilinear form and the approximating space that are made to guarantee the stability and convergence of Galerkin finite element discretizations; see, e.g., [1]. Furthermore, because of the nature of the assumptions (3.3) and (3.5), the inf-sup condition on the bilinear form $b(\cdot,\cdot)$ is satisfied merely by assuming that (3.22) holds. Thus, by merely guaranteeing that the discrete constraint equations within the discretized optimal control problem are uniquely solvable for any given discrete control, i.e., assuming that the "inner" inf-sup conditions hold, we have that the "outer" inf-sup condition on the bilinear form $b(\cdot,\cdot)$ holds. The latter, of course, is crucial to the stability and convergence of finite element approximations to any saddle-point problem, including the optimality systems we consider here.

Remark 3.8. The discrete optimality system (3.20) or its matrix equivalent (3.24) has the typical saddle-point structure, and thus, the stability and convergence of the approximations they define depend on the bilinear form $b(\cdot,\cdot) = b_1(\cdot,\cdot) + b_2(\cdot,\cdot)$ satisfying the discrete inf-sup condition (2.11) with respect to $V^h = \Phi^h \times \Theta^h$ and $S^h = \Lambda^h$. In the current context, this assumption is satisfied (see Remark 3.7) merely by assuming that (3.22) holds for the bilinear form $b_1(\cdot,\cdot)$ and for the spaces Φ^h and Λ_h. Thus, as discussed in Remark 3.7, the stability and convergence of solutions of (3.20) or (3.24) depends solely on the ability to stably solve, given any discrete control variable, the discrete state equation for a discrete state variable. On the other hand, if (3.22) does not hold, then there exists a $\phi_0^h \in \Phi^h$ such that $\phi_0^h \neq 0$ and $b_1(\phi_0^h,\psi^h) = 0$ for all $\psi^h \in \Lambda^h$. Then, $b(\{\phi_0^h,0\},\{\psi^h\}) = b_1(\phi_0^h,\psi^h) = 0$ for all $\psi^h \in \Lambda^h$ so that

$$\sup_{\psi^h\in\Lambda^h,\,\psi^h\neq 0} \frac{b(\{\phi_0^h,0\},\{\psi^h\})}{\|\psi^h\|_\Lambda} = 0.$$

It can be shown that this implies that the discrete inf-sup condition (2.11) does not hold so that (3.20) or its matrix equivalent (3.24) may not be solvable, i.e., the coefficient matrix in (3.24) may not be invertible. In fact, the assumptions (3.22) imply that $\mathbb{B}_1$ is uniformly invertible. This and the facts (which follow from (3.3)) that the symmetric matrices $\mathbb{A}_1$ and $\mathbb{A}_2$ are positive semidefinite and positive definite, respectively, are enough to guarantee that the coefficient matrix in (3.24) is invertible. On the other hand, if (3.22) does not hold so that the matrix $\mathbb{B}_1$ has a nontrivial null space, then under the other assumptions that have been made, one cannot guarantee the invertibility of the coefficient matrix in (3.24).

Remark 3.9. Solving the discrete optimality system (3.20) or, equivalently, the linear system (3.24) is often a formidable task. If the constraint equations (3.4) are a system of partial differential equations, then the last (block) row of (3.24) represents a Galerkin finite element discretization of that system. The discrete adjoint equations, i.e., the first row in (3.24), are also a discretization of a system of partial differential equations. Moreover, the dimension of the discrete adjoint vector $\vec{\boldsymbol{\lambda}}$ is essentially the same as that of discrete state vector $\vec{\boldsymbol{\phi}}$. Thus, (3.24) is at least twice the size (we have yet to account for the discrete control variables in $\vec{\boldsymbol{\theta}}$) of the discrete system corresponding to the discretization of the partial differential equation constraints. Thus, if these equations are difficult to approximate, the discrete optimality system will be even more difficult to deal with. For this reason, there have been many approaches suggested for uncoupling the three components of discrete optimality systems such as (3.20) or, equivalently, (3.24). See, e.g., [18] for a discussion of several of these approaches. We note that these approaches rely on the invertibility of the matrices $\mathbb{B}_1$ and $\mathbb{A}_2$, properties that follow from (3.22) and (3.3), respectively.

4. Least-squares finite element methods for the optimality system.

Even if the state equation (3.4) (or (3.16)) involves a symmetric, positive definite operator B_1, i.e., even if the bilinear form $b_1(\cdot,\cdot)$ is symmetric and strongly coercive, the discrete optimality system (3.20) (or (3.24)) obtained through a Galerkin discretization is indefinite. For example, if $B_1 = -\Delta$ with zero boundary conditions, then $\mathbb{B}_1$ is a symmetric, positive definite matrix, but the coefficient matrix in (3.24) is indefinite. In order to obtain a discrete optimality system that is symmetric and positive definite, we will apply a least-squares finite element discretization. In fact, these desirable properties for the discrete system will remain in place even if the state system bilinear form $b_1(\cdot,\cdot)$ is only weakly coercive, i.e., even if the operator B_1 is merely invertible and not necessarily positive definite.

Given a system of partial differential equations, there are many ways to define least-squares finite element methods for determining approximate solutions. Practicality issues can be used to select the “best” methods from among the many choices available. See, e.g., [6] for a discussion of what factors enter into the choice of a particular least-squares finite element method for a given problem. Here, we will consider the most straightforward means for defining a least-squares finite element method. When, in section 5, we consider a specific example, we will return to a discussion of practicality issues in the choice of a least-squares finite element formulation.

4.1. A least-squares finite element method for a generalization of the optimality system.

We start with the generalized form of the optimality system (3.19) written in operator form, i.e.,

$$\left\{\begin{array}{lllllll} A_1\phi & & & + & B_1^*\lambda & = f & \text{in } \Phi^*, \\ & & A_2\theta & + & B_2^*\lambda & = s & \text{in } \Theta^*, \\ B_1\phi & + & B_2\theta & & & = g & \text{in } \Lambda^*, \end{array}\right. \tag{4.1}$$

where $(f,s,g) \in \Phi^* \times \Theta^* \times \Lambda^*$ is a general data triple and $(\phi,\theta,\lambda) \in \Phi \times \Theta \times \Lambda$ is the corresponding solution triple. In the same way that Theorem 3.3 was proved, we have the following result.

PROPOSITION 4.1. *Let the assumptions* (3.3) *and* (3.5) *hold. Then, for any* $(f,s,g) \in \Phi^* \times \Theta^* \times \Lambda^*$*, the generalized optimality system* (4.1) *has a unique solution* $(\phi,\theta,\lambda) \in \Phi \times \Theta \times \Lambda$. *Moreover,*

$$\|\phi\|_\Phi + \|\theta\|_\Theta + \|\lambda\|_\Lambda \le C\big(\|f\|_{\Phi^*} + \|s\|_{\Theta^*} + \|g\|_{\Lambda^*}\big). \tag{4.2}$$

A least-squares functional can be defined by summing the squares of the norms of the residuals of the three equations in (4.1) to obtain

$$\mathcal{K}(\phi,\theta,\lambda;f,s,g) = \|A_1\phi + B_1^*\lambda - f\|^2_{\Phi^*} + \|A_2\theta + B_2^*\lambda - s\|^2_{\Theta^*} + \|B_1\phi + B_2\theta - g\|^2_{\Lambda^*}. \tag{4.3}$$

Clearly, the unique solution of (4.1) is also the solution of the problem

$$\min_{(\phi,\theta,\lambda)\in\Phi\times\Theta\times\Lambda} \mathcal{K}(\phi,\theta,\lambda;f,s,g). \tag{4.4}$$

The first-order necessary conditions corresponding to (4.4) are easily found to be

$$B\big((\phi,\theta,\lambda),(\mu,\nu,\psi)\big) = F\big((\mu,\nu,\psi);(f,s,g)\big) \quad \forall\,(\mu,\nu,\psi)\in\Phi\times\Theta\times\Lambda, \tag{4.5}$$

where

$$\begin{aligned} B\big((\phi,\theta,\lambda),(\mu,\nu,\psi)\big) &= (A_1\mu + B_1^*\psi, A_1\phi + B_1^*\lambda)_{\Phi^*} \\ &+(A_2\nu + B_2^*\psi, A_2\theta + B_2^*\lambda)_{\Theta^*} + (B_1\mu + B_2\nu, B_1\phi + B_2\theta)_{\Lambda^*} \\ &\forall\,(\phi,\theta,\lambda),\ (\mu,\nu,\psi)\in\Phi\times\Theta\times\Lambda \end{aligned} \tag{4.6}$$

and

$$\begin{aligned} F\big((\mu,\nu,\psi);(f,s,g)\big) &= (A_1\mu + B_1^*\psi, f)_{\Phi^*} + (A_2\nu + B_2^*\psi, s)_{\Theta^*} \\ &+(B_1\mu + B_2\nu, g)_{\Lambda^*} \quad \forall\,(\mu,\nu,\psi)\in\Phi\times\Theta\times\Lambda. \end{aligned} \tag{4.7}$$

LEMMA 4.2. *Let the assumptions* (3.3) *and* (3.5) *hold. Then, the bilinear form* $B(\cdot,\cdot)$ *is symmetric and continuous on* $(\Phi\times\Theta\times\Lambda)\times(\Phi\times\Theta\times\Lambda)$*, and the linear functional* $F(\cdot)$ *is continuous on* $(\Phi\times\Theta\times\Lambda)$*. Moreover, the bilinear form* $B(\cdot,\cdot)$ *is coercive on* $(\Phi\times\Theta\times\Lambda)$*, i.e.,*

$$B\big((\phi,\theta,\lambda),(\phi,\theta,\lambda)\big) \ge C(\|\phi\|_\Phi^2 + \|\theta\|_\Theta^2 + \|\lambda\|_\Lambda^2) \quad \forall\,(\phi,\theta,\lambda)\in\Phi\times\Theta\times\Lambda. \tag{4.8}$$

Proof. The symmetry and continuity of the form $B(\cdot,\cdot)$ and the continuity of the form $F(\cdot)$ are clear. From (4.6), we have that

$$B\big((\phi,\theta,\lambda),(\phi,\theta,\lambda)\big) = \|A_1\phi + B_1^*\lambda\|_{\Phi^*}^2 + \|A_2\theta + B_2^*\lambda\|_{\Theta^*}^2 + \|B_1\phi + B_2\theta\|_{\Lambda^*}^2. \tag{4.9}$$

Clearly, for any $(\phi,\theta,\lambda)\in\Phi\times\Theta\times\Lambda$, there exists $(f,s,g)\in\Phi^*\times\Theta^*\times\Lambda^*$ such that (ϕ,θ,λ) is a solution of (4.1). This observation and Proposition 4.1 then yield that

$$\begin{aligned} \|\phi\|_\Phi^2 + \|\theta\|_\Theta^2 + \|\lambda\|_\Lambda^2 &\le C\big(\|f\|_{\Phi^*}^2 + \|s\|_{\Theta^*}^2 + \|g\|_{\Lambda^*}^2\big) \\ &= C\big(\|A_1\phi + B_1^*\lambda\|_{\Phi^*}^2 + \|A_2\theta + B_2^*\lambda\|_{\Theta^*}^2 + \|B_1\phi + B_2\theta\|_{\Lambda^*}^2\big) \\ &\forall\,(\phi,\theta,\lambda)\in\Phi\times\Theta\times\Lambda. \end{aligned} \tag{4.10}$$

Combining (4.9) and (4.10) then easily yields (4.8). □

Remark 4.3. Since

$$\begin{aligned} \mathcal{K}(\phi,\theta,\lambda;0,0,0) &= \|A_1\phi + B_1^*\lambda\|_{\Phi^*}^2 + \|A_2\theta + B_2^*\lambda\|_{\Theta^*}^2 + \|B_1\phi + B_2\theta\|_{\Lambda^*}^2 \\ &= B\big((\phi,\theta,\lambda),(\phi,\theta,\lambda)\big), \end{aligned}$$

the coercivity and continuity of the bilinear form $B(\cdot,\cdot)$ are equivalent to stating that the functional $\mathcal{K}(\phi,\theta,\lambda;0,0,0)$ is norm-equivalent, i.e., that there exist constants $\gamma_1 > 0$ and $\gamma_2 > 0$ such that

$$\gamma_1(\|\phi\|_\Phi^2 + \|\theta\|_\Theta^2 + \|\lambda\|_\Lambda^2) \le \mathcal{K}(\phi,\theta,\lambda;0,0,0) \le \gamma_2(\|\phi\|_\Phi^2 + \|\theta\|_\Theta^2 + \|\lambda\|_\Lambda^2) \tag{4.11}$$

for all $(\phi,\theta,\lambda) \in \Phi \times \Theta \times \Lambda$.

PROPOSITION 4.4. *Let the assumptions* (3.3) *and* (3.5) *hold. Then, for any* $(f,s,g) \in \Phi^* \times \Theta^* \times \Lambda^*$*, the problem* (4.5) *has a unique solution* $(\phi,\theta,\lambda) \in \Phi \times \Theta \times \Lambda$*. Moreover, this solution coincides with the solution of the problems* (4.1) *and* (4.4) *and satisfies the estimate* (4.2).

Proof. The results follow from Lemma 4.2 and the Lax–Milgram lemma. □

We define a finite element discretization of (4.1) or, equivalently, of (4.5) by choosing conforming finite element subspaces $\Phi^h \subset \Phi$, $\Theta^h \subset \Theta$, and $\Lambda^h \subset \Lambda$ and then requiring that $(\phi^h,\theta^h,\lambda^h) \in \Phi^h \times \Theta^h \times \Lambda^h$ satisfy

$$B\big((\phi^h,\theta^h,\lambda^h),(\mu^h,\nu^h,\psi^h)\big) = F\big((\mu^h,\nu^h,\psi^h);(f,s,g)\big) \qquad \forall\,(\mu^h,\nu^h,\psi^h) \in \Phi^h \times \Theta^h \times \Lambda^h. \tag{4.12}$$

Note that $(\phi^h,\theta^h,\lambda^h)$ can also be characterized as the solution of the problem

$$\min_{(\phi^h,\theta^h,\lambda^h)\in\Phi^h\times\Theta^h\times\Lambda^h} \mathcal{K}(\phi^h,\theta^h,\lambda^h;f,s,g).$$

PROPOSITION 4.5. *Let the assumptions* (3.3) *and* (3.5) *hold. Then, for any* $(f,h,g) \in \Phi^* \times \Theta^* \times \Lambda^*$*, the problem* (4.12) *has a unique solution* $(\phi^h,\theta^h,\lambda^h) \in \Phi^h \times \Theta^h \times \Lambda^h$*. Moreover, we have the optimal error estimate*

$$\begin{aligned}&\|\phi-\phi^h\|_\Phi + \|\theta-\theta^h\|_\Theta + \|\lambda-\lambda^h\|_\Lambda \\ &\qquad \le C\Big(\inf_{\widetilde{\phi}^h\in\Phi^h}\|\phi-\widetilde{\phi}^h\|_\Phi + \inf_{\widetilde{\theta}^h\in\Theta^h}\|\theta-\widetilde{\theta}^h\|_\Theta + \inf_{\widetilde{\lambda}^h\in\Lambda^h}\|\lambda-\widetilde{\lambda}^h\|_\Lambda\Big),\end{aligned} \tag{4.13}$$

where $(\phi,\theta,\lambda) \in \Phi \times \Theta \times \Lambda$ *is the unique solution of the problem* (4.5) *or, equivalently, of the problems* (4.1) *or* (4.4).

Proof. The results follow from Lemma 4.2 and from standard finite element analyses. □

4.2. A least-squares finite element method for the optimality system. The results of section 4.1 easily specialize to the optimality system (3.19). Indeed, letting $f = A_1\widehat{\phi} \in \widehat{\Phi}^* \subset \Phi^*$ and $s = 0$, we have that (4.1) reduces to (3.19). We now have the least-squares functional

$$\mathcal{K}(\phi,\theta,\lambda;\widehat{\phi},g) = \|A_1\phi + B_1^*\lambda - A_1\widehat{\phi}\|^2_{\Phi^*} + \|A_2\theta + B_2^*\lambda\|^2_{\Theta^*} + \|B_1\phi + B_2\theta - g\|^2_{\Lambda^*}, \tag{4.14}$$

the minimization problem

$$\min_{(\phi,\theta,\lambda)\in\Phi\times\Theta\times\Lambda} \mathcal{K}(\phi,\theta,\lambda;\widehat{\phi},g), \tag{4.15}$$

and the first-order necessary conditions

$$B\big((\phi,\theta,\lambda),(\mu,\nu,\psi)\big) = F\big((\mu,\nu,\psi);(A_1\widehat{\phi},0,g)\big) \quad \forall\,(\mu,\nu,\psi) \in \Phi \times \Theta \times \Lambda, \tag{4.16}$$

where $B(\cdot,\cdot)$ and $F(\cdot)$ are defined as in (4.6) and (4.7), respectively.

We define a finite element discretization of (4.16) by again choosing conforming finite element subspaces $\Phi^h \subset \Phi$, $\Theta^h \subset \Theta$, and $\Lambda^h \subset \Lambda$ and then requiring that $(\phi^h,\theta^h,\lambda^h) \in \Phi^h \times \Theta^h \times \Lambda^h$ satisfy

$$B\big((\phi^h,\theta^h,\lambda^h),(\mu^h,\nu^h,\psi^h)\big) = F\big((\mu^h,\nu^h,\psi^h);(A_1\widehat{\phi},0,g)\big) \qquad \forall\,(\mu^h,\nu^h,\psi^h) \in \Phi^h \times \Theta^h \times \Lambda^h. \tag{4.17}$$

Then, Proposition 4.5 takes the following form.

THEOREM 4.6. *Let the assumptions* (3.3) *and* (3.5) *hold. Then, for any* $(\widehat{\phi}, g) \in \widehat{\Phi}^* \times \Lambda^*$, *the problem* (4.17) *has a unique solution* $(\phi^h, \theta^h, \lambda^h) \in \Phi^h \times \Theta^h \times \Lambda^h$. *Moreover, we have the optimal error estimate: There exists a constant* $C > 0$ *whose value is independent of* h, *such that*

$$\begin{aligned} &\|\phi - \phi^h\|_\Phi + \|\theta - \theta^h\|_\Theta + \|\lambda - \lambda^h\|_\Lambda \\ &\qquad \le C\Big(\inf_{\widetilde{\phi}^h \in \Phi^h} \|\phi - \widetilde{\phi}^h\|_\Phi + \inf_{\widetilde{\theta}^h \in \Theta^h} \|\theta - \widetilde{\theta}^h\|_\Theta + \inf_{\widetilde{\lambda}^h \in \Lambda^h} \|\lambda - \widetilde{\lambda}^h\|_\Lambda\Big), \end{aligned} \tag{4.18}$$

where $(\phi, \theta, \lambda) \in \Phi \times \Theta \times \Lambda$ *is the unique solution of the problem* (4.16) *or, equivalently, of the problems* (3.19) *or* (3.18). *Note also that* $(\phi, \theta) \in \Phi \times \Theta$ *is the unique solution of the problem* (3.6).

Remark 4.7. The discrete problem (4.17) is equivalent to the linear algebraic system

$$\begin{pmatrix} \mathbb{K}_1 & \mathbb{C}_1^T & \mathbb{C}_2^T \\ \mathbb{C}_1 & \mathbb{K}_2 & \mathbb{C}_3^T \\ \mathbb{C}_2 & \mathbb{C}_3 & \mathbb{K}_3 \end{pmatrix} \begin{pmatrix} \vec{\boldsymbol{\phi}} \\ \vec{\boldsymbol{\theta}} \\ \vec{\boldsymbol{\lambda}} \end{pmatrix} = \begin{pmatrix} \vec{\mathbf{f}} \\ \vec{\mathbf{h}} \\ \vec{\mathbf{g}} \end{pmatrix}. \tag{4.19}$$

Indeed, if one chooses bases $\{\mu_j^h(\mathbf{x})\}_{j=1}^J$, $\{\nu_k^h(\mathbf{x})\}_{k=1}^K$, and $\{\psi_\ell^h(\mathbf{x})\}_{\ell=1}^L$ for Φ_h, Θ_h, and Λ_h, respectively, we then have $\phi^h = \sum_{j=1}^J \phi_j \mu_j^h$, $\theta^h = \sum_{k=1}^K \theta_k \mu_k^h$, and $\lambda^h = \sum_{\ell=1}^L \lambda_\ell \psi_\ell^h$ for some sets of coefficients $\{\phi_j\}_{j=1}^J$, $\{\theta_k\}_{k=1}^K$, and $\{\lambda_\ell\}_{\ell=1}^L$ that are determined by solving (4.19). In (4.19), we have that $\vec{\boldsymbol{\phi}} = (\phi_1, \dots, \phi_J)^T$, $\vec{\boldsymbol{\theta}} = (\theta_1, \dots, \theta_K)^T$, $\vec{\boldsymbol{\lambda}} = (\lambda_1, \dots, \lambda_L)^T$,

$$\begin{aligned}
&\big(\mathbb{K}_1\big)_{ij} = (A_1\mu_i, A_1\mu_j)_{\Phi^*} + (B_1\mu_i, B_1\mu_j)_{\Lambda^*} && \text{for } i,j = 1,\dots,J, \\
&\big(\mathbb{K}_2\big)_{ik} = (A_2\nu_i, A_1\nu_k)_{\Theta^*} + (B_2\nu_i, B_2\nu_k)_{\Lambda^*} && \text{for } i,k = 1,\dots,K, \\
&\big(\mathbb{K}_3\big)_{i\ell} = (B_1^*\psi_i, B_1^*\psi_\ell)_{\Phi^*} + (B_2\psi_i, B_2\psi_\ell)_{\Theta^*} && \text{for } i,\ell = 1,\dots,L, \\
&\big(\mathbb{C}_1\big)_{ij} = (B_2\nu_i, B_1\mu_j)_{\Lambda^*} && \text{for } i = 1,\dots,K,\ j = 1,\dots,J, \\
&\big(\mathbb{C}_2\big)_{ij} = (B_1^*\psi_i, A_1\nu_j)_{\Phi^*} && \text{for } i = 1,\dots,L,\ j = 1,\dots,J, \\
&\big(\mathbb{C}_3\big)_{ik} = (B_2^*\psi_i, A_2\nu_k)_{\Theta^*} && \text{for } i = 1,\dots,L,\ k = 1,\dots,K, \\
&\big(\vec{\mathbf{f}}\big)_i = (A_1\mu_i, A_1\widehat{\phi})_{\Phi^*} + (B_1\mu_i, g)_{\Lambda^*} && \text{for } i = 1,\dots,J, \\
&\big(\vec{\mathbf{h}}\big)_i = (B_2\nu_i, g)_{\Lambda^*} && \text{for } i = 1,\dots,K, \\
&\big(\vec{\mathbf{g}}\big)_i = (B_1^*\psi_i, A_1\widehat{\phi})_{\Phi^*} && \text{for } i = 1,\dots,L.
\end{aligned}$$

Remark 4.8. It easily follows from Lemma 4.2 that the coefficient matrix of (4.19) is *symmetric and positive definite.* This should be compared to the linear system (3.24) that results from a Galerkin finite element discretization of the optimality system (3.18) for which the coefficient matrix is symmetric and *indefinite.*

Remark 4.9. The stability of the discrete problem (4.17), the convergence and optimal accuracy of the approximate solution $(\phi^h, \theta^h, \lambda^h)$, and the symmetry and positive definiteness of the discrete system (4.19) obtained by the least-squares finite element method follow from the assumptions (3.3) and (3.5) that guarantee the well posedness of the infinite-dimensional optimization problem (3.6) and its corresponding optimality system (3.18). It is important to note that all of these desirable properties of the least-squares finite element method do not require that the bilinear form $b_1(\cdot,\cdot)$ and that the finite element spaces Φ^h and Λ^h satisfy the inner (see Remark 3.6) inf-sup conditions (3.22) that are necessary for the well posedness of the Galerkin finite element discretization (3.20) of the optimality system (3.18). In fact, this is why least-squares finite element methods are often an attractive alternative to Galerkin discretizations; see, e.g., [6].

Remark 4.10. The observations made in Remark 3.9 about the possible need to uncouple the equations in (3.24) hold as well for the linear system (4.19). Uncoupling approaches for (3.24) rely on the invertibility of the matrices $\mathbb{B}_1$ and $\mathbb{A}_2$; the first of these is, in general, nonsymmetric and indefinite, even when the necessary discrete inf-sup conditions in (3.22) are satisfied. For (4.19), uncoupling strategies would rely on the invertibility of the matrices $\mathbb{K}_1$, $\mathbb{K}_2$, and $\mathbb{K}_3$; all three of these matrices are symmetric and positive definite even when (3.22) is not satisfied. An example of a simple uncoupling strategy is to apply a block-Gauss–Seidel method to (4.19), which would proceed as follows.

> Start with initial guesses $\vec{\boldsymbol{\phi}}^{(0)}$ and $\vec{\boldsymbol{\theta}}^{(0)}$ for the discretized state and control; then, for $k = 1, 2, \ldots$, successively solve the linear systems
>
> $$\begin{aligned} \mathbb{K}_3\vec{\boldsymbol{\lambda}}^{(k+1)} &= \vec{\mathbf{g}} - \mathbb{C}_2\vec{\boldsymbol{\phi}}^{(k)} - \mathbb{C}_3\vec{\boldsymbol{\theta}}^{(k)}, \\ \mathbb{K}_1\vec{\boldsymbol{\phi}}^{(k+1)} &= \vec{\mathbf{f}} - \mathbb{C}_1^T\vec{\boldsymbol{\theta}}^{(k)} - \mathbb{C}_2^T\vec{\boldsymbol{\lambda}}^{(k+1)}, \\ \mathbb{K}_2\vec{\boldsymbol{\theta}}^{(k+1)} &= \vec{\mathbf{h}} - \mathbb{C}_1\vec{\boldsymbol{\phi}}^{(k+1)} - \mathbb{C}_3^T\vec{\boldsymbol{\lambda}}^{(k+1)} \end{aligned} \tag{4.20}$$
>
> until satisfactory convergence is achieved, e.g., until some norm of the difference between successive iterates is less than some prescribed tolerance.

Since the coefficient matrix in (4.19) is symmetric and positive definite, this iteration will converge. Moreover, all three coefficient matrices $\mathbb{K}_3$, $\mathbb{K}_1$, and $\mathbb{K}_2$ of the linear systems in (4.20) are themselves symmetric and positive definite so that very efficient solution methodologies, including parallel ones, can be applied for their solution. We also note that, in order to obtain faster convergence rates, better uncoupling iterative methods, e.g., over-relaxation schemes or a conjugate gradient method, can be applied instead of the Gauss–Seidel iteration of (4.20).

Remark 4.11. The discrete problem (4.17) (or equivalently, (4.19)) resulting from the least-squares method for the optimality system (3.19) can be viewed as a Galerkin discretization of the system

$$\begin{aligned} &(A_1^*A_1 + B_1^*B_1)\phi + (B_1^*B_2)\theta + (A_1^*B_1^*)\lambda = (A_1^*A_1)\widehat{\phi} + (B_1^*)g && \text{in } \Phi, \\ &(A_2^*A_2 + B_2^*B_2)\theta + (A_2^*B_2^*)\lambda + (B_2^*B_1)\phi = (B_2^*)g && \text{in } \Theta, \\ &(B_1B_1^* + B_2B_2^*)\lambda + (B_1A_1)\phi + (B_2A_2)\theta = (B_1A_1)\widehat{\phi} && \text{in } \Lambda. \end{aligned} \tag{4.21}$$

The first equation of this system is the sum of A_1^* applied to the first equation of the optimality system (3.19) and B_1^* applied to the third equation of that system. The other equations of (4.21) are related to the equations of (3.19) in a similar manner.

The system (4.21) shows that the discrete system (4.19) essentially involves the discretization of "squares" of operators, e.g., $A_1^*A_1$, $B_1^*B_1$, etc. This observation has a profound effect in how one chooses the form of the constraint equation in (3.6), i.e., the form of (3.16). We will return to this point in the next section when we consider a concrete example.

5. Example: Optimization problems for the Stokes system. Let Ω denote an open, bounded domain in $\mathcal{R}^s$, $s = 2$ or 3, with boundary Γ. Let $\mathbf{u}$ and p denote the velocity and pressure fields, respectively, and let $\boldsymbol{\theta}$ denote a distributed control. Then, consider the Stokes system

$$(5.1)\qquad \left\{\begin{array}{lcl} -\Delta\mathbf{u} + \nabla p + \boldsymbol{\theta} & = & \mathbf{g} \\ \nabla\cdot\mathbf{u} & = & 0 \end{array}\right. \quad \text{in } \Omega, \qquad \mathbf{u} = \mathbf{0} \quad \text{on } \Gamma, \qquad \int_\Omega p\, d\Omega = 0$$

and the functionals

$$(5.2)\qquad \text{Case I:}\qquad \mathcal{J}_1(\mathbf{u},\boldsymbol{\theta}) = \frac{1}{2}\int_\Omega |\nabla\times\mathbf{u}|^2\, d\Omega + \frac{\delta}{2}\int_\Omega |\boldsymbol{\theta}|^2\, d\Omega,$$

$$(5.3)\qquad \text{Case II:}\qquad \mathcal{J}_2(\mathbf{u},\boldsymbol{\theta};\widehat{\mathbf{u}}) = \frac{1}{2}\int_\Omega |\mathbf{u}-\widehat{\mathbf{u}}|^2\, d\Omega + \frac{\delta}{2}\int_\Omega |\boldsymbol{\theta}|^2\, d\Omega,$$

where $\mathbf{g}$ and $\widehat{\mathbf{u}}$ are given functions. We study the two problems of finding $(\mathbf{u}, p, \boldsymbol{\theta})$ that minimizes the functional in either (5.2) or (5.3), subject to the Stokes system (5.1) being satisfied. In the first case, i.e., for the functional (5.2), the problem we study is to find a distributed control function $\boldsymbol{\theta}$ that minimizes, in the $\mathbf{L}^2(\Omega)$ sense, the vorticity over the flow domain Ω. In the second case, i.e., for the functional (5.3), the problem we study is to find a distributed control function $\boldsymbol{\theta}$ such that flow velocity $\mathbf{u}$ matches as well as possible, in the $\mathbf{L}^2(\Omega)$ sense, a given velocity field $\widehat{\mathbf{u}}$.

In Remark 4.11, it was noted that least-squares finite element methods for optimization problems result in the "squaring" of the constraint operator, in this case, of the Stokes system (5.1). This results in biharmonic-type terms appearing in the system corresponding to (4.21) or, equivalently, in (4.9). A conforming finite element discretization would then require the use of continuously differentiable approximation spaces. In order to overcome this impracticality, it has become a standard procedure in least-squares finite element methods to write the state system in an equivalent first-order formulation; see, e.g., [6] for a detailed discussion of this issue.

There are many ways to rewrite the Stokes system (5.1) as a first-order system of partial differential equations. Here, we choose the *velocity-vorticity-pressure formulation* that is the most commonly used system for this purpose. Let $\boldsymbol{\omega} = \nabla\times\mathbf{u}$ denote the vorticity. Then, using the well-known vector identity $-\triangle\mathbf{u} = \nabla\times\nabla\times\mathbf{u} - \nabla(\nabla\cdot\mathbf{u}) = \nabla\times\boldsymbol{\omega} - \nabla(\nabla\cdot\mathbf{u})$, the Stokes system (5.1) can be expressed as

$$(5.4)\qquad \left\{\begin{array}{lcl} \nabla\times\boldsymbol{\omega} + \nabla p + \boldsymbol{\theta} & = & \mathbf{g} \\ \nabla\cdot\mathbf{u} & = & 0 \\ \nabla\times\mathbf{u} - \boldsymbol{\omega} & = & \mathbf{0} \end{array}\right. \quad \text{in } \Omega, \qquad \mathbf{u} = \mathbf{0} \quad \text{on } \Gamma, \qquad \int_\Omega p\, d\Omega = 0.$$

Note that the functional (5.2) can now be written as

$$(5.5)\qquad \text{Case I:}\qquad \mathcal{J}_1(\boldsymbol{\omega},\boldsymbol{\theta}) = \frac{1}{2}\int_\Omega |\boldsymbol{\omega}|^2\, d\Omega + \frac{\delta}{2}\int_\Omega |\boldsymbol{\theta}|^2\, d\Omega.$$

Thus, the optimization problems we study are to find $(\mathbf{u}, \boldsymbol{\omega}, p, \boldsymbol{\theta})$ that minimizes the functional in either (5.3) or (5.5), subject to the Stokes system in the form (5.4) being satisfied.

5.1. Precise statement of optimization problems. We recall the space $L^2(\Omega)$ of all square integrable functions with norm $\|\cdot\|_0$ and inner product $(\cdot,\cdot)$, the space $L^2_0(\Omega) \equiv \{q \in L^2(\Omega) : \int_\Omega p d\Omega = 0\}$, the space $H^1(\Omega) \equiv \{v \in L^2(\Omega) : \nabla v \in [L^2(\Omega)]^s\}$, and the space $H^1_0(\Omega) \equiv \{v \in H^1(\Omega) : v = 0 \text{ on } \Gamma\}$. A norm for functions $v \in H^1(\Omega)$ is given by $\|v\|_1 \equiv (\|\nabla v\|^2 + \|v\|_0^2)^{1/2}$. The dual space of $H^1_0(\Omega)$ is denoted by $H^{-1}(\Omega)$. The corresponding spaces of vector-valued functions are denoted in bold face, e.g., $\mathbf{H}^1(\Omega) = [H^1(\Omega)]^s$ is the space of vector-valued functions each of whose components belongs to $H^1(\Omega)$. We note the following equivalence of norms [16]:

$$\widetilde{C}_1\|\mathbf{v}\|_1^2 \le \|\nabla\times\mathbf{v}\|_0^2 + \|\nabla\cdot\mathbf{v}\|_0^2 \le \widetilde{C}_2\|\mathbf{v}\|_1^2 \qquad \forall\,\mathbf{v}\in\mathbf{H}^1_0(\Omega) \tag{5.6}$$

for some constants $\widetilde{C}_1 > 0$ and $\widetilde{C}_2 > 0$.

Let $\Phi = \Lambda = \mathbf{H}^1_0(\Omega) \times \mathbf{L}^2(\Omega) \times L^2_0(\Omega)$ and $\Theta = \mathbf{L}^2(\Omega)$ so that $\Phi^* = \Lambda^* = \mathbf{H}^{-1}(\Omega) \times \mathbf{L}^2(\Omega) \times L^2_0(\Omega)$ and $\Theta^* = \mathbf{L}^2(\Omega)$. Let $\widehat{\Phi} = \widetilde{\Phi} = \mathbf{L}^2(\Omega) \times \mathbf{L}^2(\Omega) \times L^2_0(\Omega)$. Then, $\Phi \subset \widehat{\Phi} = \widetilde{\Phi} = \widehat{\Phi}^* \subset \Phi^*$. For $\phi = \{\mathbf{u}, \boldsymbol{\omega}, p\} \in \Phi$, we define the norm

$$\|\phi\|_\Phi = \left(\|\mathbf{u}\|_1^2 + \|\boldsymbol{\omega}\|_0^2 + \|p\|_0^2\right)^{1/2}$$

and likewise for the other product spaces.

We make the associations of

trial functions:	$\phi = \{\mathbf{u}, \boldsymbol{\omega}, p\} \in \Phi$,	$\theta = \{\boldsymbol{\theta}\} \in \Theta$,	$\lambda = \{\mathbf{v}, \boldsymbol{\sigma}, q\} \in \Lambda$,
test functions:	$\mu = \{\widetilde{\mathbf{u}}, \widetilde{\boldsymbol{\omega}}, \widetilde{p}\} \in \Phi$,	$\nu = \{\widetilde{\boldsymbol{\theta}}\} \in \Theta$,	$\psi = \{\widetilde{\mathbf{v}}, \widetilde{\boldsymbol{\sigma}}, \widetilde{r}\} \in \Lambda$,
data:	$g = \{\mathbf{g}, \mathbf{0}, 0\} \in \Lambda^*$,	$\widehat{\phi} = \{\widehat{\mathbf{u}}, \mathbf{0}, 0\} \in \widehat{\Phi}$.	

We next define the bilinear forms

$$a_1(\phi,\mu) = \begin{cases} (\widetilde{\boldsymbol{\omega}}, \boldsymbol{\omega}) & \text{for Case I} \\ (\widetilde{\mathbf{u}}, \mathbf{u}) & \text{for Case II} \end{cases} \qquad \forall\,\phi = \{\mathbf{u}, \boldsymbol{\omega}, p\} \in \widehat{\Phi},\;\; \mu = \{\widetilde{\mathbf{u}}, \widetilde{\boldsymbol{\omega}}, \widetilde{p}\} \in \widehat{\Phi},$$

$$a_2(\theta,\nu) = \delta(\boldsymbol{\theta}, \widetilde{\boldsymbol{\theta}}) \qquad \forall\,\theta = \{\boldsymbol{\theta}\} \in \Theta,\;\; \nu = \{\widetilde{\boldsymbol{\theta}}\} \in \Theta,$$

$$b_1(\phi,\psi) = (\boldsymbol{\omega}, \nabla\times\widetilde{\mathbf{v}}) - (p, \nabla\cdot\widetilde{\mathbf{v}}) + (\nabla\times\mathbf{u} - \boldsymbol{\omega}, \widetilde{\boldsymbol{\sigma}}) - (\nabla\cdot\mathbf{u}, \widetilde{r})$$
$$\forall\,\phi = \{\mathbf{u}, \boldsymbol{\omega}, p\} \in \Phi,\;\; \psi = \{\widetilde{\mathbf{v}}, \widetilde{\boldsymbol{\sigma}}, \widetilde{r}\} \in \Lambda,$$

$$b_2(\theta,\psi) = (\boldsymbol{\theta}, \widetilde{\mathbf{v}}) \qquad \forall\,\theta = \{\boldsymbol{\theta}\} \in \Theta,\;\; \psi = \{\widetilde{\mathbf{v}}, \widetilde{\boldsymbol{\sigma}}, \widetilde{r}\} \in \Lambda.$$

For $\mathbf{g} \in \mathbf{H}^{-1}(\Omega)$, we also define the linear functional

$$\langle g, \psi\rangle_{\Lambda^*,\Lambda} = \langle \mathbf{g}, \widetilde{\mathbf{v}}\rangle_{\mathbf{H}^{-1}(\Omega),\mathbf{H}^1_0(\Omega)} \qquad \forall\,\psi = \{\widetilde{\mathbf{v}}, \widetilde{\boldsymbol{\sigma}}, \widetilde{r}\} \in \Lambda.$$

The operators associated with the bilinear forms are then

$$\begin{aligned} &A_1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \text{for Case I,} \qquad A_1 = \begin{pmatrix} I & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \text{for Case II,} \\ &A_2 = \delta I, \qquad B_1 = \begin{pmatrix} 0 & \nabla\times & \nabla \\ \nabla\times & -I & 0 \\ -\nabla\cdot & 0 & 0 \end{pmatrix}, \qquad B_2 = \begin{pmatrix} I \\ 0 \\ 0 \end{pmatrix}. \end{aligned} \tag{5.7}$$

It is now easily seen that the functionals $\mathcal{J}_1(\cdot,\cdot)$ and $\mathcal{J}_2(\cdot,\cdot;\cdot)$ defined in (5.5) and (5.3), respectively, can be written in the form (3.2). Likewise, the Stokes system (5.4) can be written in the form (3.4). Thus, the two optimization problems for the Stokes system can both be written in the form (3.6), with $\mathcal{J}(\cdot,\cdot)$ being either $\mathcal{J}_1(\cdot,\cdot)$ or $\mathcal{J}_2(\cdot,\cdot)$ as appropriate. Thus, if the assumptions (3.3) and (3.5) can be verified in the context of the two optimization problems for the Stokes system, then all the results of section 4 will apply to those systems.

Proposition 5.1. *Let the spaces Φ, $\widehat{\Phi}$, Θ, and Λ and the bilinear forms $a_1(\cdot,\cdot)$, $a_2(\cdot,\cdot)$, $b_1(\cdot,\cdot)$, and $b_2(\cdot,\cdot)$ be defined as in this section. Then, the assumptions* (3.3) *and* (3.5) *are satisfied.*

Proof. The four inequalities in (3.3) and the first two inequalities in (3.5) are easily verified with $C_1 = 1$, $C_2 = \delta$, $K_2 = \delta$, $c_1 = 3$, and $c_2 = 1$. The third inequality in (3.5) is verified if, for any $\phi = \{\mathbf{u}, \boldsymbol{\omega}, p\} \in \Phi$, one can find a $\widetilde{\psi} = \{\widetilde{\mathbf{v}}, \widetilde{\boldsymbol{\sigma}}, \widetilde{r}\} \in \Lambda$ such that

$$\begin{aligned} b_1(\phi, \widetilde{\psi}) &= (\boldsymbol{\omega}, \nabla\times\widetilde{\mathbf{v}}) - (p, \nabla\cdot\widetilde{\mathbf{v}}) + (\nabla\times\mathbf{u} - \boldsymbol{\omega}, \widetilde{\boldsymbol{\sigma}}) - (\nabla\cdot\mathbf{u}, \widetilde{r}) \\ &\geq k_1\|\phi\|_\Phi\|\widetilde{\psi}\|_\Lambda = k_1\big(\|\mathbf{u}\|_1^2 + \|\boldsymbol{\omega}\|_0^2 + \|p\|_0^2\big)^{1/2}\big(\|\widetilde{\mathbf{v}}\|_1^2 + \|\widetilde{\boldsymbol{\sigma}}\|_0^2 + \|\widetilde{r}\|_0^2\big)^{1/2} \end{aligned}$$

for some constant $k_1 > 0$. To this end, for any $\phi = \{\mathbf{u}, \boldsymbol{\omega}, p\} \in \Phi$, let $\widetilde{\psi} = \{\widetilde{\mathbf{v}}, \widetilde{\boldsymbol{\sigma}}, \widetilde{r}\} \in \Lambda$ satisfy the system

$$\nabla\times\widetilde{\mathbf{v}} = \boldsymbol{\omega}, \qquad \nabla\cdot\widetilde{\mathbf{v}} = -p, \qquad \widetilde{\boldsymbol{\sigma}} = \nabla\times\mathbf{u}, \qquad \text{and} \qquad \widetilde{r} = -\nabla\cdot\mathbf{u}$$

in Ω. Clearly, from the last two equations, we have that

$$\|\widetilde{\boldsymbol{\sigma}}\|_0^2 + \|\widetilde{r}\|_0^2 = \|\nabla\times\mathbf{u}\|_0^2 + \|\nabla\cdot\mathbf{u}\|_0^2 \leq \widetilde{C}_2\|\mathbf{u}\|_1^2.$$

Also, since $\widetilde{\mathbf{v}} \in \mathbf{H}_0^1(\Omega)$, we have from the first two equations and (5.6) that

$$\widetilde{C}_1\|\widetilde{\mathbf{v}}\|_1^2 \leq (\|\nabla\times\widetilde{\mathbf{v}}\|_0^2 + \|\nabla\cdot\widetilde{\mathbf{v}}\|_0^2) = (\|\boldsymbol{\omega}\|_0^2 + \|p\|_0^2).$$

Combining the last two results yields that

$$\Big(\|\widetilde{\mathbf{v}}\|_1^2 + \|\widetilde{\boldsymbol{\sigma}}\|_0^2 + \|\widetilde{r}\|_0^2\Big) \leq \max\left\{\frac{1}{\widetilde{C}_1}, \widetilde{C}_2\right\}\Big(\|\mathbf{u}\|_1^2 + \|\boldsymbol{\omega}\|_0^2 + \|p\|_0^2\Big).$$

Then, with $\phi = \{\mathbf{u}, \boldsymbol{\omega}, p\} \in \Phi$ and $\widetilde{\psi} = \{\widetilde{\mathbf{v}}, \widetilde{\boldsymbol{\sigma}}, \widetilde{r}\} \in \Lambda$, we have that

$$\begin{aligned} b_1(\phi, \widetilde{\psi}) &= \|\boldsymbol{\omega}\|_0^2 + \|p\|_0^2 + \|\nabla\times\mathbf{u}\|_0^2 + \|\nabla\cdot\mathbf{u}\|_0^2 - (\boldsymbol{\omega}, \nabla\times\mathbf{u}) \\ &\geq \|\boldsymbol{\omega}\|_0^2 + \|p\|_0^2 + \|\nabla\times\mathbf{u}\|_0^2 + \|\nabla\cdot\mathbf{u}\|_0^2 - \|\boldsymbol{\omega}\|_0\|\nabla\times\mathbf{u}\|_0 \\ &\geq \tfrac{1}{2}\|\boldsymbol{\omega}\|_0^2 + \|p\|_0^2 + \tfrac{1}{2}\|\nabla\times\mathbf{u}\|_0^2 + \|\nabla\cdot\mathbf{u}\|_0^2 \\ &\geq \tfrac{1}{2}\min\{1, \widetilde{C}_1\}\Big(\|\mathbf{u}\|_1^2 + \|\boldsymbol{\omega}\|_0^2 + \|p\|_0^2\Big) \\ &\geq \frac{\min\{1,\widetilde{C}_1\}}{2\sqrt{\max\left\{\frac{1}{\widetilde{C}_1}, \widetilde{C}_2\right\}}}\Big(\|\mathbf{u}\|_1^2 + \|\boldsymbol{\omega}\|_0^2 + \|p\|_0^2\Big)^{1/2}\Big(\|\widetilde{\mathbf{v}}\|_1^2 + \|\widetilde{\boldsymbol{\sigma}}\|_0^2 + \|\widetilde{r}\|_0^2\Big)^{1/2} \\ &= \frac{\min\{1,\widetilde{C}_1\}}{2\sqrt{\max\left\{\frac{1}{\widetilde{C}_1}, \widetilde{C}_2\right\}}}\|\phi\|_\Phi\|\widetilde{\psi}\|_\Lambda. \end{aligned}$$

Thus, with $k_1 = \min\{1, \widetilde{C}_1\}/(2\sqrt{\max\{\frac{1}{\widetilde{C}_1}, \widetilde{C}_2\}})$, the third inequality in (3.5) is verified. Note that k_1 depends only on the comparability constants in (5.6). □

Remark 5.2. We have now verified the assumptions (3.3) and (3.5) for the two optimization problems of finding $(\mathbf{u}, \boldsymbol{\omega}, p, \boldsymbol{\theta})$ that minimize either the functional in (5.3) or (5.5), subject to the Stokes system in the form (5.4) being satisfied. Thus, all the results of sections 3.1 and 3.2 hold. In particular, with the associations already defined between spaces, operators, etc., we could use the Lagrange multiplier rule to characterize the solutions of the optimization problems as solutions of the optimality system (3.19).

Remark 5.3. We could apply, as in section 3.3, a Galerkin finite element method for determining approximate solutions of the optimality system (3.19). Such an approach, unlike least-squares finite element discretizations, does not involve the "squaring" of operators so that there is no need to transform the Stokes system (5.1) into an equivalent first-order form as in (5.4); one would then also use the form (5.2) for the functional $\mathcal{J}_1$ instead of the from (5.5). We then would have $\phi = \{\mathbf{u}, p\}$, $\theta = \{\boldsymbol{\theta}\}$, etc., and use, instead of the operators defined in (5.7), the operators

$$\begin{aligned} &A_1 = \begin{pmatrix} \nabla\times & 0 \\ 0 & 0 \end{pmatrix} \quad \text{for Case I,} \qquad A_1 = \begin{pmatrix} I & 0 \\ 0 & 0 \end{pmatrix} \quad \text{for Case II,} \\ &A_2 = \delta I, \qquad B_1 = \begin{pmatrix} -\Delta & \nabla \\ -\nabla\cdot & 0 \end{pmatrix}, \qquad B_2 = \begin{pmatrix} I \\ 0 \end{pmatrix}. \end{aligned} \tag{5.8}$$

The assumptions (3.3) and (3.5) can also be verified for the bilinear forms associated with these operators.

Remark 5.4. As noted in section 3.3, a Galerkin discretization of the optimality system (3.19) using either of the forms (5.7) or (5.8) for the operators requires that the assumptions in (3.22) hold. If one uses (5.8), one can easily show that the finite element spaces for the velocity and pressure approximations have to satisfy the inf-sup condition [12, 13, 16, 17]

$$\inf_{q^h \in S^h, q^h \neq 0} \sup_{\mathbf{v}^h \in \mathbf{V}^h, \mathbf{v}^h \neq \mathbf{0}} \frac{\displaystyle\int_\Omega q^h \nabla \cdot \mathbf{v}^h \, d\Omega}{\|q^h\|_0 \|\mathbf{v}^h\|_1} \geq \gamma \tag{5.9}$$

for some constant $\gamma > 0$. This condition guarantees the unique solvability of the discrete Stokes system and restricts the choice of finite element spaces used for the velocity and pressure approximations; see [12, 13, 17] for details. In particular, one cannot use piecewise polynomial spaces of the same order and defined with respect to the same grid for the velocity and pressure approximations. If one instead uses (5.7), an even more onerous inf-sup condition is required of the finite element spaces for the velocity, vorticity, and pressure.

Remark 5.5. Note that (5.9) is a *third* level of inf-sup conditions that we have encountered in our deliberations: (5.9) is necessary and sufficient to guarantee that the inf-sup condition (3.22) holds; the latter is necessary and sufficient to guarantee that the inf-sup condition (2.11) holds.

5.2. Least-squares finite element methods for the two optimization problems. Using the associations of spaces and variables defined in section 5.1 and the operators defined in (5.7), it is easy to see that the least-squares functional (4.14) is given by, for the example problems we are considering,

$$
\begin{aligned}
&\mathcal{K}\big(\{\mathbf{u},\boldsymbol{\omega},p\},\boldsymbol{\theta},\{\mathbf{v},\boldsymbol{\sigma},q\};\widehat{\mathbf{u}},\mathbf{g}\big)\\
&\quad = \|\nabla\times\boldsymbol{\sigma}+\nabla q+\delta_2(\mathbf{u}-\widehat{\mathbf{u}})\|_{-1}^2+\|\nabla\times\mathbf{v}-\boldsymbol{\sigma}+\delta_1\boldsymbol{\omega}\|_0^2+\|\nabla\cdot\mathbf{v}\|_0^2\\
&\qquad +\|\delta\boldsymbol{\theta}+\mathbf{v}\|_0^2\\
&\qquad +\|\nabla\times\boldsymbol{\omega}+\nabla p+\boldsymbol{\theta}-\mathbf{g}\|_{-1}^2+\|\nabla\times\mathbf{u}-\boldsymbol{\omega}\|_0^2+\|\nabla\cdot\mathbf{u}\|_0^2,
\end{aligned}
\tag{5.10}
$$

where

$$
\delta_1=\begin{cases}1 & \text{for Case I,}\\ 0 & \text{for Case II,}\end{cases}\qquad\text{and}\qquad \delta_2=\begin{cases}0 & \text{for Case I,}\\ 1 & \text{for Case II.}\end{cases}
$$

We also have the bilinear form

$$
\begin{aligned}
&B\big(\{\mathbf{u},\boldsymbol{\omega},p\},\boldsymbol{\theta},\{\mathbf{v},\boldsymbol{\sigma},q\};\{\widetilde{\mathbf{u}},\widetilde{\boldsymbol{\omega}},\widetilde{p}\},\widetilde{\boldsymbol{\theta}},\{\widetilde{\mathbf{v}},\widetilde{\boldsymbol{\sigma}},\widetilde{q}\}\big)\\
&\quad = \Big(\nabla\times\boldsymbol{\sigma}+\nabla q+\delta_2\mathbf{u},\,\nabla\times\widetilde{\boldsymbol{\sigma}}+\nabla\widetilde{q}+\delta_2\widetilde{\mathbf{u}}\Big)_{-1}\\
&\qquad +\Big(\nabla\times\mathbf{v}-\boldsymbol{\sigma}+\delta_1\boldsymbol{\omega},\,\nabla\times\widetilde{\mathbf{v}}-\widetilde{\boldsymbol{\sigma}}+\delta_1\widetilde{\boldsymbol{\omega}}\Big)+\Big(\nabla\cdot\mathbf{v},\,\nabla\cdot\widetilde{\mathbf{v}}\Big)\\
&\qquad +\Big(\delta\boldsymbol{\theta}+\mathbf{v},\,\delta\widetilde{\boldsymbol{\theta}}+\widetilde{\mathbf{v}}\Big)\\
&\qquad +\Big(\nabla\times\boldsymbol{\omega}+\nabla p+\boldsymbol{\theta},\,\nabla\times\widetilde{\boldsymbol{\omega}}+\nabla\widetilde{p}+\widetilde{\boldsymbol{\theta}}\Big)_{-1}\\
&\qquad +\Big(\nabla\times\mathbf{u}-\boldsymbol{\omega},\,\nabla\times\widetilde{\mathbf{u}}-\widetilde{\boldsymbol{\omega}}\Big)+\Big(\nabla\cdot\mathbf{u},\,\nabla\cdot\widetilde{\mathbf{u}}\Big),
\end{aligned}
\tag{5.11}
$$

where $(\cdot,\cdot)_{-1}$ denotes the inner product in $\mathbf{H}^{-1}(\Omega)$, and the linear functional

$$
\begin{aligned}
&F\big(\{\widetilde{\mathbf{u}},\widetilde{\boldsymbol{\omega}},\widetilde{p}\},\widetilde{\boldsymbol{\theta}},\{\widetilde{\mathbf{v}},\widetilde{\boldsymbol{\sigma}},\widetilde{q}\};\widehat{\mathbf{u}},\mathbf{g}\big)\\
&\quad = \Big(\delta_2\widehat{\mathbf{u}},\,\nabla\times\widetilde{\boldsymbol{\sigma}}+\nabla\widetilde{q}+\delta_2\widetilde{\mathbf{u}}\Big)_{-1}+\Big(\mathbf{g},\,\nabla\times\widetilde{\boldsymbol{\omega}}+\nabla\widetilde{p}+\widetilde{\boldsymbol{\theta}}\Big)_{-1}.
\end{aligned}
\tag{5.12}
$$

Then, as in (4.16), we have that the unique minimizer of the least-squares functional (5.10) can be characterized as being the solution of the problem: Find $\{\mathbf{u},\boldsymbol{\omega},p\}\in\mathbf{H}_0^1(\Omega)\times\mathbf{L}^2(\Omega)\times L_0^2(\Omega)$, $\boldsymbol{\theta}\in\mathbf{L}^2(\Omega)$, and $\{\mathbf{v},\boldsymbol{\sigma},q\}\in\mathbf{H}_0^1(\Omega)\times\mathbf{L}^2(\Omega)\times L_0^2(\Omega)$ such that

$$
\begin{aligned}
&B\big(\{\mathbf{u},\boldsymbol{\omega},p\},\boldsymbol{\theta},\{\mathbf{v},\boldsymbol{\sigma},q\};\{\widetilde{\mathbf{u}},\widetilde{\boldsymbol{\omega}},\widetilde{p}\},\widetilde{\boldsymbol{\theta}},\{\widetilde{\mathbf{v}},\widetilde{\boldsymbol{\sigma}},\widetilde{q}\}\big)=F\big(\{\widetilde{\mathbf{u}},\widetilde{\boldsymbol{\omega}},\widetilde{p}\},\widetilde{\boldsymbol{\theta}},\{\widetilde{\mathbf{v}},\widetilde{\boldsymbol{\sigma}},\widetilde{q}\};\widehat{\mathbf{u}},\mathbf{g}\big)\\
&\qquad \forall\,\{\widetilde{\mathbf{u}},\widetilde{\boldsymbol{\omega}},\widetilde{p}\}\in\mathbf{H}_0^1(\Omega)\times\mathbf{L}^2(\Omega)\times L_0^2(\Omega),\ \ \widetilde{\boldsymbol{\theta}}\in\mathbf{L}^2(\Omega),\\
&\qquad\qquad \{\widetilde{\mathbf{v}},\widetilde{\boldsymbol{\sigma}},\widetilde{q}\}\in\mathbf{H}_0^1(\Omega)\times\mathbf{L}^2(\Omega)\times L_0^2(\Omega).
\end{aligned}
\tag{5.13}
$$

To define least-squares finite element approximations of the optimization problems, we first choose conforming finite element subspaces $\mathbf{V}^h\subset\mathbf{H}_0^1(\Omega)$, $\mathbf{W}^h\subset\mathbf{L}^2(\Omega)$, $S^h\subset L_0^2(\Omega)$, and $\mathbf{T}^h\subset\mathbf{L}^2(\Omega)$. We then minimize the functional in (5.10) over the subspaces or, equivalently, solve the problem: Find $\{\mathbf{u}^h,\boldsymbol{\omega}^h,p^h\}\in\mathbf{V}^h\times\mathbf{W}^h\times S^h$,

$\boldsymbol{\theta}^h \in \mathbf{T}^h$, and $\{\mathbf{v}^h, \boldsymbol{\sigma}^h, q^h\} \in \mathbf{V}^h \times \mathbf{W}^h \times S^h$ such that

$$\begin{aligned}
&B\big(\{\mathbf{u}^h, \boldsymbol{\omega}^h, p^h\}, \boldsymbol{\theta}^h, \{\mathbf{v}^h, \boldsymbol{\sigma}^h, q^h\}; \{\widetilde{\mathbf{u}}^h, \widetilde{\boldsymbol{\omega}}^h, \widetilde{p}^h\}, \widetilde{\boldsymbol{\theta}}^h, \{\widetilde{\mathbf{v}}^h, \widetilde{\boldsymbol{\sigma}}^h, \widetilde{q}^h\}\big) \\
&\qquad = F\big(\{\widetilde{\mathbf{u}}^h, \widetilde{\boldsymbol{\omega}}^h, \widetilde{p}^h\}, \widetilde{\boldsymbol{\theta}}^h, \{\widetilde{\mathbf{v}}^h, \widetilde{\boldsymbol{\sigma}}^h, \widetilde{q}^h\}; \widehat{\mathbf{u}}, \mathbf{g}\big) \\
&\qquad\qquad \forall\, \{\widetilde{\mathbf{u}}^h, \widetilde{\boldsymbol{\omega}}^h, \widetilde{p}\}^h \in \mathbf{V}^h \times \mathbf{W}^h \times S^h,\ \ \widetilde{\boldsymbol{\theta}}^h \in \mathbf{T}^h, \\
&\qquad\qquad\quad \{\widetilde{\mathbf{v}}^h, \widetilde{\boldsymbol{\sigma}}^h, \widetilde{q}^h\} \in \mathbf{V}^h \times \mathbf{W}^h \times S^h.
\end{aligned} \tag{5.14}$$

Proposition 5.1 and the results of section 4 allow us to prove the following results.

THEOREM 5.6. *Let $\Phi = \Lambda = \mathbf{H}_0^1(\Omega) \times \mathbf{L}^2(\Omega) \times L_0^2(\Omega)$, and let $\Theta = \mathbf{L}^2(\Omega)$. Then,*

(i) *the bilinear form $B(\cdot;\cdot)$ defined in* (5.11) *is symmetric, continuous, and coercive on $\{\Phi \times \Theta \times \Lambda\} \times \{\Phi \times \Theta \times \Lambda\}$.*

Let $\widehat{\mathbf{u}} \in \mathbf{L}^2(\Omega)$ and $\mathbf{g} \in \mathbf{H}^{-1}(\Omega)$ be given. Then

(ii) *the linear functional $F(\cdot)$ defined in* (5.12) *is continuous on $\{\Phi \times \Theta \times \Lambda\}$;*

(iii) *the problem* (5.13) *has a unique solution $(\{\mathbf{u}, \boldsymbol{\omega}, p\}, \boldsymbol{\theta}, \{\mathbf{v}, \boldsymbol{\sigma}, q\}) \in \Phi \times \Theta \times \Lambda$.*

Let $\mathbf{V}^h \subset \mathbf{H}_0^1(\Omega)$, $\mathbf{W}^h \subset \mathbf{L}^2(\Omega)$, $S^h \subset L_0^2(\Omega)$, and $\mathbf{T}^h \subset \mathbf{L}^2(\Omega)$, and let $\Phi^h = \Lambda^h = \mathbf{V}^h \times \mathbf{W}^h \times S^h$ and $\Theta^h = \mathbf{T}^h$. Then,

(iv) *the discrete problem* (5.13) *has a unique solution $(\{\mathbf{u}^h, \boldsymbol{\omega}^h, p^h\}, \boldsymbol{\theta}^h, \{\mathbf{v}^h, \boldsymbol{\sigma}^h, q^h\}) \in \Phi^h \times \Theta^h \times \Lambda^h$;*

(v) *we have the error estimate*

$$\begin{aligned}
&\|\mathbf{u} - \mathbf{u}^h\|_1 + \|\boldsymbol{\omega} - \boldsymbol{\omega}^h\|_0 + \|p - p^h\|_0 + \|\boldsymbol{\theta} - \boldsymbol{\theta}^h\|_0 \\
&\qquad + \|\mathbf{v} - \mathbf{v}^h\|_1 + \|\boldsymbol{\sigma} - \boldsymbol{\sigma}^h\|_0 + \|q - q^h\|_0 \\
&\le C\Big(\inf_{\widetilde{\mathbf{u}}^h \in \mathbf{V}^h} \|\mathbf{u} - \widetilde{\mathbf{u}}^h\|_1 + \inf_{\widetilde{\boldsymbol{\omega}}^h \in \mathbf{W}^h} \|\boldsymbol{\omega} - \widetilde{\boldsymbol{\omega}}^h\|_0 + \inf_{\widetilde{p}^h \in S^h} \|p - \widetilde{p}^h\|_0 \\
&\qquad + \inf_{\widetilde{\boldsymbol{\theta}}^h \in \mathbf{T}^h} \|\boldsymbol{\theta} - \widetilde{\boldsymbol{\theta}}^h\|_0 + \inf_{\widetilde{\mathbf{v}}^h \in \mathbf{V}^h} \|\mathbf{v} - \widetilde{\mathbf{v}}^h\|_1 \\
&\qquad + \inf_{\widetilde{\boldsymbol{\sigma}}^h \in \mathbf{W}^h} \|\boldsymbol{\sigma} - \widetilde{\boldsymbol{\sigma}}^h\|_0 + \inf_{\widetilde{q}^h \in S^h} \|q - \widetilde{q}^h\|_0 \Big).
\end{aligned} \tag{5.15}$$

Proof. The results follow in a straightforward manner from Proposition 5.1 along with Lemma 4.2, Proposition 4.4, and Theorem 4.6. □

Remark 5.7. Following Remark 4.8, the discrete problem (5.13) is equivalent to a linear algebraic system having a symmetric, positive definite coefficient matrix. In the case of a Galerkin discretization of the optimality system, the coefficient matrix is indefinite.

Remark 5.8. Following Remark 4.9, the results in Theorem 5.6 about the solution of the discrete problem (5.13) follow merely from the conformity of the finite element subspaces, i.e., merely from the inclusions $\mathbf{V}^h \subset \mathbf{H}_0^1(\Omega)$, $\mathbf{W}^h \subset \mathbf{L}^2(\Omega)$, $S^h \subset L_0^2(\Omega)$, and $\mathbf{T}^h \subset \mathbf{L}^2(\Omega)$. In particular, unlike the case of Galerkin finite element discretizations of the optimality system, they do not require that the finite element spaces satisfy additional conditions such as (5.9); see Remark 5.4. In particular, in (5.13), one can choose the same degree piecewise polynomials defined with respect to the same grid for all variables.

Remark 5.9. The discrete problem (5.13) is a rather formidable one in that it involves many unknowns, i.e., 10 scalar fields in two dimensions and 17 scalar fields in three dimensions. However, following Remark 4.10, the discrete problem (5.13) can be efficiently uncoupled, more so than is the case for Galerkin finite element discretizations of optimality systems.

Remark 5.10. A practical Galerkin finite element discretization of the optimality system can use a formulation in terms of the operators defined in (5.8) while the least-squares based discretization employs a formulation in terms of the operators defined in (5.7). Thus, the latter approach involves more unknowns compared to the former that involves 8 scalar fields in two dimensions and 11 scalar fields in three dimensions. This apparent disadvantage of the least-squares approach should be balanced against the advantages discussed in Remarks 5.7, 5.8, and 5.9.

Remark 5.11. Suppose one chooses continuous, piecewise polynomial finite element spaces of degree r for the approximation of all variables; this is permissible for least-squares finite element methods; see Remark 5.8. Suppose also that the solution of the optimality system satisfies $\mathbf{u} \in \mathbf{H}^{r+1}(\Omega) \cap \mathbf{H}_0^1(\Omega)$, $\boldsymbol{\omega} \in \mathbf{H}^r(\Omega)$, $p \in H^r(\Omega) \cap L_0^2(\Omega)$, $\boldsymbol{\theta} \in \mathbf{H}^r(\Omega)$, $\mathbf{v} \in \mathbf{H}^{r+1}(\Omega) \cap \mathbf{H}_0^1(\Omega)$, $\boldsymbol{\sigma} \in \mathbf{H}^r(\Omega)$, and $q \in H^r(\Omega) \cap L_0^2(\Omega)$. Then, the error estimate (5.15) implies that

$$\begin{aligned} &\|\mathbf{u}-\mathbf{u}^h\|_1 + \|\boldsymbol{\omega}-\boldsymbol{\omega}^h\|_0 + \|p-p^h\|_0 + \|\boldsymbol{\theta}-\boldsymbol{\theta}^h\|_0 \\ &\qquad\qquad + \|\mathbf{v}-\mathbf{v}^h\|_1 + \|\boldsymbol{\sigma}-\boldsymbol{\sigma}^h\|_0 + \|q-q^h\|_0 = O(h^r), \end{aligned} \tag{5.16}$$

where h is a measure of the grid size.

5.2.1. Circumventing the use of negative norms. The least-squares functional (5.10) makes use of the $\mathbf{H}^{-1}(\Omega)$ norm. As a result, both the bilinear from $B(\cdot;\cdot)$ and the linear functional $F(\cdot)$ appearing in least-squares finite element discretization (5.14) of the optimality system involve the $H^{-1}(\Omega)$ inner product $(\cdot,\cdot)_{-1}$. Computing the $H^{-1}(\Omega)$ inner product of two functions essentially requires the solution of a Poisson problem, i.e., for two functions $\omega, \sigma \in H^{-1}(\Omega)$, we can write

$$(\omega,\sigma)_{-1} = \int_\Omega \omega v \, d\Omega, \qquad \text{where} \qquad -\Delta v = \sigma \quad \text{in } \Omega \quad \text{and} \quad v = 0 \quad \text{on } \Gamma.$$

Having to solve a Poisson problem every time one has to evaluate the $H^{-1}(\Omega)$ inner product of two functions renders impractical the implementation of (5.14).

There is substantial temptation to avoid the appearance of negative norms in the least-squares finite element formulation by simply replacing the negative norm in (5.10) with the $\mathbf{L}^2(\Omega)$ norm, i.e., to base a least-squares finite element method on the functional

$$\begin{aligned} &\widetilde{\mathcal{K}}(\{\mathbf{u},\boldsymbol{\omega},p\},\boldsymbol{\theta},\{\mathbf{v},\boldsymbol{\sigma},q\};\widehat{\mathbf{u}},\mathbf{g}) \\ &\quad = \|\nabla\times\boldsymbol{\sigma} + \nabla q + \delta_2(\mathbf{u}-\widehat{\mathbf{u}})\|_0^2 + \|\nabla\times\mathbf{v} - \boldsymbol{\sigma} + \delta_1\boldsymbol{\omega}\|_0^2 + \|\nabla\cdot\mathbf{v}\|_0^2 \\ &\qquad + \|\delta\boldsymbol{\theta} + \mathbf{v}\|_0^2 + \|\nabla\times\boldsymbol{\omega} + \nabla p + \boldsymbol{\theta} - \mathbf{g}\|_0^2 + \|\nabla\times\mathbf{u} - \boldsymbol{\omega}\|_0^2 + \|\nabla\cdot\mathbf{u}\|_0^2 \end{aligned}$$

instead of the functional (5.10); note that now we would have to choose $\Phi = \Lambda = \mathbf{H}_0^1(\Omega) \times \mathbf{H}^1(\Omega) \times L_0^2(\Omega)$. Doing this would indeed lead to a discrete problem involving only easily implementable $L^2(\Omega)$ inner products. However, in this case, the norm-equivalence relation does not hold (see [6, 7]) so that the resulting bilinear form associated with the minimization of the functional $\widetilde{\mathcal{K}}$ is not coercive. As a result, the discrete problem will not have a (uniformly, as $h \to 0$) positive definite coefficient matrix, and the least-squares finite element approximations may not be stable and will certainly not be optimally accurate.

Another approach for avoiding the use of $H^{-1}(\Omega)$ inner products is to replace the velocity-vorticity-pressure formulation (5.4) of the Stokes problem with another first-order formulation whose residuals, when measured in $L^2(\Omega)$ norms, do result in a norm-equivalent functional. Such formulations, involving additional unknowns and redundant equations, were developed in [14, 15]. For example, if we use the velocity-velocity gradient-pressure formulation due to [14], we would employ the least-squares functional

$$\begin{aligned}
&\widehat{\mathcal{K}}\big(\{\mathbf{u},\mathbf{U},p\},\boldsymbol{\theta},\{\mathbf{v},\mathbf{V},q\};\widehat{\mathbf{u}},\mathbf{g}\big)\\
&\quad= \|\nabla\cdot\mathbf{V}+\nabla q+\delta_2(\mathbf{u}-\widehat{\mathbf{u}})\|_0^2+\|(\nabla\mathbf{v})^T-\mathbf{V}+\delta_1\boldsymbol{\omega}\|_0^2+\|\nabla\cdot\mathbf{v}\|_0^2\\
&\qquad\quad+\|\delta\boldsymbol{\theta}+\mathbf{v}\|_0^2+\|-\nabla\cdot\mathbf{U}+\nabla p+\boldsymbol{\theta}-\mathbf{g}\|_0^2+\|(\nabla\mathbf{u})^T-\mathbf{U}\|_0^2+\|\nabla\cdot\mathbf{u}\|_0^2\\
&\qquad\quad+\|\nabla(\mathrm{Tr}\mathbf{V})\|_0^2+\|\nabla\times\mathbf{V}\|_0^2+\|\nabla(\mathrm{Tr}\mathbf{U})\|_0^2+\|\nabla\times\mathbf{U}\|_0^2,
\end{aligned}$$

where $(\cdot)^T$ and $\mathrm{Tr}(\cdot)$ denote the transpose and the trace of a tensor and where the components of $\boldsymbol{\omega}$ can be easily expressed as linear combinations of the off-diagonal elements of the tensor $\mathbf{U}$. Instead of the vorticity $\boldsymbol{\omega}=\nabla\times\mathbf{u}$ and adjoint vorticity $\boldsymbol{\sigma}=\nabla\times\mathbf{v}$, the new variables introduced to effect the first-order formulation are $\mathbf{U}=(\nabla\mathbf{u})^T$ and $\mathbf{V}=(\nabla\mathbf{v})^T$. Also, now we have that $\Phi=\Lambda=\mathbf{H}_0^1(\Omega)\times Q\times L_0^2(\Omega)$, where $Q=\{\mathbf{V}\in[H^1(\Omega)]^9 \mid \mathbf{V}\times\mathbf{n}=0\}$. The equations whose residuals appear in the last line of the definition of $\widehat{\mathcal{K}}$ are all redundant in the sense that they are all already implied by the other equations. Note that now we have even more unknowns than that for the velocity-vorticity-pressure; e.g., in three dimensions, the least-squares discrete problem resulting from minimizing the functional $\widehat{\mathcal{K}}$ would now involve 27 scalar fields. Furthermore, the addition of redundant equations requires more regular data and solutions and precludes the use of the least-squares methodology in, e.g., nonconvex polygonal domains.

A third and more practical approach to avoiding the use of $H^{-1}(\Omega)$ inner products is to replace the functional (5.10) by the mesh-weighted functional

$$\begin{aligned}
&\widetilde{\mathcal{K}}_h\big(\{\mathbf{u},\boldsymbol{\omega},p\},\boldsymbol{\theta},\{\mathbf{v},\boldsymbol{\sigma},q\};\widehat{\mathbf{u}},\mathbf{g}\big)\\
&\quad= h^2\|\nabla\times\boldsymbol{\sigma}+\nabla q+\delta_2(\mathbf{u}-\widehat{\mathbf{u}})\|_0^2+\|\nabla\times\mathbf{v}-\boldsymbol{\sigma}+\delta_1\boldsymbol{\omega}\|_0^2+\|\nabla\cdot\mathbf{v}\|_0^2\\
&\qquad\quad+\|\delta\boldsymbol{\theta}+\mathbf{v}\|_0^2+h^2\|\nabla\times\boldsymbol{\omega}+\nabla p+\boldsymbol{\theta}-\mathbf{g}\|_0^2+\|\nabla\times\mathbf{u}-\boldsymbol{\omega}\|_0^2+\|\nabla\cdot\mathbf{u}\|_0^2.
\end{aligned}$$

This approach is motivated by the finite element inverse inequality $C\|\omega^h\|_0\le h^{-1}\|\omega^h\|_{-1}$ which leads to the norm "equivalence" $Ch\|\omega^h\|_0\le\|\omega^h\|_{-1}\le\|\omega^h\|_0$ between the $H^{-1}(\Omega)$ and $L^2(\Omega)$ norms of finite element functions. One can then show, using the analyses developed in [6], that one obtains an optimal convergence for the functional $\widetilde{\mathcal{K}}_h$, even though this functional is not norm-equivalent. One possible drawback of this approach is that the condition number of the resulting matrix may be too large for the practical use of some iterative solution techniques.

Perhaps the most practical approach to avoiding the use of $H^{-1}(\Omega)$ inner products is to replace the $H^{-1}(\Omega)$ norm terms in the functional (5.10) by more sophisticated "equivalent" discrete norms that involve only $L^2(\Omega)$ norms. Such ideas have been widely used in the least-squares finite element literature; see, e.g., [4, 10, 11]. As noted above, the computation of negative norms requires inversion of a Laplacian operator (with zero boundary conditions). It was shown in [10] that for finite element functions, it is equivalent to use the discrete minus one inner product

$$(\omega^h, \sigma^h)_h = \big((L^h + h^2 I)\omega^h, \sigma^h\big)_0\,,$$

where L^h is a discrete inverse Laplacian operator (with zero boundary conditions) that is spectrally equivalent to the inverse Laplacian operator itself. In practice, the computation of $L^h\omega^h$ for any finite element function ω^h is often implemented by using a few multigrid cycles, which makes its computation very efficient. The application of this approach in our context results in the minimization of the functional

$$\begin{aligned}&\overline{\mathcal{K}}_h\big(\{\mathbf{u}^h, \boldsymbol{\omega}^h, p^h\}, \boldsymbol{\theta}^h, \{\mathbf{v}^h, \boldsymbol{\sigma}^h, q^h\}; \widehat{\mathbf{u}}, \mathbf{g}\big)\\ &\quad = \|\nabla\times\boldsymbol{\sigma}^h + \nabla q^h + \delta_2(\mathbf{u}^h - \widehat{\mathbf{u}})\|_h^2 + \|\nabla\times\mathbf{v}^h - \boldsymbol{\sigma}^h + \delta_1\boldsymbol{\omega}^h\|_0^2 + \|\nabla\cdot\mathbf{v}^h\|_0^2\\ &\qquad + \|\delta\boldsymbol{\theta}^h + \mathbf{v}^h\|_0^2 + \|\nabla\times\boldsymbol{\omega}^h + \nabla p^h + \boldsymbol{\theta}^h - \mathbf{g}\|_h^2 + \|\nabla\times\mathbf{u}^h - \boldsymbol{\omega}^h\|_0^2 + \|\nabla\cdot\mathbf{u}^h\|_0^2,\end{aligned}$$

where $\|\omega^h\|_h^2 = ((L^h + h^2 I)\omega^h, \omega^h)_0$. Using the techniques of [4], it can be shown that this functional leads to a practical least-squares finite element method yielding positive definite coefficient matrices and an error estimate such as (5.16).

6. Concluding remarks.

Optimization and control problems governed by partial differential equations are most often solved by Lagrange multiplier techniques that lead to variational equations consisting of the state system, an adjoint-state system, and optimality conditions. Galerkin discretizations of such systems result in discrete problems that are not only formidable in size but are indefinite so that their iterative solution is difficult.

In this paper, we formulated a new approach for the finite element discretization of optimality systems that is based on the application of least-squares principles. The main advantage of this formulation is seen in the better possibilities that it affords for the uncoupling of the discrete optimality equations and their efficient iterative solution. Least-squares principles result in symmetric and positive definite algebraic systems. Moreover, for the optimization and control problems considered in this paper, these linear systems have a 3 × 3 block structure where the diagonal blocks themselves are symmetric and positive definite. As an example of a simple but convergent uncoupling strategy, we considered a block-Gauss–Seidel method. To illustrate the issues involved in the formulation of effective and practical least-squares methods, we considered two optimization problems for the Stokes equations.

LOCAL PROJECTION STABILIZATION FOR THE OSEEN PROBLEM AND ITS INTERPRETATION AS A VARIATIONAL MULTISCALE METHOD*

M. BRAACK† AND E. BURMAN‡

Abstract. We propose to apply the recently introduced local projection stabilization to the numerical computation of the Oseen equation at high Reynolds number. The discretization is done by nested finite element spaces. Using a priori error estimation techniques, we prove the convergence of the method. The a priori estimates are independent of the local Peclet number and give a sufficient condition for the size of the stabilization parameters in order to ensure optimality of the approximation when the exact solution is smooth. Moreover, we show how this method may be cast in the framework of variational multiscale methods. We indicate what modeling assumptions must be made to use the method for large eddy simulations.

Key words. stabilized finite elements, Galerkin methods, multiscale

1. Introduction.

In this paper, we advocate the use of the two-level stabilization scheme (see Becker and Braack [3]) for the computation of solutions of the Navier–Stokes equations at high Reynolds number. This is one in a group of more recently developed stabilized methods, such as, for instance, Guermond [14], Becker and Braack [2], Burman and Hansbo [5, 6], and Rebollo and Delgado [18].

A main advantage of this approach is that it shares similar conservation properties with a standard Galerkin finite element method. Moreover, one does not need to resort to space-time finite elements for time stepping in order to stay consistent but can apply any higher-order finite difference scheme for the discretization in time. We prove optimal order a priori error estimates for the method. The method remains stable independent of the local Reynolds number. It should be noted that the method is not residual based in the way the streamline upwind Petrov–Galerkin (SUPG) method is, but is flexible with respect to the subgrid model, thus leaving open the possibility of subgrid models that are more complex than the linear one considered here. Of course, the possibility of using Galerkin least-squares (GLS) or residual-free bubbles as a subgrid model remains and will be discussed.

An attractive feature of this method is that it can be cast in the framework of the variational multiscale (VMS) method of [15] as we shall show. The stabilization is acting only on the smallest resolved scales of the flow. Hence, contrary to the method of [15], our large scales do not need any additional stabilization. In fact, the fine scale

fluctuations allow for both the satisfaction of the inf-sup condition and stabilization of the convective terms.

We begin in section 2 with the variational formulation of the Oseen equations and their discretization by finite elements in space. The local projection stabilization for the Oseen system is formulated in section 3. Afterwards, an a priori error analysis is presented in section 4. There we consider the case of smooth solutions (velocities and pressure are both in the Sobolev space $H^2(\Omega)$) and discuss the behavior of the method for less regular solutions. We present some variants of the stabilization operator and discuss the relation to more standard stabilization techniques in section 5. An interpretation of the stabilization in terms of a VMS method is given in section 6. In a numerical test case, discussed in section 7, we investigate the convergence order for a given exact Navier–Stokes solution and compare the kinetic energy of a nonstationary driven cavity flow with the numerical dissipation. We finish with a short conclusion in section 8. In forthcoming work we will give numerical evidence of the performance of the numerical scheme for turbulent flow in three space dimensions.

2. Variational formulation of the Oseen system.

Let $\Omega \subset \mathbb{R}^d$, $d \in \{2, 3\}$, be a polygonal domain with boundary $\partial\Omega$. The velocities will be denoted by $v = v(x, t)$ and the pressure by $p = p(x, t)$. The gradient in space is denoted by ∇, and the divergence with respect to space is denoted by div. The Navier–Stokes equations read

$$\left.\begin{array}{rcl} \partial_t v + \operatorname{div}(v \otimes v) - \mu\Delta v + \nabla p &=& f, \\ \operatorname{div} v &=& 0 \end{array}\right\} \quad \text{in } \Omega, \tag{2.1}$$

subject to some initial condition $v(\cdot, 0) = v_0$ and suitable boundary conditions for v.

In the analysis, we will consider the Oseen system as an important linearization of (2.1). For ease of presentation, we suppose homogeneous Dirichlet boundary conditions:

$$\left.\begin{array}{rcll} \sigma\, v + \operatorname{div}(\beta \otimes v) - \mu\Delta v + \nabla p &=& f & \text{in } \Omega, \\ \operatorname{div} v &=& 0 & \text{in } \Omega, \\ v &=& 0 & \text{on } \partial\Omega, \end{array}\right\} \tag{2.2}$$

with some given solenoidal vector field β and $\sigma > 0$.

For the variational formulation we use the notation $(\cdot, \cdot)$ for the L^2-scalar product over Ω. The velocity is sought in the Sobolev space $V := [H_0^1(\Omega)]^d$, and the pressure is sought in the space of square-integrable functions with zero mean, $Q := L_0^2(\Omega)$. The product space for the vector $u = \{v, p\}$ is denoted by $X := V \times Q$.

We introduce the bilinear form $A(u, \varphi)$ defined by

$$A(u, \varphi) := (\sigma v, \psi) - (\beta \otimes v, \nabla\psi) - (p, \operatorname{div}\psi) + (\operatorname{div} v, \xi) + (\mu\nabla v, \nabla\psi),$$

and consider f as an element of X' defined by $\langle f, \varphi\rangle := (f, \psi)$ for a test function $\varphi = \{\psi, \xi\} \in X$. The variational formulation of the Oseen problem (2.2) reads

$$u \in X : \quad A(u, \varphi) = \langle f, \varphi\rangle \quad \forall \varphi \in X. \tag{2.3}$$

In order to solve this problem numerically we choose in the following section a finite dimensional subspace, $X_h \subset X$.

2.1. Discrete Galerkin formulation.

We consider shape regular meshes $\mathcal{T}_h = \{K\}$ of hexahedral elements K with the minimum mesh size $h = \min\{h_K : K \in \mathcal{T}_h\}$

(quadrilateral elements for the academical case $d = 2$). The finite element spaces Q_h^r result from isoparametric transformations of polynomials on a reference cell $\hat{K}$:

$$Q_h^r(\Omega, \mathbb{R}) := \{\varphi \in C(\Omega, \mathbb{R}) : \varphi|_K = \hat{\varphi} \circ T_K^{-1}\},$$

where $\hat{\varphi}$ denotes an arbitrary polynomial of maximal degree r on the reference cell $\hat{K}$, and $T_K : \hat{K} \to K$ denotes a polynomial transformation of the same type and degree r. We will treat (bi-/tri-)linear elements ($r = 1$) and (bi-/tri-)quadratic elements ($r = 2$) simultaneously in the analysis. These finite element spaces will simply be called Q_1 in the case of $r = 1$ and Q_2 elements in the case $r = 2$. The discrete pressure space Q_h is the subspace of Q_h^r with zero mean, and the velocity space V_h is the subspace with vanishing trace:

$$Q_h := Q \cap Q_h^r(\Omega, \mathbb{R}), \quad V_h := V \cap [Q_h^r(\Omega, \mathbb{R}^d)]^d.$$

The product space is denoted by X_h:

$$X_h := V_h \times Q_h.$$

In the Galerkin formulation of (2.3) for the space X_h, a discrete solution $u_h \in X_h$ is sought such that

$$A(u_h, \varphi) = \langle f, \varphi \rangle \quad \forall \varphi \in X_h.$$

This formulation is not stable due to the following reasons: (i) violation of the discrete inf-sup (or Babuska–Brezzi) condition for velocity and pressure approximation and (ii) dominating advection (and reaction). Therefore, in the following we present and analyze a stabilization technique based on local projection.

3. Definition of the local projection stabilization. The two-level finite element formulation is as follows: find $u_h \in X_h$ such that

$$A(u_h, \varphi) + S_h(u_h, \varphi) = \langle f, \varphi \rangle \quad \forall \varphi \in X_h. \tag{3.1}$$

In order to specify the stabilization term $S_h(\cdot, \cdot)$, we have to introduce further notations. The discontinuous analogue of Q_h^r is denoted by $Q_{h,disc}^r$:

$$Q_{h,disc}^r(\Omega, \mathbb{R}) := \{\varphi \in L^2(\Omega, \mathbb{R}) : \varphi|_K = \hat{\varphi} \circ T_K^{-1}\}.$$

Furthermore, let $\mathcal{T}_{2h}$ be the coarser mesh obtained by a "global coarsening" of $\mathcal{T}_h$. Obviously, the finer mesh $\mathcal{T}_h$ contains 2^d times more elements than $\mathcal{T}_{2h}$. The corresponding finite element spaces are denoted by $Q_{2h} \subset Q_h$ and $V_{2h} \subset V_h$. Let D_h^v and D_h^p be the following space for pressure and velocities, respectively, of functions allowing discontinuities across elements of $\mathcal{T}_{2h}$:

$$\begin{aligned} D_h^v &:= [Q_{2h,disc}^{r-1}(\Omega, \mathbb{R})]^d, \\ D_h^p &:= Q_{2h,disc}^{r-1}(\Omega, \mathbb{R}). \end{aligned}$$

In the case $r = 1$, these spaces contain patchwise ($K \in V_{2h}$) constants; for $r = 2$, they contain patchwise linear elements. We will make use of the L^2-projection operator

$$\bar{\pi}_h : L^2(\Omega) \to D_h^p,$$

characterized by the property

$$(v - \bar{\pi}_h v, \phi) = 0 \quad \forall \phi \in D_h^p.$$

The operator giving the space fluctuations is denoted by

$$\bar{\varkappa}_h := i - \bar{\pi}_h,$$

with the identity mapping i. We use the same notation $\bar{\pi}_h$, $\bar{\varkappa}_h$ for the mappings on vector-valued functions, for instance, $\bar{\pi}_h : L^2(\Omega)^d \to D_h^v$.

The subgrid model is given by

$$S_h(u, \varphi) := (\delta \bar{\varkappa}_h \nabla v, \bar{\varkappa}_h \nabla \psi) + (\alpha \bar{\varkappa}_h \nabla p, \bar{\varkappa}_h \nabla \xi). \tag{3.2}$$

The parameters α and δ are taken patchwise constant and depend on the local mesh size. The optimal choice of these stabilization parameters will be a result of the following analysis.

We like to end this section with a brief discussion on the numerical costs of the scheme compared to more standard stabilized schemes. Compared to the standard Galerkin formulation, the subgrid models (3.2) lead to a larger stencil in the stiffness matrix due to the projection $\bar{\varkappa}_h$. However, no couplings between pressure and velocities are introduced. Furthermore, a cheaper preconditioner may be used with a smaller stencil as proposed and analyzed for the Stokes system in [2].

4. A priori error analysis.

To tune the stabilization parameters α and δ we use a priori error estimation. Assuming sufficient regularity of the underlying solution, the parameters are chosen in such a way that the method has optimal convergence properties independent of the viscosity. We will prove under the assumption of sufficiently regular pressure and velocity $v \in [H_0^2(\Omega)]^3$, $p \in H^2(\Omega) \cap L_0^2(\Omega)$, that a certain scaling of α and δ gives optimal convergence of the velocities independent of the Reynolds number. A similar result is then proved for the L^2-norm of the pressure. We consider only the interesting case of high Reynolds number, hence assuming that $\mu \leq |\beta| h$. First we prove an estimate for a mesh-dependent norm including the H^1-norm of the velocities and a "subgrid model" error:

$$|\!|\!| u |\!|\!| = |\!|\!| \{v, p\} |\!|\!| := \Big(\|\sigma^{1/2} v\|^2 + \|\mu^{1/2} \nabla v\|^2 + S_h(u, u) \Big)^{1/2},$$

where $\|\cdot\|$ stands for the L^2-norm in Ω. We then use this estimate to recover control of the pressure and show that the L^2-norm error of the pressure is bounded by the mesh-dependent norm of the error of the state vector u_h.

4.1. Properties of the subgrid model.

By the following coercivity result we deduce existence and uniqueness of the discrete velocities.

Lemma 4.1. *We have the coercivity property*

$$|\!|\!| u |\!|\!|^2 = A(u, u) + S_h(u, u) \quad \forall u \in X. \tag{4.1}$$

Proof. The proof follows immediately by integration by parts. □

We have the following approximate Galerkin orthogonality.

Lemma 4.2. *Let $u \in X$ be the solution of the weak formulation of* (2.2) *and let $u_h \in X_h$ be the solution of its discrete version* (3.1). *Then it holds that*

$$A(u - u_h, \varphi) = S_h(u_h, \varphi), \quad \varphi \in X_h.$$

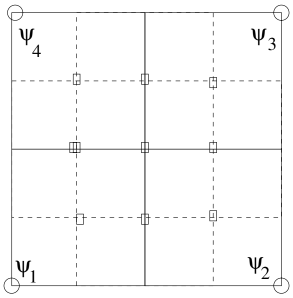

FIG. 4.1. *A patch K of four Q_2 cells in two dimensions with the linears ψ_i used in the proof of Lemmas* 4.4 *and* 4.5.

Proof. The proof is obtained by subtracting (3.1) from the weak formulation of (2.2). □

Since the method is not strongly consistent in the sense that we do not have full Galerkin orthogonality, we must analyze the asymptotic behavior of the subgrid model, i.e., the dependence with respect to the mesh size h. We first prove a result for a modified Clément interpolation operator introduced in [2], here with a generalization to P_2 elements, and use this approximation result to show the asymptotic behavior of the stabilization term.

In the next lemma, we consider for a cell $K \in \mathcal{T}_{2h}$, the space of functions in Q_h with support in K. This space will be denoted by $Q_h(K)$ and has the dimension $(2r-1)^d$. Analogously, the subspace of D_h^p consisting of functions with support in K will be denoted by $D_h^p(K)$. This space has the dimension r^d. For $r = 1$, this space consists only of the patchwise constants. For $r = 2$, a possible basis of these subspaces is indicated in Figure 4.1.

LEMMA 4.3. *The local L^2-orthogonal projection $\pi_K : D_h^p(K) \to Q_h(K)$, characterized for $\psi \in D_h^p(K)$ by the property*

$$(\pi_K\psi, \phi) = (\psi, \phi) \quad \forall \phi \in Q_h(K),$$

is injective.

Proof. We assume $\pi_K\psi = 0$ for $\psi \in D_h^p(K)$. Then $(\psi, \phi) = 0$ for all $\phi \in Q_h(K)$ due to the orthogonality property. In the case $r = 1$, $D_h^p(K)$ consists of constant functions, so that either $\psi = 0$ or $\int_K \phi = 0$ for all $\phi \in Q_h(K)$. Since the latter is not valid (for instance, taking the Lagrange nodal basis function associated to the interior node of K), it follows $\psi = 0$. For $r = 2$, we take as $\phi_i \in Q_h(K)$, $i = 1, \dots, 2^d$, the Lagrange nodal functions associated to the center nodes of the child cells K_i. Since these ϕ_i have a sign, ψ must have zeros in the interior of all child cells K_i, $i = 1, \dots, 2^d$. For a d-linear ψ this is possible only if $\psi = 0$. □

LEMMA 4.4. *Let $\{\psi_1, \dots, \psi_{r^d}\}$ be an arbitrary basis of $D_h^p(K)$. Then the matrix $M = (m_{ij})$, $i, j \in \{1, \dots, r^d\}$, with entries*

$$m_{ij} = (\psi_i, \pi_K\psi_j)_K,$$

is symmetric and positive definite.

Proof. Since $\pi_K\psi_j \in Q_h(K)$, it follows due to the orthogonality property of the L^2-projection that

$$m_{ij} = (\psi_i, \pi_K\psi_j) = (\pi_K\psi_i, \pi_K\psi_j).$$

It follows that M is symmetric. Furthermore, for $\alpha \in \mathbb{R}^{r^d}$ and $\psi_\alpha = \sum \alpha_i \psi_i$ it holds that

$$\begin{aligned} \alpha^T M \alpha &= (\psi_\alpha, \pi_K \psi_\alpha)_K \\ &= (\pi_K \psi_\alpha, \pi_K \psi_\alpha)_K \\ &= \|\pi_K \psi_\alpha\|_K^2. \end{aligned}$$

Since π_K is injective, M is positive definite. □

Remark. The analogous results are valid for vector-valued projections $\pi_K : D_h^v(K) \to V_h(K)$, where $D_h^v(K) \subset D_h^v$ and $V_h(K) \subset V_h$ are defined analogously as $D_h^p(K)$ and $Q_h(K)$, respectively.

In the following, the norm in $H^s(\Omega)$ will be denoted by $\|\cdot\|_s$. The corresponding norms in subsets $K \subset \Omega$ will be denoted by $\|\cdot\|_{s,K}$. Furthermore, we use the notation $\lesssim$ to indicate that there may arise mesh-independent constants in the estimates.

LEMMA 4.5. *There is an interpolation operator*

$$j_h : V \to V_h$$

with the orthogonality property

$$(v - j_h v, \psi) = 0 \quad \forall \psi \in D_h^v, \forall v \in V, \tag{4.2}$$

that has optimal approximation properties in the L^2-norm and H^1-seminorm

$$\|v - j_h v\| \lesssim h^l \|v\|_l \quad \forall v \in [H^l(\Omega)]^d,\ 0 \le l \le r+1, \tag{4.3}$$

$$\|\nabla(v - j_h v)\| \lesssim h^{l-1} \|v\|_l \quad \forall v \in [H^l(\Omega)]^d,\ 0 \le l \le r+1, \tag{4.4}$$

with $r \in \{1, 2\}$, and is H^1-stable:

$$\|j_h v\|_1 \lesssim \|v\|_1 \quad \forall v \in [H^1(\Omega)]^d. \tag{4.5}$$

Proof. The construction uses the Scott and Zhang variant of the Clément interpolation operator $j_h^{Cl} : V \to V_h$ (see [19] and Clément [8]), which already fulfills the approximation properties (4.3) and (4.4), maintains homogeneous Dirichlet values, and has the stability property (4.5). In order to ensure (4.2), we define j_h in the form

$$j_h = j_h^{Cl} + m_h,$$

with a local projection $m_h : V \to \tilde{V}_h$ onto the subspace

$$\tilde{V}_h := \bigoplus_{K \in \mathcal{T}_{2h}} V_h(K) \subset V_h.$$

In order to fulfill (4.2) this mapping must satisfy

$$(m_h v, \psi) = (v - j_h^{Cl} v, \psi), \quad \forall \psi \in D_h^v(K), \forall K \in \mathcal{T}_{2h}. \tag{4.6}$$

If we take a basis $\psi_{K,i}$ of $D_h^v(K)$, $m_h v$ can be expressed on each patch $K \in \mathcal{T}_{2h}$ as a linear combination of the $\pi_K \psi_{K,i}$. Hence property (4.6) is equivalent to solving for each K the linear system $M\alpha = \beta$, with the regular matrix M of Lemma 4.4 and the right-hand side β with coefficients

$$\beta_i = (v - j_h^{Cl} v, \psi_{K,i})_K.$$

Hence, j_h is well defined. In order to prove the approximation property in the L^2-norm (4.3) we will show that

$$\|m_h v\|_K \lesssim \|v - j_h^{Cl} v\|_K, \tag{4.7}$$

because due to (4.7) it follows:

$$\begin{aligned} \|v - j_h v\| &= \|v - j_h^{Cl} v + m_h v\| \\ &\le \|v - j_h^{Cl} v\| + \|m_h v\| \\ &\lesssim \|v - j_h^{Cl} v\|. \end{aligned}$$

Let us verify (4.7): The (v-dependent) solution vector α contains the coefficients of $m_h v$ in the basis $\pi_K \psi_{K,i}$. Similarly, the projection of $m_h v$ onto the vectors $\psi_{K,i}$ can be expressed as a linear combination of the $\psi_{K,i}$ with coefficients $\bar\alpha_{K,i}$:

$$\bar\pi_h m_h v = \sum_{i=1}^{r^d} \bar\alpha_{K,i} \psi_{K,i}.$$

Now, the equality

$$(\bar\pi_h m_h v, \psi_{K,i})_K = (m_h v, \psi_{K,i})_K, \quad i = 1, \dots, r^d, \tag{4.8}$$

can be written with the help of the matrix $N = (n_{ij})$ with coefficients $n_{ij} = (\psi_{K,i}, \psi_{K,j})$:

$$N\bar\alpha = M\alpha.$$

The local mass matrix N is symmetric and positive definite as well. It then follows that

$$\begin{aligned} \lambda_{min}(M)\, \|m_h v\|_K^2 &\le (M\alpha)^T \cdot M\alpha \\ &= (N\bar\alpha)^T N\bar\alpha \\ &\le \lambda_{max}(N)\, \|\bar\pi_h m_h v\|_K^2. \end{aligned}$$

We conclude that there holds on each patch $K \in \mathcal{T}_{2h}$

$$\|m_h v\|_K^2 \lesssim \|\bar\pi_h m_h v\|_K^2 = (m_h v, \bar\pi_h(m_h v))_K, \tag{4.9}$$

where the constant is independent of the mesh size. We estimate on each patch $K \in \mathcal{T}_{2h}$ due to (4.9):

$$\begin{aligned} \|m_h v\|_K^2 &\lesssim \int_K (v - j_h^{Cl} v) \bar\pi_h m_h v \, dx \\ &\le \|v - j_h^{Cl} v\|_K \, \|\bar\pi_h m_h v\|_K \\ &\lesssim \|v - j_h^{Cl} v\|_K \, \|m_h v\|_K, \end{aligned}$$

where we used the L^2-stability of $\bar\pi_h$ in the last inequality. Thus (4.7) follows.

For proving (4.4) we proceed in a similar fashion by applying an inverse estimate:

$$\begin{aligned} \|\nabla m_h v\|^2 &\lesssim \sum_{K \in \mathcal{T}_h} h_K^{-2} \|m_h v\|_K^2 \\ &= \sum_{K \in \mathcal{T}_h} h_K^{-2} \|v - j_h^{Cl} v\|_K^2 \\ &\lesssim \sum_{K \in \mathcal{T}_h} h_K^{2(l-1)} \|v\|_{l,\widetilde{K}}^2 \\ &\lesssim h^{2(l-1)} \|v\|_l^2. \end{aligned}$$

The stability (4.5) follows also due to this last estimate, the stability of j_h^{CL}, and (4.7). □

Remark. The interpolation operator j_h^{Cl} maintains *homogeneous* Dirichlet conditions on (parts of) $\partial\Omega$. For polynomial Dirichlet conditions, the interpolation introduced by Melenk and Wohlmuth [16] can be used. The interpolation operator j_h acts on the velocity space, but the result holds true of course for the scalar space $L^2(\Omega)$. We will therefore use the notation j_h also for the interpolation operator acting on the state variable $u = \{v, p\}$.

In the following analysis, we make use of the interpolation and stability properties of $\bar{\varkappa}_h$.

LEMMA 4.6. *The fluctuation operator $\bar{\varkappa}_h$ has the following interpolation and stability properties:*

$$\|\bar{\varkappa}_h \nabla v\| \lesssim h^r \|v\|_{r+1} \quad \forall v \in H^{r+1}(\Omega), \tag{4.10}$$

$$\|\bar{\varkappa}_h v\| \lesssim \|v\| \qquad \forall v \in L^2(\Omega). \tag{4.11}$$

Proof. The interpolation property (4.10) is an immediate consequence of the patch-wise interpolation of $\bar{\pi}_h$ for the H^1 function $w := \nabla v$:

$$\|\bar{\varkappa}_h \nabla v\|_K = \|w - \bar{\pi}_h w\|_K \lesssim h_K^r \|w\|_{r,K} \le h_K^r \|v\|_{r+1,K} \quad \forall K \in \mathcal{T}_{2h}.$$

Stability of $\bar{\varkappa}_h$ is due to the L^2-stability of $\bar{\pi}_h$:

$$\|\bar{\varkappa}_h v\| \le \|v\| + \|\bar{\pi}_h v\| \lesssim \|v\|. \qquad \square$$

LEMMA 4.7. *For the interpolation operator j_h of Lemma* 4.5 *we have for all $u \in X \cap [H^{r+1}(\Omega)]^{d+1}$*

$$S_h(j_h u, j_h u)^{1/2} \lesssim (\delta^{1/2} + \alpha^{1/2}) h^r (\|v\|_{r+1} + \|p\|_{r+1}).$$

Proof. We start with adding and subtracting u:

$$\begin{aligned} S_h(j_h u, j_h u) &= S_h(u + j_h u - u, u + j_h u - u) \\ &\le S_h(u,u) + S_h(j_h u - u, j_h u - u) + 2 S_h(j_h u - u, u) \\ &\le 2(S_h(u,u) + S_h(j_h u - u, j_h u - u)). \end{aligned}$$

For the first term the result follows immediately by the interpolation property (4.10):

$$\begin{aligned} S_h(u,u) &\le \delta \|\bar{\varkappa}_h \nabla v\|^2 + \alpha \|\bar{\varkappa}_h \nabla p\|^2 \\ &\lesssim \delta h^{2r} \|v\|_{r+1}^2 + \alpha h^{2r} \|p\|_{r+1}^2. \end{aligned}$$

For the second term $S_h(j_h u - u, j_h u - u)$ we have

$$\begin{aligned} \delta \|\bar{\varkappa}_h \nabla (j_h v - v)\|^2 &\lesssim \delta \|\nabla (j_h v - v)\|^2 \\ &\lesssim \delta h^{2r} \|v\|_{r+1}^2, \end{aligned}$$

using the L^2-stability (4.11) of the local projector $\bar{\varkappa}_h$ and the interpolation property (4.4) of j_h. For the pressure contribution of course the same holds. □

4.2. A priori estimate for smooth velocities and pressure. In this subsection, we prove the following a priori estimate for the discrete solution of (3.1).

THEOREM 4.8. *If the solution $u = \{v, p\}$ of* (2.2) *satisfies $u \in [H^{r+1}(\Omega)]^{d+1}$, then we have the a priori estimate*

$$\|\!|u - u_h|\!\| \lesssim a h^{r+\frac{1}{2}} \left(\|v\|_{r+1} + \|p\|_{r+1}\right) \tag{4.12}$$

with

$$a = h^{-1/2}(\mu^{1/2} + \delta^{1/2} + \alpha^{1/2}) + h^{1/2}(\sigma^{1/2} + \delta^{-1/2} + \alpha^{-1/2}). \tag{4.13}$$

Before proceeding with the proof of this theorem, let us briefly comment on its interpretation. An immediate consequence of the inequality (4.12) is that for convection dominated flow, $\delta \sim h$ and $\alpha \sim h$ are the optimal choice of the parameters, yielding an h-independent constant a and the (optimal) convergence order of $h^{r+1/2}$. The positive powers of δ and α in (4.13) represent the dissipative character of the stabilization terms. It follows that too much dissipation will have a negative effect on the precision. The presence of $\delta^{-1/2}$ and $\alpha^{-1/2}$ in (4.13) is due to the stabilizing effect of the subgrid model: The dissipation of the small-scale energy into the unresolved scales avoids artificial energy concentrations on the small scales due to the conservation properties of the Galerkin method. As expected, precision deteriorates for small values of δ and α due to spurious oscillations.

Proof. In the standard fashion we decompose the error in $u - u_h = \eta + \xi$ into an interpolation part $\eta = u - j_h u$ and a projection part $\xi = j_h u - u_h$. Clearly, $\|\!|\eta|\!\| \leq C a h^{r+1/2}$ using the interpolation Lemma 4.5 and the asymptotic bound for the stabilization term of Lemma 4.7. Consider now the discrete error ξ. By coercivity (Lemma 4.1) and the Galerkin orthogonality property (Lemma 4.2) we have

$$\begin{aligned} \|\!|\xi|\!\|^2 &= A(\xi, \xi) + S_h(\xi, \xi) \\ &= A(\eta, \xi) + S_h(j_h u, \xi). \end{aligned}$$

The second term on the right-hand side is bounded by applying the Cauchy–Schwarz inequality followed by Lemma 4.7:

$$\begin{aligned} S_h(j_h u, \xi) &\leq S_h(j_h u, j_h u)^{1/2} S_h(\xi, \xi)^{1/2} \\ &\lesssim (\mu^{1/2} + \alpha^{1/2}) h^r (\|v\|_{r+1} + \|p\|_{r+1}) \|\!|\xi|\!\|. \end{aligned}$$

For the first term on the right-hand side we use the Cauchy–Schwarz inequality and integration by parts, writing ξ^p and ξ^v for the discrete pressure and the velocity error, respectively:

$$A(\eta, \xi) \leq \|\!|\eta|\!\| \, \|\!|\xi|\!\| - (p - j_h p, \operatorname{div} \xi^v) - (v - j_h v, \nabla \xi^p) - (\beta \otimes (v - j_h v), \nabla \xi^v). \tag{4.14}$$

We now use the orthogonality property of the quasi-interpolation operator to obtain upper bounds:

$$\begin{aligned} |(p - j_h p, \operatorname{div} \xi^v)| &= |(p - j_h p, \operatorname{div} \xi^v - \overline{\pi} \operatorname{div} \xi^v)| \\ &\leq \|\delta^{-1/2}(p - j_h p)\| \, \|\delta^{1/2}(\operatorname{div} \xi^v - \overline{\pi} \operatorname{div} \xi^v)\| \\ &\leq \|\delta^{-1/2}(p - j_h p)\| \, S_h(\xi, \xi)^{1/2}, \end{aligned}$$

$$\begin{aligned} |(v - j_h v, \nabla \xi^p)| &= (v - j_h v, \nabla \xi^p - \overline{\pi} \nabla \xi^p) \\ &\leq \|\alpha^{-1/2}(v - j_h v)\| \, \|\alpha^{1/2}(\nabla \xi^p - \overline{\pi} \nabla \xi^p)\| \\ &\leq \|\alpha^{-1/2}(v - j_h v)\| \, S_h(\xi, \xi)^{1/2}, \end{aligned}$$

$$\begin{aligned} |(\beta \otimes (v - j_h v), \nabla \xi^v)| &= |(v - j_h v, (\beta \cdot \nabla) \xi^v - \overline{\pi} (\beta \cdot \nabla) \xi^v)| \\ &\leq \|\delta^{-1/2}(v - j_h v)\| \, S_h(\xi, \xi)^{1/2}. \end{aligned}$$

In summary, we get

$$\begin{aligned}A(\eta,\xi) &\le |\!|\!|\eta|\!|\!|\,|\!|\!|\xi|\!|\!| + (\|\delta^{-1/2}(p-j_hp)\| + \|(\alpha^{-1/2}+\delta^{-1/2})(v-j_hv)\|)S_h(\xi,\xi)^{1/2}\\ &\le \big(|\!|\!|\eta|\!|\!| + \|\delta^{-1/2}(p-j_hp)\| + \|(\alpha^{-1/2}+\delta^{-1/2})(v-j_hv)\|\big)\,|\!|\!|\xi|\!|\!|.\end{aligned}$$

The assertion follows using interpolation properties (4.3) and (4.4) of the quasi interpolant j_h. □

We proceed and prove that the pressure also has optimal convergence properties in the L^2-norm.

LEMMA 4.9. *Let $u = \{v, p\}$ be the solution of* (2.2) *and let $u_h = \{v_h, p_h\}$ be the solution of* (3.1)*. Then there holds*

$$\|p - p_h\| \lesssim a|\!|\!|u - u_h|\!|\!|,$$

where $a = \sigma^{1/2} + |\beta|\sigma^{-1/2} + \mu^{1/2} + \delta^{1/2} + \alpha^{-1/2}h$.

Proof. Following [12], by the surjectivity of the divergence operator there exists $v_p \in [H_0^1(\Omega)]^d$ such that $p - p_h = \operatorname{div} v_p$ and $\|v_p\|_{1,\Omega} \lesssim \|p - p_h\|$. By the H^1-stability property of the quasi interpolant j_h we then have

$$\|j_hv_p\|_{1,\Omega} \lesssim \|p - p_h\|. \tag{4.15}$$

Consider now the equality $p - p_h = \operatorname{div} v_p$. This gives

$$\|p - p_h\|^2 = (p - p_h, \operatorname{div} v_p).$$

We now subtract j_hv_p from v_p in the right-hand side and use the Galerkin orthogonality property in Lemma 4.2 for the test function $\{j_hv_p, 0\}$:

$$\begin{aligned}\|p-p_h\|^2 = (p-p_h, \operatorname{div}(v_p - j_hv_p)) - (\mu\nabla(v-v_h), \nabla j_hv_p)\\ +(\sigma(v-v_h), j_hv_p) + (\beta\otimes(v-v_h), \nabla(j_hv_p)) - S_h(u-u_h, \{j_hv_p, 0\}).\end{aligned}$$

We estimate the resulting parts separately. For the first term we integrate by parts and use the orthogonality property (4.2) of the quasi-interpolation operator j_h to obtain

$$\begin{aligned}(p-p_h, \operatorname{div}(v_p - j_hv_p)) &= (\nabla(p-p_h), v_p - j_hv_p)\\ &= (\bar{\varkappa}_h\nabla(p-p_h), v_p - j_hv_p)\\ &\le S_h(\{0, p-p_h\}, \{0, p-p_h\})^{1/2}\|\alpha^{-1/2}(v_p - j_hv_p)\|\\ &\lesssim \alpha^{-1/2}h|\!|\!|u-u_h|\!|\!|\|v_p\|_1\\ &\lesssim \alpha^{-1/2}h|\!|\!|u-u_h|\!|\!|\,\|p-p_h\|,\end{aligned}$$

where we used the stability property of v_p in the last inequality. Furthermore, we have

$$\begin{aligned}&(\sigma(v-v_h), j_hv_p) + (\beta\otimes(v-v_h), \nabla(j_hv_p))\\ &= (\sigma(v-v_h), j_hv_p) - (v-v_h, (\beta\cdot\nabla)j_hv_p)\\ &\le (\sigma^{1/2} + |\beta|\sigma^{-1/2})|\!|\!|u-u_h|\!|\!|\,\|j_hv_p\|_1.\end{aligned}$$

Similarly we obtain, after application of the Cauchy–Schwarz inequality and (4.11),

$$\begin{aligned}&(\mu\nabla(v-v_h), \nabla j_hv_p) - S_h(u-u_h, \{j_hv_p, 0\})\\ &\le \|\mu^{1/2}\nabla(v-v_h)\|\|\mu^{1/2}\nabla j_hv_p\| + S_h(u-u_h, u-u_h)^{1/2}S_h(\{j_hv_p, 0\}, \{j_hv_p, 0\})^{1/2}\\ &\le |\!|\!|u-u_h|\!|\!|\,(\mu^{1/2}+\delta^{1/2})\|j_hv_p\|_1.\end{aligned}$$

Collecting terms and using (4.15) gives the assertion. □

COROLLARY 4.10. *For the solution of* (3.1) *there holds*

$$\|p_h\|^2 \lesssim \vert\kern-0.25ex\vert\kern-0.25ex\vert u_h \vert\kern-0.25ex\vert\kern-0.25ex\vert^2 + \|f\|^2 = (f, v_h) + \|f\|^2.$$

Hence the pressure is unique.

Proof. Modifying the proof of Lemma 4.9 considering not $p - p_h$ but simply p_h and introducing the right-hand side instead of using Galerkin orthogonality, we have

$$\|p_h\| \lesssim a \vert\kern-0.25ex\vert\kern-0.25ex\vert u_h \vert\kern-0.25ex\vert\kern-0.25ex\vert + \|f\|$$

and conclude by applying Lemma 4.1. □

4.3. Lower regularities. The aim of the smoothness assumptions above is to show that the discretization allows for the quasi-optimal a priori error estimates that are characteristic for stabilized methods. However, for the case of high Reynolds number flows this may seem overly optimistic, and we will therefore discuss what we may prove rigorously in the case where the pressure is only in $H^1(\Omega)$ and the velocities are in $[H^2(\Omega)]^d$. In order to recover optimality of the estimate, the pressure stabilization has to be reduced to $\alpha \sim h^2$. Otherwise, the error would be dominated by the term $\alpha^{1/2}\|p\|_1$, which would lead to a convergence order of only $h^{1/2}$.

LEMMA 4.11. *In the case of less regular velocities and pressure, $v \in [H^2(\Omega)]^d$ and $p \in H^1(\Omega)$, and the use of the stabilization*

$$S_h(u, \varphi) = (\delta \nabla \varkappa_h v, \nabla \varkappa_h \psi) + (\alpha \nabla \varkappa_h p, \nabla \varkappa_h \xi) + (\bar{\varkappa}_h \, div \, v_h, \bar{\varkappa}_h \, div \, \psi),$$

with $\delta \sim h$ and $\alpha \sim h^2$, it holds for $v \in [H^2(\Omega)]^d$, $p \in H^1(\Omega)$, and high local Peclet number that

$$\vert\kern-0.25ex\vert\kern-0.25ex\vert u - u_h \vert\kern-0.25ex\vert\kern-0.25ex\vert \lesssim h^{3/2}\|v\|_2 + h\|p\|_1.$$

Furthermore, for lower regularity $v \in [H^{1+\epsilon}(\Omega)]^d$, $p \in L^2(\Omega)$ with $\epsilon > 0$ and under the assumption

$$\|v - j_h v\| \lesssim h^{1+\epsilon}\|v\|_{1+\epsilon}, \tag{4.16}$$

we have at least convergence $\vert\kern-0.25ex\vert\kern-0.25ex\vert u - u_h \vert\kern-0.25ex\vert\kern-0.25ex\vert \to 0$ for $h \to 0$.

Proof. We begin with the case $v \in [H^2(\Omega)]^d$, $p \in H^1(\Omega)$. The regularity of the pressure is necessary only for the upper bound of the stabilizing term of Lemma 4.7. The lower regularity gives the modified upper bound

$$S_h(j_h u, j_h u)^{1/2} \lesssim \delta^{1/2} h \|v\|_2 + \alpha^{1/2}\|p\|_1.$$

Due to the decrease of the pressure stabilization to $\alpha \sim h^2$ it follows from the proof of Theorem 4.8 that the control of the incompressibility condition has to be increased. This is warranted due to the additional stabilization term

$$\|\bar{\varkappa}_h \operatorname{div} v_h\| \le S_h(u_h, u_h). \tag{4.17}$$

Hence, we deduce

$$\begin{aligned} |(p - j_h p, \operatorname{div} \xi^v)| &= |(p - j_h p, \operatorname{div} \xi^v - \overline{\pi} \operatorname{div} \xi^v)| \\ &\le \|p - j_h p\| \, S_h(u_h, u_h). \end{aligned}$$

For the case $v \in H^{1+\epsilon}(\Omega)$ and $p \in L^2(\Omega)$, of course we cannot expect to get any convergence order. On the other hand, the choice $\alpha \sim h^2$ and (4.17) allow us to prove convergence by a density argument, provided that the interpolants converge. The Scott–Zhang operator is no longer well defined on the space of L^2-functions, and we therefore replace it by the L^2-projection. Assuming quasi-uniform meshes, the same estimate holds. First we check the stabilization operator $S(j_h u, j_h u)$. Using the stability of the projection $\bar{\varkappa}_h$, the L^2-projection onto a piecewise constant on element K, $\pi_{0,K}$, and an inverse inequality, we deduce that

$$\begin{aligned} S(j_h u, j_h u) &\lesssim \sum_K \left(\delta_K \|\nabla j_h v\|_K^2 + \alpha_K \|\nabla j_h p\|_K^2\right) \\ &\lesssim \sum_K \left(h_K \|\nabla v\|_K^2 + \|j_h p - \pi_{0,K} p\|_K^2\right) \\ &\lesssim \sum_K \left(h_K \|\nabla v\|_K^2 + \|p - j_h p\|_K^2 + \|p - \pi_{0,K} p\|_K^2\right) \\ &\to 0 \quad (\text{for } h \to 0). \end{aligned}$$

Convergence of the other terms are achieved in a similar fashion assuming (4.16). □

In the case of low local Reynolds number, i.e., $|\beta| h < \mu$, and if $\{v, p\} \in [H^2(\Omega)]^d \times H^1(\Omega)$, one easily shows that the choice $\delta = 0$ and $\alpha \sim h^2$ leads to optimal a priori error estimates in the energy norm by Theorem 4.8. An error estimate in the L^2-norm for the velocities may then be recovered using a standard Nitsche duality argument.

5. Variants of local projection stabilization.

5.1. Local projection in streamline direction. It should also be noted that from the practical viewpoint it may be more advantageous to use the streamline derivative in the part of the subgrid model acting on the velocity in order to minimize crosswind diffusion; for instance,

$$\begin{aligned} (5.1) \quad S_h^\beta(u, \varphi) := {} & (\delta \bar{\varkappa}_h (\beta \cdot \nabla) v, \bar{\varkappa}_h (\beta \cdot \nabla) \psi) + (\delta \bar{\varkappa}_h \operatorname{div} v, \bar{\varkappa}_h \operatorname{div} \psi) \\ & + (\alpha \bar{\varkappa}_h \nabla p, \bar{\varkappa}_h \nabla \xi). \end{aligned}$$

The following lemma states the fact that the proposed stabilization term (5.1) involving only diffusion in streamline direction can be bounded by the triple norm. As a consequence, taking (5.1) does not affect the order of the numerical scheme.

LEMMA 5.1. *If $\beta \in [W^{1,\infty}(\Omega)]^d$, then it holds for all $v \in V_h$ that*

$$(5.2) \qquad \|\delta^{1/2} \bar{\varkappa}_h (\beta \cdot \nabla) v\| \le C_\beta |||\{v, 0\}|||,$$

where $C_\beta \sim \delta^{1/2} \|\beta\|_{W^{1,\infty}(\Omega)} \sigma^{-1/2} + \|\beta\|_\infty$.

Proof. The proof follows by adding and subtracting $\bar{\pi}_h \beta$, where $\bar{\pi}_h$ denotes the projection on D_h^v (here denoting the space of piecewise constants on the macropatches, regardless of the approximation). We apply the triangle inequality and the H^1 stability of $\bar{\varkappa}_h$:

$$\begin{aligned} \|\delta^{1/2} \bar{\varkappa}_h (\beta \cdot \nabla) v\| &\le \|\delta^{1/2} \bar{\varkappa}_h ((\beta - \bar{\pi}_h \beta) \cdot \nabla) v\| + \|\delta^{1/2} \bar{\varkappa}_h ((\bar{\pi}_h \beta) \nabla) v\| \\ &\lesssim \|\delta^{1/2} ((\beta - \bar{\pi}_h \beta) \cdot \nabla) v\| + \|\delta^{1/2} \bar{\varkappa}_h ((\bar{\pi}_h \beta) \nabla) v\|. \end{aligned}$$

The second term on the right-hand side is simply bounded by

$$\begin{aligned} \|\delta^{1/2} \bar{\varkappa}_h ((\bar{\pi}_h \beta) \nabla) v\| &\le \|\beta\|_\infty \|\delta^{1/2} \bar{\varkappa}_h \nabla v\| \\ &\le \|\beta\|_\infty S_h(u, u)^{1/2}. \end{aligned}$$

The first term can be estimated by the approximation property of $\bar{\pi}_h$ and a local inverse inequality:

$$\begin{aligned}\|((\beta - \bar{\pi}_h\beta)\cdot\nabla)v\| &\lesssim \sum_{K\in\mathcal{T}_{2h}} \|\bar{\varkappa}\beta\|_{K,\infty} h_K^{-1}\|v\|_K \\ &\leq \|\beta\|_{W^{1,\infty}(\Omega)}\|v\|.\end{aligned}$$

This gives

$$\begin{aligned}\|\delta^{1/2}\bar{\varkappa}_h(\beta\cdot\nabla)v\| &\lesssim \|\beta\|_\infty S_h(u,u)^{1/2} + \delta^{1/2}\|\beta\|_{W^{1,\infty}(\Omega)}\|v\| \\ &\leq C_\beta |\!|\!|\{v,0\}|\!|\!| \qquad \square\end{aligned}$$

Note that this result is valid immediately (without any assumptions on β) if the form (5.1) is used in the definition of the triple norm.

5.2. Projection onto a coarser mesh. As a further alternative we may use the nodal interpolant $\pi_h : Q_h \to Q_{2h}$ and take as fluctuation filter $\varkappa_h := i - \pi_h$. The stabilization term for the Oseen system can now be taken as

$$S_h(u,\varphi) := (\delta\nabla\varkappa_h v, \nabla\varkappa_h\psi) + (\alpha\nabla\varkappa_h p, \nabla\varkappa_h\xi). \tag{5.3}$$

When the triple norm $|\!|\!|\cdot|\!|\!|$ is designed with the term $S_h(\cdot,\cdot)$, the coercivity property of Lemma 4.1 and the perturbed Galerkin orthogonality of Lemma 4.2 still hold for this variant. Also the estimate in Lemma 4.7 is still valid if we assume that $u \in H^2(\Omega)^{d+1}$ holds in order to be able to apply the nodal interpolant on u.

This variant can be considered as a generalization of the concept for advection equations of Guermond [11, 14].

5.3. Relation to classical stabilized methods. In this section, we will show the relation between the local projection method analyzed in this paper and the GLS method or the residual-free bubble method. A key feature of the proposed method is the weak consistency: The fact that the stabilization enjoys the right asymptotic behavior without strong consistency allows us to decouple the stabilization of the pressure and the velocities and, even more importantly, allows us to decouple the stabilization from time-stepping terms and source terms. However, to show the relation to the GLS we will reintroduce the strong consistency. Our aim is to show that by using the local projection stabilization we may in fact use GLS on the fine scales only, whereas the coarse scales are stable thanks to the interaction between coarse and fine scales. To this end we consider the full residual

$$\rho(u) := \sigma v + \operatorname{div}(\beta\otimes v) - \mu\Delta v + \nabla p$$

in the stabilization

$$S_{gls}(u_h,\varphi) := (\delta\bar{\varkappa}_h\rho(u_h), \bar{\varkappa}_h\rho(\varphi))_h + (\delta\bar{\varkappa}_h \operatorname{div} v_h, \bar{\varkappa}_h \operatorname{div}\psi), \tag{5.4}$$

where $(\cdot,\cdot)_h := \sum_K (\cdot,\cdot)_K$. To make the formulation strongly consistent we perturb the right-hand side and obtain

$$A(u_h,\varphi) + S_{gls}(u_h,\varphi) = (f, \psi + \delta\bar{\varkappa}_h\rho(\varphi))_h \quad \forall\varphi\in X_h. \tag{5.5}$$

The consistency follows, because for the exact solution u we have

$$S_{gls}(u,\varphi) - (f,\delta\bar{\varkappa}_h\rho(\varphi))_h = (\delta\bar{\varkappa}_h(\rho(u)-f), \bar{\varkappa}_h\rho(\varphi))_h = 0.$$

We have thus reformulated the local projection method as a GLS formulation with the stabilization acting only as a filter on the small scales. An important difference, however, is that the local projection approach using (5.4) does not impose any artificial boundary conditions on the solution in contrast to the case of residual-free bubbles. This should be a definite advantage for nonlinear problems. We take as triple norm

$$|\!|\!|u|\!|\!|_{gls} := \left(\|\sigma^{1/2}v\|^2 + \|\mu^{1/2}\nabla v\|^2 + \|\delta^{\frac{1}{2}}\bar{\varkappa}_h(\beta\cdot\nabla v + \nabla p)\|^2\right)^{1/2}.$$

Note that we still have coercivity. In fact, after minor modifications, Theorem 4.8 remains true for (5.4).

Lemma 5.2. *It holds that*

$$|\!|\!|u - u_h|\!|\!|_{gls} \lesssim h^{r+\frac{1}{2}}\left(\|v\|_{r+1} + \|p\|_{r+1}\right)$$

if $\delta \lesssim \min(\frac{h}{\mu}, \frac{1}{\sigma})$ *with a constant depending on the constant in the* L^2*-stability of the projection* $\bar{\varkappa}_h$ *and the constant in the inverse inequality.*

Proof. We first note that

$$\begin{aligned} S_{gls}(u - j_h u, u - j_h u) = {} & (\delta\bar{\varkappa}_h\rho(u - j_h u_h), \bar{\varkappa}_h\rho(u - j_h u))_h \\ & + (\delta\bar{\varkappa}_h \operatorname{div}(v - j_h v_h), \bar{\varkappa}_h \operatorname{div}(v - j_h v)) \end{aligned}$$

has the right asymptotic, which is immediate, assuming optimal approximation for the second derivatives. One may then show, using the stability of the local projection and standard inverse inequalities, that provided δ satisfies the upper bound in the supposition, there holds

$$\frac{1}{2}\|\delta^{\frac{1}{2}}\bar{\varkappa}_h(\beta\cdot\nabla v_h + \nabla p_h)\|^2 - \frac{1}{2}\|\sigma^{1/2}v_h\|^2 - \frac{1}{2}\|\mu\nabla v_h\|^2 \lesssim S_{gls}(u_h, u_h).$$

The proof now follows from (4.14) in the following fashion (considering here only the modified terms):

$$\begin{aligned} A(\eta,\xi) &\le |\!|\!|\eta|\!|\!|_{gls}\,|\!|\!|\xi|\!|\!|_{gls} - (v - j_h v, \beta\cdot\nabla\xi^v + \nabla\xi^p) \\ &\le |\!|\!|\eta|\!|\!|_{gls}\,|\!|\!|\xi|\!|\!|_{gls} - (\delta^{-1/2}(v - j_h v), \delta^{1/2}\bar{\varkappa}_h(\beta\cdot\nabla\xi^v + \nabla\xi^p)) \\ &\le \left(|\!|\!|\eta|\!|\!|_{gls} + \|\delta^{-1/2}(v - j_h v)\|\right)|\!|\!|\xi|\!|\!|_{gls}. \qquad \square \end{aligned}$$

5.4. Extension to triangular meshes. Until now, we have considered meshes $\mathcal{T}_h$ with quadrilateral (or hexahedral) elements. The corresponding finite elements are d-linear ($r = 1$) or d-quadratic ($r = 2$). This raises the question of whether the described method is applicable also on elements with triangles ($d = 2$) or tetrahedrons ($d = 3$). Of course, the definition of the method carries over to those triangulations without any modification if the patches are defined properly. It has to be assured that for a patch $K \in \mathcal{T}_h$, test functions with support inside K do exist.

Bisection on triangles creates four smaller triangles out of one triangle; see Figure 5.1(a). Since no inner points are created, this strategy would not work in the case $r = 1$: The spaces $V_h(K)$ used in Lemma 4.3 would be empty in this particular case. However, possible patches are sketched in Figure 5.1(b) and (c). In the case $r = 2$ and $d = 2$, bisection leads to spaces $V_h(K)$ of dimension three corresponding to the three internal edges inside the patch; see Figure 5.1(a). The space $D_h(K)$ has the same dimension and can be represented by test functions corresponding to the three nodes of K. Hence, we have $\dim D_h(K) \le \dim V_h(K)$, and the mapping π_K can be defined to be injective. A similar situation occurs for $d = 3$ and $r = 2$: $\dim V_h(K) = 6$ and $\dim D_h(K) = 4$.

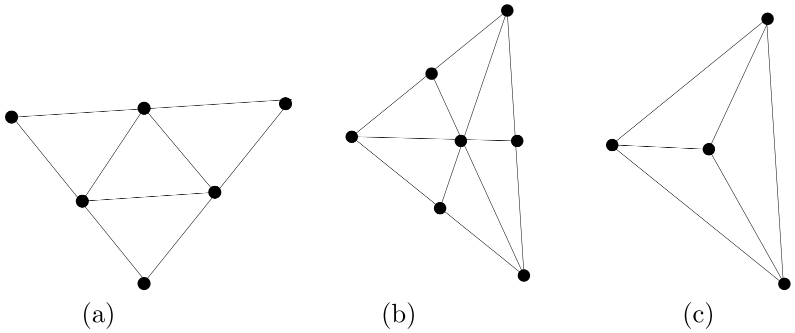

FIG. 5.1. *Possible patches of triangles:* (a) *bisection does not create inner nodes and is therefore not suitable for local projection stabilization in the case $r = 1$;* (b) *and* (c) *create inner nodes.*

6. Link to the variational multiscale method.

Today one of the major challenges in computational fluid dynamics is the accurate computation of different quantities in turbulent flow. Recently, several new approaches have been proposed such as the dynamic multilevel methodology (DML) of Dubois, Jauberteau, and Temam [10] or the VMS method of Hughes, Mazzei, and Jansen [15]. In the latter work, reference is made to residual-free bubble techniques (see Brezzi and Russo [4]) and subgrid viscosity as introduced by Guermond [14] to motivate an approach to large eddy simulation (LES), where the turbulence model acts only on the fine scales. In the following section we will show how the local projection method may be cast in the VMS framework, leading to a stabilized finite element method suitable for high Reynolds number flows.

6.1. Variational formulation of the Navier–Stokes equations.

Let $I := [0, T]$ be the time interval. The velocities are sought in the Bochner space $\mathcal{V}^v := H^1(I, V)$, and the pressure in $\mathcal{V}^p := L^2(I, Q)$. The product space will be denoted by $\mathcal{V} := \mathcal{V}^v \times \mathcal{V}^p$. The test functions are in the space $\mathcal{W} := L^2(I, X)$. The L^2-scalar product over the space-time slab $\Omega_T := \Omega \times I$ will be denoted by $(\cdot, \cdot)_{\Omega_T}$, and its norm by $\|\cdot\|_{\Omega_T}$. Introducing now the state vector $u = \{v, p\} \in \mathcal{V}$, we may write the standard variational formulation of the Navier–Stokes equations (2.1): Find $u \in \mathcal{V}$ such that $v(\cdot, 0) = v_0$ and

$$B(u, \varphi) = \langle f, \varphi \rangle \quad \forall \varphi \in \mathcal{W}, \tag{6.1}$$

where $B(u, \varphi)$ is defined for $\varphi = \{\psi, \xi\}$ by

$$B(u, \varphi) := (\partial_t v, \psi)_{\Omega_T} - (v \otimes v, \nabla \psi)_{\Omega_T} + (\mu \nabla v, \nabla \psi)_{\Omega_T} - (p, \operatorname{div} \psi)_{\Omega_T} + (\operatorname{div} v, \xi)_{\Omega_T}.$$

6.2. Separation of scales on the continuous level.

In the VMS formulation as introduced in [15], a scale separation is performed and the turbulence model acts only on the finer scales. However, as always in turbulence modeling certain model assumptions on the interaction between the scales are made.

To clarify our model assumptions, we use the three-level partition proposed in Collis [9]. Hence we consider a scale separation in large resolved scales denoted by $\bar{v}$, small resolved scales denoted by $\tilde{v}$, and unresolved scales denoted by $\hat{v}$. The solution space is partitioned in a corresponding manner:

$$\mathcal{V} = \bar{\mathcal{V}} \oplus \tilde{\mathcal{V}} \oplus \hat{\mathcal{V}}.$$

The function space $\mathcal{W}$ is partitioned similarly, $\mathcal{W} = \bar{\mathcal{W}} \oplus \tilde{\mathcal{W}} \oplus \hat{\mathcal{W}}$, with corresponding test functions, for instance, $\bar{\varphi} = \{\bar{\psi}, \bar{\xi}\} \in \bar{\mathcal{W}}$. We now write the exact equations of motions for each scale:

$$B(u, \bar{\varphi}) = \langle f, \bar{\varphi}\rangle \quad \forall \bar{\varphi} \in \bar{\mathcal{W}}, \tag{6.2}$$

$$B(u, \tilde{\varphi}) = \langle f, \tilde{\varphi}\rangle \quad \forall \tilde{\varphi} \in \tilde{\mathcal{W}}, \tag{6.3}$$

$$B(u, \hat{\varphi}) = \langle f, \hat{\varphi}\rangle \quad \forall \hat{\varphi} \in \hat{\mathcal{W}}. \tag{6.4}$$

Introducing the linearized Navier–Stokes operator

$$\begin{aligned} B'(u, u', \varphi) := {} & (\partial_t v', \hat{\psi})_{\Omega_T} - (v' \otimes v + v \otimes v', \nabla\psi)_{\Omega_T} \\ & -(p', \nabla \cdot \psi)_{\Omega_T} + (\mu\nabla v', \nabla\psi)_{\Omega_T} + (\nabla \cdot v', \xi)_{\Omega_T}, \end{aligned}$$

the Reynolds stress projection

$$R(v, \psi) := (v \otimes v, \nabla\psi)_{\Omega_T},$$

and the cross-stress projection operator

$$C(v, \hat{v}, \psi) := (v \otimes \hat{v} + \hat{v} \otimes v, \nabla\psi)_{\Omega_T},$$

we may reformulate the exact equations for each scale in a fashion that makes evident the coupling between the scales. Following Collis [9], the exact solution $\bar{v} \in \bar{\mathcal{V}}$ for the resolved large scales fulfills for all $\bar{\varphi} \in \bar{\mathcal{W}}$ the equation

$$\begin{aligned} B(\bar{u}, \bar{\varphi}) + B'(\bar{u}, \tilde{u}, \bar{\varphi}) - R(\tilde{v}, \bar{\psi}) = {} & \langle f, \bar{\varphi}\rangle \\ & -B'(\bar{u}, \hat{u}, \bar{\varphi}) - R(\hat{v}, \bar{\psi}) + C(\tilde{v}, \hat{v}, \bar{\psi}). \end{aligned} \tag{6.5}$$

The first line in (6.5) includes the influence of the resolved scales on the large scales, whereas the second line includes the influence of the unresolved scales on the large scales. In the same fashion, the small resolved scales $\tilde{v} \in \tilde{\mathcal{V}}$ fulfill for all $\tilde{\varphi} \in \tilde{\mathcal{W}}$

$$\begin{aligned} B'(\bar{u}, \tilde{u}, \tilde{\varphi}) - R(\tilde{v}, \tilde{\psi}) = {} & \langle f, \tilde{\varphi}\rangle - B(\bar{u}, \tilde{\varphi}) \\ & -B'(\bar{u}, \hat{u}, \tilde{\varphi}) - R(\hat{v}, \tilde{\psi}) + C(\tilde{v}, \hat{v}, \tilde{\psi}). \end{aligned} \tag{6.6}$$

The unresolved scales $\hat{v} \in \hat{\mathcal{V}}$ finally satisfy the following equation for all $\hat{\varphi} \in \hat{\mathcal{W}}$

$$B'(\bar{u} + \tilde{u}, \hat{u}, \hat{\varphi}) + R(\hat{v}, \hat{\psi}) = \langle f, \hat{\varphi}\rangle - B(\bar{u} + \tilde{u}, \hat{\varphi}).$$

It follows that the equation for the unresolved scales is driven by the residual of the resolved scales. With the equations written in this form it is easy to state the modeling assumptions as follows:

(M1) The unresolved scales $\hat{v}$ have no "direct" influence on the large scales. This means that the second line of (6.5) is set to zero:

$$-B'(\bar{u}, \hat{u}, \bar{\varphi}) - R(\hat{v}, \bar{\psi}) + C(\tilde{v}, \hat{v}, \bar{\psi}) = 0 \quad \forall \bar{\varphi} \in \bar{\mathcal{W}}. \tag{6.7}$$

(M2) The influence of the unresolved scales on the small scales is modeled by an artificial viscosity term

$$S : \mathcal{X} \times \mathcal{X} \to \mathbb{R},$$

with $\mathcal{X} := (\bar{\mathcal{V}} \oplus \tilde{\mathcal{V}}) \cup (\bar{\mathcal{W}} \oplus \tilde{\mathcal{W}})$, acting only on the small resolved scales. Hence we assume in (6.6) that for $\tilde{\varphi} \in \tilde{\mathcal{W}}$

$$S(\tilde{u}, \tilde{\varphi}) \approx B'(\bar{u}, \hat{u}, \tilde{\varphi}) + R(\hat{v}, \tilde{\psi}) - C(\tilde{v}, \hat{v}, \tilde{\psi}). \tag{6.8}$$

The first modeling assumption (M1) can be expected to hold true when the main features of the flow are resolved. This is the large eddy assumption. The second modeling assumption (M2) implies that the unresolved scales only have the effect of dissipating energy from the small resolved scales. Heuristically one may argue that if assumption (M1) is satisfied, then the exact form or size of the subgrid model is of less importance *as long as it allows for a sufficient rate of dissipation of energy from the resolved small scales to the unresolved scales.* Insufficient dissipation may cause buildup of energy in high frequency modes (by the conservation properties of the Galerkin method) leading to spurious oscillations. Excessive dissipation will cause too much damping of the resolved small scales leading to poorer resolution of the large scales through the Reynolds stress coupling.

Using these modeling assumptions and the L^2-projection Πv_0 of the initial conditions onto the resolved scales $\bar{\mathcal{V}}^v \oplus \tilde{\mathcal{V}}^v$ we arrive at the formulation $(\bar{v}+\tilde{v})(\cdot,0) = \Pi v_0$ and

$$\begin{aligned} B(\bar{u}+\tilde{u},\bar{\varphi}) &= \langle f,\bar{\varphi}\rangle \quad \forall\bar{\varphi}\in\bar{\mathcal{W}}, \\ B(\bar{u}+\tilde{u},\tilde{\varphi}) + S(\tilde{v},\tilde{\varphi}) &= \langle f,\tilde{\varphi}\rangle \quad \forall\tilde{\varphi}\in\tilde{\mathcal{W}}. \end{aligned} \tag{6.9}$$

We choose the subgrid viscosity term to be coercive on the small resolved scales $\tilde{u}$, i.e., $S(\tilde{u},\tilde{u}) \geq c\|\nabla\tilde{u}\|^2$ for all $\tilde{u}\in\tilde{\mathcal{W}}$, symmetric $S(u,\varphi)=S(\varphi,u)$ for all $u,\varphi\in\mathcal{X}$, and such that it vanishes on the large resolved scales

$$S(\cdot,\bar{\varphi}) = 0 \quad \forall\bar{\varphi}\in\bar{\mathcal{W}}\cup\bar{\mathcal{V}}. \tag{6.10}$$

6.3. Separation of scales on the discrete level. We introduce some finite element approximation $\mathcal{V}_h$ of $\mathcal{V}$ that will represent the resolved scales $\mathcal{V}_h = \bar{\mathcal{V}}\oplus\tilde{\mathcal{V}}$. This space is then decomposed into large and small resolved scales by choosing $\bar{\mathcal{V}} = \mathcal{V}_H$, where $\mathcal{V}_H \subset \mathcal{V}_h$. To indicate its dependence on h, we equip the subgrid viscosity with a subscript, $S_h(\cdot,\cdot)$. The same discrete space is used for the test space $\mathcal{W}_h = \bar{\mathcal{W}}\oplus\tilde{\mathcal{W}}$. The discrete version of (6.9) becomes the following: Find $u_h\in\mathcal{V}_h$ such that $v_h(\cdot,0) = \pi v_0$ and

$$B(u_h,\varphi) + S_h(\tilde{u}_h,\tilde{\varphi}) = \langle f,\varphi\rangle \quad \forall\varphi\in\mathcal{W}_h, \tag{6.11}$$

or, using the scale separation property (6.10) of $S_h(\cdot,\cdot)$,

$$B(v_h,\varphi) + S_h(u_h,\varphi) = \langle f,\varphi\rangle \quad \forall\varphi\in\mathcal{W}_h. \tag{6.12}$$

Note also that by the properties of $S_h(\cdot,\cdot)$ we have Galerkin orthogonality for the discretization error $u-u_h$ on the large resolved scales:

$$B(u-u_h,\bar{\varphi}) = 0 \quad \forall\bar{\varphi}\in\mathcal{W}_H. \tag{6.13}$$

Let us partition the time interval I into subintervals $I_n = (t_{n-1},t_n]$, $n=1,\ldots,N$, with $0=t_0<t_1<\cdots<t_N=T$ and $\tau_n := t_n - t_{n-1}$. We also introduce the space time slabs $Q_n := I_n\times\Omega$. As the time integration scheme, we use the Crank–Nicholson scheme. It means that we choose piecewise d-linears for the ansatz functions and as test spaces piecewise constants (discontinuous), precisely,

$$\mathcal{V}_h = P_\tau^1(I,X_h), \quad \mathcal{W}_h = P_\tau^0(I,X_h).$$

The spaces $\mathcal{V}_H$ and $\mathcal{W}_H$ are defined analogously by using X_H. With these finite element spaces we now propose the following finite element method: Find $u_h \in u_0 + \mathcal{V}_h$, so that in the nth time step it holds for the restriction $u^n = \{v^n, p^n\} := u_h|_{I_n}$:

$$A_n(u^n, \varphi) + S_h(u^n, \varphi) = g_n(u^{n-1}, \varphi) \quad \forall \varphi \in \mathcal{W}_h, \tag{6.14}$$

with

$$\begin{aligned} A_n(u,\varphi) &:= (\tau_n^{-1} v, \psi) - (v \otimes v, \nabla \psi) - (p, \operatorname{div} \psi) + (\operatorname{div} v, \xi) + (\mu \nabla v, \nabla \psi),\\ g_n(u,\varphi) &:= \langle f, \varphi \rangle + (\tau_n^{-1} v, \psi) - (\mu \nabla v, \nabla \psi) + (v \otimes v, \nabla \psi) - S_h(u, \varphi). \end{aligned}$$

As mentioned before, a widely used linearization of (6.14) is the Oseen linearization (2.3) with $\sigma := \tau_n^{-1}$ and β a suitable approximation on v^n (for instance, the last iterate in the nonlinear iteration).

With these notations, we may take as subgrid model (3.2) or (5.3) with parameters δ and α depending on h. If triangular or tetrahedral meshes are used, both subgrid operators satisfy (6.10) exactly and the analysis stated before shows that they are equivalent. On quadrilateral and hexahedral meshes, the stabilization (5.3) also satisfies (6.10) exactly. If version (3.2) is used on quadrilateral meshes, a small residual may remain due to the cross-term of Q_1 and Q_2 elements. Consequently, we do not have exact scale separation for (3.2) on quadrilaterals and hexahedrons.

7. Numerical example.

Finally, we show numerical examples of this stabilization strategy. As the first step, the convergence rates of $v, \nabla v$ and of p in L^2 are checked numerically on tensor grids and on locally refined meshes. In the next step, we investigate the difference of the kinetic energy of a nonstationary driven cavity flow with the numerical dissipation.

7.1. Convergence order for an exact Navier–Stokes solution.

In order to check that the theoretical proven convergence order is also obtained numerically, we consider a stationary Navier–Stokes problem with known exact smooth solution in the unit square $\Omega := (0,1)^2$:

$$\begin{aligned} v_x(x,y) &:= -\cos(x)\,\sin(y)\,(2\pi^2 + 1),\\ v_y(x,y) &:= \sin(x)\,\cos(y)\,(2\pi^2 - 1),\\ p(x,y) &:= 2(\cos(x) + \cos(y)). \end{aligned}$$

The right-hand side f is obtained by applying the Navier–Stokes operator to this solution. The solution is independent of the viscosity ν since the Laplacian applied to v vanishes; $\Delta v = 0$. However, this is not the case for the discrete solutions. The viscosity is set to $\nu = 10^{-6}$ so that this is smaller than the mesh size.

We investigate the convergence order of v in L^2 and in the H^1 seminorm, and for the pressure we check the L^2-error. Theorem 4.8 assures at least

$$\|\nu \nabla (v - v_h)\| \le |\!|\!| u - u_h |\!|\!| \;=\; \mathcal{O}(h^{r+1/2}).$$

Since $\nu < h$, we expect at least $\mathcal{O}(h^{r-1/2})$ for $\|\nabla(v - v_h)\|$. Due to Theorem 4.9, we get the same order of convergence for $\|p - p_h\|$. With a standard duality argument we obtain one order more for the L^2-error in the velocities. This expectation is summed up in Table 7.1 (second column with label "theoretically") for the case $r = 2$.

Let us first consider the case of equidistant tensor grids; see Figure 7.1 and the third column of Table 7.1. We clearly observe for this example the superconvergence behavior.

Table 7.1

Theoretical and practical convergence rates for different quantities. The practical convergence rates summarize the results of the numerical example.

	Theoretically	Practice Uniform meshes	Practice Nonuniform meshes
$\|\nabla(v-v_h)\|$	$h^{1.5}$	h^2	$h^{1.8}$
$\|v-v_h\|$	$h^{2.5}$	h^3	$h^{2.6}$
$\|p-p_h\|$	$h^{1.5}$	h^2	$h^{1.9}$

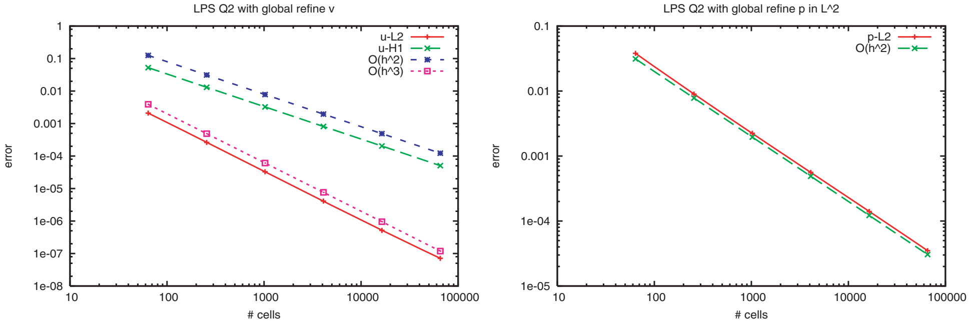

Fig. 7.1. *Convergence for stabilized biquadratic elements (Q_2) on equidistant tensor grids in dependence of the number of cells. Left: $\|v-v_h\| = \mathcal{O}(h^3)$ and $\|\nabla(v-v_h)\| = \mathcal{O}(h^2)$. Right: $\|p-p_h\| = \mathcal{O}(h^2)$.*

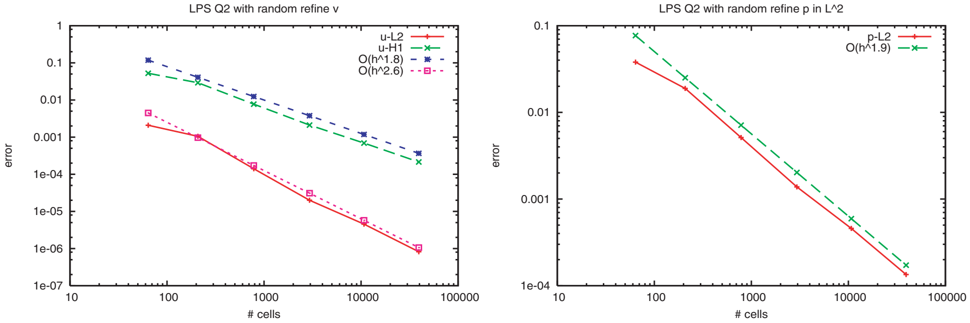

Fig. 7.2. *Convergence for stabilized biquadratic elements (Q_2) on randomly locally refined grids in dependence of the number of cells. Left: $\|v-v_h\| = \mathcal{O}(h^{2.6})$ and $\|\nabla(v-v_h)\| = \mathcal{O}(h^{1.8})$. Right: $\|p-p_h\| = \mathcal{O}(h^{1.9})$.*

On locally refined meshes superconvergence cannot be expected to such an extent. Therefore, we perform the same computations on a sequence of meshes which are obtained by refining approximately 50% of the cells by random. The meshes will be kept quasi-uniform with a ratio between the largest and the smallest mesh size bounded by 3. In order to compare with tensor grids we consider the "global mesh size" $h := n^{-1/2}$. In Figure 7.2 the convergence behavior is plotted on such locally refined meshes. The observed convergence rates are listed in the last column of Table 7.1. As expected, the convergence is reduced compared to tensor grids but is

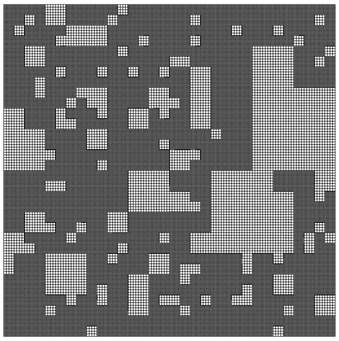

FIG. 7.3. *One of the locally refined meshes used in the numerical example. The refinement is performed by random.*

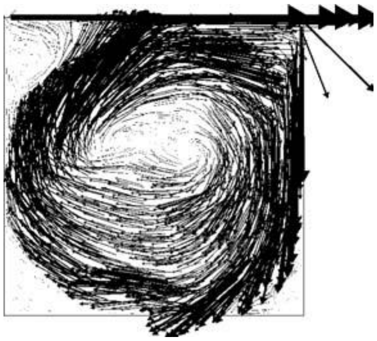

FIG. 7.4. *Flow field of the driven cavity problem at $Re = 10^4$ and $t = 20\,s$.*

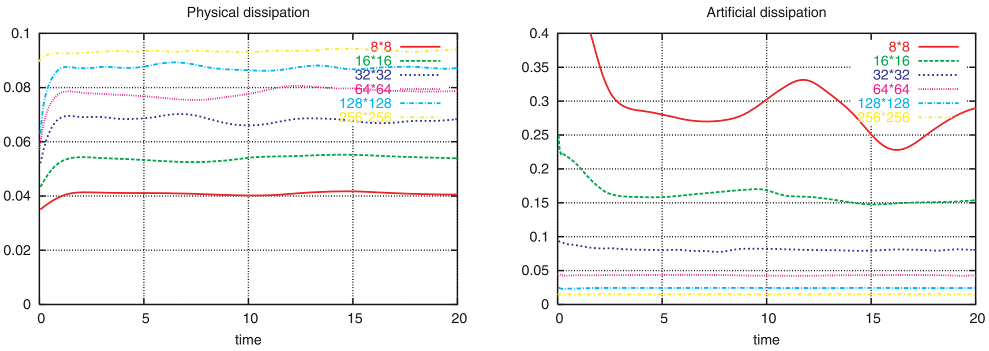
still better than the theoretical results. Note that this is not a fault of the proof but is simply due to superconvergence on parts of the domain. We show one of the used meshes in Figure 7.3.

7.2. Driven cavity flow at $Re = 10^5$. The considered problem is a standard nonstationary driven cavity flow in the unit square $\Omega = (0,1)^2 \subset \mathbb{R}^2$. As boundary conditions, we have for the vertical velocity component homogeneous Dirichlet conditions $v_y = 0$ on $\partial\Omega$; for the horizontal velocity component we have $v_x = 1$ on $\partial\Omega \cap \{y = 1\}$ and $v_x = 0$ elsewhere.

Although the configuration has been investigated for many years, it is still not clear when the transition to nonsteady flow exactly occurs. Auteri, Parolini, and Quartapelle [1] found the first Hopf bifurcation at about $Re = 8018$ with a second-order spectral projection method on a mesh with 160^2 nodes. The computation of Peng, Shiau, and Hwang [17] shows that the transition to a periodic solution occurs at $Re = 7\,402 \pm 4$. They state that the flow becomes "chaotic" for $Re > 11\,000$. Further investigations can be found in [7, 13, 20], each with their own critical Reynolds number for the first Hopf bifurcation, but all in the range between 7 400 and 8 375. Hence, in order to guarantee a nonstationary flow we choose for our computations the Reynolds number $Re = 10^4$.

The initial solution $u|_{t=0}$ is chosen as the stationary solution at lower Reynolds number ($Re = 10^3$). The time step in the Crank–Nicholson scheme is chosen constant $\Delta t = 0.05\,s$. In Figure 7.4 the flow is shown at time instant $t = 20\,s$.



Physical dissipation

Artificial dissipation

Fig. 7.5. *Physical dissipation (left) and artificial dissipation (right) for the driven cavity problem at $Re = 10^4$.*

Table 7.2
Mean values of physical and artificial dissipation and their ratio for the sequence of meshes.

# Q_2 cells	8^2	16^2	32^2	64^2	128^2	256^2	512^2
$\overline{e}^h_{art}$	0.299	0.162	0.0810	0.04278	0.0243	0.0149	0.00937
$\overline{e}^h_{phy}$	0.0407	0.0536	0.0677	0.0782	0.0868	0.0934	0.0967
Ratio	7.34	3.02	1.20	0.55	0.28	0.16	0.097

We compare the physical dissipation $e^h_{phy}(t)$ and artificial dissipation $e^h_{art}(t)$, given by

$$\begin{aligned} e^h_{phy}(t) &:= \nu^{1/2}\|\nabla v_h(t)\|, \\ e^h_{art}(t) &:= S_h(u_h(t), u_h(t))^{1/2} \end{aligned}$$

on a sequence of equidistant tensor grids with 8^2 to 256^2 Q_2 cells (which corresponds to 3 151 875 DOFs). In Figure 7.5, these two quantities are plotted in time. On the coarsest mesh considered, the physical dissipation stabilizes slightly above 0.04. This quantity increases under mesh refinement, reaching nearly 0.1 on the mesh with 256^2 Q_2 cells. At the same time, the artificial dissipation part e^h_{art} decreases from about 0.3 to below of 0.01.

For such time-dependent flows, physical meaningful quantities are time averages, denoted by overbars. For example, the mean of physical dissipation will be denoted by

$$\overline{e}^h_{phy} := \frac{1}{T}\int_0^T e^h_{phy}(t)\, dt.$$

In Table 7.2, the averaged quantities and the ratio of artificial to physical dissipation are listed. While the artificial dissipation dominates the physical dissipation on the coarsest mesh, it becomes less than 10% on the finest mesh.

Although it cannot be expected that a solution u_H on a coarse mesh $\mathcal{T}_H$ shows quantitatively the same information as the solution u_h on the finest mesh $\mathcal{T}_h$, time averages should be comparable if the mesh is reasonably fine. We may hope that $\overline{u}_H$ coincides well with the L^2-projection of $\overline{u}_h$ onto X_H, denoted by $\Pi_H\overline{u}_h$. This is illustrated in Figures 7.6 and 7.7, where the isolines of the time-averaged velocity components are shown for the grid with 32^2 Q_2 cells. Although the mesh size differs by a factor of 2^4, the two time averages coincide quite well.

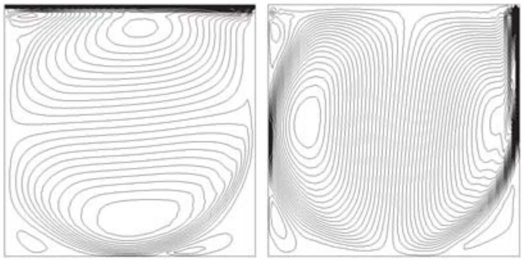


FIG. 7.6. *Time-averaged velocities on a grid with* 32×32 Q_2 *cells; isolines of horizontal velocity component (left) and vertical velocity component (right).*

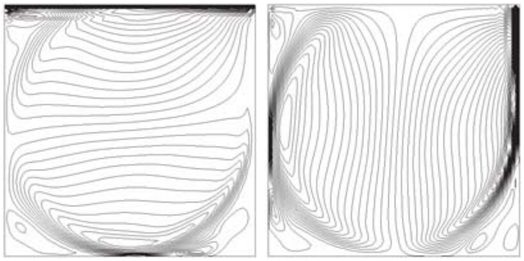

FIG. 7.7. *Time-averaged solution on a grid with* 512×512 Q_2 *cells* L^2*-projected onto the finite element space with* 32×32 Q_2 *cells,* $\Pi_H \overline{u}_h$*; isolines of horizontal velocity component (left) and vertical velocity component (right).*

8. Concluding remarks. We have proposed and analyzed a stabilized finite element method for the Oseen system based on local projections. To assure stability for the equal-order interpolation of velocity and pressure and for the case of high Reynolds number, a sufficient condition on the characteristic length scale of the subgrid model is established. This condition coincides with the condition for optimal-order convergence for the stabilized method when the underlying exact solution is smooth. We have discussed how the choices of stabilization parameters may influence the precision of the computation. Moreover, we have shown that the method can be formulated in a multiscale setting, hence rigorously establishing a link between stabilized methods and the VMS method for Navier–Stokes equations. We hope that this contribution will give additional insight into the close relationship between VMS and stabilized finite element methods. More extensive numerical simulations will be reported in a forthcoming paper.

GENERALIZED LAGUERRE INTERPOLATION AND PSEUDOSPECTRAL METHOD FOR UNBOUNDED DOMAINS*

GUO BEN-YU[†], WANG LI-LIAN[‡], AND WANG ZHONG-QING[†]

Abstract. In this paper, error estimates for generalized Laguerre–Gauss-type interpolations are derived in nonuniformly weighted Sobolev spaces weighted with $\omega_{\alpha,\beta}(x) = x^\alpha e^{-\beta x},\ \alpha > -1, \beta > 0$. Generalized Laguerre pseudospectral methods are analyzed and implemented. Two model problems are considered. The proposed schemes keep spectral accuracy and, with suitable choice of basis functions, lead to sparse and symmetric linear systems.

Key words. generalized Laguerre–Gauss-type interpolations, pseudospectral method, unbounded domains, exterior problems

1. Introduction.

With the extensive applications of Legendre- and Chebyshev-spectral approximations to PDEs in bounded domains (cf. [2, 3, 4, 6, 7, 8]), considerable progress has been made recently in using spectral methods for solving PDEs in unbounded domains. Among the existing methods, the direct and commonly used approach is based on orthogonal systems in infinite intervals, i.e., the Hermite and Laguerre spectral methods (see, e.g., [5, 6, 9, 10, 17, 19]). In earlier studies, one usually considers Laguerre approximations in spaces weighted with e^{-x}, which are not the most appropriate in some cases. For instance, the approximations of some differential equations in financial mathematics, fluid dynamics, quantum mechanics, and astronomical physics involve different weight functions for derivatives of different orders. In such cases, we have to consider the generalized Laguerre approximation with weight function $\omega_\alpha(x) = x^\alpha e^{-x},\ \alpha > -1$, which was used recently for two-dimensional exterior problems; see [11]. Indeed, from both theoretical and computational points of view, it is more interesting to consider an orthogonal system with a more general weight function: $\omega_{\alpha,\beta}(x) = x^\alpha e^{-\beta x},\ \alpha > -1,\ \beta > 0$. One obvious advantage is that it can provide us a variety of choices of polynomial bases to fit exact solutions of underlying differential equations with various asymptotic behaviors at infinity. Moreover, as we will see later, some other good by-products can be obtained using this new family of orthogonal polynomials.

In actual computations, it is more preferable to use the Laguerre interpolation. As we know, there have been many results on the Laguerre polynomial approximation (e.g., see, [2, 5, 6, 8, 10, 11, 12, 13, 14, 17]), but only a few papers dealing with the error analysis of Laguerre interpolation. Recently, some authors developed the

Laguerre interpolation—for example, the Laguerre interpolation ($\alpha=0,\beta=1$) with its applications to approximation of differential equations (see [19]) and the standard generalized Laguerre interpolation ($\alpha>-1,\beta=1$), which are very useful for approximation of integral equations (see [15, 16]). The objective of this paper is to analyze the generalized Laguerre–Gauss-type interpolation errors with a more general weight $\omega_{\alpha,\beta}(x),\alpha>-1,\beta>0$. In the special case of $\alpha=0,\beta=1$, our new results are better than the previous ones. Moreover, we derive the approximation results in nonuniformly weighted Sobolev spaces, which enables us to develop and analyze efficient generalized Laguerre pseudospectral approximations of a large class of problems in unbounded domains.

This paper is organized as follows. In section 2, we present some basic results on this new generalized Laguerre–Gauss-type interpolation. In section 3, we establish the main approximation results on the generalized Laguerre–Gauss and Laguerre–Gauss–Radau interpolations, which provide us useful tools for numerical analysis of generalized Laguerre pseudospectral methods for unbounded domains. Section 4 is devoted to the generalized Laguerre pseudospectral method for unbounded domains as an important application of the generalized Laguerre–Gauss interpolation. In section 5, we develop a pseudospectral method for exterior problems as an application of the generalized Laguerre–Gauss–Radau interpolation. In section 6, we present some numerical results, which demonstrate the spectral accuracy of proposed schemes. The final section is for some concluding remarks.

2. Generalized Laguerre–Gauss-type interpolations.

In this section, we shall introduce the new generalized Laguerre–Gauss-type interpolations, and study the asymptotic behaviors of the interpolation nodes and weights.

2.1. Notation and preliminaries.

Let $\Lambda=(0,\infty)$ and $\chi(x)$ be a certain weight function on Λ in the usual sense. We define the weighted space $L^2_\chi(\Lambda)$ as usual with the inner product $(u,v)_\chi$ and the norm $\|v\|_\chi$. For simplicity, we denote $\partial_x^k v(x)=\frac{d^k}{dx^k}v(x), k\ge 1$. For any integer $m\ge 0$, $H^m_\chi(\Lambda)=\{v\mid \partial_x^k v\in L^2_\chi(\Lambda), 0\le k\le m\}$ with the seminorm $|v|_{m,\chi}$ and the norm $\|v\|_{m,\chi}$. For any real $r>0$, we define the space $H^r_\chi(\Lambda)$ and its norm $\|v\|_{r,\chi}$ by space interpolation as in [1]. For $\chi(x)\equiv 1$, we drop the subscript χ in the previous notations as usual.

Let $\omega_{\alpha,\beta}(x)=x^\alpha e^{-\beta x}$, $\alpha>-1$, $\beta>0$. In particular, we denote $\omega_\alpha(x)=\omega_{\alpha,1}(x)=x^\alpha e^{-x}$. The new generalized Laguerre polynomial of degree l is defined by

$$\mathcal{L}_l^{(\alpha,\beta)}(x)=\frac{1}{l!}x^{-\alpha}e^{\beta x}\partial_x^l(x^{l+\alpha}e^{-\beta x}),\quad l=0,1,\dots .$$

Let $\mathcal{L}_l^{(\alpha)}(x)$ be the usual generalized Laguerre polynomials that are mutually orthogonal with the weight function $\omega_\alpha(x)$. It is noted that $\mathcal{L}_l^{(\alpha)}(x)=\mathcal{L}_l^{(\alpha,1)}(x)$, and

$$\mathcal{L}_l^{(\alpha,\beta)}(x)=\mathcal{L}_l^{(\alpha)}(y)=\mathcal{L}_l^{(\alpha)}(\beta x),\quad y=\beta x. \tag{2.1}$$

Therefore, it is straightforward to derive the following properties (cf. [18]):

$$\mathcal{L}_l^{(\alpha,\beta)}(0)=\mathcal{L}_l^{(\alpha)}(0)=\frac{\Gamma(l+\alpha+1)}{\Gamma(\alpha+1)\Gamma(l+1)},\quad l\ge 0, \tag{2.2}$$

$$\partial_x\mathcal{L}_l^{(\alpha,\beta)}(x)=-\beta\mathcal{L}_{l-1}^{(\alpha+1,\beta)}(x),\quad l\ge 1, \tag{2.3}$$

$$(l+1)\mathcal{L}_{l+1}^{(\alpha,\beta)}(x)=(2l+\alpha+1-\beta x)\mathcal{L}_l^{(\alpha,\beta)}(x)-(l+\alpha)\mathcal{L}_{l-1}^{(\alpha,\beta)}(x),\quad l\ge 1, \tag{2.4}$$

(2.5)
$$\mathcal{L}_l^{(\alpha,\beta)}(x) = \mathcal{L}_l^{(\alpha+1,\beta)}(x) - \mathcal{L}_{l-1}^{(\alpha+1,\beta)}(x) = \beta^{-1}\Big(\partial_x \mathcal{L}_l^{(\alpha,\beta)}(x) - \partial_x \mathcal{L}_{l+1}^{(\alpha,\beta)}(x)\Big), \quad l \geq 1.$$

The generalized Laguerre polynomials form a complete $L^2_{\omega_{\alpha,\beta}}(\Lambda)$-orthogonal system,

$$\Big(\mathcal{L}_l^{(\alpha,\beta)}, \mathcal{L}_m^{(\alpha,\beta)}\Big)_{\omega_{\alpha,\beta}} = \gamma_l^{(\alpha,\beta)}\delta_{l,m}, \quad \gamma_l^{(\alpha,\beta)} = \frac{\Gamma(l+\alpha+1)}{\beta^{\alpha+1}\Gamma(l+1)}, \tag{2.6}$$

where $\delta_{l,m}$ is the Kronecker symbol. Hence, for any $v \in L^2_{\omega_{\alpha,\beta}}(\Lambda)$, we can write

$$v(x) = \sum_{l=0}^{\infty} \hat{v}_l^{(\alpha,\beta)} \mathcal{L}_l^{(\alpha,\beta)}(x), \qquad \hat{v}_l^{(\alpha,\beta)} = \frac{1}{\gamma_l^{(\alpha,\beta)}}(v, \mathcal{L}_l^{(\alpha,\beta)})_{\omega_{\alpha,\beta}}. \tag{2.7}$$

For integer $N > 0$, $\mathbb{P}_N$ stands for the set of algebraic polynomials of degree $\leq N$. We denote by c a generic positive constant independent of N, β, and any function.

2.2. Generalized Laguerre–Gauss and Laguerre–Gauss–Radau interpolations. Let $\xi_{G,N,j}^{(\alpha,\beta)}$ and $\xi_{R,N,j}^{(\alpha,\beta)}$, $0 \leq j \leq N$, be the zeros of $\mathcal{L}_{N+1}^{(\alpha,\beta)}(x)$ and $x\partial_x \mathcal{L}_{N+1}^{(\alpha,\beta)}(x)$, respectively. They are arranged in ascending order. Denote $\omega_{Z,N,j}^{(\alpha,\beta)}$, $0 \leq j \leq N$, $Z = G, R$, the corresponding Christoffel numbers such that

$$\int_\Lambda \phi(x)\omega_{\alpha,\beta}(x)\,dx = \sum_{j=0}^{N} \phi\Big(\xi_{Z,N,j}^{(\alpha,\beta)}\Big)\omega_{Z,N,j}^{(\alpha,\beta)} \quad \forall \phi \in \mathbb{P}_{2N+\lambda_Z}, \tag{2.8}$$

where $\lambda_z = 1$ and 0 for $Z = G$ and R, respectively. In particular, the usual generalized Laguerre–Gauss-type quadrature nodes and weights are denoted by $\xi_{Z,N,j}^{(\alpha)} := \xi_{Z,N,j}^{(\alpha,1)}$ and $\omega_{Z,N,j}^{(\alpha)} := \omega_{Z,N,j}^{(\alpha,1)}$, $Z = G, R$, respectively. Thanks to (2.1), we have $\xi_{Z,N,j}^{(\alpha,\beta)} = \frac{1}{\beta}\xi_{Z,N,j}^{(\alpha)}$. We next derive the expressions of the weights. Indeed,

$$\omega_{G,N,j}^{(\alpha,\beta)} = \frac{1}{\partial_x \mathcal{L}_{N+1}^{(\alpha,\beta)}\big(\xi_{G,N,j}^{(\alpha,\beta)}\big)} \int_\Lambda \frac{\mathcal{L}_{N+1}^{(\alpha,\beta)}(x)}{x - \xi_{G,N,j}^{(\alpha,\beta)}}\omega_{\alpha,\beta}(x)dx, \quad 0 \leq j \leq N, \tag{2.9}$$

which, along with formula (15.3.5) of [18], leads to

(2.10)
$$\omega_{G,N,j}^{(\alpha,\beta)} = \frac{1}{\beta^{\alpha+1}}\omega_{G,N,j}^{(\alpha)} = \frac{\Gamma(N+\alpha+2)}{\beta^\alpha \Gamma(N+2)} \frac{1}{\xi_{G,N,j}^{(\alpha,\beta)}\Big[\partial_x \mathcal{L}_{N+1}^{(\alpha,\beta)}\big(\xi_{G,N,j}^{(\alpha,\beta)}\big)\Big]^2}, \quad 0 \leq j \leq N.$$

Similarly, for the Gauss–Radau weights, we have

(2.11)
$$\omega_{R,N,j}^{(\alpha,\beta)} = \frac{1}{\partial_x\Big[x\partial_x \mathcal{L}_{N+1}^{(\alpha,\beta)}(x)\Big]\big|_{x=\xi_{R,N,j}^{(\alpha,\beta)}}} \int_\Lambda \frac{x\partial_x \mathcal{L}_{N+1}^{(\alpha,\beta)}(x)}{x - \xi_{R,N,j}^{(\alpha,\beta)}}\omega_{\alpha,\beta}(x)dx, \quad 0 \leq j \leq N,$$

which, together with formula (3.6.2) of [6], yields

(2.12)
$$\omega_{R,N,j}^{(\alpha,\beta)} = \frac{1}{\beta^{\alpha+1}}\omega_{R,N,j}^{(\alpha)} = \begin{cases} \dfrac{(\alpha+1)\Gamma^2(\alpha+1)\Gamma(N+1)}{\beta^{\alpha+1}\Gamma(N+\alpha+2)}, & j = 0, \\[2ex] \dfrac{\Gamma(N+\alpha+1)}{\beta^\alpha \Gamma(N+2)} \dfrac{1}{\mathcal{L}_{N+1}^{(\alpha,\beta)}(\xi_{R,N,j}^{(\alpha,\beta)})\partial_x \mathcal{L}_N^{(\alpha,\beta)}(\xi_{R,N,j}^{(\alpha,\beta)})}, & 1 \leq j \leq N. \end{cases}$$

Note that the earlier two types of quadratures have close relations:

$$\xi^{(\alpha,\beta)}_{R,N,j} = \xi^{(\alpha+1,\beta)}_{G,N-1,j-1}, \quad \omega^{(\alpha,\beta)}_{R,N,j} = \left(\xi^{(\alpha,\beta)}_{R,N,j}\right)^{-1} \omega^{(\alpha+1,\beta)}_{G,N-1,j-1}, \quad 1 \le j \le N. \tag{2.13}$$

Indeed, the first identity follows from (2.3). Moreover, using (2.3), (2.9), (2.13), and the definition of $\xi^{(\alpha+1,\beta)}_{G,N-1,j-1}$, we obtain from (2.11) that for $1 \le j \le N$,

$$\begin{aligned} \omega^{(\alpha,\beta)}_{R,N,j} &= \frac{1}{\partial_x \left(x\mathcal{L}^{(\alpha+1,\beta)}_N(x)\right)\big|_{x=\xi^{(\alpha,\beta)}_{R,N,j}}} \int_\Lambda \frac{x\mathcal{L}^{(\alpha+1,\beta)}_N(x)}{x-\xi^{(\alpha,\beta)}_{R,N,j}} \omega_{\alpha,\beta}(x)\,dx \\ &= \frac{1}{\xi^{(\alpha,\beta)}_{R,N,j}\partial_x \mathcal{L}^{(\alpha+1,\beta)}_N\left(\xi^{(\alpha+1,\beta)}_{G,N-1,j-1}\right)} \int_\Lambda \frac{\mathcal{L}^{(\alpha+1,\beta)}_N(x)}{x-\xi^{(\alpha+1,\beta)}_{G,N-1,j-1}} \omega_{\alpha+1,\beta}(x)\,dx \\ &= \left(\xi^{(\alpha,\beta)}_{R,N,j}\right)^{-1} \omega^{(\alpha+1,\beta)}_{G,N-1,j-1}. \end{aligned} \tag{2.14}$$

To obtain the interpolation error estimates, it is necessary to study the asymptotic behaviors of generalized Laguerre–Gauss interpolation nodes and weights.

- Using Theorem 8.9.2 of [18], we can verify that for a certain fixed number $\eta > 0$,

$$2\beta^{\frac{1}{2}}\left(\left(\xi^{(\alpha,\beta)}_{G,N,j}\right)\right)^{\frac{1}{2}} = \frac{1}{\sqrt{N+1}}\big(j\pi + \mathcal{O}(1)\big) \quad \text{if } 0 < \left(\xi^{(\alpha,\beta)}_{G,N,j}\right) \le \frac{\eta}{\beta}. \tag{2.15}$$

- Theorem 6.31.3 of [18] reveals that for large j,

$$\frac{c_1 j^2}{\beta(N+\frac{\alpha}{2}+\frac{3}{2})} < \left(\xi^{(\alpha,\beta)}_{G,N,j}\right) < \frac{c_2 j^2}{\beta(N+\frac{\alpha}{2}+\frac{3}{2})}, \quad c_1 \cong \frac{\pi^2}{4}, \quad c_2 \cong 4. \tag{2.16}$$

- Let $\tilde{N} = 2(N+1)+\alpha+1$. By Theorem 6.31.2 of [18], the largest node satisfies

$$\xi^{(\alpha,\beta)}_{G,N,N} < \beta^{-1}\left(\tilde{N} + \left(\tilde{N}^2 + \frac{1}{4} - \alpha^2\right)^{1/2}\right) \cong 4\beta^{-1}(N+1). \tag{2.17}$$

- We can verify from formula (15.3.15) of [18] that for a certain fixed number $\eta > 0$,

$$\omega^{(\alpha,\beta)}_{G,N,j} \cong \frac{\pi}{\sqrt{\beta N}} e^{-\beta \xi^{(\alpha,\beta)}_{G,N,j}} \left(\xi^{(\alpha,\beta)}_{G,N,j}\right)^{\alpha+\frac{1}{2}} \quad \text{if } 0 < \left(\xi^{(\alpha,\beta)}_{G,N,j}\right) \le \frac{\eta}{\beta}. \tag{2.18}$$

- Let $\xi^{(\alpha,\beta)}_{G,N,-1} := 0$. By the formulae (2.4), (2.5), and (2.7) of [15],

$$\begin{aligned} \omega^{(\alpha,\beta)}_{G,N,j} &= \frac{1}{\beta^{\alpha+1}} \omega^{(\alpha)}_{G,N,j} \sim \frac{1}{\beta^{\alpha+1}} \omega_\alpha\left(\xi^{(\alpha)}_{G,N,j}\right)\left(\xi^{(\alpha)}_{G,N,j+1} - \xi^{(\alpha)}_{G,N,j}\right) \\ &= \omega_{\alpha,\beta}(\xi^{(\alpha,\beta)}_{G,N,j})\left(\xi^{(\alpha,\beta)}_{G,N,j} - \xi^{(\alpha,\beta)}_{G,N,j-1}\right), \quad 0 \le j \le N. \end{aligned} \tag{2.19}$$

- Thanks to the relation (2.13), we deduce from (2.18) and (2.19) that

$$\begin{aligned} \omega^{(\alpha,\beta)}_{R,N,j} &= \left(\xi^{(\alpha+1,\beta)}_{G,N-1,j-1}\right)^{-1} \omega^{(\alpha+1,\beta)}_{G,N-1,j-1} \\ &\cong \frac{\pi}{\sqrt{\beta(N-1)}} e^{-\beta \xi^{(\alpha,\beta)}_{R,N,j}} \left(\xi^{(\alpha,\beta)}_{R,N,j}\right)^{\alpha+\frac{1}{2}} \quad \text{if } 0 < \xi^{(\alpha,\beta)}_{R,N,j} \le \frac{\eta}{\beta}, \quad 1 \le j \le N, \end{aligned} \tag{2.20}$$

and

$$\begin{aligned}
\omega_{R,N,j}^{(\alpha,\beta)} &= \left(\xi_{R,N,j}^{(\alpha,\beta)}\right)^{-1} \omega_{G,N-1,j-1}^{(\alpha+1,\beta)} \\
&\sim \left(\xi_{R,N,j}^{(\alpha,\beta)}\right)^{-1} \omega_{\alpha+1,\beta}\left(\xi_{G,N-1,j-1}^{(\alpha+1,\beta)}\right)\left(\xi_{G,N-1,j-1}^{(\alpha+1,\beta)} - \xi_{G,N-1,j-2}^{(\alpha+1,\beta)}\right) \\
&= \omega_{\alpha,\beta}\left(\xi_{R,N,j}^{(\alpha,\beta)}\right)\left(\xi_{R,N,j}^{(\alpha,\beta)} - \xi_{R,N,j-1}^{(\alpha,\beta)}\right), \quad 1 \le j \le N.
\end{aligned} \tag{2.21}$$

For notational convenience, we now introduce the discrete inner product and norm,

$$(u,v)_{\omega_{\alpha,\beta},Z,N} = \sum_{j=0}^{N} u\left(\xi_{Z,N,j}^{(\alpha,\beta)}\right) v\left(\xi_{Z,N,j}^{(\alpha,\beta)}\right) \omega_{Z,N,j}^{(\alpha,\beta)},$$

$$\|v\|_{\omega_{\alpha,\beta},Z,N} = (v,v)_{\omega_{\alpha,\beta},Z,N}^{\frac{1}{2}}, \quad Z = G, R.$$

By the exactness of (2.8),

$$(\phi,\psi)_{\omega_{\alpha,\beta},Z,N} = (\phi,\psi)_{\omega_{\alpha,\beta}} \quad \forall \phi\psi \in \mathbb{P}_{2N+\delta_Z}, \tag{2.22}$$

where $\delta_Z = 1, 0$ for $Z = G, R$, respectively. In particular,

$$\|\phi\|_{\omega_{\alpha,\beta},Z,N} = \|\phi\|_{\omega_{\alpha,\beta}} \quad \forall \phi \in \mathbb{P}_N, \quad Z = G, R. \tag{2.23}$$

The generalized Laguerre–Gauss interpolant $\mathcal{I}_{Z,N,\alpha,\beta} v \in \mathbb{P}_N$ is defined by

$$\mathcal{I}_{Z,N,\alpha,\beta} v\left(\xi_{Z,N,j}^{(\alpha,\beta)}\right) = v\left(\xi_{Z,N,j}^{(\alpha,\beta)}\right), \quad Z = G, R, \quad 0 \le j \le N. \tag{2.24}$$

3. Generalized Laguerre interpolation error estimates.

In this section, we estimate the interpolation errors in weighted Sobolev spaces, which provide useful tools for the analysis of generalized Laguerre pseudospectral methods.

3.1. $L^2_{\omega_{\alpha,\beta}}(\Lambda)$-orthogonal projection.

We first recall the $L^2_{\omega_{\alpha,\beta}}(\Lambda)$-orthogonal projection $P_{N,\alpha,\beta} : L^2_{\omega_{\alpha,\beta}}(\Lambda) \to \mathbb{P}_N$, defined by

$$(P_{N,\alpha,\beta} v - v, \phi)_{\omega_{\alpha,\beta}} = 0 \quad \forall \phi \in \mathbb{P}_N.$$

In order to describe approximation errors precisely, we introduce the nonuniformly weighted Sobolev space $A^r_{\alpha,\beta}(\Lambda)$. For any integer $r \ge 0$, its seminorm and norm are given by

$$|v|_{A^r_{\alpha,\beta}} = \|\partial_x^r v\|_{\omega_{\alpha+r,\beta}}, \quad \|v\|_{A^r_{\alpha,\beta}} = \left(\sum_{k=0}^{r} |v|^2_{A^k_{\alpha,\beta}}\right)^{\frac{1}{2}}.$$

For any real $r > 0$, we define the space $A^r_{\alpha,\beta}(\Lambda)$ by space interpolation as in [1].

We have the following basic result; see Theorem 2.1 of [12].

Lemma 3.1. *For any $v \in A^r_{\alpha,\beta}(\Lambda)$, an integer r, and $0 \le \mu \le r$,*

$$\|P_{N,\alpha,\beta} v - v\|_{A^\mu_{\alpha,\beta}} \le c(\beta N)^{\frac{\mu - r}{2}} |v|_{A^r_{\alpha,\beta}}. \tag{3.1}$$

In the analysis of generalized Laguerre–Gauss–Radau interpolation approximation (cf. the proof of Theorem 3.7), we need to estimate $|P_{N,\alpha,\beta} v(0) - v(0)|$.

LEMMA 3.2. *For any $v \in A^r_{\alpha,\beta}(\Lambda)$ and an integer $r > \alpha + 1$,*

$$|P_{N,\alpha,\beta}v(0) - v(0)| \le c(\beta N)^{\frac{\alpha-r+1}{2}} |v|_{A^r_{\alpha,\beta}}. \tag{3.2}$$

Proof. Let $\lambda_l^{(\beta)} = \beta l$. By virtue of (2.3) and (2.6), we find that for $l \ge r$,

$$|v|^2_{A^r_{\alpha,\beta}} = \sum_{l=r}^{\infty} \beta^{2r} \gamma_{l-r}^{(\alpha+r,\beta)} \big(\hat{v}_l^{(\alpha,\beta)}\big)^2, \quad d_{l,r}^{\alpha,\beta} := \frac{(\lambda_l^{(\beta)})^r \gamma_l^{(\alpha,\beta)}}{\gamma_{l-r}^{(\alpha+r,\beta)}} \le c\beta^{2r}.$$

Therefore,

$$\sum_{l=N+1}^{\infty} \big(\lambda_l^{(\beta)}\big)^r \gamma_l^{(\alpha,\beta)} \big(\hat{v}_l^{(\alpha,\beta)}\big)^2 = \sum_{l=N+1}^{\infty} d_{l,r}^{\alpha,\beta} \gamma_{l-r}^{(\alpha+r,\beta)} \big(\hat{v}_l^{(\alpha,\beta)}\big)^2 \le c|v|^2_{A^r_{\alpha,\beta}}. \tag{3.3}$$

Consequently, using (2.2), (2.6), (3.3), and the Cauchy–Schwarz inequality leads to

$$\begin{aligned}
|P_{N,\alpha,\beta}v(0) - v(0)| &= \Big| \sum_{l=N+1}^{\infty} \hat{v}_l^{(\alpha,\beta)} \mathcal{L}_l^{(\alpha,\beta)}(0) \Big| \\
&\le \left(\sum_{l=N+1}^{\infty} (\lambda_l^{(\beta)})^{-r} (\mathcal{L}_l^{(\alpha,\beta)}(0))^2 (\gamma_l^{(\alpha,\beta)})^{-1} \right)^{\frac{1}{2}} \left(\sum_{l=N+1}^{\infty} (\lambda_l^{(\beta)})^{r} \gamma_l^{(\alpha,\beta)} (\hat{v}_l^{(\alpha,\beta)})^2 \right)^{\frac{1}{2}} \\
&\le c\beta^{\frac{\alpha-r+1}{2}} \left(\sum_{l=N+1}^{\infty} \frac{\Gamma(l+\alpha+1)}{l^r \Gamma(l+1)} \right)^{\frac{1}{2}} |v|_{A^r_{\alpha,\beta}}.
\end{aligned}$$

By the Stirling formula, $\Gamma(s+1) = \sqrt{2\pi s} s^s e^{-s}(1 + \mathcal{O}(s^{-\frac{1}{5}}))$. Thus, for $r > \alpha + 1$,

$$\sum_{l=N+1}^{\infty} \frac{\Gamma(l+\alpha+1)}{l^r \Gamma(l+1)} \le c \sum_{l=N+1}^{\infty} l^{\alpha-r} \le cN^{\alpha-r+1}.$$

This completes the proof. □

The approximation errors stated in Lemma 3.1 are measured in the space $A^{\mu}_{\alpha,\beta}(\Lambda)$. However, when we apply the generalized Laguerre approximation to numerical solutions of differential and integral equations, we oftentimes need to estimate them in the standard weighted Sobolev space $H^r_{\omega_{\alpha,\beta}}(\Lambda)$, stated later.

LEMMA 3.3. *If $v \in H^{\mu}_{\omega_{\alpha,\beta}}(\Lambda) \cap A^r_{\alpha-1,\beta}(\Lambda) \cap A^r_{\alpha-\mu,\beta}(\Lambda)$, then for integers $1 \le \mu \le r$,*

$$|P_{N,\alpha,\beta}v - v|_{\mu,\omega_{\alpha,\beta}} \le c\beta^{-\frac{1}{2}} (\beta N)^{\mu - \frac{r}{2}} \big(|v|_{A^r_{\alpha-1,\beta}} + |v|_{A^r_{\alpha-\mu,\beta}} \big). \tag{3.4}$$

Proof. We have

$$|P_{N,\alpha,\beta}v - v|_{1,\omega_{\alpha,\beta}} \le \|P_{N,\alpha,\beta}\partial_x v - \partial_x v\|_{\omega_{\alpha,\beta}} + \|P_{N,\alpha,\beta}\partial_x v - \partial_x P_{N,\alpha,\beta} v\|_{\omega_{\alpha,\beta}}. \tag{3.5}$$

By (3.1) with $\mu = 0$, the first term at the right side of the previous inequality is bounded above by $c(\beta N)^{\frac{1-r}{2}} |v|_{A^r_{\alpha-1,\beta}}$. Hence, it remains to estimate the second term. To do this, let $\partial_x v(x) = \sum_{l=0}^{\infty} \hat{\hat{v}}_l^{(\alpha,\beta)} \mathcal{L}_l^{(\alpha,\beta)}(x)$. By virtue of (2.5) and (2.7), we can derive that $\hat{\hat{v}}_l^{(\alpha,\beta)} = -\beta \sum_{p=l+1}^{\infty} \hat{v}_p^{(\alpha,\beta)}$. Thus, we follow the same lines as in [2, 8] to deduce that

$$\begin{aligned} P_{N,\alpha,\beta}\partial_x v(x) - \partial_x P_{N,\alpha,\beta} v(x) &= -\beta \sum_{l=0}^{N} \mathcal{L}_l^{(\alpha,\beta)}(x) \left(\sum_{p=l+1}^{\infty} \hat{v}_p^{(\alpha,\beta)} \right) \\ &\quad + \beta \sum_{l=0}^{N-1} \mathcal{L}_l^{(\alpha,\beta)}(x) \left(\sum_{p=l+1}^{N} \hat{v}_p^{(\alpha,\beta)} \right) = \hat{\hat{v}}_N^{(\alpha,\beta)} \sum_{l=0}^{N} \mathcal{L}_l^{(\alpha,\beta)}(x). \end{aligned} \tag{3.6}$$

Accordingly, we use (2.6) and (3.1) with $\mu = 0$ to obtain that

$$\begin{aligned} \|P_{N,\alpha,\beta}\partial_x v - \partial_x P_{N,\alpha,\beta} v\|_{\omega_{\alpha,\beta}}^2 &= \big(\hat{\hat{v}}_N^{(\alpha,\beta)}\big)^2 \gamma_N^{(\alpha,\beta)} \sum_{l=0}^{N} \gamma_l^{(\alpha,\beta)} \big(\gamma_N^{(\alpha,\beta)}\big)^{-1} \\ &\le \|P_{N-1,\alpha,\beta}\partial_x v - \partial_x v\|_{\omega_{\alpha,\beta}}^2 \sum_{l=0}^{N} \gamma_l^{(\alpha,\beta)} \big(\gamma_N^{(\alpha,\beta)}\big)^{-1} \\ &\le c(\beta N)^{1-r} |v|_{A_{\alpha-1,\beta}^r}^2 \sum_{l=0}^{N} \gamma_l^{(\alpha,\beta)} \big(\gamma_N^{(\alpha,\beta)}\big)^{-1}. \end{aligned} \tag{3.7}$$

If $\alpha \ge 0$, then $\gamma_l^{(\alpha,\beta)}$ increases as l increases. In this case,

$$\sum_{l=0}^{N} \gamma_l^{(\alpha,\beta)} \big(\gamma_N^{(\alpha,\beta)}\big)^{-1} \le N + 1. \tag{3.8}$$

For $-1 < \alpha < 0$, we use the Stirling formula to deduce that for a suitably large integer $M < N$ and $l \ge M$,

$$\gamma_l^{(\alpha,\beta)} \sim \beta^{-\alpha-1} \Big(1 + \frac{\alpha}{l}\Big)^{l+\frac{1}{2}} (l+\alpha)^{\alpha} \sim \beta^{-\alpha-1} l^{\alpha}. \tag{3.9}$$

Hence, for certain $c_1 > 0$,

$$\sum_{l=0}^{N} \gamma_l^{(\alpha,\beta)} \big(\gamma_N^{(\alpha,\beta)}\big)^{-1} \le cN^{-\alpha} \left(c_1 + c \sum_{l=M}^{N} l^{\alpha} \right) \le cN^{-\alpha}(c_1 + cN^{1+\alpha}) \le cN. \tag{3.10}$$

Inserting (3.8) and (3.10) into (3.7), we obtain the desired result with $\mu = 1$.

Now, we use induction to derive the desired result with $\mu \ge 2$. We shall use the following inverse inequality:

$$\|\phi\|_{r,\omega_{\alpha,\beta}} \le c(\beta N)^r \|\phi\|_{\omega_{\alpha,\beta}} \quad \forall \phi \in \mathbb{P}_N, \quad r > 0.$$

Assume that (3.4) holds for $\mu - 1$. Then we obtain that

$$\begin{aligned} &|P_{N,\alpha,\beta} v - v|_{\mu,\omega_{\alpha,\beta}} \le |P_{N,\alpha,\beta}\partial_x v - \partial_x v|_{\mu-1,\omega_{\alpha,\beta}} + |P_{N,\alpha,\beta}\partial_x v - \partial_x P_{N,\alpha,\beta} v|_{\mu-1,\omega_{\alpha,\beta}} \\ &\quad \le c\beta^{-\frac{1}{2}} (\beta N)^{\mu-1-\frac{r-1}{2}} (|v|_{A_{\alpha-2,\beta}^r} + |v|_{A_{\alpha-\mu,\beta}^r}) + c(\beta N)^{\mu-1} \|P_{N,\alpha,\beta}\partial_x v \\ &\qquad - \partial_x P_{N,\alpha,\beta} v\|_{\omega_{\alpha,\beta}} \le c\beta^{-\frac{1}{2}} (\beta N)^{\mu-\frac{r}{2}-\frac{1}{2}} (|v|_{A_{\alpha-2,\beta}^r} + |v|_{A_{\alpha-\mu,\beta}^r}) \\ &\qquad + c\beta^{-\frac{1}{2}} (\beta N)^{\mu-\frac{r}{2}} |v|_{A_{\alpha-1,\beta}^r}. \end{aligned} \tag{3.11}$$

By the definition of $|\cdot|_{A^r_{\alpha,\beta}}$, we have that

$$|v|_{A^r_{\alpha-2,\beta}} = \|\partial_x^r v\|_{\omega_{\alpha+r-2,\beta}} \le c(|v|_{A^r_{\alpha-\mu,\beta}} + |v|_{A^r_{\alpha-1,\beta}}).$$

This fact with (3.11) implies the desired result. □

3.2. Generalized Laguerre interpolation approximations. We first study the stability of generalized Laguerre–Gauss interpolation.

THEOREM 3.4. *For any* $v \in H^1_{\omega_{\alpha,\beta}}(\Lambda) \cap A^1_{\alpha,\beta}(\Lambda)$,

$$\|\mathcal{I}_{G,N,\alpha,\beta} v\|_{\omega_{\alpha,\beta}} \le c\Big(\beta^{-1}N^{-\frac{1}{2}}|v|_{1,\omega_{\alpha,\beta}} + (1+\beta^{-\frac{1}{2}})(\ln N)^{\frac{1}{2}}\|v\|_{A^1_{\alpha,\beta}}\Big). \tag{3.12}$$

Proof. By (2.23) and (2.24),

$$\|\mathcal{I}_{G,N,\alpha,\beta} v\|^2_{\omega_{\alpha,\beta}} = \|\mathcal{I}_{G,N,\alpha,\beta} v\|^2_{\omega_{\alpha,\beta},G,N} = \sum_{j=0}^{N} v^2\big(\xi^{(\alpha,\beta)}_{G,N,j}\big)\omega^{(\alpha,\beta)}_{G,N,j} := A_N + B_N, \tag{3.13}$$

where

$$A_N = \sum_{\xi^{(\alpha,\beta)}_{G,N,j} \le \frac{\eta}{\beta}} v^2\big(\xi^{(\alpha,\beta)}_{G,N,j}\big)\omega^{(\alpha,\beta)}_{G,N,j}, \quad B_N = \sum_{\xi^{(\alpha,\beta)}_{G,N,j} > \frac{\eta}{\beta}} v^2\big(\xi^{(\alpha,\beta)}_{G,N,j}\big)\omega^{(\alpha,\beta)}_{G,N,j}.$$

We first estimate A_N. For simplicity of statements, let

$$\Delta^{(\alpha,\beta)}_j = \Big[\xi^{(\alpha,\beta)}_{G,N,j-1},\ \big(\xi^{(\alpha,\beta)}_{G,N,j}\big)\Big], \quad |\Delta^{(\alpha,\beta)}_j| = \xi^{(\alpha,\beta)}_{G,N,j} - \xi^{(\alpha,\beta)}_{G,N,j-1},$$
$$\delta^{(\alpha,\beta)}_{j,+} = \big(\xi^{(\alpha,\beta)}_{G,N,j}\big)^{\frac{1}{2}} + \big(\xi^{(\alpha,\beta)}_{G,N,j-1}\big)^{\frac{1}{2}}, \quad \delta^{(\alpha,\beta)}_{j,-} = \big(\xi^{(\alpha,\beta)}_{G,N,j}\big)^{\frac{1}{2}} - \big(\xi^{(\alpha,\beta)}_{G,N,j-1}\big)^{\frac{1}{2}}.$$

By (13.7) of [2], we know that for any $u \in H^1(a,b)$,

$$\sup_{x\in[a,b]} |u(x)| \le c\bigg(\frac{1}{\sqrt{b-a}}\|u\|_{L^2(a,b)} + \sqrt{b-a}\|\partial_x u\|_{L^2(a,b)}\bigg). \tag{3.14}$$

Thus, by (2.18) and (3.14),

$$\begin{aligned} A_N &\le \frac{c}{\sqrt{\beta N}} \sum_{\xi^{(\alpha,\beta)}_{G,N,j} \le \frac{\eta}{\beta}} \big(\xi^{(\alpha,\beta)}_{G,N,j}\big)^{\frac{1}{2}} \sup_{x\in\Delta^{(\alpha,\beta)}_j} |x^{\alpha} v^2(x)| \\ &\le \frac{c}{\sqrt{\beta N}} \sum_{\xi^{(\alpha,\beta)}_{G,N,j} \le \frac{\eta}{\beta}} \bigg(\big(\xi^{(\alpha,\beta)}_{G,N,j}\big)^{\frac{1}{2}} \big(\delta^{(\alpha,\beta)}_{j,+}\big)^{-1}\big(\delta^{(\alpha,\beta)}_{j,-}\big)^{-1} \|x^{\frac{\alpha}{2}} v\|^2_{L^2\left(\Delta^{(\alpha,\beta)}_j\right)} \\ &\quad + \big(\xi^{(\alpha,\beta)}_{G,N,j}\big)^{\frac{1}{2}} \delta^{(\alpha,\beta)}_{j,+}\delta^{(\alpha,\beta)}_{j,-}\Big(\|x^{\frac{\alpha}{2}}\partial_x v\|^2_{L^2\left(\Delta^{(\alpha,\beta)}_j\right)} + \|x^{\frac{\alpha}{2}-1} v\|^2_{L^2\left(\Delta^{(\alpha,\beta)}_j\right)}\Big)\bigg). \end{aligned} \tag{3.15}$$

We now bound the terms in the previous summation. Using (2.15) yields

$$\begin{aligned} \big(\xi^{(\alpha,\beta)}_{G,N,j}\big)^{\frac{1}{2}} \delta^{(\alpha,\beta)}_{j,+}\delta^{(\alpha,\beta)}_{j,-} \|x^{\frac{\alpha}{2}-1} v\|^2_{L^2\left(\Delta^{(\alpha,\beta)}_j\right)} &\le \big(\xi^{(\alpha,\beta)}_{G,N,j}\big)^{\frac{1}{2}} \big(\delta^{(\alpha,\beta)}_{j,+}\big)^2 \int_{\Delta^{(\alpha,\beta)}_j} x^{\alpha-2} v^2(x)dx \\ &\le c\big(\xi^{(\alpha,\beta)}_{G,N,j}\big)^{\frac{3}{2}} \big(\xi^{(\alpha,\beta)}_{G,N,j-1}\big)^{-2} \int_{\Delta^{(\alpha,\beta)}_j} x^{\alpha} v^2(x)dx \\ &\le c\sqrt{\beta N}\|x^{\frac{\alpha}{2}} v\|^2_{L^2\left(\Delta^{(\alpha,\beta)}_j\right)}. \end{aligned} \tag{3.16}$$

The expression (2.15) implies that for $0 < \xi^{(\alpha,\beta)}_{G,N,j} \le \frac{\eta}{\beta}$,

$$\delta^{(\alpha,\beta)}_{j,-} \sim \frac{1}{\sqrt{\beta N}}, \quad \big(\xi^{(\alpha,\beta)}_{G,N,j}\big)^{\frac{1}{2}}(\delta^{(\alpha,\beta)}_{j,+})^{-1} \le c, \quad \big(\xi^{(\alpha,\beta)}_{G,N,j}\big)^{\frac{1}{2}}\delta^{(\alpha,\beta)}_{j,+} \le \frac{c}{\beta}. \tag{3.17}$$

Hence, plugging (3.16) and (3.17) into (3.15) gives

$$\begin{aligned} A_N &\le c \sum_{\Delta^{(\alpha,\beta)}_j} \Big(\|x^{\frac{\alpha}{2}} v\|^2_{L^2\left(\Delta^{(\alpha,\beta)}_j\right)} + \beta^{-2}N^{-1}\|x^{\frac{\alpha}{2}}\partial_x v\|^2_{L^2\left(\Delta^{(\alpha,\beta)}_j\right)}\Big) \\ &\le c(\|v\|^2_{\omega_{\alpha,\beta}} + \beta^{-2}N^{-1}|v|^2_{1,\omega_{\alpha,\beta}}). \end{aligned} \tag{3.18}$$

We next estimate B_N in (3.13). By (2.19) and (2.17),

$$\begin{aligned} B_N &\le c \sum_{\xi^{(\alpha,\beta)}_{G,N,j} > \frac{\eta}{\beta}} v^2\big(\xi^{(\alpha,\beta)}_{G,N,j}\big)\omega_{\alpha,\beta}\big(\xi^{(\alpha,\beta)}_{G,N,j}\big)\Big(\xi^{(\alpha,\beta)}_{G,N,j} - \xi^{(\alpha,\beta)}_{G,N,j-1}\Big) \\ &\le c \sup_{x > \frac{\eta}{\beta}} |v^2(x)\omega_{\alpha+1,\beta}(x)| \sum_{\xi^{(\alpha,\beta)}_{G,N,j} > \frac{\eta}{\beta}} \frac{1}{\xi^{(\alpha,\beta)}_{G,N,j}}\Big(\xi^{(\alpha,\beta)}_{G,N,j} - \xi^{(\alpha,\beta)}_{G,N,j-1}\Big) \\ &\le c \sup_{x > \frac{\eta}{\beta}} |v^2(x)\omega_{\alpha+1,\beta}(x)| \int_{\frac{\eta}{\beta}}^{4\beta^{-1}(N+1)} \frac{1}{x}dx. \end{aligned}$$

By a similar argument as in the derivation of Lemma 2.2 of [11], we deduce that

$$\sup_{x\in\Lambda} |v^2(x)\omega_{\alpha+1,\beta}(x)| \le \max(\alpha+1, 2/\beta)\|v\|^2_{A^1_{\alpha,\beta}}. \tag{3.19}$$

Consequently,

$$B_N \le c(1+1/\beta)\ln N \|v\|^2_{A^1_{\alpha,\beta}}. \tag{3.20}$$

The combination of (3.13), (3.18), (3.20), and the fact $\|v\|_{\omega_{\alpha,\beta}} \le \|v\|_{A^1_{\alpha,\beta}}$ leads to the desired result. □

With the aid of the previous theorem, we are able to estimate the interpolation error.

Theorem 3.5. *If $v \in A^r_{\alpha-1,\beta}(\Lambda) \cap A^r_{\alpha,\beta}(\Lambda)$, then for integer $r \ge 1$,*

$$\|\mathcal{I}_{G,N,\alpha,\beta}v - v\|_{\omega_{\alpha,\beta}} \le c(\beta N)^{\frac{1}{2}-\frac{r}{2}}\Big(\beta^{-1}|v|_{A^r_{\alpha-1,\beta}} + (1+\beta^{-\frac{1}{2}})(\ln N)^{\frac{1}{2}}|v|_{A^r_{\alpha,\beta}}\Big). \tag{3.21}$$

If, in addition, $v \in A^r_{\alpha-\mu,\beta}(\Lambda)$, then for integers $1 \le \mu \le r$,

$$\begin{aligned} |\mathcal{I}_{G,N,\alpha,\beta}v - v|_{\mu,\omega_{\alpha,\beta}} \le c(\beta N)^{\mu+\frac{1}{2}-\frac{r}{2}}\Big(&\beta^{-1}(|v|_{A^r_{\alpha-1,\beta}} + N^{-\frac{1}{2}}|v|_{A^r_{\alpha-\mu,\beta}}) \\ &+ (1+\beta^{-\frac{1}{2}})(\ln N)^{\frac{1}{2}}|v|_{A^r_{\alpha,\beta}}\Big). \end{aligned} \tag{3.22}$$

Proof. The use of (3.12), (3.1), and (3.4) with $\mu = 1$ leads to

$$\begin{aligned} &\|\mathcal{I}_{G,N,\alpha,\beta}v - P_{N,\alpha,\beta}v\|_{\omega_{\alpha,\beta}} = \|\mathcal{I}_{G,N,\alpha,\beta}(P_{N,\alpha,\beta}v - v)\|_{\omega_{\alpha,\beta}} \\ &\quad \le c\beta^{-1}N^{-\frac{1}{2}}|P_{N,\alpha,\beta}v - v|_{1,\omega_{\alpha,\beta}} + c(1+\beta^{-\frac{1}{2}})(\ln N)^{\frac{1}{2}}\|P_{N,\alpha,\beta}v - v\|_{A^1_{\alpha,\beta}} \\ &\quad \le c(\beta N)^{\frac{1}{2}-\frac{r}{2}}\Big(\beta^{-1}|v|_{A^r_{\alpha-1,\beta}} + (1+\beta^{-\frac{1}{2}})(\ln N)^{\frac{1}{2}}|v|_{A^r_{\alpha,\beta}}\Big). \end{aligned} \tag{3.23}$$

Thus, using the previous formula and (3.1) with $\mu = 0$ yields

$$\begin{aligned}\|\mathcal{I}_{G,N,\alpha,\beta}v - v\|_{\omega_{\alpha,\beta}} &\le \|\mathcal{I}_{G,N,\alpha,\beta}v - P_{N,\alpha,\beta}v\|_{\omega_{\alpha,\beta}} + \|P_{N,\alpha,\beta}v - v\|_{\omega_{\alpha,\beta}} \\ &\le c(\beta N)^{\frac{1}{2}-\frac{r}{2}}\Big(\beta^{-1}|v|_{A^r_{\alpha-1,\beta}} + (1+\beta^{-\frac{1}{2}})(\ln N)^{\frac{1}{2}}|v|_{A^r_{\alpha,\beta}}\Big).\end{aligned} \tag{3.24}$$

This implies (3.21). Next, by (3.4), (3.23), and the inverse inequality as before, we deduce that

$$\begin{aligned}&|\mathcal{I}_{G,N,\alpha,\beta}v - v|_{\mu,\omega_{\alpha,\beta}} \le |\mathcal{I}_{G,N,\alpha,\beta}v - P_{N,\alpha,\beta}v|_{\mu,\omega_{\alpha,\beta}} + |P_{N,\alpha,\beta}v - v|_{\mu,\omega_{\alpha,\beta}} \\ &\quad\le c(\beta N)^{\mu}\|\mathcal{I}_{G,N,\alpha,\beta}v - P_{N,\alpha,\beta}v\|_{\omega_{\alpha,\beta}} + c\beta^{-\frac{1}{2}}(\beta N)^{\mu-\frac{r}{2}}(|v|_{A^r_{\alpha-1,\beta}} + |v|_{A^r_{\alpha-\mu,\beta}}) \\ &\quad\le c(\beta N)^{\mu+\frac{1}{2}-\frac{r}{2}}\Big(\beta^{-1}\big(|v|_{A^r_{\alpha-1,\beta}} + N^{-\frac{1}{2}}|v|_{A^r_{\alpha-\mu,\beta}}\big) + (1+\beta^{-\frac{1}{2}})(\ln N)^{\frac{1}{2}}|v|_{A^r_{\alpha,\beta}}\Big).\end{aligned} \tag{3.25}$$

This completes the proof. □

We now turn to the generalized Laguerre–Gauss–Radau interpolation. We first study the stability of interpolation, stated later.

Theorem 3.6. *For any $v \in H^1_{\omega_{\alpha,\beta}}(\Lambda) \cap A^1_{\alpha,\beta}(\Lambda)$,*

$$\begin{aligned}\|\mathcal{I}_{R,N,\alpha,\beta}v\|_{\omega_{\alpha,\beta}} \le c\Big(&(\beta N)^{-\frac{\alpha+1}{2}}|v(0)| + \beta^{-1}N^{-\frac{1}{2}}|v|_{1,\omega_{\alpha,\beta}} \\ &+ (1+\beta^{-\frac{1}{2}})(\ln N)^{\frac{1}{2}}\|v\|_{A^1_{\alpha,\beta}}\Big).\end{aligned} \tag{3.26}$$

In particular, for $|\alpha| < 1$,

$$\|\mathcal{I}_{R,N,\alpha,\beta}v\|_{\omega_{\alpha,\beta}} \le c\Big(\beta^{-1}N^{-\frac{1}{2}}|v|_{1,\omega_{\alpha,\beta}} + (1+\beta^{-\frac{1}{2}})(\ln N)^{\frac{1}{2}}\|v\|_{A^1_{\alpha,\beta}}\Big). \tag{3.27}$$

Proof. Let η be the positive constant in (2.15). By the exactness (2.23),

$$\|\mathcal{I}_{R,N,\alpha,\beta}v\|^2_{\omega_{\alpha,\beta}} = \|\mathcal{I}_{R,N,\alpha,\beta}v\|^2_{\omega_{\alpha,\beta},R,N} = v^2(0)\omega^{(\alpha,\beta)}_{R,N,0} + \widetilde{A}_N + \widetilde{B}_N,$$

where

$$\widetilde{A}_N = \sum_{0<\xi^{(\alpha,\beta)}_{R,N,j}\le\frac{\eta}{\beta}} v^2(\xi^{(\alpha,\beta)}_{R,N,j})\omega^{(\alpha,\beta)}_{R,N,j}, \quad \widetilde{B}_N = \sum_{\xi^{(\alpha,\beta)}_{R,N,j}>\frac{\eta}{\beta}} v^2(\xi^{(\alpha,\beta)}_{R,N,j})\omega^{(\alpha,\beta)}_{R,N,j}.$$

Using the Stirling formula, we have $\omega^{(\alpha,\beta)}_{R,N,0} \le c(\beta N)^{-\alpha-1}$. On the other hand, we observe from (2.13) that the interior nodes $\xi^{(\alpha,\beta)}_{R,N,j}$, $1 \le j \le N$, satisfy asymptotic properties (2.15) and (2.16), while the corresponding weights $\omega^{(\alpha,\beta)}_{R,N,j}$, $1 \le j \le N$, fulfill (2.20) and (2.21). Thus, we can follow the same lines as in the proof of Theorem 3.4 to derive that

$$\widetilde{A}_N \le c(\|v\|^2_{\omega_{\alpha,\beta}} + \beta^{-2}N^{-1}|v|^2_{1,\omega_{\alpha,\beta}}), \quad \widetilde{B}_N \le c(1+\beta^{-1})\ln N\|v\|^2_{A^1_{\alpha,\beta}}.$$

Then the result (3.26) follows from the previous statements.

We next prove (3.27). For any $x \in [0, \frac{1}{\beta}]$ and $|\alpha| < 1$,

$$|v(x) - v(0)| \le \left(\int_0^{\frac{1}{\beta}} x^{-\alpha}e^{\beta x}\,dx\right)^{\frac{1}{2}}\|\partial_x v\|_{L^2_{\omega_{\alpha,\beta}}(0,\frac{1}{\beta})} \le c\beta^{\frac{\alpha-1}{2}}\|\partial_x v\|_{L^2_{\omega_{\alpha,\beta}}(0,\frac{1}{\beta})}. \tag{3.28}$$

Now, let $|v(x_*)| = \min_{x\in[0,1/\beta]} |v(x)|$. Clearly, for $|\alpha| < 1$,

$$|v(x_*)| \le \beta \int_0^{\frac{1}{\beta}} |v(x)|\, dx \le c\beta^{\frac{\alpha+1}{2}} \|v\|_{L^2_{\omega_{\alpha,\beta}}(0,\frac{1}{\beta})}. \tag{3.29}$$

The previous formula with (3.28) gives

$$|v(0)| \le |v(x_*)| + |v(x_*) - v(0)| \le c\Big(\beta^{\frac{\alpha+1}{2}} \|v\|_{\omega_{\alpha,\beta}} + \beta^{\frac{\alpha-1}{2}} |v|_{1,\omega_{\alpha,\beta}}\Big). \tag{3.30}$$

If $0 \le \alpha < 1$, then by (3.30) and the fact $\|v\|_{\omega_{\alpha,\beta}} \le \|v\|_{A^1_{\alpha,\beta}}$, we derive that

$$(\beta N)^{-\frac{\alpha+1}{2}} |v(0)| \le c\Big(\beta^{-1} N^{-\frac{1}{2}} |v|_{1,\omega_{\alpha,\beta}} + (1+\beta^{-\frac{1}{2}})(\ln N)^{\frac{1}{2}} \|v\|_{A^1_{\alpha,\beta}}\Big),$$

which, along with (3.26), leads to (3.27) with $0 \le \alpha < 1$. For $-1 < \alpha < 0$, we change slightly the derivation of (3.28) to obtain that for any $x \in [0, \frac{1}{\beta}]$,

$$|v(x) - v(0)| \le \int_0^{\frac{1}{\beta}} |\partial_x v(x)|\, dx \le c\beta^{\frac{\alpha}{2}} \|\partial_x v\|_{L^2_{\omega_{\alpha+1,\beta}}(0,\frac{1}{\beta})}.$$

Correspondingly, (3.30) becomes

$$|v(0)| \le c\Big(\beta^{\frac{\alpha+1}{2}} \|v\|_{\omega_{\alpha,\beta}} + \beta^{\frac{\alpha}{2}} \|\partial_x v\|_{\omega_{\alpha+1,\beta}}\Big) \le c\beta^{\frac{\alpha+1}{2}} (1+\beta^{-\frac{1}{2}}) \|v\|_{A^1_{\alpha,\beta}}.$$

Then the result (3.27) with $-1 < \alpha < 0$ follows from formula (3.26) and the fact $N^{-\frac{\alpha+1}{2}} \le c$. □

The following two theorems describe the error of interpolation $\mathcal{I}_{R,N,\alpha,\beta} v$.

THEOREM 3.7. *If $v \in A^r_{\alpha,\beta}(\Lambda) \cap A^r_{\alpha-1,\beta}(\Lambda)$, then for an integer $r \ge 1$ and $r > \alpha + 1$,*

$$\|\mathcal{I}_{R,N,\alpha,\beta} v - v\|_{\omega_{\alpha,\beta}} \le c(\beta N)^{\frac{1}{2}-\frac{r}{2}} \Big(\beta^{-1} |v|_{A^r_{\alpha-1,\beta}} + (1+\beta^{-\frac{1}{2}})(\ln N)^{\frac{1}{2}} |v|_{A^r_{\alpha,\beta}}\Big). \tag{3.31}$$

In particular, if $|\alpha| < 1$, then the previous result holds for all integers $r \ge 1$.

Proof. As a consequence of (3.26),

$$\begin{aligned} \|\mathcal{I}_{R,N,\alpha,\beta} v - P_{N,\alpha,\beta} v\|_{\omega_{\alpha,\beta}} &= \|\mathcal{I}_{R,N,\alpha,\beta}(P_{N,\alpha,\beta} v - v)\|_{\omega_{\alpha,\beta}} \\ &\le c(\beta N)^{-\frac{\alpha+1}{2}} |P_{N,\alpha,\beta} v(0) - v(0)| + c\beta^{-1} N^{-\frac{1}{2}} |P_{N,\alpha,\beta} v - v|_{1,\omega_{\alpha,\beta}} \\ &\quad + c(1+\beta^{-\frac{1}{2}})(\ln N)^{\frac{1}{2}} \|P_{N,\alpha,\beta} v - v\|_{A^1_{\alpha,\beta}}. \end{aligned} \tag{3.32}$$

According to Lemma 3.2, the first term on the right-hand side of (3.32) is bounded above by $c(\beta N)^{-\frac{r}{2}} |v|_{A^r_{\alpha,\beta}}$ for an integer $r > \alpha + 1$. The other two terms can be estimated by using Lemmas 3.1 and 3.3 with $\mu = 1$ (cf. the proof of (3.21)).

If $|\alpha| < 1$, we use (3.27) to derive (3.32), which does not contain the term $|P_{N,\alpha,\beta} v(0) - v(0)|$, and consequently does not require $r > \alpha + 1$. □

We can follow the same approach as for the proof of (3.22) to derive the following result.

THEOREM 3.8. *If $v \in A^r_{\alpha,\beta}(\Lambda) \cap A^r_{\alpha-1,\beta}(\Lambda) \cap A^{r-1}_{\alpha-\mu,\beta}(\Lambda)$, then for integers $1 \le \mu \le r$ and $r > \alpha + 1$,*

$$\begin{aligned} |\mathcal{I}_{R,N,\alpha,\beta} v - v|_{\mu,\omega_{\alpha,\beta}} \le & c(\beta N)^{\mu+\frac{1}{2}-\frac{r}{2}} \Big(\beta^{-1}\Big(|v|_{A^r_{\alpha-1,\beta}} + N^{-\frac{1}{2}} |v|_{A^r_{\alpha-\mu,\beta}}\Big) \\ & + (1+\beta^{-\frac{1}{2}})(\ln N)^{\frac{1}{2}} |v|_{A^r_{\alpha,\beta}}\Big). \end{aligned} \tag{3.33}$$

In particular, for $|\alpha| < 1$, the previous result holds for all integers $r \ge 1$.

4. Generalized Laguerre pseudospectral method for unbounded domains. This section is devoted to the generalized pseudospectral method based on the generalized Laguerre–Gauss interpolation. Throughout this section, let $\Omega = \Lambda \times S$ and S be the unit spherical surface, $S = \{(\lambda, \theta) | \ 0 \le \lambda < 2\pi, \ \ -\frac{\pi}{2} \le \theta < \frac{\pi}{2}\}$. The Laplacian operator on Ω is given by

$$\Delta v(\rho,\lambda,\theta) = \frac{1}{\rho^2}\partial_\rho(\rho^2\partial_\rho v(\rho,\lambda,\theta)) + \frac{1}{\rho^2\cos\theta}\partial_\theta(\cos\theta\partial_\theta v(\rho,\lambda,\theta)) + \frac{1}{\rho^2\cos^2\theta}\partial_\lambda^2 v(\rho,\lambda,\theta).$$

We consider the following problem:

$$\begin{cases} -\Delta W(\rho,\lambda,\theta) + \mu W(\rho,\lambda,\theta) = F(\rho,\lambda,\theta), \quad \mu > 0, \quad \text{in } \Omega, \\ W(\rho,\lambda+2\pi,\theta) = W(\rho,\lambda,\theta). \end{cases} \tag{4.1}$$

Here, we look for the solution of (4.1) such that $\rho^{\frac{1}{2}} W(\rho,\lambda,\theta) \to 0$ as $\rho \to 0$ and $\rho^{\frac{3}{2}} W(\rho,\lambda,\theta) \to 0$ as $\rho \to \infty$. In addition, the solution $W(\rho,\lambda,\theta)$ satisfies the pole condition, namely, $\partial_\lambda W(\rho,\lambda,\theta) = 0$ for $\theta = \pm\frac{\pi}{2}$.

It is noted that the usual weighted (with the weight $e^{-\beta\rho}$) Galerkin variational formulation of (4.1), on which the generalized Laguerre approximations are often based, is not well posed. One possible way to remedy this deficiency is to find a suitable variable transform such that the weighted variational formulation of the transformed equation becomes well posed. Motivated by [10], we make the variable transform

$$W(\rho,\lambda,\theta) = e^{-\frac{\beta}{2}\rho} U(\rho,\lambda,\theta), \quad F(\rho,\lambda,\theta) = e^{-\frac{\beta}{2}\rho} f(\rho,\lambda,\theta), \tag{4.2}$$

which converts (4.1) into

$$\begin{aligned} &-\partial_\rho^2 U(\rho,\lambda,\theta) - \frac{1}{\rho}(2-\beta\rho)\partial_\rho U(\rho,\lambda,\theta) - \frac{1}{\rho^2\cos\theta}\partial_\theta(\cos\theta\partial_\theta U(\rho,\lambda,\theta)) \\ &\quad - \frac{1}{\rho^2\cos^2\theta}\partial_\lambda^2 U(\rho,\lambda,\theta) + \frac{1}{\rho}\Big(\mu\rho + \beta - \frac{\beta^2}{4}\rho\Big) U(\rho,\lambda,\theta) = f(\rho,\lambda,\theta). \end{aligned} \tag{4.3}$$

To focus on our main idea, we consider only the spherically symmetric case, in which U and f are independent of λ and θ, denoted by $U(\rho)$ and $f(\rho)$, respectively. Accordingly,

$$-\partial_\rho^2 U(\rho) - \frac{1}{\rho}(2-\beta\rho)\partial_\rho U(\rho) + \frac{1}{\rho}\Big(\mu\rho + \beta - \frac{\beta^2}{4}\rho\Big) U(\rho) = f(\rho). \tag{4.4}$$

In addition, $\rho^{\frac{1}{2}} U(\rho) \to 0$ as $\rho \to 0$ and $\rho^{\frac{3}{2}} e^{-\frac{\beta}{2}\rho} U(\rho)$ as $\rho \to \infty$.

With the previous general setup, we now derive a weak formulation of (4.4). First, we observe that for any $v \in H^1_{\omega_{2,\beta}}(\Lambda)$, we have $\partial_\rho v(\rho) = o(\rho^{-\frac{3}{2}})$ and $v(\rho) = o(\rho^{-\frac{1}{2}})$ as $\rho \to 0$, and $\partial_\rho v(\rho) \sim v(\rho) = o(\rho^{-\frac{3}{2}} e^{\frac{\beta\rho}{2}})$ as $\rho \to \infty$. Consequently, if $v \in H^1_{\omega_{2,\beta}}(\Lambda) \cap L^2_{\omega_{1,\beta}}(\Lambda)$, then $\rho^2 v(\rho)\partial_\rho v(\rho) e^{-\beta\rho} \to 0$ as $\rho \to 0, \infty$. Hence, we obtain a weak formulation of (4.4). It is to find $U \in H^1_{\omega_{2,\beta}}(\Lambda) \cap L^2_{\omega_{1,\beta}}(\Lambda)$ such that

$$a_{\mu,\beta}(U,v) = (f,v)_{\omega_{2,\beta}} \quad \forall v \in H^1_{\omega_{2,\beta}}(\Lambda) \cap L^2_{\omega_{1,\beta}}(\Lambda), \tag{4.5}$$

where the bilinear form is defined by

$$a_{\mu,\beta}(u,v) = (\partial_\rho u, \partial_\rho v)_{\omega_{2,\beta}} + \Big(\mu - \frac{\beta^2}{4}\Big)(u,v)_{\omega_{2,\beta}} + \beta(u,v)_{\omega_{1,\beta}}.$$

One can verify that $a_{\mu,\beta}(\cdot,\cdot)$ is continuous and elliptic in $\big(H^1_{\omega_{2,\beta}}(\Lambda)\cap L^2_{\omega_{1,\beta}}(\Lambda)\big)^2$. Indeed,

$$|a_{\mu,\beta}(u,v)|\le c\big((1+\beta)\|u\|_{1,\omega_{2,\beta}}+\beta^{\frac12}\|u\|_{\omega_{1,\beta}}\big)\big((1+\beta)\|v\|_{1,\omega_{2,\beta}}+\beta^{\frac12}\|v\|_{\omega_{1,\beta}}\big),\tag{4.6}$$

and for $\mu>\frac{\beta^2}{4}$, we have

$$a_{\mu,\beta}(v,v)\ge c\big(\|v\|^2_{1,\omega_{2,\beta}}+\beta\|v\|^2_{\omega_{1,\beta}}\big).\tag{4.7}$$

Therefore, if $f\in(H^1_{\omega_{2,\beta}}(\Lambda)\cap L^2_{\omega_{1,\beta}}(\Lambda))'$, then (4.5) admits a unique solution.

The corresponding pseudospectral scheme for (4.5) is to seek $u_N(\rho)\in\mathbb{P}_N$ such that

$$a_{\mu,\beta,N}(u_N,\phi)=(f,\phi)_{\omega_{2,\beta},G,N}\quad\forall\phi\in\mathbb{P}_N,\tag{4.8}$$

where

$$a_{\mu,\beta,N}(u,v)=(\partial_\rho u,\partial_\rho v)_{\omega_{2,\beta},G,N}+\Big(\mu-\frac{\beta^2}{4}\Big)(u,v)_{\omega_{2,\beta},G,N}+\beta(u,v)_{\omega_{1,\beta},G,N}.$$

According to (2.22), (4.8) is equivalent to

$$a_{\mu,\beta}(u_N,\phi)=(\mathcal{I}_{G,N,2,\beta}f,\phi)_{\omega_{2,\beta}}\quad\forall\phi\in\mathbb{P}_N.\tag{4.9}$$

Before analyzing the convergence of (4.8), we first consider a special orthogonal projection $P^1_{N,\beta}:H^1_{\omega_{2,\beta}}(\Lambda)\cap L^2_{\omega_{1,\beta}}(\Lambda)\to\mathbb{P}_N$, defined by

$$\big(\partial_\rho(P^1_{N,\beta}v-v),\partial_\rho\phi\big)_{\omega_{2,\beta}}+\big(P^1_{N,\beta}v-v,\phi\big)_{\omega_{2,\beta}}+\big(P^1_{N,\beta}v-v,\phi\big)_{\omega_{1,\beta}}=0\quad\forall\phi\in\mathbb{P}_N.\tag{4.10}$$

To analyze its approximation error, we need the following two imbedding inequalities which are the special cases of Lemmas 2.1 and 2.2 of [12].

- If $v\in L^2_{\omega_{0,\beta}}(\Lambda)$, $\partial_\rho v\in L^2_{\omega_{2,\beta}}(\Lambda)$, and $v(\frac{1}{\beta})=0$, then

$$\|v\|_{\omega_{0,\beta}}\le c\|\partial_\rho v\|_{\omega_{2,\beta}}.\tag{4.11}$$

- If $v\in H^1_{\omega_{2,\beta}}(\Lambda)\cap L^2_{\omega_{0,\beta}}(\Lambda)$, then

$$\|v\|^2_{\omega_{2,\beta}}\le 8\beta^{-2}\big(\|\partial_\rho v\|^2_{\omega_{2,\beta}}+\|v\|^2_{\omega_{0,\beta}}\big).\tag{4.12}$$

LEMMA 4.1. *For any $v\in H^1_{\omega_{2,\beta}}(\Lambda)\cap L^2_{\omega_{1,\beta}}(\Lambda)\cap A^r_{1,\beta}(\Lambda)$ and integer $r\ge1$,*

$$\|P^1_{N,\beta}v-v\|_{1,\omega_{2,\beta}}+\|P^1_{N,\beta}v-v\|_{\omega_{1,\beta}}\le c(1+\beta^{-1})(\beta N)^{\frac{1-r}{2}}|v|_{A^r_{1,\beta}}.\tag{4.13}$$

Proof. By projection theorem and the Cauchy–Schwarz inequality,

$$\begin{aligned}\|P^1_{N,\beta}v-v\|^2_{1,\omega_{2,\beta}}+\|P^1_{N,\beta}v-v\|^2_{\omega_{1,\beta}}&\le\|\phi-v\|^2_{1,\omega_{2,\beta}}+\|\phi-v\|^2_{\omega_{1,\beta}}\\&\le|\phi-v|^2_{1,\omega_{2,\beta}}+\frac32\|\phi-v\|^2_{\omega_{2,\beta}}+\frac12\|\phi-v\|^2_{\omega_{0,\beta}}\quad\forall\phi\in\mathbb{P}_N.\end{aligned}$$

Taking $\phi(\rho)=P_{N,1,\beta}v(\rho)-P_{N,1,\beta}v(\frac1\beta)+v(\frac1\beta)$, we have from (4.11), (4.12), and (3.1) that

$$\begin{aligned}\|P^1_{N,\beta}v-v\|^2_{1,\omega_{2,\beta}}+\|P^1_{N,\beta}v-v\|^2_{\omega_{1,\beta}}&\le c(1+\beta^{-2})\|\partial_\rho(\phi-v)\|^2_{\omega_{2,\beta}}\\&=c(1+\beta^{-2})|P_{N,1,\beta}v-v|^2_{A^1_{1,\beta}}\le c(1+\beta^{-2})(\beta N)^{1-r}|v|^2_{A^r_{1,\beta}}.\end{aligned}$$ □

We now go back to the convergence analysis of scheme (4.8). Let $U_N = P^1_{N,\beta}U$; then by (4.5) and (4.10),

$$a_{\mu,\beta}(U_N, \phi) = -G(\phi) + (\mathcal{I}_{G,N,2,\beta}f, \phi)_{\omega_{2,\beta}} \quad \forall \phi \in \mathbb{P}_N, \tag{4.14}$$

where

$$G(\phi) = \Big(\mu - \frac{\beta^2}{4} - 1\Big)(U - U_N, \phi)_{\omega_{2,\beta}} + (\beta - 1)(U - U_N, \phi)_{\omega_{1,\beta}} + (\mathcal{I}_{G,N,2,\beta}f - f, \phi)_{\omega_{2,\beta}}.$$

Set $\widetilde{U}_N = u_N - U_N$. Then by (4.9) and (4.14),

$$a_{\mu,\beta}(\widetilde{U}_N, \phi) = G(\phi) \quad \forall \phi \in \mathbb{P}_N. \tag{4.15}$$

Taking $\phi = \widetilde{U}_N$ in the previous formula and using (4.7) give

$$\|\widetilde{U}_N\|^2_{1,\omega_{2,\beta}} + \beta\|\widetilde{U}_N\|^2_{\omega_{1,\beta}} \le c|G(\widetilde{U}_N)|. \tag{4.16}$$

Hence, it suffices to estimate $|G(\widetilde{U}_N)|$. For simplicity, we shall use the following notation:

$$\begin{aligned}
B^{(1)}_{N,\beta,r}(v) &= c(1+\beta^2)^2(1+\beta^{-1})^2(\beta N)^{1-r}|v|^2_{A^r_{1,\beta}},\\
B^{(2)}_{N,\beta,r}(v) &= c(1+\beta)^2(1+\beta^{-1})^2(\beta N)^{1-r}|v|^2_{A^r_{1,\beta}},\\
B^{(3)}_{N,\beta,s}(v) &= c(\beta N)^{1-s}\Big(\beta^{-2}|v|^2_{A^{s-1}_{1,\beta}} + (1+\beta^{-1})\ln N|v|^2_{A^s_{2,\beta}}\Big).
\end{aligned}$$

By virtue of (4.13) and (3.21), for integers $r, s \ge 1$,

$$|G(\widetilde{U}_N)| \le B^{(1)}_{N,\beta,r}(U) + B^{(2)}_{N,\beta,r}(U) + B^{(3)}_{N,\beta,s}(f) + \frac{1}{2}\|\widetilde{U}_N\|^2_{\omega_{2,\beta}} + \frac{\beta}{2}\|\widetilde{U}_N\|^2_{\omega_{1,\beta}}.$$

Plugging the previous formula into (4.16) leads to an estimate for $\|\widetilde{U}_N\|^2_{1,\omega_{2,\beta}} + \beta\|\widetilde{U}_N\|^2_{\omega_{1,\beta}}$. Since $U - u_N = U - P^1_{N,\beta}U - \widetilde{U}_N$, we use (4.13) again to reach the following conclusion.

Theorem 4.2. *Let U and u_N be the solutions of* (4.5) *and* (4.8), *respectively, and let $\mu > \frac{1}{4}\beta^2$. If $U \in A^r_{1,\beta}(\Lambda)$ and $f \in A^s_{1,\beta}(\Lambda) \cap A^s_{2,\beta}(\Lambda)$ with integers $r, s \ge 1$, then*

$$\|U - u_N\|^2_{1,\omega_{2,\beta}} + \beta\|U - u_N\|^2_{\omega_{1,\beta}} \le c\Big(B^{(1)}_{N,\beta,r}(U) + B^{(2)}_{N,\beta,r}(U) + B^{(3)}_{N,\beta,s}(f)\Big).$$

Remark 4.1. *After solving $u_N(\rho)$ from* (4.8), *we evaluate the numerical solution of the original problem by $w_N(\rho) = e^{-\frac{\beta}{2}\rho}u_N(\rho)$. Indeed, a direct computation leads to*

$$\begin{aligned}
\|W - w_N\|_{1,\hat{\omega}_2} + \sqrt{\beta}\|W - w_N\|_{\hat{\omega}_1} &\le (1+\beta)\|U - u_N\|_{1,\omega_{2,\beta}} + \sqrt{\beta}\|U - u_N\|_{\omega_{1,\beta}}\\
&= \mathcal{O}(N^{\frac{1-r}{2}} + (\ln N)^{\frac{1}{2}}N^{\frac{1-s}{2}}),
\end{aligned}$$

where $\hat{\omega}_\alpha(\rho) = \rho^\alpha = \omega_{\alpha,0}(\rho)$. A combination of the previous formula and (3.19) *with $\alpha = 1$ yields*

$$\begin{aligned}
\sup_{\rho\in\Lambda}|\rho(W - w_N)| &= \sup_{\rho\in\Lambda}|(U - u_N)\rho e^{-\frac{\beta}{2}\rho}| \le c\|U - u_N\|_{A^1_{1,\beta}}\\
&\le c(|U - u_N|_{1,\omega_{2,\beta}} + \|U - u_N\|_{\omega_{1,\beta}}) = \mathcal{O}(N^{\frac{1-r}{2}} + (\ln N)^{\frac{1}{2}}N^{\frac{1-s}{2}}).
\end{aligned}$$

Hence, a spectral accuracy is expected from theoretical analysis.

Remark 4.2. *Given $\mu > 0$, we can always choose the adjustable factor β such that $\mu > \frac{1}{4}\beta^2$, which guarantees the well-posedness of our Galerkin formulation.*

5. Generalized Laguerre pseudospectral method for exterior problems. This section is for the generalized Laguerre pseudospectral method based on Gauss–Radau interpolation for exterior problems. As an example, we consider the following equation induced by the spherically symmetric solution of the three-dimensional problem:

$$\begin{cases} -\dfrac{1}{\rho^2}\partial_\rho(\rho^2\partial_\rho W(\rho)) + \mu W(\rho) = F(\rho), \quad \mu > 0, \quad \rho > 1, \\ \lim\limits_{\rho\to\infty} \rho^{\frac{3}{2}} W(\rho) = 0, \quad W(1) = g. \end{cases} \tag{5.1}$$

For simplicity, let $g = 0$. We first shift the interval $[1, \infty)$ to $[0, \infty)$ by using the variable transform: $\rho = x + 1$, $W(\rho) = V(x)$, $F(\rho) = G(x)$. Then (5.1) becomes

$$\begin{cases} -\dfrac{1}{(x+1)^2}\partial_x((x+1)^2\partial_x V(x)) + \mu V(x) = G(x), \quad \mu > 0, \quad x > 0, \\ \lim\limits_{x\to\infty} x^{\frac{3}{2}} V(x) = V(0) = 0. \end{cases} \tag{5.2}$$

As mentioned earlier, it is necessary to make the following transformation:

$$V(x) = e^{-\frac{\beta}{2}x}U(x), \quad G(x) = (x+1)^{-2}e^{-\frac{\beta}{2}x}f(x).$$

Then (5.2) is rewritten as

$$\begin{cases} -\partial_x^2 U(x) - \dfrac{1}{x+1}(2 - \beta(x+1))\partial_x U(x) + \dfrac{1}{x+1}\Big(\Big(\mu - \dfrac{1}{4}\beta^2\Big)(x+1) + \beta\Big)U(x) \\ \quad = \dfrac{1}{(x+1)^2} f(x), \quad \mu > 0, \quad x > 0, \\ \lim\limits_{x\to\infty} x^{\frac{3}{2}} e^{-\frac{\beta}{2}x} U(x) = U(0) = 0. \end{cases} \tag{5.3}$$

Now, let $\sigma_{\alpha,\beta}(x) = (x+1)^\alpha e^{-\beta x}$, and denote ${}_0H^1_{\sigma_{2,\beta}}(\Lambda) := \{v \in H^1_{\sigma_{2,\beta}}(\Lambda) : u(0) = 0\}$. A weak form of (5.3) is to find $U \in {}_0H^1_{\sigma_{2,\beta}}(\Lambda) \cap L^2_{\sigma_{1,\beta}}(\Lambda)$ such that

$$\widetilde{a}_{\mu,\beta}(U, v) = (f, v)_{\omega_{0,\beta}} \quad \forall v \in {}_0H^1_{\sigma_{2,\beta}}(\Lambda) \cap L^2_{\sigma_{1,\beta}}(\Lambda), \tag{5.4}$$

where the bilinear form

$$\widetilde{a}_{\mu,\beta}(u, v) = (\partial_x u, \partial_x v)_{\sigma_{2,\beta}} + \Big(\mu - \frac{1}{4}\beta^2\Big)(u, v)_{\sigma_{2,\beta}} + \beta(u, v)_{\sigma_{1,\beta}}.$$

One can verify readily that

$$|\widetilde{a}_{\mu,\beta}(u, v)| \le c\big((1+\beta)\|u\|_{1,\sigma_{2,\beta}} + \beta^{\frac{1}{2}}\|u\|_{\sigma_{1,\beta}}\big)\big((1+\beta)\|v\|_{1,\sigma_{2,\beta}} + \beta^{\frac{1}{2}}\|v\|_{\sigma_{1,\beta}}\big), \tag{5.5}$$

and for $\mu > \frac{1}{4}\beta^2$,

$$|\widetilde{a}_{\mu,\beta}(v, v)| \ge c\big(\|v\|^2_{1,\sigma_{2,\beta}} + \beta\|v\|^2_{\sigma_{1,\beta}}\big). \tag{5.6}$$

Hence, if $f \in (H^1_{\sigma_{2,\beta}}(\Lambda) \cap L^2_{\sigma_{1,\beta}}(\Lambda))'$, then (5.4) has a unique solution.

The generalized Laguerre pseudospectral scheme for (5.4) is to seek $u_N \in {}_0\mathbb{P}_N := \{u \in \mathbb{P}_N : u(0) = 0\}$ such that

$$\widetilde{a}_{\mu,\beta,N}(u_N, \phi) = (f, \phi)_{\omega_{0,\beta},R,N} \quad \forall \phi \in {}_0\mathbb{P}_N, \tag{5.7}$$

where

$$\begin{aligned}\widetilde{a}_{\mu,\beta,N}(u,v) &= (\partial_x u, \partial_x v)_{\omega_{2,\beta},R,N} + 2(\partial_x u, \partial_x v)_{\omega_{1,\beta},R,N} + (\partial_x u, \partial_x v)_{\omega_{0,\beta},R,N}\\ &+\Big(\mu - \frac{1}{4}\beta^2\Big)(u,v)_{\omega_{2,\beta},R,N} + \Big(2\mu - \frac{1}{2}\beta^2 + \beta\Big)(u,v)_{\omega_{1,\beta},R,N}\\ &+\Big(\mu - \frac{1}{4}\beta^2 + \beta\Big)(u,v)_{\omega_{0,\beta},R,N}.\end{aligned}$$

According to (2.22), (5.7) is equivalent to

$$\widetilde{a}_{\mu,\beta}(u_N, \phi) = (\mathcal{I}_{R,N,0,\beta} f, \phi)_{\omega_{0,\beta}} \quad \forall \phi \in {}_0\mathbb{P}_N. \tag{5.8}$$

5.1. A specific orthogonal projection. We next consider a specific orthogonal projection that will be used in numerical analysis of generalized Laguerre pseudospectral method for exterior problems. Let ${}_0H^1_{\omega_{\alpha,\beta}}(\Lambda) := \{v \in H^1_{\omega_{\alpha,\beta}}(\Lambda) : v(0) = 0\}$. Note that $H^1_{\omega_{2,\beta}}(\Lambda) \cap H^1_{\omega_{0,\beta}}(\Lambda) \subseteq H^1_{\sigma_{2,\beta}}(\Lambda) \cap L^2_{\sigma_{1,\beta}}(\Lambda)$. The orthogonal projection ${}_0\Pi^1_{N,\beta} : {}_0H^1_{\omega_{2,\beta}}(\Lambda) \cap H^1_{\omega_{0,\beta}}(\Lambda) \to {}_0\mathbb{P}_N$ is defined by

$$\big(\partial_x({}_0\Pi^1_{N,\beta} v - v), \partial_x \phi\big)_{\sigma_{2,\beta}} + \big({}_0\Pi^1_{N,\beta} v - v, \phi\big)_{\sigma_{2,\beta}} = 0 \quad \forall \phi \in {}_0\mathbb{P}_N. \tag{5.9}$$

In order to analyze approximation error of the previous projection, we need another auxiliary orthogonal projection. To do this, we introduce the space $H^1_{\omega_{2,\beta},\omega_{0,\beta}}(\Lambda)$, equipped with the norm $\|v\|_{1,\omega_{2,\beta},\omega_{0,\beta}} = (\|\partial_x v\|^2_{\omega_{2,\beta}} + \|v\|^2_{\omega_{0,\beta}})^{\frac{1}{2}}$.

The orthogonal projection $\widetilde{P}^1_{N,\beta} : H^1_{\omega_{2,\beta},\omega_{0,\beta}}(\Lambda) \to \mathbb{P}_N$ is defined by

$$\big(\partial_x(\widetilde{P}^1_{N,\beta} v - v), \partial_x \phi\big)_{\omega_{2,\beta}} + \big(\widetilde{P}^1_{N,\beta} v - v, \phi\big)_{\omega_{0,\beta}} = 0 \quad \forall \phi \in \mathbb{P}_N. \tag{5.10}$$

LEMMA 5.1. *If $v \in H^1_{\omega_{2,\beta},\omega_{0,\beta}}(\Lambda) \cap A^r_{1,\beta}(\Lambda)$ and an integer $r \geq 1$, then*

$$\|\widetilde{P}^1_{N,\beta} v - v\|_{1,\omega_{2,\beta},\omega_{0,\beta}} \leq c(\beta N)^{\frac{1-r}{2}} |v|_{A^r_{1,\beta}}.$$

Proof. By projection theorem,

$$\|\widetilde{P}^1_{N,\beta} v - v\|_{1,\omega_{2,\beta},\omega_{0,\beta}} \leq \|\phi - v\|_{1,\omega_{2,\beta},\omega_{0,\beta}} \quad \forall \phi \in \mathbb{P}_N.$$

We take $\phi(x) = P_{N,1,\beta} v(x) - P_{N,1,\beta} v(\frac{1}{\beta}) + v(\frac{1}{\beta})$. Then by (4.11) and (3.1),

$$\|\phi - v\|_{1,\omega_{2,\beta},\omega_{0,\beta}} \leq c\|\partial_x(\phi - v)\|_{\omega_{2,\beta}} = c|P_{N,1,\beta} v - v|_{A^1_{1,\beta}} \leq c(\beta N)^{\frac{1-r}{2}} |v|_{A^r_{1,\beta}}.$$

This completes the proof. □

We are ready to estimate $\|{}_0\Pi^1_{N,\beta} v - v\|_{1,\sigma_{2,\beta}}$. We shall use the fact that for $v \in H^1_{\omega_{\alpha,\beta}}(\Lambda)$, $v(0) = 0$ and $\alpha < 1$, we have (see Lemma 2.2 of [12])

$$\|v\|_{\omega_{\alpha,\beta}} \leq c\beta^{-1} \|\partial_x v\|_{\omega_{\alpha,\beta}}. \tag{5.11}$$

LEMMA 5.2. *For any $v \in A^r_{0,\beta}(\Lambda)$ with $v(0) = 0$ and an integer $r \geq 2$,*

$$\|{}_0\Pi^1_{N,\beta} v - v\|_{1,\sigma_{2,\beta}} \leq c(1 + \beta^{-2})(\beta N)^{1-\frac{r}{2}} |v|_{A^r_{0,\beta}}.$$

Proof. By projection theorem,

$$\|{}_0\Pi^1_{N,\beta} v - v\|_{1,\sigma_{2,\beta}} \leq \|\phi - v\|_{1,\sigma_{2,\beta}} \leq c(\|\phi - v\|_{1,\omega_{2,\beta}} + \|\phi - v\|_{1,\omega_{0,\beta}}) \quad \forall \phi \in {}_0\mathbb{P}_N.$$

Taking

$$\phi(x) = \int_0^x \widetilde{P}^1_{N-1,\beta}\partial_\xi v(\xi)\,d\xi \in {}_0\mathbb{P}_N,$$

we have from Lemma 5.1 that

$$\|\partial_x(\phi - v)\|_{\omega_{0,\beta}} = \|\widetilde{P}^1_{N-1,\beta}\partial_x v - \partial_x v\|_{\omega_{0,\beta}} \le c(\beta N)^{1-\frac{r}{2}}|v|_{A^r_{0,\beta}}, \tag{5.12}$$

which, along with (5.11) with $\alpha = 0$, gives

$$\|\phi - v\|_{\omega_{0,\beta}} \le c\beta^{-1}\|\partial_x(\phi - v)\|_{\omega_{0,\beta}} \le c\beta^{-1}(\beta N)^{1-\frac{r}{2}}|v|_{A^r_{0,\beta}}. \tag{5.13}$$

Moreover, thanks to (4.12) with $\alpha = 2$, we have from Lemma 5.1 that

$$\begin{aligned}\|\partial_x(\phi - v)\|_{\omega_{2,\beta}} &= \|\widetilde{P}^1_{N-1,\beta}\partial_x v - \partial_x v\|_{\omega_{2,\beta}} \\ &\le c\beta^{-1}(\|\partial_x(\widetilde{P}^1_{N-1,\beta}\partial_x v - \partial_x v)\|_{\omega_{2,\beta}} + \|\widetilde{P}^1_{N-1,\beta}\partial_x v - \partial_x v\|_{\omega_{0,\beta}}) \\ &\le c\beta^{-1}(\beta N)^{1-\frac{r}{2}}|v|_{A^r_{0,\beta}}.\end{aligned} \tag{5.14}$$

Furthermore, using (4.12), (5.13), and (4.13) leads to

$$\|\phi - v\|_{\omega_{2,\beta}} \le c\beta^{-1}(\|\partial_x(\phi - v)\|_{\omega_{2,\beta}} + \|\phi - v\|_{\omega_{0,\beta}}) \le c\beta^{-2}(\beta N)^{1-\frac{r}{2}}|v|_{A^r_{0,\beta}}. \tag{5.15}$$

Finally, a combination of (5.12)–(5.15) leads to the desired result. □

5.2. Convergence analysis. Let $U_N = {}_0\Pi^1_{N,\beta}U$. Then by (5.4) and (5.9),

$$\widetilde{a}_{\mu,\beta}(U_N, \phi) = -\widetilde{G}(\phi) + (\mathcal{I}_{R,N,0,\beta}f, \phi)_{\omega_{0,\beta}} \quad \forall \phi \in {}_0\mathbb{P}_N, \tag{5.16}$$

where

$$\widetilde{G}(\phi) = \Big(\mu - \frac{1}{4}\beta^2 - 1\Big)(U - U_N, \phi)_{\sigma_{2,\beta}} + \beta(U - U_N, \phi)_{\sigma_{1,\beta}} + (\mathcal{I}_{R,N,0,\beta}f - f, \phi)_{\omega_{0,\beta}}.$$

Set $\widetilde{U}_N = u_N - U_N$. Then subtracting (5.16) from (5.8) yields

$$\widetilde{a}_{\mu,\beta}(\widetilde{U}_N, \phi) = \widetilde{G}(\phi) \quad \forall \phi \in {}_0\mathbb{P}_N. \tag{5.17}$$

Taking $\phi = \widetilde{U}_N$ in the previous formula and using (5.6), we obtain

$$\|\widetilde{U}_N\|^2_{1,\sigma_{2,\beta}} + \beta\|\widetilde{U}_N\|^2_{\sigma_{1,\beta}} \le c|\widetilde{G}(\widetilde{U}_N)|. \tag{5.18}$$

Thus, it suffices to estimate $|\widetilde{G}(\widetilde{U}_N)|$. For simplicity, we will use the following notation:

$$\begin{aligned}\widetilde{B}^{(1)}_{N,\beta,r}(v) &= c(\beta^2 + 1)^2(1 + \beta^{-2})^2(\beta N)^{2-r}|v|^2_{A^r_{0,\beta}}, \\ \widetilde{B}^{(2)}_{N,\beta,r}(v) &= c(1 + \beta^{-2})^2\beta(\beta N)^{2-r}|v|^2_{A^r_{0,\beta}}, \\ \widetilde{B}^{(3)}_{N,\beta,s}(v) &= c\beta^{-1}(\beta N)^{1-s}\Big(\beta^{-2}\|\partial_x^s v\|^2_{\omega_{s-1,\beta}} + (1 + \beta^{-1})\ln N|v|^2_{A^s_{0,\beta}}\Big).\end{aligned}$$

By virtue of Theorem 3.7 and Lemma 5.2, for integers $r \ge 2$ and $s \ge 1$,

$$|\widetilde{G}(\widetilde{U}_N)| \le \widetilde{B}^{(1)}_{N,\beta,r}(U) + \widetilde{B}^{(2)}_{N,\beta,r}(U) + \widetilde{B}^{(3)}_{N,\beta,s}(f) + \frac{1}{2}\|\widetilde{U}_N\|^2_{\sigma_{2,\beta}} + \frac{\beta}{2}\|\widetilde{U}_N\|^2_{\sigma_{1,\beta}}.$$

Plugging the previous formula into (5.18) leads to an estimate for $\|\widetilde{U}_N\|^2_{1,\sigma_{2,\beta}} + \beta\|\widetilde{U}_N\|^2_{\sigma_{1,\beta}}$. Finally, we use Lemma 5.2 again to reach the following conclusion.

THEOREM 5.3. *Let U and u_N be the solutions of* (5.4) *and* (5.7)*, respectively, and $\mu > \frac{1}{4}\beta^2$. If $U \in A^r_{0,\beta}(\Lambda)$ with $U(0) = 0$, and $f \in A^s_{0,\beta}(\Lambda)$ and $\partial^s_x f \in L^2_{\omega_{s-1,\beta}}(\Lambda)$ with integers $r \geq 2$ and $s \geq 1$, then*

$$\|U - u_N\|^2_{1,\sigma_{2,\beta}} + \beta\|U - u_N\|^2_{\sigma_{1,\beta}} \leq \widetilde{B}^{(1)}_{N,\beta,r}(U) + \widetilde{B}^{(2)}_{N,\beta,r}(U) + \widetilde{B}^{(3)}_{N,\beta,s}(f).$$

6. Numerical results. We present numerical results to illustrate the efficiency of the proposed schemes.

6.1. The scheme (4.8). We first take a look at the matrix form of the system (4.8). We take the base functions $\psi_j(\rho) = \mathcal{L}^{(1,\beta)}_j(\rho)$ and let $\mathbb{P}_N = \text{span}\{\psi_0, \psi_1, \ldots, \psi_N\}$. By (2.5) and (2.3), we have

$$\psi_j(\rho) = \frac{1}{\beta}\Big(\partial_\rho \mathcal{L}^{(1,\beta)}_j(\rho) - \partial_\rho \mathcal{L}^{(1,\beta)}_{j+1}(\rho)\Big) = -\mathcal{L}^{(2,\beta)}_{j-1}(\rho) + \mathcal{L}^{(2,\beta)}_j(\rho).$$

This fact together with (2.3) and (2.6) leads to

$$a_{jk} := (\partial_\rho\psi_k, \partial_\rho\psi_j)_{\omega_{2,\beta}} = \beta^2\gamma^{(2,\beta)}_{k-1}\delta_{j,k}, \quad m_{jk} := (\psi_k, \psi_j)_{\omega_{1,\beta}} = \gamma^{(1,\beta)}_k\delta_{j,k},$$
$$s_{jk} := (\psi_k, \psi_j)_{\omega_{2,\beta}} = \begin{cases} -\gamma^{(2,\beta)}_{k-1}, & j = k-1, \\ \gamma^{(2,\beta)}_{k-1} + \gamma^{(2,\beta)}_k, & j = k, \\ -\gamma^{(2,\beta)}_k, & j = k+1, \\ 0 & \text{otherwise}. \end{cases}$$

Next, we set

$$\begin{aligned} &u_N(\rho) = \sum_{j=0}^N \hat{u}_j\psi_j(\rho), \quad \mathbf{u} = (\hat{u}_0, \hat{u}_1, \cdots, \hat{u}_N)^T, \quad f_j = \ (f, \psi_j)_{\omega_{2,\beta},G,N}, \\ &\mathbf{f} = (f_0, f_1, \ldots, f_N)^T, \quad A = (a_{jk})_{0\leq j,k\leq N}, \quad M = (m_{jk})_{0\leq j,k\leq N}, \\ &S = (s_{jk})_{0\leq j,k\leq N}. \end{aligned} \tag{6.1}$$

Then the system (4.9) becomes

$$\Big(A + \Big(\mu - \frac{\beta^2}{4}\Big)S + \beta M\Big)\mathbf{u} = \mathbf{f}. \tag{6.2}$$

It is seen that this system is symmetric, tridiagonal, and easy to be inverted.

We now present some numerical results using the previous scheme to solve (4.1) with spherically symmetric solution $W(\rho)$. Basically, we find $u_N(\rho)$ from the system (6.2), and then evaluate the numerical solution by $w_N(\rho) = e^{-\frac{\beta}{2}\rho}u_N(\rho)$. In the following computations, let $\mu = 5$ in (4.8).

Example 1. We take the test function $W(\rho) = e^{-\gamma\rho}\sin h\rho$, with $\gamma > 0$, which decays exponentially at infinity. The corresponding solution of formula (4.4) is $U(\rho) = e^{(\beta/2-\gamma)\rho}\sin h\rho$. We measure the errors in two ways:

(i) maximum pointwise error:

$$\max_{0\leq j\leq N}\Big|\Big(W(\xi^{1,\beta}_{G,N,j}) - w_N(\xi^{1,\beta}_{G,N,j})\Big)\xi^{1,\beta}_{G,N,j}\Big| \sim \sup_{\rho\in\Lambda}|\rho(W(\rho) - w_N(\rho))|;$$

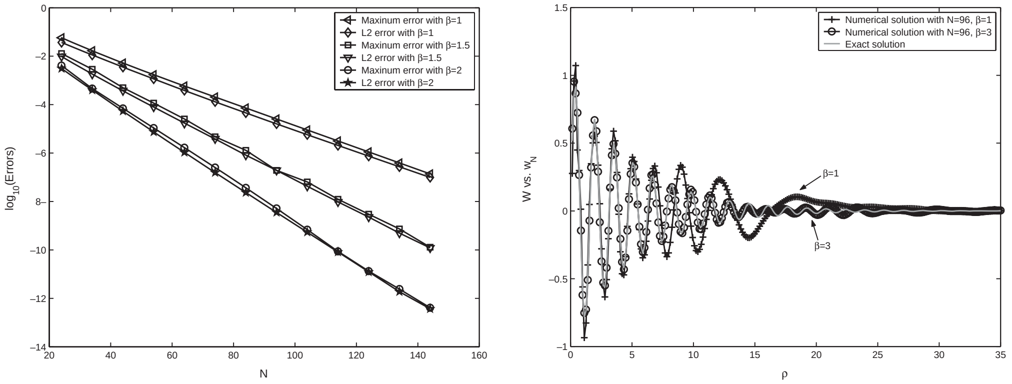

FIG. 6.1. *Convergence rate: Example* 1 *with* $\gamma = 1$ *and* $h = 3$ *on the left. Generalized Laguerre approximation: Example* 1 *with* $\gamma = 0.2$ *and* $h = 4$ *on the right.*

(ii) discrete L^2-error:

$$\|W - w_N\|_N := \|U - u_N\|_{\omega_{1,\beta},G,N} \sim \|W - w_N\|_{\hat{\omega}_1}.$$

In the left part of Figure 6.1, we plot the $\log_{10}$ of maximum error and the $\log_{10}$ of L^2-error against various N for $\gamma = 1,\ h = 3$, and different β. As predicted in Theorem 4.2 and Remark 4.1, the approximate solution will converge faster than any algebraic power, which is confirmed by the error behaviors (like $e^{-cN}, c > 0$) as shown in the figure. We also see that for fixed N, the scheme with $\beta = 2$ or $\beta = 1.5$ produces better numerical results than that with $\beta = 1$ (the usual generalized Laguerre approximation).

To see more clearly the role of β, we compare in the right part of Figure 6.1 the exact solution with $\gamma = 0.2$ and $h = 4$ with the numerical solution obtained by our pseudospectral scheme with $N = 96$ and $\beta = 1, 3$. Notice that the approximation solution with $\beta = 1$ exhibits an observable error, while the numerical solution with $\beta = 3$ is virtually indistinguishable with the exact solution. This example demonstrates that a suitable choice of the parameter β can raise the accuracy, and also enhance greatly the resolution capabilities of the generalized Laguerre approximations.

Example 2. We take $W(\rho) = \frac{\rho}{(\rho+1)^k}$ with $k > 1$, which decays algebraically at infinity. It is clear that $\rho^{\frac{3}{2}} W(\rho) \to 0$, as $\rho \to \infty$, if $k > \frac{5}{2}$.

In Figure 6.2, we plot the $\log_{10}$ of L^2-errors vs. $\sqrt{N}$ for different k and β. We see that the convergence rates are of order $O(e^{-c\sqrt{N}})$ for all cases, which are somewhat better than those predicted in Theorem 4.2 and Remark 4.1 (no more than order k). We also observe that for larger N, better numerical result can be obtained by choosing suitable $\beta < 1$ if the solution decays slowly (cf. the left part of Figure 6.2, where $W(\rho) = O(\rho^{-1.51})$), while conversely for the solution decaying very fast (cf. the right part of Figure 6.2, where $W(\rho) = O(\rho^{-4})$).

Example 3. We take $W(\rho) = \frac{\sin h\rho}{(1+\rho)^k}$ with $k > 0$, which decays algebraically with oscillation.

In Figure 6.3, we plot the $\log_{10}$ of L^2-errors vs. $\log_{10} N$. In the left part, we take $h = 3,\ k = 4$, and $\beta = 1, 2, 3, 4$, while in the right part, we fix $\beta = 2$ and $h = 3$, and test different $k = 3, 4, 5$. It is clear that in all cases, the errors decay at certain

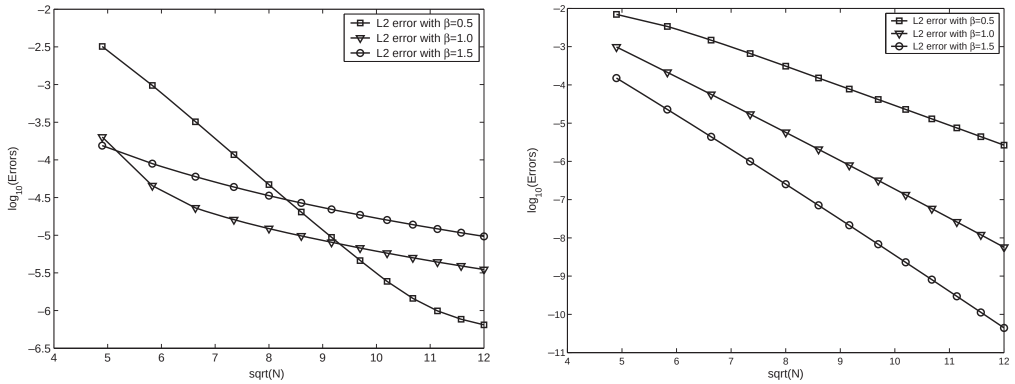

FIG. 6.2. *Convergence rate of generalized Laguerre pseudospectral method: Example* 2 *with* $k = 2.51$ *on the left; Example* 2 *with* $k = 5$ *on the right.*

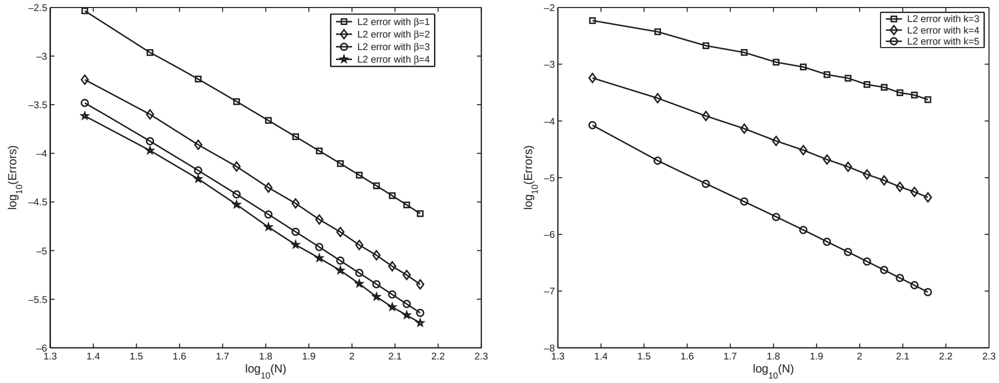

FIG. 6.3. *Convergence rate of generalized Laguerre pseudospectral method: Example* 3 *with* $h = 3$ *and* $k = 4$ *on the left; Example* 3 *with* $h = 3$ *and* $\beta = 2$ *on the right.*

algebraic rate. Once again, we see from the left part of this figure that a suitable parameter β can produce better numerical results. On the other hand, the right part shows that the faster the exact solution decays, the smaller the numerical errors would be. The previous facts coincide again well with our theoretical results.

6.2. The scheme (5.8). We next describe an efficient implementation for scheme (5.8). Set $\psi_j(x) := \mathcal{L}_j^{(0,\beta)}(x) - \mathcal{L}_{j+1}^{(0,\beta)}(x)$, $j \geq 0$, $\beta > 0$. Clearly, $\psi_j(0) = 0$. Hence, ${}_0\mathbb{P}_N = \text{span}\{\psi_0, \psi_1, \ldots, \psi_{N-1}\}$. We now study the structures of the corresponding matrices. Thanks to (2.5), we have $\partial_x \psi_j(x) = \beta \mathcal{L}_j^{(0,\beta)}(x)$, which, along with (2.3), implies that $(1+x)^2 \partial_x \psi_j(x)$ is a linear combination of $\mathcal{L}_l^{(0,\beta)}$, $j-2 \leq l \leq j+2$. This fact with (2.3), (2.5), and (2.6) leads to

$$\begin{aligned} a_{jk} &:= (\partial_x \psi_k, \partial_x \psi_j)_{\sigma_{2,\beta}} = 0 \quad &&\text{if} \quad |j-k| > 2, \\ b_{jk} &:= (\psi_k, \psi_j)_{\sigma_{2,\beta}} = 0 &&\text{if} \quad |j-k| > 3, \\ c_{jk} &:= (\psi_k, \psi_j)_{\sigma_{1,\beta}} = 0 &&\text{if} \quad |j-k| > 2. \end{aligned} \tag{6.3}$$

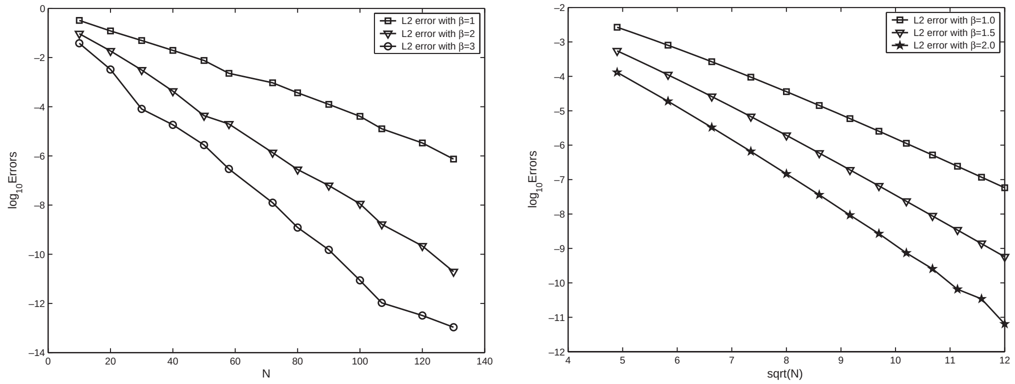

FIG. 6.4. *Convergence rate: Example* 4 *with* $\gamma = 1$ *and* $h = 3$ *on the left; Example* 5 *with* $h = 1$ *and* $k = 5$ *on the right.*

By setting

$$\begin{aligned} &u_N = \sum_{j=0}^{N-1} \hat{u}_j \psi_j(\rho), \quad \mathbf{u} = (\hat{u}_0, \hat{u}_1, \ldots, \hat{u}_{N-1})^{\mathrm{T}}, \\ &f_j = (f, \psi_j)_{\omega_{0,\beta},R,N}, \quad \mathbf{f} = (f_0, f_1, \ldots, f_{N-1})^{\mathrm{T}}, \\ &A = (a_{jk})_{0\le j,k\le N-1}, \quad B = (b_{jk})_{0\le j,k\le N-1}, \quad C = (c_{jk})_{0\le j,k\le N-1}, \end{aligned} \tag{6.4}$$

the system (5.8) becomes

$$\Big(A + \Big(\mu - \frac{\beta^2}{4}\Big)B + \beta C\Big)\mathbf{u} = \mathbf{f}. \tag{6.5}$$

The coefficient matrix is symmetric and has only several nonvanishing diagonals. Moreover, the nonzero entries can be determined explicitly by using properties of generalized Laguerre polynomials as shown in section 2.

We present below two numerical examples to show the efficiency of generalized Laguerre pseudospectral methods for exterior problems. Let $\mu = 5$ in (5.7).

Example 4. We take the test function $W(\rho) = e^{-\gamma(\rho-1)} \sin h(\rho - 1)$ with $\gamma > 0$ and $\rho \ge 1$, which decays exponentially at infinity. The corresponding solution of (5.3) is $U(\rho) = e^{(\beta/2-\gamma)\rho} \sin h\rho$. We denote the discrete L^2-error by $\|W - w_N\|_N := \|U - u_N\|_{\omega_{0,\beta},R,N}$.

In the left part of Figure 6.4, we plot the $\log_{10}$ of L^2-error against various N for $\gamma = 1,\ h = 3$, and different β. We observe a convergence rate of order $O(e^{-cN})$, as predicted in Theorem 5.3. Moreover, for fixed N, the scheme with $\beta = 3$ or $\beta = 2$ produces better numerical results than that with $\beta = 1$.

Example 5. We take $W(\rho) = \frac{\sin(h(\rho-1))}{\rho^k}$ with $k > 0$ and $\rho \ge 1$, which decays algebraically with oscillation. It is clear that $\rho^{\frac{3}{2}} W(\rho) \to 0$, as $\rho \to \infty$, if $k > \frac{3}{2}$.

In the right part of Figure 6.4, we plot the $\log_{10}$ of L^2-error vs. $\sqrt{N}$ for $h = 1,\ k = 5$, and different β. It is seen that the convergence rates are of order $O(e^{-c\sqrt{N}})$, which are somewhat better than what were predicted in Theorem 5.3 (no more than order k). Once again, the error behaviors confirm that a suitable choice of β gives better numerical results than that obtained from the usual generalized Laguerre approximation ($\beta = 1$).

7. Concluding remarks. In this paper, we established a set of results on generalized Laguerre–Gauss-type interpolation in nonuniformly weighted Sobolev spaces with the weight function $\omega_{\alpha,\beta}(x) = x^{\alpha}e^{-\beta x},\ \alpha > -1, \beta > 0$, which provided us useful tools in developing and analyzing generalized pseudospectral methods for a variety of problems in unbounded domains.

Several advantages justified our choice of working on the orthogonal system $\{\mathcal{L}_l^{(\alpha,\beta)}(x)\}$ with general parameters $\alpha > -1, \beta > 0$.

- The parameter α played an essential part in forming the pseudospectral schemes, which was chosen to agree with the degree of singular coefficients of leading terms in underlying equations. For instance, we take $\alpha = 2$ for three-dimensional problems as in (4.1) and (5.1), while we should take $\alpha = 1$ for two-dimensional problems.
- The adjustable parameter β offers great flexibility to match various asymptotic behaviors of the solutions at infinity. In fact, a suitable choice of β depends on certain coefficients which determine the asymptotic behaviors of solutions such as the parameter μ in (4.1) and (5.1).
- The parameter β somehow played a role similar to a scaling factor, which could improve the numerical resolution. But they are not exactly the same. Indeed, in the scaling method with variable transformation, one approximates the function $v(\beta x)$ by the basis $\{\mathcal{L}_l^{(\alpha)}(\beta x)\}$. However, we approximate the function $v(x)$ directly.
- As shown in sections 4 and 5, we could always choose a suitable value of β to guarantee the well-posedness of our Galerkin formulation, provided that some conditions are fulfilled.
- From theoretical point of view, our analysis included usual Laguerre ($\alpha = 0$ and $\beta = 1$) and standard generalized Laguerre ($\alpha > -1$ and $\beta = 1$) approximations as special cases. Moreover, our estimates improved the previously published results for the special case $\alpha = 0$ and $\beta = 1$ (cf. [19]). Roughly speaking, the factor $N^{\gamma}, \gamma > 0$ appearing in the upper bound of the interpolation error of [19] is now replaced by $\ln N$.

In this paper, our pseudospectral method was designed for transformed equations (cf. (4.4) and (5.3)). We may also take the generalized Laguerre functions $\widehat{\mathcal{L}}_l^{(\alpha,\beta)}(x) = e^{-\frac{\beta}{2}x}\mathcal{L}_l^{(\alpha,\beta)}(x)$ as the base functions that are mutually orthogonal with the weight $\hat{\omega}_{\alpha}(x) = x^{\alpha}$. In this case, the weights of Gauss quadrature, $\hat{\omega}_{Z,N,j}^{(\alpha,\beta)} = e^{\beta\xi_{Z,N,j}^{(\alpha,\beta)}}\omega_{Z,N,j}^{(\alpha,\beta)},\ Z = G, R,\ 0 \le j \le N$. Then, the pseudospectral scheme for (4.4) is to find $w_N \in \widehat{\mathbb{P}}_N := \{\phi : \phi = e^{-\frac{\beta}{2}x}\psi \quad \forall \psi \in \mathbb{P}_N\}$ such that

$$(\partial_x w_N, \partial_x \phi)_{\hat{\omega}_2,G,N} + \mu(w_N, \phi)_{\hat{\omega}_2,G,N} = (f, \phi)_{\hat{\omega}_2,G,N} \quad \forall \phi \in \widehat{\mathbb{P}}_N,$$

where $(\cdot,\cdot)_{\hat{\omega}_2,G,N}$ is the corresponding discrete inner product.

IDENTIFICATION OF ASYMPTOTIC DECAY TO SELF-SIMILARITY FOR ONE-DIMENSIONAL FILTRATION EQUATIONS*

LAURENT GOSSE† AND GIUSEPPE TOSCANI‡

Abstract. The objective of this paper is the derivation and the analysis of a simple explicit numerical scheme for general one-dimensional filtration equations. It is based on an alternative formulation of the problem using the pseudoinverse of the density's repartition function. In particular, the numerical approximations can be proven to satisfy a contraction property for a Wasserstein metric. Various numerical results illustrate the ability of this numerical process to capture the time-asymptotic decay towards self-similar solutions even for fast-diffusion equations.

Key words. degenerate parabolic equation, porous medium equation, Wasserstein metric

1. Introduction and examples.

This paper focuses onto the numerical analysis of the following Cauchy problem:

$$\partial_t u = \partial_{xx}\Phi(u), \quad u(t=0,x) = u_0(x) \geq 0, \quad x \in \mathbb{R},\ t > 0, \tag{1.1}$$

where $u_0 \in L^1(\mathbb{R})$ and $\Phi \in C^2(\mathbb{R}^+)$. It is also customary to assume $\Phi : \mathbb{R}^+ \to \mathbb{R}^+$ to be increasing. In the special case $\Phi(u) = u^m$, $m > 1$, one speaks about the *porous media equation* which describes the flow of a gas through a porous interface according to some constitutive relation linking its velocity to the pressure like Darcy's law. Another interesting situation corresponds to $0 < m < 1$ and is referred to as the *fast-diffusion equation*. The general case of the *filtration equations* can be encountered within the theory of heat transfer assuming the thermal conductivity to be a function of the temperature. A comprehensive introduction to these topics is provided in [25].

The numerical analysis of (1.1) is delicate for at least two reasons: the appearance of singularities for solutions with compact support when $\Phi'(0) = 0$, and the so-called retention property, which means that its size keeps growing as time increases; we shall briefly recall in section 2 theoretical results which are useful on a computational level. Implicit discretizations are thus of common use after, e.g., [6, 14, 20, 21, 17, 16, 23] (other references of interest are [1, 2, 11, 12, 13, 15, 18, 19, 22]); it leads to the resolution of a strictly elliptic problem for $w = \Phi(u)$ at every time-step Δt. Unfortunately, this very stable approach is of little help when investigating the *long-time behavior* of (1.1). Indeed, because of its spreading dynamics, the equation will ask for repetitive regridding. We refer to [3, 8, 7, 9, 10, 24, 25, 26, 27] for theoretical background on the asymptotics of (1.1), mainly in the case $\Phi(u) = u^m$, $m > 1$. We stress that one of the goals of the present work is to provide a tool which allows to achieve numerical studies for the cases still unknown.

This paper is, therefore, intended to introduce a new numerical approach able to solve both issues in a one-dimensional (1D) context. Loosely speaking, it consists in considering the *repartition function* ϱ of the density u, which is a monotone function, discretizing its values and evolving in time its pseudoinverse $X(t,\varrho)$ which satisfies (3.4) for $t>0$. This Lagrangian strategy is explained in detail in section 3.1, whereas stability and convergence properties are stated in section 3.2. Interestingly, a discrete contraction principle in a Wasserstein metric is shown in section 3.3.

At last, section 4 is concerned with numerical results: we check the decay towards a Gaussian distribution for the heat equation together with two cases of fast-diffusion equations. Then we come to present a decay towards the so-called Barenblatt–Pattle similarity profile for $\Phi(u)=\frac{u^2}{2}$ and a doubly degenerate Buckley–Leverett equation. Finally, some concluding remarks are drawn together with possible extensions to, e.g., viscous pressureless gas equations [4] and radial solutions of two-dimensional (2D) filtration equations.

2. L^1 theory for general porous media equations.

We first notice that there is no restriction in assuming $\Phi(0)=0$ in (1.1). A *weak solution* is generally defined as a distribution $u\in L^2_{loc}(\mathbb{R}^+;L^2(\mathbb{R}))$ such that $\Phi(u)\in L^2_{loc}(\mathbb{R}^+;H^1(\mathbb{R}))$, thus satisfying (1.1) in a weak sense for test functions belonging to $H^1(\mathbb{R})$. Existence and uniqueness results in this framework are recalled for instance in [20, 21]; we shall not pursue in this direction here.

2.1. Existence and uniqueness with nonnegative data.

We follow [25] and are focused hereafter with the Cauchy problem for slow-diffusion equations:

$$\partial_t u=\partial_{xx}(u^m),\quad u(t=0,.)=u_0\in L^1(\mathbb{R}),\quad x\in\mathbb{R},\ t>0. \tag{2.1}$$

We assume $m>1$ and $u_0\geq 0$ in order to study nonnegative L^1 solutions, (e.g., densities) with finite mass. In this context, asymptotics for (2.1) are now well known.

Definition 2.1. *A nonnegative function $u\in C^0(\mathbb{R}^+;L^1(\mathbb{R}))$ is a strong solution of* (2.1) *if*

- $u^m,\partial_t u,\partial_{xx}(u^m)\in L^1_{loc}(\mathbb{R}^+_*;L^1(\mathbb{R}))$,
- $\partial_t u=\partial_{xx}(u^m)$ *holds almost everywhere in* $\mathbb{R}^+_*\times\mathbb{R}$,
- $u(t=0,.)=u_0$.

In contrast to strongly parabolic equations for which $\Phi'(u)\neq 0$, strong solutions are not by no means classical; it is known that they are endowed with Hölder C^α continuity in space only. In one dimension, the exponent has been found to be $\alpha=\min(1,1/(m-1))$ [26]. Relying on the regularity properties of strong solutions to (2.1), we deduce easily two important properties of strong solutions:

- $\int_{\mathbb{R}}u(t,x)\,dx=\int_{\mathbb{R}}u_0(x)\,dx$ for all $t\in\mathbb{R}^+_*$ (conservation of mass);
- $\int_{\mathbb{R}}\max(0,u_1(t,x)-u_2(t,x))\,dx\leq\int_{\mathbb{R}}\max(0,u_1(s,x)-u_2(s,x))\,dx$ for all $t\geq s\geq 0$ (L^1-contraction property).

This last property of course implies uniqueness of strong solutions in the sense of Definition 2.1. A quite general result reads as follows.

Theorem 2.2. *For all $0\leq u_0\in L^1(\mathbb{R})$, there exists a unique strong solution of* (2.1), *$u\in C^0(\mathbb{R}^+;L^1(\mathbb{R}))\cap L^\infty(\mathbb{R}^+_*\times\mathbb{R})$, which satisfies*

- *for all $1\leq p\leq+\infty$, $u_0\in L^p(\mathbb{R})\Rightarrow\|u(t,.)\|_{L^p(\mathbb{R})}\leq\|u_0\|_{L^p(\mathbb{R})}$, $t>0$;*
- *let $v=\frac{mu^{m-1}}{m-1}$; it holds that $\partial_{xx}v(t,\cdot)\geq\frac{1}{(1+m)t}$ (semisuperharmonicity).*

Refined regularity properties are now given.

PROPOSITION 2.3. *Let $u_0 \in L^1 \cap C^0(\mathbb{R})$ be strictly positive and let u be its corresponding strong solution. Then $u \in C^\infty(\mathbb{R}_*^+ \times \mathbb{R}) \cap C^0(\mathbb{R}^+ \times \mathbb{R})$ is strictly positive and realizes a classical solution of* (2.1).

For instance, $u_0(x) = \frac{1}{\pi(1+x^2)}$ generates a unique classical solution of (2.1); this class of initial data will be extensively studied numerically. More generally, one can consider $u_0(x) = \frac{C_p}{(1+x^2)^p}$, $p \geq 1$.

2.2. Asymptotic decay towards source solutions. We observe that equation (1.1) can be rewritten as

$$\partial_t u = \partial_x (D(u)\partial_x u), \qquad D(u) = \Phi'(u).$$

In the special case of (2.1), $D(u) = mu^{m-1}$ is often called the *diffusivity*. It is a well-known fact that degeneracy levels for which Φ' vanishes, (e.g., at $u = 0$ for $\Phi(u) = u^m$) induce a phenomenon called *finite speed of propagation.*

THEOREM 2.4. *Let $0 \leq u_0 \in L^1 \cap L^\infty(\mathbb{R})$ and let u be the corresponding strong solution of* (2.1). *Assume that u_0 is supported in a bounded set of $\mathbb{R}$. Then for any positive time $t > 0$, the support of $u(t,.)$ is also bounded.*

The support of $u(t,\cdot)$ is generally strictly bigger than the one of u_0; this is the *retention property.* Making use of modern analytical tools, one can be more precise [7].

THEOREM 2.5. *Let $(u_0, v_0) \in L^1 \cap L^\infty(\mathbb{R})$ be nonnegative with unit masses and u, v their corresponding strong solutions in the sense of Definition* 2.1. *We define*

$$\Omega_u(t) = \{x \in \mathbb{R} \textit{ such that } u(t,x) > 0\}$$

and the analogue for v. Then it holds true that for all $t > 0$,

- $|\inf(\Omega_u(t)) - \inf(\Omega_v(t))| \leq W_\infty^0$,
- $|\sup(\Omega_u(t)) - \sup(\Omega_v(t))| \leq W_\infty^0$,

where the constant $W_\infty^0 \in \mathbb{R}^+$ depends only on m, u_0, v_0.

Its proof is based on a careful use of a Monge–Kantorowich related metric that we shall discuss in more detail later on; see section 3.3 and [28]. Indeed, as a particular case of (2.1), one can make the following mild hypotheses on the data:

$$u_0 \in L^1 \cap L^\infty(\mathbb{R}), \quad \int_{\mathbb{R}} x.u_0(x)\,dx = 0, \quad \Omega_u(0) \subset \text{ compact of } \mathbb{R}.$$

Then, as $t \to +\infty$, the corresponding strong solution to (2.1) decays towards a *similarity* (or source-type) solution,

$$U(t,x,C) = \frac{1}{t^\mu} \max\left\{0, \left(C - k\frac{x^2}{t^{2\mu}}\right)^{\frac{1}{m-1}}\right\}, \quad \mu = \frac{1}{1+m}, \quad k = \mu\frac{m-1}{2m}, \tag{2.2}$$

the normalization constant $C > 0$ ensuring that $U(t,.,C)$ has unit mass. One can also define the so-called *similarity variable* $\alpha(t)$ solution of

$$\alpha'(t) = \frac{1}{\alpha(t)^m}, \qquad \alpha(0) = 0 \tag{2.3}$$

for which (2.2) reads

$$U(t,x,C) = \frac{1}{\alpha(t)} \max\left\{0, \left(\tilde{C} - \frac{m-1}{2m}\frac{x^2}{\alpha(t)^2}\right)^{\frac{1}{m-1}}\right\}. \tag{2.4}$$

Of course, plugging $U(t, x, \|u_0\|_{L^1})$, $t \geq \tau > 0$, in place of v inside Theorem 2.5 yields an easy bound on the support of any strong solution of (2.1).

It has recently been shown that even for the general case (1.1) for which results are more sparse than (2.1), the third moment of $u(t,x)$ can play the role of an auxiliary variable in order to investigate the long-time behavior.

THEOREM 2.6 (see Toscani [24]). *Let* $0 \leq u_0 \in L^1 \cap L^\infty(\mathbb{R})$ *be of compact support in* $\mathbb{R}$*, u the corresponding strong solution of* (2.1)*, and* $E(t)$ *its third moment:*

$$E(t) = \int_{\mathbb{R}} \frac{x^2}{2} u(t,x)\, dx.$$

Then the similarity variable $\alpha(t)$ *satisfies, as* $t \to +\infty$*,*

$$\frac{E(t)}{\alpha(t)^2} \to E_B = \int_{\mathbb{R}} \frac{x^2}{2} U(t=1, x, C)\, dx,$$

where E_B *is the third moment of the source solution* (2.4) *at time* $t = 1$.

Hence a feasible route to study numerically the long-time asymptotics of (1.1) is to consider its *scaled solutions*,

$$f(t,x) = \sqrt{E(t)}\; u\Big(t, x\sqrt{E(t)}\Big), \tag{2.5}$$

which can hopefully be expected to stabilize as $t \to +\infty$ onto an asymptotic profile $f_\infty(x)$ independent of t. Of course, in case one considers (2.1) with convenient initial data, $f(t,.)$ will converge onto the corresponding Barenblatt–Pattle similarity solution according to the decay results of, e.g., [7, 26]; $t \mapsto E(t)$ is also expected to display a powerlike behavior.

3. An explicit numerical approximation.

We consider now a slightly more general problem than (2.1); namely, (1.1) completed by $0 \leq u_0 \in L^1 \cap L^\infty(\mathbb{R})$, compactly supported with unit mass. We shall also assume for convenience that the second moment vanishes:

$$\int_{\mathbb{R}} x u_0(x)\, dx = 0.$$

This property propagates for $t > 0$, as is easily seen from the formal computation:

$$\partial_t \int_{\mathbb{R}} x u(t,x)\, dx = -\int_{\mathbb{R}} \partial_x \Phi(u)(t,x)\, dx = 0.$$

3.1. Derivation of the numerical process.

As we can already notice, the decay towards similarity solutions can be slow, and because of the retention property, a direct simulation of (1.1) (or even (2.1)) will surely require quite a big computational domain with a possibly fine mesh. This clearly constitutes a numerical difficulty we propose to overcome in an original way, as follows.

- Let us introduce the distribution function associated to the probability density u_0,

$$\varrho_0(x) = \int_{-\infty}^{x} u_0(y)\, dy \in [0,1], \qquad \varrho_0 \in W^{1,1}_{loc}(\mathbb{R}),$$

which is obviously nondecreasing in the x variable. We can thus define its (nondecreasing) pseudoinverse:

$$\begin{array}{rccl} x_0: & [0,1] & \to & \mathbb{R}, \\ & \bar{\varrho} & \mapsto & x_0(\bar{\varrho}) := \inf\{y \in \mathbb{R} \text{ such that } \varrho_0(y) = \bar{\varrho}\}. \end{array} \tag{3.1}$$

If (1.1) holds in the sense of distributions, then also

$$\partial_t \varrho = \partial_x(\Phi(\partial_x \varrho)), \qquad \varrho(t=0,.) = \varrho_0, \tag{3.2}$$

from which one gets $u(t,x) = \partial_x \varrho(t,x)$.

- For any $\bar{\varrho} \in [0,1]$, we can define the *reciprocal mapping*,

$$\begin{array}{rccl} X: & \mathbb{R}^+ & \to & \mathbb{R}, \\ & t & \mapsto & X(t,\bar{\varrho}), \end{array}$$

by means of the implicit function theorem in case $\partial_x \varrho \neq 0$ such that

$$X(t=0,\bar{\varrho}) = x_0(\bar{\varrho}), \qquad \varrho(t, X(t,\bar{\varrho})) = \bar{\varrho}. \tag{3.3}$$

From the second condition in (3.3), one deduces easily

$$\frac{d}{dt}\varrho(t, X(t,\bar{\varrho})) = (\partial_t \varrho + \partial_t X . \partial_x \varrho)(t, X(t,\bar{\varrho})) = 0.$$

This yields the time evolution of $X(.,\varrho)$ (we drop the overbar for ease of reading),

$$\partial_t X = -\frac{\partial_t \varrho}{\partial_x \varrho} = -\frac{\partial_x(\Phi(\partial_x \varrho))}{\partial_x \varrho} \Rightarrow \partial_t X + \partial_\varrho \left(\Phi\left(\frac{1}{\partial_\varrho X} \right) \right) = 0, \tag{3.4}$$

since $\partial_\varrho X = 1/\partial_x \varrho$ holds for smooth enough functions.

Therefore, our numerical approach to (1.1) with convenient (unit mass, centered) initial data stems from computing the pseudoinverse of ϱ_0, $X(t=0,\cdot)$, evolving it in time by means of an *explicit* marching scheme for (3.4) in order to deduce the values of $\varrho(t, X(t,.)) \in [0,1]$ thanks to (3.3). Working on this pseudoinverse $X(t,.)$ allows us to pass through the expanding support issue for any arbitrary large time $t > 0$ since the computational domain is now fixed, $\varrho \in [0,1]$. The retention phenomenon manifests itself through the constant increase of $|\sup_\varrho(X(t,\varrho))|$ and $|\inf_\varrho(X(t,\varrho))|$ as t grows.

We now discretize the ϱ and t axes and define

$$X_k^n \simeq X(t^n, \varrho_k), \qquad t^n = n\Delta t \text{ for } k \in \mathcal{K} \subset \mathbb{N},\ n \in \mathbb{N}. \tag{3.5}$$

A numerical scheme for (3.4) reads

$$X_k^{n+1} = X_k^n - \frac{\Delta t}{|C_k|}\left\{ \Phi\left(\frac{\varrho_{k+1} - \varrho_k}{X_{k+1}^n - X_k^n} \right) - \Phi\left(\frac{\varrho_k - \varrho_{k-1}}{X_k^n - X_{k-1}^n} \right) \right\}, \tag{3.6}$$

where $|C_k| = \varrho_{k+\frac{1}{2}} - \varrho_{k-\frac{1}{2}}$ stands for the width of the control cell centered on ϱ_k with $\varrho_{k+\frac{1}{2}} = \varrho_0(x_{k+\frac{1}{2}})$. As ϱ_0 is at least absolutely and Lipschitz continuous, a convenient choice is given by linear interpolation, $\varrho_{k+\frac{1}{2}} = \frac{1}{2}(\varrho_k + \varrho_{k+1})$, which yields

$$|C_k| = \frac{1}{2}(\varrho_{k+1} - \varrho_{k-1}).$$

Equation (3.6) should be completed with boundary conditions at the edges of the computational domain $\varrho \in [0,1]$. For convenience, we selected Neumann-type conditions: $\Phi(u) = \Phi(\partial_x \varrho) = 0$ in $\varrho = 0$ and $\varrho = 1$. This gives on the left side

$$X_0^{n+1} = X_0^n - \frac{\Delta t}{|C_0|}\Phi\left(\frac{\varrho_1 - \varrho_0}{X_1^n - X_0^n}\right) \leq X_0^n,$$

together with a similar expression on the right side. This furthermore yields,

$$\forall n \in \mathbb{N}, \quad \sum_k |C_k| X_k^n = \sum_k |C_k| X_k^0 \simeq \int_0^1 X(t=0,\varrho)\, d\varrho = \int_{\mathbb{R}} x u_0(x)\, dx.$$

We stress that the ϱ_k's stand for a cumulative mass variable and thus do *not* depend on time. In order to reconstruct $\tilde{\varrho}(t^n,.)$, an approximation of $\varrho(t,.)$ at a given time $t \simeq t^n$, one has to interpolate the family of numerical values ϱ_k, X_k^n, t^n, since

$$\tilde{\varrho}(t^n, X_k^n) = \varrho_k \simeq \varrho(t^n, X_k^n),$$

up to the numerical truncation errors on X_k^n coming from the discretization (3.6). Then one deduces $u(t^n,.)$ by centered divided differences; such a numerical differentiation process may weaken the convergence though. An obvious consequence of this discretization is that the total variation in space of $\tilde{\varrho}(t,.)$ is constant in time.

Other useful quantities for the study of the asymptotic behavior of (2.1) are the moments $m_{2n+1}(t) = \int_{\mathbb{R}} x^{2n} u(t,x)\, dx$, $n \in \mathbb{N}$, which satisfy

$$\frac{d}{dt} m_{2n+1}(t) = 2n(2n-1) m_{2n-1}(t) \text{ for } \Phi(u) = u^m.$$

In the general case of (1.1), one still has

$$\text{(3.7)} \qquad \frac{d}{dt} m_3(t) = 2\int_{\mathbb{R}} \Phi(u)(t,x)\, dx, \qquad m_3(t) = 2E(t) = \int_0^1 X(t,\varrho)^2\, d\varrho.$$

This last equality provides us with a very convenient way to compute the scaled solution $f(t^n,.)$ (2.5) relying on our marching scheme (3.6).

3.2. Stability and consistency of the scheme. To fix ideas, we introduce now a regular computational mesh determined by $\Delta x > 0$, $x_k := k\Delta x$, $k \in \mathbb{N}$. Then we compute the sequence $u_k^0 = u_0(x_k)$ and thus $X_k^0 = X(0,\varrho_k) = x_k$ with $\varrho_0(x_k) = \varrho_k$.

Of course, because of the retention property, the derivation of bounds for the X_k^n's is doomed in advance because we expect $\sup_\varrho X(t,\varrho)$ to diverge when $t \to +\infty$. However, we can prove that the scheme (3.6) is *monotonicity-preserving.*

LEMMA 3.1. *Let* $0 < u_0 \in L^1 \cap L^\infty(\mathbb{R})$ *and let* $\Phi \in C^1(\mathbb{R})$ *be an increasing function; we denote* $0 < a := \inf_{k\in\mathcal{K}} \left(X_{k+1}^0 - X_k^0\right)$. *Then, under the CFL condition,*

$$\text{(3.8)} \qquad \frac{\Delta t}{a^2} \sup_k \left\{ \frac{\varrho_{k+1} - \varrho_k}{|C_k|} \Phi'\left(\frac{\varrho_{k+1} - \varrho_k}{X_{k+1}^0 - X_k^0}\right)\right\} \leq 1,$$

the scheme (3.6) *is monotonicity-preserving. Moreover, there hold, for* $n \in \mathbb{N}$,

$$\text{(3.9)} \qquad \sum_k |\delta X_{k+\frac{1}{2}}^n| \left|\frac{\delta \varrho_{k+\frac{1}{2}}}{\delta X_{k+\frac{1}{2}}^n}\right|^p \leq \|u_0\|_{L^p(\mathbb{R})}^p, \qquad p \geq 1,$$

and the uniform Lipschitz estimate

$$\sup_k \left| \frac{\delta \varrho_{k+\frac{1}{2}}}{\delta X^n_{k+\frac{1}{2}}} \right| \leq \|u_0\|_{L^\infty(\mathbb{R})}. \tag{3.10}$$

The estimates (3.9) and (3.10) are of course the discrete analogues of the continuous ones recalled in Theorem 2.2.

Proof. We first want to prove that $X^{n+1}_{k+1} - X^{n+1}_k$ is a positive combination of its neighbors at time t^n. To this end, we proceed by induction: let us assume that $X^n_{k+1} - X^n_k \geq a > 0$; from (3.6) we get

$$\begin{aligned} X^{n+1}_{k+1} - X^{n+1}_k = X^n_{k+1} - X^n_k - \Bigg\{ \frac{\Delta t}{|C_{k+1}|} \left(\Phi\Big(\frac{\varrho_{k+2} - \varrho_{k+1}}{X^n_{k+2} - X^n_{k+1}}\Big) - \Phi\Big(\frac{\varrho_{k+1} - \varrho_k}{X^n_{k+1} - X^n_k}\Big) \right) \\ - \frac{\Delta t}{|C_k|} \left(\Phi\Big(\frac{\varrho_{k+1} - \varrho_k}{X^n_{k+1} - X^n_k}\Big) - \Phi\Big(\frac{\varrho_k - \varrho_{k-1}}{X^n_k - X^n_{k-1}}\Big) \right) \Bigg\}. \end{aligned}$$

Thanks to the hypothesis, we can apply the mean-value theorem to the function Φ in the preceding expression. We introduce some notation: $\delta X^n_{k+\frac{1}{2}} := X^n_{k+1} - X^n_k \geq 0$, $\delta \varrho_{k+\frac{1}{2}} := \varrho_{k+1} - \varrho_k \geq 0$, and so on. This boils down to

$$\begin{aligned} \delta X^{n+1}_{k+\frac{1}{2}} = \delta X^n_{k+\frac{1}{2}} - \Bigg\{ \frac{\Delta t}{|C_{k+1}|} \Phi'_{k+1} \left(\frac{\delta \varrho_{k+\frac{3}{2}} \delta X^n_{k+\frac{1}{2}} - \delta \varrho_{k+\frac{1}{2}} \delta X^n_{k+\frac{3}{2}}}{\delta X^n_{k+\frac{3}{2}} \delta X^n_{k+\frac{1}{2}}} \right) \\ - \frac{\Delta t}{|C_k|} \Phi'_k \left(\frac{\delta \varrho_{k+\frac{1}{2}} \delta X^n_{k-\frac{1}{2}} - \delta \varrho_{k-\frac{1}{2}} \delta X^n_{k+\frac{1}{2}}}{\delta X^n_{k+\frac{1}{2}} \delta X^n_{k-\frac{1}{2}}} \right) \Bigg\}, \end{aligned}$$

where Φ'_{k+1}, Φ'_k stand for some midpoint values of the derivative of Φ at time t^n. Now, taking into account the signs of all the present quantities and rearranging terms, we obtain

$$\begin{aligned} \delta X^{n+1}_{k+\frac{1}{2}} = \delta X^n_{k+\frac{1}{2}} \left\{ 1 - \frac{\Delta t \Phi'_{k+1}}{\delta X^n_{k+\frac{3}{2}} \delta X^n_{k+\frac{1}{2}}} \frac{\delta \varrho_{k+\frac{3}{2}}}{|C_{k+1}|} - \frac{\Delta t \Phi'_k}{\delta X^n_{k+\frac{1}{2}} \delta X^n_{k-\frac{1}{2}}} \frac{\delta \varrho_{k-\frac{1}{2}}}{|C_k|} \right\} \\ + \frac{\Delta t \Phi'_{k+1}}{\delta X^n_{k+\frac{3}{2}} \delta X^n_{k+\frac{1}{2}}} \frac{\delta \varrho_{k+\frac{1}{2}}}{|C_{k+1}|} \delta X^n_{k+\frac{3}{2}} + \frac{\Delta t \Phi'_k}{\delta X^n_{k+\frac{1}{2}} \delta X^n_{k-\frac{1}{2}}} \frac{\delta \varrho_{k+\frac{1}{2}}}{|C_k|} \delta X^n_{k-\frac{1}{2}}. \end{aligned}$$

From this positive combination, we infer that

$$\begin{aligned} \frac{\delta X^{n+1}_{k+\frac{1}{2}}}{\delta \varrho_{k+\frac{1}{2}}} = \frac{\delta X^n_{k+\frac{1}{2}}}{\delta \varrho_{k+\frac{1}{2}}} \left\{ 1 - \frac{\Delta t \Phi'_{k+1}}{\delta X^n_{k+\frac{3}{2}} \delta X^n_{k+\frac{1}{2}}} \frac{\delta \varrho_{k+\frac{3}{2}}}{|C_{k+1}|} - \frac{\Delta t \Phi'_k}{\delta X^n_{k+\frac{1}{2}} \delta X^n_{k-\frac{1}{2}}} \frac{\delta \varrho_{k-\frac{1}{2}}}{|C_k|} \right\} \\ + \frac{\Delta t \Phi'_{k+1}}{\delta X^n_{k+\frac{3}{2}} \delta X^n_{k+\frac{1}{2}}} \frac{\delta \varrho_{k+\frac{3}{2}}}{|C_{k+1}|} \left(\frac{\delta X^n_{k+\frac{3}{2}}}{\delta \varrho_{k+\frac{3}{2}}} \right) + \frac{\Delta t \Phi'_k}{\delta X^n_{k+\frac{1}{2}} \delta X^n_{k-\frac{1}{2}}} \frac{\delta \varrho_{k-\frac{1}{2}}}{|C_k|} \left(\frac{\delta X^n_{k-\frac{1}{2}}}{\delta \varrho_{k-\frac{1}{2}}} \right), \end{aligned}$$

which is the desired convex combination under the condition (3.8); this ensures $X^{n+1}_{k+1} - X^{n+1}_k \geq a > 0$. Since $\mathbb{R}^+_* \ni x \mapsto 1/x$ is a convex function, the estimates (3.9) and (3.10) follow by Jensen's inequality. ∎

We stress that the monotonicity property of the X^n_k's is crucial in order to define an approximation $\tilde{\varrho}(t^n, .)$ as being the graph of a monovalued function, which is the least one may expect in this context. In particular, for $p = 1$, (3.9) boils down to $\sup_k \varrho_k \leq 1$.

Of course, in practice, one could obey the restriction (3.8) according to the *real* value of $\inf_k \left(X_{k+1}^n - X_k^n\right)$ at time t^n in order to allow Δt to vary in an *adaptive* way as times increase. We took advantage of this in the numerical tests shown subsequently. In order to keep $\Delta t > 0$, one needs to assume that $X(t,.)$ is strictly increasing, which implies that $u_0 > 0$. This can be partially dropped in practice; see section 4.

The next lemma is an important step towards the convergence result.

LEMMA 3.2. *The scheme* (3.6) *is consistent with* (3.2).

Proof. Let us define the function $\varrho^{\Delta x}$ defined by C^1 interpolation of the values

$$\forall\ (k,n) \in \mathcal{K} \times \mathbb{N}, \qquad \varrho^{\Delta x}(t^n, X_k^n) = \varrho_k. \tag{3.11}$$

From the very definition of $\varrho^{\Delta x}$ (3.11) and the scheme (3.6), one derives

$$\begin{aligned}\varrho^{\Delta x}(t^n, X_k^n) &= \varrho^{\Delta x}(t^{n+1}, X_k^{n+1}) \\ &= \varrho^{\Delta x}\left(t^{n+1}, X_k^n - \frac{\Delta t}{|C_k|}\left\{\Phi\Big(\frac{\varrho_{k+1}-\varrho_k}{X_{k+1}^n - X_k^n}\Big) - \Phi\Big(\frac{\varrho_k - \varrho_{k-1}}{X_k^n - X_{k-1}^n}\Big)\right\}\right).\end{aligned}$$

Then the mean-value theorem gives for some $\zeta_k^{n+1} = \lambda X_k^n + (1-\lambda)X_k^{n+1}$, $\lambda \in [0,1]$,

$$\begin{aligned}\varrho^{\Delta x}(t^{n+1}, X_k^{n+1}) = \varrho^{\Delta x}(t^n, X_k^n)& \\ + \frac{\Delta t}{|C_k|}\partial_x \varrho^{\Delta x}(t^{n+1}, \zeta_k^{n+1})&\left\{\Phi\Big(\frac{\varrho_{k+1}-\varrho_k}{X_{k+1}^n - X_k^n}\Big) - \Phi\Big(\frac{\varrho_k - \varrho_{k-1}}{X_k^n - X_{k-1}^n}\Big)\right\}.\end{aligned}$$

We now observe that

$$\frac{\partial_x \varrho^{\Delta x}(t^{n+1}, \zeta_k^{n+1})}{|C_k|} = \frac{\partial_x \varrho^{\Delta x}(t^{n+1}, \zeta_k^{n+1})}{\varrho^{\Delta x}(t^{n+1}, X_{k+\frac12}^{n+1}) - \varrho^{\Delta x}(t^{n+1}, X_{k-\frac12}^{n+1})} = \frac{1}{X_{k+\frac12}^{n+1} - X_{k-\frac12}^{n+1}}$$

up to high-order terms. Replacing the other values ϱ_k inside (3.6) by the corresponding $\varrho^{\Delta x}(t^n,.)$ leads to the following *finite volume* discretization of (3.2):

$$\begin{aligned}\varrho^{\Delta x}(t^{n+1}, X_k^n) &= \varrho^{\Delta x}(t^n, X_k^n) + \frac{\Delta t}{X_{k+\frac12}^{n+1} - X_{k-\frac12}^{n+1}} \\ \times \left\{\Phi\Big(\frac{\varrho^{\Delta x}(t^n, X_{k+1}^n) - \varrho^{\Delta x}(t^n, X_k^n)}{X_{k+1}^n - X_k^n}\Big)\right. &- \left.\Phi\Big(\frac{\varrho^{\Delta x}(t^n, X_k^n) - \varrho^{\Delta x}(t^n, X_{k-1}^n)}{X_k^n - X_{k-1}^n}\Big)\right\}.\end{aligned} \tag{3.12}$$ □

We now derive a time-modulus of equicontinuity for the aforementioned scheme.

LEMMA 3.3. *Under the assumptions of Lemma* 3.1 *and the CFL restriction* (3.8), *the scheme* (3.12) *satisfies*

$$\sup_k |\varrho^{\Delta x}(t^{n+1}, X_k^n) - \varrho^{\Delta x}(t^n, X_k^n)| = O(\sqrt{\Delta t}). \tag{3.13}$$

Proof. This readily follows from the expression (3.12), the CFL condition, and the Lipschitz estimate (3.10). □

THEOREM 3.4. *Under the assumptions of Lemma* 3.1 *and the CFL restriction* (3.8), *the sequence of approximate solutions* $\varrho^{\Delta x}$ *is relatively compact as* $\Delta x \to 0$ *in* $L^p_{loc}(\mathbb{R}_*^+ \times \mathbb{R})$; *it converges towards the unique solution in the sense of distributions of*

$$\partial_t \varrho = \partial_x(\Phi(\partial_x \varrho)), \quad \varrho(t=0,.) = \varrho_0 \in W^{1,p}(\mathbb{R}), \quad 1 \leq p \leq +\infty.$$

Proof. The proof is a bare consequence of the preceding lemmas together with a time-modulus of equicontinuity, as we explain now. Let us start from (3.12); multiplying by a smooth function with compact support $\varphi(t^{n+1}, X_k^n)$ and summing gives

$$\frac{1}{\Delta t}\sum_{k,n} |X^{n+1}_{k+\frac12} - X^{n+1}_{k-\frac12}|\varphi(t^{n+1}, X_k^n)\Big(\varrho^{\Delta x}(t^{n+1}, X_k^n) - \varrho^{\Delta x}(t^n, X_k^n)\Big)$$
$$= \sum_{k,n} \varphi(t^{n+1}, X_k^n)\left\{\Phi\left(\frac{\delta\varrho_{k+\frac12}}{\delta X^n_{k+\frac12}}\right) - \Phi\left(\frac{\delta\varrho_{k-\frac12}}{\delta X^n_{k-\frac12}}\right)\right\}.$$

Summing by parts yields

$$\frac{1}{\Delta t}\sum_{k,n} \varrho^{\Delta x}(t^n, X_k^n)\Big(-\varphi(t^{n+1}, X_k^n)|X^{n+1}_{k+\frac12} - X^{n+1}_{k-\frac12}| + \varphi(t^n, X_k^n)|X^n_{k+\frac12} - X^n_{k-\frac12}|\Big)$$
$$= \sum_{k,n} \Phi\left(\frac{\delta\varrho_{k+\frac12}}{\delta X^n_{k+\frac12}}\right)\Big(\varphi(t^{n+1}, X_k^n) - \varphi(t^{n+1}, X^n_{k+1})\Big).$$

We deduce, using the preceding notation,

$$\frac{1}{\Delta t}\sum_{k,n} \varrho^{\Delta x}(t^n, X_k^n)\Big(-\varphi(t^{n+1}, X_k^n)\delta X_k^{n+1} + \varphi(t^n, X_k^n)\delta X_k^n\Big)$$
$$-\sum_{k,n} \Phi\left(\frac{\delta\varrho_{k+\frac12}}{\delta X^n_{k+\frac12}}\right)\Big(\varphi(t^{n+1}, X_k^n) - \varphi(t^{n+1}, X^n_{k+1})\Big) = 0.$$

We can rewrite this in integral form as follows:

$$\sum_{k,n} \int_{t^n}^{t^{n+1}} \int_{X^n_{k-\frac12}}^{X^n_{k+\frac12}} \varrho^{\Delta x}(t^n, X_k^n)\Big(-\frac{\varphi(t^{n+1}, X_k^n) - \varphi(t^n, X_k^n)}{\Delta t}\Big)$$
$$+\Phi\left(\frac{\delta\varrho_{k+\frac12}}{\delta X^n_{k+\frac12}}\right)\Big(\frac{\varphi(t^n, X^n_{k+1}) - \varphi(t^n, X_k^n)}{\delta X_k^n}\Big)\,dx\,dt$$
$$= \Delta t\sum_{k,n} \varrho(t^n, X_k^n)\varphi(t^n, X_k^n)(\delta X_k^{n+1} - \delta X_k^n)$$
$$+\Phi\left(\frac{\delta\varrho_{k+\frac12}}{\delta X^n_{k+\frac12}}\right)\Big(\varphi(t^{n+1}, X_k^n) - \varphi(t^{n+1}, X^n_{k+1}) - \varphi(t^n, X_k^n) + \varphi(t^n, X^n_{k+1})\Big).$$

At this point, we use the fact that $\Phi(\delta\varrho/\delta X)$ and $\varrho(t^n, X_k^n)$ are bounded, and φ is smooth in both variables; then we rewrite the first term of the right-hand side as

$$-\sum_{k,n}\Delta t\int_{X^n_{k-\frac12}}^{X^n_{k+\frac12}} (\varrho^{\Delta x}\varphi)(t^n, X_k^n) - (\varrho^{\Delta x}\varphi)(t^{n-1}, X_k^{n-1})\,dx$$

and the second term as

$$-\sum_{k,n}\Delta t\int_{t^n}^{t^{n+1}}\int_{X_k^n}^{X^n_{k+1}} \Phi\left(\frac{\delta\varrho_{k+\frac12}}{\delta X^n_{k+\frac12}}\right)\partial_{tx}\varphi(\tau, \xi)\,d\xi\,d\tau.$$

Now, since $0 < u_0 \in L^1 \cap L^\infty(\mathbb{R})$, ϱ_0 is a strictly increasing Lipschitz function of x; hence the family $(X_k^n)_k$ covers the whole axis $\mathbb{R}$. Then, by regularity, $|X^n_{k+1} - X^n_k| \to 0$

and $|X_k^{n+1} - X_k^n| \to 0$ for $n \in \mathbb{N}$ as $\Delta x \to 0$ since by Lemma 3.1, (3.6) is a convex combination. This is enough to derive the weak form of the equation. Uniqueness in the limit follows from the classical argument of Oleinik for weak solutions; see [25]. □

We close this section by mentioning that the assumption $u_0 > 0$ in Lemma 3.1 is essentially needed in order to ensure that $(X_k^n)_{k\in\mathbb{N}}$ permits us to cover the whole real line as $\Delta x \to 0$. We shall consider in section 4.4 initial data of compact support which are strictly positive only inside their support; in this case, only the support of $u(n\Delta t, .)$ can be expected to be recovered.

3.3. Study of the Wasserstein metric. We mainly follow [7, 10, 28] to study *contraction properties* of the scheme (3.6) within the Wasserstein metric framework. Denoting $\mathbb{P}_p(\mathbb{R})$ as the set of all probability measures on $\mathbb{R}$ with moments of order $1 \le p < +\infty$ and $\Pi(\nu_1, \nu_2)$ as any of the probability measures on $\mathbb{R}^2$ admitting $\nu_{1,2} \in \mathbb{P}_p(\mathbb{R})$ as marginal distributions, the *Wasserstein p-metric* reads

$$W_p(\nu_1,\nu_2) := \left(\inf_{\pi\in\Pi(\nu_1,\nu_2)} \int_{\mathbb{R}^2} |x-y|^p \, d\pi(x,y) \right)^{\frac{1}{p}}, \qquad 1 \le p < +\infty. \tag{3.14}$$

Any probability measure admits a distribution function, which can be chosen right-continuous, nondecreasing, and taking values inside $[0,1]$. A nondecreasing pseudoinverse can be defined as for (3.1). Hence if X_1, X_2 stand for the pseudoinverses of the repartition functions of $\nu_1, \nu_2 \in \mathbb{P}_p(\mathbb{R})$, the distance (3.14) can be rewritten as

$$W_p(\nu_1,\nu_2) := \left(\int_0^1 |X_1(\varrho) - X_2(\varrho)|^p \, d\varrho \right)^{\frac{1}{p}}, \qquad 1 \le p < +\infty. \tag{3.15}$$

According to (1.1), a formal computation leads easily to a contraction property for the metric $W_2(.,.)$. Let $X(t,\varrho), Y(t,\varrho)$ stand for two reciprocal mappings associated to nonnegative and centered initial data of (1.1) $u_0, v_0 \in L^1 \cap L^\infty(\mathbb{R})$ with unit mass

$$\begin{aligned} \frac{d}{dt}\int_0^1 |X(t,\varrho) - Y(t,\varrho)|^2 \, d\varrho &= -2\int_0^1 (X-Y)\partial_\varrho \left\{ \Phi\Big(\frac{1}{\partial_\varrho X}\Big) - \Phi\Big(\frac{1}{\partial_\varrho Y}\Big) \right\}(t,\varrho)\, d\varrho \\ &= 2\int_0^1 \partial_\varrho(X-Y) \left\{ \Phi\Big(\frac{1}{\partial_\varrho X}\Big) - \Phi\Big(\frac{1}{\partial_\varrho Y}\Big) \right\}(t,\varrho)\, d\varrho \\ &\le 0, \end{aligned}$$

because Φ is increasing. Then a similar property can be shown to hold for the outcome of the explicit scheme (3.6).

THEOREM 3.5. *Let u_0, v_0 be two nonnegative initial data in $L^1 \cap L^\infty(\mathbb{R})$ for* (1.1) *and let X, Y be their reciprocal mappings. Under the CFL restriction* (3.8)*, the scheme* (3.6) *is contractive in any Wasserstein metric W_p; more precisely, there holds,*

$$\forall n \in \mathbb{N}, \quad \sum_k |C_k||X_k^{n+1} - Y_k^{n+1}|^p \le \sum_k |C_k||X_k^n - Y_k^n|^p, \quad p \ge 1. \tag{3.16}$$

Proof. Mimicking the preceding formal computation, we aim at establishing

$$\delta W_p := \frac{1}{\Delta t}\sum_k |C_k| \left\{ |X_k^{n+1} - Y_k^{n+1}|^p - |X_k^n - Y_k^n|^p \right\} \le 0.$$

We get from (3.6) that

$$\begin{aligned} X_k^{n+1} - Y_k^{n+1} &= X_k^n - Y_k^n - \left\{ \frac{\Delta t}{|C_k|} \left(\Phi\Big(\frac{\varrho_{k+1}-\varrho_k}{X_{k+1}^n - X_k^n}\Big) - \Phi\Big(\frac{\varrho_k - \varrho_{k-1}}{X_k^n - X_{k-1}^n}\Big)\right)\right. \\ &\qquad \left. - \frac{\Delta t}{|C_k|} \left(\Phi\Big(\frac{\varrho_{k+1}-\varrho_k}{Y_{k+1}^n - Y_k^n}\Big) - \Phi\Big(\frac{\varrho_k - \varrho_{k-1}}{Y_k^n - Y_{k-1}^n}\Big)\right)\right\} \\ &= X_k^n - Y_k^n - \frac{\Delta t}{|C_k|} \left\{ \Big(\Phi_{k+\frac12}(X_{k+1}^n - X_k^n) - \Phi_{k+\frac12}(Y_{k+1}^n - Y_k^n)\Big)\right. \\ &\qquad \left. - \Big(\Phi_{k-\frac12}(X_k^n - X_{k-1}^n) - \Phi_{k-\frac12}(Y_k^n - Y_{k-1}^n)\Big)\right\}, \end{aligned}$$

where we used the notation

$$\Phi_{k+\frac12}(\delta X) := \Phi\Big(\frac{\varrho_{k+1}-\varrho_k}{\delta X}\Big).$$

Thanks to the bound given by Lemma 3.1, we know that $\delta X \geq a > 0$, so the function $\Phi_{k+\frac12}$ is smooth and the mean-value theorem can be applied. The outcome is

$$\begin{aligned} X_k^{n+1} - Y_k^{n+1} &= (X_k^n - Y_k^n)\left(1 + \frac{\Delta t}{|C_k|}\big(\Phi'_{k+\frac12} + \Phi'_{k-\frac12}\big)\right) \\ &\quad - \frac{\Delta t}{|C_k|}\Phi'_{k+\frac12}(X_{k+1}^n - Y_{k+1}^n) - \frac{\Delta t}{|C_k|}\Phi'_{k-\frac12}(X_{k-1}^n - Y_{k-1}^n), \end{aligned}$$

with $\Phi'_{k+\frac12}$ standing for some midpoint value of the derivative of $\Phi_{k+\frac12}$ with respect to δX. Hence, since

$$\Phi'_{k+\frac12}(\delta X) = -\frac{\varrho_{k+1}-\varrho_k}{\delta X^2}\Phi'\Big(\frac{\varrho_{k+1}-\varrho_k}{\delta X}\Big),$$

the CFL condition (3.8) ensures that the last expression is a convex combination. By means of Jensen's inequality, and thanks to the fact that the fluxes are null on the borders of the domain, this yields $\delta W_p \leq 0$ and we are done. □

A consequence of this is that in case one would want to use the discretization (3.6) for a problem (1.1) with a partly atomic probability measure, one can initialize the scheme with a somewhat smoother initial data relying on this contraction property. Moreover, this also ensures that the propagation speed of the free boundaries is correct relying on Theorem 2.5.

We stress that the estimate (3.16) doesn't imply a decay of the support $(X_k^n)_{k\in\mathcal{K}}$ which would somewhat contradict the retention phenomenon. Indeed, the CFL condition (3.8) cannot allow us to choose $Y_k^n \equiv 0$.

4. Numerical results.

All the following tests have been carried out relying on the explicit scheme (3.6); the initial data u_0 is sampled on a set of 257 points, which gives a space-step Δx equal to the length of the domain divided by 256. The ϱ_k's are then deduced by numerical quadrature. The time-step is chosen in an adaptive way, as explained after the proof of Lemma 3.1.

4.1. Validation: The heat equation.

In order to test the scheme on a simple and well-known case, we set up (1.1) with $\Phi(u) = \frac{u}{2}$. The initial data is chosen rather far away from the expected equilibrium state:

$$u_0(x) = \frac12\left(\frac{1}{\pi(1+(x-5)^2)} + \frac{1}{\pi(1+(x+5)^2)}\right), \qquad x \in [-20, 20]. \tag{4.1}$$

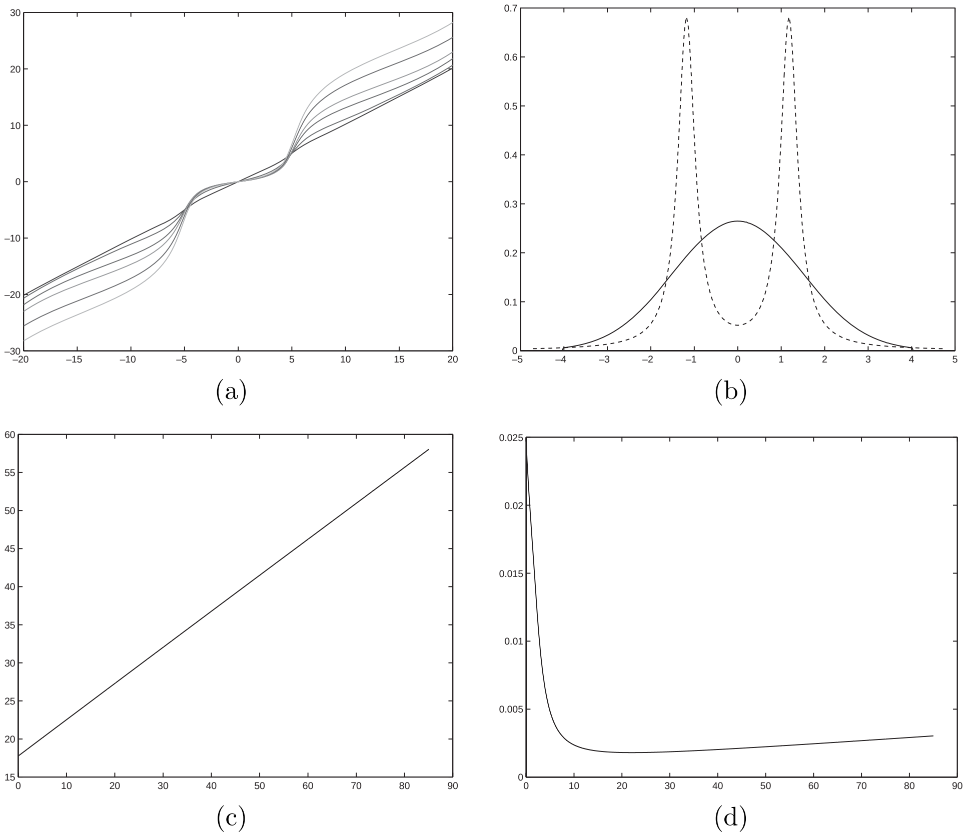

FIG. 1. (a) *Numerical values for* $X(t,x)$ *for* $t = 1, 5, 15, 25, 45, 65$*;* (b) *scaled initial data* $f(t = 0, .)$ (*dotted line*) *and stationary solution* f_∞ (*solid line*)*;* (c) *evolution of* $E(t)$ *with time* t*;* (d) *evolution of* Δt *with time* t.

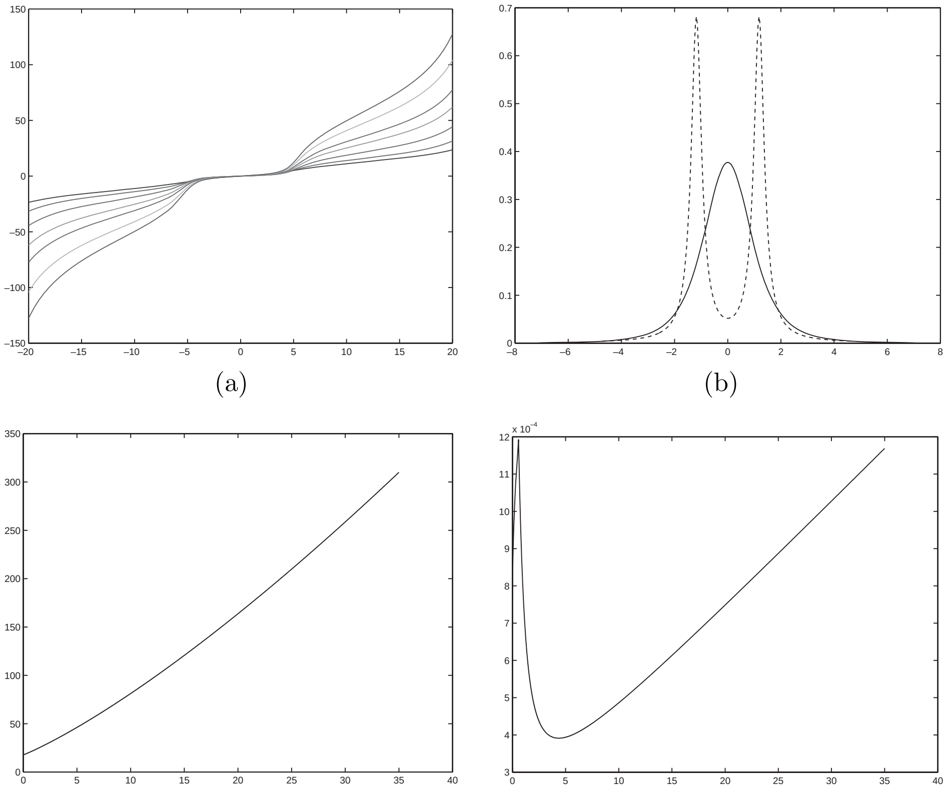
We observe that even if $\int_{\mathbb{R}} x^2 u_0(x)\,dx$ isn't bounded, one can set up the scheme (3.6) for x inside a compact interval of $\mathbb{R}$. The results at time $t = 85$ are displayed in Figure 1. Along with the evolution of X_k^n as $t^n = 1, 5, 15, 25, 45, 65$, we observe a linear increase of $t \mapsto E(t)$ as shown theoretically and a correct decay onto a Gaussian distribution for the scaled solution $f(t, .)$. We show the corresponding (numerically) stationary profile. The time-step decreases a lot when the two bumps merge but increases afterwards as the solution $u(t, .)$ no longer changes its shape.

4.2. Two cases of fast-diffusion equations. We now display in Figures 2 and 3 a similar experiment with two fast-diffusion equations, respectively, $\Phi(u) = \sqrt{u}$ and $\Phi(u) = u^{\frac{1}{4}}$. The initial data and the computational domain are still given by (4.1). Several major differences show up in this case compared to the heat equation:

- the support of the solution extends much more quickly as the exponent m is decreased, as can be seen on the graphs of the X_k^n's;
- the scaled solutions $f(t, .)$ stabilize at much earlier times ($t \simeq$ 25–30);
- the asymptotic profile is more peaked with a lower value of m;
- the mapping $t \mapsto E(t)$ now looks convex.

However, as for the heat equation, the asymptotic solution has infinite support and is thus C^∞ as a consequence of Proposition 2.3; see also [26]. We stress that the tails



(a) (b)

(c) (d)

FIG. 2. (a) *Numerical values for* $X(t,x)$ *for* $t = 0.5, 2, 5, 10, 15, 25, 35$*,* $m = 0.5$*;* (b) *scaled initial data* $f(t = 0, .)$ (*dotted line*) *and stationary solution* f_∞ (*solid line*)*;* (c) *evolution of* $E(t)$ *with time* t*;* (d) *evolution of* Δt *with time* t*.*

of the initial data can be seen to be close to the ones of the asymptotic profile; see [24] for remarks in this direction.

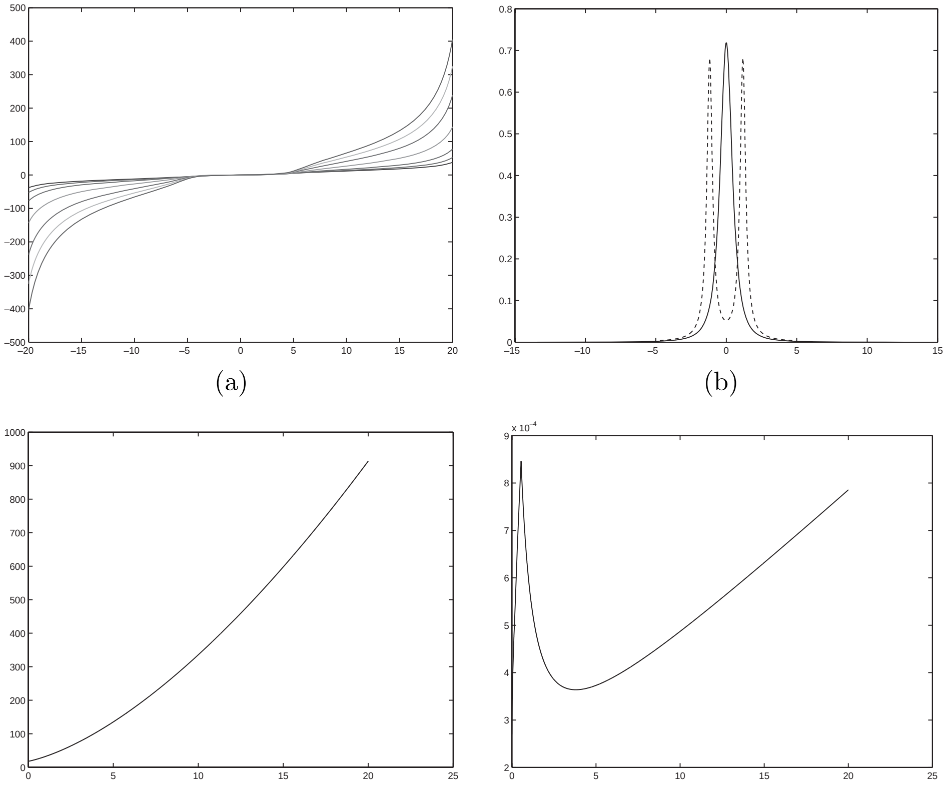
4.3. The porous media equation and Barenblatt's solution. We investigated the case of the classical porous medium equation, namely, $\Phi(u) = \frac{u^2}{2}$ with the data (4.1). Since it isn't compactly supported, we didn't observe the well-known decay towards the corresponding Barenblatt–Pattle solution, but instead, f_∞ exhibits a similar profile with two tails on each side, as shown in Figure 4. Also the mapping $t \mapsto E(t)$ looks concave and the stabilization time is much greater than in the two preceding examples ($t \simeq 200$). The variations of the time-step are moderate in comparison with the fast-diffusion equations.

4.4. Buckley–Leverett's doubly degenerate equation. Finally, we studied a more singular problem given by (1.1) with

$$\Phi(u) = \frac{u^2}{u^2 + 0.5(1-u)^2}.$$

The derivative Φ' vanishes at two points $u = 0$ and $u = 1$. We set up the following smooth initial data extended by zero outside of $[-1, 1]$:

$$u_0 = \cos(\pi x/2)^2, \qquad x \in [-1, 1].$$



(a)

(b)

(c)

(d)

FIG. 3. (a) *Numerical values for $X(t,x)$ for $t = 0.5, 1, 2, 5, 10, 15, 20$, $m = 0.25$;* (b) *scaled initial data $f(t = 0, .)$* (*dotted line*) *and stationary solution f_∞* (*solid line*)*;* (c) *evolution of $E(t)$ with time t;* (d) *evolution of Δt with time t.*

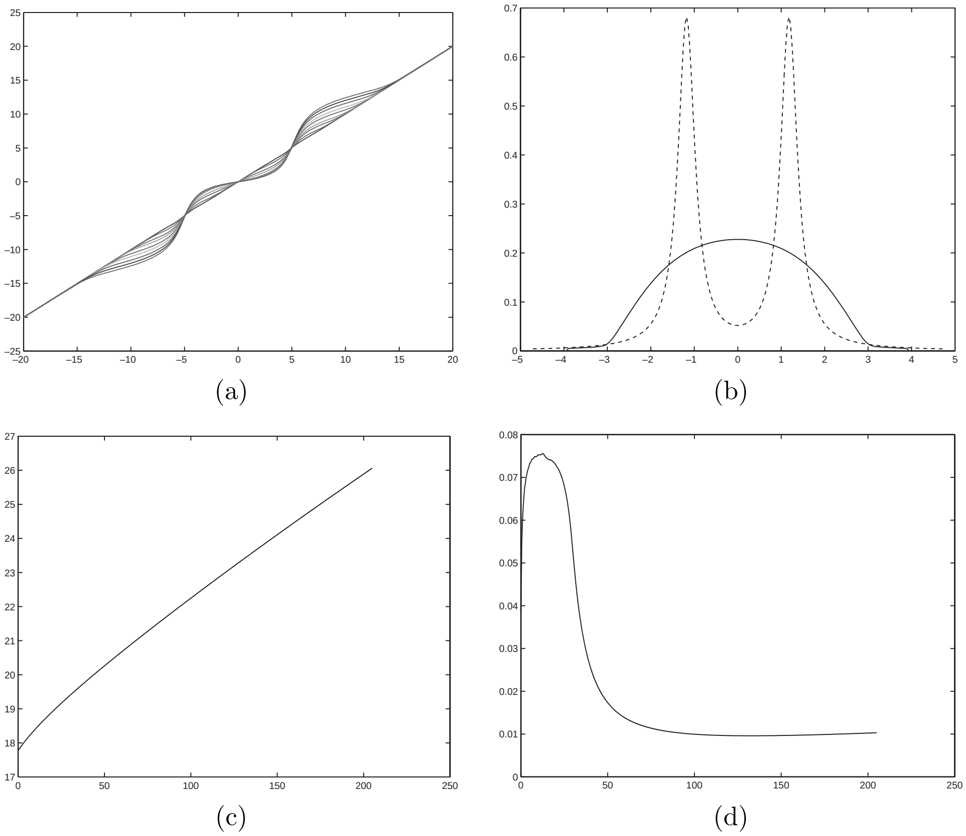
In this case, even if this hasn't been rigorously proven yet, we may expect to observe a decay of this compactly supported function towards a Barenblatt–Pattle profile asymptotically. This can be observed in Figure 5. We can also check that this problem shares other features with the slow-diffusion equation since the mapping $t \mapsto E(t)$ seems concave. However, the support of the solution grows more quickly as times increase.

5. Conclusion and outlook. We introduced and studied analytically in this paper a new numerical scheme for 1D filtration equations of the type (1.1). As a main feature, it allows us to observe the asymptotic decay of solutions towards self-similar ones without requesting important changes of the computational domain (as it would be the case for a conventional discretization; see, e.g., [14, 17, 16, 18, 20, 21, 23]). Moreover, a contraction property in Wasserstein metrics can be easily established. As a final remark, let us stress that a similar derivation can be applied to 1D nonlinear Fokker–Planck equations,

$$\partial_t u = \partial_x(\partial_x V(t,x)u) + \partial_{xx}(\Phi(u)),$$

for which the evolution of the reciprocal mapping $X(t,\varrho)$ would be given by (see [10])

$$\partial_t X + (\partial_x V)(t,X) + \partial_\varrho(\Phi(1/\partial_\varrho X)) = 0,$$



(a) (b)

(c) (d)

FIG. 4. (a) *Numerical values for $X(t, x)$ for $t = 1, 5, 15, 25, 45, 65, 95, 125, 155$;* (b) *scaled initial data $f(t = 0, .)$* (*dotted line*) *and stationary solution f_∞* (*solid line*)*;* (c) *evolution of $E(t)$ with time t;* (d) *evolution of Δt with time t.*

thus only asking for mild changes with respect to (3.4)–(3.6). Very fast diffusion equations could also be handled within the present framework, i.e., $\partial_t u + \partial_{xx}(u^{-m}) = 0$, $0 < m < 1$.

From this last computation, one can, moreover, extract information concerning radial solutions of 2D equations; let $u(t, x, y)$ solve $\partial_t u = \Delta\Phi(u)$, Δ standing for the Laplace operator in $\mathbb{R}^2$, while meeting the requirement that $u(t, x, y) = \tilde{u}(t, r)$, $r = \sqrt{x^2 + y^2}$. Then one deduces easily an equation on $\tilde{u}$, namely, $\partial_t \tilde{u} = \partial_{rr}\Phi(\tilde{u}) + \frac{1}{r}\partial_r \Phi(\tilde{u})$, for which the last term creates a difficulty with respect to the aforementioned Fokker–Planck computation. This can be circumvented as follows: one observes that

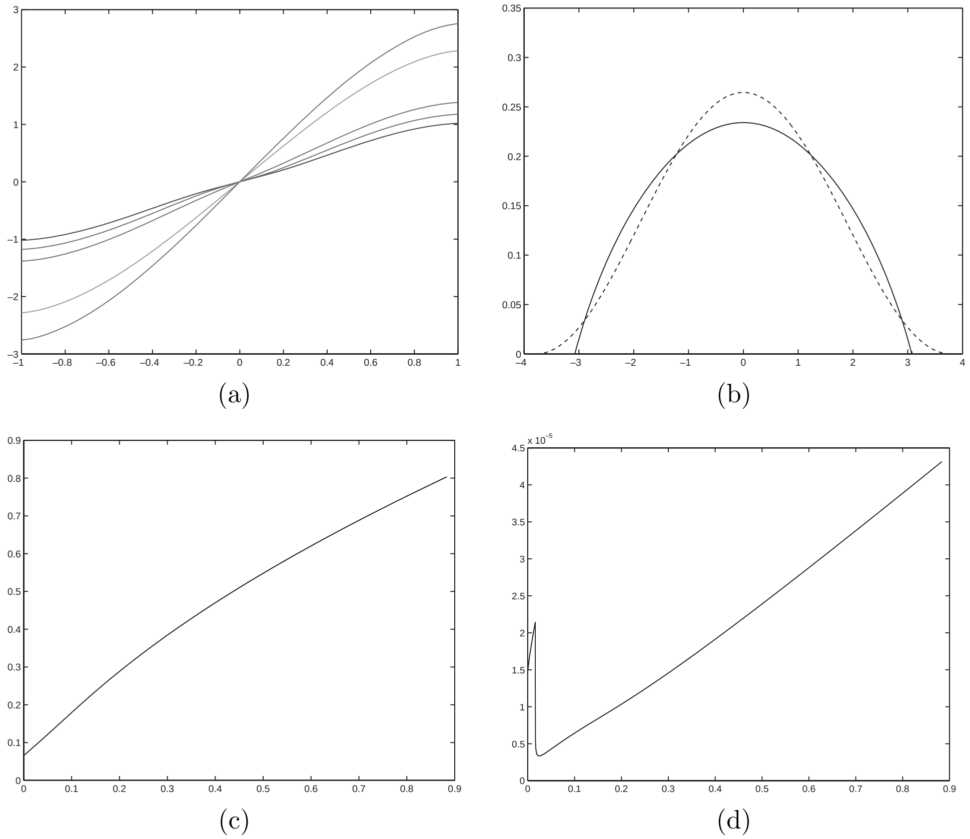
$$\varrho(t, r) = \int_0^r s\, \tilde{u}(t, s)\, ds, \qquad \partial_t \int_0^\infty s\, \tilde{u}(t, s)\, ds \equiv 0.$$

Then it is possible to define R as the reciprocal mapping such that,

$$\forall \bar{\varrho} \in [0, 1], \qquad \varrho(t, R(t, \bar{\varrho})) = \bar{\varrho},$$

and satisfying the equation

$$\partial_t R + R\partial_\varrho \Phi\left(\frac{1}{R\partial_\varrho R}\right) = 0.$$



(a) (b)

(c) (d)

Fig. 5. (a) *Numerical values for* $X(t,x)$ *for* $t = 0.05, 0.1, 0.2, 0.5, 0.88$*;* (b) *scaled initial data* $f(t=0,.)$ (*dotted line*) *and stationary solution* f_∞ (*solid line*)*;* (c) *evolution of* $E(t)$ *with time* t*;* (d) *evolution of* Δt *with time* t.

A third possible extension is suggested in [4, 5] for “viscous pressureless gas equations”; in this case, the pseudoinverse evolves according to

$$\partial_t X = v_0(\varrho) - \partial_\varrho(\Phi(1/\partial_\varrho X)),$$

where Φ can be computed explicitly from the Eulerian viscosity term. The function $\Phi(u) = u\ln(u)$ is of special interest as it corresponds to a linear perturbation in Eulerian coordinates. In this context, $v_0(\varrho)$ is implicitly defined from the initial velocity in Eulerian coordinates via $v_0(\varrho) = u_0 \circ X(t=0,\varrho)$.

GALERKIN METHODS BASED ON HERMITE SPLINES FOR SINGULAR PERTURBATION PROBLEMS[*]

SONG-TAO LIU[†] AND YUESHENG XU[†‡]

Abstract. We develop Galerkin methods for solving the singularly perturbed two-point boundary value problem of high-order elliptic differential equations. These methods are based on Hermite splines with knots adapted to the singular behavior of the solution of the problem. We prove an optimal order of uniform convergence for the method with respect to the perturbation parameter. Specifically, we present a sufficient condition on the mesh of grid points that ensures the corresponding approximate solution has the optimal order of uniform convergence in the energy norm. We also construct *optimal* meshes that satisfy the sufficient condition. Numerical examples are presented to illustrate the method and the corresponding theoretical estimates.

Key words. singular perturbation, Galerkin methods, Hermite splines, grid meshes, optimal order of uniform convergence

1. Introduction.

The numerical solution of the singularly perturbed two-point boundary value problem is a challenging task. The effect of the boundary layers makes it difficult to develop numerical methods for solving the problem with an optimal order of uniform convergence (cf. [B, LT, O, SO1, SO2, TT]). Many authors have tried to tackle this difficulty. Bakhvalov [B] introduced special grids based on mesh generating functions and used them to develop numerical methods for solving the problems. Uniformly convergent classical difference schemes on the special meshes may be found in [G, V]. The Shishkin mesh is one of the simplest piecewise equidistant meshes. The uniform convergence of the Shishkin mesh has been discussed in [MOS, RST, S]. For the Shishkin mesh, Sun and Stynes [SS1, SS2] provided almost optimal uniform convergence results for the finite element methods for the singularly perturbed high-order elliptic two-point boundary value problem based on piecewise polynomial approximations. Their results show that the traditional finite element methods using the Shishkin mesh are suitable for the high-order singularly perturbed problems. Tang and Trummer [TT] proposed a pseudospectral methods for treating the boundary layer problem for the singular perturbation problem. A recent paper of Roos and Linss [RL] studied convergence properties of the simple upwind difference scheme and a Galerkin method on generalized Shishkin grids. Sufficient conditions on the mesh-characterizing function for the convergence of the method, uniformly with respect to the perturbation parameter, are proposed. The idea was extended in [L] to the two-dimensional case.

We introduce in this paper an optimal Galerkin method for solving the singularly perturbed high-order elliptic two-point boundary value problem of reaction-diffusion type using Hermite splines with knots adapted to the boundary layer behavior of the solution. The main results of this paper include a simple sufficient condition on the mesh-sizes which ensures the *optimal* order of *uniform* convergence of the Galerkin method based on the Hermite splines built on the mesh. The order is the same as the approximation order of the Hermite spline space with *uniform* knots. We also construct an optimal mesh which realizes the sufficient condition. In this construction, we combine ideas from [QS, QST, RST, SS1, SS2, V] and those from [CHX]. That is, we choose the mesh-size for each of the subintervals so that the error of the Hermite spline approximation on each subinterval is bounded in an optimal order uniformly with respect to the perturbation parameter. In this development, we use estimates of the derivatives of the exact solution to guide the design of the mesh.

This paper is organized into five sections. In section 2, we outline a setting of reaction-diffusion-type problems and describe the Galerkin methods for solving such problems. We propose in section 3 a sufficient condition on the mesh-size which ensures the optimal order of uniform convergence of the approximate solution. In section 4, we construct a specific mesh which satisfies the condition and generates a Hermite spline approximate solution having the optimal order of uniform convergence. Finally, in section 5, we present numerical experiments that demonstrate the methods and confirm the theoretical estimates.

2. The Galerkin method based on Hermite splines of arbitrary knots. We describe in this section the Galerkin method for solving reaction-diffusion problems using the Hermite splines of arbitrary knots. For this purpose, we describe the singularly perturbed high-order elliptic two-point boundary value problem of reaction-diffusion type. Let $m \geq 2$ be an integer, let $\varepsilon \in (0, 1]$ be a perturbation parameter, and let a_j, $j \in Z_{2(m-1)+1}$ with $Z_m := \{0, 1, \ldots, m-1\}$, and f be sufficiently smooth functions defined on $I := [0, 1]$. We introduce the differential operator L_ε by

$$\begin{aligned} L_\varepsilon u := {} & (-1)^m \varepsilon^2 u^{(2m)} + (-1)^{m-1}\big(a_{2(m-1)} u^{(m-1)}\big)^{(m-1)} \\ & + \sum_{k=2}^{m} (-1)^{m-k}\big(a_{2(m-k)+1} u^{(m-k+1)} + a_{2(m-k)} u^{(m-k)}\big)^{(m-k)} \end{aligned}$$

and consider the boundary value problem

$$\begin{aligned} (L_\varepsilon u)(x) &= f(x), \qquad x \in (0, 1), \\ u^{(j)}(0) = u^{(j)}(1) &= 0, \qquad j \in Z_m. \end{aligned} \tag{2.1}$$

We denote by $L_2(I)$ the space of real-valued square integrable functions on I with the associated inner product $(\cdot, \cdot)$. Let $H^k(I)$, $k = 1, 2, \ldots, m$, be the Sobolev spaces on I with the norm $\|\cdot\|_k$ and the seminorm $|\cdot|_k$ (see, for example, [C]). For convenience, we let $H^0(I) := L_2(I)$ and $\|\cdot\|_0 := \|\cdot\|_{L_2(I)}$. We denote by $\|\cdot\|_\infty$ the essential maximum norm on $L_\infty(I)$ and by $\|\cdot\|_{k,\infty}$ the maximum norm on $C^k(I)$ for $k \in Z_m$, i.e., $\|u\|_{k,\infty} := \sum_{j=0}^{k} \|u^{(j)}\|_\infty$. Let $H_0^m := H_0^m(I)$ be the closure of the set $\{v \in C^m(I) : v^{(k)}(0) = v^{(k)}(1) = 0,\ k \in Z_m\}$ in the Sobolev norm $\|\cdot\|_m$. The energy norm is defined by $\|v\|_\varepsilon := \{\varepsilon^2 |v|_m^2 + \|v\|_{m-1}^2\}^{1/2}$.

The bilinear form $A_\varepsilon(\cdot,\cdot)$ is defined by

$$A_\varepsilon(u,v) := \left(\varepsilon^2 u^{(m)}, v^{(m)}\right) + \left(a_{2(m-1)}u^{(m-1)}, v^{(m-1)}\right) \\ + \sum_{k=2}^{m} \left(a_{2(m-k)+1}u^{(m-k+1)} + a_{2(m-k)}u^{(m-k)}, v^{(m-k)}\right).$$

We now present a sufficient condition that guarantees the coercivity of the bilinear form. To this end, we introduce an index set by $I^+ := \{j : \alpha_j \geq 0,\ j \in Z_m\}$, where constants $\alpha_{m-1} \leq a_{2(m-1)}$ and $\alpha_{m-k} \leq a_{2(m-k)} - \frac{1}{2}a'_{2(m-k)+1}$, $k = 2, 3, \ldots, m$. We assume that there is a decomposition for α_j, $j \in I^- := Z_m \setminus I^+$, that is,

$$\alpha_j = \sum_{k \in I^+ \cap \{j+1, j+2, \ldots, m-1\}} \alpha_{j,k}$$

such that $\eta_k \geq 0$, for $k \in I^+ \setminus \{m-1\}$, and $\eta_{m-1} > 0$, where

$$\eta_k := \alpha_k + \sum_{j \in I^-, j<k} \alpha_{j,k} 2^{-(k-j)} \quad \text{for} \quad k \in I^+.$$

Then, by making use of the estimate

$$|v|_{s-1}^2 \leq \frac{|v|_s^2}{2}, \quad v \in H_0^m(I), \quad s \in N_m := \{1, 2, \ldots, m\},$$

we have the coercivity of the bilinear form $A_\varepsilon(\cdot,\cdot)$, i.e.,

$$A_\varepsilon(v,v) \geq \varepsilon^2 |v|_m^2 + \eta_{m-1}|v|_{m-1}^2.$$

By integration by parts, we rewrite boundary value problem (2.1) in a variational form in which we seek $u \in H_0^m$ such that

$$A_\varepsilon(u,v) = (f,v) \ \text{ for all } \ v \in H_0^m. \tag{2.2}$$

The solution of (2.2) is a weak solution of (2.1). Equation (2.2) will serve as the basic equation for numerical computation of the solution. Under the hypotheses on a_j, it can be proved that there exist positive constants c_1, c_2 such that

$$|A_\varepsilon(v,w)| \leq c_1 \|v\|_\varepsilon \|w\|_\varepsilon, \qquad v, w \in H_0^m, \tag{2.3}$$

and

$$A_\varepsilon(v,v) \geq c_2 \|v\|_\varepsilon^2, \qquad v \in H_0^m. \tag{2.4}$$

Thus, the bilinear form $A_\varepsilon(\cdot,\cdot)$ is coercive with respect to $\|\cdot\|_\varepsilon$. By the Lax–Milgram theorem, existence and uniqueness of the solution of (2.2) are guaranteed. Since the coefficient functions a_k, $k \in Z_{2(m-1)+1}$, and f are sufficiently smooth, we know that the solution is also sufficiently smooth [Gr, GT], and thus it is identical to the classical solution. For this reason, we will not distinguish the weak solution from the classical one.

We now introduce the space of the Hermite splines. Let N be a positive integer and let $0 = x_0 < x_1 < \cdots < x_N = 1$ be an arbitrary mesh of the interval I with $h_i := x_i - x_{i-1}$, $i \in \mathbb{N}_N$, and $h := \max\{h_i : i \in \mathbb{N}_N\}$. We denote by I_i the interval

$[x_{i-1}, x_i)$. For a positive integer r, we let $P_{2r}(I_i)$ denote the space of polynomials of degree $2r-1$ on I_i. The space of the Hermite splines is defined by

$$V_N := \{v(x) \in H_0^r(I) : v|_{I_i} \in P_{2r}(I_i),\ i \in \mathbb{N}_N\}. \tag{2.5}$$

It can be seen that $V_N \subset H_0^r(I)$ and by the Sobolev embedding theorem, $V_N \subset C_0^{r-1}(I)$. The dimension of V_N is $r(N-1)$. For $v \in C_0^{r-1}(I)$ we denote by Πv its Hermite spline interpolant from V_N satisfying the conditions $(\Pi v)^{(k)}(x_i) = v^{(k)}(x_i)$, $k \in Z_r$, $i \in \mathbb{N}_{N-1}$. It is well known (cf. [Sc]) that there exists a positive constant c such that for all $v \in C_0^{2r}(I_i)$,

$$|v - \Pi v|_{j,\infty,I_i} \leq c h_i^{2r-j} |v|_{2r,\infty,I_i}, \qquad j \in Z_{2r+1}, \tag{2.6}$$

where $|v|_{k,\infty,I_i}$ denotes the maximum norm of $v^{(k)}$ on the interval I_i. Here and in what follows, constant c is used to denote the generic positive constant that is independent of ε and the mesh.

In order to have a conforming Galerkin method, we require $r \geq m$ through out the rest of this paper. The Galerkin method based on the Hermite splines is to seek $u_N \in V_N$ such that

$$A_\varepsilon(u_N, v) = (f, v), \qquad v \in V_N. \tag{2.7}$$

Recalling that u satisfies (2.2), we have that $A_\varepsilon(u - u_N, v) = 0$, $v \in V_N$. By Cea's lemma [C], this equation implies that

$$\|u - u_N\|_\varepsilon \leq c \inf_{v \in V_N} \|u - v\|_\varepsilon. \tag{2.8}$$

We next consider the *discrete* Galerkin method, which takes into account the effect of numerical integration required for computing the inner products. We let a_k^N, $k \in Z_{2(m-1)+1}$, and f^N be the Hermite spline interpolation of degree $2\ell - 1$ to a_k and f, respectively, with uniform knots $\frac{j}{N}$, $j \in Z_{N+1}$. Then we have the approximation orders

$$\|a_k^N - a_k\|_\infty \leq c N^{-2\ell} \|a_k\|_{2\ell,\infty} \quad \text{and} \quad \|f^N - f\|_\infty \leq c N^{-2\ell} \|f\|_{2\ell,\infty}. \tag{2.9}$$

The *discrete* bilinear form is

$$\begin{aligned} A_\varepsilon^N(u,v) := {}& \big(\varepsilon^2 u^{(m)}, v^{(m)}\big) + \big(a_{2(m-1)}^N u^{(m-1)}, v^{(m-1)}\big) \\ &+ \sum_{k=2}^{m} \big(a_{2(m-k)+1}^N u^{(m-k+1)} + a_{2(m-k)}^N u^{(m-k)}, v^{(m-k)}\big). \end{aligned}$$

Correspondingly, the discrete Galerkin method is to seek $u_N^N \in V_N$ such that

$$A_\varepsilon^N(u_N^N, v) = (f^N, v), \qquad v \in V_N. \tag{2.10}$$

It was proved in Lemma 4.1 of [SS1] that $A_\varepsilon^N(\cdot,\cdot)$ is coercive with respect to $\|\cdot\|_\varepsilon$. This leads to the following estimate of error between u_N and u_N^N.

THEOREM 2.1. *Let u_N and u_N^N be the solution of* (2.7) *and* (2.10), *respectively. Suppose that a_k and f are approximated by a_k^N and f^N, respectively, with errors* (2.9). *Then*

$$\|u_N - u_N^N\|_\varepsilon \leq c N^{-2\ell} (\|f\|_{2\ell,\infty} + \|u\|_\varepsilon).$$

Proof. To prove this theorem, we set $B_\varepsilon(v) := A_\varepsilon^N(u_N^N, v) - A_\varepsilon(u_N, v)$ and observe from (2.7) and (2.10) that

$$B_\varepsilon(v) = (f^N - f, v), \qquad v \in V_N. \tag{2.11}$$

Using the definition of A_ε and A_ε^N with a rearrangement of terms leads to the equation

$$\begin{aligned} B_\varepsilon(v) = A_\varepsilon^N(u_N^N - u_N, v) &+ \sum_{k=1}^{m} \big((a_{2(m-k)}^N - a_{2(m-k)}) u_N^{(m-k)}, v^{(m-k)} \big) \\ &+ \sum_{k=2}^{m} \big((a_{2(m-k)+1}^N - a_{2(m-k)+1}) u_N^{(m-k+1)}, v^{(m-k)} \big). \end{aligned}$$

Letting $v = u_N^N - u_N$ in the equation above and using the coercivity of A_ε^N and the first estimate of (2.9), we conclude that

$$c\|u_N - u_N^N\|_\varepsilon^2 - cN^{-2\ell}\|u_N\|_{m-1}\|u_N - u_N^N\|_\varepsilon \le B_\varepsilon\big(u_N^N - u_N\big).$$

On the other hand, by (2.11) and the second estimate of (2.9), we have that

$$B_\varepsilon\big(u_N^N - u_N\big) = \big(f^N - f, u_N^N - u_N\big) \le cN^{-2\ell}\|f\|_{2\ell,\infty}\|u_N^N - u_N\|_\varepsilon.$$

Combining the above two estimates, we obtain that

$$\|u_N - u_N^N\|_\varepsilon \le cN^{-2\ell}(\|f\|_{2\ell,\infty} + \|u_N\|_{m-1}). \tag{2.12}$$

Noting that

$$\|u_N\|_{m-1} \le \|u_N\|_\varepsilon \le \|u - u_N\|_\varepsilon + \|u\|_\varepsilon \le \|u\|_\varepsilon + c \inf_{v \in V_N} \|u - v\|_\varepsilon \le c\|u\|_\varepsilon,$$

the desired estimate follows from (2.12). □

3. The optimal order of uniform convergence. In this section, we derive a sufficient condition on the meshes having $O(N)$ number of grid points that ensures the corresponding approximate solution u_N having optimal order of uniform convergence. For this purpose, we recall properties of the solution for the singularly perturbed boundary value problems (2.1). From the book [O], we may write the solution u of problem (2.1) in terms of sufficiently differentiable functions E, F, G for which

$$u = E + F + G,$$

and such that for all $x \in I$ and for $j \in \mathbb{N} = \{0, 1, \dots\}$,

$$\begin{aligned} |G^{(j)}(x)| \le c, \quad |E^{(j)}(x)| &\le c\varepsilon^{m-1-j} \exp(-\alpha x/\varepsilon), \\ |F^{(j)}(x)| &\le c\varepsilon^{m-1-j} \exp(-\alpha(1-x)/\varepsilon). \end{aligned} \tag{3.1}$$

Here, constant $\alpha = \alpha_{m-1}$. Clearly, functions G, E, F describe, respectively, the reduced problem solution and two boundary layers at endpoints 0, 1.

Based on estimates (3.1), we introduce a generating function defined by

$$h^0(x) := \frac{\varepsilon}{N} \exp\left(\frac{\alpha x}{2r\varepsilon}\right), \tag{3.2}$$

and choose the mesh-sizes h_i, $i \in \mathbb{N}_{\tilde{N}}$, to satisfy the condition that

$$h_i \leq \min\{h^0(x_{i-1}), h^0(1-x_i), 1/N\} \tag{3.3}$$

and

$$\tilde{N} \leq cN. \tag{3.4}$$

Meshes having this property are called *optimal meshes*. A construction of optimal meshes will be presented in the next section. The construction of these meshes is motivated by the equal distribution of errors in the subintervals. We remark that these meshes improve the convergence order of the well-known Bakhvalov meshes and Shishkin meshes. We will prove that they lead to the optimal order of convergence and linear complexity. Recall that the Bakhvalov-type meshes map equidistant grids to nonuniform meshes by using the layer functions or their modifications. The Shishkin meshes, which are piecewise uniform meshes, are particularly simple in their constructions. It is not clear in the literature from a theoretical point of view if the Bakhvalov-type meshes give the optimal order of uniform convergence. Nonetheless, it is known from [SS1, SS2] that the Shishkin meshes give the optimal uniform convergence order *up to a logarithmic factor*.

Lemma 3.1. *Let E, F, and G be functions satisfying the condition* (3.1) *and let h_i be chosen according to* (3.3). *Then*

$$\|E - \Pi E\|_j \leq cN^{-2r+j}, \quad j \in Z_r, \quad \|E - \Pi E\|_\varepsilon \leq cN^{-2r+m}, \tag{3.5}$$

$$\|F - \Pi F\|_j \leq cN^{-2r+j}, \quad j \in Z_r, \quad \|F - \Pi F\|_\varepsilon \leq cN^{-2r+m}, \tag{3.6}$$

and

$$\|G - \Pi G\|_j \leq cN^{-2r+j}, \quad j \in Z_r, \quad \|G - \Pi G\|_\varepsilon \leq cN^{-2r+m}\max\{\varepsilon, N^{-1}\}. \tag{3.7}$$

Proof. The proof for (3.7) is standard. We present only the proof for the estimate for E, since the one for F is obtained similarly. To this end, we first estimate $|E - \Pi E|_{m,\infty,I_i}$, $i \in \mathbb{N}_{\tilde{N}}$. By estimate (2.6), there exists a positive constant c such that

$$\varepsilon|E - \Pi E|_{m,\infty,I_i} \leq c\varepsilon|E|_{2r,\infty,I_i} h_i^{2r-m}. \tag{3.8}$$

Using (3.3), we obtain that

$$h_i \leq h^0(x_{i-1}) = \frac{\varepsilon}{N}\exp\left(\frac{\alpha x_{i-1}}{2r\varepsilon}\right). \tag{3.9}$$

Substituting the bound on $|E|_{2r,\infty,I_i}$ and (3.9) into the right-hand side of (3.8) yields

$$\varepsilon|E - \Pi E|_{m,\infty,I_i} \leq c\varepsilon(\varepsilon^{m-1-2r})\exp\left(-\frac{\alpha x_{i-1}}{\varepsilon}\right)\left[\frac{\varepsilon}{N}\exp\left(\frac{\alpha x_{i-1}}{2r\varepsilon}\right)\right]^{2r-m} \leq cN^{-2r+m}.$$

Next, we estimate $|E - \Pi E|_{j,\infty,I_i}$ for $j \in Z_r$. By using Lemma 2.6, the bound (3.9) on h_i and the hypothesis on the function E, we have that

$$|E - \Pi E|_{j,\infty,I_i} \leq |E|_{2r,\infty,I_i} h_i^{2r-j} \leq cN^{-2r+j}\varepsilon^{m-j}\exp\left(-\frac{j\alpha x_{i-1}}{2r\varepsilon}\right)$$

for $j \in Z_r$. Thus, we have for $j \in Z_r$ that

$$|E - \Pi E|_{j,\infty,I_i} \le cN^{-2r+j}. \tag{3.10}$$

It follows from (3.10) that

$$\|(E - \Pi E)^{(j)}\|_2 \le \left(\sum_{i=1}^{\tilde{N}} |E - \Pi E|^2_{j,\infty,I_i} |I_i| \right)^{1/2} \le cN^{-2r+j},$$

which yields the desired results. □

We now use Lemma 3.1 to estimate the error of interpolation Πu, where u is the solution of problem (2.1).

Proposition 3.2. *Let u be the solution of problem* (2.1) *and let h_i, $i \in \mathbb{Z}_{\tilde{N}+1}$, be chosen according to* (3.3). *Then there exists a positive constant c independent of ε or N such that*

$$\|u - \Pi u\|_j \le cN^{-2r+j}, \quad j \in Z_r, \quad \textit{and} \quad \|u - \Pi u\|_\varepsilon \le cN^{-2r+m}. \tag{3.11}$$

Proof. Since the solution u of problem (2.1) has the form $u = E + F + G$, where functions E, F, and G satisfy condition (3.1), using the estimates in Lemma 3.1 for the functions E, F, and G, respectively, we conclude the desired estimate in the proposition. □

Our next task is to establish an error bound on $\|\Pi u - u_N\|_\varepsilon$.

Lemma 3.3. *Let u and u_N be the solutions of problems* (2.2) *and* (2.7), *respectively. Suppose that the mesh satisfies condition* (3.3). *Then*

$$\|\Pi u - u_N\|_\varepsilon \le cN^{-2r+m}.$$

Moreover, if $r = m$, then

$$\|\Pi u - u_N\|_{m-1} \le cN^{-m-1} \quad \textit{and} \quad |\Pi u - u_N\|_\varepsilon \le cN^{-m-1}.$$

Proof. To prove the first estimate, we note that $A_\varepsilon(u - u_N, \Pi u - u_N) = 0$, and observe that

$$\|\Pi u - u_N\|^2_\varepsilon \le cA_\varepsilon(\Pi u - u_N, \Pi u - u_N) = cA_\varepsilon(\Pi u - u, \Pi u - u_N). \tag{3.12}$$

Inequality (3.12) implies that $\|\Pi u - u_N\|_\varepsilon \le c\|\Pi u - u\|_\varepsilon$. By Proposition 3.2, we conclude the first estimate.

To obtain the special results when r is chosen as m, we estimate $A_\varepsilon(\Pi u - u, \Pi u - u_N)$. To do this, we first prove that

$$\big((\Pi u - u)^{(m)}, (\Pi u - u_N)^{(m)}\big) = 0. \tag{3.13}$$

Recall that the function $\Pi u - u$ has the interpolation property that $(\Pi u - u)^{(j)}(x_i) = 0$, $j \in Z_m$, $i \in Z_{\tilde{N}+1}$. Using integration by parts with this interpolation property, we conclude for any polynomial p of degree $m - 1$ on interval I_i that

$$\int_{x_{i-1}}^{x_i} (\Pi u - u)^{(m)}(x) p(x)\, dx = \int_{x_{i-1}}^{x_i} (\Pi u - u)(x) p^{(m)}(x)\, dx = 0.$$

Since $(\Pi u - u_N)^{(m)}|_{I_i}$ is a polynomial of degree $m-1$, $i \in \mathbb{N}_{\tilde{N}}$, we see that (3.13) holds. Combining (3.13) and the formula of $A_\varepsilon(\Pi u - u, \Pi u - u_N)$, we obtain that

$$\begin{aligned} A_\varepsilon(\Pi u - u, \Pi u - u_N) = {} & \big(a_{2(m-1)}(\Pi u - u)^{(m-1)}, (\Pi u - u_N)^{(m-1)}\big) \\ & + \sum_{k=2}^{m} \big(a_{2(m-k)}(\Pi u - u)^{(m-k)} + a_{2(m-k)+1} \\ & \times (\Pi u - u)^{(m-k+1)}, (\Pi u - u_N)^{(m-k)}\big). \end{aligned}$$

It follows that

$$A_\varepsilon(\Pi u - u, \Pi u - u_N) \le c\|\Pi u - u\|_{m-1}\|\Pi u - u_N\|_{m-1}.$$

Using the first estimate of Proposition 3.2, we find that

$$A_\varepsilon(\Pi u - u, \Pi u - u_N) \le cN^{-m-1}\|\Pi u - u_N\|_\varepsilon. \tag{3.14}$$

Combining (3.12) and (3.14) proves this third estimate. The second estimate follows directly from the third. ∎

Next we estimate the errors $u - u_N$ and $u - u_N^N$.

THEOREM 3.4. *Let u, u_N, and u_N^N be the solutions of problems* (2.2), (2.7), *and* (2.10)*, respectively. Suppose that the mesh satisfies condition* (3.3). *Then*

$$\|u - u_N\|_\varepsilon \le cN^{-2r+m}, \qquad \|u - u_N^N\|_\varepsilon \le c(N^{-2r+m} + N^{-2\ell}).$$

Moreover, if $r = m$, then

$$\begin{aligned} &\|u - u_N\|_{m-1} \le cN^{-m-1}, \quad \|u - u_N^N\|_\varepsilon \le c(N^{-m} + N^{-2\ell}), \\ &\|u - u_N^N\|_{m-1} \le c(N^{-m-1} + N^{-2\ell}). \end{aligned}$$

Proof. The estimate on $\|u - u_N\|_\varepsilon$ is a direct consequence of Proposition 3.2 and Lemma 3.3, while the estimate on $\|u - u_N^N\|_\varepsilon$ is obtained by using the first estimate of this theorem and Theorem 2.1.

Next, we prove the special results when we choose $r = m$. According to Proposition 3.2, if $r = m$, we have that $\|u - \Pi u\|_{m-1} \le cN^{-m-1}$. Combining this estimate with the first estimate in Proposition 3.2, we arrive at the inequality

$$\|u - u_N\|_{m-1} \le \|u - \Pi u\|_{m-1} + \|\Pi u - u_N\|_{m-1} \le N^{-m-1}.$$

The estimates on $\|u - u_N^N\|_\varepsilon$ follow directly from the second estimate of this theorem with $r = m$. To prove the last estimate, we note that

$$\|u - u_N^N\|_{m-1} \le \|u - u_N\|_{m-1} + \|u_N - u_N^N\|_{m-1} \le \|u - u_N\|_{m-1} + \|u_N - u_N^N\|_\varepsilon.$$

The third estimate in this theorem and the result of Theorem 2.1 ensure the last estimate. ∎

Theorem 3.4 suggests that the Hermite spline approximations of an appropriate order for a_k and f must be used to ensure optimal order of approximation of u_N^N.

4. A construction of optimal meshes. We describe a specific construction of a mesh of interval I and prove that it is optimal in the sense that it satisfies both conditions (3.3) and (3.4).

We define the grid points according to the generating function h^0 by the recursive formula

$$x_0 := 0, \quad x_i := x_{i-1} + h^0(x_{i-1}), \quad i = 1, 2, \ldots, M, \tag{4.1}$$

where M is a positive integer such that

$$h^0(x_{M-1}) < 1/N \quad \text{and} \quad h^0(x_M) \geq 1/N. \tag{4.2}$$

We consider two cases. In the first case where $x_M < 1/2$, $x_0 < x_1 < \cdots < x_M$ forms a mesh for the interval $[0, x_M]$ and by symmetry, $1 - x_M < 1 - x_{M-1} < \cdots < 1 - x_0$ forms a mesh for the interval $[1 - x_M, 1]$. For the middle interval $[x_M, 1 - x_M]$, we define a uniform mesh with $N_1 := \lfloor (1 - 2x_M)N \rfloor + 1$ grid points such that the mesh-size $\tilde{h} := (1 - 2x_M)/N_1 \leq 1/N$, where $\lfloor x \rfloor$ denotes the largest integer not greater than x. Thus, points

$$x_j = x_{j-1} + \tilde{h}, \quad j = M+1, M+2, \ldots, M+N_1,$$

subdivide the middle interval. Set $x_{M+N_1+j} := 1 - x_{M-j}$, $j \in Z_{M+1}$. Hence the mesh

$$\Delta : \quad 0 = x_0 < x_1 < \cdots < x_{2M+N_1} = 1$$

is the desired mesh for I, which consists of three parts, the left and right meshes for the boundary layers and the middle uniform mesh. We now describe a construction when the second case $x_M \geq 1/2$ occurs. In this case, there is no middle uniform mesh. Note that there exists a nonnegative integer μ such that

$$x_{M-\mu-1} < \frac{1}{2} \leq x_{M-\mu} < \cdots < x_M.$$

We let $M' := M - \mu$ and observe that

$$x_{M'-1} < 1/2 \quad \text{and} \quad x_{M'} \geq 1/2. \tag{4.3}$$

We use M' to replace M in (4.1). Clearly, the integer M' satisfying condition (4.3) is less than or equal to the integer M satisfying condition (4.2). We redefine $x_{M'} := 1/2$ and $x_{M'+j} = 1 - x_{M'-j}$, $j \in \mathbb{N}_{M'}$. Thus, in this case

$$\Delta : 0 = x_0 < x_1 < \cdots < x_{2M'} = 1$$

is a desired mesh for interval I.

The main purpose of this section is to show that the Hermite spline interpolation developed based on the mesh constructed above has an optimal order of convergence and the *linear* order of computational complexity measured by the number of grid points. For this purpose, we consider a sequence x_n generated by a given generating function g. Suppose that y_0 is given and g is a real-valued function defined on the real line. We define a sequence x_n by letting

$$x_0 = y_0, \quad x_n = x_{n-1} + g(x_{n-1}), \quad n \in \mathbb{N}.$$

We call x_n the sequence generated by y_0 and g. The next lemma is concerned with this sequence.

LEMMA 4.1. *Suppose that $y_0 < y_1$ and g is a real-valued nondecreasing function on R. Let x_n be the sequence generated by y_0 and g. If $g(y_0) > 0$, then there exists a unique integer M_g such that*

$$x_{M_g} \leq y_1 \quad \textit{and} \quad x_{M_g} + g(x_{M_g}) > y_1.$$

Proof. By the definition of sequence x_n and the hypothesis on g, we find that x_n is a strictly increasing sequence. Set $g_0 := g(y_0)$ and observe by induction that $x_n \geq x_0 + ng_0$ for $n \in \mathbb{N}$. Thus, by hypothesis that $g_0 > 0$ we obtain that $\lim_{n\to\infty} x_n = \infty$. It follows that there exists a positive integer n such that $x_n > y_1$. Choose n_0 as the smallest of such integers n. We conclude that $x_{n_0} > y_1$ and $x_{n_0-1} \leq y_1$, proving the lemma. ◻

We will call (y_0, y_1, g) an admissible triple if $y_0 < y_1$, g is nondecreasing and $g(y_0) > 0$, and call M_g the index determined by the admissible triple in the last lemma. Let $\mathcal{A}$ denote the class of admissible triples. We define a mapping $\mathcal{M}$ from $\mathcal{A}$ to positive integers by assigning to each triple the index M_g and denote it by

$$M_g = \mathcal{M}(y_0, y_1, g). \tag{4.4}$$

Lemma 4.1 ensures that the integer M_g is well defined. In the next lemma, we compare two indices M_{g_1} and M_{g_2} corresponding to two generating functions g_1 and g_2.

LEMMA 4.2. *Suppose that (y_0, y_1, g_1) and (y_0, y_1, g_2) are two admissible triples. If $g_1 \leq g_2$, then*

$$\mathcal{M}(y_0, y_1, g_1) \geq \mathcal{M}(y_0, y_1, g_2).$$

Proof. Let $M_{g_i} := \mathcal{M}(y_0, y_1, g_i)$ for $i = 1, 2$. Suppose that for each $i = 1, 2$, x_n^i, $n \in Z_{M_{g_i}+1}$, there are two sequences generated by y_0 and g_i. It can be shown by induction on n that $x_n^1 \leq x_n^2$, $n \in \mathbb{N}$. Thus, the result of this lemma follows. ◻

We next consider a specific generating function g which is an affine function.

LEMMA 4.3. *Suppose that $y_0 < y_1$ and for $k > 0$ and $h_0 := ky_0 + b > 0$, and define $g(x) = kx + b$. Let $M_g := \mathcal{M}(y_0, y_1, g)$. Then*

$$\left(\frac{(1+k)^{M_g} - 1}{k}\right) h_0 \leq y_1 - y_0.$$

Proof. Suppose that x_n, $n \in Z_{M_g+1}$, is the sequence of points generated by the nondecreasing function g and set $h_n := x_{n+1} - x_n$. Hence, $h_n = g(x_n) = g(x_{n-1} + h_{n-1})$. By the definition of g, we have that

$$h_n = kx_{n-1} + kh_{n-1} + b = g(x_{n-1}) + kh_{n-1} = h_{n-1} + kh_{n-1} = (1+k)h_{n-1}.$$

Repeatedly using this equation, we obtain the formula that $h_n = (1+k)^n h_0$. Consequently, we conclude that

$$x_{M_g} - y_0 = \sum_{j=0}^{M_g-1} h_j = h_0 \sum_{j=0}^{M_g-1} (1+k)^j = \left(\frac{(1+k)^{M_g} - 1}{k}\right) h_0.$$

Noting that $x_{M_g} \leq y_1$, this completes the proof. ◻

To estimate the complexity of the Hermite spline interpolation based on the grid points constructed at the beginning of this section, we need to estimate the integer M appearing in the mesh. To this end, we consider a special admissible triple (x^*, x', h^0), where h^0 is defined by (3.2) and

$$x^* := \frac{\varepsilon}{\beta} \log\left(\frac{N}{\beta}\right) \quad \text{and} \quad x' := \frac{\varepsilon}{\beta} \log\left(\frac{1}{\varepsilon}\right) \quad \text{with} \quad \beta := \frac{\alpha}{2r}.$$

LEMMA 4.4. *Suppose that ε and N satisfy the condition*

$$\frac{e}{e^{2^{\gamma(N-1)}}} < \varepsilon < \frac{\beta}{N} \tag{4.5}$$

for some positive constant γ independent of ε and N. Then $\mathcal{M}(x^*, x', h^0) < \gamma(N-1)$.

Proof. The hypothesis $\varepsilon < \beta/N$ ensures that $x^* < x'$ and thus (x^*, x', h^0) is an admissible triple. We will use Lemmas 4.2 and 4.3 to estimate the index M_{h^0} generated by h^0.

Let $y_0 := x^*$, $y_1 := x'$. It can be verified that

$$h^0(y_0) = \frac{\varepsilon}{\beta} \quad \text{and} \quad \frac{d}{dx} h^0(y_0) = 1.$$

Choose $k = 1$, $h_0 := \frac{\varepsilon}{\beta}$, and $b := h_0 - k y_0$ and define $g(x) := kx + b$. Thus (y_0, y_1, g) is an admissible triple. Note that the straight line $y = g(x)$ passes through the point $(y_0, h^0(y_0))$ with slope $k = 1$. It is easily confirmed that $g(x) < h^0(x)$ for all $x > y_0$. By Lemma 4.2, we have that

$$\mathcal{M}(y_0, y_1, h^0) \le \mathcal{M}(y_0, y_1, g).$$

Let $M_g := \mathcal{M}(y_0, y_1, g)$. It follows from Lemma 4.3 that $h_0\left(2^{M_g} - 1\right) \le y_1 - y_0 \le y_1$. This leads to the estimate

$$M_g \le \log_2\left(\ln\left(\frac{1}{\varepsilon}\right) + 1\right). \tag{4.6}$$

By hypothesis that $\frac{e}{e^{2^{\gamma(N-1)}}} < \varepsilon$, we conclude that $\log_2(\ln(1/\varepsilon) + 1) < \gamma(N-1)$. This proves the result of this lemma. □

We are now ready to prove the main result of this section.

THEOREM 4.5. *Let u be the solution of problem* (2.1)*, let Δ be the mesh constructed as above, and let Π be the piecewise polynomial interpolation operator associated with the mesh Δ. Then Πu satisfies the error bound* (3.11)*. If, in addition, the condition* (4.5) *is satisfied, then the number of grid points is bounded by cN.*

Proof. By the construction of the mesh Δ, it is ready to verify that the mesh satisfies condition (3.3) and thus, by Proposition 3.2, Πu satisfies the error bound (3.11).

It remains to prove the bound on the number of grid points in the mesh Δ. Recalling that the number of the grid points in the mesh is $\tilde{N} = 2M + N_1$ for case one and $\tilde{N} = 2M'$ for case two, it suffices to prove that N_1, M, and M' are bonded by a constant multiple of N. Because

$$N_1 = \lfloor (1 - 2x_M)N \rfloor + 1 \le N + 1 \le 2N \quad \text{and} \quad M' < M$$

we need only to show that $M \le cN$.

We consider one case in the construction of the mesh. Recalling the definition of x^*, we divide the interval $[0, x_M]$ into two intervals $I_1 := [0, x^*]$ and $I_2 := [x^*, x_M]$ and estimate the number of grid points in these intervals separately. Let M_1 and M_2 denote the number of grid points in intervals I_1 and I_2, respectively. Then $x_{M_1} \leq x^* \leq x_{M_1+1}$ and $M = M_1 + M_2$.

We now estimate the value of M_1 with the help of the integral of function $\phi(x) := 1/h^0(x)$, $x \in I$. To this end, we introduce a piecewise linear function

$$\underline{\phi}(x) := \phi(x_{i-1}) \frac{x_i - x}{x_i - x_{i-1}}, \quad x \in [x_{i-1}, x_i), \quad i \in \mathbb{N}_{M_1}.$$

Using the definition of ϕ and noticing that ϕ is decreasing on $[0, x_{M_1}]$, we find for $x \in (x_{i-1}, x_i)$ that

$$\phi'(x) := -\frac{\beta}{\varepsilon h^0(x)} = -\frac{\beta}{\varepsilon}\phi(x) \geq -\frac{\beta}{\varepsilon}\phi(x_{i-1}).$$

Also, for $x \in (x_{i-1}, x_i)$, we have that $\underline{\phi}'(x) = -\phi^2(x_{i-1})$. Condition $x_i < x^*$ implies that $\beta/\varepsilon \leq \phi(x_{i-1})$. It follows from this inequality and the fact that ϕ is decreasing on $[x_{i-1}, x_i)$ that $\phi'(x) \geq \underline{\phi}'(x)$ for $x \in (x_{i-1}, x_i)$. This estimate with the fact that $\phi(x_{i-1}) = \underline{\phi}(x_{i-1})$ implies that

$$\underline{\phi}(x) \leq \phi(x), \qquad x \in [0, x_{M_1}). \tag{4.7}$$

By the construction of the grid points x_i and the definition of function ϕ, we obtain that

$$\int_0^{x_{M_1}} \underline{\phi}(x)\, dx = \frac{1}{2}\sum_{i=1}^{M_1} \phi(x_{i-1})(x_i - x_{i-1}) = \frac{M_1}{2}. \tag{4.8}$$

On the other hand, we have the estimate

$$\int_0^{x_{M_1}} \phi(x)\, dx \leq \int_0^1 \frac{dx}{h^0(x)} \leq \frac{N}{\beta}. \tag{4.9}$$

Combining (4.7), (4.8), and (4.9), we conclude that $M_1 \leq \frac{2N}{\beta}$.

We next prove that $M_2 < \gamma N$. Recalling the mesh generating procedure, we have that $h^0(x) \leq 1/N$, $x \in [0, x_{M-1}]$. The definition of x' implies that $h^0(x') = 1/N$. Noting that h^0 is a strictly monotone increasing function, from inequalities

$$h^0(x_{M-1}) < h^0(x') = \frac{1}{N} \leq h^0(x_M)$$

we immediately obtain that $x_{M-1} < x' \leq x_M$. By Lemma 4.4, we conclude that $M_2 < \gamma N$. Therefore, in this case we have that $M \leq (\frac{2}{\beta} + \gamma)N$, completing the proof of this theorem. □

We remark that the mesh generating function can be modified to be

$$h^0(x) = S\frac{\varepsilon}{N} \exp\left(\frac{\alpha x}{2r\varepsilon}\right),$$

where S is a constant. The purpose of introducing the constant S is to adjust the number of grid points to be distributed in the boundary layers at two ends. For example, if S is larger, then by our construction, fewer grid points will be generated for the boundary layer. Its effect is illustrated in the numerical examples given in the next section. The constant S does not affect the convergence order, nor the order of the number of grid points.

5. Numerical examples. In this section, we present numerical examples to demonstrate the method and to verify the theoretical results proved in this paper. We begin with an introduction of the space of the cubic Hermite splines which correspond to $r = 2$. For $x \in [-1, 1]$ we assume

$$\begin{aligned}&\psi_{10}(x) := (x+1)^2(1-2x), \quad \psi_{11}(x) := (1-x)^2(2x+1),\\ &\psi_{20}(x) := x(x+1)^2, \quad \psi_{21}(x) := x(x-1)^2\end{aligned}$$

and define two cubic splines ϕ_1 and ϕ_2 on $\mathbb{R}$ by

$$\phi_1(x) := \begin{cases}\psi_{10}(x), & x \in [-1,0],\\ \psi_{11}(x), & x \in (0,1],\\ 0, & x \in \mathbb{R}\setminus[-1,1],\end{cases} \quad \text{and} \quad \phi_2(x) := \begin{cases}\psi_{20}(x), & x \in [-1,0],\\ \psi_{21}(x), & x \in (0,1],\\ 0, & x \in \mathbb{R}\setminus[-1,1].\end{cases}$$

It can be verified that they satisfy the Hermite interpolation conditions

$$\phi_1(j) = \delta(j), \quad \phi_1'(j) = 0, \quad \phi_2(j) = 0, \quad \phi_1'(j) = \delta(j), \quad j \in \mathbb{Z},$$

where for $j \in \mathbb{Z}$, $\delta(j) = 0$ if $j \neq 0$ and 1 if $j = 0$. Applications of the Hermite cubic splines in the numerical solution of boundary value problems of ordinary differential equations may be found in [JL]. On a mesh $0 < x_0 < x_1 < \cdots < x_{\tilde{N}} = 1$, we may scale and shift ϕ_1, ϕ_2 to construct the basis functions for the space $V_{\tilde{N}}$ by

$$\phi_{1,i}(x) := \begin{cases}\psi_{10}(\frac{x-x_i}{x_i-x_{i-1}}), & x \in [x_{i-1}, x_i],\\ \psi_{11}(\frac{x-x_i}{x_{i+1}-x_i}), & x \in (x_i, x_{i+1}],\\ 0, & x \in I\setminus[x_{i-1}, x_{i+1}],\end{cases}$$

and

$$\phi_{2,i}(x) := \begin{cases}\psi_{20}(\frac{x-x_i}{x_i-x_{i-1}}), & x \in [x_{i-1}, x_i],\\ \frac{h_{i+1}}{h_i}\psi_{21}(\frac{x-x_i}{x_{i+1}-x_i}), & x \in (x_i, x_{i+1}],\\ 0, & x \in I\setminus[x_{i-1}, x_{i+1}],\end{cases}$$

for $i \in \mathbb{N}_{\tilde{N}-1}$. According to the interpolation properties of ϕ_1 and ϕ_2, we may verify for $i \in \mathbb{N}_{\tilde{N}-1}$ and $j \in Z_{\tilde{N}+1}$ that

$$\phi_{1,i}(x_j) = \delta(i-j), \quad \phi_{1,i}'(x_j) = 0, \quad \phi_{2,i}(x_j) = 0, \quad \phi_{2,i}'(x_j) = \frac{1}{h_i}\delta(i-j).$$

The space $V_{\tilde{N}}$ of the cubic (corresponding to $m = 2$) Hermite splines is defined by $V_{\tilde{N}} := \operatorname{span}\{\phi_{i,j} : i = 1, 2,\ j \in \mathbb{N}_{\tilde{N}-1}\}$. It is easily seen that $V_{\tilde{N}}$ is a dense subspace of $H_0^2(I)$.

Example 1. In this example, we consider the reaction-diffusion problem given by

$$\begin{aligned}\varepsilon^2 u^{(4)}(x) + ((1 + x(1-x))u')' &= f(x), \qquad x \in (0,1),\\ u(0) = u'(0) = u(1) = u'(1) &= 0,\end{aligned}$$

where f is chosen so that this problem has the exact solution

$$u = \varepsilon\left(\frac{\exp(-x/\varepsilon) + \exp(-(1-x)/\varepsilon)}{1 + \exp(-1/\varepsilon)} - 1\right) + \frac{1 - \exp(-1/\varepsilon)}{1 + \exp(-1/\varepsilon)}x(1-x) + x^2(1-x)^2.$$

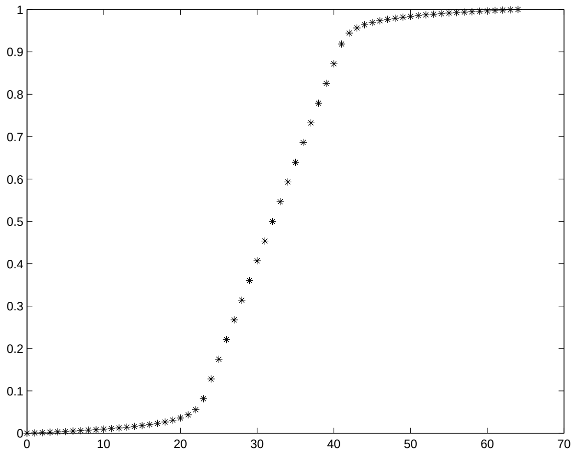

FIG. 1.

The solution exhibits two boundary layers near $x = 0$ and $x = 1$. The weak form of this problem corresponds to $m = 2$.

The generating function for this example is chosen as

$$h^0(x) = \frac{4\varepsilon}{N} \exp\left(\frac{x}{4\varepsilon}\right),$$

that is, we choose $S := \frac{2m}{\alpha} = 4$. We first present a figure that shows the distribution of the grid points for this problem. In this figure we choose $\alpha = 1$ and $\varepsilon = 3.905 \times 10^{-3}$ and $N = 21$. Correspondingly, the total number of grid points is 64. According to our method, we have 21 grid points distributed in each of the two boundary layers near $x = 0$ and $x = 1$. The graph in Figure 1 shows the distribution of 64 grid points.

To illustrate the optimal order of the uniform convergence of the proposed method, we set $e_{\tilde{N}} := u - u_{\tilde{N}}^{\tilde{N}}$. In Table 1, we compare the values of $\|e_{\tilde{N}}\|_\varepsilon$ and the convergence order O of the proposed method based on the optimal mesh with those results based on the Shishkin mesh (see p. 126 of [SS1]). The convergence order O is computed numerically by the formula

$$O = \log\left(\frac{e_{\tilde{N}_1}}{e_{\tilde{N}_2}}\right) / \log\left(\frac{\tilde{N}_2}{\tilde{N}_1}\right),$$

where $\tilde{N}_1$, $\tilde{N}_2$ are two neighboring numbers of grid points in the table. The numerical results show evidently that the proposed optimal mesh provides the optimal order $O \approx m = r = 2$ of convergence for $\|e_{\tilde{N}}\|_\varepsilon$, and it performs better than the Shishkin mesh.

To verify the estimate in norm $\|\cdot\|_{m-1}$, a result in Theorem 3.4, we list in Table 2 the values of $\|e_{\tilde{N}}\|_1$ and convergence order O. We observe that the computed convergence order is $O = 3$.

Example 2. We consider the second order reaction-diffusion problems

$$\begin{aligned} -\varepsilon^2 u''(x) + (2 + \sin(x))u(x) &= f(x), \qquad x \in (0,1), \\ u(0) = u(1) &= 0, \end{aligned}$$

Table 1

Comparison of convergence orders for numerical methods using the proposed mesh and the Shishkin mesh.

	Proposed mesh			Shishkin mesh

MULTIADAPTIVE GALERKIN METHODS FOR ODES III: A PRIORI ERROR ESTIMATES*

ANDERS LOGG†

Abstract. The multiadaptive continuous/discontinuous Galerkin methods mcG(q) and mdG(q) for the numerical solution of initial value problems for ordinary differential equations are based on piecewise polynomial approximation of degree q on partitions in time with time steps which may vary for different components of the computed solution. In this paper, we prove general order a priori error estimates for the mcG(q) and mdG(q) methods. To prove the error estimates, we represent the error in terms of a discrete dual solution and the residual of an interpolant of the exact solution. The estimates then follow from interpolation estimates, together with stability estimates for the discrete dual solution.

Key words. multiadaptivity, individual time steps, local time steps, ODE, continuous Galerkin, discontinuous Galerkin, mcG(q), mdG(q), a priori error estimates, existence, stability, Peano kernel theorem, interpolation estimates, piecewise smooth

1. Introduction.

This is part 3 in a sequence of papers [32, 33] on multiadaptive Galerkin methods, mcG(q) and mdG(q), for approximate (numerical) solution of ODEs of the form

$$\begin{aligned} \dot{u}(t) &= f(u(t), t), \quad t \in (0, T], \\ u(0) &= u_0, \end{aligned} \tag{1.1}$$

where $u : [0, T] \to \mathbb{R}^N$ is the solution to be computed, $u_0 \in \mathbb{R}^N$ a given initial condition, $T > 0$ a given final time, and $f : \mathbb{R}^N \times (0, T] \to \mathbb{R}^N$ a given function that is Lipschitz-continuous in u and bounded.

In the previous two parts of our series on multiadaptive Galerkin methods, we proved a posteriori error estimates, through which the time steps are adaptively determined from residual feedback and stability information, obtained by solving a dual linearized problem. In this paper, we prove a priori error estimates for mcG(q) and mdG(q). We also prove the stability estimates and interpolation estimates which are essential to the a priori error analysis.

Standard methods for the time-discretization of (1.1) require that the resolution is equal for all components $U_i(t)$ of the computed approximate solution $U(t)$ of (1.1). This includes all standard Galerkin or Runge–Kutta methods; see [9, 4, 23, 24, 41, 2]. Using the same time step sequence $k = k(t)$ for all components could become very costly if the different components of the solution exhibit multiple time scales of different magnitudes. We therefore propose a new representation of the solution in which the difference in time scales is reflected in the *componentwise* time-discretization of (1.1), that is, each component $U_i(t)$ is computed using an individual time step sequence $k_i = k_i(t)$.

The multiadaptive Galerkin methods mcG(q) and mdG(q) first presented in [32] are formulated as extensions of the standard continuous and discontinuous Galerkin methods cG(q) and dG(q), studied earlier in detail by Hulme [28, 27], Jamet [29], Delfour, Hager, and Trochu [7], Eriksson, Johnson, and Thomée [16, 30, 11, 12, 10, 13, 14, 15, 8], and Estep et al. [17, 18, 19, 21, 20]. As such, the analysis of the mcG(q) and mdG(q) methods can be carried out within the existing framework, but the extension to multiadaptive time-stepping leads to some technical challenges, in particular, proving the appropriate interpolation estimates.

Local (multiadaptive) time-stepping has been explored before to some extent for specific applications, including specialized integrators for the n-body problem [37, 5, 1] and low-order methods for conservation laws [39, 22, 6]. Early attempts at local time-stepping include [25, 26]. Recently, a new class of related methods, known as asynchronous variational integrators (AVI) with local time steps, has been proposed [31].

1.1. Main results. The main results of this paper are a priori error estimates for the mcG(q) and mdG(q) methods, respectively, of the form

$$\|e(T)\|_{l_p} \leq CS(T) \big\| k^{2q} u^{(2q)} \big\|_{L_\infty([0,T],l_1)} \tag{1.2}$$

and

$$\|e(T)\|_{l_p} \leq CS(T) \big\| k^{2q+1} u^{(2q+1)} \big\|_{L_\infty([0,T],l_1)} \tag{1.3}$$

for $p = 2$ or $p = \infty$, where C is an interpolation constant, $S(T)$ is a (computable) stability factor, and $k^{2q}u^{(2q)}$ (or $k^{2q+1}u^{(2q+1)}$) combines local time steps $k_i = k_i(t)$ with derivatives of the exact solution u. The norm $L_\infty(I, \|\cdot\|)$ is defined by $\|v\|_{L_\infty(I,\|\cdot\|)} = \sup_{t\in I} \|v(t)\|$. These estimates state that the mcG(q) method is of order $2q$ and that the mdG(q) method is of order $2q + 1$ in the local time step. We refer to section 6.2 for the exact results. It should be noted that superconvergence is obtained only at synchronized time levels, such as the end-point $t = T$. For the general nonlinear problem, we obtain exponential estimates for the stability factor $S(T)$. In [34], we prove that for a parabolic model problem, the stability factor remains bounded and of unit size, independent of T (up to a logarithmic factor).

1.2. Notation. The following notation is used throughout this paper. Each component $U_i(t)$, $i = 1, \ldots, N$, of the approximate m(c/d)G(q) solution $U(t)$ of (1.1) is a piecewise polynomial on a partition of $(0, T]$ into M_i subintervals. Subinterval j for component i is denoted by $I_{ij} = (t_{i,j-1}, t_{ij}]$, and the length of the subinterval is given by the *local time step* $k_{ij} = t_{ij} - t_{i,j-1}$. This is illustrated in Figure 1. On each subinterval I_{ij}, $U_i|_{I_{ij}}$ is a polynomial of degree q_{ij} and we refer to $(I_{ij}, U_i|_{I_{ij}})$ as an *element*.

Furthermore, we shall assume that the interval $(0, T]$ is partitioned into blocks between certain synchronized time levels $0 = T_0 < T_1 < \cdots < T_M = T$. We refer to the set of intervals $\mathcal{T}_n$ between two synchronized time levels T_{n-1} and T_n as a *time slab*:

$$\mathcal{T}_n = \{I_{ij} : T_{n-1} \leq t_{i,j-1} < t_{ij} \leq T_n\}.$$

We denote the length of a time slab by $K_n = T_n - T_{n-1}$. We also refer to the entire collection of intervals I_{ij} as the partition $\mathcal{T}$.

Since different components use different time steps, a local interval I_{ij} may contain nodal points for other components, that is, some $t_{i'j'} \in (t_{i,j-1}, t_{ij})$. We denote the set of such internal nodes on a local interval I_{ij} by $\mathcal{N}_{ij}$.

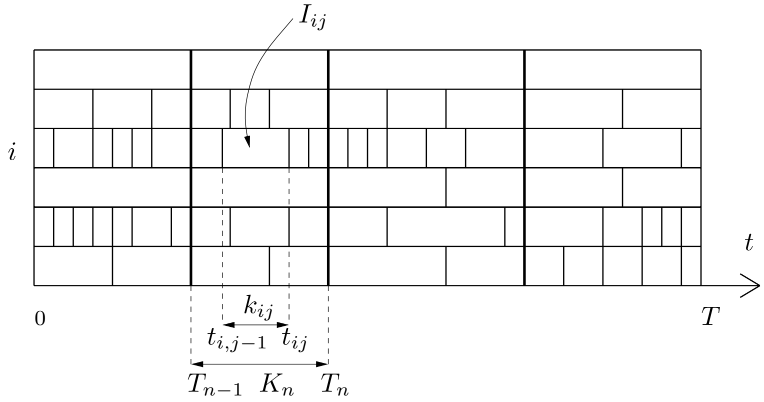

FIG. 1. *Individual partitions of the interval* $(0,T]$ *for different components. Elements between common synchronized time levels are organized in time slabs. In this example, we have* $N = 6$ *and* $M = 4$.

1.3. Outline of the paper. The outline of this paper is as follows. In section 2, we give the full definition of the multiadaptive Galerkin methods mcG(q) and mdG(q). We also introduce the dual methods mcG(q)* and mdG(q)*, which are of importance to the a priori error analysis. In sections 3 and 4, respectively, we then prove existence and stability of the discrete solutions as defined in section 2.

In section 5, we prove the interpolation estimates that we later use to prove the a priori error estimates in section 6. Proving the interpolation estimates is technically challenging, since the function to be interpolated may be discontinuous within the interval of interpolation. To measure the regularity of the interpolated function, it is then necessary to take into consideration the size of the jump in function value and derivatives at each point of discontinuity.

Finally, in section 7, we present some numerical evidence for the a priori error estimates by solving a simple model problem and showing that we obtain the predicted convergence rates, k^{2q} and k^{2q+1}, respectively, for the mcG(q) and mdG(q) methods.

2. Definition of methods. In this section, we give the definitions of the multiadaptive Galerkin methods mcG(q) and mdG(q). The multiadaptive methods are obtained as extensions of the standard (monoadaptive) Galerkin methods cG(q) and dG(q) by extending the trial and test spaces to allow individual time step sequences for different components.

As an important tool for the a priori error analysis in section 6, we also introduce the discrete dual problem and the discrete dual methods mcG(q)* and mdG(q)*.

2.1. Multiadaptive continuous Galerkin, mcG(q). To formulate the mcG(q) method, we define the *trial space* V and the *test space* $\hat{V}$ as

$$\begin{aligned} V &= \left\{ v \in [\mathcal{C}([0,T])]^N : v_i|_{I_{ij}} \in \mathcal{P}^{q_{ij}}(I_{ij}),\ j = 1,\ldots,M_i,\ i = 1,\ldots,N \right\}, \\ \hat{V} &= \left\{ v : v_i|_{I_{ij}} \in \mathcal{P}^{q_{ij}-1}(I_{ij}),\ j = 1,\ldots,M_i,\ i = 1,\ldots,N \right\}, \end{aligned} \tag{2.1}$$

where $\mathcal{P}^q(I)$ denotes the linear space of polynomials of degree q on an interval $I \subset \mathbb{R}$. In other words, V is the space of vector-valued continuous piecewise polynomials of degree $q = (q_i(t))$ with $q_i(t) \geq 1$ on the partition $\mathcal{T}$, and $\hat{V}$ is the space of vector-valued (possibly discontinuous) piecewise polynomials of degree $q - 1 = (q_i(t) - 1)$ on the same partition.

We now define the mcG(q) method for (1.1) as follows: Find $U \in V$ with $U(0) = u_0$ such that

$$\int_0^T (\dot{U}, v)\,dt = \int_0^T (f(U,\cdot), v)\,dt \quad \forall v \in \hat{V}, \tag{2.2}$$

where $(\cdot,\cdot)$ denotes the $\mathbb{R}^N$ inner product. With a suitable choice of test function v, it follows that the global problem (2.2) can be restated as a sequence of successive local problems for each component: For $i = 1, \ldots, N$, $j = 1, \ldots, M_i$, find $U_i|_{I_{ij}} \in \mathcal{P}^{q_{ij}}(I_{ij})$ with $U_i(t_{i,j-1})$ given such that

$$\int_{I_{ij}} \dot{U}_i v\,dt = \int_{I_{ij}} f_i(U,\cdot) v\,dt \quad \forall v \in \mathcal{P}^{q_{ij}-1}(I_{ij}), \tag{2.3}$$

where the initial condition is specified for $i = 1, \ldots, N$ by $U_i(0) = u_i(0)$.

We define the *residual* R of the approximate solution U by $R_i(U,t) = \dot{U}_i(t) - f_i(U(t),t)$. In terms of the residual, we can rewrite (2.3) in the form

$$\int_{I_{ij}} R_i(U,\cdot) v\,dt = 0 \quad \forall v \in \mathcal{P}^{q_{ij}-1}(I_{ij}), \quad j = 1, \ldots, M_i, \quad i = 1, \ldots, N, \tag{2.4}$$

that is, the residual is orthogonal to the test space on each local interval. We refer to (2.4) as the *Galerkin orthogonality* of the mcG(q) method.

2.2. Multiadaptive discontinuous Galerkin, mdG(q). For mdG(q), we define the trial and test spaces by

$$V = \hat{V} = \{v : v_i|_{I_{ij}} \in \mathcal{P}^{q_{ij}}(I_{ij}),\ j = 1, \ldots, M_i,\ i = 1, \ldots, N\}, \tag{2.5}$$

that is, both trial and test functions are vector-valued (possibly discontinuous) piecewise polynomials of degree $q = (q_i(t))$ with $q_i(t) \geq 0$ on the partition $\mathcal{T}$. By definition, the mdG(q) solution $U \in V$ is left-continuous.

We now define the mdG(q) method for (1.1) as follows: Find $U \in V$ with $U(0^-) = u_0$ such that

$$\sum_{i=1}^{N} \sum_{j=1}^{M_i} \left[[U_i]_{i,j-1} v_i\big(t_{i,j-1}^+\big) + \int_{I_{ij}} \dot{U}_i v_i\,dt \right] = \int_0^T (f(U,\cdot), v)\,dt \quad \forall v \in \hat{V}, \tag{2.6}$$

where $[U_i]_{i,j-1} = U_i(t_{i,j-1}^+) - U_i(t_{i,j-1}^-)$ denotes the jump in $U_i(t)$ across the node $t = t_{i,j-1}$, and where $v(t^+) = \lim_{s \to t^+} v(s)$.

The mdG(q) method in local form, corresponding to (2.3), reads as follows: For $i = 1, \ldots, N$, $j = 1, \ldots, M_i$, find $U_i|_{I_{ij}} \in \mathcal{P}^{q_{ij}}(I_{ij})$ such that

$$[U_i]_{i,j-1} v(t_{i,j-1}) + \int_{I_{ij}} \dot{U}_i v\,dt = \int_{I_{ij}} f_i(U,\cdot) v\,dt \quad \forall v \in \mathcal{P}^{q_{ij}}(I_{ij}), \tag{2.7}$$

where the initial condition is specified for $i = 1, \ldots, N$ by $U_i(0^-) = u_i(0)$.

The residual R is defined on the inner of each local interval I_{ij} by $R_i(U,t) = \dot{U}_i(t) - f_i(U(t),t)$. In terms of the residual, (2.7) can be restated in the form

$$[U_i]_{i,j-1} v\big(t_{i,j-1}^+\big) + \int_{I_{ij}} R_i(U,\cdot) v\,dt = 0 \quad \forall v \in \mathcal{P}^{q_{ij}}(I_{ij}) \tag{2.8}$$

for $j = 1, \ldots, M_i$, $i = 1, \ldots, N$. We refer to (2.8) as the Galerkin orthogonality of the mdG(q) method.

2.3. The dual problem. The dual problem is the standard tool for error analysis, a priori or a posteriori, of Galerkin finite element methods for the numerical solution of differential equations; see [8, 3]. For the a posteriori error analysis of the multiadaptive Galerkin methods mcG(q) and mdG(q) in [32], we formulate a continuous dual problem. For the a priori error analysis of this paper, we formulate instead a discrete dual problem. The discrete dual problem was first introduced for the family of discontinuous Galerkin methods dG(q) in [16]. As we shall see, the discrete dual problem can be expressed as a Galerkin method for a continuous problem.

The discrete dual solution $\Phi : [0,T] \to \mathbb{R}^N$ is a Galerkin approximation of the exact solution $\phi : [0,T] \to \mathbb{R}^N$ of the continuous dual problem

$$\begin{aligned} -\dot{\phi}(t) &= J^\top(\pi u, U, t)\phi(t) + g(t), \quad t \in [0,T), \\ \phi(T) &= \psi, \end{aligned} \tag{2.9}$$

where πu is an interpolant or a projection of the exact solution u of (1.1), $g : [0,T] \to \mathbb{R}^N$ is a given function, $\psi \in \mathbb{R}^N$ is a given initial condition, and

$$J^\top(\pi u, U, t) = \left(\int_0^1 \frac{\partial f}{\partial u}(s\pi u(t) + (1-s)U(t), t)\, ds \right)^\top, \tag{2.10}$$

that is, an appropriate mean value of the transpose of the Jacobian of the right-hand side $f(\cdot, t)$ evaluated at $\pi u(t)$ and $U(t)$. Note that by the chain rule, we have

$$J(\pi u, U, \cdot)(U - \pi u) = f(U, \cdot) - f(\pi u, \cdot). \tag{2.11}$$

The data (ψ, g) of the dual problem allow us to obtain error estimates for different functionals $L_{\psi,g}$ of the error $e = U - u$.

We define below two new Galerkin methods for the dual problem (2.9): the dual methods mcG$(q)^*$ and mdG$(q)^*$. We will later use the mcG$(q)^*$ method to express the error of the mcG(q) solution of (1.1) in terms of the mcG$(q)^*$ solution of (2.9). Similarly, we will express the error of the mdG(q) solution of (1.1) in terms of the mdG$(q)^*$ solution of (2.9).

2.4. Multiadaptive dual continuous Galerkin, mcG$(q)^*$. In the formulation of the dual method of mcG(q), we interchange the trial and test spaces of mcG(q). With the same definitions of V and $\hat{V}$ as in (2.1), we thus define the mcG$(q)^*$ method for (2.9) as follows: Find $\Phi \in \hat{V}$ with $\Phi(T^+) = \psi$ such that

$$\int_0^T (\dot{v}, \Phi)\, dt = \int_0^T (J(\pi u, U, \cdot)v, \Phi) + L_{\psi,g}(v) \tag{2.12}$$

for all $v \in V$ with $v(0) = 0$, where

$$L_{\psi,g}(v) \equiv (v(T), \psi) + \int_0^T (v, g)\, dt. \tag{2.13}$$

Notice the extra condition that the test functions should vanish at $t = 0$, which is introduced to make the dimension of the test space equal to the dimension of the trial space. Integrating by parts, (2.12) can alternatively be expressed in the form

$$\sum_{i=1}^N \sum_{j=1}^{M_i} \left[-[\Phi_i]_{ij} v_i(t_{ij}) - \int_{I_{ij}} \dot{\Phi}_i v_i\, dt \right] = \int_0^T (J^\top(\pi u, U, \cdot)\Phi + g, v)\, dt. \tag{2.14}$$

2.5. Multiadaptive dual discontinuous Galerkin, mdG$(q)^*$. With the same definitions of V and $\hat{V}$ as in (2.5), we define the mdG$(q)^*$ method for (2.9) as follows: Find $\Phi \in \hat{V}$ with $\Phi(T^+) = \psi$ such that

$$\sum_{i=1}^{N} \sum_{j=1}^{M_i} \left[[v_i]_{i,j-1} \Phi_i\big(t_{i,j-1}^+\big) + \int_{I_{ij}} \dot{v}_i \Phi_i \, dt \right] = \int_0^T (J(\pi u, U, \cdot) v, \Phi) \, dt + L_{\psi,g}(v) \tag{2.15}$$

for all $v \in V$ with $v(0^-) = 0$. Integrating by parts, (2.15) can alternatively be expressed in the form

$$\sum_{i=1}^{N} \sum_{j=1}^{M_i} \left[-[\Phi_i]_{ij} v_i\big(t_{ij}^-\big) - \int_{I_{ij}} \dot{\Phi}_i v_i \, dt \right] = \int_0^T (J^\top(\pi u, U, \cdot)\Phi + g, v) \, dt. \tag{2.16}$$

3. Existence of solutions.

To prove existence of the discrete mcG(q), mdG(q), mcG$(q)^*$, and mdG$(q)^*$ solutions defined in the previous section, we formulate fixed point iterations for the construction of solutions. Existence then follows from the Banach fixed point theorem if the time steps are sufficiently small.

Lemma 3.1 (fixed point iteration). *Let $\mathcal{T}_n$ be a time slab with synchronized time levels T_{n-1} and T_n. With time reversed for the dual methods (to simplify the notation), the* mcG(q)*,* mdG(q)*,* mcG$(q)^*$*, and* mdG$(q)^*$ *methods can all be expressed in the following form: For all $I_{ij} \in \mathcal{T}_n$, find $\{\xi_{ijn}\}$ (the degrees of freedom for U_i on I_{ij}) such that*

$$\xi_{ijn} = u_i(0) + \int_0^{t_{i,j-1}} f_i(U, \cdot) \, dt + \int_{I_{ij}} w_n^{[q_{ij}]}(\tau_{ij}(t)) f_i(U, \cdot) \, dt, \tag{3.1}$$

where $\tau_{ij}(t) = (t - t_{i,j-1})/(t_{ij} - t_{i,j-1})$ and $\{w_n^{[q_{ij}]}\}$ is a set of polynomial weight functions on $[0, 1]$.

Proof. The result follows from the definitions of the mcG(q), mdG(q), mcG$(q)^*$, and mdG$(q)^*$ methods, using an appropriate basis for the trial and test spaces. See [34] for details. □

Theorem 3.2 (existence of solutions). *Let $K = \max K_n$ be the maximum time slab length and define the Lipschitz constant $L_f > 0$ by*

$$\|f(x,t) - f(y,t)\|_{l_\infty} \le L_f \|x - y\|_{l_\infty} \quad \forall t \in [0, T] \ \forall x, y \in \mathbb{R}^N. \tag{3.2}$$

If now

$$K C L_f < 1, \tag{3.3}$$

where $C = C(q) > 0$ is a constant depending only on the order and method, the fixed point iteration (3.1) *converges to the unique solution of* (2.2), (2.6), (2.12), *and* (2.15), *respectively.*

Proof. The result follows by Lemma 3.1 and an application of the Banach fixed point theorem. See [34] for details. □

4. Stability of solutions.

Write the dual problem (2.9) for $\phi = \phi(t)$ in the form

$$\begin{aligned} -\dot{\phi}(t) + A^\top(t)\phi(t) &= g, \quad t \in [0, T), \\ \phi(T) &= \psi. \end{aligned} \tag{4.1}$$

For simplicity, we consider only the case $g = 0$. With $w(t) = \phi(T - t)$, we have $\dot{w}(t) = -\dot{\phi}(T - t) = -A^\top(T - t)w(t)$, and so (4.1) can be written as a forward problem for w in the form

$$\begin{aligned} \dot{w}(t) + B(t)w(t) = 0, \quad t \in (0, T], \\ w(0) = w_0, \end{aligned} \tag{4.2}$$

where $w_0 = \psi$ and $B(t) = A^\top(T - t)$. Below, w represents either u or $\phi(T - \cdot)$ and, correspondingly, W represents either the discrete mc/dG(q) approximation U of u or the discrete mc/dG(q)* approximation Φ of ϕ.

4.1. A general exponential estimate.

The general exponential stability estimate is based on the following version of the discrete Gronwall inequality.

Lemma 4.1 (discrete Gronwall inequality). *Assume that $z, a : \mathbb{N} \to \mathbb{R}$ are nonnegative, $a(m) \leq 1/2$ for all m, and $z(n) \leq C + \sum_{m=1}^{n} a(m)z(m)$ for all n. Then $z(n) \leq 2C \exp(\sum_{m=1}^{n-1} 2a(m))$ for $n = 1, 2, \ldots$.*

Proof. By a standard discrete Gronwall inequality [38], $z(n) \leq C \exp(\sum_{m=0}^{n-1} a(m))$ if $z(n) \leq C + \sum_{m=0}^{n-1} a(m)z(m)$ for $n \geq 1$ and $z(0) \leq C$. Here, $(1 - a(n))z(n) \leq C + \sum_{m=1}^{n-1} a(m)z(m)$, and so $z(n) \leq 2C + \sum_{m=1}^{n-1} 2a(m)z(m)$, since $1 - a(n) \geq 1/2$. The result now follows if we take $a(0) = z(0) = 0$. □

Theorem 4.2 (stability estimate). *Let W be the* mcG(q), mdG(q), mcG(q)*, *or* mdG(q)* *solution of* (4.2). *Then there is a constant $C = C(q)$, depending only on the highest order* $\max q_{ij}$, *such that if $K_n C \|B\|_{L_\infty([T_{n-1},T_n],l_p)} \leq 1$ for $n = 1, \ldots, M$, then*

$$\|W\|_{L_\infty([T_{n-1},T_n],l_p)} \leq C\|w_0\|_{l_p} \exp\left(\sum_{m=1}^{n-1} K_m C \|B\|_{L_\infty([T_{m-1},T_m],l_p)}\right) \tag{4.3}$$

for $n = 1, \ldots, M$, $1 \leq p \leq \infty$.

Proof. By Lemma 3.1, we can write the mcG(q), mdG(q), mcG(q)*, and mdG(q)* methods in the form $\xi_{ijn'} = w_i(0) + \int_0^{t_{i,j-1}} f_i(W, \cdot)\, dt + \int_{I_{ij}} w_{n'}^{[q_{ij}]}(\tau_{ij}(t)) f_i(W, \cdot)\, dt$. Applied to the linear model problem (4.2), we have $\xi_{ijn'} = w_i(0) - \int_0^{t_{i,j-1}} (BW)_i\, dt - \int_{I_{ij}} w_{n'}^{[q_{ij}]}(\tau_{ij}(t))(BW)_i\, dt$, and so

$$\begin{aligned} |\xi_{ijn'}| &\leq |w_i(0)| + \left| \int_0^{t_{i,j-1}} (BW)_i\, dt \right| + \left| \int_{I_{ij}} w_{n'}^{[q_{ij}]}(\tau_{ij}(t))(BW)_i\, dt \right| \\ &\leq |w_i(0)| + C \int_0^{t_{ij}} |(BW)_i|\, dt \leq |w_i(0)| + C \int_0^{T_n} |(BW)_i|\, dt, \end{aligned}$$

where T_n is smallest synchronized time level for which $t_{ij} \leq T_n$. It now follows that for all $t \in [T_{n-1}, T_n]$, we have $|W_i(t)| \leq C|w_i(0)| + C \int_0^{T_n} |(BW)_i|\, dt$, and so

$$\|W(t)\|_{l_p} \leq C\|w_0\|_{l_p} + C \int_0^{T_n} \|BW\|_{l_p}\, dt = C\|w_0\|_{l_p} + C \sum_{m=1}^{n} \int_{T_{m-1}}^{T_m} \|BW\|_{l_p}\, dt.$$

The result now follows by letting $\bar{W}_n = \|W\|_{L_\infty([T_{n-1},T_n],l_p)}$. □

Remark 4.1. *See* [34] *for an extension to multiadaptive time-stepping of the strong stability estimate Lemma* 6.1 *for parabolic problems in* [11].

5. Interpolation estimates. In this section, we introduce a pair of carefully chosen interpolants, $\pi_{\mathrm{cG}}^{[q]}$ and $\pi_{\mathrm{dG}}^{[q]}$, which are central to the a priori error analysis of the mcG(q) and mdG(q) methods. The interpolants are defined in section 5.1. In section 5.2, we discuss the interpolation of piecewise smooth functions, that is, the interpolation of functions which may be discontinuous within the interval of interpolation, and then present the basic general interpolation estimates for the two interpolants $\pi_{\mathrm{cG}}^{[q]}$ and $\pi_{\mathrm{dG}}^{[q]}$.

For the a priori error analysis of the mcG(q) and mdG(q) methods, we will also need a special interpolation estimate for the function $\varphi = J^\top \Phi$, where J is the Jacobian of the right-hand side f of (1.1) and Φ is the discrete dual solution as defined in section 2, including estimates for the size of the jump in function value and derivatives for the function φ at points of discontinuity. These estimates are proved in section 5.3, based on a representation formula for the mcG(q) and mdG(q) solutions of (1.1).

5.1. Interpolants. The interpolant $\pi_{\mathrm{cG}}^{[q]} : V \rightarrow \mathcal{P}^q([a,b])$ is defined by the following conditions:

$$\begin{aligned} &\pi_{\mathrm{cG}}^{[q]} v(a) = v(a) \quad \text{and} \quad \pi_{\mathrm{cG}}^{[q]} v(b) = v(b), \\ &\int_a^b \big(v - \pi_{\mathrm{cG}}^{[q]} v\big) w \, dx = 0 \quad \forall w \in \mathcal{P}^{q-2}([a,b]), \end{aligned} \tag{5.1}$$

where V denotes the set of functions that are piecewise $\mathcal{C}^{q+1}$ and bounded on $[a,b]$. In other words, $\pi_{\mathrm{cG}}^{[q]} v$ is the polynomial of degree q that interpolates v at the end-points of the interval $[a,b]$ and additionally satisfies $q-1$ projection conditions. This is illustrated in Figure 2. We also define the dual interpolant $\pi_{\mathrm{cG}^*}^{[q]}$ as the standard L_2-projection onto $\mathcal{P}^{q-1}([a,b])$.

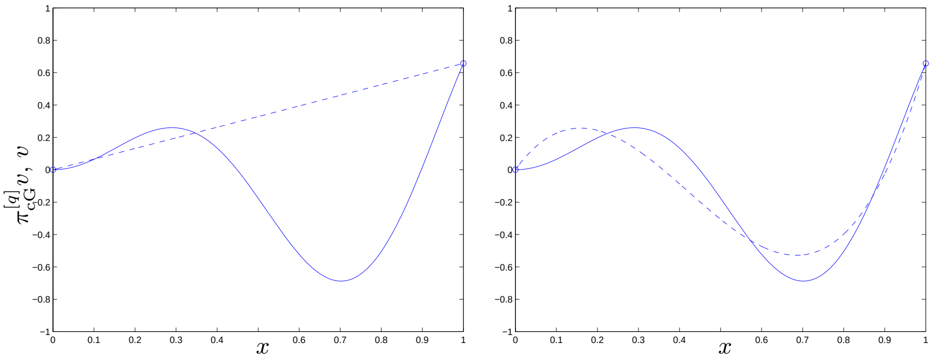

FIG. 2. *The interpolant* $\pi_{\mathrm{cG}}^{[q]} v$ *(dashed) of the function* $v(x) = x\,\sin(7x)$ *(solid) on* $[0,1]$ *for* $q = 1$ *(left) and* $q = 3$ *(right).*

The interpolant $\pi_{\mathrm{dG}}^{[q]} : V \rightarrow \mathcal{P}^q([a,b])$ is defined by the following conditions:

$$\begin{aligned} &\pi_{\mathrm{dG}}^{[q]} v(b) = v(b), \\ &\int_a^b \big(v - \pi_{\mathrm{dG}}^{[q]} v\big) w \, dx = 0 \quad \forall w \in \mathcal{P}^{q-1}([a,b]), \end{aligned} \tag{5.2}$$

that is, $\pi_{\mathrm{dG}}^{[q]} v$ is the polynomial of degree q that interpolates v at the right end-point of the interval $[a,b]$ and additionally satisfies q projection conditions. This is illustrated

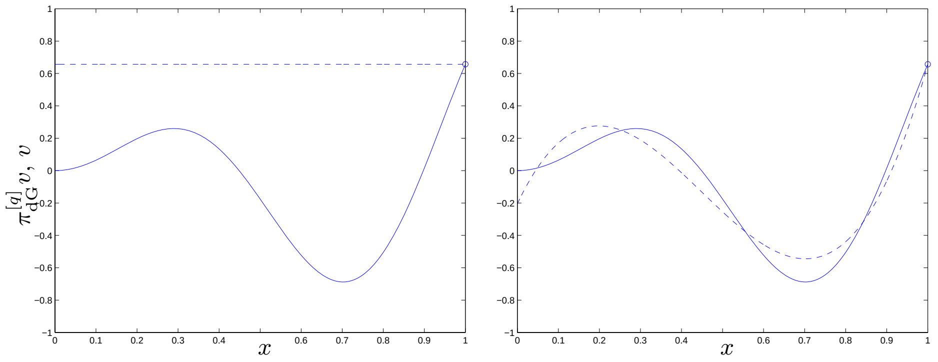

FIG. 3. *The interpolant $\pi_{\mathrm{dG}}^{[q]}v$ (dashed) of the function $v(x) = x\,\sin(7x)$ (solid) on $[0,1]$ for $q = 0$ (left) and $q = 3$ (right).*

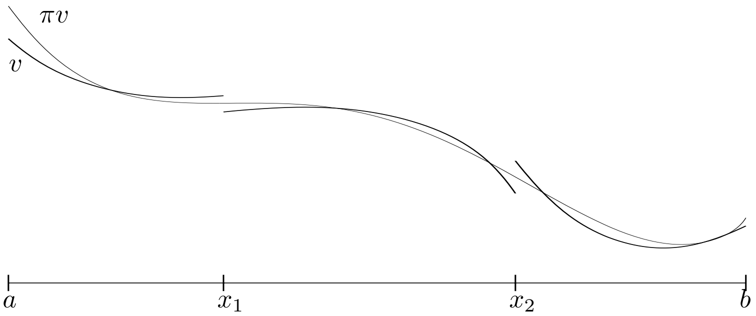

FIG. 4. *A piecewise smooth function v and its interpolant πv.*

in Figure 3. The dual interpolant $\pi_{\mathrm{dG}^*}^{[q]}$ is defined similarly, with the difference being that the left end-point $x = a$ is used for interpolation.

5.2. Basic interpolation estimates. To estimate the size of the interpolation error $\pi v - v$ for a given function v, we express the interpolation error in terms of the regularity of v and the length of the interpolation interval, $k = b - a$. Specifically, when $v \in \mathcal{C}^{q+1}([a,b]) \subset V$ for some $q \geq 0$, we obtain estimates of the form

$$\big\|(\pi v)^{(p)} - v^{(p)}\big\| \leq Ck^{q+1-p}\big\|v^{(q+1)}\big\|, \quad p = 0, \dots, q+1, \tag{5.3}$$

where $\|\cdot\| = \|\cdot\|_{L_\infty([a,b])}$ denotes the maximum norm on $[a,b]$. This estimate is a simple consequence of the Peano kernel theorem [40] if one can show that the interpolant $\pi : V \to \mathcal{P}^q([a,b]) \subset V$ is linear and bounded on V and that π is exact on $\mathcal{P}^q([a,b]) \subset V$, that is, $\pi v = v$ for all $v \in \mathcal{P}^q([a,b])$.

In the general case, where the interpolated function v is only piecewise smooth (see Figure 4), we also need to include the size of the jump $[v^{(p)}]_x$ in function value and derivatives at each point x of discontinuity within (a,b) to measure the regularity of the interpolated function v. In [34], we prove the following extensions of the basic estimate (5.3).

LEMMA 5.1. *If π is linear and bounded on V and is exact on $\mathcal{P}^q([a,b]) \subset V$, then there is a constant $C = C(q) > 0$ such that for all v piecewise $\mathcal{C}^{q+1}$ on $[a,b]$ with*

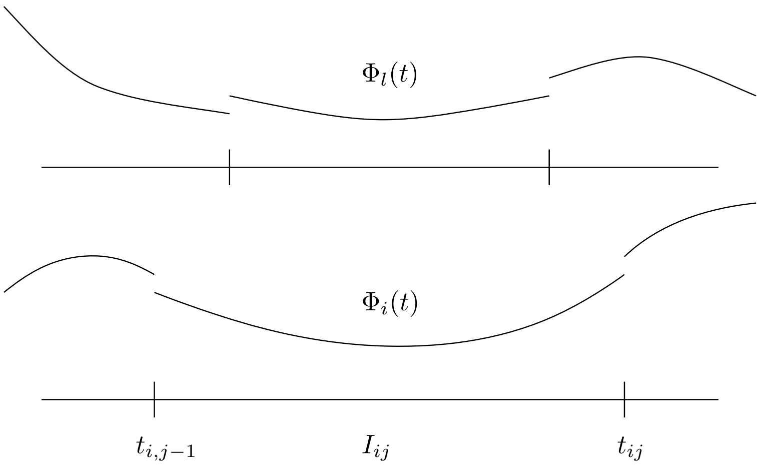

FIG. 5. *If some other component $l \neq i$ has a node within I_{ij}, then Φ_l may be discontinuous within I_{ij}, causing φ_i to be discontinuous within I_{ij}.*

discontinuities at $a < x_1 < \cdots < x_n < b$,

$$\big\|(\pi v)^{(p)} - v^{(p)}\big\| \leq Ck^{r+1-p}\big\|v^{(r+1)}\big\| + C\sum_{j=1}^{n}\sum_{m=0}^{r} k^{m-p}\big|\big[v^{(m)}\big]_{x_j}\big| \tag{5.4}$$

for $p = 0, \ldots, r+1$, $r = 0, \ldots, q$.

LEMMA 5.2. *If π is linear and bounded on V and is exact on $\mathcal{P}^q([a,b]) \subset V$, then there is a constant $C = C(q) > 0$ such that for all v piecewise $\mathcal{C}^{q+1}$ on $[a,b]$ with discontinuities at $a < x_1 < \cdots < x_n < b$,*

$$\big\|(\pi v)^{(p)}\big\| \leq C\big\|v^{(p)}\big\| + C\sum_{j=1}^{n}\sum_{m=0}^{p-1} k^{m-p}\big|\big[v^{(m)}\big]_{x_j}\big| \tag{5.5}$$

for $p = 0, \ldots, q$.

Lemmas 5.1 and 5.2 apply to both the $\pi_{\mathrm{cG}}^{[q]}$ interpolant (for $q \geq 1$) and the $\pi_{\mathrm{dG}}^{[q]}$ interpolant (for $q \geq 0$) defined in section 5.1. The linearity of both interpolants follows directly from the definition of the interpolants. The proofs that both interpolants are bounded and exact on $\mathcal{P}^q([a,b])$ are given in detail in [34] and [35].

5.3. A special interpolation estimate.

To prove a priori error estimates for mcG(q) and mdG(q) in section 6, we need to estimate the interpolation error $\pi\varphi - \varphi$ for the function φ defined by

$$\varphi_i = (J^\top(\pi u, u, \cdot)\Phi)_i = \sum_{l=1}^{N} J_{li}(\pi u, u, \cdot)\Phi_l, \quad i = 1, \ldots, N. \tag{5.6}$$

We note that φ_i may be discontinuous within I_{ij} if I_{ij} contains a node for some other component, which is generally the case. This is illustrated in Figure 5. Note that on the right-hand side f is linearized around a mean value of πu and u.

An interpolation estimate for $\pi\varphi - \varphi$ follows directly from Lemma 5.1. To use this estimate, we need to estimate the size of the jump in function value and derivatives at each internal node t_{ij} of the partition $\mathcal{T}$. To obtain this estimate, we need to make a number of additional assumptions on the right-hand side f of (1.1) and the partition $\mathcal{T}$. These assumptions are discussed in section 5.3.2. Based on the assumptions and the representation formula presented in section 5.3.1, we obtain the jump estimates in section 5.3.3 and, finally, in section 5.3.4, the interpolation estimate for φ.

5.3.1. A representation formula. The proof of jump estimates for the multiadaptive Galerkin methods mcG(q) and mdG(q) is based on expressing the solutions as certain interpolants. These representations are obtained as follows. Let U be the mcG(q) or mdG(q) solution of (1.1) and define, for $i = 1, \dots, N$,

$$\tilde{U}_i(t) = u_i(0) + \int_0^t f_i(U(s), s)\, ds. \tag{5.7}$$

Similarly, for Φ the mcG(q)* or mdG(q)* solution of (2.9), we define, for $i = 1, \dots, N$,

$$\tilde{\Phi}_i(t) = \psi_i + \int_t^T f_i^*(\Phi(s), s)\, ds, \tag{5.8}$$

where $f^*(\Phi, \cdot) = J^\top(\pi u, U, \cdot)\Phi + g$. We note that $\dot{\tilde{U}} = f(U, \cdot)$ and $-\dot{\tilde{\Phi}} = f^*(\Phi, \cdot)$.

It now turns out that U can be expressed as an interpolant of $\tilde{U}$. Similarly, Φ can be expressed as an interpolant of $\tilde{\Phi}$. We present these representations in Lemmas 5.3 and 5.4. We remind the reader about the interpolants $\pi_{\mathrm{cG}}^{[q]}$, $\pi_{\mathrm{cG}^*}^{[q]}$, $\pi_{\mathrm{dG}}^{[q]}$, and $\pi_{\mathrm{dG}^*}^{[q]}$, defined in section 5.1.

LEMMA 5.3. *The* mcG(q) *solution U of* (1.1) *can expressed in the form $U = \pi_{\mathrm{cG}}^{[q]}\tilde{U}$. Similarly, the* mcG($q$)* *solution Φ of* (2.9) *can be expressed in the form $\Phi = \pi_{\mathrm{cG}^*}^{[q]}\tilde{\Phi}$, that is, $U_i = \pi_{\mathrm{cG}}^{[q_{ij}]}\tilde{U}_i$ and $\Phi_i = \pi_{\mathrm{cG}^*}^{[q_{ij}]}\tilde{\Phi}_i$ on each local interval I_{ij}.*

Proof. The representation formulas follow by the definitions of the mcG(q) and mcG(q)* methods and the interpolants $\pi_{\mathrm{cG}}^{[q]}$ and $\pi_{\mathrm{cG}^*}^{[q]}$. See [34] for details. □

LEMMA 5.4. *The* mdG(q) *solution U of* (1.1) *can expressed in the form $U = \pi_{\mathrm{dG}}^{[q]}\tilde{U}$. Similarly, the* mdG($q$)* *solution Φ of* (2.9) *can be expressed in the form $\Phi = \pi_{\mathrm{dG}^*}^{[q]}\tilde{\Phi}$, that is, $U_i = \pi_{\mathrm{dG}}^{[q_{ij}]}\tilde{U}_i$ and $\Phi_i = \pi_{\mathrm{dG}^*}^{[q_{ij}]}\tilde{\Phi}_i$ on each local interval I_{ij}.*

Proof. The representation formulas follow by the definitions of the mdG(q) and mdG(q)* methods and the interpolants $\pi_{\mathrm{dG}}^{[q]}$ and $\pi_{\mathrm{dG}^*}^{[q]}$. See [34] for details. □

5.3.2. Assumptions. To estimate the size of the jump in function value and derivatives for the function φ defined in (5.6), we make the following assumptions. Given a time slab $\mathcal{T}$, assume that for each pair of local intervals I_{ij} and I_{mn} within the time slab, we have

$$q_{ij} = q_{mn} = \bar{q} \tag{A1}$$

and

$$k_{ij} > \alpha\, k_{mn} \tag{A2}$$

for some $\bar{q} \geq 0$ and some $\alpha \in (0, 1)$. The dependence on α in the error estimates is weak (see Remark 5.1), so assumption (A2) does not prevent multiadaptivity.

We also assume that the problem (1.1) is autonomous,

$$\partial f_i / \partial t = 0, \quad i = 1, \dots, N, \tag{A3}$$

noting that the dual problem nevertheless will be nonautonomous in general. Furthermore, we assume that

$$\text{(A4)} \qquad \|f_i\|_{D^{\bar{q}+1}(\mathcal{T})} < \infty, \quad i = 1, \dots, N,$$

where $\|\cdot\|_{D^p(\mathcal{T})}$ is defined for $v : \mathbb{R}^N \to \mathbb{R}$ and $p \geq 0$ by $\|v\|_{D^p(\mathcal{T})} = \max_{n=0,\dots,p} \|D^n v\|_{L_\infty(\mathcal{T},l_\infty)}$, with the norm $\|D^n v\|_{L_\infty(\mathcal{T},l_\infty)}$ defined by $\|D^n v\, w^1 \cdots w^n\|_{L_\infty(\mathcal{T})} \leq \|D^n v\|_{L_\infty(\mathcal{T},l_\infty)} \|w^1\|_{l_\infty} \cdots \|w^n\|_{l_\infty}$ for all $w^1, \dots, w^n \in \mathbb{R}^N$, and $D^n v$ the nth-order tensor given by

$$D^n v\, w^1 \cdots w^n = \sum_{i_1=1}^{N} \cdots \sum_{i_n=1}^{N} \frac{\partial^n v}{\partial x_{i_1} \cdots \partial x_{i_n}} w^1_{i_1} \cdots w^n_{i_n}.$$

Furthermore, we choose $C_f \geq \max_{i=1,\dots,N} \|f_i\|_{D^{\bar{q}+1}(\mathcal{T})}$ such that

$$\text{(5.9)} \qquad \|d^p/dt^p (\partial f/\partial u)^\top (x(t))\|_{l_\infty} \leq C_f C_x^p$$

for $p = 0, \dots, \bar{q}$, and

$$\text{(5.10)} \qquad \left\| [d^p/dt^p (\partial f/\partial u)^\top (x(t))]_t \right\|_{l_\infty} \leq C_f \sum_{n=0}^{p} C_x^{p-n} \left\| \left[x^{(n)} \right]_t \right\|_{l_\infty}$$

for $p = 0, \dots, \bar{q} - 1$ and any given $x : \mathbb{R} \to \mathbb{R}^N$, where $C_x > 0$ denotes a constant such that $\|x^{(n)}\|_{L_\infty(\mathcal{T},l_\infty)} \leq C_x^n$ for $n = 1, \dots, p$. Note that $C_f = C_f(t)$ defines a piecewise constant function on the partition $0 = T_0 < T_1 < \cdots < T_M = T$. Note also that assumption (A4) implies that each f_i is bounded by C_f.

We further assume that there is a constant $c_k > 0$ such that

$$\text{(A5)} \qquad k_{ij} C_f \leq c_k$$

for each local interval I_{ij}. We summarize the list of assumptions as follows:

(A1) the local orders q_{ij} are equal within each time slab;
(A2) the local time steps k_{ij} are semiuniform within each time slab;
(A3) f is autonomous;
(A4) f and its derivatives are bounded;
(A5) the local time steps k_{ij} are small.

5.3.3. Estimates of derivatives and jumps. To estimate higher-order derivatives, we face the problem of taking higher-order derivatives of $f(U(t), t)$ with respect to t. In Lemmas 5.5 and 5.6, we present basic estimates for composite functions $v \circ x$ with $v : \mathbb{R}^N \to \mathbb{R}$ and $x : \mathbb{R} \to \mathbb{R}^N$. The proofs are based on a straightforward application of the chain rule and Leibniz rule and are given in full detail in [34].

LEMMA 5.5. *Let $v : \mathbb{R}^N \to \mathbb{R}$ be $p \geq 0$ times differentiable in all its variables, let $x : \mathbb{R} \to \mathbb{R}^N$ be p times differentiable, and let $C_x > 0$ be a constant such that $\|x^{(n)}\|_{L_\infty(\mathbb{R},l_\infty)} \leq C_x^n$ for $n = 1, \dots, p$. Then there is a constant $C = C(p) > 0$ such that*

$$\text{(5.11)} \qquad \left\| \frac{d^p (v \circ x)}{dt^p} \right\|_{L_\infty(\mathbb{R})} \leq C \|v\|_{D^p(\mathbb{R})} C_x^p.$$

LEMMA 5.6. *Let $v : \mathbb{R}^N \to \mathbb{R}$ be $p + 1 \geq 1$ times differentiable in all its variables, let $x : \mathbb{R} \to \mathbb{R}^N$ be p times differentiable, except possibly at some $t \in \mathbb{R}$, and let*

$C_x > 0$ be a constant such that $\|x^{(n)}\|_{L_\infty(\mathbb{R},l_\infty)} \leq C_x^n$ for $n = 1,\dots,p$. Then there is a constant $C = C(p) > 0$ such that

$$\left|\left[\frac{d^p(v\circ x)}{dt^p}\right]_t\right| \leq C\|v\|_{D^{p+1}(\mathbb{R})}\sum_{n=0}^{p} C_x^{p-n}\big\|\left[x^{(n)}\right]_t\big\|_{l_\infty}. \tag{5.12}$$

We now prove estimates for derivatives and jumps of the mcG(q) or mdG(q) solution U of the general nonlinear problem (1.1), under the assumptions listed in section 5.3.2. Similarly, one can obtain estimates for the discrete dual solution Φ and the function φ defined in (5.6), from which the desired interpolation estimates follow.

To obtain estimates for the multiadaptive solution U, we first prove estimates for the function $\tilde{U}$ defined in section 5.3.1. The estimates for U then follow by induction.

To simplify the estimates, we introduce the following notation. For given $p > 0$, let $C_{U,p} \geq C_f$ be a constant such that

$$\big\|U^{(n)}\big\|_{L_\infty(\mathcal{T},l_\infty)} \leq C_{U,p}^n, \quad n = 1,\dots,p. \tag{5.13}$$

For $p = 0$, we define $C_{U,0} = C_f$. Temporarily, we assume that there is a constant $c_k' > 0$ such that for each p,

$$k_{ij}C_{U,p} \leq c_k'. \tag{A5$'$}$$

This assumption will be removed in Lemma 5.9. In the following lemma, we use assumptions (A1), (A3), and (A4) to derive estimates for $\tilde{U}$ in terms of $C_{U,p}$ and C_f.

LEMMA 5.7 (derivative and jump estimates for $\tilde{U}$). *Let U be the* mcG(q) *or* mdG(q) *solution of* (1.1) *and define $\tilde{U}$ as in* (5.7)*. If assumptions* (A1), (A3), *and* (A4) *hold, then there is a constant $C = C(\bar{q}) > 0$ such that*

$$\big\|\tilde{U}^{(p)}\big\|_{L_\infty(\mathcal{T},l_\infty)} \leq CC_{U,p-1}^p, \quad p = 1,\dots,\bar{q}+1, \tag{5.14}$$

and

$$\big\|\left[\tilde{U}^{(p)}\right]_{t_{i,j-1}}\big\|_{l_\infty} \leq C\sum_{n=0}^{p-1} C_{U,p-1}^{p-n}\big\|\left[U^{(n)}\right]_{t_{i,j-1}}\big\|_{l_\infty}, \quad p = 1,\dots,\bar{q}+1, \tag{5.15}$$

for each local interval I_{ij}, where $t_{i,j-1}$ is an internal node of the time slab $\mathcal{T}$.

Proof. By definition, $\tilde{U}_i^{(p)} = \frac{d^{p-1}}{dt^{p-1}}f_i(U)$, and so the results follow directly by Lemmas 5.5 and 5.6, noting that $C_f \leq C_{U,p-1}$. □

By Lemma 5.7, we now obtain the following estimate for the size of the jump in function value and derivatives for U.

LEMMA 5.8 (jump estimates for U). *Let U be the* mcG(q) *or* mdG(q) *solution of* (1.1)*. If assumptions* (A1)–(A5) *and* (A5$'$) *hold, then there is a constant $C = C(\bar{q}, c_k, c_k', \alpha) > 0$ such that*

$$\big\|\left[U^{(p)}\right]_{t_{i,j-1}}\big\|_{l_\infty} \leq Ck_{ij}^{r+1-p}C_{U,r}^{r+1}, \quad p = 0,\dots,r+1, \quad r = 0,\dots,\bar{q}, \tag{5.16}$$

for each local interval I_{ij}, where $t_{i,j-1}$ is an internal node of the time slab $\mathcal{T}$.

Proof. The proof is by induction. We first note that at $t = t_{i,j-1}$, we have

$$\begin{aligned}\left[U_i^{(p)}\right]_t &= U_i^{(p)}(t^+) - \tilde{U}_i^{(p)}(t^+) + \tilde{U}_i^{(p)}(t^+) - \tilde{U}_i^{(p)}(t^-) + \tilde{U}_i^{(p)}(t^-) - U_i^{(p)}(t^-)\\ &\equiv e_+ + e_0 + e_-.\end{aligned}$$

By Lemma 5.3 (or Lemma 5.4), U is an interpolant of $\tilde{U}$ and so, by Lemma 5.1, we have

$$|e_+| \le C k_{ij}^{r+1-p} \big\| \tilde{U}_i^{(r+1)} \big\|_{L_\infty(I_{ij})} + C \sum_{x \in \mathcal{N}_{ij}} \sum_{m=1}^{r} k_{ij}^{m-p} \big| \big[\tilde{U}_i^{(m)} \big]_x \big|$$

for $p = 0, \ldots, r+1$ and $r = 0, \ldots, \bar{q}$. Note that the second sum starts at $m = 1$ rather than at $m = 0$, since $\tilde{U}$ is continuous. Similarly, we have

$$|e_-| \le C k_{i,j-1}^{r+1-p} \big\| \tilde{U}_i^{(r+1)} \big\|_{L_\infty(I_{i,j-1})} + C \sum_{x \in \mathcal{N}_{i,j-1}} \sum_{m=1}^{r} k_{i,j-1}^{m-p} \big| \big[\tilde{U}_i^{(m)} \big]_x \big|.$$

To estimate e_0, we note that $e_0 = 0$ for $p = 0$, since $\tilde{U}$ is continuous. For $p = 1, \ldots, \bar{q}+1$, Lemma 5.7 gives $|e_0| = |[\tilde{U}_i^{(p)}]_t| \le C \sum_{n=0}^{p-1} C_{U,p-1}^{p-n} \|[U^{(n)}]_t\|_{l_\infty}$. By assumption (A2), it then follows that (5.16) holds for $r = 0$.

Assume now that (5.16) holds for $r = \bar{r} - 1 \ge 0$. Then, by Lemma 5.7 and assumption (A5′), it follows that

$$\begin{aligned} |e_+| &\le C k_{ij}^{\bar{r}+1-p} C_{U,\bar{r}}^{\bar{r}+1} + C \sum_{x \in \mathcal{N}_{ij}} \sum_{m=1}^{\bar{r}} k_{ij}^{m-p} \sum_{n=0}^{m-1} C_{U,m-1}^{m-n} \big\| [U^n]_x \big\|_{l_\infty} \\ &\le C k_{ij}^{\bar{r}+1-p} C_{U,\bar{r}}^{\bar{r}+1} + C \sum k_{ij}^{m-p} C_{U,m-1}^{m-n} k_{ij}^{(\bar{r}-1)+1-n} C_{U,\bar{r}-1}^{(\bar{r}-1)+1} \\ &\le C k_{ij}^{\bar{r}+1-p} C_{U,\bar{r}}^{\bar{r}+1} \Big(1 + \sum (k_{ij} C_{U,\bar{r}-1})^{m-1-n} \Big) \le C k_{ij}^{\bar{r}+1-p} C_{U,\bar{r}}^{\bar{r}+1}. \end{aligned}$$

Similarly, we obtain the estimate $|e_-| \le C k_{ij}^{\bar{r}+1-p} C_{U,\bar{r}}^{\bar{r}+1}$. Finally, we use Lemma 5.7 and assumption (A5′) to obtain the estimate

$$\begin{aligned} |e_0| &\le C \sum_{n=0}^{p-1} C_{U,p-1}^{p-n} \big\| [U^n]_t \big\|_{l_\infty} \le C \sum_{n=0}^{p-1} C_{U,p-1}^{p-n} k_{ij}^{(\bar{r}-1)+1-n} C_{U,\bar{r}-1}^{(\bar{r}-1)+1} \\ &= C k_{ij}^{\bar{r}+1-p} C_{U,\bar{r}}^{\bar{r}+1} \sum_{n=0}^{p-1} (k_{ij} C_{U,\bar{r}})^{p-1-n} \le C k_{ij}^{\bar{r}+1-p} C_{U,\bar{r}}^{\bar{r}+1}. \end{aligned}$$

Summing up, we thus obtain $|[U_i^{(p)}]_t| \le |e_+| + |e_0| + |e_-| \le C k_{ij}^{\bar{r}+1-p} C_{U,\bar{r}}^{\bar{r}+1}$, and so (5.16) follows by induction. □

By Lemmas 5.7 and 5.8, we now obtain the following estimate for derivatives of the solution U.

Lemma 5.9 (derivative estimates for U). *Let* U *be the* mcG(q) *or* mdG(q) *solution of* (1.1). *If assumptions* (A1)–(A5) *hold, then there is a constant* $C = C(\bar{q}, c_k, \alpha) > 0$ *such that*

$$\big\| U^{(p)} \big\|_{L_\infty(\mathcal{T}, l_\infty)} \le C C_f^p, \quad p = 1, \ldots, \bar{q}. \tag{5.17}$$

Proof. By Lemma 5.3 (or Lemma 5.4), U is an interpolant of $\tilde{U}$ and so, by Lemma 5.1, we have

$$\big\| U_i^{(p)} \big\|_{L_\infty(I_{ij})} = \big\| (\pi \tilde{U}_i)^{(p)} \big\|_{L_\infty(I_{ij})} \le C' \big\| \tilde{U}_i^{(p)} \big\|_{L_\infty(I_{ij})} + C' \sum_{x \in \mathcal{N}_{ij}} \sum_{m=1}^{p-1} k_{ij}^{m-p} \big| \big[\tilde{U}_i^{(m)} \big]_x \big|$$

for some constant $C' = C'(\bar{q})$. For $p = 1$, we thus obtain the estimate

$$\|\dot{U}_i\|_{L_\infty(I_{ij})} \leq C' \|\dot{\tilde{U}}_i\|_{L_\infty(I_{ij})} = C' \|f_i(U)\|_{L_\infty(I_{ij})} \leq C' C_f$$

by assumption (A4), and so (5.17) holds for $p = 1$.

For $p = 2, \ldots, \bar{q}$, assuming that (A5$'$) holds for $C_{U,p-1}$, we use Lemmas 5.7 and 5.8 (with $r = p - 1$) and assumption (A2) to obtain

$$\begin{aligned}\big\|U_i^{(p)}\big\|_{L_\infty(I_{ij})} &\leq C C_{U,p-1}^p + C \sum_{x \in \mathcal{N}_{ij}} \sum_{m=1}^{p-1} k_{ij}^{m-p} \sum_{n=0}^{m-1} C_{U,m-1}^{m-n} \big\| \big[U^{(n)}\big]_x \big\|_{l_\infty} \\ &\leq C C_{U,p-1}^p + C \sum k_{ij}^{m-p} C_{U,m-1}^{m-n} k_{ij}^{(p-1)+1-n} C_{U,p-1}^{(p-1)+1} \\ &\leq C C_{U,p-1}^p \Big(1 + \sum (k_{ij} C_{U,m-1})^{m-n}\Big) \leq C C_{U,p-1}^p,\end{aligned}$$

where $C = C(\bar{q}, c_k, c_k', \alpha)$. This holds for all components i and all local intervals I_{ij} within the time slab $\mathcal{T}$, and so

$$\big\|U^{(p)}\big\|_{L_\infty(\mathcal{T}, l_\infty)} \leq C C_{U,p-1}^p, \quad p = 1, \ldots, \bar{q},$$

where by definition $C_{U,p-1}$ is a constant such that $\|U^{(n)}\|_{L_\infty(\mathcal{T}, l_\infty)} \leq C_{U,p-1}^n$ for $n = 1, \ldots, p-1$. Starting at $p = 1$, we now define $C_{U,1} = C_1 C_f$ with $C_1 = C' = C'(\bar{q})$. It then follows that (A5$'$) holds for $C_{U,1}$ with $c_k' = C' c_k$, and thus

$$\big\|U^{(2)}\big\|_{L_\infty(\mathcal{T}, l_\infty)} \leq C C_{U,2-1}^2 = C C_{U,1}^2 \equiv C_2 C_f^2,$$

where $C_2 = C_2(\bar{q}, c_k, \alpha)$. We may thus define $C_{U,2} = \max(C_1 C_f, \sqrt{C_2} C_f)$. Continuing, we note that (A5$'$) holds for $C_{U,2}$, and thus

$$\big\|U^{(3)}\big\|_{L_\infty(\mathcal{T}, l_\infty)} \leq C C_{U,3-1}^3 = C C_{U,2}^3 \equiv C_3 C_f^3,$$

where $C_3 = C_3(\bar{q}, c_k, \alpha)$. In this way, we obtain a sequence of constants $C_1, \ldots, C_{\bar{q}}$, depending only on $\bar{q}$, c_k, and α, such that $\|U^{(p)}\|_{L_\infty(\mathcal{T}, l_\infty)} \leq C_p C_f^p$ for $p = 1, \ldots, \bar{q}$, and so (5.17) follows if we take $C = \max_{i=1,\ldots,\bar{q}} C_i$. □

Having now removed the additional assumption (A5$'$), we obtain the following version of Lemma 5.8.

LEMMA 5.10 (jump estimates for U). *Let U be the* mcG(q) *or* mdG(q) *solution of* (1.1). *If assumptions* (A1)–(A5) *hold, then there is a constant $C = C(\bar{q}, c_k, \alpha) > 0$ such that*

$$\big\| \big[U^{(p)}\big]_{t_{i,j-1}} \big\|_{l_\infty} \leq C k_{ij}^{\bar{q}+1-p} C_f^{\bar{q}+1}, \quad p = 0, \ldots, \bar{q}, \tag{5.18}$$

for each local interval I_{ij}, where $t_{i,j-1}$ is an internal node of the time slab $\mathcal{T}$.

Similarly, we obtain estimates for the discrete dual solution Φ and the function φ. In Lemma 5.11, we present the estimates for the function φ.

LEMMA 5.11 (estimates for φ). *Let φ be defined as in* (5.6). *If assumptions* (A1)–(A5) *hold, then there is a constant $C = C(\bar{q}, c_k, \alpha) > 0$ such that*

$$\big\|\varphi_i^{(p)}\big\|_{L_\infty(I_{ij})} \leq C C_f^{p+1} \|\Phi\|_{L_\infty(\mathcal{T}, l_\infty)}, \quad p = 0, \ldots, q_{ij}, \tag{5.19}$$

and

$$\big|\big[\varphi_i^{(p)}\big]_x\big| \leq C k_{ij}^{r_{ij}-p} C_f^{r_{ij}+1} \|\Phi\|_{L_\infty(\mathcal{T}, l_\infty)} \quad \forall x \in \mathcal{N}_{ij}, \quad p = 0, \ldots, q_{ij} - 1, \tag{5.20}$$

with $r_{ij} = q_{ij}$ for the mcG(q) *method and $r_{ij} = q_{ij} + 1$ for the* mdG(q) *method. This holds for each local interval I_{ij} within the time slab $\mathcal{T}$.*

5.3.4. Interpolation estimates. Using the basic interpolation estimate of section 5.2, we now obtain the following important interpolation estimates for the function φ.

LEMMA 5.12 (interpolation estimates for φ). *Let φ be defined as in* (5.6). *If assumptions* (A1)–(A5) *hold, then there is a constant $C = C(\bar{q}, c_k, \alpha) > 0$ such that*

$$\left\|\pi_{\mathrm{cG}}^{[q_{ij}-2]}\varphi_i - \varphi_i\right\|_{L_\infty(I_{ij})} \leq Ck_{ij}^{q_{ij}-1}C_f^{q_{ij}}\|\Phi\|_{L_\infty(\mathcal{T},l_\infty)}, \quad q_{ij} = \bar{q} \geq 2, \tag{5.21}$$

and

$$\left\|\pi_{\mathrm{dG}}^{[q_{ij}-1]}\varphi_i - \varphi_i\right\|_{L_\infty(I_{ij})} \leq Ck_{ij}^{q_{ij}}C_f^{q_{ij}+1}\|\Phi\|_{L_\infty(\mathcal{T},l_\infty)}, \quad q_{ij} = \bar{q} \geq 1, \tag{5.22}$$

for each local interval I_{ij} within the time slab $\mathcal{T}$.

Proof. To prove (5.21), we use Lemma 5.1, with $r = q_{ij} - 2$ and $p = 0$, together with Lemma 5.11, to obtain

$$\begin{aligned}\left\|\pi_{\mathrm{cG}}^{[q_{ij}-2]}\varphi_i - \varphi_i\right\|_{L_\infty(I_{ij})} &\leq Ck_{ij}^{q_{ij}-1}\left\|\varphi_i^{(q_{ij}-1)}\right\|_{L_\infty(I_{ij})} + C\sum_{x\in\mathcal{N}_{ij}}\sum_{m=0}^{q_{ij}-2}k_{ij}^m\left|\left[\varphi_i^{(m)}\right]_x\right| \\ &\leq Ck_{ij}^{q_{ij}-1}C_f^{q_{ij}}\|\Phi\|_{L_\infty(\mathcal{T},l_\infty)} + C\sum_{x\in\mathcal{N}_{ij}}\sum_{m=0}^{q_{ij}-2}k_{ij}^m k_{ij}^{q_{ij}-m}C_f^{q_{ij}+1}\|\Phi\|_{L_\infty(\mathcal{T},l_\infty)} \\ &= Ck_{ij}^{q_{ij}-1}C_f^{q_{ij}}\|\Phi\|_{L_\infty(\mathcal{T},l_\infty)} + Ck_{ij}^{q_{ij}}C_f^{q_{ij}+1}\|\Phi\|_{L_\infty(\mathcal{T},l_\infty)},\end{aligned}$$

from which the estimate follows. The estimate for $\pi_{\mathrm{dG}}^{[q_{ij}-1]}\varphi_i - \varphi_i$ is obtained similarly. ▯

REMARK 5.1. *Note that there is only a weak dependence on c_k and α, since the jump term contains an extra factor k_{ij}. If higher-order terms can be ignored, then the dependence on c_k and α can be removed.*

6. A priori error estimates.

To prove a priori error estimates for the mcG(q) and mdG(q) methods, we derive error representations in section 6.1 and then obtain the a priori error estimates in section 6.2 for the general nonlinear case. We refer to [34] for a sharp a priori error estimate in the case of a parabolic model problem.

6.1. Error representation.

For each of the two methods, mcG(q) and mdG(q), we represent the error in terms of the discrete dual solution Φ and an interpolant πu of the exact solution u of (1.1), using the special interpolants $\pi u = \pi_{\mathrm{cG}}^{[q]}u$ or $\pi u = \pi_{\mathrm{dG}}^{[q]}u$ defined in section 5.

We write the error $e = U - u$ in the form

$$e = \bar{e} + (\pi u - u), \tag{6.1}$$

where $\bar{e} \equiv U - \pi u$ is represented in terms of the discrete dual solution and the residual of the interpolant. An estimate for the second part of the error, $\pi u - u$, follows directly from an interpolation estimate.

In Lemma 6.1, we present the error representation for the mcG(q) method, and then present the corresponding representation for the mdG(q) method in Lemma 6.2. The error representations are obtained directly by choosing $\bar{e}$ as a test function for the discrete dual problems (2.12) and (2.15).

LEMMA 6.1 (error representation for mcG(q)). *Let U be the* mcG(q) *solution of* (1.1)*, let Φ be the corresponding* mcG(q)* *solution of the dual problem* (2.9)*, and let*

πu be any trial space approximation of the exact solution u of (1.1) *that interpolates u at the end-points of every local interval. Then*

$$L_{\psi,g}(\bar{e}) \equiv (\bar{e}(T), \psi) + \int_0^T (\bar{e}, g)\, dt = -\int_0^T (R(\pi u, \cdot), \Phi)\, dt,$$

where $\bar{e} \equiv U - \pi u$.

LEMMA 6.2 (error representation for mdG(q)). *Let U be the* mdG(q) *solution of* (1.1)*, let Φ be the corresponding* mdG(q)* *solution of the dual problem* (2.9)*, and let πu be any trial space approximation of the exact solution u of* (1.1) *that interpolates u at the right end-point of every local interval. Then*

$$L_{\psi,g}(\bar{e}) = -\sum_{i=1}^{N}\sum_{j=1}^{M_i}\left[[\pi u_i]_{i,j-1}\Phi_i\big(t_{i,j-1}^{+}\big) + \int_{I_{ij}} R_i(\pi u, \cdot)\Phi_i\, dt\right],$$

where $\bar{e} \equiv U - \pi u$.

With a special choice of interpolant, $\pi u = \pi_{\mathrm{cG}}^{[q]} u$ and $\pi u = \pi_{\mathrm{dG}}^{[q]} u$, respectively, we obtain the following versions of the error representations.

COROLLARY 6.3 (error representation for mcG(q)). *Let U be the* mcG(q) *solution of* (1.1) *and let Φ be the corresponding* mcG(q)* *solution of the dual problem* (2.9). *Then*

$$L_{\psi,g}(\bar{e}) = \int_0^T \big(f\big(\pi_{\mathrm{cG}}^{[q]} u, \cdot\big) - f(u, \cdot), \Phi\big)\, dt.$$

Proof. Integrate by parts and use the definition of the interpolant $\pi_{\mathrm{cG}}^{[q]}$. □

COROLLARY 6.4 (error representation for mdG(q)). *Let U be the* mdG(q) *solution of* (1.1) *and let Φ be the corresponding* mdG(q)* *solution of the dual problem* (2.9). *Then*

$$L_{\psi,g}(\bar{e}) = \int_0^T \big(f\big(\pi_{\mathrm{dG}}^{[q]} u, \cdot\big) - f(u, \cdot), \Phi\big)\, dt.$$

Proof. Integrate by parts and use the definition of the interpolant $\pi_{\mathrm{dG}}^{[q]}$. □

6.2. A priori error estimates for the general nonlinear problem. Using the error representations of section 6.1, the stability estimates of section 4, and the interpolation estimates of section 5, we now prove our main results: a priori error estimates for general order mcG(q) and mdG(q).

THEOREM 6.5 (a priori error estimate for mcG(q)). *Let U be the* mcG(q) *solution of* (1.1) *and let Φ be the corresponding* mcG(q)* *solution of the dual problem* (2.9). *Then there is a constant $C = C(q) > 0$ such that*

$$|L_{\psi,g}(\bar{e})| \leq CS(T)\big\|k^{q+1}\bar{u}^{(q+1)}\big\|_{L_\infty([0,T],l_2)}, \tag{6.2}$$

where $(k^{q+1}\bar{u}^{(q+1)})_i(t) = k_{ij}^{q_{ij}+1}\|u_i^{(q_{ij}+1)}\|_{L_\infty(I_{ij})}$ for $t \in I_{ij}$, and where the stability factor $S(T)$ is given by $S(T) = \int_0^T \|J^\top(\pi_{\mathrm{cG}}^{[q]} u, u, \cdot)\Phi\|_{l_2}\, dt$. Furthermore, if assumptions (A1)–(A5) *hold, then there is a constant $C = C(q, c_k, \alpha) > 0$ such that*

$$|L_{\psi,g}(\bar{e})| \leq C\bar{S}(T)\big\|k^{2q}\bar{\bar{u}}^{(2q)}\big\|_{L_\infty([0,T],l_1)}, \tag{6.3}$$

where $(k^{2q}\bar{\bar{u}}^{(2q)})_i(t) = k_{ij}^{2q_{ij}} C_f^{q_{ij}-1} \|u_i^{(q_{ij}+1)}\|_{L_\infty(I_{ij})}$ *for* $t \in I_{ij}$, *and where the stability factor* $\bar{S}(T)$ *is given by*

$$\bar{S}(T) = \int_0^T C_f \|\Phi\|_{L_\infty(\mathcal{T},l_\infty)}\, dt = \sum_{n=1}^M K_n C_f \|\Phi\|_{L_\infty(\mathcal{T}_n,l_\infty)}.$$

Proof. By Corollary 6.3, we obtain

$$L_{\psi,g}(\bar{e}) = \int_0^T \big(f(\pi_{\mathrm{cG}}^{[q]}u,\cdot) - f(u,\cdot),\Phi\big)\, dt = \int_0^T \big(\pi_{\mathrm{cG}}^{[q]}u - u, J^\top\big(\pi_{\mathrm{cG}}^{[q]}u,u,\cdot\big)\Phi\big)\, dt.$$

By Lemma 5.1, it now follows that

$$|L_{\psi,g}(\bar{e})| \leq C\|k^{q+1}\bar{u}^{q+1}\|_{L_\infty([0,T],l_2)} \int_0^T \big\|J^\top\big(\pi_{\mathrm{cG}}^{[q]}u,u,\cdot\big)\Phi\big\|_{l_2}\, dt,$$

which proves (6.2). To prove (6.3), we note that by definition, $\pi_{\mathrm{cG}}^{[q_{ij}]}u_i - u_i$ is orthogonal to $\mathcal{P}^{q_{ij}-2}(I_{ij})$ for each local interval I_{ij}, and so, recalling that $\varphi = J^\top(\pi_{\mathrm{cG}}^{[q]}u,u,\cdot)\Phi$,

$$L_{\psi,g}(\bar{e}) = \sum_{i,j}\int_{I_{ij}} \big(\pi_{\mathrm{cG}}^{[q_{ij}]}u_i - u_i\big)\varphi_i\, dt = \sum_{i,j}\int_{I_{ij}} \big(\pi_{\mathrm{cG}}^{[q_{ij}]}u_i - u_i\big)\big(\varphi_i - \pi_{\mathrm{cG}}^{[q_{ij}-2]}\varphi_i\big)\, dt,$$

where we take $\pi_{\mathrm{cG}}^{[q_{ij}-2]}\varphi_i \equiv 0$ for $q_{ij} = 1$. By Lemmas 5.1 and 5.12, it now follows that

$$\begin{aligned}
|L_{\psi,g}(\bar{e})| &\leq \int_0^T \big|\big(\pi_{\mathrm{cG}}^{[q]}u - u, \varphi - \pi_{\mathrm{cG}}^{[q-2]}\varphi\big)\big|\, dt \\
&= \int_0^T \big|\big(k^{q-1}C_f^{q-1}\big(\pi_{\mathrm{cG}}^{[q]}u - u\big), k^{-(q-1)}C_f^{-(q-1)}\big(\varphi - \pi_{\mathrm{cG}}^{[q-2]}\varphi\big)\big)\big|\, dt \\
&\leq C\big\|k^{2q}\bar{\bar{u}}^{(2q)}\big\|_{L_\infty([0,T],l_1)} \int_0^T C_f\|\Phi\|_{L_\infty(\mathcal{T},l_\infty)}\, dt \\
&= C\bar{S}(T)\big\|k^{2q}\bar{\bar{u}}^{(2q)}\big\|_{L_\infty([0,T],l_1)},
\end{aligned}$$

where $\bar{S}(T) = \int_0^T C_f\|\Phi\|_{L_\infty(\mathcal{T},l_\infty)}\, dt = \sum_{n=1}^M K_n C_f \|\Phi\|_{L_\infty(\mathcal{T}_n,l_\infty)}$. □

Similarly, we obtain the following a priori error estimate for the mdG(q) method.

THEOREM 6.6 (a priori error estimate for mdG(q)). *Let* U *be the* mdG(q) *solution of* (1.1) *and let* Φ *be the corresponding* mdG(q)* *solution of the dual problem* (2.9). *Then there is a constant* $C = C(q) > 0$ *such that*

$$|L_{\psi,g}(\bar{e})| \leq CS(T)\big\|k^{q+1}\bar{u}^{(q+1)}\big\|_{L_\infty([0,T],l_2)}, \tag{6.4}$$

where $(k^{q+1}\bar{u}^{(q+1)})_i(t) = k_{ij}^{q_{ij}+1}\|u_i^{(q_{ij}+1)}\|_{L_\infty(I_{ij})}$ *for* $t \in I_{ij}$, *and where the stability factor* $S(T)$ *is given by* $S(T) = \int_0^T \|J^\top(\pi_{\mathrm{dG}}^{[q]}u,u,\cdot)\Phi\|_{l_2}\, dt$. *Furthermore, if assumptions* (A1)–(A5) *hold, then there is a constant* $C = C(q, c_k, \alpha) > 0$ *such that*

$$|L_{\psi,g}(\bar{e})| \leq C\bar{S}(T)\big\|k^{2q+1}\bar{\bar{u}}^{(2q+1)}\big\|_{L_\infty([0,T],l_1)}, \tag{6.5}$$

where $(k^{2q+1}\bar{\bar{u}}^{(2q+1)})_i(t) = k_{ij}^{2q_{ij}+1}C_f^{q_{ij}}\|u_i^{(q_{ij}+1)}\|_{L_\infty(I_{ij})}$ *for* $t \in I_{ij}$, *and where the stability factor* $\bar{S}(T)$ *is given by*

$$\bar{S}(T) = \int_0^T C_f \|\Phi\|_{L_\infty(\mathcal{T},l_\infty)}\, dt = \sum_{n=1}^M K_n C_f \|\Phi\|_{L_\infty(\mathcal{T}_n,l_\infty)}.$$

Using the stability estimate proved in section 4, we obtain the following bound for the stability factor $\bar{S}(T)$.

LEMMA 6.7. *Assume that $K_n C_q C_f \leq 1$ for all time slabs $\mathcal{T}_n$, with $C_q > 0$ the constant in Theorem* 4.2*, and take $g = 0$ in* (2.9)*. Then*

$$\bar{S}(T) \leq \|\psi\|_{l_\infty} e^{C_q \bar{C}_f T}, \tag{6.6}$$

where $\bar{C}_f = \max_{[0,T]} C_f$.

Proof. By Theorem 4.2, we obtain

$$\|\Phi\|_{L_\infty(\mathcal{T}_n, l_\infty)} \leq C_q \|\psi\|_{l_\infty} \exp\left(\sum_{m=n+1}^{M} K_m C_q C_f \right) \leq C_q \|\psi\|_{l_\infty} e^{C_q \bar{C}_f (T - T_n)},$$

and so

$$\begin{aligned} \bar{S}(T) = \sum_{n=1}^{M} K_n C_f \|\Phi\|_{L_\infty(\mathcal{T}_n, l_\infty)}\, dt &\leq \|\psi\|_{l_\infty} \sum_{n=1}^{M} K_n C_q \bar{C}_f e^{C_q \bar{C}_f (T - T_n)} \\ &\leq \|\psi\|_{l_\infty} \int_0^T C_q \bar{C}_f e^{C_q \bar{C}_f t}\, dt \leq \|\psi\|_{l_\infty} e^{C_q \bar{C}_f T}. \qquad \square \end{aligned}$$

Finally, we rewrite the estimates of Theorems 6.5 and 6.6 for special choices of data ψ and g. We first take $\psi = 0$. With $g_n = 0$ for $n \neq i$, $g_i(t) = 0$ for $t \notin I_{ij}$, and

$$g_i(t) = \operatorname{sgn}(\bar{e}_i(t))/k_{ij}, \quad t \in I_{ij},$$

we obtain $L_{\psi,g}(\bar{e}) = \frac{1}{k_{ij}} \int_{I_{ij}} |\bar{e}_i(t)|\, dt$ and so $\|\bar{e}_i\|_{L_\infty(I_{ij})} \leq C L_{\psi,g}(\bar{e})$ by an inverse estimate. By definition, it follows that $\|e_i\|_{L_\infty(I_{ij})} \leq C L_{\psi,g}(\bar{e}) + C k_{ij}^{q_{ij}+1} \|u_i^{q_{ij}+1}\|_{L_\infty(I_{ij})}$. Note that for this choice of g, we have $\|g\|_{L_1([0,T], l_2)} = \|g\|_{L_1([0,T], l_\infty)} = 1$.

We also make the choice $g = 0$. Noting that $\bar{e}(T) = e(T)$, since $\pi u(T) = u(T)$, we obtain

$$L_{\psi,g}(\bar{e}) = (e(T), \psi) = |e_i(T)|$$

for $\psi_i = \operatorname{sgn}(e_i(T))$ and $\psi_n = 0$ for $n \neq i$, and

$$L_{\psi,g}(\bar{e}) = (e(T), \psi) = \|e(T)\|_{l_2}$$

for $\psi = e(T)/\|e(T)\|_{l_2}$. Note that for both choices of ψ, we have $\|\psi\|_{l_\infty} \leq 1$.

With these choices of data, we obtain the following versions of the a priori error estimates.

COROLLARY 6.8 (a priori error estimate for mcG(q)). *Let U be the* mcG(q) *solution of* (1.1)*. Then there is a constant $C = C(q) > 0$ such that*

$$\|e\|_{L_\infty([0,T], l_\infty)} \leq C S(T) \left\| k^{q+1} \bar{u}^{(q+1)} \right\|_{L_\infty([0,T], l_2)}, \tag{6.7}$$

where the stability factor $S(T) = \int_0^T \|J^\top(\pi_{\mathrm{cG}}^{[q]} u, u, \cdot)\Phi\|_{l_2}\, dt$ is taken as the maximum over $\psi = 0$ and $\|g\|_{L_1([0,T], l_\infty)} = 1$. Furthermore, if assumptions (A1)–(A5) *and the assumptions of Lemma* 6.7 *hold, then there is a constant $C = C(q, c_k, \alpha)$ such that*

$$\|e(T)\|_{l_p} \leq C \bar{S}(T) \left\| k^{2q} \bar{u}^{(2q)} \right\|_{L_\infty([0,T], l_1)} \tag{6.8}$$

for $p = 2, \infty$, where the stability factor $\bar{S}(T)$ is given by $\bar{S}(T) = e^{C_q \bar{C}_f T}$.

Corollary 6.9 (a priori error estimate for mdG(q)). *Let U be the* mdG(q) *solution of* (1.1). *Then there is a constant $C = C(q) > 0$ such that*

$$\|e\|_{L_\infty([0,T],l_\infty)} \leq CS(T) \big\| k^{q+1} \bar{u}^{(q+1)} \big\|_{L_\infty([0,T],l_2)}, \tag{6.9}$$

where the stability factor $S(T) = \int_0^T \|J^\top(\pi_{\mathrm{dG}}^{[q]} u, u, \cdot)\Phi\|_{l_2}\, dt$ is taken as the maximum over $\psi = 0$ and $\|g\|_{L_1([0,T],l_\infty)} = 1$. Furthermore, if assumptions (A1)–(A5) *and the assumptions of Lemma* 6.7 *hold, then there is a constant $C = C(q, c_k, \alpha)$ such that*

$$\|e(T)\|_{l_p} \leq C\bar{S}(T) \big\| k^{2q+1} \bar{\bar{u}}^{(2q+1)} \big\|_{L_\infty([0,T],l_1)} \tag{6.10}$$

for $p = 2, \infty$, where the stability factor $\bar{S}(T)$ is given by $\bar{S}(T) = e^{C_q \bar{C}_f T}$.

The stability factor $S(T)$ that appears in the a priori error estimates is obtained from the discrete solution Φ of the dual problem (4.1), and can thus be computed by solving the discrete dual problem. Numerical computation of the stability factor reveals the exact nature of the problem, in particular, whether or not the problem is parabolic; if the stability factor is of unit size and does not grow, then the problem is parabolic by definition; see [36].

6.3. A note on quadrature errors.

The error representations presented in section 6.1 are based on the Galerkin orthogonalities of the mcG(q) and mdG(q) methods. In particular, for the mcG(q) method, we assume that

$$\int_0^T (R(U, \cdot), \Phi)\, dt = 0.$$

In the presence of quadrature errors, this term is nonzero. As a result, we obtain an additional term of the form

$$\int_0^T (\tilde{f}(U, \cdot) - f(U, \cdot), \Phi)\, dt,$$

where $\tilde{f}$ is the interpolant of f corresponding the quadrature rule that is used. A convenient choice of quadrature for the mcG(q) method is Lobatto quadrature with $q+1$ nodal points [32], which means that the quadrature error is of order $2(q+1)-2 = 2q$ and so (super)convergence of order $2q$ is obtained also in the presence of quadrature errors. Similarly for the mdG(q) method, we use Radau quadrature with $q+1$ nodal points, which means that the quadrature error is of order $2(q+1) - 1 = 2q+1$, and so the $2q+1$ convergence order of mdG(q) is also maintained under quadrature.

7. A numerical example.

We conclude by demonstrating the convergence of the multiadaptive methods in the case of a simple test problem.

Consider the problem

$$\begin{aligned} \dot{u}_1 &= u_2, \\ \dot{u}_2 &= -u_1, \\ \dot{u}_3 &= -u_2 + 2u_4, \\ \dot{u}_4 &= u_1 - 2u_3, \\ \dot{u}_5 &= -u_2 - 2u_4 + 4u_6, \\ \dot{u}_6 &= u_1 + 2u_3 - 4u_5 \end{aligned} \tag{7.1}$$

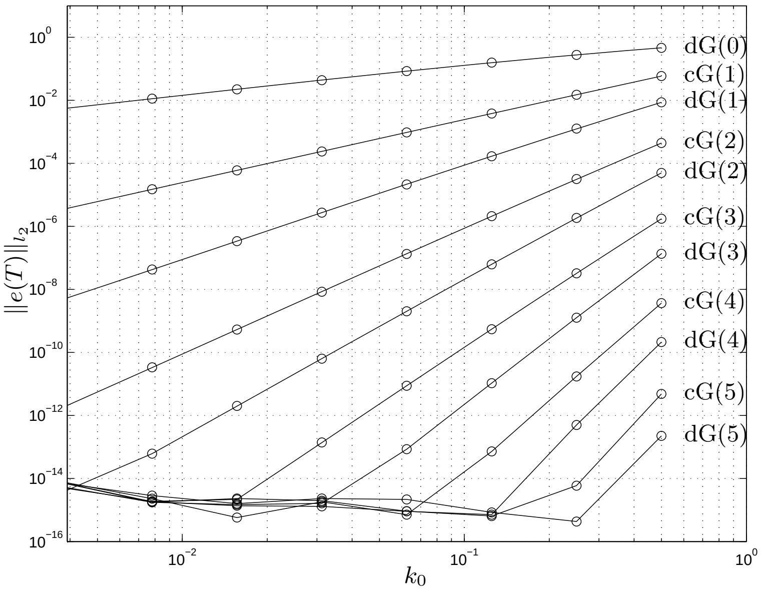

FIG. 6. *Convergence of the error at final time for the solution of the test problem* (7.1) *with* mcG(q) *and* mdG(q), $q \leq 5$.

TABLE 1
Order of convergence p for mcG(q).

mcG(q)	1	2	3	4	5
p	1.99	3.96	5.92	7.82	9.67
$2q$	2	4	6	8	10

TABLE 2
Order of convergence p for mdG(q).

mdG(q)	0	1	2	3	4	5
p	0.92	2.96	4.94	6.87	9.10	–
$2q+1$	1	3	5	7	9	11

on $[0,1]$ with initial condition $u(0) = (0,1,0,2,0,3)$. The solution is given by $u(t) = (\sin t, \cos t, \sin t + \sin 2t, \cos t + \cos 2t, \sin t + \sin 2t + \sin 4t, \cos t + \cos 2t + \cos 4t)$. For given $k_0 > 0$, we take $k_i(t) = k_0$ for $i = 1,2$, $k_i(t) = k_0/2$ for $i = 3,4$, and $k_i(t) = k_0/4$ for $i = 5,6$, and study the convergence of the error $\|e(T)\|_{l_2}$ with decreasing k_0. From the results presented in Figure 6 and Tables 1 and 2, it is clear that the predicted order of convergence is obtained.

NEW A PRIORI FEM ERROR ESTIMATES FOR EIGENVALUES[*]

ANDREW V. KNYAZEV[†] AND JOHN E. OSBORN[‡]

Abstract. We analyze the Ritz–Galerkin method for symmetric eigenvalue problems and prove a priori eigenvalue error estimates. For a simple eigenvalue, we prove an error estimate that depends mainly on the approximability of the corresponding eigenfunction and provide explicit values for all constants. For a multiple eigenvalue we prove, in addition, what is apparently the first truly a priori error estimates that show the levels of the eigenvalue errors depending on approximability of eigenfunctions in the corresponding eigenspace. These estimates reflect a known phenomenon that different eigenfunctions in the corresponding eigenspace may have different approximabilities, thus resulting in different levels of errors for the approximate eigenvalues. For clustered eigenvalues, we derive eigenvalue error bounds that do not depend on the width of the cluster. Our results are readily applicable to the classical Ritz method for compact symmetric integral operators and to finite element method eigenvalue approximation for symmetric positive definite differential operators.

1. Introduction.

We revisit the classical subject of a priori eigenvalue error estimates for the Ritz–Galerkin approximation of symmetric eigenvalue problems, with application to finite element method (FEM) eigenvalue approximation. A priori estimates have traditionally been used to prove the convergence of FEM eigenvalue approximation and to determine the convergence rate when the mesh is refined. These estimates are typically based on the approximability of the eigenfunctions by the FEM subspace and can be used to explain certain interesting features of eigenvalue approximation. For example, see [1, 2, 3, 4] for explanations of why the third vibration mode of an L-shaped membrane is easier to approximate than the first two, and why two Ritz values approximating a double eigenvalue may converge at different rates.

The main result of the present paper—briefly stated—is that the eigenvalue errors depend mainly on just the approximability of the corresponding invariant subspaces, whether the eigenvalues are well separated, multiple, or clustered. Our results differ from those in [2, 3, 4] in particular in that the information required by the new estimates is minimal and is covered by *explicitly given constants* that can be relatively easily obtained a posteriori from approximate eigenvalues and eigenfunctions. The question of whether our theorems give completely *computable eigenvalue bounds* thus is reduced to explicitly estimating the main factor, namely the approximability of invariant subspaces.

[*] Received by the editors August 6, 2004; accepted for publication (in revised form) July 25, 2005; published electronically January 27, 2006. Preliminary results of this paper were presented at the meeting "State of the Art in the Finite Element Method" at the City University of Hong Kong in 1998. An extended version of the paper was published as a technical report by the Center for Computational Mathematics of the University of Colorado at Denver [15].

Computing the approximability is, however, difficult except in fairly trivial situations. One traditional approach is to use approximation theory results based on the smoothness of the eigenfunctions. Many results of this type are known, but usually the constants in the estimates are generic and not easily computable in practice. Assessing the smoothness of the eigenfunctions, meaning obtaining an estimate for an appropriate higher Sobolev norm of the eigenfunction in question, can be done using an appropriate regularity theory for the underlying partial differential equation. Much is known about the regularity of the eigenfunctions, but, again, the constants are typically generic and cannot be easily estimated, with rather trivial exceptions. Nevertheless, a priori eigenvalue error analysis is a classical approach that has proved to be useful.

Early examples of a priori eigenvalue error estimates can be found, e.g., in [17]. Later, it became clear that the eigenvalue error was governed by the approximability of the exact eigenfunctions by the approximation space. In [5], Birkhoff et al. showed that the error for the jth eigenvalue was bounded by a constant times the sum of the norms squared of the approximation errors of the all eigenfunctions corresponding to the first j eigenvalues. In [22], Weinberger improved this result, showing that in the estimate for the relative eigenvalue error the constant simply equals one; see Remark 2.1 for the exact formulation. Knyazev in [11] (see also [8]) further improved this result by replacing the norms of the approximation errors of individual eigenfunctions with the angle that measures the approximability of the invariant subspace spanned by these eigenfunctions. We reproduce this latter result by Knyazev in the present paper, in Theorem 2.4, and show that it is sharp.

The estimates of [5, 22, 11] suggest that the jth eigenvalue error depends on the approximability of all the eigenfunctions in the corresponding eigenspace, as well as of all the eigenfunctions corresponding to the previous eigenvalues. In reality, this is not the case. Numerical experiments for the L-shaped membrane eigenvalue problem show that the accuracy of approximation for the third eigenvalue is significantly better than for the first two. This can be explained as follows. We first note that the first two eigenfunctions of the L-shaped membrane eigenvalue problem are singular because of the re-entrant corner, but the third eigenfunction is analytic because of symmetry, and hence easily approximated, especially by the p-method (see [1]). Second, Vainikko in Krasnosel'skii et al. [16] and Chatelin [7] derive estimates of the eigenvalue error mainly in terms of just the approximability of the eigenfunctions in the corresponding eigenspace. Coupling this approximability result with this eigenvalue error estimate, we obtain the accurate eigenvalue approximation for the third eigenvalue.

Moreover, Vainikko in Krasnosel'skii et al. [16] and Chatelin [7] show that the multiplicative constant in the estimate of the relative eigenvalue error approaches 1 under the approximability assumption on the family of the approximating spaces; see section 3.2 for details. In [3], Babuška and Osborn determine that the closeness of the constant to 1 depends on the approximability of the operator of the original problem by the Ritz method; again, see section 3.2.

Our first main results—Theorems 2.7 and 3.2—clarify the estimate of [3] and improve the constant. All our constants are explicitly given, and no asymptotic assumptions are made. In the FEM context, our results are readily applicable for a fixed mesh without making the traditional assumption, cf. Strang and Fix [2], that the mesh size is small enough.

When the eigenvalue of interest is of multiplicity $q > 1$, different eigenfunctions in the corresponding eigenspace may have different approximabilities, thus resulting in different levels of error for the approximate eigenvalues; i.e., the q Ritz values, corresponding to the multiple eigenvalue, may approach the eigenvalue with different rates. It is important to have eigenvalue error estimates that capture this phenomenon.

The error bounds of Krasnosel'skii et al. [16] and Chatelin [7] effectively require approximability of all eigenfunctions in the corresponding eigenspace that provides an estimate for the largest eigenvalue error only. In [2, 3, 4], Babuška and Osborn perform analysis that differentiates levels of eigenvalue error depending on approximability of different eigenfunctions in the eigenspace, but their estimates are not truly a priori, except for the estimate for the smallest eigenvalue error, which depends mainly on the approximability of the most easily approximated eigenfunction within the eigenspace.

Our results for multiple eigenvalues—Theorems 2.11 and 3.3—clarify and improve these results of [2, 3, 4]. For example, if the eigenspace is spanned by three eigenfunctions of different approximation qualities, our results estimate the corresponding quality of each of the three Ritz values.

Error estimates for clustered eigenvalues are not well examined in the literature. The results presented in this paper are valid for clustered eigenvalues, as well as for multiple eigenvalues, and give error estimates that do not depend on the width of the cluster. Ovtchinnikov in [19], independently derives similar estimates, which he calls "cluster robust." Our estimates, compared to those of [19], are more compact and use less information.

In our proofs, we heavily use approximation error estimates for eigenspaces and invariant subspaces obtained by Knyazev in [13].

The paper intentionally contains some material that may be considered redundant, in order to improve readability. A critic once wrote about Beethoven's Symphony No. 2 in D major, op. 36 that it "would surely benefit from the abbreviation of some passages and the deletion of others." If we are allowed to use musical terms in our defense and to compare our paper to a symphony, it consists of four movements:

The first, fast, movement is subsections 2.1–2.5. Subsection 2.1 sets the stage for an abstract setting of a compact symmetric operator on a Hilbert space. We briefly introduce the angles instruments in the developmental subsection 2.2 and then, in subsection 2.3, the main theme, a priori estimates for eigenvalues. Subsection 2.4 is the most important in the first movement—it brings us the main theme in its most "ideal" form in Theorem 2.7, without a proof. Theorem 2.7 is an error estimate for a jth eigenvalue mainly in terms of the approximation error of the corresponding eigenfunctions. In subsection 2.5, the theme appears with slight variations for multiple and clustered eigenvalues. It becomes apparent that a major development is needed.

The second, slow, movement is the massive subsection 2.6. The main theme is significantly extended and generalized, with a complete vigorous proof, to carry a considerable improvement, in Theorem 2.11, for multiple and clustered eigenvalues. A number of possible variations surface at the end of the second movement.

The third, dance-like, movement is subsection 3.1, which is a brief reminiscence of the first two movements. The same theme is essentially repeated, but in a different key, for the variational Galerkin method in a context applicable to FEM eigenvalue approximation for second order symmetric positive definite differential operators. Our last main results—Theorem 3.2 and Theorem 3.3—appear in this subsection.

The fast finale, subsection 3.2, takes the material of the previous movement and contrasts it from earlier work. It opens in a relaxed manner and cites several well-known results. In closing, it reaches a climax by showing how to obtain differential levels of eigenvalue error depending on approximability of different eigenfunctions in the eigenspace.

It would, of course, be appealing to have practical numerical examples of our a priori analysis providing computable eigenvalue bounds, e.g., for the Laplacian in a polygonal domain. It is known that the eigenfunctions of the Laplacian are smooth (analytic, in fact) inside the domain, but are generally singular in the corners. In certain cases, however, the eigenfunction is smooth, e.g., the already discussed third eigenfunction of the Laplacian in the L-shaped domain is smooth. It is very interesting to try to use this kind of information to compute eigenvalue bounds. But due to the difficulties of computing the approximability of invariant subspaces, discussed in the first paragraphs of the introduction, such a project lies beyond the scope of this paper. For some computational examples we refer to [3, 4].

2. Estimates for a compact symmetric operator.

2.1. An abstract eigenvalue problem. We consider in this section a compact symmetric positive definite operator T defined on a real separable Hilbert space H, with inner product (u,v) and norm $\|u\| = \sqrt{(u,u)}$. The spectral theory of such operators is well known; see, e.g., [9]. The spectrum consists of nonzero eigenvalues of finite multiplicity, together with 0, which is in the continuous spectrum. The eigenvectors can be chosen to be orthonormal. We denote the eigenvalues and corresponding eigenvectors of T by $\mu_1 \geq \mu_2 \geq \cdots > 0$ and $u_1, u_2, \ldots,$ where $(u_i, u_j) = \delta_{ij}$. We are interested in approximating the eigenpairs (μ_i, u_i) of T by the Ritz method. Given a finite-dimensional subspace $\tilde{U}$ of H, referred to as the trial subspace, the Ritz approximation to T is the operator $\tilde{T} = (\tilde{Q}T)|_{\tilde{U}}$, where $\tilde{Q}$ is the orthogonal projector onto $\tilde{U}$. The operator $\tilde{T}$ is symmetric positive definite. The eigenpairs of $\tilde{T}$ are called the Ritz pairs of T; we regard them as approximations of the eigenpairs of T. We denote the eigenvalues and corresponding eigenvectors of $\tilde{T}$ by $\tilde{\mu}_1 \geq \tilde{\mu}_2 \geq \cdots \geq \tilde{\mu}_n > 0$, where $n = \dim \tilde{U}$, and $\tilde{u}_1, \tilde{u}_2, \ldots, \tilde{u}_n$, where $(\tilde{u}_i, \tilde{u}_j) = \delta_{ij}$. The numbers $\tilde{\mu}_i$ are called the Ritz values and the vectors $\tilde{u}_i$ are called the Ritz vectors. In this paper we are specifically concerned with approximating the eigenvalues of T by Ritz values as $\mu_i \approx \tilde{\mu}_i$. It is an immediate consequence of the max-min characterization of eigenvalues that $\tilde{\mu}_i \leq \mu_i, i = 1, \ldots, n$.

We make the assumptions that operator T is positive definite and compact just to simplify the arguments. The majority of our results in this section can be easily modified to hold without these assumptions. The most important modification is a replacement of the ratios such as $(\mu_j - \tilde{\mu}_j)/\mu_j$ that appear in the left-hand sides of most of our estimates below with $(\mu_j - \tilde{\mu}_j)/(\mu_j - \mu_{inf})$, where μ_{inf} is the algebraically smallest point of the spectrum of T (when T is positive definite, evidently $\mu_{inf} = 0$). Such a modification makes our estimates invariant with respect to a scalar shift $T - \alpha I$ in T for any real scalar α.

2.2. Principal angles between subspaces. If M and N are nontrivial finite-dimensional subspaces of H, we will quantify the approximability of M by N using the sine of the largest principal angle from M to N, which is defined by

$$\sin \angle\{M; N\} = \sup_{u \in M, \|u\|=1} \text{dist}\,(u, N) = \sup_{u \in M, \|u\|=1} \inf_{v \in N} \|u - v\|. \tag{2.1}$$

For nonzero vectors u and v, if $M = \text{span}\{u\}$, we write $\sin \angle\{u; N\}$ for $\sin \angle\{M; N\}$; and if $M = \text{span}\{u\}$ and $N = \text{span}\{v\}$, we write $\sin \angle\{u; v\}$ for $\sin \angle\{M; N\}$.

It is immediate that $0 \leq \sin \angle\{M; N\} \leq 1$ and that $\sin \angle\{M; N\} = 0$ if and only if $M \subseteq N$. If $\dim M > \dim N$, then $\sin \angle\{M; N\} = 1$. If $\dim M = \dim N < \infty$, then $\sin \angle\{M; N\} = \sin \angle\{N; M\}$. In the remainder of this paper, we will typically have $\dim M \leq \dim N$.

We will need the following simple observations; cf. Lemma 3.4 of [6].

LEMMA 2.1. *Let the subspace M be split into an orthogonal sum of subspaces $M = M_1 \oplus M_2$. Then (see* [15]*),*

$$\sin^2 \angle\{M; N\} \leq \sin^2 \angle\{M_1; N\} + \sin^2 \angle\{M_2; N\}. \tag{2.2}$$

Applying (2.2) recursively, we immediately obtain the following.

COROLLARY 2.2. *Let vectors $\{u_i, i = 1, \ldots, \dim M\}$ form an orthogonal basis for the subspace M. Then*

$$\sin^2 \angle\{M; N\} \leq \sum_i \sin^2 \angle\{u_i; N\}. \tag{2.3}$$

We call angle $\angle\{M; N\}$ the largest since it is also well known (see, e.g., [14]), so that smaller angles between subspaces can be defined as follows. Using P and Q, the orthogonal projectors onto M and N, respectively, the sine of the largest angle equals the largest singular value of the operator $(I - Q)P$. Introducing the notation $s_1((I-Q)P) \geq s_2((I-Q)P) \geq \cdots \geq s_{\dim M}((I-Q)P)$ for the $\dim M$ *largest* singular values of the operator $(I-Q)P$, we define the ith angle from subspace M to subspace N using its sine: $\sin \angle_i\{M; N\} = s_{\dim M-i+1}((I - Q)P)$, $i = 1, \ldots, \dim M$, assuming that all angles lie on the closed interval $[0, \pi/2]$. The complete set of $\dim M$ angles from subspace M to subspace N gives detailed information on approximability of M by N; e.g., if the smallest angle vanishes, the subspaces M and N have a nontrivial intersection.

Later in the paper we use the following property of angles (see [14]):

$$\angle_j\{M; N\} = \inf_{L \subseteq M,\, \dim L = j} \angle\{L; N\},\ j = 1, \ldots, \dim M. \tag{2.4}$$

Finally, we will also need the following generalization of Corollary 2.2.

LEMMA 2.3. *Let vectors $\{u_i, i = 1, \ldots, \dim M\}$ form an orthogonal basis for the subspace M and be arranged in such a way that*

$$\angle\{u_1; N\} \leq \cdots \leq \angle\{u_{\dim M}; N\}.$$

Then

$$\sin^2 \angle_j\{M; N\} \leq \sum_{i=1}^{j} \sin^2 \angle\{u_i; N\}, \qquad j = 1, \ldots, \dim M. \tag{2.5}$$

Proof. We deduce from (2.4) that

$$\sin^2 \angle_j\{M; N\} \leq \sin^2 \angle\{\operatorname{span}\{u_1, \ldots, u_j\}; N\}.$$

Now, the statement of the lemma, (2.5), immediately follows from (2.3) applied to $M = \operatorname{span}\{u_1, \ldots, u_j\}$. □

2.3. Estimates based on the approximability of all previous eigenvectors. Sharp eigenvalue error estimates are usually derived under the assumption that the eigenvector corresponding to the eigenvalue being estimated is well approximated by the trial subspace.

We derive an estimate for the error in approximating μ_j, the jth eigenvalue of T, by $\tilde{\mu}_j$, the jth Ritz value of T, i.e., the jth eigenvalue of $\tilde{T}$. Let $U_{1,\ldots,j}$ denote the span of the eigenvectors $u_1, \dots, u_j$, and let $P_{1,\dots,j}$ be the orthogonal projector onto $U_{1,\dots,j}$. For $u \neq 0$, let $\mu(u) = (Tu, u)/(u, u) = (u, u)_T/(u, u)$ be the Rayleigh quotient associated with T. Here $(\cdot, \cdot)_T$ is a second inner product on H. We will refer to orthogonality in $(\cdot, \cdot)_T$ as T-orthogonality. Note that $\mu(u) > 0$ since T is positive definite.

Our first theorem is known; it was proved in [11] and reproduced in [8]. For the particular case $j = \dim \tilde{U}$, a different proof was then suggested in [10, 12].

THEOREM 2.4. *For $j = 1, 2, \dots, n = \dim \tilde{U}$ we have*

$$0 \leq \frac{\mu_j - \tilde{\mu}_j}{\mu_j} \leq \sin^2 \angle\{U_{1,\dots,j}; \tilde{U}\} = \|(I - \tilde{Q})P_{1,\dots,j}\|^2. \tag{2.6}$$

The estimate (2.6) is sharp; see [15].

Remark 2.1. By Corollary 2.2 we have

$$\sin^2 \angle\{U_{1,\dots,j}; \tilde{U}\} \leq \sum_{i=1}^{j} \sin^2 \angle\{u_i; \tilde{U}\} = \sum_{i=1}^{j} \|(I - \tilde{Q})u_i\|^2;$$

therefore, the estimate

$$\frac{\mu_j - \tilde{\mu}_j}{\mu_j} \leq \sum_{i=1}^{j} \|(I - \tilde{Q})u_i\|^2 \tag{2.7}$$

follows directly from Theorem 2.4. Estimate (2.7) is well known (see, e.g., [20, 22]); on the right-hand side we have the sum of the squares of the approximation errors for the eigenvectors $u_1, \dots, u_j$. If $j = 1$, the estimates (2.6) and (2.7) are identical.

2.4. Estimates based mainly on the approximability of the target eigenvector. Theorem 2.4 has a major weakness; namely, the right-hand side of estimate (2.6) for the target eigenvalue μ_j involves the approximability of all functions in $U_{1,\dots,j}$. The result thus suggests that the eigenvalue error $(\mu_j - \tilde{\mu}_j)/\mu_j$ depends on the approximation errors for all eigenfunctions $u_1, \dots, u_j$. We now mention two results suggesting that this is not the case; that, in fact, the ratio $(\mu_j - \tilde{\mu}_j)/\mu_j$ depends mainly on just the approximation error for u_j, the target eigenfunction. First, consider the following

LEMMA 2.5. *For $j = 1, 2, \dots, n = \dim \tilde{U}$, the estimate*

$$\begin{aligned} \frac{\mu_j - \tilde{\mu}_j}{\mu_j} &= \|(I - \tilde{P}_j)u_j\|^2 - \frac{1}{\mu_j}((I - P_j)\tilde{u}_j, T(I - P_j)\tilde{u}_j) \\ &\leq \sin^2 \angle\{u_j, \tilde{u}_j\} \end{aligned} \tag{2.8}$$

holds, where $\tilde{P}_j$ is the orthogonal projector onto $\operatorname{span}\{\tilde{u}_j\}$.

The first line of (2.8) follows from the chain of identities in the proof of Lemma 3.5 of [6].

Next consider the following lemma.

LEMMA 2.6. *If $(\tilde{u}_j, u_j) \neq 0$, the estimate*

$$\begin{aligned} \frac{\mu_j - \tilde{\mu}_j}{\mu_j} &= \|(I - \tilde{Q})u_j\|^2 + \frac{1}{\mu_j}\left(T(I - \tilde{Q})u_j, \frac{(I - P_j)\tilde{u}_j}{\|P_j\tilde{u}_j\|}\right) \\ &\leq \left(1 + \frac{\|(I - \tilde{Q})T\|}{\mu_j} \frac{\tan \angle\{u_j, \tilde{u}_j\}}{\sin \angle\{u_j, \tilde{U}\}}\right) \sin^2 \angle\{u_j, \tilde{U}\} \end{aligned} \tag{2.9}$$

holds, where P_j is the orthogonal projector onto $\operatorname{span}\{u_j\}$.

The identity in the first line of (2.9) is based on an argument from the proof of Theorem 4.1 in [3] (see also [18]). For a complete proof, see [15].

It is informative to compare (2.8) with (2.9). The first term on the right-hand side of the first line of (2.8) is larger than that of (2.9). However, the second term in the first line of (2.8) is negative, and thus is dropped in the second line of (2.8). The second term on the right-hand side in the first line of (2.9), while generally not negative, in typical applications (when $\|(I - \tilde{Q})T\|$ is small) is significantly smaller compared to the first term; in other words, the term added to 1 in the second line of (2.9) in such applications is small because of the multiplier $\|(I - \tilde{Q})T\|$. We conclude that both (2.8) and (2.9) suggest that $(\mu_j - \tilde{\mu}_j)/\mu_j$ depends mainly on the approximation error for u_j.

Both estimates (2.8) and (2.9), in addition to being dependent on the eigenfunction u_j, depend explicitly on the approximate eigenfunction $\tilde{u}_j$: (2.8) in the main term and (2.9) in the constant. Our next theorem is based on a novel alternative technique, where the approximate eigenfunction $\tilde{u}_j$ is not used in the proof and does not appear in the theorem statement.

Theorem 2.7. *For a fixed index j such that $1 \le j \le n = \dim \tilde{U}$, suppose that*

$$\min_{i=1,\dots,j-1} |\tilde{\mu}_i - \mu_j| \neq 0. \tag{2.10}$$

Then

$$\begin{aligned} 0 \le \frac{\mu_j - \tilde{\mu}_j}{\mu_j} &\le \|(I - \tilde{Q} + \tilde{P}_{1,\dots,j-1})u_j\|^2 \\ &\le \left(1 + \frac{\|(I - \tilde{Q})T\tilde{P}_{1,\dots,j-1}\|^2}{\min_{i=1,\dots,j-1} |\tilde{\mu}_i - \mu_j|^2}\right) \sin^2 \angle\{u_j; \tilde{U}\}, \end{aligned} \tag{2.11}$$

where $\tilde{P}_{1,\dots,j-1}$ is the orthogonal projector onto $\tilde{U}_{1,\dots,j-1} = \operatorname{span}\{\tilde{u}_1, \dots, \tilde{u}_{j-1}\}$ (if $j = 1$, we define $\tilde{P}_{1,\dots,j-1} = 0$ and do not use (2.10)*).*

For brevity, we do not prove the theorem here, but instead refer to [15], and to our proof of Theorem 2.11 later in the paper, which is a generalization of Theorem 2.7.

Since $\|(I - \tilde{Q} + \tilde{P}_{1,\dots,j-1})u_j\| \le \|(I - \tilde{P}_j)u_j\|$, our new estimate (2.11) clearly improves (2.8). A direct comparison of the constants in (2.9) and (2.11) in a general case does not appear to be simple because of the unresolved dependence of (2.9) on $\tilde{u}_j$. However, we have

$$\begin{aligned} \frac{\|(I - \tilde{Q})T\tilde{P}_{1,\dots,j-1}\|^2}{\min_{i=1,\dots,j-1} |\tilde{\mu}_i - \mu_j|^2} &\le \frac{\|(I - \tilde{Q})T\|^2}{\min_{i=1,\dots,j-1} |\tilde{\mu}_i - \mu_j|^2} \\ &\le \frac{\|(I - \tilde{Q})T\|}{\mu_j}, \end{aligned}$$

assuming

$$\|(I - \tilde{Q})T\| \le \frac{\min_{i=1,\dots,j-1} |\tilde{\mu}_i - \mu_j|^2}{\mu_j}. \tag{2.12}$$

Since $\tan \angle\{u_j, \tilde{u}_j\} \ge \sin \angle\{u_j, \tilde{U}\}$, we can conclude that our estimate (2.11) is sharper than (2.9) under the assumption (2.12). We note that in the FEM context assumption (2.12) is realistic as, for typical problems, $\|(I - \tilde{Q})T\|$ vanishes when the mesh parameter tends to zero.

Let us finally comment that the ratio

$$\frac{\|(I-\tilde{Q})T\tilde{P}_{1,\dots,j-1}\|^2}{\min_{i=1,\dots,j-1}|\tilde{\mu}_i-\mu_j|^2}=\frac{\|(I-\tilde{Q})(T/\mu_j)\tilde{P}_{1,\dots,j-1}\|^2}{\min_{i=1,\dots,j-1}|\tilde{\mu}_i/\mu_j-1|^2}$$

in (2.11) is "dimensionless," i.e., invariant with respect to scaling of T. Here, the quantity in the denominator, $\min_{i=1,\dots,j-1}(\tilde{\mu}_i/\mu_j-1)$, in the limit, where all $\tilde{\mu}_i\to\mu_i$, turns into μ_{j-1}/μ_j-1, the one-sided relative gap in the spectrum at μ_j.

2.5. Corollaries of Theorems 2.4 and 2.7 for multiple eigenvalues. Here we address in details the case when the eigenvalue μ_j is a multiple of multiplicity $q>1$. Our Theorems 2.4 and 2.7 hold for multiple eigenvalues since we never assumed the eigenvalues were simple. However, the case of multiple eigenvalues has special features, which we want to highlight. Let us start with the simplest case, where we are interested only in estimates for the largest eigenvalue μ_1. From Theorem 2.4 we easily derive the following.

Corollary 2.8. *Let*

$$\mu_1=\mu_2=\dots=\mu_q>\mu_{q+1}$$

and $q\le n=\dim\tilde{U}$. *For* $j=1,2,\dots,q$ *we have*

$$\begin{aligned}0\le\frac{\mu_1-\tilde{\mu}_j}{\mu_1}&\le\inf_{\substack{U_{1,\dots,j}\subset U_{1,\dots,q}\\ \dim U_{1,\dots,j}=j}}\sin^2\angle\{U_{1,\dots,j};\tilde{U}\}\\ &=\sin^2\angle_j\{U_{1,\dots,q};\tilde{U}\}.\end{aligned}\tag{2.13}$$

Estimate (2.13) has two important properties. First, it controls the error for *every* Ritz values corresponding to the first eigenvalue μ_1. Second, it shows that different Ritz values may have different approximation qualities, depending on approximability of the eigenspace $U_{1,\dots,q}$ by the trial subspace $\tilde{U}$ of the Ritz method, where the approximability is measured by the angles from $U_{1,\dots,q}$ to $\tilde{U}$ and, thus, can be estimated a priori.

In general, the multiple eigenvalue of interest may not be the largest:

$$\mu_{p-1}>\mu_p=\mu_{p+1}=\dots=\mu_j=\dots=\mu_{p+q-1}>\mu_{p+q}.\tag{2.14}$$

Applying Theorem 2.4, we obtain the following.

Corollary 2.9. *Suppose* (2.14) *is satisfied and* $p+q-1\le n$. *For any index* $j=p,p+1,\dots,p+q-1$ *we have*

$$0\le\frac{\mu_p-\tilde{\mu}_j}{\mu_p}\le\inf_{\substack{U_{1,\dots,p-1}\subset U_{1,\dots,j}\subset U_{1,\dots,p+q-1}\\ \dim U_{1,\dots,j}=j}}\sin^2\angle\{U_{1,\dots,j};\tilde{U}\}.$$

Proof. The subspace $U_{1,\dots,j}$ has a fixed part $U_{1,\dots,p-1}\subset U_{1,\dots,j}$, but the rest of it we can choose within $U_{p,\dots,\min\{p+q-1,n\}}$ as we like. □

Corollary 2.9 preserves the desired properties of Corollary 2.8; i.e., it provides a different estimate for each Ritz value of interest, but it requires approximability of all previous eigenvectors.

Let us now turn our attention to Theorem 2.7. The only relevant assumption in Theorem 2.7 is that (2.10) is satisfied so that the denominator in the constant in

Theorem 2.7 is not zero. Let us analyze the likely behavior of this constant for the particular case $q = 2$ so that

$$\mu_{p-1} > \mu_p = \mu_{p+1} > \mu_{p+2}. \tag{2.15}$$

There are two relevant possibilities for j in Theorem 2.7: $j = p$ or $j = p+1$. Assuming that all Ritz values $\tilde{\mu}_i$ approximate the corresponding eigenvalues μ_i, which is typical for FEM applications (see section 3.2 for details), we observe that in (2.10)

$$\min_{i=1,\ldots,j-1} |\tilde{\mu}_i - \mu_j| \approx \mu_{j-1} - \mu_j.$$

Thus, if $j = p$, the denominator is asymptotically positive; specifically, it is asymptotically equal to $\mu_{p-1} - \mu_p$, and the estimate of Theorem 2.7 is asymptotically valid; while if $j = p + 1$, the denominator in the constant in Theorem 2.7 asymptotically vanishes. This discussion demonstrates that Theorem 2.7 provides an asymptotically valid estimate only for one out of the $q = 2$ Ritz values. On the positive side, however, we can freely choose the eigenvector u_j within the eigenspace corresponding to μ_p to minimize the right-hand side of (2.11). Let us reformulate Theorem 2.7 to reflect these observations.

Corollary 2.10. *Suppose that the eigenvalue μ_p, where $p > 1$, has multiplicity $q > 1$ so that* (2.14) *holds, and that $p + q - 1 \leq n$, and denote the corresponding eigenspace by $U_{p,\ldots,p+q-1}$. As in Theorem* 2.7, *suppose that*

$$\min_{i=1,\ldots,p-1} |\tilde{\mu}_i - \mu_p| \neq 0.$$

Then

$$\begin{aligned} 0 \leq \frac{\mu_p - \tilde{\mu}_p}{\mu_p} &\leq \min_{u \in U_{p,\ldots,p+q-1},\, \|u\|=1} \|(I - \tilde{Q} + \tilde{P}_{1,\ldots,p-1})u\|^2 \\ &\leq \left(1 + \frac{\|(I-\tilde{Q})T\tilde{P}_{1,\ldots,p-1}\|^2}{\min_{i=1,\ldots,p-1} |\tilde{\mu}_i - \mu_p|^2}\right) \min_{u \in U_{p,\ldots,p+q-1},\, \|u\|=1} \sin^2 \angle\{u; \tilde{U}\} \\ &= \left(1 + \frac{\|(I-\tilde{Q})T\tilde{P}_{1,\ldots,p-1}\|^2}{\min_{i=1,\ldots,p-1} |\tilde{\mu}_i - \mu_p|^2}\right) \sin^2 \angle_1\{U_{p,\ldots,p+q-1}; \tilde{U}\}. \end{aligned} \tag{2.16}$$

Proof. We take $j = p$ in Theorem 2.7 and notice that we can choose u_j to be any normalized vector in the eigenspace $U_{p,\ldots,p+q-1}$ and finally use (2.4). □

It is useful to compare Corollary 2.9 with Corollary 2.10. Corollary 2.9 gives different estimates for every Ritz value out of the q Ritz values corresponding to the multiple eigenvalue μ_p, but requires approximability of all previous eigenvectors. In Corollary 2.10, the approximability of previous eigenvectors appears only in the constant, but it gives an estimate only for the largest Ritz value out of the q.

We want to obtain a result that combines the advantages of Corollaries 2.9 and 2.10 and removes their weaknesses. E.g., if $q = 3$ and the eigenspace corresponding to the triple eigenvalue μ_p is spanned by eigenfunctions of different approximation quality, we want to have three error estimates for μ_p reflecting it and not depending strongly on approximability of previous eigenfunctions.

2.6. A new estimate that covers multiple and clustered eigenvalues.

Our new result is a generalization of Theorem 2.7 that gives us the desired estimates for a multiple eigenvalue corresponding to an eigenspace spanned by eigenfunctions of different approximation quality. In addition, the new estimate also covers the case of clustered eigenvalues, i.e., the constant in the new estimate does not depend on the width of the eigenvalue cluster.

THEOREM 2.11.[1] *For fixed indexes j and m satisfying $1 \le j \le n$ and $1 \le m \le j$, let $U_{j-m+1,\dots,j}$ be the m-dimensional invariant subspace corresponding to eigenvalues $\mu_{j-m+1} \ge \cdots \ge \mu_j$ and $P_{j-m+1,\dots,j}$ be the orthogonal projector on $U_{j-m+1,\dots,j}$. If*

$$\min_{i=1,\dots,j-m} |\tilde{\mu}_i - \mu_j| \ne 0, \tag{2.17}$$

then

$$\begin{aligned} 0 \le \frac{\mu_j - \tilde{\mu}_j}{\mu_j} &\le \|(I - \tilde{Q} + \tilde{P}_{1,\dots,j-m})P_{j-m+1,\dots,j}\|^2 \\ &\le \left(1 + \frac{\|(I-\tilde{Q})T\tilde{P}_{1,\dots,j-m}\|^2}{\min_{i=1,\dots,j-m}|\tilde{\mu}_i - \mu_j|^2}\right)\|(I-\tilde{Q})P_{j-m+1,\dots,j}\|^2, \end{aligned} \tag{2.18}$$

where $\tilde{P}_{1,\dots,j-m}$ is the orthogonal projector onto $\tilde{U}_{1,\dots,j-m} = \operatorname{span}\{\tilde{u}_1, \dots, \tilde{u}_{j-m}\}$ (if $j = m$, we set $\tilde{P}_{1,\dots,j-m} = 0$ and do not use (2.17)*). If $m = j$, the present theorem turns into Theorem* 2.4*; if $m = 1$, it turns into Theorem* 2.7.

Proof. The operators $I - \tilde{Q} + \tilde{P}_{1,\dots,j-m}$ and $P_{j-m+1,\dots,j}$ are orthogonal projectors; thus, $\|(I - \tilde{Q} + \tilde{P}_{1,\dots,j-m})P_{j-m+1,\dots,j}\| \le 1$. If $\|(I - \tilde{Q} + \tilde{P}_{1,\dots,j-m})P_{j-m+1,\dots,j}\| = 1$, the first estimate in (2.18) is trivially true. Now we suppose

$$\|(I - \tilde{Q} + \tilde{P}_{1,\dots,j-m})P_{j-m+1,\dots,j}\| < 1. \tag{2.19}$$

Then, since $\dim U_{j-m+1,\dots,j} = m$, the subspace $(\tilde{Q} - \tilde{P}_{1,\dots,j-m})U_{j-m+1,\dots,j}$ is also m-dimensional by Theorem 6.34 in Chapter I in [9].

We choose a normalized vector $\bar{u}$ such that

$$\bar{u} \in (\tilde{Q} - \tilde{P}_{1,\dots,j-m})U_{j-m+1,\dots,j}, \qquad \mu(\bar{u}) = \min_{w \in (\tilde{Q} - \tilde{P}_{1,\dots,j-m})U_{j-m+1,\dots,j} \setminus \{0\}} \mu(w),$$

and introduce the orthogonal and T-orthogonal decomposition

$$\bar{u} = u + v, \quad u \in U_{1,\dots,j}, \quad v \in U_{1,\dots,j}^{\perp}.$$

Since $\bar{u} \in (\tilde{Q} - \tilde{P}_{1,\dots,j-m})U_{j-m+1,\dots,j}$, $\|\bar{u}\| = 1$, and $u = \bar{u} - v$ is the orthogonal projection of $\bar{u}$ onto $U_{1,\dots,j}$, we see, using again Theorem 6.34 in Chapter I in [9], that

$$\begin{aligned} \|v\| &= \sin \angle\{\bar{u}; U_{1,\dots,j}\} \\ &\le \sin \angle\{\bar{u}; U_{j-m+1,\dots,j}\} \\ &\le \sin \angle\{(\tilde{Q} - \tilde{P}_{1,\dots,j-m})U_{j-m+1,\dots,j}; U_{j-m+1,\dots,j}\} \\ &= \|(I - \tilde{Q} + \tilde{P}_{1,\dots,j-m})P_{j-m+1,\dots,j}\|. \end{aligned} \tag{2.20}$$

It now follows from (2.19) and (2.20) that $\|v\| < 1$; thus $u \ne 0$, and $\mu(u)$ is defined.

We next prove the following chain of inequalities:

$$\mu(\bar{u}) \le \tilde{\mu}_j \le \mu_j \le \mu(u). \tag{2.21}$$

[1] It came to our attention that a similar result was independently obtained in the revised version of [19] to appear in *Linear Algebra and Its Applications.*

Indeed, the first inequality,

$$\begin{aligned}\mu(\bar{u}) &= \min_{w\in(\tilde{Q}-\tilde{P}_{1,\dots,j-m})U_{j-m+1,\dots,j}\setminus\{0\}} \mu(w)\\ &\le \max_{\substack{W\subseteq \operatorname{Im}(\tilde{Q}-\tilde{P}_{1,\dots,j-m})\\ \dim W=m}} \min_{w\in W\setminus\{0\}} \mu(w)=\tilde{\mu}_j,\end{aligned}$$

follows from the min-max principle for Ritz values, since the dimension of the subspace $(\tilde{Q}-\tilde{P}_{1,\dots,j-m})U_{j-m+1,\dots,j}$ is m. The second inequality, $\tilde{\mu}_j \le \mu_j$, is an immediate consequence of the max-min principle. The third inequality, $\mu_j \le \mu(u)$, follows from the fact that $u \in U_{1,\dots,j}$.

The identity

$$\mu(\bar{u}) = \frac{(Tu,u)+(Tv,v)}{(u,u)+(v,v)}$$

can be rewritten as

$$\mu(u)-\mu(\bar{u}) = \begin{cases} [\mu(\bar{u})-\mu(v)]\dfrac{(v,v)}{(u,u)},\ v\neq 0,\\ 0,\ v=0.\end{cases} \tag{2.22}$$

For $v \neq 0$, it follows directly from (2.21) and (2.22) that

$$\begin{aligned}0\le \mu_j-\tilde{\mu}_j &\le \mu(u)-\mu(\bar{u})\\ &= [\mu(\bar{u})-\mu(v)]\frac{(v,v)}{(u,u)}\\ &\le \tilde{\mu}_j\frac{\|v\|^2}{\|u\|^2} \qquad\qquad (\text{since } \mu(v)>0);\end{aligned}$$

hence, since $\|v\|^2+\|u\|^2=1$ and $(\mu_j-\tilde{\mu}_j)(1-\|v\|^2)\le\tilde{\mu}_j\|v\|^2$, we get

$$0\le\frac{\mu_j-\tilde{\mu}_j}{\mu_j}\le\|v\|^2. \tag{2.23}$$

If $v=0$, then from (2.22) we see that $\mu(u)=\mu(\bar{u})$, which, together with (2.21), shows that $\tilde{\mu}_j=\mu_j$. Thus, estimate (2.23) is also valid for $v=0$.

Combining estimates (2.20) and (2.23), we obtain the first estimate in (2.18).

Finally, by Lemma 2.1,

$$\|(I-(\tilde{Q}-\tilde{P}_{1,\dots,j-m}))P_{j-m+1,\dots,j}\|^2\le\|(I-\tilde{Q})P_{j-m+1,\dots,j}\|^2+\|\tilde{P}_{1,\dots,j-m}P_{j-m+1,\dots,j}\|^2.$$

The second term can be estimated using Theorem 3.2 of [13]:

$$\|\tilde{P}_{1,\dots,j-m}P_{j-m+1,\dots,j}\|\le\frac{\|(I-\tilde{Q})T\tilde{P}_{1,\dots,j-m}\|}{\min_{i=1,\dots,j-m}|\tilde{\mu}_i-\mu_j|}\|(I-\tilde{Q})P_{j-m+1,\dots,j}\|.$$

Combining the first estimate in (2.18) with the last two inequalities completes the proof. □

Alternatively, Lemma 2.1 can be used to estimate $\|\tilde{P}_{1,\dots,j-m}P_{j-m+1,\dots,j}\|$, which results in

$$\begin{aligned}\|\tilde{P}_{1,\dots,j-1}P_{j-m+1,\dots,j}\|^2 &= \left\|\sum_{i=1}^{j-1}\tilde{P}_iP_{j-m+1,\dots,j}\right\|^2\\ &\le\sum_{i=1}^{j-1}\|\tilde{P}_iP_{j-m+1,\dots,j}\|^2.\end{aligned}$$

Every term $\|\tilde{P}_i P_{j-m+1,\dots,j}\|^2$ in the sum above can be estimated using results of [13]. For simplicity, let $m = 1$; then by Theorem 2.1 in [13],

$$\|\tilde{P}_i P_j\| \le \frac{\|T\tilde{u}_i - \tilde{\mu}_i \tilde{u}_i\|}{|\tilde{\mu}_i - \mu_j|} \sin \angle\{u_j; \tilde{U}\},$$

where $\|\tilde{u}_i\| = \|u_j\| = 1$, so we get

$$0 \le \frac{\mu_j - \tilde{\mu}_j}{\mu_j} \le \left(1 + \sum_{i=1}^{j-1} \frac{\|T\tilde{u}_i - \tilde{\mu}_i \tilde{u}_i\|^2}{|\tilde{\mu}_i - \mu_j|^2}\right) \sin^2 \angle\{u_j; \tilde{U}\},$$

which in some cases may provide a smaller constant compared to that of (2.18) with $m = 1$.

Remark 2.2. A careful examination of the proof of the first estimate in (2.18) of Theorem 2.11 shows that we can replace the orthoprojector $P_{j-m+1,\dots,j}$ with an orthoprojector P_L to any m-dimensional subspace L of $U_{1,\dots,j}$: the argument still holds and the first estimate in (2.18) can be improved:

$$0 \le \frac{\mu_j - \tilde{\mu}_j}{\mu_j} \le \inf_{L \subseteq U_{1,\dots,j},\, \dim L = m} \|(I - \tilde{Q} + \tilde{P}_{1,\dots,j-m}) P_L\|^2. \tag{2.24}$$

The right-hand side of (2.24) allows a nice geometric interpretation, using definition (2.4) of the angles between subspaces:

$$\inf_{L \subseteq U_{1,\dots,j},\, \dim L = m} \|(I - \tilde{Q} + \tilde{P}_{1,\dots,j-m}) P_L\|^2 = \sin^2 \angle_m\{U_{1,\dots,j}; \tilde{U} \cap (\tilde{U}_{1,\dots,j-m})^\perp\}.$$

This may lead to a potential improvement of the second estimate (2.18)—provided one can estimate the right-hand side of (2.24) using terms similar to those of the second estimate in (2.18).

We can derive a simple estimate of the right-hand side of (2.24), using the fact, which follows from dimensionality arguments, that

$$\dim (\tilde{U}_{1,\dots,j-m})^\perp \cap U_{1,\dots,j} \ge m.$$

Since

$$\|(I - \tilde{Q} + \tilde{P}_{1,\dots,j-m})u\| = \|(I - \tilde{Q})u\|,\ u \in (\tilde{U}_{1,\dots,j-m})^\perp \cap U_{1,\dots,j},$$

restricting the choice of L to the intersection above in (2.24) we derive that

$$0 \le \frac{\mu_j - \tilde{\mu}_j}{\mu_j} \le \inf_{L \subseteq (\tilde{U}_{1,\dots,j-m})^\perp \cap U_{1,\dots,j},\, \dim L = m} \|(I - \tilde{Q}) P_L\|^2. \tag{2.25}$$

In FEM applications typically (because of the approximability assumption) we have $\dim((\tilde{U}_{1,\dots,j-m})^\perp \cap U_{1,\dots,j}) = m$ so the inf in (2.25) is then redundant.

Estimate (2.25) improves (2.6). We note that m is a free parameter in (2.25) and can be chosen arbitrarily, $1 \le m \le j$. We finally note that (2.25) is not truly an a priori estimate since the right-hand side of it depends on the Ritz vectors $\tilde{u}_1, \dots, \tilde{u}_{j-m}$ that are not known a priori.

Let us now reformulate Theorem 2.11 in the context of the multiple eigenvalue in order to obtain a generalization of Corollary 2.10. Theorem 2.11 gives us enough flexibility to establish a different error estimate for each of the q Ritz values corresponding to the multiple eigenvalue of multiplicity q.

Corollary 2.12. *Suppose that the eigenvalue μ_p, where $p > 1$, has multiplicity $q > 1$ so that* (2.14) *holds and that $p + q - 1 \leq n$. Suppose that*

$$\min_{i=1,\dots,p-1} |\tilde{\mu}_i - \mu_p| \neq 0.$$

Then, for $j = p, \dots, p+q-1$, we have

$$\begin{aligned} 0 \leq \frac{\mu_p - \tilde{\mu}_j}{\mu_p} &\leq \|(I - \tilde{Q} + \tilde{P}_{1,\dots,p-1})P_{p,\dots,j}\|^2 \\ &\leq \left(1 + \frac{\|(I-\tilde{Q})T\tilde{P}_{1,\dots,p-1}\|^2}{\min_{i=1,\dots,p-1}|\tilde{\mu}_i - \mu_p|^2}\right)\|(I-\tilde{Q})P_{p,\dots,j}\|^2, \end{aligned} \tag{2.26}$$

where $\tilde{P}_{1,\dots,p-1}$ is the orthogonal projector onto $\tilde{U}_{1,\dots,p-1} = \operatorname{span}\{\tilde{u}_1, \dots, \tilde{u}_{p-1}\}$ and $P_{p,\dots,j}$ is the orthogonal projector onto any $(j-p+1)$-dimensional subspace of the eigenspace $U_{p,\dots,p+q-1}$ corresponding to the eigenvalue μ_p. The optimal choice of the projector $P_{p,\dots,j}$ allows us to replace the term $\|(I-\tilde{Q})P_{p,\dots,j}\|^2$ in estimate (2.26) *with $\sin^2 \angle_{j-p+1}\{U_{p,\dots,p+q-1}, \tilde{U}\}$.*

Proof. We simply take $m = j - p + 1$ in Theorem 2.11. □

To see the improvement of Corollary 2.12 over Theorem 2.7, consider the following situation. Suppose μ_2 has multiplicity 2, so $p = q = 2$. Then

$$\min_{i=1,\dots,p-1} |\tilde{\mu}_i - \mu_p| \approx \mu_1 - \mu_2 > 0,$$

provided $\tilde{\mu}_1$ is close enough to μ_1. Taking $j = 2$ in Corollary 2.12 yields

$$\frac{\mu_2 - \tilde{\mu}_2}{\mu_2} \lesssim \left(1 + \frac{\|(I-\tilde{Q})T\tilde{P}_1\|^2}{(\mu_1 - \mu_2)^2}\right)\|(I-\tilde{Q})P_2\|^2, \tag{2.27}$$

while taking $j = 3$ yields

$$\frac{\mu_3 - \tilde{\mu}_3}{\mu_3} = \frac{\mu_2 - \tilde{\mu}_3}{\mu_2} \lesssim \left(1 + \frac{\|(I-\tilde{Q})T\tilde{P}_1\|^2}{(\mu_1 - \mu_2)^2}\right)\|(I-\tilde{Q})P_{2,3}\|^2. \tag{2.28}$$

In (2.27), the eigenvalue error is bounded by a constant that is slightly larger than 1 times the square of the best approximation error for u_2; while in (2.28), we have the square of the best approximation error for $\operatorname{span}\{u_2, u_3\}$ = the eigenspace for $\mu_2 = \mu_3$. Note that estimating $(\mu_3 - \tilde{\mu}_3)/\mu_3$ with Theorem 2.7 yields no asymptotically valid estimate (cf. the discussion preceding Corollary 2.10).

Results giving different estimates for $(\mu_p - \tilde{\mu}_j)/\mu_p$, $j = p, \dots, p+q-1$ (cf. Corollaries 2.9 and 2.12) were first proved in [2]; see also [3, 4]. Our presentation simplifies and clarifies the analysis in [2, 3] and provides explicit constants. In section 3.2 we compare these results in detail. For an example of a multiple eigenvalue with eigenfunctions of differing approximabilities, see [2, 4].

Let us finally highlight the opportunities that Theorem 2.11 provides for error estimates of clustered eigenvalues in the following situation. Let

$$\mu_1 > \mu_2 \approx \mu_3 > \mu_4,$$

and suppose we are interested in error estimates for μ_2 and μ_3, assuming that $\tilde{\mu}_1 \approx \mu_1$ and $\tilde{\mu}_2 \approx \mu_2$. We do not even need Theorem 2.11 to estimate the error for μ_2: Theorem

2.7 with $j = 2$ already gives us an asymptotically valid estimate (2.27), and the fact that μ_2 is clustered (or multiple as above) is irrelevant. Theorem 2.7 with $j = 3$ does not provide an asymptotically valid estimate for the error in μ_3 since the term $|\mu_3 - \tilde{\mu}_2| \approx 0$ appears in the denominator.

Applying Theorem 2.11 with $j = 3$ we have the option of choosing the free parameter $m = 1$, 2, or 3. Taking $m = 1$ reduces Theorem 2.11 to Theorem 2.7, which does not work well in this situation as we just discussed. Taking $m = 2$ yields a good estimate

$$\frac{\mu_3 - \tilde{\mu}_3}{\mu_3} \lesssim \left(1 + \frac{\|(I - \tilde{Q})T\tilde{P}_1\|^2}{(\mu_1 - \mu_3)^2}\right) \|(I - \tilde{Q})P_{2,3}\|^2. \tag{2.29}$$

Taking $m = 3$ reduces Theorem 2.11 to Theorem 2.4,

$$\frac{\mu_3 - \tilde{\mu}_3}{\mu_3} \leq \|(I - \tilde{Q})P_{1,2,3}\|^2. \tag{2.30}$$

Comparing the right-hand sides of (2.29) and (2.30), we see that (2.29) provides a sharper estimate than (2.30) if $\mu_1 - \mu_3$ is large enough and u_1 cannot be well approximated by the trial subspace. To summarize, choosing different m in Theorem 2.11 allows us to reduce the constants in estimating errors for clustered eigenvalues at the cost of enlarging the invariant subspace that needs to be well approximated by the trial subspace. Note that in neither (2.29) nor (2.30) does the constant depend on the width of the eigenvalue cluster $\mu_2 \approx \mu_3$. Ovtchinnikov in [19] calls such estimates "cluster robust."

3. Application to the variational Galerkin method and comparisons.

We now consider the previous abstract results in two important contexts. First, suppose we have an eigenvalue problem for a symmetric positive compact integral operator T defined on $H = L_2$ and apply the classical Ritz method for integral operators. All our results apply immediately and provide relative eigenvalue error estimates for the largest eigenvalues in terms of L_2 approximability of the corresponding eigenfunctions.

Our second application is to the variational Galerkin method for symmetric positive definite differential operators. Here, we essentially need to reformulate our results for the inverse of T, but the operator T cannot be just simply replaced with its inverse since this would change the Ritz values. A proper inversion involves a simultaneous change of the scalar product as it is implicitly done in the next subsection. Our estimates of the previous section have to be somewhat rewritten in this context, since they are not invariant with respect to such an inversion.

3.1. The variational Galerkin method.

Suppose, as above, that H is a real separable Hilbert space with inner product (u, v) and norm $\|u\| = \sqrt{(u, u)}$, and suppose we are given two symmetric bilinear forms $B(u.v)$ and $D(u, v)$ on $H \times H$. The bilinear form $B(u, v)$ is assumed to satisfy

$$|B(u, v)| \leq C_1\|u\|\|v\| \quad \text{for all } u, v \in H \tag{3.1}$$

and

$$C_0\|u\|^2 \leq B(u, u) \quad \text{for all } u \in H \quad \text{with } C_0 > 0. \tag{3.2}$$

It follows from (3.1) and (3.2) that $\|u\|_B = \sqrt{B(u, u)}$ and $\|u\|$ are equivalent norms on H. For the remainder of this section we use $B(u, v)$ and $\|u\|_B$ as the inner product and norm, respectively, on H, and denote the resulting space by H_B. We also measure all angles in H_B, i.e., with respect to $B(u,v)$. Regarding $D(u,v)$ we assume that $0 < D(u,u)$ for all nonzero vectors $u \in H$ and that the unit ball of the norm $||\cdot||_D$ is compact in H.

We consider the following variationally formulated symmetric eigenvalue problem:

$$\left\{ \begin{array}{l} \text{Seek } \lambda \in R \text{ and } 0 \neq u \in H_B \text{ satisfying} \\ B(u,v) = \lambda D(u,v) \text{ for all } v \in H_B. \end{array} \right. \tag{3.3}$$

Under our assumptions, problem (3.3) has eigenvalues $0 < \lambda_1 \leq \lambda_2 \leq \cdots \nearrow +\infty$ and corresponding eigenvectors $u_1, u_2, \ldots$, which satisfy $B(u_i, u_j) = \lambda_i D(u_i, u_j) = \delta_{ij}$.

We are interested in approximating the eigenpairs of (3.3) by the variational Ritz method. Toward this end, we suppose we are given a finite-dimensional subspace $\tilde{U}$ of H_B, and consider the following finite-dimensional, variationally formulated eigenvalue problem:

$$\left\{ \begin{array}{l} \text{Seek } \tilde{\lambda} \in R \text{ and } 0 \neq \tilde{u} \in \tilde{U} \text{ satisfying} \\ B(\tilde{u},v) = \lambda D(\tilde{u},v), \text{ for all } v \in \tilde{U}. \end{array} \right. \tag{3.4}$$

Problem (3.4), being a finite-dimensional eigenvalue problem, has $n = \dim \tilde{U}$ positive eigenvalues $\tilde{\lambda}_1 \leq \tilde{\lambda}_2 \leq \cdots \leq \tilde{\lambda}_n$, and corresponding eigenvectors $\tilde{u}_1, \tilde{u}_2, \ldots, \tilde{u}_n$, which satisfy $B(\tilde{u}_i, \tilde{u}_j) = \tilde{\lambda}_i D(\tilde{u}_i, \tilde{u}_j) = \delta_{ij}, i,j = 1,\ldots,n$. The Poincaré inequalities $\lambda_i \leq \tilde{\lambda}_i$, $i = 1,\ldots,n$, and the min-max characterization of eigenvalues of problems (3.3) and (3.4) hold under our assumptions. We then view $\tilde{\lambda}_i$ as an approximation to λ_i, i.e., $\lambda_i \approx \tilde{\lambda}_i, i = 1,\ldots,n$.

Next we introduce the operator $T : H_B \to H_B$ defined by

$$\left\{ \begin{array}{l} Tf \in H_B, \\ B(Tf,v) = D(f,v) \text{ for all } v \in H_B \end{array} \right. \tag{3.5}$$

and the operator $\tilde{T} : \tilde{U} \to \tilde{U}$ defined by

$$\left\{ \begin{array}{l} \tilde{T}f \in \tilde{U},\ f \in \tilde{U}, \\ B(\tilde{T}f,v) = D(f,v) \text{ for all } v \in \tilde{U}. \end{array} \right. \tag{3.6}$$

The operator T is the solution operator for the "boundary value problem" corresponding to the eigenvalue problem (3.3). By our assumption, the unit ball of $\|\cdot\|_D$ is compact in H and, therefore, in H_B, thus, the operator T is compact in H_B. Of course, $\tilde{T}$, being an operator on a finite-dimensional space, is also compact. It follows directly from definition (3.5) that T is symmetric and positive definite on H_B and from definition (3.6) that $\tilde{T}$ is symmetric and positive definite on $\tilde{U}$ (with respect to $B(u,v)$). It is easily seen that, if, as above, $\tilde{Q}$ is the orthogonal projector of H_B onto $\tilde{U}$, then $\tilde{T} = (\tilde{Q}T)|_{\tilde{U}}$.

The eigenvalues of problem (3.3) and of the operator T are reciprocals: $\lambda_i = 1/\mu_i$, $i = 1,2,\ldots$; problem (3.3) and the operator T have the same eigenvectors u_i. Likewise, the eigenvalues of problem (3.4) and of the operator $\tilde{T}$ are reciprocals: $\tilde{\lambda}_i = 1/\tilde{\mu}_i$, $i = 1,2,\ldots,n$; problem (3.4) and the operator $\tilde{T}$ have the same eigenvectors $\tilde{u}_i$. As in the previous section, we choose $\{u_i\}$ and $\{\tilde{u}_i\}$ to be orthonormal systems, in the context of the present section, that is, in H_B.

The FEM approximation of eigenvalue problems for symmetric differential operators can be viewed as a variational Ritz method, and the FEM eigenvalue errors can be estimated using the theorems of the previous section.

We can utilize Theorems 2.4 and 2.7, applied to T and $\tilde{T}$ on H_B, to estimate the eigenvalue error $(\tilde{\lambda}_i - \lambda_i)/\tilde{\lambda}_i$. Here $U_{1,\dots,j}$ denotes the span of the eigenvectors $u_1, \dots, u_j$, and $P_{1,\dots,j}$ is the H_B orthogonal projector onto $U_{1,\dots,j}$.

THEOREM 3.1. *For $j = 1, \dots, n = \dim \tilde{U}$ we have*

$$0 \le \frac{\tilde{\lambda}_j - \lambda_j}{\tilde{\lambda}_j} \le \sin^2 \angle_B\{U_{1,\dots,j}; \bar{U}\} = \|(I - \tilde{Q})P_{1,\dots,j}\|_B^2. \tag{3.7}$$

Remark 3.1. By analogy with Remark 2.1, from Theorem 3.1 we get the following estimate, mathematically equivalent to estimate (2.7):

$$0 \le \frac{\tilde{\lambda}_j - \lambda_j}{\tilde{\lambda}_j} \le \sum_{i=1}^{j} \|(I - \tilde{Q})u_i\|_B^2,$$

which can be rewritten as

$$0 \le \frac{\tilde{\lambda}_i - \lambda_i}{\lambda_i} \le \frac{\sum_{i=1}^{j} \|(I - \tilde{Q})u_i\|_B^2}{1 - \sum_{i=1}^{j} \|(I - \tilde{Q})u_i\|_B^2}, \tag{3.8}$$

assuming that the denominator in the latter expression is positive. Estimate (3.8) is well known (see, e.g., Theorem 2.1 in Chapter 4 of [22]); a similar estimate is proved in [5].

To formulate the next theorem—an analogue of Theorem 2.7—we recall that $\tilde{P}_{1,\dots,j-1}$ is the orthogonal projector of H_B onto $\tilde{U}_{1,\dots,j-1} = \operatorname{span}\{\tilde{u}_1, \dots, \tilde{u}_{j-1}\}$, where $\tilde{u}_i$ are eigenvectors of (3.4).

THEOREM 3.2. *For a fixed index j such that $1 \le j \le n = \dim \tilde{U}$, suppose*

$$\min_{1,\dots,j-1} |\tilde{\lambda}_i - \lambda_j| \neq 0. \tag{3.9}$$

Then

$$\begin{aligned} 0 \le \frac{\tilde{\lambda}_j - \lambda_j}{\tilde{\lambda}_j} &\le \|(I - \tilde{Q} + \tilde{P}_{1,\dots,j-1})u_j\|_B^2 \\ &\le \left(1 + \max_{i=1,\dots,j-1} \frac{\tilde{\lambda}_i^2 \lambda_j^2}{|\tilde{\lambda}_i - \lambda_j|^2} \|(I - \tilde{Q})T\tilde{P}_{1,\dots,j-1}\|_B^2\right) \sin^2 \angle_B\{u_j; \tilde{U}\}. \end{aligned} \tag{3.10}$$

Similarly, we can apply Theorem 2.11 to obtain the following.

THEOREM 3.3. *For fixed indexes j and m satisfying $1 \le j \le n$ and $1 \le m \le j$, let $U_{j-m+1,\dots,j}$ be the m-dimensional invariant subspace corresponding to eigenvalues $\lambda_j \ge \cdots \ge \lambda_{j-m+1}$, and let $P_{j-m+1,\dots,j}$ be the H_B orthogonal projector on $U_{j-m+1,\dots,j}$. If*

$$\min_{i=1,\dots,j-m} |\tilde{\lambda}_i - \lambda_j| \neq 0, \tag{3.11}$$

then

$$\begin{aligned} 0 \le \frac{\tilde{\lambda}_j - \lambda_j}{\tilde{\lambda}_j} &\le \|(I - \tilde{Q} + \tilde{P}_{1,\dots,j-m})P_{j-m+1,\dots,j}\|_B^2 \\ &\le \left(1 + \max_{i=1,\dots,j-m} \frac{\tilde{\lambda}_i^2 \lambda_j^2}{|\tilde{\lambda}_i - \lambda_j|^2} \|(I - \tilde{Q})T\tilde{P}_{1,\dots,j-m}\|_B^2\right) \|(I - \tilde{Q})P_{j-m+1,\dots,j}\|_B^2, \end{aligned} \tag{3.12}$$

where $\tilde{P}_{1,\dots,j-m}$ *is the* H_B *orthogonal projector onto* $\tilde{U}_{1,\dots,j-m} = \operatorname{span}\{\tilde{u}_1, \dots, \tilde{u}_{j-m}\}$ *(if* $j = m$*, we set* $\tilde{P}_{1,\dots,j-m} = 0$ *and do not use* (3.11)*). If* $m = j$*, the present theorem turns into Theorem* 3.1*; if* $m = 1$*, it turns into Theorem* 3.2*.*

Let us finally reformulate Theorem 3.3 in the context of the multiple eigenvalue by analogy with Corollary 2.12.

Corollary 3.4. *Suppose that the eigenvalue* λ_p*, where* $p > 1$*, has multiplicity* $q > 1$*, so that*

$$\lambda_{p-1} < \lambda_p = \lambda_{p+1} = \cdots = \lambda_{p+q-1} < \lambda_{p+q} \tag{3.13}$$

holds, and that $p + q - 1 \le n$*. Suppose that*

$$\min_{i=1,\dots,p-1} |\tilde{\lambda}_i - \lambda_p| \neq 0.$$

Then, for $j = p, \dots, p + q - 1$*, we have*

$$0 \le \frac{\tilde{\lambda}_j - \lambda_p}{\tilde{\lambda}_j} \le \|(I - \tilde{Q} + \tilde{P}_{1,\dots,p-1})P_{p,\dots,j}\|_B^2$$

$$\le \left(1 + \max_{i=1,\dots,p-1} \frac{\tilde{\lambda}_i^2 \lambda_p^2}{|\tilde{\lambda}_i - \lambda_p|^2} \|(I - \tilde{Q})T\tilde{P}_{1,\dots,p-1}\|_B^2\right) \|(I - \tilde{Q})P_{p,\dots,j}\|_B^2, \tag{3.14}$$

where $\tilde{P}_{1,\dots,p-1}$ *is the* H_B *orthogonal projector onto* $\tilde{U}_{1,\dots,p-1} = \operatorname{span}\{\tilde{u}_1, \dots, \tilde{u}_{p-1}\}$ *and* $P_{p,\dots,j}$ *is the* H_B *orthogonal projector onto any* $(j - p + 1)$*-dimensional subspace of the eigenspace* $U_{p,\dots,p+q-1}$ *corresponding to the eigenvalue* λ_p*. The main term, the multiplier* $\|(I-\tilde{Q})P_{p,\dots,j}\|_B^2$*, in* (3.14) *can be replaced with* $\sin^2 \angle_{j-p+1}\{U_{p,\dots,p+q-1}, \tilde{U}\}$ *by choosing the projector* $P_{p,\dots,j}$ *in the optimal way, where the angle is measured in* H_B*.*

3.2. Comparison with known asymptotic estimates for eigenvalues. Estimate (3.10) should be compared with estimates of Vainikko in Krasnosel'skii et al. [16], Chatelin [7], and Babuška and Osborn [3], all of which address a slightly different context that we now describe.

In addition to all assumptions of the previous subsection, let $\{U^h\}$ be a family of finite-dimensional subspaces of H_B depending on a parameter $h > 0$ called the mesh parameter. For a fixed h, we use $U^h = \tilde{U}$ as the trial subspace for the variational Ritz method. Let $Q^h = \tilde{Q}$ be the H_B orthogonal projector on U^h. We make the following approximability assumption on the family $\{U^h\}$:

$$\|(I - Q^h)u\|_{H_B} = \inf_{v^h \in U^h} \|u - v^h\|_{H_B} \to 0 \quad \text{as } h \to 0 \quad \text{for each } u \in H_B. \tag{3.15}$$

To be consistent with our new h-based notation, we denote the approximate eigenvalues by $\lambda_j^h = \tilde{\lambda}_j$ and the corresponding eigenvectors by $u_j^h = \tilde{u}_j$. It is well known that under assumption (3.15) we have $\lambda_j^h \to \lambda_j$ as $h \to 0$ for each fixed j.

We compare our results to estimates of [3, 7, 16] that are asymptotic, $h \to 0$, upper (and lower) bounds for the ratio $(\lambda_j^h - \lambda_j)/\lambda_j^h$ in [7, 16] and for the ratio $(\lambda_j^h - \lambda_j)/\lambda_j$ (notice a slightly different denominator) in [3]. Since

$$\frac{\lambda_j^h - \lambda_j}{\lambda_j} = \frac{\lambda_j^h - \lambda_j}{\lambda_j^h} + \frac{(\lambda_j^h - \lambda_j)^2}{\lambda_j \lambda_j^h},$$

where the second term in the sum on the right can be asymptotically ignored, the results of [7, 16] asymptotically estimate the same eigenvalue errors as those of [3]. Results of [3] provide upper bounds for $(\lambda_j^h - \lambda_j)/\lambda_j$ that trivially serve also as upper bounds for $(\lambda_j^h - \lambda_j)/\lambda_j^h$. Moreover, it is possible to show that the lower bounds for $(\lambda_j^h - \lambda_j)/\lambda_j$ in [3] also hold for $(\lambda_j^h - \lambda_j)/\lambda_j^h$ without any changes. Here, we will formulate all the results (except for (3.23)) in terms of $(\lambda_j^h - \lambda_j)/\lambda_j^h$ to be consistent with our estimates.

We start our discussion with the case of a simple eigenvalue λ_j and later turn our attention to the case of multiple eigenvalues. The convergence rate for a simple eigenvalue is determined by the following well-known result: let real r_j^h be defined by

$$0 \le \frac{\lambda_j^h - \lambda_j}{\lambda_j^h} = \left(1 + r_j^h\right) \|(I - Q^h)u_j\|_B^2; \tag{3.16}$$

then $r_j^h \to 0$ as $h \to 0$; see subsection 18.6 (pp. 285–286) of [16] and subsection 6.2 (pp. 315–317) of [7]. Babuška and Osborn [3] showed that

$$|r_j^h| \le d_j \sup_{\|g\|_D = 1} \|(I - Q^h)Tg\|_B^2 \to 0 \tag{3.17}$$

and that (cf. (2.9))

$$|r_j^h| \le d_j \sup_{\|g\|_B = 1} \|(I - Q^h)Tg\|_B \to 0, \tag{3.18}$$

where $d_j > 0$ are unknown generic constants.

Our present estimate (3.10) using the h notation takes the form (3.16) with

$$r_j^h \le \max_{i=1,\dots,j-1} \frac{(\lambda_i^h)^2 \lambda_j^2}{|\lambda_i^h - \lambda_j|^2} \|(I - Q^h)TP_{1,\dots,j-1}^h\|_B^2. \tag{3.19}$$

The first multiplier in the right-hand side of (3.19) is asymptotically (as $h \to 0$) a constant,

$$\frac{(\lambda_i^h)^2 \lambda_j^2}{|\lambda_i^h - \lambda_j|^2} \to \frac{\lambda_{j-1}^2 \lambda_j^2}{|\lambda_{j-1} - \lambda_j|^2},$$

provided that the eigenvalue λ_j is simple. The second multiplier is bounded by

$$\begin{aligned} \|(I - Q^h)TP_{1,\dots,j-1}^h\|_B^2 &\le \|(I - Q^h)T\|_B^2 \\ &= \sup_{\|g\|_B = 1} \|(I - Q^h)Tg\|_B^2 \\ &\le \frac{1}{\lambda_1} \sup_{\|g\|_D = 1} \|(I - Q^h)Tg\|_B^2; \end{aligned}$$

thus, our estimate (3.19) is an improvement of both estimates (3.17) (our constant is explicitly written) and (3.18) (we have the small multiplier squared) of [3]. However, our estimate (3.19) provides only an upper bound for r_j^h, while (3.17) and (3.18) also give the lower bounds because they estimate the absolute value $|r_j^h|$. Let us note that the denominator $|\lambda_{j-1} - \lambda_j|^2$ may be small, but the term in the numerator is bounded from above by a constant times $\sup_{\|g\|_D = 1} \|(I - Q^h)Tg\|_B^2 \to 0$ as $h \to 0$.

Now suppose eigenvalue λ_p has multiplicity q so that (3.13) holds, and let $P_{p,\dots,p+q-1}$ be the H_B orthogonal projector on the q-dimensional eigenspace, corresponding to $\lambda_p = \lambda_{p+1} = \cdots = \lambda_{p+q-1}$ as in Corollary 3.4 in subsection 18.6 (pp. 285–286) of Krasnosel'skii et al. [16] and Chatelin in subsection 6.2 (pp. 315–317) of [7] prove that

$$0 \le \frac{\lambda_j^h - \lambda_p}{\lambda_j^h} = \left(1 + r_j^h\right) \frac{\|(I - Q^h) P_{p,\dots,p+q-1} u_j^h\|_B^2}{\|P_{p,\dots,p+q-1} u_j^h\|_B^2}, \qquad j = p, \dots, p+q-1, \tag{3.20}$$

where $r_j^h \to 0$ as $h \to 0$. An evident difficulty in using estimate (3.20) for a priori error analysis is that the approximate eigenfunctions u_{j+i-1}^h are not known a priori. If we consider the worst case, it leads to the estimate, which bounds the error for all q Ritz values, using

$$\|(I - Q^h) P_{p,\dots,p+q-1}\|_B^2 = \sin^2 \angle\{U_{p,\dots,p+q-1}; U_h\}. \tag{3.21}$$

Let us remind the reader that an angle without an index denotes the largest angle, according to our agreement in subsection 2.2, and that in this and the previous subsections all angles are measured in H_B.

In some cases (see [2, 4] for examples), the eigenspace may be spanned by eigenfunctions of different approximation qualities, and it is interesting to analyze how this affects the error for different Ritz values. As mentioned in the introduction, such results were first proved by Babuška and Osborn in [2]. In [3], they completed such an analysis for the smallest of the q Ritz values, using

$$\inf_{u \in U_{p,\dots,p+q-1},\, \|u\|_B = 1} \|(I - Q^h) u\|_B^2 = \sin^2 \angle_1\{U_{p,\dots,p+q-1}; U_h\}, \tag{3.22}$$

which depends on the approximability of the most easily approximated eigenfunction in the eigenspace. Thus, estimates based on (3.21) and (3.22) represent two extremes: (3.21) uses the largest angle and serves to estimate the largest error (thus effectively all q errors at once), while (3.22) uses the smallest angle and can estimate only one, the smallest, eigenvalue error.

For the intermediate multiple eigenvalue error, Babuška and Osborn in [3] established the following result: for $j = p, \dots, p+q-1$ let the quantities r_j^h be redefined by

$$0 \le \frac{\lambda_j^h - \lambda_p}{\lambda_p} = \left(1 + r_p^h\right) \inf_{\substack{u \in U_{p,\dots,p+q-1}, \\ u \in (U^h_{p,\dots,j-1})^{\perp_B}, \\ \|u\|_B = 1}} \|(I - Q^h) u\|_B^2; \tag{3.23}$$

then

$$|r_j^h| \le d_j \sup_{\|g\|_B = 1} \|(I - Q^h) T g\|_B, \tag{3.24}$$

with generic constants $d_j > 0$, and where the orthogonal complement $\left(U^h_{p,\dots,j-1}\right)^{\perp_B}$ is taken in H_B. In [4], it is shown that r_j^h in (3.23) are bounded, but more detailed estimates (3.24) appear only in [3].

We note that the constraints on u in (3.23) are similar to those in (2.25) except that (2.25) involves orthogonalization to all previous Ritz vectors, while (3.23) needs only orthogonalization to previous Ritz vectors corresponding to the multiple eigenvalue under consideration. Both (2.25) and (3.23) are not truly a priori estimates since their right-hand sides depends on Ritz vectors that are not known a priori.

In contrast, our estimate (3.14) can be formulated as follows: let for $j = p, \dots, p + q - 1$ the quantities r_j^h be yet again redefined by

$$0 \le \frac{\lambda_j^h - \lambda_p}{\lambda_j^h} = \left(1 + r_j^h\right) \sin^2 \angle_{j-p+1}\{U_{p,\dots,p+q-1}, U^h\}; \tag{3.25}$$

then

$$r_j^h \le \max_{i=1,\dots,p-1} \frac{(\lambda_i^h)^2 \lambda_p^2}{|\lambda_i^h - \lambda_p|^2} \|(I - Q^h) T P_{1,\dots,p-1}^h\|_B^2.$$

We have already shown that our upper bound for r_p^h is better than that given by estimate (3.24): the constant is explicitly written and the h-dependent part is smaller. Let us turn our attention to the main term of the right-hand side of (3.25), namely, the $\sin^2 \angle_{j-p+1}\{U_{p,\dots,p+q-1}, U^h\}$ multiplier, and demonstrate that it is smaller than the main term of the right-hand side of (3.23) and that it can be easily estimated from above using (2.5).

We first highlight again that this multiplier can be estimated a priori since it does not depend on Ritz vectors, contrary to the main term of estimate (3.23). Second, we can directly compare the main terms in (3.23) and (3.25). Indeed, by (2.4), and since $\dim\{\left(U_{p,\dots,j-1}^h\right)^\perp \cap U_{p,\dots,p+q-1}\} \ge j - p + 1$, we have for $j = p, \dots, p + q - 1$:

$$\begin{aligned}
\sin^2 \angle_{j-p+1}\{U_{p,\dots,p+q-1}, U^h\} &= \inf_{L \subseteq U_{p,\dots,p+q-1},\, \dim L = j-p+1} \sin^2 \angle\{L; U^h\} \\
&\le \sin^2 \angle\{\left(U_{p,\dots,j-1}^h\right)^\perp \cap U_{p,\dots,p+q-1}; U^h\} \\
&= \inf_{\substack{u \in U_{p,\dots,p+q-1}, \\ u \in \left(U_{p,\dots,j-1}^h\right)^\perp, \\ \|u\|_B = 1}} \|(I - Q^h) u\|_B^2,
\end{aligned}$$

so our estimate (3.25) is sharper than (3.23).

Using the term $\sin^2 \angle_{j-p+1}\{U_{p,\dots,p+q-1}, U^h\}$ has yet another advantage: namely, it permits the application of (2.5). Suppose the vectors $\{u_i, i = p, \dots, p + q - 1\}$ form an orthogonal basis for the subspace $U_{p,\dots,p+q-1}$ and are arranged in such a way that

$$\angle\{u_p; U^h\} \le \cdots \le \angle\{u_{p+q-1}; U^h\}.$$

Then, by (2.5),

$$\sin^2 \angle_{j-p+1}\{U_{p,\cdots,p+q-1}; U^h\} \le \sum_{i=p}^{j} \sin^2 \angle\{u_i; U^h\}, \qquad j = p, \dots, p + q - 1.$$

In other words, if the eigenspace $U_{p,\dots,p+q-1}$ is spanned by eigenfunctions of different approximation qualities, our result assesses the quality of each of the Ritz values corresponding to the multiple eigenvalue.

Conclusions. We derive eigenvalue error bounds for the Ritz method that have several novel features:

- For a simple eigenvalue, our estimates improve those previously known and provide explicit values for all constants.

- For a multiple eigenvalue we prove, in addition, what is apparently the first truly a priori error estimates that show the levels of the eigenvalue errors depending on approximability of eigenfunctions in the corresponding eigenspace.
- For clustered eigenvalues, our results provide elegant eigenvalue error bounds that do not depend on the width of the cluster.

In the FEM eigenvalue approximation context, our results improve earlier known results and are readily applicable for a fixed mesh without making the traditional assumption about the mesh size being small enough.

SHARP CONVERGENCE ESTIMATES FOR THE PRECONDITIONED STEEPEST DESCENT METHOD FOR HERMITIAN EIGENVALUE PROBLEMS*

E. E. OVTCHINNIKOV†

Abstract. The paper is concerned with convergence estimates for the preconditioned steepest descent method for the computation of the smallest eigenvalue of a Hermitian operator. Available estimates are reviewed and new estimates are introduced that improve on the known ones in certain respects. In addition to the estimates for the error reduction after one iteration, we consider estimates for the so-called asymptotic convergence factor defined as the upper limit of the average error reduction per iteration. The paper focuses on sharp estimates, i.e., those that cannot be improved without using additional information.

Key words. eigenvalue computation, preconditioning, steepest descent, convergence estimates

1. Introduction.

The steepest descent method is a classical method for finding minima of smooth real-valued functionals that is based on the following simple and natural idea. Let $\psi(v)$ be a real-valued smooth functional in a Euclidean space $\mathcal{E}$, which we for the moment assume for simplicity to be real. Given an approximation u^i to the minimum point u of $\psi(v)$, we look for the next approximation u^{i+1} in the direction in which $\psi(v)$ decreases faster than in any other direction. Since $\psi(v)$ is assumed to be smooth, this steepest descent direction is opposite to the direction of the gradient of $\psi(v)$ at $v = u^i$, which we denote $\nabla\psi(u^i)$. Hence, we arrive at the iterative scheme

$$u^{i+1} = u^i - \omega_i \nabla\psi(u^i), \tag{1.1}$$

where ω_i are suitably chosen parameters. A natural choice for ω_i is the minimum argument of $\psi_i(\omega) \equiv \psi(u^i - \omega\nabla\psi(u^i))$, and it is this particular choice that has become associated with the term "steepest descent method."[1]

The steepest descent method can be used to solve the linear system $Lu = f$ with a Hermitian positive definite operator L owing to the fact that the solution u of this system minimizes the functional $\phi(v) = (Lv, v) - 2(v, f)$. It can also be used to find the smallest eigenvalue λ_1 of a Hermitian operator L, which minimizes the Rayleigh quotient functional $\lambda(v) = (Lv, v)/(v, v)$.

The gradient of a functional ψ at a point v is orthogonal to the level set of ψ to which v belongs, i.e., the set of w such that $\psi(w) = \psi(v)$. Hence, one way to understand the convergence behavior of the steepest descent method is to analyze the shape of the level sets. In the case of the linear system $Lu = f$ with a Hermitian positive definite L, we have $\psi(v) = \phi(v) = \phi(u) + (L(v-u), (v-u))$, and hence each

†University of Westminster, London HA1 3TP, UK (eeo@wmin.ac.uk).

[1] A more proper term would be "locally optimal steepest descent method" because "steepest" actually refers to the direction of the descent rather than to any particular point in that direction. In this paper the term "steepest descent" is used in the general sense in order to cover the results in [1] and [7, 8], which are given for a different choice of ω_i.

level set is an ellipsoid with the center at u and the axes collinear to the eigenvectors u_j of L. The respective lengths of the semiaxes are $1/\sqrt{\lambda_j}$, where λ_j are the respective eigenvalues. If the condition number of L; i.e., the ratio λ_{-1}/λ_1 of the largest eigenvalue[2] λ_{-1} to λ_1 is large then the level sets of $\phi(u)$ in the plane $\operatorname{span}\{u_1, u_{-1}\}$ look like those of a very narrow ravine, and the convergence can be slow. Indeed, if we take $u^0 = u + (1/\lambda_1)u_1 + (1/\lambda_{-1})u_{-1}$ as the initial guess and use locally optimal ω_i, then the iterates u^i approach u zigzagging across the bottom of the "ravine" (the axis collinear to u_1), and the convergence is slow.

Introducing a new scalar product in $\mathcal{E}$ changes the geometry of this space and hence the shape of the level sets of functionals. Indeed, if we introduce the scalar product $(\cdot,\cdot)_L = (L\cdot,\cdot)$ and the corresponding norm $\|\cdot\|_L = (\cdot,\cdot)_L^{1/2}$, then $\phi(v) = \phi(u) + \|v-u\|_L^2$, i.e., the level sets are spherical, and hence the steepest descent direction at any $u^0 \in \mathcal{E}$ points to the solution u. In the general case, if we use the scalar product $(\cdot,\cdot)_N$, where N is a Hermitian positive definite operator, then the shape of the level sets depends on the condition number of $N^{-1}L$: the smaller the condition number, the closer the level sets to spherical, and hence the faster the convergence. Denoting $K = N^{-1}$, we have in the above scalar product $\nabla\phi(u) = 2K(Lu - f)$, and the iterative scheme (1.1) becomes what is known as the preconditioned steepest descent (PSD):

$$u^{i+1} = u^i - \tau_i K r^i, \quad r^i = Lu^i - f. \tag{1.2}$$

In a similar way, in the case of the functional $\lambda(u)$ we arrive at the iterative scheme

$$u_1^{i+1} = u_1^i - \tau_i K r_1^i, \quad r_1^i = (L - \lambda_1^i)u_1^i, \tag{1.3}$$

where u_1^i approximate u_1, $\lambda_1^i = \lambda(u_1^i)$, and τ_i minimizes $\lambda^i(\tau) \equiv \lambda(u_1^i - \tau K r_1^i)$.

Since $Kr^i = KLu^i - Kf$, (1.2) can be viewed as an iterative scheme for solving the system $KLu = Kf$. This a more familiar interpretation of the preconditioning for a linear system that also explains the terminology: K (or, sometimes $N = K^{-1}$) is called the preconditioner because the multiplication of the system by K changes the condition number of this system. In the case of an eigenvalue problem, however, such an interpretation is not very helpful because the multiplication of $Lu = \lambda u$ by K results in $KLu = \lambda K u$, and it is not so obvious why the solution of the latter generalized eigenvalue problem is any easier than that of the former standard eigenvalue problem. Turning to the above geometrical interpretation and assuming λ_1 to be simple, we observe first that the level sets of $\lambda(v)$ in the vicinity of u_1 are coaxial cones with the axis collinear to u_1 and ellipsoidal cross-sections. Considerations similar to the above suggest that the speed of convergence of the steepest descent iterations is determined by the "roundness" of the level sets, which is reflected by the "roundness" of their orthogonal cross-sections. It is not difficult to see that if v lies in an orthogonal cross-section, i.e., $v - u_1$ is orthogonal to an eigenvector u_1 corresponding to λ_1, then

$$\begin{aligned}\lambda(v) &= \lambda_1 + ((L-\lambda_1)(v-u_1),(v-u_1)) + \mathcal{O}\left(\|v-u_1\|^4\right)\\ &= \lambda_1 + (K(L-\lambda_1)(v-u_1),(v-u_1))_N + \mathcal{O}\left(\|v-u_1\|^4\right).\end{aligned}$$

Hence, one is led to the conclusion that asymptotically the convergence of (1.3) is determined by the condition number of the operator $K(L-\lambda_1)$ restricted to the

[2] In using this negative index for the largest eigenvalue we follow the notation of [13].

subspace orthogonal to u_1, and indeed, the asymptotic estimate from [14] shows that this is the case.

The nonasymptotic quantitative convergence analysis of the preconditioned steepest descent method for eigenvalue problems proved to be much more difficult than the above simple considerations and several decades had passed before a nonasymptotic convergence result equivalent to that in [14] was obtained. A comprehensive review of the convergence results that were obtained in those decades can be found in [1]—in this paper we only mention some of them, focusing on their accuracy. Special attention is paid to the convergence estimates that are *sharp*, i.e., cannot be improved without using additional information. Such estimates have obvious theoretical importance, being pieces of ultimate knowledge about the convergence properties of the PSD method. Recent research in which the author takes part suggests that the accuracy of the convergence estimates for PSD may be of indirect practical importance, as these estimates can be employed in the *a posteriori* error estimation. It is observed in [4] that $\tilde{\lambda}_1 - \lambda_1 \le (\tilde{\lambda}_1 - \lambda_{PSD})/(1 - q_{PSD})$, where $\tilde{\lambda}_1$ is an approximation to λ_1, λ_{PSD} is the new approximation to λ_1 computed by the PSD method and q_{PSD} is the upper bound for the eigenvalue error reduction after one PSD iteration. Hence, the accuracy of the bound q_{PSD} affects the accuracy of the above eigenvalue error estimate.

In this paper we show that the convergence estimate in [14] is asymptotically sharp, i.e., the main term in the error bound it provides cannot be made smaller without using additional information. We show that the same holds for some other available convergence results. Further, we present sharp estimates for the so-called *asymptotic convergence factor* (cf. section 5), which, in a sense, represents the average error reduction per iteration, and, in this particular respect, gives one a better idea about the long-term convergence behavior than the worst error reduction after one iteration. Finally, we present new sharp nonasymptotic convergence estimates and compare them with the available ones.

It should be noted that the results of this paper can also be applied to the PSD for the generalized eigenvalue problem $\hat{L}\hat{u} = \lambda \hat{M}\hat{u}$ with Hermitian $\hat{L}$ and Hermitian positive definite $\hat{M}$. Indeed, the gradient of the Rayleigh quotient $\hat{\lambda}(\hat{v}) = (\hat{L}\hat{v}, \hat{v})/(\hat{M}\hat{v}, \hat{v})$ in the scalar product $(\hat{K}^{-1}\cdot, \cdot)$ is proportional to $\hat{K}(\hat{L} - \hat{\lambda}(\hat{v})\hat{M})\hat{v}$ and hence the iterations (1.1) become

$$\hat{u}_1^{i+1} = \hat{u}_1^i - \tau_i \hat{K}\hat{r}_1^i, \quad \hat{r}_1^i = (\hat{L} - \hat{\lambda}(\hat{u}_1^i)\hat{M})\hat{u}_1^i. \tag{1.4}$$

Denoting $u_1^i = \hat{M}^{1/2}\hat{u}_1^i$, $L = \hat{M}^{-1/2}\hat{L}M^{-1/2}$, and $K = \hat{M}^{1/2}\hat{K}\hat{M}^{1/2}$ we have $\hat{\lambda}(\hat{u}_1^i) = \lambda(u_1^i)$ and $\hat{K}\hat{r}_1^i = \hat{M}^{-1/2}Kr_1^i$ and hence (1.4) transforms into (1.3).

The outline of the paper is as follows. In section 2 we discuss the very first convergence result for the iterations (1.3), obtained in asymptotic form by Samokish [14], and its remarkable features, in particular, its relation to the superlinearly convergent (exact) Jacobi–Davidson method [15]. In section 3 we review and compare some available nonasymptotic convergence results. In section 4 we analyze the asymptotic accuracy of the estimate by Samokish and two nonasymptotic estimates: one by Knyazev in [5] and the other by the author in [11]. We show that all three are asymptotically sharp under their respective assumptions by providing for each a simple example whereby the ratio of the two consecutive eigenvalue errors asymptotically coincide with its theoretical upper limit given in the respective estimate. In section 5 we strengthen the above asymptotical sharpness results by showing that in each case the aforementioned ratio remains asymptotically close to its upper limit at all iterations. In section 6 we introduce new sharp convergence estimates using what appears to be a novel approach to the convergence analysis of the PSD iterations (1.3). We introduce a Hermitian positive definite operator that maps the residual vector onto the error vector $u_1^i - \omega u_1$, where ω is a nonzero scalar, and we estimate the reduction in the eigenvalue error after one iteration (1.3) via the closeness of the preconditioner to the above "ideal" preconditioner. We note that in the case where L is positive definite, the closeness of K to the "ideal" preconditioner can be easily estimated via the condition number of KL, thus producing a convergence result given in more familiar terms. Finally, in section 7 we consider some block versions of the PSD method and discuss available convergence results. Using the asymptotical results of sections 4 and 5, we show that the convergence estimate for a particular block version of PSD obtained by the author in [12] is asymptotically sharp.

In the paper we enumerate the eigenvalues λ_i in increasing order and, apart form section 7, without taking multiplicity into account, i.e, λ_2 is the second *distinct* eigenvalue etc. The eigenvectors are assumed to be normalized. As already specified above, the operator L is assumed to be Hermitian and, for some results, positive definite. The preconditioner K is always assumed to be Hermitian positive definite. Below, $\mathcal{E}$ is no longer assumed to be real.

2. The estimate by Samokish.

The first convergence result for the iterations (1.3) in a Hilbert space was obtained in 1958 by B. A. Samokish[3] [14]. For the reader's convenience, this result is reproduced below in the nonasymptotic form and in the finite-dimensional (Euclidean) case.

THEOREM 2.1. *Let κ_1 and κ_{-1} be, respectively, the smallest positive and largest eigenvalue of $K(L-\lambda_1)$. Denote $\epsilon_i = \sqrt{\|K\|(\lambda_1^i - \lambda_1)}$, where $\lambda_1^i = \lambda(u_1^i)$ and the sequence u_1^i is generated by* (1.3) *with locally optimal τ_i. If*

$$\tau(\sqrt{\kappa_{-1}} + \epsilon_i)\epsilon_i < 1, \tag{2.1}$$

where $\tau = 2/(\kappa_1 + \kappa_{-1})$, then

$$\lambda_1^{i+1} - \lambda_1 \le \left(\frac{\gamma_1 + \tau\sqrt{\kappa_{-1}}\epsilon_i}{1 - \tau(\sqrt{\kappa_{-1}} + \epsilon_i)\epsilon_i} \right)^2 (\lambda_1^i - \lambda_1), \tag{2.2}$$

where

$$\gamma_1 = \frac{1-\xi_1}{1+\xi_1}, \quad \xi_1 = \frac{\kappa_1}{\kappa_{-1}}. \tag{2.3}$$

Proof. Denote $L_1 = L - \lambda_1$, $u = u_1^i$, $\lambda = \lambda_1^i$, $r = (L-\lambda)u$, $u' = u_1^{i+1}$, $\lambda' = \lambda_1^{i+1}$ and $\epsilon = \epsilon_i$, and assume $\|u\| = 1$. We have

$$u' = u - \tau K r = (1 - \tau K L_1)u + \tau(\lambda - \lambda_1)Ku. \tag{2.4}$$

It is easy to see that

$$\|(1 - \tau K L_1)v\|_{L_1}^2 \le \gamma_1 \|v\|_{L_1}^2 \tag{2.5}$$

[3] Essentially the same estimate was later reproduced independently in [10] in the context of the generalized Davidson method and in the finite-dimensional case (cf. [11]).

and that $\|v\|_{L_1}^2 = (\lambda(v) - \lambda_1)\|v\|^2$. Hence,

$$\begin{aligned}\|u'\|_{L_1} = \sqrt{\lambda' - \lambda_1}\|u'\| &\leq \gamma_1\|u\|_{L_1} + \tau(\lambda - \lambda_1)\|Ku\|_{L_1} \\ &\leq \gamma_1\sqrt{\lambda - \lambda_1} + \tau(\lambda - \lambda_1)\sqrt{\kappa_{-1}}\|u\|_K \\ &\leq \gamma_1\sqrt{\lambda - \lambda_1} + \tau(\lambda - \lambda_1)\sqrt{\kappa_{-1}\|K\|} \\ &= (\gamma_1 + \tau\sqrt{\kappa_{-1}}\epsilon)\sqrt{\lambda - \lambda_1}.\end{aligned}$$

Since $\|u'\| \geq 1 - \tau\|Kr\|$, it remains to estimate $\|Kr\|$. We have $r = (L - \lambda)u = L_1 u - (\lambda - \lambda_1)u$, and hence

$$\begin{aligned}\|Kr\| \leq \|KL_1u\| + (\lambda - \lambda_1)\|Ku\| &\leq \sqrt{\|K\|}\|L_1u\|_K + (\lambda - \lambda_1)\|K\| \\ &\leq \sqrt{\kappa_{-1}\|K\|}\|u\|_{L_1} + (\lambda - \lambda_1)\|K\| = \sqrt{\kappa_{-1}}\epsilon + \epsilon^2,\end{aligned}$$

and we arrive at (2.2). □

The above simple estimate, obtained by Samokish in the asymptotic form, is a very remarkable one. First of all, it is the first ever convergence estimate for an iterative method for eigenvalue problems using what is essentially the preconditioning technique in all but name.[4] At the same time, as we will see in the next section, until quite recently it remained asymptotically more accurate than any of the estimates for the PSD method that have been obtained ever since. Another remarkable feature of (2.2) is its similarity to the convergence estimate for the PSD method for linear systems. Indeed, in the case of the degenerate system $(L - \lambda_1)u = f$ we have

$$\|u^{i+1} - u\|_{L-\lambda_1} \leq \gamma_1\|u^i - u\|_{L-\lambda_1}, \tag{2.6}$$

whereas in the case of the eigenvalue problem $Lu = \lambda u$ we have (cf. the proof of Theorem 2.1):

$$\|u_1^{i+1} - u_1\|_{L-\lambda_1} \leq \gamma_1\|u_1^i - u_1\|_{L-\lambda_1} + \mathcal{O}\left(\|u_1^i - u_1\|_{L-\lambda_1}^2\right).$$

Yet another remarkable fact about (2.2) is that until quite recently it remained the only estimate for the preconditioned steepest descent that predicted superlinear convergence for certain preconditioners. Indeed, consider the preconditioner K given by

$$K = (\alpha P_1 + (L - \lambda_1))^{-1}, \tag{2.7}$$

where $\alpha > 0$ and P_1 is the orthogonal projector onto the invariant subspace corresponding to λ_1. We have $\xi_1 = 1$ and hence $\gamma_1 = 0$, and by Theorem 2.1 the convergence of (1.3) is superlinear. We note that the PSD with the preconditioner given by (2.7) (which might be called quasi-optimal since it delivers superlinear convergence) is closely related to the Jacobi–Davidson method [15], whereby $g = Kr_1^i$ is computed by approximately solving the system

$$L_i g \equiv (\alpha P_{1,i} + (1 - P_{1,i})(L - \lambda_1^i)(1 - P_{1,i}))g = r_1^i,$$

where $P_{1,i}$ is the orthogonal projector onto $\operatorname{span}\{u_1^i\}$ and $\alpha > 0$ is an arbitrary parameter.[5] It is easy to see that L_i^{-1} converges to K given by (2.7) as $i \to \infty$,

[4] Strictly speaking the term "preconditioning" should not be used in the context of [14], where the steepest descent is applied to an unbounded operator in a Hilbert space.

[5] It is not difficult to see that g does not depend on α and α may actually be excluded from the computations; this parameter is introduced here merely to make the operator L_i positive definite.

which, in particular, implies that if this system is solved exactly, then the Jacobi–Davidson method converges superlinearly (for the case of inexact solution, see, e.g., [9, 11]; see also [10] where the above is used as a motivation for rediscovering the Samokish estimate).

3. Some other estimates. We have seen above that obtaining an asymptotical convergence estimate for PSD is a relatively simple task. As mentioned in the introduction, obtaining nonasymptotic convergence estimates proved to be much more difficult. Until quite recently one of the best available nonasymptotic convergence results for this method has been the following estimate by D'yakonov and Orekhov [3]: assuming that L is positive definite and that $\lambda_1^i < \lambda_2$, we have

$$\lambda_1^{i+1} - \lambda_1 \le q(\lambda_1^i)(\lambda_1^i - \lambda_1), \tag{3.1}$$

where

$$q(\lambda) = \max\left\{1 - \xi\frac{\lambda_2 - \lambda_1}{\lambda_2}, \frac{1 - \xi\frac{\lambda_2 - \lambda_1^i}{\lambda_2}}{1 + \xi\frac{\lambda_2 - \lambda_1^i}{\lambda_2}\frac{\lambda_1^i - \lambda_1}{\lambda_1}}\right\}, \quad \xi = cond(KL)^{-1}.$$

Compared to (2.2), the above estimate is asymptotically less accurate. Indeed, in the subspace orthogonal to the invariant subspace corresponding to λ_1 we have

$$\frac{\lambda_2 - \lambda_1}{\lambda_2}L \le L - \lambda_1 \le \frac{\lambda_{-1} - \lambda_1}{\lambda_{-1}}L.$$

Hence, $\xi_1 \ge \tilde{\xi}_1$, where

$$\tilde{\xi}_1 = \xi\frac{\lambda_2 - \lambda_1}{\lambda_2}\frac{\lambda_{-1}}{\lambda_{-1} - \lambda_1} \ge \xi\frac{\lambda_2 - \lambda_1}{\lambda_2}, \tag{3.2}$$

and we see that the error reduction factor in (2.2) is asymptotically less than a square of that in (3.1).

Recent papers [7, 8, 6] consider a version of PSD, referred to as PINVIT (for Preconditioned INVerse ITerations), whereby $\tau_i = 1$ and K is scaled so that the smallest and largest eigenvalues of KL are, respectively, $1 - \gamma$ and $1 + \gamma$ for some $\gamma < 1$. A sharp convergence estimate for PINVIT is given in [8]; the explicit form of this estimate is fairly cumbersome, but the two-dimensional analysis in section 5 of [7] implies that it can be formulated as follows:

$$\Delta_k(\lambda^{i+1}) \le q(\gamma, \lambda_k, \lambda_{k+1}, \lambda^i)^2\Delta_k(\lambda^i), \quad \Delta_k(\lambda) = \frac{\lambda - \lambda_k}{\lambda_{k+1} - \lambda}, \tag{3.3}$$

where k is such that $\lambda_k \le \lambda^i < \lambda_{k+1}$ and $q(u, v, w, t)$ is the solution of the equation

$$q = \frac{v}{w} + u\left(1 - \frac{v}{w}\right)\sqrt{\cos^2\alpha + q^2\sin^2\alpha}, \quad \sin^2\alpha = \frac{w}{t}\frac{t - v}{w - v}.$$

If $k = 1$, then, according to (3.3), the error in λ_1 is reduced by a factor that approaches $(\gamma + (1-\gamma)\lambda_1/\lambda_2)^2$ as λ^i approaches λ_1. We observe that the above asymptotic factor is noticeably smaller than that by (3.1), but is still greater than that in (2.2).

The next estimate of this section is a particular case of the estimate of Theorem 3.3 in [5]. Assuming that $\lambda_1^i < \lambda_2$ we have

$$\Delta_1(\lambda_1^{i+1}) \le \left(1 - (1 - \tilde{\gamma}_1^2)\max\{\xi, g_i\}\right)\Delta_1(\lambda_1^i), \quad \tilde{\gamma}_1 = \frac{1 - \tilde{\xi}_1}{1 + \tilde{\xi}_1}, \tag{3.4}$$

where $\Delta_1(\lambda)$ is the same as in (3.3), $\tilde{\xi}_1$ is given by (3.2), and

$$g_i = (1 + \eta\tilde{\gamma}_1^2\epsilon_i)^{-1}\left(1 + \frac{\eta^2\xi\epsilon_i}{4}\right)^{-1}\left(1 + \eta\sqrt{\frac{\tilde{\gamma}_1^2\epsilon_i}{\xi + (\tilde{\gamma}_1^2 - \xi)\epsilon_i}}\right)^{-1},$$

where $\eta = \xi^{-1} - 1$ and $\epsilon_i = (\lambda_2/\lambda_1^i)(\lambda_1^i - \lambda_1)/(\lambda_2 - \lambda_1)$. By the above estimate, the error in λ_1 is reduced after each iteration by a factor that approaches $\tilde{\gamma}_1^2$ as $i \to \infty$. This asymptotic factor is smaller than those in the previous two estimates. Still, the estimate (3.4) is less accurate than (2.2) in the sense that $\tilde{\gamma}_1 \geq \gamma_1$ and, furthermore, $\tilde{\gamma}_1$ is always positive, whereas $\gamma_1 = 0$; e.g., for K given by (2.7).

The last convergence result of this section approaches the estimate by Samokish much closer than any of the above: assuming $\lambda_1^i < \lambda_2$, and denoting by $\kappa_{-1,\alpha}$ the largest eigenvalue of $K(\alpha P_1 + (L - \lambda_1))$, we have [11]

$$\lambda_1^{i+1} - \lambda_1 \leq \gamma_{1,i,\alpha}^2(\lambda_1^i - \lambda_1), \tag{3.5}$$

where

$$\gamma_{1,i,\alpha} = \frac{1 - \xi_{1,\alpha}(1 - \epsilon_i)}{1 + \xi_{1,\alpha}(1 - \epsilon_i)}, \quad \xi_{1,\alpha} = \frac{\kappa_1}{\kappa_{-1,\alpha}},$$

$$\epsilon_i = \frac{(\sigma + 4)\delta_i}{\sigma\delta_i + (1 + \delta_i)^2}, \quad \delta_i = \frac{\lambda_1^i - \lambda_1}{\lambda_2 - \lambda_1}, \quad \sigma = \frac{\lambda_2 - \lambda_1}{\alpha}.$$

We observe that

$$\gamma_{1,i,\alpha} = \gamma_{1,\alpha} + \mathcal{O}\left(\lambda_1^i - \lambda_1\right), \quad \gamma_{1,\alpha} = \frac{1 - \xi_{1,\alpha}}{1 + \xi_{1,\alpha}},$$

and hence if K is the pseudoinverse of $L - \lambda_1$, in which case $\kappa_1 = \kappa_{-1,\alpha} = 1$ and $\gamma_{1,\alpha} = 0$, then $\lambda_1^{i+1} = \mathcal{O}\left((\lambda_1^i - \lambda_1)^3\right)$, i.e., the convergence is cubic (in this respect (3.5) is even more accurate than (2.2), which predicts quadratic convergence). Furthermore, substituting $\sqrt{\lambda_1^i - \lambda_1}$ for α, we obtain $\gamma_{1,i,\alpha} = \gamma_1 + \mathcal{O}\left(\sqrt{\lambda_1^i - \lambda_1}\right)$, i.e., the estimate (3.5) is asymptotically equivalent to (2.2).

4. Asymptotical sharpness. The estimates (2.2), (3.4), and (3.5) are rather cumbersome and difficult to grasp—however, their asymptotics is fairly simple. Indeed, it is not difficult to see that (2.2), (3.4), and (3.5) imply, respectively, the following three estimates:

$$\lambda_1^{i+1} - \lambda_1 \leq \left(\gamma_1 + \mathcal{O}\left(\sqrt{\lambda_1^i - \lambda_1}\right)\right)^2(\lambda_1^i - \lambda_1), \tag{4.1}$$

$$\lambda_1^{i+1} - \lambda_1 \leq \left(\tilde{\gamma}_1 + \mathcal{O}\left(\sqrt{\lambda_1^i - \lambda_1}\right)\right)^2(\lambda_1^i - \lambda_1), \tag{4.2}$$

$$\lambda_1^{i+1} - \lambda_1 \leq \left(\gamma_{1,\alpha} + \mathcal{O}\left(\lambda_1^i - \lambda_1\right)\right)^2(\lambda_1^i - \lambda_1). \tag{4.3}$$

We remind the reader that

$$\gamma_1 = \frac{1 - \xi_1}{1 + \xi_1}, \quad \tilde{\gamma}_1 = \frac{1 - \tilde{\xi}_1}{1 + \tilde{\xi}_1}, \quad \gamma_{1,\alpha} = \frac{1 - \xi_{1,\alpha}}{1 + \xi_{1,\alpha}}, \tag{4.4}$$

where ξ_1 is the ratio of the smallest positive to the largest eigenvalue of $K(L-\lambda_1)$, $\tilde{\xi}_1$ is given by (3.2) with $\xi = cond(KL)^{-1}$, and $\xi_{1,\alpha}$ is the ratio of the smallest positive eigenvalue of $K(L-\lambda_1)$ to the largest eigenvalue of $K(\alpha P_1 + (L-\lambda_1))$. In this section we show that the previous three estimates are asymptotically sharp, i.e., the main terms on the right-hand side cannot be made smaller without using additional information. We start with (4.1) and (4.3).

THEOREM 4.1. *For any* $0 \le \gamma < 1$ *there exist* u_1^i *and* K *such that* $\gamma_1 = \gamma$ *and*

$$\lambda_1^{i+1} - \lambda_1 = \left(\gamma_1 + \mathcal{O}\left(\lambda_1^i - \lambda_1\right)\right)^2 (\lambda_1^i - \lambda_1).$$

Proof. Let $K = (\omega P_1 + (L-\lambda_1)P_2 + \kappa^{-1}(L-\lambda_1)P)^{-1}$, where $\omega > 0$, $P_i = (\cdot, u_i)u_i$, $i = 1,2$, $P = 1 - P_1 - P_2$, and $\kappa \ge 1$. In the notation of Theorem 2.1, we obviously have $\kappa_1 = 1$ and $\kappa_{-1} = \kappa$, and hence $\xi_1 = \kappa^{-1}$ and $\gamma_1 = (\kappa-1)/(\kappa+1)$. To simplify the notation, let us denote $u = u_1^i$, $\lambda = \lambda_1^i$, $\tilde{u} = u_1^{i+1}$, and $\tilde{\lambda} = \lambda_1^{i+1}$. Let $u = u_1 + x_2 u_2 + x_3 u_3$, where x_2 and x_3 are real numbers. Elementary calculations show that

$$\tau = \frac{(\lambda_2-\lambda_1)x_2^2 + \kappa(\lambda_3-\lambda_1)x_3^2}{(\lambda_2-\lambda_1)x_2^2 + \kappa^2(\lambda_3-\lambda_1)x_3^2} + \delta_\tau \equiv \tau_* + \delta_\tau,$$

where $|\delta_\tau| \le c_\tau \epsilon^2$, $\epsilon = \sqrt{x_2^2 + x_3^2}$, and c_τ does not depend on x_2 and x_3; we observe that $\kappa^{-1} \le \tau_* \le 1$. Thus, $\tilde{u} = \tilde{x}_1 u_1 + \tilde{x}_2 u_2 + \tilde{x}_3 u_3$, where $\tilde{x}_1 = 1 - \tau(\lambda_1 - \lambda)/\omega$ and

$$\begin{aligned}
\tilde{x}_2 &= \left(1 - \tau\frac{\lambda_2-\lambda}{\lambda_2-\lambda_1}\right)x_2 = (1 - \tau_* + \delta_2)x_2 \\
&= \left(\frac{\kappa(\kappa-1)(\lambda_3-\lambda_1)x_3^2}{(\lambda_2-\lambda_1)x_2^2 + \kappa^2(\lambda_3-\lambda_1)x_3^2} + \delta_2\right)x_2, \\
\tilde{x}_3 &= \left(1 - \tau\kappa\frac{\lambda_3-\lambda}{\lambda_3-\lambda_1}\right)x_3 = (1 - \kappa\tau_* + \delta_3)x_3 \\
&= \left(\frac{(1-\kappa)(\lambda_2-\lambda_1)x_2^2}{(\lambda_2-\lambda_1)x_2^2 + \kappa^2(\lambda_3-\lambda_1)x_3^2} + \delta_3\right)x_3,
\end{aligned}$$

where $|\delta_i| \le c_i\epsilon^2$ and c_i does not depend on x_2 and x_3, $i = 2,3$. Now, if $(\lambda_2-\lambda_1)x_2^2 = \kappa(\lambda_3-\lambda_1)x_3^2$, then $1 - \tau_* = \kappa\tau_* - 1 = (\kappa-1)/(\kappa+1)$ and we have

$$\tilde{x}_2 = \left(\frac{\kappa-1}{\kappa+1} + \delta_2\right)x_2, \quad \tilde{x}_3 = -\left(\frac{\kappa-1}{\kappa+1} - \delta_3\right)x_3,$$

and hence

$$\begin{aligned}
\tilde{\lambda} = \lambda(\tilde{u}) = \frac{\lambda_1 + \lambda_2\tilde{x}_2^2 + \lambda_3\tilde{x}_3^2}{\tilde{x}_1^2 + \tilde{x}_2^2 + \tilde{x}_3^2} &= \lambda_1 + \frac{(\lambda_2-\lambda_1)\tilde{x}_2^2 + (\lambda_3-\lambda_1)\tilde{x}_3^2}{1+\epsilon^2} \\
&= \lambda_1 + \left(\frac{\kappa-1}{\kappa+1} + \mathcal{O}\left(\epsilon^2\right)\right)^2 \frac{(\lambda_2-\lambda_1)x_2^2 + (\lambda_3-\lambda_1)x_3^2}{1+\epsilon^2}
\end{aligned}$$

$$= \lambda_1 + \left(\frac{\kappa-1}{\kappa+1} + \mathcal{O}\left(\epsilon^2\right)\right)^2 (\lambda - \lambda_1) = \lambda_1 + \left(\gamma_1 + \mathcal{O}\left(\lambda-\lambda_1\right)\right)^2(\lambda-\lambda_1). \qquad \square$$

THEOREM 4.2. *For any* $0 \le \gamma < 1$ *there exist* u_1^i *and* K *such that* $\gamma_{1,\alpha} = \gamma$ *and*

$$\lambda_1^{i+1} - \lambda_1 = \left(\gamma_{1,\alpha} + \mathcal{O}\left(\lambda_1^i - \lambda_1\right)\right)^2 (\lambda_1^i - \lambda_1).$$

Proof. We just use the proof of Theorem 4.1 with $\omega = \alpha$, observing that $\kappa_1 = 1$ and $\kappa_{-1,\alpha} = \kappa$, and hence $\xi_{1,\alpha} = \kappa^{-1}$ and $\gamma_{1,\alpha} = (\kappa - 1)/(\kappa + 1)$. □

THEOREM 4.3. *Let L be positive definite. For any $0 < \xi \leq 1$ there exist u_1^i and K such that $cond(KL) = \xi^{-1}$ and*

$$\lambda_1^{i+1} - \lambda_1 = \left(\tilde{\gamma}_1 + \mathcal{O}\left(\lambda_1^i - \lambda_1\right)\right)^2 \left(\lambda_1^i - \lambda_1\right). \tag{4.5}$$

Proof. Using the notation of the proof of Theorem 4.1, let us take $K = L^{-1}(1 - P) + \kappa L^{-1}P$, where $\kappa \geq 1$. The smallest eigenvalue of KL is obviously 1 and the largest is κ; hence $\xi = \kappa^{-1}$. Let $u = u_1 + x_2u_2 + x_{-1}u_{-1}$, where u_{-1} is an eigenvector of L corresponding to its largest eigenvalue λ_{-1}, and x_2 and x_{-1} are real numbers. Elementary calculations show that the locally optimal value of τ is

$$\tau = \frac{\frac{(\lambda_2-\lambda_1)^2}{\lambda_2}x_2^2 + \kappa\frac{(\lambda_{-1}-\lambda_1)^2}{\lambda_{-1}}x_{-1}^2}{\frac{(\lambda_2-\lambda_1)^3}{\lambda_2^2}x_2^2 + \kappa^2\frac{(\lambda_{-1}-\lambda_1)^3}{\lambda_{-1}^2}x_{-1}^2} + \mathcal{O}\left(\epsilon^2\right),$$

where $\epsilon = \sqrt{x_2^2 + x_{-1}^2}$. Thus, $\tilde{u} = \tilde{x}_1u_1 + \tilde{x}_2u_2 + \tilde{x}_{-1}u_{-1}$, where $\tilde{x}_1 = 1 - \tau(\lambda_1 - \lambda)/\lambda_1$ and

$$\tilde{x}_2 = \left(1 - \tau\frac{\lambda_2 - \lambda}{\lambda_2}\right)x_2 = \left(\frac{\left(\kappa\frac{\lambda_{-1}-\lambda_1}{\lambda_{-1}} - \frac{\lambda_2-\lambda_1}{\lambda_2}\right)\kappa\frac{(\lambda_{-1}-\lambda_1)^2}{\lambda_{-1}}x_{-1}^2}{\frac{(\lambda_2-\lambda_1)^3}{\lambda_2^2}x_2^2 + \kappa^2\frac{(\lambda_{-1}-\lambda_1)^3}{\lambda_{-1}^2}x_{-1}^2} + \mathcal{O}\left(\epsilon^2\right)\right)x_2$$

$$\tilde{x}_{-1} = \left(1 - \tau\kappa\frac{\lambda_{-1} - \lambda}{\lambda_{-1}}\right)x_{-1} = \left(\frac{\left(\frac{\lambda_2-\lambda_1}{\lambda_2} - \kappa\frac{\lambda_{-1}-\lambda_1}{\lambda_{-1}}\right)\frac{(\lambda_2-\lambda_1)^2}{\lambda_2}x_2^2+}{\frac{(\lambda_2-\lambda_1)^3}{\lambda_2^2}x_2^2 + \kappa^2\frac{(\lambda_{-1}-\lambda_1)^3}{\lambda_{-1}^2}x_{-1}^2} + \mathcal{O}\left(\epsilon^2\right)\right)x_{-1}.$$

If x_2 and x_{-1} are such that

$$\frac{(\lambda_2 - \lambda)^2}{\lambda_2}x_2^2 = \kappa\frac{(\lambda_{-1} - \lambda)^2}{\lambda_{-1}}x_{-1}^2,$$

then

$$\tilde{x}_2 = \left(\frac{\kappa\frac{\lambda_{-1}-\lambda_1}{\lambda_{-1}} - \frac{\lambda_2-\lambda_1}{\lambda_2}}{\frac{\lambda_2-\lambda_1}{\lambda_2} + \kappa\frac{\lambda_{-1}-\lambda_1}{\lambda_{-1}}} + \mathcal{O}\left(\epsilon^2\right)\right)x_2 = \left(\tilde{\gamma}_1 + \mathcal{O}\left(\epsilon^2\right)\right)x_2,$$

$$\tilde{x}_{-1} = \left(\frac{\frac{\lambda_2-\lambda_1}{\lambda_2} - \kappa\frac{\lambda_{-1}-\lambda_1}{\lambda_{-1}}}{\frac{\lambda_2-\lambda_1}{\lambda_2} + \kappa\frac{\lambda_{-1}-\lambda_1}{\lambda_{-1}}} + \mathcal{O}\left(\epsilon^2\right)\right)x_{-1} = -\left(\tilde{\gamma}_1 + \mathcal{O}\left(\epsilon^2\right)\right)x_{-1},$$

and we arrive at (4.5). □

Remark 1. The fact that (4.2) is sharp does not contradict the fact that it is less accurate than (4.1) because (4.2) uses less accurate information about K and L; instead of ξ_1, the ratio of the smallest positive to the largest eigenvalue of $K(L - \lambda_1)$ that is used in (4.1), the estimate (4.2) uses its lower bound $\tilde{\xi}_1$.

5. Sharp upper bounds for the asymptotic convergence factor. For any nonzero u_1^0 that is not an eigenvector of L corresponding to λ_1 the following quantity can be introduced:

$$q_1(u_1^0) = \varlimsup_{i\to\infty} q_{1,i}(u_1^0), \quad q_{1,i}(u_1^0) \equiv \left(\frac{\lambda_1^i - \lambda_1}{\lambda_1^0 - \lambda_1}\right)^{\frac{1}{i}},$$

where u_1^i is the sequence generated by (1.3) starting with the initial guess u_1^0, and $\lambda_1^i = \lambda(u_1^i)$. In this paper we refer to $q_1(u_1^0)$ as the *asymptotic convergence factor* (a.c.f.) for the sequence $\{u_1^i\}_{i=0}^{\infty}$. We observe that

$$q_{1,i}(u_1^0) = \left(\frac{\lambda_1^i - \lambda_1}{\lambda_1^{i-1} - \lambda_1} \frac{\lambda_1^{i-1} - \lambda_1}{\lambda_1^{i-2} - \lambda_1} \cdots \frac{\lambda_1^1 - \lambda_1}{\lambda_1^0 - \lambda_1} \right)^{\frac{1}{i}};$$

i.e., $q_{1,i}(u_1^0)$ is the geometrical average of the error reductions on the first i iterations (1.3). The estimates (4.1), (4.2), and (4.3) imply that γ_1^2, $\tilde{\gamma}_1^2$, and $\gamma_{1,\alpha}^2$ are upper bounds for the a.c.f. $q_1(u_1^0)$. In this section we show that these bounds are sharp in the sense that by a proper choice of K each of them can be made equal to the supremum of $q_1(u_1^0)$ taken over all initial guesses u_1^0 for which u_1^i converge to an eigenvector corresponding to λ_1. Below we denote the latter quantity by q_1, i.e.,

$$q_1 \equiv \sup_{u_1^0 \in \mathcal{E} : \lambda(u_1^0) > \lambda_1, q_1(u_1^0) < 1} q_1(u_1^0). \tag{5.1}$$

THEOREM 5.1. *For any $\gamma \in [0, 1)$ there exists K such that $q_1 = \gamma_1^2 = \gamma^2$.*

Proof. First, let us show that $q_1 \le \gamma_1^2$. In view of the condition $q_1(u_1^0) < 1$ we only need to consider sequences u_1^i that converge to an eigenvector corresponding to λ_1. Denote by $\gamma_{1,i}^2$ the coefficient in front of $\lambda_1^i - \lambda_1$ in (2.2). For any sequence of u_1^i in focus there exists i_0 such that $\lambda_1^{i_0} < \lambda_2$ and $\gamma_{1,i_0} < 1$. Hence, using (2.2) for $i \ge i_0$ and the fact that $\lambda_1^{i+1} \le \lambda_1^i$, we have

$$\begin{aligned} \ln \frac{\lambda_1^i - \lambda_1}{\lambda_1^0 - \lambda_1} \le \ln \frac{\lambda_1^i - \lambda_1}{\lambda_1^{i_0} - \lambda_1} &\le \ln \prod_{j=i_0}^{i-1} \left(\frac{\gamma_1 + \tau\sqrt{\kappa_{-1}}\epsilon_j}{1 - \tau(\sqrt{\kappa_{-1}} + \epsilon_j)\epsilon_j} \right)^2 \\ &\le 2((i - i_0)\ln \gamma_1 + \delta_i) \end{aligned} \tag{5.2}$$

where

$$\delta_i = \sum_{j=i_0}^{i-1} (\ln(1 + \tau\sqrt{\kappa_{-1}}\epsilon_j/\gamma_1) - \ln(1 - \tau(\sqrt{\kappa_{-1}} + \epsilon_j)\epsilon_j)).$$

Denoting $a = \tau\sqrt{\kappa_{-1}}/\gamma_1$ and $b = \tau(\sqrt{\kappa_{-1}} + \epsilon_{i_0})$ and using elementary estimates $\ln(1 + x) \le x$ and $-\ln(1 - x) \le x(1 - \ln(1 - x))$ we obtain for δ_i the upper bound that does not depend on i:

$$\delta_i \le \sum_{j=i_0}^{i-1} (a\epsilon_j + b\epsilon_j(1 - \ln(1 - b\epsilon_j))) \le \frac{a}{1 - \gamma_{1,i_0}}\epsilon_{i_0} + \frac{b(1 - \ln(1 - b\epsilon_{i_0}))}{1 - \gamma_{1,i_0}}\epsilon_{i_0}.$$

Hence, dividing (5.2) by i and passing to the limit $i \to \infty$, we obtain $q_1(u_1^0) \le \gamma_1^2$.

Now, let us take the same K as in the proof of Theorem 4.1, in which case $\gamma_1 = \gamma$. If $\gamma_1 = \gamma = 0$, then $q_1(u_1^0) = 0$ for any sequence u_1^0 that converges to an eigenvector in $\mathcal{I}_1$ (cf. above), and hence $q_1 = 0$. Below we consider the case $\gamma_1 > 0$, i.e., $\kappa > 1$. Let $u_1^0 = u_1 + x_{2,0}u_2 + x_{3,0}u_3$, where $x_{2,0}$ and $x_{3,0}$ are real numbers such that

$$(\lambda_2 - \lambda_1)x_{2,0}^2 = \kappa(\lambda_3 - \lambda_1)x_{3,0}^2.$$

From the proof of Theorem 4.1 we see that $u_1^i = x_{1,i}u_1 + x_{2,i}u_2 + x_{3,i}u_3$ for some real $x_{1,i}, x_{2,i}$ and $x_{3,i}$, and that the ratio of $x_{2,i}^2 + x_{3,i}^2$ to $x_{1,i}^2$ decreases on each iteration. Let us rescale u_1^i so that $x_{1,i} = 1$. Denoting $\epsilon_i = \sqrt{x_{2,i}^2 + x_{3,i}^2}$, we have $x_{2,i} = \epsilon_i \cos\psi_i$ and $x_{3,i} = \epsilon_i \sin\psi_i$. Consulting the proof of Theorem 4.1, we observe that $u_1^{i+1} = x_{1,i+1}u_1 + x_{2,i+1}u_2 + x_{3,i+1}u_3$, where

$$\begin{aligned} x_{1,i+1} &= 1 + \delta_{1,i}, \\ x_{2,i+1} &= \left(\frac{\kappa(\kappa-1)(\lambda_3-\lambda_1)x_{3,i}^2}{(\lambda_2-\lambda_1)x_{2,i}^2 + \kappa^2(\lambda_3-\lambda_1)x_{3,i}^2} + \delta_{2,i} \right) x_{2,i}, \\ x_{3,i+1} &= \left(\frac{(1-\kappa)(\lambda_2-\lambda_1)x_{2,i}^2}{(\lambda_2-\lambda_1)x_{2,i}^2 + \kappa^2(\lambda_3-\lambda_1)x_{3,i}^2} + \delta_{3,i} \right) x_{3,i}, \end{aligned}$$

$|\delta_{j,i}| \le c\epsilon_i^2$, and c does not depend on ψ_i and ϵ_i. From the above relationships we obtain

$$\tan\psi_{i+1} = \frac{(1-\kappa)\tan^2\psi_0 + \delta_{3,i}(\tan^2\psi_0 + \kappa\tan^2\psi_i)}{(\kappa-1)\tan^2\psi_i + \delta_{2,i}(\tan^2\psi_0 + \kappa\tan^2\psi_i)} \tan\psi_i. \tag{5.3}$$

Hence, denoting $t_i = |\tan\psi_i/\tan\psi_0|$, we have

$$t_{i+1} = \left| \frac{1 - \frac{\delta_{3,i}}{\kappa-1}(1+\kappa t_i^2)}{1 + \frac{\delta_{2,i}}{\kappa-1}(\kappa + t_i^{-2})} \right| t_i^{-1}.$$

Recalling that $|\delta_{j,i}| \le c\epsilon_i^2$, and denoting $\varepsilon_i = c\epsilon_i^2/(\kappa-1)$, we observe that if $\varepsilon_i(\kappa + t_i^{-2}) < 1$, then

$$t_{i+1} \le \frac{1 + \varepsilon_i(1+\kappa t_i^2)}{1 - \varepsilon_i(\kappa + t_i^{-2})} t_i^{-1},$$

and if $\varepsilon_i(1+\kappa t_i^2) < 1$, then

$$t_{i+1}^{-1} \le \frac{1 + \varepsilon_i(\kappa + t_i^{-2})}{1 - \varepsilon_i(1+\kappa t_i^2)} t_i.$$

Assume that λ_1^0 is close enough to λ_1 so that $\gamma_{1,0} < 1$. Since $\gamma_{1,i} \le \gamma_{1,j}$ for $i > j$, we have $\lambda_1^i - \lambda_1 \le \gamma_{1,0}^{2i}(\lambda_1^0 - \lambda_1)$. Further,

$$\epsilon_i^2 = \tan^2(u_1^i, u_1) \le (\lambda_1^i - \lambda_1)/(\lambda_2 - \lambda_1^i)$$

(cf., e.g., [5]), and thus

$$\varepsilon = \sum_{i=0}^{\infty} \varepsilon_i = \frac{c}{\kappa-1}\sum_{i=0}^{\infty} \epsilon_i^2 = \sum_{i=0}^{\infty} \mathcal{O}\left(\lambda_1^i - \lambda_1\right) = \mathcal{O}\left(\lambda_1^0 - \lambda_1\right).$$

Hence, applying Lemma A.1, we have $\tan^2\psi_i = \tan^2\psi_0\,(1 + \mathcal{O}(\varepsilon))$ and

$$\begin{aligned} \tilde{x}_{2,i+1} &= \left(\frac{(\kappa-1)\tan^2\psi_i}{\tan^2\psi_0 + \kappa\tan^2\psi_i} + \delta_{2,i} \right) x_{2,i} = \left(\frac{\kappa-1}{\kappa+1} + \mathcal{O}(\varepsilon) \right) x_{2,i}, \\ \tilde{x}_{3,i+1} &= \left(\frac{(1-\kappa)\tan^2\psi_0}{\tan^2\psi_0 + \kappa\tan^2\psi_i} + \delta_{3,i} \right) x_{3,i} = \left(\frac{1-\kappa}{\kappa+1} + \mathcal{O}(\varepsilon) \right) x_{3,i}, \end{aligned}$$

and hence

$$\begin{aligned}\lambda_1^{i+1} - \lambda_1 &= \frac{(\lambda_2 - \lambda_1)\tilde{x}_{2,i+1}^2 + (\lambda_3 - \lambda_1)\tilde{x}_{3,i+1}^2}{\tilde{x}_{1,i+1}^2 + \tilde{x}_{2,i+1}^2 + \tilde{x}_{3,i+1}^2} \\ &= \left(\frac{\kappa - 1}{\kappa + 1} + \mathcal{O}(\varepsilon)\right)^2 \frac{(\lambda_2 - \lambda_1)x_{2,i}^2 + (\lambda_3 - \lambda_1)x_{3,i}^2}{1 + \mathcal{O}(\epsilon_i^2)} \\ &= (\gamma_1 + \mathcal{O}(\varepsilon))^2 \left(1 + \mathcal{O}\left(\epsilon_i^2\right)\right)(\lambda_1^i - \lambda_1) \\ &= (\gamma_1 + \mathcal{O}(\varepsilon))^2 (\lambda_1^i - \lambda_1) = (\gamma_1 + \mathcal{O}(\varepsilon))^{2(i+1)} (\lambda_1^0 - \lambda_1).\end{aligned}$$

Thus, $q_1 \geq (\gamma_1 - \delta)^2$, where $\delta = \mathcal{O}(\varepsilon) = \mathcal{O}\left(\lambda(u_1^0) - \lambda_1\right)$, provided that $\lambda(u_1^0) - \lambda_1$ is small enough and, by taking supremum over all such u_1^0, we obtain $q_1 = \gamma_1^2 = \gamma^2$. □

By introducing certain modifications into the above calculations, we obtain the respective results in terms of $\gamma_{1,\alpha}$ and $\tilde{\gamma}_1$.

THEOREM 5.2. *For any $\gamma \in [0, 1)$ there exists K such that $q_1 = \gamma_{1,\alpha}^2 = \gamma^2$.*

Proof. We just need to use the proof of Theorem 5.1 with $\omega = \alpha$ in the definition of K. □

THEOREM 5.3. *For any $\xi \in [0, 1)$ there exists K such that $q_1 = \tilde{\gamma}_1^2$, where $\tilde{\gamma}_1$ is given by* (4.4) *with $\tilde{\xi}_1 = \xi$.*

Proof. Let K be the same as in the proof of Theorem 4.3. Comparing the formulas for $\tilde{x}_2$ and $\tilde{x}_3$ in the proof of Theorem 4.1 with those for $\tilde{x}_2$ and $\tilde{x}_{-1}$ in the proof of Theorem 4.3, we observe that the latter formulas can be obtained by changing κ in the former as follows:

$$\kappa \to \kappa \frac{\lambda_2}{\lambda_2 - \lambda_1} \frac{\lambda_{-1} - \lambda_1}{\lambda_{-1}}.$$

It is not difficult to verify that in order to prove Theorem 5.3 we just need to change κ in the above way in the proof of Theorem 5.1. □

6. New sharp estimates. We have already seen in section 2 that with some preconditioners the convergence of PSD can be superlinear. Actually, there even exists a preconditioner that delivers one-step convergence: assuming that $\lambda_1^0 = \lambda(u_1^0) < \lambda_2$, let us consider

$$K = (\alpha P_1 + (L - \lambda_1^0)(1 - P_1))^{-1},$$

where $\alpha > 0$. Taking $\tau_0 = 1$, we have

$$\begin{aligned}u_1^1 &= u_1^0 - K(L - \lambda_1^0)u_1^0 = u_1^0 - K((L - \lambda_1^0)P_1 + (L - \lambda_1^0)(1 - P_1)) \\ &= u_1^0 - (\alpha P_1 + (L - \lambda_1^0)(1 - P_1))^{-1}((\lambda_1 - \lambda_1^0)P_1 + (L - \lambda_1^0)(1 - P_1)) \\ &= u_1^0 - \left(\frac{\lambda_1 - \lambda_1^0}{\alpha} P_1 + 1 - P_1\right) u_1^0 = \left(1 + \frac{\lambda_1^0 - \lambda_1}{\alpha}\right) P_1 u_1^0\end{aligned}$$

(note that the above assumption on λ_1^0 implies $P_1 u_1^0 \neq 0$), and hence $\lambda_1^1 = \lambda_1$. The result below shows that in the case of a general Hermitian positive K the reduction in the eigenvalue error on ith iteration can be estimated via the closeness of K to (a multiple of) $(\alpha P_1 + (L - \lambda_1^i)(1 - P_1))^{-1}$.

THEOREM 6.1. *Let P_1 be the orthogonal projector onto the invariant subspace of L corresponding to λ_1, and denote*

$$L_{\alpha,\lambda} = \alpha P_1 + (L - \lambda)(1 - P_1).$$

If $\lambda_1^i < \lambda_2$, then the following estimate is valid for iterations (1.3) *with the locally optimal choice of τ_i:*

$$\Delta(\lambda_1^{i+1}) \le \frac{\gamma_{\alpha,\lambda_1^i}^2}{1+\left(1-\gamma_{\alpha,\lambda_1^i}^2\right)\frac{\lambda_1^i-\lambda_1}{\alpha}}\Delta(\lambda_1^i), \tag{6.1}$$

where $\alpha > 0$,

$$\Delta(\lambda) = \frac{\lambda-\lambda_1}{\lambda_2-\lambda}, \quad \gamma_{\alpha,\lambda} = \frac{1-\xi_{\alpha,\lambda}}{1+\xi_{\alpha,\lambda}}, \quad \xi_{\alpha,\lambda} = \frac{\kappa_{1,\alpha,\lambda}}{\kappa_{-1,\alpha,\lambda}},$$

and $\kappa_{1,\alpha,\lambda}$ and $\kappa_{-1,\alpha,\lambda}$ are, respectively, the smallest and the largest eigenvalue of $KL_{\alpha,\lambda}$. The estimate (6.1) *is sharp in the sense that for any L, $\lambda \in [\lambda_1, \lambda_2)$, $\alpha > 0$, and $\gamma \in [0,1]$ there exist K and u_1^i such that $\gamma_{\alpha,\lambda_1^i} = \gamma$, $\lambda(u_1^i) = \lambda$, and both sides of* (6.1) *coincide.*

Proof. See section A.1. □

Note that if L is positive definite, then

$$\alpha_0 L \le \alpha P_1 + (L-\lambda)(1-P_1) \le \alpha^0 L,$$

where

$$\alpha_0 = \min\left\{\frac{\alpha}{\lambda_1}, \frac{\lambda_2-\lambda}{\lambda_2}\right\}, \quad \alpha^0 = \max\left\{\frac{\alpha}{\lambda_1}, \frac{\lambda_{-1}-\lambda}{\lambda_{-1}}\right\}.$$

The above relationship shows that $\xi_{\alpha,\lambda} \ge cond(KL)^{-1}\alpha_0/\alpha^0$.

The arbitrariness of the parameter α reflects the fact that one-step convergence discussed at the beginning of this section takes place for any nonzero value of α. Below we use two particular choices of α to obtain estimates that are sharp and at the same time rather simple in appearance.

Theorem 6.2. *Assuming that $\lambda_1^i \equiv \lambda(u_1^i) < \lambda_2$, the following estimate is valid for iterations* (1.3) *with the locally optimal choice of τ_i:*

$$\lambda_1^{i+1} - \lambda_1 \le \gamma_{\lambda,i}^2(\lambda_1^i - \lambda_1), \quad \gamma_{\lambda,i} = \frac{1-\xi_{\lambda,i}}{1+\xi_{\lambda,i}}, \tag{6.2}$$

where $\xi_{\lambda,i}$ is the inverse of the condition number of the operator

$$K((\lambda_2-\lambda_1^i)P_1 + (L-\lambda_1^i)(1-P_1)),$$

and P_1 is the orthogonal projector onto the invariant subspace of L corresponding to λ_1. The estimate (6.2) *is sharp in the sense that for any L, $\lambda \in [\lambda_1, \lambda_2)$ and $\gamma \in [0,1]$ there exist K and u_1^i such that $\gamma_{\lambda,i} = \gamma$, $\lambda_1^i \equiv \lambda(u_1^i) = \lambda$, and both sides of* (6.2) *coincide.*

Proof. For $\alpha = \lambda_2 - \lambda_1^i$ we have $(\lambda_1^i - \lambda_1)/\alpha = \Delta(\lambda_1^i)$. Hence, denoting $\tan^2\phi_i = \Delta(\lambda_1^i)$ and $\tan^2\phi_{i+1} = \Delta(\lambda_1^{i+1})$, we obtain

$$\tan^2\phi_{i+1} \le \frac{\gamma_{\lambda,i}^2\tan^2\phi_i}{1+\tan^2\phi_i - \gamma_{1,i}^2\tan^2\phi_i} = \frac{\gamma_{\lambda,i}^2\sin^2\phi_i}{1-\gamma_{\lambda,i}^2\sin^2\phi_i},$$

which implies $\sin^2\phi_{i+1} \le \gamma_{\lambda,i}^2\sin^2\phi_i$, i.e.,

$$\frac{\lambda_1^{i+1}-\lambda_1}{\lambda_2-\lambda_1} \le \gamma_{\lambda,i}^2\frac{\lambda_1^i-\lambda_1}{\lambda_2-\lambda_1}.$$

The sharpness of (6.2) follows trivially from the sharpness of (6.1). □

A different choice of α leads to the following estimate in terms of the inverses $\mu_j = 1/\lambda_j$ of the eigenvalues of L.

THEOREM 6.3. *In the notation and under the assumptions of Theorem* 6.2, *with the additional assumption that L is positive definite, the following estimate is valid for the inverses $\mu_j^i = 1/\lambda_j^i$ of the approximate eigenvalues generated by* (1.3)*:*

$$\mu_1 - \mu_1^{i+1} \leq \gamma_{\mu,i}^2(\mu_1 - \mu_1^i), \quad \gamma_{\mu,i} = \frac{1-\xi_{\mu,i}}{1+\xi_{\mu,i}}, \tag{6.3}$$

where $\xi_{\mu,i}$ is the inverse of the condition number of the operator

$$K\left(\frac{\mu_1^i - \mu_2}{\mu_1}P_1 + (\mu_1^i L - I)(1-P_1)\right),$$

and $\mu_j = 1/\lambda_j$. The estimate (6.3) *is sharp in the sense that for any L, $\mu \in [\mu_2, \mu_1)$, and $\gamma \in [0,1]$ there exist K and u_1^i such that $\gamma_{\mu,i} = \gamma$, $\mu_1^i \equiv \mu(u_1^i) \equiv 1/\lambda(u_1^i) = \mu$, and both sides of* (6.3) *coincide.*

Proof. For $\alpha = (\mu_1^i - \mu_2)/(\mu_1\mu_1^i)$ we have

$$\frac{\lambda_1^i - \lambda_1}{\alpha} = \frac{\mu_1 - \mu_1^i}{\mu_1^i - \mu_2}.$$

Hence, substituting the above α into (6.1) we arrive at (6.3) in the same way as in the proof of Theorem 6.2. Again, the sharpness of (6.3) follows from the sharpness of (6.1). □

Since

$$(\mu_1^i - \mu_2)L \leq \frac{\mu_1^i - \mu_2}{\mu_1}P_1 + (\mu_1^i L - I)(1-P_1) \leq (\mu_1^i - \mu_{-1})L,$$

the above result has the following corollary.

COROLLARY 6.4. *In the notation and under the assumptions of Theorem* 6.3, *the following estimate is valid:*

$$\mu_1 - \mu_1^{i+1} \leq \tilde{\gamma}_{\mu,i}^2(\mu_1 - \mu_1^i), \tag{6.4}$$

where

$$\tilde{\gamma}_{\mu,i} = \frac{1-\tilde{\xi}_{\mu,i}}{1+\tilde{\xi}_{\mu,i}}, \quad \tilde{\xi}_{\mu,i} = \xi\frac{\mu_1^i - \mu_2}{\mu_1^i - \mu_{-1}},$$

and ξ is the inverse of the condition number of KL.

Let us compare the new estimates with those discussed previously in this paper.

Compared with the original asymptotic estimate by Samokish, the new estimates have the obvious advantage of being nonasymptotic, i.e., not containing unknown asymptotically insignificant terms. Compared with the estimate (2.2) reproducing the estimate by Samokish in nonasymptotic form, the new estimates have the advantage of being valid under a weaker assumption $\lambda_1^i < \lambda_2$ as compared to (2.1). Yet another advantage of (6.2) and (6.3) is the fact that these estimates are sharp, i.e., cannot be further improved without using additional information. At the same time, it should be admitted that the main asymptotic term in (2.2) is generally smaller than those in the new estimates.

Turning to the estimates (3.3) and (3.4), we observe first that they should be compared with the estimate (6.4), which is given in the same terms. It is not difficult to verify that the main asymptotic term in (6.4) coincides with that in (3.4) and is smaller than that in (3.3). At the same time, (6.4) is the simplest of the three estimates at hand.

7. Estimates for block versions of PSD. The block PSD (BPSD) methods combine the idea of the preconditioned steepest descent with the Rayleigh–Ritz method in the following manner: the new subspace $\mathcal{H}^{i+1}$ spans the first n Ritz vectors (enumerated in the ascending order of the corresponding Ritz values) in a trial subspace that contains the subspace

$$\mathcal{H}^{i+\frac{1}{2}} = \operatorname{span}\{u_j^i - \tau_{ij} K r_j^i\}_{j=1}^n, \tag{7.1}$$

where $u_1^i, \ldots, u_n^i$ are the Ritz vectors of L in $\mathcal{H}^i$ corresponding to the Ritz values λ_j^i, and $r_j^i = r(u_j^i) = Lu_j^i - \lambda_j^i u_j^i$. We remind the reader that the Ritz values and vectors in a subspace $\mathcal{V}$, denoted below by $\lambda_j(\mathcal{V})$ and $u_j(\mathcal{V})$, are the eigenpairs of the projection of L onto $\mathcal{V}$, i.e., of the problem

$$(Lu_j(\mathcal{V}), v) = \lambda_j(\mathcal{V})(u_j(\mathcal{V}), v) \quad \forall\, v \in \mathcal{V}. \tag{7.2}$$

In [1, 6] a version of the BPSD method is studied where $\tau_{ij} = 1$ and $\mathcal{H}^{i+1} = \mathcal{H}^{i+\frac{1}{2}}$; below we refer to this version as "the simple BPSD." In [2], $\mathcal{H}^{i+1}$ is defined in the same way but with each τ_{ij} being locally optimal, i.e., minimizing $\lambda(u_j^i - \tau_{ij} K r_j^i)$. In yet another BPSD method, $\mathcal{H}^{i+1}$ is defined as follows:

$$\mathcal{H}^{i+1} = \operatorname{span}\{u_j(\mathcal{H}_{lo}^{i+\frac{1}{2}})\}_{j=1}^n, \quad \mathcal{H}_{lo}^{i+\frac{1}{2}} = \mathcal{H}^i + \operatorname{span}\{K r_j^i\}_{j=1}^n. \tag{7.3}$$

We note that $\mathcal{H}_{lo}^{i+\frac{1}{2}} \supset \mathcal{H}^{i+\frac{1}{2}}$ for any τ_{ij}, and hence, by the minimax principle, the Ritz values in $\mathcal{H}_{lo}^{i+\frac{1}{2}}$ are not greater, and hence not further away from the exact ones, than those in any $\mathcal{H}^{i+\frac{1}{2}}$ of the form (7.1). Hence, (7.3) might be called locally optimal BPSD.

In [1] one can find the following asymptotic convergence estimate[6] for the simple BPSD:

$$\lambda_k^i - \lambda_k \le c_\varepsilon \left(q(\gamma, \lambda_k, \lambda_{n+1}, \lambda_k) + \varepsilon\right)^{2i}, \tag{7.4}$$

where $q(u, v, w, t)$ is the same as in (3.3), and ε is an arbitrary small positive real number. By considering the initial subspace

$$\mathcal{H}^0 = \operatorname{span}\{u_1, \ldots, u_{j-1}, u_j + \tau u_{n+1}, u_{j+1}, \ldots, u_n\} \tag{7.5}$$

it is not difficult to verify that (7.4) is asymptotically (as $\sin(\mathcal{H}^0, \mathcal{I}_n) \to 0$, where $\mathcal{I}_n = \operatorname{span}\{u_1, \ldots, u_n\}$) sharp in the sense that $q(\gamma, \lambda_k, \lambda_{n+1}, \lambda_k)$ cannot generally be replaced with any smaller value. In [6] one can find the following much more pessimistic estimate that essentially coincides with (3.3):

$$\Delta_k(\lambda_j^{i+1}) \le q(\gamma, \lambda_k, \lambda_{k+1}, \lambda_j^i)^2 \Delta_k(\lambda^i), \tag{7.6}$$

[6] The cited paper also has a nonasymptotic estimate, which is more cumbersome and is not reproduced here for simplicity of presentation.

where k is such that $\lambda_k \leq \lambda_j^i < \lambda_{k+1}$ and $q(u, v, w, t)$ and $\Delta_k(\lambda)$ are the same as in (3.3). Surprisingly, the above estimate is sharp, which appears to be in contradiction with the previous estimate. The explanation of this "contradiction" is actually quite simple: (7.4) assumes that $\mathcal{H}^0$ is sufficiently close to $\mathcal{I}_n$, whereas (7.6) makes no assumptions about the subspace $\mathcal{H}^i$ (cf. [1]), and it is not difficult to verify that in the case

$$\mathcal{H}^i = \operatorname{span}\{u_1, \ldots, u_{j-1}, u_k + \tau u_{k+1}, u_{k+2}, \ldots, u_{n+1}\}, \tag{7.7}$$

the factor $q(\gamma, \lambda_k, \lambda_{k+1}, \lambda_j^i)^2$ cannot be replaced by any smaller value. Note also that if we define the a.c.f. for λ_k as

$$q_k(\mathcal{H}^0) = \overline{\lim_{i\to\infty}} \left(\frac{\lambda_k^i - \lambda_k}{\lambda_k^0 - \lambda_k} \right)^{\frac{1}{i}}, \tag{7.8}$$

then $q(\gamma, \lambda_k, \lambda_{k+1}, \lambda_k)^2$ is an upper bound for $q_k(\mathcal{H}^0)$ taken over all $\mathcal{H}^0$ for which kth Ritz value λ_k^i converges to λ_k, as can be seen from the estimate (7.6) and the example of the initial subspace given by (7.7). However, if we reduce the set of initial subspaces $\mathcal{H}^0$ to those for which $\mathcal{H}^i$ converges to $\mathcal{I}_n$, then we have a smaller upper bound $q(\gamma, \lambda_k, \lambda_{n+1}, \lambda_k)^2$.

Apart from the assumptions on the subspace $\mathcal{H}^i$, the above two estimates differ in the following: (7.6) is recursive, i.e., it estimates the reduction in the error after one iteration, whereas (7.4) is not. Recursive estimates are more convenient than nonrecursive in certain respects, but, as has been pointed out in [12], it is not generally possible to obtain for BPSD iterations a convergence estimate of the form $\lambda_j^{i+1} - \lambda_j \leq q(\lambda_j^i - \lambda_j)$ even if we make assumptions that would guarantee that λ_j^i converges to λ_j. The latter observation has led to the idea to look for estimates for groups of eigenpairs rather than for individual ones. This novel approach to the convergence analysis of subspace iterations resulted in the following estimate[7] for the locally optimal BPSD (7.3): assuming that L is positive definite and $\mu_k^i > \mu_{k+1}$ and $\mu_m^i > \mu_{m+1}$ (where μ's are the inverses of λ's) for some $k \leq m$, one has

$$\sum_{j=1}^{k} (\mu_j - \mu_j^{i+1}) \leq \frac{\gamma_{k,m}^2 + \varepsilon_{k,m,i}}{1 + \varepsilon_{k,m,i}} \sum_{j=1}^{k} (\mu_j - \mu_j^i), \tag{7.9}$$

where

$$\gamma_{k,m} = \frac{1 - \xi_{k,m}}{1 + \xi_{k,m}}, \quad \xi_{k,m} = \xi \frac{\mu_k - \mu_{m+1}}{\mu_k - \mu_{-1}} \tag{7.10}$$

and

$$\varepsilon_{k,m,i} = \mathcal{O}\left(\tan^2(\mathcal{I}_k^i, \mathcal{I}_k)_L\right) + \mathcal{O}\left(\sin^2(\mathcal{I}_m^i, \mathcal{I}_m)_L\right) + \mathcal{O}\left(\sum_{j=1}^{k} \|r_j^i\|_{L^{-1}}^2 \right),$$

where $\mathcal{I}_l^i = \operatorname{span}\{u_1^i, \ldots, u_l^i\}$ and $\mathcal{I}_l = \operatorname{span}\{u_1, \ldots, u_l\}$. The above estimate is cluster robust in the sense that $\varepsilon_{k,m,i}$ does not depend on the distances between $\mu_1, \ldots, \mu_k$; moreover, for $k < m$ any distances between consecutive eigenvalues (precisely, those

[7] For simplicity, here we present this result in asymptotic form.

between μ_k and μ_{k+1} and between μ_m and μ_{m+1}) appear only in the asymptotically insignificant term $\varepsilon_{k,m,i}$.

From (7.9) it is not difficult to derive the following estimate for the a.c.f. defined by (7.8):

$$(7.11)\quad q_k(\mathcal{H}^0) \le \gamma_{k,m}^2 \ \forall\ \mathcal{H}^0 \subset \mathcal{E} : \lambda_m(\mathcal{H}^0) < \lambda_{m+1},\ 1 \le k \le m \le n = \dim \mathcal{H}^0.$$

The assumption on $\lambda_m(\mathcal{H}^0)$ in the above estimate is essential and reflects the positive effect of the convergence of λ_m^i to λ_m on the convergence of λ_k^i to λ_k for $k < m$. Indeed, if λ_m^i converges to λ_m for some $m > k$, then for some i_0 we have $\lambda_k^{i_0} < \lambda_k$ and $\lambda_m^{i_0} < \lambda_m$ (cf. [12]) and the a.c.f. is bounded from above by $\gamma_{k,m}^2$, whereas in the case of $\mathcal{H}^0$ given by (7.7) we can only take $m = k$, which yields a larger upper bound $\gamma_{k,k}^2$, similar to that following from (7.6).

Using the results of the previous section, it is easy to show that the estimate (7.11) is sharp in the following sense.

THEOREM 7.1. *For any $\xi \in [0, 1)$ there exists K such that*

$$(7.12)\qquad q_k = \sup_{\mathcal{H}^0 : \mathcal{I}_m^i \to \mathcal{I}_m} q_k(\mathcal{H}^0) = \gamma_{k,m}^2,$$

where $\gamma_{k,m}$ is given by (7.10) *with $\xi_{k,m} = \xi$.*

Proof. From (7.11) it follows that $q_k \le \gamma_{k,m}^2$. To prove that $q_k = \gamma_{k,m}^2$, consider the case of $\mathcal{H}^0$ given by

$$\mathcal{H}^0 = \operatorname{span}\{u_1, \ldots, u_{k-1}, u_k + \tau u_{m+1}, u_{k+1}, \ldots, u_m, u_{m+2}, \ldots, u_{n+1}\}.$$

Let P be the orthogonal projector onto the invariant subspace corresponding to λ_{m+2} and let $K = L^{-1}(1 - P) + \xi L^{-1} P$. It is easy to see that with such K and $\mathcal{H}^0$ we have $u_j^i = u_j$ for $j = 1, \ldots, k-1, k+1, \ldots, m$, whereas u_k^i is computed recursively by (1.3). Let L' be the restriction of L to the subspace orthogonal to $u_1, \ldots, u_{k-1}, u_{k+1}, \ldots, u_m$. The eigenvalues of L' listed in increasing order are $\lambda_k, \lambda_{m+1}, \lambda_{m+2}, \ldots$, and PSD iterations for computing the minimal eigenvalue of L' started from u_k^0 produce the same sequence u_k^i as (7.3). It remains to be noted that the value of $\tilde{\gamma}_1$ for L' coincides with $\gamma_{k,m}$. Hence, by applying Theorem 5.3 to these iterations, we see that $q_k = \gamma_{k,m}^2$. □

Appendix A. Auxiliary results.

A.1. The proof of Theorem 6.1. To simplify the notation, let us denote $u = u_1^i$, $\lambda = \lambda_1^i$, $u' = u_1^{i+1}$, $\lambda' = \lambda_1^{i+1}$, $\kappa_1 = \kappa_{1,\alpha,\lambda_1^i}$, $\kappa_{-1} = \kappa_{-1,\alpha,\lambda_1^i}$, $\gamma = \gamma_{\alpha,\lambda_1^i}$, and $L_\lambda = L_{\alpha,\lambda_1^i}$ (we note that L_λ is positive definite in view of the assumption that $\lambda < \lambda_2$).

Denoting $v = L_\lambda^{1/2} u$ and $v' = L_\lambda^{1/2} u'$, and taking $\tau_i = \tau_* \equiv 2/(\kappa_1 + \kappa_{-1})$, we have

$$v' = v - \tau L_\lambda^{1/2} K L_\lambda^{1/2} L_\lambda^{-1/2}(L - \lambda) L_\lambda^{-1/2} v = v - \hat{K}(-\epsilon P_1 + P_1^\perp) v,$$

where $\epsilon = (\lambda - \lambda_1)/\alpha$, $P_1^\perp = 1 - P_1$ and $\hat{K} = \tau_* L_\lambda^{1/2} K L_\lambda^{1/2}$; we note that $1 - \gamma \le \hat{K} \le 1 + \gamma$. Hence,

$$v' = v - (-\epsilon P_1 + P_1^\perp) v - (\hat{K} - 1)(-\epsilon P_1 + P_1^\perp) v = (1 + \epsilon) P_1 v - w,$$

where $w = (\hat{K} - 1)(-\epsilon P_1 + P_1^\perp) v$. From the above relationship we have

$$\|P_1 v'\| \ge (1 + \epsilon)\|P_1 v\| - \|P_1 w\|, \quad \|P_1^\perp v'\| = \|P_1^\perp w\|,$$

and for w we have

$$\|w\| \le \gamma\|(-\epsilon P_1 + P_1^\perp)v\| = \gamma\sqrt{\epsilon^2\|P_1 v\|^2 + \|P_1^\perp v\|^2} = \gamma\|P_1 v\|\sqrt{\epsilon^2 + t^2},$$

where $t = \|P_1^\perp v\|/\|P_1 v\|$. Since

$$\|P_1 v\|^2 = \|P_1 L_\lambda^{1/2} u\|^2 = \|L_\lambda^{1/2} P_1 u\|^2 = \|P_1 u\|_{L_\lambda}^2 = \alpha\|P_1 u\|^2$$

and

$$\|P_1^\perp v\|^2 = \|P_1^\perp u\|_{L_\lambda}^2 = ((L-\lambda)P_1^\perp u, P_1^\perp u) = (\lambda - \lambda_1)\|P_1 u\|^2,$$

we have $t^2 = \epsilon$, and hence

$$\|w\| \le \gamma\|P_1 v\|\sqrt{\epsilon(1+\epsilon)}.$$

Now, denoting $\cos\omega = \|P_1 w\|/\|w\|$, $\omega \ge 0$, we have

$$\|P_1 v'\| \ge (1+\epsilon)\|P_1 v\| - \|w\|\cos\omega, \quad \|P_1^\perp v'\| = \|w\|\sin\omega,$$

and hence

$$\frac{\|P_1^\perp v'\|^2}{\|P_1 v'\|^2} \le \frac{\|w\|^2\sin^2\omega}{((1+\epsilon)\|P_1 v\| - \|w\|\cos\omega)^2} \le \frac{\gamma^2\epsilon(1+\epsilon)\sin^2\omega}{\left(1+\epsilon-\gamma\sqrt{\epsilon(1+\epsilon)}\cos\omega\right)^2}$$

$$= \frac{\epsilon}{1+\epsilon}\gamma^2\frac{\sin^2\omega}{\left(1-\sqrt{\frac{\epsilon}{1+\epsilon}}\gamma\cos\omega\right)^2} = a^2\frac{1-x^2}{(1-ax)^2} \equiv f(x), \tag{A.1}$$

where $a = \gamma\sqrt{\epsilon/(1+\epsilon)} \le 1$ and $x = \cos\omega$. Elementary calculations show that the maximum of $f(x)$ on $[0,1]$ is achieved at $x = a$, hence the right-hand side of (A.1) is not greater than

$$f(a) = \frac{a^2}{1-a^2} = \frac{\epsilon\gamma^2}{1+(1-\gamma^2)\epsilon} = \frac{\gamma^2}{1+(1-\gamma^2)\frac{\lambda-\lambda_1}{\alpha}}\frac{\lambda-\lambda_1}{\alpha}.$$

It remains to estimate the left-hand side of (A.1) from below. We have (cf. the above calculations for $\|P_1 v\|$ and $\|P_1^\perp v\|$):

$$\|P_1 v'\|^2 = \|P_1 u'\|_{L_\lambda}^2 = \alpha\|P_1 u'\|^2$$

and

$$\begin{aligned}\|P_1^\perp v'\|^2 &= ((L-\lambda)P_1^\perp u', P_1^\perp u') = ((L-\lambda_1)P_1^\perp u', P_1^\perp u') - (\lambda-\lambda_1)\|P_1^\perp u'\|^2\\ &= (\lambda'-\lambda_1)\|u'\|^2 - (\lambda-\lambda_1)\|P_1^\perp u'\|^2 = (\lambda'-\lambda_1)\|P_1 u'\|^2 - (\lambda-\lambda')\|P_1^\perp u'\|^2.\end{aligned}$$

Let us now verify that $\lambda' \le \lambda$. Assuming that the opposite is true, we would have $\|P_1^\perp v'\|^2 \ge (\lambda'-\lambda_1)\|P_1 u'\|^2$ and (A.1) would imply

$$\frac{\lambda'-\lambda_1}{\alpha} \le \frac{\|P_1^\perp v'\|^2}{\|P_1 v'\|^2} \le \frac{\gamma^2}{1+(1-\gamma^2)\frac{\lambda-\lambda_1}{\alpha}}\frac{\lambda-\lambda_1}{\alpha} \le \frac{\lambda-\lambda_1}{\alpha},$$

which is a contradiction. Hence, $\lambda' \le \lambda$ and, using the well-known estimate (see, e.g., [5])

$$\frac{\|P_1^\perp u'\|^2}{\|P_1 u'\|^2} = \tan^2(u', \mathcal{I}_1) \le \frac{\lambda' - \lambda_1}{\lambda_2 - \lambda'},$$

where $\mathcal{I}_1$ is the invariant subspace corresponding to λ_1, we obtain

$$\frac{\|P_1^\perp v'\|^2}{\|P_1 v'\|^2} = \frac{1}{\alpha}\left(\lambda' - \lambda_1 - (\lambda - \lambda')\frac{\|P_1^\perp u'\|^2}{\|P_1 u'\|^2}\right)$$
$$\ge \frac{1}{\alpha}\left(\lambda' - \lambda_1 - (\lambda - \lambda')\frac{\lambda' - \lambda_1}{\lambda_2 - \lambda'}\right) = \frac{\lambda' - \lambda_1}{\lambda_2 - \lambda'}\frac{\lambda_2 - \lambda}{\alpha},$$

which, together with the above estimate for the right-hand side, leads to (6.1).

To prove that (6.1) is sharp, let us denote $\phi = \arctan\sqrt{\epsilon} > 0$, where $\epsilon = (\lambda - \lambda_1)/\alpha$, and consider the case $v = x_1 u_1 + x_2 u_2 + x_3 u_3$, where u_1, u_2, and u_3 are eigenvectors corresponding to $\lambda_1 < \lambda_2 < \lambda_3$ (any of these eigenvalues may be multiple), and

$$x_1 = \cos\phi, \quad x_2 = -\frac{\gamma\sin\phi}{\sqrt{1 + (1-\gamma^2)\tan^2\phi}}, \quad x_3 = \frac{\sqrt{1-\gamma^2}\tan\phi}{\sqrt{1 + (1-\gamma^2)\tan^2\phi}}$$

(note that $x_2^2 + x_3^2 = \sin^2\phi$). Let $\cos\omega = \gamma\sqrt{\epsilon/(1+\epsilon)} = \gamma\sin\phi$, and denote $\hat{w} = \cos\omega \cdot u_1 + \sin\omega \cdot u_2$, $v^\perp = -\epsilon P_1 v + P_1^\perp v$ (we have $(v^\perp, v) = -\epsilon\|P_1 v\|^2 + \|P_1^\perp v\|^2 = -\tan^2\phi\cos^2\phi + \sin^2\phi = 0$, hence the notation) and $\hat{v}^\perp = v^\perp/\|v^\perp\|$. Let $K = L_\lambda^{-1/2}\hat{K}L_\lambda^{-1/2}$, where $\hat{K}$ is defined by

$$\hat{K}u = u + \gamma(u - 2(u,z)z), \quad z = \|\hat{v}^\perp - \hat{w}\|^{-1}(\hat{v}^\perp - \hat{w}).$$

It is easy to verify that $\kappa_1 = 1 - \gamma$ and $\kappa_{-1} = 1 + \gamma$ (hence $\tau_* = 1$) and that $(\hat{K} - 1)\hat{v}^\perp = \gamma\hat{w}$. Since

$$\|v^\perp\|^2 = \epsilon^2\|P_1 v\|^2 + \|P_1^\perp v\|^2 = \tan^4\phi\cos^2\phi + \sin^2\phi = \tan^2\phi$$

we have

$$\begin{aligned} w = (\hat{K} - 1)v^\perp = \|v^\perp\|(\hat{K} - 1)\hat{v}^\perp &= \gamma\tan\phi\left(\gamma\sin\phi \cdot u_1 + \sqrt{1 - \gamma\sin^2\phi} \cdot u_2\right) \\ &= \gamma^2\tan\phi\sin\phi \cdot u_1 + \gamma\tan\phi\sqrt{1 - \gamma\sin^2\phi} \cdot u_2 \\ &= \gamma^2\tan^2\phi\cos\phi \cdot u_1 + \gamma\sin\sqrt{1 + (1-\gamma^2)\tan^2\phi} \cdot u_2 \end{aligned}$$

and hence

$$\begin{aligned} v' = (1+\epsilon)P_1 v - w &= (1 + (1-\gamma^2)\tan^2\phi)\cos\phi \cdot u_1 - \gamma\sin\sqrt{1 + (1-\gamma^2)\tan^2\phi} \cdot u_2 \\ &= (1 + (1-\gamma^2)\tan^2\phi)(x_1 u_1 + x_2 u_2) \end{aligned}$$

Since $v' \in \operatorname{span}\{u_1, u_2\}$, and therefore $u' \in \operatorname{span}\{u_1, u_2\}$, we have

$$\frac{\|P_1^\perp v'\|^2}{\|P_1 v'\|^2} = \frac{x_2^2}{x_1^2} = \frac{\gamma^2\tan^2\phi}{1 + (1-\gamma^2)\tan^2\phi}, \quad \frac{\|P_1^\perp u'\|^2}{\|P_1 u'\|^2} = \frac{\lambda' - \lambda_1}{\lambda_2 - \lambda'}.$$

Further,

$$\frac{\|P_1^\perp v'\|^2}{\|P_1 v'\|^2} = \frac{((L-\lambda)P_1^\perp u', P_1^\perp u')}{\alpha\|P_1 u'\|^2} = \frac{\lambda_2-\lambda}{\alpha}\frac{\|P_1^\perp u'\|^2}{\|P_1 u'\|^2} = \frac{\lambda_2-\lambda}{\alpha}\frac{\lambda'-\lambda_1}{\lambda_2-\lambda'}.$$

Recalling that $\tan^2\phi = \epsilon^2 = (\lambda-\lambda_1)/\alpha$, and observing that λ' is a function of λ, γ, and α, we arrive at the identity

$$\Delta(\lambda') = \frac{\gamma^2}{1+(1-\gamma^2)\frac{\lambda-\lambda_1}{\alpha}}\Delta(\lambda), \quad \lambda\in[\lambda_1,\lambda_2), \quad \gamma\in[0,1], \quad \alpha>0.$$

It remains to be shown that $\lambda' \le \lambda(u-\tau K(L-\lambda)u)$ for any τ. Let us denote $v'_\tau = v-\tau\hat{K}v^\perp$ and $u'_\tau = L_\lambda^{-1/2}v'_\tau$. Using the fact that $v' = (1+(1-\gamma^2)\tan^2\phi)(x_1u_1+x_2u_2)$ (cf. above), we have

$$\begin{aligned} v'_\tau &= v-\tau(v^\perp+w) = v'-(\tau-1)(v^\perp+w) = v'-(\tau-1)(v-v') \\ &= v'-(\tau-1)((1+(1-\gamma^2)\tan^2\phi)^{-1}v'+x_3u_3-v') \equiv \beta v'-(\tau-1)x_3u_3, \end{aligned}$$

and hence $u'_\tau = \beta u' - (\lambda_3-\lambda)^{-1/2}(\tau-1)x_3u_3$. Since $u'\in\operatorname{span}\{u_1,u_2\}$, this implies $\lambda(u'_\tau)\ge\lambda(u')=\lambda'$.

A.2. Auxiliary result used in Theorem 5.1.

LEMMA A.1. *Let ϵ be a sequence of positive real numbers such that*

$$\epsilon = \sum_{i=0}^{\infty}\epsilon_i < \infty.$$

Let κ be a positive real number and let t_i be a sequence of positive real numbers starting with $t_0=1$ and satisfying the following conditions: if $\epsilon_i(\kappa+t_i^{-2})<1$, then

$$t_{i+1} \le \frac{1+\epsilon_i(\kappa t_i^2+1)}{1-\epsilon_i(\kappa+t_i^{-2})}t_i^{-1} \tag{A.2}$$

and if $\epsilon_i(\kappa t_i^2+1)<1$, then

$$t_{i+1}^{-1} \le \frac{1+\epsilon_i(\kappa+t_i^{-2})}{1-\epsilon_i(\kappa t_i^2+1)}t_i. \tag{A.3}$$

If ϵ is small enough, then

$$t^{-1}\le t_i\le t = 1+c\,\epsilon, \tag{A.4}$$

where $c>0$ does not depend on i and ϵ.

Proof. Consider the following function:

$$\Phi_\epsilon(t) = F(\epsilon(\kappa t^2+1)) + F(\epsilon(\kappa+t^2)), \quad F(x) = x(1-\ln(1-x)). \tag{A.5}$$

For $\epsilon<\epsilon_\kappa\equiv\min\{(4\kappa+1)^{-1},(\kappa+4)^{-1}\}$, the definition domain of $\Phi_\epsilon(t)$ (as a real function of the real argument t) includes the interval $[1,2]$. Obviously, $\Phi_\epsilon(t)\to0$ as $\epsilon\to0$: let $\epsilon<\epsilon_\kappa$ be small enough so that $\Phi_\epsilon(2)<\ln 2$. Since $\Phi_\epsilon(1)>\ln 1$, the equation $\Phi_\epsilon(t)=\ln t$ has a solution $t=t(\epsilon)\in[1,2]$ that has the following asymptotics in ϵ: $t=\exp(F(\epsilon(\kappa t^2+1))+F(\epsilon(\kappa+t^2)))=1+\mathcal{O}(\epsilon)$.

Let us now denote $a = \kappa t^2 + 1$ and $b = \kappa + t^2$, and consider the sequence u_n defined as follows:

$$u_0 = 1, \quad u_n = \prod_{k=0}^{n-1} \frac{1+\epsilon_{2k+1}a}{1-\epsilon_{2k+1}b}\frac{1+\epsilon_{2k}b}{1-\epsilon_{2k}a}, \ n > 0$$

(note that $\epsilon_i a \le \epsilon(4\kappa+1) < 1$ and $\epsilon_i b \le \epsilon(\kappa+4) < 1$). Using elementary inequalities $\ln(1+x) \le x$ and $-\ln(1-x) \le x(1-\ln(1-x))$, we have

$$\begin{aligned}\ln u_n &= \sum_{k=0}^{n-1}(\ln(1+\epsilon_{2k+1}a) + \ln(1+\epsilon_{2k}b) - \ln(1-\epsilon_{2k+1}b) - \ln(1-\epsilon_{2k}a)) \\ &\le \sum_{k=0}^{n-1}(\epsilon_{2k+1}a + \epsilon_{2k}b + \epsilon_{2k+1}b + \epsilon_{2k}a - \epsilon_{2k+1}b\ln(1-\epsilon_{2k+1}b) - \epsilon_{2k}a\ln(1-\epsilon_{2k}a))\end{aligned}$$

and, since $\ln(1-x) \le 0$ for $0 < x \le 1$ and $\epsilon_i \le \epsilon$,

$$\begin{aligned}\ln u_n &\le (a(1-\ln(1-\epsilon a)) + b(1-\ln(1-\epsilon b)))\sum_{k=0}^{n}(\epsilon_{2k}+\epsilon_{2k+1}) \\ &\le (a(1-\ln(1-\epsilon a)) + b(1-\ln(1-\epsilon b)))\epsilon = \Phi_\epsilon(t) = \ln t;\end{aligned}$$

i.e., $u_n \le t$. By similar arguments, for the sequence

$$v_0 = 1, \quad v_n = \prod_{k=0}^{n-1} \frac{1+\epsilon_{2k+1}b}{1-\epsilon_{2k+1}a}\frac{1+\epsilon_{2k}a}{1-\epsilon_{2k}b}, \ n > 0$$

we have $v_n \le t$.

Let us now turn to the sequence t_i. Since $t_0 = 1 \le t$ and $\epsilon_0(\kappa+t_0^{-2}) < \epsilon(\kappa+4) < 1$, we have

$$t_1 \le \frac{1+\epsilon_0(\kappa t_0^2+1)}{1-\epsilon_0(\kappa+t_0^{-2})}t_0^{-1} \le \frac{1+\epsilon_0(\kappa t^2+1)}{1-\epsilon_0(\kappa+t^2)} \le \frac{1+\epsilon_1(\kappa+t^2)}{1-\epsilon_1(\kappa t^2+1)}\frac{1+\epsilon_0(\kappa t^2+1)}{1-\epsilon_0(\kappa+t^2)} = v_1 \le t$$

and, since $\epsilon_0(\kappa t_0^2+1) < \epsilon(4\kappa+1) < 1$, we have

$$t_1^{-1} \le \frac{1+\epsilon_0(\kappa+t_0^{-2})}{1-\epsilon_0(\kappa t_0^2+1)}t_0 \le \frac{1+\epsilon_0(\kappa+t^2)}{1-\epsilon_0(\kappa t^2+1)} \le u_1 \le t.$$

Using the above two estimates we, in turn, obtain

$$\begin{aligned}t_2 &\le \frac{1+\epsilon_1(\kappa t_1^2+1)}{1-\epsilon_1(\kappa+t_1^{-2})}t_1^{-1} \le \frac{1+\epsilon_1(\kappa t_1^2+1)}{1-\epsilon_1(\kappa+t_1^{-2})}\frac{1+\epsilon_0(\kappa+t_0^{-2})}{1-\epsilon_0(\kappa t_0^2+1)}t_0 \\ &\le \frac{1+\epsilon_1(\kappa t^2+1)}{1-\epsilon_1(\kappa+t^2)}\frac{1+\epsilon_0(\kappa+t^2)}{1-\epsilon_0(\kappa t^2+1)} = u_1 \le t \\ t_2^{-1} &\le \frac{1+\epsilon_1(\kappa+t_1^{-2})}{1-\epsilon_1(\kappa t_1^2+1)}t_1 \le \frac{1+\epsilon_1(\kappa+t_1^{-2})}{1-\epsilon_1(\kappa t_1^2+1)}\frac{1+\epsilon_0(\kappa t_0^2+1)}{1-\epsilon_0(\kappa+t_0^{-2})}t_0^{-1} \\ &\le \frac{1+\epsilon_1(\kappa+t^2)}{1-\epsilon_1(\kappa t^2+1)}\frac{1+\epsilon_0(\kappa t^2+1)}{1-\epsilon_0(\kappa+t^2)} = v_1 \le t\end{aligned}$$

etc. □
