$$\|u-u_h\|_V + \|\mathbf{p}-\mathbf{p}_h\|_{L^2(\Omega)^2} + \|\lambda - \lambda_h\|_{H^{\frac{1}{2}}(\Gamma_c)} \leq C(\delta,u,\mathbf{p})h^{\frac{3}{4}}, \tag{60}$$

where $C(\delta, u, \mathbf{p})$ *depends linearly on* $\|u_{|\Omega^\ell}\|_{H^2(\Omega^\ell)}$, $\|\mathbf{p}_{|\Omega^\ell}\|_{H^1(\Omega^\ell)^2}$, *and* $\|\operatorname{div}\mathbf{p}_{|\Omega^\ell}\|_{H^1(\Omega^\ell)^2}$, $\ell = 1, 2$.

Remark 4.7. The global error estimate (59) is only $O(h^{\frac{1}{2}})$ because the approximation of the Lagrange multiplier λ by functions of M_h^0 cannot provide better results even if λ is more regular, as can be seen in (55).

5. Numerical experiments.

In order to perform the computations, the matrix formulation of problem (27) is derived. It is readily checked that $(u_h, \mathbf{p}_h, \lambda_h) \in V_h \times \mathbf{X}_h \times M_h$ is a solution of (27) if and only if $(u_h, \mathbf{p}_h, \lambda_h)$ is a saddle-point of the Lagrangian defined on $V_h \times \mathbf{X}_h \times M_h$ by

$$\mathcal{L}(v_h, \mathbf{q}_h, \mu_h) = \mathcal{J}(v_h, \mathbf{q}_h) + \int_{\Gamma_c} \mu_h.(\mathbf{q}_h.\nu)\, d\sigma, \tag{61}$$

which means that $(u_h, \mathbf{p}_h, \lambda_h)$ satisfies

$$\mathcal{L}(u_h, \mathbf{p}_h, \mu_h) \le \mathcal{L}(u_h, \mathbf{p}_h, \lambda_h) \le \mathcal{L}(v_h, \mathbf{q}_h, \lambda_h) \quad \forall (v_h, \mathbf{q}_h) \in V_h \times \mathbf{X}_h,\ \forall \mu_h \in M_h.$$

Let $\mathbf{V}$, $\mathbf{U}$ denote the vectors with the entries given by the nodal values of the functions $(v_h, \mathbf{q}_h)$ and $(u_h, \mathbf{p}_h)$, respectively. Let M and Λ be the vectors with the entries given by the nodal values of μ_h and λ_h, respectively, for the three different choices of the space M_h, namely $M_h = M_h^1$, $M_h = M_h^{1,*}$, or $M_h = M_h^0$. Therefore, the saddle-point problem for Lagrangian (61) can be rewritten in finite dimensional setting:
Find $\mathbf{U} = (u_h, \mathbf{p}_h)$ and Λ, defined by the following max-min condition:

$$\max_{SM \ge 0} \left(\min_{\mathbf{V}} \frac{1}{2} {}^t\mathbf{V}\mathbf{K}\mathbf{V} - {}^t\mathbf{V}\mathbf{F} + ({}^t\mathbf{V}\,\mathbf{L})SM \right), \tag{62}$$

where $\mathbf{K}$ denotes the stiffness matrix, $\mathbf{F}$ is the vector corresponding to the external loading, and the matrix S expresses the sign conditions for multipliers (24)–(26).

Given a triangularization $\mathcal{T}_h$ of Ω, let N denote the number of nodes in Ω and N_T the number of elements in $\mathcal{T}_h$. Denote by $(w_i)_{i=1}^N$ the Lagrange finite element basis of V_h and let (Φ_i) stand for the basis in the space $\mathbf{X}_h$. Each vector function Φ_i either is of the form $(w_i, 0)$, $1 \le i \le N$, $(b_i, 0)$, $1 \le i \le N_T$, or is given by $(0, w_i)$, $1 \le i \le N$, $(0, b_i)$, $1 \le i \le N_T$, respectively, where b_i denotes a bubble function. Then the matrix K is defined by

$$\mathbf{K} = \begin{pmatrix} A_\delta & {}^tB_1 & {}^tB_2 \\ -B_1 & G_1 & 0 \\ -B_2 & 0 & G_2 \end{pmatrix},$$

and the right-hand side takes the form

$$\mathbf{F} = \begin{pmatrix} D\,F \\ 0 \\ 0 \end{pmatrix},$$

with $F = (f_i)_i$, $D = (\int_\Omega w_i\, w_j\, dx)_{ij}$, $i, j = 1, \dots, N$, and $A_\delta = \delta\, D$. The matrices B_1 and B_2 are defined by $(B_1)_{ij} = (\int_\Omega w_j \partial_1 \Phi_i^{(1)}\, dx)_{ij}$ and $(B_2)_{ij} = (\int_\Omega w_j \partial_2 \Phi_i^{(2)}\, dx)_{ij}$, $j = 1, \dots, N$, $i = 1, \dots, N + N_T$. Finally,

$$G_1 = G_2 = \begin{pmatrix} D & (\int_\Omega w_i\, b_j\, dx)_{ij} \\ (\int_\Omega b_i\, w_j\, dx)_{ij} & (\int_\Omega b_i^2\, dx)\delta_{ij} \end{pmatrix},$$

where δ_{ij} is the Kronecker symbol.

Let N_c denote the number of nodes on Γ_c and let us denote by $(\psi_i)_i$, $1 \le i \le N_c$ the basis in the space $W_h^1(\Gamma_c)$ and by $(\varphi_i)_i$ the basis of $W_h^0(\Gamma_c)$, $1 \le i \le N_c - 1$. We have a specific form of S for each particular choice of M_h, namely

- if M_h is M_h^0 or M_h^1 then S is given by the identity matrix,
- if $M_h = M_h^{1,*}$, then S is given by $S_{ij} = \int_{\Gamma_c} \psi_i \, \psi_j \, d\Gamma$, $1 \le i, j \le N_c$.

Finally, the *coupling* matrix

$$L = \begin{pmatrix} 0 \\ L_1 \\ L_2 \end{pmatrix}$$

is defined in the following way:

- If $M_h = M_h^1$ or $M_h = M_h^{1,*}$, then

$$(L^1)_{ij} = \begin{cases} \int_{\Gamma_c} \psi_j \, ((w_i, 0).\nu) \, d\Gamma, & 1 \le i \le N, \ 1 \le j \le N_c, \\ 0, & 1 \le i \le N_T, \ 1 \le j \le N_c, \end{cases}$$

and

$$(L^2)_{ij} = \begin{cases} \int_{\Gamma_c} \psi_j \, ((0, w_i).\nu) \, d\Gamma, & 1 \le i \le N, \ 1 \le j \le N_c, \\ 0, & 1 \le i \le N_T, \ 1 \le j \le N_c. \end{cases}$$

- If $M_h = M_h^0$, then

$$(L^1)_{ij} = \begin{cases} \int_{\Gamma_c} \varphi_j \, ((w_i, 0).\nu) \, d\Gamma, & 1 \le i \le N, \ 1 \le j \le N_c - 1, \\ 0, & 1 \le i \le N_T, \ 1 \le j \le N_c, \end{cases}$$

and

$$(L^2)_{ij} = \begin{cases} \int_{\Gamma_c} \varphi_j \, ((0, w_i).\nu) \, d\Gamma, & 1 \le i \le N, \ 1 \le j \le N_c - 1, \\ 0, & 1 \le i \le N_T, \ 1 \le j \le N_c. \end{cases}$$

The solution $(\mathbf{U}, \Lambda)$ of (62) satisfies the saddle-point conditions and we have

$$\mathbf{U} = \mathbf{K}^{-1}(\mathbf{F} - L \, S\Lambda). \tag{63}$$

Therefore, for $\Phi = S\Lambda$, the saddle-point problem (62) can be rewritten as a quadratic programming problem

$$\min_{\Phi \ge 0} \left(\frac{1}{2} {}^t\Phi {}^tL\mathbf{K}^{-1}L\Phi - {}^t\Phi {}^tL\mathbf{K}^{-1}\mathbf{F} + \frac{1}{2} {}^t\mathbf{F}\mathbf{K}^{-1}\mathbf{F} \right). \tag{64}$$

If $\overline{\Phi}$ is the solution of (64) then $\Lambda = S^{-1}\overline{\Phi}$. The solution $\mathbf{U}$ is obtained by solving (63).

We note that eliminating the bubbles yields problems (64) and (63) with reduced matrices to be solved and, therefore, with reduced number of unknowns.

In all the numerical experiments, the domain $\Omega =]0, 4[\times]0, 1[$ is fixed, and data are selected as follows: $f = 1$, $\delta = 0.1$.

In the first example the numerical comparison of the three methods corresponding to $M_h = M_h^0$, $M_h = M_h^1$, and $M_h = M_h^{1,*}$ is performed. This comparison is limited to the case of only one global triangulation in the whole domain Ω, which is in fact our goal. It can be expected, as for classical unilateral contact problems, that different

triangulations of Ω^1 and Ω^2 with nonmatching grids at the crack Γ_c lead to the same numerical results. For $\Gamma_c =]0,4[\times \left\{\frac{1}{2}\right\}$ the relative errors $\|u - u_h\|_{L^2(\Omega)}$, $\|\mathbf{p} - \mathbf{p}_h\|_{L^2(\Omega)}$, and $\|\lambda - \lambda_h\|_{L^2(\Gamma_c)}$ are computed. Since the exact solution is not available, we use (as usual) a reference solution obtained for the sufficiently fine mesh, namely for the triangulation which is made of 3308 elements, with 1725 degrees of freedom and 114 vertices on Γ_c. In Tables 1–4, the relative errors are reported as a function of the degrees of freedom (dof). The respective convergence curves, which represent the logarithms of the relative errors in function of the logarithms of dof, are given by Figures 3–5. The three methods lead to similar approximation results, and this fact agrees with the theoretical estimates and it is also in accordance with previous numerical studies for classical unilateral contact problems (see, e.g., [14]). Since the solution is sufficiently smooth (in particular, u is continuous), the norm of λ is relatively small, which explains the fact that the relative error for λ is quite large (compared to the others errors). In addition, the approximation results for $\mathbf{p}$ could be significantly improved by employing finite elements other than the stabilized linear elements ($\mathcal{P}_B$), which are known to be less efficient for the approximation of functions in $\mathbf{X}$.

In the second example, we present the isolines of u, p_1, and p_2 with various cuts. The plots are obtained by the interpolation of the computed solution $(u_h, \mathbf{p}_h)$ on a new regular and coarse mesh. Figures 6–8 correspond to $\Gamma_c =]1,3[\times \left\{\frac{3}{4}\right\}$; as expected from the symmetry of the domain (with respect to Γ_c) and of the data, the solution $(u, \mathbf{p})$ is smooth. In Figures 9–11, the crack line $\Gamma_c =]0,1[\times \left\{\frac{1}{4}\right\}$ touches the boundary at one of its endpoints, and the domain is not symmetric.

6. Conclusion. We performed the convergence analysis and derived the error estimates. The variational formulation was constructed and implemented. The numerical results are in full agreement with the theoretical estimates.

The further applications of the proposed numerical methods concern the contact problems in elasticity with the Coulomb friction.

Appendix. In this appendix, we give the proof of Lemma 4.1, which states the following abstract error:

$$\|u-u_h\|_V^2+\|\mathbf{p}-\mathbf{p}_h\|_{L^2(\Omega)^2}^2 \le c\big(|A(\mathbf{U}-\mathbf{U}_h,\mathbf{U}-\mathbf{V}_h)|+|d(\mu_h-\lambda,\mathbf{p}-\mathbf{p}_h)+d(\lambda-\lambda_h,\mathbf{p}-\mathbf{q}_h) \\ + d(\lambda-\mu_h,\mathbf{p})+d(\lambda_h,\mathbf{p})+d(\mu_h,\mathbf{p}_h)| + \inf_{v_h\in V_h}\|u-v_h\|_V^2 + \|\lambda-\lambda_h\|^2\big).$$

Proof. We have

$$\delta\|u-u_h\|_V^2 = a_\delta(u-u_h,u-u_h) = a_\delta(u-u_h,u-v_h)+a_\delta(u-u_h,v_h-u_h), \quad v_h\in V_h.$$

Noting that $V_h \subset V$ and subtracting the first lines of (23) and (27) (with $v = u_h - v_h$), we obtain

$$\delta\|u-u_h\|_V^2 = a_\delta(u-u_h,u-v_h)+b(u_h-v_h,\mathbf{p}-\mathbf{p}_h) \\ = a_\delta(u-u_h,u-v_h)+b(u-v_h,\mathbf{p}-\mathbf{p}_h)+b(u_h-u,\mathbf{p}-\mathbf{q}_h)+b(u_h-u,\mathbf{p}_h-\mathbf{q}_h) \quad \forall \mathbf{q}_h\in\mathbf{X}_h.$$

Since $\mathbf{X}_h \subset \mathbf{X}$, subtracting the second lines of (23) and (27) (with $\mathbf{q}$ and $\mathbf{q}_h$ replaced by $\mathbf{p}_h - \mathbf{q}_h$) yields

$$\begin{aligned}\delta\|u-u_h\|_V^2 &= a_\delta(u-u_h,u-v_h)+b(u_h-v_h,\mathbf{p}-\mathbf{p}_h)\\ &= a_\delta(u-u_h,u-v_h)+b(u-v_h,\mathbf{p}-\mathbf{p}_h)+b(u_h-u,\mathbf{p}-\mathbf{q}_h)\\ &\quad + g(\mathbf{q}_h-\mathbf{p}_h,\mathbf{p}-\mathbf{p}_h)+d(\lambda-\lambda_h,\mathbf{q}_h-\mathbf{p}_h), \quad \mathbf{q}_h\in\mathbf{X}_h\\ &= a_\delta(u-u_h,u-v_h)+b(u-v_h,\mathbf{p}-\mathbf{p}_h)+b(u_h-u,\mathbf{p}-\mathbf{q}_h)\\ &\quad + g(\mathbf{q}_h-\mathbf{p},\mathbf{p}-\mathbf{p}_h)+g(\mathbf{p}-\mathbf{p}_h,\mathbf{p}-\mathbf{p}_h)+d(\lambda-\lambda_h,\mathbf{p}_h-\mathbf{q}_h).\end{aligned}$$

Noting that $d(\lambda_h,\mathbf{p}_h)=0$, we deduce that for all $\mu_h\in M_h$

$$\begin{aligned}d(\lambda-\lambda_h,\mathbf{p}_h-\mathbf{q}_h) &= d(\lambda,\mathbf{p}_h-\mathbf{q}_h)+d(\lambda_h,\mathbf{q}_h)\\ &= d(\mu_h-\lambda,\mathbf{p}-\mathbf{p}_h)+d(\lambda-\lambda_h,\mathbf{p}-\mathbf{q}_h)+d(\lambda-\mu_h,\mathbf{p})\\ &\quad + d(\lambda_h,\mathbf{p})+d(\mu_h,\mathbf{p}_h).\end{aligned}$$

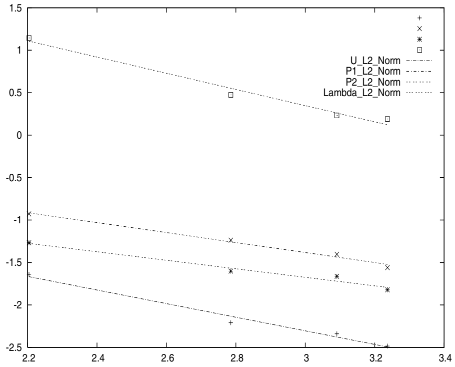

FIG. 3. *Convergence rate with $M_h = M_h^0$.*

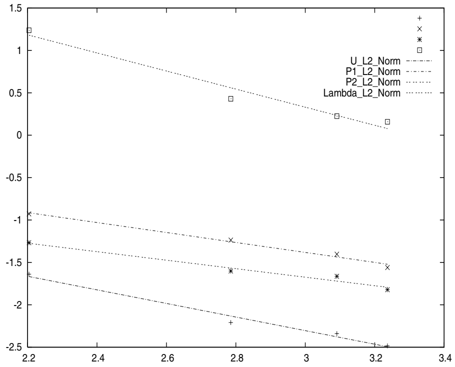

FIG. 4. *Convergence rate with $M_h = M_h^1$.*

Thus, we obtain (from the definition of $g(.,.)$)

$$\begin{aligned}\|\mathbf{p}-\mathbf{p}_h\|^2_{L^2(\Omega)^2} \le \delta\|u-u_h\|_V^2 &+ \big(|a_\delta(u-u_h,u-v_h)| + b(u-v_h,\mathbf{p}-\mathbf{p}_h)\\ &+ b(u_h-u,\mathbf{p}-\mathbf{q}_h) + g(\mathbf{q}_h-\mathbf{p},\mathbf{p}-\mathbf{p}_h)| + |d(\mu_h-\lambda,\mathbf{p}-\mathbf{p}_h)\\ &d(\lambda-\lambda_h,\mathbf{p}-\mathbf{q}_h) + d(\lambda-\mu_h,\mathbf{p}) + d(\lambda_h,\mathbf{p}) + d(\mu_h,\mathbf{p}_h)|\big),\end{aligned}$$

and this inequality is written as

$$\begin{aligned}\|\mathbf{p}-\mathbf{p}_h\|^2_{L^2(\Omega)^2} \le \delta\|u-u_h\|_V^2 &+ \big(|A(\mathbf{U}-\mathbf{U}_h,\mathbf{U}-\mathbf{V}_h)| + |d(\mu_h-\lambda,\mathbf{p}-\mathbf{p}_h)\\ &d(\lambda-\lambda_h,\mathbf{p}-\mathbf{q}_h) + d(\lambda-\mu_h,\mathbf{p}) + d(\lambda_h,\mathbf{p}) + d(\mu_h,\mathbf{p}_h)|\big).\end{aligned} \tag{65}$$

Next, we have

$$\begin{aligned}b(u_h-v_h,\mathbf{q}_h) &= b(u_h-u,\mathbf{q}_h) + b(u-v_h,\mathbf{q}_h)\\ &= g(\mathbf{p}-\mathbf{p}_h,\mathbf{q}_h) + d(\lambda-\lambda_h,\mathbf{q}_h) + b(u-v_h,\mathbf{q}_h)\\ &\le g(\mathbf{p}-\mathbf{p}_h,\mathbf{q}_h) + d(\lambda-\lambda_h,\mathbf{q}_h) + b(u-v_h,\mathbf{q}_h),\end{aligned}$$

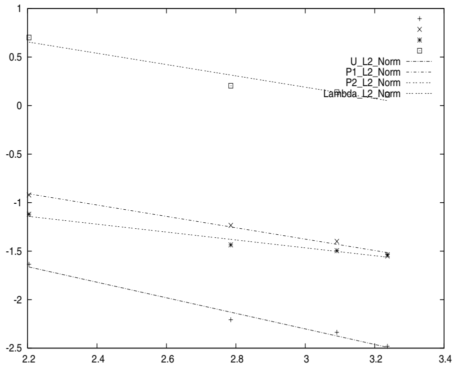

FIG. 5. *Convergence rate with* $M_h = M_h^{1,*}$.

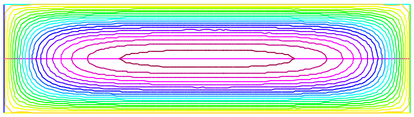

FIG. 6. *Isolines of* u.

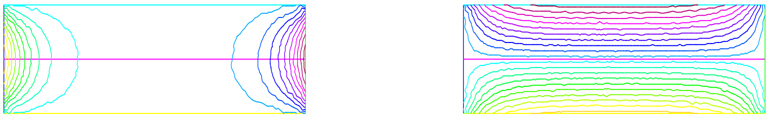

FIG. 7. *Isolines of* p_1 *(left) and* p_2 *(right).*

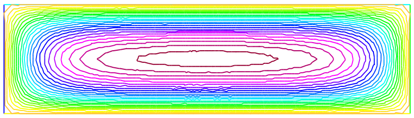

FIG. 8. *Isolines of* u.

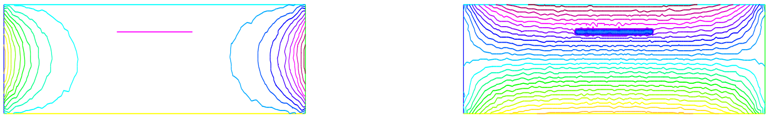

FIG. 9. *Isolines of* p_1 *(left) and* p_2 *(right).*

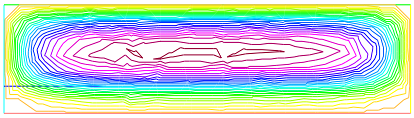

FIG. 10. *Isolines of* u.

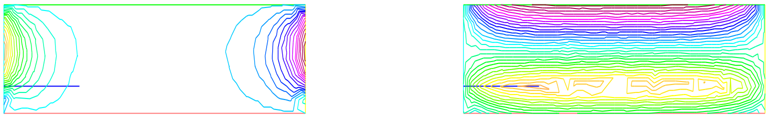

FIG. 11. *Isolines of* p_1 *(left) and* p_2 *(right).*

and using the inf-sup condition (19), we derive

$$\begin{aligned}\|u_h - v_h\|_V &\leq \gamma^{-1} \sup_{\mathbf{q}_h \in \mathbf{X}_h} \frac{|b(u - v_h, \mathbf{q}_h) + g(\mathbf{p} - \mathbf{p}_h, \mathbf{q}_h) + d(\lambda - \lambda_h, \mathbf{q}_h)|}{\|\mathbf{q}_h\|_{\mathbf{X}}} \\ &\leq \gamma^{-1}\big(\|b\| \|u - v_h\|_V + \|g\|\, \|\mathbf{p} - \mathbf{q}_h\|_{L^2(\Omega)^2} + \|d\|\, \|\lambda - \lambda_h\|\big),\end{aligned}$$

where $\|b\|$, $\|g\|$, and $\|d\|$ denote the norms of the bilinear forms, from which, combining with the triangle inequality, we have

(66)

$$\|u - u_h\|_V \leq \big((1 + \gamma^{-1}\|b\|) \inf_{v_h \in V_h} \|u - v_h\|_V + \gamma^{-1}\|g\|\, \|\mathbf{p} - \mathbf{p}_h\|_{L^2(\Omega)^2} + \gamma^{-1}\|d\|\, \|\lambda - \lambda_h\|\big).$$

Inserting in (65) yields

$$\begin{aligned}(1 - \delta\gamma^{-1}\|g\|)\, \|\mathbf{p} - \mathbf{p}_h\|^2_{L^2(\Omega)^2} &\leq \delta\,\big((1 + \gamma^{-1}\|b\|) \inf_{v_h \in V_h} \|u - v_h\|^2_V + \gamma^{-1}\|d\|\, \|\lambda - \lambda_h\|^2\big) \\ &\quad + \big(|A(\mathbf{U} - \mathbf{U}_h, \mathbf{U} - \mathbf{V}_h)| + |d(\mu_h - \lambda, \mathbf{p} - \mathbf{p}_h) d(\lambda - \lambda_h, \mathbf{p} - \mathbf{q}_h) \\ &\qquad + d(\lambda - \mu_h, \mathbf{p}) + d(\lambda_h, \mathbf{p}) + d(\mu_h, \mathbf{p}_h)|\big),\end{aligned}$$

from which

(67)

$$\begin{aligned}\|\mathbf{p} - \mathbf{p}_h\|^2_{L^2(\Omega)^2} &\leq C(\delta, \gamma, \|b\|, \|g\|, \|d\|)\left(\inf_{v_h \in V_h} \|u - v_h\|^2_V + \|\lambda - \lambda_h\|^2\right) \\ &\quad + \big(|A(\mathbf{U} - \mathbf{U}_h, \mathbf{U} - \mathbf{V}_h) + |d(\mu_h - \lambda, \mathbf{p} - \mathbf{p}_h) + d(\lambda - \lambda_h, \mathbf{p} - \mathbf{q}_h) \\ &\qquad + d(\lambda - \mu_h, \mathbf{p}) + d(\lambda_h, \mathbf{p}) + d(\mu_h, \mathbf{p}_h)|\big).\end{aligned}$$

The inequality (38) follows easily from (67) and (66). □

TENSOR-KRYLOV METHODS FOR SOLVING LARGE-SCALE SYSTEMS OF NONLINEAR EQUATIONS*

BRETT W. BADER†

Abstract. This paper develops and investigates iterative tensor methods for solving large-scale systems of nonlinear equations. Direct tensor methods for nonlinear equations have performed especially well on small, dense problems where the Jacobian matrix at the solution is singular or ill-conditioned, which may occur when approaching turning points, for example. This research extends direct tensor methods to large-scale problems by developing three tensor-Krylov methods that base each iteration upon a linear model augmented with a limited second-order term, which provides information lacking in a (nearly) singular Jacobian. The advantage of the new tensor-Krylov methods over existing large-scale tensor methods is their ability to solve the local tensor model to a specified accuracy, which produces a more accurate tensor step. The performance of these methods in comparison to Newton-GMRES and tensor-GMRES is explored on three Navier–Stokes fluid flow problems. The numerical results provide evidence that tensor-Krylov methods are generally more robust and more efficient than Newton-GMRES on some important and difficult problems. In addition, the results show that the new tensor-Krylov methods and tensor-GMRES each perform better in certain situations.

1. Introduction.

This paper describes a new class of methods for solving the nonlinear equations problem

$$\text{given } F : \mathbb{R}^n \to \mathbb{R}^n, \quad \text{find } x_* \in \mathbb{R}^n \text{ such that } F(x_*) = 0, \tag{1.1}$$

where it is assumed that $F(x)$ is at least once continuously differentiable. Large-scale systems of nonlinear equations defined by (1.1) arise in many practical situations, including systems produced by finite-difference or finite-element discretizations of boundary value problems for ordinary and partial differential equations.

Standard direct methods, such as Newton's method, are impractical on large-scale problems because of their high linear algebra costs and large memory requirements. Thus, most current practical approaches for solving large problems involve approximately solving a local linear model and then using these "inexact" steps to locate the next point.

Two inexact versions of tensor methods already exist for solving large problems. Bouaricha [5] describes an implementation of a tensor method using Krylov subspace methods for linear equations, which involves constructing an inexact tensor step from the approximate solutions of two linear systems (with the same Jacobian matrix). In addition, Feng and Pulliam [18] have developed a "tensor-GMRES" method, which first finds the Newton-GMRES step and then solves for an approximate tensor step.

We propose three variants of a new approach for solving the large-scale nonlinear equations problem (1.1). These new methods are an extension of the class of standard tensor methods [28], which base each iteration on a simplified quadratic model of $F(x)$ such that the quadratic term is a low-rank secant approximation that augments the standard linear model. Specifically, the new algorithms are an amalgamation of various techniques, including tensor methods for nonlinear equations [28], Krylov subspace techniques [8], and an inexact solver framework [14], that make them well-suited for large-scale problems. Given the parallels to Newton-Krylov methods [8], we call the new algorithms "tensor-Krylov" methods. In a manner similar to Newton-GMRES, the tensor-Krylov methods calculate an inexact tensor step from a specially chosen Krylov subspace that facilitates the solution of a minimization subproblem at each step. The Krylov subspace generated is different from the standard implementation of GMRES and requires some modifications to a block-Krylov solver.

The key feature of these new methods is that the step satisfies the local tensor model to within a specified tolerance, making it possible to control the quality of the step. In addition, the new tensor-Krylov methods are aptly suited to target problems where the Jacobian at the root is singular or, at least, very ill-conditioned. Newton-based methods do not handle singular problems well because they converge linearly to the solution and, in some cases, with poor accuracy [11, 12, 13, 21]. On the other hand, tensor methods are superlinearly convergent on singular problems under mild conditions [17].

Because the tensor-Krylov methods borrow elements from both direct tensor methods and linear Krylov subspace methods, these topics are reviewed before introducing the tensor-Krylov formulations. Section 2 reviews direct tensor methods for solving small-scale systems of nonlinear equations and includes background on pertinent large-scale methods, namely linear Krylov subspace methods, Newton-GMRES, and existing large-scale tensor methods. Then section 3 describes three different approaches for solving the local tensor model using a Krylov-based method and wraps these local Krylov solvers into a large-scale method with options for various global strategies. With the complete tensor-Krylov nonlinear solver fully discussed, section 4 describes several fluid flow benchmark problems that serve as ambitious test problems. Finally, section 5 makes some concluding remarks and discusses directions for future research.

Throughout this paper, a subscript k refers to the current iterate of a nonlinear solver. We denote the Jacobian $F'(x)$ by $J(x)$ and abbreviate $J(x_k)$ as J_k. Similarly, $F(x_k)$ is abbreviated often as F_k. When the context is clear, we may drop the subscript k on J_k, F_k, a_k, and s_k while still referring to the current values at an iteration.

2. Background and review.

In this section, we introduce standard methods for solving systems of nonlinear equations. We provide a brief review of standard methods in section 2.1 and a short introduction to tensor methods in section 2.2. We extend these methods to large-scale problems in sections 2.3 and 2.4 by reviewing Newton-Krylov methods and existing large-scale tensor methods, respectively. General references for topics in nonlinear solvers include [15], [20], and [25].

2.1. Standard methods. In this paper, we will refer to a class of methods, which we will call standard methods, for solving (1.1) that are based on a linear local model. Most notable among these methods is Newton's method, which bases each iteration upon a linear local model $M_N(x_k + d)$ of the function $F(x)$ around the current iterate $x_k \in \mathbb{R}^n$:

$$M_N(x_k + d) = F(x_k) + J(x_k)d, \tag{2.1}$$

where $d \in \mathbb{R}^n$ is the step and $J(x_k) \in \mathbb{R}^{n\times n}$ is either the current Jacobian matrix or an approximation to it. A root of this local model provides the Newton step

$$d_N = -J(x_k)^{-1}F(x_k),$$

which is used to reach the next trial point. Thus, Newton's method is defined when J_k is nonsingular and consists of updating the current point with the Newton step

$$x_{k+1} = x_k + d_N. \tag{2.2}$$

Due to large arithmetic and storage costs, implementations of Newton's method using direct factorizations of $J(x_k)$ are not practical for large-scale problems.

2.2. Tensor methods. Tensor methods solve (1.1) by including more information in the local model than Newton's method. By solving this augmented local model, tensor methods tend to generate steps of better quality than standard methods, thus reaching the solution faster. The local tensor model has the generic form

$$M_T(x_k + d) = F_k + J_k d + \tfrac{1}{2}T_k dd, \tag{2.3}$$

where $T_k \in \mathbb{R}^{n\times n\times n}$ is a tensor, which includes second-order information and is where these methods get their name. This term is selected so that the model interpolates $p \le \sqrt{n}$ previous function values in the recent history of iterates, which makes T_k a rank p tensor. Most often p is 1 or 2, but computational evidence in [28] suggests that $p > 1$ actually adds little to the computational performance of the direct method.

For this paper, we focus on the case of $p = 1$ because the tensor-Krylov methods only use one secant update. In this case, the tensor model about x_k reduces to

$$M_T(x_k + d) = F_k + J_k d + \tfrac{1}{2}a_k(s_k^T d)^2, \tag{2.4}$$

where

$$a_k \in \mathbb{R}^n = \frac{2(F_{k-1} - F_k - J_k s_k)}{(s_k^T s_k)^2}, \tag{2.5}$$

$$s_k \in \mathbb{R}^n = x_{k-1} - x_k. \tag{2.6}$$

After forming the model, we use it to determine the step to the next trial point. Because (2.4) may not have a root, one solves the minimization subproblem

$$\min_{d\in\mathbb{R}^n} \|M_T(x_k + d)\|_2\,, \tag{2.7}$$

and a root or minimizer of the model is the tensor step. Due to the special form of (2.4), the solution of (2.7) in the nonsingular case reduces to solving a quadratic equation followed by solving a system of $n - 1$ linear equations in as many unknowns.

A practical approach for solving (2.7), which relates to the presentation of tensor-Krylov methods in section 3, uses two orthogonal transformations to reduce the problem to two subproblems that are more easily solved. Briefly, the first transformation finds an orthogonal $Q_1 \in \mathbb{R}^{n\times n}$ such that $s/\|s\|$ is the last column and permits a change in variables

$$d = Q_1\hat{d}.$$

The second transformation finds an orthogonal $Q_2 \in \mathbb{R}^{n\times n}$ such that $Q_2 J_k Q_1$ is upper triangular. Thus, applying the two transformations to (2.4) and setting it equal to zero yields the following triangular system of n equations in n unknowns

$$Q_2 F + Q_2 J Q_1 \hat{d} + \tfrac{1}{2} Q_2 a \|s\|^2 \hat{d}_n^2 = 0, \tag{2.8}$$

where $\hat{d}_n \in \mathbb{R}$ is the quadratic variable.

Then, breaking (2.8) into two smaller problems, the solution to (2.7) continues by first solving for $\hat{d}_n$ by minimizing the quadratic equation appearing in the last row of (2.8) and choosing the smaller magnitude minimizer if there are two. Using the value of $\hat{d}_n$ in (2.8), a triangular linear system of size $(n-1)\times(n-1)$ is revealed. Finally, the complete solution to (2.7) is found by solving this resultant system for the remaining components of $\hat{d}$ and then reversing the variable space transformation from the first step, $d = Q_1\hat{d}$.

2.3. Newton-Krylov methods. Up to this point, this review has discussed direct methods for the solution of small, dense problems such that the local model is solved using direct factorizations of the Jacobian matrix. Large, sparse systems often are solved successfully using a class of "inexact" Newton methods:

$$x_{k+1} = x_k + d_k, \quad \text{where} \quad J(x_k)d_k = -F(x_k) + r_k, \quad \|r_k\| \le \eta_k \|F(x_k)\|, \tag{2.9}$$

where the local model typically is solved only approximately at each step using a less expensive approach. Successively better approximations at each iteration preserve the rapid convergence behavior of Newton's method when nearing the solution. The computational savings reflected in this less expensive inner iteration are usually partially offset with more outer iterations, but the overall savings still are quite significant on large-scale problems.

The most common methods for approximately solving the local Newton model in (2.9) are Krylov-based methods. Newton-Krylov methods have the appeal of requiring almost no matrix storage due to their exclusive use of Jacobian-vector products, which may be calculated by a finite-difference directional derivative.

A linear Krylov subspace method is a projection method that seeks an approximate solution x_m to the linear system $Ax = b$ from an m-dimensional affine subspace $x_0 + \mathcal{K}_m$. Here, $\mathcal{K}_m$ is the Krylov subspace

$$\mathcal{K}_m(A, r_0) = span\{r_0, Ar_0, A^2r_0, \ldots, A^{m-1}r_0\},$$

where $r_0 = b - Ax_0$ is the residual at an initial guess x_0. A popular Krylov subspace method is the Generalized Minimum Residual method (GMRES) [26], which computes a solution $x_m \in x_0 + \mathcal{K}_m$ such that the residual norm over all vectors in $x_0 + \mathcal{K}_m$ is minimized. That is, at the mth step, GMRES finds x_m such that $\|b - Ax_m\|_2$ is minimized for all $x_m \in x_0 + \mathcal{K}_m$. One drawback of GMRES is the storage requirement of an orthogonal basis, which could be larger than a sparse Jacobian matrix unless m is kept small. Other Krylov methods, such as BiCGSTAB and TFQMR (see, e.g., [25]), do not have these additional storage requirements but may not be as robust. Newton-GMRES is a popular algorithm for solving large-scale problems and will be the standard algorithm in our numerical experiments.

2.4. Previous large-scale, sparse tensor methods. The large-scale tensor methods described in this paper are not the first tensor methods aimed at large-scale problems. Two other methods have been proposed, and we will discuss them now.

Bouaricha [5] describes a large-scale implementation of a tensor method using Krylov subspace methods for linear equations (GMRES and FOM), which involves constructing an inexact tensor step from the approximate solutions of $J^{-1}F_k$ and $J^{-1}F_{k-1}$. The approach involves finding the values $s^TJ^{-1}F_k$ and $s^TJ^{-1}a_k$, which are used to calculate an approximate value of s^Td_T, which multiplies $J^{-1}a_k$ in the final computation of the step. More precise details regarding an efficient implementation may be found in [1] or [5].

Despite some favorable results in [5], we have found Bouaricha's method to be not as competitive on more practical problems. The two main disadvantages of this method stem from the fact that two linear systems must be solved for each outer iteration and that an accurate value of s^Td_T is not calculated, which may lead to spurious steps. Due to these theoretical disadvantages and based upon our own numerical experience with the algorithm in [1], we will not consider any numerical comparisons with Bouaricha's algorithm.

Feng and Pulliam [18] describe another large-scale tensor method that they call "tensor-GMRES." It uses a Krylov subspace projection technique, namely GMRES, to find the approximate Newton step $d_N = d_0 + V_m y_m$. The Arnoldi process in GMRES generates a Hessenberg matrix H_m and an orthonormal basis for the Krylov subspace $\mathcal{K}_m$ in the columns of V_m. Given these key matrices, their algorithm proceeds to solve a projected version of the tensor model (2.4) along a subspace that spans the Newton step direction (i.e., the approximate tensor step is in the span of the Krylov subspace $\mathcal{K}_m^N$ and d_0, or equivalently the span of the matrix $[V_m, d_0]$). Thus, their algorithm solves the least-squares problem

$$\min_{d \in \{d_0\} \cup \mathcal{K}_m^N} \left\| F_k + J_k d + \tfrac{1}{2} P a (s^T d)^2 \right\|, \tag{2.10}$$

where P is the projection matrix $P = Y(Y^TY)^{-1}Y^T$ and $Y = J_k[V_m, d_0]$.

The algorithm has some difficult algebra (details may be found in [18]), but the design is actually rather straightforward. The algorithm may be viewed as an extension of Newton-GMRES, where the inexact Newton step is calculated via GMRES in the standard way. The tensor step is calculated subsequently using the Krylov subspace information generated for the Newton step. In this way, the method is also consistent with preconditioning techniques and a matrix-free implementation, which makes it appealing for general use.

The extra work and storage beyond the GMRES method is actually quite small, and the analysis in [18] shows that the same superlinear convergence properties for the unprojected tensor model considered in [17] also hold for the projected tensor model in (2.10). These properties are evident in the numerical results of [18], which show the superlinear convergence behavior of tensor-GMRES on the singular and nearly singular problems, where the Newton-GMRES method exhibits linear convergence due to a lack of sufficient first-order information. The margin of improvement (in terms of reduction of nonlinear iterations over Newton's method) spanned 20–55 percent on the simpler problems and 32–60 percent on the more difficult Euler problem.

However, there are a few potential disadvantages related to the Feng and Pulliam method. The variable space restriction on d in the minimization problem (2.10) illustrates a possible disadvantage, particularly when using preconditioners or restarted GMRES. The norm of the projected tensor model is only minimized to the extent that the Krylov subspace for the Newton-GMRES step is large enough to capture important directions in the tensor step. For example, consider using an *exact* preconditioner, i.e., J_k itself. One iteration of GMRES solves the Newton equations exactly, and the Newton step direction is along v_1, the first basis vector in V_m. Then, according to the Feng–Pulliam method, the approximate tensor step that solves (2.10) could only be a scalar multiple of the direction v_1 (assuming that $d_0 = 0$). A similar example may be developed when using restarted GMRES in the Feng–Pulliam method—if GMRES converges soon after a restart, then the orthonormal basis V_m is smaller than before the restart. A smaller basis may lead to a tensor step that solves (2.10) with more error due to fewer degrees of freedom.

Despite these hypothetical examples, it is unclear whether solving (2.10) in a smaller variable space will adversely affect the practical performance of this method when using preconditioners or restarted GMRES. Because the Newton step tends to undershoot (or overshoot) when first-order information is lacking in the local model, the solution to the tensor model is often nearly along the Newton direction, so the subspace restriction on d might not be a problem. The fact remains, however, that the Feng–Pulliam method solves the *projected* tensor model (2.10), which loses some information in the projection. In addition, the relative stopping tolerance η_k in the Newton-GMRES step has no direct relationship with the error in the tensor model.

3. Tensor-Krylov methods.

The new tensor-Krylov methods differ from previous large-scale tensor methods in their ability to solve the local tensor model to a specified tolerance. Using either the methods of Bouaricha or Feng and Pulliam, the residual error $\|M_T(x_k + d)\|$ must be computed explicitly, making it difficult to assess the quality of the approximate tensor step that they compute. In addition, the new methods avoid the costly solution of two linear systems (as in Bouaricha's method) and compute the solution to the full tensor model, as opposed to a projected tensor model (as in the Feng–Pulliam method).

In the same manner that GMRES is an algorithm for solving linear systems and Newton-GMRES is the nonlinear solver, we make a distinction between the solver for the local tensor model and the nonlinear solver. In this section, we describe three procedures for iteratively solving the local tensor model that use the concepts from linear Krylov subspace methods. We restrict ourselves to the rank-one tensor model in (2.4)–(2.6), which only interpolates the function value at the previous iterate. Because (2.4) may or may not have a root, we seek a solution to the minimization problem

$$\min_{d \in \mathcal{K}_m} \|M_T(x_k + d)\|_2 = \min_{d \in \mathcal{K}_m} \left\| F_k + J_k d + \tfrac{1}{2} a_k (s_k^T d)^2 \right\|_2, \tag{3.1}$$

where $\mathcal{K}_m$ is a specially chosen Krylov subspace that facilitates the solution of the quadratic model. The three tensor-Krylov methods differ in their choice of $\mathcal{K}_m$, which becomes their signature difference and dictates the algorithm. We differentiate the three variants by the size of their initial block subspace, identifying them as block-2, block-2+, and block-3. The reason for considering three variants is related to their complexity and usefulness as a block algorithm. The block-3 method is the most straightforward and most likely the best block implementation, while the block-2 methods are more complex but may work better in scalar implementations.

In sections 3.1–3.3, we start with a description of the three Krylov-based techniques for solving the local tensor model. Due to space considerations, we describe only the block-2 method in detail and refer to [1] for more detailed information on the other two methods. Section 3.1 covers all aspects of the block-2 method that are important to a nonlinear equations solver, including block-Krylov subspace issues, residual calculation, stopping conditions, preconditioning and scaling techniques, computation of the Newton step, and cost. Section 3.4 wraps the local solver into a complete tensor-Krylov algorithm for solving large-scale systems of nonlinear equations, and section 3.5 discusses the global strategies for the tensor-Krylov algorithm.

3.1. Block-2 method. The block-2 algorithm proceeds in a block-Krylov-like fashion, operating on a matrix of initial vectors V instead of the single residual vector of a linear system. In particular, this method uses a block-Krylov subspace composed of two initial vectors.

We begin by rearranging the local tensor model and noting that it looks like a linear system involving a linear combination of two right-hand sides:

$$Jd = -F_k - \tfrac{1}{2}a\beta^2, \tag{3.2}$$

where $\beta \equiv s^T d$. The right-hand side spans only the directions F_k and a; the vector s appears in the inner product $\beta = s^T d$, which is a scalar multiple for a that is unknown. Thus, the premise of the block-2 method is that we start with the initial block Krylov subspace $\mathcal{K}_0 = span\{a, F_k\}$ and build $\mathcal{K}_m = span\{a, F_k, Ja, JF_k, J^2a, J^2F_k, \dots\}$ to solve (3.1). Specifically, we consider the block of initial vectors

$$R_0 = [(Jd_0 + F_k),\ a], \tag{3.3}$$

where $d_0 \in \mathbb{R}^n$ is some initial guess for the step. Because the starting matrix R_0 uses the residual $F_k + Jd_0$, which depends on d_0, the block-2 method may be restarted with successively better initial guesses in a manner similar to restarted GMRES.

The first step of the algorithm computes the QR-factorization of R_0,

$$R_0 = VR = [v_1, v_2]R, \tag{3.4}$$

where $V \in \mathbb{R}^{n\times 2} = [v_1, v_2]$ is unitary and $R \in \mathbb{R}^{2\times 2}$ is upper triangular. A block-Arnoldi process then creates additional columns of an orthonormal basis V_m that spans the block-Krylov subspace

$$span\{V, JV, J^2V, J^3V, \dots\}. \tag{3.5}$$

There are several block-Arnoldi versions available for implementation, and the particular variant is not critical to the implementation of the tensor-Krylov method. The standard procedure works on a whole block $V \in \mathbb{R}^{n\times t}$ and adds t vectors—$t = 2$ in this case—to the subspace at a time. This procedure may work well when considering cache memory performance and may be considered in future research. However, we decided to implement the single-vector version of block-Arnoldi to more closely correspond with the scalar implementation of GMRES. The version in Algorithm 3.1 is very similar to the standard Arnoldi algorithm, which operates on a single vector at a time and is due to Ruhe [22] (see also [25]) for the symmetric case (block Lanczos).

Algorithm 3.1. Block Arnoldi Process—Ruhe's variant.

```
1. Choose $t$ initial orthonormal vectors $\{v_i\}_{i=1,\dots,t}$.
2. Choose a number of Arnoldi iterations to perform and set to $m$.
3. For $k = 1, \dots, m$ :
    (a) Set $j := k + t - 1$
    (b) Compute $w := Jv_k$
    (c) For $i = 1, 2, \dots, j$
        i. $h_{ik} := (w, v_i)$
        ii. $w := w - h_{ik} v_i$
    (d) $h_{j+1,k} := \|w\|_2$
    (e) If $h_{j+1,k} \neq 0$, then set $v_{j+1} := w/h_{j+1,k}$;
        Else if $t = 1$, then Stop;
        Else set $t := t - 1$ and continue.
```

The first step of the algorithm is to multiply a single vector, v_1, by the Jacobian matrix J and orthonormalize the resulting vector w against all j vectors $v_1, \dots, v_j$ ($j = t$ at the first iteration) in the orthonormal basis, building the subspace one vector at a time. Thus, a vector from the initial block $\{v_i\}_{i=1,\dots,t}$ is multiplied by J every t steps. Step 3(e) avoids a division by zero and is commonly referred to as the breakdown condition. In the scalar case ($t = 1$), a breakdown condition indicates that the solution is in the subspace spanned by the k basis vectors computed thus far. Here in the block case, we modify the usual condition to reduce the block dimension by one until it eventually reduces to the scalar case.

After m steps on the initial matrix $V \in \mathbb{R}^{n\times 2}$ defined in (3.4), the block-Arnoldi process produces an orthogonal matrix $V_{m+2} \in \mathbb{R}^{n\times(m+2)}$ and a matrix $\bar{H}_m \in \mathbb{R}^{(m+2)\times m}$ whose nonzero entries are the elements h_{ik} computed in the process. It is important to note that $\bar{H}_m$ is banded upper Hessenberg with two subdiagonals. The orthonormal basis V_{m+2} and the matrix $\bar{H}_m$ have an important relationship,

$$JV_m = V_{m+2}\bar{H}_m. \tag{3.6}$$

Continuing with the solution to (3.1), let the approximate solution at the mth iteration be

$$d = d_0 + V_m y, \tag{3.7}$$

where $V_m \in \mathbb{R}^{n\times m}$ is an orthonormal basis for the Krylov subspace generated in (3.5) and $y \in \mathbb{R}^m$ is unknown. Substituting (3.7) into the tensor model yields

$$\begin{aligned} M_T(x_k + d) &= F_k + Jd + \tfrac{1}{2}a(s^T d)^2 \\ &= F_k + Jd_0 + JV_m y + \tfrac{1}{2}a(s^T d_0 + s^T V_m y)^2 \\ &= r_0 + JV_m y + \tfrac{1}{2}a(s^T d_0 + s^T V_m y)^2, \end{aligned} \tag{3.8}$$

where $r_0 = F_k + Jd_0$, which is also the residual for the Newton model when using the initial guess d_0. Having r_0 permits the calculation of the approximate Newton step later in the algorithm.

Let $Q_1 \in \mathbb{R}^{m\times m}$ be an orthogonal matrix that has $V_m^T s / \left\|V_m^T s\right\|$ in the last column, and let the vector $\hat{y} \in \mathbb{R}^m$ be defined by the following transformation:

$$y = Q_1 \hat{y}. \tag{3.9}$$

Then, using Q_1 and $\hat{y}$, the simplification of (3.8) continues:

$$\begin{aligned} M_T(x_k+d) &= r_0 + JV_m y + \tfrac{1}{2}a(s^T d_0 + s^T V_m y)^2 \\ &= r_0 + JV_m Q_1 \hat{y} + \tfrac{1}{2}a(s^T d_0 + (V_m^T s)^T Q_1 \hat{y})^2 \\ &= r_0 + JV_m Q_1 \hat{y} + \tfrac{1}{2}a(s^T d_0 + \left\|V_m^T s\right\| \hat{y}_m)^2, \end{aligned} \tag{3.10}$$

where $\hat{y}_m$ is the mth element of $\hat{y}$ and limits the quadratic part to a single unknown. After the next step, we will discuss a good choice for efficiently constructing the orthogonal matrix Q_1 that retains a desirable structure for solving this problem.

From (3.3) and (3.4), let $\bar{r}_1 \in \mathbb{R}^{m+2}$ and $\bar{a} \in \mathbb{R}^{m+2}$ denote the first and second columns of R, respectively, padded with m zeros to a length $m+2$. These definitions, along with (3.6), permit a change in the function space of (3.10):

$$\begin{aligned} M_T(x_k+d) &= r_0 + JV_m Q_1 \hat{y} + \tfrac{1}{2}a(s^T d_0 + \left\|V_m^T s\right\| \hat{y}_m)^2 \\ &= r_0 + V_{m+2}\bar{H}_m Q_1 \hat{y} + \tfrac{1}{2}a(s^T d_0 + \left\|V_m^T s\right\| \hat{y}_m)^2 \\ &= V_{m+2}\left(\bar{r}_1 + \bar{H}_m Q_1 \hat{y} + \tfrac{1}{2}\bar{a}(s^T d_0 + \left\|V_m^T s\right\| \hat{y}_m)^2\right). \end{aligned} \tag{3.11}$$

Because the column-vectors of V_{m+2} are orthonormal, the original least-squares problem of (3.1) may be simplified:

$$\min_{d\in\mathcal{K}_m} \left\|M_T(x_k+d)\right\|_2 = \min_{d\in\mathcal{K}_m} \left\|V_{m+2}^T M_T(x_k+d)\right\|_2, \tag{3.12}$$

where

$$V_{m+2}^T M_T(x_k+d) = \bar{r}_1 + \bar{H}_m Q_1 \hat{y} + \tfrac{1}{2}\bar{a}(s^T d_0 + \left\|V_m^T s\right\| \hat{y}_m)^2. \tag{3.13}$$

At this point, we want to preserve some structure of the problem by requiring that the product $\bar{H}_m Q_1$ does not need expensive updates to transform it to upper triangular form. In other words, we want the banded Hessenberg structure of $\bar{H}_m$ to be retained after multiplication with Q_1, adding at most another subdiagonal. That restriction may be accomplished with an orthonormal Q_1 that is itself a Hessenberg matrix. Efficiently constructing such an orthogonal matrix Q_1 in this algorithm involves some careful algebra, which we now discuss.

Let the orthonormal matrix Q_1 be represented by an orthogonal matrix times a diagonal scaling matrix:

$$Q_1 = \hat{Q}_1 D.$$

The diagonal scaling matrix has diagonal entries $D_{ii} = \frac{1}{\|\hat{Q}_1[:,i]\|}$ so that the columns in Q_1 have unit length. The last column in $\hat{Q}_1$ is the m-dimensional vector $V_m^T s$, and constructing an orthogonal Hessenberg matrix using this last column involves only two updates on the mth iteration: the (m,m) and $(m,m-1)$ elements. We define $\hat{Q}_1$ recursively:

$$\hat{Q}_1 = \begin{pmatrix} \hat{Q}_1[1:m-1;1:m-2] & \hat{Q}_1[1:m-1;m-1] & V_{m-1}^T s \\ 0 & \frac{-(V_{m-1}^T s)^2}{v_m^T s} & v_m^T s \end{pmatrix}, \tag{3.14}$$

where the initial $\hat{Q}_1[1;1] = v_1^T s$. The matrix Q_1 may be represented by three vectors: the mth column of $\hat{Q}_1$ holding $V_m^T s$, the subdiagonal of $\hat{Q}_1$, and the entries in the diagonal scaling matrix. In addition, because only the two elements in the last row are new on the mth iteration, the product $\bar{H}_m Q_1$ has only two newly updated columns, which can be computed in $2(m+1)+2$ multiplications. Using a simple example with $m=4$, we may represent this graphically:

$$\bar{H}_m Q_1 = \begin{pmatrix} x & x & x & \star \\ x & x & x & \star \\ x & x & x & \star \\ & x & x & \star \\ & & x & \star \\ & & & \star \end{pmatrix} \begin{pmatrix} x & x & x & x \\ x & x & x & x \\ & x & x & x \\ & & \star & \star \end{pmatrix} = \begin{pmatrix} x & x & (x+\star) & (x+\star) \\ x & x & (x+\star) & (x+\star) \\ x & x & (x+\star) & (x+\star) \\ x & x & (x+\star) & (x+\star) \\ & x & (x+\star) & (x+\star) \\ & & \star & \star \end{pmatrix},$$

where a $\star$ represents a new number on the mth iteration and an x represents a nonzero from a previous iteration.

Given that the matrix $\bar{H}_m$ has two subdiagonals and that the matrix product $\bar{H}_m Q_1$ has three subdiagonals, the structure of (3.13) is

$$V_{m+2}^T M_T(x_k+d) = \begin{pmatrix} \star \\ \\ \\ \\ \\ \\ \\ \\ \end{pmatrix} + \begin{pmatrix} \star & \star & \star & \cdots & \star & \star \\ \star & \star & \star & & \star & \star \\ \star & \star & \star & & \star & \star \\ \star & \star & \star & & \star & \star \\ & \star & \star & & \star & \star \\ & & \star & \cdots & \star & \star \\ & & & \ddots & \vdots & \vdots \\ & & & & \star & \star \end{pmatrix} \hat{y} + \begin{pmatrix} \star \\ \star \\ \\ \\ \\ \\ \\ \\ \end{pmatrix} (s^T d_0 + \left\| V_m^T s \right\| \hat{y}_m)^2.$$

Eliminating the subdiagonals of $\bar{H}_m Q_1$ may be accomplished with a series of Givens rotations or Householder reflections. Let $Q_2 \in \mathbb{R}^{(m+2)\times(m+2)}$ be the product of all Givens rotations or Householder reflections applied to the system, and let the variables $\tilde{r}_1$, $\tilde{a}$, and $\tilde{H}_m$ denote the following transformed vectors:

$$\tilde{r}_1 \equiv Q_2 \bar{r}_1, \tag{3.15}$$

$$\tilde{a} \equiv Q_2 \bar{a}, \tag{3.16}$$

$$\tilde{H}_m \equiv Q_2 \bar{H}_m Q_1. \tag{3.17}$$

Using (3.15)–(3.17), we may premultiply (3.13) by Q_2 as a step toward the least-squares solution:

$$Q_2 V_{m+2}^T M_T(x_k+d) = \tilde{r}_1 + \tilde{H}_m \hat{y} + \tfrac{1}{2}\tilde{a}(s^T d_0 + \left\| V_m^T s \right\| \hat{y}_m)^2, \tag{3.18}$$

which has the following structure:

$$Q_2 V_{m+2}^T M_T(x_k+d) = \begin{pmatrix} \star \\ \star \\ \star \\ \vdots \\ \star \\ \star \\ \star \end{pmatrix} + \begin{pmatrix} \star & \star & \star & \cdots & \star \\ & \star & \star & & \star \\ & & \star & \cdots & \star \\ & & & \ddots & \vdots \\ & & & & \star \\ \\ \\ \end{pmatrix} \hat{y} + \begin{pmatrix} \star \\ \star \\ \star \\ \vdots \\ \star \\ \star \\ \star \end{pmatrix} (s^T d_0 + \left\| V_m^T s \right\| \hat{y}_m)^2.$$

This system has $m+2$ equations in m unknowns, and the last three rows are quadratic equations in the variable $\hat{y}_m$.

By the orthonormality of Q_2 and V_{m+2}, minimizing $\left\|Q_2 V_{m+2}^T M_T(x_k+d)\right\|$ is the same as minimizing $\|M_T(x_k+d)\|$. Thus, the solution to (3.1) involves minimizing the last three rows of (3.18), which requires finding the optimum value for $\hat{y}_m$:

(3.19)

$$\min_{\hat{y}_m\in\mathbb{R}} \left\|\tilde{r}_1[m:m+2] + \tilde{H}_m[m:m+2,m]\hat{y}_m + \tfrac{1}{2}\tilde{a}[m:m+2](s^T d_0 + \left\|V_m^T s\right\| \hat{y}_m)^2\right\|.$$

Problem (3.19), which has a closed-form solution, involves minimizing a quartic equation in a single unknown. The minimizers correspond to the critical points of the quartic equation in the objective function of (3.19) are thus among the real roots of a cubic equation found by differentiating the quartic equation with respect to $\hat{y}_m$. Thus, (3.19) can have one or two minimizers, in which case we choose the minimizer that makes $\beta = (s^T d_0 + \|s\|\,\hat{y}_m)$ have smaller magnitude. This choice is not necessarily the global minimizer of (3.19). Justification for choosing the smaller magnitude minimizer comes both from the step itself and from considering the sequence of iterates. Choosing the smaller magnitude minimizer is consistent with the approach used in direct tensor methods and results in the inexact tensor step being closer to the inexact Newton step. Also, if we consider the sequence of values $\{\beta_j\}$ for the first j iterations, then this sequence converges to a single number when choosing the smaller magnitude minimizer. If we were to choose the global minimizer, then the sequence $\{\beta_j\}$ could oscillate between two numbers, and thus the residual error would not necessarily be monotonically decreasing (β enters into the residual calculation via $\frac{1}{2}a\beta^2$). Hence, the smaller magnitude minimizer has more theoretical appeal and is used here.

As a simpler alternative for determining $\hat{y}_m$, we mention an approach that would approximately minimize $\left\|Q_2 V_{m+2}^T M_T(x_k+d)\right\|$. Instead of solving a quartic equation, we solve the single quadratic equation in the mth row of (3.18), choosing the root such that $\beta = (s^T d_0 + \left\|V_m^T s\right\| \hat{y}_m)$ has smaller magnitude. If the equation does not have a root, then we choose the value of $\hat{y}_m$ that minimizes the quadratic equation. The difference between $\hat{y}_m$ found in this manner and $\hat{y}_m$ found by minimizing (3.19) is usually negligible once the relative residual decreases by about two orders of magnitude.

Once the minimizer $\hat{y}_m$ is determined, the remaining elements of $\hat{y}$ may be found by computing a single right-hand side using the value $\hat{y}_m$ and solving the resultant $(m-1)\times(m-1)$ linear system found by neglecting the last 3 rows of (3.18).

At this stage, the vector $\hat{y}$ contains the coefficients for the linear combination of basis vectors $\{v_i\}$. Thus, the approximate tensor step that solves (3.1) is

$$d_T = d_0 + V_m Q_1 \hat{y}.$$

The decision for stopping the Arnoldi process so that the approximate step solves the tensor model to a specified tolerance appears before the computation of the explicit step, which is at an inconvenient location. GMRES has a similar dilemma but uses an efficient approach in its least-squares solution. With GMRES, the least-squares error $\|b-Ax\|_2$ is equal to the last element of $Qe_1\|b\|$, where Q is the product of all Givens rotations to transform the Hessenberg matrix to upper triangular form and e_1 is the unit vector $(1,0,0,\dots)^T$. Similarly, the last 3 rows of (3.18) pertain to the least-squares error of the local tensor model and may be used in stopping conditions.

There are two possible implementations for computing a stopping condition in these Krylov-based methods, and they are fundamentally similar. Both may be checked without explicitly computing the approximate step d_m after each step in the Arnoldi process.

The practical stopping condition that is used in our numerical tests is similar to GMRES in that it involves computing the norm of the remaining rows below the triangular part of $\tilde{H}_m$. That is, we neglect the contribution from the quadratic equation in row m of (3.18) and only calculate the norm of the last two rows when computing the least-squares error. This computation does not include any contribution from $\tilde{H}_m$ because its last two rows contain only zeroes. Thus, the practical stopping condition may be simplified to

$$\left\| \tilde{r}_1[m+1:m+2] + \tilde{a}[m+1:m+2]\tilde{\beta}_m^2 \right\| \leq \eta_k \left\| F(x_k) \right\|_2, \tag{3.20}$$

where η_k is the relative stopping tolerance and the norm covers only the last two rows of the vectors $\tilde{r}_3$ and $\tilde{a}$. We point out that (3.20) requires the computation of $\tilde{\beta}_m$ at each iteration m. Calculating $\tilde{\beta}_m$ is an $\mathcal{O}(1)$ calculation using the first-order condition for a minimizer of $|q(\tilde{\beta})|$.

Another stopping condition, which is briefly mentioned here but covered in more detail in [1], considers how close the residual norm at the approximate step d_m comes to the minimum residual norm at the exact step d_T. In other words, the comparison is

$$\| M_T(x_k + d_m) \| - \| M_T(x_k + d_T) \| \leq \eta_k \| F(x_k) \| . \tag{3.21}$$

A practical implementation of (3.21) is straightforward. The residual error $\|M_T(x_k + d_m)\|$ equals the minimum value calculated in (3.19), and the current estimate of $\|M_T(x_k + d_T)\|$ at the mth iteration equals the value of the quadratic equation on the mth row.

Of the two conditions, (3.20) is a more demanding test than (3.21), and an implementation using (3.20) may require more iterations before satisfying the same relative tolerance.

Algorithm 3.2 describes the whole process for computing the approximate tensor step d_T. The algorithm is a basic implementation that progressively updates $\bar{H}_m$ to $\tilde{H}_m$ after each step in the Arnoldi process.

Algorithm 3.2. Block-2 Iterative Tensor Method.

```
1. Choose a relative residual tolerance $\eta \in [0,1)$ and maximum subspace dimension $m_{max}$.
2. Given the local tensor model $M_T(x_k + d) = F_k + Jd + \frac{1}{2}a(s^T d)^2$, previous function value $F_{k-1}$, and initial guess $d_0$, form the block of initial vectors $R_0 = [(Jd_0 + F_k), a]$, where $a = \frac{2(F_{k-1} - F_k - Js)}{(s^T s)^2}$ and $s = x_{k-1} - x_k$.
3. Perform a partial QR-factorization on $R_0$ such that $R_0 = [v_1, v_2]R = VR$.
4. For $m = 1, 2, \ldots, m_{max}$ do:
    (a) Let the two columns of $R$, appended with $m$ zeroes to a length $m+2$, be labeled $\bar{r}_1$ and $\bar{r}_2$, respectively.
    (b) Form the vector $Jv_m$ and orthogonalize it against the previous $v_1, \ldots, v_{m+1}$
```

vectors via the block Arnoldi process, Algorithm 3.1:

$$\begin{aligned} &w := Jv_m \\ &h_{i,m} := (w, v_i),\ i = 1, 2, \ldots, m+1 \\ &w := w - \sum_{i=1}^{m+1} h_{i,m} v_i \\ &h_{m+2,m} := \|w\|_2 \\ &v_{m+2} := w/h_{m+2,m}. \end{aligned}$$

(c) Define $\bar{H}_m$ to be the $(m+2)\times m$ upper banded Hessenberg matrix whose nonzero entries are the coefficients $h_{ij}, 1 \le i \le m+3, 1 \le j \le m$, and define $V_m = [v_1, v_2, \ldots, v_m]$.

(d) Let $Q_1 \in \mathbb{R}^{m\times m}$ be an orthogonal Hessenberg matrix that has $V_m^T s / \left\|V_m^T s\right\|$ in the last column and be computed via (3.14), and let the vector $\hat{y} \in \mathbb{R}^m$ be defined by the following transformation $y = Q_1 \hat{y}$.

(e) Let $\bar{h}_{m-1}$ and $\bar{h}_m$ denote the two newly updated columns of the matrix-matrix product $\bar{H}_m Q_1$.

(f) Using Householder reflections, transform the $(m+2)\times m$ system $\bar{r}_1 + \bar{H}_m Q_1 \hat{y} + \frac{1}{2}\bar{a}(s^T d_0 + \left\|V_m^T s\right\| \hat{y}_m)^2$ into $\tilde{r}_1 + \tilde{H}_m \hat{y} + \frac{1}{2}\tilde{a}(s^T d_0 + \left\|V_m^T s\right\| \hat{y}_m)^2$, which involves applying all previous reflections to $\bar{h}_{m-1}$ and $\bar{h}_m$, followed by two new reflections to zero three elements in $\bar{h}_{m-1}$ and two elements in $\bar{h}_m$. Apply these reflections to the vectors $\tilde{r}_1$ and $\tilde{a}$.

(g) Find the minimizer $\hat{y}_m$ of (3.19) such that $\beta = (s^T d_0 + \left\|V_m^T s\right\| \hat{y}_m)$ has smaller magnitude and minimizes the least-squares error in (3.19).

(h) Let ρ_m represent the error estimate of solving the local tensor model. Either set ρ_m equal to the norm of the last 2 rows of (3.18), or set ρ_m equal to the norm of the last 3 rows of (3.18) minus the absolute value of the mth row.

(i) If $\rho_m \le \eta \|F_k\|$, then proceed to step 5 to calculate the approximate step.

5. Form the approximate solution:

(a) Find the remaining $m-1$ elements of the vector $\hat{y}$ by solving the first $m-1$ rows of the linear system

$$\tilde{H}_m \hat{y} = -\tilde{r}_1 - \tilde{h}_m \hat{y}_m - \tfrac{1}{2}\tilde{a}(s^T d_0 + \left\|V_m^T s\right\| \hat{y}_m)^2,$$

where $\tilde{h}_m$ is the mth column of $\tilde{H}_m Q_1$.

(b) Form the approximate step $d_T = d_0 + V_m Q_1 \hat{y}$.

Just as with the Newton-GMRES algorithm, Algorithm 3.2 may be implemented matrix-free. Jacobian-vector products may be approximated by

$$J(x)v \approx \frac{F(x+\sigma v) - F(x)}{\sigma}.$$

In addition, we may apply preconditioning to accelerate convergence of the iterative methods. Consider a matrix M that approximates the current Jacobian J in some manner and is simple enough to permit inexpensive solutions to linear systems of the form $Mx = b$. Then, given M, the following left-preconditioned tensor model can be formed and solved:

$$\min_{d\in\mathcal{K}_m} \left\|M^{-1}F_k + M^{-1}Jd + \tfrac{1}{2}M^{-1}a(s^T d)^2\right\|. \tag{3.22}$$

The iterative tensor algorithms outlined above requires only minor modifications to incorporate left preconditioning—replace the call to Jv with $M^{-1}Jv$ in the Arnoldi process and premultiply all occurrences of F_k and a by M^{-1}. A separate subroutine that computes the action of M^{-1} times a vector is all that is needed.

Right preconditioning transforms the variable space. Given a preconditioner M, the following right-preconditioned tensor model can be formed and solved:

$$\min_{u \in \mathcal{K}_m} \left\| F_k + JM^{-1}u + \tfrac{1}{2}a(s^T M^{-1}u)^2 \right\|, \tag{3.23}$$

where the approximate step d is found from the solution of $Md = u$. Once again, the iterative tensor algorithm requires only minor modifications—replace the call to Jv with $JM^{-1}v$ in the Arnoldi process and replace the starting vector s in R_0 with $M^{-T}s$. If the matrix M^{-1} is not explicitly stored, then $M^{-T}s$ may be difficult to compute. The algorithm may be modified to avoid this step, however.

Of the two forms, right preconditioning is mildly preferred over left preconditioning because the norm of the residual $\|M_T(x_k + d)\|$, which enters directly into the stopping conditions, is unaffected with right preconditioning. In addition, right preconditioning guarantees that the inexact Newton step is a descent direction on the function, which is of paramount importance to a linesearch global strategy. With left preconditioning (with either GMRES or the Krylov-based tensor methods), the Newton step $d_N \in \mathcal{K}$ is no longer guaranteed to be a descent direction on $F(x)$, which has dire consequences in linesearch global strategies because backtracking along a step presupposes that the direction is a descent direction for eventual step acceptance. An advantage of left preconditioning is that the relative residual reduction can be a better indicator of true error reduction, thereby producing a more accurate step.

Scaling is of particular importance when solving systems of nonlinear equations, as noted in [15], and is a subject that is closely related to preconditioning. We only mention here that variable and function scaling is possible in the Krylov-based tensor method and may be implemented in a manner similar to preconditioning. Often it is desirable to scale the system on the left and precondition on the right to address the issues above.

An important remark about Algorithm 3.2 is that the Newton model is carried through the procedure, so the Newton step is calculated readily at the end of the algorithm and permits greater flexibility with the global strategy. In a manner similar to GMRES, we solve the linear least-squares problem

$$\min_{\hat{y} \in \mathbb{R}^m} \left\| \tilde{r}_1 + \tilde{H}_m \hat{y} \right\|,$$

which involves a back substitution with the upper triangular matrix $\tilde{H}_m$ and right-hand side $-\tilde{r}_1$. Then the approximate Newton step is given by

$$d_N = d_0 + V_m Q_1 \hat{y}.$$

Calculating the Newton step in addition to the tensor step adds a minimal cost. It involves a back substitution ($\frac{1}{2}m^2$ multiplications), matrix-vector product (m^2 multiplications), and a linear combination of basis vectors (nm multiplications), which is the dominant cost.

The cost of Algorithm 3.2 is very similar to the cost of GMRES. The extra work beyond GMRES involves the following:

1. Computation of one extra Jacobian-vector product to get a,

2. Partial QR-factorization of the $n \times 2$ matrix of initial vectors R_0 ($4n$ multiplications to get the second column of both Q and R),
3. Orthogonalization against one extra vector in the Gram–Schmidt process ($2nm$ multiplications),
4. Formation of an orthogonal Q_1 (nm multiplications for $V_m^T s$),
5. Computation of the new columns in the matrix-matrix product $\bar{H}_m Q_1$ (m^2 multiplications),
6. Orthogonal transformations involving Q_2 to form $\tilde{H}_m$ ($8m^2$ multiplications, if using Householder reflections),
7. Matrix-vector multiplication $Q_1 \hat{y}$ (m^2 multiplications).

Thus, when considering only the leading terms, the total cost beyond GMRES is $4n + 3nm + 6m^2$ multiplications plus one Jacobian-vector product. The bulk of the cost of GMRES is due to Gram–Schmidt orthogonalization in the Arnoldi process, $\mathcal{O}(nm^2)$, so the extra cost of the iterative Krylov-based tensor method is minor. This method compares favorably with the tensor-GMRES of Feng and Pulliam, which costs $5n + 4nm + 2m^2$ multiplications plus one extra Jacobian-vector product beyond GMRES.

As a final remark, extending these methods to run in parallel should be straightforward. Because the tensor-Krylov method uses the same basic vector and matrix operations as GMRES, we don't expect any implementation issues.

3.2. Block-2+ method. It is conceivable that the block-2 method above could generate a Krylov subspace for a step that minimizes (3.1) but does not include any information in the direction s, thereby neglecting any contribution from the second-order term $\frac{1}{2}a(s^T d)^2$. The aim of the the block-2+ method is to explicitly include the direction s in the subspace so that the inner product $s^T d$ is fully captured in the Krylov subspace while still working with a block of dimension two. Here we only mention the discriminating feature of this method and refer to [1] or [2] for the algorithmic details.

The problem that we are solving changes to finding the step d that solves the minimization problem

$$\min_{d \in \{s\} \cup \mathcal{K}_m} \left\| F_k + Jd + \tfrac{1}{2}a(s^T d)^2 \right\|_2 . \tag{3.24}$$

The procedure is basically the same as the block-2 method in section 3.1 but with some extra algebra and a special technique for augmenting the standard block-Krylov subspace with the new direction s at *each* Arnoldi iteration. This approach contrasts with the usual implementation of augmented Krylov subspace methods [10] and is discussed in [1].

3.3. Block-3 method. The block-3 algorithm for solving (3.1) proceeds in a block-Krylov-like fashion, operating on a matrix of three initial vectors instead of the single residual r_0 of a linear system. By choosing three vectors, we may include information on the three known vectors in the local tensor model (s, a, and F_k) and allow a transformation of the variable space and function space in a manner similar to the method of orthogonal transformations of section 2.2. To that end, we consider the block of initial vectors

$$R_0 = [s,\ (Jd_0 + F_{k-1}),\ (Jd_0 + F_k)]. \tag{3.25}$$

The rationale for choosing these specific vectors is as follows. The vector s is listed first in order to isolate the inner product $s^T d$ (via $\|s\|\, v_1^T d$) and later create a single quadratic equation in a single unknown. The second vector is the residual involving the previous function value F_{k-1} and is needed for computing the tensor term a, (2.5). The third vector is the residual of the Newton equations, and it may be placed as the second or third column in R_0. Collectively, these three vectors are chosen specifically to compute the tensor term a later in the algorithm in addition to fully characterizing the local tensor model (i.e., the three known vectors F_k, a, s) with this initial subspace.

The block-3 algorithm is procedurally different from the block-2 algorithm because it uses orthogonal transformations and permutation matrices to switch rows and columns to isolate a quadratic equation in the mth row. After the block-Arnoldi process adds a basis vector and an extra column to $\bar{H}_m$, we perform a series of plane rotations to put the matrix $\bar{H}_m$ in upper triangular form. In its current ordering, the quadratic equation would not be isolated to a single variable in the first row and should be switched to the mth row. So we permute the first row and column with the mth row and column to facilitate an easier solution. After all of the orthogonal transformations and row/column permutations, the structure of the simplified problem is

$$QP_L V_{m+3}^T M_T(x_k + d) = \begin{pmatrix} \star \\ \star \\ \star \\ \vdots \\ \star \\ \star \\ \star \\ \star \end{pmatrix} + \begin{pmatrix} \star & \star & \star & \cdots & \star \\ & \star & \star & & \star \\ & & \star & \cdots & \star \\ & & & \ddots & \vdots \\ & & & & \star \\ & & & & \\ & & & & \\ & & & & \end{pmatrix} \hat{y} + \begin{pmatrix} \star \\ \star \\ \star \\ \vdots \\ \star \\ \star \\ \star \\ \star \end{pmatrix} (s^T d_0 + \|s\|\, \hat{y}_m)^2.$$

Otherwise, the block-3 algorithm is similar to the block-2 algorithm above.

3.4. Tensor-Krylov methods. With the introduction of the Krylov-based iterative methods for solving the local tensor model in sections 3.1–3.3, we return to solving the general nonlinear equations problem (1.1). The following algorithm outlines the tensor-Krylov algorithm, which at every outer iteration calls a Krylov-based iterative method for solving the local tensor model.

Algorithm 3.3. Tensor-Krylov Method.

1. Given the nonlinear equations problem $F(x)$, choose a starting point x_0 and set the maximum iteration counter k_{max}.
2. For $k = 0, 1, 2, \ldots, k_{max}$, do:
   (a) Choose a forcing term tolerance $\eta_k \in [0, 1)$.
   (b) If $k = 0$, then calculate the Newton-GMRES step d_N according to the relative tolerance η_k and proceed to step 2e.
   (c) Form the local tensor model $M_T(x_k + d) = F_k + Jd + \frac{1}{2}a(s^T d)^2$, where $F_k = F(x_k)$, $F_{k-1} = F(x_{k-1})$, $J = F'(x_k)$, $s = x_{k-1} - x_k$, and $a = \frac{2(F_{k-1} - F_k - Js)}{(s^T s)^2}$.
   (d) Compute the inexact tensor step d_T according to the relative tolerance η_k by approximately solving the local tensor model according to the methods of sections 3.1, 3.2, or 3.3.
   (e) Set $x_{k+1} = x_k + \lambda d$, where d and λ are chosen according to a linesearch strategy that uses the directions d_T and/or d_N.
   (f) If x_{k+1} is an acceptable approximation to a root of $F(x)$, then stop and signal a success.

When referring to Algorithm 3.3 that uses a specific Krylov-based local solver in step 2d as defined in sections 3.1, 3.2, or 3.3 (i.e., the block-2, block-2+, or block-3 methods), we will abbreviate the method as TK2, TK2+, and TK3, respectively.

The main advantage of this method over previous inexact tensor methods is that the inexact tensor step d_T satisfies the local tensor model to within the specified tolerance η_k. The tensor-GMRES method, on the other hand, computes the solution of a *projected* tensor model, which is missing second-order information in the direction of s and may compute a less desirable step. The Bouaricha method [5] uses the exact model, but the relationship $\|M(x + d_T)\| < \eta_k \|F_k\|$ is not guaranteed, thereby raising the possibility of less accurate steps.

3.5. Global strategy and step selection. Algorithm 3.3 needs a robust strategy for global convergence if neither the full tensor step nor Newton step is satisfactory in step 2e. While step 2e uses a linesearch strategy, a trust region strategy is still viable, albeit less straightforward. Here we discuss details regarding a linesearch implementation in the tensor-Krylov method.

The standard tensor linesearch of [28] and the TENSOLVE linesearch of [5, 6] are straightforward applications of backtracking along the tensor step, if it is a descent direction, or otherwise along the Newton direction. The curvilinear linesearch implementation of [4] requires a little adaptation. Because the curvilinear linesearch for tensor methods has posted encouraging results and has a nice theoretical basis, we will focus primarily on this linesearch implementation in the tensor-Krylov algorithm.

The curvilinear step $d_T(\lambda)$ is the solution of the modified tensor model $\lambda F + Jd + \frac{1}{2}a(s^T d)^2$, where λ is the linesearch parameter. Thus, in the tensor-Krylov algorithm, the local tensor model is likewise changed and recomputed. Fortunately, the scalar λ is carried through the process in a straightforward manner, irrespective of method, as will now be discussed. For this discussion, we focus on the block-2 method in Algorithm 3.2, but the procedure applies to the block-2+ and block-3 methods in the obvious way. The only trick to this implementation involves the scaling of the initial guess d_0; all other aspects are intuitive.

The derivation involves changing the block of initial vectors in (3.3) to include λ in the Newton residual,

$$R_0 = [\lambda(Jd_0 + F_k),\ a]. \tag{3.26}$$

The scalar λ follows through the steps of Algorithm 3.2 and changes (3.18) to

$$Q_2 V_{m+2}^T M_T(x_k + d) = \lambda \tilde{r}_1 + \tilde{H}_m \hat{y} + \tfrac{1}{2}\tilde{a}(s^T d_0 + \left\|V_m^T s\right\| \hat{y}_m)^2, \tag{3.27}$$

which only differs by λ multiplying $\tilde{r}_1$. Up to this point in the algorithm, the presence of λ does not require any new computations. To be more precise, the basis vectors in V and the matrix $\tilde{H}_m$ are unchanged. The presence of λ in (3.27) does change the calculation of the vector $\hat{y}_m$, and the corresponding change in (3.19) is

$$\min_{\hat{y}_m \in \mathbb{R}} \left\| \lambda \tilde{r}_1 + \tilde{H}_m \hat{y} + \tfrac{1}{2}\tilde{a}(s^T d_0 + \left\|V_m^T s\right\| \hat{y}_m)^2 \right\|.$$

The remaining elements of $\hat{y}$ are found by solving the triangular system with a right-hand side modified by λ and the newly computed $\hat{y}_m$. Finally, the change in (3.26) corresponds to scaling both F_k and d_0 by λ, so the curvilinear step changes to

$$d_T(\lambda) = \lambda d_0 + V_m Q_1 \hat{y}, \tag{3.28}$$

where $\hat{y}$ is also a function of λ, as noted above.

We reiterate that the scalar λ may multiply $\tilde{r}_1$ after all orthogonal transformations, so the initial work in generating a Krylov basis and performing the subsequent orthogonal transformations to calculate d_T is not repeated for computing $d_T(\lambda)$. That is, the matrix of basis vectors V_m used in (3.28) contains the same vectors from the original computation of d_T; only the vector $\hat{y}$ depends on λ.

The additional cost of the curvilinear linesearch per trial is an extra backsolve per λ-value (an extra $\frac{1}{2}m^2$ multiplications) plus a linear combination of basis vectors (nm multiplications), which is the dominant cost. However, if using right preconditioning, one application of the preconditioner must be used, which increases the cost further. While these costs are more than in the other linesearches, they are probably still less than the cost of evaluating $F(x)$ and certainly less than the cost of evaluating $J(x)$ or the total cost of generating the Krylov subspace for the original computation of d_T. Alternative implementations that use other simplifications or approximations are discussed in [1].

It should be noted that other large-scale tensor methods, such as the tensor-GMRES method of Feng and Pulliam [18], could employ the curvilinear linesearch even though these other methods have subtle differences in calculating an inexact tensor step. This is because the curvilinear step is calculated from a simple scalar multiplication of the function value in the local tensor model and may be carried through the algebra of the step calculation to arrive at a parametric form of the curvilinear step.

As a final note, it is unclear how best to employ the adaptive forcing terms of Eisenstat and Walker [16] in the curvilinear linesearch or in tensor methods, in general. The theory behind adaptive forcing is to reduce oversolving of the linear system, especially when far from the nonlinear solution, which tends to prevent the approximate Newton step from being excessively long (e.g., if the Jacobian has small singular values) or from being nearly orthogonal to the gradient of $\|F\|$ (e.g., if the Jacobian is ill-conditioned); see [31]. It is not clear how the same theory should be applied to a tensor method. The simplified quadratic term augmenting the linear system provides good directional information when dealing with ill-conditioned systems, so a more accurate solution provides a qualitatively better step than the Newton step. On the other hand, we also wish to avoid oversolving the tensor model when possible, which argues for a larger η_k. Thus, appropriate forcing terms for tensor methods, or perhaps just more reasonable safeguards, are still open questions at this stage.

4. Computational results and discussion.

This section describes numerical tests aimed at comparing the tensor-Krylov methods with Newton-GMRES and tensor-GMRES [18]. Other numerical tests may be found in [1], and results on several ill-conditioned problems are included in [3].

4.1. Test results for the Chan problem.

To first highlight some basic differences among the various classes of methods with a numerical example, we present results of solving a simplified model of combustion phenomena using Matlab implementations. The problem is an elliptic PDE considered by Chan [9] that has multiple turning points and is given by

$$\Delta u + \lambda \left(1 + \frac{u + u^2/2}{1 + u^2/100} \right) = 0 \text{ in } \Omega, \quad u = 0 \text{ on } \partial\Omega, \tag{4.1}$$

where Δ is the Laplace operator, $\lambda \in \mathbb{R}$ is a parameter, Ω is the domain $[0,1] \times [0,1]$, and $\partial\Omega$ is the boundary of Ω. For our tests, we set $\lambda = 7.978735$, which is very close

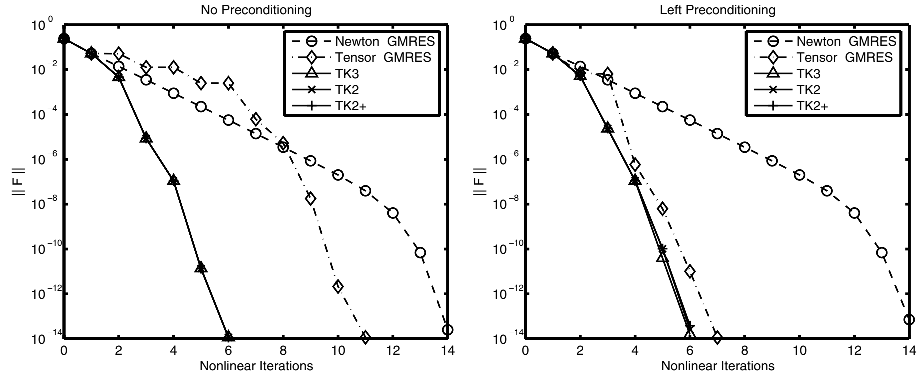

Fig. 4.1. *Iteration histories on the Chan problem with and without preconditioning.*

to a turning point in the problem. We used a centered differences discretization with 31×31 uniformly spaced grid points and started from the zero vector. We used the Laplacian as our preconditioner and used a constant forcing term of $\eta_k = 10^{-4}$. All methods converged to the same point.

Figure 4.1 presents the iteration history of all methods when solving with no preconditioning and with left preconditioning. Both plots show that Newton-GMRES has a long stretch of linear convergence rate due to the nearly singular Jacobian at the solution. The three tensor-Krylov methods have roughly the same quality of steps (as evidenced by their nearly identical trajectories). Tensor-GMRES does not share the same trajectory as the tensor-Krylov methods, which indicates that the projection of the tensor term in (2.10) loses some critical directional information. Similar numerical behavior is observed for different starting points, preconditioners, and/or values of the forcing term η_k on this problem, indicating that tensor-GMRES has some inherent difficulty with this type of problem.

4.2. Test results on fluid flow benchmark problems. For a broader comparison, we consider a couple of CFD benchmark problems described in [30] that are used for verification of fluid flow codes and solution algorithms: the 2D backward-facing step problem and the 2D and 3D thermal convection problem.

We implemented the algorithms in a software package called NOX [19], which is a C++ object-oriented nonlinear solver package being developed at Sandia National Laboratories. For objective comparisons, all of the methods, including Newton-GMRES and tensor-GMRES, used the same Arnoldi process (modified Gram–Schmidt) as the tensor-Krylov methods. That choice granted us more control over the algorithm and assured us of a controlled experiment. Thus, the results in this section do not reflect the most efficient and optimized implementations available.

We set up the numerical experiments to closely correspond to those in [30], using many of the same conditions and parameters. A successful termination was declared when both of the following stopping conditions were satisfied:

$$\|F(x_k)\| \leq \varepsilon_F \, \|F(x_0)\| \tag{4.2}$$

and

$$\frac{1}{\sqrt{n}} \, \|W d_k\| < 1, \tag{4.3}$$

where n is the total number of unknowns, d_k is the full Newton or tensor step, and W is a diagonal scaling matrix with entries

$$W_{ii} = \frac{1}{\varepsilon_r \left|x_{k_i}\right| + \varepsilon_a},$$

in which x_{k_i} is the ith element of the current solution x_k. We used the same parameters as in [30]: $\varepsilon_F = 10^{-2}$, $\varepsilon_r = 10^{-3}$, and $\varepsilon_a = 10^{-8}$.

In practice, the step length criterion (4.3) is more stringent than (4.2) and is necessary to resolve finer details of the fluid flow and transport by requiring that each ith element of the Newton or tensor step be small relative to its current value x_{k_i}. All successful runs, except for two noted in section 4.2.1, satisfied (4.2) with at least $\varepsilon_F = 10^{-8}$ and converged to the same solution. The last several iterations in each run were needed to satisfy (4.3).

If the test problem required more than 200 nonlinear (outer) iterations or if there was a linesearch failure (i.e., $f(x_c + \lambda d) \leq f(x_c) + \alpha\lambda\nabla f(x_c)^T d$, where $f(x) \equiv \frac{1}{2}\left\|F(x)\right\|_2$ and $\alpha = 10^{-4}$, could not be satisfied with $\lambda > 10^{-12}$ in at most 40 backtracks), then we declared a failure for the run.

The tests in [30] used a variety of forcing terms, particularly the adaptive forcing terms of Eisenstat and Walker [16]. As mentioned in section 3.5, more research is needed to determine how best to apply adaptive forcing terms to tensor methods. Consequently, we have used a constant forcing term of $\eta_k = 10^{-4}$ in the 2D problems and $\eta_k = 10^{-2}$ in the 3D problem. As in [30], we allowed the local solver (i.e., GMRES or its tensor-Krylov equivalent) a restart value of 200 with a maximum of 600 total iterations. If the local solver did not satisfy the desired tolerance within the 600 iterations, then we used the step computed thus far and tested for step acceptance with our global strategies. Restarting became more of an issue as the problem difficulty increased.

We used an explicit Jacobian, which our PDE code computed efficiently by a combination of analytic evaluation and numerical differentiation, and enabled the option for maximum accuracy in the Jacobian. We employed right preconditioning in all cases using an ILUT preconditioner [24], and we performed no variable or function scaling in the problems. The initial approximation was the zero vector for all cases.

We used a standard backtracking linesearch procedure for Newton-GMRES and used the complete tensor-GMRES algorithm in [18], including their globalization. For the tensor-Krylov methods, we used the curvilinear linesearch due to favorable theoretical and performance considerations in [4]. For selecting the linesearch parameter at each trial step, we used the λ-halving procedure (dividing λ by two at each inner iteration). Quadratic backtracking was an option, but it generally required more iterations and function evaluations than λ-halving across all methods in preliminary tests on these problems, so it was not used.

All tests were performed on a dual 3GHz Pentium Xeon desktop computer with 2GB of RAM, which was more than sufficient for these problems. However, the computer was not dedicated to these tests, so the timing statistics provided are only approximate and could be off by 10 percent or more relative to each other.

The fluid flow problems are set up using a particular spatial discretization of the governing steady-state transport equations for momentum and heat transfer in flowing fluids. These governing PDEs are given below. The unknown quantities in these equations are the fluid velocity vector ($\mathbf{u}$), the hydrodynamic pressure (P), and the temperature (T).

$$\text{Conservation of mass: } \nabla \cdot \mathbf{u} = 0 \tag{4.4}$$

$$\text{Momentum transport: } \rho\, \mathbf{u} \cdot \nabla \mathbf{u} - \nabla \cdot \mathbf{T} - \rho \mathbf{g} = 0 \tag{4.5}$$

$$\text{Energy transport: } \rho C_p \mathbf{u} \cdot \nabla T + \nabla \cdot \mathbf{q} = 0 \tag{4.6}$$

In these equations, $\mathbf{g}$ is the gravity vector, and ρ and C_p are the density and specific heat at constant pressure of the bulk fluid, respectively. The constitutive equations for the stress tensor $\mathbf{T}$ and heat flux $\mathbf{q}$ are

$$\begin{aligned} \mathbf{T} &= -P\mathbf{I} + \mu(\nabla \mathbf{u} + \nabla \mathbf{u}^T), \\ \mathbf{q} &= -\kappa \nabla T, \end{aligned}$$

where μ is the dynamic viscosity and κ is the thermal conductivity of the fluid.

The particular spatial discretization of (4.4)–(4.6) that we use is from a finite element reacting flow code called MPSalsa [27] developed at Sandia National Laboratories. MPSalsa generates an algebraic system of equations by a pressure-stabilized Petrov–Galerkin finite element formulation of the low Mach number Navier–Stokes equations with heat transport. This scheme uses equal-order interpolation of velocity and pressure, and we enabled the option for streamline upwinding to limit oscillations due to high grid Reynolds numbers. Since the publication of [30], the pressure-stabilized streamline upwinding Petrov–Galerkin formulation in MPSalsa has been changed to a Galerkin least squares–type method [29]. This stabilization method is slightly less dissipative, and the nonlinear convergence behavior for difficult problems can be less robust at higher Reynolds numbers. Consequently, this change precludes direct comparisons with results in [30].

To complete a problem's specification, boundary conditions are imposed on the governing PDEs, which we discuss in the subsections that follow. The problems differ only in their boundary conditions and in whether they use (4.4)–(4.6) or only (4.4)–(4.5). The next three subsections describe the test problems and their results.

4.2.1. Backward-facing step problem. This problem consists of a rectangular channel with a 1×30 aspect ratio in which a reentrant backward-facing step (i.e., a sudden expansion in the channel width) is simulated by injecting fluid with a fully developed parabolic velocity profile in the upper half of the inlet boundary and imposing a zero velocity on the lower half. The channel geometry and flowing fluid produce recirculation zones beneath the entering flow on the lower wall and, for sufficiently fast flow, farther downstream on the upper wall. This problem requires the solution of (4.4)–(4.5) on the unit square with the following Dirichlet boundary conditions:

$$\begin{aligned} \mathbf{u} = 24y(\tfrac{1}{2} - y)U_0\hat{x} \text{ at } x = 0,\ 0 \le y \le \tfrac{1}{2}, \\ \mathbf{u} = 0 \text{ at } x = 0,\ -\tfrac{1}{2} \le y < 0, \\ \mathbf{u} = 0 \text{ at } y = -\tfrac{1}{2}, \tfrac{1}{2}, \\ \mathbf{T}_{xx} = \mathbf{T}_{xy} = 0 \text{ at } x = 30, \end{aligned}$$

where $\hat{x}$ is the unit vector in the x-direction. Once the governing equations and boundary conditions are nondimensionalized, the Reynolds number (Re) appears, which is a measure of inertial forces to viscous forces. In our experiments, we increased the Reynolds number up to 800, which increases the nonlinear inertial terms in the momentum equation and makes the solution more difficult to obtain. Beyond Re = 800, it is not clear that the problem is stable and admits a physical solution. All solutions for this problem were computed on a 20 × 400 unequally spaced mesh, which has 25,263 unknowns.

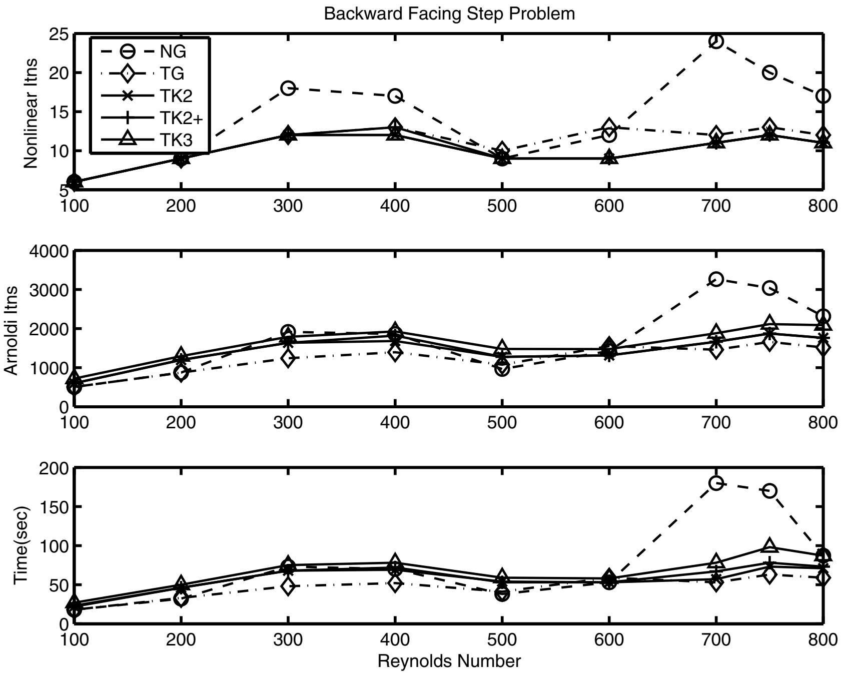

Fig. 4.2. *Results of the backward-facing step problem for the following methods: Newton-GMRES (○, dashed line), tensor-GMRES (◇, dash-dotted line), TK2 (×, solid line), TK2+ (+, solid line), and TK3 (△, solid line).*

The plots in Figure 4.2 show that all of the methods require about 10–12 iterations, on average, to solve, with Newton-GMRES requiring considerably more iterations in some cases. Newton's method tended to be more erratic, having slight difficulty at Re = 300 and 400, improvements at Re = 500 and 600, and then more difficulty on the three hardest problems. The two Newton solutions at Re = 700 and 750 actually converged to a local minimizer of the linesearch merit function yet still satisfied the relative residual reduction criterion of 10^{-2}. If ε_F in (4.2) were 10^{-3}, then these two runs would have been linesearch failures.

All of the tensor-Krylov methods share almost the exact same level of performance in terms of nonlinear iterations. Tensor-GMRES requires slightly more nonlinear iterations than the tensor-Krylov methods, but its local solve with GMRES is more efficient. Thus, for this problem, tensor-GMRES is more efficient than the tensor-Krylov methods by a small margin, and TK2 and TK2+ are more efficient than TK3 by about the same amount. There appears to be no distinct difference between TK2 and TK2+.

4.2.2. Thermal convection problem. This problem consists of the thermal convection (or buoyancy-driven) flow of a fluid in a differentially heated square cavity in the presence of gravity. It requires the solution of (4.4)–(4.6) on the unit square with the following Dirichlet and Neumann boundary conditions:

$$T = T_{cold},\ \mathbf{u} = 0 \text{ at } x = 0, \tag{4.7}$$

$$T = T_{hot},\ \mathbf{u} = 0 \text{ at } x = 1, \tag{4.8}$$

$$\frac{\partial T}{\partial y} = 0,\ \mathbf{u} = 0 \text{ at } y = 0, 1. \tag{4.9}$$

Once the governing equations and boundary conditions are nondimensionalized, two parameters appear: the Prandtl number (Pr) and the Rayleigh number (Ra). In our experiments, we fixed Pr = 1 and increased the Rayleigh number from Ra = 10^4 up to 2×10^7, which increases the nonlinear effects of the convection terms and makes the solution more difficult to obtain. The range in [30] is Ra = 10^3 to 10^6, but we shifted the range to explore the effectiveness of tensor methods on more difficult problems. We used a 100 × 100 equally spaced mesh, which has 40,804 unknowns. On this size mesh, it is unclear whether the choice of Ra $> 10^6$ admits a physically accurate and/or stable solution, but we are interested only in the relative performance of the numerical methods on this problem, which remain valid comparisons.

Figure 4.3 shows the overall performance of the methods on this problem. While difficult to see, Newton-GMRES performs a little better than the other methods on the easiest problem difficulties (Ra $\leq 10^5$). Yet as the Rayleigh number increases, Newton-GMRES requires increasingly more work to solve the problems. For Ra $\geq 10^7$, Newton-GMRES fails to solve the problem in 200 iterations. Thus, the trend for Newton-GMRES is a clear degradation in performance as the problem becomes more difficult to solve. In contrast, the tensor-Krylov methods with the curvilinear linesearch are much less affected by the transition and see a much smaller increase in execution time. Results of the tensor-Krylov methods with the old standard tensor linesearch (not shown) are less impressive but are still better than Newton-GMRES and tensor-GMRES on the harder problems.

Among the tensor-Krylov methods, TK2 is virtually identical to TK2+ in terms of nonlinear iterations, Arnoldi iterations, and execution time. Both are more efficient than TK3, which required more Arnoldi iterations at all Rayleigh numbers. This was due in part to restarts of the TK3 method. At Ra $\geq 3 \times 10^6$, restarts contributed to an increasing number of Arnoldi iterations for TK3. For both TK2 and TK2+, the local model was solved in less than 200 Arnoldi iterations.

Tensor-GMRES only does well on this problem at the easier difficulties (Ra $\leq 10^5$) due to fewer nonlinear iterations and an efficient use of GMRES. However, tensor-GMRES is unable to solve the most difficult problems in 200 nonlinear iterations or less at Ra $> 5 \times 10^6$, whereas all tensor-Krylov methods are able to solve the hardest problems. Even when employing the standard linesearch, the tensor-Krylov methods can solve up to Ra = 10^7 but fail on the hardest problem at Ra = 2×10^7.

4.2.3. 3D Thermal convection problem. This final problem uses slightly different test conditions to help assess the applicability for very large problems. The 3D version of this problem has the same boundary conditions as (4.7)–(4.9) but with an additional boundary condition in 3D

$$\frac{\partial T}{\partial z} = 0,\ \mathbf{u} = 0 \text{ at } z = 0, 1. \tag{4.10}$$

All solutions were computed on a $32 \times 32 \times 32$ equally spaced grid, resulting in 179,685 unknowns for the discretized problem. To force more restarts, we reduced the restart

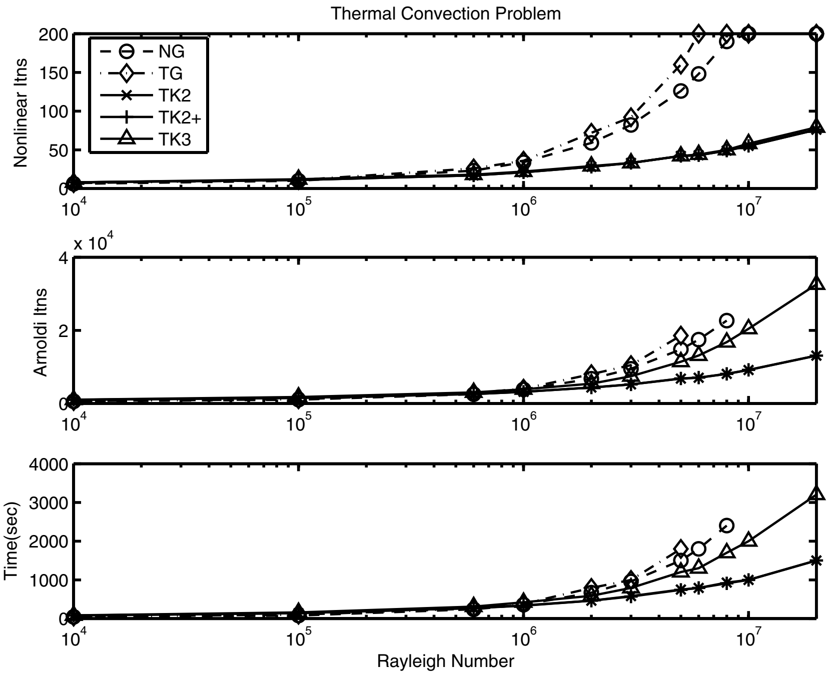

FIG. 4.3. *2D Thermal convection problem results for the following methods: Newton-GMRES (○, dashed line), tensor-GMRES (◇, dash-dotted line), TK2 (×, solid line), TK2+ (+, solid line), and TK3 (△, solid line). Only results for the successful runs are included in the bottom two plots.*

value to 75 and allowed a maximum of 225 total iterations. The quality of the preconditioner did not permit a restart value much less than 75 across all problem difficulties in this experiment.

Figure 4.4 shows the results for this problem. As the Rayleigh number increases, restarts become increasingly more important, and all methods start to suffer, especially the tensor methods. Without restarts, the results for all methods more closely resemble the 2D results in Figure 4.3. Up until about Ra $= 6 \times 10^6$, Newton-GMRES is the best method. At Ra $= 10^7$, TK2 and TK2+ outperform Newton-GMRES, but at harder difficulties, they produce less accurate steps and fail to solve in 200 nonlinear iterations. TK3 is adversely affected by restarts from the beginning.

Here, TK2 and TK2+ are better at restarting than TK3. We believe this is because in a single restart cycle, the block-2 methods have a polynomial expansion of the block-Krylov subspace that contains higher orders of the Jacobian matrix. That is, after m Arnoldi iterations, the block-2 methods have terms in the Krylov subspace up to $J^{\frac{m}{2}-1}$, whereas the block-3 method has terms up to $J^{\frac{m}{3}-1}$. For comparison, GMRES includes terms up to J^{m-1}.

Figure 4.4 also shows some evidence that tensor-GMRES loses effectiveness when restarting. A smaller subspace provides less information in the projection of the tensor term (i.e., $Pa(s^T d)^2$) as well as including a smaller basis for solving the minimization problem in (2.10), where $Pa(s^T d)^2$ acts as another right-hand side but the Krylov subspace generated by GMRES starts with the residual $F_k + J_k d_0$.

Other numerical tests investigating restarts that were performed in [1] support these findings. In addition, the tensor-Krylov methods tended to stall more frequently

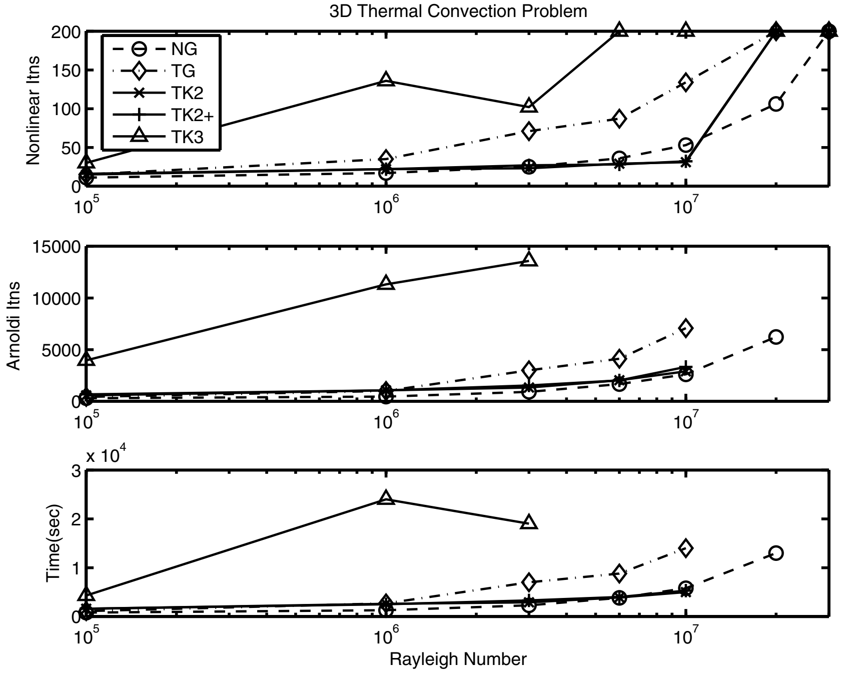

FIG. 4.4. *3D Thermal convection problem results for the following methods: Newton-GMRES (○, dashed line), tensor-GMRES (◇, dash-dotted line), TK2 (×, solid line), TK2+ (+, solid line), and TK3 (△, solid line). Only results for the successful runs are included in the bottom two plots.*

than restarted GMRES. That is, restarting the method did not always appreciably improve the step after another m iterations. This behavior may be attributed to the block-Krylov style of the Arnoldi process, which retains a constant vector in R_0 at each restart (i.e., s and/or a, depending upon the algorithm), keeping part of the subspace unchanged. Restarts rely on a new and different subspace to make progress.

5. Summary and conclusions.

The main objective of this research was to combine approaches based on direct tensor methods and Krylov subspace methods into an effective large-scale nonlinear equations solver. We developed three Krylov-based methods for iteratively solving the local tensor model, and we incorporated these three local solvers into an inexact nonlinear solver framework for different versions of a "tensor-Krylov" method, which we denoted TK2, TK2+, and TK3. The new tensor-Krylov methods are especially effective at solving large-scale problems that possess Jacobians at the solution that are highly ill-conditioned or singular. Algorithms based on Newton's method exhibit very slow convergence on such problems.

The new methods proposed in this paper solve the local tensor model in a novel fashion. Their costs per iteration are similar to GMRES, requiring only one Jacobian-vector product at each iteration and $O(nm)$ additional arithmetic operations beyond GMRES per solve. Relative to previous iterative tensor methods, they are the only methods that produce an approximate tensor step that solves the local tensor model to within a specified accuracy. In addition, these methods can compute an exact solution to the tensor model in at most n iterations (in exact arithmetic). The new tensor-Krylov methods can also utilize much of the technology developed for Newton-Krylov methods, including preconditioning and restarting.

Our numerical results suggest that the new tensor-Krylov methods clearly have some advantages over Newton-GMRES, especially as the problem becomes more difficult to solve or more ill-conditioned. In addition, the tensor-Krylov methods have some potential advantages over tensor-GMRES that make them likely to be beneficial on some important problems. Overall, tensor-GMRES and the tensor-Krylov methods are fairly similar—sometimes tensor-GMRES is better due to its efficient use of restarted GMRES(m), and sometimes tensor-Krylov methods are better due to a more accurate tensor step.

There are many different research questions at this point to explore. We mention four future extensions here. First, adaptive forcing terms like the form by Eisenstat and Walker [16] may help improve robustness. Second, an improved restart strategy may be necessary for some difficult problems, as witnessed with the 3D thermal convection problem results. One alternative to restarting is incomplete orthogonalization [7, 23], which would require modifications to the algorithms but may be a better strategy for coping with difficult problems. Third, changing the current scalar implementation of the block-Arnoldi method to a true block implementation (i.e., simultaneously multiplying a block of vectors by the Jacobian) may improve memory efficiency and make the tensor-Krylov methods even more economical and attractive. Fourth, the current tensor-Krylov and tensor-GMRES implementations need to manipulate data structures that are inaccessible in many linear solver packages, so we would like to simplify these methods and investigate better ways to incorporate standalone linear algebra packages. These changes would make the methods possibly more efficient, more robust, and more accessible than their current implementations.

Acknowledgments. Special thanks is owed to Prof. Robert Schnabel for his guidance and supervision of this research. The author is grateful to Michele Benzi and the anonymous referee for their constructive comments in the review process that helped improve this paper.

EXISTENCE TESTS FOR SOLUTIONS OF NONLINEAR EQUATIONS USING BORSUK'S THEOREM[*]

ANDREAS FROMMER[†] AND BRUNO LANG[†]

Abstract. We show how interval arithmetic can be used in connection with Borsuk's theorem to computationally prove the existence of a solution of a system of nonlinear equations. It turns out that this new test, which can be checked computationally in several different ways, is more general than an existing test based on Miranda's theorem in the sense that it is successful for a larger set of situations. A numerical example is included.

Key words. nonlinear systems, Miranda's existence theorem, Borsuk's theorem, computational verification, interval analysis

1. Introduction.

One of the most common problems in numerical analysis is to find a zero $\mathbf{x}^*$ of a nonlinear mapping

$$\mathbf{f} : D \subseteq \mathbb{R}^n \to \mathbb{R}^n, \qquad \mathbf{x} \mapsto (f_1(\mathbf{x}), \ldots, f_n(\mathbf{x})).$$

Any numerical method will usually only deliver an approximation $\mathbf{x}^0$ to $\mathbf{x}^*$, i.e., $\mathbf{f}(\mathbf{x}^0)$ will be fairly small, but not equal to zero. The question therefore arises whether there really exists an "exact" zero $\mathbf{x}^*$ of $\mathbf{f}$ in a (sufficiently small) neighborhood of $\mathbf{x}^0$ and whether there is a computational method to obtain such a neighborhood. Among the most successful such methods are Moore's existence test [11] and an existence test based on Miranda's theorem [12]. Both these tests rely on the use of interval arithmetic. We assume that the reader is familiar with the basics of interval arithmetic as described in [2], for example.

To fix our notation let us use square brackets to denote interval quantities. So $\mathbb{IR} = \{[a] = [\underline{a}, \overline{a}] : \underline{a} \le \overline{a}\}$ is the space of all (compact) intervals, $[\mathbf{x}] = ([x_1], \ldots, [x_n])^T$ with $[x_i] = [\underline{x}_i, \overline{x}_i] \in \mathbb{IR}$ is an interval vector, and, similarly, $[A] = ([a_{ij}])$ is an interval matrix. Given $[a] = [\underline{a}, \overline{a}] \in \mathbb{IR}$, it will sometimes be useful to denote the bounds of $[a]$ in a different way as

$$\underline{a} = \inf[a], \qquad \overline{a} = \sup[a].$$

For any interval $[a]$, let

$$\mathrm{mid}[a] = \frac{\underline{a} + \overline{a}}{2}$$

denote its midpoint; this is similar for interval vectors and interval matrices.

Assume now that for a given interval vector $[\mathbf{x}]$ and a fixed $\hat{\mathbf{x}} \in [\mathbf{x}]$ we know an interval matrix (*slope matrix*) $[Y]$ such that

$$\mathbf{f}(\mathbf{x}) - \mathbf{f}(\hat{\mathbf{x}}) \in [Y] \cdot (\mathbf{x} - \hat{\mathbf{x}}) \quad \text{for all } \mathbf{x} \in [\mathbf{x}]; \tag{1.1}$$

i.e., for each $\mathbf{x} \in [\mathbf{x}]$ there is a matrix $Y_{\mathbf{x}} \in [Y]$ such that

$$\mathbf{f}(\mathbf{x}) - \mathbf{f}(\hat{\mathbf{x}}) = Y_{\mathbf{x}} \cdot (\mathbf{x} - \hat{\mathbf{x}}).$$

If $\mathbf{f}$ is (Fréchet-)differentiable, $[Y]$ could be taken to be the interval hull $\Box D\mathbf{f}$ of the set $D\mathbf{f} = \{\mathbf{f}'(\mathbf{z}) : \mathbf{z} \in [\mathbf{x}]\}$, i.e., the intersection of all interval matrices containing $D\mathbf{f}$. In a more constructive manner, if $\mathbf{f}'(\mathbf{x})$ admits an interval arithmetic evaluation $\mathbf{f}'([\mathbf{x}])$ in the sense of [2], we can take $[Y] = \mathbf{f}'([\mathbf{x}]) \supseteq \Box D\mathbf{f}$.

Now, let $A \in \mathbb{R}^{n\times n}$ be some nonsingular matrix. Then Moore's existence test means checking the inclusion (1.2) given in the following theorem.

THEOREM 1.1. *Let* $\hat{\mathbf{x}} \in [\mathbf{x}]$ *and assume that*

$$[\mathbf{x}]^1 := \hat{\mathbf{x}} - A\mathbf{f}(\hat{\mathbf{x}}) + (I - A[Y])([\mathbf{x}] - \hat{\mathbf{x}}) \subseteq [\mathbf{x}]. \tag{1.2}$$

Then $[\mathbf{x}]^1$ *contains a zero* $\mathbf{x}^*$ *of* $\mathbf{f}$.

This theorem dates back to [11]. It follows from the fact that, due to the inclusion property of interval arithmetic, the interval vector $[\mathbf{x}]^1$ contains the range of the continuous function $\mathbf{x} - A\mathbf{f}(\mathbf{x}) = \hat{\mathbf{x}} - A \cdot \mathbf{f}(\hat{\mathbf{x}}) + (\mathbf{x} - \hat{\mathbf{x}}) - A \cdot (\mathbf{f}(\mathbf{x}) - \mathbf{f}(\hat{\mathbf{x}})) = \hat{\mathbf{x}} - A\mathbf{f}(\hat{\mathbf{x}}) + (I - AY_{\mathbf{x}})(\mathbf{x} - \hat{\mathbf{x}})$ for $\mathbf{x} \in [\mathbf{x}]$. By Brouwer's theorem, this function therefore has a fixed point which is a zero of $\mathbf{f}$. Often A is taken as (an approximation to) the inverse of $\mathbf{f}'(\mathrm{mid}[\mathbf{x}])$.

The Miranda existence test is based on Miranda's existence theorem [10], which generalizes the intermediate value theorem to higher dimensions. The key idea is to consider the signs of components of $\mathbf{f}$ on opposite facets of an interval vector $[\mathbf{x}]$. Let us denote these facets by $[\mathbf{x}]^{i,+}, [\mathbf{x}]^{i,-}$, i.e.,

$$\left.\begin{aligned} [\mathbf{x}]^{i,+} &= ([x_1], \dots, [x_{i-1}], \overline{x}_i, [x_{i+1}], \dots, [x_n])^T, \\ [\mathbf{x}]^{i,-} &= ([x_1], \dots, [x_{i-1}], \underline{x}_i, [x_{i+1}], \dots, [x_n])^T \end{aligned}\right\} \; i = 1, \dots, n.$$

Miranda's existence theorem reads as follows.

THEOREM 1.2. *Assume that* $\mathbf{f} : [\mathbf{x}] \subseteq \mathbb{R}^n \to \mathbb{R}^n$ *is continuous and that*

$$f_i(\mathbf{x}) \ge 0 \textit{ for } \mathbf{x} \in [\mathbf{x}]^{i,+}, \;\; f_i(\mathbf{x}) \le 0 \textit{ for } \mathbf{x} \in [\mathbf{x}]^{i,-}, \quad i = 1, \dots, n. \tag{1.3}$$

Then $[\mathbf{x}]$ *contains a zero* $\mathbf{x}^*$ *of* $\mathbf{f}$.

Miranda's theorem essentially requires that each component f_i is of constant and opposite sign on the opposite faces $[\mathbf{x}]^{i,\pm}$. In practice, the theorem is not applied to the function $\mathbf{f}$ under consideration but to a *preconditioned* (affinely transformed) function $\mathbf{g} : [\mathbf{x}] \to \mathbb{R}^n$, where

$$\mathbf{g}(\mathbf{x}) = A \cdot \mathbf{f}(\mathbf{x}).$$

Again, A denotes some nonsingular matrix, and often A is taken as an approximation to the inverse of $\mathbf{f}'(\mathrm{mid}[\mathbf{x}])$.

Let $\mathrm{Rg}(g_i, [\mathbf{z}])$ denote the range of g_i over some interval vector $[\mathbf{z}]$. The continuity of g_i implies that $\mathrm{Rg}(g_i, [\mathbf{z}])$ is an interval. Then, verifying (1.3) for the function $\mathbf{g}$ is equivalent to checking, for each $i \in \{1, \dots, n\}$, the conditions

$$\sup \mathrm{Rg}(g_i, [\mathbf{x}]^{i,-}) \le 0 \le \inf \mathrm{Rg}(g_i, [\mathbf{x}]^{i,+}). \tag{1.4}$$

There are several ways to use interval arithmetic for enclosing the ranges in (1.4) into intervals $[m]^{i,\pm}$.

Naive: In a naive implementation, the exact ranges are replaced with the interval arithmetic evaluations of the functions over the facets,

$$[m_{\mathrm{N}}]^{i,\pm} := g_i([\mathbf{x}]^{i,\pm}).$$

Centered: A more sophisticated technique is due to Moore and Kioustelidis [12]. It works as follows: As before, let $\hat{\mathbf{x}} \in [\mathbf{x}]$ and let $[Y]$ be a slope matrix fulfilling (1.1). Since

$$\begin{aligned}\mathbf{g}(\mathbf{x}) - \mathbf{g}(\hat{\mathbf{x}}) &= A \cdot (\mathbf{f}(\mathbf{x}) - \mathbf{f}(\hat{\mathbf{x}})) \\ &= (A \cdot Y_{\mathbf{x}}) \cdot (\mathbf{x} - \hat{\mathbf{x}}),\end{aligned}$$

$A \cdot [Y]$ is a slope matrix for $\mathbf{g}$, and therefore we have, for $i = 1, \dots, n$,

$$\mathrm{Rg}(g_i, [\mathbf{x}]^{i,\pm}) \subseteq g_i(\hat{\mathbf{x}}) + (A \cdot [Y])_i \cdot ([\mathbf{x}]^{i,\pm} - \hat{\mathbf{x}}) =: [m_{\mathrm{C}}]^{i,\pm},$$

where $(\cdots)_i$ denotes the ith row of a matrix.

Facet-centered: Similar to [12], suppose now that for each facet $[\mathbf{x}]^{i,\pm}$ a point $\hat{\mathbf{x}}^{i,\pm} \in [\mathbf{x}]^{i,\pm}$ is given and an interval row vector (*slope vector*) $[\mathbf{y}]^{i,\pm}$ is known such that

$$g_i(\mathbf{x}) - g_i(\hat{\mathbf{x}}^{i,\pm}) \in [\mathbf{y}]^{i,\pm} \cdot (\mathbf{x} - \hat{\mathbf{x}}^{i,\pm}) \text{ for all } \mathbf{x} \in [\mathbf{x}]^{i,\pm}. \tag{1.5}$$

For example, $\hat{\mathbf{x}}^{i,\pm}$ might be the midpoint of the facet $[\mathbf{x}]^{i,\pm}$, and $[\mathbf{y}]^{i,+}$ and $[\mathbf{y}]^{i,-}$ might be taken as the ith row of $A \cdot \mathbf{f}'([\mathbf{x}]^{i,\pm})$ or $A \cdot \mathbf{f}'([\mathbf{x}])$. Of course, other choices are also possible. Then, for $i = 1, \dots, n$,

$$\mathrm{Rg}(g_i, [\mathbf{x}]^{i,\pm}) \subseteq g_i(\hat{\mathbf{x}}^{i,\pm}) + [\mathbf{y}]^{i,\pm} \cdot ([\mathbf{x}]^{i,\pm} - \hat{\mathbf{x}}^{i,\pm}) =: [m_{\mathrm{F}}]^{i,\pm}.$$

(Note that in the original paper [12], $\hat{\mathbf{x}}$ and $\hat{\mathbf{x}}^{i,\pm}$ are assumed to be the midpoints of $[\mathbf{x}]$ and $[\mathbf{x}]^{i,\pm}$, respectively, and that $[Y]$ and $[\mathbf{y}]^{i,\pm}$ are enclosures for the derivatives $\mathbf{f}'$ over $[\mathbf{x}]$ and of g_i' over $[\mathbf{x}]^{i,\pm}$, respectively. These requirements can be relaxed as formulated above.) The resulting computational tests are summarized in the following definition.

Definition 1.3. *The term* Miranda test *means checking, for each* $i \in \{1, \dots, n\}$, *one of the conditions*

$$\sup[m_{\mathrm{N}}]^{i,-} \le 0 \le \inf[m_{\mathrm{N}}]^{i,+}\,, \tag{1.6a}$$

$$\sup[m_{\mathrm{C}}]^{i,-} \le 0 \le \inf[m_{\mathrm{C}}]^{i,+}\,, \tag{1.6b}$$

$$\sup[m_{\mathrm{F}}]^{i,-} \le 0 \le \inf[m_{\mathrm{F}}]^{i,+}\,. \tag{1.6c}$$

Note that we do *not* require the same condition to be checked for all i.

By the inclusion property of interval arithmetic we know that each of the conditions (1.6a)–(1.6c) implies (1.4). So $\mathbf{g}$ and therefore $\mathbf{f}$ has a zero $\mathbf{x}^*$ in $[\mathbf{x}]$.

The question of how the Miranda criterion compares to the Moore criterion was raised in [3] and settled in [14, 8]. Indeed in [8] the Miranda test was shown to be more powerful than the Moore test in the sense that if (1.2) holds for some $[\mathbf{x}]$, $\hat{\mathbf{x}}$, $[Y]$, and A then (1.6b) also holds for $i = 1, \dots, n$ with the same $[\mathbf{x}]$, $\hat{\mathbf{x}}$, $[Y]$, and A.

As a further result in this direction we now show that, at the cost of some additional function evaluations, formulation (1.6c) of the Miranda test is more powerful than (1.6b).

THEOREM 1.4. *If* (1.6b) *is satisfied for some* i*,* $[\mathbf{x}]$*,* $\hat{\mathbf{x}}$*,* $[Y]$ *and* A*, then with the same* i*,* $[\mathbf{x}]$ *and* A *also* (1.6c) *holds true provided that we choose* $\hat{\mathbf{x}}^{i,\pm}$ *as the orthogonal projection of* $\hat{\mathbf{x}}$ *onto the facet* $[\mathbf{x}]^{i,\pm}$*,*

$$\hat{\mathbf{x}}^{i,\pm} = (\hat{x}_1, \dots, \hat{x}_{i-1}, [x_i]^{i,\pm}, \hat{x}_{i+1}, \dots, \hat{x}_n)$$

and that $[\mathbf{y}]^{i,\pm}$ *is a subset of the ith row of* $A \cdot [Y]$*.*

Proof. First note that the $[x_i]^{i,\pm}$ are point intervals, $[x_i]^{i,+} = \sup[x_i]$, and $[x_i]^{i,-} = \inf[x_i]$. Since

$$\begin{aligned} \hat{\mathbf{x}}^{i,\pm} - \hat{\mathbf{x}} &= (0, \dots, 0, [x_i]^{i,\pm} - \hat{x}_i, 0, \dots, 0)^T \qquad \text{and} \\ [\mathbf{x}]^{i,\pm} - \hat{\mathbf{x}}^{i,\pm} &= ([x_1]^{i,\pm} - \hat{x}_1, \dots, [x_{i-1}]^{i,\pm} - \hat{x}_{i-1}, 0, \\ &\qquad [x_{i+1}]^{i,\pm} - \hat{x}_{i+1}, \dots, [x_n]^{i,\pm} - \hat{x}_n)^T, \end{aligned}$$

by the definition of $[Y]$ we have

$$\begin{aligned} g_i(\hat{\mathbf{x}}^{i,\pm}) &\in g_i(\hat{\mathbf{x}}) + (A[Y])_i \cdot (\hat{\mathbf{x}}^{i,\pm} - \hat{\mathbf{x}}) \\ &= g_i(\hat{\mathbf{x}}) + (A[Y])_{ii} \cdot ([x_i]^{i,\pm} - \hat{x}_i), \end{aligned}$$

and therefore, making use of $[\mathbf{y}]^{i,\pm} \subseteq (A \cdot [Y])_i$,

$$\begin{aligned} [m_{\mathrm{F}}]^{i,\pm} &= g_i(\hat{\mathbf{x}}^{i,\pm}) + [\mathbf{y}]^{i,\pm} \cdot ([\mathbf{x}]^{i,\pm} - \hat{\mathbf{x}}^{i,\pm}) \\ &\subseteq g_i(\hat{\mathbf{x}}^{i,\pm}) + \sum_{\ell \neq i} (A[Y])_{i\ell} \cdot ([x_\ell]^{i,\pm} - \hat{x}_\ell) \\ &\subseteq g_i(\hat{\mathbf{x}}) + (A[Y])_{ii} \cdot ([x_i]^{i,\pm} - \hat{x}_i) + \sum_{\ell \neq i} (A[Y])_{i\ell} \cdot ([x_\ell]^{i,\pm} - \hat{x}_\ell) \\ &= g_i(\hat{\mathbf{x}}) + (A[Y])_i \cdot ([\mathbf{x}]^{i,\pm} - \hat{\mathbf{x}}) \\ &= [m_{\mathrm{C}}]^{i,\pm}. \end{aligned}$$

Thus, (1.6b) implies (1.6c). □

Note. (i) The compatibility condition $[\mathbf{y}]^{i,\pm} \subseteq (A \cdot [Y])_i$ for the slopes is not a triviality since $[Y]$ contains slopes relative to the point $\hat{\mathbf{x}}$, whereas the slopes in $[\mathbf{y}]^{i,\pm}$ are relative to the point $\hat{\mathbf{x}}^{i,\pm}$. The condition is, however, certainly fulfilled for two simple choices, $[Y] = \mathbf{f}'([\mathbf{x}])$ and $[\mathbf{y}]^{i,\pm} = (A \cdot [Y])_i$, or $[Y] = \mathbf{f}'([\mathbf{x}])$ and $[\mathbf{y}]^{i,\pm} = (A \cdot \mathbf{f}'([\mathbf{x}]^{i,\pm}))_i$.

(ii) If $\hat{\mathbf{x}}$ is the midpoint of $[\mathbf{x}]$, then the orthogonal projections $\hat{\mathbf{x}}^{i,\pm}$ are the midpoints of the respective facets.

Another fixed point test, which will not be discussed further in the present paper, is based on Kantorovich's theorem. As pointed out in [1], Kantorovich's theorem is weaker than Borsuk's in the sense that the prerequisites of Kantorovich's theorem being fulfilled implies those of Borsuk's theorem to be fulfilled, too. Note that the cited paper ranks different fixed point *theorems* with respect to their strength without

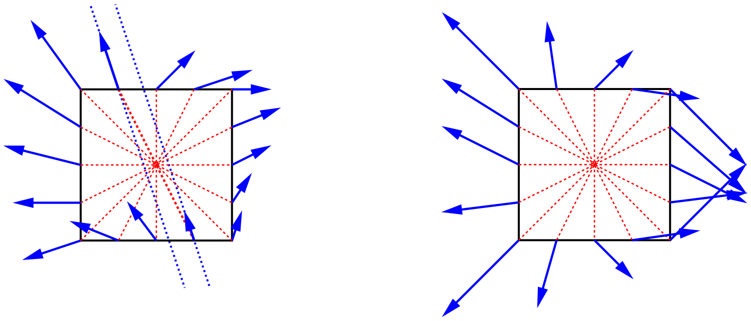

Fig. 2.1. *Illustration of Borsuk's theorem. In the left picture, there is a pair of opposite points on $\partial\Omega$ such that* $\mathbf{f}$ *points in the same direction, i.e., condition* (2.1) *is* not *fulfilled. By contrast, there is no such pair of points in the right picture, and therefore Borsuk's theorem guarantees the existence of a zero in this case.*

addressing the issue of their implementation in computational tests. Concerning such tests, [13] concludes that a computational test based on Kantorovich's theorem is not much stronger, but significantly more costly, than the Moore test.

2. Tests based on Borsuk's theorem.

Let $\Omega \subseteq \mathbb{R}^n$ be an open, bounded, convex set that is symmetric with respect to its center $\mathbf{x}^0$, i.e., $\mathbf{x}^0+\mathbf{y} \in \Omega$ iff $\mathbf{x}^0-\mathbf{y} \in \Omega$. Then Borsuk's theorem [6, 7] can be formulated as follows.

Theorem 2.1. *Assume that* $\mathbf{f} : \overline{\Omega} \to \mathbb{R}^n$ *is continuous and that for all* $\mathbf{x} = \mathbf{x}^0 + \mathbf{y} \in \partial\Omega$*, the topological boundary of* Ω*, we have*

$$\mathbf{f}(\mathbf{x}^0+\mathbf{y}) \neq \lambda \mathbf{f}(\mathbf{x}^0-\mathbf{y}) \text{ for all } \lambda > 0. \tag{2.1}$$

Then $\mathbf{f}$ *has a zero in* $\overline{\Omega}$.

This theorem can in particular be applied in the case when $\overline{\Omega} = [\mathbf{x}]$ is an interval vector; cf. Figure 2.1.

Similarly to the Miranda existence test, we now derive three range-based criteria for (2.1). Later on we will show how these criteria can be checked computationally using interval arithmetic. Note that the boundary of $[\mathbf{x}]$ is given by the facets $[\mathbf{x}]^{i,\pm}$ defined before, and $\mathbf{x}^0+\mathbf{y} \in [\mathbf{x}]^{i,+}$ iff $\mathbf{x}^0-\mathbf{y} \in [\mathbf{x}]^{i,-}$. We again consider the preconditioned function $\mathbf{g}(\mathbf{x}) = A \cdot \mathbf{f}(\mathbf{x})$, $\mathbf{x} \in [\mathbf{x}]$, with a nonsingular matrix A, and for easier exposition we assume that $\mathbf{f}$ (and therefore $\mathbf{g}$) has no zero on $\partial[\mathbf{x}]$, the boundary of $[\mathbf{x}]$.

First we note that, for any vectors $\mathbf{u}, \mathbf{v} \neq \mathbf{0}$, the Cauchy–Schwarz inequality yields

$$-1 \leq \frac{\langle\, \mathbf{u}, \mathbf{v}\, \rangle}{\|\mathbf{u}\| \cdot \|\mathbf{v}\|} \leq +1,$$

the value $+1$ being attained iff $\mathbf{u}$ and $\mathbf{v}$ are collinear and point into the same direction. Thus, condition (2.1) from Borsuk's theorem is equivalent to

$$\sup \mathrm{Rg}(\sigma, [\mathbf{x}]^{i,+}) < 1 \tag{2.2}$$

being fulfilled for each $i \in \{1, \dots, n\}$, where for $\mathbf{x}^0 + \mathbf{y} \in [\mathbf{x}]^{i,+}$ we define

$$\sigma(\mathbf{x}^0 + \mathbf{y}) = \frac{\langle\, \mathbf{g}(\mathbf{x}^0 + \mathbf{y}), \mathbf{g}(\mathbf{x}^0 - \mathbf{y})\, \rangle}{\|\mathbf{g}(\mathbf{x}^0 + \mathbf{y})\| \cdot \|\mathbf{g}(\mathbf{x}^0 - \mathbf{y})\|}. \tag{2.3}$$

So one criterion is (2.2) to be fulfilled for $i = 1, \dots, n$.

To derive the remaining two (sufficient) range-based criteria, we assume that for some $\mathbf{x}^0 + \mathbf{y} \in \partial[\mathbf{x}]$ the function $\mathbf{g}$ does *not* fulfill (2.1). This means that for some $i \in \{1, \dots, n\}$ with $\mathbf{x}^0 + \mathbf{y} \in [\mathbf{x}]^{i,+}$ and for some $\lambda > 0$ we would have

$$g_j(\mathbf{x}^0 + \mathbf{y}) = \lambda g_j(\mathbf{x}^0 - \mathbf{y}), \qquad j = 1, \dots, n. \tag{2.4}$$

This would imply

$$\lambda = \frac{g_j(\mathbf{x}^0 + \mathbf{y})}{g_j(\mathbf{x}^0 - \mathbf{y})} \in \frac{\mathrm{Rg}(g_j, [\mathbf{x}]^{i,+})}{\mathrm{Rg}(g_j, [\mathbf{x}]^{i,-})} \quad \text{for all } j = 1, \dots, n,$$

invoking extended interval arithmetic [15] in the case $0 \in \mathrm{Rg}(g_j, [\mathbf{x}]^{i,-})$. Therefore (2.1) is certainly fulfilled if

$$\bigcap_{j=1}^{n} \frac{\mathrm{Rg}(g_j, [\mathbf{x}]^{i,+})}{\mathrm{Rg}(g_j, [\mathbf{x}]^{i,-})} \cap (0, \infty) = \emptyset \tag{2.5}$$

for each $i \in \{1, \dots, n\}$, which is our second criterion.

The third criterion is also obtained from (2.4). Given a slope matrix $[Y]$ according to (1.1), condition (2.4) would imply

$$g_j(\mathbf{x}^0) + (A \cdot Y_+)_j \cdot \mathbf{y} = \lambda \left(g_j(\mathbf{x}^0) - (A \cdot Y_-)_j \cdot \mathbf{y} \right) \tag{2.6}$$

with matrices $Y_+, Y_- \in [Y]$. Transforming further, (2.6) yields

$$\begin{aligned} (1 - \lambda) \cdot g_j(\mathbf{x}^0) &= -(A \cdot (\lambda Y_- + Y_+))_j \cdot \mathbf{y} \\ &\in -(A \cdot (\lambda[Y] + [Y]))_j \cdot ([\mathbf{x}]^{i,+} - \mathbf{x}^0) \\ &= -\,(\lambda + 1)\,(A \cdot [Y])_j \cdot ([\mathbf{x}]^{i,+} - \mathbf{x}^0), \end{aligned}$$

the last equality holding because $\lambda > 0$. Thus, we finally obtain

$$\frac{\lambda - 1}{\lambda + 1} g_j(\mathbf{x}^0) \in (A \cdot [Y])_j \cdot ([\mathbf{x}]^{i,+} - \mathbf{x}^0). \tag{2.7}$$

This gives us a condition on the range of $(\lambda - 1)/(\lambda + 1)$, because (2.7) implies

$$\frac{\lambda - 1}{\lambda + 1} \in \frac{(A \cdot [Y])_j \cdot ([\mathbf{x}]^{i,+} - \mathbf{x}^0)}{g_j(\mathbf{x}^0)}$$

with the convention that the division of an interval by 0 is defined as

$$\frac{[a]}{0} = \begin{cases} \mathbb{R} & \text{if } 0 \in [a], \\ \emptyset & \text{else.} \end{cases}$$

For $\lambda > 0$, the range of $(\lambda-1)/(\lambda+1)$ is contained in $(-1, 1)$. Putting things together, we see that if (2.4) holds, we have

$$\frac{\lambda - 1}{\lambda + 1} \in \bigcap_{j=1}^{n} \frac{(A \cdot [Y])_j \cdot ([\mathbf{x}]^{i,+} - \mathbf{x}^0)}{g_j(\mathbf{x}^0)} \cap (-1, 1).$$

Since the existence of a zero of $\mathbf{g}$ in $[\mathbf{x}]$ is guaranteed by Borsuk's theorem if (2.4) does *not* hold for $i = 1, \ldots, n$, we obtain the following, third, criterion: If

$$\underbrace{\bigcap_{j=1}^{n} \frac{(A \cdot [Y])_j \cdot ([\mathbf{x}]^{i,+} - \mathbf{x}^0)}{g_j(\mathbf{x}^0)}}_{=:\, [b_{\mathrm{M}}]^i} \cap (-1, 1) = \emptyset \tag{2.8}$$

for each $i \in \{1, \ldots, n\}$, then $\mathbf{g}$ (and thus $\mathbf{f} = A^{-1}\mathbf{g}$) has a zero $\mathbf{x}^*$ in $[\mathbf{x}]$.

At first glance it may be surprising that the opposite facets $[\mathbf{x}]^{i,-}$ do not at all enter criterion (2.8). But since $[\mathbf{x}]^{i,-} - \mathbf{x}^0 = -([\mathbf{x}]^{i,+} - \mathbf{x}^0)$, we have

$$\bigcap_{j=1}^{n} \frac{(A \cdot [Y])_j \cdot ([\mathbf{x}]^{i,-} - \mathbf{x}^0)}{g_j(\mathbf{x}^0)} = -\bigcap_{j=1}^{n} \frac{(A \cdot [Y])_j \cdot ([\mathbf{x}]^{i,+} - \mathbf{x}^0)}{g_j(\mathbf{x}^0)}$$

so that substituting $[\mathbf{x}]^{i,+}$ by $[\mathbf{x}]^{i,-}$ in (2.8) just produces an equivalent condition to (2.8).

We will now discuss several ways for checking the above three criteria computationally with the use of interval arithmetic.

While the formulation (2.8) is directly amenable to interval evaluation, the exact ranges in (2.2) and (2.5) must be replaced with quantities that can be computed effectively.

For the criterion (2.5), the naive, centered, and facet-centered techniques described in the context of the Miranda test lead to the interval quantities

$$[b_{\mathrm{N}}]^i := \bigcap_{j=1}^{n} \frac{g_j([\mathbf{x}]^{i,+})}{g_j([\mathbf{x}]^{i,-})},$$

$$[b_{\mathrm{C}}]^i := \bigcap_{j=1}^{n} \frac{g_j(\hat{\mathbf{x}}) + (A \cdot [Y])_j \cdot ([\mathbf{x}]^{i,+} - \hat{\mathbf{x}})}{g_j(\hat{\mathbf{x}}) + (A \cdot [Y])_j \cdot ([\mathbf{x}]^{i,-} - \hat{\mathbf{x}})},$$

$$[b_{\mathrm{F}}]^i := \bigcap_{j=1}^{n} \frac{g_j(\hat{\mathbf{x}}^{i,+}) + [\mathbf{y}_j]^{i,+} \cdot ([\mathbf{x}]^{i,+} - \hat{\mathbf{x}}^{i,+})}{g_j(\hat{\mathbf{x}}^{i,-}) + [\mathbf{y}_j]^{i,-} \cdot ([\mathbf{x}]^{i,-} - \hat{\mathbf{x}}^{i,-})},$$

where again $[Y]$ is a slope matrix fulfilling (1.1), $\hat{\mathbf{x}}$ is a given point in the box $[\mathbf{x}]$ (not necessarily its midpoint), the $\hat{\mathbf{x}}^{i,\pm}$ are given points on the facets ($\hat{\mathbf{x}}^{i,\pm} \in [\mathbf{x}]^{i,\pm}$), and the $[\mathbf{y}_j]^{i,\pm}$ are row vectors such that $g_j(\mathbf{x}) - g_j(\hat{\mathbf{x}}^{i,\pm}) \in [\mathbf{y}_j]^{i,\pm} \cdot (\mathbf{x} - \hat{\mathbf{x}}^{i,\pm})$ for all $\mathbf{x} \in [\mathbf{x}]^{i,\pm}$.

In (2.2) the exact range $\mathrm{Rg}(\sigma, [\mathbf{x}]^{i,+})$ must be enclosed in an interval $[b_{\mathrm{S}}]^i$. Since a naive interval-arithmetic evaluation of the function σ defined in (2.3) suffers severely from the dependence problem [9, p. 4], higher-order methods should be applied to obtain a reasonably narrow enclosure of the range, e.g., by decomposing the domain into smaller subdomains or by using Taylor models [4, 5].

The computational tests resulting from the criteria (2.8), (2.5), and (2.2) are summarized in the following definition; note that $[b_{\mathrm{M}}]^i$ is defined in (2.8).

Definition 2.2. *The term* Borsuk test *denotes checking, for each* $i \in \{1, \ldots, n\}$, *one of the conditions*

$$[b_{\mathrm{M}}]^i \cap (-1, 1) = \emptyset, \tag{2.9}$$

$$[b_{\mathrm{N}}]^i \cap (0, \infty) = \emptyset, \tag{2.10a}$$

$$[b_{\mathrm{C}}]^i \cap (0, \infty) = \emptyset, \tag{2.10b}$$

$$[b_{\mathrm{F}}]^i \cap (0, \infty) = \emptyset, \tag{2.10c}$$

$$\sup [b_{\mathrm{S}}]^i < 1. \tag{2.11}$$

Again, we do not have to require the same condition to be checked for all i.

With the same arguments as in the proof to Theorem 1.4 we can show that (2.10c) is more powerful than (2.10b), provided that $\hat{\mathbf{x}}^{i,\pm}$ is chosen as the orthogonal projection of $\hat{\mathbf{x}}$ onto the facet $[\mathbf{x}]^{i,\pm}$ and that $[\mathbf{y}_j]^{i,\pm}$ is a subset of the jth row of $A \cdot [Y]$. We do not explicitly formulate this as a theorem here.

We can also show that the Borsuk test compares favorably to the Miranda test.

Theorem 2.3. *Each variant* (2.10a)–(2.10c) *of the Borsuk test is more powerful than the corresponding variant* (1.6a)–(1.6c) *of the Miranda test in the sense that if* (1.6a) *(respectively,* (1.6b), *respectively,* (1.6c)*) is satisfied for some* i, $[\mathbf{x}]$, $\hat{\mathbf{x}}$, $\hat{\mathbf{x}}^{i,\pm}$, A, $[Y]$ *and* $[\mathbf{y}]^{i,\pm}$, *then* (2.10a) *(respectively,* (2.10b), *respectively,* (2.10c)*) also holds true with the same* i, $[\mathbf{x}]$, $\hat{\mathbf{x}}$, $\hat{\mathbf{x}}^{i,\pm}$, A *and* $[Y]$, *provided that the* $[\mathbf{y}_j]^{i,\pm}$ *are chosen such that* $[\mathbf{y}_i]^{i,\pm} \subseteq [\mathbf{y}]^{i,\pm}$ *is fulfilled.*

Proof. We will only consider the naive variant, the arguments for the centered and face-centered cases being the same. If (1.6a) is fulfilled, then

$$\frac{g_i([\mathbf{x}]^{i,+})}{g_i([\mathbf{x}]^{i,-})} \subseteq (-\infty, 0],$$

extended interval arithmetic coming into play if $\sup g_i([\mathbf{x}]^{i,-}) = 0$. This immediately implies

$$\bigcap_{j=1}^{n} \frac{g_j([\mathbf{x}]^{i,+})}{g_j([\mathbf{x}]^{i,-})} \cap (0, \infty) = \emptyset,$$

with the empty intersection being already enforced by the single component $j = i$. Thus (2.10a) also holds true. □

Note. If A is an approximation to the inverse of $\mathbf{f}'(\hat{\mathbf{x}})$, if $\hat{\mathbf{x}}$ is a good approximation to a zero of $\mathbf{f}$, and if the box $[\mathbf{x}]$ is *sufficiently small*, then the function $\mathbf{g}(\mathbf{x}) + \hat{\mathbf{x}}$ is a small perturbation of the identity on $[\mathbf{x}]$, and therefore empty intersections in (2.10a)–(2.10c) will typically be caused by the component $j = i$, i.e., the corresponding condition of the Miranda test would be fulfilled as well. Under these circumstances, the variants (2.10a)–(2.10c) of the Borsuk test are hardly more powerful than the Miranda variants (1.6a)–(1.6c). The situation can be substantially different for larger boxes.

The variants (2.9) and (2.11) are completely different. In particular, (2.11) may be significantly more powerful than any variant of the Miranda test *provided that narrow enclosures for the range of* σ *are available.*

3. An example. In this section we present an example showing that the Borsuk test may be able to verify the existence of a zero in situations where Miranda-based tests as well as the Moore test must fail. Consider the function

$$\mathbf{f}(u,v) = \begin{pmatrix} 4 - 2(u-1)^2 \\ (2-(u+1)^2)\cdot(2-(v-1)^2) \end{pmatrix},$$

which has a unique zero $\mathbf{x}^* = (u^*, v^*) = (1-\sqrt{2}, 1-\sqrt{2})$ in the box $[\mathbf{x}] = [u] \times [v] = [-1,1] \times [-1,1]$.

For future reference, we note that

$$[\mathbf{x}]^{1,\pm} = \{\pm 1\} \times [-1,1], \qquad [\mathbf{x}]^{2,\pm} = [-1,1] \times \{\pm 1\},$$

$$\mathbf{x}^0 = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \qquad \mathbf{f}(\mathbf{x}^0) = \begin{pmatrix} 2 \\ 1 \end{pmatrix},$$

$$\mathbf{f}(1,1) = \begin{pmatrix} 4 \\ -4 \end{pmatrix}, \qquad \mathbf{f}(1,-1) = \begin{pmatrix} 4 \\ 4 \end{pmatrix}, \tag{3.1}$$

$$\mathbf{f}(-1,1) = \begin{pmatrix} -4 \\ 4 \end{pmatrix}, \qquad \mathbf{f}(-1,-1) = \begin{pmatrix} -4 \\ -4 \end{pmatrix}, \tag{3.2}$$

$$\mathbf{f}'(u,v) = \begin{pmatrix} -4(u-1) & 0 \\ -2(u+1)\left(2-(v-1)^2\right) & -2\left(2-(u+1)^2\right)(v-1) \end{pmatrix}.$$

In this two-dimensional example the facets of the rectangle $[\mathbf{x}]$ are just its sides.

3.1. Miranda-based tests. We first show that *no* test based on Miranda's theorem is applicable to $\mathbf{f}$ and $[\mathbf{x}]$, *even if arbitrary preconditioning is allowed.* To this end consider the function

$$\mathbf{g}(u,v) = \underbrace{\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}}_{A} \cdot \mathbf{f}(u,v), \quad \alpha, \beta, \gamma, \delta \in \mathbb{R}. \tag{3.3}$$

We will now show that for any nonsingular A, the function g does not satisfy the assumptions of Miranda's theorem. Since $\mathbf{g}$'s property of having—or not having—constant (different) sign on opposite sides of $[\mathbf{x}]$ is invariant to row scaling, we may assume that, at the upper right corner $(1,1)$, each component g_j takes either a specified nonzero value, say 4, or is zero.

Case 1. $g_1(1,1) = g_2(1,1) = 0$. By (3.3) and (3.1), this implies $\mathbf{0} = A \cdot (4,-4)^T$, i.e., A must be singular, which is a contradiction.

Case 2. $g_1(1,1) = g_2(1,1) = 4$. Then, from (3.3) and (3.1) we obtain

$$\begin{aligned} 4\alpha - 4\beta &= 4, \\ 4\gamma - 4\delta &= 4, \end{aligned}$$

or $\beta = \alpha - 1$, $\delta = \gamma - 1$. Combining these relations with (3.3) and (3.2) yields

$$\mathbf{g}(-1,1) = \begin{pmatrix} \alpha & \alpha - 1 \\ \gamma & \gamma - 1 \end{pmatrix} \cdot \begin{pmatrix} -4 \\ 4 \end{pmatrix} = \begin{pmatrix} -4 \\ -4 \end{pmatrix},$$

implying that both g_1 and g_2 change sign on the upper side $[\mathbf{x}]^{2,+}$ of the box.

Case 3. $g_1(1,1) = 4$, $g_2(1,1) = 0$. Then, (3.3) and (3.1) give

$$4\alpha - 4\beta = 4,$$
$$4\gamma - 4\delta = 0,$$

or $\beta = \alpha - 1$, $\delta = \gamma$. As in Case 2, the first of these two equations implies that g_1 changes sign on the upper side $[\mathbf{x}]^{2,+}$. Noting that $\gamma \neq 0$ because A is nonsingular, a short calculation shows that g_2 takes the constant sign $\operatorname{sgn}(\gamma)$ on the upper side but changes sign on the lower side $[\mathbf{x}]^{2,-}$ since, according to (3.3), (3.1), and (3.2),

$$g_2(1,-1) = \begin{pmatrix} \gamma & \gamma \end{pmatrix} \cdot \begin{pmatrix} 4 \\ 4 \end{pmatrix} = 8\gamma,$$
$$g_2(-1,-1) = \begin{pmatrix} \gamma & \gamma \end{pmatrix} \cdot \begin{pmatrix} -4 \\ -4 \end{pmatrix} = -8\gamma.$$

Case 4. $g_1(1,1) = 0$, $g_2(1,1) = 4$. This case is completely symmetric to Case 3, with g_2 changing sign on $[\mathbf{x}]^{2,+}$ and g_1 changing sign on $[\mathbf{x}]^{2,-}$.

To summarize, in all cases none of the components g_1 and g_2 takes (constant) different sign on the opposite sides $[\mathbf{x}]^{2,+}$ and $[\mathbf{x}]^{2,-}$. Thus, no nonsingular preconditioning matrix A leads to the prerequisites of Miranda's theorem being fulfilled. Therefore the Miranda test as well as the Moore test cannot be successful.

3.2. Applying Borsuk's theorem. Now we show that the Borsuk test according to Definition 2.2 is successful for this example, demonstrating that the assumptions for Borsuk's theorem can be checked computationally. Unless explicitly stated otherwise, plain interval arithmetic is used for evaluating expressions over a box. No preconditioning is necessary, i.e., $A = I_2$ and $\mathbf{g} \equiv \mathbf{f}$.

With the simplest choice $[Y] = \mathbf{f}'([\mathbf{x}])$ we obtain $A \cdot [Y] = \mathbf{f}'([\mathbf{x}]) = \mathbf{g}'([\mathbf{x}])$, leading to $(A \cdot [Y])_j = g'_j([\mathbf{x}])$.

Interval evaluation of $\mathbf{g}' \equiv \mathbf{f}'$ on $[\mathbf{x}] = [u] \times [v] = [-1,1] \times [-1,1]$ yields

$$\begin{aligned}\mathbf{g}'([\mathbf{x}]) &= \begin{pmatrix} -4([u]-1) & 0 \\ -2([u]+1)(2-([v]-1)^2) & -2(2-([u]+1)^2)([v]-1) \end{pmatrix} \\ &= \begin{pmatrix} [0,8] & 0 \\ [-8,8] & [-8,8] \end{pmatrix}.\end{aligned}$$

In all our computations we assume that the formula $[a]^2 = [\langle [a] \rangle^2, |[a]|^2]$ is used to compute the range of the square function over some interval $[a]$, where the *magnitude* $|[a]|$ and the *mignitude* $\langle [a] \rangle$ denote the maximum and minimum, respectively, absolute values of elements in $[a]$.

$i = 1$ *(right and left side)*: Evaluating $[b_{\mathrm{M}}]^i$ from (2.8) for $i = 1$ yields

$$\begin{aligned}[b_{\mathrm{M}}]^1 &= \frac{g'_1([\mathbf{x}]) \cdot ([\mathbf{x}]^{1,+} - \mathbf{x}^0)}{g_1(\mathbf{x}^0)} \cap \frac{g'_2([\mathbf{x}]) \cdot ([\mathbf{x}]^{1,+} - \mathbf{x}^0)}{g_2(\mathbf{x}^0)} \\ &= \frac{([0,8], 0) \cdot (1, [-1,1])^T}{2} \cap \frac{([-8,8],[-8,8]) \cdot (1,[-1,1])^T}{1} \\ &= [0,4].\end{aligned}$$

Since $[b_{\mathrm{M}}]^1 \cap (-1,1) \neq \emptyset$, (2.9) could not be verified for $i = 1$. By contrast,

$$\begin{aligned}
[b_{\mathrm{N}}]^1 &= \frac{g_1([\mathbf{x}]^{1,+})}{g_1([\mathbf{x}]^{1,-})} \cap \frac{g_2([\mathbf{x}]^{1,+})}{g_2([\mathbf{x}]^{1,-})} \\
&= \frac{4 - 2(1-1)^2}{4 - 2(-1-1)^2} \cap \frac{(2-(1+1)^2)(2-([-1,1]-1)^2)}{(2-(-1+1)^2)(2-([-1,1]-1)^2)} \\
&= \frac{4}{-4} \cap \frac{[-4,4]}{[-4,4]} \\
&= -1 \cap \mathbb{R} \\
&= -1\,,
\end{aligned}$$

showing (2.10a) for $i = 1$.

$i = 2$ *(upper and lower side)*: Choosing $\hat{\mathbf{x}}$ as the midpoint of $[\mathbf{x}]$, $\hat{\mathbf{x}}^{i,\pm}$ as the midpoint of the facet $[\mathbf{x}]^{i,\pm}$, and the slope vector $[\mathbf{y}_j]^{i,\pm}$ as the jth row of $A \cdot [Y] = \mathbf{g}'([\mathbf{x}])$, short calculations show that

$$\begin{aligned}
[b_{\mathrm{M}}]^2 &= \frac{g_1'([\mathbf{x}]) \cdot ([\mathbf{x}]^{2,+} - \mathbf{x}^0)}{g_1(\mathbf{x}^0)} \cap \frac{g_2'([\mathbf{x}]) \cdot ([\mathbf{x}]^{2,+} - \mathbf{x}^0)}{g_2(\mathbf{x}^0)} \\
&= \frac{([0,8],0) \cdot ([-1,1],1)^T}{2} \cap \frac{([-8,8],[-8,8]) \cdot ([-1,1],1)^T}{1} \\
&= \frac{[-8,8]}{2} \cap \frac{[-16,16]}{1} \\
&= [-4,4],
\end{aligned}$$

implying $[b_{\mathrm{M}}]^2 \cap (-1,1) \neq \emptyset$,

$$\begin{aligned}
[b_{\mathrm{N}}]^2 &= \frac{g_1([\mathbf{x}]^{2,+})}{g_1([\mathbf{x}]^{2,-})} \cap \frac{g_2([\mathbf{x}]^{2,+})}{g_2([\mathbf{x}]^{2,-})} \\
&= \frac{4 - 2([-1,1]-1)^2}{4 - 2([-1,1]-1)^2} \cap \frac{(2-([-1,1]+1)^2) \cdot (2-(1-1)^2)}{(2-([-1,1]+1)^2) \cdot (2-((-1)-1)^2)} \\
&= \frac{[-4,4]}{[-4,4]} \cap \frac{[-4,4]}{[-4,4]} \\
&= \mathbb{R},
\end{aligned}$$

meaning $[b_{\mathrm{N}}]^2 \cap (0,\infty) \neq \emptyset$, and similarly,

$$\begin{aligned}
[b_{\mathrm{C}}]^2 &= \frac{g_1(\hat{\mathbf{x}}) + g_1'([\mathbf{x}]) \cdot ([\mathbf{x}]^{2,+} - \hat{\mathbf{x}})}{g_1(\hat{\mathbf{x}}) + g_1'([\mathbf{x}]) \cdot ([\mathbf{x}]^{2,-} - \hat{\mathbf{x}})} \cap \frac{g_2(\hat{\mathbf{x}}) + g_2'([\mathbf{x}]) \cdot ([\mathbf{x}]^{2,+} - \hat{\mathbf{x}})}{g_2(\hat{\mathbf{x}}) + g_2'([\mathbf{x}]) \cdot ([\mathbf{x}]^{2,-} - \hat{\mathbf{x}})} \\
&= \frac{2 + ([0,8],0) \cdot ([-1,1],1)^T}{2 + ([0,8],0) \cdot ([-1,1],-1)^T} \cap \frac{1 + ([-8,8],[-8,8]) \cdot ([-1,1],1)}{1 + ([-8,8],[-8,8]) \cdot ([-1,1],-1)} \\
&= \frac{[-6,10]}{[-6,10]} \cap \frac{[-15,17]}{[-15,17]} \\
&= \mathbb{R}
\end{aligned}$$

and

$$\begin{aligned}[b_{\mathrm{F}}]^2 &= \frac{g_1(\mathrm{mid}[\mathbf{x}]^{2,+}) + g_1'([\mathbf{x}]) \cdot ([\mathbf{x}]^{2,+} - \mathrm{mid}[\mathbf{x}]^{2,+})}{g_1(\mathrm{mid}[\mathbf{x}]^{2,-}) + g_1'([\mathbf{x}]) \cdot ([\mathbf{x}]^{2,-} - \mathrm{mid}[\mathbf{x}]^{2,-})} \\ &\qquad \cap \frac{g_2(\mathrm{mid}[\mathbf{x}]^{2,+}) + g_2'([\mathbf{x}]) \cdot ([\mathbf{x}]^{2,+} - \mathrm{mid}[\mathbf{x}]^{2,+})}{g_2(\mathrm{mid}[\mathbf{x}]^{2,-}) + g_2'([\mathbf{x}]) \cdot ([\mathbf{x}]^{2,-} - \mathrm{mid}[\mathbf{x}]^{2,-})} \\ &= \frac{g_1(0,1) + ([0,8],0) \cdot ([-1,1],0)^T}{g_1(0,-1) + ([0,8],0) \cdot ([-1,1],0)^T} \\ &\qquad \cap \frac{g_2(0,1) + ([-8,8],[-8,8]) \cdot ([-1,1],0)^T}{g_2(0,-1) + ([-8,8],[-8,8]) \cdot ([-1,1],0)^T} \\ &= \frac{[-6,10]}{[-6,10]} \cap \frac{[-6,10]}{[-10,6]} \\ &= \mathbb{R}.\end{aligned}$$

So none of the conditions (2.9) and (2.10a)–(2.10c) is fulfilled for $i = 2$. To check the remaining condition (2.11), we enclose the range of the function σ over $[\mathbf{x}]^{2,+}$. Note that, in order to have $\mathbf{x}^0 + \mathbf{y} \in [\mathbf{x}]^{2,+}$, the offset $\mathbf{y}$ must be of the form $\mathbf{y} = (u,1)^T$ with $u \in [-1,1]$. Therefore $\mathbf{x}^0 + \mathbf{y} = (u,1)^T$ and $\mathbf{x}^0 - \mathbf{y} = (-u,-1)^T$. This gives

$$\begin{aligned}\sigma(\mathbf{x}^0 + \mathbf{y}) &= \frac{\langle\, \mathbf{g}(u,1), \mathbf{g}(-u,-1)\,\rangle}{\|\mathbf{g}(u,1)\| \cdot \|\mathbf{g}(-u,-1)\|} \\ &= \frac{\left\langle \begin{pmatrix} 4-2(u-1)^2 \\ (2-(u+1)^2)\cdot 2 \end{pmatrix}, \begin{pmatrix} 4-2(-u-1)^2 \\ (2-(-u+1)^2)\cdot(-2) \end{pmatrix} \right\rangle}{\left\| \begin{pmatrix} 4-2(u-1)^2 \\ (2-(u+1)^2)\cdot 2 \end{pmatrix} \right\| \cdot \left\| \begin{pmatrix} 4-2(-u-1)^2 \\ (2-(-u+1)^2)\cdot(-2) \end{pmatrix} \right\|} \\ &= \frac{\nu}{\delta}\end{aligned}$$

with

$$\begin{aligned}\nu &= (4-2(u-1)^2)\cdot(4-2(-u-1)^2) \\ &\qquad - 4(2-(u+1)^2)\cdot(2-(-u+1)^2)\ , \\ \delta &= \sqrt{(4-2(u-1)^2)^2 + 4(2-(u+1)^2)^2} \\ &\qquad \cdot \sqrt{(4-2(-u-1)^2)^2 + 4(2-(-u+1)^2)^2}\ .\end{aligned}$$

Using these expressions for the numerator and denumerator, respectively, and plain interval arithmetic for their evaluation over $[u] = [-1,1]$, again causes too much overestimation:

$$\frac{[\nu]}{[\delta]} = \frac{[-32,32]}{\sqrt{[0,32]}\cdot\sqrt{[0,32]}} \ = \ \mathbb{R}.$$

Other ways for bounding the range, however, yield the required result:

- A symbolic term optimizer detects that $\nu \equiv 0$ and therefore replaces the term ν/δ representing σ with 0. Evaluating this term immediately yields

$$\sup_{\mathbf{x}^0+\mathbf{y}\in[\mathbf{x}]^{2,+}} \sigma(\mathbf{y}) = 0 < 1.$$

  This extreme situation is, of course, not very likely to occur in practice.

- Taylor arithmetic [5] can be used to reduce the heavy dependence of the variables within the term ν/δ. Indeed, in our example an order-4 Taylor model—implemented, e.g., using the COSY INFINITY software [4]—shows that the range of σ is contained in the interval $[b_{\mathrm{S}}]^2 = [-10^{-12}, +10^{-12}]$, which is bounded away from $+1$.
- Subdividing the domain for $\mathbf{y}$ is another way to reduce the overestimation. In our example, dividing $[u]$ into 8 equally sized subintervals and using naive interval evaluation of the expression ν/δ over these subintervals shows that the range of σ is a subset of $[b_{\mathrm{S}}]^2 = [-0.8394, +0.8394]$, which is also bounded below 1.

Since (2.10a) holds for $i = 1$ and (2.11) is fulfilled for $i = 2$, Borsuk's theorem guarantees the existence of a zero $\mathbf{x}^*$ of $\mathbf{g}$ (and $\mathbf{f}$) in the (rather large) box $[\mathbf{x}]$.

4. Concluding remarks. We have presented a new method for *automatically* verifying the existence of a zero of a nonlinear function $\mathbf{f}$ within some interval vector $[\mathbf{x}]$. Our test is based on a theorem by Borsuk and can be implemented in several different ways. For some of these, similar criteria based on a theorem by Miranda are known. We could show that in these cases our test is at least as powerful as the corresponding Miranda test.

The Borsuk test also allows for formulations that have no Miranda analogue and may be applicable in situations where no Miranda-based test can be successful. This fact has been illustrated by a numerical example.

From a complexity point of view, it is important that the Borsuk test can be implemented to complement the Miranda test in the following way: If we first apply the Miranda test and one of the conditions (1.6a)–(1.6c) can be verified for some i then, by Theorem 2.3, we know that the respective condition (2.10a)–(2.10c) is fulfilled as well. Thus, the (more expensive) Borsuk test must be applied only to those components i for which the Miranda test has failed.

As Borsuk's theorem only requires that the function does not point in the same direction at opposite boundary points, *different preconditioning* $\mathbf{g}^{(i)} = A_i \cdot \mathbf{f}$ might be used on each pair $[\mathbf{x}]^{i,\pm}$ of opposite facets. The potential benefits of this additional flexibility, which is not available in Miranda-based tests, will be explored in the future.

GALERKIN FINITE ELEMENT METHODS FOR STOCHASTIC PARABOLIC PARTIAL DIFFERENTIAL EQUATIONS*

YUBIN YAN[†]

Abstract. We study the finite element method for stochastic parabolic partial differential equations driven by nuclear or space-time white noise in the multidimensional case. The discretization with respect to space is done by piecewise linear finite elements, and in time we apply the backward Euler method. The noise is approximated by using the generalized L_2-projection operator. Optimal strong convergence error estimates in the L_2 and $\dot{H}^{-1}$ norms with respect to the spatial variable are obtained. The proof is based on appropriate nonsmooth data error estimates for the corresponding deterministic parabolic problem. The computational analysis and numerical example are given.

Key words. stochastic parabolic partial differential equations, finite element method, additive noise

1. Introduction.

We study the finite element approximation of the stochastic parabolic partial differential equation

$$du + Au\,dt = \sigma(u)dW \quad \text{for } 0 < t \le T, \quad \text{with } u(0) = u_0, \tag{1.1}$$

in a Hilbert space H, with inner product $(\cdot,\cdot)$ and norm $\|\cdot\|$, where $u(t)$ is an H-valued random process; A is a linear, self-adjoint, positive definite, not necessarily bounded operator with a compact inverse, densely defined in $\mathcal{D}(A) \subset H$; and σ is a nonlinear operator-valued function defined on H which we will specify later. Here $W(t)$ is a Wiener process defined on a filtered probability space $(\Omega, \mathcal{F}, \mathbf{P}, \{\mathcal{F}_t\}_{t\ge 0})$ and $u_0 \in H$.

For the sake of simplicity, we shall concentrate on the case $A = -\Delta$, where Δ stands for the Laplacian operator subject to homogeneous Dirichlet boundary conditions, and $H = L_2(\mathcal{D})$, where $\mathcal{D}$ is a bounded convex domain in $\mathbf{R}^d$, $d = 1, 2, 3$, with a sufficiently smooth boundary $\partial\mathcal{D}$.

Many models in physics, chemistry, biology, population dynamics, neurophysiology, etc., are described by stochastic partial differential equations; see Da Prato and Zabczyk [8], Walsh [29], etc. The existence, uniqueness, and properties of the solutions of such equations have been well studied; see Curtain and Falb [4], [5], Da Prato [6], Da Prato and Lunardi [7], Da Prato and Zabczyk [8], Dawson [10], Gozzi [12], Peszat and Zabczyk [23], Walsh [29], etc. However, numerical approximation of such equations has not been studied thoroughly.

We assume that $W(t)$ is a Wiener process with covariance operator Q. This process may be considered in terms of its Fourier series. Suppose that Q is a bounded, linear, self-adjoint, positive definite operator on H, with eigenvalues $\gamma_l > 0$ and corresponding eigenfunctions e_l. Let β_l, $l = 1, 2, \ldots,$ be a sequence of real-valued

[†] Department of Automatic Control and Systems Engineering, The University of Sheffield, Mappin Street, Sheffield, S1 3JD, UK (Y.Yan@sheffield.ac.uk).

independently and identically distributed Brownian motions. Then

$$W(t) = \sum_{l=1}^{\infty} \gamma_l^{1/2} e_l \beta_l(t)$$

is a Wiener process with covariance operator Q.

If Q is in trace class, then $W(t)$ is an H-valued process. If Q is not in trace class, for example, $Q = I$, then $W(t)$ does not belong to H, in which case $W(t)$ is called a cylindrical Wiener process.

Let $L_2^0 = HS(Q^{1/2}(H), H)$ denote the space of Hilbert–Schmidt operators from $Q^{1/2}(H)$ to H, i.e.,

$$L_2^0 = \left\{ \psi \in L(H) : \sum_{l=1}^{\infty} \|\psi Q^{1/2} e_l\|^2 < \infty \right\},$$

with norm $\|\psi\|_{L_2^0} = (\sum_{l=1}^{\infty} \|\psi Q^{1/2} e_l\|^2)^{1/2}$, where $L(H)$ is the space of bounded linear operators from H to H.

Let $\mathbf{E}$ denote the expectation. Let $\psi \in L_2^0$. Then $\int_0^t \psi(s)\, dW(s)$ can be defined, and the following isometry property holds:

$$\mathbf{E}\left\| \int_0^t \psi(s)\, dW(s) \right\|^2 = \int_0^t \|\mathbf{E}\psi(s)\|_{L_2^0}^2\, ds. \tag{1.2}$$

Following Da Prato and Zabczyk [8, Chapter 7], we assume that $\sigma : H \to L_2^0$ satisfies the following global Lipschitz and growth conditions:

(i) $\|\sigma(x) - \sigma(y)\|_{L_2^0} \leq C\|x - y\| \quad \forall x, y \in H$,

(ii) $\|\sigma(x)\|_{L_2^0} \leq C\|x\| \quad \forall x \in H$.

Then (1.1) admits a unique mild solution which has the form

$$u(t) = E(t)u_0 + \int_0^t E(t-s)\sigma(u(s))\, dW(s), \tag{1.3}$$

where $E(t) = e^{-tA}$ is the analytic semigroup generated by $-A$. Moreover,

$$\sup_{t \in [0,T]} \mathbf{E}\|u(t)\|^2 \leq C(1 + \mathbf{E}\|u_0\|^2).$$

Note that if $\mathrm{Tr}(Q) = \infty$, then the identity mapping $\sigma(u) = I$ does not satisfy the condition (ii). In order to cover this important case, we introduce a modified version of (ii), i.e.,

(ii′) $\|A^{(\beta-1)/2}\sigma(x)\|_{L_2^0} \leq C\|x\|$ for some $\beta \in [0,1]$, $\forall x \in H$.

We see that (ii) is the special case $\beta = 1$ of (ii′). If $\sigma(\cdot) = I$, the condition (ii′) reduces to $\|A^{(\beta-1)/2}\|_{L_2^0} \leq C$.

The numerical approximation for (1.1) started with the work by Greksch and Kloeden [13] and Gyöngy and Nualart [16]. Further contributions include Allen, Novosel, and Zhang [1], Benth and Gjerde [2], Davie and Gaines [9], Du and Zhang [11], Gyöngy [14], [15], Hausenblas [17], [18], Kloeden and Shott [19], Lord and Rougemont [20], Printems [24], Shardlow [25], Theting [26], [27], Müller-Gronbach and Ritter [21], and Yan [31], [30].

In this paper we will consider error estimates for approximations of (1.1) based on the finite element method in space and the backward Euler method in time. The noise will be approximated by using generalized the L_2-projection operator defined below.

Let S_h be a family of finite element spaces, where S_h consists of continuous piecewise polynomials of degree ≤ 1 with respect to the triangulation $\mathcal{T}_h$ of Ω. For simplicity, we always assume that $\{S_h\} \subset H_0^1 = H_0^1(\mathcal{D}) = \{v \in L_2(\mathcal{D}),\ \nabla v \in L_2(\mathcal{D}),\ v|_{\partial\mathcal{D}} = 0\}$.

To introduce the finite element formulation of (1.1), we will use the generalized L_2-projection operator $P_h : \dot{H}^{-1} \to S_h$ defined by (see Chrysafinos and Hou [3])

$$(P_h v, \chi) = \langle v, \chi \rangle \quad \forall \chi \in S_h \subset \dot{H}^1,\ \forall v \in \dot{H}^{-1}, \tag{1.4}$$

where $\langle \cdot, \cdot \rangle$ denotes the pairing between $\dot{H}^{-1}$ and $\dot{H}^1$. One can easily show that P_h is well defined by introducing a basis $\{\varphi_i\}_{i=1}^{N_h}$ and solving for $P_h v = \sum_{j=1}^{N_h} \alpha_j \varphi_j$ from the equations $(\sum_{j=1}^{N_h} \alpha_j \varphi_j, \varphi_i) = \langle v, \varphi_i \rangle$. Also it is evident that when $v \in L_2(\mathcal{D})$, $P_h v$ is the standard L_2-projection operator; see Thomée [28].

The semidiscrete problem corresponding to (1.1) is to find the process $u_h(t) = u_h(\cdot, t) \in S_h$ such that

$$du_h + A_h u_h \, dt = P_h \sigma(u_h) \, dW \quad \text{for } 0 < t \leq T, \quad \text{with } u_h(0) = P_h u_0, \tag{1.5}$$

where $A_h : S_h \to S_h$ is the discrete analogue of A, defined by

$$(A_h \psi, \chi) = A(\psi, \chi) \quad \forall \psi, \chi \in S_h. \tag{1.6}$$

Here $A(\cdot, \cdot)$ is the bilinear form obtained from the operator A.

Let $E_h(t) = e^{-tA_h}$, $t \geq 0$. Then (1.5) admits a unique mild solution

$$u_h(t) = E_h(t) P_h u_0 + \int_0^t E_h(t-s) P_h \sigma(u_h(s)) \, dW(s).$$

Let $\dot{H}^s = \dot{H}^s(\mathcal{D}) = \mathcal{D}(A^{s/2})$ with norm $|v|_s = \|A^{s/2} v\|$ for any $s \in \mathbf{R}$. For any Hilbert space H, we define

$$L_2(\Omega; H) = \left\{ v : \mathbf{E}\|v\|_H^2 = \int_\Omega \|v(\omega)\|_H^2 \, d\mathbf{P}(\omega) < \infty \right\},$$

with norm $\|v\|_{L_2(\Omega;H)} = (\mathbf{E}\|v\|_H^2)^{1/2}$.

Let k be a time step and $t_n = nk$ with $n \geq 1$. We define the backward Euler method

$$\frac{U^n - U^{n-1}}{k} + A_h U^n = \frac{1}{k} \int_{t_{n-1}}^{t_n} P_h \sigma(U^{n-1}) \, dW(s), \quad n \geq 1, \quad U^0 = P_h u_0. \tag{1.7}$$

With $r(\lambda) = 1/(1-\lambda)$, we can rewrite (1.7) in the form

$$\begin{aligned} U^n &= r(kA_h) U^{n-1} + \int_{t_{n-1}}^{t_n} r(kA_h) P_h \sigma(U^{n-1}) \, dW(s), \quad n \geq 1, \\ U^0 &= P_h u_0. \end{aligned} \tag{1.8}$$

Our main results in this paper are the following theorems.

Theorem 1.1. *Let U^n and $u(t_n)$ be the solutions of* (1.8) *and* (1.1)*, respectively. Assume that σ satisfies* (i) *and* (ii′)*. Assume that $u_0 \in L_2(\Omega; \dot{H}^\beta)$, $0 \leq \beta \leq 1$. Then there exists a constant $C = C(T)$ such that, for $t_n \in [0,T]$ and $0 \leq \gamma < \beta \leq 1$,*

$$\|U^n - u(t_n)\|_{L_2(\Omega;H)} \leq C(k^{\gamma/2} + h^\beta)\Big(\|u_0\|_{L_2(\Omega;\dot{H}^\beta)} + \sup_{0\leq s\leq T}\|u(s)\|_{L_2(\Omega;H)}\Big). \tag{1.9}$$

In particular, if σ satisfies (i) *and* (ii)*, then we have, for $u_0 \in L_2(\Omega;\dot{H}^1)$ and $0 \leq \gamma < 1$,*

$$\|U^n - u(t_n)\|_{L_2(\Omega;H)} \leq C(k^{\gamma/2} + h)\Big(\|u_0\|_{L_2(\Omega;\dot{H}^1)} + \sup_{0\leq s\leq T}\|u(s)\|_{L_2(\Omega;H)}\Big). \tag{1.10}$$

When $\sigma(\cdot) = I$, we have the following error estimates.

Theorem 1.2. *Let U^n and $u(t_n)$ be the solutions of* (1.8) *and* (1.1)*, respectively. Assume that $\sigma(\cdot) = I$. Further assume that $u_0 \in L_2(\Omega;\dot{H}^\beta)$, $0 \leq \beta \leq 1$. If $\|A^{(\beta-1)/2}\|_{L_2^0} < \infty$ for some $\beta \in [0,1]$, then we have, for $l = 0,1$ with $\ell_k = \log(T/k)$, where $T = t_n$,*

$$\|U^n - u(t_n)\|_{L_2(\Omega;\dot{H}^{-l})} \leq C(k^{(\beta+l)/2} + h^{\beta+l})\Big(\|u_0\|_{L_2(\Omega;\dot{H}^\beta)} + \ell_k^l\|A^{(\beta-1)/2}\|_{L_2^0}\Big). \tag{1.11}$$

In particular, if $W(t)$ is an H-valued Wiener process with $\mathrm{Tr}(Q) < \infty$*, then we have, for $u_0 \in L_2(\Omega;\dot{H}^1)$,*

$$\|U^n - u(t_n)\|_{L_2(\Omega;\dot{H}^{-l})} \leq C(k^{(1+l)/2} + h^{1+l})\Big(\|u_0\|_{L_2(\Omega;\dot{H}^1)} + \ell_k^l\,\mathrm{Tr}(Q)^{1/2}\Big). \tag{1.12}$$

This paper is organized as follows. In section 2, we give some regularity results for the mild solution of (1.1) and some error estimates of the corresponding deterministic problem. In section 3, we prove main theorems. In section 4, we consider how to compute the approximate solution U^n numerically in the additive noise case. Finally, in section 5, we give the numerical simulations.

2. Regularity of (1.1) and error estimates for the deterministic problem.

In this section, we give some results in order to prove the main theorems.

2.1. Regularity of the mild solution of (1.1).

In this section we will consider the regularity of the mild solution of (1.1). We have the following theorem.

Theorem 2.1. *Assume that σ satisfies* (i) *and* (ii′)*. Let $u(t)$ be the mild solution* (1.3) *of* (1.1)*. Then we have, for $u_0 \in L_2(\Omega;\dot{H}^\beta)$,*

$$\|u(t)\|_{L_2(\Omega;\dot{H}^\beta)} \leq C\Big(\|u_0\|_{L_2(\Omega;\dot{H}^\beta)} + \sup_{0\leq s\leq t}\|u(s)\|_{L_2(\Omega;H)}\Big). \tag{2.1}$$

In particular, if σ satisfies (i) *and* (ii)*, then we have, for $u_0 \in L_2(\Omega;\dot{H}^1)$,*

$$\|u(t)\|_{L_2(\Omega;\dot{H}^1)} \leq C\Big(\|u_0\|_{L_2(\Omega;\dot{H}^1)} + \sup_{0\leq s\leq t}\|u(s)\|_{L_2(\Omega;H)}\Big). \tag{2.2}$$

To prove this theorem, we need some regularity results which are related to the fact that $E(t) = e^{-tA}$ is an analytic semigroup on H. For later use, we collect some results in the next two lemmas; see Thomée [28] or Pazy [22].

LEMMA 2.2. *For any $\mu, \nu \in \mathbf{R}$ and $l \geq 0$, there is a $C > 0$ such that*

$$|D_t^l E(t)v|_\nu \leq Ct^{-(\nu-\mu)/2-l}|v|_\mu \quad \text{for } t > 0, \quad 2l + \nu \geq \mu, \tag{2.3}$$

and

$$\int_0^t s^\mu |D_t^l E(s)v|_\nu^2 \, ds \leq C|v|_{2l+\nu-\mu-1}^2 \quad \text{for } t \geq 0, \quad \mu \geq 0. \tag{2.4}$$

LEMMA 2.3. *For any $\mu \geq 0$, $0 \leq \nu \leq 1$, there is a $C > 0$ such that*

$$\|A^\mu E(t)\| \leq Ct^{-\mu} \quad \text{for } t > 0, \tag{2.5}$$

and

$$\|A^{-\nu}(I - E(t))\| \leq Ct^\nu \quad \text{for } t \geq 0. \tag{2.6}$$

Proof. Recall that the mild solution has the form

$$u(t) = E(t)u_0 + \int_0^t E(t-s)\sigma(u(s)) \, dW(s).$$

Thus, for any $\beta \geq 0$, using the stability of $E(t)$ and the isometry (1.2),

$$\begin{aligned}
\mathbf{E}|u(t)|_\beta^2 &\leq 2\mathbf{E}|E(t)u_0|_\beta^2 + 2\mathbf{E}\left\| \int_0^t A^{\beta/2}E(t-s)\,\sigma(u(s))dW(s) \right\|^2 \\
&\leq 2\mathbf{E}|u_0|_\beta^2 + 2\mathbf{E}\int_0^t \|A^{\beta/2}E(t-s)\sigma(u(s))\|_{L_2^0}^2 \, ds \\
&= 2\mathbf{E}|u_0|_\beta^2 + 2\mathbf{E}\int_0^t \|A^{1/2}E(t-s)A^{(\beta-1)/2}\sigma(u(s))\|_{L_2^0}^2 \, ds.
\end{aligned}$$

By (ii′) and Lemma 2.2, we have

$$\begin{aligned}
&\mathbf{E}\int_0^t \|A^{1/2}E(t-s)A^{(\beta-1)/2}\sigma(u(s))\|_{L_2^0}^2 \, ds \\
&\quad \leq \left(\int_0^t \|A^{1/2}E(t-s)\|^2 \, ds \right) \sup_{0 \leq s \leq t} \mathbf{E}\|u(s)\|^2 \leq C \sup_{0 \leq s \leq t} \mathbf{E}\|u(s)\|^2.
\end{aligned}$$

Thus we get

$$\mathbf{E}|u(t)|_\beta^2 \leq C\left(\mathbf{E}|u_0|_\beta^2 + \sup_{0 \leq s \leq t} \mathbf{E}\|u(s)\|^2 \right),$$

which implies (2.1) by noting that

$$\left(\sup_{0 \leq s \leq t} \mathbf{E}\|u(s)\|^2 \right)^{1/2} \leq \sup_{0 \leq s \leq t} \left(\mathbf{E}\|u(s)\|^2 \right)^{1/2} = \sup_{0 \leq s \leq t} \|u(s)\|_{L_2(\Omega;H)}.$$

In particular, if (ii) holds, then $\beta = 1$, and we get (2.2). □

We remark that in Theorem 2.1, if $\sigma(\cdot) = I$, the condition (ii′) reduces to the condition $\|A^{(\beta-1)/2}\|_{L_2^0} \leq C$.

In the case of $\sigma(\cdot) = I$, by the proof of Theorem 2.1, we obtain the following.

Corollary 2.4. *Let $u(t)$ be the mild solution* (1.3) *of* (1.1). *Assume that $\sigma(\cdot) = I$. If $\|A^{(\beta-1)/2}\|_{L_2^0} < \infty$ for some $\beta \in [0,1]$, then we have, for fixed $t \in [0,T]$,*

$$\|u(t)\|_{L_2(\Omega;\dot{H}^\beta)} \le C\Big(\|u_0\|_{L_2(\Omega;\dot{H}^\beta)} + \|A^{(\beta-1)/2}\|_{L_2^0}\Big) \quad \text{for } u_0 \in L_2(\Omega;\dot{H}^\beta). \tag{2.7}$$

In particular, if $W(t)$ is an H-valued Wiener process with covariance operator Q, $\mathrm{Tr}(Q) < \infty$, *then we have*

$$\|u(t)\|_{L_2(\Omega;\dot{H}^1)} \le C\Big(\|u_0\|_{L_2(\Omega;\dot{H}^1)} + \mathrm{Tr}(Q)^{1/2}\Big) \quad \text{for } u_0 \in L_2(\Omega;\dot{H}^1). \tag{2.8}$$

If $\sigma(\cdot) = I$ and $d = 1$, then we may specialize to $Q = I$.

Corollary 2.5. *Assume that $\sigma(\cdot) = I$. Let $u(t)$ be the solution of* (1.1) *and $A = -\frac{\partial^2}{\partial x^2}$ with $\mathcal{D}(A) = H_0^1(0,1) \cap H^2(0,1)$. Assume that $W(t)$ is a cylindrical Wiener process with $Q = I$. Then we have, for every $\beta \in [0,1/2)$,*

$$\|u(t)\|_{L_2(\Omega;\dot{H}^\beta)} \le C(1 + \|u_0\|_{L_2(\Omega;\dot{H}^\beta)}) \quad \text{for } u_0 \in L_2(\Omega;\dot{H}^\beta).$$

Proof. By (2.7), it suffices to check in what case $\|A^{(\beta-1)/2}\|_{L_2^0} < \infty$. It is well known that A has eigenvalues $\lambda_j = j^2\pi^2$, $j = 1, 2, \dots$, and corresponding eigenfunctions $\varphi_j = \sqrt{2}\sin j\pi x$, $j = 1, 2, \dots$, which form an orthonormal basis in $H = L_2(0,1)$. Thus, we have

$$\|A^{(\beta-1)/2}\|_{L_2^0}^2 = \sum_{j=1}^\infty \|A^{(\beta-1)/2}\varphi_j\|^2 = \sum_{j=1}^\infty \lambda_j^{\beta-1},$$

which is convergent if $\beta \in [0,1/2)$. The proof is complete. □

We note that in Corollary 2.4 we require the condition $\|A^{(\beta-1)/2}\|_{L_2^0} < \infty$ for $\beta \in [0,1]$. The following lemma shows that this condition is equivalent to having that $W(t)$ is $\dot{H}^{\beta-1}$-valued. In particular, $W(t) \in \dot{H}^{-1}$, which is important when applying the finite element method.

Lemma 2.6. *Assume that $W(t)$ is a Wiener process with covariance operator Q. Assume that A and Q have the same eigenvectors. Then the following statements hold.*

(i) *If $\|A^{(\beta-1)/2}\|_{L_2^0} < \infty$ for some $\beta \in [0,1]$, then*

$$W(t) = \sum_{l=1}^\infty Q^{1/2} e_l \beta_l(t), \quad t \ge 0,$$

defines an $\dot{H}^{\beta-1}$-valued Wiener process with covariance operator $\tilde{Q}$, $\mathrm{Tr}(\tilde{Q}) < \infty$. *In particular, $\tilde{Q} = Q$ if* $\mathrm{Tr}(Q) < \infty$.

(ii) *If $W(t) = \sum_{l=1}^\infty Q^{1/2} e_l \beta_l(t)$, $t \ge 0$, is an $\dot{H}^{\beta-1}$-valued Wiener process with the covariance operator $\tilde{Q}$,* $\mathrm{Tr}(\tilde{Q}) < \infty$, *then*

$$\|A^{(\beta-1)/2}\|_{L_2^0} < \infty \quad \text{for some } \beta \in [0,1].$$

Proof. We first prove (i). With $\{\gamma_l, e_l\}_{l=1}^\infty$ the eigensystem of Q in H, it is easy to show that $g_l = Q^{1/2} e_l = \gamma_l^{1/2} e_l$ is an orthogonal basis of $Q^{1/2}(H)$. In fact,

$$(g_l, g_k)_{Q^{1/2}(H)} = (Q^{-1/2} g_l, Q^{1/2} g_k) = (e_l, e_k) = \delta_{l,k}.$$

Note that

$$\sum_{l=1}^{\infty} |g_l|_{\beta-1}^2 = \sum_{l=1}^{\infty} \|A^{(\beta-1)/2} Q^{1/2} e_l\|^2 = \|A^{(\beta-1)/2}\|_{L_2^0} < \infty,$$

which means that the embedding of $Q^{1/2}(H)$ into $\dot{H}^{\beta-1}$ is Hilbert–Schmidt. By Lemma 4.11 in Da Prato and Zabczyk [8], $W(t)$ defines an $\dot{H}^{\beta-1}$-valued Wiener process with covariance operator $\tilde{Q}$, $\mathrm{Tr}(\tilde{Q}) < \infty$. It is obvious that $\tilde{Q} = Q$ if $\mathrm{Tr}(Q) < \infty$.

We now turn to (ii). Since $W(t) = \sum_{l=1}^{\infty} Q^{1/2} e_l \beta_l(t)$, $t \geq 0$, is an $\dot{H}^{\beta-1}$-valued Wiener process with the covariance operator $\tilde{Q}$, $\mathrm{Tr}(\tilde{Q}) < \infty$, we have

$$\mathbf{E}|W(t)|_{\beta-1}^2 < \infty.$$

With $\{\lambda_l, e_l\}_{l=1}^{\infty}$ the eigensystem of A in H, we have

$$\mathbf{E}|W(t)|_{\beta-1}^2 = \mathbf{E}\left|\sum_{l=1}^{\infty} Q^{1/2} e_l \beta_l(t)\right|_{\beta-1}^2 = \mathbf{E}\sum_{l=1}^{\infty} \lambda_l^{\beta-1} \gamma_l \beta_l(t)^2 = t\|A^{(\beta-1)/2}\|_{L_2^0},$$

which implies that $\|A^{(\beta-1)/2}\|_{L_2^0} < \infty$ for $\beta \in [0,1]$. The proof is complete. □

We also need regularity in time of the solution of (1.1); see Printems [24, Proposition 3.4].

LEMMA 2.7. *Assume that* (ii′) *holds. Let u be the mild solution of* (1.1). *Then we have, for $0 \leq \gamma < \beta \leq 1$,*

$$\begin{aligned} \mathbf{E}\|u(t_2) - u(t_1)\|^2 &\leq C(t_2 - t_1)^{\gamma} \mathbf{E}|u_0|_{\gamma}^2 \\ &\quad + C(t_2 - t_1)^{\gamma} \sup_{0 \leq s \leq T} \mathbf{E}\|u(s)\|^2. \end{aligned} \tag{2.9}$$

2.2. Error estimates for the deterministic problem. In order to prove error estimates for the stochastic parabolic partial differential equation in the fully discrete case, we need some error estimates for the corresponding deterministic parabolic problem.

We first introduce some operators. Consider the stationary problem

$$-\Delta u = f \text{ in } \mathcal{D}, \quad \text{with } u = 0 \text{ on } \partial\mathcal{D}, \tag{2.10}$$

where $f \in \dot{H}^{-1}$.

The variational form of (2.10) is to find $u \in H_0^1$ such that

$$(\nabla u, \nabla \phi) = \langle f, \phi \rangle \quad \forall \phi \in H_0^1, \tag{2.11}$$

where $\langle \cdot, \cdot \rangle$ denotes the duality pairing between $\dot{H}^{-1}$ and H_0^1.

Let $S_h \subset H_0^1$ be the finite element space. The semidiscrete problem of (2.11) is to find $u_h \in S_h$ such that

$$(\nabla u_h, \nabla \chi) = \langle f, \chi \rangle \quad \forall \chi \in S_h. \tag{2.12}$$

By the Lax–Milgram lemma, there exist unique solutions $u \in H_0^1$ and $u_h \in S_h$ such that (2.11) and (2.12) hold. Moreover the following stability result holds:

$$|u|_1 \leq C|f|_{-1} \quad \forall f \in \dot{H}^{-1}. \tag{2.13}$$

The standard error estimates read

$$\|u_h - u\| \le Ch^s |u|_s, \quad s = 1, 2. \tag{2.14}$$

Let $G : \dot{H}^{-1} \to H_0^1$ denote the exact solution operator of (2.10), i.e., $u = Gf$. We define the linear operator $G_h : \dot{H}^{-1} \to S_h$ by $G_h f = u_h$, so that $u_h = G_h f \in S_h$ is the approximate solution of (2.11). It is easy to see that G_h is self-adjoint, positive semidefinite on H, and positive definite on S_h. Introducing the elliptic projection $R_h : H_0^1 \to S_h$ by

$$(\nabla R_h v, \nabla \chi) = (\nabla v, \nabla \chi) \quad \forall v \in H_0^1,$$

we see that $G_h = R_h G$, and $R_h v$ is the finite element approximation of the solution of the corresponding elliptic problem with exact solution v. By (2.14), we get

$$\|R_h v - v\| \le Ch^s |v|_s, \quad s = 1, 2.$$

Hence, using (2.13) and the elliptic regularity estimate, we have

$$\big\| \big(G_h - G\big) f \big\| = \|(R_h - I) G f\| \le Ch^s |Gf|_s = Ch^s |f|_{s-2} \quad \text{for } s = 1, 2, \tag{2.15}$$

which we need below.

Let $E_{kh} = r(kA_h)$ and $E(t_n) = e^{-t_n A}$, where $r(\lambda) = 1/(1+\lambda)$ is introduced in (1.8). We have

Lemma 2.8. *Let $F_n = E_{kh}^n P_h - E(t_n)$. Then*

$$\|F_n v\| \le C(k^{\beta/2} + h^{\beta}) |v|_\beta \quad \textit{for } v \in \dot{H}^\beta,\ 0 \le \beta \le 1, \tag{2.16}$$

and

$$\left(k \sum_{j=1}^n \|F_j v\|^2 \right)^{1/2} \le C(k^{\beta/2} + h^\beta) |v|_{\beta-1} \quad \textit{for } v \in \dot{H}^{\beta-1},\ 0 \le \beta \le 1. \tag{2.17}$$

Furthermore, in the weak norm,

$$|F_n v|_{-1} \le C(k^{\beta/2} + h^\beta) |v|_{\beta-1} \quad \textit{for } v \in \dot{H}^{\beta-1},\ 1 \le \beta \le 2, \tag{2.18}$$

and, with $\ell_k = \log(T/k)$, where $T = t_n$,

$$\left(k \sum_{j=1}^n |F_j v|_{-1}^2 \right)^{1/2} \le C(k^{\beta/2} + h^\beta) \ell_k |v|_{\beta-2} \quad \textit{for } v \in \dot{H}^{\beta-2},\ 1 \le \beta \le 2. \tag{2.19}$$

Proof. Here we prove only (2.17) in detail. Other proofs are similar. We define $u(t_n) = u^n = E(t_n) v$, $U^n = E_{kh}^n P_h v$, and $e^n = F_n v$. By interpolation theory, it suffices to show that

$$\left(k \sum_{j=1}^n \|F_j v\|^2 \right)^{1/2} \le C |v|_{-1} \tag{2.20}$$

and

$$\left(k\sum_{j=1}^{n}\|F_j v\|^2\right)^{1/2} \le C(k^{1/2}+h)\|v\|. \tag{2.21}$$

With $\partial_t e^n = (e^n - e^{n-1})/k$, we have the following error equation:

$$G_h\partial_t e^n + e^n = \rho^n + G_h\tau^n, \tag{2.22}$$

where $\rho^n = (G_h - G)u_t(t_n)$ and $\tau^n = u_t(t_n) - \partial_t u^n$.

Taking the inner product of (2.22) with e^n, we get

$$(G_h\partial_t e^n, e^n) + (e^n, e^n) = (\rho^n, e^n) + (G_h\tau^n, e^n).$$

By summation on n, using the inequality $(\rho^n, e^n) \le \frac{1}{2}(\|\rho^n\|^2 + \|e^n\|^2)$, and noting that $G_h e^0 = 0$, we have

(2.23)

$$(G_h e_n, e_n) + k\sum_{j=1}^{n}\|e_j\|^2 \le Ck\sum_{j=1}^{n}\|\rho^j\|^2 + Ck\sum_{j=1}^{n}\|G\tau^j\|^2 + Ck\sum_{j=1}^{n}\|(G_h - G)\tau^j\|^2.$$

Here, using Lemma 2.2, we have, since $\rho^j = \rho(s) + \int_s^{t_j}\rho_t(\tau)\,d\tau$,

$$\begin{aligned} k\sum_{j=1}^{n}\|\rho^j\|^2 &= k\|\rho\|^2 + \sum_{j=2}^{n}\int_{t_{j-1}}^{t_j}\|\rho^j\|^2\,ds \\ &\le k\|\rho\|^2 + 2\sum_{j=2}^{n}\int_{t_{j-1}}^{t_j}\left(\|\rho(s)\|^2 + \left\|\int_s^{t_j}\rho_t(\tau)\,d\tau\right\|^2\right)ds \\ &\le k\|\rho\|^2 + 2\int_{t_1}^{t_n}\|\rho(s)\|^2\,ds + 2\sum_{j=2}^{n}\int_{t_{j-1}}^{t_j}\left((t_j - s)\int_s^{t_j}\|\rho_t(\tau)\|^2\,d\tau\right)ds \\ &\le k\|\rho\|^2 + 2\int_{t_1}^{t_n}\|\rho(s)\|^2\,ds + 2k\sum_{j=2}^{n}\int_{t_{j-1}}^{t_j}\tau\|\rho_t(\tau)\|^2\,d\tau \\ &\le Ck\|u\|^2 + Ch^2\int_0^{t_n}|u(s)|_1^2\,ds + Ck\int_0^{t_n}\tau\|u_t(\tau)\|^2\,d\tau \le C(k+h^2)\|v\|^2, \end{aligned} \tag{2.24}$$

and, by Taylor's formula,

$$\begin{aligned} k\sum_{j=1}^{n}\|(G_h - G)\tau^j\|^2 &\le Ckh^2|\tau^1|_{-1}^2 + Ckh^2\sum_{j=2}^{n}|\tau^j|_{-1}^2 \\ &= Ckh^2\left|u_t(k) - \frac{1}{k}\int_0^k u_t(\tau)\,d\tau\right|_{-1}^2 + Ckh^2\sum_{j=2}^{n}\left|\frac{1}{k}\int_{t_{j-1}}^{t_j}(s - t_{j-1})u_{tt}(s)\,ds\right|_{-1}^2 \\ &\le Ch^2\|v\|^2 + Ch^2\sum_{j=2}^{n}\int_{t_{j-1}}^{t_j}k(s - t_{j-1})|u_{tt}(s)|_{-1}^2\,ds \\ &\le Ch^2\|v\|^2 + Ch^2\sum_{j=2}^{n}\int_{t_{j-1}}^{t_j}s^2|u_{tt}(s)|_{-1}^2\,ds \le Ch^2\|v\|^2, \end{aligned}$$

and

$$k\sum_{j=1}^{n}\|G\tau^j\|^2 = k\sum_{j=1}^{n}\left\|\frac{1}{k}\int_{t_{j-1}}^{t_j}(s-t_{j-1})u_t(s)\,ds\right\|^2$$
$$\le k\sum_{j=1}^{n}\int_{t_{j-1}}^{t_j}(s-t_{j-1})\|u_t(s)\|^2\,ds \le Ck\int_0^{t_n} s\|u_t(s)\|^2\,ds \le k\|v\|^2.$$

We therefore obtain

$$(G_h e^n, e^n)^{1/2} + \left(k\sum_{j=1}^{n}\|e^j\|^2\right)^{1/2} \le C(k^{1/2}+h)\|v\|, \tag{2.25}$$

which implies that (2.21) holds. □

3. Proofs of Theorems 1.1 and 1.2. In this section, we will consider the proofs of Theorems 1.1 and 1.2.

Proof of Theorem 1.1. We have, by (1.8), with $E_{kh}^n = r(kA_h)^n$,

$$U^n = E_{kh}^n P_h u_0 + \sum_{j=1}^{n}\int_{t_{j-1}}^{t_j} E_{kh}^{n-j}P_h\sigma(U^{j-1})\,dW(s),$$

and, by the definition of the mild solution of (1.1), with $E(t)=e^{-tA}$,

$$u(t_n) = E(t_n)u_0 + \int_0^{t_n} E(t_n-s)\sigma(u(s))\,dW(s).$$

Defining $e^n = U^n - u(t_n)$ and $F_n = E_{kh}^n P_h - E(t_n)$, we write

$$\begin{aligned} e^n &= F_n u_0 + \sum_{j=1}^{n}\int_{t_{j-1}}^{t_j} r(kA_h)^{n-j}P_h\Big(\sigma(U^{j-1}) - \sigma(u(t_{j-1}))\Big)\,dW(s) \\ &\quad + \sum_{j=1}^{n}\int_{t_{j-1}}^{t_j} r(kA_h)^{n-j}P_h\Big(\sigma(u(t_{j-1})) - \sigma(u(s))\Big)\,dW(s) \\ &\quad + \sum_{j=1}^{n}\int_{t_{j-1}}^{t_j}\Big(r(kA_h)^{n-j}P_h - E(t_n-t_j)\Big)\sigma(u(s))\,dW(s) \\ &\quad + \sum_{j=1}^{n}\int_{t_{j-1}}^{t_j}\Big(E(t_n-t_j) - E(t_n-s)\Big)\sigma(u(s))\,dW(s) \\ &= \sum_{j=1}^{5} I_j. \end{aligned}$$

Thus

$$\|e^n\|_{L_2(\Omega;H)} \le C\sum_{j=1}^{5}\|I_j\|_{L_2(\Omega;H)}.$$

For I_1, we have, by (2.16) with $v=u_0$,

$$\|I_1\| = \|F_n u_0\| \le C(k^{\beta/2}+h^\beta)|u_0|_\beta,$$

which implies that $\|I_1\|_{L_2(\Omega;H)} \le C(k^{\beta/2}+h^\beta)\|u_0\|_{L_2(\Omega;\dot H^\beta)}$.

For I_2, we have, by isometry, the stability of $r(\lambda)$, and the Lipschitz condition (i),

$$\begin{aligned}
\|I_2\|^2_{L_2(\Omega;H)} &= \mathbf{E}\left\|\sum_{j=1}^n \int_{t_{j-1}}^{t_j} r(kA_h)^{n-j}P_h\Big(\sigma(U^{j-1})-\sigma(u(t_{j-1}))\Big)\,dW(s)\right\|^2\\
&= k\sum_{j=1}^n \mathbf{E}\Big\|r(kA_h)^{n-j}P_h\Big(\sigma(U^{j-1})-\sigma(u(t_{j-1}))\Big)\Big\|^2_{L_2^0}\\
&\le k\sum_{j=1}^n \|r(kA_h)^{n-j}P_h\|^2\,\mathbf{E}\|\sigma(U^{j-1})-\sigma(u(t_{j-1}))\|^2_{L_2^0}\\
&\le Ck\sum_{j=1}^n \mathbf{E}\|U^{j-1}-u(t_{j-1})\|^2 = C\sum_{j=1}^n\int_{t_{j-1}}^{t_j}\mathbf{E}\|e^{j-1}\|^2\,ds\\
&\le Ck\sum_{j=1}^n \|e^j\|^2.
\end{aligned}$$

For I_3, we have, by Lemma 2.7, for $0\le\gamma<\beta\le 1$,

$$\begin{aligned}
\|I_3\|^2_{L_2(\Omega;H)} &= \sum_{j=1}^n\int_{t_{j-1}}^{t_j}\mathbf{E}\Big\|r(kA_h)^{n-j}P_h\Big(\sigma(u(t_{j-1}))-\sigma(u(s))\Big)\Big\|^2_{L_2^0}\,ds\\
&\le C\sum_{j=1}^n\int_{t_{j-1}}^{t_j}\mathbf{E}\|u(t_{j-1})-u(s)\|^2\,ds\\
&\le C\left(\sum_{j=1}^n\int_{t_{j-1}}^{t_j}(s-t_{j-1})^\gamma\,ds\right)\left(\mathbf{E}|u_0|_\gamma^2+\sup_{0\le s\le T}\mathbf{E}\|u(s)\|^2\right)\\
&\le Ck^\gamma\left(\mathbf{E}|u_0|_\gamma^2+\sup_{0\le s\le T}\mathbf{E}\|u(s)\|^2\right).
\end{aligned}$$

For I_4, we have

$$\begin{aligned}
\|I_4\|^2_{L_2(\Omega;H)} &= \mathbf{E}\left\|\sum_{j=1}^n\int_{t_{j-1}}^{t_j}F_{n-j}\sigma(u(s))\,dW(s)\right\|^2\\
&= \sum_{j=1}^n\int_{t_{j-1}}^{t_j}\mathbf{E}\|F_{n-j}A^{(1-\beta)/2}A^{(\beta-1)/2}\sigma(u(s))\|^2_{L_2^0}\,ds\\
&\le C\left(k\sum_{j=1}^n\|F_jA^{(1-\beta)/2}\|^2\right)\sup_{0\le s\le T}\mathbf{E}\|u(s)\|^2.
\end{aligned}$$

We will show that

$$k\sum_{j=1}^n\|F_jA^{(1-\beta)/2}\|^2\le C(k^\beta+h^{2\beta}). \tag{3.1}$$

Assuming this for the moment, we get

$$\|I_4\|^2_{L_2(\Omega;H)}\le C(k^\beta+h^{2\beta})\sup_{0\le s\le T}\mathbf{E}\|u(s)\|^2.$$

For I_5, we have

$$\begin{aligned}\|I_5\|^2_{L_2(\Omega;H)} &= \mathbf{E}\left\|\sum_{j=1}^n \int_{t_{j-1}}^{t_j} (E(t_n - t_j) - E(t_n - s))\sigma(u(s))\,dW(s)\right\|^2 \\ &= \sum_{j=1}^n \int_{t_{j-1}}^{t_j} \mathbf{E}\|(E(t_n - t_j) - E(t_n - s))A^{(1-\beta)/2}A^{(\beta-1)/2}\sigma(u(s))\|^2_{L_2^0}\,ds \\ &\le C\left(\sum_{j=1}^n \int_{t_{j-1}}^{t_j} \|(E(t_n - t_j) - E(t_n - s))A^{(1-\beta)/2}\|^2\,ds\right) \sup_{0\le s\le T} \mathbf{E}\|u(s)\|^2.\end{aligned}$$

Noting that, by Lemmas 2.2 and 2.3,

$$\begin{aligned}&\sum_{j=1}^n \int_{t_{j-1}}^{t_j} \|(E(t_n - t_j) - E(t_n - s))A^{(1-\beta)/2}\|^2\,ds \\ &= \sum_{j=1}^n \int_{t_{j-1}}^{t_j} \|A^{1/2}E(t_n - t_j)A^{-\beta/2}(I - E(t_j - s))\|^2\,ds \\ &\le Ck^\beta \sum_{j=1}^n \int_{t_{j-1}}^{t_j} \|A^{1/2}E(t_n - t_j)\|^2\,ds \\ &= Ck^\beta \left(\sum_{j=1}^n k\|A^{1/2}E(t_n - t_j)\|^2\right) \le Ck^\beta,\end{aligned}$$

we have

$$\|I_5\|^2_{L_2(\Omega;H)} \le Ck^\beta \sup_{0\le s\le T} \mathbf{E}\|u(s)\|^2.$$

It remains to show (3.1). In fact, by (2.17),

$$\begin{aligned}k\sum_{j=1}^n \|F_j A^{(1-\beta)/2}\|^2 &= k\sum_{j=1}^n \left(\sup_{v\ne 0} \frac{\|F_j A^{(1-\beta)/2}v\|}{\|v\|}\right)^2 \\ &= \sup_{v\ne 0} \frac{k\sum_{j=1}^n \|F_j A^{(1-\beta)/2}v\|^2}{\|v\|^2} \\ &\le \sup_{v\ne 0} \frac{C(k^\beta + h^{2\beta})|A^{(1-\beta)/2}v|^2_{\beta-1}}{\|v\|^2} \le C(k^\beta + h^{2\beta}).\end{aligned}$$

Together these estimates show, for $0 \le \gamma < \beta \le 1$,

$$\begin{aligned}\mathbf{E}\|e^n\|^2 \le C(k^\gamma + h^{2\beta})\mathbf{E}|u_0|^2_\beta + Ck\sum_{j=1}^n \mathbf{E}\|e^j\|^2 \\ + C(k^\gamma + h^{2\beta}) \sup_{0\le s\le T} \mathbf{E}\|u(s)\|^2.\end{aligned} \tag{3.2}$$

By the discrete Gronwall lemma, we get

$$\mathbf{E}\|e^n\|^2 \le C(k^\gamma + h^{2\beta})\Big(\mathbf{E}|u_0|^2_\beta + \sup_{0\le s\le T} \mathbf{E}\|u(s)\|^2\Big), \tag{3.3}$$

which implies that

$$\|e^n\|_{L_2(\Omega;H)} \leq C(k^{\gamma/2} + h^{\beta})\Big(\mathbf{E}|u_0|_{L_2(\Omega;\dot{H}^{\beta})} + \sup_{0\leq s\leq T} \|u(s)\|_{L_2(\Omega;H)}\Big). \tag{3.4}$$

The proof is now complete. □

Now we turn to the proof of Theorem 1.2.

Proof of Theorem 1.2. We first consider the case $l = 0$. We have, by (1.8), with $E_{kh}^n = r(kA_h)^n$, noting that $\sigma(\cdot) = I$,

$$U^n = E_{kh}^n P_h u_0 + \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} E_{kh}^{n-j+1} P_h \, dW(s),$$

and, by the definition of the mild solution of (1.1), with $E(t) = e^{-tA}$,

$$u(t_n) = E(t_n)u_0 + \int_0^{t_n} E(t_n - s)\, dW(s).$$

Defining $e^n = U^n - u(t_n)$ and $F_n = E_{kh}^n P_h - E(t_n)$, we write

$$\begin{aligned} e^n &= F_n u_0 + \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} F_{n-j+1}\, dW(s) \\ &\quad + \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \Big(E(t_n - t_{j-1}) - E(t_n - s)\Big)\, dW(s) \\ &= I + II + III. \end{aligned}$$

Thus

$$\|e^n\|_{L_2(\Omega;H)} \leq C\Big(\|I\|_{L_2(\Omega;H)} + \|II\|_{L_2(\Omega;H)} + \|III\|_{L_2(\Omega;H)}\Big).$$

For I, we have, by (2.16) with $v = u_0$,

$$\|I\| = \|F_n u_0\| \leq C(k^{\beta/2} + h^{\beta})|u_0|_{\beta},$$

which implies that $\|I\|_{L_2(\Omega;H)} \leq C(k^{\beta/2} + h^{\beta})\|u_0\|_{L_2(\Omega;\dot{H}^{\beta})}$.

For II, we have, by the isometry property,

$$\begin{aligned} \|II\|_{L_2(\Omega;H)}^2 &= \mathbf{E}\left\|\sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} F_{n-j+1}\, dW(s)\right\|^2 = \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \|F_{n-j+1}\|_{L_2^0}^2\, ds \\ &= \sum_{l=1}^{\infty} \left(k \sum_{j=1}^{n} \|F_{n-j+1} Q^{1/2} e_l\|^2\right), \end{aligned}$$

where $\{e_l\}$ is any orthonormal basis in H. Using (2.17) with $v = Q^{1/2}e_l$, we obtain

$$\begin{aligned} \|II\|_{L_2(\Omega;H)}^2 &\leq C \sum_{l=1}^{\infty} (k^{\beta} + h^{2\beta})|Q^{1/2}e_l|_{\beta-1}^2 \\ &= C \sum_{l=1}^{\infty} (k^{\beta} + h^{2\beta})\|A^{(\beta-1)/2}Q^{1/2}e_l\|^2 = C(k^{\beta} + h^{2\beta})\|A^{(\beta-1)/2}\|_{L_2^0}^2. \end{aligned}$$

For III, we have, by the isometry property,

$$\|III\|^2_{L_2(\Omega;H)} = \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \left\| \Big(E(t_n - t_{j-1}) - E(t_n - s) \Big) \right\|^2_{L_2^0} ds$$
$$= \sum_{l=1}^{\infty} \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \left\| A^{-\beta/2} \Big(E(s - t_{j-1}) - I \Big) A^{\beta/2} E(t_n - s) Q^{1/2} e_l \right\|^2 ds.$$

Using (2.6), and (2.4) with $v = A^{(\beta-1)/2} Q^{1/2} e_l$, we obtain

$$(3.5) \qquad \|III\|^2_{L_2(\Omega;H)} \le Ck^\beta \sum_{l=1}^{\infty} \int_0^{t_n} \|A^{1/2} E(t_n - s) A^{(\beta-1)/2} Q^{1/2} e_l\|^2 \, ds$$
$$\le Ck^\beta \sum_{l=1}^{\infty} \|A^{(\beta-1)/2} Q^{1/2} e_l\|^2 = Ck^\beta \|A^{(\beta-1)/2}\|^2_{L_2^0},$$

which completes the proof of (1.9).

In particular, if $W(t)$ is a Wiener process with $\mathrm{Tr}(Q) < \infty$, then we can choose $\beta = 1$ since $\|I\|_{L_2^0} = \mathrm{Tr}(Q)$.

Now we turn to the case $l = 1$. We have, by (2.18),

$$\|I\|_{L_2(\Omega;\dot{H}^{-1})} \le Ch^{\beta+1} \|u_0\|_{L_2(\Omega;\dot{H}^\beta)} \quad \text{for } 0 \le \beta \le 1.$$

For II, we have, by the isometry property and (2.19) with $v = Q^{1/2} e_l$,

$$\|II\|^2_{L_2(\Omega;\dot{H}^{-1})} = \mathbf{E} \left\| \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} A^{-1/2} F_{n-j+1} \, dW(s) \right\|^2$$
$$= \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \|A^{-1/2} F_{n-j+1}\|^2_{L_2^0} \, ds$$
$$= \sum_{l=1}^{\infty} \left(k \sum_{j=1}^{n} \|A^{-1/2} F_{n-j+1} Q^{1/2} e_l\|^2 \right)$$
$$\le C(k^{\beta+1} + h^{2(\beta+1)}) \ell_k^2 \sum_{l=1}^{\infty} \|A^{(\beta-1)/2} Q^{1/2} e_l\|^2$$
$$\le C(k^{\beta+1} + h^{2(\beta+1)}) \ell_k^2 \|A^{(\beta-1)/2}\|^2_{L_2^0}.$$

For III, we have, by the isometry property,

$$\|III\|^2_{L_2(\Omega;\dot{H}^{-1})} = \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \left\| A^{-1/2} \Big(E(t_n - t_{j-1}) - E(t_n - s) \Big) \right\|^2_{L_2^0} ds$$
$$= \sum_{l=1}^{\infty} \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \left\| A^{-(\beta+1)/2} \Big(E(s - t_{j-1}) - I \Big) A^{1/2} E(t_n - s) A^{(\beta-1)/2} Q^{1/2} e_l \right\|^2 ds.$$

Following the proof of (3.5), we get

$$\|III\|^2_{L_2(\Omega;\dot{H}^{-1})} \le Ck^\beta \|A^{(\beta-2)/2}\|^2_{L_2^0},$$

which completes the proof of (1.11).

Similarly, if $W(t)$ is a Wiener process with $\mathrm{Tr}(Q) < \infty$, then we can choose $\beta = 1$. □

If $\sigma(\cdot) = I$ and $d = 1$, we can specialize to the case $Q = I$.

Corollary 3.1. *Let U^n and $u(t_n)$ be the solutions of* (1.8) *and* (1.1)*, respectively. Assume that $\sigma(\cdot) = I$. Assume that $A = -\frac{\partial^2}{\partial x^2}$ and $\mathcal{D}(A) = H_0^1(0,1) \cap H^2(0,1)$. If $W(t)$ is a cylindrical Wiener process with $Q = I$, then we have, for $u_0 \in L_2(\Omega; \dot{H}^\beta)$, for $l = 0, 1$, with $\ell_k = \log(T/k)$, where $T = t_n$,*

$$\|U^n - u(t_n)\|_{L_2(\Omega;\dot{H}^{-l})} \le C(k^{(\beta+l)/2} + h^{(\beta+l)})\big(\|u_0\|_{L_2(\Omega;\dot{H}^\beta)} + \ell_k\big) \quad \text{for } 0 \le \beta < \frac{1}{2}.$$

4. Computational analysis.

In this section we consider how to compute the approximate solution U^n of the solution u of (1.1). For simplicity, we assume that $\sigma(\cdot) = I$. Recall that the Wiener process $W(t)$ with covariance operator Q has the form (see Da Prato and Zabczyk [8, Chapter 4])

$$W(t) = \sum_{j=1}^{\infty} \gamma_j^{1/2} e_j \beta_j(t), \tag{4.1}$$

where $\{\gamma_j, e_j\}_{j=1}^\infty$ is an eigensystem of Q, and $\{\beta_j(t)\}_{j=1}^\infty$ are independently and identically distributed (iid) real-valued Brownian motions. If $\mathrm{Tr}(Q) < \infty$, then $W(t)$ is an H-valued process. In fact,

$$\mathbf{E}\|W(t)\|^2 = \mathbf{E}\sum_{j=1}^{\infty} \gamma_j \beta_j(t)^2 = \sum_{j=1}^{\infty} \gamma_j \big(\mathbf{E}\beta_j(t)^2\big) = t\,\mathrm{Tr}(Q) < \infty.$$

If $\mathrm{Tr}(Q) = \infty$, for example $Q = I$, then $W(t)$ is not H-valued.

Let U^n be the approximation in S_h of $u(t)$ at $t = t_n = nk$. The backward Euler method is to find $U^n \in S_h$ such that, with $\bar{\partial}U^n = (U^n - U^{n-1})/k$, $n \ge 1$, $U^0 = P_h u_0$,

$$(\bar{\partial}U^n, \chi) + (A_h U^n, \chi) = \left(\frac{1}{k}\int_{t_{n-1}}^{t_n} P_h\, dW(s), \chi\right) \quad \forall \chi \in S_h, \tag{4.2}$$

where A_h, P_h are defined in the introduction.

Since $W(t)$ is $\dot{H}^{\beta-1}$-valued with $\beta \in [0,1]$, $P_h W(t)$ is well defined. We therefore can write

$$\int_{t_{n-1}}^{t_n} P_h\, dW(s) = P_h\big(W(t_n) - W(t_{n-1})\big) = P_h \sum_{j=1}^{\infty} \gamma_j^{1/2}\big(\beta_j(t_n) - \beta_j(t_{n-1})\big).$$

Here

$$\frac{1}{\sqrt{k}}\Big(\beta_j(t_n) - \beta_j(t_{n-1})\Big) = \mathcal{N}(0,1),$$

where $\mathcal{N}(0,1)$ is the real-valued Gaussian random variable.

Thus the right-hand side of (4.2) can be computed by truncating the following series to J terms:

$$\left(\frac{1}{k}\int_{t_{n-1}}^{t_n} P_h\,dW(s),\chi\right) = \left(\frac{1}{k}\sum_{j=1}^{\infty}\gamma_j^{1/2}e_j\big(\beta_j(t_n)-\beta_j(t_{n-1})\big),\chi\right) \tag{4.3}$$
$$= \frac{1}{k}\sum_{j=1}^{\infty}\gamma_j^{1/2}\big(\beta_j(t_n)-\beta_j(t_{n-1})\big)(e_j,\chi)$$
$$\approx \frac{1}{k}\sum_{j=1}^{J}\gamma_j^{1/2}\big(\beta_j(t_n)-\beta_j(t_{n-1})\big)(e_j,\chi).$$

Denote by N_h the dimension of S_h. Below we will show that it is sufficient to choose $J = N_h$ in order to achieve the required convergence order. To see this, let us consider the semidiscrete approximation solution u_h of u of (1.1). Recall that the semidiscrete solution u_h satisfies

$$u_h(t) = E_h(t)P_hu_0 + \int_0^t E_h(t-s)P_h\,dW(s) \tag{4.4}$$
$$= E_h(t)P_hu_0 + \sum_{j=1}^{\infty}\int_0^t E_h(t-s)P_he_j\gamma_j^{1/2}\,d\beta_j(s).$$

Truncating the series in the right-hand side of (4.4), we have

$$u_h^J(t) = E_h(t)P_hu_0 + \sum_{j=1}^{J}\int_0^t E_h(t-s)P_he_j\gamma_j^{1/2}\,d\beta_j(s). \tag{4.5}$$

We then have the following lemma with respect to the L_2 norm in space.

LEMMA 4.1. *Let u_h^J and u_h be defined by (4.4) and (4.5), respectively. Assume that $\{S_h\}$ is defined on a quasi-uniform family of triangulations, and let N_h be the dimension of S_h. Assume that $\|A^{(\beta-1)/2}\|_{L_2^0} < \infty$ for some $\beta \in [0,1]$. If $J \geq N_h$, then we have, for $t > 0$,*

$$\|u_h^J(t) - u_h(t)\|_{L_2(\Omega,H)} \leq Ch^{\beta}\|A^{(\beta-1)/2}\|_{L_2^0}. \tag{4.6}$$

Proof. We have, by the isometry property, with $F_h(t) = E_h(t)P_h - E(t)$,

$$\mathbf{E}\|u_h^J(t)-u_h(t)\|^2 = \mathbf{E}\left\|\sum_{j=J+1}^{\infty}\int_0^t E_h(t-s)P_he_j\gamma_j^{1/2}\,d\beta_j(s)\right\|^2$$
$$= \sum_{j=J+1}^{\infty}\gamma_j\int_0^t\|E_h(t-s)P_he_j\|^2\,ds$$
$$\leq 2\sum_{j=J+1}^{\infty}\gamma_j\int_0^t\|E(t-s)e_j\|^2\,ds$$
$$+ 2\sum_{j=J+1}^{\infty}\gamma_j\int_0^t\|F_h(t-s)e_j\|^2\,ds$$
$$= I + II.$$

For I, we have

$$\begin{aligned} I &= 2\sum_{j=J+1}^{\infty}\gamma_j\int_0^t e^{-2(t-s)\lambda_j}\,ds \le \sum_{j=J+1}^{\infty}\gamma_j\lambda_j^{-1} \\ &= \sum_{j=J+1}^{\infty}\lambda_j^{-\beta}\lambda_j^{\beta-1}\gamma_j \le \lambda_{J+1}^{-\beta}\|A^{(\beta-1)/2}\|_{L_2^0}^2. \end{aligned}$$

For II, we have, noting that $\int_0^t \|F_h(t)v\|^2\,dt \le Ch^{\beta}|v|_{\beta-1}^2$ (see Thomée [28]),

$$II \le Ch^{2\beta}\sum_{j=J+1}^{\infty}\gamma_j|e_j|_{\beta-1}^2 \le Ch^{2\beta}\sum_{j=1}^{\infty}|Q^{1/2}e_j|_{\beta-1}^2 = Ch^{2\beta}\|A^{(\beta-1)/2}\|_{L_2^0}^2.$$

Thus we get

$$\mathbf{E}\|u_h^J(t)-u_h(t)\|^2 \le C(\lambda_{J+1}^{-\beta}+h^{2\beta})\|A^{(\beta-1)/2}\|_{L_2^0}^2.$$

Hence (4.6) follows from the following obvious facts: with some constant C which may be different in different inequalities,

$$\lambda_{J+1}^{-1} \le CJ^{-2/d} \le CN_h^{-2/d} \le Ch^2,$$

where d is the dimension of the spatial domain $\mathcal{D}$. □

Under the same assumptions as in Lemma 4.1, we can also show the following results with respect to the weak norm in space:

$$\|u_h^J(t)-u_h(t)\|_{L_2(\Omega,\dot{H}^{-1})} \le Ch^{\beta+1}\ell_h\|A^{(\beta-1)/2}\|_{L_2^0}.$$

5. Numerical illustrations. In this section, we will show some numerical experiments. We consider the following one-dimensional stochastic partial differential equation driven by white noise (see Allen, Novosel, and Zhang [1] and also Du and Zhang [11]):

$$\begin{cases} \frac{\partial u}{\partial t}(t,x) - \frac{\partial^2 u}{\partial^2 x}(t,x) + bu(t,x) = \frac{\partial^2 W}{\partial t\partial x}(t,x) + g(t,x), \quad t>0, \\ u(0,x) = 10x^2(1-x)^2, \quad 0\le x\le 1, \\ u(t,0)=u(t,1)=0, \quad t\ge 0, \end{cases} \tag{5.1}$$

where $\frac{\partial^2 W}{\partial t\partial x}$ denotes the mixed second order derivative of the Brownian sheet and $b=0.5$, and

$$g(t,x) = 10(1+b)x^2(1-x)^2e^t - 10(2-12x+12x^2)e^t.$$

Let U^n be the approximation in S_h of $u(t)$ at $t=t_n=nk$. Define the following backward Euler method of (5.1), with $\bar\partial U^n = (U^n-U^{n-1})/k$, $n\ge 1$, $U^0 = P_h u_0$:

(5.2)
$$(\bar\partial U^n,\chi) + ((U^n)',\chi') + b(U^n,\chi) = \left(\frac{1}{k}\int_{t_{n-1}}^{t_n} P_h\,dW(s),\chi\right) + (g^n,\chi) \quad \forall\chi\in S_h,$$

where $(U^n)',\chi'$ denote the derivatives with respect to the spatial variable, where $W(t)$ is given by (4.1) with $\gamma_j=1$.

Table 5.1
Ratios of error by using different time steps.

i	k_i	$S(k_i)/S(k_{i+1})$	$D(k_i)/D(k_{i+1})$
1	2^{-1}	1.1705	2.3468
2	2^{-2}	1.1801	2.2778
3	2^{-3}	1.2041	2.2562
4	2^{-4}	1.2322	2.1845
5	2^{-5}	1.2441	2.1025
6	2^{-6}	1.2049	2.0938
7	2^{-7}		

We approximate the stochastic integral $\int_{t_{n-1}}^{t_n} P_h dW(s)$ by

$$\left(\int_{t_{n-1}}^{t_n} P_h dW, \chi\right) \approx \left(\sum_{j=1}^{N_h} \gamma_j^{1/2} e_j(\beta_j(t) - \beta_{j-1}(t)), \chi\right),$$

where $e_j = \sqrt{2}\sin j\pi x$. By Corollary 3.1 and section 4, we see that there exists a constant $C > 0$ such that

$$\|U^n - u(t_n)\|_{L_2(\Omega,H)} \le C(k^{\beta/2} + h^{\beta}) \quad \text{for } 0 \le \beta < \frac{1}{2}. \tag{5.3}$$

In our experiment, we want to see how the error estimates in (5.3) depend on k. To do this, we choose fixed small $h > 0$ and a sequence of moderate time steps k_i. In Table 5.1, we choose $h = 2^{-8}$ and different time steps $k_i = 2^{-i}$, $i = 1, \dots, 7$. We consider $M = 100$ simulations. For each simulation ω_j, $j = 1, 2, \dots, M$, we generate N_h independent Brownian motions $\beta_l(t)$, $l = 1, 2, \dots, N_h$, and compute $U^n \approx u(t_n)$ at time $t_n = 1$ by using the different time step k_i. We then compute the following L_2 norm of the error at $t_n = 1$ for each simulation ω_j, $j = 1, 2, \dots, M$,

$$\epsilon(k_i, \omega_j) = \epsilon(k_i, \omega_j, t_n) = \|U^n(\omega_j) - u(t_n, \omega_j)\|^2,$$

where the "true" solution $u(t_n, \omega_j)$ is approximated by a solution computed by small time step $k = 2^{-10}$ and space step $h = 2^{-8}$. We then average $\epsilon(k_i, \omega_j)$ with respect to ω_j to obtain the following approximation of $\|U^n - u(t_n)\|_{L_2(\Omega,H)}$ for fixed time step k_i:

$$\begin{aligned} S(k_i) &= \left(\frac{1}{M}\sum_{j=1}^{M} \epsilon(k_i, \omega_j)\right)^{1/2} = \left(\frac{1}{M}\sum_{j=1}^{M} \|U^n(\omega_j) - u(t_n, \omega_j)\|^2\right)^{1/2} \\ &\approx \|U^n - u(t_n)\|_{L_2(\Omega,H)}, \end{aligned}$$

where

$$\|U^n - u(t_n)\|_{L_2(\Omega,H)} = \left(\int_{\Omega} \|U^n(\omega) - u(t_n, \omega)\|^2 \, d\mathbf{P}(\omega)\right)^{1/2}.$$

Since the convergence order is almost $O(k^{1/4})$, we expect that

$$\frac{S(k_i)}{S(k_{i+1})} \approx \left(\frac{k_i}{k_{i+1}}\right)^{1/4} = 2^{1/4} \approx 1.19$$

Table 5.2
The approximation of $\mathbf{E}u(1,0.5)$ *and* $\mathbf{E}(u(1,0.5))^2$.

h	k	$\mathbf{E}U(1,0.5)$	$\mathbf{E}(U(1,0.5))^2$

1/32	1/32	1.7003	2.8975

for sufficiently small h such that the error estimates are dominated by k_i. Table 5.1 shows that the numerical result is consistent with the above analysis. To compare with the deterministic convergence order, which is $O(k)$ for the backward Euler method, in Table 5.1, we also compute $D(k_i) = \|U^n - u(t_n)\|$, the L_2 norm of the error at time $t_n = 1$ for fixed time step k_i in the deterministic case. We see that $\frac{D(k_i)}{D(k_{i+1})} \approx 2$, as expected.

In Allen, Novosel, and Zhang [1] and Du and Zhang [11], they show the numerical approximation of $\mathbf{E}(u(t,x))$ and $\mathbf{E}(u(t,x)^2)$ at time $t = 1$ and $x = 0.5$ for (5.1). In Table 5.2, we obtain approximation values similar to those in their papers for different pairs k, h. In our experiment, for each pair (k,h), 1000 runs are performed and N_h independent Brownian motions are generated in each run. We then calculate the average. In Table 5.2, $U(1,0.5)$ denotes the approximation of $u(t,x)$ at $t = 1$ and $x = 0.5$. The computational results converge as k and h approach 0.

Let us review the numerical methods in [1] and [11]. They consider both finite element and finite difference methods for (5.1). They approximate the space-time white noise by using piecewise constant functions on a partition $[t_{n-1}, t_n] \times [x_{j-1}, x_j]$, $1 \le n \le N$, $1 \le j \le J$, of $[0,T] \times [0,1]$. More precisely, with $k = t_n - t_{n-1}$ and $h = x_j - x_{j-1}$,

$$dW(t,x) \approx d\hat{W}(t,x) = \frac{\partial^2 \hat{W}(t,x)}{\partial t \partial x} dt dx = \frac{1}{kh} \sum_{n=1}^{N} \sum_{j=1}^{J} \eta_{nj} \sqrt{kh} \chi_n(t) \chi_j(x) dt dx,$$

where

$$\chi_n(t) = \begin{cases} 1, & t_{n-1} \le t \le t_n, \\ 0 & \text{otherwise}, \end{cases} \qquad \chi_j(x) = \begin{cases} 1, & x_{j-1} \le x \le x_j, \\ 0 & \text{otherwise}, \end{cases}$$

and

$$\eta_{nj} = \frac{1}{kh} \int_{t_{n-1}}^{t_n} \int_{x_{j-1}}^{x_j} dW(t,x) = \mathcal{N}(0,1),$$

where $\mathcal{N}(0,1)$ is the standard real-valued Gaussian random variable and η_{nj} are independently and identically distributed. It is obvious that $\frac{\partial^2 \hat{W}}{\partial t \partial x} \in L_2(0,1)$ for fixed $t \in [0,T]$, $\omega \in \Omega$. Applying the standard finite element and finite difference methods for the new "simpler" problems, they obtain the approximate solution $U^n \approx u(t_n)$ and the corresponding error estimates. For example, using the backward Euler method, the finite element approximate solution U^n satisfies, with $\ell_k = 1 + \log(T/k)$,

$$\|U^n - u(t_n)\|_{L_2(\Omega;H)} \leq C\ell_k(k^{1/4} + h^{1/2}),$$

which is consistent with our estimates in Corollary 3.1.

We can also approximate the stochastic integral by

$$\left(\int_{t_{n-1}}^{t_n} d\hat{W}_h, \chi \right) = \left(\sum_{j=1}^{N_h} \alpha_j^{1/2} \varphi_j (\beta_j(t) - \beta_{j-1}(t)), \chi \right),$$

where

$$\hat{W}_h = \sum_{j=1}^{N_h} \alpha_j^{1/2} \varphi_j \beta_j(t),$$

where φ_j is the finite element basis and α_j is decided specially by solving the following linear system in order to compare the approximation (4.3):

$$\sum_{j=1}^{N_h} \alpha_j (\varphi_j, \chi)^2 = \sum_{j=1}^{N_h} \gamma_j (e_j, \chi)^2 \quad \forall \chi \in S_h.$$

The right-hand side of the above system is related to the Wiener process $P_h W$. Recall that $P_h W$ is an S_h-valued Wiener process with covariance operator $Q_h = P_h Q$ and

$$(Q_h \chi, \chi) = (P_h Q \chi, \chi) = \sum_{j=1}^{\infty} \gamma_j (e_j, \chi)^2 \quad \forall \chi \in S_h.$$

Below we will give a lemma to show the property of the covariance operator of $\hat{W}_h$.

LEMMA 5.1. *$\hat{W}_h$ is an S_h-valued Wiener process with covariance operator $\hat{Q}_h$, where $\hat{Q}_h$ satisfies*

$$(\hat{Q}_h \chi, \chi) = \sum_{j=1}^{N_h} \gamma_j (e_j, \chi)^2.$$

Proof. Noting that α_j is decided by the linear system

$$\sum_{j=1}^{N_h} \alpha_j (\varphi_j, \chi)^2 = \sum_{j=1}^{N_h} \gamma_j (e_j, \chi)^2,$$

we have

$$\begin{aligned}(\mathbf{E}(\hat{W}_h \otimes \hat{W}_h)\chi, \chi) &= (t\hat{Q}_h \chi, \chi) = \mathbf{E}(\hat{W}_h, \chi)^2 \\ &= t \sum_{j=1}^{N_h} \alpha_j (\varphi_j, \chi)^2 = t \sum_{j=1}^{N_h} \gamma_j (e_j, \chi)^2 \quad \forall \chi \in S_h. \qquad \square\end{aligned}$$

Acknowledgments. I wish to express my sincere gratitude to my supervisor Dr. Stig Larsson, Chalmers University of Technology, who suggested the topic of this paper, for his support and valuable criticism. I thank Dr. Tony Shardlow for helpful discussions for the numerical illustrations, and also the referees for a number of valuable comments.

PSEUDO-TRANSIENT CONTINUATION FOR NONSMOOTH NONLINEAR EQUATIONS [*]

K. R. FOWLER[†] AND C. T. KELLEY[‡]

Abstract. Pseudo-transient continuation is a Newton-like iterative method for computing steady-state solutions of differential equations in cases where the initial data are far from a steady state. The iteration mimics a temporal integration scheme, with the time step being increased as steady state is approached. The iteration is an inexact Newton iteration in the terminal phase.

In this paper we show how steady-state solutions to certain ordinary and differential algebraic equations with nonsmooth dynamics can be computed with the method of pseudo-transient continuation. An example of such a case is a discretized PDE with a Lipschitz continuous, but nondifferentiable, constitutive relation as part of the nonlinearity. In this case we can approximate a generalized derivative with a difference quotient.

The existing theory for pseudo-transient continuation requires Lipschitz continuity of the Jacobian. Newton-like methods for nonsmooth equations have been globalized by trust-region methods, smooth approximations, and splitting methods in the past, but these approaches are not designed to find steady-state solutions of time-dependent problems. The method in this paper synthesizes the ideas from nonsmooth calculus and the method of pseudo-transient continuation.

1. Introduction.

In this paper we show how pseudo-transient continuation (Ψtc) can be used to solve a class of nonsmooth nonlinear equations. Ψtc is a predictor-corrector method for efficient integration of a time-dependent differential equation to steady state. The objective of the method is not temporal accuracy but rather to resolve the transient behavior of the solution until the iteration is close to steady state, and then to increase the "time step" and transition to a fast Newton-like method.

In this paper we extend the theoretical convergence results of [8, 19] to problems with certain nonsmooth nonlinearities and, thereby, partially explain the results reported in [9, 11]. We also show how generalized derivatives can be approximated by finite differences, and how these approximate derivatives can be used effectively both in locally convergent iterations, such as those which arise in temporal integration, and in the context of Ψtc. This aspect of the work is motivated by several papers on simulation of unsaturated flow [11, 15, 16, 25, 32, 33], in which Lipschitz continuous spline approximations to the non-Lipschitz continuous van Genuchten [35] and Mualem [26] constitutive laws are used. These nonsmooth functions are then differentiated with finite differences as if they were smooth. Our results explain the success reported

in those papers. Another aspect of the paper is an extension of the local results in [10, 22, 28, 30].

Ψtc methods are particularly appropriate for the types of nonsmooth nonlinearities which we discuss in this paper. Traditional methods, such as line searches, for globalizing iterative methods for nonlinear equations can fail as commonly implemented in practice for both smooth and nonsmooth equations [8, 9, 19]. The existing global convergence results for nonsmooth nonlinear equations are based on either line searches for an inexact Newton formulation [10, 23], a sequence of smooth approximations [5, 31], methods based on the one-dimensional secant method [29], or explicit treatment of the nonsmoothness [21]. Only the latter two approaches admit approximation of the generalized Jacobian by a difference, and we use the ideas of [29] in this paper. Ψtc allows one to deal with the nonsmoothness directly and exploits the dynamics to guarantee convergence to x^*, the solution one wants.

In section 2 we review the relevant results from nonsmooth analysis (section 2.1) and Ψtc (section 2.2). Then we describe the setting for the new results. In section 3 we show how finite difference approximations of generalized Jacobians affect the local convergence of inexact Newton methods for nonsmooth problems. We use those results in section 4, where we state and prove our local and global convergence results for Ψtc. We present a numerical example in section 5.

Some extensions of our results to infinite dimensions are possible, using ideas from [6,12,13,20,34] if the appropriate compactness conditions hold. These extensions will be explored in a subsequent paper.

2. Previous results.

In this section we review the prior results about Ψtc and nonsmooth analysis that we will need for this paper.

In this paper the norm will be the scaled discrete l^2 norm on R^N,

$$\|w\| = \frac{1}{\sqrt{N}}\|w\|_2,$$

unless stated otherwise. The ball of radius ϵ about a point $x \in R^N$ will be denoted by

$$\mathcal{B}(x, \epsilon) = \{z \mid \|x - z\| < \epsilon\}.$$

As is standard, we will let x^* denote the solution of $F(x) = 0$, and let

$$e = x - x^*$$

denote the error. We will let $(x)_i$ denote the ith component of the vector x.

2.1. Nonsmooth analysis.

In this section we review the concepts from nonsmooth analysis [7, 24] that we will need for our convergence results. We then state the local convergence result from [22, 30] that we extend in this paper.

Let $F : R^N \to R^N$ be locally Lipschitz continuous. This implies that F is Fréchet differentiable almost everywhere. We let D_F denote the set of points where F is Fréchet differentiable. The generalized Jacobian [7] of F at $x \in R^N$ is the set

$$\partial F(x) = \mathrm{co}\left\{ \lim_{x_j \to x; x_j \in D_F} F'(x_j) \right\}, \tag{2.1}$$

where co denotes the convex hull.

We will consider extensions of the Newton-like iteration

$$x_{n+1} = x_n - V_n^{-1} F(x_n), \tag{2.2}$$

where $V_n \in \partial F(x_n)$. Our results will be stated in terms of an inexact formulation,

$$x_{n+1} = x_n + s, \tag{2.3}$$

where

$$\|V_n s + F(x_n)\| \le \eta_n \|F(x_n)\| \tag{2.4}$$

and $V_n \in \partial F(x_n)$.

The concept of semismoothness [24, 30] is critical for the results in this paper.

Definition 2.1. *F is semismooth at $x \in R^N$ if F is locally Lipschitz continuous and, for all $w \in R^N$, the limit*

$$\lim_{V \in \partial F(x+tw'), w' \to w, t \downarrow 0} \{Vw'\} \tag{2.5}$$

exists.

Semismoothness is a useful concept [6, 30, 34] in the proofs of convergence and local convergence rates of the iteration (2.2). In the standard theory for Lipschitz continuously differentiable F, local quadratic convergence follows from nonsingularity of the Jacobian $F'(x^*)$ at the solution and the Lipschitz continuity of F'. To obtain convergence rates, in the nonsmooth case, one must prove that the Newton iteration is well defined and quantify the degree of nonsmoothness.

Lemma 2.2, taken from [28], and Lemma 2.4 are the results that are needed to prove local superlinear convergence of (2.2).

Lemma 2.2. *F is semismooth at $x \in R^N$ if and only if*

$$\lim_{w \to 0, V \in \partial F(x+w)} \frac{\|F(x+w) - F(x) - Vw\|}{\|w\|} = 0. \tag{2.6}$$

If F is semismooth, then [30] the directional derivatives

$$F'(x : w) = \lim_{h \to 0} \frac{F(x+hw) - F(x)}{h}$$

exist for all $x, w \in R^N$.

To obtain convergence rates one needs a stronger condition than semismoothness [30].

Definition 2.3. *F is semismooth of order p at x if for all $w \in R^N$ and $V \in \partial F(x+w)$*

$$F(x+w) - F(x) - Vw = O(\|w\|^{1+p}) \tag{2.7}$$

as $w \to 0$.

Lemma 2.4. *Let F be semismooth, let $F(x^*) = 0$, and assume that all matrices in $\partial F(x^*)$ are nonsingular. Then there are M and Δ such that if $x \in \mathcal{B}(x^*, \Delta)$ and $V \in \partial F(x)$, then $\|V^{-1}\| \le M$.*

These results have been used to prove several convergence theorems [10, 22, 28, 30] for (2.2) and (2.3). Theorem 2.5 is a combination of these local convergence results and is the basis for the new algorithms in this paper.

THEOREM 2.5. *Let $F : R^N \to R^N$ with $F(x^*) = 0$. Assume that F is semismooth at x^* and that all matrices in $\partial F(x^*)$ are nonsingular. Then there are $\bar{\eta}, \bar{\delta}, K > 0$ such that if $x_0 \in \mathcal{B}(x^*, \bar{\delta})$ and $\eta_n \le \bar{\eta}$, then the inexact Newton iteration* (2.3) *converges to x^* and*

$$\|e_{n+1}\| \le K\eta_n \|e_n\| + o(\|e_n\|).$$

Moreover, if F is semismooth of order p at x^*, then

$$\|e_{n+1}\| \le K(\eta_n \|e_n\| + \|e_n\|^{1+p}).$$

In previous work [12, 17, 20, 21] on nonsmooth nonlinear equations in function spaces and their discretizations, we used properties of the solution to isolate a smooth component of the nonlinearity. Each problem required a different approach, and all assumed that the nonsmooth component was small. In those papers, mesh-independent convergence results were obtained, and standard implementations of matrix-free Newton–Krylov methods worked well.

The formulation we consider in this paper is different. Here one does not have to explicitly split the operator into smooth and nonsmooth parts, a significant advantage in complicated applications [32]. However, we know of no general proofs of mesh-independent convergence rates, a problem also mentioned in [34]. In fact, the numerical results in section 5 show mesh-dependent performance of the iteration, especially in the midrange. Mesh-dependent convergence was also reported in [5]. In section 5.4 we illustrate this phenomenon and show how a nested iteration can overcome it.

Numerical differentiation, a topic we consider in section 3.1, is a simple matter if the smooth and nonsmooth parts of the nonlinearity are split. Here, we use methods from [29], which can prove accuracy only if one is differentiating in coordinate directions, and only then for special classes of operators. Since the directions in a matrix-free Newton–Krylov solver are not predictable, neither the results in [29] nor our results apply to those methods.

2.2. Pseudo-transient continuation. The objective of Ψtc, as we present it here, is to find the steady-state solution of the semiexplicit index-one differential algebraic equation (DAE)

$$D \begin{pmatrix} u \\ v \end{pmatrix}' = - \begin{pmatrix} f(u,v) \\ g(u,v) \end{pmatrix} = -F(x), \quad x(0) = x_0. \tag{2.8}$$

Here $x = (u, v)^T \in C([0, \infty], R^{N_1+N_2})$. The functions $u : [0, \infty] \to R^{N_1}$ and $v : [0, \infty] \to R^{N_2}$ are to be found. The differential variables u and the algebraic variables v are clearly separated in the semiexplicit case where

$$D = \begin{pmatrix} D_{11} & 0 \\ 0 & 0 \end{pmatrix},$$

where D_{11} is a nonsingular scaling matrix. A good general reference for DAEs is [4].

We assume that the initial data for (2.8) are consistent (i.e., $g(u(0), v(0)) = 0$) and seek the solution x^* to $F(x^*) = 0$ that satisfies

$$\lim_{t\to\infty} x(t) = x^*.$$

If (2.8) is a discretization in space of a PDE and the initial data are far from the desired steady state, the application of a conventional method, such as a line search [18], to the time-independent equation

$$F(x) = 0$$

may fail to converge. Possible failure modes [9] are stagnation of the iteration at a singularity of F', the Jacobian of F, and finding a solution other than x^*.

We formulate Ψtc as

$$x_{n+1} = x_n - (\delta_n^{-1} D + F'(x_n))^{-1} F(x_n). \tag{2.9}$$

In (2.9), $\{\delta_n\}$ is adjusted to efficiently find the steady-state solution rather than to enforce temporal accuracy.

The convergence results in [8, 19] assume that the time step was updated with "switched evolution relaxation" (SER) [27], i.e.,

$$\delta_n = \max\left(\delta_{n-1} \frac{\|F(x_{n-1})\|}{\|F(x_n)\|}, \delta_{max}\right). \tag{2.10}$$

In [8] the authors prove convergence for smooth F under the assumptions that the DAE has index one in a certain uniform sense, that it has a global solution in time, and that the solution converges to a steady state. The convergence result for the exact $\eta = 0$ case is

$$\|x_{n+1} - x^*\| = O(\|x_n - x^*\|(\delta_{max}^{-1} + \|x_n - x^*\|)) \tag{2.11}$$

as $n \to \infty$.

In this paper we relax the smoothness assumptions and consider the iteration

$$x_{n+1} = x_n + s, \tag{2.12}$$

where

$$\|(\delta_n^{-1} D + V(x_n))s + F(x_n)\| \leq \eta_n \|F(x_n)\|, \tag{2.13}$$

where $V(x_n)$ is near to the set $\partial F(x_n)$ in the sense that

$$V(x_n) \in \mathcal{D}(F, x_n, C, h), \text{ for some small } h, \tag{2.14}$$

where, for $x \in R^N$ and $h \geq 0$,

$$\mathcal{D}(F, x, C, h) = \{V \mid \|V - \bar{V}\| \leq Ch \text{ for some } \bar{V} \in \partial F(\bar{x}) \text{ and } \|x - \bar{x}\| \leq h\}. \tag{2.15}$$

The sense in which $V(x_n)$ is close to $\partial F(x_n)$ is technical because $\partial F(x)$ is a set-valued function of x. The requirement that $V(x_n) \in \mathcal{D}(F, x_n, C, h)$ is, in a sense, a requirement that a combination of the forward and backward errors be small.

In [8,9,11,19] we report on computational results that show that both the local and global phases of the Ψtc iteration perform as (2.11) predicts even if the nonlinearity is nonsmooth [8, 9, 11] and the derivative is approximated by differencing [11, 14, 15, 32].

3. Local convergence theory. In this section we analyze the accuracy of a finite difference approximation of a generalized Jacobian in the case where the nonsmoothness arises from a substitution operator. The approximation is accurate in a combined forward and backward sense, and this affects not only the convergence speed of an inexact Newton iteration but also the limiting accuracy.

3.1. Finite difference approximations. The results in this paper are motivated in part by our experience with nonsmooth nonlinear substitution operators. A substitution operator on R^N has the form

$$\Phi(x) = (\phi(x_1), \ldots, \phi(x_N))^T, \tag{3.1}$$

where $\phi : R \rightarrow R$. The generalized Jacobian of Φ is the set of diagonal matrices

$$\partial\Phi(x) = (\partial\phi(x_1), \ldots, \partial\phi(x_N))^T.$$

In this section, we consider maps that are compositions of smooth maps with substitution operators. Let

$$G(x) = S(\Phi(x)),$$

where S is continuously differentiable. S is then strictly differentiable in the sense of [7], and hence the definition (2.1) of ∂G implies (see Theorem 2.6.6 and its corollary in [7]) that

$$\partial G(x) = S'(\Phi(x))\partial\Phi(x),$$

where S' is the Jacobian of S. Of interest here is the approximation of ∂G with a finite difference approximation using the coordinate directions.

Let $\partial_h^F G(x)$ be the matrix whose ith column is

$$\frac{G(x + h1_i) - G(x)}{h},$$

where 1_i is the unit vector in the ith coordinate direction. We show that there is $C > 0$ such that the forward difference $\partial_h^F G$ approximates $\partial G(x)$ in the sense described by (2.15).

Theorem 3.1 can be derived from Lemma 2.3 of [29], which considers one-sided difference approximations and derivatives by taking averages. We give a direct proof which allows us to exhibit $\bar{x}$ as a function of x.

THEOREM 3.1. *Let $\phi : R \rightarrow R$ be Lipschitz continuous and differentiable except at finitely many points $\{\xi_i\}_{i=1}^M$. Let S be Lipschitz continuously differentiable in R^N. Then there is $C > 0$ such that for all h sufficiently small*

$$\partial_h^F G(x) \in \mathcal{D}(G, x, C, h). \tag{3.2}$$

Proof. We begin by showing that it suffices to prove the result for scalar functions. Differentiability of S and the Lipschitz continuity of ϕ imply that

$$\begin{aligned} G(x + h1_i) - G(x) &= S'(\Phi(x))(\Phi(x + h1_i) - \Phi(x)) + O(h^2) \\ &= S'(\Phi(\bar{x}))(\Phi(x + h1_i) - \Phi(x)) + O(h^2) \end{aligned}$$

for all $\bar{x}$ such that $\|\bar{x} - x\| \leq h$. Hence we need only prove the result for substitution operators.

Since Φ is a substitution operator, the ith component of $\Phi(x + h1_i) - \Phi(x)$ is

$$\phi((x)_i + h) - \phi((x)_i),$$

and we need only consider scalar functions. Now let

$$h < \min_{i,j} \|\xi_i - \xi_j\|_\infty;$$

then at most one ξ is in the interval $[(x)_i, (x)_i + h]$. If ϕ is differentiable in the interval $[(x)_i, (x)_i + h]$, then

$$\frac{\phi((x)_i + h) - \phi((x)_i)}{h} = \phi'((x)_i) + O(h)$$

and we let the ith component of $\bar{x}$ be $(x)_i$.

Now assume that $\xi_j \in [(x)_i, (x)_i + h]$ for some j. Let $\phi'_+(\xi_j)$ and $\phi'_-(\xi_j)$ be the right- and left-handed derivatives at ξ_j:

$$\phi'_\pm(\xi_j) = \lim_{h\to 0} \frac{\phi(\xi_j \pm h) - \phi(\xi_j)}{\pm h}.$$

Let $\xi_j - (x)_i = \nu h$ for $\nu \in [0, 1]$. Then

$$\begin{aligned} \phi((x)_i + h) - \phi((x)_i) &= \phi(\xi_j + (1-\nu)h) - \phi(\xi_j - \nu h) \\ &= \phi(\xi_j + (1-\nu)h) - \phi(\xi_j) + \phi(\xi_j) - \phi(\xi_j - \nu h) \\ &= (1-\nu)\phi'_+(\xi_j) + \nu\phi'_-(\xi_j) + O(h^2). \end{aligned}$$

Since

$$(1-\nu)\phi'_+(\xi_j) + \nu\phi'_-(\xi_j) \in \partial\phi(\xi_j)$$

for all $\nu \in [0, 1]$, the proof is complete with $(\bar{x})_i = \xi_j$. □

A similar result holds for central differences. Let $\partial_h^C G(x)$ be the matrix whose ith column is

$$\frac{G(x + h1_i) - G(x - h1_i)}{2h}.$$

If S is Lipschitz continuously twice differentiable and ϕ is piecewise Lipschitz continuously twice differentiable, then the statement of Theorem 3.1 with

$$\|V - \bar{V}\| \le Ch$$

in (2.15) is replaced by

$$\|V - \bar{V}\| \le Ch^2. \tag{3.3}$$

3.2. Local convergence. If the generalized Jacobian is approximated by a finite difference, one cannot expect asymptotic convergence, because the accuracy in the terminal phase of the iteration will be limited by the accuracy in the derivative. We quantify this in Theorem 3.2, which extends the existing local convergence theorems for inexact Newton methods for semismooth equations. The new assumption that $V(x) \in \mathcal{D}(F, x, C, h)$ is motivated by the results in section 3.1.

THEOREM 3.2. *Assume that F is semismooth at x^*, that $F(x^*) = 0$, and that all matrices in $\partial F(x^*)$ are nonsingular. Assume that there is $C > 0$ such that*

$$V(x) \in \mathcal{D}(F, x, C, h) \tag{3.4}$$

for all x sufficiently near x^*.

Then there is ϵ such that if $x_0 \in \mathcal{B}(x^*, \epsilon)$, $\{\eta_n\}$, and h are sufficiently small, then the iteration

$$x_{n+1} = x_n + s, \tag{3.5}$$

where

$$\|V(x_n)s + F(x_n)\| \le \eta \|F(x_n)\|, \tag{3.6}$$

converges to x^*. Moreover, there is $K > 0$ such that

$$\|e_{n+1}\| \le K((\eta_n + h)\|e_n\| + h) + o(\|e_n\|), \tag{3.7}$$

or, if F is semismooth of order p at x^*, then

$$\|e_{n+1}\| \le K((\eta_n + h)\|e_n\| + \|e_n\|^{1+p} + h). \tag{3.8}$$

Proof. The plan of the proof is to compare x_{n+1} with the Newton iteration from $\bar{x}_n$, where $\bar{x}_n$ is the point specified in the definition of $\mathcal{D}$. We can then apply Theorem 2.5.

Let ϵ and h be small enough so that

$$\|V^{-1}\| \le M \text{ for all } V \in \partial F(x) \text{ and } x \in \mathcal{B}(x^*, h + \epsilon), \tag{3.9}$$

which we can do by Lemma 2.4. We assume that $x_n \in \mathcal{B}(x^*, \epsilon)$ and will show, reducing ϵ and h if necessary, that (3.8) holds and therefore that $x_{n+1} \in \mathcal{B}(x^*, \epsilon)$.

By assumption, there are $\overline{x}_n \in \mathcal{B}(x_n, h)$ and $\bar{V}_n \in \partial F(\overline{x}_n)$ such that

$$\|V(x_n) - \bar{V}_n\| \le Ch.$$

Hence the step s is nearly an inexact Newton step from $\bar{x}_n$.

By (3.9), for h sufficiently small,

$$\|V(x_n)^{-1}\| \le 1/(M^{-1} - Ch) \le 2M,$$

and hence

$$\|s\| \le 2M(\eta_n + 1)\|F(x_n)\|.$$

Therefore,

$$\begin{aligned} \|\bar{V}_n s + F(\bar{x}_n)\| &\le \|V(x_n)s + F(\bar{x}_n)\| + Ch\|s\| \\ &\le \|V(x_n)s + F(x_n)\| + \|F(x_n) - F(\bar{x}_n)\| + Ch\|s\| \\ &\le \eta_n\|F(x_n)\| + Lh + Ch(2M(1 + \eta_n)\|F(x_n)\|), \end{aligned} \tag{3.10}$$

where L is the Lipschitz constant of F. Since

$$\|F(x_n)\| \le \|F(\bar{x}_n)\| + Lh,$$

we may set

$$K_0 = 1 + 2L + 2MC(1 + \eta_n) \le 1 + 2L + 4MC$$

and obtain

$$\|\bar{V}_n s + F(\bar{x}_n)\| \leq K_0((\eta_n + h)\|F(\bar{x}_n)\| + h). \tag{3.11}$$

The inexact Newton condition (3.6) and (3.11) imply that

$$x_{n+1} = x_n + s = \bar{x}_n - \bar{V}_n^{-1}(F(\bar{x}_n) + r_n),$$

where

$$r_n = \bar{V}_n^{-1}(\bar{x}_n - x_n) - (\bar{V}_n s + F(\bar{x}_n)).$$

Hence

$$\|\bar{V}_n^{-1} r_n\| \leq MK_0((\eta_n + h)\|F(\bar{x}_n)\| + h) + h,$$

and

$$\begin{aligned}\|e_{n+1}\| &= \|\bar{e}_n - \bar{V}_n^{-1}F(\bar{x}_n) + \bar{V}_n^{-1} r_n\| \\ &\leq MK_0((\eta_n + h)\|F(\bar{x}_n)\| + h) + h + o(\|\bar{e}_n\|).\end{aligned}$$

If F is semismooth of order p at x^*, then (2.7) implies that there is $K_1 > 0$ such that

$$\begin{aligned}\|e_{n+1}\| &= \|\bar{e}_n - \bar{V}_n^{-1}F(\bar{x}_n) + \bar{V}_n^{-1} r_n\| \\ &\leq K_1\|\bar{e}_n\|^{1+p} + MK_0((\eta_n + h)\|F(\bar{x}_n)\| + h) + h.\end{aligned}$$

Since $\|F(\bar{x}_n)\| \leq L\|\bar{e}_n\|$ and $\|\bar{e}_n\| \leq \|e_n\| + h$, we obtain (3.8) with

$$K = 2K_1 + MK_0(1 + L) + 1$$

and complete the proof. □

3.3. Optimal choice of *h*. If $\bar{x}_n \neq x_n$, then the estimates (3.7) and (3.8) do not imply convergence but stagnation once the error is $O(h)$. This is analogous to convergence results [18] for Newton's method when there are errors, such as floating point roundoff, in the evaluation of F. In this case, however, h is larger than floating point roundoff, and we can combine Theorems 3.1 and 3.2 to estimate the optimal choice of h.

Suppose that F is piecewise C^1 (and hence semismooth of order 1 [24]) and can be evaluated up to an absolute error of ϵ_F. If we incorporate the error in F into the result of Theorem 3.1 in the standard way [18], we obtain

$$\partial_h^F F(x) \in \mathcal{D}(G, x, C', h'),$$

where $h' = O(h + \epsilon_F/h)$. Then the estimate (3.8) becomes

$$\|e_{n+1}\| \leq K((\eta_n + h + \epsilon_F/h)\|e_n\| + \|e_n\|^2 + h). \tag{3.12}$$

If we solve the equation for the step exactly, then $\eta_n = 0$. In that case, if $\|e_n\| = O(h^{1/2})$, then

$$\|e_{n+1}\| = O\left(\frac{\epsilon_F}{h^{1/2}} + h\right). \tag{3.13}$$

The term on the right-hand side of (3.13) is minimized when

$$h = O(\epsilon_F^{2/3}). \tag{3.14}$$

If, for example, $\epsilon_F \approx 10^{-15}$ is double precision floating point roundoff, (3.14) would say that the best results would be obtained if $h \approx 10^{-10}$, rather than 10^{-8} as a conventional analysis would predict. We provide numerical evidence for this in section 5.3.

4. Convergence of Ψtc.

The analysis of Ψtc in this paper follows the pattern of [8, 19], considering the iteration in two phases. For phase one, the initial or global phase, we show that Ψtc is a consistent convergent scheme for integration of the DAE. The scheme will be first order if F is semismooth of order 1, order p if F is semismooth of order $p < 1$, and convergent but with no order if F is merely semismooth.

From the analysis of the global phase we will conclude that, for sufficiently small δ_0, the iteration will approach x^*. For the second local phase of the iteration, we show that if x is near x^* and $\{\delta_n\}$ is bounded away from zero, then $\delta_n \to \delta_{max}$, and the terminal phase of convergence can be described by the results in section 3.

The analysis of the local phase does not depend on the dynamics, and we will defer the detailed assumptions on the DAE until section 4.2.

4.1. Local phase.

We consider the local phase first, as we did in [8, 19], in order to establish targets for the integration in the global phase. We seek to find ϵ_L so that if $x_0 \in \mathcal{B}(x^*, \epsilon_L)$ and $\{\delta_n\}$ remains bounded away from zero, then $\{x_n\}$ and $\{\delta_n\}$ in (2.12) satisfy $x_n \to x^*$ and $\delta_n \to \delta_{max}$.

The local convergence rates in the terminal phase depend on the following assumption.

ASSUMPTION 4.1. *F is semismooth at x^*. There are $C, h, \beta, \epsilon_L > 0$ such that for all $x \in \mathcal{B}(x^*, \epsilon_L)$ and all $\delta > 0$*

$$\|(D + \delta V(x))^{-1} D\| \leq 1/(1 + \beta\delta) \tag{4.1}$$

and

$$V(x) \in \mathcal{D}(F, x, C, h).$$

Note that Assumption 4.1 does not imply that every element in $\partial F(x^*)$ is nonsingular. It is an assumption on the particular element $V(x) \in \mathcal{D}(F, x, C, h)$, and the possibility of a singular matrix in $\partial F(x^*)$ is left open.

THEOREM 4.1. *Let the assumptions of Theorem 3.2 and Assumption 4.1 hold. Let $\{\delta_n\}$ be given by (2.10). Then there are C_T and ϵ_T such that if $\{\eta_n\}$ is sufficiently small and $x_0 \in \mathcal{B}(x^*, \epsilon_T)$, then either $\inf_n \delta_n = 0$ or $\delta_n \to \delta_{max}$, the Ψtc iteration converges, and, for n sufficiently large,*

$$\|e_{n+1}\| \leq C_T((\eta_n + \delta_n^{-1} + h)\|e_n\| + h) + o(\|e_n\|) \tag{4.2}$$

or, if F is semismooth of order p,

$$\|e_{n+1}\| \leq C_T(\|e_n\|^{1+p} + (\eta_n + \delta_n^{-1} + h)\|e_n\| + h). \tag{4.3}$$

Proof. We assume that x_0 is near enough to x^* so that the conclusions of Theorem 3.2 hold. If $x_n \in \mathcal{B}(\epsilon_T)$, then, following the proof of Theorem 3.2,

$$e_{n+1} = e_n - (\delta_n^{-1} D + \bar{V}_n)^{-1} F(\bar{x}_n) + r_n,$$

where

$$\|r_n\| = O((\eta_n + h)\|F(\bar{x}_n)\| + h).$$

Semismoothness and our assumptions imply that

$$F(\bar{x}_n) - \bar{V}_n e_n = O(h) + o(\|e_n\|)$$

and hence

$$\begin{aligned} e_{n+1} &= e_n - (\delta_n^{-1} D + \bar{V}_n)^{-1} \bar{V}_n e_n + R_n \\ &= (\delta_n^{-1} D + \bar{V}_n)^{-1} \delta_n^{-1} D e_n + R_n, \end{aligned}$$

where

$$R_n = O((\eta_n + h)\|F(\bar{x}_n)\| + h) + o(\|e_n\|).$$

If $\delta_n > \delta^*$ for all n, then Assumption 4.1 implies that

$$\|(\delta_n^{-1} D + \bar{V}_n)^{-1} \delta_n^{-1} D\| < 1/(1 + \beta\delta^*).$$

This implies that the iteration is q-linearly convergent, and hence $\delta_n \to \delta_{max}$ and $x_n \to x^*$.

The completion of the proof for large δ_n is a direct consequence of Theorem 3.2, since the inexact Newton condition

$$\|(\delta_n^{-1} D + V(x_n))s + F(x_n)\| \leq \eta_n \|F(x_n)\|$$

implies that there is C_h such that

$$\|V(x_n)s + F(x_n)\| \leq (\eta_n + C_h h)\|F(x_n)\| + \delta_n^{-1}\|D_{11}\|\|s\|,$$

and then C and η_n in (3.10) can be replaced by $C + \|D_{11}\|$ and $\eta_n + \delta_n^{-1} + C_h h$. This implies convergence if δ_{max} is sufficiently large. □

4.2. Global phase. In the analysis of the global phase we must assume that the Ψtc iteration is, for small δ, a stable explicit method for the DAE (2.8). To do this we must assume that the DAE is consistent and has index one. In the smooth case, one can express this in terms of the nonsingularity of g_v, the Jacobian of g with respect to the algebraic variables. In the nonsmooth case, however, one must take the limit in (2.1) in all components together. This means that the index assumption is more technical, using the nonsingularity of the matrix pencil $\delta^{-1}D + V(x)$ in part 7 of Assumption 4.2.

We assume that $V(x) \in \mathcal{D}(F, x, C, h)$ for a sufficiently small h. We decompose operators $V \in \partial F$ into blocks

$$V(x) = \begin{pmatrix} V_{uu} & V_{uv} \\ V_{vu} & V_{vv} \end{pmatrix}, \tag{4.4}$$

where $V_{uu} \in \partial_u f$, …, $V_{vv} \in \partial_v g$.

With this in mind we can formulate our assumptions on the dynamics. Define a neighborhood of the trajectory from x_0 as

$$S(\epsilon) = \{z \mid \inf_{t \geq 0} \|z - x(t)\| \leq \epsilon\}. \tag{4.5}$$

ASSUMPTION 4.2. $g(u_0, v_0) = 0$*; i.e., the initial values* (u_0, v_0) *are consistent.*

There are $\epsilon_G \in (0, \epsilon_T/2)$*, where* ϵ_T *is the radius from Theorem* 4.1*, such that the following hold:*

1. F *is semismooth in* $S(\epsilon_G)$*.*
2. *For all* $z_0 \in S(\epsilon_S)$*, the solution of* $Dz' = -F(z), z(0) = z_0$ *exists,* $z(t) \in S(\epsilon_G)$ *for all* t*, and* $\lim_{t\to\infty} z(t) = x^*$*.*

3. *$V(x) \in \mathcal{D}(F, x, C, h)$ for all $x \in S(\epsilon_G)$.*
4. *$V_{vv}(x)$ is nonsingular for all $x \in S(\epsilon_G)$, and there is M_V such that $\|V_{vv}(x)^{-1}\| \leq M_V$ for all $x \in S(\epsilon_S)$.*
5. *There is M_I such that for all h sufficiently small, $\delta > 0$, $x \in S(\epsilon_G)$, and $V \in \mathcal{D}(F, x, C, h)$, $D_{11} + \delta V_{uu}$ is nonsingular and*
$$\|(D_{11} + \delta V_{uu})^{-1}\| \leq M_I.$$
6. *There is $M_D > 0$ such that for all $x \in S(\epsilon_G)$*
$$\|V(x)\| \leq M_D.$$
7. *$(\delta^{-1} D + V(x))$ is nonsingular for all $x \in S(\epsilon_G)$, and $\delta > 0$.*

We analyze the global phase by showing that the global truncation error of the scheme

$$x_{n+1} = x_n - (\delta_n^{-1} D + V(x_n))^{-1} F(x_n)$$

is of order p, i.e.,

$$\|x_n - x(t_n)\| = O(\delta_{max}^p),$$

where $\delta_{max} = \max_{0 \leq m \leq n} \delta_m$. Since the SER formula implies that $\delta_{max} = O(\delta_0)$, this will imply, similarly to [8, 19], that if δ_0 is sufficiently small, then the Ψtc iteration will correctly track the solution until x_n is in the ball of local convergence required by Theorem 4.1.

We will use a simple consequence of pth order semismoothness.

LEMMA 4.2. *Let Assumption* 4.2 *hold. Let $x(t)$ be the solution to* (2.8). *Let $\delta > 0$ and let*

$$\sigma = \begin{pmatrix} \sigma^u \\ \sigma^v \end{pmatrix} = x(t + \delta) - x(t).$$

Then, for δ, h sufficiently small,

$$(D + \delta V(x(t)))\sigma = -\delta F(x(t)) + O(\delta h) + o(\delta^2), \tag{4.6}$$

and if F is semismooth of order p,

$$(D + \delta V(x(t)))\sigma = -\delta F(x(t)) + O(\delta^{2+p} + \delta h), \tag{4.7}$$

uniformly in t.

Proof. In the interest of brevity, we will give the proof for $h = 0$ and F semismooth of order p. The analysis for $h > 0$ and semismooth F follows the outlines of the proofs of Theorems 3.2 and 4.1.

Write $x(t) = (u(t), v(t))^T$. By integrating the DAE (2.8), we see that u is a Lipschitz continuous function of t. The semismoothness of F and the nonsingularity of V_{vv} (from parts 1 and 4 of Assumption 4.2) imply that v is a Lipschitz continuous function of u and hence also a Lipschitz continuous function of t. This Lipschitz continuity implies that

$$\|\sigma\| = O(\delta),$$

uniformly in t. Integrate (2.8) over the interval $[t, t+\delta]$ and use the Lipschitz continuity of F to obtain

$$D\sigma = -\int_t^{t+\delta} F(x(\tau))\,d\tau = -\delta F(x(t+\delta)) + O(\delta^2), \tag{4.8}$$

uniformly in t.

By the definition of semismoothness with $x = x(t+\delta)$ and $w = -\sigma$, we have, for δ sufficiently small,

$$\begin{aligned} F(x(t+\delta)) &= F(x(t)) + V(x(t))\sigma + O(\|\sigma\|^{1+p}) \\ &= F(x(t)) + V(x(t))\sigma + O(\delta^{1+p}). \end{aligned} \tag{4.9}$$

The estimate (4.9) is uniform in t because the set $\{x(t)\,|\,t \geq 0\}$ is compact.

Hence, multiplying (4.9) by δ and substituting into (4.8),

$$(D + \delta V(x(t)))\sigma = -\delta F(x(t)) + O(\delta^{2+p}),$$

as asserted. □

Lemma 4.2 will imply convergence of Ψtc in the same way as in the smooth case [8]. The objective is to show that for δ_0 sufficiently small, the Ψtc iteration remains in the tube $S(\epsilon_G)$. We will give a proof that is more general than the one in [8] in that it uses Assumption 4.2 rather than the stronger one in [8].

In the analysis we will let $\|\cdot\|$ denote the Euclidean norm on any of $R^N = R^{N_1+N_2}$, R^{N_1}, or R^{N_2}. The dimension will be clear from the context.

THEOREM 4.3. *Let Assumptions* 4.1 *and* 4.2 *hold. Then if* δ_0, $\{\eta_n\}$, *and* h *are sufficiently small and* $\{\delta_n\}$ *is bounded from below, then* $x_n \to x^*$ *and* (4.2) *holds. If* F *is semismooth of order* p, *then* (4.3) *holds.*

Proof. We begin with the special case in which F is semismooth of order p and $\eta_n = 0$ for all n. Part 2 of Assumption 4.2 implies that there is T such that $x(t) \in \mathcal{B}(x^*, \epsilon_T/2)$, the ball of local convergence from Theorem 4.1, for all $t \geq T$.

Let

$$t_n = \sum_{k=0}^{n} \delta_k.$$

We will use Lemma 4.2 to show that if δ_0 is sufficiently small and the sequence $\{\delta_n\}$ is bounded from below, then the Ψtc iteration is an accurate integrator for (2.8) in the sense that

$$\|x_n - x(t_n)\| = O(\delta^p + h), \tag{4.10}$$

where $\delta = \max_{0\leq k\leq n} \delta_k$. Hence, we can select δ_0 and h such that $x_n \in S(\epsilon_G)$ until $t_n > T$.

We begin by dividing (2.9) and (4.7) into the u and v components. We set

$$e_n = x_n - x(t_n) = \begin{pmatrix} e_n^u \\ e_n^v \end{pmatrix}, \; s_n = x_{n+1} - x_n = \begin{pmatrix} s_n^u \\ s_n^v \end{pmatrix}$$

and

$$\sigma_n = x(t_{n+1}) - x(t_n) = \begin{pmatrix} \sigma_n^u \\ \sigma_n^v \end{pmatrix}.$$

First note that if $V \in \mathcal{D}(F, x_n, C, h)$, then $V \in \mathcal{D}(F, x(t_n), C, h + \|e_n\|)$. Hence if $\|e_n\|$ is sufficiently small, Lemma 4.2 implies that

$$(D + \delta_n V)\sigma_n = -\delta F(x(t_n)) + O(\delta_n^{2+p} + \delta_n(h + \|e_n\|)). \tag{4.11}$$

We write the u component of (2.9) as

$$(D_{11} + \delta_n V_{uu})s_n^u + V_{uv}s_n^v = f(u_n, v_n), \tag{4.12}$$

and the u component of (4.11) as

$$(D_{11} + \delta_n V_{uu})\sigma_n^u + \delta_n V_{uv}\sigma_n^v = -f(u(t_n), v(t_n)) + O(\delta_n^{2+p} + \delta_n(h + \|e_n\|)). \tag{4.13}$$

Subtract (4.13) from (4.12) and use part 6 of Assumption 4.2 to obtain

$$(D_{11} + \delta_n V_{uu})(e_{n+1}^u - e_n^u) = O(\delta_n(\|e_n\| + \|e_{n+1}^v\|) + \delta_n^{2+p} + \delta_n h). \tag{4.14}$$

Hence, we may use part 5 of Assumption 4.2 to obtain

$$\|e_{n+1}^u\| \leq \|e_n^u\| + O(\delta_n(\|e_n\| + \|e_{n+1}^v\|) + \delta_n^{2+p} + \delta_n h). \tag{4.15}$$

The v component of (2.9) is

$$V_{vu}s_n^u + V_{vv}s_n^v = -g(u_n, v_n) = -V_{uv}e_n^u - V_{vv}e_n^v + O(\delta_n^{1+p} + h\delta_n + \|e_n\|\delta_n), \tag{4.16}$$

where we use the facts that $g(u(t), v(t)) = 0$ and $V \in \mathcal{D}(F, x(t_n), C, h + \|e_n\|)$ in the last equality. Adding $V_{uv}e_n^u + V_{vv}e_n^v$ to both sides of (4.16) and noting that $s_n = e_{n+1} - e_n$ yields

$$V_{vv}e_n^v = -V_{vu}e_{n+1}^u + O(\delta_n^{1+p} + \delta_n h + \delta_n\|e_n\|). \tag{4.17}$$

Parts 4 and 6 from Assumption 4.2 and (4.17) imply that

$$\|e_{n+1}^v\| = O(\|e_{n+1}^u\| + \delta_n\|e_n\| + \delta_n^{1+p} + \delta_n h). \tag{4.18}$$

Equations (4.15) and (4.18) together imply that there is $L > 0$ such that

$$\begin{gathered} \|e_{n+1}^u\| \leq (1 + \delta_n L)\|e_n\| + \delta_n L\|e_{n+1}^v\| + O(\delta_n^{1+p} + \delta_n h) \\ \text{and} \\ \|e_{n+1}^v\| \leq L\|e_{n+1}^u\| + \delta_n\|e_n\| + O(\delta_n^{1+p} + \delta_n h). \end{gathered} \tag{4.19}$$

So, if we define a new norm on R^N by

$$|||(u, v)^T||| = L\|u\| + \|v\|,$$

then

$$|||e_{n+1}||| = |||e_n||| + O(\delta_n|||e_n||| + \delta_n^{1+p} + \delta_n h). \tag{4.20}$$

Our assumption that $\{\delta_n\}$ is bounded from below implies that there is n^* such that $t_{n^*} = T^* \geq T$. Then, as is standard in the analysis of numerical methods for initial value problems [1], we may let $\delta_* = \max_{0 \le n \le n^*} \delta_n$ and use (4.20) to conclude that, for $0 \le n \le n^*$,

$$|||e_n||| = O(\delta_*^p + h),$$

which proves (4.10), because $||| \cdot |||$ is equivalent to the Euclidean norm on R^N.

If F is semismooth and $\{\eta_n\}$ is nonzero, then (4.10) becomes (see [19])

$$\|x_n - x(t_n)\| = O\left(h + \sum_{n=0}^{n^*} \eta_n \delta_n \right) + o(1) \text{ as } \delta_0 \to 0, \tag{4.21}$$

and the convergence result still holds if, say, $\eta_n = O(\delta_*)$ for all $0 \le n \le n^*$. □

5. Numerical example.

We illustrate the results with a simple one-dimensional example taken from [2,3,5]. This example is sufficient to illustrate the convergence results in this paper and allows us to refine the grids to a degree that was not possible in the two- and three-dimensional results that motivated this paper [11,15,16,25,32, 33].

We use direct methods to compute the Newton step in this section, so $\eta_n = 0$. In all but section 5.3, we compute $V \in \partial F(x)$ analytically, so $h = 0$ in those computations.

This example, taken from [5], is a Lipschitz reformulation of the boundary value problem [2,3]

$$-u_{zz} + \lambda \max(0, u)^p = 0, \quad z \in (0,1),$$

with boundary data

$$u(0) = u(1) = 0$$

and $p \in (0,1)$.

The reformulation adds a new variable

$$v = \begin{cases} u^p & \text{if } u \ge 0, \\ u & \text{if } u < 0 \end{cases}$$

to obtain a Lipschitz continuous elliptic-algebraic system, $F(x) = 0$, where $x = (u,v)^T$ and

$$F(x) = \begin{pmatrix} f(u,v) \\ g(u,v) \end{pmatrix} = \begin{pmatrix} -u_{zz} + \lambda \max(0,v) \\ u - \omega(v) \end{pmatrix} = 0, \tag{5.1}$$

where

$$\omega(v) = \begin{cases} v^{1/p} & \text{if } v \ge 0, \\ v & \text{if } v < 0. \end{cases}$$

We use SER (2.10) to control the sequence $\{\delta_n\}$ and use

$$D = \begin{pmatrix} I & 0 \\ 0 & 0 \end{pmatrix}$$

in (2.9).

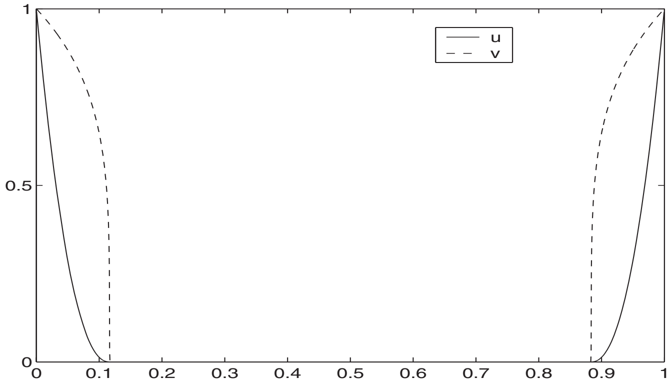

FIG. 5.1. *Solution.*

The reason we formulate the problem with DAE (rather than ODE) dynamics is that the pseudo-time variable should not be added to both equations in (5.1) but to only the first. The reason for this is that the true time-dependent system is

$$u_t = u_{zz} - \lambda \max(0, u)^p$$

and that the auxiliary variable v is used only to make the nonlinearity Lipschitz continuous. One might think that an ODE formulation would work equally well, but, in fact, the ODE formulation, which does not model the physics, failed to converge in our testing.

We discretize the problem with central differences, using a difference increment of δ_z. The nonsmooth nonlinearity is a substitution operator, and its generalized Jacobian is a set of diagonal matrices.

We report on several computations with $p = 0.1$ and $\lambda = 200$. This choice leads to a large "dead core" [2, 3], a region in which the solution vanishes. We plot the solution in Figure 5.1.

$\delta_0 = 1$ and $\delta_{max} = 10^6$ for all the computations. We terminate the nonlinear iteration when either

$$\|F(x_n)\|/\|F(x_0)\| < 10^{-13} \quad \text{or} \quad \|s_n\| < 10^{-10}, \tag{5.2}$$

where $s_n = x_{n+1} - x_n$. In the tables we see the superlinear convergence clearly in the reduction in the norms of the steps; this is consistent with the estimate $s_n = -e_n + o(\|e_n\|)$ which follows from local superlinear convergence. The superlinear convergence is less visible in the residual norms, because the generalized Jacobians become more ill-conditioned as the mesh is refined. The residual norms begin to stagnate after a reduction of 10^{12}.

5.1. Exact computation of the generalized Jacobian. For the results in this section we compute the generalized Jacobian analytically. If we let L_{δ_z} be the discretized Laplacian, we can write

$$F(x) = \begin{pmatrix} f(u,v) \\ g(u,v) \end{pmatrix} = \begin{pmatrix} -L_{\delta_z} u \\ u - v - \max(0,v)^{1/p} \end{pmatrix} + \begin{pmatrix} \lambda \\ 1 \end{pmatrix} \max(0, v). \tag{5.3}$$

In the above and in the discussion that follows, functions of vectors, $\max(0, v)^{1/p}$, for example, are understood to mean componentwise evaluation.

We use the known result for the scalar function $\max(0,v)$,

$$\partial \max(0,v) = \begin{cases} 0 & \text{if } v < 0, \\ [0,1] & \text{if } v = 0, \\ 1 & \text{if } v > 0, \end{cases}$$

to obtain

$$\partial F = \begin{pmatrix} -L_{\delta_z} & 0 \\ 1 & -1-(1/p)\max(0,v)^{(1-p)/p} \end{pmatrix} + \begin{pmatrix} 0 & \lambda \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 0 & 0 \\ 0 & \partial \max(0,v). \end{pmatrix} \tag{5.4}$$

The notation should be clear. The 2, 2 blocks in the matrices denote multiplication operators in the continuous case, and diagonal matrices in the discrete case. We use this notation because of its compactness and close connection to the original differential equation.

The calculations in this section use $V(x_n) \in \partial F(x_n)$. We may use any choice from the set-valued map $\partial \max(0,v)$ and we choose $V \in \partial F$ using

$$\chi(v) = \left\{ \begin{array}{ll} 0 & \text{if } v \leq 0, \\ 1 & \text{if } v > 0 \end{array} \right\} \in \partial \max(0,v).$$

Had we used $\chi(v) = 1$ when $v = 0$, then $\mu(v)$ would vanish when $\mu = 0$, leading to singularity of V_{vv}. Note that the global convergence result does not require that all elements of V_{vv} be nonsingular for all choices of $V \in \partial F$, only that we choose one for which it is. The local convergence result does require that all elements of ∂F be nonsingular, as they are.

In Figure 5.2 we plot the norms of the steps and nonlinear residuals together with the growth of δ for a mesh of width $\delta_z = 1/2048$. δ grows smoothly in the early phase of the iteration and reaches its maximum rapidly. The superlinear convergence is clearly visible in the curve for the norms of the steps. The Jacobian of the nonlinear residual has a condition number of $O(1/h^2)$, and hence the residual norm reflects the error less accurately.

5.2. Verification of the assumptions. We will now explore verification of Assumptions 4.1 and 4.2 for the case $h = 0$. The case $h \neq 0$ is similar, requiring only the addition of an $O(h)$ perturbation to ∂F. We have not verified part 2 of Assumption 4.2, though we have done numerical experiments that indicate its validity. F is clearly semismooth, and we are using $V \in \partial F$ for all x. So parts 1 and 3 in Assumption 4.2 hold trivially.

Let

$$V(x) = \begin{pmatrix} -L_{\delta_z} & 0 \\ 1 & -1-(1/p)\max(0,v)^{(1-p)/p} \end{pmatrix} + \begin{pmatrix} 0 & \lambda \\ 0 & 1 \end{pmatrix} \chi(v).$$

Since the set $S(\epsilon_G)$ is compact, $\|v\|$ is bounded on $S(\epsilon_G)$, which implies part 6 of Assumption 4.2.

Now V_{vv} is the operator of componentwise multiplication by

$$-\mu(v) = -1-(1/p)\max(0,v)^{(1-p)/p} + \chi(v).$$

This operator is negative semidefinite. To see this, note that

$$\mu(v) = 1+(1/p)\max(0,v)^{(1-p)/p} - \chi(v) = \left\{ \begin{array}{ll} (1/p)\max(0,v)^{(1-p)/p} & \text{if } v > 0, \\ 1 & \text{if } v \leq 0 \end{array} \right\} > 0.$$

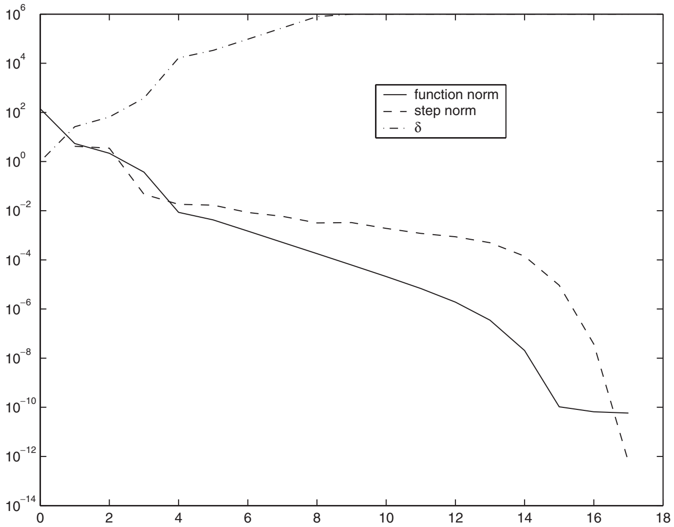

FIG. 5.2. *Analytic generalized Jacobian.*

To verify part 4 of Assumption 4.2, we observe that the smallest nonzero component of $v(t)$ is bounded away from zero. This follows from the boundary conditions on the differential equation and the compactness of $S(\epsilon_G)$. Hence

$$V_{vv}\eta = -\mu(v)\eta$$

has a uniformly bounded inverse, as assumed. We will now use part 4 of Assumption 4.2 in the verification of the remaining assumptions.

We now verify the bounds on the inverse, (4.1) in Assumption 4.1 and part 5 of Assumption 4.2. As part of that process, we will also verify the nonsingularity assumption, part 7 of Assumption 4.2.

We seek to solve

$$(D + \delta V)(\xi, \eta)^T = (\phi, \psi)^T,$$

which we write as two equations:

$$\begin{aligned} &(I - \delta L_{\delta_z})\xi + \lambda\chi(v)\eta = \phi, \\ &\delta\xi + \delta V_{vv}\eta = \psi. \end{aligned} \tag{5.5}$$

We may eliminate η by using the second equation in (5.5),

$$\eta = -V_{vv}^{-1}(\xi - \delta^{-1}\psi), \tag{5.6}$$

and hence

$$(I - \delta L_{\delta_z} - \lambda\chi(v)V_{vv}^{-1})\xi = \phi - \delta^{-1}\lambda\chi(v)V_{vv}^{-1}\psi. \tag{5.7}$$

Since $-\delta L_{\delta_z}$ is positive definite and $\delta, \lambda, \mu, \chi \geq 0$, we have

$$\|(I - \delta L_{\delta_z} - \lambda\chi(v)V_{vv}^{-1})^{-1}\| \leq \|(I - \delta L_{\delta_z})^{-1}\| \leq \|I\| = 1. \tag{5.8}$$

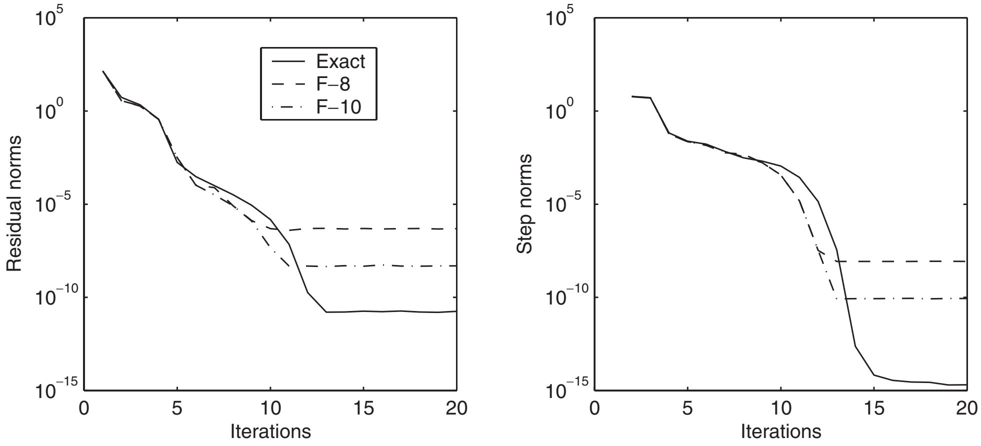

FIG. 5.3. *Norms of the steps and residuals.*

Hence we may solve for ξ, proving nonsingularity of $(D + \delta V)$.

The bound on V_{vv} and (5.8) imply

$$\|\xi\| \leq (\|\phi\| + \delta^{-1}\lambda M_V \|\psi\|). \tag{5.9}$$

Combining (5.9) with (5.6) completes the verification of part 5 of Assumption 4.2. To verify (4.1), we set $\psi = 0$ and use the second inequality in (5.8).

5.3. Computation of the generalized Jacobian by differences. For the results in this section we compute the generalized Jacobian with several choices of differences. The results were similar for all the meshes. In Figure 5.3 we plot residual and step norm histories for

- analytic generalized Jacobian (Exact),
- forward differences, increment 10^{-8} (F-8), and
- forward differences, increment 10^{-10} (F-10)

for a mesh of width $\delta_z = 1/2048$ and 20 iterations. In this way we can clearly see the point at which the iteration stagnates. As we predicted in section 3.3, the iteration is more accurate when the difference increment is $10^{-10} \approx \epsilon^{2/3}$ than it is with the standard choice of $10^{-8} \approx \epsilon^{1/2}$.

5.4. Mesh dependence and nested iteration. We used the analytic ∂F (5.4) in the computations reported in this section.

In Figure 5.4 we plot the progress of the iteration for mesh sizes of $1/128, 1/512$, and $1/2048$, terminating the iteration when $\|s\| < 10^{-13}$. In this way we can examine the dependence of the convergence on the mesh width. While the convergence in the early phase is identical for the three meshes and superlinear in the terminal phase, the global convergence becomes slower as the mesh is refined.

Nested iteration or grid sequencing means solving the problem to high precision on a coarse mesh, interpolating to a finer mesh in such a way that the interpolation error can be corrected with a few (e.g., one) iterations and continuing this until one has a solution on a target, finest mesh. We set $\delta = 10^6$ for the finer meshes, under the assumption that we are in the locally convergent phase of the iteration.

For this example, one would hope not only to eliminate the mesh-dependency in the iteration history that one sees in Figure 5.4, but also to approximate the solution up to truncation error at each level.

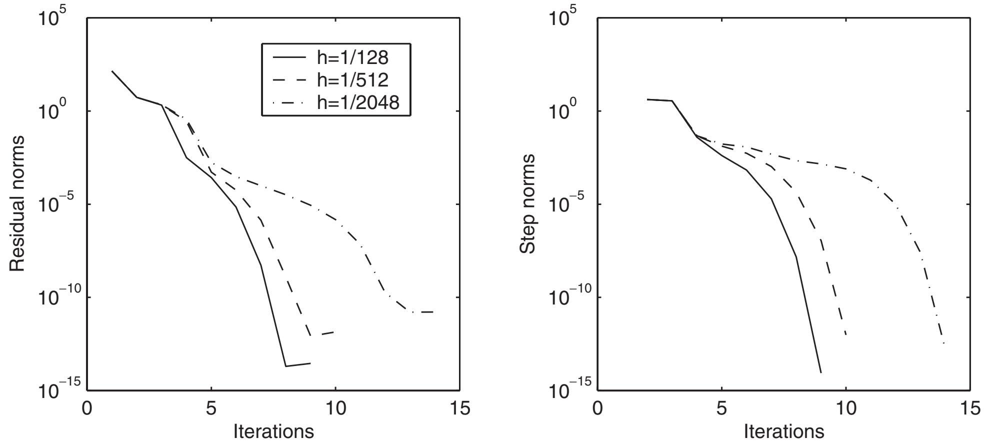

FIG. 5.4. *Mesh-dependence of convergence.*

TABLE 5.1
Step norms: $p = 0.1$, nested iteration.

3	6.59e-05		3.83e-09			1.76e-11
4	2.73e-05					
5	9.74e-08					

This was a successful strategy. However, the results must be interpreted in light of the continuity properties of the solution. $u^* \in C^2[0,1]$, and hence $u^* \in H^2[0,1]$. However, if $p < 1/2$, $v^* = (u^*)^p \notin H^2[0,1]$. This means that linear interpolation will not approximate v^* to second order if $p < 1/2$. To partially address this, we interpolate u from the coarse to fine mesh with linear interpolation and then compute v as

$$v = \max(0, u)^p.$$

This give us a better initial approximation of v on the finer mesh than directly interpolating v, but not, as Table 5.1 shows, a second order accurate one.

In Tables 5.1 and 5.2 we report the residual and step norms on a sequence of meshes $\{2^{-n}\}_{n=6}^{11}$ for $p = 0.1$ and $p = 0.5$. The initial steps at each mesh reflect both the error in the initial iterate and the truncation error in the interpolation.

The iterations for both values of p show that we have recovered mesh independence in the sense that the iteration requires a roughly constant number of steps to terminate at each level. The table for $p = 0.5$ clearly shows second order convergence. The interpolation error for $p = 0.1$ is visible in the sizes of the initial steps.

Acknowledgments. The authors thank Xiaojun Chen for several useful conversations. We also appreciate the efforts of Liqun Qi and two anonymous referees in making us aware of [29] and clearing up several of our misconceptions about semismooth functions.

NUMERICAL PERIODIC NORMALIZATION FOR CODIM 1 BIFURCATIONS OF LIMIT CYCLES*

YU. A. KUZNETSOV[†], W. GOVAERTS[‡], E. J. DOEDEL[§], AND A. DHOOGE[‡]

Abstract. Explicit computational formulas for the coefficients of the periodic normal forms for all codim 1 bifurcations of limit cycles in generic autonomous ODEs are derived. They include second-order coefficients for the fold (limit point) bifurcation, as well as third-order coefficients for the flip (period-doubling) and Neimark–Sacker (torus) bifurcations. The formulas are independent of the dimension of the phase space and involve solutions of certain boundary-value problems on the interval $[0,T]$, where T is the period of the critical cycle, as well as multilinear functions from the Taylor expansion of the right-hand sides near the cycle. The formulas allow us to distinguish between sub- and supercritical bifurcations, in agreement with earlier asymptotic expansions of the bifurcating solutions. Our formulation makes it possible to use robust numerical boundary-value algorithms based on orthogonal collocation, rather than shooting techniques, which greatly expands its applicability. The actual implementation is described in detail. We include three numerical examples, in which codim 2 singularities are detected along branches of codim 1 bifurcations of limit cycles as zeros of the periodic normal form coefficients.

1. Introduction.

Isolated periodic orbits (limit cycles) of smooth differential equations

$$\dot{u} = f(u,\alpha), \quad u \in \mathbb{R}^n, \ \alpha \in \mathbb{R}^m, \tag{1.1}$$

play an important role in applications. In generic systems of the form (1.1) depending on one control parameter (i.e., with $m = 1$) a hyperbolic limit cycle exists for an open interval of parameter values α. At a boundary of such an interval, the limit cycle may not exist, degenerating into an equilibrium or an orbit homoclinic to an equilibrium or another nonhyperbolic limit cycle (see, for example, [3]). We do not consider such cases here, instead focusing on those where the cycle does exist at the boundary parameter values but loses its hyperbolicity due to the presence of a nontrivial multiplier μ, with $|\mu| = 1$.

The codim 1 bifurcations of limit cycles in generic systems (1.1) are well understood (see, for example, [8, 10, 3]). Let $u_0(t)$ be a periodic solution (with minimal period) corresponding to a limit cycle Γ of (1.1). The standard approach to the theoretical and numerical analysis of local bifurcations of limit cycles is based on *Poincaré maps*: Given a transversal section Σ to Γ at $u_0(0)$, such a map assigns to each point y of Σ close to $u_0(0)$ another point $\mathcal{P}(y,\alpha)$, where the orbit of (1.1) starting

at y intersects Σ again close to $u_0(0)$. In local coordinates in Σ, the Poincaré map will be represented by a smooth map $\mathcal{P} : \mathbb{R}^{n-1} \times \mathbb{R}^m \to \mathbb{R}^{n-1}$. The cycle corresponds to a fixed point y_0 of $\mathcal{P}(\cdot, \alpha)$; the eigenvalues of its linearization at the fixed point are the nontrivial multipliers of the periodic solution. Once the Poincaré map is introduced, the theory of local bifurcations of maps can be applied.

It is well known (see, for example, [8, 10, 1] for the general theory and [3] for computational formulas) that in generic smooth one-parameter families of maps

$$y \mapsto \mathcal{P}(y, \alpha), \quad y \in \mathbb{R}^{n-1},\ \alpha \in \mathbb{R}^1, \tag{1.2}$$

only the following three bifurcations of fixed points occur:

(1) *The fold.* The fixed point y_0 has a simple eigenvalue $\lambda_1 = 1$ and no other eigenvalues on the unit circle, while the restriction of (1.2) to a one-dimensional center manifold $\mathcal{W}^c(y_0)$ at the critical parameter value has the form $\xi \mapsto \xi + \tilde{b}\xi^2 + O(\xi^3)$, where $\tilde{b} \neq 0$. At the critical parameter value, two fixed points coalesce. This bifurcation is often called a *saddle-node bifurcation*, a *fold*, or a *limit point (LP)*, since two periodic solutions of (1.1) collide and disappear when the parameter passes the critical value. If $\mathcal{A}v = \mathcal{P}_y v$ and $\mathcal{B}(u, v) = \mathcal{P}_{yy}[u, v]$ are evaluated at the critical fixed point y_0, then

$$\tilde{b} = \frac{1}{2}\langle q^*, \mathcal{B}(q, q)\rangle, \tag{1.3}$$

where $\mathcal{A}q = q$, $\mathcal{A}^{\mathrm{T}}q^* = q^*$, and $\langle q^*, q\rangle = 1$. Here and in what follows, $\langle u, v\rangle = u^{\mathrm{H}}v = \bar{u}^{\mathrm{T}}v$ is the standard scalar product in an appropriate complex (or real) finite-dimensional vector space; here, $\mathbb{R}^{n-1}$. It should also be noted that the coefficient $\tilde{b}$ is not uniquely defined but depends on the normalization of q. A similar remark holds for all other normal form coefficients.

(2) *The flip.* The fixed point y_0 has a simple eigenvalue $\lambda_1 = -1$ and no other eigenvalues on the unit circle, while the restriction of (1.2) to a one-dimensional center manifold $\mathcal{W}^c(y_0)$ at the critical parameter value can be transformed to the normal form $\xi \mapsto -\xi + \tilde{c}\xi^3 + O(\xi^4)$, where $\tilde{c} \neq 0$. For nearby parameter values, a cycle of period 2 bifurcates from the fixed point. This is a *period-doubling (PD)* of the periodic solution of (1.1); i.e., there are nearby periodic solutions of approximately double (minimal) period. If $\mathcal{C}(u, v, w) = \mathcal{P}_{yyy}[u, v, w]$ is evaluated at y_0, then

$$\tilde{c} = \frac{1}{6}\langle p^*, \mathcal{C}(p, p, p) + 3\mathcal{B}(p, (I_{n-1} - \mathcal{A})^{-1}\mathcal{B}(p, p))\rangle, \tag{1.4}$$

where I_{n-1} is the $(n-1) \times (n-1)$ identity matrix, $\mathcal{A}p = -p$, $\mathcal{A}^{\mathrm{T}}p^* = -p^*$, and $\langle p^*, p\rangle = 1$.

(3) *The Neimark–Sacker (NS) bifurcation.* The fixed point y_0 has simple critical eigenvalues $\lambda_{1,2} = e^{\pm i\theta}$ and no other eigenvalues on the unit circle. Assume that

$$e^{iq\theta} - 1 \neq 0, \quad q = 1, 2, 3, 4 \ \text{ (no strong resonances)}.$$

Then the restriction of (1.2) to a two-dimensional center manifold $\mathcal{W}^c(y_0)$ at the critical parameter value can be transformed to the normal form $\eta \mapsto \eta e^{i\theta}(1 + \tilde{d}|\eta|^2) + O(|\eta|^4)$, where η is a complex variable and $\tilde{d}$ is a complex number. Further assume that Re $\tilde{d} \neq 0$. Under the above assumptions, a unique *closed invariant curve* around the fixed point appears when the parameter crosses the critical value. This curve corresponds to an *invariant torus*, on which the flow of (1.1) contains periodic or quasi-periodic motions. One has the following expression for $\tilde{d}$:

$$\tilde{d} = \frac{1}{2}e^{-i\theta}\langle v^*, \mathcal{C}(v,v,\bar{v}) + 2\mathcal{B}(v,(I_{n-1}-\mathcal{A})^{-1}\mathcal{B}(v,\bar{v})) + \mathcal{B}(\bar{v},(e^{2i\theta}I_{n-1}-\mathcal{A})^{-1}\mathcal{B}(v,v))\rangle, \tag{1.5}$$

where $\mathcal{A}v = e^{i\theta}v,\ \mathcal{A}^{\mathrm{T}}v^* = e^{-i\theta}v^*$, and $\langle v^*, v\rangle = 1$.

Although existing software (e.g., CONTENT [11]) can compute the normal form coefficients at codim 1 bifurcations of fixed points of general maps using (1.3)–(1.5), application of these capabilities to limit cycle analysis has been limited. One reason for this is the necessity to compute the Poincaré map (1.2) and its derivatives $(\mathcal{A}, \mathcal{B}, \mathcal{C}, \mathcal{D}, \dots)$ numerically. Finite differences work for low-dimensional nonstiff systems (1.1), where they allow the approximation of the Jacobian matrix $\mathcal{A} = \mathcal{P}_y$ with reasonable accuracy. However, this approach fails when the cycle has multipliers with a very big or very small modulus, i.e., when (1.1) is stiff. In general, finite-difference approximations of higher-order partial derivatives (i.e., $\mathcal{B}, \mathcal{C}, \mathcal{D}, \dots$) have very low accuracy due to loss of significant digits and are therefore unreliable. Better results for computing $\mathcal{B}$ and higher-order derivative tensors can be achieved by simultaneous numerical integration of the periodic solution and the corresponding variational equations over the period.

This method has been successfully used in [6] to compute normal form coefficients of the Poincaré map at the fold-flip bifurcation in a four-dimensional atmosphere circulation model. An interesting alternative to numerical integration of the variational equations is to compute the higher-order derivatives of the Poincaré map $\mathcal{P}$ by *automatic differentiation* [12] of the (for example, C-) code used to compute the Poincaré map; see [13, 14]. Both approaches, however, rely on the possibility of accurately finding the periodic solution by shooting, which is not always the case.

There are at least two approaches to the analysis of the limit cycle bifurcations that are not directly based on the Poincaré map and its derivatives. Since it is known which periodic solutions can bifurcate at generic codim 1 bifurcations of limit cycles, one can compute the Taylor series for the period $T(\varepsilon)$, for the corresponding parameter $\alpha(\varepsilon)$, and for the bifurcating solution itself, as functions of the solution amplitude ε. The solvability of the linear systems is guaranteed by the *Fredholm alternative*. This approach, which is conceptually similar to the *Lyapunov–Schmidt method*, has been successfully applied to all codim 1 bifurcations of limit cycles in [5, Chapter XI]. The resulting asymptotic expressions use the derivatives of the right-hand side of (1.1) with respect to u and α and involve solutions to linear boundary-value problems (BVPs) (on the interval $[0,T]$ in the LPC (limit point of cycles) and NS cases and on the interval $[0,2T]$ for the PD bifurcation). They allow one to distinguish between sub- and supercritical bifurcations. However, these formulas are rather involved—in particular, for the NS case, where one has to distinguish between various subharmonic and quasi-periodic solutions—and to our knowledge they have not been implemented in bifurcation software.

There is another theoretical approach [8] for the analysis of limit cycle bifurcations in (1.1), which avoids the Poincaré map reduction. First, in a neighborhood of Γ in $W^c(\Gamma)$, *normal coordinates* can be chosen so that the restricted system (1.1) becomes a nonautonomous T-*periodic* system in $\mathbb{R}^{n-1}$. This periodic system can be considered as an autonomous system with one cyclic variable (mod T). Near the bifurcation, this system can be restricted to an (n_c+1)-dimensional invariant *center manifold*

$W^c(\Gamma)$, thus giving a periodic n_c-dimensional system of ODEs. One can then apply (in general, $2T$-) periodic coordinate transformations to this system and write it as the sum of an autonomous n_c-dimensional normal form and higher-order periodic terms. The autonomous part of this *periodic normal form* allows one to study local and global bifurcations of (1.1) near the critical cycle. This approach is very useful for the theoretical analysis of limit cycle bifurcations (see [8] and [4] for normal forms for some codim 2 cases).

Since the late 1980s, an improvement of the latter approach is known [15], which combines the computation of the center manifold with the normalization of the ODEs restricted to this manifold. This technique leads to simple formulas for the computation of normal form coefficients in two codim 1 cases of equilibrium bifurcations in ODEs (derived earlier with the Lyapunov–Schmidt method), as well as in all five codim 2 cases (see [16]). Although a similar normalization technique was introduced in [17] for time-periodic systems and in [18, 7] for limit cycle bifurcations, it has remained mainly a theoretical tool up to now. There are no numerical algorithms for the computation of the coefficients of the normal forms on $W^c(\Gamma)$ that are based on this approach and that have been implemented in available bifurcation software.

Below we derive a powerful numerical normalization tool based on this technique. In a sense, we combine the periodic normal forms derived in [18] with the Fredholm alternative used in [5]. It should be noted that the idea to apply Fredholm's solvability condition to compute the normal form coefficients for time-periodic systems can be traced back to [17]. The main difference between our approach and that of [17] and [18] is that we avoid Fourier series solutions of the linear BVPs, instead solving them numerically using orthogonal collocation for discretization as in AUTO [19]. This leads to simple and explicit algorithms for the normal form coefficients. A further simplification occurs because we consider only the critical normal forms, and therefore we do not need derivatives of $f(u, \alpha)$ with respect to α. Our results fully agree with the asymptotic expansions for the bifurcating solutions derived in [5].

This paper is organized as follows. In section 2 we fix notation and formulate the periodic normalization on the center manifold. Then we apply this technique to derive explicit formulas to compute the critical normal form coefficients for fold, PD, and torus bifurcations of limit cycles. The formulas are independent of the dimension of the phase space and involve solutions to certain BVPs on the interval $[0, T]$, where T is the period of the critical cycle, as well as multilinear functions from the Taylor expansion of the right-hand sides of (1.1) near the cycle. In section 3 we show that our algorithms fit very well into the BVP-collocation framework of existing continuation software such as AUTO [19], CONTENT [11], and MATCONT [20]. Three numerical examples are given in section 4. Future work is discussed in section 5.

2. Periodic normalization on the center manifold.

Write (1.1) at the critical parameter values as

$$\dot{u} = F(u), \tag{2.1}$$

and suppose that it has a periodic solution $u_0(t) = u_0(t + T)$, where $T > 0$ is its (minimal) period. Develop $F(u_0(t) + v)$ into the Taylor series

$$F(u_0(t) + v) = F(u_0(t)) + A(t)v + \frac{1}{2}B(t; v, v) + \frac{1}{6}C(t; v, v, v) + O(\|v\|^4), \tag{2.2}$$

where

$$A(t)v = F_u(u_0(t))v, \quad B(t, v, v) = F_{uu}(u_0(t))[v, v], \quad C(t; v, v, v) = F_{uuu}(u_0(t))[v, v, v].$$

The multilinear forms A, B, and C are periodic in t with period T.

Consider the initial-value problem for the fundamental matrix solution $Y(t)$, namely,

$$\frac{dY}{dt} = A(t)Y, \quad Y(0) = I_n, \tag{2.3}$$

where I_n is the $n \times n$ identity matrix. The monodromy matrix $M = Y(T)$ always has a "trivial" eigenvalue $\mu_n = 1$. The cycle is hyperbolic if there are no other eigenvalues with $|\mu| = 1$ and is nonhyperbolic otherwise.

The cycle has a fold bifurcation if the eigenvalue $\mu_1 = 1$ of $Y(T)$ corresponds to a two-dimensional Jordan block and if there are no other critical eigenvalues of the monodromy matrix. The cycle has a period-doubling (flip) bifurcation if $\mu_1 = -1$ is simple and is the only nontrivial critical eigenvalue of $Y(T)$. Finally, at an NS (torus) bifurcation, there is a simple pair of nonreal eigenvalues $\mu_{1,2} = e^{\pm i\theta}$, such that $e^{iq\theta} \neq 1$ for $q = 1, 2, 3, 4$ (no strong resonances), and $Y(T)$ has no further critical multipliers other than 1. We will refer to these conditions as the *spectral assumptions*.

To describe the periodic normal forms for the three critical cases mentioned above, we parametrize the corresponding (n_c+1)-dimensional center manifold $W^c(\Gamma)$ near Γ by (τ, ξ), where $\tau \in [0, T]$ or $[0, 2T]$, and ξ is a real or complex coordinate, depending on the bifurcation. It follows from [18] that it is possible to select the ξ-coordinates so that the restriction of (2.1) to the corresponding critical center manifold $W^c(\Gamma)$ will take one of the following *periodic normal forms*.

The periodic normal form at the LPC bifurcation is

$$\left\{ \begin{array}{rcl} \dfrac{d\tau}{dt} & = & 1 - \xi + a\xi^2 + \cdots, \\ \dfrac{d\xi}{dt} & = & b\xi^2 + \cdots, \end{array} \right. \tag{2.4}$$

where $\tau \in [0, T]$, ξ is a real coordinate on $W^c(\Gamma)$ that is transverse to Γ, $a, b \in \mathbb{R}$, and the dots denote nonautonomous T-periodic $O(\xi^3)$-terms. One can show that b and $\tilde{b}$ vanish together, where $\tilde{b}$ is obtained via the Poincaré map reduction and given by (1.3).

The periodic normal form at the PD bifurcation is

$$\left\{ \begin{array}{rcl} \dfrac{d\tau}{dt} & = & 1 + a\xi^2 + \cdots, \\ \dfrac{d\xi}{dt} & = & c\xi^3 + \cdots, \end{array} \right. \tag{2.5}$$

where $\tau \in [0, 2T]$, ξ is a real coordinate on $W^c(\Gamma)$ that is transverse to Γ, $a, c \in \mathbb{R}$, and the dots denote nonautonomous $2T$-periodic $O(\xi^4)$-terms. The coefficient c determines the stability of the critical cycle; if $c \neq 0$, then sign c = sign $\tilde{c}$, where $\tilde{c}$ is obtained via the Poincaré map reduction and given by (1.4).

In the absence of strong resonances, the periodic normal form at the NS bifurcation is

$$\left\{ \begin{array}{rcl} \dfrac{d\tau}{dt} & = & 1 + a|\xi|^2 + \cdots, \\ \dfrac{d\xi}{dt} & = & \dfrac{i\theta}{T}\xi + d\xi|\xi|^2 + \cdots, \end{array} \right. \tag{2.6}$$

where $\tau \in [0,T]$, ξ is a complex coordinate on $W^c(\Gamma)$ that is complementary to τ, $a \in \mathbb{R}, d \in \mathbb{C}$, and the dots denote nonautonomous T-periodic $O(|\xi|^4)$-terms. If Re $d \neq 0$, then sign(Re d) = sign(Re $\tilde{d}$), where $\tilde{d}$ is given by (1.5), obtained via the Poincaré map reduction.

In view of the above, we can assume that a parametrization of the center manifold $W^c(\Gamma)$ has been selected so that the restriction of (2.1) to this manifold has one of the normal forms (2.4), (2.5), or (2.6). The Taylor expansions of T- or $2T$-periodic unknown functions involved in these parametrizations can be found by solving appropriate BVPs on $[0,T]$ or $[0,2T]$, respectively, so that (2.1) restricted to $W^c(\Gamma)$ will have the corresponding periodic normal form. The coefficients a, b, and c arise from the solvability conditions for the BVPs as integrals of scalar products over $[0,T]$, involving quadratic and cubic terms of (2.1) near the periodic solution u_0, as well as the critical eigenfunctions.

The following (or similar) construction will often be used below. Denote by $\mathcal{C}^k([a,b],\mathbb{R}^n)$ the space of k times continuously differentiable functions on $[a,b]$, with values in $\mathbb{R}^n$. Let $\varphi \in \mathcal{C}^1([0,T],\mathbb{R}^n)$ be the only solution of the BVP

$$\left\{\begin{array}{rcl} \dot{\varphi}(\tau) - A(\tau)\varphi(\tau) & = & 0,\ \tau \in [0,T], \\ \varphi(T) - \varphi(0) & = & 0, \\ \int_0^T \langle \varphi(\tau), \varphi(\tau)\rangle d\tau - 1 & = & 0, \end{array}\right.$$

and let $\varphi^* \in \mathcal{C}^1([0,T],\mathbb{R}^n)$ be a nontrivial solution of the adjoint BVP

$$\left\{\begin{array}{rcl} \dot{\varphi}^*(\tau) + A^{\mathrm{T}}(\tau)\varphi^*(\tau) & = & 0,\ \tau \in [0,T], \\ \varphi^*(T) - \varphi^*(0) & = & 0. \end{array}\right. \tag{2.7}$$

If $h \in \mathcal{C}^1([0,T],\mathbb{R}^n)$ is a solution of the singular BVP

$$\left\{\begin{array}{rcl} \dot{h}(\tau) - A(\tau)h(\tau) & = & g(\tau),\ \tau \in [0,T], \\ h(T) - h(0) & = & 0, \end{array}\right. \tag{2.8}$$

then $g \in \mathcal{C}^1([0,T],\mathbb{R}^n)$ satisfies

$$\int_0^T \langle \varphi^*(\tau), g(\tau)\rangle \, d\tau = 0. \tag{2.9}$$

Indeed, taking into account (2.7), we see that this integral equals

$$\int_0^T \langle \varphi^*(\tau), \dot{h}(\tau) - A(\tau)h(\tau)\rangle \, d\tau = -\int_0^T \langle \dot{\varphi}^*(\tau) + A^{\mathrm{T}}(\tau)\varphi^*(\tau), h(\tau)\rangle \, d\tau = 0.$$

We will refer to (2.9) as the *Fredholm solvability condition*. If (2.9) holds, then the problem (2.8) has a unique solution h, satisfying

$$\int_0^T \langle \varphi^*(\tau), h(\tau)\rangle \, d\tau = 0.$$

2.1. The fold bifurcation.

The two-dimensional critical center manifold $W^c(\Gamma)$ at the LPC bifurcation can be parametrized locally by (τ, ξ) as

$$u = u_0(\tau) + \xi v(\tau) + H(\tau, \xi), \quad \tau \in [0,T],\ \xi \in \mathbb{R}, \tag{2.10}$$

where H satisfies $H(T,\xi)=H(0,\xi)$ and has the Taylor expansion

$$H(\tau,\xi)=\frac{1}{2}h_2(\tau)\xi^2+O(\xi^3), \tag{2.11}$$

with $h_2(T)=h_2(0)$, while

$$\left\{\begin{array}{rcl} \dot{v}(\tau)-A(\tau)v(\tau)-F(u_0(\tau)) &=& 0,\ \tau\in[0,T],\\ v(T)-v(0) &=& 0,\\ \int_0^T\langle v(\tau),F(u_0(\tau))\rangle d\tau &=& 0. \end{array}\right. \tag{2.12}$$

The function v exists due to Lemma 2 of [18]. Note that (2.12) implies

$$\int_0^T\langle\varphi^*(\tau),F(u_0(\tau))\rangle\, d\tau=0 \tag{2.13}$$

for any φ^* satisfying (2.7). Moreover, due to the spectral assumptions at the LPC-point, we can also assume that

$$\int_0^T\langle\varphi^*(\tau),v(\tau)\rangle d\tau=1. \tag{2.14}$$

Therefore, φ^* is the unique solution of the BVP

$$\left\{\begin{array}{rcl} \dot{\varphi}^*(\tau)+A^{\mathrm{T}}(\tau)\varphi^*(\tau) &=& 0,\ \tau\in[0,T],\\ \varphi^*(T)-\varphi^*(0) &=& 0,\\ \int_0^T\langle\varphi^*(\tau),v(\tau)\rangle d\tau-1 &=& 0. \end{array}\right. \tag{2.15}$$

The function $h_2(\tau)$ can be found by solving an appropriate BVP, assuming that (2.1) restricted to $W^c(\Gamma)$ has the periodic normal form (2.4). The coefficient b arises from the solvability condition for the BVP as an integral over the interval $[0,T]$ of scalar products. Specifically, these scalar products involve the quadratic terms of (1.1) near the periodic solution u_0, the (generalized) eigenfunction v, and the adjoint eigenfunction φ^* defined by (2.15).

Substitute (2.10) into (2.1), using (2.2), (2.4), and (2.11), as well as

$$\frac{du}{dt}=\frac{\partial u}{\partial\xi}\frac{d\xi}{dt}+\frac{\partial u}{\partial\tau}\frac{d\tau}{dt}.$$

Collecting the ξ^0-terms in the resulting equation, we get the identity

$$\dot{u}_0=F(u_0),$$

where u_0 is the periodic solution of (2.1).

The ξ^1-terms provide another identity, namely,

$$\dot{v}-A(\tau)v-\dot{u}_0=0,$$

due to (2.12).

Finally, collecting the ξ^2-terms, we obtain the equation for h_2,

$$\dot{h}_2-A(\tau)h_2=B(\tau;v,v)-2a\dot{u}_0+2\dot{v}-2bv, \tag{2.16}$$

to be solved in the space of vector-functions on $[0,T]$ satisfying $h_2(T) = h_2(0)$. The differential operator $\frac{d}{d\tau} - A(\tau)$ is singular in this space, with $\dot{u}_0$ as the eigenfunction corresponding to zero eigenvalue. The null-eigenfunction φ^* of the adjoint operator $-\frac{d}{d\tau} - A^{\mathrm{T}}(\tau)$ is defined by (2.15). Thus, the Fredholm solvability condition implies that

$$\int_0^T \langle \varphi^*(\tau), B(\tau; v(\tau), v(\tau)) - 2a\dot{u}_0(\tau) + 2\dot{v}(\tau) - 2bv(\tau)\rangle \, d\tau = 0.$$

Using (2.13) and (2.14), we get the expression

$$b = \frac{1}{2}\int_0^T \langle \varphi^*(\tau), B(\tau; v(\tau), v(\tau)) + 2A(\tau)v(\tau)\rangle \, d\tau. \tag{2.17}$$

Here v and φ^* are defined by (2.12) and (2.15), respectively. Therefore, the critical coefficient b in the periodic normal form for the LPC bifurcation has been computed. The bifurcation is nondegenerate if $b \neq 0$. Note that the coefficient a does not enter into (2.17) due to (2.13).

2.2. The period-doubling bifurcation. The two-dimensional critical center manifold $W^c(\Gamma)$ at the PD bifurcation can be parametrized locally by (τ, ξ) as

$$u = u_0(\tau) + \xi w(\tau) + H(\tau, \xi), \quad \tau \in [0, 2T], \ \xi \in \mathbb{R}, \tag{2.18}$$

where the function H satisfies $H(2T, \xi) = H(0, \xi)$. It has the Taylor expansion

$$H(\tau, \xi) = \frac{1}{2}h_2(\tau)\xi^2 + \frac{1}{6}h_3(\tau)\xi^3 + O(\xi^4), \tag{2.19}$$

with $h_j(2T) = h_j(0)$, while

$$w(\tau) = \begin{cases} v(\tau), & \tau \in [0,T], \\ -v(\tau - T), & \tau \in [T, 2T], \end{cases} \tag{2.20}$$

with

$$\left\{ \begin{array}{rcl} \dot{v}(\tau) - A(\tau)v(\tau) & = & 0, \ \tau \in [0,T], \\ v(T) + v(0) & = & 0, \\ \int_0^T \langle v(\tau), v(\tau)\rangle d\tau - 1 & = & 0. \end{array} \right. \tag{2.21}$$

The function v exists due to Lemma 5 of [18].

The parametrization (2.18) provides a two-cover of $W^c(\Gamma)$ that is locally diffeomorphic to the Möbius band (see Figure 2.1).

The functions $h_2(\tau)$ and $h_3(\tau)$ can be found by solving appropriate BVPs, assuming that (2.1) restricted to $W^c(\Gamma)$ has the periodic normal form (2.5). The coefficients a and c arise from the solvability conditions for the BVPs as integrals of scalar products over the interval $[0,T]$. Specifically, these scalar products involve the quadratic and cubic terms of (1.1) near the periodic solution u_0, the eigenfunction v, and a similar adjoint eigenfunction v^* satisfying

$$\left\{ \begin{array}{rcl} \dot{v}^*(\tau) + A^{\mathrm{T}}(\tau)v^*(\tau) & = & 0, \ \tau \in [0,T], \\ v^*(T) + v^*(0) & = & 0, \\ \int_0^T \langle v^*(\tau), v(\tau)\rangle d\tau - 1/2 & = & 0. \end{array} \right. \tag{2.22}$$

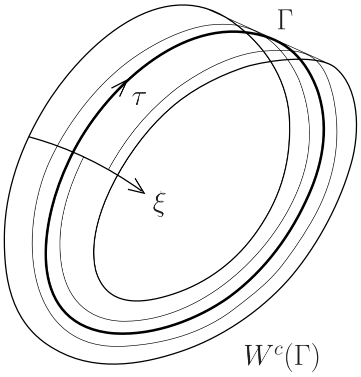

FIG. 2.1. *Center manifold $W^c(\Gamma)$ at the PD bifurcation.*

Similarly to (2.20), define

$$w^*(\tau) = \begin{cases} v^*(\tau), & \tau \in [0,T], \\ -v^*(\tau - T), & \tau \in [T, 2T]. \end{cases} \tag{2.23}$$

Note that

$$\int_0^{2T} \langle w^*(\tau), w(\tau)\rangle d\tau = 1. \tag{2.24}$$

To derive the normal form coefficients, we proceed as in section 2.1, namely, we substitute (2.18) into (2.1) and use (2.2), as well as (2.5) and (2.19).

Collecting the ξ^0-terms in the resulting equation, we get the identity

$$\dot{u}_0 = F(u_0),$$

where u_0 is the T-periodic solution of (2.1).

The ξ^1-terms provide the identity

$$\dot{w} = A(\tau)w,$$

due to (2.20) and (2.21).

Collecting the ξ^2-terms, we obtain the equation for h_2,

$$\dot{h}_2 - A(\tau)h_2 = B(\tau; w, w) - 2a\dot{u}_0, \tag{2.25}$$

to be solved in the space of functions on $[0, 2T]$ satisfying $h_2(2T) = h_2(0)$. In this space, the differential operator $\frac{d}{d\tau} - A(\tau)$ is singular with two linearly independent null-functions: $\psi = \dot{u}_0$ and w.

Thus, two Fredholm solvability conditions are involved, namely,

$$\int_0^{2T} \langle w^*(\tau), B(\tau; w(\tau), w(\tau)) - 2a\dot{u}_0(\tau)\rangle \, d\tau = 0,$$

which holds automatically for any a, due to (2.23) and the T-periodicity of the right-hand side of (2.25), and

$$\int_0^{2T} \langle \psi^*(\tau), B(\tau; w(\tau), w(\tau)) - 2a\dot{u}_0(\tau)\rangle \, d\tau = 0,$$

where ψ^* satisfies

$$\left\{ \begin{array}{rcl} \dot{\psi}^*(\tau) + A^{\mathrm{T}}(\tau)\psi^*(\tau) & = & 0, \ \tau \in [0,T], \\ \psi^*(T) - \psi^*(0) & = & 0, \\ \int_0^T \langle \psi^*(\tau), F(u_0(\tau)) \rangle \, d\tau - 1/2 & = & 0, \end{array} \right. \tag{2.26}$$

and is extended to $[T, 2T]$ by periodicity. Note that $\int_0^{2T} \langle \psi^*(\tau), F(u_0(\tau)) \rangle \, d\tau \neq 0$, since 0 is a semisimple eigenvalue of the differential operator $\frac{d}{d\tau} - A(\tau)$. This leads to the expression

$$a = \frac{1}{2} \int_0^{2T} \langle \psi^*(\tau), B(\tau; w(\tau), w(\tau)) \rangle \, d\tau$$

or, equivalently,

$$a = \int_0^{T} \langle \psi^*(\tau), B(\tau; v(\tau), v(\tau)) \rangle \, d\tau, \tag{2.27}$$

where v and ψ^* are defined by (2.21) and (2.26), respectively.

With a defined in this way, let h_2 be the unique solution of (2.25) in the space of functions on $[0, 2T]$ satisfying $h_2(0) = h_2(2T)$, as well as two orthogonality conditions:

$$\int_0^{2T} \langle w^*(\tau), h_2(\tau) \rangle \, d\tau = 0,$$

which holds automatically, due to the T-periodicity of h_2 ($h_2(0) = h_2(T)$), and

$$\int_0^{2T} \langle \psi^*(\tau), h_2(\tau) \rangle \, d\tau = 0,$$

which is equivalent to

$$\int_0^{T} \langle \psi^*(\tau), h_2(\tau) \rangle \, d\tau = 0.$$

Thus h_2 is the unique solution of the BVP

$$\left\{ \begin{array}{rcl} \dot{h}_2(\tau) - A(\tau)h_2(\tau) - B(\tau; v(\tau), v(\tau)) + 2aF(u_0(\tau)) & = & 0, \ \tau \in [0,T], \\ h_2(T) - h_2(0) & = & 0, \\ \int_0^T \langle \psi^*(\tau), h_2(\tau) \rangle \, d\tau & = & 0, \end{array} \right. \tag{2.28}$$

extended by periodicity to $[T, 2T]$. Collecting the ξ^3-terms, we get the equation for h_3,

$$\dot{h}_3 - A(\tau)h_3 = C(\tau; w, w, w) + 3B(\tau; w, h_2) - 6a\dot{w} - 6cw, \tag{2.29}$$

which again must be solved in the space of functions on $[0, 2T]$ satisfying $h_3(2T) = h_3(0)$. Its solvability implies

$$\int_0^{2T} \langle w^*(\tau), C(\tau; w(\tau), w(\tau), w(\tau)) + 3B(\tau; w(\tau), h_2(\tau)) - 6a\dot{w}(\tau) - 6cw(\tau) \rangle \, d\tau = 0.$$

Taking into account (2.24), we obtain

$$c = \frac{1}{6}\int_0^{2T} \langle w^*(\tau), C(\tau; w(\tau), w(\tau), w(\tau)) + 3B(\tau; w(\tau), h_2(\tau)) - 6aA(\tau)w(\tau)\rangle \, d\tau$$

and finally,

$$c = \frac{1}{3}\int_0^{T} \langle v^*(\tau), C(\tau; v(\tau), v(\tau), v(\tau)) + 3B(\tau; v(\tau), h_2(\tau)) - 6aA(\tau)v(\tau)\rangle \, d\tau, \tag{2.30}$$

where a is defined by (2.27), h_2 is the solution of (2.28), and v and v^* are defined by (2.21) and (2.22), respectively. Thus, the critical coefficient c in the periodic normal form for the PD bifurcation has been computed. The critical cycle is stable within the center manifold if $c < 0$ and is unstable if $c > 0$. In the former case, the bifurcation is supercritical, while in the latter case it is subcritical.

2.3. The torus bifurcation. The three-dimensional critical center manifold $W^c(\Gamma)$ at the NS bifurcation can be parametrized locally by (τ, ξ) as

$$u = u_0(\tau) + \xi v(\tau) + \bar{\xi}\bar{v}(\tau) + H(\tau, \xi, \bar{\xi}), \quad \tau \in [0, T], \ \xi \in \mathbb{C}, \tag{2.31}$$

where the real function H satisfies $H(T, \xi, \bar{\xi}) = H(0, \xi, \bar{\xi})$, and has the Taylor expansion

$$\begin{aligned} H(\tau, \xi, \bar{\xi}) = {} & \frac{1}{2}h_{20}(\tau)\xi^2 + h_{11}(\tau)\xi\bar{\xi} + \frac{1}{2}h_{02}(\tau)\bar{\xi}^2 \\ & + \frac{1}{6}h_{30}(\tau)\xi^3 + \frac{1}{2}h_{21}(\tau)\xi^2\bar{\xi} + \frac{1}{2}h_{12}(\tau)\xi\bar{\xi}^2 + \frac{1}{6}h_{03}(\tau)\bar{\xi}^3 \\ & + O(|\xi|^4), \end{aligned} \tag{2.32}$$

with $h_{ij}(T) = h_{ij}(0)$ and $h_{ij} = \bar{h}_{ji}$ so that h_{11} is real, while

$$\left\{ \begin{array}{rcl} \dot{v}(\tau) - A(\tau)v(\tau) + \dfrac{i\theta}{T}v(\tau) & = & 0, \ \tau \in [0, T], \\ v(T) - v(0) & = & 0, \\ \int_0^T \langle v(\tau), v(\tau)\rangle d\tau - 1 & = & 0. \end{array} \right. \tag{2.33}$$

The function v exists due to Lemma 2 of [18]. Recall that $\langle u, v\rangle = u^{\mathrm{H}}v = \bar{u}^{\mathrm{T}}v$.

Note that

$$w(\tau) = \exp\left(\frac{i\theta\tau}{T}\right) v(\tau)$$

satisfies

$$\left\{ \begin{array}{rcl} \dot{w}(\tau) - A(\tau)w(\tau) & = & 0, \ \tau \in [0, T], \\ w(T) - e^{i\theta}w(0) & = & 0, \\ \int_0^T \langle w(\tau), w(\tau)\rangle d\tau - 1 & = & 0, \end{array} \right.$$

which is often used in the defining system for the NS bifurcation.

As in the previous cases, the functions $h_{ij}(\tau)$ can be found by solving appropriate BVPs, assuming that (2.1) restricted to $W^c(\Gamma)$ has the periodic normal form (2.6).

Also introduce the adjoint eigenfunction v^* that satisfies

$$(2.34)\qquad \left\{\begin{array}{rcl} \dot{v}^*(\tau) + A^{\mathrm{T}}(\tau)v^*(\tau) - \frac{i\theta}{T}v^*(\tau) & = & 0,\ \tau \in [0,T], \\ v^*(T) - v^*(0) & = & 0, \\ \int_0^T \langle v^*(\tau), v(\tau)\rangle d\tau - 1 & = & 0. \end{array}\right.$$

Substitute (2.31) into (2.1), using (2.2), (2.6), and (2.32), as well as

$$\frac{du}{dt} = \frac{\partial u}{\partial \xi}\frac{d\xi}{dt} + \frac{\partial u}{\partial \bar{\xi}}\frac{d\bar{\xi}}{dt} + \frac{\partial u}{\partial \tau}\frac{d\tau}{dt}.$$

The ξ-independent terms in the resulting equation give the usual identity

$$\dot{u}_0 = F(u_0).$$

The ξ-terms give another identity, namely,

$$\dot{v} - A(\tau)v + \frac{i\theta}{T}v = 0,$$

while the $\bar{\xi}$-terms lead to the corresponding complex-conjugate identity.

Collecting the coefficients of the ξ^2- or $\bar{\xi}^2$-terms leads to the equation

$$(2.35)\qquad \dot{h}_{20} - A(\tau)h_{20} + \frac{2i\theta}{T}h_{20} = B(\tau; v, v)$$

or its complex-conjugate. This equation has a unique solution $h_{20}(\tau)$ satisfying $h_{20}(T) = h_{20}(0)$, since $e^{2i\theta}$ is not a multiplier of the critical cycle by the spectral assumptions. Thus, h_{20} can be found from the BVP

$$(2.36)\qquad \left\{\begin{array}{rcl} \dot{h}_{20}(\tau) - A(\tau)h_{20}(\tau) + \frac{2i\theta}{T}h_{20}(\tau) - B(\tau; v(\tau), v(\tau)) & = & 0,\ \tau \in [0,T], \\ h_{20}(T) - h_{20}(0) & = & 0. \end{array}\right.$$

The $|\xi|^2$-terms give

$$(2.37)\qquad \dot{h}_{11} - A(\tau)h_{11} = B(\tau; v, \bar{v}) - a\dot{u}_0,$$

where $h_{11}(T) = h_{11}(0)$. The differential operator $\frac{d}{d\tau} - A(\tau)$ has a nontrivial kernel spanned by $\dot{u}_0$. The null-eigenfunction of the adjoint operator $-\frac{d}{d\tau} - A^{\mathrm{T}}(\tau)$ is φ^*, given by the equation

$$(2.38)\qquad \left\{\begin{array}{rcl} \dot{\varphi}^*(\tau) + A^{\mathrm{T}}(\tau)\varphi^*(\tau) & = & 0,\ \tau \in [0,T], \\ \varphi^*(T) - \varphi^*(0) & = & 0, \\ \int_0^T \langle \varphi^*(\tau), F(u_0(\tau))\rangle d\tau - 1 & = & 0. \end{array}\right.$$

Note that $\int_0^T \langle \varphi^*(\tau), F(u_0(\tau))\rangle d\tau \neq 0$, since the trivial multiplier 1 is simple, due to the spectral assumptions. The Fredholm solvability condition implies

$$(2.39)\qquad a = \int_0^T \langle \varphi^*(\tau), B(\tau; v(\tau), \bar{v}(\tau))\rangle\ d\tau.$$

With a defined in this way, let h_{11} be the unique solution of (2.37) satisfying $h_{11}(T) = h_{11}(0)$ and

$$\int_0^T \langle \varphi^*(\tau), h_{11}(\tau) \rangle \, d\tau = 0,$$

i.e.,

$$\tag{2.40} \left\{ \begin{array}{rcl} \dot{h}_{11}(\tau) - A(\tau)h_{11}(\tau) - B(\tau; v(\tau), \bar{v}(\tau)) + aF(u_0(\tau)) & = & 0, \ \tau \in [0,T], \\ h_{11}(T) - h_{11}(0) & = & 0, \\ \int_0^T \langle \varphi^*(\tau), h_{11}(\tau) \rangle \, d\tau & = & 0. \end{array} \right.$$

Other spectral conditions assure the solvability of linear equations for h_{30}, h_{12}, and h_{03}. Since these coefficients are not used below, we do not write the corresponding equations explicitly.

Finally, the coefficients of the $\xi^2\bar{\xi}$-terms give the singular equation

$$\dot{h}_{21} - Ah_{21} + \frac{i\theta}{T} h_{21} = 2B(\tau; h_{11}, v) + B(\tau; h_{20}, \bar{v}) + C(\tau; v, v, \bar{v}) - 2a\dot{v} - 2dv.$$

If one takes into account (2.34), the Fredholm solvability condition implies

$$\begin{aligned} d = & \frac{1}{2} \int_0^T \langle v^*(\tau), B(\tau; h_{11}(\tau), v(\tau)) + B(\tau; h_{20}(\tau), \bar{v}(\tau)) + C(\tau; v(\tau), v(\tau), \bar{v}(\tau)) \rangle \, d\tau \\ & - a \int_0^T \langle v^*(\tau), A(\tau)v(\tau) \rangle \, d\tau + \frac{ia\theta}{T}, \end{aligned} \tag{2.41}$$

where a is defined by (2.39), h_{11} and h_{20} by (2.40) and (2.36), respectively, and v and v^* satisfy (2.33) and (2.34), respectively. Thus, the critical coefficient d in the periodic normal form for the NS bifurcation has been computed. The critical cycle is stable within the center manifold if Re $d < 0$ and is unstable if Re $d > 0$. In the former case, the NS bifurcation is supercritical, while in the latter case it is subcritical.

3. Implementation issues.

Numerical implementation of the formulas derived in the preceding sections requires the evaluation of integrals of scalar functions over $[0,T]$ and the solution of nonsingular linear BVPs with integral constraints. Such tasks can be carried out with continuation software such as AUTO [19], CONTENT [11], and MATCONT [20]. In these software packages, periodic solutions to (1.1) are computed with the method of *orthogonal collocation* with piecewise polynomials applied to properly formulated BVPs. The standard BVP for the periodic solutions is formulated on the unit interval $[0,1]$, so that the period T becomes a parameter, and it involves an integral phase condition:

$$\tag{3.1} \left\{ \begin{array}{rcl} \dot{x}(\tau) - Tf(x(\tau), \alpha) & = & 0, \ \tau \in [0,1], \\ x(0) - x(1) & = & 0, \\ \int_0^1 \langle x(\tau), \dot{\xi}(\tau) \rangle \, d\tau & = & 0, \end{array} \right.$$

where ξ is a previously calculated periodic solution, rescaled to $[0,1]$.

In the orthogonal collocation method [21], the problem (3.1) is replaced by the following discretization:

$$
\tag{3.2}
\begin{cases}
\displaystyle\sum_{j=0}^{m} x_{i,j}\dot{\ell}_{i,j}(\zeta_{i,k}) - Tf\left(\sum_{j=0}^{m} x_{i,j}\ell_{i,j}(\zeta_{i,k}),\alpha\right) & = \quad 0,\\
x_{0,0} - x_{N-1,m} & = \quad 0,\\
\displaystyle\sum_{i=0}^{N-1}\sum_{j=0}^{m-1}\sigma_{i,j}\langle x_{i,j},\dot{\xi}_{i,j}\rangle + \sigma_{N,0}\langle x_{N,0},\dot{\xi}_{N,0}\rangle & = \quad 0.
\end{cases}
$$

Here $x_{i,j}$ is the approximation of $x(\tau)$ at $m+1$ equidistant mesh points

$$\tau_{i,j} = \tau_i + \frac{j}{m}(\tau_{i+1} - \tau_i), \quad j = 0, 1, \ldots, m,$$

on each of N intervals $[\tau_i, \tau_{i+1}]$, where

$$0 = \tau_0 < \tau_1 < \cdots < \tau_N = 1.$$

The $\ell_{i,j}(\tau)$'s are the Lagrange basis polynomials, while $\zeta_{i,j}$ $(j = 1, \ldots, m)$ are Gauss points [2], i.e., the roots of the Legendre polynomial of degree m, all relative to the interval $[\tau_i, \tau_{i+1}]$.

With this choice of collocation points $\zeta_{i,j}$, the approximation error at the mesh points has order of accuracy m,

$$\|x(\tau_{i,j}) - x_{i,j}\| = \mathcal{O}(h^m),$$

where $h = \max_{i=1,2,\ldots,N}\{t_i\},\ t_i = \tau_i - \tau_{i-1}$ $(i = 1, \ldots, N)$, while for the main mesh points τ_i it has order of accuracy $2m$,

$$\|x(\tau_i) - x_{i,0}\| = \mathcal{O}(h^{2m})$$

("superconvergence").

The integration weight $\sigma_{i,j}$ of $\tau_{i,j}$ is given by $w_{j+1}t_{i+1}$ for $0 \le i \le N-1$ and $0 < j < m$. For $i = 0, \ldots, N-2$, the integration weight of $\tau_{i,m}$ $(\tau_{i,m} = \tau_{i+1,0})$ is given by $\sigma_{i,m} = w_{m+1}t_{i+1} + w_1 t_{i+2}$, and the integration weights of τ_0 and τ_N are given by $w_1 t_1$ and $w_{m+1}t_N$, respectively. In the above expressions, w_{j+1} is the Lagrange quadrature coefficient.

The numerical continuation of the solutions of (3.2) leads to structured, sparse linear systems, which in AUTO [19] and CONTENT [11] are solved by an efficient, specially adapted elimination algorithm that computes the multipliers as a by-product, without explicitly using the Poincaré map. To detect codim 1 bifurcations, one can specify test functions that are based on computing multipliers [22, 19] or on solving appropriate bordered linear BVPs [23].

Once a codim 1 bifurcation has been detected, one can compute the normal form coefficients using the formulas derived in the previous sections. All BVPs are reformulated on the unit interval $[0, 1]$, and all integrals are scaled accordingly. Moreover, if the bordering methods from [23] are used to continue LPC, PD, and NS bifurcations of limit cycles, then the computation of the normal form coefficients requires little extra effort, since all necessary eigenfunctions have already been computed, either while evaluating the test functionals or their gradients. These coefficients then serve as test functions for detecting codim 2 singularities of limit cycles due to *nonlinear degeneracies* of LPC, PD, or NS bifurcations, i.e., the cusp (CPC), the degenerate period-doubling (DP), and the degenerate NS or Chenciner (CH) bifurcation. Byproducts of these computations are test functions for detecting certain codim 2 singularities of limit cycles due to *linear degeneracies*, namely, the strong 1:1 resonance (R1), the strong 1:2 resonance (R2), the fold-Neimark–Sacker bifurcation (FN), and the fold-flip bifurcation (FF).

3.1. Discretization symbols. It is convenient to discretize all computed functions using the *same mesh* as in (3.2). For a given vector function $\eta \in \mathcal{C}^1([0,1], \mathbb{R}^n)$ we consider three different discretizations:

- $\eta_M \in \mathbb{R}^{(Nm+1)n}$, the vector of the function values at the mesh points;
- $\eta_C \in \mathbb{R}^{Nmn}$, the vector of the function values at the collocation points;
- $\eta_W = \left[\begin{smallmatrix}\eta_{W_1}\\ \eta_{W_2}\end{smallmatrix}\right] \in \mathbb{R}^{Nmn} \times \mathbb{R}^n$, where η_{W_1} is the vector of the function values at the collocation points multiplied by the Gauss–Legendre weights and the lengths of the corresponding mesh intervals, and $\eta_{W_2} = \eta(0)$.

Formally we also introduce the structured sparse matrix $L_{C\times M}$ that converts a vector η_M of function values at the mesh points into a vector η_C of its values at the collocation points, namely, $\eta_C = L_{C\times M}\eta_M$. This matrix is never formed explicitly; its entries are approximated by the $\ell_{i,j}(\zeta_{i,k})$-coefficients in (3.2). We also need a matrix $A_{C\times M}$ such that $A_{C\times M}\eta_M = (A(t)\eta(t))_C$. Again this matrix need not be formed explicitly. On the other hand, we do need the matrix $(D - TA(t))_{C\times M}$ explicitly; it is defined by $(D - TA(t))_{C\times M}\eta_M = (\dot{\eta}(t) - TA(t)\eta(t))_C$. Finally, let the tensors $B_{C\times M\times M}$ and $C_{C\times M\times M\times M}$ be defined by $B_{C\times M\times M}\eta_{1M}\eta_{2M} = (B(t;\eta_1(t), \eta_2(t)))_C$ and

$$C_{C\times M\times M\times M}\eta_{1M}\eta_{2M}\eta_{3M} = (C(t;\eta_1(t), \eta_2(t), \eta_3(t)))_C$$

for all $\eta_i \in \mathcal{C}^1([0,1], \mathbb{R}^n)$. (These tensors are not formed explicitly.)

Let $f(t), g(t) \in \mathcal{C}^0([0,1], \mathbb{R})$ be two scalar functions. Then the integral $\int_0^1 f(t)dt$ is represented by $\sum_{i=0}^{N-1}\sum_{j=1}^{m}\omega_j (f_C)_{i,j} t_{i+1} = \sum_{i=0}^{N-1}\sum_{j=1}^{m}(f_{W_1})_{i,j}$, where $(f_C)_{i,j} = f(\zeta_{i,j})$ and ω_j is the Gauss–Legendre quadrature coefficient. The integral $\int_0^1 f(t)g(t)dt$ is approximated with Gauss–Legendre by $f_{W_1}^{\mathrm{T}} g_C \approx f_{W_1}^{\mathrm{T}} L_{C\times M} g_M$, where equality holds if $g(t)$ is a piecewise polynomial of degree m or less on the given mesh. For vector functions $f(t), g(t) \in \mathcal{C}^0([0,1], \mathbb{R}^n)$, the integral $\int_0^1 \langle f(t), g(t)\rangle \, dt$ is formally approximated by the same expression: $f_{W_1}^{\mathrm{T}} g_C \approx f_{W_1}^{\mathrm{T}} L_{C\times M} g_M$, where again we have equality if $g(t)$ is a piecewise polynomial of degree m or less on the given mesh. Concerning the accuracy of the quadrature formulas, we first note that accuracy is not an important issue for the phase integral in (3.1), as this equation only selects a specific solution from the continuum of solutions obtained by phase shifts. Similarly, the discretization of the normalization integrals, for example, in (2.15), does not affect the inherent accuracy, including superconvergence at the main mesh points τ_i of the solution of the discretized BVP. Discretization of integrals, as specified above, follows the standard Gauss quadrature error, which has order of accuracy $2m$ if, as mentioned, the function $g(t)$ is a piecewise polynomial of degree m or less on the given mesh and if $f(t)$ is sufficiently smooth (in a piecewise sense). Otherwise, still assuming sufficient piecewise smoothness, the order of accuracy of the numerical integrals is $m + 1$ if m is odd, and $m + 2$ if m is even. In particular, for the often used choice $m = 4$, the integrals would then have order of accuracy 6.

We now consider the LPC, PD, and NS cases separately.

3.2. LPC bifurcation. The first task is to rescale the computed functions to the interval $[0,1]$. We start by defining $u_1(t) = u_0(Tt)$ for $t \in [0,1]$. The linear BVPs (2.12) and (2.15) are replaced by

$$\left\{\begin{array}{rcl} \dot{v}_1(t) - TA(t)v_1(t) - TF(u_1(t)) & = & 0, \ t \in [0,1], \\ v_1(0) - v_1(1) & = & 0, \\ \int_0^1 \langle v_1(t), F(u_1(t))\rangle dt & = & 0, \end{array}\right. \tag{3.3}$$

where $v(\tau) = v_1(\tau/T)$, and

$$\left\{\begin{array}{rcl} \dot{\varphi}_1^*(t) + TA^{\mathrm{T}}(t)\varphi_1^*(t) & = & 0, \ t \in [0,1], \\ \varphi_1^*(0) - \varphi_1^*(1) & = & 0, \\ \int_0^1 \langle \varphi_1^*(t), \varphi_1^*(t)\rangle dt - 1 & = & 0, \end{array}\right. \tag{3.4}$$

respectively. We then compute $I = \int_0^1 \langle \varphi_1^*(t), v_1(t)\rangle dt$. If $I = 0$, then we have a strong 1:1 resonance (a limit cycle with two nontrivial multipliers equal to 1). If not, then we rescale φ^* so that $I = 1$. It then follows that $\varphi^*(\tau) = \varphi_1^*(\tau/T)/T$. Thus, we obtain

$$b = \frac{1}{2}\int_0^1 \langle \varphi_1^*(t), B(t; v_1(t), v_1(t)) + 2A(t)v_1(t)\rangle \, dt. \tag{3.5}$$

We compute v_{1M} by solving the discretization of (3.3)

$$\left[\begin{array}{c} (D - TA(t))_{C\times M} \\ \delta_0 - \delta_1 \\ (g_{W_1})^{\mathrm{T}} L_{C\times M} \end{array}\right] v_{1M} = \left[\begin{array}{c} Tg_C \\ 0 \\ 0 \end{array}\right], \tag{3.6}$$

where $g(t) = F(u_1(t))$.

It is more efficient to compute φ_{1W}^* than φ_{1M}^*, since φ_1^* will be used only to compute integrals of the form $\int_0^1 \langle \varphi_1^*(t), \zeta(t)\rangle dt$. Moreover, φ_{1W}^* can be computed with the same matrix used in (3.6), thus saving factorization costs. Formally, the computation of φ_{1W}^* is based on Proposition A.1 from the appendix. Instead of approximating φ_1^* by solving

$$\left[\begin{array}{c} (D + TA^{\mathrm{T}}(t))_{C\times M} \\ \delta_0 - \delta_1 \end{array}\right] \varphi_{1M}^* = 0,$$

we remark that $\left[\begin{smallmatrix} \varphi_1^* \\ \varphi_1^*(0) \end{smallmatrix}\right]$ is orthogonal to the range of $\left[\begin{smallmatrix} D-TA(t) \\ \delta_0-\delta_1 \end{smallmatrix}\right]$. By discretization we obtain

$$(\varphi_{1W}^*)^{\mathrm{T}} \left[\begin{array}{c} (D - TA(t))_{C\times M} \\ \delta_0 - \delta_1 \end{array}\right] = 0.$$

To normalize $\varphi_{1W_1}^*$, we require

$$\sum_{i=0}^{N-1}\sum_{j=1}^{m} \left|(\varphi_{1W_1}^*)_{i,j}\right|_1 = 1. \tag{3.7}$$

Here $|.|_1$ denotes the 1-norm (sum of absolute values) of a vector. This choice is convenient for computational reasons. Then $\int_0^1 \langle \varphi_1^*(t), v_1(t)\rangle dt$ is approximated by $(\varphi_{1W_1}^*)^{\mathrm{T}} L_{C\times M} v_{1M}$, and if this quantity is nonzero, φ_{1W}^* is rescaled to ensure $\int_0^1 \langle \varphi_1^*(t), v_1(t)\rangle dt = 1$.

The integral (3.5) is finally approximated by

$$b = \frac{1}{2}(\varphi_{1W_1}^*)^{\mathrm{T}}(B_{C\times M\times M} v_{1M} v_{1M} + 2A_{C\times M} v_{1M}). \tag{3.8}$$

3.3. PD bifurcation. Again, we rescale the computed quantities to the interval $[0,1]$. The linear BVPs (2.21) and (2.22) are replaced by

$$\left\{\begin{array}{rcl} \dot{v_1}(t) - TA(t)v_1(t) &=& 0,\ t\in[0,1],\\ v_1(0)+v_1(1) &=& 0,\\ \int_0^1 \langle v_1(t), v_1(t)\rangle dt - 1 &=& 0, \end{array}\right. \tag{3.9}$$

where $v(\tau) = v_1(\tau/T)/\sqrt{T}$, and

$$\left\{\begin{array}{rcl} \dot{v_1}^*(t) + TA^{\mathrm{T}}(t)v_1^*(t) &=& 0,\ t\in[0,1],\\ v_1^*(0)+v_1^*(1) &=& 0,\\ \int_0^1 \langle v_1^*(t), v_1^*(t)\rangle dt - 1/2 &=& 0, \end{array}\right. \tag{3.10}$$

respectively. We note that the last equation in (3.10) differs from the last equation in (2.22). We then compute $I = \int_0^1 \langle v_1^*(t), v_1(t)\rangle dt$. If $I=0$, then we have a strong 1:2 resonance (a limit cycle with two multipliers equal to -1). If not, then we rescale v_1^* so that $I = 1/2$, which corresponds to the normalization condition used in (3.10). It then follows that $v^*(\tau) = v_1^*(\tau/T)/\sqrt{T}$.

We also replace (2.26) by

$$\left\{\begin{array}{rcl} \dot{\psi}_1^*(t) + TA^{\mathrm{T}}(t)\psi_1^*(t) &=& 0,\ t\in[0,1],\\ \psi_1^*(0)-\psi_1^*(1) &=& 0,\\ \int_0^1 \langle \psi_1^*(t), \psi_1^*(t)\rangle\, dt - 1 &=& 0. \end{array}\right. \tag{3.11}$$

Again, the last equation in (3.11) differs from the last equation in (2.26). We then compute $I = \int_0^1 \langle \psi_1^*(t), F(u_1(t))\rangle dt$. If $I=0$, then we have a fold-flip bifurcation. If not, then we rescale ψ_1^* so that $I=1$. It then follows that $\psi^*(\tau) = \psi_1^*(\tau/T)/T$.

This leads to the expression

$$a_1 = \int_0^1 \langle \psi_1^*(t), B(t; v_1(t), v_1(t))\rangle\, dt, \tag{3.12}$$

where $a_1 = aT$.

With a_1 defined in this way, let $h_{2,1}$ be the unique solution of the BVP

$$\left\{\begin{array}{rcl} \dot{h}_{2,1}(t) - TA(t)h_{2,1}(t) - B(t; v_1(t), v_1(t)) + 2a_1F(u_1(t)) &=& 0,\ t\in[0,1],\\ h_{2,1}(0)-h_{2,1}(1) &=& 0,\\ \int_0^1 \langle \psi_1^*(t), h_{2,1}(t)\rangle\, dt &=& 0, \end{array}\right. \tag{3.13}$$

where $h_2(\tau) = h_{2,1}(\tau/T)$.

Therefore we obtain

$$\begin{aligned} c = \frac{1}{3}\int_0^1 &\left\langle v_1^*(t), \frac{1}{T}C(t; v_1(t), v_1(t), v_1(t)) + 3B(t; v_1(t), h_{2,1}(t))\right\rangle\, dt \\ &- \frac{2a_1}{T}\int_0^1 \langle v_1^*(t), A(t)v_1(t)\rangle\, dt. \end{aligned} \tag{3.14}$$

We compute v_{1M} by solving

$$\begin{bmatrix} (D - TA(t))_{C\times M} \\ \delta_0 + \delta_1 \end{bmatrix} v_{1M} = 0. \tag{3.15}$$

We normalize v_{1M} by requiring $\sum_{i=0}^{N-1}\sum_{j=0}^{m}\sigma_j\langle (v_{1M})_{i,j},(v_{1M})_{i,j}\rangle = 1$, where σ_j is the Lagrange quadrature coefficient.

As in the LPC case, it is more efficient to compute v_{1W}^*, rather than v_M^*, since v_1^* will be used only to compute integrals of the form $\int_0^1\langle v_1^*(t),\zeta(t)\rangle dt$. Moreover, v_{1W}^* can be computed with the same matrix in (3.15), thus saving factorization costs. Formally, the computation of v_{1W}^* is based on Proposition A.2 (see the appendix). Instead of approximating v_1^* by solving

$$\begin{bmatrix} (D+TA^{\mathrm{T}}(t))_{C\times M} \\ \delta_0+\delta_1 \end{bmatrix} v_{1M}^* = 0,$$

we observe that $\left[\begin{smallmatrix} v_1^* \\ v_1^*(0)\end{smallmatrix}\right]$ is orthogonal to the range of $\left[\begin{smallmatrix} D-TA(t) \\ \delta_0+\delta_1\end{smallmatrix}\right]$. By discretization we obtain

$$(v_{1W}^*)^{\mathrm{T}}\begin{bmatrix} (D-TA(t))_{C\times M} \\ \delta_0+\delta_1 \end{bmatrix} = 0.$$

To normalize $v_{1W_1}^*$, we require $\sum_{i=0}^{N-1}\sum_{j=1}^{m}\left|(v_{1W_1}^*)_{i,j}\right|_1 = 1$. Then $\int_0^1\langle v_1^*(t),v_1(t)\rangle dt$ is approximated by $(v_{1W_1}^*)^{\mathrm{T}}L_{C\times M}v_{1M}$. If this quantity is nonzero, then v_{1W}^* is rescaled so that $\int_0^1\langle v_1^*(t),v_1(t)\rangle dt = 1/2$.

From Proposition A.1 it follows that we can approximate ψ_1^* like v_1^*, namely, we compute ψ_{1W}^* by solving

$$(\psi_{1W}^*)^{\mathrm{T}}\begin{bmatrix} (D-TA(t))_{C\times M} \\ \delta_0-\delta_1 \end{bmatrix} = 0,$$

and normalize $\psi_{1W_1}^*$ by requiring

$$\sum_{i=0}^{N-1}\sum_{j=1}^{m}\left|(\psi_{1W_1}^*)_{i,j}\right|_1 = 1.$$

Then $\int_0^1\langle\psi_1^*(t),F(u_1(t))\rangle dt$ is approximated by $(\psi_{1W_1}^*)^{\mathrm{T}}(F(u_1(t)))_C$ and if this quantity is nonzero, ψ_{1W}^* is rescaled so that $\int_0^1\langle\psi_1^*(t),F(u_1(t))\rangle dt = 1$.

Having found v_{1M} and ψ_{1W}^*, a_1 can be computed using (3.12) as

$$a_1 = (\psi_{1W_1}^*)^{\mathrm{T}}B_{C\times M\times M}v_{1M}v_{1M}.$$

Next, $(h_{2,1})_M$ is found by solving the discretization of (3.13), namely,

$$\begin{bmatrix} (D-TA(t))_{C\times M} \\ \delta_0-\delta_1 \\ (\psi_{W_1}^*)^{\mathrm{T}}L_{C\times M} \end{bmatrix}(h_{2,1})_M = \begin{bmatrix} B_{C\times M\times M}v_{1M}v_{1M}+2a_1g_C \\ 0 \\ 0 \end{bmatrix},$$

where $g_C = (F(u_1(t)))_C$.

Finally, (3.14) is approximated by

$$\begin{aligned} c = {}& \frac{1}{3T}(v_{1W_1}^*)^{\mathrm{T}}\left(C_{C\times M\times M\times M}v_{1M}v_{1M}v_{1M}+3TB_{C\times M\times M}v_{1M}(h_{2,1})_M\right) \\ & -\frac{2a_1}{T}(v_{1W_1}^*)^{\mathrm{T}}A_{C\times M}v_{1M}. \end{aligned} \tag{3.16}$$

3.4. Torus bifurcation. As before, we first rescale the time variable to the unit time interval. The linear BVPs (2.33) and (2.34) are replaced by

$$\left\{\begin{array}{rcl} \dot{v_1}(t) - TA(t)v_1(t) + i\theta v_1(t) & = & 0,\ t \in [0,1], \\ v_1(0) - v_1(1) & = & 0, \\ \int_0^1 \langle v_1(t), v_1(t)\rangle dt - 1 & = & 0, \end{array}\right. \tag{3.17}$$

where $v(\tau) = v_1(\tau/T)/\sqrt{T}$, and

$$\left\{\begin{array}{rcl} \dot{v_1}^*(t) + TA^{\mathrm{T}}(t)v_1^*(t) - i\theta v_1^*(t) & = & 0,\ t \in [0,1], \\ v_1^*(0) - v_1^*(1) & = & 0, \\ \int_0^1 \langle v_1^*(t), v_1^*(t)\rangle dt - 1 & = & 0, \end{array}\right. \tag{3.18}$$

respectively. Note that the last equation in (3.18) differs from the last equation in (2.34). To rescale v_1^* we first compute $I = \int_0^1 \langle v_1^*(t), v_1(t)\rangle dt$. If $I \neq 0$, then we rescale v_1^* so that $I = 1$. (The case $I = 0$ corresponds to a bifurcation of codimension three or higher.) It then follows that $v^*(\tau) = v_1^*(\tau/T)/\sqrt{T}$.

We also replace (2.38) by

$$\left\{\begin{array}{rcl} \dot{\varphi_1}^*(t) + TA^{\mathrm{T}}(t)\varphi_1^*(\tau) & = & 0,\ t \in [0,1], \\ \varphi_1^*(0) - \varphi_1^*(1) & = & 0, \\ \int_0^1 \langle \varphi_1^*(t), \varphi_1^*(t)\rangle dt - 1 & = & 0. \end{array}\right. \tag{3.19}$$

Again, note that the last equation in (3.19) differs from the last equation in (2.38). Now compute $I = \int_0^1 \langle \varphi_1^*(t), F(u_1(t))\rangle dt$. If $I = 0$, then we have a fold-Neimark–Sacker bifurcation. If $I \neq 0$, then we rescale φ_1^* so that $I = 1$. It follows that $\varphi^*(\tau) = \varphi_1^*(\tau/T)/T$. (2.36) is replaced by

$$\left\{\begin{array}{rcl} \dot{h}_{20,1}(t) - A(t)h_{20,1}(t) + 2i\theta h_{20,1}(t) - B(t; v_1(t), v_1(t)) & = & 0,\ t \in [0,1], \\ h_{20,1}(0) - h_{20,1}(1) & = & 0, \end{array}\right. \tag{3.20}$$

where $h_{20}(\tau) = h_{20,1}(\tau/T)$. This leads to the expression

$$a_1 = \int_0^1 \langle \varphi_1^*(\tau), B(t; v_1(t), \bar{v}_1(t))\rangle\ dt, \tag{3.21}$$

where $a = a_1/T$.

With a_1 defined in this way, let $h_{11,1}$ be the unique solution of the BVP

$$\left\{\begin{array}{rcl} \dot{h}_{11,1}(t) - A(t)h_{11,1}(t) - B(t; v_1(t), \bar{v}_1(t)) + a_1F(u_1(t)) & = & 0,\ t \in [0,1], \\ h_{11,1}(0) - h_{11,1}(1) & = & 0, \\ \int_0^1 \langle \varphi_1^*(t), h_{11,1}(t)\rangle\ dt & = & 0, \end{array}\right. \tag{3.22}$$

where $h_{11}(\tau) = h_{11,1}(\tau/T)$.

Finally we obtain

$$\begin{aligned} d = {} & \frac{1}{2}\int_0^1 \langle v_1^*(t), B(t; h_{11,1}(t), v_1(t)) + B(t; h_{20,1}(t), \bar{v}_1(t))\rangle\ dt \\ & + \frac{1}{2T}\int_0^1 \langle v_1^*(t), C(t; v_1(t), v_1(t), \bar{v}_1(t))\rangle\ dt - \frac{a_1}{T}\int_0^1 \langle v_1^*(t), A(t)v_1(t)\rangle\ dt + \frac{ia_1\theta}{T^2}. \end{aligned} \tag{3.23}$$

We compute v_{1M} by solving

$$\left[\begin{array}{c}(D-TA(t)+i\theta I_n)_{C\times M}\\ \delta_0-\delta_1\end{array}\right] v_{1M}=0, \tag{3.24}$$

where $(D-TA(t)+i\theta I_n)_{C\times M}$ is defined like $(D-TA(t))_{C\times M}$. We normalize v_{1M} by requiring that $\sum_{i=0}^{N-1}\sum_{j=0}^{m}\sigma_j\langle (v_{1M})_{i,j},(v_{1M})_{i,j}\rangle=1$, where σ_j is the Lagrange quadrature coefficient. Again, it is more efficient to compute v_{1W}^* than v_M^*, since v_1^* will be used only to compute integrals of the form $\int_0^1\langle v_1^*(t),\zeta(t)\rangle dt$. Moreover, v_{1W}^* can be computed with the same matrix in (3.23). Formally, the computation of v_{1W}^* is based on Proposition A.3 from the appendix. Instead of approximating v_1^* by solving

$$\left[\begin{array}{c}(D+TA^{\mathrm{T}}(t)-i\theta I_n)_{C\times M}\\ \delta_0+\delta_1\end{array}\right] v_{1M}^*=0,$$

we remark that $\left[\begin{smallmatrix}v_1^*\\ v_1^*(0)\end{smallmatrix}\right]$ is orthogonal to the range of $\left[\begin{smallmatrix}D-TA(t)+i\theta\\ \delta_0+\delta_1\end{smallmatrix}\right]$. By discretization we obtain

$$(v_{1W}^*)^{\mathrm{H}}\left[\begin{array}{c}(D-TA(t)+i\theta I_n)_{C\times M}\\ \delta_0+\delta_1\end{array}\right]=0.$$

To normalize $v_{1W_1}^*$ we require that $\sum_{i=0}^{N-1}\sum_{j=1}^{m}\left|(v_{1W_1}^*)_{i,j}\right|_1=1$. Then $\int_0^1\langle v_1^*(t),v_1(t)\rangle dt$ is approximated by $(v_{1W_1}^*)^{\mathrm{T}}L_{C\times M}v_{1M}$. If this quantity is nonzero, then v_{1W}^* is rescaled so that $\int_0^1\langle v_1^*(t),v_1(t)\rangle dt=1$.

From Proposition A.1 it follows that we can approximate φ_1^* like v_1^*. To be precise, we compute φ_{1W}^* by solving

$$(\varphi_{1W}^*)^{\mathrm{T}}\left[\begin{array}{c}(D-TA(t))_{C\times M}\\ \delta_0-\delta_1\end{array}\right]=0,$$

and we normalize $\varphi_{1W_1}^*$ by requiring that $\sum_{i=0}^{N-1}\sum_{j=1}^{m}\left|(\varphi_{1W_1}^*)_{i,j}\right|_1=1$. Then the integral $\int_0^1\langle\varphi_1^*(t),F(u_1(t))\rangle dt$ is approximated by $(\varphi_{1W_1}^*)^{\mathrm{T}}(F(u_1(t)))_C$. If this quantity is nonzero, then φ_{1W}^* is rescaled, so that $\int_0^1\langle\varphi_1^*(t),F(u_1(t))\rangle dt=1$. We compute $(h_{20,1})_M$ by solving

$$\left[\begin{array}{c}(D-TA(t)+2i\theta I_n)_{C\times M}\\ \delta_0-\delta_1\end{array}\right](h_{20,1})_M=\left[\begin{array}{c}B_{C\times M\times M}v_{1M}v_{1M}\\ 0\end{array}\right].$$

The coefficient a_1 can be approximated using (3.21) as

$$a_1=(\varphi_{W_1}^*)^{\mathrm{T}}B_{C\times M\times M}v_{1M}\bar{v}_{1M},$$

while $(h_{11,1})_M$ is found by solving the discretization of (3.22),

$$\left[\begin{array}{c}(D-TA(t))_{C\times M}\\ \delta_0-\delta_1\\ (\varphi_{W_1}^*)^{\mathrm{T}}L_{C\times M}\end{array}\right](h_{11,1})_M=\left[\begin{array}{c}B_{C\times M\times M}v_{1M}\bar{v}_{1M}-a_1(F(u_1(t)))_C\\ 0\\ 0\end{array}\right].$$

The normal form coefficient d defined by (3.23) is approximated by

(3.25)

$$\begin{aligned} d\ &=\ \frac{1}{2}(v_{1W_1}^*)^{\mathrm{T}}(B_{C\times M\times M}(h_{11,1})_M v_{1M}+B_{C\times M\times M}(h_{20,1})_M\bar{v}_{1M})\\ &\quad+\frac{1}{2T}(v_{1W_1}^*)^{\mathrm{T}}C_{C\times M\times M\times M}v_{1M}v_{1M}\bar{v}_{1M}-\frac{a_1}{T}(v_{1W_1}^*)^{\mathrm{T}}A_{C\times M}v_{1M}+\frac{ia_1\theta}{T^2}.\end{aligned}$$

4. Examples. The computations in this section are done with MATCONT [20]. In particular, the bordering methods from [23] are used to continue the codim 1 bifurcations of limit cycles in two parameters. The algorithms described above for computing the normal form coefficients are also implemented in the current version of MATCONT.

4.1. The LPC normal form coefficient in the ABC-reaction. We have computed the normal form coefficient b of (2.4) in a model of a continuously stirred tank reactor, with consecutive A → B → C reactions, as studied by Doedel and Heinemann [24]. It has three state variables, u_1, u_2, and u_3, and five parameters, p_1, p_2, p_3, p_4, and p_5:

$$\left\{ \begin{array}{lcl} \dot{u_1} & = & -u_1 + p_1(1-u_1)e^{u_3}, \\ \dot{u_2} & = & -u_2 + p_1(1-u_1-p_5u_2)e^{u_3}, \\ \dot{u_3} & = & -u_3 - p_3u_3 + p_1p_4(1-u_1+p_2p_5u_2)e^{u_3}. \end{array} \right. \tag{4.1}$$

This model is used as a demo in the AUTO manual [19]. In the notation of [24], we have $u_1 = y$, where $1-y$ is the concentration of reactant A; $u_2 = z$, the concentration of reactant B; $u_3 = \theta$, the temperature; $p_1 = D$, the Damkohler number; $p_2 = \alpha$, the ratio of reaction heats; $p_3 = \beta$, the heat transfer coefficient; $p_4 = B$, the adiabatic temperature rise; and $p_5 = \sigma$, the selectivity ratio.

In Figure 4.1 the equilibrium curve computed with MATCONT is represented. The parameter values are $p_2 = 1$, $p_3 = 1.5$, $p_4 = 8$, $p_5 = 0.04$, with free parameter p_1, starting from the equilibrium at $p_1 = 0.1$, for which $u_1 \approx 0.13304$, $u_2 \approx 0.13223$, and $u_3 \approx 0.42833$. The curve of equilibria contains four Hopf points, labeled by H, which we call, from left to right, $\mathsf{H}_1, \mathsf{H}_2, \mathsf{H}_3, \mathsf{H}_4$, respectively. As shown in [24], in the case $p_2 = 1$, the Hopf points H_1 and H_4 are connected by a family of periodic solutions, and H_2 and H_3 are similarly connected. The family of solutions that connects H_1 to H_4 contains three fold bifurcations of periodic solutions, as also observed in [24]. We continue the first fold bifurcation of periodic solutions numerically in two parameters p_1 and p_2, with the discretization parameters $N = 30$ (mesh intervals) and $m = 4$ (collocation points). This family contains a cusp point of periodic orbits (CPC) detected in MATCONT as a zero of the coefficient b computed with (3.8). In Figure 4.2(a)–(c) we present the normal form coefficient b, the first component u_1 of the state variables vector, and p_2, respectively, as functions of p_1.

(b) *The family in the* (α, β)*-space.*

Fig. 4.3.

4.2. The PD normal form coefficient in a feedback control system. We have used (3.16) to compute the PD normal form coefficient c of (2.5) in a feedback control system, described in [25, 9] and further used in [3, Example 5.4, p. 178]:

$$\left\{\begin{array}{rcl} \dot{x} & = & y, \\ \dot{y} & = & z, \\ \dot{z} & = & -\alpha z - \beta y - x + x^2. \end{array}\right. \tag{4.2}$$

Due to the special structure of this system, a good approximation to the PD curve can be found by the harmonic balance method; cf. [26, 27].

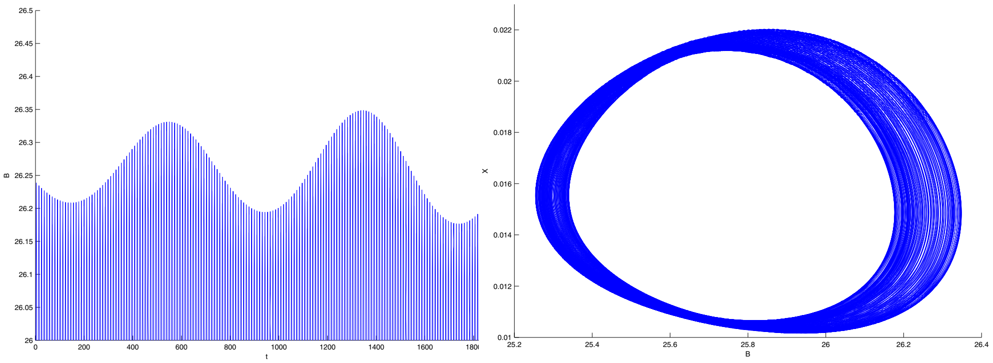
We have computed a family of periodic orbits of (4.2) numerically, as described in the CL_MATCONT manual and in [28], starting from the Hopf point for $\alpha = 1$ and $\beta = 1$ at $(0, 0, 0)$. We used $N = 20$ (mesh intervals) and $m = 4$ (collocation points) for the discretization. We detected two PD points with period $6.36407\dots$ at $\alpha \approx \pm 0.6303020$, respectively. The noncritical multipliers at the first PD point are inside the unit circle, so the periodic orbit could be stable. At the second PD point there is one multiplier outside the unit circle, and therefore the orbit is unstable. At the PD points the normal form coefficients c were computed. At the first PD point we find that $c \approx -0.04267737 < 0$. Therefore, the critical periodic orbit at the first PD point is stable, and a stable limit cycle with approximately double period exists for nearby parameter values. This was confirmed by computing the bifurcating periodic orbit and its multipliers. At the second PD point the normal form coefficient is $c \approx 0.04268605 > 0$. Hence the periodic orbit with double period is unstable in the center manifold. By computing the orbit with doubled period and monitoring the multipliers near this second PD point, we found that it has indeed two multipliers outside the unit circle. From the first PD point we computed the branch of PD cycles (see Figure 4.3). The normal form coefficient c is used as a test function. We also use $I = \int_0^1 \langle v_1^*(t), v_1(t) \rangle dt$ as another test function. We detected (at $\alpha = 0$) two strong 1:2 resonances R2 on this curve, where there are two multipliers equal to -1.

4.3. The NS normal form coefficient in a chemical model. The following model of the peroxidase-oxidase reaction was studied by Steinmetz and Larter [29]:

$$\left\{\begin{array}{rcl} \dot{A} & = & -k_1 ABX - k_3 ABY + k_7 - k_{-7} A, \\ \dot{B} & = & -k_1 ABX - k_3 ABY + k_8, \\ \dot{X} & = & k_1 ABX - 2k_2 X^2 + 2k_3 ABY - k_4 X + k_6, \\ \dot{Y} & = & -k_3 ABY + 2k_2 X^2 - k_5 Y, \end{array}\right. \tag{4.3}$$

where A, B, X, Y are state variables and k_1, k_2, k_3, k_4, k_5, k_6, k_7, k_8, and k_{-7} are parameters. The following (approximate) values correspond to an unstable equilibrium in (4.3):

Variable	Value	Parameter	Value
A	31.78997	k_1	0.1631021
B	1.45468	k_2	1250
X	0.01524586	k_3	0.046875
Y	0.1776113	k_4	20
		k_5	1.104
		k_6	0.001
		k_7	4.235322
		k_8	0.5
		k_{-7}	0.1175

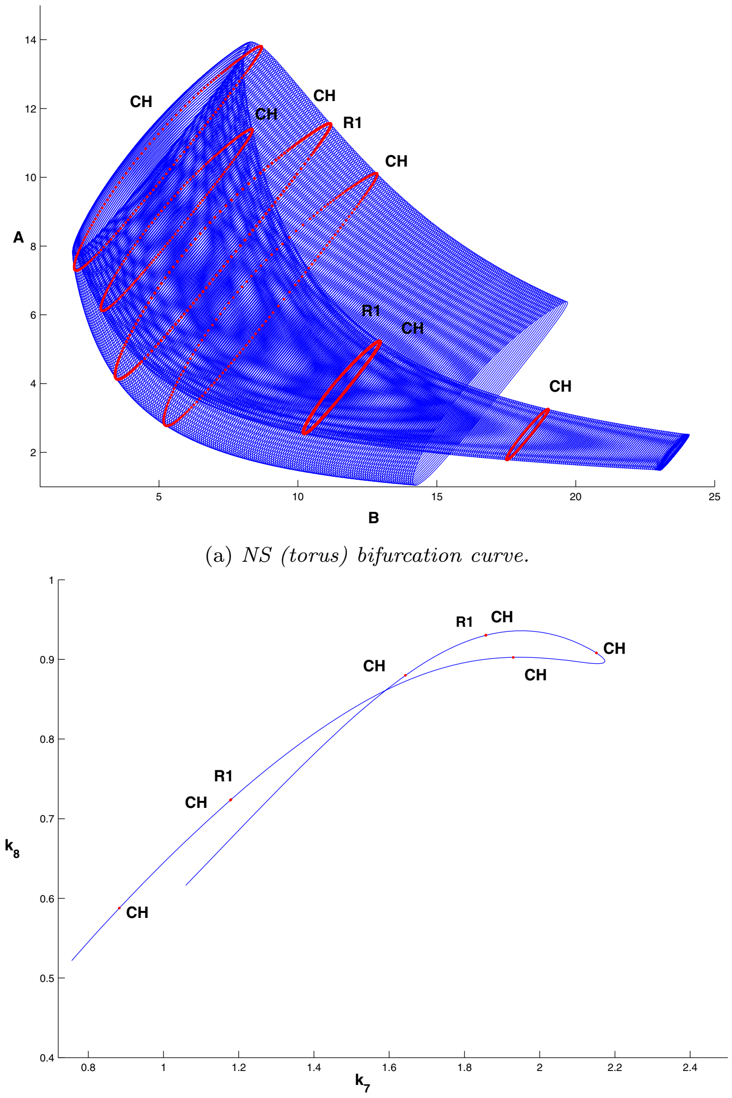


(a) *Modulated oscillations.*

(b) *Orbits on a stable 2-torus.*

FIG. 4.4.

We continued this equilibrium with decreasing k_7, keeping all other parameters fixed. We found a Hopf point at $k_7 \approx 0.712475$, where the first Lyapunov coefficient is negative. We then computed the family of stable limit cycles that bifurcates from the Hopf point. At $k_7 \approx 0.716434$ a *torus* (NS) bifurcation occurs. The real part of normal form coefficient d of (2.6) at this point is Re $d \approx -1.405999 \cdot 10^{-6}$, and therefore the emanating tori would be stable, locally. If we start a time integration from a point on the critical limit cycle, with a slightly increased parameter value, namely, $k_7 = 0.7167$, then after a transient period the orbit exhibits modulated oscillations with two frequencies near the limit cycle (see Figure 4.4). This is a motion on a stable two-dimensional torus that arises from the NS bifurcation. The NS point can be used as a starting point for the two-parameter continuation of the corresponding codim 1 bifurcation, using k_7 and k_8 as control parameters and $N = 50$, $m = 4$ as discretization parameters. We monitored Re d of the normal form coefficient d, computed with (3.25), during this continuation; it vanishes in a Chenciner bifurcation point (CH). The computed bifurcation curve is presented in Figures 4.5(a) and 4.5(b), in the (A, B)-plane and in the (k_7, k_8)-plane, respectively. The NS curve contains two additional codim 2 points, where a triple multiplier $\mu = 1$ is present (also counting the trivial multiplier). These are 1:1 strong resonance points [3] denoted by R1 in the figure. Between the 1:1 points, the *NS* curve is a *neutral saddle cycle* curve. Near such codim 2 points complicated homoclinic structures exist.



(a) *NS (torus) bifurcation curve.*

(b) *Codim 2 bifurcation points on the NS curve.*

FIG. 4.5.

It should be noted that the algorithm for the NS continuation, as implemented in MATCONT, is sufficiently robust to pass through the 1:1 resonance points (within a 10^{-3} parameter-range).

5. Discussion. The formulas for the normal form coefficients derived in this paper allow numerical verification of the nondegeneracy conditions (see [3]) for all codim 1 limit cycle bifurcations. In particular, the coefficients for the PD and torus bifurcations allow one to distinguish between sub- and supercritical cases.

These coefficients serve as test functions for detecting codim 2 bifurcations of limit cycles. One may try to use them to set up defining equations for the corresponding codim 2 bifurcations in three control parameters. However, any Newton-like continuation scheme would require the derivatives of the coefficients with respect to parameters, period, and the discretization variables. This problem requires further analysis.

The new algorithms fit very well into the BVP-framework (see [30, 23]) of AUTO [19], CONTENT [11], and, particularly, MATCONT [20], which contains our current prototype implementation.

The underlying technique can also be used to derive the coefficients of the periodic normal forms for codim 2 singularities of limit cycles. Although periodic normal forms are known in most of these codim 2 cases (see [8, 4]), substantial work remains to be done on the derivation and implementation of formulas for their coefficients. When implemented, such formulas will allow one to verify the nondegeneracy conditions for the codim 2 bifurcations.

A comparison of the numerical periodic normalization proposed in the current paper with the computation of normal form coefficients of the Poincaré map via automatic differentiation is also a task in future work.

Appendix A. Kernels of some differential-difference operators. In section 3 we used the orthogonality with respect to the following inner product: If $\zeta_1, \zeta_2 \in \mathcal{C}^0([0,1], \mathbb{C}^n)$ and $\eta_1, \eta_2 \in \mathbb{C}^n$, then

$$\left\langle \begin{bmatrix} \zeta_1 \\ \eta_1 \end{bmatrix}, \begin{bmatrix} \zeta_2 \\ \eta_2 \end{bmatrix} \right\rangle = \int_0^1 \langle \zeta_1(t), \zeta_2(t) \rangle \, dt + \langle \eta_1, \eta_2 \rangle = \int_0^1 \zeta_1^{\mathrm{H}}(t)\zeta_2(t)dt + \eta_1^{\mathrm{H}}\eta_2.$$

If this inner product vanishes, then we say that the corresponding vectors are orthogonal and write

$$\begin{bmatrix} \zeta_1 \\ \eta_1 \end{bmatrix} \perp \begin{bmatrix} \zeta_2 \\ \eta_2 \end{bmatrix}.$$

In section 3 we also used the following propositions.

PROPOSITION A.1. *Consider two differential-difference operators*

$$\phi_{1,2} : \mathcal{C}^1([0,1], \mathbb{R}^n) \to \mathcal{C}^0([0,1], \mathbb{R}^n) \times \mathbb{R}^n,$$

where

$$\phi_1(\zeta) = \begin{bmatrix} \dot{\zeta} - TA\zeta \\ \zeta(0) - \zeta(1) \end{bmatrix}, \quad \phi_2(\zeta) = \begin{bmatrix} \dot{\zeta} + TA^{\mathrm{T}}\zeta \\ \zeta(0) - \zeta(1) \end{bmatrix}.$$

If $\zeta \in \mathcal{C}^1([0,1], \mathbb{R}^n)$, *then* $\zeta \in \mathrm{Ker}(\phi_1)$ *if and only if*

$$\begin{bmatrix} \zeta \\ \zeta(0) \end{bmatrix} \perp \phi_2(\mathcal{C}^1([0,1], \mathbb{R}^n)),$$

and $\zeta \in \mathrm{Ker}(\phi_2)$ *if and only if*

$$\begin{bmatrix} \zeta \\ \zeta(0) \end{bmatrix} \perp \phi_1(\mathcal{C}^1([0,1], \mathbb{R}^n)).$$

Proof. If ζ is in the kernel of ϕ_1, then $\dot{\zeta} - TA(t)\zeta = 0$ and $\zeta(0) - \zeta(1) = 0$. For all $g \in \mathcal{C}^1([0,1], \mathbb{R}^n)$ we have

$$\begin{aligned}
&\textstyle\int_0^1 g(t)^{\mathrm{T}}\dot{\zeta}(t)dt - \int_0^1 Tg(t)^{\mathrm{T}}A(t)\zeta(t)dt = 0\\
\Rightarrow&\\
&\textstyle g(t)^{\mathrm{T}}\zeta(t)|_0^1 - \int_0^1 \dot{g}(t)^{\mathrm{T}}\zeta(t)dt - \int_0^1 Tg(t)^{\mathrm{T}}A(t)\zeta(t)dt = 0\\
\Rightarrow&\\
&\textstyle g(1)^{\mathrm{T}}\zeta(1) - g(0)^{\mathrm{T}}\zeta(0) - \int_0^1 (\dot{g}(t) + TA(t)^{\mathrm{T}}g(t))^{\mathrm{T}}\zeta(t)dt = 0\\
\Rightarrow&\\
&\textstyle -(g(0) - g(1))^{\mathrm{T}}\zeta(0) - \int_0^1 (\dot{g}(t) + TA(t)^{\mathrm{T}}g(t))^{\mathrm{T}}\zeta(t)dt = 0\\
\Rightarrow&\\
&\left\langle \begin{bmatrix} \dot{g} + TA^{\mathrm{T}}g \\ g(0) - g(1) \end{bmatrix}, \begin{bmatrix} \zeta \\ \zeta(0) \end{bmatrix} \right\rangle = 0.
\end{aligned}$$

Conversely, assume that $\langle [\begin{smallmatrix} \zeta \\ \zeta(0) \end{smallmatrix}], [\begin{smallmatrix} \dot{g} + TA^{\mathrm{T}}g \\ g(0) - g(1) \end{smallmatrix}] \rangle = 0$ for all $g \in \mathcal{C}^1([0,1], \mathbb{R}^n)$. Then

$$\begin{aligned}
&\textstyle\int_0^1 \zeta^{\mathrm{T}}(t)(\dot{g}(t) + TA(t)^{\mathrm{T}}g(t))dt + \zeta^{\mathrm{T}}(0)(g(0) - g(1)) = 0\\
\Rightarrow&\\
&\textstyle \zeta(1)^{\mathrm{T}}g(1) - \zeta(0)^{\mathrm{T}}g(0) + \zeta(0)^{\mathrm{T}}(g(0) - g(1)) - \int_0^1 (\dot{\zeta}(t) - TA(t)\zeta(t))^{\mathrm{T}}g(t)dt = 0\\
\Rightarrow&\\
&\textstyle -(\zeta(0) - \zeta(1))^{\mathrm{T}}g(1) - \int_0^1 (\dot{\zeta}(t) - TA(t)\zeta(t))^{\mathrm{T}}g(t)dt = 0.
\end{aligned}$$

If $\dot{\zeta}(t) - TA(t)\zeta(t) \neq 0$, then there exists a $g(t)$ with $g(1) = 0$ such that

$$\int_0^1 (\dot{\zeta}(t) - TA(t)\zeta(t))^{\mathrm{T}}g(t)dt \neq 0.$$

This is impossible, so $\dot{\zeta}(t) + TA(t)^{\mathrm{T}}\zeta(t) = 0$. Hence $(\zeta(0) - \zeta(1))^{\mathrm{T}}g(1) = 0$ for all g; hence $\zeta(0) - \zeta(1) = 0$. From $\dot{\zeta}(t) - TA(t)\zeta(t) = 0$ and $\zeta(0) = \zeta(1)$ it follows that $\zeta \in \mathrm{Ker}(\phi_1)$.

The proof of the second assertion is similar. □

PROPOSITION A.2. *Consider* $\phi_{1,2} : \mathcal{C}^1([0,1], \mathbb{R}^n) \to \mathcal{C}^0([0,1], \mathbb{R}^n) \times \mathbb{R}^n$, *where*

$$\phi_1(\zeta) = \begin{bmatrix} \dot{\zeta} - TA\zeta \\ \zeta(0) + \zeta(1) \end{bmatrix}, \phi_2(\zeta) = \begin{bmatrix} \dot{\zeta} + TA^{\mathrm{T}}\zeta \\ \zeta(0) + \zeta(1) \end{bmatrix}.$$

If $\zeta \in \mathcal{C}^1([0,1], \mathbb{R}^n)$, *then* $\zeta \in \mathrm{Ker}(\phi_1)$ *if and only if*

$$\begin{bmatrix} \zeta \\ \zeta(0) \end{bmatrix} \perp \phi_2(\mathcal{C}^1([0,1], \mathbb{R}^n)),$$

and $\zeta \in Ker(\phi_2)$ *if and only if*

$$\begin{bmatrix} \zeta \\ \zeta(0) \end{bmatrix} \perp \phi_1(\mathcal{C}^1([0,1], \mathbb{R}^n)).$$

Proof. The proof is as in Proposition A.1. □

PROPOSITION A.3. *Consider* $\phi_{1,2} : \mathcal{C}^1([0,1], \mathbb{C}^n) \to \mathcal{C}^0([0,1], \mathbb{C}^n) \times \mathbb{C}^n$, *where*

$$\phi_1(\zeta) = \begin{bmatrix} \dot{\zeta} - TA\zeta + i\theta I_n \\ \zeta(0) - \zeta(1) \end{bmatrix}, \phi_2(\zeta) = \begin{bmatrix} \dot{\zeta} + TA^{\mathrm{T}}\zeta - i\theta I_n \\ \zeta(0) - \zeta(1) \end{bmatrix}.$$

If $\zeta \in \mathcal{C}^1([0,1],\mathbb{C}^n)$*, then* $\zeta \in \mathrm{Ker}(\phi_1)$ *if and only if*

$$\begin{bmatrix} \zeta \\ \zeta(0) \end{bmatrix} \perp \phi_2(\mathcal{C}^1([0,1],\mathbb{C}^n)),$$

and $\zeta \in \mathrm{Ker}(\phi_2)$ *if and only if*

$$\begin{bmatrix} \zeta \\ \zeta(0) \end{bmatrix} \perp \phi_1(\mathcal{C}^1([0,1],\mathbb{C}^n)).$$

Proof. The proof is as in Proposition A.1. □

WEAK BV CONVERGENCE OF A MOVING FINITE-ELEMENT METHOD FOR SINGULAR AXISYMMETRIC HARMONIC MAPS[*]

MORGAN PIERRE[†]

Abstract. We prove the convergence of a moving finite-element method for the minimization of a relaxed Dirichlet energy among axisymmetric maps from the disc into the sphere. The optimal mesh and the discrete minimizer exist for a discrete relaxed energy. Similarly to the true solution, the discrete minimizer has a boundary layer. Because of the consistency error introduced by the discretization of the energy, this discrete minimizer is nonconforming. We show that it converges to the solution of the continuous problem in an appropriate BV space. The proof is done for three different piecewise linear finite-element discretizations.

1. Introduction.

Moving mesh methods have been developed in the past three decades for problems whose solutions have sharp layers (see [3, 11, 17] and the references therein). They consist in moving automatically the nodes of a given initial mesh to new locations, the number and connectivity of nodes being fixed. For steady-state problems in which the true solution minimizes an energy functional, there exists a natural optimality criterion for the positioning of the nodes, which has been successfully used by several authors [5, 9, 10, 15]. The idea is to look for the triangulation that minimizes the discrete energy obtained by a finite-element discretization (moving finite elements). In other words, we deal with a constrained optimization problem: the unknowns are, as usual, the values of the discrete solution at the nodes (for a piecewise linear approximation), but also the position of the nodes; the constraints are given by the topology of the triangulation.

From a computational point of view, one major difficulty is the strong nonlinearity of the problem with respect to the nodes; another difficulty is the possibility of tangling. From a mathematical point of view, the existence of an optimal triangulation is a consequence of the continuity of the energy, if one allows degenerate triangles [4]; the optimal triangulation may not be unique. Furthermore, the discrete solution computed together with the optimal mesh converges to the true solution as the number of nodes tends to infinity. This assertion is an immediate consequence of a density result, but it holds only when the elements are conforming and when the energy is computed exactly. If the energy is computed with a quadrature formula, as this happens most often, it may be false because of the consistency error. For instance, if a discrete solution has a discrete energy level lower than the energy level of the true solution, then for every optimal mesh, the discrete energy level will be even lower. To our knowledge, there is no study of the convergence of an optimal mesh method that takes into consideration the consistency error.

The aim of this paper is precisely to prove the convergence of an optimal mesh method in the presence of a consistency error. The solution of the continuous problem that we consider minimizes a relaxed Dirichlet energy among axisymmetric maps from the disc into the sphere. It is defined on $[0, 1]$ and has a "boundary layer of zero thickness" at 0 or, equivalently, a discontinuity. Because of the consistency error introduced by the discretization of the energy, the discrete minimizer is nonconforming; the main difficulty is to find appropriate error estimators.

The continuous problem has been studied by Alouges and the author [2]. Harmonic maps into the unit sphere are a simplified model for liquid crystals (see, for instance, [1]). The singularities arising in the context of harmonic maps can be roughly depicted as "boundary layers with zero thickness." In order to describe them, Giaquinta, Modica, and Souček [7, 8] have proposed to consider the graph of the unknown as a Cartesian current and to understand the convergence of minimizing currents. In our problem, we were able to simplify this approach by using weak *BV* convergence (which, in codimension 1, is equivalent to the convergence of Cartesian currents [7]).

In [2], we also computed the optimal mesh and we showed numerical evidence of the convergence of the solution as the number of nodes tends to infinity. The energy of the piecewise linear approximation could not be computed exactly because of a cosine term, so we used two different quadrature formulas: the midpoint formula (see Figures 4.1 and 4.2) and the Gaussian formula with two nodes. The optimal mesh and the discrete minimizer exist for a discrete relaxed energy. Similarly to the true solution, the graph of the discrete solution has a vertical part at 0. In order to compute this, we used an appropriate change of variable for the mesh variables and we implemented a projected conjugate gradient algorithm.

The paper is organized as follows. For the reader's convenience, we sum up in section 2 the main results obtained in [2] for the continuous problem. In section 3, we prove the convergence of the moving finite-element method, under the assumption that the discrete energy is computed exactly: the elements here are conforming. In section 4, the elements are nonconforming because of the midpoint formula; we introduce an external approximation [14] in the *BV* space, which allows us to prove the convergence. In section 5, we deal with the midpoint formula for the S^1 formulation of the problem. In section 6, we sum up the main results and we discuss the extension of the method in higher dimension.

2. The continuous problem. A map $u : B^2 \to S^2$ from the unit disc into the unit sphere is called *axially symmetric* if there exists an angle function $\theta : [0, 1] \to \mathbb{R}$ (θ is the latitude) which depends only on $r := \sqrt{x^2 + y^2}$ such that

$$u(x, y) = \left(\cos\theta(r)\frac{x}{r}, \cos\theta(r)\frac{y}{r}, \sin\theta(r)\right) \quad \forall (x, y) \in B^2.$$

If u is axisymmetric with angle function $\theta(r)$, its Dirichlet energy is

$$E(\theta) := \pi \int_0^1 \frac{\cos^2\theta}{r} + r\theta'^2 dr = \frac{1}{2}\int_{B^2} |\nabla u|^2 dxdy =: E(u). \tag{2.1}$$

Define the space of bounded energy functions with boundary condition α

$$\mathcal{E}_\alpha := \left\{\theta \in \mathcal{C}^0(]0, 1]),\ \theta(1) = \alpha,\ \frac{\cos\theta}{\sqrt{r}} \in L^2(0, 1),\ \text{and}\ \sqrt{r}\theta' \in L^2(0, 1)\right\}. \tag{2.2}$$

For every $\theta \in \mathcal{E}_\alpha$ there exists $k \in \mathbb{Z}$ such that $\lim_{r\to 0}\theta(r) = -\pi/2 + k\pi$. The integer k is called the $1d$ degree of θ. Thus $\mathcal{E}_\alpha = \bigcup_{k\in\mathbb{Z}} \mathcal{E}_{\alpha,k}$, where

$$\mathcal{E}_{\alpha,k} := \{\theta \in \mathcal{E}_\alpha,\ \theta(0) = -\pi/2 + k\pi\}. \tag{2.3}$$

We consider the following minimization problem:

$$\text{Minimize } E(\theta) \text{ in } \mathcal{E}_{\alpha,k}. \tag{2.4}$$

In general, the class $\mathcal{E}_{\alpha,k}$ does not have a minimizer. The theory for the two-dimensional Dirichlet problem (see [16] for instance) explains this by an energy concentration at $r = 0$ for minimizing sequences (*bubbling*). We were able to describe in a BV space this phenomenon of loss of compactness by concentration.

Recall that if $I =]a, b[$ is an open bounded interval,

$$BV(I) := \{y \in L^1(I),\ |y'|_{BV(I)} < \infty\},$$

where for all $y \in L^1(I)$, the total mass of y' is defined by

$$|y'|_{BV(I)} := \sup\left\{\int_I y(r)\varphi'(r)dr \mid \varphi \in \mathcal{C}_c^\infty(I,\mathbb{R}),\ ||\varphi||_\infty \le 1\right\}.$$

The space $BV(I)$ is a Banach space for the norm $\|y_n\|_{BV(I)} = |y'|_{BV(I)} + \|y\|_{L^1(I)}$. We will use the following.

Definition 2.1 (weak BV convergence). *Let $(y_n)_n$ be a sequence of functions in $BV(I)$ and let $y \in BV(I)$. Then $(y_n)_n$ converges weakly to y in $BV(I)$ if $\sup_n |y_n'|_{BV(I)} < \infty$ and $y_n \xrightarrow[n\to\infty]{} y$ strongly in $L^1(I)$. In this case, we have the following bound: $|y'|_{BV(I)} \le \liminf_n |y_n'|_{BV(I)}$.*

The injection $BV(I) \subset L^1(I)$ is compact [7], so every sequence $(y_n)_n$ in $BV(I)$ such that $\sup_n \|y_n\|_{BV(I)} < \infty$ converges, up to a subsequence, weakly in $BV(I)$ to some $y \in BV(I)$.

Turning back to (2.4), let $F \in \mathcal{C}^1(\mathbb{R},\mathbb{R})$ be the change of variable defined by

$$F(0) = 0 \text{ and } F'(\varphi) = |\cos\varphi| \quad \forall\varphi \in \mathbb{R}. \tag{2.5}$$

We recall that $F(\varphi + l\pi) = (\sin\varphi) + 2l$ for all $\varphi \in [-\pi/2, \pi/2]$ and for all $l \in \mathbb{Z}$. Then a fundamental inequality is the lower bound of the energy by the degree.

Lemma 2.2 (Alouges and Pierre). *For every $\theta \in \mathcal{E}_{\alpha,k}$,*

$$E(\theta) \ge 2\pi \int_0^1 |\theta' \cos\theta| dr \ge 2\pi \left|F(-\pi/2 + k\pi) - F(\alpha)\right|. \tag{2.6}$$

Moreover, $\Lambda_{\alpha,k} := \inf_{\theta\in\mathcal{E}_{\alpha,k}} E(\theta) = 2\pi\,|F(-\pi/2 + k\pi) - F(\alpha)|$.

From (2.6) it is clear that $F(\theta)$ belongs to $W^{1,1}(]0,1[) \subset BV(]0,1[)$ for every $\theta \in \mathcal{E}_{\alpha,k}$. In order to describe the concentration at $r = 0$ as the jump of a BV function, we included $[0,1]$ in $[-1,1]$ by symmetrization. For all $y := F \circ \theta$ with $\theta \in \mathcal{E}_\alpha$, its extension of degree k on $[-1,1]$ is the BV function built as

$$P_k(y)(r) := \begin{cases} y(r) & \text{if} \quad r \in [0,1], \\ -y(-r) + 4k - 2 & \text{if} \quad r \in [-1,0[. \end{cases}$$

Notice that if $\theta \in \mathcal{E}_{\alpha,k}$, then $y := P_k \circ F(\theta)$ is continuous on $[-1,1]$. Now we define as subsets of $BV(]-1,1[)$ the class $\mathcal{E}_{\alpha,k}$ and its "closure":

$$\mathcal{Y}_{\alpha,k} := P_k \circ F(\mathcal{E}_{\alpha,k}) \quad \text{and} \quad \overline{\mathcal{Y}}_{\alpha,k} := P_k \circ F(\mathcal{E}_\alpha). \tag{2.7}$$

The *BV* frame allowed us to introduce the following *relaxed energy*:

$$\overline{E}(y) := \inf\left\{\liminf_n E(y_n) \mid y_n \in \mathcal{Y}_{\alpha,k},\ y_n \rightharpoonup y \text{ weakly in } BV(]-1,1[)\right\} \quad \forall y \in \overline{\mathcal{Y}}_{\alpha,k}. \tag{2.8}$$

The relaxed energy is a lower semicontinuous (l.s.c.) extension of E called the *Lebesgue extension of* E [8]. In the following we use the notation $y = y_{\theta,k}$ for every $y \in \overline{\mathcal{Y}}_{\alpha,k}$ such that $y = P_k \circ F(\theta)$. In [2], we proved that

$$\overline{E}(y_{\theta,k}) = E(\theta) + 4|\theta(0) - (-\pi/2 + k\pi)| \qquad (y_{\theta,k} \in \overline{\mathcal{Y}}_{\alpha,k}). \tag{2.9}$$

With these definitions we obtained the existence and uniqueness.

THEOREM 2.3 (Alouges and Pierre). *Let* $(\alpha,k) \in [-\pi/2, 0] \times \mathbb{Z}$. *Then* $\inf_{y\in\overline{\mathcal{Y}}_{\alpha,k}} \overline{E}(y) = \inf_{\theta\in\mathcal{E}_{\alpha,k}} E(\theta)$, *and there exists a unique minimizer* $y_{\underline{\theta},k}$ *for* $\overline{E}$ *in* $\overline{\mathcal{Y}}_{\alpha,k}$. *Moreover, if* $(y_{\theta_n,k})_n$ *is a minimizing sequence for* $\overline{E}$ *in* $\overline{\mathcal{Y}}_{\alpha,k}$, *then* $y_{\theta_n,k} \underset{n\to\infty}{\rightharpoonup} y_{\underline{\theta},k}$ *weakly in* $BV(]-1,1[)$ *and* $\sqrt{r}\theta'_n \underset{n\to\infty}{\rightharpoonup} \sqrt{r}\underline{\theta}'$ *weakly in* $L^2(0,1)$.

In Theorem 2.3 the solution $y_{\underline{\theta},k}$ is regular (i.e., continuous on $[-1,1]$) if and only if $(\alpha,k) = (-\pi/2, 0)$ or $(\alpha,k) \in]-\pi/2, 0] \times \{0,1\}$. This corresponds exactly to the cases where problem (2.4) has a solution. In this case any minimizing sequence $(\theta_n)_n$ in $\mathcal{E}_{\alpha,k}$ converges strongly in the sense that $E(\theta_n) \xrightarrow[n\to\infty]{} E(\underline{\theta})$. We point out for the latter purpose that the minimizer $y_{\underline{\theta},k}$ is known explicitly. In particular, for $\alpha = -\pi/2$ then $\underline{\theta} \equiv -\pi/2$. If $\alpha \in]-\pi/2, 0]$, then $\underline{\theta} = \theta_{\alpha,1}$ for $k \geq 1$ and $\underline{\theta} = \theta_{\alpha,0}$ for $k \leq 0$, where $\theta_{\alpha,1}$ and $\theta_{\alpha,0}$ can be computed from

$$\theta' = \varepsilon \cos\theta \quad (0 < r \leq 1), \quad \theta(1) = \alpha, \tag{2.10}$$

with $\varepsilon = +1$ for $\theta_{\alpha,1}$ and $\varepsilon = -1$ for $\theta_{\alpha,0}$, respectively.

3. Conforming moving finite elements.

3.1. Moving finite elements and discrete relaxed energy. We use moving continuous P_1 elements to discretize the space $\mathcal{E}_{\alpha,k}$. Let

$$\mathcal{E}^N_{\alpha,k} := \Big\{\theta^N \in \mathcal{C}^0([0,1]),\ \theta^N(0) = -\frac{\pi}{2} + k\pi,\ \theta^N(1) = \alpha, \quad \text{and there exist}$$
$$r_0 = 0 < \cdots < r_N = 1 \text{ such that } \theta^N \text{ is affine on every } [r_i, r_{i+1}]\Big\}.$$

Since $\mathcal{E}^N_{\alpha,k} \subset \mathcal{E}_{\alpha,k}$, the elements here are *conforming* [14]. A function $\theta^N \in \mathcal{E}^N_{\alpha,k}$ is uniquely defined by the values $r_0 = 0 < \cdots < r_N = 1$ and $\theta_i := \theta^N(r_i)$ for $i \in \{0, \ldots, N\}$. Throughout section 3 we use the identification

$$\theta^N \simeq (r_0, r_1, \ldots, r_N, \theta_0, \ldots, \theta_N). \tag{3.1}$$

In particular, $\mathcal{E}^N_{\alpha,k} \simeq D^N$, where $D^N \subset \mathbb{R}^{2N+2}$ is defined by

$$D^N := \left\{r_0 = 0 < r_1 < \cdots < r_N = 1,\ \theta_0 = -\frac{\pi}{2} + k\pi, \theta_1, \ldots, \theta_N = \alpha\right\}. \tag{3.2}$$

In the remainder of this paper, we define various discrete energies E^N, which are consistent approximations of the exact energy E. A numerical solution to problem (2.4) is a minimizer of $E^N(r_0, r_1, \dots, r_N, \theta_0, \theta_1, \dots, \theta_N)$ in D^N under the constraints $r_0 = 0 < r_1 < \cdots < r_N = 1$. In order to guarantee the existence of a minimizer, we introduce an l.s.c. extension of E^N on the closure

$$\overline{D^N} = \left\{ r_0 = 0 \leq r_1 \leq \cdots \leq r_N = 1,\ \theta_0 = -\frac{\pi}{2} + k\pi, \theta_1, \dots, \theta_N = \alpha \right\}. \tag{3.3}$$

The following well-known lemma [6] gives such an extension (compare with (2.8)).

Lemma 3.1. *Let $D \subset \mathbb{R}^m$ and suppose $E : D \to [0, \infty)$ is continuous on D. Then $\overline{E} : \overline{D} \to [0, \infty]$, defined on the closure of D in $\mathbb{R}^m$ by*

$$\overline{E}(x) := \inf \left\{ \liminf_n E(x_n) \mid x_n \in D,\ x_n \to x \right\} \qquad (x \in \overline{D}),$$

is an extension of E which is l.s.c. on $\overline{D}$.

In the following we will extend the identification (3.1), in order to associate to every element $(r_0, \dots, \theta_N) \in \overline{D^N}$ its "P_1 interpolate" y^N, which is a BV function as in the continuous case.

3.2. Exact discretization. In the remainder of section 3 we suppose that E^N is exact. For every $\theta^N \in \mathcal{E}^N_{\alpha,k}$ that corresponds to $(r_0, \dots, r_N, \theta_0, \dots, \theta_N) \in D^N$, let

$$E^N(\theta^N) := \pi \sum_{i=0}^{N-1} \left(\int_{r_i}^{r_{i+1}} \frac{\cos^2 \theta^N}{r} dr \right) + \frac{(\theta_{i+1} - \theta_i)^2}{2} \left(\frac{r_{i+1} + r_i}{r_{i+1} - r_i} \right). \tag{3.4}$$

It is clear from (3.4) that E^N is continuous on D^N. Lemma 3.1 gives an l.s.c. extension $\overline{E^N}$ of E^N on $\overline{D^N}$. Clearly,

$$E^N(r_0, \dots, \theta_N) \geq \frac{\pi}{2} \sum_{i=0}^{N-1} (\theta_{i+1} - \theta_i)^2, \tag{3.5}$$

and by continuity of the right-hand side, the same estimate holds for $\overline{E^N}$. Thus, every minimizing sequence for $\overline{E^N}$ in $\overline{D^N}$ is bounded, and converges up to a subsequence to a minimizer. In particular, there exists a minimizer for $\overline{E^N}$ in $\overline{D^N}$.

Extending the identification $\mathcal{E}^N_{\alpha,k} \simeq D^N$, we want to see the minimizer for $\overline{E^N}$ as an element of $BV(]-1, 1[)$ as in the continuous case (2.7). Let

$$\mathcal{Y}^N_{\alpha,k} := P_k \circ F\big(\mathcal{E}^N_{\alpha,k}\big) \subset W^{1,1}(]-1, 1[) \tag{3.6}$$

denote the class $\mathcal{E}^N_{\alpha,k}$ in coordinates y. For every $y^N \in \mathcal{Y}^N_{\alpha,k}$ we denote $E^N(y^N) := E^N(\theta^N)$ where θ^N is the unique element in $\mathcal{E}^N_{\alpha,k}$ such that $y^N = P_k \circ F(\theta^N)$. The closure of $\mathcal{Y}^N_{\alpha,k}$ is defined by

$$\overline{\mathcal{Y}^N_{\alpha,k}} := \Big\{ y^N \in \overline{\mathcal{Y}}_{\alpha,k} \mid \exists\, y_n \in \mathcal{Y}^N_{\alpha,k},\ \sup_n E^N(y_n) < \infty \text{ and } y_n \underset{n\to\infty}{\rightharpoonup} y^N \text{ weakly in } BV(]-1, 1[) \Big\}. \tag{3.7}$$

We can now see the discrete relaxed energy as an analogue of (2.8).

Definition 3.2 (discrete relaxed energy). *For every $y^N \in \overline{\mathcal{Y}^N_{\alpha,k}}$,*

$$\overline{\overline{E^N}}(y^N) := \inf \left\{ \liminf_n E^N(y_n) \mid y_n \in \mathcal{Y}^N_{\alpha,k},\ y_n \underset{n\to\infty}{\rightharpoonup} y^N \text{ weakly in } BV \right\}. \tag{3.8}$$

Since $E^N(\theta^N) = E(\theta^N)$ for all $\theta^N \in \mathcal{E}^N_{\alpha,k}$, it is clear that $\overline{\mathcal{Y}^N_{\alpha,k}} \subset \overline{\mathcal{Y}}_{\alpha,k}$ and $\overline{E}(y^N) \leq \overline{\overline{E^N}}(y^N)$ for all $y^N \in \overline{\mathcal{Y}^N_{\alpha,k}}$. Moreover, by extending the identification $\mathcal{E}^N_{\alpha,k} \simeq D^N$ it is easy to see that

$$\overline{\mathcal{Y}^N_{\alpha,k}} \simeq \left\{ (r_0, \dots, \theta_N) \in \overline{D^N} \mid \overline{E^N}(r_0, \dots, \theta_N) < \infty \right\}$$

and that both definitions for the relaxed energy are equivalent, i.e., $\overline{\overline{E^N}}(y^N) = \overline{E^N}(r_0, \dots, \theta_N)$ for all $y^N \in \overline{\mathcal{Y}^N_{\alpha,k}}$, which corresponds to $(r_0, \dots, \theta_N) \in \overline{D^N}$. In the following we denote $\overline{\overline{E^N}} = \overline{E^N}$.

In order to prove that the discrete minimizer for the exact energy tends to the continuous minimizer when $N \to \infty$, we only need, by Theorem 2.3, to build a minimizing sequence made of P_1 elements. This is an easy density.

Lemma 3.3. *There exists a minimizing sequence for E in $\mathcal{E}_{\alpha,k}$ made of continuous P_1 finite elements.*

Proof. By P_1 interpolation [14], the energy of any regular function in $\mathcal{E}_{\alpha,k}$ can be approximated as closely as desired by a P_1 function in $\mathcal{E}_{\alpha,k}$. Clearly, $\inf_{\mathcal{E}_{\alpha,k}} E = \inf_{\mathcal{C}^2([0,1]) \cap \mathcal{E}_{\alpha,k}} E$, and this concludes the proof. □

As a consequence, we have the following proposition.

Proposition 3.4. *For every integer N let y^N be a minimizer for $\overline{E^N}$ in $\overline{\mathcal{Y}^N_{\alpha,k}}$. Then $(y^N)_N$ is a minimizing sequence for $\overline{E}$ in $\overline{\mathcal{Y}}_{\alpha,k}$. In particular, $y^N \underset{N\to\infty}{\rightharpoonup} \underline{y}$ weakly in $BV(]-1,1[)$, where $\underline{y}$ is the unique minimizer for $\overline{E}$ in $\overline{\mathcal{Y}}_{\alpha,k}$.*

4. Midpoint formula.

We use the same notation as in section 3.1. The difficulty now is that the integral in formula (3.4) cannot be computed exactly. It is necessary to use a quadrature formula, which introduces a *consistency error.* In section 4 we choose the midpoint formula. For every $\theta^N \in \mathcal{E}^N_{\alpha,k}$, which corresponds to $(r_0, \dots, \theta_N) \in D^N$,

$$E^N(\theta^N) := 2\pi \sum_{i=0}^{N-1} E_i(\theta^N), \tag{4.1}$$

where for all $i \in \{0, \dots, N-1\}$

$$E_i(\theta^N) := \left[\cos^2\left(\frac{\theta_i + \theta_{i+1}}{2}\right) \left(\frac{r_{i+1} - r_i}{r_{i+1} + r_i}\right) + \left(\frac{\theta_{i+1} - \theta_i}{2}\right)^2 \left(\frac{r_{i+1} + r_i}{r_{i+1} - r_i}\right) \right]. \tag{4.2}$$

The function E_i is defined on $\mathcal{E}^N_{\alpha,k} \simeq D^N$ and depends only on θ_i, θ_{i+1} and the ratio $t_i = r_i / r_{i+1}$.

It is clear from (4.2) that E^N is continuous on D^N. Lemma 3.1 gives an l.s.c. extension $\overline{E^N}$ of E^N on $\overline{D^N}$. By the same argument as in section 3.2, there exists a minimizer for $\overline{E^N}$ in $\overline{D^N}$. Figures 4.1 and 4.2 show the corresponding minimizer obtained in [2] for $\alpha = -\pi/4$, $k = 3$, $N = 23$ and $\alpha = -\pi/2$, $k = 1$, $N = 10$, respectively. Notice that a vertical part in the graph of the minimizer can only occur at $r = 0$, since if $r_i = r_{i+1} > 0$ and $\overline{E^N}(\theta^N) < \infty$, then $\theta_i = \theta_{i+1}$.

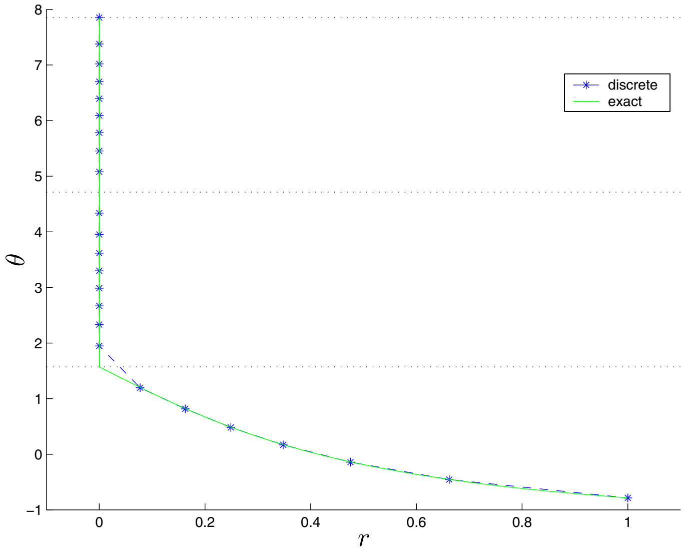

FIG. 4.1. *Midpoint for* $\alpha = -\pi/4$, $k = 3$, $N = 23$.

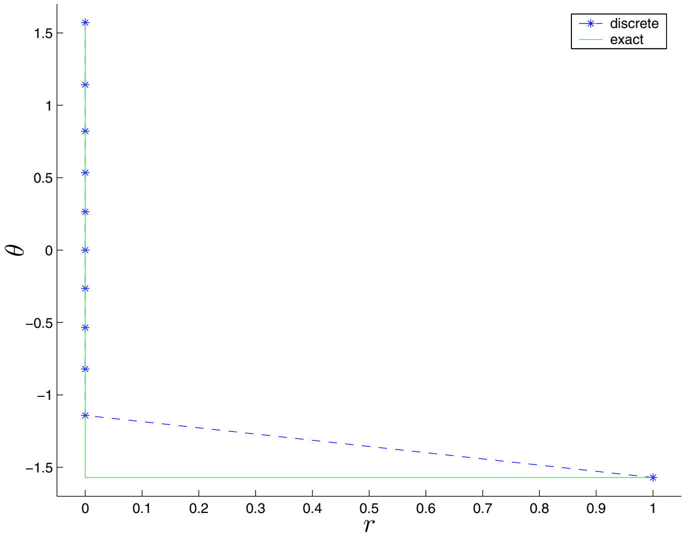

FIG. 4.2. *Midpoint for* $\alpha = -\pi/2$, $k = 1$, $N = 10$.

4.1. Discrete Euler–Lagrange equation. The first fundamental idea in the rest of section 4 is the change of variable

$$X_i := \frac{r_{i+1} - r_i}{r_{i+1} + r_i} = \frac{1 - t_i}{1 + t_i}. \tag{4.3}$$

With this formulation,

$$E_i(X_i, \theta_i, \theta_{i+1}) = \cos^2\left(\frac{\theta_i + \theta_{i+1}}{2}\right) X_i + \left(\frac{\theta_{i+1} - \theta_i}{2}\right)^2 \frac{1}{X_i}. \tag{4.4}$$

We recall that the values $r_0 = 0$, $r_N = 1$, $\theta_0 = -\pi/2 + k\pi$, and $\theta_N = \alpha$ are fixed, so $t_0 = 0$ and $X_0 = 1$. Thus E^N is a function of $(X_1, \ldots, X_{N-1}, \theta_1, \ldots, \theta_{N-1})$ denoted E_X^N and defined on $]0,1[^{N-1} \times \mathbb{R}^{N-1}$. It is clear that the map

$$\begin{aligned} D^N \cap \mathbb{R}^{N-1} &\to]0,1[^{N-1}, \\ (r_1, \ldots, r_{N-1}) &\to \left(t_1, \ldots, t_i = \frac{r_i}{r_{i+1}}, \ldots, t_{N-1}\right) \end{aligned} \tag{4.5}$$

is a smooth diffeomorphism: for all $(t_1, \ldots, t_{N-1}) \in]0,1[^{N-1}$ the inverse in $D^N \cap \mathbb{R}^{N-1}$ is computed by $r_i = t_i r_{i+1}$ for $i = N-1, N-2, \ldots, 1$. Thus

$$\inf_{D^N} E^N(r_0, \ldots, \theta_N) = \inf_{]0,1[^{N-1} \times \mathbb{R}^{N-1}} E_X^N(X_1, \ldots, X_{N-1}, \theta_1, \ldots, \theta_{N-1}). \tag{4.6}$$

The second fundamental idea is a well-known inequality, but we state it as a lemma because of its importance. The proof is immediate.

LEMMA 4.1. *Let $(a,b) \in \mathbb{R}^2$. Then*

$$\inf_{X \in]0,1]} \left(a^2 X + \frac{b^2}{X}\right) = \begin{cases} 2|ab| & \textit{if} \quad |a| > |b|, \ \textit{obtained for } X = \dfrac{|b|}{|a|}, \\ a^2 + b^2 & \textit{if} \quad |a| \leq |b|, \ \textit{obtained for } X = 1. \end{cases}$$

In particular we have $\inf_{X_i \in]0,1[} E_i(X_i, \theta_i, \theta_{i+1}) = J(\theta_i, \theta_{i+1})$ for all (θ_i, θ_{i+1}), where $J : \mathbb{R}^2 \to \mathbb{R}$ is defined by

$$J(\theta, \tilde{\theta}) := \begin{cases} 2\dfrac{|\tilde{\theta} - \theta|}{2}\left|\cos\left(\dfrac{\theta + \tilde{\theta}}{2}\right)\right| & \text{if } \dfrac{|\tilde{\theta} - \theta|}{2} \leq \left|\cos\left(\dfrac{\theta + \tilde{\theta}}{2}\right)\right|, \\ \left(\dfrac{\tilde{\theta} - \theta}{2}\right)^2 + \cos^2\left(\dfrac{\theta + \tilde{\theta}}{2}\right) & \text{if } \dfrac{|\tilde{\theta} - \theta|}{2} \geq \left|\cos\left(\dfrac{\theta + \tilde{\theta}}{2}\right)\right|. \end{cases} \tag{4.7}$$

The following result is a discrete version of the Euler–Lagrange equation (2.10).

PROPOSITION 4.2. *Let $(r_i^N, \theta_i^N)_{0 \leq i \leq N}$ be a minimizer for $\overline{E^N}$ in $\overline{D^N}$, with $\theta_N = \alpha$. Then for all $i \in \{0, \ldots, N-1\}$ such that $r_{i+1} > 0$ and*

$$(\theta_i \neq \theta_{i+1}) \ \textit{or} \ \left(\theta_i = \theta_{i+1} \not\equiv \frac{\pi}{2} \pmod{\pi}\right), \tag{4.8}$$

$$\frac{r_{i+1} - r_i}{r_{i+1} + r_i} = \begin{cases} \dfrac{|\theta_{i+1} - \theta_i|}{2\left|\cos\left(\frac{\theta_i + \theta_{i+1}}{2}\right)\right|} & \textit{if } \dfrac{|\theta_{i+1} - \theta_i|}{2} < \left|\cos\left(\dfrac{\theta_i + \theta_{i+1}}{2}\right)\right|, \\ 1 & \textit{if } \dfrac{|\theta_{i+1} - \theta_i|}{2} \geq \left|\cos\left(\dfrac{\theta_i + \theta_{i+1}}{2}\right)\right|. \end{cases} \tag{4.9}$$

Proof. Lemma 4.1 and equality (4.6) imply

$$\overline{E^N}(r_0, \ldots, \theta_N) = 2\pi \sum_{i=0}^{N-1} J(\theta_i, \theta_{i+1}). \tag{4.10}$$

For all $i \in \{0,\dots,N\}$ let $\overline{E_i}$ be the l.s.c. extension of E_i on $\overline{D^N}$ from Lemma 3.1. It is clear from the definition that $\overline{E^N}(r_0,\dots,\theta_N) \geq 2\pi\sum_{i=0}^{N-1}\overline{E_i}(r_0,\dots,\theta_N)$, and this together with Lemma 4.1 implies $\overline{E_i}(r_0,\dots,\theta_N) = J(\theta_i,\theta_{i+1})$ for all i.

Now assume there exists $i \in \{0,\dots,N-1\}$ with $r_{i+1} > 0$ such that (4.8) is satisfied and (4.9) is not satisfied. Necessarily, $r_i < r_{i+1}$, otherwise $r_i = r_{i+1} > 0$ would imply $\theta_i = \theta_{i+1}$, with $\cos((\theta_i+\theta_{i+1})/2) \neq 0$ by (4.8), and (4.9) would be satisfied. So X_i belongs to $]0,1]$. We apply Lemma 4.1 by noticing that the minimizer $X \in]0,1]$ given in the lemma is unique except for $a = b = 0$. This is not possible here by assumption (4.8) and X_i is not the minimizer since (4.9) is not satisfied, so $E_i(X_i,\theta_i,\theta_{i+1}) > J(\theta_i,\theta_{i+1})$. It is clear by continuity that $E_i(X_i,\theta_i,\theta_{i+1}) = \overline{E_i}(r_i,r_{i+1},\theta_i,\theta_{i+1})$, hence a contradiction, and this concludes the proof. □

In agreement with Figure 4.2 we have the following.

Corollary 4.3. *If $\alpha = -\pi/2$ and $(r_i^N,\theta_i^N)_{0\leq i\leq N}$ is a minimizer for $\overline{E^N}$ in $\overline{D^N}$, then $r_0 = r_1 = \cdots = r_{i_N} = 0$, where $i_N := \max\{i \mid \theta_i \neq -\pi/2\}$.*

Proof. If $r_{i_N+1} = 0$, then the assertion is proved. Otherwise, $r_{i_N+1} > 0$, and since $\theta_{i_N} \neq -\pi/2$, $\theta_{i_N+1} = -\pi/2$, we can apply Proposition 4.2 with $i = i_N$. We find $(r_{i_N+1} - r_{i_N})/(r_{i_N+1} + r_{i_N}) = 1$, so $r_{i_N} = 0$ as expected. □

Remark. The numerical computations show that $(\theta_i^N)_{0\leq i\leq N}$ is monotone, but we have not been able to prove it.

4.2. Upper bound for the degree. Similarly to the continuous case (2.6), the energy E^N defined by the midpoint formula (4.1) is greater than the degree. The proof of this assertion is based on the following (stronger) lemma. We recall that J is defined by (4.7) and F by (2.5).

Lemma 4.4. *Let $(\theta,\tilde{\theta}) \in \mathbb{R}^2$. If $\theta \neq \tilde{\theta}$, then $J(\theta,\tilde{\theta}) > |F(\theta) - F(\tilde{\theta})|$.*

Proof. First assume there exists $l \in \mathbb{Z}$ such that $[\theta,\tilde{\theta}] \subset [\pi/2 + l\pi, \pi/2 + (l+1)\pi]$. Then $|\tilde{\theta} - \theta|/2 > |\sin((\tilde{\theta}-\theta)/2)|$ and $\cos((\theta+\tilde{\theta})/2) \neq 0$, so by Lemma 4.1

$$J(\theta,\tilde{\theta}) > 2\left|\sin\left(\frac{\tilde{\theta}-\theta}{2}\right)\right|\left|\cos\left(\frac{\theta+\tilde{\theta}}{2}\right)\right|. \tag{4.11}$$

The right-hand side of (4.11) being equal to $|\sin\tilde{\theta} - \sin\theta| = |F(\theta) - F(\tilde{\theta})|$, Lemma 4.4 is proved.

If the previous assumption is not satisfied, there exists $l \in \mathbb{Z}$ such that

$$\frac{\pi}{2} + l\pi \in]\theta,\tilde{\theta}[. \tag{4.12}$$

Let $m \geq 1$ denote the number of $l \in \mathbb{Z}$ that satisfy (4.12). Assume $\theta < \tilde{\theta}$ (the proof for $\theta > \tilde{\theta}$ is similar). Then we have a monotone sequence

$$\theta < \frac{\pi}{2} + l\pi < \frac{\pi}{2} + (l+1)\pi < \cdots < \frac{\pi}{2} + (l+m-1)\pi < \tilde{\theta},$$

where l is the smallest integer that satisfies (4.12). We define $h := \pi/2 + l\pi - \theta$ and $k := \tilde{\theta} - (\pi/2 + (l+m-1)\pi)$. Notice that $h \in]-0,\pi]$ and $k \in]0,\pi]$. Then,

$$\begin{aligned}\left|F(\theta) - F(\tilde{\theta})\right| &= |1 - \cos h| + 2(m-1) + |1 - \cos k|,\\ &= 2(m-1) + 2\sin^2\left(\frac{h}{2}\right) + 2\sin^2\left(\frac{k}{2}\right).\end{aligned} \tag{4.13}$$

On the other hand,

$$J(\theta,\tilde{\theta}) = \inf_{X\in]0,1]} \cos^2\left(m\frac{\pi}{2}+\frac{h-k}{2}\right)X + \left(\frac{h+k+(m-1)\pi}{2}\right)^2\frac{1}{X}.$$

Case $m=1$. Since $\sin^2(\frac{h-k}{2}) \le |\frac{h-k}{2}|^2 \le (\frac{h+k}{2})^2$, from Lemma 4.1

$$J(\theta,\tilde{\theta}) = \sin^2\left(\frac{h-k}{2}\right) + \left(\frac{h+k}{2}\right)^2. \tag{4.14}$$

With (4.13) and (4.14), Lemma 4.5, which follows, concludes the proof for $m=1$.

Case $m\ge 2$. Since

$$\cos^2\left(\frac{m\pi}{2}+\frac{h-k}{2}\right) \le 1 \le \left(\frac{\pi}{2}\right)^2 \le \left(\frac{h+k+(m-1)\pi}{2}\right)^2,$$

with Lemma 4.1 we get

$$J(\theta,\tilde{\theta}) = \cos^2\left(\frac{m\pi}{2}+\frac{h-k}{2}\right) + \left(\frac{h+k+(m-1)\pi}{2}\right)^2. \tag{4.15}$$

If $m=2$, then from (4.13) and (4.15), Lemma 4.6 which follows, concludes the proof. If $m\ge 3$, then by (4.15),

$$J(\theta,\tilde{\theta}) \ge \left(\frac{(m-1)\pi}{2}\right)^2 > 2(m+1) \ge 2(m-1) + 2\sin^2\left(\frac{h}{2}\right) + 2\sin^2\left(\frac{k}{2}\right).$$

The relation (4.13) concludes the proof. □

LEMMA 4.5. *For all* $(h,k)\in[0,\pi]^2$ *with* $(h,k)\ne(0,0)$,

$$\sin^2\left(\frac{h-k}{2}\right) + \left(\frac{h+k}{2}\right)^2 > 2\sin^2\left(\frac{h}{2}\right) + 2\sin^2\left(\frac{k}{2}\right).$$

Proof. Let $G:\mathbb{R}^2\to\mathbb{R}$ be defined by

$$G(h,k) := \sin^2\left(\frac{h-k}{2}\right) + \left(\frac{h+k}{2}\right)^2 - 2\sin^2\left(\frac{h}{2}\right) - 2\sin^2\left(\frac{k}{2}\right).$$

Let $(\underline{h},\underline{k})$ be a minimizer for G in $[0,\pi]\times[0,\pi]$ and assume that $(\underline{h},\underline{k})\in]0,\pi[^2$. Then $(\partial_h G,\partial_k G)(\underline{h},\underline{k}) = (0,0)$. A computation gives

$$\partial_h G(h,k) = \frac{\sin(h-k)}{2} + \frac{k-h}{2} + (h-\sin h) \quad \forall (h,k)\in[0,\pi]^2.$$

If $\pi\ge k\ge h>0$, then $|\sin(h-k)|\le(k-h)$ and $h\ge\sin h$, so $\partial_h G(h,k)\ge k/2>0$: thus $\underline{k}<\underline{h}$. Using the symmetry $G(h,k)=G(k,h)$ the condition $\partial_k G(\underline{h},\underline{k})=0$ implies this time $\underline{k}>\underline{h}$, hence a contradiction. Therefore $(\underline{h},\underline{k})\in\partial\left([0,\pi]^2\right)$. Now from the preceding, we have $\partial_h G(h,\pi)\ge 0$ for all $h\in[0,\pi]$, so $G(h,\pi)\ge G(0,\pi)>0$ for all $h\in[0\pi]$. Moreover, $G(h,0)=(h/2)^2-\sin^2(h/2)>0$ for all $h\in]0,\pi]$. By symmetry $G(h,k)>0$ on $\partial\left([0,\pi]^2\right)-\{(0,0)\}$ and this concludes the proof. □

LEMMA 4.6. *For all* $(h,k)\in[0,\pi]^2$,

$$\cos^2\left(\frac{h-k}{2}\right) + \left(\frac{h+k+\pi}{2}\right)^2 > 2 + 2\sin^2\left(\frac{h}{2}\right) + 2\sin^2\left(\frac{k}{2}\right).$$

Proof. The proof is similar to the previous one. Let $G : \mathbb{R}^2 \to \mathbb{R}$ be defined by

$$G(h,k) := \cos^2\left(\frac{h-k}{2}\right) + \left(\frac{h+k+\pi}{2}\right)^2 - 2\sin^2\left(\frac{h}{2}\right) - 2\sin^2\left(\frac{k}{2}\right) - 2.$$

Let $(\underline{h},\underline{k})$ be a minimizer for G in $[0,\pi]\times[0,\pi]$. Since for all $(h,k)\in[0,\pi]^2$,

$$\begin{aligned}\partial_h G(h,k) &= -\frac{\sin(h-k)}{2} + \frac{h+k+\pi}{2} - \sin h,\\ &\geq \frac{\pi}{2} - \frac{\sin(h-k)}{2} - \sin h > 0,\end{aligned} \tag{4.16}$$

necessarily $(\underline{h},\underline{k}) \in \partial\left([0,\pi]^2\right)$. Moreover, from (4.16), $G(h,0) \geq G(0,0) > 0$ and $G(h,\pi) \geq G(0,\pi) > 0$ for all $h\in[0,\pi]$. The symmetry $G(h,k) = G(k,h)$ concludes the proof. □

Lemma 4.4 implies the upper bound on the degree (compare with Lemma 2.2).

PROPOSITION 4.7. *For all $\theta^N \in \mathcal{E}^N_{\alpha,k}$ which corresponds to $(r_0,\dots,\theta_N)\in D^N$,*

$$E^N(r_0,\dots,\theta_N) \geq 2\pi\int_0^1 |(\theta^N)'\cos\theta^N|dr \geq \Lambda_{\alpha,k}. \tag{4.17}$$

Proof. Let $\theta^N \in \mathcal{E}^N_{\alpha,k}$. Recall that $F(\theta)$ is a primitive of $|\cos\theta|$ on $\mathbb{R}$. On $[r_i, r_{i+1}]$, $(\theta^N)'$ is constant, so $\int_{r_i}^{r_{i+1}} |(\theta^N)'\cos\theta^N|dr = |F(\theta_{i+1}) - F(\theta_i)|$. On the other hand, by Lemma 4.1, for all $i\in\{0,\dots,N-1\}$, $E_i(\theta^N) \geq J(\theta_i,\theta_{i+1})$. Together with Lemma 4.4, a summation on all $i\in\{0,\dots,N-1\}$ concludes the proof (the value of the infimum $\Lambda_{\alpha,k} := \inf_{\mathcal{E}_{\alpha,k}} E$ is given in Lemma 2.2). □

As a consequence, we have the following lemma.

LEMMA 4.8. *For E^N given by the midpoint formula, $\inf_{D^N} E^N \xrightarrow[N\to\infty]{} \Lambda_{\alpha,k}$.*

Proof. By Proposition 4.7, it is sufficient to find a sequence $(\theta^N)_N$, with $\theta^N \in \mathcal{E}^N_{\alpha,k}$ for every N, such that $E^N(\theta^N) \xrightarrow[N\to\infty]{} \Lambda_{\alpha,k}$. Let $\epsilon > 0$. By Lemma 3.3, for N large enough, there exists $\theta^N \in \mathcal{E}^N_{\alpha,k}$, which corresponds to $(r_0,\dots,\theta_N)\in D^N$, such that $E(\theta^N) < \Lambda_{\alpha,k} + \epsilon$. Define $I^M\theta^N$ as the P_1 interpolate of θ^N with respect to the uniform subdivision of each $[r_i,r_{i+1}]$ into M segments. Then $I^M\theta^N$ belongs to $\mathcal{E}^{NM}_{\alpha,k}$ and for M large enough, $E^{NM}(I^M\theta^N) \leq E(\theta^N) + \epsilon \leq \Lambda_{\alpha,k} + 2\epsilon$, and this concludes the proof (recall that $(\inf_{D^N} E^N)_N$ is nonincreasing). □

4.3. Nonconforming moving elements.

In order to see the minimizer for $\overline{E^N}$ as a BV function, we use the y coordinates as in section 3.2. Recall that $\mathcal{Y}^N_{\alpha,k}$ (3.6) denotes the class $\mathcal{E}^N_{\alpha,k}$ in the y coordinates. For every $y^N \in \mathcal{Y}^N_{\alpha,k}$ we denote $E^N(y^N) := E^N(\theta^N)$, where $\theta^N \in \mathcal{E}^N_{\alpha,k}$ satisfies $y^N = P_k \circ F(\theta^N)$. We point out that, as a consequence of Proposition 4.7,

$$2\pi\int_0^1 |(y^N)'|dr \leq E^N(y^N) \quad \forall y^N \in \mathcal{Y}^N_{\alpha,k}. \tag{4.18}$$

The closure of $\mathcal{Y}^N_{\alpha,k}$ for the midpoint formula is defined by

$$\begin{aligned}\overline{\overline{\mathcal{Y}^N_{\alpha,k}}} := \Big\{y^N \in BV(]-1,1[) \mid \exists\, y_n \in \mathcal{Y}^N_{\alpha,k},\ \sup_n E^N(y_n) < \infty\\ \text{and } y_n \underset{n\to\infty}{\rightharpoonup} y^N \text{ weakly in } BV(]-1,1[)\Big\}.\end{aligned}$$

In order to describe $\overline{\overline{\mathcal{Y}^N_{\alpha,k}}}$ we introduce the following Hilbert space:

$$V_\alpha := \left\{\theta \in \mathcal{C}^0(]0,1]) \mid \theta(1) = \alpha,\ \sqrt{r}\theta' \in L^2(0,1)\right\}. \tag{4.19}$$

The space V_α is an affine Hilbert space for the norm $(\theta^2(1) + \int_0^1 r\theta'^2 dr)^{1/2}$, which is isomorphic to the space of radial functions in $H^1(B^2)$ with Dirichlet boundary condition α. The upper bound $E^N(\theta^N) \geq 2\pi \int_0^1 r(\theta^N)'^2 dr$ which is true for all $\theta^N \in \mathcal{E}^N_{\alpha,k}$ implies that for all $y^N \in \overline{\overline{\mathcal{Y}^N_{\alpha,k}}}$ there exists a unique $\theta \in V_\alpha$ such that $y^N = F \circ P_k(\theta)$. Moreover, θ is a continuous P_1 element with respect to a subdivision consisting of M segments for some $M \leq N$; θ is called the *regular part* of y^N. Since $E^N \neq E$, $\overline{\overline{\mathcal{Y}^N_{\alpha,k}}} \not\subset \overline{\mathcal{Y}}_{\alpha,k}$. The elements in $\overline{\overline{\mathcal{Y}^N_{\alpha,k}}}$ are *nonconforming.* However, $\overline{\overline{\mathcal{Y}^N_{\alpha,k}}} \subset F \circ P_k\,(V_\alpha)$ for all N and $\mathcal{E}_\alpha \subset V_\alpha$, so $\overline{\mathcal{Y}}_{\alpha,k} \subset F \circ P_k\,(V_\alpha)$: we have an *external approximation* of $\overline{\mathcal{Y}}_{\alpha,k}$ [14].

We define the discrete relaxed energy as in the continuous case (2.8).

Definition 4.9 (discrete relaxed energy). *For every $y^N \in \overline{\overline{\mathcal{Y}^N_{\alpha,k}}}$*

$$\overline{\overline{E^N}}(y^N) := \inf\left\{\liminf_n E^N(y_n) \mid y_n \in \mathcal{Y}^N_{\alpha,k},\ y_n \underset{n\to\infty}{\rightharpoonup} y^N \textit{ weakly in } BV\right\}. \tag{4.20}$$

By extending the identification $\mathcal{E}^N_{\alpha,k} \simeq D^N$ it is easy to show that

$$\overline{\overline{\mathcal{Y}^N_{\alpha,k}}} \simeq \left\{(r_0, \dots, \theta_N) \in \overline{D^N} \mid \overline{E^N}(r_0, \dots, \theta_N) < \infty\right\},$$

and that Definition 4.9 is equivalent to the one given by Lemma 3.1, i.e., $\overline{\overline{E^N}}(y^N) = \overline{E^N}(r_0, \dots, \theta_N)$ for all $y^N \in \overline{\overline{\mathcal{Y}^N_{\alpha,k}}}$, which corresponds to $(r_0, \dots, \theta_N) \in \overline{D^N}$. In the following we denote $\overline{\overline{E^N}} = \overline{E^N}$.

4.4. Convergence analysis. We begin by proving an intermediate convergence result.

Lemma 4.10. *Let $(r_i^N, \theta_i^N)_{0\leq i\leq N}$ be a minimizer for $\overline{E^N}$ in $\overline{D^N}$. Then*

$$\max_{0\leq i\leq N}\left\{|\theta^N_{i+1} - \theta^N_i|\right\} \xrightarrow[N\to\infty]{} 0. \tag{4.21}$$

Proof. Assume (4.21) is false. Then there exist a subsequence $\left(\theta_i^{N'}\right)_{0\leq i\leq N'}$ and $\beta > 0$ such that $\min_{N'} \max_{0\leq i<N'}\{|\theta^{N'}_{i+1} - \theta^{N'}_i|\} \geq \beta$. By definition (4.7), J is continuous on $\mathbb{R}^2$. Thus from Lemma 4.4 for every $M > \beta > 0$,

$$\epsilon(\beta, M) := \min_{\substack{|\tilde\theta-\theta|\geq\beta \\ |\theta|\leq M,\ |\tilde\theta|\leq M}} \left\{J(\theta, \tilde\theta) - |F(\tilde\theta) - F(\theta)|\right\} > 0. \tag{4.22}$$

Now let $M := \sup_{N'} \max_{0\leq i\leq N'} \left|\theta^{N'}_i\right|$. Since the corresponding sequence $(y^{N'})_{N'}$ is uniformly bounded in $BV(]-1,1[)$ by (4.18), we have $M < \infty$. Using successively (4.10), Lemma 4.4, and (4.22), we obtain

$$\overline{E^{N'}}\left(r_0^{N'}, \dots, \theta^{N'}_{N'}\right) \geq \Lambda_{\alpha,k} + 2\pi\epsilon(\beta, M).$$

On the other hand, from Lemma 4.8 we get for N' large enough

$$\overline{E^{N'}}\left(r_0^{N'}, \dots, \theta^{N'}_{N'}\right) < \Lambda_{\alpha,k} + 2\pi\epsilon(\beta, M),$$

a contradiction, and this concludes the proof of Lemma 4.10. □

We can state the main convergence result as follows.

THEOREM 4.11. *For every integer N, let y^N be a minimizer for $\overline{E^N}$ in $\overline{\overline{\mathcal{Y}^N_{\alpha,k}}}$ and let $\theta^N \in V_\alpha$ be the regular part of y^N defined in section 4.3. Then,*

$$\overline{E^N}(y^N) \xrightarrow[N\to\infty]{} \Lambda_{\alpha,k}, \tag{4.23}$$

$$y^N \quad\rightharpoonup\quad y \text{ weakly in } BV(]-1,1[), \tag{4.24}$$

$$\sqrt{r}(\theta^N)' \quad\rightharpoonup\quad \sqrt{r}\underline{\theta}' \text{ weakly in } L^2(0,1), \tag{4.25}$$

where $y = y_{\underline{\theta},k}$ is the unique minimizer for $\overline{E}$ in $\overline{\mathcal{Y}}_{\alpha,k}$.

Proof. Equation (4.23) is given by Lemma 4.8. Estimate (4.18) shows that $(y^N)_N$ is uniformly bounded in BV. Moreover, $\sqrt{r}(\theta^N)'$ is uniformly bounded in L^2. So there exist $\theta \in V_\alpha$ and $y = P_k \circ F(\theta) \in BV$ such that, up to a subsequence,

$$\begin{aligned} y^N &\underset{N\to\infty}{\rightharpoonup} y \text{ weakly in } BV(]-1,1[),\\ \sqrt{r}(\theta^N)' &\underset{N\to\infty}{\rightharpoonup} \sqrt{r}\theta' \text{ weakly in } L^2(]0,1[). \end{aligned} \tag{4.26}$$

Case $\alpha = -\pi/2$. Lemma 4.10 and Corollary 4.3 imply that θ^N converges uniformly to $-\pi/2$ on $[0,1]$, so $\theta \equiv -\pi/2$, and the uniqueness concludes the proof.

Case $\alpha \in]-\pi/2, \pi/2[$. We assume $k \geq 1$, the proof for $k \leq 0$ being similar. The idea is to pass at the limit in the discrete version of the Euler–Lagrange equation (4.9) in order to prove the uniqueness of the limit. Define

$$\underline{r} := \max\{r \in]0,1[, \theta(r) = \pm\pi/2\} < 1 \tag{4.27}$$

(if $\theta(r) \in]-\pi/2, \pi/2[$ for all $r \in]0,1]$, then we set $\underline{r} := 0$).

We first show that $\underline{r} := 0$. For all N let $\underline{r}^N := \max\{r \in]0,1[, \theta^N(r) = \pm\pi/2\} < 1$. Let $(r_0^N, \dots, r_N^N, \theta_0^N, \dots, \theta_N^N) \in \overline{D^N}$ be the minimizer in $\overline{D^N}$ corresponding to $y^N \in \overline{\overline{\mathcal{Y}^N_{\alpha,k}}}$. We define the important index

$$i_N := \min\left\{i \in \{0,\dots,N\} \mid r_i > \underline{r}^N\right\}. \tag{4.28}$$

The interest of i_N is the following: from the proof of Lemma 4.4, i_N is the unique index such that $r_{i_N}^N > 0$ and $r_{i_N-1}^N = 0$ (see Figure 4.1). Moreover, by Proposition 4.2

$$\left(\frac{r_{i+1}^N - r_i^N}{r_{i+1}^N + r_i^N}\right)\left|\cos\left(\frac{\theta_i^N + \theta_{i+1}^N}{2}\right)\right| = \frac{|\theta_{i+1}^N - \theta_i^N|}{2} \quad \forall i \in \{i_N, \dots, N-1\}. \tag{4.29}$$

Lemma 4.12, which follows the proof, gives a natural result concerning i_N.

Let $s \in]\underline{r}, 1[$ and define

$$\beta(s) := \min\left\{\left(\min_{r\in[s,1]} \theta(r) + \frac{\pi}{2}\right), \left(\frac{\pi}{2} - \max_{[s,1]} \theta(r)\right)\right\} > 0.$$

The compact inclusion $H^1([s,1]) \subset \mathcal{C}^0([s,1])$ implies that θ^N converges uniformly to θ on $[s,1]$. Thus for N large enough, $\theta^N(r) \in [-\pi/2 + \beta(s)/2, \pi/2 - \beta(s)/2]$ for all $r \in [s,1]$. In particular, $\min_{[s,1]} \cos\theta^N \geq \sin(\beta(s)/2) > 0$ for all N large enough. Using (4.29) and Lemma 4.10 we obtain

$$\max_{\substack{i\in\{0,\dots,N-1\}\\ r_i^N \geq s}} (r_{i+1}^N - r_i^N) \xrightarrow[N\to\infty]{} 0. \tag{4.30}$$

This means that we have a family of subdivisions whose maximal mesh-size tends to 0 as $N \to \infty$. More precisely, let $i_{s,N} := \min\left\{i \mid r_i^N > s\right\} \geq i_N$. It is clear by the same proof as for Lemma 4.12 that $r_{i_{s,N}}^N \xrightarrow[N\to\infty]{} s$. Similarly, setting $t \in \,]s,1[$ and letting $i_{t,N} := \min\{i \mid r_i^N > t\} \geq i_{s,N}$, we have $r_{i_{t,N}}^N \xrightarrow[N\to\infty]{} t$. Thus $s < r_{i_{s,N}}^N < \cdots < r_{i_{t,N}-1}^N \leq t$ is a family of subdivisions of $[s,t]$ whose maximum step-size tends to 0.

Now let $i \in \{i_{s,N}-1,\dots,N-1\}$ such that $r_{i+1}^N > r_i^N$ (the case $r_{i+1}^N = r_i^N$ is not a problem since $\theta_i^N = \theta_{i+1}^N$). On $[r_i^N, r_{i+1}^N]$, (4.29) can be written

$$\left(\frac{2}{r_i^N + r_{i+1}^N}\right)\cos^2\left(\frac{\theta_i^N + \theta_{i+1}^N}{2}\right) = \left(\frac{r_i^N + r_{i+1}^N}{2}\right)(\theta^N)'^2. \tag{4.31}$$

Multiplying by $(r_{i+1}^N - r_i^N)$ and summing on all $i_{s,N} \leq i < i_{t,N}$, we obtain

$$\int_s^t g^N(r)dr = \int_s^t r(\theta^N)'^2 dr + \gamma(s,t,N), \tag{4.32}$$

where g^N is the piecewise constant function given by the left-hand side of (4.31) on every $[r_i, r_{i+1}]$. Here $\gamma(s,t,N)$ corresponds to the integration on $[s, r_{i_{s,N}}^N] \cup [r_{i_{t,N}-1}^N, t]$ and $\gamma(s,t,N) \xrightarrow[N\to\infty]{} 0$ (s and t are fixed). The uniform convergence of θ^N on $[s,1]$, Lemma 4.12, and (4.30) imply that $g^N \xrightarrow[N\to\infty]{} \cos^2\theta/r$ uniformly on $[s,t]$. On the other hand, $\sqrt{r}(\theta^N)' \rightharpoonup \sqrt{r}\theta'$ weakly in $L^2(0,1)$, so by passing to the limit in (4.32) and using l.s.c. of the L^2 norm we get $\int_s^t r\theta'^2 dr \leq \int_s^t (\cos^2\theta/r)dr$. This is true for every $\underline{r} < s < t < 1$, so $r\theta'^2(r) \leq \cos^2\theta(r)/r$ for a.e. $r \in [\underline{r}, 1]$.

This is equivalent to

$$-\frac{\cos\theta}{r} \leq \theta' \leq \frac{\cos\theta}{r} \quad \text{for a.e. } r \in [\underline{r}, 1]. \tag{4.33}$$

The two solutions of the Cauchy problem corresponding to the two equality cases in (4.33) with initial condition $\theta(1) = \alpha$ are $\theta_{\alpha,0}$ and $\theta_{\alpha,1}$ (see (2.10)). The regularity of $(r,\Theta) \to \cos\Theta/r$ on $]0,\infty[\,\times\,\mathbb{R}$ implies $\theta_{\alpha,0}(r) \leq \theta(r) \leq \theta_{\alpha,1}(r)$ for all $r \in [\underline{r}, 1]$. Since $-\pi/2 < \theta_{\alpha,0}(r) < \theta_{\alpha,1}(r) < \pi/2$ for all $r \in \,]0,1]$ we obtain $\underline{r} = 0$ as expected.

Now set $\epsilon > 0$ and let $i_{\epsilon,N} := \min\{i \mid r_i^N > \epsilon\}$ again. Equality (4.10) yields

$$\frac{\overline{E^N}(y^N)}{2\pi} = \sum_{i<i_{\epsilon,N}} J(\theta_i^N, \theta_{i+1}^N) + \sum_{i\geq i_{\epsilon,N}} J(\theta_i^N, \theta_{i+1}^N). \tag{4.34}$$

Denote $S_{\epsilon,N}^+$ the previous sum on the indexes $i \geq i_{\epsilon,N}$. Then, using the previous function g^N, (4.31), and the definition (4.7) of J

$$\begin{aligned}\int_\epsilon^1 g^N(r)dr &= 2\sum_{i\geq i_{\epsilon,N}}\left(\frac{r_{i+1}^N - r_i^N}{r_{i+1}^N + r_i^N}\right)\cos^2\left(\frac{\theta_i^N + \theta_{i+1}^N}{2}\right) + \gamma(\epsilon,N)\\ &= S_{\epsilon,N}^+ + \gamma(\epsilon,N)\end{aligned}$$

Here $\gamma(\epsilon,N)$ corresponds to the integration on $[\epsilon, r_{i_{\epsilon,N}}^N]$ so $\gamma(\epsilon,N) \xrightarrow[N\to\infty]{} 0$ (ϵ is fixed). We deduce $S_{\epsilon,N}^+ \leq \overline{E^N}(y^N)/(2\pi) - \left|F(-\pi/2 + k\pi) - F(\theta^N(r_{i_{\epsilon,N}}^N)\right|$ from (4.34) and Lemma 4.4. Letting $N \to \infty$ and using the uniform convergence on $[\epsilon,1]$,

$$\int_\epsilon^1 \frac{\cos^2\theta}{r}dr \leq \frac{\Lambda_{\alpha,k}}{2\pi} - \left|F\left(-\frac{\pi}{2} + k\pi\right) - F(\theta(\epsilon))\right|.$$

In particular with (4.33), $E(\theta) \leq 2\pi \int_0^1 \cos^2\theta/r dr \leq \Lambda_{\alpha,k} < \infty$, so $\theta \in \mathcal{E}_{\alpha,l}$ with necessarily $l = 1$ or $l = 0$ since $\underline{r} = 0$. Moreover, using the continuity of θ at $r = 0$,

$$E(\theta) \leq \Lambda_{\alpha,k} - 2\pi|F(-\pi/2 + k\pi) - F(\theta(0))|.$$

The case $l = 0$ is impossible since $\Lambda_{\alpha,k} - 2\pi|F(-\pi/2 + k\pi) - F(-\pi/2)| < 0$ (see the remark following (2.6)). Thus $l = 1$, and since $\Lambda_{\alpha,k} - |F(-\pi/2+k\pi) - F(\pi/2)| = \Lambda_{\alpha,1}$, θ is a minimizer in $\mathcal{E}_{\alpha,1}$. In other words $\theta = \theta_{\alpha,1}$. The uniqueness of the limit θ concludes the proof. □

Lemma 4.12. *Let i_N be defined by* (4.28). *Then* $r^N_{i_N} \xrightarrow[N\to\infty]{} \underline{r}$.

Proof. First notice that the uniform convergence of θ^N on $[\underline{r}+\epsilon, 1]$ for every $\epsilon > 0$ implies that $\underline{r}^N \xrightarrow[N\to\infty]{} \underline{r}$. Assume by contradiction that $r^N_{i_N}$ does not converge to $\underline{r}$ as N tends to infinity. Since $\underline{r}^N < r^N_{i_N} \leq 1$, there exists a subsequence of indexes $(i_{N'})_{N'}$ such that $r^{N'}_{i_{N'}} \xrightarrow[N'\to\infty]{} b$ and $\theta^{N'}_{i_{N'}-1} \xrightarrow[N'\to\infty]{} \varphi$, with $\underline{r} < b \leq 1$ and $\varphi \notin]-\pi/2, \pi/2[$. Now $\theta^{N'}_{i_{N'}} = \theta^{N'}(r^N_{i_{N'}})$ tends to $\theta(b) \in]-\pi/2, \pi/2[$, so $|\theta^{N'}_{i_{N'}-1} - \theta^{N'}_{i_{N'}}| \xrightarrow[N\to\infty]{} |\varphi - b| \neq 0$. This contradicts Lemma 4.10 and concludes the proof. □

5. The S^1 formulation.

In this section, we apply the moving finite-element method to the S^1 formulation of problem (2.4): the energy is a quadratic functional of S^1-valued maps. This shows how the method could apply to the Dirichlet problem for S^2-valued maps in dimension 2 or 3 of domain, as considered in [8].

5.1. The continuous formulation.

Every function $\theta \in \mathcal{E}_{\alpha,k}$ can be seen as the S^1-valued map $u : [0,1] \to S^1 \subset \mathbb{R}^2$:

$$u(r) := (\cos\theta(r), \sin\theta(r)) =: (c(r), s(r)) \quad \forall r \in [0,1].$$

The Dirichlet energy with this formulation is given by

$$E(u) := \pi \int_0^1 \frac{c^2(r)}{r} + r|u'(r)|^2 dr. \tag{5.1}$$

This is a quadratic energy: it allows us to define the space of maps with bounded energy

$$H^1_{axi} := \left\{ u = (c,s) \in \mathcal{C}^0(]0,1], \mathbb{R}^2) \mid u(1) = (\cos\alpha, \sin\alpha),\ E(u) < \infty \right\},$$

which is an affine Hilbert space, isomorphic to the subspace of $H^1(B^2, \mathbb{R}^3)$ made of axisymmetric vector fields with boundary condition α. The identification $\theta \simeq u$ allows us to see $\mathcal{E}_{\alpha,k}$ as a subset of H^1_{axi}. We denote this subset by $\mathcal{U}_{\alpha,k}$.

One point of interest regarding this formulation is that $\mathcal{U}_{\alpha,k}$ has the metric induced by the norm in H^1_{axi} (whereas $\mathcal{E}_{\alpha,k}$ does not have a canonical metric). In fact, $\mathcal{U}_{\alpha,k}$ is connected and closed for the strong H^1_{axi} topology, but it is not closed for the weak H^1_{axi} topology. By Theorem 2.3, E has a minimizer in the class $\mathcal{U}_{\alpha,k}$ if and only if $(\alpha,k) = (-\pi/2, 0)$ or $(\alpha,k) \in]-\pi/2, 0] \times \{0,1\}$. If (α,k) does not satisfy this assumption, then a minimizing sequence in $\mathcal{U}_{\alpha,k}$ converges weakly in H^1_{axi}, but not strongly: a part of the energy concentrates at 0.

For the extension to higher dimension and for numerical applications, the S^1 formulation is interesting. However, it is not convenient for the mathematical description of the limit of minimizing sequences (singular minimizers). Since the codimension is 2, the boundary layer is not completely described by a discontinuity. The weak BV

convergence would have to be replaced by the convergence in the sense of currents, as in [8]. But even in this context, it is not clear how one could introduce the change of variable F.

5.2. Midpoint formula, conforming element, and discrete degree. We use a discretization based on P_1 elements in H^1_{axi}. The integer N is fixed. Let $r_0 = 0 < \cdots < r_N = 1$ be a subdivision of $[0,1]$ and let $(u_i)_{0\le i\le N} \in (S^1)^{N+1}$ represent a P_1 element in H^1_{axi}. For all $i \in \{0,\dots,N\}$ we denote $u_i = (c_i, s_i) \in \mathbb{R}^2$, where $c_i^2 + s_i^2 = 1$. We define $E^N(r_0,\dots,u_N) := 2\pi \sum_{i=0}^{N-1} E_i(r_0,\dots,u_N)$, where for all i

$$E_i(r_0,\dots,u_N) := \frac{(c_i + c_{i+1})^2}{|u_i + u_{i+1}|^2}\left(\frac{r_{i+1} - r_i}{r_{i+1} + r_i}\right) + \frac{|u_i - u_{i+1}|^2}{|u_i + u_{i+1}|^2}\left(\frac{r_{i+1} + r_i}{r_{i+1} - r_i}\right). \tag{5.2}$$

Here $|\cdot|$ is the euclidean norm in $\mathbb{R}^2$. The function E_i is defined on

$$D_u^N := \{r_0 = 0 < \cdots < r_N = 1\} \times \left\{(u_i)_{0\le i\le N} \in (S^1)^{N+1},\ u_{i+1} \neq -u_i\right\}. \tag{5.3}$$

Let $u^N = (c^N, s^N)$ be the unique P_1 element in H^1_{axi} defined by the values $u^N(r_i) = u_i$ for all $i \in \{0,\dots,N\}$, i.e., $u^N \in \mathcal{C}^0([0,1],\mathbb{R}^2)$ and u^N is affine on every $[r_i, r_{i+1}]$. Assume $u_{i+1} \neq -u_i$ for all i. Since $|u^N| \ge |u_i + u_{i+1}|/2 > 0$ on $[r_i, r_{i+1}]$, the map $u^N/|u^N|$ belongs to $\mathcal{C}^0([0,1], S^1)$. The discrete energy (5.2) is the approximation of $E(u^N/|u^N|)$ by the midpoint formula. Notice that the quadratic energy $E(u^N)$ does not have good properties for the optimal mesh method [13].

Now set $\alpha \in [-\pi/2, \pi/2]$ and assume $u^N(1) = (\cos\alpha, \sin\alpha)$ is given. Then, the map $u^N/|u^N|$ admits a unique lift $\theta^N \in \mathcal{C}^0([0,1],\mathbb{R})$ such that $\theta^N(1) = \alpha$ and $u^N(r) = (\cos\theta^N(r), \sin\theta^N(r))$. Since $E(\theta^N) = E(u^N) < \infty$, $\theta^N \in \mathcal{E}_{\alpha,k}$ for a unique $k \in \mathbb{Z}$. The integer k such that $\theta^N(0) = -\pi/2 + k\pi$ is the degree of u.

Now, the discrete formulation of problem (2.4) is

$$\text{Minimize } E^N \text{ on } D^N_{u,\alpha,k} = \left\{(r_0,\dots,u_N) \in D^N_u \,\middle|\, u^N(1) = \alpha \text{ and } \deg(u) = k\right\}. \tag{5.4}$$

The conditions $u_{i+1} \neq -u_i$ and u^N affine on $[r_i, r_{i+1}]$ imply $|\theta^N(r_{i+1}) - \theta^N(r_i)| < \pi$, so $|\theta(0)| < (N+1)\pi$. Conversely, it is possible to construct for all $\epsilon > 0$ a function $\theta^N \in \mathcal{C}^0([0,1])$ such that $\pi > \theta^N(r_{i+1}) - \theta^N(r_i) \ge \pi - \epsilon$, and for ϵ small enough $\theta(0) \ge \alpha + N\pi - N\epsilon \ge -\pi/2 + (N-1)\pi$. Then $k \ge N-1$ (and similarly we can have $k \le -N+2$). So for any $k \in \mathbb{Z}$, if N is large enough, $D^N_{u,\alpha,k}$ is not empty. Notice also that by the identification $u^N \simeq \theta^N$, every $D^N_{u,\alpha,k}$ is connected (as in the continuous case).

Figure 5.1 shows the numerical solution to (5.4) obtained by a projected gradient algorithm with the change of variable X_i (4.3) for $\alpha = -\pi/4$, $k = 2$, and $N = 17$; the circles of radius 1 represent the cylinder $[0,1] \times S^1$ in which the true solution lives. The results are comparable to the computations with the midpoint formula in codimension 1 (Figures 4.1 and 4.2).

5.3. Upper bound for the degree. The following lemma is the equivalent of Lemma 4.4, which is itself the key of the proof of the convergence Theorem 4.11. Therefore, seeing the discrete S^1 energy E^N (5.2) as a function of $(r_0,\dots,\theta_N)$, it is possible to obtain a convergence result similar to Theorem 4.11 for any sequence of minimizing lifts $(\theta^N)_N$.

LEMMA 5.1. *Let $0 \le r_i < r_{i+1} \le 1$ and let $(\theta_i, \theta_{i+1}) \in \mathbb{R}^2$ such that $0 < |\theta_{i+1} - \theta_i| < \pi$. Define $u_j := (\cos\theta_j, \sin\theta_j)$ for $j = i, i+1$.*

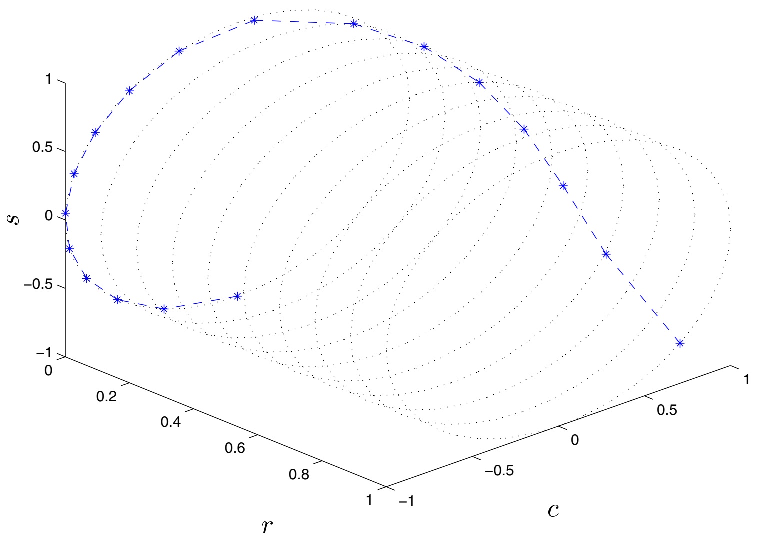

FIG. 5.1. *Midpoint for* S^1 *with* $\alpha = -\pi/4$, $k = 2$, $N = 17$.

Then $E_i(r_i, r_{i+1}, u_i, u_{i+1}) > |F(\theta_{i+1}) - F(\theta_i)|$.

In particular, $E^N(r_0, \dots, u_N) \geq \Lambda_{\alpha,k}$ for all $(r_0, \dots, u_N) \in D^N_{u,\alpha,k}$.

Proof. Assume $[\theta_i, \theta_{i+1}] \subset [\pi/2 + l\pi, \pi/2 + (l+1)\pi]$ for some $l \in \mathbb{Z}$. By Lemma 4.1

$$\begin{aligned} E_i(r_i, r_{i+1}, u_i, u_{i+1}) &\geq 2\frac{|\cos\theta_i + \cos\theta_{i+1}| \cdot |u_{i+1} - u_i|}{|u_i + u_{i+1}|^2}| \\ &\geq 2\frac{\left|\cos\left(\frac{\theta_{i+1}-\theta_i}{2}\right)\right| \cdot \left|\sin\left(\frac{\theta_{i+1}-\theta_i}{2}\right)\right|}{\left|\cos\left(\frac{\theta_i+\theta_{i+1}}{2}\right)\right|} \\ &> |\sin\theta_{i+1} - \sin\theta_i| = |F(\theta_{i+1}) - F(\theta_i)|. \end{aligned}$$

If the previous assumption is not satisfied, we assume without loss of generality $\theta_i < \theta_{i+1}$. There exists $l \in \mathbb{Z}$ such that $\pi/2 + (l-1)\pi < \theta_i < \pi/2 + l\pi < \theta_{i+1} < \pi/2 + (l+1)\pi$. We define $h := \pi/2 + l\pi - \theta_i$ and $k := \theta_{i+1} - (\pi/2 + l\pi)$. Notice that $h \in]0, \pi[$, $k \in]0, \pi[$, and $h + k < \pi$. Then with $X_i = (r_{i+1} - r_i)/(r_{i+1} + r_i) \in]0, 1[$

$$E_i(r_i, r_{i+1}, u_i, u_{i+1}) = \frac{|\sin h - \sin k|^2}{4\cos^2\left(\frac{h+k}{2}\right)} X_i + \frac{\left|\sin^2\left(\frac{h+k}{2}\right)\right|}{\cos^2\left(\frac{h+k}{2}\right)} \frac{1}{X_i}.$$

Using Lemmas 5.2 and 4.1

$$E_i(r_i, r_{i+1}, u_i, u_{i+1}) \geq \frac{|\sin h - \sin k|^2}{4\cos^2\left(\frac{k+h}{2}\right)} + \frac{\sin^2\left(\frac{k+h}{2}\right)}{\cos^2\left(\frac{k+h}{2}\right)}.$$

On the other hand (4.13) yields $|F(\theta_{i+1}) - F(\theta_i)| = 2\sin^2(h/2) + 2\sin^2(k/2)$. The following lemma concludes the proof. □

LEMMA 5.2. *For all* $(h, k) \in [0, \pi]^2$ *such that* $h + k < \pi$,

$$\left|\frac{\sin h - \sin k}{2}\right|^2 \leq \sin^2\left(\frac{h+k}{2}\right).$$

Proof. The proof is similar to the proof of Lemma 4.5. □

LEMMA 5.3. *For all* $(h,k) \in [0,\pi]^2$ *such that* $0 < h+k < \pi$,

$$\frac{|\sin h - \sin k|^2}{4\cos^2\left(\frac{k+h}{2}\right)} + \frac{\sin^2\left(\frac{k+h}{2}\right)}{\cos^2\left(\frac{k+h}{2}\right)} > 2\sin^2\left(\frac{h}{2}\right) + 2\sin^2\left(\frac{k}{2}\right).$$

Proof. Define $K := \{(h,k) \in [0,\pi]^2 \mid h+k \leq \pi \text{ and } k \leq h\}$ and $G : K \to \mathbb{R}$ by

$$G(h,k) = \left(\frac{\sin h - \sin k}{2}\right)^2 + \sin^2\left(\frac{h+k}{2}\right) - 2\left(\sin^2\left(\frac{h}{2}\right) + \sin^2\left(\frac{k}{2}\right)\right)\cos^2\left(\frac{h+k}{2}\right).$$

Then G admits a minimizer $(\underline{h},\underline{k})$ on K. We have

$$\partial_h G(h,k) = \cos\left(\frac{h+k}{2}\right)\left[A(h,k) + \left(2\sin^2\left(\frac{h}{2}\right) + 2\sin^2\left(\frac{k}{2}\right)\right)\sin\left(\frac{h+k}{2}\right)\right],$$

with

$$A(h,k) := \cos(h)\sin\left(\frac{h-k}{2}\right) + \sin\left(\frac{h+k}{2}\right) - \sin(h)\cos\left(\frac{h+k}{2}\right).$$

Now

$$A(h,k) = \sin\left(\frac{h-k}{2} - h\right) + \sin(h)\left[\cos\left(\frac{h-k}{2}\right) - \cos\left(\frac{h+k}{2}\right)\right] + \sin\left(\frac{h+k}{2}\right),$$

so for all $(h,k) \in \overset{\circ}{K}$, $0 < (h-k)/2 < (h+k)/2 < \pi/2$ and $\partial_h G(h,k) > 0$. Thus $(\underline{h},\underline{k}) \in \partial K$. We have $\partial_h G(h,k) > 0$ for all $(h,k) \in \partial K$ such that $0 < h+k < \pi$ and this concludes the proof. □

6. Conclusion.

The main results in this paper are the convergence Theorem 4.11 for the midpoint formula and the external approximation by *BV* functions introduced in section 4.3. They are based on the *BV* bound given by the discrete energy in Proposition 4.7, which is the discrete equivalent of Lemma 2.2. Lemma 5.1 provides the same *BV* bound for the S^1 formulation discretized by the midpoint formula. For the quadratic discretized energy obtained by suppressing the term $|u_i + u_{i+1}|^2$ in formula (5.2), such a bound does not hold and the optimal mesh method does not converge [13]. Thus, the discretized problem should mimic the properties of the continuous problem. For the Gaussian quadrature with two nodes instead of the midpoint formula, the numerical computations [2] indicate that $\min_{\mathcal{E}_{\alpha,k}} E^N > \Lambda_{\alpha,k}$, but we have not been able to prove this.

As pointed out in the introduction, the results of section 3 apply directly in every dimension to every steady-state problem in which the solution minimizes an energy functional. Indeed, Lemma 3.1 provides an l.s.c. extension of the discrete energy, and this guarantees the existence of a discrete minimizer in the closure of its domain of definition, provided the discrete energy is coercive in the sense of (3.5). Assuming that the elements are conforming and that the energy is exact, a density result is enough to show the convergence of the method.

For a triangulation, closing the constraints means that we allow degenerate triangles. Concerning the Poisson equation, the optimal mesh might have such degenerate triangles, but the discrete minimizer is continuous [4]; for regular elliptic problems, one expects the same behavior. For the two- or three-dimensional formulation of problem (2.4) as in [8], or the Plateau problem, which is similar, the graph of the true solution may have a vertical part; one expects a similar vertical part for the discrete solution; in particular, the optimal mesh would have degenerate triangles. Using conforming elements as in section 5.2, we would obtain in two or three dimensions a convergence result similar to Proposition 3.4: the minimizing sequence would converge in the sense of currents (rather than in the weak BV sense), but only up to a subsequence because the limit is not unique.

For practical reasons, we have not yet computed numerical solutions for the two- or three-dimensional formulation of problem (2.4). However, we can refer the reader to [9, 12] for numerical simulations concerning the Plateau problem and elliptic problems with large gradients.

AN EULER–BERNOULLI BEAM WITH DYNAMIC CONTACT: DISCRETIZATION, CONVERGENCE, AND NUMERICAL RESULTS*

JEONGHO AHN[†] AND DAVID E. STEWART[†]

Abstract. In this paper, we formulate a time-discretization using the implicit Euler method for contact conditions and the midpoint rule for the elastic part of the equations. The energy functional is defined, and convergence for the time-discretization is investigated. Our time-discretization leads to energy dissipation. Using this time discretization and the finite element method with B-spline basis functions, we compute numerical solutions. We show that there is a converging subsequence, and the limit of any such converging subsequence is a solution of the dynamic impact problem. In order to solve the linear complementarity problem that arises in the numerical method, we use a smoothed guarded Newton method. We also investigate numerically the question of whether the numerical solutions converge strongly to their limit and if energy is conserved for the limit. Our numerical results give some evidence that this is so.

1. Introduction.

The Euler–Bernoulli equation is an approximate equation for a thin beam such as a rod. Combining this with Signorini contact conditions will give our formulation of the Euler–Bernoulli beam with frictionless contact. The solution $u(x,t)$ of our formulation represents the vertical displacement of the rod from an initially horizontal position for time t and position x along the beam. For small displacements, we have a linear relationship between stress and strain. The Euler–Bernoulli equation is

$$\rho A \frac{\partial^2 u}{\partial t^2} = -EI\frac{\partial^4 u}{\partial x^4} + f(x,t) \quad \text{in } (0,L)\times(0,T],$$

where L is the length of the rod, A is the area of the cross-section of the rod, ρ is the density of the rod, E is the Young modulus for the rod, and I is the second moment of inertia. Note that I is given by $I = \int_{\mathcal{A}}(y-\overline{y})^2 dx\,dy$, where $\mathcal{A}$ is the cross-section of the rod as a subset of the plane and $\overline{y}$ is the vertical center of area, which is $\overline{y} = \int_{\mathcal{A}} y\,dx\,dy / \int_{\mathcal{A}} dx\,dy$. The function $f(x,t)$ is the body force applied to the rod, and time t is between the initial time $t=0$ and some fixed time $t=T$. We denote vectors and matrices by bold letters.

This problem that we are considering is close to Schatzman's model [13], which has been studied in the literature. Her analysis is based on the use of characteristics, and conservation of energy is shown. We note that Euler–Bernoulli beam's boundary conditions are different from those of Schatzman's model.

In the purely elastic case, Euler–Bernoulli beams are not dissipative, and there are no characteristics. While the question of whether there can be conservation of

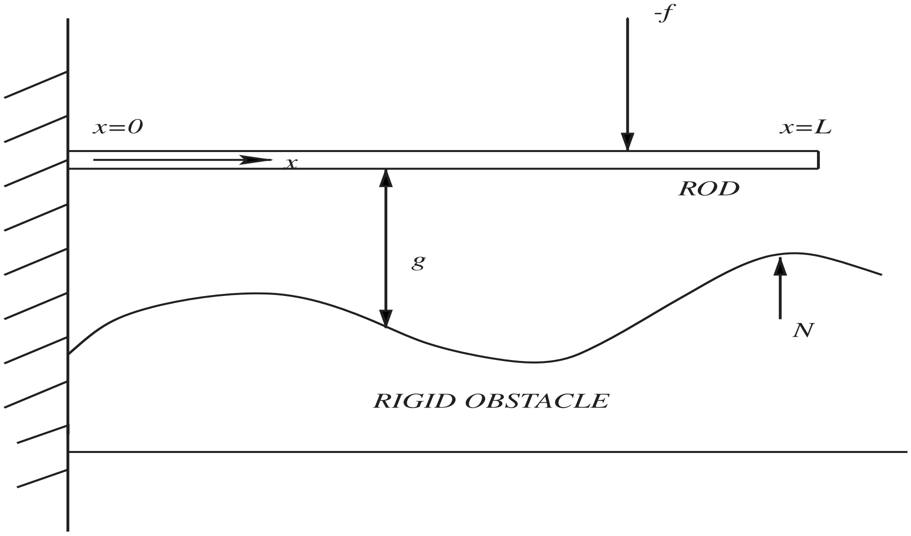

FIG. 1. *Euler–Bernoulli beam with frictionless contact.*

energy for Signorini contact conditions is an open one, this paper gives some evidence that energy is conserved generically.

The Euler–Bernoulli beam with Signorini contact conditions comes from the physical situation illustrated in Figure 1.

The boundary conditions can be identified from the figure. Suppose that the end of the rod at $x = 0$ is clamped horizontally. Then the boundary condition of $x = 0$ has the homogeneous *essential* boundary conditions, i.e., $u(0, t) = u_x(0, t) = 0$. If the end of rod is free, then we have the *natural* boundary conditions $u_{xx}(L, t) = u_{xxx}(L, t) = 0$. Note that subscripts denote derivatives with respect to the subscripted variables. These last two boundary conditions can be obtained from the usual variational techniques.

If we impose frictionless Signorini contact conditions along the length of the rod, we represent the equation of motion as

$$\rho A \frac{\partial^2 u}{\partial t^2} = -EI \frac{\partial^4 u}{\partial x^4} + f(x, t) + N(x, t), \tag{1.1}$$

where from contact criterion, the magnitude of the vertical contact forces (pressures), $N(x, t)$ satisfy the linear complementary problem (LCP) with the complementarity conditions

$$0 \le N(x, t) \quad \perp \quad u(x, t) + g(x) \ge 0 \qquad \text{for all } x \in (0, L),\ t > 0. \tag{1.2}$$

Note that ρA, EI, f, and g are given, while the unknowns are the functions u and N. Note that $g(x)$, called the *gap function*, displays a measure of the initial normalized "gap" between the rod and the rigid foundation, where the position of the rod is on the same as its clamped point of the rod horizontally. Note that for vectors $\mathbf{a}$, $\mathbf{b}$, $0 \le \mathbf{a} \perp \mathbf{b} \ge 0$ means that $\mathbf{a}$, $\mathbf{b} \ge 0$ componentwise and $\mathbf{a}^T\mathbf{b} = 0$. If a and b are scalars, both are nonnegative and either a or b is zero. From the physical point of view, the LCP condition can be interpreted in the following way: When there is a gap between the rod and rigid foundation, i.e., the rod does not reach to rigid foundation, the contact force N must be zero; when there is a contact force, the rod touches the rigid foundation, i.e., there is no gap between them. We assume that applied body force $f(x,t) = f(x)$. So the body force f and gap function g do not depend on time t. We also assume that the gap function $g(x) \geq 0$. Thus we are led to consider solving the following PDE:

$$\rho A u_{tt} = -EI u_{xxxx} + f(x) + N(x,t) \quad \text{in } (0,L) \times (0,T], \tag{1.3}$$

$$0 \leq N(x,t) \perp u(x,t) + g(x) \geq 0 \quad \text{in } (0,L) \times (0,T], \tag{1.4}$$

$$u(0,t) = u_x(0,t) = 0 \quad \text{on } (0,T], \tag{1.5}$$

$$u_{xx}(L,t) = u_{xxx}(L,t) = 0 \quad \text{on } (0,T], \tag{1.6}$$

$$u(x,0) = u^0(x) \quad \text{in } (0,L), \tag{1.7}$$

$$u_t(x,0) = v^0(x) \quad \text{in } (0,L). \tag{1.8}$$

We will assume that $f \in L^2(0,L)$, $u^0 \in H^2_{cf}(0,L)$, $v^0 \in L^2(0,L)$, $g \in C[0,L]$, and that $g(0) > 0$. Note that $H^2_{cf}(0,L)$ is the subset of $H^2(0,L)$, which satisfies the clamped end condition at $x = 0$ ("c" denotes "clamped," while "f" denotes "free"). In this paper, we focus on a numerical approach to the PDE, since the existence of solutions to the PDE has been already shown in [1]. Note that (1.7), (1.8) are the initial conditions for displacement and velocity, respectively.

2. Convergence of the time discretization.

In this section we set up a time-discretization. Also, the convergence for our semidiscretization is investigated. The following section will consider discretization in both time and space. Note that throughout this paper, C refers to a quantity that depends only on the data of the problem and not on the parameters of the approximations used but that may be different in each occurrence.

2.1. Formulation of the discrete-time problem.

In order to obtain a numerical formulation, we will employ a hybrid of two numerical schemes in time:

- Elasticity (u_{xxxx})—Midpoint rule is used,
- Contact condition—Implicit Euler is used.

First we consider a partition of time: $0 = t_0 < t_1 < t_2 < \cdots < t_l < t_{l+1} < \cdots < T$.

We denote by $u^l(x)$ numerical solution of displacement $u(x,t_l)$ and by $v^l(x)$ numerical solution of velocity $v(x,t_l)$ and $N^l(x)$ numerical solution of magnitude of contact force, $N(x,t_l)$, respectively, at each discretized time $t_l = lh$. Then the time step size is $h = t_{l+1} - t_l$ for $l \geq 0$. From (1.3), we take $\rho A = EI = 1$ by proper scaling.

Using our numerical scheme, we establish a numerical formulation:

$$\frac{v^{l+1} - v^l}{h} = -\left(\frac{u^{l+1}_{xxxx} + u^l_{xxxx}}{2}\right) + f(x) + N^l, \tag{2.1}$$

$$\frac{u^{l+1} - u^l}{h} = \frac{v^{l+1} + v^l}{2}, \tag{2.2}$$

$$0 \leq N^l \perp u^{l+1} + g \geq 0, \tag{2.3}$$

where $u^l = u^l(x)$, $v^l = v^l(x)$, $N^l = N^l(x)$ for each $l \geq 0$.

2.2. Energy dissipation in the semidiscrete case.

In this subsection, we will see that numerical formulations (2.1–2.3) cause energy dissipation.

Now we define the energy functional that is dependent on displacement u and velocity v:

$$E(u,v)=\frac{1}{2}\int_0^L\left(|v|^2+|u_{xx}|^2\right)\,dx-\int_0^L f\cdot u\,dx. \tag{2.4}$$

The first term $\frac{1}{2}\int_0^L |v|^2dx$ is the kinetic energy, the second term $\frac{1}{2}\int_0^L |u_{xx}|^2dx$ is the elastic energy, and the last term $-\int_0^L f\cdot u\,dx$ is the external potential energy.

Lemma 2.1. *In the semidiscrete case, energy is dissipated.*

Proof. We want to show that $E(u^{l+1},v^{l+1})\le E(u^l,v^l)$. Using (2.1)–(2.2), we have

$$\begin{aligned}\int_0^L \frac{|v^{l+1}|^2-|v^l|^2}{2h}\,dx &= -\int_0^L \frac{(u^{l+1}_{xxxx}+u^l_{xxxx})(u^{l+1}-u^l)}{2h}\,dx\\ &\quad+\int_0^L \frac{f\cdot(u^{l+1}-u^l)}{h}\,dx+\int_0^L \frac{N^l\cdot(u^{l+1}-u^l)}{h}\,dx. \end{aligned}\tag{2.5}$$

Multiplying by h on both sides of (2.5) and using integration by parts and the boundary conditions, we obtain

$$\begin{aligned}\int_0^L \frac{|v^{l+1}|^2-|v^l|^2}{2}\,dx &= -\int_0^L \frac{|u^{l+1}_{xx}|^2-|u^l_{xx}|^2}{2}\,dx\\ &\quad+\int_0^L f\cdot(u^{l+1}-u^l)\,dx+\int_0^L N^l\cdot(u^{l+1}-u^l)\,dx.\end{aligned}$$

Thus from the LCP condition (2.3),

$$\begin{aligned}\frac{1}{2}\int_0^L\left(|v^{l+1}|^2-|v^l|^2\right)dx &= -\frac{1}{2}\int_0^L\left(|u^{l+1}_{xx}|^2-|u^l_{xx}|^2\right)dx+\int_0^L f\cdot(u^{l+1}-u^l)\,dx\\ &\quad+\int_0^L N^l\cdot(u^{l+1}+g)\,dx-\int_0^L N^l\cdot(u^l+g)\,dx\\ &\le -\frac{1}{2}\int_0^L\left(|u^{l+1}_{xx}|^2-|u^l_{xx}|^2\right)dx+\int_0^L f\cdot(u^{l+1}-u^l)\,dx\end{aligned}\tag{2.6}$$

as $\int_0^L N^l\cdot(u^{l+1}+g)\,dx=0$ by (2.3), but N^l and $u^l+g\ge 0$ so $\int_0^L N^l\cdot(u^l+g)\,dx\ge 0$. Therefore we have

$$\begin{aligned}E(u^{l+1},v^{l+1}) &= \left(\frac{1}{2}\int_0^L\left(|v^{l+1}|^2+|u^{l+1}_{xx}|^2\right)dx\right)-\int_0^L f\cdot u^{l+1}\,dx\\ &\le\left(\frac{1}{2}\int_0^L |v^l|^2+|u^l_{xx}|^2\,dx\right)-\int_0^L f\cdot u^l\,dx=E(u^l,v^l)\end{aligned}$$

as desired. □

From (2.6), we observe that the energy E is conserved if $N^l=0$ and energy is dissipated by the LCP condition (2.3) if $N^l(x)>0$ for some $x\in(0,L)$. Assume that the initial energy is finite. Then Lemma 2.1 shows that $v^l\in L^2(0,L)$ and $u^l\in H^2_{cf}(0,L)$ for all l and $h>0$ and that they are bounded in these spaces independently of l and $h>0$.

2.3. Convergence of the semidiscrete scheme. Since the fourth-order differential operator $K = \partial^4/\partial x^4$ is an elliptic self-adjoint with our boundary condition, we have orthonormal basis ϕ_i with $\partial^4\phi_i/\partial x^4 = \lambda_i\phi_i$ satisfying the homogeneous boundary conditions $\phi_i(0) = \phi_i'(0) = \phi_i''(L) = \phi_i'''(L) = 0$. We order the eigenvalues λ_i so that $0 < \lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_i \leq \cdots$ and $\lim_{i\to\infty}\lambda_i = \infty$. Properties of these eigenfunctions are discussed in [1]. For the PDE system (1.3–1.8), we can write the discrete-time solution quantities as $u^l(x) = \sum_{i=1}^{\infty} u_i^l\phi_i(x)$, $v^l(x) = \sum_{i=1}^{\infty} v_i^l\phi_i(x)$, and $N^l(x) = \sum_{i=1}^{\infty} N_i^l\phi_i(x)$.

So using the above numerical solution expressions and the numerical formulation (2.1–2.2), for any $i \geq 1$ we have

$$\frac{v_i^{l+1} - v_i^l}{h} = -\lambda_i\left(\frac{u_i^{l+1} + u_i^l}{2}\right) + N_i^l, \tag{2.7}$$

$$\frac{u_i^{l+1} - u_i^l}{h} = \frac{v_i^{l+1} + v_i^l}{2}. \tag{2.8}$$

Note that when we investigate the convergence of our numerical scheme, we will not consider the external body force $f(x)$.

LEMMA 2.2. *From* (2.7) *and* (2.8), u_i^{l+1} *and* v_i^{l+1} *are expressed in terms of* u_i^l *and* v_i^l *for each* $i \geq 1$ *and each* $l \geq 0$ *in the following way:*

$$\begin{aligned}\begin{bmatrix} u_i^{l+1} \\ v_i^{l+1} \end{bmatrix} &= \begin{bmatrix} 1 & 0 \\ 0 & \lambda_i^{1/2} \end{bmatrix}\begin{bmatrix} \cos\chi_i & \sin\chi_i \\ -\sin\chi_i & \cos\chi_i \end{bmatrix}\begin{bmatrix} 1 & 0 \\ 0 & \lambda_i^{-1/2} \end{bmatrix}\begin{bmatrix} u_i^l \\ v_i^l \end{bmatrix} \\ &\quad + \frac{hN_i^l}{1 + h^2\lambda_i/4}\begin{bmatrix} \frac{h}{2} \\ 1 \end{bmatrix},\end{aligned} \tag{2.9}$$

where $\chi_i = \chi(h\lambda_i^{1/2})$*, i.e., function* χ_i *depends only on* $h\lambda_i^{1/2}$*.*

Proof. From (2.8), we have

$$v_i^{l+1} = \frac{2}{h}(u_i^{l+1} - u_i^l) - v_i^l. \tag{2.10}$$

Multiplying by h on (2.7) and plugging (2.10) into (2.7), we obtain

$$\frac{2}{h}(u_i^{l+1} - u_i^l) - 2v_i^l = -\frac{h}{2}(\lambda_i u_i^{l+1} + \lambda_i u_i^l) + hN_i^l. \tag{2.11}$$

Thus multiplying by $h/2$ on (2.11), we have the discrete-time solution at the next step:

$$u_i^{l+1} = (1 + h^2\lambda_i/4)^{-1}\left[(1 - h^2\lambda_i/4)u_i^l + hv_i^l + h^2N_i^l/2\right].$$

Using (2.10), we obtain the next step's velocity:

$$v_i^{l+1} = \frac{1}{1 + h^2\lambda_i/4}\left[-h\lambda_i u_i^l + (1 - h^2\lambda_i/4)v_i^l + hN_i^l\right].$$

Therefore, solving the equations for u^{l+1} and v^{l+1} in terms of u^l and v^l gives

$$\begin{bmatrix} u_i^{l+1} \\ v_i^{l+1} \end{bmatrix} = \frac{1}{1 + h^2\lambda_i/4}\begin{bmatrix} 1 - h^2\lambda_i/4 & h \\ -h\lambda_i & 1 - h^2\lambda_i/4 \end{bmatrix}\begin{bmatrix} u_i^l \\ v_i^l \end{bmatrix} + \frac{hN_i^l}{1 + h^2\lambda_i/4}\begin{bmatrix} \frac{h}{2} \\ 1 \end{bmatrix}.$$

The above system can be written as

$$\begin{bmatrix} u_i^{l+1} \\ v_i^{l+1} \end{bmatrix} = \frac{1}{1+h^2\lambda_i/4} \begin{bmatrix} 1 & 0 \\ 0 & \lambda_i^{\frac{1}{2}} \end{bmatrix} \begin{bmatrix} 1-\frac{h^2}{4}\lambda_i & h\lambda_i^{\frac{1}{2}} \\ -h\lambda_i^{\frac{1}{2}} & 1-\frac{h^2}{4}\lambda_i \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & \lambda_i^{-\frac{1}{2}} \end{bmatrix} \begin{bmatrix} u_i^l \\ v_i^l \end{bmatrix} + \frac{hN_i^l}{1+h^2\lambda_i/4} \begin{bmatrix} \frac{h}{2} \\ 1 \end{bmatrix}.$$

Note that we have

$$\left(\frac{1-h^2\lambda_i/4}{1+h^2\lambda_i/4}\right)^2 + \left(\frac{h\lambda_i^{1/2}}{1+h^2\lambda_i/4}\right)^2 = 1.$$

So we can write

$$\sin\chi_i = \frac{h\lambda_i^{1/2}}{1+h^2\lambda_i/4}, \qquad \cos\chi_i = \frac{1-h^2\lambda_i/4}{1+h^2\lambda_i/4},$$

where $\chi_i = \chi(h\lambda_i^{1/2})$. Hence the result follows. □

Indeed, we can require that χ_i be restricted to $[0,\pi]$.

Remark 2.1. Consider a sequence of vectors $\mathbf{z}_{l+1} = \mathbf{C}\mathbf{z}_l + \mathbf{b}_l$, for $l \in \mathbf{N}$. Then we have

$$\mathbf{z}_l = \mathbf{C}^l \mathbf{z}_0 + \sum_{j=0}^{l-1} \mathbf{C}^{l-1-j}\mathbf{b}_j.$$

It is easy to prove this formula using mathematical induction.

Lemma 2.3. *From* (2.7) *and* (2.8), u_i^l *for each* $l \geq 1$ *can be expressed as*

$$u_i^l = u_i^0 \cos(l\chi_i) + v_i^0 \sin(l\chi_i)/\lambda_i^{1/2} + \frac{h}{1+h^2\lambda_i/4} \sum_{j=0}^{l-1} \left(\frac{h\cos((l-1-j)\chi_i)}{2} + \frac{\sin((l-1-j)\chi_i)}{\lambda_i^{1/2}} \right) N_i^j, \tag{2.12}$$

where u_i^0 *and* v_i^0 *are coefficients for the initial displacement and velocity, respectively.*

Proof. In order to apply Remark 2.1, we set

$$\mathbf{z}_l = \begin{bmatrix} u_i^l \\ v_i^l \end{bmatrix}, \mathbf{C} = \begin{bmatrix} 1 & 0 \\ 0 & \lambda_i^{1/2} \end{bmatrix} \begin{bmatrix} \cos\chi_i & \sin\chi_i \\ -\sin\chi_i & \cos\chi_i \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & \lambda_i^{-1/2} \end{bmatrix}, \mathbf{b}_l = \begin{bmatrix} \frac{h}{2}N_i^l \\ N_i^l \end{bmatrix}.$$

So from Lemma 2.2, we have

$$\begin{bmatrix} u_i^l \\ v_i^l \end{bmatrix} = \left(\begin{bmatrix} 1 & 0 \\ 0 & \lambda_i^{1/2} \end{bmatrix} \begin{bmatrix} \cos\chi_i & \sin\chi_i \\ -\sin\chi_i & \cos\chi_i \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & \lambda_i^{-1/2} \end{bmatrix} \right)^l \begin{bmatrix} u_i^0 \\ v_i^0 \end{bmatrix} + \frac{h}{1+h^2\lambda_i/4} \sum_{j=0}^{l-1} \left(\begin{bmatrix} 1 & 0 \\ 0 & \lambda_i^{1/2} \end{bmatrix} \begin{bmatrix} \cos\chi_i & \sin\chi_i \\ -\sin\chi_i & \cos\chi_i \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & \lambda_i^{-1/2} \end{bmatrix} \right)^{l-1-j} \begin{bmatrix} \frac{h}{2}N_i^j \\ N_i^j \end{bmatrix}.$$

By mathematical induction,

$$\begin{bmatrix} u_i^l \\ v_i^l \end{bmatrix} = \begin{bmatrix} \cos(l\chi_i) & \lambda_i^{-1/2}\sin(l\chi_i) \\ -\lambda_i^{1/2}\sin(l\chi_i) & \cos(l\chi_i) \end{bmatrix} \begin{bmatrix} u_i^0 \\ v_i^0 \end{bmatrix} + \frac{h}{1+h^2\lambda_i/4} \sum_{j=0}^{l-1} \begin{bmatrix} \cos((l-1-j)\chi_i) & \lambda_i^{-1/2}\sin((l-1-j)\chi_i) \\ -\lambda_i^{1/2}\sin((l-1-j)\chi_i) & \cos((l-1-j)\chi_i) \end{bmatrix} \begin{bmatrix} \frac{h}{2}N_i^j \\ N_i^j \end{bmatrix}.$$

Multiplying by row vector [1, 0] on both sides of the above system, the coefficient u_i^l of $u^l(x)$ is obtained as desired. □

We define the impulse response function (or fundamental solution of the time-discretization) for fixed $x^* \in (0, L)$ to be

$$w^l(x) = \sum_{i=1}^{\infty} w_i^l \phi_i(x),$$

where $w_i^l = (h\cos(l\chi_i)/2 + \sin(l\chi_i)/\lambda_i^{1/2})/(1 + h^2\lambda_i/4)$. Similar to the fundamental solution of the PDE system, we extend $w_i^l = 0$ for $l < 0$. Thus using this form of impulse response function with Lemma 2.3, we have

$$u_i^l = u_i^0 \cos(l\chi_i) + v_i^0 \frac{\sin(l\chi_i)}{\lambda_i^{1/2}} + h\sum_{j=0}^{l-1} w_i^{l-j-1} N_i^j. \tag{2.13}$$

Recalling the fundamental solution of the PDE system, we define the impulse response function for fixed $x^* \in (0, L)$ as

$$w^l(\cdot, x^*) = \sum_{i=1}^{\infty} w_i^l \phi_i(x^*)\phi_i(\cdot). \tag{2.14}$$

Lemma 2.4. *Using the impulse response function $w^l(\cdot)$, the discrete-time solution $u^l(\cdot)$ can be expressed as*

$$u^l(\cdot) = \sum_{i=1}^{\infty} u_i^0 \cos(l\chi_i)\cdot\phi_i(\cdot) + \sum_{i=1}^{\infty} v_i^0 \frac{\sin(l\chi_i)}{\lambda_i^{1/2}}\phi_i(\cdot) + h\sum_{j=0}^{l-1}\int_0^L w^{l-j-1}(\cdot, x^*)N^j(x^*)dx^*.$$

Proof. Employing (2.13) for fixed $x^* \in (0, L)$, we have

$$\sum_{i=1}^{\infty} u_i^l\phi_i(\cdot) = \sum_{i=1}^{\infty} u_i^0 \cos(l\chi_i)\cdot\phi_i(\cdot) + \sum_{i=1}^{\infty} v_i^0 \frac{\sin(l\chi_i)}{\lambda_i^{1/2}}\phi_i(\cdot) + h\sum_{j=0}^{l-1}\sum_{i=1}^{\infty} w_i^{l-j-1}N_i^j\phi_i(\cdot).$$

Since $N^j(\cdot) = \sum_{r=1}^{\infty} N_r^j\phi_r(\cdot)$ and ϕ_i is orthonormal basis in $L^2(0, L)$, we have

$$N_i^j = \int_0^L \sum_{r=1}^{\infty} N_r^j \phi_r(x^*)\phi_i(x^*)dx^* = \int_0^L N^j(x^*)\phi_i(x^*)dx^*.$$

Thus we obtain

$$\begin{aligned} &u^l(\cdot) \\ &= \sum_{i=1}^{\infty} u_i^0 \cos(l\chi_i)\cdot\phi_i(\cdot) + \sum_{i=1}^{\infty} v_i^0 \frac{\sin(l\chi_i)}{\lambda_i^{1/2}}\phi_i(\cdot) + h\sum_{j=0}^{l-1}\sum_{i=1}^{\infty} w_i^{l-j-1}\phi_i(\cdot)\int_0^L N^j(x^*)\phi_i(x^*)dx^* \\ &= \sum_{i=1}^{\infty} u_i^0 \cos(l\chi_i)\cdot\phi_i(\cdot) + \sum_{i=1}^{\infty} v_i^0 \frac{\sin(l\chi_i)}{\lambda_i^{1/2}}\phi_i(\cdot) + h\sum_{j=0}^{l-1}\int_0^L w^{l-j-1}(\cdot, x^*)N^j(x^*)dx^*, \end{aligned}$$

as required. □

We now need a lemma giving some basic bounds on the function $\chi(s)$. These basic bounds will be used to establish a uniform Hölder continuity result for the discrete fundamental solution w and then for the solution u_h of the discrete-time problem.

LEMMA 2.5. *If* $\cos\chi(s) = (1 - s^2/4)/(1 + s^2/4)$ *and* $\sin\chi(s) = s/(1+s^2/4)$, *then* $\chi(s) \leq s$ *for* $0 \leq s \leq 2$.

Proof. Taking a derivative $\sin\chi(s)$ with respect to s, we have

$$\frac{d\,\sin\chi(s)}{d\chi}\frac{d\chi}{ds} = \frac{d}{ds}\left(\frac{s}{1+s^2/4}\right) = \frac{1}{1+s^2/4}\cdot\frac{1-s^2/4}{1+s^2/4} < \cos\chi(s) \quad \text{for } s \neq 2.$$

So if $s \neq 2$, $d\chi/ds < 1$. Since $\chi(0) = 0$, we have $\chi(s) \leq s$ for $s \geq 0$, using Proposition 3.7 in [1]. If $s = 2$, $\cos\chi(2) = 0$. Therefore $\chi(2) = \pi/2 < 2$, and the result follows. ▯

LEMMA 2.6. *The following uniform Hölder continuity property holds for* $p = 2\gamma$, $0 < p \leq 1$*:*

$$\left|\frac{\sin\left((l+r)\chi(h\lambda^{1/2})\right) - \sin\left(l\chi(h\lambda^{1/2})\right)}{\lambda^\gamma}\right| \leq C_p \cdot (rh)^p,$$

where C_p *is independent of* h *and* λ.

Proof. Suppose $r \geq 1$. Then we have

$$\left|\frac{\sin\left((l+r)\chi(h\lambda^{1/2})\right) - \sin\left(l\chi(h\lambda^{1/2})\right)}{\lambda^\gamma}\right| \leq \frac{2}{\lambda^\gamma}\left|\sin\left(\frac{r\chi}{2}\right)\right|.$$

Since $r\chi - \sin(r\chi/2) \geq 0$ for $r\chi \geq 0$, we have

$$\lambda^{-\gamma}\left|\sin\left((l+r)\chi\right) - \sin(l\chi)\right| \leq 2\lambda^{-\gamma}\min(r\chi, 1).$$

Applying Lemma 2.5 for $h\lambda^{1/2} \leq 2$,

$$\lambda^{-\gamma}\left|\sin\left((l+r)\chi\right) - \sin(l\chi)\right| \leq 2\lambda^{-\gamma}\min(rh\lambda^{1/2}, 1), \tag{2.15}$$

and for $h\lambda^{1/2} \geq 2$, (2.15) also holds by inspection as $rh\lambda^{1/2} > 1$. Dividing by $(rh)^p$ on both sides of (2.15),

$$\frac{\lambda^{-\gamma}\left|\sin\left((l+r)\chi\right) - \sin\left(l\chi\right)\right|}{(rh)^p} \leq 2\lambda^{-\gamma}(rh)^{-p}\min(rh\lambda^{1/2}, 1). \tag{2.16}$$

Thus, from (2.16), if $rh\lambda^{1/2} \leq 1$,

$$\begin{aligned}\lambda^{-\gamma}\left|\sin\left((l+r)\chi\right) - \sin\left(l\chi\right)\right|(rh)^{-p} &\leq 2\lambda^{-\gamma}(rh)^{-p}(rh\lambda^{1/2})\\ &= 2\lambda^{-\gamma+1/2}(rh)^{1-p}\\ &\leq 2\lambda^{-\gamma+1/2}\lambda^{p/2-1/2} = 2\lambda^{p/2-\gamma}.\end{aligned}$$

If $rh\lambda^{1/2} \geq 1$, $\left|\lambda^{-\gamma}\sin\left((l+r)\chi\right) - \lambda^{-\gamma}\sin\left(l\chi\right)\right|(rh)^{-p} \leq 2\lambda^{-\gamma}(rh)^{-p} \leq 2\lambda^{p/2-\gamma}$. Thus putting $p = 2\gamma$, we have

$$\lambda^{-\gamma}\left|\sin\left((l+r)\chi(h\lambda^{1/2})\right) - \sin\left(l\chi(h\lambda^{1/2})\right)\right| \leq 2(rh)^p,$$

as required. ▯

Let the value $u_h(\cdot,t)$ be a continuous piecewise linear interpolant of $u_h(\cdot,lh)=u^l$ and $u_h(\cdot,(l+1)h)=u^{l+1}$ for $t\in[lh,(l+1)h]$. Then recalling Lemma 2.4, the value of $u_h(\cdot,lh)$ computed at step l is expressed as

$$\begin{aligned} u_h(\cdot,lh) &= \sum_{i=1}^{\infty} u_i^0\cos(l\chi_i)\cdot\phi_i(\cdot)+\sum_{i=1}^{\infty} v_i^0\frac{\sin(l\chi_i)}{\lambda_i^{1/2}}\phi_i(\cdot)\\ &\quad + h\sum_{j=0}^{l-1}\int_0^L w_h(\cdot,(l-j-1)h,x^*)N^j(x^*)dx^*, \end{aligned} \tag{2.17}$$

where $w_h(\cdot,lh,x^*)=\sum_{i=1}^{\infty}(h\cos(l\chi_i)/2+\sin(l\chi_i)/\lambda_i^{1/2})\phi_i(\cdot)\phi_i(x^*)/(1+h^2\lambda_i/4)$. Now we define the discrete-time contact force $N_h(x,t)$ as

$$N_h(x,t)=h\sum_{j=0}^{\lfloor T/h\rfloor-1}\delta(t-(j+1)h)N^j(x),$$

where δ is the Dirac-δ function and $\lfloor T/h\rfloor$ is the number of time steps. We also identify N_h with a nonnegative Borel measure on $[0,L]\times[0,T]$ by

$$N_h(B)=\int_B N_h(x,t)\,dx\,dt,$$

where B is any Borel set in $[0,L]\times[0,T]$. It can be shown easily that the Borel measures N_h can be expressed in another way:

$$\int_0^T\int_0^L N_h(x,t)\,dx\,dt=h\sum_{l=0}^{\lfloor T/h\rfloor-1}\int_0^L N^l(x)\,dx. \tag{2.18}$$

Lemma 2.7. *The Borel measures N_h are uniformly bounded as measures on $[0,L]\times[0,T]$ as $h\downarrow 0$ for $v^0\in L^2(0,L)$ and $u^0\in H^2_{cf}(0,L)$.*

Proof. Multiplying h and $x^2/2$ on both sides in (2.1) and taking integrals on both sides in (2.1),

$$\int_0^L\frac{x^2}{2}(v^{l+1}-v^l)dx=-\frac{h}{2}\int_0^L\frac{x^2}{2}(u^{l+1}_{xxxx}+u^l_{xxxx})dx+h\int_0^L\frac{x^2}{2}N^l dx.$$

Note that we do not consider the body force $f(x)$. Thus, taking the sum over $l\geq 0$ and using an integration by parts,

$$\begin{aligned} h&\sum_{l=0}^{\lfloor T/h\rfloor-1}\int_0^L\frac{x^2}{2}N^l(x)\,dx\\ &=\sum_{l=0}^{\lfloor T/h\rfloor-1}\int_0^L\frac{x^2}{2}(v^{l+1}-v^l)dx+\frac{h}{2}\sum_{l=0}^{\lfloor T/h\rfloor-1}\int_0^L\frac{x^2}{2}(u^{l+1}_{xxxx}+u^l_{xxxx})dx\\ &=\sum_{l=0}^{\lfloor T/h\rfloor-1}\int_0^L\frac{x^2}{2}(v^{l+1}-v^l)dx+\frac{h}{2}\sum_{l=0}^{\lfloor T/h\rfloor-1}\int_0^L(u^{l+1}_{xx}+u^l_{xx})dx\\ &\leq\frac{L^2}{2}(\|v^{\lfloor T/h\rfloor}\|_{L^2(0,L)}+\|v^0\|_{L^2(0,L)})+TL^{1/2}\cdot\max_{0\leq l\leq\lfloor T/h\rfloor}\|u^l_{xx}\|_{L^2(0,L)}. \end{aligned} \tag{2.19}$$

We want to show that $\int_0^L N^l dx$ is bounded by $\int_0^L \frac{x^2}{2} N^l dx$ for all $l \geq 0$. Since $g(0) > 0$ and $u(0, t_{l+1}) = \partial u(0, t_{l+1})/\partial x = 0$ and $u^{l+1} \in H^2_{cf}(0, L)$, there is an $\eta > 0$ such that $u^{l+1}(x) > -g(x)$ for all $x \in [0, \eta]$. So by the LCP condition of the numerical formulation, $N^l = 0$ for $0 \leq x \leq \eta$. Since $N^l \geq 0$ and $x^2/2 \geq \eta^2/2 > 0$ for $[\eta, L]$, we have

$$\int_0^L \frac{x^2}{2} N^l dx = \int_\eta^L \frac{x^2}{2} N^l dx \geq \frac{\eta^2}{2} \int_\eta^L N^l dx = \frac{\eta^2}{2} \int_0^L N^l dx. \tag{2.20}$$

So by (2.18), the Borel measure N_h is bounded, independent of h as $h \downarrow 0$. The proof is complete. □

LEMMA 2.8. *The discrete-time solution $t \mapsto u_h(\cdot, t)$ is uniformly Hölder continuous into $H^\beta(0, L)$ as $h \downarrow 0$ with an exponent $0 < p \leq 1$ and $\beta > 0$ in the following sense:*

$$\| u_h(\cdot, (l + r)h) - u_h(\cdot, lh) \|_{H^\beta(0,L)} \leq C_p (rh)^p$$

for integers l and r, where $\beta/2 + p < 3/4$ and C_p is independent of h.

Proof. Applying (2.17), the last term of $u_h(\cdot, (l + r)h)$ becomes

$$h \sum_{j=0}^{l+r-1} \int_0^L w_h(\cdot, (l + r - j - 1)h, x^*) N^j(x^*) dx^*. \tag{2.21}$$

Similarly, the last term of $u_h(\cdot, lh)$ becomes

$$\sum_{j=0}^{l-1} \int_0^L w_h(\cdot, (l - j - 1)h, x^*) N^j(x^*) dx^*. \tag{2.22}$$

We denote (2.21) by (I) and (2.22) by (II). Thus, using Lemma 2.4, we have

$$\begin{aligned} &\| u_h(\cdot, (l + r)h) - u_h(\cdot, lh) \|_{H^\beta(0,L)} \\ &\quad \leq \left\| \sum_{i=1}^\infty u_i^0 \left(\cos\left((l + r)\chi_i\right) - \cos(l\chi_i) \right) \phi_i(x) \right\|_{H^\beta(0,L)} \\ &\qquad + \left\| \sum_{i=1}^\infty v_i^0 \frac{\sin\left((l + r)\chi_i\right) - \sin(l\chi_i)}{\lambda_i^{1/2}} \phi_i(x) \right\|_{H^\beta(0,L)} \\ &\qquad + h \left\| \int_0^L ((\mathrm{I}) - (\mathrm{II})) dx^* \right\|_{H^\beta(0,L)}. \end{aligned} \tag{2.23}$$

Using Lemma 2.6 and Proposition 3.3 in [1], in the first term of (2.23) we have

$$\begin{aligned} &\left\| \sum_{i=1}^\infty u_i^0 \left(\cos\left((l + r)\chi_i\right) - \cos(l\chi_i) \right) \phi_i(x) \right\|^2_{H^\beta(0,L)} \\ &\quad = \sum_{i=1}^\infty \left(\cos\left((l + r)\chi_i\right) - \cos(l\chi_i) \right)^2 \lambda_i^{\beta/2} (u_i^0)^2 + \sum_{i=1}^\infty \left(\cos\left((l + r)\chi_i\right) - \cos(l\chi_i) \right)^2 (u_i^0)^2 \\ &\quad = \sum_{i=1}^\infty \left[\frac{\cos\left((l + r)\chi_i\right) - \cos(l\chi_i)}{\lambda_i^{p/2}} \right]^2 \left(\lambda_i^{\beta/2+p-1} \cdot \lambda_i (u_i^0)^2 + \lambda_i^{p-1} \cdot \lambda_i (u_i^0)^2 \right) \\ &\quad = (rh)^{2p} \sum_{i=1}^\infty \lambda_i (u_i^0)^2 \left[\lambda_i^{\beta/2+p-1} + \lambda_i^{p-1} \right]. \end{aligned}$$

Similarly, in the second term of (2.23), we have

$$\left\|\sum_{i=1}^{\infty} v_i^0 \frac{\sin\left((l+r)\chi_i\right)-\sin(l\chi_i)}{\lambda_i^{1/2}}\phi_i(x)\right\|_{H^\beta(0,L)}^2 = (rh)^{2p}\sum_{i=1}^{\infty}\lambda_i(v_i^0)^2\left[\lambda_i^{\beta/2+p-1}+\lambda_i^{p-1}\right].$$

Note that since $v^0 \in L^2(0,L)$ and $u^0 \in H^2_{cf}(0,L)$, $\|v^0\|^2_{L^2(0.L)} = \sum_i (v_i^0)^2 < \infty$ and $|u^0|^2_{H^2(0,L)} = \sum_i \lambda_i(u_i^0)^2 < \infty$. Similarly in the third term of (2.23),

$$\begin{aligned}
&\left\|\int_0^L ((\mathrm{I})-(\mathrm{II}))dx^*\right\|_{H^\beta(0,L)} \\
&\quad\le h\int_0^L \|(\mathrm{I})-(\mathrm{II})\|_{H^\beta(0,L)}dx^* \\
&\quad\le h\int_0^L \sum_{j=0}^{l-1}\left\|\left(w_h(\cdot,(l+r-j-1)h,x^*)-w_h(\cdot,(l-j-1)h,x^*)\right)N^j(x^*)\right\|_{H^\beta(0,L)}dx^* \\
&\quad\quad+ h\int_0^L \sum_{j=l}^{l+r-1}\left\|w_h(\cdot,(l+r-j-1)h,x^*)N^j(x^*)\right\|_{H^\beta(0,L)}dx^*.
\end{aligned} \tag{2.24}$$

Recall that $w_h(\cdot,lh,x^*) = \sum_{i=1}^{\infty}(h\cos(l\chi_i)/2+\sin(l\chi_i)/\lambda_i^{1/2})\phi_i(\cdot)\phi_i(x^*)/(1+h^2\lambda_i/4)$ and $\max_{0\le x\le L}|\phi_i(x)| \le M$ as proved in Lemma 3.2 in [1]. Note that $\lambda_i^{1/2}h/(1+\lambda_ih^2/4) \le 1$ and $1/(1+\lambda_ih^2/4) \le 1$ for $\lambda_i^{1/2}h \ge 0$. In the first term of (2.24) for $0 \le j \le l-1$, it can be shown that we have

$$\begin{aligned}
&\|\left(w_h(\cdot,(l+r-j-1)h,x^*)-w_h(\cdot,(l-j-1)h,x^*)\right)N^j(x^*)\|^2_{H^\beta(0,L)} \\
&\quad\le \left(\frac{5}{4}+\sqrt{2}\right)M^2|N^j(x^*)|^2(rh)^{2p}\sum_{i=1}^{\infty}\left(\lambda_i^{\beta/2+p-1}+\lambda_i^{p-1}\right).
\end{aligned} \tag{2.25}$$

Similar to the second term of (2.24), for $l \le j \le l+r-1$ we have

$$\begin{aligned}
&\|w_h(\cdot,(l+r-j-1)h,x^*)N^j(x^*)\|^2_{H^\beta(0,L)} \\
&\quad\le C|N^j(x^*)|^2(rh)^{2p}\sum_{i=1}^{\infty}\left(\lambda_i^{\beta/2+p-1}+\lambda_i^{p-1}\right).
\end{aligned} \tag{2.26}$$

Note that for sufficiently large i, there exist $C > 0$ such that $\lambda_i \le Ci^4$. This was shown in Lemma 3.2 of [1]. Therefore by (2.18) and Lemma 2.7 and integral test, the result follows, provided that $\beta/2+p < 3/4$. □

Note that the condition of Lemma 2.8 is the same case as for the penalty method.

Lemma 2.9. *In a certain subsequence with $h \downarrow 0$, the time-discretized functions u_h, v_h, and N_h converge to a solution, u_h uniformly in $C([0,L]\times[0,T])$, v_h weak* in $L^\infty(0,T;L^2(0,L))$, and N_h weak* in the space of measures on $[0,L]\times[0,T]$. Furthermore, the solution (u, N) converged by (u_h, N_h) satisfies the complementarity condition $0 \le u+g \perp N \ge 0$ in the weak sense.*

Proof. By Lemma 2.7 and the Riesz representation theorem [8, Thm. 4.2, p. 268] and Alaoglu's theorem [12, Thm. 6.62, p. 203], a subsequence converges $N_h \rightharpoonup^* N$ as measures. Since $N_h \ge 0$, $N \ge 0$. Then since $C^p(0,T;H^\beta(0,L))$ is compactly embedded in $C([0,L]\times[0,T])$, by the Arzela–Ascoli theorem [8, pp. 57–59] there exists a suitable subsequence of u_h corresponding to subsequence of N_h such that $u_h \to u$ in $C([0,L]\times[0,T])$. We also denote this subsequence by u_h and restrict our attention to this subsequence. Since $u_h + g \geq 0$ for each $h > 0$, it follows that $u + g \geq 0$.

Since v_h is uniformly bounded in $L^\infty(0,T;L^2(0,L))$ and $L^\infty(0,T;L^2(0,L)) \simeq L^1(0,T;L^2(0,L))^*$, by Alaoglu's theorem there is a weak* converging subsequence, also denoted v_h, and we restrict our attention to this subsequence.

Since $u_h(\cdot,t)$ is an interpolant of $u_h(\cdot,lh)$ and $u_h(\cdot,(l+1)h)$, and $N_h(x,t) = h\sum_{j=0}^{\lfloor T/h\rfloor-1}\delta(t-(j+1)h)N^j(x)$ for $t\in[lh,\,(l+1)h]$, we have

$$\begin{aligned}
&\int_0^T\int_0^L N_h(x,t)(u_h(x,t)+g(x))\,dx\,dt\\
&\quad= h\int_0^T\int_0^L\left[\sum_{j=0}^{\lfloor T/h\rfloor-1}\delta(t-(j+1)h)N^j(x)\right](u_h(x,t)+g(x))\,dxdt\\
&\quad= h\int_0^L\left[\sum_{j=0}^{\lfloor T/h\rfloor-1}\int_0^T\delta(t-(j+1)h)(u_h(x,t)+g(x))\,dt\right]N^j(x)\,dx\\
&\quad= h\int_0^L\sum_{j=0}^{\lfloor T/h\rfloor-1}N^j(x)(u^{j+1}(x)+g(x))\,dx = 0.
\end{aligned}$$

So taking limits in the subsequence gives

$$0 = \int_0^T\int_0^L N_h(x,t)(u_h(x,t)+g(x))\,dxdt \to \int_0^T\int_0^L N(x,t)(u(x,t)+g(x))\,dxdt = 0$$

as desired. □

2.4. Do the discrete-time solutions converge strongly? While we cannot fully answer this question at this time, we will lay the groundwork in this section for the numerical evidence to be presented later for strong convergence.

We recall the expression of numerical solutions (discrete time solutions) $u^l(x)$ at each discretized time t_l such as $u^l(x) = \sum_{i=1}^\infty u_i^l\phi_i(x)$. Note that we write $u_i^{l;h}$ and $v_i^{l;h}$ instead of u_i^l and v_i^l, respectively, in order to show the dependence on $h > 0$ more explicitly. Then we consider numerical trajectories $u_h(x,t)$ by piecewise continuous linear interpolation of $u_h(x,t_l) = u^{l;h}(x)$ and $v_h(x,t)$ by the piecewise constant interpolation of $v_h(x,t_l) = v^{l;h}(x)$ for each $l \geq 0$. So we express these as $u_h(x,t) = \sum_{i=1}^\infty u_i^h(t)\phi_i(x)$ and $v_h(x,t) = \sum_{i=1}^\infty v_i^h(t)\phi_i(x)$. Then the value of $u_i^h(t)$ is the linear interpolant of $u_i^h(lh) = u_i^{l;h}$ and $u_i^h((l+1)h) = u_i^{l+1;h}$ for $t\in[lh,(l+1)h]$.

Let $\mathbf{u}^{l;h} = (u_1^{l;h}, u_2^{l;h}, u_3^{l;h},\ldots)$, $\mathbf{v}^{l;h} = (v_1^{l;h}, v_2^{l;h}, v_3^{l;h},\ldots)$, and $\boldsymbol{\omega}^{l;h} = (\omega_1^{l;h},\omega_2^{l;h},\omega_3^{l;h},\ldots)$, where $\omega_i^{l;h} = \lambda_i^{1/2}u_i^{l;h}$ for $i \geq 1$. We use notation ℓ^2 as the Hilbert space of sequences $\mathbf{x} = (x_1,x_2,x_3,\ldots)$, where $\|\mathbf{x}\|_{\ell^2} = \sqrt{\sum_i^\infty |x_i|^2} < \infty$. Using the energy functional, it can be shown easily that

$$E(u^l,v^l) = \sum_{i=1}^\infty\left(\left(v_i^{l;h}\right)^2 + \lambda_i\left(u_i^{l;h}\right)^2\right)$$

and $\boldsymbol{\omega}^{l;h}$, $\mathbf{v}^{l;h}$ are uniformly bounded in ℓ^2.

Now suppose that we do not consider body force f in the energy function. Thus by the energy boundedness we have

$$\sum_{i=1}^{\infty} \lambda_i \left(u_i^h(t)\right)^2 \text{ and } \sum_{i=1}^{\infty} \left(v_i^h(t)\right)^2 < \infty.$$

So $\boldsymbol{\omega}^h$, $\mathbf{v}^h \in \ell^2$ and are uniformly bounded in ℓ^2, where $\boldsymbol{\omega}^h = (\omega_1^h(t), \omega_2^h(t), \omega_3^h(t), \ldots)$ and $\mathbf{v}^h = (v_1^h(t), v_2^h(t), v_3^h(t), \ldots)$. Thus there are a subsequence of $\mathbf{v}^h$ and a subsequence of $\boldsymbol{\omega}^h$ that are convergent to $\mathbf{v}(t)$ and $\boldsymbol{\omega}(t)$, respectively, in ℓ^2, as $h \downarrow 0$. These facts induce Lemma 2.10.

By inspection of the eigenfunctions, the frequency of oscillation is proportional on $\lambda^{1/4}$. So high frequency modes correspond to large eigenvalues, and low frequency modes correspond to small eigenvalues. Also, only the elastic energy defines the modes, since they are eigenfunctions of the fourth-order operator $K = \partial^4/\partial x^4$ in the continuous case, or eigenvectors of $\mathbf{M}^{-1}\mathbf{K}$ in the fully discretized case, which will be considered in the following section. In the next lemma, it is shown that the amount of energy in the high frequency modes is negligible under the assumption of the strong convergence. In the physical point of view, energy in the high frequency modes is equivalent to heat. In section 3, the fact that $\boldsymbol{\omega}^{l;h}$, $\mathbf{v}^{l;h}$ are uniformly bounded in ℓ^2 will be supported by numerical evidence. The detailed argument will be presented in subsections 3.5 and 3.6.

Lemma 2.10. *Let $t \in [lh, (l+1)h]$ for any $l \geq 1$. Suppose that $\boldsymbol{\omega}^{l;h} \to \boldsymbol{\omega}(t)$ and $\mathbf{v}^{l;h} \to \mathbf{v}(t)$ (strongly) in ℓ^2, as $h \downarrow 0$, $lh \to t$. Then we have*

$$\lim_{c\to\infty} \limsup_{h\downarrow 0} \frac{1}{2} \sum_{i;i\geq c} \left(|v_i^{l;h}|^2 + \lambda_i |u_i^{l;h}|^2\right) = 0.$$

Proof. For the fixed $l \geq 1$ and any $c \geq 1$, we obtain

$$\left(\sum_{i=c}^{\infty} |\omega_i^{l;h}|^2\right)^{1/2} \leq \left(\sum_{i=c}^{\infty} |\omega_i^{l;h} - \omega_i(t)|^2\right)^{1/2} + \left(\sum_{i=c}^{\infty} |\omega_i(t)|^2\right)^{1/2}.$$

Since $\|\boldsymbol{\omega}^{l;h} - \boldsymbol{\omega}(t)\|_{\ell^2} \to 0$ as $h \downarrow 0$, $lh \to t$, we obtain

$$\limsup_{h\downarrow 0} \left(\sum_{i=c}^{\infty} |\omega_i^{l;h}|^2\right)^{1/2} \leq \limsup_{h\downarrow 0} \left[\left(\sum_{i=c}^{\infty} |\omega_i^{l;h} - \omega_i(t)|^2\right)^{1/2} + \left(\sum_{i=c}^{\infty} |\omega_i(t)|^2\right)^{1/2}\right]$$

$$= \limsup_{h\downarrow 0} \left(\sum_{i=c}^{\infty} |\omega_i(t)|^2\right)^{1/2}. \tag{2.27}$$

Since $\sum_{i=c}^{\infty} |\omega_i(t)|^2 = \|\boldsymbol{\omega}(t)\|_{\ell^2}^2 - \sum_{i=1}^{c-1} |\omega_i(t)|^2$, we have

$$\lim_{c\to\infty} \sum_{i=c}^{\infty} |\omega_i(t)|^2 = \|\boldsymbol{\omega}(t)\|_{\ell^2}^2 - \lim_{c\to\infty} \sum_{i=1}^{c-1} |\omega_i(t)|^2 = \|\boldsymbol{\omega}(t)\|_{\ell^{2-}}^2 - \|\boldsymbol{\omega}(t)\|_{\ell^2}^2 = 0. \tag{2.28}$$

Thus, combining (2.27) with (2.28),

$$\lim_{c\to\infty} \limsup_{h\downarrow 0} \left(\sum_{i=c}^{\infty} |\omega_i^{l;h}|^2\right)^{1/2} \leq 0.$$

Since $|\omega_i^{l;h}|^2 = \lambda_i |u_i^{l;h}|^2 \geq 0$ for each $i \geq 1$, we have for elastic energy

$$\lim_{c\to\infty} \limsup_{h\downarrow 0} \sum_{i;i\geq c} |\omega_i^{l;h}|^2 = \lim_{c\to\infty} \limsup_{h\downarrow 0} \sum_{i;i\geq c} \lambda_i |u_i^{l;h}|^2 = 0.$$

Similar to the above argument, we have for kinetic energy

$$\lim_{c\to\infty} \limsup_{h\downarrow 0} \sum_{i;i\geq c} |v_i^{l;h}|^2 = 0.$$

Therefore the result follows. □

We note that in general, $\mathbf{u}^l \rightharpoonup \mathbf{u}$ in ℓ^p with $1 < p < \infty$ if and only if $\lim_{l\to\infty} u_i^l = u_i$ for $i \geq 1$ and $\sup_{1\leq l<\infty} \|\mathbf{u}^l\|_{\ell^p} < \infty$.

3. Discretization in time and space.

3.1. Finite element method and B-splines. The finite element method is one of the most popular numerical methods for solving static elliptic boundary value problems. So we will approximate the solution in the spatial domain $[0, L]$, using the finite element method [4, 6]. We partition the domain $[0, L]$ into

$$0 = x_0 < x_1 < x_2 < x_3 < x_4 < \cdots < x_{m+1} = L.$$

We denote $k = x_{i+1} - x_i$ as size of subinterval $[x_{i+1}, x_i]$ for $i \geq 1$. Let

$$V = H_{cf}(0, L) = \{w \in H^2(0, L) \mid w(0) = w'(0) = 0\},$$

where $H_{cf}(0, L)$ is a subset of Sobolev space $H^2(0, L)$, using the same norm. We choose B-spline functions $\psi_i(x)$, $1 \leq i \leq m+1$ for the basis functions. The B-spline will be a cubic spline [2, pp. 166–176] with nodes x_i, $i = 1, 2, 3, \ldots, m+1$. Note that unlike the usual piecewise continuous linear basis function, we need $m+1$ basis functions from the construction of a B-spline. Thus the finite element space becomes

$$V_k = \operatorname{span}\{\, \psi_i \mid 1 \leq i \leq m+1 \,\}.$$

These basis function will need to be in H_{cf}^2. Thus we can construct the standard B-spline function $B(s)$, according to the property of B-splines and the condition that $B(0) = 1$, $B(s) = B(-s)$, and $B'(0) = 0$:

$$B(s) = \frac{2}{3} \begin{cases} 1 + \frac{3}{4}|s|^3 - \frac{3}{2}|s|^2 & \text{if } |s| \leq 1, \\ \frac{1}{4}(2 - |s|)^3 & \text{if } 1 \leq |s| \leq 2, \\ 0 & \text{if } |s| \geq 2. \end{cases}$$

Thus $B(s)$ is piecewise cubic on interval $[i, i+1]$ for $i \in \mathbb{Z}$. For most basis functions $i = 2, 3, \ldots, m+1$, we use shifted B-splines:

$$\psi_i(x) = B\left(\frac{x}{k} - i\right) = B\left(\frac{x - x_i}{k}\right),$$

where $x_i = i\,k$, $1 \leq i \leq m+1$. In order to satisfy essential boundary condition, we need to change the first basis function:

$$\psi_1(x) = 2\left(B\left(\frac{x}{k} + 1\right) + B\left(\frac{x}{k} - 1\right)\right) - B\left(\frac{x}{k}\right).$$

We write the approximate solution u^l, v^l, N^l as

$$u^l(x) = \sum_{i=1}^{m+1} \widehat{u}_i^l \psi_i(x),\ v^l(x) = \sum_{i=1}^{m+1} \widehat{v}_i^l \psi_i(x),\ \text{and } N^l = \sum_{i=1}^{m+1} \widehat{N}_i^l \psi_i(x). \tag{3.1}$$

In this section we want to use $\widehat{u}_i^l$ to indicate coefficients of the basis functions in the finite elements, in contrast to u_i^l, which indicate coefficients of the eigenfunctions. Using (2.2), we have discrete-time equations of motion

$$\frac{2}{h^2}u^{l+1} + \frac{1}{2}u_{xxxx}^{l+1} = \frac{2}{h^2}u^l - \frac{1}{2}u_{xxxx}^l + \frac{2}{h}v^l + f(x) + N^l. \tag{3.2}$$

First setting $u^l(x) = \sum_{i=1}^{m+1} \widehat{u}_i^l \psi_i(x)$ and multiplying by basis function $\psi_i(x)$ on both sides of (3.2) and by integrating by parts, we obtain the Galerkin approximation for one time step:

$$\left(\mathbf{M} + \frac{h^2}{4}\mathbf{K}\right)\mathbf{u}^{l+1} = \left(\mathbf{M} - \frac{h^2}{4}\mathbf{K}\right)\mathbf{u}^l + h\mathbf{M}\mathbf{v}^l + \frac{h^2}{2}\left(\mathbf{f} + \mathbf{M}\mathbf{N}^l\right), \tag{3.3}$$

$$\mathbf{v}^{l+1} = \frac{2}{h}(\mathbf{u}^{l+1} - \mathbf{u}^l) - \mathbf{v}^l, \tag{3.4}$$

where the mass ($\mathbf{M}$) and stiffness matrices ($\mathbf{K}$) have the following forms, respectively:

$$M_{ij} = \int_0^L \psi_i \psi_j \, dx \text{ and } K_{ij} = \int_0^L \psi_i'' \psi_j'' \, dx.$$

From (3.3) and (3.4) we will obtain numerical solutions $\mathbf{u}^l = (\widehat{u}_1^l, \widehat{u}_2^l, \dots, \widehat{u}_{m+1}^l)^T$, $\mathbf{v}^l = (\widehat{v}_1^l, \widehat{v}_2^l, \dots, \widehat{v}_{m+1}^l)^T$, and $\mathbf{N}^l = (\widehat{N}_1^l, \widehat{N}_2^l, \dots, \widehat{N}_{m+1}^l)^T$ at each discretized time t_l. Also note that $\mathbf{f} = (f_1, f_2, \dots, f_{m+1})$ is the load vector, where $f_i = \int_0^l f(x)\psi_i(x)\,dx$. Recalling that each basis function is $\psi_i(x) = B((x - x_i)/k)$, the mass and stiffness matrices are banded matrix with three subdiagonals and three superdiagonals. Note that these matrices $\mathbf{M}$ and $\mathbf{K}$ are symmetric positive definite.

3.2. Energy dissipation in the fully discrete case. If the fully discrete scheme has the same linear complementary condition as the semidiscrete case, energy dissipation can fail to hold. This was indeed observed in some preliminary computations. So in the fully discrete case, we need to modify the complementarity condition in order to guarantee energy dissipation. Following the definition of energy functional (2.4) and (3.1), we can define energy functional in the fully discrete case:

$$E(\mathbf{u}^l, \mathbf{v}^l) = \frac{1}{2}\left((\mathbf{v}^l)^T \mathbf{M}\mathbf{v}^l + (\mathbf{u}^l)^T \mathbf{K}\mathbf{u}^l\right) - \mathbf{f}\cdot\mathbf{u}^l. \tag{3.5}$$

LEMMA 3.1. *If we have complementarity condition*

$$\mathbf{0} \le \mathbf{M}\mathbf{N}^l \quad \perp \quad \mathbf{u}^{l+1} + \mathbf{g} \ge \mathbf{0}, \tag{3.6}$$

where $\mathbf{g} = (g_1, g_2, \dots, g_{m+1})^T$ *and* $g_i = g(x_i)$ *and with the discrete equations of motion* (3.3), (3.4)*, then energy is dissipated.*

Proof. Using numerical formulation (2.1)–(2.2) and (3.1), we have

$$\frac{1}{2h}\left(\sum_{i=1}^{m+1} \widehat{v}_i^{\,l+1}\psi_i(x) - \sum_{i=1}^{m+1} \widehat{v}_i^{\,l}\psi_i(x)\right)\left(\sum_{j=1}^{m+1} \widehat{v}_j^{\,l+1}\psi_j(x) + \sum_{j=1}^{m+1} \widehat{v}_j^{\,l}\psi_j(x)\right)$$

$$= -\frac{1}{2h}\left(\sum_{i=1}^{m+1}\widehat{u}_i^{\,l+1}\psi_i^{''''}(x) + \sum_{i=1}^{m+1}\widehat{u}_i^{\,l}\psi_i^{''''}(x)\right)\left(\sum_{j=1}^{m+1}\widehat{u}_j^{\,l+1}\psi_j(x) - \sum_{j=1}^{m+1}\widehat{u}_j^{\,l}\psi_j(x)\right)$$
$$+ \frac{1}{h}f\left(\sum_{j=1}^{m+1}\widehat{u}_j^{\,l+1}\psi_j(x) - \sum_{j=1}^{m+1}\widehat{u}_j^{\,l}\psi_j(x)\right)$$
$$+ \frac{1}{h}\sum_{i=1}^{m+1}\widehat{N}_i^{\,l}\psi_i(x)\left(\sum_{j=1}^{m+1}\widehat{u}_j^{\,l+1}\psi_j(x) - \sum_{j=1}^{m+1}\widehat{u}_j^{\,l}\psi_j(x)\right).$$

Then taking the integral with respect to x and using integration by parts and using mass and stiffness matrix,

$$\frac{1}{2}\left((\mathbf{v}^{l+1})^T\mathbf{M}\mathbf{v}^l - (\mathbf{v}^l)^T\mathbf{M}\mathbf{v}^l\right)$$
$$= -\frac{1}{2}\left((\mathbf{u}^{l+1})^T\mathbf{K}\mathbf{u}^{l+1} - (\mathbf{u}^l)^T\mathbf{K}\mathbf{u}^l\right) + \mathbf{f}^T(\mathbf{u}^{l+1} - \mathbf{u}^l) + (\mathbf{N}^l)^T\mathbf{M}(\mathbf{u}^{l+1} - \mathbf{u}^l)$$
$$= -\frac{1}{2}((\mathbf{u}^{l+1})^T\mathbf{K}\mathbf{u}^{l+1} - (\mathbf{u}^l)^T\mathbf{K}\mathbf{u}^l) + \mathbf{f}^T(\mathbf{u}^{l+1} - \mathbf{u}^l) + (\mathbf{N}^l)^T\mathbf{M}(\mathbf{u}^{l+1} + \mathbf{g} - \mathbf{u}^l - \mathbf{g}).$$

Thus by the complementarity condition (3.6), we have

$$E(\mathbf{u}^{l+1}, \mathbf{v}^{l+1}) = \frac{1}{2}\left((\mathbf{v}^{l+1})^T\mathbf{M}\mathbf{v}^l + (\mathbf{u}^{l+1})^T\mathbf{K}\mathbf{u}^{l+1}\right) - \mathbf{f}\cdot\mathbf{u}^{l+1}$$
$$\leq \frac{1}{2}\left((\mathbf{v}^l)^T\mathbf{M}\mathbf{v}^{l+1} + (\mathbf{u}^l)^T\mathbf{K}\mathbf{u}^l\right) - \mathbf{f}\cdot\mathbf{u}^l = E(\mathbf{u}^l, \mathbf{v}^l),$$

as required. □

Notice that we apply the complementarity condition in Lemma 3.1, when we compute numerical solutions.

3.3. Convergence of the numerical scheme in time and space. In this subsection, we investigate the convergence of contact force N in the fully discretization. As we constructed the mass matrix $\mathbf{M}$ in subsection 3.1, we obtain the mass matrix $\mathbf{M} = \frac{4}{9}k \cdot \mathbf{B}$, where $\mathbf{B}$ is a 3-banded matrix. In Lemma 3.2, we will see that the inverse of $\mathbf{B}$ is bounded in the matrix 1-norm, based on the boundedness of its spectrum [2, p. 588] and results on inverses of banded matrices [5]. Let $[r_1, r_2]$, $r_1 > 0$ be an interval containing the spectrum of $\mathbf{B}$.

LEMMA 3.2. *Set* $r = r_2/r_1$, $q := q(r) := (\sqrt{r}-1)\ (\sqrt{r}+1)$, $C_0 = (1+r^{1/2})/(2r_1 r)$, *and* $\varpi = q^{2/3}$. *For any subinterval* $k > 0$, *we have*

$$\left\|\mathbf{B}^{-1}\right\|_1 \leq C\left(1 + 2\frac{\varpi}{1-\varpi}\right),$$

where $C := C(r_1, r) := \max\{r_1^{-1}, C_0\}$.

Proof. Using Propositions 2.1 and 2.2 in [5, p. 492], we have

$$\left\|\mathbf{B}^{-1}\right\|_1 = \max_{1\leq j\leq m+1}\sum_{i=1}^{m+1}\left|B_{ij}^{-1}\right| \leq C \max_{1\leq j\leq m+1}\sum_{i=1}^{m+1}\varpi^{|i-j|}. \tag{3.7}$$

To bound (3.7) simply, take $m \to \infty$. Then since $0 < \varpi < 1$,

$$\left\|\mathbf{B}^{-1}\right\|_1 \leq C\max_j\sum_{i=1}^{\infty}\varpi^{|i-j|} \leq C\sum_{i=-\infty}^{\infty}\varpi^i = C\left(1 + 2\frac{\varpi}{1-\varpi}\right),$$

as required. □

Recalling (2.18), let Borel measure $N_{h,k}$ be

$$\int_0^T \int_0^L N_{h,k}(x,t)\,dx\,dt = h \sum_{l=0}^{\lfloor T/h \rfloor -1} \int_0^L \sum_{i=1}^{m+1} \widehat{N}_i{}^l \psi_i(x) dx.$$

LEMMA 3.3. *Suppose that* (3.6) *is satisfied. Then Borel measures $N_{h,k}$ are uniformly bounded as measures on $[0,L]\times[0,T]$ as $h\downarrow 0$ and $k\downarrow 0$, i.e.,*

$$\int_0^T \int_0^L |N_{h,k}(x,t)|\,dx\,dt \le C,$$

where C does not depend on h, k.

Proof. Since $x \mapsto x^2/2$ is a quadratic function that satisfies the clamped end conditions at $x=0$, we can take $x^2/2 = \sum_{i=1}^{m+1} \alpha_i \psi_i(x)$ in the finite element space V_k as it is a spanned by a set of B-splines. The coefficients α_i can be exactly computed to be

$$\alpha_i = \begin{cases} k^2/6, & i=1, \\ \left(x_i^2 - k^2/3\right)/2, & i>1. \end{cases}$$

As we can see, $\alpha_i - x_i^2/2 \to 0$ as $k \to 0$. Using an argument similar to Lemma 2.7, we have

$$\int_0^L \frac{x^2}{2} N^l dx = \int_\eta^L \frac{x^2}{2} N^l dx = \int_\eta^L \sum_{i=1}^{m+1} \alpha_i \psi_i(x) \sum_{j=1}^{m+1} \widehat{N}_j^l \psi_j(x) dx.$$

Since $x^2/2 \ge \eta^2/2$ for $x \in [\eta, L]$ and $\mathbf{M}\mathbf{N}^l \ge \mathbf{0}$, we obtain

$$\begin{aligned}\int_0^L \frac{x^2}{2} N^l dx &\ge \int_0^L \sum_{i=1}^{m+1} \alpha_i \psi_i(x) \sum_{j=1}^{m+1} \widehat{N}_j^l \psi_j(x) = \sum_{j=1}^{m+1} \alpha_i \int_0^L \psi_i \psi_j dx\, \widehat{N}_j^l \\ &= \sum_{j=1}^{m+1} \alpha_i \int_0^L \psi_i \psi_j dx\, \widehat{N}_j^l = \sum_{i=1}^{m+1} \alpha_i \left(\mathbf{M}\mathbf{N}^l\right)_i.\end{aligned}$$

Since there is an $\eta > 0$ where $\widehat{u}_i^{l+1} + g(x_i) > 0$ for all $0 \le x_i \le \eta$ and all l, and $0 \le \mathbf{u}^l + \mathbf{g} \perp \mathbf{M}\,\mathbf{N}^l \ge 0$, we see that $(\mathbf{M}\,\mathbf{N}^l)_i = 0$ whenever $0 \le x_i \le \eta$. Thus

$$\sum_{i=1}^{m+1} \alpha_i \left(\mathbf{M}\mathbf{N}^l\right)_i \ge \min_{k\,i\ge\eta} \alpha_i \left\|\mathbf{M}\mathbf{N}^l\right\|_1 \ge \left(\frac{\eta^2}{2} - \frac{k^2}{6}\right) \left\|\mathbf{M}\mathbf{N}^l\right\|_1 \ge \frac{\eta^2}{4} \left\|\mathbf{M}\mathbf{N}^l\right\|_1$$

for sufficiently small $k>0$. From (2.19), $h\eta^2 \sum_{l=0}^{\lfloor T/h\rfloor -1} \left\|\mathbf{M}\mathbf{N}^l\right\|_1 \le C$, where C does not depend on h, k.

Therefore by Lemma 3.2,

$$\begin{aligned} h \sum_{l=0}^{\lfloor T/h\rfloor -1} \int_0^L \left| \sum_{i=1}^{m+1} \widehat{N}_i^l \psi_i(x) \right| dx &\le h \sum_{l=0}^{\lfloor T/h\rfloor -1} \sum_{i=1}^{m+1} \left|\widehat{N}_i^l\right| \|\psi_i\|_{L^1(0,L)} \\ &\le O(k)\, h \sum_{l=0}^{\lfloor T/h\rfloor -1} \left\|\mathbf{N}^l\right\|_1 \le O(k)\, h \sum_{l=0}^{\lfloor T/h\rfloor -1} \left\|\mathbf{M^{-1}}\mathbf{M}\mathbf{N}^l\right\|_1 \end{aligned}$$

$$\begin{aligned}&\le O(k)\left\|\mathbf{M}^{-1}\right\|_1 h\sum_{l=0}^{\lfloor T/h\rfloor-1}\left\|\mathbf{M}\mathbf{N}^l\right\|_1\\&=\frac{1}{\eta^2}O(k)O\left(\frac{1}{k}\right)=O(1),\end{aligned}$$

as required. □

We now need to show that any weak* limiting measure N is necessarily nonnegative. This is needed as the numerical method requires $\mathbf{M}\,\mathbf{N}^l\ge\mathbf{0}$ rather than $\mathbf{N}^l\ge\mathbf{0}$.

Lemma 3.4. *If N is a weak* limit of a subsequence $N_{h,k}\rightharpoonup^* N$ in the space of measures on $[0,T]\times[0,L]$, then $N\ge 0$.*

Proof. Suppose that $N_{h,k}\rightharpoonup^* N$ as measures on $[0,T]\times[0,L]$. Then for any continuous $\varphi\colon[0,T]\times[0,L]\to\mathbb{R}$, $\int_0^T\int_0^L\varphi(x,t)N_{h,k}(x,t)\,dx\,dt\to\int_0^T\int_0^L\varphi(x,t)N(x,t)\,dx\,dt$ in the subsequence with h, $k\to 0$. To show that $N\ge 0$ consider any $\varphi\colon[0,T]\times[0,L]\to\mathbb{R}_+$. Let $\varphi_k(x,t)=\sum_{i=1}^{m+1}\varphi(x_i,t)\psi_i(x)$, which is a pseudo-interpolant. Since φ is continuous on a compact set, it is uniformly continuous, and so for any $\epsilon>0$ there is a $\delta>0$ such that if $|x-x'|<\delta$ and $|t-t'|<\delta$ then $|\varphi(x,t)-\varphi(x',t')|<\epsilon$. If $x_i\le x\le x_{i+1}$ then $\psi_j(x)=0$ unless $i-1\le j\le i+2$. Choosing $0<k<\delta/2$, we see that

$$|\varphi(x,t)-\varphi_k(x,t)|\le\sum_{j=i-1}^{i+2}|\varphi(x,t)-\varphi(x_j,t)|\,\psi_j(x)\le\sum_{j=i-1}^{i+2}\epsilon\,\psi_j(x)=\epsilon.$$

Since this is true for all (x,t), $\varphi_k\to\varphi$ uniformly in $C([0,T]\times[0,L])$. Thus $\iint\varphi_k N_{h,k}\to\iint\varphi N$ as $h,k\to 0$ in a suitable subsequence. Now

$$\begin{aligned}\int_0^T\int_0^L\varphi_k(x,t)N_{h,k}(x,t)\,dx\,dt&=h\sum_{l=0}^{\lfloor T/h\rfloor-1}\int_0^L\sum_{i=1}^{m+1}\varphi(x_i,t_l)\psi_i(x)\sum_{j=1}^{m+1}N_j^l\psi_j(x)\,dx\\&=h\sum_{l=0}^{\lfloor T/h\rfloor-1}\sum_{i=1}^{m+1}\varphi(x_i,t_l)(\mathbf{M}\,\mathbf{N}^l)_i\ge 0,\end{aligned}$$

since $\mathbf{M}\,\mathbf{N}^l\ge\mathbf{0}$ and $\varphi(x_i,t_l)\ge 0$ for all i and l. Taking the limit in the subsequence gives

$$\int_0^T\int_0^L\varphi(x,t)N(x,t)\,dx\,dt\ge 0.$$

Since this holds for all continuous nonnegative φ, it follows that $N\ge 0$ in the sense of measures. □

From Lemmas 3.3 and 3.4 we see that there is a subsequence $N_{h,k}$ that converges weak* to a nonnegative measure N. It can also be shown that there are subsequences in which $u_{h,k}\rightharpoonup^* u$ in $L^\infty(0,T;H^2_{cf}(0,L))$ and $v_{h,k}\rightharpoonup^* v$ in $L^\infty(0,T;L^2(0,L))$ with $u_t=v$ and $v_t=-u_{xxxx}+N(x,t)$ by integrating against sufficiently smooth functions over $[0,T]\times[0,L]$. It is also clear that the numerical solutions $u_{h,k}$ are in a compact subset of $L^2([0,T]\times[0,L])$, and so $u_{h,k}+g\ge 0$ implies in the limit that $u+g\ge 0$ (continuity of the limit ensures that this holds everywhere, not just almost everywhere). To show that $u+g\perp N$ in the limit, we need a compactness result.

Noting that $du_{h,k}/dt(t) = \frac{1}{2}(v_{h,k}(t) + v_{h,k}(t-h))$ (with $v_{h,k}(t) = v^0$ for $-h \leq t < 0$), we see that $du_{h,k}/dt$ is uniformly bounded in $L^\infty(0,T;L^2(0,L))$ while $u_{h,k}$ is uniformly bounded in $C(0,T;H^2_{cf}(0,L))$. If we pick $0 < \theta < 1$ we can obtain the following bounds in the interpolation space $H^{2\theta}_{cf}(0,L) := [L^2(0,L),\, H^2_{cf}(0,L)]_\theta \subseteq H^{2\theta}(0,L)$ (see Kuttler [7, section 22.6, equation (62)], Triebel [16, Thm. 1.3.3(g)], and Bramble and Zhang [3, Appendix A, Thms. A.1 and A.2]):

$$\begin{aligned}\|u_{h,k}(t) - u_{h,k}(s)\|_{H^{2\theta}(0,L)} &\leq C_\theta\ \|u_{h,k}(t) - u_{h,k}(s)\|^\theta_{H^2(0,L)}\ \|u_{h,k}(t) - u_{h,k}(s)\|^{1-\theta}_{L^2(0,L)}\\ &\leq C_\theta\ \left(\|u_{h,k}(t)\|_{H^2(0,L)} + \|u_{h,k}(s)\|_{H^2(0,L)}\right)^\theta\\ &\qquad\times\left(\int_s^t \frac{1}{2}\,\|v_{h,k}(\tau) + v_{h,k}(\tau-h)\|_{L^2(0,L)}\,d\tau\right)^{1-\theta}\\ &\leq C_\theta\ \left(2\sqrt{2E^0}\right)^\theta\left(\sqrt{2E^0}\right)^{1-\theta}|t-s|^{1-\theta}\end{aligned}$$

so that the numerical trajectories $u_{h,k}$ are uniformly Hölder continuous as functions $[0,T] \to H^{2\theta}(0,L)$. Note that $E^0 := E(u^0,v^0)$ is the initial energy. For $2\theta > 1/2$, $H^{2\theta}(0,L)$ is compactly embedded into $C[0,L]$ [15, Props. 4.3 and 4.4], so by the Arzela–Ascoli theorem [8, Thm. III.3.1, p. 57] there is a convergent subsequence in $C([0,T]\times[0,L])$. Taking such a subsequence, we note that if $g_k(x) = \sum_{i=1}^{m+1} g_i\psi_i(x)$, $g_k \to g$ uniformly and so

$$\begin{aligned}\int_0^T\int_0^L (u_{h,k}(x,t) + g_k(x))\,N_{h,k}(x,t)\,dx\,dt &= \sum_{l=1}^{\lfloor T/h\rfloor-1}\sum_{i,j=1}^{m+1}\left(\widehat{u}_i^{l+1} + g_i\right)\widehat{N}_j^l\int_0^L \psi_i(x)\psi_j(x)\,dxh\\ &= \sum_{l=1}^{\lfloor T/h\rfloor-1}(\mathbf{u}^{l+1} + \mathbf{g})^T\mathbf{M}\,\mathbf{N}^l h = 0\end{aligned}$$

since $\mathbf{0} \leq \mathbf{u}^{l+1} + \mathbf{g} \perp \mathbf{M}\,\mathbf{N}^l \geq \mathbf{0}$. Taking the limit in the subsequence then gives

$$\int_0^T\int_0^L (u(x,t) + g(x))\,N(x,t)\,dx\,dt = 0$$

as desired. Thus there is a subsequence in which we get the desired convergence, and the limit for any converging subsequence satisfies the conditions for a solution.

3.4. Nonsmooth Newton method. To solve the linear system (3.3) for one time step with the linear complementarity condition (3.6), we consider using the nonsmooth Newton method (see Qi and Sun [11] for details). In order to find the next step solution $\mathbf{u}^{l+1}$ from the linear system (3.3) and the complementarity condition (3.6), we consider the mapping $\mathbf{F} : \mathbf{R}^{m+1} \to \mathbf{R}^{m+1}$:

$$\mathbf{F} : \mathbf{u}^{l+1} \mapsto \min(\mathbf{M}\mathbf{N}^l, \mathbf{u}^{l+1} + \mathbf{g}). \tag{3.8}$$

Note that $\min(\mathbf{a},\mathbf{b})$ is meant componentwise for vectors $\mathbf{a}$ and $\mathbf{b}$, and so $\min(\mathbf{a},\mathbf{b}) = \mathbf{0}$ is equivalent to $0 \leq \mathbf{a} \perp \mathbf{b} \geq 0$. Thus the complementarity condition (3.6) is equivalent to $\mathbf{F}(\mathbf{u}^{l+1}) = \mathbf{0}$. Since $\mathbf{M}\mathbf{N}^l$ is implicitly a function of $\mathbf{u}^{l+1}$ via the linear system (3.3), we can express $\mathbf{M}\mathbf{N}^l$ as

$$\mathbf{M}\mathbf{N}^l = \frac{2}{h^2}\left[\left(\mathbf{M} + \frac{h^2}{4}\mathbf{K}\right)\mathbf{u}^{l+1} - \left(\mathbf{M} - \frac{h^2}{4}\mathbf{K}\right)\mathbf{u}^l - h\mathbf{M}\mathbf{v}^l\right] - \mathbf{f}. \tag{3.9}$$

Table 3.1
Average number of linear systems solved per time step.

	$k = 1/5$	$k = 1/25$	$k = 1/50$	$k = 1/500$
$h = 1/10$	20.48	28.08	29.36	35.79
$h = 1/20$	19.68	25.95	26.99	27.23
$h = 1/50$	19.20	23.36	23.96	18.28
$h = 1/100$	19.19	22.79	23.01	19.14
$h = 1/1000$	19.28	22.87	19.87	14.60

We can find the next approximate solution $\mathbf{u}^{l+1}$ by using the nonsmooth Newton method:

$$\mathbf{u}_{n+1}^{l+1} = \mathbf{u}_n^{l+1} - \nabla\mathbf{F}(\mathbf{u}_n^{l+1})^{-1}F(\mathbf{u}_n^{l+1}) \text{ for } n \geq 0.$$

Even though $\mathbf{F}$ is a nonsmooth function, Newton's method can still converge superlinearly since $\mathbf{F}$ is a *semismooth* function [10, 9]. This is because max and min are semismooth functions, and Newton's method for semismooth function still converges locally at a superlinear rate provided $\mathbf{F}$ is "BD regular" [11]. That is, it converges superlinearly provided $\partial_B\mathbf{F}(\mathbf{u}) := \{\lim_{j\to\infty}\nabla\mathbf{F}(\mathbf{u}_j) \mid \lim_{j\to\infty}\mathbf{u}_j = \mathbf{u}\}$ does not contain any singular matrices.

In practice, in order to obtain computation, we use a smooth approximation $\theta_\alpha(a,b)$ to $\min(a,b)$

$$\theta_\alpha(a,b) = \frac{1}{2}\left((a+b) - h_\alpha(a-b) + \alpha\right),$$

where $h_\alpha(y) = \sqrt{y^2+\alpha^2} - \alpha$ is an approximation to $|y|$. $\alpha > 0$ is chosen by an adaptive strategy reducing by a factor of 10 or increasing by a factor of 2 in order to succeed the guarded Newton method. The number α is called a smoothing parameter. Clearly, as $\alpha \to 0$, we have

$$\theta_\alpha(a,b) \to \min(a,b). \tag{3.10}$$

At each stage we solve $\mathbf{F}_\alpha(\mathbf{u}) := \theta_\alpha(\mathbf{MN}^l, \mathbf{u}^{l+1} + \mathbf{g}) = 0$ using a guarded Newton method and then reduce α, usually by a factor of 10, and repeat the procedure until α is sufficiently small. We use the function $\|\mathbf{F}_\alpha(\mathbf{u})\|_2$ as the merit function for the guarded Newton method.

This method has proven to be quite efficient, typically requiring only 20 to 30 linear solves per time step, as can be seen in Table 3.1. This means that the time for the computations per time step grows linearly with the size of the problem as shown in Table 3.3.

3.5. Numerical evidence for strong convergence. In this subsection, we present the numerical evidence that our numerical solutions converge strongly (via Lemma 2.10), and our method of obtaining and assessing this evidence. Let $\boldsymbol{\phi}_i$ be the ith eigenvector with eigenvalue λ_i of the generalized eigenproblem (3.11). Then we have

$$\boldsymbol{\phi}_i^T\mathbf{M}\boldsymbol{\phi}_i = 1 \text{ and } \mathbf{K}\boldsymbol{\phi}_i = \lambda_i\mathbf{M}\boldsymbol{\phi}_i, \tag{3.11}$$

where $\boldsymbol{\phi}_i = ((\phi_i)_1, (\phi_i)_2, (\phi_i)_3, \ldots, (\phi_i)_{m+1})$. Note that this is the Galerkin discretization of the eigenfunction problem $\partial^4\phi_i(x)/\partial x^4 = \lambda_i\phi_i(x)$ and $\int_0^L \phi_i(x)^2 = 1$ with our boundary conditions. Also note that $\mathbf{M}^{-1}\mathbf{K}$ is self-adjoint with respect to the inner products $\langle \mathbf{z}, \mathbf{w}\rangle_{\mathbf{M}} = \mathbf{z}^T\mathbf{M}\mathbf{w}$ and $\langle \mathbf{z}, \mathbf{w}\rangle_{\mathbf{K}} = \mathbf{z}^T\mathbf{K}\mathbf{w}$. So for any given function $\beta : \mathbf{R} \to \mathbf{R}$, we can define $\beta(\mathbf{M}^{-1}\mathbf{K})$ via $\beta(\mathbf{M}^{-1}\mathbf{K})\boldsymbol{\phi}_i = \beta(\lambda_i)\boldsymbol{\phi}_i$. In particular, let $\kappa^*(\lambda) = 1$ if $\lambda \le \lambda_c$ and $\kappa^*(\lambda) = 0$ otherwise. The $\kappa^*(\mathbf{M}^{-1}\mathbf{K})\mathbf{z}$ is the projection onto $\operatorname{span}\{\boldsymbol{\phi}_i \mid i = 1, 2, \dots,$ and $\lambda_i \le \lambda_c\}$ that is orthogonal with respect to both $\langle \cdot, \cdot\rangle_{\mathbf{M}}$ and $\langle \cdot, \cdot\rangle_{\mathbf{K}}$. The elastic energy in the modes i with $\lambda_i \le \lambda_c$ is therefore $\frac{1}{2}(\kappa^*(\mathbf{M}^{-1}\mathbf{K})\mathbf{u})^T\mathbf{K}\,\kappa^*(\mathbf{M}^{-1}\mathbf{K})\mathbf{u}$ and the kinetic energy is $\frac{1}{2}(\kappa^*(\mathbf{M}^{-1}\mathbf{K})\mathbf{v})^T\mathbf{M}\,\kappa^*(\mathbf{M}^{-1}\mathbf{K})\mathbf{v}$. Since $\kappa^*(\mathbf{M}^{-1}\mathbf{K})$ is not easily computable without performing a complete (and expensive) eigenvalue/eigenvector decomposition of $\mathbf{M}^{-1}\mathbf{K}$, we will instead construct a rational approximation to it.

Choosing $\lambda_c > 0$ for any cut-off $c \ge 1$, we have $(1/\lambda_c)\mathbf{M}^{-1}\mathbf{K}\boldsymbol{\phi}_i = (\lambda_i/\lambda_c)\boldsymbol{\phi}_i$. Thus for any large integer $p > 0$,

$$\left(\mathbf{I} + \left(\frac{1}{\lambda_c}\mathbf{M}^{-1}\mathbf{K}\right)^{2p}\right)^{-1}\boldsymbol{\phi}_i = \frac{1}{1 + (\lambda_i/\lambda_c)^{2p}}\boldsymbol{\phi}_i.$$

Then we fix a continuous map κ of λ, which approximates the step function $\kappa^*(\lambda)$:

$$\kappa(\lambda) = \frac{1}{(1 + (\lambda/\lambda_c)^{2p})} \text{ and then } \kappa(\mathbf{M}^{-1}\mathbf{K}) = \left(\mathbf{I} + \left(\frac{1}{\lambda_c}\mathbf{M}^{-1}\mathbf{K}\right)^{2p}\right)^{-1}. \tag{3.12}$$

Employing (3.11), it can be proved that at each time step $l \ge 1$, the energy in the fully discrete case with no body force is

$$\frac{1}{2}\left((\mathbf{v}^l)^T\mathbf{M}\mathbf{v}^l + (\mathbf{u}^l)^T\mathbf{K}\mathbf{u}^l\right) = \frac{1}{2}\sum_{i=1}^{m+1}\left(|\widehat{v}_i^l|^2 + \lambda_i|\widehat{u}_i^l|^2\right). \tag{3.13}$$

Using (3.13), we can demonstrate numerical evidence using Lemma 2.10 that the convergence is strong. The ratio

$$\frac{(\kappa(\mathbf{M}^{-1}\mathbf{K})\mathbf{u}^l)^T\mathbf{K}\,\kappa(\mathbf{M}^{-1}\mathbf{K})\mathbf{u}^l + (\kappa(\mathbf{M}^{-1}\mathbf{K})\mathbf{v}^l)^T\mathbf{M}\,\kappa(\mathbf{M}^{-1}\mathbf{K})\mathbf{v}^l}{(\mathbf{u}^l)^T\mathbf{K}\,\mathbf{u}^l + (\mathbf{v}^l)^T\mathbf{M}\,\mathbf{v}^l}$$

is the ratio of the elastic and kinetic energy in the modes with $\lambda_i \le \lambda_c$ to the total elastic and kinetic energy for the numerical solution at time step l. Following Lemma 2.10, this should go to one as $\lambda_c \uparrow \infty$, uniformly in the numerical parameters $h > 0$, l and $k > 0$. Of course, for *fixed* $k > 0$, this will happen as $\lambda_c \uparrow \infty$ anyway. So we need to first fix λ_c and then compute these ratios for k and h becoming small; from the apparent limits of the energy ratios for several fixed λ_c, we observe the overall trend as $\lambda_c \uparrow \infty$. This will be done in subsection 3.6.

3.6. Computing $\boldsymbol{\kappa}(\mathbf{M}^{-1}\mathbf{K})\mathbf{z}$.

In this subsection, we discuss how to efficiently compute $\kappa(\mathbf{M}^{-1}\mathbf{K})\mathbf{z}$. Note that we do not compute $\kappa^*(\mathbf{M}^{-1}\mathbf{K})$ directly using an eigendecomposition of $\mathbf{M}^{-1}\mathbf{K}$, as this is computationally expensive. So we use a rational function $\kappa(\lambda)$ to approximate the step function $\kappa^*(\lambda)$. We can then compute $\kappa(\mathbf{M}^{-1}\mathbf{K})\mathbf{z}$ for any vector $\mathbf{z}$. For simplicity we choose

$$\kappa(\lambda) = \frac{1}{1 + (\lambda/\lambda_c)^{2p}} \text{ for } p \text{ moderately large.}$$

Table 3.2

The number of nodes	c	$h=1/10$	$h=1/50$	$h=1/100$
500	10	0.650153	0.407755	0.380260
	30	0.910487	0.812236	0.777214
	100	0.997099	0.986641	0.972011
	300	0.999846	0.999166	0.997870
1000	10	0.653481	0.412869	0.378693
	30	0.917148	0.855211	0.755536
	100	0.997575	0.981944	0.968371
	300	0.999846	0.998196	0.997980

In fact, we implement this function for $p = 5$. The key to efficient computation of $\kappa(\mathbf{M}^{-1}\mathbf{K})\mathbf{z}$ is the factorization of $\kappa(\lambda)$. The zeros of the denominator (3.12) are solutions of $(\lambda_j/\lambda_c)^{2p} = -1$. The solutions of this equation are

$$\lambda_j/\lambda_c = \zeta_j := \exp((2j+1)\pi i/2p), \quad j = 0, 1, 2, \ldots, 2p-1, \text{ where } i = \sqrt{-1}.$$

Thus since $\kappa(\lambda) = \lambda_c^{2p}(\lambda - \lambda_c\zeta_0)^{-1}(\lambda - \lambda_c\zeta_1)^{-1}\cdots(\lambda - \lambda_c\zeta_{2p-1})^{-1}$, we have

$$\kappa(\mathbf{M}^{-1}\mathbf{K}) = \lambda_c^{2p}(\mathbf{K} - \lambda_c\zeta_0\mathbf{M})^{-1}\mathbf{M}(\mathbf{K} - \lambda_c\zeta_1\mathbf{M})^{-1}\cdots\mathbf{M}(\mathbf{K} - \lambda_c\zeta_{2p-1}\mathbf{M})^{-1}\mathbf{M}.$$

The right side of the linear system $(\mathbf{K} - \lambda_c\zeta_j\mathbf{M})\mathbf{z} = \mathbf{w}$ has matrices over the complex numbers $\mathbf{C}$. We can change the complex matrix into two real ones so that we have an equivalent real banded matrix with double the bandwidth. Thus the linear system $(\mathbf{K} - \lambda_c\zeta_j\mathbf{M})\mathbf{z} = \mathbf{w}$ can be solved as a banded system with an upper and lower bandwidth of six, which can be done in $O(m+1)$ time. The matrix-vector products $\mathbf{Mz}$ can also be computed in $O(m+1)$ time. Thus $\kappa(\mathbf{M}^{-1}\mathbf{K})\mathbf{z}$ can be computed in just $O(p(m+1))$ time.

The ratios contained in Table 3.2 are obtained as follows: Let $E(\mathbf{u}^l, \mathbf{v}^l)$ be the total energy in actual computation and let $E_c(\mathbf{u}^l, \mathbf{v}^l)$ be the energy in the low frequency modes. Then the ratio that we use is

$$\tau = \frac{\sum_{l=0}^{\lfloor T/h \rfloor} E_c(\mathbf{u}^l, \mathbf{v}^l)}{\sum_{l=0}^{\lfloor T/h \rfloor} E(\mathbf{u}^l, \mathbf{v}^l)}.$$

Looking across the rows of Table 3.2, we note that there does seem to be some slow convergence of the ratios as h goes to zero, and this ratio increases as m (the number of grid nodes) increases; this limit seems to be very close to one for large λ_c. By picking $c = 100$, i.e., the lowest 100 out of 500 or 1000 possible modes, we can account for about 97 percent of the total kinetic and elastic energy. This implies that we can account for almost all the energy in the bottom 100 frequency modes and account for about 75 percent of the total energy in the bottom 30 modes. So Table 3.2 presents substantial numerical evidence of the applicability of Lemma 2.10 and, therefore, of strong convergence of the numerical solutions.

3.7. Numerical experiments and discussion of the results. The package that we used for handling the matrices and vectors is Meschach [14], which uses the C programming language. We took particular advantage of the banded matrix routines in that package. Our numerical experiments were performed on a Hewlett-Packard Visualize B2000.

In this subsection, we show our numerical simulation results. In our computation, we take the length of the rod to be $L = 20$ and the initial displacement $u^0(x) = x^2/4$,

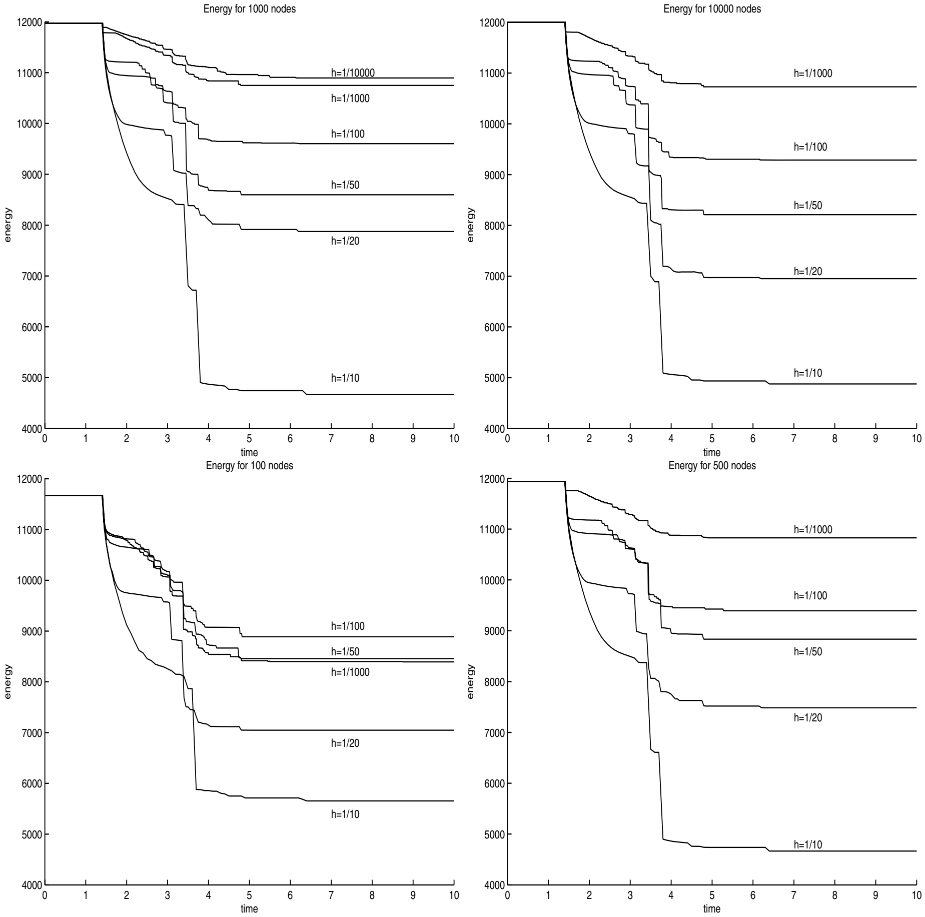

Fig. 2. *Energy function.*

which is consistent with the essential boundary condition and the initial velocity $v^0(x) = -2 \cdot x$ and gap function $g(x) = (x - 12)^2$, and the end time $T = 10$. We assume that the rod is moving downward, in a negative direction in simulation. The gap function g indicates the distance between the rigid foundation and the initial position where the rod is located vertically. Note that the potential energy is not included in our computation.

From the energy functional in (3.5) in the fully-discrete case, we obtain four graphs for the total energy in Figure 2. According to those graphs, our numerical implementation supports the energy dissipation that we anticipated theoretically. The first graph shows that the energy function using 100 nodes is erratic. Indeed, we anticipated that the smaller time step size h we used, the higher the energy. This appears to be true for all the cases except for $k = 0.2$ and for $h = 0.01$ and $h = 0.001$. We would conjecture that the reason is that the approximations are not sufficiently refined for this value of k. On the other hand, other graphs show that energy conservation is expected as step size h becomes smaller and smaller.

In Figure 3, the motion of the rod is presented. Each curve is the profile of the rod at a given time. In this simulation, we used $k = 1/1000$ in space and a time step of $h = 1/100$. According to our numerical experiments, that case brings the most

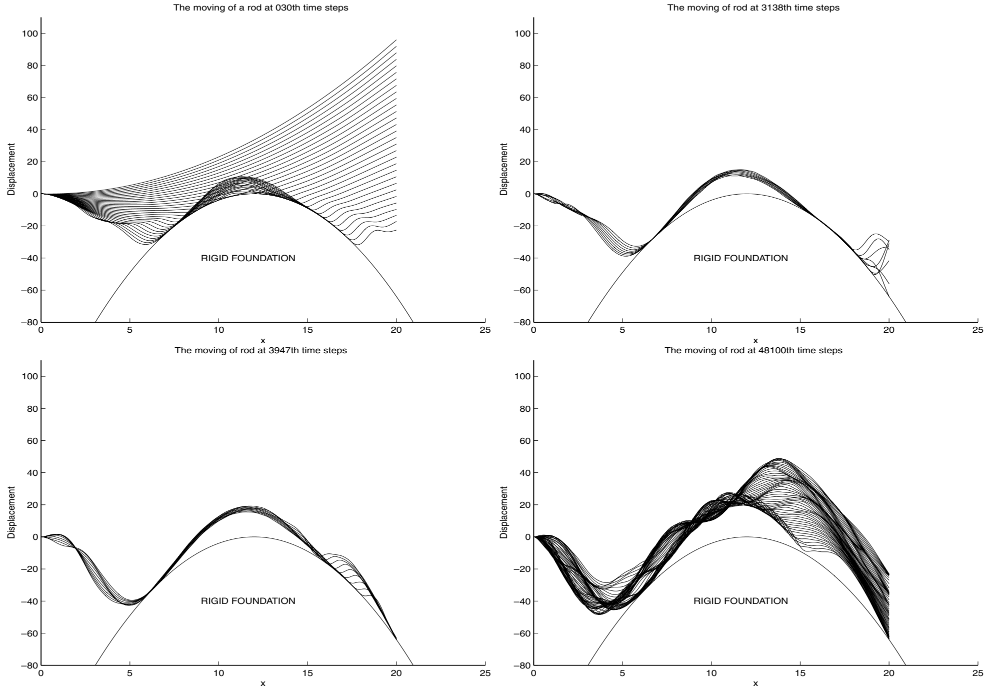

FIG. 3. *Flow of solution.*

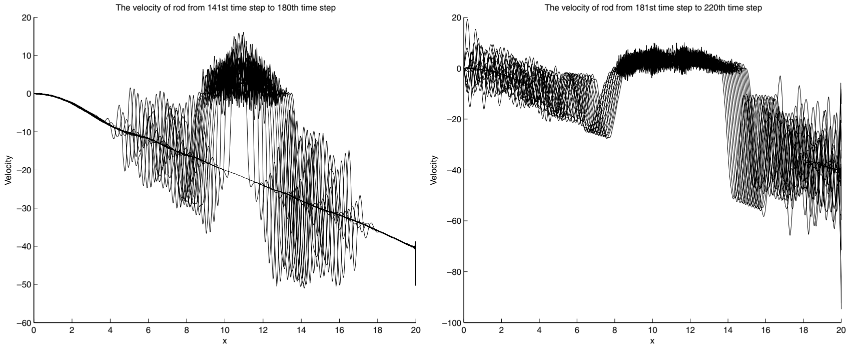

FIG. 4. *The velocity of the rod at each time step* 141–220.

comfortable and solid result. An interesting point is that the end of the rod touches the rigid foundation at some time step, and it oscillates very rapidly. See the pictures at the top right and bottom left of Figure 3.

Figures 4 and 5 present the velocity of the rods. Particularly in Figure 4, high frequencies appear when the rod touches the rigid foundation. So we would guess by the phenomenon that the rate of deformation of the rod is very fast in the time steps. Figure 5 shows the velocity after the rod bounces away from the rigid foundation.

Finally, we have 3-dimensional pictures showing the contact force in Figure 6. When the end of the rod touches the rigid foundation, the contact force is largest there. Even though the number of nodes in the two pictures are different and they show different magnitudes for the contact force, the graphs have a similar shape.

Table 3.3 shows the speed of the computations. Note that in the case of $k = 1/500$

we use the different convergence criterion $\|\mathbf{F}(\mathbf{u})\|_2 < \epsilon$ for stopping. This was necessary because of difficulties with roundoff and ill-conditioning in the stiffness matrix $\mathbf{K}$. So instead we used $\|\nabla\mathbf{F}(\mathbf{u})^{-1}\mathbf{F}(\mathbf{u})\|_2 < \epsilon$ to avoid these numerical difficulties. So in Table 3.3, we can see that the ratio of times differs from the other cases.

4. Conclusion.

In this paper we consider semidiscrete and fully discrete approximations to the motion of an Euler–Bernoulli beam with frictionless contact. For both the semidiscrete and fully discrete approximations, we are able to show that there is a subsequence of the discrete approximations that converges (albeit in a sufficiently weak sense) to a (weak) solution of the PDE and the Signorini contact conditions. The fully discrete approximation was developed using the finite element method using B-splines to construct the basis functions. This scheme was implemented, and the linear complementarity problems (LCPs) that arise at each time step were solved using a smoothed guarded Newton method applied to a reformulation of the LCP as a nonsmooth equation. These methods turn out to be quite efficient, especially since the one-dimensional structure of the problem results in banded matrices when handled properly. Furthermore, the number of linear systems solved per time-step seems not to grow as the discretization parameters (h in time and k in space) go to zero.

Open questions of particular interest to the authors are the question of strong convergence of the solutions and the related question of whether the limiting solution conserves energy or not. A numerical scheme is devised in this paper to test the question of strong convergence in a computationally efficient manner. The results from the computation give evidence that the numerical solutions for our problem do indeed converge strongly, and, even though the time-discretization is dissipative, the limit solution also conserves energy. No analytical demonstration of energy conservation is given; it can be demonstrated to be false in general, but it may be true generically.

Acknowledgments. We would like to acknowledge the comments of an anonymous referee, which improved the presentation of this paper and prompted us to complete the convergence proof for the discretization in both time and space.

A POSTERIORI ERROR ESTIMATIONS OF SOME CELL-CENTERED FINITE VOLUME METHODS[*]

SERGE NICAISE[†]

Abstract. This paper presents the natural framework to residual based a posteriori error estimation of some cell-centered finite volume methods for the Laplace equation in $\mathbb{R}^d, d = 2$ or 3. For that purpose we associate with the finite volume solution a reconstructed approximation, which is a kind of Morley interpolant. The error is then the difference between the exact solution and this Morley interpolant. The residual error estimator is based on the jump of normal and tangential derivatives of the Morley interpolant. We then prove the equivalence between the discrete H^1 seminorm of the error and the residual error estimator. Numerical tests confirm our theoretical results.

Key words. finite volume method, cell-centered method, a posteriori error estimates

AMS subject classifications. 65N30, 65N15

DOI. 10.1137/S0036142903437787

1. Introduction.

The finite volume method is a well-adapted method for the discretization of various partial differential equations and is very popular in the engineering community [24]. The mathematical community recently started to analyze it in detail. Presently, existence and uniqueness results as well as a priori error estimates are available for a quite large class of problems; we refer to [10] and the references cited there. Contrary to the finite element methods [26], a posteriori error estimates for finite volume methods are less developed, and until now only a few results have been obtained in that direction. See [14, 22, 1, 12, 13] for cell-centered finite volume methods, [17, 19, 25, 23] for vertex-centered methods, and [2, 3, 15, 16] for finite volume element methods. Since finite volume methods have some similarities with the finite element methods, we may hope that this gap will be filled soon.

The goal of our paper is to present the natural framework to residual based a posteriori (efficient and reliable) error estimation of some cell-centered finite volume methods for linear elliptic equations. In a first attempt we restrict ourselves to the Laplace equation in $\mathbb{R}^d, d = 2$ or 3. The case of diffusion–convection–reaction equations will be only sketched; for details, we refer to a forthcoming paper [20]. The key idea is the reconstruction of a piecewise polynomial approximation of the finite volume solution, its principal property being that the mean of its flux through any edge/face of the mesh is equal to the numerical flux through that edge/face (this interpolant is consequently smoother than the approximated solution). This reconstructed approximation is then a kind of Morley interpolant of the finite volume solution. In general a Morley interpolant is not in H^1, and therefore the Morley interpolant may be considered as a nonconforming approximation of the exact solution. The second key idea is to use the Helmholtz decomposition of the error, the difference between the exact solution and this Morley interpolant, as was done in [7] for the a posteriori error analysis of a nonconforming finite element approximation of the Laplace equation. As in

[7] the residual error estimator is then naturally based on the jump of normal and tangential derivatives of the Morley interpolant. We finally show the equivalence between the discrete H^1 seminorm of the error and the residual error estimator. The proof of the upper error bound uses the Helmholtz decomposition of the error and some quasi-orthogonality relations obtained using the above-mentioned property of the Morley interpolant. The proof of the lower error bound is more standard and simply uses some Green's formulas and inverse inequalities as for finite element methods [26].

Note that our purposes also require the introduction of new finite elements of Morley type on rectangles and tetrahedra.

We further give explicitly the size of the constants appearing in the error estimates by estimating the constants involved in the interpolation error estimates (using some related eigenvalue problems and extension techniques) and in some inverse inequalities. In particular, we obtain constants in the upper error bound that are quite close to unity.

The idea to interpolate the finite volume solution by a smoother function having the above-mentioned property on the flux was presented in [12] in an L^1 framework for time-dependent nonlinear convection–diffusion equations in $\mathbb{R}^d \times \mathbb{R}^+$. In that paper the authors obtain a reliable estimator in an L^1-norm, instead of the energy norm. Furthermore, their interpolant is a piecewise linear Lagrange interpolant on a dual mesh. As a consequence, to guarantee the property on the flux, the (primal) mesh has to be admissible in the sense of [10, Def. 9.1], a deep obstacle for adaptivity. To avoid this admissibility condition and use the energy norm framework, we need to use the natural degrees of freedom on the mesh, namely, the mean of the flux on the edges/faces, and consequently use higher order polynomials.

The outline of the paper is as follows: In section 2 we describe the so-called cell-centered method for the Laplace equation on a mesh made of triangles, rectangles, or tetrahedra. Some standard inverse inequalities and interpolation error estimates are recalled in section 3, where some constants are specified as explicitly as possible. Section 4 is devoted to the introduction of some finite elements of Morley type. In section 5 we introduce the Morley interpolant of the approximated solution and prove its main properties. The upper and lower error bounds are then deduced in section 6. The upper error bound is based on the properties of the Morley interpolant and the use of the Helmholtz decomposition of the error, while the lower error bound is proved in a quite standard way. In section 7 we briefly describe how to extend our results to diffusion–convection–reaction equations. Finally, section 8 is devoted to numerical experiments that confirm our theoretical considerations.

2. Discretization of the Laplace equation. Let Ω be an open subset of $\mathbb{R}^d$, $d = 2$ or 3, with a polygonal ($d = 2$) or polyhedral ($d = 3$) boundary Γ.

As usual, we denote by $L^2(\cdot)$ the Lebesgue spaces and by $H^s(\cdot)$, $s \geq 0$, the standard Sobolev spaces. If D is an open subset of $\mathbb{R}^d$, $d = 2$ or 3, the usual norm and seminorm of $H^s(D)$ are denoted by $\| \cdot \|_{s,D}$ and $| \cdot |_{s,D}$. For brevity the $L^2(D)$-norm will be denoted by $\| \cdot \|_D$ and in the case $D = \Omega$, we will drop the index Ω. The space $H_0^1(\Omega)$ is defined, as usual, by $H_0^1(\Omega) := \{v \in H^1(\Omega)/v = 0 \text{ on } \Gamma\}$. In what follows the symbol $| \cdot |$ will denote either the Euclidean norm in $\mathbb{R}^d$, $d = 2$ or 3, or the length of a line segment, or the area of a plane face, or finally the measure of a domain of $\mathbb{R}^d$.

We consider the standard elliptic problem: for $f \in L^2(\Omega)$ let $u \in H_0^1(\Omega)$ be the variational solution of

$$-\Delta u = f \text{ in } \Omega, \tag{1}$$

which means that u satisfies

$$\int_\Omega \nabla u \cdot \nabla v \, dx = \int_\Omega f v \, dx \quad \forall v \in H_0^1(\Omega). \tag{2}$$

To approximate this problem by a finite volume scheme we fix a family of meshes $T_h, h > 0$, regular in Ciarlet's sense [4, p. 124]. In two dimensions we assume that all elements of T_h are either triangles or rectangles, while in three dimensions the mesh consists only of tetrahedra. For $K \in T_h$ we recall that h_K is the diameter of K and $h = \max_{K \in T_h} h_K$.

For any edge/face E of K, we denote by $h_{E,K}$ its height in K, namely, $h_{E,K} = \frac{d|K|}{|E|}$ if K is a triangle or a tetrahedron and $h_{E,K} = \frac{|K|}{|E|}$ if K is a rectangle. For an edge/face E, its mean height is $h_E = \frac{1}{2}(h_{E,K} + h_{E,L})$, when E is the edge/face of K and L. The regularity of the mesh implies in particular that for any edge/face E of K one has

$$\sigma_1 h_{E,K} \le h_K \le \sigma_2 h_{E,K}, \tag{3}$$

$$\sigma_3 h_{E,K} \le h_E \le \sigma_4 h_{E,K} \tag{4}$$

for some positive constants $\sigma_i, i = 1, \dots, 4$, depending on the aspect ratio of T_h.

Let us define E_h as the set of edges ($d = 2$) or faces ($d = 3$) of the triangulation and set $E_h^{int} = \{E \in E_h / E \subset \Omega\}$ the set of interior edges/faces of T_h, while $E_h^{ext} = E_h \setminus E_h^{int}$ is the set of exterior edges/faces of T_h.

For an edge E of a two-dimensional (2D) element K, introduce $n_{K,E} = (n_x, n_y)$ the unit outward normal vector to K along E. Similarly for a face E of a tetrahedron K, set $n_{K,E} = (n_x, n_y, n_z)$ the unit outward normal vector to K on E. Furthermore, for each edge/face E, we fix one of the two normal vectors and denote it by n_E. In two dimensions additionally introduce the tangent vector $t_{K,E} = n_{K,E}^\perp := (-n_y, n_x)^\top$ such that it is oriented positively (with respect to K); similarly set $t_E := n_E^\perp$.

The jump of some function v across an edge/face E at a point $y \in E$ is defined as

$$\begin{aligned} [\![v(y)]\!]_E &:= \lim_{\alpha \to +0} v(y + \alpha n_E) - v(y - \alpha n_E) \quad \forall E \in E_h^{int}, \\ [\![v(y)]\!]_E &:= v(y) \quad \forall E \in E_h^{ext}. \end{aligned}$$

For any $K \in T_h$ or $E \in E_h$, we denote by $\mathcal{M}_K \chi$ and $\mathcal{M}_E \chi$ the mean of χ on K and E, respectively, i.e.,

$$\mathcal{M}_K \chi = \frac{1}{|K|} \int_K \chi(x) \, dx \quad \forall K \in T_h, \qquad \mathcal{M}_E \chi = \frac{1}{|E|} \int_E \chi(x) \, ds(x) \quad \forall E \in E_h.$$

Finally, we will need local subdomains (also called patches). As usual, let ω_K be the union of all elements having a common edge/face with K. Similarly let ω_E be the union of both elements having E as edge/face.

The finite volume approximation u_h of u is piecewise constant on T_h, i.e., $u_h := (u_K)_{K \in T_h}$ (u_K being the approximation of $u(x_K)$ for $K \in T_h$, x_K being the "center" of the box K). To deduce the approximated equation satisfied by u_h, we first integrate (1) on a control volume K and use the divergence formula to obtain

$$- \sum_{E \in E_K} \int_E \nabla u \cdot n_{K,E} \, ds = \int_K f(x) \, dx \quad \forall K \in T_h, \tag{5}$$

where E_K is the set of edges/faces of K. The diffusion flux $\int_E \nabla u \cdot n_{K,E}$ is approximated by a numerical diffusion flux $F_{K,E}(u_h)$ obtained using quadrature rules and finite differences (see, e.g., [10]) and is consequently a linear combination of some values of u_h around E [10, 5, 6]. For our further uses we do not need its exact form but the principle of conservation of flux is required: $F_{K,E}(u_h) = -F_{L,E}(u_h)$ for $E = \bar{K} \cap \bar{L}$. These approximations lead to the following system. Find a solution $u_h := (u_K)_{K \in T_h}$ of

$$- \sum_{E \in E_K} F_{K,E}(u_h) = \int_K f(x)\, dx \quad \forall K \in T_h. \tag{6}$$

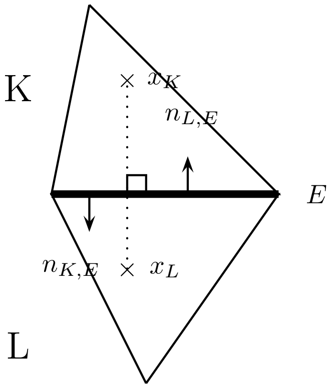

FIG. 1. *The standard orthogonality condition.*

If the mesh T_h is admissible in the sense of [10, Def. 9.1], i.e., satisfies standard orthogonality conditions (see Figure 1), then the numerical diffusion flux is defined by

$$\begin{aligned} F_{K,E}(u_h) &:= \frac{|E|(u_L - u_K)}{d(x_K, x_L)} \quad \text{if } E = \overline{K} \cap \overline{L}, \\ F_{K,E}(u_h) &:= -\frac{|E| u_K}{d(x_K, \Gamma)} \quad \text{if } E \subset \overline{K} \cap \partial\Omega. \end{aligned} \tag{7}$$

For general meshes, a possible choice for $F_{K,E}(u_h)$ is proposed in [5, 6] using the diamond cell method.

From now on we suppose that system (6) is well defined. This is the case if the mesh T_h is admissible in the sense of [10] and if $F_{K,E}(u_h)$ is given by (7) (see, for instance, [10]); while for an arbitrary mesh and the choice of $F_{K,E}(u_h)$ from [5, 6], system (6) is well defined under some geometrical conditions on the mesh [5, 6].

3. Some analytic tools.

3.1. Bubble functions, extension operator, and inverse inequalities.

For our further analysis we require standard bubble functions and extension operators that satisfy certain properties recalled here for the sake of completeness.

We need two types of bubble functions, namely, b_K and b_E associated with an element K and an edge/face E, respectively. For a triangle or a tetrahedron K, denoting by $\lambda_{a_i^K}$, $i = 1, \ldots, d+1$, the barycentric coordinates of K and by $a_i^E, i = 1, \ldots, d$, the vertices of the edge/face $E \subset \partial K$, we recall that $b_K = (d+1)^{d+1}\prod_{i=1}^{d+1} \lambda_{a_i^K}$ and $b_E = d^d \prod_{i=1}^{d} \lambda_{a_i^E}$.

For a rectangle K we here enumerate its vertices in a clockwise sense. Denoting by $\lambda_{a_i^K}$, $i = 1, \dots, 4$, the "barycentric" coordinates of K, namely, $\lambda_{a_i^K}$ is the unique element in $\mathbb{Q}_1(K)$ such that $\lambda_{a_i^K}(a_j^K) = \delta_{i,j}$, then we recall that $b_K = 8\lambda_{a_1^K}\lambda_{a_3^K}$ and $b_E = 4\lambda_{a_1^K}(\lambda_{a_2^K} + \lambda_{a_3^K})$ if the endpoints of the edge E are a_1^K and a_2^K.

One recalls that $b_K = 0$ on ∂K, $b_E = 0$ on $\partial\omega_E$, $\|b_K\|_{\infty,K} = \|b_E\|_{\infty,\omega_E} = 1$.

In two dimensions for an edge $E \subset \partial K$ using temporarily the local coordinates system (x, y) such that E is included into the x-axis, then the extension $F_{\text{ext}}(v_E)$ of $v_E \in C(E)$ to K is defined by $F_{\text{ext}}(v_E)(x, y) = v_E(x)$. We proceed similarly in three dimensions.

Now we may recall the so-called inverse inequalities, whose proof uses classical scaling techniques and the fact that all norms are equivalent in a finite-dimensional space [26].

LEMMA 3.1 (inverse inequalities). *Let $K \in T_h$, $E \in E_K$, $v_K \in \mathbb{P}_{k_0}(K)$, and $v_E \in \mathbb{P}_{k_1}(E)$ for some nonnegative integers k_0 and k_1. Then there exist positive constants β_0, β_1 (resp., α_0, α_1, and α_2) depending on the form of K (triangle, rectangle, or tetrahedron), on the aspect ratio of the mesh T_h, and on the polynomial degree k_0 (resp., k_1) such that*

$$\|v_K b_K^{1/2}\|_K^2 \le \|v_K\|_K^2 \le \beta_0 \|v_K b_K^{1/2}\|_K^2, \tag{8}$$

$$\|\nabla(v_K b_K)\|_K^2 \le \beta_1 h_K^{-2} \|v_K\|_K^2, \tag{9}$$

$$\|v_E b_E^{1/2}\|_E^2 \le \|v_E\|_E^2 \le \alpha_0 \|v_E b_E^{1/2}\|_E^2, \tag{10}$$

$$\|F_{\text{ext}}(v_E) b_E\|_K^2 \le \alpha_1 h_K \|v_E\|_E^2, \tag{11}$$

$$\|\nabla(F_{\text{ext}}(v_E) b_E)\|_K^2 \le \alpha_2 h_K^{-1} \|v_E\|_E^2. \tag{12}$$

Remark 3.2. In the above lemma, if K is a square and $k_1 = 2$, then $\alpha_0 = \frac{10+\sqrt{30}}{4} \approx 1.967$, $\alpha_1 = \frac{8(6+\sqrt{21})}{315} \approx 0.269$, $\alpha_2 = \frac{8(56+\sqrt{881})}{105} \approx 6.528$. These numbers are obtained by reducing estimates (10)–(12) to an eigenvalue problem. Namely using the standard basis of $\mathbb{P}_2$, estimate (12) is equivalent to $(AX, X) \le \alpha_2(BX, X)$ for all $X \in \mathbb{R}^3$, where A and B are two explicit 3×3 matrices. Therefore, α_2 is the largest eigenvalue of the matrix $B^{-1/2} \cdot A \cdot B^{1/2}$, or equivalently the largest eigenvalue of the matrix $B^{-1} \cdot A$, since B is invertible. A direct calculation yields the value of α_2. The other estimates are proved in the same manner. □

3.2. Interpolation error estimates. Here we collect some standard interpolation error estimates but we specify as explicitly as possible the involved constants. As usual we start with the reference elements, which are the unit triangle $\hat{K}$ of vertices $(0, 0), (1, 0), (0, 1)$, the unit square $\hat{K}$ of vertices $(0, 0), (1, 0), (0, 1), (1, 1)$, or the unit tetrahedron $\hat{K}$ of vertices $(0, 0, 0), (1, 0, 0), (0, 1, 0), (0, 0, 1)$.

LEMMA 3.3. *Let $\hat{E}$ be the edge/face of $\hat{K}$ included in the axis/plane $x_d = 0$. Then there exist two positive constants μ and α such that for all $v \in H^1(\hat{K})$, the following estimates hold:*

$$\|v - \mathcal{M}_{\hat{K}} v\|_{\hat{K}} \le \mu \|\nabla v\|_{\hat{K}}, \tag{13}$$

$$\|v - \mathcal{M}_{\hat{E}} v\|_{\hat{E}} \le \alpha \|\nabla v\|_{\hat{K}}. \tag{14}$$

If $\hat{K}$ is the reference square, then $\mu = \frac{1}{\pi}$ and $\alpha = \frac{1}{\sqrt{\pi \tanh \pi}} \approx 0.565244$. If $\hat{K}$ is the reference triangle, then $\mu = \frac{1}{\pi}$ and $\alpha = \frac{1}{\mu_1}$, where μ_1^2 is the first positive root of *the transcendental equation*

$$\sinh x + \tan x = 0. \tag{15}$$

This means that $\alpha \approx 0.730276$. *If* $\hat{K}$ *is the reference tetrahedron, then* $\mu \leq \frac{(2(11+4\sqrt{6}))^{1/4}}{\sqrt{3}\pi} \approx 0.466715$ *and* $\alpha \leq \frac{(2(11+4\sqrt{6}))^{1/4}}{\sqrt{\pi \tanh \pi}} \approx 1.43549$.

Proof. The two estimates are Poincaré-like inequalities and follow from the Bramble–Hilbert lemma. But this argument does not give an estimate for μ and α. Therefore, we argue as follows. For the first estimate, denote by λ_1^2 the first positive eigenvalue of the Laplace operator on $\hat{K}$ with Neumann boundary conditions. Then by the min-max principle, we know that $\lambda_1^2 = \min_{\substack{v \in H^1(\hat{K}) \\ v \neq 0, \mathcal{M}_{\hat{K}} v = 0}} \frac{\|\nabla v\|_{\hat{K}}^2}{\|v\|_{\hat{K}}^2}$. This identity is equivalent to

$$\lambda_1^2 \|v\|_{\hat{K}}^2 \leq \|\nabla v\|_{\hat{K}}^2 \quad \forall v \in H^1(\hat{K}) : \mathcal{M}_{\hat{K}} v = 0.$$

We then obtain (13) with $\mu = \lambda_1^{-1}$.

If $\hat{K}$ is the unit square, it is well known that $\lambda_1^2 = \pi^2$ and consequently $\mu = \frac{1}{\pi}$. If $\hat{K}$ is the reference triangle, we use the following extension operator from $\hat{K}$ to the unit square $(0,1)^2$, temporarily denoted by $\hat{S}$. Namely, for $v \in H^1(\hat{K})$, we define its extension Ev to $\hat{S}$ by

$$\begin{aligned} &Ev(y_1, y_2) = v(y_1, y_2) \quad \text{if } (y_1, y_2) \in \hat{K}, \\ &Ev(y_1, y_2) = v(1 - y_2, 1 - y_1) \quad \text{if } (y_1, y_2) \in \hat{S} \setminus \hat{K}. \end{aligned}$$

Note that $Ev \in H^1(\hat{S})$ and from $\|v\|_{\hat{K}}^2 = \|v\|_{\hat{S}}^2$, $\|\nabla v\|_{\hat{K}}^2 = \|\nabla v\|_{\hat{S}}^2$, we easily get

$$\min_{\substack{v \in H^1(\hat{K}) \\ v \neq 0, \mathcal{M}_{\hat{K}} v = 0}} \frac{\|\nabla v\|_{\hat{K}}^2}{\|v\|_{\hat{K}}^2} \geq \min_{\substack{v \in H^1(\hat{S}) \\ v \neq 0, \mathcal{M}_{\hat{S}} v = 0}} \frac{\|\nabla v\|_{\hat{S}}^2}{\|v\|_{\hat{S}}^2} = \pi^2.$$

On the other hand, one readily checks that the function $\psi(x, y) = \sqrt{2}(\cos(\pi x) + \cos(\pi(1 - y))$ is an eigenvector of the eigenvalue π^2 of the Laplace operator with Neumann boundary conditions in $\hat{K}$. Therefore, we actually have $\lambda_1^2 = \pi^2$.

We use a similar argument for the reference tetrahedron. Namely we use an extension operator from $\hat{K}$ to the standard reference pentahedron $\hat{P} = \hat{E} \times (0, 1)$. For that purpose denote by $\hat{K}_2$ and $\hat{K}_3$ the tetrahedra of vertices $(1,0,0), (0,1,0), (0,0,1), (1,0,1)$ and $(0,1,0), (0,0,1), (1,0,1), (0,1,1)$, respectively. We remark that $\hat{P} = \hat{K} \cup \hat{K}_2 \cup \hat{K}_3$, that $\hat{K}$ and $\hat{K}_2$ have a common face, and similarly that $\hat{K}_2$ and $\hat{K}_3$ have a common face. Note further that $|\hat{K}| = |\hat{K}_2| = |\hat{K}_3| = \frac{1}{6}$. Therefore, as before there exists an affine transformation F_1 which maps $\hat{K}$ onto $\hat{K}_2$ and let their common face be invariant. Similarly denote by F_2 the affine transformation which maps $\hat{K}_2$ onto $\hat{K}_3$ and let their common face be invariant. Denote by $A_i, i = 1, 2$, the 3×3 matrices and by $b_i \in \mathbb{R}^3, i = 1, 2$, such that $F_i(x) = A_i x + b_i$ for all $x \in \mathbb{R}^3$. Now we are able to define the extension operator E: for $v \in H^1(\hat{K})$, we define

$$\begin{aligned} &Ev(y) = v(y), \quad \text{if } y \in \hat{K}, \qquad Ev(y) = v(F_1^{-1}(y)) \quad \text{if } y \in \hat{K}_2, \\ &Ev(y) = v(F_1^{-1}(F_2^{-1}(y))) \quad \text{if } y \in \hat{K}_3. \end{aligned}$$

Using the above properties between the tetrahedra $\hat{K}, \hat{K}_2$, and $\hat{K}_3$ and some changes of variables, we readily check that $Ev \in H^1(\hat{P})$ and satisfies $\int_{\hat{P}} Ev(y)\, dy = 3 \int_{\hat{K}} v(x)\, dx$, and

$$\int_{\hat{P}} |Ev(y)|^2\, dy = 3 \int_{\hat{K}} |v(x)|^2\, dx, \int_{\hat{P}} |\nabla Ev(y)|^2\, dy = \int_{\hat{K}} \nabla v(x)^\top \cdot T \cdot \nabla v(x)\, dx,$$

where the matrix T is given by

$$T = Id + (A_1^\top A_1)^{-1} + A_1^{-1}(A_2^\top A_2)^{-1}A_1^{-\top} = \begin{pmatrix} 5 & -2 & 0 \\ -2 & 3 & -1 \\ 0 & -1 & 5 \end{pmatrix}.$$

An easy calculation yields $\|T\|_2 = \sqrt{2(11+4\sqrt{6})} \approx 6.44949$.

These identities directly lead to

$$\min_{\substack{v\in H^1(\hat{K})\\ v\neq 0, \mathcal{M}_{\hat{K}}v=0}} \frac{\|\nabla v\|^2_{\hat{K}}}{\|v\|^2_{\hat{K}}} \geq \frac{3}{\|T\|_2} \min_{\substack{v\in H^1(\hat{P})\\ v\neq 0, \mathcal{M}_{\hat{P}}v=0}} \frac{\|\nabla v\|^2_{\hat{P}}}{\|v\|^2_{\hat{P}}} = \frac{3\pi^2}{\|T\|_2}.$$

We then conclude that $\mu \leq \sqrt{\frac{\|T\|_2}{3\pi^2}}$.

For the second estimate, we start with the following nonstandard eigenvalue problem in the unit square $\hat{K} = (0,1)^2$. Find λ^2 and $v \in H^1(\hat{K})$ solution of

$$\int_{\hat{K}} \nabla v \cdot \nabla w = \lambda^2 \int_{\hat{E}} vw \quad \forall w \in H^1(\hat{K}). \tag{16}$$

For this eigenvalue problem, let us show that the min-max principle holds at least for the first positive eigenvalue $\tilde{\lambda}_1^2$. Namely $\tilde{\lambda}_1^2$ is characterized by

$$\tilde{\lambda}_1^2 = \min_{\substack{v\in H^1(\hat{K})\\ \|v\|_{\hat{E}}\neq 0, \mathcal{M}_{\hat{E}}v=0}} \frac{\|\nabla v\|^2_{\hat{K}}}{\|v\|^2_{\hat{E}}}. \tag{17}$$

Denote by m the above right-hand side. Consider a minimizing sequence v_n of the above minimum, namely, for all $n \in \mathbb{N}$, let $v_n \in H^1(\hat{K})$ be such that

$$\mathcal{M}_{\hat{E}}v_n = 0, \qquad \|v_n\|_{\hat{E}} = 1, \qquad \|\nabla v_n\|^2_{\hat{K}} \to m \text{ as } n \to \infty.$$

Since $\|\nabla v\|_{\hat{K}} + \|v\|_{\hat{E}}$ is a norm on $H^1(\hat{K})$ equivalent to the standard norm, the sequence $(v_n)_n$ is bounded in $H^1(\hat{K})$. Therefore, there exists a subsequence, still denoted by $(v_n)_n$, such that

$$v_n \to v \text{ in } H^1(\hat{K}) \text{ as } n \to \infty.$$

From the above properties of the sequence $(v_n)_n$, we deduce that v satisfies

$$\mathcal{M}_{\hat{E}}v = 0, \qquad \|v\|_{\hat{E}} = 1, \qquad \|\nabla v\|^2_{\hat{K}} = m.$$

It remains to show that v is an eigenvector of problem (16) corresponding to the eigenvalue m. For that purpose let us fix $z \in H^1(\hat{K})$ such that

$$\mathcal{M}_{\hat{E}}z = 0 \quad \text{and} \quad \int_{\hat{E}} vz = 0. \tag{18}$$

Consider the mapping

$$\Phi : \mathbb{R} \to \mathbb{R} : \alpha \to \frac{\|\nabla(v+\alpha z)\|^2_{\hat{K}}}{1+\alpha^2\|z\|^2_{\hat{K}}}.$$

From the above minimization problem and the properties of v, the mapping Φ hits its minimum at $\alpha = 0$. Since Φ is smooth, we deduce that $\Phi'(0) = 0$, or

$$\int_{\hat{K}} \nabla v \cdot \nabla z = 0. \tag{19}$$

Since any $w \in H^1(\hat{K})$ such that $\mathcal{M}_{\hat{E}} w = 0$ may be written in the form $w = \beta v + z$, with $\beta \in \mathbb{R}$ and $z \in H^1(\hat{K})$ satisfying (18), we deduce that

$$\int_{\hat{K}} \nabla v \cdot \nabla w = \beta \int_{\hat{K}} \nabla v \cdot \nabla v + \int_{\hat{K}} \nabla v \cdot \nabla z.$$

By the properties of v and identity (19), we conclude that

$$\int_{\hat{K}} \nabla v \cdot \nabla w = \beta m = m \int_{\hat{E}} vw;$$

this last identity follows from (18).

To find the first eigenvalue of problem (16), we remark that its strong form is

$$\begin{cases} -\Delta v = 0 \text{ in } \hat{K}, \\ \frac{\partial v}{\partial n} \;=\; \lambda^2 v \text{ on } \hat{E}, \\ \frac{\partial v}{\partial n} \;=\; 0 \text{ on } \partial\hat{K} \setminus \hat{E}. \end{cases}$$

Using the standard argument of separation of variables, one finds a family of eigenvalues, its smallest one being $\pi \tanh \pi \approx 3.12988$. In order to be sure that this value is the smallest eigenvalue of problem (16), we penalize it by an integral term in $\hat{K}$. Namely, for any $\epsilon > 0$, we consider the problem

$$\int_{\hat{K}} \nabla v \cdot \nabla w = \lambda_\epsilon^2 \left(\int_{\hat{E}} vw + \epsilon \int_{\hat{K}} vw \right) \quad \forall w \in H^1(\hat{K}). \tag{20}$$

This problem is an eigenvalue problem related to a selfadjoint nonnegative operator. For that problem one can find all the eigenvalues by separation of variables. Since the eigenvalues of (20) depend continously on ϵ, the first positive eigenvalue $\tilde{\lambda}_{1,\epsilon}^2$ tends to the first eigenvalue of problem (16). By direct calculations one shows that

$$\tilde{\lambda}_{1,\epsilon}^2 \to \pi \tanh \pi.$$

We therefore conclude that $\tilde{\lambda}_1^2 = \pi \tanh \pi$. By the above "min-max" principle (17), we deduce that $\alpha = 1/\tilde{\lambda}_1$.

For the unit triangle, we start with the minization problem (17) (as before $\tilde{\lambda}_1^2$ is the first positive eigenvalue of problem (16)). Using the extension operator E from $\hat{K}$ to $\hat{S}$, we deduce that

$$\tilde{\lambda}_1^2 = \min_{\substack{v \in H^1(\hat{K}) \\ \|v\|_{\hat{E}} \neq 0, \mathcal{M}_{\hat{E}} v = 0}} \frac{\|\nabla v\|_{\hat{K}}^2}{\|v\|_{\hat{E}}^2} \geq \min_{\substack{v \in H^1(\hat{S}) \\ \|v\|_{\hat{E}} + \|v\|_{\hat{F}} \neq 0, \mathcal{M}_{\hat{E} \cup \hat{F}} v = 0}} \frac{\|\nabla v\|_{\hat{S}}^2}{\|v\|_{\hat{E}}^2 + \|v\|_{\hat{F}}^2},$$

where $\hat{F}$ is the edge of $\hat{S}$ included into the line $x_1 = 1$. The right-hand side is related to the eigenvalue problem: find λ^2 and $v \in H^1(\hat{S})$ solution of

$$\int_{\hat{S}} \nabla v \cdot \nabla w = \lambda^2 \int_{\hat{E} \cup \hat{F}} vw \quad \forall w \in H^1(\hat{S}). \tag{21}$$

The same arguments as before give, as first positive eigenvalue μ_1^2, the first positive root of the transcendental equation (15).

As for the first estimate we deduce that μ_1^2 is the first positive eigenvalue of problem (16). Indeed, if $w(x_1, x_2)$ is the eigenvector of problem (21) associated with the eigenvalue μ_1^2, then one readily checks that $v(x_1, x_2) = w(x_1, x_2) - w(1-x_2, 1-x_1)$ is an eigenvector of problem (16) associated with the eigenvalue μ_1^2.

As before the situation is not so convenient for the unit tetrahedron Therefore, we first state the following estimate on the reference prism $\hat{P}$:

$$\|v - \mathcal{M}_{\hat{E}} v\|_{\hat{E}} \le \frac{1}{\sqrt{\pi \tanh \pi}} \|\nabla v\|_{\hat{P}} \quad \forall v \in H^1(\hat{P}),$$

obtained as for the unit square. Now, using the extension operator E and this estimate, we may write

$$\|v - \mathcal{M}_{\hat{E}} v\|_{\hat{E}} = \|Ev - \mathcal{M}_{\hat{E}} Ev\|_{\hat{E}} \le \frac{1}{\sqrt{\pi \tanh \pi}} \|\nabla Ev\|_{\hat{P}} \le \frac{1}{\sqrt{\pi \tanh \pi}} \sqrt{\|T\|_2} \|\nabla v\|_{\hat{K}};$$

this last estimate follows from the above properties of Ev. □

Remark 3.4. To our knowledge, the exact value of μ is not explicitly known for the unit tetrahedron. Numerical tests give for λ_1^2 the approximated value $\lambda_1^2 \approx 14.444208445$. This gives for μ the approximated value $\mu \approx 0.26312$, which is relatively smaller than our theoretical upper bound. Similarly the exact value of α is not explicitly known for the unit tetrahedron; an approximated value is 0.340355, and therefore our theoretical upper bound is far from being optimal.

In the above arguments, the main difference between the unit triangle and the unit tetrahedron concerns the extension operator. For the triangle, the extension operator uses an orthogonal transformation, which is impossible for the unit tetrahedron. That last case still requires more investigations. □

The above lemma and scaling arguments lead to the following lemma.

Lemma 3.5. *There exist two positive constants μ and α depending on $\hat{K}$ such that for all $K \in T_h$ and $v \in H^1(K)$, the following estimates hold:*

$$\|v - \mathcal{M}_K v\|_K \le \mu \hat{\rho}^{-1} h_K \|\nabla v\|_K, \tag{22}$$

$$\|v - \mathcal{M}_E v\|_E \le \alpha \hat{\rho}^{-1} h_{E,K}^{-1/2} h_K \|\nabla v\|_K, \tag{23}$$

where E is an edge/face of K, and $\hat{\rho}$ is the diameter of the inscribed ball of $\hat{K}$.

4. Some finite elements of Morley type. As already mentioned the main idea of our a posteriori error analysis is to use an interpolant p satisfying

$$\int_E \frac{\partial p}{\partial n_{K,E}} \, ds = F_{K,E}(u_h) \quad \forall E \in E_K.$$

This means that we need to use finite elements having as degrees of freedom the mean of the normal derivative of p on each edge/face. The simplest element is the so-called Morley triangle [18, 4] usually used for the approximation of the plate problem. For our further uses we extend this kind of elements to rectangles and tetrahedra. We start by recalling the Morley triangle as well as a recent extension due to Nilssen, Tai, and Winther [21] and then introduce our new elements.

4.1. Triangles. Here K is a (nondegenerate) triangle with vertices a_i^K, $i = 1, 2, N_f := 3$.

The standard Morley triangle is defined by the triple (K, P_K, Σ_K) [18, 4], where $P_K = \mathbb{P}_2(K)$ and

$$\Sigma_K = \{p(a_i)\}_{i=1,\ldots,N_f} \cup \left\{ \int_E \frac{\partial p}{\partial n_{K,E}}\, ds \right\}_{E \in E_K}. \tag{24}$$

Note that this element is not a C^0-element; an extension which has this property was recently built in [21, sect. 4], where they take

$$\begin{aligned} P_K &= \mathbb{P}_2(K) \oplus \mathbb{P}_1(K) b_K = \{q + p b_K : q \in \mathbb{P}_2(K), p \in \mathbb{P}_1(K)\}, \\ \Sigma_K &= \{p(a_i^K)\}_{i=1,2,3} \cup \{p(m_E)\}_{E \in E_K} \cup \left\{ \int_E \frac{\partial p}{\partial n_{K,E}}\, ds \right\}_{E \in E_K}. \end{aligned}$$

4.2. Rectangles. Here K is a (nondegenerate) rectangle of vertices a_i^K, $i = 1, \ldots, N_f := 4$.

The first element is defined by $P_K = \mathbb{P}_2(K) \oplus \operatorname{Span}\{x^3 - 3xy^2, y^3 - 3yx^2\}$ with degrees of freedom Σ_K defined by (24). We readily check that the triple (K, P_K, Σ_K) is a finite element. The above choice is motivated by the fact that $\Delta q \in \mathbb{R}\ \forall q \in P_K$, since $x^3 - 3xy^2$ and $y^3 - 3yx^2$ are the unique homogeneous polynomials of degree 3 which are harmonic.

The second example is to take $P_K = \mathbb{Q}_2(K)$ and $\Sigma_K := \{p(a_i^K)\}_{i=1,\ldots,5} \cup \{\int_E \frac{\partial p}{\partial n_{K,E}}\, ds\}_{E \in E_K}$, where a_5^K is the center of gravity of K.

4.3. Tetrahedra. Here K is a (nondegenerate) tetrahedron with vertices a_i^K, $i = 1, 2, 3, N_f := 4$.

Inspired from the second triangular example from [21] we choose $P_K = \mathbb{P}_1(K) \oplus \mathbb{P}_1(K) b_K = \{q + p b_K : p, q \in \mathbb{P}_1(K)\}$, and Σ_K defined by (24).

Similar to Lemma 4.1 of [21] (adapted to our setting) we can prove the following lemma.

Lemma 4.1. *The above triple (K, P_K, Σ_K) is a C^0-finite element.*

5. The Morley interpolant.

5.1. Definition. For any vertex a of the triangulation we fix $(w_K(a))_{K \in T_h : a \in K}$ suitable weights of interpolation around K. Since our analysis below is independent of their choice, we do not describe them. They may be obtained using a discrete projection of piecewise constant functions over affine functions on ω_a [5, 6], a standard technique to get a recovered gradient at the vertex a, leading further to the $\mathbb{P}_1$-exactness. Namely for any vertex a the weights $w_K(a)$ may be fixed such that $w(a) = \sum_{K \subset \omega_a} w_K(a) u_K$, where $w \in \mathbb{P}_1(\omega_a)$ is the discrete projection of u_h on $\mathbb{P}_1(\omega_a)$, i.e., $w \in \mathbb{P}_1(\omega_a)$ is the unique minimizer of

$$\sum_{K \subset \omega_a} |q(x_K) - u_K|^2, \quad q \in \mathbb{P}_1(\omega_a).$$

This choice implies that if u_h were $\mathbb{P}_1(\omega_a)$, then we would have $w = u_h$ in ω_a. For instance, if ω_a is made of four squares, then this choice yields $w_K(a) = 1/4$.

We now introduce the Morley finite element space

$$
\begin{aligned}
V_h := \Big\{ & v_h \in L^2(\Omega) : v_{h|K} \in P_K \ \forall K \in T_h, \\
& v_{h|K}(a_i^K) = v_{h|L}(a_j^L) \ \forall K, L \in T_h, i, j \in \{1, \dots, N_f\} : a_i^K = a_j^L, \\
& v_{h|K}(a_i^K) = 0 \ \forall K, L \in T_h, i \in \{1, \dots, N_f\} : a_i^K \in \Gamma, \\
& \int_E \frac{\partial v_{h|K}}{\partial n_E}\, ds = \int_E \frac{\partial v_{h|L}}{\partial n_E}\, ds \ \forall E \in E_h, K, L \in T_h : E = K \cap L \Big\}.
\end{aligned}
$$

Since V_h is not necessarily included into $H_0^1(\Omega)$, the space V_h is equipped with the norm $|\cdot|_{1,h} := (\sum_{K \in T_h} |\cdot|_{1,K}^2)^{1/2}$. Notice that V_h is indeed included into $H_0^1(\Omega)$ for the second-triangular example and for our three-dimensional (3D) example.

Definition 5.1. *For $u_h = (u_K)_{K \in T_h}$, we define its Morley interpolant $I_M u_h$ as the unique element v_h in V_h satisfying*

$$
v_{h|K}(a_i^K) = \sum_{L \in T_h : a_i^K \in L} w_L(a_i^K) u_L \quad \forall K \in T_h, \quad i \in \{1, \dots, N_f\} : a_i^K \in \Omega, \tag{25}
$$

$$
v_{h|K}(a_i^K) = 0 \quad \forall K \in T_h, \quad i \in \{1, \dots, N_f\} : a_i^K \in \Gamma, \tag{26}
$$

$$
\int_E \frac{\partial v_{h|K}}{\partial n_{K,E}}\, ds = F_{K,E}(u_h) \quad \forall E \in E_K, \quad K \in T_h. \tag{27}
$$

For the second triangular element we have to add the conditions

$$
\begin{aligned}
& v_{h|K}(m_E) = v_{h|L}(m_E) = \tfrac{1}{2}(u_K + u_L) \quad \forall E \in E_h, \quad K, L \in T_h : E = K \cap L, \\
& v_{h|K}(m_E) = 0 \quad \forall E \in E_h, \quad K \in T_h : E \subset K \cap \Gamma.
\end{aligned}
$$

Similarly for the first-rectangular element we must add $v_{h|K}(a_5^K) = u_K$ for all $K \in T_h$.

5.2. Some useful properties. We first prove a basic property of the Morley interpolant.

Lemma 5.2. *If u_h is solution of* (6)*, then $I_M u_h$ satisfies*

$$
\int_K \Delta(I_M u_h)\, dx = -\int_K f(x)\, dx \quad \forall K \in T_h. \tag{28}
$$

Proof. By Green's formula and property (27) satisfied by $I_M u_h$, we have

$$
\int_K \Delta(I_M u_h)\, dx = \sum_{E \in E_K} \int_E \frac{\partial(I_M u_h)}{\partial n_{K,E}}\, ds = \sum_{E \in E_K} F_{K,E}(u_h),
$$

and we conclude by (6). □

Now we prove some quasi-orthogonality relations that will be used for the upper error bound. We first define the gradient jump of $I_M u_h$ in the normal and tangential direction by

$$
\begin{aligned}
& J_{E,n}(u_h) = \left[\!\left[\tfrac{\partial}{\partial n_E}(I_M u_h) \right]\!\right]_E \quad \forall E \in E_h^{int}, \\
& J_{E,t}(u_h) = \begin{cases} \left[\!\left[\tfrac{\partial}{\partial t_E}(I_M u_h) \right]\!\right]_E \quad \forall E \in E_h & \text{for nonconforming 2D cases,} \\ 0 \quad \forall E \in E_h & \text{for conforming cases.} \end{cases}
\end{aligned}
$$

Lemma 5.3. *If u is a solution of* (2) *and u_h is a solution of* (6)*, then*

$$
\begin{aligned}
\sum_{K \in T_h} \int_K \nabla(u - I_M u_h) \cdot \nabla \chi\, dx = & \sum_{K \in T_h} \int_K (f + \Delta I_M u_h)(\chi - \mathcal{M}_K \chi)\, dx \\
& - \sum_{E \in E_h^{int}} \int_E J_{E,n}(u_h)(\chi - \mathcal{M}_E \chi)\, ds \quad \forall \chi \in H_0^1(\Omega).
\end{aligned} \tag{29}
$$

Proof. For brevity denote the left-hand side of (29) by $I_1(\chi)$. By (2) and Green's formula on each triangle K, and recalling that $\chi \in H_0^1(\Omega)$, we may write

$$\begin{aligned} I_1(\chi) &= \int_\Omega f\chi\,dx + \sum_{K\in T_h}\int_K \Delta(I_M u_h)\chi\,dx - \sum_{K\in T_h}\int_{\partial K}\frac{\partial(I_M u_h)}{\partial n_K}\chi\,ds \\ &= \sum_{K\in T_h}\int_K (f+\Delta(I_M u_h))\chi\,dx - \sum_{E\in E_h^{int}}\int_E J_{E,n}(u_h)\chi\,ds. \end{aligned}$$

Using identity (28), we arrive at

$$I_1(\chi) = \sum_{K\in T_h}\int_K (f+\Delta(I_M u_h))(\chi - \mathcal{M}_K\chi)\,dx - \sum_{E\in E_h^{int}}\int_E J_{E,n}(u_h)\chi\,ds.$$

The conclusion now follows from the fact that $\int_E J_{E,n}(u_h)\,ds = 0$, for all $E\in E_h^{int}$, due to (27) and the principle of conservation of flux, $F_{K,E}(u_h) = -F_{L,E}(u_h)$, if $E = K\cap L$, $K, L\in T_h$. □

COROLLARY 5.4. *Under the assumptions of Lemma* 5.3 *the next estimate holds*

$$\begin{aligned} |I_1(\chi)| \le \sqrt{2}\Big\{&\frac{\mu^2}{\hat\rho^2}\sum_{K\in T_h} h_K^2\|f+\Delta(I_M u_h)\|_K^2 \\ &+ \frac{\alpha^2 N_f}{4\hat\rho^2}\sum_{K\in T_h}\sum_{E\in E_h^{int}\cap E_K} h_{E,K}^{-1}h_K^2\|J_{E,n}(u_h)\|_E^2\Big\}^{1/2}|\chi|_{1,\Omega}. \end{aligned} \tag{30}$$

Proof. Identity (29) and Cauchy–Schwarz's inequality yield

$$\begin{aligned} |I_1(\chi)| &\le \sum_{K\in T_h}\|f+\Delta(I_M u_h)\|_K\|\chi-\mathcal{M}_K\chi\|_K + \sum_{E\in E_h^{int}}\|J_{E,n}(u_h)\|_E\|\chi-\mathcal{M}_E\chi\|_E \\ &\le \sum_{K\in T_h}\|f+\Delta(I_M u_h)\|_K\|\chi-\mathcal{M}_K\chi\|_K \\ &\quad + \frac{1}{2}\sum_{K\in T_h}\sum_{E\in E_h^{int}\cap E_K}\|J_{E,n}(u_h)\|_E\|\chi-\mathcal{M}_E\chi\|_E. \end{aligned}$$

By the interpolation error estimates (22) and (23), we obtain

$$|I_1(\chi)| \le \sum_{K\in T_h} h_K\left(\frac{\mu}{\hat\rho}\|f+\Delta(I_M u_h)\|_K + \frac{\alpha}{2\hat\rho}\sum_{E\in E_h^{int}\cap E_K} h_{E,K}^{-1/2}\|J_{E,n}(u_h)\|_E\right)|\chi|_{1,K}.$$

We conclude by the discrete Cauchy–Schwarz's inequality and the well-known estimate $(\sum_{i=1}^l a_i)^2 \le l\sum_{i=1}^l a_i^2$, valid for $l = 2,3,4$ and all real numbers a_i. □

LEMMA 5.5. *Assume that* $d = 2$. *If* u *is the solution of* (2) *and* u_h *is the solution of* (6), *then*

$$\sum_{K\in T_h}\int_K \nabla(u - I_M u_h)\cdot \operatorname{curl} g\,dx = \sum_{E\in E_h}\int_E J_{E,t}(u_h)(g - \mathcal{M}_E g)\,ds \quad \forall g\in H^1(\Omega), \tag{31}$$

where $\operatorname{curl} g = (\partial_2 g, -\partial_1 g)^\top$ *is the vectorial curl of* g.

Proof. Denote the left-hand side of (31) by $I_2(g)$. Green's formula on each element K leads to (see Theorem I.2.11 of [11])

$$I_2(g) = -\sum_{K\in T_h}\int_{\partial K}\frac{\partial}{\partial t}(u - I_M u_h)g\,ds = \sum_{E\in E_h}\int_E J_{E,t}(u_h)g\,ds,$$

since $u \in H_0^1(\Omega)$ and $g \in H^1(\Omega)$. The conclusion follows from the property

$$\int_E J_{E,t}(u_h)\,ds = 0. \tag{32}$$

Indeed, if $a_E^i, i = 1, 2$, are the two extremities of E, we have $\int_E J_{E,t}(u_h)\,ds = [\![u_h]\!]_E(a_E^1) - [\![u_h]\!]_E(a_E^2)$. Using properties (25) and (26), we have $[\![u_h]\!]_E(a_E^i) = 0$, $i = 1, 2$, and therefore (32) holds. □

COROLLARY 5.6. *Under the assumptions of Lemma* 5.5 *the following estimate holds:*

$$|I_2(g)| \leq \frac{\alpha}{\hat\rho}\sqrt{N_f}\left\{\sum_{K\in T_h}\sum_{E\in E_K} h_{E,K}^{-1}h_K^2\|J_{E,t}(u_h)\|_E^2\right\}^{1/2}|g|_{1,\Omega}. \tag{33}$$

Remark 5.7. The above fundamental properties are only based on the definition of the scheme (6), the continuity of the interpolant at the interior nodes, the property (26), and the interpolation property (27). Therefore, our further analysis works for any finite element (K, P_K, Σ_K) such that the associated interpolant satisfies these properties. But the finite element and the definition of the interpolant should be well chosen in order to guarantee the convergence of $I_M u_h$ to the exact solution u. That is the reason of the introduction of the weights $w_K(a)$ in (25) since it was shown in [5, 6] that for a triangulation made of rectangles, the choice of the weights described at the beginning of section 5.1 guarantees the convergence of u_h to u. Convergence analysis for arbitrary triangulations and appropriate weights is still to be done, but it is outside the scope of this paper. □

6. Error estimators.

6.1. Residual error estimators.

The exact element residual is defined by $R_K := f + \Delta I_M u_h$ on K. As usual this exact residual is replaced by some finite-dimensional approximation called approximate element residual $r_K \in \mathbb{P}_k(K)$. A realistic choice is to take $r_K = \mathcal{M}_K f + \Delta I_M u_h$ since in the case $\Delta I_M u_h \in \mathbb{R}$ we have (thanks to Lemma 5.2) $r_K = 0$.

DEFINITION 6.1 (residual error estimator). *The local and global residual error estimators and approximation terms are defined by*

$$\eta_K^2 := h_K^2\left(\|r_K\|_K^2 + \sum_{E\in E_K\cap E_h^{int}} h_{E,K}^{-1}\|J_{E,n}(u_h)\|_E^2 + \sum_{E\in E_K} h_{E,K}^{-1}\|J_{E,t}(u_h)\|_E^2\right),$$

$$\eta^2 := \sum_{K\in T_h}\eta_K^2,$$

$$\zeta_K^2 := \sum_{K'\subset\omega_K} h_{K'}^2\|R_{K'} - r_{K'}\|_{K'}^2, \qquad \zeta^2 := \sum_{K\in T_h}\zeta_K^2.$$

6.2. Upper error bound.

THEOREM 6.2. *Let u be a solution of* (2) *and let u_h be a solution of* (6). *Then the error $e := u - I_M u_h$ is bounded by*

$$|e|_{1,h} \leq c_{up}(\eta + \zeta), \tag{34}$$

where $c_{up} = \frac{1}{\hat{\rho}} \max\{2\mu, \alpha N_f^{1/2}\}$.

Proof. Denote by $\nabla_h e$ the brokent gradient of e, namely,

$$(\nabla_h e)_{|K} = \nabla e_{|K} \text{ on } K \quad \forall K \in T_h.$$

As in Theorem 3.1 of [7] we use its Helmholtz decomposition

$$\nabla_h e = \nabla \chi + \operatorname{curl} \psi, \tag{35}$$

with $\chi \in H_0^1(\Omega)$ and $\psi \in H^1(\Omega)$ if $d = 2$ and $\chi = e$ and $\psi = 0$ if $d = 3$ such that

$$|\chi|_{1,\Omega}^2 + |\psi|_{1,\Omega}^2 \leq |e|_{1,h}^2. \tag{36}$$

This estimate is direct in three dimensions, while in two dimensions it directly follows from the identity $\int_\Omega \nabla \chi \cdot \operatorname{curl} \psi = 0$, a consequence of Green's formula (recalling that $\chi = 0$ on the boundary).

Owing to identity (35) we may write (with the notation from Lemmas 5.3 and 5.5)

$$|e|_{1,h}^2 = \int_\Omega |\nabla_h e|^2 \, dx = \int_\Omega \nabla_h e \cdot (\nabla \chi + \operatorname{curl} \psi) \, dx = I_1(\chi) + I_2(\psi).$$

Using estimates (30) and (33), we obtain

$$|e|_{1,h}^2 \leq \sqrt{2} \left(\frac{\mu^2}{\hat{\rho}^2} \Xi^2 + \frac{\alpha^2 N_f}{4\hat{\rho}^2} \eta_n^2 \right)^{1/2} |\chi|_{1,\Omega} + \frac{\alpha N_f^{1/2}}{\hat{\rho}} \eta_t |\psi|_{1,\Omega},$$

where for brevity we set $\Xi^2 = \sum_{K \in T_h} h_K^2 \|f + \Delta(I_M u_h)\|_K^2$ and

$$\eta_n^2 = \sum_{K \in T_h} \sum_{E \in E_h^{int} \cap E_K} h_{E,K}^{-1} h_K^2 \|J_{E,n}(u_h)\|_E^2, \eta_t^2 = \sum_{K \in T_h} \sum_{E \in E_K} h_{E,K}^{-1} h_K^2 \|J_{E,t}(u_h)\|_E^2.$$

By the discrete Cauchy–Schwarz inequality and estimate (36), we obtain

$$\begin{aligned} |e|_{1,h}^2 \leq \frac{2\mu^2}{\hat{\rho}^2} \Xi^2 + \frac{\alpha^2 N_f}{2\hat{\rho}^2} \eta_n^2 + \frac{\alpha^2 N_f}{\hat{\rho}^2} \eta_t^2 \leq \frac{4\mu^2}{\hat{\rho}^2} \zeta^2 \\ + \frac{4\mu^2}{\hat{\rho}^2} \sum_{K \in T_h} h_K^2 \|r_K\|_K^2 + \frac{\alpha^2 N_f}{\hat{\rho}^2} (\eta_n^2 + \eta_t^2); \end{aligned}$$

this last estimate follows from the well-known estimate $(a+b)^2 \leq 2a^2 + 2b^2$, valid for all real numbers a, b. By the definition of c_{up} and η the above estimate implies that $|e|_{1,h} \leq c_{up}(\xi^2 + \eta^2)^{1/2} \leq c_{up}(\eta + \xi)$. □

Remark 6.3. Thanks to Lemma 3.3, we can estimate the constant c_{up} appearing in the above upper bound. For a triangulation made of rectangles, then $c_{up} = 2 \max\{\frac{1}{\pi}, \alpha\} = 2\alpha \approx 1.13049$. For a triangulation made of triangles, then $c_{up} = \frac{1}{\hat{\rho}} \max\{\frac{2}{\pi}, \sqrt{3}\alpha\} = \frac{\sqrt{3}\alpha}{\hat{\rho}} \approx 2.15928$. Finally for a mesh made of tetrahedra, one has $c_{up} \leq 2 \frac{(2(11+4\sqrt{6}))^{1/4}}{\sqrt{\pi \tanh \pi}} \approx 9.27912$. For that last case, by Remark 3.4, a numerical upper bound for c_{up} is 2.20009. In both cases, the exact value, or the numerical upper bound for the tetrahedral case, of c_{up} is quite close to unity. □

6.3. Lower error bound.

Theorem 6.4. *For all elements K, the following local lower error bound holds*

$$\eta_K \leq c_{low}(\|\nabla_h e\|_{\omega_K} + \zeta_K), \tag{37}$$

where $c_{low}^2 = \max\{2\beta_0^2\beta_1 + 2N_f\alpha_0^2\sigma_1^{-1}\sigma_2^2\sigma_3(3\alpha_2\sigma_4^{-1} + 8\alpha_1\beta_0^2\beta_1\sigma_1^{-1}\sigma_4), 2\beta_0^2 + 8N_f\alpha_0^2\alpha_1(1 + 2\beta_0^2)\sigma_1^{-1}\sigma_2^2\sigma_3\sigma_4\}$.

Proof.

Element residual. For a fixed element K denote $w_K = r_K b_K$ which belongs to $H_0^1(K)$. From the definition of R_K and integration by parts, we may write

$$\begin{aligned}\int_K r_K w_K &= \int_K (r_K - R_K)w_K - \int_K \Delta(u - I_M u_h)w_K \\ &= \int_K (r_K - R_K)w_K + \int_K \nabla e \cdot \nabla w_K.\end{aligned}$$

By Cauchy–Schwarz's inequality and the inverse inequalities (8) and (9), we conclude that

$$h_K\|r_K\|_K \;\leq\; \beta_0(\beta_1^{1/2}\|\nabla e\|_K + h_K\|r_K - R_K\|_K). \tag{38}$$

Normal jump. Fix an arbitrary $E \in E_h^{int}$. Recall that $J_{E,n}(u_h) \in \mathbb{P}_k(E)$ for some $k \in \mathbb{N}$ and set $w_E := F_{\text{ext}}(J_{E,n}(u_h))b_E \in H_0^1(\omega_E)$. By elementwise partial integration, we get

$$\begin{aligned}\int_E J_{E,n}(u_h)w_E = -\sum_{K\subset\omega_E}\int_{\partial K}\frac{\partial e}{\partial n_K}w_E &= -\sum_{K\subset\omega_E}\int_K(\nabla e\cdot\nabla w_E + \Delta e w_E)\,dx \\ &\leq \|\nabla_h e\|_{\omega_E}\,\|\nabla w_E\|_{\omega_E} \;+ \sum_{K\subset\omega_E}\|\Delta e\|_K\|w_E\|_K.\end{aligned}$$

Inequalities (10)–(12) and properties (3) and (4) in the previous estimate lead to

$$h_E\|J_{E,n}(u_h)\|_E^2 \;\leq\; 2\alpha_0^2\sigma_1^{-1}\left(2\alpha_2\sigma_4^{-1}\|\nabla_h e\|_{\omega_E}^2 + 2\alpha_1\sigma_4\sum_{K\subset\omega_E}h_K^2\|R_K\|_K^2\right).$$

By estimate (38) we arrive at

$$\begin{aligned}h_E\|J_{E,n}(u_h)\|_E^2 \leq{}& 4\alpha_0^2\sigma_1^{-1}(\alpha_2\sigma_4^{-1} + 4\alpha_1\sigma_4\beta_0^2\beta_1)\|\nabla_h e\|_{\omega_E}^2 \\ &+ 8\alpha_0^2\alpha_1\sigma_1^{-1}\sigma_4(1+2\beta_0^2)\sum_{K\subset\omega_E}h_K^2\|R_K - r_K\|_K^2.\end{aligned} \tag{39}$$

Tangential jump (in two dimensions). For a fixed edge E set $w_E := F_{\text{ext}}(J_{E,t}(u_h))$ $b_E \in H_0^1(\omega_E)$. For $u \in H^1(\omega_E)$ and $w_E \in H_0^1(\omega_E)$, partial integration leads to

$$0 = \int_{\partial\omega_E}\frac{\partial u}{\partial t}w_E \;=\; -\int_{\omega_E}\nabla u\cdot\operatorname{curl} w_E.$$

For $I_M u_h$ we integrate elementwise and obtain using the above identity

$$\begin{aligned}\int_E J_{E,t}(u_h)w_E = -\sum_{K\subset\omega_E}\int_{\partial K}\frac{\partial(I_M u_h)}{\partial t}w_E &= \sum_{K\subset\omega_E}\int_K\nabla(I_M u_h)\cdot\operatorname{curl} w_E \\ &= -\sum_{K\subset\omega_E}\int_K\nabla(u - I_M u_h)\cdot\operatorname{curl} w_E \leq \|\nabla_h e\|_{\omega_E}\,\|\nabla w_E\|_{\omega_E}.\end{aligned}$$

The inverse inequalities (10) and (12), as well as (3) and (4), lead to

$$h_E \|J_{E,t}(u_h)\|_E^2 \ \leq \ 2\alpha_0^2 \alpha_2 \sigma_1^{-1} \sigma_4^{-1} \|\nabla_h e\|_{\omega_E}^2. \tag{40}$$

The conclusion follows from estimates (38)–(40) and properties (3) and (4). ∎

Remark 6.5. In the above proof, we see that if $r_K = 0$, then the constant c_{low} reduces to $c_{low}^2 = 2N_f \alpha_0^2 \sigma_1^{-1} \sigma_2^2 \sigma_3 \max\{3\alpha_2 \sigma_4^{-1}, 2\alpha_1 \sigma_4\}$. Let us illustrate this constant c_{low} in the particular case considered in the next section. Take a triangulation made of squares, build the Morley interpolant with the help of the first rectangular element from section 4, and choose $r_K = 0$. Then by Remark 3.2, we have $c_{low} = \sqrt{24\alpha_0^2 \alpha_2} \approx 24.622$. ∎

7. Diffusion–convection–reaction equations. In this section we describe how to extend the above results to diffusion–convection–reaction equations; for details we refer the reader to [20].

Consider the linearized diffusion–convection–reaction problem: for $f \in L^2(\Omega)$ let $u \in H_0^1(\Omega)$ be the unique solution of

$$Au := \operatorname{div}(-\epsilon \nabla u + \mathbf{v} u) + bu = f \text{ in } \Omega, \tag{41}$$

where ϵ is a fixed positive constant, $\mathbf{v} \in \mathbb{R}^d$, and b is a nonnegative real number.

Integrating (41) on a control volume K and using the divergence formula, we obtain

$$\sum_{E \in E_K} \int_E (-\epsilon \nabla u + \mathbf{v} u) \cdot n_{K,E} \, ds + \int_K bu \, dx = \int_K f(x) \, dx \quad \forall K \in T_h.$$

The continuous diffusion flux $-\epsilon \nabla u \cdot n_{K,E}$ is approximated as before, the convection flux $\mathbf{v} u \cdot n_{K,E}$ by a first order upwind scheme, and the reaction term $\int_K u$ by a simple quadrature formula (see [10]). These approximations lead to the following system. Find $u_h := (u_K)_{K \in T_h}$, the solution of

$$\sum_{E \in E_K} \left(-\epsilon F_{K,E}(u_h) + v_{K,E} F_E^C(u_h)\right) + bF_K^R(u_h) = \int_K f(x) \, dx \quad \forall K \in T_h, \tag{42}$$

where $v_{K,E} = \mathbf{v} \cdot n_{K,E}$, the quantity $F_{K,E}(u_h)$ is supposed to satisfy the principle of conservation of flux, while the quantities $F_E^C(u_h)$ and $F_K^R(u_h)$ are, respectively, defined by

$$F_E^C(u_h) := |E| u_{E,+}, \tag{43}$$

where for $E \in E_h^{int}$, $u_{E,+} = u_{K_{E,+}}$, $K_{E,+}$ being the upstream control volume, i.e., $v_{K_{E,+},E} \geq 0$; while for $E \in \bar{K} \cap \Gamma$, $u_{E,+} = u_K$ if $v_{K,E} \geq 0$, and $u_{E,+} = 0$ else. $F_K^R(u_h) = |K| u_K$.

For a restricted admissible mesh in the sense of [10, Def. 9.4], if the numerical diffusion fluxes $F_{K,E}(u_h)$ are given by (7), then system (42) is well defined as proved in [9]. For a general mesh as here, we simply assume that system (42) has a unique solution.

As for the Laplace operator, we associate with the finite volume solution u_h its Morley interpolant $I_M u_h$. This interpolant is related to the quantities involved in (42), namely, the diffusion and convection fluxes, and the reaction term. For that purpose, for each element K, we build a C^0-finite element (K, P_K, Σ_K) having as degrees of freedom the mean of the normal derivative and of the function on each edge, as well as the mean on K. For instance, if K is a triangle, we may take

$$P_K = \{q + (p + \alpha b_K)b_K : q \in \mathbb{P}_2(K), p \in \mathbb{P}_1(K), \alpha \in \mathbb{R}\},$$
$$\Sigma_K = \left\{p(a_i^K)\right\}_{i=1,2,3} \cup \left\{\int_K p\right\} \cup \left\{\int_E p\,ds\right\}_{E\in E_K} \cup \left\{\int_E \frac{\partial p}{\partial n_{K,E}}\,ds\right\}_{E\in E_K}.$$

Then for $u_h = (u_K)_{K\in T_h}$, we define its interpolant $I_M u_h$ as the unique element v_h in $V_h \cap H_0^1(\Omega)$ satisfying (25)–(27) and

$$\int_E v_h\,ds = F_E^C(u_h) \quad \forall E \in E_h^{int}, \qquad \int_K v_h\,dx = F_K^R(u_h) \quad \forall K \in T_h.$$

The key point of our a posteriori analysis is the following basic property of the Morley interpolant, obtained using Green's formula and the above properties of $I_M u_h$.

LEMMA 7.1. *If u_h is a solution of* (42), *then $I_M u_h$ satisfies*

$$\int_K (A(I_M u_h) - f)\,dx = 0 \quad \forall K \in T_h : \text{meas}_{d-1}(K \cap \Gamma) = 0.$$

This property and similar arguments to those used before allow us to prove the following error bounds.

THEOREM 7.2. *Let u be a solution of* (41), *and let u_h be a solution of* (42). *Then the error is bounded by*

$$(44)\qquad \int_\Omega \left(\epsilon|\nabla e|^2 + \left(\frac{1}{2}\text{div}\,\mathbf{v} + b\right)|e|^2\right)^{1/2} \le c_1(\eta + \zeta),$$

where c_1 is a positive constant depending on the aspect ratio of the mesh and of the size of ϵ.

For all elements K, the following local lower error bound holds:

$$(45)\qquad \eta_K \le c_2\left(\left(\int_{\omega_K} \left(\epsilon|\nabla e|^2 + \left(\frac{1}{2}\text{div}\,\mathbf{v} + b\right)|e|^2\right)\right)^{1/2} + \zeta_K\right),$$

where c_2 is a positive constant depending on the aspect ratio of the mesh and of the size of ϵ.

Remark 7.3. 1. By modifying appropriately the estimator η_K, we may skip the dependence of c_1 with respect to ϵ and give explicitly the dependence of c_2 on this parameter; see [20].

2. In the case of a large Peclet number $Pe \equiv \epsilon^{-1}|\mathbf{v}|$ and/or large number $\Gamma \equiv \epsilon^{-1}b$, problem (41) is singularly perturbed and the solution may generate sharp boundary or interior layers, where the solution of the limit problem (corresponding to $\epsilon = 0$) is not smooth or does not satisfy the Dirichlet boundary condition. In that case, the use of anisotropic meshes is recommended. This will be addressed in [20]. □

8. Numerical results. In this section we present two numerical tests that illustrate the efficiency and reliability of our estimator. The second example further indicates that our estimator is appropriate for adaptivity. Additionally, for both examples we provide the order of convergence of the error $|e|_{1,h}$; both cases confirm that $I_M u_h$ is a good approximation of u.

8.1. A smooth solution. The first example is for a smooth solution in the unit square $]0,1[^2$ and quasi-uniform meshes made of squares. Namely, we consider problem (1) in $]0,1[^2$ with the following prescribed exact solution $u(x,y) = xy(1-x)(1-y)$. The meshes are uniform ones made of squares of size $h = 1/n$ for $n = 4, 8, \dots, 256$ obtained by dividing each segment in n subintervals. Since the meshes are made of squares we use the scheme (6) with the numerical diffusion flux given by (7); furthermore, the Morley interpolant is built using the first-rectangular element from subsection 4.2 and the weights $w_K(a) = 1/4$.

We first investigate the order of convergence of the approximated solution u_h as well as its interpolant $I_M u_h$ to the exact solution u in different norms. Namely, we present in Figure 2 the following norms: $\|\bar{u} - u_h\|$ (where $\bar{u}$ is piecewise constant on T_h and is equal to $u(x_K)$ on each K); $|u - u_h|_{1,T_h}$ (where the mesh-depending norm $|\cdot|_{1,T_h}$ is defined in [10, Def. 9.3]); $\|u - I_M u_h\|$; and $|u - I_M u_h|_{1,h}$. These quantities are illustrated in Figure 2 by lines 1–4, respectively, in a double logarithmic scale so that the slope of the curve corresponds to the order of convergence. Theorem 9.3 of [10] yields the order of convergence 1 for $|u - u_h|_{1,T_h}$. Figure 2 even reveals a better order of convergence of about 1.5, probably due to the smoothness of u. For the L^2-norms, we remark a quadratic order of convergence, a usual phenomenon. On the other hand, for the discrete H^1-norm of the reconstructed approximation, we also see a quadratic order of convergence. This seems to be a superconvergence effect, probably due to the smoothness of the solution and of the use of structured meshes.

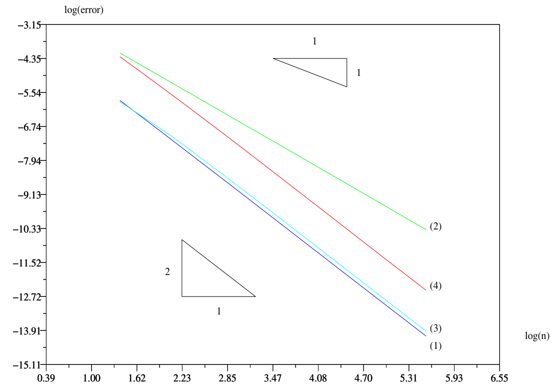

FIG. 2. *Illustration of different norms for test* 1.

Now we investigate the main theoretical results which are the upper and lower error bounds (34) and (37). In order to present them appropriately, we consider the ratios

$$q_{up} := \frac{|u - I_M u_h|_{1,h}}{\eta + \xi} \text{ as a function of } |\log n|,$$

$$q_{low} := \max_{K \in T_h} \frac{\eta_K}{\|\nabla(u - I_M u_h)\|_{\omega_K} + \xi_K} \text{ as a function of } |\log n|.$$

The first ratio q_{up} is frequently referred to as the effectivity index. It measures the reliability of the estimator and is related to the global upper error bound. The second ratio is related to the local lower error bound and measures the efficiency of the estimator. From our theoretical considerations, both ratios should be bounded from above which is confirmed experimentally as shown in Figure 3. Hence our estimator is reliable and efficient.

In Figure 4 we compare the discrete H^1 seminorm $|u - I_M u_h|_{1,h}$ and the global error estimator η with respect to n. We remark that the orders of convergence are the same (namely, 2). This figure further confirms the equivalence between $|u - I_M u_h|_{1,h}$ and η. All related quantities are summarized in Table 1.

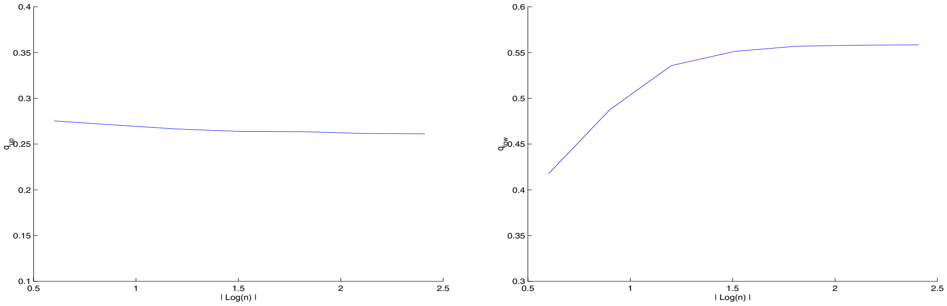

FIG. 3. q_{up} *(left) and* q_{low} *(right) in dependence of* $|\log n|$ *for test* 1.

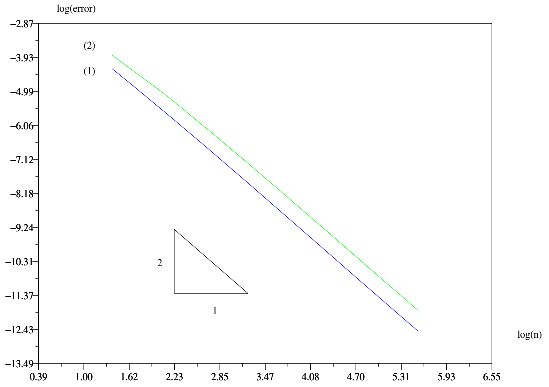

FIG. 4. *Comparison between* $-\ln |u - I_M u_h|_{1,h}$ *(line* (1)*) and* $-\ln \eta$ *(line* (2)*) with respect to* $\ln n$ *for test* 1.

8.2. A nonsmooth solution. For the second example we use the L-shaped domain $\Omega :=]-1,1[^2 \setminus]0,1[\times]-1,0[$ with the exact singular solution given in polar coordinates by $u = r^{2/3} \sin\left(\frac{2\theta}{3}\right)$ considered as a solution of the Dirichlet problem with nonhomogeneous Dirichlet boundary conditions. As before the domain is discretized using uniform meshes made of squares of size $h = 1/n$ for $n = 4, 8, \ldots, 256$. Since u presents singular behavior near the origin and uniform meshes are used, we have a reduction of the order of convergence from 1 to 2/3 for the norm $|u - u_h|_{1,h}$ (see Theorem 2.4 of [8] and Figure 5). From Figure 5 we notice the same phenomenon of reduction of the order of convergence for the other norms.

Again we have tested the rate of convergence of $\Vert\bar{u}-u_h\Vert$, $|u-u_h|_{1,T_h}$, $\Vert u-I_M u_h\Vert$, and $|u-I_M u_h|_{1,h}$. Here we notice that both discrete H^1-norms have a rate of convergence of $2/3$ and that the rate of convergence of the L^2-norms is twice, namely, $4/3$.

As before we further check the boundedness of the ratios q_{up} and q_{low}. These quantities are given in Table 2 and illustrated in Figures 6 and 7. From these figures we can draw the same conclusion as before, namely, the efficiency and reliability of our estimator.

From Tables 1 and 2, we see that the experimental bounds for q_{up} and q_{low} are quite smaller than the theoretical ones. This is quite realistic since the experimental

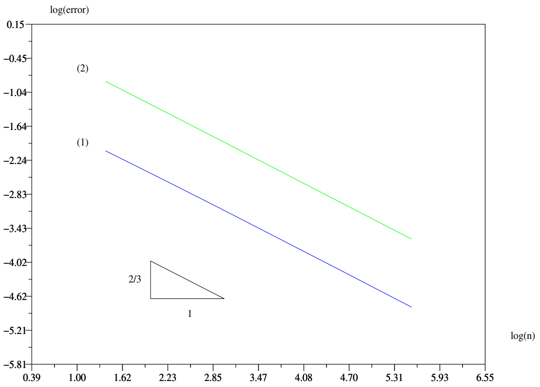

FIG. 7. *Comparison between $-\ln|u - I_M u_h|_{1,h}$ (line* (1)*) and $-\ln\eta$ (line* (2)*) with respect to $\ln n$ for test* 2.

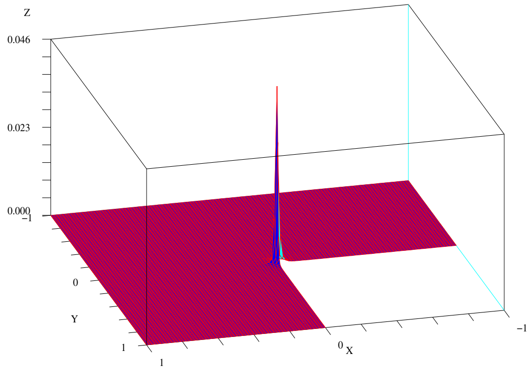

FIG. 8. *Distribution of the local estimator for test* 2 *and $n = 64$.*

values depend on the chosen solution, while the theoretical analysis always considers the worse case.

Finally, in Figure 8 we give the distribution of the local residual error estimators for our second example with the mesh corresponding to $n = 64$. From this figure we may conclude that our estimator is appropriate for adaptivity, since it detects the region of large errors, namely, the neighborhood of the origin.

9. Conclusions.

We have proposed and rigorously analyzed a new a posteriori error estimator for a cell-centered finite volume method that is reliable and efficient. This estimator is based on the construction of an appropriate interpolant of Morley type and the use of a Helmholtz decomposition of the error. The size of the constants appearing in the error estimates has been given as explicitly as possible, as a function of the aspect ratio of the mesh and of the form of the elements (triangles, rectangles, or tetrahedra). Some numerical experiments confirm our theoretical predictions and show that our estimator is appropriate for adaptivity.

The extension of our method to diffusion–convection–reaction equations is briefly described; the details are postponed to a forthcoming paper.

Adaptive algorithms are not considered here since they require more investigations. They will be considered in forthcoming works.

Acknowledgments. I am very grateful to Karim Djadel (University of Lille, France) who conducted the numerical experiments presented in section 8. I further thank Joachim Schöberl (University of Linz, Austria) and Philipp Frauenfelder (ETH Zürich, Switzerland) who gave me the numerical values of μ and α presented in Remark 3.4 and obtained using their *hp*-FEM code.

NUMERICAL RECONSTRUCTION OF HEAT FLUXES[*]

JIANLI XIE[†] AND JUN ZOU[‡]

Abstract. This paper studies the reconstruction of heat fluxes on an inner boundary of a heat conductive system when the measurement of temperature in a small subregion near the outer boundary of the physical domain is available. We will first consider two different regularization formulations for this severely ill-posed inverse problem and justify their well-posedness; then we will propose two fully discrete finite element methods to approximate the resultant nonlinear minimization problems. The existence and uniqueness of the discrete minimizers and convergence of the finite element solution are rigorously demonstrated. A conjugate gradient method is formulated to solve the nonlinear finite element optimization problems. Numerical experiments are given to demonstrate the stability and effectiveness of the proposed reconstruction methods.

Key words. numerical reconstruction, heat flux, regularization, optimization, finite elements

1. Introduction.

Consider a heat conductive system which occupies an open bounded domain Ω with an outer boundary Γ_o and an inner boundary Γ_i; see Figure 1. We are interested in a heat conductive system which can be modeled by the parabolic equation

$$\frac{\partial u}{\partial t} = \nabla \cdot (\alpha(x,t)\nabla u) \qquad \text{in} \quad \Omega \times (0,T), \tag{1.1}$$

assuming the initial condition

$$u(x,0) = u_0(x) \qquad \text{in} \quad \Omega \tag{1.2}$$

and the heat flux exchanges through the outer and inner boundaries Γ_o and Γ_i as follows:

$$-\alpha(x,t)\frac{\partial u}{\partial n} = c(x,t)(u(x,t) - u_a(x,t)) \qquad \text{on} \quad \Gamma_o \times (0,T), \tag{1.3}$$

$$-\alpha(x,t)\frac{\partial u}{\partial n} = q(x,t) \qquad \text{on} \quad \Gamma_i \times (0,T). \tag{1.4}$$

Here $\alpha(x,t)$ is the heat conductivity, $c(x,t)$ and $u_a(x,t)$ are specified functions, and $q(x,t)$ is the heat flux on the inner boundary Γ_i.

The forward initial-boundary value problem (1.1)–(1.4) has been well studied. The focus of this paper is on a physically more interesting and challenging inverse problem: Is it possible to effectively reconstruct the heat flux $q(x,t)$ on the inner boundary Γ_i for all time $t \in [0,T]$ when Γ_i is inaccessible?

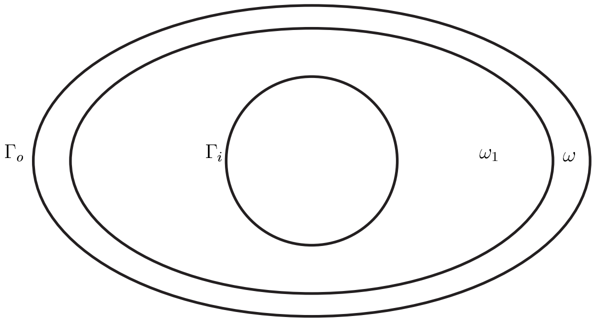

FIG. 1. *Physical domain* $\Omega = \omega_1 \cup (\bar{\omega} \setminus \Gamma_o)$.

In order to possibly reconstruct the heat flux $q(x,t)$, some extra information on the temperature $u(x,t)$ is needed. One choice is to assume the temperature data available in a small subregion ω near the outer boundary Γ_o (see Figure 1). Some high furnaces in steel companies are such examples, where special small devices are installed inside the furnaces but near the outer boundary to measure temperature.

This reconstruction problem is known to be a severely ill-posed inverse problem. One of the main difficulties in the reconstruction comes from both the space and time dependence of the heat flux $q(x,t)$ and the fact that the inner boundary is away from the small measurement subregion. The most severe instability of an inverse problem is triggered when the reconstruction involves some profile at the initial time and on some large boundary portion of a physical domain [7], [17], [19], [20], as is the case encountered here. As far as ill-posed inverse problems are concerned, not much work is found in the literature addressing numerical reconstructions of some physical profiles of both space and time; even less work can be found on convergence and stability analysis for numerical reconstruction methods. We refer readers to [1], [2], [3], [8], [9], [18], and the references therein for numerical reconstructions of profiles of some time-independent parameters in parabolic and elliptic systems.

The aim of this paper is to justify both theoretically and numerically the validation and effectiveness of two regularization formulations for solving the aforementioned severely ill-posed inverse problem of heat flux reconstruction. Indeed, as will be seen from the theory, numerical analysis, and simulations developed in what follows, the regularization methods are very stable and effective in numerical reconstruction of heat fluxes, without any constraints enforced on the search space of heat fluxes if appropriate regularizations are selected. In particular, the resulting nonlinear finite element minimization systems can be efficiently solved by conjugate gradient method.

The rest of this paper is organized as follows. In section 2, we investigate the first formulation with an L^2-regularization of both space and time for the heat flux and validate the "true" well-posedness of the formulation under no constraints on the search space of heat fluxes. In section 3, we study the ill-posedness of heat flux reconstruction and the stability of the regularization. In section 4, we study an alternative formulation of the inverse problem, which uses an L^2-regularization in space and H^1-regularization in time. As will be seen, this formulation turns out to be able to demonstrate much more satisfactory reconstructions. Regarding the approximation of the regularized nonlinear minimization systems, it is very tricky and essential to decide how to effectively discretize in both time and space the nonlinear optimizations and the associated parabolic equation so that the resulting fully discrete schemes converge. For this purpose, two fully discrete finite element approximations are proposed in sections 5 and 6, and the unique existence of discrete minimizers and their convergence to the continuous minimizer are rigorously demonstrated. For solving the nonlinear finite element minimization systems involved in the formulations, a conjugate gradient method is formulated in section 7, and the numerical experiments are presented in section 8 to verify the effectiveness of the proposed reconstruction methods.

We end this section with some useful notation. We define

$$H^m(0,T;B) = \Big\{u(t) \in B \text{ for a.e. } t \in (0,T) \text{ and } \|u\|_{H^m(0,T;B)} < \infty\Big\}$$

for a Banach space B and $m \geq 0$, with its norm given by

$$\|u\|_{H^m(0,T;B)} = \left\{\sum_{k=0}^{m} \int_0^T \|u^{(k)}(t)\|_B^2 dt\right\}^{1/2}.$$

For a given domain $\mathcal{O}$, $H^m(\mathcal{O})$ stands for the standard Sobolev space of mth order for any $m \geq 0$. The norms and seminorms of $H^m(\mathcal{O})$ are denoted by $\|\cdot\|_{m,\mathcal{O}}$ and $|\cdot|_{m,\mathcal{O}}$, respectively. When $m = 0$, we write $L^2(\mathcal{O}) = H^0(\mathcal{O})$ with the norm $\|\cdot\|_{0,\mathcal{O}}$. The domain $\mathcal{O}$ in the subindex will be dropped if $\mathcal{O} = \Omega$.

Further, C is frequently used to denote a generic constant, which depends only on the given data such as domain Ω and coefficients in (1.1)–(1.4) and is independent of unknown functions involved and the discrete time step τ and mesh size h.

2. First regularization formulation.

Recall that the inverse problem of interest here is to reconstruct the heat flux $q(x,t)$ in (1.4) on the inner boundary Γ_i, given the temperature measurement $z(x,t) \approx u(x,t)$ in the small subdomain ω (cf. Figure 1). The first approach we will study for solving the inverse problem is to formulate it into the following constrained minimizing process with L^2-regularization in both space and time for possible heat fluxes:

$$\min J(q) = \frac{1}{2}\int_0^T\!\!\int_\omega (u(q)-z)^2 dxdt + \frac{\beta}{2}\int_0^T\!\!\int_{\Gamma_i} q^2 dsdt \tag{2.1}$$

subject to $q \in L^2(0,T;L^2(\Gamma_i))$ and $u(q) \equiv u(q)(\cdot,t) \in H^1(\Omega)$ satisfying

$$u(x,0) = u_0(x) \qquad \text{in} \quad \Omega, \tag{2.2}$$

$$\int_\Omega \frac{\partial u}{\partial t} v dx + \int_\Omega \alpha \nabla u \cdot \nabla v dx + \int_{\Gamma_o} c\, u\, v ds = \int_{\Gamma_o} c\, u_a v ds - \int_{\Gamma_i} q\, v ds \tag{2.3}$$

for all $v \in H^1(\Omega)$ and for a.e. $t \in (0,T)$.

In what follows, we will demonstrate that the inverse problem for reconstruction of heat flux is an ill-posed problem and that the formulation (2.1)–(2.3) is a true regularization of the inverse problem; that is, the minimizer q not only exists uniquely, but also depends on the observation data z continuously.

For the subsequent analysis, we often use the following compactness result (cf. [13]).

LEMMA 2.1. *Suppose that $B_0 \subset B \subset B_1$ are Banach spaces, B_0 and B_1 are reflexive, and B_0 is compactly embedded into B. Let*

$$W = \left\{v;\ v \in L^2(0,T;B_0),\ v' = \frac{dv}{dt} \in L^2(0,T;B_1)\right\},$$

with the norm $\|v\|_W = \|v\|_{L^2(0,T;B_0)} + \|v'\|_{L^2(0,T;B_1)}$. *Then* W *is compactly embedded into* $L^2(0,T;B)$.

Throughout this section, the parameter functions $\alpha(x,t)$, $c(x,t)$, and $u_a(x,t)$ in (1.1)–(1.4) are assumed to satisfy the following natural conditions:

$$\begin{gathered} \alpha(x,t) \ge \alpha_0 > 0 \quad \text{for a.e.} \quad (x,t) \in \Omega \times (0,T), \\ c(x,t) \ge c_0 > 0 \quad \text{for a.e.} \quad (x,t) \in \Gamma_o \times (0,T), \\ \alpha(x,t) \in L^2(0,T;L^2(\Omega)); \quad c(x,t),\ u_a(x,t) \in L^2(0,T;L^2(\Gamma_o)). \end{gathered} \tag{2.4}$$

We start with the following unique existence.

THEOREM 2.2. *There exists a unique minimizer to the optimization problem* (2.1)–(2.3).

Proof. Clearly $\min J(q)$ is finite over $L^2(0,T;L^2(\Gamma_i))$; thus there exists a minimizing sequence $\{q^n\}$ such that

$$\lim_{n\to\infty} J(q^n) = \inf J(q). \tag{2.5}$$

This implies the boundedness of $\{q^n\}$ in $L^2(0,T;L^2(\Gamma_i))$ and thus the existence of such a subsequence, still denoted[1] as q^n, and $\{q^n\}$ converges to q^* weakly in $L^2(0,T;L^2(\Gamma_i))$. We now prove that this q^* is the unique minimizer of (2.1)–(2.3). We divide the proof into four steps.

Step 1. Letting $u^n \equiv u(q^n)(x,t)$, we show that there exists a subsequence of $\{u^n\}$ such that

$$u^n \to u^* \text{ weakly in } L^2(0,T;H^1(\Omega)) \text{ and } L^2(0,T;L^2(\Gamma_o)). \tag{2.6}$$

By the definition of $u(q^n)$ in (2.2)–(2.3), $u^n \in H^1(\Omega)$ satisfies $u^n(x,0) = u_0(x)$, and

$$\int_\Omega \frac{\partial u^n}{\partial t} v dx + \int_\Omega \alpha \nabla u^n \cdot \nabla v dx + \int_{\Gamma_o} c\, u^n v ds = \int_{\Gamma_o} c\, u_a v ds - \int_{\Gamma_i} q^n v ds \tag{2.7}$$

holds for any $v \in H^1(\Omega)$ and a.e. $t \in (0,T)$. Taking $v = u^n$ in (2.7), we obtain

$$\frac{1}{2}\frac{d}{dt}\|u^n\|_0^2 + \int_\Omega \alpha |\nabla u^n|^2 dx + \int_{\Gamma_o} c\,|u^n|^2 ds = \int_{\Gamma_o} c\, u_a u^n ds - \int_{\Gamma_i} q^n u^n ds. \tag{2.8}$$

Integrating over $(0,t)$, we derive

$$\begin{aligned} &\frac{1}{2}\|u^n(\cdot,t)\|_0^2 + \int_0^t\!\!\int_\Omega \alpha |\nabla u^n(x,t)|^2 dxdt + \int_0^t\!\!\int_{\Gamma_o} c(x,t)|u^n(x,t)|^2 dsdt \\ &= \frac{1}{2}\|u_0\|_0^2 + \int_0^t\!\!\int_{\Gamma_o} c(x,t)u_a(x,t)u^n(x,t)dsdt - \int_0^t\!\!\int_{\Gamma_i} q^n(x,t)u^n(x,t)dsdt; \end{aligned}$$

then by the Cauchy–Schwarz inequality and assumptions in (2.4), we have

$$\begin{aligned} &\frac{1}{2}\|u^n(\cdot,t)\|_0^2 + \alpha_0 \|\nabla u^n\|^2_{L^2(0,t;L^2(\Omega))} + c_0 \|u^n\|^2_{L^2(0,t;L^2(\Gamma_o))} \\ &\le \frac{1}{2}\|u_0\|_0^2 + \|c\, u_a\|_{L^2(0,T;L^2(\Gamma_o))} \|u^n\|_{L^2(0,t;L^2(\Gamma_o))} + \|q^n\|_{L^2(0,T;L^2(\Gamma_i))} \|u^n\|_{L^2(0,t;L^2(\Gamma_i))} \\ &\le \frac{1}{2}\|u_0\|_0^2 + C\Big(\|u^n\|_{L^2(0,t;L^2(\Gamma_o))} + \|u^n\|_{L^2(0,t;L^2(\Gamma_i))}\Big). \end{aligned}$$

[1] Where no confusion exists, throughout this paper we shall always use the same notation to denote a subsequence taken from some sequence.

Using the Sobolev trace theorem, we can estimate the above last term as follows, a technique that will be frequently used in the subsequent analysis:

$$\begin{aligned}\|u^n\|^2_{L^2(0,t;L^2(\Gamma_i))} &= \int_0^t \|u^n(\cdot,s)\|^2_{L^2(\Gamma_i)}ds \le \int_0^t \|u^n(\cdot,s)\|^2_{H^{1/2}(\Gamma_i)}ds\\ &\le \int_0^t \|u^n(\cdot,s)\|^2_{H^1(\Omega)}ds\\ &= \int_0^t \|u^n(\cdot,s)\|^2_{L^2(\Omega)}ds + \int_0^t \|\nabla u^n(\cdot,s)\|^2_{L^2(\Omega)}ds\\ &\le \Big(\|u^n\|_{L^2(0,t;L^2(\Omega))} + \|\nabla u^n\|_{L^2(0,t;L^2(\Omega))}\Big)^2.\end{aligned}$$

Taking the square root on both sides, plugging the result into the previous estimate, and then using Young's inequality, we obtain

$$\begin{aligned}\|u^n(\cdot,t)\|_0^2 &\le \|u^n(\cdot,t)\|_0^2 + \alpha_0\|\nabla u^n\|^2_{L^2(0,t;L^2(\Omega))} + c_0\|u^n\|^2_{L^2(0,t;L^2(\Gamma_o))}\\ &\le \|u_0\|_0^2 + C + \int_0^t \|u^n(\cdot,s)\|^2_{L^2(\Omega)}ds.\end{aligned} \tag{2.9}$$

This gives the boundedness of $\{u^n\}$ in $L^\infty(0,T;L^2(\Omega))$ by applying Gronwall's inequality; then using this bound one can get the boundedness of $\{u^n\}$ in $L^2(0,T;H^1(\Omega))$ and $L^2(0,T;L^2(\Gamma_o))$ from the second inequality in (2.9). Now the convergence in (2.6) follows immediately from this boundedness.

Step 2. We prove $u^* = u(q^*)$. Taking any function $\Psi(t) \in C^1[0,T]$ with $\Psi(T) = 0$, multiplying both sides of (2.7) by Ψ, and then integrating over $t \in (0,T)$, we get

$$\begin{aligned}&\int_0^T\int_{\Gamma_o} c\,u_a v\Psi(t)dsdt - \int_0^T\int_{\Gamma_i} q^n v\Psi(t)dsdt\\ &= -\int_0^T\int_\Omega u^n v\Psi'(t)dxdt + \int_0^T\int_\Omega \alpha\nabla u^n\cdot\nabla v\Psi(t)dxdt\\ &\quad-\int_\Omega \Psi(0)u_0(x)vdx + \int_0^T\int_{\Gamma_o} c\,u^n v\Psi(t)dsdt.\end{aligned}$$

By the weak convergence of q^n and u^n, we deduce from above that

$$\begin{aligned}&\int_0^T\int_{\Gamma_o} c\,u_a v\Psi(t)dsdt - \int_0^T\int_{\Gamma_i} q^* v\Psi(t)dsdt\\ &= \int_0^T\int_\Omega \alpha\nabla u^*\cdot\nabla v\Psi(t)dxdt + \int_0^T\int_{\Gamma_o} c\,u^* v\Psi(t)dsdt\\ &\quad-\int_\Omega \Psi(0)u_0(x)vdx - \int_0^T\int_\Omega u^* v\Psi'(t)dxdt.\end{aligned} \tag{2.10}$$

Noting that (2.10) is also true for any $\Psi(t) \in C_0^\infty(0,T)$, by integration by parts over $t \in (0,T)$ for the last term we have

$$\int_\Omega \frac{\partial u^*}{\partial t}vdx + \int_\Omega \alpha\nabla u^*\cdot\nabla vdx + \int_{\Gamma_o} c\,u^* vds = \int_{\Gamma_o} c\,u_a vds - \int_{\Gamma_i} q^* vds \qquad \forall v \in H^1(\Omega)$$

for a.e. $t \in (0,T)$. Using this and integration by parts again for the last term in (2.10) shows that $u^*(x,0) = u_0(x)$. This verifies $u^* = u(q^*)$.

Step 3. We prove the strong convergence

$$\lim_{n\to\infty}\int_0^T\int_\omega |u^n - z|^2 dxdt = \int_0^T\int_\omega |u^* - z|^2 dxdt. \tag{2.11}$$

It suffices to prove the strong convergence of $\{u^n\}$ in $L^2(0,T;L^2(\Omega))$. By Lemma 2.1, we need only show the boundedness of $\{\frac{\partial u^n}{\partial t}\}$ in $L^2(0,T;(H^1(\Omega))')$.

It follows from (2.7) that for any $v \in L^2(0,T;H^1(\Omega))$,

$$\left|\left\langle \frac{\partial u^n}{\partial t}, v\right\rangle\right| \le C(\|u^n\|_{H^1(\Omega)} + \|u^n\|_{L^2(\Gamma_o)} + \|u_a\|_{L^2(\Gamma_o)} + \|q^n\|_{L^2(\Gamma_i)})\|v\|_{H^1(\Omega)}; \tag{2.12}$$

this, along with the boundedness of $\{u^n\}$ proved in Step 1, implies the boundedness of $\{\frac{\partial u^n}{\partial t}\}$ in $L^2(0,T;(H^1(\Omega))')$.

Step 4. We prove q^* is a unique minimizer to the system (2.1)–(2.3). Using the results in Step 3 and the lower semicontinuity of a norm, we have

$$\begin{aligned} J(q^*) &= \frac{1}{2}\int_0^T\int_\omega |u(q^*) - z|^2 dxdt + \frac{\beta}{2}\int_0^T\int_{\Gamma_i} |q^*|^2 dsdt \\ &\le \lim_{n\to\infty}\int_0^T\int_\omega |u(q^n) - z|^2 dxdt + \frac{\beta}{2}\lim_{n\to\infty}\inf\int_0^T\int_{\Gamma_i} |q^n|^2 dsdt \\ &\le \lim_{n\to\infty}\inf J(q^n) = \inf J(q), \end{aligned} \tag{2.13}$$

so q^* is indeed a minimizer. The uniqueness of minimizers is a consequence of the convexity of $u(q)$ and the strict convexity of $J(q)$. □

PROPOSITION 2.3. *Assume that $\{q^n\}$, with $q^n \in L^2(0,T;L^2(\Gamma_i))$, is a minimizing sequence of $J(q)$ in* (2.1)*; then $\{q^n\}$ converges to the unique minimizer of $J(q)$ strongly in $L^2(0,T;L^2(\Gamma_i))$.*

Proof. From the proof of Theorem 2.2, we know any subsequence of $\{q^n\}$ has a subsequence converging weakly to the unique minimizer of $J(q)$. Thus the whole sequence $\{q^n\}$ converges weakly to the unique minimizer of $J(q)$. Further, one notices from (2.5), (2.11), and (2.13) that

$$\lim_{n\to\infty}\int_0^T\int_{\Gamma_i} |q^n|^2 dsdt = \int_0^T\int_{\Gamma_i} |q^*|^2 dsdt;$$

thus the weak and norm convergences imply the strong convergence. □

3. Ill-posedness of heat flux reconstruction and stability of the regularization.

Next, we study the ill-posedness of heat flux reconstruction and stability of the regularization system (2.1)–(2.3). The following theorem confirms the ill-posedness of the heat flux reconstruction problem (1.1)–(1.4).

THEOREM 3.1. *Let $u(q)$ be a mapping from $L^2(0,T;L^2(\Gamma_i))$ to $L^2(0,T;L^2(\omega))$, defined by the system* (2.2)*–*(2.3) *associated with any given heat flux q in $L^2(0,T;L^2(\Gamma_i))$. Then there exists a sequence $\{q^n\}$ from $L^2(0,T;L^2(\Gamma_i))$ such that $u(q^n) \to 0$ but $\|q^n\|_{L^2(0,T;L^2(\Gamma_i))} \to \infty$, and the inverse of $u(\cdot)$ is unbounded.*

Proof. From the proof of Theorem 2.2, we know for any bounded sequence $\{q^n\}_{n=1}^\infty$ there exists a subsequence $\{q^{n_k}\}_{k=1}^\infty$ such that $\{u(q^{n_k})\}_{k=1}^\infty$ is strongly convergent in $L^2(0,T;L^2(\omega))$. Therefore, as an operator from $L^2(0,T;L^2(\Gamma_i))$ to $L^2(0,T;L^2(\omega))$,

$u(\cdot)$ is compact. On the other hand, one can directly verify that $u(\cdot)$ is a one-to-one mapping and can be decomposed into $u(q) = w(q) + u(0)$, where $w(q)(\cdot, t) \in H^1(\Omega)$ solves the parabolic system (1.1)–(1.4) with $w(q)(x, 0) = 0$ in Ω and $u_a \equiv 0$. The rest of the proof follows the routine procedure; for example, see [10, pp. 13–14]. □

The next theorem shows that the solution q to the regularization system (2.1)–(2.3) depends continuously on the observation data z, so system (2.1)–(2.3) is a "true" regularization to the original inverse problem $u(q) = z$. The detailed proof can be found in [14].

Theorem 3.2. *Let $\{z^n\}$ be a sequence such that*

$$z^n \to z \quad in \quad \mathrm{L}^2(0, \mathrm{T}; \mathrm{L}^2(\omega)) \quad as \quad \mathrm{n} \to \infty, \tag{3.1}$$

and let $\{q^n\}$ be the minimizers of problem (2.1)–(2.3) *with z replaced by z^n. Then the whole sequence $\{q^n\}$ converges in $L^2(0, T; L^2(\Gamma_i))$ to the unique minimizer of* (2.1)–(2.3).

4. An alternative formulation. In this section, we investigate an alternative formulation for reconstruction of heat fluxes in the heat conductive system (1.1)–(1.4), using an L^2-regularization in space and H^1-regularization in time for heat fluxes. As one can see from numerical results in section 8, this new formulation is able to generate more satisfactory reconstructions. This results in the following constrained minimization:

(4.1)
$$\min J(q) = \frac{1}{2}\int_0^T\int_\omega (u(q) - z)^2 dxdt + \frac{\beta}{2}\left(\int_{\Gamma_i} q^2(x, 0)ds + \int_0^T\int_{\Gamma_i} |q_t(x, t)|^2 dsdt\right)$$

subject to $q \in H^1(0, T; L^2(\Gamma_i))$ and $u(q) \equiv u(q)(\cdot, t) \in H^1(\Omega)$ satisfying

$$u(x, 0) = u_0(x) \qquad \text{in} \quad \Omega, \tag{4.2}$$

$$\int_\Omega \frac{\partial u}{\partial t} v dx + \int_\Omega \alpha \nabla u \cdot \nabla v dx + \int_{\Gamma_o} c\, u\, v ds = \int_{\Gamma_o} c\, u_a v ds - \int_{\Gamma_i} q\, v ds \tag{4.3}$$

for all $v \in H^1(\Omega)$ and a.e. $t \in (0, T)$.

The following theorem justifies the well-posedness of the system (4.1)–(4.3) and its stability with respect to the observation data.

Theorem 4.1. *There exists a unique minimizer to the optimization problem* (4.1)–(4.3), *and the minimizer depends on the observation data z continuously.*

Proof. It is clear that $\min J(q)$ is finite over $H^1(0, T; L^2(\Gamma_i))$; thus there exists a minimizing sequence $\{q^n\}$ such that

$$\lim_{n\to\infty} J(q^n) = \inf J(q).$$

This implies the boundedness of $\{q^n\}$ in $H^1(0, T; L^2(\Gamma_i))$ and the existence of a subsequence, still denoted as $\{q^n\}$, such that

$$\begin{aligned} q^n &\to q^* \text{ weakly in } L^2(0, T; L^2(\Gamma_i)), \\ \frac{\partial q^n}{\partial t} &\to p^* \text{ weakly in } L^2(0, T; L^2(\Gamma_i)), \\ q^n(x, 0) &\to q_0^* \text{ weakly in } L^2(\Gamma_i). \end{aligned}$$

We can show that $p^* = \partial q^*/\partial t$ and $q^*(x,0) = q_0^*$. In fact, taking any function $\varphi(x) \in L^2(\Gamma_i)$ and $\psi(t) \in C_0^\infty(0,T)$, we deduce

$$\int_0^T\int_{\Gamma_i} \frac{\partial}{\partial t} q^n(x,t)\varphi(x)\psi(t)dsdt = -\int_0^T\int_{\Gamma_i} q^n(x,t)\varphi(x)\psi'(t)dsdt.$$

Passing to the limit, we derive

$$\int_0^T\int_{\Gamma_i} p^*(x,t)\varphi(x)\psi(t)dsdt = -\int_0^T\int_{\Gamma_i} q^*(x,t)\varphi(x)\psi'(t)dsdt.$$

This shows $p^* = \partial q^*/\partial t$.

Then letting $\varphi(x) \in L^2(\Gamma_i)$ and $\psi(t) \in C^\infty(0,T)$ with $\psi(T) = 0$ and $\psi(0) = 1$, we obtain

$$\int_0^T\int_{\Gamma_i} \frac{\partial}{\partial t} q^n(x,t)\varphi(x)\psi(t)dsdt = \int_{\Gamma_i} q^n(x,0)\varphi(x)ds - \int_0^T\int_{\Gamma_i} q^n(x,t)\varphi(x)\psi'(t)dsdt.$$

By the weak convergence of $\partial q^n/\partial t$, $q^n(x,0)$, and q^n, we deduce

$$\int_0^T\int_{\Gamma_i} \frac{\partial}{\partial t} q^*(x,t)\varphi(x)\psi(t)dsdt = \int_{\Gamma_i} q_0^*(x)\varphi(x)ds - \int_0^T\int_{\Gamma_i} q^*(x,t)\varphi(x)\psi'(t)dsdt.$$

Integrating by parts the left-hand side, we obtain for any $\varphi(x) \in L^2(\Gamma_i)$ that

$$\int_{\Gamma_i} q_0^*(x)\varphi(x)ds = \int_{\Gamma_i} q^*(x,0)\varphi(x)ds,$$

which implies $q^*(x,0) = q_0^*$. The rest of the proof is similar to those of Theorems 2.2 and 3.2. □

Similarly to Proposition 2.3, we have the following strong convergence (cf. [14]).

PROPOSITION 4.2. *Any minimizing sequence $\{q^n\}$ of $J(q)$ in (4.1) over $H^1(0,T;$ $L^2(\Gamma_i))$ converges to the unique minimizer of $J(q)$ strongly in $H^1(0,T;L^2(\Gamma_i))$.*

5. Finite element approximation of system (2.1)–(2.3) and its convergence. We now propose a fully discrete finite element method for solving the continuous minimization problem (2.1)–(2.3). For the sake of exposition, we study in detail the case where the outer and inner boundaries Γ_o and Γ_i are both circles centered at the origin; see Figure 2. The subsequent results can be extended to more general domains by combining the analysis used here and the finite element analysis for the case when the approximation of the physical domain is involved [4].

Let us start with a triangulation of the domain Ω. To do so, we generate a set of circles all centered at the origin, starting with Γ_i and ending with Γ_o. Next we choose a set of quasi-uniformly distributed points on Γ_o, which are then connected to the origin to yield a set of radial lines, and the intersections of these lines with all the previous generated circles also yield a partition of each circle; see Figure 2. Now the triangulation $\mathcal{T}^h$ of Ω is formed by these sectorial elements. The arc segments on Γ_o and Γ_i generate naturally two triangulations of Γ_o and Γ_i, respectively, denoted by Γ_o^h and Γ_i^h.

For each sectorial element K, say $K = \{(r\cos\theta, r\sin\theta);\ r_1 \le r \le r_2, \theta_1 \le \theta \le \theta_2\}$, there exists a one-to-one mapping $\hat{F}_K : \hat{K} \to K$ such that $K = \hat{F}_K(\hat{K})$, where $\hat{K}$

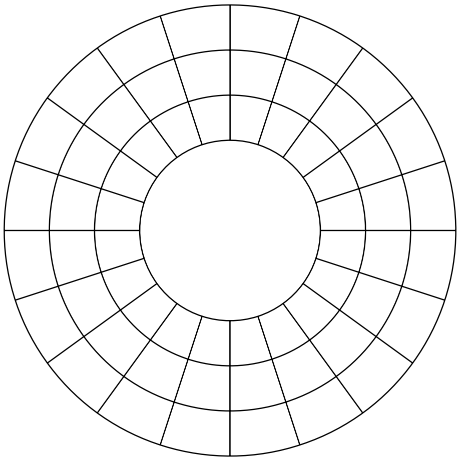

FIG. 2. *Circular partition of* Ω *and partition of each circle.*

is a rectangular reference element. For example, if $\hat{K} = [0,1] \times [0,1]$, we can take $\hat{F}_K$ as

$$\begin{cases} x = (r\,r_2 + (1-r)r_1)\cos(\theta\,\theta_2 + (1-\theta)\theta_1), \\ y = (r\,r_2 + (1-r)r_1)\sin(\theta\,\theta_2 + (1-\theta)\theta_1). \end{cases} \tag{5.1}$$

Now we can define the finite element space V^h to be

$$V^h = \Big\{ v_h \in C(\bar{\Omega});\ v_h(x)\big|_K = \hat{v} \circ \hat{F}_K^{-1}(x)\ \forall \hat{v} \in \mathcal{Q}_1(\hat{K}) \Big\},$$

where $\mathcal{Q}_1(\hat{K})$ is the space of bilinear functions on the reference element $\hat{K}$, and $V^h_{\Gamma_o}$, $V^h_{\Gamma_i}$ are the restrictions of V^h on Γ_o and Γ_i, respectively.

To fully discretize the system (2.1)–(2.3), we also need the time discretization. For this, we divide the time interval $[0,T]$ into M equally spaced subintervals using nodal points

$$\Delta: \quad 0 = t_0 < t_1 < \cdots < t_M = T \tag{5.2}$$

with $t_n = n\tau$, $\tau = T/M$. For a continuous mapping $u : [0,T] \to L^2(\Omega)$, we define $u^n = u(\cdot, t_n)$ for $0 \le n \le M$. For a given sequence $\{u^n\}_{n=0}^M \subset L^2(\Omega)$, we define its difference quotient and the averaging $\bar{u}^n$ of a function $u(\cdot,t)$ as follows:

$$\partial_\tau u^n = \frac{u^n - u^{n-1}}{\tau}, \quad \bar{u}^n = \frac{1}{\tau}\int_{t_{n-1}}^{t_n} u(\cdot,t)dt, \tag{5.3}$$

where for $n = 0$, we let $\bar{u}^0 = u(\cdot, 0)$.

In our subsequent convergence analysis, we need a crucial projection operator Q_h from $L^2(\Omega)$ into V^h defined on sectorial elements, which should possess the following L^2- and H^1-stability and optimal L^2-norm error estimate:

$$\lim_{h\to 0} \|v - Q_h v\|_1 = 0 \quad \forall v \in H^1(\Omega), \tag{5.4}$$

$$\|Q_h v\|_0 \le C\|v\|_0, \quad \|Q_h v\|_1 \le C\|v\|_1 \quad \forall v \in H^1(\Omega), \tag{5.5}$$

$$\|v - Q_h v\|_0 \le Ch\|v\|_1 \quad \forall v \in H^1(\Omega). \tag{5.6}$$

Noting that the transform $\hat{F}_K$: $\hat{K} \to K$ is not of polynomial type and that the functions in V^h may not be piecewise polynomials, the standard L^2-projection operator from $L^2(\Omega)$ into V^h (cf. [16]) does not satisfy these properties. Instead, we introduce a novel weighted L^2-projection operator Q_h from $L^2(\Omega)$ into V^h as follows:

$$\sum_{K\in\mathcal{T}^h}\int_K (Q_h w)\, v\, |J_K^{-1}(x,y)|\, dxdy = \sum_{K\in\mathcal{T}^h}\int_K w\, v\, |J_K^{-1}(x,y)|\, dxdy \quad \forall\, w \in L^2(\Omega), v \in V^h,$$

where $J_K(x,y) = \hat{J}_K(r,\theta)$ for all x, y and r, θ defined by (5.1) and $\hat{J}_K(r,\theta)$ is the Jacobian determinant of the transform $\hat{F}_K$. One can show that this weighted operator Q_h is well-defined, and it possesses all the properties (5.4), (5.5), and (5.6). The detailed proof was given in Xie [14].

Now we are ready to formulate the finite element approximation of the minimization (2.1)–(2.3). We approximate the heat flux $q(x,t)$ by a piecewise constant function $q_{h,\tau}(x,t)$ over the time partition Δ in (5.2):

$$q_{h,\tau}(x,t) = \sum_{n=1}^{M} \chi_n(t) q_h^n(x), \tag{5.7}$$

where $q_h^n(x) \in V_{\Gamma_i}^h$ and $\chi_n(t)$ is the characteristic function on the interval (t_{n-1}, t_n).

Using the composite trapezoidal rule for the time discretization of the first integral in (2.1) and the exact time integration for the second term, the fully discrete finite element approximation to problem (2.1)–(2.3) can be formulated as follows:

$$\min J_{h,\tau}(q_{h,\tau}) = \frac{\tau}{2}\sum_{n=0}^{M} \alpha_n \int_\omega (u_h^n - z^n)^2 dx + \frac{\beta\tau}{2}\sum_{n=1}^{M}\int_{\Gamma_i} |q_h^n|^2 ds \tag{5.8}$$

over all $q_h^n \in V_{\Gamma_i}^h$ with $u_h^n \equiv u_h^n(q_{h,\tau}) \in V^h$ satisfying

$$u_h^0 = Q_h u_0(x), \tag{5.9}$$

$$\begin{aligned}&\int_\Omega \partial_\tau u_h^n \phi_h dx + \int_\Omega \bar{a}^n \nabla u_h^n \cdot \nabla \phi_h dx + \int_{\Gamma_o} \bar{c}^n u_h^n \phi_h ds\\ &= \int_{\Gamma_o} \bar{c}^n \bar{u}_a^n \phi_h ds - \int_{\Gamma_i} q_h^n \phi_h ds \quad \forall \phi_h \in V^h\end{aligned} \tag{5.10}$$

for $n = 1, 2, \ldots, M$. Here $\{\alpha_n\}$ are the coefficients of the composite trapezoidal rule, i.e., $\alpha_0 = \alpha_M = \frac{1}{2}$ and $\alpha_n = 1$ for all $n \neq 0, M$.

For convenience, the minimization of $J_{h,\tau}$ also shall be regarded as the minimization over the product space $\prod_{n=1}^M V_{\Gamma_i}^h$, and we will often write (5.8) as

$$\min J_{h,\tau}(\{q_h^1, q_h^2, \ldots, q_h^M\}) = \frac{\tau}{2}\sum_{n=0}^{M} \alpha_n \int_\omega (u_h^n - z^n)^2 dx + \frac{\beta\tau}{2}\sum_{n=1}^{M}\int_{\Gamma_i} |q_h^n|^2 ds. \tag{5.11}$$

Before verifying the existence of a unique minimizer to the finite element minimization (5.8)–(5.10), we first derive some useful a priori estimates on the discrete solutions u_h^n to the system (5.9)–(5.10).

In the rest of this section, we assume on the functions $\alpha(x,t)$ and $c(x,t)$ in (1.1)–(1.4) that

$$\alpha \in H^1(0,T;L^\infty(\Omega)) \quad \text{and} \quad c \in H^1(0,T;L^\infty(\Gamma_o))$$

and introduce two related constants

$$C_1 = \|\alpha\|_{H^1(0,T;L^\infty(\Omega))}, \quad C_2 = \|c\|_{H^1(0,T;L^\infty(\Gamma_o))}.$$

The following auxiliary lemma (cf. [14]) will be needed in the subsequent analysis.

Lemma 5.1. *For any*

$$f \in H^1(0,T;L^\infty(\Omega)) \quad \textit{and} \quad g \in L^2(0,T;L^\infty(\Omega)),$$

we have the estimates

$$\|\bar{f}^n - \bar{f}^{n-1}\|_{L^\infty(\Omega)} \le \sqrt{\tau}\|f_t\|_{L^2(t_{n-2},t_n;L^\infty(\Omega))}, \tag{5.12}$$

$$\|\bar{f}^n\bar{g}^n - \overline{fg}^n\|_{L^2(\Omega)} \le \frac{2}{3}\|f_t\|_{L^2(t_{n-1},t_n;L^\infty(\Omega))}\, \|g\|_{L^2(t_{n-1},t_n;L^2(\Omega))}. \tag{5.13}$$

Lemma 5.2. *Assume that u_h^n is the solution of the finite element system* (5.9)–(5.10) *corresponding to $q_{h,\tau}$. Then we have the following stability estimates:*

$$\max_{1\le n\le M}\|u_h^n\|_0^2 + \tau\sum_{n=1}^M \|\nabla u_h^n\|_0^2 + \tau\sum_{n=1}^M \|u_h^n\|_{0,\Gamma_o}^2$$
$$\le C\,(\|u_0\|_0^2 + C_2^2\|u_a\|_{L^2(0,T;L^2(\Gamma_o))}^2 + \|q_{h,\tau}\|_{L^2(0,T;L^2(\Gamma_i))}^2), \tag{5.14}$$

$$\max_{1\le n\le M}\|\nabla u_h^n\|_0^2 + \max_{1\le n\le M}\|u_h^n\|_{0,\Gamma_o}^2 + \tau\sum_{n=1}^M \|\partial_\tau u_h^n\|_0^2$$
$$\le C\,\tau^{-1}(\|u_0\|_1^2 + C_2^2\|u_a\|_{L^2(0,T;L^2(\Gamma_o))}^2 + \|q_{h,\tau}\|_{L^2(0,T;L^2(\Gamma_i))}^2), \tag{5.15}$$

$$\tau\sum_{n=1}^M \|\partial_\tau u_h^n\|_{(H^1(\Omega))'}^2$$
$$\le C\,(C_1^2 + C_2^2 + \tau^{-1}h^2)\,(\|u_0\|_0^2 + C_2^2\|u_a\|_{L^2(0,T;L^2(\Gamma_o))}^2 + \|q_{h,\tau}\|_{L^2(0,T;L^2(\Gamma_i))}^2). \tag{5.16}$$

Proof. The proof of (5.14) follows directly by taking $\phi_h = \tau u_h^n$ in (5.10) and then applying the Sobolev trace theorem and Young's and Gronwall's inequalities.

Next, we show (5.15). Taking $\phi_h = \tau\partial_\tau u_h^n = u_h^n - u_h^{n-1}$ in (5.10), we obtain

$$\tau\|\partial_\tau u_h^n\|_0^2 + \int_\Omega \bar{\alpha}^n \nabla u_h^n \cdot \nabla(u_h^n - u_h^{n-1})dx + \int_{\Gamma_o} \bar{c}^n u_h^n(u_h^n - u_h^{n-1})ds$$
$$= \int_{\Gamma_o} \bar{c}^n \bar{u}_a^n(u_h^n - u_h^{n-1})ds - \int_{\Gamma_i} q_h^n(u_h^n - u_h^{n-1})ds.$$

Summing up the above equation over $n = 1, 2, \ldots, k \le M$, we obtain

$$\begin{aligned}
&\tau \sum_{n=1}^{k} \|\partial_\tau u_h^n\|_0^2 + \frac{1}{2}\sum_{n=1}^{k}\int_\Omega \bar{\alpha}^n(|\nabla u_h^n|^2 - |\nabla u_h^{n-1}|^2)dx \\
&\quad + \frac{1}{2}\sum_{n=1}^{k}\int_{\Gamma_o} \bar{c}^n(|u_h^n|^2 - |u_h^{n-1}|^2)ds \\
&\le \sum_{n=1}^{k}\int_{\Gamma_o} \bar{c}^n \bar{u}_a^n(u_h^n - u_h^{n-1})ds - \sum_{n=1}^{k}\int_{\Gamma_i} q_h^n(u_h^n - u_h^{n-1})ds.
\end{aligned}$$

Then using the discrete integration by parts formula

$$\sum_{n=1}^{k}(a_n - a_{n-1})b_n = a_k b_k - a_0 b_0 - \sum_{n=1}^{k} a_{n-1}(b_n - b_{n-1}), \tag{5.17}$$

where b_0 appearing on the right-hand side can be any real number, we derive

$$\begin{aligned}
&\tau \sum_{n=1}^{k} \|\partial_\tau u_h^n\|_0^2 + \frac{1}{2}\alpha_0\|\nabla u_h^k\|_0^2 + \frac{1}{2}c_0\|u_h^k\|_{0,\Gamma_o}^2 \\
&\le \frac{1}{2}\int_\Omega \bar{\alpha}^0|\nabla u_h^0|^2dx + \frac{1}{2}\sum_{n=1}^{k}\int_\Omega(\bar{\alpha}^n - \bar{\alpha}^{n-1})|\nabla u_h^{n-1}|^2dx \\
&\quad + \frac{1}{2}\int_{\Gamma_o}\bar{c}^0|u_h^0|^2ds + \frac{1}{2}\sum_{n=1}^{k}\int_{\Gamma_o}(\bar{c}^n - \bar{c}^{n-1})|u_h^{n-1}|^2ds \\
&\quad + \int_{\Gamma_o}\bar{c}^k\bar{u}_a^k u_h^k ds - \sum_{n=1}^{k}\int_{\Gamma_o}(\bar{c}^n\bar{u}_a^n - \bar{c}^{n-1}\bar{u}_a^{n-1})u_h^{n-1}ds \\
&\quad - \int_{\Gamma_i} q_h^k u_h^k ds + \sum_{n=1}^{k}\int_{\Gamma_i}(q_h^n - q_h^{n-1})u_h^{n-1}ds,
\end{aligned}$$

where $\bar{u}_a^0$ and q_h^0 are taken to be 0. We now estimate the terms on the right-hand side of the above inequality. First, for those terms without summation, we can deduce by using the properties of Q_h and the Sobolev trace theorem that

$$\frac{1}{2}\int_\Omega \bar{\alpha}^0|\nabla u_h^0|^2dx + \frac{1}{2}\int_{\Gamma_o}\bar{c}^0|u_h^0|^2ds \le C\,(C_1 + C_2)\|u_0\|_1^2,$$

$$\int_{\Gamma_o}\bar{c}^k\bar{u}_a^k u_h^k ds \le \frac{1}{2}\|\bar{c}^k\bar{u}_a^k\|_{0,\Gamma_o}^2 + \frac{1}{2}\|u_h^k\|_{0,\Gamma_o}^2 \le \tau^{-1}\left(\tau\sum_{n=1}^{k}\|\bar{c}^n\bar{u}_a^n\|_{0,\Gamma_o}^2 + \tau\sum_{n=1}^{M}\|u_h^n\|_{0,\Gamma_o}^2\right),$$

$$\int_{\Gamma_i} q_h^k u_h^k ds \le \frac{1}{2}\|q_h^k\|_{0,\Gamma_i}^2 + \frac{1}{2}\|u_h^k\|_1^2 \le \tau^{-1}\left(\|q_{h,\tau}\|_{L^2(0,T;L^2(\Gamma_i))}^2 + \tau\sum_{n=1}^{M}\|u_h^n\|_1^2\right).$$

Using (5.12) we have the following estimates:

$$\sum_{n=1}^{k}\int_\Omega(\bar{\alpha}^n - \bar{\alpha}^{n-1})|\nabla u_h^{n-1}|^2dx \le \frac{4}{3}C_1\sqrt{\tau}\sum_{n=1}^{k}\|\nabla u_h^{n-1}\|_0^2,$$

$$\sum_{n=1}^{k}\int_{\Gamma_o}(\bar{c}^n - \bar{c}^{n-1})|u_h^{n-1}|^2ds \le \frac{4}{3}C_2\sqrt{\tau}\sum_{n=1}^{k}\|u_h^{n-1}\|_{0,\Gamma_o}^2.$$

Applying the Cauchy–Schwarz inequality and the Sobolev trace theorem, we have

$$\sum_{n=1}^{k}\int_{\Gamma_o}(\bar{c}^n\bar{u}_a^n-\bar{c}^{n-1}\bar{u}_a^{n-1})u_h^{n-1}ds\le\sum_{n=1}^{k}\|\bar{c}^n\bar{u}_a^n\|_{0,\Gamma_o}^2+\sum_{n=1}^{k}\|u_h^{n-1}\|_{0,\Gamma_o}^2,$$
$$\sum_{n=1}^{k}\int_{\Gamma_i}(q_h^n-q_h^{n-1})u_h^{n-1}ds\le\sum_{n=1}^{k}\|q_h^n\|_{0,\Gamma_i}^2+\sum_{n=1}^{k}\|u_h^{n-1}\|_1^2.$$

Combining all these estimates with (5.14), we obtain (5.15).

It remains to show (5.16). For any $\phi\in H^1(\Omega)$, taking $\phi_h=Q_h\phi$ in (5.10), we have

$$\int_\Omega\partial_\tau u_h^nQ_h\phi dx+\int_\Omega\bar{\alpha}^n\nabla u_h^n\nabla Q_h\phi dx+\int_{\Gamma_o}\bar{c}^nu_h^nQ_h\phi ds=\int_{\Gamma_o}\bar{c}^n\bar{u}_a^nQ_h\phi ds-\int_{\Gamma_i}q_h^nQ_h\phi ds.$$

Using the property of Q_h in (5.5) and the Cauchy–Schwarz inequality, we derive

$$\left|\int_\Omega\partial_\tau u_h^nQ_h\phi dx\right|\le C\left(C_1\|\nabla u_h^n\|_0+C_2\|u_h^n\|_{0,\Gamma_o}+C_2\|\bar{u}_a^n\|_{0,\Gamma_o}+\|q_h^n\|_{0,\Gamma_i}\right)\|\phi\|_1.$$

On the other hand, applying the Cauchy–Schwarz inequality and the property of Q_h in (5.6), we obtain

$$\left|\int_\Omega\partial_\tau u_h^n(\phi-Q_h\phi)dx\right|\le Ch\|\partial_\tau u_h^n\|_0\|\phi\|_1.$$

It follows from the above two inequalities that for any $\phi\in H^1(\Omega)$,

$$\left|\int_\Omega\partial_\tau u_h^n\phi dx\right|\le C\left(C_1\|\nabla u_h^n\|_0+C_2\|u_h^n\|_{0,\Gamma_o}+C_2\|\bar{u}_a^n\|_{0,\Gamma_o}\right.$$
$$\left.+\|q_h^n\|_{0,\Gamma_i}+h\|\partial_\tau u_h^n\|_0\right)\|\phi\|_1,$$

which implies

$$\|\partial_\tau u_h^n\|_{(H^1(\Omega))'}\le C\left(C_1\|\nabla u_h^n\|_0+C_2\|u_h^n\|_{0,\Gamma_o}+C_2\|\bar{u}_a^n\|_{0,\Gamma_o}+\|q_h^n\|_{0,\Gamma_i}+h\|\partial_\tau u_h^n\|_0\right).$$

Taking squares on both sides and adding up over $n=1,\dots,M$, (5.16) then follows from (5.14) and (5.15). □

Remark 5.3. Fortunately, the unbounded factor τ^{-1} in the estimate (5.15) can be cancelled in the subsequent convergence analysis; see (5.28) and the last estimate in the proof of Lemma 5.5.

Based on the stability estimates (5.14)–(5.16), we are now ready to show the existence and uniqueness of minimizers to the finite element system (5.9)–(5.11).

THEOREM 5.4. *There exists a unique minimizer to the finite element system* (5.9)–(5.11).

Proof. By the stability estimates of Lemma 5.2 and the same argument as in Theorem 2.2, we know there exists a minimizing sequence $\{q_h^{1,k},q_h^{2,k},\dots,q_h^{M,k}\}_{k=1}^\infty$ such that

$$\lim_{k\to\infty}J_{h,\tau}(\{q_h^{1,k},q_h^{2,k},\dots,q_h^{M,k}\})=\inf_{\{q_h^n\}_{n=1}^M\in V_\Gamma^h}J_{h,\tau}(\{q_h^1,q_h^2,\dots,q_h^M\}),$$

and

$$q_h^{n,k} \to q_h^{n,*} \quad \text{in any norm for} \quad n = 1, 2, \ldots, M \quad \text{as} \quad k \to \infty.$$

Next, we prove $\{q_h^{1,*}, q_h^{2,*}, \ldots, q_h^{M,*}\}$ is the unique minimizer of (5.9)–(5.11). Let $q_{h,\tau}^k$ and $q_{h,\tau}^*$ be the functions defined in (5.7) by $\{q_h^{n,k}\}_{n=1}^M$ and $\{q_h^{n,*}\}_{n=1}^M$, respectively; then $u_h^n(q_{h,\tau}^k)$ and $u_h^n(q_{h,\tau}^*)$ are the finite element solutions to (5.9)–(5.10) corresponding to $q_{h,\tau}^k$ and $q_{h,\tau}^*$, respectively.

Let $w_h^{n,k} = u_h^n(q_{h,\tau}^k) - u_h^n(q_{h,\tau}^*)$; then $w_h^{0,k} = 0$ and for $n = 1, 2, \ldots, M$, $w_h^{n,k}$ solves

$$\int_\Omega \partial_\tau w_h^{n,k} \phi_h dx + \int_\Omega \bar{\alpha}^n \nabla w_h^{n,k} \cdot \nabla \phi_h dx + \int_{\Gamma_o} \bar{c}^n w_h^{n,k} \phi_h ds$$
$$= \int_{\Gamma_i} (q_h^{n,*} - q_h^{n,k}) \phi_h ds \quad \forall \phi_h \in V^h.$$

Taking $\phi_h = \tau w_h^{n,k}$ in the above equation, one can directly show by Gronwall's inequality that

$$\max_{1 \le n \le M} \|w_h^{n,k}\|_0^2 \le C\tau \sum_{n=1}^M \|q_h^{n,*} - q_h^{n,k}\|_{0,\Gamma_i}^2. \tag{5.18}$$

This proves $w_h^{n,k} \to 0$, and so we have $u_h^n(q_{h,\tau}^k) \to u_h^n(q_{h,\tau}^*)$ as $k \to \infty$.

The rest of the proof is basically the same as that of Theorem 2.2. □

The remaining part of this section is devoted to one of the central issues of our interest: Will the discrete minimizer of the system (5.8)–(5.10) converge to the global minimizer of the continuous problem (2.1)–(2.3)? If yes, is the convergence only weak or can it be strong in some norm? To answer this question, we need some preparations.

For a given function $f \in C([0, T]; X)$, with X being a Banach space, we define a step function approximation, based on the time partition (5.2):

$$S_\Delta f(x, t) = \sum_{n=1}^M \chi_n(t) f(x, t_n). \tag{5.19}$$

We know (cf. [21]) that

$$\lim_{\tau \to 0} \int_0^T \|S_\Delta f(\cdot, t) - f(\cdot, t)\|_X^2 dt = 0. \tag{5.20}$$

Next, we shall demonstrate a most important and technical result in the paper: for any weakly convergent sequence $q_{h,\tau}$ in $L^2(0, T; L^2(\Gamma_i))$ with respect to h and τ, the corresponding finite element solution $u_h^n(q_{h,\tau})$ defined in (5.9)–(5.10) will converge strongly in $L^2(0, T; L^2(\omega))$. More accurately, we have the following lemma.

LEMMA 5.5. *If $q_{h,\tau}$ converges to some q weakly in $L^2(0, T; L^2(\Gamma_i))$ as h and τ tend to* 0, *then*

$$\tau \sum_{n=0}^M \alpha_n \int_\omega (u_h^n(q_{h,\tau}) - z^n)^2 dx \to \int_0^T \int_\omega (u(q) - z)^2 dx dt.$$

Proof. For $1 \le n \le M$, we shall use the following notation:

$$u_h^n = u_h^n(q_{h,\tau}), \quad u^n = u(q)(\cdot, t_n).$$

By (5.20), we can directly verify

$$\lim_{\tau\to 0} \tau \sum_{n=0}^{M} \alpha_n \int_\omega (u^n - z^n)^2 dx = \int_0^T \int_\omega (u(q) - z)^2 dx dt.$$

Therefore it suffices to show

$$\lim_{\substack{h\to 0\\ \tau\to 0}} \tau \sum_{n=0}^{M} \alpha_n \int_\omega (u_h^n - z^n)^2 dx = \lim_{\substack{h\to 0\\ \tau\to 0}} \tau \sum_{n=0}^{M} \alpha_n \int_\omega (u^n - z^n)^2 dx$$

or, equivalently,

$$\lim_{\substack{h\to 0\\ \tau\to 0}} \tau \sum_{n=0}^{M} \int_\omega (u_h^n - u^n)^2 dx = 0. \tag{5.21}$$

For this, we construct two interpolations based on $\{u_h^n\}$: the first one is the piecewise linear interpolation over the time partition (5.2),

$$u_{h,\tau}(x,t) = \frac{t - t_{n-1}}{\tau} u_h^n + \frac{t_n - t}{\tau} u_h^{n-1}, \qquad t \in (t_{n-1}, t_n),$$

while the second one is the piecewise constant interpolation

$$\tilde{u}_{h,\tau}(x,t) = \sum_{n=1}^{M} \chi_n(t) u_h^n(x).$$

By straightforward computations, we have

$$\|\tilde{u}_{h,\tau}\|^2_{L^2(0,T;H^1(\Omega))} = \tau \sum_{n=1}^{M} \|u_h^n\|_1^2, \quad \left\| \frac{\partial}{\partial t} u_{h,\tau} \right\|^2_{L^2(0,T;(H^1(\Omega))')} = \tau \sum_{n=1}^{M} \|\partial_\tau u_h^n\|^2_{(H^1(\Omega))'}$$

and

$$\begin{aligned} &\|u_{h,\tau}\|^2_{L^2(0,T;H^1(\Omega))} \\ &= \frac{\tau}{3} \sum_{n=1}^{M} \int_\Omega (|u_h^n|^2 + |u_h^{n-1}|^2 + u_h^n u_h^{n-1} + |\nabla u_h^n|^2 + |\nabla u_h^{n-1}|^2 + \nabla u_h^n \cdot \nabla u_h^{n-1}) dx \\ &\le \tau \sum_{n=0}^{M} \|u_h^n\|_1^2. \end{aligned}$$

These, together with the stability estimates (5.14)–(5.16), indicate that both $\{u_{h,\tau}\}$ and $\{\tilde{u}_{h,\tau}\}$ are bounded in $L^2(0,T;H^1(\Omega))$ and $\{\frac{\partial}{\partial t} u_{h,\tau}\}$ is bounded in $L^2(0,T;(H^1(\Omega))')$. So by Lemma 2.1 there exist a subsequence of $\{u_{h,\tau}\}$ such that

$$u_{h,\tau} \to u^* \text{ weakly in } L^2(0,T;H^1(\Omega)) \text{ and strongly in } L^2(0,T;L^2(\Omega)), \tag{5.22}$$

$$\frac{\partial}{\partial t} u_{h,\tau} \to v^* \text{ weakly in } L^2(0,T;(H^1(\Omega))'), \tag{5.23}$$

and a subsequence of $\{\tilde{u}_{h,\tau}\}$ such that

$$\tilde{u}_{h,\tau} \to \tilde{u}^* \text{ weakly in } L^2(0,T;H^1(\Omega)) \tag{5.24}$$

for some $u^*, \tilde{u}^* \in L^2(0,T;H^1(\Omega))$ and $v^* \in L^2(0,T;(H^1(\Omega))')$.

From (5.23), we know for any $\varphi(x) \in H^1(\Omega)$ and $\psi(t) \in C_0^\infty(0,T)$,

$$\lim_{\substack{h\to 0\\ \tau\to 0}} \int_0^T\int_\Omega \frac{\partial u_{h,\tau}(x,t)}{\partial t}\varphi(x)\psi(t)dxdt = \int_0^T\int_\Omega v^*(x,t)\varphi(x)\psi(t)dxdt. \tag{5.25}$$

Integrating by parts the left-hand side and using (5.22), we obtain

$$-\int_0^T\int_\Omega u^*(x,t)\varphi(x)\psi'(t)dxdt = \int_0^T\int_\Omega v^*(x,t)\varphi(x)\psi(t)dxdt,$$

which gives

$$v^*(x,t) = \frac{\partial u^*(x,t)}{\partial t}. \tag{5.26}$$

Next, taking any $\varphi(x) \in H^1(\Omega)$ and $\psi(t) \in C^1[0,T]$ with $\psi(T) = 0$, integrating by parts to both sides of (5.25), and noting (5.26), we get

$$\begin{aligned}&\lim_{\substack{h\to 0\\ \tau\to 0}} \left\{-\int_\Omega Q_h u_0(x)\varphi(x)\psi(0)dx - \int_0^T\int_\Omega u_{h,\tau}(x,t)\varphi(x)\psi'(t)dxdt\right\}\\ &= -\int_\Omega u^*(x,0)\varphi(x)\psi(0)dx - \int_0^T\int_\Omega u^*(x,t)\varphi(x)\psi'(t)dxdt.\end{aligned}$$

By the convergence property of Q_h and (5.22) we obtain

$$u^*(x,0) = u_0(x). \tag{5.27}$$

Next, we show $u^*(x,t) = \tilde{u}^*(x,t)$. In fact, by direct computing and (5.15), we obtain

$$\int_0^T \|u_{h,\tau}(\cdot,t) - \tilde{u}_{h,\tau}(\cdot,t)\|_0^2 dt = \frac{\tau^3}{3}\sum_{n=1}^M \|\partial_\tau u_h^n\|_0^2 \le C\tau; \tag{5.28}$$

this with (5.22) proves that $\tilde{u}_{h,\tau}$ converges to $\tilde{u}^*$ strongly in $L^2(0,T;L^2(\Omega))$ and $u^*(x,t) = \tilde{u}^*(x,t)$.

Below we will show $u^* = u(q)$. For any $\varphi(x) \in H^1(\Omega)$ and $\psi(t) \in C_0^\infty(0,T)$, let $\phi(x,t) = \varphi(x)\psi(t)$ and $\phi_{h,\tau}(x,t) = \sum_{n=1}^M \chi_n(t)Q_h\phi(x,t_n)$. Then we have

$$\begin{aligned}&\int_0^T \|\phi(\cdot,t) - \phi_{h,\tau}(\cdot,t)\|_1^2 dt\\ &\le 2\int_0^T \|\phi(\cdot,t) - S_\Delta\phi(\cdot,t)\|_1^2 dt + 2\int_0^T \|S_\Delta\phi(\cdot,t) - \phi_{h,\tau}(\cdot,t)\|_1^2 dt\\ &\le 2\int_0^T \|\phi(\cdot,t) - S_\Delta\phi(\cdot,t)\|_1^2 dt + 2\,T\max_{0\le t\le T}|\psi(t)|^2\,\|Q_h\varphi(\cdot) - \varphi(\cdot)\|_1^2.\end{aligned}$$

Therefore by (5.20) and the convergence property of Q_h, we deduce

$$\phi_{h,\tau} \text{ converges to } \phi \text{ strongly in } L^2(0,T;H^1(\Omega)). \tag{5.29}$$

By direct computations we have the following equalities:

$$\int_0^T\int_\Omega \frac{\partial}{\partial t}u_{h,\tau}(x,t)\phi_{h,\tau}(x,t)dxdt = \tau\sum_{n=1}^M\int_\Omega \partial_\tau u_h^n Q_h\phi(x,t_n)dx,$$

$$\int_0^T\int_\Omega \alpha(x,t)\nabla\tilde{u}_{h,\tau}(x,t)\nabla\phi_{h,\tau}(x,t)dxdt = \tau\sum_{n=1}^M\int_\Omega \bar{\alpha}^n\nabla u_h^n\nabla Q_h\phi(x,t_n)dx,$$

$$\int_0^T\int_{\Gamma_o} c(x,t)\tilde{u}_{h,\tau}(x,t)\phi_{h,\tau}(x,t)dsdt = \tau\sum_{n=1}^M\int_{\Gamma_o} \bar{c}^n u_h^n Q_h\phi(x,t_n)ds,$$

$$-\int_0^T\int_{\Gamma_o} c(x,t)u_a(x,t)\phi_{h,\tau}(x,t)dsdt = -\tau\sum_{n=1}^M\int_{\Gamma_o} \overline{cu}_a^n Q_h\phi(x,t_n)ds,$$

$$\int_0^T\int_{\Gamma_i} q_{h,\tau}(x,t)\phi_{h,\tau}(x,t)dsdt = \tau\sum_{n=1}^M\int_{\Gamma_i} q_h^n Q_h\phi(x,t_n)ds;$$

adding them together and using the discrete parabolic equation (5.10), we obtain

$$\begin{aligned}&\int_0^T\int_\Omega \frac{\partial}{\partial t}u_{h,\tau}(x,t)\phi_{h,\tau}(x,t)dxdt + \int_0^T\int_\Omega \alpha(x,t)\nabla\tilde{u}_{h,\tau}(x,t)\nabla\phi_{h,\tau}(x,t)dxdt\\ &+\int_0^T\int_{\Gamma_o} c(x,t)\tilde{u}_{h,\tau}(x,t)\phi_{h,\tau}(x,t)dsdt - \int_0^T\int_{\Gamma_o} c(x,t)u_a(x,t)\phi_{h,\tau}(x,t)dsdt\\ &= -\int_0^T\int_{\Gamma_i} q_{h,\tau}(x,t)\phi_{h,\tau}(x,t)dsdt + \tau\sum_{n=1}^M\int_{\Gamma_o}(\bar{c}^n\bar{u}_a^n - \overline{cu}_a^n)Q_h\phi(x,t_n)ds.\end{aligned}\tag{5.30}$$

Taking the limit as h and τ tend to 0 and using the convergence (5.22)–(5.24) and (5.29), we derive that for any $\varphi(x)\in H^1(\Omega)$ and $\psi(t)\in C_0^\infty(0,T)$

$$\begin{aligned}&\int_0^T\int_\Omega \frac{\partial u^*}{\partial t}\varphi(x)\psi(t)dxdt + \int_0^T\int_\Omega \alpha\nabla u^*\cdot\nabla\varphi(x)\psi(t)dxdt + \int_0^T\int_{\Gamma_o} c\,u^*\varphi(x)\psi(t)dsdt\\ &= \int_0^T\int_{\Gamma_o} c\,u_a\varphi(x)\psi(t)dsdt - \int_0^T\int_{\Gamma_i} q\,\varphi(x)\psi(t)dsdt,\end{aligned}\tag{5.31}$$

where we have used the limit

$$\lim_{\substack{h\to 0\\ \tau\to 0}}\tau\sum_{n=1}^M\int_{\Gamma_o}(\bar{c}^n\bar{u}_a^n - \overline{cu}_a^n)Q_h\phi(x,t_n)ds = 0.\tag{5.32}$$

To see this, it follows from (5.13), the trace theorem, and the Cauchy–Schwarz inequality that

$$\begin{aligned}&\tau\sum_{n=1}^M\int_{\Gamma_o}(\bar{c}^n\bar{u}_a^n - \overline{cu}_a^n)Q_h\phi(x,t_n)ds\\ &\le C\,\tau\max_{0\le t\le T}|\psi(t)|\,\|Q_h\varphi\|_1\sum_{n=1}^M\left\|\bar{c}^n\bar{u}_a^n - \overline{cu}_a^n\right\|_{0,\Gamma_o}\\ &\le C\,\tau\max_{0\le t\le T}|\psi(t)|\,\|\varphi\|_1\left(\sum_{n=1}^M\|c_t\|^2_{L^2(t_{n-1},t_n;L^\infty(\Gamma_o))}\right)^{\frac12}\left(\sum_{n=1}^M\|u_a\|^2_{L^2(t_{n-1},t_n;L^2(\Gamma_o))}\right)^{\frac12}\\ &\le C\,\tau\max_{0\le t\le T}|\psi(t)|\,\|\varphi\|_1\,\|c_t\|_{L^2(0,T;L^\infty(\Gamma_o))}\,\|u_a\|_{L^2(0,T;L^2(\Gamma_o))}.\end{aligned}$$

Clearly, the fact that $u^* = u(q)$ follows then from (5.31).

Now we can show the desired relation (5.21). For this, setting $f(x,t) = u_{h,\tau}(x,t) - u(x,t)$, we can write and estimate using Lemma 5.2 as follows:

$$\begin{aligned}
&\tau \sum_{n=1}^{M} \int_\Omega (u_h^n - u^n)^2 dx - \int_0^T \|u_{h,\tau}(\cdot,t) - u(\cdot,t)\|_0^2 dt \\
&= \sum_{n=1}^{M} \int_{t_{n-1}}^{t_n} \int_\Omega \Big(|f(x,t_n)|^2 - |f(x,t)|^2 \Big) dx dt \\
&\le \left\{ \sum_{n=1}^{M} \int_{t_{n-1}}^{t_n} \|f(\cdot,t_n) + f(\cdot,t)\|_0^2 dt \right\}^{\frac{1}{2}} \left\{ \sum_{n=1}^{M} \int_{t_{n-1}}^{t_n} \|f(\cdot,t_n) - f(\cdot,t)\|_0^2 dt \right\}^{\frac{1}{2}} \\
&\le C \left\{ \sum_{n=1}^{M} \int_{t_{n-1}}^{t_n} \|f(\cdot,t_n) - f(\cdot,t)\|_0^2 dt \right\}^{\frac{1}{2}}.
\end{aligned}$$

By (5.22), the second term at the left-hand side of the above inequality tends to 0 as $h, \tau \to 0$. But the last term can be estimated as follows:

$$\begin{aligned}
&\sum_{n=1}^{M} \int_{t_{n-1}}^{t_n} \|f(\cdot,t_n) - f(\cdot,t)\|_0^2 dt \\
&= \sum_{n=1}^{M} \int_{t_{n-1}}^{t_n} \|u - u^n + (t_n - t)\partial_\tau u_h^n\|_0^2 dt \\
&\le 2 \sum_{n=1}^{M} \int_{t_{n-1}}^{t_n} \|u - u^n\|_0^2 dt + 2 \sum_{n=1}^{M} \int_{t_{n-1}}^{t_n} \int_\Omega (t_n - t)^2 |\partial_\tau u_h^n|^2 dx dt \\
&= 2 \sum_{n=1}^{M} \int_{t_{n-1}}^{t_n} \|u - u^n\|_0^2 dt + \frac{2}{3}\tau^3 \sum_{n=1}^{M} \|\partial_\tau u_h^n\|_0^2.
\end{aligned}$$

From (5.20) and (5.15), the last two terms both tend to 0, and (5.21) follows. □

Finally, we are ready to show the main convergence results of this section.

THEOREM 5.6. *Let $\{q_{h,\tau}^*\}$ be a sequence of minimizers to the finite element minimization problem* (5.8)–(5.10)*; then as h and τ tend to* 0*, the whole sequence $\{q_{h,\tau}^*\}$ converges strongly in $L^2(0,T;L^2(\Gamma_i))$ to the unique minimizer of the continuous problem* (2.1)–(2.3).

Proof. Using the stability estimate (5.14), it is easy to know that $J_{h,\tau}(q_{h,\tau}^*) \le C$ for some constant C independent of h and τ. This implies that $\{q_{h,\tau}^*\}$ is bounded in $L^2(0,T;L^2(\Gamma_i))$ and there exists a subsequence of $\{q_{h,\tau}^*\}$, still denoted as $\{q_{h,\tau}^*\}$, such that $q_{h,\tau}^* \to q^*$ weakly in $L^2(0,T;L^2(\Gamma_i))$ as $h, \tau \to 0$.

Now for any $q \in L^2(0,T;L^2(\Gamma_i))$ and any fixed $\varepsilon > 0$, by the density results there exists a $q_\varepsilon \in H^1(0,T;H^{1/2}(\Gamma_i))$ such that

$$\|q - q_\varepsilon\|_{L^2(0,T;L^2(\Gamma_i))} \le \varepsilon.$$

Then we define an extension $\tilde{q}_\varepsilon$ of q_ε as follows: $\tilde{q}_\varepsilon \in H^1(\Omega)$ solves

$$-\Delta \tilde{q}_\varepsilon = 0 \;\text{ in }\; \Omega, \quad \tilde{q}_\varepsilon = q_\varepsilon \;\text{ on }\; \Gamma_i, \quad \tilde{q}_\varepsilon = 0 \;\text{ on }\; \Gamma_o.$$

One can verify that $\tilde{q}_\varepsilon \in H^1(0,T;H^1(\Omega))$ and $\|\tilde{q}_\varepsilon\|_{H^1(0,T;H^1(\Omega))} \le C\|q_\varepsilon\|_{H^1(0,T;H^{1/2}(\Gamma_i))}$. Define

$$\tilde{q}_\varepsilon^{h,\tau}(x,t) = \sum_{n=1}^{M} \chi_n(t) Q_h \tilde{q}_\varepsilon(x,t_n).$$

Let $q_\varepsilon^{h,\tau}$ be the restriction of $\tilde{q}_\varepsilon^{h,\tau}$ on Γ_i; then $q_\varepsilon^{h,\tau} \in V_{\Gamma_i}^h$ and for any $\varepsilon > 0$,

$$\begin{aligned}
&\|q_\varepsilon^{h,\tau} - q_\varepsilon\|^2_{L^2(0,T;L^2(\Gamma_i))} \le \|q_\varepsilon^{h,\tau} - q_\varepsilon\|^2_{L^2(0,T;H^{1/2}(\Gamma_i))} \le C\|\tilde{q}_\varepsilon^{h,\tau} - \tilde{q}_\varepsilon\|^2_{L^2(0,T;H^1(\Omega))} \\
&= C\sum_{n=1}^{M}\int_{t_{n-1}}^{t_n} \|Q_h\tilde{q}_\varepsilon(\cdot,t_n) - \tilde{q}_\varepsilon(\cdot,t)\|_1^2 dt \\
&\le C\sum_{n=1}^{M}\int_{t_{n-1}}^{t_n} \|Q_h\tilde{q}_\varepsilon(\cdot,t_n) - Q_h\tilde{q}_\varepsilon(\cdot,t) + Q_h\tilde{q}_\varepsilon(\cdot,t) - \tilde{q}_\varepsilon(\cdot,t)\|_1^2 dt \\
&\le C\int_0^T \|S_\Delta\tilde{q}_\varepsilon(\cdot,t) - \tilde{q}_\varepsilon(\cdot,t)\|_1^2 dt + C\int_0^T \|Q_h\tilde{q}_\varepsilon(\cdot,t) - \tilde{q}_\varepsilon(\cdot,t)\|_1^2 dt.
\end{aligned}$$

Thus $q_\varepsilon^{h,\tau} \to q_\varepsilon$ in $L^2(0,T;L^2(\Gamma_i))$ as $h,\tau \to 0$. Using this and Lemma 5.5, we can derive

$$\begin{aligned}
J(q^*) &\le \lim_{\substack{h\to 0\\ \tau\to 0}} \frac{\tau}{2}\sum_{n=0}^{M}\alpha_n \int_\omega (u_h^n(q_{h,\tau}^*) - z^n)^2 dx + \frac{\beta}{2}\liminf_{\substack{h\to 0\\ \tau\to 0}} \int_0^T\int_{\Gamma_i} |q_{h,\tau}^*|^2 ds dt \\
&\le \liminf_{\substack{h\to 0\\ \tau\to 0}} J_{h,\tau}(q_{h,\tau}^*) \le \liminf_{\substack{h\to 0\\ \tau\to 0}} J_{h,\tau}(q_\varepsilon^{h,\tau}) \\
&= \frac{1}{2}\int_0^T\int_\omega (u(q_\varepsilon) - z)^2 dx dt + \frac{\beta}{2}\int_0^T\int_{\Gamma_i} q_\varepsilon^2 ds dt \\
&= J(q_\varepsilon).
\end{aligned}$$

Letting $\varepsilon \to 0$, we deduce

$$J(q^*) \le J(q) \qquad \forall\ q \in L^2(0,T;L^2(\Gamma_i)), \tag{5.33}$$

which indicates that q^* is the unique minimizer of the continuous problem (2.1)–(2.3).

The strong convergence follows by the same trick as used in Proposition 2.3. □

Remark 5.7. All the results obtained in this paper can be naturally extended to a three-dimensional domain Ω with every two-dimensional cross-section being the domain as in Figure 2.

6. Finite element approximation of system (4.1)–(4.3) and its convergence. Next, we shall discuss the discretization of system (4.1)–(4.3). As we did for system (2.1)–(2.3), we use the composite trapezoidal rule for the time discretization of the first integral in (4.1) and the exact time integration for the second term. But as the time derivative of the identifying parameter $q(x,t)$ is involved in the regularization term now, we cannot ensure the convergence of the resultant fully discrete scheme for the entire system (4.1)–(4.3) if the backward Euler scheme is still used for approximating the parabolic problem (4.3). Instead we shall adopt the Crank–Nicolson scheme. This results in the following finite element approximation of (4.1)–(4.3):

(6.1)

$$\min J_{h,\tau}(q_{h,\tau}) = \frac{\tau}{2}\sum_{n=0}^{M}\alpha_n\int_\omega (u_h^n - z^n)^2 dx + \frac{\beta}{2}\left(\int_{\Gamma_i} |q_h^0|^2 ds + \tau\sum_{n=1}^{M}\int_{\Gamma_i} |\partial_\tau q_h^n|^2 ds\right)$$

over all $q_h^n \in V_{\Gamma_i}^h$ with $u_h^n \equiv u_h^n(q_{h,\tau}) \in V^h$ satisfying $u_h^0 = Q_h u_0$ in Ω and

$$\int_\Omega \partial_\tau u_h^n \phi_h dx + \int_\Omega \bar{\alpha}^n \nabla \frac{u_h^n + u_h^{n-1}}{2} \cdot \nabla \phi_h dx + \int_{\Gamma_o} \bar{c}^n \frac{u_h^n + u_h^{n-1}}{2} \phi_h ds$$
$$= \int_{\Gamma_o} \bar{c}^n \bar{u}_a^n \phi_h ds - \int_{\Gamma_i} \frac{q_h^n + q_h^{n-1}}{2} \phi_h ds \quad \forall \phi_h \in V^h \tag{6.2}$$

for $n = 1, 2, \ldots, M$. Here $\{\alpha_n\}$ are the coefficients of the composite trapezoidal rule: $\alpha_0 = \alpha_M = \frac{1}{2}$ and $\alpha_n = 1$ for all $n \neq 0, M$. The heat flux q is approximated by $q_{h,\tau}$, a piecewise linear interpolation based on $\{q_h^n\}$ over the time partition Δ in (5.2):

$$q_{h,\tau}(x,t) = \frac{t - t_{n-1}}{\tau} q_h^n + \frac{t_n - t}{\tau} q_h^{n-1}, \qquad t \in (t_{n-1}, t_n). \tag{6.3}$$

For the fully discrete finite element scheme (6.1)–(6.2), we can show (cf. [14]) the following theorem.

Theorem 6.1. *There exists a unique minimizer to the finite element problem* (6.1)*–*(6.2)*.*

In the rest of this section, we study the convergence of the discrete minimizer of (6.1)–(6.2) to the global minimizer of the continuous problem (4.1)–(4.3). For this purpose, we assume on functions $\alpha(x,t)$, $c(x,t)$, and $u_a(x,t)$ in (1.1)–(1.4) that

$$\alpha \in W^{1,\infty}(0,T; L^\infty(\Omega)) \quad \text{and} \quad c,\ u_a \in W^{1,\infty}(0,T; L^\infty(\Gamma_o)) \tag{6.4}$$

and introduce three related constants:

$$C_1 = \|\alpha\|_{W^{1,\infty}(0,T;L^\infty(\Omega))}, \quad C_2 = \|c\|_{W^{1,\infty}(0,T;L^\infty(\Gamma_o))}, \quad C_3 = \|u_a\|_{W^{1,\infty}(0,T;L^\infty(\Gamma_o))}. \tag{6.5}$$

Using these constants, we can derive the following estimates (cf. [14]):

$$\|\bar{\alpha}^n - \bar{\alpha}^{n-1}\|_{L^\infty(\Omega)} \le C_1\, \tau, \quad \|\bar{c}^n \bar{u}_a^n - \bar{c}^{n-1} \bar{u}_a^{n-1}\|_{L^\infty(\Gamma_o)} \le \frac{5}{3} C_2 C_3\, \tau. \tag{6.6}$$

For the convergence analysis, we first establish some stability estimates of the finite element solution to (6.2).

Lemma 6.2. *Let u_h^n be the finite element solution of system* (6.2) *corresponding to the given heat flux $\{q_h^n\}_{n=0}^M$; then we have the following stability estimates:*

$$\max_{1\le n\le M} \|u_h^n\|_0^2 + \tau \sum_{n=1}^M \left\| \nabla \frac{u_h^n + u_h^{n-1}}{2} \right\|_0^2 + \tau \sum_{n=1}^M \left\| \frac{u_h^n + u_h^{n-1}}{2} \right\|_{0,\Gamma_o}^2$$
$$\le C \left(\|u_0\|_0^2 + C_2^2 C_3^2 + \tau \sum_{n=0}^M \|q_h^n\|_{0,\Gamma_i}^2 \right), \tag{6.7}$$

$$\tau \sum_{n=1}^M \|\partial_\tau u_h^n\|_0^2 + \max_{1\le n\le M} \|\nabla u_h^n\|_0^2 + \max_{1\le n\le M} \|u_h^n\|_{0,\Gamma_o}^2$$
$$\le C \left(\|u_0\|_1^2 + C_2^2 C_3^2 + \max_{1\le n\le k} \|q_h^n\|_{0,\Gamma_i}^2 + \tau \sum_{n=1}^M \|\partial_\tau q_h^n\|_{0,\Gamma_i}^2 + \tau \sum_{n=0}^M \|q_h^n\|_{0,\Gamma_i}^2 \right). \tag{6.8}$$

Proof. Taking $\phi_h = \tau \frac{u_h^n + u_h^{n-1}}{2}$ in (6.2), we have

$$\frac{1}{2}\|u_h^n\|_0^2 - \frac{1}{2}\|u_h^{n-1}\|_0^2 + \alpha_0 \tau \left\| \nabla \frac{u_h^n + u_h^{n-1}}{2} \right\|_0^2 + c_0 \tau \left\| \frac{u_h^n + u_h^{n-1}}{2} \right\|_{0,\Gamma_o}^2$$
$$\leq \tau \int_{\Gamma_o} \bar{c}^n \bar{u}_a^n \frac{u_h^n + u_h^{n-1}}{2} ds - \tau \int_{\Gamma_i} \frac{q_h^n + q_h^{n-1}}{2} \frac{u_h^n + u_h^{n-1}}{2} ds.$$

Summing up the above equation over $n = 1, 2, \ldots, k \leq M$, we derive

$$\frac{1}{2}\|u_h^k\|_0^2 - \frac{1}{2}\|u_h^0\|_0^2 + \alpha_0 \tau \sum_{n=1}^k \left\| \nabla \frac{u_h^n + u_h^{n-1}}{2} \right\|_0^2 + c_0 \tau \sum_{n=1}^k \left\| \frac{u_h^n + u_h^{n-1}}{2} \right\|_{0,\Gamma_o}^2$$
$$\leq \tau \sum_{n=1}^k \int_{\Gamma_o} \bar{c}^n \bar{u}_a^n \frac{u_h^n + u_h^{n-1}}{2} ds - \tau \sum_{n=1}^k \int_{\Gamma_i} \frac{q_h^n + q_h^{n-1}}{2} \frac{u_h^n + u_h^{n-1}}{2} ds;$$

then (6.7) follows by applying the trace theorem and Young's and Gronwall's inequalities.

Next, taking $\phi_h = \tau \partial_\tau u_h^n$ in (6.2), we have

$$\tau \|\partial_\tau u_h^n\|_0^2 + \frac{1}{2} \int_\Omega \bar{\alpha}^n (|\nabla u_h^n|^2 - |\nabla u_h^{n-1}|^2) dx + \frac{1}{2} \int_{\Gamma_o} \bar{c}^n (|u_h^n|^2 - |u_h^{n-1}|^2) ds$$
$$= \int_{\Gamma_o} \bar{c}^n \bar{u}_a^n (u_h^n - u_h^{n-1}) ds - \int_{\Gamma_i} \frac{q_h^n + q_h^{n-1}}{2} (u_h^n - u_h^{n-1}) ds.$$

Summing up the above equation over $n = 1, 2, \ldots, k \leq M$ and using the formula (5.17), we deduce

$$\tau \sum_{n=1}^k \|\partial_\tau u_h^n\|_0^2 + \frac{1}{2} \alpha_0 \|\nabla u_h^k\|_0^2 + \frac{1}{2} c_0 \|u_h^k\|_{0,\Gamma_o}^2$$
$$\leq \frac{1}{2} \int_\Omega \bar{\alpha}^0 |\nabla u_h^0|^2 dx + \frac{1}{2} \sum_{n=1}^k \int_\Omega (\bar{\alpha}^n - \bar{\alpha}^{n-1}) |\nabla u_h^{n-1}|^2 dx$$
$$+ \frac{1}{2} \int_{\Gamma_o} \bar{c}^0 |u_h^0|^2 ds + \frac{1}{2} \sum_{n=1}^k \int_{\Gamma_o} (\bar{c}^n - \bar{c}^{n-1}) |u_h^{n-1}|^2 ds$$
$$+ \int_{\Gamma_o} \bar{c}^k \bar{u}_a^k u_h^k ds - \int_{\Gamma_o} \bar{c}^0 \bar{u}_a^0 u_h^0 ds - \sum_{n=1}^k \int_{\Gamma_o} (\bar{c}^n \bar{u}_a^n - \bar{c}^{n-1} \bar{u}_a^{n-1}) u_h^{n-1} ds$$
$$- \frac{1}{2} \int_{\Gamma_i} (q_h^k + q_h^{k-1}) u_h^k ds + \frac{1}{2} \int_{\Gamma_i} q_h^0 u_h^0 ds$$
$$+ \sum_{n=1}^k \int_{\Gamma_i} \left(\frac{q_h^n + q_h^{n-1}}{2} - \frac{q_h^{n-1} + q_h^{n-2}}{2} \right) u_h^{n-1} ds.$$

We now estimate all the terms on the right-hand side above. First, for those terms without summation, we can easily deduce

$$\int_\Omega \bar{\alpha}^0 |\nabla u_h^0|^2 dx + \int_{\Gamma_o} \bar{c}^0 |u_h^0|^2 ds \le C\,(C_1 + C_2)\|u_0\|_1^2,$$

$$\int_{\Gamma_o} \bar{c}^0 \bar{u}_a^0 u_h^0 ds + \frac{1}{2}\int_{\Gamma_i} q_h^0 u_h^0 ds \le C\,(C_2 C_3 + \|q_h^0\|_{0,\Gamma_i})\|u_0\|_1,$$

$$\int_{\Gamma_o} \bar{c}^k \bar{u}_a^k u_h^k ds \le \frac{1}{4} c_0 \|u_h^k\|_{0,\Gamma_o}^2 + C\,C_2^2 C_3^2,$$

$$-\frac{1}{2}\int_{\Gamma_i} (q_h^k + q_h^{k-1}) u_h^k ds \le \frac{1}{4}\alpha_0 \|\nabla u_h^k\|_0^2 + C\Big(\max_{1\le n\le M} \|u_h^n\|_0^2 + \max_{1\le n\le M} \|q_h^n\|_{0,\Gamma_i}^2\Big).$$

Using (6.6), we obtain the following estimates:

$$\frac{1}{2}\sum_{n=1}^k \int_\Omega (\bar{\alpha}^n - \bar{\alpha}^{n-1}) |\nabla u_h^{n-1}|^2 dx \le \frac{1}{2} C_1\,\tau \sum_{n=1}^k \|\nabla u_h^{n-1}\|_0^2,$$

$$\frac{1}{2}\sum_{n=1}^k \int_{\Gamma_o} (\bar{c}^n - \bar{c}^{n-1}) |u_h^{n-1}|^2 ds \le \frac{1}{2} C_2\,\tau \sum_{n=1}^k \|u_h^{n-1}\|_{0,\Gamma_o}^2,$$

$$-\sum_{n=1}^k \int_{\Gamma_o} (\bar{c}^n \bar{u}_a^n - \bar{c}^{n-1}\bar{u}_a^{n-1}) u_h^{n-1} ds \le C\,\tau \sum_{n=1}^k \|u_h^{n-1}\|_{0,\Gamma_o}^2 + C.$$

For the last term, we use the Cauchy–Schwarz inequality to obtain

$$\sum_{n=1}^k \int_{\Gamma_i} \left(\frac{q_h^n + q_h^{n-1}}{2} - \frac{q_h^{n-1} + q_h^{n-2}}{2} \right) u_h^{n-1} ds$$

$$\le \frac{1}{2}\tau \sum_{n=1}^k \|u_h^{n-1}\|_{0,\Gamma_i}^2 + \frac{1}{8\tau}\sum_{n=1}^k \left\| (q_h^n + q_h^{n-1}) - (q_h^{n-1} + q_h^{n-2}) \right\|_{0,\Gamma_i}^2$$

$$\le C\,\tau \sum_{n=1}^k \Big(\|\nabla u_h^{n-1}\|_0^2 + \|u_h^{n-1}\|_0^2 + \|\partial_\tau q_h^n\|_{0,\Gamma_i}^2 \Big).$$

Now (6.8) follows by combining all of the above estimates and using Gronwall's inequality. □

As we did for the finite element system (5.8)–(5.10), we need the following crucial technical result for the convergence of the finite element approximation (6.1)–(6.2).

LEMMA 6.3. *If $q_{h,\tau}$ converges to some q weakly in $H^1(0,T;L^2(\Gamma_i))$ as h and τ tend to* 0*, then*

$$\lim_{\substack{h\to 0\\ \tau\to 0}} \tau \sum_{n=0}^M \alpha_n \int_\omega (u_h^n(q_h^n) - z^n)^2 dx = \int_0^T\!\!\int_\omega (u(q) - z)^2 dx dt.$$

Proof. As in the proof of Lemma 5.5, it suffices to show (5.21).

We first construct two interpolations based on $\{u_h^n\}$: one is a piecewise linear interpolation over the time partition Δ,

$$u_{h,\tau}(x,t) = \frac{t - t_{n-1}}{\tau} u_h^n + \frac{t_n - t}{\tau} u_h^{n-1}, \quad t \in (t_{n-1}, t_n) \quad \text{for} \;\; n = 1, 2, \ldots, M,$$

and the other is a piecewise constant interpolation,

$$\tilde{u}_{h,\tau}(x,t) = \frac{1}{2}(u_h^n + u_h^{n-1}), \quad t \in (t_{n-1}, t_n) \quad \text{for} \quad n = 1, 2, \dots, M.$$

Using the definition of $q_{h,\tau}$ in (6.3) and the simple identity

$$q_h^n = \tau \sum_{k=1}^{n} \partial_\tau q_h^k + q_h^0,$$

we can directly see that

$$\tau \sum_{n=1}^{M} \|\partial_\tau q_h^n\|_{0,\Gamma_i}^2 = \tau \sum_{n=1}^{M} \left\| \frac{\partial}{\partial t} q_{h,\tau} \right\|_{0,\Gamma_i}^2 = \left\| \frac{\partial}{\partial t} q_{h,\tau} \right\|_{L^2(0,T;L^2(\Gamma_i))}^2,$$

$$\|q_h^n\|_{0,\Gamma_i}^2 \le 2\tau T \sum_{k=1}^{n} \|\partial_\tau q_h^k\|_{0,\Gamma_i}^2 + 2\|q_h^0\|_{0,\Gamma_i}^2.$$

With these relations, the assumption on $q_{h,\tau}$, and the stability estimates (6.7)–(6.8), we can easily check that both $\{u_{h,\tau}\}$ and $\{\tilde{u}_{h,\tau}\}$ are bounded in $L^2(0,T;H^1(\Omega))$ and that $\{\frac{\partial}{\partial t} u_{h,\tau}\}$ is bounded in $L^2(0,T;L^2(\Omega))$. So there exist a subsequence $\{u_{h,\tau}\}$ such that

$$u_{h,\tau} \to u^* \text{ weakly in } L^2(0,T;H^1(\Omega)) \text{ and strongly in } L^2(0,T;L^2(\Omega)),$$

$$\frac{\partial}{\partial t} u_{h,\tau} \to \frac{\partial u^*}{\partial t} \text{ weakly in } L^2(0,T;L^2(\Omega)),$$

and a subsequence $\{\tilde{u}_{h,\tau}\}$ such that

$$\tilde{u}_{h,\tau} \to \tilde{u}^* \text{ weakly in } L^2(0,T;H^1(\Omega)) \tag{6.9}$$

for some $u^* \in H^1(0,T;L^2(\Omega))$ and $\tilde{u}^* \in L^2(0,T;H^1(\Omega))$. We can further show that $u^*(x,0) = u_0(x)$ and $u^* = \tilde{u}^*$ using the fact that

$$\int_0^T \|u_{h,\tau}(\cdot,t) - \tilde{u}_{h,\tau}(\cdot,t)\|_0^2 dt = \frac{\tau^3}{12} \sum_{n=1}^{M} \|\partial_\tau u_h^n\|_0^2 \to 0. \tag{6.10}$$

Next, we show $u^* = u(q)$. Let $\phi_{h,\tau}(x,t)$ be defined as in the proof of Lemma 5.5. By simple computations we have the following equalities:

$$\int_0^T \int_\Omega \frac{\partial}{\partial t} u_{h,\tau}(x,t) \phi_{h,\tau}(x,t) dx dt = \tau \sum_{n=1}^{M} \int_\Omega \partial_\tau u_h^n Q_h \phi(x,t_n) dx,$$

$$\int_0^T \int_\Omega \alpha(x,t) \nabla \tilde{u}_{h,\tau}(x,t) \nabla \phi_{h,\tau}(x,t) dx dt = \tau \sum_{n=1}^{M} \int_\Omega \bar{\alpha}^n \nabla \frac{u_h^n + u_h^{n-1}}{2} \nabla Q_h \phi(x,t_n) dx,$$

$$\int_0^T \int_{\Gamma_o} c(x,t) \tilde{u}_{h,\tau}(x,t) \phi_{h,\tau}(x,t) ds dt = \tau \sum_{n=1}^{M} \int_{\Gamma_o} \bar{c}^n \frac{u_h^n + u_h^{n-1}}{2} Q_h \phi(x,t_n) ds,$$

$$\int_0^T \int_{\Gamma_o} c(x,t) u_a(x,t) \phi_{h,\tau}(x,t) ds dt = \tau \sum_{n=1}^{M} \int_{\Gamma_o} \overline{cu}_a^n Q_h \phi(x,t_n) ds,$$

$$\int_0^T \int_{\Gamma_i} q_{h,\tau}(x,t) \phi_{h,\tau}(x,t) ds dt = \tau \sum_{n=1}^{M} \int_{\Gamma_i} \frac{q_h^n + q_h^{n-1}}{2} Q_h \phi(x,t_n) ds.$$

Adding them together and using (6.2), we obtain a similar equation to (5.30). The rest of the proof is basically the same as that in Lemma 5.5. □

By virtue of Lemma 6.3, we can show the convergence of the finite element approximation (6.1)–(6.2), following the same lines as for Theorem 5.6; see Xie [14].

THEOREM 6.4. *Let* $\{q^*_{h,\tau}\}$ *be a sequence of minimizers to the discrete minimization problem* (6.1)–(6.2)*; then as* h *and* τ *tend to* 0*, the whole sequence* $\{q^*_{h,\tau}\}$ *converges strongly in* $H^1(0,T;L^2(\Gamma_i))$ *to the unique minimizer of the continuous problem* (4.1)–(4.3).

7. Solutions of finite element minimizaton problems.

In this section, we shall formulate a conjugate gradient algorithm to solve the nonlinear finite element minimization problems (5.8)–(5.10) and (6.1)–(6.2). We present details only for system (6.1)–(6.2), while the algorithm for system (5.8)–(5.10) can be formulated similarly; for details of the latter system, we refer to Xie [14].

We first derive the Gateaux derivative of the cost functional $J_{h,\tau}(q_{h,\tau})$ in (6.1), or the form $J_{h,\tau}(\{q_h^0,\dots,q_h^M\})$. Let $N=\dim(V^h_{\Gamma_i})$, and let $\{\psi_i\}_{i=1}^N$ be the basis of $V^h_{\Gamma_i}$. For any element from space $V^h_{\Gamma_i}\times\cdots\times V^h_{\Gamma_i}$, say $\{q_h^0,\dots,q_h^M\}$, let $\mathcal{U}_h^n\equiv u_h^n(q_{h,\tau})'p_{h,\tau}$ be the Gateaux derivative of solution $u_h^n(q_{h,\tau})$ to (6.1)–(6.2) in the direction $p_{h,\tau}$, or $\{p_h^0,\dots,p_h^M\}$. We easily see that $\mathcal{U}_h^0=0$, and for $n=1,2,\dots,M$ and any $\phi_h\in V^h$, the derivative $\mathcal{U}_h^n\in V^h$ satisfies

$$\int_\Omega \partial_\tau\mathcal{U}_h^n\phi_h dx+\int_\Omega \bar\alpha^n\nabla\frac{\mathcal{U}_h^n+\mathcal{U}_h^{n-1}}{2}\cdot\nabla\phi_h dx+\int_{\Gamma_o}\bar c^n\frac{\mathcal{U}_h^n+\mathcal{U}_h^{n-1}}{2}\phi_h ds$$
$$=-\int_{\Gamma_i}\frac{p_h^n+p_h^{n-1}}{2}\phi_h ds.$$

This enables us to derive the first and second derivatives of the cost functional $J_{h,\tau}$ in (6.1):

$$J_{h,\tau}(q_{h,\tau})'p_{h,\tau}=\tau\sum_{n=1}^M\alpha_n\int_\omega(u_h^n-z^n)\mathcal{U}_h^n dx+\beta\left(\int_{\Gamma_i}q_h^0p_h^0ds+\tau\sum_{n=1}^M\int_{\Gamma_i}\partial_\tau q_h^n\,\partial_\tau p_h^n ds\right),\tag{7.1}$$

$$J_{h,\tau}(q_{h,\tau})''p_{h,\tau}r_{h,\tau}=\tau\sum_{n=1}^M\alpha_n\int_\omega\Big(u_h^n(q_{h,\tau})'p_{h,\tau}\Big)\Big(u_h^n(q_{h,\tau})'r_{h,\tau}\Big)dx+\beta\left(\int_{\Gamma_i}p_h^0r_h^0ds+\tau\sum_{n=1}^M\int_{\Gamma_i}\partial_\tau p_h^n\,\partial_\tau r_h^n ds\right).\tag{7.2}$$

Clearly, evaluating the derivatives of $J_{h,\tau}$ at a given point $q_{h,\tau}$ using formula (7.1) is extremely expensive. To reduce the cost, we introduce an adjoint equation for the Crank–Nicolson scheme (6.2), which seems to have not been studied in the literature before. This needs to be done carefully in order to meet our final goal. A discrete sequence $\{w_h^n\}_{n=0}^M$ is defined in such a way that $w_h^M=0$ and $w_h^n\in V^h$ for $n\neq M$ solves

$$-\int_\Omega\frac{w_h^n-w_h^{n-1}}{\tau}\phi_h dx+\int_\Omega\frac{\bar\alpha^{n+1}\nabla w_h^n+\bar\alpha^n\nabla w_h^{n-1}}{2}\cdot\nabla\phi_h dx$$
$$+\int_{\Gamma_o}\frac{\bar c^{n+1}w_h^n+\bar c^n w_h^{n-1}}{2}\phi_h ds=\alpha_n\int_\omega(u_h^n-z^n)\phi_h dx\quad\forall\phi_h\in V^h.\tag{7.3}$$

Now taking $\phi_h = \mathcal{U}_h^n$ in (7.3), we can rewrite the first term in $J_{h,\tau}(q_{h,\tau})'p_{h,\tau}$ as

$$\begin{aligned} J_{h,\tau}^1 = &-\sum_{n=1}^{M}\int_\Omega \frac{w_h^n - w_h^{n-1}}{\tau}\mathcal{U}_h^n dx + \sum_{n=1}^{M}\int_\Omega \frac{\bar{\alpha}^{n+1}\nabla w_h^n + \bar{\alpha}^n\nabla w_h^{n-1}}{2}\cdot\nabla\mathcal{U}_h^n dx \\ &+\sum_{n=1}^{M}\int_{\Gamma_o}\frac{\bar{c}^{n+1}w_h^n + \bar{c}^n w_h^{n-1}}{2}\mathcal{U}_h^n ds. \end{aligned}$$

Then using formula (5.17), the identity[2]

$$\sum_{n=1}^{k}(a_n + a_{n-1})b_n = a_k b_k - a_0 b_0 + \sum_{n=1}^{k} a_{n-1}(b_n + b_{n-1}),$$

and the equation for $\mathcal{U}_h^n$, we obtain

$$\begin{aligned} J_{h,\tau}^1 = &\sum_{n=1}^{M}\int_\Omega \frac{\mathcal{U}_h^n - \mathcal{U}_h^{n-1}}{\tau} w_h^{n-1}dx + \sum_{n=1}^{M}\int_\Omega \bar{\alpha}^n\nabla\frac{\mathcal{U}_h^n + \mathcal{U}_h^{n-1}}{2}\cdot\nabla w_h^{n-1}dx \\ &+\sum_{n=1}^{M}\int_{\Gamma_o}\bar{c}^n\frac{\mathcal{U}_h^n + \mathcal{U}_h^{n-1}}{2}w_h^{n-1}ds \\ = &-\sum_{n=1}^{M}\int_{\Gamma_i}\frac{p_h^n + p_h^{n-1}}{2}w_h^{n-1}ds. \end{aligned}$$

This, along with (7.1), leads to a very simple formula for evaluating the derivative of $J_{h,\tau}$:

$$\begin{aligned} J_{h,\tau}(q_{h,\tau})'p_{h,\tau} = \int_{\Gamma_i}\Bigg(\beta q_h^0 p_h^0 + \sum_{n=1}^{M}\Bigg\{&\frac{\beta(q_h^n - q_h^{n-1})(p_h^n - p_h^{n-1})}{\tau} \\ &- \frac{\tau(p_h^n + p_h^{n-1})w_h^{n-1}}{2}\Bigg\}\Bigg)ds. \end{aligned} \tag{7.4}$$

Next, we are going to formulate the conjugate gradient method for the nonlinear minimization (6.1). Let us first establish one-to-one correspondences between finite element functions and their coefficient vectors. For any $q_h^j \in V_{\Gamma_i}^h$, we write its representation in terms of the basis $\{\psi_i\}_{i=1}^N$ as

$$q_h^j = \sum_{i=1}^{N} q_i^j \psi_i.$$

Then each finite element function $q_{h,\tau}$ or $\{q_h^0, q_h^1, \dots, q_h^M\}$ corresponds uniquely to an $(M+1)N$-dimensional vector

$$\mathbf{q} = (q_1^0, \dots, q_N^0, q_1^1, \dots, q_N^1, q_1^2, \dots, q_N^2, \dots, q_1^M, \dots, q_N^M)^T.$$

[2] This crucial identity has not been seen in the literature before and has no continuous counterpart, unlike the widely used identity (5.17) that is known as the discrete integration by parts formula.

Letting $f(\mathbf{q}) = J_{h,\tau}(q_{h,\tau})$, one can directly verify the relation for the first derivatives of $f(\mathbf{q})$,

$$\frac{\partial f(\mathbf{q})}{\partial q_i^j} = J_{h,\tau}(\{q_h^0, q_h^1, \ldots, q_h^M\})'(\{0, \ldots, \psi_i, \ldots, 0\}),$$

and the relation for the Hessian $H = (h_{ij})$,

$$h_{ik} :\equiv \frac{\partial^2 f(\mathbf{q})}{\partial q_i^j \partial q_k^l} = J_{h,\tau}(\{q_h^0, q_h^1, \ldots, q_h^M\})''(\{0, \ldots, \psi_i, \ldots, 0\})(\{0, \ldots, \psi_k, \ldots, 0\}).$$

This leads to the following expression:

$$f(\mathbf{q}) = \frac{1}{2}\mathbf{q}^T H \mathbf{q} + \nabla f(\mathbf{0})^T \mathbf{q} + f(\mathbf{0}).$$

We see that the evaluation of the Hessian H is extremely expensive. Fortunately, only its products with vectors are needed in the conjugate gradient method, and such products can be done with much less cost by noting the identity that $H\mathbf{q} = \nabla f(\mathbf{q}) - \nabla f(\mathbf{0})$ and the simple formula (7.4).

We are now ready to state the conjugate gradient algorithm for solving the discrete minimization problem (6.1)–(6.2). We shall use $(J_{h,\tau}(q_{h,\tau}))'$ for $\nabla f(\mathbf{q})$ to emphasize the dependence of the first order derivatives on mesh size h and time step τ.

Conjugate Gradient Algorithm

Step 1. Given a tolerance ε, compute $\tilde{\mathbf{g}}_0 = (J_{h,\tau}(0))'$.

Step 2. Given an initial guess $q_{h,\tau}^{(0)}$, solve the direct problem (6.2) and the adjoint equation (7.3), then compute $\mathbf{g}_0 = (J_{h,\tau}(q_{h,\tau}^{(0)}))'$ by using (7.4). Set $\mathbf{d}_0 := -\mathbf{g}_0$ and $k := 0$.

Step 3. Solve the one-dimensional problem

$$J_{h,\tau}(q_{h,\tau}^{(k)} + \alpha_k d_{h,\tau}^{(k)}) = \min_{\alpha} J_{h,\tau}(q_{h,\tau}^{(k)} + \alpha d_{h,\tau}^{(k)})$$

by computing

$$\alpha_k = -\frac{\mathbf{g}_k^T \mathbf{d}_k}{\mathbf{d}_k^T((J_{h,\tau}(d_{h,\tau}^{(k)}))' - \tilde{\mathbf{g}}_0)}.$$

Set $q_{h,\tau}^{(k+1)} := q_{h,\tau}^{(k)} + \alpha_k d_{h,\tau}^{(k)}$ and $k := k+1$. Compute

$$\mathbf{g}_k = (J_{h,\tau}(q_{h,\tau}^{(k)}))',$$
$$\beta_k = \frac{\mathbf{g}_k^T \mathbf{g}_k}{\mathbf{g}_{k-1}^T \mathbf{g}_{k-1}},$$
$$\mathbf{d}_k = -\mathbf{g}_k + \beta_k \mathbf{d}_{k-1}.$$

Step 4. If $\|\mathbf{g}_k\| \leq \varepsilon \|\mathbf{g}_0\|$, stop; otherwise goto Step 3.

8. Numerical experiments. In this section we show some numerical experiments on heat flux reconstructions using the two regularization methods (5.8)–(5.10) and (6.1)–(6.2). The physical domain Ω is taken to be $\Omega = \{(x, y);\ (\frac{1}{2})^2 \leq x^2 + y^2 \leq 1\}$. The domain Ω is triangulated as in Figure 2 using sectorial elements, with each

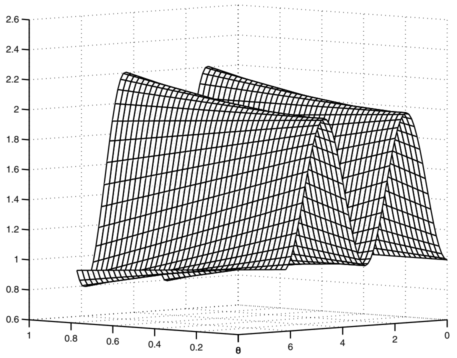

FIG. 3. *Exact q.*

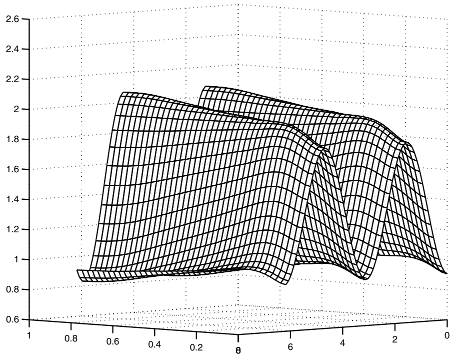

FIG. 4. *Method* (6.1) *used,* $\beta = 7 \times 10^{-6}$*, iter* $= 21$*, error* $= 4.19 \times 10^{-2}$.

circle divided into 60 arcs of equal length. The time interval $[0, 1]$ is divided into 40 equally spaced subintervals. For the conjugate gradient method, we take the tolerance $\epsilon = 10^{-4}$, and the initial guess $q^{(0)}_{h,\tau}$ of the heat flux is taken to be a constant zero everywhere in the whole space-time domain. In all three-dimensional figures shown below, the x-axis stands for the time interval varying from 0 to 1 and the y-axis stands for the inner boundary $\Gamma_i = \{(x, y);\ x^2 + y^2 = (\frac{1}{2})^2\}$ represented by the polar coordinate θ varying from 0 to 2π, while the z-axis shows the magnitude of the heat flux at each point (t, θ). The errors listed under each figure are the relative L^2-norm errors between the exact and numerically reconstructed heat fluxes.

In our simulations, the coefficients α, c, and u_a in (1.1) and (1.3) are taken to be $\alpha(x, t) = 1, c(x, t) = 1$, and $u_a(x, t) = 0$. In order to select more general and difficult profiles of heat fluxes for our tests, we add a source term $f(x, t)$ in (1.1). As our first example, we try the exact solution $u(x, y, t)$ and the heat flux $q(x, y, t)$ to be reconstructed as follows:

$$u(x, y, t) = x^2 + 2y^2 + t + \sin(xyt), \quad q(x, y, t) = 4x^2 + 8y^2 + 4xyt\cos(xyt).$$

Instead of the exact data $u(x, y, t)$, we use the perturbed data of the form $z(x, y, t) = u(x, y, t) + \delta\, u(x, y, t)$ as the measurement data, with the noise level $\delta = 1\%$ (1% relative noise pointwise). We first test the case when the measurement region is taken to be $\omega = \{(x, y);\ (\frac{3}{4})^2 \leq x^2 + y^2 \leq 1\}$. Figure 3 plots the exact heat flux, while Figure 4 shows the numerically reconstructed heat flux using the finite element method

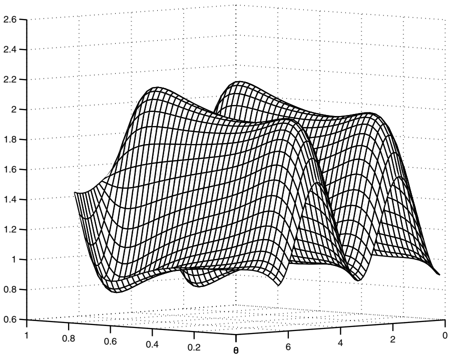

FIG. 5. *Method* (5.8) *used,* $\beta = 2 \times 10^{-6}$, *iter* $= 5$, *error* $= 7.73 \times 10^{-2}$.

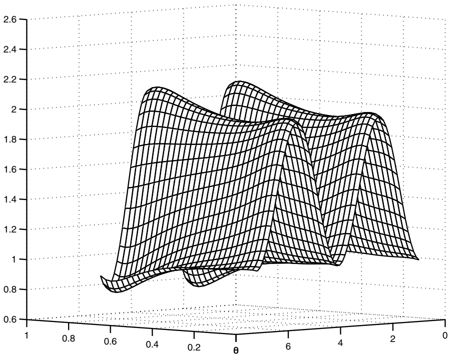

FIG. 6. *Method* (5.8) *used, plots from the initial* 4 *and last* 5 *time points removed, error* $= 3.09 \times 10^{-2}$.

(6.1) with L^2-regularization in space but H^1-regularization in time for heat fluxes. From Figure 4 we see that the numerical reconstruction works very well, considering the difficult oscillation of the heat flux in space. Also the conjugate gradient iteration performs very stably for such an oscillating heat flux, starting with a very bad initial guess of constant zero everywhere in the space-time domain. Figure 5 presents the numerical reconstruction using the finite element method (5.8) with L^2-regularization in both space and time for heat fluxes. One finds that the quality of reconstruction is far from satisfactory compared to the result we have seen in Figure 4 using the finite element method (6.1); the reconstruction is especially bad near the initial and terminal time. But interestingly, when we remove the bad reconstruction at a few initial and terminal time points, the remaining reconstruction seems very satisfactory again; see Figure 6.

We have also tried to see the effects of the measurement region. When the measurement region is reduced to a smaller subdomain $\omega = \{(x, y);\, (\frac{4}{5})^2 \le x^2 + y^2 \le 1\}$, the numerical reconstructions are not affected too much; see Figures 7 and 8.

As our second example, we take the exact solutions $u(x, y, t)$ and $q(x, y, t)$ in (1.1) and (1.4) as the following functions:

$$u(x, y, t) = \sin \pi t(x \cos \pi y + y \sin \pi x),$$
$$q(x, y, t) = 2 \sin \pi t(\pi xy(\cos \pi x - \sin \pi y) + x \cos \pi y + y \sin \pi x).$$

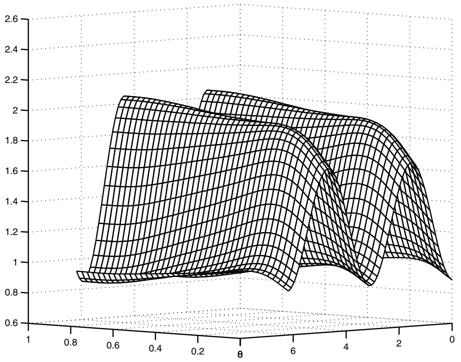

FIG. 7. *Method* (6.1) *used,* $\beta = 10^{-5}$*, iter* $= 23$*, error* $= 5.25 \times 10^{-2}$.

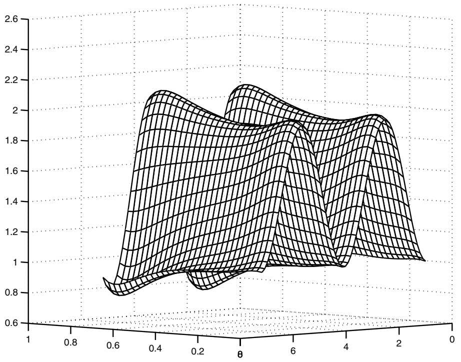

FIG. 8. *Method* (5.8) *used,* $\beta = 6 \times 10^{-6}$*, iter* $= 13$*, plots from the initial* 4 *and last* 5 *time points removed, error* $= 3.57 \times 10^{-2}$.

Again, the perturbed data $z(x, y, t) = u(x, y, t) + \delta\, u(x, y, t)$, with 1% noise pointwise, is taken to be the measurement data in ω. We first test the case when the measurement region is taken to be $\omega = \{(x, y);\ (\frac{3}{4})^2 \le x^2 + y^2 \le 1\}$. Figure 9 plots the exact heat flux q, which appears to be very challenging for numerical reconstruction as it oscillates widely in both time and space direction. Figure 10 shows the numerically reconstructed heat flux using the finite element method (6.1) with L^2-regularization in space but H^1-regularization in time for heat fluxes. This demonstrates very satisfactory performance of the numerical reconstruction algorithm, especially the stability and effectiveness of the conjugate gradient iteration, considering that it is such an oscillating heat flux and that it starts with a very bad initial guess of constant zero everywhere in the space-time domain. Figure 11 presents the numerical reconstruction using the finite element method (5.8) with L^2-regularization in both space and time for heat fluxes. Again its quality of reconstruction is not as good as the one obtained using the finite element method (6.1), and the accuracy is much worse.

When the measurement subregion is reduced to a smaller subdomain $\omega = \{(x, y);\ (\frac{4}{5})^2 \le x^2 + y^2 \le 1\}$, again the numerical reconstructions have not been affected much, as we have seen in the first example.

9. Concluding remarks. The inverse problem of reconstructing profiles of both time- and space-dependent heat fluxes on an inner boundary of a heat conductive

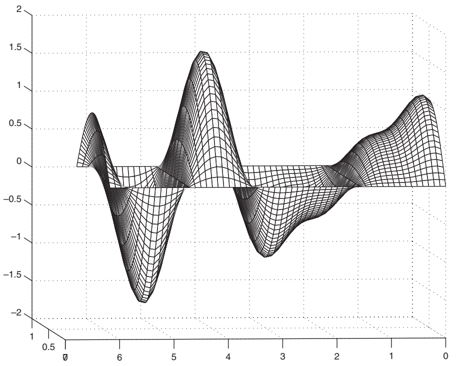

Fig. 9. *The exact q.*

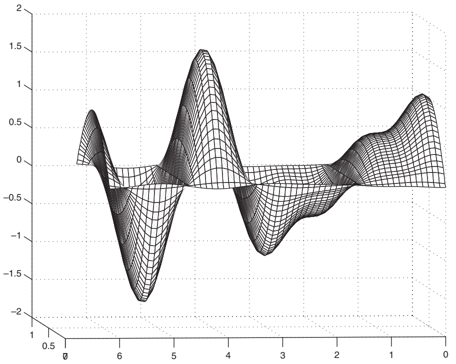

Fig. 10. *Method* (6.1) *used*, $\beta = 10^{-9}$, *iter* $= 30$, *error* $= 3.68 \times 10^{-2}$.

system is investigated. The reconstruction problem is severely ill-posed as it involves the heat flux profile at the initial time and on the inner boundary. Validation and effectiveness of two regularization formulations are justified both theoretically and numerically for the reconstruction, without any constraints enforced on the search spaces of heat fluxes when appropriate regularizations are selected. Regarding the approximation of the regularized nonlinear minimization systems, it is very tricky and essential to decide how to effectively discretize in both time and space the nonlinear optimizations and the associated parabolic equation and its adjoint so that the resulting fully discrete schemes converge. Two such discrete approaches are proposed to approximate two nonlinear minimization formulations: the first uses the backward Euler scheme in time, while the second requires the Crank–Nicolson scheme, with both adopting piecewise linear finite elements for space approximation and the trapezoidal and midpoint rules for discretization of the cost functionals. A novel weighted discrete projection operator Q_h is introduced which possesses both L^2- and H^1-stability and L^2-optimal error estimate, crucial to the success of convergence analysis of two fully discrete schemes. The resulting nonlinear finite element minimization systems are shown to be well suited for the solutions by conjugate gradient method. Numerical experiments have demonstrated the stability and effectiveness of the reconstruction algorithms.

There exists little work on numerical reconstruction of both time- and space-dependent physical profiles, and even less on convergence analysis of numerical reconstruction methods. As we have seen, the convergence analyses of the fully discrete schemes are much more difficult and trickier than the cases with only space-dependent profiles. This paper provides a relatively complete study on reconstruction of both time- and space-dependent heat fluxes, including well-posedness of the regularized systems, convergence of fully discrete approximations, numerical algorithms for solving discrete nonlinear minimizations, and numerical experiments. Most technical tools should be useful in theoretical and numerical analysis of regularization methods for other inverse problems.

Acknowledgment. The authors wish to thank an anonymous referee for his constructive comments.

CONVERGENCE OF THE LAGRANGE–GALERKIN METHOD FOR THE EQUATIONS MODELLING THE MOTION OF A FLUID-RIGID SYSTEM[*]

JORGE SAN MARTÍN[†], JEAN-FRANÇOIS SCHEID[‡], TAKÉO TAKAHASHI[‡], AND MARIUS TUCSNAK[‡]

Abstract. In this paper, we consider a Lagrange–Galerkin scheme to approximate a two-dimensional fluid-rigid body problem. The equations of the system are the Navier–Stokes equations in the fluid part, coupled with ordinary differential equations for the dynamics of the rigid body. In this problem, the equations of the fluid are written in a domain whose variation is one of the unknowns. We introduce a numerical method based on the use of characteristics and on finite elements with a fixed mesh. Our main result asserts the convergence of this scheme.

Key words. fluid-structure interaction, incompressible Navier–Stokes equations, finite element method, Lagrange–Galerkin method

1. Introduction.

The aim of this paper is to analyze a Lagrange–Galerkin approximation of the equations modelling the motion of a two-dimensional rigid body immersed in a fluid. We first briefly describe the equations modelling this system. Assume that the system fluid-rigid body occupies a bounded domain $\mathcal{O}$ in $\mathbb{R}^2$ with a regular boundary $\partial\mathcal{O}$. The solid is supposed to occupy at each instant t a closed connected subset $B(t) \subset \mathcal{O}$ which is surrounded by a viscous homogeneous fluid filling the domain $\Omega(t) = \mathcal{O}\backslash B(t)$.

The motion of the fluid is described by the classical Navier–Stokes equations, whereas the motion of the rigid body is governed by the balance equations for linear and angular momentum (Newton's laws). More precisely, we consider the following system coupling partial differential and ordinary differential equations:

$$\rho_f \frac{\partial \mathbf{u}}{\partial t} - \nu\Delta\mathbf{u} + \rho_f(\mathbf{u}\cdot\nabla)\mathbf{u} + \nabla p = \rho_f \mathbf{f}, \quad \mathbf{x} \in \Omega(t), \quad t \in [0,T], \tag{1.1}$$

$$\operatorname{div}\mathbf{u} = 0, \quad \mathbf{x} \in \Omega(t), \quad t \in [0,T], \tag{1.2}$$

$$\mathbf{u} = 0, \quad \mathbf{x} \in \partial\mathcal{O}, \quad t \in [0,T], \tag{1.3}$$

$$\mathbf{u} = \boldsymbol{\zeta}'(t) + \omega(t)(\mathbf{x} - \boldsymbol{\zeta}(t))^{\perp}, \quad \mathbf{x} \in \partial B(t), \quad t \in [0,T], \tag{1.4}$$

$$M\boldsymbol{\zeta}''(t) = -\int_{\partial B(t)} \boldsymbol{\sigma}\mathbf{n}\,\mathrm{d}\Gamma + \rho_s \int_{B(t)} \mathbf{f}(\mathbf{x},t)\,\mathrm{d}\mathbf{x}, \quad t \in [0,T], \tag{1.5}$$

(1.6)
$$J\omega'(t) = -\int_{\partial B(t)} (\mathbf{x} - \boldsymbol{\zeta}(t))^{\perp} \cdot \boldsymbol{\sigma}\mathbf{n} \, \mathrm{d}\Gamma + \rho_s \int_{B(t)} (\mathbf{x} - \boldsymbol{\zeta}(t))^{\perp} \cdot \mathbf{f}(\mathbf{x}, t) \, \mathrm{d}\mathbf{x}, \quad t \in [0, T],$$

$$\mathbf{u}(\mathbf{x}, 0) = \mathbf{u}_0(\mathbf{x}), \quad \mathbf{x} \in \Omega(0), \tag{1.7}$$

$$\boldsymbol{\zeta}(0) = \boldsymbol{\zeta}_0 \in \mathbb{R}^2, \quad \boldsymbol{\zeta}'(0) = \boldsymbol{\zeta}_1 \in \mathbb{R}^2, \quad \omega(0) = \omega_0 \in \mathbb{R}. \tag{1.8}$$

In the above equations the unknowns are $\mathbf{u}(\mathbf{x}, t)$ (the Eulerian velocity field of the fluid), $p(\mathbf{x}, t)$ (the pressure of the fluid), $\boldsymbol{\zeta}(t)$ (the position of the mass center of the rigid body), and $\omega(t)$ (the angular velocity of the rigid body). The domain $B(t)$ is defined by

$$B(t) = \{\mathbf{R}_{-\theta(t)}\mathbf{y} + \boldsymbol{\zeta}(t), \ \mathbf{y} \in B\},$$

where

$$\theta(t) = \int_0^t \omega(s) \, \mathrm{d}s, \tag{1.9}$$

$B = B(0)$, and $\mathbf{R}_\theta$ is the rotation matrix of angle θ. Moreover, we have denoted by $\partial B(t)$ the boundary of the rigid body at instant t and by $\mathbf{n}(\mathbf{x}, t)$ the unit normal to $\partial B(t)$ at the point $\mathbf{x}$ directed to the interior of the rigid body.

The constants ρ_f and ρ_s are, respectively, the density of the fluid and the density of the rigid body. In what follows, we assume that the densities of the fluid and of the solid are equal, that is

$$\rho_f = \rho_s = 1, \tag{1.10}$$

and that the rigid body is a ball in $\mathbb{R}^2$. Assumption (1.10) is clearly restrictive but it is important for the forthcoming analysis (see Remarks 2.1 and 2.4 below). On the contrary, the assumption that the rigid body is a ball is not essential but avoids some technicalities.

The constants M and J are the mass and the moment of inertia of the rigid body, and the positive constant ν is the viscosity of the fluid. Moreover, $\mathbf{f}(\mathbf{x}, t)$ is the applied force (per unit mass).

For all $\mathbf{x} = \binom{x_1}{x_2}$, we denote by $\mathbf{x}^\perp$ the vector $\mathbf{x}^\perp = \binom{x_2}{-x_1}$. If $\mathbf{x}, \mathbf{y} \in \mathbb{R}^2$, then $\mathbf{x} \cdot \mathbf{y}$ stands for the inner product of $\mathbf{x}$ and $\mathbf{y}$ and $|\mathbf{x}|$ stands for the corresponding norm. We have also denoted by w' and w'' the derivatives of a function w depending only on the time t.

Finally, the stress tensor (also called the Cauchy stress) is defined by

$$\boldsymbol{\sigma}(\mathbf{x}, t) = -p(\mathbf{x}, t)\mathbf{Id} + 2\nu\mathbf{D}(\mathbf{u}), \tag{1.11}$$

where $\mathbf{Id}$ is the identity matrix and $\mathbf{D}(\mathbf{u})$ is the tensor field defined by

$$D(u)_{k,l} = \frac{1}{2}\left(\frac{\partial u_k}{\partial x_l} + \frac{\partial u_l}{\partial x_k}\right).$$

The main difficulties of this problem are that

- the equations of the structure are coupled with those of the fluid,
- the domain of the fluid is variable, and it is one of the unknowns of the problem (we thus have a free boundary problem).

The well-posedness of this type of system has been recently studied in a large number of papers (see, for instance, Desjardins and Esteban [6], Gunzburger, Lee, and Seregin [17], San Martín, Starovoitov, and Tucsnak [25], Grandmont and Maday [16], Takahashi [27], and the references therein).

The literature on the numerical approximation of the solution of (1.1)–(1.8) also contains a large number of recent papers. Some of these papers are based on an arbitrary Lagrangian Eulerian (ALE) formulation; see, for example, Grandmont, Guimet, and Maday [15], Nobile [22], Maury and Glowinski [21], Maury [19], [20], Formaggia and Nobile [9], and Farhat, Geuzaine, and Grandmont [8]. In the ALE method, at each time step, the mesh is moved with an arbitrary velocity in the fluid to follow the motion of the rigid body. The stability of the ALE method is studied in [9] (in the case of the finite element context) and in [8] (in the case of the finite volume context). We also mention the work of Gastaldi [11], where, in the case of an advection-diffusion equation in a moving two-dimensional domain, a priori error estimates that are optimal both in space and time have been obtained.

Another approach, developed by Glowinski et al. [14], [13] is based on a fictitious domain formulation: the rigid bodies are filled by the surrounding fluid, and the constraint of rigid body motion is relaxed by introducing a distributed Lagrange multiplier.

As far as we know, the only proof of the convergence of one of these methods is given in [15] for a simplified problem in one space dimension. The main novelty brought in by our paper consists of the fact that we construct a new approximation method using a fixed mesh and that we prove a convergence result. This method is inspired by the Galerkin–Lagrange approximation, which is commonly used for Navier–Stokes equations (see Pironneau [23] and Süli [26]).

The remaining part of this paper is organized as follows. In section 2 we introduce some function spaces and semidiscretize our problem with respect to the time variable. In section 3 we give the full discretization of the problem and state the main result. Section 4 is devoted to the study of the finite element spaces that were introduced in the previous section. Section 5 is devoted to the study of a change of variables that plays an important role in the proof of the main result. In section 6 we prove the consistency of our scheme. Finally, in section 7 we give the proof of the main result.

2. Notation and preliminaries.

2.1. Notation and function spaces. Throughout this paper, we shall use the classical Sobolev spaces $H^s(\Omega)$, $H^s_0(\Omega)$, $H^{-s}(\Omega)$, $s \geqslant 0$, and the space of Lipschitz continuous functions $C^{0,1}(\overline{\Omega})$ on the closure of Ω. We also define

$$L^2_0(\Omega) = \left\{ f \in L^2(\Omega) \;\middle|\; \int_\Omega f \, \mathrm{d}\mathbf{x} = 0 \right\}$$

and denote by $\mathcal{L}^2_0(\Omega)$, $\mathcal{H}^s(\Omega)$, $\mathcal{H}^s_0(\Omega)$, $\mathcal{H}^{-s}(\Omega)$, $s \geqslant 0$, the spaces $\left[L^2_0(\Omega)\right]^2$, $[H^s(\Omega)]^2$, $[H^s_0(\Omega)]^2$, $[H^{-s}(\Omega)]^2$. The usual inner product in $\mathcal{L}^2(\mathcal{O})$ will be denoted by

$$(\mathbf{u}, \mathbf{v}) = \int_{\mathcal{O}} \mathbf{u} \cdot \mathbf{v} \, \mathrm{d}\mathbf{x} \quad \forall \mathbf{u}, \mathbf{v} \in \mathcal{L}^2(\mathcal{O}). \tag{2.1}$$

If $\mathbf{A}$ is a matrix, we denote by $\mathbf{A}^*$ its transpose. For any 2×2 matrices $\mathbf{A}, \mathbf{B} \in \mathcal{M}_{2\times 2}$, we denote by $\mathbf{A} : \mathbf{B}$ their inner product $\mathbf{A} : \mathbf{B} = \mathrm{Trace}(\mathbf{A}^*\mathbf{B})$, and by $|\mathbf{A}|$ the corresponding norm. For convenience, we use the same notation as in (2.1) for the inner product in $L^2(\mathcal{O}, \mathcal{M}_{2\times 2})$, that is,

$$(\mathbf{A},\mathbf{B}) = \int_{\mathcal{O}} \mathbf{A} : \mathbf{B} \ \mathrm{d}\mathbf{x} \quad \forall \mathbf{A}, \mathbf{B} \in L^2(\mathcal{O}, \mathcal{M}_{2\times 2}). \tag{2.2}$$

We also define the spaces

$$\mathcal{K}(\boldsymbol{\zeta}) = \{\mathbf{u} \in \mathcal{H}_0^1(\mathcal{O}) \mid \mathbf{D}(\mathbf{u}) = 0 \quad \text{in } B(\boldsymbol{\zeta})\} \tag{2.3}$$

and

$$\widehat{\mathcal{K}}(\boldsymbol{\zeta}) = \{\mathbf{u} \in \mathcal{H}_0^1(\mathcal{O}) \mid \operatorname{div} \mathbf{u} = 0 \text{ in } \mathcal{O}, \quad \mathbf{D}(\mathbf{u}) = 0 \text{ in } B(\boldsymbol{\zeta})\}, \tag{2.4}$$

where $\boldsymbol{\zeta} \in \mathbb{R}^2$ and $B(\boldsymbol{\zeta}) = \{\mathbf{x} \in \mathbb{R}^2, |\mathbf{x} - \boldsymbol{\zeta}| \leqslant 1\}$. According to Lemma 1.1 of [29, p. 18], for any $\mathbf{u} \in \mathcal{K}(\boldsymbol{\zeta})$, there exist $\mathbf{l}_{\mathbf{u}} \in \mathbb{R}^2$ and $\omega_{\mathbf{u}} \in \mathbb{R}$ such that

$$\mathbf{u}(\mathbf{y}) = \mathbf{l}_{\mathbf{u}} + \omega_{\mathbf{u}} (\mathbf{y} - \boldsymbol{\zeta})^{\perp} \quad \forall \mathbf{y} \in B(\boldsymbol{\zeta}).$$

These spaces are specific to our problem. In fact, if the solution $\mathbf{u}$ of (1.1)–(1.8) is extended by

$$\mathbf{u}(\mathbf{x},t) = \boldsymbol{\zeta}'(t) + \omega(t)(\mathbf{x} - \boldsymbol{\zeta}(t))^{\perp} \quad \forall \mathbf{x} \in B(\boldsymbol{\zeta}(t)),$$

then we easily see that $\mathbf{u}(t) \in \widehat{\mathcal{K}}(\boldsymbol{\zeta}(t))$.

In what follows, the solution $\mathbf{u}$ *of* (1.1)–(1.8) *will be extended as above.*

We also notice that, by using (1.10), for any $\mathbf{u}, \mathbf{v} \in \mathcal{K}(\boldsymbol{\zeta})$ we have

$$(\mathbf{u},\mathbf{v}) = \int_{\mathcal{O}\setminus B(\boldsymbol{\zeta})} \mathbf{u} \cdot \mathbf{v} \ \mathrm{d}\mathbf{x} + M \mathbf{l}_{\mathbf{u}} \cdot \mathbf{l}_{\mathbf{v}} + J \omega_{\mathbf{u}} \, \omega_{\mathbf{v}}. \tag{2.5}$$

Remark 2.1. In the case of different densities $\rho_F \neq \rho_S$, the natural inner product to be used seems to be

$$\langle \mathbf{u}, \mathbf{v} \rangle_{\zeta} = \rho_F \int_{\mathcal{O}\setminus B(\boldsymbol{\zeta})} \mathbf{u} \cdot \mathbf{v} \ \mathrm{d}\mathbf{x} + M \mathbf{l}_{\mathbf{u}} \cdot \mathbf{l}_{\mathbf{v}} + J \omega_{\mathbf{u}} \, \omega_{\mathbf{v}},$$

which clearly depends on the position of the ball. This fact would considerably complicate the further analysis.

An important ingredient of the numerical method we use is given by the characteristic functions whose level lines are the integral curves of the velocity field. More precisely (see, for instance, [23], [26]), the characteristic function $\widetilde{\boldsymbol{\psi}} : [0,T]^2 \times \mathcal{O} \to \mathcal{O}$ is defined as the solution of the initial value problem

$$\begin{cases} \dfrac{d}{dt} \widetilde{\boldsymbol{\psi}}(t; s, \mathbf{x}) = \mathbf{u}(\widetilde{\boldsymbol{\psi}}(t; s, \mathbf{x}), t), \\ \widetilde{\boldsymbol{\psi}}(s; s, \mathbf{x}) = \mathbf{x}. \end{cases} \tag{2.6}$$

It is well known that the material derivative $D_t \mathbf{u} = \partial \mathbf{u}/\partial t + (\mathbf{u} \cdot \nabla)\mathbf{u}$ of $\mathbf{u}$ at instant t_0 satisfies

$$D_t \mathbf{u}(\mathbf{x}, t_0) = \frac{d}{dt} \Big[\mathbf{u}(\widetilde{\boldsymbol{\psi}}(t; t_0, \mathbf{x}), t) \Big]_{|t=t_0}. \tag{2.7}$$

Remark 2.2. By using a classical result of Liouville (see, for instance, Arnold [1, p. 251]), if

$$\boldsymbol{\zeta} \in \mathcal{H}^2(0,T), \quad \omega \in H^1(0,T), \quad \mathbf{u} \in C([0,T];\widehat{\mathcal{K}}(\boldsymbol{\zeta}(t))),$$

then we have that

$$\det \mathbf{J}_{\widetilde{\boldsymbol{\psi}}} = 1, \tag{2.8}$$

where we have denoted by

$$\mathbf{J}_{\widetilde{\boldsymbol{\psi}}} = \left(\frac{\partial \widetilde{\psi}_i}{\partial y_j}\right)_{i,j}$$

the jacobian matrix of the transformation $\mathbf{y} \mapsto \widetilde{\boldsymbol{\psi}}(\mathbf{y})$.

2.2. Weak form and semidiscretization scheme. In this subsection we give a weak form of (1.1)–(1.8) which is then used to discretize the problem with respect to time.

The fact that (2.9) is called a "weak formulation" of the system (1.1)–(1.8) is justified by the following result.

LEMMA 2.3. *Assume that*

$$\mathbf{u} \in L^2(0,T;\mathcal{H}^2(\Omega(t))) \cap H^1(0,T;\mathcal{L}^2(\Omega(t))) \cap C([0,T];\mathcal{H}^1(\Omega(t))),$$
$$p \in L^2(0,T;H^1(\Omega(t))),$$
$$\boldsymbol{\zeta} \in \mathcal{H}^2(0,T), \quad \omega \in H^1(0,T)$$

and that $\mathbf{u}$ *is extended by*

$$\mathbf{u}(\mathbf{x},t) = \boldsymbol{\zeta}'(t) + \omega(t)(\mathbf{x} - \boldsymbol{\zeta}(t))^{\perp} \quad \forall \mathbf{x} \in B(\boldsymbol{\zeta}(t)).$$

Then $(\mathbf{u},p,\boldsymbol{\zeta},\omega)$ *is the solution of* (1.1)–(1.8) *if and only if* $\mathbf{u}(t) \in \widehat{\mathcal{K}}(\boldsymbol{\zeta}(t))$ *for all* t *and* $(\mathbf{u},p)$ *satisfies*

$$\left(\frac{d}{dt}\left[\mathbf{u} \circ \widetilde{\boldsymbol{\psi}}\right](t), \boldsymbol{\varphi}\right) + 2\nu\left(\mathbf{D}(\mathbf{u}(t)), \mathbf{D}(\boldsymbol{\varphi})\right) - \int_{\Omega(t)} (\operatorname{div} \boldsymbol{\varphi}) p(t)\ \mathrm{d}\mathbf{x} \\ = (\mathbf{f}(t), \boldsymbol{\varphi}) \quad \forall \boldsymbol{\varphi} \in \mathcal{K}(\boldsymbol{\zeta}(t)). \tag{2.9}$$

We skip the proof of Lemma 2.3 since it is similar to the proof of the corresponding result for the classical Navier–Stokes system (see, for instance, [24, Chap. 12]).

Remark 2.4. In the case of different densities $\rho_F \neq \rho_S$, a similar weak statement can be obtained (see, for instance, [5]). In this case $\mathbf{u}$ in the first term of (2.9) should be replaced by $\rho\mathbf{u}$, where $\rho = \rho_F$ in the fluid and $\rho = \rho_S$ in the moving solid. Thus ρ would depend on the time and a transport equation for ρ should be added to the system.

By using the weak formulation given above we can derive a semidiscrete version of our system. For $N \in \mathbb{N}^*$ we denote $\Delta t = T/N$ and $t_k = k\Delta t$ for $k = 0,\dots,N$. Denote by $(\mathbf{u}^k, \boldsymbol{\zeta}^k) \in \widehat{\mathcal{K}}(\boldsymbol{\zeta}^k) \times \mathbb{R}^2$ the approximation of the solution of (1.1)–(1.8) at the time $t = t_k$. We approximate the position of the rigid ball at instant t_{k+1} by $\boldsymbol{\zeta}^{k+1}$, which is defined by the relation

$$\boldsymbol{\zeta}^{k+1} = \boldsymbol{\zeta}^k + \mathbf{u}^k(\boldsymbol{\zeta}^k)\Delta t. \tag{2.10}$$

We then define characteristic function $\overline{\boldsymbol{\psi}}$ associated to the semidiscretized velocity field as the solution of

$$\left\{\begin{array}{l}\dfrac{d}{dt}\overline{\boldsymbol{\psi}}(t;t_{k+1},\mathbf{x})=\mathbf{u}^k(\overline{\boldsymbol{\psi}}(t;t_{k+1},\mathbf{x})),\\ \overline{\boldsymbol{\psi}}(t_{k+1};t_{k+1},\mathbf{x})=\mathbf{x},\end{array}\right. \tag{2.11}$$

and we denote

$$\overline{\boldsymbol{X}}^{\boldsymbol{k}}(\mathbf{x})=\overline{\boldsymbol{\psi}}(t_k;t_{k+1},\mathbf{x})\quad\forall\mathbf{x}\in\mathcal{O}. \tag{2.12}$$

One can easily check that $\overline{\boldsymbol{X}}^{\boldsymbol{k}}(\mathcal{O})=\mathcal{O}$.

We next define $\mathbf{u}^{k+1}\in\widehat{\mathcal{K}}(\boldsymbol{\zeta}^{k+1})$ as the solution of the following Stokes type system:

$$\left(\frac{\mathbf{u}^{k+1}-\mathbf{u}^k\circ\overline{\boldsymbol{X}}^{\boldsymbol{k}}}{\Delta t},\boldsymbol{\varphi}\right)+2\nu\left(\mathbf{D}(\mathbf{u}^{k+1}),\mathbf{D}(\boldsymbol{\varphi})\right)=(\mathbf{f}^{k+1},\boldsymbol{\varphi})\quad\forall\boldsymbol{\varphi}\in\widehat{\mathcal{K}}(\boldsymbol{\zeta}^{k+1}), \tag{2.13}$$

where $\mathbf{f}^{k+1}=\mathbf{f}(t_{k+1})$.

The above equation can be rewritten by using a mixed formulation. To achieve this, we first define

$$M(\boldsymbol{\zeta})=\left\{p\in L^2_0(\mathcal{O})\mid p=0\text{ in }B(\boldsymbol{\zeta})\right\}, \tag{2.14}$$

$$a(\mathbf{u},\mathbf{v})=2\nu\int_{\mathcal{O}}\mathbf{D}(\mathbf{u}):\mathbf{D}(\mathbf{v})\,\mathrm{d}\mathbf{x}\quad\forall\mathbf{u},\mathbf{v}\in\mathcal{H}^1(\mathcal{O}), \tag{2.15}$$

$$b(\mathbf{u},p)=-\int_{\mathcal{O}}\operatorname{div}(\mathbf{u})p\,\mathrm{d}\mathbf{x}\quad\forall\mathbf{u}\in\mathcal{H}^1(\mathcal{O}),\quad\forall p\in L^2_0(\mathcal{O}). \tag{2.16}$$

With the above notation, it is clear that (2.13) is equivalent to the system

$$\left(\frac{\mathbf{u}^{k+1}-\mathbf{u}^k\circ\overline{\boldsymbol{X}}^{\boldsymbol{k}}}{\Delta t},\boldsymbol{\varphi}\right)+a(\mathbf{u}^{k+1},\boldsymbol{\varphi})+b(\boldsymbol{\varphi},p^{k+1})=(\mathbf{f}^{k+1},\boldsymbol{\varphi})\quad\forall\boldsymbol{\varphi}\in\mathcal{K}(\boldsymbol{\zeta}^{k+1}), \tag{2.17}$$

$$b(\mathbf{u}^{k+1},q)=0\quad\forall q\in M(\boldsymbol{\zeta}^{k+1}) \tag{2.18}$$

of unknowns $(\mathbf{u}^{k+1},p^{k+1})\in\mathcal{K}(\boldsymbol{\zeta}^{k+1})\times M(\boldsymbol{\zeta}^{k+1})$.

Remark 2.5. The requirement $p=0$ in $B(\boldsymbol{\zeta})$ for the definition of $M(\boldsymbol{\zeta})$ allows us to define the form b on the whole domain $\mathcal{O}$. This extension does not affect the form b since $\operatorname{div}(\mathbf{u})=0$ in $B(\boldsymbol{\zeta})$ for all $\mathbf{u}\in\mathcal{K}(\boldsymbol{\zeta})$.

It is well known (see, for example, [12, Corollary I.4.1., p. 61]) that the mixed formulation (2.17), (2.18) is a well-posed problem, provided that the spaces $\mathcal{K}(\boldsymbol{\zeta})$, $M(\boldsymbol{\zeta})$ and the bilinear form b satisfy an *inf-sup* condition. The fact that this *inf-sup* condition is satisfied in our case follows from the result below.

LEMMA 2.6. *Suppose that $\boldsymbol{\zeta}\in\mathcal{O}$ is such that $d(\boldsymbol{\zeta},\partial\mathcal{O})=1+\eta$, with $\eta>0$. Then there exists a constant $\beta>0$, depending only on η and on $\mathcal{O}$, such that for all $q\in M(\boldsymbol{\zeta})$ there exists $\mathbf{u}\in\mathcal{K}(\boldsymbol{\zeta})$ with*

$$\int_{\mathcal{O}}\operatorname{div}(\mathbf{u})\,q\,\mathrm{d}\mathbf{x}\geq\beta\|\mathbf{u}\|_{\mathcal{H}^1(\mathcal{O})}\|q\|_{L^2(\mathcal{O})}. \tag{2.19}$$

The proof of the above result can be obtained by slightly modifying the approach used for the mixed formulation of the standard Stokes system (see, for instance [12, p. 81]), so it is left to the reader.

3. Full discretization and statement of the main result. In order to discretize the problem (2.17), (2.18) with respect to the space variable we introduce two families of finite element spaces. We first define a family of finite element spaces that approximate the space $\mathcal{K}(\boldsymbol{\zeta})$ defined in (2.3). Let h denote a discretization parameter, $0 < h < 1$, and let P_1 be the space of all affine functions in $\mathbb{R}^2$.

Consider a quasi-uniform triangulation $\mathcal{T}_h$ of $\mathcal{O}$, as defined, for instance, in [2, p. 106] (this assumption will be accepted in the remainder of this paper and will allow us to make use of inverse estimates). If $T \in \mathcal{T}_h$ is a triangle of vertices $\mathbf{x}_1,\ \mathbf{x}_2$, and $\mathbf{x}_3$, we denote by $\varphi_1(\mathbf{x})$, $\varphi_2(\mathbf{x})$, and $\varphi_3(\mathbf{x})$ the corresponding barycentric coordinates of $\mathbf{x} \in \mathbb{R}^2$ with respect to the vertices $\mathbf{x}_1,\ \mathbf{x}_2$, and $\mathbf{x}_3$ (see, for instance, [4, p. 45] for the definition of barycentric coordinates). We associate to this triangulation two classical approximation spaces used in the mixed finite element methods for the Stokes system. The first space, classically used for the approximation of the velocity field in the mixed statement of the Stokes system, is denoted by $\mathcal{W}_h$ and is defined as the subspace of $\mathcal{H}_0^1(\mathcal{O})$ formed by the P_1-bubble finite elements associated to $\mathcal{T}_h$. More precisely, $\boldsymbol{\varphi} \in \mathcal{W}_h$ if and only if

$$\boldsymbol{\varphi}(\mathbf{x}) = \varphi_1(\mathbf{x})\boldsymbol{\alpha_1} + \varphi_2(\mathbf{x})\boldsymbol{\alpha_2} + \varphi_3(\mathbf{x})\boldsymbol{\alpha_3} + \frac{\varphi_1(\mathbf{x})\varphi_2(\mathbf{x})\varphi_3(\mathbf{x})}{\displaystyle\int_T \varphi_1\varphi_2\varphi_3 \, \mathrm{d}\mathbf{x}}\boldsymbol{\lambda} \qquad \forall\, \mathbf{x} \in T$$

for some constant vectors $\boldsymbol{\alpha_1},\ \boldsymbol{\alpha_2},\ \boldsymbol{\alpha_3},\ \boldsymbol{\lambda} \in \mathbb{R}^2$. We may notice that all functions in $\mathcal{W}_h$ are continuous.

The second space, classically used for the approximation of the pressure in mixed statements of the Stokes system, is denoted by E_h and is defined by

$$E_h = \left\{ q \in C(\overline{\mathcal{O}}) \ \middle|\ q_{|T} \in P_1(T) \right\}. \tag{3.1}$$

For our problem we use two spaces that are related to the presence of the rigid body. The first one, which is used for the approximation of the velocity field, is denoted by $\mathcal{K}_h(\boldsymbol{\zeta})$ and defined by

$$\mathcal{K}_h(\boldsymbol{\zeta}) = \mathcal{W}_h \cap \mathcal{K}(\boldsymbol{\zeta}) \quad \forall \boldsymbol{\zeta} \in \mathcal{O}.$$

The second one, which is used for the approximation of the pressure, is denoted by $M_h(\boldsymbol{\zeta})$ and defined by

$$M_h(\boldsymbol{\zeta}) = E_h \cap M(\boldsymbol{\zeta}) \quad \forall \boldsymbol{\zeta} \in \mathcal{O}.$$

We also define the finite element space (see [23])

$$\mathcal{R}_h = \{\mathbf{rot}\ \varphi_h, \quad \varphi_h \in E_h, \quad \varphi_h = 0 \text{ on } \partial\mathcal{O}\}.$$

We denote by $\mathbf{P}$ the orthogonal projection from $\mathcal{L}^2$ onto $\mathcal{R}_h$. More precisely, if $\mathbf{u} \in \mathcal{L}^2(\mathcal{O})$, then $\mathbf{Pu} \in \mathcal{R}_h$ satisfies

$$(\mathbf{u} - \mathbf{Pu}, \mathbf{r}_h) = 0 \quad \forall \mathbf{r}_h \in \mathcal{R}_h.$$

Let N be a positive integer. We denote $\Delta t = T/N$ and $t_k = k\Delta t$. Assume that the approximate solution $(\mathbf{u}_h^k, p_h^k, \boldsymbol{\zeta}_h^k)$ of (1.1)–(1.8) at $t = t_k$ is known. We describe below the numerical scheme allowing us to determinate the approximate solution $(\mathbf{u}_h^{k+1}, p_h^{k+1}, \boldsymbol{\zeta}_h^{k+1})$ at $t = t_{k+1}$. First, we compute $\boldsymbol{\zeta}_h^{k+1} \in \mathbb{R}^2$ by

$$\boldsymbol{\zeta}_h^{k+1} = \boldsymbol{\zeta}_h^k + \mathbf{u}_h^k(\boldsymbol{\zeta}_h^k)\Delta t. \tag{3.2}$$

We denote by $\mathbf{P}\mathbf{u}_h^k$ the projection of $\mathbf{u}_h^k$ onto $\mathcal{R}_h$. Then we define the characteristic function $\overline{\boldsymbol{\psi}}_{\boldsymbol{h}}^{\boldsymbol{k}}$ associated to the fully discretized velocity field as the solution of

$$\left\{\begin{aligned} &\frac{d}{dt}\overline{\boldsymbol{\psi}}_{\boldsymbol{h}}^{\boldsymbol{k}}(t;t_{k+1},\mathbf{x}) = \mathbf{P}\mathbf{u}_h^k(\overline{\boldsymbol{\psi}}_{\boldsymbol{h}}^{\boldsymbol{k}}(t;t_{k+1},\mathbf{x})),\\ &\overline{\boldsymbol{\psi}}_{\boldsymbol{h}}^{\boldsymbol{k}}(t_{k+1};t_{k+1},\mathbf{x}) = \mathbf{x}. \end{aligned}\right. \tag{3.3}$$

We also define

$$\overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}(\mathbf{x}) = \overline{\boldsymbol{\psi}}_{\boldsymbol{h}}^{\boldsymbol{k}}(t_k;t_{k+1},\mathbf{x}) \quad \forall \mathbf{x} \in \mathcal{O}, \tag{3.4}$$

and as for the problem (2.11), one can check that $\overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}(\mathcal{O}) = \mathcal{O}$ (see Remark 3.1 below).

Then we define $(\mathbf{u}_h^{k+1}, p_h^{k+1}) \in \mathcal{K}_h(\boldsymbol{\zeta}_h^{k+1}) \times M_h(\boldsymbol{\zeta}_h^{k+1})$ as the solution of the problem

$$\left(\frac{\mathbf{u}_h^{k+1} - \mathbf{u}_h^k \circ \overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}}{\Delta t}, \boldsymbol{\varphi}\right) + a(\mathbf{u}_h^{k+1}, \boldsymbol{\varphi}) + b(\boldsymbol{\varphi}, p_h^{k+1}) = (\mathbf{f}_h^{k+1}, \boldsymbol{\varphi}) \quad \forall \boldsymbol{\varphi} \in \mathcal{K}_h(\boldsymbol{\zeta}_h^{k+1}), \tag{3.5}$$

$$b(\mathbf{u}_h^{k+1}, q) = 0 \quad \forall q \in M_h(\boldsymbol{\zeta}_h^{k+1}), \tag{3.6}$$

where $\mathbf{f}_h^{k+1}$ is the $\mathcal{L}^2$-projection of $\mathbf{f}^{k+1} = \mathbf{f}(t_{k+1})$ on $(E_h)^2$. We take $\boldsymbol{\zeta}_h^0 = \boldsymbol{\zeta}^0$, and the initial approximate velocity $\mathbf{u}_h^0$ is the $\mathcal{H}_0^1$-projection of $\mathbf{u}_0$ onto $\mathcal{K}_h(\boldsymbol{\zeta}_h^0)$.

Remark 3.1. In (3.3), we use the projection of $\mathbf{u}_h^k$ on $\mathcal{R}_h$ rather than the function $\mathbf{u}_h^k$ itself because $\operatorname{div}(\mathbf{P}\mathbf{u}_h^k) = 0$ in $\mathcal{O}$. By using a classical result of Liouville, this implies that $\det \mathbf{J}_{\overline{\boldsymbol{\psi}}_{\boldsymbol{h}}^{\boldsymbol{k}}} = 1$ and in particular that $\det \mathbf{J}_{\overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}} = 1$. This property, combined with the fact that the velocity field $\mathbf{P}\mathbf{u}_h^k$ vanishes along the boundary $\partial\mathcal{O}$, entails the invariance property of the whole domain $\mathcal{O}$ through $\overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}$, i.e., $\overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}(\mathcal{O}) = \mathcal{O}$. Moreover, since $\mathbf{P}\mathbf{u}_h^k$ is constant in each triangle, the initial value problem (3.3) can be solved exactly.

In what follows, we suppose that

$$\begin{aligned} &\mathbf{f} \in C([0,T];\mathcal{H}^1(\mathcal{O})), \quad \mathbf{u}_0 \in \mathcal{H}^2(\Omega), \quad \operatorname{div}(\mathbf{u}_0) = 0 \quad \text{in } \Omega,\\ &\mathbf{u}_0 = 0 \quad \text{on } \partial\mathcal{O}, \quad \mathbf{u}_0(\mathbf{y}) = \boldsymbol{\zeta}_1 + \omega_0(\mathbf{y} - \boldsymbol{\zeta}_0)^\perp \quad \text{on } \partial B. \end{aligned} \tag{3.7}$$

The corresponding solution $(\mathbf{u}, p, \boldsymbol{\zeta}, \omega)$ of problem (1.1)–(1.8) will be assumed to satisfy the following regularity hypotheses:

$$\left\{\begin{aligned} &\mathbf{u} \in C([0,T];\mathcal{H}^2(\Omega(t))) \cap H^1(0,T;\mathcal{L}^2(\Omega(t))),\\ &D_t^2\mathbf{u} \in L^2(0,T;\mathcal{L}^2(\Omega(t))), \quad \mathbf{u} \in C([0,T];\mathcal{C}^{0,1}(\overline{\mathcal{O}}))\\ &p \in C([0,T];\mathcal{H}^1(\Omega(t))), \quad \boldsymbol{\zeta} \in \mathcal{H}^3(0,T), \quad \omega \in H^2(0,T). \end{aligned}\right. \tag{3.8}$$

Moreover, we assume that

$$\operatorname{dist}(B(t), \partial\mathcal{O}) > 0 \quad \forall t \in [0,T]. \tag{3.9}$$

The hypotheses (3.8) and (3.9) imply the existence of $\eta > 0$ such that

$$\operatorname{dist}(B(t), \partial\mathcal{O}) > 3\eta \quad \forall t \in [0,T]. \tag{3.10}$$

THEOREM 3.2. *Let $C_0 > 0$ be a fixed constant. Suppose that $\mathcal{O}$ is the interior of a convex polygon and that $(\mathbf{u}, p, \boldsymbol{\zeta}, \omega)$ is a solution of* (1.1)–(1.8) *satisfying* (3.8) *and* (3.9)*. Moreover, assume that $\mathbf{f}$ and $\mathbf{u}_0$ satisfy* (3.7)*. Consider the functions $\boldsymbol{\zeta}_h^k$, $\mathbf{u}_h^k$, and p_h^k defined in this section. Then there exist two positive constants C and τ^* not depending on h and Δt such that for all $0 < \Delta t \leqslant \tau^*$ and for all $h \leqslant C_0 (\Delta t)^2$ we have*

$$\sup_{1 \leqslant k \leqslant N} \left(|\boldsymbol{\zeta}(t_k) - \boldsymbol{\zeta}_h^k| + \|\mathbf{u}(t_k) - \mathbf{u}_h^k\|_{\mathcal{L}^2(\mathcal{O})} \right) \leqslant C\Delta t.$$

Remark 3.3. For the Navier–Stokes system, the same type of result is obtained in [23] for $h \leqslant C_0\Delta t$ and in [26] for $h^2 \leqslant C_0 \Delta t \leqslant C_1 h^\sigma$ and $\sigma > 1/2$ (for h and Δt small enough).

Remark 3.4. It can be easily checked, by using the fact that $\det \mathbf{J}_{\overline{\boldsymbol{\psi}_h^k}} = 1$, that our method is unconditionally stable.

4. Some properties of the finite element spaces. Next we give some technical results on the finite element spaces introduced above. Throughout this section we consider $\boldsymbol{\zeta} \in \mathcal{O}$ such that $\operatorname{dist}(B(\boldsymbol{\zeta}), \partial\mathcal{O}) > 2\eta$ and we suppose that $h < \eta$. Therefore, we have that

$$\operatorname{dist}(B(\boldsymbol{\zeta}), \partial\mathcal{O}) > 2h. \tag{4.1}$$

Notice that, by definition, if $q \in M_h(\boldsymbol{\zeta})$, then $q = 0$ in $B(\boldsymbol{\zeta})$. Since q is a P_1 function in each triangle, it follows that $q_{|A_h} = 0$, where

$$A_h = \bigcup_{\substack{T \in \mathcal{T}_h \\ \overset{\circ}{T} \cap \overset{\circ}{B}(\boldsymbol{\zeta}) \neq \emptyset}} T.$$

Moreover, if we denote by Q_h the union of all triangles $T \in \mathcal{T}_h$ such that the three vertices of T are contained in $\overline{A_h}$, then, by using again the fact that q is a P_1 function in each triangle, it follows that

$$q_{|Q_h} = 0 \qquad \forall\, q \in M_h(\boldsymbol{\zeta}).$$

A similar argument shows that

$$\mathbf{D}(\mathbf{u})_{|A_h} = 0 \qquad \forall\, \mathbf{u} \in \mathcal{K}_h(\boldsymbol{\zeta}).$$

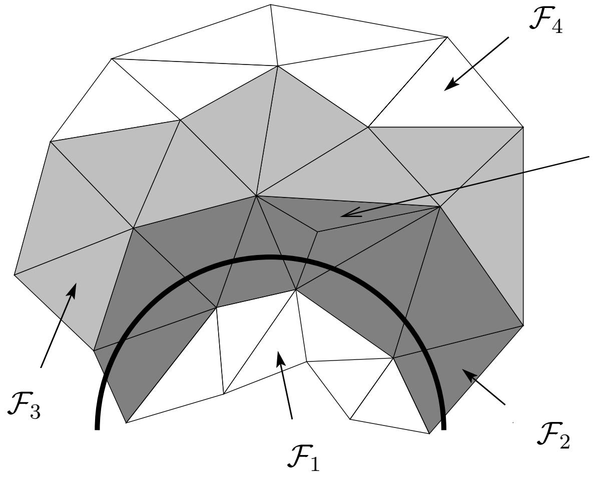
In order to study the properties of the spaces $\mathcal{K}_h(\boldsymbol{\zeta})$ and $M_h(\boldsymbol{\zeta})$ defined above we divide the triangles in $\mathcal{T}_h$ into four categories. These categories are defined as follows (see Figure 1):

- $\mathcal{F}_1$ is the subset of $\mathcal{T}_h$ formed by all triangles $T \in \mathcal{T}_h$ such that $\overline{T} \subset B(\boldsymbol{\zeta})$.
- $\mathcal{F}_2$ is the subset formed by all triangles $T \in \mathcal{T}_h \setminus \mathcal{F}_1$ such that $\overline{T} \subset \overline{Q}_h$.
- $\mathcal{F}_3$ is the subset formed by all triangles $T \in \mathcal{T}_h$ such that $\overline{T} \cap \overline{Q_h} \neq \emptyset$ and $T \not\subset \overline{Q_h}$.
- $\mathcal{F}_4 = \mathcal{T}_h \setminus (\mathcal{F}_1 \cup \mathcal{F}_2 \cup \mathcal{F}_3)$.

LEMMA 4.1. *There exists a positive constant C_1 (not depending on the position of $B(\boldsymbol{\zeta})$) such that*

$$\inf_{\mathbf{v}_h \in \mathcal{K}_h(\boldsymbol{\zeta})} \|\mathbf{v} - \mathbf{v}_h\|_{L^2(\mathcal{O})} \leqslant C_1 h^{\frac{3}{2}} \left(\|\mathbf{v}\|_{\mathcal{H}^2(\mathcal{O} \setminus B(\boldsymbol{\zeta}))} + \|\mathbf{v}\|_{\mathcal{H}^2(B(\boldsymbol{\zeta}))} \right),$$
$$\inf_{\mathbf{v}_h \in \mathcal{K}_h(\boldsymbol{\zeta})} \|\mathbf{v} - \mathbf{v}_h\|_{\mathcal{H}^1(\mathcal{O})} \leqslant C_1 \sqrt{h} \left(\|\mathbf{v}\|_{\mathcal{H}^2(\mathcal{O} \setminus B(\boldsymbol{\zeta}))} + \|\mathbf{v}\|_{\mathcal{H}^2(B(\boldsymbol{\zeta}))} \right),$$

for all $\mathbf{v} \in \mathcal{K}(\boldsymbol{\zeta}) \cap \mathcal{H}^2(\mathcal{O} \setminus B(\boldsymbol{\zeta}))$.



This kind of triangle is not included in A_h since $T \cap B = \emptyset$, but it is included in Q_h since its three vertices are in $\overline{A_h}$.

FIG. 1. *Splitting of the triangulation into four families of triangles.*

Proof. Let $\mathbf{v} \in \mathcal{K}(\boldsymbol{\zeta}) \cap \mathcal{H}^2(\mathcal{O} \setminus B(\boldsymbol{\zeta}))$. This means, in particular, that

$$\mathbf{v}(\mathbf{x}) = \mathbf{l} + \omega \mathbf{x}^{\perp} \qquad \forall\, \mathbf{x} \in B(\boldsymbol{\zeta}),$$

for some $\mathbf{l} \in \mathbb{R}^2$ and $\omega \in \mathbb{R}$. In the remaining part of this section we denote

$$\mathbf{R}(\mathbf{x}) = \mathbf{l} + \omega \mathbf{x}^{\perp} \qquad \forall\, \mathbf{x} \in \mathbb{R}^2.$$

We denote by $\mathbf{v}_{Ih}$ the unique function in $(E_h)^2$ which agrees with $\mathbf{v}$ at every node $\mathbf{x}_j$ of the triangulation $\mathcal{T}_h$ (recall the definition of E_h in (3.1)). Then we consider the function $\mathbf{v}_h \in (E_h)^2$ whose value in a node $\mathbf{x_j}$ of $\mathcal{T}_h$ is defined by

$$\mathbf{v_h}(\mathbf{x_j}) = \begin{cases} \mathbf{R}(\mathbf{x_j}) & \text{if} \quad \mathbf{x_j} \in \overline{A_h}, \\ \mathbf{v}_{Ih}(\mathbf{x_j}) & \text{if} \quad \mathbf{x_j} \notin \overline{A_h}. \end{cases}$$

Since $\mathbf{v_h}$ is affine in each triangle, it follows that

$$\mathbf{v_h}(\mathbf{x}) = \mathbf{R}(\mathbf{x}) \qquad \forall\, \mathbf{x} \in \overline{Q_h}. \tag{4.2}$$

We will show that there exists a positive constant C_1 (not depending on the position of $B(\boldsymbol{\zeta})$) such that

$$\|\mathbf{v} - \mathbf{v}_h\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C_1 h^{\frac{3}{2}} \left(\|\mathbf{v}\|_{\mathcal{H}^2(\mathcal{O} \setminus B(\boldsymbol{\zeta}))} + \|\mathbf{v}\|_{\mathcal{H}^2(B(\boldsymbol{\zeta}))} \right), \tag{4.3}$$

$$\|\mathbf{v} - \mathbf{v}_h\|_{\mathcal{H}^1(\mathcal{O})} \leqslant C_1 \sqrt{h} \left(\|\mathbf{v}\|_{\mathcal{H}^2(\mathcal{O} \setminus B(\boldsymbol{\zeta}))} + \|\mathbf{v}\|_{\mathcal{H}^2(B(\boldsymbol{\zeta}))} \right). \tag{4.4}$$

In order to prove the above inequalities, we divide the domain $\mathcal{O}$ into four parts:

$$\mathcal{O} = B(\boldsymbol{\zeta}) \cup (Q_h \setminus B(\boldsymbol{\zeta})) \cup \left(\bigcup_{T \in \mathcal{F}_3} T \right) \cup \left(\bigcup_{T \in \mathcal{F}_4} T \right).$$

Let us first remark that

$$\mathbf{v} = \mathbf{R} \ \text{ in } B(\boldsymbol{\zeta}). \tag{4.5}$$

On the other hand it is clear that Q_h is contained in the closed ball of center $\boldsymbol{\zeta}$ and radius $1+h$, denoted by $B_h(\boldsymbol{\zeta})$. Let us remark that the ball $B_h(\boldsymbol{\zeta})$ is included in the domain $\mathcal{O}$ due to condition (4.1). According to a classical result (see, for instance, Lemma 5.11 in Fujita and Sauer [10]), there exists a universal constant $C > 0$, such that for all $\boldsymbol{\varphi} \in \mathcal{H}^1(\mathcal{O} \setminus B(\boldsymbol{\zeta}))$,

$$\|\boldsymbol{\varphi}\|_{\mathcal{L}^2(B_h(\boldsymbol{\zeta})\setminus B(\boldsymbol{\zeta}))} \leq C\left(\sqrt{h}\|\boldsymbol{\varphi}\|_{\mathcal{L}^2(\partial B(\boldsymbol{\zeta}))} + h\|\nabla\boldsymbol{\varphi}\|_{[L^2(B_h(\boldsymbol{\zeta})\setminus B(\boldsymbol{\zeta}))]^4}\right). \tag{4.6}$$

The above relation with $\boldsymbol{\varphi} = \mathbf{v} - \mathbf{R}$ and (4.5) imply that

$$\|\mathbf{v}-\mathbf{R}\|_{\mathcal{L}^2(B_h(\boldsymbol{\zeta})\setminus B(\boldsymbol{\zeta}))} \leqslant Ch\,\|\nabla\left(\mathbf{v}-\mathbf{R}\right)\|_{[L^2(B_h(\boldsymbol{\zeta})\setminus B(\boldsymbol{\zeta}))]^4}. \tag{4.7}$$

By again applying Lemma 5.11 in [10] (this time for the function $\nabla\left(\mathbf{v}-\mathbf{R}\right)$), we obtain that

$$\begin{aligned}\|\nabla\left(\mathbf{v}-\mathbf{R}\right)\|_{[L^2(B_h(\boldsymbol{\zeta})\setminus B(\boldsymbol{\zeta}))]^4} \leqslant C\Big(\sqrt{h}\,\|\nabla\left(\mathbf{v}-\mathbf{R}\right)\|_{[L^2(\partial B(\boldsymbol{\zeta}))]^4} \\ + h\,\|\nabla\left(\mathbf{v}-\mathbf{R}\right)\|_{[H^1(\mathcal{O}\setminus B(\boldsymbol{\zeta}))]^4}\Big).\end{aligned}$$

The above inequality, combined with the trace theorem in Sobolev spaces, gives that

$$\|\nabla\left(\mathbf{v}-\mathbf{R}\right)\|_{[L^2(B_h(\boldsymbol{\zeta})\setminus B(\boldsymbol{\zeta}))]^4} \leq C\sqrt{h}\|\mathbf{v}-\mathbf{R}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))}. \tag{4.8}$$

From (4.7) and (4.8) it follows that

$$\|\mathbf{v}-\mathbf{R}\|_{\mathcal{L}^2(B_h(\boldsymbol{\zeta})\setminus B(\boldsymbol{\zeta}))} \leqslant Ch^{\frac{3}{2}}\|\mathbf{v}-\mathbf{R}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))}. \tag{4.9}$$

The above relation implies, by using the fact that $Q_h \subset B_h(\boldsymbol{\zeta})$ and (4.2), that

$$\|\mathbf{v}-\mathbf{v_h}\|_{\mathcal{L}^2(Q_h\setminus B(\boldsymbol{\zeta}))} \leq Ch^{\frac{3}{2}}\|\mathbf{v}-\mathbf{R}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))}. \tag{4.10}$$

Consequently, we have that

$$\|\mathbf{v}-\mathbf{v}_h\|_{\mathcal{L}^2(Q_h\setminus B(\boldsymbol{\zeta}))} \leqslant C_1 h^{\frac{3}{2}}\left(\|\mathbf{v}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))} + \|\mathbf{v}\|_{\mathcal{H}^2(B(\boldsymbol{\zeta}))}\right). \tag{4.11}$$

On the other hand, (4.8) and (4.9) imply that

$$\|\mathbf{v}-\mathbf{R}\|_{\mathcal{H}^1(B_h(\boldsymbol{\zeta})\setminus B(\boldsymbol{\zeta}))} \leq Ch^{\frac{1}{2}}\|\mathbf{v}-\mathbf{R}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))}.$$

The above relation implies, by using the fact that $Q_h \subset B_h(\boldsymbol{\zeta})$ and (4.2), that

$$\|\mathbf{v}-\mathbf{v_h}\|_{\mathcal{H}^1(Q_h\setminus B(\boldsymbol{\zeta}))} \leq Ch^{\frac{1}{2}}\|\mathbf{v}-\mathbf{R}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))},$$

which clearly implies

$$\|\mathbf{v}-\mathbf{v_h}\|_{\mathcal{H}^1(Q_h\setminus B(\boldsymbol{\zeta}))} \leq C\sqrt{h}\left(\|\mathbf{v}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))} + \|\mathbf{v}\|_{\mathcal{H}^2(B(\boldsymbol{\zeta}))}\right). \tag{4.12}$$

Let us now consider a triangle $T \in \mathcal{F}_3$. In order to estimate the restriction of $\mathbf{v}-\mathbf{v_h}$ to T we use the interpolating function $\mathbf{v}_{Ih}$. More precisely, we have

$$\|\mathbf{v}-\mathbf{v}_h\|_\alpha \leq \|\mathbf{v}-\mathbf{v}_{Ih}\|_\alpha + \|\mathbf{v}_{Ih}-\mathbf{v}_h\|_\alpha, \quad \alpha \in \{0,1\}, \tag{4.13}$$

where $\|\cdot\|_\alpha$ stands for the $\mathcal{L}^2$-norm or the $\mathcal{H}^1$-norm on T. We first estimate the second term in the right-hand side of (4.13). Since the function $\mathbf{v}_{Ih} - \mathbf{v}_h$ is affine in T, we have

$$\mathbf{v}_{Ih}(\mathbf{x}) - \mathbf{v}_h(\mathbf{x}) = \sum_{i=1}^{3} (\mathbf{v}_{Ih}(\mathbf{x}_i) - \mathbf{v}_h(\mathbf{x}_i))\, \varphi_i(x),$$

where $(\mathbf{x}_i)$ are the nodes of T and (φ_i) are the corresponding Lagrange barycentric functions. We have

$$\|\mathbf{v}_{Ih} - \mathbf{v}_h\|_\alpha \leq \sum_{i=1}^{3} |\mathbf{v}_{Ih}(\mathbf{x}_i) - \mathbf{v}_h(\mathbf{x}_i)|\, \|\varphi_i\|_\alpha. \tag{4.14}$$

A simple calculation shows that

$$\|\varphi_i\|_{L^2(T)} \leq Ch \tag{4.15}$$

and

$$\|\nabla\varphi_i\|_{L^2(T)} \leq C. \tag{4.16}$$

Since the mesh is quasi-uniform, the constant C can be chosen independent of the triangle. We now estimate $|\mathbf{v}_{Ih}(\mathbf{x}_i) - \mathbf{v}_h(\mathbf{x}_i)|$. Since $T \not\subset Q_h$, it follows that T has at most two nodes in Q_h and, consequently, at least one node such that $\mathbf{v}_{Ih}(\mathbf{x}_i) - \mathbf{v}_h(\mathbf{x}_i) = 0$. Therefore we tackle only the nodes in Q_h. If $\mathbf{x}_i$ is a node in Q_h, then

$$|\mathbf{v}_{Ih}(\mathbf{x}_i) - \mathbf{v}_h(\mathbf{x}_i)| = |\mathbf{v}(\mathbf{x}_i) - \mathbf{R}(\mathbf{x}_i)|\,. \tag{4.17}$$

Relations (4.14), (4.15), and (4.17) imply that

$$\begin{aligned}\|\mathbf{v}_{Ih} - \mathbf{v}_h\|_{\mathcal{L}^2(T)} &\leqslant Ch\, \|\mathbf{v} - \mathbf{R}\|_{\mathcal{L}^\infty(T)} \\ &\leqslant Ch \left(\|\mathbf{v} - \mathbf{v}_{Ih}\|_{\mathcal{L}^\infty(T)} + \|\mathbf{v}_{Ih} - \mathbf{R}\|_{\mathcal{L}^\infty(T)} \right).\end{aligned}$$

By using a classical interpolation error (see, for example, [2, Corollary 4.4.7]) and an inverse estimate (see, for example, [2, Lemma 4.5.3]), the above inequality yields

$$\|\mathbf{v}_{Ih} - \mathbf{v}_h\|_{\mathcal{L}^2(T)} \leqslant Ch \left(h\, \|\mathbf{v}\|_{\mathcal{H}^2(T)} + h^{-1}\, \|\mathbf{v}_{Ih} - \mathbf{R}\|_{\mathcal{L}^2(T)} \right),$$

which implies that

$$\begin{aligned}\|\mathbf{v}_{Ih} - \mathbf{v}_h\|_{\mathcal{L}^2(T)} &\leqslant C \left(h^2\, \|\mathbf{v}\|_{\mathcal{H}^2(T)} + \|\mathbf{v}_{Ih} - \mathbf{v}\|_{\mathcal{L}^2(T)} + \|\mathbf{v} - \mathbf{R}\|_{\mathcal{L}^2(T)} \right) \\ &\leqslant C \left(h^2\, \|\mathbf{v}\|_{\mathcal{H}^2(T)} + \|\mathbf{v} - \mathbf{R}\|_{\mathcal{L}^2(T)} \right).\end{aligned}$$

Above we have used again a classical result on the interpolation error (see, for example, [2, Theorem 4.4.4]).

Now, summing up the above relation for all triangles $T \in \mathcal{F}_3$ we obtain that

$$\|\mathbf{v}_{Ih} - \mathbf{v}_h\|_{\mathcal{L}^2\left(\bigcup_{T\in\mathcal{F}_3} T\right)} \leqslant C \left(h^2\, \|\mathbf{v}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))} + \|\mathbf{v} - \mathbf{R}\|_{\mathcal{L}^2\left(\bigcup_{T\in\mathcal{F}_3} T\right)} \right). \tag{4.18}$$

In order to estimate the last term in the right-hand side of (4.18) we proceed as previously by introducing the closed ball $B_{2h}(\boldsymbol{\zeta})$ of center $\boldsymbol{\zeta}$ and radius $1+2h$. This ball is included in $\mathcal{O}$ thanks to (4.1). It is clear that all triangles of $\mathcal{F}_3$ are contained in $B_{2h}(\boldsymbol{\zeta}) \setminus B(\boldsymbol{\zeta})$. Then we can once again use Lemma 5.11 in Fujita and Sauer [10] and prove an estimate similar to (4.9), namely,

$$\|\mathbf{v}-\mathbf{R}\|_{\mathcal{L}^2(B_{2h}(\boldsymbol{\zeta})\setminus B(\boldsymbol{\zeta}))} \leqslant Ch^{\frac{3}{2}} \|\mathbf{v}-\mathbf{R}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))}. \tag{4.19}$$

From (4.18) and (4.19) we deduce that

$$\|\mathbf{v}_{Ih}-\mathbf{v}_h\|_{\mathcal{L}^2\left(\bigcup_{T\in\mathcal{F}_3} T\right)} \leqslant Ch^{\frac{3}{2}} \left(\|\mathbf{v}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))} + \|\mathbf{v}\|_{\mathcal{H}^2(B(\boldsymbol{\zeta}))}\right). \tag{4.20}$$

The above relation, combined with (4.13) and with an interpolation error estimate (see [2, Theorem 4.4.4]), implies that

$$\|\mathbf{v}-\mathbf{v}_h\|_{\mathcal{L}^2\left(\bigcup_{T\in\mathcal{F}_3} T\right)} \leqslant Ch^{\frac{3}{2}} \left(\|\mathbf{v}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))} + \|\mathbf{v}\|_{\mathcal{H}^2(B(\boldsymbol{\zeta}))}\right). \tag{4.21}$$

Now we turn to the H^1-estimate for the family $\mathcal{F}_3$ of triangles. From the usual inverse inequality (see [2, Lemma 4.5.3]) and the L^2-estimate (4.20) we obtain

$$\|\nabla(\mathbf{v}_{Ih}-\mathbf{v}_h)\|_{\left[L^2\left(\bigcup_{T\in\mathcal{F}_3} T\right)\right]^4} \leq C_1 h^{\frac{1}{2}} \left(\|\mathbf{v}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))} + \|\mathbf{v}\|_{\mathcal{H}^2(B(\boldsymbol{\zeta}))}\right), \tag{4.22}$$

which implies, together with (4.13) and an interpolation error estimate (see [2, Theorem 4.4.4]), that

$$\|\nabla(\mathbf{v}-\mathbf{v}_h)\|_{\left[L^2\left(\bigcup_{T\in\mathcal{F}_3} T\right)\right]^4} \leq C_1 h^{\frac{1}{2}} \left(\|\mathbf{v}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))} + \|\mathbf{v}\|_{\mathcal{H}^2(B(\boldsymbol{\zeta}))}\right). \tag{4.23}$$

Finally, we consider the case of the triangle family $\mathcal{F}_4$. Interpolation error estimates lead to

$$\|\mathbf{v}-\mathbf{v}_h\|_{L^2\left(\bigcup_{T\in\mathcal{F}_4} T\right)} \leq C_1 h^2 \|\mathbf{v}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))} \tag{4.24}$$

and

$$\|\nabla(\mathbf{v}-\mathbf{v}_h)\|_{L^2\left(\bigcup_{T\in\mathcal{F}_4} T\right)} \leq C_1 h \|\mathbf{v}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))}. \tag{4.25}$$

Relations (4.11), (4.21), (4.24) and the fact that $\mathbf{v}=\mathbf{v}_h$ in $B(\boldsymbol{\zeta})$ imply (4.3). Moreover, (4.12), (4.23), (4.25) and the fact that $\mathbf{v}=\mathbf{v}_h$ in $B(\boldsymbol{\zeta})$ imply (4.4). □

LEMMA 4.2. *There exists a positive constant C_2 (independent of the position of $B(\boldsymbol{\zeta})$) such that*

$$\inf_{q_h\in M_h(\boldsymbol{\zeta})} \|q-q_h\|_{L^2(\mathcal{O})} \leqslant C_2 h^{\frac{1}{2}} \|q\|_{H^1(\mathcal{O}\setminus B(\boldsymbol{\zeta}))} \tag{4.26}$$

for all $q \in M(\boldsymbol{\zeta}) \cap H^1(\mathcal{O}\setminus B(\boldsymbol{\zeta}))$.

Proof. The proof of this lemma is similar to that of Lemma 4.1. Consider a function $q \in M(\boldsymbol{\zeta}) \cap H^1(\mathcal{O} \setminus B(\boldsymbol{\zeta}))$. According to a classical result (see, for example, [3, Theorem IX.7]), there exists $\widetilde{q} \in H^1(\mathcal{O})$ such that

$$\widetilde{q}_{|\mathcal{O}\setminus B(\boldsymbol{\zeta})} = q, \quad \|\widetilde{q}\|_{H^1(\mathcal{O})} \leq C\|q\|_{H^1(\mathcal{O}\setminus B(\boldsymbol{\zeta}))}, \tag{4.27}$$

and it can be proved that we can choose the constant C independent of the position of $B(\boldsymbol{\zeta})$. Moreover, by a classical interpolation argument (see, for example, [2, Theorem 4.4.4]), there exists $\widetilde{q}_h \in E_h$ such that

$$\|\widetilde{q} - \widetilde{q}_h\|_{L^2(\mathcal{O})} \leq Ch\|\widetilde{q}\|_{H^1(\mathcal{O})}.$$

The above relation and (4.27) clearly imply that there exists a constant $C > 0$ such that

$$\|q - \widetilde{q}_h\|_{L^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))} \leq Ch\|q\|_{H^1(\mathcal{O}\setminus B(\boldsymbol{\zeta}))}. \tag{4.28}$$

Denote by q_h the function in E_h satisfying the conditions

$$q_h(\mathbf{x}_i) = 0 \;\text{ if }\; \mathbf{x}_i \in \overline{A_h},$$

$$q_h(\mathbf{x}_i) = \widetilde{q}_h(\mathbf{x}_i) \;\text{ if }\; \mathbf{x}_i \in \mathcal{T}_h \setminus \overline{A_h}.$$

Then as in the proof of Lemma 4.1, we can show that

$$\|q - q_h\|_{L^2(\mathcal{O})} \leqslant C_2 h^{\frac{1}{2}}\|q\|_{H^1(\mathcal{O}\setminus B(\boldsymbol{\zeta}))}. \qquad \square$$

We next show that the finite element spaces $\mathcal{K}_h(\boldsymbol{\zeta})$, $M_h(\boldsymbol{\zeta})$ and the bilinear form b satisfy a discrete *inf-sup* condition. This proves in particular that the approximate problem (3.5)–(3.6) is well-posed (see [12, Theorem II.1.1., p. 114]). More precisely, the following result holds.

LEMMA 4.3. *There exists a constant $\beta^* > 0$ such that for all $q_h \in M_h(\boldsymbol{\zeta})$ there exists $\mathbf{u}_h \in \mathcal{K}_h(\boldsymbol{\zeta})$ with*

$$\int_{\mathcal{O}} \operatorname{div}(\mathbf{u}_h) q_h \, \mathrm{d}\mathbf{x} \geqslant \beta^* \|\mathbf{u}_h\|_{\mathcal{H}^1(\mathcal{O})}\|q_h\|_{L^2(\mathcal{O})}. \tag{4.29}$$

Proof. Let $q_h \in M_h(\boldsymbol{\zeta})$. Since $M_h(\boldsymbol{\zeta}) \subset M(\boldsymbol{\zeta})$, Lemma 2.6 yields the existence of $\mathbf{u} \in \mathcal{K}(\boldsymbol{\zeta})$ such that

$$\int_{\mathcal{O}} \operatorname{div}(\mathbf{u}) q_h \, \mathrm{d}\mathbf{x} \geqslant \beta\|\mathbf{u}\|_{\mathcal{H}^1(\mathcal{O})}\|q_h\|_{L^2(\mathcal{O})},$$

with β independent of q_h. In order to prove the conclusion of the lemma it suffices to show the existence of $\mathbf{u}_h \in \mathcal{K}_h(\boldsymbol{\zeta})$ such that

$$\int_{\mathcal{O}} \operatorname{div}(\mathbf{u}_h) q_h \, \mathrm{d}\mathbf{x} = \int_{\mathcal{O}} \operatorname{div}(\mathbf{u}) q_h \, \mathrm{d}\mathbf{x}, \tag{4.30}$$

$$\|\mathbf{u}_h\|_{\mathcal{H}^1(\mathcal{O})} \leqslant C\|\mathbf{u}\|_{\mathcal{H}^1(\mathcal{O})}, \tag{4.31}$$

where C is a constant independent of q_h.

Note that (4.30) is equivalent to

$$\int_{\mathcal{O}} \mathbf{u}_h \cdot \nabla q_h \ \mathrm{d}\mathbf{x} = \int_{\mathcal{O}} \mathbf{u} \cdot \nabla q_h \ \mathrm{d}\mathbf{x}.$$

Since ∇q_h is constant in each triangle and vanishes in any triangle from $\mathcal{F}_1 \cup \mathcal{F}_2$, in order to check (4.30), it suffices to show that

$$\int_T \mathbf{u}_h \ \mathrm{d}\mathbf{x} = \int_T \mathbf{u} \ \mathrm{d}\mathbf{x} \qquad \forall\, T \in \mathcal{F}_3 \cup \mathcal{F}_4. \tag{4.32}$$

Note first that if $\mathbf{u}_h \in \mathcal{K}_h(\boldsymbol{\zeta})$, then for any triangle $T \in \mathcal{T}_h$ of vertices $\mathbf{x}_1,\ \mathbf{x}_2,\ \mathbf{x}_3$ and of corresponding barycentric functions $\varphi_1,\ \varphi_2,\ \varphi_3$, we have

$$\mathbf{u}_h(\mathbf{x}) = \overline{\mathbf{u}}_h(x) + \frac{\varphi_1(\mathbf{x})\varphi_2(\mathbf{x})\varphi_3(\mathbf{x})}{\displaystyle\int_T \varphi_1\varphi_2\varphi_3 \ \mathrm{d}\mathbf{x}}\boldsymbol{\lambda} \qquad \forall\, \mathbf{x} \in T, \tag{4.33}$$

where $\overline{\mathbf{u}}_h \in \mathcal{C}(\overline{\mathcal{O}})$ satisfies

$$\overline{\mathbf{u}}_h(x) = \varphi_1(\mathbf{x})\boldsymbol{\alpha_1} + \varphi_2(\mathbf{x})\boldsymbol{\alpha_2} + \varphi_3(\mathbf{x})\boldsymbol{\alpha_3} \qquad \forall\, \mathbf{x} \in T, \tag{4.34}$$

for some constant vectors $\boldsymbol{\alpha_1},\ \boldsymbol{\alpha_2},\ \boldsymbol{\alpha_3},\ \boldsymbol{\lambda} \in \mathbb{R}^2$ (these constants depend on the triangle T). Notice that, since the restriction of $\mathbf{u}_h$ to triangles in $\mathcal{F}_1 \cup \mathcal{F}_2$ is a rigid velocity field, the constant $\boldsymbol{\lambda}$ in (4.33) is equal to zero for all triangles in $\mathcal{F}_1 \cup \mathcal{F}_2$. If $\overline{\mathbf{u}}_h$ satisfies (4.34) and $T \in \mathcal{F}_3 \cup \mathcal{F}_4$, then condition (4.32) holds provided that

$$\lambda = \int_T (\mathbf{u} - \overline{\mathbf{u}}_h) \ \mathrm{d}\mathbf{x} \qquad \forall\, T \in \mathcal{F}_3 \cup \mathcal{F}_4. \tag{4.35}$$

Some simple calculations show that there exists a constant $C > 0$ (independent of the triangle) such that

$$\left\| \frac{\varphi_1\varphi_2\varphi_3}{\displaystyle\int_T \varphi_1\varphi_2\varphi_3 \ \mathrm{d}\mathbf{x}} \right\|_{H^1(T)} \leqslant \frac{C}{h^2}. \tag{4.36}$$

Moreover, (4.35) and the Cauchy–Schwarz inequality imply that

$$|\lambda| \leqslant Ch\|\mathbf{u} - \overline{\mathbf{u}}_h\|_{\mathcal{L}^2(T)} \qquad \forall\, T \in \mathcal{F}_3 \cup \mathcal{F}_4, \tag{4.37}$$

for some constant C. From (4.33), (4.36), and (4.37) it follows that

$$\|\mathbf{u}_h\|_{\mathcal{H}^1(T)} \leqslant \|\overline{\mathbf{u}}_h\|_{\mathcal{H}^1(T)} + \frac{C}{h}\|\mathbf{u} - \overline{\mathbf{u}}_h\|_{\mathcal{L}^2(T)} \qquad \forall\, T \in \mathcal{F}_3 \cup \mathcal{F}_4. \tag{4.38}$$

The remaining part of the proof is devoted to the construction of $\overline{\mathbf{u}}_h$ such that $\mathbf{u}_h$ satisfies (4.31). According to a classical result (see, for instance, [12, Theorem I.A.2., p. 101]), there exists a function $\overline{\mathbf{u}}_h^c \in C(\overline{\mathcal{O}})$ which is affine in each triangle $T \in \mathcal{T}_h$ such that

$$\|\mathbf{u} - \overline{\mathbf{u}}_h^c\|_{\mathcal{L}^2(T)} \leq Ch\|\mathbf{u}\|_{\mathcal{H}^1(T)}, \tag{4.39}$$

$$\|\overline{\mathbf{u}}_h^c\|_{\mathcal{H}^1(T)} \leq C\|\mathbf{u}\|_{\mathcal{H}^1(T)}, \tag{4.40}$$

with the constant C independent of h. We are now in a position to define $\overline{\mathbf{u}}_h$. This function is defined by

$$\overline{\mathbf{u}_h}(\mathbf{x}) = \begin{cases} \overline{\mathbf{u}}_h^c(\mathbf{x}) & \text{if} \quad \mathbf{x} \in \bigcup\limits_{T\in\mathcal{F}_4} T, \\ \mathbf{R}(\mathbf{x}) & \text{if} \quad \mathbf{x} \in \bigcup\limits_{T\in\mathcal{F}_1\cup\mathcal{F}_2} T, \end{cases} \tag{4.41}$$

where $\mathbf{R}$ is the extension of $\mathbf{u}_{|B(\boldsymbol{\zeta})}$ (which is a rigid velocity field) to $\mathbb{R}^2$. We remark that relation (4.41) also defines the values of $\overline{\mathbf{u}}_h$ in the triangles of $\mathcal{F}_3$. Indeed, the vertices of each triangle in $\mathcal{F}_3$ are also vertices of a triangle in either $\mathcal{F}_2$ or in $\mathcal{F}_4$. In order to prove (4.31) we estimate the terms in the right-hand side of (4.38). We first consider a triangle $T \in \mathcal{F}_4$. By using the fact that $\overline{\mathbf{u}}_h = \overline{\mathbf{u}}_h^c$ in T, (4.39), and (4.40), we obtain that

$$\|\overline{\mathbf{u}}_h\|_{\mathcal{H}^1(T)} + \frac{1}{h}\|\mathbf{u} - \overline{\mathbf{u}}_h\|_{\mathcal{L}^2(T)} \leq C\|\mathbf{u}\|_{\mathcal{H}^1(T)} \qquad \forall\, T \in \mathcal{F}_4, \tag{4.42}$$

with the constant C independent of $\mathbf{u}$. We next consider a triangle $T \in \mathcal{F}_3$. We first notice that

$$\begin{aligned} \|\overline{\mathbf{u}}_h\|_{\mathcal{H}^1(T)} + \frac{1}{h}\|\mathbf{u} - \overline{\mathbf{u}}_h\|_{\mathcal{L}^2(T)} &\leq \|\overline{\mathbf{u}}_h^c\|_{\mathcal{H}^1(T)} + \frac{1}{h}\|\mathbf{u} - \overline{\mathbf{u}}_h^c\|_{\mathcal{L}^2(T)} \\ &\quad + \|\overline{\mathbf{u}}_h^c - \overline{\mathbf{u}}_h\|_{\mathcal{H}^1(T)} + \frac{1}{h}\|\overline{\mathbf{u}}_h - \overline{\mathbf{u}}_h^c\|_{\mathcal{L}^2(T)} \qquad \forall\, T \in \mathcal{F}_3. \end{aligned} \tag{4.43}$$

The first two terms in the right-hand side of (4.43) can be directly estimated by using (4.39) and (4.40). Moreover, by using inverse estimates (see, for example, [2, Lemma 4.5.3]), there exists a positive constant C independent of h such that

$$\|\overline{\mathbf{u}}_h^c - \overline{\mathbf{u}}_h\|_{\mathcal{H}^1(T)} + \frac{1}{h}\|\overline{\mathbf{u}}_h - \overline{\mathbf{u}}_h^c\|_{\mathcal{L}^2(T)} \leqslant C\,\|\overline{\mathbf{u}}_h^c - \overline{\mathbf{u}}_h\|_{\mathcal{L}^\infty(T)} \qquad \forall\, T \in \mathcal{F}_3.$$

The above relation and the fact that $\overline{\mathbf{u}}_h$ is equal either to $\mathbf{R}$ or to $\overline{\mathbf{u}}_h^c$ in the vertices of a triangle $T \in \mathcal{F}_3$ imply that

$$\|\overline{\mathbf{u}}_h^c - \overline{\mathbf{u}}_h\|_{\mathcal{H}^1(T)} + \frac{1}{h}\|\mathbf{u}_h - \overline{\mathbf{u}}_h^c\|_{\mathcal{L}^2(T)} \leq C\,\|\overline{\mathbf{u}}_h^c - \mathbf{R}\|_{\mathcal{L}^\infty(T)} \qquad \forall\, T \in \mathcal{F}_3.$$

The above inequality, combined once again with an inverse inequality, implies that

$$\|\overline{\mathbf{u}}_h^c - \overline{\mathbf{u}}_h\|_{\mathcal{H}^1(T)} + \frac{1}{h}\|\mathbf{u}_h - \overline{\mathbf{u}}_h^c\|_{\mathcal{L}^2(T)} \leq \frac{C}{h}\|\overline{\mathbf{u}}_h^c - \mathbf{R}\|_{\mathcal{L}^2(T)} \qquad \forall\, T \in \mathcal{F}_3. \tag{4.44}$$

On the other hand,

$$\|\overline{\mathbf{u}}_h^c - \mathbf{R}\|_{\mathcal{L}^2(T)} \leq \|\overline{\mathbf{u}}_h^c - \mathbf{u}\|_{\mathcal{L}^2(T)} + \|\mathbf{u} - \mathbf{R}\|_{\mathcal{L}^2(T)} \qquad \forall\, T \in \mathcal{F}_3. \tag{4.45}$$

Combining (4.39), (4.45), (4.44), and (4.43), we obtain

$$\|\overline{\mathbf{u}}_h\|_{\mathcal{H}^1(T)} + \frac{1}{h}\|\mathbf{u} - \overline{\mathbf{u}}_h\|_{\mathcal{L}^2(T)} \leq C\|\mathbf{u}\|_{\mathcal{H}^1(T)} + \frac{C}{h}\|\mathbf{u} - \mathbf{R}\|_{\mathcal{L}^2(T)} \qquad \forall\, T \in \mathcal{F}_3. \tag{4.46}$$

We recall that all triangles of $\mathcal{F}_3$ are contained in $B_{2h}(\boldsymbol{\zeta})\setminus B(\boldsymbol{\zeta})$. Therefore, by taking the sum of the above relations for all $T \in \mathcal{F}_3$ and by using (4.6), combined with the fact that $\mathbf{u} = \mathbf{R}$ on $\partial B(\boldsymbol{\zeta})$, we obtain

$$\|\overline{\mathbf{u}}_h\|_{\mathcal{H}^1\left(\bigcup_{T\in\mathcal{F}_3} T\right)} + \frac{1}{h}\|\mathbf{u}-\overline{\mathbf{u}}_h\|_{\mathcal{L}^2\left(\bigcup_{T\in\mathcal{F}_3} T\right)} \leq C\|\mathbf{u}\|_{\mathcal{H}^1(B_{2h}(\boldsymbol{\zeta})\setminus B(\boldsymbol{\zeta}))}. \tag{4.47}$$

Now by combining (4.42) and (4.47) in (4.38), we obtain

$$\|\mathbf{u}_h\|_{\mathcal{H}^1\left(\bigcup_{T\in\mathcal{F}_3\cup\mathcal{F}_4} T\right)} \leq C\|\mathbf{u}\|_{\mathcal{H}^1(\mathcal{O}\setminus B(\boldsymbol{\zeta}))}. \tag{4.48}$$

We next consider the triangles $T \in \mathcal{F}_1 \cup \mathcal{F}_2$. By using the fact that $\mathbf{u}_h = \overline{\mathbf{u}}_h = \mathbf{R}$ in T, we obtain that

$$\|\mathbf{u}_h\|_{\mathcal{H}^1\left(\bigcup_{T\in\mathcal{F}_1\cup\mathcal{F}_2} T\right)} = \|\mathbf{R}\|_{\mathcal{H}^1\left(\bigcup_{T\in\mathcal{F}_1\cup\mathcal{F}_2} T\right)}.$$

A simple calculation shows that the right-hand side of the above relation is bounded by $C\|\mathbf{u}\|_{\mathcal{H}^1(B(\boldsymbol{\zeta}))}$, where C is a constant independent of h. We thus obtain

$$\|\mathbf{u}_h\|_{\mathcal{H}^1\left(\bigcup_{T\in\mathcal{F}_1\cup\mathcal{F}_2} T\right)} \leq C\|\mathbf{u}\|_{\mathcal{H}^1(B(\boldsymbol{\zeta}))}. \tag{4.49}$$

If we join (4.48) and (4.49), we see that the function $\mathbf{u}_h$ satisfies (4.31). This concludes the proof of the lemma. □

Now, we are in position to introduce a projector in $\mathcal{K}_h(\boldsymbol{\zeta}) \times M_h(\boldsymbol{\zeta})$ that will be a key ingredient in the proof of the convergence result.

LEMMA 4.4. *Suppose that* $\mathbf{V} \in \mathcal{K}(\boldsymbol{\zeta})$ *and that* $P \in M(\boldsymbol{\zeta})$. *Then there exists a unique couple* $(\mathbf{V}_h, P_h)$ *in* $\mathcal{K}_h(\boldsymbol{\zeta}) \times M_h(\boldsymbol{\zeta})$ *such that*

$$\left\{\begin{array}{rcll} a\left(\mathbf{V}-\mathbf{V}_h, \boldsymbol{\varphi}\right) + b\left(\boldsymbol{\varphi}, P-P_h\right) & = & 0 & \forall\, \boldsymbol{\varphi} \in \mathcal{K}_h(\boldsymbol{\zeta}), \\ b\left(\mathbf{V}-\mathbf{V}_h, q\right) & = & 0 & \forall\, q \in M_h(\boldsymbol{\zeta}). \end{array}\right. \tag{4.50}$$

Moreover, if we suppose in addition that $\mathbf{V}_{|\mathcal{O}\setminus B(\boldsymbol{\zeta})} \in \mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}))$ *and that* $P_{|\mathcal{O}\setminus B(\boldsymbol{\zeta})} \in H^1(\mathcal{O}\setminus B(\boldsymbol{\zeta}))$, *then there exists a positive constant* C *such that*

$$\|\mathbf{V}-\mathbf{V}_h\|_{\mathcal{L}^2(\mathcal{O})} \leqslant Ch.$$

Proof. The result in Lemma 4.3 combined with Theorem 1.1 in [12, p. 114] implies the existence and uniqueness of $(\mathbf{V}_h, P_h)$ in $\mathcal{K}_h(\boldsymbol{\zeta}) \times M_h(\boldsymbol{\zeta})$, satisfying (4.50) together with

$$\|\mathbf{V}-\mathbf{V}_h\|_{\mathcal{H}^1(\mathcal{O})}+\|P-P_h\|_{L^2(\mathcal{O})} \leqslant C\left\{\inf_{\mathbf{v}\in\mathcal{K}_h(\boldsymbol{\zeta})}\|\mathbf{V}-\mathbf{v}\|_{\mathcal{H}^1(\mathcal{O})} + \inf_{q\in M_h(\boldsymbol{\zeta})}\|P-q\|_{L^2(\mathcal{O})}\right\}.$$

Using Lemmas 4.1 and 4.2, we obtain

$$\|\mathbf{V}-\mathbf{V}_h\|_{\mathcal{H}^1(\mathcal{O})} + \|P-P_h\|_{L^2(\mathcal{O})} \leqslant Ch^{1/2}\left\{\|\mathbf{V}\|_{\mathcal{H}^2(\mathcal{O}\setminus B)} + \|\mathbf{V}\|_{\mathcal{H}^2(B)} + \|P\|_{H^1(\mathcal{O})}\right\}.$$

Moreover, by applying the usual Aubin–Nitsche duality argument (see, for example, [12, p. 119]), one can easily prove

$$\|\mathbf{V}-\mathbf{V}_h\|_{\mathcal{L}^2(\mathcal{O})} \leqslant Ch\left\{\|\mathbf{V}\|_{\mathcal{H}^2(\mathcal{O}\setminus B)} + \|\mathbf{V}\|_{\mathcal{H}^2(B)} + \|P\|_{H^1(\mathcal{O})}\right\}. \qquad □$$

5. Definition and properties of the change of variables. In order to prove Theorem 3.2, we should be able to compare the exact solution, which is rigid in the ball $B(\boldsymbol{\zeta}(t_k))$, with the approximate solution, which is rigid in the ball $B(\boldsymbol{\zeta}_h^k)$. This will be achieved by the use of a change of variables that maps the exact ball onto the approximate one. This section is devoted to the description and main properties of this transformation.

5.1. Change of variables. In this section, we suppose that $\mathcal{O}$ is convex. In what follows, we need a change of variables, transforming a function in $\widehat{\mathcal{K}}(\boldsymbol{\zeta}_1)$ into a function in $\widehat{\mathcal{K}}(\boldsymbol{\zeta}_2)$, where $\boldsymbol{\zeta}_i \in \mathcal{O}$ are such that

$$\operatorname{dist}(\boldsymbol{\zeta}_i, \partial\mathcal{O}) > 1 + 2\eta, \quad i \in \{1,2\}, \quad \text{with } \eta > 0. \tag{5.1}$$

In this case, $B(\boldsymbol{\zeta}_i)$ is contained in $\mathcal{O}$ and the distance between $B(\boldsymbol{\zeta}_i)$ and $\partial\mathcal{O}$ is greater than 2η. Let $\xi \in C^\infty(\mathbb{R}^2, \mathbb{R})$ be a compactly supported function such that

- $\xi = 1$ if $\mathbf{x} \in \mathcal{O}$ and $\operatorname{dist}(\mathbf{x}, \partial\mathcal{O}) > 2\eta$,
- $\xi = 0$ if $\mathbf{x} \notin \mathcal{O}$ or $\operatorname{dist}(\mathbf{x}, \partial\mathcal{O}) \leqslant \eta$.

Let $\boldsymbol{\Lambda}$ be the mapping defined by

$$\boldsymbol{\Lambda}(\mathbf{x}) = \left[(\boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2) \cdot \mathbf{x}^\perp\right] (\mathbf{rot}\ \xi) + \xi(\boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2) \quad \forall \mathbf{x} \in \mathbb{R}^2. \tag{5.2}$$

We need several properties of the field $\boldsymbol{\Lambda}$ and of the associated flow. Since these properties are similar to those proved in [27] we state them here without proof.

Lemma 5.1. *Let $\boldsymbol{\Lambda}$ be the mapping defined by* (5.2)*. Then we have*

(i) $\boldsymbol{\Lambda} = 0$ *outside* $\mathcal{O}$,

(ii) $\operatorname{div} \boldsymbol{\Lambda} = 0$ *in* $\mathbb{R}^2$,

(iii) $\boldsymbol{\Lambda}(\mathbf{x}) = \boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2$ *if* $\mathbf{x} \in \mathcal{O}$ *and if* $\operatorname{dist}(\mathbf{x}, \partial\mathcal{O}) > 2\eta$.

In other words, the restriction of $\boldsymbol{\Lambda}$ to a neighborhood of $\partial\mathcal{O}$ is zero and $\boldsymbol{\Lambda}$ is a translation when restricted to points of $\mathcal{O}$ at distance to $\partial\mathcal{O}$ larger than 2η.

We consider next the initial value problem

$$\begin{cases} \dfrac{d}{d\lambda}\boldsymbol{\psi}(\lambda) = \boldsymbol{\Lambda}(\boldsymbol{\psi}(\lambda)), \quad \lambda > 0, \\ \boldsymbol{\psi}(0) = \mathbf{y}, \end{cases} \tag{5.3}$$

with $\boldsymbol{\Lambda}$ given by (5.2).

Lemma 5.2. *For all $\mathbf{y} \in \mathbb{R}^2$, the initial value problem* (5.3) *admits a unique solution $\boldsymbol{\psi}(\lambda, \mathbf{y})$ on* $[0,1]$*. Denote*

$$\mathbf{X}_{\boldsymbol{\zeta}_2,\boldsymbol{\zeta}_1}(\mathbf{y}) = \mathbf{X}(\mathbf{y}) = \boldsymbol{\psi}(1, \mathbf{y}). \tag{5.4}$$

Then $\mathbf{X}$ is a C^∞-diffeomorphism from $\mathcal{O}$ onto itself, and $\mathbf{X}(B(\boldsymbol{\zeta}_2)) = B(\boldsymbol{\zeta}_1)$. If we denote by

$$\mathbf{J_X} = \left(\frac{\partial X_i}{\partial y_j}\right)_{i,j}$$

the jacobian matrix of the transformation $\mathbf{y} \mapsto \mathbf{X}(\mathbf{y})$, then the above change of variables satisfies

$$\det \mathbf{J_X}(\mathbf{y}) = 1 \quad \forall \mathbf{y} \in \mathbb{R}^2. \tag{5.5}$$

We denote by

$$\mathbf{Y}_{\boldsymbol{\zeta}_2,\boldsymbol{\zeta}_1} = \mathbf{Y} = \mathbf{X}^{-1} \tag{5.6}$$

the inverse of $\mathbf{X}$ on $\mathcal{O}$.

5.2. Properties of the change of variables. In this subsection, we use the change of variables defined by the mapping $\mathbf{X}$ in Lemma 5.2 to transform functions in $\widehat{\mathcal{K}}(\boldsymbol{\zeta}_1)$ (resp., $\mathcal{K}(\boldsymbol{\zeta}_1)$, $M(\boldsymbol{\zeta}_1)$) into functions in $\widehat{\mathcal{K}}(\boldsymbol{\zeta}_2)$ (resp., $\mathcal{K}(\boldsymbol{\zeta}_2)$, $M(\boldsymbol{\zeta}_2)$). We also give the expressions of $\Delta\mathbf{u}$ and ∇p after the transformation.

Consider $(\mathbf{u},\ p) \in \mathcal{H}^1(\mathcal{O}) \times L^2(\mathcal{O})$ and define as in [18] the functions $(\mathbf{U},\ P) \in \mathcal{H}^1(\mathcal{O}) \times L^2(\mathcal{O})$ by

$$\mathbf{U}(\mathbf{y}) = \mathbf{J}_{\mathbf{Y}}(\mathbf{X}(\mathbf{y}))\mathbf{u}(\mathbf{X}(\mathbf{y})) \quad \forall \mathbf{y} \in \mathcal{O}, \tag{5.7}$$

$$P(\mathbf{y}) = p(\mathbf{X}(\mathbf{y})) \quad \forall \mathbf{y} \in \mathcal{O}. \tag{5.8}$$

We can easily check, by using the definition of $\boldsymbol{\Lambda}$, that

$$\mathbf{X}(\mathbf{y}) = \mathbf{y} + \boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2 \quad \forall \mathbf{y} \in B(\boldsymbol{\zeta}_2), \tag{5.9}$$

$$\mathbf{Y}(\mathbf{x}) = \mathbf{x} - \boldsymbol{\zeta}_1 + \boldsymbol{\zeta}_2 \quad \forall \mathbf{x} \in B(\boldsymbol{\zeta}_1), \tag{5.10}$$

Consequently, if $\mathbf{u} \in \mathcal{K}(\boldsymbol{\zeta}_1)$, then $\mathbf{U} \in \mathcal{K}(\boldsymbol{\zeta}_2)$ and if $p \in M(\boldsymbol{\zeta}_1)$, then $P \in M(\boldsymbol{\zeta}_2)$.

By using (5.5), we obtain the following result (see, for instance, [18, Proposition 2.4]).

LEMMA 5.3. *If* $\mathbf{X}$ *is defined by* (5.4)*, then for all* $\mathbf{u} \in \mathcal{H}^1(\mathcal{O})$*, the function* $\mathbf{U}$ *defined as above satisfies the relation*

$$\operatorname{div}\,[\mathbf{U}(\mathbf{y})] = \operatorname{div}\,[\mathbf{u}(\mathbf{X}(\mathbf{y}))] \quad \forall \mathbf{y} \in \mathcal{O}.$$

This lemma implies in particular that if $\mathbf{u} \in \widehat{\mathcal{K}}(\boldsymbol{\zeta}_1)$, then $\mathbf{U} \in \widehat{\mathcal{K}}(\boldsymbol{\zeta}_2)$.

In order to write down the expressions of $\Delta\mathbf{u}$ and ∇p after the change of variables, we define (see [18])

$$\begin{aligned}[\mathbf{L}\mathbf{U}]_i = \sum_{j,k} \frac{\partial}{\partial y_j}\left(g^{jk}\frac{\partial U_i}{\partial y_k}\right) + 2\sum_{j,k,l} g^{kl}\Gamma^i_{jk}\frac{\partial U_j}{\partial y_l} \\ + \sum_{j,k,l}\left\{\frac{\partial}{\partial y_k}(g^{kl}\Gamma^i_{jl}) + \sum_m g^{kl}\Gamma^m_{jl}\Gamma^i_{km}\right\}U_j,\end{aligned} \tag{5.11}$$

$$[\mathbf{G}P]_i = \sum_{j=1}^{2} g^{ij}\frac{\partial P}{\partial y_j}, \tag{5.12}$$

where we denote (see, for instance, [7])

$$g^{ij} = \sum_k \frac{\partial Y_i}{\partial x_k}\frac{\partial Y_j}{\partial x_k} \quad \text{(metric contravariant tensor)}, \tag{5.13}$$

$$g_{ij} = \sum_k \frac{\partial X_k}{\partial y_i}\frac{\partial X_k}{\partial y_j} \quad \text{(metric covariant tensor)}, \tag{5.14}$$

and

$$\Gamma^k_{ij} = \frac{1}{2}\sum_l g^{kl}\left\{\frac{\partial g_{il}}{\partial y_j} + \frac{\partial g_{jl}}{\partial y_i} - \frac{\partial g_{ij}}{\partial y_l}\right\} \quad \text{(Christoffel symbol)}. \tag{5.15}$$

We are now in position to write down the expressions of $\Delta\mathbf{u}$ and ∇p after the change of variables (see again [18] for details).

Proposition 5.4. *Suppose that*

$$(\mathbf{u}, p) \in \mathcal{H}^2(\mathcal{O} \setminus B(\boldsymbol{\zeta}_1)) \times H^1(\mathcal{O} \setminus B(\boldsymbol{\zeta}_1)).$$

Then, we have that

$$(\mathbf{U}, P) \in \mathcal{H}^2(\mathcal{O} \setminus B(\boldsymbol{\zeta}_2)) \times H^1(\mathcal{O} \setminus B(\boldsymbol{\zeta}_2)).$$

Moreover, for all $\mathbf{y} \in \mathcal{O} \setminus B(\boldsymbol{\zeta}_2)$, *we have that*

$$[\mathbf{L}\mathbf{U}](\mathbf{y}) = \mathbf{J}_{\mathbf{Y}}(\mathbf{X}(\mathbf{y}))\ [(\Delta \mathbf{u}) \circ \mathbf{X}]\,(\mathbf{y}), \quad [\mathbf{G}P](\mathbf{y}) = \mathbf{J}_{\mathbf{Y}}(\mathbf{X}(\mathbf{y}))\ [(\nabla p) \circ \mathbf{X}]\,(\mathbf{y}).$$

In the remaining part of this section, we denote by C a positive constant which may depend only on ξ and $\mathcal{O}$. We give below (without proofs) several estimates of the dependence of the change of variables defined in (5.4) on the points $\boldsymbol{\zeta}_1$ and $\boldsymbol{\zeta}_2$. For the proofs of these estimates, we refer to [27] and [28].

Lemma 5.5. *Let* $\boldsymbol{\Lambda}$ *be the function defined by* (5.2). *Then, for all* $\boldsymbol{\zeta}_1,\ \boldsymbol{\zeta}_2 \in \mathcal{O}$ *satisfying* (5.1) *we have*

$$\|\boldsymbol{\Lambda}\|_{\mathcal{L}^\infty(\mathcal{O})} \leqslant C\,|\boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2|\,, \quad \|\nabla \boldsymbol{\Lambda}\|_{[L^\infty(\mathcal{O})]^4} \leqslant C\,|\boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2|\,,$$

$$\left\|\frac{\partial^2 \boldsymbol{\Lambda}}{\partial x_i \partial x_j}\right\|_{\mathcal{L}^\infty(\mathcal{O})} \leqslant C\,|\boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2|\,, \quad \left\|\frac{\partial^3 \boldsymbol{\Lambda}}{\partial x_i \partial x_j \partial x_k}\right\|_{\mathcal{L}^\infty(\mathcal{O})} \leqslant C\,|\boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2|\,.$$

Lemma 5.6. *Let* $\boldsymbol{\Lambda}$, $\boldsymbol{\zeta}_1$, $\boldsymbol{\zeta}_2$ *be as in Lemma* 5.5. *Then the functions* $\mathbf{X}$ *and* $\mathbf{Y}$ *defined by* (5.4) *and* (5.6) *satisfy the following inequalities:*

$$\|\mathbf{X}\|_{\mathcal{L}^\infty(\mathcal{O})} \leqslant C, \quad \|\mathbf{Y}\|_{\mathcal{L}^\infty(\mathcal{O})} \leqslant C,$$

$$\|\mathbf{J}_{\mathbf{X}} - \mathbf{Id}\|_{[L^\infty(\mathcal{O})]^4} \leqslant C\,|\boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2|\,, \quad \|\mathbf{J}_{\mathbf{Y}} - \mathbf{Id}\|_{[L^\infty(\mathcal{O})]^4} \leqslant C\,|\boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2|\,,$$

$$\left\|\frac{\partial^2 Y_i}{\partial x_j \partial x_k}\right\|_{L^\infty(\mathcal{O})} \leqslant C\,|\boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2|\,, \quad \left\|\frac{\partial^2 X_i}{\partial y_j \partial y_k}\right\|_{L^\infty(\mathcal{O})} \leqslant C\,|\boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2|\,,$$

$$\left\|\frac{\partial^3 Y_i}{\partial x_j \partial x_l \partial x_k}\right\|_{L^\infty(\mathcal{O})} \leqslant C\,|\boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2|\,, \quad \left\|\frac{\partial^3 X_i}{\partial y_j \partial y_l \partial y_k}\right\|_{L^\infty(\mathcal{O})} \leqslant C\,|\boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2|\,.$$

Lemma 5.7. *Let* $\boldsymbol{\Lambda}$, $\boldsymbol{\zeta}_1$, $\boldsymbol{\zeta}_2$ *be as in Lemma* 5.5. *Moreover, suppose that*

$$(\mathbf{U}, P) \in \mathcal{H}^2(\mathcal{O} \setminus B(\boldsymbol{\zeta}_2)) \times H^1(\mathcal{O} \setminus B(\boldsymbol{\zeta}_2))$$

and that $\mathbf{L}$ *and* $\mathbf{G}$ *are given by* (5.11) *and* (5.12). *Then we have*

(i) $\|\nu[(\mathbf{L} - \Delta)\mathbf{U}]\|_{\mathcal{L}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}_2))} \leqslant C\,|\boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2|\ \ \|\mathbf{U}\|_{\mathcal{H}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}_2))}$,

(ii) $\|[(\nabla - \mathbf{G})P]\|_{\mathcal{L}^2(\mathcal{O}\setminus B(\boldsymbol{\zeta}_2))} \leqslant C\,|\boldsymbol{\zeta}_1 - \boldsymbol{\zeta}_2|\ \ \|P\|_{H^1(\mathcal{O}\setminus B(\boldsymbol{\zeta}_2))}$.

6. Consistency of the fully discretized scheme. This section is devoted to the consistency of our fully discretized scheme. The main result in this section asserts that the solution $(\mathbf{u}, p, \boldsymbol{\zeta}, \omega)$ of (1.1)–(1.8) satisfies the scheme (3.2)–(3.6) with consistency errors that will be estimated. Since $(\mathbf{u}(t_k), p(t_k))$ belongs to $\mathcal{K}(\boldsymbol{\zeta}(t_k)) \times M(\boldsymbol{\zeta}(t_k))$ and not to $\mathcal{K}(\boldsymbol{\zeta}_h^k) \times M(\boldsymbol{\zeta}_h^k)$, we need the change of variables introduced in the previous section.

6.1. Consistency in time. In this subsection we show that the exact values at instants $t = t_k$ of a strong solution of (1.1)–(1.8) satisfy a perturbed version of the semidiscretized problem introduced in subsection 2.2 and we estimate these perturbations with respect to the time step. The precise statement is given in Lemma 6.1 below.

Consider the solution $(\mathbf{u}, p, \boldsymbol{\zeta}, \omega)$ of (1.1)–(1.8) and assume that (3.8) and (3.10) hold. In what follows, we will use the notation

$$\widetilde{\boldsymbol{X}}(\mathbf{x}) = \widetilde{\boldsymbol{\psi}}(t_k; t_{k+1}, \mathbf{x}) \quad \forall \mathbf{x} \in \mathcal{O}, \tag{6.1}$$

where $\widetilde{\boldsymbol{\psi}}$ is defined by relation (2.6). Note that $\widetilde{\boldsymbol{X}}(\mathcal{O}) = \mathcal{O}$.

Let $\boldsymbol{\varepsilon}_k$, $\boldsymbol{\delta}_k$, $\boldsymbol{\alpha}_k$, $\boldsymbol{\beta}_k$, γ_k be quantities defined by

$$\boldsymbol{\varepsilon}_k = \boldsymbol{\zeta}(t_{k+1}) - \boldsymbol{\zeta}(t_k) - \boldsymbol{\zeta}'(t_k)\Delta t, \tag{6.2}$$

$$\boldsymbol{\delta}_k(t, \mathbf{x}) = \mathbf{u}(\widetilde{\boldsymbol{\psi}}(t; t_{k+1}, \mathbf{x}), t) - \mathbf{u}(\widetilde{\boldsymbol{\psi}}(t; t_{k+1}, \mathbf{x}), t_k), \tag{6.3}$$

$$\boldsymbol{\alpha}_k = \frac{\mathbf{u}(t_{k+1}) - \mathbf{u}(t_k) \circ \widetilde{\boldsymbol{X}}}{\Delta t} - \frac{d}{dt}\left[\mathbf{u} \circ \widetilde{\boldsymbol{\psi}}\right](t_{k+1}), \tag{6.4}$$

$$\boldsymbol{\beta}_k = \frac{\boldsymbol{\zeta}'(t_{k+1}) - \boldsymbol{\zeta}'(t_k)}{\Delta t} - \boldsymbol{\zeta}''(t_{k+1}), \tag{6.5}$$

$$\gamma_k = \frac{\omega'(t_{k+1}) - \omega'(t_k)}{\Delta t} - \omega''(t_{k+1}). \tag{6.6}$$

By using the fact that $\mathbf{u}\left(\boldsymbol{\zeta}(t_k), t_k\right) = \boldsymbol{\zeta}'(t_k)$ and relations (2.6), (1.1), (1.5), and (1.6) together with the above definitions, we infer that the exact solution $(\mathbf{u}, p, \boldsymbol{\zeta}, \omega)$ satisfies

$$\boldsymbol{\zeta}(t_{k+1}) = \boldsymbol{\zeta}(t_k) + \mathbf{u}\left(\boldsymbol{\zeta}(t_k), t_k\right)\Delta t + \boldsymbol{\varepsilon}_k, \tag{6.7}$$

$$\left\{\begin{aligned} &\frac{d}{dt}\widetilde{\boldsymbol{\psi}}(t; t_{k+1}, \mathbf{x}) = \mathbf{u}\left(\widetilde{\boldsymbol{\psi}}(t; t_{k+1}, \mathbf{x}), t_k\right) + \boldsymbol{\delta}_k(t, \mathbf{x}), \\ &\widetilde{\boldsymbol{\psi}}(t_{k+1}; t_{k+1}, \mathbf{x}) = \mathbf{x} \end{aligned}\right. \tag{6.8}$$

for all $\mathbf{x} \in \mathcal{O}$ and for all $t \in [t_k, t_{k+1}]$, together with

$$\frac{\mathbf{u}(t_{k+1}) - \mathbf{u}(t_k) \circ \widetilde{\boldsymbol{X}}}{\Delta t} - \nu\Delta\mathbf{u}(t_{k+1}) + \nabla p(t_{k+1}) = \mathbf{f}^{k+1} + \boldsymbol{\alpha}_k \quad \text{in } \mathcal{O} \setminus B(\boldsymbol{\zeta}(t_{k+1})), \tag{6.9}$$

$$M\frac{\boldsymbol{\zeta}'(t_{k+1}) - \boldsymbol{\zeta}'(t_k)}{\Delta t} = -\int_{\partial B(\boldsymbol{\zeta}(t_{k+1}))} \boldsymbol{\sigma}(t_{k+1})\mathbf{n}\ \mathrm{d}\Gamma + \int_{B(\boldsymbol{\zeta}(t_{k+1}))} \mathbf{f}^{k+1}\ \mathrm{d}\mathbf{x} + \boldsymbol{\beta}_k, \tag{6.10}$$

$$\begin{aligned} J\frac{\omega(t_{k+1}) - \omega(t_k)}{\Delta t} = &-\int_{\partial B(\boldsymbol{\zeta}(t_{k+1}))} (\mathbf{y} - \boldsymbol{\zeta}(t_{k+1}))^{\perp} \cdot \boldsymbol{\sigma}(t_{k+1})\mathbf{n}\ \mathrm{d}\Gamma \\ &+ \int_{B(\boldsymbol{\zeta}(t_{k+1}))} (\mathbf{y} - \boldsymbol{\zeta}(t_{k+1}))^{\perp} \cdot \mathbf{f}^{k+1}\ \mathrm{d}\mathbf{x} + \gamma_k. \end{aligned} \tag{6.11}$$

Moreover, if we denote

$$\theta(t) = \int_0^t \omega(s)\ \mathrm{d}s$$

and by $\mathbf{R}_\theta$ the rotation matrix of angle θ, then we also define the matrix $\mathbf{E}_k$ by

$$\mathbf{R}_{\theta(t_{k+1})-\theta(t_k)} = \mathbf{Id} - \Delta t\,\omega(t_{k+1})\mathbf{R}_{-\pi/2} + \mathbf{E}_k. \tag{6.12}$$

By using the Taylor–Lagrange inequality, we easily obtain the following consistency error estimates.

Lemma 6.1. *The elements $\boldsymbol{\alpha}_k$, $\boldsymbol{\beta}_k$, γ_k, $\boldsymbol{\delta}_k$, $\boldsymbol{\varepsilon}_k$, and $\mathbf{E}_k$ defined by* (6.2)–(6.6) *satisfy the following inequalities:*

$$\begin{gathered} |\boldsymbol{\varepsilon}_k| \leqslant C\,(\Delta t)^2, \quad \|\boldsymbol{\delta}_k\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))} \leqslant C\Delta t \left\|\frac{\partial \mathbf{u}}{\partial t}\right\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))}, \\ \|\boldsymbol{\alpha}_k\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\sqrt{\Delta t}\left\|\frac{d^2}{dt^2}[\mathbf{u}\circ\widetilde{\boldsymbol{\psi}}]\right\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))}, \\ |\boldsymbol{\beta}_k| \leqslant C\Delta t, \quad |\gamma_k| \leqslant C\Delta t, \quad |\mathbf{E}_k| \leqslant C\,(\Delta t)^2. \end{gathered} \tag{6.13}$$

6.2. Transformed system. We need to compare $\mathbf{u}(t_k) \in \mathcal{K}(\boldsymbol{\zeta}(t_k))$, which is a rigid velocity field in $B(\boldsymbol{\zeta}(t_k))$, with $\mathbf{u}_h^k \in \mathcal{K}(\boldsymbol{\zeta}_h^k)$, which is a rigid velocity field in $B(\boldsymbol{\zeta}_h^k)$. This will be done by using the change of variables introduced in section 5.1. To this end, we suppose that $|\boldsymbol{\zeta}_h^k - \boldsymbol{\zeta}(t_k)| < \eta$. This hypothesis and (3.10) imply that

$$\operatorname{dist}(B(\boldsymbol{\zeta}(t_k)), \partial\mathcal{O}) > 2\eta. \tag{6.14}$$

With this assumption, we can transform $\mathbf{u}(t_k)$ by using the change of variables introduced in section 5.1: we denote (see (5.4), (5.6))

$$\mathbf{X}^k = \mathbf{X}_{\boldsymbol{\zeta}_h^k,\boldsymbol{\zeta}(t_k)}, \quad \mathbf{Y}^k = \mathbf{Y}_{\boldsymbol{\zeta}_h^k,\boldsymbol{\zeta}(t_k)}. \tag{6.15}$$

We also define (see (5.7) and (5.8))

$$\begin{gathered} \mathbf{U}^k(\mathbf{y}) = \mathbf{J}_{\mathbf{Y}^k}(\mathbf{X}^k(\mathbf{y}))\mathbf{u}\left(\mathbf{X}^k(\mathbf{y}), t_k\right), \quad P^k(\mathbf{y}) = p^k(\mathbf{X}^k(\mathbf{y})), \\ \boldsymbol{S}^k = -P^k\,\mathbf{Id} + 2\nu\mathbf{D}(\mathbf{U}^k), \quad \mathbf{F}^k(\mathbf{y}) = \mathbf{J}_{\mathbf{Y}^k}(\mathbf{X}^k(\mathbf{y}))\mathbf{f}(\mathbf{X}^k(\mathbf{y}), t_k). \end{gathered} \tag{6.16}$$

We recall that, according to Lemma 5.3, $\mathbf{U}^k \in \widehat{\mathcal{K}}(\boldsymbol{\zeta}_h^k)$ and $P^k \in M(\boldsymbol{\zeta}_h^k)$. We introduce the following notation that will be useful in what follows:

$$\widehat{\boldsymbol{X}} = \mathbf{Y}^k \circ \widetilde{\boldsymbol{X}} \circ \mathbf{X}^{k+1} \tag{6.17}$$

and

$$\widehat{\mathbf{J}} = \left(\mathbf{J}_{\mathbf{Y}^{k+1}} \circ \mathbf{X}^{k+1}\right)\left(\mathbf{J}_{\mathbf{X}^k} \circ \widehat{\boldsymbol{X}}\right). \tag{6.18}$$

Before stating the main result of this section, we give some properties on the characteristics. First note that, according to Lemma 5.2, we have

$$\mathbf{X}^{k+1}(B(\boldsymbol{\zeta}_h^{k+1})) = B(\boldsymbol{\zeta}(t_{k+1})), \tag{6.19}$$

$$\mathbf{Y}^k(B(\boldsymbol{\zeta}(t_k))) = B(\boldsymbol{\zeta}_h^k).$$

Moreover, we can easily check that the function $\widetilde{\boldsymbol{X}}$ defined by (6.1) satisfies

$$\widetilde{\boldsymbol{X}}(\mathbf{x}) = \boldsymbol{\zeta}(t_k) + \mathbf{R}_{\theta(t_{k+1})-\theta(t_k)}(\mathbf{x} - \boldsymbol{\zeta}(t_{k+1})) \quad \forall \mathbf{x} \in B(\boldsymbol{\zeta}(t_{k+1})). \tag{6.20}$$

Consequently, we have

$$\widetilde{\boldsymbol{X}}(B(\boldsymbol{\zeta}(t_{k+1}))) = B(\boldsymbol{\zeta}(t_k)),$$

and therefore, we obtain

$$\widehat{\boldsymbol{X}}(B(\boldsymbol{\zeta}_h^{k+1})) = B(\boldsymbol{\zeta}_h^k). \tag{6.21}$$

We summarize some of the above properties in the following diagram:

$$\begin{tikzcd}
B(\boldsymbol{\zeta}_h^{k+1}) \arrow[r, "\mathbf{X}^{k+1}"] \arrow[d, "\widehat{\boldsymbol{X}}"'] & B(\boldsymbol{\zeta}(t_{k+1})) \arrow[d, "\widetilde{\boldsymbol{X}}"] \\
B(\boldsymbol{\zeta}_h^k) & B(\boldsymbol{\zeta}(t_k)) \arrow[l, "\mathbf{Y}^k"]
\end{tikzcd}$$

Next, we turn to the main result of this subsection: we show that $\mathbf{U}^{k+1}$ and P^{k+1} satisfy a mixed weak formulation with test functions in $\mathcal{K}(\boldsymbol{\zeta}_h^{k+1})$ and $M(\boldsymbol{\zeta}_h^{k+1})$.

Proposition 6.2. *The functions* $(\mathbf{U}^{k+1}, P^{k+1})$ *defined by* (6.16) *satisfy*

$$\begin{aligned} \left(\frac{1}{\Delta t}\left[\mathbf{U}^{k+1} - \widehat{\mathbf{J}}\left(\mathbf{U}^k \circ \widehat{\boldsymbol{X}}\right)\right], \boldsymbol{\varphi}\right) + a(\mathbf{U}^{k+1}, \boldsymbol{\varphi}) + b(\boldsymbol{\varphi}, P^{k+1}) \\ = (\mathbf{f}_h^{k+1}, \boldsymbol{\varphi}) + (\mathbf{A}_k, \boldsymbol{\varphi}) \quad \forall \boldsymbol{\varphi} \in \mathcal{K}(\boldsymbol{\zeta}_h^{k+1}), \end{aligned} \tag{6.22}$$

$$b(\mathbf{U}^{k+1}, q) = 0 \quad \forall q \in M(\boldsymbol{\zeta}_h^{k+1}), \tag{6.23}$$

with

(6.24)

$$\|\mathbf{A}_k\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\left(|\boldsymbol{\zeta}(t_{k+1}) - \boldsymbol{\zeta}_h^{k+1}| + h + \Delta t + C\sqrt{\Delta t}\left\|\frac{d^2}{dt^2}[\mathbf{u} \circ \widetilde{\boldsymbol{\psi}}]\right\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))}\right).$$

Proof.

First step. We transform (6.9).

By using Proposition 5.4, we have that $\mathbf{U}^{k+1}$ and P^{k+1} satisfy

$$\begin{aligned} &\left(\mathbf{J}_{\mathbf{Y}^{k+1}} \circ \mathbf{X}^{k+1}\right) \frac{\mathbf{u}(t_{k+1}) - \mathbf{u}(t_k) \circ \widetilde{\boldsymbol{X}}}{\Delta t} \circ \mathbf{X}^{k+1} - \nu[\mathbf{L}^{k+1}\mathbf{U}^{k+1}] + [\mathbf{G}^{k+1}P^{k+1}] \\ &\quad = \left(\mathbf{J}_{\mathbf{Y}^{k+1}} \circ \mathbf{X}^{k+1}\right)(\mathbf{f}(\mathbf{X}^{k+1}, t_{k+1})) + \left(\mathbf{J}_{\mathbf{Y}^{k+1}} \circ \mathbf{X}^{k+1}\right)(\boldsymbol{\alpha}_{k+1} \circ \mathbf{X}^{k+1}), \\ &\qquad \text{in } \mathcal{O} \setminus B(\boldsymbol{\zeta}_h^{k+1}). \end{aligned}$$

The above relation and (6.16) imply

$$\begin{aligned} &\frac{1}{\Delta t}\left[\mathbf{U}^{k+1} - \left(\mathbf{J}_{\mathbf{Y}^{k+1}} \circ \mathbf{X}^{k+1}\right)\left(\mathbf{J}_{\mathbf{X}^k} \circ \widehat{\boldsymbol{X}}\right)\left(\mathbf{U}^k \circ \widehat{\boldsymbol{X}}\right)\right] - \nu\Delta\mathbf{U}^{k+1} + \nabla P^{k+1} \\ &= \nu[(\mathbf{L}^{k+1} - \Delta)\mathbf{U}^{k+1}] + [(\nabla - \mathbf{G}^{k+1})P^{k+1}] + \mathbf{F}^{k+1} + \left(\mathbf{J}_{\mathbf{Y}^{k+1}} \circ \mathbf{X}^{k+1}\right)(\boldsymbol{\alpha}_{k+1} \circ \mathbf{X}^{k+1}), \\ &\qquad \text{in } \quad \mathcal{O} \setminus B(\boldsymbol{\zeta}_h^{k+1}), \end{aligned} \tag{6.25}$$

where $\widehat{\boldsymbol{X}}$ is defined by (6.17).

By taking the inner product of the previous equation with $\boldsymbol{\varphi} \in \mathcal{K}(\boldsymbol{\zeta}_h^{k+1})$ and by using (6.18), we obtain

$$\text{(6.26)} \quad \int_{\mathcal{O}\setminus B(\boldsymbol{\zeta}_h^{k+1})} \left(\frac{1}{\Delta t} \left[\mathbf{U}^{k+1} - \widehat{\mathbf{J}} \left(\mathbf{U}^k \circ \widehat{\boldsymbol{X}} \right) \right] \cdot \boldsymbol{\varphi} \right) \, \mathrm{d}\mathbf{y} \\ - \int_{\mathcal{O}\setminus B(\boldsymbol{\zeta}_h^{k+1})} \left(\operatorname{div} \boldsymbol{S}^{k+1} \cdot \boldsymbol{\varphi} \right) \, \mathrm{d}\mathbf{y} = \int_{\mathcal{O}\setminus B(\boldsymbol{\zeta}_h^{k+1})} \mathbf{F}^{k+1} \cdot \boldsymbol{\varphi} \, \mathrm{d}\mathbf{y} + A_1$$

with

$$\text{(6.27)} \quad A_1 = \int_{\mathcal{O}\setminus B(\boldsymbol{\zeta}_h^{k+1})} \left(\nu[(\mathbf{L}^{k+1} - \Delta)\mathbf{U}^{k+1}] + [(\nabla - \mathbf{G}^{k+1})P^{k+1}] \right) \cdot \boldsymbol{\varphi} \, \mathrm{d}\mathbf{y} \\ + \int_{\mathcal{O}\setminus B(\boldsymbol{\zeta}_h^{k+1})} \left(\mathbf{J}_{\mathbf{Y}^{k+1}} \circ \mathbf{X}^{k+1} \right) \left(\boldsymbol{\alpha}_{k+1} \circ \mathbf{X}^{k+1} \right) \cdot \boldsymbol{\varphi} \, \mathrm{d}\mathbf{y}.$$

Second step. We transform the integral

$$\int_{B(\boldsymbol{\zeta}_h^{k+1})} \frac{\mathbf{U}^{k+1} - \widehat{\mathbf{J}} \left(\mathbf{U}^k \circ \widehat{\boldsymbol{X}} \right)}{\Delta t} \cdot \boldsymbol{\varphi} \, \mathrm{d}\mathbf{y}$$

by using (6.10)–(6.11). From (5.3) (with $\mathbf{Y}^{k+1}$ as in (6.15)), combined with (5.9) and with (5.10), we obtain that

$$\text{(6.28)} \qquad \mathbf{J}_{\mathbf{Y}^{k+1}}(\mathbf{x}) = \mathbf{Id} \quad \forall \mathbf{x} \in B(\boldsymbol{\zeta}(t_{k+1})).$$

The above relation, (6.16), and (5.9) imply that for all $\mathbf{y} \in B(\boldsymbol{\zeta}_h^{k+1})$,

$$\text{(6.29)} \qquad \mathbf{U}^{k+1}(\mathbf{y}) = \mathbf{u} \left(\mathbf{y} + \boldsymbol{\zeta}(t_{k+1}) - \boldsymbol{\zeta}_h^{k+1}, t_{k+1} \right).$$

In particular, we have that

$$\text{(6.30)} \qquad \mathbf{U}^{k+1}(\mathbf{y}) = \boldsymbol{\zeta}'(t_{k+1}) + \omega(t_{k+1})(\mathbf{y} - \boldsymbol{\zeta}_h^{k+1})^{\perp} \quad \forall \mathbf{y} \in B(\boldsymbol{\zeta}_h^{k+1}).$$

Similarly, we have

$$\text{(6.31)} \qquad \mathbf{U}^{k}(\mathbf{y}) = \boldsymbol{\zeta}'(t_{k}) + \omega(t_{k})(\mathbf{y} - \boldsymbol{\zeta}_h^{k})^{\perp} \quad \forall \mathbf{y} \in B(\boldsymbol{\zeta}_h^{k}).$$

Relations (6.19) and (6.21) yield

$$\text{(6.32)} \qquad \left(\mathbf{J}_{\mathbf{Y}^{k+1}} \circ \mathbf{X}^{k+1} \right) \left(\mathbf{J}_{\mathbf{X}^{k}} \circ \widehat{\boldsymbol{X}} \right) = \mathbf{Id} \quad \text{in} \quad B(\boldsymbol{\zeta}_h^{k+1}).$$

Simple calculations combined with relations (5.9) and (6.20) yield

$$\widehat{\boldsymbol{X}}(\mathbf{y}) = \mathbf{R}_{\theta(t_{k+1})-\theta(t_k)}(\mathbf{y} - \boldsymbol{\zeta}_h^{k+1}) + \boldsymbol{\zeta}_h^{k} \quad \forall \mathbf{y} \in B(\boldsymbol{\zeta}_h^{k+1}).$$

The above relation, (6.32), and (6.31) imply that for all $\mathbf{y} \in B(\boldsymbol{\zeta}_h^{k+1})$, we have that

$$\widehat{\mathbf{J}}(\mathbf{U}^k \circ \widehat{\boldsymbol{X}})(\mathbf{y}) = \boldsymbol{\zeta}'(t_k) + \omega(t_k)\mathbf{R}_{\theta(t_{k+1})-\theta(t_k)}(\mathbf{y} - \boldsymbol{\zeta}_h^{k+1})^{\perp}.$$

By using (6.12), the previous equality can be written as

$$\begin{aligned}\widehat{\mathbf{J}}(\mathbf{U}^k \circ \widehat{\boldsymbol{X}})(\mathbf{y}) &= \boldsymbol{\zeta}'(t_k) + \omega(t_k)(\mathbf{y} - \boldsymbol{\zeta}_h^{k+1})^\perp \\ &\quad + \Delta t\ \omega(t_k)\omega(t_{k+1})(\mathbf{y} - \boldsymbol{\zeta}_h^{k+1}) + \omega(t_k)\mathbf{E}_k(\mathbf{y} - \boldsymbol{\zeta}_h^{k+1})^\perp \quad \forall \mathbf{y} \in B(\boldsymbol{\zeta}_h^{k+1}).\end{aligned}$$

By taking the inner product of the above relation with $\boldsymbol{\varphi} \in \mathcal{K}(\boldsymbol{\zeta}_h^{k+1})$ and by integrating on $B(\boldsymbol{\zeta}_h^{k+1})$, we obtain that

$$\begin{aligned}(6.33)\quad \int_{B(\boldsymbol{\zeta}_h^{k+1})} \widehat{\mathbf{J}}(\mathbf{U}^k \circ \widehat{\boldsymbol{X}})(\mathbf{y}) \cdot \boldsymbol{\varphi}\ \mathrm{d}\mathbf{y} &= M\mathbf{l}_{\boldsymbol{\varphi}} \cdot \boldsymbol{\zeta}'(t_k) + J\omega(t_k)\omega_{\boldsymbol{\varphi}} \\ &\quad + \omega(t_k) \int_{B(\boldsymbol{\zeta}_h^{k+1})} \mathbf{E}_k(\mathbf{y} - \boldsymbol{\zeta}_h^{k+1})^\perp \cdot \boldsymbol{\varphi}\ \mathrm{d}\mathbf{y}.\end{aligned}$$

Relation (6.30) implies that, for all $\boldsymbol{\varphi} \in \mathcal{K}(\boldsymbol{\zeta}_h^{k+1})$, we have

$$\int_{B(\boldsymbol{\zeta}_h^{k+1})} \mathbf{U}^{k+1} \cdot \boldsymbol{\varphi}\ \mathrm{d}\mathbf{y} = M\mathbf{l}_{\boldsymbol{\varphi}} \cdot \boldsymbol{\zeta}'(t_{k+1}) + J\omega(t_{k+1})\omega_{\boldsymbol{\varphi}}.$$

The above equality and (6.33) yield that, for all $\boldsymbol{\varphi} \in \mathcal{K}(\boldsymbol{\zeta}_h^{k+1})$, we have

$$\begin{aligned}\int_{B(\boldsymbol{\zeta}_h^{k+1})} \frac{\mathbf{U}^{k+1} - \widehat{\mathbf{J}}(\mathbf{U}^k \circ \widehat{\boldsymbol{X}})}{\Delta t} \cdot \boldsymbol{\varphi}\ \mathrm{d}\mathbf{y} &= M\mathbf{l}_{\boldsymbol{\varphi}} \cdot \frac{\boldsymbol{\zeta}'(t_{k+1}) - \boldsymbol{\zeta}'(t_k)}{\Delta t} \\ &\quad + J\frac{\omega(t_{k+1}) - \omega(t_k)}{\Delta t}\omega_{\boldsymbol{\varphi}} - \frac{\omega(t_k)}{\Delta t} \int_{B(\boldsymbol{\zeta}_h^{k+1})} \mathbf{E}_k(\mathbf{y} - \boldsymbol{\zeta}_h^{k+1})^\perp \cdot \boldsymbol{\varphi}\ \mathrm{d}\mathbf{y}.\end{aligned}$$

The above relation and (6.10)–(6.11) imply that

$$\begin{aligned}(6.34)\quad \int_{B(\boldsymbol{\zeta}_h^{k+1})} \frac{\mathbf{U}^{k+1} - \widehat{\mathbf{J}}(\mathbf{U}^k \circ \widehat{\boldsymbol{X}})}{\Delta t} \cdot \boldsymbol{\varphi}\ \mathrm{d}\mathbf{y} &= -\mathbf{l}_{\boldsymbol{\varphi}} \cdot \int_{\partial B(\boldsymbol{\zeta}(t_{k+1}))} \boldsymbol{\sigma}^{k+1}\mathbf{n}\ \mathrm{d}\Gamma \\ - \omega_{\boldsymbol{\varphi}} \int_{\partial B(\boldsymbol{\zeta}(t_{k+1}))} (\mathbf{y} - \boldsymbol{\zeta}(t_{k+1}))^\perp \cdot \boldsymbol{\sigma}^{k+1}\mathbf{n}\ \mathrm{d}\Gamma &+ \mathbf{l}_{\boldsymbol{\varphi}} \cdot \int_{B(\boldsymbol{\zeta}(t_{k+1}))} \mathbf{f}^{k+1}\ \mathrm{d}\mathbf{x} \\ + \omega_{\boldsymbol{\varphi}} \int_{B(\boldsymbol{\zeta}(t_{k+1}))} &(\mathbf{x} - \boldsymbol{\zeta}(t_{k+1}))^\perp \cdot \mathbf{f}^{k+1}(x)\ \mathrm{d}\mathbf{x} \\ &+ \mathbf{l}_{\boldsymbol{\varphi}} \cdot \boldsymbol{\beta}_k + \omega_{\boldsymbol{\varphi}}\gamma_k - \frac{\omega(t_k)}{\Delta t} \int_{B(\boldsymbol{\zeta}_h^{k+1})} \mathbf{E}_k(\mathbf{y} - \boldsymbol{\zeta}_h^{k+1})^\perp \cdot \boldsymbol{\varphi}\ \mathrm{d}\mathbf{y}.\end{aligned}$$

On the other hand, by using relations (5.9), (5.10), and (6.28), we easily obtain that

$$\int_{\partial B(\boldsymbol{\zeta}_h^{k+1})} \boldsymbol{S}^{k+1}\mathbf{n}\ \mathrm{d}\Gamma = \int_{\partial B(\boldsymbol{\zeta}(t_{k+1}))} \boldsymbol{\sigma}^{k+1}\mathbf{n}\ \mathrm{d}\Gamma$$

and that

$$\int_{\partial B(\boldsymbol{\zeta}_h^{k+1})} (\mathbf{y} - \boldsymbol{\zeta}_h^{k+1})^\perp \cdot \boldsymbol{S}^{k+1}\mathbf{n}\ \mathrm{d}\Gamma = \int_{\partial B(\boldsymbol{\zeta}(t_{k+1}))} (\mathbf{y} - \boldsymbol{\zeta}(t_{k+1}))^\perp \cdot \boldsymbol{\sigma}^{k+1}\mathbf{n}\ \mathrm{d}\Gamma.$$

The above relations and (6.34) yield that

$$(6.35)\quad \int_{B(\boldsymbol{\zeta}_h^{k+1})} \frac{\mathbf{U}^{k+1} - \widehat{\mathbf{J}}(\mathbf{U}^k \circ \widehat{\boldsymbol{X}})}{\Delta t} \cdot \boldsymbol{\varphi} \, \mathrm{d}\mathbf{y} = - \int_{\partial B(\boldsymbol{\zeta}_h^{k+1})} \Big(\boldsymbol{S}^{k+1} \mathbf{n} \Big) \cdot \boldsymbol{\varphi} \, \mathrm{d}\Gamma$$
$$+ \int_{B(\boldsymbol{\zeta}_h^{k+1})} \mathbf{F}^{k+1} \cdot \boldsymbol{\varphi} \, \mathrm{d}\mathbf{y} + \mathbf{l}_{\boldsymbol{\varphi}} \cdot \boldsymbol{\beta}_k + \omega_{\boldsymbol{\varphi}} \gamma_k - \frac{\omega(t_k)}{\Delta t} \int_{B(\boldsymbol{\zeta}_h^{k+1})} \mathbf{E}_k (\mathbf{y} - \boldsymbol{\zeta}_h^{k+1})^{\perp} \cdot \boldsymbol{\varphi} \, \mathrm{d}\mathbf{y}.$$

Third step. By integrating by parts, we have that

$$(6.36)\quad 2\nu \int_{\mathcal{O} \setminus B(\boldsymbol{\zeta}_h^{k+1})} \mathbf{D}(\mathbf{U}^{k+1}) : \mathbf{D}(\boldsymbol{\varphi}) \, \mathrm{d}\mathbf{y} - \int_{\mathcal{O} \setminus B(\boldsymbol{\zeta}_h^{k+1})} P^{k+1} \operatorname{div}(\boldsymbol{\varphi}) \, \mathrm{d}\mathbf{y}$$
$$= \int_{\partial B(\boldsymbol{\zeta}_h^{k+1})} \Big(\boldsymbol{S}^{k+1} \mathbf{n} \Big) \cdot \boldsymbol{\varphi} \, \mathrm{d}\Gamma - \int_{\mathcal{O} \setminus B(\boldsymbol{\zeta}_h^{k+1})} \operatorname{div}(\boldsymbol{S}^{k+1}) \cdot \boldsymbol{\varphi} \, \mathrm{d}\mathbf{y}.$$

Summing (6.36), (6.35), and (6.26) yields (6.22) with

$$(\mathbf{A}_k, \boldsymbol{\varphi}) = (\mathbf{F}^{k+1} - \mathbf{f}_h^{k+1}, \boldsymbol{\varphi}) + \mathbf{l}_{\boldsymbol{\varphi}} \cdot \boldsymbol{\beta}_k + \omega_{\boldsymbol{\varphi}} \gamma_k - \frac{\omega(t_k)}{\Delta t} \int_{B(\boldsymbol{\zeta}_h^{k+1})} \mathbf{E}_k (\mathbf{y} - \boldsymbol{\zeta}_h^{k+1})^{\perp} \cdot \boldsymbol{\varphi} \, \mathrm{d}\mathbf{y}$$
$$+ \int_{\mathcal{O} \setminus B(\boldsymbol{\zeta}_h^{k+1})} \big(\nu [(\mathbf{L}^{k+1} - \Delta) \mathbf{U}^{k+1}] + [(\nabla - \mathbf{G}^{k+1}) P^{k+1}] \big) \cdot \boldsymbol{\varphi} \, \mathrm{d}\mathbf{y}$$
$$+ \int_{\mathcal{O} \setminus B(\boldsymbol{\zeta}_h^{k+1})} \big(\mathbf{J}_{\mathbf{Y}^{k+1}} \circ \mathbf{X}^{k+1} \big) \left(\boldsymbol{\alpha}_{k+1} \circ \mathbf{X}^{k+1} \right) \cdot \boldsymbol{\varphi} \, \mathrm{d}\mathbf{y}.$$

The above relation, combined with relation (3.7) and Lemmas 5.6, 5.7, and 6.1, implies the proposition. □

6.3. Some results on characteristics. In this subsection, we give some results on the functions $\mathbf{X}^k$, $\widehat{\boldsymbol{X}}$, and $\overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}$ that will be used in the proof of the main result.

LEMMA 6.3. *There exists a positive constant C independent of h and k such that*

$$\|\mathbf{X}^{k+1} - \mathbf{X}^k\|_{\mathcal{L}^\infty(\mathcal{O})} \leqslant C \left(\|\mathbf{u}_h^k - \mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})} \Delta t + |\boldsymbol{\varepsilon}_k| \right).$$

Proof. We denote by $\boldsymbol{\Lambda}^k$ (resp., $\boldsymbol{\Lambda}^{k+1}$) the mapping defined by (5.2) with $\boldsymbol{\zeta}_1 = \boldsymbol{\zeta}(t_k)$ and $\boldsymbol{\zeta}_2 = \boldsymbol{\zeta}_h^k$ (resp., $\boldsymbol{\zeta}_1 = \boldsymbol{\zeta}(t_{k+1})$ and $\boldsymbol{\zeta}_2 = \boldsymbol{\zeta}_h^{k+1}$). Let $\boldsymbol{\psi}^k$ and $\boldsymbol{\psi}^{k+1}$ be the solution of (5.3) corresponding to the velocity fields $\boldsymbol{\Lambda}^k$ and $\boldsymbol{\Lambda}^{k+1}$, respectively.

By using (5.3), we have that

$$(\boldsymbol{\psi}^{k+1} - \boldsymbol{\psi}^k)(\lambda) = \int_0^\lambda \boldsymbol{\Lambda}^{k+1}(\boldsymbol{\psi}^{k+1}(\mu)) - \boldsymbol{\Lambda}^k(\boldsymbol{\psi}^k(\mu)) \, \mathrm{d}\mu.$$

Therefore, by Lemma 5.5, there exists a positive constant C such that for all $\lambda \in [0,1]$, we have that

$$\left| (\boldsymbol{\psi}^{k+1} - \boldsymbol{\psi}^k)(\lambda) \right| \leqslant \|\boldsymbol{\Lambda}^{k+1} - \boldsymbol{\Lambda}^k\|_{\mathcal{L}^\infty(\mathcal{O})} + C \int_0^\lambda \left| (\boldsymbol{\psi}^{k+1}(\mu) - \boldsymbol{\psi}^k(\mu)) \right| \, \mathrm{d}\mu.$$

The above inequality and Gronwall's lemma yield

$$\left| (\boldsymbol{\psi}^{k+1} - \boldsymbol{\psi}^k)(\lambda) \right| \leqslant C \|\boldsymbol{\Lambda}^{k+1} - \boldsymbol{\Lambda}^k\|_{\mathcal{L}^\infty(\mathcal{O})}$$

for all $\lambda \in [0,1]$. In particular, for $\lambda = 1$, we have that

$$\|\mathbf{X}^{k+1} - \mathbf{X}^k\|_{\mathcal{L}^\infty(\mathcal{O})} \leqslant C\|\mathbf{\Lambda}^{k+1} - \mathbf{\Lambda}^k\|_{\mathcal{L}^\infty(\mathcal{O})}. \tag{6.37}$$

By using relation (5.2), there exists a positive constant C such that

$$\|\mathbf{\Lambda}^{k+1} - \mathbf{\Lambda}^k\|_{\mathcal{L}^\infty(\mathcal{O})} \leqslant C|\boldsymbol{\zeta}(t_{k+1}) - \boldsymbol{\zeta}_h^{k+1} - \boldsymbol{\zeta}(t_k) + \boldsymbol{\zeta}_h^k|.$$

The above relation, combined with (3.2) and (6.7), yields

$$\|\mathbf{\Lambda}^{k+1} - \mathbf{\Lambda}^k\|_{\mathcal{L}^\infty(\mathcal{O})} \leqslant C|\mathbf{u}_h^k(\boldsymbol{\zeta}_h^k) - \mathbf{u}\left(\boldsymbol{\zeta}(t_k), t_k\right)|\Delta t + C|\boldsymbol{\varepsilon}_k|. \tag{6.38}$$

On the other hand, by (6.29), we have $\mathbf{u}\left(\boldsymbol{\zeta}(t_k), t_k\right) = \mathbf{U}^k(\boldsymbol{\zeta}_h^k)$ and, moreover, $\mathbf{u}_h^k - \mathbf{U}^k \in \mathcal{K}(\boldsymbol{\zeta}_h^k)$. Then, owing to (2.5), we readily check that

$$|\mathbf{u}_h^k(\boldsymbol{\zeta}_h^k) - \mathbf{U}^k(\boldsymbol{\zeta}_h^k)| \leqslant \frac{1}{\sqrt{M}}\|\mathbf{u}_h^k - \mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})}. \tag{6.39}$$

Therefore, the above relation and (6.38) imply that

$$\|\mathbf{\Lambda}^{k+1} - \mathbf{\Lambda}^k\|_{\mathcal{L}^\infty(\mathcal{O})} \leqslant C\|\mathbf{u}_h^k - \mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})}\Delta t + C|\boldsymbol{\varepsilon}_k|. \tag{6.40}$$

Relations (6.37) and (6.40) yield the conclusion of the lemma. □

A similar estimate holds for the jacobian matrices $\mathbf{J}_{\mathbf{X}^{k+1}}$ and $\mathbf{J}_{\mathbf{X}^k}$. Since the proof of this estimate is completely similar to the proof of Lemma 6.3, we give below only its statement and skip the proof.

Lemma 6.4. *There exists a positive constant C independent of k and h such that*

$$\|\mathbf{J}_{\mathbf{X}^{k+1}} - \mathbf{J}_{\mathbf{X}^k}\|_{\mathcal{L}^\infty(\mathcal{O})} \leqslant C\left(\|\mathbf{u}_h^k - \mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})}\Delta t + |\boldsymbol{\varepsilon}_k|\right).$$

The functions $\widehat{\boldsymbol{X}}$ and $\overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}$ are close to the identity in the sense made precise below.

Lemma 6.5. *The functions $\widehat{\boldsymbol{X}}$ and $\overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}$ defined by* (6.17) *and* (3.4) *satisfy the following estimates:*

$$\|\widehat{\boldsymbol{X}} - \mathbf{Id}\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\left(|\boldsymbol{\varepsilon}_k| + \Delta t\|\mathbf{U}^k - \mathbf{u}_h^k\|_{\mathcal{L}^2(\mathcal{O})} + \sqrt{\Delta t}\|\boldsymbol{\delta}_k\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))} + \Delta t\right), \tag{6.41}$$

$$\|\widehat{\boldsymbol{X}} - \overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\left(|\boldsymbol{\varepsilon}_k| + \Delta t\|\mathbf{U}^k - \mathbf{u}_h^k\|_{\mathcal{L}^2(\mathcal{O})} + \sqrt{\Delta t}\|\boldsymbol{\delta}_k\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))} + h\Delta t\right). \tag{6.42}$$

Proof. Let us define

$$\widehat{\boldsymbol{\psi}}(t; t_{k+1}, \mathbf{y}) = \mathbf{Y}^k(\widetilde{\boldsymbol{\psi}}(t; t_{k+1}, \mathbf{X}^{k+1}(\mathbf{y}))), \tag{6.43}$$

where $\widetilde{\boldsymbol{\psi}}$ is defined by (2.6). Note that $\widehat{\boldsymbol{\psi}}(t_k; t_{k+1}, \mathbf{y}) = \widehat{\boldsymbol{X}}(\mathbf{y})$ for all $\mathbf{y} \in \mathcal{O}$.

We have that

$$\frac{d}{dt}\widehat{\boldsymbol{\psi}}(t; t_{k+1}, \mathbf{y}) = \mathbf{J}_{\mathbf{Y}^k}(\widetilde{\boldsymbol{\psi}}(t; t_{k+1}, \mathbf{X}^{k+1}(\mathbf{y})))\frac{d}{dt}\widetilde{\boldsymbol{\psi}}(t; t_{k+1}, \mathbf{X}^{k+1}(\mathbf{y})).$$

By using (6.8) we obtain that

$$\begin{aligned}\frac{d}{dt}\widehat{\boldsymbol{\psi}}(t; t_{k+1}, \mathbf{y}) = {} & \left[\mathbf{J}_{\mathbf{Y}^k} \circ \mathbf{X}^k\right](\widehat{\boldsymbol{\psi}}(t; t_{k+1}, \mathbf{y}))\left[\mathbf{u}\left(\mathbf{X}^k\left(\widehat{\boldsymbol{\psi}}(t; t_{k+1}, \mathbf{y})\right), t_k\right)\right] \\ & + \left[\mathbf{J}_{\mathbf{Y}^k} \circ \mathbf{X}^k\right](\widehat{\boldsymbol{\psi}}(t; t_{k+1}, \mathbf{y}))\left[\boldsymbol{\delta}_k\left(t, \mathbf{X}^k\left(\widehat{\boldsymbol{\psi}}(t; t_{k+1}, \mathbf{y})\right)\right)\right].\end{aligned}$$

The above relation and (6.16) yield

$$\frac{d}{dt}\widehat{\boldsymbol{\psi}}(t;t_{k+1},\mathbf{y}) = \mathbf{U}^k(\widehat{\boldsymbol{\psi}}(t;t_{k+1},\mathbf{y})) + \left[\mathbf{J}_{\mathbf{Y}^k}\circ\mathbf{X}^k\right](\widehat{\boldsymbol{\psi}}(t;t_{k+1},\mathbf{y}))\left[\boldsymbol{\delta}_k\left(t,\mathbf{X}^k\left(\widehat{\boldsymbol{\psi}}(t;t_{k+1},\mathbf{y})\right)\right)\right]. \tag{6.44}$$

On the other hand, we have that

$$\widehat{\boldsymbol{\psi}}(t_{k+1};t_{k+1},\mathbf{y}) = \mathbf{Y}^k\circ\mathbf{X}^{k+1}(\mathbf{y}). \tag{6.45}$$

Therefore, by using (6.44) and (6.45), we get

$$\widehat{\boldsymbol{X}}(\mathbf{y})-\mathbf{y} = \mathbf{Y}^k\circ\mathbf{X}^{k+1}(\mathbf{y})-\mathbf{y}-\int_{t_k}^{t_{k+1}}\mathbf{U}^k(\widehat{\boldsymbol{\psi}}(t;t_{k+1},\mathbf{y}))\,\mathrm{d}t - \int_{t_k}^{t_{k+1}}\left[\mathbf{J}_{\mathbf{Y}^k}\circ\mathbf{X}^k\right](\widehat{\boldsymbol{\psi}}(t;t_{k+1},\mathbf{y}))\left[\boldsymbol{\delta}_k\left(t,\mathbf{X}^k\left(\widehat{\boldsymbol{\psi}}(t;t_{k+1},\mathbf{y})\right)\right)\right]\,\mathrm{d}t,$$

which yields

$$\|\widehat{\boldsymbol{X}}-\mathbf{Id}\|_{\mathcal{L}^2(\mathcal{O})} \leqslant \|\mathbf{Y}^k\circ\mathbf{X}^{k+1}-\mathbf{Id}\|_{\mathcal{L}^2(\mathcal{O})} + \int_{t_k}^{t_{k+1}}\left\|\mathbf{U}^k(\widehat{\boldsymbol{\psi}}(s))\right\|_{\mathcal{L}^2(\mathcal{O})}\,\mathrm{d}s + C\sqrt{\Delta t}\|\boldsymbol{\delta}_k\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))}. \tag{6.46}$$

By Lemma 5.6, there exists a positive constant C such that

$$\|\mathbf{Y}^k\circ\mathbf{X}^{k+1}-\mathbf{Id}\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\|\mathbf{X}^{k+1}-\mathbf{X}^k\|_{\mathcal{L}^\infty(\mathcal{O})}.$$

The above relation and Lemma 6.3 yield

$$\|\mathbf{Y}^k\circ\mathbf{X}^{k+1}-\mathbf{Id}\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\left(\Delta t\|\mathbf{u}_h^k-\mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})}+|\boldsymbol{\varepsilon}_k|\right). \tag{6.47}$$

Relations (6.46) and (6.47), together with (3.8) and (6.16), imply

$$\|\widehat{\boldsymbol{X}}-\mathbf{Id}\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\left(\Delta t\|\mathbf{u}_h^k-\mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})}+|\boldsymbol{\varepsilon}_k|\right)+C\Delta t+\sqrt{\Delta t}\|\boldsymbol{\delta}_k\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))}.$$

Therefore, we deduce (6.41).

Now we turn to the proof of (6.42): by using (3.3), (6.44), and (6.45), we obtain

$$\widehat{\boldsymbol{\psi}}(t;t_{k+1},\mathbf{y})-\overline{\boldsymbol{\psi}}_{\boldsymbol{h}}^{\boldsymbol{k}}(t;t_{k+1},\mathbf{y}) = \mathbf{Y}^k\circ\mathbf{X}^{k+1}(\mathbf{y})-\mathbf{y} - \int_t^{t_{k+1}}\left(\mathbf{U}^k(\widehat{\boldsymbol{\psi}}(s;t_{k+1},\mathbf{y}))-\mathbf{P}\mathbf{u}_h^k(\overline{\boldsymbol{\psi}}_{\boldsymbol{h}}^{\boldsymbol{k}}(s;t_{k+1},\mathbf{y}))\right)\,\mathrm{d}s - \int_t^{t_{k+1}}(\mathbf{J}_{\mathbf{Y}^k}\circ\mathbf{X}^k)(\widehat{\boldsymbol{\psi}}(s;t_{k+1},\mathbf{y}))\left[\boldsymbol{\delta}_k\left(s,\mathbf{X}^k\left(\widehat{\boldsymbol{\psi}}(s;t_{k+1},\mathbf{y})\right)\right)\right]\,\mathrm{d}s,$$

which yields

$$\|\widehat{\boldsymbol{\psi}}(t)-\overline{\boldsymbol{\psi}}_{\boldsymbol{h}}^{\boldsymbol{k}}(t)\|_{\mathcal{L}^2(\mathcal{O})} \leqslant \|\mathbf{Y}^k\circ\mathbf{X}^{k+1}-\mathbf{Id}\|_{\mathcal{L}^2(\mathcal{O})} + \int_t^{t_{k+1}}\left\|\mathbf{U}^k(\widehat{\boldsymbol{\psi}}(s))-\mathbf{P}\mathbf{u}_h^k(\overline{\boldsymbol{\psi}}_{\boldsymbol{h}}^{\boldsymbol{k}}(s))\right\|_{\mathcal{L}^2(\mathcal{O})}\,\mathrm{d}s + C\sqrt{\Delta t}\|\boldsymbol{\delta}_k\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))}. \tag{6.48}$$

Relations (6.48) and (6.47) imply

$$\begin{aligned}\|\widehat{\boldsymbol{\psi}}(t)-\overline{\boldsymbol{\psi}}_{\boldsymbol{h}}^{\boldsymbol{k}}(t)\|_{\mathcal{L}^2(\mathcal{O})} &\leqslant C\left(\Delta t\|\mathbf{u}_h^k-\mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})}+|\boldsymbol{\varepsilon}_k|\right)\\ &\quad+\int_t^{t_{k+1}}\left\|\mathbf{U}^k(\widehat{\boldsymbol{\psi}}(s))-\mathbf{P}\mathbf{u}_h^k(\overline{\boldsymbol{\psi}}_{\boldsymbol{h}}^{\boldsymbol{k}}(s))\right\|_{\mathcal{L}^2(\mathcal{O})}\,\mathrm{d}s+C\sqrt{\Delta t}\|\boldsymbol{\delta}_k\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))}.\end{aligned}$$

By using (3.8) and Remark 3.1, we have that

$$\begin{aligned}\|\widehat{\boldsymbol{\psi}}(t)-\overline{\boldsymbol{\psi}}_{\boldsymbol{h}}^{\boldsymbol{k}}(t)\|_{\mathcal{L}^2(\mathcal{O})} &\leqslant C\left(\Delta t\|\mathbf{u}_h^k-\mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})}+|\boldsymbol{\varepsilon}_k|+\Delta t\|\mathbf{U}^k-\mathbf{P}\mathbf{u}_h^k\|_{\mathcal{L}^2(\mathcal{O})}\right)\\ &\quad+C\int_t^{t_{k+1}}\left\|\widehat{\boldsymbol{\psi}}(s)-\overline{\boldsymbol{\psi}}_{\boldsymbol{h}}^{\boldsymbol{k}}(s)\right\|_{\mathcal{L}^2(\mathcal{O})}\,\mathrm{d}s+C\sqrt{\Delta t}\|\boldsymbol{\delta}_k\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))}.\end{aligned}$$

Therefore, by Gronwall's lemma, we get that

$$\begin{aligned}\|\widehat{\boldsymbol{\psi}}(t)-\overline{\boldsymbol{\psi}}_{\boldsymbol{h}}^{\boldsymbol{k}}(t)\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\Big(&\Delta t\|\mathbf{u}_h^k-\mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})}+|\boldsymbol{\varepsilon}_k|+\Delta t\|\mathbf{U}^k-\mathbf{P}\mathbf{u}_h^k\|_{\mathcal{L}^2(\mathcal{O})}\\ &+\sqrt{\Delta t}\|\boldsymbol{\delta}_k\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))}\Big).\end{aligned}$$

In particular for $t=t_k$, we obtain that

$$\begin{aligned}\|\widehat{\boldsymbol{X}}-\overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\Big(&\Delta t\|\mathbf{u}_h^k-\mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})}+|\boldsymbol{\varepsilon}_k|+\Delta t\|\mathbf{U}^k-\mathbf{P}\mathbf{u}_h^k\|_{\mathcal{L}^2(\mathcal{O})}\\ &+\sqrt{\Delta t}\|\boldsymbol{\delta}_k\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))}\Big).\end{aligned}\tag{6.49}$$

Since $\mathbf{P}$ is an orthogonal projection in $\mathcal{L}^2(\mathcal{O})$, we have that

$$\|\mathbf{U}^k-\mathbf{P}\mathbf{u}_h^k\|_{\mathcal{L}^2(\mathcal{O})}\leqslant\|\mathbf{U}^k-\mathbf{u}_h^k\|_{\mathcal{L}^2(\mathcal{O})}+\|\mathbf{P}\mathbf{U}^k-\mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})}.\tag{6.50}$$

Now, since $\mathbf{U}^k\in\mathcal{H}_0^1(\mathcal{O})$ and $\operatorname{div}(\mathbf{U}^k)=0$, there exists a stream function $\psi\in H^2(\mathcal{O})\cap H_0^1(\mathcal{O})$ of $\mathbf{U}^k$, i.e., $\mathbf{U}^k=\mathbf{rot}\ \psi$. Let ψ_h be the Lagrange interpolated function of ψ on the triangulation $\mathcal{T}_h$. We denote $\widetilde{\mathbf{U}_h^k}=\mathbf{rot}\ \psi_h$. Since $\widetilde{\mathbf{U}_h^k}\in\mathcal{R}_h$, we have that

$$\begin{aligned}\|\mathbf{P}\mathbf{U}^k-\mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})}&\leqslant\|\widetilde{\mathbf{U}_h^k}-\mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})}=\|\mathbf{rot}\ (\psi-\psi_h)\|_{\mathcal{L}^2(\mathcal{O})}\\ &\leqslant Ch\|\psi\|_{H^2(\mathcal{O})}\leqslant Ch\|\mathbf{U}^k\|_{\mathcal{H}^1(\mathcal{O})}.\end{aligned}$$

The above equation, (6.49), and (6.50) imply the result. □

7. Proof of the main result.

We can now prove Theorem 3.2.

First step. Assume that $h\leq C(\Delta t)^2$. We first show that if (3.10) holds and if

$$\operatorname{dist}(B(\boldsymbol{\zeta}_h^k),\partial\mathcal{O})>2\eta,\quad \operatorname{dist}(B(\boldsymbol{\zeta}_h^{k+1}),\partial\mathcal{O})>2\eta,\tag{7.1}$$

then there exist two positive constants C_0 and C_1 independent of Δt and h such that the error $e_h^k=\|\mathbf{U}^k-\mathbf{u}_h^k\|_{\mathcal{L}^2(\mathcal{O})}+|\boldsymbol{\zeta}(t_k)-\boldsymbol{\zeta}_h^k|$ satisfies the following inequality:

$$e_h^{k+1}\leqslant e_h^k(1+C_0\Delta t)+C_0\Delta t\beta_h^k,\tag{7.2}$$

where

$$\sum_{k=0}^N\beta_h^k\leqslant C_1.$$

Let us remark that assumption (7.1) together with (3.10) allows us to perform the change of variables defined in section 5 and to define $\mathbf{U}^k$, $\mathbf{U}^{k+1}$, and P^{k+1} (see (6.16)).

By using (4.50), there exists $(\mathbf{U}_h^{k+1}, P_h^{k+1}) \in \mathcal{K}_h(\boldsymbol{\zeta}_h^{k+1}) \times M_h(\boldsymbol{\zeta}_h^{k+1})$ such that

$$\left\{ \begin{array}{rcl} a\left(\mathbf{U}^{k+1} - \mathbf{U}_h^{k+1}, \boldsymbol{\varphi}\right) + b\left(\boldsymbol{\varphi}, P^{k+1} - P_h^{k+1}\right) & = & 0 \quad \forall \boldsymbol{\varphi} \in \mathcal{K}_h(\boldsymbol{\zeta}_h^{k+1}) \\ b\left(\mathbf{U}^{k+1} - \mathbf{U}_h^{k+1}, q\right) & = & 0 \quad \forall q \in M_h(\boldsymbol{\zeta}_h^{k+1}). \end{array} \right. \tag{7.3}$$

Subtracting (7.3) and (3.5) from (6.22) yields

$$\begin{aligned} \frac{1}{\Delta t}\left(\mathbf{U}^{k+1} - \mathbf{u}_h^{k+1}, \boldsymbol{\varphi}\right) + a(\mathbf{U}_h^{k+1} - \mathbf{u}_h^{k+1}, \boldsymbol{\varphi}) + b(\boldsymbol{\varphi}, P_h^{k+1} - p_h^{k+1}) \\ = \frac{1}{\Delta t}\left(\widehat{\mathbf{J}}\left(\mathbf{U}^k \circ \widehat{\boldsymbol{X}}\right) - \mathbf{u}_h^k \circ \overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}, \boldsymbol{\varphi}\right) + (\mathbf{A}_k, \boldsymbol{\varphi}) \quad \forall \boldsymbol{\varphi} \in \mathcal{K}(\boldsymbol{\zeta}_h^{k+1}), \\ b(\mathbf{U}_h^{k+1} - \mathbf{u}_h^{k+1}, q) = 0 \quad \forall q \in M_h(\boldsymbol{\zeta}_h^{k+1}). \end{aligned}$$

In particular, for $\boldsymbol{\varphi} = \mathbf{U}_h^{k+1} - \mathbf{u}_h^{k+1}$ and $q = P_h^{k+1} - p_h^{k+1}$, we easily obtain that

$$\begin{aligned} \left\|\mathbf{U}_h^{k+1} - \mathbf{u}_h^{k+1}\right\|_{\mathcal{L}^2(\mathcal{O})} \leqslant \left\|\widehat{\mathbf{J}}\left(\mathbf{U}^k \circ \widehat{\boldsymbol{X}}\right) - \mathbf{u}_h^k \circ \overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}\right\|_{\mathcal{L}^2(\mathcal{O})} \\ + \Delta t\|\mathbf{A}_k\|_{\mathcal{L}^2(\mathcal{O})} + \left\|\mathbf{U}^{k+1} - \mathbf{U}_h^{k+1}\right\|_{\mathcal{L}^2(\mathcal{O})}. \end{aligned} \tag{7.4}$$

On the other hand, since

$$\widehat{\mathbf{J}} = \left(\mathbf{J}_{\mathbf{Y}^{k+1}} \circ \mathbf{X}^{k+1}\right)\left(\mathbf{J}_{\mathbf{X}^k} \circ \widehat{\boldsymbol{X}}\right),$$

we have that

$$\begin{aligned} \left\|\widehat{\mathbf{J}}\left(\mathbf{U}^k \circ \widehat{\boldsymbol{X}}\right) - \mathbf{u}_h^k \circ \overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}\right\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\left\|\left(\mathbf{J}_{\mathbf{Y}^{k+1}} \circ \mathbf{X}^{k+1}\right)\left(\mathbf{J}_{\mathbf{X}^k} \circ \widehat{\boldsymbol{X}}\right) - \mathbf{Id}\right\|_{\mathcal{L}^2(\mathcal{O})} \\ + \left\|\mathbf{U}^k \circ \widehat{\boldsymbol{X}} - \mathbf{U}^k \circ \overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}\right\|_{\mathcal{L}^2(\mathcal{O})} \\ + \left\|\mathbf{U}^k \circ \overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}} - \mathbf{u}_h^k \circ \overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}\right\|_{\mathcal{L}^2(\mathcal{O})}. \end{aligned} \tag{7.5}$$

Since $\left(\mathbf{J}_{\mathbf{Y}^{k+1}} \circ \mathbf{X}^{k+1}\right)\mathbf{J}_{\mathbf{X}^{k+1}} = \mathbf{Id}$, we infer from Lemma 5.6 that

$$\begin{aligned} \left\|\left(\mathbf{J}_{\mathbf{Y}^{k+1}} \circ \mathbf{X}^{k+1}\right)\left(\mathbf{J}_{\mathbf{X}^k} \circ \widehat{\boldsymbol{X}}\right) - \mathbf{Id}\right\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\|\widehat{\boldsymbol{X}} - \mathbf{Id}\|_{\mathcal{L}^2(\mathcal{O})}\, |\boldsymbol{\zeta}(t_k) - \boldsymbol{\zeta}_h^k| \\ + C\|\mathbf{J}_{\mathbf{X}^k} - \mathbf{J}_{\mathbf{X}^{k+1}}\|_{\mathcal{L}^2(\mathcal{O})}. \end{aligned}$$

By using Lemmas 6.4 and 6.5 and the above inequality, we obtain that

$$\begin{aligned} \left\|\left(\mathbf{J}_{\mathbf{Y}^{k+1}} \circ \mathbf{X}^{k+1}\right)\left(\mathbf{J}_{\mathbf{X}^k} \circ \widehat{\boldsymbol{X}}\right) - \mathbf{Id}\right\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\Big(\Delta t|\boldsymbol{\zeta}(t_k) - \boldsymbol{\zeta}_h^k| \\ + \Delta t\|\mathbf{u}_h^k - \mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})} + \sqrt{\Delta t}\|\boldsymbol{\delta}_k\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))} + |\boldsymbol{\varepsilon}_k|\Big). \end{aligned} \tag{7.6}$$

By using (3.8) and Lemma 5.6, we easily check that

$$\|\mathbf{U}^k \circ \widehat{\boldsymbol{X}} - \mathbf{U}^k \circ \overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\|\widehat{\boldsymbol{X}} - \overline{\boldsymbol{X}}_{\boldsymbol{h}}^{\boldsymbol{k}}\|_{\mathcal{L}^2(\mathcal{O})}.$$

The above inequality, relations (7.4), (7.5), and (7.6), Lemma 6.5, and the fact that $\det \mathbf{J}_{\overline{\boldsymbol{X}}_h^k} = 1$ imply that

$$\begin{aligned}\|\mathbf{U}_h^{k+1} - \mathbf{u}_h^{k+1}\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\Big(&\Delta t|\boldsymbol{\zeta}(t_k) - \boldsymbol{\zeta}_h^k| + \Delta t\|\mathbf{u}_h^k - \mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})} \\ &+ \sqrt{\Delta t}\|\boldsymbol{\delta}_k\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))} + |\boldsymbol{\varepsilon}_k| + h\Delta t\Big) \\ &+ \|\mathbf{U}^k - \mathbf{u}_h^k\|_{\mathcal{L}^2(\mathcal{O})} + \Delta t\|\mathbf{A}_k\|_{\mathcal{L}^2(\mathcal{O})} + \|\mathbf{U}^{k+1} - \mathbf{U}_h^{k+1}\|_{\mathcal{L}^2(\mathcal{O})}.\end{aligned} \tag{7.7}$$

By using Lemma 4.4, Proposition 6.2, and Lemma 6.1, we have the following inequalities:

$$\|\mathbf{U}^{k+1} - \mathbf{U}_h^{k+1}\|_{\mathcal{L}^2(\mathcal{O})} \leqslant Ch,$$

$$\|\mathbf{A}_k\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\left(|\boldsymbol{\zeta}(t_{k+1}) - \boldsymbol{\zeta}_h^{k+1}| + h + \Delta t + C\sqrt{\Delta t}\left\|\frac{d^2}{dt^2}[\mathbf{u}\circ\widetilde{\boldsymbol{\psi}}]\right\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))}\right),$$

$$\|\boldsymbol{\delta}_k\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))} \leqslant C\Delta t\left\|\frac{\partial\mathbf{u}}{\partial t}\right\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))},$$

$$|\boldsymbol{\varepsilon}_k| \leqslant C\,(\Delta t)^2.$$

The above inequalities and (7.7) yield that

$$\begin{aligned}\|\mathbf{U}^{k+1} - \mathbf{u}_h^{k+1}\|_{\mathcal{L}^2(\mathcal{O})} \leqslant \|\mathbf{U}^k - \mathbf{u}_h^k\|_{\mathcal{L}^2(\mathcal{O})} + C\Bigg(&(\Delta t)^2 + h\Delta t + h \\ &+ \Delta t|\boldsymbol{\zeta}(t_{k+1}) - \boldsymbol{\zeta}_h^{k+1}| + \Delta t\|\mathbf{U}^k - \mathbf{u}_h^k\|_{\mathcal{L}^2(\mathcal{O})} \\ &+ (\Delta t)^{3/2}\left\|\frac{\partial\mathbf{u}}{\partial t}\right\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))} + (\Delta t)^{3/2}\left\|\frac{d^2}{dt^2}[\mathbf{u}\circ\widetilde{\boldsymbol{\psi}}]\right\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))}\Bigg).\end{aligned} \tag{7.8}$$

On the other hand, (3.2), (6.7), (6.31), and (6.39) imply that

$$\begin{aligned}|\boldsymbol{\zeta}(t_{k+1}) - \boldsymbol{\zeta}_h^{k+1}| &\leqslant |\boldsymbol{\zeta}(t_k) - \boldsymbol{\zeta}_h^k| + \Delta t|\mathbf{u}_h^k(\boldsymbol{\zeta}_h^k) - \mathbf{u}\left(\boldsymbol{\zeta}(t_k), t_k\right)| + |\boldsymbol{\varepsilon}_k| \\ &\leqslant |\boldsymbol{\zeta}(t_k) - \boldsymbol{\zeta}_h^k| + C\Delta t\|\mathbf{u}_h^k - \mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})} + |\boldsymbol{\varepsilon}_k|.\end{aligned} \tag{7.9}$$

Combining (7.8) and (7.9), we obtain that

$$\begin{aligned}&\|\mathbf{U}^{k+1} - \mathbf{u}_h^{k+1}\|_{\mathcal{L}^2(\mathcal{O})} + |\boldsymbol{\zeta}(t_{k+1}) - \boldsymbol{\zeta}_h^{k+1}| \\ &\qquad \leqslant (1 + C\Delta t)\left(|\boldsymbol{\zeta}(t_k) - \boldsymbol{\zeta}_h^k| + \|\mathbf{u}_h^k - \mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})}\right) \\ &\qquad + C\Bigg(h + (\Delta t)^2 + h\Delta t + (\Delta t)^{3/2}\left\|\frac{\partial\mathbf{u}}{\partial t}\right\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))} \\ &\qquad\qquad + (\Delta t)^{3/2}\left\|\frac{d^2}{dt^2}[\mathbf{u}\circ\widetilde{\boldsymbol{\psi}}]\right\|_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))}\Bigg).\end{aligned}$$

The above inequality and the hypothesis $h \leqslant C\,(\Delta t)^2$ imply the existence of a positive constant C_0 such that

$$\begin{aligned}&\|\mathbf{U}^{k+1} - \mathbf{u}_h^{k+1}\|_{\mathcal{L}^2(\mathcal{O})} + |\boldsymbol{\zeta}(t_{k+1}) - \boldsymbol{\zeta}_h^{k+1}| \\ &\qquad \leqslant (1 + C_0\Delta t)\left(|\boldsymbol{\zeta}(t_k) - \boldsymbol{\zeta}_h^k| + \|\mathbf{u}_h^k - \mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})}\right) \\ &\qquad + C_0\Delta t\left(\Delta t + \left\|\frac{\partial\mathbf{u}}{\partial t}\right\|^2_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))} + \left\|\frac{d^2}{dt^2}[\mathbf{u}\circ\widetilde{\boldsymbol{\psi}}]\right\|^2_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))}\right),\end{aligned}$$

which is exactly (7.2).

Second step. We show that if Δt is small enough, then the error $e_h^k = \|\mathbf{U}^k - \mathbf{u}_h^k\|_{\mathcal{L}^2(\mathcal{O})} + |\boldsymbol{\zeta}(t_k) - \boldsymbol{\zeta}_h^k|$ satisfies $e_h^k \leqslant C_1 \Delta t$ with a constant C_1 independent of k, Δt, and h. This fact implies, in particular, that (7.1) holds.

Define

$$C_1 = C_0 \exp(C_0 T) \left(\left\| \frac{\partial \mathbf{u}}{\partial t} \right\|^2_{\mathcal{L}^2(\mathcal{O}\times(0,T))} + \left\| \frac{d^2}{dt^2}[\mathbf{u} \circ \widetilde{\boldsymbol{\psi}}] \right\|^2_{\mathcal{L}^2(\mathcal{O}\times(0,T))} \right) + \exp(C_0 T).$$

It can be easily checked that

$$(1 + C_0 \Delta t)^n \, C_0 \left(\left\| \frac{\partial \mathbf{u}}{\partial t} \right\|^2_{\mathcal{L}^2(\mathcal{O}\times(0,T))} + \left\| \frac{d^2}{dt^2}[\mathbf{u} \circ \widetilde{\boldsymbol{\psi}}] \right\|^2_{\mathcal{L}^2(\mathcal{O}\times(0,T))} \right) + (1 + C_0 \Delta t)^n - 1 \leqslant C_1 \quad \forall n \in \{0, \dots, N\}.$$

Moreover, there exists a positive constant C_2 such that

$$\|\mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C_2.$$

Let $N_0 \in \mathbb{N}$ be such that $(2C_1 + C_2)\Delta t < \eta$ for all $N \geqslant N_0$. Next we prove by induction over k that for $N \geqslant N_0$ and for $k \in \{0, \dots, N\}$ we have

$$\tag{7.10} |\boldsymbol{\zeta}(t_k) - \boldsymbol{\zeta}_h^k| + \|\mathbf{u}_h^k - \mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})} \leqslant \Bigg[(1 + C_0 \Delta t)^k - 1 + C_0 (1 + C_0 \Delta t)^k \left(\left\| \frac{\partial \mathbf{u}}{\partial t} \right\|^2_{\mathcal{L}^2(\mathcal{O}\times(0,t_k))} + \left\| \frac{d^2}{dt^2}[\mathbf{u} \circ \widetilde{\boldsymbol{\psi}}] \right\|^2_{\mathcal{L}^2(\mathcal{O}\times(0,t_k))} \right) \Bigg] \Delta t.$$

The relation (7.10) is true for $k = 0$. Suppose that we have shown (7.10) for a given $k \geqslant 0$. Then, we deduce that

$$\tag{7.11} |\boldsymbol{\zeta}(t_k) - \boldsymbol{\zeta}_h^k| \leqslant C_1 \Delta t < \eta$$

and therefore, by using (3.10), we have that $\operatorname{dist}(B(\boldsymbol{\zeta}_h^k), \partial\mathcal{O}) > 2\eta$.

By using (3.2) and (3.10), we also have that

$$\begin{aligned} |\boldsymbol{\zeta}_h^{k+1} - \boldsymbol{\zeta}_h^k| &\leqslant \frac{1}{\sqrt{\pi}} \left(\|\mathbf{U}^k - \mathbf{u}_h^k\|_{\mathcal{L}^2(\mathcal{O})} + \|\mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})} \right) \Delta t \\ &\leqslant \frac{C_1 + C_2}{\sqrt{\pi}} \Delta t. \end{aligned}$$

The above relation, the fact that $(2C_1 + C_2)\Delta t < \eta$, and (7.11) imply that

$$\operatorname{dist}(B(\boldsymbol{\zeta}_h^{k+1}), \partial\mathcal{O}) > 2\eta.$$

Thus, we can apply the first step of the proof to obtain that

$$\begin{aligned} &|\boldsymbol{\zeta}(t_{k+1}) - \boldsymbol{\zeta}_h^{k+1}| + \|\mathbf{u}_h^{k+1} - \mathbf{U}^{k+1}\|_{\mathcal{L}^2(\mathcal{O})} \\ &\quad \leqslant (1 + C_0 \Delta t) \Big(|\boldsymbol{\zeta}(t_k) - \boldsymbol{\zeta}_h^k| + \|\mathbf{u}_h^k - \mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})} \Big) \\ &\qquad + C_0 \Delta t \left(\Delta t + \left\| \frac{\partial \mathbf{u}}{\partial t} \right\|^2_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))} + \left\| \frac{d^2}{dt^2}[\mathbf{u} \circ \widetilde{\boldsymbol{\psi}}] \right\|^2_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))} \right). \end{aligned}$$

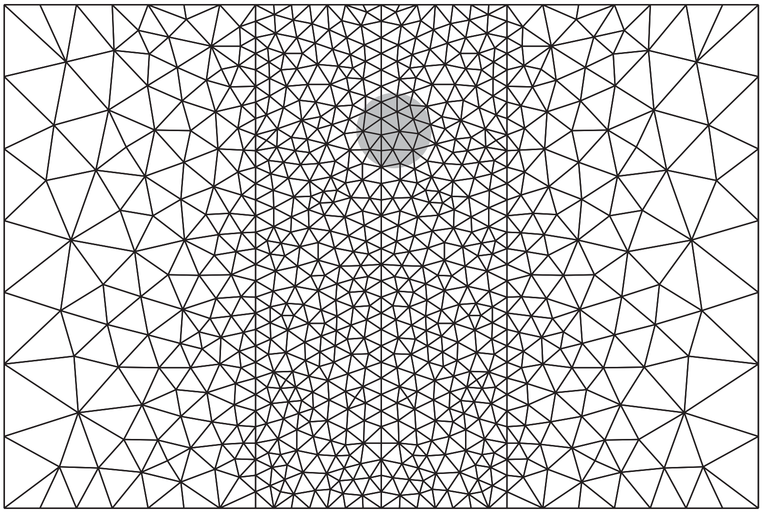


FIG. 2. *Initial position and mesh.*

The above relation and (7.10) imply that

$$\begin{aligned}|\boldsymbol{\zeta}(t_{k+1}) - \boldsymbol{\zeta}_h^{k+1}| + \|\mathbf{u}_h^{k+1} - \mathbf{U}^{k+1}\|_{\mathcal{L}^2(\mathcal{O})} &\leqslant (1+C_0\Delta t)[(1+C_0\Delta t)^k - 1]\Delta t \\ &+ C_0(1+C_0\Delta t)^{k+1}\left(\left\|\frac{\partial \mathbf{u}}{\partial t}\right\|^2_{\mathcal{L}^2(\mathcal{O}\times(0,t_k))} + \left\|\frac{d^2}{dt^2}[\mathbf{u}\circ\widetilde{\boldsymbol{\psi}}]\right\|^2_{\mathcal{L}^2(\mathcal{O}\times(0,t_k))}\right)\Delta t \\ &+ C_0\Delta t\left(\Delta t + \left\|\frac{\partial \mathbf{u}}{\partial t}\right\|^2_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))} + \left\|\frac{d^2}{dt^2}[\mathbf{u}\circ\widetilde{\boldsymbol{\psi}}]\right\|^2_{\mathcal{L}^2(\mathcal{O}\times(t_k,t_{k+1}))}\right),\end{aligned}$$

which implies (7.10) for $k+1$.

Third step. From the previous steps we conclude that if Δt is small enough and if $h \leqslant C(\Delta t)^2$, then

$$|\boldsymbol{\zeta}(t_k) - \boldsymbol{\zeta}_h^k| + \|\mathbf{u}_h^k - \mathbf{U}^k\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C_1\Delta t \qquad \forall\, k \in \{0,\dots,N\}.$$

The above relation, Lemma 5.6, (3.8), and Lemma 4.4 imply that if Δt is small enough and if $h \leqslant C(\Delta t)^2$, then

$$|\boldsymbol{\zeta}(t_k) - \boldsymbol{\zeta}_h^k| + \|\mathbf{u}_h^k - \mathbf{u}(t_k)\|_{\mathcal{L}^2(\mathcal{O})} \leqslant C\Delta t \qquad \forall\, k \in \{0,\dots,N\},$$

which is the conclusion of the theorem. □

8. Concluding remarks. We implemented the numerical method we proposed, and several numerical tests have been performed. Let us briefly describe the results obtained in the case of a rigid ball falling vertically under the action of a vertical force oriented downward. At instant $t = 0$ the velocity field in the fluids and in the solid is supposed to vanish.

We use a mesh with 1432 triangles and 752 vertices (see Figure 2).

Far from the ball the space discretization parameter is $h_1 \approx 0.57$, whereas in the neighborhood of the ball it is given by $h_2 \approx 0.12$. For the time discretization, we choose the time step $\Delta t = 0.1$. Moreover, we choose the radius of the ball equal

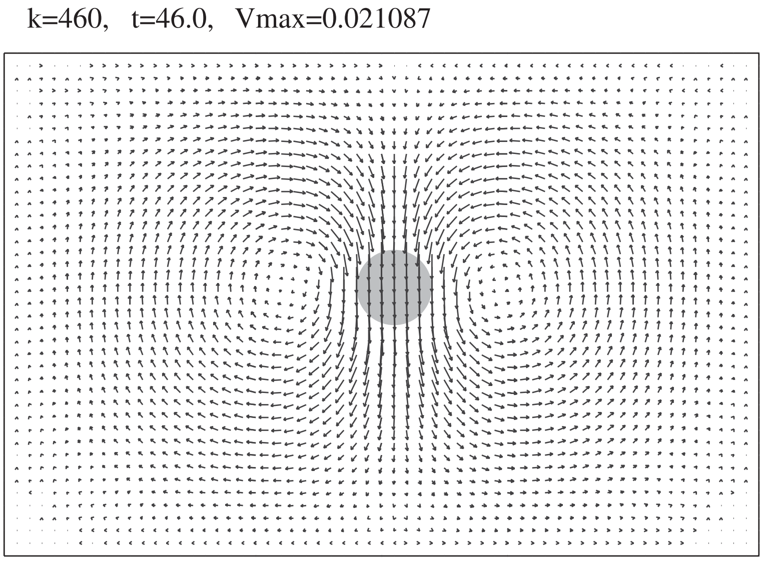

FIG. 3. *Position and velocity field at time $t = 46.0$.*

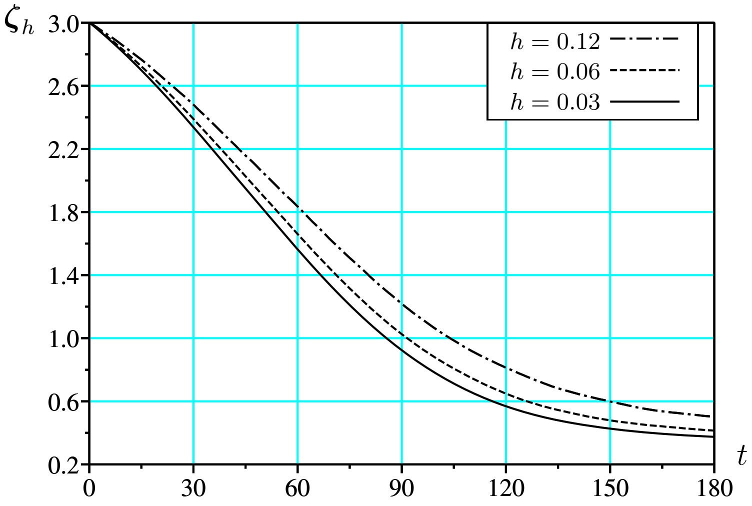

FIG. 4. *Position of the ball.*

to 0.3, the viscosity $\mu = 1$, and the downward force of intensity equal to one (all quantities are given in International System (IS) units). In Figure 3 we represent the configuration of the system for $k = 460$ (corresponding to $t = 46.0$).

We repeated the calculation twice by dividing each mesh size by two (this means that each triangle was each time divided into four smaller triangles). More precisely, we used the meshes described in the table below.

	h	Triangles	Vertices	CPU time
Mesh 1	0.12	1432	752	3 hours
Mesh 2	0.06	5728	2935	11 hours
Mesh 3	0.03	22912	11597	8 days

The last column represents the time used by a Pentium IV computer with a 2.4 GHz CPU clock to achieve the calculation.

In Figure 4 we represented the height of the center of the ball versus the time t for the different meshes.

A DISCONTINUOUS SUBGRID EDDY VISCOSITY METHOD FOR THE TIME-DEPENDENT NAVIER–STOKES EQUATIONS*

SONGUL KAYA† AND BÉATRICE RIVIÈRE‡

Abstract. In this paper we provide an error analysis of a subgrid scale eddy viscosity method using discontinuous polynomial approximations for the numerical solution of the incompressible Navier–Stokes equations. Optimal continuous in time error estimates of the velocity are derived. The analysis is completed with some error estimates for two fully discrete schemes, which are first and second order in time, respectively.

Key words. error analysis, Navier–Stokes, discontinuous Galerkin, fully discrete scheme, high order method

1. Introduction.

The goal of this paper is to formulate and analyze a subgrid eddy viscosity method for solving the incompressible time-dependent Navier–Stokes equations. If the separation point between large and small scales is held fixed, the model can be viewed as a large eddy simulation (LES) model. On the other hand, if the separation point is decreased as the mesh size tends to zero, the model can be viewed (and analyzed, as herein) as a numerical regularization of the Navier–Stokes equations.

For many flows in nature, capturing all the scales in a numerical simulation is an impossible task, since the scale separation may span several orders of magnitude. Global diffusion is the traditional phenomenology to model the dispersive effects of unresolved scales on resolved scales. The traditional approach for incorporating the effects of unresolved scales on the resolved ones for the Navier–Stokes equations utilizes eddy viscosity models. These models, first formulated by Boussinesq [5] and developed by Taylor and Prandlt [10], introduce a dissipation mechanism (Smagorinsky [29]). Standard eddy viscosity models act on all scales of motion, and their effects can be too diffusive on the coarse scales (Lewandowski [26] and Iliescu and Layton [19]). The idea of applying the eddy viscosity models on only the small scales results in the subgrid eddy viscosity method, introduced and analyzed by Guermond [14], Layton [24], and John and Kaya [20]. This subgrid eddy viscosity method can also be thought of as an extension to general domains and boundary conditions of the spectral vanishing viscosity idea of Maday and Tadmor [27]. Recently, Hughes, Mazzei, and Jansen [17] proposed a variational multiscale method (VMM) in which the diffusion acts only at the finest resolved scales. VMM is a promising approach in multiscale turbulence modelling. There are different choices on how to define coarse and small scales within the VMM framework. One approach is to define fluctuations via bubble functions and means via L^2 projection (Guermond [14] and Hughes [16]). Another possibility is to

define fluctuations via the finest resolved scales in a hierarchy of finite element spaces, and means via elliptic or Stokes projection (Layton [24], Kaya and Layton [22], and Hughes [18]).

For any numerical method, the error equation arising from the Navier–Stokes equations contains a convection-like term and a reaction (or stretching) term. Discontinuous Galerkin (DG) methods, first introduced in the work of Reed and Hill [28] and Lesaint and Raviart [25], are particularly efficient in controlling convective error terms. On the other hand, (generally nonlinear) eddy viscosity models are, in a sense, intended to give some control of the error's reaction-like terms. Indeed, the exponential sensitivity of trajectories of the Navier–Stokes equations (arising from reaction-like terms) is widely believed to be limited to the small scales. It is thus conjectured that by modelling their action on the large scales, the exponential sensitivity introduced by the reaction-like terms will be contained.

DG methods have recently become more popular in the science and engineering community. They use piecewise polynomial functions with no continuity constraint across element interfaces. As a result, variational formulations must include jump terms across interfaces [31]. The DG methods offers several advantages, including (i) flexibility in the design of the meshes and in the construction of trial and test spaces, (ii) local conservation of mass, (iii) h-p adaptivity, and (iv) higher order local approximations. DG methods have become widely used for solving computational fluid problems, especially diffusion and pure convection problems [3]. The reader should refer to Cockburn, Karniadakis, and Shu [6] for a historical review of DG methods. For the steady-state Navier–Stokes equations, a totally discontinuous finite element method is formulated in [12], while in [21], the velocity is approximated by discontinuous polynomials that are pointwise divergence-free, and the pressure by continuous polynomials.

Combining DG and eddy viscosity techniques is clearly advantageous. While convective effects are accurately modelled by DG, the dispersive effects of small scales on the large scales are correctly taken into account with the eddy viscosity model. Besides, due to the absence of continuity constraints, one can select various basis functions (such as hierarchical basis functions) for the coarse and refined scales. As an appropriate first step, we consider in this paper the combination of DG methods with a linear eddy viscosity model. We show that the errors are optimal with respect to the mesh size and depend on the Reynolds number in a reasonable fashion. The particular eddy viscosity model considered here was introduced in [24], and complete numerical analysis for Navier–Stokes equations was performed in [20] where it was combined with the classical finite element method.

The outline of the paper is as follows. The model problem and notation are presented in section 2. In section 3, a variational formulation and scheme are introduced. Section 4 contains the continuous in time algorithm, some stability results, and some error estimates. In section 5 , two fully discrete schemes are formulated and analyzed. Conclusions are given in the last section.

2. Notation and preliminaries.

We consider the time-dependent Navier–Stokes equations for incompressible flow as follows:

$$\boldsymbol{u}_t - \nu \Delta \boldsymbol{u} + \boldsymbol{u} \cdot \nabla \boldsymbol{u} + \nabla p = \boldsymbol{f} \quad \text{in } \Omega \text{ for } 0 < t \leq T, \tag{2.1}$$

$$\nabla \cdot \boldsymbol{u} = 0 \quad \text{in } \Omega \text{ for } 0 < t \leq T, \tag{2.2}$$

$$\boldsymbol{u} = \boldsymbol{u}_0 \quad \text{in } \Omega \text{ for } t = 0, \tag{2.3}$$

$$\boldsymbol{u} = 0 \quad \text{on } \partial\Omega \text{ for } 0 < t \leq T, \tag{2.4}$$

where $\boldsymbol{u}$ is the fluid velocity, p the pressure, $\boldsymbol{f}$ the external force, $\nu > 0$ the kinematic viscosity, and $\Omega \subset \mathbb{R}^2$ a bounded, simply connected domain with polygonal boundary $\partial\Omega$. We also impose the usual normalization condition on the pressure, namely, that $\int_\Omega p = 0$.

Let $\mathcal{K}_h = \{E_j, j = 1, \dots, N_h\}$ denote a nondegenerate triangulation of the domain Ω. Let h denote the maximum diameter of the elements E_j in $\mathcal{K}_h$. We denote the edges of $\mathcal{K}_h$ by $\{e_1, e_2, \dots, e_{P_h}, e_{P_h+1}, \dots, e_{M_h}\}$, where $e_k \subset \Omega$ for $1 \le k \le P_h$ and $e_k \subset \partial\Omega$ for $P_{h+1} \le k \le M_h$. With each edge we associate a normal unit vector $\mathbf{n}_k$. For $k > P_h$, the unit vector $\mathbf{n}_k$ is taken to be outward normal to $\partial\Omega$. Let e_k be an edge shared by elements E_i and E_j with $\mathbf{n}_k$ exterior to E_i. We define the jump $[\phi]$ and average $\{\phi\}$ of a function ϕ by

$$[\phi] = (\phi|_{E_i})|_{e_k} - (\phi|_{E_j})|_{e_k}, \quad \{\phi\} = \frac{1}{2}(\phi|_{E_i})|_{e_k} + \frac{1}{2}(\phi|_{E_j})|_{e_k}.$$

If e belongs to the boundary $\partial\Omega$, the jump and average of ϕ coincide with its trace on e. We shall use standard notation for Sobolev spaces [1]. For any nonnegative integer s and $r \ge 1$, the classical Sobolev space on a domain $E \subset \mathbb{R}^2$ is

$$W^{s,r}(E) = \{v \in L^r(E) : \forall\, |m| \le s,\, \partial^m v \in L^r(E)\},$$

where $\partial^m v$ are the partial derivatives of v of order $|m|$. The usual norm in $W^{s,r}(E)$ is denoted by $\|\cdot\|_{s,r,E}$ and the seminorm by $|\cdot|_{s,r,E}$. The L^2 inner-product is denoted by $(\cdot,\cdot)_E$ and by $(\cdot,\cdot)$ if $E = \Omega$. For the Hilbert space $H^s(E) = W^{s,2}(E)$, the norm is denoted by $\|\cdot\|_{s,E}$. By $H_0^1(E)$ we shall understand the subspace of $H^1(E)$ functions that vanish on ∂E. Throughout the paper, boldface characters denote vector quantities. Define

$$\boldsymbol{V} = \{\boldsymbol{v} \in \boldsymbol{H}_0^1(\Omega) : \quad \nabla \cdot \boldsymbol{v} = 0\}, \quad \boldsymbol{H} = \{\boldsymbol{v} \in L^2(\Omega)^2 : \quad \nabla \cdot \boldsymbol{v} = 0, \boldsymbol{v} = \boldsymbol{0}\}.$$

For any function $\boldsymbol{\phi}$ that depends on time t and space $\boldsymbol{x}$, denote

$$\boldsymbol{\phi}(t)(\boldsymbol{x}) = \boldsymbol{\phi}(t, \boldsymbol{x}) \quad \forall t \in [0, T], \forall \boldsymbol{x} \in \Omega.$$

If Y denotes a functional space in the space variable with the norm $\|\cdot\|_Y$ and if $\boldsymbol{\phi} = \boldsymbol{\phi}(t, \boldsymbol{x})$, then for $s > 0$

$$\|\boldsymbol{\phi}\|_{L^s(0,T;Y)} = \left[\int_0^T \|\boldsymbol{\phi}(t)\|_Y^s dt\right]^{1/s}, \quad \|\boldsymbol{\phi}\|_{L^\infty(0,T;Y)} = \max_{0 \le t \le T} \|\boldsymbol{\phi}(t)\|_Y.$$

Recall that for a vector function $\boldsymbol{\phi}$, the tensor $\nabla\boldsymbol{\phi}$ is defined as $(\nabla\boldsymbol{\phi})_{i,j} = \frac{\partial \phi_i}{\partial x_j}$ and the tensor product of two tensors $\boldsymbol{T}$ and $\boldsymbol{S}$ is defined as $\boldsymbol{T} : \boldsymbol{S} = \sum_{i,j} T_{ij} S_{ij}$. We define the following *broken* norm for positive s:

$$|\!|\!|\cdot|\!|\!|_s = \left[\sum_{j=1}^{N_h} \|\cdot\|_{s,E_j}^2\right]^{1/2}.$$

From [30], if $\boldsymbol{f} \in L^2(0, T; \boldsymbol{V}')$ and $\boldsymbol{u}_0 \in \boldsymbol{H}$, there exists a solution $(\boldsymbol{u}, p)$ of (2.1)–(2.4) such that $\boldsymbol{u} \in L^\infty(0, T; L^2(\Omega)^2) \cap L^2(0, T; \boldsymbol{V})$. In addition, we will assume that $\boldsymbol{u} \in L^\infty(0, T; \boldsymbol{W}^{2,4/3}(\Omega))$ and $p \in L^\infty(0, T; W^{1,4/3}(\Omega))$ for the DG formulation to be well defined. For the analysis obtained in sections 4 and 5, we require extra regularity on the solution: $\boldsymbol{u} \in L^\infty(0,T;\boldsymbol{H}^2(\Omega)), p \in L^2(0,T;H^1(\Omega))$. This assumption is valid if the data is more regular [30]: $\boldsymbol{f} \in L^\infty(0,T;\boldsymbol{H}), \boldsymbol{f}_t \in L^2(0,T;\boldsymbol{V}'), \boldsymbol{f}(0) \in \boldsymbol{H}$, $\boldsymbol{u}_0 \in \boldsymbol{H}^2(\Omega) \cap \boldsymbol{V}$. The following functional spaces are defined:

$$\begin{aligned}\boldsymbol{X} &= \{\boldsymbol{v} \in (L^2(\Omega))^2 : \boldsymbol{v}|_{E_j} \in \boldsymbol{W}^{2,4/3}(E_j) \quad \forall E_j \in \mathcal{K}_h\},\\ Q &= \{q \in L_0^2(\Omega) : q|_{E_j} \in W^{1,4/3}(E_j) \quad \forall E_j \in \mathcal{K}_h\},\end{aligned}$$

where $L_0^2(\Omega)$ is given by

$$L_0^2(\Omega) = \left\{ q \in L^2(\Omega) : \int_\Omega q = 0 \right\}.$$

We associate to $(\boldsymbol{X}, Q)$ the following norms:

$$\|\boldsymbol{v}\|_X = (\|\!|\nabla \boldsymbol{v}\|\!|_0^2 + J(\boldsymbol{v},\boldsymbol{v}))^{\frac{1}{2}} \quad \forall \boldsymbol{v} \in \boldsymbol{X}, \quad \|q\|_Q = \|q\|_{0,\Omega} \quad \forall q \in Q,$$

where the jump term J is defined as

$$J(\boldsymbol{u},\boldsymbol{v}) = \sum_{k=1}^{M_h} \frac{\sigma}{|e|} \int_{e_k} [\boldsymbol{u}] \cdot [\boldsymbol{v}]. \tag{2.5}$$

In this jump term, $|e|$ denotes the measure of the edge e and σ is a constant parameter that will be specified later.

Recall the following property of norm $\|\cdot\|_X$ [12]: for each real number $p \in [2,\infty)$ there exists a constant $C(p)$ such that

$$\|\boldsymbol{v}\|_{L^p(\Omega)} \leq C(p)\|\boldsymbol{v}\|_X \quad \forall \boldsymbol{v} \in \boldsymbol{X}. \tag{2.6}$$

For any positive integer r, the finite-dimensional subspaces are

$$\begin{aligned}\boldsymbol{X}^h &= \{\boldsymbol{v}^h \in \mathbf{X} : \boldsymbol{v}^h \in (\mathbb{P}_r(E_j))^2 \quad \forall E_j \in \mathcal{K}_h\},\\ Q^h &= \{q^h \in Q : q^h \in \mathbb{P}_{r-1}(E_j) \quad \forall E_j \in \mathcal{K}_h\}.\end{aligned}$$

We assume that for each integer $r \geq 1$, there exists an operator $R_h \in \mathcal{L}(\boldsymbol{H}^1(\Omega); \boldsymbol{X}^h)$ such that

$$\|R_h(\boldsymbol{v}) - \boldsymbol{v}\|_X \leq Ch^r |\boldsymbol{v}|_{r+1,\Omega} \quad \forall \boldsymbol{v} \in \boldsymbol{H}^{r+1}(\Omega) \cap \boldsymbol{H}_0^1(\Omega), \tag{2.7}$$

$$\|\boldsymbol{v} - \boldsymbol{R}_h(\boldsymbol{v})\|_{0,E_j} \leq Ch_{E_j}^{r+1} |\boldsymbol{v}|_{r+1,\Delta_{E_j}} \quad \forall \boldsymbol{v} \in \boldsymbol{H}^{r+1}(\Omega),\ 1 \leq j \leq N_h, \tag{2.8}$$

where Δ_{E_j} is a suitable macro element containing E_j. Note that for $r = 1, 2$, and 3, the existence of this interpolant follows from [8, 7, 9]. The bounds (2.7) and (2.8) are proved in [12] and in [13], respectively.

Also, for each integer $r \geq 1$, there is an operator $r_h \in \mathcal{L}(L_0^2(\Omega); Q_h)$ such that for any E_j in $\mathcal{K}_h$

$$\int_{E_j} z_h(r_h(q) - q) = 0 \quad \forall z_h \in \mathbb{P}_{r-1}(E_j), \forall q \in L_0^2(\Omega), \tag{2.9}$$

$$\|q - r_h(q)\|_{m,E_j} \leq Ch_{E_j}^{r-m} |q|_{r,E_j} \quad \forall q \in H^r(\Omega) \cap L_0^2(\Omega), m = 0, 1. \tag{2.10}$$

Finally, we recall some standard trace and inverse inequalities, which hold true on each element E in $\mathcal{K}_h$, with diameter h_E (see [11]):

$$\|\boldsymbol{v}\|_{0,e} \le C(h_E^{-1/2}\|\boldsymbol{v}\|_{0,E} + h_E^{1/2}\|\nabla \boldsymbol{v}\|_{0,E}) \quad \forall e \in \partial E, \quad \forall \boldsymbol{v} \in \boldsymbol{X}, \tag{2.11}$$

$$\|\nabla\boldsymbol{v}\|_{0,e} \le C(h_E^{-1/2}\|\nabla\boldsymbol{v}\|_{0,E} + h_E^{1/2}\|\nabla^2 \boldsymbol{v}\|_{0,E}) \quad \forall e \in \partial E, \quad \forall \boldsymbol{v} \in \boldsymbol{X}, \tag{2.12}$$

$$\|\boldsymbol{v}\|_{L^4(e)} \le Ch_E^{-3/4}(\|\boldsymbol{v}\|_{0,E} + h_E\|\nabla \boldsymbol{v}\|_{0,E}) \quad \forall e \in \partial E, \quad \forall \boldsymbol{v} \in \boldsymbol{X}, \tag{2.13}$$

$$\|\boldsymbol{v}^h\|_{0,e} \le Ch_E^{-1/2}\|\boldsymbol{v}^h\|_{0,E} \quad \forall e \in \partial E, \quad \forall \boldsymbol{v}^h \in \boldsymbol{X}^h, \tag{2.14}$$

$$\|\nabla\boldsymbol{v}^h\|_{0,e} \le Ch_E^{-1/2}\|\nabla\boldsymbol{v}^h\|_{0,E} \quad \forall e \in \partial E, \quad \forall \boldsymbol{v}^h \in \boldsymbol{X}^h, \tag{2.15}$$

$$\|\nabla\boldsymbol{v}^h\|_{0,E} \le Ch_E^{-1}\|\boldsymbol{v}^h\|_{0,E} \quad \forall \boldsymbol{v}^h \in \boldsymbol{X}^h, \tag{2.16}$$

$$\|\boldsymbol{v}^h\|_{L^4(E)} \le Ch_E^{-1/2}\|\boldsymbol{v}^h\|_{0,E} \quad \forall \boldsymbol{v}^h \in \boldsymbol{X}^h. \tag{2.17}$$

3. Variational formulation and scheme.

Let us first define the bilinear forms $a : \boldsymbol{X} \times \boldsymbol{X} \to \mathbb{R}$ and $b : \boldsymbol{X} \times Q \to \mathbb{R}$:

$$a(\boldsymbol{v}, \boldsymbol{w}) = \sum_{j=1}^{N_h} \int_{E_j} \nabla \boldsymbol{v} : \nabla \boldsymbol{w} - \sum_{k=1}^{M_h} \int_{e_k} (\{\nabla \boldsymbol{v}\}\mathbf{n}_k \cdot [\boldsymbol{w}] - \epsilon_0 \{\nabla \boldsymbol{w}\}\mathbf{n}_k \cdot [\boldsymbol{v}]), \tag{3.1}$$

$$b(\boldsymbol{v}, q) = -\sum_{j=1}^{N_h} \int_{E_j} q \nabla \cdot \boldsymbol{v} + \sum_{k=1}^{M_h} \int_{e_k} \{p\}[\boldsymbol{v}] \cdot \mathbf{n}_k, \tag{3.2}$$

where ϵ_0 takes the constant value 1 or -1. Throughout the paper, we will assume the following hypothesis: if $\epsilon_0 = 1$, the jump parameter σ is chosen to be equal to 1; if $\epsilon_0 = -1$, the jump parameter σ is bounded below by $\sigma_0 > 0$ and σ_0 is sufficiently large. Based on this assumption, we can easily prove the following lemma.

LEMMA 3.1. *There is a constant $\kappa > 0$ such that*

$$a(\boldsymbol{v}^h, \boldsymbol{v}^h) + J(\boldsymbol{v}^h, \boldsymbol{v}^h) \ge \kappa \|\boldsymbol{v}^h\|_X^2 \quad \forall \boldsymbol{v}^h \in \boldsymbol{X}^h. \tag{3.3}$$

In addition to these bilinear forms, we consider the following upwind discretization of the term $\boldsymbol{u} \cdot \nabla \boldsymbol{z}$:

$$\begin{aligned} c(\boldsymbol{u}, \boldsymbol{z}, \boldsymbol{\theta}) = &\sum_{j=1}^{N_h} \left(\int_{E_j} (\boldsymbol{u} \cdot \nabla \boldsymbol{z}) \cdot \boldsymbol{\theta} + \int_{\partial E_j^-} |\{\boldsymbol{u}\} \cdot \boldsymbol{n}_{E_j}| (\boldsymbol{z}^{\text{int}} - \boldsymbol{z}^{\text{ext}}) \cdot \boldsymbol{\theta}^{int} \right) \\ &+ \frac{1}{2} \sum_{j=1}^{N_h} \int_{E_j} (\nabla \cdot \boldsymbol{u}) \boldsymbol{z} \cdot \boldsymbol{\theta} - \frac{1}{2} \sum_{k=1}^{M_h} \int_{e_k} [\boldsymbol{u}] \cdot \boldsymbol{n}_k \{\boldsymbol{z} \cdot \boldsymbol{\theta}\} \end{aligned} \tag{3.4}$$

for all $\boldsymbol{u}, \boldsymbol{z}, \boldsymbol{\theta}$ in $\mathbf{X}$ and where on each element the inflow boundary is

$$\partial E_j^- = \{\boldsymbol{x} \in \partial E_j : \{\boldsymbol{u}\} \cdot \mathbf{n}_{E_j} < 0\},$$

and the superscript int (resp., ext) refers to the trace of the function on a side of E_j coming from the interior of E_j (resp., coming from the exterior of E_j on that side). Note that the form c is not linear with respect to its first argument but is linear with respect to its second and third arguments. To avoid any confusion, if necessary, in the analysis, we will explicitly write $c(\boldsymbol{u}, \boldsymbol{z}, \boldsymbol{\theta}) = c_{\boldsymbol{w}}(\boldsymbol{u}, \boldsymbol{z}, \boldsymbol{\theta})$ when the inflow boundaries ∂E_j^- are defined with respect to the velocity $\{\boldsymbol{w}\}$. We finally recall the positivity of c proved in [12]:

$$c(\boldsymbol{u}, \boldsymbol{z}, \boldsymbol{z}) \ge 0 \quad \forall \boldsymbol{u}, \boldsymbol{z} \in \boldsymbol{X}. \tag{3.5}$$

With these forms, we consider a variational problem of (2.1)–(2.4): for all $t > 0$ find $\boldsymbol{u}(t) \in \boldsymbol{X}$ and $p(t) \in Q$ satisfying

$$(\boldsymbol{u}_t(t), \boldsymbol{v}) + \nu(a(\boldsymbol{u}(t), \boldsymbol{v}) + J(\boldsymbol{u}(t), \boldsymbol{v})) \\ + c(\boldsymbol{u}(t), \boldsymbol{u}(t), \boldsymbol{v}) + b(\boldsymbol{v}, p(t)) = (\boldsymbol{f}(t), \boldsymbol{v}) \quad \forall \boldsymbol{v} \in \boldsymbol{X}, \tag{3.6}$$

$$b(\boldsymbol{u}(t), q) = 0 \quad \forall q \in Q, \tag{3.7}$$

$$(\boldsymbol{u}(0), \boldsymbol{v}) = (\boldsymbol{u}_0, \boldsymbol{v}) \quad \forall \boldsymbol{v} \in \boldsymbol{X}. \tag{3.8}$$

We shall now show the equivalence of the strong and weak solutions.

Lemma 3.2. *Every strong solution of* (2.1)–(2.4) *is also a solution of* (3.6)–(3.8) *and conversely.*

Proof. Fix $t > 0$. Let $(\boldsymbol{u}, p)$ be the solution of (2.1)–(2.4). Since $\boldsymbol{u}(t) \in \boldsymbol{H}_0^1(\Omega)$, by the trace theorem $[\boldsymbol{u}(t)] \cdot \boldsymbol{n}_k = 0$ on each edge. Also, $\nabla \cdot \boldsymbol{u}(t) = 0$; thus $\boldsymbol{u}$ satisfies (3.7). Multiplying the Navier–Stokes equation (2.1) by $\boldsymbol{v} \in \boldsymbol{X}$, integrating over each element, and summing over all elements yield

$$\sum_{j=1}^{N_h} \int_{E_j} (\boldsymbol{u}_t \cdot \boldsymbol{v} + \nu \nabla \boldsymbol{u} : \nabla \boldsymbol{v}) - \nu \sum_{k=1}^{M_h} \int_{e_k} [\nabla \boldsymbol{u} \mathbf{n}_k \cdot \boldsymbol{v}] + \sum_{j=1}^{N_h} \int_{E_j} \boldsymbol{u} \cdot \nabla \boldsymbol{u} \cdot \boldsymbol{v} \\ - \sum_{j=1}^{N_h} \int_{E_j} p \nabla \cdot \boldsymbol{v} + \sum_{k=1}^{M_h} \int_{e_k} [p \boldsymbol{v} \cdot \mathbf{n}_k] = \int_\Omega \boldsymbol{f} \cdot \boldsymbol{v}.$$

The boundary terms are rewritten as

$$\sum_{k=1}^{M_h} \int_{e_k} [\nabla \boldsymbol{u} \boldsymbol{n}_k . \boldsymbol{v}] = \sum_{k=1}^{M_h} \int_{e_k} \{\nabla \boldsymbol{u}\} \boldsymbol{n}_k \cdot [\boldsymbol{v}] + \sum_{k=1}^{M_h} \int_{e_k} [\nabla \boldsymbol{u}] \boldsymbol{n}_k \cdot \{\boldsymbol{v}\}.$$

The first part of the lemma is then obtained because the jumps of $\boldsymbol{u}, \nabla \boldsymbol{u} \boldsymbol{n}_k$, and p are zero almost everywhere.

Conversely, let $(\boldsymbol{u}, p)$ be a solution to (3.6)–(3.8). First, let E belong to $\mathcal{K}_h$ and choose $\boldsymbol{v} \in \mathcal{D}(E)^2$, extended by zero outside E. Then, $(\boldsymbol{u}, p)$ satisfy in the sense of distributions

$$\boldsymbol{u}_t - \nu \Delta \boldsymbol{u} + \boldsymbol{u} \cdot \nabla \boldsymbol{u} + \nabla p = \boldsymbol{f}, \quad \nabla \cdot \boldsymbol{u} = 0 \quad \text{in} \quad E. \tag{3.9}$$

Next consider $\boldsymbol{v} \in \mathcal{C}^1(\bar{E})$ such that $\boldsymbol{v} = \boldsymbol{0}$ on ∂E, extended by zero outside E, and $\nabla \boldsymbol{v} \cdot \boldsymbol{n} = 0$ on ∂E except on one side e_k. We multiply (3.9) by $\boldsymbol{v}$ and integrate by parts. We then obtain

$$\int_{e_k} \{\nabla \boldsymbol{v}\} \boldsymbol{n}_k \cdot [\boldsymbol{u}] = 0,$$

which implies that $[\boldsymbol{u}] = \boldsymbol{0}$ almost everywhere on e_k. If e_k belongs to the boundary $\partial\Omega$, this implies that $\boldsymbol{u}|_{e_k} = \boldsymbol{0}$. Thus, $\boldsymbol{u} \in \boldsymbol{H}_0^1(\Omega)$. Finally, choose $\boldsymbol{v} \in \mathcal{C}^1(\bar{E})$, with $\boldsymbol{v} = \boldsymbol{0}$ on ∂E except on one side e_k, extended by zero outside of E. Multiplying (3.9) by v and integrating by parts, we have

$$\int_{e_k} (-\nu \nabla \boldsymbol{u} \boldsymbol{n}_E + p \boldsymbol{n}_E) \cdot \boldsymbol{v} = \int_{e_k} \{-\nu \nabla \boldsymbol{u} \boldsymbol{n}_E + p \boldsymbol{n}_E\} \cdot \boldsymbol{v}.$$

Since $\boldsymbol{v}$ is arbitrary, this means that the quantity $-\nu\nabla\boldsymbol{u}\boldsymbol{n}_k + p\boldsymbol{n}_k$ is continuous across e_k. Therefore, (3.9) is satisfied over the entire domain Ω. The initial condition (2.3) is straightforward. □

We recall a discrete inf-sup condition and a property satisfied by R_h (see [12]).

LEMMA 3.3. *There exists a positive constant β_0, independent of h such that*

$$\inf_{q^h\in Q^h} \sup_{\boldsymbol{v}^h\in\mathbf{X}^h} \frac{b(\boldsymbol{v}^h, q^h)}{\|\boldsymbol{v}^h\|_X \, \|q^h\|_0} \geq \beta_0. \tag{3.10}$$

Furthermore, the operator R_h satisfies

$$b(R_h(\boldsymbol{v}) - \boldsymbol{v}, q^h) = 0 \quad \forall q^h \in Q^h, \quad \forall \boldsymbol{v} \in \boldsymbol{H}_0^1(\Omega). \tag{3.11}$$

In order to subtract the artificial diffusion introduced by the eddy viscosity on the coarse grid, we consider a coarsening of the mesh $\mathcal{K}_h$, namely $\mathcal{K}_H$, such that the fine mesh $\mathcal{K}_h$ is a refinement of $\mathcal{K}_H$ (so typically $h \ll H$). Denote by $\boldsymbol{L}$ the space of tensors $L^2(\Omega)^{2\times 2}$ and consider the finite-dimensional subspace of $\boldsymbol{L}$:

$$\boldsymbol{L}_H = \{\boldsymbol{S} \in \boldsymbol{L} : S_{ij}|_\Sigma \in \mathbb{P}_{r-1}(\Sigma)\, \forall \Sigma \in \mathcal{K}_H\}.$$

Let $P_H : \boldsymbol{L} \to \boldsymbol{L}_H$ denote the L^2 orthogonal projection on $\boldsymbol{L}_H$ and let I denote the identity mapping. Since P_H is a projection, we have the following properties:

$$\|I - P_H\| \leq 1, \tag{3.12}$$

$$\|(I - P_H)\nabla\boldsymbol{v}\|_{0,\Omega} \leq CH^r|\boldsymbol{v}|_{r+1,\Omega} \quad \forall \boldsymbol{v} \in \boldsymbol{H}^{r+1}(\Omega). \tag{3.13}$$

Throughout the paper, the variable C will denote a generic positive constant that will take different values at different places but will be independent of h, H, ν, and ν_T. Define the following bilinear $g : \boldsymbol{X} \times \boldsymbol{X} \to \mathbb{R}$:

$$g(\boldsymbol{v}, \boldsymbol{w}) = \sum_{j=1}^{N_h} \int_{E_j} (I - P_H)\nabla\boldsymbol{v} : (I - P_H)\nabla\boldsymbol{w} \quad \forall \boldsymbol{v}, \boldsymbol{w} \in \boldsymbol{X}.$$

For all $t > 0$, we seek a discontinuous approximation $(\boldsymbol{u}^h(t), p^h(t)) \in \mathbf{X}^h \times Q^h$ such that

$$\begin{aligned} &(\boldsymbol{u}_t^h(t), \boldsymbol{v}^h) + \nu(a(\boldsymbol{u}^h(t), \boldsymbol{v}^h) + J(\boldsymbol{u}^h(t), \boldsymbol{v}^h)) + \nu_T g(\boldsymbol{u}^h(t), \boldsymbol{v}^h) \\ &+ c(\boldsymbol{u}^h(t), \boldsymbol{u}^h(t), \boldsymbol{v}^h) + b(\boldsymbol{v}^h, p^h(t)) = (\boldsymbol{f}(t), \boldsymbol{v}^h) \quad \forall \boldsymbol{v}^h \in \boldsymbol{X}^h, \end{aligned} \tag{3.14}$$

$$b(\boldsymbol{u}^h(t), q^h) = 0 \quad \forall q^h \in Q^h, \tag{3.15}$$

$$(\boldsymbol{u}^h(0), \boldsymbol{v}^h) = (\boldsymbol{u}_0, \boldsymbol{v}^h) \quad \forall \boldsymbol{v}^h \in \boldsymbol{X}^h. \tag{3.16}$$

LEMMA 3.4. *There exists a unique solution to* (3.14)–(3.16).

Proof. Equations (3.14) and (3.15) reduce to the ordinary differential system

$$\frac{d\boldsymbol{u}^h}{dt} + \nu A\boldsymbol{u}^h + B\boldsymbol{u}^h + \nu_T G\boldsymbol{u}^h = \mathbf{F}.$$

By continuity, a solution exists. To prove uniqueness, we choose $\boldsymbol{v}^h = \boldsymbol{u}^h$ in (3.14) and $q^h = p^h$ in (3.15); we apply the coercivity equation (3.3) and the generalized Cauchy–Schwarz

$$\frac{1}{2}\frac{d}{dt}\|\boldsymbol{u}^h\|_{0,\Omega}^2 + \nu\kappa\|\boldsymbol{u}^h\|_X^2 \leq \|\boldsymbol{f}\|_{L^{4/3}(\Omega)}\|\boldsymbol{u}^h\|_{L^4(\Omega)} \leq \frac{\nu\kappa}{2}\|\boldsymbol{u}^h\|_X^2 + \frac{C}{\nu\kappa}\|\boldsymbol{f}\|_{L^{4/3}(\Omega)}^2.$$

Integrating over $[0,t]$ yields

$$\|\boldsymbol{u}^h(t)\|^2_{L^\infty(0,T;L^2(\Omega))} + \nu\kappa\|\boldsymbol{u}^h\|^2_{L^2(0,T;X)} \leq \|\boldsymbol{u}^h(0)\|^2_0 + \frac{C}{\nu\kappa}\|\boldsymbol{f}\|^2_{L^2(0,T;L^{4/3}(\Omega))}.$$

Since $\boldsymbol{u}^h$ is bounded in $L^\infty(0,T;L^2(\Omega)^2)$, it is unique [4]. The existence and uniqueness of p^h are obtained from the inf-sup condition stated above. □

Remark 1. From a continuum mechanics point of view, it might be advantageous to consider the symmetrized velocity tensor. In this case, the bilinear form a is replaced by

$$a(\boldsymbol{v},\boldsymbol{w}) = \sum_{j=1}^{N_h}\int_{E_j}\nabla^s\boldsymbol{v} : \nabla^s\boldsymbol{w} - \sum_{k=1}^{M_h}\int_{e_k}(\{\nabla^s\boldsymbol{v}\}\mathbf{n}_k\cdot[\boldsymbol{w}] - \epsilon_0\{\nabla^s\boldsymbol{w}\}\mathbf{n}_k\cdot[\boldsymbol{v}]),$$

where $\nabla^s\boldsymbol{v} = 0.5(\nabla\boldsymbol{v} + \nabla\boldsymbol{v}^T)$ and the term relating the coarse and refined meshes is replaced by $\sum_{j=1}^{N_h}\int_{E_j}(I-P_H)\nabla^s\boldsymbol{u} : (I-P_H)\nabla^s\boldsymbol{v}^h$. It is easy to check that all the results proved in this paper also hold true for the symmetrized tensor formulation.

4. Semidiscrete a priori error estimate. In this section, a priori error estimates for the continuous in time problem are derived. The estimates are optimal in the fine mesh size h. The effects of the coarse scale appear as higher order terms.

THEOREM 4.1. *Let $(\boldsymbol{u},p)$ be the solution of* (2.1)–(2.4) *satisfying $\boldsymbol{u}\in L^\infty(0,T;\boldsymbol{H}^2(\Omega)), p\in L^2(0,T;H^1(\Omega))$. In addition, we assume that $\boldsymbol{u}_t\in L^2(0,T;\boldsymbol{H}^{r+1}(\Omega))$, $\boldsymbol{u}\in L^\infty(0,T;\boldsymbol{H}^{r+1}(\Omega))$, and $p\in L^2(0,T;\boldsymbol{H}^r(\Omega))$. Then, the continuous in time solution $\boldsymbol{u}_h$ satisfies*

$$\begin{aligned}&\|\boldsymbol{u}-\boldsymbol{u}^h\|_{L^\infty(0,T;L^2(\Omega))} + \kappa^{1/2}\nu^{1/2}\|\boldsymbol{u}-\boldsymbol{u}^h\|_{L^2(0,T;X)}\\ &\qquad + \nu_T^{1/2}\|(I-P_H)\nabla(\boldsymbol{u}-\boldsymbol{u}^h)\|_{L^2(0,T;L^2(\Omega))}\\ &\leq Ce^{CT(\nu^{-1}+1)}[h^r((\nu+\nu^{-1}+\nu_T)^{1/2}|\boldsymbol{u}|_{L^2(0,T;H^{r+1}(\Omega))} + \nu^{-1/2}|p|_{L^2(0,T;H^r(\Omega))}\\ &\qquad + |\boldsymbol{u}_t|_{L^2(0,T;H^{r+1}(\Omega))}) + \nu_T^{1/2}H^r|\boldsymbol{u}|_{L^2(0,T;H^{r+1}(\Omega))}] + Ch^r|\boldsymbol{u}_0|_{r+1,\Omega},\end{aligned}$$

where C is a positive constant independent of h, H, ν and ν_T.

Proof. We fix $t>0$ and for simplicity, we drop the argument in t. Defining $\boldsymbol{e}^h = \boldsymbol{u}-\boldsymbol{u}^h$ and subtracting (3.14), (3.15), (3.16) from (3.6), (3.7), (3.8), respectively, yields

$$\begin{aligned}&(\boldsymbol{e}^h_t,\boldsymbol{v}^h) + \nu a(\boldsymbol{e}^h,\boldsymbol{v}^h) + \nu J(\boldsymbol{e}^h,\boldsymbol{v}^h) + \nu_T g(\boldsymbol{e}^h,\boldsymbol{v}^h) + c(\boldsymbol{u},\boldsymbol{u},\boldsymbol{v}^h)\\ &\quad - c(\boldsymbol{u}^h,\boldsymbol{u}^h,\boldsymbol{v}^h) = -b(\boldsymbol{v}^h,p-p^h) + \nu_T g(\boldsymbol{u},\boldsymbol{v}^h) \quad \forall\boldsymbol{v}^h\in\boldsymbol{X}_h, \quad \forall t>0,\end{aligned} \tag{4.1}$$

$$b(\boldsymbol{e}^h,q^h) = 0 \quad \forall q^h\in Q^h, \quad \forall t>0, \tag{4.2}$$

$$(\boldsymbol{e}^h(0),\boldsymbol{v}^h) = 0, \quad \forall\boldsymbol{v}^h\in\boldsymbol{X}^h. \tag{4.3}$$

Decompose the error $\boldsymbol{e}^h = \boldsymbol{\eta} - \boldsymbol{\phi}^h$, where $\boldsymbol{\phi}^h = \boldsymbol{u}^h - R_h(\boldsymbol{u})$ and $\boldsymbol{\eta}$ is the interpolation error $\boldsymbol{\eta} = \boldsymbol{u} - R_h(\boldsymbol{u})$. Set $\boldsymbol{v}^h = \boldsymbol{\phi}^h$ in (4.1) and $q^h = r_h(p) - p_h$ in (4.2):

$$\begin{aligned}&(\boldsymbol{\phi}^h_t,\boldsymbol{\phi}^h) + \nu a(\boldsymbol{\phi}^h,\boldsymbol{\phi}^h) + \nu J(\boldsymbol{\phi}^h,\boldsymbol{\phi}^h) + \nu_T g(\boldsymbol{\phi}^h,\boldsymbol{\phi}^h)\\ &\quad + c_{\boldsymbol{u}^h}(\boldsymbol{u}^h,\boldsymbol{u}^h,\boldsymbol{\phi}^h) - c_{\boldsymbol{u}}(\boldsymbol{u},\boldsymbol{u},\boldsymbol{\phi}^h) = (\boldsymbol{\eta}_t,\boldsymbol{\phi}^h) + \nu a(\boldsymbol{\eta},\boldsymbol{\phi}^h) + \nu J(\boldsymbol{\eta},\boldsymbol{\phi}^h)\\ &\quad + \nu_T g(\boldsymbol{\eta},\boldsymbol{\phi}^h) + b(\boldsymbol{\phi}^h,p-r_h(p)) - \nu_T g(\boldsymbol{u},\boldsymbol{\phi}^h) \quad \forall t>0.\end{aligned} \tag{4.4}$$

We now bound the terms on the right hand-side of (4.4). The first three terms are rewritten as

$$\begin{aligned}(\boldsymbol{\eta}_t, \boldsymbol{\phi}^h) + \nu a(\boldsymbol{\eta}, \boldsymbol{\phi}^h) + \nu J(\boldsymbol{\eta}, \boldsymbol{\phi}^h) &= (\boldsymbol{\eta}_t, \boldsymbol{\phi}^h) + \nu \sum_{j=1}^{N_h} \int_{E_j} \nabla \boldsymbol{\eta} : \nabla \boldsymbol{\phi}^h \\ - \nu \sum_{k=1}^{M_h} \int_{e_k} \{\nabla \boldsymbol{\eta}\} \boldsymbol{n}_k \cdot [\boldsymbol{\phi}^h] &+ \nu \epsilon_0 \sum_{k=1}^{M_h} \int_{e_k} \{\nabla \boldsymbol{\phi}^h\} \boldsymbol{n}_k \cdot [\boldsymbol{\eta}] + \nu J(\boldsymbol{\eta}, \boldsymbol{\phi}^h) \\ &= S_1 + \cdots + S_5.\end{aligned}$$

Using the Cauchy–Schwarz and Young's inequalities and the approximation result (2.7), the first two terms are bounded as follows:

$$\begin{aligned}S_1 &\le \|\boldsymbol{\eta}_t\|_{0,\Omega} \|\boldsymbol{\phi}^h\|_{0,\Omega} \le \frac{1}{2} \|\boldsymbol{\phi}^h\|_{0,\Omega}^2 + C h^{2r+2} |\boldsymbol{u}_t|_{r+1,\Omega}^2, \\ S_2 &\le \nu \sum_{j=1}^{N_h} \|\nabla \boldsymbol{\eta}\|_{0,E_j} \|\nabla \boldsymbol{\phi}^h\|_{0,E_j} \le \frac{\kappa \nu}{8} \|\nabla \boldsymbol{\phi}^h\|_0^2 + C \nu h^{2r} |\boldsymbol{u}|_{r+1,\Omega}^2.\end{aligned}$$

To bound the third term, we insert the standard Lagrange interpolant of degree r, denoted by $L_h(\boldsymbol{u})$:

$$\begin{aligned}- \nu \sum_{k=1}^{M_h} \int_{e_k} \{\nabla \boldsymbol{\eta}\} \boldsymbol{n}_k \cdot [\boldsymbol{\phi}^h] &= - \nu \sum_{k=1}^{M_h} \int_{e_k} \{\nabla (\boldsymbol{u} - L_h(\boldsymbol{u}))\} \boldsymbol{n}_k \cdot [\boldsymbol{\phi}^h] \\ &\quad - \nu \sum_{k=1}^{M_h} \int_{e_k} \{\nabla (L_h(\boldsymbol{u}) - R_h(\boldsymbol{u}))\} \boldsymbol{n}_k \cdot [\boldsymbol{\phi}^h].\end{aligned}$$

By using inequalities (2.12) and (2.15), the definition of the jump (2.5), and the approximation results (2.7), the third term can be bounded by

$$S_3 \le \frac{\kappa \nu}{12} J(\boldsymbol{\phi}^h, \boldsymbol{\phi}^h) + C \nu h^{2r} |\boldsymbol{u}|_{r+1,\Omega}^2.$$

Then, from the trace inequalities (2.11) and (2.15) and the approximation result (2.7), we have

$$\begin{aligned}S_4 &\le C \nu \left(\sum_{k=1}^{M_h} \frac{\sigma}{|e|} \|[\boldsymbol{\eta}]\|_{0,e_k}^2 \right)^{1/2} \left(\sum_{k=1}^{M_h} \frac{|e|}{\sigma} \|\{\nabla \boldsymbol{\phi}^h\}\|_{0,e_k}^2 \right)^{1/2} \\ &\le \frac{\kappa \nu}{8} \|\nabla \boldsymbol{\phi}^h\|_0^2 + C \nu h^{2r} |\boldsymbol{u}|_{r+1,\Omega}^2.\end{aligned}$$

The jump term is bounded by the approximation result (2.7) as follows:

$$S_5 \le \frac{\kappa \nu}{12} J(\boldsymbol{\phi}^h, \boldsymbol{\phi}^h) + C \nu J(\boldsymbol{\eta}, \boldsymbol{\eta}) \le \frac{\kappa \nu}{12} J(\boldsymbol{\phi}^h, \boldsymbol{\phi}^h) + C \nu h^{2r} |\boldsymbol{u}|_{r+1,\Omega}^2.$$

The eddy viscosity term in the right-hand side of (4.4) is bounded by (3.12) and (2.7):

$$\nu_T g(\boldsymbol{\eta}, \boldsymbol{\phi}^h) \le \frac{\nu_T}{4} \|(I - P_H) \nabla \boldsymbol{\phi}^h\|_0^2 + C \nu_T h^{2r} |\boldsymbol{u}|_{r+1,\Omega}^2.$$

Because of (2.9), the pressure term is reduced to

$$b(\boldsymbol{\phi}^h, p - r_h(p)) = \sum_{k=1}^{M_h} \int_{e_k} \{p - r_h(p)\}[\boldsymbol{\phi}^h] \cdot \boldsymbol{n}_k,$$

which is bounded by using the Cauchy–Schwarz inequality, trace inequality (2.11), and the approximation result (2.10):

$$\begin{aligned} b(\boldsymbol{\phi}^h, p - r_h(p)) &\leq C \left(\|p - r_h(p)\|_0^2 + \sum_{j=1}^{N_h} h_{E_j}^2 |p - r_h(p)|_{1,E_j}^2 \right)^{1/2} J(\boldsymbol{\phi}^h, \boldsymbol{\phi}^h)^{1/2} \\ &\leq \frac{\kappa\nu}{12} J(\boldsymbol{\phi}^h, \boldsymbol{\phi}^h) + C\frac{h^{2r}}{\nu} |p|_{r,\Omega}^2. \end{aligned}$$

The last term on the right-hand side of (4.4), corresponding to the consistency error, is bounded using the Cauchy–Schwarz inequality and the bound (3.13):

$$\nu_T g(\boldsymbol{u}, \boldsymbol{\phi}^h) \leq \frac{\nu_T}{4} \|\!|(I - P_H)\nabla \boldsymbol{\phi}^h\|\!|_0^2 + C\nu_T H^{2r} |\boldsymbol{u}|_{r+1,\Omega}^2.$$

Thus far, the terms in the right-hand side of (4.4) are bounded by

$$\begin{aligned} &\frac{1}{2}\|\boldsymbol{\phi}^h\|_0^2 + Ch^{2r}|\boldsymbol{u}_t|_{r+1,\Omega}^2 + C(\nu + \nu_T)h^{2r}|\boldsymbol{u}|_{r+1,\Omega}^2 + C\frac{h^{2r}}{\nu}|p|_{r,\Omega}^2 \\ &\quad + C\nu_T H^{2r}|\boldsymbol{u}|_{r+1,\Omega}^2 + \frac{\kappa\nu}{4}\|\boldsymbol{\phi}^h\|_X^2 + \frac{\nu_T}{2}\|\!|(I - P_H)\nabla\boldsymbol{\phi}^h\|\!|_0^2. \end{aligned}$$

Consider now the nonlinear terms in (4.4). We first note that since $\boldsymbol{u}$ is continuous, the second term in (3.4) vanishes and can be replaced by a similar quantity with a different domain of integration:

$$c_{\boldsymbol{u}}(\boldsymbol{u}, \boldsymbol{u}, \boldsymbol{\phi}^h) = c_{\boldsymbol{u}^h}(\boldsymbol{u}, \boldsymbol{u}, \boldsymbol{\phi}^h).$$

Therefore, adding and subtracting the interpolant $R_h(\boldsymbol{u})$ yields

$$\begin{aligned} c_{\boldsymbol{u}^h}(\boldsymbol{u}^h, \boldsymbol{u}^h, \boldsymbol{\phi}^h) - c_{\boldsymbol{u}^h}(\boldsymbol{u}, \boldsymbol{u}, \boldsymbol{\phi}^h) &= c_{\boldsymbol{u}^h}(\boldsymbol{u}^h, \boldsymbol{\phi}^h, \boldsymbol{\phi}^h) + c_{\boldsymbol{u}^h}(\boldsymbol{\phi}^h, \boldsymbol{u}, \boldsymbol{\phi}^h) \\ &- c_{\boldsymbol{u}^h}(\boldsymbol{\phi}^h, \boldsymbol{\eta}, \boldsymbol{\phi}^h) - c_{\boldsymbol{u}^h}(\boldsymbol{\eta}, R_h(\boldsymbol{u}), \boldsymbol{\phi}^h) - c_{\boldsymbol{u}^h}(\boldsymbol{u}, \boldsymbol{\eta}, \boldsymbol{\phi}^h). \end{aligned}$$

To simplify the writing, we drop the subscript $\boldsymbol{u}_h$ and write $c(\cdot,\cdot,\cdot)$ for $c_{\boldsymbol{u}_h}(\cdot,\cdot,\cdot)$. From inequality (3.5), the first term is positive. We then bound the other terms. We first note that we can rewrite the form c as

$$c(\boldsymbol{\phi}^h, \boldsymbol{u}, \boldsymbol{\phi}^h) = \sum_{j=1}^{N_h} \int_{E_j} (\boldsymbol{\phi}^h \cdot \nabla \boldsymbol{u}) \cdot \boldsymbol{\phi}^h - \frac{1}{2} b(\boldsymbol{\phi}^h, \boldsymbol{u} \cdot \boldsymbol{\phi}^h). \tag{4.5}$$

The first term, using the L^p bound (2.6), is bounded by

$$\begin{aligned} \sum_{j=1}^{N_h} \int_{E_j} (\boldsymbol{\phi}^h \cdot \nabla \boldsymbol{u}) \cdot \boldsymbol{\phi}^h &\leq \|\boldsymbol{\phi}^h\|_{L^4(\Omega)} \|\nabla \boldsymbol{u}\|_{L^4(\Omega)} \|\boldsymbol{\phi}^h\|_{L^2(\Omega)} \\ &\leq \frac{\kappa\nu}{64}\|\boldsymbol{\phi}^h\|_X^2 + \frac{C}{\nu}\|\boldsymbol{u}\|_{L^\infty(0,T;W^{2,4/3}(\Omega))}^2 \|\boldsymbol{\phi}^h\|_{0,\Omega}^2. \end{aligned}$$

Let $\boldsymbol{c}_1$ and $\boldsymbol{c}_2$ be the piecewise constant vectors such that

$$\boldsymbol{c}_1|_{E_j} = \frac{1}{|E_j|}\int_{E_j} \boldsymbol{u}, \quad \boldsymbol{c}_2|_{E_j} = \frac{1}{|E_j|}\int_{E_j} \boldsymbol{\phi}^h, \quad 1 \le j \le N_h.$$

We rewrite using (4.2) and (3.11):

$$b(\boldsymbol{\phi}^h, \boldsymbol{u}\cdot\boldsymbol{\phi}^h) = b(\boldsymbol{\phi}^h, \boldsymbol{u}\cdot\boldsymbol{\phi}^h - \boldsymbol{c}_1\cdot\boldsymbol{c}_2) = b(\boldsymbol{\phi}^h, (\boldsymbol{u}-\boldsymbol{c}_1)\cdot\boldsymbol{\phi}^h) + b(\boldsymbol{\phi}^h, \boldsymbol{c}_1\cdot(\boldsymbol{\phi}^h - \boldsymbol{c}_2)).$$

Then, expanding the first term,

$$\begin{aligned} b(\boldsymbol{\phi}^h, (\boldsymbol{u}-\boldsymbol{c}_1)\cdot\boldsymbol{\phi}^h) &= -\sum_{j=1}^{N_h}\int_E (\boldsymbol{u}-\boldsymbol{c}_1)\cdot\boldsymbol{\phi}^h \nabla\cdot\boldsymbol{\phi}^h \\ &+ \sum_{k=1}^{M_h}\int_{e_k} \{(\boldsymbol{u}-\boldsymbol{c}_1)\cdot\boldsymbol{\phi}^h\}[\boldsymbol{\phi}^h]\cdot\boldsymbol{n}_k = S_6 + S_7. \end{aligned}$$

The first term is bounded, for $s > 2$, using the inverse inequality (2.16) and (2.6):

$$\begin{aligned} S_6 &\le C\sum_{j=1}^{N_h} \|\boldsymbol{u}-\boldsymbol{c}_1\|_{L^s(E_j)}\|\boldsymbol{\phi}^h\|_{L^{\frac{2s}{s-2}}(E_j)}\|\nabla\boldsymbol{\phi}^h\|_{L^2(E_j)} \\ &\le C\|\boldsymbol{\phi}^h\|_{0,\Omega}|\boldsymbol{u}|_{W^{1,s}(\Omega)}\|\boldsymbol{\phi}^h\|_{L^{\frac{2s}{s-2}}(\Omega)} \\ &\le C\|\boldsymbol{\phi}^h\|_{0,\Omega}|\boldsymbol{u}|_{W^{1,s}(\Omega)}\|\boldsymbol{\phi}^h\|_X \le \frac{\kappa\nu}{64}\|\boldsymbol{\phi}^h\|_X^2 + \frac{C}{\nu}\|\boldsymbol{u}\|^2_{L^\infty(0,T;W^{2,4/3}(\Omega))}\|\boldsymbol{\phi}^h\|_0^2. \end{aligned}$$

The bound for the second term is more technical. First, passing to the reference element $\hat{E}$ and using the trace inequality (2.14), we obtain

$$\begin{aligned} S_7 &\le C\sum_{k=1}^{M_h} |e_k||E|^{-1/2}\|\boldsymbol{\phi}^h\|_{0,E}\|(\hat{\boldsymbol{u}}-\hat{\boldsymbol{c}}_1)\cdot\hat{\boldsymbol{\phi}}^h\|_{\hat{e}} \\ &\le C\sum_{k=1}^{M_h} |e_k||E|^{-1/2}\|\boldsymbol{\phi}^h\|_{0,E}(\|(\hat{\boldsymbol{u}}-\hat{\boldsymbol{c}}_1)\cdot\hat{\boldsymbol{\phi}}^h\|_{0,\hat{E}} + \|\hat{\nabla}((\hat{\boldsymbol{u}}-\hat{\boldsymbol{c}}_1)\cdot\hat{\boldsymbol{\phi}}^h)\|_{0,\hat{E}}). \end{aligned}$$

The L^2 term is bounded, for $s > 2$, as

$$\begin{aligned} \|(\hat{\boldsymbol{u}}-\hat{\boldsymbol{c}}_1)\cdot\hat{\boldsymbol{\phi}}^h\|_{0,\hat{E}} &\le \|\hat{\boldsymbol{u}}-\hat{\boldsymbol{c}}_1\|_{L^s(\hat{E})}\|\hat{\boldsymbol{\phi}}^h\|_{L^{\frac{2s}{s-2}}(\hat{E})} \\ &\le h|E|^{-1/s-(s-2)/(2s)}|\boldsymbol{u}|_{W^{1,s}(E)}\|\boldsymbol{\phi}^h\|_{L^{\frac{2s}{s-2}}(E)} \le C|\boldsymbol{u}|_{W^{1,s}(E)}\|\boldsymbol{\phi}^h\|_{L^{\frac{2s}{s-2}}(E)}. \end{aligned}$$

Note that for the gradient term we write

$$\|\hat{\nabla}((\hat{\boldsymbol{u}}-\hat{\boldsymbol{c}}_1)\cdot\hat{\boldsymbol{\phi}}^h)\|_{0,\hat{E}} = \|(\hat{\nabla}\hat{\boldsymbol{u}}\cdot\hat{\boldsymbol{\phi}}^h + (\hat{\boldsymbol{u}}-\hat{\boldsymbol{c}}_1)\cdot\nabla\hat{\boldsymbol{\phi}}^h)\|.$$

Let us first bound

$$\begin{aligned} \|\hat{\nabla}\hat{\boldsymbol{u}}\cdot\hat{\boldsymbol{\phi}}^h\|_{0,\hat{E}} &\le \|\hat{\nabla}\hat{\boldsymbol{u}}\|_{L^s(\hat{E})}\|\hat{\boldsymbol{\phi}}^h\|_{L^{\frac{2s}{s-2}}(\hat{E})} \\ &\le Ch|E|^{-1/s}\|\nabla\boldsymbol{u}\|_{L^s(E)}|E|^{-(s-2)/2s}\|\boldsymbol{\phi}^h\|_{L^{\frac{2s}{s-2}}(E)} \le C\|\nabla\boldsymbol{u}\|_{L^s(E)}\|\boldsymbol{\phi}^h\|_{L^{\frac{2s}{s-2}}(E)}. \end{aligned}$$

Now the other term is

$$\|(\hat{\boldsymbol{u}}-\hat{\boldsymbol{c}}_1)\cdot\hat{\nabla}\hat{\boldsymbol{\phi}}^h\|_{0,\hat{E}} \le \|\hat{\boldsymbol{u}}-\hat{\boldsymbol{c}}_1\|_{L^\infty(\hat{E})}\|\hat{\nabla}\hat{\boldsymbol{\phi}}^h\|_{0,\hat{E}} \le Ch\|\boldsymbol{u}\|_{L^\infty(E)}\|\nabla\boldsymbol{\phi}^h\|_{0,E}.$$

Combining all the bounds above and using (2.6), we have

$$S_7 \le C\sum_{j=1}^{N_h}\|\boldsymbol{\phi}^h\|_{0,E_j}\Big[|\boldsymbol{u}|_{W^{1,s}(E_j)}\|\boldsymbol{\phi}^h\|_{L^{\frac{2s}{s-2}}(E_j)}$$
$$+\|\nabla\boldsymbol{u}\|_{L^s(E_j)}\|\boldsymbol{\phi}^h\|_{L^{\frac{2s}{s-2}}(E_j)} + h|\boldsymbol{u}|_{L^\infty(E_j)}\|\nabla\boldsymbol{\phi}^h\|_{L^2(E_j)}\Big] \le \frac{\kappa\nu}{32}\|\boldsymbol{\phi}^h\|_X^2 + \frac{C}{\nu}\|\boldsymbol{\phi}^h\|_0^2.$$

Now,

$$b(\boldsymbol{\phi}^h, \boldsymbol{c}_1\cdot(\boldsymbol{\phi}^h-\boldsymbol{c}_2)) = -\sum_{j=1}^{N_h}\int_E \boldsymbol{c}_1\cdot(\boldsymbol{\phi}^h-\boldsymbol{c}_2)\nabla\cdot\boldsymbol{\phi}^h$$
$$+\sum_{k=1}^{M_h}\int_{e_k}\{\boldsymbol{c}_1\cdot(\boldsymbol{\phi}^h-\boldsymbol{c}_2)\}[\boldsymbol{\phi}^h]\cdot\boldsymbol{n}_k = S_8+S_9.$$

The first term is bounded by (2.16):

$$S_8 \le C\sum_{j=1}^{N_h}\|\boldsymbol{c}_1\|\|\boldsymbol{\phi}^h-\boldsymbol{c}_2\|_{0,E_j}h^{-1}\|\boldsymbol{\phi}^h\|_{0,E_j}$$
$$\le C\sum_{j=1}^{N_h}\|\boldsymbol{c}_1\|\|\nabla\boldsymbol{\phi}^h\|_{0,E_j}\|\boldsymbol{\phi}^h\|_{0,E_j} \le \frac{\kappa\nu}{64}\|\boldsymbol{\phi}^h\|_X^2 + \frac{C}{\nu}\|\boldsymbol{u}\|^2_{L^\infty([0,T]\times\Omega)}\|\boldsymbol{\phi}^h\|^2_{0,\Omega}.$$

Similarly, the second term is bounded as

$$S_9 \le C\sum_{j=1}^{N_h}\|\boldsymbol{c}_1\|\|\nabla\boldsymbol{\phi}^h\|_{0,E_j}\|\boldsymbol{\phi}_h\|_{0,E_j} \le \frac{\kappa\nu}{64}\|\boldsymbol{\phi}^h\|_X^2 + \frac{C}{\nu}\|\boldsymbol{u}\|^2_{L^\infty([0,T]\times\Omega)}\|\boldsymbol{\phi}^h\|^2_{0,\Omega}.$$

Thus,

$$c(\boldsymbol{\phi}^h,\boldsymbol{u},\boldsymbol{\phi}^h) \le \frac{5\kappa\nu}{64}\|\boldsymbol{\phi}^h\|_X^2 + \frac{C}{\nu}\|\boldsymbol{\phi}^h\|^2_{0,\Omega}.$$

Let us now bound $c(\boldsymbol{\phi}^h,\boldsymbol{\eta},\boldsymbol{\phi}^h)$:

$$c(\boldsymbol{\phi}^h,\boldsymbol{\eta},\boldsymbol{\phi}^h) = \sum_{j=1}^{N_h}\left(\int_{E_j}(\boldsymbol{\phi}^h\cdot\nabla\boldsymbol{\eta})\cdot\boldsymbol{\phi}^h + \int_{\partial E_j^-}|\{\boldsymbol{\phi}^h\}\cdot\boldsymbol{n}_{E_j}|(\boldsymbol{\eta}^{\text{int}}-\boldsymbol{\eta}^{\text{ext}})\cdot\boldsymbol{\phi}^{h,int}\right)$$
$$-\frac{1}{2}b(\boldsymbol{\phi}^h,\boldsymbol{\eta}\cdot\boldsymbol{\phi}^h).$$

The first term is easily bounded:

$$\sum_{j=1}^{N_h}\int_{E_j}(\boldsymbol{\phi}^h\cdot\nabla\boldsymbol{\eta})\cdot\boldsymbol{\phi}^h \le \sum_{j=1}^{N_h}\|\boldsymbol{\phi}^h\|_{0,E_j}\|\boldsymbol{\phi}^h\|_{L^4(E_j)}\|\nabla\boldsymbol{\eta}\|_{L^4(E_j)}$$
$$\le \frac{\kappa\nu}{32}\|\boldsymbol{\phi}^h\|_X^2 + \frac{C}{\nu}\|\boldsymbol{u}\|^2_{L^\infty(0,T;W^{2,4/3}(\Omega))}\|\boldsymbol{\phi}^h\|^2_{0,\Omega}.$$

The second term is bounded using inequalities (2.13), (2.16), (2.6), and (2.8):

$$\sum_{j=1}^{N_h}\int_{\partial E_j^-}|\{\boldsymbol{\phi}^h\}\cdot\boldsymbol{n}_{E_j}|(\boldsymbol{\eta}^{\rm int}-\boldsymbol{\eta}^{\rm ext})\cdot\boldsymbol{\phi}^{h,int}\le C\sum_{j=1}^{N_h}\|\boldsymbol{\phi}^h\|_{L^4(\partial E_j)}\|\boldsymbol{\eta}\|_{L^4(\partial E_j)}\|\boldsymbol{\phi}^h\|_{L^2(\partial E_j)}$$
$$\le C\sum_{j=1}^{N_h}h^{-3/2}h^{r+1}|\boldsymbol{u}|_{r+1,\Omega}\|\boldsymbol{\phi}^h\|_{0,\Omega}^2\le\frac{\kappa\nu}{64}\|\boldsymbol{\phi}^h\|_X^2+C\|\boldsymbol{u}\|_{L^\infty(0,T;H^{r+1}(\Omega))}^2\|\boldsymbol{\phi}^h\|_{0,\Omega}^2.$$

The last term in $c(\boldsymbol{\phi}^h,\boldsymbol{\eta},\boldsymbol{\phi}^h)$ is bounded like the terms S_6, S_7, S_8, and S_9 of $c(\boldsymbol{\phi}^h,\boldsymbol{u},\boldsymbol{\phi}^h)$. The remaining nonlinear terms are bounded in a similar fashion:

$$c_{\boldsymbol{u}^h}(\boldsymbol{\eta},R_h(\boldsymbol{u}),\boldsymbol{\phi}^h)=\sum_{j=1}^{N_h}\int_{E_j}(\boldsymbol{\eta}\cdot\nabla R_h(\boldsymbol{u}))\cdot\boldsymbol{\phi}^h$$
$$+\sum_{j=1}^{N_h}\int_{\partial E_j^-}|\{\boldsymbol{\eta}\}\cdot\boldsymbol{n}_{E_j}|(R_h(\boldsymbol{u})^{\rm int}-R_h(\boldsymbol{u})^{\rm ext})\cdot\boldsymbol{\phi}^{h,{\rm int}}+\frac{1}{2}\sum_{j=1}^{N_h}\int_{E_j}(\nabla\cdot\boldsymbol{\eta})R_h(\boldsymbol{u})\cdot\boldsymbol{\phi}^h$$
$$-\frac{1}{2}\sum_{k=1}^{M_h}\int_{e_k}[\boldsymbol{\eta}]\cdot\boldsymbol{n}_k\{R_h(\boldsymbol{u})\cdot\boldsymbol{\phi}^h\}=S_{10}+\cdots+S_{13}.$$

Using the bound (2.6) and the approximation result (2.7), we have

$$S_{10}\le\|\boldsymbol{\eta}\|_{L^2(\Omega)}\|\nabla R_h(\boldsymbol{u})\|_{L^4(\Omega)}\|\boldsymbol{\phi}^h\|_{L^4(\Omega)}\le\frac{\kappa\nu}{64}\|\boldsymbol{\phi}^h\|_X^2+C\|\boldsymbol{u}\|_{L^\infty([0,T]\times\Omega)}^2h^{2r}|\boldsymbol{u}|_{r+1,\Omega}^2.$$

The inequalities (2.11), (2.14), and (2.6) and the approximation result (2.7) yield

$$S_{11}\le C\sum_{j=1}^{N_h}h_{E_j}^{-1/2}(\|\boldsymbol{\eta}\|_{0,E_j}+h_{E_j}\|\nabla\boldsymbol{\eta}\|_{0,E_j})h_{E_j}^{-1/2}\|\boldsymbol{\phi}^h\|_{0,E_j}$$
$$\le C\|\boldsymbol{\phi}^h\|_{0,\Omega}^2+C\|\boldsymbol{u}\|_{L^\infty([0,T]\times\Omega)}^2h^{2r}|\boldsymbol{u}|_{r+1,\Omega}^2.$$

Similarly, we have

$$S_{12}\le\sum_{j=1}^{N_h}\|\boldsymbol{u}\|_{L^\infty([0,T]\times\Omega)}\|\boldsymbol{\phi}^h\|_{0,E_j}\|\nabla\cdot\boldsymbol{\eta}\|_{0,E_j}$$
$$\le C\|\boldsymbol{\phi}^h\|_{0,\Omega}^2+C\|\boldsymbol{u}\|_{L^\infty([0,T]\times\Omega)}^2h^{2r}|\boldsymbol{u}|_{r+1,\Omega}^2.$$

Note that S_{13} is bounded exactly like S_{11}. The other nonlinear term is bounded using (2.7) and (2.14):

$$c_{\boldsymbol{u}^h}(\boldsymbol{u},\boldsymbol{\eta},\boldsymbol{\phi}^h)=\sum_{j=1}^{N_h}\int_{E_j}(\boldsymbol{u}\cdot\nabla\boldsymbol{\eta})\cdot\boldsymbol{\phi}^h+\sum_{j=1}^{N_h}\int_{\partial E_j^-}|\{\boldsymbol{u}\}\cdot\boldsymbol{n}_{E_j}|(\boldsymbol{\eta}^{\rm int}-\boldsymbol{\eta}^{\rm ext})\cdot\boldsymbol{\phi}^{h,{\rm int}}$$
$$\le C\sum_{j=1}^{N_h}\|\boldsymbol{u}\|_{L^\infty([0,T]\times\Omega)}\|\nabla\boldsymbol{\eta}\|_{0,E_j}\|\boldsymbol{\phi}^h\|_{0,E_j}+C\sum_{j=1}^{N_h}\|\boldsymbol{u}\|_{L^\infty([0,T]\times\Omega)}\|\boldsymbol{\eta}\|_{0,\partial E_j}\|\boldsymbol{\phi}^h\|_{0,\partial E_j}$$
$$\le C\|\boldsymbol{\phi}^h\|_{0,\Omega}^2+C\|\boldsymbol{u}\|_{L^\infty([0,T]\times\Omega)}^2h^{2r}|\boldsymbol{u}|_{r+1,\Omega}^2.$$

Combining all bounds above and using (3.3), we obtain

$$\frac{1}{2}\frac{d}{dt}\|\boldsymbol{\phi}^h\|_0^2 + \frac{\kappa\nu}{2}\|\boldsymbol{\phi}^h\|_X^2 + \frac{\nu_T}{2}\|(I-P_H)\nabla\boldsymbol{\phi}^h\|_0^2 \le C\left(\frac{1}{\nu}+1\right)\|\boldsymbol{\phi}^h\|_0^2$$
$$+ Ch^{2r}\left(\nu + \frac{1}{\nu} + \nu_T\right)|\boldsymbol{u}|_{r+1,\Omega}^2 + C\frac{h^{2r}}{\nu}|p|_{r,\Omega}^2 + Ch^{2r}|\boldsymbol{u}_t|_{r+1,\Omega}^2 + C\nu_T H^{2r}|\boldsymbol{u}|_{r+1,\Omega}^2.$$

Integrating from 0 to t, noting that $\|\boldsymbol{\phi}^h(0)\|_0$ is of the order h^r, and using Gronwall's lemma, yield

$$\|\boldsymbol{\phi}^h(t)\|_0^2 + \kappa\nu\|\boldsymbol{\phi}^h\|_{L^2(0,t;X)}^2 + \nu_T\|(I-P_H)\nabla\boldsymbol{\phi}^h\|_{L^2(0,t;L^2(\Omega))}^2$$
$$\le Ce^{C(1+\nu^{-1})}h^{2r}[(\nu+\nu^{-1}+\nu_T)|\boldsymbol{u}|_{L^2(0,T;H^{r+1}(\Omega))}^2 + \nu^{-1}|p|_{L^2(0,T;H^r(\Omega))}^2$$
$$+|\boldsymbol{u}_t|_{L^2(0,T;H^{r+1}(\Omega))}^2 + \nu_T H^{2r}|\boldsymbol{u}|_{L^2(0,T;H^{r+1}(\Omega))}^2] + Ch^r|\boldsymbol{u}_0|_{r+1,\Omega}^2,$$

where the constant C is independent of ν, ν_T, h, H but depends on $\|\boldsymbol{u}\|_{L^\infty(0,T;W^{2,4/3}(\Omega))}$. The theorem is obtained using the approximation results (2.7) and (2.8) and the following inequality:

$$\|\boldsymbol{u}(t)-\boldsymbol{u}^h(t)\|_0^2 + \kappa\nu\|\boldsymbol{u}(t)-\boldsymbol{u}^h(t)\|_{L^2(0,T;X)}^2 + \nu_T\|(I-P_H)\nabla(\boldsymbol{u}(t)-\boldsymbol{u}^h(t))\|_{L^2(0,T;L^2(\Omega))}^2$$
$$\le \|\boldsymbol{\phi}^h(t)\|_0^2 + \kappa\nu\|\boldsymbol{\phi}^h\|_{L^2(0,T;X)}^2 + \nu_T\|(I-P_H)\nabla\boldsymbol{\phi}^h\|_{L^2(0,T;L^2(\Omega))}^2$$
$$+\|\boldsymbol{\eta}(t)\|_0^2 + \kappa\nu\|\boldsymbol{\eta}\|_{L^2(0,T;X)}^2 + \nu_T\|(I-P_H)\nabla\boldsymbol{\eta}\|_{L^2(0,T;L^2(\Omega))}^2. \qquad \square$$

Remark 2. One of the most important properties of Theorem 4.1 is that the new method improves its robustness with respect to the Reynolds number. In most cases, error estimations of Navier–Stokes equations give a Gronwall constant that depends on the Reynolds number as $1/\nu^3$. In contrast, this approach leads to a better error estimate with a Gronwall constant depending on $1/\nu$. Optimal convergence rates are obtained for Theorem 4.1 if ν_T and H are appropriately chosen.

COROLLARY 4.2. *Assume that $\nu_T = h^\beta$ and $H = h^{1/\alpha}$. If the relation $\beta \ge 2r(\alpha-1)/\alpha$ is satisfied, then the estimate becomes*

$$\|\boldsymbol{u}-\boldsymbol{u}^h\|_{L^\infty(0,T;L^2(\Omega))} + \|\boldsymbol{u}-\boldsymbol{u}^h\|_{L^2(0,T;X)} = \mathcal{O}(h^r).$$

For example, one may choose for a linear approximation the pair $(\nu_T, H) = (h, h^{1/2})$, for quadratic approximation $(\nu_T, H) = (h, h^{3/4})$ or $(\nu_T, H) = (h^2, h^{1/2})$, and for cubic approximation $(\nu_T, H) = (h, h^{5/6})$ or $(\nu_T, H) = (h^2, h^{2/3})$.

THEOREM 4.3. *Under the assumptions of Theorem* 4.1 *and if $a(\cdot,\cdot)$ is symmetric ($\epsilon_0 = -1$), the following estimate holds true:*

$$\|\boldsymbol{u}_t - \boldsymbol{u}_t^h\|_{L^2(0,T;L^2(\Omega))} + \nu^{1/2}\|\boldsymbol{u}-\boldsymbol{u}^h\|_{L^\infty(0,T;X)} \le Ce^{CT\nu^{-1}}[h^r|\boldsymbol{u}_0|_{r+1,\Omega}$$
$$+ h^r|\boldsymbol{u}|_{L^2(0,T;H^{r+1}(\Omega))} + h^r|\boldsymbol{u}_t|_{L^2(0,T;H^{r+1}(\Omega))} + C\nu_T H^r h^{-1}|\boldsymbol{u}|_{L^2(0,T;H^{r+1}(\Omega))}],$$

where C is a positive constant independent of h, H, ν and ν_T. If $a(\cdot,\cdot)$ is nonsymmetric ($\epsilon_0 = 1$), the estimate is suboptimal, of order h^{r-1}.

Proof. We just give the outline of the proof. We introduce the modified Stokes problem: for any $t > 0$, find $(\boldsymbol{u}^S(t), p^S(t)) \in \boldsymbol{X}^h \times Q^h$ such that

$$\nu(a(\boldsymbol{u}^S(t),\boldsymbol{v}^h) + J(\boldsymbol{u}^S(t),\boldsymbol{v}^h)) + \nu_T g(\boldsymbol{u}^S(t),\boldsymbol{v}^h) + b(\boldsymbol{v}^h, p^S(t))$$
$$= \nu(a(\boldsymbol{u}(t),\boldsymbol{v}^h) + J(\boldsymbol{u}(t),\boldsymbol{v}^h)) + \nu_T g(\boldsymbol{u}(t),\boldsymbol{v}^h) + b(\boldsymbol{v}^h, p(t)) \quad \forall \boldsymbol{v}^h \in \boldsymbol{X}^h, \tag{4.6}$$
$$b(\boldsymbol{u}^S(t), q^h) = 0 \quad \forall q^h \in Q^h. \tag{4.7}$$

For any $t > 0$, there exists a unique solution to (4.6), (4.7). Furthermore, it is easy to show that the solution satisfies the error estimate

$$\begin{aligned} &\kappa^{1/2}\nu^{1/2}\|\boldsymbol{u}(t) - \boldsymbol{u}^S(t)\|_X + \nu_T^{1/2}\|(I - P_H)\nabla(\boldsymbol{u} - \boldsymbol{u}^S)\|_{0,\Omega} \\ &\le h^r((\nu + \nu^{-1} + \nu_T)^{1/2}|\boldsymbol{u}|_{r+1,\Omega} + \nu^{-1/2}|p|_{r,\Omega} + |\boldsymbol{u}_t|_{r+1,\Omega}) + \nu_T^{1/2}H^r|\boldsymbol{u}|_{r+1,\Omega} \quad \forall t > 0. \end{aligned}$$

Define $\boldsymbol{\eta} = \boldsymbol{u} - \boldsymbol{u}^S$ and $\boldsymbol{\xi} = \boldsymbol{u}^h - \boldsymbol{u}^S$, and choose the test function $\boldsymbol{v}^h = \boldsymbol{\xi}_t$. The resulting error equation is

$$\begin{aligned} &\|\boldsymbol{\xi}_t\|^2_{0,\Omega} + \nu a(\boldsymbol{\xi}, \boldsymbol{\xi}_t) + \frac{\nu}{2}\frac{d}{dt}J(\boldsymbol{\xi}, \boldsymbol{\xi}) + \frac{\nu_T}{2}\frac{d}{dt}g(\boldsymbol{\xi}, \boldsymbol{\xi}) \\ &= (\boldsymbol{\eta}_t, \boldsymbol{\xi}_t) - \nu_T g(\boldsymbol{u}, \boldsymbol{\xi}_t) + c(\boldsymbol{u}, \boldsymbol{u}, \boldsymbol{\xi}_t) - c(\boldsymbol{u}^h, \boldsymbol{u}^h, \boldsymbol{\xi}_t). \end{aligned} \tag{4.8}$$

The first two terms in the right-hand side of (4.8) are bounded as in Theorem 4.1. A detailed argument is given in [23]. Let us rewrite the nonlinear terms

$$\begin{aligned} c(\boldsymbol{u}, \boldsymbol{u}, \boldsymbol{\xi}_t) - c(\boldsymbol{u}^h, \boldsymbol{u}^h, \boldsymbol{\xi}_t) &= c(\boldsymbol{\xi}, \boldsymbol{\xi}, \boldsymbol{\xi}_t) - c(\boldsymbol{\xi}, \boldsymbol{\eta}, \boldsymbol{\xi}_t) + c(\boldsymbol{\xi}, \boldsymbol{u}, \boldsymbol{\xi}_t) \\ &\quad - c(\boldsymbol{\eta}, \boldsymbol{u}^h, \boldsymbol{\xi}_t) + c(\boldsymbol{u}, \boldsymbol{\xi}, \boldsymbol{\xi}_t) - c(\boldsymbol{u}, \boldsymbol{\eta}, \boldsymbol{\xi}_t). \end{aligned}$$

We assume that $\boldsymbol{\xi}$ belongs to $L^\infty((0,T) \times \Omega)$. L^p bounds, inverse inequality, and approximation results give the bounds for each nonlinear term as in Theorem 4.1. Collecting all the bounds with (4.8) gives

$$\begin{aligned} &\|\boldsymbol{\xi}_t\|^2_{0,\Omega} + \nu a(\boldsymbol{\xi}, \boldsymbol{\xi}_t) + \frac{\nu}{2}\frac{d}{dt}J(\boldsymbol{\xi}, \boldsymbol{\xi}) + \frac{\nu_T}{2}\frac{d}{dt}g(\boldsymbol{\xi}, \boldsymbol{\xi}) \\ &\le \frac{1}{2}\|\boldsymbol{\xi}_t\|^2_{0,\Omega} + C\|\boldsymbol{\xi}\|^2_X + Ch^{2r}|\boldsymbol{u}|^2_{r+1,\Omega} + Ch^{2r}|\boldsymbol{u}_t|^2_{r+1,\Omega} + C\nu_T^2 H^{2r}h^{-2}|\boldsymbol{u}|^2_{r+1,\Omega}. \end{aligned} \tag{4.9}$$

In the case where the bilinear form a is symmetric ($\epsilon_0 = -1$), the inequality becomes

$$\begin{aligned} &\frac{1}{2}\|\boldsymbol{\xi}_t\|^2_{0,\Omega} + \frac{\nu}{2}\frac{d}{dt}\|\boldsymbol{\xi}\|^2_X + \frac{\nu_T}{2}\frac{d}{dt}g(\boldsymbol{\xi}, \boldsymbol{\xi}) \\ &\le C\|\boldsymbol{\xi}\|^2_X + Ch^{2r}|\boldsymbol{u}|^2_{r+1,\Omega} + Ch^{2r}|\boldsymbol{u}_t|^2_{r+1,\Omega} + C\nu_T^2 H^{2r}h^{-2}|\boldsymbol{u}|^2_{r+1,\Omega}. \end{aligned} \tag{4.10}$$

Integrating from 0 to t and using Gronwall's lemma yield

$$\begin{aligned} &\|\boldsymbol{\xi}_t\|^2_{L^2(0,T;L^2(\Omega))} + \nu\|\boldsymbol{\xi}\|^2_{L^\infty(0,T;X)} + \nu_T \max_{0\le t\le T} g(\boldsymbol{\xi}, \boldsymbol{\xi}) \le Ce^{CT\nu^{-1}}[h^{2r}|\boldsymbol{u}_0|^2_{r+1,\Omega} \\ &+ Ch^{2r}|\boldsymbol{u}|^2_{L^2(0,T;H^{r+1}(\Omega))} + Ch^{2r}|\boldsymbol{u}_t|^2_{L^2(0,T;H^{r+1}(\Omega))} + C\nu_T^2 H^{2r}h^{-2}|\boldsymbol{u}|^2_{L^2(0,T;H^{r+1}(\Omega))}]. \end{aligned}$$

In the case where the bilinear form a is nonsymmetric, we rewrite (4.9) as

$$a(\boldsymbol{\xi}, \boldsymbol{\xi}_t) = \frac{1}{2}\frac{d}{dt}|\!|\!|\nabla\boldsymbol{\xi}|\!|\!|^2_0 - \sum_{k=1}^{M_h}\int_{e_k}\{\nabla\boldsymbol{\xi}\}\boldsymbol{n}_k\cdot[\boldsymbol{\xi}_t] + \sum_{k=1}^{M_h}\int_{e_k}\{\nabla\boldsymbol{\xi}_t\}\boldsymbol{n}_k\cdot[\boldsymbol{\xi}].$$

The bound is then suboptimal: $\mathcal{O}(h^{r-1})$. □

We now derive an error estimate for the pressure.

THEOREM 4.4. *We keep the assumptions of Theorem* 4.1 *and we consider the case where* $a(\cdot,\cdot)$ *is symmetric* ($\epsilon_0 = -1$) *and* $\nu \le 1$. *Then the solution* p^h *satisfies* *the following error estimate:*

$$\begin{aligned}\|p^h - r_h(p)\|_{L^2(0,T;L^2(\Omega))} \le Ce^{CT\nu^{-1}}[\nu h^r|\boldsymbol{u}_0|_{r+1,\Omega}\\ + \nu h^r|\boldsymbol{u}|_{L^2(0,T;H^{r+1}(\Omega))} + \nu h^r|\boldsymbol{u}_t|_{L^2(0,T;H^{r+1}(\Omega))} + C\nu\nu_T H^r h^{-1}|\boldsymbol{u}|_{L^2(0,T;H^{r+1}(\Omega))}]\\ + C\nu^{1/2}h^r|\boldsymbol{u}_0|_{r+1,\Omega} + C\nu h^r|\boldsymbol{u}|_{L^2(0,T;H^{r+1}(\Omega))} + C\nu h^r|p|_{L^2(0,T;H^r(\Omega))}\\ + C\nu_T H^r|\boldsymbol{u}|_{L^2(0,T;H^{r+1}(\Omega))}\\ + Ce^{CT(\nu^{-1}+1)}[h^r((\nu+\nu^{-1}+\nu_T)^{1/2}|\boldsymbol{u}|_{L^2(0,T;H^{r+1}(\Omega))} + \nu^{-1/2}|p|_{L^2(0,T;H^r(\Omega))}\\ + |\boldsymbol{u}_t|_{L^2(0,T;H^{r+1}(\Omega))}) + \nu_T^{1/2}H^r|\boldsymbol{u}|_{L^2(0,T;H^{r+1}(\Omega))}] + Ch^r|\boldsymbol{u}_0|_{r+1,\Omega},\end{aligned}$$

where C is independent of $h, H, \nu,$ and ν_T. Again, if $a(\cdot,\cdot)$ is nonsymmetric ($\epsilon_0 = 1$), the estimate is suboptimal.

Proof. The error equation can be written for all $\boldsymbol{v}^h$ in $\boldsymbol{X}^h$:

$$\begin{aligned}-b(\boldsymbol{v}^h, p^h - r_h(p)) = (\boldsymbol{u}_t^h - \boldsymbol{u}_t, \boldsymbol{v}^h) + \nu a(\boldsymbol{u}^h - \boldsymbol{u}, \boldsymbol{v}^h) + \nu J(\boldsymbol{u}^h - \boldsymbol{u}, \boldsymbol{v}^h)\\ + \nu_T g(\boldsymbol{u}^h - \boldsymbol{u}, \boldsymbol{v}^h) + c(\boldsymbol{u}^h, \boldsymbol{u}^h, \boldsymbol{v}^h) - c(\boldsymbol{u}, \boldsymbol{u}, \boldsymbol{v}^h) + \nu_T g(\boldsymbol{u}, \boldsymbol{v}^h) - b(\boldsymbol{v}^h, p - r_h(p)).\end{aligned}$$

From the inf-sup condition (3.10), there is $\boldsymbol{v}^h \in \boldsymbol{X}^h$ such that

$$b(\boldsymbol{v}^h, p^h - r_h(p)) = -\|p^h - r_h(p)\|_0^2, \quad \|\boldsymbol{v}^h\|_X \le \frac{1}{\beta_0}\|p^h - r_h(p)\|_{0,\Omega}.$$

Thus, we have

$$\begin{aligned}\|p^h - r_h(p)\|_{0,\Omega}^2 = (\boldsymbol{u}_t^h - \boldsymbol{u}_t, \boldsymbol{v}^h) + \nu\sum_{j=1}^{N_h}\int_{E_j}\nabla(\boldsymbol{u}^h - \boldsymbol{u}) : \nabla\boldsymbol{v}^h\\ - \nu\sum_{k=1}^{M_h}\int_{e_k}\{\nabla(\boldsymbol{u}^h - \boldsymbol{u})\}\boldsymbol{n}_k\cdot[\boldsymbol{v}^h] + \nu\epsilon_0\sum_{k=1}^{M_h}\int_{e_k}\{\nabla\boldsymbol{v}^h\}\boldsymbol{n}_k\cdot[\boldsymbol{u}^h - \boldsymbol{u}] + \nu J(\boldsymbol{u}^h - \boldsymbol{u}, \boldsymbol{v}^h)\\ + \nu_T g(\boldsymbol{u}^h - \boldsymbol{u}, \boldsymbol{v}^h) + c(\boldsymbol{u}^h, \boldsymbol{u}^h, \boldsymbol{v}^h) - c(\boldsymbol{u}, \boldsymbol{u}, \boldsymbol{v}^h) + \nu_T g(\boldsymbol{u}, \boldsymbol{v}^h) - b(\boldsymbol{v}^h, p - r_h(p)).\end{aligned}$$

All the terms above can be handled as in Theorem 4.1. The resulting inequality is

$$\begin{aligned}\|p^h - r_h(p)\|_{0,\Omega}^2 \le C\nu^2\|\boldsymbol{u}_t^h - \boldsymbol{u}_t\|_{0,\Omega}^2 + C\nu^2\|\boldsymbol{u}^h - \boldsymbol{u}\|_X^2 + C\nu^2 h^{2r}|\boldsymbol{u}|_{r+1,\Omega}^2\\ + C\nu^2 h^{2r}|p|_{r,\Omega}^2 + C\nu_T^2 H^{2r}|\boldsymbol{u}|_{r+1,\Omega}^2 + C\nu_T^2 g(\boldsymbol{u}^h - \boldsymbol{u}, \boldsymbol{u}^h - \boldsymbol{u}) + C\|\boldsymbol{u}^h - \boldsymbol{u}\|_{0,\Omega}^2.\end{aligned}$$

We now integrate from 0 to T and use Theorem 4.1 and Theorem 4.3 to conclude. □

5. Fully discrete scheme. In this section, we formulate two fully discrete finite element schemes for the discontinuous eddy viscosity method. Let Δt denote the time step, let $M = T/\Delta t$, and let $0 = t_0 < t_1 < \cdots < t_M = T$ be a subdivision of the interval $(0,T)$. We denote the function ϕ evaluated at the time t_m by ϕ_m and the average of ϕ at two successive time levels by $\phi_{m+\frac{1}{2}} = \frac{1}{2}(\phi_m + \phi_{m+1})$.

Scheme 1: Given $\boldsymbol{u}_0^h$, find $(\boldsymbol{u}_m^h)_{m\ge1}$ in $\boldsymbol{X}^h$ and $(p_m^h)_{m\ge1}$ in Q^h such that

$$\begin{aligned}\frac{1}{\Delta t}(\boldsymbol{u}_{m+1}^h - \boldsymbol{u}_m^h, \boldsymbol{v}^h) + \nu(a(\boldsymbol{u}_{m+1}^h, \boldsymbol{v}^h) + J(\boldsymbol{u}_{m+1}^h, \boldsymbol{v}^h)) + c(\boldsymbol{u}_m^h, \boldsymbol{u}_{m+1}^h, \boldsymbol{v}^h)\\ + \nu_T g(\boldsymbol{u}_{m+1}^h, \boldsymbol{v}^h) + b(\boldsymbol{v}^h, p_{m+1}^h) = (\boldsymbol{f}_{m+1}, \boldsymbol{v}^h) \quad \forall \boldsymbol{v}^h \in \boldsymbol{X}^h,\end{aligned} \tag{5.1}$$

$$b(\boldsymbol{u}_{m+1}^h, q^h) = 0 \quad \forall q^h \in Q^h. \tag{5.2}$$

Scheme 2: Given $\tilde{\boldsymbol{u}}_0^h, \tilde{\boldsymbol{u}}_1^h, \tilde{p}_1^h$, find $(\tilde{\boldsymbol{u}}_m^h)_{m\geq 2}$ in $\boldsymbol{X}^h$ and $(\tilde{p}_m^h)_{m\geq 2}$ in Q^h such that

$$\begin{aligned}&\frac{1}{\Delta t}(\tilde{\boldsymbol{u}}_{m+1}^h - \tilde{\boldsymbol{u}}_m^h, \boldsymbol{v}^h) + \nu(a(\tilde{\boldsymbol{u}}_{m+\frac{1}{2}}^h, \boldsymbol{v}^h) + J(\tilde{\boldsymbol{u}}_{m+\frac{1}{2}}^h, \boldsymbol{v}^h)) + c(\tilde{\boldsymbol{u}}_{m+\frac{1}{2}}^h, \tilde{\boldsymbol{u}}_{m+\frac{1}{2}}^h, \boldsymbol{v}^h)\\ &\quad + \nu_T g(\tilde{\boldsymbol{u}}_{m+\frac{1}{2}}^h, \boldsymbol{v}^h) + b(\boldsymbol{v}^h, \tilde{p}_{m+\frac{1}{2}}^h) = (\boldsymbol{f}_{m+\frac{1}{2}}, \boldsymbol{v}^h) \quad \forall \boldsymbol{v}^h \in \boldsymbol{X}^h,\end{aligned} \tag{5.3}$$

$$b(\tilde{\boldsymbol{u}}_{m+1}^h, q^h) = 0 \quad \forall q^h \in Q^h. \tag{5.4}$$

For both schemes, the initial velocity is defined to be the L^2 projection of $\boldsymbol{u}_0$. Scheme 1 is based on a backward Euler discretization. Scheme 2 is based on a Crank–Nicolson discretization, and requires the velocity and pressure at the first step. The approximations $\tilde{\boldsymbol{u}}_1^h$ and $\tilde{p}_1^h$ can be obtained by a first order scheme (see [2]). We will show that Scheme 1 is first order in time and Scheme 2 is second order in time. First, we prove the stability of the schemes.

Lemma 5.1. *The solution* $(\boldsymbol{u}_m^h)_m$ *of* (5.1), (5.2) *remains bounded in the following sense:*

$$\|\boldsymbol{u}_m^h\|_{0,\Omega}^2 \leq K, \quad m = 0, \dots, M,$$
$$\Delta t \sum_{m=0}^{M-1} \|\boldsymbol{u}_{m+1}^h\|_X^2 \leq \frac{K}{2\nu}, \quad \Delta t \sum_{m=0}^{M-1} |||(I - P_H)\nabla \boldsymbol{u}_{m+1}^h|||_0^2 \leq \frac{K}{2\nu_T},$$

where $K = \|\boldsymbol{u}_0\|_{0,\Omega}^2 + \|\boldsymbol{f}\|_{L^2([0,T]\times\Omega)}^2$.

The solution $(\tilde{\boldsymbol{u}}_m^h)_m$ *of* (5.3), (5.4) *remains bounded in the following sense:*

$$\|\tilde{\boldsymbol{u}}_m^h\|_{0,\Omega}^2 \leq \tilde{K}, \quad m = 0, \dots, M,$$
$$\Delta t \sum_{m=0}^{M-1} \|\tilde{\boldsymbol{u}}_{m+1}^h\|_X^2 \leq \frac{\tilde{K}}{2\nu}, \quad \Delta t \sum_{m=0}^{M-1} \|(I - P_H)\nabla \tilde{\boldsymbol{u}}_{m+1}^h\|_{0,\Omega}^2 \leq \frac{\tilde{K}}{2\nu_T},$$

where $\tilde{K} = \|\boldsymbol{u}_0\|_{0,\Omega}^2 + 2\|\boldsymbol{f}\|_{L^2([0,T]\times\Omega)}^2$.

Proof. Choose $\boldsymbol{v}^h = \boldsymbol{u}_{m+1}^h$ in (5.1) and $q^h = p_{m+1}^h$ in (5.2). We multiply by $2\Delta t$ and sum over m. Then, from the positivity of c and (3.3), we have

$$\begin{aligned}&\|\boldsymbol{u}_m^h\|_{0,\Omega}^2 - \|\boldsymbol{u}_0^h\|_{0,\Omega}^2 + 2\kappa\nu\Delta t \sum_{j=0}^{m-1} \|\boldsymbol{u}_{j+1}^h\|_X^2 + 2\nu_T \Delta t \sum_{j=0}^{m-1} |||(I - P_H)\nabla \boldsymbol{u}_{j+1}^h|||_0^2\\ &\qquad \leq \Delta t \sum_{j=0}^{m-1} \|\boldsymbol{f}_{j+1}\|_{0,\Omega}^2 + \Delta t \sum_{j=0}^{m-1} \|\boldsymbol{u}_{j+1}^h\|_{0,\Omega}^2.\end{aligned}$$

The result is obtained by using a discrete version of Gronwall's lemma [15] and the fact that $\|\boldsymbol{u}_0^h\|_{0,\Omega} \leq \|\boldsymbol{u}_0\|_{0,\Omega}$.

For Scheme 2, the proof is similar. Choose $\boldsymbol{v}^h = \tilde{\boldsymbol{u}}_{m+\frac{1}{2}}$ in (5.3) and $q^h = \tilde{p}_{m+\frac{1}{2}}^h$ in (5.4). The rest of the proof follows as above. See [23] for more details. ∎

THEOREM 5.2. *Under the assumptions of Theorem* 4.1 *and if* $\boldsymbol{u}_t$ *and* $\boldsymbol{u}_{tt}$ *belong to* $L^\infty(0,T;L^2(\Omega))$*, there is a constant* C *independent of* h, H, ν*, and* ν_T *such that*

$$\max_{m=0,\dots,M}\|\boldsymbol{u}_m-\boldsymbol{u}_m^h\|_{0,\Omega}+\left(\nu\kappa\Delta t\sum_{m=0}^{M-1}\|\boldsymbol{u}_{m+1}-\boldsymbol{u}_{m+1}^h\|_X^2\right)^{1/2}$$
$$+\left(\nu_T\Delta t\sum_{m=0}^{M}|\!|\!|(I-P_H)(\nabla\boldsymbol{u}_{m+1}-\boldsymbol{u}_{m+1}^h)|\!|\!|_0^2\right)^{1/2}\leq Ch^r|\boldsymbol{u}_0|_{r+1,\Omega}$$
$$+Ce^{CT\nu^{-1}}[h^r(\nu+\nu^{-1}+\nu_T)^{1/2}|\boldsymbol{u}|_{L^2(0,T;H^{r+1}(\Omega))}+\nu_T^{1/2}H^r|\boldsymbol{u}|_{L^2(0,T;H^{r+1}(\Omega))}$$
$$+\nu^{-1/2}\Delta t(\|\boldsymbol{u}_t\|_{L^\infty(0,T;L^2(\Omega))}+\|\boldsymbol{u}_{tt}\|_{L^\infty(0,T;L^2(\Omega))})+h^r\nu^{-1/2}|p|_{L^2(0,T;H^r(\Omega))}].$$

Proof. As in the continuous case, we set $\boldsymbol{e}_m=\boldsymbol{u}_m-\boldsymbol{u}_m^h$. We subtract from (5.1) and (5.2) equations (3.14) and (3.15) evaluated at time $t=t_{m+1}$.

$$(\boldsymbol{u}_t(t_{m+1}),\boldsymbol{v}^h)-\frac{1}{\Delta t}(\boldsymbol{u}_{m+1}^h-\boldsymbol{u}_m^h,\boldsymbol{v}^h)+\nu[a(\boldsymbol{e}_{m+1},\boldsymbol{v}^h)+J(\boldsymbol{e}_{m+1},\boldsymbol{v}^h)]$$
$$+\nu_Tg(\boldsymbol{e}_{m+1},\boldsymbol{v}^h)+c(\boldsymbol{u}_{m+1},\boldsymbol{u}_{m+1},\boldsymbol{v}^h)-c(\boldsymbol{u}_m^h,\boldsymbol{u}_{m+1}^h,\boldsymbol{v}^h)$$
$$+b(\boldsymbol{v}^h,p_{m+1}-p_{m+1}^h)=\nu_Tg(\boldsymbol{u}_{m+1},\boldsymbol{v}^h)\quad\forall\boldsymbol{v}^h\in\boldsymbol{X}^h,\tag{5.5}$$
$$b(\boldsymbol{e}_{m+1},q^h)=0\quad\forall q^h\in Q^h.\tag{5.6}$$

Define $\boldsymbol{\phi}_m=\boldsymbol{u}_m^h-(R_h(\boldsymbol{u}))_m$, $\boldsymbol{\eta}_m=\boldsymbol{u}_m-(R_h(\boldsymbol{u}))_m$. Choose $\boldsymbol{v}^h=\boldsymbol{\phi}_{m+1}$ in (5.5) and $q^h=p_{m+1}^h$ in (5.6). Adding and subtracting the interpolant and using (3.3) yield the following error equation:

$$\frac{1}{2\Delta t}(\|\boldsymbol{\phi}_{m+1}\|_{0,\Omega}^2-\|\boldsymbol{\phi}_m\|_{0,\Omega}^2)+\nu\kappa\|\boldsymbol{\phi}_{m+1}\|_X^2+\nu_T|\!|\!|(I-P_H)\nabla\boldsymbol{\phi}_{m+1}|\!|\!|_0^2$$
$$+c(\boldsymbol{u}_m^h,\boldsymbol{u}_{m+1}^h,\boldsymbol{\phi}_{m+1})-c(\boldsymbol{u}_{m+1},\boldsymbol{u}_{m+1},\boldsymbol{\phi}_{m+1})+b(\boldsymbol{\phi}_{m+1},p_{m+1}^h-p_{m+1})$$
$$\leq\left\|\frac{\partial\boldsymbol{u}}{\partial t}(t_{m+1})-\frac{1}{\Delta t}(\boldsymbol{u}_{m+1}-\boldsymbol{u}_m)\right\|_{0,\Omega}\|\boldsymbol{\phi}_{m+1}\|_{0,\Omega}+\frac{1}{\Delta t}\left\|\boldsymbol{\eta}_{m+1}-\boldsymbol{\eta}_m\right\|_{0,\Omega}\|\boldsymbol{\phi}_{m+1}\|_{0,\Omega}$$
$$+\nu|a(\boldsymbol{\eta}_{m+1},\boldsymbol{\phi}_{m+1})+J(\boldsymbol{\eta}_{m+1},\boldsymbol{\phi}_{m+1})|+\nu_T|\!|\!|(I-P_H)\nabla\boldsymbol{\eta}_{m+1}|\!|\!|_0|\!|\!|(I-P_H)\nabla\boldsymbol{\phi}_{m+1}|\!|\!|_0$$
$$+\nu_T|\!|\!|(I-P_H)\nabla\boldsymbol{u}_{m+1}|\!|\!|_0|\!|\!|(I-P_H)\nabla\boldsymbol{\phi}_{m+1}|\!|\!|_0.$$

We rewrite the nonlinear terms

$$c_{\boldsymbol{u}_m^h}(\boldsymbol{u}_m^h,\boldsymbol{u}_{m+1}^h,\boldsymbol{\phi}_{m+1})-c_{\boldsymbol{u}_{m+1}}(\boldsymbol{u}_{m+1},\boldsymbol{u}_{m+1},\boldsymbol{\phi}_{m+1})$$
$$=c_{\boldsymbol{u}_m^h}(\boldsymbol{u}_m^h,\boldsymbol{u}_{m+1}^h,\boldsymbol{\phi}_{m+1})-c_{\boldsymbol{u}_m^h}(\boldsymbol{u}_{m+1},\boldsymbol{u}_{m+1},\boldsymbol{\phi}_{m+1}).$$

We now drop the subscript $\boldsymbol{u}_m^h$:

$$c_{\boldsymbol{u}_m^h}(\boldsymbol{u}_m^h,\boldsymbol{u}_{m+1}^h,\boldsymbol{\phi}_{m+1})-c_{\boldsymbol{u}_m^h}(\boldsymbol{u}_{m+1},\boldsymbol{u}_{m+1},\boldsymbol{\phi}_{m+1})$$
$$=c(\boldsymbol{u}_m^h,\boldsymbol{\phi}_{m+1},\boldsymbol{\phi}_{m+1})-c(\boldsymbol{\phi}_m,\boldsymbol{\eta}_{m+1},\boldsymbol{\phi}_{m+1})+c(\boldsymbol{\phi}_m,\boldsymbol{u}_{m+1},\boldsymbol{\phi}_{m+1})$$
$$-c(\boldsymbol{\eta}_m,\boldsymbol{u}_{m+1}^I,\boldsymbol{\phi}_{m+1})-c(\boldsymbol{u}_m,\boldsymbol{\eta}_{m+1},\boldsymbol{\phi}_{m+1})-c(\boldsymbol{u}_{m+1}-\boldsymbol{u}_m,\boldsymbol{u}_{m+1},\boldsymbol{\phi}_{m+1}).$$

Thus, we rewrite the error equation as

$$\begin{aligned}&\frac{1}{2\Delta t}(\|\boldsymbol{\phi}_{m+1}\|^2_{0,\Omega}-\|\boldsymbol{\phi}_m\|^2_{0,\Omega})+\nu\kappa\|\boldsymbol{\phi}_{m+1}\|^2_X+\nu_T|\!|\!|(I-P_H)\nabla\boldsymbol{\phi}_{m+1}|\!|\!|^2_0\\&+c(\boldsymbol{u}^h_m,\boldsymbol{\phi}_{m+1},\boldsymbol{\phi}_{m+1})\leq|c(\boldsymbol{\phi}_m,\boldsymbol{\eta}_{m+1},\boldsymbol{\phi}_{m+1})|+|c(\boldsymbol{\phi}_m,\boldsymbol{u}_{m+1},\boldsymbol{\phi}_{m+1})|\\&+|c(\boldsymbol{\eta}_m,\boldsymbol{u}^I_{m+1},\boldsymbol{\phi}_{m+1})|+|c(\boldsymbol{u}_m,\boldsymbol{\eta}_{m+1},\boldsymbol{\phi}_{m+1})|+|c(\boldsymbol{u}_{m+1}-\boldsymbol{u}_m,\boldsymbol{u}_{m+1},\boldsymbol{\phi}_{m+1})|\\&+|b(\boldsymbol{\phi}_{m+1},p^h_{m+1}-p_{m+1})|+\left\|\frac{\partial\boldsymbol{u}}{\partial t}(t_{m+1})-\frac{1}{\Delta t}(\boldsymbol{u}_{m+1}-\boldsymbol{u}_m)\right\|_{0,\Omega}\|\boldsymbol{\phi}_{m+1}\|_{0,\Omega}\\&+\frac{1}{\Delta t}\|\boldsymbol{\eta}_{m+1}-\boldsymbol{\eta}_m\|_{0,\Omega}\|\boldsymbol{\phi}_{m+1}\|_{0,\Omega}+\nu|a(\boldsymbol{\eta}_{m+1},\boldsymbol{\phi}_{m+1})+J(\boldsymbol{\eta}_{m+1},\boldsymbol{\phi}_{m+1})|\\&+\nu_T|\!|\!|(I-P_H)\nabla\boldsymbol{\eta}_{m+1}|\!|\!|_0|\!|\!|(I-P_H)\nabla\boldsymbol{\phi}_{m+1}|\!|\!|_0\\&+\nu_T|\!|\!|(I-P_H)\nabla\boldsymbol{u}_{m+1}|\!|\!|_0|\!|\!|(I-P_H)\nabla\boldsymbol{\phi}_{m+1}|\!|\!|_0\leq|T_0|+\cdots+|T_{10}|.\end{aligned}$$

We want to bound the terms $T_0,T_2,\ldots,T_{10}$. T_0 can be handled as in Theorem 4.1. Then, T_0 is bounded as

$$T_0\leq\frac{\kappa\nu}{6}\|\boldsymbol{\phi}_{m+1}\|^2_X+C\nu^{-1}(\|\boldsymbol{u}\|^2_{L^\infty(0,T;H^{r+1}(\Omega))}+\|\boldsymbol{u}\|^2_{L^\infty(0,T;W^{2,4/3}(\Omega))})\|\boldsymbol{\phi}_m\|^2_{0,\Omega}.$$

Also, the term T_1 is bounded exactly like the term (4.5) in the proof of Theorem 4.1. Here, the constant vectors are

$$\boldsymbol{c}_1=\frac{1}{|E_j|}\int_{E_j}\boldsymbol{u}_{m+1},\quad\boldsymbol{c}_2=\frac{1}{|E_j|}\int_{E_j}\boldsymbol{\phi}_{m+1}.$$

Then, T_1 can be rewritten as

$$\begin{aligned}T_1=&\sum_{j=1}^{N_h}\int_{E_j}(\boldsymbol{\phi}_m\cdot\nabla\boldsymbol{u}_{m+1})\cdot\boldsymbol{\phi}_{m+1}-\frac{1}{2}b(\boldsymbol{\phi}_m,(\boldsymbol{u}_{m+1}-\boldsymbol{c}_1)\cdot\boldsymbol{\phi}_{m+1})\\&-\frac{1}{2}b(\boldsymbol{\phi}_m,\boldsymbol{c}_1\cdot(\boldsymbol{\phi}_{m+1}-\boldsymbol{c}_2))\leq\frac{\kappa\nu}{24}\|\boldsymbol{\phi}_{m+1}\|^2_X+C\nu^{-1}\|\boldsymbol{\phi}_m\|^2_{0,\Omega}.\end{aligned}$$

Expanding T_2, we obtain

$$\begin{aligned}T_2=&\sum_{j=1}^{N_h}\int_{E_j}(\boldsymbol{\eta}_m\cdot\nabla\boldsymbol{u}^I_{m+1})\cdot\boldsymbol{\phi}_{m+1}+\sum_{j=1}^{N_h}\int_{\partial E_j^-}|\{\boldsymbol{\eta}_m\}\cdot\boldsymbol{n}_{E_j}|(\boldsymbol{u}^{I,\text{int}}_{m+1}-\boldsymbol{u}^{I,\text{ext}}_{m+1})\cdot\boldsymbol{\phi}^{int}_{m+1}\\&+\frac{1}{2}\sum_{j=1}^{N_h}\int_{E_j}(\nabla\cdot\boldsymbol{\eta}_m)\boldsymbol{u}^I_{m+1}\cdot\boldsymbol{\phi}_{m+1}-\frac{1}{2}\sum_{k=1}^{P_h}\int_{e_k}[\boldsymbol{\eta}_m]\cdot\boldsymbol{n}_k\{\boldsymbol{u}^I_{m+1}\cdot\boldsymbol{\phi}_{m+1}\}\\&=T_{21}+\cdots+T_{24}.\end{aligned}$$

The bound for T_{21} is obtained using (2.6) and (2.8):

$$\begin{aligned}T_{21}&\leq\|\boldsymbol{\eta}_m\|_{0,\Omega}\|\nabla\boldsymbol{u}^I_{m+1}\|_{L^4(\Omega)}\|\boldsymbol{\phi}_{m+1}\|_{L^4(\Omega)}\\&\leq\frac{\kappa\nu}{24}\|\boldsymbol{\phi}_{m+1}\|^2_X+C\nu^{-1}h^{2r}\|\boldsymbol{u}\|^2_{L^\infty(0,T;W^{2,4/3}(\Omega))}|\boldsymbol{u}_m|^2_{r+1,\Omega}.\end{aligned}$$

Similarly for the term T_{22}, the inequalities (2.7) and (2.14) give

$$\begin{aligned}T_{22}&\leq C\sum_{j=1}^{N_h}\|\boldsymbol{\eta}_m\|_{L^2(\partial E_j)}\|\boldsymbol{u}^I_{m+1}\|_{L^\infty(\Omega)}\|\boldsymbol{\phi}_{m+1}\|_{L^2(\partial E_j)}\\&\leq\frac{\kappa\nu}{24}\|\boldsymbol{\phi}_{m+1}\|^2_X+C\nu^{-1}h^{2r}\|\boldsymbol{u}\|^2_{L^\infty([0,T]\times\Omega)}|\boldsymbol{u}_m|^2_{r+1,\Omega}.\end{aligned}$$

The estimate of T_{23} is obtained by using a bound on interpolant, the Cauchy–Schwarz inequality, the approximation result (2.7), Young's inequality, and L^p bound (2.6):

$$T_{23} \leq \frac{\kappa\nu}{24}\|\boldsymbol{\phi}_{m+1}\|_X^2 + C\nu^{-1}h^{2r}\|\boldsymbol{u}\|^2_{L^\infty([0,T]\times\Omega)}|\boldsymbol{u}_m|^2_{r+1,\Omega}.$$

The term T_{24} is bounded exactly as for T_{22}. Because of the regularity of $\boldsymbol{u}$ and the approximation result (2.7), we can bound T_3:

$$\begin{aligned} T_3 &\leq C\|\boldsymbol{u}_m\|_{L^\infty(\Omega)}h^r|\boldsymbol{u}_{m+1}|_{r+1,\Omega}\|\boldsymbol{\phi}_{m+1}\|_{0,\Omega} \\ &\leq \frac{\kappa\nu}{24}\|\boldsymbol{\phi}_{m+1}\|_X^2 + C\nu^{-1}h^{2r}\|\boldsymbol{u}\|^2_{L^\infty([0,T]\times\Omega)}|\boldsymbol{u}_m|^2_{r+1,\Omega}. \end{aligned}$$

The term T_4 is bounded using the estimate (2.6):

$$\begin{aligned} T_4 &\leq \Delta t\|\boldsymbol{u}_t\|_{L^\infty(t_m,t_{m+1};L^2(\Omega))}\|\nabla\boldsymbol{u}_{m+1}\|_{L^4(\Omega)}\|\boldsymbol{\phi}_{m+1}\|_{L^4(\Omega)} \\ &\leq \frac{\kappa\nu}{24}\|\boldsymbol{\phi}_{m+1}\|_X^2 + C\nu^{-1}\Delta t^2\|\boldsymbol{u}_t\|^2_{L^\infty(t_m,t_{m+1};L^2(\Omega))}\|\boldsymbol{u}\|^2_{L^\infty(0,T;W^{2,4/3}(\Omega))}. \end{aligned}$$

By property of the interpolant (3.11) and properties of $r_h(p)$, (2.9), and (2.10), we now bound T_5:

$$\begin{aligned} T_5 &= b(\boldsymbol{\phi}_{m+1}, p^h_{m+1} - (r_h(p))_{m+1}) - b(\boldsymbol{\phi}_{m+1}, p_{m+1} - (r_h(p))_{m+1}) \\ &= -b(\boldsymbol{\phi}_{m+1}, p_{m+1} - (r_h(p))_{m+1}) = \sum_{k=1}^{M_h}\int_{e_k}\{p_{m+1} - (r_h(p))_{m+1}\}[\boldsymbol{\phi}_{m+1}]\cdot\boldsymbol{n}_k \\ &\leq \sum_{k=1}^{M_h}\|[\boldsymbol{\phi}_{m+1}]\|_{0,e_k}|e_k|^{1/2-1/2}\|p_{m+1}\|_{0,e_k} \leq \frac{\kappa\nu}{24}\|\boldsymbol{\phi}_{m+1}\|_X^2 + C\nu^{-1}h^{2r}|p_{m+1}|^2_{r,\Omega}. \end{aligned}$$

From a Taylor expansion, we have

$$T_6 \leq C\Delta t\|\boldsymbol{\phi}_{m+1}\|_X\|\boldsymbol{u}_{tt}(t^*)\|_{0,\Omega} \leq \frac{\kappa\nu}{24}\|\boldsymbol{\phi}_{m+1}\|_X^2 + C\nu^{-1}\Delta t^2\|\boldsymbol{u}_{Tm}\|^2_{L^\infty(0,T;L^2(\Omega))}.$$

To bound T_7, we assume that $h \leq \Delta t$ and we use (2.8) and (2.6):

$$\begin{aligned} T_7 &\leq \frac{\kappa\nu}{24}\|\boldsymbol{\phi}_{m+1}\|_X^2 + C\nu^{-1}\frac{h^{2r+2}}{\Delta t^2}(|\boldsymbol{u}_{m+1}|^2_{r+1,\Omega} + |\boldsymbol{u}_m|^2_{r+1,\Omega}) \\ &\leq \frac{\kappa\nu}{24}\|\boldsymbol{\phi}_{m+1}\|_X^2 + C\nu^{-1}h^{2r}(|\boldsymbol{u}_{m+1}|^2_{r+1,\Omega} + |\boldsymbol{u}_m|^2_{r+1,\Omega}). \end{aligned}$$

The terms T_8, T_9, and T_{10} are exactly bounded as in Theorem 4.1. (See [23] for details.) Combining all the bounds of the terms $T_0, \ldots, T_{10}$, multiplying by $2\Delta t$, and summing over m, we obtain

$$\begin{aligned} &\|\boldsymbol{\phi}_{m+1}\|^2_{0,\Omega} - \|\boldsymbol{\phi}_0\|^2_{0,\Omega} + \nu\kappa\Delta t\sum_{i=0}^m\|\boldsymbol{\phi}_{i+1}\|_X^2 + \nu_T\Delta t\sum_{i=0}^m\|(I - P_H)\nabla\boldsymbol{\phi}_{i+1}\|_0^2 \\ &\leq Ce^{CT\nu^{-1}}[h^{2r}(\nu + \nu^{-1} + \nu_T)|\boldsymbol{u}|^2_{L^2(0,T;H^{r+1}(\Omega))} + \nu_T H^{2r}|\boldsymbol{u}|^2_{L^2(0,T;H^{r+1}(\Omega))} \\ &+ \nu^{-1}\Delta t^2(\|\boldsymbol{u}_t\|^2_{L^\infty(0,T;L^2(\Omega))} + \|\boldsymbol{u}_{tt}\|^2_{L^\infty(0,T;L^2(\Omega))}) + h^{2r}\nu^{-1}|p|^2_{L^2(0,T;H^r(\Omega))}]. \end{aligned}$$

The final result is obtained by noting that $\|\boldsymbol{\phi}_0\|_{0,\Omega}$ is of order h^r and by using approximation results and a triangle inequality. ∎

THEOREM 5.3. *Assume that* $\boldsymbol{u}_{tt}\in L^\infty(0,T;(H^1(\Omega))^2)$, $p_{tt}\in L^\infty(0,T;H^1(\Omega))$, $\boldsymbol{u}_{ttt}\in L^\infty(0,T;(H^2(\Omega))^2)$, *and* $\boldsymbol{f}_{tt}\in L^\infty(0,T;(L^2(\Omega))^2)$. *Under the assumptions of Theorem* 4.1, *there is a constant* C *independent of* h,H,ν, *and* ν_T *such that*

$$\begin{aligned}&\max_{m=0,\ldots,M}\|\boldsymbol{u}_m-\tilde{\boldsymbol{u}}_m\|_{0,\Omega}+\left(\nu\kappa\Delta t\sum_{m=0}^{M-1}\|\boldsymbol{u}_{m+1}-\tilde{\boldsymbol{u}}_{m+1}\|_X^2\right)^{1/2}\\&+\left(\nu_T\Delta t\sum_{m=0}^{M-1}|\!|\!|(I-P_H)\nabla\boldsymbol{u}_{m+1}-\tilde{\boldsymbol{u}}_{m+1}|\!|\!|_0^2\right)^{1/2}\le Ce^{CT\nu^{-1}}[h^r\nu^{-1/2}\|p\|_{L^2(0,T;H^r(\Omega))}\\&\quad+h^r(\nu+\nu^{-1}+\nu_T)^{1/2}\|\boldsymbol{u}\|_{L^2(0,T;H^{r+1}(\Omega))}+\Delta t^2\nu^{1/2}\|\boldsymbol{u}_{ttt}\|_{L^\infty(0,T;H^2(\Omega))}\\&\quad+\Delta t^2\nu^{-1/2}(\|\boldsymbol{u}_{tt}\|_{L^\infty(0,T;H^1(\Omega))}+\|p_{tt}\|_{L^\infty(0,T;H^1(\Omega))}+\|\boldsymbol{u}_{ttt}\|_{L^\infty(0,T;L^2(\Omega))}\\&\quad+\|\boldsymbol{f}_{tt}\|_{L^\infty(0,T;L^2(\Omega))})+\nu_T^{1/2}H^r|\boldsymbol{u}|_{L^2(0,T;H^{r+1}(\Omega))}]+Ch^r|\boldsymbol{u}_0|_{r+1,\Omega}.\end{aligned}$$

Proof. The proof is derived in a similar fashion as for the backward Euler scheme. Using the same notation, the error equation is obtained by subtracting (3.6) evaluated at the time $t=t_{m+1/2}$ from (5.3) and adding and subtracting the interpolant $(R_h(\boldsymbol{u}))_{m+1/2}$. After some manipulation, we obtain

$$\begin{aligned}&\frac{1}{2\Delta t}(\|\boldsymbol{\phi}_{m+1}\|_{0,\Omega}^2-\|\boldsymbol{\phi}_m\|_{0,\Omega}^2)+\nu\kappa\|\boldsymbol{\phi}_{m+\frac12}\|_X^2+\nu_T|\!|\!|(I-P_H)\nabla\boldsymbol{\phi}_{m+\frac12}|\!|\!|_0^2\\&+c(\tilde{\boldsymbol{u}}^h_{m+\frac12},\boldsymbol{\phi}^h_{m+\frac12},\boldsymbol{\phi}_{m+\frac12})\le|c(\boldsymbol{\phi}_{m+\frac12},\boldsymbol{\eta}_{m+\frac12},\boldsymbol{\phi}_{m+\frac12})|+|c(\boldsymbol{\phi}_{m+\frac12},\boldsymbol{u}_{m+\frac12},\boldsymbol{\phi}_{m+\frac12})|\\&\qquad+|c(\boldsymbol{\eta}_{m+\frac12},\boldsymbol{u}^I_{m+\frac12},\boldsymbol{\phi}_{m+\frac12})|+|c(\boldsymbol{u}_{m+\frac12},\boldsymbol{\eta}_{m+\frac12},\boldsymbol{\phi}_{m+\frac12})|\\&+|c(\boldsymbol{u}_{m+\frac12}-\boldsymbol{u}(t_{m+\frac12}),\boldsymbol{u}_{m+\frac12},\boldsymbol{\phi}_{m+\frac12})|+|c(\boldsymbol{u}(t_{m+\frac12}),\boldsymbol{u}_{m+\frac12}-\boldsymbol{u}(t_{m+\frac12}),\boldsymbol{\phi}_{m+\frac12})|\\&+|b(\boldsymbol{\phi}_{m+\frac12},\tilde{p}^h_{m+\frac12}-p(t_{m+\frac12}))|+\left\|\boldsymbol{u}_t(t_{m+\frac12})-\frac{1}{\Delta t}(\boldsymbol{u}_{m+1}-\boldsymbol{u}_m)\right\|_{0,\Omega}\|\boldsymbol{\phi}_{m+\frac12}\|_{0,\Omega}\\&+\frac{1}{\Delta t}\|\boldsymbol{\eta}_{m+1}-\boldsymbol{\eta}_m\|_{0,\Omega}\|\boldsymbol{\phi}_{m+\frac12}\|_{0,\Omega}+\|\boldsymbol{f}_{m+\frac12}-\boldsymbol{f}(t_{m+\frac12})\|_{0,\Omega}\|\boldsymbol{\phi}_{m+\frac12}\|_{0,\Omega}\\&\quad+\nu|a(\boldsymbol{u}(t_{m+\frac12})-\boldsymbol{u}^I_{m+\frac12},\boldsymbol{\phi}_{m+1})+J(\boldsymbol{u}(t_{m+\frac12})-\boldsymbol{u}^I_{m+\frac12},\boldsymbol{\phi}_{m+1})|\\&\qquad+\nu_T|\!|\!|(I-P_H)\nabla\boldsymbol{\eta}_{m+\frac12}|\!|\!|_0|\!|\!|(I-P_H)\nabla\boldsymbol{\phi}_{m+\frac12}|\!|\!|_0\\&\quad+\nu_T|\!|\!|(I-P_H)\nabla\boldsymbol{u}_{m+\frac12}|\!|\!|_0|\!|\!|(I-P_H)\nabla\boldsymbol{\phi}_{m+\frac12}|\!|\!|_0\le A_0+\cdots+A_{13}.\end{aligned}$$

The terms $A_0,A_1,A_2,A_3,A_8,A_{11}$, and A_{12} are bounded exactly like the terms T_0,T_1,T_2, T_3,T_7,T_9, and T_{10}, respectively. From a Taylor expansion, we bound the terms A_4 and A_5:

$$\begin{aligned}A_4+A_5&=\sum_{j=1}^{N_h}\int_{E_j}((\boldsymbol{u}_{m+\frac12}-\boldsymbol{u}(t_{m+\frac12}))\cdot\nabla\boldsymbol{u}_{m+\frac12})\cdot\boldsymbol{\phi}_{m+\frac12}\\&\quad+\sum_{j=1}^{N_h}\int_{E_j}\boldsymbol{u}(t_{m+\frac12})\cdot\nabla(\boldsymbol{u}_{m+\frac12}-\boldsymbol{u}(t_{m+\frac12}))\cdot\boldsymbol{\phi}_{m+\frac12}\\&=\frac{\Delta t^2}{8}\sum_{j=1}^{N_h}\int_{E_j}(\boldsymbol{u}_{tt}(t^*)\cdot\nabla\boldsymbol{u}_{m+\frac12})\cdot\boldsymbol{\phi}_{m+\frac12}+\frac{\Delta t^2}{8}\sum_{j=1}^{N_h}\int_{E_j}\boldsymbol{u}(t_{m+\frac12})\cdot\nabla(\boldsymbol{u}_{tt}(t^*))\cdot\boldsymbol{\phi}_{m+\frac12}\\&\le\frac{\kappa\nu}{64}\|\boldsymbol{\phi}_{m+\frac12}\|_X^2+C\nu^{-1}\Delta t^4\|\boldsymbol{u}_{tt}\|^2_{L^\infty(0,T;H^1(\Omega))}\|\boldsymbol{u}\|^2_{L^\infty(0,T;W^{2,4/3}(\Omega))}.\end{aligned}$$

With (3.7), (3.11), and (5.4), the pressure term can be rewritten as

$$\begin{aligned}
A_6 &= b(\boldsymbol{\phi}_{m+\frac{1}{2}}, \tilde{p}^h_{m+\frac{1}{2}} - p_{m+\frac{1}{2}}) + b(\boldsymbol{\phi}_{m+\frac{1}{2}}, p_{m+\frac{1}{2}} - p(t_{m+\frac{1}{2}}))\\
&= -\, b(\boldsymbol{\phi}_{m+\frac{1}{2}}, p_{m+\frac{1}{2}} - (r_h(p))_{m+\frac{1}{2}}) + b(\boldsymbol{\phi}_{m+\frac{1}{2}}, p_{m+\frac{1}{2}} - p(t_{m+\frac{1}{2}}))\\
&= \sum_{k=1}^{M_h} \int_{e_k} \{p_{m+\frac{1}{2}} - (r_h(p))_{m+\frac{1}{2}}\}[\boldsymbol{\phi}_{m+\frac{1}{2}}] \cdot \boldsymbol{n}_k - \sum_{j=1}^{N_h} \int_{E_j} (p_{m+\frac{1}{2}} - p(t_{m+\frac{1}{2}}))\nabla \cdot \boldsymbol{\phi}_{m+\frac{1}{2}}\\
&\quad + \sum_{k=1}^{M_h} \int_{e_k} \{p_{m+\frac{1}{2}} - p(t_{m+\frac{1}{2}})\}[\boldsymbol{\phi}_{m+\frac{1}{2}}] \cdot \mathbf{n}_k\\
&\le \frac{\kappa\nu}{64}\|\boldsymbol{\phi}_{m+\frac{1}{2}}\|_X^2 + C\nu^{-1}h^{2r}(|p_{m+1}|^2_{r,\Omega} + |p_m|^2_{r,\Omega}) + C\nu^{-1}\Delta t^4 \|p_{tt}\|^2_{L^\infty(0,T;H^1(\Omega))}.
\end{aligned}$$

We now bound A_7, using a Taylor expansion:

$$A_7 \le C\Delta t^2 \|\boldsymbol{u}_{ttt}(t^*)\|_{0,\Omega}\|\boldsymbol{\phi}_{m+\frac{1}{2}}\|_{0,\Omega} \le \frac{\kappa\nu}{64}\|\boldsymbol{\phi}_{m+\frac{1}{2}}\|_X^2 + C\nu^{-1}\Delta t^4\|\boldsymbol{u}_{ttt}\|^2_{L^\infty(0,T;L^2(\Omega))}.$$

Also using a Taylor expansion, we bound A_9:

$$A_9 \le C\nu^{-1}\Delta t^4 \|\boldsymbol{f}_{tt}\|^2_{L^\infty(0,T;L^2(\Omega))} + \frac{\kappa\nu}{64}\|\boldsymbol{\phi}_{m+\frac{1}{2}}\|_X^2.$$

Finally the last term A_{10} is handled as follows:

$$\begin{aligned}
A_{10} &= \nu[a(\boldsymbol{\eta}_{m+\frac{1}{2}}, \boldsymbol{\phi}_{m+\frac{1}{2}}) + J(\boldsymbol{\eta}_{m+\frac{1}{2}}, \boldsymbol{\phi}_{m+\frac{1}{2}})]\\
&\quad + \nu[a(\boldsymbol{u}(t_{m+\frac{1}{2}}) - \boldsymbol{u}_{m+\frac{1}{2}}, \boldsymbol{\phi}_{m+\frac{1}{2}}) + J(\boldsymbol{u}(t_{m+\frac{1}{2}}) - \boldsymbol{u}_{m+\frac{1}{2}}, \boldsymbol{\phi}_{m+\frac{1}{2}})] = A_{101} + A_{102}.
\end{aligned}$$

The term A_{101} is bounded like T_8. The term A_{102} reduces to

$$\begin{aligned}
A_{102} &= \nu \sum_{j=1}^{N_h} \int_{E_j} \nabla(\boldsymbol{u}(t_{m+\frac{1}{2}}) - \boldsymbol{u}_{m+\frac{1}{2}}) : \nabla\boldsymbol{\phi}_{m+\frac{1}{2}}\\
&\quad - \nu \sum_{k=1}^{M_h} \int_{e_k} \{\nabla(\boldsymbol{u}(t_{m+\frac{1}{2}}) - \boldsymbol{u}_{m+\frac{1}{2}})\boldsymbol{n}_k\}[\boldsymbol{\phi}_{m+\frac{1}{2}}] \le \frac{\kappa\nu}{64}\|\boldsymbol{\phi}_{m+\frac{1}{2}}\|_X^2\\
&\quad + C\nu\Delta t^4 \|\boldsymbol{u}_{tt}\|^2_{L^\infty(0,T;H^2(\Omega))}.
\end{aligned}$$

Combining all the bounds above yields

$$\begin{aligned}
&\frac{1}{2\Delta t}(\|\boldsymbol{\phi}_{m+1}\|^2_{0,\Omega} - \|\boldsymbol{\phi}_m\|^2_{0,\Omega}) + \frac{\nu\kappa}{2}\|\boldsymbol{\phi}_{m+\frac{1}{2}}\|_X^2 + \frac{\nu_T}{2}\vert\vert\vert(I - P_H)\nabla\boldsymbol{\phi}_{m+\frac{1}{2}}\vert\vert\vert_0^2\\
&\le C\nu^{-1}(\|\boldsymbol{\phi}_m\|^2_{0,\Omega} + \|\boldsymbol{\phi}_{m+1}\|^2_{0,\Omega}) + Ch^{2r}(\nu + \nu^{-1} + \nu_T)(|\boldsymbol{u}_{m+1}|^2_{r+1,\Omega} + |\boldsymbol{u}_m|^2_{r+1,\Omega})\\
&\quad + Ch^{2r}\nu^{-1}(|p_{m+1}|^2_{r,\Omega} + |p_m|^2_{r,\Omega}) + C\Delta t^4\nu\|\boldsymbol{u}_{ttt}\|^2_{L^\infty(0,T;H^2(\Omega))}\\
&\quad + C\Delta t^4\nu^{-1}(\|\boldsymbol{u}_{tt}\|^2_{L^\infty(0,T;H^1(\Omega))} + \|p_{tt}\|^2_{L^\infty(0,T;H^1(\Omega))} + \|\boldsymbol{u}_{ttt}\|^2_{L^\infty(0,T;L^2(\Omega))}\\
&\quad + \|\boldsymbol{f}_{tt}\|^2_{L^\infty(0,T;L^2(\Omega))}) + C\nu_T H^{2r}(|\boldsymbol{u}_{m+1}|^2_{r+1,\Omega} + |\boldsymbol{u}_m|^2_{r+1,\Omega}).
\end{aligned}$$

The end of the proof is similar to that of Theorem 5.2. □

Corollary 5.4. *Assume that $\nu_T = h^\beta$ and $H = h^{1/\alpha}$, where $\beta \geq 2r(\alpha-1)/\alpha$ (see Corollary 4.2); then the estimates in Theorems 5.2 and 5.3 are optimal:*

$$\max_{m=0,\ldots,M} \|\boldsymbol{u}_m - \boldsymbol{u}_m^h\|_{0,\Omega} + \left(\Delta t \sum_{m=0}^{M-1} \|\boldsymbol{u}_{m+1} - \boldsymbol{u}_{m+1}^h\|_X^2\right)^{1/2} = \mathcal{O}(h^r + \Delta t),$$

$$\max_{m=0,\ldots,M} \|\boldsymbol{u}_m - \tilde{\boldsymbol{u}}_m\|_{0,\Omega} + \left(\Delta t \sum_{m=0}^{M-1} \|\boldsymbol{u}_{m+1} - \tilde{\boldsymbol{u}}_{m+1}\|_X^2\right)^{1/2} = \mathcal{O}(h^r + \Delta t^2).$$

Remark 3. The analysis presented in this paper is applicable to the three-dimensional Navier–Stokes equations assuming that the L^p bound (2.6) and the inf-sup condition (3.10) hold true.

6. Conclusion. In this paper, we have analyzed the stability and convergence of totally discontinuous schemes for solving the time-dependent Navier–Stokes equations. Both semidiscrete approximation and fully discrete approximation are constructed for velocity. In addition, semidiscrete approximation of pressure is obtained. We showed that these estimations are optimal. Numerical experiments are currently under investigation.

A FINITE DIFFERENCE SCHEME FOR OPTION PRICING IN JUMP DIFFUSION AND EXPONENTIAL LÉVY MODELS*

RAMA CONT† AND EKATERINA VOLTCHKOVA†

Abstract. We present a finite difference method for solving parabolic partial integro-differential equations with possibly singular kernels which arise in option pricing theory when the random evolution of the underlying asset is driven by a Lévy process or, more generally, a time-inhomogeneous jump-diffusion process. We discuss localization to a finite domain and provide an estimate for the localization error under an integrability condition on the Lévy measure. We propose an explicit-implicit finite difference scheme which can be used to price European and barrier options in such models. We study stability and convergence of the scheme proposed and, under additional conditions, provide estimates on the rate of convergence. Numerical tests are performed with smooth and nonsmooth initial conditions.

Key words. parabolic integro-differential equations, finite difference methods, Lévy process, jump-diffusion models, option pricing, viscosity solutions

1. Introduction.

The shortcomings of diffusion models in representing the risk related to large market movements have led to the development of various option pricing models with jumps, where large returns are represented as discontinuities in prices as a function of time. Models with jumps allow for a more realistic representation of price dynamics and greater flexibility in modelling and have been the focus of much recent work [11].

Exponential Lévy models, where the market price of an asset is represented as the exponential $S_t = \exp(rt + X_t)$ of a Lévy process X_t, offer analytically tractable examples of positive jump processes which are simple enough to allow a detailed study both in terms of statistical properties and as models for risk-neutral dynamics, i.e., option pricing models. Option pricing with exponential Lévy models is discussed in [11, 17, 24]. The flexibility of choice of the Lévy process X allows us to calibrate the model to market prices of options and reproduce a wide variety of implied volatility skews/smiles [12]. The Markov property of the price allows us to express prices of European and barrier options in terms of solutions of partial integro-differential equations (PIDEs) that involve, in addition to a (possibly degenerate) second-order differential operator, a nonlocal integral term that requires specific treatment at both the theoretical and numerical levels [13].

In this paper, we propose a finite difference scheme for solving such PIDEs. Our numerical solution is based on splitting the operator into a local and a nonlocal part: we treat the local term using an implicit step and the nonlocal term using an explicit step. This idea, previously used for nonlinear PDEs [3], allows for an efficient numerical implementation. Some difficulties arise due to the nonlocal character of the

integral operator, nonsmoothness of initial conditions, the singularity at zero of the integral kernel, and the possible degeneracy of the diffusion coefficient. We resolve these difficulties in the framework of viscosity solutions and provide error estimates in each case, under assumptions which are easily verified on the Lévy density. We study the consistency and stability of this scheme, show its convergence to the solution of the PIDE, and study its numerical performance in two examples, the Merton model with Gaussian jumps and the infinite activity variance Gamma model. Our scheme can be used for European and barrier options and can also be extended to the case of nonconstant coefficients.

1.1. Relation to previous literature. Various numerical methods for solving such parabolic integro-differential equations have been proposed in the recent literature [2, 25, 16, 31]. In the case where the characteristic function of the log-price is known analytically, the fast Fourier transform of Carr and Madan [9] can be used for pricing European options. Though our finite difference method requires more operations than the fast Fourier transform [9], our method does not require a closed form expression for the characteristic function of the log-price and can also handle barrier options (i.e., boundary value problems).

Finite difference schemes for PIDEs have been proposed in [2, 16, 30], but a rigorous analysis of consistency, stability, and convergence is absent from these studies. By appealing to the formalism of viscosity solutions, our analysis allows fairly general hypotheses on the model and applies to models based on pure-jump Lévy processes such as the variance Gamma model [23], hyperbolic models [17], and the normal inverse Gaussian (NIG) model [7].

For jump-diffusion models with finite jump intensity, Andersen and Andreasen [2] proposed an operator splitting method where the differential part is treated using a Crank–Nicholson step and the jump integral is computed using an explicit time step. Our method applies more generally to models with infinite activity, i.e., singular integral kernels; in addition, we propose an analysis of the convergence of our algorithm, which is absent in [2].

Using a variational formulation of the integro-differential equation, Zhang [31] studied a finite difference scheme in the case of jump-diffusion models having finite intensity and possessing all exponential moments (see also [16]). These conditions rule out all models in the literature except the Merton model: our analysis does not require such restrictive conditions. The variational formulation has been recently extended by Matache, von Petersdorff, and Schwab [25] to the infinite activity case using a wavelet Galerkin method. While the approach of [25] is more general than the above approaches, it does not allow us to treat singular cases such as the variance Gamma model [23].

1.2. Outline. Section 2 starts by recalling facts about Lévy processes and exponential Lévy models. In section 3 we briefly discuss, following [13], the characterization of prices of European and barrier options in exponential Lévy models in terms of viscosity solutions of PIDEs.

Solving such PIDEs by finite difference methods involves several approximations: localization of the equation to a bounded domain, treatment of the singularity due to small jumps, discretization of the equation in space, and iteration in time. We discuss localization errors in section 4 and provide an estimate for the localization errors under an integrability condition on the Lévy measure. In section 5 we propose an explicit-implicit finite difference scheme and study consistency, stability, and convergence of the scheme proposed. Convergence properties of the scheme are studied in section

6: we show that the scheme is monotone, unconditionally stable, and consistent and exhibit conditions for its convergence to the solution of the PIDE. Under further conditions on the scheme, we are able to give an estimate of the rate of convergence in section 6.4. Finally, in section 7, numerical tests are performed for smooth and nonsmooth initial conditions to assess the effect of various numerical parameters on the accuracy of the scheme.

2. Exponential Lévy models.

We consider here the class of exponential Lévy models: the risk-neutral dynamics of the underlying asset is given by $S_t = \exp(rt + X_t)$, where X_t is a time-homogeneous jump-diffusion (Lévy) process.

2.1. Lévy processes: Definitions.

A Lévy process is a stochastic process X_t with stationary independent increments which is continuous in probability. Without loss of generality we assume that $X_0 = 0$. The characteristic function of X_t has the following form, called the Lévy–Khinchin representation [27]:

$$E[e^{izX_t}] = e^{-t\psi(z)} = \exp\left\{t\left(-\frac{\sigma^2 z^2}{2} + i\gamma z + \int_{-\infty}^{\infty}(e^{izx} - 1 - izx1_{|x|\le 1})\nu(dx)\right)\right\}, \tag{2.1}$$

where $\sigma > 0$ and γ are real constants and ν is a positive measure verifying

$$\int_{-1}^{+1} x^2\nu(dx) < \infty, \qquad \int_{|x|>1}\nu(dx) < \infty. \tag{2.2}$$

The random process X can be interpreted as the superposition of a Brownian motion with drift and an infinite superposition of independent (compensated) Poisson processes with various jump sizes x, $\nu(dx)$ being the intensity of jumps of size x. In general ν is not a finite measure: $\int \nu(dx)$ need not be finite. In the case where $\lambda = \int \nu(dx) < +\infty$, the measure ν can be normalized to define a *probability measure* μ, which can now be interpreted as the distribution of jump sizes:

$$\mu(dx) = \frac{\nu(dx)}{\lambda}.$$

The jumps of X are then described by a *compound Poisson* process with λ as jump intensity (average number of jumps per unit time) and $\mu(.)$ as jump size distribution. In this case the truncation of small jumps is not needed, and the Lévy–Khinchin representation reduces to

$$E[e^{izX_t}] = \exp\left\{t\left(-\frac{\sigma^2 z^2}{2} + i\gamma_0(\nu)z + \int_{-\infty}^{\infty}(e^{izx} - 1)\nu(dx)\right)\right\}.$$

A Lévy process is a Markov process; its infinitesimal generator $L^X : f \to L^X f$ is an integro-differential operator defined by the expression

$$\begin{aligned} L^X f(x) &= \lim_{t\to 0}\frac{E[f(x+X_t)] - f(x)}{t} \\ &= \frac{\sigma^2}{2}\frac{\partial^2 f}{\partial x^2} + \gamma\frac{\partial f}{\partial x} + \int \nu(dy)\left[f(x+y) - f(x) - y1_{\{|y|\le 1\}}\frac{\partial f}{\partial x}(x)\right], \end{aligned} \tag{2.3}$$

which is well defined for $f \in C^2(\mathbb{R})$ with compact support.

2.2. Exponential Lévy models. Let $(S_t)_{t\in[0,T]}$ be the price of a financial asset modelled as a stochastic process on a filtered probability space $(\Omega,\mathcal{F},\mathcal{F}_t,\mathbb{Q})$. Under the hypothesis of absence of arbitrage there exists a measure equivalent to $\mathbb{Q}$ under which (S_t) is a martingale. We will assume in what follows that $\mathbb{Q}$ is a martingale measure.

Exponential Lévy models assume that the (risk-neutral) dynamics of S_t under $\mathbb{Q}$ is represented as the exponential of a Lévy process:

$$S_t = S_0 e^{rt+X_t}. \tag{2.4}$$

Here X_t is a Lévy process with characteristic triplet (σ,γ,ν), and the interest rate r is included for ease of notation. Different exponential Lévy models proposed in the financial modelling literature simply correspond to different choices for the Lévy measure ν; see [11, Chap. 3] for a review. The absence of arbitrage then imposes that $\hat{S}_t = S_t e^{-rt} = \exp X_t$ is a martingale, which is equivalent to the following conditions on the triplet (σ,γ,ν):

$$\int_{|y|>1} \nu(dy)e^y < \infty, \tag{2.5}$$

$$\gamma = \gamma(\sigma,\nu) = -\frac{\sigma^2}{2} - \int (e^y - 1 - y1_{|y|\leq 1})\nu(dy). \tag{2.6}$$

We will assume this relation holds in what follows. The infinitesimal generator L^X then becomes

$$L^X f(x) = \frac{\sigma^2}{2}\left[\frac{\partial^2 f}{\partial x^2} - \frac{\partial f}{\partial x}\right] + \int_{-\infty}^{\infty} \nu(dy)\ \left[f(x+y) - f(x) - (e^y-1)\frac{\partial f}{\partial x}(x)\right]. \tag{2.7}$$

We will also use the notation $Y_t = rt + X_t$. The infinitesimal generator of Y_t is

$$Lf = L^X f + r\frac{\partial f}{\partial x}. \tag{2.8}$$

3. Partial integro-differential equation for option prices. The value of an option is defined as a discounted conditional expectation of its terminal payoff H_T under the risk-adjusted martingale measure (sometimes called risk-neutral probability) $\mathbb{Q}$:

$$C_t = E[e^{-r(T-t)}H_T|\mathcal{F}_t].$$

For a European call or put, $H_T = H(S_T)$. From the Markov property, $C_t = C(t,S)$, where

$$C(t,S) = E[e^{-r(T-t)}H(S_T)|S_t = S]. \tag{3.1}$$

Introducing the change of variable $\tau = T-t$, $x = \ln(S/S_0)$, and defining $h(x) = H(S_0e^x)$ and $u(\tau,x) = e^{r\tau}C(T-\tau,S_0e^x)$, then

$$u(\tau,x) = E[h(x+Y_\tau)]. \tag{3.2}$$

If u is sufficiently smooth—for example, $u \in C^{1,2}$ with bounded derivatives—then by applying Ito's formula to $u(t,X_t)$ between 0 and T one can show [8] that it is a classical solution of the Cauchy problem:

$$\frac{\partial u}{\partial \tau} = Lu \quad \text{on } (0,T]\times\mathbb{R}, \qquad u(0,x) = h(x), \quad x\in\mathbb{R}. \tag{3.3}$$

Barrier options lead to initial-boundary value problems. Consider, for instance, an up-and-out call option with maturity T, strike K, and (upper) barrier $U > S_0$. The terminal payoff is given by

$$H_T = (S_T - K)^+ 1_{T<\theta},$$

where $\theta = \inf\{t \geq 0 \mid S_t \geq U\}$, the first moment when the barrier is crossed. Due to the strong Markov property of Lévy processes, it is possible to express the value of the option $C_t = e^{-r(T-t)} E[H_T|\mathcal{F}_t]$ as a deterministic function of time t and current stock value S_t before the barrier is crossed. Namely, for any $(t, S) \in [0, T] \times (0, \infty)$ we can define

$$C_b(t, S) = e^{-r(T-t)}\ E[H(Se^{Y_{T-t}})1_{T<\theta_t}], \tag{3.4}$$

where $H(S) = (S-K)^+$, $\{Y_{s-t},\ s \geq t\}$ is a Lévy process, and $\theta_t = \inf\{s \geq t \mid Se^{Y_{s-t}} \geq U\}$, the first exit time after t. Then,

$$C_t = C_b(t,\ S_t)1_{t\leq\theta} \tag{3.5}$$

for all $t \leq T$. Note that outside of the set $\{t \leq \theta\}$ the objects C_t and $C_b(t, S_t)$ are different: if the barrier has already been crossed, C_t will always be zero, but $C_b(t, S_t)$ may become positive if the stock returns to the region below the barrier. By going to the log variables we define

$$u_b(\tau, x) = e^{r\tau} C_b(T - \tau, S_0e^x). \tag{3.6}$$

Again, if u_b is smooth the Itô formula can be used to show [8] that u_b is a solution of the following initial-boundary value problem:

$$\begin{aligned} &\frac{\partial u}{\partial \tau} = Lu \qquad \text{on } (0, T] \times (-\infty, \log(U/S_0)), \\ u(0, x) = h(x), \quad x < \log(U/S_0); \qquad &u(\tau, x) = 0, \quad x \geq \log(U/S_0). \end{aligned}$$

Prices of down-and-out or double barrier options are defined similarly. In the case of pure jump models where $\sigma = 0$, these smoothness conditions can fail to hold; counterexamples are given in [13]. In this case the option price should be seen as a viscosity solution of the PIDE, as discussed below.

3.1. Viscosity solutions for integro-differential equations.

Existence and uniqueness of (classical) solutions for the PIDEs considered above in Sobolev–Hölder spaces have been studied in [8, 18] in the case where the diffusion component is nondegenerate: for a Lévy process this simply means $\sigma > 0$, but more generally these results apply to jump diffusion where the diffusion coefficient is bounded away from zero. However, many of the models in the financial modelling literature are pure jump models with $\sigma = 0$, for which such results are not available. In fact, in pure jump models with finite variation (3.3) is formally a *first* order in the price variable so the effect of the jump term is more like a convection term rather than a diffusion term. A notion of solution that yields existence and uniqueness for such equations without requiring nondegeneracy of coefficients or a priori knowledge of smoothness of solutions is the notion of viscosity solution, introduced by Crandall and Lions for PDEs (see [14]) and extended to integro-differential equations of the type considered here in [1, 4, 26, 28, 29].

Denote by USC (respectively, LSC) the class of upper semicontinuous (respectively, lower semicontinuous) functions $u : (0,T] \times \mathbb{R} \to \mathbb{R}$ and by $C_p^+([0,T] \times \mathbb{R})$ the set of measurable functions on $[0,T] \times \mathbb{R}$ with polynomial growth of degree p at $+\infty$ and bounded on $[0,T] \times \mathbb{R}^-$:

$$\varphi \in C_p^+([0,T] \times \mathbb{R}) \iff \exists C > 0,\ |\varphi(t,x)| \le C(1 + |x|^p\, 1_{x>0}). \tag{3.7}$$

Let $O = (l,u) \subseteq \mathbb{R}$ be an open interval, $\partial O = \{l,u\}$ its boundary, and $g \in C_p^+([0,T] \times \mathbb{R} \setminus O)$ a continuous function. Consider the following initial-boundary value problem on $[0,T] \times \mathbb{R}$:

$$\frac{\partial u}{\partial \tau} = Lu \qquad \text{on } (0,T] \times O, \tag{3.8}$$

$$u(0,x) = h(x), \quad x \in O; \qquad u(\tau,x) = g(\tau,x), \quad x \notin O. \tag{3.9}$$

Definition 3.1 (viscosity solution). *A function $u \in USC$ is a viscosity subsolution of* (3.8)–(3.9) *if for any test function $\varphi \in C^2([0,T] \times \mathbb{R}) \cap C_p^+([0,T] \times \mathbb{R})$ and any global maximum point $(\tau,x) \in [0,T] \times \mathbb{R}$ of $u - \varphi$, the following properties are verified:*

$$\text{if } (\tau,x) \in (0,T] \times O, \qquad \left(\frac{\partial \varphi}{\partial \tau} - L\varphi\right)(\tau,x) \le 0, \tag{3.10}$$

$$\text{if } \tau = 0,\ x \in \overline{O}, \qquad \min\left\{\left(\frac{\partial \varphi}{\partial \tau} - L\varphi\right)(\tau,x),\ u(\tau,x) - h(x)\right\} \le 0,$$

$$\text{if } \tau \in (0,T],\ x \in \partial O, \qquad \min\left\{\left(\frac{\partial \varphi}{\partial \tau} - L\varphi\right)(\tau,x),\ u(\tau,x) - g(\tau,x)\right\} \le 0,$$

$$\text{if } x \notin \overline{O}, \qquad u(\tau,x) \le g(\tau,x). \tag{3.11}$$

A function $u \in LSC$ is a viscosity supersolution of (3.8)–(3.9) *if, for any test function $\varphi \in C^2([0,T] \times \mathbb{R}) \cap C_p^+([0,T] \times \mathbb{R})$ and any global minimum point $(\tau,x) \in [0,T] \times \mathbb{R}$ of $u - \varphi$, we have*

$$\text{if } (\tau,x) \in (0,T] \times O, \qquad \left(\frac{\partial \varphi}{\partial \tau} - L\varphi\right)(\tau,x) \ge 0,$$

$$\text{if } \tau = 0,\ x \in \overline{O}, \qquad \max\left\{\left(\frac{\partial \varphi}{\partial \tau} - L\varphi\right)(\tau,x),\ u(\tau,x) - h(x)\right\} \ge 0,$$

$$\text{if } \tau \in (0,T],\ x \in \partial O, \qquad \max\left\{\left(\frac{\partial \varphi}{\partial \tau} - L\varphi\right)(\tau,x),\ u(\tau,x) - g(\tau,x)\right\} \ge 0,$$

$$\text{if } x \notin \overline{O}, \qquad u(\tau,x) \ge g(\tau,x).$$

A function $u \in C_p^+([0,T] \times \mathbb{R})$ is called a viscosity solution of (3.8)–(3.9) *if it is both a subsolution and a supersolution. This function is then continuous on* $(0,T] \times \mathbb{R}$.

Note that the initial and boundary conditions are verified in a viscosity sense. The definition also includes the case of initial value problems: $O = \mathbb{R}$. Existence and uniqueness of viscosity solutions for such parabolic integro-differential equations in the case $O = \mathbb{R}$ are discussed in [1] in the case where ν is a finite measure and in [4] and [26] for general Lévy measures. Growth conditions other than $u \in C_p^+$ can be considered (see, e.g., [1, 4]) with additional conditions on the Lévy measure ν. The main tool for showing uniqueness is the comparison principle: if u, v are viscosity solutions and $u(0,x) \geq v(0,x)$, then for all $\tau \in [0,T]$, $u(\tau,x) \geq v(\tau,x)$. This property can be extended to subsolutions and supersolutions in the following sense [1, 20].

PROPOSITION 3.2 (comparison principle for semicontinuous solutions [1, 20]). *If $u \in USC$ is a subsolution and $v \in LSC$ is a supersolution of* (3.8)–(3.9) *with $O = \mathbb{R}$ and h is a continuous function, then $u \leq v$ on $[0,T] \times \mathbb{R}$.*

Proofs and extensions can be found in [1] for the case where ν is a bounded measure; the case of a general Lévy measure has recently been treated in [20].

3.2. Option prices as viscosity solutions of PIDEs.

The following result, whose proof in a more general setting is given in [13], shows that values of European and barrier options with Lipschitz payoff function can be expressed in terms of (viscosity) solutions of (3.8)–(3.9).

PROPOSITION 3.3 (option prices as viscosity solutions). *Let the payoff function H verify the Lipschitz condition on its domain of definition,*

$$|H(S_1) - H(S_2)| \leq C|S_1 - S_2| \qquad \forall S_1, S_2 \in (S_0e^l, S_0e^u), \tag{3.12}$$

and let $h(x) = H(S_0e^x)$ have polynomial growth at infinity. Then the following hold:

1. *The forward value of a European option $u(\tau,x)$ defined by* (3.2) *is the unique viscosity solution of the Cauchy problem* (3.3).
2. *If the forward value $u_b(\tau,x)$ of a knockout (single or double) barrier option defined by* (3.6) *is continuous, then it is a viscosity solution of* (3.8)–(3.9) *(with $g \equiv 0$).*

The assumptions on the payoff function apply to put options, single-barrier knockout puts, double barrier knockout options and also to the log-contract. One can then retrieve call options by put-call parity. For barrier options, continuity holds in particular if $\nu(\mathbb{R}) < \infty$ and $\sigma > 0$ but also in pure jump models with infinite activity [13]. For barrier options with rebate, the zero boundary condition has to be replaced by the value of the rebate, as in the case of diffusion models.

4. Localization estimates.

In order to solve numerically the PIDE, we first localize the variables and the integral term to bounded domains. This section discusses estimates for the localization error using a probabilistic approach.

4.1. Localization to a bounded domain.

To solve numerically the initial-boundary value problem (3.8)–(3.9) in the case of an unbounded domain O, we first truncate the domain to an interval $x \in (-A, A)$. Usually, this leads us to define some boundary conditions at $x = -A$ and $x = A$. As noted above, the operator L is nonlocal: computing the integral term at a point $x \in (-A, A)$ requires knowledge of $u(\tau, \cdot)$ on $\{x + y \mid y \in \operatorname{supp} \nu\}$, which in most examples is equal to the whole real line $\mathbb{R}$. In the case of knock-out barrier options, a natural boundary condition is given by the zero extension (or the rebate). In other cases, this extension is done by imposing a numerical boundary condition. Choosing $u(\tau,x) = g(\tau,x)$ for some given continuous function g with polynomial growth will lead to a probabilistic interpretation of the solution of the localized problem.

Although many choices are possible for the boundary condition g, we will consider here two cases. The simplest choice is $g = 0$, i.e., extend the solution by zero outside the domain. Another extension is given by the payoff function (the initial condition) itself, $g(\tau,x) = h(x)$, which is asymptotically close to the solution at infinity. We will see that both choices lead to a localization error that exponentially decreases with the domain size. Let us define $u_A(\tau,x)$ as the solution of the localized problem

$$\frac{\partial u_A}{\partial \tau} = Lu_A, \qquad (0,T]\times(-A,A), \tag{4.1}$$
$$u_A(0,x)=h(x), \qquad x\in(-A,A); \qquad u_A(\tau,x)=g(\tau,x), \qquad x\notin(-A,A),$$

where $g=0$ or $g(\tau,x)=h(x)$.

PROPOSITION 4.1. *Assume that h is bounded ($||h||_\infty<\infty$) and*

$$\exists\alpha>0, \int_{|x|>1} e^{\alpha|x|}\nu(dx)<\infty. \tag{4.2}$$

Let $u(\tau,x)$ be the solution of (3.3) *and let $u_A(\tau,x)$ be the (viscosity) solution of* (4.1) *with boundary condition $g=0$ or $g(\tau,x)=h(x)$. Then*

$$|u(\tau,x)-u_A(\tau,x)|\le 2C_{\tau,\alpha}||h||_\infty e^{-\alpha(A-|x|)} \qquad \forall x\in(-A,A), \tag{4.3}$$

where the constant $C_{\tau,\alpha}$ does not depend on A.

Proof. The proof is based on the probabilistic representation [8, 13] of the solutions of (5.1) and (4.1). Let us define $M_\tau^x=\sup_{t\in[0,\tau]}|Y_t+x|$. Then

$$\begin{aligned} u(\tau,x) &= \mathbb{E}[h(Y_\tau+x)],\\ u_A(\tau,x) &= \mathbb{E}[h(Y_\tau+x)1_{\{M_\tau^x<A\}}] \qquad \text{if } g=0,\\ \text{or } u_A(\tau,x) &= \mathbb{E}[h(Y_\tau+x)1_{\{M_\tau^x<A\}}+h(Y_{\theta(x)}+x)1_{\{M_\tau^x\ge A\}}], \end{aligned}$$

where $\theta(x)=\inf\{t\ge0,|Y_t+x|\ge A\}$ is the first exit time of Y_t+x from $[-A,A]$. Subtracting u_A from u gives

$$\begin{aligned} |u(\tau,x)-u_A(\tau,x)| &= |\mathbb{E}h(Y_\tau+x)1_{\{M_\tau^x\ge A\}}|\\ &\le ||h||_\infty\mathbb{Q}(M_\tau^x\ge A) \quad \text{for } g=0, \end{aligned}$$

and in the case $g(\tau,x)=h(x)$ we obtain

$$\begin{aligned} |u(\tau,x)-u_A(\tau,x)| &\le \mathbb{E}|h(Y_\tau+x)1_{\{M_\tau^x\ge A\}}|+\mathbb{E}|h(Y_{\theta(x)}+x)1_{\{M_\tau^x\ge A\}}|\\ &\le 2||h||_\infty\mathbb{Q}(M_\tau^x\ge A). \end{aligned}$$

So, in both cases

$$|u(\tau,x)-u_A(\tau,x)|\le 2||h||_\infty\mathbb{Q}(M_\tau^x\ge A). \tag{4.4}$$

Theorem 25.18 of [27] together with (4.2) implies

$$C_{\tau,\alpha}=\mathbb{E}e^{\alpha M_\tau^0}<\infty. \tag{4.5}$$

Therefore, Chebyshev's inequality applies, and we obtain

$$\mathbb{Q}(M_\tau^0\ge A)\le C_{\tau,\alpha}e^{-\alpha A}. \tag{4.6}$$

Now, to pass from M_τ^0 to M_τ^x, we use the following implications:

$$\begin{array}{rrcl} & \sup|Y_t+x| & \le & \sup|Y_t|+|x|\\ \Rightarrow & (\sup|Y_t+x|\ge A & \Rightarrow & \sup|Y_t|+|x|\ge A)\\ \Rightarrow & \mathbb{Q}(M_\tau^x\ge A) & \le & \mathbb{Q}(M_\tau^0\ge A-|x|)\\ & & \le & C_{\tau,\alpha}e^{-\alpha(A-|x|)} \quad \text{by (4.6)}. \end{array}$$

Combining the last inequality with (4.4) gives the desired result. □

Remark 1. In the case of a put option, $\|h\|_\infty < \infty$ and Proposition 4.1 applies. In other examples, h may be unbounded; in this case it is still possible to obtain an exponentially decreasing localization error under additional restrictions on ν. Note that for the call option, although the payoff grows exponentially, one can transform the problem into pricing a put using put-call parity in order to obtain a smaller localization error.

Remark 2. An exponential bound on localization error in the L_2-norm is given in [25] using analytical methods. The advantage of the probabilistic approach is to provide a local (pointwise) estimate. For instance, our estimate (4.3) reflects the intuitive fact that the localization error is more pronounced near the boundary.

The above result implies that the localization error decreases uniformly on each closed subinterval of $(-A, A)$:

$$|u(\tau,x) - u_A(\tau,x)| \le k e^{-\alpha\delta A} \qquad \text{for } |x| \le (1-\delta)A,$$

where $0 < \delta < 1$.

Assumption (4.2) means that the tails of ν have to decrease exponentially, which is true in all examples considered in the option pricing literature (except Carr and Wu's log-stable model [10]). Note that in an exponential Lévy model we already have $\int_1^{+\infty} e^{\alpha x}\nu(\mathrm{d}x) < \infty$ for all $\alpha \le 1$, because of the martingale condition, so (4.2) is a condition on the negative jumps.

4.2. Truncation of the integral. To compute numerically the integral term, we need to reduce the region of integration to a bounded interval. In terms of the jump process, this amounts to the truncation of large jumps. We will now give an estimate for the error resulting from this approximation. Recall that the solution of the Cauchy problem (3.3) (in the European case where $O = \mathbb{R}$) for a Lipschitz payoff function H is

$$u(\tau,x) = \mathbb{E}[H(S_0 e^{x+r\tau+X_\tau})], \tag{4.7}$$

where X_τ is a Lévy process with the triplet (γ,σ,ν). Let us define a new process $\tilde{X}_\tau$ characterized by the Lévy triplet $(\tilde{\gamma},\sigma,\nu\mathbf{1}_{x\in[B_l,B_r]})$, where $\tilde{\gamma}$ is such that $\exp(rt+\tilde{X}_t)$ remains a martingale:

$$\tilde{\gamma} = -\frac{\sigma^2}{2} - \int_{B_l}^{B_r} (e^y - 1 - y1_{|y|\le 1})\nu(dy).$$

We now define

$$\tilde{u}(\tau,x) = \mathbb{E}[H(S_0 e^{x+r\tau+\tilde{X}_\tau})] \tag{4.8}$$

and we estimate the difference between $\tilde{u}$ and the true solution u.

PROPOSITION 4.2. *Let H be Lipschitz: $|H(S_1)-H(S_2)| \le c|S_1-S_2|$. Assume that there exists $\alpha_r, \alpha_l > 0$, such that $\int_1^\infty e^{(1+\alpha_r)y}\nu(dy) < \infty$ and $\int_{-\infty}^{-1} |y|e^{\alpha_l|y|}\nu(dy) < \infty$.*

If u and $\tilde{u}$ are defined by (4.7) *and* (4.8), *respectively, then*

$$|u(\tau,x) - \tilde{u}(\tau,x)| \le 2c\, S_0 e^{x+r\tau}\tau(C_1 e^{-\alpha_l|B_l|} + C_2 e^{-\alpha_r|B_r|}). \tag{4.9}$$

Proof. Let us denote $R_\tau = X_\tau - \tilde{X}_\tau$, $R_\tau \perp\!\!\!\perp \tilde{X}_\tau$. We have

$$\begin{aligned}|u(\tau,x) - \tilde{u}(\tau,x)| &= |\mathbb{E}[H(S_0 e^{x+r\tau+\tilde{X}_\tau+R_\tau})] - \mathbb{E}[H(S_0 e^{x+r\tau+\tilde{X}_\tau})]| \\ &\le c\, S_0 e^{x+r\tau}\mathbb{E}[e^{\tilde{X}_\tau}|e^{R_\tau}-1|] = c\, S_0 e^{x+r\tau}\mathbb{E}|e^{R_\tau}-1|.\end{aligned}$$

By construction, $\mathbb{E}[e^{R_\tau}-1]=0$. Since $|e^{R_\tau}-1|=(e^{R_\tau}-1)+2(1-e^{R_\tau})^+$ and $(1-e^{R_\tau})^+\le|R_\tau|$, we obtain

$$|u(\tau,x)-\tilde{u}(\tau,x)|\le 2c\,S_0e^{x+r\tau}\mathbb{E}|e^{R_\tau}|. \tag{4.10}$$

The Lévy triplet of R_τ is $(\gamma-\tilde{\gamma},0,\nu\mathbf{1}_{x\notin[B_l,B_r]})$ with

$$\gamma-\tilde{\gamma}=-\int_{y\notin[B_l,B_r]}(e^y-1)\nu(dy).$$

One can write $R_\tau=P_\tau+N_\tau$, where P_τ and N_τ are characterized by $(\int_{-\infty}^{B_l}(1-e^y)\nu(\mathrm{d}y),0,\nu\mathbf{1}_{x>B_r})$ and $(-\int_{B_r}^{\infty}(e^y-1)\nu(\mathrm{d}y),0,\nu\mathbf{1}_{x<B_l})$, respectively. We assume without loss of generality that $B_l<-1$, $B_r>1$.[1] Since P_τ has nonnegative drift, no Brownian component, and only positive jumps bounded from below by $B_r>0$, we have $P_\tau\ge 0$ (recall that $P_0=0$). Conversely, N_τ has only negative jumps (bounded from above by $B_l<0$) and nonpositive drift. In consequence, $N_\tau\le 0$. Therefore,

$$\begin{aligned}\mathbb{E}|R_\tau|\le\mathbb{E}|P_\tau|+\mathbb{E}|N_\tau|\;&=\;\mathbb{E}P_\tau-\mathbb{E}N_\tau\\&=\tau\left[\int_{-\infty}^{B_l}(1-e^y-y)\nu(\mathrm{d}y)+\int_{B_r}^{\infty}(e^y-1+y)\nu(\mathrm{d}y)\right]\\&\le\tau\left[2\int_{-\infty}^{B_l}|y|\nu(\mathrm{d}y)+2\int_{B_r}^{\infty}e^y\nu(\mathrm{d}y)\right].\end{aligned}\tag{4.11}$$

Using the hypotheses on ν, we obtain

$$\begin{aligned}\mathbb{E}|R_\tau|&\le\tau\left(2e^{-\alpha_l|B_l|}\int_{-\infty}^{B_l}|y|e^{\alpha_l|y|}\nu(\mathrm{d}y)+2e^{-\alpha_r|B_r|}\int_{B_r}^{\infty}e^{(1+\alpha_r)y}\nu(\mathrm{d}y)\right)\\&\le\tau(C_1e^{-\alpha_l|B_l|}+C_2e^{-\alpha_r|B_r|}),\end{aligned}$$

which we substitute into (4.10). □

Remark 3. The hypotheses on ν in Proposition 4.2 are a little stronger than (4.2). We require them to obtain an exponential decay of the truncation error. However, we can use estimate (4.11) directly. In other words, existence of the integrals in (4.11) suffices to obtain a convergence of $\tilde{u}$ to u as $|B_l|$ and $|B_r|$ grow to infinity, but this convergence does not necessarily occur at an exponential rate.

Remark 4. The requirements are different for the left and right tails of ν. For example, in the variance Gamma model with $\nu(x)=a\exp(-\eta_\pm|x|)/|x|$ one needs η_+ to be greater than 1, and η_- only positive. Proposition 4.9 then applies with $\alpha_l<\eta_-$ and $\alpha_r<\eta_+-1$.

Using Propositions 4.1 and 4.2 we can fix in advance $[-A,A]$ and $[B_l,B_r]$ to have a given bound on the respective errors. In what follows we will assume this has been done and concentrate on the numerical solution of the localized problem.

[1] Clearly, if (4.9) is true for such values, it is true for all B_l, B_r, up to change of the constants. On the other hand, this estimate is not useful if ν has a bounded support. For example, if there are only negative jumps, we will take $B_r=0$, but in this case $\nu\mathbf{1}_{x\le B_r}=\nu$, and there is no truncation error due to B_r.

5. An explicit-implicit finite difference scheme. We now present a numerical procedure for solving the PIDE:

$$\frac{\partial u}{\partial \tau} = Lu, \qquad (0,T]\times O, \tag{5.1}$$

$$u(\tau,x) = g(\tau,x), \quad x \in O^c, \tag{5.2}$$

$$u(0,x) = h(x), \qquad x \in O, \tag{5.3}$$

where L is defined by (2.8), $O^c = \mathbb{R}\setminus O$, and $g \in C_p^+([0,T]\times\mathbb{R}\setminus O)$ is a continuous function.

Our method is based on splitting the operator L into two parts:

$$\frac{\partial u}{\partial \tau} = Du + Ju,$$

where D and J stand for the differential and integral parts of L, respectively. We replace Du with a finite difference approximation $D_\Delta u$ and Ju with the trapezoidal quadrature approximation $J_\Delta u$ and use the following explicit-implicit time-stepping scheme:

$$\frac{u^{n+1}-u^n}{\Delta t} = D_\Delta u^{n+1} + J_\Delta u^n.$$

We treat the integral part in an explicit time stepping in order to avoid the inversion of the nonsparse matrix J_Δ. We show that this does not affect the stability of the scheme: it is unconditionally stable like the fully implicit scheme but does not require us to invert the dense matrix J_Δ. We first describe the space discretization and the time-stepping scheme in the case of a jump-diffusion model where the jump intensity is finite. Next, we deal with the singular case $\nu(\mathbb{R}) = +\infty$ using an approach similar to the "vanishing viscosity" method [14].

5.1. Explicit-implicit scheme: Finite intensity case. We suppose here that $\nu(\mathbb{R}) = \lambda < +\infty$. Then the integro-differential operator can be written as $Lu \equiv Du + Ju$, where

$$Du = \frac{\sigma^2}{2}\frac{\partial^2 u}{\partial x^2} - \left(\frac{\sigma^2}{2} - r + \alpha\right)\frac{\partial u}{\partial x} - \lambda u, \qquad Ju = \int_{B_l}^{B_r} \nu(dy) u(\tau, x+y), \tag{5.4}$$

and $\alpha = \int_{B_l}^{B_r}(e^y - 1)\nu(\mathrm{d}y)$.

We introduce a uniform grid on $[0,T]\times[-A,A]$: $\tau_n = n\Delta t$, $n = 0,\dots,M$, $x_i = -A + i\Delta x$, $i \in \{0,\dots,N\}$, with $\Delta t = T/M$, $\Delta x = 2A/N$. Let $\{u_i^n\}$ be the solution of the numerical scheme, to be defined below.

To approximate the integral terms we use the trapezoidal quadrature rule with the same step Δx. Let K_l, K_r be such that $[B_l, B_r] \subset [(K_l - 1/2)\Delta x, (K_r + 1/2)\Delta x]$. Then

$$\int_{B_l}^{B_r} \nu(dy) u(\tau, x_i + y) \approx \sum_{j=K_l}^{K_r} \nu_j u_{i+j}, \lambda \approx \hat{\lambda} = \sum_{j=K_l}^{K_r} \nu_j,$$

$$\alpha \approx \hat{\alpha} = \sum_{j=K_l}^{K_r} (e^{y_j} - 1)\nu_j, \qquad \text{where } \nu_j = \int_{(j-1/2)\Delta x}^{(j+1/2)\Delta x} \nu(\mathrm{d}y). \tag{5.5}$$

The space derivatives are discretized using finite differences:

$$\left(\frac{\partial^2 u}{\partial x^2}\right)_i \approx \frac{u_{i+1} - 2u_i + u_{i-1}}{(\Delta x)^2}, \tag{5.6}$$

$$\left(\frac{\partial u}{\partial x}\right)_i \approx \begin{cases} \frac{u_{i+1}-u_i}{\Delta x} & \text{if} \quad \sigma^2/2 - r + \hat{\alpha} < 0 \\ \frac{u_i - u_{i-1}}{\Delta x} & \text{if} \quad \sigma^2/2 - r + \hat{\alpha} \geq 0. \end{cases} \tag{5.7}$$

The choice of approximation for the first-order derivative is determined by stability requirement and will be discussed later (section 6). Since the two cases are treated similarly, let us suppose without loss of generality that $\sigma^2/2 - r + \hat{\alpha} < 0$.

Using (5.5)–(5.7) we obtain $Du \approx D_\Delta u$, $Ju \approx J_\Delta u$, where

$$(D_\Delta u)_i = \frac{\sigma^2}{2} \frac{u_{i+1} - 2u_i + u_{i-1}}{(\Delta x)^2} - \left(\frac{\sigma^2}{2} - r + \hat{\alpha}\right) \frac{u_{i+1} - u_i}{\Delta x} - \hat{\lambda} u_i, \tag{5.8}$$

$$(J_\Delta u)_i = \sum_{j=K_l}^{K_r} \nu_j u_{i+j}. \tag{5.9}$$

Finally, we replace problem (4.1) with the following time-stepping scheme:

Initialization:

$$u_i^0 = h(x_i), \qquad i \in \{0, \ldots, N\}, \tag{5.10}$$

$$u_i^0 = g(0, x_i) \qquad \text{otherwise.} \tag{5.11}$$

(**S**) For $n = 0, \ldots, M-1$,

$$\frac{u_i^{n+1} - u_i^n}{\Delta t} = (D_\Delta u^{n+1})_i + (J_\Delta u^n)_i \quad \text{if } i \in \{0, \ldots, N\}, \tag{5.12}$$

$$u_i^{n+1} = g(\ (n+1)\Delta t, x_i) \qquad \text{if } i \notin \{0, \ldots, N\}. \tag{5.13}$$

5.2. Explicit-implicit scheme: Infinite intensity case. If $\nu(\mathbb{R}) = +\infty$, the above method cannot be applied directly. The idea is to come down to a nonsingular case by approximating the process X_τ by an appropriate finite activity process with a modified diffusion coefficient.

The procedure is similar to the one described in section 4.2, but this time we deal with small jumps. Given $\varepsilon > 0$ let us define a process X_τ^ε characterized by the Lévy triplet $(\gamma(\varepsilon), \sqrt{\sigma^2 + \sigma^2(\varepsilon)}, \nu \mathbf{1}_{|x| \geq \varepsilon})$, where

$$\sigma^2(\varepsilon) = \int_{-\varepsilon}^{\varepsilon} y^2 \nu(\mathrm{d}y),$$

and $\gamma(\varepsilon)$ is determined by the martingale condition

$$\gamma(\varepsilon) = -\frac{\sigma^2 + \sigma^2(\varepsilon)}{2} - \int_{|y| \geq \varepsilon} (e^y - 1 - y 1_{|y| \leq 1}) \nu(dy).$$

This means that we replace the jumps of size smaller than ε by a Brownian motion $\sigma(\varepsilon) W_\tau$. Therefore, X_τ^ε has jumps of finite intensity. The function u^ε defined as

$$u^\varepsilon(\tau, x) = \mathbb{E}[h(x + r\tau + X_\tau^\varepsilon)] \equiv \mathbb{E}[h(x + Y_\tau^\varepsilon)] \tag{5.14}$$

satisfies the following Cauchy problem:

$$\begin{aligned} \frac{\partial u^\varepsilon}{\partial \tau} &= L^\varepsilon u^\varepsilon, \qquad (0,T]\times\mathbb{R}, \\ u^\varepsilon(0,x) &= h(x), \qquad x\in\mathbb{R}, \end{aligned} \tag{5.15}$$

where

$$\begin{aligned} L^\varepsilon f = \frac{\sigma^2+\sigma^2(\varepsilon)}{2}\frac{\partial^2 f}{\partial x^2} - \left(\frac{\sigma^2+\sigma^2(\varepsilon)}{2} - r + \alpha(\varepsilon)\right)\frac{\partial f}{\partial x} - \lambda(\varepsilon)f(x) \\ + \int_{|y|\geq\varepsilon}\nu(dy)f(x+y), \end{aligned} \tag{5.16}$$

and $\alpha(\varepsilon) = \int_{|y|\geq\varepsilon}(e^y-1)\nu(\mathrm{d}y)$, $\lambda(\varepsilon) = \int_{|y|\geq\varepsilon}\nu(\mathrm{d}y)$.

Note that even if $\sigma = 0$, L^ε contains a nonzero diffusion term, as in the vanishing viscosity method, with the difference that we also have additional terms in the first- and zeroth-order terms in order to conserve the martingale property. The next theorem gives an estimate of the rate of convergence for this "compensated vanishing viscosity" approximation.

THEOREM 5.1. *Let h be Lipschitz: $|h(x)-h(y)| \leq c\,|x-y|$. Let u and u^ε be defined by* (4.7) *and* (5.14)*, respectively. Then*

$$|u(\tau,x) - u^\varepsilon(\tau,x)| \leq C\frac{\int_{-\varepsilon}^{\varepsilon}|y|^3\nu(\mathrm{d}y)}{\sigma^2(\varepsilon)}. \tag{5.17}$$

Proof. We essentially use [11, Proposition 6.2] with the only difference being that we also adjust the drift parameter γ to preserve the martingale property. Let us define $Z_\tau = Y_\tau - (\gamma-\gamma(\varepsilon))\tau$. Then,

$$\begin{aligned} |u(\tau,x) - u^\varepsilon(\tau,x)| &= |\mathbb{E}[h(x+Y_\tau)] - \mathbb{E}[h(x+Y_\tau^\varepsilon)]| \\ &\leq |\mathbb{E}[h(x+Z_\tau)] - \mathbb{E}[h(x+Y_\tau^\varepsilon)]| + \\ &\quad + |\mathbb{E}[h(x+Z_\tau+(\gamma-\gamma(\varepsilon))\tau)] - \mathbb{E}[h(x+Z_\tau)]|. \end{aligned} \tag{5.18}$$

Since h is Lipschitz, it is almost everywhere differentiable with $|h'| \leq c$. By [11, Proposition 6.2] we have

$$|\mathbb{E}[h(x+Z_\tau)] - \mathbb{E}[h(x+Y_\tau^\varepsilon)]| \leq K\,c\,\frac{\int_{-\varepsilon}^{\varepsilon}|y|^3\nu(\mathrm{d}y)}{\sigma^2(\varepsilon)} \tag{5.19}$$

with $K < 16.5$. The second term may be estimated as follows:

$$|\mathbb{E}[h(x+Z_\tau+(\gamma-\gamma(\varepsilon))\tau)] - \mathbb{E}[h(x+Z_\tau)]| \leq c\,|\gamma-\gamma(\varepsilon)|\tau,$$

where

$$\begin{aligned} |\gamma-\gamma(\varepsilon)| &= \left|\frac{\sigma^2(\varepsilon)}{2} - \int_{|y|<\varepsilon}(e^y-1-y)\nu(\mathrm{d}y)\right| \\ &= \left|\frac{1}{2}\int_{|y|<\varepsilon}\nu(\mathrm{d}y)\int_0^y e^s(y-s)^2ds\right| \leq \frac{e^\varepsilon}{6}\int_{-\varepsilon}^{\varepsilon}|y|^3\nu(\mathrm{d}y). \end{aligned} \tag{5.20}$$

Since $\sigma^2(\varepsilon) \to 0$ as $\varepsilon \to 0$, (5.20) converges faster than (5.19) and therefore may be neglected. □

Remark 5. If $\lim_{x\to 0} \nu(x)|x|^{1+\beta} = a > 0$, with $0 \le \beta < 2$, then (5.17) gives

$$|u(\tau, x) - u^{\varepsilon}(\tau, x)| \le C(\beta)\varepsilon,$$

so the approximation error is proportional to ε. This case includes all practical examples used in option pricing such as variance Gamma, NIG, and tempered stable processes.

6. Convergence.

We study in this section the convergence of the finite difference scheme presented above. In the usual approach to the convergence of finite difference schemes for PDEs, consistency and stability ensure convergence under regularity assumptions on the solution such as uniform boundedness of the derivatives. This approach is not feasible here because, even for a European put option, the second derivative (Gamma of the option) is *never* uniformly bounded in t.

6.1. Monotonicity.

Monotonicity is an important property for pricing applications: it guarantees that a (discrete) comparison principle holds for the numerical solution so arbitrage inequalities will be verified exactly and not only as $\Delta t, \Delta x \to 0$, leading to arbitrage-free approximations. The following result shows that the scheme above is monotone.

Proposition 6.1 (monotonicity). *Scheme* (S) *is monotone: if* u^0, v^0 *are two bounded initial conditions, then*

$$u^0 \ge v^0 \quad \Rightarrow \quad \forall n \ge 1,\ u^n \ge v^n.$$

Proof. We start by rewriting (5.12) in the following form:

$$-c\Delta t u_{i-1}^{n+1} + (1 + a\Delta t)u_i^{n+1} - b\Delta t u_{i+1}^{n+1} = u_i^n + \Delta t \sum_j \nu_j u_{i+j}^n, \tag{6.1}$$

where[2]

$$\begin{aligned} a &= \frac{\sigma^2}{(\Delta x)^2} - \left(\frac{\sigma^2}{2} - r + \hat{\alpha}\right)\frac{1}{\Delta x} + \hat{\lambda} \ge 0, \\ b &= \frac{\sigma^2}{2(\Delta x)^2} - \left(\frac{\sigma^2}{2} - r + \hat{\alpha}\right)\frac{1}{\Delta x} \ge 0, \\ c &= \frac{\sigma^2}{2(\Delta x)^2} \ge 0. \end{aligned} \tag{6.2}$$

Notice that $a = b + c + \hat{\lambda}$.

Let u^n and v^n be two solutions of (S) corresponding to the initial conditions $h(x)$ and $f(x)$, respectively, and let $h(x) \ge f(x)$ for all $x \in \mathbb{R}$. Let us show by induction that $w^n = u^n - v^n \ge 0$ for all $n \ge 0$. We have $w_i^0 = h(x_i) - f(x_i) \ge 0$ for all $i \in \mathbb{Z}$. Let $w^n \ge 0$ and suppose that $\inf_{i\in\mathbb{Z}} w_i^{n+1} < 0$. Since for all $i \in \mathbb{Z}\backslash\{0, \dots, N\}$,

[2] We recall that the case $\sigma^2/2 - r + \hat{\alpha} < 0$ is considered. If $\sigma^2/2 - r + \hat{\alpha} \ge 0$, we change the approximation of the first-order derivative (see (5.7)) to have $a, b, c \ge 0$, which is needed for stability and monotonicity.

$w_i^{n+1} = h(x_i) - f(x_i) \geq 0$, this implies that there exists $i_0 \in \{0, \dots, N\}$, such that $w_{i_0}^{n+1} = \inf_{i\in\mathbb{Z}} w_i^{n+1}$. Using (6.1) we obtain that

$$\begin{aligned}\inf_{i\in\mathbb{Z}} w_i^{n+1} = w_{i_0}^{n+1} &= -c\Delta t w_{i_0}^{n+1} + (1 + a\Delta t)w_{i_0}^{n+1} - b\Delta t w_{i_0}^{n+1} - \hat{\lambda}\Delta t w_{i_0}^{n+1}\\ &\geq -c\Delta t w_{i_0-1}^{n+1} + (1 + a\Delta t)w_{i_0}^{n+1} - b\Delta t w_{i_0+1}^{n+1}\\ &= w_{i_0}^n + \Delta t \sum_j \nu_j w_{i_0+j}^n \geq 0, \qquad (6.3)\end{aligned}$$

which contradicts the assumption. Therefore, $\inf_{i\in\mathbb{Z}} w_i^{n+1} \geq 0$, and, consequently $w^{n+1} \geq 0$. □

It is convenient to rewrite the scheme as follows:

$$\begin{aligned}u(\tau_n, x_i) &= F_\Delta[u(\tau_n - \Delta t, \cdot)](x_i), \quad n = 1, \dots, M,\ i \in \{0, \dots, N\},\\ u(\tau_n, x_i) &= g(\tau_n, x_i), \quad n = 0, \dots, M,\ i \notin \{0, \dots, N\},\\ u(0, x_i) &= h(x_i), \quad i \in \{0, \dots, N\}.\end{aligned} \qquad (6.4)$$

Let u^Δ be the solution of the scheme (6.4) defined on the grid $Q_\Delta = \{(\tau_n, x_i) \mid n = 0, \dots, M,\ i \in \mathbb{Z}\}$. One can define super- and subsolutions for the scheme by analogy with the definitions in section 3.

DEFINITION 6.2. *A function w^Δ defined on Q_Δ is a supersolution of the scheme* (6.4) *if*

$$\begin{aligned}w^\Delta(\tau_n, x_i) &\geq F_\Delta[w^\Delta(\tau_n - \Delta t, \cdot)](x_i), \quad n = 1, \dots, M,\ i \in \{0, \dots, N\},\\ w^\Delta(\tau_n, x_i) &\geq g(\tau_n, x_i), \quad n = 0, \dots, M,\ i \notin \{0, \dots, N\},\\ w^\Delta(0, x_i) &\geq h(x_i), \quad i \in \{0, \dots, N\}.\end{aligned}$$

A function z^Δ on Q_Δ is a subsolution of (6.4) *if*

$$\begin{aligned}z^\Delta(\tau_n, x_i) &\leq F_\Delta[z^\Delta(\tau_n - \Delta t, \cdot)](x_i), \quad n = 1, \dots, M,\ i \in \{0, \dots, N\},\\ z^\Delta(\tau_n, x_i) &\leq g(\tau_n, x_i), \quad n = 0, \dots, M,\ i \notin \{0, \dots, N\},\\ z^\Delta(0, x_i) &\leq h(x_i), \quad i \in \{0, \dots, N\}.\end{aligned}$$

In particular, the scheme is unconditionally stable in the sup norm. The following result extends the discrete comparison principle to sub- and supersolutions.

LEMMA 1. *For any supersolution w and any subsolution z of* (6.4) *we have*

$$z^\Delta \leq u^\Delta \leq w^\Delta \quad \text{on } Q_\Delta.$$

Proof. For $n = 0$ or $i \notin \{0, \dots, N\}$ the above inequalities are satisfied by definition. For $n > 0$, $i \in \{0, \dots, N\}$, they follow directly from the monotonicity of the scheme. Indeed, if $z^\Delta(\tau_n - \Delta t, \cdot) \leq u^\Delta(\tau_n - \Delta t, \cdot) \leq w^\Delta(\tau_n - \Delta t, \cdot)$, then, for $i \in \{0, \dots, N\}$, we obtain

$$\begin{aligned}z^\Delta(\tau_n, x_i) &\leq F_\Delta[z^\Delta(\tau_n - \Delta t, \cdot)](x_i) \leq F_\Delta[u^\Delta(\tau_n - \Delta t, \cdot)](x_i) = u^\Delta(\tau_n, x_i)\\ &= F_\Delta[u^\Delta(\tau_n - \Delta t, \cdot)](x_i) \leq F_\Delta[w^\Delta(\tau_n - \Delta t, \cdot)](x_i) \leq w^\Delta(\tau_n, x_i). \qquad □\end{aligned}$$

6.2. Consistency. We now show the consistency of the scheme in the uniform norm for the following class of test functions $v : [0,T] \times \mathbb{R} \mapsto \mathbb{R}$:

$$H = \Big\{ v \in C^{1,2}((0,T] \times O), v \text{ uniformly continuous on}[0,T] \times \mathbb{R},$$

$$\frac{\partial v}{\partial \tau}, \frac{\partial v}{\partial x}, \frac{\partial^2 v}{\partial x^2} \text{ uniformly continuous on}(0,T] \times O \Big\}. \tag{6.5}$$

Proposition 6.3 (consistency in the uniform norm). *For any $v \in H$ and any $\varepsilon > 0$,*

$$\exists \Delta > 0, \quad \left| \frac{v(\tau_n, x_i) - v(\tau_{n-1}, x_i)}{\Delta t} - L_\Delta v(\tau_n, x_i) - \left(\frac{\partial v}{\partial \tau} - Lv \right)(\tau, x) \right| < \varepsilon \tag{6.6}$$

for all Δt, $\Delta x > 0$, $(\tau, x) \in (0,T] \times O$, $n \geq 1$, $i \in \{0, \ldots, N\}$, *such that* $\sup\{\Delta t, \Delta x, |\tau_n - \tau|, |x_i - x|\} < \Delta$.

Proof. Let $\sup\{\Delta t, \Delta x, |\tau_n - \tau|, |x_i - x|\} < \Delta$. We have to prove that the expression in (6.6) is bounded by $\alpha(\Delta)$ independently of $(\tau, x), (\tau_n, x_i) \in (0,T] \times O$, such that $\alpha(\Delta) \to 0$ as $\Delta \to 0$. We have

$$\left| \frac{v(\tau_n, x_i) - v(\tau_{n-1}, x_i)}{\Delta t} - \frac{\partial v}{\partial \tau}(\tau, x) \right| = \left| \frac{1}{\Delta t} \int_{\tau_{n-1}}^{\tau_n} \left(\frac{\partial v}{\partial \tau}(t, x_i) - \frac{\partial v}{\partial \tau}(\tau, x) \right) dt \right| \tag{6.7}$$

$$\leq \sup_{t \in (\tau_{n-1}, \tau_n)} \left| \frac{\partial v}{\partial \tau}(t, x_i) - \frac{\partial v}{\partial \tau}(\tau, x) \right| \leq \sup_{\substack{t,\, \tau \,\in\, (0,T],\, y,\, x \,\in\, O \\ |t - \tau| \,\leq\, 2\Delta \\ |y - x| \,\leq\, \Delta}} \left| \frac{\partial v}{\partial \tau}(t, y) - \frac{\partial v}{\partial \tau}(\tau, x) \right| \xrightarrow{\Delta \downarrow 0} 0,$$

since $\frac{\partial v}{\partial \tau}$ is uniformly continuous by assumption.

Consider now the terms in Dv (the differential part of Lv). Using Taylor expansion up to the second order we obtain

$$\begin{aligned} &\left| \frac{v(\tau_n, x_{i-1}) - 2v(\tau_n, x_i) + v(\tau_n, x_{i+1})}{\Delta x^2} - \frac{\partial^2 v}{\partial x^2}(\tau, x) \right| \\ &\qquad = \left| \frac{1}{\Delta x^2} \int_{x_{i-1}}^{x_{i+1}} \left(\frac{\partial^2 v}{\partial x^2}(\tau_n, y) - \frac{\partial^2 v}{\partial x^2}(\tau, x) \right) (\Delta x - |x_i - y|) dy \right| \\ &\qquad \leq 2 \sup_{y \in (x_{i-1}, x_{i+1})} \left| \frac{\partial^2 v}{\partial x^2}(\tau_n, y) - \frac{\partial^2 v}{\partial x^2}(\tau, x) \right| \\ &\qquad \leq 2 \sup_{\substack{t,\, \tau \,\in\, (0,T],\, y,\, x \,\in\, O \\ |t - \tau| \,\leq\, \Delta \\ |y - x| \,\leq\, 2\Delta}} \left| \frac{\partial^2 v}{\partial x^2}(t, y) - \frac{\partial^2 v}{\partial x^2}(\tau, x) \right| \xrightarrow{\Delta \downarrow 0} 0, \end{aligned}$$

as $\frac{\partial^2 v}{\partial x^2}$ is uniformly continuous on $(0,T] \times O$. In the same way, we show that

$$\begin{aligned} \left| \frac{v(\tau_n, x_{i+1}) - v(\tau_n, x_i)}{\Delta x} - \frac{\partial v}{\partial x}(\tau, x) \right| &= \left| \frac{1}{\Delta x} \int_{x_i}^{x_{i+1}} \left(\frac{\partial v}{\partial x}(\tau_n, y) - \frac{\partial v}{\partial x}(\tau, x) \right) dy \right| \\ &\leq \sup_{\substack{t,\, \tau \,\in\, (0,T],\, y,\, x \,\in\, O \\ |t - \tau| \,\leq\, \Delta \\ |y - x| \,\leq\, 2\Delta}} \left| \frac{\partial v}{\partial x}(t, y) - \frac{\partial v}{\partial x}(\tau, x) \right| \xrightarrow{\Delta \downarrow 0} 0. \end{aligned}$$

Since $|1 - e^{y_j - y}| \leq \Delta x$ if $\Delta x \leq 1$ and $|y_j - y| \leq \Delta x/2$, we also have

$$
\begin{aligned}
(6.8)\quad |\alpha - \hat{\alpha}| &= \left| \int_{B_l}^{B_r} (e^y - 1)\nu(\mathrm{d}y) - \sum_{j=K_l}^{K_r} (e^{y_j} - 1)\nu_j \right| \\
&= \left| \sum_{j=K_l}^{K_r} \int_{(j-1/2)\Delta x}^{(j+1/2)\Delta x} (1 - e^{y_j - y}) e^y \nu(\mathrm{d}y) \right| \leq \Delta x \left| \sum_{j=K_l}^{K_r} \int_{(j-1/2)\Delta x}^{(j+1/2)\Delta x} e^y \nu(\mathrm{d}y) \right| \\
&= \Delta x \int_{B_l}^{B_r} e^y \nu(\mathrm{d}y) = (\alpha + \lambda)\Delta x.
\end{aligned}
$$

Therefore, using previous estimates and uniform boundedness of $\frac{\partial v}{\partial x}$ on $(0, T] \times O$, we obtain

$$
\begin{aligned}
|(D_\Delta v)(\tau_n, x_i) - (Dv)(\tau, x)| &= \left| \frac{\sigma^2}{2} \left[\frac{v(\tau_n, x_{i-1}) - 2v(\tau_n, x_i) + v(\tau_n, x_{i+1})}{\Delta x^2} - \frac{\partial^2 v}{\partial x^2}(\tau, x) \right] \right. \\
&\left. + \left(\frac{\sigma^2}{2} - r + \hat{\alpha} \right) \left[\frac{v(\tau_n, x_{i+1}) - v(\tau_n, x_i)}{\Delta x} - \frac{\partial v}{\partial x}(\tau, x) \right] + (\alpha - \hat{\alpha}) \frac{\partial v}{\partial x}(\tau, x) \right| \overset{\Delta \downarrow 0}{\longrightarrow} 0.
\end{aligned}
$$

The integral part can be estimated as follows:

$$
\begin{aligned}
&(6.9)\\
&|(J_\Delta v)(\tau_{n-1}, x_i) - (Jv)(\tau, x)| = \left| \sum_{j=K_l}^{K_r} v(\tau_{n-1}, x_i + y_j)\nu_j - \int_{B_l}^{B_r} v(\tau, x + y)\nu(\mathrm{d}y) \right| \\
&\qquad = \left| \sum_{j=K_l}^{K_r} \int_{(j-1/2)\Delta x}^{(j+1/2)\Delta x} (v(\tau_{n-1}, x_i + y_j) - v(\tau, x + y))\nu(\mathrm{d}y) \right| \\
&\qquad \leq \lambda \Delta \sup_{\substack{\theta_1, \theta_2 \in [0,T],\ \xi_1, \xi_2 \in \mathbb{R} \\ |\theta_1 - \theta_2| \leq 2\Delta \\ |\xi_1 - \xi_2| \leq 3\Delta/2}} |v(\theta_1, \xi_1) - v(\theta_2, \xi_2)| \overset{\Delta \downarrow 0}{\longrightarrow} 0,
\end{aligned}
$$

since v is uniformly continuous on $[0, T] \times \mathbb{R}$. Combining all these estimates gives (6.6). □

6.3. Convergence. A general approach for obtaining convergence of finite difference schemes in the case of nonsmooth solutions was developed by Barles and Souganidis [6] who showed that, when subsolutions/supersolutions verify a strong comparison principle, the solution of any monotone, locally consistent scheme converges uniformly on compact sets to the solution of the limit equation. The idea of [6] is to show that the pointwise limits

$$
(6.10)\qquad \underline{u}(\tau, x) = \liminf_{(\Delta t, \Delta x) \to 0\ (\tau_n, x_i) \to (\tau, x)} u^{(\Delta t, \Delta x)}(\tau_n, x_i),
$$

$$
(6.11)\qquad \overline{u}(\tau, x) = \limsup_{(\Delta t, \Delta x) \to 0\ (\tau_n, x_i) \to (\tau, x)} u^{(\Delta t, \Delta x)}(\tau_n, x_i)
$$

define sub-/supersolutions and then apply the comparison principle to conclude $\overline{u} = \underline{u} = u$. As noted above, our scheme (5.12) is monotone and locally consistent, but the comparison principles [1, 20] available for the PIDEs considered here require uniform continuity properties which may not hold for $\overline{u}$ and $\underline{u}$ defined as in (6.10)–(6.11). Therefore we cannot directly apply the Barles–Souganidis result to obtain convergence.[3]

We avoid this problem by considering smooth sub-/supersolutions and deriving inequalities linking them with $\overline{u}, \underline{u}$.

Definition 6.4. *A function $w \in H$ is a smooth supersolution of the problem* (5.1)–(5.3) *if it verifies the following inequalities:*

$$\frac{\partial w}{\partial \tau}(\tau, x) - Lu(\tau, x) \geq 0, \quad (\tau, x) \in (0, T] \times O, \tag{6.12}$$

$$w(\tau, x) \geq g(\tau, x), \quad x \in O^c, \tag{6.13}$$

$$w(0, x) \geq h(x), \quad x \in O. \tag{6.14}$$

A function $z \in H$ is a smooth subsolution of the problem (5.1)–(5.3) *if it satisfies* (6.12)–(6.14) *with the reverse inequalities.*

Lemma 2. *Let $w(\tau, x)$ be a smooth supersolution and let $z(\tau, x)$ be a smooth subsolution of the problem* (5.1)–(5.3). *Then for all $\varepsilon > 0$, there exists $\Delta > 0$ such that*

$$\forall \Delta t, \Delta x \leq \Delta, \forall n \geq 0, \forall i \in \mathbb{Z}, \; z(\tau_n, x_i) - \varepsilon < u^{\Delta}(\tau_n, x_i) < w(\tau_n, x_i) + \varepsilon. \tag{6.15}$$

Proof. Choose b such that $0 < b(T+1) < \varepsilon$ and let $\bar{w}(\tau, x) = w(\tau, x) + b(\tau + 1)$. If $i \notin \{0, \ldots, N\}$, we have

$$\bar{w}(\tau_n, x_i) = w(\tau_n, x_i) + b(\tau_n + 1) \geq g(\tau_n, x_i) + b(\tau_n, x_i) \geq g(\tau_n, x_i). \tag{6.16}$$

If $i \in \{0, \ldots, N\}$,

$$\bar{w}(0, x_i) = w(0, x_i) + b \geq h(x_i) + b \geq h(x_i). \tag{6.17}$$

If $n \geq 1$, $i \in \{0, \ldots, N\}$, we obtain by Proposition 6.3

$$\begin{aligned} &\frac{\bar{w}(\tau_n, x_i) - \bar{w}(\tau_n - \Delta t, x_i)}{\Delta t} - L_\Delta \bar{w}(\tau_n, x_i) \\ &\quad = \frac{w(\tau_n, x_i) - w(\tau_n - \Delta t, x_i)}{\Delta t} - L_\Delta w(\tau_n, x_i) + b(1 + \hat{\lambda}\Delta t) \\ &\qquad\qquad \to \left(\frac{\partial w}{\partial \tau}(\tau, x) - Lu(\tau, x) \right) + b > 0, \end{aligned} \tag{6.18}$$

as $\Delta t, \Delta x \to 0$, $(\tau_n, x_i) \to (\tau, x)$, uniformly on $(0, T] \times O$. Therefore, for any sufficiently small $\Delta > 0$, for all $\Delta t, \Delta x \leq \Delta$, we have

$$\frac{\bar{w}(\tau_n, x_i) - \bar{w}(\tau_n - \Delta t, x_i)}{\Delta t} - L_\Delta \bar{w}(\tau_n, x_i) \geq 0$$

or, equivalently,

$$\bar{w}(\tau_n, x_i) \geq F_\Delta[\bar{w}(\tau_n - \Delta t, \cdot)](x_i) \qquad \forall n \geq 1, \; \forall i \in \{0, \ldots, N\}. \tag{6.19}$$

[3] Note also that the Barles–Souganidis method does not yield a rate of convergence either: this issue is treated in section 6.4 below.

By (6.16), (6.17), and (6.19), the function $\bar{w}$ is a supersolution of (6.4). So, Lemma 1 implies that

$$u^{\Delta}(\tau_n, x_i) \le \bar{w}(\tau_n, x_i) \le w(\tau_n, x_i) + b(T+1) < w(\tau_n, x_i) + \varepsilon \qquad \forall n \ge 0,\ \forall i \in \mathbb{Z},$$

which is the desired property. The lower bound $z(\tau_n, x_i) - \varepsilon$ can be proved in the same manner. □

Corollary 6.5. *Let $\underline{u}$ and $\overline{u}$ be the functions defined by* (6.10)–(6.11). *For any smooth subsolution $z(\tau, x)$ and any supersolution $w(\tau, x)$ of the problem* (5.1)–(5.3), *we have, for all $(\tau, x) \in [0, T] \times \mathbb{R}$,*

$$z(\tau, x) \le \underline{u}(\tau, x) \le \overline{u}(\tau, x) \le w(\tau, x). \tag{6.20}$$

Proof. By the definition of upper and lower limits, (6.15) implies (6.20). □

We are now ready to give our main result on the convergence of the scheme. We assume $\sigma > 0$ since, as explained in section 5.2, the scheme introduces a viscosity term $\sigma(\varepsilon) > 0$ even in the pure jump case where $\sigma = 0$.

Theorem 6.6. *In the European case ($O = \mathbb{R}$) with $\sigma > 0$, if h is a bounded piecewise continuous function on $\mathbb{R}$, then for all $\tau > 0$ and all $x \in \mathbb{R}$, the discrete solution converges to the solution of the continuous problem:*

$$\lim_{\substack{(\Delta t, \Delta x) \to 0 \\ (\tau_n, x_i) \to (\tau, x)}} u^{(\Delta t, \Delta x)}(\tau_n, x_i) = u(\tau, x).$$

Proof. If $\underline{h}, \overline{h} \in C^\infty(\mathbb{R})$ are such that $\underline{h} \le h \le \overline{h}$, then $z(\tau, x) = \mathbb{E}[\underline{h}(x + Y_\tau)]$ and $w(\tau, x) = \mathbb{E}[\overline{h}(x + Y_\tau)]$ are solutions in H of (5.1) and therefore, respectively, a subsolution and a supersolution of the Cauchy problem (5.1), (5.3). By Corollary 6.5, we obtain (6.20). If $w(\tau, x) - u(\tau, x)$ and $u(\tau, x) - z(\tau, x)$ could be made arbitrarily small, this would imply that there exists a limit of $u^{(\Delta t, \Delta x)}(\tau_n, x_i)$ equal to $u(\tau, x)$. So, it remains to construct appropriate smooth approximations $\underline{h}$ and $\overline{h}$ of h.

Let $\xi_1, \dots, \xi_I$ be the discontinuity points of h. We will suppose that the jumps of h are bounded by K. Given $\varepsilon > 0$, we choose $\underline{h}, \overline{h} \in C^\infty(\mathbb{R})$ such that

$$\begin{aligned} \underline{h}(x) \le h(x) \le \overline{h}(x) \quad & \forall x \in \mathbb{R}, \\ |\overline{h}(x) - \underline{h}(x)| \le \varepsilon \quad & \forall x \notin \bigcup_{i=1}^{I} (\xi_i - \varepsilon, \xi_i + \varepsilon), \\ |\overline{h}(x) - \underline{h}(x)| \le K \quad & \forall x \in \bigcup_{i=1}^{I} (\xi_i - \varepsilon, \xi_i + \varepsilon). \end{aligned}$$

Then we have

$$\begin{aligned} w(\tau, x) - z(\tau, x) &= \mathbb{E}[\overline{h}(x + Y_\tau) - \underline{h}(x + Y_\tau)] \\ &\le \varepsilon \mathbb{Q}\left(x + Y_\tau \notin \bigcup_{i=1}^{I} (\xi_i - \varepsilon, \xi_i + \varepsilon) \right) + K \mathbb{Q}\left(x + Y_\tau \in \bigcup_{i=1}^{I} (\xi_i - \varepsilon, \xi_i + \varepsilon) \right) \\ &\le \varepsilon + K \mathbb{Q}\left(x + Y_\tau \in \bigcup_{i=1}^{I} (\xi_i - \varepsilon, \xi_i + \varepsilon) \right). \end{aligned} \tag{6.21}$$

Denoting $\Omega_\varepsilon = \{x + Y_\tau \in \bigcup_{i=1}^{I}(\xi_i - \varepsilon, \xi_i + \varepsilon)\}$ we obtain $\bigcap_{\varepsilon>0}\Omega_\varepsilon = \{x + Y_\tau \in \{\xi_1, \dots, \xi_I\}\}$. Since σ is strictly positive, Y_τ has an absolutely continuous distribution for $\tau > 0$, so we have $\mathbb{Q}(x + Y_\tau \in \{\xi_1, \dots, \xi_I\}) = 0$. Consequently,

$$\mathbb{Q}\left(x + Y_\tau \in \bigcup_{i=1}^{I}(\xi_i - \varepsilon, \xi_i + \varepsilon)\right) \xrightarrow{\varepsilon\downarrow 0} 0.$$

We have shown that the expression in (6.21) goes to zero as $\varepsilon \to 0$. The inequalities (6.20) together with $z(\tau, x) \le u(\tau, x) \le w(\tau, x)$ then imply that $\underline{u}(\tau, x) = \overline{u}(\tau, x) = u(\tau, x)$. The proof is complete. □

Remark 6. If $\tau = 0$, we obtain

$$\mathbb{Q}\left(x + Y_\tau \in \bigcup_{i=1}^{I}(\xi_i - \varepsilon, \xi_i + \varepsilon)\right) \xrightarrow{\varepsilon\downarrow 0} \mathbb{Q}(x \in \{\xi_1, \dots, \xi_I\}) = 1_{\{x\in\{\xi_1,\dots,\xi_I\}\}}.$$

So, the scheme does not converge to the initial condition at the discontinuity points of h. However, this has no practical importance since we do not need to calculate the solution numerically at $\tau = 0$.

Together with Proposition 5.1, Theorem 6.6 allows us to compute option prices in all the examples of exponential Lévy models given in section 2. Theorem 6.6 does not yield the rate of convergence; we now use a different approach to obtain an estimate on the rate of convergence under a further condition on the scheme.

6.4. Rate of convergence. In the viscosity solution framework, results on convergence rates for numerical schemes have been obtained by Crandall and Lions [15] for first-order equations and by Krylov [21, 22] for second-order parabolic PDEs; see also [5]. Our approach is inspired by [22] but is somewhat simpler and yields better bounds, given that we are dealing with a linear equation.

First, let us write the scheme in the following form: $u(\tau_n, x_i) = u(\tau_{n-1}, x_i) + L_\Delta u(\tau_n, x_i)\Delta t$, where (in the case $\sigma^2/2 - r + \hat{\alpha} < 0$)

$$\begin{aligned} L_\Delta u(\tau, x) = {}& \frac{\sigma^2}{2}\frac{u(\tau, x + \Delta x) - 2u(\tau, x) + u(\tau, x - \Delta x)}{\Delta x^2} \\ & - \left(\frac{\sigma^2}{2} - r + \hat{\alpha}\right)\frac{u(\tau, x + \Delta x) - u(\tau, x)}{\Delta x} - \hat{\lambda} u(\tau, x) + \sum_{j=K_l}^{K_r} \nu_j u(\tau - \Delta t, x + j\Delta x). \end{aligned}$$

As previously, we assume $\sigma > 0$.[4]

Consider the grid $\{(\tau_n, x_i),\ n = 0, \dots, M,\ i \in \mathbb{N}\}$, where $\tau_n = n\Delta t$, $x_i = x_0 + i\Delta x$. Given $J \subset \{0, \dots, M\}$, we denote by $\mathcal{B}_{J\times\mathbb{N}}$ the space of bounded functions on $\{(\tau_n, x_i),\ n \in J,\ i \in \mathbb{N}\}$ with the norm

$$\|v\|_J = \sup_{n\in J,\ i\in\mathbb{N}} |v(\tau_n, x_i)|. \tag{6.22}$$

For $(v(x_i),\ i \in \mathbb{N})$ we write

$$\|v\| = \sup_{i\in\mathbb{N}} |v(x_i)|. \tag{6.23}$$

The following (see appendix) is a slightly improved version of a result in [22].

[4] The infinite activity pure-jump case being reduced to this one; see section 5.2.

LEMMA 3. *Consider, for $\xi \in \mathcal{B}_{\{1,\dots,M\}\times\mathbb{N}}$, the problem*

$$v(0,x_i) = h(x_i), \qquad i \in \mathbb{N}, \tag{6.24}$$

$$v(\tau_n,x_i) = v(\tau_{n-1},x_i) + L_\Delta v(\tau_n,x_i)\Delta t + \xi(\tau_n,x_i), \quad n=1,\dots,M,\ i\in\mathbb{N}. \tag{6.25}$$

(i) *For any $\xi \in \mathcal{B}_{\{1,\dots,M\}\times\mathbb{N}}$ the problem* (6.24)–(6.25) *has a unique solution $v(\xi) \in \mathcal{B}_{\{0,\dots,M\}\times\mathbb{N}}$.*

(ii) *If $v_i = v(\xi_i)$, where $\xi_i \in \mathcal{B}_{\{1,\dots,M\}\times\mathbb{N}}$, $i=1,2$, then*

$$\|v_1(\tau_n,\cdot) - v_2(\tau_n,\cdot)\| \le \sum_{k=1}^{n} \|\xi_1(\tau_k,\cdot) - \xi_2(\tau_k,\cdot)\|, \quad n=1,\dots,M. \tag{6.26}$$

We will consider payoff functions h which verify the following conditions.

ASSUMPTION 6.1. *$h : \mathbb{R} \mapsto \mathbb{R}$ is continuous on $\mathbb{R}$ and there exists $\xi_1,\dots,\xi_I \in \mathbb{R}$ such that h is C^∞ on $]\xi_i,\xi_{i+1}[$ for $i=0,\dots,I-1$ and for all $n\ge 0$, for all $x \notin \{\xi_1,\dots,\xi_I\}$, $|h^{(n)}(x)| \le K$.*

For example, the payoff of a put option $h(x) = (1-e^x)^+$ verifies these conditions.

LEMMA 4. *Let h verify Assumption* 6.1 *and let $u(\tau,x) = \mathbb{E}[h(x+X_\tau)]$ be the viscosity solution of the problem*

$$\frac{\partial u}{\partial \tau}(\tau,x) = Lu(\tau,x), \qquad (\tau,x) \in (0,T]\times\mathbb{R}, \tag{6.27}$$

$$u(0,x) = h(x), \qquad x \in \mathbb{R}. \tag{6.28}$$

Then, for all $\tau > 0$ and $m,n \in \mathbb{N}$, $m+n>0$, we have

$$\left\| \frac{\partial^{m+n} u}{\partial \tau^m \partial x^n}(\tau,\cdot) \right\| \le \frac{C}{(\sqrt{\tau})^{2m+n-1}}. \tag{6.29}$$

The constant C depends only on m, n, K, T, and coefficients of the operator L (σ, r, α, and λ).

Using this lemma we prove the following consistency result.

LEMMA 5. *If u solves* (6.27)–(6.28)*, then, for all $k \ge 1$,*

$$\|Lu(\tau_k,\cdot) - L_\Delta u(\tau_k,\cdot)\| \le C\left[\frac{\Delta x^2}{\tau_k^{3/2}} + \frac{\Delta x}{\tau_k^{1/2}} + \Delta x + 2(\sqrt{\tau_k} - \sqrt{\tau_{k-1}})\right], \tag{6.30}$$

with $C = C(K,T,r,\sigma,\lambda,\alpha)$.

Under a CFL-type condition, we obtain the following rate of convergence.

THEOREM 6.7. *Assume that the initial condition h verifies Assumption* 6.1. *Let u be the unique solution of* (6.27)–(6.28) *and let u_Δ be the solution of* (6.24)–(6.25) *with $\xi = 0$. If $c_1 \le \Delta t/\Delta x^2 \le c_2$, then*

$$\|u - u_\Delta\|_{\{0,\dots,M\}} \le C\Delta x, \tag{6.31}$$

where C depends only on T, K, and coefficients of the operator L (σ, r, α, and λ).

Proof. The function $u(\tau_n,x_i)$ solves (6.24)–(6.25) with $\xi(\tau_k,x_i) = \int_{\tau_{k-1}}^{\tau_k} Lu(s,x_i)ds - L_\Delta u(\tau_k,x_i)\Delta t$. From Lemma 3,

$$\begin{aligned}\|u(\tau_n,\cdot) - u_\Delta(\tau_n,\cdot)\| &\le \sum_{k=1}^{n} \left\| \int_{\tau_{k-1}}^{\tau_k} Lu(s,\cdot)ds - L_\Delta u(\tau_k,\cdot)\Delta t \right\| \\ &\le \sum_{k=1}^{n} \left\| \int_{\tau_{k-1}}^{\tau_k} (Lu(s,\cdot) - Lu(\tau_k,\cdot))ds \right\| + \sum_{k=1}^{n} \|Lu(\tau_k,\cdot) - L_\Delta u(\tau_k,\cdot)\|\,\Delta t.\end{aligned} \tag{6.32}$$

Let us look at the first term:

$$\left|\int_{\tau_{k-1}}^{\tau_k}(Lu(s,x)-Lu(\tau_k,x))ds\right| = \left|\int_{\tau_{k-1}}^{\tau_k}ds\int_s^{\tau_k}\frac{\partial^2 u}{\partial\tau^2}(\theta,x)d\theta\right|$$
$$\leq C\int_{\tau_{k-1}}^{\tau_k}ds\int_s^{\tau_k}\frac{d\theta}{\theta^{3/2}} \leq C\Delta t\int_{\tau_{k-1}}^{\tau_k}\frac{ds}{s^{3/2}}$$

by Lemma 4. Therefore,

$$\sum_{k=1}^{n}\left\|\int_{\tau_{k-1}}^{\tau_k}(Lu(s,\cdot)-Lu(\tau_k,\cdot))ds\right\| \leq C\left[\int_0^{\Delta t}ds\int_s^{\Delta t}\frac{d\theta}{\theta^{3/2}}+\Delta t\int_{\Delta t}^{T}\frac{ds}{s^{3/2}}\right]$$
$$= C\left[2\Delta t+\Delta t\frac{2(\sqrt{T}-\sqrt{\Delta t})}{\sqrt{T}\sqrt{\Delta t}}\right] \leq 4C\sqrt{\Delta t}. \tag{6.33}$$

To estimate the second term in (6.32), note that

$$\sum_{k=1}^{n}\frac{\Delta t}{\sqrt{\tau_k}} = \sum_{k=1}^{n}\int_{\tau_{k-1}}^{\tau_k}\frac{ds}{\sqrt{\tau_k}} \leq \sum_{k=1}^{n}\int_{\tau_{k-1}}^{\tau_k}\frac{ds}{\sqrt{s}} = 2\sqrt{\tau_n}$$

and

$$\sum_{k=1}^{n}\frac{\Delta t}{\tau_k^{3/2}} = \frac{1}{\sqrt{\Delta t}}\sum_{k=1}^{n}\frac{1}{k^{3/2}} \leq \frac{C}{\sqrt{\Delta t}},$$

since the series $\sum_{k=1}^{\infty}1/k^{3/2}$ converges. Using Lemma 5, we obtain

$$\sum_{k=1}^{n}\|Lu(\tau_k,\cdot)-L_\Delta u(\tau_k,\cdot)\|\Delta t \leq C\left[\Delta x^2/\sqrt{\Delta t}+2\sqrt{\tau_n}\Delta x+\tau_n\Delta x+2\sqrt{\tau_n}\Delta t\right]$$
$$\leq C\left[\Delta x^2/\sqrt{\Delta t}+\Delta x+\Delta t\right]. \tag{6.34}$$

If $c_1 \leq \Delta t/\Delta x^2 \leq c_2$, the estimates (6.32), (6.33), and (6.34) imply (6.31). □

7. Numerical results. We now illustrate the performance of the scheme proposed above with two examples. The computations were done in variance Gamma models with Lévy density

$$\nu(x) = a\frac{\exp(-\eta_\pm|x|)}{|x|}$$

and two sets of parameters: $a = 6.25$, $\eta_- = 14.4$, $\eta_+ = 60.2$ (VG1) and $a = 0.5$, $\eta_- = 2.7$, $\eta_+ = 5.9$ (VG2), and a Merton model with Gaussian jumps in log-price with volatility $\sigma = 15\%$ and Lévy density

$$\nu(x) = 0.1\frac{e^{-x^2/2}}{\sqrt{2\pi}}$$

for a put of maturity of $T = 1$ year. Both of these models satisfy the hypotheses of sections 4.1 and 4.2: the Lévy densities have exponentially decreasing tails. The Black–Scholes implied volatilities computed from prices of put options are shown in Figure 7.1: as expected, they display a "smile" (convex) feature as a function of the

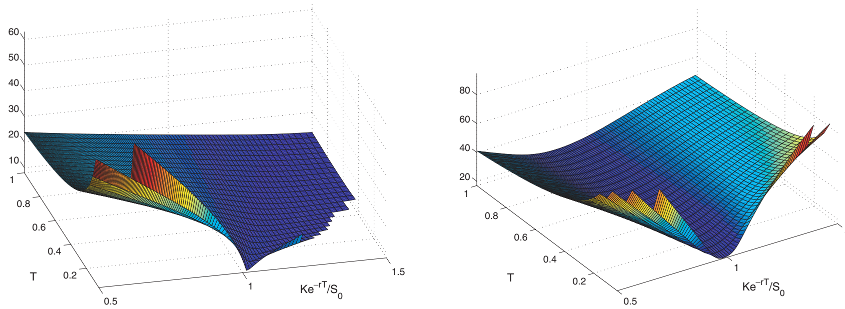

FIG. 7.1. *Black–Scholes implied volatilities for put options, as a function of strike and maturity. Left: variance Gamma model. Right: Merton jump-diffusion model.*

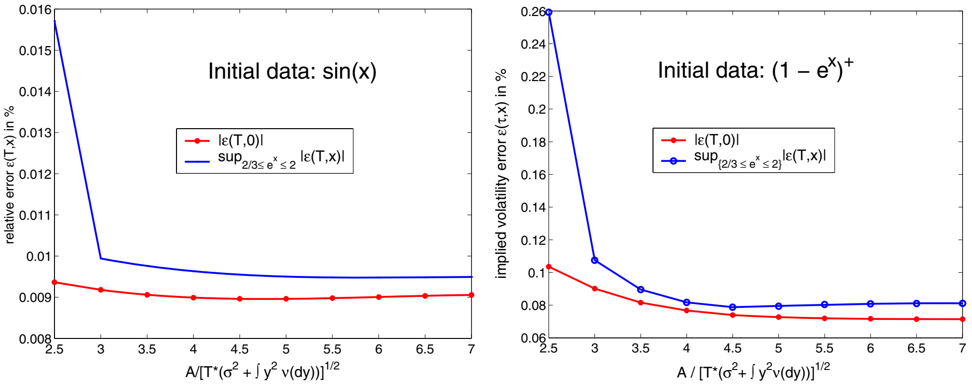

FIG. 7.2. *Influence of domain size on localization error for the explicit-implicit finite difference scheme. Left: smooth initial condition* $h(x) = \sin(x)$ *in Merton jump-diffusion model. Right: put option in Merton jump-diffusion model.*

strike of the option, which flattens out with increasing maturity. These two models have been chosen since in each case there is an alternative method for computing the solution of the PIDE: in the Merton model the solution can be expressed as a series expansion, and in the variance Gamma model a closed form expression for the characteristic function is available, so one can use Carr and Madan's FFT method [9]. Comparing our finite difference solution to these alternative solutions (computed with high precision) allows us to study the behavior of various error terms in relation with the parameters of the scheme.

The error metric which is relevant from the point of view of financial applications is the error in terms of Black–Scholes implied volatility:

$$\varepsilon(\tau, x) = |\Sigma^{\mathrm{PIDE}}(\tau, x) - \Sigma^{\mathrm{FFT}}(\tau, x)| \qquad \text{in} \quad \%,$$

where Σ denotes the Black–Scholes implied volatility computed by inverting the Black–Scholes formula with respect to the volatility parameter and applying it to the computed option price. We have computed both pointwise errors at $x = 0$ (i.e., forward at-the-money options) and uniform errors on the computational range $x \in [\log(2/3), \log(2)]$. This range contains all options prices quoted on the market.

The localization error is shown in Figure 7.2 for the Merton model: domain size A is represented in terms of its ratio to the standard deviation of X_T. An

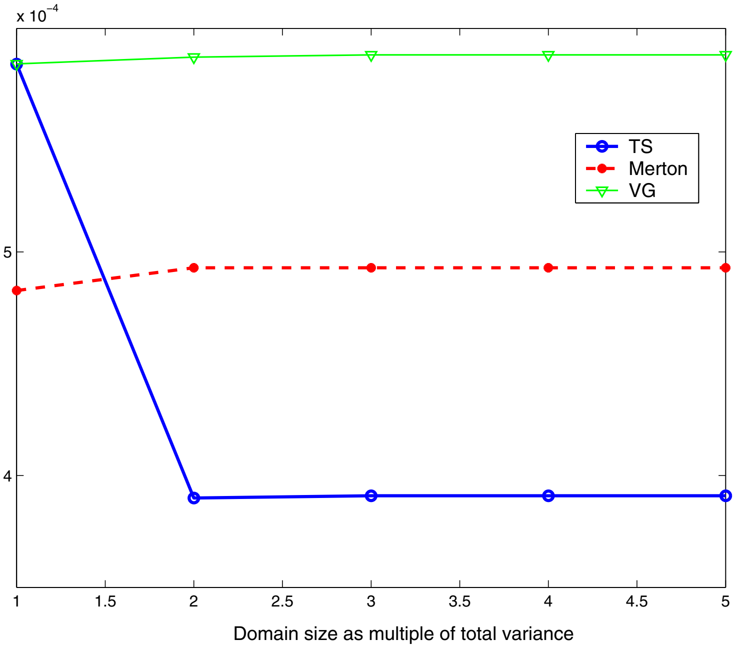

FIG. 7.3. *Influence of domain size on localization error for the explicit-implicit finite difference scheme: put option in tempered stable, Merton, and variance Gamma models.*

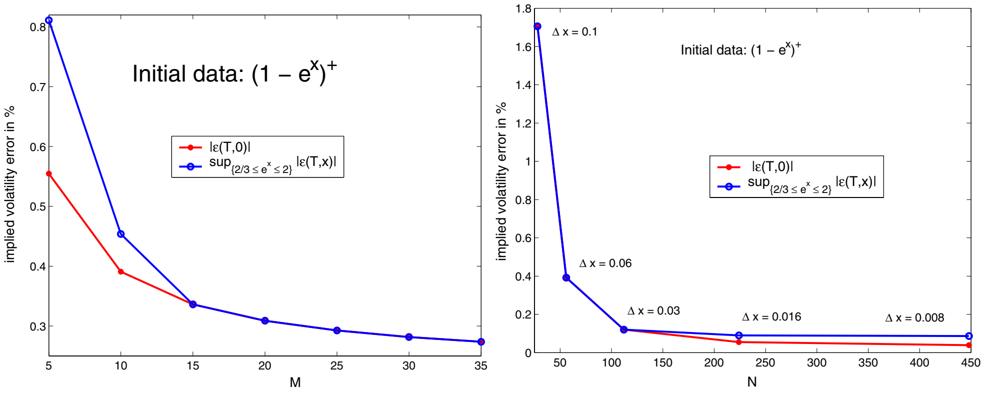

FIG. 7.4. *Numerical accuracy for a put option in the Merton model. Left: influence of number of time steps M, $\Delta x = 0.05$, $\Delta t = T/M$. Right: influence of number of space steps N, $\Delta x = 2A/N$, $\Delta t = 0.02$.*

acceptable level is obtained for values of order $\simeq 5$. Notice that as soon as this ratio is greater than or equal to 3, the uniform and pointwise errors are quite close to each other, indicating that we are out of the zone of influence of the numerical boundary conditions. Figure 7.3 shows the same analysis for the variance Gamma model.

Figure 7.4 illustrates the decay of numerical error when $\Delta t, \Delta x \to 0$, i.e., when the number of time/space steps is increased. The behavior is quite similar to the case of the Black–Scholes model.

Figure 7.5 illustrates the behavior of the error (for a fixed grid size) as a function of maturity for two initial conditions: a smooth one (forward contract) and a

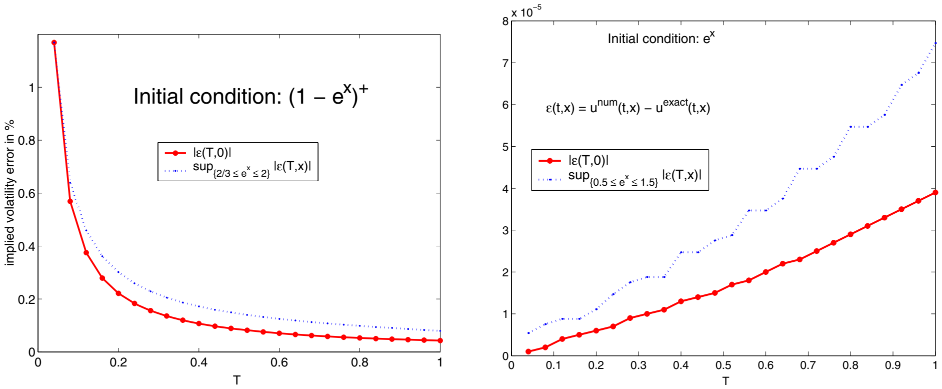

FIG. 7.5. *Decrease of error with maturity in the Merton model. Left: nonsmooth initial condition (put option) $h(x) = (1 - e^x)^+$. Right: smooth initial condition $h(x) = e^x$.*

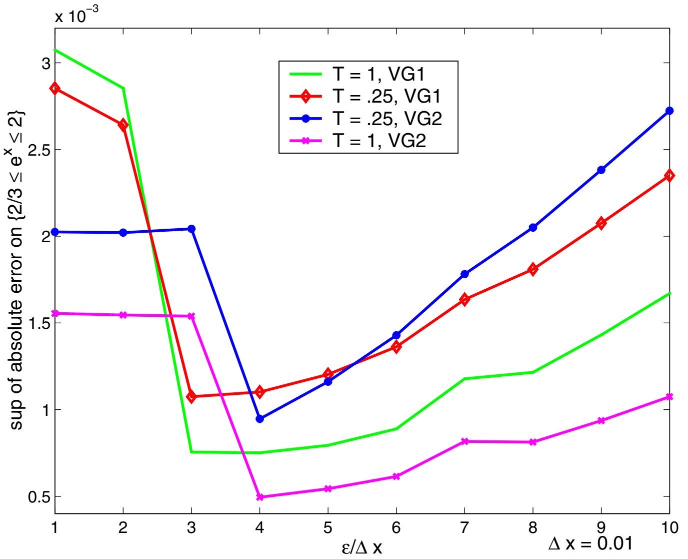

FIG. 7.6. *Influence of truncation of small jumps on numerical error in various variance Gamma models. Put option.*

nonsmooth one (put option). We observe that a nonsmooth initial condition leads to a lack of accuracy for small T. This phenomenon, which is not specific to models with jumps, can be overcome using an irregular time-stepping scheme which exploits the smoothness in time of the solution. Matache, von Petersdorff, and Schwab [25] have suggested using irregularly (logarithmically) spaced time stepping, more refined near maturity, in order to improve this convergence. Note that scheme introduces a "numerical viscosity" $\sigma(\varepsilon)$, so even when the underlying model is a pure-jump Lévy process this numerical diffusion term has a regularizing effect.

In the case of infinite activity models, an additional parameter which influences the solution is the truncation parameter ε for the small jumps. Whereas the error in Proposition 5.1 vanishes when $\varepsilon \to 0$, for a fixed Δx the discretization error *increases* as $\varepsilon \to 0$: the constant in (6.31) is of order $\lambda(\varepsilon)$, which increases with ε. This suggests that there is an optimal choice $\varepsilon(\Delta x) > 0$ for a given Δx. The optimal choice of ε is not universal and depends on the growth of the Lévy density near zero. Figure 7.6

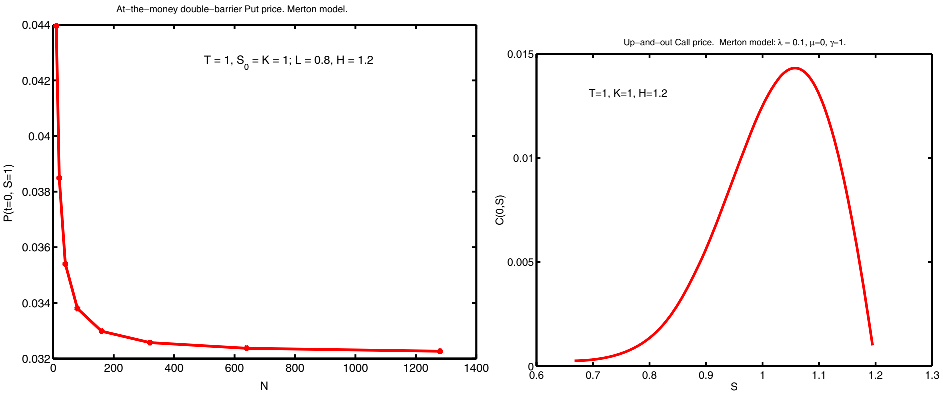

Fig. 7.7. *Left: at-the-money double-barrier put price as a function of the number of space steps. Barrier levels: $L = 0.8$, $H = 1.2$. Right: up-and-out call price in the Merton model. Barrier level: $H = 1.2$.*

Table 7.1

Examples of numerical values for at-the-money option prices. $S = K = 100$, $T = 1$, $A = 5\sqrt{\sigma^2 + \int y^2\nu(dy)}$, $dt = 0.02$, $dx = 0.01$. *The truncation parameter ε is chosen according to Figure* 7.6.

Model	Put	t	Up-and-out call	t	Double-barrier put	t
		sec.	$H = 120$	sec.	$L = 80$, $H = 120$	sec.
VG1	6.72	0.5	2.73	0.2	2.42	0.1
VG2	8.38	0.9	3.34	0.5	1.68	0.1
Merton	11.04	1.2	1.17	0.5	3.35	4

illustrates this phenomenon for the variance Gamma model.

The last two figures give examples of boundary value problems for barrier options in the Merton model. Figure 7.7 (right) shows the price of an up-and-out call. Figure 7.7 (left) illustrates the numerical convergence of a double-barrier put price as the number N of space steps increases.

In Table 7.1, we give some examples of option values obtained with our numerical scheme as well as the corresponding computation time in seconds.

Appendix A. Proofs of lemmas.

A.1. Proof of Lemma 3. To prove (i), we rewrite (6.24)–(6.25) as $v(\tau, x) = \Psi_\Delta v(\tau, x)$, where Ψ_Δ is a contraction, and apply the fixed point theorem. Define

$$p_\Delta = \frac{1}{\Delta t} + \frac{\sigma^2}{\Delta x^2} + \left|\frac{\sigma^2}{2} - r + \hat{\alpha}\right| + \hat{\lambda} + 1 \geq 1$$

such that $\Phi_\Delta v(\tau_n, x_i) = -\frac{v(\tau_n, x_i) - v(\tau_{n-1}, x_i)}{\Delta t} + L_\Delta v(\tau_n, x_i) + p_\Delta v(\tau_n, x_i)$ is monotone: if $v \geq 0$, then $\Phi_\Delta v \geq 0$. Φ_Δ verifies

$$\text{(A.1)} \qquad \Phi_\Delta e^{-2\tau} = e^{-2\tau}\left[p_\Delta - (1 - e^{-2\Delta t})\left(\frac{1}{\Delta t} + \hat{\lambda}\right)\right] \leq e^{-2\tau}(p_\Delta - 1)$$

for small Δt (for example, this property holds as soon as $\Delta t \le 0.7$). We now define $\tilde{v}(\tau,x) = e^{2\tau} v(\tau,x)$, $\tilde{\xi}(\tau,x) = (\Delta t)^{-1} p_\Delta^{-1} e^{2\tau}\xi(\tau,x)$ and rewrite (6.24)–(6.25) as

$$\tilde{v}(0,x_i) = h(x_i), \quad i \in \mathbb{N},$$

$$\text{(A.2)}\quad \tilde{v}(\tau_n,x_i) = p_\Delta^{-1} e^{2\tau_n}\Phi_\Delta[e^{-2\tau_n}\tilde{v}(\tau_n,x_i)] + \tilde{\xi}(\tau_n,x_i), \quad n=1,\dots,M,\ i \in \mathbb{N},$$

or, equivalently, $\tilde{v}(\tau_n,x_i) = \Psi_\Delta \tilde{v}(\tau_n,x_i)$, $\quad n = 0,\dots,M,\ \ i \in \mathbb{N}$, with

$$\Psi_\Delta \tilde{v}(\tau_n,x_i) = 1_{n\in\{1,\dots,M\}}(p_\Delta^{-1} e^{2\tau_n}\Phi_\Delta[e^{-2\tau_n}\tilde{v}(\tau_n,x_i)] + \tilde{\xi}(\tau_n,x_i)) + 1_{n=0}h(x_i).$$

Ψ_Δ defines an operator on $\mathcal{B}_{\{0,\dots,M\}\times\mathbb{N}}$. Moreover, Ψ_Δ is a contraction,

$$\begin{aligned}|\Psi_\Delta\tilde{v}_1(\tau_n,x_i) - \Psi_\Delta\tilde{v}_2(\tau_n,x_i)| &= 1_{n\in\{1,\dots,M\}} p_\Delta^{-1} e^{2\tau_n}|\Phi_\Delta[e^{-2\tau_n}(\tilde{v}_1-\tilde{v}_2)](\tau_n,x_i)|\\ &\le 1_{n\in\{1,\dots,M\}} p_\Delta^{-1} e^{2\tau_n}\|\tilde{v}_1-\tilde{v}_2\|_{\{0,\dots,M\}}\Phi_\Delta[e^{-2\tau_n}],\end{aligned}$$

since $v_1 - v_2 \le \|\tilde{v}_1-\tilde{v}_2\|_{\{0,\dots,M\}}$ and Φ_Δ is monotone. Using (A.1), we obtain

$$\|\Psi_\Delta\tilde{v}_1 - \Psi_\Delta\tilde{v}_2\|_{\{0,\dots,M\}} \le (1-p_\Delta^{-1})\|\tilde{v}_1-\tilde{v}_2\|_{\{0,\dots,M\}},$$

so Ψ_Δ is a contraction and the fixed point theorem entails (i).

To prove (ii), first assume that for all k, i, $\xi_1(\tau_k,x_i) \ge \xi_2(\tau_k,x_i)$ and show that in this case, $v_1 \ge v_2$. Let $v = v_1 - v_2$. We have $v(0,x_i) = 0$. Suppose that $v(\tau_{n-1},x_i) \ge 0$. Given $\varepsilon > 0$, let us take $i(\varepsilon)$ such that $v(\tau_n,x_{i(\varepsilon)}) \le \inf_i v(\tau_n,x_i) + \varepsilon \le v(\tau_n,x_i)+\varepsilon$, for all i. Then, for all $i \in \mathbb{N}$, we have

$$\begin{aligned}&\inf_i v(\tau_n,x_i) \ge v(\tau_n,x_{i(\varepsilon)}) - \varepsilon\\ &= -c\Delta t v(\tau_n,x_{i(\varepsilon)}) + (1+a\Delta t)v(\tau_n,x_{i(\varepsilon)}) - b\Delta t v(\tau_n,x_{i(\varepsilon)}) - \hat{\lambda}\Delta t v(\tau_n,x_{i(\varepsilon)}) - \varepsilon\\ &\ge -c\Delta t(v(\tau_n,x_{i(\varepsilon)-1})+\varepsilon) + (1+a\Delta t)v(\tau_n,x_{i(\varepsilon)}) - b\Delta t(v(\tau_n,x_{i(\varepsilon)+1})+\varepsilon)\\ &\qquad -\hat{\lambda}\Delta t(\inf_i v(\tau_n,x_i)+\varepsilon) - \varepsilon\\ &= v(\tau_{n-1},x_{i(\varepsilon)}) + \Delta t\sum_j \nu_j v(\tau_{n-1},x_{i(\varepsilon)+j}) + (\xi_1-\xi_2)(\tau_n,x_{i(\varepsilon)}) - \hat{\lambda}\Delta t\inf_i v(\tau_n,x_i)\\ &\qquad -(1+a\Delta t)\varepsilon \ge -\hat{\lambda}\Delta t\inf_i v(\tau_n,x_i) - (1+a\Delta t)\varepsilon.\end{aligned}$$

Therefore $\inf_i v(\tau_n,x_i) \ge -\frac{1+a\Delta t}{1+\hat{\lambda}\Delta t}\varepsilon$.

Taking the limit $\varepsilon \to 0$, we obtain $\inf_i v(\tau_n,x_i) \ge 0$, so $v = v_1 - v_2 \ge 0$.

Consider now the general case. Let $v(\tau_n,x_i) = v_1(\tau_n,x_i) + \sum_{k=1}^n \|\xi_1(\tau_k,\cdot) - \xi_2(\tau_k,\cdot)\|$. Then v solves (6.24)–(6.25) with $\xi(\tau_n,x_i) = v(\tau_n,x_i) - v(\tau_{n-1},x_i) - L_\Delta v(\tau_n,x_i)\Delta t$. We have

$$\begin{aligned}\xi(\tau_n,x_i) &= \xi_1(\tau_n,x_i) + \|\xi_1(\tau_n,\cdot)-\xi_2(\tau_n,\cdot)\| - L_\Delta\left[\sum_{k=1}^n \|\xi_1(\tau_k,\cdot)-\xi_2(\tau_k,\cdot)\|\right]\Delta t\\ &= \xi_1(\tau_n,x_i) + (1+\hat{\lambda}\Delta t)\|\xi_1(\tau_n,\cdot)-\xi_2(\tau_n,\cdot)\| \ge \xi_2(\tau_n,x_i).\end{aligned}$$

But as shown above this implies $v(\tau_n,x_i) \ge v_2(\tau_n,x_i)$, so

$$v_2(\tau_n,x_i) - v_1(\tau_n,x_i) \le \sum_{k=1}^n \|\xi_1(\tau_k,\cdot)-\xi_2(\tau_k,\cdot)\|.$$

Interchanging v_1 with v_2, we obtain (6.26).

A.2. Proof of Lemma 4. By definition,

$$u(\tau,x) = h(x) * \tilde{p}_\tau(x) = h(x) * \tilde{p}_\tau^W(x) * \tilde{p}_\tau^{(X-W)}(x), \tag{A.3}$$

where $p_\tau(x) = \tilde{p}_\tau(-x)$ is the density of X_τ, and $\tilde{p}_\tau^W(-x)$, $\tilde{p}_\tau^{(X-W)}(-x)$ are densities of the processes σW_τ and $(X_\tau - \sigma W_\tau)$, respectively. Therefore,

$$\left\| \frac{\partial^{m+n} u}{\partial \tau^m \partial x^n}(\tau,\cdot) \right\| \le \left\| \frac{\partial^{m+n}(h * \tilde{p}_\tau^W)}{\partial \tau^m \partial x^n} \right\|. \tag{A.4}$$

The derivatives of h may have jumps at $\xi_1,\dots,\xi_I$; denote these jumps by $a_i^{(n)} = h^{(n)}(\xi_i+) - h^{(n)}(\xi_i-)$. Then, for all $n \ge 1$, $i = 1,\dots,I$, $|a_i^{(n)}| \le 2K$. Using standard properties of convolution products we obtain

$$\begin{aligned}\frac{\partial^n (h * \tilde{p}_\tau^W)}{\partial x^n}(x) = (h^{(n)} * \tilde{p}_\tau^W)(x) + \sum_{i=1}^{I} \Bigg[a_i^{(n-1)} \tilde{p}_\tau^W(x-\xi_i) + a_i^{(n-2)} \frac{\partial \tilde{p}_\tau^W}{\partial x}(x-\xi_i) + {} \\ \cdots + a_i^{(1)} \frac{\partial^{n-2} \tilde{p}_\tau^W}{\partial x^{n-2}}(x-\xi_i) \Bigg],\end{aligned} \tag{A.5}$$

where $h^{(n)}$ is the nth pointwise derivative of h. For all $n \ge 0$, we have

$$\frac{\partial^n \tilde{p}_\tau^W}{\partial x^n}(x) = \frac{1}{(\sqrt{\tau})^{n+1}} \frac{\partial^n \tilde{p}_1^W}{\partial x^n}\left(\frac{x}{\sqrt{\tau}} \right). \tag{A.6}$$

Consequently, for all $n \ge 1$,

$$\begin{aligned}\left\| \frac{\partial^n (h * \tilde{p}_\tau^W)}{\partial x^n} \right\| &\le \|h^{(n)}\| + 2KI \left(\|\tilde{p}_\tau^W\| + \left\| \frac{\partial \tilde{p}_\tau^W}{\partial x} \right\| + \cdots + \left\| \frac{\partial^{n-2} \tilde{p}_\tau^W}{\partial x^{n-2}} \right\| \right) \\ &\le K + 2KI \left(\frac{1}{\sqrt{\tau}} \|\tilde{p}_1^W\| + \frac{1}{(\sqrt{\tau})^2} \left\| \frac{\partial \tilde{p}_1^W}{\partial x} \right\| + \cdots + \frac{1}{(\sqrt{\tau})^{n-1}} \left\| \frac{\partial^{n-2} \tilde{p}_1^W}{\partial x^{n-2}} \right\| \right) \\ &\le \frac{K}{(\sqrt{\tau})^{n-1}} \left[T^{\frac{n-1}{2}} + 2I \left(T^{\frac{n-2}{2}} \|\tilde{p}_1^W\| + T^{\frac{n-1}{2}} \left\| \frac{\partial \tilde{p}_1^W}{\partial x} \right\| + \cdots + \left\| \frac{\partial^{n-2} \tilde{p}_1^W}{\partial x^{n-2}} \right\| \right) \right] \\ &= \frac{C}{(\sqrt{\tau})^{n-1}},\end{aligned}$$

so (6.29) is verified for $m = 0$ and $n \ge 1$. Proceed by induction on m: assume (6.29) for $m-1$ and $n \ge 1$. For any $f \in C^\infty(\mathbb{R})$, we have

$$\begin{aligned}|Lf(x)| &= \left| \frac{\sigma^2}{2} \frac{\partial^2 f}{\partial x^2}(x) - \left(\frac{\sigma^2}{2} - r + \alpha \right) \frac{\partial f}{\partial x}(x) - \lambda f(x) + \int_{B_l}^{B_r} \nu(dy) f(x+y) \right| \\ &\le \frac{\sigma^2}{2} \left| \frac{\partial^2 f}{\partial x^2}(x) \right| + |\sigma^2/2 - r + \alpha| \left| \frac{\partial f}{\partial x}(x) \right| + 2\lambda \|f\|.\end{aligned}$$

Applying this result to $f = \partial^{m+n-1} u^{(\mu)} / \partial \tau^{m-1} \partial x^n$ and using $\partial_\tau u = Lu$, we obtain

$$\begin{aligned}&\left| \frac{\partial^{m+n} u}{\partial \tau^m \partial x^n}(\tau,x) \right| = \left| \frac{\partial}{\partial \tau} \left(\frac{\partial^{m-1+n} u}{\partial \tau^{m-1} \partial x^n} \right)(\tau,x) \right| = \left| L \left(\frac{\partial^{m-1+n} u}{\partial \tau^{m-1} \partial x^n} \right)(\tau,x) \right| \\ &\le \frac{\sigma^2}{2} \left\| \frac{\partial^{m-1+n+2} u}{\partial \tau^{m-1} \partial x^{n+2}}(\tau,\cdot) \right\| + \left| \frac{\sigma^2}{2} - r + \alpha \right| \left\| \frac{\partial^{m-1+n+1} u}{\partial \tau^{m-1} \partial x^{n+1}}(\tau,\cdot) \right\| + 2\lambda \left\| \frac{\partial^{m-1+n} u}{\partial \tau^{m-1} \partial x^n}(\tau,\cdot) \right\| \\ &\le \frac{C(K,T,m,n,r,\sigma,\lambda,\alpha)}{(\sqrt{\tau})^{2(m-1)+(n+2)-1}} = \frac{C}{(\sqrt{\tau})^{2m+n-1}}.\end{aligned}$$

We have thus shown (6.29) for $m \geq 0$, $n \geq 1$. For $m \geq 1$, $n = 0$, we proceed similarly, by induction on m starting from

$$\left\|\frac{\partial u}{\partial \tau}(\tau,\cdot)\right\| = \|Lu(\tau,\cdot)\| \leq \frac{\sigma^2}{2}\left\|\frac{\partial^2 u}{\partial x^2}(\tau,\cdot)\right\| + \left|\frac{\sigma^2}{2} - r + \alpha\right| \left\|\frac{\partial u}{\partial x}(\tau,\cdot)\right\| + 2\lambda \|u(\tau,\cdot)\| \leq \frac{C}{\sqrt{\tau}},$$

since $\|u(\tau,\cdot)\| = \|h * \tilde{p}_\tau^W\| \leq \|h\| \leq K$.

A.3. Proof of Lemma 5. We have

$$|Lu(\tau_k,x_i) - L_\Delta u(\tau_k,x_i)| \leq |Du(\tau_k,x_i) - D_\Delta u(\tau_k,x_i)| + |Ju(\tau_k,x_i) - J_\Delta u(\tau_{k-1},x_i)|,$$

where D and J are the differential and integral parts of L defined by (5.4), and D_Δ, J_Δ are their approximations given by (5.8)–(5.9). Recall that $|\alpha - \hat{\alpha}| \leq (\alpha+\lambda)\Delta x$ by (6.8). From Taylor's formula, there exist $\xi_1, \eta_1, \xi_2 \in [x_{i-1}, x_{i+1}]$ such that

$$\begin{aligned}
|Du(\tau_k,x_i) - D_\Delta u(\tau_k,x_i)| &= \left| \frac{\sigma^2}{2}\frac{\Delta x^2}{24}\left[\frac{\partial^4 u}{\partial x^4}(\tau_k,\xi_1) + \frac{\partial^4 u}{\partial x^4}(\tau_k,\eta_1)\right]\right. \\
&\quad \left. + \left(\frac{\sigma^2}{2} - r + \hat{\alpha}\right)\frac{\Delta x}{2}\frac{\partial^2 u}{\partial x^2}(\tau_k,\xi_2) + (\alpha - \hat{\alpha})\frac{\partial u}{\partial x}(\tau_k,x_i)\right| \\
\leq \frac{\Delta x^2}{12}\frac{\sigma^2}{2}\left\|\frac{\partial^4 u}{\partial x^4}(\tau_k,\cdot)\right\| &+ \frac{\Delta x}{2}|\sigma^2/2 - r + \alpha| \left\|\frac{\partial^2 u}{\partial x^2}(\tau_k,\cdot)\right\| + \Delta x(\alpha+\lambda)\left\|\frac{\partial u}{\partial x}(\tau_k,\cdot)\right\| \\
&\leq C[\Delta x^2/\tau_k^{3/2} + \Delta x/\tau_k^{1/2} + \Delta x]
\end{aligned}$$

by Lemma 4. The integral part can be estimated as follows:

$$\begin{aligned}
|Ju(\tau_k,x_i) - J_\Delta u(\tau_{k-1},x_i)| &= \left|\sum_{j=K_l}^{K_r} u(\tau_{k-1},x_{i+j})\nu_j - \int_{B_l}^{B_r} u(\tau_k,x_i+y)\nu(dy)\right| \\
&= \left|\sum_{j=K_l}^{K_r}\int_{y_{j-1/2}}^{y_{j+1/2}} [u(\tau_{k-1},x_i+y_j) - u(\tau_k,x_i+y)]\nu(dy)\right| \\
&\leq \left|\sum_{j=K_l}^{K_r}[u(\tau_{k-1},x_i+y_j) - u(\tau_k,x_i+y_j)]\nu_j\right| + \left|\sum_{j=K_l}^{K_r}\int_{y_{j-1/2}}^{y_{j+1/2}}[u(\tau_k,x_i+y_j) \right. \\
&\qquad \left. - u(\tau_k,x_i+y)]\nu(dy)\right| \\
&\leq \left|\sum_{j=K_l}^{K_r}\nu_j\int_{\tau_{k-1}}^{\tau_k}\frac{\partial u}{\partial \tau}(s,x_i+y_j)ds\right| + \left|\sum_{j=K_l}^{K_r}\int_{y_{j-1/2}}^{y_{j+1/2}}\nu(dy)\int_{x_i+y_j}^{x_i+y}\frac{\partial u}{\partial x}(\tau_k,\xi)d\xi\right| \\
&\leq \lambda\int_{\tau_{k-1}}^{\tau_k}\left\|\frac{\partial u}{\partial \tau}(s,\cdot)\right\|ds + \frac{\lambda\Delta x}{2}\left\|\frac{\partial u}{\partial x}(\tau_k,\cdot)\right\| \leq C\left[\int_{\tau_{k-1}}^{\tau_k}\frac{ds}{\sqrt{s}} + \Delta x\right] \\
&= C\left[2(\sqrt{\tau_k} - \sqrt{\tau_{k-1}}) + \Delta x\right].
\end{aligned}$$

Assembling the various terms we obtain (6.30).

INCOMPRESSIBLE FINITE ELEMENTS VIA HYBRIDIZATION. PART I: THE STOKES SYSTEM IN TWO SPACE DIMENSIONS*

BERNARDO COCKBURN† AND JAYADEEP GOPALAKRISHNAN‡

Abstract. In this paper, we introduce a new and efficient way to compute exactly divergence-free velocity approximations for the Stokes equations in two space dimensions. We begin by considering a mixed method that provides an exactly divergence-free approximation of the velocity and a continuous approximation of the vorticity. We then rewrite this method solely in terms of the tangential fluid velocity and the pressure on mesh edges by means of a new hybridization technique. This novel formulation bypasses the difficult task of constructing an exactly divergence-free basis for velocity approximations. Moreover, the discrete system resulting from our method has fewer degrees of freedom than the original mixed method since the pressure and the tangential velocity variables are defined just on the mesh edges. Once these variables are computed, the velocity approximation satisfying the incompressibility condition exactly, as well as the continuous numerical approximation of the vorticity, can at once be obtained locally. Moreover, a discontinuous numerical approximation of the pressure within elements can also be obtained locally. We show how to compute the matrix system for our tangential velocity-pressure formulation on general meshes and present in full detail such computations for the lowest-order case of our method.

1. Introduction.

In this paper, we introduce a new and efficient way to compute exactly divergence-free velocity approximations for the Stokes equations in two space dimensions. We proceed as follows. First, we consider the mixed method for the Stokes equations studied in [12, 13, 20]. This method provides a continuous approximation for the vorticity and an exactly divergence-free approximation of the velocity. Then we introduce a new hybridization technique that allows us to reduce the original method to a *mixed method for the Lagrange multipliers* arising from the hybridization, namely, the tangential fluid velocity and the pressure along mesh edges. This novel implementation of the method requires neither the introduction of stream function variables (as in [12, 13, 20]) nor the construction of a globally divergence-free finite element basis. We thus avoid the difficulties in construction of a globally divergence-free basis as well as the increase in degrees of freedom that accompanies the introduction of the stream function. Our new *tangential velocity-pressure* formulation has fewer degrees of freedom as both the unknowns are defined only on mesh edges. Moreover, after solving for these unknowns, the original exactly divergence-free numerical approximation of the fluid velocity and the original continuous numerical approximation of the vorticity can be easily computed in an element-by-element fashion. An

approximation to the pressure inside the elements can also be computed in this way, a feature made possible by the hybridization procedure.

Let us describe the hybridization technique we propose. Recall that the Stokes equations couple the fluid velocity $\boldsymbol{u}$ and the pressure p by the equations

$$-\boldsymbol{\Delta u} + \mathbf{grad}\, p = \boldsymbol{f} \qquad \text{on } \Omega, \tag{1.1}$$

$$\operatorname{div} \boldsymbol{u} = 0 \qquad \text{on } \Omega, \tag{1.2}$$

$$\boldsymbol{u} = \boldsymbol{g} \qquad \text{on } \partial\Omega. \tag{1.3}$$

Here, $\boldsymbol{f} \in L^2(\Omega)^2$ and $\boldsymbol{g} \in H^{1/2}(\partial\Omega)^2$ are given data. For simplicity, we assume that $\Omega \subseteq \mathbb{R}^2$ is a (bounded connected) polygon. To define the mixed method, we introduce the vorticity

$$\omega = \operatorname{curl} \boldsymbol{u} := \frac{\partial}{\partial x} u_y - \frac{\partial}{\partial y} u_x,$$

where $\boldsymbol{u} = (u_x, u_y)$, and rewrite the Stokes system as

$$\omega - \operatorname{curl} \boldsymbol{u} = 0 \qquad \text{on } \Omega, \tag{1.4}$$

$$\mathbf{curl}\, \omega + \mathbf{grad}\, p = \boldsymbol{f} \qquad \text{on } \Omega, \tag{1.5}$$

$$\operatorname{div} \boldsymbol{u} = 0 \qquad \text{on } \Omega, \tag{1.6}$$

$$\boldsymbol{u} \cdot \boldsymbol{t} = g_t \qquad \text{on } \partial\Omega, \tag{1.7}$$

$$\boldsymbol{u} \cdot \boldsymbol{n} = g_n \qquad \text{on } \partial\Omega. \tag{1.8}$$

Here, $g_t = \boldsymbol{g} \cdot \boldsymbol{t}$ and $g_n = \boldsymbol{g} \cdot \boldsymbol{n}$, where $\boldsymbol{n}$ denotes the outward unit normal on $\partial\Omega$ and $\boldsymbol{t}$ the unit tangent vector on $\partial\Omega$ oriented such that Ω is on the left as we move in the direction of $\boldsymbol{t}$ along $\partial\Omega$. Note that to obtain (1.5), we made use of the identity

$$-\boldsymbol{\Delta u} = \mathbf{curl}\, \operatorname{curl} \boldsymbol{u} - \mathbf{grad}\, \operatorname{div} \boldsymbol{u},$$

where

$$\mathbf{curl}\, \omega = \left(\frac{\partial \omega}{\partial y}, -\frac{\partial \omega}{\partial x} \right).$$

To give a weak formulation of the above problem, define the spaces

$$\begin{aligned} \mathcal{W} \quad &= H^1(\Omega), \\ \mathcal{V} \quad &= \{\boldsymbol{v} \in H(\operatorname{div}, \Omega) : \operatorname{div} \boldsymbol{v} = 0\}, \\ \mathcal{V}(b) &= \{\boldsymbol{v} \in \mathcal{V} : \boldsymbol{v} \cdot \boldsymbol{n}|_{\partial\Omega} = b\} \end{aligned}$$

for any $b \in H^{-1/2}(\partial\Omega)$. The weak formulation seeks the pair of functions satisfying

$$(\omega, \tau)_\Omega - (\boldsymbol{u}, \mathbf{curl}\, \tau)_\Omega = (g_t, \tau)_{\partial\Omega} \qquad \text{for all } \tau \in \mathcal{W}, \tag{1.9}$$

$$(\boldsymbol{v}, \mathbf{curl}\, \omega)_\Omega = (\boldsymbol{f}, \boldsymbol{v})_\Omega \qquad \text{for all } \boldsymbol{v} \in \mathcal{V}(0). \tag{1.10}$$

Here, $(\cdot, \cdot)_\Omega$ denotes the $L^2(\Omega)$ (or $L^2(\Omega)^2$) inner product. Note that since the velocity test functions are taken in the space $\mathcal{V}(0)$, the pressure is no longer present in this variational formulation. By classical existence results for the Stokes system, it is easy to show that there is a unique solution for the above system of equations, provided that the compatibility condition

$$(g_n, 1)_{\partial\Omega} = 0 \tag{1.11}$$

is satisfied. We assume throughout that (1.11) holds.

Now the approximate solution is sought in the finite element subspaces of the above defined spaces:

$$\begin{aligned} \mathcal{W}_h &= \{w \in \mathcal{W} : w|_K \in P_{k+1}(K) \text{ for all } K \in \mathcal{T}\}, \\ \mathcal{V}_h &= \{\boldsymbol{v} \in \mathcal{V} : \boldsymbol{v}|_K \in P_k(K)^2 \text{ for all } K \in \mathcal{T}\}. \end{aligned}$$

Here $\mathcal{T}$ denotes a finite element triangulation of Ω. Let $\mathcal{V}_h(b) = \mathcal{V}(b) \cap \mathcal{V}_h$ and $g_{n,h}$ be the $L^2(\partial\Omega)$-orthogonal projection of the boundary data g_n onto the space

$$\{\boldsymbol{v}_h \cdot \boldsymbol{n}|_{\partial\Omega} : \boldsymbol{v}_h \in \mathcal{V}_h\}.$$

Then the discrete mixed formulation seeks $(\omega_h, \boldsymbol{u}_h)$ in $\mathcal{W}_h \times \mathcal{V}_h(g_{n,h})$ satisfying

$$(\omega_h, \tau)_\Omega - (\boldsymbol{u}_h, \mathbf{curl}\,\tau)_\Omega = (g_t, \tau)_{\partial\Omega} \qquad \text{for all } \tau \in \mathcal{W}_h, \tag{1.12}$$

$$(\boldsymbol{v}, \mathbf{curl}\,\omega_h)_\Omega = (\boldsymbol{f}, \boldsymbol{v})_\Omega \qquad \text{for all } \boldsymbol{v} \in \mathcal{V}_h(0). \tag{1.13}$$

We assume that the latter space is nonempty. A three-dimensional version of the above mixed discretization was studied in [12, 13, 20, 22], where the existence of a unique solution was established. Note that this is a conforming method since

$$\mathcal{W}_h \times \mathcal{V}_h(0) \subset \mathcal{W} \times \mathcal{V}(0) \subset H^1(\Omega) \times \mathcal{V}.$$

This implies, in particular, that in order to implement the method in the above form, we must face the difficult task of constructing bases for the finite-dimensional space of globally divergence-free velocities $\mathcal{V}_h(0)$.

The construction of an exactly divergence-free finite element basis has been a long-standing research question [14]. Piecewise divergence-free approximations have been investigated in [2, 17, 18], but their normal components are not continuous in general. Basis functions for finite-dimensional spaces of *weakly* divergence-free functions were constructed in [15, 16, 24]. However, this construction proved to be extremely difficult to extend to spaces of polynomials of higher degree. Exactly divergence-free finite element spaces have been studied, but known results require the use of polynomials of degree four or higher for the two-dimensional case [19, 23], and no similar result exists for the three-dimensional case. The difficulty of constructing exactly incompressible finite element spaces was overcome in [12] by setting the divergence-free spaces as the curl of an appropriate space of stream functions. Unfortunately, the introduction of the stream function increases degrees of freedom. In contrast, our approach to overcoming this difficulty via hybridization actually results in a reduction in degrees of freedom.

Recently, globally divergence-free approximations were devised by using discontinuous Galerkin methods with polynomials of degree one or higher in the framework of the Navier–Stokes equations [10]. To achieve this, the fact that the divergence-free condition is enforced element-by-element is exploited to construct an element-by-element postprocessing of the discontinuous approximation that automatically results in an exactly divergence-free velocity. A similar technique in the framework of discontinuous Galerkin methods for Darcy flow was developed in [3]. Unfortunately, such approaches cannot be used for conforming mixed methods since they rely on the fact that the discontinuous Galerkin methods enforce the equations element-by-element.

The main idea of our procedure is to look for approximations in discrete spaces that have *no* continuity constraints across mesh interfaces and introduce new sets of equations that guarantee that the new approximation *coincides* with the original approximation $(\omega_h, \boldsymbol{u}_h)$ given by (1.12)–(1.13). This approach is inspired by hybridization techniques used in the context of mixed methods for second-order elliptic problems [1, 5, 8, 11]. We proceed in two steps. The objective of the first step is to circumvent construction of divergence-free finite element bases. Hence, in this step, we relax the continuity of the normal components of the approximate velocity across interelement boundaries and use a velocity space of functions with no interelement continuity. As a direct consequence, the pressure reappears in the equations, but only on the edges if the approximate velocities are divergence-free inside each element. Then, new equations are introduced to enforce the continuity of the normal component of the velocity across interelement boundaries. A similar hybridization technique, but in the framework of discontinuous Galerkin methods for the Stokes problem, is explored in [7].

The objective of the second step is the eventual elimination of both the original unknowns (velocity and vorticity) from the equations. To do this, we must develop a new hybridization technique for the vorticity. Such a hybridization is far more involved than the previous one since the vorticity is continuous across interelement boundaries. Indeed, all the previously known hybridization procedures relaxed continuity of spaces with edge (or face in three dimensions) degrees of freedom. Examples include hybridization techniques for the Raviart–Thomas and Brezzi–Douglas–Marini (BDM) methods for scalar second-order elliptic problems which involve finite element subspaces of $H(\mathrm{div}, \Omega)$. Hybridization of the Morley element method for the biharmonic problem [1] also involved such spaces with edge degrees of freedom. However, hybridization techniques to relax continuity constraints of finite element subspaces of $H^1(\Omega)$ with vertex degrees of freedom have remained unknown until now. While this may have led to a widespread belief that methods using spaces of this type are not amenable to hybridization, in this paper we show otherwise. We show how one can approximate vorticity in a space of functions which have no continuity conditions across element interfaces while imposing the natural continuity properties of the vorticity as an equation of the method.

After the above mentioned hybridizations, we proceed to adapt the methodology introduced in [8] to eliminate the vorticity and velocity from the hybridized method. This elimination is far from obvious but is greatly facilitated by the fact that both the vorticity and the velocity are in spaces of functions with no interelement continuity and by the fact that both the pressure and the tangential velocity are defined only on the mesh edges. This allows us to express the vorticity and velocity in terms of the pressure and tangential velocity. Then, we show how to characterize these Lagrange multipliers as the only solution of a new mixed method. We view this method as a “tangential velocity-pressure discretization” for the Stokes equation wherein the unknowns are all on the mesh edges.

Notice that since the unknowns are defined only on the edges, this system is smaller than the original one. Moreover, once the Lagrange multipliers are obtained, vorticity and velocity approximations can be obtained by *local* element-by-element computations. An interesting feature of our mixed method for the Lagrange multipliers is that it is possible to further eliminate the pressure Lagrange multiplier and form one Schur complement equation for the tangential velocity Lagrange multiplier. This equation can be easily solved using well-established iterative techniques for symmetric positive definite systems.

We should note that ours is not the first paper to give hybridized methods for the Stokes problem. A hybrid formulation involving deviatoric stresses, hydrostatic pressure, and velocity was given in [6, 25]. Note also that some domain decomposition methods result from hybridization performed at the subdomain level. For example, in [4], the method gives rise to an indefinite system for the velocity nodes on the subdomain boundaries and the mean values of the pressure on the subdomains. However, none of the above mentioned methods provide incompressible velocities.

The paper is organized as follows. In section 2, we give a detailed description of the hybridization of the original conforming mixed method. The resulting method is written as a method for the two original variables *and* two additional Lagrange multipliers. Then, in section 3, we show how to eliminate the former two variables from the equations and characterize the Lagrange multipliers alone as the unique solution of a mixed method. This characterization (Theorem 3.1) is an extension to the Stokes system of what was done for hybridized mixed methods for second-order elliptic problems in [8] and is one of our main results. In section 4, we construct the bases for the Lagrange multipliers, and in section 5, we discuss some key implementation aspects of the method. These include the construction of the Schur complement matrix for the tangential velocity and the detailed computation of the matrices of the method for the lowest-order case. Section 6 concludes the paper.

2. The hybridized mixed method.

In this section, we present the hybridization of the mixed method in full detail as described in the introduction. Let us emphasize once again that this is carried out in two steps. The objective of the first is to avoid having to construct finite-dimensional spaces of divergence-free velocities. The objective of the second is the eventual elimination of the original variables from the equations. Note that the actual elimination is not carried out until section 3.

2.1. First hybridization: Introduction of pressure on the mesh edges.

We begin by relaxing the continuity of the normal component of the approximate velocity $\boldsymbol{u}_h$ across interelement boundaries. Thus, instead of seeking velocity approximations in the space $\mathcal{V}_h$, we seek approximations in the space

$$V_h = \{\boldsymbol{v} : \boldsymbol{v}|_K \in P_k(K)^2 \text{ and } \operatorname{div}(\boldsymbol{v}|_K) = 0 \text{ for all } K \in \mathcal{T}\}.$$

This forces us to weakly impose (1.5) in a different way. Indeed, if we multiply (1.5) by a test function $\boldsymbol{v}_h \in V_h$ and integrate over the element K, we obtain

$$(\mathbf{curl}\,\omega, \boldsymbol{v}_h)_K + (\mathbf{grad}\,p, \boldsymbol{v}_h)_K = (\boldsymbol{f}, \boldsymbol{v}_h)_K,$$

and hence,

$$(\mathbf{curl}\,\omega, \boldsymbol{v}_h)_K + (p, \boldsymbol{v}_h \cdot \boldsymbol{n})_{\partial K} = (\boldsymbol{f}, \boldsymbol{v}_h)_K.$$

Replacing ω and p by their respective approximations, ω_h and p_h, and adding over the elements of the triangulation, we obtain one equation of the method:

$$(\boldsymbol{v}_h, \mathbf{curl}\,\omega_h)_\Omega + \sum_{e\in\mathcal{E}} (p_h, [\![\boldsymbol{v}_h \cdot \boldsymbol{n}]\!])_e = (\boldsymbol{f}, \boldsymbol{v}_h)_\Omega \quad \text{for all } \boldsymbol{v}_h \in V_h.$$

Here, we are using the following notation: For $\boldsymbol{v} \in V_h$ the jump of the normal component of $\boldsymbol{v}$ across interelement boundaries, denoted by $[\![\boldsymbol{v} \cdot \boldsymbol{n}]\!]$, is defined on the set

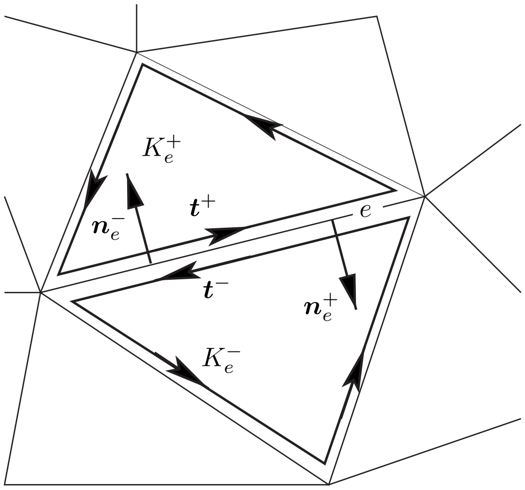

FIG. 1. *Notation for elements, normals, and tangents near an edge e.*

$\mathcal{E}$ of all edges of the triangulation $\mathcal{T}$ as follows. On every interior edge e in $\mathcal{E}$ shared by two mesh triangles K_e^+ and K_e^- we define

$$[\![\boldsymbol{v}\cdot\boldsymbol{n}]\!]_e = \boldsymbol{v}_e^+\cdot\boldsymbol{n}_e^+ + \boldsymbol{v}_e^-\cdot\boldsymbol{n}_e^-,$$

where $\boldsymbol{n}_e^+$ and $\boldsymbol{n}_e^-$ denote the outward unit normals on the boundaries of K_e^+ and K_e^-, respectively (see Figure 1) and $\boldsymbol{v}_e^\pm(\boldsymbol{x}) = \lim_{\epsilon\downarrow 0}\boldsymbol{v}(\boldsymbol{x}-\epsilon\,\boldsymbol{n}_e^\pm)$. On edges $e\subset\partial\Omega$, we set $[\![\boldsymbol{v}\cdot\boldsymbol{n}]\!]_e = \boldsymbol{v}|_{\partial\Omega}\cdot\boldsymbol{n}$. By $[\![\boldsymbol{v}\cdot\boldsymbol{n}]\!]$ (without any subscript) we mean the function that is defined on the union of all edges in $\mathcal{E}$ and equals $[\![\boldsymbol{v}\cdot\boldsymbol{n}]\!]_e$ on each edge $e\in\mathcal{E}$.

Now, in accordance with the hybridization paradigm, we impose the continuity of the normal component of the velocity $\boldsymbol{u}_h$ across interelement boundaries through the equation

$$\sum_{e\in\mathcal{E}}(q_h,\,[\![\boldsymbol{u}_h\cdot\boldsymbol{n}]\!])_e = (g_n,q_h)_{\partial\Omega}\quad\text{for all } q_h\in P_h,$$

where P_h is defined naturally by

$$P_h = \{p : p = [\![\boldsymbol{v}\cdot\boldsymbol{n}]\!] \text{ for some } \boldsymbol{v}\in V_h\}. \tag{2.1}$$

Notice that in the above equation, we are also incorporating the boundary condition on the normal component of the velocity.

Thus, after the first hybridization of the mixed method, we are seeking an approximation $(\omega_h,\boldsymbol{u}_h,p_h)\in\mathcal{W}_h\times V_h\times P_h$ satisfying

$$(\omega_h,\tau_h)_\Omega - (\boldsymbol{u}_h,\mathbf{curl}\,\tau_h)_\Omega = (g_t,\tau_h)_{\partial\Omega}\quad\text{for all } \tau_h\in\mathcal{W}_h, \tag{2.2}$$

$$(\boldsymbol{v}_h,\mathbf{curl}\,\omega_h)_\Omega + \sum_{e\in\mathcal{E}}(p_h,\,[\![\boldsymbol{v}_h\cdot\boldsymbol{n}]\!])_e = (\boldsymbol{f},\boldsymbol{v}_h)_\Omega\quad\text{for all } \boldsymbol{v}_h\in V_h, \tag{2.3}$$

$$\sum_{e\in\mathcal{E}}(q_h,\,[\![\boldsymbol{u}_h\cdot\boldsymbol{n}]\!])_e = (g_n,q_h)_{\partial\Omega}\quad\text{for all } q_h\in P_h. \tag{2.4}$$

Note that although the original mixed method (1.12)–(1.13) did not involve the pressure variable, the pressure reappears upon hybridization, but only along the mesh edges. We shall call p_h the "pressure Lagrange multiplier." The above discrete formulation has a unique solution, as we show next.

PROPOSITION 2.1. *There is a unique solution* $(\omega_h, \boldsymbol{u}_h, p_h) \in \mathcal{W}_h \times V_h \times P_h$ *for the hybridized mixed method* (2.2)–(2.4)*, and the solution components* ω_h *and* $\boldsymbol{u}_h$ *are the same as the solution of* (1.12)–(1.13).

Proof. We show that if g_n, g_t, and $\boldsymbol{f}$ are equal to zero, then $\omega_h, \boldsymbol{u}_h$, and p_h are also zero. First, (2.4) implies $\boldsymbol{u}_h \in \mathcal{V}_h(0)$. Moreover, (2.2)–(2.3) implies that ω_h and $\boldsymbol{u}_h$ satisfy (1.12)–(1.13) with zero data. By uniqueness of solutions of (1.12)–(1.13), we find that $\omega_h = 0$ and $\boldsymbol{u}_h = 0$. This together with (2.3) implies that p_h is zero. Hence there is a unique solution for (2.2)–(2.4). It is easy to see that if ω_h and $\boldsymbol{u}_h$ satisfy (2.2)–(2.4), then they also satisfy (1.12)–(1.13); hence the equivalence of both problems. □

Before proceeding to describe the second hybridization, let us point out that the first allows us to recover an approximation for the pressure inside the elements in an element-by-element fashion. To define such an approximation, we follow a technique of [7]. We define the pressure π_h on the triangle K as the element of $P_k(K)$ such that

$$-(\pi_h, \operatorname{div} \boldsymbol{v})_K = (\boldsymbol{f}, \boldsymbol{v})_K - (\mathbf{curl}\, \omega_h, \boldsymbol{v})_K - (\boldsymbol{v} \cdot \boldsymbol{n}, p_h)_{\partial K} \tag{2.5}$$

for all $\boldsymbol{v}$ in $P_k(K)^2 + \boldsymbol{x}\, P_k(K)$, where $\boldsymbol{n}$ denotes the outward unit normal to K. That (2.5) uniquely defines π_h follows from two facts:

(i) div : $P_k(K)^2 + \boldsymbol{x}\, P_k(K) \mapsto P_k(K)$ is a surjection;

(ii) If $\operatorname{div} \boldsymbol{v} = 0$ for a $\boldsymbol{v}$ in $P_k(K)^2 + \boldsymbol{x}\, P_k(K)$, then $\boldsymbol{v} \in P_k(K)^2$ and the right-hand side of the above equation is zero by the definition of the hybridized method.

The idea of recovering pressure approximations a posteriori as in (2.5) from approximations of other variables is old (see, e.g., [15]), but because hybridization provides p_h, we are able to compute π_h locally in our case. Thus our method can simultaneously provide approximations to the *velocity*, *vorticity*, and *pressure*.

2.2. Second hybridization: Introduction of the tangential velocity variable. Now we relax the continuity of the approximate vorticity ω_h across mesh edges in the interior of the domain. Thus, instead of considering continuous approximations in the space $\mathcal{W}_h$, we formulate a method using the space

$$W_h = \{w : w|_K \in P_{k+1}(K) \text{ for all } K \in \mathcal{T}\}.$$

This forces us to weakly impose (1.4) in a different way. Indeed, if we multiply that equation by a test function $\tau_h \in W_h$ and integrate over the element K, we obtain

$$(\omega, \tau_h)_K - (\boldsymbol{u}, \mathbf{curl}\, \tau_h)_K - (\boldsymbol{u} \cdot \boldsymbol{t}, \tau_h)_{\partial K} = 0,$$

where $\boldsymbol{t}$ denotes the unit tangent vector along ∂K oriented as in Figure 1. Here and elsewhere to simplify notation, we do not explicitly indicate the dependence of $\boldsymbol{t}$ on the underlying boundary (such as ∂K above). Denoting the tangential component of the velocity $\boldsymbol{u}$ on the interelement boundaries by

$$\boldsymbol{\lambda} = (\boldsymbol{u} \cdot \boldsymbol{t})\, \boldsymbol{t},$$

we can rewrite the above equation as

$$(\omega, \tau_h)_K - (\boldsymbol{u}, \mathbf{curl}\, \tau_h)_K - (\boldsymbol{\lambda}, \tau_h \boldsymbol{t})_{\partial K} = 0.$$

Next, replacing ω, $\boldsymbol{u}$, and $\boldsymbol{\lambda}$ by their respective approximations ω_h, $\boldsymbol{u}_h$, and $\boldsymbol{\lambda}_h$, we obtain, after adding over the elements K of the triangulation,

$$(\omega_h, \tau_h)_\Omega - (\boldsymbol{u}_h, \mathbf{curl}\, \tau_h)_\Omega - \sum_{e \in \mathcal{E} \setminus \partial\Omega} (\boldsymbol{\lambda}_h,\, [\![\tau_h \boldsymbol{t}]\!]_e)_e = (g_t, \tau_h)_{\partial\Omega}. \tag{2.6}$$

Here, the "tangential jump" of τ across interelement boundaries, $[\![\tau \boldsymbol{t}]\!]$, is defined as follows. For every interior edge $e \in \mathcal{E}$ shared by triangles K_e^+ and K_e^-, let

$$[\![\tau \boldsymbol{t}]\!]_e = \tau_e^+ \boldsymbol{t}^+ + \tau_e^- \boldsymbol{t}^-,$$

where, as before, $\tau_e^\pm(\boldsymbol{x}) = \lim_{\epsilon \downarrow 0} \tau(\boldsymbol{x} - \epsilon\, \boldsymbol{n}_e^\pm)$, and $\boldsymbol{t}^+$ and $\boldsymbol{t}^-$ are unit tangent vectors along the boundaries of K_e^+ and K_e^-, respectively, oriented in accordance with our previous notation: Unit tangent vectors along the boundary of a domain are given the orientation that leaves the domain on its left (see Figure 1). Hence $\boldsymbol{t}^+ = -\boldsymbol{t}^-$ on e. It is convenient to adopt the convention that the jump $[\![\tau \boldsymbol{t}]\!]$ on the boundary of Ω vanishes:

$$[\![\tau \boldsymbol{t}]\!]_e = 0 \qquad \text{for edges } e \subset \partial\Omega.$$

By $[\![\tau \boldsymbol{t}]\!]$ (without any subscript), we mean the function defined on the union of all edges in $\mathcal{E}$ that equals $[\![\tau \boldsymbol{t}]\!]_e$ on each edge $e \in \mathcal{E}$. With these conventions, we can now write (2.6) as

$$(\omega_h, \tau_h)_\Omega - (\boldsymbol{u}_h, \mathbf{curl}\, \tau_h)_\Omega - \sum_{e \in \mathcal{E}} (\boldsymbol{\lambda}_h,\, [\![\tau_h \boldsymbol{t}]\!])_e = (g_t, \tau_h)_{\partial\Omega}.$$

Now, proceeding as in the first hybridization, we impose the continuity of the vorticity by using the equation

$$\sum_{e \in \mathcal{E}} (\boldsymbol{\mu}_h,\, [\![\omega_h \boldsymbol{t}]\!])_e = 0 \qquad \text{for all } \boldsymbol{\mu}_h \in M_h, \tag{2.7}$$

where the space M_h is given by

$$M_h = \{\boldsymbol{\mu} : \boldsymbol{\mu} = [\![\tau \boldsymbol{t}]\!] \text{ for some } \tau \in W_h\}.$$

The above choice is dictated by the fact that a function $w \in W_h$ is continuous if and only if $[\![w \boldsymbol{t}]\!] = 0$. Clearly, if ω_h satisfies (2.7), then it belongs to the space $\mathcal{W}_h \subset H^1(\Omega)$.

Summarizing our considerations so far, the hybridized mixed method gives an approximation $(\omega_h, \boldsymbol{u}_h, \boldsymbol{\lambda}_h, p_h) \in W_h \times V_h \times M_h \times P_h$ defined by

$$(\omega_h, \tau_h)_\Omega - (\boldsymbol{u}_h, \mathbf{curl}\, \tau_h)_\Omega - \sum_{e \in \mathcal{E}} (\boldsymbol{\lambda}_h,\, [\![\tau_h \boldsymbol{t}]\!])_e = (g_t, \tau_h)_{\partial\Omega}, \tag{2.8}$$

$$(\boldsymbol{v}_h, \mathbf{curl}\, \omega_h)_\Omega + \sum_{e \in \mathcal{E}} (p_h,\, [\![\boldsymbol{v}_h \cdot \boldsymbol{n}]\!])_e = (\boldsymbol{f}, \boldsymbol{v}_h)_\Omega, \tag{2.9}$$

$$\sum_{e \in \mathcal{E}} (q_h,\, [\![\boldsymbol{u}_h \cdot \boldsymbol{n}]\!])_e = (g_n, q_h)_{\partial\Omega}, \tag{2.10}$$

$$\sum_{e \in \mathcal{E}} (\boldsymbol{\mu}_h,\, [\![\omega_h \boldsymbol{t}]\!])_e = 0 \tag{2.11}$$

for all $\tau_h \in W_h, \boldsymbol{v}_h \in V_h, q_h \in P_h$, and $\boldsymbol{\mu}_h \in M_h$. By arguments similar to those used in the proof of Proposition 2.1, it is easy to prove the following result.

Proposition 2.2. *There is a unique solution* $(\omega_h, \boldsymbol{u}_h, \boldsymbol{\lambda}_h, p_h) \in W_h \times V_h \times M_h \times P_h$ *for the hybridized mixed method* (2.8)–(2.11)*, and the solution components* ω_h *and* $\boldsymbol{u}_h$ *satisfy* (1.12)–(1.13).

At this point, the number of unknowns of our method seems to have proliferated, and it is far from evident that the hybridization we just described has any advantage at all. However, in the next section we show that the structure of this hybridized method allows us to easily eliminate the velocity $\boldsymbol{u}_h$ and the vorticity ω_h from the above equations.

3. A characterization of the Lagrange multipliers.

In this section, we eliminate the velocity and vorticity unknowns from the equations of the previously given hybridized mixed method using the methodology developed in [8]. As a result, we obtain a characterization of the tangential velocity and pressure Lagrange multipliers.

3.1. The main result.

We begin by defining *local* maps that lift functions defined on the boundary of the elements of the triangulation into functions on the domain Ω: Define $(w(\boldsymbol{\lambda}), \boldsymbol{u}(\boldsymbol{\lambda})) \in W_h \times V_h$ and $(\mathcal{w}(p), \mathbf{u}(p)) \in W_h \times V_h$ by

$$(w(\boldsymbol{\lambda}), \tau)_K - (\boldsymbol{u}(\boldsymbol{\lambda}), \mathbf{curl}\,\tau)_K = (\boldsymbol{\lambda}, \tau \boldsymbol{t})_{\partial K} \qquad \text{for all } \tau \in W_h, \tag{3.1}$$

$$(\boldsymbol{v}, \mathbf{curl}\; w(\boldsymbol{\lambda}))_K = 0 \qquad \text{for all } \boldsymbol{v} \in V_h, \tag{3.2}$$

$$(\mathcal{w}(p), \tau)_K - (\mathbf{u}(p), \mathbf{curl}\,\tau)_K = 0 \qquad \text{for all } \tau \in W_h, \tag{3.3}$$

$$(\boldsymbol{v}, \mathbf{curl}\; \mathcal{w}(p))_K = -(p, \boldsymbol{v} \cdot \boldsymbol{n})_{\partial K} \qquad \text{for all } \boldsymbol{v} \in V_h. \tag{3.4}$$

In addition it is convenient to define the local mappings $(w(g_t), \boldsymbol{u}(g_t))$ and $(\mathsf{w}(\boldsymbol{f}), \mathbf{u}(\boldsymbol{f}))$ in $W_h \times V_h$ as follows:

$$(w(g_t), \tau)_K - (\boldsymbol{u}(g_t), \mathbf{curl}\,\tau)_K = (g_t, \tau)_{\partial K \cap \partial\Omega} \qquad \text{for all } \tau \in W_h, \tag{3.5}$$

$$(\boldsymbol{v}, \mathbf{curl}\; w(g_t))_K = 0 \qquad \text{for all } \boldsymbol{v} \in V_h, \tag{3.6}$$

$$(\mathsf{w}(\boldsymbol{f}), \tau)_K - (\mathbf{u}(\boldsymbol{f}), \mathbf{curl}\,\tau)_K = 0 \qquad \text{for all } \tau \in W_h, \tag{3.7}$$

$$(\boldsymbol{v}, \mathbf{curl}\; \mathsf{w}(\boldsymbol{f}))_K = (\boldsymbol{f}, \boldsymbol{v})_K \qquad \text{for all } \boldsymbol{v} \in V_h. \tag{3.8}$$

Note that all four pairs of local maps above are given as solutions of a single mixed problem, but with different right-hand sides. That all four maps are well defined follows from the unique solvability of the mixed problem (which is the original mixed problem restricted to one element). Although all four maps use the same mixed problem, we have chosen to explicitly distinguish each of them so as to delineate the dependence of the final solution on the data components and the Lagrange multipliers.

The main result of this section characterizes the Lagrange multipliers as the unique solution of a variational equation involving the bilinear forms

$$a(\boldsymbol{\lambda}, \boldsymbol{\mu}) = (w(\boldsymbol{\lambda}), w(\boldsymbol{\mu}))_\Omega, \tag{3.9}$$

$$b(\boldsymbol{\mu}, p) = -\sum_{K \in \mathcal{T}} (\boldsymbol{u}(\boldsymbol{\mu}), \mathbf{curl}\; \mathcal{w}(p))_K, \tag{3.10}$$

$$c(p, q) = (\mathcal{w}(p), \mathcal{w}(q))_\Omega \tag{3.11}$$

and the linear functionals

$$\ell_1(\boldsymbol{\mu}) = (\boldsymbol{f}, \boldsymbol{u}(\boldsymbol{\mu}))_\Omega - (g_t, w(\boldsymbol{\mu}))_{\partial\Omega}, \tag{3.12}$$

$$\ell_2(q) = (\boldsymbol{f}, \mathbf{u}(q))_\Omega + (g_n, q)_{\partial\Omega} - (g_t, \mathcal{w}(q))_{\partial\Omega}. \tag{3.13}$$

Theorem 3.1. *The Lagrange multiplier* $(\boldsymbol{\lambda}_h, p_h) \in M_h \times P_h$ *of the hybridized mixed method* (2.8)–(2.11) *is the unique solution of*

$$a(\boldsymbol{\lambda}_h, \boldsymbol{\mu}) + b(\boldsymbol{\mu}, p_h) = \ell_1(\boldsymbol{\mu}) \qquad \text{for all } \boldsymbol{\mu} \in M_h \text{ and} \tag{3.14}$$

$$b(\boldsymbol{\lambda}_h, q) - c(p_h, q) = \ell_2(q) \qquad \text{for all } q \in P_h. \tag{3.15}$$

Moreover, the solution components ω_h *and* $\boldsymbol{u}_h$ *of the hybridized mixed method* (2.8)–(2.11) *can be determined locally as follows:*

$$\omega_h = w(\boldsymbol{\lambda}_h) + \mathcal{W}(p_h) + w(g_t) + \mathsf{w}(\boldsymbol{f}), \tag{3.16}$$

$$\boldsymbol{u}_h = \boldsymbol{u}(\boldsymbol{\lambda}_h) + \boldsymbol{\mathfrak{u}}(p_h) + \boldsymbol{u}(g_t) + \boldsymbol{\mathsf{u}}(\boldsymbol{f}). \tag{3.17}$$

3.2. Proof. To prove the above result, we follow the approach introduced in [8]. Accordingly, the first step will be to use the local maps to rewrite the first two equations of the hybridized method, namely (2.8) and (2.9). This will yield (3.16) and (3.17). Next, the two remaining equations of the hybridized method, namely (2.10) and (2.11), will be used to characterize the pressure and tangential velocity Lagrange multipliers of the method. In order to carry out these steps, we need to obtain a few identities involving the local mappings. This is done in the first lemma below. Then, in a second lemma, we show how to rewrite (2.10) and (2.11) solely in terms of the multipliers. In this way, we eliminate the vorticity and velocity and at the same time obtain a variational characterization of the Lagrange multipliers. Let us now state and prove the lemmas.

Lemma 3.2 (elementary identities). *On any mesh element* $K \in \mathcal{T}$, *for any* $\boldsymbol{\lambda} \in M_h, \boldsymbol{\mu} \in M_h, p \in P_h$, *and* $q \in P_h$, *we have the following orthogonality properties for the local vorticity maps:*

$$(w(\boldsymbol{\lambda}), \mathcal{W}(p))_K = 0, \tag{3.18}$$

$$(w(\boldsymbol{\lambda}), \mathsf{w}(\boldsymbol{f}))_K = 0, \tag{3.19}$$

$$(w(g_t), \mathcal{W}(p))_K = 0, \tag{3.20}$$

$$(w(g_t), \mathsf{w}(\boldsymbol{f}))_K = 0. \tag{3.21}$$

Moreover, we have the following identities for the bilinear forms a, b, and c:

$$a_K(\boldsymbol{\lambda}, \boldsymbol{\mu}) := (w(\boldsymbol{\lambda}), w(\boldsymbol{\mu}))_K = (\boldsymbol{\lambda}, w(\boldsymbol{\mu})\boldsymbol{t})_{\partial K}, \tag{3.22}$$

$$b_K(\boldsymbol{\lambda}, p) := -(\boldsymbol{u}(\boldsymbol{\lambda}), \mathbf{curl}\ \mathcal{W}(p))_K = (\boldsymbol{u}(\boldsymbol{\lambda}) \cdot \boldsymbol{n}, p)_{\partial K} = (\boldsymbol{\lambda}, \mathcal{W}(p)\boldsymbol{t})_{\partial K}, \tag{3.23}$$

$$c_K(p, q) := (\mathcal{W}(p), \mathcal{W}(q))_K = -(q, \boldsymbol{\mathfrak{u}}(p) \cdot \boldsymbol{n})_{\partial K}. \tag{3.24}$$

Finally, we have the following identities related to the linear forms ℓ_1 *and* ℓ_2*:*

$$(\boldsymbol{f}, \boldsymbol{u}(\boldsymbol{\mu}))_K = -(\mathsf{w}(\boldsymbol{f})\boldsymbol{t}, \boldsymbol{\mu})_{\partial K}, \tag{3.25}$$

$$(w(\boldsymbol{\mu}), g_t)_{\partial K \cap \partial \Omega} = (\boldsymbol{\mu}, w(g_t)\, \boldsymbol{t})_{\partial K}, \tag{3.26}$$

$$(\boldsymbol{f}, \boldsymbol{\mathfrak{u}}(q))_K = -(\boldsymbol{\mathsf{u}}(\boldsymbol{f}) \cdot \boldsymbol{n}, q)_{\partial K}, \tag{3.27}$$

$$(\mathcal{W}(q), g_t)_{\partial K \cap \partial \Omega} = (q, \boldsymbol{u}(g_t) \cdot \boldsymbol{n})_{\partial K}. \tag{3.28}$$

Proof. Let us begin by proving the orthogonality identities. Equation (3.18) is obtained by setting $\tau = w(\boldsymbol{\lambda})$ in (3.3) and using (3.2). The proof of (3.19) is analogous. Equations (3.20) and (3.21) follow from similar arguments, as the equations defining the liftings of g_t and $\boldsymbol{\lambda}$ have the same structure.

Next, let us prove the identities associated with the bilinear forms $a(\cdot,\cdot)$, $b(\cdot,\cdot)$, and $c(\cdot,\cdot)$. Equation (3.22) is obtained as follows. Setting $\tau = w(\boldsymbol{\mu})$ in the definition of the liftings (3.1), we get

$$\begin{aligned}(w(\boldsymbol{\lambda}), \boldsymbol{w}(\boldsymbol{\mu}))_K &= (\boldsymbol{u}(\boldsymbol{\lambda}), \mathbf{curl}\; w(\boldsymbol{\mu}))_K + (\boldsymbol{\lambda}, w(\boldsymbol{\mu})\,\boldsymbol{t})_{\partial K}\\ &= (\boldsymbol{\lambda}, w(\boldsymbol{\mu})\,\boldsymbol{t})_{\partial K},\end{aligned}$$

by (3.2) with $\boldsymbol{\lambda} = \boldsymbol{\mu}$ and $\boldsymbol{v} = \boldsymbol{u}(\boldsymbol{\lambda})$. Let us prove (3.23). Taking $\boldsymbol{v} = \boldsymbol{u}(\boldsymbol{\lambda})$ in (3.4), we get

$$\begin{aligned}(\boldsymbol{u}(\boldsymbol{\lambda})\cdot\boldsymbol{n}, p)_{\partial K} &= -(\boldsymbol{u}(\boldsymbol{\lambda}), \mathbf{curl}\; \mathrm{w}(p))_K\\ &= (\boldsymbol{\lambda}, \mathrm{w}(p)\,\boldsymbol{t})_{\partial K} - (w(\boldsymbol{\lambda}), \mathrm{w}(p))_K \quad \text{by (3.1) with } \tau = \mathrm{w}(p),\\ &= (\boldsymbol{\lambda}, \mathrm{w}(p)\,\boldsymbol{t})_{\partial K},\end{aligned}$$

by the orthogonality property (3.18). Now let us prove (3.24). We have, by (3.3) with $\tau = \mathrm{w}(q)$,

$$\begin{aligned}(\mathrm{w}(p), \mathrm{w}(q))_K &= (\mathbf{u}(p), \mathbf{curl}\; \mathrm{w}(q))_K\\ &= -(q, \mathbf{u}(p)\cdot\boldsymbol{n})_{\partial K},\end{aligned}$$

by (3.4) with $p = q$ and $\boldsymbol{v} = \mathbf{u}(p)$.

Finally, let us consider the last set of identities. We first prove (3.25). Setting $\boldsymbol{v} = \boldsymbol{u}(\boldsymbol{\mu})$ in (3.8), we get

$$\begin{aligned}(\boldsymbol{f}, \boldsymbol{u}(\boldsymbol{\mu}))_K &= (\boldsymbol{u}(\boldsymbol{\mu}), \mathbf{curl}\; \mathsf{w}(\boldsymbol{f}))_K\\ &= (w(\boldsymbol{\mu}), \mathsf{w}(\boldsymbol{f}))_K - (\boldsymbol{\mu}, \mathsf{w}(\boldsymbol{f})\,\boldsymbol{t})_{\partial K},\end{aligned}$$

by (3.1) with $\boldsymbol{\lambda} = \boldsymbol{\mu}$ and $\tau = \mathsf{w}(\boldsymbol{f})$. The desired equation follows by using the already established orthogonality property (3.19). Next, let us prove (3.26). Setting $\tau = w(\boldsymbol{\mu})$ in (3.5) and then using (3.2), we get

$$\begin{aligned}(g_t, w(\boldsymbol{\mu}))_{\partial K\cap\partial\Omega} &= (w(\boldsymbol{\mu}), w(g_t))_K\\ &= (\boldsymbol{\mu}, w(g_t)\boldsymbol{t})_{\partial K} + (\boldsymbol{u}(\boldsymbol{\mu}), \mathbf{curl}\,(w(g_t)))_K,\end{aligned}$$

by (3.1) with $\boldsymbol{\lambda} = \boldsymbol{\mu}$ and $\tau = w(g_t)$. Equation (3.26) follows from (3.6). Equation (3.27) is obtained as follows:

$$\begin{aligned}(\boldsymbol{f}, \mathbf{u}(q))_K &= (\mathbf{u}(q), \mathbf{curl}\; \mathsf{w}(\boldsymbol{f}))_K && \text{by (3.8) with } \boldsymbol{v} = \mathbf{u}(q),\\ &= (\mathrm{w}(q), \mathsf{w}(\boldsymbol{f}))_K && \text{by (3.3) with } p = q \text{ and } \tau = \mathsf{w}(\boldsymbol{f}),\\ &= (\mathbf{u}(\boldsymbol{f}), \mathbf{curl}\; \mathrm{w}(q))_K && \text{by (3.7) with } \tau = \mathrm{w}(q),\\ &= -(q, \mathbf{u}(\boldsymbol{f}))_K,\end{aligned}$$

by (3.4) with $p = q$ and $\boldsymbol{v} = \mathbf{u}(\boldsymbol{f})$. Finally, let us prove (3.28). By (3.5) with $\tau = \mathrm{w}(q)$, we have

$$\begin{aligned}(\mathrm{w}(q), g_t)_{\partial K\cup\partial\Omega} &= (w(g_t), \mathrm{w}(q))_K - (\boldsymbol{u}(g_t), \mathbf{curl}\; \mathrm{w}(q))_K,\\ &= -(\boldsymbol{u}(g_t), \mathbf{curl}\; \mathrm{w}(q))_K \qquad \text{by (3.20)},\\ &= (q, \boldsymbol{u}(g_t)\cdot\boldsymbol{n})_{\partial K},\end{aligned}$$

by (3.4) with $p = q$ and $\boldsymbol{v} = \boldsymbol{u}(g_t)$. This completes the proof. $\square$

LEMMA 3.3 (the jump conditions). *For arbitrary $\boldsymbol{\lambda} \in M_h$ and $p \in P_h$ set*

$$\widetilde{\omega}_h^{\boldsymbol{\lambda},p} = w(\boldsymbol{\lambda}) + \mathcal{W}(p) + w(g_t) + \mathsf{w}(\boldsymbol{f}),$$
$$\widetilde{\boldsymbol{u}}_h^{\boldsymbol{\lambda},p} = \boldsymbol{u}(\boldsymbol{\lambda}) + \boldsymbol{\mathfrak{u}}(p) + \boldsymbol{u}(g_t) + \boldsymbol{\mathsf{u}}(\boldsymbol{f}).$$

Let $(\omega_h, \boldsymbol{u}_h, \boldsymbol{\lambda}_h, p_h)$ be the unique solution of (2.8)–(2.11). *Then the following statements are equivalent:*

A. *For all $\boldsymbol{\mu} \in M_h$ and $q \in P_h$,*

$$\sum_{e\in\mathcal{E}} (\boldsymbol{\mu},\, \llbracket \widetilde{\omega}_h^{\boldsymbol{\lambda},p} \boldsymbol{t} \rrbracket)_e = 0 \quad \textit{and} \quad \sum_{e\in\mathcal{E}} (q,\, \llbracket \widetilde{\boldsymbol{u}}_h^{\boldsymbol{\lambda},p} \cdot \boldsymbol{n} \rrbracket)_e = (g_n, q)_{\partial\Omega}.$$

B. $\widetilde{\omega}_h^{\boldsymbol{\lambda},p} = \omega_h$ *and* $\widetilde{\boldsymbol{u}}_h^{\boldsymbol{\lambda},p} = \boldsymbol{u}_h$.

C. $\boldsymbol{\lambda} = \boldsymbol{\lambda}_h$ *and* $p = p_h$.

D. $a(\boldsymbol{\lambda}, \boldsymbol{\mu}) + b(\boldsymbol{\mu}, p) = \ell_1(\boldsymbol{\mu})$ *for all* $\boldsymbol{\mu} \in M_h$ *and* $b(\boldsymbol{\lambda}, q) - c(p, q) = \ell_2(q)$ *for all* $q \in P_h$.

Proof. A $\Longrightarrow$ B: By adding the equations defining $(w(\boldsymbol{\lambda}), \boldsymbol{u}(\boldsymbol{\lambda}))$, $(\mathcal{W}(p), \boldsymbol{\mathfrak{u}}(p))$, $(\mathsf{w}(\boldsymbol{f}), \boldsymbol{\mathsf{u}}(\boldsymbol{f}))$, and $(w(g_t), \boldsymbol{u}(g_t))$, we find that $\widetilde{\omega}_h^{\boldsymbol{\lambda},p}$ and $\widetilde{\boldsymbol{u}}_h^{\boldsymbol{\lambda},p}$ satisfy the first two equations of our hybridized mixed method, i.e.,

$$(\widetilde{\omega}_h^{\boldsymbol{\lambda},p}, \tau_h)_\Omega - (\widetilde{\boldsymbol{u}}_h^{\boldsymbol{\lambda},p}, \mathbf{curl}\,\tau_h)_\Omega - \sum_{e\in\mathcal{E}} (\boldsymbol{\lambda},\, \llbracket \tau_h \boldsymbol{t} \rrbracket)_e = (g_t, \tau_h)_{\partial\Omega},$$
$$(\boldsymbol{v}_h, \mathbf{curl}\,\widetilde{\omega}_h^{\boldsymbol{\lambda},p})_\Omega + \sum_{e\in\mathcal{E}} (p,\, \llbracket \boldsymbol{v}_h \cdot \boldsymbol{n} \rrbracket)_e = (\boldsymbol{f}, \boldsymbol{v}_h)_\Omega,$$

for all $\tau_h \in W_h$ and $\boldsymbol{v}_h \in V_h$. Since statement A holds, they also satisfy the remaining equations of the method. By uniqueness of solutions of the hybridized mixed method (as given by Proposition 2.2) we get statement B.

B $\Longrightarrow$ C: By linear superposition,

$$\omega_h = w(\boldsymbol{\lambda}_h) + \mathcal{W}(p_h) + w(g_t) + \mathsf{w}(\boldsymbol{f}), \tag{3.29}$$
$$\boldsymbol{u}_h = \boldsymbol{u}(\boldsymbol{\lambda}_h) + \boldsymbol{\mathfrak{u}}(p_h) + \boldsymbol{u}(g_t) + \boldsymbol{\mathsf{u}}(\boldsymbol{f}). \tag{3.30}$$

Comparing these equations with the definitions of $\widetilde{\omega}_h^{\boldsymbol{\lambda},p}$ and $\widetilde{\boldsymbol{u}}_h^{\boldsymbol{\lambda},p}$, we find that statement B implies

$$w(\boldsymbol{\lambda}_h) + \mathcal{W}(p_h) = w(\boldsymbol{\lambda}) + \mathcal{W}(p), \tag{3.31}$$
$$\boldsymbol{u}(\boldsymbol{\lambda}_h) + \boldsymbol{\mathfrak{u}}(p_h) = \boldsymbol{u}(\boldsymbol{\lambda}) + \boldsymbol{\mathfrak{u}}(p). \tag{3.32}$$

In particular,

$$w(\boldsymbol{\lambda}_h - \boldsymbol{\lambda}) + \mathcal{W}(p_h - p) = 0.$$

Since the two terms on the left-hand side above are $L^2(\Omega)$-orthogonal by (3.18), they both must vanish. Moreover, by the definition of $\boldsymbol{\mathfrak{u}}(\cdot)$ (see (3.3)), $w(\boldsymbol{\lambda}_h - \boldsymbol{\lambda}) = 0$ implies

$$(\boldsymbol{\mathfrak{u}}(p_h - p), \mathbf{curl}\,\tau)_K = 0 \quad \text{for all } K \in \mathfrak{T}, \tau \in W_h.$$

Hence $\boldsymbol{\mathfrak{u}}(p_h - p) = 0$. By (3.32) we also get $\boldsymbol{u}(\boldsymbol{\lambda}_h - \boldsymbol{\lambda}) = 0$. Thus,

$$w(\boldsymbol{\lambda}_h - \boldsymbol{\lambda}) = \mathcal{W}(p_h - p) = 0, \qquad \boldsymbol{u}(\boldsymbol{\lambda}_h - \boldsymbol{\lambda}) = \boldsymbol{\mathfrak{u}}(p_h - p) = \mathbf{0},$$

so $\boldsymbol{\lambda}_h - \boldsymbol{\lambda} = 0$ and $p_h - p = 0$.

C $\implies$ D: We know by (3.29)–(3.30) and the last two equations of the hybridized mixed method that

$$\Theta := \sum_{e\in\mathcal{E}} \big(\boldsymbol{\mu},\, [\![\big(w(\boldsymbol{\lambda}_h) + \mathscr{w}(p_h) + \mathsf{w}(\boldsymbol{f}) + w(g_t)\big)\boldsymbol{t}]\!]\big)_e = 0,$$

$$\Psi := \sum_{e\in\mathcal{E}} \big(q,\, [\![\big(\boldsymbol{u}(\boldsymbol{\lambda}_h) + \mathbf{u}(p_h) + \mathbf{u}(\boldsymbol{f}) + \boldsymbol{u}(g_t)\big)\cdot\boldsymbol{n}]\!]\big)_e - (g_n, q)_{\partial\Omega} = 0.$$

Hence, it suffices to show that

$$\Theta = a(\boldsymbol{\lambda},\boldsymbol{\mu}) + b(\boldsymbol{\mu}, p) - \ell_1(\boldsymbol{\mu}), \tag{3.33}$$

$$\Psi = b(\boldsymbol{\lambda}, q) - c(p,q) - \ell_2(q). \tag{3.34}$$

To do this, let us split $\Theta =: \theta_1 + \theta_2 + \theta_3 + \theta_4$, where

$$\begin{aligned}
\theta_1 &:= \sum_{e\in\mathcal{E}} \big(\boldsymbol{\mu},\, [\![w(\boldsymbol{\lambda})]\!]\boldsymbol{t}\big)_e = (w(\boldsymbol{\lambda}), w(\boldsymbol{\mu}))_\Omega && \text{by (3.22)},\\
\theta_2 &:= \sum_{e\in\mathcal{E}} \big(\boldsymbol{\mu},\, [\![\mathscr{w}(p)\boldsymbol{t}]\!]\big)_e = -\sum_{K\in\mathcal{T}} (\boldsymbol{u}(\boldsymbol{\mu}), \mathbf{curl}\ \mathscr{w}(p))_K && \text{by (3.23)},\\
\theta_3 &:= \sum_{e\in\mathcal{E}} \big(\boldsymbol{\mu},\, [\![\mathsf{w}(\boldsymbol{f})\boldsymbol{t}]\!]\big)_e = -(\boldsymbol{f}, \boldsymbol{u}(\boldsymbol{\mu}))_\Omega && \text{by (3.25)},\\
\theta_4 &:= \sum_{e\in\mathcal{E}} \big(\boldsymbol{\mu},\, [\![w(g_t)\boldsymbol{t}]\!]\big)_e = (g_t, w(\boldsymbol{\mu}))_{\partial\Omega} && \text{by (3.26)}.
\end{aligned}$$

Hence

$$\begin{aligned}
\theta_1 &= a(\boldsymbol{\lambda},\boldsymbol{\mu}) && \text{by (3.9)},\\
\theta_2 &= b(\boldsymbol{\mu}, p) && \text{by (3.10)},\\
\theta_3 + \theta_4 &= -\ell_1(\boldsymbol{\mu}) && \text{by (3.12)}.
\end{aligned}$$

This proves (3.33).

To prove (3.34), we split $\Psi =: \psi_1 + \psi_2 + \psi_3 + \psi_4 + \psi_5$, where

$$\begin{aligned}
\psi_1 &:= \sum_{e\in\mathcal{E}} \big(q,\, [\![\boldsymbol{u}(\boldsymbol{\lambda})\cdot\boldsymbol{n}]\!]\big)_e = -\sum_{K\in\mathcal{T}} (\boldsymbol{u}(\boldsymbol{\lambda}), \mathbf{curl}\ \mathscr{w}(q))_K && \text{by (3.23)},\\
\psi_2 &:= \sum_{e\in\mathcal{E}} \big(q,\, [\![\mathbf{u}(p)\cdot\boldsymbol{n}]\!]\big)_e = -(\mathscr{w}(p), \mathscr{w}(q))_\Omega && \text{by (3.24)},\\
\psi_3 &:= \sum_{e\in\mathcal{E}} \big(q,\, [\![\mathbf{u}(\boldsymbol{f})\cdot\boldsymbol{n}]\!]\big)_e = -(\boldsymbol{f}, \mathbf{u}(q))_\Omega && \text{by (3.27)},\\
\psi_4 &:= \sum_{e\in\mathcal{E}} \big(q,\, [\![\boldsymbol{u}(g_t)\cdot\boldsymbol{n}]\!]\big)_e = (g_t, \mathscr{w}(q))_{\partial\Omega} && \text{by (3.28)},\\
\psi_5 &:= -(g_n, q)_{\partial\Omega}.
\end{aligned}$$

Hence

$$\begin{aligned}
\psi_1 &= b(\boldsymbol{\lambda}, q) && \text{by (3.10)},\\
\psi_2 &= -c(p,q) && \text{by (3.11)},\\
\psi_3 + \psi_4 + \psi_5 &= -\ell_2(\boldsymbol{\mu}) && \text{by (3.13)}.
\end{aligned}$$

Adding the above equations, we obtain (3.34).

D $\Longrightarrow$ A: If statement D holds, then, by the previous step, we have

$$\sum_{e\in\mathcal{E}} \big(\boldsymbol{\mu},\, [\![\big(w(\boldsymbol{\lambda}) + \mathcal{w}(p) + \mathsf{w}(\boldsymbol{f}) + w(g_t)\big)\boldsymbol{t}]\!]\big)_e = 0,$$
$$\sum_{e\in\mathcal{E}} \big(q,\, [\![\big(\boldsymbol{u}(\boldsymbol{\lambda}) + \mathbf{u}(p) + \mathbf{u}(\boldsymbol{f}) + \boldsymbol{u}(g_t)\big)\cdot\boldsymbol{n}]\!]\big)_e = (g_n, q)_{\partial\Omega},$$

which is statement A. □

Proof of Theorem 3.1. The proof of the theorem is immediate from the previous lemmas: The first assertion of the theorem follows from the equivalence of statements C and D of Lemma 3.3. The second follows from the first by linear superposition. Thus Theorem 3.1 is proved. □

4. Local bases for Lagrange multipliers.

For the hybridized method to be of practical use, it is imperative that we develop computable bases of locally supported functions for the multiplier spaces P_h and M_h.

4.1. The pressure space.

We begin with a characterization of the space of pressure Lagrange multipliers arising from the first hybridization.

PROPOSITION 4.1. *The space P_h defined in* (2.1) *is characterized by*

$$P_h = \left\{ p : p|_e \in P_k(e) \text{ for all } e\in\mathcal{E} \text{ and } \sum_{e\in\mathcal{E}} (p,1)_e = 0 \right\}.$$

Proof. Let Q_h denote the set in the right-hand side above. To show that $P_h \subseteq Q_h$, consider any $\boldsymbol{v}_h \in V_h$ and let $p_h = [\![\boldsymbol{v}_h\cdot\boldsymbol{n}]\!]$. Then $[\![\boldsymbol{v}_h\cdot\boldsymbol{n}]\!]_e \in P_k(e)$ and

$$\sum_{e\in\mathcal{E}} (p_h,1)_e \,\mathrm{d}s = \sum_{K\in\mathcal{T}} (\boldsymbol{v}_h\cdot\boldsymbol{n},1)_{\partial K} = \sum_{K\in\mathcal{T}} (\operatorname{div}\boldsymbol{v}_h,1)_K = 0.$$

Hence $P_h \subseteq Q_h$.

To show the reverse inclusion, consider any $p_h \in Q_h$. Then there is a function $\widetilde{\boldsymbol{v}}_h \in \widetilde{V}_h := \{\boldsymbol{r} : \boldsymbol{r}|_K = \boldsymbol{x}p_k(\boldsymbol{x}) + \boldsymbol{q}_k$ for some $p_k \in P_k(K)$ and $\boldsymbol{q}_k \in P_k(K)^2\}$ such that

$$[\![\widetilde{\boldsymbol{v}}_h\cdot\boldsymbol{n}]\!]_e = p_h|_e \quad \text{for all } e\in\mathcal{E}.$$

Note that $\operatorname{div}(\widetilde{\boldsymbol{v}}_h|_K)$ is not zero in general. Let S_h be the space of functions whose average on Ω is zero and whose restriction to each mesh element $K\in\mathcal{T}$ is in $P_k(K)$. The function $s_h(\boldsymbol{x})$, defined by

$$s_h|_K = \operatorname{div}(\widetilde{\boldsymbol{v}}_h|_K) \quad \text{for all } K\in\mathcal{T},$$

is in S_h because p_h is in Q_h:

$$(s_h,1)_\Omega = \sum_{K\in\mathcal{T}} (\operatorname{div}\widetilde{\boldsymbol{v}}_h,1)_K = \sum_{K\in\mathcal{T}} (\widetilde{\boldsymbol{v}}_h\cdot\boldsymbol{n},1) = \sum_{e\in\mathcal{E}} (p_h,1)_e = 0.$$

Now, the space $\widetilde{V}_h \cap H_0(\operatorname{div},\Omega)$ is a standard Raviart–Thomas space, and by its well-known properties, $\operatorname{div} : \widetilde{V}_h \cap H_0(\operatorname{div},\Omega) \mapsto S_h$ is a surjection. Hence, there is a $\boldsymbol{z}_h \in \widetilde{V}_h \cap H_0(\operatorname{div},\Omega)$ such that

$$\operatorname{div}\boldsymbol{z}_h = s_h.$$

Then $\boldsymbol{v}_h = \widetilde{\boldsymbol{v}}_h - \boldsymbol{z}_h$ is in V_h and $[\![\boldsymbol{v}_h \cdot \boldsymbol{n}]\!]_e = [\![\widetilde{\boldsymbol{v}}_h \cdot \boldsymbol{n}]\!]_e = p_h|_e$. Hence $Q_h \subseteq P_h$. □

In view of Proposition 4.1, the function q_h belongs to the space P_h if and only if it belongs to

$$\widetilde{P}_h = \{p : p|_e \in P_k(e) \text{ for all } e \in \mathcal{E}\}$$

and satisfies

$$\sum_{e\in\mathcal{E}} (q_h, 1)_e = 0. \tag{4.1}$$

Thus we need only construct a local basis for $\widetilde{P}_h$ and then enforce the last equation. Obviously, we can construct a basis for $\widetilde{P}_h$ by taking the union of local bases for $P_k(e)$, say Legendre polynomials, on every edge $e \in \mathcal{E}$. In practice, the constraint (4.1) can be handled a posteriori in a very simple way, as shown in section 5.

4.2. The lowest-order tangential velocity space. In the remainder of this section, we construct a local basis for the space M_h of tangential velocity Lagrange multipliers. In this subsection, we study the lowest-order case. In the next, we show how our considerations here generalize to the higher-order case.

In order to explicitly give a local basis for M_h, we introduce some more notation. Let K be a mesh triangle and let x be one of its vertices. We denote by $\mathit{\Lambda}_{x,K}$ the union of the two edges of K that are connected to the vertex x. Let

$$\hat{\mathit{\Lambda}}_h = \{\mathit{\Lambda}_{x,K} : x \text{ is a vertex of } \mathcal{T} \text{ and } K \in \mathcal{T}\}.$$

For all $\mathit{\Lambda} \in \hat{\mathit{\Lambda}}_h$, we denote by $K_\mathit{\Lambda}$ the (unique) triangle $K \in \mathcal{T}$ such that $\mathit{\Lambda} \subseteq \partial K$, and by $x_\mathit{\Lambda}$ we denote the common vertex of $\mathit{\Lambda}$ and $K_\mathit{\Lambda}$. Let $\phi_\mathit{\Lambda}$ denote the function (that is discontinuous in general) which vanishes on all $K \in \mathcal{T}$ except on $K_\mathit{\Lambda}$, where it equals the linear function that is one on $x_\mathit{\Lambda}$ and zero on the remaining two vertices of $K_\mathit{\Lambda}$. We define a basis for M_h using the functions

$$\boldsymbol{\psi}_\mathit{\Lambda} = [\![\phi_\mathit{\Lambda}\, \boldsymbol{t}]\!].$$

Obviously $\boldsymbol{\psi}_\mathit{\Lambda} \in M_h$, but not all of $\boldsymbol{\psi}_\mathit{\Lambda}, \mathit{\Lambda} \in \hat{\mathit{\Lambda}}_h$, are linearly independent; e.g., the functions $\boldsymbol{\psi}_\mathit{\Lambda}$ for all $\mathit{\Lambda}$ connected to one vertex are linked by one equation. Therefore, for every mesh vertex x (including $x \in \partial\Omega$), we arbitrarily pick one element $\mathit{\Lambda} \in \hat{\mathit{\Lambda}}_h$ with vertex $x_\mathit{\Lambda} = x$, denote it by $\triangledown_x$ (see Figure 2), and "omit" it: Define

$$\mathit{\Lambda}_h = \hat{\mathit{\Lambda}}_h \setminus \{\triangledown_x : \text{ for all mesh vertices } x\}.$$

Proposition 4.2. *The set $\mathcal{B} = \{\boldsymbol{\psi}_\mathit{\Lambda} : \mathit{\Lambda} \in \mathit{\Lambda}_h\}$ is a basis for M_h when $k = 0$.*

Proof. Obviously the span of $\mathcal{B}$ is contained in M_h. Hence it suffices to prove that

$$\operatorname{card} \mathcal{B} = \dim M_h \tag{4.2}$$

and

$$\mathcal{B} \text{ is a linearly independent set.} \tag{4.3}$$

To prove (4.2), let us first count the dimension of M_h. Defining $T_h : W_h \mapsto M_h$ by

$$T_h \tau = [\![\tau \boldsymbol{t}]\!],$$

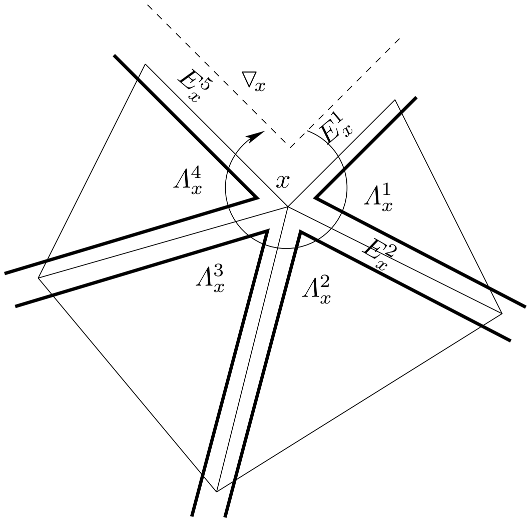

FIG. 2. *Construction of basis functions supported near a mesh vertex x.*

we note that M_h is the range of T_h. Since the null space of T_h is $\mathcal{W}_h$, by the rank-nullity theorem, we find that

$$\dim(M_h) = \operatorname{rank}(T_h) = \dim(W_h) - \dim(\mathcal{W}_h). \tag{4.4}$$

In the lowest-order case, this easily gives

$$\dim(M_h) = 3n_K - n_V,$$

where n_K and n_V are the number of triangles and vertices of the mesh, respectively. Now, since

$$\operatorname{card}\mathcal{B} = \operatorname{card}\Lambda_h = \operatorname{card}\hat{\Lambda}_h - n_V = 3n_K - n_V,$$

we immediately see that (4.2) holds.

To prove (4.3), let $\boldsymbol{\mu}$ be any linear combination of the basis elements:

$$\boldsymbol{\mu} = \sum_{\Lambda\in\Lambda_h} c_\Lambda \boldsymbol{\psi}_\Lambda. \tag{4.5}$$

Then, consider $\boldsymbol{\mu}|_{\nabla_x}$ for any mesh vertex x (including $x \in \partial\Omega$). Enumerate all $\Lambda \in \Lambda_h$ with vertex x as $\Lambda_x^1, \Lambda_x^2, \ldots, \Lambda_x^{N_x}$ and all edges in $\mathcal{E}$ connected to x as $E_x^1, E_x^2, \ldots E_x^{N_x+1}$, as in Figure 2. The enumerations are such that the two edges of Λ_x^j are E_x^j and E_x^{j+1}. Let μ_x^i be the function defined on E_x^i that equals the magnitude of $\boldsymbol{\mu}|_{E_x^i}$. Observe that the limit of $\mu_x^1(y)$ as y approaches x along the edge E_x^1 is $|c_{\Lambda_x^1}|$. Similarly, the limit of $\mu_x^{N_x}(y)$ as y approaches x along the edge $E_x^{N_x+1}$ is $|c_{\Lambda_x^{N_x}}|$. Also note that the limit of $\mu_x^j(y)$ as y approaches x along the edge E_x^j is $|c_{\Lambda_x^j} - c_{\Lambda_x^{j-1}}|$ for all $j = 2, 3, \ldots, N_x - 1$.

Now suppose $\boldsymbol{\mu} \equiv \mathbf{0}$. We have to show that all the coefficients c_Λ in (4.5) are zero. Since $\boldsymbol{\mu}$ vanishes everywhere, in particular, for a mesh vertex x, the function $\mu_x^j(y)$ vanishes on the edge E_x^j. Hence its limit as y approaches x along the edge E_x^j

equals zero. Thus,

$$\begin{aligned} |c_{\Lambda_x^1}| = |c_{\Lambda_x^{N_x}}| &= 0 && \text{and} \\ |c_{\Lambda_x^j} - c_{\Lambda_x^{j-1}}| &= 0 && \text{for all } j = 2, \ldots, N_x - 1. \end{aligned}$$

This implies that $c_{\Lambda_x^j} = 0$ for all j. The above argument applies to every mesh vertex, so all the coefficients c_Λ in (4.5) are zero. Hence (4.3) follows. □

4.3. Basis for the space of tangential velocities. By augmenting the basis $\mathcal{B}$ for the lowest-order case constructed above with some locally supported functions, it is possible to construct a basis for M_h of any order. Define $\mathcal{B}_e^{(k+1)}$ to be any basis for the set of polynomials on edge e of degree at most $k+1$ that vanishes at both endpoints of e. Let $\mathcal{E}_0$ denote the set of all *interior* edges of the mesh $\mathcal{T}$. Then we have the following result.

THEOREM 4.3. *The set*

$$\mathcal{B}^{(k+1)} = \left(\bigcup_{e \in \mathcal{E}_0} \mathcal{B}_e^{(k+1)} \right) \cup \mathcal{B}$$

is a basis for M_h.

Proof. It is easy to see that each element of $\mathcal{B}_e^{(k+1)}$ can be written as $[\![\phi \boldsymbol{t}]\!]$ for some $\phi \in W_h$. Hence the span of $\mathcal{B}^{(k+1)}$ is contained in M_h. As in the proof of Proposition 4.2, it now suffices to prove that

$$\operatorname{card} \mathcal{B}^{(k+1)} = \dim(M_h) \tag{4.6}$$

and that $\mathcal{B}^{(k+1)}$ is a linearly independent set. Since functions in $\mathcal{B}_e^{(k+1)}$ vanish at endpoints of their edge of support, by a minor modification of the arguments in the proof of Proposition 4.2, the linear independence of $\mathcal{B}^{(k+1)}$ follows.

To prove (4.6), observe that $\operatorname{card} \mathcal{B}_e^{(k+1)} = \dim(P_{k+1}(e)) - 2 = k$. Since

$$\operatorname{card} \mathcal{E}_0 = 3n_K - n_E,$$

where n_E denotes the number of all edges of $\mathcal{T}$ (including boundary edges), we have

$$\begin{aligned} \operatorname{card} \mathcal{B}^{(k+1)} &= \operatorname{card} \mathcal{B} + \sum_{e \in \mathcal{E}_0} \operatorname{card} \mathcal{B}_e^{(k+1)} \\ &= (3n_K - n_V) + (3n_K - n_E)k \\ &= 3n_K(k+1) - n_V - kn_E. \end{aligned} \tag{4.7}$$

Now, let us show that this equals $\dim(M_h)$. Since, by (4.4), $\dim(M_h) = \dim(W_h) - \dim(\mathcal{W}_h)$, we need to compute the dimension of the spaces W_h and $\mathcal{W}_h$. The number of degrees of freedom of $\mathcal{W}_h$ can be computed by splitting them into vertex degrees of freedom (one per vertex), edge degrees of freedom (k per edge), and interior degrees of freedom ($\dim(P^{k-2})$ per triangle):

$$\dim(\mathcal{W}_h) = n_K \left(\frac{1}{2}(k-1)k \right) + kn_E + n_V.$$

Now, since

$$\dim(W_h) = n_K \frac{1}{2}(k+2)(k+3) = n_K \left(3(k+1) + \frac{1}{2}(k-1)k \right),$$

the dimension of M_h can immediately be seen to be equal to $\operatorname{card} \mathcal{B}^{(k+1)}$, as calculated in (4.7). Hence (4.6) follows. □

5. Some implementation aspects. In this section, we first point out some general issues in implementing the Lagrange multiplier system. Afterward we specialize to a detailed discussion of the lowest-order case. We exhibit explicit expressions for all the local mappings in the lowest-order case. We also show how traditional finite element ideas such as matrix assembly through local element stiffness matrices apply for the Lagrange multiplier system, provided that the local matrices are properly defined.

5.1. The matrix equations. In order to solve for $\boldsymbol{\lambda}_h$ and p_h satisfying (3.14)–(3.15), we use the previously introduced local basis. Let $\boldsymbol{\psi}^{(i)}$, $i = 1, 2, \ldots, N_M$, be an enumeration of the basis for M_h introduced in section 4. Let $p^{(l)}$, $l = 1, 2, \ldots, N_P$, denote any basis for $\widetilde{P}_h$ with the property that a basis function is supported on just one edge. With respect to these bases, let A, B, and C denote the matrices associated to the bilinear forms $a(\cdot,\cdot)$, $b(\cdot,\cdot)$, and $c(\cdot,\cdot)$, respectively:

$$\begin{aligned} \mathsf{A}_{ij} &= (w(\boldsymbol{\psi}^{(j)}), w(\boldsymbol{\psi}^{(i)}))_\Omega, \\ \mathsf{B}_{lj} &= -(\mathbf{curl}\, \mathcal{w}(p^{(l)}), \boldsymbol{u}(\boldsymbol{\psi}^{(j)}))_\Omega, \\ \mathsf{C}_{lm} &= (\mathcal{w}(p^{(m)}), \mathcal{w}(p^{(l)}))_\Omega. \end{aligned}$$

Then the Lagrange multiplier system (3.14)–(3.15) takes the following matrix form:

$$\begin{bmatrix} \mathsf{A} & \mathsf{B}^t \\ \mathsf{B} & -\mathsf{C} \end{bmatrix} \begin{bmatrix} \Lambda \\ \mathsf{P} \end{bmatrix} = \begin{bmatrix} \mathsf{L}_1 \\ \mathsf{L}_2 \end{bmatrix}. \tag{5.1}$$

Here the Λ and P are vectors of coefficients of $\boldsymbol{\lambda}_h$ and p_h, respectively, i.e.,

$$\boldsymbol{\lambda}_h = \sum_{i=1}^{N_M} \Lambda_i\, \boldsymbol{\psi}^{(i)} \quad \text{and} \quad p_h = \sum_{l=1}^{N_P} \mathsf{P}_l\, p^{(l)}.$$

Notice that we have used a basis for the space $\widetilde{P}_h$ and not for the space P_h. In view of Proposition 4.1, we therefore anticipate the pressure to be given only up to a constant. This, of course, reflects the fact that the pressure in the Stokes system is also defined up to a constant.

To clarify how one can deal with this in practical implementations, let us examine the null space of

$$\mathsf{M} := \begin{bmatrix} \mathsf{A} & \mathsf{B}^t \\ \mathsf{B} & -\mathsf{C} \end{bmatrix}.$$

If $\mathsf{M} \left[\begin{smallmatrix} \Lambda \\ \mathsf{P} \end{smallmatrix} \right] = 0$, then

$$a(\boldsymbol{\lambda}_h, \boldsymbol{\mu}) + b(\boldsymbol{\mu}, p_h) = 0 \qquad \text{for all } \boldsymbol{\mu} \in M_h \text{ and} \tag{5.2}$$

$$b(\boldsymbol{\lambda}_h, q) - c(p_h, q) = 0 \qquad \text{for all } q \in \widetilde{P}_h. \tag{5.3}$$

Now, an immediate consequence of the definition of the liftings is that for any constant function $\kappa \in \widetilde{P}_h$

$$\mathcal{w}(\kappa) = 0 \quad \text{and} \quad \mathbf{u}(\kappa) = \mathbf{0}. \tag{5.4}$$

Any $q \in \widetilde{P}_h$ can be decomposed as $q = \mathring{q} + \bar{q}$, where $\mathring{q} \in P_h$ and $\bar{q}$ is a constant function ($\bar{q}$ equals the global mean of q). Decomposing both p_h and q this way in (5.2)–(5.3), we find that

$$\begin{aligned} a(\boldsymbol{\lambda}_h, \boldsymbol{\mu}) + b(\boldsymbol{\mu}, \mathring{p}_h) &= 0 \qquad && \text{for all } \boldsymbol{\mu} \in M_h \text{ and} \\ b(\boldsymbol{\lambda}_h, \mathring{q}) - c(\mathring{p}_h, \mathring{q}) &= 0 \qquad && \text{for all } \mathring{q} \in P_h. \end{aligned}$$

By the unique solvability of (3.14)–(3.15) asserted by Theorem 3.1, we conclude that both $\boldsymbol{\lambda}_h$ and $\mathring{p}_h$ vanish. Thus, $\mathsf{M} \left[\begin{smallmatrix} \mathsf{\Lambda} \\ \mathsf{P} \end{smallmatrix}\right] = 0$ if and only if $\boldsymbol{\lambda}_h = \mathbf{0}$ and p_h equals a constant function. The null space of M is therefore equal to the span of $\left[\begin{smallmatrix} 0 \\ 1_{\mathsf{P}} \end{smallmatrix}\right]$, where 1_{P} denotes the vector of coefficients of $\kappa \equiv 1 \in \widetilde{P}_h$. Note that if b denotes the vector $\left[\begin{smallmatrix} \mathsf{L}_1 \\ \mathsf{L}_2 \end{smallmatrix}\right]$ on the right-hand side of (5.1), then by (5.4),

$$\mathsf{b} \cdot \left[\begin{smallmatrix} 0 \\ 1_{\mathsf{P}} \end{smallmatrix}\right] = \ell_1(0) + \ell_2(\kappa) = 0.$$

Thus (5.1) has a solution, and if $\left[\begin{smallmatrix} \mathsf{\Lambda} \\ \mathsf{P} \end{smallmatrix}\right]$ is a solution, then all solutions are of the form $\left[\begin{smallmatrix} \mathsf{\Lambda} \\ \mathsf{P} \end{smallmatrix}\right] + \alpha \left[\begin{smallmatrix} 0 \\ 1_{\mathsf{P}} \end{smallmatrix}\right]$ for some $\alpha \in \mathbb{R}$.

To compute one solution to (5.1), one can now apply variations of standard techniques. For example, if one uses a Krylov space iteration such as MINRES for solving (5.1), then the nth iterate x_n is in $\mathsf{x}_0 + \operatorname{span}\{\mathsf{r}_0, \mathsf{M}\mathsf{r}_0, \mathsf{M}^2\mathsf{r}_0, \ldots, \mathsf{M}^{n-1}\mathsf{r}_0\}$, where $\mathsf{r}_0 = \mathsf{b} - \mathsf{M}\mathsf{x}_0$ and x_0 is the initial iterate. Since $\left[\begin{smallmatrix} 0 \\ 1_{\mathsf{P}} \end{smallmatrix}\right] \cdot (\mathsf{M}^j \mathsf{r}_0) = 0$ for all $j \geq 0$, if the initial iterate x_0 satisfies $\mathsf{x}_0 \cdot \left[\begin{smallmatrix} 0 \\ 1_{\mathsf{P}} \end{smallmatrix}\right] = 0$, then all further iterates x_n satisfy $\mathsf{x}_n \cdot \left[\begin{smallmatrix} 0 \\ 1_{\mathsf{P}} \end{smallmatrix}\right] = 0$. Hence by adjusting the final pressure iterate by a scalar multiple of 1_{P}, we can obtain the pressure Lagrange multiplier of zero mean. If one uses a direct solver instead, one can convert (5.1) to an invertible system by simply deleting the row and column of M corresponding to one fixed pressure degree of freedom.

5.2. The Schur complement matrix for the tangential velocity.

Many standard stable choices of mixed finite elements for Stokes equations result in a velocity-pressure discretization of the form (5.1). There is often a preference for solving the discrete system using a positive definite Schur complement system obtained by eliminating the velocity variable (the Schur complement matrix being $\mathsf{C} + \mathsf{B}\mathsf{A}^{-1}\mathsf{B}^t$), because iterative solvers for positive definite systems are well developed. However, this is not feasible for our method, because in contrast to the standard methods, our matrix A in (5.1) is not invertible in general.

But we can obtain an alternate Schur complement system for our discretization by utilizing a feature of our method that is usually not found in standard methods for Stokes equations, namely, the invertibility of the other diagonal block (C) on a subspace. More precisely, we have the following result.

Proposition 5.1. *For any $q_h \in \widetilde{P}_h$, $c(q_h, q_h) = 0$ if and only if q_h is constant.*

Proof. It is obvious from (5.4) that if q_h is constant, then $c(q_h, q_h) = 0$. To prove the converse, we observe that $c(q_h, q_h) = 0$ implies $\mathcal{W}(q_h) = 0$, so from (3.4) it follows that

$$\sum_{e \in \mathcal{E}} (q_h,\, \llbracket \boldsymbol{v} \cdot \boldsymbol{n} \rrbracket)_e = \sum_{e \in \mathcal{E}} (q_h - \bar{q}_h,\, \llbracket \boldsymbol{v} \cdot \boldsymbol{n} \rrbracket)_e = 0 \quad \text{for all } \boldsymbol{v} \in V_h, \tag{5.5}$$

where

$$\bar{q}_h = \frac{\sum_{e \in \mathcal{E}} \int_e q_h \, \mathrm{d}s}{\sum_{e \in \mathcal{E}} \int_e \mathrm{d}s}$$

is the global mean of q_h. By Proposition 4.1, there is a $\boldsymbol{v} \in V_h$ such that $q_h - \bar{q}_h = \llbracket \boldsymbol{v} \cdot \boldsymbol{n} \rrbracket$. Hence (5.5) implies that $q_h - \bar{q}_h \equiv 0$. □

The above proposition readily implies that the matrix C restricted to the orthogonal complement $1_{\mathsf{P}}^{\perp} := \{\mathsf{Q} : \mathsf{Q} \cdot 1_{\mathsf{P}} = 0\}$ is invertible. Therefore, rewriting (5.1) as

$$\begin{bmatrix} \mathsf{C} & -\mathsf{B} \\ -\mathsf{B}^t & -\mathsf{A} \end{bmatrix} \begin{bmatrix} \mathsf{P} \\ \Lambda \end{bmatrix} = - \begin{bmatrix} \mathsf{L}_2 \\ \mathsf{L}_1 \end{bmatrix} \tag{5.6}$$

and eliminating P, we get an alternate Schur complement system:

$$(\mathsf{B}^t\mathsf{C}^{-1}\mathsf{B} + \mathsf{A})\Lambda = \mathsf{L}_1 + \mathsf{B}^t\mathsf{C}^{-1}\mathsf{L}_2. \tag{5.7}$$

Note that the two applications of C^{-1} above make sense because Range$(\mathsf{B}) \subseteq 1_{\mathsf{P}}^{\perp}$ (since $1_{\mathsf{P}} \cdot \mathsf{B}\Lambda = b(\boldsymbol{\lambda}_h, \kappa) = 0$) and $\mathsf{L}_2 \in 1_{\mathsf{P}}^{\perp}$ (since $1_{\mathsf{P}} \cdot \mathsf{L}_2 = \ell_2(\kappa) = 0$). The Schur complement matrix in (5.7) is invertible because (5.6) uniquely determines Λ. Thus (5.7) is a symmetric and positive definite system, well suited to solution by minimization algorithms such as conjugate gradients.

5.3. The local mappings for lowest-order case. We now give explicit expressions for the local maps which define the Lagrange multiplier bilinear forms in the lowest-order case, i.e., $k = 0$. A simple computation gives that, on any triangle T, we have

$$\begin{aligned} w(\boldsymbol{\lambda}) &= \frac{1}{|T|}\int_{\partial T\setminus\partial\Omega} \boldsymbol{\lambda}\cdot\boldsymbol{t}\, \mathrm{d}s, & \boldsymbol{u}(\boldsymbol{\lambda}) &= \frac{1}{|T|}\int_{\partial T\setminus\partial\Omega} \boldsymbol{\lambda}\cdot\boldsymbol{t}\,(\boldsymbol{x}-\boldsymbol{x}_T)^{\perp}\,\mathrm{d}s, \\ w(g_t) &= \frac{1}{|T|}\int_{\partial T\cap\partial\Omega} g_t\,\mathrm{d}s, & \boldsymbol{u}(g_t) &= \frac{1}{|T|}\int_{\partial T\cap\partial\Omega} g_t\,(\boldsymbol{x}-\boldsymbol{x}_T)^{\perp}\,\mathrm{d}s, \\ \mathcal{W}(p) &= \boldsymbol{\mathcal{W}}_p^T \times (\boldsymbol{x}-\boldsymbol{x}_T), & \mathbf{u}(p) &= -\frac{1}{|T|}\int_T (\boldsymbol{x}-\boldsymbol{x}_T)^{\perp}\,\mathcal{W}(p)\,\mathrm{d}x, \\ \mathsf{w}(\boldsymbol{f}) &= \mathbf{w}_{\boldsymbol{f}}^T \times (\boldsymbol{x}-\boldsymbol{x}_T), & \mathbf{u}(\boldsymbol{f}) &= -\frac{1}{|T|}\int_T (\boldsymbol{x}-\boldsymbol{x}_T)^{\perp}\,\mathsf{w}(\boldsymbol{f})\,\mathrm{d}x, \end{aligned}$$

where the point $\boldsymbol{x}_T$ denotes the barycenter of the triangle T,

$$\boldsymbol{\mathcal{W}}_p^T = -\frac{1}{|T|}\int_{\partial T} p\,\boldsymbol{n}\,\mathrm{d}s, \qquad \mathbf{w}_{\boldsymbol{f}}^T = \frac{1}{|T|}\int_T \boldsymbol{f}\,\mathrm{d}x.$$

We have used standard notation for vector operations above, e.g., for vectors $\boldsymbol{a} = (a_1, a_2)$ and $\boldsymbol{b} = (b_1, b_2)$,

$$\boldsymbol{a}\times\boldsymbol{b} = a_1\,b_2 - a_2\,b_1, \qquad \boldsymbol{a}^{\perp} = (-a_2, a_1).$$

It is easy to simplify the above expressions to obtain the local mappings of our Lagrange multiplier basis functions. We first give the liftings of $\boldsymbol{\psi}_{\mathit{\Lambda}}$ for a basis function $\boldsymbol{\psi}_{\mathit{\Lambda}}$ associated with a $\mathit{\Lambda} \in \mathit{\Lambda}_h$. Let K be the triangle formed by vertices $\boldsymbol{x}_1, \boldsymbol{x}_2$, and $\boldsymbol{x}_3$. Let e_i denote the edge of K opposite to vertex $\boldsymbol{x}_i$, and let $\boldsymbol{n}_i$ denote the outward unit normal of K on edge e_i. These notations, when superscripted by L, R, $-$, or $+$, denote the corresponding geometrical parameters of adjacent triangles K^L, K^R, K_e^-, or $K \equiv K_e^+$, respectively, as illustrated in Figure 3.

Consider the basis function associated to $\mathit{\Lambda} \in \mathit{\Lambda}_h$ with vertex $\boldsymbol{x}_3$ and $\mathit{\Lambda} \subseteq \partial K$ as marked in Figure 3. The liftings $w_{\mathit{\Lambda}} := w(\boldsymbol{\psi}_{\mathit{\Lambda}})$ and $\boldsymbol{u}_{\mathit{\Lambda}} := \boldsymbol{u}(\boldsymbol{\psi}_{\mathit{\Lambda}})$ are supported on

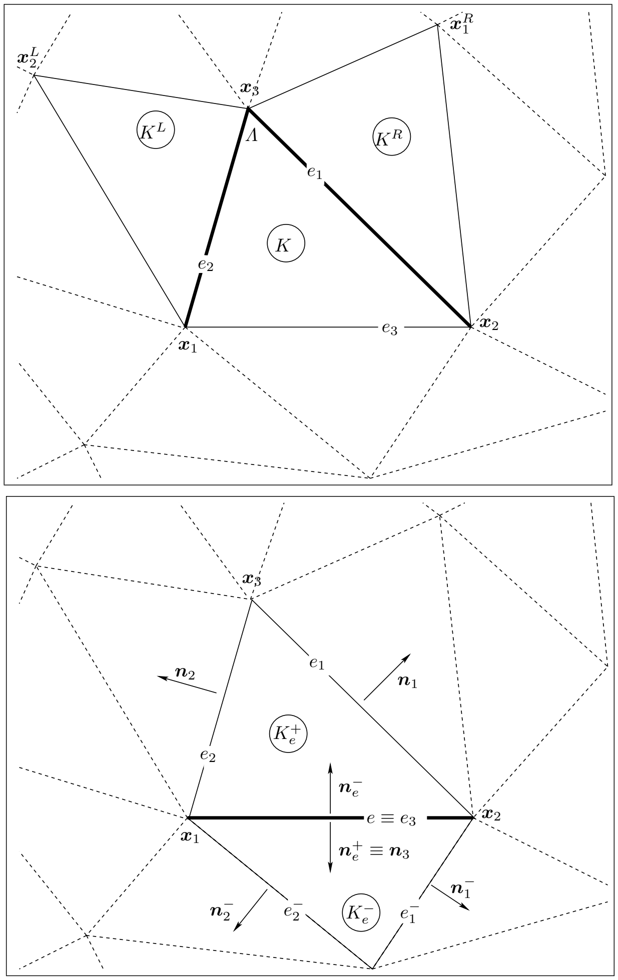

FIG. 3. *Illustration of triangles where liftings associated to a wedge Λ and an edge e are nonzero.*

$K \cup K^R \cup K^L$ and are given by

$$
\begin{aligned}
w_\Lambda &= \frac{|e_1| + |e_2|}{2|K|}, &\quad \boldsymbol{u}_\Lambda &= \frac{|e_1|}{6|K|}(\boldsymbol{x}_3 - \boldsymbol{x}_1)^\perp + \frac{|e_2|}{6|K|}(\boldsymbol{x}_3 - \boldsymbol{x}_2)^\perp &\quad &\text{on } K,\\
w_\Lambda &= -\frac{|e_2|}{2|K^L|}, &\quad \boldsymbol{u}_\Lambda &= -\frac{|e_2|}{6|K^L|}(\boldsymbol{x}_3 - \boldsymbol{x}_2^L)^\perp &\quad &\text{on } K^L,\\
w_\Lambda &= -\frac{|e_1|}{2|K^R|}, &\quad \boldsymbol{u}_\Lambda &= -\frac{|e_1|}{6|K^R|}(\boldsymbol{x}_3 - \boldsymbol{x}_1^R)^\perp &\quad &\text{on } K^R.
\end{aligned}
$$

Here, $|e|$ denotes the length of the edge e and $|K|$ denotes the area of the triangle K. The points $\boldsymbol{x}_1^R$ and $\boldsymbol{x}_2^L$ are shown in Figure 3.

Next, let us display the liftings associated with the pressure. To treat this case, consider an edge e shared by $K \equiv K_e^+$ and another triangle K_e^-. Let p_e denote the indicator function of edge e. The liftings $\mathrm{w}_e := \mathrm{w}(p_e)$ and $\mathbf{u}_e := \mathbf{u}(p_e)$ are supported on $K_e^+ \cup K_e^-$. Using the notation of Figure 3 wherein $e \equiv e_3$, we can express the

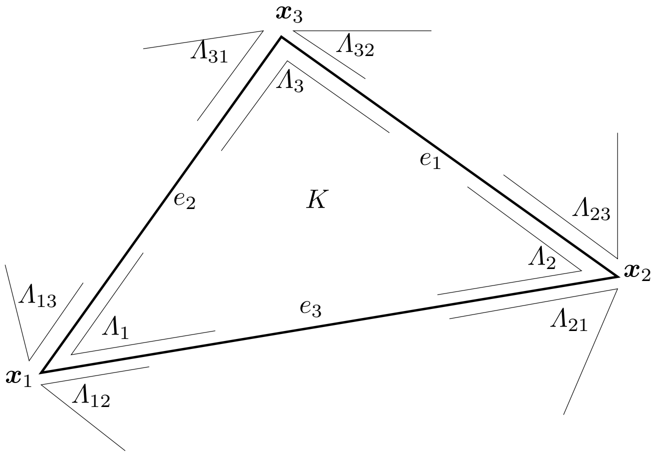

FIG. 4. *Geometry in local element matrix calculations.*

liftings on $K_e^{\pm}$ by

$$\mathsf{w}_e(\boldsymbol{x}) = \boldsymbol{\mathsf{w}}_e^{\pm} \times (\boldsymbol{x} - \boldsymbol{x}_{K_e^{\pm}}), \qquad \mathbf{u}_e(\boldsymbol{x}) = \frac{1}{36}\sum_{\ell=1}^{3} (\boldsymbol{\mathsf{w}}_e^{\pm} \cdot \boldsymbol{E}_\ell^{\pm})\boldsymbol{E}_\ell^{\pm},$$

where, in accordance with our previous notation, $\boldsymbol{x}_{K_e^{\pm}}$ denotes the barycenter of $K_e^{\pm}$,

$$\boldsymbol{\mathsf{w}}_e^{\pm} = -\frac{1}{|K_e^{\pm}|}\boldsymbol{n}_e^{\pm}|e|,$$

and $\boldsymbol{E}_\ell^{\pm} = \boldsymbol{n}_\ell^{\pm}|e_\ell^{\pm}|$. Here $\boldsymbol{n}_e^{\pm}$ is as illustrated in Figures 1 and 3.

Finally, we give formulae for the local mappings associated with the body force on the triangle K. If $\boldsymbol{f}$ is supported only on K, then $\mathsf{w}(\boldsymbol{f})$ and $\mathbf{u}(\boldsymbol{f})$ are supported only on K. Their values on K are given by

$$\mathsf{w}(\boldsymbol{f}) = \boldsymbol{\mathsf{w}} \times (\boldsymbol{x} - \boldsymbol{x}_K), \qquad \mathbf{u}(\boldsymbol{f}) = \frac{1}{36}\sum_{\ell=1}^{3} (\boldsymbol{\mathsf{w}} \cdot \boldsymbol{E}_\ell)\boldsymbol{E}_\ell,$$

where, as before, $\boldsymbol{E}_\ell = |e_\ell|\boldsymbol{n}_\ell$ and

$$\boldsymbol{\mathsf{w}} = \frac{1}{|K|}\int_K \boldsymbol{f}\,\mathrm{d}x.$$

5.4. The local element matrices for the lowest-order case. It is possible to “assemble” the global stiffness matrix of the Lagrange multiplier equations (3.14)–(3.15) just as one does for traditional finite element methods, provided that appropriate local element stiffness matrices are defined for our method. We illustrate this in the lowest-order case.

First, we enumerate the degrees of freedom local to an element as in Figure 4. In this enumeration, we include the omitted elements of $\hat{\Lambda}_h$. The omissions can be taken care of during assembly simply by not assembling the rows and columns corresponding to the omitted elements of $\hat{\Lambda}_h$ (just as one would handle zero Dirichlet boundary conditions when solving the Dirichlet problem with standard finite elements). Figure 4 shows nine elements of $\hat{\Lambda}_h$ connected to K, which we have enumerated as Λ_1, Λ_2, Λ_3, Λ_{12}, Λ_{21}, Λ_{13}, Λ_{31}, Λ_{23}, and Λ_{32}, or in short, Λ_I for all I in the index set $\mathcal{I} := \{1, 2, 3, 12, 21, 13, 31, 23, 32\}$. The local matrices are made using nine functions in M_h whose local mappings are nonzero on K, namely $\boldsymbol{\psi}_{\Lambda_I}$ for all $I \in \mathcal{I}$. The local stiffness matrix of an element K has the form

$$\begin{bmatrix} \mathsf{A}^{(K)} & (\mathsf{B}^{(K)})^t \\ \mathsf{B}^{(K)} & -\mathsf{C}^{(K)} \end{bmatrix},$$

where

$$\begin{aligned}
\mathsf{A}^{(K)}_{IJ} &= \int_K w(\boldsymbol{\psi}_{\Lambda_I})\, w(\boldsymbol{\psi}_{\Lambda_J})\, \mathrm{d}x, && I, J \in \mathcal{I},\\
\mathsf{B}^{(K)}_{LJ} &= -\int_K \mathbf{curl}\, \mathrm{w}(p_L) \cdot \boldsymbol{u}(\boldsymbol{\psi}_{\Lambda_J})\, \mathrm{d}x, && J \in \mathcal{I}, \quad L \in \{1, 2, 3\},\\
\mathsf{C}^{(K)}_{LM} &= \int_K \mathrm{w}(p_L)\, \mathrm{w}(p_M)\, \mathrm{d}x, && L, M \in \{1, 2, 3\}.
\end{aligned}$$

Here p_L denotes the characteristic function of the edge e_L in Figure 4. We can calculate the integrals above after substituting the previously given expressions for the liftings of the basis functions in the integrands.

In order to give explicit expressions for $\mathsf{A}^{(K)}$, $\mathsf{B}^{(K)}$, and $\mathsf{C}^{(K)}$, suppose that $\{i, j, k\}$ is any permutation of $\{1, 2, 3\}$. Let σ_j equal zero if the edge e_j is contained in the boundary $\partial\Omega$, and let σ_j equal one otherwise. Define

$$\begin{aligned}
W_I &= \begin{cases} \sigma_i |e_i| + \sigma_j |e_j| & \text{if } I = k,\\ -|e_k| & \text{if } I = ij, \end{cases}\\
\boldsymbol{U}_I &= \begin{cases} \sigma_i |e_i| (\boldsymbol{x}_k - \boldsymbol{x}_i)^\perp + \sigma_j |e_j| (\boldsymbol{x}_k - \boldsymbol{x}_j)^\perp & \text{if } I = k,\\ -|e_k| (\boldsymbol{x}_i - \boldsymbol{x}_k)^\perp & \text{if } I = ij. \end{cases}
\end{aligned}$$

Then,

$$\begin{aligned}
\mathsf{A}^{(K)}_{IJ} &= \frac{1}{4|K|} W_I W_J,\\
\mathsf{B}^{(K)}_{LJ} &= \frac{1}{6|K|} \boldsymbol{E}_L \cdot \boldsymbol{U}_J,\\
\mathsf{C}^{(K)}_{LM} &= \frac{1}{36|K|} \sum_{\ell=1}^{3} (\boldsymbol{E}_L \cdot \boldsymbol{E}_\ell)(\boldsymbol{E}_M \cdot \boldsymbol{E}_\ell),
\end{aligned}$$

where, as before, $\boldsymbol{E}_L = \boldsymbol{n}_L |e_L|$ for all $L \in \{1, 2, 3\}$. With these local matrices, one can assemble all the global matrices of our method as simply as those of any other finite element method.

6. Conclusion.

We have developed new hybridization techniques which, when applied to a well-known conforming mixed method for the Stokes problem, result in a new "tangential velocity-pressure" discretization. The advantages of the new method include fewer globally coupled degrees of freedom and numerical velocity approximations that satisfy the incompressibility condition exactly. Our results are achieved by using the methodology introduced in [8] to study hybridized mixed methods for second-order elliptic problems.

In a forthcoming sequel [9], we will discuss the extension of the ideas here to the Stokes problem in three space dimensions, variable degree incompressible finite elements, and other boundary conditions.

INCOMPRESSIBLE FINITE ELEMENTS VIA HYBRIDIZATION. PART II: THE STOKES SYSTEM IN THREE SPACE DIMENSIONS[*]

BERNARDO COCKBURN[†] AND JAYADEEP GOPALAKRISHNAN[‡]

Abstract. We introduce a method that gives exactly incompressible velocity approximations to Stokes flow in three space dimensions. The method is designed by extending the ideas in Part I [B. Cockburn and J. Gopalakrishnan, *SIAM J. Numer. Anal.*, 43 (2005), pp. 1627–1650] of this series, where the Stokes system in two space dimensions was considered. Thus we hybridize a vorticity-velocity formulation to obtain a new mixed method coupling approximations of tangential velocity and pressure on mesh faces. Once this relatively small tangential velocity-pressure system is solved, it is possible to recover a globally divergence-free numerical approximation of the fluid velocity, an approximation of the vorticity whose tangential component is continuous across interelement boundaries, and a discontinuous numerical approximation of the pressure. The main difference between our method here and that of the two-dimensional case treated in Part I is in the use of Nédélec elements, which necessitates development of new hybridization techniques. We also generalize the method to allow for varying polynomial degrees on different mesh elements and to incorporate certain nonstandard but physically relevant boundary conditions.

1. Introduction.

This is a sequel to our paper [7] in which we introduced a new hybridized method for the Stokes equations in two space dimensions. Here we generalize the ideas presented in [7] to the Stokes system in three space dimensions. We also extend the method to allow variable degrees of approximation on different mesh elements. As in [7], the three-dimensional version of our method simultaneously yields an exactly divergence-free numerical approximation of the fluid velocity and a continuous numerical approximation of the vorticity. A discontinuous numerical approximation of the pressure can also be recovered separately. These three approximations are obtained in an element-by-element fashion after one global system for certain Lagrange multipliers arising from the hybridization is solved. This global system represents a new "tangential velocity-pressure" discretization of the Stokes system on the mesh faces because the Lagrange multipliers are approximations to the pressure and tangential fluid velocity on element interfaces.

We are hybridizing a mixed formulation that has previously appeared in the literature [9, 14] (cf. [1, 3]). However, the previous works resort to introduction of a stream function variable to obtain exactly divergence-free numerical velocities. This approach is beset with significant difficulties in three dimensions: (i) While the stream function is a scalar function in two dimensions, in three dimensions it is a vector function, so its introduction into the method, as in [14], leads to a significant increase in

number of degrees of freedom. (ii) The stream function is not uniquely defined. While in two dimensions it is defined up to a constant, in three dimensions one has to impose a nontrivial "gauge condition." (iii) The definition of the stream function must take into account the topology of the three-dimensional domain. For domains that are not simply connected, one must find "cuts" and base the definition of finite element spaces for the stream function on them (see [1]). Finding such cuts in automatic computation is not easy. (iv) Formulations involving the stream function alone lead to fourth-order problems (see, e.g., [1, 9]) and hence to badly conditioned matrices. Notwithstanding these difficulties, the use of the stream function has hitherto been the only successful approach in obtaining exactly incompressible approximations of all orders in three dimensions. The search for exactly incompressible numerical approximations to Stokes flow has a rich history. References to some previous attempts can be found in [4, 7, 11].

All the above-mentioned difficulties disappear in our approach via hybridization. Because we do not introduce the stream function, our method requires nothing special to be done when the computational domain has nontrivial topology. For the same reason we never encounter a fourth-order operator—our matrices represent discretizations of operators of second order only. Moreover, while the introduction of the stream function results in an increase in degrees of freedom in some of the previous works, our approach using hybridization actually results in a decrease in degrees of freedom, as we shall see in section 3.

As we move from two to three space dimensions, the main difference we encounter is in the treatment of vorticity. When considering finite element approximations to vorticity, we now have to use the $H(\mathbf{curl}\,,\Omega)$-conforming Nédélec elements [13], while in two dimensions we used the simpler $H^1(\Omega)$-conforming finite elements. However, the velocity approximation is treated in exactly the same way as in the two-dimensional case—it continues to be in an $H(\mathrm{div},\Omega)$-conforming subspace of exactly divergence-free functions. Another important similarity between the two- and three-dimensional cases is in the structure of the method and equations, so we are able to easily adapt the elimination procedure which we developed in [7] to three dimensions. The result is a Lagrange multiplier system that is completely analogous to the two-dimensional case.

The introduction of Nédélec spaces necessitates development of new hybridization techniques in three dimensions. Indeed, the Nédélec space has edge degrees of freedom, and none of the existing hybridization techniques handle them. To elaborate, consider the following sequence of spaces:

$$H^1(\Omega)/\mathbb{R} \xrightarrow{\mathbf{grad}} H(\mathbf{curl}\,,\Omega) \xrightarrow{\mathbf{curl}} H(\mathrm{div},\Omega) \xrightarrow{\mathrm{div}} L^2(\Omega).$$

As we traverse the sequence from right to left, the continuity conditions on the spaces become more complex. Finite element subspaces of $H(\mathrm{div},\Omega)$ consist of functions whose normal component is continuous across element interfaces. Hybridization techniques to relax such continuity are well known, and they are the basis for the hybridized Raviart–Thomas and Brezzi–Douglas–Marini (BDM)-type methods [2, 5]. Such hybridizations relaxed continuity of finite element subspaces across interior mesh faces using traces from (just) two elements sharing an interior mesh face. However, once we move on to finite element subspaces of $H(\mathbf{curl}\,,\Omega)$, the continuity constraints are more complicated, as reflected by the fact that these spaces have edge degrees of freedom which are connected to multiple elements. Moving further left to $H^1(\Omega)$, we find finite element subspaces having vertex degrees of freedom, adding another layer of complexity. Since all previously known hybridization techniques relaxed continuity across mesh faces, we find a widespread belief that methods using edge and vertex degrees of freedom are not amenable to hybridization. In this paper, we dispel this belief by hybridizing a method that uses Nédélec spaces having edge degrees of freedom. It is also possible to hybridize methods that use $H^1(\Omega)$-subspaces, as we demonstrated in [7].

We make two other extensions in this paper. The first extends to the Stokes system what was done for second-order elliptic equations in [6]. Thus, we exploit the ease of construction of variable degree methods via hybridization to give a variable degree version of the original mixed method. Our hybridized variable degree method does not require one to implement transition elements. This is quite convenient considering that transitional Nédélec elements are not trivial to implement. Second, we show how one can incorporate boundary conditions involving the pressure and tangential vorticity into our method. Although such boundary conditions are physically relevant, few methods are known that can incorporate them naturally.

We have kept the organization of this paper very similar to that of Part I [7] to render the analogies and differences with the two-dimensional case transparent. We introduce the variable degree method in section 2. In section 3, we briefly present the elimination strategy to obtain a reduced Lagrange multiplier system. A computable basis for the space of Lagrange multipliers of variable degree is given in section 4, and full details of the lowest-order case are given in section 5. Finally, in section 6, we show how to incorporate other boundary conditions.

2. The variable degree hybridized mixed method.

The three-dimensional Stokes problem is to find a fluid velocity field $\boldsymbol{u}$ and pressure p satisfying

$$-\boldsymbol{\Delta u} + \mathbf{grad}\, p = \boldsymbol{f} \qquad \text{on } \Omega, \tag{2.1}$$

$$\operatorname{div} \boldsymbol{u} = 0 \qquad \text{on } \Omega, \tag{2.2}$$

$$\boldsymbol{u} = \boldsymbol{g} \qquad \text{on } \partial\Omega. \tag{2.3}$$

Here we assume that Ω is a bounded connected domain with polyhedral boundary $\partial\Omega$ such that Ω lies on only one side of $\partial\Omega$ locally, the data $\boldsymbol{f}$ is in $L^2(\Omega)^3$, and $\boldsymbol{g} \in H^{1/2}(\partial\Omega)^3$. We do not assume that Ω is simply connected. We also do not assume that $\partial\Omega$ is connected. We require the data $\boldsymbol{g}$ to satisfy the compatibility condition

$$(g_n, 1)_{\partial\Omega} = 0,$$

where $g_n = \boldsymbol{g} \cdot \boldsymbol{n}$ and $\boldsymbol{n}$ is the outward unit normal on $\partial\Omega$. Under this assumption, it is well known that the Stokes problem has a unique solution.

Let us reformulate the Stokes problem by introducing vorticity $\boldsymbol{\omega} = \mathbf{curl}\, \boldsymbol{u}$. Using the identity

$$-\boldsymbol{\Delta u} = \mathbf{curl}\, \mathbf{curl}\, \boldsymbol{u} - \mathbf{grad} \operatorname{div} \boldsymbol{u},$$

the Stokes system (2.1)–(2.3) can be rewritten as

$$\boldsymbol{\omega} - \mathbf{curl}\, \boldsymbol{u} = 0 \qquad \text{on } \Omega, \tag{2.4}$$

$$\mathbf{curl}\, \boldsymbol{\omega} + \mathbf{grad}\, p = \boldsymbol{f} \qquad \text{on } \Omega, \tag{2.5}$$

$$\operatorname{div} \boldsymbol{u} = 0 \qquad \text{on } \Omega, \tag{2.6}$$

$$\boldsymbol{u}_{\mathsf{T}} = \boldsymbol{g}_{\mathsf{T}} \qquad \text{on } \partial\Omega, \tag{2.7}$$

$$\boldsymbol{u} \cdot \boldsymbol{n} = \boldsymbol{g} \cdot \boldsymbol{n} \qquad \text{on } \partial\Omega, \tag{2.8}$$

where we have split (2.3) into two equations, one in the direction of the outward unit normal $\boldsymbol{n}$ on $\partial\Omega$, and the other in the tangent plane; i.e., $\boldsymbol{g}_{\mathsf{T}} := \boldsymbol{g} - (\boldsymbol{g}\cdot\boldsymbol{n})\boldsymbol{n}$ denotes the tangential component of $\boldsymbol{g}$.

There is a well-known weak problem based on this reformulation. Define $\mathcal{W} = H(\mathbf{curl}\,,\Omega)$ and

$$\mathcal{V}(b) = \{\boldsymbol{v} \in H(\mathrm{div},\Omega) : \mathrm{div}\,\boldsymbol{v} = 0 \text{ and } \boldsymbol{v}\cdot\boldsymbol{n}|_{\partial\Omega} = b\}$$

for any $b \in H^{-1/2}(\partial\Omega)$. Then $(\boldsymbol{\omega},\boldsymbol{u})$ is the only element of $\mathcal{W}\times\mathcal{V}(g_n)$ satisfying

$$(2.9) \qquad (\boldsymbol{\omega},\boldsymbol{\tau})_\Omega - (\boldsymbol{u},\mathbf{curl}\,\boldsymbol{\tau})_\Omega = (\boldsymbol{g}_{\mathsf{T}},\boldsymbol{\tau})_{\partial\Omega} \qquad \text{for all } \boldsymbol{\tau}\in\mathcal{W},$$

$$(2.10) \qquad (\boldsymbol{v},\mathbf{curl}\,\boldsymbol{\omega})_\Omega = (\boldsymbol{f},\boldsymbol{v})_\Omega \qquad \text{for all } \boldsymbol{v}\in\mathcal{V}(0).$$

Here $(\cdot,\cdot)_\Omega$ denotes the $L^2(\Omega)$ (or $L^2(\Omega)^3$) innerproduct. Note that the pressure has disappeared in this mixed formulation.

One way to develop a hybridized mixed method that discretizes (2.9)–(2.10) is to first approximate the weak formulation by a conforming mixed method and then relax the continuity constraints of the discrete spaces. Here, we motivate the construction of our variable degree hybridized mixed method (2.9)–(2.10) by another equivalent approach using the differential problem (2.4)–(2.8). Suppose the domain Ω is meshed by a tetrahedral mesh $\mathcal{T}$ (satisfying the usual finite element assumptions). To each tetrahedron K we associate a degree $k(K)$ and the following pair of spaces:

$$\begin{aligned} W(K) &= P_{k(K)}(K)^3 \oplus S_{k(K)+1}(K),\\ V(K) &= \{\boldsymbol{v}\in P_{k(K)}(K)^3 :\ \mathrm{div}\,\boldsymbol{v} = 0\}, \end{aligned}$$

where $P_\ell(K)^3$ denotes the set of vector functions whose (three) components are polynomials of degree at most ℓ and $S_\ell(K)$ is the set of all vector functions $\boldsymbol{p}_\ell(\boldsymbol{x})$ whose components are homogeneous polynomials of degree ℓ satisfying $\boldsymbol{p}_\ell(\boldsymbol{x})\cdot\boldsymbol{x} = 0$. Define the variable degree Nédélec space with no continuity conditions by

$$W_h = \{\boldsymbol{w} : \boldsymbol{w}|_K \in W(K) \text{ for all } K\in\mathcal{T}\}.$$

While the vorticity is approximated in W_h, the velocity is approximated in

$$V_h = \{\boldsymbol{v} : \boldsymbol{v}|_K \in V(K) \text{ for all } K\in\mathcal{T}\}.$$

The numerical method is motivated by requiring that (2.4) and (2.5) be satisfied weakly on each element K: Multiplying (2.4) and (2.5) by test functions $\boldsymbol{\tau}\in W(K)$ and $\boldsymbol{v}\in V(K)$ and integrating by parts,

$$\begin{aligned} (\boldsymbol{\omega},\boldsymbol{\tau})_K - (\boldsymbol{u},\mathbf{curl}\,\boldsymbol{\tau})_K - (\boldsymbol{u}_{\mathsf{T}},\boldsymbol{n}\times\boldsymbol{\tau})_{\partial K} &= 0,\\ (\boldsymbol{v},\mathbf{curl}\,\boldsymbol{\omega})_K + (\boldsymbol{v}\cdot\boldsymbol{n},p)_{\partial K} &= (\boldsymbol{f},\boldsymbol{v})_K, \end{aligned}$$

where $\boldsymbol{u}_{\mathsf{T}}$ denotes the tangential component of $\boldsymbol{u}$ on ∂K. Therefore we require that the discrete approximations to vorticity and velocity, namely, $\boldsymbol{\omega}_h$ and $\boldsymbol{u}_h$, respectively, satisfy

$$\begin{aligned} (\boldsymbol{\omega}_h,\boldsymbol{\tau})_K - (\boldsymbol{u}_h,\mathbf{curl}\,\boldsymbol{\tau})_K - (\boldsymbol{\lambda}_h,\boldsymbol{n}\times\boldsymbol{\tau})_{\partial K} &= 0,\\ (\boldsymbol{v},\mathbf{curl}\,\boldsymbol{\omega}_h)_K + (\boldsymbol{v}\cdot\boldsymbol{n},p_h)_{\partial K} &= (\boldsymbol{f},\boldsymbol{v})_K, \end{aligned}$$

where we have introduced two additional approximations $\boldsymbol{\lambda}_h \approx \boldsymbol{u}_{\mathsf{T}}$ and $p_h \approx p$, which we shall call Lagrange multiplier approximations of the tangential velocity and pressure, respectively.

The description of the method is completed by adding appropriate continuity conditions for $\boldsymbol{\omega}_h$ and $\boldsymbol{u}_h$ at the element interfaces. Since $\boldsymbol{\omega}_h$ and $\boldsymbol{u}_h$ are to approximate $\boldsymbol{\omega}$ and $\boldsymbol{u}$ in (2.9)–(2.10), the functional setting of (2.9)–(2.10) clarifies the continuity constraints to be put on $\boldsymbol{\omega}_h$ and $\boldsymbol{u}_h$. To make this precise, let us introduce some more notation: Let $\mathcal{F}$ denote the set of all faces of the triangulation $\mathcal{T}$. On every interior face in $F \in \mathcal{F}$ shared by two tetrahedra K_F^+ and K_F^- we define

$$\begin{aligned} [\![\boldsymbol{v}\cdot\boldsymbol{n}]\!]_F &= \boldsymbol{v}_F^+\cdot\boldsymbol{n}_F^+ + \boldsymbol{v}_F^-\cdot\boldsymbol{n}_F^-,\\ [\![\boldsymbol{n}\times\boldsymbol{v}]\!]_F &= \boldsymbol{n}_F^+\times\boldsymbol{v}_F^+ + \boldsymbol{n}_F^-\times\boldsymbol{v}_F^-, \end{aligned}$$

where $\boldsymbol{n}_F^+$ and $\boldsymbol{n}_F^-$ denote the outward unit normals on the boundaries of K_F^+ and K_F^-, respectively, and $\boldsymbol{v}_F^\pm(\boldsymbol{x}) = \lim_{\epsilon\downarrow 0}\boldsymbol{v}(\boldsymbol{x}-\epsilon\,\boldsymbol{n}_F^\pm)$. On faces $e \subset \partial\Omega$ we set

$$[\![\boldsymbol{v}\cdot\boldsymbol{n}]\!]_F = \boldsymbol{v}|_{\partial\Omega}\cdot\boldsymbol{n} \quad\text{and}\quad [\![\boldsymbol{n}\times\boldsymbol{v}]\!]_F = 0.$$

By $[\![\boldsymbol{v}\cdot\boldsymbol{n}]\!]$ (without subscripts) we mean the function that is defined on the union of all the faces and equals $[\![\boldsymbol{v}\cdot\boldsymbol{n}]\!]_F$ on each face $e \in \mathcal{F}$. The function $[\![\boldsymbol{n}\times\boldsymbol{v}]\!]$ is similarly defined. Then here are our spaces of Lagrange multipliers:

$$P_h = \{p: \quad p = [\![\boldsymbol{v}\cdot\boldsymbol{n}]\!] \text{ for some } \boldsymbol{v}\in V_h\}, \tag{2.11}$$

$$M_h = \{\boldsymbol{\mu}: \quad \boldsymbol{\mu} = [\![\boldsymbol{n}\times\boldsymbol{v}]\!] \text{ for some } \boldsymbol{v}\in W_h\}. \tag{2.12}$$

They are ideal for imposing the natural continuity conditions of the Sobolev spaces $\mathcal{W}$ and $\mathcal{V}$ on the discrete approximations $\boldsymbol{\omega}_h$ and $\boldsymbol{v}_h$; e.g.,

$$\sum_{F\in\mathcal{F}} (\boldsymbol{\mu},\, [\![\boldsymbol{n}\times\boldsymbol{\omega}_h]\!])_F = 0 \quad \text{for all } \boldsymbol{\mu}\in M_h$$

implies that $\boldsymbol{\omega}_h \in H(\mathbf{curl}\,)$.

Thus we have motivated the following definition of our variable degree hybridized mixed method: Find $(\boldsymbol{\omega}_h, \boldsymbol{u}_h, \boldsymbol{\lambda}_h, p_h) \in W_h \times V_h \times M_h \times P_h$ satisfying

$$(\boldsymbol{\omega}_h, \boldsymbol{\tau}_h)_\Omega - (\boldsymbol{u}_h, \mathbf{curl}\,\boldsymbol{\tau}_h)_\Omega - \sum_{F\in\mathcal{F}} (\boldsymbol{\lambda}_h,\, [\![\boldsymbol{n}\times\boldsymbol{\tau}_h]\!])_F = (\boldsymbol{g}_{\mathsf{T}}, \boldsymbol{n}\times\boldsymbol{\tau}_h)_{\partial\Omega}, \tag{2.13}$$

$$(\boldsymbol{v}_h, \mathbf{curl}\,\boldsymbol{\omega}_h)_\Omega + \sum_{F\in\mathcal{F}} (p_h,\, [\![\boldsymbol{v}_h\cdot\boldsymbol{n}]\!])_F = (\boldsymbol{f}, \boldsymbol{v}_h)_\Omega, \tag{2.14}$$

$$\sum_{F\in\mathcal{F}} (q_h,\, [\![\boldsymbol{u}_h\cdot\boldsymbol{n}]\!])_F = (g_n, q_h)_{\partial\Omega}, \tag{2.15}$$

$$\sum_{F\in\mathcal{F}} (\boldsymbol{\mu}_h,\, [\![\boldsymbol{n}\times\boldsymbol{\omega}_h]\!])_F = 0 \tag{2.16}$$

for all $\boldsymbol{\tau}_h \in W_h$, $\boldsymbol{v}_h \in V_h$, $q_h \in P_h$, and $\boldsymbol{\mu}_h \in M_h$.

Proposition 2.1. *There is a unique solution for the system* (2.13)–(2.16).

Proof. Since the system is square, we need only verify that when $\boldsymbol{f}$ and $\boldsymbol{g}$ are zero, all solution components vanish. Zero data implies that $\boldsymbol{\omega}_h$ and $\boldsymbol{u}_h$ lie in the following two spaces, respectively:

$$\mathcal{W}_h = W_h \cap \mathcal{W}, \qquad \mathcal{V}_h(0) = V_h \cap \mathcal{V}(0).$$

Therefore we find from (2.13) and (2.14) that

$$(\boldsymbol{\omega}_h, \boldsymbol{\tau}_h)_\Omega - (\boldsymbol{u}_h, \mathbf{curl}\, \boldsymbol{\tau}_h)_\Omega = 0 \quad \text{for all } \boldsymbol{\tau}_h \in \mathcal{W}_h, \tag{2.17}$$

$$(\boldsymbol{v}_h, \mathbf{curl}\, \boldsymbol{\omega}_h)_\Omega = 0 \quad \text{for all } \boldsymbol{v}_h \in \mathcal{V}_h(0). \tag{2.18}$$

Note that for the mixed method (2.17)–(2.18) to make sense, the spaces therein must be nonempty, as we have tacitly assumed. Setting $\boldsymbol{v}_h = \boldsymbol{u}_h$ in (2.18) and adding these equations, one immediately finds that $(\boldsymbol{\omega}_h, \boldsymbol{\tau}_h)_\Omega = 0$ for all $\boldsymbol{\tau}_h \in \mathcal{W}_h$, and thus $\boldsymbol{\omega}_h = 0$. Now that $\boldsymbol{\omega}_h$ vanishes from (2.17), we have

$$(\boldsymbol{u}_h, \mathbf{curl}\, \boldsymbol{\tau}_h)_\Omega = 0 \quad \text{for all } \boldsymbol{\tau}_h \in \mathcal{W}_h. \tag{2.19}$$

By a well-known property of the Nédélec space, we have that on each element **curl** $W(K) = V(K)$. Moreover, $[\![\boldsymbol{n} \cdot \mathbf{curl}\, \boldsymbol{w}]\!]_F = 0$ whenever $[\![\boldsymbol{n} \times \boldsymbol{w}]\!]_F = 0$ for every interior mesh face F. Hence, it is easy to see that for the variable degree spaces $\mathcal{W}_h$ and $\mathcal{V}_h(0)$ we have (cf. [9, Lemma III.5.1])

$$\mathcal{V}_h(0) \subset \mathbf{curl}\ \mathcal{W}_h.$$

Therefore, in (2.19) we can choose $\boldsymbol{\tau}_h$ such that $\mathbf{curl}\, \boldsymbol{\tau}_h = \boldsymbol{u}_h$, and thus $\boldsymbol{u}_h$ vanishes. Finally, since $\boldsymbol{\omega}_h$ and $\boldsymbol{u}_h$ vanish from (2.13) and (2.14), we find that the Lagrange multipliers $\boldsymbol{\lambda}_h$ and p_h must vanish as well. □

In the uniform degree case, our hybridized mixed method is equivalent to the mixed method considered in [14] in the following sense: Our $\boldsymbol{\omega}_h$ and $\boldsymbol{u}_h$ coincide with vorticity and velocity approximations discussed there. Therefore, the error estimates proven there apply to our solution components $\boldsymbol{\omega}_h$ and $\boldsymbol{u}_h$. It may appear at this point that our method has too many unknowns. But as we shall see in the next section, it is possible to eliminate all but the Lagrange multiplier variables from (2.13)–(2.16), thus making our formulation more attractive.

Before proceeding to the above-mentioned elimination, let us note one advantage that results from hybridization: Since hybridization provides an approximation to the pressure on the mesh faces through the Lagrange multiplier p_h, we can compute an approximation to the pressure inside mesh elements in a completely local (element-by-element) fashion. Borrowing an idea from [4], we define the pressure π_h on the triangle K as the element of $P_{k(K)}(K)$ such that

$$-(\pi_h, \operatorname{div} \boldsymbol{v})_K = (\boldsymbol{f}, \boldsymbol{v})_K - (\mathbf{curl}\, \boldsymbol{\omega}_h, \boldsymbol{v})_K - (\boldsymbol{v} \cdot \boldsymbol{n}, p_h)_{\partial K} \tag{2.20}$$

for all $\boldsymbol{v}$ in $P_{k(K)}(K)^3 + \boldsymbol{x}\, P_{k(K)}(K)$, where $\boldsymbol{n}$ denotes the outward unit normal to K. That (2.20) uniquely defines π_h follows from two facts: (i) div : $P_{k(K)}(K)^3 + \boldsymbol{x}\, P_{k(K)}(K) \mapsto P_{k(K)}(K)$ is a surjection, and (ii) if $\operatorname{div} \boldsymbol{v} = 0$ for a $\boldsymbol{v}$ in $P_{k(K)}(K)^3 + \boldsymbol{x}\, P_{k(K)}(K)$, then $\boldsymbol{v} \in P_{k(K)}(K)^3$ and the right-hand side of (2.20) is zero by the definition of the hybridized method. Thus our method can simultaneously provide approximations to the velocity, vorticity, and pressure.

3. A characterization of the Lagrange multipliers.

3.1. The Lagrange multiplier equation. We now show how one can eliminate the vorticity as well as the velocity variables from our hybridized mixed method (2.13)–(2.16) and arrive at a system of equations involving the Lagrange multipliers alone. Our arguments here are a straightforward generalization of the arguments in [7].

We define *lifting* maps that map functions defined on element interfaces into functions on Ω: Define $(\boldsymbol{w}(\boldsymbol{\lambda}), \boldsymbol{u}(\boldsymbol{\lambda})) \in W_h \times V_h$ and $(\mathsf{w}(p), \mathbf{u}(p)) \in W_h \times V_h$ element-by-element as follows:

$$(\boldsymbol{w}(\boldsymbol{\lambda}), \boldsymbol{\tau})_K - (\boldsymbol{u}(\boldsymbol{\lambda}), \mathbf{curl}\,\boldsymbol{\tau})_K = (\boldsymbol{\lambda}, \boldsymbol{n} \times \boldsymbol{\tau})_{\partial K} \qquad \text{for all } \boldsymbol{\tau} \in W(K), \tag{3.1}$$

$$(\boldsymbol{v}, \mathbf{curl}\ \boldsymbol{w}(\boldsymbol{\lambda}))_K = 0 \qquad \text{for all } \boldsymbol{v} \in V(K), \tag{3.2}$$

$$(\mathsf{w}(p), \boldsymbol{\tau})_K - (\mathbf{u}(p), \mathbf{curl}\,\boldsymbol{\tau})_K = 0 \qquad \text{for all } \boldsymbol{\tau} \in W(K), \tag{3.3}$$

$$(\boldsymbol{v}, \mathbf{curl}\ \mathsf{w}(p))_K = -(p, \boldsymbol{v} \cdot \boldsymbol{n})_{\partial K} \qquad \text{for all } \boldsymbol{v} \in V(K). \tag{3.4}$$

In addition, define $(\mathbf{w}(\boldsymbol{f}), \mathbf{u}(\boldsymbol{f}))$ and $(\boldsymbol{w}(\boldsymbol{g}_{\mathsf{T}}), \boldsymbol{u}(\boldsymbol{g}_{\mathsf{T}}))$ in $W_h \times V_h$ by

$$(\mathbf{w}(\boldsymbol{f}), \boldsymbol{\tau})_K - (\mathbf{u}(\boldsymbol{f}), \mathbf{curl}\,\boldsymbol{\tau})_K = 0 \qquad \text{for all } \boldsymbol{\tau} \in W(K), \tag{3.5}$$

$$(\boldsymbol{v}, \mathbf{curl}\ \mathbf{w}(\boldsymbol{f}))_K = (\boldsymbol{f}, \boldsymbol{v})_K \qquad \text{for all } \boldsymbol{v} \in V(K), \tag{3.6}$$

$$(\boldsymbol{w}(\boldsymbol{g}_{\mathsf{T}}), \boldsymbol{\tau})_K - (\boldsymbol{u}(\boldsymbol{g}_{\mathsf{T}}), \mathbf{curl}\,\boldsymbol{\tau})_K = (\boldsymbol{g}_{\mathsf{T}}, \boldsymbol{n} \times \boldsymbol{\tau})_{\partial K \cap \partial\Omega} \qquad \text{for all } \boldsymbol{\tau} \in W(K), \tag{3.7}$$

$$(\boldsymbol{v}, \mathbf{curl}\ \boldsymbol{w}(\boldsymbol{g}_{\mathsf{T}}))_K = 0 \qquad \text{for all } \boldsymbol{v} \in V(K). \tag{3.8}$$

Note that all of the above local problems are uniquely solvable. Hence, these local maps are well defined.

The main result of this section characterizes the Lagrange multipliers as the unique solution of a variational equation involving the bilinear forms

$$\begin{aligned} a(\boldsymbol{\lambda}, \boldsymbol{\mu}) &= (\boldsymbol{w}(\boldsymbol{\lambda}), \boldsymbol{w}(\boldsymbol{\mu}))_{\Omega}, \\ c(p, q) &= (\mathsf{w}(p), \mathsf{w}(q))_{\Omega}, \\ b(\boldsymbol{\mu}, p) &= -\sum_{K \in \mathcal{T}} (\boldsymbol{u}(\boldsymbol{\mu}), \mathbf{curl}\ \mathsf{w}(p))_K \end{aligned}$$

and the functionals

$$\ell_1(\boldsymbol{\mu}) = (\boldsymbol{f}, \boldsymbol{u}(\boldsymbol{\mu}))_{\Omega} - (\boldsymbol{g}_{\mathsf{T}}, \boldsymbol{w}(\boldsymbol{\mu}))_{\partial\Omega}, \tag{3.9}$$

$$\ell_2(q) = (\boldsymbol{f}, \mathbf{u}(q))_{\Omega} + (g_n, q)_{\partial\Omega} - (\boldsymbol{g}_{\mathsf{T}}, \mathsf{w}(q))_{\partial\Omega}. \tag{3.10}$$

THEOREM 3.1. *The Lagrange multiplier* $(\boldsymbol{\lambda}_h, p_h) \in M_h \times P_h$ *of the hybridized mixed method* (2.13)–(2.16) *is the unique solution of*

$$a(\boldsymbol{\lambda}_h, \boldsymbol{\mu}) + b(\boldsymbol{\mu}, p_h) = \ell_1(\boldsymbol{\mu}) \qquad \textit{for all } \boldsymbol{\mu} \in M_h \textit{ and} \tag{3.11}$$

$$b(\boldsymbol{\lambda}_h, q) - c(p_h, q) = \ell_2(q) \qquad \textit{for all } q \in P_h. \tag{3.12}$$

Moreover, the solution components ω_h *and* $\boldsymbol{u}_h$ *of the hybridized mixed method* (2.13)–(2.16) *can be determined locally as follows:*

$$\omega_h = \boldsymbol{w}(\boldsymbol{\lambda}_h) + \mathsf{w}(p_h) + \boldsymbol{w}(g_t) + \mathbf{w}(\boldsymbol{f}), \tag{3.13}$$

$$\boldsymbol{u}_h = \boldsymbol{u}(\boldsymbol{\lambda}_h) + \mathbf{u}(p_h) + \boldsymbol{u}(g_t) + \mathbf{u}(\boldsymbol{f}). \tag{3.14}$$

The proof of this theorem proceeds exactly along the lines of the proof of the analogous theorem in [7].

4. Local bases for Lagrange multipliers.

It is clear from section 3 that one should, in practice, implement our hybridized mixed method not in its direct form (2.13)–(2.16), but rather in the reduced form (3.11)–(3.12). This requires a computable basis for the Lagrange multiplier spaces M_h and P_h. Local bases for W_h and V_h are obvious as they do not have continuity constraints across mesh faces. But bases for the Lagrange multiplier spaces are not immediate from their definition, so we develop local bases for P_h and M_h in this section. Note that the construction of the basis for the space of tangential velocities in three space dimensions differs significantly from that of the two-dimensional case.

4.1. The space of interface pressures.

We begin with a characterization of the space of pressure Lagrange multipliers arising from the first hybridization. To state it, define

$$k(F) = \max\{k(K) : K \in \mathfrak{T} \text{ and } K \text{ has } F \text{ as a face}\} \tag{4.1}$$

for every $F \in \mathfrak{F}$, and set $P(F)$ equal to the space of polynomials of degree at most $k(F)$ on the face F.

PROPOSITION 4.1. *The space P_h defined in* (2.11) *is characterized by*

$$P_h = \left\{ p : p|_F \in P(F) \textit{ for all } F \in \mathfrak{F} \textit{ and } \sum_{F\in\mathfrak{F}} (p,1)_F = 0 \right\}.$$

Note that the use of variable degree spaces requires the pressure Lagrange multiplier to have the *maximum* of the degrees from adjacent elements.

The proof of this proposition is quite similar to that of the two-dimensional case considered in [7]. The two main steps of the proof are as follows. In the first, one constructs a local extension $\widetilde{\boldsymbol{v}}_h$ of any given $p \in P_h$ into the Raviart–Thomas space

$$R_h = \{\boldsymbol{r} : \boldsymbol{r}|_K = \boldsymbol{x}p(\boldsymbol{x}) + \boldsymbol{q} \text{ for some } p \in P_{k(K)}(K) \text{ and } \boldsymbol{q} \in P_{k(K)}(K)^3\}$$

such that $[\![\widetilde{\boldsymbol{v}}_h \cdot \boldsymbol{n}]\!] = p$. In the second, one uses a global correction $\boldsymbol{z}_h \in R_h \cap H_0(\text{div}, \Omega)$ such that $\boldsymbol{v}_h = \widetilde{\boldsymbol{v}}_h - \boldsymbol{z}_h$ is in V_h and satisfies $[\![\boldsymbol{v}_h \cdot \boldsymbol{n}]\!] = p$. This is possible by the surjectivity of the divergence map

$$\text{div} : R_h \cap H_0(\text{div}, \Omega) \mapsto S_h,$$

where $S_h = \{v : v|_K \in P_{k(K)}(K) \text{ and average of } v \text{ on } \Omega \text{ is zero}\}$. While this surjectivity is a well-known property for uniform degree spaces, for the variable degree Raviart–Thomas space, it follows from our results in [6]. The remaining details of the proof of Proposition 4.1 are identical to its two-dimensional analogue in [7], so we omit them.

By Proposition 4.1, the Lagrange multiplier space P_h can be identified with $\widetilde{P}_h/\mathbb{R}$, where

$$\widetilde{P}_h = \{p : p|_F \in P_k(F) \text{ for all } F \in \mathfrak{F}\}.$$

Obviously, we can construct a basis for $\widetilde{P}_h$ by taking the union of local bases for $P_k(F)$, say Legendre polynomials, on every edge $F \in \mathfrak{F}$. It is enough to construct such a basis in computations.

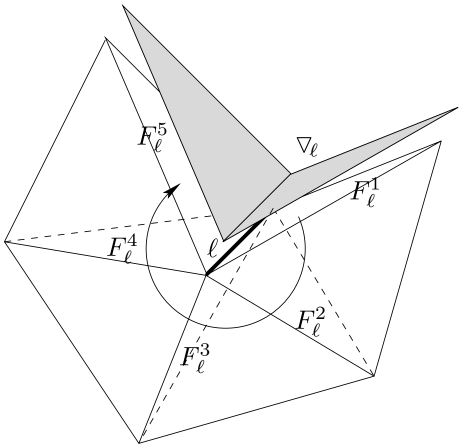

FIG. 1. *Construction of basis functions supported near a mesh edge ℓ.*

4.2. The lowest-order tangential velocity space. Now, we begin the construction of a local basis for the space M_h of tangential velocity Lagrange multipliers. In this subsection, we study the lowest-order case, which is easier to describe. In the next subsection, we consider the general case.

In order to explicitly give a local basis for M_h, we introduce some more notation. Let K be a tetrahedron in $\mathcal{T}$ and let ℓ be one of its edges. We denote by $\varLambda_{\ell,K}$ the union of the two faces of K that share the edge ℓ. Define the collection of such *wedges* by

$$\hat{\varLambda}_h = \{\varLambda_{\ell,K} : \ell \text{ is an edge of } \mathcal{T} \text{ and } K \in \mathcal{T}\}.$$

For all $\varLambda \in \hat{\varLambda}_h$, we denote by $K_\varLambda$ the (unique) tetrahedron $K \in \mathcal{T}$ such that $\varLambda \subseteq \partial K$. The edge of a wedge $\varLambda$ is the common edge of the two faces that form $\varLambda$. This edge is denoted by $\ell_\varLambda$. Let β_i and β_j be the barycentric coordinate functions (with respect to the tetrahedron $K_\varLambda$) associated with the two endpoints of $\ell_\varLambda$. Set

$$\boldsymbol{\phi}_\varLambda = \begin{cases} \beta_i \,\boldsymbol{\nabla}\, \beta_j - \beta_j \,\boldsymbol{\nabla}\, \beta_i & \text{on } K_\varLambda, \\ 0 & \text{on all other } K \in \mathcal{T}. \end{cases}$$

We define a basis for M_h using the functions

$$\boldsymbol{\psi}_\varLambda = [\![\boldsymbol{n} \times \boldsymbol{\phi}_\varLambda]\!].$$

Since $\boldsymbol{\phi}_\varLambda \in W_h$, the functions $\boldsymbol{\psi}_\varLambda$ are in M_h by definition. But not all of $\boldsymbol{\psi}_\varLambda, \varLambda \in \hat{\varLambda}_h$ are linearly independent; e.g., the functions $\boldsymbol{\psi}_\varLambda$ for all $\varLambda$ connected to one edge are linked by one equation. Therefore, for every mesh edge ℓ (including edges $\ell \subset \partial\Omega$), we arbitrarily pick one wedge $\varLambda \in \hat{\varLambda}_h$ with edge $\ell_\varLambda = \ell$, denote it by $\triangledown_\ell$ (see Figure 1), and "omit" it: Define

$$\varLambda_h = \hat{\varLambda}_h \setminus \{\triangledown_\ell : \text{ for all mesh edges } \ell\}.$$

PROPOSITION 4.2. *The set $\mathcal{B}_0 = \{\boldsymbol{\psi}_\varLambda : \varLambda \in \varLambda_h\}$ is a basis for M_h whenever $k(K) = 0$ for all $K \in \mathcal{T}$.*

Proof. Since the span of $\mathcal{B}_0$ is contained in M_h, it suffices to prove that

$$\operatorname{card}\mathcal{B}_0 = \dim M_h \tag{4.2}$$

and

$$\mathcal{B}_0 \text{ is a linearly independent set.} \tag{4.3}$$

To prove (4.2), let us first count the dimension of M_h. Defining $T_h : W_h \mapsto M_h$ by

$$T_h \boldsymbol{\tau} = [\![\boldsymbol{n} \times \boldsymbol{\tau}]\!],$$

we note that M_h is the range of T_h. Since the null space of T_h is $\mathcal{W}_h$, by the rank-nullity theorem, we find that

$$\dim(M_h) = \operatorname{rank}(T_h) = \dim(W_h) - \dim(\mathcal{W}_h). \tag{4.4}$$

Now, $W(K)$ in the lowest-order case is a space of dimension six. Since the number of degrees of freedom of the conforming lowest-order Nédélec space $\mathcal{W}_h$ equals the number of edges n_E in the mesh, we find that

$$\dim(M_h) = 6n_K - n_E,$$

where n_K is the number of tetrahedra in the mesh $\mathcal{T}$. Thus

$$\operatorname{card}\mathcal{B}_0 = \operatorname{card}\Lambda_h = \operatorname{card}\hat{\Lambda}_h - n_E = 6n_K - n_E,$$

which coincides with $\dim M_h$.

Now, let us prove (4.3). We want to show that if

$$\boldsymbol{\mu} = \sum_{\Lambda \in \Lambda_h} c_\Lambda \boldsymbol{\psi}_\Lambda \tag{4.5}$$

vanishes, then all the coefficients c_Λ are zero. Notice that the function $\boldsymbol{\mu}$, in general, is not well defined at the edge ℓ, as the limits of $\boldsymbol{\mu}$ from various faces sharing the edge ℓ can differ. In order to examine these limits, we introduce the following notation. Enumerate all $\Lambda \in \Lambda_h$ with edge ℓ as $\Lambda_\ell^1, \Lambda_\ell^2, \ldots, \Lambda_\ell^{N_\ell}$ and all faces in $\mathcal{F}$ sharing the edge ℓ as $F_\ell^1, F_\ell^2, \ldots, F_\ell^{N_\ell+1}$ (see Figure 1) in such a way that the two faces of Λ_ℓ^j are F_ℓ^j and F_ℓ^{j+1}, and the two faces of $\triangledown_\ell$ are F_ℓ^1 and $F_\ell^{N_\ell+1}$. Let $\boldsymbol{t}_F$ be the unit tangent vector along ∂F fixed by arbitrarily choosing one of the two possible orientations. Let $\boldsymbol{n}_F$ be a unit vector normal to F chosen by the right-hand rule and

$$\boldsymbol{\nu}_F = \boldsymbol{t}_F \times \boldsymbol{n}_F. \tag{4.6}$$

Note that both the choices of orientation for $\boldsymbol{t}_F$ yield the same $\boldsymbol{\nu}_F$, which represents the outward unit normal of F relative to the plane containing F.

Our proof proceeds by examining the following functions on the edge ℓ:

$$\mu_\ell^i := (\boldsymbol{\mu}|_{F_\ell^i}) \cdot \boldsymbol{\nu}_{F_\ell^i}\big|_\ell = \sum_{\Lambda \in \Lambda_h} c_\Lambda \Big(\boldsymbol{\psi}_\Lambda|_{F_\ell^i} \cdot \boldsymbol{\nu}_{F_\ell^i} \Big)\Big|_\ell .$$

Now, there are at most five $\varLambda \in \varLambda_h$ such that $\boldsymbol{\psi}_\varLambda$ is nonzero on the face F_ℓ^1. Moreover, only one of them has nonzero normal trace $\boldsymbol{\psi}_\varLambda \cdot \boldsymbol{\nu}_{F_\ell^i}$ on ℓ, namely, $\boldsymbol{\psi}_{\varLambda_\ell^1}$. Hence

$$\mu_\ell^1 = c_{\varLambda_\ell^1} \left(\boldsymbol{\psi}_{\varLambda_\ell^1}|_{F_\ell^i} \cdot \boldsymbol{\nu}_{F_\ell^1} \right)\Big|_\ell .$$

It then follows that

$$|\mu_\ell^1| = \left|\boldsymbol{\nu}_{F_\ell^1} \cdot (c_{\varLambda_\ell^1} \boldsymbol{\psi}_{\varLambda_\ell^1})\big|_\ell\right| = \left|c_{\varLambda_\ell^1}\, (\boldsymbol{\nu}_{F_\ell^1} \times \boldsymbol{n}_{F_\ell^1}) \cdot \boldsymbol{\phi}_{\varLambda_\ell^1}\big|_\ell\right| = \left|c_{\varLambda_\ell^1}\, (\boldsymbol{t}_{F_\ell^1} \cdot \boldsymbol{\phi}_{\varLambda_\ell^1})\big|_\ell\right| = \frac{1}{h_\ell} |c_{\varLambda_\ell^1}|,$$

where h_ℓ denotes the length of the edge ℓ. Similarly, we also find that $|\mu_\ell^{N_\ell+1}| = |c_\varLambda^{N_\ell+1}|$ and

$$|\mu_\ell^j| = \frac{1}{h_\ell} |c_{\varLambda_x^j} - c_{\varLambda_x^{j-1}}| \qquad \text{for all } j = 2, \dots, N_\ell.$$

If $\boldsymbol{\mu}$ vanishes everywhere, then for any mesh edge ℓ the function μ_ℓ^j defined above must vanish on the edge ℓ. Hence

$$\begin{aligned} |c_{\varLambda_\ell^1}| = |c_{{\varLambda_\ell}^{N_\ell+1}}| &= 0, && \text{and} \\ |c_{\varLambda_\ell^j} - c_{\varLambda_\ell^{j+1}}| &= 0 && \text{for all } j = 2, \dots, N_\ell. \end{aligned}$$

Hence $c_{\varLambda_\ell^j} = 0$ for all j. This argument applies to every mesh edge, so all the coefficients $c_\varLambda$ in (4.5) are zero. Hence (4.3) follows. □

4.3. The higher-order space of tangential velocities. In this subsection we show how to construct a local basis for the Lagrange multiplier space M_h in the general case of the higher-order spaces and the variable degree method. Here there is one important difference compared to the two-dimensional case. In the two-dimensional case [7], we were able to obtain a basis for the higher-order space by augmenting the lowest-order basis with some edge basis functions. In the three-dimensional case, however, we cannot expect to get a basis for the higher-order space by just augmenting $\mathcal{B}_0$ with some face basis functions. This is because while in two dimensions a vertex represents at most one degree of freedom, in three dimensions an edge can have more than one degree of freedom associated to it. Thus we must add to $\mathcal{B}_0$ functions that represent face degrees of freedom as well as functions that represent the additional edge degrees of freedom.

In order to give a basis explicitly, as well as to understand the nature of our space of tangential velocities, it is convenient to recall a basis for the Nédélec space given in [10]. For any integer $k \geq 0$ and any N-simplex D ($N = 2$ or 3 for our purposes), the Nédélec space is

$$W_k(D) = P_k(D)^N \oplus S_{k+1}(D).$$

Let $\beta_1, \dots, \beta_{N+1}$ denote the $N+1$ barycentric coordinate functions of the N-simplex D. Let $I_{lm}(N, k)$ denote the set of all multi-indices $\boldsymbol{\alpha} := (\alpha_1, \dots, \alpha_N)$ (where α_i are nonnegative integers) such that $\alpha_i = 0$ for all i not equal to l or m and $\alpha_l + \alpha_m = k$. Similarly, $I_{lmn}(N, k)$ is the set of multi-indices $\boldsymbol{\alpha}$ with $\alpha_i = 0$ for all i not equal to l, m, or n, and $\alpha_l + \alpha_m + \alpha_n = k$. Using powers of barycentric coordinates (for

$\boldsymbol{\alpha} = (\alpha_1, \dots, \alpha_{N+1})$, we define $\boldsymbol{\beta}^{\boldsymbol{\alpha}} := \beta_1^{\alpha_1} \dots \beta_{N+1}^{\alpha_{N+1}})$, we introduce the following sets of functions:

$$\mathcal{B}_{lm}^{(D)} = \bigcup_{\boldsymbol{\alpha} \in I_{lm}(N+1,k)} \big\{\boldsymbol{\beta}^{\boldsymbol{\alpha}}(\beta_l \boldsymbol{\nabla} \beta_m - \beta_m \boldsymbol{\nabla} \beta_l)\big\}, \tag{4.7}$$

$$\begin{aligned} \mathcal{B}_{lmn}^{(D)} = \bigcup_{\boldsymbol{\alpha} \in I_{lmn}(N+1,k-1)} & \big\{\boldsymbol{\beta}^{\boldsymbol{\alpha}}(\beta_l\beta_m \boldsymbol{\nabla} \beta_n - \beta_m\beta_n \boldsymbol{\nabla} \beta_l), \\ & \boldsymbol{\beta}^{\boldsymbol{\alpha}}(\beta_m\beta_n \boldsymbol{\nabla} \beta_l - \beta_n\beta_l \boldsymbol{\nabla} \beta_m)\big\}. \end{aligned} \tag{4.8}$$

From the results of [10], it now follows that if D is a triangle, then the union of the sets $\mathcal{B}_{12}^{(D)}$, $\mathcal{B}_{23}^{(D)}$, $\mathcal{B}_{31}^{(D)}$, and $\mathcal{B}_{123}^{(D)}$ forms a basis for the Nédélec space $W_k(D)$. If D is a tetrahedron instead, then a basis for $W_k(D)$ is

$$\mathcal{B}_{12}^{(D)} \cup \mathcal{B}_{13}^{(D)} \cup \mathcal{B}_{14}^{(D)} \cup \mathcal{B}_{23}^{(D)} \cup \mathcal{B}_{24}^{(D)} \cup \mathcal{B}_{34}^{(D)} \cup \mathcal{B}_{123}^{(D)} \cup \mathcal{B}_{124}^{(D)} \cup \mathcal{B}_{134}^{(D)} \cup \mathcal{B}_{234}^{(D)} \cup \mathcal{B}_{1234}^{(D)},$$

where

$$\begin{aligned} \mathcal{B}_{1234}^{(D)} := \bigcup \{ & \boldsymbol{\beta}^{\boldsymbol{\alpha}}(\beta_1\beta_2\beta_3 \boldsymbol{\nabla} \beta_4 - \beta_2\beta_3\beta_4 \boldsymbol{\nabla} \beta_1), \boldsymbol{\beta}^{\boldsymbol{\alpha}}(\beta_2\beta_3\beta_4 \boldsymbol{\nabla} \beta_1 - \beta_3\beta_4\beta_1 \boldsymbol{\nabla} \beta_2), \\ & \boldsymbol{\beta}^{\boldsymbol{\alpha}}(\beta_3\beta_4\beta_1 \boldsymbol{\nabla} \beta_2 - \beta_4\beta_3\beta_2 \boldsymbol{\nabla} \beta_1) : \boldsymbol{\alpha} \in I_{1234}(N+1, k-2)\}. \end{aligned}$$

Note that the basis functions in (4.7) are "edge" basis functions, those in (4.8) are "face" basis functions, and those in $\mathcal{B}_{1234}^{(D)}$ are "interior" basis functions, in the sense explained in [10].

Since the Lagrange multiplier space M_h is obtained using the tangential traces of functions in W_h, it is instructive to study the space of tangential traces of the Nédélec space on one tetrahedron K. Let $\boldsymbol{a}_1$, $\boldsymbol{a}_2$, $\boldsymbol{a}_3$, and $\boldsymbol{a}_4$ be the vertices of K; let F_{lmn} be the face formed by $\boldsymbol{a}_l$, $\boldsymbol{a}_m$, and $\boldsymbol{a}_n$; and let e_{ij} be the edge formed by $\boldsymbol{a}_i$ and $\boldsymbol{a}_j$. We denote by $\boldsymbol{n} \times W_k(K)$ the space of functions on ∂K of the form $\boldsymbol{n} \times \boldsymbol{w}$ for some $\boldsymbol{w} \in W_k(K)$. Recall that for any N-dimensional domain D, the Raviart–Thomas space of polynomials is $R_k(D) = \boldsymbol{x}P_k(D) + P_k(D)^N$, where $\boldsymbol{x}$ is the coordinate vector on D. Define the Raviart–Thomas space on the manifold ∂K by

$$\begin{aligned} R_k(\partial K) = \{\boldsymbol{r} : \ & \boldsymbol{r}|_{F_{ijl}} \in R_k(F_{ijl}) \text{ and} \\ & (\boldsymbol{r}|_{F_{ijl}}) \cdot \boldsymbol{\nu}_{F_{ijl}} + (\boldsymbol{r}|_{F_{ijm}}) \cdot \boldsymbol{\nu}_{F_{ijm}} = 0 \text{ on } e_{ij} \text{ for all } i,j,l,m\}, \end{aligned}$$

where we have used the notation in (4.6). Then we have the following result.

PROPOSITION 4.3. *The space of tangential traces of the Nédélec space* $\boldsymbol{n} \times W_k(K)$ *is the Raviart–Thomas space* $R_k(\partial K)$.

Proof. We begin by proving that $\boldsymbol{n} \times W_k(K) \subseteq R_k(\partial K)$. Let the tangential component of $\boldsymbol{w} \in W_k(K)$ on ∂K be denoted by $\boldsymbol{w}_\mathsf{T}$. We first prove that $\boldsymbol{w}_\mathsf{T}$ on face F_{lmn} is in $R_k(F_{lmn})$. It is easy to see from the structure of the basis functions in (4.7) that if $\boldsymbol{w} \in \mathcal{B}_{ij}^{(K)}$, then $\boldsymbol{w}_\mathsf{T}|_{F_{lmn}}$ is zero if i or j does not belong to $\{l,m,n\}$. If both i and j are in $\{l,m,n\}$, then $\boldsymbol{w}_\mathsf{T}|_{F_{lmn}} \in \mathcal{B}_{ij}^{(F_{lmn})}$. Therefore, we find that $\boldsymbol{w}_\mathsf{T}|_{F_{lmn}}$ is in the Nédélec space $W_k(F_{lmn})$.

In two dimensions, the Nédélec space is the "rotated" Raviart–Thomas space. Indeed, if D is a triangle in the x-y plane, then

$$W_k(D) = P_k(K)^2 \oplus S_{k+1}(K) = P_k(K)^2 \oplus \begin{pmatrix} -y \\ x \end{pmatrix} P_k(K).$$

Since $\boldsymbol{n}\times\boldsymbol{w}|_{F_{lmn}}$ is $\boldsymbol{w}_{\mathsf{T}}|_{F_{lmn}}$ rotated (by an angle of $\pi/2$), it follows that the tangential trace $\boldsymbol{n}\times\boldsymbol{w}$ on F_{lmn} is in the Raviart–Thomas space $R_k(F_{lmn})$.

To show the continuity of the normal components of $\boldsymbol{n}\times\boldsymbol{w}$ across edges of ∂K, consider an edge e_{ij} shared by two faces F_{ijl} and F_{ijm}. Then by (4.6) and the continuity of the tangential components of the Nédélec space, we have the following equalities on e_{ij}:

$$\begin{aligned}(\boldsymbol{n}\times\boldsymbol{w})|_{F_{ijl}}\cdot\boldsymbol{\nu}_{F_{ijl}} &= (\boldsymbol{\nu}_{F_{ijl}}\times\boldsymbol{n})\cdot\boldsymbol{w}|_{Fijl} = -\boldsymbol{t}_{F_{ijl}}\cdot\boldsymbol{w}|_{Fijl}\\ &= \boldsymbol{t}_{F_{ijm}}\cdot\boldsymbol{w}|_{Fijm} = -(\boldsymbol{n}\times\boldsymbol{w})|_{Fijm}\cdot\boldsymbol{\nu}_{F_{ijm}}.\end{aligned}$$

Thus $\boldsymbol{n}\times\boldsymbol{w}$ is in $R_k(\partial K)$ whenever $\boldsymbol{w}\in W_k(K)$. It is easy to see that all functions in $R_k(\partial K)$ can be obtained as tangential traces of $W_k(K)$. $\square$

Now we are ready to describe the building blocks of a basis for the general higher-order M_h arising from the variable degree Nédélec spaces. The basis is divided into two parts: one corresponding to the interior faces of the mesh and another corresponding to the wedges in Λ_h. The former is easy to describe: Let $\mathcal{F}_0$ denote the set of all interior faces of the mesh $\mathcal{T}$. For any face $F\in\mathcal{F}_0$, define

$$\mathring{V}(F) = \{\boldsymbol{w}\in R_{k(F)}(F) : \boldsymbol{w}|_{\partial F}\cdot\boldsymbol{\nu}_F = 0 \text{ on } \partial F\},$$

where $k(F)$ is the *maximum* of the degrees from either side of F, as defined in (4.1). Let $\mathring{\mathcal{B}}_F$ be a basis for $\mathring{V}(F)$.

To describe the wedge basis functions, recall the notations introduced in the previous subsection. Now we additionally require that for every mesh edge ℓ, the "omitted wedge" $\triangledown_\ell$ is associated to a tetrahedron (having ℓ as an edge and) having the *minimal* degree: More precisely, we choose $\triangledown_\ell$ such that

$$k(K_{\triangledown_\ell}) = \min_{i=1,\ldots,N_\ell} k(K_{\Lambda^i_\ell}). \tag{4.9}$$

For all the remaining $\Lambda\in\Lambda_h$, we define the following Raviart–Thomas-type space:

$$R(\Lambda) = \{\boldsymbol{r}\in R_{k(K_\Lambda)}(\partial K_\Lambda) :\ \boldsymbol{r} \text{ is supported on } \Lambda\}.$$

Just as we decompose the standard Raviart–Thomas space, we can decompose $R(\Lambda)$ into subspaces corresponding to interior and boundary degrees of freedom: If F_Λ^+ and F_Λ^- denote the two faces of Λ and $\mathring{R}(F_\Lambda^\pm) = \{\boldsymbol{r}\in R_{k(K_\Lambda)}(\partial K_\Lambda) :\ \boldsymbol{r}$ is supported on $F_\Lambda^\pm\}$, we can decompose $R(\Lambda) = \mathring{R}(F_\Lambda^+)\oplus\mathring{R}(F_\Lambda^-)\oplus V(\Lambda)$, where $V(\Lambda)$ is a subspace that is linearly independent, to $\mathring{R}(F_\Lambda^+)\oplus\mathring{R}(F_\Lambda^-)$; e.g., we can choose $V(\Lambda)$ to be the $L^2(\Lambda)$-orthogonal complement of $\mathring{R}(F_\Lambda^+)\oplus\mathring{R}(F_\Lambda^-)$ in $R(\Lambda)$. (Another alternative is suggested in the next paragraph.) Let $\mathcal{B}_\Lambda$ be a basis for $V(\Lambda)$. Our next theorem shows that such wedge basis functions together with the face basis functions form a basis for the global space M_h.

Particular examples of $\mathcal{B}_\Lambda$ and $\mathring{\mathcal{B}}_F$ are easy to exhibit. We give one conveniently implementable choice that follows from the previous results of [10]. Let $\Lambda\in\Lambda_h$ and let β_i, $i=1,2,3,4$, denote the barycentric coordinates of K_Λ such that β_i and β_j are associated to the two endpoints of the edge ℓ_Λ. Define

$$\boldsymbol{\phi}_\Lambda^{(\boldsymbol{\alpha})} = \begin{cases}\boldsymbol{\beta}^{\boldsymbol{\alpha}}(\beta_i\,\boldsymbol{\nabla}\,\beta_j - \beta_j\,\boldsymbol{\nabla}\,\beta_i) & \text{on } K_\Lambda,\\ 0 & \text{on all other } K\in\mathcal{T}\end{cases}$$

for all $\boldsymbol{\alpha} \in I_{ij}(4, k(K_\Lambda))$ and

$$\boldsymbol{\psi}_\Lambda^{(\boldsymbol{\alpha})} = [\![\boldsymbol{n} \times \boldsymbol{\phi}_\Lambda^{(\boldsymbol{\alpha})}]\!].$$

We can choose

$$\mathcal{B}_\Lambda = \{\boldsymbol{\psi}_\Lambda^{(\boldsymbol{\alpha})} : \boldsymbol{\alpha} \in I_{ij}(4, k(K_\Lambda))\}.$$

For an example of a face basis, let $F \in \mathcal{F}_0$. If β_i, β_j, and β_k are the three barycentric coordinate functions of the face F, then we may choose

$$\mathring{\mathcal{B}}_F = \bigcup_{\boldsymbol{\alpha} \in I_{ijk}(3, k(F)-1)} \Big\{ \boldsymbol{\beta}^{\boldsymbol{\alpha}} (\beta_i \beta_j \,\boldsymbol{\nabla}\, \beta_k - \beta_j \beta_k \,\boldsymbol{\nabla}\, \beta_i) \times \boldsymbol{n}_F, \quad \boldsymbol{\beta}^{\boldsymbol{\alpha}} (\beta_j \beta_k \,\boldsymbol{\nabla}\, \beta_i - \beta_k \beta_i \,\boldsymbol{\nabla}\, \beta_j) \times \boldsymbol{n}_F \Big\}. \tag{4.10}$$

The following theorem gives a basis for M_h.

THEOREM 4.4. *The set*

$$\mathcal{B} = \Big(\bigcup_{\Lambda \in \Lambda_h} \mathcal{B}_\Lambda \Big) \cup \Big(\bigcup_{F \in \mathcal{F}_0} \mathring{\mathcal{B}}_F \Big)$$

is a basis for M_h.

Proof. It follows from Proposition 4.3 that elements of $\mathring{\mathcal{B}}_F$ and $\mathcal{B}_\Lambda$ can be written as $[\![\boldsymbol{n} \times \boldsymbol{\phi}]\!]$ for some $\boldsymbol{\phi} \in W_h$. Hence the span of $\mathcal{B}$ is contained in M_h. It now suffices to prove that

$$\operatorname{card} \mathcal{B} = \dim(M_h) \tag{4.11}$$

and that $\mathcal{B}$ is a linearly independent set. For any $\boldsymbol{\mu} \in \mathring{\mathcal{B}}_F$, the normal trace from F on ∂F vanishes:

$$(\boldsymbol{\mu}|_{\partial F}) \cdot \boldsymbol{\nu}_F = 0.$$

The normal traces of functions in $\mathcal{B}_\Lambda$ from Λ on ℓ_Λ are linearly independent. Hence by a minor modification of the arguments in the proof of Proposition 4.2, the linear independence of $\mathcal{B}$ follows from the linear independence of functions within $\mathcal{B}_\Lambda$ and $\mathring{\mathcal{B}}_F$.

To prove (4.11), let us first count the number of elements in $\mathcal{B}$. The dimension of $\mathring{V}(F)$ can be calculated easily (either directly or using (4.10)). It equals

$$\operatorname{card} \mathring{\mathcal{B}}_F = 2 \operatorname{card} I_{123}(3, k(F)-1) = k(F)\big(k(F)+1\big).$$

Moreover,

$$\operatorname{card} \mathcal{B}_\Lambda = \operatorname{card} I_{12}(4, k(K_\Lambda)) = k(K_\Lambda) + 1.$$

Thus,

$$\operatorname{card} \mathcal{B} = \sum_{\Lambda \in \Lambda_h} (k(K_\Lambda) + 1) + \sum_{F \in \mathcal{F}_0} k(F)\big(k(F)+1\big). \tag{4.12}$$

Now let us compute the dimension of M_h by using the identity (see (4.4))

$$\dim(M_h) = \dim(W_h) - \dim(\mathcal{W}_h).$$

By the tangential continuity conditions on the variable degree space $\mathcal{W}_h$, we find that the space of traces $\boldsymbol{n}_F \times \boldsymbol{w}$ on a face $F \in \mathcal{F}$ for $\boldsymbol{w} \in \mathcal{W}_h$ is $R_{\underset{\sim}{k}(F)}(F)$, where

$$\underset{\sim}{k}(F) = \min\{k(K) : K \in \mathcal{T} \text{ and } K \text{ has } F \text{ as a face}\}.$$

Furthermore, the tangential component $\boldsymbol{w} \cdot \boldsymbol{t}$ on an edge E is in $P_{\underset{\sim}{k}(E)}(E)$, where

$$\underset{\sim}{k}(E) = \min\{k(K) : K \in \mathcal{T} \text{ and } K \text{ has } E \text{ as an edge}\}.$$

Splitting the global degrees of freedom of $\mathcal{W}_h$ as edge degrees of freedom, face degrees of freedom, and interior degrees of freedom, we find that

$$\dim(\mathcal{W}_h) = \sum_{E\in\mathcal{E}} \big(\underset{\sim}{k}(E)+1\big) + \sum_{F\in\mathcal{F}} \underset{\sim}{k}(F)\big(\underset{\sim}{k}(F)+1\big) + \sum_{K\in\mathcal{T}} \frac{1}{2}\big(k(K)-1\big)k(K)\big(k(K)+1\big).$$

Consequently,

$$\begin{aligned} \dim(W_h) - \dim(\mathcal{W}_h) = {}& \left(\sum_{K\in\mathcal{T}} 6\big(k(K)+1\big) - \sum_{E\in\mathcal{E}} \big(\underset{\sim}{k}(E)+1\big)\right) \\ & + \left(\sum_{K\in\mathcal{T}} 4k(K)\big(k(K)+1\big) - \sum_{F\in\mathcal{F}} \underset{\sim}{k}(F)\big(\underset{\sim}{k}(F)+1\big)\right). \end{aligned} \tag{4.13}$$

Because of (4.4), it suffices to show that the above equals card $\mathcal{B}$.

In order to do this, we simplify the right-hand side of (4.13). Observe that by rearrangement,

$$\sum_{K\in\mathcal{T}} 4k(K)\big(k(K)+1\big) = \sum_{F\in\mathcal{F}} \Big(k(K_F^+)\big(k(K_F^+)+1\big) + k(K_F^-)\big(k(K_F^-)+1\big)\Big),$$

where $K_F^\pm$ is as defined earlier and one of $k(K_F^\pm)$ is understood to vanish if $F \subseteq \partial\Omega$. Hence

$$\sum_{K\in\mathcal{T}} 4k(K)\big(k(K)+1\big) - \sum_{F\in\mathcal{F}} \underset{\sim}{k}(F)\big(\underset{\sim}{k}(F)+1\big) = \sum_{F\in\mathcal{F}_0} k(F)\big(k(F)+1\big).$$

Similarly, denoting by K_ℓ^i, $i = 1, 2, \ldots, N_\ell$, the tetrahedra in $\mathcal{T}$ which have ℓ as an edge, the rearrangement

$$\sum_{K\in\mathcal{T}} 6\big(k(K)+1\big) = \sum_{\ell\in\mathcal{E}} \sum_{i=1}^{N_\ell} \big(k(K_\ell^i)+1\big)$$

implies, in view of (4.9), that

$$\begin{aligned} \sum_{K\in\mathcal{T}} 6\big(k(K)+1\big) - \sum_{E\in\mathcal{E}} \big(\underset{\sim}{k}(E)+1\big) &= \sum_{\ell\in\mathcal{E}} \left(\sum_{i=1}^{N_\ell} k(K_\ell^i)+1\right) - \sum_{\ell\in\mathcal{E}} \big(k(K_{\triangledown_\ell})+1\big) \\ &= \sum_{\Lambda\in\Lambda_h} \big(k(K_\Lambda)+1\big). \end{aligned}$$

Using these identities in (4.13), we obtain

$$\dim(W_h) - \dim(\mathcal{W}_h) = \sum_{\mathit{\Lambda} \in \mathit{\Lambda}_h} \big(k(K_{\mathit{\Lambda}}) + 1\big) + \sum_{F \in \mathcal{F}_0} k(F)\big(k(F) + 1\big),$$

which coincides with card $\mathcal{B}$ as computed in (4.12). Hence (4.11) follows. $\square$

5. Formulae for the lowest-order case. In [7], we discussed a few implementation techniques to implement and solve the two-dimensional analogue of the Lagrange multiplier system (3.11)–(3.12). The considerations there apply to the three-dimensional case as well. In particular, one can form the stiffness matrix of (3.11)–(3.12) and then perform one further elimination (of the pressure multiplier) to obtain a Schur complement system involving the tangential velocity variable $\boldsymbol{\lambda}_h$ alone. We do not repeat this and other details discussed in [7]. However, since the formulae for the liftings change in three dimensions, we give here new formulae for the liftings as well as local stiffness matrices for the lowest-order case.

First, consider the local maps which define the linear and bilinear forms in (3.11)–(3.12) for the lowest-order case (i.e., $k(K) = 0$ for all $K \in \mathcal{T}$). Let K be any tetrahedron in $\mathcal{T}$. Simple computations show that

$$\begin{aligned}
\boldsymbol{w}(\boldsymbol{\lambda}) &= \frac{1}{|K|}\int_{\partial K\setminus\partial\Omega} \boldsymbol{\lambda} \times \boldsymbol{n}\,\mathrm{d}s, &\quad \boldsymbol{u}(\boldsymbol{\lambda}) &= \frac{1}{2|K|}\int_{\partial K\setminus\partial\Omega} (\boldsymbol{x} - \boldsymbol{x}_K) \times (\boldsymbol{n} \times \boldsymbol{\lambda})\,\mathrm{d}s,\\
\boldsymbol{w}(\boldsymbol{g}_{\mathsf{T}}) &= \frac{1}{|K|}\int_{\partial K\cap\partial\Omega} \boldsymbol{g}_{\mathsf{T}} \times \boldsymbol{n}\,\mathrm{d}s, &\quad \boldsymbol{u}(\boldsymbol{g}_{\mathsf{T}}) &= \frac{1}{2|K|}\int_{\partial K\cap\partial\Omega} (\boldsymbol{x} - \boldsymbol{x}_K) \times (\boldsymbol{n} \times \boldsymbol{g}_{\mathsf{T}})\,\mathrm{d}s,\\
\mathcal{w}(p) &= \mathcal{w}_p^K \times (\boldsymbol{x} - \boldsymbol{x}_K), &\quad \mathbf{u}(p) &= \frac{1}{2|K|}\int_K (\boldsymbol{x} - \boldsymbol{x}_K) \times \mathcal{w}(p)\,\mathrm{d}x,\\
\mathsf{w}(\boldsymbol{f}) &= \mathsf{w}_{\boldsymbol{f}}^K \times (\boldsymbol{x} - \boldsymbol{x}_K), &\quad \mathsf{u}(\boldsymbol{f}) &= \frac{1}{2|K|}\int_K (\boldsymbol{x} - \boldsymbol{x}_K) \times \mathsf{w}(\boldsymbol{f})\,\mathrm{d}x,
\end{aligned}$$

where the point $\boldsymbol{x}_K$ denotes the barycenter of the tetrahedron K,

$$\mathcal{w}_p^K = -\frac{1}{2|K|}\int_{\partial K} p\,\boldsymbol{n}\,\mathrm{d}s, \quad \text{and} \quad \mathsf{w}_{\boldsymbol{f}}^K = \frac{1}{2|K|}\int_K \boldsymbol{f}\,\mathrm{d}x.$$

Here and elsewhere we use $|X|$ to denote the measure of X.

In order to implement (3.11)–(3.12), one uses the basis for M_h and P_h described previously, applies the above local lifting maps to the basis functions, and forms local stiffness matrices of the bilinear forms of $a(\cdot,\cdot)$ and $b(\cdot,\cdot)$. In line with these steps, we next simplify the above expressions in the case of a lowest-order basis function of M_h and P_h. Let K be the tetrahedron formed by vertices $\boldsymbol{x}_1$, $\boldsymbol{x}_2$, $\boldsymbol{x}_3$, and $\boldsymbol{x}_4$. Let F_i denote the face of K opposite to vertex x_i, and let $\boldsymbol{n}_i$ denote the outward unit normal of K on the face F_i. We first give the lifting of $\boldsymbol{\psi}_{\mathit{\Lambda}}$, a basis function associated with $\mathit{\Lambda} \in \mathit{\Lambda}_h$ with $K_{\mathit{\Lambda}} = K$ (see Figure 2). Since we are considering the lowest-order case, by definition,

$$\boldsymbol{\psi}_{\mathit{\Lambda}} = \begin{cases} \boldsymbol{n}_3 \times (\beta_1\,\boldsymbol{\nabla}\,\beta_2 - \beta_2\,\boldsymbol{\nabla}\,\beta_1) & \text{on face } F_3,\\ \boldsymbol{n}_4 \times (\beta_1\,\boldsymbol{\nabla}\,\beta_2 - \beta_2\,\boldsymbol{\nabla}\,\beta_1) & \text{on face } F_4,\\ 0 & \text{on all other mesh faces.} \end{cases}$$

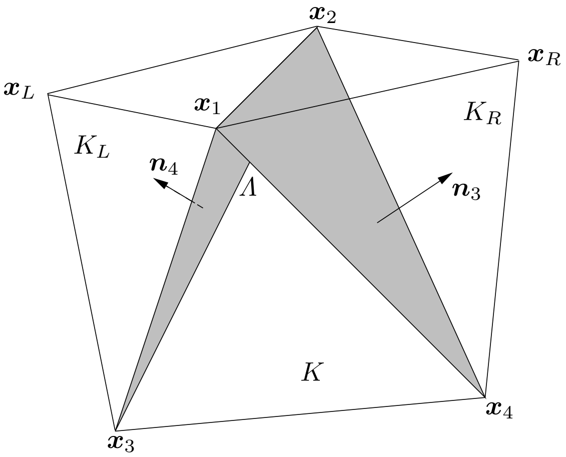

FIG. 2. *The lifting of the basis function from Λ is supported on three mesh tetrahedra K, K_L, and K_R.*

It is easily seen that the above expression is equal to the following:

$$\boldsymbol{\psi}_\Lambda = \begin{cases} -\dfrac{1}{2|F_3|}(\boldsymbol{x}-\boldsymbol{x}_4) & \text{on face } F_3, \\ -\dfrac{1}{2|F_4|}(\boldsymbol{x}-\boldsymbol{x}_3) & \text{on face } F_4, \\ 0 & \text{on all other mesh faces.} \end{cases}$$

The computations are simplified by working with the latter expression for $\boldsymbol{\psi}_\Lambda$, which also illustrates the connection of the tangential traces with the Raviart–Thomas space. The liftings $\boldsymbol{w}_\Lambda := \boldsymbol{w}(\boldsymbol{\psi}_\Lambda)$ and $\boldsymbol{u}_\Lambda := \boldsymbol{u}(\boldsymbol{\psi}_\Lambda)$ are supported on three tetrahedra, unless Λ intersects $\partial\Omega$. Since the formulae one obtains when Λ intersects $\partial\Omega$ are similar to the remaining cases, we consider only the case shown in Figure 2, where the lifting is supported on the three tetrahedra shown, namely, K, K_L, and K_R. Letting $\boldsymbol{x}_{ij} = \boldsymbol{x}_i - \boldsymbol{x}_j$ for any subscripts i and j, we have

$$\begin{aligned}
\boldsymbol{w}_\Lambda &= -\frac{(\boldsymbol{x}_{31}+\boldsymbol{x}_{32})\times\boldsymbol{n}_4}{6|K_L|} \quad \text{and} \\
\boldsymbol{u}_\Lambda &= \frac{-1}{48|K_L|}\Big[(\boldsymbol{x}_{13}\times\boldsymbol{n}_4)\times\boldsymbol{x}_{L1} + (\boldsymbol{x}_{23}\times\boldsymbol{n}_4)\times\boldsymbol{x}_{L2}\Big] \quad \text{on } K_L, \\
\boldsymbol{w}_\Lambda &= -\frac{(\boldsymbol{x}_{41}+\boldsymbol{x}_{42})\times\boldsymbol{n}_3}{6|K_R|} \quad \text{and} \\
\boldsymbol{u}_\Lambda &= \frac{-1}{48|K_R|}\Big[(\boldsymbol{x}_{14}\times\boldsymbol{n}_3)\times\boldsymbol{x}_{R1} + (\boldsymbol{x}_{24}\times\boldsymbol{n}_3)\times\boldsymbol{x}_{R2}\Big] \quad \text{on } K_R, \\
\boldsymbol{w}_\Lambda &= \left[\frac{(\boldsymbol{x}_{31}+\boldsymbol{x}_{32})\times\boldsymbol{n}_4}{6|K|} + \frac{(\boldsymbol{x}_{41}+\boldsymbol{x}_{42})\times\boldsymbol{n}_3}{6|K|}\right] \quad \text{and} \\
\boldsymbol{u}_\Lambda &= \frac{1}{48|K|}\Big[(\boldsymbol{x}_{13}\times\boldsymbol{n}_4)\times\boldsymbol{x}_{41} + (\boldsymbol{x}_{23}\times\boldsymbol{n}_4)\times\boldsymbol{x}_{42} + (\boldsymbol{x}_{14}\times\boldsymbol{n}_3)\times\boldsymbol{x}_{31} \\
&\qquad + (\boldsymbol{x}_{24}\times\boldsymbol{n}_3)\times\boldsymbol{x}_{32}\Big] \quad \text{on } K.
\end{aligned}$$

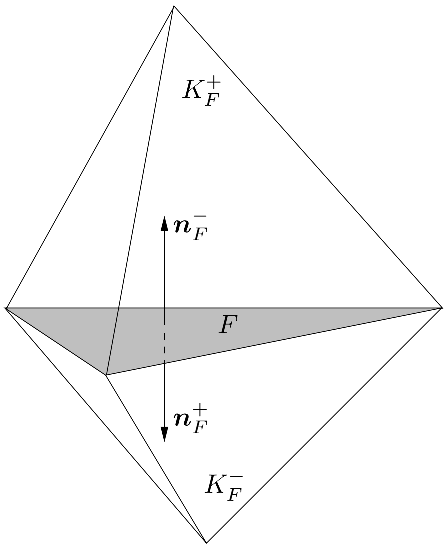

FIG. 3. *The lifting of the pressure basis function from a face F is supported on the tetrahedra adjacent to the face F.*

Next, let us derive the liftings associated with the pressure. To treat this case, consider a face F (shared by the tetrahedra K_F^+ and K_F^-; see Figure 3). Let p_F denote the indicator function of edge F. The liftings $\mathcal{w}_F := \mathcal{w}(p_F)$ and $\mathbf{u}_F := \mathbf{u}(p_F)$ are supported on $K_F^+ \cup K_F^-$. Let $\boldsymbol{x}_i^\pm$, $i = 1, \dots, 4$, denote any enumeration of the four vertices of $K_F^\pm$. In accordance with our previous notation, set $\boldsymbol{x}_{K_F^\pm}$ equal to the barycenter of $K_F^\pm$ and $\boldsymbol{x}_{iK} = \boldsymbol{x}_i^\pm - \boldsymbol{x}_{K_F^\pm}$. We can express the liftings on $K_F^\pm$ by

$$\mathcal{w}_F(\boldsymbol{x})|_{K_F^\pm} = \mathcal{w}^\pm \times (\boldsymbol{x} - \boldsymbol{x}_{K_F^\pm}), \qquad \mathbf{u}_F(\boldsymbol{x})|_{K_F^\pm} = \frac{1}{40}\sum_{i=1}^{4} \boldsymbol{x}_{iK} \times (\mathcal{w}^\pm \times \boldsymbol{x}_{iK}),$$

where

$$\mathcal{w}^\pm = -\frac{|F|}{2|K_F^\pm|}\boldsymbol{n}_F^\pm$$

and $\boldsymbol{n}_F^\pm$ denotes the outward unit normal of $K_F^\pm$ on F (see Figure 3).

The formulae for the maps associated with the body force are similar. If $\boldsymbol{f}$ is supported only on K, then $\mathsf{w}(\boldsymbol{f})$ and $\mathsf{u}(\boldsymbol{f})$ are supported only on K. Their values on K are given by

$$\mathsf{w}(\boldsymbol{f}) = \mathsf{w} \times (\boldsymbol{x} - \boldsymbol{x}_K), \qquad \mathsf{u}(\boldsymbol{f}) = \frac{1}{40}\sum_{i=1}^{4} \boldsymbol{x}_{iK} \times (\mathsf{w} \times \boldsymbol{x}_{iK}),$$

where

$$\mathsf{w} = \frac{1}{2|K|}\int_K \boldsymbol{f}\, \mathrm{d}x.$$

Now that we have expressions for the liftings of the basis functions, we can easily compute the local stiffness matrices of the bilinear forms $a(\cdot,\cdot)$ and $b(\cdot,\cdot)$ with respect to the basis. Once the local matrices are made, one assembles them to get the global matrices in much the same way as one does for standard finite element methods. To compute the local stiffness matrix, we first list the degrees of freedom local to an element. In this list, we include the omitted elements of $\hat{\Lambda}_h$. The omissions can be taken care of after assembly by simply deleting the rows and columns corresponding to the omitted elements of $\hat{\Lambda}_h$. To geometrically identify the degrees of freedom on an element K, let $\boldsymbol{x}_i$ denote the vertices of K and let E_{ij} denote the edge of K with endpoints $\boldsymbol{x}_i$ and $\boldsymbol{x}_j$. There are six wedge degrees of freedom interior to K, which we denote by Λ_{ij} for $ij \in \mathcal{I}_0 := \{12, 13, 14, 23, 24, 34\}$. The wedge Λ_{ij} is geometrically identified as the wedge contained in ∂K with edge E_{ij}. In addition, there are twelve degrees of freedom from wedges "exterior" to K that contribute to the local stiffness matrix of K. We denote these as Λ_{ijk} for $ijk \in \mathcal{I}_1 := \{ijk : ij \in \mathcal{I}_0$ and k does not equal i or $j\}$ (cf. [7, Figure 4]). The wedge Λ_{ijk} is the (unique) wedge with edge E_{ij}, whose one face coincides with the face of K formed by vertices $\boldsymbol{x}_i$, $\boldsymbol{x}_j$, and $\boldsymbol{x}_k$, and whose other face is not contained in ∂K. Thus all wedge degrees of freedom within an element can be identified using the index set $\mathcal{I} = \mathcal{I}_0 \cup \mathcal{I}_1$. The pressure degrees of freedom are easier to enumerate: There is one for each face of K, so they can be identified using the index set $\mathcal{L} := \{1, 2, 3, 4\}$. The local stiffness matrices associated to an element K can now be given by

$$\mathsf{A}^{(K)}_{IJ} = \int_K \boldsymbol{w}(\boldsymbol{\psi}_{\Lambda_I}) \cdot \boldsymbol{w}(\boldsymbol{\psi}_{\Lambda_J})\, \mathrm{d}x, \qquad I, J \in \mathcal{I},$$

$$\mathsf{B}^{(K)}_{LJ} = -\int_K \mathbf{curl}\, \mathsf{w}(p_L) \cdot \boldsymbol{u}(\boldsymbol{\psi}_{\Lambda_J})\, \mathrm{d}x, \qquad J \in \mathcal{I}, \quad L \in \mathcal{L},$$

$$\mathsf{C}^{(K)}_{LM} = \int_K \mathsf{w}(p_L) \cdot \mathsf{w}(p_M)\, \mathrm{d}x, \qquad L, M \in \mathcal{L}.$$

Here, as before, p_L denotes the characteristic function of the face F_L for all $L \in \mathcal{L}$.

We can calculate the integrals above after substituting the previously given expressions for the liftings of the basis functions into the integrands. To take into account modifications required near the boundary $\partial\Omega$, let σ_j equal zero if the face F_j is contained in the boundary $\partial\Omega$ and let σ_j equal one otherwise. The simplified expressions for $\mathsf{A}^{(K)}$, $\mathsf{B}^{(K)}$, and $\mathsf{C}^{(K)}$ for any element K are given below. Suppose that $\{i, j, k, l\}$ is any permutation of $\{1, 2, 3, 4\}$. Then define

$$\boldsymbol{W}_I = \begin{cases} \sigma_l(\boldsymbol{x}_{ki} + \boldsymbol{x}_{kj}) \times \boldsymbol{n}_l + \sigma_k(\boldsymbol{x}_{li} + \boldsymbol{x}_{lj}) \times \boldsymbol{n}_k & \text{if } I = ij, \\ -\sigma_l(\boldsymbol{x}_{ki} + \boldsymbol{x}_{kj}) \times \boldsymbol{n}_l & \text{if } I = ijk, \end{cases}$$

$$\boldsymbol{U}_I = \begin{cases} \sigma_l(\boldsymbol{x}_{ik} \times \boldsymbol{n}_l) \times \boldsymbol{x}_{li} + (\boldsymbol{x}_{jk} \times \boldsymbol{n}_l) \times \boldsymbol{x}_{kj} & \\ \qquad + \sigma_k(\boldsymbol{x}_{il} \times \boldsymbol{n}_k) \times \boldsymbol{x}_{ki} + (\boldsymbol{x}_{jl} \times \boldsymbol{n}_k) \times \boldsymbol{x}_{lj} & \text{if } I = ij, \\ -\sigma_l(\boldsymbol{x}_{ik} \times \boldsymbol{n}_l) \times \boldsymbol{x}_{li} + (\boldsymbol{x}_{jk} \times \boldsymbol{n}_l) \times \boldsymbol{x}_{kj} & \text{if } I = ijk. \end{cases}$$

After a few simplifications, one finds that

$$\mathsf{A}^{(K)}_{IJ} = \frac{1}{36|K|} \boldsymbol{W}_I \cdot \boldsymbol{W}_J,$$

$$\mathsf{B}^{(K)}_{LJ} = \frac{1}{48|K|} \boldsymbol{E}_L \cdot \boldsymbol{U}_J,$$

$$\mathsf{C}^{(K)}_{LM} = \frac{1}{80|K|} \sum_{\ell=1}^{4} (\boldsymbol{E}_L \times \boldsymbol{x}_{\ell K}) \cdot (\boldsymbol{E}_M \times \boldsymbol{x}_{\ell K}),$$

where $\boldsymbol{E}_L = \boldsymbol{n}_L|F_L|$ for all $L \in \mathcal{L}$. Using these local matrices, it is quite easy to implement the lowest-order case of our method, even for general tetrahedral meshes. For the variable degree and higher-order cases, one would need to select a good basis for the polynomial spaces involved on one element and then perform the above steps within a computer implementation. Our calculations above, besides showing the essential simplicity of our discretization in the lowest-order case, also clarify the data structures one would need in implementing the method.

6. Extension to other boundary conditions.

Although the previously considered Dirichlet boundary condition on velocity is the most commonly occurring boundary condition in the Stokes problem, other types of boundary conditions are also encountered in practice. One can have boundary conditions on pressure of the form

$$p = s$$

and boundary conditions on tangential vorticity of the form

$$\boldsymbol{n} \times \boldsymbol{\omega} = \boldsymbol{r}.$$

Here s and $\boldsymbol{r}$ are functions prescribed on parts of the boundary $\partial\Omega$. We now show how one may incorporate such boundary conditions into our hybridized discretization. Note that the above types of boundary conditions are difficult to impose in a natural fashion in many existing methods—see remarks in [11, section 4.3] and [12]. They are often practically important. For example, pressure is often used as an outflow condition. The tangential vorticity boundary condition is useful when matching an exterior potential flow since vorticity is known to decay faster than velocity. The tangential vorticity boundary condition has been considered previously in [8] in formulations with the stream function.

Assume that the polyhedral boundary $\partial\Omega$ is partitioned into three disjoint subsets Γ_1, Γ_2, and Γ_3 such that each mesh face $F \in \mathcal{F}$ on the boundary $\partial\Omega$ is contained in one and only one of these three subsets. We consider the Stokes equations (2.1)–(2.2) with the following boundary conditions:

$$\begin{aligned} \boldsymbol{u} &= \boldsymbol{g} && \text{on } \Gamma_1,\\ \left.\begin{aligned}\boldsymbol{n}\times\boldsymbol{\omega} &= \boldsymbol{r}\\ \boldsymbol{u}\cdot\boldsymbol{n} &= g_n\end{aligned}\right\} && && \text{on } \Gamma_2,\\ \left.\begin{aligned}p &= s\\ \boldsymbol{u}_{\mathsf{T}} &= \boldsymbol{g}_{\mathsf{T}}\end{aligned}\right\} && && \text{on } \Gamma_3.\end{aligned}$$

A straightforward generalization of our method can be obtained in this case.

To describe this generalization, we first redefine the jump-functions as follows: The functions $[\![\boldsymbol{n}\cdot\boldsymbol{v}]\!]$ and $[\![\boldsymbol{n}\times\boldsymbol{\tau}]\!]$ are defined just as before on the interior faces, but for mesh faces F on the boundary we set

$$[\![\boldsymbol{n}\cdot\boldsymbol{v}]\!]_F = \begin{cases} 0 \text{ for all faces } F \subseteq \Gamma_3,\\ \boldsymbol{n}\cdot\boldsymbol{v} \text{ for the remaining faces } F \subseteq \partial\Omega\setminus\Gamma_3\end{cases}$$

and

$$[\![\boldsymbol{n}\times\boldsymbol{\tau}]\!]_F = \begin{cases} 0 \text{ for all faces } F \subseteq \Gamma_3\cup\Gamma_1,\\ \boldsymbol{n}\times\boldsymbol{\tau} \text{ for the remaining faces } F \subseteq \partial\Omega\setminus(\Gamma_3\cup\Gamma_1).\end{cases}$$

Then along the lines of the derivation of (2.13)–(2.16), we can derive the following hybridized mixed formulation: Find $(\boldsymbol{\omega}_h, \boldsymbol{u}_h, \boldsymbol{\lambda}_h, p_h) \in W_h \times V_h \times M_h \times P_h$ satisfying

$$\begin{aligned}(\boldsymbol{\omega}_h, \boldsymbol{\tau}_h)_\Omega - (\boldsymbol{u}_h, \mathbf{curl}\,\boldsymbol{\tau}_h)_\Omega - \sum_{F\in\mathcal{F}} (\boldsymbol{\lambda}_h, [\![\boldsymbol{n}\times\boldsymbol{\tau}_h]\!])_F &= (\boldsymbol{g}_{\mathsf{T}}, \boldsymbol{n}\times\boldsymbol{\tau}_h)_{\Gamma_1\cup\Gamma_3},\\ (\boldsymbol{v}_h, \mathbf{curl}\,\boldsymbol{\omega}_h)_\Omega + \sum_{F\in\mathcal{F}} (p_h, [\![\boldsymbol{v}_h\cdot\boldsymbol{n}]\!])_F &= (\boldsymbol{f}, \boldsymbol{v}_h)_\Omega - (s, \boldsymbol{v}_h\cdot\boldsymbol{n})_{\Gamma_3},\\ \sum_{F\in\mathcal{F}} (q_h, [\![\boldsymbol{u}_h\cdot\boldsymbol{n}]\!])_F &= (g_n, q_h)_{\Gamma_1\cup\Gamma_2},\\ \sum_{F\in\mathcal{F}} (\boldsymbol{\mu}_h, [\![\boldsymbol{n}\times\boldsymbol{\omega}_h]\!])_F &= (\boldsymbol{\mu}_h, \boldsymbol{r})_{\Gamma_2}\end{aligned}$$

for all $\boldsymbol{\tau}_h \in W_h, \boldsymbol{v}_h \in V_h, q_h \in P_h, \boldsymbol{\mu}_h \in M_h$. Here W_h and V_h are the same spaces as before. The spaces of Lagrange multipliers P_h and M_h continue to be defined by (2.11) and (2.12), but now with the revised definition of jump-functions.

For this formulation, we can prove, by a minor modification of the argument used in Proposition 2.1, that there is one and only one solution. Moreover, the entire analysis of section 3 goes through with minor changes. We obtain a reduced Lagrange multiplier system and can formulate a theorem entirely analogous to Theorem 3.1. The discussion of the liftings and the basis functions in the previous sections continues to apply for these boundary conditions.

The method we presented in this paper gives a powerful alternative for problems in computational fluid mechanics which require exactly divergence-free solutions for their successful treatment. Applications to such problems, the error analysis of the method, and the design of good preconditioners for solving the resulting matrix equations are subjects of ongoing work.

FINITE VOLUME METHODS ON SPHERES AND SPHERICAL CENTROIDAL VORONOI MESHES*

QIANG DU† AND LILI JU‡

Abstract. We study in this paper a finite volume approximation of linear convection-diffusion equations defined on a sphere using the spherical Voronoi meshes, in particular the spherical centroidal Voronoi meshes. The high quality of spherical centroidal Voronoi meshes is illustrated through both theoretical analysis and computational experiments. In particular, we show that the L^2 error of the approximate solution is of quadratic order when the underlying mesh is given by a spherical centroidal Voronoi mesh. We also demonstrate numerically the high accuracy and the superconvergence of the approximate solutions.

Key words. finite volume method, spherical Voronoi tessellations, spherical centroidal Voronoi tessellations, error estimates, convection-diffusion equations

1. Introduction.

The numerical solution of partial differential equations defined on spheres is an active research subject in the scientific community. The subject is related to a number of important applications such as weather forecasting and climate modeling. For example, the numerical solution of linear convection-diffusion equations and nonlinear shallow water equations in spherical geometry can be used to test numerical algorithms for more complex atmospheric circulation models. Though these models were often solved with spectral methods or traditional finite difference methods in spherical coordinates, methods that use quasi-uniform tessellations of the sphere are gradually gaining popularity as the grid-based methods offer great potential when combined with massive parallelism and local adaptivity.

To get efficient and accurate numerical solutions of PDEs, it is well known that grid quality plays an important role and high quality grid generation is often a significant part of the overall solution process. In this regard, there were many recent studies on the approximations of PDEs defined on spheres using various spherical grids, such as grids based on Bucky-balls [19], icosahedral grids [2, 32, 33], skipped grids [22], grids from a gnomonic (cubed sphere) mapping [24], etc. In standard Euclidean geometry, the so-called Voronoi–Delaunay grids have always been very popular grids used in both finite element and finite volume methods [28]. Other spherical grids have also been studied; see, for example, [16].

In [8, 9], we proposed a high quality spherical grid based on the spherical centroidal Voronoi tessellation (SCVT), which can be used for both data assimilation purposes and for the numerical solution of PDEs on spheres. A very recent study made in [31] on both the global and the local uniformity of spherical grids indicated

that the SCVT grid with a uniform density measures better than many other variations, and, when used to discretize a model Poisson equation on the sphere, the SCVT-based grid tends to produces the smallest local truncation errors among all the grids under consideration. In [9], a finite volume approximation to a second order linear elliptic equation using the spherical Voronoi meshes was studied, and a first order error estimate for the discrete H^1 norm was obtained under some grid regularity assumptions. Preliminary numerical experiments demonstrated the good performance of the finite volume scheme when implemented with the spherical centroidal Voronoi meshes (SCVMs) that include both the SCVT and its dual (Delaunay) triangular grid. The SCVM enjoys some optimization properties [8] and they can also be defined with a nonuniform density function. They offer excellent local grid regularity and global mesh conformity as well as flexible mesh adaptivity. Thus, the SCVM naturally becomes an optimal grid in some sense, or at least a practically *safe* choice for discretizing PDEs on the sphere.

In this paper, we make further attempts to substantiate the optimality of SCVMs both theoretically and computationally. Our main results include a carefully designed finite volume scheme for a general second order convection-diffusion equation defined on a sphere. When implemented with the SCVM, we present a rigorous quadratic order L^2 error estimate for such a discrete scheme whose proof relies critically on the geometric properties of the SCVT. We further demonstrate through experiments the superconvergent properties of the numerical solutions and their gradients solved using our modified finite volume scheme and the SCVT-based grid. All these findings provide compelling reasons for regarding the SCVTs with the uniform density as arguably the best alternative for near uniform partitions of the sphere and the SCVT-based grids the optimal triangular grids to use for the numerical solution of many PDEs defined on spheres.

We point out that the conclusions given in this paper can be readily adapted to problems defined on the two-dimensional (2d) Euclidean plane. The analysis for the spherical case is somewhat more involved than the planar case since we must deal with the differences between spherical triangles and planar triangles.

The paper is organized as follows: we first introduce the model equation, along with some notation used in the paper. Then in section 2, we briefly recall the basic theory of the spherical centroidal Voronoi meshes. Some discrete function spaces and a finite volume scheme for linear convection-diffusion equations on the sphere given in [9] are discussed in section 3. With a suitable modification to the finite volume scheme, a rigorous L^2 error estimate is given in section 4 for SCVMs. In section 5, a superconvergent gradient recovery scheme is provided, and in section 6 we present some numerical experiments. Some concluding remarks are given in section 7.

We now introduce the model equation to be considered. First, let $\mathbb{S}^2$ denote the sphere (surface of the ball) having radius $r > 0$, i.e., $\mathbb{S}^2 = \big\{\mathbf{x} \in \mathbb{R}^3 \mid |\mathbf{x}| = r\big\}$. Let ∇_s denote the tangential gradient operator [13, 17] on $\mathbb{S}^2$ defined by

$$\nabla_s u(\mathbf{x}) = (\nabla_{s,1}, \nabla_{s,2}, \nabla_{s,3})u(\mathbf{x}) = \nabla u(\mathbf{x}) - (\nabla u(\mathbf{x}) \cdot \vec{\mathbf{n}}_{\mathbb{S}^2,\mathbf{x}})\vec{\mathbf{n}}_{\mathbb{S}^2,\mathbf{x}}\,,$$

where $\nabla = (D_1, D_2, D_3)$ denotes the general gradient operator in $\mathbb{R}^3$ and $\vec{\mathbf{n}}_{\mathbb{S}^2,\mathbf{x}}$ is the unit outer normal vector to $\mathbb{S}^2$ at $\mathbf{x} = (x_1, x_2, x_3)$. We consider the second order elliptic equation on the sphere given by

$$\nabla_s \cdot \big(-a(\mathbf{x})\nabla_s u(\mathbf{x}) + \vec{\mathbf{v}}(\mathbf{x})u(\mathbf{x})\big) + b(\mathbf{x})u(\mathbf{x}) = f(\mathbf{x}) \qquad \text{for } \mathbf{x} \in \mathbb{S}^2\,. \tag{1.1}$$

Note that since $\mathbb{S}^2$ has no boundary, there is no boundary condition imposed.

We use the standard notation $L^p(\mathbb{S}^2)$, $W^{m,p}(\mathbb{S}^2)$ for Sobolev spaces on $\mathbb{S}^2$ (viewed as a compact, 2d Riemannian manifold) [17], equipped with norms $\|\cdot\|_{L^p(\mathbb{S}^2)}$ and $\|\cdot\|_{W^{m,p}(\mathbb{S}^2)}$. We set $H^m(\mathbb{S}^2) = W^{m,2}(\mathbb{S}^2)$ and use the standard inner product $(u, v) = \int_{\mathbb{S}^2} u(\mathbf{x})v(\mathbf{x})\, ds(\mathbf{x})$ for $u, v \in L^2(\mathbb{S}^2)$.

Let the data in (1.1) satisfy the following assumptions.

Assumption 1. $f \in L^2(\mathbb{S}^2)$, $a \in C^1(\mathbb{S}^2)$, $b \in L^\infty(\mathbb{S}^2)$, and $\vec{\mathbf{v}} \in C^1(\mathbb{S}^2, \mathbb{R}^3)$ such that $a(\mathbf{x}) \geq \alpha_1 > 0$, $b(\mathbf{x}) \geq 0$, and $\nabla_s \cdot \vec{\mathbf{v}}(\mathbf{x}) + b(\mathbf{x}) \geq \alpha_2 > 0$, a.e.

For any $u, v \in H^1(\mathbb{S}^2)$, define the bilinear functional $\mathcal{A}$ such that

$$\begin{aligned}\mathcal{A}(u,v) = &\int_{\mathbb{S}^2} a(\mathbf{x})\big(\nabla_s u(\mathbf{x}) \cdot \nabla_s v(\mathbf{x})\big) + u(\mathbf{x})\big(\vec{\mathbf{v}}(\mathbf{x}) \cdot \nabla_s v(\mathbf{x})\big)\, ds(\mathbf{x}) \\ &+ \int_{\mathbb{S}^2} b(\mathbf{x})u(\mathbf{x})v(\mathbf{x})\, ds(\mathbf{x}).\end{aligned} \tag{1.2}$$

We easily see, for some constant $C > 0$, that

$$\mathcal{A}(u, v) \leq C\|u\|_{H^1(S^2)}\|v\|_{H^1(S^2)}.$$

The problem (1.1) has a unique weak solution $u \in H^2(\mathbb{S}^2)$ such that

$$\mathcal{A}(u, v) = (f, v), \quad \forall\, v \in H^1(\mathbb{S}^2) \tag{1.3}$$

and u satisfies the H^2 regularity estimate $\|u\|_{H^2(\mathbb{S}^2)} \leq C\|f\|_{L^2(\mathbb{S}^2)}$ for some constant $C > 0$. Though the same conclusion holds under weaker conditions on $\vec{\mathbf{v}}$ and b (and $\nabla_s \cdot \vec{\mathbf{v}}(\mathbf{x}) + b(\mathbf{x})$), for simplicity Assumption 1 is made throughout the paper.

2. Spherical centroidal Voronoi meshes. Let $d(\mathbf{x}, \mathbf{y})$ denote the geodesic distance between $\mathbf{x}$ and $\mathbf{y}$ on $\mathbb{S}^2$, i.e., $d(\mathbf{x}, \mathbf{y}) = r \arccos[(\mathbf{x} \cdot \mathbf{y})/r^2]$, where arccos denotes the inverse cosine. We also use $m(\cdot)$ to denote the standard measure (surface area or curve length) of the argument. Given a set of distinct points $\{\mathbf{x}_i\}_{i=1}^n \subset \mathbb{S}^2$, the corresponding spherical Voronoi regions $\{V_i\}_{i=1}^n$ are defined by

$$V_i = \left\{\mathbf{x} \in \mathbb{S}^2 \mid d(\mathbf{x}_i, \mathbf{x}) < d(\mathbf{x}_j, \mathbf{x}) \text{ for } j = 1, \dots, n \text{ and } j \neq i\right\}, \quad 1 \leq i \leq n\,.$$

$\{V_i\}_{i=1}^n$ forms a *Voronoi tessellation* or *Voronoi diagram* of $\mathbb{S}^2$ associated with the generators $\{\mathbf{x}_i\}_1^n$. Each Voronoi cell V_i is an open convex spherical polygon on $\mathbb{S}^2$ with geodesic arcs making up its boundary. It is also well known that the dual tessellation (in a graph-theoretical sense) to a Voronoi tessellation of $\mathbb{S}^2$ consists of spherical triangles which form the *Delaunay triangulation.*

Given a density function ρ defined on $\mathbb{S}^2$, for any spherical region $V \subset \mathbb{S}^2$, the *constrained mass centroid* $\mathbf{x}^c$ of V on $\mathbb{S}^2$ is given by the solution of

$$\min_{\mathbf{x} \in V} F(\mathbf{x})\,, \qquad \text{where} \qquad F(\mathbf{x}) = \int_V \rho(\mathbf{y})|\mathbf{y} - \mathbf{x}|^2\, ds(\mathbf{y})\,. \tag{2.1}$$

As in [7, 8, 9], a Voronoi tessellation of $\mathbb{S}^2$ is called a *constrained centroidal Voronoi tessellation* (CCVT) of $\mathbb{S}^2$ or, specifically, SCVT if and only if the points $\{\mathbf{x}_i\}_{i=1}^m$ which serve as the generators of the associated spherical Voronoi tessellation $\{V_i\}_{i=1}^k$ are also the constrained mass centroids of those Voronoi regions. For any set of points $\{\widetilde{\mathbf{x}}_i\}_{i=1}^n$ on $\mathbb{S}^2$ and any spherical tessellation $\{\widetilde{V}_i\}_{i=1}^n$ of $\mathbb{S}^2$, the corresponding *energy*

$$\mathcal{K}\big(\{\widetilde{\mathbf{x}}_i, \widetilde{V}_i\}_{i=1}^n\big) = \sum_{i=1}^n \int_{\widetilde{V}_i} \rho(\mathbf{x})\|\mathbf{x} - \widetilde{\mathbf{x}}_i\|^2\, ds(\mathbf{x})$$

is minimized only if $\{\widetilde{\mathbf{x}}_i, \widetilde{V}_i\}_{i=1}^n$ are a SCVT [8]. Consequently, SCVMs have many good geometric properties [8, 9]. A constant density function ρ leads to *uniformly* distributed SCVTs, and a nonconstant density function provides systematically a nonuniform distribution of points while the accumulation of SCVT generators still remains locally regular.

Constructing a constrained mass centroid from (2.1) may be cumbersome. In [8], it has been shown that one can compute first the standard centroid $\mathbf{x}_i^*$ of V_i in $\mathbb{R}^3$, then compute $\mathbf{x}_i^c$ using the fact that it is the projection of $\mathbf{x}_i^*$ onto $\mathbb{S}^2$ along the normal direction at $\mathbf{x}_i^c$. We refer to [8, 9, 21] for both deterministic and probabilistic algorithms for the construction of SCVTs. Figure 2.1 shows some examples of SCVTs associated with a constant density. More examples, including SCVTs with nonuniform densities, can be found in [9].

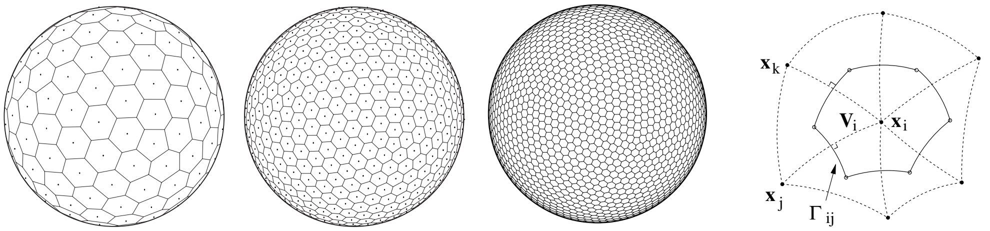

FIG. 2.1. *SCVTs for a constant density function with* 162, 642, *and* 2562 *generators, and an illustration of a spherical Voronoi region and its dual triangles.*

Given a spherical Voronoi mesh $\mathcal{W} = \{\mathbf{x}_i, V_i\}_{i=1}^n$, following [9], we refer to a pair of generators $\mathbf{x}_i$ and $\mathbf{x}_j$ as *neighbors* if and only if $\Gamma_{i,j} = \overline{V}_i \cap \overline{V}_j \neq \emptyset$. For Voronoi meshes, $\Gamma_{i,j}$ can only be a point or a geodesic arc on the sphere. For each $\mathbf{x}_i$, let χ_i be the set of the indices of its neighbors $\mathbf{x}_j$'s such that $m(\Gamma_{i,j}) > 0$. Let $\overline{\mathbf{x}_i\mathbf{x}_j}$ be the vector from $\mathbf{x}_i$ to $\mathbf{x}_j$, and let $\widetilde{\mathbf{x}_i\mathbf{x}_j}$ be the geodesic arc joining $\mathbf{x}_i$ and $\mathbf{x}_j$. From the construction of spherical Voronoi tessellations, it is known that $\widetilde{\mathbf{x}_i\mathbf{x}_j}$ is perpendicular to Γ_{ij} and the plane determined by $\Gamma_{i,j}$ and the origin bisects $\widetilde{\mathbf{x}_i\mathbf{x}_j}$ at its midpoint $\mathbf{x}_{ij}$ [9]; see Figure 2.1. Thus, $|\mathbf{x}_i - \mathbf{x}| = |\mathbf{x}_j - \mathbf{x}|$ for $\mathbf{x} \in \Gamma_{ij}$ and for $k = i, j$, $\vec{\mathbf{n}}_{\mathbf{x},V_k}$ is parallel to $\overline{\mathbf{x}_i\mathbf{x}_j}$ where $\vec{\mathbf{n}}_{\mathbf{x},V_k}$ is the outer unit normal vector to the boundary of V_k, taken to lie in the tangent plane of $\mathbb{S}^2$ at $\mathbf{x}$.

Let $h_i = \max_{\mathbf{y}\in V_i} d(\mathbf{x}_i, \mathbf{y})$, and we define the *mesh quality norm* by $h = \max_i h_i$. h gives the maximum geodesic distance between any particular generator $\mathbf{x}_i$ and the points in its associated cell V_i, and it has been used in [8] for the polynomial interpolation on the sphere.

Given a Voronoi mesh $\mathcal{W} = \{\mathbf{x}_i, V_i\}_{i=1}^m$, we define the *mesh regularity norm* σ by

$$\sigma = \min_{1\le i\le n} \sigma_i, \quad \text{where} \quad \sigma_i = \min_{j\in\chi_i} \sigma_{ij} \quad \text{and} \quad \sigma_{ij} = d(\mathbf{x}_i, \mathbf{x}_j)/(2h_i)\,. \tag{2.2}$$

If $\mathbf{x}_i, \mathbf{x}_j$, and $\mathbf{x}_k$ are neighbors for each other in $\mathcal{W}$, we denote by $\tilde{T}_{ijk}$ the spherical triangle determined by $\mathbf{x}_i, \mathbf{x}_j$, and $\mathbf{x}_k$, and by T_{ijk} the corresponding planar triangle (see Figure 2.1). In addition, let $\tilde{\mathcal{T}} = \{\tilde{T}_{ijk} \,|\, ijk \in \Sigma\}$, $\mathcal{T} = \{T_{ijk} \,|\, ijk \in \Sigma\}$ where $\Sigma = \{\, ijk \,|\, i, j, k \text{ are neighbors in } \mathcal{W}\}$. $\tilde{\mathcal{T}}$ gives the spherical Delaunay triangulation of $\mathbb{S}^2$ associated with the generators $\{\mathbf{x}_i\}_{i=1}^n$.

Meshes of the type $\mathcal{W} = \{\mathbf{x}_i, V_i\}_{i=1}^n$ are used as control (or finite) volumes for the discretization method discussed below. Our use of these meshes is particularly motivated by the covolume mesh approaches in the numerical solution of PDEs [28, 29] and for applications to nonlinear problems [6, 12, 30].

3. A finite volume method on spherical Voronoi tessellations. Without loss of generality, we consider the case of the unit sphere S^2 in what follows.

3.1. Some definitions and geometric properties. For any $\mathbf{x}$, let $\mathcal{P}(\mathbf{x}) = \mathbf{x}/|\mathbf{x}|$ be the projection onto the unit sphere S^2. $\mathcal{P}$ is also a one-to-one smooth function that maps $\mathbf{S}^* = \cup_{T_{ijk}\in\mathcal{T}} T_{ijk}$ to $\mathbb{S}^2 = \cup_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \tilde{T}_{ijk}$.

Clearly, $\mathbf{S}^* \cap \mathbb{S}^2 = \{\mathbf{x}_i\}_{i=1}^n$. Moreover, for any $\mathbf{x} \in \mathbb{S}^2$ and $\mathbf{x}', \mathbf{x}'' \in \tilde{T}_{ijk}$, we have

$$\begin{cases} |\mathbf{x} - \mathcal{P}^{-1}(\mathbf{x})| \le ch^2, \\ (1-ch^2)d(\mathbf{x}',\mathbf{x}'') \le |\mathcal{P}^{-1}(\mathbf{x}') - \mathcal{P}^{-1}(\mathbf{x}'')| \le (1+ch^2)d(\mathbf{x}',\mathbf{x}''), \\ m(T_{ijk}) \le m(\tilde{T}_{ijk}) \le (1+ch^2)m(T_{ijk}), \end{cases} \tag{3.1}$$

where c is a generic constant for h small.

Let $\Omega = \{\mathbf{x} \,|\, 1-ch^2 < |\mathbf{x}| < 1+ch^2\}$; then $\cup T_{ijk} \subset \Omega$ and $\cup\tilde{T}_{ijk} \subset \Omega$. For any $u \in H^2(\mathbb{S}^2)$, define the function Eu, the extension of u in Ω, by $Eu(\mathbf{y}) = u(\mathbf{y}/|\mathbf{y}|)$ for any $\mathbf{y} \in \Omega$. The following results have been shown in [9].

Proposition 1. *For any $\mathbf{y} \in \Omega$ and $\mathbf{x} = \mathbf{y}/|\mathbf{y}| \in \mathbb{S}^2$, and $i, j = 1, 2, 3$,*

$$\begin{cases} \nabla_s u(\mathbf{x}) = \nabla Eu(\mathbf{x}), \quad \nabla(D_i Eu)(\mathbf{x}) = \nabla_s(\nabla_{s,i} u)(\mathbf{x}) - (\nabla_{s,i} u(\mathbf{x}))\vec{\mathbf{n}}_{\mathbb{S}^2,\mathbf{x}}, \\ |\mathbf{y}|\ \nabla Eu(\mathbf{y}) = \nabla Eu(\mathbf{x}), \quad |\mathbf{y}|^2 D_i D_j Eu(\mathbf{y}) = D_i D_j Eu(\mathbf{x}). \end{cases} \tag{3.2}$$

By (3.1) and Proposition 1, the following result can be obtained using a proof similar to that used in Lemma 1 in [13].

Proposition 2. *There exists a generic constant $c > 0$ such that for any $ijk \in \Sigma$,*

$$\begin{cases} C_1\|u\|_{L^2(\tilde{T}_{ijk})} \le \|Eu|_{\mathbf{S}^*}\|_{L^2(T_{ijk})} \le C_2\|u\|_{L^2(\tilde{T}_{ijk})}, \\ C_3\|u\|_{H^1(\tilde{T}_{ijk})} \le \|Eu|_{\mathbf{S}^*}\|_{H^1(T_{ijk})} \le C_4\|u\|_{H^1(\tilde{T}_{ijk})}, \\ \|Eu|_{\mathbf{S}^*}\|_{H^2(T_{ijk})} \le C_5\|u\|_{H^2(\tilde{T}_{ijk})}. \end{cases} \tag{3.3}$$

We call u^L a piecewise linear function on $\mathbf{S}^*$ if and only if

$$u^L(\mathbf{x}^*) = \lambda_i u^L(\mathbf{x}_i) + \lambda_j u^L(\mathbf{x}_j) + \lambda_k u^L(\mathbf{x}_k), \quad \forall\, \mathbf{x}^* \in T_{ijk},$$

where $\lambda_i, \lambda_j, \lambda_k$ are the barycentric coordinates of $\mathbf{x}^*$ in the planar triangle T_{ijk}.

Let $\mathcal{V}_{\mathcal{W}}$ be the space of piecewise constant functions associated with a spherical Voronoi mesh $\mathcal{W} = \{\mathbf{x}_i, V_i\}_{i=1}^n$,

$$\mathcal{V}_{\mathcal{W}} = \{u \mid u(\mathbf{x}) \ \text{ is constant on each cell } \ V_i\}, \tag{3.4}$$

and denote by $\mathcal{U}_{\mathcal{W}}$ the space of all functions u_h on $\mathbb{S}^2$ such that $u_h(\mathbf{x}) = u^L(\mathcal{P}^{-1}(\mathbf{x}))$ for $\mathbf{x} \in \mathbb{S}^2$, where u^L is a piecewise linear function on $\mathbf{S}^*$ with $\{u^L(\mathbf{x}_i) = u_h(\mathbf{x}_i)\}_{i=1}^n$, i.e., $Eu_h(\mathbf{x}^*) = u^L(\mathbf{x}^*)$ for any $\mathbf{x}^* \in \mathbf{S}^*$.

If we interpret the Sobolev space on $\mathbf{S}^*$ in the piecewise sense, then it is easy to get $u_h \in H^1(\mathbb{S}^2)$ for any $u_h \in \mathcal{U}_{\mathcal{W}}$ using (3.2) and the fact that $Eu_h = u^L \in H^1(\mathbf{S}^*)$.

We now state some standard estimates on $\mathcal{P}_{\mathcal{U}}(u)$ and $\mathcal{P}_{\mathcal{V}}(u)$ which are the interpolants on $\mathcal{U}_{\mathcal{W}}$ and $\mathcal{V}_{\mathcal{W}}$, respectively, of a function u defined on $\mathbb{S}^2$.

Proposition 3. *For any $u \in H^2(\mathbb{S}^2)$, there exists a generic constant $C > 0$ such that*

$$\begin{cases} \|u - \mathcal{P}_{\mathcal{U}}(u)\|_{L^2(\mathbb{S}^2)} + h\|u - \mathcal{P}_{\mathcal{U}}(u)\|_{H^1(\mathbb{S}^2)} \le Ch^2\|u\|_{H^2(\mathbb{S}^2)}, \\ \|u - \mathcal{P}_{\mathcal{V}}(u)\|_{L^2(\mathbb{S}^2)} \le Ch\|u\|_{H^2(\mathbb{S}^2)}. \end{cases} \tag{3.5}$$

Proof. Note that $\mathcal{P}_{\mathcal{U}}(u)(\mathbf{x}) = u^L(\mathcal{P}^{-1}(\mathbf{x}))$ with

$$u^L(\mathbf{x}^*) = \lambda_i u(\mathbf{x}_i) + \lambda_j u(\mathbf{x}_j) + \lambda_k u(\mathbf{x}_k) \quad \forall\, \mathbf{x}^* \in T_{ijk}.$$

Using the estimate for the linear interpolation on planar triangles and the relation

$$u(\mathbf{x}) - \mathcal{P}_{\mathcal{U}}(u)(\mathbf{x}) = \tilde{u}(\mathcal{P}^{-1}(\mathbf{x})) - u^L(\mathcal{P}^{-1}(\mathbf{x})),$$

where $\tilde{u} = Eu|_{\mathbf{S}^*}$, we obtain by (3.1) and Proposition 2 that

$$\begin{aligned}
\|u - \mathcal{P}_{\mathcal{U}}(u)\|_{L^2(\mathbb{S}^2)} &= \left(\sum_{\tilde{T}_{ijk} \in \tilde{\mathcal{T}}} \int_{\tilde{T}_{ijk}} |u(\mathbf{x}) - \mathcal{P}_{\mathcal{U}}(u)(\mathbf{x})|^2 \, ds(\mathbf{x}) \right)^{1/2} \\
&= \left(\sum_{\tilde{T}_{ijk} \in \tilde{\mathcal{T}}} \int_{\tilde{T}_{ijk}} |\tilde{u}(\mathcal{P}^{-1}(\mathbf{x})) - u^L(\mathcal{P}^{-1}(\mathbf{x}))|^2 \, ds(\mathbf{x}) \right)^{1/2} \\
&\le C \left(\sum_{T_{ijk} \in \mathcal{T}} \int_{T_{ijk}} |\tilde{u}(\mathbf{x}^*) - u^L(\mathbf{x}^*)|^2 \, ds(\mathbf{x}^*) \right)^{1/2} \qquad (3.6) \\
&\le Ch^2 \left(\sum_{T_{ijk} \in \mathcal{T}} \|\tilde{u}\|^2_{H^2(T_{ijk})} \right)^{1/2} \\
&\le Ch^2 \left(\sum_{\tilde{T}_{ijk} \in \tilde{\mathcal{T}}} \|u\|^2_{H^2(\tilde{T}_{ijk})} \right)^{1/2} = Ch^2 \|u\|_{H^2(\mathbb{S}^2)}\,.
\end{aligned}$$

The other estimates can be proved in similar manners. We omit the details. □

For given functions $u, v \in \mathcal{V}_{\mathcal{W}}$, or $\mathcal{U}_{\mathcal{W}}$, we define, similar to [27], the discrete inner products and norms associated with a spherical Voronoi mesh $\mathcal{W} = \{\mathbf{x}_i, V_i\}_{i=1}^n$ by the following:

$$\begin{cases}
(u,v)_{\mathcal{W}} = \displaystyle\sum_{i=1}^n m(V_i) u(\mathbf{x}_i) v(\mathbf{x}_i)\,, \quad \|u\|^2_{0,\mathcal{W}} = (u,u)_{\mathcal{W}}, \\
|u|^2_{1,\mathcal{W}} = \displaystyle\frac{1}{2} \sum_{i=1}^n \sum_{j \in \chi_i} m(\Gamma_{ij}) d(\mathbf{x}_i, \mathbf{x}_j) \left(\frac{u(\mathbf{x}_i) - u(\mathbf{x}_j)}{|\mathbf{x}_i - \mathbf{x}_j|} \right)^2, \\
\|u\|^2_{1,\mathcal{W}} = \|u\|^2_{0,\mathcal{W}} + |u|^2_{1,\mathcal{W}}.
\end{cases}$$

Norms for general function spaces can also be defined.

We conclude with some norm equivalence results under mesh regularity assumptions. For convenience, we assume that all three angles of T_{ijk} are less than 90°. This is generally valid for the triangles in the SCVMs with sufficiently large (no smaller than 42, for example, for the constant density) number of vertices (generators) or, equivalently, sufficient small h. Using (3.1), Propositions 1 and 2, and similar arguments as those in Proposition 1 of section 2.1 in [26], we have the following.

PROPOSITION 4. *For any $u_h \in \mathcal{U}_{\mathcal{W}}$, there exist some constants $\{C_i > 0\}_{i=1}^4$,*

$$\begin{cases}
C_1 \|u_h\|_{0,\mathcal{W}} \le \|u_h\|_{L^2(\mathbb{S}^2)} \le C_2 \|u_h\|_{0,\mathcal{W}}, \\
C_3 \|u_h\|_{1,\mathcal{W}} \le \|u_h\|_{H^1(\mathbb{S}^2)} \le C_4 \|u_h\|_{1,\mathcal{W}}.
\end{cases} \qquad (3.7)$$

The results of Proposition 4 are in fact valid for more general Voronoi–Delaunay meshes that satisfy the local mesh regular properties. Let $l(\tilde{T}_{ijk})$ be the maximum number of spherical Voronoi regions V_m having nonempty intersection $V_m \cap \tilde{T}_{ijk}$ for any spherical triangle $\tilde{T}_{ijk}$, and let $l(V_m)$ be the maximum number of spherical triangles $\tilde{T}_{ijk}$ needed to cover any spherical Voronoi region V_m; we need all the $\{l(\tilde{T}_{ijk})\}$ and $\{l(V_m)\}$ to be bounded above by a constant integer independent of h. Under those conditions and the mesh regularity conditions, the above equivalence of norms still holds.

3.2. A finite volume discretization scheme. Based on Green's formula, a finite volume method for (1.1) was proposed in [9]. Set $\{u_i^h = u^h(\mathbf{x}_i)\}_{i=1}^n$ and let the approximate flux $\mathcal{F}_{ij}$ be defined by

$$\mathcal{F}_{ij} = -m(\Gamma_{ij}) a_{ij} \frac{u_j^h - u_i^h}{|\mathbf{x}_j - \mathbf{x}_i|} \approx \int_{\Gamma_{ij}} (-a(\mathbf{x}) \nabla_s u(\mathbf{x})) \cdot \vec{\mathbf{n}}_{\mathbf{x},V_i} \, d\gamma(\mathbf{x}) \,, \tag{3.8}$$

where $a_{ij} m(\Gamma_{ij}) = \int_{\Gamma_{ij}} a(\mathbf{x}) \, d\gamma(\mathbf{x})$. An up-wind approximate convection flux $\mathcal{V}_{i,j}$ was defined in [18] by

$$\mathcal{V}_{ij} = \beta_{ij}^+ u_i^h + \beta_{ij}^- u_j^h \approx \int_{\Gamma_{ij}} (\vec{\mathbf{v}}(\mathbf{x}) u(\mathbf{x})) \cdot \vec{\mathbf{n}}_{\mathbf{x},V_i} \, d\gamma(\mathbf{x}) \,, \tag{3.9}$$

where $\beta_{ij}^+ = (\beta_{ij} + |\beta_{ij}|)/2$, $\beta_{ij}^- = (\beta_{ij} - |\beta_{ij}|)/2$, and $\beta_{ij} = \int_{\Gamma_{ij}} \vec{\mathbf{v}}(\mathbf{x}) \cdot \vec{\mathbf{n}}_{\mathbf{x},V_i} \, d\gamma(\mathbf{x})$.

For all V_i, let f_i and b_i denote, respectively, the mean value of f and b on V_i; i.e.,

$$f_i = \frac{1}{m(V_i)} \int_{V_i} f(\mathbf{x}) \, ds(\mathbf{x}) \qquad \text{and} \qquad b_i = \frac{1}{m(V_i)} \int_{V_i} b(\mathbf{x}) \, ds(\mathbf{x}) \,. \tag{3.10}$$

The finite volume scheme given in [9] is defined as follows: find $u^h \in \mathcal{V}_{\mathcal{W}}$ such that

$$(\mathcal{L}^h u^h)_i = \frac{1}{m(V_i)} \sum_{j \in \chi_i} \left(\mathcal{F}_{ij} + \mathcal{V}_{ij} \right) + b_i u_i^h = f_i \qquad \text{for} \quad i = 1, \dots, n \,. \tag{3.11}$$

Since $\mathcal{F}_{ij} = -\mathcal{F}_{ji}$ and $\mathcal{V}_{ij} = -\mathcal{V}_{ji}$ for neighboring $\mathbf{x}_i$ and $\mathbf{x}_j$ with $m(\Gamma_{ij}) > 0$, the above scheme satisfies the discrete conservation law

$$\sum_{i=1}^n \sum_{j \in \chi_i} (\mathcal{F}_{ij} + \mathcal{V}_{ij}) = 0 \,.$$

Note that an approximate convection flux of the form $\mathcal{V}_{i,j} = (u_i^h + u_j^h)\beta_{ij}/2$ leads to a central difference scheme. A stability condition such as

$$P_i = \max_{j \in \chi_i} \frac{|\beta_{ij}| \cdot |\mathbf{x}_i - \mathbf{x}_j|}{2m(\Gamma_{ij}) a_{ij}} \le 1 \quad \text{for} \quad i = 1, \dots, n$$

is needed in such a case. P_i is called the local Peclet number [18, 27].

3.3. Previous results and a modified scheme. Assuming that $\mathcal{W}$ is *regular* in the sense that σ is not *too small*, i.e., it remains bounded from below as $h \to 0$, then the following result has been proved in [9].

THEOREM 1. *Let Assumption* 1 *be satisfied and the mesh be regular, and let* $\mathcal{F}_{ij}$*,* $\mathcal{V}_{ij}$*,* f_i*, and* b_i *be defined by* (3.8)–(3.10)*. Then the discrete system* (3.11) *has a unique* *solution $u^h \in \mathcal{V}_\mathcal{W}$. Furthermore, assume that the unique solution u of* (1.1) *belongs to $H^2(\mathbb{S}^2)$; then there exists a constant $C > 0$ only depending on a, $\vec{\mathbf{v}}$, b, and σ such that*

$$\|e^h\|_{1,\mathcal{W}} \le Ch\|u\|_{H^2(\mathbb{S}^2)}\ , \tag{3.12}$$

where $e^h = \{e_i^h = u(\mathbf{x}_i) - u_i^h\}$.

Note that Theorem 1 holds for general regular spherical Voronoi meshes. For more existing studies on the finite volume methods, especially when applied to solve second order elliptic on the 2d plane, we refer to [1, 3, 4, 5, 12, 14, 15, 20, 26, 25, 28, 29, 34, 35].

To get second order accuracy for the L^2 estimates, the order of approximation for the convection term used in the original scheme needs to be improved with better integration rules. For this purpose, let us define the bilinear functionals $\mathcal{A}^*$ and $\mathcal{A}_\mathcal{W}$ such that

$$\mathcal{A}^*(u, v^h) = \sum_{i=1}^n v^h(\mathbf{x}_i)\mathcal{A}^*(u, \psi_i)\ , \quad \mathcal{A}_\mathcal{W}(u, v^h) = \sum_{i=1}^n v^h(\mathbf{x}_i)\mathcal{A}_\mathcal{W}(u, \psi_i) \tag{3.13}$$

for any $u \in H^2(\mathbb{S}^2) \cup \mathcal{U}_\mathcal{W}$ and $v^h \in \mathcal{V}_\mathcal{W}$, where

$$\mathcal{A}^*(u, \psi_i) = \int_{\partial V_i} (-\nabla_s u(\mathbf{x}) + \vec{\mathbf{v}}(\mathbf{x})u(\mathbf{x})) \cdot \vec{\mathbf{n}}_{\mathbf{x},V_i}\ d\gamma(\mathbf{x}) + \int_{V_i} b(\mathbf{x})P_\mathcal{V}(u)(\mathbf{x})\ ds(\mathbf{x})\ ,$$

$$\mathcal{A}_\mathcal{W}(u, \psi_i) = \sum_{j\in\chi_i} \mathcal{F}_{ij}(u) + \int_{\partial V_i} \mathcal{P}_\mathcal{U}(u)(\mathbf{x})(\vec{\mathbf{v}}(\mathbf{x}) \cdot \vec{\mathbf{n}}_{\mathbf{x},V_i})\ d\gamma(\mathbf{x}) + m(V_i)b_i u(\mathbf{x}_i)\ .$$

Comparing $\mathcal{A}_\mathcal{W}$ with the finite volume scheme (3.11), we have in fact replaced only the convection term $\mathcal{V}_{ij}$ by $\int_{\partial V_i} \mathcal{P}_\mathcal{U}(u)(\mathbf{x})(\vec{\mathbf{v}}(\mathbf{x})\cdot\vec{\mathbf{n}}_{\mathbf{x},V_i})\ d\gamma(\mathbf{x})$. Note that no change is made for a pure diffusion problem containing only the second order terms $\nabla_s \cdot (a(\mathbf{x})\nabla_s u(\mathbf{x}))$. Our discrete problem here is then as follows: find $u_h \in \mathcal{U}_\mathcal{W}$ such that

$$\mathcal{A}_\mathcal{W}(u_h, v^h) = (f, v^h) \quad \forall\ v^h \in \mathcal{V}_\mathcal{W}\ , \tag{3.14}$$

i.e.,

$$\mathcal{A}_\mathcal{W}(u_h, \psi_i) = f_i \qquad \text{for} \quad i = 1, 2, \dots, n.$$

Formulations like the above for finite volume methods have been used, for instance, in [26]. Combining Proposition 3 and Proposition 4, it can be shown that the error estimate of Theorem 1 still holds for the above u_h using analysis similar to that used in [9].

THEOREM 2. *Suppose that Assumption* 1 *is satisfied. Let $\mathcal{F}_{ij}$ be defined by* (3.8). *Then the discrete system* (3.14) *has a unique solution $u_h \in \mathcal{U}_\mathcal{W}$. Furthermore, assume that the unique solution u of* (1.1) *belongs to $H^2(\mathbb{S}^2)$; then there exists a constant $C > 0$ only depending on a, $\vec{\mathbf{v}}$, b, and σ such that for $e_h = u - u_h$, we have*

$$\|e_h\|_{H^1(\mathbb{S}^2)} \le Ch\|u\|_{H^2(\mathbb{S}^2)}\ . \tag{3.15}$$

Proof. Notice that $\|\mathcal{P}_\mathcal{U}(u) - u_h\|_{1,\mathcal{W}} = \|e_h\|_{1,\mathcal{W}}$; then we have

$$\begin{aligned}\|e_h\|_{H^1(\mathbb{S}^2)} &= \|u - u_h\|_{H^1(\mathbb{S}^2)}\\ &\le \|u - \mathcal{P}_\mathcal{U}(u)\|_{H^1(\mathbb{S}^2)} + \|\mathcal{P}_\mathcal{U}(u) - u_h\|_{H^1(\mathbb{S}^2)}\\ &\le C_1 h\|u\|_{H^2(\mathbb{S}^2)} + C_2\|\mathcal{P}_\mathcal{U}(u) - u_h\|_{1,\mathcal{W}}\\ &= C_1 h\|u\|_{H^2(\mathbb{S}^2)} + C_2\|e_h\|_{1,\mathcal{W}} \le Ch\|u\|_{H^2(\mathbb{S}^2)},\end{aligned}$$

where the conclusion of Theorem 1 has been used. ☐

4. L^2 error estimate on SCVMs.

An improved error estimate in the L^2 norm is generally expected for our finite volume approximations of second order elliptic equations. However, it is shown here that the quadratic order error estimate can only be proved when the grid satisfies certain geometric constraints. In fact, a part of the estimate depends critically on the property that if $\mathcal{W} = \{\mathbf{x}_i, V_i\}_{i=1}^n$ is an SCVT of $\mathbb{S}^2$ corresponding to a density function ρ, then

$$\int_{V_i} \rho(\mathbf{x})(\mathbf{x}_i^* - \mathbf{x})\, ds(\mathbf{x}) = 0, \quad \forall\, i = 1, 2, \dots, n,$$

where $\mathbf{x}_i^*$ is the standard mass centroid of V_i, whose projection $\mathbf{x}_i^c$ (through the standard map $\mathcal{P}$) onto the sphere coincides with $\mathbf{x}_i$. We note that so far we have not been able to extend the elegant analysis of the covolume schemes for planar Poisson equations in [28, 29] to our context, nor we have found any improvement of the results there for the SCVT-based meshes. Thus, we resort to a more traditional approach of obtaining estimates through appropriate weak forms.

For the rest of the section, only those schemes based on SCVMs are analyzed.

4.1. A technical lemma.

For the interpolation operator $\mathcal{P}_{\mathcal{V}}$, we present a better approximation result that requires the properties of the SCVMs.

Lemma 1. *Suppose that $\mathcal{W} = \{\mathbf{x}_i, V_i\}_{i=1}^n$ is an SCVT of $\mathbb{S}^2$ with the density function ρ satisfying $\rho \in C^1(\mathbb{S}^2)$ and $\rho(\mathbf{x}) > 0$ for any $\mathbf{x} \in \mathbb{S}^2$. Then, for any $w \in H^2(\mathbb{S}^2)$, there exits a constant $C > 0$ such that*

$$\left| \int_{V_i} (w - \mathcal{P}_{\mathcal{V}}(w))\ ds(\mathbf{x}) \right| \le C h^2 m(V_i)^{1/2} \|w\|_{H^2(V_i)}, \quad i = 1, \dots, n. \tag{4.1}$$

Proof. Let us assume that $w \in C^2(\mathbb{S}^2)$; then it is easy to see that $Ew \in C^2(\Omega)$. Consider the spherical Voronoi region V_i associated with $\mathbf{x}_i$, for any $\mathbf{x} \in V_i$. We have

$$\begin{aligned} w(\mathbf{x}_i) - w(\mathbf{x}) &= Ew(\mathbf{x}_i) - Ew(\mathbf{x}) \\ &= \nabla Ew(\mathbf{x}) \cdot (\mathbf{x}_i - \mathbf{x}) + \int_0^1 H(Ew)(t\mathbf{x} + (1-t)\mathbf{x}_i)(\mathbf{x}_i - \mathbf{x}) \cdot (\mathbf{x}_i - \mathbf{x}) t dt, \end{aligned}$$

where $H(Ew)(\mathbf{x})$ denotes the Hessian matrix of Ew at $\mathbf{x}$. Thus

$$\left| \int_{V_i} w - \mathcal{P}_{\mathcal{V}}(w)\ ds(\mathbf{x}) \right| \le E_1 + E_2 + E_3,$$

where, with $\mathbf{x}_i^*$ being the mass centroid of V_i in R^3 with the density ρ, we have

$$\begin{aligned} E_1 &= \left| \int_{V_i} \nabla Ew(\mathbf{x}) \cdot (\mathbf{x}_i^* - \mathbf{x})\ ds(\mathbf{x}) \right| = \left| \int_{V_i} \nabla_s w(\mathbf{x}) \cdot (\mathbf{x}_i^* - \mathbf{x})\ ds(\mathbf{x}) \right|, \\ E_2 &= \left| \int_{V_i} \nabla Ew(\mathbf{x}) \cdot (\mathbf{x}_i - \mathbf{x}_i^*)\ ds(\mathbf{x}) \right| = \left| \int_{V_i} \nabla_s w(\mathbf{x}) \cdot (\mathbf{x}_i - \mathbf{x}_i^*)\ ds(\mathbf{x}) \right|, \\ E_3 &= \int_{V_i} \int_0^1 |H(Ew)(t\mathbf{x} + (1-t)\mathbf{x}_i)(\mathbf{x}_i - \mathbf{x}) \cdot (\mathbf{x}_i - \mathbf{x})| t dt\ ds(\mathbf{x}). \end{aligned}$$

Using the property of the SCVT that $\int_{V_i} \rho(\mathbf{x})(\mathbf{x}_i^* - \mathbf{x})\, ds(\mathbf{x}) = 0$, we have

$$\begin{aligned} E_1 &= \left| \int_{V_i} \nabla_s w(\mathbf{x}) \cdot (\mathbf{x}_i^* - \mathbf{x}) - \frac{\rho(\mathbf{x})}{\rho(\mathbf{x}_i)} \Pi_{\mathcal{V}}(\nabla_s w) \cdot (\mathbf{x}_i^* - \mathbf{x})\, ds(\mathbf{x}) \right| \\ &\leq \left| \int_{V_i} \frac{\rho(\mathbf{x}) - \rho(\mathbf{x}_i)}{\rho(\mathbf{x}_i)} \nabla_s w(\mathbf{x}) \cdot (\mathbf{x}_i^* - \mathbf{x})\, ds(\mathbf{x}) \right| \\ &\quad + \left| \int_{V_i} \frac{\rho(\mathbf{x})}{\rho(\mathbf{x}_i)} (\nabla_s w(\mathbf{x}) - \Pi_{\mathcal{V}}(\nabla_s w)) \cdot (\mathbf{x}_i^* - \mathbf{x})\, ds(\mathbf{x}) \right|, \end{aligned}$$

where $\Pi_{\mathcal{V}}$ denotes the L^2 projection on $\mathcal{V}_{\mathcal{W}}$. Denoting the two terms on the right-hand side of the last equation by E_4 and E_5, respectively, we have

$$\begin{aligned} E_4 &\leq h \int_{V_i} \frac{\max_{\mathbf{x}\in\Omega} |\nabla E\rho(\mathbf{x})|}{|\rho(\mathbf{x}_i)|} |\nabla_s w(\mathbf{x})|\, \|\mathbf{x}_i^* - \mathbf{x}\|\, ds(\mathbf{x}) \\ &\leq 2h^2 \int_{V_i} \frac{\max_{\mathbf{x}\in\Omega} |\nabla_s \rho(\mathbf{x})|}{|\rho(\mathbf{x}_i)|} |\nabla_s w(\mathbf{x})|\, ds(\mathbf{x}) \qquad (4.2) \\ &\leq Ch^2 \int_{V_i} |\nabla_s w(\mathbf{x})|\, ds(\mathbf{x}) \leq Ch^2 m(V_i)^{1/2} \|w\|_{H^2(V_i)} \end{aligned}$$

and

$$\begin{aligned} E_5 &\leq \int_{V_i} \frac{\max_{\mathbf{x}\in\Omega} |\rho(\mathbf{x})|}{|\rho(\mathbf{x}_i)|} |\nabla_s w(\mathbf{x}) - \Pi_{\mathcal{V}}(\nabla_s w)|\, \|\mathbf{x}_i^* - \mathbf{x}\|\, ds(\mathbf{x})| \\ &\leq C \|\nabla_s w - \Pi_{\mathcal{V}}(\nabla_s w)\|_{L^2(V_i)} \left(\int_{V_i} \|\mathbf{x}_i^* - \mathbf{x}\|^2\, ds(\mathbf{x}) \right)^{1/2} \qquad (4.3) \\ &\leq Ch^2 m(V_i)^{1/2} \|w\|_{H^2(V_i)}. \end{aligned}$$

Combining (4.2) and (4.3), we get

$$E_1 \leq Ch^2 m(V_i)^{1/2} \|w\|_{H^2(V_i)}\ . \qquad (4.4)$$

Consider E_2. Since $\mathbf{x}_i = \mathbf{x}_i^*/|\mathbf{x}_i^*|$, by (3.1) we know that $|\mathbf{x}_i - \mathbf{x}_i^*| < ch^2$. Thus

$$\begin{aligned} E_2 &\leq Ch^2 \left(\int_{V_i} |\nabla_s w(\mathbf{x})|^2\, ds(\mathbf{x}) \right)^{1/2} \left(\int_{V_i} ds(\mathbf{x}) \right)^{1/2} \qquad (4.5) \\ &\leq Ch^2 m(V_i)^{1/2} \|w\|_{H^1(V_i)}. \end{aligned}$$

On the other hand, for E_3, let $V_i^t = \{\mathbf{x}^* = t\mathbf{x} + (1-t)\mathbf{x}_i \mid \mathbf{x} \in V_i\}$. By changing variable $\mathbf{x}^* = t\mathbf{x} + (1-t)\mathbf{x}_i$ and using $ds(\mathbf{x}) \leq 2ds(\mathbf{x}^*)/t^2$, we get

$$E_3 \leq 2h^2 \int_0^1 \int_{V_i^t} (|H(Ew)|/t)\, ds(\mathbf{x}^*) dt\ .$$

Obviously, $m(V_i^t) \leq t^2 m(V_i)$. By a proof similar to that given in [9], we get

$$\begin{aligned} E_3 &\leq 2h^2 \int_0^1 \left(\int_{V_i^t} |H(Ew)|^2\, ds(\mathbf{x}^*) \right)^{1/2} m(V_i)^{1/2} dt \\ &\leq Ch^2 m(V_i)^{1/2} \|w\|_{H^2(V_i)}\ . \qquad (4.6) \end{aligned}$$

Finally, we obtain (4.1) for $u \in H^2(\mathbb{S}^2)$ by combining (4.4) and (4.5) with (4.6) and invoking a density argument. □

Note that in the planar case we have $E_2 = 0$ instead of (4.5).

4.2. Estimates for the weak forms. For simplicity, we assume $a(\mathbf{x}) = 1$. We first compare the bilinear forms (1.2) and (3.13). Let $\vec{\mathbf{n}}_{\mathbf{x},\tilde{T}_{ijk}}$ be the unit outer normal at $\mathbf{x} \in \partial\tilde{T}_{ijk}$ of the boundary of $\tilde{T}_{ijk}$ that is tangent to $\mathbb{S}^2$. By Green's formula, for $\mathcal{W} \in H^2(\mathbb{S}^2)$ we have

$$\begin{aligned}
\mathcal{A}(u-u_h, \mathcal{P}_{\mathcal{U}}(w)) &= \int_{\mathbb{S}^2} \nabla_s(u-u_h)\cdot\nabla_s\mathcal{P}_{\mathcal{U}}(w)\; ds(\mathbf{x}) \\
&= \sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \left(\int_{\tilde{T}_{ijk}} \nabla_s(u-u_h)\cdot\nabla_s\mathcal{P}_{\mathcal{U}}(w) + (u-u_h)(\vec{\mathbf{v}}\cdot\nabla_s\mathcal{P}_{\mathcal{U}}(w))\; ds(\mathbf{x}) \right) \\
&\qquad + \int_{\mathbb{S}^2} b(u-u_h)\mathcal{P}_{\mathcal{U}}(w)\; ds(\mathbf{x}) \\
&= \sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \left(\int_{\tilde{T}_{ijk}} -\triangle_s(u-u_h)\mathcal{P}_{\mathcal{U}}(w) + (\nabla_s\cdot(u-u_h)\vec{\mathbf{v}})\mathcal{P}_{\mathcal{U}}(w)\; ds(\mathbf{x}) \right. \\
&\qquad \left. + \int_{\partial\tilde{T}_{ijk}} (\nabla_s(u-u_h)\cdot\vec{\mathbf{n}}_{\mathbf{x},\tilde{T}_{ijk}})\mathcal{P}_{\mathcal{U}}(w) - (u-u_h)(\vec{\mathbf{v}}\cdot\vec{\mathbf{n}}_{\mathbf{x},\tilde{T}_{ijk}})\mathcal{P}_{\mathcal{U}}(w)\; d\gamma(\mathbf{x}) \right) \\
&\qquad + \int_{\mathbb{S}^2} b(u-u_h)\mathcal{P}_{\mathcal{U}}(w)\; ds(\mathbf{x})\ ,
\end{aligned} \tag{4.7}$$

$$\begin{aligned}
\mathcal{A}^*(u-u_h, \mathcal{P}_{\mathcal{V}}(w)) &= \sum_{i=1}^{n} \mathcal{P}_{\mathcal{V}}(w)(\mathbf{x}_i)\mathcal{A}^*(u-u_h, \psi_i) \\
&= \sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \left(\int_{\tilde{T}_{ijk}} -\triangle_s(u-u_h)\mathcal{P}_{\mathcal{V}}(w) + (\nabla_s\cdot(u-u_h)\vec{\mathbf{v}})\mathcal{P}_{\mathcal{V}}(w)\; ds(\mathbf{x}) \right. \\
&\qquad \left. + \int_{\partial\tilde{T}_{ijk}} (\nabla_s(u-u_h)\cdot\vec{\mathbf{n}}_{\mathbf{x},\tilde{T}_{ijk}})\mathcal{P}_{\mathcal{V}}(w) - (u-u_h)(\vec{\mathbf{v}}\cdot\vec{\mathbf{n}}_{\mathbf{x},\tilde{T}_{ijk}})\mathcal{P}_{\mathcal{V}}(w)\; d\gamma(\mathbf{x}) \right) \\
&\qquad + \int_{\mathbb{S}^2} bP_{\mathcal{V}}(u-u_h)\mathcal{P}_{\mathcal{V}}(w)\; ds(\mathbf{x}).
\end{aligned} \tag{4.8}$$

We now compare the first term of each functional.

LEMMA 2. *There is a constant $C > 0$ such that for $u \in H^3(\mathbb{S}^2)$ and $w \in H^2(\mathbb{S}^2)$,*

$$\left| \sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \int_{\tilde{T}_{ijk}} \triangle_s u(\mathcal{P}_{\mathcal{U}}(w) - \mathcal{P}_{\mathcal{V}}(w))\; ds(\mathbf{x}) \right| \le Ch^2 \|u\|_{H^3(\mathbb{S}^2)} \|w\|_{H^2(\mathbb{S}^2)}\ . \tag{4.9}$$

Proof. Letting E denote the left-hand side of (4.9), we have

$$\begin{aligned}
E &= \left| \sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \int_{\tilde{T}_{ijk}} \triangle_s u(\mathcal{P}_{\mathcal{U}}(w) - \mathcal{P}_{\mathcal{V}}(w))\; ds(\mathbf{x}) \right| \\
&\le \left| \sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \int_{\tilde{T}_{ijk}} \triangle_s u(\mathcal{P}_{\mathcal{U}}(w) - w)\; ds(\mathbf{x}) \right| + \left| \sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \int_{\tilde{T}_{ijk}} \triangle_s u(\mathcal{P}_{\mathcal{V}}(w) - w)\; ds(\mathbf{x}) \right| \\
&\le \left| \sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \int_{\tilde{T}_{ijk}} \triangle_s u(\mathcal{P}_{\mathcal{U}}(w) - w)\; ds(\mathbf{x}) \right| + \left| \sum_{i=1}^{n} \int_{V_i} \Pi_{\mathcal{V}}(\triangle_s u)(\mathcal{P}_{\mathcal{V}}(w) - w)\; ds(\mathbf{x}) \right| \\
&\qquad + \left| \sum_{i=1}^{n} \int_{V_i} (\triangle_s u(\mathbf{x}) - \Pi_{\mathcal{V}}(\triangle_s u))(\mathcal{P}_{\mathcal{V}}(w) - w)\; ds(\mathbf{x}) \right|,
\end{aligned} \tag{4.10}$$

where $\Pi_{\mathcal{V}}$ denotes the L^2 projection on $\mathcal{V}_{\mathcal{W}}$. Using Proposition 3 and the Cauchy–Schwarz inequality, we get

$$\left| \sum_{\tilde{T}_{ijk} \in \tilde{\mathcal{T}}} \int_{\tilde{T}_{ijk}} \triangle_s u(\mathcal{P}_{\mathcal{U}}(w) - w) \, ds(\mathbf{x}) \right| \le Ch^2 \|u\|_{H^2(\mathbb{S}^2)} \|w\|_{H^2(\mathbb{S}^2)}.$$

Using Lemma 1, we have

$$\begin{aligned} \left| \sum_{i=1}^n \int_{V_i} \Pi_{\mathcal{V}}(\triangle_s u)(\mathcal{P}_{\mathcal{V}}(w) - w) \, ds(\mathbf{x}) \right| &\le Ch^2 \sum_{i=1}^n |\Pi_{\mathcal{V}}(\triangle_s u)|_{V_i}| \, m(V_i)^{1/2} \|w\|_{H^2(V_i)} \\ &= Ch^2 \|\Pi_{\mathcal{V}}(\triangle_s u)\|_{L^2(\mathbb{S}^2)} \|w\|^2_{H^2(\mathbb{S}^2)} \\ &\le Ch^2 \|u\|_{H^2(\mathbb{S}^2)} \|w\|_{H^2(\mathbb{S}^2)} \end{aligned}$$

$$\left| \sum_{i=1}^n \int_{V_i} (\triangle_s u(\mathbf{x}) - \Pi_{\mathcal{V}}(\triangle_s u))(\mathcal{P}_{\mathcal{V}}(w) - w) \, ds(\mathbf{x}) \right| \le Ch^2 \|u\|_{H^3(\mathbb{S}^2)} \|w\|_{H^2(\mathbb{S}^2)} \; .$$

Thus we obtain the estimate (4.9) in the lemma. □

Now we are ready to show the following.

LEMMA 3. *Let $u_h \in \mathcal{U}_{\mathcal{W}}$ be the unique solution of the discrete system* (3.14) *and assume that the unique variational solution u of* (1.1) *belongs to $H^3(\mathbb{S}^2)$. Then, for any $w \in H^2(\mathbb{S}^2)$, there exists a constant $C > 0$ such that*

$$|\mathcal{A}(u - u_h, \mathcal{P}_{\mathcal{U}}(w)) - \mathcal{A}^*(u - u_h, \mathcal{P}_{\mathcal{V}}(w))| \le Ch^2 \|u\|_{H^3(\mathbb{S}^2)} \|w\|_{H^2(\mathbb{S}^2)}. \tag{4.11}$$

Proof. By equation (4.8) we obtain

$$\mathcal{A}(u - u_h, \mathcal{P}_{\mathcal{U}}(w)) - \mathcal{A}^*(u - u_h, \mathcal{P}_{\mathcal{V}}(w)) = E_1 + E_2 + E_3 + E_4 + E_5 + E_6, \tag{4.12}$$

where

$$\begin{aligned} E_1 &= - \sum_{\tilde{T}_{ijk} \in \tilde{\mathcal{T}}} \int_{\tilde{T}_{ijk}} \triangle_s u(\mathcal{P}_{\mathcal{U}}(w) - \mathcal{P}_{\mathcal{V}}(w)) \, ds(\mathbf{x}) \; , \\ E_2 &= \sum_{\tilde{T}_{ijk} \in \tilde{\mathcal{T}}} \int_{\tilde{T}_{ijk}} \triangle_s u_h(\mathcal{P}_{\mathcal{U}}(w) - \mathcal{P}_{\mathcal{V}}(w)) \, ds(\mathbf{x}) \; , \\ E_3 &= \sum_{\tilde{T}_{ijk} \in \tilde{\mathcal{T}}} \int_{\partial \tilde{T}_{ijk}} (\nabla_s (u - u_h) \cdot \vec{\mathbf{n}}_{\mathbf{x}, \tilde{T}_{ijk}})(\mathcal{P}_{\mathcal{V}}(w) - \mathcal{P}_{\mathcal{U}}(w)) \, d\gamma(\mathbf{x}) \; , \\ E_4 &= \sum_{\tilde{T}_{ijk} \in \tilde{\mathcal{T}}} \int_{\tilde{T}_{ijk}} (\nabla_s \cdot (u - u_h)\vec{\mathbf{v}})(\mathcal{P}_{\mathcal{U}}(w) - \mathcal{P}_{\mathcal{V}}(w)) \, ds(\mathbf{x}) \; , \\ E_5 &= \sum_{\tilde{T}_{ijk} \in \tilde{\mathcal{T}}} \int_{\partial \tilde{T}_{ijk}} (u - u_h)(\vec{\mathbf{v}} \cdot \vec{\mathbf{n}}_{\mathbf{x}, \tilde{T}_{ijk}})(\mathcal{P}_{\mathcal{V}}(w) - \mathcal{P}_{\mathcal{U}}(w)) \, d\gamma(\mathbf{x}) \; , \\ E_6 &= \int_{\mathbb{S}^2} b((u - u_h)\mathcal{P}_{\mathcal{U}}(w) - P_{\mathcal{V}}(u - u_h)\mathcal{P}_{\mathcal{V}}(w)) \, ds(\mathbf{x}) \; . \end{aligned}$$

Consider E_1. By Lemma 2 we have

$$|E_1| \le Ch^2 \|u\|_{H^3(\mathbb{S}^2)} \|w\|_{H^2(\mathbb{S}^2)}. \tag{4.13}$$

As for E_2, using Proposition 3 and Theorem 2 we have

$$\begin{aligned} |E_2| &\le \sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \int_{\tilde{T}_{ijk}} |\triangle_s u_h(\mathcal{P}_{\mathcal{U}}(w)-\mathcal{P}_{\mathcal{V}}(w))|\, ds(\mathbf{x}) \\ &\le Ch \sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \int_{\tilde{T}_{ijk}} |\nabla_s u_h|\, |(\mathcal{P}_{\mathcal{U}}(w)-\mathcal{P}_{\mathcal{V}}(w))|\, ds(\mathbf{x}) \qquad (4.14) \\ &\le Ch^2\|u_h\|_{H^1(\mathbb{S}^2)}\|w\|_{H^2(\mathbb{S}^2)} \le Ch^2\|u\|_{H^2(\mathbb{S}^2)}\|w\|_{H^2(\mathbb{S}^2)}. \end{aligned}$$

According to the continuity of $\nabla_s u$ on each $\partial\tilde{T}_{ijk}$, we have

$$\sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \int_{\partial\tilde{T}_{ijk}} (\nabla_s u\cdot\vec{\mathbf{n}}_{\mathbf{x},\tilde{T}_{ijk}})(\mathcal{P}_{\mathcal{V}}(w)-\mathcal{P}_{\mathcal{U}}(w))\, d\gamma(\mathbf{x}) = 0,$$

and thus we get

$$E_3 = \sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \int_{\partial\tilde{T}_{ijk}} (\nabla_s u_h\cdot\vec{\mathbf{n}}_{\mathbf{x},\tilde{T}_{ijk}})(\mathcal{P}_{\mathcal{V}}(w)-\mathcal{P}_{\mathcal{U}}(w))\, d\gamma(\mathbf{x})\ . \qquad (4.15)$$

Additionally, on each edge $\tilde{L}$ of $\tilde{T}_{ijk}$, by symmetry with respect to the midpoint of $\tilde{L}$, we have that $\nabla_s u_h(z_1)\cdot\vec{\mathbf{n}}_{\mathbf{x},\tilde{T}_{ijk}}$ is an even function for $\mathbf{x}\in\tilde{L}$ while $\mathcal{P}_{\mathcal{V}}(w)-\mathcal{P}_{\mathcal{U}}(w)$ is odd. Thus,

$$\int_{\tilde{L}} (\nabla_s u_h\cdot\vec{\mathbf{n}}_{\mathbf{x},\tilde{T}_{ijk}})(\mathcal{P}_{\mathcal{V}}(w)-\mathcal{P}_{\mathcal{U}}(w))\, d\gamma(\mathbf{x}) = 0.$$

Thus we have

$$E_3 = 0. \qquad (4.16)$$

About E_4, we have by Theorem 2 that

$$\begin{aligned} |E_4| &\le \sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \int_{\tilde{T}_{ijk}} |(\nabla_s\cdot(u-u_h)\vec{\mathbf{v}})(\mathcal{P}_{\mathcal{U}}(w)-\mathcal{P}_{\mathcal{V}}(w))|\, ds(\mathbf{x}) \\ &\le \sup_{\mathbf{x}\in\mathbb{S}^2}(|\vec{\mathbf{v}}|+|\nabla_s\vec{\mathbf{v}}|) \sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \int_{\tilde{T}_{ijk}} |\nabla_s(u-u_h)|\, |\mathcal{P}_{\mathcal{U}}(w)-\mathcal{P}_{\mathcal{V}}(w)|\, ds(\mathbf{x}) \qquad (4.17) \\ &\le Ch\|u-u_h\|_{H^1(\mathbb{S}^2)}\|w\|_{H^2(\mathbb{S}^2)} \le Ch^2\|u\|_{H^2(\mathbb{S}^2)}\|w\|_{H^2(\mathbb{S}^2)}. \end{aligned}$$

About E_5, using Trace theorem [17] and Theorem 2 we have

$$\begin{aligned} |E_5| &\le \sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \int_{\partial\tilde{T}_{ijk}} |(u-u_h)(\vec{\mathbf{v}}\cdot\vec{\mathbf{n}}_{\mathbf{x},\tilde{T}_{ijk}})(\mathcal{P}_{\mathcal{V}}(w)-\mathcal{P}_{\mathcal{U}}(w))|\, d\gamma(\mathbf{x}) \\ &\le \sup_{\mathbf{x}\in\mathbb{S}^2}(|\vec{\mathbf{v}}|)\left(\sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \int_{\partial\tilde{T}_{ijk}} |u-u_h|^2\, d\gamma(\mathbf{x})\right)^{1/2} \\ &\quad \cdot\left(\sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \int_{\partial\tilde{T}_{ijk}} |\mathcal{P}_{\mathcal{V}}(w)-\mathcal{P}_{\mathcal{U}}(w)|^2\, d\gamma(\mathbf{x})\right)^{1/2} \qquad (4.18) \\ &\le C\left(\sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} \|u-u_h\|^2_{H^1(\tilde{T}_{ijk})}\right)^{1/2}\left(\sum_{\tilde{T}_{ijk}\in\tilde{\mathcal{T}}} h^2\|w\|^2_{H^2(\tilde{T}_{ijk})}\right)^{1/2}. \\ &\le Ch\|u-u_h\|_{H^1(\mathbb{S}^2)}\|w\|_{H^2(\mathbb{S}^2)} \le Ch^2\|u\|_{H^2(\mathbb{S}^2)}\|w\|_{H^2(\mathbb{S}^2)}. \end{aligned}$$

About E_6, by Proposition 3 and Theorem 2 we have

$$
\begin{aligned}
|E_6| \le & \left| \int_{\mathbb{S}^2} b(u-u_h)(\mathcal{P}_{\mathcal{U}}(w) - \mathcal{P}_{\mathcal{V}}(w))\, ds(\mathbf{x}) \right| \\
& + \left| \int_{\mathbb{S}^2} b((u-u_h) - \mathcal{P}_{\mathcal{V}}(u-u_h))(\mathcal{P}_{\mathcal{V}}(w))\, ds(\mathbf{x}) \right| \\
\le & C\|u-u_h\|_{L^2(\mathbb{S}^2)}\, \|\mathcal{P}_{\mathcal{U}}(w) - \mathcal{P}_{\mathcal{V}}(w)\|_{L^2(\mathbb{S}^2)} \\
& + Ch\|u-u_h\|_{H^1(\mathbb{S}^2)}\, \|\mathcal{P}_{\mathcal{V}}(w)\|_{L^2(\mathbb{S}^2)} \\
\le & Ch^2\|u\|_{H^2(\mathbb{S}^2)}\|w\|_{H^2(\mathbb{S}^2)}.
\end{aligned} \tag{4.19}
$$

Combining (4.12)–(4.14) and (4.16)–(4.19), we get (4.11). □

We see from the above proof that the extra regularity of $u \in H^3(\mathbb{S}^2)$ is only required for estimating the term E_1 (which is given in Lemma 2); the other terms merely require $u \in H^2(\mathbb{S}^2)$.

LEMMA 4. *Let $u_h \in \mathcal{U}_{\mathcal{W}}$ be the unique solution of the discrete system* (3.14) *and assume that the unique variational solution u of* (1.1) *belongs to $H^2(\mathbb{S}^2)$. Then, for any $w \in H^2(\mathbb{S}^2)$, there exists a constant $C > 0$ such that*

$$
|\mathcal{A}_{\mathcal{W}}(u_h, \mathcal{P}_{\mathcal{V}}(w)) - \mathcal{A}^*(u_h, \mathcal{P}_{\mathcal{V}}(w))| \le Ch^2\|u\|_{H^2(\mathbb{S}^2)}\|w\|_{H^2(\mathbb{S}^2)}\ . \tag{4.20}
$$

Proof. Since $\mathcal{P}_{\mathcal{V}}(u_h)|_{V_i} = u_h(\mathbf{x}_i)$ and $\mathcal{P}_{\mathcal{V}}(w)|_{V_i} = w(\mathbf{x}_i)$, we have

$$
\sum_{i=1}^n \int_{\partial V_i} (u_h - \mathcal{P}_{\mathcal{U}}(u_h))(\vec{\mathbf{v}} \cdot n_{\mathbf{x},V_i})\mathcal{P}_{\mathcal{V}}(w)\, d\gamma(\mathbf{x}) = 0,
$$

$$
\sum_{i=1}^n \left(\int_{V_i} b\mathcal{P}_{\mathcal{V}}(u_h)\mathcal{P}_{\mathcal{V}}(w)\, ds(\mathbf{x}) - m(V_i) b_i u_h(\mathbf{x}_i) w(\mathbf{x}_i) \right) = 0.
$$

Thus

$$
\begin{aligned}
& \mathcal{A}^*(u_h, \mathcal{P}_{\mathcal{V}}(w)) - \mathcal{A}_{\mathcal{W}}(u_h, \mathcal{P}_{\mathcal{V}}(w)) \\
& \quad = \sum_{i=1}^n \left(\int_{\partial V_i} (-\nabla_s u_h(\mathbf{x}) \cdot \vec{\mathbf{n}}_{\mathbf{x},V_i})\mathcal{P}_{\mathcal{V}}(w)\, d\gamma(\mathbf{x}) - \sum_{j\in\chi_i} \mathcal{F}_{ij}(u_h)\mathcal{P}_{\mathcal{V}}(w) \right) \\
& \quad = \sum_{i=1}^n \sum_{j\in\chi_i} m(\Gamma_{ij})\xi_{ij} w(x_i)\, ,
\end{aligned} \tag{4.21}
$$

with

$$
\begin{aligned}
\xi_{ij} &= -\frac{1}{m(\Gamma_{ij})} \int_{\partial\Gamma_{ij}} \nabla_s u_h(\mathbf{x}) \cdot \vec{\mathbf{n}}_{\mathbf{x},V_i}\, d\gamma(\mathbf{x}) + \frac{u_h(\mathbf{x}_i) - u_h(\mathbf{x}_j)}{|\mathbf{x}_i - \mathbf{x}_j|} \\
&= -\frac{1}{m(\Gamma_{ij})} \int_{\partial\Gamma_{ij}} \nabla_s u_h(\mathbf{x}) \cdot \vec{\mathbf{n}}_{\mathbf{x},V_i}\, d\gamma(\mathbf{x}) + \nabla E u_h(\mathbf{x}^*) \cdot \vec{\mathbf{n}}_{\mathbf{x},V_i}\, ,
\end{aligned}
$$

for any $\mathbf{x} \in \Gamma_{ij}$, $\mathbf{x}^* = \mathcal{P}^{-1}(\mathbf{x})$. Since $|\mathbf{x} - \mathbf{x}^*| \le Ch^2$, by Proposition 1

$$
|\nabla E u_h(\mathbf{x}^*) - \nabla_s u_h(\mathbf{x})| \le Ch^2 |\nabla E u_h(\mathbf{x}^*)|.
$$

Then we get

$$
\xi_{ij} \le \frac{Ch^2 |u_h(\mathbf{x}_i) - u_h(\mathbf{x}_j)|}{|\mathbf{x}_i - \mathbf{x}_j|}\ . \tag{4.22}
$$

It is also easy to find that

$$E=\sum_{i=1}^{n}\sum_{j\in\chi_i} m(\Gamma_{ij})\xi_{ij}w(\mathbf{x}_i)=-\frac{1}{2}\sum_{i=1}^{n}\sum_{j\in\chi_i} m(\Gamma_{ij})\xi_{ij}|\mathbf{x}_i-\mathbf{x}_j|\frac{w(\mathbf{x}_i)-w(\mathbf{x}_j)}{|\mathbf{x}_i-\mathbf{x}_j|}\ .$$

By Proposition 4 and Theorem 2 we have that

$$\begin{aligned}|E| &\le \sum_{i=1}^{n}\sum_{j\in\chi_i} m(\Gamma_{ij})\xi_{ij}d(\mathbf{x}_i,\mathbf{x}_j)\frac{|w(\mathbf{x}_i)-w(\mathbf{x}_j)|}{|\mathbf{x}_i-\mathbf{x}_j|}\\ &\le 2\left(\frac{1}{2}\sum_{i=1}^{n}\sum_{j\in\chi_i} m(\Gamma_{ij})d(\mathbf{x}_i,\mathbf{x}_j)\xi_{ij}^2\right)^{1/2}\\ &\quad\cdot\left(\frac{1}{2}\sum_{i=1}^{n}\sum_{j\in\chi_i} m(\Gamma_{ij})d(\mathbf{x}_i,\mathbf{x}_j)\left(\frac{w(\mathbf{x}_i)-w(\mathbf{x}_j)}{|\mathbf{x}_i-\mathbf{x}_j|}\right)^2\right)^{1/2}\\ &\le Ch^2|u_h|_{1,\mathcal{W}}|w|_{1,\mathcal{W}}\le Ch^2\|u_h\|_{H^1(\mathbb{S}^2)}\|\mathcal{P}_{\mathcal{U}}(w)\|_{H^1(\mathbb{S}^2)}\\ &\le Ch^2\|u\|_{H^2(\mathbb{S}^2)}\|w\|_{H^2(\mathbb{S}^2)}.\end{aligned}\tag{4.23}$$

Combining (4.21) and (4.23), we thus get (4.20). □

We note that the results of the above lemmas hold for more general $a=a(\mathbf{x})$ as well, but some slight modifications of the proofs are needed.

4.3. Main result.

We now present our main result on the L^2 error estimate.

THEOREM 3. *Let Assumption* 1 *be satisfied and additionally we assume that* $b\in H^1(\mathbb{S}^2)$. *Suppose that* $\mathcal{W}=\{\mathbf{x}_i,V_i\}_{i=1}^n$ *is an SCVM of* $\mathbb{S}^2$ *with the density function* ρ *satisfying* $\rho\in C^1(\mathbb{S}^2)$ *and* $\rho(\mathbf{x})>0$ *for any* $\mathbf{x}\in\mathbb{S}^2$. *Let* $\mathcal{F}_{ij}$ *be defined by* (3.8). *Then the discrete system* (3.14) *has a unique solution* $u_h\in\mathcal{U}_{\mathcal{W}}$. *Furthermore, assume that the unique solution* u *of* (1.1) *belongs to* $H^3(\mathbb{S}^2)$. *Then there exists a constant* $C>0$ *only depending on* ρ, a, $\vec{\mathbf{v}}$, b, *and* σ *such that*

$$\|e_h\|_{L^2(\mathbb{S}^2)}\le Ch^2\|u\|_{H^3(\mathbb{S}^2)},\tag{4.24}$$

where $e_h(\mathbf{x})=u(\mathbf{x})-u_h(\mathbf{x})$.

Proof. Since $u-u_h\in H^1(\mathbb{S}^2)$, according to (1.3) we know that there exists a weak solution $w\in H^2(\mathbb{S}^2)$ satisfying

$$\mathcal{A}(w,v)=(u-u_h,v)\quad\forall\, v\in H^1(\mathbb{S}^2).$$

Putting $v=u-u_h$ in the above equality, we get

$$||u-u_h||^2_{L^2(\mathbb{S}^2)}=(u-u_h,u-u_h)=\mathcal{A}(w,u-u_h).\tag{4.25}$$

Furthermore, from the H^2 regularity estimate, we have

$$||w||_{H^2(\mathbb{S}^2)}\le C||u-u_h||_{L^2(\mathbb{S}^2)}\tag{4.26}$$

for some constant $C>0$.

For the interpolants $\mathcal{P}_{\mathcal{U}}(w)$ and $\mathcal{P}_{\mathcal{V}}(w)$, we have

$$\mathcal{A}^*(u,\mathcal{P}_{\mathcal{V}}(w))+\int_{\mathbb{S}^2} b(u-P_{\mathcal{V}}(u))\mathcal{P}_{\mathcal{V}}(w)\,ds(\mathbf{x})=(f,\mathcal{P}_{\mathcal{V}}(w))$$

and

$$\mathcal{A}_{\mathcal{W}}(u_h, \mathcal{P}_{\mathcal{V}}(w)) = (f, \mathcal{P}_{\mathcal{V}}(w))\ .$$

Consequently, we get

$$\begin{aligned} \|u-u_h\|^2_{L^2(\mathbb{S}^2)} \le\ & |\mathcal{A}(u-u_h, w-\mathcal{P}_{\mathcal{U}}(w))| \\ & + |\mathcal{A}(u-u_h, \mathcal{P}_{\mathcal{U}}(w)) - \mathcal{A}^*(u-u_h, \mathcal{P}_{\mathcal{V}}(w))| \\ & + |\mathcal{A}^*(u_h, \mathcal{P}_{\mathcal{V}}(w)) - \mathcal{A}_{\mathcal{W}}(u_h, \mathcal{P}_{\mathcal{V}}(w))| \\ & + \left| \int_{\mathbb{S}^2} b(u - P_{\mathcal{V}}(u))\mathcal{P}_{\mathcal{V}}(w)\ ds(\mathbf{x}) \right|. \end{aligned} \tag{4.27}$$

According to Theorem 2, Proposition 3, and (4.26), we get

$$\begin{aligned} |\mathcal{A}(u-u_h, w-\mathcal{P}_{\mathcal{U}}(w))| &\le C\|u-u_h\|_{H^1(\mathbb{S}^2)}\ \|w-\mathcal{P}_{\mathcal{U}}(w)\|_{H^1(\mathbb{S}^2)} \\ &\le Ch^2\|u\|_{H^2(\mathbb{S}^2)}\ \|w||_{H^2(\mathbb{S}^2)} \\ &\le Ch^2\|u\|_{H^2(\mathbb{S}^2)}\ \|u-u_h\|_{L^2(\mathbb{S}^2)}. \end{aligned} \tag{4.28}$$

By Lemma 3 and (4.26), we get

$$\begin{aligned} |\mathcal{A}(u-u_h, \mathcal{P}_{\mathcal{U}}(w)) - \mathcal{A}^*(u-u_h, \mathcal{P}_{\mathcal{V}}(w))| &\le Ch^2\|u\|_{H^3(\mathbb{S}^2)}\|w\|_{H^2(\mathbb{S}^2)} \\ &\le Ch^2\|u\|_{H^3(\mathbb{S}^2)}\|u-u_h\|_{L^2(\mathbb{S}^2)}\ . \end{aligned} \tag{4.29}$$

Again, by Lemma 4 and (4.26), we have

$$\begin{aligned} |\mathcal{A}_{\mathcal{W}}(u_h, \mathcal{P}_{\mathcal{V}}(w)) - \mathcal{A}^*(u_h, \mathcal{P}_{\mathcal{V}}(w))| &\le Ch^2\|u\|_{H^2(\mathbb{S}^2)}\|w\|_{H^2(\mathbb{S}^2)} \\ &\le Ch^2\|u\|_{H^2(\mathbb{S}^2)}\|u-u_h\|_{L^2(\mathbb{S}^2)}\ . \end{aligned} \tag{4.30}$$

It is easy to see that

$$\begin{aligned} \left| \int_{\mathbb{S}^2} b(u-P_{\mathcal{V}}(u))\mathcal{P}_{\mathcal{V}}(w)\ ds(\mathbf{x}) \right| &= \left| \sum_{i=1}^n \int_{V_i} b(u-P_{\mathcal{V}}(u))\mathcal{P}_{\mathcal{V}}(w)\ ds(\mathbf{x}) \right| \\ &\le \left| \sum_{i=1}^n \int_{V_i} \Pi_{\mathcal{V}}(b)(u-P_{\mathcal{V}}(u))\mathcal{P}_{\mathcal{V}}(w)\ ds(\mathbf{x}) \right| \\ &\quad + \left| \sum_{i=1}^n \int_{V_i} (b-\Pi_{\mathcal{V}}(b))(u-P_{\mathcal{V}}(u))\mathcal{P}_{\mathcal{V}}(w)\ ds(\mathbf{x}) \right|. \end{aligned}$$

Using a proof similar to Lemmas 1 and 2, we can get

$$\begin{aligned} \left| \int_{\mathbb{S}^2} b(u-P_{\mathcal{V}}(u))\mathcal{P}_{\mathcal{V}}(w)\ ds(\mathbf{x}) \right| &\le Ch^2\|u\|_{H^2(\mathbb{S}^2)}\|w\|_{H^2(\mathbb{S}^2)} \\ &\le Ch^2\|u\|_{H^2(\mathbb{S}^2)}\|u-u^h\|_{L^2(\mathbb{S}^2)}. \end{aligned} \tag{4.31}$$

Combining (4.28), (4.29), and (4.30), we get

$$\|u-u_h\|^2_{L^2(\mathbb{S}^2)} \le Ch^2\|u\|_{H^3(\mathbb{S}^2)}\|u-u_h\|_{L^2(\mathbb{S}^2)},$$

which means

$$\|e_h\|_{L^2(\mathbb{S}^2)} = \|u-u_h\|_{L^2(\mathbb{S}^2)} \le Ch^2\|u\|_{H^3(\mathbb{S}^2)}.$$

We end the proof by noting that the case of general $a(\mathbf{x})$ can be verified similarly. □

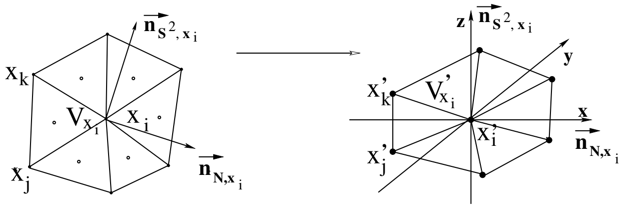
Remark 1. Extra regularity on the exact solution is required to get the quadratic order error estimates, though in the standard finite element literature such a requirement is not needed in general. This is seen as a consequence of the quadrature approximations to the standard weak forms of the equations. From the proof of Lemma 3, it is easy to see that the regularity in $H^3(\mathbb{S}^2)$ can in fact be further weakened to, for instance, $W^{3,p}(\mathbb{S}^2)$ for $p > 1$.

Remark 2. The quadratic order error estimates depend critically on the properties of the SCVMs. The proof is not valid for a general spherical Voronoi mesh. Such an L^2 error estimate has not been given in the literature even for the planar finite volume methods based on the general Voronoi–Delaunay meshes. With other choices of the covolumes which are not of the Voronoi–Delaunay type, a quadratic order estimate has been proved in [26] for 2d diffusion equations. A first order L^2 error estimate has been given in [20].

5. Superconvergent gradient recovery. In this section, we discuss how to postprocess the finite volume solutions to obtain their tangential gradients in the longitude and latitude directions. Let us rewrite (1.1) in the spherical coordinate system (ϕ, θ) defined by $\mathbf{x} = (r \sin\phi \cos\theta, r \sin\phi \sin\theta, r \cos\phi)$ for $\phi \in [0, \pi]$ and $\theta \in [0, 2\pi)$. Ignoring the radial component, we may denote $\vec{\mathbf{v}}(\phi, \theta) = (v_1(\phi, \theta), v_2(\phi, \theta))$, where v_1 and v_2 are the (orthogonal) components of $\vec{\mathbf{v}}$ in the ϕ and θ directions, respectively, on the tangential surface of $\mathbb{S}^2$ at $\mathbf{x}$. We also have

$$\nabla_s u(\phi, \theta) = \left(\frac{1}{r} \frac{\partial u}{\partial \phi}, \ \frac{1}{r \sin\phi} \frac{\partial u}{\partial \theta} \right), \quad \nabla_s \cdot \vec{\mathbf{v}}(\phi, \theta) = \frac{1}{r \sin\phi} \left(\frac{\partial}{\partial \phi}(v_1 \sin\phi) + \frac{\partial v_2}{\partial \theta} \right).$$

For any generator $\mathbf{x}_i$ in $\mathcal{W}$, let $V_{\mathbf{x}_i} = \cup_{\mathbf{x}_i \in T_{ijk}} T_{ijk}$ and $\vec{\mathbf{n}}_{N,\mathbf{x}_i}$ be the unit vector on $S_{\mathbf{x}_i}$ along the ϕ direction. A map $H_{\mathbf{x}_i} : V_{\mathbf{x}_i} \to \mathbb{R}^2$ is defined by first projecting $V_{\mathbf{x}_i}$ onto the tangential plane $S_{\mathbf{x}_i}$ of $\mathbb{S}^2$ at $\mathbf{x}_i$ ($S_{\mathbf{x}_i} \perp \vec{\mathbf{n}}_{\mathbb{S}^2,\mathbf{x}_i}$ at $\mathbf{x}_i$) and then moving $S_{\mathbf{x}_i}$ to the (x, y)-plane via an affine map such that $\vec{\mathbf{n}}_{\mathbb{S}^2,\mathbf{x}_i}$ is mapped to the z-axis and $\vec{\mathbf{n}}_{N,\mathbf{x}_i}$ to the x-axis; see Figure 5.1. Let $V_i' = H_{\mathbf{x}_i}(V_{\mathbf{x}_i})$.



$\vec{\mathbf{n}}_{S^2,x_i}$
x_k
V_{x_i}
x_i
x_j
$\vec{\mathbf{n}}_{N,x_i}$
z
$\vec{\mathbf{n}}_{S^2,x_i}$
y

FIG. 5.1. *The mapping $H_{\mathbf{x}_i}$.*

On each planar triangle $\triangle \mathbf{x}_i' \mathbf{x}_j' \mathbf{x}_k' = H_{\mathbf{x}_i}(T_{ijk})$, we uniquely determine a linear function $\overline{u}_{T_{ijk}}$ by setting $\overline{u}_{T_{ijk}}(\mathbf{x}_i') = u_h(\mathbf{x}_i)$, $\overline{u}_{T_{ijk}}(\mathbf{x}_j') = u_h(\mathbf{x}_j)$, and $\overline{u}_{T_{ijk}}(\mathbf{x}_k') = u_h(\mathbf{x}_k)$. Now we define

$$\overline{\nabla}_s u_h(\mathbf{x}_i) = \frac{1}{q} \sum_{T_{ijk} \subset V_{\mathbf{x}_i}} \left(\frac{\partial \overline{u}_{T_{ijk}}}{\partial x}, \ \frac{\partial \overline{u}_{T_{ijk}}}{\partial y} \right), \tag{5.1}$$

where $q = \text{Card}(\{T_{ijk} \mid T_{ijk} \subset V_{\mathbf{x}_i}\})$. We also let

$$D(u, u_h) = \left(\sum_{i \in I} |\nabla_s u(\mathbf{x}_i) - \overline{\nabla}_s u_h(\mathbf{x}_i)|^2 m(V_i) \right)^{1/2}. \tag{5.2}$$

The index set I may be taken to be the set of all Voronoi generators or a large portion of the generator set. In light of the recent studies on the finite element gradient recovery [36] at mesh symmetric points, the close relationship between finite element and finite volume schemes [3, 34], and the nice properties of SCVMs, we expect that for the finite volume solution with SCVMs, there exists the estimate $D(u, u_h) = O(h^2)$. Such results are to be numerically investigated in the next section.

6. Numerical experiments.

Let $\mathbb{S}^2$ be the unit sphere. We now present numerical results that are summarized in the following two examples, with each example containing two separate experiments (corresponding to two different exact solutions) but with one identical exact solution. In our experiments, the finite volume meshes are taken to be the SCVMs corresponding to a constant density function with various different numbers of generators.

For our first example, we choose the exact solution to be

$$u_1(\phi, \theta) = \sin^2 \phi \cos^2 \theta \tag{6.1}$$

and study two different model problems whose data are given in Table 6.1.

Table 6.1

Data for model problems		$a(\phi,\theta)$	$v_1(\phi,\theta)$	$v_2(\phi,\theta)$	$b(\phi,\theta)$
I	no convection	1	0	0	1
II	convection dominated	0.05	$1+\sin\phi$	$1+\sin\theta$	$3.0+\sin^2\phi$

Approximate solutions were obtained using the finite volume scheme (3.11) with the central difference scheme and the uniformly distributed SCVM based on the constant density function $\rho = 1$ (as in Figure 2.1). In Table 6.2, errors in the approximate solution are listed against the number of generators.

Table 6.2

n		$\|u_1 - u_{1,h}\|_{L^2(\mathbb{S}^2)}$	$D(u_1, u_{1,h})$	$\|u_2 - u_{2,h}\|_{L^2(\mathbb{S}^2)}$	$D(u_2, u_{2,h})$
162	I	4.038E-02	1.331E-01	4.032E-01	4.313E-00
	II	6.406E-02	1.655E-01	5.962E-01	4.314E-00
642	I	1.021E-02	3.444E-02	1.370E-01	1.178E-00
	II	1.612E-02	4.214E-02	1.241E-01	1.115E-00
2562	I	2.556E-03	8.788E-03	2.687E-02	3.115E-01
	II	3.994E-03	1.161E-02	3.033E-02	2.908E-01
10242	I	6.362E-04	2.221E-03	7.445E-03	7.902E-02
	II	1.004E-03	3.072E-03	7.577E-03	7.346E-02
40962	I	1.631E-04	5.269E-04	2.080E-04	1.745E-02
	II	2.375E-04	8.132E-04	2.072E-04	1.797E-02

For the second example, the exact solution of (1.1) is chosen to be

$$u_2(\phi, \theta)) = \sin^2(2\phi) \cos(4\theta). \tag{6.2}$$

Errors in the approximate solution are again given in Table 6.2. As the exact solution (6.2) is more complex than (6.1), the largest 2% of the pointwise gradient errors $|\nabla_s u_2(\mathbf{x}_i) - \overline{\nabla}_s u_{2,h}(\mathbf{x}_i)|$ was removed from the estimate when computing the $D(u_2, u_{2,h})$. These relatively larger errors concentrate near the 12 defect points of the SCVM (i.e., those Voronoi cells with only 5 neighbors) where the mesh lacks perfect symmetry.

From the numerical values given in the tables we see that, for both the L^2 errors and the gradient recovery errors $D(u, u_h)$, the trend of quadratic order convergence is very evident as we refine the mesh.

7. Conclusion. High quality spherical grids have many applications. Many strategies have already been studied in atmospheric and geophysical simulations for producing good spherical grids [31]. Though many of these choices produce good quality grids, in general the recently proposed concept of SCVT [8, 9] yields grids superior to most of existing ones. Our study here on a finite volume approximation of linear convection diffusion equations based on the SCVM demonstrated further their optimality from both theoretical and computational standpoints.

Further studies can be carried out to explore the local energy equipartition property and hierarchical SCVMs for multiresolution analysis, to validate superconvergent gradient recovery through analytical means. The application of the SCVM to Ginzburg–Landau models has been studied recently [10, 11] and we expect to find many more applications to other complex physical problems in the future.

ERROR ESTIMATION FOR REDUCED-ORDER MODELS OF DYNAMICAL SYSTEMS[*]

CHRIS HOMESCU[†], LINDA R. PETZOLD[†], AND RADU SERBAN[‡]

Abstract. The use of reduced-order models to describe a dynamical system is pervasive in science and engineering. Often these models are used without an estimate of their error or range of validity. In this paper we consider dynamical systems and reduced models built using proper orthogonal decomposition. We show how to compute estimates and bounds for these errors by a combination of small sample statistical condition estimation and error estimation using the adjoint method. Most importantly, the proposed approach allows the assessment of *regions of validity* for reduced models, i.e., ranges of perturbations in the original system over which the reduced model is still appropriate. Numerical examples validate our approach: the error norm estimates approximate well the forward error, while the derived bounds are within an order of magnitude.

Key words. model reduction, proper orthogonal decomposition, small sample statistical condition estimation, adjoint method

1. Introduction.

Model reduction of dynamical systems described by differential equations is ubiquitous in science and engineering [2]. Reduced models are used for efficient simulation [17, 31] and control [18, 28]. Moreover, the process of creating low-order models forces the researcher to isolate and quantify the dominant physical mechanisms, revealing effective design decisions that would not have been identified through numerical simulation, experiments, or "black box" optimization methods [30].

The proper orthogonal decomposition (POD) method has been used extensively in a variety of fields including fluid dynamics [23], identification of coherent structures [12, 21], and control [27] and inverse problems [19]. The method has been employed for industrial applications such as supersonic jet modeling [5], turbine flows [6], thermal processing of foods [3], and study of the dynamic wind pressures acting on buildings [16], to name only a few.

Depending on the field of research, POD is also known as principal component analysis (statistics [14]), Karhunen–Loève decomposition (signal analysis and pattern recognition [9]), and the method of empirical orthogonal functions (EOFs) in geophysical fluid dynamics [7, 24] and meteorology [1, 8, 29]. Principal components related techniques (PCAs) are the main dimension-reduction methods in analysis of multivariate data, addressing the need to compress or decompose data for eliminating the redundancy of high throughput measurements such as spatial, spectra, or image data. PCA involves a mathematical procedure that transforms a number of (possibly) correlated variables into a (smaller) number of uncorrelated variables called principal

components. The PCA components account for as much of the variability in the data as possible. The EOFs form a set of basis functions which specify a transformation on a set of empirical signals. The result is a set of signals that, phenomenologically speaking, are statistically independent, i.e., have maximum variance. Thus, information is evenly distributed among the signals, as well as the equally measurable values of each signal, resulting in maximum information entropy and robustness to noise.

All the above reduction methods attempt to maximize the expectation of the energy in a basis set. It was shown that such an optimal basis is given by the eigenfunctions of the integral equation whose kernel is the averaged autocorrelation function. In practice, the covariance matrix is constructed based on measurements of the state, and the existing model projected onto those eigenvectors which correspond to the largest eigenvalues. Assessing the optimality of these reduction methods (POD, PCA, and EOF) is a *norm dependent* statement. For example, it was shown in [12] that for a given number of modes, POD is the most efficient choice among all linear decompositions in the sense that it retains, on average, the greatest possible kinetic energy.

As soon as one contemplates the use of a reduced model, questions concerning the quality of the approximation become paramount. To judge the quality of the reduced model, it is important to estimate its error. An algorithm for estimating the error of a class of reduction methods based on projection techniques was presented in [32]. In this approach, the original problem is linearized around the initial time. The resulting first-order error estimates are valid for only a small number of time steps (during which the Jacobian matrix can be considered constant). First-order estimates of POD errors were used in [20] to extend the concept of domain decomposition as a dynamic a posteriori verification and, if necessary, correction of the approximate solution. Error estimates for reduced models, more precisely the error for certain functionals of the solution, were obtained in [25]. The authors employed the dual-weighted-residual method, which makes use of the solution of an adjoint system.

In the context of fluid dynamics, bounds for the errors resulting from POD model reduction of 2-dimensional (2-D) Navier–Stokes equations were computed in [19]. In that work, the approximation error was decomposed into a contribution that arises due to the POD spatial approximation (measured in terms of the spectral properties specifying the POD basis) and the approximation error due to the backward Euler scheme for time integration. The resulting estimates made use of certain inequalities that, although valid for the nonlinear evolution problem considered, may not be satisfied for other examples. For models that contain discontinuities, for example, if the solution involves shocks, it was found in [22] that the POD reduced model was able to represent a shock in a given location only if one of the snapshots used to build the model has a discontinuity in the same location. This may require an unacceptably large number of snapshots to achieve sufficient accuracy of the approximate solution. To overcome this limitation a domain decomposition technique was introduced, using a reduced-order model over the majority of the computational domain while solving the full equations in a small region. Given an approximate solution (with unknown accuracy) generated with a set of POD basis functions, the error is estimated by augmenting the POD basis with top hat basis functions and computing the first-order change in the solution due to the additional basis functions. By comparing against the results from a solution of known accuracy, such as one of the snapshots used to generate the POD basis, the need for domain decomposition and its spatial extent can be determined.

Bounds of POD errors, but not estimates, were considered in [26], as well as effects (on the reduced-order model) of small perturbations in the ensemble of data from which the POD-reduced order model was constructed.

In the present work we take the analysis of reduced models one step further by analyzing the influence of perturbations to the original system on the quality of the approximation given by the reduced model. This question is of particular interest in applications (such as control and inverse problems) in which reduced models are used not just to approximate the solution of the original system that provided the data used in constructing the reduced model, but rather to approximate the solution of systems perturbed from the original one. To the best of our knowledge, there are no published results to address the estimation of the model reduction error of such perturbed systems.

We base our approach on a combination of the small sample statistical condition estimation (SCE) method [15] and error estimation using the adjoint method. Using this framework, we define *regions of validity* of the reduced models, that is, ranges of perturbations in the original system over which the reduced model is still appropriate. We consider perturbations in both the initial conditions and in parameters describing the dynamical system itself. The proposed approach is particularly attractive because the resulting error bounds do not rely on the solution of the perturbed system. In this sense, we provide an a priori assessment of the validity of the model-reduction approximation. We note that our approach is based on linearization. For large enough perturbations, knowledge of the solution of the perturbed system would be required.

Unlike the method presented in [32], our estimates and bounds are valid over the entire time interval considered, not in a neighborhood of the initial time. Moreover, we obtain estimates for the continuous error, as opposed to its discrete approximation. Although we study only a particular projection-based model reduction technique (POD) among those considered in [32], the methodology developed here for POD can be easily extended to other types of projection. Compared to the approach taken in [19], our method is applicable to a larger class of problems, our main requirement being that the norm of the POD-based error is small enough for the linearized error equation to be a good enough approximation. Furthermore, our estimates are independent of the time integration method. We note also that our use of adjoint models for error estimation is similar to that employed in [25]. However, as will be seen below, the use of the SCE method enables the derivation of error "condition numbers" and allows effective treatment of the region of validity problem.

In the context of integration of ordinary differential equations (ODE), the SCE method combined with the adjoint approach has been used in [4] for estimation and control of the global integration error.

The remainder of this paper is organized as follows. In sections 2 and 3 we briefly describe the use of POD for model reduction and, respectively, the SCE method for norm estimation. In section 3.1 we motivate our proposed approach of using SCE, combined with error estimation using the adjoint method, to estimate the errors due to the use of a reduced-order model. In section 4 we analyze errors arising purely from the model reduction itself: the total approximation error and the subspace integration error. In section 5 we analyze regions of validity of POD reduced models. In section 6 we present numerical results for two example problems. The first one is obtained from the semidiscretization of time-dependent partial differential equation (PDE), namely advection-diffusion, while the second example models a pollution chemical reaction mechanism. Finally, section 7 summarizes our results and describes our plans for future research.

2. POD-based reduced models. POD provides a method for finding the best approximating affine subspace to a given set of data. When using POD for model reduction of dynamical systems, the data are time snapshots of the solution obtained via numerical simulations or from experiments. Consider the ODE system

$$\frac{dy}{dt} = f(y,t)\,, \quad y(t_0) = y_0\,, \tag{2.1}$$

for $t \in [t_0, t_f]$, with $y, y_0 \in R^n$ and $f : R^n \times R \to R^n$. Consider next the solutions of (2.1) at m time points, collected in the $n \times m$ matrix $\mathcal{Y} = [y(t_1) - \bar{y}, y(t_2) - \bar{y}, \dots y(t_m) - \bar{y}]$, where $\bar{y}$ is the mean of these observations. POD seeks a subspace $S \in R^n$ and the corresponding projection matrix P_S so that the total square distance

$$\|\mathcal{Y} - P\mathcal{Y}\|^2 = \sum_{i=1}^{m} \|\,(y(t_i) - \bar{y}) - P\,(y(t_i) - \bar{y})\,\|^2$$

is minimized. Let $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_m \geq 0$ be the ordered eigenvalues of the *correlation matrix* $R = \mathcal{Y}\mathcal{Y}^T$. Then the minimum value of $\|\mathcal{Y} - P\mathcal{Y}\|^2$ over all k-dimensional subspaces S, with $k \leq n$, is given by $\sum_{j=k+1}^{n} \lambda_j$. Moreover, the minimizing S is the invariant subspace corresponding to the eigenvalues $\lambda_1, \dots, \lambda_k$. Using the singular value decomposition (SVD) [10] of the observation matrix, $U^T \mathcal{Y} V = \Sigma$, the projection matrix corresponding to the optimal POD subspace S is obtained as

$$P = \rho\rho^T \in R^{n \times n}\ , \tag{2.2}$$

where ρ is the matrix of projection onto S, the subspace spanned by the reduced basis obtained from the SVD. The matrix $\rho \in R^{n \times k}$ consists of the columns V_i $(i = 1, \dots, k)$, the singular vectors corresponding to the k largest singular values.

Without loss of generality, for the sake of simplicity in presentation we assume in what follows that $\bar{y} = 0$.

In a coordinate system embedded in S, the projection of a point $y \in R^n$ onto S is represented by $z = \rho^T y \in R^k$, while in the full space the same projection is expressed as $\rho z = Py \in R^n$.

A POD-based reduced model that approximates the original problem (2.1) can then be constructed [26] by projecting onto S the vector field $f(y,t)$ at each point $y \in S$. Therefore

$$\frac{dz}{dt} = \rho^T f(\rho z, t)\,, \quad z(t_0) = \rho^T y_0\,. \tag{2.3}$$

In full space, the approximate solution $\widetilde{y}$ is the solution of the ODE initial-value problem (IVP)

$$\frac{d\widetilde{y}}{dt} = Pf(\widetilde{y}, t)\,, \quad \widetilde{y}(t_0) = Py_0\,. \tag{2.4}$$

3. Small sample statistical method for condition estimation. The SCE method, originally proposed in [15], offers an efficient means for condition estimation for general matrix functions, at the cost of allowing moderate relative errors in the estimate. The basic idea is described below (for complete details, see [11, 15]).

For any vector $x \in R^n$, if u is selected uniformly and randomly from the unit sphere S_{n-1}, the expected value of $u^T x$ is proportional to the norm of x:

$$E(|u^T x|) = W_n \|x\| \,.$$

The *Wallis factor* W_n is defined as

$$W_1 = 1\,, \quad W_n = \begin{cases} \dfrac{1 \cdot 3 \cdots (n-2)}{2 \cdot 4 \cdots (n-1)} & n \text{ odd} \\ \dfrac{2}{\pi} \dfrac{2 \cdot 4 \cdots (n-2)}{1 \cdot 3 \cdots (n-1)} & n \text{ even} \end{cases}$$

and can be approximated with $W_n \approx \sqrt{2/(\pi(n-1/2))}$. Therefore $\xi = |u^T x|/W_n$ is an estimate for the norm $\|x\|$. This estimate is first order in the sense that the probability of a relative error in the estimate is inversely proportional to the size of the error. That is, for $\gamma > 1$,

$$\Pr\left(\frac{\|x\|}{\gamma} \leq \xi \leq \gamma \|x\|\right) \geq 1 - \frac{2}{\pi\gamma} + O\left(\gamma^{-2}\right) \,.$$

Additional function evaluations can improve the estimation procedure. Suppose that we obtain estimates $\xi_1, \xi_2, \ldots, \xi_q$ corresponding to orthogonal vectors $u_1, u_2, \ldots, u_q$ selected uniformly and randomly from the unit sphere S_{n-1}. The expected value of the norm of the projection of x onto the span $\mathcal{U}$ generated by $u_1, u_2, \ldots, u_q$ is

$$E\left(\sqrt{|u_1^T x|^2 + |u_2^T x|^2 + \cdots + |u_q^T x|^2}\right) = \frac{W_n}{W_q} \|x\| \,.$$

The analysis in [15] shows that the estimate $\nu(q) = (W_q/W_n)\sqrt{|u_1^T x|^2 + \cdots + |u_q^T x|^2}$ is qth order accurate; i.e., a relative error of size γ in the estimate occurs with probability proportional to γ^{-q}. For example,

$$\begin{aligned} \Pr\left(\frac{\|x\|}{\gamma} \leq \nu(2) \leq \gamma \|x\|\right) &\approx 1 - \frac{\pi}{4\gamma^2}\,, \\ \Pr\left(\frac{\|x\|}{\gamma} \leq \nu(3) \leq \gamma \|x\|\right) &\approx 1 - \frac{32}{3\pi^2\gamma^3}\,, \\ \Pr\left(\frac{\|x\|}{\gamma} \leq \nu(4) \leq \gamma \|x\|\right) &\approx 1 - \frac{81\pi^2}{512\gamma^4}\,. \end{aligned}$$

3.1. SCE for estimation of approximation errors in model reduction.

All error estimates derived in this paper begin with the linearizations of one of the ODEs, (2.1), (2.3), or (2.4), or perturbations of these. Thus the error estimates are based on solutions of linear error equations. To estimate the norm $\|e(t_f)\|$ of an error vector $e(t) \in R^n$ at $t = t_f$, we need to evaluate quantities $u_j^T e(t_f)$ for some random vector u_j selected uniformly from the unit sphere S_{n-1}. The norm estimate is then

$$||e(t_f)|| \approx \frac{W_q}{W_n} \sqrt{\sum_{j=1}^{q} |u_j^T e(t_f)|^2}\,. \tag{3.1}$$

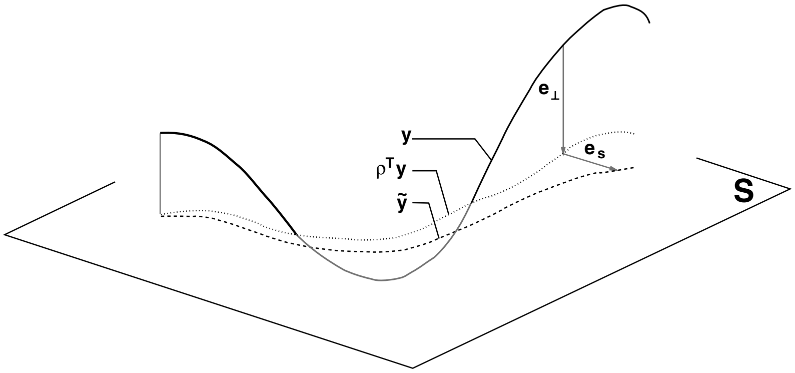

FIG. 4.1. *Solution and error components for POD-reduced models. y is the solution of the original ODE, $z = \rho^T y$ is its projection on the subspace S, and $\widetilde{y}$ is the solution of the reduced model. The error component $e_\perp \in S^\perp$, while the subspace integration error component $e_S \in S$.*

The scalar products $u_j^T e(t_f)$ can be computed efficiently using an adjoint model (to the corresponding linear error equation) with final conditions at t_f based on the vector u_j. However, this approach naturally raises the question: *"What is the advantage of using (typically more than one) solution(s) of the adjoint system to estimate the norm of a quantity that can be otherwise obtained with only one forward ODE solution (of the error equation)?"* Our method is motivated by the fact that we are interested not only in estimating the error for one given ODE system, but rather in estimating (as efficiently as possible) the behavior of such errors for families of related ODE systems, based on different values of problem parameters. In section 5 we study the concept of *regions of validity of reduced models*, i.e., the range of perturbations in the original ODE (2.1) over which the reduced model (2.3) is still appropriate. An approach based on forward error equations involves solving repeatedly such error equations (for each value of interest of the perturbation). On the other hand, an approach combining SCE estimates and adjoint models (as described in our paper) can be used to define what we term "condition numbers" for these error equations. While these condition numbers can provide only approximate upper bounds for the norms of the errors under investigation, they have the undeniable advantage of allowing a priori estimates of the errors induced by perturbations, i.e., before having to solve such a perturbed system (or even a reduced perturbed system).

4. Estimation of the approximation error. We begin by estimating the difference between the solution of the POD-reduced model (2.4) and the solution of the original equation (2.1). The total approximation error $e = \widetilde{y} - y$ can be split [26] into the subspace approximation error $e_\perp = \rho^T y - y$ and the error introduced by the integration in the subspace S, $e_S = \widetilde{y} - \rho^T y$:

$$e = \widetilde{y} - y = \left(\widetilde{y} - \rho^T y\right) + \left(\rho^T y - y\right) = e_S + e_\perp\,. \tag{4.1}$$

The error component $e_\perp$ is orthogonal to S, while the component e_S is parallel to S (see Figure 4.1). Algebraically, this is expressed as $Pe_\perp(t) = 0$ and $Pe_S(t) = e_S(t)$.

4.1. Total approximation error. Subtracting (2.1) from (2.4) yields an equation for the total error e,

$$\frac{de}{dt} = Pf(\widetilde{y},t) - f(y,t) = Pf(\widetilde{y},t) - f(\widetilde{y},t) + f(\widetilde{y},t) - f(y,t)$$

$$= (P - I)f(\widetilde{y}, t) - \mathbf{J}(\widetilde{y}, t)(y - \widetilde{y}) + O(\|e\|)\,,$$

where $\mathbf{J}$ is the Jacobian of the function f, i.e., $\mathbf{J} = \partial f/\partial y$, and we define $Q = I - P$. Thus, to a first-order approximation, the error function satisfies

$$\frac{de}{dt} = \mathbf{J}(\widetilde{y}, t)e(t) - Qf(\widetilde{y}, t)\,, \quad e(t_0) = -Qy_0\,. \tag{4.2}$$

Let the matrix function $\Phi(t) \in R^{n\times n}$ satisfy

$$\frac{d\Phi}{dt} = \mathbf{J}(\widetilde{y}, t)\Phi\,, \quad \Phi(t_0) = I_n\,.$$

Then

$$e(t_f) = -\int_{t_0}^{t_f} \Phi(t_f)\Phi^{-1}(\tau)Qf(\widetilde{y}\,(\tau), \tau)\,d\tau - \Phi(t_f)Qy_0\,.$$

For a random vector u uniformly selected from the unit sphere S_{n-1}, we have

$$u^Te(t_f) = -\int_{t_0}^{t_f} u^T\Phi(t_f)\Phi^{-1}(\tau)Qf(\widetilde{y}\,(\tau), \tau)\,d\tau - u^T\Phi(t_f)Qy_0\,.$$

It is straightforward to verify that the solution $\lambda \in R^n$ of the adjoint system,

$$\frac{d\lambda}{dt} = -\mathbf{J}^T(\widetilde{y}, t)\lambda\,, \quad \lambda(t_f) = u, \tag{4.3}$$

satisfies $\lambda^T(s) = u^T\Phi(t_f)\Phi^{-1}(s)$ and $\lambda^T(t_0) = z^T\Phi(t_f)$. Therefore the quantity $u^Te(t_f)$ is simply

$$u^Te(t_f) = -\int_{t_0}^{t_f} \lambda^T(\tau)Qf(\widetilde{y}\,(\tau), \tau)\,d\tau - \lambda^T(t_0)Qy_0\,. \tag{4.4}$$

The SCE estimate for the norm of $e(t_f)$ is obtained by combining (3.1) and (4.4):

$$\|e(t_f)\| \approx \frac{W_q}{W_n}\sqrt{\sum_{j=1}^{q}\left|\int_{t_0}^{t_f} \lambda^T(\tau)Qf(\widetilde{y}\,(\tau), \tau)\,d\tau + \lambda^T(t_0)^TQy_0\right|^2}\,. \tag{4.5}$$

The value of the integral is $\xi(t_0)$, where ξ satisfies the quadrature equation

$$\frac{d\xi}{dt} = -\lambda^T(t)Qf(\widetilde{y}\,(t), t)\,, \quad \xi(t_f) = 0\,. \tag{4.6}$$

Algorithm 1 summarizes our approach.

It may seem more efficient to compute the SCE norm estimate using a POD-reduced adjoint system to evaluate λ in (4.5). Although the same projection can be used to model-reduce the adjoint system, this approach still requires knowledge of the mean of the adjoint solution, which is unavailable without a solution of the adjoint system (4.3). In other words, the approximation subspace is parallel to S but not identical to it. This issue can be circumvented if we are not considering error components outside the subspace S. This estimate is presented next. Its main advantage is given by the fact that the differential equations are solved in a space of dimension $k \ll n$, where n is the dimension of the solution for the original problem.

Algorithm 1 Estimate for the total approximation error

```
Provide the matrix of measurement data $\mathcal{Y}$
Set the POD dimension $k$
Construct POD projection matrices $\rho$ and $P$
Select uniformly and randomly $q$ orthogonal vectors $u_i$ from the unit sphere $S_{n-1}$
Solve (2.3) for $z$ and compute $\widetilde{y}(t) = \rho z(t)$
Initialize $s = 0$
for $i = 1$ to $q$ do
  Set $\lambda(t_f) = u_i$ and $\xi(t_f) = 0$
  Solve (4.3)+(4.6) for $\lambda$ and $\xi$
  Update $s \leftarrow s + \left[\psi(t_0) + \lambda^T(t_0)^T Q y_0\right]^2$
end for
Compute Wallis factors $W_q$ and $W_n$
Compute the SCE norm estimate $\|e\| = (W_q/W_n) \cdot \sqrt{s}$
```

4.2. Subspace integration error. Starting with its definition, $e_S = \widetilde{y} - \rho^T y$, the subspace integration error is readily found to obey, in a first-order approximation, the following ODE:

$$\frac{de_S}{dt} = \frac{d\,\widetilde{y}}{dt} - P\frac{dy}{dt} = P\left(f(\widetilde{y},t) - f(y,t)\right)$$
$$\approx P\mathbf{J}(\widetilde{y},t)e(t) = P\mathbf{J}(\widetilde{y},t)\left(e_S + e_\perp\right)\,.$$

The starting point $\widetilde{y}(t_0)$ is the projection $\rho^T y(t_0)$ of $y(t_0)$ onto S, yielding the initial condition $e_S(t_0) = 0$. Thus, the subspace integration error is governed by an ODE with the subspace approximation error $e_\perp(t)$ as forcing term,

$$\frac{de_S}{dt} = P\mathbf{J}(\widetilde{y},t)e_S + P\mathbf{J}(\widetilde{y},t)e_\perp\,, \quad e_S(t-0) = 0\,. \tag{4.7}$$

We note that the linearization in (4.7) is directly related (through the projection matrix P) to the linearization of the full model, $f(\widetilde{y},t) - f(y,t) \approx \mathbf{J}(\widetilde{y},t)(\widetilde{y} - y)$. Since we assume that we operate in a region where the full model linearization is valid, this implies that the linearization in (4.7) is valid for the region considered.

If h are the S-coordinates of e_S, i.e., $h = \rho^T e_S \in R^k$, we have $e_S = \rho h$ and therefore

$$\frac{dh}{dt} = \rho^T\mathbf{J}(\widetilde{y},t)\rho h + \rho^T\mathbf{J}(\widetilde{y},t)e_\perp\,, \quad h(t_0) = 0\,, \tag{4.8}$$

where we have used that $\rho^T\rho = I_k$. Now let $\psi \in R^{k\times k}$ be the fundamental matrix of (4.8); i.e,

$$\frac{d\psi}{dt} = \rho^T\mathbf{J}(\widetilde{y},t)\rho\psi\,, \quad \psi(t_0) = I_k\,.$$

Then, for a random vector v uniformly selected from the unit sphere S_{k-1}, we have

$$v^T h(t_f) = \int_{t_0}^{t_f} v^T\psi(t_f)\psi^{-1}(\tau)\rho^T\mathbf{J}(\widetilde{y}\,(\tau),\tau)e_\perp(\tau)\,d\tau\,.$$

The solution μ of the adjoint system

$$\frac{d\mu}{dt} = -\rho^T\mathbf{J}^T(\widetilde{y},t)\rho\mu\,, \quad \mu(t_f) = v, \tag{4.9}$$

satisfies $\mu^T(\tau) = v^T\psi(t_f)\psi^{-1}(\tau)$, for all $\tau \in [t_0, t_f]$, and therefore

$$v^T h(t_f) = \int_{t_0}^{t_f} \mu^T(\tau)\rho^T\mathbf{J}(\widetilde{y}\,(\tau),\tau)e_\perp(\tau)\,d\tau\,,$$

yielding the following SCE estimate for the norm of the subspace integration error:

$$\|e_S(t_f)\| = \|h(t_f)\| \approx \frac{W_q}{W_n}\sqrt{\sum_{j=1}^{q}\left|\int_{t_0}^{t_f}\mu_j^T(\tau)\rho^T\mathbf{J}(\widetilde{y}\,(\tau),\tau)e_\perp(\tau)\,d\tau\right|^2}\,, \tag{4.10}$$

where μ_j is the solution of (4.9) with final condition $\mu(t_f) = v_j$.

Bounds for the subspace integration error can be obtained as follows. We have

$$\begin{aligned}\left|\int_{t_0}^{t_f}\mu^T(\tau)\rho^T\mathbf{J}(\widetilde{y}\,(\tau),\tau)e_\perp(\tau)\,d\tau\right| &\le \int_{t_0}^{t_f}\left|\mu^T(\tau)\rho^T\mathbf{J}(\widetilde{y}\,(\tau),\tau)e_\perp(\tau)\right|\,d\tau\\ &\le \|\mathbf{J}^T\rho\mu\|_{L_1}\cdot\|e_\perp\|_{L_\infty}\,,\end{aligned}$$

where the last inequality is Hölder's inequality, $\|f^Tg\|_{L_1} \le \|f\|_{L_p}\cdot\|g\|_{L_q}$, $1/p+1/q = 1$, for $p = 1$ and $q = \infty$, applied to vector-valued functions $f, g : [t_0, t_f] \to R^n$ for which the L_p norm is defined as

$$||f||_{L_p} = \left(\int_{t_0}^{t_f}||f(\tau)||_p^p\,d\tau\right)^{1/p}\,,\ \text{where } ||f(\tau)||_p = \left(\sum_{i=1}^{n}|f_i(\tau)|^p\right)^{1/p}\,.$$

Therefore

$$\|e_S(t_f)\| \le \kappa(e_S)\cdot\|e_\perp\|_{L_\infty}\,, \tag{4.11}$$

where

$$\kappa(e_S) = \frac{W_q}{W_n}\sqrt{\sum_{j=1}^{q}\|J^T\rho\mu_j\|_{L_1}^2} = \sqrt{\sum_{j=1}^{q}\left(\int_{t_0}^{t_f}\left|J^T(\widetilde{y}\,(\tau),\tau)\rho\mu_j(\tau)\right|\,d\tau\right)^2}\,.$$

The quantity $\kappa(e_S)$ can be seen as a "condition number" for the subspace integration error.

The expressions derived above require knowledge of the projection error $e_\perp$ at all times in $[t_0, t_f]$. While the projection error may not be readily available, its norm can be easily related to the error associated with the choice of the POD subspace. For this, a more convenient formulation of the POD approximation is to find a subspace $S \subset R^n$ which minimizes the total square distance defined as

$$d^2 = \|y - Py\|_{L_2}^2 = \int_{t_0}^{t_f}\|y(\tau) - Py(\tau)\|_2^2\,d\tau\,. \tag{4.12}$$

The solution to this problem requires the construction of the correlation matrix $R = \int_{t_0}^{t_f} y(\tau)y(\tau)^T\,d\tau$. If $\lambda_1 \ge \cdots \ge \lambda_m \ge 0$ are the ordered eigenvalues of the symmetric positive semidefinite matrix R, then the minimum value of d^2 over all k-dimensional affine subspaces S passing through $\bar{y}$ is given by $\sum_{j=k+1}^{n}\lambda_j$. The minimizing S is the invariant subspace corresponding to the eigenvalues $\lambda_1, \ldots, \lambda_k$, while the projection matrix ρ consists of the unit eigenvectors corresponding to these k largest eigenvalues. We also have that

$$||e_\perp||_{L_\infty} \leq ||e_\perp||_{L_2} \equiv \sqrt{\sum_{j=k+1}^{n} \lambda_j}\,.$$

Employing observations as data points for a trapezoidal approximation for the integral (4.12) leads to the same subspace S as the one obtained with the POD definition in section 2, while the corresponding optimal total square distances will be proportional.

5. Regions of validity for POD-reduced models.

Once a reduced model is constructed, we wish to apply it to simulate systems that are close in some sense to the system that was used for generating the reduced model. This raises the issue of defining the range of initial conditions and parameters over which the reduced model can be used with acceptable accuracy.

In the following section we denote by a small letter (e.g., y) any solution of the unperturbed system and by a capital letter (e.g., Y) any solution of a perturbed system.

If $Y \in R^n$ is the solution of an ODE obtained by applying a perturbation to (2.1), either in the initial conditions or in the right-hand side, the issue of the errors introduced by this perturbation, in addition to the model reduction error $e(t)$, can be addressed from two different perspectives:

- When the reduced model, with a POD projection matrix based on the solution of the unperturbed ODE, is used to approximate the perturbed solution Y, it is of interest to estimate the error $E_1 = \widetilde{Y} - Y$, where $\widetilde{Y}$ is the solution of an ODE of the form (2.4), with P based on y.
- Alternatively, we may want estimates for the cumulative error (due to the POD model reduction and the perturbation in the original ODE), $E_2 = \widetilde{Y} - y$. Note that calculating $E_2 = \widetilde{Y} - y$ is completely equivalent to computing $\widetilde{y} - Y$ (by considering y to be a perturbation to Y).

It is important to realize that *useful* estimates should not rely on the solution Y (or $\widetilde{Y}$) of the perturbed system (or its POD reduction). Indeed, such error estimates are desired with the sole objective of deciding whether or not to solve these systems.

In this section we begin by analyzing the errors E_1 and E_2 induced by a perturbation δy_0 in the initial conditions of (2.1) and then by treating the case of perturbations δp in model parameters affecting the right-hand side. For each of these two cases, Figure 5.1 illustrates the solutions of the unperturbed and perturbed full- and reduced-order models, as well as the corresponding errors e, E_1, and E_2.

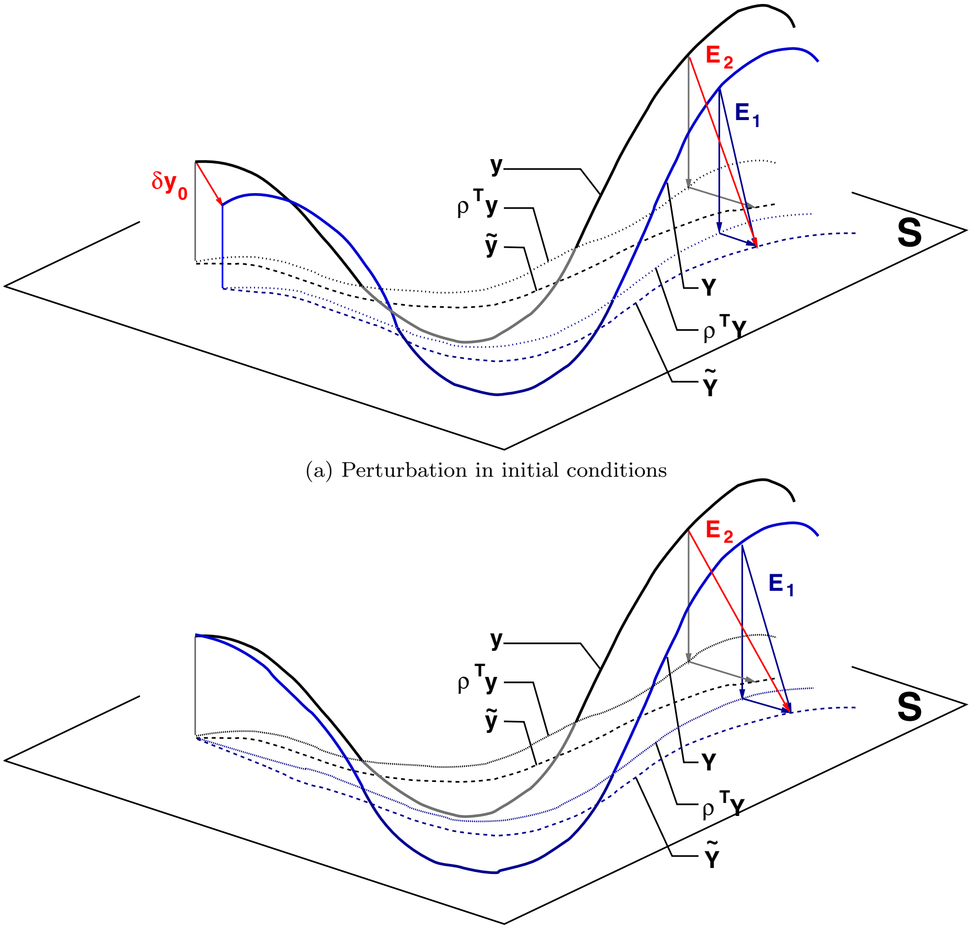
5.1. Perturbations in initial conditions.

Here, Y and $\widetilde{Y}$ are solutions of the ODEs

$$\frac{dY}{dt} = f(Y,t)\,, \quad Y(t_0) = Y_0 = y_0 + \delta y_0\,, \tag{5.1}$$

$$\frac{d\widetilde{Y}}{dt} = Pf(\widetilde{Y},t)\,, \quad \widetilde{Y}(t_0) = PY_0 = P(y_0 + \delta y_0), \tag{5.2}$$

which were obtained by perturbing the initial conditions of (2.1).



(a) Perturbation in initial conditions

(b) Perturbation in right-hand side

Fig. 5.1. *Error components in model reduction of perturbed systems. The solution of the perturbed system and the solution of the reduced perturbed system are denoted by Y and $\widetilde{Y}$, respectively. The error E_1 represents the error committed in reducing the perturbed model, while E_2 is the cumulative error (perturbation + model reduction).*

5.1.1. Estimation of $E_1 = \widetilde{Y} - Y$. An SCE estimate like (4.5) is not useful in the sense described above, as it would be based on the error equation

$$\frac{dE_1}{dt} = \mathbf{J}(\widetilde{Y}, t)E_1 - Qf(\widetilde{Y}, t)\,, \quad E_1(t_0) = -Q(y_0 + \delta y_0 - \bar{y})\,, \tag{5.3}$$

which is a linearization around the (unknown) trajectory $\widetilde{Y}(t)$.

Instead, let us focus on estimating the norm of $\Delta(t_f) = E_1(t_f) - e(t_f)$, with which the norm $\|E_1(t_f)\|$ could be bounded by

$$\big|\|e(t_f)\| - \|\Delta(t_f)\|\big| \le \|E_1(t_f)\| \le \|e(t_f)\| + \|\Delta(t_f)\|\,. \tag{5.4}$$

Any estimates of $\|\Delta(t_f)\|$ would require solving the POD-reduced perturbed system (5.2). However, as in section 4.2, this problem can be circumvented by splitting the error Δ into two components: $\Delta_\perp$ orthogonal to S and Δ_S parallel to S. Using the fact that $Q\,\widetilde{Y} = Q\,\widetilde{y} = 0$, we have

$$\Delta_\perp = Q\Delta = Q(\widetilde{Y} - \widetilde{y}) - (Y - y) = -Q(Y - y)$$

and

$$\Delta_S = \Delta - \Delta_\perp = (\widetilde{Y} - \widetilde{y}) - P(Y - y)\,.$$

We evaluate the influence of δy_0 on each component separately. Retaining only the first-order term of a Taylor series for $\Delta_\perp$ around $\delta y_0 = 0$ and using the fact that $\Delta_\perp = 0$ for $\delta y_0 = 0$, we get

$$\Delta_\perp = -Q\,\frac{dY}{d\delta y_0}\bigg|_{\delta y_0 = 0} \delta y_0\ .$$

The sensitivity matrix dY/dy_0 is nothing but the fundamental matrix corresponding to the linearization of (2.1). It is then easy to see that if λ is now the solution of

$$\frac{d\lambda}{dt} = -\mathbf{J}^T(y,t)\lambda\,, \quad \lambda(t_f) = Qu, \quad \text{for some } u \in R^n\,, \tag{5.5}$$

then $u^T\Delta_\perp(t_f) = -\lambda^T(t_0)\cdot\delta y_0$.

Therefore, an SCE estimate of $\|\Delta_\perp(t_f)\|$ can be based on the solutions of systems (5.5) with vectors u_j uniformly and randomly selected from the unit sphere S_{n-1}. However, taking into account that $\Delta_\perp$ is orthogonal to S, a more accurate estimate can be obtained by using vectors from the sphere S_{n-k-1} embedded in $S^\perp$, instead of selecting vectors $u \in S_{n-1}$ and projecting them onto $S^\perp$, the orthogonal complement of S. If u' is the representation in R^n of such a vector, then $Qu' = u'$. Thus we have the same adjoint system (5.5), but the probability that the estimate lies within a given factor γ of the true norm $\|\Delta_\perp(t_f)\|$ is now higher (see section 3).

In practice we use the approximation $y \approx \widetilde{y}$ in evaluating the Jacobian in (5.5), with $\widetilde{y}$ computed from the solution z of the k-dimensional ODE (2.3) and obtain the following SCE estimate:

$$\|\Delta_\perp(t_f)\| \approx \frac{W_q}{W_n}\sqrt{\sum_{j=1}^{q}|u_j'^T\Delta_\perp(t_f)|^2} = \frac{W_q}{W_n}\sqrt{\sum_{j=1}^{q}|\lambda^T(t_0)\delta y_0|^2}\,,$$

where λ is the solution of $d\lambda/dt = -\mathbf{J}^T(\widetilde{y},t)\lambda$, $\lambda(t_f) = Qu_j'$. Hölder's inequality (for $p = q = 2$) gives $|\lambda^T(t_0)\delta y_0| \le \|\lambda(t_0)\|_2\cdot\|\delta y_0\|_2$, which implies

$$\|\Delta_\perp(t_f)\| \le \kappa_1\cdot\|\delta y_0\|\,, \tag{5.6}$$

where the "condition number" for the orthogonal component of Δ is defined as

$$\kappa_1 = \frac{W_q}{W_n}\sqrt{\sum_{j=1}^{q}\|\lambda(t_0)\|_2^2}\,.$$

With the assumption $\mathbf{J}(y,t) \approx \mathbf{J}(\widetilde{y},t)$, the Δ component parallel to S, $\Delta_S = \Delta - \Delta_\perp = (\widetilde{Y} - \widetilde{y}) - P(Y - y)$, satisfies, up to first order,

$$\frac{d\Delta_S}{dt} = \left(Pf(\widetilde{Y},t) - Pf(\widetilde{y},t)\right) - P\left(f(Y,t) - f(y,t)\right) \approx P\mathbf{J}(\widetilde{y},t)\Delta_S\ .$$

Since at the initial time $\Delta_S(t_0) = 0$, to a first-order approximation $\Delta_S(t) = 0$ for all $t \geq t_0$. In other words, a perturbation to the initial conditions of the original ODE does not introduce additional subspace integration errors. As a consequence, $\Delta(t_f) \approx \Delta_\perp(t_f)$ and, combining (5.4) and (5.6), we have

$$\|E_1(t_f)\| \leq \|e(t_f)\| + \kappa_1 \cdot \|\delta y_0\| \,. \tag{5.7}$$

Note that when using SCE estimates for the norms involved in the above bounds, the true value of $\|E_1(t_f)\|$ may not be bracketed by these bounds.

5.1.2. Estimation of $\boldsymbol{E_2 = \widetilde{y} - Y}$. Subtracting the ODEs satisfied by $\widetilde{y}$ and Y, the error E_2 satisfies, to a first-order approximation,

$$\frac{dE_2}{dt} = \mathbf{J}(\widetilde{y}, t)E_2 - Qf(\widetilde{y}, t)\,, \quad E_2(t_0) = -Qy_0 - \delta y_0\,. \tag{5.8}$$

For a uniformly selected random vector $u \in S_{n-1}$ and with λ the solution of (4.3), we have

$$\begin{aligned} u^T E_2(t_f) &= -\int_{t_0}^{t_f} \lambda^T(\tau) Q f(\widetilde{y}\,(\tau), \tau)\, d\tau - \lambda^T(t_0)\,(Qy_0 + \delta y_0) \\ &= u^T e(t_f) - \lambda^T(t_0)\delta y_0\,, \end{aligned} \tag{5.9}$$

where $e(t_f)$ is the approximation error for the original system, defined by (4.1). Straightforward calculations yield

$$\|E_2(t_f)\| \leq \|e(t_f)\| + \kappa_2 \cdot \|\delta y_0\|\,, \tag{5.10}$$

where

$$\kappa_2 = \frac{W_q}{W_n} \sqrt{\sum_{j=1}^{q} \|\lambda(t_0)\|_2^2}\,.$$

We first note that the new condition number κ_2 has the exact same form as κ_1 obtained in section 5.1.1, the only difference being in the final conditions used for the adjoint variables λ_j. Secondly, the SCE bound estimate (5.10) is more accurate than the SCE bound estimate for the norm of $E_1(t_f)$ (which is based on the additional approximation $E_1 \approx e + \Delta_\perp$, ignoring Δ_S and using $y \approx \widetilde{y}$ in the adjoint system). Furthermore, as seen from (5.9), an SCE estimate for $\|E_2(t_f)\|$ can be computed without need for Y or $\widetilde{Y}$, unlike for $\|E_1(t_f)\|$.

5.2. Perturbations in model parameters. Now let Y be the solution of the ODE system

$$\frac{dY}{dt} = f(Y, t, p + \delta p)\,, \quad Y(t_0) = y_0\,, \tag{5.11}$$

representing a perturbation in some model parameters affecting the right-hand side of (2.1). As in section 5.1, let $\widetilde{Y}$ be the solution of a POD-based reduced-order model obtained from (5.11) using the same POD projection matrix as for the model reduction of the unperturbed system. Then $\widetilde{Y}$ satisfies

$$\frac{d\widetilde{Y}}{dt} = Pf(\widetilde{Y}, t, p + \delta p)\,, \quad \widetilde{Y}(t_0) = Py_0\,.$$

5.2.1. Estimation of $\boldsymbol{E_1 = \widetilde{Y} - Y}$. Similar to section 5.1.1, we decompose the error $\Delta = E_1 - e$ into its components $\Delta_\perp \in S^\perp$ and $\Delta_S \in S$. We retain only the first-order term from the Taylor expansion of $\Delta_\perp$ around $\delta p = 0$,

$$\Delta_\perp = -Q \left.\frac{dY}{d\delta p}\right|_{\delta p=0} \delta p\,.$$

The sensitivity matrix $\Psi = dY/d\delta p$ satisfies

$$\frac{d\Psi}{dt} = \mathbf{J}(y,t,p)\Psi + \mathbf{K}(y,t,p)\,, \quad \Psi(t_0) = 0\,,$$

where $\mathbf{K} = \partial f/\partial p$ is the Jacobian of f with respect to p. In terms of the fundamental matrix Φ of the linearization of (2.1), we have

$$\Psi(t_f) = \int_{t_0}^{t_f} \Phi(t_f)\Phi^{-1}(\tau)\mathbf{K}(y(\tau),\tau,p)\,d\tau,$$

and thus

$$u^T\Delta_\perp(t_f) = -\left(\int_{t_0}^{t_f} \lambda^T(\tau)\mathbf{K}(y(\tau),\tau,p)\,d\tau\right)\cdot \delta p\,,$$

where λ is the solution of (5.5) and $u \in R^n$.

The observations in section 5.1.1 remain valid: (a) using vectors u' from the S_{n-k-1} sphere embedded in $S^\perp$ gives a more accurate SCE error norm estimate; (b) a more efficient adjoint solution can be obtained assuming $\mathbf{J}(y,t,p) \approx \mathbf{J}(\widetilde{y},t,p)$ and $\mathbf{K}(y,t,p) \approx \mathbf{K}(\widetilde{y},t,p)$.

The SCE estimate of the norm of $\Delta_\perp$ is then

$$\|\Delta_\perp(t_f)\| \approx \frac{W_q}{W_n}\sqrt{\sum_{j=1}^{q}\left|\int_{t_0}^{t_f} \lambda^T(\tau)\mathbf{K}(\widetilde{y}\,(\tau),\tau,p)\,\delta p\,d\tau\right|^2}\,,$$

bounded by $\|\Delta_\perp(t_f)\| \le \kappa_1 \cdot \|\delta p\|$, where κ_1 is now defined as

$$\kappa_1 = \frac{W_q}{W_n}\sum_{j=1}^{q} \|\lambda^T\mathbf{K}\|_{L_1}^2.$$

In complete analogy with section 5.1.1, if $\mathbf{J}(y,t,p) \approx \mathbf{J}(\widetilde{y},t,p)$ and $\mathbf{K}(y,t,p) \approx \mathbf{K}(\widetilde{y},t,p)$, the component Δ_S parallel to S satisfies to a first-order approximation

$$\frac{d\Delta_S}{dt} = P\mathbf{J}(\widetilde{y},t,p)\Delta_S\,, \quad \Delta_S(t_0) = 0,$$

and therefore $\Delta_S(t) = 0$, for all $t \ge t_0$. As a consequence, $\Delta(t_f) \approx \Delta_\perp(t_f)$ and

$$\|E_1(t_f)\| \le \|e(t_f)\| + \kappa_1 \cdot \|\delta p\|_\infty\,.$$

5.2.2. Estimation of $\boldsymbol{E_2 = \widetilde{y} - Y}$. Following a similar approach to section 5.2.1, for a uniformly selected random vector $u \in S_{n-1}$ and with $\lambda_{\widetilde{y}}$ the solution of

(4.3),

$$\begin{aligned} u^T E_2(t_f) &= -\int_{t_0}^{t_f} \lambda^T(\tau)\, \Big[Q f(\widetilde{y}(\tau), \tau, p) + \mathbf{K}(\widetilde{y}(\tau), \tau, p)\, \delta p \Big]\, d\tau \\ &\qquad\qquad -\lambda^T(t_0) Q y_0 \\ &= u^T e(t_f) - \int_{t_0}^{t_f} \lambda^T(\tau) \mathbf{K}(\widetilde{y}(\tau), \tau, p)\, \delta p\, d\tau\,, \end{aligned} \tag{5.12}$$

where $e(t_f)$ is the approximation error for the original system, defined by (4.1). As in section 5.1.2, it follows that

$$\|E_2(t_f)\| \le \|e(t_f)\| + \kappa_2 \cdot \|\delta p\|_\infty\,, \tag{5.13}$$

where the condition number κ_2 is now

$$\kappa_2 = \frac{W_q}{W_n} \sqrt{\sum_{j=1}^{q} \|\lambda^T \mathbf{K}\|_{L_1}^2}\,.$$

The above SCE bound estimate for the norm of $E_2(t_f)$ is again more accurate than the one derived in section 5.2.1 for the bound on the norm of $E_1(t_f)$. Furthermore, starting from (5.12), an SCE estimate for $\|E_2(t_f)\|$ can be computed without need for Y or $\widetilde{Y}$, unlike for $\|E_1(t_f)\|$ in section 5.2.1.

6. Examples. We consider reduced-order ODE examples that are representative of problems derived from spatial discretization of PDEs (linear advection-diffusion) or directly obtained from physical phenomena (a pollution model). Additional examples are described in [13].

For each example, two figures with numerical results are provided (Figures 6.2 and 6.3 for the first example and Figures 6.4 and 6.5 for the second one). The estimates (and bounds) were obtained using $q = 1$ (blue), $q = 2$ (green), and $q = 3$ (red), where q is the number of orthogonal vectors used by the SCE.

Figure 6.2 contains POD approximation errors as functions of the dimension of the subspace S. The norm of the total approximation error at the final time, $\|e(t_f)\| = \|\widetilde{y}(t_f) - y(t_f)\|$, is given in plot (a), while the norm of the subspace integration error at the final time, computed in the subspace S, i.e., $\|e_S(t_f)\|$, is presented in plot (b). The solid (black) lines represent the corresponding norms computed by the forward integration of the error equations (4.2) and (4.8), respectively. The dotted (colored) lines describe SCE estimates (4.5) and (4.10), respectively, for different values of q. The dashed (colored) lines appear only in plot (b) and represent the bounds of (4.11) for different values of q.

The first four plots in Figure 6.3 contain estimates of errors induced by a perturbation δy_0 in the initial conditions. Plot (a) presents the norm of the total approximation error of the perturbed system at the final time, $\|E_1(t_f)\| = \|\,\widetilde{Y}(t_f) - Y(t_f)\|$, as a function of the subspace dimension k. Plot (b) contains the norm of the cumulative error of the perturbed system at the final time, $\|E_2(t_f)\| = \|\widetilde{y}(t_f) - Y(t_f)\|$, as a function of the subspace dimension k. Plots (c) and (d) present the error bounds for $\|E_1(t_f)\|$ and $\|E_2(t_f)\|$, respectively, as predicted by the condition numbers κ_1 and κ_2 over a range of perturbations δy_0, for a given value of k. The solid (black) line represents the norm computed by the forward integration of the error equations (5.3) and

Table 6.1
The sum of ignored eigenvalues Λ_k and their relative size Λ.

(5.8), respectively. For different values of q, the dashed (colored) lines represent SCE estimates of the upper bound of (5.7) in plots (a) and (b), and of (5.10) in plots (c) and (d). For different values of q, the dotted (colored) lines represent SCE estimates for $\|E_1(t_f)\|$ in plot (a) and for $\|E_2(t_f)\|$ in plot (b).

The last four plots in Figure 6.3 contain estimates of errors induced by a perturbation δp in the model parameters. The corresponding plots (e), (f), (g), and (h) are in a format which is analogous to the one above.

The (blue) line made of circles represents the norm of the true (nonlinear) error, $e(t) = \widetilde{y}(t) - y(t)$, where $\widetilde{y}$ is the solution of (2.4) and y is the solution of (2.1).

Dimension of the POD subspace. Let $\Lambda_k = \sum_{i=k+1}^{n} \lambda_i$ be the sum of the eigenvalues ignored in the construction of the POD-reduced model and $\Lambda = \Lambda_k / \sum_{i=1}^{n} \lambda_i$ be its relative size compared to the sum of all eigenvalues. The POD subspace dimension k is selected such that the relative error is very close to one, yet k is sufficiently small. A relative error near zero means that a high percentage of the energy for the full model was captured by the reduced-order model. The values of Λ_k and Λ, for the numerical examples considered in this paper, are presented in Table 6.1.

To assess how well the full model is approximated by the POD-based reduced model, we present in Figure 6.1 the behavior of the norm of the total error over the given time interval for both examples considered in the paper. The dimension of the POD subspace is denoted by k and has values $(5, 6, 7)$ for the 1-D advection-diffusion example and $(7, 8, 9)$ for the pollution example.

Number of orthogonal vectors for the SCE estimate. We considered one, two, and three SCE vectors for our numerical examples. As expected, having just one SCE vector yielded the worst estimate in most of the cases. Nevertheless, even that estimate was, in many cases, good enough to warrant its inclusion in our results.

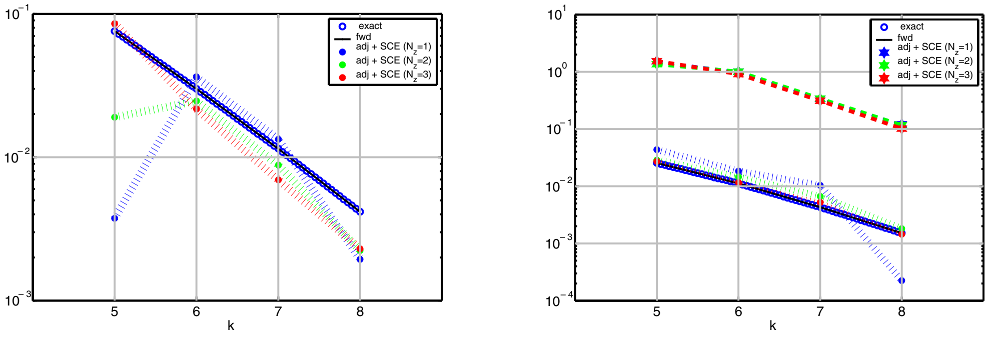
6.1. Linear advection-diffusion model. We consider the 1-D problem

$$\begin{aligned} & u_t = p_1 u_{xx} + p_2 u_x \\ \text{with BC} \quad & u(0,t) = u(2,t) = 0 \\ \text{and IC} \quad & u(x,0) = u_0(x) = x(2-x)e^{2x} \,. \end{aligned}$$

The PDE is discretized on a uniform grid of size $n+2$ with central differencing. With $y_i(t) = u(x_i, t)$ and eliminating boundary values, we obtain the following size n ODE system:

$$\frac{dy_i}{dt} = p_1 \frac{y_{i+1} - 2y_i + y_{i-1}}{\Delta x^2} + p_2 \frac{y_{i+1} - y_{i-1}}{2\Delta x} \,, \quad y_i(0) = u_0(x_i) \,.$$

The problem parameters were $p_1 = 0.5$, $p_2 = 1.0$, and $N = 100$. Results for this problem are shown in Figures 6.2 and 6.3. The POD projection matrices were based on $m = 100$ data points equally spaced in the interval $[t_0, t_f] = [0.0, 0.3]$. The estimate of the total error is consistently close to the exact value, with the estimates corresponding to $q = 2, 3$ almost identical to the subspace integration error. The bounds are within an order of magnitude for both IC and RHS perturbations. The RHS perturbation increases the distance between the bounds and the forward error. That was expected, since the RHS perturbation changes the advection coefficient p_2, which is dominant for the time window considered.



(a) Total error

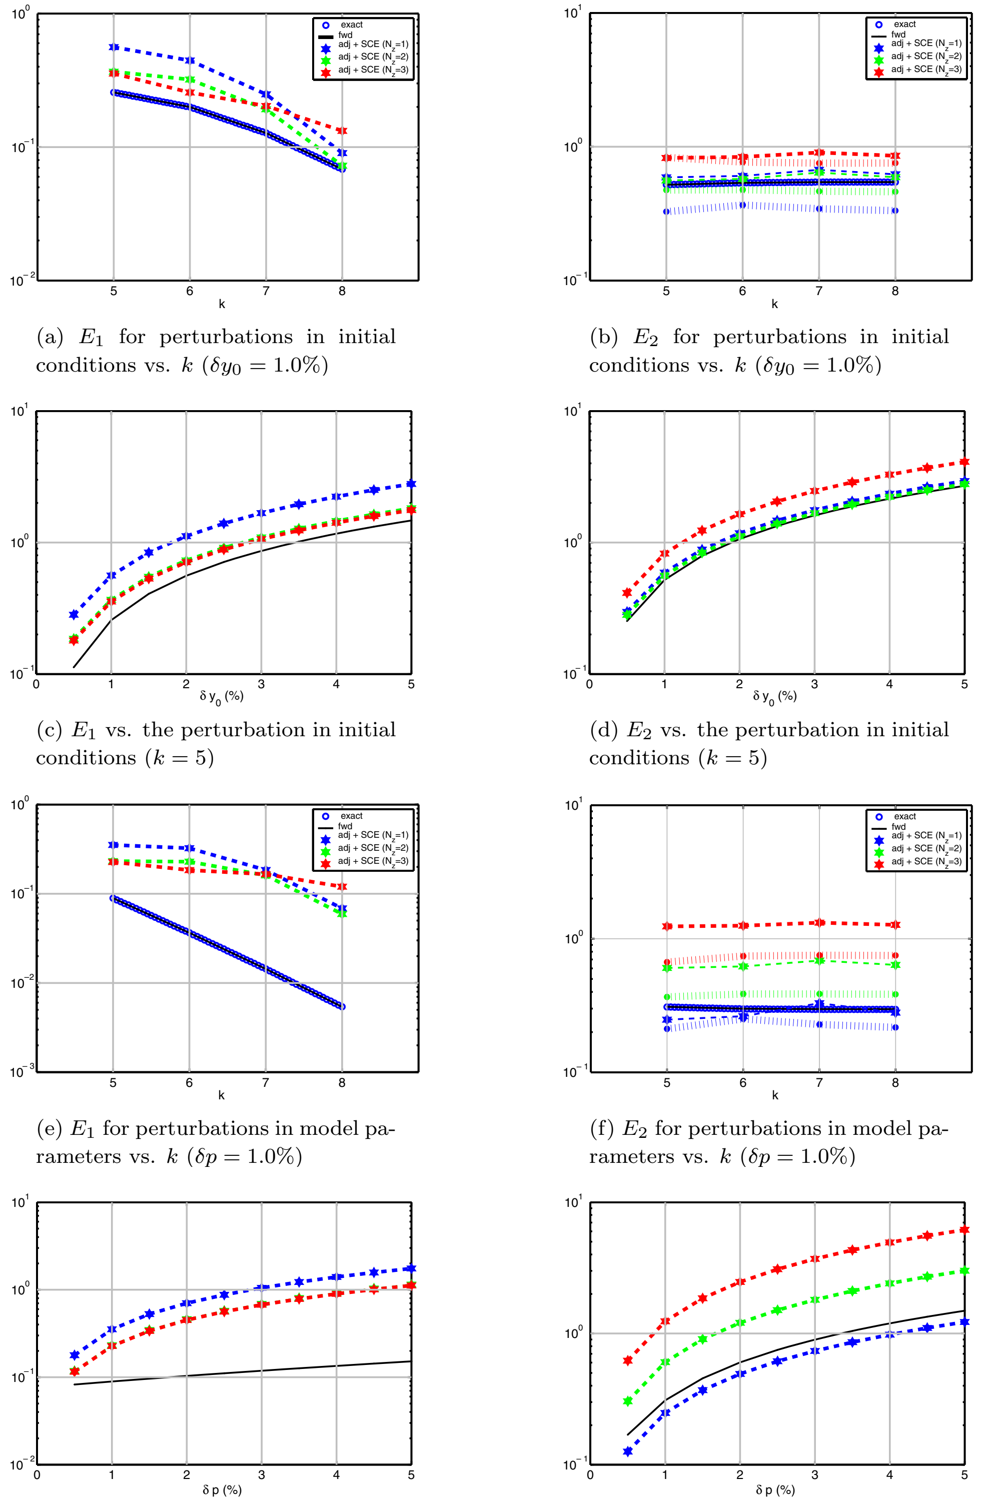
(b) Subspace integration error

FIG. 6.2. *1-D advection-diffusion example. Model-reduction error.*

6.2. Pollution model. Next we consider the chemical reactions from an air pollution model described in [33]. This is a highly nonlinear stiff ODE system consisting of 25 reactions and 20 species. The problem is of the form

$$\frac{dy}{dt} = f(y) \,, \quad y(0) = y_0, \quad y \in R^{20} \,,$$

where the function $f(y)$ is defined by



(a) E_1 for perturbations in initial conditions vs. k ($\delta y_0 = 1.0\%$)

(b) E_2 for perturbations in initial conditions vs. k ($\delta y_0 = 1.0\%$)

(c) E_1 vs. the perturbation in initial conditions ($k = 5$)

(d) E_2 vs. the perturbation in initial conditions ($k = 5$)

(e) E_1 for perturbations in model parameters vs. k ($\delta p = 1.0\%$)

(f) E_2 for perturbations in model parameters vs. k ($\delta p = 1.0\%$)

(g) E_1 vs. the perturbation in model parameters ($k = 5$)

(h) E_2 vs. the perturbation in model parameters ($k = 5$)

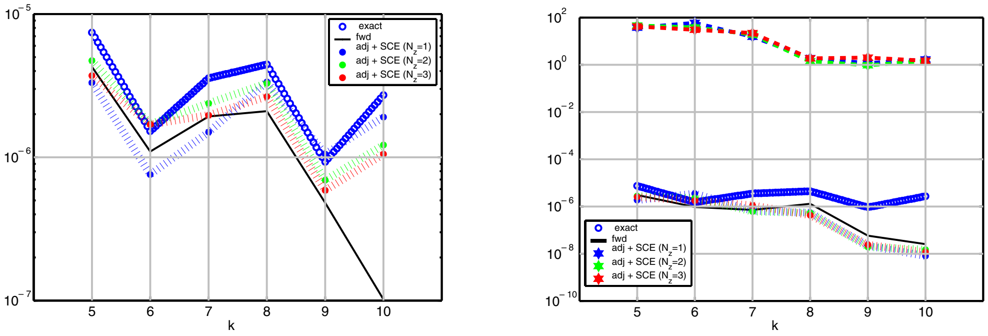
Numerical results depicting the approximation errors and the regions of validity at $t_f = 1.0$ are presented in Figures 6.4 and 6.5, respectively. The POD projection matrix was based on $m = 1000$ data points equally spaced in the interval $[t_0, t_f] = [0.0, 1.0]$.

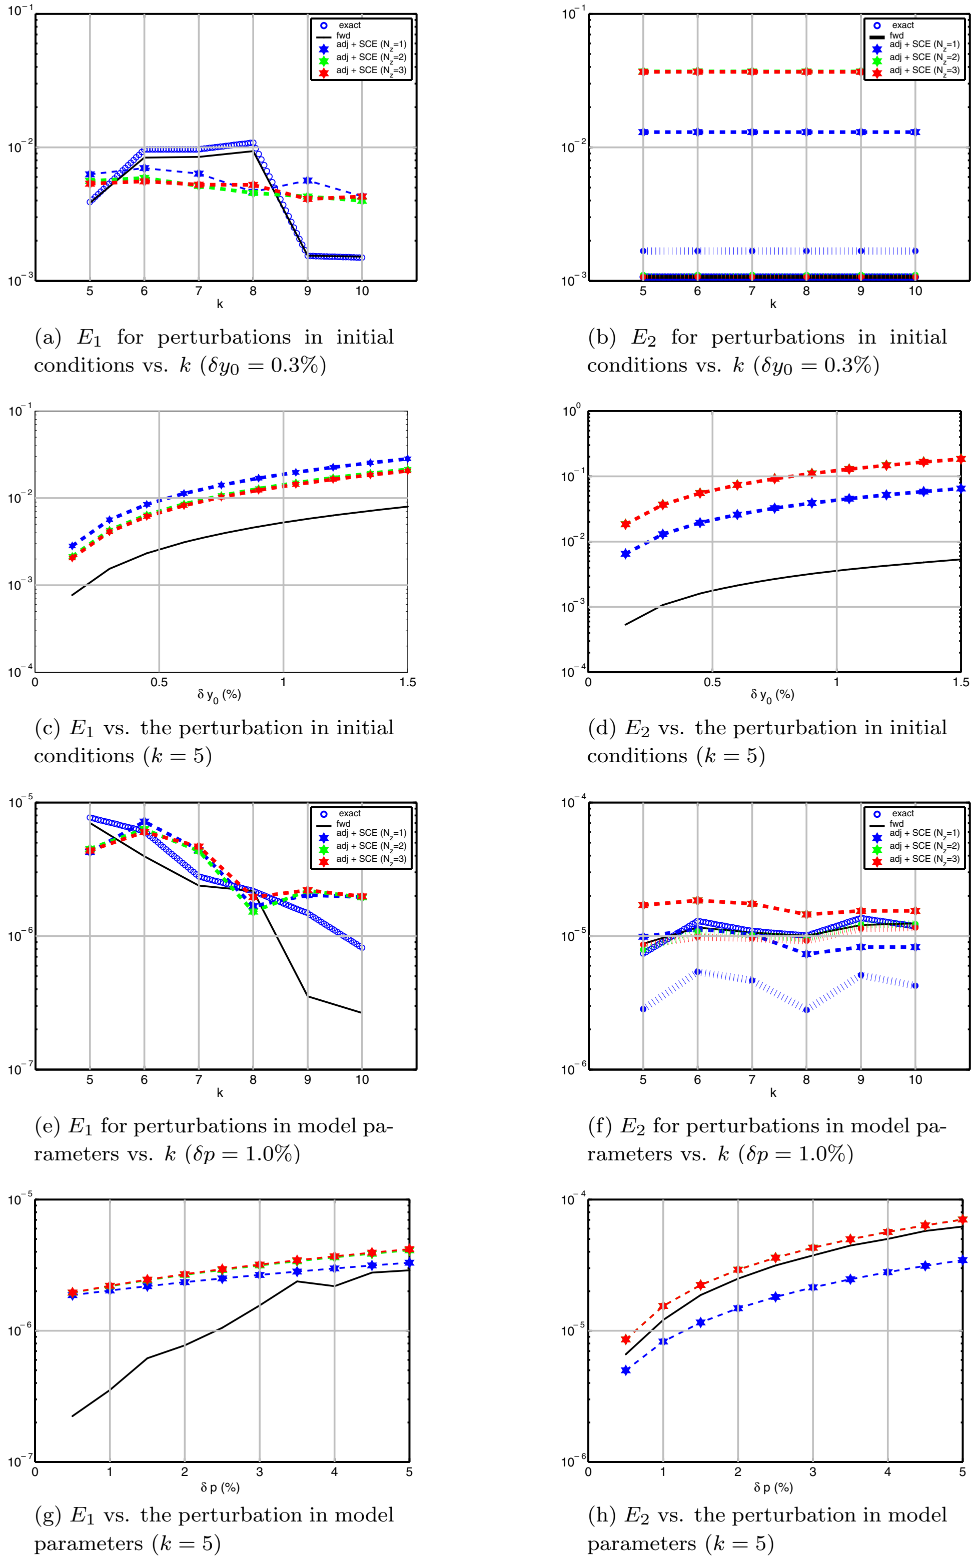


(a) Total error

(b) Subspace integration error

FIG. 6.4. *Pollution example. Model-reduction error.*

For $k = 5, 6, 7$ the total error and the subspace integration error are very well approximated by estimates corresponding to $q = 2$ or 3. For $k = 8, 9, 10$ the estimates are not as good, although they remain within an order of magnitude. We believe that



(a) E_1 for perturbations in initial conditions vs. k ($\delta y_0 = 0.3\%$)

(b) E_2 for perturbations in initial conditions vs. k ($\delta y_0 = 0.3\%$)

(c) E_1 vs. the perturbation in initial conditions ($k = 5$)

(d) E_2 vs. the perturbation in initial conditions ($k = 5$)

(e) E_1 for perturbations in model parameters vs. k ($\delta p = 1.0\%$)

(f) E_2 for perturbations in model parameters vs. k ($\delta p = 1.0\%$)

(g) E_1 vs. the perturbation in model parameters ($k = 5$)

(h) E_2 vs. the perturbation in model parameters ($k = 5$)

FIG. 6.5. *Pollution example. Regions of validity.*

this behavior is related to the fact that the POD error (either absolute or relative) is very small. We note that the problem was solved using relative tolerances of 10^{-4} and absolute tolerance of 10^{-7}. Thus one can expect a less uniform behavior if the results are in the neighborhood of 10^{-7}.

Finally, we note that due to the fact that the problem parameters k_j have orders of magnitude ranging from 10^{-3} to 10^{12}, we have limited the RHS perturbation only to perturbations in k_4, k_5, and k_7.

6.3. More examples. In [13] we include more test problems derived from spatial discretization of PDEs (Burgers's PDE or the Brusselator PDE) or directly obtained from physical phenomena (HIRES High Irradiance Response). The results obtained for those examples confirm our approach, in the sense that the SCE estimates offer a good approximation for the errors of the POD-reduced models. For more details, the reader may consult [13], which is available online.

7. Conclusions and future work.

We have presented effective methods for estimating approximation errors due to the use of POD-based reduced-order models and for evaluating regions of validity of such reduced models. The bounds defining these regions of validity are a priori, in the sense that they do not rely on the solution of the perturbed system. The proposed approach, based on SCE norm estimates combined with the adjoint method, allows the definition and construction of so-called error condition numbers which can be used to assess the size of errors induced by perturbations (in initial conditions or in the model itself) without having to solve the perturbed system. The effectiveness of the proposed methods was demonstrated on several test problems.

We are currently investigating the applicability of this technique to the estimation of errors from other types of reduced-order models, as well as considering more complex models than those presented both in this paper and in [13]. Thus we will consider models which exhibit more interesting (e.g., oscillatory or chaotic) behavior in their POD-reduced model. For example, we think that our method to efficiently compute the error corresponding to different perturbations may be useful in conjunction with reduced models in oceanography or atmospheric sciences (recent advances [21] present POD-based reduced models that can approximate well even the bifurcation behavior of the flow).

B-SERIES AND ORDER CONDITIONS FOR EXPONENTIAL INTEGRATORS*

HÅVARD BERLAND[†], BRYNJULF OWREN[†], AND BÅRD SKAFLESTAD[†]

Abstract. We introduce a general format of numerical ODE-solvers which include many of the recently proposed exponential integrators. We derive a general order theory for these schemes in terms of *B*-series and bicolored rooted trees. To ease the construction of specific schemes we generalize an idea of Zennaro [*Math. Comp.,* 46 (1986), pp. 119–133] and define natural continuous extensions in the context of exponential integrators. This leads to a relatively easy derivation of some of the most popular recently proposed schemes. The general format of schemes considered here makes use of coefficient functions which will usually be selected from some finite dimensional function spaces. We will derive lower bounds for the dimension of these spaces in terms of the order of the resulting schemes. Finally, we illustrate the presented ideas by giving examples of new exponential integrators of orders 4 and 5.

Key words. exponential integrators, splitting methods, natural continuous extensions, Runge–Kutta schemes

1. Introduction.

Numerical integration schemes which use the matrix exponential go back all the way to Certaine [4], but there are also early papers by Lawson [15], Nørsett [20], Ehle and Lawson [6], and Friedli [7] to mention just a few. Recently there has been a revived interest in these schemes, in particular for the solution of nonlinear partial differential equations; see for instance [11, 17, 5, 3, 14, 13]. For a thorough review of the history of exponential integrators; see [16] and the references therein. The integrators found in these papers are derived in rather different ways, and they are formulated for different types of systems of differential equations. On this note, we consider the autonomous nonlinear system of ordinary differential equations

$$\dot{u} = Lu + N(u), \qquad u(0) = u_0. \tag{1.1}$$

Here L is a matrix and $N(u)$ a nonlinear mapping. The order theory we consider is valid for a large class of exponential integrators, including the Runge–Kutta–Munthe-Kaas (RKMK) schemes [17], the commutator-free Lie group integrators [3], and those schemes of Cox and Matthews [5], as well as Krogstad [14] which reduce to classical Runge–Kutta schemes when $L = 0$.

We present the general format for integrators of (1.1) as

$$N_r = N\big(\exp(c_r hL)\, u_0 + h \sum_{j=1}^{s} a_r^j(hL)\, N_j\big), \quad r = 1, \dots, s \tag{1.2}$$

$$u_1 = \exp(hL)\, u_0 + h \sum_{r=1}^{s} b^r(hL)\, N_r. \tag{1.3}$$

[†]Department of Mathematical Sciences, NTNU, N-7491 Trondheim, Norway (havard.berland@math.ntnu.no, brynjulf.owren@math.ntnu.no, bard.skaflestad@math.ntnu.no).

Here we assume that the functions $a_r^j(z)$ and $b^r(z)$ are at least p times continuously differentiable at $z=0$ for integration schemes of order p.

Table 1
Examples of schemes in general format for exponential integrators.

(a) RKMK, order 4

0				
$\frac{1}{2}$	$\frac{1}{2}\phi_0(z/2)$			
$\frac{1}{2}$	$\frac{z}{8}\phi_0(z/2)$	$\frac{1}{2}(1-\frac{z}{4})\phi_0(z/2)$		
1			$\phi_0(z)$	
	$\frac{1}{6}\phi_0(z)(1+\frac{z}{2})$	$\frac{1}{3}\phi_0(z)$	$\frac{1}{3}\phi_0(z)$	$\frac{1}{6}\phi_0(z)(1-\frac{z}{2})$

(b) Commutator-free, order 4

0				
$\frac{1}{2}$	$\frac{1}{2}\phi_0(z/2)$			
$\frac{1}{2}$		$\frac{1}{2}\phi_0(z/2)$		
1	$\frac{z}{4}\phi_0(z/2)^2$		$\phi_0(z/2)$	
	$\frac{1}{2}\phi_0(z)-\frac{1}{3}\phi_0(z/2)$	$\frac{1}{3}\phi_0(z)$	$\frac{1}{3}\phi_0(z)$	$-\frac{1}{6}\phi_0(z)+\frac{1}{3}\phi_0(z/2)$

Table 1 gives the coefficient functions $a_r^j(z)$ and $b^r(z)$ for the fourth order RKMK scheme introduced in [18] in this general format when applied to the problem (1.1) with an affine Lie group action, and the commutator-free scheme of order 4 from [3]; in both tables $\phi_0(z) = (\mathrm{e}^z - 1)/z$.

For deriving order conditions, we expand the coefficient functions in powers of z,

$$a_r^j(z) = \sum_{k\geq 0} \alpha_r^{j,k} z^k \quad \text{and} \quad b^r(z) = \sum_{k\geq 0} \beta^{r,k} z^k,$$

where the sum may terminate with a remainder term. For the schemes we consider here, these functions are in fact all entire. If $N(u) = 0$ in (1.1), then any scheme in the above class will reproduce the exact solution in every step. Whereas if $L = 0$, the scheme (1.2)–(1.3) reduces to a classical Runge–Kutta method with coefficients $a_r^j = \alpha_r^{j,0}$ and $b^r = \beta^{r,0}$. This scheme is henceforth called *the underlying Runge–Kutta scheme*. We will always assume that $c_r = \sum_j \alpha_r^{j,0},\ 1 \leq r \leq s$.

The schemes proposed by Friedli [7] closely resemble the format (1.2)–(1.3), the difference being that the coefficient functions a_{rj} (resp. b_r) are evaluated in $c_r hL$ rather than in hL, thus a nontrivial discrepancy may occur whenever $c_r = 0$. And even though Friedli explicitly requires that the functions $a_{rj}(z)$ and $b_r(z)$ be of the form

$$\int_0^1 \mathrm{e}^{(1-\theta)z} p(\theta)\,\mathrm{d}\theta, \qquad p(\theta) \text{ polynomial},$$

his analysis holds also for the case of more general coefficient functions, so that the order conditions he obtains for $p \leq 4$ are almost identical to those derived in section 2 here. However, the order theory presented here is general.

We will discuss conditions on the coefficients $\alpha_r^{j,k}$ and $\beta^{r,k}$ under which the scheme (1.2)–(1.3) has order of consistency p for problems of the type (1.1). We will use the well known approach involving rooted trees; see, for instance, [9, 2]. The conditions we find will depend only on the first $\alpha_r^{j,k}$ for $k \le p-2$ and on $\beta^{j,k}$ for $k \le p-1$. On this note we will not address issues related to the behavior of the coefficient functions $a_r^j(z)$ and $b^r(z)$ for large values of z.

In the recent paper [12], an order theory for explicit exponential integrators is presented and its application to semilinear parabolic problems is discussed. While classical or nonstiff order conditions are usually derived by assuming that a Lipschitz constant exists, one needs to account for the unboundedness of the operator L whenever PDEs are considered. It is found that a set of additional order conditions must be satisfied to guarantee convergence order p under suitable assumptions; one requires the linear operator L to be the infinitesimal generator of an analytic semigroup, and that the nonlinear function satisfies a Lipschitz condition. The authors are also able to give an example where order reduction is seen numerically for schemes not satisfying the additional conditions. But the conditions are rather restrictive, and in [13] exponential integrators of (nonstiff) order four are tried out numerically for a number of well-known semilinear PDEs, and no order reduction is seen, despite the fact that these integrators do not satisfy all the required conditions for order four as given in [12]. This shows that the issue of determining the order behavior of exponential integrators for PDEs is indeed a subtle one, and remains today in an unsatisfactory state of nonresolution.

2. *B*-series and order conditions. Repeated differentiation of (1.1) with respect to time yields

$$\begin{aligned}
\frac{\mathrm{d}^2u}{\mathrm{d}t^2} &= L\dot{u} + N'(\dot{u}) \\
&= L^2u + LN + N'(Lu) + N'(N) \\
\frac{\mathrm{d}^3u}{\mathrm{d}t^3} &= L^3u + L^2N + LN'(Lu) + LN'(N) \\
&\quad + N''(Lu, Lu) + 2N''(Lu, N) + N'(L^2u) \\
&\quad + N'(LN) + N''(N, N) + N'N'(Lu) + N'N'(N),
\end{aligned}$$

etc. The exact solution of (1.1) has a formal expansion

$$u(h) = \sum_{q=0}^{\infty} \frac{h^q}{q!} \left.\frac{\mathrm{d}^q}{\mathrm{d}h^q}\right|_{h=0} u(h),$$

where each term in the qth derivative corresponds in an obvious way to a rooted bicolored tree. Let for instance $\bullet \sim F(\bullet) = N(u)$ and $\circ \sim F(\circ) = Lu$ be the two trees with one node. Next, define B_+ as the operation which takes a finite set of trees $\{\tau_1, \dots, \tau_\mu\}$ and connects their roots to a new common black root. Similarly, $\tau = W_+(\tau')$ connects the root of τ' to a new white root resulting in the tree τ associated to $F(\tau) = L \cdot F(\tau')$. It suffices here to allow W_+ to act on a single tree and not on a set of trees. To each tree τ with q nodes formed this way, there exists precisely one term, $F(\tau)$ called an elementary differential, in the qth derivative of the solution of (1.1). For $q > 1$ it is defined recursively as

$$F(B_+(\tau_1, \dots, \tau_\mu))(u) = N^{(\mu)}(F(\tau_1), \dots, F(\tau_\mu))(u) \tag{2.1}$$

$$F(W_+(\tau'))(u) = LF(\tau')(u). \tag{2.2}$$

We may denote by T the set of all bicolored trees such that each white node has at most one child, and set $T = T_b \cup T_w$ the union of trees with black and white roots, respectively. Introducing the empty set $\emptyset$, and using the convention $B_+(\emptyset) = \bullet$, $W_+(\emptyset) = \circ$, we may write

$$T \cup \emptyset = \bigcup_{m \geq 0} W_+^m(T_b \cup \emptyset), \quad T_w = \bigcup_{m \geq 1} W_+^m(T_b \cup \emptyset). \tag{2.3}$$

The same bicolored trees used here also appear in the linearly implicit W-methods; see Steihaug and Wolfbrandt [21] as well as the text [10] by Hairer and Wanner. Following, for instance, the text by Hairer, Lubich, and Wanner [8], we may work with formal B-series. For an arbitrary map $\boldsymbol{c} : T \cup \emptyset \to \mathbf{R}$, we let the formal series

$$B(\boldsymbol{c}, u) = \boldsymbol{c}(\emptyset)u + \sum_{\tau \in T} \frac{h^{|\tau|}}{\sigma(\tau)} \boldsymbol{c}(\tau) F(\tau)(u) \tag{2.4}$$

be a B-series, where $\sigma(\tau)$ is the symmetry coefficient defined as $\sigma(\bullet) = \sigma(\circ) = 1$, and for $\tau = B_+(\tau_1, \ldots, \tau_\mu)$,

$$\sigma(\tau) = \sigma(\tau_1) \cdots \sigma(\tau_\mu)\, m_1! \cdot m_2! \cdots ,$$

where the m_is count the number of equal trees among $\tau_1, \ldots, \tau_\mu$.

The further derivation of order conditions is based on the assumption that both the exact and numerical solution possess B-series of the form (2.4), say $B(\boldsymbol{e}, u_0)$ and $B(\boldsymbol{u}_1, u_0)$, respectively. We refer to [1] for details, and present only the final result.

Theorem 2.1. *Let $T' \subset T$ be the set of bicolored rooted trees such that every white node has precisely one child. An exponential integrator defined by* (1.2)–(1.3) *has order of consistency p if*

$$\boldsymbol{u}_1(\tau) = \frac{1}{\gamma(\tau)} \quad \textit{for all } \tau \in T' \textit{ such that } |\tau| \leq p,$$

where

$$\begin{aligned} \boldsymbol{u}_1(\emptyset) = \boldsymbol{U}_r(\emptyset) &= 1, \quad 1 \leq r \leq s, \\ \boldsymbol{u}_1(W_+^m B_+(\tau_1, \ldots, \tau_\mu)) &= \sum_{r=1}^{s} \beta^{r,m} \boldsymbol{U}_r(\tau_1) \cdots \boldsymbol{U}_r(\tau_\mu) \\ \boldsymbol{U}_r(W_+^m B_+(\tau_1, \ldots, \tau_\mu)) &= \sum_{j=1}^{s} \alpha_r^{j,m} \boldsymbol{U}_j(\tau_1) \cdots \boldsymbol{U}_j(\tau_\mu). \end{aligned}$$

The trees in T' with at most four nodes are listed in Table 2. Note that even though all trees in the set T feature in the B-series for the exact and numerical solutions, it suffices to consider a subset T' consisting of all trees in T except those with a terminal white node. There is an interesting connection between the set of trees T' and the trees used to develop the order theory for composition methods in [19]. White nodes appear as connected strings of nodes which, except for the root, have exactly one parent and one child, and always terminate in a black node. Therefore one can remove all white nodes and assign to the terminating black node the number of removed nodes plus one. Black nodes not connected to a white node are assigned the number one. These multilabelled trees are precisely those appearing in [19], they can also be identified as the set of rooted trees of nonempty sets. The generating function for these trees is well known,

$$M(x) = \frac{x}{1-x}\ \exp\left(M(x) + \frac{M(x^2)}{2} + \frac{M(x^3)}{3} + \cdots\right).$$

The number of order conditions for each order 1 to 9 is 1, 2, 5, 13, 37, 108, 332, 1042, and 3360.

3. Construction of exponential integrators.

The schemes of Lawson [15] are exponential integrators derived simply by introducing a change of variable, $w(t) = \mathrm{e}^{-tL}\, u(t)$ in (1.1), and by applying a standard Runge–Kutta scheme to the resulting ODE. This approach results in a formula for w_1 in terms of w_0. By setting $u_n = \mathrm{e}^{tL}\, w_n$ one gets a scheme of the form (1.2)–(1.3) in which

$$a_r^j(z) = \alpha_r^{j,0}\,\mathrm{e}^{(c_r - c_j)z} \quad \text{and} \quad b^r(z) = \beta^{r,0}\,\mathrm{e}^{(1-c_r)z},$$

as noted by Lawson in [15].

This scheme has order p if the underlying scheme determined by $\alpha_r^{j,0}$ and $\beta^{r,0}$ is of order p. This gives us a very useful tool for constructing exponential integrators with given underlying Runge–Kutta schemes. We express this in the following proposition.

PROPOSITION 3.1. *Suppose that the coefficients $\alpha_r^{j,0}$ and $\beta^{r,0}$, $1 \le r, j \le s$ define a Runge–Kutta scheme of order p. Then, any exponential integrator of the form* (1.2)–(1.3) *satisfying*

$$\alpha_r^{j,m} = \frac{1}{m!}(a_r^j)^{(m)}(0) = \frac{1}{m!}\alpha_r^{j,0}(c_r - c_j)^m, \quad 0 \le m \le p-2, \tag{3.1}$$

$$\beta^{r,m} = \frac{1}{m!}(b_r^j)^{(m)}(0) = \frac{1}{m!}\beta^{r,0}(1 - c_r)^m, \quad 0 \le m \le p-1, \tag{3.2}$$

is of order p. In the above expression we use $0^0 := 1$.

Proof. Order conditions for exponential integrators of order p involve $\alpha_r^{j,m}$ for $0 \le m \le p-2$ and $\beta^{r,m}$ for $0 \le m \le p-1$. On the other hand, the Lawson schemes must satisfy the order conditions for exponential integrators, and their values for these coefficients are precisely those specified in the proposition. □

It is convenient to introduce finite dimensional function spaces V_a and V_b to which the respective coefficient functions $a_r^j(z)$ and $b^r(z)$ will belong. For the purpose of calculations, it is also useful to work with basis functions ψ_k for these spaces,

$$a_r^j(z) = \sum_{k=0}^{K_a - 1} A_r^{j,k}\psi_k(z) \quad \text{and} \quad b^r(z) = \sum_{k=0}^{K_b - 1} B^{r,k}\psi_k(z), \tag{3.3}$$

where $K_a = \dim(V_a)$ and $K_b = \dim(V_b)$. There is a technical assumption that we will adopt to the end of this note.

ASSUMPTION 3.2. *Any finite dimensional function space V of dimension K used for coefficient functions $a_r^j(z)$ or $b^r(z)$ has the property that the map from V to $\mathbf{R}^K$ defined by*

$$f \mapsto\ (f(0), f'(0), \ldots, f^{(K-1)}(0))^T$$

is injective. Equivalently, any function in V is uniquely determined by its first K Taylor coefficients.

3.1. Deriving schemes with natural continuous extensions. The approach of Krogstad in [14] is to approximate the nonlinear function $N(u(t_0 + \theta h))$, $0 < \theta < 1$

with a polynomial in θ. Assuming that the functions $a_r^j(z)$ for the internal stages are given, one lets $N(u(t_n+\theta h))$ be approximated by

$$\bar{N}(t_0+\theta h)=\sum_{r=1}^{s} w_r'(\theta)N_r, \tag{3.4}$$

where $N_r = N(U_r)$ are the stage derivatives and $w_r(\theta)$ are polynomials of degree d, with $w(0) = 0$, such that $\bar{N}(t_0+\theta h)$ approximates $N(u(t_0+\theta h))$ uniformly for $0<\theta<1$ to a given order. Replacing the exact problem with the approximate one, $\dot{v}=Lv+\bar{N}(t),\ v(t_0)=u_0$ one finds

$$u_1 := v(t_0+h)=\mathrm{e}^{hL}u_0+\sum_{r=1}^{s} b^r(hL)N_r, \quad \text{where } b^r(z)=\int_0^1 \mathrm{e}^{(1-\theta)z}w_r'(\theta)\,\mathrm{d}\theta;$$

we then define the functions

$$\phi_k(z)=\int_0^1 \mathrm{e}^{(1-\theta)z}\theta^k\,\mathrm{d}\theta,\ k=0,1,\dots. \tag{3.5}$$

Thus, here the function space $V_b=\operatorname{span}\{\phi_0,\dots,\phi_{d-1}\}$, so $\psi_k=\phi_k$ and $K_b=d$ in (3.3). Cox and Matthews [5] presented a fourth order scheme using these basis functions with $K_b=3$. Krogstad [14] also derived a variant of their method by using a continuous extension as just explained. In [22] Zennaro developed a theory which generalizes the collocation polynomial idea to arbitrary Runge–Kutta schemes. The approach was called natural continuous extensions (NCE). By making a slight modification to the approach of Zennaro, one can find a useful way of deriving exponential integrators as well as providing them with a continuous extension.

Suppose $w_1(\theta),\dots,w_s(\theta)$ are given polynomials of degree d, and that the stage derivatives $N_1,\dots,N_s$ of an exponential integrator are given from (1.2). We define the $d-1$ degree polynomial $\bar{N}(t)$ by (3.4).

Definition 3.3. *We call $\bar{N}(t)$ of* (3.4) *a natural continuous n-extension (NCNE) of degree d of the exponential integrator* (1.2)–(1.3) *if*

1. $$w_r(0)=0,\quad w_r(1)=b^r(0),\qquad r=1,\dots,s,$$

2. $$\max_{t_0\le t\le t_1}|N(u(t))-\bar{N}(t)|=\mathcal{O}(h^{d-1}), \tag{3.6}$$

   where $u(t)$ is the exact solution of (1.1) *satisfying $u(t_0)=u_0$;*

3. $$\int_{t_0}^{t_1} G(t)(N(u(t))-\bar{N}(t))\,\mathrm{d}t=\mathcal{O}(h^{p+1}) \tag{3.7}$$

   for every smooth matrix-valued function $G(t)$.

It is important to note that the polynomial $\bar{N}(t)$ only depends on the stages N_r and the weights $b^r(0)=\beta^{r,0}$ corresponding to the underlying Runge–Kutta scheme. We also observe that since the $w_r(\theta)$ does not depend on L, an NCNE as defined above is also an NCE in the sense of Zennaro for the system $\dot{u}=N(u)$. Before discussing the existence of NCNEs, we motivate their usefulness in designing exponential integrators. Suppose an underlying Runge–Kutta method has been chosen, and that an NCNE has been found. Then we can determine the functions $b^r(z)$ in order to obtain an exponential Runge–Kutta method of the same order as the underlying scheme.

THEOREM 3.4. *If $\bar{N}(t)$ defined from* (3.4) *is an NCNE of degree d for a pth order scheme, then the functions*

$$b^r(z) = \int_0^1 \mathrm{e}^{(1-\theta)z} w'(\theta)\,\mathrm{d}\theta = \beta^{r,0} + z\int_0^1 \mathrm{e}^{(1-\theta)z} w(\theta)\,\mathrm{d}\theta,$$

define the weights of an exponential integrator of order p.

Proof. The exponential integrator we consider is obtained by replacing (1.1) by

$$\dot{v} = Lv + \bar{N}(t), \qquad v(t_0) = u_0 \tag{3.8}$$

over the interval $[t_0, t_1]$ and by solving (3.8) exactly. We subtract (3.8) from (1.1) to obtain

$$\dot{u} - \dot{v} = L(\dot{u} - \dot{v}) + \big(N(u) - \bar{N}(t)\big).$$

We may solve this equation to obtain

$$u(t_1) - v(t_1) = \int_{t_0}^{t_1} \mathrm{e}^{(t_1-t)L}\big(N(u(t)) - \bar{N}(t)\big)\,\mathrm{d}t = \mathcal{O}(h^{p+1}),$$

the last equality is thanks to (3.7). □

A reinterpretation of a result by Zennaro [22] combined with Proposition 3.1 leads to the following theorem.

THEOREM 3.5. *Suppose that an underlying Runge–Kutta scheme with coefficients $\alpha_r^{j,0}$ and $\beta^{r,0}$ of order p is given. Then it is possible to find a set of coefficient functions $a_r^j(z)$ with $a_r^j(0) = \alpha_r^{j,0}$ such that an NCNE of degree $d = \lfloor\frac{p+1}{2}\rfloor$ exists. Moreover, if $\bar{N}(t)$ is a NCNE of degree d, then*

$$\left\lfloor \frac{p+1}{2} \right\rfloor \le d \le \min(\nu^*, p),$$

where ν^* is the number of distinct elements among $c_1, \dots, c_s$.

COROLLARY 3.6. *For every underlying Runge–Kutta scheme, there exists an exponential integrator whose coefficient functions $b^r(z)$ are in the linear span of the functions $\{\phi_0(z), \dots, \phi_{d-1}(z)\}$, where $d = \lfloor\frac{p+1}{2}\rfloor$.*

Note, in particular, that one can derive fourth order exponential integrators using linear combinations of just $\phi_0(z)$ and $\phi_1(z)$ for $b^r(z)$, which is one less than what Cox and Matthews used; we present a specific example in section 4.

3.2. Lower bounds for K_a and K_b. We start establishing lower bounds for the number of necessary basis functions ψ_k by proving an ancillary result.

LEMMA 3.7. *Let $q \ge 0$ be an integer. The matrix $T_q \in \mathbf{R}^{d\times d}$ with elements*

$$(T_q)_{m+1,k+1} = \frac{1}{(q+m+k+1)!}, \quad 0 \le m, k \le d-1$$

is invertible.

Proof. Let $w = (w_1, \ldots, w_d)^T \in \mathbf{R}^d$ be arbitrary, and consider the polynomial

$$p(x) = \sum_{k=0}^{d-1} w_{k+1} \frac{x^{q+d+k}}{(q+d+k)!}.$$

We compute

$$p^{(d-m-1)}(1) = \sum_{k=0}^{d-1} w_{k+1} \frac{1}{(q+m+k+1)!} = (T_q w)_{m+1}, \quad 0 \le m \le d-1.$$

So $T_q w = 0$ is equivalent to $p^{(j)}(1) = 0$ for $0 \le j \le d-1$. Since $p(x)$ is of the form $x^{q+d} r(x)$ where $r(x)$ is a polynomial of degree at most $d-1$, it follows that $p(x) \equiv 0$ so that $w = 0$. □

As $\phi_k^{(m)}(0) = m!k!/(m+k+1)!$ for ϕ_k defined by (3.5), we get as an immediate consequence of this lemma that the function spaces $V = \mathrm{span}(\phi_q, \ldots, \phi_{q+K-1})$, $q \ge 0$ satisfy Assumption 3.2.

Theorem 3.8. *For an exponential integrator of order p, the dimension of the function spaces V_a and V_b are bounded from below as follows:*

$$K_a = \dim V_a \ge \left\lfloor \frac{p}{2} \right\rfloor, \quad K_b = \dim V_b \ge \left\lfloor \frac{p+1}{2} \right\rfloor. \tag{3.9}$$

Proof. We will show that using smaller values of K_a or K_b than dictated by (3.9) is incompatible with the order conditions for a scheme of order p. Let V_a and V_b be arbitrary function spaces, satisfying Assumption 3.2, let V denote either of them, and let $d = \dim V$. If $f \in V$, then there are numbers $w_0, \ldots, w_{d-1}$ such that

$$f^{(d)}(0) = \sum_{m=0}^{d-1} w_m \, f^{(m)}(0). \tag{3.10}$$

Suppose now that $d_a := \dim V_a = \lfloor p/2 \rfloor - 1$ and $d_b := \dim V_b = \lfloor (p+1)/2 \rfloor - 1$.

Consider the bicolored trees $\tau_q^{m,k}$ defined by

$$\tau_q^{m,k} = B_+^q \big(W_+^m B_+ (\overbrace{\bullet, \ldots, \bullet}^{k}) \big)$$

which consist of a string of $q \ge 0$ black nodes followed by a string of $m > 0$ white nodes with a bushy tree of $k+1$ black nodes grafted onto the topmost leaf of the white nodes. We shall use these trees with $q = 0$ for proving the bound on K_b and with $q = 1$ for K_a. The density of $\tau_q^{m,k}$ is given by

$$\gamma(\tau_q^{m,k}) = \frac{(q+m+k+1)!}{\mathrm{k}!}.$$

The trees corresponding to order conditions for a scheme of order p have at most p nodes, $|\tau_q^{m,k}| = q+m+k+1 \le p \Rightarrow 0 \le k \le p-m-1-q$. The definition of d_a and d_b implies that $p-2 \ge 2d_a$ and $p-1 \ge 2d_b$. If we set $q = 1$, $m = d_a$ we thus obtain conditions for $0 \le k \le d_a$, whereas $q = 0$, $m = d_b$ results in $0 \le k \le d_b$.

The conditions corresponding to $\tau_1^{d_a,k}$ can be expressed as

$$\frac{1}{d_a!} \sum_{r,j=1}^{s} \beta^{r,0} (a_r^j)^{(d_a)}(0) c_j^k = \frac{k!}{(d_a+k+2)!}, \quad 0 \le k \le d_a$$

which, upon insertion of $(a_r^j)^{(d_a)}(0) = \sum w_m (a_r^j)^{(m)}(0)$ as in (3.10), yields

$$\frac{k!\,d_a!}{(k+d_a+2)!} = \sum_{m=0}^{d_a-1} w_m \left(\sum_{r=1}^{s} \beta^{r,0} (a_r^j)^{(m)}(0) c_j^k \right) = \sum_{m=0}^{d_a-1} w_m \, \frac{m!\,k!}{(m+k+2)!}.$$

The conditions for $\tau_0^{d_b,k}$ similarly yield

$$\frac{k!\,d_b!}{(k+d_b+1)!} = \sum_{m=0}^{d_b-1} w_m \left(\sum_{r=1}^{s} (b^r)^{(m)}(0)\, c_r^k \right) = \sum_{m=0}^{d_b-1} w_m \frac{m!\,k!}{(m+k+1)!}.$$

In both cases ($d = d_a$ or d_b), we end up with a $(d+1) \times d$ linear system of equations for determining w_m, $m = 0, \ldots, d-1$. This system is of the form

$$\sum_{m=0}^{d-1} \frac{m!\,k!}{(q+m+k+1)!}\, w_m = \frac{k!\,d!}{(q+k+d+1)!}, \quad 0 \le k \le d$$

for $q \in \{0, 1\}$ and is solvable only if the matrix with elements

$$(T_q)_{m+1,k+1} = \frac{m!\,k!}{(q+m+k+1)!}, \quad 0 \le m, k \le d$$

is singular. However, Lemma 3.7 implies that the matrix T_q is invertible so the linear system is inconsistent. It is hence not possible to choose $K_a = d_a$ or $K_b = d_b$. □

Some remarks regarding the implications of Theorem 3.8 are in order. First, note that the bounds in the theorem are not proved to be sharp; however, Theorem 3.5 ensures that the lower bound is attainable for the dimension of V_b if a basis is given by the functions ϕ_k of (3.5). However, this result does not apply to the space V_a of the functions $a_r^j(z)$. For instance, in the case $p = 5$, one can prove that it is indeed possible to take $K_a = 2$, but V_a cannot be the span of ϕ_0 and ϕ_1. But an example of a feasible two-dimensional space is that with basis $\psi_0(z) = \phi_1(z)$ and $\psi_1(z) = \phi_1(\frac{3}{5}z)$. A particular scheme is given in Table 4, though the usefulness of the bounds are questionable in this particular example. Using say $V_b = \mathrm{span}\{\phi_0, \phi_1, \phi_2\}$ combined with the above choice of V_a requires the computation with a total of 4 basis functions, whereas only 3 are necessary if one instead chooses $V_a = V_b$.

Furthermore, we note that the minimum attainable value of the parameters K_a and K_b depend only on the order p of the underlying Runge–Kutta scheme and the choice of the basis functions ψ_k. Specifically, the coefficients of the underlying Runge–Kutta scheme do not influence the minimum values of K_a and K_b.

4. Examples of exponential integrators.

In this section we will present examples of exponential integrators. For fourth order methods, one will notice that some well-known schemes are obtained for particular choices of the free parameters, suggesting that a search on the entire space of parameters may result in schemes which in some sense may have better properties than the known methods. The scheme of order 5 presented at the end is only included as an illustration of the proposed procedure for solving the order conditions. It remains a subject of future research to establish to which extent higher order exponential integrators are useful for practical purposes.

The procedure we have used in constructing schemes may be summarized as follows:

1. Choose an underlying Runge–Kutta scheme. This determines $\alpha_r^{j,0}$ and $\beta^{r,0}$.

TABLE 3
Coefficient function for a fourth order ETD scheme with classical RK4 as underlying scheme. Basis functions given by (3.5).

$$
\begin{aligned}
a_2^1(z) &= -(\tfrac{1}{2} + \rho_1)\phi_0(z) + (2\rho_1 + 2)\phi_1(z)\\
a_3^1(z) &= (1 + \rho_1 - \tfrac{1}{4}(\rho_2 + \rho_3))\phi_0(z) + (-2 - 2\rho_1 + \tfrac{1}{2}(\rho_2 + \rho_3))\phi_1(z)\\
a_3^2(z) &= (-1 + \tfrac{1}{4}(\rho_2 + \rho_3))\phi_0(z) + (3 - \tfrac{1}{2}(\rho_2 + \rho_3)\phi_1(z)\\
a_4^1(z) &= \tfrac{1}{2}(\rho_2 + \rho_3)\phi_0(z) - (\rho_2 + \rho_3)\phi_1(z)\\
a_4^2(z) &= -\frac{\rho_2}{2}\phi_0(z) + \rho_2\phi_1(z)\\
a_4^3(z) &= (1 - \tfrac{1}{2}\rho_3)\phi_0(z) + \rho_3\phi_1(z)
\end{aligned}
$$

$$
\begin{aligned}
b^1(z) &= (1 + \gamma_2)\,\phi_0(z) + (-3 - 6\gamma_2)\,\phi_1(z) + (6\gamma_2 + 2)\,\phi_2(z)\\
b^2(z) &= (-\gamma_1 - 2\gamma_2)\,\phi_0(z) + (6\gamma_1 + 12\gamma_2 + 2)\phi_1(z) + (-6\gamma_1 - 12\gamma_2 - 2)\,\phi_2(z)\\
b^3(z) &= \gamma_1\,\phi_0(z) + (-6\gamma_1 + 2)\,\phi_1(z) + (6\gamma_1 - 2)\,\phi_2(z)\\
b^4(z) &= \gamma_2\,\phi_0(z) + (-6\gamma_2 - 1)\,\phi_1(z) + (6\gamma_2 + 2)\,\phi_2(z)
\end{aligned}
$$

2. Choose basis functions $\psi_k(z)$ for the coefficient functions and determine K_a and K_b.
3. Use the order conditions for the trees of the form $W_+^m(\tau_C)$, where τ_C is a tree with only black nodes, and determine $\beta^{r,m}$, for $1 \leq m \leq K_b - 1$; see also (3.2).
4. Identify order conditions which are linear in $c'_r = \sum_{j=1}^s \alpha_r^{j,1}$ and which otherwise depend only on $\beta_r^{j,m}$, $0 \leq m \leq K_b - 1$ and $\alpha_r^{j,0}$, and solve for c'_r.
5. Identify remaining conditions which depend linearly on $\alpha_r^{j,1}$. Solve for $\alpha_r^{j,1}$ together with $c'_r = \sum_{j=1}^s \alpha_r^{j,1}$. Repeat this procedure to solve for $\alpha_r^{j,m}$, $2 \leq m \leq K_a - 1$.
6. $\beta^{r,m}$ are now uniquely determined for $m \geq K_b$ and $\alpha_r^{j,m}$ for $m \geq K_a$ by (3.10). Verify all remaining order conditions for $\beta^{r,m}$, $K_b \leq m \leq p - 1$ and for $\alpha_r^{j,m}$, $K_a \leq m \leq p-2$. If inconsistencies appear, the basis functions are not feasible.
7. Verify all remaining order conditions.

In most cases we have considered, once $\alpha_r^{j,0}$ and $\beta^{r,0}$ have been chosen, one can find the remaining $\alpha_r^{j,m}$ independently of the $\beta^{r,m}$. Most of the exponential integrators we find in the literature are based on the classical fourth order scheme of Kutta, and it is typical that one can combine $a_r^j(z)$ from one scheme with $b^r(z)$ from another scheme and still get overall order four.

In the class of ETD schemes, proposed by Cox and Matthews in [5] and Krogstad in [14], the space V_b is spanned by the three functions ϕ_0, ϕ_1, and ϕ_2 of (3.5). However, in the former reference, $\dim V_a = 2$ with a basis $\{\phi_0(z/2), z\phi_0(z/2)^2\}$. This V_a coincides with the one used in [3] given in Table 1(a).

Another choice is to use $\phi_k(z)$ of (3.5) both for V_a and V_b. In Table 3 we characterise all resulting schemes with $K_a = 2$ and $K_b = 3$. It is interesting to note that Theorem 3.8 predicts $K_a \geq 2$ and $K_b \geq 2$, and indeed, by choosing $\gamma_1 = \frac{1}{3}$ and $\gamma_2 = -\frac{1}{3}$, we see that ϕ_2 disappears from the $b^r(z)$-functions. Choosing $\gamma_1 = \gamma_2 = 0$, we recover the $b^r(z)$-functions obtained in [5].

Letting V_b be spanned by $\psi_0(z) = \phi_0(z)$ and $\psi_1(z) = \phi_0(z/2)$, one obtains the

TABLE 4

Coefficient functions for a fifth order exponential integrator with Fehlberg's fifth order RK as the underlying scheme. Here $a_i^j(z) = a_i^j\phi_1(z) + \hat{a}_i^j\phi_1(\frac{3}{5}z)$.

unique solution

$$\begin{aligned}
b^1(z) &= \tfrac{1}{2}\phi_0(z) - \tfrac{1}{3}\phi_0(z/2) \\
b^2(z) &= b^3(z) = \tfrac{1}{3}\phi_0(z) \qquad (4.1)\\
b^4(z) &= -\tfrac{1}{6}\phi_0(z) + \tfrac{1}{3}\phi_0(z/2).
\end{aligned}$$

These weights coincide with the ones derived in the fourth order scheme in [3] given in Table 1. Yet another choice is to let V_b consist of functions of the form $p(z)\phi_0(z)$, where $p(z)$ is a polynomial of degree 1, and we recover $b^r(z)$ as in Table 1(b).

Finally, we give an example of a fifth order exponential integrator based on a scheme of Fehlberg. As indicated in section 3.2, we take $\dim V_a = 2$ with basis $\psi_0(z) = \phi_1(z)$ and $\psi_1(z) = \phi_1(\frac{3}{5}z)$. For V_b we use the basis $\psi_k(z) = \phi_k(z)$ for $k = 0, 1, 2$. The resulting coefficient functions are given in Table 4.

In summary, this paper presents a complete order theory for exponential integrators of the form (1.2)–(1.3). From deriving order conditions by means of bicolored trees to proving bounds for the lowest possible number of basis functions, the results presented herein provide a general framework for constructing schemes of this type. A number of issues are, however, not addressed in the present paper. These include systematically choosing basis functions ψ_k, and how to construct schemes with low error constants.

Exponential integrators are interesting from the point of view of handling unbounded or stiff operators, yet the order theory does not say anything about what happens for large eigenmodes of L in (1.1). Determining conditions for favorable behavior in light of such operators should be an arena for future work.

Acknowledgments. Thanks to Christian Bower for advice regarding the enumeration of bicolored trees, and to an anonymous referee for suggesting a simpler proof of Lemma 3.7.

SUPERCONVERGENCE OF THE VELOCITY IN MIMETIC FINITE DIFFERENCE METHODS ON QUADRILATERALS[*]

M. BERNDT[†], K. LIPNIKOV[†], M. SHASHKOV[†], M. F. WHEELER[‡], AND I. YOTOV[§]

Abstract. Superconvergence of the velocity is established for mimetic finite difference approximations of second-order elliptic problems over h^2-uniform quadrilateral meshes. The superconvergence result holds for a full tensor coefficient. The analysis exploits the relation between mimetic finite differences and mixed finite element methods via a special quadrature rule for computing the scalar product in the velocity space. The theoretical results are confirmed by numerical experiments.

Key words. mixed finite element, mimetic finite difference, tensor coefficient, superconvergence

1. Introduction.

We consider the numerical approximation of a linear second-order elliptic problem. In porous medium applications, this equation models single phase Darcy flow and is usually written as a first-order system for the fluid pressure p and velocity $\mathbf{u}$:

$$\begin{aligned} \mathbf{u} &= -\mathbf{K}\,\mathrm{grad}\,p && \text{in} \quad \Omega, \\ \mathrm{div}\,\mathbf{u} &= f && \text{in} \quad \Omega, \\ \mathbf{u}\cdot\mathbf{n} &= g && \text{on} \quad \partial\Omega, \end{aligned} \tag{1.1}$$

where $\Omega \subset \Re^2$, $\mathbf{n}$ is the outward unit normal to $\partial\Omega$, and $\mathbf{K} \in \Re^{2\times 2}$ is a symmetric uniformly positive definite full tensor representing the rock permeability divided by the fluid viscosity. We assume that system (1.1) satisfies the compatibility condition

$$\int_\Omega f\,d\mathbf{x} + \int_{\partial\Omega} g\,ds = 0.$$

In this paper, we analyze the convergence of a mimetic finite difference (MFD) method on quadrilateral meshes. The method uses discrete operators that preserve certain critical properties of the original continuum differential operators. Conservation laws, solution symmetries, and the fundamental identities and theorems of vector

and tensor calculus are examples of such properties. This "mimetic" technique has been applied successfully to several applications including diffusion [22, 15, 18], magnetic diffusion and electromagnetics [14], continuum mechanics [17], and gas dynamics [8]. For problem (1.1), the mimetic technique uses discrete flux $\mathcal{G}$ and divergence $\mathcal{DIV}$ operators for the continuum operators $-\mathbf{K}\text{grad}$ and div, respectively, which are adjoint to each other, i.e., $\mathcal{G} = \mathcal{DIV}^*$. It is straightforward to extend the MFD method to locally refined meshes with hanging nodes [16], unstructured three-dimensional meshes composed of hexahedra, tetrahedra, and any cell type having three faces intersecting at each vertex.

A connection between the MFD method and the mixed finite element (MFE) method with Raviart–Thomas finite elements has been established in [4]. In particular, it was shown that the scalar product in the velocity space proposed in [15] for MFD methods can be viewed as a quadrature rule in the context of MFE methods. Another closely related method is the control-volume MFE method [7, 9].

MFE discretizations on quadrilateral grids have been studied in [25, 26, 2, 13]. These methods are based on the Piola transformation [25, 6], which preserves continuity of the normal component of the velocity $\mathbf{u}$ across mesh edges. Unfortunately, this results in the necessity to integrate rational functions over quadrilaterals. The task becomes even more complicated when the diffusion tensor is full and nonconstant. The results in [4] provide an efficient numerical quadrature rule with a minimal number of points. Moreover, the connection between the two methods allows for extensions of MFE methods to general polygons and polyhedra.

The aforementioned connection provides a suitable functional frame for rigorous analysis of convergence of mimetic discretizations. In [4], first-order convergence for the fluid pressure and velocity was shown. In this paper, we establish velocity superconvergence for MFD discretizations of (1.1) on h^2-uniform quadrilateral meshes (as defined in (2.2)–(2.3)). Precise calculation of the fluid velocity is important for porous media and other applications. The points or lines where the numerical solution is superclose to the exact solution may be used to improve the accuracy of the overall simulation. Various superconvergence results for MFE methods have been established for rectangular meshes [21, 19, 27, 10, 11, 12, 3, 1] and general quadrilateral meshes [2, 13].

In [13], velocity superconvergence is established for the MFE discretization of (1.1) on h^2-uniform quadrilateral grids. In this paper, we exploit the relation between MFD methods and MFE methods with the quadrature rule (3.10) to establish superconvergence for velocities in MFD discretizations. In particular, we show that the computed normal velocities are superclose to the true normal velocities at the midpoints of the edges. In [18], an alternative quadrature is introduced, which preserves symmetry of the exact solution on polar grids. This symmetry preservation is important for problems of radiation transport in the asymptotic diffusion limit. The analysis of superconvergence for symmetry-preserving quadratures is left for future investigation.

The paper outline is as follows. In section 2, we describe the MFE method for (1.1). In section 3, the MFD method is presented and related to the MFE method with a quadrature rule. The main superconvergence results are presented in section 4. Superconvergence of the normal velocities at the midpoints of the edges is established in section 5. In section 6, numerical experiments are given that confirm the theoretical results.

FIG. 2.1. *h^2-uniform quadrilateral grid.*

2. The MFE method. To simplify the exposition, we assume without loss of generality that $g = 0$, i.e., homogeneous Neumann boundary conditions are imposed on $\partial\Omega$.

Throughout this paper, we shall use the notation $\|\cdot\|_{k,D}$, $\|\cdot\|_{\mathrm{div},D}$, and $\|\cdot\|_D$ for the norms on the Hilbert spaces $H^k(D)$, $H(\mathrm{div}; D)$, and $L_2(D)$, respectively, where $D \subset \Omega$. In addition, $|\cdot|_{k,D}$ will denote the seminorm on $H^k(D)$. To simplify notation, we shall omit the subscript D when $D = \Omega$. Finally, we denote by $(\cdot,\cdot)$ the L^2-inner product on Ω of either scalar or vector functions. Let

$$\mathbf{V} = \{\mathbf{v} \in H(\mathrm{div};\Omega) : \mathbf{v}\cdot\mathbf{n} = 0 \text{ on } \partial\Omega\} \quad \text{and} \quad W = \left\{ w \in L_2(\Omega) : \int_\Omega w\, d\mathbf{x} = 0 \right\}.$$

The variational formulation of (1.1) is as follows: find a pair $(\mathbf{u}, p) \in \mathbf{V} \times W$ such that

$$\begin{aligned} (\mathbf{K}^{-1}\mathbf{u}, \mathbf{v}) - (p, \mathrm{div}\, \mathbf{v}) &= 0, \\ (\mathrm{div}\, \mathbf{u}, w) &= (f, w) \qquad \forall\, (\mathbf{v}, w) \in \mathbf{V} \times W. \end{aligned} \tag{2.1}$$

For the discretization of (2.1), denote by $\mathcal{T}_h$ a *shape-regular* partition (see [5, Remark 2.2, p. 113]) of $\bar{\Omega}$ into convex quadrilateral elements of diameter not greater than h. For two examples of shape-regular grids, see Figure 6.1. We assume that the grid is h^2-uniform. Following [13], the quadrilateral partition $\mathcal{T}_h$ is called h^2-uniform if each element is an h^2-parallelogram, i.e.,

$$\|(\mathbf{r}_2 - \mathbf{r}_1) - (\mathbf{r}_3 - \mathbf{r}_4)\| \le Ch^2, \tag{2.2}$$

and any two adjacent quadrilaterals form an h^2-parallelogram, i.e.,

$$\|(\mathbf{r}_2 - \mathbf{r}_1) - (\mathbf{r}_2' - \mathbf{r}_1')\| \le Ch^2, \tag{2.3}$$

where $\mathbf{r}_1'$, $\mathbf{r}_2'$, $\mathbf{r}_3'$, and $\mathbf{r}_4'$ are the vertices of the adjacent element (see Figure 2.1).

For any convex quadrilateral e, there exists a bijection mapping $\mathbf{F}_e : \hat{e} \to e$, where $\hat{e}$ is the reference unit square with vertices $\hat{\mathbf{r}}_1 = (0, 0)^T$, $\hat{\mathbf{r}}_2 = (1, 0)^T$, $\hat{\mathbf{r}}_3 = (1, 1)^T$, and $\hat{\mathbf{r}}_4 = (0, 1)^T$. Denote by $\mathbf{r}_i = (x_i, y_i)^T$, $i = 1, 2, 3, 4$, the four corresponding vertices of element e as shown in Figure 2.2. Then, $\mathbf{F}_e$ is the bilinear mapping given by

$$\mathbf{F}_e(\hat{\mathbf{r}}) = \mathbf{r}_1 (1 - \hat{x})(1 - \hat{y}) + \mathbf{r}_2\, \hat{x}(1 - \hat{y}) + \mathbf{r}_3\, \hat{x}\hat{y} + \mathbf{r}_4 (1 - \hat{x})\hat{y}. \tag{2.4}$$

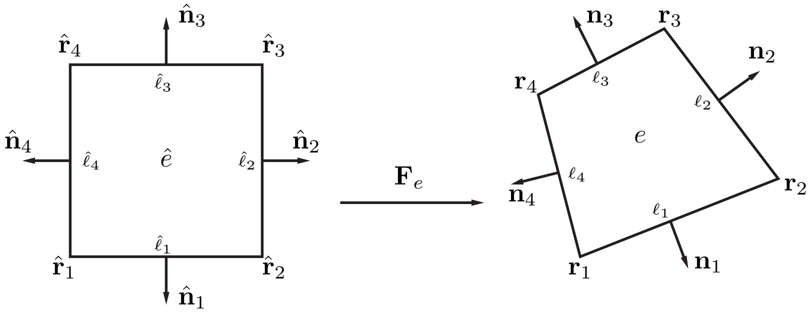

FIG. 2.2. *Bilinear mapping and orientation of normal vectors.*

Note that the Jacobi matrix $\mathbf{DF}_e$ and its Jacobian J_e are linear functions of $\hat{x}$ and $\hat{y}$. Indeed, straightforward computations yield

$$\mathbf{DF}_e = [(1-\hat{y})\,\mathbf{r}_{21} + \hat{y}\,\mathbf{r}_{34},\ (1-\hat{x})\,\mathbf{r}_{41} + \hat{x}\,\mathbf{r}_{32}] \tag{2.5}$$

and

$$J_e = 2|T_{124}| + 2(|T_{123}| - |T_{124}|)\hat{x} + 2(|T_{134}| - |T_{124}|)\hat{y}, \tag{2.6}$$

where $\mathbf{r}_{ij} = \mathbf{r}_i - \mathbf{r}_j$ and $|T_{ijk}|$ is the area of the triangle with vertices $\mathbf{r}_i$, $\mathbf{r}_j$, and $\mathbf{r}_k$. Since e is convex, the Jacobian J_e is always positive, i.e., $J_e > 0$.

Let ℓ_i and $\hat{\ell}_i$, $i = 1, 2, 3, 4$, be the edges of e and $\hat{e}$, respectively. Let $\mathbf{n}_i$ and $\hat{\mathbf{n}}_i$ be the unit outward normal vectors to ℓ_i and $\hat{\ell}_i$, respectively (see Figure 2.2). Similarly, let $\boldsymbol{\tau}_i$ and $\hat{\boldsymbol{\tau}}_i$ be the unit tangential vectors to ℓ_i and $\hat{\ell}_i$, respectively. It is easy to see from (2.5) that for any edge ℓ_i,

$$\mathbf{n}_i = \frac{1}{|\ell_i|} J_e \mathbf{DF}_e^{-T} \hat{\mathbf{n}}_i \qquad \text{and} \qquad \boldsymbol{\tau}_i = \frac{1}{|\ell_i|} \mathbf{DF}_e \hat{\boldsymbol{\tau}}_i. \tag{2.7}$$

The reader is referred to [6] for suitable choices for the pair of finite element spaces $\mathbf{V}^h \subset \mathbf{V}$ and $W^h \subset W$. In this paper, we consider the lowest-order Raviart–Thomas finite element spaces RT_0 [25, 20] defined on the reference element $\hat{e}$ as

$$\hat{\mathbf{V}}(\hat{e}) = P_{1,0}(\hat{e}) \times P_{0,1}(\hat{e}), \qquad \hat{W}(\hat{e}) = P_0(\hat{e}),$$

where $P_{1,0}$ (or $P_{0,1}$) denotes the space of polynomials linear in the $\hat{x}$ (or $\hat{y}$) variable and constant in the other variable, and P_0 denotes the space of constant functions. The velocity space on any convex quadrilateral e is defined through the Piola transformation [6]

$$\frac{1}{J_e}\mathbf{DF}_e :\ L_2(\hat{e}) \times L_2(\hat{e}) \to L_2(e) \times L_2(e) \qquad \forall e \in \mathcal{T}_h.$$

The RT_0 spaces on $\mathcal{T}_h$ are given by

$$\begin{aligned} \mathbf{V}^h &= \{\mathbf{v} \in \mathbf{V}\ :\ \mathbf{v}|_e = J_e^{-1}\mathbf{DF}_e \hat{\mathbf{v}} \circ \mathbf{F}_e^{-1},\ \hat{\mathbf{v}} \in \hat{\mathbf{V}}(\hat{e}) \quad \forall e \in \mathcal{T}_h\}, \\ W^h &= \{w \in W\ :\ w|_e = \hat{w} \circ \mathbf{F}_e^{-1},\ \hat{w} \in \hat{W}(\hat{e}) \quad \forall e \in \mathcal{T}_h\}. \end{aligned} \tag{2.8}$$

Two properties of Piola's transformation will be important in our analysis. For any $\hat{\mathbf{v}} \in \hat{\mathbf{V}}(\hat{e})$ and the related $\mathbf{v} = J_e^{-1}\mathbf{DF}_e \hat{\mathbf{v}} \circ \mathbf{F}_e^{-1}$,

$$J_e \mathrm{div}\ \mathbf{v} = \widehat{\mathrm{div}}\ \hat{\mathbf{v}} \qquad \text{and} \qquad |\ell_i|\,\mathbf{v}\cdot\mathbf{n}_i = \hat{\mathbf{v}}\cdot\hat{\mathbf{n}}_i. \tag{2.9}$$

Note that since $\mathbf{V}^h \subset H(\text{div};\Omega)$, any vector in $\mathbf{V}^h$ has continuous normal components on the edges. A function in W^h is uniquely determined by its values at the cell-centers and a vector in $\mathbf{V}^h$ is uniquely determined by its normal components on the edges. Therefore, $\dim W^h = N_p$ and $\dim \mathbf{V}^h = N_e$, where N_p is the number of elements and N_e is the number of interior edges. Let $\{\psi_i^h\}$, $i = 1, N_p$, be a basis for W^h such that

$$\psi_i^h(c_j) = \delta_{ij} \equiv \begin{cases} 1, & i = j, \\ 0, & i \neq j, \end{cases}$$

where c_j is the center of element e_j, $j = 1, N_p$. Similarly, let ϕ_i^h, $i = 1, N_e$, be a basis for $\mathbf{V}^h$ such that $\phi_i^h \cdot \mathbf{n}_j = \delta_{ij}$, where $\mathbf{n}_j$ is a fixed unit normal vector on edge ℓ_j, $j = 1, N_e$. In order to simplify notation, we use the same way for global and local indexing of mesh edges and corresponding normal vectors.

Given the finite element spaces $\mathbf{V}^h$ and W^h, we define the discrete problem: find $(\mathbf{u}^h,\, p^h) \in \mathbf{V}^h \times W^h$ such that

$$\begin{aligned} (\mathbf{K}^{-1}\mathbf{u}^h,\, \mathbf{v}^h)_h - (p^h,\, \text{div}\, \mathbf{v}^h) &= 0, \\ (\text{div}\, \mathbf{u}^h,\; w^h) &= (f,\, w^h) \qquad \forall\, (\mathbf{v}^h,\, w^h) \in \mathbf{V}^h \times W^h, \end{aligned} \tag{2.10}$$

where $(\cdot,\, \cdot)_h$ is a continuous bilinear form corresponding to the application of a numerical quadrature rule for computing $(\cdot,\, \cdot)$. A detailed discussion of this quadrature rule is given in section 3.

3. MFD discretizations.

In this section, we derive an MFD discretization of (1.1) and show its connection with the MFE method (2.10).

The *first* step in the mimetic technique is to specify discrete degrees of freedom for pressure and velocity. The discrete pressure unknowns are defined at the centers of the quadrilaterals, one unknown per mesh cell. The discrete velocities are defined at the midpoints of mesh edges as normal components. In other words, an edge-based unknown is a scalar and represents the orthogonal projection of a velocity vector onto the unit vector $\mathbf{n}_i$ normal to the mesh edge ℓ_i.

The *second* step in the mimetic technique is to equip the spaces of discrete pressures and velocities with scalar products. We denote the vector space of cell-centered pressures by Q^d. The dimension of Q^d equals the number of mesh cells N_p. The scalar product on the vector space Q^d is given by

$$[p^d,\, q^d]_{Q^d} = \sum_{i=1}^{N_p} |e_i|\, p_i^d\, q_i^d \qquad \forall p^d,\; q^d \in Q^d, \tag{3.1}$$

where $|e_i|$ denotes the area of cell e_i and p_i^d, q_i^d are cell-centered pressure components.

It is easy to see that the vector space Q^d is isometric to the MFE space W^h in (2.8). Indeed, for any $p^h \in W^h$, there exists a unique $p^d = (p_1^d, p_2^d, \ldots, p_{N_p}^d)^T \in Q^d$ such that $p^h = \sum_{i=1}^{N_p} p_i^d \psi_i^h$ and

$$(p^h,\, q^h) = [p^d,\, q^d]_{Q^d}.$$

Note that the discrete MFD pressure variable, p_i^d, corresponds to the value of the MFE pressure function at the cell-center, $p^h(c_i)$.

We denote the vector space of edge-based velocities by X^d. The dimension of X^d equals the number of interior mesh edges N_e. The scalar product on X^d is given by

$$[\mathbf{u}^d,\,\mathbf{v}^d]_{X^d} = \sum_{e\in\mathcal{T}_h} [\mathbf{u}^d,\,\mathbf{v}^d]_{X^d,e}, \tag{3.2}$$

where $[\mathbf{u}^d,\,\mathbf{v}^d]_{X^d,e}$ is a scalar product over cell e involving only the normal velocity components on cell edges. Recall that a velocity vector can be recovered from two orthogonal projections on any two noncollinear vectors. Since the mesh cell is convex, any pair of normal vectors to edges with a common point satisfies the above requirement. The orthogonal projections are exactly the degrees of freedom associated with cell edges. As shown in Figure 3.1, four recovered velocity vectors can be associated with the four vertices of the quadrilateral. For example, velocity $\mathbf{v}_1$ is recovered from its projections onto the normal vectors $\mathbf{n}_1$ and $\mathbf{n}_2$. For a general quadrilateral e, we denote by $\mathbf{v}^d(\mathbf{r}_j)$ the velocity recovered at jth vertex $\mathbf{r}_j$, $j = 1, 2, 3, 4$. Then, the cell-based scalar product is given by

$$[\mathbf{u}^d,\,\mathbf{v}^d]_{X^d,e} = \frac{1}{2}\sum_{j=1}^{4} |T_j|\,\mathbf{K}^{-1}(\mathbf{r}_j)\mathbf{u}^d(\mathbf{r}_j)\cdot\mathbf{v}^d(\mathbf{r}_j), \tag{3.3}$$

where $|T_j|$ is the area of the triangle with vertices $\mathbf{r}_{j-1}$, $\mathbf{r}_j$, and $\mathbf{r}_{j+1}$ (see Figures 2.2 and 3.1). For example, triangles T_1 and T_4 are the shaded triangles in Figure 3.1. Note that (3.3) is indeed an inner product, since $\mathbf{K}$ is a symmetric and positive definite tensor and

$$[\mathbf{v}^d,\mathbf{v}^d]_{X^d} \geq C|||\mathbf{v}^d|||^2, \tag{3.4}$$

where $|||\cdot|||$ is the Euclidean vector norm.

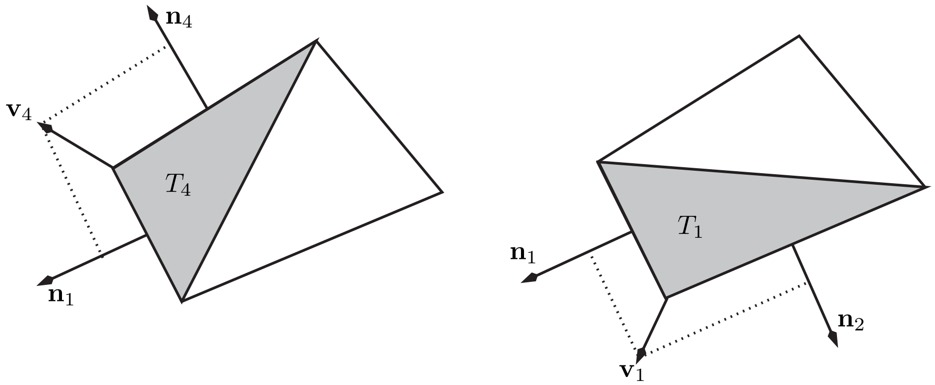

FIG. 3.1. *Recovered vectors* $\mathbf{v}_1$, $\mathbf{v}_4$ *and triangles* T_1, T_4.

The vector space X^d is isomorphic to the MFE space $\mathbf{V}^h$ in (2.8), since both spaces have the same definitions of degrees of freedom. In particular, for any $\mathbf{v}^h \in \mathbf{V}^h$, there exists a unique $\mathbf{v}^d = (v_1^d, v_2^d, \ldots, v_{N^e}^d)^T \in X^d$ such that $\mathbf{v}^h = \sum_{i=1}^{N_e} v_i^d \phi_i^h$. Note that the discrete MFD velocity variable, v_i^d, corresponds to the MFE normal velocity component, $\mathbf{v}^h\cdot\mathbf{n}_i$, on edge ℓ_i.

The *third* step in the mimetic technique is to derive a discrete approximation to the divergence operator, $\mathcal{DIV} : X^d \to Q^d$, which we shall refer to as the *prime* operator. For a cell e, the Gauss divergence theorem gives

$$\mathcal{DIV}\,\mathbf{u}^d|_e = \frac{1}{|e|}\left(u_1^d|\ell_1| + u_2^d|\ell_2| + u_3^d|\ell_3| + u_4^d|\ell_4|\right), \tag{3.5}$$

where $u_1^d, \dots, u_4^d$ are the normal velocity components on element e and the normal vectors are oriented as shown in Figure 2.2.

The *fourth* step in the mimetic technique is to derive a discrete flux operator $\mathcal{G}$ (for the continuous operator $-\mathbf{K}\mathrm{grad}$) adjoint to the discrete divergence operator $\mathcal{DIV}$ with respect to scalar products (3.1) and (3.2), i.e.,

$$[\mathcal{DIV}\mathbf{u}^d,\, p^d]_{Q^d} \equiv [\mathbf{u}^d,\, \mathcal{G}p^d]_{X^d} \qquad \forall \mathbf{u}^d \in X^d \qquad \forall p^d \in Q^d.$$

To derive the explicit formula for $\mathcal{G}$, we consider an auxiliary scalar product $\langle\cdot\,,\,\cdot\rangle$ and relate it to scalar products (3.1) and (3.2). Denote by $\langle\cdot\,,\,\cdot\rangle$ the standard vector dot product. Then

$$[p^d,\, q^d]_{Q^d} = \langle \mathcal{D}p^d,\, q^d\rangle \qquad \text{and} \qquad [\mathbf{u}^d,\, \mathbf{v}^d]_{X^d} = \langle \mathcal{M}\mathbf{u}^d,\, \mathbf{v}^d\rangle,$$

where $\mathcal{D}$ is a diagonal matrix, $\mathcal{D} = \mathrm{diag}\{|e_1|, \dots, |e_{N_p}|\}$, and $\mathcal{M}$ is a sparse symmetric mass matrix with a 5-point stencil. Restricted to a cell, this stencil connects edge-based unknowns if and only if the corresponding edges have a common point. Combining the last two formulae, we get

$$\begin{aligned}[\mathbf{u}^d,\, \mathcal{DIV}^*p^d]_{X^d} &= \langle \mathbf{u}^d,\, \mathcal{M}\,\mathcal{DIV}^*p^d\rangle = [\mathcal{DIV}\mathbf{u}^d,\, p^d]_{Q^d} \\ &= \langle \mathbf{u}^d,\, \mathcal{DIV}^t\,\mathcal{D}\,p^d\rangle \qquad \forall \mathbf{u}^d \in X^d \quad \forall p^d \in Q^d,\end{aligned}$$

where $\mathcal{DIV}^t$ is the adjoint of $\mathcal{DIV}$ with respect to the auxiliary scalar product. Therefore,

$$\mathcal{G} = \mathcal{M}^{-1}\,\mathcal{DIV}^t\,\mathcal{D}. \tag{3.6}$$

The MFD method approximating first-order system (1.1) may be summarized as follows:

$$\mathbf{u}^d = \mathcal{G}\,p^d, \qquad \mathcal{DIV}\,\mathbf{u}^d = f^d, \tag{3.7}$$

where $f^d = (f_1^d, \dots, f_{N_p}^d)^t$, and entry f_i^d is the integral average of f over cell e_i.

The basic tool for the error analysis of the discrete solution $(\mathbf{u}^d,\, p^d) \in X^d \times Q^d$ is based on the following transformation. Multiplying the first equation in (3.7) by $\mathcal{M}\mathbf{v}^d$ and the second one by $\mathcal{D}q^d$, we get

$$\begin{aligned}[\mathbf{u}^d,\, \mathbf{v}^d]_{X^d} - [p^d,\, \mathcal{DIV}\,\mathbf{v}^d]_{Q^d} &= 0, \\ [q^d,\, \mathcal{DIV}\,\mathbf{u}^d]_{Q^d} &= [f^d,\, q^d]_{Q^d} \qquad \forall (\mathbf{v}^d,\, q^d) \in X^d \times Q^d.\end{aligned} \tag{3.8}$$

Using the isomorphism between the finite element space $\mathbf{V}^h \times W^h$ and the vector space $X^d \times Q^d$, we define finite element functions p^h, q^h, f^h, $\mathbf{u}^h$, and $\mathbf{v}^h$ corresponding to vectors p^d, q^d, f^d, $\mathbf{u}^d$, and $\mathbf{v}^d$, respectively. Then

$$[p^d,\, \mathcal{DIV}\,\mathbf{v}^d]_{Q^d} = (p^h,\, \mathrm{div}\ \mathbf{v}^h) \qquad \text{and} \qquad [q^d,\, \mathcal{DIV}\,\mathbf{u}^d]_{Q^d} = (q^h,\, \mathrm{div}\ \mathbf{u}^h).$$

The definition of f^d implies that

$$[f^d,\, q^d]_{Q^d} = (f^h,\, q^h) = (f,\, q^h).$$

Finally, by introducing the quadrature rule

$$(\mathbf{K}^{-1}\mathbf{u}^h,\, \mathbf{v}^h)_h \equiv [\mathbf{u}^d,\, \mathbf{v}^d]_{X^d}, \tag{3.9}$$

we reduce problem (3.7) to the finite element problem (2.10).

The scalar product in the space of velocities given by (3.3) is obviously not unique. In the context of MFE methods, it is a quadrature rule for numerical integration of $(\mathbf{K}^{-1}\mathbf{u}^h,\, \mathbf{v}^h)$:

$$(\mathbf{K}^{-1}\mathbf{u}^h,\, \mathbf{v}^h)_{h,e} = \frac{1}{2}\sum_{j=1}^{4} |T_j|\, \mathbf{K}^{-1}(\mathbf{r}_j)\mathbf{u}^h(\mathbf{r}_j) \cdot \mathbf{v}^h(\mathbf{r}_j), \tag{3.10}$$

where $\mathbf{u}^h(\mathbf{r}_j)$ is the recovered velocity at vertex $\mathbf{r}_j$. In the context of MFE methods, we shall refer to (3.10) as the MFD quadrature rule. The global scalar product is obtained by summing over quadrilaterals, i.e.,

$$(\mathbf{K}^{-1}\mathbf{u}^h,\, \mathbf{v}^h)_h = \sum_{e\in\mathcal{T}_h} (\mathbf{K}^{-1}\mathbf{u}^h,\, \mathbf{v}^h)_{h,e}. \tag{3.11}$$

Note that (3.4) implies that there exists a constant $C_0 > 0$ such that

$$(\mathbf{K}^{-1}\mathbf{v}^h, \mathbf{v}^h)_h \geq C_0\|\mathbf{v}^h\|^2 \qquad \forall \mathbf{v}^h \in \mathbf{V}^h. \tag{3.12}$$

It was shown in [4] that the element quadrature rule (3.10) is exact for any constant vector $\mathbf{u}^h$, constant tensor $\mathbf{K}$, and $\mathbf{v}^h \in \mathbf{V}^h$.

4. Superconvergence estimates for the velocity. We begin by recalling the mixed projection operator $\Pi : H^1(\Omega) \times H^1(\Omega) \to \mathbf{V}^h$ satisfying

$$(\operatorname{div}(\Pi\,\mathbf{v} - \mathbf{v}),\, w) = 0 \qquad \forall w \in W^h. \tag{4.1}$$

The operator Π is defined locally on each element e by

$$\widehat{\Pi\mathbf{v}} = \hat{\Pi}\hat{\mathbf{v}},$$

where $\hat{\Pi} : H^1(\hat{e}) \times H^1(\hat{e}) \to \hat{\mathbf{V}}(\hat{e})$ is the reference element projection operator satisfying

$$\int_{\hat{\ell}_i} (\hat{\Pi}\hat{\mathbf{v}} - \hat{\mathbf{v}}) \cdot \hat{\mathbf{n}}_i = 0, \quad i = 1, 2, 3, 4. \tag{4.2}$$

The approximation properties of Π have been established in [25, 26]:

$$\|\Pi\mathbf{v}\|_{\mathrm{div}} \leq C\|\mathbf{v}\|_1, \tag{4.3}$$

$$\|\Pi\mathbf{v} - \mathbf{v}\| \leq Ch\|\mathbf{v}\|_1, \tag{4.4}$$

$$\|\operatorname{div}(\Pi\mathbf{v} - \mathbf{v})\| \leq Ch\|\mathbf{v}\|_2. \tag{4.5}$$

The following lemma gives several approximation properties of $\hat{\Pi}$ which will be used in the analysis.

LEMMA 4.1. *The operator* $\hat{\Pi}$ *defined in* (4.2) *satisfies, for any* $\hat{\mathbf{v}} = (\hat{v}_1,\, \hat{v}_2)$ *in* $H^1(\hat{e}) \times H^1(\hat{e})$, *the following:*

$$\int_{\hat{e}} \frac{\partial}{\partial \hat{x}}(\hat{\Pi}\hat{\mathbf{v}} - \hat{\mathbf{v}})_1\, d\hat{x}\, d\hat{y} = 0, \quad \int_{\hat{e}} \frac{\partial}{\partial \hat{y}}(\hat{\Pi}\hat{\mathbf{v}} - \hat{\mathbf{v}})_2\, d\hat{x}\, d\hat{y} = 0, \tag{4.6}$$

$$\left\|\frac{\partial}{\partial \hat{x}}(\hat{\Pi}\hat{\mathbf{v}})_1\right\|_{\hat{e}} \leq C\left\|\frac{\partial}{\partial \hat{x}}\hat{v}_1\right\|_{\hat{e}}, \quad \left\|\frac{\partial}{\partial \hat{y}}(\hat{\Pi}\hat{\mathbf{v}})_2\right\|_{\hat{e}} \leq C\left\|\frac{\partial}{\partial \hat{y}}\hat{v}_2\right\|_{\hat{e}}, \tag{4.7}$$

$$\|\hat{\Pi}\hat{\mathbf{v}}\|_{1,\hat{e}} \leq C\|\hat{\mathbf{v}}\|_{1,\hat{e}}. \tag{4.8}$$

Proof. The identities in (4.6) follow easily from definition (4.2). In particular, writing (4.2) for the two vertical edges gives

$$\int_0^1 (\hat{\Pi}\hat{\mathbf{v}} - \hat{\mathbf{v}})_1(0,\hat{y})\,d\hat{y} = 0, \qquad \int_0^1 (\hat{\Pi}\hat{\mathbf{v}} - \hat{\mathbf{v}})_1(1,\hat{y})\,d\hat{y} = 0.$$

Subtracting the above equations and applying the fundamental theorem of calculus implies the first identity in (4.6). The proof of the second identity is similar. Note that (4.6) means that $\frac{\partial}{\partial \hat{x}}(\hat{\Pi}\hat{\mathbf{v}})_1$ and $\frac{\partial}{\partial \hat{y}}(\hat{\Pi}\hat{\mathbf{v}})_2$ are the L^2-orthogonal projections of $\frac{\partial}{\partial \hat{x}}\hat{v}_1$ and $\frac{\partial}{\partial \hat{y}}\hat{v}_2$, respectively, onto the space of constants, which implies (4.7). Finally, it is easy to see that (4.2) implies

$$\|\hat{\Pi}\hat{\mathbf{v}}\|_{\hat{e}} \le C\|\hat{\mathbf{v}}\|_{1,\hat{e}},$$

which, combined with (4.7), gives (4.8). ☐

We also make use of the L^2-projection operator $P_h : W \to W^h$ such that for $p \in W$,

$$(P_h\, p - p,\, w) = 0 \qquad \forall w \in W^h. \tag{4.9}$$

Denote the quadrature error by

$$\sigma(\mathbf{q},\mathbf{v}) \equiv (\mathbf{q},\mathbf{v}) - (\mathbf{q},\mathbf{v})_h. \tag{4.10}$$

The variational formulation (2.1) and the discrete problem (2.10) give rise to the error equations

$$\begin{aligned} (\mathbf{K}^{-1}(\Pi\mathbf{u} - \mathbf{u}^h), \mathbf{v}^h)_h &= (P_h p - p^h, \operatorname{div}\mathbf{v}^h) \\ &\qquad + (\mathbf{K}^{-1}(\Pi\mathbf{u} - \mathbf{u}), \mathbf{v}^h) - \sigma(\mathbf{K}^{-1}\Pi\mathbf{u}, \mathbf{v}^h), \\ (\operatorname{div}(\Pi\mathbf{u} - \mathbf{u}^h), w^h) &= 0, \end{aligned} \tag{4.11}$$

where we used (4.9) and (4.1) in the first and second equations, respectively. We note that, using (2.9), the second equation in (4.11) gives

$$0 = (\operatorname{div}(\Pi\mathbf{u} - \mathbf{u}^h), w^h)_e = (\widehat{\operatorname{div}}(\hat{\Pi}\hat{\mathbf{u}} - \hat{\mathbf{u}}^h), \hat{w}^h)_{\hat{e}} \qquad \forall w^h \in W_h.$$

Since $\widehat{\operatorname{div}}\,\hat{\mathbf{V}}^h = \hat{W}_h$, taking $\hat{w}^h = \widehat{\operatorname{div}}(\hat{\Pi}\hat{\mathbf{u}} - \hat{\mathbf{u}}^h)$ implies that $\widehat{\operatorname{div}}(\hat{\Pi}\hat{\mathbf{u}} - \hat{\mathbf{u}}^h) = 0$ and therefore, by (2.9),

$$\operatorname{div}(\Pi\mathbf{u} - \mathbf{u}^h) = 0. \tag{4.12}$$

Taking $\mathbf{v}^h = \Pi\mathbf{u} - \mathbf{u}^h \in \mathbf{V}^h$ and $w^h = P_h p - p^h$ in (4.11) gives

$$(\mathbf{K}^{-1}(\Pi\mathbf{u} - \mathbf{u}^h), \Pi\mathbf{u} - \mathbf{u}^h)_h = (\mathbf{K}^{-1}(\Pi\mathbf{u} - \mathbf{u}), \Pi\mathbf{u} - \mathbf{u}^h) - \sigma(\mathbf{K}^{-1}\Pi\mathbf{u}, \Pi\mathbf{u} - \mathbf{u}^h). \tag{4.13}$$

The estimate for the first term on the right-hand side of (4.13) follows from Theorem 5.1 in [13] and (4.12):

$$\begin{aligned} &(\mathbf{K}^{-1}(\Pi\mathbf{u} - \mathbf{u}), \Pi\mathbf{u} - \mathbf{u}^h) \\ &\qquad \le C\,h^2\left(\|\mathbf{u}\|_2\|\Pi\mathbf{u} - \mathbf{u}^h\| + \|\mathbf{u}\|_1\|\operatorname{div}(\Pi\mathbf{u} - \mathbf{u}^h)\|\right) \\ &\qquad = C\,h^2\|\mathbf{u}\|_2\,\|\Pi\mathbf{u} - \mathbf{u}^h\|. \end{aligned} \tag{4.14}$$

The second term on the right-hand side of (4.13) can be bounded using Lemma 4.3:

$$|\sigma(\mathbf{K}^{-1}\Pi\mathbf{u}, \Pi\mathbf{u} - \mathbf{u}^h)| \leq C\, h^2 \|\mathbf{u}\|_2 \|\Pi\mathbf{u} - \mathbf{u}^h\|. \tag{4.15}$$

Combining (4.14), (4.15), and (3.12), we obtain the following superconvergence result.

THEOREM 4.2. *Let* $\mathbf{K}^{-1} \in W^{2,\infty}(\Omega)$. *For the velocity* $\mathbf{u}^h$ *of the MFE method* (2.1), *on* h^2*-uniform quadrilateral grids, there exists a positive constant* C *independent of* h *such that*

$$\|\Pi\mathbf{u} - \mathbf{u}^h\| \leq C\, h^2 \|\mathbf{u}\|_2. \tag{4.16}$$

We now proceed to prove estimate (4.15).

LEMMA 4.3. *Let* $\mathbf{v} \in \mathbf{V}^h$, *and let* $\mathbf{K}^{-1} \in W^{2,\infty}(\Omega)$. *There exists a positive constant* C *independent of* h *such that*

$$|\sigma(\mathbf{K}^{-1}\Pi\mathbf{u}, \mathbf{v})| \leq C\, h^2 (\|\mathbf{u}\|_2 \, \|\mathbf{v}\| + \|\mathbf{u}\|_1 \|\mathrm{div}\, \mathbf{v}\|). \tag{4.17}$$

Proof. For an element $e \in \mathcal{T}^h$, we define the error

$$\sigma_e(\mathbf{K}^{-1}\Pi\mathbf{u}, \mathbf{v}) = \int_e \mathbf{K}^{-1}\Pi\mathbf{u} \cdot \mathbf{v}\, d\mathbf{x} - (\mathbf{K}^{-1}\Pi\mathbf{u}, \mathbf{v})_{h,e}. \tag{4.18}$$

With (3.10), the second term on the right-hand side of (4.18) can be written as

(4.19)

$$\begin{aligned}
(\mathbf{K}^{-1}\Pi\mathbf{u}, \mathbf{v})_{h,e} &= \frac{1}{2}\sum_{j=1}^{4} |T_j| \mathbf{K}^{-1}(\mathbf{r}_j)\Pi\mathbf{u}(\mathbf{r}_j) \cdot \mathbf{v}(\mathbf{r}_j) \\
&= \frac{1}{2}\sum_{j=1}^{4} |T_j| \hat{\mathbf{K}}^{-1}(\hat{\mathbf{r}}_j) \left(\frac{1}{J_e}\mathbf{DF}_e\hat{\Pi}\hat{\mathbf{u}}\right)(\hat{\mathbf{r}}_j) \cdot \left(\frac{1}{J_e}\mathbf{DF}_e\hat{\mathbf{v}}\right)(\hat{\mathbf{r}}_j) \\
&= \frac{1}{2}\sum_{j=1}^{4} \frac{|T_j|}{J_e(\hat{\mathbf{r}}_j)} \frac{1}{J_e(\hat{\mathbf{r}}_j)} \mathbf{DF}_e^T(\hat{\mathbf{r}}_j)\hat{\mathbf{K}}^{-1}(\hat{\mathbf{r}}_j)\mathbf{DF}_e(\hat{\mathbf{r}}_j)\, \hat{\Pi}\hat{\mathbf{u}}(\hat{\mathbf{r}}_j) \cdot \hat{\mathbf{v}}(\hat{\mathbf{r}}_j) \\
&= \frac{1}{4}\sum_{j=1}^{4} \mathbf{B}_e(\hat{\mathbf{r}}_j)\, \hat{\Pi}\hat{\mathbf{u}}(\hat{\mathbf{r}}_j) \cdot \hat{\mathbf{v}}(\hat{\mathbf{r}}_j) \\
&\equiv (\mathbf{B}_e\hat{\Pi}\hat{\mathbf{u}}, \hat{\mathbf{v}})_T,
\end{aligned}$$

where the subscript T denotes the trapezoidal rule on element $\hat{e}$ and we define $\mathbf{B}_e = \frac{1}{J_e}\mathbf{DF}_e^T\hat{\mathbf{K}}^{-1}\mathbf{DF}_e$. Here we used (2.6) to conclude that $\frac{|T_j|}{J_e(\hat{\mathbf{r}}_j)} = \frac{1}{2}$. Considering the first term on the right-hand side of (4.18), we obtain

$$\begin{aligned}
\int_e \mathbf{K}^{-1}\Pi\mathbf{u} \cdot \mathbf{v}\, d\mathbf{x} &= \int_{\hat{e}} \hat{\mathbf{K}}^{-1}\frac{1}{J_e}\mathbf{DF}_e\hat{\Pi}\hat{\mathbf{u}} \cdot \frac{1}{J_e}\mathbf{DF}_e\hat{\mathbf{v}} J_e \; d\hat{\mathbf{x}} \\
&= \int_{\hat{e}} \frac{1}{J_e}\mathbf{DF}_e^T\hat{\mathbf{K}}^{-1}\mathbf{DF}_e\hat{\Pi}\hat{\mathbf{u}} \cdot \hat{\mathbf{v}} \; d\hat{\mathbf{x}} \\
&= \int_{\hat{e}} \mathbf{B}_e\hat{\Pi}\hat{\mathbf{u}} \cdot \hat{\mathbf{v}} \; d\hat{\mathbf{x}}.
\end{aligned} \tag{4.20}$$

Substituting (4.19) and (4.20) into (4.18), we obtain

$$\sigma_e(\mathbf{K}^{-1}\Pi\mathbf{u}, \mathbf{v}) = \int_{\hat{e}} \mathbf{B}_e\hat{\Pi}\hat{\mathbf{u}} \cdot \hat{\mathbf{v}} \; d\hat{\mathbf{x}} - \big(\mathbf{B}_e\hat{\Pi}\hat{\mathbf{u}}, \hat{\mathbf{v}}\big)_T \equiv \sigma_{\hat{e}}\big(\mathbf{B}_e\hat{\Pi}\hat{\mathbf{u}}, \hat{\mathbf{v}}\big). \tag{4.21}$$

Hereafter we shall omit the subscripts e and $\hat{e}$. Let

$$E(f) \equiv \int_{\hat{e}} f(\hat{x},\hat{y})d\hat{x}\,d\hat{y} - (f)_T$$

be the error of the trapezoidal rule for integrating a function $f(\hat{x},\hat{y})$ on $\hat{e}$. Then,

$$\sigma(\mathbf{B}\hat{\Pi}\hat{\mathbf{u}},\hat{\mathbf{v}}) = E\big((\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1\hat{v}_1\big) + E\big((\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_2\hat{v}_2\big). \tag{4.22}$$

We next bound the first term on the right-hand side in (4.22). The argument for the bound on the second term is similar.

Using the trapezoidal rule error representation from Lemma A.1 based on the Peano kernel theorem (see [23, Theorem 5.2-3, p. 142]), we write

$$\begin{aligned} E((\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1\hat{v}_1) &= \int_0^1\int_0^1 \phi(\hat{x})\frac{\partial^2}{\partial\hat{x}^2}\big((\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1\hat{v}_1\big)(\hat{x},0)\,d\hat{x}\,d\hat{y} \\ &\quad+ \int_0^1\int_0^1 \phi(\hat{y})\frac{\partial^2}{\partial\hat{y}^2}(\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1(0,\hat{y})\hat{v}_1(0,\hat{y})\,d\hat{x}\,d\hat{y} \\ &\quad+ \int_0^1\int_0^1 \psi(\hat{x},\hat{y})\frac{\partial^2}{\partial\hat{x}\partial\hat{y}}\big((\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1\hat{v}_1\big)(\hat{x},\hat{y})\,d\hat{x}\,d\hat{y} \\ &\equiv (I) + (II) + (III), \end{aligned} \tag{4.23}$$

where $\phi(t) = t(t-1)/2$ and $\psi(s,t) = (1-s)(1-t) - 1/4$. Denote by B_{11}, B_{12}, B_{21}, and B_{22} the components of the tensor $\mathbf{B}$. Since $\hat{v}_1(0,\hat{y})$ is constant in $\hat{y}$, the second term in (4.23) is

$$\begin{aligned} (II) &= \int_0^1\int_0^1 \phi(\hat{y})\frac{\partial^2}{\partial\hat{y}^2}B_{11}(0,\hat{y})(\hat{\Pi}\hat{\mathbf{u}})_1(0,\hat{y})\hat{v}_1(0,\hat{y})\,d\hat{x}\,d\hat{y} \\ &\quad+ \int_0^1\int_0^1 \phi(\hat{y})\frac{\partial^2}{\partial\hat{y}^2}B_{12}(0,\hat{y})(\hat{\Pi}\hat{\mathbf{u}})_2(0,\hat{y})\hat{v}_1(0,\hat{y})\,d\hat{x}\,d\hat{y} \\ &\quad+ 2\int_0^1\int_0^1 \phi(\hat{y})\frac{\partial}{\partial\hat{y}}B_{12}(0,\hat{y})\frac{\partial}{\partial\hat{y}}(\hat{\Pi}\hat{\mathbf{u}})_2(0,\hat{y})\hat{v}_1(0,\hat{y})\,d\hat{x}\,d\hat{y} \\ &\equiv (II)_1 + (II)_2 + (II)_3. \end{aligned} \tag{4.24}$$

Using (4.8), for the first two terms on the right-hand side, we have

$$|(II)_1| + |(II)_2| \le C|\mathbf{B}|_{2,\infty,\hat{e}}\|\hat{\mathbf{u}}\|_{1,\hat{e}}\|\hat{v}_1\|_{\hat{e}}.$$

Since $\frac{\partial}{\partial\hat{y}}(\hat{\Pi}\hat{\mathbf{u}})_2$ is a constant, we rewrite the last term in (4.24) as

$$\begin{aligned} (II)_3 &= 2\int_0^1\int_0^1 \phi(\hat{y})\frac{\partial}{\partial\hat{y}}B_{12}(0,\hat{y})\frac{\partial}{\partial\hat{y}}(\hat{\Pi}\hat{\mathbf{u}})_2(\hat{x},\hat{y})\hat{v}_1(0,\hat{y})\,d\hat{x}\,d\hat{y} \\ &\le C|\mathbf{B}|_{1,\infty,\hat{e}}\left\|\frac{\partial}{\partial\hat{y}}(\hat{\Pi}\hat{\mathbf{u}})_2\right\|_{\hat{e}}\|\hat{v}_1\|_{\hat{e}} \le C|\mathbf{B}|_{1,\infty,\hat{e}}|\hat{\mathbf{u}}|_{1,\hat{e}}\|\hat{v}_1\|_{\hat{e}}, \end{aligned}$$

using (4.7). A combination of the last two bounds implies that

$$|(II)| \le C\big(|\mathbf{B}|_{2,\infty,\hat{e}}\|\hat{\mathbf{u}}\|_{1,\hat{e}} + |\mathbf{B}|_{1,\infty,\hat{e}}|\hat{\mathbf{u}}|_{1,\hat{e}}\big)\|\hat{v}_1\|_{\hat{e}}. \tag{4.25}$$

For the last term in (4.23), since $\hat{v}_1(\hat{x},\hat{y})$ is constant in $\hat{y}$, we have

$$(4.26)\quad (III) = \int_0^1\int_0^1 \psi(\hat{x},\hat{y})\frac{\partial^2}{\partial\hat{x}\partial\hat{y}}(\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1(\hat{x},\hat{y})\hat{v}_1(\hat{x},\hat{y})\,d\hat{x}\,d\hat{y} + \int_0^1\int_0^1 \psi(\hat{x},\hat{y})\frac{\partial}{\partial\hat{y}}(\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1(\hat{x},\hat{y})\frac{\partial}{\partial\hat{x}}\hat{v}_1(\hat{x},\hat{y})\,d\hat{x}\,d\hat{y} \equiv (III)_1 + (III)_2.$$

Using (4.7),

$$(4.27)\qquad |(III)_1| \le C(|\mathbf{B}|_{2,\infty,\hat{e}}\|\hat{\mathbf{u}}\|_{1,\hat{e}} + |\mathbf{B}|_{1,\infty,\hat{e}}|\hat{\mathbf{u}}|_{1,\hat{e}})\|\hat{v}_1\|_{\hat{e}}.$$

To bound $(III)_2$ we note that $\frac{\partial}{\partial\hat{x}}\hat{v}_1(\hat{x},\hat{y})$ is a constant and $\int_0^1\int_0^1 \psi(\hat{x},\hat{y})\,d\hat{x}\,d\hat{y} = 0$. Therefore, by the Bramble–Hilbert lemma [5], and using (4.7),

$$(4.28)\quad |(III)_2| \le C\left|\frac{\partial}{\partial\hat{y}}(\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1\right|_{1,\hat{e}}\|\hat{v}_1\|_{\hat{e}} \le C(|\mathbf{B}|_{2,\infty,\hat{e}}\|\hat{\mathbf{u}}\|_{1,\hat{e}} + |\mathbf{B}|_{1,\infty,\hat{e}}|\hat{\mathbf{u}}|_{1,\hat{e}})\|\hat{v}_1\|_{\hat{e}}.$$

The first term in the error representation (4.23) is

$$(4.29)\qquad (I) = \int_0^1\int_0^1 \phi(\hat{x})\frac{\partial^2}{\partial\hat{x}^2}(\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1(\hat{x},0)\,\hat{v}_1(\hat{x},0)\,d\hat{x}\,d\hat{y} + 2\int_0^1\int_0^1 \phi(\hat{x})\frac{\partial}{\partial\hat{x}}(\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1(\hat{x},0)\frac{\partial}{\partial\hat{x}}\hat{v}_1(\hat{x},0)\,d\hat{x}\,d\hat{y} = (I)_1 + (I)_2.$$

The first term on the right-hand side can be bounded in a way similar to (II):

$$(4.30)\qquad |(I)_1| \le C(|\mathbf{B}|_{2,\infty,\hat{e}}\|\hat{\mathbf{u}}\|_{1,\hat{e}} + |\mathbf{B}|_{1,\infty,\hat{e}}|\hat{\mathbf{u}}|_{1,\hat{e}})\|\hat{v}_1\|_{\hat{e}}.$$

We rewrite the second term on the right-hand side in (4.29) as

$$(4.31)\quad \frac{1}{2}(I)_2 = \int_0^1\int_0^1 \phi(\hat{x})\left(\frac{\partial}{\partial\hat{x}}(\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1(\hat{x},0) - \frac{\partial}{\partial\hat{x}}(\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1(\hat{x},\hat{y})\right)\frac{\partial}{\partial\hat{x}}\hat{v}_1(\hat{x},0)\,d\hat{x}\,d\hat{y} + \int_0^1\int_0^1 \phi(\hat{x})\frac{\partial}{\partial\hat{x}}(\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1(\hat{x},\hat{y})\frac{\partial}{\partial\hat{x}}\hat{v}_1(\hat{x},0)\,d\hat{x}\,d\hat{y} \equiv (I)_{2,1} + (I)_{2,2}.$$

To estimate the first term in (4.31), we write

$$\frac{\partial}{\partial\hat{x}}(\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1(\hat{x},\hat{y}) - \frac{\partial}{\partial\hat{x}}(\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1(\hat{x},0) = \int_0^{\hat{y}} \frac{\partial^2}{\partial\hat{x}\partial\hat{y}}(\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1(\hat{x},\hat{t})\,d\hat{t}.$$

This allows us to bound the first term in (4.31) in a way similar to bounds (4.25) and (4.30):

$$(4.32)\qquad |(I)_{2,1}| \le C(|\mathbf{B}|_{2,\infty,\hat{e}}\|\hat{\mathbf{u}}\|_{1,\hat{e}} + |\mathbf{B}|_{1,\infty,\hat{e}}|\hat{\mathbf{u}}|_{1,\hat{e}})\|\hat{v}_1\|_{\hat{e}}.$$

The second term on the right-hand side in (4.31) can be rewritten as

$$(4.33)\quad (I)_{2,2} = \int_0^1\int_0^1 \phi(\hat{x})\frac{\partial}{\partial\hat{x}}(\mathbf{B}(\hat{\Pi}\hat{\mathbf{u}} - \hat{\mathbf{u}}))_1(\hat{x},\hat{y})\frac{\partial}{\partial\hat{x}}\hat{v}_1(\hat{x},\hat{y})\,d\hat{x}\,d\hat{y} + \int_0^1\int_0^1 \phi(\hat{x})\frac{\partial}{\partial\hat{x}}(\mathbf{B}\hat{\mathbf{u}})_1(\hat{x},\hat{y})\frac{\partial}{\partial\hat{x}}\hat{v}_1(\hat{x},\hat{y})\,d\hat{x}\,d\hat{y} \equiv (I)_{2,2,1} + (I)_{2,2,2},$$

where we used that $\frac{\partial}{\partial \hat{x}}\hat{v}_1(\hat{x},0) = \frac{\partial}{\partial \hat{x}}\hat{v}_1(\hat{x},\hat{y})$ on e, since $\hat{v}_1$ is a constant in $\hat{y}$.

To estimate the second term in (4.33), we use the identity

$$\frac{\partial}{\partial \hat{x}}\hat{v}_1 = -\frac{\partial}{\partial \hat{y}}\hat{v}_2 + \widehat{\operatorname{div}}\,\hat{\mathbf{v}}. \tag{4.34}$$

We rewrite $(I)_{2,2,2}$ as

$$\begin{aligned}(I)_{2,2,2} &= -\int_0^1\int_0^1 \phi(\hat{x})\,\frac{\partial}{\partial \hat{x}}(\mathbf{B}\hat{\mathbf{u}})_1\,\frac{\partial}{\partial \hat{y}}\hat{v}_2\,d\hat{x}\,d\hat{y} + \int_0^1\int_0^1 \phi(\hat{x})\,\frac{\partial}{\partial \hat{x}}(\mathbf{B}\hat{\mathbf{u}})_1\,\widehat{\operatorname{div}}\,\hat{\mathbf{v}}\,d\hat{x}\,d\hat{y}\\
&= \int_{\hat{\ell}_1} - \int_{\hat{\ell}_3}\phi(\hat{x})\,\frac{\partial}{\partial \hat{x}}(\mathbf{B}\hat{\mathbf{u}})_1\,\hat{v}_2\,d\hat{x} + \int_0^1\int_0^1 \phi(\hat{x})\,\frac{\partial^2}{\partial \hat{x}\partial \hat{y}}(\mathbf{B}\hat{\mathbf{u}})_1\,\hat{v}_2\,d\hat{x}\,d\hat{y}\\
&\quad + \int_0^1\int_0^1 \phi(\hat{x})\,\frac{\partial}{\partial \hat{x}}(\mathbf{B}\hat{\mathbf{u}})_1\,\widehat{\operatorname{div}}\,\hat{\mathbf{v}}\,d\hat{x}\,d\hat{y}.\end{aligned} \tag{4.35}$$

Clearly, the last two terms can be bounded by

$$C(|(\mathbf{B}\hat{\mathbf{u}})_1|_{2,\hat{e}}\|\hat{v}_2\|_{\hat{e}} + |(\mathbf{B}\hat{\mathbf{u}})_1|_{1,\hat{e}}\|\widehat{\operatorname{div}}\,\hat{\mathbf{v}}\|_{\hat{e}}). \tag{4.36}$$

We postpone the estimate of the edge integrals in (4.35) for later.

To bound the first term on the right-hand side in (4.33), we have

$$\begin{aligned}(I)_{2,2,1} &= \int_0^1\int_0^1 \phi(\hat{x})\frac{\partial}{\partial \hat{x}}B_{11}(\hat{x},\hat{y})(\hat{\Pi}\hat{\mathbf{u}} - \hat{\mathbf{u}})_1(\hat{x},\hat{y})\frac{\partial}{\partial \hat{x}}\hat{v}_1(\hat{x},\hat{y})\,d\hat{x}\,d\hat{y}\\
&\quad + \int_0^1\int_0^1 \phi(\hat{x})B_{11}(\hat{x},\hat{y})\frac{\partial}{\partial \hat{x}}(\hat{\Pi}\hat{\mathbf{u}} - \hat{\mathbf{u}})_1(\hat{x},\hat{y})\frac{\partial}{\partial \hat{x}}\hat{v}_1(\hat{x},\hat{y})\,d\hat{x}\,d\hat{y}\\
&\quad + \int_0^1\int_0^1 \phi(\hat{x})\frac{\partial}{\partial \hat{x}}B_{12}(\hat{x},\hat{y})(\hat{\Pi}\hat{\mathbf{u}} - \hat{\mathbf{u}})_2(\hat{x},\hat{y})\frac{\partial}{\partial \hat{x}}\hat{v}_1(\hat{x},\hat{y})\,d\hat{x}\,d\hat{y}\\
&\quad + \int_0^1\int_0^1 \phi(\hat{x})B_{12}(\hat{x},\hat{y})\frac{\partial}{\partial \hat{x}}(\hat{\Pi}\hat{\mathbf{u}} - \hat{\mathbf{u}})_2(\hat{x},\hat{y})\frac{\partial}{\partial \hat{x}}\hat{v}_1(\hat{x},\hat{y})\,d\hat{x}\,d\hat{y}\\
&\equiv (I)_{2,2,1,1} + (I)_{2,2,1,2} + (I)_{2,2,1,3} + (I)_{2,2,1,4}.\end{aligned} \tag{4.37}$$

Since $\hat{\Pi}\hat{\mathbf{u}}$ is exact for constants, using the Bramble–Hilbert lemma and the inverse inequality, we can bound the first and the third terms in (4.37) as

$$|(I)_{2,2,1,1}| + |(I)_{2,2,1,3}| \le C|\mathbf{B}|_{1,\infty,\hat{e}}|\hat{\mathbf{u}}|_{1,\hat{e}}\|\hat{v}_1\|_{\hat{e}}. \tag{4.38}$$

For the second term in (4.37), a Taylor expansion of B_{11} about any fixed point $(\hat{x}_0,\hat{y}_0) \in \hat{e}$ gives

$$(I)_{2,2,1,2} = \int_0^1\int_0^1 \phi(\hat{x})B_{11}(\hat{x}_0,\hat{y}_0)\frac{\partial}{\partial \hat{x}}(\hat{\Pi}\hat{\mathbf{u}} - \hat{\mathbf{u}})_1(\hat{x},\hat{y})\frac{\partial}{\partial \hat{x}}\hat{v}_1(\hat{x},\hat{y})\,d\hat{x}\,d\hat{y} + R, \tag{4.39}$$

where

$$|R| \le C|\mathbf{B}|_{1,\infty,\hat{e}}|\hat{\mathbf{u}}|_{1,\hat{e}}\|\hat{v}_1\|_{\hat{e}}, \tag{4.40}$$

using (4.7) for the last inequality. To bound the first term on the right-hand side in (4.39), we note that

$$(\phi^2)''(\hat{x}) = 6\phi(\hat{x}) + \frac{1}{2}, \quad (\phi^2)'(0) = (\phi^2)'(1) = 0.$$

Therefore, using (4.6), we have

$$\begin{aligned}
&\int_0^1\int_0^1 \phi(\hat{x})B_{11}(\hat{x}_0,\hat{y}_0)\frac{\partial}{\partial\hat{x}}(\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}})_1(\hat{x},\hat{y})\frac{\partial}{\partial\hat{x}}\hat{v}_1(\hat{x},\hat{y})\,d\hat{x}\,d\hat{y}\\
&\quad=\frac{1}{6}\int_0^1\int_0^1 \frac{\partial^2}{\partial\hat{x}^2}(\phi^2)(\hat{x})B_{11}(\hat{x}_0,\hat{y}_0)\frac{\partial}{\partial\hat{x}}(\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}})_1(\hat{x},\hat{y})\frac{\partial}{\partial\hat{x}}\hat{v}_1(\hat{x},\hat{y})\,d\hat{x}\,d\hat{y}\\
&\quad=-\frac{1}{6}\int_0^1\int_0^1 \frac{\partial}{\partial\hat{x}}(\phi^2)(\hat{x})B_{11}(\hat{x}_0,\hat{y}_0)\frac{\partial^2}{\partial\hat{x}^2}(\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}})_1(\hat{x},\hat{y})\frac{\partial}{\partial\hat{x}}\hat{v}_1(\hat{x},\hat{y})\,d\hat{x}\,d\hat{y}\\
&\quad\le C|\mathbf{B}|_{\infty,\hat{e}}|\hat{\mathbf{u}}|_{2,\hat{e}}\|\hat{v}_1\|_{\hat{e}}.
\end{aligned}\tag{4.41}$$

A combination of (4.39)–(4.41) gives

$$|(I)_{2,2,1,2}|\le C(|\mathbf{B}|_{1,\infty,\hat{e}}|\hat{\mathbf{u}}|_{1,\hat{e}}+|\mathbf{B}|_{\infty,\hat{e}}|\hat{\mathbf{u}}|_{2,\hat{e}})\|\hat{v}_1\|_{\hat{e}}.\tag{4.42}$$

To complete the estimate of $(I)_{2,2,1}$, it remains to bound $(I)_{2,2,1,4}$. Using that $\frac{\partial}{\partial\hat{x}}(\hat{\Pi}\hat{\mathbf{u}})_2=0$ and (4.34), we have

(4.43)

$$\begin{aligned}
(I)_{2,2,1,4}&=\int_0^1\int_0^1\phi(\hat{x})B_{12}\frac{\partial}{\partial\hat{x}}\hat{u}_2\frac{\partial}{\partial\hat{y}}\hat{v}_2\,d\hat{x}\,d\hat{y}-\int_0^1\int_0^1\phi(\hat{x})B_{12}\frac{\partial}{\partial\hat{x}}\hat{u}_2\,\widehat{\operatorname{div}\mathbf{v}}\,d\hat{x}\,d\hat{y}\\
&=\int_{\hat{\ell}_3}-\int_{\hat{\ell}_1}\phi(\hat{x})\,B_{12}\frac{\partial}{\partial\hat{x}}\hat{u}_2\,\hat{v}_2\,d\hat{x}-\int_0^1\int_0^1\phi(\hat{x})\frac{\partial}{\partial\hat{y}}\left(B_{12}\frac{\partial}{\partial\hat{x}}\hat{u}_2\right)\hat{v}_2\,d\hat{x}\,d\hat{y}\\
&\quad-\int_0^1\int_0^1\phi(\hat{x})B_{12}\frac{\partial}{\partial\hat{x}}\hat{u}_2\,\widehat{\operatorname{div}\mathbf{v}}\,d\hat{x}\,d\hat{y}.
\end{aligned}$$

The last two terms above are bounded by

$$C[(|\mathbf{B}|_{1,\infty,\hat{e}}|\hat{\mathbf{u}}|_{1,\hat{e}}+|\mathbf{B}|_{\infty,\hat{e}}|\hat{\mathbf{u}}|_{2,\hat{e}})\|\hat{v}_2\|_{\hat{e}}+|\mathbf{B}|_{\infty,\hat{e}}|\hat{\mathbf{u}}|_{1,\hat{e}}\|\widehat{\operatorname{div}\mathbf{v}}\|_{\hat{e}}].\tag{4.44}$$

Combining (4.23)–(4.44), we obtain

$$E\big((\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1\hat{v}_1\big)=T_1+T_2+T_3,\tag{4.45}$$

where

$$\begin{aligned}
|T_1|\le C[&(|\mathbf{B}|_{2,\infty,\hat{e}}\|\hat{\mathbf{u}}\|_{1,\hat{e}}+|\mathbf{B}|_{1,\infty,\hat{e}}|\hat{\mathbf{u}}|_{1,\hat{e}}+|\mathbf{B}|_{\infty,\hat{e}}|\hat{\mathbf{u}}|_{2,\hat{e}})\|\hat{\mathbf{v}}\|_{\hat{e}}\\
&+(|\mathbf{B}|_{1,\infty,\hat{e}}|\hat{\mathbf{u}}|_{\hat{e}}+|\mathbf{B}|_{\infty,\hat{e}}|\hat{\mathbf{u}}|_{1,\hat{e}})\|\widehat{\operatorname{div}\mathbf{v}}\|_{\hat{e}}],
\end{aligned}\tag{4.46}$$

$$T_2=\int_{\hat{\ell}_1}-\int_{\hat{\ell}_3}\phi(\hat{x})\,\frac{\partial}{\partial\hat{x}}(\mathbf{B}\hat{\mathbf{u}})_1(\hat{x},\hat{y})\,\hat{v}_2(\hat{x},\hat{y})\,d\hat{x},\tag{4.47}$$

and

$$T_3=\int_{\hat{\ell}_3}-\int_{\hat{\ell}_1}\phi(\hat{x})\,B_{12}(\hat{x},\hat{y})\frac{\partial}{\partial\hat{x}}\hat{u}_2(\hat{x},\hat{y})\hat{v}_2(\hat{x},\hat{y})\,d\hat{x}.$$

Using Lemma 4.4 below, T_1 can be bounded as follows:

(4.48)

$$\begin{aligned}
|T_1|\le C\,&\big[\big(h^2\|\mathbf{K}^{-1}\|_{2,\infty,e}\|\mathbf{u}\|_{1,e}+h\|\mathbf{K}^{-1}\|_{1,\infty,e}\,h|\mathbf{u}|_{1,e}+\|\mathbf{K}^{-1}\|_{\infty,e}\,h^2|\mathbf{u}|_{2,e}\big)\,\|\hat{\mathbf{v}}\|_{\hat{e}}\\
&\quad+\big(h\|\mathbf{K}^{-1}\|_{1,\infty,e}\|\mathbf{u}\|_{e}+\|\mathbf{K}^{-1}\|_{\infty,e}h\|\mathbf{u}\|_{1,e}\big)\,h\|\operatorname{div}\mathbf{v}\|_{e}\big]\\
&\le C\,h^2\,(\|\mathbf{K}^{-1}\|_{2,\infty,e}\|\mathbf{u}\|_{2,e}\|\mathbf{v}\|_{e}+\|\mathbf{K}^{-1}\|_{1,\infty,e}\|\mathbf{u}\|_{1,e}\|\operatorname{div}\mathbf{v}\|_{e}),
\end{aligned}$$

using the fact that $|\hat{\mathbf{u}}|_{j,\hat{e}} \le Ch^j \|\mathbf{u}\|_{j,e}$ and $\|\widehat{\operatorname{div} \hat{\mathbf{v}}}\|_{\hat{e}} \le Ch\|\operatorname{div} \mathbf{v}\|_e$ (see [13, Lemma 5.5]).

The term $\sum_e T_2$ is treated in Lemma 4.5 below.

Finally, term T_3 in (4.45) can be rewritten as

$$T_3 = \int_{\hat{\ell}_3} - \int_{\hat{\ell}_1} \phi(\hat{s})\, B_{12}(\hat{s},\hat{y}) \frac{\partial}{\partial \hat{s}} (\hat{\mathbf{u}} \cdot \hat{\mathbf{n}}_k) \hat{\mathbf{v}} \cdot \hat{\mathbf{n}}_k \, d\hat{s}.$$

A similar term appears in the proof of Theorem 5.1 in [13]. Following the argument there, it can be shown that

$$\left| \sum_e T_3 \right| \le C \sum_e h^2 \|\mathbf{u}\|_{2,e} \|\mathbf{v}\|_e. \tag{4.49}$$

A combination of estimates (4.45), (4.48), (4.51), and (4.49) implies that

$$\sum_e |E\big((\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_1 \hat{v}_1\big)| \le Ch^2 (\|\mathbf{u}\|_2 \|\mathbf{v}\| + \|\mathbf{u}\|_1 \|\operatorname{div} \mathbf{v}\|).$$

The argument for $E((\mathbf{B}\hat{\Pi}\hat{\mathbf{u}})_2 \hat{v}_2)$ is analogous. This completes the proof of the lemma. □

We next give the proofs of the two auxiliary lemmas used in the above argument.

Lemma 4.4. *If $\mathbf{K}^{-1} \in W^{2,\infty}(\Omega)$, then for all $e \in \mathcal{T}_h$ there exists a positive constant C independent of h such that*

$$|\mathbf{B}|_{s,\infty,\hat{e}} \le C\, h^s \, \|\mathbf{K}^{-1}\|_{s,\infty,e}, \qquad s = 0,1,2.$$

Proof. First, for a quasi-uniform mesh, we have

$$c_1\, h \le \|\mathbf{DF}\|_{\infty,\hat{e}} \le c_2\, h, \quad c_3\, h^2 \le \|J\|_{\infty,\hat{e}} \le c_4\, h^2$$

with some positive constants c_1–c_4. This implies that

$$\|\mathbf{B}\|_{\infty,\hat{e}} \le C\, \|\hat{\mathbf{K}}^{-1}\|_{\infty,\hat{e}}. \tag{4.50}$$

Second, for an h^2-uniform mesh, we have additional estimates. Let $\alpha = (\alpha_1, \alpha_2)$, $\alpha_i \ge 0$, be a double index, and let $|\alpha| = \alpha_1 + \alpha_2$. In the case $|\alpha| = 1$, the definition of the bilinear mapping (2.4)–(2.6) and (2.2) imply that

$$\|\hat{\partial}^\alpha \mathbf{DF}\|_{\infty,\hat{e}} \le C\, h^2 \qquad \text{and} \qquad \left\| \hat{\partial}^\alpha \frac{1}{J} \mathbf{DF} \right\|_{\infty,\hat{e}} \le C.$$

In the case $|\alpha| = 2$, we have the estimates

$$\|\hat{\partial}^\alpha \mathbf{DF}\|_{\infty,\hat{e}} = 0 \qquad \text{and} \qquad \left\| \hat{\partial}^\alpha \frac{1}{J} \mathbf{DF} \right\|_{\infty,\hat{e}} \le C\, h.$$

As a result, we get

$$\|\hat{\partial}^\alpha \mathbf{B}\|_{\infty,\hat{e}} \le C\, (h \|\hat{\mathbf{K}}^{-1}\|_{\infty,\hat{e}} + \|\hat{\partial}^\alpha \hat{\mathbf{K}}^{-1}\|_{\infty,\hat{e}})$$

for $|\alpha| = 1$ and

$$\|\hat{\partial}^\alpha \mathbf{B}\|_{\infty,\hat{e}} \le C\, (h^2\, \|\hat{\mathbf{K}}^{-1}\|_{\infty,\hat{e}} + h\, \|\hat{\partial}^{\alpha-1} \hat{\mathbf{K}}^{-1}\|_{\infty,\hat{e}} + \|\hat{\partial}^\alpha \hat{\mathbf{K}}^{-1}\|_{\infty,\hat{e}})$$

for $|\alpha| = 2$. Since $\hat{\mathbf{K}}^{-1} = \mathbf{K}^{-1} \circ \mathbf{F}$, using the chain rule and $\|\hat{\partial}^\alpha \mathbf{F}\|_{\infty,\hat{e}} \le C\, h^{|\alpha|}$ for $|\alpha| \le 2$, we obtain

$$\|\hat{\partial}^\alpha \hat{\mathbf{K}}^{-1}\|_{\infty,\hat{e}} \le C\, h^{|\alpha|}\, \|\mathbf{K}^{-1}\|_{|\alpha|,\infty,e}, \quad |\alpha| = 0, 1, 2,$$

which implies

$$\|\hat{\partial}^\alpha \mathbf{B}\|_{\infty,\hat{e}} \le C\, h^{|\alpha|} \|\mathbf{K}^{-1}\|_{|\alpha|,\infty,e}, \quad |\alpha| = 0, 1, 2,$$

completing the proof. □

LEMMA 4.5. *If* $\mathbf{K}^{-1} \in W^{2,\infty}(\Omega)$*, then*

$$\sum_e T_2 = 0, \tag{4.51}$$

where T_2 *is defined in* (4.47).

Proof. Summing over all elements in (4.47), we have

$$\sum_e T_2 = \sum_e \sum_{k=1,3} \int_{\hat{\ell}_k} \phi(\hat{s})\, \frac{\partial}{\partial \hat{s}}((\mathbf{B}\hat{\mathbf{u}}) \cdot \hat{\boldsymbol{\tau}}_k)\hat{\mathbf{v}} \cdot \hat{\mathbf{n}}_k \, d\hat{s}. \tag{4.52}$$

Using (2.7), we have that for any edge ℓ,

$$(\mathbf{B}\hat{\mathbf{u}}) \cdot \hat{\boldsymbol{\tau}} = \frac{1}{J}\mathbf{DF}^T \hat{\mathbf{K}}^{-1}\mathbf{DF}\hat{\mathbf{u}} \cdot |\ell|\mathbf{DF}^{-1}\boldsymbol{\tau} = |\ell|(\mathbf{K}^{-1}\mathbf{u}) \cdot \boldsymbol{\tau}.$$

Therefore, using (2.9), the sum in (4.52) becomes

$$\sum_e T_2 = \sum_e \sum_{k=1,3} |\ell_k|^2 \int_{\ell_k} \phi(s)\, \frac{\partial}{\partial s}\big((\mathbf{K}^{-1}\mathbf{u}) \cdot \boldsymbol{\tau}_k\big)\mathbf{v} \cdot \mathbf{n}_k \, ds. \tag{4.53}$$

Since $\mathbf{v} \in \mathbf{V}^h$, $\mathbf{v} \cdot \mathbf{n} = 0$ on exterior edges and $\mathbf{v} \cdot \mathbf{n}$ is continuous across interior edges. The assumed regularity for $\mathbf{K}$ and $\mathbf{u}$ implies that $\mathbf{K}^{-1}\mathbf{u}$ and $\frac{\partial}{\partial s}(\mathbf{K}^{-1}\mathbf{u})$ are continuous across interior edges. Note that each interior edge ℓ appears twice in the sum in (4.53), which now can be rewritten as a sum of interior edge integrals

$$\sum_e T_2 = \sum_\ell |\ell|^2 \int_\ell \phi(s)\, \frac{\partial}{\partial s}((\mathbf{K}^{-1}\mathbf{u}) \cdot \boldsymbol{\tau})[\mathbf{v} \cdot \mathbf{n}] \, ds = 0,$$

where $[\mathbf{v} \cdot \mathbf{n}]$ denotes the jump in the normal component of $\mathbf{v}$. □

5. Superconvergence to the average edge fluxes and at the edge midpoints. We now discuss how the superconvergence result from section 4 can be applied to obtain superconvergence for the computed velocity to the average edge fluxes and at the midpoints of the edges. Define, for any $\mathbf{v} \in (H^1(\Omega))^2$,

$$\forall e \in \mathcal{T}_h, \quad |||\mathbf{v}|||_e^2 = \sum_{k=1}^{4} \left(\int_{\ell_k} \mathbf{v} \cdot \mathbf{n}_k \, ds \right)^2, \tag{5.1}$$

$$|||\mathbf{v}|||^2 = \sum_{e \in \mathcal{T}_h} |||\mathbf{v}|||_e^2. \tag{5.2}$$

Using the well-known property of the Piola transformation [6],

$$\int_\ell \mathbf{v}\cdot\mathbf{n}\,ds = \int_{\hat\ell} \hat{\mathbf{v}}\cdot\hat{\mathbf{n}}\,d\hat{s} \quad \forall\,\mathbf{v}\in(H^1(\Omega))^2, \tag{5.3}$$

and transforming to the reference element and back, it is easy to see that $|||\cdot|||$ is a norm on $\mathbf{V}^h$ and there exist constants c_1 and c_2 independent of h such that

$$c_1\|\mathbf{v}\| \le |||\mathbf{v}||| \le c_2\|\mathbf{v}\| \quad \forall\,\mathbf{v}\in\mathbf{V}^h.$$

It is clear from (4.2) and (5.3) that $|||\Pi\mathbf{v}-\mathbf{v}|||=0$ for any $\mathbf{v}\in(H^1(\Omega))^2$. Therefore,

$$|||\mathbf{u}-\mathbf{u}^h||| \le |||\Pi\mathbf{u}-\mathbf{u}^h||| \le c_2\|\Pi\mathbf{u}-\mathbf{u}^h\| \le Ch^2\,\|\mathbf{u}\|_2, \tag{5.4}$$

using Theorem 4.2. This implies edgewise superconvergence of the computed velocity $\mathbf{u}^h\cdot\mathbf{n}$ to $\frac{1}{|\ell|}\int_\ell \mathbf{u}\cdot\mathbf{n}\,ds$ in a discrete L^2-sense.

Remark 5.1. *The superconvergence result* (5.4) *implies similar superconvergence for* $|||\mathbf{u}-\mathbf{u}^h|||_M$ *with*

$$|||\mathbf{v}|||_M^2 = \sum_{e\in\mathcal{T}_h}\sum_{k=1}^{4} |\ell_k|^2(\mathbf{v}\cdot\mathbf{n}_k)^2(m_k),$$

where m_k *is the midpoint of* ℓ_k. *Our choice of reporting the results in* $|||\cdot|||$ *is motivated by the fact that average fluxes are easier to measure than pointwise values and therefore are of greater practical interest.*

6. Numerical experiments. In this section, we present the details of the numerical implementation. Instead of solving saddle point problem (2.10), we reduce it to an equivalent system with a symmetric positive definite matrix using the standard hybridization technique.

Let $\mathbf{V}_e^h$ be the restriction of $\mathbf{V}^h$ to quadrilateral e and Λ_ℓ^h be the space of constant functions over edge ℓ. Define

$$\tilde{\mathbf{V}}^h = \prod_e \mathbf{V}_e^h \quad\text{and}\quad \Lambda^h = \prod_\ell \Lambda_\ell^h.$$

Note that the normal component of $\mathbf{v}^h\in\mathbf{V}^h$ is continuous across interior mesh edges and $\mathbf{v}^h\cdot\mathbf{n}=0$ on exterior edges. Therefore,

$$\mathbf{V}^h = \left\{\tilde{\mathbf{v}}^h\in\tilde{\mathbf{V}}^h:\ \sum_e(\mu^h,\,\tilde{\mathbf{v}}^h\cdot\mathbf{n}_e)_{\partial e}=0 \quad \forall\mu^h\in\Lambda^h\right\},$$

where $\mathbf{n}_e$ is the outward normal vector for quadrilateral e.

It has been shown by many authors (see, e.g., [6]) that the original formulation (2.10) is equivalent to the mixed-hybrid formulation: find $(\tilde{\mathbf{u}}^h,\,p^h,\,\lambda^h)\in\tilde{\mathbf{V}}^h\times W^h\times\Lambda^h$ such that

$$\begin{aligned}(\mathbf{K}^{-1}\tilde{\mathbf{u}}^h,\,\tilde{\mathbf{v}}^h)_{h,e}-(p^h,\,\mathrm{div}\,\tilde{\mathbf{v}}^h)_e+(\lambda^h,\,\tilde{\mathbf{v}}^h\cdot\mathbf{n}_e)_{\partial e} &= 0 && \forall\tilde{\mathbf{v}}^h\in\tilde{\mathbf{V}}^h,\\ (\mathrm{div}\,\tilde{\mathbf{u}}^h,\ w^h)_e &= (f,\,w^h)_e && \forall w^h\in W^h,\\ \sum_e(\mu^h,\,\tilde{\mathbf{u}}^h\cdot\mathbf{n}_e)_{\partial e} &= 0 && \forall\mu^h\in\Lambda^h.\end{aligned} \tag{6.1}$$

System (6.1) can be written in the matrix form as

$$\begin{pmatrix} M & B^T & C^T \\ B & 0 & 0 \\ C & 0 & 0 \end{pmatrix} \begin{pmatrix} u \\ p \\ \lambda \end{pmatrix} = \begin{pmatrix} 0 \\ f \\ 0 \end{pmatrix}, \tag{6.2}$$

where

$$D = \begin{pmatrix} M & B^T \\ B & 0 \end{pmatrix}$$

is a block-diagonal matrix (after a permutation of columns and rows) with as many blocks as mesh elements. Each block is a 5×5 matrix. Therefore, vectors u and p can be explicitly eliminated from (6.2) resulting in a system

$$S\,\lambda = b, \tag{6.3}$$

where S is a sparse symmetric positive definite matrix. For logically rectangular meshes, S has at most seven nonzero elements in each row and column. Its nonzero entries represent connections between edge-based unknowns belonging to the same cell.

Problem (6.3) was solved with the preconditioned conjugate gradient (PCG) method. In the numerical experiments, we used one V-cycle of the algebraic multigrid method [24] as a preconditioner. The stopping criterion for the PCG method was the relative decrease in the norm of the residual by a factor of 10^{-12}.

We solved the boundary problem (1.1) with a known analytic solution

$$p(x,\,y) = x^3\,y^2 + x\,\cos(xy)\,\sin(x)$$

and tensor coefficient

$$\mathbf{K}(x,\,y) = \begin{pmatrix} (x+1)^2 + y^2 & -xy \\ -xy & (x+1)^2 \end{pmatrix}.$$

It is pertinent to note here that the superconvergence result established in the previous section for the homogeneous Neumann boundary condition can be extended to the case of general Neumann boundary value problem.

In example 1, the computational domain Ω is the unit square. The computational grid is constructed from a uniform rectangular grid via the mapping

$$x(\xi,\eta) = \xi + 0.06\,\sin(2\pi\eta)\,\sin(2\pi\xi), \qquad y(\xi,\eta) = \eta + 0.06\,\sin(2\pi\eta)\,\sin(2\pi\xi),$$

where $0 < \eta, \xi < 1$, and subsequent random distortion of mesh node positions (see Figure 6.1). The maximum value of the distortion is proportional to the square of the local mesh size; i.e., the resulting grid satisfies assumptions (2.2) and (2.3). We test both Neumann and Dirichlet boundary conditions. The results for the Neumann problem are shown in Table 6.1. The convergence rates were computed using the linear regression for the data in the rows for $1/h = 32, 64, 128, 256$. In addition to norm (5.2), we show the convergence rate in the discrete L_∞-norm:

$$|||\mathbf{u} - \mathbf{u}^h|||_\infty = \max_{\ell_k} \left| \frac{1}{|\ell_k|} \int_{\ell_k} \mathbf{u}\cdot\mathbf{n}_k\,ds \;\, - \mathbf{u}^h\cdot\mathbf{n}_k \right|,$$

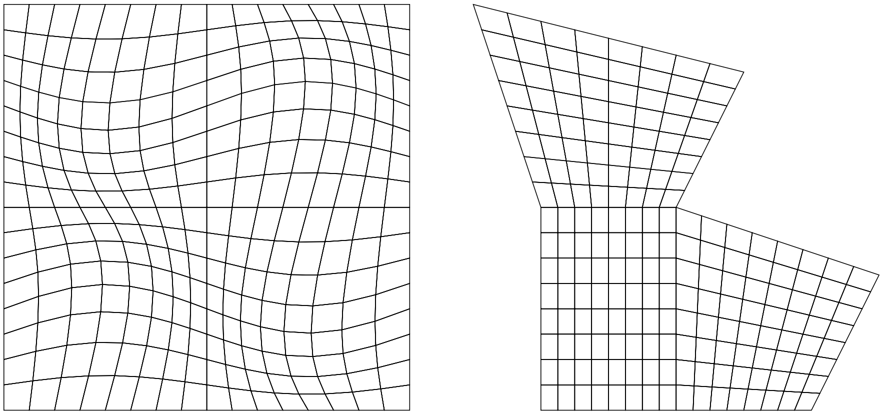

Fig. 6.1. *Examples of meshes used in numerical experiments.*

Table 6.1
Convergence rates for example 1: Neumann boundary conditions.

$1/h$	$\|\|\|\mathbf{u}-\mathbf{u}^h\|\|\|_\infty$	$\|\|\|\mathbf{u}-\mathbf{u}^h\|\|\|$	$\|\|\|p-p^h\|\|\|_\infty$	$\|\|\|p-p^h\|\|\|$
8	8.32e-2	5.47e-2	4.75e-3	1.45e-3
16	2.84e-2	1.69e-2	1.57e-3	3.99e-4
32	8.84e-3	4.49e-3	4.40e-4	1.03e-4
64	2.42e-3	1.14e-3	1.16e-4	2.59e-5
128	6.32e-4	2.87e-4	2.96e-5	6.48e-6
256	1.61e-4	7.17e-5	7.49e-6	1.62e-6
Rate	1.93	1.99	1.96	2.00

where the maximum is taken over all mesh edges. The convergence rates for the pressure variable are shown in the following discrete norms:

$$|||p-p^h|||^2 = \sum_{e_i \in \mathcal{T}_h} |p(c_i) - p^h(c_i)|^2\, |e_i|$$

and

$$|||p-p^h|||_\infty = \max_{e_i \in \mathcal{T}_h} |p(c_i) - p^h(c_i)|,$$

where c_i is the geometric center of element e_i. The use of the geometric center instead of the mass center is due to the following property of the MFD method. The method is exact for linear solutions when the pressure variable, $p(c_i)$, is evaluated at the geometric center c_i [15]. The second-order convergence rate is observed for both the pressure and velocity variables in the discrete L_2- and L_∞-norms.

In the case of Dirichlet boundary conditions, a loss of one half order in the convergence rate for the velocity in the L_2-norm is expected (see, e.g., [12, 3]). The convergence rates are shown in Table 6.2. Note that the velocity convergence rate in the L_2-norm is larger than the theoretical bound of $O(h^{1.5})$. However, the convergence rate in the L_∞-norm is only $O(h)$.

In example 2, the computational domain Ω consists of three quadrilaterals (see Figure 6.1). A sequence of grids is obtained by uniform refinement of these quadrilaterals. The left bottom corner of the domain is located at the point $(1, 0)$. The results

Rate	1.61	2.00	1.94	2.01

of our numerical experiments are shown in Table 6.3. We realize that the grid is only locally h^2-uniform. However, the second-order convergence rate for the velocity variable in the L_2 norm is attained.

7. Conclusion. We have proved the superconvergence estimate for the velocity variable on h^2-uniform quadrilateral grids when the exact integration of velocities is replaced by a novel 4-point quadrature rule. The theoretical results for the full diffusion tensor have been confirmed with numerical experiments.

Appendix. Representation of the trapezoidal rule error.

Lemma A.1. *Let $f(x, y)$ be a function defined on a rectangular domain $[a, b] \times [c, d]$. The trapezoidal rule error*

$$E(f) \equiv \int_a^b \int_c^d f(x,y)\,dx\,dy - (f)_T$$

can be represented as

$$\begin{aligned} E(f) = (d-c)\int_a^b \frac{(x-a)(x-b)}{2}\frac{\partial^2}{\partial x^2}f(x,c)\,dx \\ + (b-a)\int_c^d \frac{(y-c)(y-d)}{2}\frac{\partial^2}{\partial y^2}f(a,y)\,dy \\ + \int_a^b\int_c^d \left((x-b)(y-d) - \frac{(b-a)(d-c)}{4}\right)\frac{\partial^2}{\partial x\partial y}f(x,y)\,dx\,dy. \end{aligned}$$

Proof. Define a function

$$g^k(x,s) \equiv (x-s)_+^k \equiv \begin{cases} (x-s)^k, & x \geq s, \\ 0, & x < s, \end{cases}$$

where $k \geq 0$. The Peano kernel theorem (see [23, Theorem 5.2-3, p. 142]) states that the error of the trapezoidal rule is given by

$$\begin{aligned} E(f) = &\int_a^b A_{2,0}(s) f^{(2,0)}(s,c)\,ds \\ &+ \int_c^d A_{0,2}(t) f^{(0,2)}(a,t)\,dt \\ &+ \int_a^b \int_c^d A_{1,1}(s,t) f^{(1,1)}(s,t)\,ds\,dt, \end{aligned} \tag{A.1}$$

where $f^{(i,j)}(x,y) = \frac{\partial^{i+j}}{\partial x^i\,\partial y^j} f(x,y)$ for $i, j \geq 0$ and

$$A_{2,0}(s) = E(g^1(x,s)), \quad A_{0,2}(t) = E(g^1(y,t)), \quad A_{1,1}(s,t) = E(g^0(x,s)g^0(y,t)).$$

Straightforward calculations give

$$\begin{aligned} A_{2,0}(s) &= \int_a^b \int_c^d g^1(s,x)\,dx\,dy - \frac{(b-a)(d-c)}{4} \sum_{j=1}^4 g(x_j, s) \\ &= (d-c)\left(\int_s^b (x-s)\,dx - \frac{b-a}{2}\,(g(a,s) - g(b,s))\right) \\ &= (d-c)\frac{(s-a)(s-b)}{2}. \end{aligned} \tag{A.2}$$

Similarly, we get

$$A_{0,2}(t) = (b-a)\frac{(t-c)(t-d)}{2} \quad \text{and} \quad A_{1,1}(s,t) = (s-b)(t-d) - \frac{(b-a)(d-c)}{4}. \tag{A.3}$$

A substitution of (A.2) and (A.3) into (A.1) completes the proof. □

A C^2 TRIVARIATE MACROELEMENT BASED ON THE WORSEY–FARIN SPLIT OF A TETRAHEDRON*

PETER ALFELD† AND LARRY L. SCHUMAKER‡

Abstract. A C^2 trivariate macroelement is constructed based on the Worsey–Farin split of a tetrahedron into twelve subtetrahedra. The element uses supersplines of degree 9 and provides optimal order approximation of smooth functions.

Key words. tetrahedral splines, macroelements, Bernstein–Bézier methods

DOI. 10.1137/040612609

1. Introduction.

This paper is a companion to our recent paper [5] in which we constructed a C^2 trivariate macroelement based on Clough–Tocher splits of a tetrahedron using polynomials of degree 13 on the subtetrahedra. The purpose of this paper is to describe an alternative C^2 macroelement which works with polynomials of degree 9 instead. To be able to use the lower-degree polynomials, we have to work with a more complicated split. Here we choose the Worsey–Farin split [23]. It divides a tetrahedron into twelve subtetrahedra, as compared with the four subtetrahedra involved in a Clough–Tocher split.

We recall [5] that a trivariate *macroelement* defined on a tetrahedron T consists of a pair $(\mathcal{S}, \Lambda)$, where $\mathcal{S}$ is a space of splines (piecewise polynomial functions) defined on a partition of T into subtetrahedra, and $\Lambda := \{\lambda_i\}_{i=1}^n$ is a set of linear functionals which define values and derivatives of a spline s at certain points in T in such a way that for any given values z_i, there is a unique spline $s \in \mathcal{S}$ with $\lambda_i s = z_i$ for $i = 1, \ldots, n$. These functionals are called the *nodal degrees of freedom* of the element. A macroelement has *smoothness* C^r provided that if the element is used to construct an interpolating spline locally on each tetrahedron of a tetrahedral partition $\triangle$, then the resulting piecewise function is C^r continuous globally. Our aim here is to construct a C^2 macroelement.

The paper is organized as follows. In section 2 we present some background material and notation. The construction of our macroelement for a single tetrahedron is presented in section 3, where we also give a minimal determining set for the space and calculate its dimension. In section 4 we collect several lemmas concerning bivariate spline spaces which are used in our construction. The macroelement space for a Worsey–Farin refinement of an arbitrary tetrahedral partition is discussed in section 5, where again we give a dimension statement and an explicit minimal determining set. Section 6 is devoted to the construction of a nodal determining set for our macroelement space and an associated Hermite interpolation operator along with an error bound for it. We conclude the paper with a number of remarks.

2. Preliminaries. Throughout the paper, we write $\mathcal{P}_d^j$ for the $\binom{d+j}{j}$-dimensional linear space of polynomials of degree d in j variables. Given a tetrahedral partition $\triangle$ of a polyhedral domain Ω, we define

$$\mathcal{S}_d^r(\triangle) := \{s \in C^r(\Omega) : s|_T \in \mathcal{P}_d^3 \quad \text{for all } T \in \triangle\}.$$

In dealing with polynomials and splines, we will use the well-known Bernstein–Bézier methods as used, for example, in [1, 2, 3, 4, 5, 6, 7, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 23, 24]. As usual, given a tetrahedron $T := \langle v_1, v_2, v_3, v_4\rangle$ and a polynomial p of degree d, we denote the B-coefficients of p by $c_{ijkl}^{T,d}$ and associate them with the domain points $\xi_{ijkl}^{T,d} := \frac{(iv_1+jv_2+kv_3+lv_4)}{d}$, where $i+j+k+l = d$. We write $\mathcal{D}_{T,d}$ for the set of all domain points associated with T. We say that the domain point $\xi_{ijkl}^{T,d}$ has *distance $d-i$ from the vertex v_1*, with similar definitions for the other vertices. We say that $\xi_{ijkl}^{T,d}$ is at a *distance $i+j$ from the edge $e := \langle v_3, v_4\rangle$*, with similar definitions for the other edges of T. If $\triangle$ is a tetrahedral partition of a set Ω, we write $\mathcal{D}_{\triangle,d}$ for the collection of all domain points associated with tetrahedra in $\triangle$, where common points in neighboring tetrahedra are not repeated. Given $\xi \in \mathcal{D}_{T,d}$, we denote the associated Bernstein polynomial by $B_\xi^{T,d}$.

Given $\rho > 0$, we refer to the set $D_\rho(v)$ of all domain points which are within a distance ρ from v as the *ball of radius ρ around v*. Similarly, we refer to the set $R_\rho(v)$ of all domain points which are at a distance ρ from v as the *shell of radius ρ around v*. If e is an edge of $\triangle$, we define the *tube of radius ρ around e* to be the set of domain points whose distance to e is at most ρ.

If F is a face of a tetrahedron T, then the domain points in $\mathcal{D}_{T,d}$ which lie on F associated with a trivariate polynomial on T can be considered to be the domain points of a bivariate polynomial of degree d defined on the triangle F. If $F := \langle v_1, v_2, v_3\rangle$ is such a face, we write $\mathcal{D}_{F,d}$ for this set of domain points. As usual, we call the set of points $D_\rho(v_1)$ in $\mathcal{D}_{F,d}$ within a distance ρ from v_1 the *disk of radius ρ around v_1*. Similarly, the set of points $R_\rho(v_1)$ in $\mathcal{D}_{F,d}$ at a distance ρ from v_1 is called the *ring of radius ρ around v_1*. We use the same notation for disks/balls and shells/rings, but the meaning will be clear from the context.

Suppose $\mathcal{S}$ is a linear subspace of $\mathcal{S}_d^0(\triangle)$, and suppose $\mathcal{M}$ is a subset of $\mathcal{D}_{\triangle,d}$. Then $\mathcal{M}$ is said to be a *determining set for $\mathcal{S}$* provided that if $s \in \mathcal{S}$ and its B-coefficients satisfy $c_\xi = 0$ for all $\xi \in \mathcal{M}$, then $s \equiv 0$. It is called a *minimal determining set* (MDS) *for $\mathcal{S}$* provided there is no smaller determining set. It is well known that $\mathcal{M}$ is an MDS for $\mathcal{S}$ if and only if setting the coefficients $\{c_\xi\}_{\xi\in\mathcal{M}}$ of a spline in $\mathcal{S}$ uniquely determines all coefficients of s. It is also known that the cardinality of any MDS for $\mathcal{S}$ equals the dimension of $\mathcal{S}$.

Now suppose $\mathcal{N}$ is a collection of linear functionals λ, where λs is defined by a combination of values or derivatives of s at a point η_λ in Ω. Then $\mathcal{N}$ is said to be a *nodal determining set* (NDS) *for $\mathcal{S}$* provided that if $s \in \mathcal{S}$ and $\lambda s = 0$ for all $\lambda \in \mathcal{N}$, then $s \equiv 0$. It is called a *nodal minimal determining set* (NMDS) *for $\mathcal{S}$* provided that there is no smaller NDS or, equivalently, for each set of real numbers $\{z_\lambda\}_{\lambda\in\mathcal{N}}$, there exists a unique $s \in \mathcal{S}$ such that $\lambda s = z_\lambda$ for all $\lambda \in \mathcal{N}$.

3. The basic macroelement on one tetrahedron. Given a tetrahedron $T := \langle v_1, v_2, v_3, v_4\rangle$, let v_T be a point in the interior of T. In this section we take v_T to be an arbitrary point in T, but to obtain a C^2 macroelement space on a general tetrahedral partition, we need to be more careful in the selection of v_T; see section 5 below. In addition, for each face F of T, let v_F be a point in the interior of F. For tetrahedral partitions with more than one tetrahedron, we will also have to choose these points in a special way. Suppose now that we connect v_T to each vertex v of T and to each point v_F, and we connect each v_F to the vertices of the face in which it lies. Then T is split into 12 subtetrahedra. This split was used in [23] to construct a C^1 piecewise cubic trivariate macroelement. We refer to it as the *Worsey–Farin split* and denote it by T_{WF}. We write $\mathcal{V}_T$, $\mathcal{E}_T$, and $\mathcal{F}_T$ for the sets of vertices, edges, and faces of T. Let $\mathcal{E}_T^c$ be the set of four edges connecting v_T to the face points v_F, and for each $F := \langle v_1, v_2, v_3\rangle \in \mathcal{F}_T$, let $\mathcal{E}_F$ be the set of three oriented edges $\langle v_i, v_F\rangle$, $i = 1, 2, 3$. We write $\mathcal{F}_T^0$ for the set of 12 faces of $\triangle_{WF}$ of the form $\langle v_T, v_F, v\rangle$, where $v \in \mathcal{V}_T$.

We need some additional notation before introducing our basic macroelement. Suppose $t := \langle v_T, v_F, v_1, v_2\rangle$ and $\tilde{t} := \langle v_T, v_F, v_2, v_3\rangle$ are two tetrahedra in T_{WF} which share the face $F := \langle v_T, v_F, v_2\rangle \in \mathcal{F}_T^0$. Let c_{ijkl} and $\tilde{c}_{ijkl}$ be the coefficients of the B-representations of $s|_t$ and $s|_{\tilde{t}}$, respectively. Then we define the linear functionals ν_F and μ_F by

$$\begin{aligned} \nu_F s &:= \tilde{c}_{0,1,3,5} - \sum_{i+j+k=5} c_{0,i+1,j,k+3} B^{t,5}_{ijk}(v_3), \\ \mu_F s &:= \tilde{c}_{1,0,3,5} - \sum_{i+j+k=5} c_{1,i,j,k+3} B^{t,5}_{ijk}(v_3), \end{aligned} \tag{3.1}$$

where $B^{t,5}_{ijk}$ are the Bernstein polynomials of degree 5 with respect to the triangle $\langle v_F, v_1, v_2\rangle$. Note that $\nu_F s$ involves coefficients of s on the shell $R_9(v_T)$, while $\mu_F s$ involves coefficients of s on the shell $R_8(v_T)$.

We now introduce our basic macroelement space as the following space of supersplines defined on T_{WF}:

$$\begin{aligned} \mathcal{S}_2(T_{WF}) := \{ s \in C^2(T) : s|_t \in \mathcal{P}_9^3 &\text{ for all } t \in T_{WF}, \\ s \in C^3(e) &\text{ for all } e \in \mathcal{E}_T, \\ s \in C^7(e) &\text{ for all } e \in \mathcal{E}_T^c, \\ \nu_F s = \mu_F s = 0 &\text{ for all } F \in \mathcal{F}_T^0, \\ s \in C^4(v) &\text{ for all } v \in \mathcal{V}_T, \\ s \in C^7(v_T) \}. \end{aligned} \tag{3.2}$$

As usual, if v is a vertex of T_{WF}, then $s \in C^\rho(v)$ means that all polynomial pieces of s defined on tetrahedra sharing the vertex v have common derivatives up to order ρ at v. If e is an edge of T_{WF}, then $s \in C^\mu(e)$ means that all subpolynomials of s defined on tetrahedra sharing the edge e have common derivatives up to order μ on e.

Before proceeding, we first make some remarks about our fairly complicated definition of $\mathcal{S}_2(T_{WF})$. The construction is the result of a considerable amount of experimentation with the first author's Java code for working with trivariate splines; see Remark 6. In creating $\mathcal{S}_2(T_{WF})$, we had two aims in mind: to create a macroelement which will be globally C^2 smooth, and to minimize the complexity and number of degrees of freedom. First, we observe that we are forced to impose the C^4 supersmoothness at the vertices of T, since otherwise we could not make macroelements on adjoining tetrahedra join with C^2 smoothness; see Remark 4. Since derivatives up to order 4 at the vertices are not allowed to interfere (or, equivalently, balls of radius 4 around the vertices are not allowed to overlap), this forces us to use polynomials of degree (at least) 9. The additional supersmoothness in the definition of $\mathcal{S}_2(T_{WF})$ has been imposed in order to remove unnecessary degrees of freedom from our macroelement. While other choices are possible, we found that this choice is the most symmetric, while at the same time providing stable computations.

For each vertex v of T, let T_v be one of the tetrahedra in T_{WF} attached to v. For each edge $e := \langle u, v\rangle$ of T, let T_e be one of the two tetrahedra containing e, and let $E_3(e)$ denote the set of domain points in the tube of radius 3 around e which do not lie in the balls $D_4(u)$ or $D_4(v)$. Finally, for each face $F := \langle v_1, v_2, v_3\rangle$ of T, let $T_{F,i} := \langle v_{_T}, v_{_F}, v_i, v_{i+1}\rangle$, $i = 1, 2, 3$, where we set $v_4 := v_1$.

Theorem 3.1. *The space $\mathcal{S}_2(T_{WF})$ has dimension* 292. *Moreover,*

$$\mathcal{M} := \bigcup_{v\in\mathcal{V}_T} \mathcal{M}_v \cup \bigcup_{e\in\mathcal{E}_T} \mathcal{M}_e \cup \bigcup_{F\in\mathcal{F}_T} \mathcal{M}_F \cup \mathcal{M}_T \tag{3.3}$$

is an MDS for $\mathcal{S}_2(T_{WF})$, where

(1) $\mathcal{M}_v := D_4(v) \cap T_v$,

(2) $\mathcal{M}_e := E_3(e) \cap T_e$,

(3) $\mathcal{M}_F := \{\xi^{T_{F,1}}_{2430}, \xi^{T_{F,2}}_{2430}, \xi^{T_{F,3}}_{2430}\}$,

(4) $\mathcal{M}_T := D_3(v_{_T}) \cap T_{v_{_T}}$.

Proof. We shall show that $\mathcal{M}$ is an MDS for $\mathcal{S}_2(T_{WF})$, which in turn implies that the dimension of $\mathcal{S}_2(T_{WF})$ is just the cardinality of $\mathcal{M}$. The cardinalities of the sets $\mathcal{M}_v$, $\mathcal{M}_e$, $\mathcal{M}_F$, $\mathcal{M}_T$ are 35, 20, 3, and 20, respectively. Since T has four vertices, six edges, and four faces, it follows that the dimension of $\mathcal{S}_2(T_{WF})$ is $4 \times 35 + 6 \times 20 + 4 \times 3 + 20 = 292$.

To show that $\mathcal{M}$ is an MDS for $\mathcal{S}_2(T_{WF})$, we need to show that setting the coefficients $\{c_\xi\}_{\xi\in\mathcal{M}}$ of a spline $s \in \mathcal{S}_2(T_{WF})$ *consistently* determines all other coefficients of s. First, for each vertex $v \in \mathcal{V}_T$, the C^4 smoothness at v implies that all coefficients corresponding to domain points in $D_4(v)$ are consistently determined. Moreover, for each edge $e \in \mathcal{E}_T$, the C^3 smoothness around e implies that the coefficients of s in the tube of radius 3 around e are consistently determined.

We now examine the coefficients corresponding to domain points on the shell $R_9(v_{_T})$, i.e., on the outer faces of T_{WF}. Let $F := \langle v_1, v_2, v_3\rangle$ be a face of this shell. We can consider the coefficients of s corresponding to the domain points on F (see Figure 1 (left)) as the coefficients of a bivariate spline $g := s|_F$ in the space $\widetilde{\mathcal{S}}^2_9(F_{CT})$ defined in (4.2) below, where F_{CT} is the Clough–Tocher split of F into three subtriangles. By the above, it is clear that all coefficients of g corresponding to the domain points marked with dots or triangles in Figure 1 (left) are already determined. But then, by Lemma 4.1 below, all other coefficients of g are determined. Repeating this argument for each face of $R_9(v_{_T})$, we conclude that the coefficients of s are determined for all domain points on the shell $R_9(v_{_T})$.

Now consider the coefficients of s corresponding to domain points lying on the shell $R_8(v_{_T})$. For each face $F := \langle v_1, v_2, v_3\rangle$ of this shell, we can consider the B-coefficients of s corresponding to domain points on F (see Figure 1 (right)) to be the coefficients of a bivariate spline g in the space $\widetilde{\mathcal{S}}^2_8(F_{CT})$ defined in (4.5) below. It is clear from the above that all coefficients of g corresponding to domain points marked with dots or triangles in Figure 1 (right) are already determined. But then by Lemma 4.2 below, all other coefficients of g are determined. Repeating this argument for each face of $R_8(v_{_T})$, we conclude that the coefficients of s are determined for all domain points on the shell $R_8(v_{_T})$.

Next we consider the shell $R_7(v_{_T})$. Let F be a face of this shell. We can consider the coefficients of s corresponding to domain points on F to be the coefficients of a bivariate spline g in $\mathcal{S}^2_7(F_{CT}) \cap C^7(v_{_F})$, which means that g is actually a polynomial

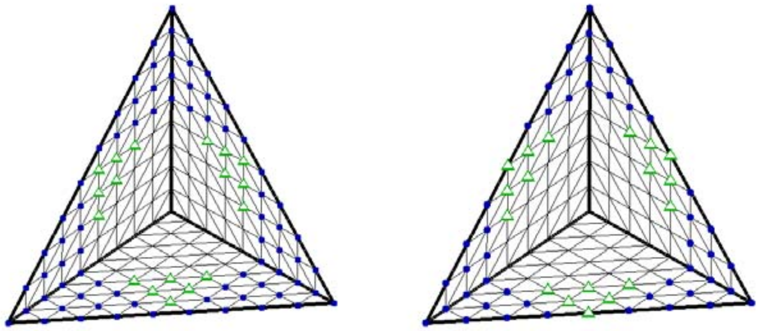

FIG. 1. *Domain points of $\mathcal{S}_2(T_{WF})$ on faces of $R_9(v_T)$ and $R_8(v_T)$, respectively.*

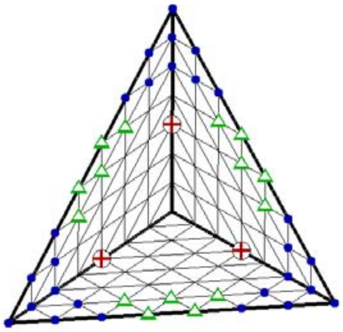

FIG. 2. *Domain points of $\mathcal{S}_2(T_{WF})$ on a face of $R_7(v_T)$.*

of degree 7. All coefficients corresponding to domain points marked with dots or triangles in Figure 2 are already determined. In addition, those corresponding to $\oplus$ are also determined as those points are in $\mathcal{M}$. It now follows from Lemma 4.3 below that all other coefficients of g are determined. Repeating this argument for each face of $R_7(v_T)$, we conclude that all coefficients of s corresponding to domain points on the shell $R_7(v_T)$ are determined.

To show that the coefficients of s corresponding to the remaining domain points in T_{WF} are determined, we note that by the C^7 smoothness at v_T, we may consider the B-coefficients of s corresponding to domain points in the ball $D_7(v_T)$ as those of a trivariate polynomial g of degree 7 considered as a spline in $\mathcal{S}_7^2(t_{WF})$, where t_{WF} is the Worsey–Farin split of the tetrahedron t whose vertices are the vertices of $D_7(v_T)$. By the above, g is determined on the faces of t. Now setting the coefficients $\{c_\xi\}_{\xi\in\mathcal{M}_T}$ is equivalent to setting the derivatives of g up to order 3 at the point v_T. But then Lemma 3.2 below shows that this combined information determines g. □

LEMMA 3.2. *Suppose $g \in \mathcal{P}_7^3$ and let $\{c_\xi\}_{\xi\in\mathcal{D}_{t,7}}$ be its set of B-coefficients relative to a tetrahedron t. Suppose we are given values for the coefficients corresponding to the set of domain points lying on the faces of t. Let w be any point in the interior of t. Then the remaining coefficients of g are uniquely determined by the values of $\{D^\alpha g(w)\}_{|\alpha|\le 3}$.*

Proof. The set of domain points in $\mathcal{D}_{t,7}$ which do not lie on the faces of t is

$\Gamma := \{\xi^{t,7}_{ijkl} : i, j, k, l \geq 1\}$. The cardinality of this set is 20. Now the equations

$$D^\alpha g(w) = z_\alpha, \quad |\alpha| \leq 3,$$

provide a linear system of 20 equations for the $\{c_\xi\}_{\xi\in\Gamma}$. We claim that this system is nonsingular. To see this, we show that if g is zero on the faces of t and $z_\alpha = 0$ for all $|\alpha| \leq 3$, then $g \equiv 0$. The fact that g vanishes on faces implies that it can be written as $g = \ell_1\ell_2\ell_3\ell_4 q$, where $q \in \mathcal{P}^3_3$, and where for $i = 1, 2, 3$, ℓ_i is a nontrivial linear polynomial which vanishes on the ith face of t. But now the condition $D^\alpha g(w) = 0$ for $|\alpha| \leq 3$ implies $D^\alpha q(w) = 0$ for $|\alpha| \leq 3$, which implies $q \equiv 0$, which in turn implies that $g \equiv 0$. □

4. Some bivariate lemmas. In this section we establish some properties of certain bivariate spline spaces defined on the well-known Clough–Tocher split of a triangle $F := \langle v_1, v_2, v_3\rangle$ in $\mathbb{R}^2$. Given $v_{\scriptscriptstyle F}$ in the interior of F, we connect it to all three vertices of F to split it into three subtriangles $F_i := \langle v_{\scriptscriptstyle F}, v_i, v_{i+1}\rangle$. Let $e_i := \langle v_i, v_{i+1}\rangle$ and $\tilde{e}_i := \langle v_i, v_{\scriptscriptstyle F}\rangle$, $i = 1, 2, 3$, where $v_4 := v_1$. Note that in this section we do not make any special assumptions about the location of $v_{\scriptscriptstyle F}$, just that it be in the interior of F. For $d \geq 2$, let

$$\mathcal{S}^2_d(F_{CT}) := \{s \in C^2(F) : s|_{F_i} \in \mathcal{P}^2_d,\ i = 1, 2, 3\}.$$

Given $1 \leq l \leq 3$, suppose $\{c_{ijk}\}$ and $\{\tilde{c}_{ijk}\}$ are the coefficients of $s \in \mathcal{S}^2_d(F_{CT})$ relative to F_{l-1} and F_l, respectively, where we identify $v_4 = v_1$. Then we define the linear functional $\tau^n_{l,m,d}$ by

$$\tau^n_{l,m,d}s := \tilde{c}_{m-n,d-m,n} - \sum_{i+j+k=n} c_{i+m-n,j,k+d-m} B^{l,n}_{ijk}(v_{l+1}), \tag{4.1}$$

where $B^{l,n}_{ijk}$ are the Bernstein polynomials of degree n relative the triangle F_{l-1}. Note that $\tau^n_{l,m,d}$ describes an individual C^n smoothness condition involving the coefficients on ring $R_m(v_l)$.

LEMMA 4.1. *Let*

$$\widetilde{\mathcal{S}}^2_9(F_{CT}) := \{s \in \mathcal{S}^2_9(F_{CT}) \cap C^7(v_{\scriptscriptstyle F}) : s \in C^4(v_{\scriptscriptstyle l}) \text{ and } \tau^5_{l,6,9}s = 0,\ l = 1, 2, 3\}. \tag{4.2}$$

Then $\dim \widetilde{\mathcal{S}}^2_9(F_{CT}) = 63$, *and the set*

$$\mathcal{M}_9 := \bigcup_{i=1}^{3} (\mathcal{M}_{v_i} \cup \mathcal{M}_{e_i})$$

is an MDS for $\widetilde{\mathcal{S}}^2_9(F_{CT})$, *where*

(1) $\mathcal{M}_v := D_4(v) \cap t_v$, *where* t_v *is some triangle of* F_{CT} *attached to* v*;*

(2) $\mathcal{M}_e$ *is the set of domain points whose distance to* $e := \langle u, v\rangle$ *is at most* 3 *and which do not lie in the disks* $D_4(u)$ *or* $D_4(v)$.

Proof. Points in the sets $\mathcal{M}_e$ are marked with small triangles in Figure 1 (left), while points in the disks $D_4(v)$ are marked with dots. By Theorem 2.2 in [19], $\dim \mathcal{S}^2_9(F_{CT}) \cap C^7(v_{\scriptscriptstyle F}) = 75$. To get the subspace $\widetilde{\mathcal{S}}^2_9(F_{CT})$, for each $l = 1, 2, 3$ we have to enforce three extra smoothness conditions at the vertex v_l to get $C^4(v_l)$ as well as the special smoothness condition corresponding to $\tau^5_{l,6,9}$. It follows that

$\dim \mathcal{S}_9^2(F_{CT}) \geq 63$. Since the cardinality of $\mathcal{M}_9$ is 63, to show that $\mathcal{M}_9$ is an MDS for $\widetilde{\mathcal{S}}_9^2(F_{CT})$ and $\dim \widetilde{\mathcal{S}}_9^2(F_{CT}) = 63$, it suffices to show that if s is a spline in $\widetilde{\mathcal{S}}_9^2(F_{CT})$ whose coefficients satisfy $c_\xi = 0$ for all $\xi \in \mathcal{M}_9$, then $s \equiv 0$. By the definition of $\mathcal{M}_9$, it is clear that all coefficients marked with dots or triangles in Figure 1 (left) are zero. We now examine the coefficients corresponding to the remaining domain points.

First consider the ring $R_5(v_1)$. All coefficients corresponding to domain points on this ring are already zero except for the three corresponding to domain points within a distance 1 of the edge $\tilde{e}_1$. To compute these three coefficients, we proceed as in Lemma 3.3 of [9] and Lemma 2.1 of [4]. The C^7 smoothness at v_F implies that s satisfies individual C^1, C^2, and C^3 continuity conditions on ring $R_5(v_1)$, i.e., $\tau_{1,5,9}^n s = 0$ for $n = 1, 2, 3$. This leads to a linear system of equations with matrix

$$M_3 := \begin{pmatrix} a_2 & a_1 & -1 \\ 2a_2a_1 & a_1^2 & 0 \\ 3a_2a_1^2 & a_1^3 & 0 \end{pmatrix}, \tag{4.3}$$

where (a_1, a_2, a_3) are the barycentric coordinates of v_3 relative to the triangle F_1. This matrix is nonsingular since its determinant is $-a_2a_1^4$ and a_1, a_2 are both nonzero. Coefficients on the rings $R_5(v_2)$ and $R_5(v_3)$ can be computed in a similar way.

Now consider the ring $R_6(v_1)$. At this point, all coefficients corresponding to domain points on the ring $R_6(v_1)$ are determined to be zero except for the five corresponding to domain points within a distance 2 of $\tilde{e}_1$. Now the C^7 smoothness at v_F implies that s satisfies individual C^1 through C^4 smoothness conditions on ring $R_6(v_1)$. Coupling this with the special smoothness condition $\tau_{1,6,9}^5 s = 0$, we are led to the system of equations $\tau_{1,6,9}^n s = 0$ for $n = 1, \ldots, 5$. The matrix of this system is

$$M_5 := \begin{pmatrix} 0 & a_2 & a_1 & -1 & 0 \\ a_2^2 & 2a_2a_1 & a_1^2 & 0 & -1 \\ 3a_2^2a_1 & 3a_2a_1^2 & a_1^3 & 0 & 0 \\ 6a_2^2a_1^2 & 4a_2a_1^3 & a_1^4 & 0 & 0 \\ 10a_2^2a_1^3 & 5a_2a_1^4 & a_1^5 & 0 & 0 \end{pmatrix}. \tag{4.4}$$

This is a nonsingular matrix since its determinant is equal to $-a_2^3a_1^9$. Coefficients on the rings $R_6(v_2)$ and $R_6(v_3)$ can be computed in a similar way. Now all remaining coefficients of s can be computed from the smoothness conditions by solving similar nonsingular 5×5 systems. We conclude that all coefficients of s must be zero, which completes the proof of the lemma. ◻

Lemma 4.2. *Let*

$$\widetilde{\mathcal{S}}_8^2(F_{CT}) := \{s \in \mathcal{S}_8^2(F_{CT}) \cap C^7(v_F) : s \in C^3(v_l) \text{ and } \tau_{l,5,8}^5 s = 0,\ l = 1, 2, 3\}. \tag{4.5}$$

Then $\dim \widetilde{\mathcal{S}}_8^2(F_{CT}) = 48$, *and the set*

$$\mathcal{M}_8 := \bigcup_{i=1}^{3} (\mathcal{M}_{v_i} \cup \mathcal{M}_{e_i})$$

is an MDS for $\widetilde{\mathcal{S}}_8^2(F_{CT})$, *where*

(1) $\mathcal{M}_v := D_3(v) \cap t_v$, *where* t_v *is some triangle of* F_{CT} *attached to* v*;*

(2) $\mathcal{M}_e$ *is the set of domain points whose distance to* $e := \langle u, v\rangle$ *is at most* 2 *and which do not lie in the disks* $D_3(u)$ *or* $D_3(v)$.

Proof. The proof is very similar to proof of Lemma 4.1, so we can be brief. By Theorem 2.2 in [19], $\dim \mathcal{S}_8^2(F_{CT}) \cap C^7(v_{\scriptscriptstyle F}) = 54$. To get the subspace $\widetilde{\mathcal{S}}_8^2(F_{CT})$, for each $l = 1, 2, 3$, we have to enforce one extra smoothness condition at the vertex v_l to get $C^3(v_l)$ along with the special smoothness condition corresponding to $\tau_{l,5,8}^5$. It follows that $\dim \widetilde{\mathcal{S}}_8^2(F_{CT}) \geq 48$. Since the cardinality of $\mathcal{M}_8$ is 48, to show that it is an MDS for $\widetilde{\mathcal{S}}_8^2(F_{CT})$ and $\dim \widetilde{\mathcal{S}}_8^2(F_{CT}) = 48$, it suffices to show that if $c_\xi = 0$ for all $\xi \in \mathcal{M}_8$, then $s \equiv 0$. We already know that all coefficients of s corresponding to domain points marked with dots or triangles in Figure 1 (right) are zero. But then the remaining coefficients can be computed from the same linear systems as in Lemma 4.1. □

Lemma 4.3. *The set*

$$\mathcal{M}_7 := \mathcal{M}_F \cap \bigcup_{i=1}^{3} (\mathcal{M}_{v_i} \cup \mathcal{M}_{e_i})$$

is an MDS for $\mathcal{P}^2 = \mathcal{S}_7^2(F_{CT}) \cap C^7(v_{\scriptscriptstyle F})$, *where*

(1) $\mathcal{M}_v := D_2(v) \cap t_v$, *where* t_v *is some triangle of* F_{CT} *attached to* v*;*

(2) $\mathcal{M}_e$ *is the set of domain points whose distance to* $e := \langle u, v\rangle$ *is at most* 1 *and which do not lie in the disks* $D_2(u)$ *or* $D_2(v)$*;*

(3) $\mathcal{M}_F := \{\xi_{430}^{F_1}, \xi_{430}^{F_2}, \xi_{430}^{F_3}\}$.

Proof. Points in $\mathcal{M}_F$ are marked with $\oplus$ in Figure 2, while points in $\mathcal{M}_e$ are marked with small triangles. Points in the disks $D_2(v)$ are marked with dots. The dimension of $\mathcal{P}_7^2$ is 36 and the cardinality of $\mathcal{M}$ is also 36. Thus, it suffices to show that $\mathcal{M}$ is a determining set. Suppose $s \in \mathcal{P}_7^2$, and $c_\xi = 0$ for all $\xi \in \mathcal{M}$. This means that the B-coefficients of s corresponding to all marked domain points in Figure 2 (left) are zero. First, we note that the coefficients corresponding to the three remaining domain points on $R_3(v_1)$ can be computed from a nonsingular 3×3 linear system with the matrix M_3 given in (4.3). The same holds for the rings $R_3(v_2)$ and $R_3(v_3)$. Now consider $R_4(v_1)$. There are four unknown coefficients corresponding to the unmarked points on this ring, and they can be computed from a system of four equations with the matrix

$$M_4 := \begin{pmatrix} 0 & a_2 & -1 & 0 \\ a_2^2 & 2a_2a_1 & 0 & -1 \\ 3a_2^2a_1 & 3a_2a_1^2 & 0 & 0 \\ 6a_2^2a_1^2 & 4a_2a_1^3 & 0 & 0 \end{pmatrix}.$$

The determinant of this matrix is $-6a_1^4a_2^3 \neq 0$. We can repeat this for the other two vertices v_2, v_3. The remaining coefficients of s are then determined exactly as in Lemmas 4.1 and 4.2. □

5. The macroelement space $\boldsymbol{\mathcal{S}_2(\triangle_{WF})}$.

We now show that the construction of the previous section can be used to define a C^2 macroelement space defined on a general tetrahedral partition, provided that the split points $v_{\scriptscriptstyle T}$ and $v_{\scriptscriptstyle F}$ are chosen appropriately. Suppose $\triangle$ is an arbitrary tetrahedral partition of a polyhedral domain Ω, and that the points $v_{\scriptscriptstyle T}$ are chosen so that for any pair of tetrahedra sharing a common face F, the line connecting the center points passes through the interior of

F. This can be insured, for example, by taking v_T to be the centers of the inscribed balls in each tetrahedron T; see [23]. We now take $\triangle_{WF}$ to be the refined partition obtained by applying the Worsey–Farin split to each tetrahedron in $\triangle$, where, for every face F shared by two tetrahedra T and $\widetilde{T}$, the split point v_F on F is taken to be the intersection of F with the line connecting v_T and $v_{\tilde{T}}$.

Let $\mathcal{V}$, $\mathcal{E}$, and $\mathcal{F}$ be the sets of vertices, edges, and faces of $\triangle$, respectively. Let V, E, F be the cardinalities of these sets, and denote the number of tetrahedra in $\triangle$ by N_T. We write $\mathcal{F}^0 = \bigcup_{T\in\triangle} \mathcal{F}_T^0$, where $\mathcal{F}_T^0$ is defined in section 3. Let $\mathcal{E}^c := \bigcup_{T\in\triangle} \mathcal{E}_T^c$, where $\mathcal{E}_T^c$ is also defined in section 3. We now define the following *macroelement space*:

$$
\begin{aligned}
\mathcal{S}_2(\triangle_{WF}) := \{ & s \in C^2(\Omega) : s|_t \in \mathcal{P}_9^3 \ \text{ for all } t \in \triangle_{WF}, \\
& s \in C^3(e) \ \text{ for all } e \in \mathcal{E}, \\
& s \in C^7(e) \ \text{ for all } e \in \mathcal{E}^c, \\
& \nu_F s = \mu_F s = 0 \ \text{ for all } F \in \mathcal{F}^0, \\
& s \in C^4(v) \ \text{ for all } v \in \mathcal{V}, \\
& s \in C^7(v_T) \ \text{ for all } T \in \triangle \}.
\end{aligned}
\tag{5.1}
$$

To define an MDS for $\mathcal{S}_2(\triangle_{WF})$ we need some more notation. For each vertex v of $\triangle$, let T_v be one of the tetrahedra in $\triangle_{WF}$ attached to v. For each edge $e := \langle u, v\rangle$ of $\triangle$, let T_e be one of the tetrahedra containing e, and let $E_3(e)$ denote the set of domain points in the tube of radius 3 around e which do not lie in the balls $D_4(u)$ or $D_4(v)$. Finally, for each face $F := \langle v_1, v_2, v_3\rangle$ of $\triangle$, let $T_{F,i} := \langle v_T, v_F, v_i, v_{i+1}\rangle$, $i = 1, 2, 3$, where v_T is the split point of some tetrahedron in $\triangle$ containing F (if F is a boundary face, there is just one such tetrahedron—otherwise, there are two).

THEOREM 5.1. *The space* $\mathcal{S}_2(\triangle_{WF})$ *has dimension* $35V + 20E + 3F + 20N_T$. *Moreover, the set*

$$
\mathcal{M} := \bigcup_{v\in\mathcal{V}} \mathcal{M}_v \cup \bigcup_{e\in\mathcal{E}} \mathcal{M}_e \cup \bigcup_{F\in\mathcal{F}} \mathcal{M}_F \cup \bigcup_{T\in\triangle} \mathcal{M}_T
\tag{5.2}
$$

is an MDS for $\mathcal{S}_2(\triangle_{WF})$, *where*

(1) $\mathcal{M}_v := D_4(v) \cap T_v$,
(2) $\mathcal{M}_e := E_3(e) \cap T_e$,
(3) $\mathcal{M}_F := \{\xi_{2430}^{T_{F,1}}, \xi_{2430}^{T_{F,2}}, \xi_{2430}^{T_{F,3}}\}$,
(4) $\mathcal{M}_T := D_3(v_T) \cap T_{v_T}$.

Proof. We shall show that $\mathcal{M}$ is an MDS for $\mathcal{S}_2(\triangle_{WF})$. This implies that the dimension of $\mathcal{S}_2(\triangle_{WF})$ is just the cardinality of $\mathcal{M}$, which is easily seen to be equal to the given formula.

To show that $\mathcal{M}$ is an MDS for $\mathcal{S}_2(T_{WF})$, we need to show that if $s \in \mathcal{S}_2(T_{WF})$, then we can set the coefficients $\{c_\xi\}_{\xi\in\mathcal{M}}$ to arbitrary values, and all other coefficients will be *consistently* determined. First, since the balls $D_4(v)$ do not overlap, it is clear that we can set all of the coefficients corresponding to the sets $\mathcal{M}_v$ to arbitrary values, and then by the C^4 smoothness at vertices, all other coefficients corresponding to domain points in balls $D_4(v)$ will be consistently determined. Similarly, since the sets $E_3(e)$ do not overlap each other or any of the balls $D_4(v)$, we can set all of the coefficients corresponding to the sets $\mathcal{M}_e$ to arbitrary values, and then by the C^3 smoothness around edges, all other coefficients corresponding to domain points in the sets $E_3(e)$ will be consistently determined.

Now we can use Lemma 4.1 to compute coefficients corresponding to the remaining domain points on the faces of the shells $R_9(v_T)$ for all T. For interior faces F, this means computing the same coefficients twice, once for each tetrahedron sharing F. But we will get the same values since these coefficients are computed in the same way using only known coefficients associated with domain points on F.

We can now use Lemma 4.2 to uniquely compute coefficients corresponding to the remaining domain points on the faces of the shells $R_8(v_{_T})$ for all T. But now we have to check that if $T := \langle v_{_T}, v_1, v_2, v_3\rangle$ and $\widetilde{T} := \langle v_{_{\tilde{T}}}, v_1, v_2, v_3\rangle$ are two tetrahedra sharing a face $F := \langle v_1, v_2, v_3\rangle$, then these computed coefficients satisfy all C^1 smoothness conditions across F. Note that the split point $v_{_F}$ lies on the line from $v_{_T}$ to $v_{_{\tilde{T}}}$. Let $g := s|_T$ and $\tilde{g} := s|_{\widetilde{T}}$. Consider the typical subtriangle $f := \langle v_{_F}, v_1, v_2\rangle$ of F_{CT}. By the geometry, each of the C^1 smoothness conditions involving coefficients associated with domain points in f reduces to a relationship of the form

$$b = sc + rd,$$

where $(r, s, 0, 0)$ are the barycentric coordinates of $v_{_T}$ with respect to the tetrahedron $\langle v_{_{\tilde{T}}}, v_{_F}, v_1, v_2\rangle$. Here b is a coefficient of g corresponding to a domain point ξ_b in t which lies at a distance 1 from F, i.e., in $F_8 := R_8(v_{_T}) \cap F$; see Figure 1 (right). Similarly, d is a coefficient of $\tilde{g}$ corresponding to a domain point ξ_d in $\tilde{t}$ which lies at a distance 1 from F, i.e., in $\widetilde{F}_8 := R_8(v_{_{\tilde{T}}}) \cap F$. The coefficient c is a coefficient of g corresponding to the domain point on F which lies on the straight line between ξ_b and ξ_d. Let Γ_8 be the set of $n := 66$ domain points in Figure 1 (right) marked with either a dot or a triangle. Let $\{b_i\}_{i=1}^n$ and $\{d_i\}_{i=1}^n$ be the corresponding coefficients of g and $\tilde{g}$, respectively, and let $\{c_i\}_{i=1}^n$ be the coefficients of g corresponding to the associated domain points on F; see Figure 1 (left). Then by the smoothness of s at vertices and around edges, it is clear that all C^1 continuity conditions with tips at points in Γ_8 are satisfied, i.e.,

$$b_i = sc_i + rd_i, \quad i = 1, \dots, n. \tag{5.3}$$

Now let ξ be any other domain point in Figure 1 (right), and let b, c, d be the coefficients entering into the C^1 smoothness condition with a tip at ξ. Then in view of Lemma 4.2, b can be computed as a linear combination of the $b_1, \dots, b_n$; i.e., there exist $\{\alpha_i\}_{i=1}^n$ such that

$$b = \sum_{i=1}^n \alpha_i b_i. \tag{5.4}$$

Since F_8, and $\tilde{F}_8$ are just scaled versions of $F_9 := F$, it follows that (5.4) also holds with b's replaced by either c's or d's. But then using (5.3), we have

$$[1,\, -s,\, -r] \begin{pmatrix} b \\ c \\ d \end{pmatrix} = [1,\, -s,\, -r] \begin{pmatrix} b_1 \cdots b_n \\ c_1 \cdots c_n \\ d_1 \cdots d_n \end{pmatrix} \begin{pmatrix} \alpha_1 \\ \vdots \\ \alpha_n \end{pmatrix} = 0,$$

which shows that the C^1 smoothness condition with tip at ξ and involving b, c, d is also satisfied.

Now for each face of F, we set the coefficients corresponding to $\mathcal{M}_F$. These sets are clearly separated from each other and from the sets $D_4(v)$ and $E_3(e)$. If F is an interior face of $\triangle$, then there are two tetrahedra T and $\widetilde{T}$ sharing the face F, and $\mathcal{M}_F$ lies in just one of them, say T. Next we use the C^2 smoothness conditions to uniquely determine the coefficients for the corresponding points in $\widetilde{T}$. Now we can use Lemma 4.3 to compute the coefficients of s corresponding to the remaining domain points on faces F of the shells $R_7(v_T)$ for all T. We now check that these computed coefficients satisfy all C^2 smoothness conditions across F. Each domain point in F_7 (see Figure 2) is the tip of a C^2 smoothness condition. Assuming a, b, c, d, e are the coefficients on $F_7, F_8, F_9, \tilde{F}_8, \tilde{F}_7$, the typical condition has the form

$$a = s^2 c + 2rsd + r^2 e,$$

where r, s are as before. By construction, these smoothness conditions are satisfied for all points ξ marked with dots, triangles, or $\oplus$ in Figure 2. There are $n = 45$ such points. Writing $\{a_i, b_i, c_i, d_i, e_i\}_{i=1}^n$ for the associated coefficients, we have

$$a_i = s^2 c_i + 2rsd_i + r^2 e_i, \quad i = 1, \ldots, n.$$

Now if ξ is any other point in F_7, then by Lemmas 4.1–4.3, there are α_i such that

$$[1,\ -s^2,\ -2rs,\ -r^2] \begin{pmatrix} a \\ c \\ d \\ e \end{pmatrix} = [1,\ -s^2,\ -2rs,\ -r^2] \begin{pmatrix} a_1 \cdots a_n \\ c_1 \cdots c_n \\ d_1 \cdots d_n \\ e_1 \cdots e_n \end{pmatrix} \begin{pmatrix} \alpha_1 \\ \vdots \\ \alpha_n \end{pmatrix} = 0,$$

which shows that the C^2 smoothness condition with tip at ξ and involving a, c, d, e is also satisfied.

To complete the proof, we now apply Lemma 3.2 to uniquely compute the coefficients of s corresponding to the remaining domain points in the balls $D_7(v_T)$ for all T. □

6. An NMDS and Hermite interpolation.

In this section we show how to construct an NMDS for the macroelement space of the previous section, and then use it to solve a certain Hermite interpolation problem. First we need some additional notation.

Given any multi-index $\alpha = (\alpha_1, \alpha_2, \alpha_3)$, we write D^α for the partial derivative $D_x^{\alpha_1} D_y^{\alpha_2} D_z^{\alpha_3}$. For each edge $e := \langle u, v\rangle$ of a tetrahedron $T \in \triangle$, suppose X_e is the plane perpendicular to e at the point u. We endow X_e with Cartesian coordinate axes whose origin lies at the point u. Then for any multi-index $\beta = (\beta_1, \beta_2)$, we define D_e^β to be the corresponding derivative. It corresponds to a directional derivative of order $|\beta| := \beta_1 + \beta_2$ in a direction lying in X_e. Associated with e we also need notation for the following sets of equally spaced points in the interior of e:

$$\eta_{e,j}^i := \frac{(i-j+1)u + jv}{i+1}, \quad j = 1, \ldots, i, \tag{6.1}$$

for all $i > 0$.

For each face $F := \langle v_1, v_2, v_3\rangle$ of $\triangle$, let D_F be the directional derivative associated with a unit normal vector to F, and let $D_{F,i}$ be the directional derivatives associated with the vectors $\langle v_i, v_F\rangle$ for $i = 1, 2, 3$, where as before v_F is the split point in the face F.

If η is a point in $\mathbb{R}^3$, we write ε_η for the point-evaluation functional associated with η, so that for any trivariate function, $\varepsilon_\eta f := f(\eta)$.

Theorem 6.1. *The set*

$$\mathcal{N} := \bigcup_{v\in\mathcal{V}} \mathcal{N}_v \cup \bigcup_{e\in\mathcal{E}} \mathcal{N}_e \cup \bigcup_{F\in\mathcal{F}} \mathcal{N}_F \cup \bigcup_{T\in\triangle} \mathcal{N}_T \tag{6.2}$$

is an NMDS for $\mathcal{S}_2(\triangle_{WF})$, where

(1) $\mathcal{N}_v := \{\varepsilon_v D^\alpha\}_{|\alpha|\le 4}$,
(2) $\mathcal{N}_e := \bigcup_{i=1}^{3} \bigcup_{j=1}^{i} \{\varepsilon_{\eta_{e,j}^i} D_e^\beta\}_{|\beta|=i}$,
(3) $\mathcal{N}_F := \{\varepsilon_{v_i} D_F^2 D_{F,i}^4\}_{i=1}^3$,
(4) $\mathcal{N}_T := \{\varepsilon_{v_T} D^\alpha\}_{|\alpha|\le 3}$.

Proof. It is easy to see that the cardinality of the set $\mathcal{N}$ matches the dimension of $\mathcal{S}_2(\triangle_{WF})$ as given in Theorem 5.1. We already know that the set $\mathcal{M}$ defined in that theorem is an MDS for $\mathcal{S}_2(\triangle_{WF})$. Thus, to show that $\mathcal{N}$ is an NMDS, it suffices to show that if $s \in \mathcal{S}_2(\triangle_{WF})$, then setting the values $\{\lambda s\}_{\lambda\in\mathcal{N}}$ determines all coefficients in the set $\{c_\xi\}_{\xi\in\mathcal{M}}$.

For each $v \in \mathcal{V}$, we can compute the coefficients in $\mathcal{M}_v$ from the values of the derivatives $D^\alpha s(v)$ corresponding to $\mathcal{N}_v$. Then for each edge $e \in \mathcal{E}$, the coefficients in $\mathcal{M}_e$ can be computed from the derivatives of s corresponding to $\mathcal{N}_e$. We now use Lemmas 4.1 and 4.2 as in the proof of Theorem 3.1 to compute all remaining coefficients corresponding to domain points on the shells $R_9(v_T)$ and $R_8(v_T)$ of tetrahedra in $\triangle$.

Now fix $F \in \mathcal{F}$, and consider the set $\mathcal{M}_F$. It consists of the three domain points $\{\xi_{2430}^{T_{F,1}}, \xi_{2430}^{T_{F,2}}, \xi_{2430}^{T_{F,3}}\}$, where $T_{F,i}$ are three tetrahedra in $\triangle_{WF}$ lying on one side of F and sharing the face F. These domain points are marked with $\oplus$ in Figure 2 (left). To compute the coefficient corresponding to $\xi_{2430}^{T_{F,1}}$, we first solve a 3×3 system of equations with associated matrix M_3 as in (4.3) to get the coefficients corresponding to the unmarked domain points on $R_3(v_1)$ in Figure 2 (left). Then the coefficient corresponding to $\xi_{2430}^{T_{F,1}}$ can be computed from the value of the derivative $D_F^2 D_{F,i}^4 s(v_1)$. The coefficients corresponding to the other two points in $\mathcal{M}_F$ can be computed in a similar way. Now we can use Lemma 4.3 to compute the coefficients of s corresponding to the remaining domain points on shells $R_7(v_T)$. Finally, as shown in the proof of Theorem 3.1, for each tetrahedron T in $\triangle$, we can use the values $\{\lambda s\}_{\lambda\in\mathcal{N}_T}$ to compute the coefficients c_ξ of s for $\xi \in \mathcal{M}_T$. □

Theorem 6.1 shows that for any function $f \in C^6(\Omega)$, there is a unique spline $s \in \mathcal{S}_2(\triangle_{WF})$ solving the Hermite interpolation problem

$$\lambda s = \lambda f \quad \text{for all } \lambda \in \mathcal{N},$$

or, equivalently,

(1) $D^\alpha s(v) = D^\alpha f(v)$ for all $|\alpha| \le 4$ and all $v \in \mathcal{V}$;
(2) $D_e^\beta s(\eta_{e,j}^i) = D_e^\beta f(\eta_{e,j}^i)$ for all $|\beta| = i$ with $1 \le j \le i$ and $1 \le i \le 3$, and for all edges e of $\triangle$;
(3) $D_F^2 D_{F,i}^4 s(v_i) = D_F^2 D_{F,i}^4 f(v_i)$, $i = 1, 2, 3$, for each face $F := \langle v_1, v_2, v_3\rangle$ of $\triangle$;
(4) $D^\alpha s(v_T) = D^\alpha f(v_T)$ for all $|\alpha| \le 3$ and all tetrahedra $T \in \triangle$.

The nodal functionals described in (6.2) involve some derivatives of order higher than 2, even though s is only C^2 globally. However, s is in $C^4(v)$ at vertices and in $C^3(e)$ around edges, and so the third and fourth derivatives appearing in $\mathcal{N}_e$ and $\mathcal{N}_v$ are well defined. But it is not in $C^6(v)$ at a vertex v, and so if F is an interior face, then the derivatives in $\mathcal{N}_F$ are applied to just one of the polynomial pieces of s which share F.

The mapping which takes functions $f \in C^6(\Omega)$ to this Hermite interpolating spline defines a linear operator $\mathcal{I}_{WF} : C^6(\Omega) \to \mathcal{S}_2(\triangle_{WF})$. The construction guarantees that $\mathcal{I}_{WF} s = s$ for every spline $s \in \mathcal{S}_2(\triangle_{WF})$, and in particular for all trivariate polynomials of degree 9. We now discuss error bounds for this interpolation process, which in turn provides an estimate for the approximation power of the space $\mathcal{S}_2(\triangle_{WF})$.

It is well known that the key to getting error bounds for these types of spline interpolation operators is to show that the construction of the interpolating spline is both *local* and *stable*. The localness of the operator is clear from the way in which the B-coefficients of the interpolating spline s are computed. More precisely, for every domain point ξ, the corresponding coefficient c_ξ of s depends only on values of f and its derivatives at points in $\mathrm{star}(T_\xi)$, where $T_\xi \in \triangle$ is a tetrahedron containing ξ. Concerning stability, we have the following.

LEMMA 6.2. *Given a tetrahedral partition $\triangle$, let $\triangle_{WF}$ be a corresponding Worsey–Farin partition, and let $\theta_{_{WF}}$ be the smallest angle between any two edges in $\triangle_{WF}$ sharing a vertex. Then*

$$|c_\xi| \le C \sum_{i=0}^{6} |\Omega_T|^i |s|_{i,\Omega_T} \quad \textit{for all } \xi \in \mathcal{D}_{\triangle_{WF},9}, \tag{6.3}$$

where Ω_T is the union of the tetrahedra in $\mathrm{star}(T)$*, $|\Omega_T|$ is its diameter, and C is a constant depending only on $\theta_{_{WF}}$.*

Proof. To see that (6.3) holds, we review the computation of the coefficients of s as described in the proof of Theorem 6.1. For domain points in balls of the form $D_4(v)$, where v is a vertex of $\triangle$, (6.3) follows from the well-known connection between B-coefficients in such a ball and derivatives at v. Then in the next step we compute coefficients in the sets $\mathcal{M}_e$ from the derivatives corresponding to $\mathcal{N}_e$. This involves solving some systems of equations whose stability depends on $\theta_{_{WF}}$. Now Lemmas 4.1 and 4.2 are used to compute coefficients corresponding to domain points on shells $R_9(v_{_T})$ and $R_8(v_{_T})$. This involves solving linear systems with matrices M_3 and M_5 whose inverses are bounded by a constant depending on $\theta_{_{WF}}$. Next we go to the shells $R_7(v_{_T})$. After solving 3×3 systems for the coefficients on the 3-rings around the vertices of a face F of such a shell, we compute the coefficients in $\mathcal{M}_F$ from the derivatives of s associated with $\mathcal{N}_F$ (this is where the sixth derivatives come in). The bound (6.3) also holds for these coefficients. Now the coefficients corresponding to the remaining coefficients on the shells $R_7(v_{_T})$ are computed from Lemma 4.3, which involves solving systems with matrices M_4 and M_5. Next, we use Lemma 3.2 to solve for the remaining 20 coefficients of $s|_{D_7(v_{_T})}$ (written as single polynomial). The matrix M_{20} of this system depends only on the barycentric coordinates (a_1, a_2, a_3, a_4) of $v_{_T}$, which are all bounded away from zero by a constant depending on $\theta_{_{WF}}$. This insures that the inverse of M_{20} is also bounded by a constant depending on $\theta_{_{WF}}$. These coefficients are then converted to the final coefficients of s on $D_7(v_{_T})$ by subdivision about the point $v_{_T}$, which is known to be stable. □

Given a tetrahedral partition $\triangle$, we write $|\triangle|$ for the diameter of the largest tetrahedron in $\triangle$.

THEOREM 6.3. *There exists a constant K depending only on $\theta_{_{WF}}$ such that for every $f \in C^{m+1}(\Omega)$ with $5 \le m \le 9$,*

$$\|D^\alpha (f - \mathcal{I}_{_{WF}} f)\|_\Omega \le K |\triangle|^{m+1-|\alpha|} |f|_{m+1,\Omega} \tag{6.4}$$

for all $|\alpha| \le m$.

Proof. Since the proof is similar to the proof of Theorem 3.3 in [5] and Theorem 6.2 in [20] (see also [17, 18] for similar arguments in the bivariate case), we can be brief. Fix $T \in \triangle$, and let $f \in C^{m+1}(\Omega)$. By Lemma 4.3.8 of [8], there exists a polynomial $q := q_{f,T} \in \mathcal{P}_9^3$ such that

$$\|D^\beta (f - q)\|_{\Omega_T} \le |(f-q)|_{|\beta|,\Omega_T} \le K_1 |\Omega_T|^{m+1-|\beta|} |f|_{m+1,\Omega_T} \tag{6.5}$$

for all $|\beta| \le m$, where Ω_T is the union of the tetrahedra in star(T). Now fix α with $|\alpha| \le m$. Then since $\mathcal{I}_{WF} q = q$,

$$\|D^\alpha(f - \mathcal{I}_{WF} f)\|_T \le \|D^\alpha(f-q)\|_T + \|D^\alpha \mathcal{I}_{WF}(f-q)\|_T.$$

It suffices to estimate the second quantity. Applying the Markov inequality [22] to each of the polynomials $\mathcal{I}_{WF}(f-q)|_{T_j}$, where $T_1, \ldots, T_{12}$ are the tetrahedra in the Worsey–Farin split of T, we have

$$\|D^\alpha \mathcal{I}_{WF}(f-q)\|_{T_j} \le K_2 |\triangle|^{-|\alpha|} \|\mathcal{I}_{WF}(f-q)\|_{T_j},$$

where K_2 is a constant depending only on θ_{WF}. Let c_ξ be the B-coefficients of the polynomial $\mathcal{I}_{WF}(f-q)|_{T_j}$ relative to the tetrahedron T_j. Then combining (6.3) with the fact that the Bernstein basis polynomials form a partition of unity, it is easy to see that

$$\|\mathcal{I}_{WF}(f-q)\|_{T_j} \le K_3 \max_{\xi \in \mathcal{D}_{T_j,d}} |c_\xi| \le K_4 \sum_{i=0}^{6} |\Omega_T|^i |f-q|_{i,\Omega_T}.$$

Taking the maximum over j and combining this with (6.5) gives

$$\|\mathcal{I}_{WF}(f-q)\|_T \le K_5 |\triangle|^{m+1} |f|_{m+1,\Omega_T},$$

which gives

$$\|D^\alpha(f - \mathcal{I}_{WF} f)\|_T \le K_6 |\triangle|^{m+1-|\alpha|} |f|_{m+1,\Omega_T}.$$

Finally, we take the maximum over all tetrahedra T in $\triangle$ to get (6.4). □

7. Remarks.

Remark 1. In the bivariate setting, C^r macroelements on various splits have been studied by several authors; see, e.g., [3, 4, 13, 14] and the references therein.

Remark 2. A C^2 trivariate polynomial macroelement defined on nonsplit tetrahedra was constructed in [16] using polynomials of degree 17. For C^r trivariate polynomial macroelements using polynomials of degree $8r+1$, see [15].

Remark 3. C^1 trivariate macroelements were constructed on the Worsey–Farin split using splines of degree 3 in [23]. Stability issues and the approximation power were not addressed. For other C^1 trivariate macroelements, see [1, 24].

Remark 4. By examining slices through T_{WF}, it can be shown that it is not possible to construct C^2 macroelements on the Worsey–Farin split using splines with smoothness less than 3 around the edges or smoothness 4 at the vertices. This in turn implies that the minimal degree possible is 9.

Remark 5. In section 5 we have shown that our local construction of a macroelement on a single tetrahedron given in Theorem 3.1 leads to a C^2 macroelement space for general tetrahedral partitions, provided, for each interior face F, we choose the split point v_F on F to lie on the line connecting the interior split points v_T and $v_{\tilde{T}}$ of the two tetrahedra T and $\widetilde{T}$ which share the face F. This geometry causes the smoothness conditions across F to be essentially univariate in nature. Tests using the Java program have shown that without this condition, we do not get C^2 continuity.

Remark 6. The Java code of the first author for examining piecewise polynomial functions on tetrahedral partitions was a key tool in developing the macroelements described in this paper. The code uses residual arithmetic to compute the dimension of trivariate spline spaces, find MDSs, and solve the smoothness equations. It can be downloaded from http://www.math.utah.edu/∼pa/3DMDS, along with associated documentation.

Remark 7. We have also used the Java code to explore the possibility of imposing additional smoothness conditions on our superspline space $\mathcal{S}_2(T_{WF})$ to get a space of dimension 272 which is uniquely determined by the domain points of Theorem 3.1, minus the set $\mathcal{M}_T$. This would give us a C^2 macroelement which is defined by *natural degrees of freedom* only, i.e., information on the boundary of the tetrahedron T that is necessary to insure the global smoothness and local construction. However, we have not been able to find a symmetric way to do this, and expect that if it can be done at all, it would require imposing various individual smoothness conditions of the form (4.1). A similar approach was successful in the bivariate case; see [3, 4], where we used it to get natural degrees of freedom for bivariate macroelement spaces.

Remark 8. We can remove the special smoothness conditions involving ν and μ in the definition (3.2) of the space $\mathcal{S}_2(T_{WF})$ to get an alternative macroelement space which has 9 degrees of freedom per face rather than 3, and thus has a total of 316 degrees of freedom rather than 292. The proof that this alternative element is C^2 proceeds along the same lines as the proof of Theorem 5.1, and the global space has dimension $35V + 20E + 9F + 20N_T$. The corresponding nodal basis (and associated Hermite interpolation operator) requires derivatives up to order 4 only, rather than the order 6 required for the element described here.

Remark 9. It is possible to create macroelements with fewer degrees of freedom by the process of *condensation*. This amounts to further restricting the spline space by forcing cross-derivatives along edges or through faces of the tetrahedron T to be of reduced degree. The main problem with this strategy is that it produces elements which no longer have the capability of reproducing the full polynomial space, and thus have reduced approximation power.

Remark 10. In this paper we have given error bounds for Hermite interpolation with our macroelement in the uniform norm. Analogous results hold for the p-norms and can be proved using appropriate quasi-interpolation operators; see section 10 of [12] for the bivariate case.

Remark 11. Using the Java code mentioned in Remark 6, one can easily check that there is a similar C^3 macroelement on the Worsey–Farin split of a tetrahedron which uses splines of degree 13 which are C^6 around the vertices, C^5 around the edges, C^9 at the centroid v_T, and C^9 along edges connecting v_T to points v_F. This space has dimension 984, with 916 natural degrees of freedom; see Remark 7.

Remark 12. We have recently learned [10] that Ming-Jun Lai and Alain Le Méhauté have independently studied C^r macroelements based on the Worsey–Farin split.

Remark 13. Using the Java software, we have also designed C^2 macroelements based on a trivariate analog of the double Clough–Tocher split of a tetrahedron which is obtained by first applying the Clough–Tocher split, and then applying it again to each of the resulting four subtetrahedra. We report on this element in [6].

Remark 14. It has recently been shown (see [15]) that if incenters are used to construct the bivariate Powell–Sabin element, then the stability of the element depends only on the smallest angle in the original triangulation before applying the Powell–Sabin splits. We conjecture that the analogous statement holds here—namely, that the stability of our element depends only on the smallest angle in the original tetrahedral partition $\triangle$ rather than on the smallest angle θ_{WF} in $\triangle_{WF}$. This is an important distinction, since even though we are using incenters, theoretically the angles in the Clough–Tocher splits of the faces could be arbitrarily small. We are still working on this conjecture.

Acknowledgment. We would like to thank Ming-Jun Lai for useful discussions.

ROBUST A POSTERIORI ERROR ESTIMATES FOR STATIONARY CONVECTION-DIFFUSION EQUATIONS[*]

R. VERFÜRTH[†]

Abstract. We analyze a posteriori error estimators for finite element discretizations of convection-dominated stationary convection-diffusion equations using locally refined, isotropic meshes. The estimators are based on either the evaluation of local residuals or the solution of discrete local problems with Dirichlet or Neumann boundary conditions. All estimators yield global upper and lower bounds for the error measured in a norm that incorporates the standard energy norm and a dual norm of the convective derivative. They are fully robust in the sense that the ratio of the upper and lower bounds is uniformly bounded with respect to the size of the convection. The estimates are also uniform with respect to the size of the zero-order reaction term and also hold for the limit case of vanishing reaction.

Key words. a posteriori error estimates, convection-diffusion equations

1. Introduction.

We consider stationary convection-diffusion equations

$$\begin{aligned} -\varepsilon\Delta u + \underline{a}\cdot\nabla u + bu &= f \quad \text{in } \Omega,\\ u &= 0 \quad \text{on } \Gamma_D,\\ \varepsilon\frac{\partial u}{\partial n} &= g \quad \text{on } \Gamma_N \end{aligned} \tag{1.1}$$

in a polygonal domain Ω in $\mathbb{R}^n$, $n \geq 2$, with Lipschitz boundary Γ consisting of two disjoint components Γ_D and Γ_N. The data have to satisfy the following conditions:

(A1) $0 < \varepsilon \ll 1$.

(A2) $\underline{a} \in W^{1,\infty}(\Omega)^n$, $b \in L^\infty(\Omega)$.

(A3) There are two constants $\beta \geq 0$ and $c_b \geq 0$, which do not depend on ε, such that $-\frac{1}{2}\operatorname{div}\underline{a} + b \geq \beta$ and $\|b\|_{L^\infty} \leq c_b\beta$.

(A4) The Dirichlet boundary Γ_D has positive $(n-1)$-dimensional Lebesgue measure and includes the inflow boundary $\{x \in \Gamma : \underline{a}(x)\cdot\underline{n}(x) < 0\}$.

Assumption (A3) allows us to handle simultaneously the case of a nonvanishing zero-order reaction term and that of absent reaction, the latter corresponding to $\beta = 0$. In the case $\beta = 0$ we set $c_b = 0$. Assumption (A1) of course means that we are interested in the convection-dominated regime.

We analyze three a posteriori error estimators for finite element discretizations (standard Galerkin or SUPG) of problem (1.1). One estimator is based on the evaluation of local residuals, and the other two are based on the solution of auxiliary local discrete convection-diffusion problems with Dirichlet or Neumann boundary conditions. All estimators yield global upper and lower bounds on the error of the finite element discretization measured in a norm that incorporates the standard energy norm of problem (1.1) and a dual norm of the convective derivative (cf. section 2 for

[†] Fakultät für Mathematik, Ruhr-Universität Bochum, D-44780 Bochum, Germany (rv@num1.ruhr-uni-bochum.de).

the definition of the norms). All estimates are fully robust in the sense that the ratio of upper and lower bounds is uniformly bounded with respect to the mesh-size, to the viscosity ε, and to the parameter β.

Our analysis is restricted to shape-regular meshes (cf. section 2). This includes locally refined meshes but excludes anisotropic elements with large aspect ratios. One could try to extend our analysis to anisotropic meshes following the lines of [6]. One then has to establish Lemmas 3.3 and 3.6 for anisotropic elements too. This is partially done in [7]. It is to be expected that the left-hand side of the upper error bound (4.7) in Theorem 4.1 will then include a factor which measures the alignment of the mesh with the error (cf. [7, Theorem 7.1]).

The present results complement and improve the results of [10] in several respects. There the analysis was restricted to the case $\beta = 1$; here we also treat the limiting case of vanishing reaction. Up to obvious modifications due to the presence of the parameter β, the residual estimator and the auxiliary local Dirichlet problems are the same here and in [10]. But here the solution of the local problem is evaluated with respect to a norm that also incorporates a mesh-dependent norm of the convective derivative. Most important, the present estimates are fully robust, whereas in [10] the ratios of the upper and lower bounds depend on the mesh-Péclet number. The present auxiliary local Neumann problems differ from their analogue in [10] by a new approximation of the convection and reaction terms. Moreover, the estimator considered here is based on a mesh-dependent norm that takes into account the convective derivative.

A comparison of the present results and of those in [10] leads to the following conclusions:

- A large ratio of the error estimators to the energy norm of the error may be attributed to a large convective derivative of the error and thus to insufficiently resolved interior and boundary layers.
- The full equivalence of the error estimators with parameter-independent constants is due to the incorporation of the convection into the norms used for evaluating the solutions of the auxiliary problems.

Our results should also be compared with those of [8]. There the residual-free bubbles method is applied to problem (1.1) with $b = 0$ and $\operatorname{div} \underline{a} = 0$, i.e., $\beta = 0$. The meshes are assumed to be shape-regular. The error estimator is a residual one and is proved to be robust. Our results for the case $\beta = 0$ and those of [8] differ in the scaling of the norm that measures the error and of the weights used in the error estimator. Such a rescaling, however, is not possible in the general case $\beta > 0$.

We have implemented the residual error estimator of section 4 for some examples. The Java applet and a user guide are available at www.ruhr-uni-bochum.de/num1. The estimators of sections 5 and 6 are much more complex both with respect to implementational and computational work. Up to now we did not have the time to implement them.

The article is organized as follows. In section 2 we present the variational formulation of problem (1.1), its finite element discretization, and the relevant norms. In section 3 we collect some auxiliary results which are needed for deriving the error bounds. In sections 4–6 we introduce the error estimators and prove their robustness. In what follows all constants are independent of the mesh-size, of the viscosity ε, and of the parameter β.

2. Variational formulation and finite element discretization. For any bounded open subset ω of Ω with Lipschitz boundary γ, we denote by $H^k(\omega)$, $k \in \mathbb{N}$,

$L^2(\omega) = H^0(\omega)$, and $L^2(\gamma)$ the usual Sobolev and Lebesgue spaces equipped with the standard norms $\|.\|_{k;\omega} = \|.\|_{H^k(\omega)}$ and $\|.\|_{0;\gamma} = \|.\|_{L^2(\gamma)}$ (cf. [1]). Similarly, $(.,.)_\omega$ and $(.,.)_\gamma$ denote the L^2-scalar products on ω and γ, respectively. If $\omega = \Omega$, we will omit the index Ω.

Set

$$H^1_D(\Omega) = \{v \in H^1(\Omega) : v = 0 \text{ on } \Gamma_D\} \tag{2.1}$$

and define the bilinear form B on $H^1(\Omega) \times H^1(\Omega)$ by

$$B(u, v) = \varepsilon(\nabla u, \nabla v) + (\underline{a} \cdot \nabla u, v) + (bu, v). \tag{2.2}$$

Then the standard variational formulation of problem (1.1) is to find $u \in H^1_D(\Omega)$ such that

$$B(u, v) = (f, v) + (g, v)_{\Gamma_N} \quad \forall v \in H^1_D(\Omega). \tag{2.3}$$

Due to assumption (A3), the natural energy norm for problem (2.3) is given by

$$|||v||| = \left\{\varepsilon\|\nabla u\|_0^2 + \beta\|u\|_0^2\right\}^{1/2}. \tag{2.4}$$

The dual space of $H^1_D(\Omega)$ is denoted by $H^1_D(\Omega)^*$ and is equipped with the dual norm

$$|||\varphi|||_* = \sup_{v \in H^1_D(\Omega)\backslash\{0\}} \frac{\langle \varphi, v\rangle}{|||v|||}, \tag{2.5}$$

where $\langle .,.\rangle$ denotes the corresponding duality pairing. This norm will be used for bounding the convective derivative.

For the finite element discretization we consider a family $\mathcal{T}_h$, $h > 0$, of partitions of Ω into simplices or parallelepipeds that satisfies the following properties.

Affine equivalence: Each element can be mapped by an invertible affine mapping onto the unit n-simplex or the unit n-cube.

Admissibility: Any two elements are either disjoint or share a complete ℓ-dimensional face $(0 \le \ell \le n-1)$.

Shape regularity: The ratio of the diameter h_K of any element K to the diameter ρ_K of the largest ball inscribed into this element is uniformly bounded.

We fix a natural number $k \ge 1$ and denote for any element K by $R_k(K)$ the space of all polynomials of total degree at most k if K is a simplex or of maximal degree at most k if K is a parallelepiped. With this definition the finite element space is given by

$$X_h = \left\{v \in C(\Omega) : v_{|K} \in R_k(K)\ \forall K \in \mathcal{T}_h, v = 0 \text{ on } \Gamma_D\right\}. \tag{2.6}$$

Next we define a bilinear form B_δ on $X_h \times X_h$ and a linear form ℓ_δ on X_h by

$$B_\delta(u_h, v_h) = B(u_h, v_h) + \sum_{K \in \mathcal{T}_h} \delta_K(-\varepsilon\Delta u_h + \underline{a} \cdot \nabla u_h + bu_h, \underline{a} \cdot \nabla v_h)_K \tag{2.7}$$

and

$$\ell_\delta(v_h) = (f, v_h) + (g, v_h)_{\Gamma_N} + \sum_{K \in \mathcal{T}_h} \delta_K(f, \underline{a} \cdot \nabla v_h)_K. \tag{2.8}$$

The δ_K are nonnegative stabilization parameters. We will always assume that

$$\delta_K \|\underline{a}\|_{L^\infty(K)} \leq c h_K \quad \forall K \in \mathcal{T}_h. \tag{2.9}$$

With these definitions, the finite element discretization of problem (1.1) consists in finding $u_h \in X_h$ such that

$$B_\delta(u_h, v_h) = \ell_\delta(v_h) \quad \forall v_h \in X_h. \tag{2.10}$$

The choice $\delta_K = 0$ for all K yields the standard Galerkin discretization; the choice $\delta_K > 0$ for all K corresponds to the SUPG-discretizations (cf., e.g., [4], [5]). Condition (2.9) is satisfied for all choices of δ_K used in practice. Assumptions (A3), (A4), and (2.9) and standard arguments for SUPG-discretizations imply that problem (2.10) admits a unique solution.

3. Auxiliary results. In this section we collect some auxiliary results and notation that will be helpful for the estimates of the subsequent sections. We start with a stability result for the bilinear form (2.2).

LEMMA 3.1. *The bilinear form* (2.2) *satisfies the upper bound*

$$B(u, v) \leq \max\{c_b, 1\} \{|||u||| + |||\underline{a} \cdot \nabla u|||_*\} |||v||| \quad \forall u, v \in H^1_D(\Omega) \tag{3.1}$$

and the inf-sup *condition*

$$\inf_{u \in H^1_D(\Omega)\backslash\{0\}} \sup_{v \in H^1_D(\Omega)\backslash\{0\}} \frac{B(u, v)}{\{|||u||| + |||\underline{a} \cdot \nabla u|||_*\} |||v|||} \geq \frac{1}{2 + \max\{c_b, 1\}}. \tag{3.2}$$

The constant c_b is the one of assumption (A3).

Proof. The upper bound (3.1) follows from assumption (A3), the definition (2.4) of the energy norm $|||.|||$, and the definition (2.5) of the dual norm $|||.|||_*$.

To prove the inf-sup condition (3.2), we fix an arbitrary function $u \in H^1_D(\Omega)$ and choose a real number θ greater than 0 and less than 1. Due to the definition (2.5) of the dual norm there is a function $v_\theta \in H^1_D(\Omega)$ with

$$|||v_\theta||| = 1 \quad \text{and} \quad (\underline{a} \cdot \nabla u, v_\theta) \geq \theta |||\underline{a} \cdot \nabla u|||_*.$$

Set $w_\theta = u + \frac{1}{1+\max\{c_b,1\}} |||u||| v_\theta$. The bilinearity of B then yields

$$B(u, w_\theta) = B(u, u) + \frac{1}{1 + \max\{c_b, 1\}} |||u||| B(u, v_\theta).$$

Integration by parts and assumptions (A3) and (A4) imply the coercivity of B, i.e.,

$$B(u, u) \geq |||u|||^2.$$

The definition of v_θ and assumption (A3) on the other hand give

$$B(u, v_\theta) = (\underline{a} \cdot \nabla u, v_\theta) + \varepsilon(\nabla u, \nabla v_\theta) + (bu, v_\theta) \geq \theta |||\underline{a} \cdot \nabla u|||_* - \max\{c_b, 1\} |||u|||.$$

Since

$$|||w_\theta||| \le \frac{2+\max\{c_b,1\}}{1+\max\{c_b,1\}}|||u|||$$

these estimates yield

$$\begin{aligned}\sup_{v\in H^1_D(\Omega)\backslash\{0\}} \frac{B(u,v)}{|||v|||} &\ge \frac{B(u,w_\theta)}{|||w_\theta|||}\\ &\ge \frac{1}{2+\max\{c_b,1\}}\{|||u|||+\theta|||\underline{a}\cdot\nabla u|||_*\}.\end{aligned}$$

Since $0<\theta<1$ and $u\in H^1_D(\Omega)$ were arbitrary, this proves the inf-sup condition (3.2). □

Remark 3.2. A similar result is established in [9]. There, however, the solution u and the test-function v are measured with respect to the same norm which is an interpolation norm between $|||.|||$ and $|||.|||+|||\underline{a}\cdot\nabla.|||_*$. The present result is better suited for our purposes, since, in what follows, we thus have to estimate Clément-type interpolants and bubble functions with respect to the energy norm and can do this by invoking standard results from the literature. It is worth noting that by the same argument a similar stability result can be established for the bilinear form B restricted to $X_h\times X_h$. One only has to replace $|||.|||_*$ by its discrete analogue for which the supremum is taken with respect to X_h instead of $H^1_D(\Omega)$. In section 5 we will use a similar result for analyzing the local auxiliary problems. Lemma 3.1 should also be compared with the results in [2]. There the norm $\sup_v B(u,v)/\|\nabla v\|_0$ is used to derive suboptimal, i.e., ε-dependent, a posteriori error bounds.

Next we introduce some notation that will be needed for the error estimates. We denote by $\mathcal{N}_h$ the set of all element vertices that do not lie on the Dirichlet boundary Γ_D and by $\mathcal{E}_h$ the set of all $(n-1)$-dimensional element faces that are not contained in Γ_D.

With each $E\in\mathcal{E}_h$ we associate a unit vector $\underline{n}_E$ that is orthogonal to E and that points to the outside of Ω if E is part of the boundary Γ. For any interior face E in Ω we denote by $[.]_E$ the jump across E in direction $\underline{n}_E$. The jump $[.]_E$ of course depends on the orientation of $\underline{n}_E$. But quantities of the form $[\underline{n}_E\cdot .]_E$ are independent thereof.

With every element K we associate two sets ω_K and $\tilde{\omega}_K$ which consist of the union of all elements that share an $(n-1)$-dimensional face with K and of the union of all elements that share at least one point with K, respectively. For a face $E\in\mathcal{E}_h$ the sets ω_E and $\tilde{\omega}_E$ are defined analogously.

For every vertex $x\in\mathcal{N}_h$ we denote by λ_x the nodal bases function which is uniquely defined by the properties

$$\lambda_{x|K}\in R_1(K)\quad \forall K\in\mathcal{T}_h,\quad \lambda_x(y)=0\quad \forall y\in\mathcal{N}_h\backslash\{x\},\quad \lambda_x(x)=1.$$

The support of a nodal bases function λ_x is denoted by ω_x and consists of all elements that share the vertex x. With this notation we can define a Clément-type interpolation operator $I_h : L^1(\Omega)\longrightarrow\{\varphi\in C(\Omega):\varphi_{|K}\in R_1(K)\text{ for all }K\in\mathcal{T}_h,\varphi=0\text{ on }\Gamma_D\}$ by (cf. [11])

$$I_h v=\sum_{x\in\mathcal{N}_h}\left\{\frac{1}{|\omega_x|}\int_{\omega_x}v\right\}\lambda_x. \tag{3.3}$$

Here $|\omega_x|$ denotes the n-dimensional Lebesgue measure of ω_x.

Lemma 3.3. *For every $S \in \mathcal{T}_h \cup \mathcal{E}_h$ denote by h_S its diameter and set*

$$\alpha_S = \min\{h_S \varepsilon^{-1/2}, \beta^{-1/2}\}. \tag{3.4}$$

Then the following estimates hold for all elements K, all faces E, and all functions $v \in H^1_D(\Omega)$:

$$\begin{aligned} \|v - I_h v\|_{0;K} &\le c_1 \alpha_K |||v|||_{\tilde{\omega}_K}, \\ \|v - I_h v\|_{0;E} &\le c_2 \varepsilon^{-1/4} \alpha_E^{1/2} |||v|||_{\tilde{\omega}_E}, \\ |||I_h v|||_K &\le c_3 |||v|||_{\tilde{\omega}_K}. \end{aligned}$$

Here $|||.|||_A$ denotes the restriction of $|||.|||$ to the measurable set A.

Proof. The proof of Lemma 3.3 follows from Lemma 3.1 in [10] and Proposition 2.1 in [11] with the arguments used in the proof of Lemma 3.2 in [10]. □

Remark 3.4. In the case $\beta = 0$ the minimum in (3.4) of course yields $\alpha_S = \varepsilon^{-1/2} h_S$ for all S.

Remark 3.5. Proposition 2.1 of [11] is only proved for simplicial elements. A close inspection of the arguments, however, reveals that they immediately carry over to parallelepipeds that are the affine image of the unit cube. The crucial point here is that the Jacobian of the transformation is constant.

Next we define element and face bubble functions that will be used in deriving lower error bounds. For every element K we denote by $\mathcal{N}_K$ the set of its vertices and set

$$\psi_K = \gamma_K \prod_{x \in \mathcal{N}_K} \lambda_x, \tag{3.5}$$

where the constant γ_K is chosen such that ψ_K equals 1 at the barycenter of K. Note that the support of ψ_K is contained in K and that $\|\psi_K\|_{L^\infty(K)} = 1$.

For every face E we set

$$\theta_E = \min\{\varepsilon^{1/2} \beta^{-1/2} h_E^{-1}, 1\} \tag{3.6}$$

and denote by $\mathcal{N}_E$ the set of its vertices. (Note that $\theta_E = 1$ in the case $\beta = 0$.) Consider first a face E that is not contained in the boundary. It is shared by exactly two elements $K_{E,1}$ and $K_{E,2}$. For $i = 1, 2$ we define an affine transformation $F_i : \mathbb{R}^n \longrightarrow \mathbb{R}^n$ as follows: We first map $K_{E,i}$ onto the reference element such that the image of E is contained in the hyperplane $\{x_n = 0\}$; then we apply the transformation $(x_1, \dots, x_{n-1}, x_n) \longrightarrow (x_1, \dots, x_{n-1}, \theta_E x_n)$; and finally we transform back using the inverse of the affine transformation of the first step. With this definition we set

$$\psi_E = \gamma_E \prod_{x \in \mathcal{N}_E} \lambda_x \circ F_i^{-1} \quad \text{on } K_{E,i}\, , i = 1, 2, \tag{3.7}$$

where the constant γ_E is chosen such that ψ_E equals 1 at the barycenter of E. Note that the support of ψ_E is contained in $F_1(K_{E,1}) \cup F_2(K_{E,2}) \subset K_{E,1} \cup K_{E,2} = \omega_E$ and that $\|\psi_E\|_{L^\infty(E)} = 1$.

If a face E is contained in the Neumann boundary Γ_N, the definition of ψ_E is modified in the obvious way taking into account that now E is the face of exactly one element K_E.

LEMMA 3.6. *The following estimates hold for all elements K, all polynomials $v \in R_k(K)$, all faces E, and all polynomials $\sigma \in R_k(E)$:*

$$\begin{aligned}
(v, \psi_K v)_K &\geq c_4 \|v\|_{0;K}^2, \\
|||\psi_K v|||_K &\leq c_5 \alpha_K^{-1} \|v\|_{0;K}, \\
(\sigma, \psi_E \sigma)_E &\geq c_6 \|\sigma\|_{0;E}^2, \\
|||\psi_E \sigma|||_{\omega_E} &\leq c_7 \varepsilon^{1/4} \alpha_E^{-1/2} \|\sigma\|_{0;E}, \\
\|\psi_E \sigma\|_{0;\omega_E} &\leq c_8 \varepsilon^{1/4} \alpha_E^{1/2} \|\sigma\|_{0;E}.
\end{aligned}$$

Here, a polynomial σ defined on a face E is continued in the canonical way to a polynomial defined on $\mathbb{R}^n$. The constants $c_4, \ldots, c_8$ depend only on the polynomial degree k and on the ratios h_K/ρ_K.

Proof. The estimates are proven with the same arguments as in the proof of Lemma 3.3 in [10]. For parallelepipeds one only has to take into account that the transformation to the unit cube is affine and thus has a constant Jacobian. □

4. A residual error estimator.

Denote by f_h, g_h, $\underline{a}_h$, and b_h the L^2-projections of the data f, g, $\underline{a}$, and b onto the space of piecewise constant functions corresponding to $\mathcal{T}_h$. For abbreviation we define element residuals R_K by

$$R_K = f_h + \varepsilon \Delta u_h - \underline{a}_h \cdot \nabla u_h - b_h u_h, \tag{4.1}$$

face residuals R_E by

$$R_E = \begin{cases} -[\varepsilon \underline{n}_E \cdot \nabla u_h]_E & \text{if } E \not\subset \Gamma, \\ g_h - \varepsilon \underline{n}_E \cdot \nabla u_h & \text{if } E \subset \Gamma_N, \\ 0 & \text{if } E \subset \Gamma_D, \end{cases} \tag{4.2}$$

elementwise data errors D_K by

$$D_K = \{f - f_h + (\underline{a}_h - \underline{a}) \cdot \nabla u_h + (b_h - b) u_h\}_{|K}, \tag{4.3}$$

and edgewise data errors D_E, $E \in \mathcal{E}_h \cap \Gamma_N$, by

$$D_E = g - g_h. \tag{4.4}$$

Here, of course, u_h denotes the solution of the discrete problem (2.10). Note that, as usual, R_K is defined elementwise. In particular, the term Δu_h has to be interpreted as the Laplacian applied to the restriction of u_h to the element K.

THEOREM 4.1. *For every element K define the error indicator η_K by*

$$\eta_K = \left\{ \alpha_K^2 \|R_K\|_{0;K}^2 + \sum_{E \in \mathcal{E}_h; E \subset \partial K} \varepsilon^{-1/2} \alpha_E \|R_E\|_{0;E}^2 \right\}^{1/2} \tag{4.5}$$

and the data error indicator Θ_K *by*

$$\Theta_K = \left\{ \alpha_K^2 \left[\|f - f_h\|_{0;K}^2 + \|(\underline{a} - \underline{a}_h) \cdot u_h\|_{0;K}^2 + \|(b - b_h)u_h\|_{0;K}^2 \right] \right. \\ \left. + \sum_{E \in \mathcal{E}_h; E \subset \partial K \cap \Gamma_N} \varepsilon^{-1/2} \alpha_E \|g - g_h\|_{0;E}^2 \right\}^{1/2}. \tag{4.6}$$

Then the error between the solutions u *and* u_h *of problems* (2.3) *and* (2.10) *is bounded from above by*

$$|||u - u_h||| + |||\underline{a} \cdot \nabla(u - u_h)|||_* \le c^* \left\{ \sum_{K \in \mathcal{T}_h} \left[\eta_K^2 + \Theta_K^2 \right] \right\}^{1/2} \tag{4.7}$$

and from below by

$$\left\{ \sum_{K \in \mathcal{T}_h} \eta_K^2 \right\}^{1/2} \le c_* \left[|||u - u_h||| + |||\underline{a} \cdot \nabla(u - u_h)|||_* + \left\{ \sum_{K \in \mathcal{T}_h} \Theta_K^2 \right\}^{1/2} \right]. \tag{4.8}$$

The constant c^* *depends only on the constants* $c_1, \dots, c_3$ *of Lemma* 3.3 *and on the ratios* h_K/ρ_K*; the constant* c_* *depends only on the constants* $c_4, \dots, c_8$ *of Lemma* 3.6 *and on the ratios* h_K/ρ_K*.*

Proof. As usual, we define the residual $R(u_h)$ of the discrete solution u_h by

$$\langle R(u_h), v \rangle = (f, v) + (g, v)_{\Gamma_N} - B(u_h, v) \quad \forall v \in H_D^1(\Omega). \tag{4.9}$$

Since $\langle R(u_h), v \rangle = B(u - u_h, v)$ for all $v \in H_D^1(\Omega)$, Lemma 3.1 implies

$$\frac{1}{1 + \max\{c_b, 1\}} |||R(u_h)|||_* \le |||u - u_h||| + |||\underline{a} \cdot \nabla(u - u_h)|||_* \\ \le \{2 + \max\{c_b, 1\}\} \, |||R(u_h)|||_*. \tag{4.10}$$

Integration by parts elementwise yields the following L^2-representation of the residual:

$$\begin{aligned} \langle R(u_h), v \rangle &= \sum_{K \in \mathcal{T}_h} (f + \varepsilon \Delta u_h - \underline{a} \cdot \nabla u_h - b u_h, v)_K \\ &\quad - \sum_{E \in \mathcal{E}_h \cap \Omega} ([\varepsilon \underline{n}_E \cdot \nabla u_h]_E, v)_E + \sum_{E \in \mathcal{E}_h \cap \Gamma_n} (g - \varepsilon \underline{n}_E \cdot \nabla u_h, v)_E \\ &= \sum_{K \in \mathcal{T}_h} (R_K, v)_K + \sum_{E \in \mathcal{E}_h} (R_E, v)_E \\ &\quad + \sum_{K \in \mathcal{T}_h} (D_K, v)_K + \sum_{E \in \mathcal{E}_h \cap \Gamma_n} (D_E, v)_E. \end{aligned} \tag{4.11}$$

Lemma 3.3 and the Cauchy–Schwarz inequality therefore imply for all $v \in H_D^1(\Omega)$

$$\begin{aligned}&\langle R(u_h),v - I_hv\rangle \\ &\qquad \le c|||v|||\Bigg\{\sum_{K\in\mathcal{T}_h}\alpha_K^2\|R_K\|_{0;K}^2 + \sum_{E\in\mathcal{E}_h}\varepsilon^{-1/2}\alpha_E\|R_E\|_{0;E}^2 \\ &\qquad\qquad + \sum_{K\in\mathcal{T}_h}\alpha_K^2\|D_K\|_{0;K}^2 + \sum_{E\in\mathcal{E}_h\cap\Gamma_n}\varepsilon^{-1/2}\alpha_E\|D_E\|_{0;E}^2\Bigg\}^{1/2}.\end{aligned} \tag{4.12}$$

The constant c depends only on the constants c_1 and c_2 of Lemma 3.3 and on the ratios h_K/ρ_K.

From the definition of problems (2.3) and (2.10) we conclude that

$$\langle R(u_h), I_hv\rangle = \sum_{K\in\mathcal{T}_h}\delta_K\{(R_K, \underline{a}\cdot\nabla I_hv)_K + (D_K, \underline{a}\cdot\nabla I_hv)_K\}.$$

Lemma 3.3, condition (2.9), and the Cauchy–Schwarz inequality therefore imply

$$\langle R(u_h), I_hv\rangle \le c|||v|||\Bigg\{\sum_{K\in\mathcal{T}_h}\alpha_K^2\big\{\|R_K\|_{0;K}^2 + \|D_K\|_{0;K}^2\big\}\Bigg\}^{1/2}. \tag{4.13}$$

Estimates (4.10), (4.12), and (4.13) and the triangle inequality for the D_K prove the upper bound (4.7).

For the proof of the lower bound (4.8) we proceed as in the proof of [12, Lemma 5.1] and define a function w_h by

$$w_h = \gamma_1\sum_{K\in\mathcal{T}_h}\alpha_K^2\psi_KR_K + \gamma_2\sum_{E\in\mathcal{E}_h}\varepsilon^{-1/2}\alpha_E\psi_ER_E. \tag{4.14}$$

The constants γ_1 and γ_2 are arbitrary at present and will be determined below. The subsequent arguments are based on the following observation:

- the supports of the ψ_K are mutually disjoint;
- the support of a ψ_K intersects the support of at most $2n$ different ψ_E's;
- the support of a ψ_E intersects the support of at most two ψ_K's;
- the support of a ψ_E intersects the support of at most $2n-2$ other ψ_E's.

Lemma 3.6 therefore yields

$$\begin{aligned}|||w_h|||^2 \le{}& \gamma_1^2\sum_{K\in\mathcal{T}_h}\alpha_K^4|||\psi_KR_K|||_K^2 \\ &+ 2\gamma_1\gamma_2\sum_{K\in\mathcal{T}_h}\Bigg\{\sum_{E;\omega_E\cap K\neq\emptyset}\alpha_K^2\varepsilon^{-1/2}\alpha_E|||\psi_KR_K|||_K|||\psi_ER_E|||_K\Bigg\} \\ &+ \gamma_2^2\sum_{E\in\mathcal{E}_h}\Bigg\{\sum_{E';\omega_E\cap\omega_{E'}\neq\emptyset}\varepsilon^{-1}\alpha_E\alpha_{E'}|||\psi_ER_E|||_{\omega_E}|||\psi_{E'}R_{E'}|||_{\omega_{E'}}\Bigg\} \\ \le{}& (2n+1)\max\{\gamma_1^2,\gamma_2^2\}\max\{c_5,c_7\}\sum_{K\in\mathcal{T}_h}\eta_K^2.\end{aligned} \tag{4.15}$$

Since $h_E \le h_K$ for all faces E of any element K, Lemma 3.6 also implies that

$$\begin{aligned}
&\sum_{K\in\mathcal{T}_h}(R_K, w_h)_K + \sum_{E\in\mathcal{E}_h}(R_E, w_h)_E \\
&\quad = \gamma_1 \sum_{K\in\mathcal{T}_h} \alpha_K^2 (R_K, \psi_K R_K)_K + \gamma_2 \sum_{E\in\mathcal{E}_h} \varepsilon^{-1/2}\alpha_E (R_E, \psi_E R_E)_E \\
&\qquad + \gamma_2 \sum_{E\in\mathcal{E}_h} \left\{ \sum_{K;K\cap\omega_E\neq\emptyset} \varepsilon^{-1/2}\alpha_E (R_K, \psi_E R_E)_K \right\} \\
&\quad \ge \gamma_1 \sum_{K\in\mathcal{T}_h} c_4 \alpha_K^2 \|R_K\|_{0;K}^2 + \gamma_2 \sum_{E\in\mathcal{E}_h} c_6 \varepsilon^{-1/2}\alpha_E \|R_E\|_{0;E}^2 \\
&\qquad - \gamma_2 \sum_{E\in\mathcal{E}_h} \left\{ \sum_{K;K\cap\omega_E\neq\emptyset} c_8 \varepsilon^{-1/4}\alpha_E^{1/2}\alpha_K \|R_K\|_{0;K} \|\psi_E R_E\|_{0;E} \right\} \\
&\quad \ge (\gamma_1 c_4 - 2n\gamma_2 c_8^2 c_6^{-1}) \sum_{K\in\mathcal{T}_h} \alpha_K^2 \|R_K\|_{0;K}^2 + \frac{1}{2}\gamma_2 c_6 \sum_{E\in\mathcal{E}_h} \varepsilon^{-1/2}\alpha_E \|R_E\|_{0;E}^2 \\
&\quad \ge \min\left\{ \gamma_1 c_4 - 2n\gamma_2 c_8^2 c_6^{-1}, \frac{1}{2}\gamma_2 c_6 \right\} \sum_{K\in\mathcal{T}_h} \eta_K^2.
\end{aligned} \tag{4.16}$$

From Lemma 3.6 we also obtain

$$\begin{aligned}
&\sum_{K\in\mathcal{T}_h}(D_K, w_h)_K + \sum_{E\in\mathcal{E}_h\cap\Gamma_n}(D_E, w_h)_E \\
&\quad = \gamma_1 \sum_{K\in\mathcal{T}_h} \alpha_K^2 (D_K, \psi_K R_K)_K \\
&\qquad + \gamma_2 \sum_{K\in\mathcal{T}_h} \left\{ \sum_{E;E\subset\partial K} \varepsilon^{-1/2}\alpha_E (D_K, \psi_E R_E)_K \right\} \\
&\qquad + \gamma_2 \sum_{E\in\mathcal{E}_h\cap\Gamma_n} \varepsilon^{-1/2}\alpha_E (D_E, \psi_E R_E)_E \\
&\quad \le \gamma_1 \sum_{K\in\mathcal{T}_h} \alpha_K^2 \|R_K\|_{0;K} \|D_K\|_{0;K} \\
&\qquad + \gamma_2 \sum_{K\in\mathcal{T}_h} \left\{ \sum_{E;E\subset\partial K} c_8 \varepsilon^{-1/4}\alpha_E^{3/2} \|R_E\|_{0;E} \|D_K\|_{0;K} \right\} \\
&\qquad + \gamma_2 \sum_{E\in\mathcal{E}_h\cap\Gamma_n} \varepsilon^{-1/2}\alpha_E \|R_E\|_{0;E} \|D_E\|_{0;E} \\
&\quad \le 2n \max\{\gamma_1, \gamma_2\} \max\{1, c_8\} \left\{ \sum_{K\in\mathcal{T}_h} \Theta_K^2 \right\}^{1/2} \left\{ \sum_{K\in\mathcal{T}_h} \eta_K^2 \right\}^{1/2}.
\end{aligned} \tag{4.17}$$

Now we choose

$$\gamma_2 = \frac{2}{c_6} \quad \text{and} \quad \gamma_1 = \frac{1}{c_4}\left(1 + \frac{4nc_8^2}{c_6^2}\right).$$

This choice gives

$$\min\left\{\gamma_1 c_4 - 2n\gamma_2 c_8^2 c_6^{-1}, \frac{1}{2}\gamma_2 c_6\right\} = 1.$$

Estimates (4.16), (4.17), and (4.15), equation (4.11), and the triangle inequality for the D_K therefore imply

$$\sum_{K\in\mathcal{T}_h} \eta_K^2 \le c\left\{\sum_{K\in\mathcal{T}_h} \eta_K^2\right\}^{1/2}\left[|||R(u_h)|||_* + \left\{\sum_{K\in\mathcal{T}_h} \Theta_K^2\right\}^{1/2}\right].$$

In combination with Lemma 3.1 this establishes the lower bound (4.8). □

5. An error estimator based on the solution of local Dirichlet problems.

In this section we present an error estimator that is based on the solution of auxiliary local discrete problems with Dirichlet boundary conditions. To this end we fix an arbitrary element K and set

$$V_K = \operatorname{span}\{\psi_{K'}v, \psi_E\sigma : K' \subset \omega_K, E \subset \partial K\backslash\Gamma_D, v \in R_k(K'), \sigma \in R_k(E)\}.$$

Then we consider the following problem: Find $v \in V_K$ such that

$$\begin{aligned}\varepsilon(\nabla v, \nabla w)_{\omega_K} &+ (\underline{a}\cdot\nabla v, w)_{\omega_K} + (bv, w)_{\omega_K}\\ &= (f_h, w)_{\omega_K} + (g_h, w)_{\partial K\cap\Gamma_N} - \varepsilon(\nabla u_h, \nabla w)_{\omega_K}\\ &\quad - (\underline{a}_h\cdot\nabla u_h, w)_{\omega_K} - (b_h u_h, w)_{\omega_K} \quad \forall w \in V_K.\end{aligned}\tag{5.1}$$

The following lemma is a discrete analogue of Lemma 3.1. It in particular implies the unique solvability of problem (5.1).

LEMMA 5.1. *Denote by π_{V_K} the L^2-projection onto V_K. Then the following estimates are valid:*

$$\begin{aligned}\sup_{v\in V_K\backslash\{0\}}\ \sup_{w\in V_K\backslash\{0\}} &\frac{\varepsilon(\nabla v, \nabla w)_{\omega_K} + (\underline{a}\cdot\nabla v, w)_{\omega_K} + (bv, w)_{\omega_K}}{\left\{|||v|||_{\omega_K}^2 + \alpha_K^2\|\pi_{V_K}(\underline{a}\cdot\nabla v)\|_{0;\omega_K}^2\right\}^{1/2}|||w|||_{\omega_K}}\\ &\le \sqrt{2}\max\{c_a, c_b, 1\}\end{aligned}\tag{5.2}$$

and

$$\begin{aligned}\inf_{v\in V_K\backslash\{0\}}\ \sup_{w\in V_K\backslash\{0\}} &\frac{\varepsilon(\nabla v, \nabla w)_{\omega_K} + (\underline{a}\cdot\nabla v, w)_{\omega_K} + (bv, w)_{\omega_K}}{\left\{|||v|||_{\omega_K}^2 + \alpha_K^2\|\pi_{V_K}(\underline{a}\cdot\nabla v)\|_{0;\omega_K}^2\right\}^{1/2}|||w|||_{\omega_K}}\\ &\ge \frac{1}{1 + 3c_a^2\max\{c_b, 1\}^2}.\end{aligned}\tag{5.3}$$

The constant c_b is that of assumption (A3). *The constant c_a depends only on the polynomial degree k and on the ratios h_K/ρ_K (cf.* (5.5) *below).*

Proof. The definition of π_{V_K} implies

$$(\underline{a}\cdot\nabla v, w)_{\omega_K} = (\pi_{V_K}(\underline{a}\cdot\nabla v), w)_{\omega_K} \quad \forall v, w \in V_K.$$

This identity, assumption (A3), and the definition (2.4) of the energy norm yield for all $v, w \in V_K$

$$\begin{aligned}\varepsilon(\nabla v, \nabla w)_{\omega_K} &+ (\underline{a}\cdot\nabla v, w)_{\omega_K} + (bv, w)_{\omega_K}\\ &\le \max\{c_b, 1\}|||v|||_{\omega_K}|||w|||_{\omega_K} + \|\pi_{V_K}(\underline{a}\cdot\nabla v)\|_{0;\omega_K}\|w\|_{0;\omega_K}.\end{aligned}\tag{5.4}$$

Since the functions in V_K vanish at the vertices of K, the norms $h_K\|\nabla.\|_{0;\omega_K}$ and $\| .\|_{0;\omega_K}$ are equivalent on V_K. Therefore $\alpha_K|||.|||_{\omega_K}$ and $\| .\|_{0;\omega_K}$ are also equivalent norms on V_K; i.e., there is a constant $c_a \geq 1$ which depends only on the polynomial degree k and on the ratios h_K/ρ_K such that

$$\frac{1}{c_a}\alpha_K|||w|||_{\omega_K} \leq \|w\|_{0;\omega_K} \leq c_a\alpha_K|||w|||_{\omega_K} \tag{5.5}$$

holds for all $w \in V_K$. Inequalities (5.4) and (5.5) prove the upper bound (5.2).

For the proof of the lower bound (5.3) we proceed as in the proof of estimate (3.2). We consider an arbitrary function $v \in V_K$ and set $w_\gamma = v + \gamma\alpha_K^2\pi_{V_K}(\underline{a}\cdot\nabla v)$. The constant γ is arbitrary at present and will be determined below. The norm equivalence (5.5) implies

$$\begin{aligned}|||w_\gamma|||_{\omega_K} &\leq |||v|||_{\omega_K} + c_a\gamma\alpha_K\|\pi_{V_K}(\underline{a}\cdot\nabla v)\|_{0;\omega_K}\\ &\leq \left\{1 + c_a^2\gamma^2\right\}^{1/2}\left\{|||v|||_{\omega_K}^2 + \alpha_K^2\|\pi_{V_K}(\underline{a}\cdot\nabla v)\|_{0;\omega_K}^2\right\}^{1/2}.\end{aligned}$$

Assumptions (A3) and (A4), integration by parts, and the definition (2.4) of the energy norm on the other hand imply that the bilinear form on the left-hand side of problem (5.1) is coercive on V_K with constant 1. Inserting w_γ as a test-function in this bilinear form therefore yields

$$\begin{aligned}&\varepsilon(\nabla v, \nabla w_\gamma)_{\omega_K} + (\underline{a}\cdot\nabla v, w_\gamma)_{\omega_K} + (bv, w_\gamma)_{\omega_K}\\ &\quad= \varepsilon(\nabla v, \nabla v)_{\omega_K} + (\underline{a}\cdot\nabla v, v)_{\omega_K} + (bv, v)_{\omega_K}\\ &\qquad+ \gamma\alpha_K^2\{\varepsilon(\nabla v, \nabla\pi_{V_K}(\underline{a}\cdot\nabla v))_{\omega_K} + (\underline{a}\cdot\nabla v, \pi_{V_K}(\underline{a}\cdot\nabla v))_{\omega_K} + (bv, \pi_{V_K}(\underline{a}\cdot\nabla v))_{\omega_K}\}\\ &\quad\geq |||v|||_{\omega_K}^2 + \gamma\alpha_K^2\|\pi_{V_K}(\underline{a}\cdot\nabla v)\|_{0;\omega_K}^2 - c_a\max\{c_b, 1\}\gamma\alpha_K|||v|||_{\omega_K}\|\pi_{V_K}(\underline{a}\cdot\nabla v)\|_{0;\omega_K}\\ &\quad\geq \left(1 - \frac{1}{2}c_a^2\max\{c_b, 1\}^2\gamma\right)|||v|||_{\omega_K}^2 + \frac{1}{2}\gamma\alpha_K^2\|\pi_{V_K}(\underline{a}\cdot\nabla v)\|_{0;\omega_K}^2.\end{aligned}$$

Now we choose $\gamma = 2/(1 + c_a^2\max\{c_b, 1\}^2)$. Since

$$\begin{aligned}&(1 + c_a^2\max\{c_b, 1\}^2)\left\{1 + \frac{4c_a^2}{(1 + c_a^2\max\{c_b, 1\}^2)^2}\right\}^{1/2}\\ &\quad= \left\{(1 + c_a^2\max\{c_b, 1\}^2)^2 + 4c_a^2\right\}^{1/2}\\ &\quad\leq 1 + 3c_a^2\max\{c_b, 1\}^2\end{aligned}$$

this proves estimate (5.3). □

We denote by $v_K \in V_K$ the unique solution of problem (5.1) and define the error indicator $\eta_{D,K}$ by

$$\eta_{D,K} = \left\{|||v_k|||_{\omega_K}^2 + \alpha_K^2\|\pi_{V_K}(\underline{a}\cdot\nabla v_K)\|_{0;\omega_K}^2\right\}^{1/2}. \tag{5.6}$$

Remark 5.2. The function $u_h + v_K$ is a finite element approximation to the solution u_K of the local convection-diffusion problem

$$\begin{aligned}-\varepsilon\Delta u_K + \underline{a}\nabla\cdot u_K + bu_K &= f_h \quad \text{in } \omega_K,\\ u_K &= u_h \quad \text{on } \partial\omega_K\backslash(\partial K \cap \Gamma_N),\\ \varepsilon\underline{n}_K\cdot\nabla u_K &= g_h \quad \text{on } \partial K \cap \Gamma_N.\end{aligned}$$

Problem (5.1) is the same as problem (5.1) in [10]. But, contrary to [10], the present error indicator also takes into account the convective derivative of v_K. This modification is crucial for obtaining fully robust error estimates.

THEOREM 5.3. *There are two constants $c_\dagger$ and $c^\dagger$ which depend only on the polynomial degree k and on the ratios h_K/ρ_K such that the estimate*

$$\frac{1}{c_\dagger}\eta_K \le \eta_{D,K} \le c^\dagger \left\{ \sum_{K'\subset\omega_K} \eta_{K'}^2 \right\}^{1/2} \tag{5.7}$$

holds for all elements K. Moreover $\eta_{D,K}$ yields the upper error bound

$$|||u-u_h||| + |||\underline{a}\cdot\nabla(u-u_h)|||_* \le \hat{c}^* \left\{ \sum_{K\in\mathcal{T}_h} \left[\eta_{D,K}^2 + \Theta_K^2\right] \right\}^{1/2} \tag{5.8}$$

and the lower error bound

$$\left\{ \sum_{K\in\mathcal{T}_h} \eta_{D,K}^2 \right\}^{1/2} \le \hat{c}_* \left[|||u-u_h||| + |||\underline{a}\cdot\nabla(u-u_h)|||_* + \left\{ \sum_{K\in\mathcal{T}_h} \Theta_K^2 \right\}^{1/2} \right]. \tag{5.9}$$

The constants $\hat{c}_*$ and $\hat{c}^*$ depend only on the polynomial degree k and on the ratios h_K/ρ_K.

Proof. In view of Theorem 4.1 we only have to prove estimate (5.7). Integration by parts of the right-hand side of problem (5.1) yields for all $w \in V_K$

$$\begin{aligned}(f_h, w)_{\omega_K} &+ (g_h, w)_{\partial K\cap\Gamma_N} - \varepsilon(\nabla u_h, \nabla w)_{\omega_K} - (\underline{a}_h\cdot\nabla u_h, w)_{\omega_K} - (b_h u_h, w)_{\omega_K} \\ &= \sum_{K'\subset\omega_K} (R_{K'}, w)_{K'} + \sum_{E\subset\partial K\backslash\Gamma_D} (R_E, w)_E.\end{aligned}$$

Hence we have

$$\begin{aligned}&\sup_{w\in V_K} \frac{1}{|||w|||_{\omega_K}} \left\{\varepsilon(\nabla v_K, \nabla w)_{\omega_K} + (\underline{a}\cdot\nabla v_K, w)_{\omega_K} + (b v_K, w)_{\omega_K}\right\} \\ &\qquad = \sup_{w\in V_K} \frac{1}{|||w|||_{\omega_K}} \left\{ \sum_{K'\subset\omega_K} (R_{K'}, w)_{K'} + \sum_{E\subset\partial K\backslash\Gamma_D} (R_E, w)_E \right\}.\end{aligned} \tag{5.10}$$

Lemma 5.1 implies that the left-hand side of (5.10) is bounded from above and from below by constant multiples of $\{|||v_K|||_{\omega_K}^2 + \alpha_K^2\|\pi_{V_K}(\underline{a}\cdot\nabla v_K)\|_{0;\omega_K}^2\}^{1/2}$. The norm equivalence (5.5) yields that the right-hand side of (5.10) is bounded from above by a constant multiple of $\left\{\sum_{K'\subset\omega_K}\eta_{K'}^2\right\}^{1/2}$. The arguments in establishing estimates (4.15) and (4.16) on the other hand show that, taking a suitable combination of functions $\psi_{K'}R_{K'}$, $K' \subset \omega_K$, and $\psi_E R_E$, $E \subset \partial K\backslash\Gamma_N$, allows us to bound the right-hand side of (5.10) from below by a constant multiple of $\{\sum_{K'\subset\omega_K}\alpha_{K'}^2\|R_{K'}\|_{0;K'}^2 + \sum_{E\subset\partial K\backslash\Gamma_D}\varepsilon^{-1/2}\alpha_E\|R_E\|_{0;E}^2\}^{1/2}$, which in turn is an upper bound for η_K. □

6. An error estimator based on the solution of local Neumann problems. In this section we present an error estimator that is based on the solution of auxiliary local discrete problems with Neumann boundary conditions. The main difficulty in constructing the discrete local problem now is to ensure the coercivity of the corresponding bilinear form. To achieve this we have to approximate the reaction b and the convection $\underline{a}$ by discrete quantities such that assumption (A3) remains valid for this approximation and such that the normal component of the discrete convection is piecewise constant on the edges, respectively, faces, of $\mathcal{T}_h$.

To this end we recall that b_h is the L^2-projection of b onto the space of piecewise constant functions corresponding to $\mathcal{T}_h$. For the approximation of the convection we denote by $\underline{a}_{\mathrm{RT}_h}$ the approximation of $\underline{a}$ in the lowest-order Raviart–Thomas space RT_0 corresponding to $\mathcal{T}_h$ which is defined by (cf. [3, sections III.3.1 and III.3.2]):

$$\underline{a}_{\mathrm{RT}_h|K} \in R_0(K)^n + \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} R_0(K) \quad \forall K \in \mathcal{T}_h,$$

$$\int_E \underline{n}_E \cdot \underline{a}_{\mathrm{RT}_h} = \int_E \underline{n}_E \cdot \underline{a} \quad \forall E \in \mathcal{E}_h.$$

Note that $\underline{n}_E \cdot \underline{a}_{\mathrm{RT}_h}$ is piecewise constant on the edges, respectively, faces. Therefore we can associate with each element K the collection of its outflow edges, respectively, faces, by setting

$$\mathcal{E}_K^+ = \{E \in \mathcal{E}_h \cap \partial K : \underline{n}_K \cdot \underline{a}_{\mathrm{RT}_h} \geq 0\},$$

where $\underline{n}_K$ denotes the outward normal to K.

With these definitions we set

$$\widetilde{V}_K = \mathrm{span}\,\{\psi_K v, \psi_E \sigma : v \in R_k(K), E \in \mathcal{E}_K^+, \sigma \in R_k(E)\}$$

and consider the following problem: Find $\widetilde{v} \in \widetilde{V}_K$ such that

$$\begin{aligned} &\varepsilon(\nabla\widetilde{v}, \nabla w)_K + (\underline{a}_{\mathrm{RT}_h} \cdot \nabla\widetilde{v}, w)_K + (b_h\widetilde{v}, w)_K \\ &\qquad = (R_K, w)_K + \sum_{E\in\mathcal{E}_K^+} (R_E, w)_E \quad \forall w \in \widetilde{V}_K. \end{aligned} \tag{6.1}$$

The following lemma is an analogue of Lemma 5.1. It in particular implies the unique solvability of problem (6.1).

Lemma 6.1. *The following estimates hold for all elements K:*

$$\begin{aligned} &\sup_{v\in\widetilde{V}_K\setminus\{0\}} \sup_{w\in\widetilde{V}_K\setminus\{0\}} \frac{\varepsilon(\nabla v, \nabla w)_K + (\underline{a}_{\mathrm{RT}_h} \cdot \nabla v, w)_K + (b_h v, w)_K}{\{|||v|||_K^2 + \alpha_K^2 \|\underline{a}_{\mathrm{RT}_h} \cdot \nabla v\|_{0;K}^2\}^{1/2} |||w|||_K} \\ &\qquad \leq \sqrt{2}\max\{\widetilde{c}_a, c_b, 1\} \end{aligned} \tag{6.2}$$

and

$$\begin{aligned} &\inf_{v\in\widetilde{V}_K\setminus\{0\}} \sup_{w\in\widetilde{V}_K\setminus\{0\}} \frac{\varepsilon(\nabla v, \nabla w)_K + (\underline{a}_{\mathrm{RT}_h} \cdot \nabla v, w)_K + (b_h v, w)_K}{\{|||v|||_K^2 + \alpha_K^2 \|\underline{a}_{\mathrm{RT}_h} \cdot \nabla v\|_{0;K}^2\}^{1/2} |||w|||_K} \\ &\qquad \geq \frac{1}{1 + 3\widetilde{c}_a^2 \max\{c_b, 1\}^2}. \end{aligned} \tag{6.3}$$

The constant c_b is that of assumption (A3). *The constant $\widetilde{c}_a$ depends only on the polynomial degree k and on the ratios h_K/ρ_K (cf.* (6.6) *below).*

Proof. Choose an arbitrary element K and keep it fixed in what follows.

Since b_h is constant on K we conclude from assumption (A3) that

$$\|b_h\|_{L^\infty(K)} = \left|\frac{1}{|K|}\int_K b_h\right| = \left|\frac{1}{|K|}\int_K b\right| \le c_b\beta.$$

From [3, sections III.3.1 and III.3.2] we know that $\operatorname{div}\underline{a}_{\mathrm{RT}_h}$ is constant on K and satisfies $\int_K \operatorname{div}\underline{a}_{\mathrm{RT}_h} = \int_K \operatorname{div}\underline{a}$. Hence we get from assumption (A3)

$$b_h - \frac{1}{2}\operatorname{div}\underline{a}_{\mathrm{RT}_h} = \frac{1}{|K|}\int_K \left\{b_h - \frac{1}{2}\operatorname{div}\underline{a}_{\mathrm{RT}_h}\right\} = \frac{1}{|K|}\int_K \left\{b - \frac{1}{2}\operatorname{div}\underline{a}\right\} \ge \beta. \tag{6.4}$$

This shows that b_h and $\underline{a}_{\mathrm{RT}_h}$ satisfy assumption (A3) with the same constants β and c_b. Hence we obtain the following analogue of estimate (5.4) for all $v, w \in \widetilde{V}_K$:

$$\begin{aligned}\varepsilon(\nabla v,\nabla w)_K &+ (\underline{a}_{\mathrm{RT}_h}\cdot\nabla v, w)_K + (b_h v, w)_K \\ &\le \max\{c_b,1\}|||v|||_K|||w|||_K + \|\underline{a}_{\mathrm{RT}_h}\cdot\nabla v\|_{0;K}\|w\|_{0;K}.\end{aligned} \tag{6.5}$$

The same arguments as in the proof of estimate (5.5) imply that there is a constant $\widetilde{c}_a \ge 1$ which depends only on the polynomial degree k and on the ratios h_K/ρ_K such that

$$\frac{1}{\widetilde{c}_a}\alpha_K|||w|||_{\omega_K} \le \|w\|_{0;\omega_K} \le \widetilde{c}_a\alpha_K|||w|||_{\omega_K} \tag{6.6}$$

holds for all $w \in \widetilde{V}_K$. Inequalities (6.5) and (6.6) prove the upper bound (6.2).

For the proof of the lower bound (6.3) we only have to check the coercivity of the bilinear form on the left-hand side of problem (6.1). Once this is done, the inf-sup condition (6.3) is established with the same arguments as in the proof of Lemma 6.1. For every $w \in \widetilde{V}_K$ we have

$$\begin{aligned}\varepsilon(\nabla w,\nabla w)_K &+ (\underline{a}_{\mathrm{RT}_h}\cdot\nabla w, w)_K + (b_h w, w)_K \\ &= \varepsilon\|\nabla w\|^2_{0;K} + \int_K \frac{1}{2}\operatorname{div}(\underline{a}_{\mathrm{RT}_h}w^2) + \int_K\left\{b_h - \frac{1}{2}\operatorname{div}\underline{a}_{\mathrm{RT}_h}\right\}w^2 \\ &= \varepsilon\|\nabla w\|^2_{0;K} + \int_{\partial K}\frac{1}{2}\underline{n}_K\cdot\underline{a}_{\mathrm{RT}_h}w^2 + \int_K\left\{b_h - \frac{1}{2}\operatorname{div}\underline{a}_{\mathrm{RT}_h}\right\}w^2 \\ &\ge \varepsilon\|\nabla w\|^2_{0;K} + \beta\|w\|^2_{0;K}.\end{aligned}$$

In the last step we have used estimate (6.4) and the definition of $\widetilde{V}_K$, which implies that $\int_{\partial K}\frac{1}{2}\underline{n}_K\cdot\underline{a}_{\mathrm{RT}_h}w^2 \ge 0$. □

We denote by $\widetilde{v}_K \in \widetilde{V}_K$ the unique solution of problem (6.1) and define the error indicator $\eta_{N,K}$ by

$$\eta_{N,K} = \left\{|||\widetilde{v}_k|||^2_K + \alpha_K^2\|\underline{a}_{\mathrm{RT}_h}\cdot\nabla\widetilde{v}_K\|^2_{0;K}\right\}^{1/2}. \tag{6.7}$$

Remark 6.2. The function $\widetilde{v}_K$ is a finite element approximation to the solution $\widetilde{u}_K$ of the local convection-diffusion problem

$$\begin{aligned}-\varepsilon\Delta\widetilde{u}_K + \underline{a}\nabla\cdot\widetilde{u}_K + b\widetilde{u}_K &= R_K \quad \text{in } K,\\ \varepsilon\underline{n}_K\cdot\nabla\widetilde{u}_K &= R_E \quad \text{on } E\ ,\ E\in\mathcal{E}_K^+,\\ \widetilde{u}_K &= 0 \quad \text{on } \partial K\backslash\cup_{E\in\mathcal{E}_K^+}E.\end{aligned}$$

Due to the approximation of the convection and reaction terms, problem (6.1) is different from problem (5.7) in [10]. Moreover the present error indicator also takes into account the convective derivative of $\widetilde{v}_K$. These modifications are crucial for obtaining fully robust error estimates.

THEOREM 6.3. *There are two constants $\widetilde{c}_\dagger$ and $\widetilde{c}^\dagger$ which depend only on the polynomial degree k and on the ratios h_K/ρ_K such that the estimate*

$$\frac{1}{\widetilde{c}_\dagger}\left\{\alpha_K^2\|R_K\|_{0;K}^2+\sum_{E\in\mathcal{E}_K^+}\varepsilon^{-1/2}\alpha_E\|R_E\|_{0;E}^2\right\}^{1/2}\le\eta_{N,K}\le\widetilde{c}^\dagger\eta_K \tag{6.8}$$

holds for all elements K. Moreover $\eta_{N,K}$ yields the upper error bound

$$|||u-u_h|||+|||\underline{a}\cdot\nabla(u-u_h)|||_*\le\widetilde{c}^*\left\{\sum_{K\in\mathcal{T}_h}\left[\eta_{N,K}^2+\Theta_K^2\right]\right\}^{1/2} \tag{6.9}$$

and the lower error bound

$$\left\{\sum_{K\in\mathcal{T}_h}\eta_{N,K}^2\right\}^{1/2}\le\widetilde{c}_*\left[|||u-u_h|||+|||\underline{a}\cdot\nabla(u-u_h)|||_*+\left\{\sum_{K\in\mathcal{T}_h}\Theta_K^2\right\}^{1/2}\right]. \tag{6.10}$$

The constants $\widetilde{c}_*$ and $\widetilde{c}^*$ depend only on the polynomial degree k and on the ratios h_K/ρ_K.

Proof. Estimate (6.8) is proven with the same arguments as estimate (5.7). The error bounds (6.9) and (6.10) follow from estimate (6.8), Theorem 4.1, and the observation that for every edge, respectively, face, E, which is not part of the Dirichlet boundary Γ_D, there is at least one element K_E with $E\in\mathcal{E}_{K_E}^+$. □

Acknowledgments. The main part of this work was carried out during a stay at the Department of Mathematics of the Polytechnico di Torino. We want to thank Prof. Claudio Canuto and Dr. Stefano Berrone for their kind hospitality and the many fruitful discussions.

ROBUST A POSTERIORI ERROR ESTIMATES FOR NONSTATIONARY CONVECTION-DIFFUSION EQUATIONS[*]

R. VERFÜRTH[†]

Abstract. We consider discretizations of convection dominated nonstationary convection-diffusion equations by A-stable θ-schemes in time and conforming finite elements in space on locally refined, isotropic meshes. For these discretizations we derive a residual a posteriori error estimator. The estimator yields upper bounds on the error which are global in space and time and lower bounds that are global in space and local in time. The error estimates are fully robust in the sense that the ratio between upper and lower bounds is uniformly bounded in time, does not depend on any step-size in space or time nor on any relation between these both, and is uniformly bounded with respect to the size of the convection. Moreover, the estimates are uniform with respect to the size of the zero-order reaction term and also hold for the limit case of vanishing reaction.

Key words. a posteriori error estimates, convection dominated convection-diffusion equations, θ-scheme

1. Introduction.

We consider nonstationary convection-diffusion equations

$$\begin{aligned} \frac{\partial u}{\partial t} - \varepsilon\Delta u + \underline{a}\cdot\nabla u + bu &= f \qquad \text{in } \Omega\times(0,T], \\ u &= 0 \qquad \text{on } \Gamma_D\times(0,T], \\ \varepsilon\frac{\partial u}{\partial n} &= g \qquad \text{on } \Gamma_N\times(0,T], \\ u &= u_0 \quad \text{in } \Omega \end{aligned} \tag{1.1}$$

in a bounded space-time cylinder with a polygonal cross-section $\Omega\subset\mathbb{R}^d$, $d\geq 2$, having a Lipschitz boundary Γ consisting of two disjoint parts Γ_D and Γ_N. The final time T is arbitrary, but kept fixed in what follows. We assume that the data satisfy the following conditions:

(A1) $f\in C(0,T;L^2(\Omega))$, $g\in C(0,T;L^2(\Gamma_N))$, $\underline{a}\in C(0,T;W^{1,\infty}(\Omega)^d)$, $b\in C(0,T;L^\infty(\Omega))$.

(A2) $0<\varepsilon\ll 1$.

(A3) There are two constants $\beta\geq 0$ and $c_b\geq 0$, which do not depend on ε, such that $-\frac{1}{2}\mathrm{div}\underline{a}+b\geq\beta$ and $\|b\|_{L^\infty(\Omega)}\leq c_b\beta$ in $(0,T]$.

(A4) The Dirichlet boundary Γ_D has positive $(d-1)$-dimensional measure and includes the inflow boundary $\{x\in\Gamma : \underline{a}(x)\cdot\underline{n}(x)<0\}$.

Assumption (A3) allows us to handle simultaneously the case of a nonvanishing zero-order reaction term and the one of absent reaction, the latter one corresponding to $\beta=0$. In the case $\beta=0$ we set $c_b=0$. Assumption (A2) of course means that we are interested in the convection-dominated regime. Assumption (A1) can be replaced

by weaker conditions concerning the temporal smoothness. Its present form, however, simplifies the analysis.

We use the A-stable θ-schemes for the time discretization of problem (1.1). The spatial discretization is based on standard conforming finite element spaces using the standard Galerkin formulation or a stabilized SUPG-scheme. The spatial meshes must be shape-regular (cf. section 2). This includes locally refined meshes but excludes anisotropic elements with large aspect ratios. For this space-time discretization we analyze a residual error estimator and establish upper and lower bounds for the error. The upper bounds are global with respect to space and time; the lower bounds are global with respect to space and local with respect to time. The ratio of upper and lower bounds is uniformly bounded with respect to any mesh-size, to the final time, to the parameter β, and—most important—to the viscosity ε. Thus the error estimates are fully robust. Contrary to standard residual error estimates, the present estimator requires the solution of an auxiliary discrete stationary reaction-diffusion problem at each time-level. This is the price that we must pay for the ε-independent bounds. The computational effort for evaluating the error estimator is thus comparable to an additional time-step for each time-level and similar to the extra work required by the now popular estimators that are based on the solution of suitable discrete adjoint problems [3].

The article is organized as follows. In section 2 we introduce some function spaces and norms. Section 3 is devoted to the finite element discretization. Using energy estimates we prove in section 4 that the error is equivalent to a residual which is defined in a suitable dual space. This residual is split into three parts: one corresponding to the approximation of the data, a contribution corresponding to a spatial error, and a part corresponding to a temporal error. The latter can be further decomposed into a diffusive and a convective part. In section 5 we derive upper and lower bounds for the spatial part of the residual. The temporal part is treated in section 6. Combining these results we obtain in section 7 a first error estimator. This estimator yields upper and lower bounds on the error and is fully robust in the sense described above. However, it is not suited for practical computations since it incorporates a dual norm of the convective derivative of the finite element solution. This contribution is due to the convective part of the temporal residual. Standard approaches bound this contribution by inverse estimates and therefore lead to estimates that are no longer robust. The results of section 7 show that sharp upper and lower bounds with parameter-independent constants for this term are mandatory for obtaining a robust and computable a posteriori error estimator. In section 8 we finally bound the critical dual norm by computable quantities based on the solution of a discrete stationary reaction-diffusion problem at each time-level. This yields our final error estimates which are stated in Theorem 8.2.

2. Function spaces. For any bounded open subset ω of Ω with Lipschitz boundary γ, we denote by $H^k(\omega)$, $k \in \mathbb{N}$, $L^2(\omega) = H^0(\omega)$, and $L^2(\gamma)$ the usual Sobolev and Lebesgue spaces equipped with the standard norms $\|.\|_{k;\omega} = \|.\|_{H^k(\omega)}$ and $\|.\|_{0;\gamma} = \|.\|_{L^2(\gamma)}$ (cf. [1]). Similarly, $(.,.)_\omega$ and $(.,.)_\gamma$ denote the scalar products of $L^2(\omega)$ and $L^2(\gamma)$, respectively. If $\omega = \Omega$, we will omit the index Ω.

Set

$$H^1_D(\Omega) = \{v \in H^1(\Omega) : v = 0 \text{ on } \Gamma_D\}. \tag{2.1}$$

We equip $H^1_D(\Omega)$ with the norm

$$|||v||| = \left\{\varepsilon\|\nabla v\|_0^2 + \beta\|v\|_0^2\right\}^{1/2}. \tag{2.2}$$

Due to assumptions (A3) and (A4) this is the natural energy norm of problem (1.1). The dual space of $H_D^1(\Omega)$ is denoted by $H_D^1(\Omega)^*$ and equipped with the norm

$$|||\varphi|||_* = \sup_{v\in H_D^1(\Omega)\setminus\{0\}} \frac{\langle\varphi, v\rangle}{|||v|||}, \tag{2.3}$$

where $\langle .,.\rangle$ denotes the corresponding duality pairing.

$H^{1/2}(\Gamma_N)$ denotes the space of Γ_N-traces of H^1-functions and is equipped with the trace norm induced by the energy norm, i.e.,

$$\|\varphi\|_{H^{1/2}(\Gamma_N)} = \inf\left\{|||v||| : v \in H_D^1(\Omega)\ ,\ v = \varphi \text{ on } \Gamma_N\right\}.$$

$H^{-1/2}(\Gamma_N)$ denotes the dual space of $H^{1/2}(\Gamma_N)$ and is equipped with the corresponding dual norm. Thus the norms of $H^{1/2}(\Gamma_N)$ and $H^{-1/2}(\Gamma_N)$ depend on the energy norm and consequently on the parameters ε and β.

For any separable Banach space V and any two numbers $a < b$ we denote by $L^2(a, b; V)$ and $L^\infty(a, b; V)$ the spaces of measurable functions u defined on (a, b) with values in V such that the function $t \to \|u(., t)\|_V$ is square integrable, respectively, essentially bounded. These are Banach spaces equipped with the norms

$$\begin{aligned}\|u\|_{L^2(a,b;V)} &= \left\{\int_a^b \|u(., t)\|_V^2 dt\right\}^{1/2},\\ \|u\|_{L^\infty(a,b;V)} &= \operatorname*{ess.sup}_{a<t<b} \|u(., t)\|_V\end{aligned}$$

(cf. [4, Vol. 5, Chap. XVIII, sect. 1]). For abbreviation we introduce the space

$$\begin{aligned}X(a, b) = \big\{u \in L^2(a, b; H_D^1(\Omega)) \cap L^\infty(a, b; L^2(\Omega)) :&\\ \partial_t u + \underline{a}\cdot\nabla u \in L^2(a, b; H_D^1(\Omega)^*)\big\}&\end{aligned} \tag{2.4}$$

and equip it with its graph norm

$$\begin{aligned}\|u\|_{X(a,b)} = \Bigg\{\operatorname*{ess.sup}_{a<t<b} \|u(., t)\|_0^2 + \int_a^b |||u(., t)|||^2 dt&\\ + \int_a^b |||(\partial_t u + \underline{a}\cdot\nabla u)(., t)|||_*^2 dt\Bigg\}^{1/2}&.\end{aligned} \tag{2.5}$$

Here the derivative $\partial_t u$ has to be understood in the distributional sense [4, Vol. 5, Chap. 18, Sect. 1].

The weak form of problem (1.1) consists in finding $u \in L^2(0, T; H_D^1(\Omega))$ such that $\partial_t u \in L^2(0, T; H_D^1(\Omega)^*)$, $u(., 0) = u_0$ in $H_D^1(\Omega)^*$, and for almost every $t \in (0, T)$ and all $v \in H_D^1(\Omega)$

$$(\partial_t u, v) + \varepsilon(\nabla u, \nabla v) + (\underline{a}\cdot\nabla u, v) + (bu, v) = (f, v) + (g, v)_{\Gamma_N}. \tag{2.6}$$

Assumptions (A1)–(A4) imply that problem (2.3) admits a unique solution [2], [4].

For later use we note that integration by parts and assumptions (A3) and (A4) imply

$$\varepsilon(\nabla v, \nabla v) + (\underline{a}\cdot\nabla v, v) + (bv, v) \geq |||v|||^2 \quad \forall v \in H_D^1(\Omega). \tag{2.7}$$

Similarly, assumption (A3) and definition (2.2) imply

$$\varepsilon(\nabla v, \nabla w) + (bv, w) \le \max\{c_b, 1\} |||v|||\, |||w||| \quad \forall v, w \in H_D^1(\Omega). \tag{2.8}$$

3. Finite element discretization. For the discretization we choose an integer $N \ge 1$ and intermediate times $0 = t_0 < t_1 < \cdots < t_N = T$ and set $\tau_n = t_n - t_{n-1}$, $1 \le n \le N$. With each intermediate time t_n, $0 \le n \le N$, we associate a partition $\mathcal{T}_{h,n}$ of Ω and a corresponding finite element space $X_{h,n}$. These have to satisfy the following conditions:

(1) *Affine equivalence:* every element $K \in \mathcal{T}_{h,n}$ can be mapped by an invertible affine mapping onto the standard reference d-simplex or the standard unit cube in $\mathbb{R}^d$.

(2) *Admissibility:* any two elements are either disjoint or share a vertex, or a complete edge, or (if $d = 3$) a complete face.

(3) *Shape-regularity:* for any element K the ratio of its diameter h_K to the diameter ρ_K of the largest inscribed ball is bounded uniformly with respect to all partitions $\mathcal{T}_{h,n}$ and to N.

(4) *Transition condition:* for $1 \le n \le N$ there is an affinely equivalent, admissible, and shape-regular partition $\widetilde{\mathcal{T}}_{h,n}$ such that it is a refinement of both $\mathcal{T}_{h,n}$ and $\mathcal{T}_{h,n-1}$ and such that $\sup_{1\le n\le N} \sup_{K\in\widetilde{\mathcal{T}}_{h,n}} \sup_{K'\in\mathcal{T}_{h,n}; K\subset K'} \frac{h_{K'}}{h_K} < \infty$.

(5) Each $X_{h,n}$ is a subset of $H_D^1(\Omega)$ and consists of continuous functions which are piecewise polynomials, the degrees being bounded uniformly with respect to all partitions $\mathcal{T}_{h,n}$ and to N.

(6) Each $X_{h,n}$ contains the space of continuous, piecewise linear finite elements corresponding to $\mathcal{T}_{h,n}$.

Condition (1) restricts quadrilateral elements to parallelograms and cubic elements to parallelepipeds. In two dimensions, triangular and quadrilateral elements may be mixed. In three dimensions this is also possible if one adds prismatic elements.

Condition (2) excludes hanging nodes.

Condition (3) is a standard one and allows for locally refined meshes. However, it excludes anisotropic elements with large aspect ratios.

Condition (4) is due to the simultaneous presence of finite element functions defined on different grids. In practice the partition $\mathcal{T}_{h,n}$ is usually obtained from $\mathcal{T}_{h,n-1}$ by a combination of refinement and of coarsening. In this case condition (4) restricts only the coarsening. It must not be too abrupt nor too strong.

We choose a parameter $\theta \in [\frac{1}{2}, 1]$ and keep it fixed in what follows. For every time-level $n \ge 1$ we introduce the abbreviations

$$\begin{aligned} f^{n\theta} &= \theta f(., t_n) + (1-\theta) f(., t_{n-1}), \\ g^{n\theta} &= \theta g(., t_n) + (1-\theta) g(., t_{n-1}), \\ \underline{a}^{n\theta} &= \theta \underline{a}(., t_n) + (1-\theta) \underline{a}(., t_{n-1}), \\ b^{n\theta} &= \theta b(., t_n) + (1-\theta) b(., t_{n-1}). \end{aligned}$$

Furthermore we denote by π_0 the L^2-projection onto $X_{h,0}$.

Then the space-time discretization of problem (1.1) consists in finding $u_h^n \in X_{h,n}$, $0 \le n \le N$, such that

$$u_h^0 = \pi_0 u_0 \tag{3.1}$$

and, for $n = 1, \dots, N$, and all $v_h \in X_{h,n}$

$$
\begin{aligned}
\left(\frac{u_h^n - u_h^{n-1}}{\tau_n}, v_h\right) &+ \varepsilon(\theta\nabla u_h^n + (1-\theta)\nabla u_h^{n-1}, \nabla v_h) \\
&+ (\underline{a}^{n\theta} \cdot \nabla(\theta u_h^n + (1-\theta)u_h^{n-1}), v_h) \\
&+ (b^{n\theta}(\theta u_h^n + (1-\theta)u_h^{n-1}), v_h) \\
&+ \sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \delta_K \bigg(\frac{u_h^n - u_h^{n-1}}{\tau_n} - \varepsilon\Delta(\theta u_h^n + (1-\theta)u_h^{n-1}) \\
&\qquad + \underline{a}^{n\theta} \cdot \nabla(\theta u_h^n + (1-\theta)u_h^{n-1}) \\
&\qquad + b^{n\theta}(\theta u_h^n + (1-\theta)u_h^{n-1})\ ,\ \underline{a}^{n\theta} \cdot \nabla v_h\bigg)_K \\
&= (f^{n\theta}, v_h) + (g^{n\theta}, v_h)_{\Gamma_N} + \sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \delta_K (f^{n\theta}, \underline{a}^{n\theta} \cdot \nabla v_h)_K.
\end{aligned}
\tag{3.2}
$$

The δ_K are nonnegative stabilization parameters. The choice $\delta_K = 0$ for all K yields the standard Galerkin discretization; the choice $\delta_K > 0$ for all K corresponds to the SUPG-discretizations (cf., e.g., [5], [6]). In what follows we will always assume that

$$
\delta_K \|\underline{a}^{n\theta}\|_{L^\infty(K)} \le h_K \quad \forall K \in \widetilde{\mathcal{T}}_{h,n},\ 0 \le n \le N.
\tag{3.3}
$$

This condition is satisfied for all choices of δ_K used in practice.

Assumptions (A3), (A4), and (3.3) and standard arguments for SUPG-discretizations (cf., e.g., [5], [6]) imply that problems (3.1), (3.2) admit a unique solution $(u_h^n)_{0\le n\le N}$. With this sequence we associate the function $u_{h,\tau}$ which is *piecewise affine* on the time-intervals $[t_{n-1}, t_n]$, $1 \le n \le N$, and which equals u_h^n at time t_n, $0 \le n \le N$. Since the function $t \to u_{h,\tau}(.,t)$ is continuous and piecewise affine with values in $H_D^1(\Omega)$, it is differentiable in the distributional sense [4, Vol. 5, Chap. XVIII, sect. 1] and its weak derivative satisfies

$$
\partial_t u_{h,\tau} = \frac{u_h^n - u_h^{n-1}}{\tau_n} \quad \text{on } (t_{n-1}, t_n).
\tag{3.4}
$$

4. The equivalence of error and residual.

With the function $u_{h,\tau}$ defined by the solution of problems (3.1), (3.2) we associate the residual $R(u_{h,\tau}) \in L^2(0,T; H_D^1(\Omega)^*)$ via

$$
\begin{aligned}
\langle R(u_{h,\tau}), v\rangle = (f, v) + (g, v)_{\Gamma_N} &- (\partial_t u_{h,\tau}, v) - \varepsilon(\nabla u_{h,\tau}, \nabla v) \\
&- (\underline{a} \cdot \nabla u_{h,\tau}, v) - (b u_{h,\tau}, v)
\end{aligned}
\tag{4.1}
$$

for all $v \in H_D^1(\Omega)$. The following lemma shows that this residual and the error $u - u_{h,\tau}$ are equivalent. Its proof is based on standard energy estimates. Recall that $H_D^1(\Omega)$ and its dual space $H_D^1(\Omega)^*$ are equipped with the energy norm $|||.|||$ and the dual norm $|||.|||_*$, respectively.

LEMMA 4.1. *For all $w \in L^2(0,T; H_D^1(\Omega))$ the following lower bound on the error holds:*

$$
\int_0^T \langle R(u_{h,\tau}), w\rangle dt \le \sqrt{2}\max\{1, c_b\}\|u - u_{h,\tau}\|_{X(0,T)} \|w\|_{L^2(0,T;H_D^1(\Omega))},
\tag{4.2}
$$

where c_b is the constant of assumption (A3). *Conversely, for all n between* 1 *and N, the error can be bounded from above by*

$$\begin{aligned}\|u-u_{h,\tau}\|_{X(0,t_n)} \leq \Big\{&2(1+\max\{1,c_b\}^2)\|u_0-\pi_0 u_0\|_0^2 \\ &+2(2+\max\{1,c_b\}^2)\|R(u_{h,\tau})\|^2_{L^2(0,t_n;H^1_D(\Omega)^*)}\Big\}^{1/2}.\end{aligned}\tag{4.3}$$

Proof. Equations (2.6) and (4.1) imply for all $v \in H^1_D(\Omega)$ that

$$\begin{aligned}&(\partial_t(u-u_{h,\tau}),v)+\varepsilon(\nabla(u-u_{h,\tau}),\nabla v) \\ &\qquad+(\underline{a}\cdot\nabla(u-u_{h,\tau}),v)+(b(u-u_{h,\tau}),v)=\langle R(u_{h,\tau}),v\rangle.\end{aligned}\tag{4.4}$$

This identity, definitions (2.2) and (2.3) of the norms $|||.|||$ and $|||.|||_*$, and inequality (2.8) yield for all $0<t<T$ and all $v\in H^1_D(\Omega)$ the estimate

$$\begin{aligned}\langle R(u_{h,\tau}),v\rangle \leq\; &|||(\partial_t(u-u_{h,\tau})+\underline{a}\cdot\nabla(u-u_{h,\tau}))(.,t)|||_*|||v||| \\ &+\max\{1,c_b\}|||(u-u_{h,\tau})(.,t)|||\;|||v|||.\end{aligned}$$

Taking into account the definitions (2.4), (2.5) of $X(0;T)$ and of its norm, this estimate proves the bound (4.2).

To prove estimate (4.3) we choose an integer n between 1 and N and a time t between 0 and t_n and insert $v=(u-u_{h,\tau})(.,t)$ in (4.4). Taking into account (2.7), this gives

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\|(u-u_{h,\tau})(.,t)\|_0^2+|||(u-u_{h,\tau})(.,t)|||^2 \\ &\quad\leq(\partial_t(u-u_{h,\tau})(.,t),(u-u_{h,\tau})(.,t))+\varepsilon(\nabla(u-u_{h,\tau})(.,t),\nabla(u-u_{h,\tau})(.,t)) \\ &\qquad+(\underline{a}\cdot\nabla(u-u_{h,\tau})(.,t),(u-u_{h,\tau})(.,t))+(b(u-u_{h,\tau})(.,t),(u-u_{h,\tau})(.,t)) \\ &\quad=\langle R(u_{h,\tau})(.,t),(u-u_{h,\tau})(.,t)\rangle \\ &\quad\leq|||R(u_{h,\tau})(.,t)|||_*|||(u-u_{h,\tau})(.,t)||| \\ &\quad\leq\frac{1}{2}|||R(u_{h,\tau})(.,t)|||_*^2+\frac{1}{2}|||(u-u_{h,\tau})(.,t)|||^2\end{aligned}$$

and thus

$$\frac{d}{dt}\|(u-u_{h,\tau})(.,t)\|_0^2+|||(u-u_{h,\tau})(.,t)|||^2\leq|||R(u_{h,\tau})(.,t)|||_*^2.$$

Integrating this estimate from 0 to t implies

$$\begin{aligned}\|(u-u_{h,\tau})(.,t)\|_0^2-\|u_0-\pi_0u_0\|_0^2+\int_0^t|||(u-u_{h,\tau})(.,s)|||^2\,ds \\ \leq\|R(u_{h,\tau})\|^2_{L^2(0,t;H^1_D(\Omega)^*)} \\ \leq\|R(u_{h,\tau})\|^2_{L^2(0,t_n;H^1_D(\Omega)^*)}.\end{aligned}$$

Since $t\in(0,t_n]$ was arbitrary, this yields

$$\|u-u_{h,\tau}\|^2_{L^\infty(0,t_n;L^2(\Omega))}\leq\|u_0-\pi_0u_0\|_0^2+\|R(u_{h,\tau})\|^2_{L^2(0,t_n;H^1_D(\Omega)^*)}\tag{4.5}$$

and

$$\|u-u_{h,\tau}\|^2_{L^2(0,t_n;H^1_D(\Omega))}\leq\|u_0-\pi_0u_0\|_0^2+\|R(u_{h,\tau})\|^2_{L^2(0,t_n;H^1_D(\Omega)^*)}.\tag{4.6}$$

Equation (4.4) and estimate (2.8), on the other hand, imply

$$|||\partial_t(u-u_{h,\tau}) + \underline{a}\cdot\nabla(u-u_{h,\tau})|||_* \le |||R(u_{h,\tau})|||_* + \max\{1,c_b\}|||u-u_{h,\tau}|||.$$

Taking the square of this inequality, integrating from 0 to t_n, and inserting estimate (4.6) we arrive at

$$\begin{aligned}
&\|\partial_t(u-u_{h,\tau}) + \underline{a}\cdot\nabla(u-u_{h,\tau})\|^2_{L^2(0,t_n;H^1_D(\Omega)^*)}\\
&\quad\le 2\|R(u_{h,\tau})\|^2_{L^2(0,t_n;H^1_D(\Omega)^*)} + 2\max\{1,c_b\}^2\|u-u_{h,\tau}\|^2_{L^2(0,t_n;H^1_D(\Omega))}\\
&\quad\le 2\max\{1,c_b\}^2\|u_0-\pi_0u_0\|^2_0\\
&\qquad + 2(1+\max\{1,c_b\}^2)\|R(u_{h,\tau})\|^2_{L^2(0,t_n;H^1_D(\Omega)^*)}.
\end{aligned}\tag{4.7}$$

Combining estimates (4.5)–(4.7) proves the bound (4.3). □

The subsequent analysis relies on an appropriate decomposition of the residual $R(u_{h,\tau})$. To this end we define a temporal residual $R_\tau(u_{h,\tau}) \in L^2(0,T;H^1_D(\Omega)^*)$ and a spatial residual $R_h(u_{h,\tau}) \in L^2(0,T;H^1_D(\Omega)^*)$ by setting, for all $v \in H^1_D(\Omega)$ and all $1 \le n \le N$,

$$\begin{aligned}
\langle R_\tau(u_{h,\tau}),v\rangle &= \varepsilon(\nabla[\theta u_h^n + (1-\theta)u_h^{n-1} - u_{h,\tau}],\nabla v)\\
&\quad + (\underline{a}^{n\theta}\cdot\nabla[\theta u_h^n + (1-\theta)u_h^{n-1} - u_{h,\tau}],v)\\
&\quad + (b^{n\theta}[\theta u_h^n + (1-\theta)u_h^{n-1} - u_{h,\tau}],v) \qquad \text{on } (t_{n-1},t_n]
\end{aligned}\tag{4.8}$$

and

$$\begin{aligned}
\langle R_h(u_{h,\tau}),v\rangle &= (f^{n\theta},v) + (g^{n\theta},v)_{\Gamma_N} - \left(\frac{u_h^n - u_h^{n-1}}{\tau_n},v\right)\\
&\quad - \varepsilon(\theta\nabla u_h^n + (1-\theta)\nabla u_h^{n-1},\nabla v)\\
&\quad - (\underline{a}^{n\theta}\cdot\nabla[\theta u_h^n + (1-\theta)u_h^{n-1}],v)\\
&\quad - (b^{n\theta}[\theta u_h^n + (1-\theta)u_h^{n-1}],v) \qquad \text{on } (t_{n-1},t_n].
\end{aligned}\tag{4.9}$$

The time discretization of the data is taken into account by a data-residual $R_D(u_{h,\tau}) \in L^2(0,T;H^1_D(\Omega)^*)$ which is defined by

$$\begin{aligned}
\langle R_D(u_{h,\tau}),v\rangle &= (f-f^{n\theta},v) + (g-g^{n\theta},v)_{\Gamma_N}\\
&\quad + ((\underline{a}^{n\theta}-\underline{a})\cdot\nabla u_{h.\tau},v) + ((b^{n\theta}-b)u_{h,\tau},v) \quad \text{on } (t_{n-1},t_n].
\end{aligned}\tag{4.10}$$

From (3.4) we obtain the decomposition

$$R(u_{h,\tau}) = R_D(u_{h,\tau}) + R_\tau(u_{h,\tau}) + R_h(u_{h,\tau}).\tag{4.11}$$

5. Estimation of the spatial residual. The techniques required for the estimation of the spatial residual $R_h(u_{h,\tau})$ are similar to those used in the stationary case [10, sect. 4]. But it should be stressed that we are not interested in estimating the error between $u_{h,\tau}$ and the solution of the variational problem obtained from the temporal semidiscretization of (1.1). Moreover, we have to pay particular attention to the fact that $u_{h,\tau}$ is the linear interpolant of the functions $(u_h^n)_{0\le n\le N}$ that live on different spatial meshes.

We denote by $\widetilde{\mathcal{E}}_{h,n}$, $1 \le n \le N$, the set of all edges (if $d = 2$), respectively, faces (if $d = 3$), of $\widetilde{\mathcal{T}}_{h,n}$. With each edge or face $E \in \widetilde{\mathcal{E}}_{h,n}$ we associate a unit vector $\underline{n}_E$

orthogonal to E such that it points to the outward of Ω if E lies on the boundary. For every edge or face E that is not contained in the boundary Γ we denote by $[.]_E$ the jump across E in direction $\underline{n}_E$. The quantity $[.]_E$ of course depends on the orientation of $\underline{n}_E$, but quantities of the form $[\underline{n}_E \cdot .]_E$ are independent thereof. With each edge, respectively, face, we associate the set ω_E which is the union of the elements that share E.

We denote by $f_{h,\tau}$, $g_{h,\tau}$, $\underline{a}_{h,\tau}$, and $b_{h,\tau}$ functions which are *piecewise constant* on the time-intervals and which, on each interval $(t_{n-1}, t_n]$, equal the L^2-projection of $f^{n\theta}$, $g^{n\theta}$, $\underline{a}^{n\theta}$, and $b^{n\theta}$ respectively onto the space of piecewise constant functions corresponding to $\mathcal{T}_{h,n}$. With this notation we define element residuals R_K, $K \in \widetilde{\mathcal{T}}_{h,n}$, $1 \le n \le N$, by

$$\begin{aligned} R_K = f_{h,\tau} &- \frac{u_h^n - u_h^{n-1}}{\tau_n} + \varepsilon\Delta(\theta u_h^n + (1-\theta)u_h^{n-1}) \\ &- \underline{a}_{h,\tau} \cdot \nabla(\theta u_h^n + (1-\theta)u_h^{n-1}) - b_{h,\tau}(\theta u_h^n + (1-\theta)u_h^{n-1}), \end{aligned} \tag{5.1}$$

edge, respectively, face, residuals R_E, $E \in \widetilde{\mathcal{E}}_{h,n}$, $1 \le n \le N$, by

$$R_E = \begin{cases} -\left[\varepsilon \underline{n}_E \cdot \nabla(\theta u_h^n + (1-\theta)u_h^{n-1})\right]_E & \text{if } E \not\subset \Gamma, \\ g_{h,\tau} - \varepsilon \underline{n}_E \cdot \nabla(\theta u_h^n + (1-\theta)u_h^{n-1}) & \text{if } E \subset \Gamma_N, \\ 0 & \text{if } E \subset \Gamma_D, \end{cases} \tag{5.2}$$

elementwise data errors D_K, $K \in \widetilde{\mathcal{T}}_{h,n}$, $1 \le n \le N$, by

$$\begin{aligned} D_K = \big\{ f^{n\theta} &- f_{h,\tau} + (\underline{a}_{h,\tau} - \underline{a}^{n\theta})\nabla \cdot (\theta u_h^n + (1-\theta)u_h^{n-1}) \\ &+ (b_{h,\tau} - b^{n\theta})(\theta u_h^n + (1-\theta)u_h^{n-1}) \big\}_{|K}, \end{aligned} \tag{5.3}$$

and edge-, respectively, facewise, data errors D_E, $E \in \widetilde{\mathcal{E}}_{h,n} \cap \Gamma_N$, $1 \le n \le N$, by

$$D_E = g^{n\theta} - g_{h,\tau}. \tag{5.4}$$

Here, of course, $(u_h^n)_{0 \le n \le N}$ denotes the solution of problems (3.1) and (3.2).

Note that, as usual, the residuals R_K are defined elementwise. In particular Δu_h^n and Δu_h^{n-1} must be interpreted as the Laplacian applied to the restriction to K of the corresponding functions. Here, we need the transition condition that $\widetilde{\mathcal{T}}_{h,n}$ is a common refinement of $\mathcal{T}_{h,n}$ and $\mathcal{T}_{h,n-1}$.

For every n between 1 and N we denote by $\mathcal{N}_{h,n}$ the set of all element vertices in $\mathcal{T}_{h,n}$ that do not lie on the Dirichlet boundary Γ_D. With every vertex $x \in \mathcal{N}_{h,n}$ we associate the nodal bases function λ_x which is uniquely defined by the properties

$$\lambda_{x|K} \in R_1(K) \quad \forall K \in \mathcal{T}_{h,n}, \quad \lambda_x(y) = 0 \quad \forall y \in \mathcal{N}_{h,n} \backslash \{x\}, \quad \lambda_x(x) = 1.$$

Here, as usual, $R_k(K)$ denotes the set of all polynomials of total degree k, if K is a simplex, and of maximal degree k, if K is a parallelepiped. The support of a nodal basis function λ_x is denoted by ω_x and consists of all elements in $\mathcal{T}_{h,n}$ that share the vertex x. With this notation we can define a Clément-type interpolation operator $I_{h,n} : L^1(\Omega) \longrightarrow \{\varphi \in C(\Omega) : \varphi_{|K} \in R_1(K) \text{ for all } K \in \mathcal{T}_{h,n}, \varphi = 0 \text{ on } \Gamma_D\}$ by (cf. [9])

$$I_{h,n} v = \sum_{x \in \mathcal{N}_{h,n}} \left\{ \frac{1}{|\omega_x|} \int_{\omega_x} v \right\} \lambda_x. \tag{5.5}$$

Here $|\omega_x|$ denotes the d-dimensional Lebesgue-measure of ω_x. Due to condition (6) of section 3 the image of $I_{h,n}$ is contained in $X_{h,n}$.

LEMMA 5.1. *For every $S \in \widetilde{\mathcal{T}}_{h,n} \cup \widetilde{\mathcal{E}}_{h,n}$, $1 \le n \le N$, denote by h_S its diameter and set*

$$\alpha_S = \min\{h_S \varepsilon^{-1/2}, \beta^{-1/2}\}. \tag{5.6}$$

Then the following estimates hold for all n between 1 and N, all elements $K \in \widetilde{\mathcal{T}}_{h,n}$, all edges, respectively, faces, E of K, and all functions $v \in H^1_D(\Omega)$:

$$\begin{aligned}\|v - I_h v\|_{0;K} &\le c_1 \alpha_K |||v|||_{\tilde{\omega}_K},\\ \|v - I_h v\|_{0;E} &\le c_2 \varepsilon^{-1/4} \alpha_E^{1/2} |||v|||_{\tilde{\omega}_K},\\ |||I_h v|||_K &\le c_3 |||v|||_{\tilde{\omega}_K}.\end{aligned}$$

Here, $\tilde{\omega}_K$ is the union of all elements in $\mathcal{T}_{h,n}$ that share at least one vertex with the element $K' \in \mathcal{T}_{h,n}$ that contains K and $|||.|||_A$ denotes the restriction of $|||.|||$ to the measurable set A.

Proof. The proof of Lemma 5.1 follows from Lemma 3.1 in [7] and Proposition 2.1 in [8] with the arguments used in the proof of Lemma 3.2 in [7]. □

Remark 5.2. In the case $\beta = 0$ the minimum in (5.6) of course yields $\alpha_S = \varepsilon^{-1/2} h_S$ for all S.

For every element $K \in \widetilde{\mathcal{T}}_{h,n}$, $1 \le n \le N$, we denote by $\mathcal{N}_K$ the set of its vertices and set

$$\psi_K = \gamma_K \prod_{x \in \mathcal{N}_K} \lambda_x, \tag{5.7}$$

where the constant γ_K is chosen such that ψ_K equals 1 at the barycenter of K. Note that the support of ψ_K is contained in K and that $\|\psi_K\|_{L^\infty(K)} = 1$.

For every edge, respectively, face, $E \in \widetilde{\mathcal{E}}_{h,n}$, $1 \le n \le N$, we set

$$\theta_E = \min\{\varepsilon^{1/2} \beta^{-1/2} h_E^{-1}, 1\} \tag{5.8}$$

and denote by $\mathcal{N}_E$ the set of its vertices. (Note that $\theta_E = 1$ in the case $\beta = 0$.) Consider first a face E that is not contained in the boundary. It is shared by exactly two elements $K_{E,1}$ and $K_{E,2}$. For $i = 1, 2$ we define an affine transformation $F_i : \mathbb{R}^n \longrightarrow \mathbb{R}^n$ as follows: We first map $K_{E,i}$ onto the reference element such that the image of E is contained in the hyperplane $\{x_d = 0\}$; then we apply the transformation $(x_1, \dots, x_{d-1}, x_d) \longrightarrow (x_1, \dots, x_{d-1}, \theta_E x_d)$; and finally we transform back using the inverse of the affine transformation of the first step. With this definition we set

$$\psi_E = \gamma_E \prod_{x \in \mathcal{N}_E} \lambda_x \circ F_i^{-1} \quad \text{on } K_{E,i},\ i = 1, 2, \tag{5.9}$$

where the constant γ_E is chosen such that ψ_E equals 1 at the barycenter of E. Note that the support of ψ_E is contained in $F_1(K_{E,1}) \cup F_2(K_{E,2}) \subset K_{E,1} \cup K_{E,2} = \omega_E$ and that $\|\psi_E\|_{L^\infty(E)} = 1$.

If an edge, respectively, face, E is contained in the Neumann boundary Γ_N, the definition of ψ_E is modified in the obvious way, taking into account that now E is the face of exactly one element K_E.

LEMMA 5.3. *The following estimates hold for all n between 1 and N, all elements $K \in \widetilde{\mathcal{T}}_{h,n}$, all polynomials $v \in R_k(K)$, all edges, respectively, faces, $E \in \widetilde{\mathcal{E}}_{h,n}$, and all polynomials $\sigma \in R_k(E)$:*

$$\begin{aligned}(v, \psi_K v)_K &\geq c_4 \|v\|_{0;K}^2,\\ |||\psi_K v|||_K &\leq c_5 \alpha_K^{-1} \|v\|_{0;K},\\ (\sigma, \psi_E \sigma)_E &\geq c_6 \|\sigma\|_{0;E}^2,\\ |||\psi_E \sigma|||_{\omega_E} &\leq c_7 \varepsilon^{1/4} \alpha_E^{-1/2} \|\sigma\|_{0;E},\\ \|\psi_E \sigma\|_{0;\omega_E} &\leq c_8 \varepsilon^{1/4} \alpha_E^{1/2} \|\sigma\|_{0;E}.\end{aligned}$$

Here, a polynomial σ defined on an edge, respectively, face, E is continued in the canonical way to a polynomial defined on $\mathbb{R}^d$. The constants $c_4, \dots, c_8$ depend only on the polynomial degree k in condition (5) *of section* 3 *and on the ratios h_K/ρ_K in condition* (3).

Proof. The estimates are proven with the same arguments as in the proof of Lemma 3.3 in [7]. For parallelepipeds one only has to take into account that the transformation to the unit cube is affine and thus has a constant Jacobian. □

With these preparations we are now ready to bound the spatial residual.

LEMMA 5.4. *For every n between 1 and N define a spatial error indicator η_h^n by*

$$\eta_h^n = \left\{ \sum_{K \in \widetilde{\mathcal{T}}_{h,n}} \alpha_K^2 \|R_K\|_{L^2(K)}^2 + \sum_{E \in \widetilde{\mathcal{E}}_{h,n}} \varepsilon^{-1/2} \alpha_E \|R_E\|_{L^2(E)}^2 \right\}^{1/2} \tag{5.10}$$

and a spatial data error indicator Θ_h^n by

$$\Theta_h^n = \left\{ \sum_{K \in \widetilde{\mathcal{T}}_{h,n}} \alpha_K^2 \|D_K\|_{L^2(K)}^2 + \sum_{E \in \widetilde{\mathcal{E}}_{h,n} \cap \Gamma_N} \varepsilon^{-1/2} \alpha_E \|D_E\|_{L^2(E)}^2 \right\}^{1/2}. \tag{5.11}$$

Then there are functions $w_n \in H_D^1(\Omega)$, $1 \leq n \leq N$, and constants $c^\dagger$ and $c_\dagger$ such that on each interval $(t_{n-1}, t_n]$, $1 \leq n \leq N$, the following estimates hold:

$$|||R_h(u_{h,\tau})|||_* \leq c^\dagger \{\eta_h^n + \Theta_h^n\} \tag{5.12}$$

and

$$\begin{aligned}(\eta_h^n)^2 &\leq \langle R_h(u_{h,\tau}), w_n \rangle + \Theta_h^n\, \eta_h^n,\\ |||w_n||| &\leq c_\dagger \eta_h^n.\end{aligned} \tag{5.13}$$

The constants $c^\dagger$ and $c_\dagger$ depend on the ratios h_K/ρ_K in condition (3) *of section* 3*. The constant $c^\dagger$ in addition depends on the ratios $h_{K'}/h_K$ in condition* (4)*. The constant $c_\dagger$ in addition depends on the maximum of the polynomial degrees of the finite element functions.*

Proof. Choose an integer n between 1 and N and keep it fixed in what follows.

Integration by parts on the elements in $\widetilde{\mathcal{T}}_{h,n}$ yields the following L^2-representation of the spatial residual:

$$\begin{aligned}\langle R_h(u_{h,\tau}), v \rangle = &\sum_{K \in \widetilde{\mathcal{T}}_{h,n}} (R_K, v)_K + \sum_{E \in \widetilde{\mathcal{E}}_{h,n}} (R_E, v)_E\\ &+ \sum_{K \in \widetilde{\mathcal{T}}_{h,n}} (D_K, v)_K + \sum_{E \in \widetilde{\mathcal{E}}_{h,n} \cap \Gamma_n} (D_E, v)_E.\end{aligned} \tag{5.14}$$

Lemma 5.1 and the Cauchy–Schwarz inequality therefore imply, for all $v \in H^1_D(\Omega)$,

$$\begin{aligned} \langle R_h(u_{h,\tau}), & v - I_{h,n}v\rangle \\ &\le c|||v|||\Bigg\{ \sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \alpha_K^2 \|R_K\|^2_{0;K} + \sum_{E\in\widetilde{\mathcal{E}}_{h,n}} \varepsilon^{-1/2}\alpha_E\|R_E\|^2_{0;E} \\ &\qquad + \sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \alpha_K^2\|D_K\|^2_{0;K} + \sum_{E\in\widetilde{\mathcal{E}}_{h,n}\cap\Gamma_n} \varepsilon^{-1/2}\alpha_E\|D_E\|^2_{0;E}\Bigg\}^{1/2}. \end{aligned} \tag{5.15}$$

The constant c depends only on the constants c_1 and c_2 of Lemma 5.1 and on the ratios h_K/ρ_K.

From the definition of problem (3.2) and definition (4.9) of the spatial residual we conclude that

$$\langle R_h(u_{h,\tau}), I_{h,n}v\rangle = \sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \delta_K\Big\{(R_K, \underline{a}^{n\theta}\cdot\nabla I_{h.n}v)_K + (D_K, \underline{a}^{n\theta}\cdot\nabla I_{h,n}v)_K\Big\}.$$

Lemma 5.1, condition (3.3), and the Cauchy–Schwarz inequality therefore imply

$$\langle R_h(u_{h,\tau}), I_{h,n}v\rangle \le c|||v|||\Bigg\{\sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \alpha_K^2\Big\{\|R_K\|^2_{0;K} + \|D_K\|^2_{0;K}\Big\}\Bigg\}^{1/2}. \tag{5.16}$$

Equation (5.14) and estimates (5.15) and (5.16) prove the upper bound (5.12).

For the proof of the lower bound (5.13) we proceed as in the proof of [9, Lem. 5.1] and define the function w_n by

$$w_n = \gamma_1 \sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \alpha_K^2\psi_K R_K + \gamma_2 \sum_{E\in\widetilde{\mathcal{E}}_{h,n}} \varepsilon^{-1/2}\alpha_E\psi_E R_E. \tag{5.17}$$

The constants γ_1 and γ_2 are arbitrary at present and will be determined below. The subsequent arguments are based on the following observations:

- The supports of the ψ_K are mutually disjoint.
- The support of a ψ_K intersects the support of at most $2d$ different ψ_E's.
- The support of a ψ_E intersects the support of at most two ψ_K's.
- The support of a ψ_E intersects the support of at most $2d-2$ other ψ_E's.

Lemma 5.3 therefore yields

$$\begin{aligned} |||w_h|||^2 \le\; & \gamma_1^2 \sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \alpha_K^4 |||\psi_K R_K|||^2_K \\ &+ 2\gamma_1\gamma_2 \sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \Bigg\{\sum_{E;\omega_E\cap K\neq\emptyset} \alpha_K^2\varepsilon^{-1/2}\alpha_E |||\psi_K R_K|||_K |||\psi_E R_E|||_K\Bigg\} \\ &+ \gamma_2^2 \sum_{E\in\widetilde{\mathcal{E}}_{h,n}} \Bigg\{\sum_{E';\omega_E\cap\omega_{E'}\neq\emptyset} \varepsilon^{-1}\alpha_E\alpha_{E'} |||\psi_E R_E|||_{\omega_E} |||\psi_{E'}R_{E'}|||_{\omega_{E'}}\Bigg\} \\ \le\; & (2d+1)\max\{\gamma_1^2,\gamma_2^2\}\max\{c_5,c_7\}\left(\eta_h^n\right)^2. \end{aligned} \tag{5.18}$$

Since $h_E \le h_K$ for all edges, respectively, faces, E of any element K, Lemma 5.3 also implies that

$$\begin{aligned}
&\sum_{K\in\widetilde{\mathcal{T}}_{h,n}} (R_K,w_n)_K + \sum_{E\in\widetilde{\mathcal{E}}_{h,n}} (R_E,w_n)_E \\
&\qquad = \gamma_1 \sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \alpha_K^2 (R_K,\psi_K R_K)_K + \gamma_2 \sum_{E\in\widetilde{\mathcal{E}}_{h,n}} \varepsilon^{-1/2}\alpha_E (R_E,\psi_E R_E)_E \\
&\qquad\quad + \gamma_2 \sum_{E\in\widetilde{\mathcal{E}}_{h,n}} \left\{ \sum_{K;K\cap\omega_E\neq\emptyset} \varepsilon^{-1/2}\alpha_E (R_K,\psi_E R_E)_K \right\} \\
&\qquad \ge \gamma_1 \sum_{K\in\widetilde{\mathcal{T}}_{h,n}} c_4 \alpha_K^2 \|R_K\|_{0;K}^2 + \gamma_2 \sum_{E\in\widetilde{\mathcal{E}}_{h,n}} c_6 \varepsilon^{-1/2}\alpha_E \|R_E\|_{0;E}^2 \\
&\qquad\quad - \gamma_2 \sum_{E\in\widetilde{\mathcal{E}}_{h,n}} \left\{ \sum_{K;K\cap\omega_E\neq\emptyset} c_8 \varepsilon^{-1/4}\alpha_E^{1/2}\alpha_K \|R_K\|_{0;K} \|\psi_E R_E\|_{0;E} \right\} \\
&\qquad \ge (\gamma_1 c_4 - 2d\gamma_2 c_8^2 c_6^{-1}) \sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \alpha_K^2 \|R_K\|_{0;K}^2 \\
&\qquad\quad + \frac{1}{2}\gamma_2 c_6 \sum_{E\in\widetilde{\mathcal{E}}_{h,n}} \varepsilon^{-1/2}\alpha_E \|R_E\|_{0;E}^2 \\
&\qquad \ge \min\left\{ \gamma_1 c_4 - 2d\gamma_2 c_8^2 c_6^{-1}, \frac{1}{2}\gamma_2 c_6 \right\} (\eta_h^n)^2 .
\end{aligned} \tag{5.19}$$

From Lemma 5.3 we also obtain

$$\begin{aligned}
&\sum_{K\in\widetilde{\mathcal{T}}_{h,n}} (D_K,w_h)_K + \sum_{E\in\widetilde{\mathcal{E}}_{h,n}\cap\Gamma_n} (D_E,w_h)_E \\
&\qquad = \gamma_1 \sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \alpha_K^2 (D_K,\psi_K R_K)_K \\
&\qquad\quad + \gamma_2 \sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \left\{ \sum_{E;E\subset\partial K} \varepsilon^{-1/2}\alpha_E (D_K,\psi_E R_E)_K \right\} \\
&\qquad\quad + \gamma_2 \sum_{E\in\widetilde{\mathcal{E}}_{h,n}\cap\Gamma_n} \varepsilon^{-1/2}\alpha_E (D_E,\psi_E R_E)_E \\
&\qquad \le \gamma_1 \sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \alpha_K^2 \|R_K\|_{0;K} \|D_K\|_{0;K} \\
&\qquad\quad + \gamma_2 \sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \left\{ \sum_{E;E\subset\partial K} c_8 \varepsilon^{-1/4}\alpha_E^{3/2} \|R_E\|_{0;E} \|D_K\|_{0;K} \right\} \\
&\qquad\quad + \gamma_2 \sum_{E\in\widetilde{\mathcal{E}}_{h,n}\cap\Gamma_n} \varepsilon^{-1/2}\alpha_E \|R_E\|_{0;E} \|D_E\|_{0;E} \\
&\qquad \le 2d \max\{\gamma_1,\gamma_2\} \max\{1,c_8\} \Theta_h^n \eta_h^n .
\end{aligned} \tag{5.20}$$

Now we choose

$$\gamma_2 = \frac{2}{c_6} \quad \text{and} \quad \gamma_1 = \frac{1}{c_4}\left(1 + \frac{4dc_8^2}{c_6^2}\right).$$

This choice gives

$$\min\left\{\gamma_1 c_4 - 2d\gamma_2 c_8^2 c_6^{-1}, \frac{1}{2}\gamma_2 c_6\right\} = 1.$$

Estimates (5.19), (5.20), and (5.18) and equation (5.14) now imply the lower bound (5.13). □

6. Estimation of the temporal residual. The following lemma provides us with sharp upper and lower bounds for the temporal residual.

LEMMA 6.1. *For every integer n between 1 and N and every real number δ larger than 0 and less than 1 there is a function $z_{n,\delta} \in L^2(0,T;H_D^1(\Omega))$ such that the following estimates hold on each interval $(t_{n-1}, t_n]$:*

$$\tag{6.1} \begin{aligned} &\left\{\int_{t_{n-1}}^{t_n} |||R_\tau(u_{h,\tau})(.,s)|||_*^2 ds\right\}^{1/2} \\ &\qquad \leq \sqrt{\frac{2}{3}}\max\{c_b, 1\}\tau_n^{1/2}\left\{|||u_h^n - u_h^{n-1}|||^2 + |||\underline{a}^{n\theta}\cdot\nabla(u_h^n - u_h^{n-1})|||_*^2\right\}^{1/2} \end{aligned}$$

and

$$\tag{6.2} \begin{aligned} &\int_{t_{n-1}}^{t_n} \langle R_\tau(u_{h,\tau})(.,s), z_{n,\delta}(.,s)\rangle ds \\ &\quad \geq \frac{\delta}{12(\delta + \max\{c_b, 1\}^2)}\tau_n\left\{|||u_h^n - u_h^{n-1}|||^2 + \delta|||\underline{a}^{n\theta}\cdot\nabla(u_h^n - u_h^{n-1})|||_*^2\right\}, \\ &\left\{\int_{t_{n-1}}^{t_n} |||z_{n,\delta}(.,s)|||^2 ds\right\}^{1/2} \\ &\quad \leq \sqrt{\frac{8}{3}}\tau_n^{1/2}\left\{|||u_h^n - u_h^{n-1}|||^2 + |||\underline{a}^{n\theta}\cdot\nabla(u_h^n - u_h^{n-1})|||_*^2\right\}^{1/2}. \end{aligned}$$

Proof. Since the function $t \to u_{h,\tau}(.,t)$ is continuous and piecewise affine with values in $H_D^1(\Omega)$, we have on each time interval $[t_{m-1}, t_m]$

$$\theta u_h^m + (1-\theta)u_h^{m-1} - u_{h,\tau} = \left[\theta - \frac{t - t_{m-1}}{\tau_m}\right](u_h^m - u_h^{m-1}).$$

For abbreviation we define for each m between 1 and N the quantity $r_m \in H_D^1(\Omega)^*$ by

$$\begin{aligned} \langle r_m, v\rangle = {}& \varepsilon(\nabla(u_h^m - u_h^{m-1}), \nabla v) + (\underline{a}^{m\theta}\cdot\nabla(u_h^m - u_h^{m-1}), v) \\ &+ (b^{m\theta}(u_h^m - u_h^{m-1}), v) \qquad \forall v \in H_D^1(\Omega). \end{aligned}$$

Then we obtain the following representation of the temporal residual

$$\tag{6.3} R_\tau(u_{h,\tau}) = \left[\theta - \frac{t - t_{m-1}}{\tau_m}\right] r_m \qquad \text{on } (t_{m-1}, t_m],\ 1 \leq m \leq N.$$

A straightforward calculation gives

$$\int_{t_{m-1}}^{t_m} \left[\theta - \frac{t-t_{m-1}}{\tau_m}\right]^2 dt = \tau_m \frac{1}{3}\left[\theta^3 + (1-\theta)^3\right]$$

and consequently

$$\frac{1}{12}\tau_m \le \int_{t_{m-1}}^{t_m} \left[\theta - \frac{t-t_{m-1}}{\tau_m}\right]^2 dt \le \frac{1}{3}\tau_m. \tag{6.4}$$

From (2.8) we conclude that

$$\begin{aligned} |||r_m|||_* &\le \max\{c_b,1\}|||u_h^m - u_h^{m-1}||| + |||\underline{a}^{m\theta}\cdot\nabla(u_h^m - u_h^{m-1})|||_* \\ &\le \sqrt{2}\max\{c_b,1\}\left\{|||u_h^m - u_h^{m-1}|||^2 + |||\underline{a}^{m\theta}\cdot\nabla(u_h^m - u_h^{m-1})|||_*^2\right\}^{1/2}. \end{aligned} \tag{6.5}$$

Inequalities (6.4) and (6.5) prove the upper bound (6.1).

Due to the definition (2.3) of $|||.|||_*$ there is for each $\delta \in (0,1)$ a function $\varphi_{m,\delta} \in H_D^1(\Omega)$ with

$$\begin{aligned} |||\varphi_{m,\delta}||| &= |||\underline{a}^{m\theta}\cdot\nabla(u_h^m - u_h^{m-1})|||_*, \\ (\underline{a}^{m\theta}\cdot\nabla(u_h^m - u_h^{m-1}), \varphi_{m,\delta}) &\ge \delta|||\underline{a}^{m\theta}\cdot\nabla(u_h^m - u_h^{m-1})|||_*^2. \end{aligned}$$

We set

$$\zeta_{m,\delta} = (u_h^m - u_h^{m-1}) + \gamma\varphi_{m,\delta}, \tag{6.6}$$

where γ is a constant that will be fixed below. Obviously we have

$$|||\zeta_{m,\delta}||| \le \max\{1,\gamma\}\left\{|||u_h^m - u_h^{m-1}||| + |||\underline{a}^{m\theta}\cdot\nabla(u_h^m - u_h^{m-1})|||_*\right\}.$$

Inequalities (2.7) and (2.8) on the other hand yield

$$\begin{aligned} \langle r_m, \zeta_{m,\delta}\rangle &\ge |||u_h^m - u_h^{m-1}|||^2 + \gamma\delta|||\underline{a}^{m\theta}\cdot\nabla(u_h^m - u_h^{m-1})|||_*^2 \\ &\quad - \gamma\max\{c_b,1\}|||u_h^m - u_h^{m-1}|||\ |||\underline{a}^{m\theta}\cdot\nabla(u_h^m - u_h^{m-1})|||_* \\ &\ge \left\{1 - \frac{1}{2}\gamma\delta^{-1}\max\{c_b,1\}^2\right\}|||u_h^m - u_h^{m-1}|||^2 \\ &\quad + \frac{1}{2}\gamma\delta|||\underline{a}^{m\theta}\cdot\nabla(u_h^m - u_h^{m-1})|||_*^2. \end{aligned}$$

Now we choose

$$\gamma = \frac{2\delta}{\delta + \max\{c_b,1\}^2}$$

and obtain

$$\begin{aligned} |||\zeta_{m,\delta}||| &\le 2\left\{|||u_h^m - u_h^{m-1}||| + |||\underline{a}^{m\theta}\cdot\nabla(u_h^m - u_h^{m-1})|||_*\right\}, \\ \langle r_m, \zeta_{m,\delta}\rangle &\ge \frac{\delta}{\delta + \max\{c_b,1\}^2}\Big\{|||u_h^m - u_h^{m-1}|||^2 \\ &\qquad + \delta|||\underline{a}^{m\theta}\cdot\nabla(u_h^m - u_h^{m-1})|||_*^2\Big\}. \end{aligned} \tag{6.7}$$

Equation (6.3) and estimates (6.4), (6.7) show that the function

$$z_{m,\delta} = \left[\theta - \frac{t-t_{m-1}}{\tau_m}\right]\zeta_{m,\delta}$$

yields the lower bounds (6.2). □

7. A preliminary a posteriori error estimate. The following lemma provides us with a posteriori error bounds which are robust in the sense described in the introduction. However, they are not suited for practical computations since they involve terms of the form $|||\underline{a}^{n\theta} \cdot \nabla(u_h^n - u_h^{n-1})|||_*$. In the next section we will bound these terms by computable quantities. Recall that $H_D^1(\Omega)^*$ is equipped with $|||.|||_*$.

LEMMA 7.1. *The error between the solution u of problem* (2.6) *and the solution $u_{h,\tau}$ of problems* (3.1), (3.2) *is bounded from above by*

$$\begin{aligned}
&\|u - u_{h,\tau}\|_{X(0,T)} \\
&\quad \leq c^* \Bigg\{ \|u_0 - \pi_0 u_0\|_0^2 \\
&\qquad + \sum_{n=1}^{N} \tau_n \Big[(\eta_h^n)^2 + |||u_h^n - u_h^{n-1}|||^2 + |||\underline{a}^{n\theta} \cdot \nabla(u_h^n - u_h^{n-1})|||_*^2 \Big] \\
&\qquad + \sum_{n=1}^{N} \tau_n \, (\Theta_h^n)^2 \\
&\qquad + \big\| f - f^{n\theta} - (\underline{a} - \underline{a}^{n\theta}) \cdot \nabla u_{h,\tau} - (b - b^{n\theta}) u_{h,\tau} \big\|_{L^2(0,T;H_D^1(\Omega)^*)}^2 \\
&\qquad + \big\| g - g_{h,\tau} \big\|_{L^2(0,T;H^{-1/2}(\Gamma_N))}^2 \Bigg\}^{1/2}
\end{aligned} \tag{7.1}$$

and on each interval $(t_{n-1}, t_n]$, $1 \leq n \leq N$, from below by

$$\begin{aligned}
&\tau_n^{1/2} \Big\{ (\eta_h^n)^2 + |||u_h^n - u_h^{n-1}|||^2 + |||\underline{a}^{n\theta} \cdot \nabla(u_h^n - u_h^{n-1})|||_*^2 \Big\}^{1/2} \\
&\leq c_* \Bigg\{ \|u - u_{h,\tau}\|_{X(t_{n-1},t_n)}^2 \\
&\qquad + \tau_n \, (\Theta_h^n)^2 \\
&\qquad + \big\| f - f^{n\theta} - (\underline{a} - \underline{a}^{n\theta}) \cdot \nabla u_{h,\tau} - (b - b^{n\theta}) u_{h,\tau} \big\|_{L^2(t_{n-1},t_n;H_D^1(\Omega)^*)}^2 \\
&\qquad + \big\| g - g_{h,\tau} \big\|_{L^2(t_{n-1},t_n;H^{-1/2}(\Gamma_N))}^2 \Bigg\}^{1/2}.
\end{aligned} \tag{7.2}$$

The quantities η_h^n and Θ_h^n are defined in (5.10) *and* (5.11), *respectively. The constants c^* and c_* depend on the ratios h_K/ρ_K. The constant c^* in addition depends on the ratios $h_{K'}/h_K$. The constant c_* in addition depends on the maximum of the polynomial degrees of the finite element functions. All constants are independent of the final time T, the viscosity ε, and the parameter β.*

Proof. The upper bound (7.1) follows from estimates (4.3), (5.12), and (6.1) and the decomposition (4.11) of the residual.

For the proof of the lower bound (7.2) we choose an integer n between 1 and N and a real number δ larger than 0 and less than 1.

First we insert the function $z_{n,\delta}$ of Lemma 6.1 into the representation (4.11) of the residual. Estimates (6.2), (5.12), and (4.2) then imply

$$\begin{aligned}
&\frac{\delta}{12(\delta+\max\{c_b,1\}^2)}\tau_n\Big\{|||u_h^n-u_h^{n-1}|||^2+\delta|||\underline{a}^{n\theta}\cdot\nabla(u_h^n-u_h^{n-1})|||_*^2\Big\}\\
&\quad\le\int_{t_{n-1}}^{t_n}\langle R_\tau(u_{h,\tau})(.,s),z_{n,\delta}(.,s)\rangle ds\\
&\quad=\int_{t_{n-1}}^{t_n}\langle R(u_{h,\tau})(.,s)-R_D(u_{h,\tau})(.,s)-R_h(u_{h,\tau})(.,s),z_{n,\delta}(.,s)\rangle ds
\end{aligned}$$

and

$$\begin{aligned}
&\int_{t_{n-1}}^{t_n}\langle R(u_{h,\tau})(.,s)-R_D(u_{h,\tau})(.,s)-R_h(u_{h,\tau})(.,s),z_{n,\delta}(.,s)\rangle ds\\
&\quad\le\sqrt{\frac{8}{3}}\tau_n^{1/2}\left\{|||u_h^n-u_h^{n-1}|||^2+|||\underline{a}^{n\theta}\cdot\nabla(u_h^n-u_h^{n-1})|||_*^2\right\}^{1/2}\\
&\quad\cdot\bigg\{2\max\{c_b,1\}^2\|u-u_{h,\tau}\|^2_{X(t_{n-1},t_n)}\\
&\qquad+\left\|f-f^{n\theta}-(\underline{a}-\underline{a}^{n\theta})\cdot\nabla u_{h,\tau}-(b-b^{n\theta})u_{h,\tau}\right\|^2_{L^2(t_{n-1},t_n;H^1_D(\Omega)^*)}\\
&\qquad+\left\|g-g_{h,\tau}\right\|^2_{L^2(t_{n-1},t_n;H^{-1/2}(\Gamma_N))}\\
&\qquad+c^\dagger\tau_n\left(\Theta_h^n\right)^2+c^\dagger\tau_n\left(\eta_h^n\right)^2\bigg\}^{1/2}.
\end{aligned}$$

Since $\delta\in(0,1)$ was arbitrary and since $\sqrt{\frac{8}{3}}\le 2$ this yields the estimate

$$\begin{aligned}
&\tau_n^{1/2}\Big\{|||u_h^n-u_h^{n-1}|||^2+|||\underline{a}^{n\theta}\cdot\nabla(u_h^n-u_h^{n-1})|||_*^2\Big\}^{1/2}\\
&\quad\le c'\Big\{2\max\{c_b,1\}^2\|u-u_{h,\tau}\|^2_{X(t_{n-1},t_n)}+c^\dagger\tau_n\left(\Theta_h^n\right)^2\\
&\qquad+\left\|f-f^{n\theta}-(\underline{a}-\underline{a}^{n\theta})\cdot\nabla u_{h,\tau}-(b-b^{n\theta})u_{h,\tau}\right\|^2_{L^2(t_{n-1},t_n;H^1_D(\Omega)^*)}\\
&\qquad+\left\|g-g_{h,\tau}\right\|^2_{L^2(t_{n-1},t_n;H^{-1/2}(\Gamma_N))}\\
&\qquad+c^\dagger\tau_n\left(\eta_h^n\right)^2\Big\}^{1/2}
\end{aligned}\tag{7.3}$$

with $c'=24(1+\max\{c_b,1\}^2)$.

Next we insert the function $(\alpha+1)(\frac{t-t_{n-1}}{\tau_n})^\alpha w_n$ into the representation (4.11) of the residual. Here w_n is the function of Lemma 5.4 and α denotes a nonnegative constant that will be determined below. Estimate (5.13) and the decomposition (4.11) of the residual then yield

$$\begin{aligned}
\tau_n\left(\eta_h^n\right)^2&\le\int_{t_{n-1}}^{t_n}(\alpha+1)\left(\frac{t-t_{n-1}}{\tau_n}\right)^\alpha\langle R_h(u_{h,\tau}),w_n\rangle dt+\tau_n\Theta_h^n\,\eta_h^n\\
&=\int_{t_{n-1}}^{t_n}(\alpha+1)\left(\frac{t-t_{n-1}}{\tau_n}\right)^\alpha\langle R(u_{h,\tau})-R_D(u_{h,\tau})-R_\tau(u_{h,\tau}),w_n\rangle dt\\
&\quad+\tau_n\Theta_h^n\,\eta_h^n.
\end{aligned}$$

Since

$$\int_{t_{n-1}}^{t_n} (\alpha+1)^2 \left(\frac{t-t_{n-1}}{\tau_n}\right)^{2\alpha} dt = \frac{(\alpha+1)^2}{2\alpha+1}\tau_n \le (2\alpha+1)\tau_n$$

and $\sqrt{\frac{2}{3}} \le 1$, estimates (4.2), (5.13), and (6.1) imply that

$$\begin{aligned}
&\int_{t_{n-1}}^{t_n} (\alpha+1) \left(\frac{t-t_{n-1}}{\tau_n}\right)^{\alpha} \langle R(u_{h,\tau}) - R_D(u_{h,\tau}), w_n\rangle dt \\
&\quad \le \sqrt{2\alpha+1}\, c_\dagger \tau_n^{1/2} \eta_h^n \Big\{ \sqrt{2}\max\{c_b, 1\} \|u - u_{h,\tau}\|_{X(t_{n-1},t_n)} \\
&\qquad + \left\| f - f^{n\theta} - (\underline{a} - \underline{a}^{n\theta})\cdot\nabla u_{h,\tau} - (b - b^{n\theta})u_{h,\tau}\right\|_{L^2(t_{n-1},t_n;H_D^1(\Omega)^*)} \\
&\qquad + \left\| g - g_{h,\tau}\right\|^2_{L^2(t_{n-1},t_n;H^{-1/2}(\Gamma_N))} \Big\}.
\end{aligned}$$

Since

$$\int_{t_{n-1}}^{t_n} (\alpha+1) \left(\frac{t-t_{n-1}}{\tau_n}\right)^{\alpha} \left[\theta - \frac{t-t_{n-1}}{\tau_n}\right] dt = \left(\theta - \frac{\alpha+1}{\alpha+2}\right)\tau_n$$

and $\sqrt{\frac{2}{3}} \le 1$, we conclude from estimates (5.13) and (6.1) that

$$\begin{aligned}
&\int_{t_{n-1}}^{t_n} (\alpha+1) \left(\frac{t-t_{n-1}}{\tau_n}\right)^{\alpha} \langle R_\tau(u_{h,\tau}), w_n\rangle dt \\
&\quad \le \left|\theta - \frac{\alpha+1}{\alpha+2}\right| \max\{c_b, 1\} c_\dagger \eta_h^n \tau_n \Big\{ |\!|\!| u_h^n - u_h^{n-1} |\!|\!| + |\!|\!| \underline{a}^{n\theta}\cdot\nabla(u_h^n - u_h^{n-1}) |\!|\!|_* \Big\}.
\end{aligned}$$

Combining these estimates and inserting (7.3) we arrive at the estimate

$$\begin{aligned}
&\tau_n \left(\eta_h^n\right)^2 \\
&\quad \le \left|\theta - \frac{\alpha+1}{\alpha+2}\right| c_\dagger c'' \tau_n \left(\eta_h^n\right)^2 \\
&\qquad + \tau_n^{1/2} \eta_h^n c_\dagger c''' \left[\sqrt{2\alpha+1} + \left|\theta - \frac{\alpha+1}{\alpha+2}\right|\right] \\
&\qquad\quad \cdot \Big\{ \|u - u_{h,\tau}\|_{X(t_{n-1},t_n)} + \tau_n^{1/2}\Theta_h^n \\
&\qquad\qquad + \left\| f - f^{n\theta} - (\underline{a} - \underline{a}^{n\theta})\cdot\nabla u_{h,\tau} - (b - b^{n\theta})u_{h,\tau}\right\|_{L^2(t_{n-1},t_n;H_D^1(\Omega)^*)} \\
&\qquad\qquad + \left\| g - g_{h,\tau}\right\|^2_{L^2(t_{n-1},t_n;H^{-1/2}(\Gamma_N))} \Big\}
\end{aligned} \tag{7.4}$$

with constants c'' and c''' that depend only on the constant c_b of assumption (A3).

Now we choose the parameter α such that the first term on the right-hand side of (7.4) is balanced by the term on the left-hand side. In case of the Crank–Nicolson scheme, i.e., $\theta = \frac{1}{2}$, this is obvious: We have to choose $\alpha = 0$. In the remaining cases $\frac{1}{2} < \theta \le 1$ we set

$$\alpha = \frac{2c_\dagger c''(2\theta - 1)}{2c_\dagger c''(1-\theta) + 1}.$$

Since we may assume that $c_\dagger c'' \geq 1$ this implies

$$\frac{\alpha+1}{\alpha+2} \leq \theta \quad \text{and} \quad \left|\theta - \frac{\alpha+1}{\alpha+2}\right| c_\dagger c'' \leq \frac{1}{2}.$$

Estimate (7.4) therefore takes the form

$$\begin{aligned} &\tau_n^{1/2}\eta_h^n \\ &\quad \leq c\Big\{ \|u - u_{h,\tau}\|_{X(t_{n-1},t_n)} + \tau_n^{1/2}\Theta_h^n \\ &\qquad + \big\|f - f^{n\theta} - (\underline{a} - \underline{a}^{n\theta})\cdot\nabla u_{h,\tau} - (b - b^{n\theta})u_{h,\tau}\big\|_{L^2(t_{n-1},t_n;H_D^1(\Omega)^*)} \\ &\qquad + \big\|g - g_{h,\tau}\big\|^2_{L^2(t_{n-1},t_n;H^{-1/2}(\Gamma_N))}\Big\} \end{aligned} \tag{7.5}$$

with a constant c that depends only on the constants c_b and $c_\dagger$. Estimates (7.3) and (7.5) obviously imply the lower bound (7.2). □

8. A robust a posteriori error estimator. In this section we derive computable and robust bounds for the terms $|||\underline{a}^{n\theta}\cdot\nabla(u_h^n - u_h^{n-1})|||_*$ in Lemma 7.1. Standard approaches bound this term by inverse estimates eventually combined with integration by parts. These approaches, however, lead to estimates which incorporate a factor $\varepsilon^{-1/2}$ and which are not robust.

The idea which leads to robust estimates is as follows: Due to the definition of the dual norm, these quantities equal the energy norm of the weak solutions of suitable stationary reaction-diffusion equations. These solutions are approximated by suitable finite element functions. The error of the approximations is estimated by robust error estimators for reaction-diffusion equations.

LEMMA 8.1. *For every integer n between 1 and N set*

$$\widetilde{X}_{h,n} = \{v \in C(\Omega) : v_{|K} \in R_1(K)\ \forall K \in \widetilde{\mathcal{T}}_{h,n},\ v = 0 \text{ on } \Gamma_D\}$$

and denote by $\widetilde{u}_h^n \in \widetilde{X}_{h,n}$ the unique solution of the discrete reaction-diffusion problem

$$\varepsilon(\nabla\widetilde{u}_h^n, \nabla v_h) + \beta(\widetilde{u}_h^n, v_h) = (\underline{a}^{n\theta}\cdot\nabla(u_h^n - u_h^{n-1}), v_h) \quad \forall v_h \in \widetilde{X}_{h,n}. \tag{8.1}$$

Define the error indicator $\widetilde{\eta}_h^n$ by

$$\begin{aligned} \widetilde{\eta}_h^n = \Bigg\{ &\sum_{K\in\widetilde{\mathcal{T}}_{h,n}} \alpha_K^2 \|\underline{a}^{n\theta}\cdot\nabla(u_h^n - u_h^{n-1}) + \varepsilon\Delta\widetilde{u}_h^n - \beta\widetilde{u}_h^n\|_{0;K}^2 \\ &+ \sum_{E\in\widetilde{\mathcal{E}}_{h,n}\setminus\Gamma_D} \varepsilon^{-1/2}\alpha_E \|[\underline{n}_E\cdot\nabla\widetilde{u}_h^n]_E\|_{0;E}^2 \Bigg\}^{1/2}. \end{aligned} \tag{8.2}$$

Then there are two constants $\widetilde{c}_\dagger$ and $\widetilde{c}^\dagger$ which depend only on the ratios h_K/ρ_K such that the following estimates are valid

$$\widetilde{c}_\dagger\{|||\widetilde{u}_h^n||| + \widetilde{\eta}_h^n\} \leq |||\underline{a}^{n\theta}\cdot\nabla(u_h^n - u_h^{n-1})|||_* \leq \widetilde{c}^\dagger\{|||\widetilde{u}_h^n||| + \widetilde{\eta}_h^n\}. \tag{8.3}$$

Proof. We choose an integer n between 1 and N and keep it fixed in what follows. Denote by $\widetilde{U}^n \in H_D^1(\Omega)$ the unique solution of the stationary reaction-diffusion equation

$$\varepsilon(\nabla\widetilde{U}^n, \nabla v) + \beta(\widetilde{U}^n, v) = (\underline{a}^{n\theta}\cdot\nabla(u_h^n - u_h^{n-1}), v) \quad \forall v \in H_D^1(\Omega).$$

The definitions (2.2) and (2.3) of the energy norm $|||.|||$ and of the dual norm $|||.|||_*$, respectively, imply that

$$|||\widetilde{U}^n||| = |||\underline{a}^{n\theta} \cdot \nabla(u_h^n - u_h^{n-1})|||_*.$$

Inserting $v_h = \widetilde{u}_h^n$ as a test function in the discrete problem (8.1) we obtain

$$|||\widetilde{u}_h^n||| \le |||\underline{a}^{n\theta} \cdot \nabla(u_h^n - u_h^{n-1})|||_*.$$

The triangle inequality therefore yields

$$\frac{1}{3}\Big\{|||\widetilde{u}_h^n||| + |||\widetilde{U}^n - \widetilde{u}_h^n|||\Big\} \le |||\underline{a}^{n\theta} \cdot \nabla(u_h^n - u_h^{n-1})|||_* \le \Big\{|||\widetilde{u}_h^n||| + |||\widetilde{U}^n - \widetilde{u}_h^n|||\Big\}.$$

Since $\underline{a}^{n\theta} \cdot \nabla(u_h^n - u_h^{n-1})$ is a piecewise polynomial we know from [7] that $\widetilde{\eta}_h^n$ yields upper and lower bounds for $|||\widetilde{U}^n - \widetilde{u}_h^n|||$ with multiplicative constants that depend only on the ratios h_K/ρ_K. This proves estimate (8.3). □

Combining Lemmas 7.1 and 8.1 we obtain our final result.

THEOREM 8.2. *The error between the solution* u *of problem* (2.6) *and the solution* $u_{h,\tau}$ *of problems* (3.1), (3.2) *is bounded from above by*

(8.4)
$$\begin{aligned}
&\|u - u_{h,\tau}\|_{X(0,T)} \\
&\quad\le \widetilde{c}^*\Bigg\{\|u_0 - \pi_0 u_0\|_0^2 + \sum_{n=1}^{N}\tau_n\Big[(\eta_h^n)^2 + |||u_h^n - u_h^{n-1}|||^2 + (\widetilde{\eta}_h^n)^2 + |||\widetilde{u}_h^n|||^2\Big] \\
&\qquad + \sum_{n=1}^{N}\tau_n\,(\Theta_h^n)^2 + \big\|f - f^{n\theta} - (\underline{a} - \underline{a}^{n\theta})\cdot\nabla u_{h,\tau} - (b - b^{n\theta})u_{h,\tau}\big\|^2_{L^2(0,T;H_D^1(\Omega)^*)} \\
&\qquad + \big\|g - g_{h,\tau}\big\|^2_{L^2(0,T;H^{-1/2}(\Gamma_N))}\Bigg\}^{1/2}
\end{aligned}$$

and on each interval $(t_{n-1}, t_n]$, $1 \le n \le N$, *from below by*

$$\begin{aligned}
&\tau_n^{1/2}\Big\{(\eta_h^n)^2 + |||u_h^n - u_h^{n-1}|||^2 + (\widetilde{\eta}_h^n)^2 + |||\widetilde{u}_h^n|||^2\Big\}^{1/2} \\
&\quad\le \widetilde{c}_*\Bigg\{\|u - u_{h,\tau}\|^2_{X(t_{n-1},t_n)} + \tau_n\,(\Theta_h^n)^2 \\
&\qquad + \big\|f - f^{n\theta} - (\underline{a} - \underline{a}^{n\theta})\cdot\nabla u_{h,\tau} - (b - b^{n\theta})u_{h,\tau}\big\|^2_{L^2(t_{n-1},t_n;H_D^1(\Omega)^*)} \\
&\qquad + \big\|g - g_{h,\tau}\big\|^2_{L^2(t_{n-1},t_n;H^{-1/2}(\Gamma_N))}\Bigg\}^{1/2}.
\end{aligned} \tag{8.5}$$

The quantities η_h^n *and* Θ_h^n *are defined in* (5.10) *and* (5.11), *respectively. The constants* $\widetilde{c}^*$ *and* $\widetilde{c}_*$ *depend on the ratios* h_K/ρ_K. *The constant* $\widetilde{c}^*$ *in addition depends on the ratios* $h_{K'}/h_K$. *The constant* $\widetilde{c}_*$ *in addition depends on the maximum of the polynomial degrees of the finite element functions. All constants are independent of the final time* T, *the viscosity* ε, *and the parameter* β.

Remark 8.3. Theorem 8.2 shows that the quantity $\tau_n^{1/2}\{(\eta_h^n)^2 + |||u_h^n - u_h^{n-1}|||^2 + (\widetilde{\eta}_h^n)^2 + |||\widetilde{u}_h^n|||^2\}^{1/2}$ is a robust error indicator in the sense described in the introduction.

The remaining terms on the right-hand side of estimate (8.4) and the second and third term on the right-hand side of estimate (8.5) are data errors. They can be bounded a priori by computable norms involving the data f, g, $\underline{a}$, and b. The term $\tau_n^{1/2}\eta_h^n$ can be interpreted as a spatial error indicator. The terms $\tau_n^{1/2}\{|||u_h^n - u_h^{n-1}|||^2 + (\widetilde{\eta}_h^n)^2 + |||\widetilde{u}_h^n|||^2\}^{1/2}$ on the other hand can be viewed as temporal error indicators.

Acknowledgments. Part of this work was carried out during a stay at the Department of Mathematics of the Polytechnico di Torino. We want to thank Prof. Claudio Canuto and Dr. Stefano Berrone for their kind hospitality and the many fruitful discussions.

CONVERGENCE OF ADAPTIVE FINITE ELEMENT METHODS FOR GENERAL SECOND ORDER LINEAR ELLIPTIC PDEs*

KHAMRON MEKCHAY[†] AND RICARDO H. NOCHETTO[‡]

Abstract. We prove convergence of adaptive finite element methods (AFEMs) for general (nonsymmetric) second order linear elliptic PDEs, thereby extending the result of Morin, Nochetto, and Siebert [*SIAM J. Numer. Anal.*, 38 (2000), pp. 466–488; *SIAM Rev.*, 44 (2002), pp. 631–658]. The proof relies on quasi-orthogonality, which accounts for the bilinear form not being a scalar product, together with novel error and oscillation reduction estimates, which now do not decouple. We show that AFEMs are a contraction for the sum of energy error plus oscillation. Numerical experiments, including oscillatory coefficients and both coercive and noncoercive convection-diffusion PDE, illustrate the theory and yield optimal meshes.

Key words. a posteriori error estimators, quasi-orthogonality, adaptive mesh refinement, error and oscillation reduction estimates, optimal meshes

1. Introduction and main result.

Let Ω be a polyhedral bounded domain in $\mathbb{R}^d$ $(d = 2, 3)$. We consider a homogeneous Dirichlet boundary value problem for a general second order elliptic partial differential equation (PDE):

$$\mathcal{L}u = -\nabla\cdot(\mathbf{A}\nabla u) + \mathbf{b}\cdot\nabla u + c\,u = f \quad \text{in } \Omega, \tag{1.1}$$

$$u = 0 \quad \text{on } \partial\Omega. \tag{1.2}$$

The choice of boundary condition is made for ease of presentation, since similar results are valid for other boundary conditions. We also assume

- $\mathbf{A} : \Omega \mapsto \mathbb{R}^{d\times d}$ is Lipschitz and symmetric positive definite with smallest eigenvalue a_- and largest eigenvalue a_+, i.e.,

$$a_-(x)\,|\xi|^2 \le \mathbf{A}(x)\xi\cdot\xi \le a_+(x)\,|\xi|^2 \quad \forall \xi \in \mathbb{R}^d, \qquad x \in \Omega; \tag{1.3}$$

- $\mathbf{b} \in [L^\infty(\Omega)]^d$ is divergence free ($\nabla\cdot\mathbf{b} = 0$ in Ω);
- $c \in L^\infty(\Omega)$ is nonnegative ($c \ge 0$ in Ω);
- $f \in L^2(\Omega)$.

The purpose of this paper is to prove the following convergence results for adaptive finite element methods (AFEMs) for (1.1)–(1.2) and document their performance computationally.

THEOREM 1.1 (convergence of AFEMs). *Let $\{u_k\}_{k\in\mathbb{N}_0}$ be a sequence of finite element solutions corresponding to a sequence of nested finite element spaces $\{\mathbb{V}_k\}_{k\in\mathbb{N}_0}$ produced by the AFEM of section* 3.5*, which involves loops of the form*

$$\mathsf{SOLVE} \rightarrow \mathsf{ESTIMATE} \rightarrow \mathsf{MARK} \rightarrow \mathsf{REFINE}.$$

There exist constants $\sigma, \gamma > 0$ and $0 < \xi < 1$, depending solely on the shape regularity of meshes, the data, the parameters used by AFEM, and a number $0 < s \leq 1$ dictated by the interior angles of $\partial\Omega$, such that if the initial meshsize h_0 satisfies $h_0^s \|\mathbf{b}\|_{L^\infty} < \sigma$, then for any two consecutive iterations k and $k+1$, we have

$$\left|\!\left|\!\left| u - u_{k+1} \right|\!\right|\!\right|^2 + \gamma \ \mathsf{osc}_{k+1}\Omega^2 \leq \xi^2 \left(\left|\!\left|\!\left| u - u_k \right|\!\right|\!\right|^2 + \gamma \ \mathsf{osc}_k \Omega^2 \right). \tag{1.4}$$

Therefore, AFEM converges with a linear rate ξ, namely,

$$\left|\!\left|\!\left| u - u_k \right|\!\right|\!\right|^2 + \gamma \ \mathsf{osc}_k \Omega^2 \leq C_0 \ \xi^{2k},$$

where $C_0 := \left|\!\left|\!\left| u - u_0 \right|\!\right|\!\right|^2 + \gamma \ \mathsf{osc}_0(\Omega)^2$.

Hereafter, $|\!|\!| \cdot |\!|\!|$ denotes the energy norm induced by the operator $\mathcal{L}$ and $\mathsf{osc}(\Omega)$, the oscillation term, stands for the information missed by the averaging process associated with FEM. This convergence result extends those of Morin, Nochetto, and Siebert [7, 8] in several ways:

- We deal with a full second order linear elliptic PDE with variable coefficients $\mathbf{A}, \mathbf{b}$, and c, whereas in [7, 8] $\mathbf{A}$ is assumed to be piecewise constant and $\mathbf{b}$ and c to vanish.
- The underlying bilinear form $\mathcal{B}$ is nonsymmetric due to the first order term $\mathbf{b} \cdot \nabla u$. Since $\mathcal{B}$ is no longer a scalar product as in [7, 8], the Pythagoras equality relating u, u_k, and u_{k+1} fails; we prove a *quasi-orthogonality* property instead.
- The oscillation terms depend on discrete solutions in addition to data. Therefore, oscillation and error cannot be reduced separately as in [7, 8].
- The oscillation terms do not involve the oscillation of the jump residuals. This is achieved by exploiting positivity and continuity of $\mathbf{A}$.
- Since error and oscillation are now coupled, in order to prove convergence we need to handle them together. This leads to a novel argument and result, the contraction property (1.4), according to which both error and oscillation decrease together.

This paper is organized as follows. In section 2, we introduce the bilinear form, the energy norm, recall existence and uniqueness of solutions, and state the quasi-orthogonality property. In section 3, we describe the procedures used in AFEM, namely, SOLVE, ESTIMATE, MARK, and REFINE; state new error and oscillation reduction estimates; present the adaptive algorithm AFEM; and prove its convergence. In section 4, we prove the quasi-orthogonality property of section 2 and the error and oscillation reduction estimates of section 3. In section 5, we present three numerical experiments to illustrate properties of AFEM. We conclude in section 6 with extensions to $\mathbf{A}$ piecewise Lipschitz with discontinuities aligned with the initial mesh, as well as noncoercive bilinear form $\mathcal{B}$ due to $\nabla \cdot \mathbf{b} \neq 0$ and a numerical experiment.

2. Discrete solution and quasi-orthogonality.

For an open set $G \subset \mathbb{R}^d$ we denote by $H^1(G)$ the usual Sobolev space of functions in $L^2(G)$ whose first derivatives are also in $L^2(G)$, endowed with the norm

$$\|u\|_{H^1(G)} := \left(\|u\|_{L^2(G)} + \|\nabla u\|_{L^2(G)} \right)^{1/2}.$$

We use the symbols $\|\cdot\|_{H^1}$ and $\|\cdot\|_{L^2}$ when $G = \Omega$. Moreover, we denote by $H_0^1(G)$ the space of functions in $H^1(G)$ that vanish on the boundary in the trace sense.

A weak solution of (1.1) and (1.2) is a function u satisfying

$$u \in H^1_0(\Omega) \ : \ \mathcal{B}[u,v] = \langle f, v\rangle \qquad \forall\, v \in H^1_0(\Omega), \tag{2.1}$$

where $\langle u, v\rangle := \int_\Omega uv$ for any $u, v \in L^2(\Omega)$, and the bilinear form is defined on $H^1_0(\Omega) \times H^1_0(\Omega)$ as

$$\mathcal{B}[u,v] := \langle \mathbf{A}\nabla u, \nabla v\rangle + \langle \mathbf{b}\cdot\nabla u + c\, u, v\rangle. \tag{2.2}$$

By the Cauchy–Schwarz inequality one can easily show the *continuity* of the bilinear form

$$|\mathcal{B}[u,v]| \le C_B \, \|u\|_{H^1} \, \|v\|_{H^1},$$

where C_B depends only on the data. Combining Poincaré inequality with the divergence free condition $\nabla\cdot\mathbf{b}=0$, one has *coercivity* in $H^1_0(\Omega)$

$$\mathcal{B}[v,v] \ge \int_\Omega a_- \, |\nabla v|^2 + cv^2 \ge c_B \, \|v\|^2_{H^1},$$

where c_B depends only on the data. Existence and uniqueness of (2.1) thus follows from the Lax–Milgram theorem [5].

We define the energy norm on $H^1_0(\Omega)$ by $|\!|\!| v |\!|\!|^2 := \mathcal{B}[v,v]$, which is equivalent to $H^1_0(\Omega)$-norm $\|\cdot\|_{H^1}$. In fact we have

$$c_B \, \|v\|^2_{H^1} \le |\!|\!| v |\!|\!|^2 \le C_B \, \|v\|^2_{H^1} \qquad \forall\, v \in H^1_0(\Omega). \tag{2.3}$$

2.1. Discrete solutions on nested meshes. Let $\{\mathcal{T}_H\}$ be a shape regular family of nested conforming meshes over Ω, that is, there exists a constant γ^* such that

$$\frac{H_T}{\rho_T} \le \gamma^* \qquad \forall\, T \in \bigcup_H \mathcal{T}_H, \tag{2.4}$$

where, for each $T \in \mathcal{T}_H$, H_T is the diameter of T and ρ_T is the diameter of the biggest ball contained in T; the global meshsize is $h_H := \max_{T\in\mathcal{T}_H} H_T$.

Let $\{\mathbb{V}_H\}$ be a corresponding family of nested finite element spaces consisting of continuous piecewise polynomials over $\mathcal{T}_H$ of fixed degree $n \ge 1$ that vanish on the boundary. Let u_H be a discrete solution of (2.1) satisfying

$$u_H \in \mathbb{V}_H \ : \ \mathcal{B}[u_H, v_H] = \langle f, v_H\rangle \qquad \forall\, v_H \in \mathbb{V}_H. \tag{2.5}$$

The effect of quadrature is not considered in this paper. Existence and uniqueness of this problem follows from the Lax–Milgram theorem, since $\mathbb{V}_H \subset H^1_0(\Omega)$.

2.2. Quasi-orthogonality. Consider two consecutive nested meshes $\mathcal{T}_H \subset \mathcal{T}_h$, i.e., $\mathcal{T}_h$ is a refinement of $\mathcal{T}_H$. For the corresponding spaces $\mathbb{V}_H \subset \mathbb{V}_h \subset H^1_0(\Omega)$, let $u_h \in \mathbb{V}_h$ and $u_H \in \mathbb{V}_H$ be the discrete solutions. Since the bilinear form is nonsymmetric, it is not a scalar product and the orthogonality relation between $u - u_H$ and $u_h - u_H$, the so-called Pythagoras equality, fails to hold. We have instead a perturbation result referred to as quasi-orthogonality provided that the initial mesh is fine enough. This result is stated below and the proof is given in section 4.

LEMMA 2.1 (quasi-orthogonality). *Let $f \in L^2(\Omega)$. There exists a constant $C^* > 0$, solely depending on the shape regularity constant γ^*, the data $\mathbf{A}, \mathbf{b}$, and c, and a* *number $0 < s \le 1$ dictated only by the interior angles of $\partial\Omega$, such that if the meshsize h_0 of the initial mesh satisfies $C^* h_0^s \|\mathbf{b}\|_{L^\infty} < 1$, then*

$$\|\!|u - u_h|\!\|^2 \le \Lambda_0 \|\!|u - u_H|\!\|^2 - \|\!|u_h - u_H|\!\|^2, \tag{2.6}$$

where $\Lambda_0 := (1 - C^* h_0^s \|\mathbf{b}\|_{L^\infty})^{-1}$. The equality holds provided $\mathbf{b} = 0$ in Ω.

3. Adaptive algorithm.

The adaptive procedure consists of loops of the form

$$\mathsf{SOLVE} \to \mathsf{ESTIMATE} \to \mathsf{MARK} \to \mathsf{REFINE}.$$

The procedure SOLVE solves (2.5) for the discrete solution u_H. The procedure ESTIMATE determines the element indicators $\eta_H(T)$ and oscillation $\mathsf{osc}_H(T)$ for all elements $T \in \mathcal{T}_H$. Depending on their relative sizes, these quantities are later used by the procedure MARK to mark elements T and thereby create a subset $\widehat{\mathcal{T}}_H$ of $\mathcal{T}_H$ of elements to be refined. Finally, procedure REFINE partitions those elements in $\widehat{\mathcal{T}}_H$ and a few more to maintain mesh conformity. These procedures are discussed in more detail below.

3.1. Procedure SOLVE: Linear solver.

We employ linear solvers, either direct or iterative methods, such as preconditioned GMRES, CG, and BICG, to solve linear system (2.5). In other words, given a mesh $\mathcal{T}_k$, an initial guess u_{k-1} for the solution, and the data $\mathbf{A}, \mathbf{b}, c, f$, SOLVE computes the discrete solution

$$u_k := \mathsf{SOLVE}(\mathcal{T}_k, u_{k-1}, \mathbf{A}, \mathbf{b}, c, f).$$

3.2. Procedure ESTIMATE: A posteriori error estimate.

Since we assume exact numerical integration, subtracting (2.5) from (2.1) yields the Galerkin orthogonality

$$\mathcal{B}[u - u_H, v_H] = 0 \qquad \forall\, v_H \in \mathbb{V}_H. \tag{3.1}$$

In addition to $\mathcal{T}_H$, let $\mathcal{S}_H$ denote the set of interior faces (edges or sides) of the mesh (triangulation) $\mathcal{T}_H$. We consider the *residual* $\mathcal{R}(u_H) \in H^{-1}(\Omega)$ defined by

$$\mathcal{R}(u_H) := f + \nabla\cdot(\mathbf{A}\nabla u_H) - \mathbf{b}\cdot\nabla u_H - c\, u_H$$

and its relation to the error $\mathcal{L}(u - u_H) = \mathcal{R}(u_H)$. It is then clear that to estimate $\|\!|u - u_H|\!\|$ we can equivalently deal with $\|\mathcal{R}(u_H)\|_{H^{-1}(\Omega)}$. To this end, we integrate by parts elementwise the bilinear form $\mathcal{B}[u - u_H, v]$ to obtain the *error representation formula*

$$\mathcal{B}[u - u_H, v] = \sum_{T\in\mathcal{T}_H} \int_T R_T(u_H) v + \sum_{S\in\mathcal{S}_H} \int_S J_S(u_H) v \qquad \forall\, v \in H_0^1(\Omega), \tag{3.2}$$

where the *element residual* $R_T(u_H)$ and the *jump residual* $J_S(u_H)$ are defined as

$$R_T(u_H) := f + \nabla\cdot(\mathbf{A}\nabla u_H) - \mathbf{b}\cdot\nabla u_H - c\, u_H \qquad \text{in } T \in \mathcal{T}_H, \tag{3.3}$$

$$J_S(u_H) := -\mathbf{A}\nabla u_H^+ \cdot \nu^+ - \mathbf{A}\nabla u_H^- \cdot \nu^- := [\![\mathbf{A}\nabla u_H]\!]_S \cdot \nu_S \qquad \text{on } S \in \mathcal{S}_H, \tag{3.4}$$

where S is the common side of elements T^+ and T^- with unit outward normals ν^+ and ν^-, respectively, and $\nu_S = \nu^-$. Whenever convenient, we will use the abbreviations $R_T = R_T(u_H)$ and $J_S = J_S(u_H)$.

3.2.1. Upper bound. For $T \in \mathcal{T}_H$ and $S \in \mathcal{S}_h$ an interior face, we define the *local error indicator* $\eta_H(T)$ by

$$\eta_H(T)^2 := H_T^2 \left\| R_T(u_H) \right\|_{L^2(T)}^2 + \sum_{S \subset \partial T} H_S \left\| J_S(u_H) \right\|_{L^2(S)}^2 . \tag{3.5}$$

Given a subset $\omega \subset \Omega$, we define the *error estimator* $\eta_H(\omega)$ by

$$\eta_H(\omega)^2 := \sum_{T \in \mathcal{T}_H,\, T \subset \omega} \eta_H(T)^2.$$

Hence, $\eta_H(\Omega)$ is the error estimator of Ω with respect to the mesh $\mathcal{T}_H$. Using (3.1), (3.2), and properties of the Clément interpolation, as shown in [1, 3, 13], we obtain the upper bound of the error in terms of the estimator,

$$|\!|\!| u - u_H |\!|\!|^2 \leq C_1 \eta_H(\Omega)^2, \tag{3.6}$$

where the constant $C_1 > 0$ depends only on the shape regularity γ^*, coercivity constant c_B, and continuity constant C_B of the bilinear form.

3.2.2. Lower bound. Using the explicit construction of Verfürth [1, 13] via bubble functions and positivity and continuity of A, we can get a local lower bound of the error in terms of local indicators and oscillation. That is, there exist constants $C_2, C_3 > 0$, depending only on the shape regularity γ^*, C_B , and c_B, such that

$$C_2\, \eta_H(T)^2 - C_3 \sum_{T \subset \omega_T} H_T^2 \left\| R_T - \overline{R_T} \right\|_{L^2(T)}^2 \leq \left\| u - u_H \right\|_{H^1(\omega_T)}^2 , \tag{3.7}$$

where the domain ω_T consists of all elements sharing at least a side with T, and $\overline{R_T}$ is any polynomial approximation of R_T on T. However, for the purpose of proving Lemmas 3.1 and 3.2, we will assume that $\overline{R_T} \in \mathbb{P}_{n-1}(T)$ is the L^2-projection of R_T. We define the *oscillation* on the elements $T \in \mathcal{T}_H$ by

$$\mathsf{osc}_H(T)^2 := H_T^2 \left\| R_T - \overline{R_T} \right\|_{L^2(T)}^2 , \tag{3.8}$$

and for a subset $\omega \subset \Omega$, we define

$$\mathsf{osc}_H(\omega)^2 := \sum_{T \in \mathcal{T}_H,\, T \subset \omega} \mathsf{osc}_H(T)^2 .$$

Remark 3.1. We see from (3.7) that if the oscillation $\mathsf{osc}_H(\omega_T)$ is small compared to the indicator $\eta_H(T)$, then a large $\eta_H(T)$ implies a large local error $\| u - u_H \|_{H^1(\omega_T)}$. This explains why refining elements with large indicators usually tend to equidistribute the errors, which is an ultimate goal of adaptivity. This idea is employed by the procedure MARK of section 3.3.

Remark 3.2. The oscillation $\mathsf{osc}_H(T)$ does not involve oscillation of the jump residual $J_S(u_H)$ as is customary [1, 13]. This result follows from the positivity and continuity of $\mathbf{A}$, and is explained in section 4.2.

Remark 3.3. The oscillation $\mathsf{osc}_H(T)$ depends on $R_T = R_T(u_H)$, which in turn depends on the discrete solution u_H. This is a fundamental difference with Morin, Nochetto, and Siebert [7, 8], where the oscillation is purely a data oscillation. It is not clear now that the oscillation will decrease when the mesh $\mathcal{T}_H$ will be refined because

u_H will also change. Controlling the decay of $\mathsf{osc}_H(T)$ is thus a major challenge addressed in this work; see sections 3.3 and 3.4. It is not possible to show that the oscillation will always decrease as the mesh gets refined as in [7, 8].

For a given mesh $\mathcal{T}_H$ and discrete solution u_H, along with the input data $\mathbf{A}, \mathbf{b}, c$, and f, the procedure $\mathsf{ESTIMATE}$ computes indicators $\eta_H(T)$ and oscillations $\mathsf{osc}_H(T)$ for all elements $T \in \mathcal{T}_H$ according to (3.5) and (3.8):

$$\{\eta_H(T), \mathsf{osc}_H(T)\}_{T\in\mathcal{T}_H} = \mathsf{ESTIMATE}(\mathcal{T}_H, u_H, \mathbf{A}, \mathbf{b}, c, f).$$

3.3. Procedure MARK.

Our goal is to devise a marking procedure, namely, to identify a subset $\widehat{\mathcal{T}}_H$ of the mesh $\mathcal{T}_H$ such that, after refining, both error and oscillation will be reduced. We use two strategies for this: Marking Strategy E deals with the error estimator and Marking Strategy O does so with the oscillation.

3.3.1. Marking Strategy E: Error reduction.

This strategy was introduced by Dörfler [4] to enforce error reduction.

Marking Strategy E. *Given a parameter $0 < \theta < 1$, construct a subset $\widehat{\mathcal{T}}_H$ of $\mathcal{T}_H$ such that*

$$\sum_{T\in\widehat{\mathcal{T}}_H} \eta_H(T)^2 \geq \theta^2 \eta_H(\Omega)^2, \tag{3.9}$$

and mark all elements in $\widehat{\mathcal{T}}_H$ for refinement.

We will see later that Marking Strategy E guarantees error reduction in the absence of oscillation terms. Since the latter account for information missed by the averaging process associated with the finite element method, we need a separate procedure to guarantee oscillation reduction.

3.3.2. Marking Strategy O: Oscillation reduction.

This procedure was introduced by Morin, Nochetto, and Siebert [7, 8] as a separate means for reducing oscillation.

Marking Strategy O. *Given a parameter $0 < \hat{\theta} < 1$ and the subset $\widehat{\mathcal{T}}_H \subset \mathcal{T}_H$ produced by Marking Strategy E, enlarge $\widehat{\mathcal{T}}_H$ such that*

$$\sum_{T\in\widehat{\mathcal{T}}_H} \mathsf{osc}_H(T)^2 \geq \hat{\theta}^2 \mathsf{osc}_H(\Omega)^2\,, \tag{3.10}$$

and mark all elements in $\widehat{\mathcal{T}}_H$ for refinement.

Given a mesh $\mathcal{T}_H$ and all information about the local error indicators $\eta_H(T)$ and oscillation $\mathsf{osc}_H(T)$, together with user parameters θ and $\hat{\theta}$, MARK generates a subset $\widehat{\mathcal{T}}_H$ of $\mathcal{T}_H$,

$$\widehat{\mathcal{T}}_H = \mathsf{MARK}(\theta, \hat{\theta}\ ;\ \mathcal{T}_H, \{\eta_H(T), \mathsf{osc}_H(T)\}_{T\in\mathcal{T}_H}).$$

3.4. Procedure REFINE.

The following interior node property, due to Morin, Nochetto, and Siebert [7, 8], is known to be necessary for error and oscillation reduction.

Interior Node Property. *Refine each marked element $T \in \widehat{\mathcal{T}}_H$ to obtain a new mesh $\mathcal{T}_h$ compatible with $\mathcal{T}_H$ such that*

> *T and the $d+1$ adjacent elements $T' \in \mathcal{T}_H$ of T, as well as their common sides, contain a node of the finer mesh $\mathcal{T}_h$ in their interior.*

In addition to the interior node property, we assume that the refinement is done in such a way that the new mesh $\mathcal{T}_h$ is conforming, which guarantees that both $\mathcal{T}_H$

and $\mathcal{T}_h$ are nested. With this property, we have a reduction factor $\gamma_0 < 1$ of element size, i.e., if $T \in \mathcal{T}_h$ is obtained by refining $T' \in \widehat{\mathcal{T}}_H$, then $h_T \le \gamma_0 H_{T'}$. For example, when $d = 2$ with triangular elements, to have the interior node property we can use the three newest bisections for each single refinement step, whence $\gamma_0 \le 1/2$.

Given a mesh $\mathcal{T}_H$ and a marked set $\widehat{\mathcal{T}}_H$, REFINE constructs the refinement $\mathcal{T}_h$ satisfying the interior node property:

$$\mathcal{T}_h = \mathsf{REFINE}(\mathcal{T}_H, \widehat{\mathcal{T}}_H).$$

Combining the marking strategies of section 3.3 with the interior node property, we obtain the following two crucial results whose proofs are given in section 4.

LEMMA 3.1 (error reduction). *There exist constants C_4 and C_5, depending only on the shape regularity constant γ^* and θ, such that*

$$\eta_H(T)^2 \le C_4 \left\| u_h - u_H \right\|^2_{H^1(\omega_T)} + C_5 \mathsf{osc}_H \omega_T{}^2 \qquad \forall\, T \in \widehat{\mathcal{T}}_H. \tag{3.11}$$

We realize that the local energy error between consecutive discrete solutions is bounded below by the local indicators for elements in the marked set $\widehat{\mathcal{T}}_H$, provided the oscillation term is sufficiently small relative to the energy error.

LEMMA 3.2 (oscillation reduction). *There exist constants $0 < \rho_1 < 1$ and $0 < \rho_2$, depending only on γ^* and $\hat{\theta}$, such that*

$$\mathsf{osc}_h \Omega^2 \le \rho_1 \mathsf{osc}_H \Omega^2 + \rho_2 \left|\!\left|\!\left| u_h - u_H \right|\!\right|\!\right|^2 . \tag{3.12}$$

We have that the oscillation reduces with a factor $\rho_1 < 1$ provided the energy error between consecutive discrete solutions is relatively small.

Remark 3.4 (coupling of error and oscillation). Lemmas 3.1 and 3.2 seem to lead to conflicting demands on the relative sizes of error and oscillation. These two concepts are indeed coupled, which contrasts with [7, 8], where the oscillation depends only on the data and reduces separately from the error. This suggests that we must handle them together, this being the main contribution of this paper. We make this assertion explicit in Theorem 1.1.

3.5. Adaptive algorithm AFEM. The adaptive algorithm consists of the loops of procedures SOLVE, $\mathsf{ESTIMATE}$, MARK, and REFINE, consecutively, given that the parameters θ and $\hat{\theta}$ are chosen according to Marking Strategies E and O.

ALGORITHM AFEM.

```
Choose parameters $0 < \theta, \hat{\theta} < 1$.
 1. Pick an initial mesh $\mathcal{T}_0$, initial guess $u_{-1} = 0$, and set $k = 0$.
 2. $u_k = \mathsf{SOLVE}(\mathcal{T}_k, u_{k-1}, \mathbf{A}, \mathbf{b}, c, f)$.
 3. $\{\eta_k(T), \mathsf{osc}_k(T)\}_{T \in \mathcal{T}_k} = \mathsf{ESTIMATE}(\mathcal{T}_k, u_k, \mathbf{A}, \mathbf{b}, c, f)$.
 4. $\widehat{\mathcal{T}_k} = \mathsf{MARK}(\theta, \hat{\theta}\ ;\ \mathcal{T}_k, \{\eta_k(T), \mathsf{osc}_k(T)\}_{T \in \mathcal{T}_k})$.
 5. $\mathcal{T}_{k+1} = \mathsf{REFINE}(\mathcal{T}_k, \widehat{\mathcal{T}_k})$.
 6. Set $k = k + 1$ and go to step 2.
```

THEOREM 1.1 (convergence of AFEM). *Let $\{u_k\}_{k \in \mathbb{N}_0}$ be a sequence of finite element solutions corresponding to a sequence of nested finite element spaces $\{\mathbb{V}^k\}_{k \in \mathbb{N}_0}$ produced by AFEM. There exist constants $\sigma, \gamma > 0$ and $0 < \xi < 1$, depending solely on the mesh regularity constant γ^*, data, parameters θ and $\hat{\theta}$, and a number $0 < s \le 1$ dictated by interior angles of $\partial\Omega$, such that if the initial meshsize h_0 satisfies $h_0^s \|\mathbf{b}\|_{L^\infty} < \sigma$, then for any two consecutive iterations k and $k+1$, we have*

$$\left|\!\left|\!\left| u - u_{k+1} \right|\!\right|\!\right|^2 + \gamma\ \mathsf{osc}_{k+1} \Omega^2 \le \xi^2 \left(\left|\!\left|\!\left| u - u_k \right|\!\right|\!\right|^2 + \gamma\ \mathsf{osc}_k \Omega^2 \right). \tag{3.13}$$

Therefore, AFEM converges with a linear rate ξ, namely,

$$|||u-u_k|||^2+\gamma\ \mathsf{osc}_k\Omega^2\le C_0\ \xi^{2k},$$

where $C_0:=|||u-u_0|||^2+\gamma\ \mathsf{osc}_0\Omega^2$.

Proof. We just prove the contraction property (3.13), which obviously implies the decay estimate. For convenience, we introduce the notation

$$e_k:=|||u-u_k|||\,,\qquad \varepsilon_k:=|||u_{k+1}-u_k|||\,,\qquad \mathsf{osc}_k:=\mathsf{osc}_k(\Omega)\,.$$

The idea is to use the quasi-orthogonality (2.6) and replace the term $|||u_{k+1}-u_k|||^2$ using new results of error and oscillation reduction estimates (3.11) and (3.12). We proceed in three steps as follows.

Step 1. We first get a lower bound for ε_k in terms of e_k. To this end, we use Marking Strategy E and the upper bound (3.6) to write

$$\theta^2e_k^2\le C_1\theta^2\eta_k(\Omega)^2\le C_1\sum_{T\in\widehat{\mathcal{T}_k}}\eta_k(T)^2.$$

Adding (3.11) of Lemma 3.1 over all marked elements $T\in\widehat{\mathcal{T}_k}$, and observing that each element can be counted at most $D:=d+2$ times due to overlap of the sets ω_T, together with $\|v\|_{H^1}^2\le c_B^{-1}\,|||v|||^2$ for all $v\in H_0^1(\Omega)$, we arrive at

$$\theta^2e_k^2\le\frac{DC_1C_4}{c_B}\ \varepsilon_k^2+DC_1C_5\ \mathsf{osc}_k^2.$$

If $\Lambda_1:=\frac{\theta^2c_B}{DC_1C_4},\Lambda_2:=\frac{C_5c_B}{C_4}$, then this implies the lower bound for ε_k^2,

$$\varepsilon_k^2\ge\Lambda_1e_k^2-\Lambda_2\mathsf{osc}_k^2. \tag{3.14}$$

Step 2. If h_0 is sufficiently small so that the quasi-orthogonality (2.6) of Lemma 2.1 holds with $\Lambda_0=(1-C^*h_0^s\,\|\mathbf{b}\|_{L^\infty})^{-1}$, then

$$e_{k+1}^2\le\Lambda_0e_k^2-\varepsilon_k^2.$$

Replacing the fraction $\beta\varepsilon_k^2$ of ε_k^2 via (3.14) we obtain

$$e_{k+1}^2\le(\Lambda_0-\beta\Lambda_1)e_k^2+\beta\Lambda_2\mathsf{osc}_k^2-(1-\beta)\varepsilon_k^2,$$

where $0<\beta<1$ is a constant to be chosen suitably. We now assert that it is possible to choose h_0 compatible with Lemma 2.1 and also that

$$0<\alpha:=\Lambda_0-\beta\Lambda_1<1.$$

A simple calculation shows that this is the case provided

$$C^*h_0^s\,\|\mathbf{b}\|_{L^\infty}<\frac{\beta\Lambda_1}{(1+\beta\Lambda_1)}<1,$$

i.e., $h_0^s\,\|\mathbf{b}\|_{L^\infty}<\sigma$ with $\sigma:=\frac{\beta\Lambda_1}{C^*(1+\beta\Lambda_1)}$. Consequently,

$$e_{k+1}^2\le\alpha e_k^2+\beta\Lambda_2\mathsf{osc}_k^2-(1-\beta)\varepsilon_k^2. \tag{3.15}$$

Step 3. To remove the last term of (3.15) we resort to the oscillation reduction estimate of Lemma 3.2

$$\mathsf{osc}_{k+1}^2 \le \rho_1 \mathsf{osc}_k^2 + \rho_2 \varepsilon_k^2.$$

We multiply it by $(1-\beta)/\rho_2$ and add it to (3.15) to deduce

$$e_{k+1}^2 + \frac{1-\beta}{\rho_2}\mathsf{osc}_{k+1}^2 \le \alpha\, e_k^2 + \left(\beta\Lambda_2 + \frac{\rho_1}{\rho_2}(1-\beta)\right)\mathsf{osc}_k^2.$$

If $\gamma := \frac{1-\beta}{\rho_2}$, then we would like to choose $\beta < 1$ in such a way that

$$\beta\Lambda_2 + \rho_1\gamma = \mu\gamma$$

for some $\mu < 1$. A simple calculation yields

$$\beta = \frac{\frac{\mu-\rho_1}{\rho_2}}{\Lambda_2 + \frac{\mu-\rho_1}{\rho_2}},$$

and shows that $\rho_1 < \mu < 1$ guarantees that $0 < \beta < 1$. Therefore,

$$e_{k+1}^2 + \gamma\ \mathsf{osc}_{k+1}^2 \le \alpha\ e_k^2 + \mu\gamma\ \mathsf{osc}_k^2$$

and the asserted estimate (3.13) follows upon taking $\xi = \max(\alpha, \mu) < 1$. □

Remark 3.5 (comparison with [7, 8]). In [7, 8] the oscillation is independent of discrete solutions, i.e., $\rho_2 = 0$, and is reduced by the factor $\rho_1 < 1$ in (3.12). Consequently, Step 3 is avoided by setting $\beta = 1$, and the decay of e_k and osc_k is monitored separately. Since this is no longer possible, e_k and osc_k are now combined and decreased together.

Remark 3.6 (splitting of ε_k). The idea of splitting ε_k is already used by Chen and Jia [2] in examining one time step for the heat equation. This is because a mass (zero order) term naturally occurs, which did not take place in [7, 8]. The elliptic operator is just the Laplacian in [2].

Remark 3.7 (effect of convection). Assuming that $h_0^s \|\mathbf{b}\|_{L^\infty} < \sigma$ implies that the local Péclet number is sufficiently small for the Galerkin method not to exhibit oscillations. This appears to be essential for u_0 to contain relevant information and guide correctly the adaptive process. This restriction is difficult to verify in practice because it involves unknown constants. However, starting from coarser meshes than needed in theory does not seem to be a problem in our examples (see section 5.3) where we carefully express the constant σ in terms of data.

Remark 3.8 (vanishing convection). If $\mathbf{b} = 0$, then Theorem 1.1 has no restriction on the initial mesh. This thus extends the convergent result of Morin, Nochetto, and Siebert [7, 8] to variable diffusion coefficient and zero order terms.

Remark 3.9 (optimal β). The choice of β can be optimized. In fact, we can easily see that

$$\alpha = \Lambda_0 - \beta\Lambda_1, \qquad \mu = \rho_1 + \frac{\beta}{1-\beta}\rho_2\Lambda_2$$

yield a unique value $0 < \beta_* < 1$ for which $\alpha = \mu$ and the contraction constant ξ of Theorem 1.1 is minimal. This β_* depends on the geometric constants Λ_0, Λ_1, and Λ_2 as well on $\theta, \hat{\theta}$, and h_0, but it is not computable.

4. Proofs of lemmas. Let $\widehat{\mathcal{T}}_H \subset \mathcal{T}_H$ be a set of marked elements obtained from procedure MARK. Let $\mathcal{T}_h$ be a refined mesh obtained from procedure REFINE, and let $\mathbb{V}_H \subset \mathbb{V}_h$ be nested spaces corresponding to compatible meshes $\mathcal{T}_H$ and $\mathcal{T}_h$, respectively. For convenience, set

$$e_h := u - u_h, \qquad e_H := u - u_H, \qquad \varepsilon_H := u_h - u_H.$$

4.1. Proof of Lemma 2.1: Quasi-orthogonality. In view of the Galerkin orthogonality (3.1), namely, $\mathcal{B}[e_h, v_h] = 0$, $v_h \in \mathbb{V}_h$, we have

$$|\!|\!| e_H |\!|\!|^2 = |\!|\!| e_h |\!|\!|^2 + |\!|\!| \varepsilon_H |\!|\!|^2 + \mathcal{B}[\varepsilon_H, e_h].$$

If $\mathbf{b} = 0$, then $\mathcal{B}$ is symmetric and $\mathcal{B}[\varepsilon_H, e_h] = \mathcal{B}[e_h, \varepsilon_H] = 0$. For $\mathbf{b} \neq 0$, instead, $\mathcal{B}[\varepsilon_H, e_h] \neq 0$, and we must account for this term. It is easy to see that $\nabla \cdot \mathbf{b} = 0$ and that integration by parts yields

$$\mathcal{B}[\varepsilon_H, e_h] = \mathcal{B}[e_h, \varepsilon_H] + \langle \mathbf{b} \cdot \nabla \varepsilon_H, e_h \rangle - \langle \mathbf{b} \cdot \nabla e_h, \varepsilon_H \rangle = 2 \langle \mathbf{b} \cdot \nabla \varepsilon_H, e_h \rangle.$$

Hence,

$$|\!|\!| e_h |\!|\!|^2 = |\!|\!| e_H |\!|\!|^2 - |\!|\!| \varepsilon_H |\!|\!|^2 - 2 \langle \mathbf{b} \cdot \nabla \varepsilon_H, e_h \rangle .$$

Using the Cauchy–Schwarz inequality and replacing the $H^1(\Omega)$-norm by the energy norm, we have for any $\delta > 0$ to be chosen later

$$-2 \langle \mathbf{b} \cdot \nabla \varepsilon_H, e_h \rangle \leq \delta \, \|e_h\|_{L^2}^2 + \frac{\|\mathbf{b}\|_{L^\infty}^2}{\delta c_B} |\!|\!| \varepsilon_H |\!|\!|^2 .$$

We then realize the need to relate $L^2(\Omega)$ and energy norms to replace $\|e_h\|_{L^2}$ by $|\!|\!| e_h |\!|\!|$. This requires a standard duality argument whose proof is reported in Ciarlet [3].

LEMMA 4.1 (duality). *Let $f \in L^2(\Omega)$ and $u \in H^{1+s}(\Omega)$ for some $0 < s \leq 1$ be the solution of* (2.1)*, where s depends on the interior angles of $\partial\Omega$ ($s = 1$ if Ω is convex). Then, there exists a constant C_D, depending only on the shape regularity constant γ^* and the data of* (1.1)*, such that*

$$\|e_h\|_{L^2} \leq C_D h^s \, \|e_h\|_{H^1} . \tag{4.1}$$

Inserting this estimate in the preceding two bounds, and using $h \leq h_0$, the mesh-size of the initial mesh, in conjunction with (2.3), we deduce

$$\left(1 - \delta {C_D}^2 c_B^{-1} h_0^{2s}\right) |\!|\!| e_h |\!|\!|^2 \leq |\!|\!| e_H |\!|\!|^2 - \left(1 - \|\mathbf{b}\|_{L^\infty}^2 (\delta c_B)^{-1}\right) |\!|\!| \varepsilon_H |\!|\!|^2 .$$

We now choose $\delta = \frac{\|\mathbf{b}\|_{L^\infty}}{C_D h_0^s}$ to equate both parentheses, as well as h_0 sufficiently small for $\delta {C_D}^2 h_0^{2s} c_B^{-1} = C^* h_0^s \, \|\mathbf{b}\|_{L^\infty} < 1$ with $C^* := C_D / c_B$. We end up with

$$|\!|\!| e_h |\!|\!|^2 \leq \frac{1}{1 - C^* h_0^s \, \|\mathbf{b}\|_{L^\infty}} |\!|\!| e_H |\!|\!|^2 - |\!|\!| \varepsilon_H |\!|\!|^2 .$$

This implies (2.6) and concludes the proof. $\square$

4.2. Proof of Lemma 3.1: Error reduction. Upon restricting the test function v in (3.2) to $\mathbb{V}_h \supset \mathbb{V}_H$, we obtain the error representation

$$\mathcal{B}[\varepsilon_H, v_h] = \sum_{T\in\mathcal{T}_H} \int_T \overline{R_T} v_h + \int_T (R_T - \overline{R_T}) v_h + \sum_{S\in\mathcal{S}_H} \int_S J_S\, v_h \qquad \forall\, v_h \in \mathbb{V}_h, \tag{4.2}$$

where we use the abbreviations $R_T = R_T(u_H)$ and $J_S = J_S(u_H)$, and $\overline{R_T} = \Pi_T^{n-1} R_T$ denotes the L_2-projection of R_T onto the space of polynomials $\mathbb{P}_{n-1}(T)$ over the element $T \in \mathcal{T}_H$. Except for avoiding the oscillation terms of the jump residual J_S, the proof goes back to [4, 7, 8]. We proceed in three steps.

Step 1. *Interior residual.* Let $T \in \mathcal{T}_H$, and let x_T be an interior node of T generated by the procedure REFINE. Let $\psi_T \in \mathbb{V}_h$ be a bubble function which satisfies $\psi_T(x_T) = 1$, vanishes on ∂T, and $0 \le \psi_T \le 1$; hence supp $\psi_T \subset T$. Since $\overline{R_T} \in \mathbb{P}_{n-1}(T)$ and $\psi_T > 0$ in a polyhedron of measure comparable with that of T, we have

$$C \left\|\overline{R_T}\right\|_{L^2(T)}^2 \le \int_T \psi_T\, \overline{R_T}^2 = \int_T \overline{R_T}(\psi_T\, \overline{R_T}).$$

Since $\psi_T \overline{R_T}$ is a piecewise polynomial of degree $\le n$ over $\mathcal{T}_h$, it is an admissible test function in (4.2) which vanishes outside T (and in particular on all $S \in \mathcal{S}_H$). Therefore,

$$\begin{aligned} C \left\|\overline{R_T}\right\|_{L^2(T)}^2 &\le \mathcal{B}[\varepsilon_H, \psi_T \overline{R_T}] + \int_T (\overline{R_T} - R_T)\psi_T \overline{R_T} \\ &\le C \left(H_T^{-1} \left\|\varepsilon_H\right\|_{H^1(T)} + \left\|R_T - \overline{R_T}\right\|_{L^2(T)} \right) \left\|\overline{R_T}\right\|_{L^2(T)}, \end{aligned}$$

because of an inverse inequality for $\psi_T \overline{R_T}$. This, together with the triangle inequality, yields the desired estimate for $H_T^2 \left\|R_T\right\|_{L^2(T)}^2$,

$$H_T^2 \left\|R_T\right\|_{L^2(T)}^2 \le C \left(\left\|\varepsilon_H\right\|_{H^1(T)}^2 + H_T^2 \left\|R_T - \overline{R_T}\right\|_{L^2(T)}^2 \right). \tag{4.3}$$

Step 2. *Jump residual.* Let $S \in \mathcal{S}_H$ be an interior side of $T_1 \in \widehat{\mathcal{T}}_H$, and let $T_2 \in \mathcal{T}_H$ be the other element sharing S. Let x_S be an interior node of S created by procedure REFINE. Let $\psi_S \in \mathbb{V}_h$ be a bubble function in $\omega_S := T_1 \cup T_2$ such that $\psi_S(x_S) = 1$, ψ_S vanishes on $\partial\omega_S$, and $0 \le \psi_S \le 1$; hence supp $\psi_S \subset \omega_S$.

Since u_H is continuous, $[\![\nabla u_H]\!]_S$ is parallel to ν_S, i.e., $[\![\nabla u_H]\!]_S = j_S\, \nu_S$. Moreover, the coefficient matrix $\mathbf{A}(x)$ being continuous implies

$$J_S = \mathbf{A}(x)\, [\![\nabla u_H]\!]_S \cdot \nu_S = j_S\, \mathbf{A}(x) \nu_S \cdot \nu_S = a(x)\, j_S,$$

where $a(x) := \mathbf{A}(x)\nu_S \cdot \nu_S$ satisfies $0 < \underline{a}_S \le a(x) \le \overline{a}_S$ with $\underline{a}_S, \overline{a}_S$ the smallest and largest eigenvalues of $\mathbf{A}(x)$ on S. Consequently,

$$\left\|J_S\right\|_{L^2(S)}^2 \le \overline{a}_S^2 \int_S j_S^2 \le C \overline{a}_S^2 \int_S j_S^2 \psi_S \le C \frac{\overline{a}_S^2}{\underline{a}_S} \int_S (j_S\, \psi_S) J_S, \tag{4.4}$$

where the second inequality follows from j_S being a polynomial and $\psi_S > 0$ in a polygon of measure comparable with that of S.

We now extend j_S to ω_S by first mapping to the reference element, next extending constantly along the normal to $\hat{S}$, and finally mapping back to ω_S. The resulting extension $\mathsf{E}_h(j_S)$ is a piecewise polynomial of degree $\le n-1$ in ω_S so that $\psi_S \mathsf{E}_h(j_S) \in \mathbb{V}_h$, and satisfies $\|\psi_S \mathsf{E}_h(j_S)\|_{L^2(\omega_S)} \leq C H_S^{1/2} \|j_S\|_{L^2(S)}$. Since $v_h = \psi_S \mathsf{E}_h(j_S)$ is an admissible test function in (4.2) which vanishes on all sides of $\mathcal{S}_H$ but S, we arrive at

$$\begin{aligned}\int_S J_S(j_S\psi_S) &= \mathcal{B}[\varepsilon_H, v_h] - \int_{T_1} R_{T_1}\, v_h - \int_{T_2} R_{T_2}\, v_h \\ &\leq C\left(H_S^{-1/2}\|\varepsilon_H\|_{H^1_S(\omega_S)} + H_S^{1/2}\sum_{i=1}^{2}\|R_{T_i}\|_{L^2(T_i)}\right)\|j_S\|_{L^2(S)}.\end{aligned} \tag{4.5}$$

Therefore,

$$H_S\|J_S\|^2_{L^2(S)} \leq C\left(\|\varepsilon_H\|^2_{H^1(\omega_S)} + \sum_{i=1}^{2} H^2_{T_i}\|R_{T_i}\|^2_{L^2(T_i)}\right). \tag{4.6}$$

Step 3. *Final estimate.* To remove the interior residual from the right-hand side of (4.6) we observe that both T_1 and T_2 contain an interior node according to procedure REFINE. Hence, (4.3) implies

$$H_S\|J_S\|^2_{L^2(S)} \leq C\left(\|\varepsilon_H\|^2_{H^1(\omega_S)} + \sum_{i=1}^{2} H^2_{T_i}\left\|R_{T_i} - \overline{R_{T_i}}\right\|^2_{L^2(T_i)}\right). \tag{4.7}$$

The asserted estimate for $\eta_H(T)^2$ is thus obtained by adding this bound to (4.3). The constant C depends on the shape regularity constant γ^* and the ratio $\overline{a}_S^2/\underline{a}_S$ of largest and smallest eigenvalues of $\mathbf{A}(x)$ for $x \in S$. □

Remark 4.1 (positivity). The use of $\mathbf{A}(x)$ being positive definite in (4.4) avoids having oscillation terms on S. This comes at the expense of a constant depending on $\overline{a}_S^2/\underline{a}_S$. If we were to proceed in the usual manner, as in [1, 9, 13], we would end up with an oscillation of the form

$$\begin{aligned}H_S^{1/2}\|(\mathbf{A}-\mathbf{A}(x_S))\,[\![\nabla u_H]\!]_S\cdot\nu_S\|_{L^2(S)} &= H_S^{1/2}\|(a-a(x_S))j_S\|_{L^2(S)} \\ &\leq C H_S^{3/2}\|\mathbf{A}\|_{W^1_\infty(S)}\|j_S\|_{L^2(S)} \\ &\leq C H_S\left\|H_S^{1/2} J_S\right\|_{L^2(S)},\end{aligned}$$

where $C > 0$ also depends on the ratio $\overline{a}_S/\underline{a}_S$ dictated by the variation of $a(x)$ on S. This oscillation can be absorbed into the term $H_S^{1/2}\|J_S\|_{L^2(S)}$ provided that the meshsize H_S is sufficiently small; see [9]. We do not need this assumption in our present discussion.

Remark 4.2 (continuity of $\mathbf{A}$). The continuity of $\mathbf{A}$ is instrumental in avoiding jump oscillations, which in turn makes computations simpler. However, jump oscillations cannot be avoided when $\mathbf{A}$ exhibits discontinuities across interelement boundaries of the initial mesh. We get instead of (4.7)

$$CH_S\|J_S\|^2_{L^2(S)} \leq \|\varepsilon_H\|^2_{H^1(\omega_S)} + \sum_{i=1}^{2} H^2_{T_i}\left\|R_{T_i} - \overline{R_{T_i}}\right\|^2_{L^2(T_i)} + H_S\left\|J_S - \overline{J_S}\right\|^2_{L^2(S)}, \tag{4.8}$$

where $\overline{J_S}$ is the best L^2-projection of J_S onto $\mathbb{P}_{n-1}(S)$. To obtain estimate (4.8) we proceed as follows. Starting from a polynomial $\overline{J_S}$, we get an estimate similar to that of (4.4),

$$C\left\|\overline{J_S}\right\|^2_{L^2(S)} \leq \int_S \psi_S \overline{J_S}^2 = \int_S J_S(\psi_S\overline{J_S}) + \int_S (\overline{J_S} - J_S)(\psi_S\overline{J_S}). \tag{4.9}$$

In contrast to (4.4), we see that the oscillation term $(\overline{J_S} - J_S)$ cannot be avoided when $\mathbf{A}$ has a discontinuity across S. We estimate the first term on the right-hand side of (4.9) exactly as we have argued with (4.5) and thereby arrive at

$$\int_S J_S(\overline{J_S}\psi_S) \le C\left(H_S^{-1/2}\,\|\varepsilon_H\|_{H^1_S(\omega_S)} + H_S^{1/2}\sum_{i=1}^{2}\|R_{T_i}\|_{L^2(T_i)}\right)\left\|\overline{J_S}\right\|_{L^2(S)}.$$

This and a further estimate of the second term on the right-hand side of (4.9) yield

$$H_S\left\|\overline{J_S}\right\|^2_{L^2(S)} \le C\left(\|\varepsilon_H\|^2_{H^1(\omega_S)} + \sum_{i=1}^{2}H_{T_i}^2\,\|R_{T_i}\|^2_{L^2(T_i)} + H_S\left\|J_S - \overline{J_S}\right\|^2_{L^2(S)}\right),$$

whence assertion (4.8) follows using the triangle inequality for $\|J_S\|_{L^2(S)}$. Combining with (4.3), we deduce an estimate for $\eta_H(T)$ similar to (3.11), namely,

$$\eta_H(T)^2 \le C\left(\|\varepsilon_H\|^2_{H^1(\omega_T)} + \mathsf{osc}_H(\omega_T)^2\right)$$

with the new oscillation term involving jumps on interior sides

$$\mathsf{osc}_H(T)^2 := H_T^2\left\|R_T - \overline{R_T}\right\|^2_{L^2(T)} + \sum_{S\subset\partial T} H_S\left\|J_S - \overline{J_S}\right\|^2_{L^2(S)}. \tag{4.10}$$

In section 6.1, we discuss the case of a discontinuous $\mathbf{A}$. We show an oscillation reduction property of $\mathsf{osc}_H(T)$, defined by (4.10), similar to Lemma 3.2.

4.3. Proof of Lemma 3.2: Oscillation reduction. The proof hinges on the Marking Strategy O and the interior node property. We point out that if $T \in \mathcal{T}_h$ is contained in $T' \in \widehat{\mathcal{T}}_H$, then REFINE gives a reduction factor $\gamma_0 < 1$ of element size

$$h_T \le \gamma_0 H_{T'}. \tag{4.11}$$

The proof proceeds in three steps as follows.

Step 1. *Relation between oscillations.* We would like to relate $\mathsf{osc}_h(T')$ and $\mathsf{osc}_H(T')$ for any $T' \in \mathcal{T}_H$. To this end, we note that for all $T \in \mathcal{T}_h$ contained in T', we can write

$$R_T(u_h) = R_T(u_H) - \mathcal{L}_T(\varepsilon_H) \qquad \text{in } T,$$

where $\varepsilon_H = u_h - u_H$ as before and

$$\mathcal{L}_T(\varepsilon_H) := -\nabla\cdot(\mathbf{A}\nabla\varepsilon_H) + \mathbf{b}\cdot\nabla\varepsilon_H + c\,\varepsilon_H \qquad \text{in } T.$$

By Young's inequality, we have for all $\delta > 0$

$$\begin{aligned}\mathsf{osc}_h(T)^2 &= h_T^2\left\|R_T(u_h) - \overline{R_T(u_h)}\right\|^2_{L^2(T)}\\ &\le (1+\delta)h_T^2\left\|R_T(u_H) - \overline{R_T(u_H)}\right\|^2_{L^2(T)} + (1+\delta^{-1})h_T^2\left\|\mathcal{L}_T(\varepsilon_H) - \overline{\mathcal{L}_T(\varepsilon_H)}\right\|^2_{L^2(T)},\end{aligned}$$

where $\overline{R_T(u_h)}$, $\overline{R_T(u_H)}$, and $\overline{\mathcal{L}_T(\varepsilon_H)}$ are L^2-projections of $R_T(u_h)$, $R_T(u_H)$, and $\mathcal{L}_T(\varepsilon_H)$ onto polynomials of degree $\le n-1$ on T. We next observe that

$$\left\|\mathcal{L}_T(\varepsilon_H) - \overline{\mathcal{L}_T(\varepsilon_H)}\right\|_{L^2(T)} \le \|\mathcal{L}_T(\varepsilon_H)\|_{L^2(T)}$$

and that, according to (4.11),

$$h_T \le \gamma_{T'} H_{T'}$$

provided $\gamma_{T'} = \gamma_0$ if $T' \in \widehat{\mathcal{T}}_H$ and $\gamma_{T'} = 1$ otherwise. Therefore, if $\mathcal{T}_h(T')$ denotes all $T \in \mathcal{T}_h$ contained in T',

$$\begin{aligned} \mathsf{osc}_h(T')^2 &= \sum_{T\in\mathcal{T}_h(T')} \mathsf{osc}_h(T)^2 \\ &\le (1+\delta)\gamma_{T'}^2 \mathsf{osc}_H(T')^2 + (1+\delta^{-1}) \sum_{T\in\mathcal{T}_h(T')} h_T^2 \left\|\mathcal{L}_T(\varepsilon_H)\right\|_{L^2(T)}^2, \end{aligned} \tag{4.12}$$

since $R_T(u_H) = R_{T'}(u_H)$ and $\overline{R_T(u_H)}$ is the best L^2-approximation of $R_{T'}(u_H)$ in T.

Step 2. *Estimate of* $\mathcal{L}_T(\varepsilon_H)$. In order to estimate $\|\mathcal{L}_T(\varepsilon_H)\|_{L^2(T)}$ in terms of $\|\varepsilon_H\|_{H^1(T)}$, we first split it as follows:

$$\|\mathcal{L}_T(\varepsilon_H)\|_{L^2(T)} \le \|\nabla\cdot(\mathbf{A}\nabla\varepsilon_H)\|_{L^2(T)} + \|\mathbf{b}\cdot\nabla\varepsilon_H\|_{L^2(T)} + \|c\,\varepsilon_H\|_{L^2(T)}.$$

We denote these terms N_A, N_B, and N_C, respectively. Since

$$N_A \le \|(\nabla\cdot\mathbf{A})\cdot\nabla\varepsilon_H\|_{L^2(T)} + \|\mathbf{A} : H(\varepsilon_H)\|_{L^2(T)},$$

where $H(\varepsilon_H)$ is the Hessian of ε_H in T, invoking the Lipschitz continuity of $\mathbf{A}$ together with an inverse estimate in T, we infer that

$$N_A \le C_A \Big(\|\nabla\varepsilon_H\|_{L^2(T)} + h_T^{-1}\|\nabla\varepsilon_H\|_{L^2(T)}\Big),$$

where C_A depends on $\mathbf{A}$ and the shape regularity constant γ^*. Besides, we readily have

$$N_B \le C_B \|\nabla\varepsilon_H\|_{L^2(T)}, \qquad N_C \le C_C \|\varepsilon_H\|_{L^2(T)},$$

where C_B and C_C depend on $\mathbf{b}$ and c. Combining these estimates, we arrive at

$$h_T^2 \|\mathcal{L}_T(\varepsilon_H)\|_{L^2(T)}^2 \le C_* \|\varepsilon_H\|_{H^1(T)}^2. \tag{4.13}$$

Step 3. *Choice of* δ. We insert (4.13) into (4.12) and add over $T' \in \mathcal{T}_H$. Recalling the definition of $\gamma_{T'}$ and utilizing (3.10), we deduce

$$\begin{aligned} \sum_{T'\in\mathcal{T}_H} \gamma_{T'}^2 \mathsf{osc}_H(T')^2 &= \gamma_0^2 \sum_{T'\in\widehat{\mathcal{T}}_H} \mathsf{osc}_H(T')^2 + \sum_{T'\in\mathcal{T}_H\setminus\widehat{\mathcal{T}}_H} \mathsf{osc}_H(T')^2 \\ &= \mathsf{osc}_H(\Omega)^2 - (1-\gamma_0^2) \sum_{T'\in\widehat{\mathcal{T}}_H} \mathsf{osc}_H(T')^2 \\ &\le (1-(1-\gamma_0^2)\hat\theta^2)\mathsf{osc}_H(\Omega)^2, \end{aligned}$$

where $\hat\theta$ is the user's parameter in (3.10). Moreover, since $C_* \|\varepsilon_H\|_{H^1}^2 \le C_o \|\!|\varepsilon_H|\!\|^2$ with $C_o = C_* c_B^{-1}$ in light of (2.3), we end up with

$$\mathsf{osc}_h(\Omega)^2 \le (1+\delta)\big(1-(1-\gamma_0^2)\hat\theta^2\big)\mathsf{osc}_H(\Omega)^2 + (1+\delta^{-1})C_o \|\!|\varepsilon_H|\!\|^2.$$

To complete the proof, we finally choose δ sufficiently small so that

$$\rho_1 = (1+\delta)\big(1-(1-\gamma_0^2)\hat\theta^2\big) < 1, \qquad \rho_2 = (1+\delta^{-1})C_o. \qquad \square$$

5. Numerical experiments. We test the performance of the adaptive algorithm AFEM with several examples. We are thus able to study how meshes adapt to various effects from lack of regularity of solutions and convexity of domains to data smoothness, boundary layers, changing boundary conditions, etc. For simplicity, we stick to the case of piecewise linear finite element on polygonal domains in $\mathbb{R}^2$. The implementation is done using the ALBERT toolbox of Schmidt and Siebert [11, 12].

5.1. Implementation. We employ the four main procedures as given by Morin, Nochetto, and Siebert [7, 8]: SOLVE, ESTIMATE, MARK, and REFINE. We slightly modified the built-in adaptive solver for elliptic problems of ALBERT toolbox [11] to make it work for the general PDE (1.1) and mixed boundary conditions, as follows:

- SOLVE: We used built-in solvers provided by ALBERT, such as GMRES and CG.
- ESTIMATE: We modified ALBERT for computing the estimator so that it works for (1.1), and added procedures for computing oscillations which are not provided.
- MARK: We employed Marking Strategies E and O to find a marked set $\widehat{\mathcal{T}}_H$.
- REFINE: We employed the three newest bisections for each refinement step to enforce the interior node property.

Remark 5.1 (quadrature). Computations of integrals involving nonconstant functions $f, \mathbf{A}, \mathbf{b}, c, g$, and the exact solution u, use a quadrature rule of order 5. Our experiments indicate that increasing the quadrature order does not change the results. We refer to [3, 11, 12] for details on quadrature.

For convenience of presentation, we introduce the following notation:

- $\mathsf{DOF_k}$:= number of elements in $\mathcal{T}_k$;
- $\mathsf{EOC_e} := \frac{\log(\mathsf{e_{k-1}}/\mathsf{e_k})}{\log(\mathsf{DOF_k}/\mathsf{DOF_{k-1}})}$, experimental order of convergence, $e_k := |\!|\!| u - u_k |\!|\!|$;
- $\mathsf{EOC}_\eta := \frac{\log(\eta_{\mathsf{k}-1}/\eta_{\mathsf{k}})}{\log(\mathsf{DOF_k}/\mathsf{DOF_{k-1}})}$, experimental order of convergence of $\eta_k := \eta_k(\Omega)$;
- $\mathsf{RF_E} := \frac{\mathsf{e_k}}{\mathsf{e_{k-1}}}$ and $\mathsf{RF_O} := \frac{\mathsf{osc_k}}{\mathsf{osc_{k-1}}}$, reduction factors of the error and the oscillation;
- $\mathsf{Eff} := \eta_\mathsf{k}/\mathsf{e_k}$, effectivity index, i.e., the ratio between the estimator and the error;
- $\mathsf{M_E}$ and $\mathsf{M_O}$ are the number of marked elements due to Marking Strategy E and the additional marked elements due to Marking Strategy O, respectively.

The experimental order of convergence $\mathsf{EOC_e}$ measures how the error e_k decreases as $\mathsf{DOF_k}$ increases. In fact we have $e_k \approx C\ \mathsf{DOF_k}^{-\mathsf{EOC_e}}$.

5.2. Experiment 1: Oscillatory coefficients and nonconvex domain. We consider PDE (1.1) with the Dirichlet boundary condition $u = g$ on the nonconvex L-shape domain $\Omega := (-1,1)^2 \backslash [0,1] \times [-1,0]$. We also take the exact solution

$$u(r) = r^{\frac{2}{3}} \sin\left(\frac{2}{3}\theta\right),$$

where $r^2 := x^2 + y^2$ and $\theta := \tan^{-1}(y/x) \in [0, 2\pi)$. We deal with variable coefficients $\mathbf{A}(x,y) = a(x,y)\mathbf{I},\ \mathbf{b}(x,y) = \mathbf{0}$, and $c(x,y)$ defined by

$$a(x,y) = \frac{1}{4 + P(\sin(\frac{2\pi x}{\epsilon}) + \sin(\frac{2\pi y}{\epsilon}))}, \tag{5.1}$$

$$c(x,y) = A_c(\cos^2(lx) + \cos^2(lx)), \tag{5.2}$$

Table 5.1

Experiment 1 (*oscillatory coefficients and nonconvex domain*): *The parameters of AFEM are* $\theta = \hat{\theta} = 0.5$, *and those controlling the oscillatory coefficients are* $P = 1.8, \epsilon = 0.4, A_c = 4.0, l = 1.0$, *as described in* (5.1) *and* (5.2). *The experimental order of convergence* $\mathsf{EOC_e}$ *is close to the optimal rate of 0.5, which indicates quasi-optimal meshes. The oscillation reduction factor* $\mathsf{RF_O}$ *is smaller than the error reduction factor* $\mathsf{RF_E}$, *which confirms that oscillation decreases faster than error. The effectivity index* Eff *is approximately* 2.0. *There are no additional marked elements from oscillation for this* $\theta = 0.5$, *i.e.,* $\mathsf{M_O} = 0$. *However, this is not the case if* $\theta < 0.3$; *see section* 5.3.

98304	9.585e-03	0.347	0.618	0.264	1.745

where P, ϵ, A_c, and l are parameters. The functions f in (1.1) and g are defined accordingly. The results are shown in Tables 5.1 and 5.2 and Figure 5.1. The observations and conclusions of this experiment are as follows:

- AFEM gives an optimal rate of convergence of order ≈ 0.5, while standard uniform refinement achieves the suboptimal rate of 0.3 as expected from theory.
- Both AFEM and FEM with uniform refinement perform with the effectivity index Eff ≈ 2.0, which gives the estimate of constant $C_1 \approx 0.5$ for upper bound (3.6); no weights have been used in (3.5). For AFEM, the reduction factors of error and oscillation are approximately 0.7 and 0.5 as DOF increases (Table 5.1). The oscillation thus decreases faster than the error and becomes insignificant asymptotically for k large. Additionally, AFEM outperforms FEM in terms of the CPU time vs. energy error.
- Figure 5.1 depicts the effect of a corner singularity and rapid variation of diffusion coefficient $a(x, y)$ in mesh grading; c does not play much of a role.
- The number of additional marked elements $\mathsf{M_O}$ due to Marking Strategy O depends on parameters θ and $\hat{\theta}$. For this example, $\mathsf{M_O} = 0$ because the parameter θ is sufficiently big; hence the condition for Marking Strategy O is automatically satisfied. Similar experiments for $\theta < 0.3$ and $\hat{\theta} = 0.5$ yield $\mathsf{M_O} \neq 0$, and $\mathsf{M_O}$ becomes even dominant for $\theta = 0.1$; see Experiment 2 for more details.

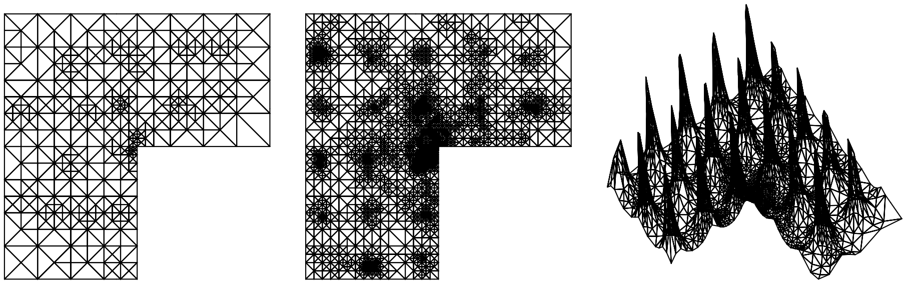

FIG. 5.1. *Experiment* 1 (*oscillatory coefficients and nonconvex domain*)*: Parameters of AFEM are* $\theta = \hat{\theta} = 0.5$, *and those of oscillatory coefficients are* $P = 1.8, \epsilon = 0.4, A_c = 1.0, l = 1.0$. *The sequence of graded meshes after* 4 *and* 7 *iterations shows that mesh refinement is dictated by geometric* (*corner*) *singularities as well as periodic variations of the diffusion coefficient but not much from the zero order term. Also on the right, a* 3*D plot of the diffusion coefficient* $a(x, y)$ *of* (5.1) *interpolated onto the mesh of iteration* 7 *is shown. This shows the combined effect of rapidly varying* $a(x, y)$ *and the exact solution* $u = r^{\frac{2}{3}} \sin(\frac{2}{3}\theta)$*: meshes are refined more where* $a(x, y)$ *has a large gradient.*

5.3. Experiment 2: Convection-dominated diffusion. We consider the convection-dominated diffusion elliptic model problem (1.1) with the Dirichlet boundary condition $u = g$ on the convex domain $\Omega := (0, 1)^2$, with the isotropic diffusion coefficient $\mathbf{A} = \epsilon \mathbf{I}$, $\epsilon = 10^{-3}$, convection velocity $\mathbf{b} = (y, \frac{1}{2} - x)$, and $c = f = 0$; note that $\nabla \cdot \mathbf{b} = 0$. The Dirichlet boundary condition $g(x, y)$ on $\partial\Omega$, a pulse, is the continuous piecewise linear function given by

$$g(x,y) = \begin{cases} 1, & \{.2 + \tau \leq x \leq .5 - \tau;\ y = 0\}, \\ 0, & \partial\Omega \setminus \{.2 \leq x \leq .5;\ y = 0\}, \\ \text{linear}, & \{(.2 \leq x \leq .2 + \tau) \text{ or } (.5 - \tau \leq x \leq .5); y = 0\}, \end{cases} \tag{5.3}$$

where τ is a parameter. This problem models the transport of a pulse from $\partial\Omega$ inside Ω and back to $\partial\Omega$. Results are reported in Table 5.3 and Figures 5.2 and 5.3 for parameters $\theta = 0.3, \hat{\theta} = 0.6, \tau = 0.005$, starting from a coarser mesh than what we would need in theory. To see whether oscillation plays any role in AFEM, Table 5.4 shows results of AFEM without using Marking Strategy O. Observations and conclusions follow:

- Tables 5.3 and 5.4 document the role of oscillation in AFEM. Without marking due to the oscillation $\mathsf{M_O} = \mathsf{0}$, the estimator $\eta(\Omega)$ still reduces at an optimal rate but the oscillation reduction $\mathsf{RF_O}$ is not stable. The factor $\mathsf{RF_O}$ approximates ρ_1 of Lemma 3.2 and thus controls the oscillation decay between consecutive iterations. In fact Table 5.4 indicates that lack of control of $\mathsf{RF_O}$ leads to more iterations for the same estimator. Tables 5.3 and 5.4 illustrate the need of Marking Strategy O to control the reduction rate of oscillations and confirm the convergence theory of AFEM. Our experiments show that the ratio $\mathsf{M_E}/\mathsf{M_O}$ depends inversely on the ratio $\theta/\hat{\theta}$. If $\theta = \hat{\theta}$, then $\mathsf{M_E}$ dominates $\mathsf{M_O}$.
- Comparison of computational costs is measured using the CPU time used by each procedure. On average, about 80% of the total CPU time is used by SOLVE; the other procedures ESTIMATE, MARK, and REFINE use about 5–10%.

Table 5.3

Experiment 2: AFEM with parameters $\theta = 0.3, \hat{\theta} = 0.6$, and $\tau = 0.005$. The optimal decay ≈ 0.5 of the estimator $\eta(\Omega)$ is computational evidence of optimal meshes. The reduction factor of oscillation $\mathsf{RF_O} := \mathsf{osc}_k/\mathsf{osc}_{k-1}$ gives an estimate of constant $\rho_1 \approx 0.5$ in Lemma 3.2. In contrast to Experiment 1, the additional marking $\mathsf{M_O}$ due to oscillation dominates $\mathsf{M_E}$ from Marking Strategy E. This controls $\mathsf{RF_O}$, the decay of oscillations, which decrease together with the error according to Theorem 1.1.

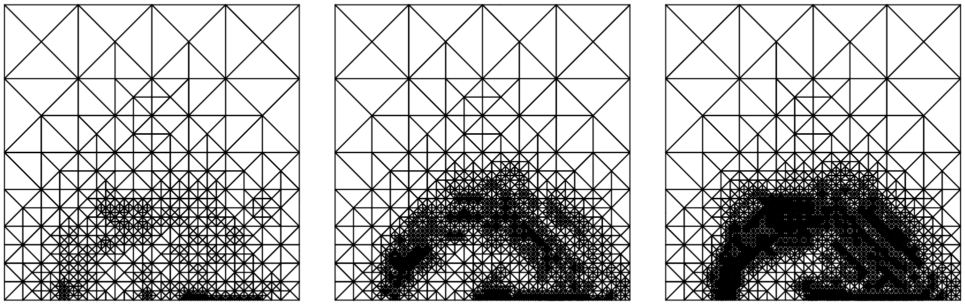

Fig. 5.2. *Experiment 2 (convection-dominated diffusion with $\epsilon = 10^{-3}, \mathbf{b} = (y, \frac{1}{2} - x)$): Adaptively refined meshes after 5, 7, and 8 iterations corresponding to Table 5.3 starting from a uniform mesh coarser than required in theory. After a few iterations, AFEM detects the region of rapid variation (circular transport of a pulse) and boundary layer in the outflow, whereas the rest of the mesh remains unchanged. Refinement in the smooth region is caused by early oscillations.*

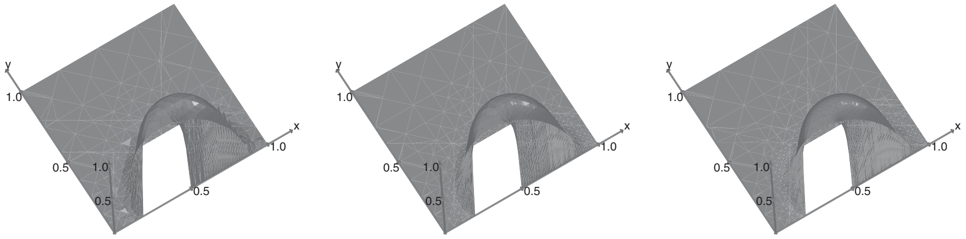

Fig. 5.3. *Experiment 2 (convection-dominated diffusion with $\epsilon = 10^{-3}, \mathbf{b} = (y, \frac{1}{2} - x)$): Plots of solutions after 5, 7, and 8 iterations. No oscillations (of Galerkin solutions) are detected after a few iterations even though AFEM is not stabilized.*

- In theory, the initial meshsize h_0 must satisfy

$$C^* B h_0 < \frac{\beta \Lambda_1}{1 + \beta \Lambda_1} = \beta_0,$$

where $B = \|\mathbf{b}\|_{L^\infty}$, $\beta_0 = O(1)$, and C^* is the constant from Lemma 2.1. In this particular case, we can express C^* in terms of ϵ and B quite explicitly.

Table 5.4

Experiment 2: AFEM performance without Marking Strategy O, using the same parameters as for Table 5.3. *The reduction factor of oscillation* $\mathsf{RF_O}$ *is not as stable as our AFEM shown in Table* 5.3. *The estimator still reduces at the optimal rate but requires a few more iterations to reach the same level as that of our AFEM.*

4250	2.84e-3	0.62	0.82
6502	2.15e-3	0.65	0.59
10209	1.66e-3	0.57	0.62

We first observe that the H^2-regularity theory gives [5]

$$\begin{cases} \mathcal{L}\varphi = \zeta & \text{in } \Omega \\ \quad \varphi = 0 & \text{on } \partial\Omega \end{cases} \implies \|\varphi\|_{H^2(\Omega)} \leq C_R B^{1/2} \epsilon^{-3/2} \|\zeta\|_{L^2(\Omega)}$$

with $C_R > 0$ independent of data. We also note that C_D of Lemma 4.1 satisfies

$$C_I C_R \left(\frac{B}{\epsilon}\right)^{\frac{3}{2}} h_0 \leq \frac{1}{2} \implies C_D = 2 C_I C_R \left(\frac{B}{\epsilon}\right)^{\frac{1}{2}},$$

where C_I is an interpolation constant solely dependent on shape regularity. This results from the usual duality argument and the fact that $\nabla \cdot \mathbf{b} = 0$, namely,

$$|\langle e_h, \zeta \rangle| = |\mathcal{B}[e_h, \varphi]| \leq C_I h_0 \left(\epsilon \|\nabla e_h\|_{L^2} + B \|e_h\|_{L^2}\right) \|\varphi\|_{H^2}.$$

We finally recall that $C^* = C_D/\epsilon$ (see section 4.1), to arrive at

$$h_0 < \frac{\beta_0}{2 C_I C_R} \left(\frac{\epsilon}{B}\right)^{3/2},$$

which is consistent with the previous restriction on h_0. We stress that this implies $h_0 \approx 10^{-4}$ in theory, whereas $h_0 \approx 10^{-1}$ works in our examples; see Figures 5.2 and 5.3.

- The local Péclet number $P_e = \frac{h_0 B}{\epsilon}$ is about 10^2 at the beginning. Since $P_e > 1$, and the Galerkin method is not stabilized, oscillations are observed in the first few iterations but cured later by AFEM via local refinement; see Figure 5.3, which displays solutions without oscillations for iterations 7 and 8. Figure 5.2 depicts several graded meshes and confirms that mesh refinement is localized around the pulse location and outflow boundary layer. Minor refinement in the smooth region is caused by early oscillations.

Table 5.5

Experiment 3 *(drift-diffusion model): Performance of AFEM with the parameters $\theta = 0.6$, $\hat{\theta} = 0.75$ and model parameters $\chi = 10$, $r_1 = 0.75$, and $\alpha = 0.04$. The optimal decay ≈ 0.5 of the estimator $\eta(\Omega)$ is computational evidence of quasi-optimal meshes. AFEM outperforms uniform refinement (compare with Table* 5.6*).*

$\mathsf{DOF_k}$	$\eta_k(\Omega)$	EOC_η	$\mathsf{RF_O}$
1154	6.645	1.880	0.267

2448	2.144	1.259	0.206
4032	1.455	0.776	0.285
6790	1.086	0.560	0.340
12188	0.737	0.663	0.253
23386	0.518	0.540	0.287
45728	0.363	0.529	0.261

5.4. Experiment 3: Drift-diffusion model. We consider a model problem that comes from a mathematical model in semiconductors and chemotaxis:

$$\begin{aligned} -\nabla\cdot(\nabla u + \chi u \nabla\psi) &= 0 \qquad && \text{in } \Omega := (0,1)^2, \\ u &= g && \text{on } \Gamma \subset \partial\Omega, \\ \partial_\nu u &= 0 && \text{on } \partial\Omega \setminus \Gamma, \end{aligned}$$

where χ is a constant. The radial function ψ is defined in Ω by

$$\psi(x,y) := \begin{cases} 1, & \{\sqrt{x^2+y^2} \le r_1\}, \\ \alpha, & \{\sqrt{x^2+y^2} \ge r_1 + \alpha\}, \\ \text{linear}, & \{r_1 < \sqrt{x^2+y^2} < r_1 + \alpha\}, \end{cases}$$

where α is a small parameter and $r_1 < 1$ is a constant. The Dirichlet boundary condition on Γ is assumed to be

$$g(x,y) = \begin{cases} 1, & \{x = 0; 0 \le y \le 0.5\} \bigcup \{y = 0; 0 \le x \le 0.5\}, \\ 0, & \{x = 1; 0.5 \le y \le 1\} \bigcup \{y = 1; 0.5 \le x \le 1\}. \end{cases}$$

We resort to the following transformation (exponential fitting) to symmetrize the problem:

$$\rho := \exp(\chi\psi)u \implies -\nabla\cdot(\exp(-\chi\psi)\nabla\rho) = 0,$$

which gives a simpler form of the model problem with a variable scalar coefficient $a = \exp(-\chi\psi)$. We apply AFEM to solve for ρ and obtain solution u via $u = \exp(-\chi\psi)\rho$. The experiment is performed using the parameters $\chi = 10.0, r_1 = 0.75$, and $\alpha = 0.04$ for the model problem, and parameters $\theta = 0.6$, $\hat{\theta} = 0.75$ for AFEM. Results are reported in Tables 5.5 and 5.6, and Figure 5.4. Conclusions and observations follow:

- From Tables 5.5 and 5.6 we see again that AFEM outperforms FEM with standard uniform refinement. Since the decay of the estimator $\eta(\Omega)$ is optimal, we have computational evidence of optimal meshes.
- Figure 5.4 displays a discrete solution u_8 and graded meshes after 8 and 10 iterations; note the drastic variation of u_8 across the annulus $r_1 < r < r_1 + \alpha$. Meshes adapt well to lack of smoothness, namely, refinement concentrates in the transition layer, where $\nabla\psi$ does not vanish, and at the midpoints of boundary sides, where boundary conditions change.

Table 5.6

6. Extensions. We extend the model problem (1.1) by considering now $\mathbf{A}$ with discontinuities aligned with the initial mesh and a nondivergence-free $\mathbf{b}$. Note that if $\nabla\cdot\mathbf{b} \neq 0$, then the bilinear form $\mathcal{B}$ may be noncoercive if $c - \frac{1}{2}\nabla\cdot\mathbf{b} \not\geq 0$.

6.1. Discontinuous A. We first observe that Lemma 4.1, and thus Lemma 2.1, still holds because the regularity H^{1+s} required in the duality argument is valid; see [6] for example. The continuity of $\mathbf{A}$ is used instead for obtaining error and oscillation reduction estimates (Lemmas 3.1 and 3.2) in that the element oscillation $\mathsf{osc}_H(T)$ does not involve oscillation of the jump residual on ∂T. Remark 4.2 shows that when $\mathbf{A}$ has discontinuities across element faces, we still obtain the error reduction estimate (3.11) of Lemma 3.1, but this time the oscillation is defined by (4.10) and involves oscillation of the jump residual. To prove convergence it suffices to show the oscillation reduction estimate (3.12), for the new concept of element oscillation, namely, $\mathsf{osc}_H(T)^2 = \mathsf{osc}_{R,H}(T)^2 + \sum_{S\subset\partial T}\mathsf{osc}_{J,H}(S)^2$ with

$$\mathsf{osc}_{R,H}(T)^2 := H_T^2 \left\| R_T(u_H) - \overline{R_T(u_H)} \right\|_{L^2(T)}^2 \qquad \forall\, T \in \mathcal{T}_H,$$

$$\mathsf{osc}_{J,H}(S)^2 := H_S \left\| J_S(u_H) - \overline{J_S(u_H)} \right\|_{L^2(S)}^2 \qquad \forall\, S \in \mathcal{S}_H.$$

We proceed in three steps as follows:

Step 1. *Oscillation of interior residual.* Invoking the same arguments as in the proof of Lemma 3.2 in section 4.3, we obtain an oscillation reduction estimate for the interior residual

$$\mathsf{osc}_{R,h}(T')^2 \leq (1+\delta)\gamma_{T'}^2 \mathsf{osc}_{R,H}(T')^2 + C_*(1+\delta^{-1}) \|\varepsilon_H\|_{H^1(T')}^2 \qquad \forall\, T' \in \mathcal{T}_H,$$

where $\mathsf{osc}_{R,h}(T')$ is defined to be $\mathsf{osc}_h(T')$ in (4.12).

Step 2. *Oscillation of jump residual.* To obtain an estimate for $\mathsf{osc}_{J,h}(S)$ we write

$$J_S(u_h) = \gamma_S \left[\!\left[\mathbf{A}\nabla u_H\right]\!\right]_S \cdot \nu_S + \left[\!\left[\mathbf{A}\nabla \varepsilon_H\right]\!\right]_S \cdot \nu_s = \gamma_S J_S(u_H) + J_S(\varepsilon_H),$$

where $\gamma_S = 1$ if $S \subset S' \in \mathcal{S}_H$ and $\gamma_S = 0$ otherwise, since $\mathbf{A}\nabla u_H$ is continuous on S in the second case. Using Young's inequality, we have for all $\delta > 0$

$$\begin{aligned}\mathsf{osc}_{J,h}(S)^2 \leq (1+\delta)\gamma_S h_S \left\| J_S(u_H) - \overline{J_S(u_H)} \right\|_{L^2(S)}^2 \\ + (1+\delta^{-1}) h_S \left\| J_S(\varepsilon_H) - \overline{J_S(\varepsilon_H)} \right\|_{L^2(S)}^2,\end{aligned}$$

where $\overline{J_S(u_H)}$ and $\overline{J_S(\varepsilon_H)}$ are L^2-projections of $J_S(u_H)$ and $J_S(\varepsilon_H)$ onto $\mathbb{P}_{n-1}(S)$. For the second term we observe that

$$\begin{aligned}\left\| J_S(\varepsilon_H) - \overline{J_S(\varepsilon_H)} \right\|_{L^2(S)} &\leq \|J_S(\varepsilon_H)\|_{L^2(S)} = \left\| \left[\!\left[\mathbf{A}\nabla\varepsilon_H\right]\!\right]_S \cdot \nu_S \right\|_{L^2(S)} \\ &\leq \left\|\mathbf{A}^+ \nabla \varepsilon_H^+ \cdot \nu_S\right\|_{L^2(S)} + \left\|\mathbf{A}^- \nabla \varepsilon_H^- \cdot \nu_S\right\|_{L^2(S)} \\ &\leq \|\mathbf{A}\|_{L^\infty(\omega_S)} \left(\left\|\nabla\varepsilon_H^+\right\|_{L^2(S)} + \left\|\nabla\varepsilon_H^-\right\|_{L^2(S)} \right) \\ &\leq C_A h_S^{-1/2} \|\varepsilon_H\|_{H^1(\omega_S)},\end{aligned}$$

where C_A depends on $\mathbf{A}$ and the shape regularity constant γ^*. For simplicity, let $\mathcal{S}_h(T')$ denote all $S \in \mathcal{S}_h$ contained in $T' \in \mathcal{T}_H$; hence

$$\begin{aligned}\mathsf{osc}_{J,h}(T')^2 &= \sum_{S \in \mathcal{S}_h(T')} \mathsf{osc}_{J,h}(S)^2 \\ &\leq (1+\delta) \sum_{S \in \mathcal{S}_h(T')} \gamma_S h_S \left\| J_S(u_H) - \overline{J_S(u_H)} \right\|_{L^2(S)}^2 + (1+\delta^{-1}) C_A \|\varepsilon_H\|_{H^1(\omega_{T'})}^2.\end{aligned}$$

In light of the reduction factor of the element size $h_S \leq \gamma_{T'} H_{S'}$, and definitions of γ_S and $\gamma_{T'}$, we obtain

$$\begin{aligned}\sum_{S \in \mathcal{S}_h(T')} \gamma_S h_S \left\| J_S(u_H) - \overline{J_S(u_H)} \right\|_{L^2(S)}^2 &\leq \gamma_{T'} \sum_{S' \in \mathcal{S}_H(T')} H_{S'} \left\| J_{S'}(u_H) - \overline{J_{S'}(u_H)} \right\|_{L^2(S')}^2 \\ &= \gamma_{T'} \mathsf{osc}_{J,H}(T')^2,\end{aligned}$$

because for $S \subset S' \subset \partial T'$, we have $J_S(u_H) = J_{S'}(u_H)$ and $\overline{J_S(u_H)}$ is the best L^2-approximation of $J_S(u_H)$ on S. Therefore,

$$\mathsf{osc}_{J,h}(T')^2 \leq (1+\delta)\gamma_{T'} \mathsf{osc}_{J,H}(T')^2 + (1+\delta^{-1}) C_A \|\varepsilon_H\|_{H^1(\omega_{T'})}^2 \qquad \forall\, T' \in \mathcal{T}_H.$$

Step 3. *Choice of* δ. Combining results from Steps 1 and 2 above using $\gamma_{T'} \leq 1$, $C_{**} = \max\{C_*, C_A\}$, and the definition of $\mathsf{osc}_h(T)$, we arrive at

$$\mathsf{osc}_h(T')^2 \leq (1+\delta)\gamma_{T'} \mathsf{osc}_H(T')^2 + C_{**}(1+\delta^{-1}) \|\varepsilon_H\|_{H^1(\omega_{T'})}^2.$$

Proceeding as in Step 3 of the proof of Lemma 3.2, this time with Marking Strategy O performed according to the new definition of $\mathsf{osc}_H(T)$, we arrive at

$$\mathsf{osc}_h(\Omega)^2 \le (1+\delta)(1-(1-\gamma_0)\hat\theta^2)\mathsf{osc}_H(\Omega)^2 + C_o(1+\delta^{-1}) \left\|\kern-0.25ex\left|\varepsilon_H\right|\kern-0.25ex\right\|^2$$

with $C_o = C_{**}c_B^{-1}$. The assertion thus follows by choosing δ sufficiently small so that

$$\rho_1 := (1+\delta)(1-(1-\gamma_0)\hat\theta^2) < 1, \qquad \rho_2 := C_o(1+\delta^{-1}).$$

6.2. Noncoercive $\boldsymbol{\mathcal{B}}$. In this section, we prove convergence of AFEM for the case $c - \frac{1}{2}\nabla\cdot\mathbf{b} \not\geq 0, c \ge 0$; the case $c < 0$ can be treated as well. According to what we have so far, the assumption of $\nabla\cdot\mathbf{b} = 0$ is used for proving quasi-orthogonality and for having equivalence between energy norm $|||v|||^2 := \mathcal{B}[v,v]$ and H^1-norm as in (2.3), where $\mathcal{B}$ is coercive. Since now $\mathcal{B}$ may be noncoercive, we cannot define the energy norm in this manner. We instead define the energy norm by $|||v|||^2 := \int_\Omega \mathbf{A}\nabla v\cdot\nabla v + c\, v^2$, and we have equivalence of norms

$$c_E \left\|v\right\|^2_{H^1(\Omega)} \le |||v|||^2 \le C_E \left\|v\right\|^2_{H^1(\Omega)}, \tag{6.1}$$

where constants c_E and C_E depend only on the data $\mathbf{A}$, c, and Ω. The lack of coercivity is now replaced by Gårding's inequality

$$|||v|||^2 - \gamma_G \left\|v\right\|^2_{L^2(\Omega)} \le \mathcal{B}[v,v] \qquad \forall\, v \in H^1_0(\Omega), \tag{6.2}$$

where $\gamma_G = \left\|\nabla\cdot\mathbf{b}\right\|_\infty/2$. To see this we integrate by parts the middle term of $\mathcal{B}[v,v]$,

$$\int_\Omega \mathbf{b}\cdot\nabla v\, v = \frac{1}{2}\int_\Omega \mathbf{b}\cdot\nabla(v^2) = -\int_\Omega \frac{\nabla\cdot\mathbf{b}}{2} v^2 \qquad \forall\, v \in H^1_0(\Omega).$$

The same calculation leads to the sharp upper bound for $\mathcal{B}[v,v]$:

$$\mathcal{B}[v,v] \le |||v|||^2 + \gamma_G \left\|v\right\|^2_{L^2(\Omega)} \qquad \forall\, v \in H^1_0(\Omega). \tag{6.3}$$

Existence and uniqueness of weak solutions follows from the maximum principle for $c \ge 0$ [5]. Schatz showed in [10] that the discrete problem (2.5) has a unique solution if the meshsize h is sufficiently small, i.e., $h \le h^*$ for some constant h^* depending on the shape regularity and data but not computable; the results in [10] are also valid for graded meshes. Assuming $h_0 \le h^*$, to prove convergence of AFEM it thus suffices to prove quasi-orthogonality. We follow the steps of Lemma 2.1.

Using the same notation as in section 4 for e_h, e_H, and ε_H, expanding $\mathcal{B}[e_H, e_H]$, and noticing that $e_H = e_h + \varepsilon_H$ and $\mathcal{B}[e_h, \varepsilon_H] = 0$, we arrive at

$$\mathcal{B}[e_h, e_h] = \mathcal{B}[e_H, e_H] - \mathcal{B}[\varepsilon_H, \varepsilon_H] - \mathcal{B}[\varepsilon_H, e_h], \tag{6.4}$$

where this time integration by parts yields

$$\begin{aligned}\mathcal{B}[\varepsilon_H, e_h] &= \mathcal{B}[e_h, \varepsilon_H] + \langle \mathbf{b}\cdot\nabla\varepsilon_H, e_h\rangle - \langle \mathbf{b}\cdot\nabla e_h, \varepsilon_H\rangle \\ &= 2\langle \mathbf{b}\cdot\nabla\varepsilon_H, e_h\rangle + \langle \nabla\cdot\mathbf{b}\, e_h, \varepsilon_H\rangle.\end{aligned}$$

Consequently, using the Cauchy–Schwarz inequality and (6.1), we have for all $\delta > 0$

$$|\mathcal{B}[\varepsilon_H, e_h]| \le (2\left\|\mathbf{b}\right\|_\infty \left\|\nabla\varepsilon_H\right\|_{L^2} + \left\|\nabla\cdot\mathbf{b}\right\|_\infty \left\|\varepsilon_H\right\|_{L^2}) \left\|e_h\right\|_{L^2} \le C_b^2\delta\, |||\varepsilon_H|||^2 + \delta^{-1}\left\|e_h\right\|^2_{L^2},$$

where constant $C_b = \max\{2\|\mathbf{b}\|_\infty, \|\nabla\cdot\mathbf{b}\|_\infty\} c_E^{-1}/2$.

Using (6.2) and (6.3) to estimate terms $\mathcal{B}[e_h, e_h]$, $\mathcal{B}[e_H, e_H]$, and $\mathcal{B}[\varepsilon_H, \varepsilon_H]$ in (6.4), and combining with the previous estimate, we infer that

$$\|\!|e_h|\!\|^2 - (\gamma_G + \delta^{-1})\|e_h\|_{L^2}^2 \le \|\!|e_H|\!\|^2 + \gamma_G\|e_H\|_{L^2}^2 - (1 - C_b^2\delta)\|\!|\varepsilon_H|\!\|^2 + \gamma_G\|\varepsilon_H\|_{L^2}^2 .$$

Since $\|\varepsilon_H\|_{L^2}^2 \le 2\|e_h\|_{L^2}^2 + 2\|e_H\|_{L^2}^2$, estimates for $\|e_h\|_{L^2}$ and $\|e_H\|_{L^2}$ of the form (4.1), obtained via duality, with $C_6 := \frac{C_D}{\sqrt{c_E}}$ imply

$$\Lambda_h \ \|\!|e_h|\!\|^2 \le \Lambda_H \|\!|e_H|\!\|^2 - \Lambda_\varepsilon \|\!|\varepsilon_H|\!\|^2 , \tag{6.5}$$

where $\Lambda_h = 1 - C_6^2 h_0^{2s}(3\gamma_G + \delta^{-1})$, $\Lambda_H = 1 + 3\gamma_G C_6^2 h_0^{2s}$, and $\Lambda_\varepsilon = 1 - C_b^2\delta$.

Consequently, to get $\Lambda_h = \Lambda_\varepsilon$, we choose δ depending on h_0 so that

$$\delta(h_0) = \frac{C_G h_0^{2s} + \sqrt{C_G^2 h_0^{4s} + 4C_b^2 C_6^2 h_0^{2s}}}{2C_b^2} > 0,$$

where $C_G = 3\gamma_G C_6^2$. We further choose h_0 sufficiently small so that $C_b^2\delta(h_0) < 1$, whence $\Lambda_h = \Lambda_\varepsilon > 0$. This can be achieved for $h_0^s \le \min\left\{C_6 C_b C_G^{-1}, (3C_6C_b)^{-1}\right\}$ because

$$\begin{aligned} C_b^2\delta(h_0) &= \frac{C_G}{2}h_0^{2s} + C_b C_6 h_0^s \sqrt{1 + h_0^{2s} C_G^2 (4C_b^2 C_6^2)^{-1}} \\ &\le 2C_b C_6 h_0^s \big(1 + h_0^s C_G (4C_b C_6)^{-1}\big) < 3C_b C_6 h_0^s \le 1. \end{aligned}$$

We conclude that if the meshsize h_0 of the initial mesh satisfies

$$h_0^s \le \min\left\{C_6 C_b C_G^{-1}, (3C_6C_b)^{-1}, (h^*)^s\right\}, \tag{6.6}$$

then quasi-orthogonality holds, i.e., for $\Lambda_0 := \Lambda_H/\Lambda_h$,

$$\|\!|e_h|\!\|^2 \le \Lambda_0 \|\!|e_H|\!\|^2 - \|\!|\varepsilon_H|\!\|^2 , \tag{6.7}$$

and Λ_0 can be made arbitrarily close to 1 by decreasing h_0. Convergence of AFEM finally follows as in Theorem 1.1.

6.3. Experiment 4: Noncoercive $\boldsymbol{\mathcal{B}}$. We repeat Experiment 2 in section 5.3 with $\mathbf{b} = (x-1, y+1)$, and thus $\mathcal{B}$ is noncoercive because $c - \frac{1}{2}\nabla\cdot\mathbf{b} = -1$. For a better view of solutions we change the boundary condition $g(x,y)$ to be 1 on the x-axis from $(.4+\tau)$ to $(.8-\tau)$, with τ defined as in (5.3). Results of AFEM with $\theta = \hat{\theta} = 0.5, \tau = 0.005$ are reported in Figure 6.1. Observations and conclusions follow:

- Figure 6.1 shows oscillations of the Galerkin solution near internal and boundary layers after 4 iterations. AFEM detects this effect and corrects it after 6 iterations by selective local refinement which does not spread in regions of smoothness.
- The resulting graded meshes are optimal and capture internal layers (diffuse boundary of pulse g being transported) and the outflow boundary layer, even though the initial uniform mesh is far coarser than required by theory; see (6.6) which is a restriction similar to that discussed in section 5.3 (Experiment 2). Moreover, the performance of AFEM as to the estimator decay and oscillation control is analogous to section 5.3 (Experiment 2).

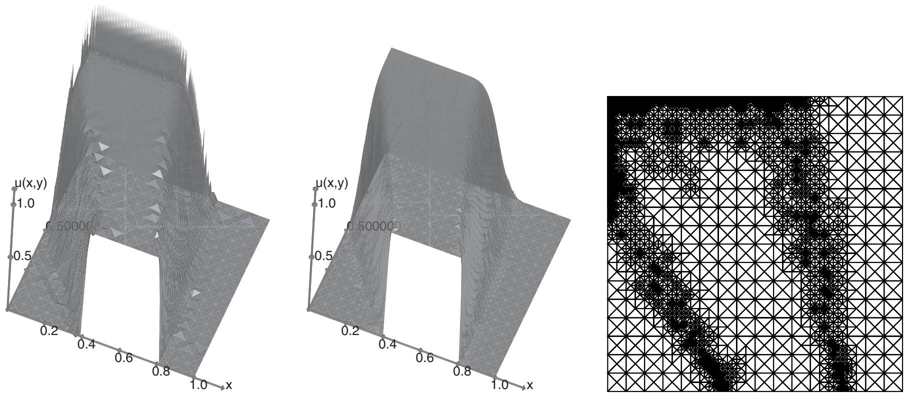

FIG. 6.1. *Experiment* 4 *(noncoercive $\mathcal{B}$ with $\epsilon = 10^{-3}, \mathbf{b} = (x-1, y+1)$): Three-dimensional plots of solutions after* 4 *and* 6 *iterations and graded mesh after* 6 *iterations. Oscillations of Galerkin solutions are observed near internal and boundary layers in a first few iterations but AFEM eliminates them after* 6 *iterations.*

Acknowledgments. We would like to thank the four referees for their careful reading and constructive comments and suggestions.

ENTROPIC DISCRETIZATION OF A QUANTUM DRIFT-DIFFUSION MODEL*

SAMY GALLEGO[†] AND FLORIAN MÉHATS[†]

Abstract. This paper is devoted to the discretization and numerical simulation of a new quantum drift-diffusion model that was recently derived. In a first step, we introduce an implicit semidiscretization in time which possesses some interesting properties: this system is well-posed, it preserves the positivity of the density, the total charge is conserved, and it is entropic (a free energy is dissipated). Then, after a discretization of the space variable, we define a numerical scheme which has the same properties and is equivalent to a convex minimization problem. These results are illustrated by some numerical simulations.

Key words. quantum drift-diffusion, Schrödinger–Poisson, entropic scheme, convex minimization

1. Introduction.

Recently, Degond and Ringhofer [15, 16] explored a new direction for quantum hydrodynamic (QHD) models by extending Levermore's moment approach [33] to the context of quantum mechanics. Their strategy consists in defining a notion of "local" quantum equilibrium as the minimizer of an entropy functional under local moment constraints. Such equilibria are defined, thanks to a relation between the thermodynamic quantities (such as the chemical potential or the temperature) and the extensive quantities (the densities), in a nonlocal way. In [15], QHD models were derived from quantum kinetic equations by moment expansions closed by these quantum equilibria. In this reference, Degond and Ringhofer also sketched an important program related to these QHD models, including, namely, the setting up of a rigorous framework for this formal modeling, the inclusion of other quantum effects (the Pauli exclusion principle, spin effects, etc.), and the numerical discretization and simulation. Following the same approach, these authors then introduced in [17] a family of ad hoc collision operators which decrease the quantum entropy and relax to the equilibria. Afterwards, this strategy was applied in [13] in order to derive quantum diffusive models: a quantum drift-diffusion (QDD) model and a quantum energy-transport (QET) model. In a work in progress [8], other diffusive models of the type of the spherical harmonic expansion (SHE) model are also constructed in the quantum framework.

All these fluid models are written as conservation laws coupled to constitutive equations. The quantum character of these models lies in these constitutive equations, which are nonlocal in space and make these systems difficult to analyze (papers [15, 13] remained at a formal level). However, an interesting property of these models is that—at least formally—a fluid entropy functional is dissipated. This feature gives an indication of the well-posedness of these systems; in addition, it is interesting to

recall that the entropic property is obtained as a by-product of the strategy of entropy minimization.

In this paper, we are interested in the QDD model with two objectives. First, the present work is a first step in the rigorous analysis of this system coupled to the Poisson equation. Second, we study the discretization of this system and its numerical simulation.

Let us now describe the main results of this paper. The QDD system is given by (2.8)–(2.10). Actually, we are not yet able to answer the question of the well-posedness of this system. Nevertheless, we introduce, instead, and analyze rigorously a semidiscretized (in time) version of this model, defined by (3.1)–(3.3), and which presents the same entropy dissipation property as the QDD system. This first set of results is given in Theorem 3.1. Next, concerning the second objective of the paper, the implicit numerical scheme (4.1)–(4.3) is defined. This scheme is well-posed and equivalent to a problem of convex minimization. Then, we show that this scheme is stable in the sense of a discrete entropy. These results concerning the numerical scheme are stated in Theorem 4.1.

We end this introduction with bibliographical notes on quantum transport modeling. The QDD system applies to the modeling of nanoscale semiconductor devices. In the semiconductor industry, the classical drift-diffusion model has been a valuable tool for many years [11, 28, 35, 37, 48]. Currently, the ongoing miniaturization of electronic devices to the nanometer scale has created the need of models which take into account quantum effects. To this aim, two strategies can be followed.

The first approach, with a radical change in the level of description, consists of choosing full quantum models such as the Schrödinger equation, the von Neumann equation, or the Wigner equation [4, 9, 12, 18, 19, 32, 38, 45, 46]. These models are well-fitted for very small devices but lead to the resolution of huge numerical systems at the intermediate scale, which is currently considered by electronic engineers. Another reason why this approach is limited to very small devices is that the question of describing collisions in quantum transport models is extremely difficult and has not yet received a completely satisfactory answer. Therefore, full quantum models are still mainly reserved to ballistic transport in small devices.

The opposite strategy consists of introducing quantum correction terms in the classical drift-diffusion model. The most common quantum correction involves the Bohm potential, which naturally appears in QHD, thanks to an analogy between the Schrödinger equation and the pressureless Euler system corrected with the Bohm potential. This analogy can be seen, thanks to the Madelung transformation [34, 50], by considering the equations satisfied by the amplitude and the phase of a wavefunction solving the Schrödinger equation (see, e.g., [13] for more details). Next, assuming that adding this Bohm potential enables us to model quantum effects in classical macroscopic systems, several models with corrective terms have been written. In a fluid context, hydrodynamics models with quantum corrections have been studied in [22, 23, 24, 25, 26, 27, 29, 44, 51]. In a diffusive context, and closest to the QDD model studied in this paper, one can find the drift-diffusion model, corrected with the Bohm potential, called the density-gradient model (it is also sometimes called the QDD model, but in this paper we shall refer it as the density-gradient model in order to avoid any confusion with the QDD model presented here). This model was introduced in [1, 2], then mathematically and numerically studied in [3, 7, 29, 30, 41, 42]. One advantage of such an approach is that it takes into account collisions, at least heuristically. Another strength is that, as this method is based on an evolution of the classical drift-diffusion model, the numerical codes currently employed in the semiconductor industry can be adapted by following this evolution. Nevertheless, one has to insist on the fact that the justification of these models is far from obvious in the case of statistical mixtures (several attempts were made to address this issue; see, for instance, [22, 23, 24, 27]). Moreover, quantum corrections involving the Bohm potential produce high order terms in these systems and make their resolution difficult, from the mathematical and numerical points of view. To conclude this description, one can also cite two other recent attempts to model quantum effects in diffusive models [6, 43]. The models presented in these works are different, but both take the form of a drift-diffusion equation, coupled to the Poisson equation, and where the quantum phenomena are taken into account by a modification of the link between the density and the quasi-Fermi potential, via the resolution of a quasi-static Schrödinger equation.

As a compromise, the QDD model studied in this paper tries to reconcile these two approaches: this model is really quantum and nonlocal, while the length scales are macroscopic and collisions are modeled. Indeed, as is shown in section 2.3, the steady states of the QDD model solve the Schrödinger–Poisson system studied in [31, 39, 40], which shows the quantum character of this model. In addition, it has been shown in [13] that, at least formally, the limit of the QDD model as $\hbar$ goes to zero is the classical drift-diffusion model, while the leading order correction term in an $\hbar$ expansion is the Bohm potential, which shows a clear link between the QDD model and the density-gradient model described above.

The paper is organized as follows. In section 2, we write a formulation of the QDD model in a bounded domain and give some of its properties. Then, in section 3, we define the semidiscretization in time of the QDD system and show that this new system is well-posed and entropic. In section 4, the numerical scheme is constructed and we analyze its properties (well-posedness, stability). Finally, in section 5, we illustrate these properties by some numerical simulations.

2. The QDD model.

This section is devoted to the presentation of the QDD model. It is not clear which precise functional framework would be adapted to a rigorous analysis of this system. Nevertheless, we can still state some properties satisfied by any smooth solution of this system. This enables us to put into perspective the results of section 3. Indeed, we shall see in section 3 that similar properties are satisfied by the solutions of the semidiscretized QDD system (3.1)–(3.3), whereas their existence can be rigorously proved.

2.1. Notation: The QDD model on a bounded domain.

Let us first give a formulation of the QDD model in the case of bounded domains. This model, which describes the evolution of a quantum system of electrons, was derived in [13] and the most convenient equivalent form of this model was written in the review paper [14]. The first equation is the equation of mass conservation:

$$\partial_t n + \mathrm{div} j = 0. \tag{2.1}$$

The second equation of the model is the constitutive equation which gives the expression of the current

$$j = n\nabla(A - V). \tag{2.2}$$

In this equation, $V(t,x)$ is the self-consistent potential (modeling the interactions between the electrons) and $A(t,x)$ is the *quantum chemical potential*, linked to the density by a relation which is nonlocal in space and which is the key of this quantum model. In order to make this relation explicit, let us introduce the operator

$$H[A] = -h^2 \Delta + A + V^{ext},$$

whose domain $D(H)$ will be defined below and where h is the dimensionless Planck constant:

$$h = \frac{\hbar}{(2m^* L^2\, kT)^{1/2}},$$

m^* being the effective mass, L a characteristic length of the device, and T the temperature. Here, $V^{ext}(x)$ is an external potential applied to the system (assumed independent of time for simplicity). In the QDD model, the electron system is at any time in a *local quantum equilibrium* (see [15, 13]) and its density matrix is

$$\varrho = \exp(-H[A]), \tag{2.3}$$

where exp denotes the exponential of the operator. Notice that when the chemical potential A differs from the electrical potential, the operator $H[A]$ is not the Hamiltonian and ϱ is not the density matrix of a global quantum equilibria as usually defined [5]. A consequence of this formula (2.3) is the relation between the density and the chemical potential, given in a weak sense by

$$\forall \phi \in L^\infty \qquad \int n\phi \, dx = \mathrm{tr}(\exp(-H[A])\, \phi). \tag{2.4}$$

Here we used the usual convention where, for any test function ϕ, $\mathrm{tr}(\exp(-H[A])\, \phi)$ denotes the trace of the composition of the exponential of the operator $-H[A]$ with the operator of multiplication by ϕ. Finally, the last equation of the model is the Poisson equation, which links the density and the self-consistent potential:

$$-\alpha \Delta V = n. \tag{2.5}$$

In this equation, α is a positive dimensionless parameter proportional to the square of the Debye length of the system; more precisely, if ε_0 and ε_r denote the vacuum permittivity and the relative permittivity of the material, if $\mathcal{N}$ denotes a characteristic density, and if e denotes the elementary charge, we have

$$\alpha = \frac{\varepsilon_0\, \varepsilon_r\, kT}{e^2\, L^2\, \mathcal{N}}.$$

A given background charge density may be taken into account in this model, for instance, by a modification of the external potential V^{ext} and a shift of the chemical potential A.

Let $\Omega \subset \mathbb{R}^d$ be a regular bounded domain ($d \leq 3$). Its boundary is denoted by $\partial\Omega$ and $\nu(x)$ is the outward unit normal vector at $x \in \partial\Omega$. All the unknowns of the system $n(t,x)$, $j(t,x)$, $A(t,x)$, and $V(t,x)$ are defined for $t \geq 0$ and $x \in \Omega$. Now, we need to make the boundary conditions for this system precise. The most simple ones, which will be studied in this paper, prescribe a vanishing current at the boundary. This no-flux boundary condition takes the form of the Neumann condition

$$\nabla(A - V) \cdot \nu = 0 \quad \text{on } \partial\Omega.$$

(Recall that we assume A and V smooth enough to give sense to this Neumann condition; for the semidiscretized model analyzed in section 3, the $W^{2,p}$ regularity obtained in Theorem 3.1 is enough.) For the self-consistent potential, we consider a Dirichlet boundary condition

$$V = 0 \quad \text{on } \partial\Omega.$$

It remains to fix the domain of the Hamiltonian $H[A]$. In [21], the QDD model was written with Dirichlet boundary conditions for the wavefunctions, as well as its discrete version. Here, for technical reasons which will be explained further (we need to ensure the positivity of the density on $\overline{\Omega}$: see the beginning of the proof of Theorem 3.1), Neumann boundary conditions are chosen:

$$D(H) = \{\phi \in H^2(\Omega) \,:\, \nabla\phi \cdot \nu = 0 \quad \text{on } \partial\Omega\}. \tag{2.6}$$

Hence, if A belongs to, say, $L^2(\Omega)$, then the operator $H[A]$ is bounded from below and has a compact resolvent. Let us denote by $(\chi_p[A])_{p=1,\dots,\infty}$ an orthogonal basis of eigenfunctions, associated with the eigenvalues $\lambda_1[A] \le \lambda_2[A] \le \cdots \le \lambda_p[A] \le \cdots$. The nonlocal relation (2.4) between n and A takes a more explicit form

$$n[A] = \sum_{p\ge 1} e^{-\lambda_p[A]} \, |\chi_p[A]|^2. \tag{2.7}$$

To summarize this part, one can write the QDD model including self-consistent effects as follows:

$$\partial_t n + \operatorname{div}(n\nabla(A - V)) = 0, \tag{2.8}$$

$$-\alpha\Delta V = n, \tag{2.9}$$

$$n = \sum_{p} e^{-\lambda_p[A]} \, |\chi_p[A]|^2, \tag{2.10}$$

where $(\lambda_p[A], \chi_p[A])_p$ denote the eigenvalues and the eigenfunctions of the Hamiltonian $H[A] = -h^2\Delta + A + V^{ext}$ whose domain is $D(H) = \{\psi \in H^2(\Omega) \,:\, \partial_\nu\psi = 0\}$. The unknowns of this system are subject to the following no-flux boundary conditions on $\partial\Omega$:

$$V = 0, \quad \partial_\nu(A - V) = 0 \quad (\partial\Omega), \tag{2.11}$$

and to a Cauchy datum $n^0(x)$.

In this paper, the following assumptions on the data will be made.

Assumption 2.1. The initial datum n^0 is continuous and positive on $\overline{\Omega}$.

Assumption 2.2. The external potential V^{ext} is nonnegative and belongs to $L^\infty(\Omega)$.

2.2. Technical lemmas: The relation between *n* and *A*. In this subsection, we gather some technical lemmas that are used in this paper. The first lemma, which is given without proof, is directly adapted from [40] (the only difference lies in the domain $D(H)$; in [40], a Dirichlet boundary condition was considered instead of our Neumann boundary condition).

LEMMA 2.3. *Let $A \in H^1(\Omega)$ and let $n[A]$ be defined by*

$$n[A] = \sum_{p\ge 1} e^{-\lambda_p[A]} \, |\chi_p[A]|^2,$$

where $\lambda_p[A]$ and $\chi_p[A]$ are the spectral elements of

$$H[A] = -h^2\Delta + A + V^{ext},$$

whose domain $D(H)$ is defined by (2.6). *Then $n[A]$ is a continuous function on $\overline{\Omega}$. Moreover, the map F defined by*

$$A \in H^1(\Omega) \mapsto F[A] := \operatorname{tr}\big(e^{-H[A]}\big) = \int n[A]\, dx \tag{2.12}$$

is well defined, Fréchet C^∞, and strictly convex. Its first derivative in the direction $\phi \in H^1(\Omega)$ reads

$$d_A F \cdot \phi = -\operatorname{tr}\big(e^{-H[A]}\,\phi\big) = -\int n[A]\phi\, dx, \tag{2.13}$$

and its second derivative reads

$$d_A^2 F \cdot \phi \cdot \phi = -\sum_{p=1}^{\infty}\sum_{q=1}^{\infty} \frac{e^{-\lambda_p[A]} - e^{-\lambda_q[A]}}{\lambda_p[A] - \lambda_q[A]} \left| \int \phi\, \chi_p\, \overline{\chi_q}\, dx \right|^2, \tag{2.14}$$

where $\frac{e^{-\lambda_p[A]} - e^{-\lambda_q[A]}}{\lambda_p[A] - \lambda_q[A]}$ conventionally equals $-e^{-\lambda_p[A]}$ if $\lambda_p[A] = \lambda_q[A]$.

Notice that this lemma gives a sense to formula (2.7) as soon as A belongs to $H^1(\Omega)$.

LEMMA 2.4. *Let A and $\widetilde{A}$ belong to $H^1(\Omega)$ and, using the notation of Lemma* 2.3, *let*

$$n = n[A] = \sum_{p\geq 1} e^{-\lambda_p[A]}\, |\chi_p[A]|^2, \quad \widetilde{n} = n[\widetilde{A}] = \sum_{p\geq 1} e^{-\lambda_p[\widetilde{A}]}\, |\chi_p[\widetilde{A}]|^2.$$

Then we have

$$\int \big(n(A - \widetilde{A}) + n - \widetilde{n}\big)\, dx \leq 0. \tag{2.15}$$

Proof. The functional $F[A]$ defined in Lemma 2.3 is convex; thus we have the inequality

$$F[\widetilde{A}] - F[A] \geq d_A F \cdot (\widetilde{A} - A).$$

The desired result is a consequence of the expression (2.13) of $d_A F$. □

2.3. Steady states and entropy dissipation. The steady states of the QDD system are well known: these are the solutions of the Schrödinger–Poisson system studied by Nier in [40]. Following this reference, the following proposition can be proved (its proof is left to the reader).

PROPOSITION 2.5. *Let $N > 0$ and let (n, A, V) be a steady state of* (2.8)–(2.10) *such that $\int n(x)\, dx = N$. Assume that n is continuous and positive on $\overline{\Omega}$. Then there exists a constant ϵ_F such that $A = V - \epsilon_F$ and (n, V, ϵ_F) is the unique solution of the Schrödinger–Poisson system under a constraint of the total charge:*

$$\begin{cases} -h^2\Delta\chi_p + (V + V^{ext})\,\chi_p = \lambda_p\,\chi_p \quad (p = 1, \ldots, \infty), \\ \chi_p \in D(H), \qquad \displaystyle\int \chi_p\, \overline{\chi_q} = \delta_{pq}, \end{cases} \tag{2.16}$$

$$-\alpha\Delta V = n = \sum_p e^{\epsilon_F - \lambda_p}\, |\chi_p|^2, \quad V \in H_0^1(\Omega), \tag{2.17}$$

$$\int n(x)\, dx = N. \tag{2.18}$$

Next, the following formal result shows that the QDD system coupled with the Poisson equation is entropic.

Proposition 2.6. *Let* (n, A, V) *be a smooth solution of* (2.8)–(2.10). *Then the following properties hold.*

(i) *The following free energy* $S(t)$ *is a decreasing function of time and is bounded from below* (*by a negative constant depending only on* Ω *and* h)*:*

$$S(t) = -\int n\,(A+1)\, dx + \frac{\alpha}{2}\int |\nabla V|^2\, dx.$$

(ii) *If* $(n^\infty, A^\infty, V^\infty)$ *is the solution of* (2.16)–(2.18) *corresponding to* $N = \int n(0,x)\, dx$, *then the following relative entropy* $\Sigma(t)$ *is the sum of two nonnegative terms and is a decreasing function of time:*

$$\Sigma(t) = -\int (n\,(A - A^\infty) + n - n^\infty)\, dx + \frac{\alpha}{2}\int |\nabla(V - V^\infty)|^2 dx.$$

Proof. By applying (2.15) with $\widetilde{A} \equiv 0$, we get

$$-\int n\,(A+1) \geq -\int n[0]\, dx.$$

Assumption 2.2 gives $V^{ext} \geq 0$. Hence, by the min-max formula, the eigenvalues $\lambda_p[0]$ of $H[0] = -h^2\Delta + V^{ext}$ satisfy $\lambda_p[0] \geq \lambda_p^\Delta$, where λ_p^Δ are the eigenvalues of $-h^2\Delta$ with Neumann boundary conditions on $\partial\Omega$. Thus, we have

$$\int n[0]\, dx \leq \sum_p e^{-\lambda_p^\Delta}$$

and S is bounded from below by a constant which depends only on Ω and h.

Let us now remark that, due to the no-flux boundary conditions (2.11), an integration of the first equation of (2.8)–(2.10) yields the conservation of the total charge:

$$\forall t \geq 0 \quad \int n(t,x)\, dx = \int n(0,x)\, dx. \tag{2.19}$$

Independently, by differentiating with respect to time the functional $F[A]$ defined by (2.12), and recalling that V^{ext} is independent of time, we get

$$\frac{d}{dt}\int n(t,x)\, dx = \frac{d}{dt}F[A(t)] = d_A F \cdot \partial_t A = -\int n(t,x)\, \partial_t A(t,x)\, dx;$$

thus, we have

$$\frac{d}{dt}\int n\,(A+1)\, dx = \int (\partial_t n) A\, dx.$$

To prove item (i), it remains to remark that the Poisson equation with Dirichlet boundary conditions yields

$$\frac{d}{dt}\frac{\alpha}{2}\int |\nabla V|^2\,dx = \int (\partial_t n)\,V\,dx.$$

Consequently, we obtain

$$\frac{d}{dt}S(t) = -\int (\partial_t n)(A-V)\,dx = -\int n\,|\nabla(A-V)|^2\,dx \le 0, \tag{2.20}$$

which proves (i). Let us now prove (ii). The fact that the first term of $\Sigma(t)$ is nonnegative stems from (2.15). In addition, since we have $A^\infty = V^\infty - \epsilon_F$, we deduce the equivalent expression

$$\begin{aligned}\Sigma(t) &= -\int (n\,(A+\epsilon_F) + n - n^\infty)\,dx \\ &\quad + \alpha\int \nabla V\cdot\nabla V^\infty\,dx + \frac{\alpha}{2}\int |\nabla(V-V^\infty)|^2 \\ &= S(t) - \epsilon_F\int n\,dx + \int n^\infty\,dx + \frac{\alpha}{2}\int |\nabla V^\infty|^2\,dx,\end{aligned}$$

where we used the Poisson equation $-\alpha\Delta V = n$. Therefore, by using (2.19), we deduce

$$\frac{d}{dt}\Sigma(t) = \frac{d}{dt}S(t) \le 0. \qquad \square$$

Remark 2.7. *Equation* (2.20) *gives the expression of the entropy dissipation. This term indicates that, as time goes to infinity, $A-V$ should converge towards a constant. Thus any transient solution of the QDD model should converge to the (unique) corresponding steady state. In order to prove rigorously this convergence, we need to control n from below, which is an open problem.*

3. Semidiscretization in time.

This section is devoted to the study of a semidiscrete version of (2.8)–(2.10), which appears as a first step towards the numerical scheme that is presented in section 4. Let $\Delta t > 0$ be the time step. For $k \in \mathbb{N}$, the semidiscretized model is written as

$$\frac{n^{k+1}-n^k}{\Delta t} + \operatorname{div}(n^k\nabla(A^{k+1}-V^{k+1})) = 0, \tag{3.1}$$

$$-\alpha\Delta V^{k+1} = n^{k+1}, \tag{3.2}$$

$$n^{k+1} = \sum_p e^{-\lambda_p[A^{k+1}]}\,|\chi_p[A^{k+1}]|^2, \tag{3.3}$$

subject to the boundary conditions

$$V^{k+1} = 0, \quad \partial_\nu(A^{k+1}-V^{k+1}) = 0. \tag{3.4}$$

Recall that, in this system, $\lambda_p[\cdot]$ and $\chi_p[\cdot]$ denote the whole sequence of eigenvalues and eigenfunctions of the operator $H[\cdot]$ defined in section 2.1 by

$$H[A] = -h^2\Delta + A + V^{ext}.$$

The unknowns are the density $n^k(x)$, the quantum chemical potential $A^k(x)$, and the self-consistent potential $V^k(x)$ for $k \in \mathbb{N}^*$. For $k = 0$, the density n^0 is given satisfying Assumption 2.1. Then, the Poisson equation enables us to define V^0. Concerning the initial chemical potential A^0, since it is not clear whether (2.7) can be inverted, we choose to let A^0 be undetermined. Notice that A^0 is not required in this model to compute (n^k, A^k, V^k) for $k \geq 1$. An alternative choice for the initial conditions would be to take an initial datum A^0, then to deduce n^0 by (2.7) and V^0 by the Poisson equation. However, it seems more interesting, for physical reasons, to start from an initial density n^0.

The main result of this section is as follows.

Theorem 3.1. *Under Assumptions* 2.1 *and* 2.2, *we have the following properties.*

(i) *The semidiscretized model* (3.1)–(3.3) *is well-posed. For all $k \in \mathbb{N}^*$, the functions $A^k \in W^{2,p}(\Omega)$, $V^k \in W^{2,p}(\Omega)$ (for any $p < \infty$), and $n^k \in C(\overline{\Omega})$ are uniquely defined and, for all k, we have $n^k > 0$ on $\overline{\Omega}$.*

(ii) *The total charge is conserved,*

$$\forall k \in \mathbb{N} \quad \int n^k \, dx = \int n^0 \, dx, \tag{3.5}$$

and the following free energy S^k, defined for $k \geq 1$, is bounded from below and decreases as k increases:

$$S^k = -\int n^k \left(A^k + 1\right) dx + \frac{\alpha}{2} \int |\nabla V^k|^2 \, dx.$$

(iii) *If $(n^\infty, A^\infty, V^\infty)$ is the solution of the Schrödinger–Poisson system* (2.16)–(2.18) *corresponding to $N = \int n^0 \, dx$, then the following relative entropy Σ^k is the sum of two nonnegative terms and decreases as k increases:*

$$\Sigma^k = -\int \left(n^k \left(A^k - A^\infty\right) + n^k - n^\infty\right) dx + \frac{\alpha}{2} \int |\nabla(V^k - V^\infty)|^2.$$

Proof. (i) Let us first give the outline of this proof. We shall proceed by induction, for any function n^k, positive and continuous on $\overline{\Omega}$, we will show that there exists a unique pair $(A^{k+1}, V^{k+1}) \in H^1(\Omega) \times H_0^1(\Omega)$ satisfying

$$\frac{n[A^{k+1}] - n^k}{\Delta t} + \operatorname{div}(n^k \nabla(A^{k+1} - V^{k+1})) = 0 \tag{3.6}$$

and

$$-\alpha \Delta V^{k+1} = n[A^{k+1}], \tag{3.7}$$

with the boundary condition (3.4), where we recall the notation

$$n[A^{k+1}] = \sum_p e^{-\lambda_p[A^{k+1}]} |\chi_p[A^{k+1}]|^2.$$

Then, as soon as (A^{k+1}, V^{k+1}) is defined, it suffices to set $n^{k+1} = n[A^{k+1}]$ and (3.1)–(3.3) is satisfied. Moreover, the first part of Lemma 2.3 shows that n^{k+1} is continuous on $\overline{\Omega}$. Hence, (3.1)–(3.3) and standard elliptic regularity estimates imply that for any $p < \infty$ we have $V^{k+1} \in W^{2,p}(\Omega)$ and $A^{k+1} \in W^{2,p}(\Omega)$. By Sobolev embeddings, we deduce that $A^{k+1} \in L^\infty(\Omega)$, which is enough to apply Krein–Rutman's theorem

[10]; the choice of Neumann boundary conditions for the eigenfunction χ_p (see (2.6)) ensures the fact that χ_1^{k+1} does not vanish on the closed domain $\overline{\Omega}$. Consequently, n^{k+1} is itself positive and continuous on $\overline{\Omega}$ and can be used to initiate the next step of the induction; we are then able to construct $(A^{k+2}, V^{k+2}, n^{k+2})$. Finally, thanks to Assumption 2.1 on the initial density n^0, all of the sequence $(A^k, V^k, n^k)_{k\geq 1}$ can be constructed by induction.

Let us now prove the claim: for any given positive and continuous function n^k, one can construct a unique corresponding (A^{k+1}, V^{k+1}) satisfying (3.6) and (3.7). This proof, inspired by [39, 40], is based on a variational argument. We introduce the following functional, defined for $A \in H^1(\Omega)$ and $V \in H_0^1(\Omega)$:

$$J(A,V) = \frac{\Delta t}{2} \int n^k \, |\nabla(A-V)|^2 \, dx + \frac{\alpha}{2} \int |\nabla V|^2 \, dx + F[A] + \int n^k \, (A-V) \, dx,$$

where $F[A]$ is defined by

$$F[A] = \mathrm{tr} e^{-H[A]} = \sum_{p\geq 1} e^{-\lambda[A]}.$$

Note that this functional J depends on n^k. By Lemma 2.3, this functional is continuous, Fréchet differentiable, and its derivative is given by

$$\begin{aligned} d_{A,V} J \cdot (\delta A, \delta V) = \Delta t & \int n^k \, \nabla(A-V) \cdot \nabla(\delta A - \delta V) \, dx \\ & + \alpha \int \nabla V \cdot \nabla \delta V \, dx \\ & - \int n[A] \, \delta A \, dx + \int n^k \, (\delta A - \delta V) \, dx, \end{aligned}$$

where $\delta A \in H^1(\Omega)$, $\delta V \in H_0^1(\Omega)$, and we recall the notation

$$n[A] = \sum_p e^{-\lambda_p[A]} \, |\chi_p[A]|^2.$$

Therefore, it is readily seen that the critical points of J satisfy (3.1)–(3.4). To prove the existence and uniqueness of A^{k+1} and V^{k+1}, it suffices to show that J is strictly convex and coercive, since its unique minimizer will be (A^{k+1}, V^{k+1}). The strict convexity is a consequence of Lemma 2.3 (which states that F is strictly convex) of the strict convexity of the functional

$$V \in H_0^1(\Omega) \longmapsto \int |\nabla V|^2 \, dx$$

and of the convexity of the functional

$$(A,V) \in H^1(\Omega) \times H_0^1(\Omega) \longmapsto \int n^k \, |\nabla(A-V)|^2 \, dx.$$

It remains to prove the coercivity with respect to $A \in H^1(\Omega)$ and $V \in H_0^1(\Omega)$. Let $(A^\varepsilon, V^\varepsilon)$ be a sequence in $H^1(\Omega) \times H_0^1(\Omega)$, parametrized by $\varepsilon > 0$, such that $J(A^\varepsilon, V^\varepsilon)$ has an upper bound independent of ε. To prove the coercivity of J, it suffices to show that $\|A^\varepsilon\|_{H^1} + \|V^\varepsilon\|_{H^1}$ can be bounded independently of ε.

Setting $a^\varepsilon = \frac{1}{|\Omega|}\int A^\varepsilon\,dx$ (where $|\Omega|$ denotes the measure of Ω), we introduce the function $B^\varepsilon = A^\varepsilon - a^\varepsilon$. We have

$$J(A^\varepsilon, V^\varepsilon) = \frac{\Delta t}{2}\int n^k\,|\nabla(B^\varepsilon - V^\varepsilon)|^2\,dx + \frac{\alpha}{2}\int |\nabla V^\varepsilon|^2\,dx$$
$$+\,e^{-a^\varepsilon}\sum_p e^{-\lambda_p[B^\varepsilon]} + \int n^k\,(B^\varepsilon - V^\varepsilon)\,dx + a^\varepsilon \int n^k\,dx \le C,$$

where C does not depend on ε. We recall that there exist two constants $\underline{n} > 0$ and $\overline{n} > 0$, independent of ε, such that

$$\underline{n} \le n^k(x) \le \overline{n} \quad \text{on } \overline{\Omega}.$$

Hence, the Cauchy–Schwarz inequality gives

(3.8)
$$\frac{\Delta t}{2}\,\underline{n}\int |\nabla(B^\varepsilon - V^\varepsilon)|^2\,dx + \frac{\alpha}{2}\int |\nabla V^\varepsilon|^2\,dx - \overline{n}\,|\Omega|^{1/2}\big(\|B^\varepsilon\|_{L^2(\Omega)} + \|V^\varepsilon\|_{L^2(\Omega)}\big)$$
$$+\,e^{-a^\varepsilon}\sum_p e^{-\lambda_p[B^\varepsilon]} + a^\varepsilon\int n^k\,dx \le J(A^\varepsilon, V^\varepsilon) \le C.$$

In addition, denoting by $\widetilde{H^1}(\Omega)$ the space of $H^1(\Omega)$ functions which have a vanishing integral on Ω, a classical compactness argument shows that, for any $a_1 > 0$ and $a_2 > 0$, the norm

$$(B, V) \in \widetilde{H^1}(\Omega) \times H^1_0(\Omega) \quad \longmapsto \quad \big(a_1\|\nabla(B - V)\|^2_{L^2(\Omega)} + a_2\|\nabla V\|^2_{L^2(\Omega)}\big)^{1/2}$$

is equivalent on this space $\widetilde{H^1}(\Omega) \times H^1_0(\Omega)$ to the standard $H^1(\Omega) \times H^1(\Omega)$ norm. Hence, there exist two constants $C_0 > 0$ and $C_1 > 0$, independent of ε, such that

$$\frac{\Delta t}{2}\,\underline{n}\int |\nabla(B^\varepsilon - V^\varepsilon)|^2\,dx + \frac{\alpha}{2}\int |\nabla V^\varepsilon|^2\,dx - \overline{n}\,|\Omega|^{1/2}\left(\|B^\varepsilon\|_{L^2(\Omega)} + \|V^\varepsilon\|_{L^2(\Omega)}\right)$$
$$\ge C_0\|B^\varepsilon\|^2_{H^1(\Omega)} + C_0\|V^\varepsilon\|^2_{H^1(\Omega)} - C_1;$$

thus (3.8) gives

$$C_0\|B^\varepsilon\|^2_{H^1(\Omega)} + C_0\|V^\varepsilon\|^2_{H^1(\Omega)} + e^{-a^\varepsilon}\sum_p e^{-\lambda_p[B^\varepsilon]} + a^\varepsilon\int n^k\,dx \le C. \tag{3.9}$$

Let us now recall that the first eigenvalue of $H[B^\varepsilon]$ is defined by

$$\lambda_1[B^\varepsilon] = \min_{\substack{\phi\,\in\,H^1(\Omega)\\ \|\phi\|_{L^2(\Omega)} = 1}} \left(h^2\int |\nabla\phi|^2\,dx + \int (B^\varepsilon + V^{ext})\,\phi^2\,dx\right).$$

By choosing the test function $\phi(x) \equiv 1/\sqrt{|\Omega|}$ in this formula, we deduce from $\int B^\varepsilon\,dx = 0$ that

$$\lambda_1[B^\varepsilon] \le \frac{1}{|\Omega|}\int V^{ext}\,dx.$$

There exists, consequently, a constant $C_2 > 0$, independent of ε, such that

$$e^{-a^\varepsilon} \sum_p e^{-\lambda_p[B^\varepsilon]} \geq C_2\, e^{-a^\varepsilon},$$

and (3.9) implies

$$C_0 \|B^\varepsilon\|^2_{H^1(\Omega)} + C_0 \|V^\varepsilon\|^2_{H^1(\Omega)} + C_2 e^{-a^\varepsilon} + a^\varepsilon \int n^k \, dx \leq C.$$

Since $\int n^k \, dx > 0$, it is clear then that $\|B^\varepsilon\|_{H^1(\Omega)}$, $\|V^\varepsilon\|_{H^1(\Omega)}$, and $|a^\varepsilon|$ are bounded independently of ε. Thus $\|A^\varepsilon\|_{H^1(\Omega)}$ is bounded, which completes the proof of coercivity.

(ii) The conservation of mass (3.5) can be easily shown by an integration of (3.1) on Ω, which gives, thanks to the boundary conditions (3.4),

$$\int n^{k+1} \, dx = \int n^k \, dx. \tag{3.10}$$

To prove the decay of the free energy, let us adapt to the semidiscrete case the proof of Proposition 2.6. By using Lemma 2.4, we have

$$\int (n^k (A^k - A^{k+1}) + n^k - n^{k+1}) \, dx \leq 0;$$

thus

$$\begin{aligned} -\int (n^{k+1}\, A^{k+1} - n^k\, A^k + n^{k+1} - n^k) \, dx & \\ = -\int (n^{k+1} - n^k)\, A^{k+1} \, dx + \int (n^k (A^k - A^{k+1}) + n^k - n^{k+1}) \, dx & \\ \leq -\int (n^{k+1} - n^k)\, A^{k+1} \, dx. & \end{aligned} \tag{3.11}$$

In addition, by using the Poisson equation (3.2), we obtain

$$\begin{aligned} \frac{\alpha}{2} \int (|\nabla V^{k+1}|^2 - |\nabla V^k|^2) \, dx &= \frac{1}{2} \int (n^{k+1}\, V^{k+1} - n^k\, V^k) \, dx \\ &= \frac{1}{2} \int (n^{k+1} - n^k)\, V^{k+1} \, dx + \frac{1}{2} \int n^k (V^{k+1} - V^k) \, dx \\ &= \frac{1}{2} \int (n^{k+1} - n^k)\, V^{k+1} \, dx + \frac{1}{2} \int V^k (n^{k+1} - n^k) \, dx. \end{aligned}$$

By remarking that

$$0 \leq \alpha \int |\nabla (V^{k+1} - V^k)|^2 dx = \int (n^{k+1} - n^k)(V^{k+1} - V^k),$$

we deduce that

$$\frac{1}{2} \int V^k (n^{k+1} - n^k) \, dx \leq \frac{1}{2} \int V^{k+1} (n^{k+1} - n^k) \, dx$$

and get

$$\frac{\alpha}{2}\int \left(|\nabla V^{k+1}|^2 - |\nabla V^k|^2\right) dx \le \int V^{k+1}(n^{k+1} - n^k)\, dx.$$

By combining this inequality and (3.11), we obtain

$$\begin{aligned} S^{k+1} - S^k &\le -\int (n^{k+1} - n^k)(A^{k+1} - V^{k+1})\, dx \\ &= \Delta t \int (A^{k+1} - V^{k+1})\, \mathrm{div}(n^k \nabla(A^{k+1} - V^{k+1}))\, dx, \end{aligned}$$

thanks to (3.1). An integration by parts, using (3.4), finally gives

$$S^{k+1} - S^k \le -\Delta t \int n^k\, |\nabla(A^{k+1} - V^{k+1})|^2\, dx \le 0.$$

This proves (ii). Finally, to prove (iii), it suffices to remark as for Proposition 2.6 that

$$\Sigma^{k+1} - \Sigma^k = S^{k+1} - S^k \le 0. \qquad \square$$

4. The fully discretized system: Construction and analysis. We complete the construction of a numerical scheme for the QDD model (2.8)–(2.10) by now discretizing system (3.1)–(3.3) with respect to the space variable. In the following section, we construct the scheme and give in Theorem 4.1 its main properties: well-posedness, charge conservation, and entropy dissipation. These properties are proved in section 4.2. Section 4.3 is devoted to the particular question of the initial step: it is shown in Proposition 4.4 that, at the discrete level, there exists a unique chemical potential A corresponding to each positive density n.

4.1. Notation and main results. For simplicity, the space dimension is now $d = 1$. The domain is $\Omega = (0, 1)$ and the space gridstep is $\Delta x = 1/(N + 1)$. The grid is composed of the points $x_i = i\Delta x$ for $i = 0, \dots, N + 1$, where $N \in \mathbb{N}$. In order to write the fully discretized finite difference numerical scheme, let us introduce the following $N \times N$ matrices of discrete derivative:

$$D^- = \frac{1}{\Delta x}\begin{pmatrix} 0 & 0 & \cdots & \\ -1 & 1 & 0 & \cdots \\ 0 & \ddots & \ddots & 0 \\ \vdots & 0 & -1 & 1 \end{pmatrix}, \quad D^+ = \frac{1}{\Delta x}\begin{pmatrix} -1 & 1 & 0 & \dots \\ 0 & -1 & 1 & \cdots \\ 0 & \ddots & \ddots & 1 \\ \vdots & \cdots & 0 & 0 \end{pmatrix},$$

$$\widetilde{D^-} = \frac{1}{\Delta x}\begin{pmatrix} 1 & 0 & \cdots & \\ -1 & 1 & 0 & \cdots \\ 0 & \ddots & \ddots & 0 \\ \vdots & 0 & -1 & 1 \end{pmatrix}, \quad \widetilde{D^+} = \frac{1}{\Delta x}\begin{pmatrix} -1 & 1 & 0 & \dots \\ 0 & -1 & 1 & \cdots \\ 0 & \ddots & \ddots & 1 \\ \vdots & \cdots & 0 & 1 \end{pmatrix},$$

$$\Delta_{Dir} = \frac{1}{\Delta x^2}\begin{pmatrix} -2 & 1 & 0 & \dots \\ 1 & -2 & \ddots & 0 \\ 0 & \ddots & \ddots & 1 \\ \vdots & \cdots & 1 & -2 \end{pmatrix}, \quad \Delta_{Neu} = \frac{1}{\Delta x^2}\begin{pmatrix} -1 & 1 & 0 & \dots \\ 1 & -2 & \ddots & 0 \\ 0 & \ddots & \ddots & 1 \\ \vdots & \cdots & 1 & -1 \end{pmatrix}.$$

Note that $\Delta_{Neu} = \widetilde{D^-}D^+ = \widetilde{D^+}D^-$. The unknowns are the following sequences of vectors in $\mathbb{R}^N$: $n^k = (n_i^k)_{1\leq i\leq N}$, $A^k = (A_i^k)_{1\leq i\leq N}$, $V^k = (V_i^k)_{1\leq i\leq N}$ and the scheme is written as

$$\frac{n^{k+1}-n^k}{\Delta t} + \frac{1}{2}\widetilde{D^-}(n^k\, D^+(A^{k+1}-V^{k+1})) + \frac{1}{2}\widetilde{D^+}(n^k\, D^-(A^{k+1}-V^{k+1})) = 0, \tag{4.1}$$

$$-\,\alpha\,\Delta_{Dir}V^k = n^k, \tag{4.2}$$

$$n^k = \sum_p \exp(-\ell_p[A^k])(X_p[A^k])^2 \tag{4.3}$$

for $k \in \mathbb{N}$ (here and in what follows, for any $(X,Y) \in \mathbb{R}^N \times \mathbb{R}^N$, XY denotes the direct product $(X_iY_i)_{1\leq i\leq N}$). In this discretized system, the definitions of $\ell_p[A]$ and $X_p[A]$ are the discrete analogue of those of $\lambda_p[A]$, $\chi_p[A]$ for the continuous problem. These quantities are the eigenvalues and the normalized eigenvectors of the discretized Hamiltonian with Neumann boundary conditions

$$M[A] = -h^2\Delta_{Neu} + \mathrm{Diag}(A + V^{ext}),$$

where $\mathrm{Diag}(A)$ denotes the diagonal matrix of coefficients $(A_i)_{1\leq i\leq N}$, and where the components of the vector V^{ext} are $V_i^{ext} = \frac{1}{\Delta x}\int_{x_{i-1/2}}^{x_{i+1/2}} V^{ext}(x)\,dx$. Of course, the index p of the eigenvalues and eigenvectors belongs now to $\{1,\dots,N\}$. Moreover, the eigenvectors are normalized with respect to the euclidean norm $\|\cdot\|_N$ associated with the scalar product on $\mathbb{R}^N$:

$$(U,V)_N = \Delta x \sum_{i=1}^N U_i\, V_i.$$

Notice that the boundary conditions are already taken into account in this scheme, the values of the unknowns for $i = 0$ or $i = N+1$ being implicitly defined. To complete (4.1)–(4.3), it suffices to add an initial condition. If Cauchy data for the continuous problem n^0 are given, the vector $n^0 \in \mathbb{R}^N$ is chosen as follows:

$$n_i^0 = \frac{1}{\Delta x}\int_{x_{i-1/2}}^{x_{i+1/2}} n^0(x)\,dx \quad \text{for } i = 1,\dots,N. \tag{4.4}$$

The numerical scheme (4.1)–(4.3) is clearly consistent with the QDD system (2.8)–(2.11). Its properties are listed in the following theorem, whose proof is developed in the three next subsections.

THEOREM 4.1. *If Assumptions* 2.1 *and* 2.2 *are satisfied, the numerical scheme* (4.1)*–*(4.4) *is consistent with* (2.8)*–*(2.11) *and has the following properties.*

(i) Well-posedness. *For all $k \in \mathbb{N}$, its numerical solution (n^k, A^k, V^k) is uniquely defined. Moreover, for all $k \in \mathbb{N}$, (A^{k+1}, V^{k+1}) is the unique minimizer of the strictly convex and coercive functional*

$$\begin{aligned}\widehat{J}(A,V) = {} & \frac{\Delta t\,\Delta x}{4}\sum_{i=1}^N n_i^k\,(D^+(A-V))_i^2 + \frac{\Delta t\,\Delta x}{4}\sum_{i=1}^N n_i^k\,(D^-(A-V))_i^2 \\ & + \frac{\alpha\,\Delta x}{2}\sum_{i=1}^N (D^+V)_i^2 + \frac{\alpha}{2\,\Delta x}(V_1)^2 + \frac{\alpha}{2\,\Delta x}(V_N)^2 \\ & + \sum_{p=1}^N \exp(-\ell_p[A]) + \Delta x \sum_{i=1}^N n_i^k\,(A_i - V_i).\end{aligned} \tag{4.5}$$

(ii) Charge conservation. *For all k and for all i we have $n_i^k > 0$ and the (discrete) total charge is conserved:*

$$\forall k \in \mathbb{N} \quad \Delta x \sum_{i=1}^{N} n_i^k = \Delta x \sum_{i=1}^{N} n_i^0. \tag{4.6}$$

(iii) Entropy dissipation. *The sequence of (discrete) free energies defined by*

(4.7)

$$S^k = -\Delta x \sum_{i=1}^{N} n_i^k \left(A_i^k + 1\right) + \frac{\alpha \Delta x}{2} \sum_{i=1}^{N} (D^+ V^k)_i^2 + \frac{\alpha}{2\,\Delta x}\left(V_1^k\right)^2 + \frac{\alpha}{2\,\Delta x}\left(V_N^k\right)^2$$

is decreasing and belongs to ℓ^∞. Moreover, there exists a constant $C > 0$ (depending only on Ω and h) such that, for any $K \in \mathbb{N}$, we have

$$\begin{aligned} -C \le S^K &+ \frac{\Delta t \Delta x}{2} \sum_{k=1}^{K} \sum_{i=1}^{N} n_i^{k-1} \left(D^+(A^k - V^k)\right)_i^2 \\ &+ \frac{\Delta t \Delta x}{2} \sum_{k=1}^{K} \sum_{i=1}^{N} n_i^{k-1} \left(D^-(A^k - V^k)\right)_i^2 \le S^0. \end{aligned} \tag{4.8}$$

4.2. Proof of well-posedness and entropy dissipation. For the sake of conciseness, we shall only sketch the proof of Theorem 4.1. Indeed, it suffices to adapt to the discrete case the proof of Theorem 3.1. These results are based on formulas of discrete integration by parts and on technical results concerning matrix analysis which are the discrete equivalents of the technical results stated in section 2.2, and that we have listed in Lemma 4.2 below.

It is worthwhile to mention that the similarity between the functional $J(A,V)$, introduced in the proof of Theorem 3.1, and the functional $\widehat{J}(A,V)$ of Theorem 4.1 is due to two useful formulas of discrete integration by parts: for any pair of vectors $(U,V) \in \mathbb{R}^N \times \mathbb{R}^N$, we have

$$\begin{aligned} -(\Delta_{Neu} U, V)_N &= -(\widetilde{D^-} D^+ U, V)_N = \left(D^+ U, D^+ V\right)_N \\ &= -(\widetilde{D^+} D^- U, V)_N = \left(D^- U, D^- V\right)_N \end{aligned} \tag{4.9}$$

and

$$-(\Delta_{Dir} U, V)_N = (D^+ U, D^+ V)_N + \frac{U_1 V_1 + U_N V_N}{\Delta x}. \tag{4.10}$$

Next, we gather in the following lemma some classical but useful technical results on matrices.

LEMMA 4.2. *Let $A \in \mathbb{R}^N$. Then the eigenvalues $\ell_p[A]$ of the matrix $M[A] = -h^2 \Delta_{Neu} + \mathrm{Diag}(A + V^{ext})$ are simple. (Up to a multiplication by -1) its first eigenvector $X_1[A]$ has positive components. The derivatives of the eigenvalues and eigenvectors of $M[A]$ with respect to A, in the direction δA, are given by*

$$\begin{aligned} d\ell_p[A] \cdot \delta A &= (\delta A \, X_p[A], X_p[A])_N, \\ dX_p[A] \cdot \delta A &= \sum_{q \ne p} \frac{1}{\ell_p[A] - \ell_q[A]} (\delta A \, X_p[A], X_q[A])_N \, X_q[A]. \end{aligned}$$

Proof. The simplicity of the eigenvalues of $M[A]$ is a general classical result for Hessenberg matrices [49], i.e., matrices $M = (m_{i,j})_{1\leq i,j\leq N}$ such that

$$m_{i,j} = 0 \text{ for } j < i-1 \quad \text{and} \quad m_{i,i-1} \neq 0 \text{ for } 2 \leq i \leq N.$$

This simplicity enables us to differentiate ℓ_p and $X_p[A]$ by using the classical perturbation theory.

Let $\lambda = 1 + \max_i |A_i|$. Then it is clear that the matrix $M[A] + \lambda I$ is invertible and satisfies the discrete maximum principle:

$$\forall Y \in \mathbb{R}^N\backslash\{0\} \quad Y \geq 0 \Longrightarrow (M[A] + \lambda I)^{-1}\, Y > 0,$$

where, for any vector $X \in \mathbb{R}^N$, the notation $X \geq 0$ (resp., $X > 0$) stands for $X_i \geq 0$ (resp., $X_i > 0$) for all $i = 1, \dots, N$. Hence the Perron–Frobenius theorem (see [49]) applies to the matrix $(M[A] + \lambda I)^{-1}$, the spectral radius of this matrix is an eigenvalue and, up to a multiplication by -1, the corresponding eigenvector has positive components. This vector is the ground state $X_1[A]$ of $M[A]$. □

REMARK 4.3. *Special care has to be taken for the initial step of the scheme. In the semidiscrete case of system* (3.1)–(3.3)*, the question of the initial step was left unsolved: for a given initial density $n^0(x)$, can we define a unique corresponding chemical potential A^0 such that* (3.3) *holds? In the fully discrete case, this question finds a positive answer, as stated in Theorem* 4.1(i). *Section* 4.3 *is devoted to this particular point of the theorem.*

4.3. Initialization of the chemical potential. As noted in Remark 4.3, one question has not been addressed yet concerning the numerical scheme (4.1)–(4.4): the computation of the initial chemical potential A^0 corresponding to the initial data n^0. While, in the continuous problem, we do not know whether (or in which functional framework) the nonlocal relation (2.7) linking n to A is invertible, this operation is possible with its discrete analogous (4.3). The aim of this section is to establish this property: we show that this problem is again equivalent to a convex minimization problem. Notice that this enables us to deduce a practical method to numerically solve this problem, by writing an algorithm for this optimization problem (see [20] for details). Note also that the possibility of inverting the constitutive relation $A \mapsto n[A]$, interesting for itself, is not mandatory for the other steps of the scheme (see Theorem 4.1(i)): the minimization of J for the computation of (A^{k+1}, V^{k+1}) does not require the knowledge of A^k. The following proposition is the main result of this subsection.

PROPOSITION 4.4. *Let $n \in (\mathbb{R}_+^*)^N$. Then there exists a unique $A \in \mathbb{R}^N$ such that*

$$n = \sum_{p=1}^{N} \exp(-\ell_p[A])\,(X_p[A])^2, \tag{4.11}$$

where $\ell_p[A]$ and $X_p[A]$ are the eigenvalues and the eigenvectors of the discrete Hamiltonian $M[A] = -h^2\Delta_{Neu} + \mathrm{Diag}(A + V^{ext})$.

Proof. Consider the functional

$$\Phi[A] = \sum_p \exp\left(-\ell_p[A]\right) + (n, A)_N. \tag{4.12}$$

Straightforward calculations using Lemma 4.2 lead to the expression of its first and second derivatives:

$$d\Phi_A \cdot \delta A = \left(n - \sum_p \exp(-\ell_p[A])\,(X_p[A])^2, \delta A\right)_N$$

and

$$d^2\Phi_A \cdot \delta A \cdot \delta A = \sum_{p=1}^{N} \exp(-\ell_p[A])(\delta A\, X_p[A],\, X_p[A])_N^2$$
$$- \sum_p \sum_{q\neq p} \frac{\exp(-\ell_p[A]) - \exp(-\ell_q[A])}{\ell_p[A]-\ell_q[A]} (\delta A\, X_p[A],\, X_q[A])_N^2.$$

It is then clear that this functional Φ is strictly convex and that its unique minimizer satisfies (4.11). To prove the existence of a solution to the problem, the major task is to prove the coercivity of this functional.

Recall that

$$\ell_1[A] = \min_{\|\phi\|_N=1}((-h^2\Delta_{Neu}\phi,\phi)_N + (\mathrm{Diag}(A+V^{ext})\phi,\phi)_N). \tag{4.13}$$

Let $i_0 \in \{1,\dots,N\}$ (arbitrary). By choosing the i_0th normalized basis vector as ϕ in (4.13) (i.e., $\phi_i = \delta_{i,i_0}/\sqrt{\Delta x}$), we obtain

$$\ell_1[A] \le A_{i_0} + \frac{2h^2}{\Delta x^2} + V_{i_0}^{ext}. \tag{4.14}$$

Hence, there exists a constant $C > 0$ depending only on Δx, h, and V^{ext} such that

$$\Phi[A] \ge C\sum_i \exp(-A_i) + \Delta x \sum_i n_i\, A_i. \tag{4.15}$$

Since for all i we have $n_i > 0$, it is clear that

$$\lim_{\|A\|\to\infty} \Phi[A] = +\infty.$$

This proves the coercivity of Φ. □

5. Numerical results. In order to simulate the QDD model, the numerical scheme (4.1)–(4.3) has been implemented by minimizing the functional $\widehat{J}$ defined by (4.5). Each strictly convex unconstrained minimization problem is solved by a Newton method (note that the Hessian matrix is explicit and always positive definite). The computation of the eigenelements of the discrete Hamiltonian $M[A]$ is performed by using the MATLAB function `eigs` [36]. For details concerning the practical implementation of the scheme, one can refer to [20].

The external potential is a discontinuous function playing the role of a double barrier structure potential and the initial density n^0 is concentrated on the left of the double barrier (see Figure 5.1). The initial step involves the inversion of the formula (4.11), i.e., the computation of the initial chemical potential A^0 corresponding to n^0. The calculation of A^0 is done by minimizing the strictly convex functional Φ defined in (4.12). Recall that A^0 is not used in the text following the algorithm.

In Figures 5.1, 5.2, 5.3, 5.4, and 5.5, we have represented, as functions of x, the density n, the total potential $V + V^{ext}$, and the electrochemical potential $A - V$ at the initial step and at different time steps: k = 3, 20, 100, 500. The parameters of these computations are the following:

Δx	Δt	h^2	α
0.01	0.005	0.02	0.1

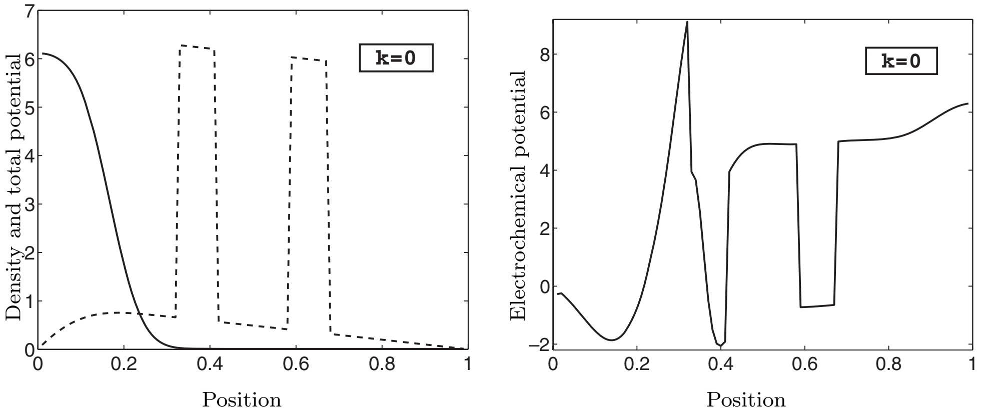

FIG. 5.1. *Numerical solution of the QDD model: Initial step. Left: The density $n(x)$ (solid line) and the total potential $(V + V^{ext})(x)$(dashed line) as functions of the position x. Right: The electrochemical potential $(A - V)(x)$.*

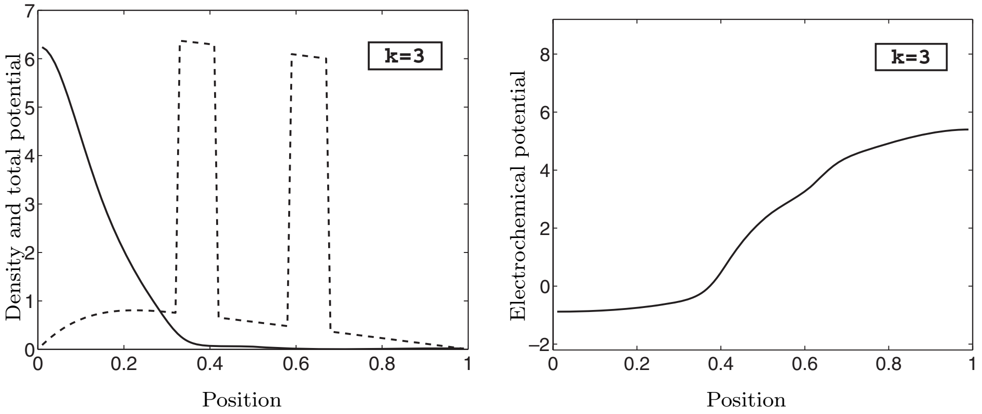

FIG. 5.2. *Numerical solution of the QDD model, after* 3 *iterations. The same quantities as in Figure* 5.1 *are represented.*

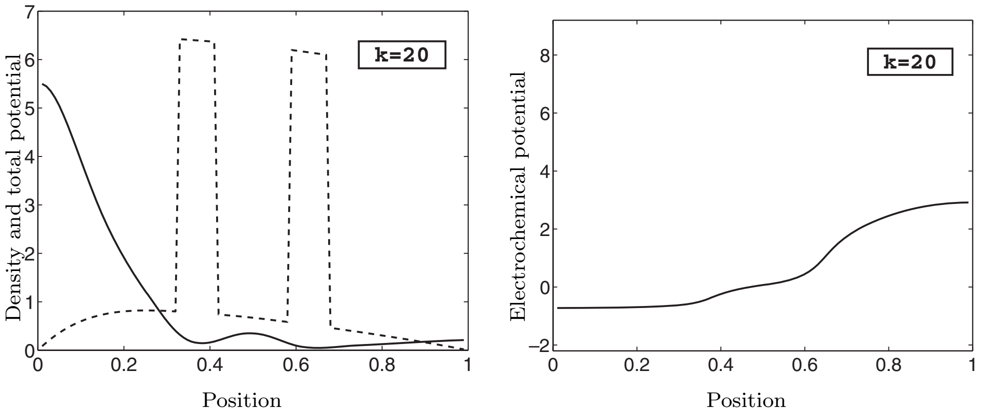

FIG. 5.3. *Numerical solution of the QDD model, after* 20 *iterations. The same quantities as in Figure* 5.1 *are represented.*

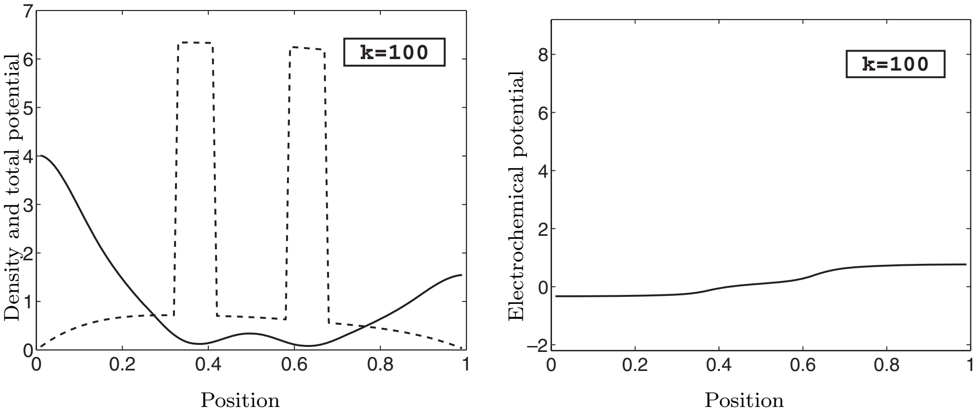

Fig. 5.4. *Numerical solution of the QDD model, after* 100 *iterations. The same quantities as in Figure* 5.1 *are represented.*

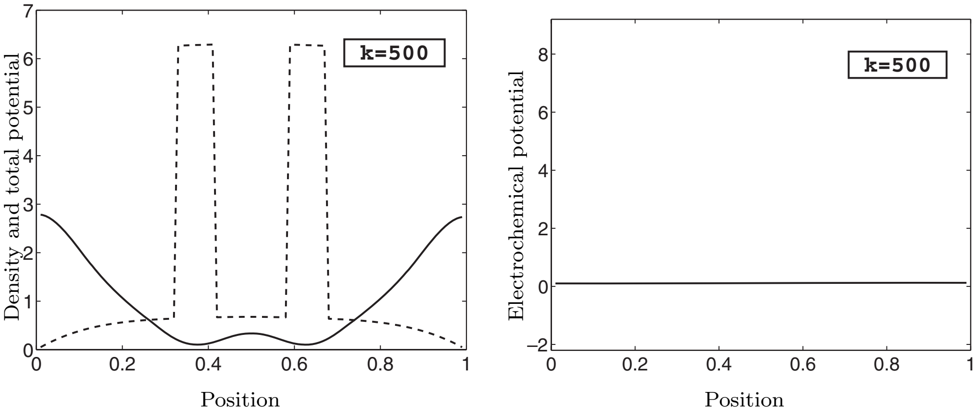

Fig. 5.5. *Numerical solution of the QDD model, after* 500 *iterations. The same quantities as in Figure* 5.1 *are represented.*

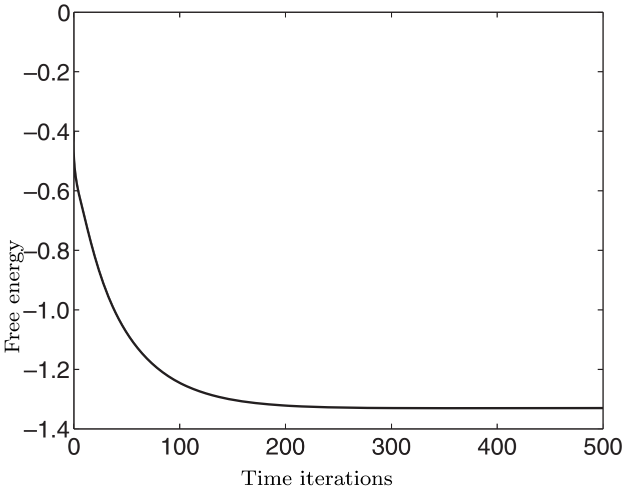

Fig. 5.6. *Free energy S^k as a function of the time step k.*

On the right-hand side of these figures, one can check that the electrochemical potential converges to a constant: at time $t = 500\Delta t$, one can consider that the system has converged to a steady state, which solves a discrete Schrödinger–Poisson system. In Figure 5.6, we show the evolution of the free energy S^k defined by (4.7) and check that it is a decreasing function, converging to a constant. In these simulations, the initial total charge is equal to 1 and this quantity is conserved during the evolution, up to a relative error of $10^{-4}\,\%$.

6. Conclusion. We have introduced a semidiscrete (in time) version (3.1)–(3.3) of the QDD model (2.8)–(2.10). We have proved that this system is well-posed and that its resolution amounts to minimizing a convex functional. Moreover, this semidiscrete model has the following interesting properties: it preserves the total charge and the positivity of the density and it dissipates the free energy. Then we have defined the numerical scheme (4.1)–(4.3) by discretizing the space variable in this system. As a consequence, this scheme possesses the same properties as the semidiscrete model. Finally, we have given some results of numerical simulations which have been performed with this scheme.

A lot of open questions arise naturally. Let us list a few of them. By passing formally to the limit in the semidiscrete model as Δt goes to zero, one obtains a solution of the initial QDD model. To make this statement rigorous, one of the most difficult points to be solved seems to be to find a bound from below for the density. Studying the long-time behavior of the semidiscrete model or the continuous model is also an interesting challenge: do their solutions converge to the solution of the Schrödinger–Poisson system studied in [39, 40]? Another important question is concerned with boundary conditions. We have chosen no-flux boundary conditions, but for practical use it is necessary to enable a current flow through the boundary. This issue will be investigated in a future work.

Acknowledgments. The authors wish to express their gratitude to Pierre Degond for initiating this work and for many helpful discussions. They would also like to thank Naoufel Ben Abdallah and Joachim Rehberg for fruitful discussions.

ON CONVERGENCE OF THE ADDITIVE SCHWARZ PRECONDITIONED INEXACT NEWTON METHOD*

HENG-BIN AN†

Abstract. The additive Schwarz preconditioned inexact Newton (ASPIN) method was recently introduced [X.-C. Cai and D. E. Keyes, *SIAM J. Sci. Comput.*, 24 (2002), pp. 183–200] to solve the systems of nonlinear equations with nonbalanced nonlinearities. Although the ASPIN method has successfully been used to solve some difficult nonlinear equations, its convergence property has not been studied since it was proposed. In this paper, the convergence property of the ASPIN method is studied, and the obtained result shows that this method is locally convergent. Furthermore, the convergence rate for the ASPIN method is discussed and the obtained result is similar to that of the inexact Newton method.

Key words. nonlinear systems, inexact Newton methods, nonlinear preconditioning, additive Schwarz, local convergence, convergence rate

1. Introduction.

Consider the nonlinear system of equations

$$F(u) = 0, \tag{1.1}$$

where $F : R^n \to R^n$ is a continuously differentiable function. For convenience of discussion, let $F = (F_1, F_2, \dots, F_n)^T$, $u = (u_1, u_2, \dots, u_n)^T$, and $J(u) = F'(u)$. A numerical solution for (1.1) is often required in many scientific and engineering computing areas such as the discretization of nonlinear partial differential equations; see [7, 16]. The inexact Newton method [8] is one of the most important and effective tools for solving such systems, in particular, when the problem is large and sparse. In applications, some global strategies, such as linesearch or trust region techniques, are often needed because the inexact Newton method is locally convergent [1, 2, 3, 4, 12]. In particular, if the linesearch backtracking technique is augmented in the inexact Newton method, then the inexact Newton with backtracking (INB) method is obtained [12, 13, 19]. This method is more robust and it can be briefly described here. Suppose $u^{(0)}$ is a given initial guess and let $u^{(k)}$ be the current approximate solution; the next approximate solution $u^{(k+1)}$ can be obtained through the following steps.

ALGORITHM 1.1 (INB [12]).

1. Inexactly solve the system

$$J\big(u^{(k)}\big)p = -F\big(u^{(k)}\big), \tag{1.2}$$

and obtain an inexact Newton direction $p^{(k)}$ such that

$$\|F\big(u^{(k)}\big) + J\big(u^{(k)}\big)p^{(k)}\| \le \eta_k \|F\big(u^{(k)}\big)\|. \tag{1.3}$$

2. Compute the new approximate solution

$$u^{(k+1)} = u^{(k)} + \lambda_k p^{(k)}.$$

†State Key Laboratory of Computational Physics, Institute of Applied Physics and Computational Mathematics, P.O. Box 8009, Beijing 100088, People's Republic of China (anhengbin@sina.com).

Here $\eta_k \in [0,1)$ is the forcing term that controls how accurately system (1.2) should be solved, and $p^{(k)}$ is the inexact Newton direction of F at $u^{(k)}$. Step 2 in Algorithm 1.1 is a linesearch procedure that is used to find a satisfied step factor $\lambda_k \in (0,1]$ and then form the next approximate solution.

Usually, we use linear iterative methods, such as the classical splitting method or the modern Krylov subspace method, to inexactly solve system (1.2). Thus, the inexact Newton method is an inner-outer iterative method. In particular, when the Krylov subspace method is used in an inner iteration, we obtain the Newton–Krylov subspace method, which has been used successfully in many areas [1, 2, 3, 4, 16].

Although the inexact Newton method works very well for most nonlinear equations, this may often fail when it is used to solve some difficult problems. Many numerical experiments show that most failed cases in the inexact Newton method result from stagnation, particularly when it is used to solve some problems with non-balanced nonlinearities [1, 6]. Usually, the stagnation phenomenon is caused by the lack of a good initial guess and/or problematic regions such as boundary layers, singularities in the domain, and/or multiphysics domain, etc. See [17]. Considering this, Cai and Keyes [6] recently proposed a nonlinearly preconditioned inexact Newton algorithm: first convert system (1.1) into another nonlinear system $\mathcal{F}(u) = 0$ such that the two systems have the same solution $u^* \in R^n$; then use Algorithm 1.1 to solve $\mathcal{F}(u) = 0$.

$\mathcal{F}$ and F may have completely different forms, but they must have the same solution. Usually, $\mathcal{F}$ has more uniform nonlinearities, so it is relatively easy to solve. In [6], an especially preconditioned case, where $\mathcal{F}$ is obtained by the single-level nonlinear additive Schwarz method, is discussed in detail. The corresponding method is the additive Schwarz preconditioned inexact Newton (ASPIN) method. Numerical results in [6] show that the ASPIN method can solve some difficult problems where the traditional inexact Newton method fails.

Although the ASPIN method has better numerical results than the traditional inexact Newton method, it is unfortunate that until now the convergence property for the ASPIN method has not been given much importance except for some preliminary convergence analysis in the context of semilinear PDEs in paper [17]. In this paper, we show that the ASPIN method is locally convergent; thus we give theoretical support for the ASPIN method. Moreover, we will discuss the convergence rate of the ASPIN method.

The rest of the paper is organized as follows. In section 2, we briefly discuss the ASPIN method, and some of its properties are listed. In section 3, we show that the ASPIN method is locally convergent, and its convergence rate is discussed in section 4. Finally, in section 5, some brief conclusions are given.

2. The ASPIN method.

Assume that $F(u^*) = 0$ and $J(u^*)$ is invertible. To find the solution u^* of system (1.1), the ASPIN method solves another nonlinear system $\mathcal{F}(u) = 0$, which is obtained from (1.1) through the additive Schwarz preconditioning technique. Specifically, the ASPIN method can be described as follows.

Let

$$S = \{1, 2, \ldots, n\}$$

be an index set, i.e., one integer corresponds to each u_i and F_i. Assume that S has a partition $\{S_1, S_2, \ldots, S_N\}$ such that

$$\bigcup_{i=1}^{N} S_i = S \quad \text{and} \quad S_i \subset S.$$

Here the subsets may overlap. Let $n_i = |S_i|$ be the dimension of S_i; then

$$\sum_{i=1}^{N} n_i \geq n.$$

Assume that

$$S_i = \{i_1, i_2, \ldots, i_{n_i}\},$$

where $i_1 < i_2 < \cdots < i_{n_i}$. For $i = 1, 2, \ldots, N$, define matrices $E_i \in R^{n_i \times n}$ by

$$(E_i)_{k,l} = \begin{cases} 1, & l = i_k, \\ 0, & l \neq i_k. \end{cases}$$

Let

$$P_i = E_i^T E_i$$

and

$$V_i = P_i R^n, \quad F_{S_i} = P_i F.$$

It is easy to see that P_i is the orthogonal projection from R^n onto V_i.

For each $u \in R^n$, we define $T_i(u) \in V_i$ such that

$$F_{S_i}(u - T_i(u)) = 0, \quad i = 1, 2, \ldots, N, \tag{2.1}$$

and let

$$\mathcal{F}(u) = \sum_{i=1}^{N} T_i(u),$$

which is referred to as the additive Schwarz preconditioned nonlinear function. The ASPIN method tries to find the solution u^* of (1.1) by solving the nonlinear system

$$\mathcal{F}(u) = 0 \tag{2.2}$$

with the inexact Newton method.

About the solvability of (2.1), we have the following proposition.

Proposition 2.1. *If $E_i J(u^*) E_i^T$ is invertible for each i, then there exists a neighborhood U of u^* and a unique continuously differentiable function $T_i : R^n \to V_i$ for each i such that* (2.1) *holds for each $u \in U$, and also $T_i(u^*) = 0$. Moreover,*

$$T_i'(u) = E_i^T \left[E_i J(u - T_i(u)) E_i^T\right]^{-1} E_i J(u - T_i(u)). \tag{2.3}$$

Proof. Theorem 1.1 in [10] shows that there exist a neighborhood U_1 of u^* and a unique continuous function $T_i : R^n \to V_i$ for each i such that (2.1) holds for each $u \in U_1$, and $T_i(u^*) = 0$. Also, we know from [10] that T_i satisfies

$$T_i(v) - T_i(u) = DT_i(v, u)(v - u), \quad v, u \in U_1, \tag{2.4}$$

where

$$DT_i(v, u) = E_i^T \left[E_i DF(v - T_i(v), u - T_i(u)) E_i^T\right]^{-1} E_i DF(v - T_i(v), u - T_i(u)),$$

while

$$DF(v - T_i(v), u - T_i(u)) = \int_0^1 J([v - T_i(v)] + t[(u - T_i(u)) - (v - T_i(v))])\, dt.$$

Since $J(u)$ is continuous and $E_i J(u^*) E_i^T$ is invertible for each i, Lemma 2.3.3 in [20] shows that there exists a neighborhood U_2 of u^* such that $E_i J(u) E_i^T$ is invertible for each $u \in U_2$. Now let $U \subset U_1 \cap U_2$ be a neighborhood of u^* such that $u - T_i(u) \in U_2$ for each $u \in U$ and for each i.

For $u \in U$, let

$$A(u) = E_i^T [E_i J(u - T_i(u)) E_i^T]^{-1} E_i J(u - T_i(u));$$

then, according to (2.4) and Lemma 2.3.3 in [20], it is easy to verify that

$$\lim_{\|h\| \to 0} \frac{\|T_i(u + h) - T_i(u) - A(u)h\|}{\|h\|} = 0.$$

Thus, $T_i(u)$ is Fréchet-differentiable, and

$$T_i'(u) = A(u) = E_i^T [E_i J(u - T_i(u)) E_i^T]^{-1} E_i J(u - T_i(u)).$$

In addition, it is easy to see from Lemma 2.3.3 in [20] that $T_i'(u)$ is continuous. □

It should be pointed out that formula (2.3) has been given in [6], but it has been obtained in a different way. In addition, it should be noted that the condition of Proposition 2.1 is satisfied for any partition of S if $J(u^*)$ is positive definite.

Since the inexact Newton method concerns the Jacobian of the system, an analysis of the basic property of the Jacobian $\mathcal{F}'(u)$ is necessary. Because $T_i(u)$ is continuous and $T_i(u^*) = 0$, we know that when u is sufficiently close to u^*, $T_i(u)$ will be sufficiently close to 0, and as a result, $u - T_i(u)$ will be close to u. Since $J(u)$ is continuous, we may replace $J(u - T_i(u))$ by $J(u)$; therefore,

$$\begin{aligned} T_i'(u) &= E_i^T \left(E_i J(u - T_i(u)) E_i^T\right)^{-1} E_i J(u - T_i(u)) \\ &\approx E_i^T \left(E_i J(u) E_i^T\right)^{-1} E_i J(u) \\ &\equiv R_i(u). \end{aligned}$$

Let

$$\mathcal{J}(u) = \mathcal{F}'(u);$$

then

$$\mathcal{J}(u) = \sum_{i=1}^N T_i'(u) \approx \sum_{i=1}^N R_i(u) \equiv B(u).$$

In implementation of the ASPIN method, the Jacobian $\mathcal{J}(u)$ is replaced by $B(u)$, since the latter is easier to use.

Remark 2.1. *From the proof of Proposition* 2.1, *we know that if $E_i J(u^*) E_i^T$ is invertible for each i, then $E_i J(u - T_i(u)) E_i^T$ and $E_i J(u) E_i^T$ are invertible in the neighborhood U of u^*. In addition, $(E_i J(u - T_i(u)) E_i^T)^{-1}$ and $(E_i J(u) E_i^T)^{-1}$ are continuous in U, so $\mathcal{J}(u)$ and $B(u)$ are all continuous in U. Furthermore, it is easy to see that*

$$\lim_{u \to u^*} \mathcal{J}(u) = \lim_{u \to u^*} B(u) = \sum_{i=1}^N E_i^T \left(E_i J(u^*) E_i^T\right)^{-1} E_i J(u^*) = \mathcal{J}(u^*). \tag{2.5}$$

From [6] and [10], we can obtain the following result.

PROPOSITION 2.2. *If $E_i J(u^*) E_i^T$ is invertible for each i, then there exists a neighborhood $D \subset U$ of u^* with U determined in Proposition* 2.1 *such that*

(i) *$\mathcal{J}(u)$ and $B(u)$ are nonsingular in D;*

(ii) *the nonlinear systems* (1.1) *and* (2.2) *are equivalent in the sense that they have the same solution in D.*

REMARK 2.2. *Remark* 2.1 *points out that $\mathcal{J}(u)$ and $B(u)$ are all continuous in $D \subset U$; thus Lemma* 2.3.3 *in* [20] *and Proposition* 2.2 *show that $\mathcal{J}(u)^{-1}$ and $B(u)^{-1}$ are continuous in D.*

For convenience of discussion, we describe the ASPIN algorithm here. Let

$$f(u) = \frac{1}{2}\mathcal{F}(u)^T \mathcal{F}(u),$$

which will be used in linesearch in the inexact Newton method. Assume that $u^{(0)}$ is a given initial guess and $u^{(k)}$ is the current approximate solution; the next approximate solution $u^{(k+1)}$ for system (2.2) can be computed through the following steps.

ALGORITHM 2.1 (ASPIN [6]).

```
0. Let $\eta_{max} \in (0,1)$, $\alpha \in (0,1)$, $0 < \theta_{min} < \theta_{max} < 1$ be given.
1. Compute the nonlinear residual $g^{(k)} = \mathcal{F}(u^{(k)})$ through the following steps.
  1.1. Find $g_i^{(k)} = T_i(u^{(k)})$ by solving the local subdomain nonlinear systems
         $F_{S_i}\big(u^{(k)} - g_i^{(k)}\big) = 0, \quad i = 1, 2, \ldots, N,$
       with the initial point $g_i^{(k)} = 0$.
  1.2. Form the global residual
         $g^{(k)} = \sum_{i=1}^{N} g_i^{(k)}.$
  1.3. Check the stopping conditions on $g^{(k)}$.
2. Find the approximate inexact Newton direction $p^{(k)}$ by solving the system
         $B(u^{(k)})p = -\mathcal{F}\big(u^{(k)}\big)$
   such that
         $\big\|\mathcal{F}\big(u^{(k)}\big) + B\big(u^{(k)}\big)p^{(k)}\big\| \le \eta_k \big\|\mathcal{F}\big(u^{(k)}\big)\big\|,$
   where $\eta_k \in [0, \eta_{max}]$ is the forcing term.
3. Perform linesearch along $p^{(k)}$:
  3.1. Let $\lambda_k = 1$.
  3.2. While $f(u^{(k)} + \lambda_k p^{(k)}) > f(u^{(k)}) + \alpha\lambda_k \mathcal{F}(u^{(k)})^T B(u^{(k)})p^{(k)}$, do
         • choose $\theta \in [\theta_{min}, \theta_{max}]$,
         • let $\lambda_k = \theta\lambda_k$.
  3.3. Let $u^{(k+1)} = u^{(k)} + \lambda_k p^{(k)}$.
```

In step 1.1 of Algorithm 2.1, N subdomain nonlinear systems have to be solved in order to evaluate the preconditioned function $\mathcal{F}$ at a given point. Step 3 of Algorithm 2.1 is the linesearch procedure to find a satisfied step. For more details about the ASPIN method, see [6].

We point out that Algorithm 2.1 can be implemented in parallel. For details about implementation, see [6, 7].

3. Local convergence of the ASPIN method. We will prove in this section that the ASPIN method is locally convergent. Note that by Propositions 2.1 and 2.2, the ASPIN method is based on the local property of $F(u)$ at the solution u^* of system (1.1), so it seems impossible to obtain a global convergence result for this method.

In this section and the following, $\|\cdot\|$ always denotes the Euclidean norm for both vectors and matrices, and $N(u,\rho) = \{v \mid \|v-u\| < \rho\}$ represents the open ball with center u and radius ρ.

Since the analysis of secondary iteration would complicate the discussion without gaining more insight into the method, we assume that

(A$_1$) the value of $\mathcal{F}$ at each iterative point is evaluated exactly, i.e., (2.1) holds with u replaced by $u^{(k)} + \lambda_k p^{(k)}$ for each k; moreover, from now on, we assume that

(A$_2$) $E_i J(u^*) E_i^T$ is invertible for each i;

(A$_3$) D represents the neighborhood determined in Proposition 2.2; and

(A$_4$) $\delta > 0$ is a fixed small number such that $N(u^*, \delta) \subset D$; in addition, the following inequalities hold for any $u \in N(u^*, \delta)$:

(I$_1$) $\|B(u)\| \le 2M$;

(I$_2$) $\|B(u)^{-1}\| \le 2M$;

(I$_3$) $\|\mathcal{J}(u)\| \le 2M$;

(I$_4$) $\|\mathcal{J}(u)^{-1}\| \le 2M$;

(I$_5$) $\|\mathcal{J}(u) - B(u)\| \le \frac{1-\eta_{max}}{4M(1+\eta_{max})}$;

(I$_6$) $\|\mathcal{F}(u) - \mathcal{F}(u^*) - \mathcal{J}(u^*)(u-u^*)\| \le \frac{1}{2M}\|u-u^*\|$,

where

$$M := \max\{\|\mathcal{J}(u^*)\|, \|\mathcal{J}(u^*)^{-1}\|\}.$$

It is easy to see from Remarks 2.1 and 2.2 that inequalities (I$_1$)–(I$_5$) may hold with δ small enough. The last inequality may hold by Lemma 3.2.10 in [20]. In addition, we assume that the parameter α in Algorithm 2.1 is small enough so that

$$64\alpha M^4 \le \frac{1-\eta_{max}}{3+\eta_{max}}. \tag{3.1}$$

It should be pointed out that the above assumptions are not so strict; see the appendix, where an example is given.

Now we show that the inexact Newton direction computed in Algorithm 2.1 is also a regular inexact Newton direction for $\mathcal{F}$ in the sense that (1.3) holds.

Proposition 3.1. *Assume that* $u \in N(u^*, \delta)$. *If*

$$\|\mathcal{F}(u) + B(u)p\| \le \eta \|\mathcal{F}(u)\|, \quad \eta \in [0, \eta_{max}], \tag{3.2}$$

then

$$\|\mathcal{F}(u) + \mathcal{J}(u)p\| \le \frac{1+\eta}{2}\|\mathcal{F}(u)\|. \tag{3.3}$$

Proof. By (I$_2$) and (3.2),

$$\begin{aligned}\|p\| &= \|B(u)^{-1}[B(u)p + \mathcal{F}(u) - \mathcal{F}(u)]\| \\ &\le (1+\eta)\|B(u)^{-1}\|\|\mathcal{F}(u)\| \\ &\le 2M(1+\eta)\|\mathcal{F}(u)\|.\end{aligned}$$

Thus, according to (I_5) and (3.2),

$$\begin{aligned}\|\mathcal{J}(u)p+\mathcal{F}(u)\| &= \|[\mathcal{J}(u)-B(u)]p+B(u)p+\mathcal{F}(u)\|\\ &\le \|\mathcal{J}(u)-B(u)\|\|p\|+\|B(u)p+\mathcal{F}(u)\|\\ &\le \frac{1-\eta_{max}}{4M(1+\eta_{max})}\cdot 2M(1+\eta)\|\mathcal{F}(u)\|+\eta\|\mathcal{F}(u)\|\\ &\le \frac{1-\eta}{2}\|\mathcal{F}(u)\|+\eta\|\mathcal{F}(u)\|\\ &\le \frac{1+\eta}{2}\|\mathcal{F}(u)\|.\end{aligned}$$

Thus we obtain the required inequality. □

REMARK 3.1. *If $u \in N(u^*,\delta)$ and (3.2) holds, then we have*

$$\begin{aligned}\mathcal{F}(u)^T B(u)p &= \mathcal{F}(u)^T[B(u)p+\mathcal{F}(u)-\mathcal{F}(u)]\\ &\le -\|\mathcal{F}(u)\|^2+\|\mathcal{F}(u)\|\|B(u)p+\mathcal{F}(u)\|\\ &\le -(1-\eta)\|\mathcal{F}(u)\|^2\\ &< 0.\end{aligned}$$

In the same way, (3.3) *shows that*

$$\mathcal{F}(u)^T\mathcal{J}(u)p<0. \tag{3.4}$$

In particular, (3.4) *shows that if $u \in N(u^*,\delta)$ and p is computed by the ASPIN method, then p is a descent direction for the function $f(u)=\frac{1}{2}\|\mathcal{F}(u)\|^2$ at point u.*[1]

The following lemma is needed in our analysis.

LEMMA 3.2 (see [4, Lemma 3.4]). *Let $u \in R^n$ and $H : R^n \to R^n$ be continuously differentiable in a neighborhood of u. Assume that $H(u) \neq 0$ and $H'(u)$ is nonsingular. If $p \in R^n$ such that*

$$\|H(u)+H'(u)p\| \le \eta\|H(u)\|, \quad \eta\in[0,1),$$

then

$$\frac{|\nabla h(u)^T p|}{\|p\|} \ge \frac{1-\eta}{(1+\eta)\kappa(H'(u))}\|\nabla h(u)\|>0,$$

where $\kappa(H'(u))$ is the condition number for $H'(u)$ and $h(u)=\frac{1}{2}H(u)^T H(u)$.

Based on Lemma 3.2, we have the following result.

LEMMA 3.3. *Assume that $u \in N(u^*,\delta)$. If*

$$\|\mathcal{F}(u)+B(u)p\| \le \eta\|\mathcal{F}(u)\|, \quad \eta\in[0,\eta_{max}],$$

then it holds that

$$|\mathcal{F}(u)^T\mathcal{J}(u)p| \ge 4\alpha|\mathcal{F}(u)^T B(u)p|.$$

Proof. According to Proposition 3.1, we have

$$\|\mathcal{F}(u)+\mathcal{J}(u)p\| \le \frac{1+\eta}{2}\|\mathcal{F}(u)\|;$$

[1] p is a descent direction for $f(u)$ if $\nabla f(u)^T p<0$. In addition, note that $\nabla f(u)=\mathcal{J}(u)^T\mathcal{F}(u)$.

therefore, by Lemma 3.2, (I_3), and (I_4),

$$\begin{aligned}|\mathcal{F}(u)^T\mathcal{J}(u)p| &\geq \frac{1-\eta}{(3+\eta)\kappa(\mathcal{J}(u))}\|\mathcal{F}(u)^T\mathcal{J}(u)\|\|p\| \\ &\geq \frac{1-\eta}{(3+\eta)\kappa(\mathcal{J}(u))\|\mathcal{J}(u)^{-1}\|}\|\mathcal{F}(u)\|\|p\| \\ &\geq \frac{1-\eta}{8M^3(3+\eta)}\|\mathcal{F}(u)\|\|p\|. \qquad (3.5)\end{aligned}$$

Thus, by (I_1), (3.5), and (3.1),

$$\begin{aligned}4\alpha|\mathcal{F}(u)^TB(u)p| &\leq 4\alpha\|B(u)\|\|\mathcal{F}(u)\|\|p\| \\ &\leq 8\alpha M\|\mathcal{F}(u)\|\|p\| \\ &\leq 8\alpha M\frac{8M^3(3+\eta)}{1-\eta}|\mathcal{F}(u)^T\mathcal{J}(u)p| \\ &\leq 64\alpha M^4\frac{3+\eta_{max}}{1-\eta_{max}}|\mathcal{F}(u)^T\mathcal{J}(u)p| \\ &\leq |\mathcal{F}(u)^T\mathcal{J}(u)p|.\end{aligned}$$

This concludes the proof. □

The following lemma shows that if u is sufficiently close to u^*, then the direction p obtained in the ASPIN method will not be too long.

LEMMA 3.4. *Assume that* $u \in N(u^*, \frac{\delta}{2})$ *with* $\|\mathcal{F}(u)\| \leq \frac{\delta}{8M}$*. If* $p \in R^n$ *such that*

$$\|\mathcal{F}(u) + B(u)p\| \leq \eta\|\mathcal{F}(u)\|, \quad \eta \in [0, \eta_{max}],$$

then $[u, u+p] \subset N(u^*, \delta)$*, where* $[u, u+p]$ *represents the line segment between* u *and* $u+p$*.*

Proof. Since $\|\mathcal{F}(u)\| \leq \frac{\delta}{8M}$, by ($\mathrm{I}_2$), we have

$$\begin{aligned}\|p\| &= \|B(u)^{-1}[B(u)p + \mathcal{F}(u) - \mathcal{F}(u)]\| \\ &\leq \|B(u)^{-1}\| \cdot [\|B(u)p + \mathcal{F}(u)\| + \|\mathcal{F}(u)\|] \\ &\leq 2M(1+\eta)\|\mathcal{F}(u)\| \\ &\leq 2M(1+\eta_{max})\|\mathcal{F}(u)\| \\ &\leq \frac{\delta(1+\eta_{max})}{4} \\ &< \frac{\delta}{2}.\end{aligned}$$

Therefore, by $u \in N(u^*, \frac{\delta}{2})$,

$$\|(u+p) - u^*\| \leq \|u - u^*\| + \|p\| < \frac{\delta}{2} + \frac{\delta}{2} = \delta,$$

that is, $u + p \in N(u^*, \delta)$. Since $u \in N(u^*, \delta)$ and $N(u^*, \delta)$ is a convex set, we have $[u, u+p] \subset N(u^*, \delta)$. □

We can now show the following theorem, which shows that the linesearch procedure along p will succeed with a nonzero step factor λ.

THEOREM 3.5. *Assume that* $u \in N(u^*, \frac{\delta}{2})$ *with*

$$\mathcal{F}(u) \neq 0, \quad \|\mathcal{F}(u)\| \leq \frac{\delta}{8M}.$$

In addition, assume that there exists $\gamma > 0$ *such that*

$$\|\nabla f(v) - \nabla f(w)\| \leq \gamma \|v - w\| \quad \forall\, v, w \in N(u^*, \delta). \tag{3.6}$$

If $p \in R^n$ *such that*

$$\|\mathcal{F}(u) + B(u)p\| \leq \eta \|\mathcal{F}(u)\|, \quad \eta \in [0, \eta_{max}],$$

then the linesearch procedure along p *in Algorithm* 2.1 *will terminate in finite iterations and the obtained* λ *satisfies*

$$\lambda \geq \min\left\{1, \frac{\alpha\theta_{min}|\mathcal{F}(u)^T\mathcal{J}(u)p|}{\gamma\|p\|^2}\right\}.$$

Proof. Because $u \in N(u^*, \frac{\delta}{2})$, Lemma 3.3 shows that

$$|\mathcal{F}(u)^T\mathcal{J}(u)p| \geq 4\alpha|\mathcal{F}(u)^T B(u)p|. \tag{3.7}$$

Since $\mathcal{F}(u)^T\mathcal{J}(u)p < 0$, $\mathcal{F}(u)^T B(u)p < 0$, (3.7) shows that

$$\mathcal{F}(u)^T\mathcal{J}(u)p \leq 4\alpha\mathcal{F}(u)^T B(u)p,$$

so

$$\mathcal{F}(u)^T\mathcal{J}(u)p - \alpha\mathcal{F}(u)^T B(u)p \leq 3\alpha\mathcal{F}(u)^T B(u)p < 0. \tag{3.8}$$

Because $u \in N(u^*, \frac{\delta}{2})$ and $\|\mathcal{F}(u)\| \leq \frac{\delta}{8M}$, Lemma 3.4 shows that $[u, u+p] \subset N(u^*, \delta)$. Thus, by the mean value theorem, there exists $\xi \in [u, u+p]$ such that

$$f(u + \lambda p) = f(u) + \lambda \nabla f(\xi)^T p.$$

Therefore,

$$\begin{aligned} f(u+\lambda p) &= f(u) + \lambda\nabla f(\xi)^T p \\ &= f(u) + \alpha\lambda\mathcal{F}(u)^T B(u)p - \alpha\lambda\mathcal{F}(u)^T B(u)p + \lambda\nabla f(\xi)^T p \\ &= f(u) + \alpha\lambda\mathcal{F}(u)^T B(u)p + \lambda\{[\nabla f(\xi)^T p - \nabla f(u)^T p] \\ &\quad +[\nabla f(u)^T p - \alpha\mathcal{F}(u)^T B(u)p]\} \\ &= f(u) + \alpha\lambda\mathcal{F}(u)^T B(u)p + \lambda\{\lambda\zeta + [\mathcal{F}(u)^T\mathcal{J}(u)p - \alpha\mathcal{F}(u)^T B(u)p]\}, \end{aligned}$$

where

$$\zeta = \frac{\nabla f(\xi)^T p - \nabla f(u)^T p}{\lambda}.$$

By (3.6), we have

$$|\zeta| \leq \gamma\|p\|^2,$$

so

$$f(u+\lambda p) \leq f(u) + \alpha\lambda\mathcal{F}(u)^T B(u)p + \lambda\left\{\lambda\gamma\|p\|^2 + [\mathcal{F}(u)^T\mathcal{J}(u)p - \alpha\mathcal{F}(u)^T B(u)p]\right\}.$$

Thus, if

$$\lambda\gamma\|p\|^2 + [\mathcal{F}(u)^T\mathcal{J}(u)p - \alpha\mathcal{F}(u)^T B(u)p] \leq 0,$$

then λ is acceptable. Since λ is reduced by a factor $\theta \leq \theta_{max} < 1$ at each iteration of the while-loop, it follows from (3.8) that the while-loop will terminate in finite steps.

Let λ be the ultimate step factor. If $\lambda = 1$, then the needed conclusion trivially holds. Now suppose that the linesearch procedure is implemented at least once, and let λ^- be the penultimate value; then the above argument shows that

$$\lambda^- \gamma \|p\|^2 + [\mathcal{F}(u)^T \mathcal{J}(u)p - \alpha \mathcal{F}(u)^T B(u)p] > 0.$$

Consequently,

$$\lambda^- > \frac{|\mathcal{F}(u)^T \mathcal{J}(u)p| - \alpha |\mathcal{F}(u)^T B(u)p|}{\gamma \|p\|^2}.$$

Therefore, it follows from (3.7) that

$$\begin{aligned} \lambda &\geq \theta_{min} \lambda^- \\ &> \theta_{min} \frac{|\mathcal{F}(u)^T \mathcal{J}(u)p| - \alpha |\mathcal{F}(u)^T B(u)p|}{\gamma \|p\|^2} \\ &\geq \theta_{min} \frac{4\alpha |\mathcal{F}(u)^T B(u)p| - \alpha |\mathcal{F}(u)^T B(u)p|}{\gamma \|p\|^2} \\ &\geq \frac{\alpha \theta_{min} |\mathcal{F}(u)^T B(u)p|}{\gamma \|p\|^2}. \end{aligned}$$

Thus, we have obtained the required conclusion. □

LEMMA 3.6. *If* $u \in N(u^*, \frac{\delta}{2})$ *and*

$$\|\mathcal{F}(u)\| < \frac{\delta}{8M}, \quad \mathcal{F}(u) \neq 0,$$

then $u_+ \in N(u^*, \frac{\delta}{2})$, *where* $u_+ = u + s$ *and* s *is a step such that*

$$\begin{aligned} \|\mathcal{F}(u) + B(u)s\| &\leq \|\mathcal{F}(u)\|, \\ \|\mathcal{F}(u_+)\| &< \|\mathcal{F}(u)\|. \end{aligned}$$

Proof. Let $y \in N(u^*, \delta)$; then by (I_6),

$$\begin{aligned} \|\mathcal{F}(y)\| &\geq \|\mathcal{J}(u^*)(y - u^*)\| - \|\mathcal{F}(y) - \mathcal{F}(u^*) - \mathcal{J}(u^*)(y - u^*)\| \\ &\geq \frac{1}{\|\mathcal{J}(u^*)^{-1}\|} \|y - u^*\| - \frac{1}{2M} \|y - u^*\| \\ &\geq \frac{1}{M} \|y - u^*\| - \frac{1}{2M} \|y - u^*\| \\ &= \frac{1}{2M} \|y - u^*\|. \end{aligned}$$

So

$$\|y - u^*\| \leq 2M \|\mathcal{F}(y)\|$$

whenever $y \in N(u^*, \delta)$.

By (I_2) and the assumption that $\|\mathcal{F}(u)\| < \frac{\delta}{8M}$, we have

$$\begin{aligned}\|s\| &= \|B(u)^{-1}\{[B(u)s + \mathcal{F}(u)] - \mathcal{F}(u)\}\| \\ &\leq \|B(u)^{-1}\| \cdot [\|B(u)s + \mathcal{F}(u)\| + \|\mathcal{F}(u)\|] \\ &\leq 4M\|\mathcal{F}(u)\| \\ &< \frac{\delta}{2},\end{aligned}$$

so

$$\|u_+ - u^*\| \leq \|u - u^*\| + \|s\| < \delta.$$

Because

$$\|\mathcal{F}(u_+)\| < \|\mathcal{F}(u)\| < \frac{\delta}{8M},$$

we have

$$\|u_+ - u^*\| \leq 2M\|\mathcal{F}(u_+)\| < \frac{\delta}{4} < \frac{\delta}{2},$$

that is, $u_+ \in N(u^*, \frac{\delta}{2})$. □

The following theorem describes the local convergence property of the ASPIN method.

Theorem 3.7. *Assume that there exists $\gamma > 0$ such that*

$$\|\nabla f(v) - \nabla f(w)\| \leq \gamma\|v - w\| \quad \forall\, v, w \in N(u^*, \delta).$$

If $u^{(0)} \in N(u^*, \frac{\delta}{2})$ such that

$$\|\mathcal{F}(u^{(0)})\| < \frac{\delta}{8M}, \quad \mathcal{F}\big(u^{(0)}\big) \neq 0,$$

then the ASPIN method can generate a sequence $\{u^{(k)}\} \subset N(u^*, \frac{\delta}{2})$ and $u^{(k)} \to u^*$.

Proof. We first prove that the ASPIN method can generate a sequence $\{u^{(k)}\} \subset N(u^*, \frac{\delta}{2})$ by induction.

(i) Since $u^{(0)} \in N(u^*, \frac{\delta}{2}) \subset N(u^*, \delta)$, and

$$\big\|\mathcal{F}\big(u^{(0)}\big) + B\big(u^{(0)}\big)p^{(0)}\big\| \leq \eta_0\big\|\mathcal{F}\big(u^{(0)}\big)\big\|, \quad \eta_0 \in [0, \eta_{max}], \tag{3.9}$$

Theorem 3.5 guarantees that a point $u^{(1)} = u^{(0)} + \lambda_0 p^{(0)} \equiv u^{(0)} + s^{(0)}$ can be generated with $\lambda_0 \in (0, 1]$ and $\|\mathcal{F}(u^{(1)})\| < \|\mathcal{F}(u^{(0)})\|$. Furthermore, it follows from (3.9) that

$$\begin{aligned}\big\|\mathcal{F}\big(u^{(0)}\big) + B\big(u^{(0)}\big)s^{(0)}\big\| &= \big\|\mathcal{F}\big(u^{(0)}\big) + B\big(u^{(0)}\big)\big(\lambda_0 p^{(0)}\big)\big\| \\ &= \big\|\lambda_0\big[B\big(u^{(0)}\big)p^{(0)} + \mathcal{F}\big(u^{(0)}\big)\big] + (1 - \lambda_0)\mathcal{F}\big(u^{(0)}\big)\big\| \\ &\leq [\lambda_0\eta_0 + (1 - \lambda_0)]\big\|\mathcal{F}\big(u^{(0)}\big)\big\| \\ &\leq \big\|\mathcal{F}\big(u^{(0)}\big)\big\|.\end{aligned}$$

Thus, Lemma 3.6 shows that $u^{(1)} \in N(u^*, \frac{\delta}{2})$.

(ii) Assume that the ASPIN method has generated $\{u^{(1)}, u^{(2)}, \ldots, u^{(k)}\} \subset N(u^*, \frac{\delta}{2})$ such that

$$\|\mathcal{F}(u^{(1)})\| > \|\mathcal{F}(u^{(2)})\| > \cdots > \|\mathcal{F}(u^{(k)})\|,$$

and also a direction $p^{(k)} \in R^n$ has been computed such that

$$\|\mathcal{F}\big(u^{(k)}\big) + B\big(u^{(k)}\big)p^{(k)}\| \le \eta_k \|\mathcal{F}\big(u^{(k)}\big)\|, \quad \eta_k \in [0, \eta_{max}]. \tag{3.10}$$

Then in the same way as above, it is easy to prove that a point $u^{(k+1)} \in N(u^*, \frac{\delta}{2})$ can be produced, and

$$\|\mathcal{F}\big(u^{(k)}\big)\| > \|\mathcal{F}\big(u^{(k+1)}\big)\|.$$

Thus, by induction, the ASPIN method can generate a sequence $\{u^{(k)}\} \subset N(u^*, \frac{\delta}{2})$.

Next we show that $f\big(u^{(k)}\big) \to 0$. By (3.10),

$$\begin{aligned} \mathcal{F}\big(u^{(k)}\big)^T B\big(u^{(k)}\big)p^{(k)} &= \mathcal{F}\big(u^{(k)}\big)^T [B\big(u^{(k)}\big)p^{(k)} + \mathcal{F}\big(u^{(k)}\big) - \mathcal{F}\big(u^{(k)}\big)] \\ &\le -2(1-\eta_{max}) f\big(u^{(k)}\big), \end{aligned} \tag{3.11}$$

and it follows that

$$\begin{aligned} f(u^{(k)} + \lambda_k p^{(k)}) &\le f\big(u^{(k)}\big) + \alpha\lambda_k \mathcal{F}\big(u^{(k)}\big)^T B\big(u^{(k)}\big)p^{(k)} \\ &\le [1 - 2\alpha\lambda_k(1-\eta_{max})] f\big(u^{(k)}\big). \end{aligned}$$

Therefore, by Theorem 3.5, we have

$$\begin{aligned} f(u^{(k)} + \lambda_k p^{(k)}) &\le \left[1 - 2\alpha(1-\eta_{max}) \frac{\alpha\theta_{min} |\mathcal{F}\big(u^{(k)}\big)^T B\big(u^{(k)}\big)p^{(k)}|}{\gamma \|p^{(k)}\|^2}\right] f\big(u^{(k)}\big) \\ &\equiv (1 - ct_k) f\big(u^{(k)}\big), \end{aligned} \tag{3.12}$$

where we set

$$c = \frac{2\alpha^2\theta_{min}(1-\eta_{max})}{\gamma}$$

and

$$t_k = \frac{|\mathcal{F}\big(u^{(k)}\big)^T B\big(u^{(k)}\big)p^{(k)}|}{\|p^{(k)}\|^2}.$$

Because $\{f\big(u^{(k)}\big)\}$ is nonnegative and strictly decreased, $\lim_{k\to\infty} f\big(u^{(k)}\big)$ exists. If $\lim_{k\to\infty} f\big(u^{(k)}\big) > 0$, then (3.12) shows that

$$\lim_{k\to\infty} \frac{f\big(u^{(k+1)}\big)}{f\big(u^{(k)}\big)} \le \lim_{k\to\infty} (1 - ct_k) \le 1,$$

so

$$\lim_{k\to\infty} (1 - ct_k) = 1$$

or, equivalently,

$$\lim_{k\to\infty} t_k = 0.$$

Since (3.11) shows that

$$\frac{2(1-\eta_{max})f\big(u^{(k)}\big)}{\|p^{(k)}\|^2} \le \frac{|\mathcal{F}\big(u^{(k)}\big)^T B\big(u^{(k)}\big)p^{(k)}|}{\|p^{(k)}\|^2} = t_k,$$

we have

$$\lim_{k\to\infty} \frac{f\big(u^{(k)}\big)}{\|p^{(k)}\|^2} = 0.$$

Because $\lim_{k\to\infty} f\big(u^{(k)}\big) > 0$, it follows that

$$\|p^{(k)}\| \to \infty \ (k \to \infty). \tag{3.13}$$

But on the other hand, by (I_2) and (3.10), we have

$$\begin{aligned}\|p^{(k)}\| &= \|B\big(u^{(k)}\big)^{-1}[B\big(u^{(k)}\big)p^{(k)} + \mathcal{F}\big(u^{(k)}\big) - \mathcal{F}\big(u^{(k)}\big)]\|\\ &\le \|B\big(u^{(k)}\big)^{-1}\| \cdot [\|B\big(u^{(k)}\big)p^{(k)} + \mathcal{F}\big(u^{(k)}\big)\| + \|\mathcal{F}\big(u^{(k)}\big)\|]\\ &\le 2M(1+\eta_k)\|\mathcal{F}\big(u^{(k)}\big)\|\\ &\le 2M(1+\eta_{max})\|\mathcal{F}(u^{(0)})\|\\ &\le \frac{\delta(1+\eta_{max})}{4},\end{aligned}$$

which contradicts (3.13). Thus, we must have $f(u^{(k)}) \to 0$. Since $\{u^{(k)}\} \subset N(u^*, \delta)$, by ($\mathrm{I}_6$),

$$\begin{aligned}\|u^{(k)} - u^*\| &= 2\|u^{(k)} - u^*\| - \|u^{(k)} - u^*\|\\ &\le 2\|\mathcal{J}(u^*)^{-1}\|\|\mathcal{J}(u^*)(u^{(k)}-u^*)\| - 2M\|\mathcal{F}\big(u^{(k)}\big) - \mathcal{F}(u^*) - \mathcal{J}(u^*)(u^{(k)}-u^*)\|\\ &\le 2M[\|\mathcal{J}(u^*)(u^{(k)} - u^*)\| - \|\mathcal{F}\big(u^{(k)}\big) - \mathcal{F}(u^*) - \mathcal{J}(u^*)(u^{(k)} - u^*)\|]\\ &\le 2M\|\mathcal{F}\big(u^{(k)}\big)\|.\end{aligned}$$

Because $\|\mathcal{F}(u^{(k)})\| = \sqrt{2f(u^{(k)})} \to 0$, we have $u^{(k)} \to u^*$. □

Now, we complete the discussion for local convergence of the ASPIN method.

4. Convergence rate of the ASPIN method. In this section, we discuss the convergence rate of the ASPIN method. We will show that the ASPIN method is quadratically convergent under suitable conditions.

The following theorem shows that under suitable assumptions, $\lambda_k = 1$ is acceptable for all k sufficiently large.

THEOREM 4.1. *Assume that $f(u)$ is twice continuously differentiable in $N(u^*, \delta)$, and there exists $\gamma > 0$ such that for any $v, w \in N(u^*, \delta)$,*

$$\begin{aligned}\|\nabla f(v) - \nabla f(w)\| &\le \gamma\|v - w\|,\\ \|\nabla^2 f(v) - \nabla^2 f(w)\| &\le \gamma\|v - w\|.\end{aligned}$$

Let $\{u^{(k)}\}$ be the sequence generated by the ASPIN method such that $u^{(k)} \to u^*$. If $\eta_k \to 0$, then $u^{(k+1)} = u^{(k)} + p^{(k)}$ for all sufficiently large k.

Proof. Because $u^{(k)} \to u^*$, without loss of generality, we may assume that $\{u^{(k)}\} \subset N(u^*, \frac{\delta}{2})$. Thus, it follows from Proposition 3.1 that

$$\|\mathcal{F}\big(u^{(k)}\big) + \mathcal{J}\big(u^{(k)}\big)p^{(k)}\| \le \frac{1+\eta_{max}}{2}\|\mathcal{F}\big(u^{(k)}\big)\|. \tag{4.1}$$

Therefore, by (I_4) and (4.1),

$$\begin{aligned} \|p^{(k)}\| &= \|\mathcal{J}\big(u^{(k)}\big)^{-1}[\mathcal{J}\big(u^{(k)}\big)p^{(k)} + \mathcal{F}\big(u^{(k)}\big) - \mathcal{F}\big(u^{(k)}\big)]\| \\ &\le \|\mathcal{J}\big(u^{(k)}\big)^{-1}\| \cdot [\|\mathcal{J}\big(u^{(k)}\big)p^{(k)} + \mathcal{F}\big(u^{(k)}\big)\| + \|\mathcal{F}\big(u^{(k)}\big)\|] \\ &\le 2M\left(\frac{1+\eta_{max}}{2} + 1\right)\|\mathcal{F}\big(u^{(k)}\big)\| \\ &= M(3+\eta_{max})\|\mathcal{F}\big(u^{(k)}\big)\|. \end{aligned} \tag{4.2}$$

Because $\|\mathcal{F}(u^{(k)})\| \to 0$, the above inequality shows that

$$\|p^{(k)}\| \to 0 \ (k \to \infty).$$

By (I_4), we have

$$\|\nabla f\big(u^{(k)}\big)\| = \|\mathcal{J}\big(u^{(k)}\big)^T\mathcal{F}\big(u^{(k)}\big)\| \ge \|\mathcal{J}\big(u^{(k)}\big)^{-1}\|^{-1}\|\mathcal{F}\big(u^{(k)}\big)\| \ge \frac{1}{2M}\|\mathcal{F}\big(u^{(k)}\big)\|;$$

thus, Lemma 3.2 in connection with (I_3), (I_4), and (4.1) shows that

$$\begin{aligned} \frac{|\nabla f\big(u^{(k)}\big)^T p^{(k)}|}{\|p^{(k)}\|} &\ge \frac{1-\frac{1+\eta_{max}}{2}}{1+\frac{1+\eta_{max}}{2}} \cdot \frac{1}{\kappa(\mathcal{J}\big(u^{(k)}\big))} \cdot \|\nabla f\big(u^{(k)}\big)\| \\ &\ge \frac{1-\eta_{max}}{3+\eta_{max}} \cdot \frac{1}{4M^2} \cdot \frac{1}{2M}\|\mathcal{F}\big(u^{(k)}\big)\| \\ &= \frac{1-\eta_{max}}{8M^3(3+\eta_{max})}\|\mathcal{F}\big(u^{(k)}\big)\|, \end{aligned}$$

or we have

$$\begin{aligned} \|\mathcal{F}\big(u^{(k)}\big)\|\|p^{(k)}\| &\le \frac{8M^3(3+\eta_{max})}{1-\eta_{max}} \cdot |\nabla f\big(u^{(k)}\big)^T p^{(k)}| \\ &\equiv a|\nabla f\big(u^{(k)}\big)^T p^{(k)}|, \end{aligned} \tag{4.3}$$

where

$$a = \frac{8M^3(3+\eta_{max})}{1-\eta_{max}}.$$

From (4.2) and (4.3), we obtain

$$\begin{aligned} \|p^{(k)}\|^2 &\le M(3+\eta_{max})\|\mathcal{F}\big(u^{(k)}\big)\|\|p^{(k)}\| \\ &\le \frac{8M^4(3+\eta_{max})^2}{1-\eta_{max}} \cdot |\nabla f\big(u^{(k)}\big)^T p^{(k)}| \\ &\equiv b|\nabla f\big(u^{(k)}\big)^T p^{(k)}|, \end{aligned}$$

where

$$b = \frac{8M^4(3+\eta_{max})^2}{1-\eta_{max}}.$$

Next we show that $\lambda_k = 1$ is acceptable for all k sufficiently large. First note that if $\mathcal{F} = (\mathcal{F}_1, \mathcal{F}_2, \ldots, \mathcal{F}_n)^T$, then

$$\begin{aligned}\nabla^2 f(u) &= \mathcal{J}(u)^T \mathcal{J}(u) + \sum_{i=1}^{n} \mathcal{F}_i(u) \nabla^2 \mathcal{F}_i(u) \\ &\equiv \mathcal{J}(u)^T \mathcal{J}(u) + S(u).\end{aligned}$$

Since $u^{(k)} \to u^*$ and $\mathcal{F}(u^*) = 0$, it follows that $\|S(u^{(k)})\| \to 0$.

For each k, by the mean value theorem, there exists a $\xi^{(k)}$ on the line segment between $u^{(k)}$ and $u^{(k)} + p^{(k)}$ such that

$$f\big(u^{(k)} + p^{(k)}\big) - f\big(u^{(k)}\big) - \frac{1}{2}\nabla f\big(u^{(k)}\big)^T p^{(k)} = \frac{1}{2}\big(\nabla f\big(u^{(k)}\big) + \nabla^2 f\big(\xi^{(k)}\big)p^{(k)}\big)^T p^{(k)}.$$

This gives

$$\begin{aligned}&\left| f\big(u^{(k)} + p^{(k)}\big) - f\big(u^{(k)}\big) - \frac{1}{2}\nabla f\big(u^{(k)}\big)^T p^{(k)} \right| \\ &= \left| \frac{1}{2}\big(\nabla f\big(u^{(k)}\big) + \nabla^2 f(\xi^{(k)})p^{(k)}\big)^T p^{(k)} \right| \\ &= \frac{1}{2}\left| \big(\nabla f\big(u^{(k)}\big) + \nabla^2 f\big(u^{(k)}\big)p^{(k)}\big)^T p^{(k)} + (p^{(k)})^T\big(\nabla^2 f(\xi^{(k)}) - \nabla^2 f\big(u^{(k)}\big)\big)p^{(k)} \right| \\ &\le \frac{1}{2}\big[\big\|\mathcal{J}\big(u^{(k)}\big)^T\big(\mathcal{F}\big(u^{(k)}\big) + \mathcal{J}\big(u^{(k)}\big)p^{(k)}\big)\big\| \cdot \|p^{(k)}\| + \big(\big\|S\big(u^{(k)}\big)\big\| + \gamma\|p^{(k)}\|\big)\|p^{(k)}\|^2\big] \\ &\le \frac{1}{2}\big[\eta_k\big\|\mathcal{J}\big(u^{(k)}\big)\big\| \cdot \big\|\mathcal{F}\big(u^{(k)}\big)\big\| \cdot \|p^{(k)}\| + \big(\big\|S\big(u^{(k)}\big)\big\| + \gamma\|p^{(k)}\|\big)\|p^{(k)}\|^2\big] \\ &\le -\frac{1}{2}\big[2aM\eta_k + b\big(\big\|S\big(u^{(k)}\big)\big\| + \gamma\|p^{(k)}\|\big)\big]\nabla f\big(u^{(k)}\big)^T p^{(k)} \\ &\equiv -\frac{1}{2}\epsilon_k \nabla f\big(u^{(k)}\big)^T p^{(k)};\end{aligned}$$

therefore,

$$f(u^{(k)} + p^{(k)}) - f\big(u^{(k)}\big) \le \frac{1}{2}(1 - \epsilon_k)\nabla f\big(u^{(k)}\big)^T p^{(k)}. \tag{4.4}$$

Since η_k, $\|S(u^{(k)})\|$, and $\|p^{(k)}\|$ all converge to zero, it follows that $\epsilon_k \to 0$. Thus, for all k sufficiently large, we have

$$\epsilon_k < \frac{1}{2},$$

and consequently, for all k sufficiently large, it follows from (4.4) and Lemma 3.3 that

$$f(u^{(k)} + p^{(k)}) - f\big(u^{(k)}\big) \le \frac{1}{4}\nabla f\big(u^{(k)}\big)^T p^{(k)} \le \alpha \mathcal{F}\big(u^{(k)}\big)^T B\big(u^{(k)}\big)p^{(k)}.$$

Thus, λ_k is acceptable for all k sufficiently large. In other word, $u^{(k+1)} = u^{(k)} + p^{(k)}$ for all k sufficiently large. □

Theorem 4.1 shows that if the ASPIN iterative sequence converges to the solution u^* of system (1.1), then step 3 in Algorithm 2.1 will not be implemented for all k sufficiently large.

The following lemma shows that both $\mathcal{J}(u)$ and $B(u)$ are Lipschitz continuous near u^*.

LEMMA 4.2. *Assume that $F(u)$ is twice continuously differentiable. Then there exists a neighborhood $V \subset N(u^*, \frac{\delta}{2})$ of u^* such that both $\mathcal{J}(u)$ and $B(u)$ are Lipschitz continuous in V.*

Proof. Since $F''(w)$, $T_i'(u)$, $[E_i J(u) E_i^T]^{-1}$, and $E_i J(u)$ are continuous in $N(u^*, \frac{\delta}{2}) \subset U$, we define the constants

$$L_1 := \sup_{u \in N(u^*, \frac{\delta}{2})} \|F''(u)\|, \quad L_2 := \max_i \sup_{u \in N(u^*, \frac{\delta}{2})} \|T_i'(u)\|$$

and

$$L_3 := \max_i \sup_{u \in N(u^*, \frac{\delta}{2})} \|[E_i J(u) E_i^T]^{-1}\|, \quad L_4 := \max_i \sup_{u \in N(u^*, \frac{\delta}{2})} \|E_i J(u)\|.$$

Thus, for any $u, v \in N(u^*, \frac{\delta}{2})$, Lemma 3.3.5 in [20] shows that

$$\|J(u) - J(v)\| \leq \max_{t \in [0,1]} \|F''(u + t(v-u))\| \|u - v\| \leq L_1 \|u - v\|, \tag{4.5}$$

and Lemma 3.2.3 in [20] shows that

$$\|T_i(u) - T_i(v)\| \leq \max_{t \in [0,1]} \|T_i'(u + t(v-u))\| \|u - v\| \leq L_2 \|u - v\|. \tag{4.6}$$

Since, for each i, $u - T_i(u) \to u^*$ when $u \to u^*$, there exists a neighborhood $V \subset N(u^*, \frac{\delta}{2})$ of u^*, which is independent of i, such that $u - T_i(u) \in N(u^*, \frac{\delta}{2})$ whenever $u \in V$. Therefore, for any $u, v \in V$, it follows from (4.5) and (4.6) that

$$\begin{aligned} \|J(u - T_i(u)) - J(v - T_i(v))\| &\leq L_1 \|(u - v) - [T_i(u) - T_i(v)]\| \\ &\leq L_1 (1 + L_2) \|u - v\|. \end{aligned} \tag{4.7}$$

At the same time, for any $u \in V$ and for each i, by the definition of L_3, we have

$$\|[E_i J(u) E_i^T]^{-1}\| \leq L_3 \tag{4.8}$$

and

$$\|[E_i J(u - T_i(u)) E_i^T]^{-1}\| \leq L_3. \tag{4.9}$$

Now set

$$G(u) = E_i J(u - T_i(u)) E_i^T, \quad H(u) = E_i J(u - T_i(u)).$$

Then for any $u, v \in V$, by (4.7), (4.9), and the definition of L_4, we have

$$\begin{aligned} \|T_i'(u) - T_i'(v)\| &= \|E_i^T G(u)^{-1} H(u) - E_i^T G(v)^{-1} H(v)\| \\ &= \|E_i^T G(u)^{-1} H(u) - E_i^T G(u)^{-1} H(v) \\ &\quad + E_i^T G(u)^{-1} H(v) - E_i^T G(v)^{-1} H(v)\| \\ &\leq \|E_i^T G(u)^{-1} H(u) - E_i^T G(u)^{-1} H(v)\| \\ &\quad + \|E_i^T G(u)^{-1} H(v) - E_i^T G(v)^{-1} H(v)\| \\ &\leq \|G(u)^{-1}\| \|H(u) - H(v)\| + \|G(u)^{-1}\| \|G(u) - G(u)\| \|G(v)^{-1}\| \|H(v)\| \\ &\leq L_3 L_1 (1 + L_2) \|u - v\| + L_3^2 L_1 (1 + L_2) L_4 \|u - v\| \\ &= L_1 L_3 (1 + L_1)(1 + L_3 L_4) \|u - v\|. \end{aligned}$$

Thus,

$$\begin{aligned}\|\mathcal{J}(u)-\mathcal{J}(v)\| &= \left\| \sum_{i=1}^{N} T_i'(u) - \sum_{i=1}^{N} T_i'(v) \right\| \leq \sum_{i=1}^{N} \|T_i'(u)-T_i'(v)\| \\ &\leq NL_1L_3(1+L_1)(1+L_3L_4)\|u-v\| \\ &\equiv L_{\mathcal{J}}\|u-v\|\end{aligned}$$

for $u, v \in V$. That is, $\mathcal{J}(u)$ is Lipschitz continuous in V.

In a similar way, by using (4.5), (4.8), and the definition of L_4, one can prove that

$$\|R_i(u)-R_i(v)\| \leq L_1L_3(1+L_3L_4)\|u-v\|$$

for any $u, v \in V$, and each i. Thus,

$$\begin{aligned}\|B(u)-B(v)\| &= \left\| \sum_{i=1}^{N} R_i(u) - \sum_{i=1}^{N} R_i'(v) \right\| \leq \sum_{i=1}^{N} \|R_i(u)-R_i(v)\| \\ &\leq NL_1L_3(1+L_3L_4)\|u-v\| \\ &\equiv L_B\|u-v\|\end{aligned}$$

for all $u, v \in V$. Therefore, $B(u)$ is Lipschitz continuous in V. □

LEMMA 4.3. *For any $u \in N(u^*, \delta)$, it holds that*

$$\frac{1}{2M}\|u-u^*\| \leq \|\mathcal{F}(u)\| \leq \left(M + \frac{1}{2M}\right)\|u-u^*\|.$$

Proof. The first part of the inequality has been proved in the proof of Lemma 3.6, and the second part is easy. □

Based on the above preparations, we now have the following result.

THEOREM 4.4. *Assume that both $F(u)$ and $f(u)$ are twice continuously differentiable in $N(u^*, \delta)$, and there exists $\gamma > 0$ such that*

$$\begin{aligned}\|\nabla f(v) - \nabla f(w)\| &\leq \gamma\|v-w\|, \\ \|\nabla^2 f(v) - \nabla^2 f(w)\| &\leq \gamma\|v-w\|\end{aligned}$$

for any $v, w \in N(u^*, \delta)$. If $\{u^{(k)}\}$ is a sequence generated by the ASPIN method such that $u^{(k)} \to u^*$ and $u^{(k+1)} = u^{(k)} + p^{(k)}$ for all sufficiently large k, then

(i) *$u^{(k)} \to u^*$ superlinearly if and only if*

$$\|r_k\| = o(\|\mathcal{F}(u^{(k)})\|),$$

where

$$r_k = \mathcal{F}(u^{(k)}) + B(u^{(k)})p^{(k)};$$

(ii) *$u^{(k)} \to u^*$ quadratically if and only if*

$$\|r_k\| = \mathcal{O}(\|\mathcal{F}(u^{(k)})\|^2).$$

Proof. Since $u^{(k+1)} = u^{(k)} + p^{(k)}$ for all sufficiently large k, without loss of generality, we assume that $u^{(k+1)} = u^{(k)} + p^{(k)}$ for all k in the following argument.

Assume that $u^{(k)} \to u^*$ superlinearly. Since

$$\begin{aligned} r_k &= \mathcal{F}\big(u^{(k)}\big) + B\big(u^{(k)}\big)p^{(k)} \\ &= \big[\mathcal{F}\big(u^{(k)}\big) - \mathcal{F}(u^*) - \mathcal{J}(u^*)\big(u^{(k)} - u^*\big)\big] \\ &\quad - \big[B\big(u^{(k)}\big) - \mathcal{J}(u^*)\big]\big(u^{(k)} - u^*\big) + B\big(u^{(k)}\big)\big(u^{(k+1)} - u^*\big), \end{aligned} \tag{4.10}$$

by Lemma 3.2.10 in [20], continuity of $B(u)$ at u^* and the assumption that $u^{(k)} \to u^*$ superlinearly, we have

$$\|r_k\| \leq o(\|u^{(k)} - u^*\|) + o(1)\|u^{(k)} - u^*\| + o(\|u^{(k)} - u^*\|).$$

Therefore, by Lemma 4.3, it follows that

$$\|r_k\| = o(\|u^{(k)} - u^*\|) = o(\|\mathcal{F}\big(u^{(k)}\big)\|).$$

Conversely, assume that $\|r_k\| = o(\|\mathcal{F}\big(u^{(k)}\big)\|)$. Since

$$\begin{aligned} u^{(k+1)} - u^* &= (u^{(k)} - u^*) + p^{(k)} \\ &= (u^{(k)} - u^*) + B\big(u^{(k)}\big)^{-1}[r_k - \mathcal{F}\big(u^{(k)}\big)] \\ &= B\big(u^{(k)}\big)^{-1}\big\{\big[B\big(u^{(k)}\big) - \mathcal{J}(u^*)\big](u^{(k)} - u^*) \\ &\qquad + r_k - \big[\mathcal{F}\big(u^{(k)}\big) - \mathcal{F}(u^*) - \mathcal{J}(u^*)(u^{(k)} - u^*)\big]\big\}, \end{aligned} \tag{4.11}$$

thus, by (I$_2$), the continuity of $B(u)$ at u^*, the assumption that $\|r_k\| = o(\|\mathcal{F}\big(u^{(k)}\big)\|)$, and Lemma 3.2.10 in [20], we have

$$\|u^{(k+1)} - u^*\| \leq 2M[o(1)\|u^{(k)} - u^*\| + o(\|\mathcal{F}\big(u^{(k)}\big)\|) + o(\|u^{(k)} - u^*\|)].$$

Therefore, by Lemma 4.3,

$$\|u^{(k+1)} - u^*\| = o(\|u^{(k)} - u^*\|) + o(\|\mathcal{F}\big(u^{(k)}\big)\|) = o(\|u^{(k)} - u^*\|).$$

Since F is twice continuously differentiable in $N(u^*, \delta)$, Lemma 4.2 shows that both $\mathcal{J}(u)$ and $B(u)$ are Lipschitz continuous in a neighborhood $V \subset N(u^*, \frac{\delta}{2})$ of u^*. Thus, there exists $L > 0$ such that for any $u \in V$,

$$\|\mathcal{J}(u) - \mathcal{J}(u^*)\| \leq L\|u - u^*\| \tag{4.12}$$

and

$$\|B(u) - B(u^*)\| \leq L\|u - u^*\|. \tag{4.13}$$

By (4.12) and Lemma 3.2.12 in [20],

$$\|\mathcal{F}(u) - \mathcal{F}(u^*) - \mathcal{J}(u^*)(u - u^*)\| \leq \frac{L}{2}\|u - u^*\|^2 \quad \forall\, u \in V. \tag{4.14}$$

In a similar way, it follows from (4.10), (4.11), (4.13), (4.14), and Lemma 4.3 that $u^{(k)} \to u^*$ quadratically if and only if

$$\|r_k\| = \mathcal{O}(\|\mathcal{F}\big(u^{(k)}\big)\|^2).$$

This concludes the proof. □

From Theorems 4.1 and 4.4, we can obtain the following result.

COROLLARY 4.5. *Assume that both $F(u)$ and $f(u)$ are twice continuously differentiable in $N(u^*, \delta)$, and there exists $\gamma > 0$ such that for any $v, w \in N(u^*, \delta)$,*

$$\|\nabla f(v) - \nabla f(w)\| \leq \gamma \|v - w\|,$$
$$\|\nabla^2 f(v) - \nabla^2 f(w)\| \leq \gamma \|v - w\|.$$

Let $\{u^{(k)}\}$ be a sequence generated by the ASPIN method such that $u^{(k)} \to u^*$. Then

(i) *$u^{(k)} \to u^*$ superlinearly if $\eta_k \to 0$;*

(ii) *$u^{(k)} \to u^*$ quadratically if $\eta_k = \mathcal{O}(\|\mathcal{F}(u^{(k)})\|)$.*

Corollary 4.5 reflects how the forcing term influences the convergence rate of the ASPIN method. This result is similar to Corollary 3.5 in [8] for the inexact Newton method. In particular, by Corollary 4.5, we can determine the convergence rate of the ASPIN method by choosing proper forcing terms.

5. Conclusion.

The inexact Newton method is one of the effective tools for solving large sparse systems of nonlinear equations. By using nonlinear additive Schwarz preconditioning technique, Cai and Keyes [6] introduced the ASPIN method. This method is very effective for solving some nonlinear problems with strong nonbalanced nonlinearities. However, the convergence of the ASPIN method is not discussed by them or others.

In this paper, we discussed the convergence property of the ASPIN method and thus we provided a theoretical support for the ASPIN method. The convergence result is local since the design of the ASPIN only concerns the local properties of the original function. Furthermore, we discussed the convergence rate for the ASPIN method, and the result shows that the convergence rate of the ASPIN method is similar to that of the inexact Newton method. Thus, we can obtain the desired convergence rate by choosing proper forcing terms.

Appendix.

We give a simple example to show that our main assumptions, inequalities (I_1)–(I_6) in section 3, are not so strict. Consider the nonlinear equations

$$\begin{cases} 2u_1 - u_2 + \lambda e^{u_1} - \lambda = 0, \\ -u_1 + 2u_2 + \lambda e^{u_2} - \lambda = 0, \end{cases}$$

where $\lambda > 0$. It is obvious that $u^* = (0,0)^T$ is a solution of the system. Let

$$S = \{1, 2\}, \quad S_1 = \{1\}, \quad S_2 = \{2\}$$

and

$$T_1(u) = \begin{pmatrix} T_{11}(u) \\ 0 \end{pmatrix}, \quad T_2(u) = \begin{pmatrix} 0 \\ T_{22}(u) \end{pmatrix},$$

where T_{11}, $T_{22} : R^2 \to R$. By $F_{S_i}(u - T_i(u)) = 0$, we have

$$2(u_i - T_{ii}(u)) - u_{3-i} + \lambda e^{u_i - T_{ii}(u)} - \lambda = 0, \quad i = 1, 2. \tag{A.1}$$

It is easy to see that $T_{ii}(u)$ are continuous functions. Furthermore, we can obtain

$$T_1'(u) = \begin{pmatrix} 1 & -\left(2 + \lambda e^{u_1 - T_{11}(u)}\right)^{-1} \\ 0 & 0 \end{pmatrix}, \quad T_2'(u) = \begin{pmatrix} 0 & 0 \\ -\left(2 + \lambda e^{u_2 - T_{22}(u)}\right)^{-1} & 1 \end{pmatrix}.$$

Thus,

$$\mathcal{J}(u) = \begin{pmatrix} 1 & -\left(2+\lambda e^{u_1 - T_{11}(u)}\right)^{-1} \\ -\left(2+\lambda e^{u_2 - T_{22}(u)}\right)^{-1} & 1 \end{pmatrix}.$$

Besides, it is easy to see that

$$B(u) = \begin{pmatrix} 1 & -\left(2+\lambda e^{u_1}\right)^{-1} \\ -\left(2+\lambda e^{u_2}\right)^{-1} & 1 \end{pmatrix}.$$

Since

$$B(u^*) = \mathcal{J}(u^*) = \begin{pmatrix} 1 & -(2+\lambda)^{-1} \\ -(2+\lambda)^{-1} & 1 \end{pmatrix},$$

so

$$M = \max\{\|\mathcal{J}(u^*)\|, \|\mathcal{J}(u^*)^{-1}\|\} = \frac{2+\lambda}{1+\lambda}.$$

Now we will choose some proper δ such that inequalities (I_1)–(I_6) hold. Let $\delta \in (0, \frac{1}{2})$ and assume that $u = (u_1, u_2)^T \in N(u^*, \delta)$. Note that if

$$A = \begin{pmatrix} 1 & a \\ b & 1 \end{pmatrix},$$

then $\|A\| \le 1 + \max\{|a|, |b|\}$. Therefore,

$$\|B(u)\| \le 1 + \max_{1\le i\le 2} (2+\lambda e^{u_i})^{-1} < 1 + (2+\lambda e^{-\delta})^{-1} < 2M.$$

In addition, since

$$B(u)^{-1} = \frac{1}{1-(2+\lambda e^{u_1})^{-1}(2+\lambda e^{u_2})^{-1}} \begin{pmatrix} 1 & (2+\lambda e^{u_1})^{-1} \\ (2+\lambda e^{u_2})^{-1} & 1 \end{pmatrix},$$

one can easily verify that

$$\|B(u)^{-1}\| \le \frac{2+\lambda e^{-\delta}}{1+\lambda e^{-\delta}} < 2M.$$

Because $u \in N(u^*, \delta)$, by (A.1), we have

$$|u_i - T_{ii}(u)| < \frac{1}{2}|u_{3-i}| < \frac{1}{2}\delta, \quad i = 1, 2. \tag{A.2}$$

Thus, one may obtain

$$\|\mathcal{J}(u)\| \le 2M, \quad \|\mathcal{J}(u)^{-1}\| \le 2M.$$

By using (A.2) and the inequality $e^x < 1 + 2x$ $(0 < x < 1)$, we have

$$\begin{aligned} \|\mathcal{J}(u) - B(u)\| &\le \max_{1\le i\le 2} |(2+\lambda e^{u_i})^{-1} - (2+\lambda e^{u_i - T_{ii}(u)})^{-1}| \\ &\le \max_{1\le i\le 2} \frac{\lambda e^{\delta}(e^{|T_{ii}(u)|}-1)}{(2+\lambda e^{-\delta})^2} \\ &\le \frac{3\delta\lambda e^{\delta}}{4+4\lambda e^{-\delta}} \\ &\le \frac{3e\lambda\delta}{4+4\lambda}. \end{aligned}$$

This shows that inequality (I_5) holds when

$$\delta \leq \frac{(1+\lambda)(1-\eta_{max})}{3e\lambda M(1+\eta_{max})} = \frac{(1+\lambda)^2(1-\eta_{max})}{3e\lambda(2+\lambda)(1+\eta_{max})}.$$

By using (A.1), (A.2), and the fact that

$$e^x > 1+x, \quad x \in (0,1), \quad \text{and} \quad e^x < 1 + \frac{1}{2}x, \quad x \in (-1,0),$$

we have

$$|u_i - T_{ii}(u)| \leq \frac{2}{4+\lambda}|u_{3-i}|, \quad i = 1,2.$$

Therefore,

$$\begin{aligned}\|\mathcal{F}(u) - \mathcal{F}(u^*) - \mathcal{J}(u^*)(u-u^*)\| &= \left\| \begin{pmatrix} T_{11}(u) - u_1 + (2+\lambda)^{-1}u_2 \\ T_{22}(u) - u_2 + (2+\lambda)^{-1}u_1 \end{pmatrix} \right\| \\ &\leq \left\| \begin{pmatrix} |T_{11}(u) - u_1| + (2+\lambda)^{-1}|u_2| \\ |T_{22}(u) - u_2| + (2+\lambda)^{-1}|u_1| \end{pmatrix} \right\| \\ &\leq \frac{3}{2+\lambda}\|u\| < 2M\|u-u^*\|.\end{aligned}$$

Thus, inequality (I_6) holds.

Summing up the above discussion, we know that if

$$\delta \leq \min\left\{ \frac{1}{2}, \frac{(1+\lambda)^2(1-\eta_{max})}{3e\lambda(2+\lambda)(1+\eta_{max})} \right\},$$

then for any $u \in N(u^*, \delta)$, inequalities (I_1)–(I_6) hold.

For this example, other assumptions in the paper can also be checked to be true.

Acknowledgments. The author thanks the anonymous referees and Carol S. Woodward for many valuable suggestions.

CONVERGENCE OF THE MIMETIC FINITE DIFFERENCE METHOD FOR DIFFUSION PROBLEMS ON POLYHEDRAL MESHES[*]

FRANCO BREZZI[†], KONSTANTIN LIPNIKOV[‡], AND MIKHAIL SHASHKOV[‡]

Abstract. The stability and convergence properties of the mimetic finite difference method for diffusion-type problems on polyhedral meshes are analyzed. The optimal convergence rates for the scalar and vector variables in the mixed formulation of the problem are proved.

Key words. compatible discretizations, mimetic finite difference method, convergence, polyhedral meshes

1. Introduction.

The main goal of this paper is to establish convergence of *mimetic discretizations* of the first-order system that describes linear stationary diffusion on unstructured polyhedral meshes. The main idea of the mimetic finite difference (MFD) method is to mimic the underlying properties of the original continuum differential operators, e.g., conservation laws, solution symmetries, and the fundamental identities and theorems of vector and tensor calculus. For the linear diffusion problem, this means that the mimetic discretizations mimic the Gauss divergence theorem needed for the local mass conservation, the symmetry between the continuous gradient and divergence operators needed for proving symmetry and positivity of the resulting discrete operator, and the null spaces of the involved operators needed for stability of the discretizations.

The MFD method has been successfully employed for solving problems of continuum mechanics [19], electromagnetics [14], gas dynamics [8], and linear diffusion on simplicial and quadrilateral meshes in both the Cartesian and polar coordinates [15, 13, 20, 17]. Recent advances in extending the mimetic discretizations to general polygonal meshes [16] have inspired us to develop the rigorous convergence theory for unstructured polygonal and polyhedral meshes.

The polyhedral elements appear naturally in reservoir models simulating thinning or tapering out ("pinching out") of geological layers. The pinchouts are modeled with mixed types of mesh elements, pentahedrons, prisms, and tetrahedrons which

are frequently obtained by collapsing some of the elements in a structured hexahedral or prismatic mesh.

Other sources of polyhedral meshes are the adaptive mesh refinement methods. A necessity to have a conformal mesh results in an abundant mesh refinement, e.g., in the methods using the red-green refinement strategy. However, the locally refined mesh may be considered as the conformal polyhedral mesh with degenerate elements (for instance, when the angle between two faces is 180°). If we know how to discretize a problem on a general polyhedral mesh, the superfluous mesh refinements can be avoided. A similar argument can be applied to nonmatching meshes which frequently may be treated as conformal polyhedral meshes with degenerate elements. This is the way followed, for instance, in [16] for two-dimensional (2D) meshes.

Allowing arbitrary shape for a mesh element provides greater flexibility in the mesh generation process, especially in the regions where the geometry is extremely complex. Even in the case of an unstructured hexahedral mesh, it may be beneficial to split the curvilinear faces into triangles in order to use more accurate discretization methods and to get a smaller number of unknowns relative to a tetrahedral partition. It is obvious that by splitting each face of a hexahedron into four triangles we get a 24-face polyhedron which is frequently nonconvex.

Some of the simulations in the fluid dynamics indicate that the polyhedral meshes may lead to superior convergence rates and accuracy relative to tetrahedral meshes. We refer readers to the CD-adapco group website (www.cd-adapco.com/news/18/newsdev.htm) for more detail. The polyhedral meshes are also used in a number of radiation–hydrodynamics applications [21, 22, 7]. For instance, one of the approaches to increase robustness of arbitrary Lagrangian–Eulerian simulations is to change the mesh connectivity which leads obviously to general polyhedral meshes.

The diffusion-type (elliptic) problems appear in many applications, for instance, the temperature equation in heat diffusion or the pressure equation in flow problems. The necessity to solve such problems arises in numerical methods for radiation transport coupled with hydrodynamics, mesh smoothing algorithms, etc. In this paper, we consider a diffusion problem formulated as a system of two first-order equations, which is suitable for deriving locally conservative discretizations.

The mimetic discretizations have demonstrated excellent robustness and accuracy in simulations; however, a rigorous convergence proof has always been lacking. The original approach to prove the convergence of these discretizations has been based on establishing the relationship between the MFD and mixed finite element methods [2, 3] which is certainly not enough for many interesting applications. In this paper, we developed a novel technique for proving convergence estimates which may be applied to the case of meshes consisting of arbitrary types of elements, e.g., tetrahedrons, pyramids, hexahedrons, degenerate polyhedrons, etc. The restrictions on a polyhedron shape imposed in section 2 still allow extremely complex elements which cover the majority of meshes used in applications. Note that the developed methodology can be applied to 2D diffusion problems on unstructured polygonal meshes with minor modifications.

The paper is organized as follows. In section 2, we describe the problem under consideration and the class of polyhedral meshes used in the convergence analysis. In section 3, we formulate the MFD method. In section 4, we prove the stability result. In section 5, we prove the convergence of mimetic discretizations. One of the key elements used in our technique, the lift property, is discussed in detail in the appendix.

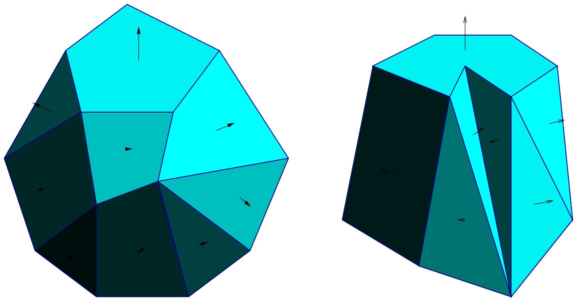

FIG. 2.1. *Two possible elements and the normal to their faces.*

2. The assumptions on the problem and on the mesh. Let us consider a model elliptic boundary value problem

$$\operatorname{div} \mathbf{F} = b, \tag{2.1}$$

$$\mathbf{F} = -\mathbf{K} \operatorname{grad} p. \tag{2.2}$$

Here p denotes a scalar function that we refer to as the pressure, $\mathbf{F}$ denotes a vector function that we refer to as the velocity, $\mathbf{K}$ denotes a full symmetric tensor, and b denotes a source function. The problem is posed in a bounded polyhedral domain $\Omega \subset \mathbb{R}^3$, and is subject to appropriate boundary conditions on $\partial\Omega$. For simplicity, we assume that the homogeneous Dirichlet boundary conditions are imposed on $\partial\Omega$. We also assume that $\mathbf{K}$ satisfies the following regularity and ellipticity property.

P1 (*regularity and ellipticity of* $\mathbf{K}$). Every component of $\mathbf{K}$ is in $W^1_\infty(\Omega)$ and $\mathbf{K}$ is strongly elliptic, meaning that there exist two positive constants κ_* and κ^* such that

$$\kappa_* \|\mathbf{v}\|^2 \leq \mathbf{v}^T \mathbf{K}(\mathbf{x})\, \mathbf{v} \leq \kappa^* \|\mathbf{v}\|^2 \quad \forall \mathbf{v} \in \mathbb{R}^3 \quad \forall \mathbf{x} \in \Omega. \tag{2.3}$$

Let $\mathcal{T}_h$ be a nonoverlapping conformal partition of Ω into polyhedral elements E. For every element E, we denote by $|E|$ its volume and by h_E its diameter. Similarly, for each face e we denote by $|e|$ its area and for every edge ℓ we denote by $|\ell|$ its length. Depending on context, we shall use ∂E either for the boundary of E or the union of element faces. We also set as usual

$$h = \sup_E h_E.$$

The elements E are assumed to be closed simply connected polyhedrons, rather general in shape (see, for instance, Figure 2.1). However, we need some basic assumptions of shape regularity. As we shall see, the assumptions are formally complicated sometimes, but they will hold for practically all partitions which are not totally unreasonable.

M1 (*assumptions on the domain* Ω). We assume that Ω is a polyhedron with a Lipschitz continuous boundary.

M2 (*number of faces and edges*). We assume that we have two positive integers N_e and N_ℓ such that every element E has at most N_e faces, and each face e has at most N_ℓ edges.

M3 (*volumes, areas, and lengths*). We assume that there exist three positive constants v_*, a_*, and l_* (for volume, area, and length, respectively) such that for

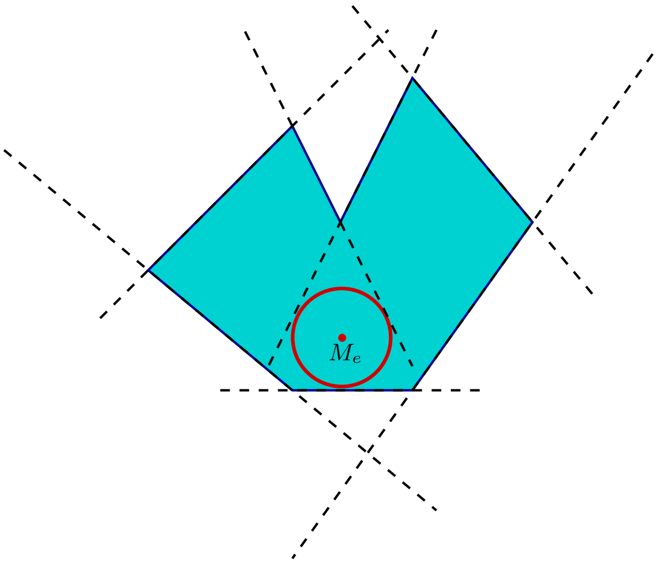

FIG. 2.2. *A star-shaped face with the circle of radius ρ_* centered at M_e.*

every element E we have

$$v_* \, h_E^3 \leq |E|, \quad a_* \, h_E^2 \leq |e|, \quad l_* \, h_E \leq |\ell| \tag{2.4}$$

for all faces e and edges ℓ of E.

M4 (*star-shaped faces*). We assume that the mesh faces are flat and that there exists a positive number γ_* such that for each element E and for each face $e \in \partial E$ there exists a point $M_e \in e$ such that e is star-shaped with respect to every point in the disk of radius $\gamma_* h_E$ centered at M_e.

We recall that e is star shaped with respect to a point $P \in e$ if every straight ray exiting from P (in the plane of e) intersects ∂e only once. In what follows we shall often use the notation

$$\rho_* = \gamma_* h_E, \tag{2.5}$$

which is illustrated in Figure 2.2.

M5 (*the pyramid property*). With the notation of Assumption M4, we further assume that for every $E \in \mathcal{T}_h$, and for every $e \in \partial E$, there exists a pyramid P_E^e *contained in* E such that its base equals e, its height equals $\gamma_* h_E$, and the projection of its vertex onto e is M_e.

M6 (*star-shaped elements*). We assume that there exists a positive number τ_* such that for each element E there exists a point $M_E \in E$ such that E is star shaped with respect to every point in the sphere of radius $\tau_* h_E$ centered at M_E.

As before, we say that E is star shaped with respect to a point $P \in E$ if every straight ray exiting from P intersects ∂E only once.

3. MFD method. Let us introduce an operator $\mathcal{G}$, $\mathcal{G}\, p = -\mathbf{K} \mathrm{grad}\, p$, which we refer to as the flux operator. Furthermore, we introduce the following scalar products:

$$(\mathbf{F}, \, \mathbf{G})_X = \int_\Omega \mathbf{F} \cdot \mathbf{K}^{-1} \mathbf{G} \, \mathrm{d}V \tag{3.1}$$

and

$$(p,\, q)_Q = \int_\Omega pq \,\mathrm{d}V \tag{3.2}$$

in the space X of velocities and in the space Q of pressures, respectively. Using the above notation, we may rewrite the Green's formula

$$\int_\Omega \mathbf{F} \cdot (\mathbf{K}^{-1} \mathcal{G}\, p) \,\mathrm{d}V = \int_\Omega p \,\mathrm{div}\, \mathbf{F} \,\mathrm{d}V \tag{3.3}$$

in the equivalent form

$$(\mathbf{F},\, \mathcal{G}\, p)_X = (p,\, \mathrm{div}\, \mathbf{F})_Q.$$

The last expression clearly states that the flux and divergence operators are adjoint to each other:

$$\mathcal{G} = \mathrm{div}^*.$$

The MFD method produces discretizations of these operators which are adjoint to each other with respect to scalar products in the discrete velocity and pressure spaces.

The *first* step of the MFD method is to specify the degrees of freedom for physical variables p and $\mathbf{F}$ and their location.

We consider the space Q^d of discrete pressures that are constant on each polyhedron E. For $\mathbf{q} \in Q^d$ we shall denote by q_E (or by $(\mathbf{q})_E$) its (constant) value on E. The dimension, N_Q, of Q^d is obviously equal to the number of polyhedrons in $\mathcal{T}_h$. In what follows, we shall denote by Q^d either the vector space $\mathbb{R}^{N_Q}$ or the space of piecewise constant functions depending on context. The identification will be obvious and no confusion should arise.

The definition of the space of discrete velocities requires some additional considerations. To every element E in $\mathcal{T}_h$ and to every face e of E we associate a number F_E^e and the vector field $F_E^e\, \mathbf{n}_E^e$, where $\mathbf{n}_E^e$ is the unit normal to e that points outside of E. We clearly make the *continuity* assumption that for each face e shared by two polyhedra E_1 and E_2, we have

$$F_{E_1}^e = -F_{E_2}^e. \tag{3.4}$$

We denote the vector space of face-based velocity unknowns by X^d. The number, N_X, of our discrete velocity unknowns is equal to the number of boundary faces plus *twice* the number of internal faces. In our theoretical discussion, we shall consider X^d as the subspace of $\mathbb{R}^{N_X}$ which verifies (3.4).

For a discrete velocity field $\mathbf{G}$ we will denote by $\mathbf{G}_E$ its restriction to the boundary of E, and by G_E^e (or by $(\mathbf{G}_E)^e$) the restriction of $\mathbf{G}_E \cdot \mathbf{n}_E$ to a face e belonging to the boundary of E. It will be convenient sometimes to use the notation

$$X_E^d := \{\text{restrictions of } X^d \text{ to the element } E\}. \tag{3.5}$$

It is clear that, in practice, condition (3.4) will make the number of *true independent unknowns* equal the total number of mesh faces. This means that, in a computer program, we shall prescribe one direction for the normal to each internal face e, and assign a single unknown G^e to each face, assuming that each of the two G_E^e coincides either with G^e (when the outward normal $\mathbf{n}_E$ on e coincides with the prescribed direction) or with $-G^e$ (otherwise).

To summarize, one pressure unknown is defined on each polyhedron and the discrete velocities are defined as face-based normal components. Once we get the degrees of freedom in Q^d and in X^d, we can define interpolation operators from the spaces of smooth enough scalar- and vector-valued functions to the discrete spaces Q^d and X^d, respectively. To every function q in $L^1(\Omega)$ we associate the element $\mathbf{q}^I \in Q^d$ defined by

$$(\mathbf{q}^I)_E := \frac{1}{|E|}\int_E q \,\mathrm{d}V \quad \forall E \in \mathcal{T}_h. \tag{3.6}$$

Similarly, for every vector-valued function $\mathbf{G} \in (L^s(\Omega))^3$, $s > 2$, with $\operatorname{div}\mathbf{G} \in L^2(\Omega)$, we define $\mathbf{G}^I \in X^d$ by

$$\left(\mathbf{G}^I_E\right)^e := \frac{1}{|e|}\int_e \mathbf{G}\cdot\mathbf{n}_E \,\mathrm{d}S \quad \forall\, E \in \mathcal{T}_h \quad \forall\, e \in \partial E. \tag{3.7}$$

In the next section, we shall prove that this interpolation operator is well defined and uniformly bounded. In what follows, we shall use bold capital letters either for vectors from X^d or for continuous vector functions depending on context and leaving no room for confusion.

The *second* step of the MFD method is to equip the spaces of discrete pressures and velocities with scalar products. The scalar product on the vector space Q^d is given by

$$[\mathbf{p},\, \mathbf{q}]_{Q^d} = \sum_{E\in\mathcal{T}_h} p_E\, q_E |E| \quad \forall\, \mathbf{p},\, \mathbf{q} \in Q^d. \tag{3.8}$$

In order to define the scalar product in X^d, we first define a scalar product $[\mathbf{F},\, \mathbf{G}]_E$ for every element $E \in \mathcal{T}_h$ in the following way. Let $e_1, e_2, \dots, e_{k_E}$ be a numbering of the faces of the element E (where k_E is clearly the total number of faces). We assume that we are given (for each E) a symmetric positive definite $k_E \times k_E$ matrix $M_E \equiv \{M_{E,i,j}\}$, and we set

$$[\mathbf{F},\, \mathbf{G}]_E = \sum_{i,j=1}^{k_E} M_{E,i,j}\, (\mathbf{F}_E)^{e_i}\, (\mathbf{G}_E)^{e_j} \quad \forall\, \mathbf{F},\, \mathbf{G} \in X^d \quad \forall E \in \mathcal{T}_h. \tag{3.9}$$

Some minimal approximation properties for the scalar product (3.9) are required. The construction of the matrix M_E is a nontrivial task for a polyhedral element. We shall return to this problem in section 5. For the time being, we just *assume* that the scalar product (3.9) has the following property.

S1 (*stability of* $[\cdot,\, \cdot]_E$). We assume that there exist two positive constants s_* and S^* independent of h and E such that, for every $\mathbf{G} \in X^d$ and for every $E \in \mathcal{T}_h$, one has

$$s_* \sum_{e\in\partial E} (G^e_E)^2\, |E| \le\, [\mathbf{G},\, \mathbf{G}]_E\, \le S^* \sum_{e\in\partial E} (G^e_E)^2\, |E|. \tag{3.10}$$

From (3.9) we can easily construct the scalar product in X^d by setting

$$[\mathbf{F},\, \mathbf{G}]_{X^d} = \sum_{E\in\mathcal{T}_h} [\mathbf{F},\, \mathbf{G}]_E \quad \forall\, \mathbf{F},\, \mathbf{G} \in X^d. \tag{3.11}$$

The *third* step of the MFD method is to derive an approximation to the divergence operator. The discrete divergence operator, $\mathcal{DIV}^d : X^d \to Q^d$, naturally arises from the Gauss divergence theorem as

$$(\mathcal{DIV}^d\, \mathbf{F})_E \overset{def}{=} \frac{1}{|E|} \sum_{e\in\partial E} F_E^e\, |e|. \tag{3.12}$$

We point out that our interpolation operators, in some sense, *commute* with the divergence operator. Indeed, for every vector field $\mathbf{G}$ smooth enough, we can use (3.12), (3.7), the Gauss divergence theorem, and (3.6) to obtain

$$(\mathcal{DIV}^d\, \mathbf{G}^I)_E = \frac{1}{|E|} \sum_{e\in\partial E} \left(\mathbf{G}_E^I\right)^e |e| = \frac{1}{|E|}\int_{\partial E} \mathbf{G}\cdot\mathbf{n}_E \,\mathrm{d}S = \frac{1}{|E|}\int_E \operatorname{div}\mathbf{G}\,\mathrm{d}V = (\operatorname{div}\mathbf{G})_E^I \tag{3.13}$$

for every element E in $\mathcal{T}_h$.

The *fourth* step of the MFD method is to define the discrete flux operator, $\mathcal{G}^d : Q^d \to X^d$, as the adjoint to the discrete divergence operator, $\mathcal{DIV}^d$, with respect to scalar products (3.8) and (3.11), i.e.,

$$[\mathbf{F},\, \mathcal{G}^d\, \mathbf{p}]_{X^d} = [\mathbf{p},\, \mathcal{DIV}^d\, \mathbf{F}]_{Q^d} \quad \forall \mathbf{p}\in Q^d \quad \forall \mathbf{F}\in X^d. \tag{3.14}$$

Using the discrete flux and divergence operators, the continuous problem (2.1), (2.2) is discretized as follows:

$$\mathcal{DIV}^d\;\; \mathbf{F}_d = \mathbf{b}, \tag{3.15}$$

$$\mathbf{F}_d = \mathcal{G}^d\, \mathbf{p}_d, \tag{3.16}$$

where $\mathbf{b} \equiv \mathbf{b}^I$ is the vector of mean values of the source function b.

4. Stability analysis. In this section we analyze the stability of the MFD discretization (3.15)–(3.16) following the well-established theory of saddle-point problems [5]. More precisely, we prove the coercivity condition (4.4) and the inf-sup condition (4.5).

Using the discrete Green's formula (3.14), we rewrite (3.15) and (3.16) in a form more suitable for analysis:

$$[\mathbf{F}_d,\, \mathbf{G}]_{X^d} - [\mathbf{p}_d,\, \mathcal{DIV}^d\, \mathbf{G}]_{Q^d} = 0 \quad \forall\, \mathbf{G}\in X^d, \tag{4.1}$$

$$[\mathcal{DIV}^d\, \mathbf{F}_d,\, \mathbf{q}]_{Q^d} = [\mathbf{b},\, \mathbf{q}]_{Q^d} \qquad \forall\, \mathbf{q}\in Q^d. \tag{4.2}$$

Let us introduce the following mesh norms on discrete spaces X^d and Q^d:

$$|||\mathbf{p}|||_{Q^d}^2 := [\mathbf{p},\, \mathbf{p}]_{Q^d}, \quad |||\mathbf{F}|||_{X^d}^2 := [\mathbf{F},\, \mathbf{F}]_{X^d},$$

and

$$|||\mathbf{F}|||_{div}^2 := |||\mathbf{F}|||_{X^d}^2 + \sum_{E\in\mathcal{T}_h} h_E^2\, \|\mathcal{DIV}^d\, \mathbf{F}\|_{L^2(E)}^2. \tag{4.3}$$

Let V^d be the space of divergence-free discrete fluxes:

$$V^d = \{\mathbf{F}\in X^d : \quad \mathcal{DIV}^d\, \mathbf{F} = 0\}.$$

We begin the stability analysis by noticing that the scalar product (3.11) is continuous. It is also obvious that the scalar product satisfies the V^d-ellipticity condition:

$$[\mathbf{F},\, \mathbf{F}]_{X^d} \geq |||\mathbf{F}|||_{div}^2 \quad \forall\, \mathbf{F} \in V^d. \tag{4.4}$$

The analysis of the inf-sup condition is more involved. Following [5], for every $\mathbf{q} \in Q^d$, we have to find a vector $\mathbf{G} \in X^d$ such that

$$[\mathcal{DIV}^d\, \mathbf{G},\, \mathbf{q}]_{Q^d} \geq \beta_* |||\mathbf{G}|||_{div}\ |||\mathbf{q}|||_{Q^d}, \tag{4.5}$$

where β_* is a positive constant independent of $\mathbf{q}$, $\mathbf{G}$, and $\mathcal{T}_h$. Let us denote by $q^h \in L^2(\Omega)$ the piecewise constant function on $\mathcal{T}_h$ with values given by the entries of the vector $\mathbf{q}$ (so that $(q^h)^I \equiv \mathbf{q}$). It is obvious that $\|q^h\|_{L^2(\Omega)} = |||\mathbf{q}|||_{Q^d}$. Let us consider the homogeneous Dirichlet boundary value problem

$$\Delta\psi = q^h \quad \text{in} \quad \Omega.$$

Since Ω has a Lipschitz-continuous boundary, there exist an $s > 2$ and a constant C^*_Ω such that

$$\|\psi\|_{W^1_s(\Omega)} \leq\, C^*_\Omega\, \|q^h\|_{L^2(\Omega)}. \tag{4.6}$$

Let $\mathbf{H} = \nabla\psi$, so that we have immediately

$$\operatorname{div} \mathbf{H} = q^h, \tag{4.7}$$

and from (4.6)

$$\|\mathbf{H}\|_{(L^s(\Omega))^3} + \left(\sum_{E \in \mathcal{T}_h} h_E^2\, \|\operatorname{div} \mathbf{H}\|^2_{L^2(E)} \right)^{1/2} \leq\, (C^*_\Omega + h)\|q^h\|_{L^2(\Omega)}. \tag{4.8}$$

We now set

$$\mathbf{G} := \mathbf{H}^I\ \equiv\ (\nabla\psi)^I, \tag{4.9}$$

where the interpolation operator is still the one defined in (3.7). Thanks to the commutative property (3.13) and to (4.7), we have

$$\mathcal{DIV}^d\ \mathbf{G} = (q^h)^I \equiv \mathbf{q}. \tag{4.10}$$

Thus, inequality (4.5) is reduced to

$$|||\mathbf{q}|||_{Q^d} \geq \beta_* |||\mathbf{G}|||_{div}. \tag{4.11}$$

At this point we need the following technical lemma.

Lemma 4.1. *Under Assumptions* M1–M6 *and* S1*, for every $s > 2$, there exists a positive constant β^*_s such that*

$$|||\mathbf{G}^I|||_{div} \leq \beta^*_s \left\{ \|\mathbf{G}\|_{(L^s(\Omega))^3} + \left(\sum_{E \in \mathcal{T}_h} h_E^2\, \|\operatorname{div} \mathbf{G}\|^2_{L^2(E)} \right)^{1/2} \right\} \tag{4.12}$$

for every $\mathbf{G} \in (L^s(\Omega))^3$ with $\operatorname{div} \mathbf{G} \in L^2(\Omega)$, and where $\mathbf{G}^I$ is defined in (3.7)*.*

Collecting (4.9) and (4.12), we get

$$|||\mathbf{G}|||_{div} = |||\mathbf{H}^I|||_{div} \leq \beta_s^* \left\{ \|\mathbf{H}\|_{(L^s(\Omega))^3} + \left(\sum_{E \in \mathcal{T}_h} h_E^2 \, \|\mathrm{div}\, \mathbf{H}\|^2_{L^2(E)} \right)^{1/2} \right\}.$$

This, together with (4.8), implies (4.11), and hence (4.5), with $\beta_* = \left(\beta_s^* \, (C_\Omega^* + h)\right)^{-1}$. Therefore, we have just to prove Lemma 4.1.

Proof of Lemma 4.1. From (3.13) we immediately have

$$|||\mathcal{DIV}^d \, \mathbf{G}^I|||_{Q^d} = |||(\mathrm{div}\, \mathbf{G})^I|||_{Q^d} \leq \|\mathrm{div}\, \mathbf{G}\|_{L^2(\Omega)}. \tag{4.13}$$

Therefore, in view of (4.3), it is sufficient to prove that there exists a constant $\widetilde{\beta_s^*}$ such that

$$|||\mathbf{G}^I|||_{X^d} \leq \widetilde{\beta_s^*} \left\{ \|\mathbf{G}\|_{(L^s(\Omega))^3} + \left(\sum_{E \in \mathcal{T}_h} h_E^2 \|\mathrm{div}\, \mathbf{G}\|^2_{L^2(E)} \right)^{1/2} \right\}. \tag{4.14}$$

The desired result (4.12) follows from (4.14) with $\beta_s^* = \widetilde{\beta_s^*} + 1$. In the following discussion, we shall make a wide use of the conjugate exponent t, depending on s through the usual formula

$$\frac{1}{s} + \frac{1}{t} = 1. \tag{4.15}$$

Assumption (3.10) implies clearly that

$$[\mathbf{G}^I, \, \mathbf{G}^I]_{X^d} \leq S^* \sum_{E \in \mathcal{T}_h} |E| \sum_{e \in \partial E} \left(G_E^e \right)^2, \tag{4.16}$$

so that we have to estimate the (G_E^e)'s in terms of $\mathbf{G}$, or, rather, in terms of the norm of $\mathbf{G}$ appearing in (4.12). Our basic instrument for that is called the *lift property*. The main difficulty, in various cases, will be to prove that the lift property holds true.

LP (lift property). For every $t < 2$ there exists a constant $\lambda^* = \lambda^*(t)$ such that for every $E \in \mathcal{T}_h$ and for every $e \in \partial E$ there exists a function φ_E^e from E to $\mathbb{R}$ that verifies

$$\varphi_E^e = 1 \quad \text{on} \quad e, \quad \varphi_E^e = 0 \quad \text{on} \quad \partial E \setminus e \tag{4.17}$$

and

$$\left\|\varphi_E^e\right\|_{L^2(E)} \leq \lambda^* h_E^{3/2}, \quad \left\|\nabla \varphi_E^e\right\|_{(L^t(E))^3} \leq \lambda^* h_E^{3/t-1}. \tag{4.18}$$

The lift property LP is proved in the appendix.

Up to an approximation of $\mathbf{G}$ by smooth functions, and passage to the limit, we have, using (3.7), (4.17), the Green's formula,

$$\begin{aligned} G_E^e = \frac{1}{|e|} \int_e \mathbf{G} \cdot \mathbf{n}_E \, \mathrm{d}S &= \frac{1}{|e|} \int_{\partial E} \varphi_E^e \mathbf{G} \cdot \mathbf{n}_E \, \mathrm{d}S \\ &= \frac{1}{|e|} \int_E \mathbf{G} \cdot \nabla \varphi_E^e \, \mathrm{d}V + \frac{1}{|e|} \int_E \varphi_E^e \, \mathrm{div}\, \mathbf{G} \, \mathrm{d}V. \end{aligned} \tag{4.19}$$

Using the Hölder inequality and (4.18) in (4.19), we then have

$$\begin{aligned}|e|\,G_E^e &\le \|\mathbf{G}\|_{L^s(E)}\left\|\nabla\varphi_E^e\right\|_{L^t(E)} + \|\mathrm{div}\,\mathbf{G}\|_{L^2(E)}\left\|\varphi_E^e\right\|_{L^2(E)}\\ &\le \lambda^*\left\{(h_E)^{3/t-1}\|\mathbf{G}\|_{L^s(E)} + (h_E)^{3/2}\,\|\mathrm{div}\,\mathbf{G}\|_{L^2(E)}\right\}.\end{aligned}$$

Taking the squares and remembering that $(a+b)^2 \le 2(a^2+b^2)$, we have

$$|e|^2\left(G_E^e\right)^2 \le 2\,(\lambda^*)^2\left\{(h_E)^{6/t-2}\|\mathbf{G}\|^2_{L^s(E)} + (h_E)^3\,\|\mathrm{div}\,\mathbf{G}\|^2_{L^2(E)}\right\}. \tag{4.20}$$

On the other hand, using conditions (2.4), we easily obtain

$$|E| \le h_E^3 = h_E^{-1}\left(h_E^2\right)^2 \le h_E^{-1}\,(a^*)^{-2}|e|^2. \tag{4.21}$$

We can now join (4.21) with (4.20) to deduce that

$$\begin{aligned}|E|\left(G_E^e\right)^2 &\le h_E^{-1}\,(a^*)^{-2}|e|^2\left(G_E^e\right)^2\\ &\le \sigma^*\left\{(h_E)^{6/t-3}\|\mathbf{G}\|^2_{L^s(E)} + (h_E)^2\,\|\mathrm{div}\,\mathbf{G}\|^2_{L^2(E)}\right\},\end{aligned} \tag{4.22}$$

where $\sigma^* = 2\,(\lambda^*)^2\,(a^*)^{-2}$. Now we can sum (4.22) over all faces e of E and then over all elements E of $\mathcal{T}_h$. We use (4.16) and Assumption M2 on the number of faces per element to get

$$\begin{aligned}|||\mathbf{G}^I|||^2_{X^d} &\le N_e\,S^*\,\sigma^*\left\{\sum_{E\in\mathcal{T}_h}(h_E)^{6/t-3}\|\mathbf{G}\|^2_{L^s(E)} + \sum_{E\in\mathcal{T}_h} h_E^2\,\|\mathrm{div}\,\mathbf{G}\|^2_{L^2(E)}\right\}\\ &\le N_e\,S^*\,\sigma^*\left\{\left(\sum_{E\in\mathcal{T}_h}\left\{(h_E)^{6/t-3}\right\}^r\right)^{1/r}\left(\sum_{E\in\mathcal{T}_h}\|\mathbf{G}\|^s_{L^s(E)}\right)^{2/s}\right.\\ &\qquad\left. + \sum_{E\in\mathcal{T}_h} h_E^2\|\mathrm{div}\,\mathbf{G}\|^2_{L^2(E)}\right\},\end{aligned} \tag{4.23}$$

where in the last step we applied the Hölder inequality with r, the conjugate exponent of $s/2$,

$$\frac{1}{r} + \frac{2}{s} = 1. \tag{4.24}$$

A simple algebraic manipulation using (4.15) and (4.24) gives

$$\sum_{E\in\mathcal{T}_h}\left\{(h_E)^{6/t-3}\right\}^r = \sum_{E\in\mathcal{T}_h} h_E^3 \le v_*^{-1}|\Omega|, \tag{4.25}$$

where we have also used (2.4) in the last step. Inserting (4.25) into (4.23), we finally get

$$|||\mathbf{G}^I|||_{X^d} \le \widetilde{\beta_s^*}\left\{\|\mathbf{G}\|_{(L^s(\Omega))^3} + \left(\sum_{E\in\mathcal{T}_h} h_E^2\|\mathrm{div}\,\mathbf{G}\|^2_{L^2(E)}\right)^{1/2}\right\}, \tag{4.26}$$

where $\widetilde{\beta_s^*}$ depends only on $\lambda^*(t)$, S^*, v_*, a_*, and N_e. This proves the assertion of the lemma. □

5. Convergence analysis.

5.1. Consistency assumption. In order to prove error estimates, we need some assumptions on the scalar product (3.11), and more precisely on the relationships between the continuous scalar product (3.1) and its discrete counterpart (3.11). Our basic assumption will be the following one.

S2 (*consistency of* $[\cdot,\cdot]_E$). For every element E, every linear function q^1 on E, and every $\mathbf{G} \in X^d$, we have

$$[(\tilde{\mathbf{K}}\,\nabla q^1)^I,\, \mathbf{G}]_E = \int_{\partial E} q^1\, \mathbf{G}_E \cdot \mathbf{n}_E \,\mathrm{d}S - \int_E q^1\,(\mathcal{DIV}^d\,\mathbf{G})_E \,\mathrm{d}V, \tag{5.1}$$

where $(\cdot)^I$ is the interpolation operator (3.7) and $\tilde{\mathbf{K}}$ is a constant tensor on E such that

$$\sup_{x\in E}\sup_{i,j} |\{\mathbf{K}(\mathbf{x})\}_{i,j} - \{\tilde{\mathbf{K}}\}_{i,j}| \le C_K^*\, h_E, \tag{5.2}$$

where C_K^* is a constant independent of E.

Note that $\tilde{\mathbf{K}}$ may be any reasonable piecewise constant approximation of $\mathbf{K}$. In practice, we use either the value of $\mathbf{K}$ at the polyhedron mass center or its mean value.

Condition (5.1) is rather new and requires some comments. First, we point out that for divergence-free vectors, $\mathbf{G} \in V^d$, it reads

$$[(\tilde{\mathbf{K}}\,\nabla q^1)^I,\, \mathbf{G}]_E = \int_{\partial E} q^1\, \mathbf{G}_E \cdot \mathbf{n}_E \,\mathrm{d}S \tag{5.3}$$

showing the remarkable property of using only *boundary integrals*. However, as $\mathcal{DIV}^d\,\mathbf{G}$ is constant in each E and q^1 is supposed to be linear, the volume integral appearing in (5.1) is not difficult to compute. Taking $\mathbf{G} = (\tilde{\mathbf{K}}\,\nabla\tilde{q}^1)^I$ (with $\tilde{q}^1$ another polynomial of degree ≤ 1) in (5.3), we conclude that Assumption S2 implies that *the scalar product* (3.11) *gives an exact value for the integral of two constant velocities.*

In the context of the local MFD method [13], and taking for simplicity $\tilde{\mathbf{K}} = \mathbf{I}$, condition (5.1) means that the discrete gradient operator is exact for linear functions, i.e., $\mathcal{G}^d\,(\mathbf{q}^1)^I$ is a constant vector whose entries are equal to ∇q^1. This property has been used in [18] to build a one-parameter family of symmetric positive definite matrices M_E for a triangle. As a particular case, this family includes the mass matrix appearing in the finite element discretizations with the Raviart–Thomas finite elements.

What is still remarkable in (5.1) is that *it does not require the construction of a lifting operator* from the values G_E^e on ∂E to the interior of E. It is not difficult to show, however, that *if* we have any reasonable lifting operator R_E, then the choice

$$[\mathbf{F},\, \mathbf{G}]_E := \int_E \tilde{\mathbf{K}}^{-1} R_E(\mathbf{F}_E) \cdot R_E(\mathbf{G}_E)\,\mathrm{d}V$$

will automatically satisfy (5.1) as well as (3.10). We have indeed the following theorem.

THEOREM 5.1. *Assume that for every element $E \in \mathcal{T}_h$ we have a lifting operator R_E acting on X_E^d (the restriction of X^d to E) and with values in $(L^2(E))^3$ such that*

$$\begin{aligned} R_E(\mathbf{G}_E)\cdot\mathbf{n}_E &\equiv \mathbf{G}_E\cdot\mathbf{n}_E \quad && \textit{on} \quad \partial E,\\ \operatorname{div} R_E(\mathbf{G}_E) &\equiv (\mathcal{DIV}^d\,\mathbf{G})_E \quad && \textit{in} \quad E \end{aligned} \tag{5.4}$$

for all $\mathbf{G} \in X^d$, *and*

$$R_E\big(\mathbf{G}_E^I\big) = \mathbf{G} \tag{5.5}$$

for all $\mathbf{G}$ *constant on* E. *Then the choices*

$$\{\tilde{\mathbf{K}}\}_{i,j} := \frac{1}{|E|}\int_E \{\mathbf{K}\}_{i,j}\,\mathrm{d}V \tag{5.6}$$

and

$$[\mathbf{F},\,\mathbf{G}]_E := \int_E \tilde{\mathbf{K}}^{-1} R_E(\mathbf{F}_E)\cdot R_E(\mathbf{G}_E)\,\mathrm{d}V \tag{5.7}$$

will automatically satisfy (5.2) *and* (5.1). *If, moreover, there exist two positive constants* c_R^* *and* C_R^*, *independent of* E *such that*

$$c_R^*\left(|E|\sum_{e\in\partial E}\big(G_E^e\big)^2\right)^{1/2} \le \|R_E(\mathbf{G})\|_{(L^2(E))^3} \le C_R^*\left(|E|\sum_{e\in\partial E}\big(G_E^e\big)^2\right)^{1/2} \tag{5.8}$$

for all $\mathbf{G} \in X^d$, *then* (3.10) *will also hold with constants* s_* *and* S^* *depending only on* c_R^*, C_R^*, *and on the constants* κ_*, κ^* *from* (2.3).

Proof. The validity of (5.2) is immediate. The validity of (5.1) is also easily checked:

$$\begin{aligned}
[(\tilde{\mathbf{K}}\,\nabla q^1)^I,\,\mathbf{G}]_E &= \int_E \tilde{\mathbf{K}}^{-1} R_E((\tilde{\mathbf{K}}\,\nabla q^1)^I_E)\cdot R_E(\mathbf{G}_E)\,\mathrm{d}V \quad \text{(use (5.5) and } \nabla q^1 = \text{const)}\\
&= \int_E \tilde{\mathbf{K}}^{-1}\tilde{\mathbf{K}}\,\nabla q^1\cdot R_E(\mathbf{G}_E)\,\mathrm{d}V \qquad \text{(use } \tilde{\mathbf{K}}^{-1}\tilde{\mathbf{K}} = Id\text{)}\\
&= \int_E \nabla q^1\cdot R_E(\mathbf{G}_E)\,\mathrm{d}V \qquad \text{(integrate by parts)}\\
&= \int_{\partial E} q^1\, R_E(\mathbf{G}_E)\cdot\mathbf{n}_E\,\mathrm{d}S - \int_E q^1\,\mathrm{div}R_E(\mathbf{G}_E)\,\mathrm{d}V \quad \text{(use (5.4))}\\
&= \int_{\partial E} q^1\,\mathbf{G}_E\cdot\mathbf{n}_E\,\mathrm{d}S - \int_E q^1\,(\mathcal{DIV}^d\,\mathbf{G})_E\,\mathrm{d}V.
\end{aligned}$$

Finally, (3.10) follows immediately from (5.7), (2.3), and (5.8) after noting that (2.3) is equivalent to

$$(\kappa^*)^{-1}\|\mathbf{v}\|^2 \le \mathbf{v}^T\mathbf{K}^{-1}(\mathbf{x})\mathbf{v} \le (\kappa_*)^{-1}\|\mathbf{v}\|^2 \quad \forall\,\mathbf{v}\in\mathbb{R}^3 \quad \forall\,\mathbf{x}\in\Omega. \tag{5.9}$$

This ends the proof of the theorem. □

A possible way of getting (5.1) is, therefore, to construct a lifting operator R_E satisfying (5.4), (5.5), and (5.8), and then define M_E following (5.7). For instance, the way followed in [16] for polygonal domains can be interpreted as the construction of a lifting operator satisfying (5.4) and (5.5).

In general, we may consider assumption (5.1) as a system of linear equations where the unknowns are the coefficients of M_E, and use it, in each element E, to construct the matrix M_E. Since the matrix M_E should be symmetric and positive definite, this is a problem with nonlinear constraints. An analytical solution has been found only for triangular elements [18].

Let us see this in more detail. We consider an element E having k_E faces. Equation (5.1) should then hold for k_E different possible choices of $\mathbf{G}_E$ and three possible choices of q^1 corresponding to $q^1=x$, $q^1=y$, and $q^1=z$. Note that for $q^1=1$, (5.1) is automatically satisfied as it is reduced to our definition of the operator $\mathcal{DIV}^d$. We have, therefore, $3k_E$ equations. It can be shown that only $3k_E-3$ equations are linearly independent. Since $\tilde{\mathbf{K}}$, and hence M_E, is symmetric, the number of unknown coefficients of M_E is $k_E(k_E+1)/2$, that is, bigger than $3k_E-3$ as soon as $k_E\geq 4$. The system will always be compatible, since we could always define a lifting R_E first by solving, for each $\mathbf{G}_E$, the Neumann problem

$$\begin{aligned} \Delta\chi &= \mathcal{DIV}^d\,\mathbf{G}_E && \text{in} \quad E,\\ \partial\chi/\partial\mathbf{n}_E &= \mathbf{G}_E\cdot\mathbf{n}_E && \text{on} \quad \partial E, \end{aligned}$$

then by taking $R_E(\mathbf{G}_E) := \nabla\chi$, and finally by defining M_E through (5.7). This would be totally impractical but shows that at least a solution M_E of (5.1), symmetric and positive definite, exists (although, in general, the solution will not be unique).

A sparsity structure could be imposed on M_E in order to reduce the number of unknowns. For instance, we can require that each face interacts only with a few neighboring faces, reducing the number of unknowns to $3k_E-3$, which equals the number of equations and makes the linear system much easier to solve on the computer (see [6] for more detail).

An advantage of this approach is that it can be rather easily extended to faces that are not flat. This is a case in which the construction of an explicit lifting operator might prove to be very difficult. We shall consider meshes with curved faces in the future publications.

5.2. Error estimate for the vector variable. Using Assumption S2, we are going to prove error estimates for our discretization. Let $(p,\,\mathbf{F})$ be the exact solution of (2.1) and (2.2), let $(\mathbf{p}_d,\mathbf{F}_d)$ be the discrete solution (see (3.15) and (3.16)), and let $\mathbf{p}^I$ and $\mathbf{F}^I$ be the interpolants of the exact solution. Finally, for every element E, we denote by p^1_E a suitable polynomial of degree ≤ 1 that approximates p, and that will be decided later on. We notice first that from (2.1), (3.13), and (3.15), we easily have

$$\mathcal{DIV}^d\,(\mathbf{F}^I-\mathbf{F}_d) = \mathbf{b}-\mathbf{b} = 0. \tag{5.10}$$

Using (2.2) and (3.16), then (3.14), and finally (5.10), we get

$$\begin{aligned} [\mathbf{F}^I-\mathbf{F}_d,\,\mathbf{F}^I-\mathbf{F}_d]_{X^d} &= [(-\mathbf{K}\,\nabla p)^I,\,\mathbf{F}^I-\mathbf{F}_d]_{X^d} - [\mathcal{G}^{\,d}\mathbf{p}_d,\mathbf{F}^I-\mathbf{F}_d]_{X^d}\\ &= [(-\mathbf{K}\,\nabla p)^I,\,\mathbf{F}^I-\mathbf{F}_d]_{X^d} - [\mathbf{p}_d,\,\mathcal{DIV}^d\,(\mathbf{F}^I-\mathbf{F}_d)]_{Q^d}\\ &= [(-\mathbf{K}\,\nabla p)^I,\,\mathbf{F}^I-\mathbf{F}_d]_{X^d}. \end{aligned} \tag{5.11}$$

Then, adding and subtracting the terms, we have

$$\begin{aligned} |||\mathbf{F}^I-\mathbf{F}_d|||^2_{X^d} &= [(-\mathbf{K}\,\nabla p)^I+(\mathbf{K}\,\nabla p^1)^I,\,\mathbf{F}^I-\mathbf{F}_d]_{X^d} + [(-\mathbf{K}\nabla p^1)^I,\,\mathbf{F}^I-\mathbf{F}_d]_{X^d}\\ &= \mathbf{I}_1 + [(-\mathbf{K}\nabla p^1+\tilde{\mathbf{K}}\nabla p^1)^I,\,\mathbf{F}^I-\mathbf{F}_d]_{X^d} + [(-\tilde{\mathbf{K}}\nabla p^1)^I,\mathbf{F}^I-\mathbf{F}_d]_{X^d}\\ &= \mathbf{I}_1+\mathbf{I}_2+[(-\tilde{\mathbf{K}}\nabla p^1)^I,\,\mathbf{F}^I-\mathbf{F}_d]_{X^d}\\ &= \mathbf{I}_1+\mathbf{I}_2+\mathbf{I}_3. \end{aligned} \tag{5.12}$$

Using (5.1) and (5.10), the third term reads

$$\mathbf{I}_3 = \sum_{E\in\mathcal{T}_h} \left\{ \int_{\partial E} p^1_E\,(\mathbf{F}^I - \mathbf{F}_d)_E \cdot \mathbf{n}_E \,\mathrm{d}S - \int_E p^1_E\,(\mathcal{DIV}^d\,(\mathbf{F}^I - \mathbf{F}_d))_E \,\mathrm{d}V \right\}$$

$$= \sum_{E\in\mathcal{T}_h} \int_{\partial E} p^1_E\,(\mathbf{F}^I - \mathbf{F}_d)_E \cdot \mathbf{n}_E \,\mathrm{d}S. \tag{5.13}$$

We are, therefore, left with the problem of estimating $\mathbf{I}_1$, $\mathbf{I}_2$, and $\mathbf{I}_3$. A first estimate of $\mathbf{I}_2$ is trivial. From (5.2) we immediately have

$$\mathbf{I}_2 \equiv [(-\mathbf{K}\nabla p^1 + \tilde{\mathbf{K}}\nabla p^1)^I,\, \mathbf{F}^I - \mathbf{F}_d]_{X^d} \le C^*_K h\, |||(\nabla p^1)^I|||_{X^d}\, |||\mathbf{F}^I - \mathbf{F}_d|||_{X^d}, \tag{5.14}$$

where p^1 still has to be defined.

Let us recall some known properties of the approximation theory. For the sake of simplicity, we assume that our solution p is in $H^2(\Omega)$. Note that with a little additional effort we could use a weaker regularity and get a lower order of convergence.

We first recall that, under Assumption M6 (*star-shaped elements*), it is possible to find a constant C^*_{app}, depending only on τ_*, such that for every element E and for every $p \in H^2(E)$ there exist a constant p^0_E and a polynomial p^1_E of degree ≤ 1 such that

$$\left\|p - p^0_E\right\|_{L^2(E)} \le C^*_{app}\, h_E\, \|p\|_{H^1(E)}, \tag{5.15}$$

$$\left\|p - p^1_E\right\|_{L^2(E)} \le C^*_{app}\, h^2_E\, \|p\|_{H^2(E)}, \quad \left\|p - p^1_E\right\|_{H^1(E)} \le C^*_{app}\, h_E\, \|p\|_{H^2(E)} \tag{5.16}$$

(see [4, Lemma 4.3.8]). Concerning the error on faces, we can use a result due to Agmon made popular in the numerical analysis community by Arnold [1]. Applied to our case, it says that there exists a constant C^*_{agm}, depending only on the constant γ_* of Assumption M4, such that for every pyramid P^e_E (as described in Assumption M5), and for every function $\chi \in H^1(P^e_E)$, we have

$$\|\chi\|^2_{L^2(e)} \le C^*_{agm}\big(h^{-1}_E \|\chi\|^2_{L^2(P^e_E)} + h_E\, \|\chi\|^2_{H^1(P^e_E)}\big). \tag{5.17}$$

It is then immediate to derive from (5.17) that

$$\|\nabla\chi\|^2_{L^2(e)} \le C^*_{agm}\big(h^{-1}_E\, \|\chi\|^2_{H^1(P^e_E)} + h_E\, \|\chi\|^2_{H^2(P^e_E)}\big) \tag{5.18}$$

for every $\chi \in H^2(E)$. Applying this to the difference $p - p^1_E$, and using (5.16), we get

$$\left\|p - p^1_E\right\|^2_{L^2(e)} + h^2_E \left\|\nabla\big(p - p^1_E\big)\right\|^2_{L^2(e)} \le C^*_{face}\, h^3_E\, \|p\|^2_{H^2(E)}, \tag{5.19}$$

where C^*_{face} depends only on τ_* and γ_*.

Now, we can finish the estimate of $\mathbf{I}_2$. Note that ∇p^1 is a constant vector. Then, (5.16) and the triangle inequality give

$$|||\big(\nabla p^1_E\big)^I|||_{X^d} = \left\|\nabla p^1_E\right\|_{L^2(E)} \le \|\nabla p\|_{L^2(E)} + \left\|\nabla(p - p^1_E)\right\|_{L^2(E)} \le \big(1 + h_E C^*_{app}\big)\|p\|_{H^2(E)}.$$

Thus, we obtain immediately from (5.14) that

$$\mathbf{I}_2 \le C^*_{I_2}\, h\, \|p\|_{H^2(\Omega)}\, |||\mathbf{F}^I - \mathbf{F}_d|||_{X^d}, \tag{5.20}$$

where $C^*_{I_2}$ equals $(1 + h_E\, C^*_{app})C^*_K$ with C^*_K given in (5.2).

The estimate of $\mathbf{I}_1$ is obtained in the following lemma.

LEMMA 5.2. *Let $p \in H^2(\Omega)$ and let, in each $E \in \mathcal{T}_h$, p^1 be such that* (5.16) *holds. Let $(\cdot)^I$ be the interpolation operator defined in* (3.7)*, and let finally $\mathbf{G} \in X^d$. Then*

$$[(-\mathbf{K}\,\nabla p)^I + (\mathbf{K}\,\nabla p^1)^I,\, \mathbf{G}]_{X^d} \le C^*_{I_1}\, h\, \|p\|_{H^2(\Omega)}\, |||\mathbf{G}|||_{X^d}, \tag{5.21}$$

where the constant $C^*_{I_1}$ is independent of p, $\mathbf{G}$, and h.

Proof. The proof follows immediately from (3.10), the definition of the interpolation operator (3.7), the Cauchy–Schwarz inequality, and the approximation results quoted above. Indeed, we have

$$\begin{aligned} |||(-\mathbf{K}\,\nabla p)^I + (\mathbf{K}\,\nabla p^1)^I|||^2_{X^d} &\le S^* \sum_{E\in\mathcal{T}_h} \sum_{e\in\partial E} \big(((-\mathbf{K}\,\nabla p)^I + (\mathbf{K}\,\nabla p^1)^I)^e_E\big)^2\, |E| \\ &\le S^* \sum_{E\in\mathcal{T}_h} \sum_{e\in\partial E} \left(\frac{1}{|e|}\int_e \mathbf{K}\,\nabla\big(p - p^1_E\big)\cdot \mathbf{n}_E\, \mathrm{d}S\right)^2 |E| \\ &\le S^* \sum_{E\in\mathcal{T}_h} \sum_{e\in\partial E} \frac{1}{|e|}\, \big\|\mathbf{K}\,\nabla\big(p - p^1_E\big)\big\|^2_{L^2(e)} |E| \\ &\le C^*_{I_1}\, h^2\, \|p\|^2_{H^2(\Omega)}, \end{aligned}$$

where $C^*_{I_1}$ depends only on a_* given in (2.4), S^* given in (3.10), κ^* given in (2.3), N_e from Assumption M2, and C^*_{face} obtained in (5.19). □

The following lemma gives an estimate for $\mathbf{I}_3$.

LEMMA 5.3. *Let $p \in H^2(\Omega)$ and let, in each $E \in \mathcal{T}_h$, p^1 be such that* (5.16) *holds. Moreover, let $\mathbf{G} \in X^d$. Then*

$$\sum_{E\in\mathcal{T}_h} \int_{\partial E} p^1\, \mathbf{G}_E \cdot \mathbf{n}_E\, \mathrm{d}S \le C^*_{I_3}\, h\, \|p\|_{H^2(\Omega)}\, |||\mathbf{G}|||_{X^d}, \tag{5.22}$$

where the constant $C^*_{I_3}$ is independent of p, $\mathbf{G}$, and h.

Proof. The first (crucial) step of the proof uses the continuity of p and the fact that $\mathbf{G}_E \cdot \mathbf{n}_E$ takes opposite values for the two elements sharing a common internal face. Then, the result follows with usual instruments such as the Cauchy–Schwarz inequality and approximation results (5.16):

$$\begin{aligned} \sum_{E\in\mathcal{T}_h} \int_{\partial E} p^1_E\, \mathbf{G}_E \cdot \mathbf{n}_E\, \mathrm{d}S &= \sum_{E\in\mathcal{T}_h} \int_{\partial E} \big(p^1_E - p\big)\, \mathbf{G}_E \cdot \mathbf{n}_E\, \mathrm{d}S \\ &\le \sum_{E\in\mathcal{T}_h} \sum_{e\in\partial E} \big\|p - p^1_E\big\|_{L^2(e)}\, \big\|G^e_E\big\|_{L^2(e)} \\ &= \sum_{E\in\mathcal{T}_h} \sum_{e\in\partial E} \big\|p - p^1_E\big\|_{L^2(e)}\, \big|G^e_E\big|\, |e|^{1/2} \\ &\le v_*^{-1/2} (C^*_{face})^{1/2} \sum_{E\in\mathcal{T}_h} h_E \|p\|_{H_2(E)} \sum_{e\in\partial E} \big|G^e_E\big|\, |E|^{1/2} \\ &\le C^*_{I_3}\, h \|p\|_{H^2(\Omega)}\, |||\mathbf{G}|||_{X^d}, \end{aligned}$$

where $C^*_{I_3} = (v_*^{-1}\, s_*^{-1}\, C^*_{face})^{1/2} N_e$. This proves the assertion of the lemma. □

Combining (5.12) with (5.20), (5.21), and (5.22), we finally get the main convergence result.

THEOREM 5.4. *Under Assumptions* P1, M1–M6, *and* S1–S2, *let* $(p, \mathbf{F})$ *be the solution of* (2.1)–(2.2), *and let* $(p_d, \mathbf{F}_d)$ *be the discrete solution, given by* (3.15)–(3.16). *Moreover, let* $\mathbf{F}^I$ *be the interpolant of* $\mathbf{F}$, *introduced in* (3.7). *Then, we have*

$$|||\mathbf{F}^I - \mathbf{F}_d|||_{X^d} \le C^* \, h \, \|p\|_{H^2(\Omega)}, \tag{5.23}$$

where C^* *depends only upon the various constants appearing in Assumptions* P1, M1–M6, *and* S1–S2.

5.3. Error estimates for the scalar variable. In order to derive estimates on the scalar variable $\mathbf{p}_d$, we shall go back to the proof of inf-sup condition (4.5). For the sake of simplicity, we assume that Ω is convex. Let ψ be the solution of

$$\begin{aligned} -\mathrm{div}(\mathbf{K}\nabla\psi) &= \mathbf{p}^I - \mathbf{p}_d \quad && \text{in } \Omega, \\ \psi &= 0 && \text{on } \partial\Omega, \end{aligned}$$

where, for simplicity, we identified $\mathbf{p}_d - \mathbf{p}^I$ with the corresponding piecewise constant function. The convexity of Ω implies that there exists a constant C_Ω^*, depending only on Ω, such that

$$\|\psi\|_{H^2(\Omega)} \le C_\Omega^* \, |||\mathbf{p}_d - \mathbf{p}^I|||_{Q^d}. \tag{5.24}$$

We now set

$$\mathbf{H} = \mathbf{K}\nabla\psi \tag{5.25}$$

and define $\mathbf{G} \in X^d$ as $\mathbf{G} = \mathbf{H}^I$, so that

$$\mathcal{DIV}^d \, \mathbf{G} = \mathbf{p}_d - \mathbf{p}^I. \tag{5.26}$$

Finally, we denote by ψ^1 a piecewise linear approximation of ψ that satisfies (5.16) for each $E \in \mathcal{T}_h$. Using (5.26), then (4.1), then (3.6) and (3.13), then integrating by parts, and finally integrating once again by parts and using (2.1) and (2.2), we get

$$\begin{aligned} |||\mathbf{p}_d - \mathbf{p}^I|||_{Q^d}^2 &= [\mathcal{DIV}^d \, \mathbf{G}, \, \mathbf{p}_d - \mathbf{p}^I]_{Q^d} \\ &= [\mathbf{F}_d, \, \mathbf{G}]_{X^d} - [\mathcal{DIV}^d \, \mathbf{G}, \, \mathbf{p}^I]_{Q^d} = [\mathbf{F}_d, \, \mathbf{G}]_{X^d} - \int_\Omega p \, \mathrm{div}(\mathbf{K}\nabla\psi) \, \mathrm{d}V \\ &= [\mathbf{F}_d, \, \mathbf{G}]_{X^d} + \int_\Omega \mathbf{K}\nabla p \cdot \nabla\psi \, \mathrm{d}V \\ &= [\mathbf{F}_d, \, \mathbf{G}]_{X^d} + \int_\Omega b \, \psi \, \mathrm{d}V. \end{aligned}$$

Now, using the definition of $\mathbf{G}$ and adding and subtracting the terms, we have

$$\begin{aligned} |||\mathbf{p}_d - \mathbf{p}^I|||_{Q^d}^2 &= [\mathbf{F}_d, \, (\mathbf{K}\nabla\psi)^I - (\mathbf{K}\nabla\psi^1)^I]_{X^d} + [\mathbf{F}_d, \, (\mathbf{K}\nabla\psi^1)^I]_{X^d} + \int_\Omega b \, \psi \, \mathrm{d}V \\ &= J_1 + [\mathbf{F}_d, \, ((\mathbf{K} - \tilde{\mathbf{K}})\nabla\psi^1)^I]_{X^d} + [\mathbf{F}_d, \, (\tilde{\mathbf{K}}\nabla\psi^1)^I]_{X^d} + \int_\Omega b \, \psi \, \mathrm{d}V \\ &= J_1 + J_2 + [\mathbf{F}_d, \, (\tilde{\mathbf{K}}\nabla\psi^1)^I]_{X^d} + \int_\Omega b \, \psi \, \mathrm{d}V. \end{aligned} \tag{5.27}$$

Using (5.21), the term J_1 can be easily bounded by

$$J_1 \equiv [\mathbf{F}_d,\, (\mathbf{K}\nabla\psi)^I - (\mathbf{K}\nabla\psi^1)^I]_{X^d} \leq C^*_{I_1}\, h\, |||\mathbf{F}_d|||_{X^d}\, \|\psi\|_{H^2(\Omega)}. \tag{5.28}$$

The term J_2 is bounded as in (5.14), (5.20) by

$$J_2 \equiv [\mathbf{F}_d,\, ((\mathbf{K} - \tilde{\mathbf{K}})\nabla\psi^1)^I]_{X^d} \leq C^*_{I_2}\, h\, |||\mathbf{F}_d|||_{X^d}\, \|\psi\|_{H^2(\Omega)}. \tag{5.29}$$

For the third term in the last line of (5.27), we can use (5.1) to obtain

$$[\mathbf{F}_d,\, (\mathbf{K}\nabla\psi^1)^I]_{X^d} = \sum_{E\in\mathcal{T}_h} \int_{\partial E} \psi^1 (\mathbf{F}_d)_E \cdot \mathbf{n}_E \,\mathrm{d}S - \int_\Omega \mathbf{b}\,\psi^1 \,\mathrm{d}V. \tag{5.30}$$

With the help of (5.22), we then get

$$\left|[\mathbf{F}_d,\, (\tilde{\mathbf{K}}\nabla\psi^1)^I]_{X^d} + \int_\Omega b\,\psi \,\mathrm{d}V\right| \leq C^*_{I_3}\, h\, |||\mathbf{F}_d|||_{X^d}\, \|\psi\|_{H^2(\Omega)} + \left|\int_\Omega (b\,\psi - \mathbf{b}\psi^1)\,\mathrm{d}V\right|, \tag{5.31}$$

where the last term is easily bounded by $2\,C^*_{app}\, h\, \|b\|_{H^1(\Omega)}\, \|\psi\|_{H^1(\Omega)}$. Collecting inequalities (5.27)–(5.31), we obtain

$$|||\mathbf{p}_d - \mathbf{p}^I|||^2_{Q^d} \leq C^*\, h\, \left\{|||\mathbf{F}_d|||_{X^d} + \|b\|_{H^1(\Omega)}\right\} \|\psi\|_{H^2(\Omega)}, \tag{5.32}$$

which, combined with estimates (5.24), Theorem 5.4, and Lemma 4.1, gives the proof of the second convergence result.

Theorem 5.5. *Under assumptions of Theorem* 5.4*, plus the convexity of* Ω*, we have*

$$|||\mathbf{p}_d - \mathbf{p}^I|||_{Q^d} \leq C^*\, h\, (\|p\|_{H^2(\Omega)} + \|b\|_{H^1(\Omega)}), \tag{5.33}$$

where the constant C^* *depends only on the constants appearing in Assumptions* P1, M1–M6*, and* S1–S2*, on* C^*_Ω *appearing in* (5.24)*, and on* β^*_s *appearing in* (4.12).

It is interesting to note that, assuming that in each element E we had a suitable lifting R_E, a better estimate for the scalar variable could be obtained. We have indeed the following theorem.

Theorem 5.6. *Together with the assumptions of Theorem* 5.5*, assume, moreover, that for each element* E *we have a lifting operator* R_E *with properties* (5.4), (5.5)*, and* (5.8) *such that*

$$\|R_E(\mathbf{G}^I) - \mathbf{G}\|_{L^2(E)} \leq C^*_{Ra}\, h_E\, \|\mathbf{G}\|_{(H^1(E))^3} \quad \forall\, \mathbf{G} \in (H^1(E))^3 \quad \forall\, E \in \mathcal{T}_h, \tag{5.34}$$

where C^*_{Ra} *is a constant independent of* $\mathbf{G}$ *and* h_E*. Then, the choice*

$$[\mathbf{F},\, \mathbf{G}]_E := \int_E \mathbf{K}^{-1} R_E(\mathbf{F}_E) \cdot R_E(\mathbf{G}_E)\,\mathrm{d}V \tag{5.35}$$

will give

$$|||\mathbf{p}_d - \mathbf{p}^I|||_{Q^d} \leq C^*\, h^2\, \left(\|p\|_{H^2(\Omega)} + \|b\|_{H^1(\Omega)}\right), \tag{5.36}$$

where the constant C^* *depends only on the constants appearing in Assumptions* P1, M1–M6*, and* S1–S2*, on* C^*_Ω *appearing in* (5.24)*, on* β^*_s *appearing in* (4.12)*, and on* C^*_{Ra} *from* (5.34).

Proof. Let $R(\mathbf{G})$ be such that $R(\mathbf{G})|_E = R_E(\mathbf{G}_E)$. Following essentially [11] and using (5.26), then (4.1), (3.6), and (3.13) (as in the previous proof) with (5.4), then integrating by parts, and finally using (2.2) and (5.35), we get

$$\begin{aligned}|||\mathbf{p}_d - \mathbf{p}^I|||^2_{Q^d} &= [\mathcal{DIV}^d\,\mathbf{G},\, \mathbf{p}_d - \mathbf{p}^I]_{Q^d}\\ &= [\mathbf{F}_d,\, \mathbf{G}]_{X^d} - \int_\Omega p \operatorname{div} R(\mathbf{G})\,\mathrm{d}V\\ &= [\mathbf{F}_d,\, \mathbf{G}]_{X^d} + \int_\Omega \nabla p \cdot R(\mathbf{G})\,\mathrm{d}V = [\mathbf{F}_d,\, \mathbf{G}]_{X^d} + \int_\Omega \mathbf{K}^{-1}\mathbf{K}\nabla p \cdot R(\mathbf{G})\,\mathrm{d}V\\ &= \int_\Omega \mathbf{K}^{-1}(R(\mathbf{F}_d) - \mathbf{F})\, R(\mathbf{G})\,\mathrm{d}V.\end{aligned}$$

Adding and subtracting $\mathbf{H}$ defined in (5.25), we get

$$\begin{aligned}|||\mathbf{p}_d - \mathbf{p}^I|||^2_{Q^d} &= \int_\Omega \mathbf{K}^{-1}(R(\mathbf{F}_d) - \mathbf{F})\,(R(\mathbf{G}) - \mathbf{H})\,\mathrm{d}V + \int_\Omega \mathbf{K}^{-1}(R(\mathbf{F}_d) - \mathbf{F})\,\mathbf{H}\,\mathrm{d}V\\ &= J_3 + \int_\Omega (R(\mathbf{F}_d) - \mathbf{F})\,\nabla\psi\,\mathrm{d}V = J_3 - \int_\Omega \psi \operatorname{div}(R(\mathbf{F}_d) - \mathbf{F})\,\mathrm{d}V\\ &= J_3 - \int_\Omega (\mathbf{b}^I - b)\psi\,\mathrm{d}V\\ &= J_3 - \int_\Omega (\mathbf{b}^I - b)(\psi - \boldsymbol{\psi}^I)\,\mathrm{d}V = J_3 + J_4. \qquad (5.37)\end{aligned}$$

In their turn, J_3 and J_4 can be easily bounded using the previous estimates and the usual arguments. Indeed, the triangle inequality, then (3.10) and (5.8), and finally (5.23) and (5.34) imply that

$$\begin{aligned}\|R(\mathbf{F}_d) - \mathbf{F}\|_{(L^2(\Omega))^3} &\le \|R(\mathbf{F}_d - \mathbf{F}^I)\|_{(L^2(\Omega))^3} + \|R(\mathbf{F}^I) - \mathbf{F}\|_{(L^2(\Omega))^3}\\ &\le C^*_R s_*^{-1/2}|||\mathbf{F}_d - \mathbf{F}^I|||_{X^d} + \|R(\mathbf{F}^I) - \mathbf{F}\|_{(L^2(\Omega))^3}\\ &\le C\, h\, \|p\|_{H^2(\Omega)}. \qquad (5.38)\end{aligned}$$

Using assumption (5.34) and (5.24), we get

$$\|R(\mathbf{G}) - \mathbf{H}\|_{(L^2(\Omega))^3} = \|R(\mathbf{H}^I) - \mathbf{H}\|_{(L^2(\Omega))^3} \le C^*_{Ra} h \|\mathbf{H}\|_{(H^1(\Omega))^3} \le Ch|||\mathbf{p}_d - \mathbf{p}^I|||_{Q^d}. \qquad (5.39)$$

The approximation property (5.15) gives the following estimates:

$$|||\mathbf{b}^I - b\|_{L^2(\Omega)} \le C^*_{app}\, h\|b\|_{H^1(\Omega)} \qquad (5.40)$$

and

$$\|\psi - \boldsymbol{\psi}^I\|_{L^2(\Omega)} \le C^*_{app}\, h\|\psi\|_{H^1(\Omega)} \le C^*_{app} C^*_\Omega\, h\, |||\mathbf{p}_d - \mathbf{p}^I|||_{Q^d}. \qquad (5.41)$$

Inserting estimates (5.38)–(5.41) into (5.37), we immediately get the result. □

Remark 5.1. *It is very likely that our additional assumption* (5.34) *is not needed, as it should be possible to deduce it from* (5.4), (5.5), *possibly with minor additional assumptions on the geometry. However, in essentially all cases in which R_E can be explicitly built, it is easy to prove directly that* (5.34) *holds true. Therefore, we decided that it would be simpler to just assume it.*

6. Conclusion. In this paper, we have considered the MFD method for the mixed formulation of the diffusion problem on polyhedral meshes. We have proved the stability of the mimetic discretizations and the optimal convergence rates for the scalar and vector variables. The key elements of our methodology are the consistency Assumption S2 and the lift property LP. In future work, we plan to extend the convergence results to polyhedral meshes with curved faces.

Appendix. Proof of the list property. The purpose of this appendix is to prove the lift property (4.17)–(4.18), which we recall for convenience of the reader.

LP (lift property). For every $t < 2$ there exists a constant $\lambda^* = \lambda^*(t)$ such that for every $E \in \mathcal{T}_h$ and for every $e \in \partial E$ there exists a function φ_E^e from E to $\mathbb{R}$ that verifies

$$\varphi_E^e = 1 \quad \text{on} \quad e, \quad \varphi_E^e = 0 \quad \text{on} \quad \partial E \backslash e \tag{A.1}$$

and

$$\|\varphi_E^e\|_{L^2(E)} \leq \lambda^* h_E^{3/2}, \quad \|\nabla \varphi_E^e\|_{(L^t(E))^3} \leq \lambda^* h_E^{3/t-1}. \tag{A.2}$$

A traditional way would be to assume that there exist a finite number of reference elements $\hat{E}_1, \ldots, \hat{E}_1$ and a positive constant L^* such that for each $E \in \mathcal{T}_h$ there is an $\hat{E}_k$ and a bi-Lipschitz map Φ_k^E from $\hat{E}_k$ to E such that

$$|\Phi_k^E|_{W^1_\infty(\hat{E}_k)} \leq L^*, \qquad \|\Phi_k^E\|_{L_\infty(\hat{E}_k)} \leq L^*\, h_E \tag{A.3}$$

and

$$|(\Phi_k^E)^{-1}|_{W^1_\infty(E)} \leq L^*, \qquad \|(\Phi_k^E)^{-1}\|_{L_\infty(E)} \leq L^*\, h_E^{-1}. \tag{A.4}$$

Then, for each reference element $\hat{E}_k$ and for each face $\hat{e}$ of $\hat{E}_k$ we could construct the harmonic function $\hat{\varphi}_{\hat{E}_k}^{\hat{e}}$ with boundary value 1 on $\hat{e}$ and zero on the other faces, and verify that it belongs to $W_t^1(\hat{E}_k)$ for every $t < 2$. Finally each function φ_E^e could be constructed by combining one of the reference functions $\hat{\varphi}_{\hat{E}_k}^{\hat{e}}$ with the corresponding map Φ_k^E. This is surely feasible but will become rather cumbersome if we want to consider a big variety of possible shapes for our elements.

We decided here to follow a different path that requires only the fact that the faces are star shaped (M4) and the pyramid property (M5), which are possibly more difficult to explain but much easier to check and to enforce. The general idea is first to build a function $\hat{\varphi}_1$ on the unit cone $\mathcal{C}_1$; then, for every h, to build a function φ_h on a cone $\mathcal{C}_h$ obtained by scaling the unit cone; and finally, for each element E and for each face e, to map the cone $\mathcal{C}_{\gamma_* h_E}$ (where γ_* is given in Assumption M4) into the pyramid P_E^e described in Assumption M5 with a Lipschitz continuous mapping. This will give us a function $\varphi = \varphi_E^e$ on the pyramid, having the right norms. This function will finally be extended by zero to the whole element E, and still it will have the right norms. But let us look at the procedure in more detail.

For each element E and for each face e of E we want to build a function $\varphi = \varphi_E^e$ with the following properties.

- The support of φ is contained in the pyramid $P = P_E^e$ satisfying Assumption M5.
- $\varphi \equiv 1$ on e and $\varphi \equiv 0$ on the other faces of P_E^e.

- φ satisfies the following estimates:

$$\text{(A.5)} \qquad ||\varphi||_{L^2(P)} \leq \lambda^* \, h_E^{3/2} \quad \text{and} \quad ||\nabla\varphi||_{(L^t(P))^3} \leq \lambda^* \, h_E^{3/t-1},$$

where the constant λ^* is independent of E and e.

As we said before, we start our work on cones: for $\rho > 0$ we shall refer to the solid

$$\mathcal{C}_\rho \equiv \{(x, y, z)\colon \; 0 \leq z \leq \rho \quad \text{and} \quad x^2 + y^2 \leq (\rho - z)^2\}$$

as the *circular cone of radius* ρ.

LEMMA A.1. *Let $\mathcal{C}_1$ be the circular cone of radius* 1*, and let $\hat{\varphi}_1$ be the harmonic function that takes value* 1 *on the base and* 0 *on the lateral boundary. Then $\hat{\varphi}_1$ belongs to $L_\infty(\mathcal{C}_1)$ and $\nabla\hat{\varphi}_1$ belongs to $(L^t(\mathcal{C}_1))^3$ for all $t < 2$.*

Proof. The first part of the statement follows from the maximum principle, which gives $0 \leq \hat{\varphi}_1 \leq 1$. The second part of the statement follows immediately from the known results concerning domains with corners (see, e.g., [12] or [10]). □

In view of the previous lemma, we set

$$\text{(A.6)} \qquad \hat{C}_t := \|\nabla\varphi_1\|_{(L^t(\mathcal{C}_1))^3}.$$

It is clear that $\hat{C}_t$ depends on t and hence on s through (4.15).

LEMMA A.2. *For every positive real number h, let $\mathcal{C}_h$ be a circular cone of radius h. Then, there exists a function φ_h taking value* 1 *on the base, value zero on the lateral surface, and satisfying*

$$\text{(A.7)} \qquad ||\varphi_h||_{L^2(\mathcal{C}_h)} \leq |\mathcal{C}_h|^{1/2} \quad \text{and} \quad ||\nabla\varphi_h||_{(L^t(\mathcal{C}_h))^3} \leq h^{3/t-1}\hat{C}_t,$$

where $|\mathcal{C}_h|$ is the volume of $\mathcal{C}_h$.

Proof. The proof follows with the usual scaling arguments (see, e.g., [9, Theorem 3.1.2]). □

Consider now a face e of E. For convenience, we assume that (a) the face e lies in the plane $z = 0$, (b) M_e, defined in Assumption M4 (*star-shaped faces*), is the origin of the axes, and (c) the polyhedron E is locally in the half-space $z > 0$. By Assumptions M4 and M5 (*the pyramid property*), there exists a γ_* such that the circular cone $\mathcal{C}_h$ having its base on the face e (with center in M_e), and radius $h = \rho_* = \gamma_* \, h_E$, is strictly contained in the pyramid P_E^e having the same vertex and base equal to e. Hence, $\mathcal{C}_h$ is contained in E.

Let us show that Assumption M4 implies the existence of a radial mapping in the plane $z = 0$ which maps the disk D_{ρ_*} with center in M_e and radius ρ_* onto the face e, is one-to-one, Lipschitz continuous together with its inverse, and with W^1_∞ norms bounded in terms of γ_* and the number of edges of e.

LEMMA A.3. *Under Assumption* M4 *there exists a map Φ_2, mapping the disk D_{ρ_*} onto the face e, which is Lipschitz continuous together with the inverse map Φ_2^{-1}. Moreover,*

$$\text{(A.8)} \qquad \|\Phi_2\|_{W^1_\infty(D_{\rho_*})} \leq C_e^* \qquad \text{and} \qquad \|\Phi_2^{-1}\|_{W^1_\infty(e)} \leq C_e^*,$$

where C_e^* depends only on the constant γ_* from Assumption M4.

Proof. To show this, we note that the plane $z = 0$ can be split in a finite number of sectors by the vertices of e. Each sector corresponds to the straight rays coming

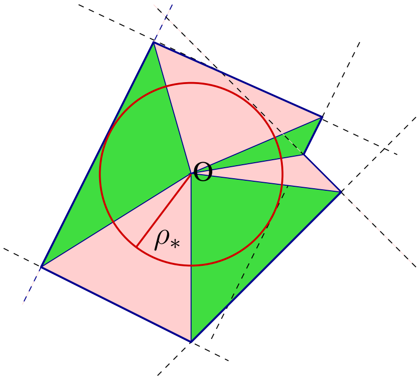

FIG. A.1. *The splitting of e in sectors.*

out of the origin M_e and intersecting the edge ℓ_k (see Figure A.1). For each point $\mathbf{P} \in D_{\rho_*}$, we first consider the ray emanating from the origin and passing through $\mathbf{P}$. This ray intersects ∂e at a point $\mathbf{V}(\mathbf{P})$. Our mapping is defined as follows:

$$\tilde{\mathbf{P}} \equiv \Phi_2(\mathbf{P}) := \frac{|\mathbf{V}(\mathbf{P})|}{\rho_*}\,\mathbf{P}. \tag{A.9}$$

It is clear that Φ_2 maps every point $\mathbf{P}$ onto a point $\tilde{\mathbf{P}}$ on the same ray so that

$$\mathbf{V}(\mathbf{P}) = \mathbf{V}(\tilde{\mathbf{P}}) \quad \forall\, \mathbf{P} \in D_{\rho^*}. \tag{A.10}$$

It is immediate to check that, on each ray, the map is continuous and monotone, and that it maps the points of the circumference of radius ρ_* onto the corresponding points of ∂e on the same ray. Hence it maps D_{ρ_*} onto e in a one-to-one way. It is also clear that the map is globally continuous, invertible, and the inverse map

$$\mathbf{P} \equiv \Phi_2^{-1}(\tilde{\mathbf{P}}) := \frac{\rho_*}{|\mathbf{V}(\mathbf{P})|}\,\tilde{\mathbf{P}} \equiv \frac{\rho_*}{|\mathbf{V}(\tilde{\mathbf{P}})|}\,\tilde{\mathbf{P}} \tag{A.11}$$

is also continuous and maps e onto D_{ρ_*}. Note that we used (A.10) in the last step.

In order to show the Lipschitz continuity, we have to bound the distance between the images $|\tilde{\mathbf{P}} - \tilde{\mathbf{Q}}|$ by a constant time the distance $|\mathbf{P} - \mathbf{Q}|$. For this, we note that Assumption M4 implies

$$1 \le \frac{|\mathbf{V}|}{\rho_*} \le \frac{h_E}{\gamma_*\, h_E} = \frac{1}{\gamma_*} \qquad \text{for every } \mathbf{V} \in \partial e. \tag{A.12}$$

As shown in Figure A.2, it also implies that for every point $\mathbf{V}$ on an edge ℓ of ∂e, the angle α_V between ℓ and the ray passing through $\mathbf{V}$ verifies

$$|\sin \alpha_V| = \frac{|\mathbf{H}_\ell|}{|\mathbf{V}|} \ge \frac{\rho_*}{|\mathbf{V}|} \ge \gamma_*, \tag{A.13}$$

where $\mathbf{H}_\ell$ is the orthogonal projection of the origin M_e on the line containing ℓ, and we used (A.12) in the last step.

The Lipschitz continuity is obvious when $\mathbf{P}$ and $\mathbf{Q}$ are on the same ray:

$$|\tilde{\mathbf{P}} - \tilde{\mathbf{Q}}| = \frac{|\mathbf{V}(\mathbf{P})|}{\rho_*}\,|\mathbf{P} - \mathbf{Q}| \le \frac{1}{\gamma_*}\,|\mathbf{P} - \mathbf{Q}|. \tag{A.14}$$

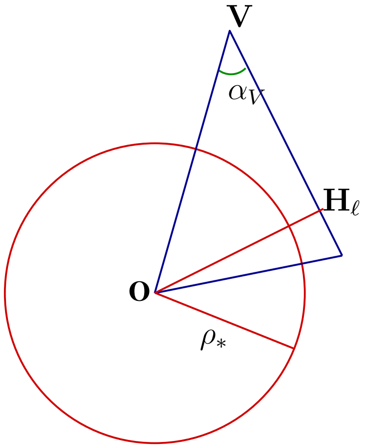

FIG. A.2. *Lower bound on* $|\sin \alpha_V|$.

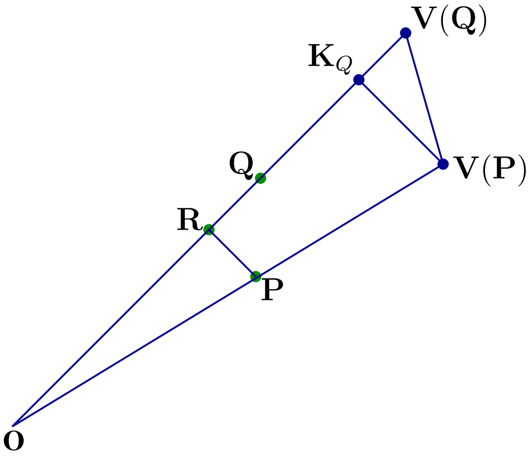

FIG. A.3. *Lipschitz continuity within a sector.*

If $\mathbf{P}$ and $\mathbf{Q}$ are on two different rays in the same sector, we first denote by $\mathbf{K}_Q$ and $\mathbf{R}$ (respectively) the orthogonal projections of $\mathbf{V}(\mathbf{P})$ (respectively, of $\mathbf{P}$) on the ray containing $\mathbf{Q}$ (see Figure A.3). Then, applying the Thaletes theorem, we get

$$\frac{|\mathbf{V}(\mathbf{P})-\mathbf{K}_Q|}{|\mathbf{V}(\mathbf{P})|}=\frac{|\mathbf{P}-\mathbf{R}|}{|\mathbf{P}|}\leq\frac{|\mathbf{P}-\mathbf{Q}|}{|\mathbf{P}|}. \tag{A.15}$$

Collecting (A.15), (A.13), and (A.12), we have

$$|\mathbf{V}(\mathbf{P})-\mathbf{V}(\mathbf{Q})|=\frac{|\mathbf{V}(\mathbf{P})-\mathbf{K}_Q|}{\left|\sin\left(\alpha_{V(Q)}\right)\right|}\leq\frac{|\mathbf{P}-\mathbf{Q}|}{\gamma_*|\mathbf{P}|}\,|\mathbf{V}(\mathbf{P})|\leq\frac{|\mathbf{P}-\mathbf{Q}|}{(\gamma_*)^2|\mathbf{P}|}\,\rho_*, \tag{A.16}$$

where obviously the role of **P** and **Q** can be interchanged. Finally, the triangle inequality together with (A.9) and (A.16) gives

$$\tag{A.17}\begin{aligned}|\tilde{\mathbf{P}}-\tilde{\mathbf{Q}}| &= \left|\frac{|\mathbf{V}(\mathbf{P})|\,\mathbf{P}-|\mathbf{V}(\mathbf{Q})|\,\mathbf{Q}}{\rho_*}\right| \le \frac{|\mathbf{V}(\mathbf{P})-\mathbf{V}(\mathbf{Q})|}{\rho_*}\,|\mathbf{P}| + \frac{|\mathbf{V}(\mathbf{Q})|}{\rho_*}\,|\mathbf{P}-\mathbf{Q}| \\ &\le \frac{|\mathbf{P}-\mathbf{Q}|}{(\gamma_*)^2} + \frac{1}{\gamma_*}|\mathbf{P}-\mathbf{Q}| = \frac{1+\gamma_*}{(\gamma_*)^2}|\mathbf{P}-\mathbf{Q}|.\end{aligned}$$

The case of **P** and **Q** belonging to different sectors can be easily deduced by inserting suitable intermediate points at the boundaries of the sectors and then using the triangle inequality.

In a similar way, we can show that the inverse mapping is also Lipschitz continuous. For instance, using (A.11) we get

$$\tag{A.18} |\mathbf{P}-\mathbf{Q}| = \left|\frac{\rho_*}{|\mathbf{V}(\tilde{\mathbf{P}})|}\tilde{\mathbf{P}} - \frac{\rho_*}{|\mathbf{V}(\tilde{\mathbf{Q}})|}\tilde{\mathbf{Q}}\right| = \frac{\rho_*}{|\mathbf{V}(\tilde{\mathbf{P}})|\,|\mathbf{V}(\tilde{\mathbf{Q}})|}\,||\mathbf{V}(\tilde{\mathbf{Q}})|\tilde{\mathbf{P}} - |\mathbf{V}(\tilde{\mathbf{P}})|\tilde{\mathbf{Q}}|.$$

Then, adding and subtracting $|\mathbf{V}(\mathbf{P})|\mathbf{P}$ and using the triangle inequality, we have

$$\tag{A.19} ||\mathbf{V}(\tilde{\mathbf{Q}})|\tilde{\mathbf{P}} - |\mathbf{V}(\tilde{\mathbf{P}})|\tilde{\mathbf{Q}}| \le |\mathbf{V}(\tilde{\mathbf{P}}) - \mathbf{V}(\tilde{\mathbf{Q}})|\,|\tilde{\mathbf{P}}| + |\mathbf{V}(\tilde{\mathbf{P}})|\,|\tilde{\mathbf{P}}-\tilde{\mathbf{Q}}|.$$

On the other hand, we can apply the argument of (A.16) to obtain

$$\tag{A.20} |\mathbf{V}(\tilde{\mathbf{P}}) - \mathbf{V}(\tilde{\mathbf{Q}})| \le \frac{|\tilde{\mathbf{P}}-\tilde{\mathbf{Q}}|}{(\gamma_*)^2|\tilde{\mathbf{P}}|}\,\rho_*.$$

Collecting (A.18), (A.19), and (A.20), and using (A.12) (this time as $\rho_*/|\mathbf{V}| \le 1$), we finally obtain

$$\tag{A.21} |\mathbf{P}-\mathbf{Q}| \le \frac{1}{(\gamma_*)^2}|\tilde{\mathbf{P}}-\tilde{\mathbf{Q}}| + |\tilde{\mathbf{P}}-\tilde{\mathbf{Q}}| = \frac{1+(\gamma_*)^2}{(\gamma_*)^2}\,|\tilde{\mathbf{P}}-\tilde{\mathbf{Q}}|.$$

This proves the assertion of the lemma. □

Now, we can construct a mapping Φ_3 from the cone $\mathcal{C}_h$ (having D_{ρ_*} as the base and with height equal to ρ_*) onto the pyramid P_E^e (having e as the base and with the same vertex as $\mathcal{C}_h$), which is Lipschitz continuous with its inverse, by taking

$$\tag{A.22} (\tilde{x},\, \tilde{y}) = \Phi_2(x,\, y), \quad \tilde{z} = z.$$

Again, the Lipschitz norms of the map Φ_3 and of its inverse depend only on γ_*. This proves the following lemma.

LEMMA A.4. *Under Assumption* M4 *there exists a map Φ_3, mapping the cone $\mathcal{C}_h$ onto the pyramid P_E^e, which is Lipschitz continuous together with the inverse map Φ_3^{-1}. Moreover,*

$$\tag{A.23} \|\Phi_3\|_{W^1_\infty(\mathcal{C}_h)} \le C^*_{pyr} \quad \textit{and} \quad \left\|\Phi_3^{-1}\right\|_{W^1_\infty(P_E^e)} \le C^*_{pyr},$$

where C^*_{pyr} depends only on the constant γ_* of Assumption M4.

The last step is to construct, for each element E and for each face $e \in \partial E$, the function φ_E^e satisfying (A.5) (with the right boundary conditions). Let

$$\varphi_E^e(x,\, y,\, z) = \varphi_h\big(\Phi_3^{-1}(x,\, y,\, z)\big),$$

where φ_h is the function from Lemma A.2 defined for the circular cone of radius $h = \rho_* = \gamma_* \, h_E$. It is clear that φ_E^e will be in $L^2(P_E^e)$, that $\nabla\varphi_E^e$ will be in $(L^t(P_E^e))^3$, and that their norms will be bounded by

$$\|\varphi_E^e\|_{L^2(P_E^e)} \leq C^*_{pyr} \, h_E^{3/2} \quad \text{and} \quad \|\nabla\varphi_E^e\|_{(L^t(P_E^e))^3} \leq \hat{C}_t \, C^*_{pyr} h_E^{3/t-1}, \tag{A.24}$$

where $\hat{C}_t$ is given in (A.6) and C^*_{pyr} depends only on γ_*. Hence φ_E^e satisfies (A.5) as required. Finally, we take the prolongation of φ_E^e (that we call again φ_E^e) by zero in $E \backslash P_E^e$.

This ends the proof of the lift property (A.1)–(A.2).

Acknowledgments. The authors thank organizers of the workshop "Compatible Spatial Discretizations for Partial Differential Equations" held at the Institute of Mathematics and Applications (IMA) in Minneapolis for drawing attention to the problem considered in this paper (the collaboration was actually started during the workshop).

PIECEWISE POLYNOMIAL COLLOCATION FOR FREDHOLM INTEGRO-DIFFERENTIAL EQUATIONS WITH WEAKLY SINGULAR KERNELS[*]

INGA PARTS[†], ARVET PEDAS[†], AND ENN TAMME[†]

Abstract. In the first part of this paper we study the regularity properties of solutions of initial- or boundary-value problems of linear Fredholm integro-differential equations with weakly singular or other nonsmooth kernels. We then use these results in the analysis of a piecewise polynomial collocation method for solving such problems numerically. The main purpose of the paper is the derivation of optimal global convergence estimates and the analysis of the attainable order of convergence of numerical solutions for all values of the nonuniformity parameter of the underlying grid.

Key words. Fredholm integro-differential equation, weakly singular kernel, piecewise polynomial collocation method, graded grid, attainable order of convergence

1. Introduction.

We present a study of the convergence behavior of a collocation method for the numerical solution of initial- or boundary-value problems of linear integro-differential equations of the form

$$\begin{aligned} &u'(t) = a(t)u(t) + f(t) + \int_0^b K(t,s)u(s)ds, \quad 0 \le t \le b, \\ &\alpha u(0) + \beta u(b) = \gamma, \end{aligned} \tag{1.1}$$

where $b, \alpha, \beta, \gamma \in \mathbf{R} = (-\infty, \infty)$, $b > 0$, and $\alpha + \beta \neq 0$. We assume that $a, f \in C^{m,\nu}[0,b]$, $K \in W^{m,\nu}(\Delta)$, $m \in \mathbf{N} = \{1, 2, \dots\}$, $\nu \in \mathbf{R}$, $\nu < 1$.

Here $C^{m,\nu}[0,b]$, $m \in \mathbf{N}$, $\nu < 1$, is defined as the collection of all continuous functions $u : [0,b] \to \mathbf{R}$, which are m times continuously differentiable in $(0,b)$ and such that the estimation

$$\left|u^{(i)}(t)\right| \le c \begin{cases} 1 & \text{if} \quad i < 1 - \nu, \\ 1 + |\log \varrho(t)| & \text{if} \quad i = 1 - \nu, \\ \varrho(t)^{1-\nu-i} & \text{if} \quad i > 1 - \nu \end{cases}$$

holds with $\varrho(t) = \min\{t, b - t\}$, $0 < t < b$, and with a constant $c = c(u)$ for all $t \in (0,b)$ and $i = 1, \dots, m$. Equipped with the norm

$$\|u\|_{m,\nu} = \max_{0 \le t \le b} |u(t)| + \sum_{i=1}^{m} \sup_{0<t<b} \left(w_{i+\nu-1}(t)\left|u^{(i)}(t)\right|\right), \quad u \in C^{m,\nu}[0,b],$$

$C^{m,\nu}[0,b]$ is a Banach space. Here

$$w_\lambda(t) = \begin{cases} 1 & \text{for} \quad \lambda < 0, \\ (1 + |\log \varrho(t)|)^{-1} & \text{for} \quad \lambda = 0, \\ \varrho(t)^\lambda & \text{for} \quad \lambda > 0, \end{cases}$$

with $t \in (0,b)$. It is easy to see that if $\mu < \nu < 1$, then $C^{m,\mu}[0,b] \subset C^{m,\nu}[0,b]$ and $\|u\|_{m,\nu} \le c\|u\|_{m,\mu}$ for $u \in C^{m,\mu}[0,b]$, with a constant $c > 0$. Notice also that[1] $C^m[0,b] \subset C^{m,\nu}[0,b]$, $m \in \mathbf{N}$, $\nu < 1$.

The set $W^{m,\nu}(\Delta)$, with $m \in \mathbf{N}$, $\nu < 1$,

$$\Delta = \{(t,s) : \ 0 \le t \le b, \ 0 \le s \le b, \ t \ne s\},$$

consists of all m times continuously differentiable functions $K : \Delta \to \mathbf{R}$ satisfying

$$\left|\left(\frac{\partial}{\partial t}\right)^i \left(\frac{\partial}{\partial t} + \frac{\partial}{\partial s}\right)^j K(t,s)\right| \le c \begin{cases} 1 & \text{if} \quad \nu + i < 0, \\ 1 + |\log|t-s|| & \text{if} \quad \nu + i = 0, \\ |t-s|^{-\nu-i} & \text{if} \quad \nu + i > 0, \end{cases} \tag{1.2}$$

with a constant $c = c(K)$ for all $(t,s) \in \Delta$ and all nonnegative integers i and j such that $i + j \le m$.

Taking $i = j = 0$, the condition (1.2) yields that $K \in W^{m,\nu}(\Delta)$ may possess a weak singularity at $t = s$ for $0 \le \nu < 1$. If $\nu < 0$, then K itself is bounded on Δ, but its derivatives may be singular at $t = s$. Often the kernel K of problem (1.1) has the form $K = K_\nu(t,s) = \kappa(t,s)|t-s|^{-\nu}$, $0 < \nu < 1$, or $K = K_0(t,s) = \kappa(t,s)\log|t-s|$, where $\kappa \in C^m(\bar{\Delta})$, with $m \in \mathbf{N}$ and $\bar{\Delta} = [0,b] \times [0,b]$. Clearly, $K_\nu \in W^{m,\nu}(\Delta)$ for $0 < \nu < 1$ and $K_0 \in W^{m,0}(\Delta)$.

Note that Fredholm integro-differential equations are used by modeling various physical processes; see, e.g., [9]. A good source of information (including numerous additional references) on applications of integral and integro-differential equations is the monograph [4].

A special case of problem (1.1), with $\alpha = 1$, $\beta = 0$, and $K(t,s) = 0$ for $s > t$, is the initial-value problem for a Volterra integro-differential equation. Volterra integro-differential equations have been studied by many authors (see, e.g., [3, 4, 5, 6, 7, 12, 15, 18, 19, 20, 21]), but Fredholm-type equations have received less attention. There is some literature on the numerical solution of Fredholm integro-differential equations in case of smooth kernels; see, e.g., [11, 13, 16, 26]. To the authors' knowledge very little has been written on the numerical solution of Fredholm integro-differential equations with weakly singular kernels [25] (in contrast to weakly singular Fredholm integral equations; see, for example, [22, 14] and, especially, [8]). In order to fill this gap, the main purpose of the present paper is to generalize the corresponding results obtained in [6, 7, 15] for weakly singular Volterra integro-differential equations to a wide class of Fredholm integro-differential equations.

In the first part of this paper (section 2) we study the regularity properties of the solution of problem (1.1) with weakly singular or other nonsmooth kernels K. Moreover, we consider the case where the derivatives of the functions a and f in (1.1) may be unbounded on the interval $[0,b]$. We then use these results in the analysis of a piecewise polynomial collocation method for solving such equations numerically. Using special graded grids, we derive optimal global convergence estimates and analyze the attainable order of global and local convergence of numerical solutions for all values of the grading exponent of the underlying grid (sections 4 and 5). In section 3 we formulate some auxiliary results which we need in the analysis of proposed algorithms and in section 6 we present a numerical example to clarify the obtained theoretical results. The main results of the paper are formulated in Theorems 2.1, 4.1, and 5.1.

[1] By $C^k(\Omega)$ we denote the set of k times ($k \ge 0$) continuously differentiable functions on $\Omega \subset \mathbf{R}^n$, $C^0(\Omega) = C(\Omega)$; by c we denote positive constants, which may be different in different inequalities (in sections 3–5 they are independent of $N \in \mathbf{N}$).

Notice that similar results for integral equations may be found, for example, in [1, 2, 4, 5, 8, 10, 14, 17, 22, 24].

2. Smoothness of the solution. In what follows, for given Banach spaces E and F we denote by $\mathcal{L}(E, F)$ the Banach space of linear bounded operators $A : E \to F$ with the norm $\|A\| = \sup\{\|Au\|_F : u \in E, \|u\|_E \leq 1\}$. The regularity of the solution of problem (1.1) is described in the following theorem.

THEOREM 2.1. *Let $a, f \in C^{m,\nu}[0, b]$, $K \in W^{m,\nu}(\Delta)$, $m \in \mathbf{N}$, $\nu \in \mathbf{R}$, $\nu < 1$, $\alpha, \beta, \gamma \in \mathbf{R}$, $\alpha + \beta \neq 0$. Moreover, assume that the homogeneous problem*

$$u'(t) = a(t)u(t) + \int_0^b K(t, s)u(s)ds, \quad \alpha u(0) + \beta u(b) = 0, \tag{2.1}$$

corresponding to the problem (1.1)*, has in the set $\{u : u \in C[0, b], u' \in L^\infty(0, b)\}$ only the trivial solution $u = 0$.*

Then problem (1.1) *has a unique solution $u \in C^{m+1,\nu-1}[0, b] \subset C^{m,\nu}[0, b]$ and u', the derivative of the solution of* (1.1)*, belongs to $C^{m,\nu}[0, b]$.*

Proof. If $\alpha + \beta \neq 0$ and $v \in L^\infty(0, b)$, then the problem

$$u'(t) = v(t), \quad \alpha u(0) + \beta u(b) = \gamma$$

has a unique solution

$$u(t) = (Jv)(t) + \frac{\gamma}{\alpha + \beta}, \quad 0 \leq t \leq b, \tag{2.2}$$

where

$$(Jv)(t) = \int_0^t v(s)ds - \frac{\beta}{\alpha + \beta} \int_0^b v(s)ds = \int_0^b \kappa(t - s)v(s)ds, \quad 0 \leq t \leq b, \tag{2.3}$$

with

$$\kappa(\tau) = \begin{cases} -\dfrac{\beta}{\alpha + \beta} & \text{if} \quad -b \leq \tau < 0, \\[2ex] 1 - \dfrac{\beta}{\alpha + \beta} & \text{if} \quad 0 < \tau \leq b. \end{cases}$$

It follows from (2.3) and the expression of the norm $\|\cdot\|_{m,\nu}$ that $J \in \mathcal{L}(C^{m,\nu}[0, b], C^{m+1,\nu-1}[0, b])$. Since $\kappa^{(i)}(\tau) = 0$ for $\tau \neq 0$ and $i = 1, 2, \ldots$, then (see [23, 24]) J is compact as an operator from $C^{m,\nu}[0, b]$ to $C^{m,\nu}[0, b]$. Further, we can write (1.1) in the form

$$u'(t) = (Au)(t) + (Tu)(t) + f(t), \quad 0 \leq t \leq b, \quad \alpha u(0) + \beta u(b) = \gamma,$$

where

$$(Au)(t) = a(t)u(t), \quad (Tu)(t) = \int_0^b K(t, s)u(s)ds, \quad 0 \leq t \leq b. \tag{2.4}$$

Therefore, if u is a solution of problem (1.1), then it can be presented in the form (2.2), where v is the solution of equation

$$v = T_1 v + f_1, \tag{2.5}$$

with $T_1 = (A+T)J$ (see (2.3)–(2.4)) and

$$f_1(t) = f(t) + \frac{\gamma}{\alpha+\beta}a(t) + \frac{\gamma}{\alpha+\beta}\int_0^b K(t,s)ds, \quad 0 \le t \le b. \tag{2.6}$$

Next we show that T_1 is compact as an operator from $C^{m,\nu}[0,b]$ into $C^{m,\nu}[0,b]$ and $f_1 \in C^{m,\nu}[0,b]$. Indeed, since $K \in W^{m,\nu}(\Delta)$, then (see [22]) $T \in \mathcal{L}(C^{m,\nu}[0,b], C^{m,\nu}[0,b])$. If $a, v \in C^{m,\nu}[0,b]$, then (cf. [6])

$$\|av\|_{m,\nu} \le c\|a\|_{m,\nu}\|v\|_{m,\nu}.$$

Therefore, $A \in \mathcal{L}(C^{m,\nu}[0,b], C^{m,\nu}[0,b])$. This together with the compactness of $J \in \mathcal{L}(C^{m,\nu}[0,b], C^{m,\nu}[0,b])$ implies that $T_1 : C^{m,\nu}[0,b] \to C^{m,\nu}[0,b]$ is linear and compact. Since $1 \in C^{m,\nu}[0,b]$, then $T1 \in C^{m,\nu}[0,b]$. This together with $f, a \in C^{m,\nu}[0,b]$ yields $f_1 \in C^{m,\nu}[0,b]$.

Further, since problem (2.1) has only the trivial solution, then equation $v = T_1 v$ has only the trivial solution $v = 0$ in $L^\infty(0,b)$ and therefore also in $C^{m,\nu}[0,b] \subset L^\infty(0,b)$. Thus, by the Fredholm alternative, $I - T_1$ has a bounded inverse $(I-T_1)^{-1} : C^{m,\nu}[0,b] \to C^{m,\nu}[0,b]$ (here I is the identity mapping), and equation (2.5) has a unique solution $v = (I-T_1)^{-1}f_1 \in C^{m,\nu}[0,b]$. This, in turn, implies that problem (1.1) has a unique solution u and

$$u = Jv + \frac{\gamma}{\alpha+\beta} \in C^{m+1,\nu-1}[0,b]. \qquad \square$$

Remark 2.1. In [6, 7] it is shown that an initial-value problem for a linear Volterra integro-differential equation in the form

$$u'(t) = a(t)u(t) + f(t) + \int_0^t K(t,s)u(s)ds, \quad 0 \le t \le b, \quad u(0) = \gamma,$$

has a unique solution and thus the corresponding homogeneous problem cannot have nontrivial solutions. Such a situation does not take place for Fredholm integro-differential equations. For example, the homogeneous problem

$$u'(t) = 2\int_0^1 u(s)ds, \quad t \in [0,b], \ u(0) = 0,$$

has the nontrivial solution $u(t) = ct$, $c \ne 0$.

Remark 2.2. In Theorem 2.1, we have assumed that $\alpha+\beta \ne 0$. Actually, Theorem 2.1 holds also in the case $\alpha = -\beta \ne 0$, for example, in the case of a periodic boundary condition $u(0) = u(b)$. In order to prove this we can use the circumstance that for every $v \in L^\infty(0,b)$ and $\gamma \in \mathbf{R}$ a problem

$$u'(t) + u(t) = v(t), \quad u(0) - u(b) = \gamma$$

has a unique solution

$$u(t) = (J_1 v)(t) + \frac{\gamma e^{-t}}{1-e^{-b}},$$

where

$$(J_1 v)(t) = e^{-t}\int_0^t v(s)e^s ds + \frac{e^{-t-b}}{1-e^{-b}}\int_0^b v(s)e^s ds, \quad 0 \le t \le b.$$

It is easy to see that $J_1 \in \mathcal{L}(C^{m,\nu}[0,b], C^{m+1,\nu-1}[0,b])$ and J_1 is compact as an operator from $C^{m,\nu}[0,b]$ into $C^{m,\nu}[0,b]$. Using J_1 instead of J, on the basis of similar arguments as in the proof of Theorem 2.1, we can see that the statement of Theorem 2.1 holds also for $\alpha+\beta=0$, $\alpha=-\beta\neq 0$.

3. Piecewise polynomial interpolation. For $N \in \mathbf{N}$, $r \in \mathbf{R}$, $r \geq 1$, let $\Pi_N = \Pi_N^{(r)} = \{t_0, \ldots, t_{2N} : 0 = t_0 < t_1 < \cdots < t_{2N} = b\}$ be a partition (a graded grid) of the interval $[0,b]$ given by the grid points

$$t_j = \frac{b}{2}\left(\frac{j}{N}\right)^r, \quad j = 0, 1, \ldots, N, \qquad (3.1)$$

$$t_{N+j} = b - t_{N-j}, \quad j = 1, \ldots, N.$$

Here the real number $r \in [1,\infty)$ characterizes the nonuniformity of the grid Π_N: For $r > 1$ the points (3.1) are more densely clustered near the endpoints of the interval $[0,b]$. It is easy to see that $t_j - t_{j-1} \leq (rb/2)N^{-1}$, $j = 1, \ldots, 2N$.

For given integers $m \geq 0$ and $-1 \leq d \leq m-1$, let $S_m^{(d)}(\Pi_N)$ be the spline space of piecewise polynomial functions on the grid Π_N:

$$S_m^{(d)}(\Pi_N) = \left\{v \in C^d[0,b] : v\big|_{\sigma_j} \in \pi_m,\ j = 1, \ldots, 2N\right\},\ 0 \leq d \leq m-1,$$

$$S_m^{(-1)}(\Pi_N) = \left\{v : v\big|_{\sigma_j} \in \pi_m,\ j = 1, \ldots, 2N\right\}.$$

Here $v\big|_{\sigma_j}$ $(j = 1, \ldots, 2N)$ is the restriction of v onto the subinterval $\sigma_j = [t_{j-1}, t_j] \subset [0,b]$, and π_m denotes the set of polynomials of degree not exceeding m. Note that the elements of $S_m^{(-1)}(\Pi_N)$ may have jump discontinuities at the interior points $t_1, \ldots, t_{2N-1}$ of the grid Π_N.

In every interval $[t_{j-1}, t_j]$, $j = 1, \ldots, 2N$, we introduce $m \geq 1$ interpolation points:

$$t_{jk} = t_{j-1} + \eta_k(t_j - t_{j-1}), \quad k = 1, \ldots, m,\ j = 1, \ldots, 2N, \qquad (3.2)$$

where $\eta_1, \ldots, \eta_m$ are some fixed parameters which do not depend on j and N and satisfy the conditions

$$0 \leq \eta_1 < \cdots < \eta_m \leq 1. \qquad (3.3)$$

To a given continuous function $v : [0,b] \to \mathbf{R}$ we assign a piecewise polynomial interpolation function $\mathcal{P}_N v \in S_{m-1}^{(-1)}(\Pi_N)$, which interpolates v at the points (3.2):

$$(\mathcal{P}_N v)(t_{jk}) = v(t_{jk}), \quad k = 1, \ldots, m,\ j = 1, \ldots, 2N.$$

Thus, $(\mathcal{P}_N v)(t)$ is independently defined in every subinterval $[t_{j-1}, t_j]$, $j = 1, \ldots, 2N$, and may be discontinuous at the points $t = t_j$, $j = 1, \ldots, 2N-1$; we may treat $\mathcal{P}_N v$ as a two-valued function at these points. Note that in the case $\eta_1 = 0$, $\eta_m = 1$, $\mathcal{P}_N v$ is a continuous function on $[0,b]$.

We also introduce an interpolation operator $\mathcal{P}_N$ which assigns to every continuous function $v : [0,b] \to \mathbf{R}$ its piecewise polynomial interpolation function $\mathcal{P}_N v$.

From [22, pp. 115–119], we obtain Lemmas 3.1–3.3 (cf. also [6]).

LEMMA 3.1. *Let the interpolation nodes* (3.2) *with grid points* (3.1) *and parameters* (3.3) *be used. Then* $\mathcal{P}_N \in \mathcal{L}(C[0,b], L^\infty(0,b))$ *and* $\|\mathcal{P}_N\|_{\mathcal{L}(C[0,b],L^\infty(0,b))} \leq c, N \in \mathbf{N}$, *with a positive constant c which is independent of N.*

LEMMA 3.2. *Let $v \in C^{m,\nu}[0,b]$, $m \in \mathbf{N}$, $\nu \in \mathbf{R}$, $\nu < 1$, and let the interpolation nodes* (3.2) *with grid points* (3.1) *and parameters* (3.3) *be used. Then the following estimates hold:*

$$\big\|v - \mathcal{P}_N v\big\|_\infty \le c \begin{cases} N^{-r(1-\nu)} & \text{for} \quad 1 \le r < \dfrac{m}{1-\nu}, \\ N^{-m}(1+\log N) & \text{for} \quad r = \dfrac{m}{1-\nu} = 1, \\ N^{-m} & \text{for} \quad r = \dfrac{m}{1-\nu} > 1 \text{ or } r > \dfrac{m}{1-\nu}, r \ge 1, \end{cases}$$

$$\int_0^b \big|v(t) - (\mathcal{P}_N v)(t)\big| dt \le c \begin{cases} N^{-r(2-\nu)} & \text{for} \quad 1 \le r < \dfrac{m}{2-\nu}, \\ N^{-m}(1+\log N) & \text{for} \quad r = \dfrac{m}{2-\nu} \ge 1, \\ N^{-m} & \text{for} \quad r > \dfrac{m}{2-\nu}, r \ge 1. \end{cases}$$

Here c is a positive constant not depending on N and

$$\big\|v - \mathcal{P}_N v\big\|_\infty = \max_{1 \le j \le 2N} \sup_{t_{j-1} < t < t_j} \big|v(t) - (\mathcal{P}_N v)(t)\big|. \tag{3.4}$$

LEMMA 3.3. *Let the conditions of Lemma* 3.2 *be fulfilled. Then*

$$\sup_{t_{j-1} < s < t_j} |v(s) - (\mathcal{P}_N v)(s)| \le c\,(t_j - t_{j-1})^m \begin{cases} 1 & \text{if} \quad m < 1-\nu, \\ 1 + |\log t_j| & \text{if} \quad m = 1-\nu, \\ t_j^{1-\nu-m} & \text{if} \quad m > 1-\nu, \end{cases}$$

for $j = 1, \ldots, N$, and

$$\sup_{t_{j-1} < s < t_j} |v(s) - (\mathcal{P}_N v)(s)| \le c\,(t_j - t_{j-1})^m \begin{cases} 1 & \text{if} \quad m < 1-\nu, \\ 1 + |\log(b - t_{j-1})| & \text{if} \quad m = 1-\nu, \\ (b - t_{j-1})^{1-\nu-m} & \text{if} \quad m > 1-\nu, \end{cases}$$

for $j = N+1, \ldots, 2N$, with a positive constant c which is independent of j and N.

4. Collocation method. Problem (1.1) is equivalent to problem (2.2), (2.5). In order to solve problem (1.1) we construct a collocation method for the numerical solution of problem (2.2), (2.5).

We look for an approximate solution u_N of (1.1) in the form

$$u_N(t) = \int_0^t v_N(s)ds - \frac{\beta}{\alpha+\beta}\int_0^b v_N(s)ds + \frac{\gamma}{\alpha+\beta}, \quad t \in [0,b], \ N \in \mathbf{N}, \tag{4.1}$$

where v_N satisfies the following conditions:

(4.2)

$$\begin{aligned} & v_N \in S_{m-1}^{(-1)}(\Pi_N), \ m \in \mathbf{N}, \\ & v_N(t_{jk}) = a(t_{jk})\Big(\int_0^{t_{jk}} v_N(s)ds - \frac{\beta}{\alpha+\beta}\int_0^b v_N(s)ds\Big) \\ & \qquad + \int_0^b K(t_{jk},s)\Big(\int_0^s v_N(\tau)d\tau - \frac{\beta}{\alpha+\beta}\int_0^b v_N(\tau)d\tau\Big)ds + f_1(t_{jk}), \\ & \qquad k = 1, \ldots, m, \ j = 1, \ldots, 2N, \end{aligned}$$

with f_1 and $\{t_{jk}\}$ given by the formulas (2.6) and (3.2), respectively.

Remark 4.1. Since $v_N \in S_{m-1}^{(-1)}(\Pi_N)$, then u_N (see (4.1)) belongs to $S_m^{(0)}(\Pi_N) \subset C[0,b]$. If $\eta_1 = 0$ and $\eta_m = 1$ (see (3.3)), then $v_N \in S_{m-1}^{(0)}(\Pi_N) \subset C[0,b]$ and $u_N \in S_m^{(1)}(\Pi_N) \subset C^1[0,b]$.

Remark 4.2. The collocation conditions (4.2) form a system of equations whose exact form is determined by the choice of a basis in $S_{m-1}^{(-1)}(\Pi_N)$ (or in $S_{m-1}^{(0)}(\Pi_N)$ if $\eta_1 = 0$ and $\eta_m = 1$). For instance, in each subinterval $[t_{j-1}, t_j] \subset [0,b]$, $j = 1, \dots, 2N$, we may use the Lagrange fundamental polynomial representation

$$v_N(t) = \sum_{k=1}^{m} c_{jk}\varphi_k\left(\frac{t - t_{j-1}}{t_j - t_{j-1}}\right), \quad t \in [t_{j-1}, t_j],\ j = 1, \dots, 2N,$$

where $c_{jk} = v_N(t_{jk})$,

$$\varphi_k(\tau) = \prod_{q=1,\ q\neq k}^{m} \left(\frac{\tau - \eta_q}{\eta_k - \eta_q}\right), \quad \tau \in [0,1],\ k = 1, \dots, m.$$

The conditions (4.2) then lead to a system of linear algebraic equations for the coefficients c_{jk}, $k = 1, \dots, m$, $j = 1, \dots, 2N$.

Remark 4.3. The conditions (4.2) have the operator equation representation

$$v_N = \mathcal{P}_N T_1 v_N + \mathcal{P}_N f_1, \quad T_1 = (A + T)J, \tag{4.3}$$

with A, T, J and $\mathcal{P}_N$, determined in sections 2 and 3, respectively.

THEOREM 4.1. *Let the conditions of Theorem* 2.1 *be fulfilled and let the interpolation nodes* (3.2) *with grid points* (3.1) *and parameters* (3.3) *be used.*

Then there exists an $N_0 \in \mathbf{N}$ such that, for $N \geq N_0$, the settings (4.2) *determine a unique approximation $v_N \in S_{m-1}^{(-1)}(\Pi_N)$ to $v = u'$, where u is the exact solution of problem* (1.1). *Moreover, if $N \geq N_0$, then an approximation u_N for u is defined by the formula* (4.1), *and the following error estimates hold:*

$$\|u - u_N\|_\infty \leq c \begin{cases} N^{-r(2-\nu)} & \textit{for} \quad 1 \leq r < \dfrac{m}{2-\nu}, \\ N^{-m}(1 + \log N) & \textit{for} \quad r = \dfrac{m}{2-\nu} \geq 1, \\ N^{-m} & \textit{for} \quad r > \dfrac{m}{2-\nu}, r \geq 1, \end{cases} \tag{4.4}$$

$$\|u' - v_N\|_\infty \leq c \begin{cases} N^{-r(1-\nu)} & \textit{for}\ \ 1 \leq r < \dfrac{m}{1-\nu}, \\ N^{-m}(1 + \log N) & \textit{for}\ \ r = \dfrac{m}{1-\nu} = 1, \\ N^{-m} & \textit{for}\ \ r = \dfrac{m}{1-\nu} > 1 \ \textit{or}\ r > \dfrac{m}{1-\nu},\ r \geq 1. \end{cases} \tag{4.5}$$

Here c is a positive constant not depending on N, and the norm $\|\cdot\|_\infty$ is defined by the formula (3.4).

Proof. Due to the assumptions of Theorem 2.1, $f_1 \in C[0,b]$ and $T_1 = (A+T)J$ is compact as an operator from $L^\infty(0,b)$ to $C[0,b]$ and to $L^\infty(0,b)$, too. Since equation $v = T_1 v$ has in $L^\infty(0,b)$ only the trivial solution $v = 0$, then there exists an inverse operator $(I - T_1)^{-1} \in \mathcal{L}(L^\infty(0,b), L^\infty(0,b))$ and equation (2.5) has a unique solution $v = (I - T_1)^{-1} f_1 \in L^\infty(0,b)$. By Theorem 2.1, $v \in C^{m,\nu}[0,b]$. A standard discussion (cf. [6]) together with Lemmas 3.1 and 3.2 yields that there exists a number $N_0 \in \mathbf{N}$ such that for $N \geq N_0$ the operator $(I - \mathcal{P}_N T_1)$ is invertible in $L^\infty(0,b)$ and

$$\left\|(I - \mathcal{P}_N T_1)^{-1}\right\|_{\mathcal{L}(L^\infty(0,b), L^\infty(0,b))} \leq c, \quad N \geq N_0. \tag{4.6}$$

Thus, (4.3) possesses a unique solution $v_N \in S_{m-1}^{(-1)}(\Pi_N)$ for $N \geq N_0$ and

$$\|v - v_N\|_\infty \leq c\|v - \mathcal{P}_N v\|_\infty, \quad N \geq N_0,$$

where $v = u' \in C^{m,\nu}[0,b]$ is the solution of (2.5). This together with Lemma 3.2 yields the estimate (4.5).

Further, using v_N, we find for $N \geq N_0$ an approximation u_N for u in the form (4.1). It follows from (2.2), (2.3), and (4.1) that

$$\begin{aligned} u(t) - u_N(t) &= (J(v - v_N))(t) \\ &= \int_0^t [v(s) - v_N(s)]ds - \frac{\beta}{\alpha + \beta} \int_0^b [v(s) - v_N(s)]ds, \quad t \in [0,b]. \end{aligned} \tag{4.7}$$

Therefore

$$\max_{0 \leq t \leq b} |u(t) - u_N(t)| \leq \left(1 + \left|\frac{\beta}{\alpha + \beta}\right|\right) \int_0^b |v(s) - v_N(s)|ds. \tag{4.8}$$

Since $T_1 = (A + T)J$, $(I - \mathcal{P}_N T_1)(v - v_N) = v - \mathcal{P}_N v$, and

$$\left(I - \mathcal{P}_N T_1\right)^{-1} = I + \left(I - \mathcal{P}_N T_1\right)^{-1} \mathcal{P}_N T_1, \quad N \geq N_0,$$

we get from (4.6) and Lemma 3.1 the estimate

$$\begin{aligned} |v(s) - v_N(s)| \leq &\left|v(s) - (\mathcal{P}_N v)(s)\right| \\ &+ c \textstyle\int_0^b \left|v(t) - (\mathcal{P}_N v)(t)\right| dt, \quad s \in [0,b], \quad N \geq N_0. \end{aligned} \tag{4.9}$$

Now it follows from (4.8) and (4.9) that

$$\|u - u_N\|_\infty \leq c \int_0^b \left|v(t) - (\mathcal{P}_N v)(t)\right| dt, \quad N \geq N_0.$$

This together with $v \in C^{m,\nu}[0,b]$ and Lemma 3.2 yields the estimate (4.4). □

5. Superconvergence phenomenon. It follows from Theorem 4.1 that by using method (4.1), (4.2), one can reach a convergence order

$$\|u - u_N\|_\infty \leq cN^{-m}, \quad \|u' - v_N\|_\infty \leq cN^{-m} \tag{5.1}$$

for sufficiently large values of the grid parameter r and for every choice of collocation parameters $\eta_1, \ldots, \eta_m$ satisfying the condition (3.3). Since $u_N \in S_m^{(0)}(\Pi_N)$, the first estimate of (5.1) is not of optimal order. In the following we show that by a careful choice of the collocation parameters (3.3) it is possible, assuming a little more regularity of functions a, f, and K, to prove a superconvergence result for values of v_N at the collocation points and improve the convergence rate of u_N in the maximum norm. We refer also to the papers [15] and [20], where similar results for initial-value problems of Volterra integro-differential equations are given.

Theorem 5.1. *Let* $a, f \in C^{m+1,\nu}[0,b],\ K \in W^{m+1,\nu}(\Delta),\ m \in \mathbf{N},\ \nu \in \mathbf{R},\ \nu < 1$*;* $\alpha, \beta, \gamma \in \mathbf{R},\ \alpha+\beta \neq 0$*, and assume that problem* (2.1) *has in the set* $\{u \in C[0,b] : u' \in L^\infty(0,b)\}$ *only the trivial solution* $u = 0$*. Moreover, let the interpolation nodes* (3.2) *with grid points* (3.1) *and parameters* (3.3) *be used and let the parameters* $\eta_1, \dots, \eta_m$ *in* (3.3) *be chosen so that the quadrature approximation*

$$\int_0^1 g(s)ds \approx \sum_{k=1}^m w_k g(\eta_k), \quad 0 \le \eta_1 < \cdots < \eta_m \le 1, \tag{5.2}$$

with appropriate weights $w_k = w_k^{(m)},\ k = 1, \dots, m$*, is exact for all polynomials* g *of degree* m*.*

Then the statements of Theorem 4.1 *are valid. Moreover, for all* $N \ge N_0$ *the following error estimates hold:*

$$\max_{k=1,\dots,m,\ j=1,\dots,2N} |u'(t_{jk}) - v_N(t_{jk})| \le c\,\Theta_N(m,\nu,r) \tag{5.3}$$

and

$$\|u - u_N\|_\infty \le c\,\Theta_N(m,\nu,r). \tag{5.4}$$

Here u *is the exact solution of problem* (1.1)*,* u_N*, and* v_N *are determined by method* (4.1), (4.2)*,* c *is a positive constant not depending on* N*,* $\|\cdot\|_\infty$ *is defined by the formula* (3.4)*, and*

$$\Theta_N(m,\nu,r) = \begin{cases} N^{-r(2-\nu)} & \textit{for} \quad 1 \le r < \frac{m+1}{2-\nu}, \\ N^{-m-1}(1+\log N) & \textit{for} \quad r = \frac{m+1}{2-\nu} \ge 1, \\ N^{-m-1} & \textit{for} \quad r > \frac{m+1}{2-\nu},\ r \ge 1. \end{cases} \tag{5.5}$$

Proof. We know from the proof of Theorem 4.1 that (4.3) has a unique solution $v_N \in S_{m-1}^{(-1)}(\Pi_N)$ for $N \ge N_0$. We have for it and v, the solution of (2.5), that

$$(I - \mathcal{P}_N T_1)(v_N - \mathcal{P}_N v) = \mathcal{P}_N T_1(\mathcal{P}_N v - v). \tag{5.6}$$

As $I - \mathcal{P}_N T_1$ is invertible in $L^\infty(0,b)$ for $N \ge N_0$, we obtain from (4.6), (5.6), and Lemma 3.1 the estimate

$$\|\mathcal{P}_N v - v_N\|_\infty \le c\|T_1(v - \mathcal{P}_N v)\|_\infty, \quad N \ge N_0. \tag{5.7}$$

Since $T_1 = (A+T)J$ and $(\mathcal{P}_N v)(t_{jk}) = v(t_{jk}),\ k = 1, \dots, m,\ j = 1, \dots, 2N$, it follows from (2.3), (2.4), and (5.7) that

$$\begin{gathered} |v(t_{jk}) - v_N(t_{jk})| \le \|\mathcal{P}_N v - v_N\|_\infty \le c \max_{0 \le t \le b} \left| \int_0^t [v(s) - (P_N v)(s)]ds \right|, \\ k = 1, \dots, m,\ j = 1, \dots, 2N,\ N \ge N_0. \end{gathered} \tag{5.8}$$

It follows from Theorem 2.1 that $v \in C^{m+1,\nu}[0,b]$. Using this we can show that

$$\max_{0 \le t \le b} \left| \int_0^t [v(s) - (P_N v)(s)]ds \right| \le c\,\Theta_N(m,\nu,r), \tag{5.9}$$

where $\Theta_N(m,\nu,r)$ is given by the formula (5.5). This together with (5.8) and $v=u'$ yields (5.3).

In order to prove (5.9) we choose $m+1$ parameters $0 \le \tilde\eta_1 < \tilde\eta_2 < \cdots < \tilde\eta_{m+1} \le 1$ such that $\{\eta_1 \ldots, \eta_m\} \subset \{\tilde\eta_1, \ldots, \tilde\eta_{m+1}\}$ and set

$$\tilde t_{jk} = t_{j-1} + \tilde\eta_k(t_j - t_{j-1}), \quad k=1,\ldots,m+1,\ j=1,\ldots,2N,$$

where $\{t_j\}$ are given by the formulas (3.1). Moreover, we introduce an operator $\tilde{\mathcal{P}}_N$ which assigns to every continuous function $z : [0,b] \to \mathbf{R}$ its piecewise polynomial interpolation function $\tilde{\mathcal{P}}_N z \in S_m^{(-1)}(\Pi_N)$ such that

$$(\tilde{\mathcal{P}}_N z)(\tilde t_{jk}) = z(\tilde t_{jk}), \quad k=1,\ldots,m+1,\ j=1,\ldots,2N.$$

Due to Lemma 3.2,

$$\int_0^b |v(s) - (\tilde{\mathcal{P}}_N v)(s)| ds \le c\,\Theta_N(m,\nu,r). \tag{5.10}$$

Further, the quadrature approximation (5.2) is exact for all polynomials of degree not exceeding m. This yields that the equality

$$\int_{t_{j-1}}^{t_j} g(s)ds = (t_j - t_{j-1}) \sum_{k=1}^m w_k g(t_{jk}) \quad (j=1,\ldots,2N)$$

holds for all polynomials g of degree not exceeding m. Therefore for $j=1,\ldots,2N$

$$\left|\int_0^{t_j} [v(s) - (P_N v)(s)]ds\right| = \left|\int_0^{t_j} [v(s) - (\tilde P_N v)(s)]ds\right| \le \int_0^b |v(s) - (\tilde P_N v)(s)|ds.$$

This together with (5.10) yields

$$\max_{1\le j\le 2N} \left|\int_0^{t_j} [v(s) - (P_N v)(s)]ds\right| \le c\,\Theta_N(m,\nu,r). \tag{5.11}$$

Fix $t \in [0,b]$ and let $n \in \{1,\ldots,2N\}$ be such that $t \in [t_{n-1}, t_n]$. Actually, we consider only the case $n=1,\ldots,N$. For $n=N+1,\ldots,2N$ the argument is similar. It follows from Lemma 3.3 that

$$\left|\int_{t_{n-1}}^t [v(s) - (\mathcal{P}_N v)(s)]ds\right| \le c(t_n - t_{n-1})^{m+1} \begin{cases} 1 & \text{if} \quad m < 1-\nu, \\ 1 + |\log t_n| & \text{if} \quad m = 1-\nu, \\ t_n^{1-\nu-m} & \text{if} \quad m > 1-\nu. \end{cases}$$

Due to (3.1),

$$\begin{aligned}(t_n - t_{n-1})^{m+1} t_n^{1-\nu-m} &\le c n^{r(2-\nu)-m-1} N^{-r(2-\nu)} \\ &\le c \begin{cases} N^{-r(2-\nu)} & \text{if} \quad r(2-\nu) < m+1, \\ N^{-m-1} & \text{if} \quad r(2-\nu) \ge m+1. \end{cases}\end{aligned}$$

Therefore

$$\left|\int_{t_{n-1}}^t [v(s) - (\mathcal{P}_N v)(s)]ds\right| \le c\,\Theta_N(m,\nu,r), \quad t \in [t_{n-1}, t_n]. \tag{5.12}$$

This together with (5.11) yields (5.9), implying the estimate (5.3).

Let us prove the statement (5.4). Fix $t \in [0, b]$, let $n \in \{1, \dots, 2N\}$ be such that $t \in [t_{n-1}, t_n]$. Using (4.7) and $u' = v$ we obtain that

$$\begin{aligned}|u(t) - u_N(t)| \le \left| \int_0^{t_{n-1}} [v(s) - v_N(s)]ds \right| + \left| \int_{t_{n-1}}^t [v(s) - v_N(s)]ds \right| \\ + \left| \frac{\beta}{\alpha+\beta} \right| \left| \int_0^b [v(s) - v_N(s)]ds \right|, \quad t \in [t_{n-1}, t_n].\end{aligned} \tag{5.13}$$

Consider the first term on the right-hand side of (5.13). We have

$$\begin{aligned}\left| \int_0^{t_{n-1}} [v(s) - v_N(s)]ds \right| \le \left| \int_0^{t_{n-1}} [v(s) - (\tilde{\mathcal{P}}_N v)(s)]ds \right| + \left| \int_0^{t_{n-1}} [(\tilde{\mathcal{P}}_N v)(s) - v_N(s)]ds \right| \\ \le \int_0^b |v(s) - (\tilde{\mathcal{P}}_N v)(s)|ds + \sum_{j=1}^{n-1} (t_j - t_{j-1}) \sum_{k=1}^m |w_k| |v(t_{jk}) - v_N(t_{jk})|.\end{aligned}$$

This together with (5.3) and (5.10) yields

$$\left| \int_0^{t_{n-1}} [v(s) - v_N(s)]ds \right| \le c\,\Theta_N(m, \nu, r). \tag{5.14}$$

In a similar way we obtain that

$$\left| \int_0^b [v(s) - v_N(s)]ds \right| \le c\,\Theta_N(m, \nu, r). \tag{5.15}$$

It remains to estimate the second term on the right-hand side of (5.13). We have

$$\begin{aligned}\left| \int_{t_{n-1}}^t [v(s) - v_N(s)]ds \right| \le \left| \int_{t_{n-1}}^t [v(s) - (\mathcal{P}_N v)(s)]ds \right| \\ + \int_{t_{n-1}}^t |(\mathcal{P}_N v)(s) - v_N(s)|ds, \quad t \in [t_{n-1}, t_n].\end{aligned} \tag{5.16}$$

By (5.8) and (5.9),

$$\int_{t_{n-1}}^t |(\mathcal{P}_N v)(s) - v_N(s)|ds \le (t - t_{n-1}) \|\mathcal{P}_N v - v_N\|_\infty \le c\,\Theta_N(m, \nu, r)$$

for all $t \in [t_{n-1}, t_n]$. This together with the estimates (5.12)–(5.16) yields (5.4). □

Remark 5.1. Problem (1.1) can be rewritten also in the form

$$u = J(A + T)u + Jf + \frac{\gamma}{\alpha + \beta}, \tag{5.17}$$

where J and A, T are defined by the formulas (2.3) and (2.4), respectively. Using (5.17) one can construct another collocation method for the numerical solution of problem (1.1); cf. [6, 18]. This method will be discussed elsewhere.

6. Numerical experiments. Consider the following boundary-value problem:

$$u'(t) = u(t) + f(t) + \int_0^1 |t-s|^{-\frac{1}{2}} u(s)ds, \quad t \in [0,1], \quad u(0)+u(1) = 2. \tag{6.1}$$

The forcing function f is selected so that $u(t) = t^{\frac{3}{2}} + (1-t)^{\frac{3}{2}}$ is the exact solution. Actually, this is problem (1.1), where $a(t) = 1$,

$$f(t) = \tfrac{3}{2}\big(t^{\frac{1}{2}} - (1-t)^{\frac{1}{2}}\big) - \big(t^{\frac{3}{2}} + (1-t)^{\frac{3}{2}}\big) - \big(t^2 + (1-t)^2\big) \int_0^1 x^{-\frac{1}{2}} (1-x)^{\frac{3}{2}} dx$$
$$- t^{\frac{1}{2}} \int_0^1 x^{-\frac{1}{2}} (1-t-xt)^{\frac{3}{2}} dx - (1-t)^{\frac{1}{2}} \int_0^1 x^{-\frac{1}{2}} (t + (1-t)x)^{\frac{3}{2}} dx,$$

$K(t,s) = |t-s|^{-\frac{1}{2}}$, $\alpha = \beta = 1$, $\gamma = 2$, and $b = 1$. Moreover, it is easy to check that $a, f \in C^{m,\nu}[0,b]$ and $K \in W^{m,\nu}(\Delta)$ with $\nu = \frac{1}{2}$ and arbitrary $m \in \mathbf{N}$.

Problem (6.1) is solved numerically by method (4.1), (4.2), in the case $m = 2$. An approximation $v_N \in S_1^{(-1)}(\Pi_N)$ to $v = u'$, the derivative of the solution u of (6.1), is presented in the form (see Remark 4.2)

$$v_N(t) = c_{j1} \frac{t_{j2} - t}{t_{j2} - t_{j1}} + c_{j2} \frac{t - t_{j1}}{t_{j2} - t_{j1}}, \ t \in [t_{j-1}, t_j], \ j = 1, \ldots, 2N,$$

where t_{j1} and t_{j2} are defined by the formula (3.2), with $m = 2$ and $0 \le \eta_1 < \eta_2 \le 1$. If $\eta_1 > 0$ or $\eta_2 < 1$, then the collocation conditions (4.2) lead to a system of $4N$ linear algebraic equations for finding the coefficients $c_{j1} = v_N(t_{j1}), \ c_{j2} = v_N(t_{j2}), \ j = 1, \ldots, 2N$. If $\eta_1 = 0$ and $\eta_2 = 1$, then $t_{j2} = t_{j+1,1} = t_j, \ j = 1, \ldots, 2N-1$, and the collocation conditions (4.2) give us a system of $2N+1$ linear algebraic equations for finding the coefficients $c_{11} = v_N(t_0), \ c_{12} = c_{21} = v_N(t_1), \ldots, c_{2N-1,2} = c_{2N,1} = v_N(t_{2N-1}), \ c_{2N,2} = v_N(t_{2N})$.

In Tables 6.1–6.4 some of the obtained numerical results for different values of the parameters N, r, η_1, and η_2 are presented. The quantities ε_N and ε'_N are the approximate values of the norms $\|u_N - u\|_\infty$ and $\|v_N - u'\|_\infty$, defined as follows:

$$\varepsilon_N = \{\max |u_N(\tau_{jk}) - u(\tau_{jk})| : k = 0, \ldots, 10, \ j = 1, \ldots, 2N\},$$
$$\varepsilon'_N = \{\max |v_N(\tau_{jk}) - u'(\tau_{jk})| : k = 0, \ldots, 10, \ j = 1, \ldots, 2N\},$$

where

$$\tau_{jk} = t_{j-1} + k\frac{t_j - t_{j-1}}{10}, \quad k = 0, \ldots, 10, \quad j = 1, \ldots, 2N.$$

The ratios $\varrho_N = \frac{\varepsilon_{N/2}}{\varepsilon_N}$ and $\varrho'_N = \frac{\varepsilon'_{N/2}}{\varepsilon'_N}$, characterizing the observed convergence rate, are also presented.

In order to facilitate the comparison of numerical experiments with theoretical results we have used the notation $\varrho_N(\delta_r)$ and $\varrho'_N(\delta'_r)$ in the headings of Tables 6.1–6.2, where δ_r and δ'_r are the ratios (that are independent of N) corresponding to the error estimates (4.4) and (4.5) of Theorem 4.1 for $m = 2$, respectively. Since these error estimates do not depend on the values of the parameters η_1 and η_2, satisfying $0 \le \eta_1 < \eta_2 \le 1$, we get the same values for δ_r and for δ'_r in Tables 6.1–6.2.

To illustrate the fact that the superconvergence of the approximate solution in the supremum norm is the result of the superconvergence of the derivative v_N at the collocation points, the errors of v_N at the collocation points, denoted by

$$\xi'_N = \{\max |v_N(t_{jk}) - u'(t_{jk})| : k = 1, \dots, m,\ j = 1, \dots, 2N\},$$

are presented in Table 6.4. Similarly to the previous analysis, we have computed the ratio $\sigma'_N = \frac{\xi'_{N/2}}{\xi'_N}$ and used the notation $\sigma'_N(\delta'_r)$, where δ'_r corresponds to the error estimate (5.3) of Theorem 5.1.

From Tables 6.1–6.4 we can see that the numerical results are in good accordance with the theoretical error estimates of Theorems 4.1 and 5.1.

Acknowledgment. The authors are grateful to both referees for their suggestions and remarks which helped to improve the presentation of the paper.

SPECTRAL METHODS BASED ON PROLATE SPHEROIDAL WAVE FUNCTIONS FOR HYPERBOLIC PDEs[*]

Q.-Y. CHEN[†], D. GOTTLIEB[†], AND J. S. HESTHAVEN[†]

Abstract. We examine the merits of using prolate spheroidal wave functions (PSWFs) as basis functions when solving hyperbolic PDEs using pseudospectral methods.

The relevant approximation theory is reviewed and some new approximation results in Sobolev spaces are established. An optimal choice of the band-limit parameter for PSWFs is derived for single-mode functions.

Our conclusion is that one might gain from using the PSWFs over the traditional Chebyshev or Legendre methods in terms of accuracy and efficiency for marginally resolved broadband solutions.

Key words. prolate spheroidal wave functions, spectral methods, penalty methods

1. Introduction.

Pseudospectral methods for PDEs [6, 13] approximate the solution by classical polynomials (usually Chebyshev or Legendre) or trigonometric polynomials. The main reason for their success is the spectral accuracy, i.e., the convergence rate depends only on the smoothness of the functions being approximated. This comes at a price, however, as the norm of the differentiation matrix is proportional to the square of the number, N, of interpolation points (or the order of the polynomials), resulting in small time-steps ($\sim N^{-2}$) [14], when using an explicit schemes for time integration.

This stringent restriction on the time-step can be attributed to the basis functions being classical orthogonal polynomials, the roots of which cluster near the boundaries of the interval, e.g., the smallest distance between any two roots of a Chebyshev polynomial of degree N is $O(N^{-2})$. In [18], it was suggested to use a singular mapping to change the basis functions to overcome this restriction, and this technique has been successfully used by many people (e.g., [1, 2, 10, 16, 20, 21]). However, as shown in [16, 20] this mapping only allows for doubling the time-step for practical N. If N is large, however, the time-step can be increased to scale as $O(N^{-1})$ [18, 10] without sacrificing the accuracy as the impact of the singular mapping becomes dominated by the finite precision. The mapping destroys the quadrature properties of the roots of the classical polynomials, which may be a disadvantage in certain applications, e.g., when filtering is needed or if integrals must be computed as part of the solution, e.g., in spectral element methods.

In this paper we assess the performance of pseudospectral methods based on prolate spheroidal wave functions (PSWF – ψ_k^c) rather than on polynomials. In [25], the authors demonstrate the merits of using PSWFs for the interpolation, integration

(quadrature), and differentiation of band-limited functions. They show, among other things, that for a prescribed accuracy fewer grid points are required for interpolation and integration than with Chebyshev polynomials. Furthermore, the differentiation matrix has a smaller condition number, approaching $O(N^{3/2})$, which suggest the possibility of increasing the time-step significantly for large values of N.

These basic observations have led to a surge of recent activity in the development of methods based on PSWFs, although the topic itself remains in its infancy. In [4, 5], the author studied the feasibility of using PSWFs as the basis functions in spectral element methods. More recently, in [3] Beylkin and Sandberg developed a two-dimensional solver for the acoustic wave equation by using a basis of approximate PSWFs. However, even basic aspects of approximation and stability theory for methods based on PSWFs remain unknown.

In this work we consider some of these issues, in particular in the context of solving hyperbolic PDEs by constructing pseudospectral methods based on quadrature points and roots associated with the PSWFs. The first step in this direction is to review and expand the relevant approximation theory. We discuss basic approximation properties such as the number of points per wavelength required to recover a meaningful result and show that only two points per wavelength are needed. Thus, the PSWF expansion recovers the Nyquist limit from Fourier theory, although defined on a finite interval. This should be contrasted with polynomial expansions where asymptotic estimates show that at least π points per wavelength are needed [14]. We derive a new result that demonstrates the spectral accuracy of approximations of smooth functions by the PSWFs.

Several variants of pseudospectral PSWF methods based on different interpolation points are subsequently discussed, the main differences being in the definition of the interpolation points, e.g., we consider genuine Gauss-type quadrature points as well as Gauss–Lobatto like points defined as the roots of $(1-x^2)(\psi_N^{2c})'$, where ψ_N^{2c} is the Nth order PSWF with bandwidth $2c$—this approach is clearly inspired by results from classical polynomials although they are in this case not associated with a quadrature. The performance of these slightly different methods are essentially equivalent although the latter choice is more appropriate for solving initial-boundary value problems. We finally consider the performance of these methods for solving a scalar hyperbolic equation as well as hyperbolic systems.

The results of our study can be summarized as follows.

- A practical relation between the two parameters, c and N, is $N = c$ to allow convergence.
- With this choice one observes spectral accuracy. When the solution is broadband and marginally resolved, the PSWF-based method is more accurate than the Chebyshev method with the same number of terms, i.e., generally more efficient.
- Theoretically the time-step Δt can be taken as $O(N^{-\frac{3}{2}})$ if $N \simeq \frac{2}{\pi}c$. However, the accuracy deteriorates significantly in this case.

The remaining part of the paper is organized as follows. In section 2, we present some mathematical background and define the PSWFs. Section 3 contains some approximation results, while section 4 deals with the construction of pseudospectral methods based on PSWFs. We discuss their stability and solve scalar hyperbolic equations as well as hyperbolic systems. In the appendix, we give the details of the proof of the main approximation result.

2. Preliminaries.

In this section, we shall summarize the notation and some general results regarding the PSWFs.

2.1. Prolate spheroidal wave functions.

A function $f(x) : [-1,1] \to [-1,1]$ is band-limited if there exist a $c > 0$ and a function $\phi(t) \in L^2[-1,1]$ such that

$$f(x) = F_c(\phi)(x) = \int_{-1}^{1} e^{icxt}\, \phi(t)\, dt.$$

It is easy to see that F_c: $L^2[-1,1] \to L^2[-1,1]$ is a compact operator, i.e., that it has eigenvalues $\lambda_0, \lambda_1, \lambda_2, \dots$, with the property $|\lambda_{i-1}| \geq |\lambda_i|\ \forall i > 0$. We shall denote by $\psi_j^c(x)$ the eigenfunction corresponding to λ_j. Then

$$\lambda_j\ \psi_j^c(x) \ = \int_{-1}^{1} e^{icxt}\ \psi_j^c(t)\, dt, \qquad x \in [-1,1], \tag{2.1}$$

and the eigenfunctions, $\{\psi_j^c\}_{j=0}^{+\infty}$, are the PSWFs. We choose to normalize them so that $\|\psi_j^c\|_{L^2[-1,1]} = 1$.

One easily checks that the PSWFs also satisfy

$$\mu_j\ \psi_j^c(x) \ = \int_{-1}^{1} \frac{\sin(c(x-t))}{x-t}\ \psi_j^c(t)\, dt, \qquad x \in [-1,1],$$

where

$$\mu_j = \frac{c}{2\pi}|\lambda_j|^2.$$

The following theorem gives some properties of the PSWFs (see [22, 25] and the references therein).

Theorem 2.1. *For all $c \geq 0$,*

- *ψ_0^c, $\psi_1^c, \dots$ are real, orthonormal, smooth, and complete in $L^2[-1,1]$, and they form a Chebyshev system* [17] *on $[-1,1]$;*
- *the ψ_k^c with even k are even functions, and those with odd k are odd;*
- *$\lambda_j = i^j|\lambda_j| \neq 0$, where i is the complex unit;*
- *among $\{\mu_j\}_{j=0}^{\infty}$, about $2c/\pi$ are very close to 1; order* $\log(c)$ *decay exponentially from 1 to nearly 0; the remaining ones are very close to 0.*

Furthermore, there exists a strictly increasing positive sequence $\chi_0, \chi_1, \dots$, such that

$$\Big((1-x^2)(\psi_j^c(x))'\Big)' + \big(\chi_j - c^2x^2\big)\psi_j^c(x) = 0. \tag{2.2}$$

When $c = 0$, the above equation reduces to the classic singular Sturm–Liouville problem with $p(x) = 1 - x^2$, $q(x) = 0$, $\omega(x) = 1$, and $\chi_j = j(j+1)$, i.e., the PSWFs with $c = 0$ are the normalized Legendre polynomials [6, 13].

Following [25], one can evaluate ψ_j^c by expressing it as

$$\psi_j^c(x) = \sum_{k=0}^{\infty} \beta_k^j \overline{P}_k(x), \qquad j = 0, 1, 2, \dots, \tag{2.3}$$

where $\overline{P}_k$ is the normalized Legendre polynomial of degree k. Substituting (2.3) into (2.2) and using the properties of the Legendre polynomials one obtains an eigenvalue problem

$$(A - \chi_j \cdot I)\beta^j = 0. \tag{2.4}$$

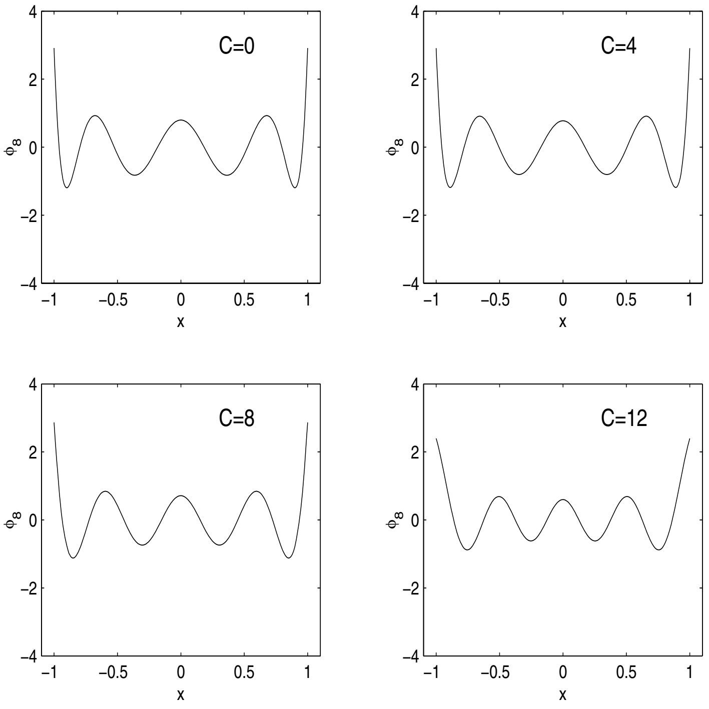

FIG. 2.1. *$\psi_8^c(x)$ for different values of c.*

Here A has the form [25]

$$\begin{cases} A_{k,k} = k(k+1) + \dfrac{2k(k+1)-1}{(2k+3)(2k-1)}\, c^2, \\ A_{k,k+2} = \dfrac{(k+2)(k+1)}{(2k+3)\sqrt{(2k+1)(2k+5)}}\, c^2, \\ A_{k+2,k} = A_{k,k+2} \end{cases}$$

for $k = 0, 1, 2, \dots$, where the remaining entries of A are zeros.

Since ψ_j^c is smooth, the coefficients β_k^j decay superalgebraically with respect to k. The following theorem [25] offers guidelines on where to truncate (2.3) to ensure a certain accuracy in the approximation of ψ_j^c.

THEOREM 2.2. *Assume ψ_m^c is the mth PSWF with band-limit c, and λ_m is the corresponding eigenvalue. If*

$$k \geq 2(\lfloor e \cdot c \rfloor + 1), \tag{2.5}$$

then $\forall c > 0$,

$$\left| \int_{-1}^{1} \psi_m^c(x) \overline{P_k(x)}\, dx \right| < \frac{1}{\lambda_m} \left(\frac{1}{2} \right)^{k-1}. \qquad \square$$

Solving (2.4) and using the corresponding eigenvector in the truncated version of (2.3) allows for the computation of one PSWF (Figure 2.1) for different values of the band-limit, c. In Figure 2.1, we note that the zeros of the PSWF move toward the center as c increases, approaching a uniform distribution. This observation suggests that by choosing a suitable $c > 0$ the PSWF method needs fewer points per wavelength to accurately resolve a wave problem as compared to approximations based on classical orthogonal polynomials. However, it also suggests that if one chooses c too large for a fixed N, the PSWF is unable to represent functions defined on the whole interval.

3. Approximation.

In this section, we consider in more detail the properties of approximations based on PSWFs. We first show that for the single wave $\cos(M\pi x)$, with the optimal $c = M\pi$, the continuous PSWF expansion converges exponentially fast when at least two PSWFs are retained per wavelength. Equivalently, two points per wavelength are required for exponential convergence of the discrete approximation. This should be contrasted with about π points per wavelength needed for methods using classical orthogonal polynomials.

The second result pertains to the approximation of a general smooth function with a finite series of PSWFs. Recall that, for an unknown function, the optimal choice of the bandwidth parameter, c, is unknown and the approximation depends on two parameters, c and N. A natural approach is assume that the parameters are related and our experiments show that $c = N$ is a good choice if we want to maintain the full accuracy (16 digits). We explain why we cannot use $c \geq (\pi/2)N$ and illustrate that there can be benefits in taking $c \simeq (\pi/2)N$, albeit at the price of a lower accuracy.

3.1. Approximation of waves-points per wavelength.

Let us consider the wave $u(x) = e^{iM\pi x}$. It follows directly from (2.1) and Theorem 2.1 that its PSWF expansion is

$$e^{iM\pi x} = \sum_{j=0}^{+\infty} \left(\lambda_j \psi_j^c(1)\right) \psi_j^c(x), \tag{3.1}$$

where $c = M\pi$.

Note that

$$|\lambda_j \psi_j^c(1)|^2 = |\lambda_j||\lambda_j \psi_j^c(1)^2|,$$

where the term $\lambda_j \psi_j^c(1)^2$ is the jth term in the expansion of $e^{i\pi M}$ (cf. (3.1)) and thus bounded—in fact it tends to zero with growing j. From [19], we know that $|\lambda_j|$ decays exponentially with j if $j > \frac{2c}{\pi} = 2M$. This establishes the result: *The accurate resolution of a wave requires two PSWFs per wave.* We recall here that expansions based on Chebyshev or Legendre polynomials require about π points per wave. Only mapped methods [20] may achieve similar resolution results for sufficiently high values of N.

In Figure 3.1, we plot the L^2-error of the truncated PSWF expansion of the function $\cos(M\pi x)$ versus $\frac{N}{M}$ (N is the number of terms in the expansion). It clearly confirms that when $N/M > 2$ the error decays exponentially.

In the above discussion we took $c = M\pi$, which is optimal. However, for general functions, we do not have a simple optimal c (see Figure 3.2) where we display the interpolation results with the PSWFs for two different functions. Clearly, the optimal c depends on the required accuracy and the function being approximated. This is due to the fact that an arbitrary function has many different modes and each mode has a distinct optimal c.

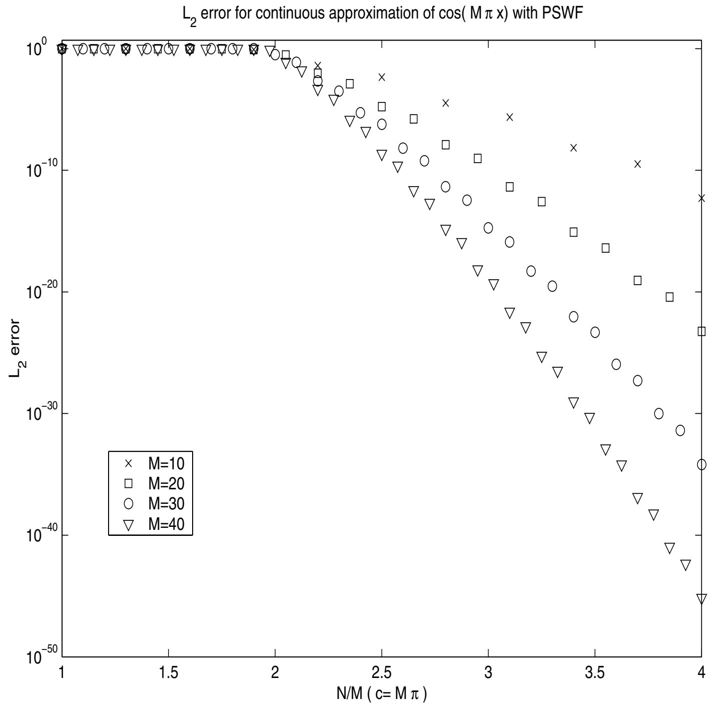

FIG. 3.1. *L^2-error of the PSWF expansion* (*truncated after N terms*) *of* $\cos(M\pi x)$ *versus* N/M. ×: $M = 10$; □: $M = 20$; ○: $M = 30$; ▽: $M = 40$.

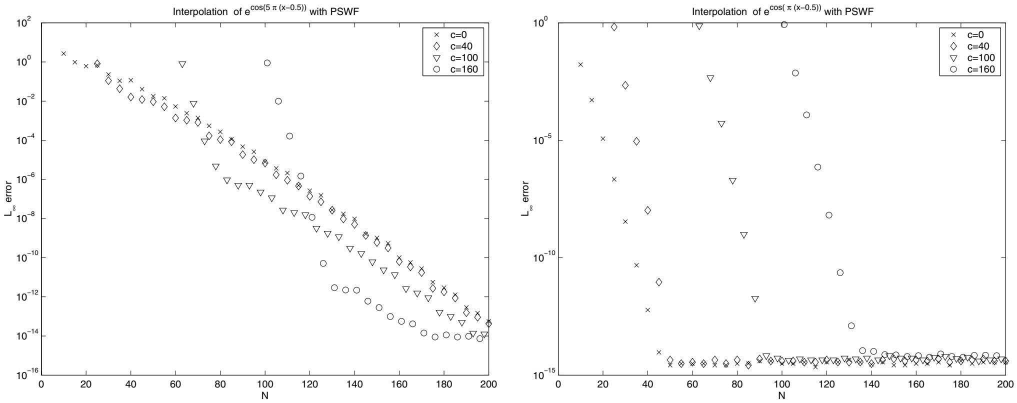

FIG. 3.2. *Demonstration that the optimal c, if it exists, depends on the specific problem and the required accuracy. Left: L_∞-error for the interpolation of* $e^{\cos(5\pi(x-0.5))}$. *For an error around* 10^{-6}, $c = 100$ *is the best choice. For an error as small as* 10^{-10}, $c = 160$ *is optimal. Right: L_∞-error for the interpolation of* $e^{\cos(\pi(x-0.5))}$. *Clearly,* $c = 0$ (*Legendre basis*) *is the best among the four choices.*

3.2. Error estimates. In this section, we consider the error estimates, in a Sobolev norm, of the PSWF expansion of a smooth function. Let $x \in [-1, 1]$, and consider the expansion $u(x) = \sum_{k=0}^{+\infty} \hat{u}_k \psi_k^c(x)$. The order of the convergence of the partial sum $u_N(x) = \sum_{k=0}^{N} \hat{u}_k \psi_k^c(x)$ is determined by

$$\|u - u_N\|_{L^2[-1,1]}^2 \leq \sum_{k=N+1}^{\infty} |\hat{u}_k|^2,$$

i.e., it depends solely on the decay rate of the coefficients $\{\hat{u}_k\}$.

Using the standard notation of $H^s[-1,1]$ for the Sobolev space of functions with distributional derivatives up to order s being square integrable in $L^2[-1,1]$, we prove in the appendix the following theorem.

Theorem 3.1. *Assume that $u \in H^s[-1,1]$ with the PSWF expansion $u(x) = \sum_{i=0}^{+\infty} \hat{u}_i \psi_i^c(x)$.*

If $q_N = \sqrt{\frac{c^2}{\chi_N}} < 1$, then

$$|\hat{u}_N| \leq D \left(N^{-\frac{2}{3}s} \|u\|_{H^s[-1,1]} + (q_N)^{\delta N} \ \|u\|_{L^2[-1,1]} \right), \tag{3.2}$$

where both δ and D are positive constants.

From (3.2) it is evident that the expansion coefficients, $\hat{u}_N$, may exhibit spectral convergence when $q_N < 1$. In [23], it is shown that if n grows with c as

$$n = \frac{2}{\pi} \left[c + b \log(2\sqrt{c}) \right]$$

for some b, then

$$\chi_n \sim c^2 + 2bc + O(1).$$

Thus

$$q_n < 1 \Leftrightarrow \chi_n > c^2 \Leftrightarrow b > 0 \Leftrightarrow n > \frac{2}{\pi} c.$$

Consequently, the finite PSWF expansion of a smooth function, $u \in C^\infty[-1,1]$,

$$\sum_{k=0}^{N} \hat{u}_k \psi_k^c(x)$$

is spectrally accurate if and only if

$$N > \frac{2}{\pi} c.$$

In Figure 3.3, we display the relationship between N and c ensuring that $q_N \leq 1$, obtained directly by solving the eigenvalue problem. This clearly confirms the above result. Figure 3.4 shows the loss of accuracy as N approaches $\frac{2}{\pi}c$. The loss of accuracy partially confirms Theorem 3.1. More precisely, the second term in (3.2) is dominant as N approaches $\frac{2}{\pi}c$, i.e., q_N approaches one. When q_N is very close to one, $(q_N)^{\delta N}$ cannot be small for any moderate N.

We notice that $c = N$ (which guarantees that q_N is bounded away from one) appears to be a good choice if one requires maximum accuracy, although larger values of c may also work if a reduced accuracy is acceptable. In section 4, we will further discuss the issue of choosing c when also considering the time-step and discrete stability.

Similar results are obtained when we use the PSWFs to interpolate a smooth function. In Figure 3.5, we compare interpolations based on PSWF and Chebyshev polynomials. Here we choose the number of grid points $N = c$. The results indicate that the PSWF interpolation is superior for functions with fine structures.

4. Solving PDEs.

In the following we shall discuss the use of the PSWFs as a basis in spectral methods for solving wave problems. Particular attention shall be paid to issues of semidiscrete and fully discrete stability.

4.1. First order wave equation.

Consider the first order one-way wave equation

$$\begin{cases} u_t = u_x, & x \in [-1, 1], \\ u(1, t) = g(t), & \\ u(x, 0) = f(x) & \end{cases} \tag{4.1}$$

for which we shall seek a numerical solution.

Consider the interpolation points $\{x_0, \ldots, x_N\}$ which will be specified later. We define the Prolate–Lagrange function as $L_j(x) = \sum_{k=0}^{N} l_{jk}\psi_k^c(x)$ such that $L_j(x_k) = \delta_{jk}$. The existence of Prolate–Lagrange functions follows from the fact that the PSWFs form a Chebyshev system [17].

In a penalty Galerkin approximation we seek an approximation to the wave problem of the form

$$u_N(x, t) = \sum_{j=0}^{N} u_N(x_j, t) L_j(x)$$

such that the vector $\vec{U} = (u_N(x_0, t), \ldots, u_N(x_N, t))^T$ satisfies the equation

$$M \frac{d\vec{U}}{dt} = S\vec{U} - \tau(u_N(1, t) - g(t))\vec{e}_N. \tag{4.2}$$

Here, the boundary condition is imposed in a penalty way [7, 12, 15]. The matrices $M = (m_{jk})$ and $S = (s_{jk})$ are defined as

$$m_{jk} = \int_{-1}^{1} L_j(x) L_k(x)\, dx, \tag{4.3}$$

$$s_{jk} = \int_{-1}^{1} L_j(x) L_k'(x)\, dx, \tag{4.4}$$

and $\vec{e}_N = (0, \dots, 1)^T$.

THEOREM 4.1 (stability). *The semidiscrete method described in* (4.2) *is stable for* $\tau \geq 1/2$.

Proof. For the stability proof it suffices to assume that $g(t) = 0$. Multiplying (4.2) by $\vec{U}^T$, we get

$$\begin{aligned}
\frac{1}{2}\frac{d}{dt}\left(\vec{U}^T M \vec{U}\right) &= \sum_{jk} u_N(x_j,t) s_{kj} u_N(x_k,t) - \tau u_N(1,t)^2 \\
&= \sum_{jk} \int_{-1}^{1} u_N(x_j,t) u_N(x_k,t) L_j(x) L_k'(x)\, dx - \tau u_N(1,t)^2 \\
&= \int_{-1}^{1} u_N(x,t) \frac{\partial u_N(x,t)}{\partial x} - \tau u_N(1,t)^2 \\
&= \frac{1}{2}\left(u_N(1,t)^2 - u_N(-1,t)^2 - 2\tau u_N(1,t)^2\right).
\end{aligned}$$

Thus, if $\tau \geq \frac{1}{2}$, then

$$\frac{d}{dt} \sum_{jk} \int_{-1}^{1} u_N(x_j,t) u_N(x_k,t) L_j(x) L_k(x)\, dx \leq 0$$

or

$$\frac{d}{dt} \int_{-1}^{1} \left(u_N(x,t)\right)^2\, dx \leq 0.$$

This proves the theorem. □

One way to implement the pseudospectral (collocation) method is to replace the integrals in (4.3) and (4.4) by quadrature formulas based on the points $\{x_k\}$. Alternatively, one can substitute the approximation $u_N(x,t)$ for u into the PDE (4.1) and require that the obtained equation is satisfied at certain collocation points (in most cases $\{x_k\}$ are used as collocation points as well).

For the PSWF collocation method, we do not have a stability proof. The difficulty is caused by the fact that the product of any two of the first N PSWFs with band-limit c is not in the space spanned by the first $2N$ PSWFs with band-limit $2c$ for which the PSWF quadrature is exact. However, when using $\{x_k\}$ as the collocation points, we numerically verify that the eigenvalues of the differentiation matrix have negative real parts.

We shall consider two sets of grid points as $\{x_k\}$: the Gauss–Lobatto PSWF points (one way to compute them is given in [8]) and the zeros of $(1-x^2)(\psi_N^{2c})'$. Note that these points must be computed from PSWF with band-limit $2c$ (see [25]). As we find the performance of the methods based on these two sets of points to be almost equivalent, the latter will be used for the PSWF collocation method if not specified otherwise.

When using explicit time discretization, e.g., Runge–Kutta schemes, one faces a stability limit on the time-step Δt. A necessary condition for stability is that the product of Δt and the largest eigenvalue of the differential matrix, being $M^{-1}(S - \tau \vec{e}_N \vec{e}_N^T)$ in the current scheme, is inside the stability region of the time-stepping scheme.

In Figure 4.1, we observe that for fixed N the magnitude of the largest eigenvalue λ of the PSWF collocation method decreases when c/N increases. So without violating

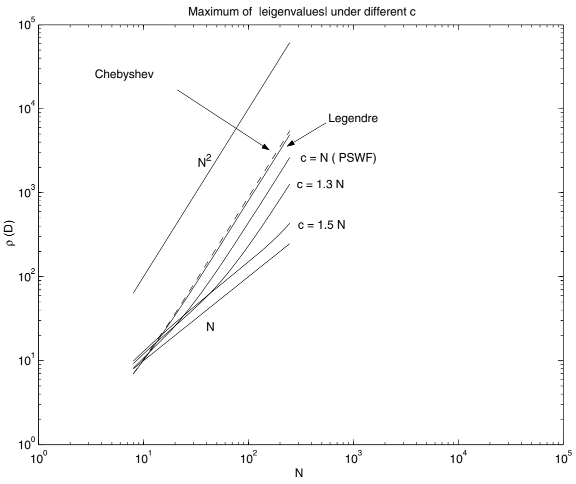

FIG. 4.1. *The largest absolute eigenvalue of the PSWF collocation method using different values of c, and the Chebyshev and Legendre collocation methods.*

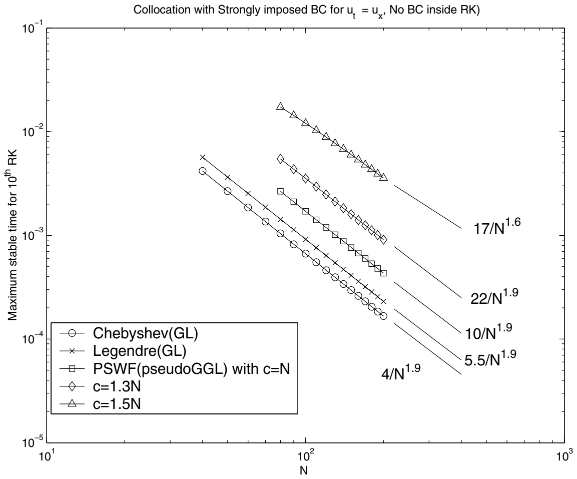

FIG. 4.2. *The largest stable time-step for the PSWF collocation method using different values of c, the Chebyshev and Legendre collocation methods. A* 10*th order explicit Runge–Kutta scheme was used.*

the stability condition, a larger c leads to larger Δt, as confirmed by Figure 4.2. When computing the largest stable time-step, we implemented a 10th order explicit Runge–Kutta scheme, the general form (mth order) for $u_t = Au$ with constant matrix A being given as [6]

$$\begin{aligned} u_1 &= u^n + \frac{\Delta t}{m}\, Au^n, \\ u_k &= u^n + \frac{\Delta t}{m+1-k}\, Au_{k-1}, \qquad k = 2, \dots, m-1, \\ u^{n+1} &= u^n + \Delta t\, Au_{m-1}. \end{aligned}$$

This ensures that the errors from the time integration are negligible.

In Figure 4.2, the largest stable time-step approaches a growth rate $O(N^{-\frac{3}{2}})$, when c goes to $(\pi/2)N$. This suggests that one can use a time-step of order $O(N^{-\frac{3}{2}})$ by letting $c = (\pi/2)N$. However, this choice of c causes a loss of accuracy, as demonstrated in Figure 3.4. In Table 4.1, we list the errors for the time-steps shown in Figure 4.2. It is evident that the accuracy is decreasing when c approaches $(\pi/2)N$. This is consistent with our analysis for the approximation using PSWFs.

Table 4.1

L_∞-error when solving $u_t = u_x$ for $u(x,t) = \cos(2\pi(x+t-0.5))$ with collocation methods. A 10th order explicit Runge–Kutta is used. For each N of each method, Δt is the largest stable time-step shown in Figure 4.2.

N	80	120	160	200
Chebyshev	3.453×10^{-14}	4.952×10^{-14}	1.521×10^{-13}	1.115×10^{-13}
Legendre	7.361×10^{-14}	1.117×10^{-12}	1.274×10^{-12}	1.592×10^{-12}
PSWF($c = N$)	9.770×10^{-15}	9.104×10^{-15}	2.081×10^{-14}	1.482×10^{-14}
PSWF($c = 1.3N$)	3.638×10^{-1}	2.860×10^{-9}	7.133×10^{-12}	9.137×10^{-14}
PSWF($c = 1.5N$)	5.022×10^{-2}	2.968×10^{-1}	8.051×10^{-2}	1.649×10^{-4}

The PSWF method offers a systematic way of balancing accuracy and stability. As a compromise, $c = N$ is used in all subsequent numerical tests. This yields a time-step which is twice the one obtained by a Legendre collocation method without sacrificing accuracy. Similar results can be obtained by using a mapping technique [16]. In some cases it may be beneficial to use a different value of c, e.g., in Figure 3.4, $c = 1.1N$ could be used if only about 10^{-9} accuracy was required. Similar improvements over the traditional Chebyshev collocation methods can also be achieved by the mapping technique which was first presented in [18], albeit at a loss of the quadrature. However, it will be impractical to use the PSWF collocation method if one wants to change c very often, as both the interpolation points and the differentiation matrix have to be recomputed when c is changed.

4.1.1. Numerical tests. The following numerical tests were carried out with a collocation method that determines a nodal approximation $u_N(x,t) = \sum_{j=0}^{N} u_N(x_j,t)L_j(x)$ such that the equation

$$\frac{\partial u_N}{\partial t} - \frac{\partial u_N}{\partial x} = 0 \tag{4.5}$$

is satisfied at the grid points $\{x_j\}$. The boundary condition is applied either strongly or by a penalty procedure as discussed above.

We considered three different initial conditions, listed in Table 4.2.

Table 4.2

Initial condition $f(x)$.

Smooth	Nonsmooth
$\cos(2\pi(x-0.5))$	
$\cos(20\pi(x-0.5))$	$\sin(20\pi(x-0.5)) + H(x-0.5)$

The Heaviside function $H(x)$ is defined as

$$H(x) = \begin{cases} 1 & \text{if } x \leq 0, \\ -1 & \text{otherwise.} \end{cases} \tag{4.6}$$

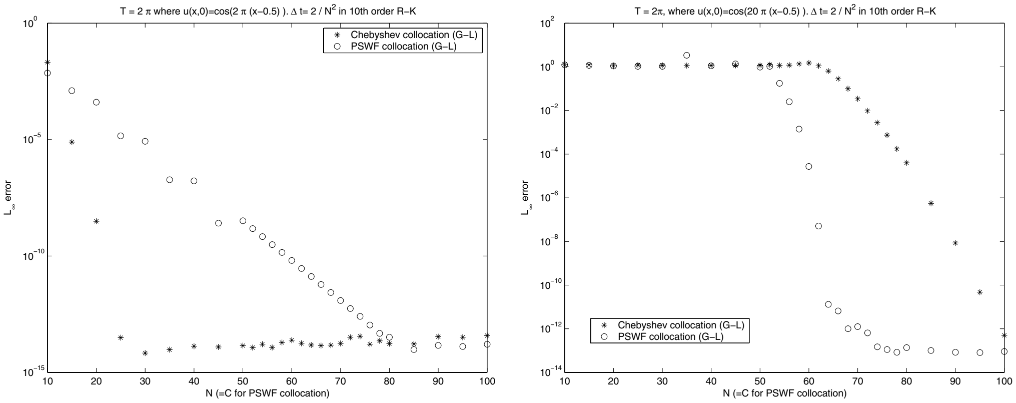

FIG. 4.3. *L_∞-error from solving $u_t = u_x$ with a collocation method and strongly imposed boundary condition. Final time: $T = 2\pi$. 10th order Runge–Kutta with $\Delta t = \frac{2}{N^2}$. Left: $u(x,t) = \cos(2\pi(x - 0.5 + t))$. Right: $u(x,t) = \cos(20\pi(x - 0.5 + t))$. ○: PSWF; ∗: Chebyshev.*

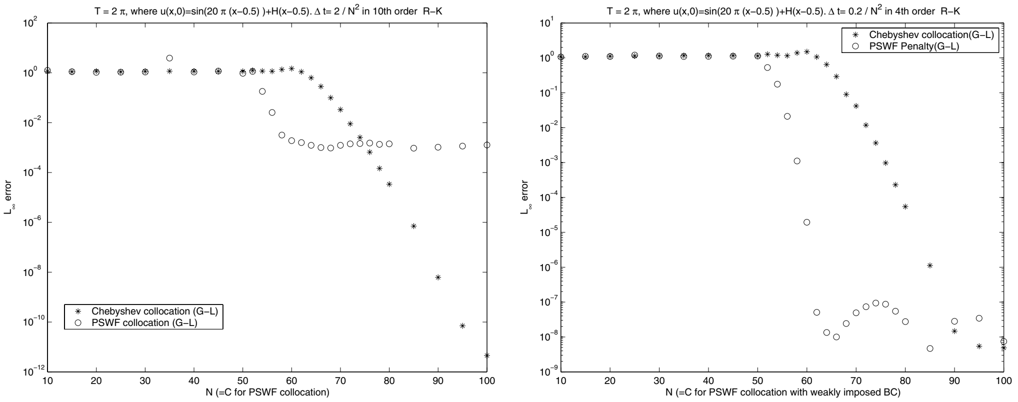

FIG. 4.4. *L_∞-error of solving $u_t = u_x$ by collocation methods. $u(x,0) = \sin(20\pi(x - 0.5)) + H(x - 0.5)$. Final time: $T = 2\pi$. Left: Chebyshev and PSWF collocation methods with strongly imposed boundary condition. Right: PSWF collocation method with weakly imposed boundary condition.*

In Figure 4.3, we show the errors from solving (4.5) with these smooth initial conditions. The Chebyshev method performs better for functions with small wave numbers, whereas the PSWF method is clearly better for functions with large wave numbers.

In Figure 4.4, we present the errors for the discontinuous initial condition. In this case the solution is discontinuous and the point of discontinuity propagates towards the boundary with a speed $a = 1$. We observe that the error does not decay below 10^{-4} when using a strongly imposed boundary condition.

When the boundary condition is imposed by a penalty procedure [7, 15, 12], the PSWF method is superior to the Chebyshev method (see the right part of Figure 4.4). We also applied the Legendre collocation method to solve the equation with discontinuous initial conditions. Similar to the PSWF collocation method, the weakly imposed boundary condition yields more accurate results than the strongly imposed boundary condition.

The improved performance with the weak imposition of the boundary condition

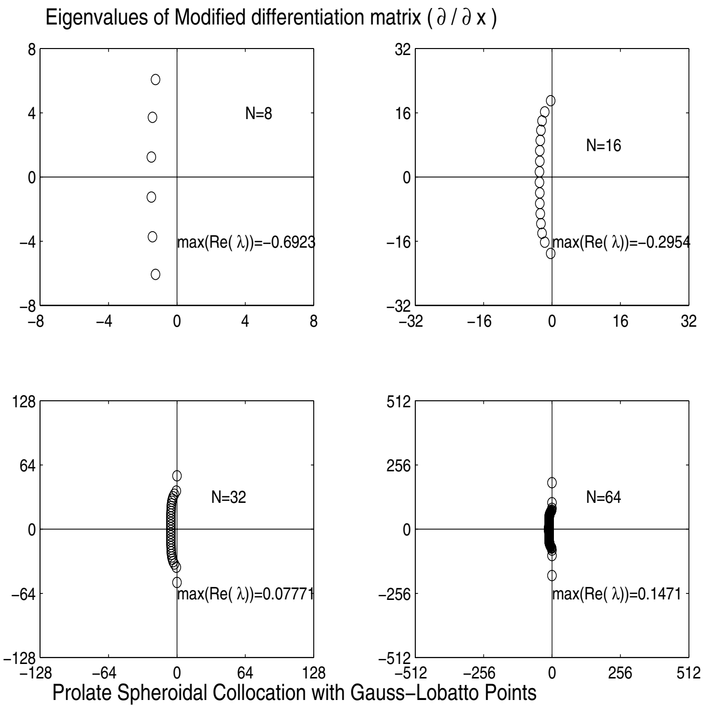

FIG. 4.5. *Eigenvalues of the differentiation matrix for the PSWF collocation method. Boundary condition is imposed strongly.*

can be linked to the behavior of the differentiation matrix. Figures 4.5 and 4.6 show the spectrum of the modified differentiation matrix for the PSWF collocation method with strongly and weakly imposed boundary conditions, respectively. We believe that the positive real parts of eigenvalues for $N = 32$ and 64 in Figure 4.5 are spurious and caused by round-off errors, as discussed in [24] for Chebyshev/Legendre spectral differentiation matrices. These results document the importance of imposing boundary conditions in a penalty way.

4.2. A cavity problem. In this section, we solve the one-dimensional Maxwell equations

$$\begin{cases} \epsilon \dfrac{\partial E}{\partial t} = \dfrac{\partial H}{\partial x}, \\ \mu \dfrac{\partial H}{\partial t} = \dfrac{\partial E}{\partial x}, \end{cases} \tag{4.7}$$

where $E(x,t)$ and $H(x,t)$ are the tangential electric and magnetic fields, and ϵ and μ are the relative permittivity and permeability of the materials.

We shall consider the test case of a one-dimensional cavity $[-1,1]$ filled with two dielectric media with a material interface at $x = 0$. Two perfectly conducting walls are located at $x = -1$ and $x = 1$. Denote by ϵ_1 and μ_1 the relative permittivity and permeability of the material at $[-1,0]$. Similarly, ϵ_2 and μ_2 are the relative permittivity and permeability of the material in $[0,1]$. The electric and magnetic fields in the two domains are denoted by E_1, H_1 and E_2, H_2.

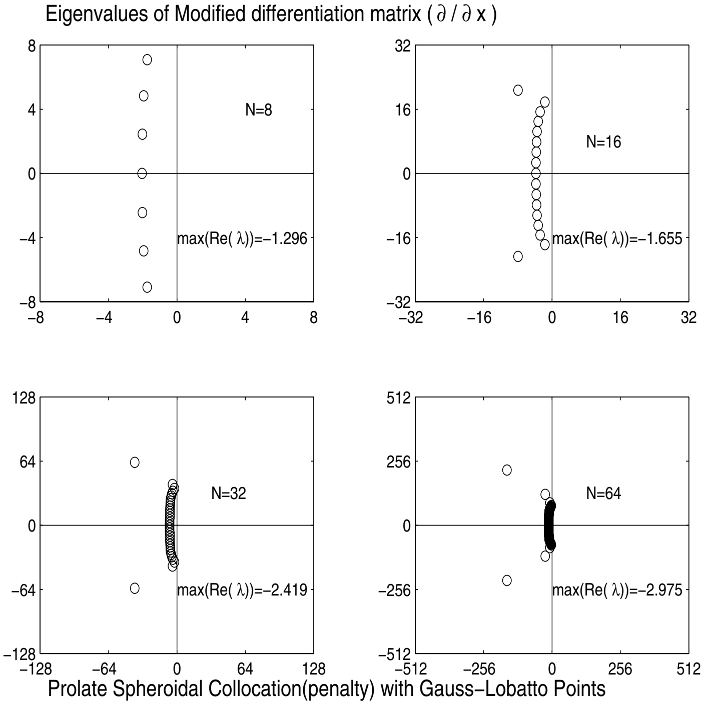

Fig. 4.6. *Eigenvalues of the differentiation matrix for the PSWF collocation method. Boundary condition is imposed weakly.*

Since the walls are perfectly conducting, the boundary conditions are

$$E_1(-1,t) = 0 \quad \text{or} \quad \frac{\partial H_1}{\partial x}|_{x=-1} = 0,$$

$$E_2(1,t) = 0 \quad \text{or} \quad \frac{\partial H_2}{\partial x}|_{x=1} = 0.$$

Denote $n_1 = \sqrt{\epsilon_1}$ and $n_2 = \sqrt{\epsilon_2}$, i.e., $\{n_i\}$ is the index of refraction. In all the following tests, we assume $\mu_1 = \mu_2 = 1.0$, $n_1 = 1$, and $n_2 = 10$.

In Figure 4.7, we display the solution at $t = 0$. (See [9] for the derivation of the exact solution.) When $n_1 \neq n_2$, the solution loses smoothness at the material interface. It is only globally C^0 in $[-1, 1]$. Thus without using domain decomposition, we can only get second order convergence with a Chebyshev or PSWF collocation method (see Figure 4.8). Because of this low order there is limited advantage to the use of the PSWF collocation method, although the PSWF method needs fewer points per wavelength to resolve the solution.

For the pointwise errors from both PSWF and Chebyshev collocations, there is a spike (Figure 4.9) propagating into the left-half domain and whose speed is the speed of a characteristic wave. It is caused by the initial condition being computed from the exact solution to the PDE, rather than an exact solution to the numerical scheme. One can remedy this by computing the initial conditions from the numerical scheme.

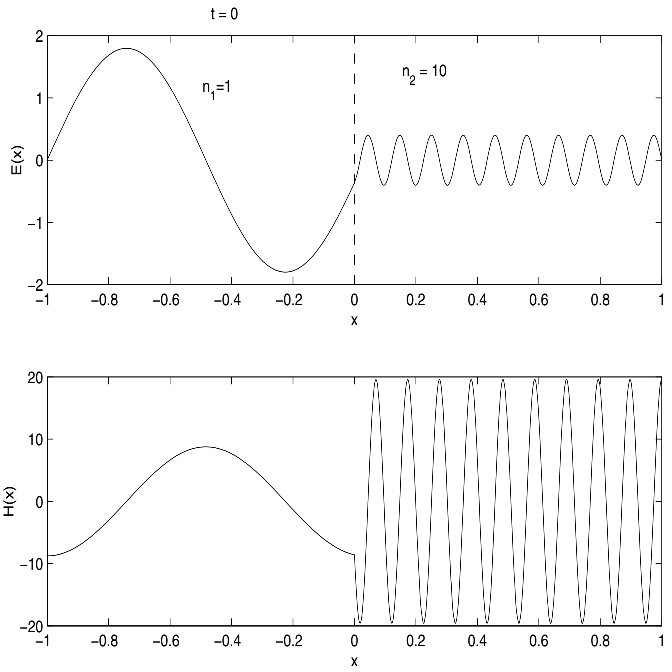

Fig. 4.7. *Exact solution at $t = 0$, $n_1 = 1.0$, $n_2 = 10.0$. Upper: electric field $E(x,t)$. Lower: magnetic field $H(x,t)$.*

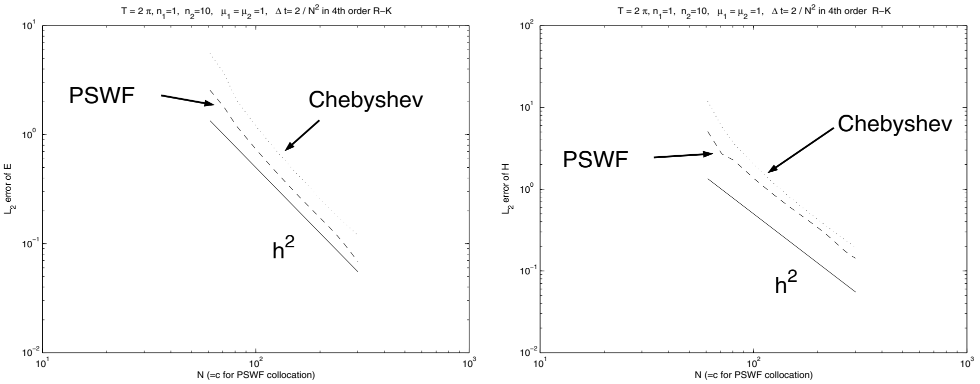

Fig. 4.8. *The discrete L_2-error at $t = 2\pi$. Strongly imposed boundary condition for the Chebyshev collocation method, weakly imposed boundary condition for the PSWF collocation method. Left: electric field $E(x,t)$. Right: magnetic field $H(x,t)$.*

Assume that the semidiscrete equation of (4.7) is

$$\begin{cases} \dfrac{d\vec{E}}{dt} = D_H\, \vec{H}, \\[2ex] \dfrac{d\vec{H}}{dt} = D_E\, \vec{E}. \end{cases} \tag{4.8}$$

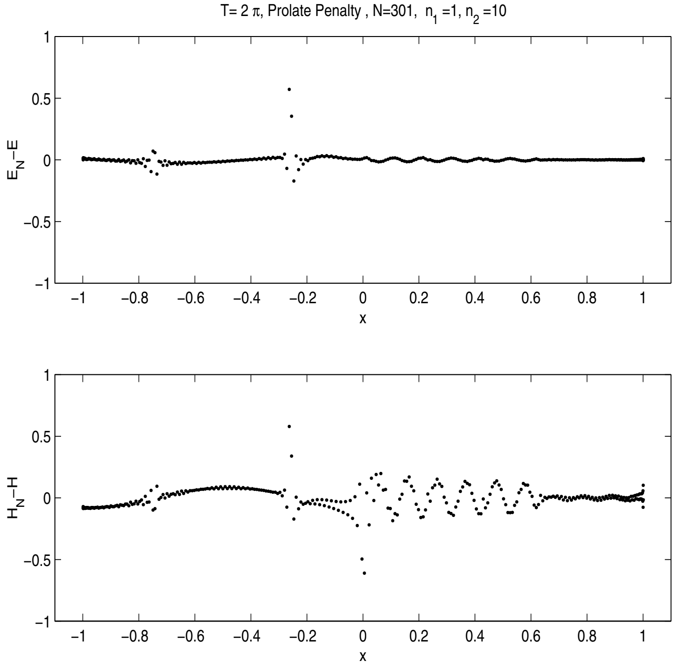

FIG. 4.9. *Pointwise error from the PSWF collocation method.* $c = N = 301$. $t = 2\pi$. *Upper: electric field. Lower: magnetic field.*

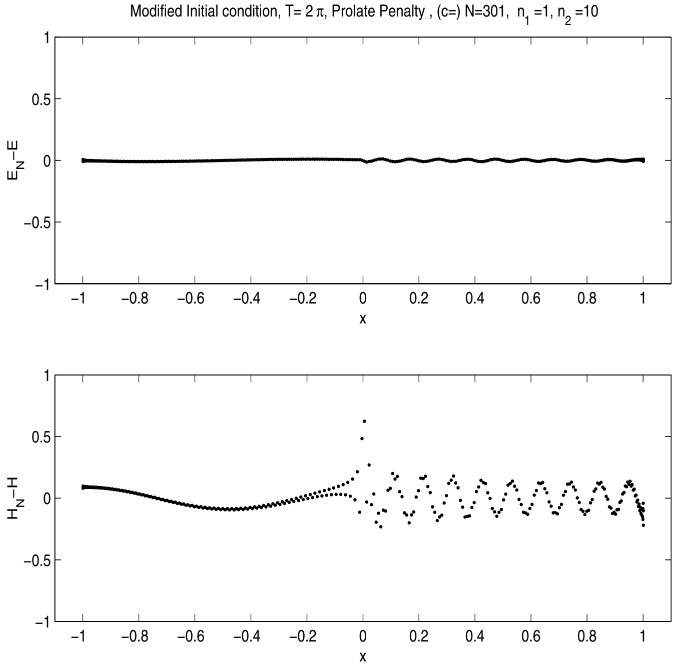

FIG. 4.10. *Pointwise errors with the initial conditions computed from the numerical scheme.*

Take the exact solution to the numerical scheme as $\vec{E} = \tilde{\vec{E}} e^{i\omega t}$ and $\vec{H} = \tilde{\vec{H}} e^{i\omega t}$, and introduce them into (4.8) to obtain an eigenvalue problem,

$$i\omega \begin{pmatrix} \tilde{\vec{E}} \\ \tilde{\vec{H}} \end{pmatrix} = \begin{pmatrix} 0 & D_H \\ D_E & 0 \end{pmatrix} \begin{pmatrix} \tilde{\vec{E}} \\ \tilde{\vec{H}} \end{pmatrix}.$$

The eigenvectors can be used as the initial conditions for the numerical scheme. The new results are shown in Figure 4.10, confirming this to be the source of the spike.

5. Conclusions. Our study of the applicability of PSWF-based methods to the numerical solution of time-dependent PDEs results in the following conclusions:

- The PSWF approximation requires two points per wavelength to resolve a single mode wave function ($\cos(m\pi x)$) if c is chosen as $c = m\pi$.
- Approximating a broadband function $u(x)$ by a finite expansion of the form $\sum_{n=0}^{N} \hat{u}_n \psi_n^c$, one obtains spectral accuracy for $N > \frac{2}{\pi} c$ with loss of accuracy when N approaches the limit. A robust choice is $N = c$.
- When solving the wave equation $u_t = u_x$ with explicit temporal schemes, the CFL bound on the time-step increases as $c \le (\pi/2)N$ increases. Asymptotically, $\Delta t = O(N^{-3/2})$ if c is very close to $(\pi/2)N$. However, this choice results in a deterioration of the accuracy. We found $c = N$ to be a good choice to ensure good accuracy and large stable time-step, the latter effectively increasing by a factor of 2 over methods based on classical orthogonal polynomials.
- For marginally resolved broadband problems, the PSWF-based method with a carefully chosen c is better than the Legendre/Chebyshev collocation methods. Fewer points are needed per wavelength for fast convergence and the allowable time-step is twice as large.
- The weak imposition of the boundary condition is necessary for the success of the method for problems with discontinuous initial conditions. By weakly applying the boundary condition, we improve the spectrum of the first order differentiation matrix of the PSWF collocation method, i.e., moving those eigenvalues with almost zero real parts a little distance away from the imaginary axis, thus introducing a small amount of dissipation.

Appendix. In this appendix, we prove Theorem 3.1.

Let $\beta_k = \beta_k^N$ be the coefficient in the expansion of ψ_N^c in terms of the normalized Legendre polynomials, i.e., $\psi_N^c(x) = \sum_{k=0}^{+\infty} \beta_k^N \overline{P}_k(x)$, where

$$\beta_k = \int_{-1}^{1} \overline{P}_k(x) \psi_N(x)\, dx.$$

The following recurrence relation for β_k is proven in [25]:

$$\begin{aligned} \frac{(k+2)(k+1)}{(2k+3)\sqrt{(2k+5)(2k+1)}}\,\beta_{k+2} &= \left(\frac{\Lambda - k(k+1)}{c^2} - \frac{2k(k+1)-1}{(2k+3)(2k-1)} \right) \beta_k \\ &\quad - \frac{k(k-1)}{(2k-1)\sqrt{(2k-3)(2k+1)}}\,\beta_{k-2}. \end{aligned} \tag{A.1}$$

Note that, from [23], $\Lambda = \chi_N = O(N^2)$. Let m be any integer satisfying

$$m = O(\Lambda^{1/3}) = O(N^{2/3}) \quad \text{and} \quad 2m(2m+1) < \frac{\ln 2}{2} \Lambda. \tag{A.2}$$

Then we have the following lemma.

LEMMA A.1. *Assume* $q = q_N = \sqrt{\frac{c^2}{\Lambda}} < 1$. *Then for any given* $k \leq 2m$, β_k *is bounded by*

$$|\beta_k| \leq \begin{cases} D\left(\frac{2}{q}\right)^k |\beta_0|, & k \text{ even}, \\ D\left(\frac{2}{q}\right)^k |\beta_1|, & k \text{ odd}, \end{cases} \tag{A.3}$$

where D *is a constant independent of* m.

Proof. We give the proof only for even k. The proof for odd k is similar.

Rewrite (A.1) as

$$\beta_{k+2} = \frac{1}{f(k+2)}\left(\frac{1}{q^2}\left(1 - \frac{k(k+1)}{\Lambda}\right) - g(k)\right)\,\beta_k - \frac{f(k)}{f(k+2)}\,\beta_{k-2}, \tag{A.4}$$

where $f(x) = \frac{x(x-1)}{(2x-1)\sqrt{(2x-3)(2x+1)}}$ and $g(x) = \frac{2x(x+1)-1}{(2x+3)(2x-1)}$. It is easy to verify that

$$1/4 \leq f(x) \leq 2\sqrt{5}/15, \qquad \frac{1}{2} \leq g(x) \leq \frac{11}{21} \qquad \text{for } x \geq 2.$$

Therefore, $f(x)/f(x+2) \leq 8\sqrt{5}/15$ when $x \geq 2$.

Since

$$k \leq 2m \Rightarrow \frac{1}{q^2}\left(1 - \frac{k(k+1)}{\Lambda}\right) \geq \frac{1}{q^2}\left(1 - \frac{\ln 2}{2}\right) > \frac{11}{21} \geq g(x) \qquad \text{for } x \geq 2,$$

the coefficient of β_k in (A.4) is positive. Hence, if we assume (A.3) is true for $k, k-2$, we can bound β_{k+2} as

$$\begin{aligned} |\beta_{k+2}| &\leq \frac{1}{f(k+2)}\left(\frac{1}{q^2}\left(1 - \frac{k(k+1)}{\Lambda}\right) - g(k)\right)\,|\beta_k| + \frac{f(k)}{f(k+2)}\,|\beta_{k-2}| \\ &\leq 4\frac{1}{q^2}\left(1 - \frac{\ln 2}{2}\right)\,D\left(\frac{2}{q}\right)^k |\beta_0| + \frac{8\sqrt{5}}{15}\,D\left(\frac{2}{q}\right)^{k-2} |\beta_0| \\ &\leq D\left(\frac{2}{q}\right)^{k+2}\left(1 - \frac{\ln 2}{2} + \frac{\sqrt{5}q^4}{30}\right)|\beta_0| \leq D\left(\frac{2}{q}\right)^{k+2} |\beta_0|. \end{aligned}$$

The last inequality follows from the facts that $q < 1$ and $1 - \frac{\ln 2}{2} + \frac{\sqrt{5}q^4}{30} < 1$. When $k = 0, 2$, (A.3) can be easily satisfied by modifying the constant D. This completes the proof. □

Define

$$A_k = \int_{-1}^{1} x^k \psi_N^c(x)\,dx. \tag{A.5}$$

One can check that $\sqrt{2}\beta_0 = A_0$ and $\sqrt{2/3}\beta_1 = A_1$.

LEMMA A.2. *Let* m *be an integer satisfying* (A.2). *Then*

$$|A_0| \leq Kq^{2m}\sqrt{\frac{2}{4m+1}}, \tag{A.6}$$

where K is a constant independent of m.

Proof. We first show that

$$|A_0| \le q^{2m}|A_{2m}| \prod_{l=1}^{m-1} \frac{1}{1-\frac{2l(2l+1)}{\Lambda}}. \tag{A.7}$$

Rewrite (2.2) as

$$\left((1-x^2)\psi'\right)' + \Lambda(1-q^2x^2)\psi = 0.$$

For $l \le m$, multiply the above equation by x^{2l}, then integrate on $[-1,1]$ to obtain

$$\begin{cases} 2l(2l-1)A_{2l-2} + \left(\Lambda - 2l(2l+1)\right)A_{2l} - \Lambda q^2 A_{2l+2} = 0, & l \ge 1, \\ A_0 - q^2 A_2 = 0, & l = 0. \end{cases}$$

Since $2m(2m+1) \le \Lambda$, all $A_0, A_2, \ldots, A_{2m+2}$ have the same sign. Thus

$$|A_{2l}| \le q^2\ |A_{2l+2}| \frac{\Lambda}{\Lambda - 2l(2l+1)} \le q^2\ |A_{2l+2}| \frac{1}{1-\frac{2l(2l+1)}{\Lambda}}.$$

Then (A.7) follows by induction.

To show (A.6), we note that $1 - x \ge e^{-2x}$ when $0 \le x \le \frac{\ln 2}{2}$. Therefore,

$$1 - \frac{2l(2l+1)}{\Lambda} \ge e^{-2\frac{2l(2l+1)}{\Lambda}} \qquad \text{if } l = 1, 2, \ldots, m-1,$$

which leads to

$$\prod_{l=1}^{m-1} \frac{1}{1-\frac{2l(2l+1)}{\Lambda}} \le e^{\frac{\sum_{l=1}^{m-1} 4l(2l+1)}{\Lambda}} \le e^{\frac{\frac{8}{3}m^3}{\Lambda}}.$$

From (A.2), $m = O(\Lambda^{1/3})$. So (A.5) yields

$$|A_{2m}| \le \|x^{2m}\|_{L^2[-1,1]}\ \|\psi\|_{L^2[-1,1]} \le \sqrt{\frac{2}{4m+1}},$$

which proves (A.6). □

In the same way, one can also show that $|A_1| \le Kq^{2m}\sqrt{\frac{2}{4m+3}}$ under the same conditions on m. We are now ready to prove Theorem 3.1.

Proof of Theorem 3.1. Assume $u(x)$ has the Legendre expansion

$$u(x) = \sum_{k=0}^{+\infty} a_k P_k(x).$$

By definition,

$$\hat{u}_N = \int_{-1}^{1} u(x)\psi_N(x)\,dx = \int_{-1}^{1} \psi_N(x)\left(\sum_{k=0}^{+\infty} a_k P_k(x)\right) dx.$$

Let M be an integer such that

$$\frac{M+1}{2m} = \gamma \frac{\ln(1/q)}{\ln(2/q)}, \tag{A.8}$$

where m is defined in (A.2) and $0 < \gamma < 1$ is a constant. Denote by $u_M(x)$ the partial sum $u_M(x) = \sum_{k=0}^{M} a_k P_k(x)$. Then

$$\hat{u}_N = \int_{-1}^{1} u_M(x)\psi_N(x)\,dx \; + \; \int_{-1}^{1} (u(x) - u_M(x))\,\psi_N(x)\,dx.$$

We use I and II to represent the first and second terms, respectively. According to the error estimate of the Legendre approximation [11, 6],

$$|II| \le \|u - u_M\|_{L^2[-1,1]}\; \|\psi_N(x)\|_{L^2[-1,1]} \le DM^{-s}\|u\|_{H^s[-1,1]},$$

where D is a constant (in the following, D is used for different constants). Now,

$$\begin{aligned}
|I| &= \left|\sum_{k=0}^{M} a_k \int_{-1}^{1} P_k(x)\psi_N(x)\,dx\right| = \left|\sum_{k=0}^{M}\left(a_k\sqrt{\frac{2}{2k+1}}\right)\;\left(\int_{-1}^{1}\overline{P}_k(x)\psi_N(x)\,dx\right)\right| \\
&\le \left(\sum_{k=0}^{M}(a_k)^2\frac{2}{2k+1}\right)^{1/2}\;\left(\sum_{k=0}^{M}\left(\int_{-1}^{1}\overline{P}_k(x)\psi_N(x)\,dx\right)^2\right)^{1/2} \\
&\le \|u\|_{L^2[-1,1]}\;\left(\sum_{k=0}^{M}\beta_k^2\right)^{1/2} \\
&\le D\|u\|_{L^2[-1,1]}\;\left(\sum_{k=0}^{M}\left(\frac{2}{q}\right)^{2k}\right)^{1/2}\quad \max\,(|\beta_0|, |\beta_1|).
\end{aligned}$$

Here Lemma A.1 is used in the last reduction.

From Lemma A.2, $\beta_0 = \frac{1}{\sqrt{2}}A_0 < Kq^{2m}\sqrt{\frac{2}{4m+1}}$ and $\beta_1 = \sqrt{3/2}A_1 < Kq^{2m}\sqrt{\frac{2}{4m+3}}$, where K is a constant. Thus

$$\begin{aligned}
|I| &\le D\|u\|_{L^2[-1,1]}\;\left(\sum_{k=0}^{M}\left(\frac{2}{q}\right)^{2k}\right)^{1/2}\quad q^{2m}\sqrt{\frac{2}{4m+3}} \\
&\le D\|u\|_{L^2[-1,1]}\;\left(\frac{2}{q}\right)^{M+1}\quad q^{2m}\sqrt{\frac{2}{4m+3}} \\
&\le D\|u\|_{L^2[-1,1]}\;\left(q\left(\frac{2}{q}\right)^{\frac{M+1}{2m}}\right)^{2m}\;\sqrt{\frac{2}{4m+3}} \\
&\le D\|u\|_{L^2[-1,1]}\;p^{2m}\sqrt{\frac{2}{4m+3}},
\end{aligned}$$

where $p = q(\frac{2}{q})^{\frac{M+1}{2m}}$.

From (A.8), $p = q^{1-\gamma}$ and $M = O(m) = O(N^{2/3})$. Combining the bounds for I and II, we get

$$|\hat{u}_N| \le D\left(N^{-\frac{2}{3}s}\|u\|_{H^s[-1,1]} + (q_N)^{\frac{2}{3}(1-\gamma)N}\;\;\|u\|_{L^2[-1,1]}\right),$$

which proves Theorem 3.1 with $\delta = \frac{2}{3}(1-\gamma)$. □

OPTIMAL SUPERCONVERGENCE ORDERS OF ITERATED COLLOCATION SOLUTIONS FOR VOLTERRA INTEGRAL EQUATIONS WITH VANISHING DELAYS*

HERMANN BRUNNER[†] AND QIYA HU[‡]

Abstract. In this paper we analyze the optimal convergence properties of collocation approximations to solutions of Volterra integral equations of the second kind with vanishing variable delays. The focus of the analysis is on the superconvergence of the (iterated) collocation approximation corresponding to collocation in the space of (discontinuous) piecewise polynomials of degree $m-1 \geq 0$. We show that on uniform meshes the iterated collocation solution possesses the global superconvergence order $m+1$, and that the solution's order of local superconvergence at the nodes of the underlying mesh cannot exceed $m+2$, in sharp contrast to problems with nonvanishing delays. Moreover, the optimal order $p^* = m+2$ can be attained only under suitable assumptions. This result also resolves a conjecture of 1997 regarding the attainable order of local superconvergence for Volterra integral equations containing a proportional delay qt with $q \in (0,1)$.

Key words. delay integral equation, proportional delays, collocation method, iterated collocation solution, optimal order of superconvergence

AMS subject classification. 65R20

1. Introduction.

In this paper we analyze the optimal orders of global and local superconvergence of iterated collocation solutions to Volterra integral equations with vanishing variable delays,

$$y(t) = f(t) + \int_0^t k_1(t,s,y(s))ds + \int_0^{\theta(t)} k_2(t,s,y(s))ds, \quad t \in J := [0,T], \tag{1.1}$$

where $\theta(t) := t - \tau(t) \geq 0$ is such that the (continuous) delay τ satisfies $\tau(0) = 0$. (Additional assumptions are stated in section 2.1.) Equation (1.1) includes the important special case where τ is the *proportional delay* $\tau(t) = (1-q)t$ with $0 < q < 1$, i.e.,

$$y(t) = f(t) + \int_0^t k_1(t,s,y(s))ds + \int_0^{qt} k_2(t,s,y(s))ds, \quad t \in J \tag{1.2}$$

(see [8, 4]).

It is well known that for classical Volterra integral equations (corresponding to $k_2 \equiv 0$ in (1.1)) the iterated collocation approximation based on collocation in the space of (discontinuous) piecewise polynomials of degree $m-1 \geq 0$ possesses the optimal superconvergence order $p^* = 2m$ at the nodes of the underlying (uniform)

mesh, provided that the collocation parameters are the m Gauss points in $(0, 1)$. For Volterra integral equations with nonvanishing delays (e.g., constant delays), this property is preserved if the mesh is suitably constrained (see [2, 3, 15, 5]).

It was shown in [4] and [23] that these superconvergence properties on uniform meshes do not carry over to (1.1) with $k_2 \not\equiv 0$ and $\tau(t) = (1-q)t$ $(0 < q < 1)$. In fact, for this proportional delay the optimal (local) superconvergence order is at most $p^* = 2m-1$ when $q \neq \frac{1}{2}$; for $q = \frac{1}{2}$ and collocation at the Gauss points it was conjectured that $p^* = 2m$.

In the present paper we investigate the attainable order of the iterated collocation approximation for the general delay integral equation (1.1). We first show that, under natural assumptions, this approximation exhibits global superconvergence of order $m+1$. We then introduce a general condition characterizing meshes for which local superconvergence at the nodes can occur for a given vanishing delay $\tau(t)$ when the collocation points are the m Gauss points. In particular, this holds when the meshes are uniform, the delay has the form $\tau(t) = (1-q)t$ with $q = \frac{1}{2}$, and m is even. This means that the conjecture mentioned above is true only when $m = 2$. Furthermore, we explain why the result no longer holds when $m \geq 3$. A key technique for proving our main result is the use of an inductive (or recursive) method, which was developed in [7], [14], and [15].

The analysis of second-kind Volterra functional integral equations with proportional delays dates back to the work of Volterra [25, pp. 92–101] and Andreoli [1]. Among the more recent contributions to this subject are the papers by Morris, Feldstein, and Bowen [18] (see pp. 518–523), Chambers [8], and Mureşan [19]; see also Brunner [5, Chap. 5]. Related functional integral equations are studied in Esser [11], Iserles and Liu [17], Piila [21], Piila and Pitkäranta [22] (application in the asymptotic membrane theory of hyperbolic shells), and Denisov and Lorenzi [10] (see [10] also for references on applications, and compare with section 6).

Fox et al. [12] were the first to investigate the numerical solution of the so-called pantograph equation,

$$y'(t) = ay(t) + by(qt), \quad t \geq 0, \quad 0 < q < 1. \tag{1.3}$$

In particular, they analyzed the numerical treatment of its integrated form (a special case of (1.2)) by a global method, the τ-method [12, pp. 292–295], and discussed the behavior of the resulting error. The 1990s brought a renewed interest by numerical analysts in (1.3) and its more general versions; see Iserles [16] for an illuminating survey of the difficulties underlying the (stability) analysis of numerical methods for pantograph-type equations. The papers by Brunner [4], Takama, Muroya, and Ishiwata [23], and Brunner, Hu, and Lin [7] focus on the question of optimal local superconvergence in (iterated) collocation solutions for (1.2). It was shown that, on uniform meshes, collocation at the Gauss points will in general not yield the classical optimal order of (local) superconvergence at the mesh points. (See also Muroya, Ishiwata, and Brunner [20].) However, the complete analysis of this problem has remained open.

This paper was above all motivated by the fact that, in order to obtain insight into the superconvergence analysis of collocation approximations for Volterra functional integral equations with *general* vanishing delays or, eventually, with *state-dependent delays*, we first need to fully understand this analysis for the pantograph integral equation (1.2) and its more general version (1.1).

2. Preliminaries.

2.1. The iterated collocation approximation. For ease of exposition, we will consider the linear version of (1.1), namely

$$y(t) = f(t) + \int_0^t K_1(t,s)y(s)ds + \int_0^{\theta(t)} K_2(t,s)y(s)ds, \quad t \in J := [0,T], \tag{2.1}$$

with $\theta(t) := t - \tau(t) \geq 0$. More precisely, we will assume that the delay τ satisfies the following conditions:

(D1) $\tau \in C^\nu(J)$ for some $\nu \geq 1$, with $\tau(0) = 0$ and $\tau(t) > 0$ for $t > 0$;

(D2) $\min_{t\in J} \theta'(t) =: q_0 > 0$.

Regularity assumptions for the given functions τ, f and K_i $(i = 1, 2)$ will be stated in Theorem 4.1 (see also [8], [4], [7], and [5]).

For given $N \in \mathbb{N}$, let $J_N := \{t_n : \; 0 = t_0 < t_1 < \cdots < t_N = T\}$ denote a mesh for the given interval J, and set $e_n := (t_{n-1}, \; t_n], \; h_n := t_n - t_{n-1}$ $(n = 1, \ldots, N)$. In the following we shall be concerned with collocation solutions u lying in the finite-dimensional collocation space

$$S_{m-1}^{(-1)}(J_N) := \{v : \; v|_{e_n} =: v_n \in \mathcal{P}_{m-1} \; (n = 1, \ldots, N)\},$$

where $m \geq 1$ and $\mathcal{P}_{m-1}$ denotes the set of (real) polynomials of degree not exceeding $m - 1$. For a given set of collocation points, $X(N) := \bigcup_{n=1}^N X_n$, with

$$X_n := \{t_{nj} := t_{n-1} + c_j h_n, \; 0 < c_1 < \cdots < c_m \leq 1 \; (n = 1, \ldots, N)\},$$

we are looking for $u \in S_{m-1}^{(-1)}(J_N)$ satisfying the collocation equations

$$u(t) = f(t) + \int_0^t K_1(t,s)u(s)ds + \int_0^{\theta(t)} K_2(t,s)u(s)ds, \quad t \in X(N). \tag{2.2}$$

The collocation equation (2.2) defines a unique approximation $u \in S_{m-1}^{(-1)}(J_N)$ whenever the mesh diameter $h := \max_{(n)} h_n$ is sufficiently small. As for classical Volterra integral equations, this approximation u will be generated recursively by successive computation of its restrictions $u_1, \ldots, u_N$ to the subintervals $e_1, \ldots, e_N$ given by the mesh J_N (compare also [6] or [5]).

When the collocation solution u is known, we obtain the iterated collocation solution u^{it} corresponding to u by setting

$$u^{it}(t) := f(t) + \int_0^t K_1(t,s)u(s)ds + \int_0^{\theta(t)} K_2(t,s)u(s)ds, \qquad t \in J. \tag{2.3}$$

Note that $u^{it}(t) = u(t)$ whenever $t \in X(N)$. We shall see that u^{it} will exhibit a higher order of convergence than u itself if the set $\{c_i\}$ is chosen judiciously (compare sections 3 and 4). However, for $m > 2$, this gain is now no longer as large as in the case of classical Volterra integral equations (Theorem 4.2).

2.2. Notation. We set $Z_N := \{t_n : 1 \leq n \leq N\}$ and define the domains

$$\Omega_1 := \{(t,s) : \; 0 \leq s \leq t \leq T\} \quad \text{and} \quad \Omega_2 := \{(t,s) : \; 0 \leq s \leq \theta(t), \; t \in J\}.$$

We introduce the linear operator $\mathcal{K} : \; L^\infty(J) \to L^\infty(J)$ by setting

$$\mathcal{K}\phi(t) := \int_0^t K_1(t,s)\phi(s)ds + \int_0^{\theta(t)} K_2(t,s)\phi(s)ds, \; t \in J.$$

For a given nonnegative integer k we define the norm $\|\cdot\|_{k,\infty}$ by

$$\|v\|_{k,\infty} := \left(\sum_{n=1}^{N} \|v\|_{k,e_n,\infty}^2\right)^{\frac{1}{2}},$$

where

$$\|v\|_{k,e_n,\infty} := \max_{0\le j\le k}\left(\sup_{t\in e_n}\left|\frac{d^j}{dt^j}v(t)\right|\right).$$

For ease of notation, the norm $\|\cdot\|_{0,e_n,\infty}$ will often be abbreviated by writing $\|\cdot\|_{e_n,\infty}$.

Finally, let $\pi_h : C(J) \to S_{m-1}^{(-1)}(J_N)$ denote the linear interpolation operator such that $\pi_h v(t_{nj}) = v(t_{nj})$ $(n = 1,\dots,N;\ j = 1,\dots,m)$ for $v \in C(J)$. It is well known (see, e.g., [14], [7]) that

$$\|\pi_h v\|_{e_n,\infty} \le C\|v\|_{e_n,\infty} \quad \text{for } v \in C(J) \tag{2.4}$$

and

$$\|(\pi_h - \mathcal{I})v\|_{j,e_n,\infty} \le Ch^{k-j}\|v\|_{k,e_n,\infty}, \quad 0 \le j \le k \le m. \tag{2.5}$$

Here, $\mathcal{I}$ denotes the identity operator.

3. A global superconvergence result. There exist a number of papers dealing with the local superconvergence properties of the iterated collocation solution u^{it} for the delay Volterra integral equations (1.1) and (1.2) at the nodes Z_N (see, for example, [4], [23], [7], and [5]). In this section, we complement these results by one on the attainable order of *global* superconvergence of u^{it} on the entire interval J. Throughout the paper C will denote a generic positive constant that is independent of N but which will depend on the length T of the interval $J = [0,T]$ and on bounds for the given functions τ, f and K_i.

THEOREM 3.1. *Let the functions f and K_i in* (2.1) *satisfy $f \in C^\nu(J)$ and $K_i \in C^\nu(\Omega_i)$ $(i = 1,2)$, and let the delay τ in $\theta(t) = t - \tau(t)$ be subject to* (D1) *and* (D2) (section 2.1))*, with $\nu \ge m+1$. If the collocation parameters $\{c_i\}$ describing the collocation points $X(N)$ satisfy the orthogonality condition*

$$\int_0^1 \prod_{i=1}^{m}(s - c_i)\, ds = 0, \tag{3.1}$$

then we have

$$\max_{t\in J}|y(t) - u^{it}(t)| \le Ch^{m+1} \quad (\text{as } h \to 0^+). \tag{3.2}$$

In the proof of Theorem 3.1 we will have to resort to the following auxiliary results whose proofs can be found in [8], [4], [5] (Lemma 3.2), [7] (Lemma 3.3), and [9, section 6] or [13, pp. 212–213] (Lemma 3.4).

LEMMA 3.2. *Let $l \ge 1$ be a given integer. Assume that the functions f, τ, and K_i in* (2.1) *satisfy f, $\tau \in C^l(J)$ and $K_i \in C^l(\Omega_i)$ $(i = 1,2)$. Then* (2.1) *has a (unique) solution $y \in C^l(J)$.*

LEMMA 3.3. *Under the assumptions stated in Theorem* 3.1 *we have*

$$\|u - y\|_{e_n,\infty} \le Ch^m\|y\|_{e_n,\infty} \tag{3.3}$$

and

$$\|u\|_{j,\infty} \le C\|y\|_{m,\infty},\ 0 \le j \le 2m. \tag{3.4}$$

The next lemma is a standard result in the superconvergence theory for ordinary differential equations and classical (regular) Fredholm and Volterra integral equations of the second kind.

LEMMA 3.4. *Let $1 \le k \le m$. Assume that the collocation parameters $\{c_i\}$ satisfy the orthogonality conditions*

$$\int_0^1 s^r \prod_{i=1}^m (s-c_i)ds = 0, \quad 0 \le r \le k-1.$$

If $\psi \in C^k(J)$ and $\varphi \in C^{m+k}(J)$, then the following estimate is valid for all e_n $(1 \le n \le N)$:

$$\left|\int_{e_n} \psi(t)(\pi - \mathcal{I})\varphi(t)dt\right| \le Ch_n^{m+k+1}\|\psi\|_{k,\infty} \cdot \|\varphi\|_{m+k,\infty}. \tag{3.5}$$

Proof of Theorem 3.1. Since $u \in S_{m-1}^{(-1)}(J_N)$, it follows from the definition of π_h that $\pi_h u = u$. Equations (2.1) and (2.2) may be written in operator form as

$$y = \mathcal{K}y + f \tag{3.6}$$

and

$$u = \pi_h\mathcal{K}u + \pi_h f, \tag{3.7}$$

respectively.

If we subtract (3.6) from (3.7) and set $e := u - y$, we obtain

$$e = \pi_h\mathcal{K}e + (\pi_h - \mathcal{I})(\mathcal{K}y + f).$$

Hence, by observing (3.6),

$$e = \pi_h\mathcal{K}e + (\pi_h - \mathcal{I})y. \tag{3.8}$$

Using an induction argument we first prove that for all $\varphi \in C^1(e_n)$,

$$\left|\int_{e_n} \varphi(s)e(s)ds\right| \le Ch^{m+2}\|\varphi\|_{1,e_n,\infty} \quad (1 \le n \le N). \tag{3.9}$$

It follows by (3.8) that for any $\psi \in C^1(e_1)$ we have

$$\left|\int_{e_1} \psi(s)e(s)ds\right| \le \int_{e_1} |\psi(s)| \cdot |\mathcal{K}e(s)|ds + \left|\int_{e_1} \psi(s)(\mathcal{I} - \pi_h)y(s)ds\right|,$$

which, together with (3.3) and (3.5), yields

$$\begin{aligned}\left|\int_{e_1} \psi(s)e(s)ds\right| \le{}& C(h_1^2\|\psi\|_{e_1,\infty} \cdot \|e\|_{e_1,\infty} \\ &+h_1^{m+2}\|\psi\|_{1,e_1,\infty} \cdot \|y\|_{m+1,e_1,\infty})\end{aligned}$$

$$\begin{aligned} &\leq Ch_1^{m+2}\|\psi\|_{1,e_1,\infty} \cdot \|y\|_{m+1,e_1,\infty} \\ &\leq Ch^{m+2}\|\psi\|_{1,e_1,\infty}. \end{aligned}$$

Here, we have used the fact that $\theta(t) = t - \tau(t) \leq t_1$ for $t \in e_1$.

Assuming that the inequality

$$\left| \int_{e_i} \varphi(s)e(s)ds \right| \leq Ch^{m+2}\|\varphi\|_{1,e_i,\infty} \tag{3.10}$$

is valid for every $\varphi \in C^1(e_i)$ $(1 \leq i \leq n)$, we need to show that, for any $\psi \in C^1(e_{n+1})$,

$$\left| \int_{e_{n+1}} \psi(s)e(s)ds \right| \leq Ch^{m+2}\|\psi\|_{1,e_{n+1},\infty}. \tag{3.11}$$

In fact, by (3.8) we have

$$\left| \int_{e_{n+1}} \psi(s)e(s)ds \right| \leq \int_{e_{n+1}} |\psi(s)| \cdot |\mathcal{K}e(s)|ds + \left| \int_{e_{n+1}} \psi(s)(\mathcal{I} - \pi_h)y(s)ds \right|. \tag{3.12}$$

It is clear that

$$\int_{e_{n+1}} |\psi(s)| \cdot |\mathcal{K}e(s)|ds \leq h_{n+1}\|\psi\|_{e_{n+1},\infty} \cdot \sup_{s\in e_{n+1}} |\mathcal{K}e(s)|. \tag{3.13}$$

For $s \in e_{n+1}$, there is an index n_s such that $\theta(s) \in (t_{n_s}, t_{n_s+1}]$. Using (3.3) and the inductive assumption (3.10), we readily derive the estimate

$$\begin{aligned} |Ke(s)| &\leq \left| \int_0^{t_n} K_1(s,\sigma)e(\sigma)d\sigma + \int_{t_n}^{s} K_1(s,\sigma)e(\sigma)d\sigma \right| \\ &\quad + \left| \int_0^{t_{n_s}} K_2(s,\sigma)e(\sigma)ds + \int_{t_{n_s}}^{\theta(s)} K_2(s,\sigma)e(\sigma)d\sigma \right| \\ &\leq C[n \cdot h^{m+2} + (s - t_n)h_{n+1}^m + n_s \cdot h^{m+2} + (\theta(s) - t_{n_s})h_{n_s+1}^m] \\ &\leq Ch^{m+1} \quad \text{for all } s \in e_{n+1}. \end{aligned} \tag{3.14}$$

Upon substitution of this estimate in (3.13) we obtain

$$\int_{e_{n+1}} |\psi(s)| \cdot |\mathcal{K}e(s)|ds \leq Ch^{m+2}\|\psi\|_{e_{n+1},\infty}.$$

This, together (3.12) and (3.5), gives (3.11). It then follows by the induction principle that the inequality (3.9) is indeed valid for all $n \leq N$.

Consider now the iterated collocation approximation u^{it}. Since (2.3) can be written as

$$u^{it} = f + \mathcal{K}u,$$

subtraction of (3.6) from this equality yields

$$e_{it} := y - u_{it} = \mathcal{K}e.$$

The estimate (3.2) then follows from (3.14) and (3.9).

4. Local superconvergence results. It is clear that the estimate (3.2) also represents the optimal local order of superconvergence result when $m = 1$, since $2m = m + 1$. Hence, we will now consider only collocation approximations $u \in S_{m-1}^{(-1)}(J_N)$ with $m \geq 2$. We will show that if collocation is based on the collocation parameters $\{c_i\}$ given by the m Gauss points in $(0, 1)$ (that is, the zeros of the shifted Legendre polynomial $P_m(2s-1)$), then the order of local superconvergence of u^{it} on Z_N cannot attain the "classical" value $p^* = 2m$ usually associated with the Gauss collocation points; we can achieve only $p^* \leq m + 2$. This implies that a key conjecture in [4] and [7] is false when $m > 2$.

Without loss of generality we may assume that $0 < \theta(t_n) \leq t_n$ for each t_n with $n \geq 1$. Thus, there is an index n' such that $\theta(t_n) \in (t_{n'}, t_{n'+1}]$. For such an index n', define $q_{n'} = (\theta(t_n) - t_{n'})/h_{n'} \in (0, 1]$. Let $L_{m+1}(s)$ be the polynomial of degree $m + 1$ defined by

$$L_{m+1}(s) = \frac{d^{m-1}}{ds^{m-1}}(s(s-1))^m, \quad s \in [0, 1].$$

It is well known that $L'_{m+1}(s) = P_m(2s-1)$.

THEOREM 4.1. *Let the functions f and K_i $(i = 1, 2)$ in* (2.1) *satisfy $f \in C^\nu(J)$, $K_i \in C^\nu(\Omega_i)$, and suppose that the delay τ is subject to the conditions* (D1) *and* (D2) *(section* 2.1*), with $\nu \geq m + 2$. Assume that the nodes $\{t_n\}$ are chosen so that*

$$|L_{m+1}(q_{n'})| \leq Ch_{n'}, \quad n = 1, \dots, N.$$

Then the iterated collocation approximation u^{it} corresponding to the collocation approximation $u \in S_{m-1}^{(-1)}(J_N)$ induces the estimate

$$\max_{t \in Z_N} |y(t) - u^{it}(t)| \leq Ch^{m+2} \quad (as\, h \to 0^+), \tag{4.1}$$

where the exponent $m + 2$ is best possible.

The proof of this key result will be given in the next section.

In the following we focus on Volterra integral equations (2.1) with *proportional delay* $\tau(t) = (1 - q)t$ $(0 < q < 1)$, corresponding to $\theta(t) = qt$.

THEOREM 4.2. *Let the functions f and K_i $(i = 1, 2)$ in* (2.1) *satisfy the assumptions stated in Theorem* 4.1. *Assume that the delay is given by $\tau(t) = (1 - q)t$, with $q = \frac{1}{2}$. If the $\{c_i\}$ are the Gauss points, then on any uniform mesh with sufficiently small diameter $h > 0$ the following is true:*

(1) *The estimate* (4.1) *is valid if and only if m is even.*

(2) *The exponent describing the convergence order in* (4.1) *cannot be replaced by $m + 3$.*

Remark 4.1. We remind the reader that if the original interval $J = [0, T]$ is replaced by $J_0 := [t_0, T]$, with $t_0 > 0$, then the delay τ is strictly positive on J. Thus, the order exponent $m + 2$ in (4.1) can be replaced, for any $m \geq 1$, by the "classical" optimal exponent $2m$ (compare [3], [5]; see also [2]).

In the proof of Theorem 4.2 we shall need the following auxiliary result.

LEMMA 4.3. *Let $k = 1$ or $k = 2$. Then for n' and $q_{n'}$ defined at the beginning of section* 4, *the estimate*

$$\left| \int_{t_{n'}}^{\theta(t_n)} \phi(s) \cdot (\mathcal{I} - \pi_h)\psi(s) ds \right| \leq Ch_{n'}^{m+k+1} \|\phi\|_{k,e_n,\infty} \cdot \|\psi\|_{m+k,e_n,\infty} \tag{4.2}$$

holds for any $\phi \in C^k(e_{n'})$ *and* $\psi \in C^{m+k}(e_{n'})$ *if and only if*

$$\left|\int_0^{q_{n'}} s^{l-1}\prod_{i=1}^{m}(s-c_i)ds\right| \le Ch_{n'}^{k+1-l}, \quad 1 \le l \le k. \tag{4.3}$$

Proof. Let $\tilde{\pi}: C[0,1] \to \mathcal{P}_m[0,1]$ denote the linear interpolation operator associated with the interpolation points $\{c_j\}$. Hence, for any $r \ge 1$ there is a polynomial $p_{r-1}(s)$ of degree $r-1$ such that

$$(I-\tilde{\pi})s^{m+r-1} = p_{r-1}(s)\cdot\prod_{j=1}^{m}(s-c_j), \quad s \in [0,1]. \tag{4.4}$$

Using (4.4) and an obvious transformation of variables, we see that the condition (4.3) is equivalent to the inequality

$$\left|\int_0^{q_{n'}} s^{r_1-1}(I-\tilde{\pi})s^{m+r_2-1}ds\right| \le Ch_{n'}^{k+2-(r_1+r_2)}, \quad r_1+r_2 \le k+1\ (r_1,\ r_2 \ge 1). \tag{4.5}$$

We will first prove that the inequality (4.4) implies the estimate (4.2). By Taylor's formula, we have

$$\phi(s) = \sum_{i=0}^{k-1}\frac{1}{i!}\phi^{(i)}(t_{n'})(s-t_{n'})^i + \frac{1}{k!}\phi^{(k)}(\xi_{n'})(s-t_{n'})^k, \quad \xi_{n'} \in (t_{n'}, s),$$

and

$$\psi(s) = \sum_{i=0}^{m+k-1}\frac{1}{i!}\psi^{(i)}(t_{n'})(s-t_{n'})^i + \frac{1}{(m+k)!}\psi^{(m+k)}(\eta_{n'})(s-t_{n'})^{m+k}, \quad \eta_{n'} \in (t_{n'}, s).$$

Noting that $(\mathcal{I}-\tilde{\pi})s^r = 0$ for $r \le m-1$, we obtain

$$\begin{aligned}
&\left|\int_{t_{n'}}^{\theta(t_n)} \phi(s)\cdot(\mathcal{I}-\pi_h)\psi(s)ds\right| \\
&\le \sum_{i=0}^{k-1}\sum_{j=m}^{m+k-1}\frac{1}{i!j!}\left|\phi^{(i)}(t_{n'})\psi^{(j)}(t_{n'})\int_{t_{n'}}^{\theta(t_n)}(s-t_{n'})^i(\mathcal{I}-\pi_h)(s-t_{n'})^j ds\right| \\
&\quad +\frac{1}{(m+k)!}\sum_{i=0}^{k-1}\frac{1}{i!}\left|\phi^{(i)}(t_{n'})\int_{t_{n'}}^{\theta(t_n)}\psi^{(m+k)}(\eta_{n'})(s-t_{n'})^{i+m+k}ds\right| \\
&\quad +\frac{1}{k!}\sum_{j=m}^{m+k-1}\frac{1}{j!}\left|\psi^{(j)}(t_{n'})\int_{t_{n'}}^{\theta(t_n)}\phi^{(k)}(\xi_{n'})(s-t_{n'})^k(\mathcal{I}-\pi_h)(s-t_{n'})^j ds\right| \\
&\quad +\frac{1}{k!(m+k)!}\left|\int_{t_{n'}}^{\theta(t_n)}\phi^{(k)}(\xi_{n'})(s-t_{n'})^k(\mathcal{I}-\pi_h)\psi^{(m+k)}(\eta_{n'})(s-t_{n'})^{m+k}ds\right| \\
&=: I_1+I_2+I_3+I_4.
\end{aligned} \tag{4.6}$$

The boundedness of the operator π_h implies that there exist constants C_j so that

$$|I_j| \le C_j h_{n'}^{m+k+1}\|\phi\|_{k,e_n,\infty}\cdot\|\psi\|_{m+k,e_n,\infty} \ (j=2,3,4). \tag{4.7}$$

The term I_1 can be estimated by resorting to (4.5): we find that

$$\begin{aligned}|I_1| &\le \sum_{i=0}^{k-1}\sum_{j=m}^{m+k-1}\frac{1}{i!j!}h_{n'}^{i+j+1}\left|\phi^{(i)}(t_{n'})\psi^{(j)}(t_{n'})\int_0^{q_{n'}}s^i(\mathcal{I}-\tilde{\pi})s^j ds\right|\\ &\le C_1\sum_{i+j<m+k}h_{n'}^{i+j+1}\left|\int_0^{q_{n'}}s^i(\mathcal{I}-\tilde{\pi})s^j ds\right|\cdot\|\phi\|_{k-1,e_n,\infty}\cdot\|\psi\|_{m+k-1,e_n,\infty}\\ &\quad +C_1\sum_{i+j\ge m+k}h_{n'}^{i+j+1}\left|\int_0^{q_{n'}}s^i(\mathcal{I}-\tilde{\pi})s^j ds\right|\cdot\|\phi\|_{k-1,e_n,\infty}\cdot\|\psi\|_{m+k-1,e_n,\infty}\\ &\le C_1 h_{n'}^{m+k+1}\|\phi\|_{k-1,e_n,\infty}\cdot\|\psi\|_{m+k-1,e_n,\infty}.\end{aligned}$$

The result (4.2) readily follows by substituting these four estimates into (4.6).

We now prove the reverse conclusion, namely that (4.2) implies (4.5). For any two positive integers r_1 and r_2 satisfying $r_1+r_2\le k+1$, we have

$$\begin{aligned}&\left|\int_{t_{n'}}^{\theta(t_n)}(s-t_{n'})^{r_1-1}(\mathcal{I}-\pi_h)(s-t_{n'})^{m+r_2-1}ds\right|\\ &\qquad = h_{n'}^{m+r_1+r_2-1}\left|\int_0^{q_{n'}}s^{r_1-1}(\mathcal{I}-\tilde{\pi})s^{m+r_2-1}ds\right|\end{aligned}$$

or

$$\begin{aligned}&\left|\int_0^{q_{n'}}s^{r_1-1}(\mathcal{I}-\tilde{\pi})s^{m+r_2-1}ds\right|\\ &\qquad = h_{n'}^{-(m+r_1+r_2-1)}\left|\int_{t_{n'}}^{\theta(t_n)}(s-t_{n'})^{r_1-1}(\mathcal{I}-\pi_h)(s-t_{n'})^{m+r_2-1}ds\right|.\end{aligned}$$

This, together with (4.2), setting $\phi(t)=(s-t_{n'})^{r_1-1}$ and $\psi(t)=(s-t_{n'})^{m+r_2-1}$, respectively, leads to (4.5).

Proof of Theorem 4.2. Since the mesh J_N is assumed to be uniform ($t_n=nh$ for $0\le n\le N$), and since $\theta(t)=qt$, we have $n'=\lfloor qn\rfloor$ (if qn is not an integer) or $n'=qn-1$ (if qn is an integer). Thus,

$$q_{n'}=qn-n'=\begin{cases} qn-\lfloor qn\rfloor & \text{if } qn \text{ is not an integer,}\\ 1 & \text{if } qn \text{ is an integer.}\end{cases}$$

In particular, for $q=\frac{1}{2}$ we obtain

$$q_{n'}=\begin{cases}\frac{1}{2} & \text{if } n \text{ is odd,}\\ 1 & \text{if } n \text{ is even.}\end{cases}$$

(1) It is well known that while the polynomial $L_{m+1}(s)$ has roots at $s=0$ and $s=1$ for every m, it has a root at $s=\frac{1}{2}$ if and only if m is even. This means that when $q=\frac{1}{2}$ and m is even, the number $q_{n'}$ is a root of the polynomial $L_{m+1}(s)$ for every n. Thus, it follows by Theorem 4.1 that the estimate (4.1) is valid when m is an even number.

To arrive at the reverse conclusion, we need only to show that the estimate

$$|e^{it}(t_1)|\le Ch^{m+2} \tag{4.8}$$

is not true when m is odd.

It follows from (3.8) that

$$e^{it}(t_1) = \mathcal{K}e(t_1) = (\mathcal{K}\pi_h\mathcal{K}e)(t_1) + (\mathcal{K}(\pi_h - \mathcal{I})y)(t_1).$$

Thus,

$$\int_0^{\theta(t_1)} (\pi_h - \mathcal{I})y(s)ds = e^{it}(t_1) - (\mathcal{K}\pi_h\mathcal{K}e)(t_1) - \int_0^{t_1} (\pi_h - \mathcal{I})y(s)ds. \tag{4.9}$$

It is easy to see (recalling the proof of Theorem 3.1) that

$$\left|(\mathcal{K}\pi_h\mathcal{K}e)(t_1) - \int_0^{t_1} (\pi_h - \mathcal{I})y(s)ds\right| \le Ch^{m+2}.$$

If the inequality (4.8) is true, it follows by (4.9) that

$$\left|\int_0^{\theta(t_1)} (\pi_h - \mathcal{I})y(s)ds\right| \le Ch^{m+2}.$$

This, together with Lemma 4.3, implies that

$$\left|\int_0^{\frac{1}{2}} \prod_{i=1}^{m} (s - c_i)ds\right| \le Ch$$

(note that $q_{1'} = \frac{1}{2}$). Thus,

$$\left|L_{m+1}\left(\frac{1}{2}\right)\right| = \left|\int_0^{\frac{1}{2}} P_m(2s-1)ds\right| = \left|\text{const} \cdot \int_0^{\frac{1}{2}} \prod_{i=1}^{m} (s - c_i)ds\right| \le Ch.$$

But $|L_{m+1}(\frac{1}{2})|$ is a positive constant when m is odd, independent of h, which contradicts the above inequality. Therefore, the inference

$$|e^{it}(t_1)| \le Ch^{m+2}$$

is false.

(2) Since the inequality (4.1) is already the optimal local superconvergence result when $m = 2$, it suffices to show that the estimate

$$|e^{it}(t_1)| \le Ch^{m+3} \tag{4.10}$$

is not valid when $m \ge 3$ is even.

Subtraction of (3.6) from (3.7) leads to

$$e = \mathcal{K}e + (\pi_h - \mathcal{I})(\mathcal{K}u + f) = \mathcal{K}e + (\pi_h - \mathcal{I})\tilde{u}. \tag{4.11}$$

Hereafter, we set $\tilde{u} := \mathcal{K}u + f$. Using the substitution technique introduced in [15], we are led to

$$e = \mathcal{K}^2 e + \mathcal{K}(\pi_h - \mathcal{I})\tilde{u} + (\pi_h - \mathcal{I})\tilde{u}.$$

Thus,

$$e^{it}(t_1) = (\mathcal{K}^3 e)(t_1) + (\mathcal{K}^2(\pi_h - \mathcal{I})\tilde{u})(t_1) + (\mathcal{K}(\pi_h - \mathcal{I})\tilde{u})(t_1). \tag{4.12}$$

It follows by (3.6)–(3.7) that

$$|(\mathcal{K}^3 e)(t_1)| \le Ch^{m+3}, \tag{4.13}$$

and hence

$$\left| \int_0^{t_1} K_1(t_1, s)(\pi_h - \mathcal{I})\tilde{u}(s)ds \right| \le Ch^{2m}. \tag{4.14}$$

Since the kernel $K_2(t,s)$ can be written as $K_2(t,s) = (t-s)\tilde{K}_2(t,s)$, where $\tilde{K}_2(t,s)$ is a (smooth) function, the use of (2.5) and (3.4)–(3.5) allows us readily to verify that

$$|(\mathcal{K}^2(\pi_h - \mathcal{I})\tilde{u})(t_1)| \le Ch^{m+3}. \tag{4.15}$$

We now deduce from (4.12) and (4.13)–(4.15) that estimate (4.10) is equivalent to

$$\left| \int_0^{\frac{1}{2}t_1} K_2(t_1, s)(\pi_h - \mathcal{I})\tilde{u}(s)ds \right| \le Ch^{m+3}. \tag{4.16}$$

It is easy to see that

$$\left| \int_0^{\frac{1}{2}} \left(s \cdot \prod_{i=1}^{m} (s - c_i) \right) ds \right| = \left| \text{const.} \int_0^{\frac{1}{2}} sP_m(2s-1)ds \right|$$

is a positive constant which cannot be bounded by Ch (as $h \to 0$). It follows by Lemma 4.3 with $k = 2$ that the inequality (4.16) does not hold. Thus, the estimate (4.10) is not valid.

Remark 4.2. The papers [4] and [7] deal with collocation methods for Volterra integral equations with proportional delays. They conjectured (based on extensive numerical experiments using $m = 2$) that when $q = \frac{1}{2}$, the optimal order of local superconvergence for the iterative collocation approximation is $2m$, provided collocation is at the Gauss points. Theorem 4.2 indicates that this conjecture is indeed true for $m = 2$ but becomes false for $m \ge 3$.

5. Proof of Theorem 4.1.

As we shall see, the proof of Theorem 4.1 has many similarities with that of Theorem 3.1 but is considerably more complex.

It suffices to prove inductively that, for all $\varphi \in C^2(J)$,

$$\left| \int_{t_{n'}}^{\theta(t_n)} \varphi(t)e(t)dt \right| \le Ch^{m+2} \|\varphi\|_{2,e_{n'},\infty} \quad (1 \le n \le N) \tag{5.1}$$

and

$$\left| \int_0^{t_n} \varphi(t)e(t)dt \right| \le Ch^{m+2} \|\varphi\|_{2,[0,t_n],\infty} \quad (1 \le n \le N). \tag{5.2}$$

To verify this we first rewrite (4.13) as

$$e(t) = \int_0^t K_1(t,s)e(s)ds + A(t), \qquad t \in J,$$

with

$$A(t) := (\pi_h - \mathcal{I})\tilde{u}(t) + \int_0^{\theta(t)} K_2(t,s)e(s)ds.$$

Let R_1 be the resolvent kernel of K_1. The classical Volterra theory (see, e.g., [6] or [5]) implies that R_1 inherits the smoothness of the kernel K_1. Thus, the solution of the above Volterra integral equation for $e(t)$ can be represented in the form

$$e(t) = A(t) + \int_0^t R_1(t,s)A(s)ds, \quad t \in J. \tag{5.3}$$

By our assumption and by Lemma 4.3 (with $k = 1$) we have

$$\left| \int_{t_{n'}}^{\theta(t_n)} \varphi(t)(\pi_h - \mathcal{I})\tilde{u}(t)dt \right| \leq Ch^{m+2}\|\varphi\|_{2,e_n,\infty}, \quad 1 \leq n \leq N \tag{5.4}$$

(recall (3.4)).

Consider first the case $n = 1$. From (5.3) we have, for any $\varphi {\in} C^2(e_1)$,

$$\begin{aligned}\int_0^{\theta(t_1)} \varphi(t)e(t)dt &= \int_0^{\theta(t_1)} \varphi(t)A(t)dt + \int_0^{\theta(t_1)} \left(\varphi(t)\int_0^t R_1(t,s)A(s)ds\right) dt \\ &= \int_0^{\theta(t_1)} \varphi(t)(\pi_h - \mathcal{I})\tilde{u}(t)dt + \int_0^{\theta(t_1)} \left(\varphi(t)\int_0^{\theta(t)} K_2(t,s)e(s)ds\right) dt \\ &\quad + \int_0^{\theta(t_1)} \left(\varphi(t)\int_0^t R_1(t,s)(\pi_h - \mathcal{I})\tilde{u}(s)ds\right) dt \\ &\quad + \int_0^{\theta(t_1)} \varphi(t)\int_0^t \left(R_1(t,s)\int_0^{\theta(s)} K_2(s,\sigma)e(\sigma)d\sigma\right) ds\, dt.\end{aligned}$$

This, together with (2.5), (3.3), and (5.4), leads to (5.1) with $n = 1$, since

$$\left| \int_0^{\theta(t_1)} \varphi(t)e(t)dt \right| \leq Ch^{m+2}\|\varphi\|_{2,e_1,\infty}. \tag{5.5}$$

In an analogous way we can now verify that (5.2) is valid for $n = 1$, by using (3.5) and (5.5).

Assume then that the inequalities

$$\left| \int_{t_{n'}}^{\theta(t_n)} \varphi(t)e(t)dt \right| \leq Ch^{m+2}\|\varphi\|_{2,e_{n'},\infty} \tag{5.6}$$

and

$$\left| \int_0^{t_n} \varphi(t)e(t)dt \right| \leq Ch^{m+2}\|\varphi\|_{2,[0,t_n],\infty} \tag{5.7}$$

hold for every $\varphi \in C^2[0,t_n]$ and for $1 \leq n < N$. We need to prove that, for any $\varphi \in C^2[0,t_{n+1}]$,

$$\left| \int_{t_{(n+1)'}}^{\theta(t_{n+1})} \varphi(t)e(t)dt \right| \leq Ch^{m+2}\|\varphi\|_{2,e_{(n+1)'},\infty} \tag{5.8}$$

and

$$\left|\int_0^{t_{n+1}} \varphi(t)e(t)dt\right| \le Ch^{m+2}\|\varphi\|_{2,[0,t_{n+1}],\infty}. \tag{5.9}$$

For any $\varphi \in C^2(e_{n+1})$, we have

$$\begin{aligned}\left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})} \varphi(t)e(t)dt\right| &= \left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})} \varphi(t)A(t)dt + \int_{t_{(n+1)'}}^{\theta(t_{n+1})} \left(\varphi(t)\int_0^t R_1(t,s)A(s)ds\right)dt\right| \\ &\le \left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})} \varphi(t)(\pi_h - \mathcal{I})\tilde{u}(t)dt\right| \\ &\quad + \left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})} \left(\varphi(t)\int_0^{\theta(t)} K_2(t,s)e(s)ds\right)dt\right| \\ &\quad + \left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})} \left(\varphi(t)\int_0^t R_1(t,s)(\pi_h - \mathcal{I})\tilde{u}(s)ds\right)dt\right| \\ &\quad + \left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})} \varphi(t)\int_0^t \left(R_1(t,s)\int_0^{\theta(s)} K_2(s,\sigma)e(\sigma)d\sigma\right)ds\,dt\right| \\ &=: I_1 + I_2 + I_3 + I_4.\end{aligned} \tag{5.10}$$

By (5.4) and (3.4) we readily obtain

$$I_1 \le Ch^{m+2}\|\varphi\|_{2,e_{(n+1)'},\infty}. \tag{5.11}$$

It follows by (2.5) and (3.5) that

$$\begin{aligned}I_3 &\le \left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})} \left(\varphi(t)\int_0^{t_{(n+1)'}} R_1(t,s)(\pi_h - \mathcal{I})\tilde{u}(s)ds\right)dt\right| \\ &\quad + \left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})} \left(\varphi(t)\int_{t_{(n+1)'}}^t R_1(t,s)(\pi_h - \mathcal{I})\tilde{u}(s)ds\right)dt\right| \\ &\le Ch^{m+2}\|\varphi\|_{2,e_{(n+1)'},\infty}.\end{aligned} \tag{5.12}$$

Here, we have used the relation

$$t - t_{(n+1)'} \le \theta(t_{n+1}) - t_{(n+1)'} \le h_{(n+1)'}, \quad t_{(n+1)'} \le t \le \theta(t_{n+1}).$$

The estimate of I_2 is similar to the one for I_3. It is clear that

$$\begin{aligned}I_2 &\le \left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})} \left(\varphi(t)\int_{\theta(t_{(n+1)'})}^{\theta(t)} K_2(t,s)e(s)ds\right)dt\right| \\ &\quad + \left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})} \left(\varphi(t)\int_0^{\theta(t_{(n+1)'})} K_2(t,s)e(s)ds\right)dt\right|.\end{aligned} \tag{5.13}$$

Since $\theta \in C^1(J)$, there is a constant γ such that

$$|\theta(t) - \theta(t_{(n+1)'})| \le \gamma|t - t_{(n+1)'}| \le \gamma h_{(n+1)'}, \quad t_{(n+1)'} \le t \le \theta(t_{n+1}).$$

It follows by (3.3) that

$$\left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})}\left(\varphi(t)\int_{\theta(t_{(n+1)'})}^{\theta(t)}K_2(t,s)e(s)ds\right)dt\right| \le Ch^{m+2}\|\varphi\|_{2,e_{(n+1)'},\infty}. \tag{5.14}$$

There is an index n'' such that $\theta(t_{(n+1)'}) \in (t_{n''}, t_{n''}+1]$. Thus,

$$\begin{aligned}
&\left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})}\left(\varphi(t)\int_{0}^{\theta(t_{(n+1)'})}K_2(t,s)e(s)ds\right)dt\right| \\
&\qquad\le \left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})}\left(\varphi(t)\int_{t_{n''}}^{\theta(t_{(n+1)'})}K_2(t,s)e(s)ds\right)dt\right| \\
&\qquad\quad+ \left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})}\left(\varphi(t)\int_{0}^{t_{n''}}K_2(t,s)e(s)ds\right)dt\right|.
\end{aligned}$$

If we now use (5.4) and (5.7) and observe that $(n+1)' \le n$, we find the estimate

$$\left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})}\left(\varphi(t)\int_{0}^{\theta(t_{(n+1)'})}K_2(t,s)e(s)ds\right)dt\right| \le Ch^{m+3}\|\varphi\|_{2,e_{(n+1)'},\infty}.$$

This result and (5.14) and (5.13) lead to

$$I_2 \le Ch^{m+3}\|\varphi\|_{2,e_{(n+1)'},\infty}. \tag{5.15}$$

Analogous to (5.15) we can also verify that

$$I_4 \le Ch^{m+3}\|\varphi\|_{2,e_{(n+1)'},\infty}.$$

Substitution of (5.11)–(5.12) and (5.15) and using the above estimate in (5.10) gives (5.8). Now consider (5.9): For any $\varphi \in C^2[0,t_{n+1}]$, we have

$$\begin{aligned}
\left|\int_0^{t_{n+1}}\varphi(t)e(t)dt\right| &= \left|\int_0^{t_{n+1}}\varphi(t)A(t)dt + \int_0^{t_{n+1}}\left(\varphi(t)\int_0^t R_1(t,s)A(s)ds\right)dt\right| \\
&\le \left|\int_0^{t_{n+1}}\varphi(t)(\pi_h-\mathcal{I})\tilde{u}(t)dt\right| \\
&\quad+\left|\int_0^{t_{n+1}}\left(\varphi(t)\int_0^{\theta(t)}K_2(t,s)e(s)ds\right)dt\right| \\
&\quad+\left|\int_0^{t_{n+1}}\left(\varphi(t)\int_0^{t}R_1(t,s)(\pi_h-\mathcal{I})\tilde{u}(s)ds\right)dt\right| \qquad (5.16)\\
&\quad+\left|\int_0^{t_{n+1}}\varphi(t)\int_0^{t}\left(R_1(t,s)\int_0^{\theta(s)}K_2(s,\sigma)e(\sigma)d\sigma\right)ds\,dt\right| \\
&=: I_1' + I_2' + I_3' + I_4'.
\end{aligned}$$

It follows by (3.5) that

$$I_1' \le Ch_{n+1}h^{m+2}\|\varphi\|_{2,[0,t_{n+1}],\infty}. \tag{5.17}$$

If we change the order of integration in I_3' (compare also [7]) and use (3.5), we obtain

$$I_3' \le Ch^{m+2}\|\varphi\|_{2,e_{(n+1)'},\infty}. \tag{5.18}$$

The estimate of I_2' is similar to that of I_3', but we now need to use the assumption on θ. By changing the order of integration, and noting that $\theta(t)$ is an increasing function, we are led to

$$\begin{aligned} I_2' &= \left|\int_0^{\theta(t_{n+1})}\left(\int_{\theta^{-1}(s)}^{t_{n+1}}\varphi(t)K_2(t,s)dt\cdot e(s)\right)ds\right| \\ &\le \left|\int_0^{t_{(n+1)'}}\left(\int_{\theta^{-1}(s)}^{t_{n+1}}\varphi(t)K_2(t,s)dt\cdot e(s)\right)ds\right| \\ &\quad + \left|\int_{t_{(n+1)'}}^{\theta(t_{n+1})}\left(\int_{\theta^{-1}(s)}^{t_{n+1}}\varphi(t)K_2(t,s)dt\cdot e(s)\right)ds\right|. \end{aligned}$$

This, together with (5.7) and (5.8), leads to

$$I_2' \le Ch^{m+2}\|\varphi\|_{2,[0,t_{n+1}],\infty} \tag{5.19}$$

(note that $\theta^{-1}\in C^2(J)$). Similarly, it is easy to verify that

$$I_4' \le Ch^{m+2}\|\varphi\|_{2,[0,t_{n+1}],\infty}.$$

Substitution of (5.17)–(5.19) and the above inequality into (5.16) yields the estimate (5.9).

Finally, it follows by the induction principle that the estimates (5.1)–(5.2) hold; hence, employing (5.1)–(5.2) in the relation

$$e_{it} = u_{it} - y = \mathcal{K}e$$

produces the desired result.

6. Extensions and open problems. The techniques underlying the proofs of the superconvergence results in the previous sections can be adapted to obtain analogous results for continuous piecewise polynomial collocation approximations to the solution of the Volterra integrodifferential equation

$$y'(t) = a(t)y(t)+b(t)y(\theta(t))+\int_0^t K_1(t,s)y(s)ds+\int_0^{\theta(t)} K_2(t,s)y(s)ds, \quad t\in J, \tag{6.1}$$

with $y(0)=y_0$ and with vanishing delay θ satisfying conditions (D1) and (D2). The corresponding superconvergence results will then also apply to an important special case of (6.1), namely the pantograph equation (1.3) (for which no superconvergence results have yet been proved). The detailed analysis will be given elsewhere.

There is, however, a class of more general Volterra functional integral equations, with a representative example given by

$$y(t) = a(t)y(pt) + f(t) + \int_{qt}^t K(t,s)y(s)ds, \quad t\in[0,T], \tag{6.2}$$

with $0<p,q<1$ (see Volterra [24], Denisov and Lorenzi [10]), for which the superconvergence analysis of (iterated) collocation solutions is not yet understood. One of the inherent difficulties lies in the fact that even the existence and uniqueness theory for the exact solution to (6.2) and its collocation approximation is no longer an elementary problem.

Acknowledgment. The authors are grateful to the three referees for their valuable comments and suggestions, which led to a considerably improved version of the paper.

THE EFFECTIVE STABILITY OF ADAPTIVE TIMESTEPPING ODE SOLVERS[*]

HARBIR LAMBA[†]

Abstract. We consider the behavior of certain adaptive timestepping methods, based upon embedded explicit Runge–Kutta pairs, when applied to dissipative ODEs. It has been observed numerically that the standard local error controls can impart desirable stability properties, but this has been rigorously verified only for very special, low-order, Runge–Kutta pairs.

The rooted-tree expansion of a certain quadratic form, central to the stability theory of Runge–Kutta methods, is derived. This, together with key assumptions on the sequence of accepted timesteps and the local error estimate, provides a general explanation for the observed stability of such algorithms on dissipative problems. Under these assumptions, which are expected to hold for "typical" numerical trajectories, two different results are proved. First, for a large class of embedded Runge–Kutta pairs of order $(1, 2)$, controlled on an error-per-unit-step basis, all such numerical trajectories will eventually enter a particular bounded set. This occurs for sufficiently small tolerances independent of the initial conditions. Second, for pairs of arbitrary orders $(p-1, p)$, operating under either error-per-step or error-per-unit-step control, similar results are obtained when an additional structural assumption (that should be valid for many cases of interest) is imposed on the dissipative vector field. Numerical results support both the analysis and the assumptions made.

Key words. error control, stability, numerical integration, ordinary differential equations

1. Introduction.

We consider adaptive timestepping ODE solvers applied to initial value problems for an autonomous system of ODEs,

$$\frac{du}{dt} = f(u), \quad u(0) = U, \tag{1.1}$$

where $u(t) \in \mathbb{R}^m$. Furthermore, the Lipschitz continuous vector field f satisfies the following structural assumption:

$$\text{(D)} \qquad \exists \alpha \geq 0,\ \beta > 0 : \ \forall u \in \mathbb{R}^m, \quad \langle f(u), u\rangle \ \leq \alpha - \beta\|u\|^2,$$

where the norm $\|\cdot\|$ is induced by the inner product $\langle\cdot,\cdot\rangle$.

A bounded closed set $\mathcal{B}$ is a *bounded absorbing set* for (1.1) if $\forall U \in \mathbb{R}^m$, $\exists t^* = t^*(U)$ such that $u(t) \in \mathcal{B}\ \forall t \geq t^*$. If a bounded absorbing set exists, then (1.1) is termed *dissipative*. Under the structural assumption (D), (1.1) is dissipative as stated in the following theorem [16].

Theorem 1.1. *Let* $\overline{B}(v, r)$ *be the closed ball with center* v*, radius* r *using the norm* $\|\cdot\|$. *Then assumption* (D) *implies the existence of bounded absorbing sets* $\mathcal{B} = \overline{B}(0, \sqrt{(\alpha+\epsilon)/\beta})\ \forall\epsilon > 0$.

The structural assumption (D) has played an important role in nonlinear stability theory, where the aim is to find conditions under which numerical schemes, when regarded as discrete dynamical systems, preserve various qualitative asymptotic features of the original ODE (such as the existence of bounded absorbing sets). However, the

vast majority of this body of work only applies to methods employing a fixed timestep, whereas most algorithms used in practice allow the timesteps to change from one step to the next. In the algorithms considered here, the timesteps are chosen so as to control an estimate of the local (one-step) error and this adaptive timestepping approach can result in extremely impressive efficiency gains.

Even though the standard error controls were not designed with stability in mind, it has been observed that such adaptive timestepping algorithms often have much better stability properties than their fixed-timestepping counterparts. This paper addresses the questions of when, and how, the stepsizes induced by the local error control will confer desirable stability properties upon the adaptive numerical method.

As mentioned above, there have been many investigations into the stability properties of Runge–Kutta methods with a fixed timestep, under various structural assumptions (e.g., [2, 1, 5, 9, 18]). We now provide a brief outline of the relevant results for dissipativity. Consider a general (implicit or explicit) s-stage Runge–Kutta scheme for (1.1) with timestep h,

$$\eta_i = U_n + h\sum_{j=1}^{s} a_{ij} f(\eta_j), \quad i = 1, \ldots, s, \tag{1.2}$$

$$U_{n+1} = U_n + h\sum_{i=1}^{s} b_i f(\eta_i), \tag{1.3}$$

and define the vector $b = (b_1, \ldots, b_s)^T$ and matrices A and B by $A(i,j) = a_{ij}$ and $B = \text{diag}(b)$.

Equations (1.2) and (1.3), after standard manipulations (see, for example, [18]), imply that

$$\|U_{n+1}\|^2 = \|U_n\|^2 + 2h\sum_{i=1}^{s} b_i\langle \eta_i, f(\eta_i)\rangle - h^2 \sum_{i,j=1}^{s} m_{ij}\langle f(\eta_i), f(\eta_j)\rangle,$$

where $m_{ij} = M(i,j)$ with $M = BA + A^T B - b^T b$. Under the structural assumption (D), with B positive semidefinite, and using the same norm $\|\cdot\|$ and inner product $\langle\cdot,\cdot\rangle$, we obtain

$$\|U_{n+1}\|^2 \leq \|U_n\|^2 + 2h\sum_{i=1}^{s} b_i(\alpha - \beta\|\eta_i\|^2) - h^2 \sum_{i,j=1}^{s} m_{ij}\langle f(\eta_i), f(\eta_j)\rangle. \tag{1.4}$$

The Runge–Kutta method is termed *algebraically stable* if the matrices M and B are both positive semidefinite. The condition on M ensures that the quadratic form

$$h^2 \sum_{i,j=1}^{s} m_{ij}\langle f(\eta_i), f(\eta_j)\rangle \tag{1.5}$$

is nonnegative, while the condition on B is used to show that the quantities $b_i(\alpha - \beta\|\eta_i\|^2)$ are negative outside a ball of sufficiently large radius in the norm $\|\cdot\|$. Together these imply the existence of bounded absorbing sets for the discrete dynamical system defined by the numerical scheme $\forall h > 0$. Thus the algebraic stability of the numerical scheme ensures that the property of dissipativity is transferred to the numerical approximation. However, M cannot be positive semidefinite for explicit Runge–Kutta methods and so all algebraically stable methods are necessarily implicit. Indeed, explicit Runge–Kutta methods using a fixed timestep often have very poor stability properties.

We now return to our discussion of adaptive schemes. While the quadratic form (1.5) cannot be forced to be nonnegative for a nonalgebraically stable method, we shall show that, under certain conditions, the constraints imposed upon the timestep sizes by the local error control will also effectively bound the *magnitude* of (1.5) (as opposed to its sign). Then, for a Runge–Kutta method with B positive definite, outside a ball of sufficiently large radius the single-summation term in (1.4) will be shown to dominate and the norm of the numerical solution to decrease. This idea underlies the approach introduced in this paper.

The class of adaptive schemes that will be analyzed is now defined. We set $U_0 = U$ and iteratively generate U_{n+1} from U_n using a timestep h_n. The equations defining a general embedded explicit Runge–Kutta pair with s stages are

$$\eta_i = U_n + h_n \sum_{j=1}^{s} a_{ij} f(\eta_j), \quad i = 1, \dots, s, \tag{1.6}$$

$$V_{n+1} = U_n + h_n \sum_{i=1}^{s} b_i f(\eta_i), \tag{1.7}$$

$$W_{n+1} = U_n + h_n \sum_{i=1}^{s} \overline{b}_i f(\eta_i). \tag{1.8}$$

Such a Runge–Kutta pair, with orders $p-1$ and p, will be referred to as a $(p-1,p)$ pair. We shall assume that the higher-order method is represented by the weights $b_1, \dots, b_s$ and the lower-order method by $\overline{b}_1, \dots, \overline{b}_s$. Thus $U_{n+1} = V_{n+1}$ when the higher-order method is used to advance the solution (extrapolation mode) and $U_{n+1} = W_{n+1}$ otherwise (nonextrapolation mode). To complement the definitions of A, B, and b, let $\overline{b} = (\overline{b}_1, \dots, \overline{b}_s)^T$ and $\overline{B} = \operatorname{diag}(\overline{b})$.

The *local error estimate* $E(U_n, h_n)$ is defined as the difference between the two approximations,

$$E(U_n, h_n) := W_{n+1} - V_{n+1}.$$

The user defines a tolerance τ, and the timesteps must satisfy the following standard local error control:

$$\|E(U_n, h_n)\| \le \sigma(\tau, U_n) h_n^{\rho}, \tag{1.9}$$

where $\rho = 0$ for error-per-step control and $\rho = 1$ for error-per-unit-step control. The quantity $\sigma(\tau, U_n)$ is a quantity closely related to the tolerance τ, and indeed may simply be equal to τ. However, we wish to allow for the possibility of absolute, relative, and mixed error controls. There are various ways in which this can be done but for simplicity we shall require only that there exists some constant $C_1 > 0$ such that

$$\sigma(\tau, u) \le C_1 \tau \|u\| \quad \forall u \in \mathbb{R}^m. \tag{1.10}$$

It should be noted that absolute or mixed error controls will need to be modified on some neighborhood of the origin in order to satisfy (1.10). However, we will be concerned exclusively with trajectories that lie entirely outside of (large) balls centered upon the origin and the choice of (1.10) will help to streamline the analysis. Also, the norms used in (1.9) and (1.10) and throughout the rest of the paper are the same as in (D).

We thus have four possible modes of operation depending upon the choice of solution-advancing method and type of error control. EPS and EPUS will denote error-per-step and error-per-unit step modes, respectively, in nonextrapolation mode, while XEPS and XEPUS are their extrapolation counterparts. We also assume the existence of a maximum timestep $h_{\max}$, independent of τ, which is a very common feature of adaptive algorithms. Throughout, we assume that the vector field f is sufficiently smooth on $\mathbb{R}^m$. These smoothness requirements are determined only by the order of the Runge–Kutta methods used to form the local error estimate. Note that no further details of the algorithm need to be specified, in particular, the way in which candidate timesteps are generated. All that is required is that the error control (1.9) is satisfied at every timestep.

While no explicit Runge–Kutta method can be algebraically stable, it has been observed [6, 18] that adaptive timestepping methods based upon explicit schemes do, for certain combinations of dissipative test problems and mode of operation, seem to have some desirable stability properties (see also [13] for a discussion of stability with regard to the existence of spurious fixed points). In particular, the numerical schemes appear to be dissipative. Of course, no amount of numerical testing can prove the existence of a bounded absorbing set for all initial data but the results do suggest that, with an extremely high degree of certainty, numerical trajectories enter and then remain within an "absorbing set" close to $\overline{B}(0, \sqrt{\alpha/\beta})$.

There have been previous analyses of the behavior of adaptive methods on dissipative ODEs that have attempted to explain this phenomenon. In [17], it was proved that very special, embedded explicit Runge–Kutta pairs generate a solution that, at each step, is a small perturbation of the solution generated by using a corresponding (implicit) algebraically stable method. In this way, the stability characteristics of this related scheme are transferred to the explicit pair. Such pairs were termed *essentially algebraically stable* and an order barrier for $(p-1, p)$ pairs, namely, that $p \leq 5$, was proved. For these pairs, applied to ODEs satisfying (D), under no additional assumptions and with an absolute error control, two different results were proved. The first, which is a discrete analogue of Theorem 1.1, stated that when such a pair is used in EPUS or XEPUS modes the numerical scheme has a bounded absorbing set for all sufficiently small tolerances τ, *independent of the initial data*. The second result, which is significantly weaker, states that for the same pairs operating in EPS or XEPS modes each numerical trajectory will again eventually enter a particular bounded absorbing set, but now the required tolerance does depend upon the initial data.

The independence of τ with respect to initial conditions is desirable, not just from a computational point of view, but also from a theoretical one, since it allows us to consider the numerical method, for a fixed sufficiently small tolerance, as a dynamical system with similar asymptotic behavior to the underlying ODE for all initial conditions. However, the set of essentially algebraically stable pairs forms a very small subset of pairs currently employed and are necessarily of low-order.

A second analysis [8] took a different approach. There it was assumed, for a general adaptive method under EPUS control, that the *actual* one-step truncation errors $T(U_n, h_n)$ (rather than the one-step error estimates) were correctly controlled at every step, in particular, that

$$T(U_n, h_n) \leq K(U)\tau h_n$$

occurred at every timestep for some constant $K(U)$. Using this assumption that the error control works correctly, positive stability results were proved for general adaptive schemes but only in the much weaker sense that the required tolerance depended upon the initial data.

Any stability properties introduced to an explicit Runge–Kutta method via a local error control are due to the size of the accepted steps. However, neither of the analyses described above explicitly considers the actual timestep sequences generated by the method (and they also only considered the case of absolute error control). In order to obtain tighter and/or more general results it is therefore natural to consider closely the timestep sequence itself, and this forms another motivation for our analysis.

The paper is organized as follows. In section 2, for a Runge–Kutta method of order r, an expansion of the quadratic form (1.5) is derived and the leading order term is proved to be at least $\mathcal{O}(h^{r+1})$. In section 3, we then use this expansion, together with the corresponding expansion of the local error estimate $E(U_n, h_n)$ at each timestep, to state and justify our two key assumptions on the numerical trajectory. The first assumption takes the form of an upper bound on the timesteps used at each point in the phase space. The second assumption is that controlling the local error estimate also bounds the magnitude of the quadratic form (1.5) at each timestep. It must be emphasized that the justification for these assumptions is that they are expected to hold for every timestep along "typical" numerical trajectories, but it seems likely that for most vector fields satisfying (D) there will be "atypical" numerical trajectories where, at one or more timesteps, they do not hold. Even when these extreme events occur, the fact that the assumptions hold for most of the timesteps should help to preserve the qualitative asymptotic features of the numerical trajectory.

We do not attempt to quantify the ways in which our assumptions can be violated and this is unsatisfactory from a rigorous mathematical viewpoint. However, using these assumptions, we shall gain valuable insights into how these algorithms behave on most simulations. The studies [15, 11, 12] have shown that even when considering the convergence to the exact solution, as $\tau \to 0$, of adaptive timestepping algorithms over finite time intervals and compact sets of initial data—arguably a more fundamental property—there are mechanisms that can give rise to the breakdown of convergence. These arise because of the possibility that the leading term of the error estimate may vanish at some point along the exact trajectory, resulting in a local increase in the size of the accepted timesteps and potential loss of convergence (or, more likely, a reduction in the rate of convergence). However, at least for generic vector fields, the probability of convergence failure is extremely small. These previous studies have therefore already demonstrated that a "worst-case analysis" is not necessarily appropriate in the context of ODE solvers, since the very small probability of failure to converge is outweighed by the superior efficiency of adaptive algorithms. In fact the situation here, where we are concerned with stability properties, is much better than that for convergence properties. This is because convergence can be destroyed by a single "bad" timestep whereas asymptotic qualitative properties are very likely to be robust in the presence of such extreme events. Nevertheless, it is hoped that the analysis presented here will stimulate further work into justifying or weakening the assumptions made.

In section 4, we present the main results. First, for embedded explicit Runge–Kutta pairs of order (1, 2), operating in EPUS or XEPUS modes with B positive-definite, any numerical trajectory satisfying the assumptions of section 3 will eventually enter a particular bounded set for all sufficiently small τ independent of U. Second, motivated by the analysis, we introduce an additional structural assumption on the vector field f:

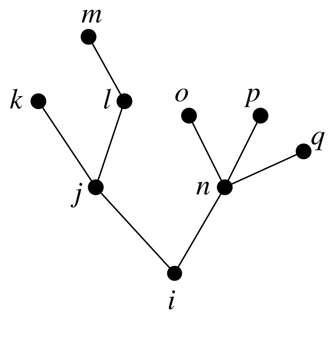
$$(\mathrm{D}') \qquad \exists \gamma > 0, R > 0 : \ \langle f(u), u \rangle \ \leq \ -\gamma \|f(u)\| \|u\| \quad \forall \|u\| \geq R.$$

Intuitively this structural assumption states that, for sufficiently large $\|u\|$, the vector field points inwards everywhere at some definite minimum nonzero angle and holds for many ODEs of interest. In particular, vector fields satisfying (D) or (D$'$) (or both) are not necessarily globally Lipschitz. Assuming that (D), (D$'$), and the assumptions on the numerical trajectory hold, then for sufficiently small τ independent of initial data, for arbitrary embedded $(p-1, p)$ pairs with B positive-definite in any mode of operation, a similar result is proved. Finally, in section 5, we present numerical results that support both the assumptions made in section 3 and the results of section 4.

2. Order conditions and the matrix M.

The Taylor series expansions in powers of h of both the exact solution to (1.1) and the one-step Runge–Kutta approximation, over some time interval $[s, s+h]$, consist of multiples of expressions involving f and its higher derivatives which rapidly become very complicated. We therefore first recall some necessary definitions and terminology from the rooted tree description of Taylor series expansions. This theory was developed by Butcher, and the reader is referred to [3, 4] for full details of all the notation, definitions, and results up to and including (2.3).

A rooted tree is an unlabeled connected graph containing no cycles and with one node identified as the "root." Each rooted tree with precisely n nodes corresponds uniquely to one term (of many) appearing at order h^n in the Taylor series. Each term is a multiple of an elementary differential of order n and this correspondence is achieved as follows. Let $f^i_{j_1, j_2, \ldots, j_r}$ denote the rth partial derivative of the ith component of f with respect to the components $j_1, j_2, \ldots, j_r$. Now attach the label i to the root of the tree and labels $j, k, l, \ldots$ to the other nodes. Then for each node, write down f with a superscript equal to the label of that node and subscripts given by the other nodes that are directly connected to it on the side away from the root node. For example, the rooted tree



corresponds to the product $f^i_{jn} f^j_{kl} f^k f^l_m f^m f^n_{opq} f^o f^p f^q$ (using the summation convention over repeated indices), which is the ith component of one particular elementary differential of order 9. Repeating the above process for each value of the index i provides each component of the elementary differential corresponding to the above (unlabeled) rooted tree. The elementary differential corresponding to a particular tree t will be denoted by the function $F(t) : \mathbb{R}^m \to \mathbb{R}^m$.

The set of all rooted trees, denoted by $\mathcal{T}$, is defined recursively as follows. The rooted tree consisting of a single node is defined as τ and any rooted tree t can be built up by joining trees $t_1, \dots, t_k$ to a new root. The rooted tree t is then written as $t = [t_1, \dots, t_k]$ (note that the order is unimportant) and m repetitions of a tree t_i are denoted by t_i^m.

We now recall some important functions that can be defined on the set $\mathcal{T}$. The function $\rho(t)$ is simply the number of nodes in t. The next three functions $\gamma(t), \sigma(t)$, and $\alpha(t)$ have important combinatorial interpretations (see [3, section 144]) and also allow for an elegant statement of Taylor series expansions. However, the following recursive definitions, also due to Butcher, are more relevant for our purposes:

$$\gamma(\tau) = 1, \quad \gamma([t_1, \dots, t_k]) = \rho([t_1, \dots, t_k]) \prod_{j=1}^{k} \gamma(t_j) \tag{2.1}$$

and

$$\sigma(\tau) = 1, \quad \sigma([t_1^{n_1}, \dots, t_k^{n_k}]) = n_1! n_2! \dots n_k! \prod_{j=1}^{k} \sigma(t_j)^{n_j},$$

where the trees $t_1, \dots, t_k$ are all distinct. Finally, the function $\alpha(t)$ is defined by

$$\alpha(t) = \frac{\rho(t)!}{\gamma(t)\sigma(t)}.$$

In [3] it is then proved that the Taylor series for the exact solution of (1.1) at time $s + h$ is

$$u(s+h) = u(s) + \sum_{t \in \mathcal{T}} \frac{\alpha(t)}{\rho(t)!} h^{\rho(t)} F(t)(u(s)). \tag{2.2}$$

The one-step numerical approximation, $\tilde{u}(s+h)$ can also be expressed in terms of elementary differentials. For a given rooted tree t and Runge–Kutta method (determined by (1.2) and (1.3)) we define the elementary weight $\Phi(t)$ as follows. Label the root of the tree i and attach labels to the other vertices. For every edge connecting vertices u and v, write down a factor a_{uv}, where u is the vertex closer to the root. Insert a final factor b_i, corresponding to the root, form the product of the above factors, and then sum every index over all of the stages. Thus the elementary weight corresponding to the tree drawn above is

$$\Phi(t) = \sum_{i,j,k,l,m,n,o,p,q=1}^{s} b_i a_{ij} a_{jk} a_{jl} a_{lm} a_{in} a_{no} a_{np} a_{nq}.$$

Now the numerical approximation can be expanded as

$$\tilde{u}(s+h) = u(s) + \sum_{t \in \mathcal{T}} \frac{\gamma(t)\alpha(t)\Phi(t)}{\rho(t)!} h^{\rho(t)} F(t)(u(s)). \tag{2.3}$$

By comparing (2.2) and (2.3), Butcher proved that a necessary and sufficient condition for a Runge–Kutta method to be of order precisely p is that $\Phi(t) = 1/\gamma(t)$ for all rooted trees t with $\rho(t) \leq p$, but not for at least one tree t with $\rho(t) = p + 1$.

The above definitions and results now enable us to prove a new expansion for the quadratic form (1.5).

LEMMA 2.1. *Let the stages $\eta_1, \ldots, \eta_s$ be generated by a Runge–Kutta method of order r using a timestep h from a solution value u. Then there exists an integer $q \geq r+1$ and scalar-valued functions $G_1(u)$ and $G_2(u,h)$ such that $G_2(u,0) = 0$ and*

$$h^2 \sum_{i,j=1}^{s} m_{ij} \langle f(\eta_i), f(\eta_j) \rangle \; = \; h^q (G_1(u) + hG_2(u,h)). \tag{2.4}$$

Proof. Consider an arbitrary rooted tree t. Comparison of the Taylor series expansion of the numerical solution (2.3) with (1.3) shows that each of the terms $hf(\eta_i)$ can be expanded as

$$hf(\eta_i) = \sum_{t \in \mathcal{T}} \frac{\gamma(t)\alpha(t)\Phi_i(t)}{\rho(t)!} h^{\rho(t)} F(t)(u),$$

where each term $\Phi_i(t)$ is derived from $\Phi(t)$ by deleting both the factor b_i and the summation over the index i. Note that each $\Phi_i(t)$ has precisely $\rho(t) - 1$ factors. Let us now fix trees T_1 and T_2 (not necessarily distinct) and consider the coefficient of $\langle F(T_1)(u), F(T_2)(u) \rangle$ in the expansion of (1.5). Using the definition of the matrix M, this is

$$\begin{aligned} &(2 - \mathcal{I}_{T_1=T_2})\, h^{\rho(T_1)+\rho(T_2)} \frac{\alpha(T_1)\alpha(T_2)\gamma(T_1)\gamma(T_2)}{\rho(T_1)!\rho(T_2)!} \sum_{i,j=1}^{s} [\Phi_i(T_1)\Phi_j(T_2) b_i a_{ij} \\ &\qquad + \Phi_i(T_1)\Phi_j(T_2) b_j a_{ji} - \Phi_i(T_1)\Phi_j(T_2) b_i b_j], \end{aligned} \tag{2.5}$$

where $\mathcal{I}_{T_1=T_2} = 1$ if $T_1 = T_2$ and 0 otherwise.

We now introduce some new notation. Given two trees $T_1 = [s_1, \ldots, s_m]$ and $T_2 = [t_1, \ldots, t_n]$ (where $m = 0$ or $n = 0$ correspond to $T_1 = \tau$ or $T_2 = \tau$, respectively) we define the tree $T_1 \nearrow T_2 := [s_1, \ldots, s_m, T_2]$, which is the tree with $\rho(T_1) + \rho(T_2)$ nodes obtained by adding a single edge between the roots of T_1 and T_2 and keeping the root of T_1 as the root of the new tree. Similarly, $T_2 \nearrow T_1 := [t_1, \ldots, t_n, T_1]$. Thus the first term in the summand of (2.5), after summation, corresponds to $\Phi(T_1 \nearrow T_2)$, the second term corresponds to $\Phi(T_2 \nearrow T_1)$, and the third term to $\Phi(T_1)\Phi(T_2)$.

Let us now assume that $\rho(T_1) + \rho(T_2) \leq r$. Then this coefficient vanishes if

$$\Phi(T_1 \nearrow T_2) + \Phi(T_2 \nearrow T_1) = \Phi(T_1)\Phi(T_2). \tag{2.6}$$

But since the Runge–Kutta method is of order r this is equivalent to the condition that

$$\frac{1}{\gamma(T_1 \nearrow T_2)} + \frac{1}{\gamma(T_2 \nearrow T_1)} = \frac{1}{\gamma(T_1)\gamma(T_2)}. \tag{2.7}$$

This is easily proved via (2.1), the recursive definition of γ. For let us suppose first that $T_1 \neq \tau \neq T_2$. Then

$$\begin{aligned} \gamma(T_1) &= \rho(T_1)\gamma(s_1)\ldots\gamma(s_m), \\ \gamma(T_2) &= \rho(T_2)\gamma(t_1)\ldots\gamma(t_n), \\ \gamma(T_1 \nearrow T_2) &= [\rho(T_1) + \rho(T_2)]\rho(T_2)\gamma(s_1)\ldots\gamma(s_m)\gamma(t_1)\ldots\gamma(t_n), \\ \gamma(T_2 \nearrow T_1) &= [\rho(T_1) + \rho(T_2)]\rho(T_1)\gamma(t_1)\ldots\gamma(t_n)\gamma(s_1)\ldots\gamma(s_m), \end{aligned}$$

and (2.7) easily follows. The remaining cases when either $T_1 = \tau$ or $T_2 = \tau$ are also easily verified.

Thus

$$h^2 \sum_{i,j=1}^{s} m_{ij} \langle f(\eta_i), f(\eta_j) \rangle \;=\; h^q (G_1(u) + hG_2(u,h))$$

for some $q \geq r+1$, with the function $G_1(u)$ being the sum of inner products of elementary differentials where the nodes in the corresponding rooted trees sum to precisely q, and the function $G_2(u,h)$ comprising the higher-order terms. □

The possibility of $q > r+1$ in the statement of Lemma 2.1 arises because, for a pair of trees T_1, T_2 with $\rho(T_1) + \rho(T_2) = n > r$, the Runge–Kutta method being of order n is a sufficient, but not necessary, condition for (2.6) to be satisfied. This is in fact the case for the improved Euler (Heun) method where (2.6) is also satisfied for the unique pair of rooted trees whose nodes sum to 3. Thus $q = 4$ even though $r = 2$.

3. Assumptions.

We now turn to the assumptions necessary for the analysis and results of section 4. Once again, the purpose of these results is to provide an explanation of the observed behavior of explicit Runge–Kutta pairs for "typical" numerical trajectories of "typical" vector fields. For the vast majority of adaptive schemes (i.e., apart from ones utilizing essentially algebraically stable pairs) it would appear that no results are possible without such assumptions. As mentioned in the introduction, similar problems arise when proving convergence results for adaptive algorithms, even for finite-time initial value problems on compact domains. This is because any method based upon a local error estimate can behave badly, even if only for a single timestep, by a sufficiently unfortunate (or devious) combination of vector field, solution value, and candidate timestep. However, both of the assumptions stated and justified below are numerically verified for every single timestep used to advance the solutions in the numerical experiments of section 5.

Assumption 1. If the local error estimate is derived from a $(p-1, p)$ explicit Runge–Kutta pair, then, for all sufficiently small $\tau > 0$, there exists a constant $K_1 > 0$, independent of U, such that for each accepted timestep h_n,

$$h_n^{p-\rho} \leq K_1 \frac{\sigma(\tau, U_n)}{\|f(U_n)\|}. \tag{3.1}$$

The intuitive reason for this assumption can be seen by following [15, 11] and expanding the local error estimate as

$$E(U_n, h_n) = h_n^p \left(B_1(U_n) + h_n B_2(U_n, h_n)\right) \tag{3.2}$$

$$= h_n^p \|f(U_n)\| (\tilde{B}_1(U_n) + h_n \tilde{B}_2(U_n, h_n)). \tag{3.3}$$

In (3.3) the expansion has simply been rescaled by a factor of $\|f(U_n)\|$. Now let us suppose that the function $\|B_1(u)\|$ is bounded away from zero along the numerical trajectory. Then if the error control is working correctly (for sufficiently small τ), and the accepted timesteps are controlled by the (nonvanishing) leading-order term of the expansion (3.2), we see that (3.1) immediately follows.

In [15, 11, 10], rigorous proofs of the upper bound (3.1) on the sequence of accepted timesteps are obtained via induction arguments for sufficiently small τ, but only for numerical trajectories lying inside a predefined compact set on which $B_1(u)$ is bounded away from zero. By restricting ourselves to ODEs satisfying (D), we now argue that (3.1) will only fail to hold in exceptional cases for any initial data.

Note first that under assumption (D), $f(u) \neq 0$ outside the ball $\overline{B}(0, \sqrt{\alpha/\beta})$. Thus, outside this ball, the leading order term of the error estimate can vanish only if $\tilde{B}_1$ does. But $\tilde{B}_1 : \mathbb{R}^m \to \mathbb{R}^m$ and so for typical vector fields will vanish only at isolated points in the phase space. In order to obtain (3.1) from (3.3), we assume the existence of constants $K, K' > 0$ (independent of τ and U_n) for τ sufficiently small such that at each step of the numerical trajectory

$$\begin{aligned}\sigma(U_n, \tau) \geq \|E(U_n, h_n)\|/h_n^\rho &\geq K h_n^{p-\rho} \max\left(B_1(u), h_n B_2(U_n, h_n)\right)\\ &\geq K h_n^{p-\rho} \|B_1(u)\|\\ &\geq KK' \|f(U_n)\| h_n^{p-\rho},\end{aligned}$$

leading immediately to (3.1) with $K_1 = 1/KK'$. The existence of the constant $K > 0$ is equivalent to assuming that at each step no catastrophic cancellation occurs between B_1 and $h_n B_2$. In order to justify the existence of the constant $K' > 0$ we need to demonstrate that, under assumption (D), $\|\tilde{B}_1(u)\|$ does not tend to 0 as $\|u\| \to \infty$ in any direction. We achieve this by showing that at least one of the rescaled elementary differentials comprising $\tilde{B}_1(u)$ cannot vanish as $\|u\| \to \infty$.

Let us suppose that the lower-order method of the pair does not increase its order on linear constant-coefficient problems.[1] Then $B_1(u)$ must contain an elementary differential of the form $cf'(u)^{p-1}f(u)$ with coefficient $c \neq 0$ (the rooted trees corresponding to such elementary differentials are often referred to as "tall trees" and contain no branches). Under the structural assumption (D), $\|f(u)\|$ must increase at least as fast as $\mathcal{O}(\|u\|)$ for sufficiently large $\|u\|$ in any given direction. Thus $\|f'(u)\|$ and $\|cf'(u)^{p-1}f(u)\|/\|f(u)\|$ cannot tend to 0 as $\|u\| \to \infty$ (although for pathological vector fields, $f'(u)$ may equal zero on arbitrarily large compact sets in the phase space). We now approach once again to the principle that catastrophic cancellation (this time between the weighted and rescaled elementary differentials comprising $\tilde{B}_1(u)$) occurs negligibly often, giving $\tilde{B}_1(u) \not\to 0$ as $\|u\| \to \infty$ in any direction. This completes our justification of (3.1).

It should be noted that for a linear constant-coefficient ODE satisfying (D), $\|\tilde{B}_1(u)\|$ is a nonzero constant, but for certain nonlinear problems we can expect $\|\tilde{B}_1(u)\|$ to grow as $\|u\|$ grows. Thus for particular classes of nonlinear problem it may be possible to strengthen the upper bound on the timestep sequence in Assumption 1 considerably (this is confirmed by numerical computations but we shall not explore this point further).

The second assumption states that the error control, which is of course designed to bound the local error estimate, also provides a bound on the magnitude of the quadratic form (1.5) for typical timesteps.

Assumption 2. For all sufficiently small τ there exists a constant $K_2 > 0$, independent of U, such that at each timestep along the numerical trajectory

$$\left| h_n^2 \sum_{i,j=1}^{s} m_{ij} \langle f(\eta_i), f(\eta_j)\rangle \right| \leq K_2 \sigma(\tau, U_n) h_n^{1+\rho} \|f(U_n)\|, \tag{3.4}$$

[1] If this mild condition is violated, then the method behaves substantially differently for such problems. Indeed if the $(p-1, p)$ pair has precisely p stages, then the local error estimate $E(u, h) \equiv 0$ and the error control fails completely. The reader is referred to [11] for further discussion of this point. We simply note that most embedded pairs used in practice satisfy this criterion.

where the matrix M is the stability matrix for the higher-order method of the $(p-1,\ p)$ Runge–Kutta pair.

We start our justification of Assumption 2 by defining

$$\hat{E}(U_n,h_n) := \left| h_n \sum_{j=1}^{s} \langle E(U_n,h_n), f(\eta_j)\rangle \right| \tag{3.5}$$

$$= \left| h_n^2 \sum_{i,j=1}^{s} (b_i - \bar{b}_i)\langle f(\eta_i), f(\eta_j)\rangle \right|. \tag{3.6}$$

The enforcement of the local error control (1.9) now allows us to bound $\hat{E}(U_n,h_n)$ from above, since

$$\begin{aligned} \hat{E}(U_n,h_n) &\le h_n \sum_{j=1}^{s} \|E\|\ \|f(\eta_j)\| \\ &\le s\sigma(\tau,U_n) h_n^{1+\rho} \max_{j=1,\dots,s} \|f(\eta_j)\|. \end{aligned} \tag{3.7}$$

We now compare the expansion (3.6) for $\hat{E}$ with that of the (absolute value of the) quadratic form for the higher-order method (1.5). From the proof of Lemma 2.1, (1.5) is a linear combination of inner products of elementary differentials. Reverting to the rooted-tree description of elementary differentials, the only inner products $\langle F(T_1)(u), F(T_2)(u)\rangle$ appearing in the expansion are those for which $\rho(T_1)+\rho(T_2) \ge p+1$, and their coefficients are of order $h_n^{\rho(T_1)+\rho(T_2)}$. The corresponding expansion for $\hat{E}$ contains those inner products $\langle F(T_1)(u), F(T_2)(u)\rangle$ for which $\max(\rho(T_1),\rho(T_2)) \ge p$, once again with coefficients of order $h_n^{\rho(T_1)+\rho(T_2)}$.

Note that the expansion of (1.5) therefore contains a (finite) number of additional inner products not appearing in that of $\hat{E}$. However, these inner products are closely related to others that are common to both expansions and so our assumption reduces to the observation that the control of the quantity $\hat{E}$ should effectively control (1.5) to within some constant. Assumption 2 now follows immediately from (3.7) by assuming that $\max_{j=1,\dots,s} \|f(\eta_j)\|$ is always close to $\|f(U_n)\|$, which of course should be the case, barring any catastrophic cancellations in the formation of the error estimate.

In principle, Assumptions 1 and 2 could be weakened considerably by, for example, only requiring that (3.1) and (3.4) hold, for a given K_1 and K_2, on a sufficiently large proportion of the numerical timesteps. However, an analysis resting on such assumptions would become far more difficult without generating any new insights into the mechanisms leading to effective numerical stability.

4. Results.

Using Assumptions 1 and 2 we are now ready to prove the main results. We start by considering the case of embedded explicit Runge–Kutta pairs with order (1, 2) in either EPUS or XEPUS mode.

THEOREM 4.1. *Consider an embedded explicit Runge–Kutta pair of order* $(1,2)$, *under either EPUS or XEPUS control, where the higher-order method has positive weights. If Assumptions* 1 *and* 2 *are satisfied and the ODE* (1.1) *satisfies* (D), *then* $\exists \tau^* > 0$ *such that* $\forall \tau \le \tau^*$, *the numerical trajectory eventually enters a compact set independent of* τ, U.

Proof. The tolerance τ is chosen sufficiently small such that Assumptions 1 and 2 are satisfied. We first consider advancing the numerical solution using the higher-order method (extrapolation mode). From (D) we have

$$\|V_{n+1}\|^2 = \|U_n\|^2 + 2h_n \sum_{i=1}^{s} b_i \langle \eta_i, f(\eta_i)\rangle - h_n^2 \sum_{i,j=1}^{s} m_{ij} \langle f(\eta_i), f(\eta_j)\rangle \tag{4.1}$$

$$\leq \|U_n\|^2 + 2h_n \sum_{i=1}^{s} b_i (\alpha - \beta\|\eta_i\|^2) - h_n^2 \sum_{i,j=1}^{s} m_{ij} \langle f(\eta_i), f(\eta_j)\rangle. \tag{4.2}$$

We now proceed by bounding the absolute value of the last term and, for sufficiently small τ, absorbing it into the previous one. From Assumptions 1 and 2 and (1.10),

$$\left| h_n^2 \sum_{i,j=1}^{s} m_{ij} \langle f(\eta_i), f(\eta_j)\rangle \right| \leq K_2 \sigma(\tau, U_n) h_n^2 \|f(U_n)\| \tag{4.3}$$

$$\leq K_1 K_2 h_n \sigma(\tau, U_n)^2 \tag{4.4}$$

$$\leq C_1^2 K_1 K_2 h_n \tau^2 \|U_n\|^2. \tag{4.5}$$

Now fix $0 < \tilde{\beta} < \beta$ and substitute (4.5) into the last term of (4.2) with

$$\tau < \sqrt{\frac{2b_1(\beta - \tilde{\beta})}{C_1^2 K_1 K_2}}.$$

Noting that $\eta_1 = U_n$ for explicit Runge–Kutta methods, we obtain

$$\|V_{n+1}\|^2 \leq \|U_n\|^2 + 2h_n \sum_{i=1}^{s} b_i (\alpha - \tilde{\beta}\|\eta_i\|^2). \tag{4.6}$$

The proof now proceeds exactly as in [17, Lemma 4.2 and Theorem DC1] by showing that the norm of the numerical solution strictly decreases until it enters, for any $\epsilon > 0$, the compact set $S = \overline{B}(0, \sqrt{((\alpha + \epsilon)/\tilde{\beta}) + h_{\max} K})$, where

$$K = \max_{\|\eta_i\| \leq \gamma_i} \left(2 \sum_{i,j=1}^{s} b_i e_{ij} \langle \eta_i, f(\eta_i)\rangle + h_{\max} \sum_{i=1}^{s} b_i \left\| \sum_{j=1}^{s} e_{ij} f(\eta_j) \right\|^2 \right) \tag{4.7}$$

and

$$e_{ij} := b_j - a_{ij}, \qquad \gamma_i^2 := \frac{\alpha}{\tilde{\beta} b_i}.$$

We now consider the nonextrapolation case. From the local error control (1.9),

$$\begin{aligned} \|W_{n+1}\|^2 - \|V_{n+1}\|^2 &= \langle W_{n+1} + V_{n+1}, W_{n+1} - V_{n+1}\rangle \\ &\leq \|W_{n+1} + V_{n+1}\| \, \|W_{n+1} - V_{n+1}\| \\ &\leq \|W_{n+1} + V_{n+1}\| \sigma(\tau, U_n) h_n \\ &\leq 2\|V_{n+1}\| \sigma(\tau, U_n) h_n + \sigma^2(\tau, U_n) h_n^2. \end{aligned}$$

While the numerical trajectory is outside the compact set $\overline{B}(0, \sqrt{((\alpha + \epsilon)/\tilde{\beta}) + h_{\max} K})$, we have already proved that, for sufficiently small τ, $\|V_{n+1}\| \leq \|U_n\|$ implying

$$\begin{aligned} \|W_{n+1}\|^2 - \|V_{n+1}\|^2 &\leq 2\|U_n\| \sigma(\tau, U_n) h_n + \sigma^2(\tau, U_n) h_n^2 \\ &\leq 2C_1 \tau \|U_n\|^2 h_n + C_1^2 \tau^2 \|U_n\|^2 h_n^2. \end{aligned} \tag{4.8}$$

Thus the bound on $\|V_{n+1}\|^2$ from (4.6) may be invoked in (4.8) to give

(4.9)
$$\|W_{n+1}\|^2 \leq \|U_n\|^2 + 2h_n \sum_{i=1}^{s} b_i(\alpha - \tilde{\beta}\|\eta_i\|^2) + 2C_1\tau\|U_n\|^2 h_n + C_1^2\tau^2\|U_n\|^2 h_n h_{\max}.$$

The argument now concludes in a very similar fashion to the extrapolation case. After reducing the tolerance τ further if necessary, the last two terms of (4.9) can be absorbed into the preceding term by reducing $\tilde{\beta}$ once again, and then redefining (increasing) K to $\tilde{K}$ via (4.7). This then proves that the numerical solution enters a set $\overline{B}(0, \sqrt{((\alpha+\epsilon)/\tilde{\beta}) + h_{\max}\tilde{K}})$ as required. □

Theorem 4.1 only states that numerical trajectories will enter a particular compact set, which is not necessarily close to the set $\overline{B}(0, \sqrt{\alpha/\beta})$. However, once a numerical trajectory has entered this set, finite-time convergence results, such as those contained in [15, 12], can be applied to prove that typical numerical trajectories (possibly after a further reduction in τ) will enter and remain within $\mathcal{O}(\tau)$ of the absorbing set $B(0, \sqrt{\alpha/\beta})$ of the ODE (1.1). Furthermore in [10], and under additional assumptions, the existence of a (local) numerical attractor that is upper-semicontinuous to the global attractor of (1.1) can be proved.

We now prove a more general result, applicable to embedded Runge–Kutta pairs of any order and under any mode of operation. Note also that Assumption 1 is no longer required.

THEOREM 4.2. *Consider an adaptive embedded Runge–Kutta pair of any order* $(p-1,p)$*, operating in EPS, XEPS, EPUS, or XEPUS mode, where the higher-order method has positive weights. If Assumption* 2 *holds and the ODE* (1.1) *satisfies both* (D) *and* (D′)*, then* $\exists\tau^* > 0$ *such that* $\forall\tau \leq \tau^*$*, the numerical trajectory eventually enters a compact set independent of* τ, U*.*

Proof. Again we consider the extrapolation case first. From Assumption 2 and (1.10),

$$\left| h_n^2 \sum_{i,j=1}^{s} m_{ij}\langle f(\eta_i), f(\eta_j)\rangle \right| \leq K_2 C_1 \|U_n\|\,\|f(U_n)\|\tau h_n^{1+\rho},$$

which upon substituting into (4.1) gives

$$\begin{aligned}\|V_{n+1}\|^2 &\leq \|U_n\|^2 + 2h_n \sum_{i=1}^{s} b_i\langle\eta_i, f(\eta_i)\rangle + K_2C_1\|U_n\|\,\|f(U_n)\|\tau h_n^{1+\rho}\\ &= \|U_n\|^2 + h_n b_1\langle\eta_1, f(\eta_1)\rangle + 2h_n\sum_{i=1}^{s}\hat{b}_i\langle\eta_i, f(\eta_i)\rangle\\ &\quad + K_2C_1\|U_n\|\,\|f(U_n)\|\tau h_n^{1+\rho},\end{aligned}$$

where $\hat{b}_1 = \frac{1}{2}b_1$ and $\hat{b}_i = b_i,\ i = 2, \ldots, s$. We now assume that $\|U_n\| > R$ and using (D′) obtain

$$\begin{aligned}\|V_{n+1}\|^2 \leq \|U_n\|^2 - h_n b_1\gamma\|U_n\|\,\|f(U_n)\| + 2h_n\sum_{i=1}^{s}\hat{b}_i\langle\eta_i, f(\eta_i)\rangle\\ + K_2C_1\|U_n\|\,\|f(U_n)\|\tau h_n^{1+\rho}.\end{aligned}$$

Choosing

$$\tau \leq \frac{b_1 \gamma}{K_2 C_1 \max(1, h_{\max})^\rho}$$

and applying (D) we have

$$\|V_{n+1}\|^2 \leq \|U_n\|^2 + 2h_n \sum_{i=1}^{s} \hat{b}_i(\alpha - \beta\|\eta_i\|^2).$$

Next we define $\tilde{\beta} = \beta/2$ to give

$$\begin{aligned} \|V_{n+1}\|^2 &\leq \|U_n\|^2 + 2h_n \sum_{i=1}^{s} b_i(\alpha - \beta\|\eta_i\|^2) - h_n b_1(\alpha - \beta\|\eta_1\|^2) \\ &\leq \|U_n\|^2 + 2h_n \sum_{i=1}^{s} b_i(\alpha - \tilde{\beta}\|\eta_i\|^2) - h_n b_1 \alpha \\ &\leq \|U_n\|^2 + 2h_n \sum_{i=1}^{s} b_i(\alpha - \tilde{\beta}\|\eta_i\|^2), \end{aligned} \tag{4.10}$$

which is identical to (4.6). Thus the proof continues in a very similar manner to that of Theorem 4.1, via the construction of a compact set S outside of which

$$2h_n \sum_{i=1}^{s} b_i(\alpha - \tilde{\beta}\|\eta_i\|^2) \leq 0.$$

While the numerical trajectory is outside the set $S \cup \overline{B}(0, R)$, its norm strictly decreases until the set is eventually entered.

For the nonextrapolation case, from (4.10) and (4.8) we once again obtain (4.9). Again, reducing $\tau, \tilde{\beta}$ and increasing K, if necessary, the numerical trajectory eventually enters some compact set $S' \cup \overline{B}(0, R)$. □

5. Numerical results. Some numerical examples are now presented to support Assumptions 1 and 2 and Theorems 4.1 and 4.2. We shall consider various embedded Runge–Kutta pairs in different operational modes. The algorithms used are all modifications of the ode23 routine supplied with MATLAB Version 4.2. This code was used (rather than, for example, the more sophisticated ODE routines in later MATLAB versions) because the timestep mechanism is particularly straightforward, containing only elements common to all such adaptive algorithms. Note that none of the previous analysis relies upon a detailed description of the timestep selection mechanism, merely that the local error control is satisfied.

Two examples of vector fields that satisfy both (D) and (D′) are the scalar ODE

$$u_t = -u|u| \tag{5.1}$$

and the linear constant-coefficient problem

$$\begin{aligned} x_t &= -y - \epsilon x, \\ y_t &= x - \epsilon y \end{aligned} \tag{5.2}$$

for $\epsilon > 0$. Note that for scalar ODEs (D) implies (D′).

A vector field that satisfies (D) but not (D$'$) is, for $\epsilon > 0$,

$$x_t = -y\sqrt{x^2+y^2} - \epsilon x, \qquad (5.3)$$
$$y_t = x\sqrt{x^2+y^2} - \epsilon y,$$

while a vector field that satisfies neither, yet has an absorbing set, is

$$x_t = y - \epsilon\frac{x}{\sqrt{x^2+y^2}}, \qquad (5.4)$$
$$y_t = -x - \epsilon\frac{y}{\sqrt{x^2+y^2}}.$$

Up to this point, we have not considered how the numerical algorithm generates candidate timesteps since we require only that the error control be satisfied. However, for the sake of completeness, we shall explicitly describe the timestep selection mechanism used in the numerical simulations. This algorithm is based upon asymptotic considerations (see, for example, [14, 7, 12]) as the tolerance τ, and thus the timesteps, tend to zero. If h_{last} was the last attempted timestep (successful or otherwise), then the next attempted timestep is defined by

$$h_{\text{next}} = \min\left(h_{\max}, \theta\left(\frac{\sigma(\tau,U)}{E(U,h_{\text{last}})}\right)^{\frac{1}{p-\rho}} h_{\text{last}}\right),$$

where U is the most recent solution value. The constant $\theta < 1$ is a "safety factor" ensuring that, provided the exact solution lies in a compact set, the proportion of rejected timesteps along numerical approximations will tend to 0 as $\tau \to 0$.

We first consider the behavior of order (1, 2) pairs with error-per-unit-step control. Figure 5.1 plots the Euclidean norm of the numerical solution against integration time for the ODEs (5.1)–(5.4) using the embedded Runge–Kutta pair consisting of the forward Euler and Heun methods, defined by

$$A = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad b = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad \bar{b} = \begin{pmatrix} \frac{1}{2} \\ \frac{1}{2} \end{pmatrix}, \qquad (5.5)$$

in extrapolation mode with $\tau = 0.1$, $\theta = 0.9$, and the norm of the initial data set to $\|U\| = 10^5$. Here, as in all subsequent results, a relative error criterion defined by

$$\sigma(\tau, u) = \tau\|u\|_2$$

was used as this results in larger timesteps and thus provides a more severe (and, arguably, more relevant) test than a pure absolute error control. Even for this relatively large value of τ, the results are in agreement with Theorem 4.1. The reduction in norm of the numerical solution for sufficiently small τ is guaranteed for (5.1)–(5.3) since this pair is essentially algebraically stable. For (5.4) the norm of the solution increases with this value of τ. If τ is reduced sufficiently, then stability of the numerical solution is recovered for this initial data but the instability reappears as $\|U\|$ is increased further, i.e., τ depends upon the initial data. In Figure 5.2, we test Assumptions 1 and 2 by plotting the calculated values of

$$k_1(U_n, h_n) = \frac{h_n^{p-\rho}\|f(U_n)\|}{\sigma(\tau, U_n)}$$

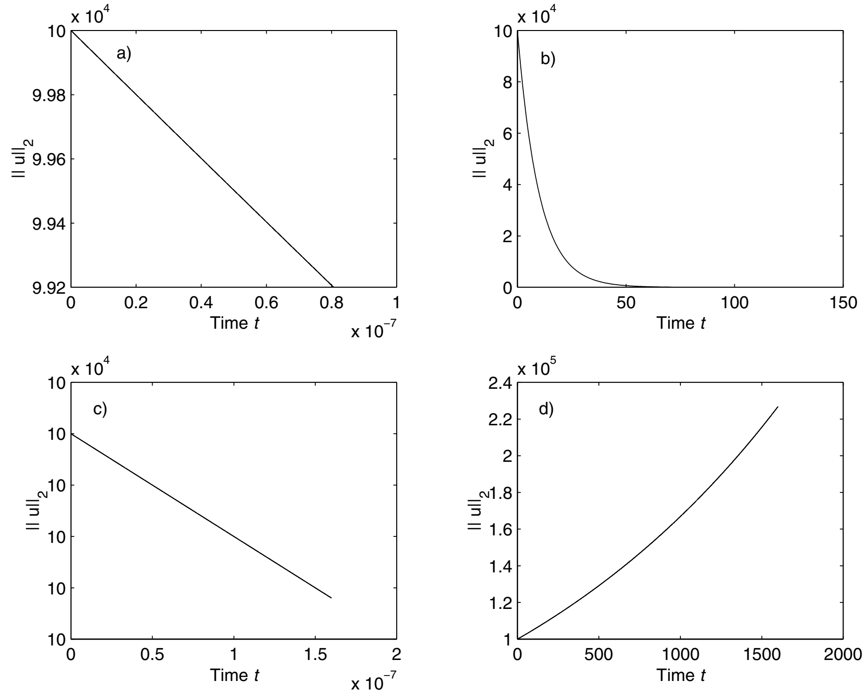


FIG. 5.1. (a)–(d) *plot the norms of the numerical solution using the embedded pair* (5.5) *in XEPUS mode for* (5.1)–(5.4)*, respectively. The values of* ϵ *used in* (b), (c), *and* (d) *are* 0.1, 1, *and* 1, *and in each case* $\tau = 0.1$. *(Note that the norm of the solution in* (c) *does decrease, as expected, but extremely slowly.)*

and

$$k_2(U_n, h_n) = \frac{\left| h_n^2 \sum_{i,j=1}^{s} m_{ij} \langle f(\eta_i), f(\eta_j) \rangle \right|}{\sigma(\tau, U_n) h_n^{1+\rho} \|f(U_n)\|}.$$

The maxima of these quantities along the numerical trajectory are the effective values of K_1 and K_2, respectively, and, if Assumptions 1 and 2 are justified, these quantities should remain bounded as $\|U_n\| \to \infty$. This is indeed the case for all four trajectories in Figure 5.1, and in Figure 5.2, k_1 and k_2 are plotted for just two of the test problems, namely, (5.1) and (5.3) (for the linear ODE (5.2), these quantities are constant along the entire numerical trajectory).

Figure 5.3 is generated exactly as Figure 5.1 but using the nonessentially algebraically stable embedded pair

$$A = \begin{pmatrix} 0 & 0 \\ 2 & 0 \end{pmatrix}, \quad \bar{b} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad b = \begin{pmatrix} \frac{3}{4} \\ \frac{1}{4} \end{pmatrix}. \tag{5.6}$$

As can be seen, the results are very similar to those using the essentially algebraically stable (EAS) pair (5.5) and suggest that, although EAS pairs have guaranteed stability properties, there is little difference between EAS and non-EAS pairs in practice.

We now consider Theorem 4.2. Figure 5.4 is generated identically to Figure 5.1 except that now the method (5.5) is being used in XEPS mode rather than XEPUS.

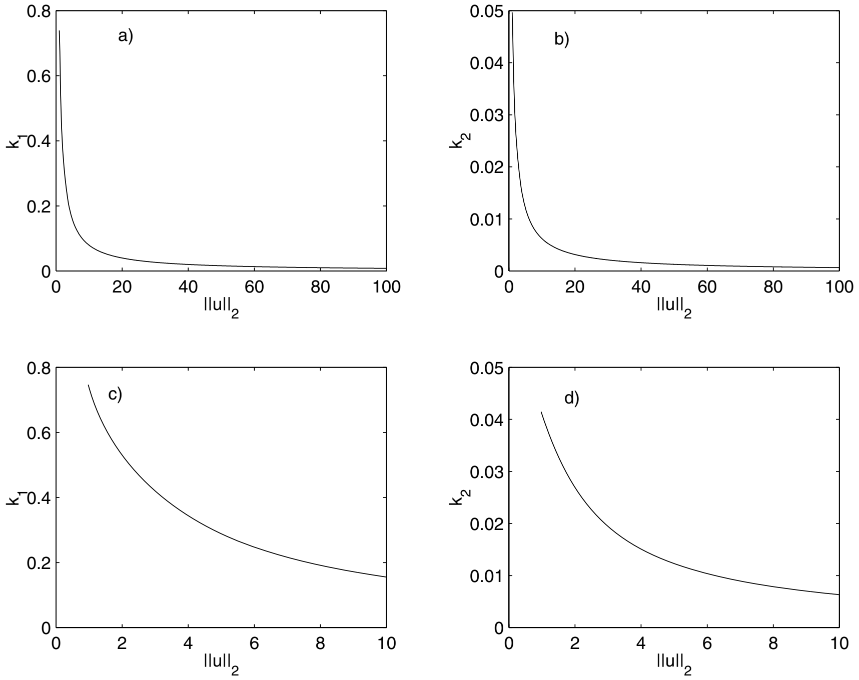

FIG. 5.2. (a) *and* (b) *show the computed values of* k_1 *and* k_2 *for a numerical trajectory of* (5.1) *while* (c) *and* (d) *are for* (5.3). *Apart from the initial data all the parameters are the same as used in Figure* 5.1(a) *and* (c).

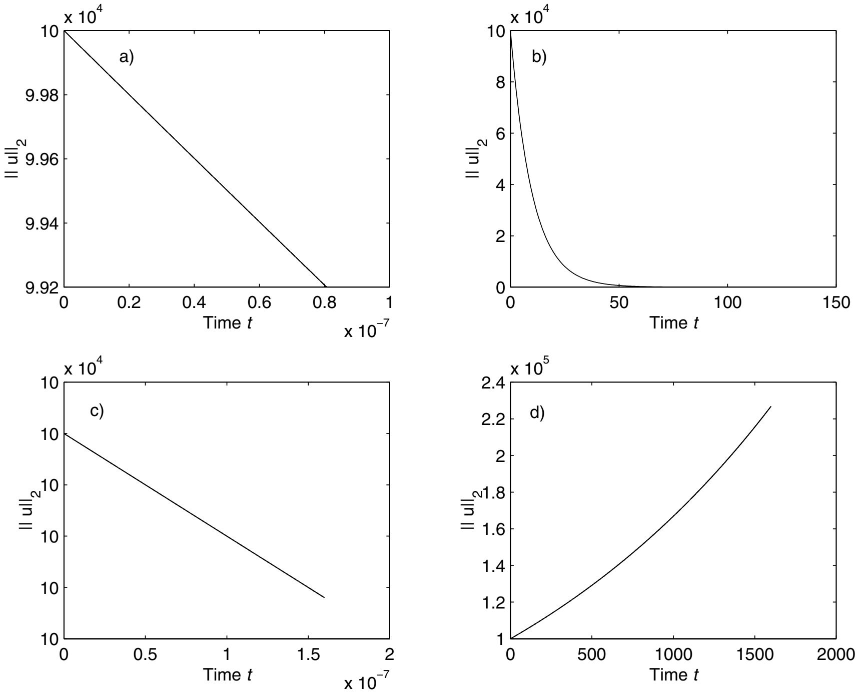

FIG. 5.3. (a)–(d) *are generated exactly as in Figure* 5.1 *but using the non-EAS pair* (5.6).

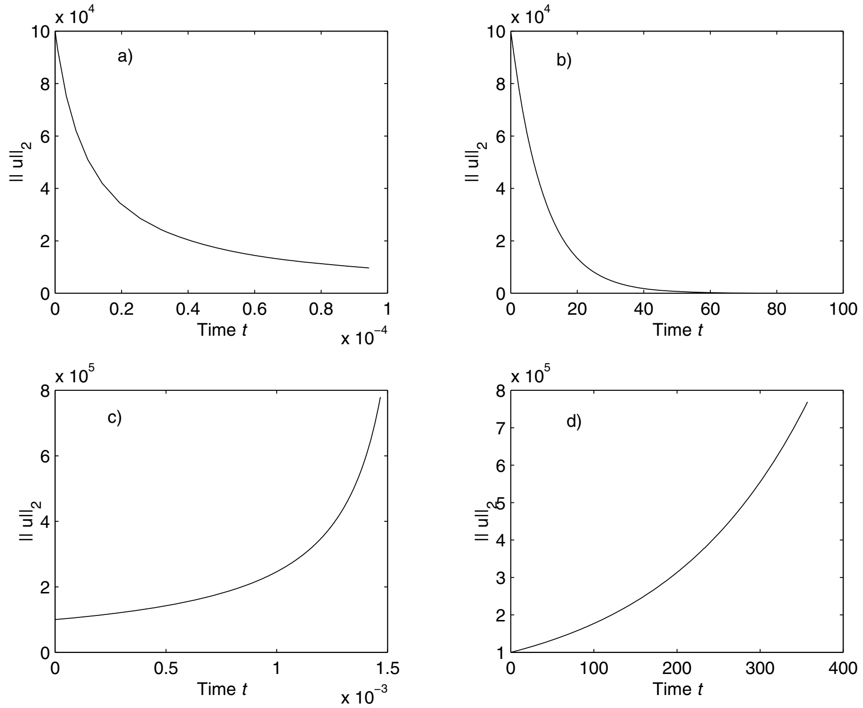

Fig. 5.4. (a)–(d) *are generated exactly as in Figure* 5.1 *but using the method* (5.5) *in XEPS rather than XEPUS mode.*

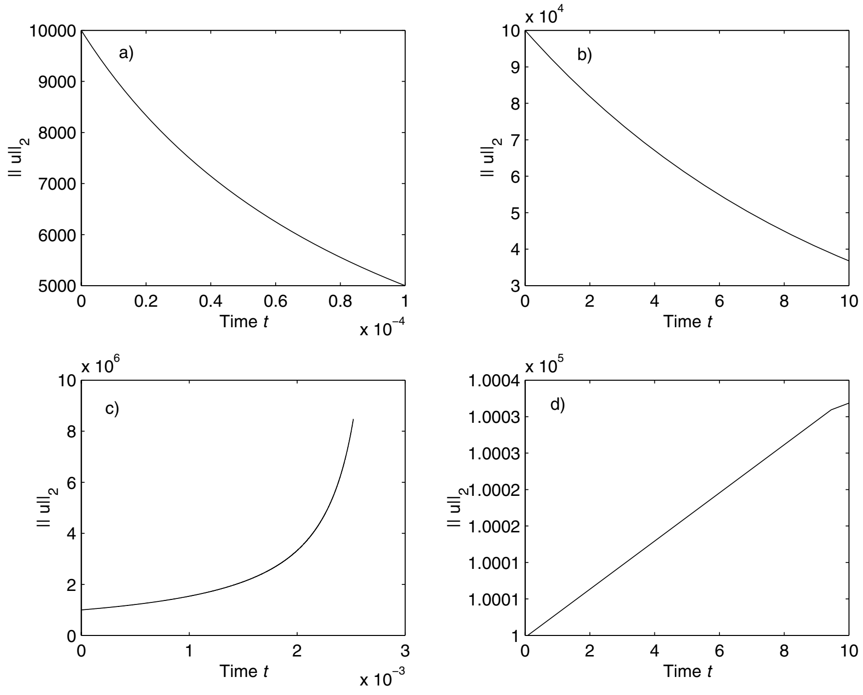

Fig. 5.5. (a)–(d) *are generated exactly as in Figure* 5.1 *but using the Fehlberg* (4, 5) *pair in XEPS mode.*

The interesting case is Figure 5.4(c), corresponding to the vector field (5.3), which satisfies (D) but not (D′). Now the norm of the numerical solution increases rather than decreases and, for any given tolerance, this phenomenon appears to occur for sufficiently large initial data.

Finally, we present results for a higher-order pair. Figure 5.5 shows the numerical results obtained using the Fehlberg (4, 5) pair in XEPS mode. Note that this embedded Runge–Kutta pair, whose coefficients are listed in [3, p. 306], does not satisfy the condition that the weights of the higher-order method are positive, but the results are similar to those obtained for other pairs that do satisfy this condition, suggesting that this condition could be weakened somewhat. Again, the importance of the additional structural assumption (D′) is revealed in Figure 5.5(c).

Acknowledgment. The author thanks one of the anonymous referees for their extremely careful reading of the original manuscript and many valuable suggestions.

ROOTS OF POLYNOMIALS EXPRESSED IN TERMS OF ORTHOGONAL POLYNOMIALS*

DAVID DAY† AND LOUIS ROMERO†

Abstract. A technique is presented for determining the roots of a polynomial $p(x)$ that is expressed in terms of an expansion in orthogonal polynomials. The roots are expressed as the eigenvalues of a nonstandard companion matrix $\mathbf{B}_n$ whose coefficients depend on the recurrence formula for the orthogonal polynomials, and on the coefficients of the orthogonal expansion. Some questions on the numerical stability of the eigenvalue problem to which they give rise are discussed. The problem of finding the roots of a transcendental function $f(x)$ can be reduced to the problem considered by approximating $f(x)$ by a Chebyshev polynomial. We illustrate the effectiveness of this convert-to-Chebyshev strategy by solving several transcendental equations using this plus our new algorithm. We analyze the numerical stability through both linear algebra theory and numerical experiments and find that this method is very well conditioned.

1. Introduction.

Suppose we want to find the real roots (especially those in $[-1,1]$) of a polynomial expressed by its Chebyshev coefficients

$$p(x) = \sum_{i=0}^{n} \gamma_i T_i(x).$$

Or more generally, $p(x)$ may be expressed in terms of polynomials $\{\phi_m(x)\}_{m\geq 0}$, each $\phi_m(x)$ of exact degree m, that are orthogonal with respect to an inner product, e.g.,

$$\langle f, g\rangle_\rho = \int_a^b f(x)\overline{g(x)}\rho(x)dx \tag{1.1}$$

for some real and positive weight function $\rho(x)$.

One way to find the roots of $p(x)$ is to express $p(x)$ as a sum of monomials, and then to calculate the roots as the eigenvalues of the standard companion matrix. However, expressing a polynomial by its monomial coefficients is not as well conditioned as the expression in terms of Chebyshev polynomials. The transformation between a polynomial of degree n in $[-1,1]$ and its expansion coefficients with respect to the monomials [12] has $\mathcal{O}((1+\sqrt{2})^{n+1})$ condition number with respect to maximum norms (over $[-1,1]$) and with respect to Chebyshev polynomials [10] has $\mathcal{O}(n)$ condition number.

†Computational Mathematics and Algorithms Department, Sandia National Laboratories, P.O. Box 5800, Albuquerque, NM 87185-1110 (dmday@sandia.gov, lromero@sandia.gov).

For the case of Chebyshev polynomials, Boyd [6] and also Battles and Trefethen [2] have proposed solving this problem by projecting to the unit circle in the complex z-plane with $x = (z + z^{-1})/2$, and using the fact that $T_k(x) = \cos(k \cos^{-1}(x))$. Their technique allows them to find the roots of $p(x)$ in terms of a standard companion matrix that depends on the coefficients $\{\gamma_k\}_{k=0}^{n}$ of the orthogonal expansion. These authors have found that this is a very successful algorithm, but the trouble is that it makes use of an eigenvalue problem of size $2n$ for a rootfinding problem of size n.

The present manuscript proposes an alternative formulation based on a nonstandard companion matrix $\mathbf{B}_n$ of dimension n. The algorithm is an extension of the technique [13] for finding the roots of the nth orthogonal polynomial $\phi_n(x)$. The technique uses the fact that any set of orthogonal polynomials satisfies a recurrence formula of the form

$$x\phi_{n-1}(x) = \sum_{i=0}^{n} \phi_i(x) h_{i,n-1}. \tag{1.2}$$

The coefficients determine an n by n matrix $\mathbf{H}_n = [h_{i,j}]_{0 \le i,j < n}$ whose eigenvalues are the roots of the nth orthogonal polynomial $\phi_n(x)$. For ortho*normal* polynomials based on certain inner products such as (1.1), $\mathbf{H}_n$ is symmetric and tridiagonal. For a general inner products, $\mathbf{H}_n$ is upper Hessenberg, that is, $h_{i,j} = 0$ for $i > j + 1 > 0$.

As a specific example, the Chebyshev polynomials satisfy the three-term recurrence $T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x)$ for $n \ge 1$, or recast in the form of (1.2), $xT_n(x) = T_{n-1}(x)\frac{1}{2} + T_{n+1}(x)\frac{1}{2}$. In this case, there holds $h_{0,1} = \frac{1}{2}$, $h_{0,1} = 1$ for $i > 0$, $h_{i,i+1} = h_{i+1,i} = \frac{1}{2}$, and otherwise $h_{i,j} = 0$. The asymmetry of $h_{0,1}$ and $h_{1,0}$ reflects the nonconstant normalization of $\{T_k\}_{k \ge 0}$: for $\rho(x) = \sqrt{1 - x^2}$ there holds $\langle T_k, T_k \rangle_\rho = \frac{\pi}{4}(1 + \delta_{k,0})$.

Our technique for finding the roots of $p(x)$ is a modification of the technique for finding the roots of $\phi_n(x)$. To express our result we use the notation

$$\mathbf{f}_n(x) = [\phi_0(x), \dots, \phi_{n-1}(x)]^T \tag{1.3}$$

for the column vector-valued function containing the first n orthogonal polynomials, and the notation

$$\mathbf{c}^T = [\gamma_0, \gamma_1, \dots, \gamma_{n-1}] \tag{1.4}$$

for the column vector containing the first n coefficients of the polynomial $p(x)$. Using this notation we have

$$p(x) = \mathbf{f}_n(x)^T \mathbf{c} + \gamma_n \phi_n(x). \tag{1.5}$$

In section 2, Theorem 2.3 shows that the roots of $p(x)$ are the eigenvalues of the nonstandard companion matrix

$$\mathbf{B}_n = \mathbf{H}_n - h_{n,n-1} \frac{\mathbf{c}}{\gamma_n} \mathbf{e}_{n-1}^T, \tag{1.6}$$

where $\mathbf{e}_{n-1} = [0, \dots, 0, 1]^T$ is a column vector of dimension n. When applied to finding roots of polynomials expressed in terms of Chebyshev polynomials for large values of n the new method promises to be something like eight times faster than the method proposed by Boyd and Battles and Trefethen. It is somewhat faster than the direct conversion to a monomials (without doubling the degree), which is unstable for large values of n.

Orthogonal polynomials have many applications. Transcendental equations may be solved with Chebyshev polynomials, as was proposed in [4] and developed further in the follow-up papers [5] and [6]. Battles and Trefethen automate, through MATLAB calls, a suite of operators on functions. The implementation is accomplished using Chebyshev polynomials of very high degree. And the operator that finds the real roots of a function is (now) implemented along the lines described here. Battles and Trefethen have pointed out that certain applications of polynomials based on the monomial form may be significantly improved by using another form based on a specific family of orthogonal polynomials.

Although the technique we present in this paper finds all of the roots of the polynomial $p(x)$, we will see that it only has desirable stability properties for finding roots in an appropriate region of the complex plane. For example, for Chebyshev polynomials we only have desirable stability properties for finding real roots in or near the interval $[-1, 1]$. Similarly, transcendental equation solvers based on the rootfinding by Chebyshev expansions have desirable stability properties only for roots in or near interval $[-1, 1]$ (see Theorem 4.2).

When we approximate a transcendental function in terms of an orthogonal polynomial expansion, the highest order coefficient γ_n converges to zero (see Theorem 4.1). For this reason, many cases of interest are near the division by zero singularity in (1.6) for $\mathbf{B}_n$. The singularity is avoided by solving a generalized eigenvalue problem as described in section 2 or [19]. However, in Theorem 4.2, we will show that if a transcendental function is approximated as a finite sum of Jacobi polynomials, the roots found by using the corresponding matrix $\mathbf{B}_n$ accurately approximate the transcendental equation roots in or near $[-1, 1]$.

If the cost of solving the eigenvalue problem becomes a computational bottleneck, then one may use a subdivision algorithm (see [7]) that decomposes the rootfinding problem into several subproblems and applies Chebyshev polynomials of lower order in each subinterval.

1.1. Summary. We begin in section 2 by reviewing a process for finding the roots of the nth orthogonal polynomial $\phi_n(x)$ as the eigenvalues of the matrix $\mathbf{H}_n$. We then show how to modify this process to construct the nonstandard companion matrix $\mathbf{B}_n$ whose eigenvalues are given by the roots of the polynomial $p(x)$ (cf. Theorem 2.3). Although classical orthogonal polynomials are emphasized over all, we abstractly define “orthogonal polynomial” (see Definition 2.1) so that our results include the monomials, and hence our results include the standard companion matrix. Lemma 2.4 presents analytical expressions for both the left and right eigenvectors in terms of the eigenvalues. In section 3 the sensitivities of polynomial roots and matrix eigenvalues are compared. Theorem 3.3 demonstrates how eigenvalue and polynomial root sensitivities coincide in certain cases.

The algorithms presented herein are not so much new as they are not widely known. The companion matrices for orthogonal polynomials were independently discovered by Hans Stetter. For a derivation of the nonstandard companion matrix based on quotient rings in algebraic geometry (see [21]). Exercise 1c on p. 148 of [21] asks the reader to derive the companion matrix for Chebyshev polynomials. On the other hand, Stetter emphasizes application to polynomials of modest degree, say 10 (cf. p. 146). The observation that the roots of the nth member of a family of orthogonal polynomials must be the eigenvalues of a companion matrix whose elements come from the coefficients of the recurrence relation for the orthogonal polynomials was well known to Jacobi [13]. Like Stetter, we show how to define “orthogonal” polynomial broadly enough to apply the observation to any polynomial. Our contribution is some analysis of the numerical stability of such methods. Example 3 of section 5 uses a degree 256 polynomal to solve a transcendental equation.

In order to concentrate on issues of interest in applications using orthogonal polynomials, we discuss the representative application of finding the roots of a scalar transcendental equation in a real interval. Representing a function by the partial sum of an exponentially convergent orthogonal expansion raises issues that must be addressed. In particular, ill-conditioning is manifested in the roots that we do not want. However, roots in a specific domain of the complex plane are well conditioned in a certain sense.

In section 3.3 representation with respect to Chebyshev polynomials, or any Jacobi polynomial, are shown to be ideal for finding roots in or quite near $[-1, 1]$. Away from $[-1, 1]$, the Jacobi polynomials are not recommended. The prerequisite results for classical orthogonal polynomials are reviewed. It is shown that for rootfinding in an interval, representing polynomials with respect to Jacobi orthogonal polynomials is ideal. But monomials are better for rootfinding in the unit disk. In particular the algorithms described herein are not designed to find all of the roots of a polynomial.

In section 4 we discuss how matrix balancing is desirable in computing the eigenvalues of $\mathbf{B}_n$. The upper Hessenberg structure of $\mathbf{B}_n$ is crucial in the explanation of the success of matrix balancing. Theorem 4.2 shows how partial sums of orthogonal expansions lead to companion matrices that are amenable to matrix balancing. We use our analytical expressions for the left and the right eigenvalues to show that the polynomial and eigenvalue sensitivities differ by a computable (and benign) factor, related to the associated Lagrange interpolation polynomials. The companion matrix formulation is numerically stable in this case.

Analysis is also included intended for a posteriori use in solving transcendental equations. An algorithm for finding the roots of a transcendental equation in $[-1, 1]$ using expansions in terms of Chebyshev polynomials is presented in section 4.2. Numerical experiments are presented in section 5 that demonstrate the reliability of the algorithm. Our results are summarized in section 6.

For expansions of transcendental equations, we explain why the companion matrix is amenable to balancing. The exponential convergence rate is related to the distance to the nearest singularity of the locally analytic function, and also applies to the (right) eigenfunctions. Balancing "factors out" the dependence of $\mathbf{B}_n$ on $1/\gamma_n$, and the balanced companion matrix eigenvalue problem is numerically stable. An algorithm for finding the roots of a transcendental equation on $[-1, 1]$ using expansions in terms of Chebyshev polynomials is presented in section 4.2. Numerical experiments are presented in section 5 that demonstrate the reliability of the algorithm.

2. Companion matrices.

Starting from a general definition of orthogonal polynomials, we review the procedure for finding the roots of orthogonal polynomials as the eigenvalues of the matrix $\mathbf{H}_n$ containing the coefficients in the recurrence formula. The discussion closely follows [13]. Next we construct a nonstandard companion matrix corresponding to a sequence of orthogonal polynomials and a given polynomial. In Theorem 2.3 we establish the equivalence between the roots of the polynomial equation and the companion matrix spectrum. In Lemma 2.4 we give an analytical expression for the right eigenvectors of $\mathbf{B}_n$. The proof exploits the connection between Vandermonde matrices and Lagrange interpolation polynomials.

Orthogonal polynomials are broadly defined here to emphasize the connection between the numerical stability of a companion matrix eigenvalue problem and the associated inner product. There is a one-to-one correspondence between inner products on polynomials and the set of sequences of univariate polynomials $\{\phi_i(x)\}_{i\geq 0}$ such that each $p_k(x)$ has degree k. The polynomials are orthonormal with respect to the polynomial inner product that is the ordinary vector inner product of expansion coefficients.

We will work over the space of complex valued continuous functions on a bounded subdomain of the complex plane.

DEFINITION 2.1. *With respect to the inner product* $\langle , \rangle$ *the sequence* $\{\phi_n(x)\}_{n\geq 0}$ *are orthogonal polynomials if each* $\phi_n(x)$ *is a polynomial of exact degree* n *and* $\langle \phi_n, \phi_m\rangle = \delta_{n,m}\sigma_n^2$. *Here* $\delta_{i,j}$ *is Kronecker's delta and* $\{\sigma_n\}_{n\geq 0}$ *is a sequence of positive real numbers. The polynomials* $\{\phi_n(x)\}_{n\geq 0}$ *are orthonormal if each* σ_n *is one. The norm induced by the inner product is denoted by* $\||\ \psi\ \|| = \langle \psi, \psi\rangle^{1/2}$.

Orthogonality implies that for $i \leq n-1$, $\||\ \phi_i\ \||^2 \ \ h_{i,n-1} = \langle \phi_i(x), x\phi_{n-1}(x)\rangle$.

Usually when discussing orthogonal polynomials we will be concerned with inner products of the form in (1.1). Orthonormal polynomials with respect to this type of inner product must satisfy a symmetric three-term recurrence formula. This is a consequence of the fact that such an inner product is symmetric with respect to multiplication; that is, $\langle xf(x), g(x)\rangle = \langle f(x), xg(x)\rangle$.

For rootfinding problems over bounded complex domains, we recommend the inner product that arises in Bergman's theory of (reproducing) kernel functions (see [18, p. 36], [22, section 11.2], or [17, Lemma 17.2.3]). For example, the monomials are orthogonal polynomials with respect to the inner product

$$\langle f, g\rangle = \frac{1}{2\pi i}\int_\Gamma f(z)\overline{g}(z)dz,$$

where the integral is taken over the circle Γ centered around the origin in the complex plane. Note that this inner product is not symmetric with respect to multiplication.

2.1. Roots of orthogonal polynomials: A review.

A way to find the roots of the nth orthogonal polynomial $\phi_n(x)$ uses the recurrence formula in (1.2). The first n instances of (1.2) combine using the matrix $\mathbf{H}_n$, the column vector $\mathbf{f}_n$, and the coefficient $h_{n,n-1}$ into the matrix equation

$$x\mathbf{f}_n^T(x) = \mathbf{f}_n^T(x)\mathbf{H}_n + \phi_n(x)h_{n,n-1}\mathbf{e}_{n-1}^T. \tag{2.1}$$

Equation (2.1) exposes the equivalence between the roots ξ root of $\phi_n(x) = 0$ and the eigenvalues of $\mathbf{H}_n$,

$$\xi\mathbf{f}_n^T(\xi) = \mathbf{f}_n^T(\xi)\mathbf{H}_n.$$

We conclude with the following result that Gautschi [13] attributes to Jacobi.

THEOREM 2.2. *The algebraic eigenvalues of* H_n *defined in* (2.1) *coincide with the algebraic roots of the degree* n *orthogonal polynomial* $\phi_n(x)$.

Proof. The result is a corollary of Theorem 2.3. □

2.2. Nonstandard companion matrices.

Assuming that $\gamma_n \neq 0$, we can use (1.5) to express $\phi_n(x)$ as

$$\phi_n(x) = \frac{p(x) - \mathbf{f}_n(x)^T\mathbf{c}}{\gamma_n}. \tag{2.2}$$

If we substitute this expression for $\phi_n(x)$ into (2.1), we arrive at the equation

$$x\mathbf{f}_n^T(x) = \mathbf{f}_n^T(x)\mathbf{H}_n + \frac{p(x) - \mathbf{f}_n(x)^T\mathbf{c}}{\gamma_n}h_{n,n-1}\mathbf{e}_{n-1}^T. \tag{2.3}$$

We now see that if ξ is a root of $p(x) = 0$, then

$$\xi \mathbf{f}_n^T(\xi) = \mathbf{f}_n(\xi)^T \mathbf{B}_n, \tag{2.4}$$

where as in (1.6)

$$\mathbf{B}_n = \mathbf{H}_n - h_{n,n-1} \frac{\mathbf{c}}{\gamma_n} \mathbf{e}_{n-1}^T.$$

This shows that if ξ is a root of $p(x)$, then it must be an eigenvalue of $\mathbf{B}_n$ with left eigenvector $\mathbf{f}_n^T(\xi)$. The converse is established in Theorem 2.3.

Equivalently, we could express the first n terms of our recurrence formula as

$$x\mathbf{f}_{n+1}(x)^T = \mathbf{f}_{n+1}^T(x) \begin{bmatrix} \mathbf{H}_n \\ h_{n,n-1}\mathbf{e}_{n-1}^T \end{bmatrix}.$$

When we combine this with the requirement that $p(x) = 0$ using (1.5), we get the system of equations

$$\mathbf{f}_{n+1}^T(\xi) \begin{bmatrix} \mathbf{H}_n & \mathbf{c} \\ h_{n,n-1}\mathbf{e}_{n-1}^T & \gamma_n \end{bmatrix} = \xi \mathbf{f}_{n+1}^T(\xi) \begin{bmatrix} \mathbf{I}_n & \mathbf{0} \\ \mathbf{0} & 0 \end{bmatrix}. \tag{2.5}$$

Any root ξ of $p(x) = 0$ must be an eigenvalue of this generalized eigenvalue problem with left eigenvector $\mathbf{f}_{n+1}(\xi)$.

As is the case for companion matrices, one may either solve the generalized eigenvalue problem in (2.5) and discard an infinite eigenvalue or find the eigenvalues as defined in (2.4).

The standard backward stable algorithms for generalized and ordinary eigenvalue problems in (2.5) and (2.4) are the QZ and QR algorithms, respectively. Because of the upper Hessenberg form of these matrices, no initial transformation to Hessenberg form is required for either QZ or QR. For computing eigenvalues only in the average case, QR is three times faster than QZ [14]. The question of which formulation to use is not an entirely solved problem. The fact that $\mathbf{B}_n$ may have a very large norm suggests that the formulation of (2.5) has superior stability properties. Numerical experiments do not confirm this hypothesis. Polynomial equations for which the formulation of (2.5) is advantageous do exist [19], but do not arise in the solution of transcendental equations. We performed numerical experiments comparing the residual norms of the polynomials evaluated at the eigenvalues computed by either QZ or QR. We observed that if QR is used without balancing, then the eigenvalues computed from the ordinary eigenvalue problem suffer roundoff errors proportional to $\|\mathbf{c}\|/\gamma_n$. QR with balancing and QZ always computed eigenvalues of the same quality even if $\|\mathbf{c}\|/\gamma_n$ is very large. Explanations are provided in Theorem 3.3 and in section 4.

Next the equivalence of the roots of the polynomial $p(x)$ and the eigenvalues of the matrix $\mathbf{B}_n$ defined in (1.6) and (2.4) is demonstrated.

THEOREM 2.3. *The roots of a polynomial p of exact degree n coincide with the eigenvalues of the generalized companion matrix $\mathbf{B}_n$ counting algebraic multiplicity.*

Proof. We have already shown that a root ξ of $p(x)$ is an eigenvalue of $\mathbf{B}_n$ with left eigenvector $\mathbf{f}_n(\xi)$. The converse follows from two properties of unreduced upper Hessenberg matrices, including $\mathbf{B}_n - \xi I_n$ for any ξ: first a nontrivial (right) null vector has nonzero last component, and second the nullity is at most one. The properties of Hessenberg matrices are discussed in [14, section 7.4.5] and, in particular, [14, Theorem 7.4.4]. If ξ is an eigenvalue of $\mathbf{H}_n$ with nontrivial (right) eigenvector $\mathbf{v} = [v_0, \ldots, v_{n-1}]^T$, then $v_{n-1} \neq 0$. Substitution of (2.2) into (2.1) yields

$$x\mathbf{f}_n^T(x) = \mathbf{f}_n^T(x)\left(\mathbf{H}_n - \frac{\mathbf{c}}{\gamma_n} h_{n,n-1}\mathbf{e}_{n-1}^T\right) + \frac{p(x)}{\gamma_n} h_{n,n-1}\mathbf{e}_{n-1}^T. \tag{2.6}$$

Inspection of the product of (2.6) and $\mathbf{v}$ implies that $p(\xi) = 0$. As a consequence of the second property, a left eigenvector of ξ must be proportional to $\mathbf{f}_n(\xi)$. □

2.3. The right eigenvectors. We have already shown that if ξ_j is the jth root of the polynomial $p(x)$, then $\mathbf{v}_j^T = \mathbf{f}_n^T(\xi_j)$ is the left eigenvector associated with the eigenvalue ξ_j of $\mathbf{B}_n$. We will now give a simple expression for the right eigenvectors $\mathbf{w}_j$ associated with this eigenvalue.

The matrix of left eigenvectors, $\mathbf{V}$, has jth row $\mathbf{v}_j$. The ith row of the inverse contains the right eigenvector $\mathbf{w}_i$. Note that the n by n matrix $\mathbf{V} = [\nu_{i,j}]$ is called a generalized Vandermonde matrix due to $\nu_{i,j} = \phi_j(\xi_i)$.

The right eigenvectors can be expressed using the interpolating polynomials. Assuming that ξ_j is a simple root of $p(x)$, the jth Lagrange interpolating polynomial associated with the roots of $p(x)$ is

$$l_j(x) = \frac{p(x)}{p'(\xi_j)(x - \xi_j)}.$$

Each interpolating polynomial $l_j(x)$ has degree $n - 1$ and satisfies $l_j(\xi_k) = \delta_{jk}$ for $0 \leq j, k < n$.

Each polynomial $l_j(x)$ has degree $n-1$ and is a linear combination of $\{\phi_k(x)\}_{k=0}^n$. Define the column vector $\mathbf{w}_j$ to contain the expansion coefficients of $l_j(x)$,

$$l_j(x) = \mathbf{f}_n^T(x)\mathbf{w}_j.$$

It follows that $\delta_{ij} = l_j(\xi_i) = \mathbf{f}_n^T(\xi_i)\mathbf{w}_j = \mathbf{v}_i^T\mathbf{w}_j$. This shows that the vector $\mathbf{w}_i$ is in fact the ith column of the inverse matrix of $\mathbf{V}$, and hence $\mathbf{w}_i$ is the right eigenvector associated with the eigenvalue ξ_i. This proves the following lemma.

LEMMA 2.4. *The companion matrix $\mathbf{B}_n$ defined in (2.4) corresponding to a polynomial $p(x)$ of exact degree n and with distinct roots, $\{\xi_j\}_{0\leq j<n}$, has as eigenvalues the roots of $p(x)$. The left eigenvector corresponding to ξ_k is $\mathbf{f}_n(\xi_k)$. Moreover, if $\{\phi_j\}$ are orthonormal polynomials, then for $l_j(x) = \frac{p(x)}{p'(\xi_j)(x-\xi_j)}$ the jth right eigenvector $\mathbf{w}_j$ has components $\mathbf{e}_k^T\mathbf{w}_j = \langle l_j, \phi_k\rangle$ and $\|\mathbf{w}_j\|_2 = |||l_j|||$.*

Proof. The comments directly before the lemma establish the following: the n by n matrix $\mathbf{W} = [\mathbf{w}_0, \ldots, \mathbf{w}_{n-1}]$ whose jth column, $\mathbf{w}_j$, contains the expansion coefficients of $l_j(x)$ with respect to $\{\phi_j(x)\}_{0\leq j<n}$, i.e., $l_j(x) = \mathbf{f}_n^T(x)w_j$, is $\mathbf{W} = \mathbf{V}^{-1}$, thus is the matrix of right eigenvectors. Next take the inner product of $l_j(x)$ with $\phi_k(x)$. By Definition 2.1, $\langle l_j, \phi_k\rangle = |||\phi_k|||^2 e_k^T w_j$. The desired representation follows in the orthonormal case. Parseval's formula readily furnishes the equivalence between the norms. □

The relationship between $|||l_j|||$ and $p(x)$ is further developed in section 4.

3. Sensitivity analysis.

Rootfinding by eigenvalue problems is popular due to its favorable stability properties compared to other methods. A stability analysis for the standard companion matrix formulation has been performed in [23]. The companion matrix form is viewed as a rank one perturbation of a bidiagonal matrix, and the inverses of the shifted companion matrices are analyzed. Here we perform a local analysis of the nonstandard companion matrix, assessing stability by comparing the polynomial root and eigenvalue the polynomial root sensitivities. The limitation of a local analysis is that it is only valid for eigenvalues that are well separated.

3.1. Polynomial root sensitivity. The perturbation theory for polynomial roots is considered following [11]. We consider some particular zero ξ of $p(x)$ as a complex valued function of the expansion coefficients with respect to the orthogonal polynomials. Denote the dependence on the coefficients $\mathbf{c}$ by $\xi(\mathbf{c})$.

LEMMA 3.1. *Suppose that a polynomial of exact degree n, $p(x) = \mathbf{f}_{n+1}^T(x)\mathbf{c}_o$, where $\mathbf{c}_o$ is an $(n+1)$-dimensional column vector, has a simple root ξ_o such that $p(\xi_o) = 0 \neq p^{'}(\xi_o)$. There exists a smooth function $\xi(\mathbf{c})$ such that $\xi(\mathbf{c}_o) = \xi_o$ and $\mathbf{f}_{n+1}^T(\xi(\mathbf{c}))\mathbf{c} = 0$ with gradient $\nabla_{\mathbf{c}}\xi(\mathbf{c}_o) = -\mathbf{f}_{n+1}^T(\xi_o)/p^{'}(\xi_o)$.*

Proof. See Example 3.10 in [21] for the proof. □

We will discuss several aspects of Lemma 3.1, starting with the excluded case of multiple roots. In the case of a root of algebraic multiplicity $m > 1$, there exist infinitesimal coefficient perturbations that change the multiplicity, and the roots are Hölder continuous with exponent $1/m$ (see Proposition 5.1 in [21] or Theorem 4.1 in [6]). Approximations to roots with nontrivial multiplicity correspond to small values of $p(\xi_o)$. Monitoring the value of the polynomial derivative at all approximate roots of interest for small values is required.

Next, the implication of Lemma 3.1 is that the norm of the gradient of a root with respect to the coefficients is proportional to $\|\mathbf{f}_{n+1}(\xi_o)\|_2$. In other words, a root ξ_o is not very sensitive to the polynomial coefficients if both $\|\mathbf{f}_{n+1}(\xi_o)\|_2$ is not "large" and $|p'(\xi_o)|$ is not "small." For all the orthogonal polynomials familiar to the authors, for sufficiently large x, $\|\mathbf{f}_{n+1}(x)\|_2$ grows exponentially as a function of n. This observation reflects the intrinsic difficulty of finding all the roots of an arbitrary polynomial. On the other hand, using a Jacobi polynomial, for a root $-1 \leq \xi_o \leq 1$, $\|\mathbf{f}_{n+1}(\xi_o)\|_2$ is not "large" (clarified in section 3.3) and no well-separated root is very sensitive to the coefficients.

3.2. Eigenvalue sensitivity. In section 3.1 we showed that the polynomial root sensitivity with respect to the coefficients is $\|\mathbf{f}_{n+1}\|$. Here the condition number of a simple eigenvalue is related to the corresponding left and right eigenvectors $\mathbf{f}_n = \mathbf{v}$ and $\mathbf{w}$. A standard result from the perturbation theory of simple eigenvalues is that under an infinitesimal perturbation $\delta\mathbf{A}$ of a matrix $\mathbf{A}$, a simple eigenvalue λ changes to $\lambda + \delta\lambda$, where $\delta\lambda = \mathbf{v}^T\delta\mathbf{A}\mathbf{w}\ /\mathbf{v}^T\mathbf{w}$. Lemma 3.2 restates the result without using infinitesimals.
