We now are in a position to prove the crucial uniform discrete inf-sup condition which guarantees the convergence of the finite element scheme applied to the mixed formulation.

THEOREM 5.7. *There exists $\beta^* > 0$ independent of h such that*

$$\inf_{\mu_h \in \mathcal{M}_h} \sup_{V_h \in \mathcal{X}_h} \frac{b((s_h \cdot a_3);\mu_h)}{\|V_h\|_{\mathcal{X}}\|\mu_h\|_{\mathcal{M}}} \ge \beta^*. \tag{27}$$

Proof. Let thus

$$\beta_h = \inf_{\mu_h \in \mathcal{M}_h} \sup_{V_h \in \mathcal{X}_h} \frac{b((s_h \cdot a_3);\mu_h)}{\|V_h\|_{\mathcal{X}}\|\mu_h\|_{\mathcal{M}}}.$$

By construction, since μ_h vanishes on $\partial\omega$, we see that $V_h = (0, R_h(\mu_h)) \in \mathcal{X}_h$ and that $\|V_h\|_{\mathcal{X}} = \|\nabla R_h(\mu_h)\|_{L^2(\omega;\mathbb{M}_{32})}$. Therefore, by Lemma 5.6,

$$\beta_h \ge C \inf_{\mu_h \in \mathcal{M}_h} \frac{\|\mu_h\|_{\mathcal{M}}}{\|\nabla R_h(\mu_h)\|_{L^2(\omega;\mathbb{M}_{32})}},$$

and it suffices to estimate the denominator from above independently of h. We can write

$$R_h(\mu_h) = R_h(\mu_h) - \mu_h a_3 + \mu_h a_3,$$

and since $\mu_h a_3 \in H^1(\omega;\mathbb{R}^3) \cap C^0(\bar{\omega};\mathbb{R}^3)$ and $R_h(\mu_h)$ is the P_1-interpolate of $\mu_h a_3$ on the triangulation, which is regular by assumption, a classical scaling argument shows that

$$\|\nabla R_h(\mu_h) - \mu_h a_3\|_{L^2(\omega;\mathbb{M}_{32})} \le C\|\nabla(\mu_h a_3)\|_{L^2(\omega;\mathbb{M}_{32})}.$$

Therefore

$$\|\nabla R_h(\mu_h)\|_{L^2(\omega;\mathbb{M}_{32})} \leq (C+1)\|\nabla(\mu_h a_3)\|_{L^2(\omega;\mathbb{M}_{32})}.$$

But we have already seen in the continuous case that

$$\|\nabla(\mu_h a_3)\|_{L^2(\omega;\mathbb{M}_{32})} \leq C\|\mu_h\|_{\mathcal{M}}.$$

We have thus obtained that

$$\|\nabla R_h(\mu_h)\|_{L^2(\omega;\mathbb{M}_{32})} \leq C\|\mu_h\|_{\mathcal{M}},$$

which completes the proof of the Theorem. □

Remark. It is fairly clear that the proof works the same if we replace P_1 interpolation by another Lagrange interpolation, for example, P_2, which is also available in FreeFem++.

The proof of Theorem 5.3 follows as in [9] or [14].

Naturally, if we assume some regularity of the solution, we obtain error estimates.

PROPOSITION 5.8. *Assume that the solution* $((u,r),\lambda)$ *of problem* (4.1) *belongs to* $H^2(\omega,\mathbb{R}^3)^3$. *Then there exists a constant* C *independent of* h *such that*

$$\|(u_h,r_h)-(u,r)\|_{\mathcal{X}} + \|\lambda_h-\lambda\|_{\mathcal{M}} \leq Ch\|((u,r),\lambda)\|_{H^2}. \tag{28}$$

Proof. See [14], for example. □

6. Numerical tests. In this section, we implement the discretization of both penalized and mixed approaches, compare them on a literature benchmark, and apply them to genuinely $W^{2,\infty}$ shells.

6.1. Implementation details. Both model formulations only require the knowledge of a_α, a_3, and $\partial_\alpha a_3$. All other quantities, either geometrical like the elasticity tensor or kinematical like the strain tensors, can be expressed by means of dot products involving these quantities. It is convenient to define these vectors as FreeFem++ functions. The dot products are expressed as FreeFem++ macros, which are then combined into other macros that eventually expand to all the other quantities of interest. The net result is that our code automatically constructs the bilinear forms, with minimal user input, typically between 10 and 20 lines of code. This works well if an analytic description of the midsurface is available. In the case of midsurfaces implicitly defined via interpolation of nodal values, as in [11], the same approach should be possible, provided the interpolated surface chart retains $W^{2,\infty}$ regularity. We plan to address this issue in a further iteration of the code.

Let us note that with respect to user input and code complexity, our approach compares favorably with classical formulations which require the computation of the covariant and mixed components of the second fundamental form and of the Christoffel symbols of the chart; see, for example, [3].

Three-dimensional visualization of the undeformed and deformed shells uses Medit,[1] a free mesh visualization software available at http://www.ann.jussieu.fr/~frey/logiciels/medit.html.

All the tests were run on 1.5GHz Apple PowerBook G4 laptops and 2GHz single-processor Apple Xserve G5.

[1] This software was designed and developed at the Laboratoire Jacques-Louis Lions of the University Pierre et Marie Curie.

6.2. The hyperbolic paraboloid shell. This test is a literature benchmark for shell elements. We use this example, in which the midsurface of the shell is represented by a chart of class C^∞, mainly to validate our code. It does not constitute a relevant test for the $W^{2,\infty}$ case.

The reference domain of the midsurface is given by

$$\omega = \{|x| + |y| < \sqrt{2}b\},$$

and the chart is defined by

$$\varphi(x, y) = \left(x, y, \frac{c}{2b^2}(x^2 - y^2)\right)^T,$$

where $b = 50$ cm and $c = 10$ cm.

The shell is clamped on $\partial\omega$ and subjected to a uniform pressure $q = 0.01$ kp/cm^2. The mechanical data are

$$E = 2.85\ 10^4 \text{ kp/cm}^2, \nu = 0.4,$$

The thickness of the shell is $e = 0.8$ cm.

The reference value for this test is the normal displacement at the center A of the shell. Its value computed by various methods is of -0.024 cm; see [3].

Due to the symmetries of the problem, we use the computational domain

$$\omega' = \{0 < x, 0 < y, x + y < \sqrt{2}b\}$$

and enforce the symmetry conditions

$$u_2 = 0, r_2 = 0 \text{ on } y = 0$$

and

$$u_1 = 0, r_1 = 0 \text{ on } x = 0.$$

These conditions are obtained by expressing the continuity of the three-dimensional Kirchhoff–Love displacement $U = u + x_3 r$ along these edges.

The following are results for both methods using mesh adaption and P_2 elements:

	Degrees of freedom	$(u \cdot a_3)(A)$	Range of values for $r \cdot a_3$
Penalized	7005	-0.0241419	$-3.46456\text{e}{-08}$ $3.52366\text{e}{-08}$
Mixed	7279	-0.0241416	$-3.52081\text{e}{-08}$ $3.51064\text{e}{-08}$

In the penalized test, the penalization parameter was $10^3 \frac{E}{2(1+\nu)}$. Both methods achieve excellent tangency for the rotation vector and similar performance in terms of the reference value, see also Figures 1 and 2.

Remark. We also performed tests on another benchmark, the Scordelis–Lo roof. Unfortunately, in this case, P_1 and P_2 elements present significant locking. (We obtain a maximum normal displacement that is only 65% of the reference value.) Until more sophisticated elements become integrated into FreeFem++, such tests cannot yield satisfactory results. We were, however, able to confirm that both Cartesian formulations provide the same (locked) result as the classical covariant formulation using P_1 and P_2 elements.

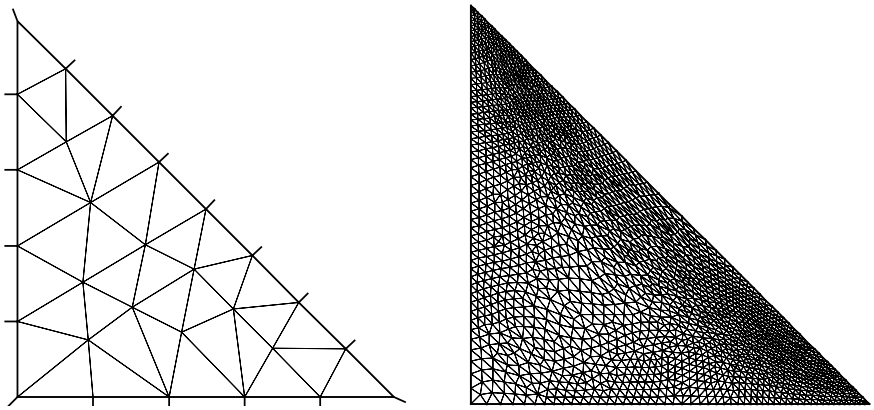

FIG. 1. *The initial and final meshes.*

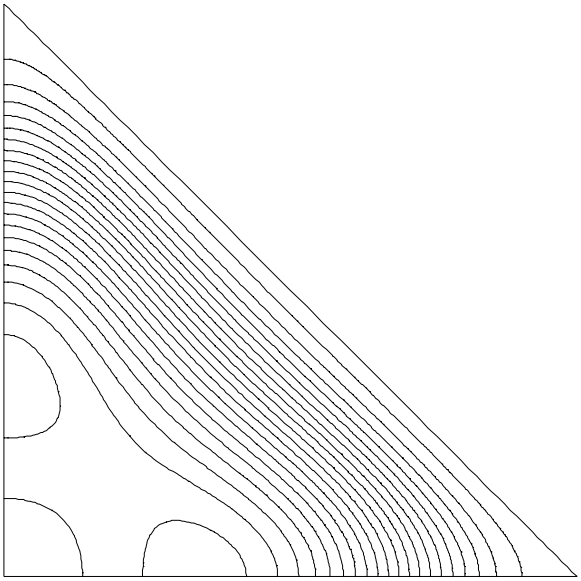

FIG. 2. *Isovalues of the normal displacement* $u \cdot a_3$*, mixed formulation.*

6.3. A plane-cylinder $W^{2,\infty}$-shell. Our next test is a genuine $W^{2,\infty}$ test with curvature discontinuities. The shell consists of a plane part and a cylindrical part with a C^1-join; see Figure 3. The reference domain of the midsurface is given by

$$\omega =]-R, R[\times]-L/2, L/2[,$$

and the chart is defined by

$$\varphi(x,y) = \begin{cases} (x, y, 0)^T & \text{if } x < 0, \\ (R\sin(x/R), y, R(1-\cos(x/R)))^T & \text{if } x \geq 0 \end{cases}$$

with $R = 300$ in. and $L = 600$ in. (These values come from the Scordelis–Lo test.) The thickness of the shell is $e = 3$ in.

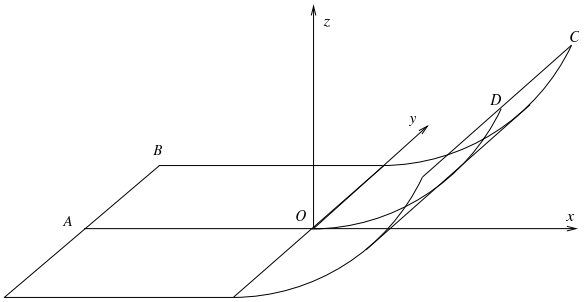

FIG. 3. *The plate-cylinder shell.*

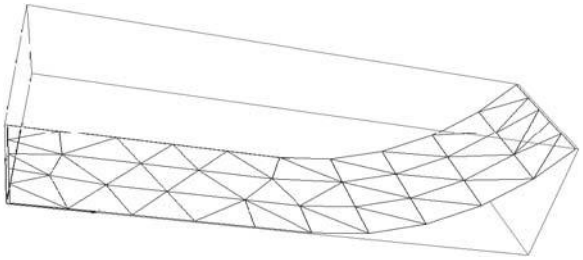

FIG. 4. *The initial mesh on the midsurface.*

The mechanical data are

$$E = 3.0 \times 10^6 \text{ psi}, \nu = 0.0.$$

The shell is submitted to a uniform downward pressure of 0.625 lb/in^2.

Concerning boundary conditions, we consider the case of hard clamping on lines AB and DC

$$u_1 = u_2 = u_3 = 0 \quad \text{and} \quad r_1 = r_2 = r_3 = 0,$$

and the shell is free on its remaining edges. Thanks to the symmetry, we only consider half of the midsurface, $y > 0$. The corresponding symmetry conditions on AD are

$$u_2 = r_2 = 0.$$

Note that the initial mesh ignores the curvature discontinuity at $x = 0$.

Note that in Medit, the coordinate axes are attached to the bounding box: although it seems that the clamped left side of the shell has moved up in Figure 5 compared to Figure 4, this is not actually the case.

It is interesting to note that mesh adaption concentrates around the curvature discontinuity, thus indicating the lack of regularity of the solution across this line. In the isovalues of Figures 6, 7, and 8, the leftmost half of the domain corresponds to the planar part of the shell for $x_1 < 0$ and the other half to the cylindrical part of the shell. The line AD is represented by the bottom side of the domain.

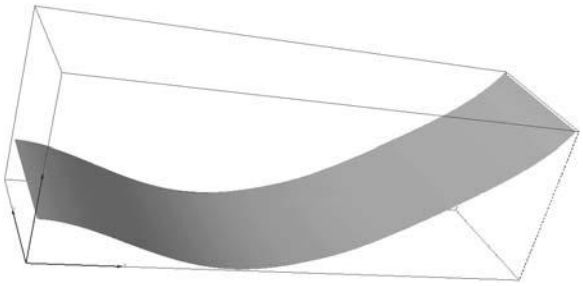

FIG. 5. *The deformed half-shell (displacement magnified by a factor of* 7*).*

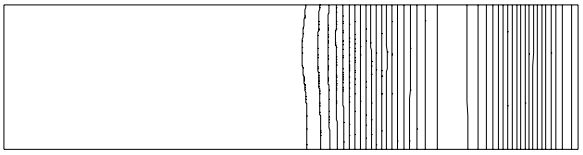

FIG. 6. *Isovalues of* u_1*. The range of values is* $[-0.967042, 0.0130627]$.

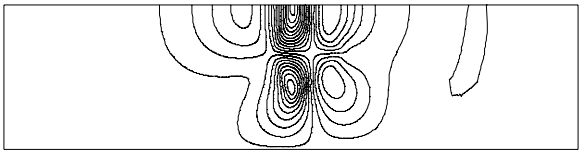

FIG. 7. *Isovalues of* u_2*. The range of values is* $[-0.00181261, 0.00234357]$.

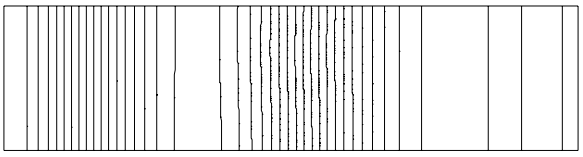

FIG. 8. *Isovalues of* u_3*. The range of values is* $[-6.31062, 0.949939]$*. (Isovalues for* $u \cdot a_3$ *are practically identical and those for* r_1 *and* λ *show similar features.)*

Note that although the pressure acts downward, the cylindrical part of the shell lifts a little bit to compensate for the large deflection of its planar part.

Concerning the rotation vector, we have the following isovalues in Figures 9 and 10. (r_1 is not represented; see Figure 8.)

To see how the mixed formulation manages to enforce the tangency constraint, we also plot the isovalues of the normal rotation $r \cdot a_3$ (Figure 11). We see that the curvature discontinuity makes it harder to capture this constraint than in the C^∞ case of the hyperbolic paraboloid.

Finally, we compare our results with those of [15] for the same geometry, but for the Koiter model, using the Argyris element on a structured mesh that respects the curvature discontinuity. The vertical displacement of point O is found to be

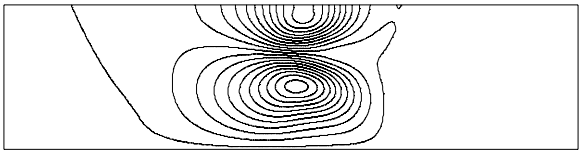

FIG. 9. *Isovalues of* r_2. *The range of values is* $[-0.0011471, 0.000972632]$.

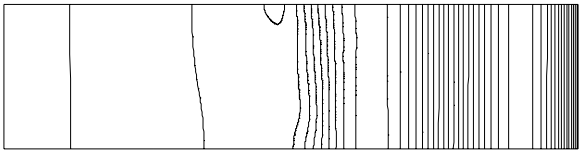

FIG. 10. *Isovalues of* r_3. *The range of values is* $[-0.00547512, 0.0128569]$.

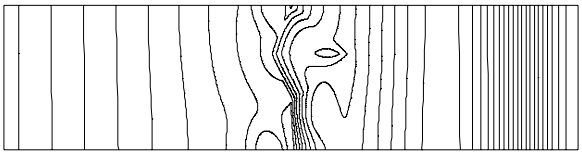

FIG. 11. *Isovalues of* $r \cdot a_3$. *The range of values is* $[-9.18161\text{e}{-06}, 0.00474402]$.

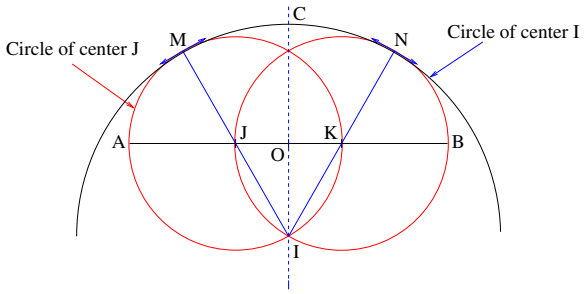

FIG. 12. *AMNB is basket handle or three-centered arch.*

approximately −4.0 in. (value based on a graph in [15]). We find $u_3(0) = -3.83631$ in., which is in good agreement.

6.4. A basket-handle tunnel. A basket-handle is a classical approximation of an arc of ellipse, and a very good one, constructed with three circles (Figure 12). It has long been used in architecture as a replacement for an ellipse. Clearly this arc presents two curvature discontinuities and the same will be true for arches based on it.

We present numerical results for a long, tunnel-like shell based on a slightly extended basket-handle arc.

We use the same mechanical data as for the plate-cylinder shell. Clamping is assumed on both rectilinear sides of the shell. These sides are of length 3000 in. The large circle radius is 400 in. and the small circle radius 200 in.

The natural chart for this shell is of class $W^{2,\infty}$. It is obtained by parametrizing

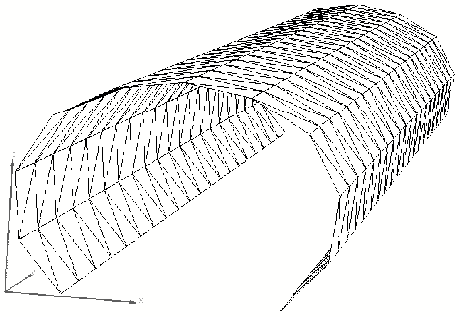

FIG. 13. *The initial mesh on the basket-handle midsurface.*

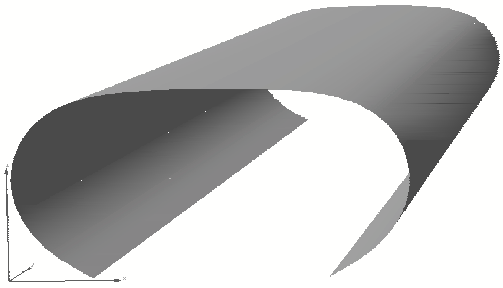

FIG. 14. *The deformed shell (displacement magnified by a factor of* 3*).*

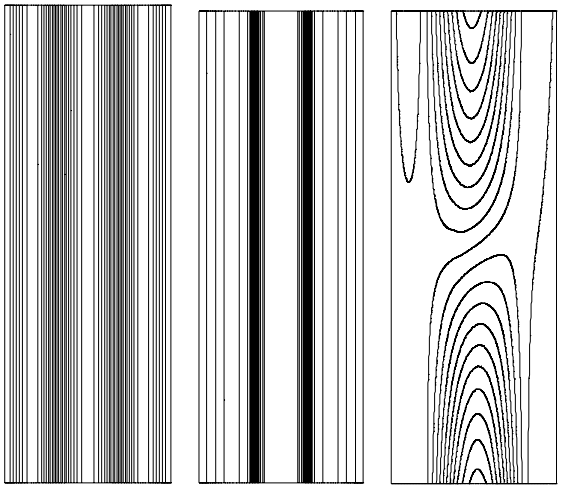

FIG. 15. *Isovalues of* $u \cdot a_3$ *(left),* $r \cdot a_3$ *(middle), and* u_2 *(right).*

the basket-handle by arclength. The computational domain is a rectangle $]-628.32, 628.32[\times]-1800, 1800[$. (We compute the whole shell without using the symmetries for better visualization.)

The vertical displacement of the center of the shell is $u_3(0,0) = -27.3815$ in. Figure 13 shows the initial mesh, Figure 14 the deformed shell, and Figure 15 various isovalues.

Remark. Naturally, the isovalues for u_2 should respect the shell symmetries. However, since the range of values for u_2 is of the order of $[-2e{-}5, 2e{-}5]$, the shape of the isovalue lines is very sensitive to errors. It nonetheless becomes more symmetrical when the mesh is further refined.

Acknowledgments. The authors wish to thank Christine Bernardi and Vivette Girault for illuminating discussions about finite element theory, Marina Vidrascu for insights on the numerics of shells, and the referees for suggestions resulting in significant simplification of some proofs.

GENERALIZED CUBIC SPLINE FRACTAL INTERPOLATION FUNCTIONS*

A. K. B. CHAND† AND G. P. KAPOOR†

Abstract. We construct a generalized C^r-Fractal Interpolation Function (C^r-FIF) f by prescribing any combination of r values of the derivatives $f^{(k)}$, $k = 1, 2, \ldots, r$, at boundary points of the interval $I = [x_0, x_N]$. Our approach to construction settles several questions of Barnsley and Harrington [*J. Approx Theory*, 57 (1989), pp. 14–34] when construction is not restricted to prescribing the values of $f^{(k)}$ at only the initial endpoint of the interval I. In general, even in the case when r equations involving $f^{(k)}(x_0)$ and $f^{(k)}(x_N)$, $k = 1, 2, \ldots, r$, are prescribed, our method of construction of the C^r-FIF works equally well. In view of wide ranging applications of the classical cubic splines in several mathematical and engineering problems, the explicit construction of cubic spline FIF $f_\Delta(x)$ through *moments* is developed. It is shown that the sequence $\{f_{\Delta_k}(x)\}$ converges to the defining data function $\Phi(x)$ on two classes of sequences of meshes at least as rapidly as the square of the mesh norm $\|\Delta_k\|$ approaches to zero, provided that $\Phi^{(r)}(x)$ is continuous on I for $r = 2, 3$, or 4.

1. Introduction.

With the advent of fractal geometry [2], the use of stochastic or deterministic fractal models [3, 4, 5] has significantly enhanced the understanding of complexities in nature and different scientific experiments. Hutchinson [6] has studied the deterministic fractal model based on the theory of Iterated Function System (IFS). Using IFS, Barnsley [3, 7] has introduced the concept of Fractal Interpolation Function (FIF) for approximation of naturally occurring functions showing some sort of self-similarity under magnification. A FIF is the fixed point of the Read–Bajraktarević operator acting on different function spaces. Generally, affine FIFs are nondifferentiable functions and the fractal dimensions of their graphs are nonintegers. The generation of FIF codes provides a powerful technique for compression of images, speeches, time series, and other data; see, e.g., [8, 9, 10].

If the experimental data are approximated by a C^r-FIF f, then one can use the fractal dimension of $f^{(r)}$ as a quantitative parameter for the analysis of experimental data. The differentiable C^r-FIF differs from the classical spline interpolation by a functional relation that gives self-similarity on small scales. Barnsley and Harrington [1] have introduced an algebraic method for the construction of a restricted class of C^r-FIF f, which interpolates the prescribed data by providing values of $f^{(k)}$, $k = 1, 2, \ldots, r$, at the initial endpoint of the interval. However, in their method of construction, specifying boundary conditions similar to those for classical splines has been found to be quite difficult to handle. Massopust [11] has attempted to generalize work in [1] by constructing smooth fractal surfaces via integration.

In the present paper, a method of construction of a C^r-fractal function is developed by removing the requirement of prescribing the values of integrals of the given FIF only at the initial endpoint x_0. Thus, a C^r-fractal function is constructed when successive r values of integrals of a FIF are prescribed in any combination at boundary points of the interval. Further, a general method is proposed to construct an interpolating C^r-FIF for the prescribed data with all possible boundary conditions. The complex algebraic method proposed in [1] uses complicated matrices and particular types of end conditions. Using the functional relations present between the values of the C^r-FIF that involve endpoints of the interval, our approach does not need the complex algebraic method in [1]. Our construction settles several queries of Barnsley and Harrington [1] such as (i) which boundary point conditions lead to uniqueness of a C^r-FIF, (ii) what happens if horizontal scalings are in reverse direction and (iii) how to build up the moment integrals theory in this case. The advantage of such a spline FIF construction is that, for prescribed data and given boundary conditions, one can have an infinite number of spline FIFs depending on the vertical scaling factors, giving thereby a large flexibility in the choice of differentiable C^r-FIFs according to the need of an experiment.

Due to the importance of the cubic splines in computer graphics, CAGD, FEM, differential equations, and several engineering applications [12, 13, 14, 15], cubic spline FIF $f_\Delta(x)$ on a mesh Δ is constructed through *moments* $M_n = f''_\Delta(x_n), n = 0, 1, 2, \ldots, N$. These cubic spline FIFs may have any types of boundary conditions as in classical splines. It is shown that the sequence $\{f_{\Delta_k}(x)\}$ converges to the defining data function $\Phi(x)$ on two classes of sequences of meshes at least as rapidly as the square of the mesh norm $\|\Delta_k\|$ converging to zero, provided that $\Phi^{(r)}(x)$ is continuous on $[x_0, x_N]$ for $r = 2, 3$, or 4.

In section 2, some basic results for FIFs are given and a general method for construction of a C^r-FIF with different boundary conditions is enunciated after developing a basic calculus of C^1-FIFs. The construction of a generalized cubic spline FIF through moments is described in section 3 with all possible boundary conditions, as in the classical splines. In section 4, two classes of sequences of meshes are defined and the convergence of suitable sequence of cubic spline FIFs $\{f_{\Delta_k}\}$ to $\Phi \in C^r[x_0, x_N]$, $r = 2, 3$, or 4, is established. Finally, in section 5, the results obtained in section 3 are illustrated by generating certain examples of cubic spline FIFs for a given data and two different sets of vertical scaling factors.

2. A general method for construction of C^r-FIF. We give the basics of the general theory of FIFs and develop the calculus of C^1-FIFs in section 2.1. The principle of construction of a C^r-FIF that interpolates the given data is described in section 2.2.

2.1. Preliminaries and calculus of C^1-FIFs. Barnsley et al. [1, 3, 8, 16, 17] have developed the theory of FIF and its extensive applications. In the following, some of the notations and results of FIF theory, which we will later need, are described.

Let K be a complete metric space with metric d and $\mathcal{H}$ be the set of nonempty compact subsets of K. Then, $\{K; \omega_n, n = 1, 2, \ldots, N\}$ is an iterated function system (IFS) if $\omega_n : K \to K$ is continuous for $n = 1, 2, \ldots, N$. An IFS is called hyperbolic if $d(\omega_n(x), \omega_n(y)) \leq sd(x, y)$ for all $x, y \in K, n = 1, 2, \ldots, N$ and $0 \leq s < 1$. Set $W(A) = \bigcup_{n=1}^{N} \omega_n(A)$ for $A \in \mathcal{H}$. The following proposition gives a condition on an IFS to have a unique attractor.

PROPOSITION 2.1 (see [3]). *Let $\{K; \omega_n, n = 1, 2, \ldots, N\}$ be a hyperbolic IFS.*

Then, it has an unique attractor G such that $h(W^m(A), G) \to 0$ as $m \to \infty$, where $h(.,.)$ is the Hausdorff metric.

Suppose a set of data points $\{(x_i, y_i) \in I \times \mathbb{R} : i = 0, 1, 2, \ldots, N\}$ is given, where $x_0 < x_1 < \cdots < x_N$ and $I = [x_0, x_N]$. Set $K = I \times D$, where D is a suitable compact set in $\mathbb{R}$. Let $L_n : I \longrightarrow I_n = [x_{n-1}, x_n]$ be the affine map satisfying

$$L_n(x_0) = x_{n-1}, \quad L_n(x_N) = x_n \tag{2.1}$$

and $F_n : K \longrightarrow D$ be a continuous function such that

$$\left.\begin{aligned} F_n(x_0, y_0) = y_{n-1},\ F_n(x_N, y_N) = y_n \\ |F_n(x, y) - F_n(x, y^*)| \le \alpha_n |y - y^*| \end{aligned}\right\}, \tag{2.2}$$

where, $(x, y),\ (x, y^*) \in K$, and $0 \le\ \alpha_n < 1$ for all $n = 1, 2, \ldots, N$. Define $\omega_n(x, y) = (L_n(x), F_n(x, y))$ for all $n = 1, 2, \ldots, N$. The definition of a FIF originates from the following proposition.

PROPOSITION 2.2 (see [3]). *The IFS $\{K; \omega_n, n = 1, 2, \ldots, N\}$ has a unique attractor G such that G is the graph of a continuous function $f : I \to \mathbb{R}$ (called FIF associated with IFS $\{K; \omega_n, n = 1, 2, \ldots, N\}$) satisfying $f(x_n) = y_n$ for $n = 0, 1, 2, \ldots, N$.*

The following observations based on Proposition 2.2 are needed in the sequel. Let $\mathcal{F} = \{f : I \to \mathbb{R} \mid f \text{ is continuous}, f(x_0) = y_0 \text{ and } f(x_N) = y_N\}$ and ρ be the sup-norm on $\mathcal{F}$. Then, $(\mathcal{F}, \rho)$ is a complete metric space. The FIF f is the unique fixed point of the Read–Bajraktarević operator T on $(\mathcal{F}, \rho)$ so that

$$Tf(x) \equiv F_n(L_n^{-1}(x), f(L_n^{-1}(x))) = f(x),\ x \in I_n, \quad n = 1, 2, \ldots, N. \tag{2.3}$$

For an affine FIF, L_n and F_n are given by

$$\left.\begin{aligned} L_n(x) = a_n x + b_n \\ F_n(x, y) = \alpha_n y + q_n(x) \end{aligned}\right\}, \quad n = 1, 2, \ldots, N, \tag{2.4}$$

where $q_n(x)$ is an affine map and $|\alpha_n| < 1$.

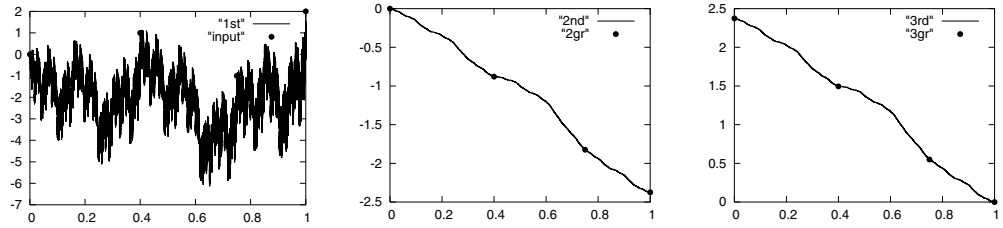
Barnsley and Harrington [1] have observed that the integral of a FIF is also a FIF, although for a different set of interpolation data, provided the value of the integral of the FIF at the initial endpoint of the interval is known. This observation is needed for developing the calculus of C^1-FIFs. Thus, let f be the FIF associated with $\{(L_n(x), F_n(x, y)),\ n = 1, 2, \ldots, N\}$, where F_n is defined by (2.4) and let the value of integral of this FIF be known at x_0. If

$$\hat{f}(x) = \hat{y}_0 + \int_{x_0}^{x} f(\tau) d\tau, \tag{2.5}$$

the function $\hat{f}$ is the FIF associated with IFS $\{(L_n(x), \hat{F}_n(x, y)),\ n = 1, 2, \ldots, N\}$, where $\hat{F}_n(x, y) = a_n \alpha_n y + \hat{q}_n(x)$, $\hat{q}_n(x) = \hat{y}_{n-1} - a_n \alpha_n \hat{y}_0 + a_n \int_{x_0}^{x} q_n(\tau) d\tau$,

$$\hat{y}_n = \hat{y}_0 + \sum_{i=1}^{n} a_i \left\{ \alpha_i (\hat{y}_N - \hat{y}_0) + \int_{x_0}^{x_N} q_i(\tau) d\tau \right\}, \quad n = 1, 2, \ldots, N-1,$$

and $\hat{y}_N = \hat{y}_0 + \sum_{i=1}^{N} a_i \int_{x_0}^{x_N} q_i(\tau) d\tau / 1 - \sum_{i=1} N a_i \alpha_i$. Here, $(x_n, \hat{y}_n), n = 0, 1, 2, \ldots, N$ are interpolation points of FIF $\hat{f}$.



(a) FIF f. (b) $\hat{f}$ with $\hat{y}_0 = 0$. (c) $\hat{f}$ with $\hat{y}_N = 0$.

FIG. 1. *FIF and its integrals.*

Remarks. 1. If the value of the integral of a FIF is known at the final endpoint x_N instead of the initial endpoint x_0, an analogue of the above result can be found by defining

$$\hat{f}(x) = \hat{y}_N - \int_x^{x_N} f(\tau)d\tau. \tag{2.6}$$

The function $\hat{f}$ is the FIF associated with $\{(L_n(x), \hat{F}_n(x,y)),\ n = 1, 2, \ldots, N\}$, where $\hat{F}_n(x,y) = a_n\alpha_n y + \hat{q}_n(x)$, $\hat{q}_n(x) = \hat{y}_n - a_n\alpha_n\hat{y}_N - a_n\int_x^{x_N} q_n(\tau)d\tau$ and the interpolation points of $\hat{f}$ are given by $\hat{y}_n = \hat{y}_N - \sum_{i=n+1}^{N} a_i\{\alpha_i(\hat{y}_N - \hat{y}_0) + \int_{x_0}^{x_N} q_i(\tau)d\tau\}$, $n = 1, 2, \ldots, N-1$ with $\hat{y}_0 = \hat{y}_N - \frac{\sum_{i=1}^{N} a_i \int_{x_0}^{x_N} q_i(\tau)d\tau}{1-\sum_{i=1}^{N} a_i\alpha_i}$. In general, a C^r-FIF interpolating a certain different set of data can be constructed when values of r successive integrals of the FIF are provided at any combination of endpoints.

2. The functional values of FIF $\hat{f}$ are, in general, different for the same set of vertical scaling factors even if $\hat{y}_0$ and $\hat{y}_N$ occurring, respectively, in (2.5) and (2.6) are the same. However, since $\hat{y}_n - \hat{y}_{n-1}$ remains the same for each n in both the cases, the nature of $\hat{f}$ remains the same in both the cases as illustrated by the following example.

Example. Let f be a FIF associated with the data $\{(0,0),\ (\frac{2}{5}, 1),\ (\frac{3}{4}, -1),\ (1,2)\}$ with vertical scaling factor $\alpha_n = 0.8$ for $n = 1, 2, 3$ (Figure 1(a)). Choosing $\hat{y}_0 = 0$, $\hat{f}(x) = \int_{x_0}^{x} f$ interpolates the set of points $\{(0,0), (\frac{2}{5}, \frac{-22}{25}), (\frac{3}{4}, \frac{-73}{40}), (1, \frac{-19}{8})\}$. FIF $\hat{f}$ is associated with the IFS generated by $L_1(x) = \frac{2}{5}x,\ L_2(x) = \frac{7}{20}x + \frac{2}{5},\ L_3(x) = \frac{1}{4}x + \frac{3}{4}$ and $\hat{F}_1(x,y) = \frac{8}{25}y - \frac{3}{25}x^2,\ \hat{F}_2(x,y) = \frac{7}{25}y - \frac{63}{100}x^2 + \frac{7}{20}x - \frac{22}{25},\ \hat{F}_3(x,y) = \frac{1}{5}y + \frac{7}{40}x^2 - \frac{1}{4}x + \frac{73}{40}$. The graph of FIF $\hat{f}$ is shown in Figure 1(b). Next, choosing $\hat{y}_N = 0$, $\hat{f}(x) = -\int_x^{x_N} f$ interpolates the set of points $\{(0, \frac{19}{8}), (\frac{2}{5}, \frac{299}{200}), (\frac{3}{4}, \frac{11}{20}), (1,0)\}$ (Figure 1(c)). In this case, the corresponding IFS contains the same $L_n(x)$ for $n = 1, 2, 3$ and $\hat{F}_1(x,y) = \frac{8}{25}y - \frac{3}{25}x^2 + \frac{323}{100},\ \hat{F}_2(x,y) = \frac{7}{25}y - \frac{63}{100}x^2 + \frac{7}{20}x + \frac{83}{100},\ \hat{F}_3(x,y) = \frac{1}{5}y + \frac{7}{40}x^2 - \frac{1}{4}x + \frac{3}{40}$. The nature of FIFs $\hat{f}$ in Figure 1(b)–(c) remains the same, since the functional values of FIF $\hat{f}$ in Figure 1(c) are shifted by $\frac{19}{8}$ from the functional values of $\hat{f}$ in Figure 1(b) so that $\hat{y}_n - \hat{y}_{n-1}$ remains the same. It is interesting to note that the corresponding functions $\hat{F}_n(x,y)$ for IFS of Figure 1(b)–(c) are not shifted by equal amount although the function $\hat{f}$ is shifted by the fixed amount $\frac{19}{8}$.

In general, the relation between the IFS of FIF f and the IFS of its integral $\hat{f}$ is given as follows [18].

PROPOSITION 2.3. *Let $\hat{f}$ be the FIF defined by* (2.5) *or* (2.6) *for a FIF f with $L_n(x)$ and $F_n(x,y)$ given by* (2.4)*. Then, f is primitive of $\hat{f}$ if and only if $\hat{f}$ is the FIF associated with the IFS $\{\mathbb{R}^2; \hat{w}_n(x,y) = (L_n(x), \hat{F}_n(x,y)), n = 1, 2, \ldots, N\}$, where*

$\hat{F}_n(x,y) = \hat{\alpha}_n y + \hat{q}_n(x)$, $\hat{\alpha}_n = a_n\alpha_n$, *and the polynomial* $\hat{q}_n(x)$ *satisfies* $\hat{q}_n' = a_n q_n$ *for* $n = 1, 2, \ldots, N$.

2.2. Principle of construction of a C^r-FIF. Our approach for the construction of a C^r-FIF that interpolates the given data is based on finding the solution of a system of equations in which any type of boundary conditions are admissible. Such a construction is more general than that of Barnsley and Harrington [1] wherein all the relevant derivatives of the FIF are restricted to be known at the initial endpoint only. The C^r-FIF interpolating prescribed set of data is found as the fixed point of a suitably chosen IFS by using the following procedure.

Let $\{(x_0, y_0), (x_1, y_1), \ldots, (x_N, y_N)\}$, $x_0 < x_1 < \cdots < x_N$, be the given data points and $\mathcal{F}^r = \{g \in C^r(I, \mathbb{R}) \mid g(x_0) = y_0 \text{ and } g(x_N) = y_N\}$, where r is some nonnegative integer and σ is the C^r-norm on $\mathcal{F}^r$. Define the Read–Bajraktarević operator T on $(\mathcal{F}^r, \sigma)$ as

$$Tg(x) = \alpha_n g(L_n^{-1}(x)) + q_n(L_n^{-1}(x)),\ x \in I_n, \quad n = 1, 2, \ldots, N,$$

where $L_n(x) = a_n x + b_n$ satisfies (2.1), $q_n(x)$ is a suitably chosen polynomial, and $|\alpha_n| < a_n^r$ for $n = 1, 2, \ldots, N$. The condition $|\alpha_n| < a_n^r < 1$ gives that T is a contractive operator on $(\mathcal{F}^r, \sigma)$. The fixed point f of T is a FIF that satisfies the functional relation, $f(L_n(x)) = \alpha_n f(x) + q_n(x)$ for $n = 1, 2, \ldots, N$. Using Proposition 2.3, it follows that f' satisfies the functional relation

$$f'(L_n(x)) = \frac{\alpha_n f'(x) + q_n'(x)}{a_n}, \quad n = 1, 2, \ldots, N.$$

Since $\frac{|\alpha_n|}{a_n} \le \frac{|\alpha_n|}{a_n^r} < 1$, f' is a fractal function. Inductively, using the above arguments, the following relations are obtained:

$$f^{(k)}(L_n(x)) = \frac{\alpha_n f^{(k)}(x) + q_n^{(k)}(x)}{a_n^k}, \quad n = 1, 2, \ldots, N, \quad k = 0, 1, 2, \ldots, r, \tag{2.7}$$

where $f^{(0)} = f$ and $q^{(0)} = q$. Since $\frac{|\alpha_n|}{a_n^k} \le \frac{|\alpha_n|}{a_n^r} < 1$, the derivatives $f^{(k)}$, $k = 2, 3, \ldots, r$ are fractal functions. In general $f^{(k)}$, $k = 1, 2, 3, \ldots, r$, interpolates a data different than the given data. In particular, $f^{(r)}$ is an affine FIF if the polynomial $q_n^{(r)}$ occurring in (2.7) with $k = r$ is affine. Thus, $q_n(x)$ is chosen as a polynomial of degree $(r+1)$. Let $q_n(x) = \sum_{k=0}^{r+1} q_{kn} x^k$, $n = 1, 2, \ldots, N$, where the coefficients q_{kn} are chosen suitably such that f interpolates the prescribed data. The continuity of $f^{(k)}$ on I implies

$$f^{(k)}(L_{n+1}(x_0)) = f^{(k)}(L_n(x_N)), \quad k = 0, 1, \ldots, r, \quad n = 1, 2, \ldots, N-1.$$

Therefore, (2.7) results in the following $(r+1)(N-1)$ join-up conditions for $k = 0, 1, \ldots, r$, $n = 1, 2, \ldots, N-1$:

$$\frac{\alpha_{n+1} f^{(k)}(x_0) + q_{n+1}^{(k)}(x_0)}{a_{n+1}^k} = \frac{\alpha_n f^{(k)}(x_N) + q_n^{(k)}(x_N)}{a_n^k}. \tag{2.8}$$

In addition, at the endpoints of the interval, (2.7) implies that the values of $f^{(k)}$ satisfy the following $2r$-conditions:

$$f^{(k)}(x_0) = \frac{\alpha_1 f^{(k)}(x_0) + q_1^{(k)}(x_0)}{a_1^k}, \quad k = 1, 2, \ldots, r, \tag{2.9}$$

and

$$f^{(k)}(x_N) = \frac{\alpha_N f^{(k)}(x_N) + q_N^{(k)}(x_N)}{a_N^k}, \quad k = 1, 2, \ldots, r. \tag{2.10}$$

Let the prescribed interpolation conditions be

$$f(x_n) = y_n, \quad n = 0, 1, \ldots, N. \tag{2.11}$$

In view of (2.8)–(2.11), the total number of conditions for f to interpolate the given data are $(r+1)(N-1) + 2r + (N+1) = (r+2)N + r$. In (2.8)–(2.10), $f^{(k)}(x_0)$ and $f^{(k)}(x_N)$ for $k = 1, 2, \ldots, r$ are $2r$ unknowns and q_{kn}, $k = 0, 1, \ldots, r+1$, $n = 1, 2, \ldots, N$, in the polynomials $q_n(x)$ are additional $(r+2)N$ unknowns. Consequently, in total $(r+2)N+2r$ number of unknowns are to be determined. The principle of construction of a C^r-FIF is to determine these unknowns by choosing additional suitable r conditions in the form of restrictions on the values of the C^r-FIF or the values of its derivatives at the boundary points of $[x_0, x_N]$ such that (2.8)–(2.11) together with these additional conditions are linearly independent. The above unknowns are determined uniquely as the solution of these linear independent system of equations. Thus, the desired C^r-FIF f interpolating the given data is constructed as the attractor of the following IFS:

$$\{\mathbb{R}^2; \omega_n(x, y) = (L_n(x), F_n(x, y) = \alpha_n y + q_n(x)), n = 1, 2, \ldots, N\},$$

where $|\alpha_n| < a_n^r$ and $q_n(x)$, $n = 1, 2, \ldots, N$, are the polynomials with coefficients q_{kn} computed by solving the linear independent system of equations, given by the above procedure. The flexibility of these choices of boundary conditions allows for the construction of a wide range of spline FIFs. Even for a given choice of boundary conditions, depending upon the nature of the problem or simply at the discretion of the user, an infinite number of suitable spline FIFs may be constructed due to the freedom of choices for vertical scaling factors in our construction.

Remarks. 1. Barnsley and Harrington's construction [1] of a C^r-FIF f is done by restricting the choice of boundary values $f^{(k)}(x)$ for $k = 1, 2, \ldots, r$, at the initial endpoint. In our above construction of C^r-FIFs, all kinds of boundary conditions are admissible.

2. It seems that Barnsley and Harrington's question—"whether there exists a FIF as a fixed point of an IFS wherein horizontal scalings are allowed in the reverse direction"—is raised [1], since the construction of a C^r-FIF is based upon restricting boundary values of $f^{(k)}$ at only initial end point of I. Such a question does not arise in our construction since the boundary values of $f^{(k)}$ for C^r-FIF f are admissible at any combination of boundary points of I.

Since the classical cubic splines play a significant role in CAGD, surface analysis, differential equation, FEM, and other applications (see, e.g., [13, 14, 15]), in the sequel a detailed construction for such cubic spline FIFs based on the above approach is given in the following section.

3. Construction of cubic spline FIFs through moments. In the present section, cubic spline FIFs f_Δ are constructed through the *moments* $M_n = f_\Delta''(x_n)$ for $n = 0, 1, 2, \ldots, N$.

DEFINITION 3.1. *A function $f_\Delta(x) \equiv f_\Delta(Y; x)$ is called a cubic spline FIF interpolating a set of ordinates $Y : y_0, y_1, y_2, \ldots, y_N$ with respect to the mesh Δ :*

$x_0 < x_1 < x_2 < \cdots < x_N$ *if* (i) $f_\Delta \in C^2[x_0, x_N]$, (ii) f_Δ *satisfies the interpolation conditions* $f_\Delta(x_n) = y_n, \quad n = 0, 1, \ldots, N$ *and* (iii) *the graph of* f_Δ *is fixed point of a IFS,* $\{\mathbb{R}^2; \omega_n(x, y), n = 1, 2, \ldots, N\}$, *where for* $n = 1, 2, \ldots, N$, $\omega_n(x, y) = (L_n(x), F_n(x, y))$, $L_n(x)$ *is defined by* (2.4), $F_n(x, y) = a_n^2\alpha_n y + a_n^2 q_n(x)$, $0 < |\alpha_n| < 1$, *and* $q_n(x)$ *is a suitable cubic polynomial.*

Using the moments M_n, $n = 0, 1, 2, \ldots, N$, a rectangular system of equations is formed for determining the polynomial $q_n(x)$ by employing the following procedure.

Using property (iii) and (2.3), it follows that $f_\Delta^{''}$ satisfies the functional equation

$$f_\Delta^{''}(L_n(x)) = \alpha_n f_\Delta^{''}(x) + \frac{c_n(x - x_0)}{x_N - x_0} + d_n, \quad n = 1, 2, \ldots, N. \tag{3.1}$$

By (2.1) and (3.1), $c_n = M_n - M_{n-1} - \alpha_n(M_N - M_0)$ and $d_n = M_{n-1} - \alpha_n M_0$. Thus, for $n = 1, 2, \ldots, N$, (3.1) can be rewritten as

$$f_\Delta^{''}(L_n(x)) = \alpha_n f_\Delta{''}(x) + \frac{(M_n - \alpha_n M_N)(x - x_0)}{x_N - x_0} + \frac{(M_{n-1} - \alpha_n M_0)(x_N - x)}{x_N - x_0}. \tag{3.2}$$

The function $f_\Delta^{''}$ being continuous on I could be twice integrated to obtain

$$\begin{aligned} f_\Delta(L_n(x)) =& a_n^2\Bigg\{\alpha_n f_\Delta(x) + \frac{(M_n - \alpha_n M_N)(x - x_0)^3}{6(x_N - x_0)} + \frac{(M_{n-1} - \alpha_n M_0)(x_N - x)^3}{6(x_N - x_0)} \\ &+ c_n^*(x_N - x) + d_n^*(x - x_0)\Bigg\}, \quad n = 1, 2, \ldots, N. \end{aligned} \tag{3.3}$$

Now using interpolation conditions and (2.1), the constants c_n^* and d_n^* are determined as

$$\begin{aligned} c_n^* &= \frac{1}{x_N - x_0}\left(\frac{y_{n-1}}{a_n^2} - \alpha_n y_0\right) - \frac{(M_{n-1} - \alpha_n M_0)(x_N - x_0)}{6}, \\ d_n^* &= \frac{1}{x_N - x_0}\left(\frac{y_n}{a_n^2} - \alpha_n y_N\right) - \frac{(M_n - \alpha_n M_N)(x_N - x_0)}{6}. \end{aligned}$$

Thus, the functional equation (3.3) for the cubic spline FIF in terms of moments can be written as

$$\begin{aligned} f_\Delta(L_n(x)) = a_n^2\Bigg\{&\alpha_n f_\Delta(x) + \frac{(M_n - \alpha_n M_N)(x - x_0)^3}{6(x_N - x_0)} + \frac{(M_{n-1} - \alpha_n M_0)(x_N - x)^3}{6(x_N - x_0)} \\ &- \frac{(M_{n-1} - \alpha_n M_0)(x_N - x_0)(x_N - x)}{6} - \frac{(M_n - \alpha_n M_N)(x_N - x_0)(x - x_0)}{6} \\ &+ \left(\frac{y_{n-1}}{a_n^2} - \alpha_n y_0\right)\frac{x_N - x}{x_N - x_0} + \left(\frac{y_n}{a_n^2} - \alpha_n y_N\right)\frac{x - x_0}{x_N - x_0}\Bigg\}, \quad n = 1, 2, \ldots, N. \end{aligned} \tag{3.4}$$

It follows by (3.4) that $f_\Delta(x)$ is continuous on $[x_0, x_N]$ and satisfies the interpolating conditions $f_\Delta(x_n) = y_n$, $n = 0, 1, 2, \ldots, N$. Further, (3.4) gives that, on $[x_{i-1}, x_i]$,

$i = 1, 2, \ldots, N,$

(3.5)
$$f'_\Delta(L_i(x)) = a_i\Bigg\{\alpha_i f'_\Delta(x) + \frac{(M_i - \alpha_i M_N)(x - x_0)^2}{2(x_N - x_0)} - \frac{(M_{i-1} - \alpha_i M_0)(x_N - x)^2}{2(x_N - x_0)} - \frac{[M_i - M_{i-1} - \alpha_i(M_N - M_0)](x_N - x_0)}{6} + \left[\frac{y_i - y_{i-1}}{a_i^2} - \alpha_i(y_N - y_0)\right]\frac{1}{x_N - x_0}\Bigg\}.$$

Denote $x_n - x_{n-1}$ by h_n = for $n = 1, 2, \ldots, N$. Since, by property (i), $f'_\Delta(x)$ is continuous at $x_1, x_2, \ldots, x_{N-1}$, $\lim_{x\to x_n^-} f'_\Delta(x) = \lim_{x\to x_n^+} f'_\Delta(x),\ n = 1, 2, \ldots, N-1$. Thus, using (3.5) for $i = n$ and $i = n + 1$, we have

(3.6)
$$\begin{aligned} &-a_{n+1}\alpha_{n+1}f'_\Delta(x_0) - \frac{\alpha_n h_n + 2\alpha_{n+1}h_{n+1}}{6}M_0 + \frac{h_n}{6}M_{n-1} + \frac{h_n + h_{n+1}}{3}M_n \\ &\quad + \frac{h_{n+1}}{6}M_{n+1} - \frac{2\alpha_n h_n + \alpha_{n+1}h_{n+1}}{6}M_N + a_n\alpha_n f'_\Delta(x_N) \\ &= \frac{y_{n+1} - y_n}{h_{n+1}} - \frac{y_n - y_{n-1}}{h_n} - (a_{n+1}\alpha_{n+1} - a_n\alpha_n)\frac{y_N - y_0}{x_N - x_0}, \quad n = 1, 2, \ldots, N-1. \end{aligned}$$

Introducing the notations,

$$\begin{aligned} &A_n^* = \frac{-6a_{n+1}\alpha_{n+1}}{h_n + h_{n+1}},\ A_n = \frac{-(\alpha_n h_n + 2\alpha_{n+1}h_{n+1})}{h_n + h_{n+1}},\ \lambda_n = \frac{h_{n+1}}{h_n + h_{n+1}}, \\ &\mu_n = 1 - \lambda_n,\ B_n = \frac{-(2\alpha_n h_n + \alpha_{n+1}h_{n+1})}{h_n + h_{n+1}},\ B_n^* = \frac{6a_n\alpha_n}{h_n + h_{n+1}}, \end{aligned}$$

for $n = 1, 2, \ldots, N-1$, the continuity relation (3.6) reduces to

(3.7)
$$\begin{aligned} &A_n^* f'_\Delta(x_0) + A_n M_0 + \mu_n M_{n-1} + 2M_n + \lambda_n M_{n+1} + B_n M_N + B_n^* f'_\Delta(x_N) \\ &\quad = \frac{6[(y_{n+1} - y_n)/h_{n+1} - (y_n - y_{n-1})/h_n]}{h_n + h_{n+1}} - \frac{6(a_{n+1}\alpha_{n+1} - a_n\alpha_n)}{h_n + h_{n+1}}\frac{y_N - y_0}{x_N - x_0}. \end{aligned}$$

Next, (3.5) with $x = x_0$ and $i = 1$ gives the following functional relation for $f'_\Delta(x_0)$:

(3.8)
$$\begin{aligned} &6(1 - a_1\alpha_1)f'_\Delta(x_0) + 2(1 - \alpha_1)h_1 M_0 + h_1 M_1 - \alpha_1 h_1 M_N \\ &\quad = 6/h_1[y_1 - y_0 - \alpha_1 a_1^2(y_N - y_0)]. \end{aligned}$$

Similarly, (3.5) with $x = x_N$ and $i = N$ gives

(3.9)
$$\begin{aligned} &-\alpha_N h_N M_0 + h_N M_{N-1} + 2(1 - \alpha_N)h_N M_N - 6(1 - a_N\alpha_N)f'_\Delta(x_N) \\ &\quad = -6/h_N[y_N - y_{N-1} - \alpha_N a_N^2(y_N - y_0)]. \end{aligned}$$

To write the system of equations given by (3.7)–(3.9) in matrix from, we introduce the following notations:

$$\begin{aligned} &A_0^* = 6(1 - a_1\alpha_1),\ A_0 = 2(1 - \alpha_1)h_1,\ \lambda_0 = h_1,\ B_0 = -\alpha_1 h_1, \\ &A_N = -\alpha_N h_N,\ \mu_N = h_N,\ B_N = 2(1 - \alpha_N)h_N,\ B_N^* = -6(1 - a_N\alpha_N), \\ &d_0 = 6/h_1[y_1 - y_0 - \alpha_1 a_1^2(y_N - y_0)],\ d_N = -6/h_N[y_N - y_{N-1} - \alpha_N a_N^2(y_N - y_0)]. \end{aligned}$$

Thus, the matrix form of defining (3.7)–(3.9) is

(3.10)
$$\begin{bmatrix} A_0^* & A_0 & \lambda_0 & 0 & 0 & \dots & 0 & 0 & 0 & B_0 & 0 \\ A_1^* & A_1+\mu_1 & 2 & \lambda_1 & 0 & \dots & 0 & 0 & 0 & B_1 & B_1^* \\ A_2^* & A_2 & \mu_2 & 2 & \lambda_2 & \dots & 0 & 0 & 0 & B_2 & B_2^* \\ A_3^* & A_3 & 0 & \mu_3 & 2 & \dots & 0 & 0 & 0 & B_3 & B_3^* \\ \vdots & \vdots & \vdots & \vdots & \vdots & & \vdots & \vdots & \vdots & \vdots & \vdots \\ A_{N-3}^* & A_{N-3} & 0 & 0 & 0 & \dots & 2 & \lambda_{N-3} & 0 & B_{N-3} & B_{N-3}^* \\ A_{N-2}^* & A_{N-2} & 0 & 0 & 0 & \dots & \mu_{N-2} & 2 & \lambda_{N-2} & B_{N-2} & B_{N-2}^* \\ A_{N-1}^* & A_{N-1} & 0 & 0 & 0 & \dots & 0 & \mu_{N-1} & 2 & \lambda_{N-1}+B_{N-1} & B_{N-1}^* \\ 0 & A_N & 0 & 0 & 0 & \dots & 0 & 0 & \mu_N & B_N & B_N^* \end{bmatrix} \begin{bmatrix} f'_\Delta(x_0) \\ M_0 \\ M_1 \\ M_2 \\ \\ \vdots \\ M_{N-2} \\ M_{N-1} \\ M_N \\ f'_\Delta(x_N) \end{bmatrix} = \begin{bmatrix} d_0 \\ d_1 \\ d_2 \\ d_3 \\ \\ \vdots \\ d_{N-3} \\ d_{N-2} \\ d_{N-1} \\ d_N \end{bmatrix},$$

where d_n, $n = 1, 2, \dots, N-1$, is given by the right side expression of (3.7) and $f'_\Delta(x_0), M_0, M_1, \dots, M_N, f'_\Delta(x_N)$ are unknowns. Equation (3.10), consisting of a coefficient matrix of order $(N+1)\times(N+3)$, is the desired rectangular matrix equation for computing the unknowns coefficients q_{kn} of the polynomial $q_n(x)$.

Boundary Conditions. By prescribing suitable boundary conditions as in the case of classical cubic splines, the rectangular matrix system of equations (3.10) reduces to a square matrix system of equations. Let the data $\{(x_n, y_n) : n = 0, 1, 2, \dots, N\}$ be generated by a continuous function Φ that is to be approximated by cubic spline FIF f_Δ. The following kinds of boundary conditions are admissible.

Boundary conditions of Type-I: In this case, the values of the first derivative are prescribed at the endpoints of the interval $[x_0, x_N]$, i.e., $f'_\Delta(x_0) = \Phi'(x_0)$, $\quad f'_\Delta(x_N) = \Phi'(x_N)$. So, (3.10) reduces to the following system of equations:

(3.11)
$$\begin{bmatrix} A_0 & \lambda_0 & 0 & 0 & \dots & 0 & 0 & 0 & B_0 \\ A_1+\mu_1 & 2 & \lambda_1 & 0 & \dots & 0 & 0 & 0 & B_1 \\ A_2 & \mu_2 & 2 & \lambda_2 & \dots & 0 & 0 & 0 & B_2 \\ A_3 & 0 & \mu_3 & 2 & \dots & 0 & 0 & 0 & B_3 \\ \vdots & \vdots & \vdots & \vdots & & \vdots & \vdots & \vdots & \vdots \\ A_{N-3} & 0 & 0 & 0 & \dots & 2 & \lambda_{N-3} & 0 & B_{N-3} \\ A_{N-2} & 0 & 0 & 0 & \dots & \mu_{N-2} & 2 & \lambda_{N-2} & B_{N-2} \\ A_{N-1} & 0 & 0 & 0 & \dots & 0 & \mu_{N-1} & 2 & \lambda_{N-1}+B_{N-1} \\ A_N & 0 & 0 & 0 & \dots & 0 & 0 & \mu_N & B_N \end{bmatrix} \begin{bmatrix} M_0 \\ M_1 \\ M_2 \\ M_3 \\ \\ \vdots \\ M_{N-3} \\ M_{N-2} \\ M_{N-1} \\ M_N \end{bmatrix} = \begin{bmatrix} d_0^1 \\ d_1^1 \\ d_2^1 \\ \\ \vdots \\ d_{N-2}^1 \\ d_{N-1}^1 \\ d_N^1 \end{bmatrix},$$

where $d_0^1 = d_0 - A_0^* f'_\Delta(x_0)$, $d_n^1 = d_n - A_n^* f'_\Delta(x_0) - B_n^* f'_\Delta(x_N)$ for $n = 1, 2, \dots, N-1$, and $d_N^1 = d_N - B_N^* f'_\Delta(x_N)$. Thus, boundary conditions of Type-I result in determination of the *complete cubic spline FIF* by using (3.11).

Boundary conditions of Type-II: In this case, the values of the second derivative given at the endpoints of the segment $[x_0, x_N]$ are prescribed as $f''_\Delta(x_0) = \Phi''(x_0) = M_0, f''_\Delta(x_N) = \Phi''(x_N) = M_N$. With these boundary conditions, (3.10) reduces to

(3.12)
$$\begin{bmatrix} A_0^* & \lambda_0 & 0 & 0 & \dots & 0 & 0 & 0 & 0 \\ A_1^* & 2 & \lambda_1 & 0 & \dots & 0 & 0 & 0 & B_1^* \\ A_2^* & \mu_2 & 2 & \lambda_2 & \dots & 0 & 0 & 0 & B_2^* \\ A_3^* & 0 & \mu_3 & 2 & \dots & 0 & 0 & 0 & B_3^* \\ \vdots & \vdots & \vdots & \vdots & & \vdots & \vdots & \vdots & \vdots \\ A_{N-3}^* & 0 & 0 & 0 & \dots & 2 & \lambda_{N-3} & 0 & B_{N-3}^* \\ A_{N-2}^* & 0 & 0 & 0 & \dots & \mu_{N-2} & 2 & \lambda_{N-2} & B_{N-2}^* \\ A_{N-1}^* & 0 & 0 & 0 & \dots & 0 & \mu_{N-1} & 2 & B_{N-1}^* \\ 0 & 0 & 0 & 0 & \dots & 0 & 0 & \mu_N & B_N^* \end{bmatrix} \begin{bmatrix} f'_\Delta(x_0) \\ M_1 \\ M_2 \\ M_3 \\ \\ \vdots \\ M_{N-3} \\ M_{N-2} \\ M_{N-1} \\ f'_\Delta(x_N) \end{bmatrix} = \begin{bmatrix} d_0^2 \\ d_1^2 \\ d_2^2 \\ \\ \vdots \\ d_{N-2}^2 \\ d_{N-1}^2 \\ d_N^2 \end{bmatrix},$$

where $d_1^2 = d_1 - (A_1+\mu_1)M_0 - B_1\mu_N$, $d_{N-1}^2 = d_{N-1} - A_{N-1}M_0 - (B_{N-1}+\lambda_{N-1})M_N$, and $d_n^2 = d_n - A_nM_0 - B_nM_N$ for $n = 0, 2, 3, \dots, N-2, N$. Taking free end conditions $M_0 = 0$ and $M_N = 0$, the *natural cubic spline FIF* is computed by using (3.12).

Boundary conditions of Type-III: In this case, the boundary conditions involve the functional values, the values of first and second derivatives of the cubic splines at both endpoints, i.e., $f_\Delta(x_0) = f_\Delta(x_N), \quad f'_\Delta(x_0) = f'_\Delta(x_N), \quad f''_\Delta(x_0) = f''_\Delta(x_N)$. With these boundary conditions, (3.10) takes the following form:

(3.13)
$$\begin{bmatrix} A_0^* & \lambda_0 & 0 & 0 & \dots & 0 & 0 & 0 & A_0+B_0 \\ A_1^*+B_1^* & 2 & \lambda_1 & 0 & \dots & 0 & 0 & 0 & A_1+B_1+\mu_1 \\ A_2^*+B_2^* & \mu_2 & 2 & \lambda_2 & \dots & 0 & 0 & 0 & A_2+B_2 \\ A_3^*+B_3^* & 0 & \mu_3 & 2 & \dots & 0 & 0 & 0 & A_3+B_3 \\ \vdots & \vdots & \vdots & \vdots & & \vdots & \vdots & \vdots & \vdots \\ A_{N-3}^*+B_{N-3}^* & 0 & 0 & 0 & \dots & 2 & \lambda_{N-3} & 0 & A_{N-3}+B_{N-3} \\ A_{N-2}^*+B_{N-2}^* & 0 & 0 & 0 & \dots & \mu_{N-2} & 2 & \lambda_{N-2} & A_{N-2}+B_{N-2} \\ A_{N-1}^*+B_{N-1}^* & 0 & 0 & 0 & \dots & 0 & \mu_{N-1} & 2 & A_{N-1}+B_{N-1}+\lambda_{N-1} \\ B_N^* & 0 & 0 & 0 & \dots & 0 & 0 & \mu_N & A_N+B_N \end{bmatrix} \begin{bmatrix} f'_\Delta(x_0) \\ M_1 \\ M_2 \\ M_3 \\ \vdots \\ M_{N-3} \\ M_{N-2} \\ M_{N-1} \\ M_N \end{bmatrix} = \begin{bmatrix} d_0 \\ d_1 \\ d_2 \\ d_3 \\ \vdots \\ d_{N-3} \\ d_{N-2} \\ d_{N-1} \\ d_N \end{bmatrix}.$$

The *periodic cubic spline FIF* is computed by using (3.13).

We confine ourselves to the boundary conditions of Type-I, Type-II, and Type-III only for the convergence results in section 4 although, in addition to the above kinds of boundary conditions, the following types of boundary conditions are also admissible in our approach.

Boundary conditions of Type-IV: In this case, the values of derivatives of given function are known at either initial or final endpoint of the interval, i.e., $f'_\Delta(x_0) = \Phi'(x_0),\ f''_\Delta(x_0) = \Phi''(x_0) = M_0$ or $f'_\Delta(x_N) = \Phi'(x_N),\ f''_\Delta(x_N) = \Phi''(x_N) = M_N$. Barnsley and Harrington [1] used the former set of conditions to obtain the cubic spline FIF by employing an involved algebraic method.

Boundary conditions of Type-V: In this type of boundary condition, two sets of conditions are possible depending on the values of different order of the derivatives at both endpoints, i.e., $f'_\Delta(x_0) = \Phi'(x_0),\ f''_\Delta(x_N) = \Phi''(x_N) = M_N$ or $f'_\Delta(x_N) = \Phi'(x_N),\ f_\Delta{}''(x_0) = \Phi''(x_0) = M_0$. In order to find the respective unknowns, the square matrix of order $(N+1)$ for the boundary conditions of Type-IV and Type-V can be obtained from (3.10).

Boundary conditions of Type-VI: Two linear equations involving $M_0,\ f'_\Delta(x_0)$, $f'_\Delta(x_N)$, and M_N are considered in this case such that these and (3.10) form a linearly independent system of equations. The resulting square matrix of order $(N+3)$ can be solved to find all $(N+3)$ unknowns simultaneously.

Using one of the above types of boundary conditions and solving the corresponding system of equations, the values $f'_\Delta(x_0), M_0, M_1, \dots, M_N$ and $f'_\Delta(x_N)$ are determined. These values of $M_n,\ n = 0, 1, 2, \dots, N$, are used in the construction of an associated IFS given by

$$\{\mathbb{R}^2; \omega_n(x,y) = (L_n(x), F_n(x,y)), n = 1, 2, \dots, N\}, \tag{3.14}$$

where $L_n(x) = a_n x + b_n$ and

(3.15)
$$\begin{aligned} F_n(x,y) = a_n^2 \Bigg\{ & \alpha_n f_\Delta(x) + \frac{(M_n - \alpha_n M_N)(x-x_0)^3}{6(x_N - x_0)} + \frac{(M_{n-1} - \alpha_n M_0)(x_N - x)^3}{6(x_N - x_0)} \\ & - \frac{(M_{n-1} - \alpha_n M_0)(x_N - x_0)(x_N - x)}{6} - \frac{(M_n - \alpha_n M_N)(x_N - x_0)(x - x_0)}{6} \\ & + \left(\frac{y_{n-1}}{a_n^2} - \alpha_n y_0\right)\frac{x_N - x}{x_N - x_0} + \left(\frac{y_n}{a_n^2} - \alpha_n y_N\right)\frac{x - x_0}{x_N - x_0} \Bigg\}. \end{aligned}$$

The graph of the desired cubic spline is the fixed point of the IFS given by (3.14).

Remarks. 1. If the vertical scaling factor $\alpha_n = 0$ for $n = 1, 2, \ldots, N$, $F_n(x, y)$ reduces to a cubic polynomial in each subinterval of I so that in this case the resulting FIF is a classical cubic spline.

2. By the fixed point theorem, with prescribed ordinates at mesh points, the nonperiodic spline FIF always exists and is unique for a given choice of vertical scaling factors. This spline FIF has simple end supports ($M_0 = 0, M_N = 0$), prescribed end moments or simple supports at points beyond mesh extremities. Similarly, the periodic spline FIF exists and is unique for a given data and a given choice of vertical scaling factors. Since the moments depend upon the vertical scaling factors α_n, by changing α_n, infinitely many nonperiodic splines or periodic splines having the same boundary conditions can be constructed. This gives an additional advantage for the applications of the cubic spline FIF over the applications of the classical cubic spline since there is no flexibility in choosing the latter once the boundary conditions are fixed.

3. Clearly, the replacement of y_n by $y_n + c$ does not affect the right-hand sides of (3.7)–(3.9). Thus, $f_\Delta(Y; x) + \eta = f_\Delta(\bar{Y}; x)$, where $\bar{Y} : \bar{y}_0, \bar{y}_1, \ldots, \bar{y}_N$ and $\bar{y}_n = y_n + \eta$, $n = 0, 1, 2, \ldots, N$, with η being a constant. Since the moments M_n do not change by the translation of the ordinates by a constant η, it follows that it is possible to associate more than one cubic spline FIF for a given set of moments M_n. This property of cubic spline FIF f_Δ is analogous to the corresponding property of the periodic classical spline [19].

4. The existence of spline FIF f_Δ gives (3.7)–(3.9). Further, if spline FIF f_Δ is periodic, adding (3.7) to (3.9) gives

$$\sum_{n=1}^{N} [(h_n + h_{n+1})M_n - 2\alpha_n h_n M_N] = 0. \tag{3.16}$$

The condition (3.16) is therefore a necessary condition for the existence of the periodic cubic spline FIF for prescribed moments M_n. With $\alpha_n = 0$ for $n = 1, 2, \ldots, N$, the condition (3.16) reduces to the necessary condition for the existence of periodic classical cubic spline associated with M_n [19, p. 17].

5. For a prescribed set of data and a suitable choice of α_n satisfying $0 \le |\alpha_n| < 1$, it follows from (3.15) that, on the space $\mathcal{F}^* = \{f \in C^2(I, \mathbb{R}) \mid f(x_0) = y_0 \text{ and } f(x_N) = y_N\}$, cubic spline FIF f_Δ is the fixed point of Read–Bajraktarević operator T^* defined by

(3.17)

$$\begin{aligned} T^* f(x) = a_n^2 \Bigg\{ & \alpha_n f(L_n^{-1}(x)) + \frac{(M_n - \alpha_n M_N)(L_n^{-1}(x) - x_0)^3}{6(x_N - x_0)} \\ & + \frac{(M_{n-1} - \alpha_n M_0)(x_N - L_n^{-1}(x))^3}{6(x_N - x_0)} - \frac{(M_{n-1} - \alpha_n M_0)(x_N - x_0)(x_N - L_n^{-1}(x))}{6} \\ & - \frac{(M_n - \alpha_n M_N)(x_N - x_0)(L_n^{-1}(x) - x_0)}{6} \\ & + \left(\frac{y_{n-1}}{a_n^2} - \alpha_n y_0\right)\frac{x_N - L_n^{-1}(x)}{x_N - x_0} + \left(\frac{y_n}{a_n^2} - \alpha_n y_N\right)\frac{L_n^{-1}(x) - x_0}{x_N - x_0} \Bigg\}, \end{aligned}$$

where $x \in I_n$ for $n = 1, 2, \ldots, N$. Since (3.10) is derived from the fixed point relation $T^* f_\Delta = f_\Delta$, the solution of each of the equations (3.11)–(3.13) is unique due to uniqueness of the fixed point. Hence, the coefficient matrices in the systems (3.11)–(3.13) are invertible.

6. The moment integral $\Phi_m = \int_I x^m \Phi(x)\ dx,\ m = 0, 1, 2, \ldots,$ of the data generating function Φ can be approximately calculated by integral moments $f_\Delta^m \equiv \int_I x^m f_\Delta(x)\ dx$ of the cubic spline FIF. One can evaluate explicitly the moment integral f_Δ^m in terms of $f_\Delta^{m-1}, f_\Delta^{m-2}, \ldots, f_\Delta^0$, the data points, the vertical scaling factors $\alpha_n, n = 1, 2, \ldots, N,$ and $Q_m = \int_I x^m Q(x)\ dx$, where $Q(x) = q_n \circ L_n^{-1}(x),\ x \in I_n$. Thus, Barnsley and Harrington's query [1] regarding the moment integrals in case of reverse horizontal scaling is already taken into account in our construction.

4. Convergence of cubic spline FIFs. Define a sequence $\{\Delta_k\}$ of meshes on $[x_0, x_N]$ as $\Delta_k : x_0 = x_{k,0} < x_{k,1} < \cdots < x_{k,N_k} = x_N$, then set $h_{k,n} = x_{k,n} - x_{k,n-1}$ and $\|\Delta_k\| = \max_{1 \le n \le N_k} h_{k,n}$.

We establish that sequences of cubic spline FIFs $\{f_{\Delta_k}(x)\}$ converge to $\Phi(x)$ on suitable sequences of meshes $\{\Delta_k\}$ at the rate of square of the mesh norm $\|\Delta_k\|$, where $\Phi \in C^r(I)$, $r = 2, 3$, or 4, is the data generating function. Since the matrices associated with the cubic spline FIF, satisfying the boundary conditions of Type-I, Type-II, or Type-III (periodic), are not, in general, diagonally dominant and $f_\Delta''(x)$ is not piecewise linear, the convergence procedure for classical cubic spline [19] cannot be adopted for establishing the convergence of the cubic spline FIF. Our convergence results for cubic spline FIFs are in fact derived by using the convergence results for classical splines.

Let $\mathcal{F}^*$ be the set of cubic spline FIFs on the given mesh Δ, interpolating the values y_n at the mesh points. From (3.17), it is clear that for $x \in I = [x_0, x_N]$,

$$f_\Delta(L_n(x)) = a_n^2 \alpha_n f_\Delta(x) + a_n^2 q_n(x), \tag{4.1}$$

where $q_n(x)$ is a cubic polynomial for $n = 1, 2, \ldots, \mathrm{N}$. Throughout the sequel, we assume $|\alpha_n| \le s < 1$ for a fixed s and denote $q_n(\alpha_n, x) \equiv q_n(x)$ for $n = 1, 2, \ldots, N$.

LEMMA 4.1. *Let $f_\Delta(x)$ and $S_\Delta(x)$, respectively, be the cubic spline FIF and the classical cubic spline with respect to the mesh $\Delta : x_0 < x_1 < \cdots < x_N$, interpolating a set of ordinates $\{y_0, y_1, \ldots, y_N\}$ at the mesh points. Let the cubic polynomial $q_n(\alpha_n, x)$ associated with the IFS for FIF $f_\Delta(x)$ satisfy*

$$\left| \frac{\partial^{1+r} q_n(\tau_n, x)}{\partial \alpha_n \partial x^r} \right| \le K_r \tag{4.2}$$

for $|\tau_n| \in (0, s a_n^r),\ x \in I_n,\ r = 0, 1, 2,$ and $n = 1, 2, \ldots, N$. Then,

$$\|f_\Delta^{(r)} - S_\Delta^{(r)}\|_\infty \le \frac{\|\Delta\|^{2-r} \max_{1 \le n \le N} |\alpha_n|}{|I|^{2-r} - \|\Delta\|^{2-r} \max_{1 \le n \le N} |\alpha_n|} (\|S_\Delta^{(r)}\|_\infty + K_r), \quad r = 0, 1, 2, \tag{4.3}$$

where $|I| = |x_N - x_0|$.

Proof. Denote $\mathcal{B}_r = [-s a_1^r, s a_1^r] \times [-s a_2^r, s a_2^r] \times \cdots \times [-s a_N^r, s a_N^r] \equiv \bigotimes_{n=1}^N [-s a_n^r, s a_n^r]$.

Let $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_N) \in \mathcal{B}_0$ and $r = 0$. Since cubic spline FIF f_Δ is unique for a set of scaling factors $\alpha \in \mathcal{B}_0$ and a prescribed boundary condition, using (3.17) the Read–Bajraktarević operator $T_\alpha^* : \mathcal{F}^* \to \mathcal{F}^*$ can be rewritten as

$$T_\alpha^* f^*(x) = a_n^2 \alpha_n f^*(L_n^{-1}(x)) + a_n^2 q_n(\alpha_n, L_n^{-1}(x)), \quad x \in I_n, n = 1, 2, \ldots, N. \tag{4.4}$$

For a given $\alpha \in \mathcal{B}_0$ and at least one $\alpha_n \ne 0$ in (4.4), cubic spline FIF f_Δ is the fixed point of T_α^*. For $\alpha^* = (0, 0, \ldots, 0) \in \mathcal{B}_0$, the classical cubic spline S_Δ is the fixed

point of $T^*_{\alpha^*}$, since in this case $q_n(\alpha_n, x)$ is a polynomial only in x for $n = 1, 2, \ldots, N$. Therefore, using (4.4), for $x \in I_n$,

$$\begin{aligned}|T^*_\alpha f_\Delta(x) - T^*_\alpha S_\Delta(x)| &= |a_n^2\alpha_n f_\Delta(L_n^{-1}(x)) + a_n^2 q_n(\alpha_n, L_n^{-1}(x)) \\ &\quad -[a_n^2\alpha_n S_\Delta(L_n^{-1}(x)) + a_n^2 q_n(\alpha_n, L_n^{-1}(x))]| \\ &\le \frac{\|\Delta\|^2}{|I|^2} \max_{1\le n\le N}|\alpha_n|\, \|f_\Delta - S_\Delta\|_\infty.\end{aligned}$$

Since the above inequality holds for $n = 1, 2, \ldots, N$, it follows that

$$\|T^*_\alpha f_\Delta - T^*_\alpha S_\Delta\|_\infty \le \frac{\|\Delta\|^2}{|I|^2} \max_{1\le n\le N}|\alpha_n|\, \|f_\Delta - S_\Delta\|_\infty. \tag{4.5}$$

Further, for $x \in I_n$, using (4.4) and Mean Value Theorem,

$$\begin{aligned}|T^*_\alpha S_\Delta(x) - T^*_{\alpha^*} S_\Delta(x)| &= |a_n^2\alpha_n S_\Delta(L_n^{-1}(x)) + a_n^2 q_n(\alpha_n, L_n^{-1}(x)) - a_n^2 q_n(0, L_n^{-1}(x))| \\ &\le a_n^2|\alpha_n|\|S_\Delta\|_\infty + a_n^2|\alpha_n|\left|\frac{\partial q_n(\tau_n, L_n^{-1}(x))}{\partial\alpha_n}\right| \\ &\le \frac{\|\Delta\|^2}{|I|^2} \max_{1\le n\le N}|\alpha_n|\, (\|S_\Delta\|_\infty + K_0).\end{aligned}$$

Since the above inequality holds for $n = 1, 2, \ldots, N$,

$$\|T^*_\alpha S_\Delta - T^*_{\alpha^*} S_\Delta\|_\infty \le \frac{\|\Delta\|^2}{|I|^2} \max_{1\le n\le N}|\alpha_n|\, (\|S_\Delta\|_\infty + K_0). \tag{4.6}$$

Using (4.5)–(4.6) together with the inequality

$$\|f_\Delta - S_\Delta\|_\infty = \|T^*_\alpha f_\Delta - T^*_{\alpha^*} S_\Delta\|_\infty \le \|T^*_\alpha f_\Delta - T^*_\alpha S_\Delta\|_\infty + \|T^*_\alpha S_\Delta - T^*_{\alpha^*} S_\Delta\|_\infty$$

gives that

$$\|f_\Delta - S_\Delta\|_\infty \le \frac{\|\Delta\|^2 \max_{1\le n\le N}|\alpha_n|}{|I|^2 - \|\Delta\|^2 \max_{1\le n\le N}|\alpha_n|}(\|S_\Delta\|_\infty + K_0).$$

This proves Lemma 4.1 for $r = 0$. For $r = 1, 2$, the proof of the lemma is analogous to the proof given above for $r = 0$, by taking $\mathcal{B}_1$, $\mathcal{B}_2$, respectively, in place of $\mathcal{B}_0$ and defining Read–Bajraktarević operator on $\mathcal{F}^*_r = \{f \in C^{2-r}(I, \mathbb{R}) \mid f(x_0) = y_0 \text{ and } f(x_N) = y_N\}$ by

$$T^* f^{(r)}(x) = a_n^{2-r} f^{(r)}(L_n^{-1}(x)) + a_n^{2-r} q_n^{(r)}(\alpha_n, L_n^{-1}(x)), \quad r = 1, 2,$$

in place of (4.4). □

For studying the convergence of cubic spline FIFs to a data generating function through sequences of meshes $\{\Delta_k\}$ on $[x_0, x_N]$, define the following types of meshes depending upon vertical scaling factors $\alpha_{k,n}$.

Class A $\{\{\Delta_k\} : \text{For each } k, \max_{1\le n\le N_k}|\alpha_{k,n}| \le \|\Delta_k\| < 1\}$.

Class B $\{\{\Delta_k\} : \text{For each } k, |\alpha_{k,i}| > \|\Delta_k\| \text{ for some } i, 1 \le i \le N_k\}$.

The convergence of a suitable sequence of cubic spline FIFs to the function Φ in $C^2[x_0, x_N]$ generating the interpolation data is described by the following theorem.

THEOREM 4.2. *Let $\Phi \in C^2[x_0, x_N]$ and cubic spline FIFs $f_{\Delta_k}(x)$ satisfy boundary conditions of Type-*I*, Type-*II*, or Type-*III *(periodic) on a sequence of meshes $\{\Delta_k\}$ on $[x_0, x_N]$ with $\lim_{k\to\infty} \|\Delta_k\| = 0$. If $\{\Delta_k\}$ is in Class A, then*

$$\|\Phi^{(r)} - f^{(r)}_{\Delta_k}\|_\infty = \circ(\|\Delta_k\|^{2-r}), \quad r = 0, 1, 2. \tag{4.7}$$

Further, if $\{\Delta_k\}$ is in Class B, then

$$\|\Phi^{(r)} - f^{(r)}_{\Delta_k}\|_\infty = \bigcirc(\|\Delta_k\|^{2-r}), \quad r = 0, 1, 2. \tag{4.8}$$

Proof. By Lemma 4.1, each element of the sequence $\{\Delta_k\}$ satisfies

$$\|f^{(r)}_{\Delta_k} - S^{(r)}_{\Delta_k}\|_\infty \le \frac{\|\Delta_k\|^{2-r} \max_{1\le n\le N_k} |\alpha_{k,n}|}{|I|^{2-r} - \|\Delta_k\|^{2-r} \max_{1\le n\le N_k} |\alpha_{k,n}|}(\|S^{(r)}_{\Delta_k}\|_\infty + K_r), \quad r = 0, 1, 2. \tag{4.9}$$

Further, it is known that [19, 20]

$$\|\Phi^{(r)} - S^{(r)}_{\Delta_k}\|_\infty \le 5\|\Delta_k\|^{2-r}\omega(\Phi^{(r)}; \|\Delta_k\|) \quad (r = 0, 1, 2), \tag{4.10}$$

where $\omega(\Phi; x)$ is the modulus of continuity of $\Phi(x)$. By using the triangle inequality and (4.10), it follows that

$$\|S^{(r)}_{\Delta_k}\|_\infty \le \|\Phi^{(r)}\|_\infty + 5\|\Delta_k\|^{2-r}\omega(\Phi^{(r)}; \|\Delta_k\|). \tag{4.11}$$

The inequality

$$\|\Phi^{(r)} - f^{(r)}_{\Delta_k}\|_\infty \le \|\Phi^{(r)} - S^{(r)}_{\Delta_k}\|_\infty + \|S^{(r)}_{\Delta_k} - f^{(r)}_{\Delta_k}\|_\infty \tag{4.12}$$

together with (4.9)–(4.11) gives

$$\begin{aligned}\|\Phi^{(r)} - f^{(r)}_{\Delta_k}\|_\infty \le{}& \|\Delta_k\|^{2-r}\Bigg\{5\omega(\Phi^{(r)}; \|\Delta_k\|) \\ &+ \frac{(\|\Phi^{(r)}\|_\infty + 5\|\Delta_k\|^{2-r}\omega(\Phi^{(r)}; \|\Delta_k\|) + K_r) \max_{1\le n\le N_k} |\alpha_{k,n}|}{|I|^{2-r} - \|\Delta_k\|^{2-r} \max_{1\le n\le N_k} |\alpha_{k,n}|}\Bigg\}.\end{aligned} \tag{4.13}$$

Since $\Phi \in C^2(I)$ and $\max_{1\le n\le N_k} |\alpha_{k,n}| \le \|\Delta_k\| < 1$, the right-hand side of (4.13) tends to zero as $k \to \infty$. The convergence result (4.7) for Class A therefore follows from the error estimate (4.13).

Next, we obtain the convergence result (4.8) for Class B. Since $\max_{1\le n_k\le N_k} |\alpha_{n_k}| \le s < 1$ (cf. definition (4.1)), (4.9) reduces to

$$\|f^{(r)}_{\Delta_k} - S^{(r)}_{\Delta_k}\|_\infty \le \frac{\|\Delta_k\|^{2-r} s}{|I|^{2-r} - \|\Delta_k\|^{2-r} s}(\|S^{(r)}_\Delta\|_\infty + K_r), \quad r = 0, 1, 2. \tag{4.14}$$

The inequalities (4.10), (4.11), and (4.14) together with (4.12) give

$$\begin{aligned}\|\Phi^{(r)} - f^{(r)}_{\Delta_k}\|_\infty \le{}& \|\Delta_k\|^{2-r}\Bigg\{5\omega(\Phi^{(r)}; \|\Delta_k\|) \\ &+ \frac{(\|\Phi^{(r)}\|_\infty + 5\|\Delta_k\|^{2-r}\omega(\Phi^{(r)}; \|\Delta_k\|) + K_r)s}{|I|^{2-r} - \|\Delta_k\|^{2-r} s}\Bigg\}.\end{aligned} \tag{4.15}$$

The convergence result (4.8) for Class B now follows from (4.15). □

The convergence of a suitable sequence of cubic spline FIFs to the function Φ in $C^3[x_0, x_N]$ generating the interpolation data is given by the following theorem.

THEOREM 4.3. *Let $\Phi \in C^3[x_0, x_N]$ and cubic spline FIFs $f_{\Delta_k}(x)$ satisfy boundary conditions of Type-*I*, Type-*II*, or Type-*III*(periodic) on a sequence of meshes $\{\Delta_k\}$ on $[x_0, x_N]$ with $\lim_{k\to\infty} \|\Delta_k\| = 0$ and $\frac{\|\Delta_k\|}{\min_{1\le n\le N_k} h_{k,n}} \le \beta < \infty$. If $\{\Delta_k\}$ is in Class A, then*

$$\|\Phi^{(r)} - f^{(r)}_{\Delta_k}\|_\infty = \circ(\|\Delta_k\|^{2-r}), \quad r = 0, 1, 2. \tag{4.16}$$

Further, if $\{\Delta_k\}$ is in Class B, then

$$\|\Phi^{(r)} - f^{(r)}_{\Delta_k}\|_\infty = \bigcirc(\|\Delta_k\|^{2-r}), \quad r = 0, 1, 2. \tag{4.17}$$

Proof. It is known that [19, 21], for $r = 0, 1, 2$,

$$\|\Phi^{(r)} - S^{(r)}_{\Delta_k}\|_\infty \le \frac{5}{3}\|\Delta_k\|^{3-r}(3 + \bar{K})\omega(\Phi^{(3)}; \|\Delta_k\|), \tag{4.18}$$

where $\bar{K} = 8\beta^2(1 + 2\beta)(1 + 3\beta)$.

Now, (4.9) and (4.18) together with (4.12) give

$$\|\Phi^{(r)} - f^{(r)}_{\Delta_k}\|_\infty \le \|\Delta_k\|^{2-r}\left\{\frac{5}{3}\|\Delta_k\|(3 + \bar{K})\omega(\Phi^{(3)}; \|\Delta_k\|) + \frac{(\|\Phi^{(r)}\|_\infty + \frac{5}{3}\|\Delta_k\|(3 + \bar{K})\omega(\Phi^{(3)}; \|\Delta_k\|) + K_r)\max_{1\le n\le N_k} |\alpha_{k,n}|}{|I|^{2-r} - \|\Delta_k\|^{2-r}\max_{1\le n\le N_k} |\alpha_{k,n}|}\right\}.$$

For the sequence of meshes in Class A or Class B, the relations (4.16)–(4.17) now follow immediately from the above error estimate. □

The convergence of a suitable sequence of cubic spline FIFs to the function Φ in $C^4[x_0, x_N]$ generating the interpolation data is described by the following theorem.

THEOREM 4.4. *Let $\Phi \in C^4[x_0, x_N]$ and cubic spline FIFs $f_{\Delta_k}(x)$ satisfy boundary conditions of Type-*I *or Type-*II *on a sequence of meshes $\{\Delta_k\}$ on $[x_0, x_N]$ with $\lim_{k\to\infty} \|\Delta_k\| = 0$ and $\frac{\|\Delta_k\|}{\min_{1\le n\le N_k} h_{k,n}} \le \beta < \infty$. If $\{\Delta_k\}$ is in Class A, then*

$$\|\Phi^{(r)} - f^{(r)}_{\Delta_k}\|_\infty = \circ(\|\Delta_k\|^{2-r}), \quad r = 0, 1, 2. \tag{4.19}$$

Further, if $\{\Delta_k\}$ is in Class B, then

$$\|\Phi^{(r)} - f^{(r)}_{\Delta_k}\|_\infty = \bigcirc(\|\Delta_k\|^{2-r}), \quad r = 0, 1, 2. \tag{4.20}$$

Proof. It is known that [22]

$$\|\Phi^{(r)} - S^{(r)}_{\Delta_k}\|_\infty \le L_r\|\Phi^{(4)}\|_\infty\|\Delta_k\|^{4-r}, \quad r = 0, 1, 2, 3, \tag{4.21}$$

where $L_0 = 5/384$, $L_1 = 1/24$, $L_2 = 3/8$, and $L_3 = (\beta + \beta^{-1})/2$. The inequalities (4.9) and (4.21) together with (4.12) give the error estimate

(4.22)

$$\|\Phi^{(r)} - f_{\Delta_k}^{(r)}\|_\infty \leq \|\Delta_k\|^{2-r} \Bigg\{ L_r \|\Phi^{(4)}\|_\infty \|\Delta_k\|^2 + \frac{(\|\Phi^{(r)}\|_\infty + L_r \|\Phi^{(4)}\|_\infty \|\Delta_k\|^{4-r} + K_r) \max_{1\leq n\leq N_k} |\alpha_{k,n}|}{|I|^{2-r} - \|\Delta_k\|^{2-r} \max_{1\leq n\leq N_k} |\alpha_{k,n}|} \Bigg\}.$$

The convergence results (4.19) and (4.20) now follow from (4.22). □

Remarks. 1. Theorem 4.4 generalizes a result of Navascués and Sebastián [23] proved only for uniform meshes with fixed vertical scaling factors.

2. If $\Phi^{(2)}$ satisfies a Hölder condition of order τ, $0 < \tau \leq 1$, Theorem 4.2 gives that, for $r = 0, 1, 2$, $\|\Phi^{(r)} - f_{\Delta_k}^{(r)}\|_\infty = \circ(\|\Delta_k\|^{2-r})$ if Δ_k is in Class A and $\|\Phi^{(r)} - f_{\Delta_k}^{(r)}\|_\infty = \bigcirc(\|\Delta_k\|^{2-r})$ if Δ_k is in Class B. This provides an analogue of the corresponding result for classical cubic splines [19, Theorem 2.3.3]. The same estimates on $\|\Phi^{(r)} - f_{\Delta_k}^{(r)}\|_\infty$ follow from Theorem 4.3 or Theorem 4.4 if $\Phi^{(3)}$ or $\Phi^{(4)}$, respectively, satisfies the Hölder condition of order τ, $0 < \tau \leq 1$.

3. It follows from Theorems 4.2–4.4 that the sequence of cubic spline FIFs $f_{\Delta_k}^{(r)}$ converges uniformly to $\Phi^{(r)}$ for $r = 0, 1$ and if Δ_k is in Class A, $f_{\Delta_k}^{(2)}(x)$ converges uniformly to $\Phi^{(2)}(x)$, since, for $r = 2$, the vertical scaling factors can be chosen suitably depending on the mesh norm.

5. Examples of cubic spline FIFs. Using the IFS given by (3.14), we first computationally generate examples of cubic spline FIFs with the set of vertical scaling factors as $\alpha_n = 0.8$, $n = 1, 2, 3$, and the interpolation data as $\{(0,0), (\frac{2}{5}, 1), (\frac{3}{4}, -1), (1, 2)\}$ for the nonperiodic splines and as $\{(0,0), (\frac{2}{5}, 1), (\frac{3}{4}, -1), (1, 0)\}$ for the periodic splines. These interpolation data give $L_1(x) = \frac{2}{5}x$, $L_2(x) = \frac{7}{20}x + \frac{2}{5}$, and $L_3(x) = \frac{1}{4}x + \frac{3}{4}$ in the IFS (3.14) for all our examples of cubic spline FIFs. For constructing an example of the cubic spline FIF with a boundary condition of Type-I, we choose $f'_\Delta(x_0) = 2$ and $f'_\Delta(x_N) = 5$. With these choices, the system of equations (3.11) is solved to get the values of moments M_0, M_1, M_2, M_3 (Table 1). These moments are now used in (3.15) for the construction of $F_n(x, y)$ (Table 2). Iterations of this IFS code generate the desired cubic spline FIF (Figure 2(a)) with a boundary condition of Type-I. Again, to construct an example of the cubic spline FIF with a boundary condition of Type-II, we choose $M_0 = 2$ and $M_3 = 5$. The values of M_1 and M_2 (Table 1) are computed by solving the system (3.12). Using (3.15), the coefficients of $F_n(x, y)$, $n = 1, 2, 3$, are computed (Table 2). The iterations of the resulting IFS code generate the cubic spline FIF (Figure 2(c)) with a boundary condition of Type-II. An example of the cubic spline FIF with a boundary condition of Type-III (periodic), i.e., $f'_\Delta(x_0) = f'_\Delta(x_3)$ is constructed and $M_0 = M_3$. The values of moments M_0, M_1, M_2, M_3 (Table 1) are computed by solving the system (3.13). The associated IFS code for the periodic cubic spline is obtained from the resulting (3.14). The desired example of the periodic cubic spline FIF (Figure 2(e)) is generated through iterations of this IFS. Similarly, with a 2nd set of vertical scaling factors as $\alpha_1 = \alpha_3 = -0.9$ and $\alpha_2 = 0.9$, the examples of cubic spline FIFs (Figure 2(b), (d), (f)) with boundary conditions of Type-I, Type-II, and Type-III are generated. We note that cubic spline FIFs given by Figure 2(a)–(b) have completely different shapes though they are generated with the same boundary conditions of Type-I, whereas the same boundary conditions give

just one interpolating classical cubic spline. Thus, in our approach, an added flexibility is offered to an experimenter depending upon the need of a problem for the choice of a suitable cubic spline FIF. Similarly, Figure 2(c)–(d) gives a comparison of shape and nature of cubic spline FIFs with a boundary condition of Type-II and Figure 2(e)–(f) gives such a comparison for periodic cubic spline FIFs to see the effect of vertical scaling factors on their shapes.

For construction of IFS for cubic spline FIFs (Figure 2(g) and 2(i)) with boundary conditions of Type-IV with first set of vertical scaling factors as $\alpha_n = 0.8, n = 1, 2, 3$, we choose $f'_\Delta(x_0) = 2$, $M_0 = 5$, and $f'_\Delta(x_3) = 2$, $M_3 = 5$, respectively. The examples of cubic spline FIFs (Figure 2(k) and 2(m)) with boundary conditions of Type-V are constructed with $\alpha_n = 0.8, n = 1, 2, 3$, by choosing $f'_\Delta(x_0) = 2$, $M_3 = 5$, and $M_0 = 2$, $f'_\Delta(x_3) = 5$, respectively. Finally, for constructing the cubic spline FIF (Figure 2(o)) with a boundary condition of Type-VI, the associated IFS is generated by choosing $\alpha_n = 0.8, n = 1, 2, 3$, and $f'_\Delta(x_0), M_0, M_3$, and $f'_\Delta(x_3)$ are chosen such that $3f'_\Delta(x_0) + 2M_0 = 1$ and $f'_\Delta(x_3) + M_3 = 2$. The examples of cubic spline FIFs (Figure 5.1(h), (j), (l), (n), (p)) with boundary conditions of Type-IV, V, or VI are analogously constructed by computing the associated IFS with $\alpha_1 = \alpha_3 = -0.9$ and $\alpha_2 = 0.9$. The effect of vertical scaling factors on the shape and nature of cubic spline FIFs with boundary conditions of Type-IV, V, or VI is demonstrated in Figure 2(g)–(p). Thus, infinitely many cubic spline FIFs with different shapes can be generated by varying scaling factor sets for any prescribed boundary conditions. This gives a vast flexibility in the choice of cubic spline FIF according to the need of the problem.

A normal-size font entry in Table 1 is for the value assumed for a parameter in a particular example. An entry in script-size font in Table 1 is for the value of the parameters that are computed by using (3.10). The entries for the coefficients of $F_n(x, y)$ in Table 2 are computed by using (3.15). All the entries in these tables are rounded off up to four decimal places.

6. Conclusion. A new method is introduced in the present work for the construction of C^r-FIFs so that the complex algebraic method in [1] for construction of C^r-FIFs using complicated matrices is no longer needed. Our method allows admissibility of any kind of boundary conditions while the boundary conditions in [1] are restricted to only at the initial endpoint x_0 of the interval $[x_0, x_N]$. In our approach, r equations involving the spline values or the values of its derivatives at the boundary points are chosen such that the resulting $(r + 2)N + 2r$ equations are linearly independent. This results in generation of a unique C^r-FIF for a prescribed data and a suitable set of vertical scaling factors. This answers a query of Barnsley and Harrington [1, p. 33], regarding uniqueness of the C^r-FIF for a suitable set of vertical scaling

FIG. 2. *Cont.*

factors. The construction of cubic spline FIFs, using the moments $M_n = f_\Delta^{''}(x_n)$, is initiated for the first time in the present work, resulting in a satisfactory generalization of the classical cubic spline theory.

For the data generating function $\Phi \in C^r[x_0, x_n]$, $r = 2, 3$, or 4, it is proved that (cf. Theorems 4.2–4.4), the sequence of cubic spline FIFs $\{f_{\Delta_k}\}$ converges to Φ with arbitrary degree of accuracy for the sequences of meshes in Class A or Class B for boundary conditions of Type-I, Type-II, or Type-III. Our convergence results in section 4 are obtained with more general conditions than those in [23] wherein only uniform meshes are considered in the case $\Phi \in C^{(4)}[x_0, x_n]$. The upper bounds on error in approximation of Φ and its derivatives by cubic spline FIFs f_Δ and its derivatives, respectively, with different boundary conditions are also obtained by results in section 4. As a consequence of our results, the data generating function Φ that satisfies $\Phi^{(2)} \in Lip\ \tau$, $0 < \tau < 1$, can be approximated satisfactorily by a fractal function f_Δ by choosing vertical scaling factors suitably such that $f_\Delta^{(2)} \in Lip\ \tau$.

The vertical scaling factors α_n are important parameters in the construction of C^r-FIFs or cubic spline FIFs. For given boundary conditions, in our approach an infinite number of C^r-FIFs or cubic spline FIFs can be constructed interpolating the same data by choosing different sets of vertical scaling factors. Thus, according to the need of an experiment for simulating objects with smooth geometrical shapes, a large flexibility in the choice of a suitable interpolating smooth fractal spline is offered by our approach. As in the case of vast applications of classical splines in CAM, CAGD, and other mathematical, engineering applications [12, 13, 14, 15], it is felt that cubic spline FIFs generated in the present work can find rich applications in some of these areas. Since the cubic spline FIF is invariant in all scales, it can also be applied to image compression and zooming problems in image processing. Further, as classical cubic splines are a special case of cubic spline FIFs, it should be possible to use cubic spline FIFs for mathematical and engineering problems where the classical spline interpolation approach does not work satisfactorily.

Acknowledgment. The authors are thankful to Dr. Ian Sloan for his valuable suggestions.

DISCRETE MAXIMAL L_p REGULARITY FOR FINITE ELEMENT OPERATORS*

MATTHIAS GEISSERT†

Abstract. Let $\{A_h\}_{h>0}$ be a family of elliptic finite element operators. Let $I = [0,T]$ and consider the problem $u_h'(t) - A_h u_h(t) = f_h(t)$, $t \in I$, $u_h(0) = 0$. In this paper, we show that for $1 < p < \infty$ the solution of that problem satisfies the estimate

$$\|u_h'\|_{L_p(I;L_p(\Omega))} + \|A_h u_h\|_{L_p(I;L_p(\Omega))} \le C\|f_h\|_{L_p(I;L_p(\Omega))},$$

where C is independent of the parameter h and f_h. In this case $\{A_h\}_{h>0}$ is said to have *discrete* maximal L_p regularity.

Key words. finite elements, maximal regularity

1. Introduction. For $T > 0$, set $I = [0,T]$ and consider the Galerkin finite element method for the approximate solution of

$$\begin{aligned} u'(t) - \Delta^D u(t) &= f(t), \quad t \in I, \\ u(0) &= 0, \end{aligned} \tag{1}$$

where Δ^D is the Dirichlet–Laplacian in $L_2(\Omega)$. Here, $\Omega \subset \mathbb{R}^N$ is a bounded, convex domain with C^2 boundary. Then the corresponding problem for the discrete Dirichlet–Laplacian Δ_h^D acting on some finite element space S_h, i.e., continuous, piecewise linear functions defined on a family of quasi-uniform triangulations with parameter h, reads as:

$$\begin{aligned} u_h'(t) - \Delta_h^D u_h(t) &= f_h(t), \quad t \in I, \\ u_h(0) &= 0. \end{aligned} \tag{2}$$

The solution u_h of (2) is given by the variation of constants formula, i.e.,

$$u_h(t) := \int_0^t T_h(t-s) f_h(s)\, \mathrm{d}s, \tag{3}$$

where $(T_h(t))_{t\ge 0} := (\mathrm{e}^{t\Delta_h^D})_{t\ge 0}$ denotes the semigroup generated by Δ_h^D. In [Tho97] stability estimates for u_h together with stability estimates for the corresponding Ritz projections are used to derive error estimates for $u - u_h$ in $L_2(\Omega)$ and $L_\infty(\Omega)$. In order to prove this stability estimates for u_h representation (3) and uniform estimates in h for $(T_h(t))_{t\ge 0}$, i.e.,

$$\|T_h(t)\|_{\mathcal{L}(S_{h,q})} \le C, \quad \|t\Delta_h^D T_h(t)\|_{\mathcal{L}(S_{h,q})} \le C, \quad t \in I,\ h > 0, \tag{4}$$

were very useful. Here, $S_{h,q}$ denotes the space S_h equipped with the $L_q(\Omega)$-norm and $1 \le q \le \infty$.

In this paper, we consider the property of maximal L_p regularity for finite element operators. Although our approach is not at all restricted to the Dirichlet–Laplacian (see Definition 2.1), for notational reasons we restrict our considerations for the time being to this case. Since Δ_h^D is a bounded operator on $S_{h,q}$, it immediately follows from (3) that Δ_h^D has *maximal L_p regularity on $S_{h,q}$*, i.e., for $h > 0$ there exists $C_h > 0$ such that

$$\|u_h'\|_{L_p(I;S_{h,q})} + \|\Delta_h^D u_h\|_{L_p(I;S_{h,q})} \le C_h \|f_h\|_{L_p(I;S_{h,q})}, \quad f_h \in L_p(I;S_{h,q}), \tag{5}$$

where u_h denotes the unique solution of (2) and $\|u_h\|^q_{L_p(I;S_{h,q})} := \int_0^T \|u_h(t)\|^p_{S_{h,q}}\,\mathrm{d}t$. If the family $\{C_h\}_{h>0}$ is uniformly bounded, we say that $\{\Delta_h^D\}_{h>0}$ has *discrete maximal L_p regularity on $S_{h,q}$*. In terms of numerical analysis, discrete maximal L_p regularity means that the numerical scheme is stable. Tracing constants in [DHP03, Remark 3.2(3)], [DHP03, Theorem 4.4], and [HP97, Proposition 2.4], it follows that $\{\Delta_h\}_{h>0}$ has discrete maximal L_p regularity on $S_{h,q}$ for $1 < p < \infty$ and $q = 2$. In this paper, we show that various families of finite element operators (see Definition 2.1) have discrete maximal L_p regularity on $S_{h,q}$ for $1 < p = q < \infty$.

In [Gei04] it is shown that discrete maximal L_p regularity on $S_{h,q}$ and the stability of the Ritz projections lead to an elegant proof for error estimates of the form

$$\|u - u_h\|_{L_p(I;L_q(\Omega))} \le Ch^2 \|f\|_{L_p(I;L_q(\Omega))}, \quad f \in L_p(I;L_q(\Omega)),\ h > 0, \tag{6}$$

where u_h denotes the solution of (2) with $f_h = P_h f$. Here, P_h denotes the orthogonal projection from $L_2(\Omega)$ onto S_h. The approach therein also allows one to treat initial values in certain interpolation spaces. Furthermore, applications of discrete maximal L_p regularity on $S_{h,q}$ to various nonlinear problems are considered. More precisely, if the solution of the linearized problem satisfies (5), there exists a strong solution to the nonlinear problem on a small interval. Since the length of the interval is reciprocally proportional to the constant C_h appearing in (5), uniform estimates for C_h, i.e., discrete maximal L_p regularity, are extremely useful. Finally, error estimates of the type $\|u - u_h\|_{L_p(I;L_q(\Omega))} \le Ch^s$ for such problems are proven. Here, s depends on the nonlinearity.

Whereas discrete maximal L_p regularity has not been considered previously, quite a few authors have dealt with estimates of the form (4) for $q = \infty$. For instance, in [CLT94] it is shown that (4) holds for elliptic operators subject to Dirichlet boundary conditions in one dimension. In fact, the authors gave resolvent estimates which imply (4). A completely different approach was used in [STW98], where (4) is shown for self-adjoint operators subject to Neumann boundary conditions in space dimension $N \ge 2$ by establishing bounds on the semigroup $(T_h(t))_{t\ge0}$ itself. A similar approach is used in [TW00] in order to show (4) for the Dirichlet–Laplacian in space dimension $N \ge 2$. This result is also proven in [BTW03] with a much simpler proof. By interpolation of the results for $q = 2$, which is trivial, and $q = \infty$, and by duality arguments (see [STW98, Corollary 2.2]), we obtain (4) for $1 \le q \le \infty$.

By [Dor93, Theorem 2.2], it follows that discrete maximal L_p regularity on $S_{h,q}$ implies (4). But the converse is not true except for $q = 2$. In this sense the present paper is a generalization and extension of the results mentioned above. However, observe that we cannot expect discrete maximal L_p regularity on $S_{h,\infty}$, since even the Dirichlet–Laplacian does not have maximal L_p regularity on $L_\infty(\Omega)$. Nevertheless we show that (5) holds with $C_h = C|\log(h)|$ for $q = \infty$.

2. Preliminaries. Let $\Omega \subset \mathbb{R}^N$, $N \geq 2$ be a bounded, convex domain with C^2 boundary. For a parameter $h > 0$ we introduce finite element operators A_h^D or A_h^N subject to Dirichlet or Neumann boundary conditions. To do this we construct finite element spaces $S_h^D \subset H_0^1(\Omega)$ and $S_h^N \subset H^1(\Omega)$.

We start with S_h^D. Let $\mathcal{T}_h^D = \{\tau_1^h, \dots, \tau_n^h\}$ be a finite set of disjoint, face-to-face, open simplexes of diameter less than h such that the set $\Omega_h^D := \overset{\circ}{\cup_{i=1}^n \tau_i}$ is convex and any vertex belonging to the boundary of Ω_h^D belongs to $\partial\Omega$. In the following, we always assume that $(\mathcal{T}_h^D)_{h>0}$ is quasi-uniform. We set $S_h^D := \{u \in C(\overline{\Omega}) : u|_\tau \text{ is linear for all } \tau \in \mathcal{T}_h^D,\ u|_{\overline{\Omega}\setminus\Omega_h} = 0\}$.

Next, we construct S_h^N. Contrary to above we construct a triangulation that fits Ω exactly. In order to do so, we introduce *wedge shaped pieces*, i.e., $C \cap \Omega$ where C is an open infinite cone with vertex $e \in \Omega$. For wedge-shape pieces, we call e and the elements of the intersection of the edges of C and $\partial\Omega$ *vertices*. Clearly all vertices but e meet the boundary $\partial\Omega$. Let $\mathcal{T}_h^N = \{\tau_1^h, \dots, \tau_n^h\}$ be a finite set of disjoint, face-to-face, open simplexes or wedge-shaped pieces of diameter less than h such that $\Omega = \Omega_h^N := \overset{\circ}{\cup_{i=1}^n \tau_i}$. Similar to above, we assume that $(\mathcal{T}_h^N)_{h>0}$ is quasi-uniform and we set $S_h^N := \{u \in C(\overline{\Omega}) : u|_\tau \text{ is linear for all } \tau \in \mathcal{T}_h^N\}$.

In what follows we write S_h instead of S_h^D or S_h^N, where $S_h \subset H$ for $H = H_0^1(\Omega)$ or $H = H^1(\Omega)$, respectively. Furthermore, we always denote the quasi-uniform family of triangulations associated to the family $(S_h)_{h>0}$ of finite element spaces by $(\mathcal{T}_h)_{h>0}$. Moreover, we write Ω_h for Ω_h^D and Ω_h^N.

Next, we introduce the finite element operators A_h associated to a sesquilinear form defined as follows: Let $H = H_0^1(\Omega)$ or $H^1(\Omega)$ and denote by $a : H \times H \to \mathbb{C}$ a sesquilinear form given by

$$a(u,v) := \sum_{i,j=1}^N \big(a_{ij}\partial_i u, \partial_j v\big)_\Omega + \sum_{i=1}^N \big(b_i \partial_i u, v\big)_\Omega + \sum_{i=1}^N \big(c_i u, \partial_i v\big)_\Omega + \big(c_0 u, v\big)_\Omega \tag{7}$$

with $a_{ij}, b_i, c_i, c_0 \in L_\infty(\Omega)$, $i,j = 1,\dots,N$. Here, $(\cdot,\cdot)_\Omega$ denotes the usual $L_2(\Omega)$ scalar product. We say that a is sectorial of angle $\varphi \in (0, \frac{\pi}{2})$ if $|\arg a(u,u)| \leq \varphi$ for $u \in H$. A form a satisfying

$$\sum_{i,j=1}^N a_{ij}(x)\xi_i\overline{\xi_j} \geq \mu|\xi|^2, \quad \text{a.a. } x \in \Omega,\ \xi \in \mathbb{C}^N, \tag{8}$$

for some $\mu > 0$ is called *elliptic*.

DEFINITION 2.1. *Let $a : H \times H \to \mathbb{C}$ be a sesquilinear form of the form (7). Assume that a is sectorial of angle $\varphi < \frac{\pi}{2}$, $a_{ij}(x) = \overline{a_{ji}(x)}$ for $x \in \Omega$, $i,j = 1,\dots,N$ and that a is elliptic.*

(a) *For $H = H_0^1(\Omega)$ let $(S_h^D)_{h>0}$ be a family of finite element spaces. We then define the finite element operators A_h^D by*

$$a(u_h, v_h) = -\big(A_h^D u_h, v_h\big)_\Omega, \quad u_h, v_h \in S_h^D.$$

(b) *For $H = H^1(\Omega)$ let $(S_h^N)_{h>0}$ be a family of finite element spaces. We then define the finite element operators A_h^N by*

$$a(u_h, v_h) = -\big(A_h^N u_h, v_h\big)_\Omega, \quad u_h, v_h \in S_h^N.$$

In the following we write A_h instead of A_h^D or A_h^N. The operators A_h are called the *finite element operators* associated to a.

3. Main result. Let $\Omega \subset \mathbb{R}^N$, $N \geq 2$ be a bounded, convex domain with C^2 boundary and let $A : D(A) \to L_2(\Omega)$ be the operator associated to the form a, where a is as in Definition 2.1, and denote the semigroup generated by A by $(T(t))_{t\geq 0}$. The following definition states assumptions on $(T(t))_{t\geq 0}$ needed for the proof of our main theorem. Let $T > 0$ and set for a multi-index α

$$\partial_1^\alpha := \frac{\partial^{\alpha_1}}{\partial x_1^{\alpha_1}} \cdots \frac{\partial^{\alpha_N}}{\partial x_N^{\alpha_N}} \text{ and } \partial_2^\alpha := \frac{\partial^{\alpha_1}}{\partial y_1^{\alpha_1}} \cdots \frac{\partial^{\alpha_N}}{\partial y_N^{\alpha_N}}.$$

DEFINITION 3.1. *Let $T > 0$ and let $(T(t))_{t\geq 0}$ be a semigroup on $L_2(\Omega)$. We say that the semigroup $(T(t))_{t\geq 0}$ satisfies the kernel estimate (KE_{Max}) if $T(t)$ is an integral operator, the derivatives $\partial_1^\alpha \partial_2^\beta K$ of its kernel $K(t,\cdot,\cdot)$ exist in $\Omega \times \Omega$ for $0 < t \leq 2T$ and there exist $C, c > 0$ such that*

$$|\partial_1^\alpha \partial_2^\beta K(t,x,y)| \leq C t^{-\frac{N+|\alpha|+|\beta|}{2}} \exp\left(-c\frac{|x-y|^2}{t}\right), \quad 0 < t \leq 2T,\ x, y \in \Omega,$$

whenever $|\alpha| = 0, |\beta| \leq 2$ or $|\alpha| \leq 2, |\beta| = 0$.

Consider the problem

$$\begin{aligned} u_h'(t) - A_h u_h(t) &= f_h(t), \quad t \in I, \\ u_h(0) &= 0 \end{aligned} \tag{9}$$

for $f_h \in L_p(I; S_{h,q})$. The main result of this paper is the following theorem.

THEOREM 3.2. *Let $N \geq 2$, $2 \leq p < \infty$ and let a, $(A_h)_{h>0}$ be as in Definition 2.1. Assume that the domain $D(A)$ of the operator A associated to a satisfies $D(A) \hookrightarrow H^2(\Omega)$ and that the semigroup $(T(t))_{t\geq 0}$ on $L_2(\Omega)$ generated by A satisfies the kernel estimate (KE_{Max}). Then there exists $C > 0$ such that*

$$\|u_h'\|_{L_p(I;S_{h,p})} + \|A_h u_h\|_{L_p(I;S_{h,p})} \leq C\|f_h\|_{L_p(I;S_{h,p})}, \quad h > 0,\ f_h \in L_p(I; S_{h,p}),$$

where u_h denotes the solution of problem (9).

Before we start to prove Theorem 3.2 we state several consequences.

Remark 3.3. The symmetry of the principal part, i.e., $a_{ij}(x) = \overline{a_{ji}}(x)$ for $x \in \Omega$, $i, j = 1, \ldots, N$, is only used for the proof of Lemma 5.7.

By [ÈdI70, Theorem 3], [DHP03, Theorem 8.2], and duality, the following corollary follows easily.

COROLLARY 3.4. *Assume that $\Omega \subset \mathbb{R}^N$, $N \geq 2$, is a bounded, convex domain of class $C^{3+\gamma}$ and that the coefficients of the form a satisfy*

$$a_{ij}, c_i \in \mathrm{C}^{2+\gamma}(\overline{\Omega}) \text{ and } b_i, c_0 \in \mathrm{C}^{1+\gamma}(\overline{\Omega}), \quad i, j = 1, \ldots, N,$$

for some $0 < \gamma < 1$. Then for $1 < p < \infty$ there exists $C > 0$ such that

$$\|u_h'\|_{L_p(I;S_{h,p})} + \|A_h u_h\|_{L_p(I;S_{h,p})} \leq C\|f_h\|_{L_p(I;S_{h,p})}, \quad h > 0,\ f_h \in L_p(I; S_{h,p}),$$

where u_h denotes the solution of (9).

Here, C^γ denotes the space of all γ-Hölder continuous functions. Furthermore, the proof of Theorem 3.2 implies the following corollary.

COROLLARY 3.5. *Let $\{A_h\}_{h>0}$ be as in Theorem 3.2. Then*

$$\|u_h'\|_{L_\infty(I;S_{h,\infty})} + \|A_h u_h\|_{L_\infty(I;S_{h,\infty})} \leq C|\log(h)|\|f_h\|_{L_\infty(I;S_{h,\infty})}, \quad h > 0,\ f_h \in L_\infty(I; S_{h,\infty}),$$

where u_h denotes the solution of (9).

4. Proof of Theorem 3.2. We start this section with the idea of the proof of Theorem 3.2. For $h > 0$ set $Q_h := I \times \Omega_h$. Let $K_h(t,\cdot,\cdot) : \Omega \times \Omega \to \mathbb{C}$ denote the kernel of $T_h(t)$ for $t > 0$. Note that $T_h(t)$ is an integral operator for $t > 0$, since S_h is a finite dimensional space. Moreover, $K_h(t,x,\cdot) \in S_h$ and $K_h(t,\cdot,y) \in S_h$ for $t > 0$, $x, y \in \Omega$. We thus have the representation

$$\overline{\big(T_h^*(t)P_h\tilde{\delta}_{x_0}\big)(y)} = \int_\Omega K_h(t,z,y)\overline{\big(P_h\tilde{\delta}_{x_0}\big)(z)}\,\mathrm{d}z = K_h(t,x_0,y), \quad t > 0,\ x_0 \in \Omega_h,\ y \in \Omega,$$

where $\tilde{\delta}_{x_0}$ is the discrete delta function, introduced in Lemma 5.4. Furthermore, the solution u_h of (9), is given by the variation of constants formula. Indeed,

$$\begin{aligned} A_h u_h(t) &= \int_0^t A_h T_h(t-s) f_h(s)\,\mathrm{d}s = \int_0^t \int_{\Omega_h} \partial_t K_h(t-s,\cdot,y) f_h(s,y)\,\mathrm{d}y\,\mathrm{d}s \\ &=: \big(\partial_t K_h * f\big)(t,\cdot), \quad t \in I,\ f_h \in L_p(I; S_{h,p}). \end{aligned}$$

In order to estimate $\|A_h u_h\|_{L_p(I;L_p(\Omega))}$, we compare the kernels $\partial_t K_h$ with a suitable truncation $\partial_t k_{\mathrm{Tr}}$ of $\partial_t K$, where $K(t,\cdot,\cdot) : \Omega \times \Omega \to \mathbb{C}$ is the kernel of $T(t)$ for $t > 0$. The precise meaning of truncation will follow in Step 2 of the proof. For the time being, we merely stress that the truncation has to be related to h. In [TW00] and [STW98] the authors introduced the *approximate kernel* $k_a : \mathbb{R}_+ \times \Omega_h \times \Omega$ defined by

$$k_a(t,x_0,y) := k_a^h(t,x_0,y) := \overline{\big(T^*(t)\tilde{\delta}_{x_0}\big)(y)}, \quad t > 0,\ x_0 \in \Omega_h,\ y \in \Omega.$$

Our approach to the proof of Theorem 3.2 relies on the representation of $\partial_t K_h$ as

$$\partial_t K_h = \partial_t K_h - \partial_t k_a + \partial_t k_a - \partial_t k_{\mathrm{Tr}} + \partial_t k_{\mathrm{Tr}}.$$

Thomée et al. showed in [TW00] and [STW98] that there exists $C > 0$ such that

$$\|\partial_t k_a(\cdot,x_0,\cdot) - \partial_t K_h(\cdot,x_0,\cdot)\|_{L_1(Q_h)} \le C, \quad h > 0,\ x_0 \in \Omega_h,$$

for the Dirichlet–Laplacian and self-adjoint operators subject to Neumann boundary conditions. We will extend these results to elliptic operators A given by a form a as above. Furthermore, we will show that

$$\|\partial_t k_a(\cdot,x_0,\cdot) - \partial_t k_{\mathrm{Tr}}(\cdot,x_0,\cdot)\|_{L_1(Q_h)} \le C, \quad h > 0,\ x_0 \in \Omega_h.$$

In this way, it is possible to compare $\partial_t K_h$ with $\partial_t k_{\mathrm{Tr}}$. Finally, we show that for $2 \le p < \infty$ there exists $C > 0$ such that

$$\|\partial_t k_{\mathrm{Tr}} * f\|_{L_p(I;L_p(\Omega_h))} \le C\|f\|_{L_p(I;L_p(\Omega_h))}, \quad h > 0,\ f \in L_p(I;L_p(\Omega_h)).$$

This will complete the proof of Theorem 3.2.

Since an easy calculation shows that

$$\|\partial_t k_{\mathrm{Tr}}\|_{L_1(Q_h)} \le C|\log(h)|, \quad h > 0,$$

Corollary 3.5 will also follow.

Proof of Theorem 3.2. Let K, k_a and K_h be as above. Adding sufficiently large λ_0 to the coefficient c_0 of the form a, we obtain

(10)
$$\mathrm{Re}\left(\sum_{i,j=1}^N a_{ij}(x)\xi_i\overline{\xi_j} + \sum_{i=1}^N b_i(x)\xi_i\overline{\eta} + \sum_{i=1}^N c_i(x)\eta\overline{\xi_i} + (c_0(x)+\lambda_0)|\eta|^2\right) \ge \mu_0\big(|\xi|^2 + |\eta|^2\big),$$
$$\text{a.a. } x \in \Omega,\ \xi \in \mathbb{C}^N,\ \eta \in \mathbb{C},$$

for some $\mu_0 > 0$. Since shifting the operator does not affect the property of maximal regularity, we may assume that the form a satisfies (10).

We firstly fix some notation. For simplicity, we identify $u \in L_p(I; L_p(\Omega))$ for some $1 < p < \infty$ with a function $\tilde{u} : Q \to \mathbb{C}$ by $\tilde{u}(t,x) = \big(u(t)\big)(x)$. For convenience, we also denote this function $\tilde{u}$ by u. If $u \in L_p(I; L_p(\Omega))$ is differentiable, we analogously write $u'(t,x)$ for $\big(u'(t)\big)(x)$. Moreover, for $s \in \mathbb{N}$ we set $\|D^s u\|_{L_q(\Omega)} = \sum_{|\alpha|=s} \|D^\alpha u\|_{L_q(\Omega)}$, where $D^\alpha = \frac{\partial^{\alpha_1}}{\partial x_1^{\alpha_1}} \cdots \frac{\partial^{\alpha_N}}{\partial x_N^{\alpha_N}}$ and we write $D = D^1$. We need two different interpolation operators I_h and $\tilde{I}_h$. As I_h acts on continuous functions $\tilde{I}_h$ acts on Sobolev spaces. Details and error estimates for the interpolation operators are given in Lemmas 5.1, 5.2, and 5.3.

Step 1. $\|\partial_t(K_h - k_a) * f\|_{L_\infty(Q_h)} \le C\|f\|_{L_\infty(Q_h)}, \quad h > 0,\ f_h \in L_\infty(I; S_{h,\infty})$.

Let $h > 0$ and $x_0 \in \Omega_h$. Throughout this step we use the notation

$$e(t,y) = K_h(t,x_0,y) - k_a(t,x_0,y), \quad (t,y) \in Q.$$

By Hölder's inequality, it clearly suffices to show that $\|e'\|_{L_1(Q)} \le C$, where C is independent of x_0 and h. We therefore decompose Q in parabolic anulli. More precisely, for $\mu_* \ge 2(N+4)$ we choose J_h such that $\mu_* h/2 \le 2^{-J_h} \le \mu_* h$ and J_0 such that $2^{-J_0} \ge \operatorname{diam} Q$. We then set

$$Q_* := \Big\{(s,y) \in Q :\ \max\Big\{|y - x_0|,\ s^{\frac{1}{2}}\Big\} \le d_*\Big\}, \quad d_* := 2^{-J_h},$$
$$Q_j := \Big\{(s,y) \in Q :\ d_j \le \max\Big\{|y - x_0|,\ s^{\frac{1}{2}}\Big\} \le 2d_j\Big\}, \quad j \in Z,\ d_j = 2^{-j}.$$

Obviously, $Q = \bigcup_{j=J_0}^{J_h} Q_j \cup Q_*$. Analogously, we define $\Omega_j := \{y \in \Omega : d_j \le |y - x_0| \le 2d_j\}$ and $\Omega_* := \{y \in \Omega : |y - x_0| \le d_*\}$. Furthermore, we set $Q_j' := Q_{j-1} \cup Q_j \cup Q_{j+1}$, $Q_j'' = (Q_j')'$, $Q_*' = Q_* \cup Q_{J_h}$, and Ω_j', Ω_j'' and Ω_j''', analogously. We also need some weighted, local norms, i.e.,

$$\|u\|_{Q_j,s_1,s_2} := \sum_{s=0}^{s_1} d_j^{-2+s} \|D^s u\|_{Q_j} + \sum_{s=0}^{s_2} d_j^s \|D^s u'\|_{Q_j}, \quad j = * \text{ or } j \in \mathbb{Z},\ 0 \le s_1, s_2 \le 1,$$

for u smooth enough. Here, $\|\cdot\|_{Q_j}$ denotes the usual $L_2(Q_j)$-norm. In order to simplify notation, throughout this step, C and c denote constants which are independet of h, μ_*, and x_0.

Hölder's inequality yields

$$\|e'\|_{L_1(Q)} \le C \sum_{j=*, j=J_0}^{J_h} d_j^{\frac{N}{2}+1} \|e\|_{Q_j,1,0}.$$

We will show

$$\sum_{j=*, j=J_0}^{J_h} d_j^{\frac{N}{2}+1} \|e\|_{Q_j,1,0} \le C\mu_*^{\frac{N}{2}+1} + C + C\mu_*^{-1} \sum_{j=*, j=J_0}^{J_h} d_j^{\frac{N}{2}+1} \|e\|_{Q_j,1,0}. \tag{11}$$

Subtracting $C\mu_*^{-1} \sum_{j=*, j=J_0}^{J_h} d_j^{\frac{N}{2}+1} \|e\|_{Q_j,1,0}$ for sufficiently large μ_* on both sides completes Step 1.

The estimate $d_*^{\frac{N}{2}+1}\|e\|_{Q_*,1,0} \le C\mu_*^{\frac{N}{2}+1}$ follows from Lemma 5.5(a). Since $d_j \ge 2(N+2)h$ for $J_0 \le j \le J_h$, we may apply Lemma 5.7 to $\|e\|_{Q_j,1,0}$. Hence there exists $C > 0$ such that

$$\|e\|_{Q_j,1,0} \le C(\|\big(De\big)(0)\|_{\Omega_j'} + d_j^{-1}\|e(0)\|_{\Omega_j'} + d_j^{-2}\|e\|_{Q_j'} \\ +(hd_j^{-1})^{\frac{N}{2}+2}\|e'\|_{Q_j'} + \|k_a - I_h k_a\|_{Q_j',1,1}\big)$$

for $J_0 \le j \le J_h$. We start by showing

(12)
$$\sum_{j=J_0}^{J_h} d_j^{\frac{N}{2}+1}\Big(\|\big(De\big)(0)\|_{\Omega_j'} + d_j^{-1}\|e(0)\|_{\Omega_j'} + (hd_j^{-1})^{\frac{N}{2}+2}\|e'\|_{Q_j'} + \|k_a - I_h k_a\|_{Q_j',1,1}\Big) \le C.$$

As $h\sum_{j=J_0}^{J_h} d_j^{-1} \le C$, it suffices to show

$$\|\big(De\big)(0)\|_{\Omega_j'} + d_j^{-1}\|e(0)\|_{\Omega_j'} + (hd_j^{-1})^{\frac{N}{2}+2}\|e'\|_{Q_j'} + \|k_a - I_h k_a\|_{Q_j',1,1} \le Chd_j^{-\frac{N}{2}-2}, \\ J_0 \le j \le J_h.$$

We first consider $\|\big(De\big)(0)\|_{\Omega_j'}$. Note that $e(0) \restriction_{\Omega_j'} = (P_h\tilde{\delta}_{x_0} - \tilde{\delta}_{x_0}) \restriction_{\Omega_j'} = P_h\tilde{\delta} \restriction_{\Omega_j'}$. Therefore, by the inverse estimate (16) in the next section,

$$\|\big(De\big)(0)\|_{\Omega_j'} \le C\|DP_h\tilde{\delta}_{x_0}\|_{\Omega_j'} \le Ch^{-1}\|P_h\tilde{\delta}_{x_0}\|_{\Omega_j'}, \quad J_0 \le j \le J_h.$$

Since, by assumption,

$$cd_j \le \text{dist }(\Omega_j', \text{supp}\,\tilde{\delta}_{x_0}) \le Cd_j, \quad J_0 \le j \le J_h, \tag{13}$$

the exponential decay of P_h on Ω (see [Tho97, Lemma 5.1] or [Gei03, Lemma 2.2.9]) and Lemma 5.4 yields

$$\|\big(De\big)(0)\|_{\Omega_j'} \le Ch^{-1}\exp\left(-c\frac{d_j}{h}\right)\|\tilde{\delta}_{x_0}\|_{\tau_0} \le Ch^{-1}\exp\left(-c\frac{d_j}{h}\right)h^{-N}h^{\frac{N}{2}} \\ \le Chd_j^{-\frac{N}{2}-2}d_j^{\frac{N}{2}+2}h^{-\frac{N}{2}-2}\exp\left(-c\frac{d_j}{h}\right) \le Chd_j^{-\frac{N}{2}-2}, \quad J_0 \le j \le J_h.$$

Analogously, $d_j^{-1}\|e(0)\|_{\Omega_j'} \le Chd_j^{-\frac{N}{2}-2}, \quad J_0 \le j \le J_h.$

Next, by Lemma 5.5(a), we obtain

$$(hd_j^{-1})^{\frac{N}{2}+2}\|e'\|_{Q_j'} \le (hd_j^{-1})^{\frac{N}{2}+2}h^{-\frac{N}{2}-1} \le Chd_j^{-\frac{N}{2}-2}, \quad J_0 \le j \le J_h.$$

Finally, we consider $d_j\|D(k_a' - I_h k_a')\|_{Q_j'}$. By the error estimate for the interpolation operators $\tilde{I}_h$ and Lemma 5.5(b), we obtain

$$d_j\|D(k_a' - I_h k_a')\|_{Q_j'} \le Cd_j h\|D^2 k_a'\|_{Q_j''} \le Chd_j^{-\frac{N}{2}-2}, \quad J_0 \le j \le J_h.$$

The remaining terms of $\|k_a - I_h k_a\|_{Q_j',1,1}$ are similary bounded and the proof of (12) is complete.

Therefore, the proof of inequality (11) will be finished once we have shown

$$\sum_{j=J_0}^{J_h} d_j^{\frac{N}{2}-1}\|e\|_{Q_j',1,0} \le C + C\mu_*^{-1}\sum_{j=J_0}^{J_h} d_j^{\frac{N}{2}+1}\|e\|_{Q_j,1,0}. \tag{14}$$

Note that $\|e\|_{Q_j'} = \sup\big\{ \int_Q v(t,x)\overline{e(t,x)}\,\mathrm{d}(t,x) : \ v \in C_c^\infty(Q_j'),\ \|v\|_{Q_j'} = 1\big\}$. Let $v \in C_c^\infty(Q_j')$ with $\|v\|_{Q_j'} = 1$ and set $w(t) := \int_t^T T(s-t)v(s)\,\mathrm{d}s$. A simple calculation shows that w is the solution of the problem

$$\left\{ \begin{array}{rcl} -w'(t) - Aw(t) &=& v(t), \quad 0 \le t < T, \\ w(T) &=& 0. \end{array} \right.$$

Multiplying this equation by e and integrating by parts, we obtain

$$\begin{aligned} \int_0^T \big(v(t),e(t)\big)_\Omega \,\mathrm{d}t &= \big(w(0),e(0)\big)_\Omega + \int_0^T \big(w(t),e'(t)\big)_\Omega \,\mathrm{d}t + \int_0^T a(w(t),e(t))\,\mathrm{d}t \\ &= \big(w(0),e(0)\big)_\Omega + \int_0^T \big(w(t)-\tilde I_h w(t),e'(t)\big)_\Omega + a(w(t) \\ &\qquad\qquad - \tilde I_h w(t),e(t))\,\mathrm{d}t \\ &=: I_1^j + I_2^j, \quad J_0 \le j \le J_h. \end{aligned}$$

Here, we have used that $\big(\chi(t),e'(t)\big)_\Omega + a(\chi(t),e(t)) = 0$ for $t \in I$ and $\chi \in S_h$.

We start by showing $\sum_{j=J_0}^{J_h} d_j^{\frac{N}{2}-1} I_1^j \le C$. Since P_h is the orthogonal projection on S_h in $L_2(\Omega)$, we obtain

$$\begin{aligned} I_1^j &= \big(w(0),P_h\tilde\delta_{x_0} - \tilde\delta_{x_0}\big)_{\Omega_h} = \big(w(0)-\chi,P_h\tilde\delta_{x_0} - \tilde\delta_{x_0}\big)_{\Omega_h} \\ &= \big(w(0)-\chi,P_h\tilde\delta_{x_0}\big)_{\Omega_j'''} + \big(w(0)-\chi,P_h\tilde\delta_{x_0} - \tilde\delta_{x_0}\big)_{\Omega_h\setminus\Omega_j'''} \\ &=: I_{11}^j + I_{12}^j, \quad \chi \in S_h,\ J_0 \le j \le J_h. \end{aligned}$$

We choose $\chi := \tilde I_h(w(0))$. By the error estimate for $\tilde I_h$ and Lemma 5.5(c)(1), we obtain

$$\begin{aligned} I_{11}^j &\le Ch\|\big(Dw\big)(0)\|_\Omega \|P_h\tilde\delta_{x_0}\|_{\Omega_j'''} \\ &\le Ch\|w\|_Q\|P_h\tilde\delta_{x_0}\|_{\Omega_j''} \le Ch\|P_h\tilde\delta_{x_0}\|_{\Omega_j'''}, \quad J_0 \le j \le J_h. \end{aligned}$$

Now, inequality (13), the exponential decay of P_h on Ω, and Lemma 5.4 yield

$$I_{11}^j \le Ch\exp\left(-c\frac{d_j}{h}\right)\|\tilde\delta_{x_0}\|_{\tau_0} \le Ch\exp\left(-c\frac{d_j}{h}\right)h^{-N}h^{\frac{N}{2}} \le Chd_j^{-\frac{N}{2}}, \quad J_0 \le j \le J_h.$$

Since $(P_h)_{h>0}$ is stable in $\mathcal{L}(L_1(\Omega))$, we get $\|P_h\tilde\delta_{x_0} - \tilde\delta_{x_0}\|_{L_1(\Omega_h)} \le C$. By the error estimate for $\tilde I_h$, we thus obtain

$$I_{12}^j \le C\|I_h w(0) - w(0)\|_{L_\infty(\Omega_h\setminus\Omega_j''')} \le Ch\|\big(Dw\big)(0)\|_{L_\infty(\Omega\setminus\Omega_j'')}, \quad J_0 \le j \le J_h.$$

Therefore, $\sum_{j=J_0}^{J_h} d_j^{\frac{N}{2}-1} I_1^j \le C$ follows from $\|Dw(0)\|_{L_\infty(\Omega\setminus\Omega_j'')} \le Cd_j^{-\frac{N}{2}}$, $J_0 \le j \le J_h$, which is a consequence of the kernel estimate (KE_{Max}).

We will show

$$\sum_{j=J_0}^{J_h} d_j^{\frac{N}{2}-1} I_2^j \le C\mu_*^{-1} \sum_{j=*,j=J_0}^{J_h} d_j^{\frac{N}{2}+1}\|e\|_{Q_j,1,0}. \tag{15}$$

This proves (14) and so (11) which completes Step 1.

By Hölder's inequality and the error estimate for $\tilde{I}_h$, there exists $C > 0$ such that for $J_0 \le j \le J_h$,

$$\begin{aligned} I_2^j &\le C \sum_{*,i=J_0}^{J_h} \|w - \tilde{I}_h w\|_{Q_i} \|e'\|_{Q_i} + C \sum_{*,i=J_0}^{J_h} \|D(w - \tilde{I}_h w)\|_{Q_i} \|De\|_{Q_i} \\ &\quad + C \sum_{*,i=J_0}^{J_h} \|D(w - \tilde{I}_h w)\|_{Q_i} \|e\|_{Q_i} + C \sum_{*,i=J_0}^{J_h} \|w - \tilde{I}_h w\|_{Q_i} \|De\|_{Q_i} \\ &\quad + C \sum_{*,i=J_0}^{J_h} \|w - \tilde{I}_h w\|_{Q_i} \|e\|_{Q_i} \\ &\le C \sum_{*,i=J_0}^{J_h} \big(\|D^2 w\|_{Q_i'} + \|Dw\|_{Q_i'}\big)\big(h^2 \|e'\|_{Q_i} + h\|e\|_{Q_i} + h\|De\|_{Q_i}\big). \end{aligned}$$

Since $h \le \mu_*^{-1} d_i$ and d_i is bounded from above, we have

$$h^2 \|e'\|_{Q_i} + h\|e\|_{Q_i} + h\|De\|_{Q_i} \le C\mu_*^{-1} d_i^2 \|e\|_{Q_i,1,0}, \quad i = *,\ J_0 \le i \le J_h.$$

Now, inequality (15) follows from Lemma 5.5(c)(2). Indeed, we have

$$\begin{aligned} \sum_{j=J_0}^{J_h} d_j^{\frac{N}{2}-1} I_2^j &\le C\mu_*^{-1} \sum_{i=*,i=J_0}^{J_h} d_i^2 \|e\|_{Q_i,1,0} \sum_{j=J_0}^{J_h} d_j^{\frac{N}{2}-1} \min\left\{d_{i-j}^{\frac{N}{2}+1}, d_{j-i}^{\frac{N}{2}+1}\right\} \\ &\le C\mu_*^{-1} \sum_{i=*,i=J_0}^{J_h} d_i^{\frac{N}{2}+1} \|e\|_{Q_i,1,0} \left(\sum_{i \ge j} d_{i-j}^2 + \sum_{j>i} d_{i-j}^N\right) \\ &\le C\mu_*^{-1} \sum_{i=*,i=J_0}^{J_h} d_i^{\frac{N}{2}+1} \|e\|_{Q_i,1,0}. \end{aligned}$$

Step 2. $\|\partial_t(k_a - k_{\mathrm{Tr}}) * f_h\|_{L_\infty(Q_h)} \le C\|f_h\|_{L_\infty(Q_h)}$, $h > 0$, $f_h \in L_\infty(I; S_{h,\infty})$.

Let $x_0 \in \Omega_h$, $\tau_0 \in \mathcal{T}_h$ with $x_0 \in \overline{\tau_0}$ and μ_*, J_0, J_h, Q_j and Q_* as above. We define the *truncated kernel* $k_{\mathrm{Tr}} : I \times \Omega_h \times \Omega \to \mathbb{C}$ by

$$k_{\mathrm{Tr}}(t, x_0, y) := k_{\mathrm{Tr}}^h(t, x_0, y) := K(t, x_0, y)\chi_{(Q^*)^c}(t, y), \quad (t, y) \in Q,\ x_0 \in \Omega_h.$$

As in Step 1, C denotes some constant which is indepedet of x_0, μ_*, and h. We will show that

$$\|\partial_t k_a(\cdot, x_0, \cdot) - \partial_t k_{\mathrm{Tr}}(\cdot, x_0, \cdot)\|_{L_1(Q_h)} \le C.$$

By the representation $k_a(t, x_0, y) = \int_{\tau_0} K(t, z, y)\overline{\tilde{\delta}_{x_0}(z)}\, \mathrm{d}z$ and $\int_{\Omega_h} \tilde{\delta}_{x_0}(x)\, \mathrm{d}x = 1$ (see Lemma 5.4), we obtain

$$\begin{aligned} |\partial_t k_a(t, x_0, y) - \partial_t k_{\mathrm{Tr}}(t, x_0, y)| &= \left| \int_{\tau_0} \partial_t K(t, z, y)\overline{\tilde{\delta}_{x_0}(z)}\, \mathrm{d}z - \partial_t K(t, x_0, y) \right| \\ &= \left| \int_{\tau_0} \big(\partial_t K(t, z, y) - \partial_t K(t, x_0, y)\big)\overline{\tilde{\delta}_{x_0}(z)}\, \mathrm{d}z \right|, \quad J_0 \le j \le J_h,\ (t, y) \in Q_j. \end{aligned}$$

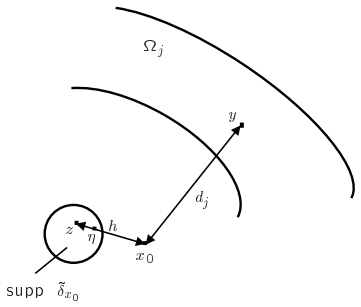

FIG. 1. *Correlation between x_0, y, and z.*

Due to the mean value theorem there exists $\eta(z)$ in the segment $\overline{zx_0}$ joining z and x_0 such that

$$|\partial_t k_a(t,x_0,y) - \partial_t k_{\mathrm{Tr}}(t,x_0,y)| \le \sum_{|\alpha|=1} \left| \int_{\tau_0} |z-x_0| \partial_t \partial_1^\alpha K(t,\eta(z),y) \overline{\tilde{\delta}_{x_0}(z)} \, \mathrm{d}z \right|.$$

Now, by Lemma B.1, there exits $C>0$ such that for $J_0 \le j \le J_h$ and $(t,y) \in Q_j$,

$$|\partial_t k_a(t,x_0,y) - \partial_t k_{\mathrm{Tr}}(t,x_0,y)| \le C \int_{\tau_0} |z-x_0| \left(\max\left\{ \min_{\eta \in \overline{zx_0}} \{|y-\eta|\}, t^{\frac{1}{2}} \right\} \right)^{-N-3} |\tilde{\delta}_{x_0}(z)| \, \mathrm{d}z.$$

Since (see Figure 1) $|z-x_0| \le h$ and $|x_0-y| \le C|y-\eta|$ for $z \in \tau_0$ and $\eta \in \overline{zx_0}$, we obtain

$$|\partial_t k_a(t,x_0,y) - \partial_t k_{\mathrm{Tr}}(t,x_0,y)| \le C h d_j^{-N-3} \int_{\tau_0} |\tilde{\delta}_{x_0}(z)| \, \mathrm{d}z \le C d_j^{-N-2} h d_j^{-1},$$
$$J_0 \le j \le J_h, \ (t,y) \in Q_j.$$

Summing, we get

$$\sum_{j=J_0}^{J_h} \|\partial_t k_a(\cdot,x_0,\cdot) - \partial_t k_{\mathrm{Tr}}(\cdot,x_0,\cdot)\|_{L_1(Q_j)} \le C \sum_{j=J_0}^{J_h} \int_{Q_j} d_j^{-N-2}(h d_j^{-1}) \, \mathrm{d}(s,y) \le C.$$

Finally, by Lemma 5.5(a), we obtain $\|\partial_t k_a(\cdot,x_0,\cdot)\|_{L_1(Q_*)} \le C$. Step 2 is complete.

Step 3. Final Step.

Recall that A_h has discrete maximal L_2 regularity on $S_{h,2}$. By (KE_{Max}) and [HP97, Theorem 3.1], the operator associated to $\partial_t K$ satisfies the assumptions of Lemma A.2. Therefore, the operators associated to $\partial_t k_{\mathrm{Tr}}$ are uniformly bounded in h in $\mathcal{L}(L_2(Q))$, and we obtain

$$\|\big(\partial_t K_h - \partial_t k_{Tr}\big) * f_h\|_{Q_h} \le C \|f_h\|_{Q_h}, \quad h>0, \ f_h \in L_2(I;S_{h,2}).$$

Due to Step 1 and Step 2 the operators associated to $\partial_t K_h - \partial_t k_a + \partial_t k_a - \partial_t k_{\mathrm{Tr}}$ are uniformly bounded in h in $\mathcal{L}(L_\infty(I;S_{h,\infty}))$. Marcinkiewicz' interpolation theorem and the identity $\partial_t K_h - \partial_t k_a + \partial_t k_a - \partial_t k_{\mathrm{Tr}} = \partial_t K_h - \partial_t k_{\mathrm{Tr}}$ yields that the operators associated to the right-hand side are uniformly bounded in h in $\mathcal{L}(L_p(I;S_{h,p}))$, $2 \le p < \infty$. Since $\partial_t K_h = \partial_t K_h - \partial_t k_{\mathrm{Tr}} + \partial_t k_{\mathrm{Tr}}$, Theorem A.2 completes the proof. ∎

5. Technical estimates. In this section we proof technical estimates needed to complete the proof of Theorem 3.2. Throughout this section we use the same notation as therein. We start by some basic properties of the finite element spaces S_h and interpolation operators.

Since we use a quasi-uniform family of triangulations, we have the following inverse inequalities:

$$\|\omega_h D^\alpha u_h\|_\tau \le Ch^{-1}\|\omega_h u_h\|_\tau, \quad h>0,\ \tau\in\mathcal{T}_h,\ \omega_h, u_h\in S_h,\ |\alpha|=1 \tag{16}$$

$$\|\omega_h u_h\|_{L_\infty(\tau)} \le Ch^{-\frac{N}{2}}\|\omega_h u_h\|_\tau, \quad h>0,\ \tau\in\mathcal{T}_h,\ \omega_h,\ u_h\in S_h. \tag{17}$$

Next, we define the *standard interpolant* $I_h : C(\overline{\Omega})\cap H \to S_h$ by $u\mapsto u_h$, where $u_h(\xi)=u(\xi)$ for all vertices ξ of $\mathcal{T}_h$, i.e., ξ is a vertex of τ for some $\tau\in\mathcal{T}_h$. Since we are dealing with piecewise linear functions, the operator I_h is well defined. The following lemma is an easy consequence of Taylor's theorem.

LEMMA 5.1. *There exists $C>0$ such that, for $h>0$ and $\tau\in\mathcal{T}_h$,*

$$\|I_h u-u\|_{L_\infty(\tau)} + h\|D(I_h u-u)\|_{L_\infty(\tau)} \le Ch^2\|D^2u\|_{L_\infty(\tau)},$$
$$u\in C(\overline{\Omega})\cap H \text{ with } u\restriction_{\overline{\tau}}\in C^2(\overline{\tau}).$$

We also need interpolation operators acting on Sobolev spaces $W_1^1(\Omega)$ or $W_{1,0}^1(\Omega)$, where $W_{1,0}^1(\Omega)$ denotes the closure of $C_c^\infty(\Omega)$ in $W_1^1(\Omega)$. We call them $\tilde I_h^D$ and $\tilde I_h^N$, respectively.

For the definition of $\tilde I_h^D$ we refer to [TW00, Lemma 2.1]. Set $U(\tau):=\{x\in\Omega : \operatorname{dist}(x,\tau)\le h\}$ for $\tau\in\mathcal{T}_h$. Then the following lemma is proved therein.

LEMMA 5.2. *Let $1\le q\le\infty$. Then there exists $C>0$ such that, for $h>0$ and $\tau\in\mathcal{T}_h^D$,*

(a) $\|\tilde I_h^D u-u\|_{L_q(\tau)} \le Ch\|Du\|_{L_q(U(\tau))}$, $u\in W_{q,0}^1(\Omega)$,

(b) $\|\tilde I_h^D u-u\|_{L_q(\tau)} \le Ch^2\sum_{s=1}^2\|D^s u\|_{L_q(U(\tau))}$, $u\in W_{q,0}^1(\Omega)$ *with* $u\restriction_{U(\tau)}\in W_q^2(U(\tau))$,

(c) $\|D(\tilde I_h^D u-u)\|_{L_q(\tau)} \le Ch\sum_{s=1}^2\|D^s u\|_{L_q(U(\tau))}$, $u\in W_{q,0}^1(\Omega)$ *with* $u\restriction_{U(\tau)}\in W_q^2(U(\tau))$.

Further, we define $\tilde I_h^N : W_1^1(\Omega)\to S_h^N$. For a boundary vertex ξ choose $\tau\in\mathcal{T}_h$ such that τ has N vertices on the boundary and let F_{bdy} denote the $(N-1)$-simplex given by those vertices. By [SZ90] there exists an affine mapping β_ξ, which is bounded on F_{bdy}, uniformly in h and ξ, such that

$$\frac{1}{|F_{bdy}|}\int_{F_{bdy}}\beta_\xi(x)u(x)\,\mathrm{d}x = u(\xi), \quad u\in C(\overline{\Omega}) \text{ linear}.$$

Moreover, by quasiuniformity, there exists $c>0$, independent of h, such that the ball $B(\xi,ch)$ with radius ch does not intersect the boundary of Ω_h for vertices $\xi\in\Omega_h$. For $u\in W_1^1(\Omega)$ we now define $\tilde I_h^N u:=u_h$, where

$$u_h(\xi)=\begin{cases}\dfrac{1}{|F_{bdy}|}\displaystyle\int_{F_{bdy}}\beta_\xi(x)u(x)\,\mathrm{d}x, & \text{vertices } \xi\in\partial\Omega_h,\\[2ex] \dfrac{1}{|B(\xi,Ch)|}\displaystyle\int_{B(\xi,Ch)}u(x)\,\mathrm{d}x, & \text{vertices } \xi\in\Omega_h.\end{cases}$$

Then, by the Bramble–Hilbert lemma, we obtain the following lemma.

LEMMA 5.3. *Let $1\le q\le\infty$. Then there exists $C>0$ such that for $h>0$ and $\tau\in\mathcal{T}_h^N$*

(a) $\|\tilde{I}_h^N u - u\|_{L_q(\tau)} \le Ch\|Du\|_{L_q(U(\tau))}$, $u \in W_q^1(\Omega)$,
(b) $\|\tilde{I}_h^N u - u\|_{L_q(\tau)} \le Ch^2\|D^2 u\|_{L_q(U(\tau))}$, $u \in W_q^1(\Omega)$ *with* $u \restriction_{U(\tau)} \in W_q^2(U(\tau))$,
(c) $\|D(\tilde{I}_h^N u - u)\|_{L_q(\tau)} \le Ch\|D^2 u\|_{L_q(U(\tau))}$, $u \in W_q^1(\Omega)$ *with* $u \restriction_{U(\tau)} \in W_q^2(U(\tau))$.

We write $\tilde{I}_h$ for $\tilde{I}_h^D$ and $\tilde{I}_h^N$. We next introduce a discrete version of the delta distribution.

LEMMA 5.4. *For $k \in \mathbb{N}$ there exist $C, c > 0$, independent of h, such that for any $x_0 \in \overline{\tau_0}$, where $\tau_0 \in \mathcal{T}_h$, there exists a function $\tilde{\delta}_{x_0} := \tilde{\delta}_{x_0}^h \in C_c^\infty(\Omega)$ with support in τ_0 such that*

(a) $\int_{\tau_0} \chi(x)\overline{\tilde{\delta}_{x_0}(x)}\,\mathrm{d}x = \chi(x_0)$, $\chi \in S_h$,
(b) $\int_{\tau_0} \tilde{\delta}_{x_0}(x)\,\mathrm{d}x = 1$,
(c) diam $\operatorname{supp}\tilde{\delta}_{x_0} \le Ch$,
(d) dist $(\operatorname{supp}\tilde{\delta}_{x_0}, \partial\tau_0) \ge ch$,
(e) $\|\tilde{\delta}_{x_0}\|_{W_\infty^k(\tau_0)} \le C|h|^{-N-k}$.

A proof may be found in [TW00, Lemma 2.2]. The next lemma states a priori estimates for e, k_a, and w.

LEMMA 5.5.

(a) *There exists $C > 0$, independent of x_0 and h, such that*

$$\|e\|_{Q,1,0} \le C\|\tilde{\delta}_{x_0}\|_{H^1(\Omega)} \le Ch^{-\frac{N}{2}-1}.$$

(b) *There exists $C > 0$, independent of x_0 and h, such that*

$$\|\partial_t^k D^\alpha k_a(\cdot, x_0, \cdot)\|_{Q_j} \le C d_j^{-\frac{N}{2}+1-2k-|\alpha|},$$
$$j = J_0, \dots, J_h + 2,\ 0 \le k \le 1,\ |\alpha| \le 2.$$

(c) *For $v \in L_2(Q)$ let $w := \int_t^T T(s-t)v(s)\,\mathrm{d}s$.*
   (1) *Then there exists $C > 0$, independent of v, such that $\|w(0)\|_{H^1(\Omega)} \le C\|v\|_Q$.*
   (2) *Assume that* $\operatorname{supp} v \subset Q_j'$ *with $\|v\|_{Q_j} = 1$. Then there exists $C > 0$, independent of v, such that*

$$\|D^\alpha w\|_{Q_i'} \le C \min\left\{d_{j-i}^{\frac{N}{2}+1}, d_{i-j}^{\frac{N}{2}+1}\right\}, \quad i, j = J_0, \dots, J_h,\ i = *,\ |\alpha| \le 2.$$

Proof.

(a) The estimate $\|\tilde{\delta}_{x_0}\|_{H^1(\Omega)} \le Ch^{-\frac{N}{2}-1}$ follows by Lemma 5.4(c) and (e). It thus remains to prove the first inequality of (a). We will prove $\|K_h(\cdot, x_0, \cdot)\|_{Q,1,0} \le C\|\tilde{\delta}_{x_0}\|_{H^1(\Omega)}$ only since $\|k_a(\cdot, x_0, \cdot)\|_{Q,1,0} \le C\|\tilde{\delta}_{x_0}\|_{H^1(\Omega)}$ follows in a similar way. By assumption, $K_h(\cdot, x_0, \cdot)$ satisfies $K_h'(t, x_0, \cdot) - A^* K_h(t, x_0, \cdot) = 0$ for $0 < t \le T$. Multiplying this equation by $K_h(\cdot, x_0, \cdot)$ and $K_h'(\cdot, x_0, \cdot)$ and integrating by parts yields

$$\|K_h(\cdot, x_0, \cdot)\|_{Q,1,0} + \|K_h(T, x_0, \cdot)\|_\Omega \le C\|P_h\tilde{\delta}_{x_0}\|_{H^1(\Omega)}$$

and

$$\|K_h'(\cdot, x_0, \cdot)\|_Q \le C\|P_h\tilde{\delta}_{x_0}\|_{H^1(\Omega)} + \|K_h(\cdot, x_0, \cdot)\|_{Q,1,0} + \|K_h(T, x_0, \cdot)\|_\Omega,$$

where we have used $K_h(0, x_0, \cdot) = P_h\tilde{\delta}_{x_0}$. Since P_h is stable in $H^1(\Omega)$, assertion (a) follows.

(b) This follows from the representation of the approximate kernel k_a and the kernel estimates given in Lemma B.1.

(c) Let $\tilde{v} : \mathbb{R}_+ \to L_2(\Omega)$ be given by $t \mapsto v(T-t,\cdot)$, $t \in I$, and $t \mapsto 0$, $t > T$. Then the solution $\tilde{w}$ of

$$\begin{aligned} \tilde{w}'(t) - A\tilde{w}(t) &= \tilde{v}(t), \quad t > 0, \\ \tilde{w}(0) &= 0, \end{aligned}$$

satisfies $\tilde{w}(t) = w(T-t)$, $t \in I$. By the assumption $D(A) \hookrightarrow H^2(\Omega)$, there exists $C > 0$, independent of w, such that

$$\|w\|_{H^1(\Omega)} \le C\|w\|_{(L_2(\Omega),H^2(\Omega))_{\frac{1}{2},2}} \le C\|w\|_{(L_2(\Omega),D(A))_{\frac{1}{2},2}}.$$

Therefore, by [Ama95, Theorem 4.10.2] there exists $C > 0$, independent of v, such that

$$\|\tilde{w}\|_{L_\infty(I;(L_2(\Omega),D(A))_{\frac{1}{2},2})} \le C\|\tilde{v}\|_{L_2(\mathbb{R}_+\times\Omega)} = C\|v\|_Q,$$

which proves (c)(1).

By the kernel estimate (KE_{Max}), there exists $C > 0$ such that for $i = *$, $j \le J_h - 3$ or $|i-j| \ge 3$, and $|\alpha| \le 2$,

$$\begin{aligned} \|D^\alpha w\|_{Q_i'} &\le C d_i^{\frac{N}{2}+1} \|D_1^\alpha w\|_{L_\infty(Q_i')} \\ &\le C d_i^{\frac{N}{2}+1} \|v\|_{L_1(Q_j')} \sup_{(t,x)\in Q_i,(s,y)\in Q_j,s>t} |D^\alpha K(s-t,x,y)| \\ &\le C d_{i+j}^{\frac{N}{2}+1} \min\{d_j^{-N-2}, d_i^{-N-2}\} \le C \min\left\{d_{i-j}^{\frac{N}{2}+1}, d_{j-i}^{\frac{N}{2}+1}\right\}. \end{aligned}$$

For $i = *$, $j > J_h - 3$ or $|i-j| < 3$ it suffices to show that $\|D^\alpha w\|_{Q_i}$ is uniformly bounded in i and j. In fact, the assumption $D(A) \hookrightarrow H^2(\Omega)$ and maximal L_2 regularity on $L_2(\Omega)$ of A yields

$$\|D^\alpha w\|_{Q_i} \le \|D^\alpha w\|_Q \le C\|v\|_Q \le C, \quad |\alpha| \le 2.$$

This proves (c)(2). ∎

We conclude this section with local estimates for e. However, for the proof we need superconvergent-type estimates given in the next lemma.

LEMMA 5.6 (superconvergent-type estimate). *There exists some $C > 0$ such that for $h > 0$, $\tau \in \mathcal{T}_h$ $z_h, \omega \in S_h$ satisfying $\|\omega\|_{L_\infty(\Omega)} \le 1$*

$$\|\omega^4 z_h - I_h(\omega^4 z_h)\|_\tau \le C(h^2\|D\omega\|_{L_\infty(\Omega)}^2 + h\|D\omega\|_{L_\infty(\Omega)})\|\omega^2 z_h\|_\tau, \tag{18}$$

$$\|D(\omega^4 z_h - I_h(\omega^4 z_h))\|_\tau \le Ch\|D\omega\|_{L_\infty(\Omega)}^2\|z_h\|_\tau + Ch\|D\omega\|_{L_\infty(\Omega)}\|Dz_h\|_\tau, \tag{19}$$

$$\|\omega^8 z_h - I_h(\omega^8 z_h)\|_\tau \le C(h^2\|D\omega\|_{L_\infty(\Omega)}^2 + h\|D\omega\|_{L_\infty(\Omega)})\|\omega^6 z_h\|_\tau, \tag{20}$$

$$\|D(\omega^8 z_h - I_h(\omega^8 z_h))\|_\tau \le C(h\|D\omega\|_{L_\infty(\Omega)}^2 + \|D\omega\|_{L_\infty(\Omega)})\|\omega^6 z_h\|_\tau. \tag{21}$$

In particular, inequalities (18)–(21) *hold with τ replaced by Ω.*

Proof. For $h > 0$ let $\tau \in \mathcal{T}_h$ and set $\chi := I_h(\omega^4 z_h)$ for $\omega, z_h \in S_h$. Note that $D^2 z_h = 0$. By the error estimate for the standard interpolant I_h, there exists $C > 0$, independent of h, z_h, ω, and τ, such that

$$\begin{aligned} \|\omega^4 z_h - \chi\|_\tau &\le h^{\frac{N}{2}}\|\omega^4 z_h - \chi\|_{L_\infty(\tau)} \le Ch^{\frac{N}{2}+2}\|D^2(\omega^4 z_h)\|_{L_\infty(\tau)} \\ &\le C\left(h^{\frac{N}{2}+2}\|D\omega\|_{L_\infty(\Omega)}^2\|\omega^2 z_h\|_{L_\infty(\tau)} + h^{\frac{N}{2}+2}\|D\omega\|_{L_\infty(\Omega)}\|\omega^2 Dz_h\|_{L_\infty(\tau)}\right). \end{aligned}$$

Now, by the inverse estimates (17) and (16) for z_h, we obtain

$$\begin{aligned}\|\omega^4 z_h - \chi\|_\tau &\le C(h^2\|D\omega\|^2_{L_\infty(\Omega)}\|\omega^2 z_h\|_\tau + h^2\|D\omega\|_{L_\infty(\Omega)}\|\omega^2 Dz_h\|_\tau)\\ &\le C(h^2\|D\omega\|^2_{L_\infty(\Omega)}\|\omega^2 z_h\|_\tau + h\|D\omega\|_{L_\infty(\Omega)}\|\omega^2 z_h\|_\tau).\end{aligned}$$

Similarly, we get (19)–(21). ∎

LEMMA 5.7. *There exists $C > 0$, independent of x_0 and h, such that for $d_j > 2(N+4)h$,*

$$\begin{aligned}\|e\|_{Q_j,1,0} \le C\Big(&\|\big(De\big)(0)\|_{\Omega'_j} + d_j^{-1}\|e(0)\|_{\Omega'_j}\\ &+ d_j^{-2}\|e\|_{Q'_j} + (hd_j^{-1})^{\frac{N}{2}+2}\|e'\|_{Q'_j} + \|k_a - I_h k_a\|_{Q'_j,1,1}\Big).\end{aligned}$$

Proof. Since $e = k_a - I_h k_a = k_a$ on $Q \setminus Q_h$, it suffices to consider the contribution of e in $Q_j \cap Q_h$. Let h and j be fixed and set for $n = 0, \dots, N+4$

$$Q_j^n := \left\{(t,x) \in Q'_j \cap Q_h : d_j - \frac{n}{N+4}d_{j-1} < \max\left\{|x-x_0|, t^{\frac12}\right\} < d_j + \frac{n}{N+4}d_j\right\}.$$

Clearly, $Q_j^0 = Q_j \cap Q_h$ and $Q_j^{N+4} = Q'_j \cap Q_h$. Throughout this proof M, C, C_1, C_2 denote constants independent of j, n, x_0, and h. By quasiuniformity there exist cut-off functions $\omega_n : Q \to [0,1]$, $n = 1, \dots, N+4$, such that $\omega_n(t,\cdot) \in S_h$, $\omega_n(\cdot,x)$ is continuously differentiable, $\omega_n \equiv 1$ on Q_j^{n-1}, $\omega_n \equiv 0$ outside Q_j^n, $\|D\omega_n\|_{L_\infty(Q)} \le Md_j^{-1}$, and $\|\omega'_n\|_{L_\infty(Q)} \le Md_j^{-2}$. Throughout this proof we set $z(t) = k_a(t) - I_h k_a(t)$ and $z_h(t) = K_h(t) - I_h k_a(t)$ for $t \in I$ to shorten notation. Note that $e(t) = z_h(t) - z(t)$. We will use the coercivity of the form a, the equation

$$\big(\chi, e'(t)\big)_\Omega + a(\chi, e(t)) = 0, \quad \chi \in S_h,\ 0 < t \le T, \tag{22}$$

and superconvergent-type estimates to prove

$$\begin{aligned}&d_j^{-1}\|\omega_n^2 De\|_Q + d_j^{-2}\|e\|_{Q_j} + d_j^{-1}\|\big(\omega_n^2 e\big)(T)\|_\Omega \\ &\le C_1\big(d_j^{-1}\|e(0)\|_{\Omega'_j} + d_j^{-2}\|e\|_{Q'_j} + (hd_j^{-1})^{\frac12}(\|e'\|_{Q_j^n} + d_j^{-1}\|De\|_{Q_j^n}) + \epsilon^{-1}\|z\|_{Q'_j,1,1} + \epsilon\|\omega_n^4 e'\|_Q\big),\end{aligned} \tag{23}$$

for $\epsilon > 0$ and

$$\begin{aligned}\|\omega_n^4 e'\|_Q \le C_2\big(&\|(De)(0)\|_{\Omega'_j} + d_j^{-1}\|e(0)\|_{\Omega'_j} + d_j^{-2}\|e\|_{Q'_j} + (hd_j^{-1})^{\frac12}\|e'\|_{Q_j^n}\\ &+ \|z\|_{Q'_j,1,1} + d_j^{-1}\|\omega_n^2 De\|_Q + d_j^{-1}\|\big(\omega_n^2 e\big)(T)\|_\Omega\big).\end{aligned} \tag{24}$$

Then, we multiply inequality (24) by $1/(2C_2)$ and add it to (23) with $\epsilon = 1/(4C_2)$. By subtracting $\epsilon\|\omega^4 e'\|_Q$, $1/2d_j^{-1}\|\big(\omega^2 e\big)(T)\|_\Omega$ and $1/2d_j^{-1}\|\omega^2 De\|_Q$ on both sides, we obtain

$$\begin{aligned}\|e'\|_{Q_j^{n-1}} + d_j^{-1}\|De\|_{Q_j^{n-1}} + d_j^{-2}\|e\|_{Q_j} \le C\big(&\|(De)(0)\|_{\Omega'_j} + d_j^{-1}\|e(0)\|_{\Omega'_j} + d_j^{-2}\|e\|_{Q'_j}\\ &+(hd_j^{-1})^{\frac12}\big(\|e'\|_{Q_j^n} + d_j^{-1}\|De\|_{Q_j^n}\big) + \|z\|_{Q'_j,1,1}\big).\end{aligned} \tag{25}$$

Since $hd_j^{-1} \le 2(N+4)$, by iteration we get

$$\begin{aligned}\|e\|_{Q_j,1,0} \le C\big(&\|\big(De\big)(0)\|_{\Omega'_j} + d_j^{-1}\|e(0)\|_{\Omega'_j} + d_j^{-2}\|e\|_{Q'_j} + (hd_j^{-1})^{\frac{N}{2}+2}\|e'\|_{Q'_j}\\ &+ \|z\|_{Q'_j,1,1} + hd_j^{-2}\|De\|_{Q'_j}\big).\end{aligned} \tag{26}$$

The last term on the right-hand side of inequality (26) may be omitted since

$$hd_j^{-2}\|De\|_{Q_j'} \le hd_j^{-2}\|Dz\|_{Q_j'} + hd_j^{-2}\|Dz_h\|_{Q_j'} \le Cd_j^{-1}\|Dz\|_{Q_j'} + Cd_j^{-2}(\|e\|_{Q_j'} + \|z\|_{Q_j'}).$$

Therefore, it remains to prove inequalities (23) and (24). For readability we suppress the dependency on t and introduce the notation

$$a_\omega^\#(u,v) := \sum_{i,j=1}^N (\omega a_{ij}\partial_i u, \partial_j v)_\Omega, \quad a^\#(u,v) := \sum_{i,j=1}^N (a_{ij}\partial_i u, \partial_j v)_\Omega \quad u,v \in H,$$

where ω is smooth enough. The term $a_\omega(u,v)$ is defined in an analogous way. Note that $a_\omega^\#$ is the principal part of a with some weight ω. For inequality (24), we start with the identity

$$\begin{aligned}
&\int_I \|\omega_n^4 e'\|_\Omega^2 + \frac{1}{2}\frac{d}{dt}a_{\omega_n^8}^\#(e,e)\ \mathrm{d}t \\
&= \int_I \big(\omega_n^8 e', e'\big)_\Omega + \frac{1}{2}a_{(\omega_n^8)'}^\#(e,e) + \mathrm{Re}\ a_{\omega_n^8}^\#(e',e) + \mathrm{Re}\ a(\omega_n^8 z_h', e) - \mathrm{Re}\ a(\omega_n^8 z_h', e)\ \mathrm{d}t \\
&= \int_I \big(- \mathrm{Re}\ (\omega_n^8 z', e')_\Omega + \frac{1}{2}a_{(\omega_n^8)'}^\#(e,e) - \mathrm{Re}\ a_{\omega_n^8}^\#(z',e)\big)\ \mathrm{d}t \\
&\quad + \mathrm{Re}\int_I a_{\omega_n^8}^\#(z_h', e) - a(\omega_n^8 z_h', e)\ \mathrm{d}t + \mathrm{Re}\int_I \big(\omega_n^8 z_h', e'\big)_\Omega + a(\omega_n^8 z_h', e)\ \mathrm{d}t \\
&=: J_1 + J_2 + J_3.
\end{aligned}$$

Noting that $d_j^{-1} > C$, where C depends on Ω only, we obtain

$$\begin{aligned}
|J_1| &\le C\|z\|_{Q_j',1,1}^2 + \frac{1}{16}\|\omega_n^4 e'\|_{Q_j'}^2 + Cd_j^{-2}\|\omega_n^2 De\|_Q^2, \\
|J_2| &\le \left| \int_I a_{z_h'}^\#(\omega_n^8, e) + \sum_{i=1}^N \big(c_i\omega_n^8 z_h', \partial_i e\big)_\Omega + \big(c_0\omega_n^8 z_h', e\big)_\Omega\ \mathrm{d}t \right| \\
&\qquad + \left| \int_I \sum_{i=1}^N \big(b_i \partial_i(\omega_n^8 z_h'), e\big)_\Omega\ \mathrm{d}t \right| \\
&=: J_{21} + J_{22}.
\end{aligned}$$

We start with the first term of J_{21}

$$\begin{aligned}
\left| \int_I a_{z_h'}^\#(\omega_n^8, e)\ \mathrm{d}t \right| &\le Cd_j^{-2}\|\omega_n^2 De\|_Q^2 + \frac{1}{16}\|\omega_n^4 z_h'\|_Q^2 \\
&\le C\|z'\|_{Q_j'}^2 + Cd_j^{-2}\|\omega_n^2 De\|_Q^2 + \frac{1}{16}\|\omega_n^4 e'\|_Q^2.
\end{aligned}$$

By similar estimates for the two remaining terms of J_{21}, we obtain

$$J_{21} \le Cd_j^{-4}\|e\|_{Q_j'}^2 + C\|z'\|_{Q_j'}^2 + Cd_j^{-2}\|\omega_n^2 De\|_Q^2 + \frac{1}{8}\|\omega_n^4 e'\|_Q^2.$$

In order to estimate J_{22}, we use integration by parts in time. Recall that μ denotes

the constant appearing in (8).

$$
\begin{aligned}
J_{22} &= \left| \sum_{i=1}^N \int_I \big(b_i\big[(\partial_i\omega_n^8)(e'+z') + \omega_n^8\partial_i(e'+z')\big](t), e(t)\big)_\Omega \,\mathrm{d}t \right| \\
&= \left| \sum_{i=1}^N \int_I \big(b_i\big((\partial_i\omega_n^8)(e'+z')\big)(t), e(t)\big)_\Omega \,\mathrm{d}t + \sum_{i=1}^N \int_I \big(b_i\big(\omega_n^8\partial_i z'\big)(t), e(t)\big)_\Omega \,\mathrm{d}t \right. \\
&\quad \left. - \sum_{i=1}^N \int_I \big(b_i\big(\partial_i e\big)(t), \big(\omega_n^8 e\big)'(t)\big)_\Omega \,\mathrm{d}t + \sum_{i=1}^N \big(b_i\big(\omega_n^8\partial_i e\big)(t), e(t)\big)_\Omega\big|_0^T \right| \\
&\le Cd_j^{-1}\|\omega_n^4 e'\|_Q\|e\|_{Q_j'} + Cd_j^{-1}\|z'\|_{Q_j'}\|e\|_{Q_j'} + C\|Dz'\|_{Q_j'}\|e\|_{Q_j'} \\
&\quad + Cd_j^{-2}\|\omega_n^2 De\|_Q\|e\|_{Q_j'} + C\|\omega_n^2 De\|_Q\|\omega_n^4 e'\|_Q + C\|\big(\omega_n^4 De\big)(T)\|_\Omega\|\big(\omega_n^2 e\big)(T)\|_\Omega \\
&\quad + C\|(De)(0)\|_{\Omega_j'}\|e(0)\|_{\Omega_j'} \\
&\le \frac{1}{16}\|\omega_n^4 e'\|_Q^2 + Cd_j^{-4}\|e\|_{Q_j'}^2 + C\|z'\|_{Q_j'}^2 + Cd_j^2\|Dz'\|_{Q_j'}^2 + Cd_j^{-2}\|\omega_n^2 De\|_{Q_j'}^2 \\
&\quad + \frac{\mu}{4}\|\big(\omega_n^4 De\big)(T)\|_\Omega^2 + Cd_j^{-2}\|\big(\omega_n^2 e\big)(T)\|_\Omega^2 + C\|(De)(0)\|_{\Omega_j'}^2 + Cd_j^{-2}\|e(0)\|_{\Omega_j'}^2.
\end{aligned}
$$

Next, we apply equality (22) with $\chi = I_h(\omega_n^8 z_h')$ to J_3.

$$
\begin{aligned}
J_3 &= \left| \int_I \big(\omega_n^8 z_h' - \chi, e'\big)_\Omega + a(\omega_n^8 z_h' - \chi, e) \,\mathrm{d}t \right| \\
&\le \big(\|\omega_n^8 z_h' - \chi\|_Q\|e'\|_{Q_j^n} + \|D(\omega_n^8 z_h' - \chi)\|_Q\|e\|_{Q_j'} + \|\omega_n^8 z_h' - \chi\|_Q\|e\|_{Q_j'}\big) \\
&\quad + C\left(\sum_{i=1}^N \left| \int_I (c_i(\omega_n^8 z_h' - \chi), \partial_i e)_\Omega + a^\#(\omega_n^8 z_h' - \chi, e) \,\mathrm{d}t \right|\right) \\
&=: J_{31} + J_{32}.
\end{aligned}
$$

By inequality (20),

$$
\|\omega_n^8 z_h' - \chi\|_Q \le Chd_j^{-1}\|\omega_n^6 z_h'\|_Q \le Chd_j^{-1}\|z'\|_{Q_j'} + Chd_j^{-1}\|e'\|_{Q_j^n}.
$$

Since $\|D(\omega_n^8 z_h' - \chi)\|_Q$ may be estimated in a similar way, we obtain

$$
J_{31} \le Cd_j^{-4}\|e\|_{Q_j'}^2 + C\|z'\|_{Q_j'}^2 + Chd_j^{-1}\|e'\|_{Q_j^n}^2 + \frac{1}{8}\|\omega_n^4 e'\|_Q^2.
$$

Estimating J_{32} is more involved. In fact, since Dz_h is constant on each $\tau \in \mathcal{T}_h$, by inverse estimates we get

$$
\begin{aligned}
\|Dz_h\|_\tau\|\omega_n^2\|_{L_\infty(\tau)} &\le h^{\frac{N}{2}}\|Dz_h\|_{L_\infty(\tau)}\|\omega_n^2\|_{L_\infty(\tau)} = h^{\frac{N}{2}}\big|Dz_h\restriction_\tau\big|\|\omega_n^2\|_{L_\infty(\tau)} \\
&= h^{\frac{N}{2}}\|\omega_n^2 Dz_h\|_{L_\infty(\tau)} \le C\|\omega_n^2 Dz_h\|_\tau, \quad \tau \in \mathcal{T}_h,
\end{aligned}
$$

which implies $|\int_I (c_i(\omega_n^8 z_h' - \chi), \partial_i z_h)_\Omega \,\mathrm{d}t| \le C\|\omega_n^4 z_h'\|_Q\|\omega_n^2 Dz_h\|_Q$ by inequality (20).

Hence, by inequality (20) again and elementary estimates,

$$\begin{aligned}\sum_{i=1}^{N}\left|\int_I (c_i(\omega_n^8 z_h' - \chi), \partial_i e)_\Omega \,\mathrm{d}t\right| &= \sum_{i=1}^{N}\Bigg|\int_I (c_i(\omega_n^8 z_h' - \chi), \partial_i z)_\Omega \\ &\qquad + (c_i(\omega_n^8 z_h' - \chi), \partial_i z_h)_\Omega \,\mathrm{d}t\Bigg| \\ &\le C\|\omega_n^4 z_h'\|_Q \|Dz\|_{Q_j'} + C\|\omega_n^4 z_h'\|_Q \|\omega_n^2 Dz_h\|_Q \\ &\le \frac{1}{16}\|\omega^4 e'\|_Q^2 + C\|z'\|_{Q_j'}^2 + C\|Dz\|_{Q_j'}^2 + C\|\omega^2 Dz_h\|_Q^2 \\ &\le \frac{1}{16}\|\omega_n^4 e'\|_Q^2 + C\|z'\|_{Q_j'}^2 + Cd_j^{-2}\|Dz\|_{Q_j'}^2 \\ &\quad + Cd_j^{-2}\|\omega_n^2 De\|_Q^2.\end{aligned}$$

Moreover, by inequality (21),

$$\begin{aligned}\left|\int_I a^{\#}(\omega^8 z_h' - \chi, z_h)\,\mathrm{d}t\right| &\le Cd_j^{-1}\sum_{\tau\in\mathcal{T}_h}\|\omega_n^6 z_h'\|_\tau \|Dz_h\|_\tau \le Cd_j^{-1}\sum_{\tau\in\mathcal{T}_h}\|\omega_n^4 z_h'\|_\tau \|\omega_n^2 Dz_h\|_\tau \\ &\le Cd_j^{-1}\left(\sum_{\tau\in\mathcal{T}_h}\|\omega_n^4 z_h'\|_\tau^2\right)^{\frac{1}{2}}\left(\sum_{\tau\in\mathcal{T}_h}\|\omega_n^2 Dz_h\|_\tau^2\right)^{\frac{1}{2}} \\ &\le \frac{1}{32}\|\omega_n^4 z_h'\|_Q^2 + Cd_j^{-2}\|\omega_n^2 Dz_h\|_Q^2.\end{aligned}$$

Using inequality (21) again, we thus obtain

$$\begin{aligned}\left|\int_I a^{\#}(\omega^8 z_h' - \chi, e)\,\mathrm{d}t\right| &\le \left|\int_I a^{\#}(\omega_n^8 z_h' - \chi, z_h) + a^{\#}(\omega_n^8 z_h' - \chi, z)\,\mathrm{d}t\right| \\ &\le \frac{1}{32}\|\omega_n^4 z_h'\|_Q^2 + Cd_j^{-2}\|\omega_n^2 Dz_h\|_Q^2 + Cd_j^{-1}\|\omega_n^6 z_h'\|_Q\|Dz\|_{Q_j'} \\ &\le \frac{1}{16}\|\omega_n^4 e'\|_Q^2 + C\|z'\|_{Q_j'}^2 + Cd_j^{-2}\|Dz\|_{Q_j'}^2 + Cd_j^{-2}\|\omega_n^2 De\|_Q^2.\end{aligned}$$

Summing $J_1 + J_2 + J_3$, we have

(27)
$$\begin{aligned}\|\omega_n^4 e'\|_Q + \frac{\mu}{2}\|(\omega_n^4 De)(T)\|_\Omega &\le C\|(De)(0)\|_{\Omega_j'}^2 + Cd_j^{-2}\|e(0)\|_{\Omega_j'}^2 + Cd_j^{-4}\|e\|_{Q_j'}^2 \\ &\quad + Chd^{-1}\|e'\|_{Q_j^n}^2 + C\|z\|_{Q_j',1,1}^2 + Cd_j^{-2}\|\omega_n^2 De\|_Q^2 \\ &\quad + Cd_j^{-2}\|(\omega_n^2 e)(T)\|_\Omega^2 + \frac{1}{2}\|\omega^4 e'\|_Q^2 + \frac{\mu}{4}\|(\omega_n^4 De)(T)\|_\Omega^2.\end{aligned}$$

Finally, subtracting the terms $\frac{1}{2}\|\omega^4 e'\|_Q^2$ and $\frac{\mu}{4}\|\omega^4 De(T)\|_\Omega$ on both sides and taking square roots yields (24).

Starting with the identity

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\omega^2 e\|_\Omega^2 + \operatorname{Re}\, a_{\omega^4}(e,e)\\
&\quad = \operatorname{Re}\, \big(\omega^4 e, e'\big)_\Omega + \frac{1}{2}\big((\omega^4)' e, e\big)_\Omega + \operatorname{Re}\, \big(a_{\omega^4}(z_h,e) - a_{\omega^4}(z,e) + a(\omega^4 z_h, e)\\
&\qquad - a(\omega^4 z_h, e)\big)\\
&\quad = \frac{1}{2}\big((\omega^4)' e, e\big)_\Omega + \operatorname{Re}\, \big(- \big(\omega^4 z, e'\big)_\Omega + a_{\omega^4}(z_h,e) - a_{\omega^4}(z,e) - a(\omega^4 z_h, e)\big)\\
&\qquad + \operatorname{Re}\, \big(\big(\omega^4 z_h, e'\big)_\Omega + a(\omega^4 z_h, e)\big)
\end{aligned}$$

and using (18) and (19), we similarly prove

$$\begin{aligned}
&\|\big(\omega^2 e\big)(T)\|_\Omega^2 - \|e(0)\|_{\Omega_j'}^2 + \|\omega^2 De\|_Q^2 + \|e\|_{Q_j'}^2\\
&\qquad \le C\epsilon^{-2} d_j^{-2}\|z\|_{Q_j',1,1}^2 + \epsilon^2 d_j^2 \|\omega^4 e'\|_Q^2 + C d_j^{-2}\|e\|_{Q_j'}^2\\
&\qquad\qquad + Ch^2\|e'\|_{Q_j^n}^2 + Chd^{-1}\|De\|_{Q_j^n}^2,\ \epsilon > 0.
\end{aligned}$$

Taking square roots and multiplying by d_j^{-1} yields (23). ∎

Appendix A. Truncation of singular integral operators. For $1 < p < \infty$ let $S \in \mathcal{L}(L_p(\mathbb{R}^N))$ be an integral operator with a kernel $K : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{C}$ satisfying

$$|K(x,y)| \le \frac{C}{|x-y|^N}, \quad x, y \in \mathbb{R}^N,\ x \ne y. \tag{28}$$

Kernel estimates of this form are well known for solutions to elliptic problems. For $\epsilon > 0$ set $\Omega_x^\epsilon := \{y \in \mathbb{R}^N : |x-y| < \epsilon\}$ and define $k_\epsilon : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{C}$ by $k_\epsilon(x,y) := \chi_{(\Omega_x^\epsilon)^c}(y) K(x,y)$ for $x, y \in \mathbb{R}^N$. The function k_ϵ is called *truncated kernel* of S. Since $\|k_\epsilon\|_{L_\infty(\mathbb{R}^N \times \mathbb{R}^N)} \le \frac{C}{\epsilon^N}$, the operator S_ϵ associated to the kernel k_ϵ is well defined on $L_p(\mathbb{R}^N)$. In [Ste93, Chapter I.7] it is shown that the family of operators $(S_\epsilon)_{\epsilon>0}$ is uniformly bounded in $\mathcal{L}(L_p(\mathbb{R}^N))$.

Let $Q := I \times \Omega$, where $\Omega \subset \mathbb{R}^N$ and $I := [0,\tau]$ for some $\tau > 0$. We will adapt this result to parabolic problems in Q. In order to do so, we adapt the kernel estimate stated above to parabolic problems. More precisely, we introduce the following definition.

Definition A.1. *Let $1 < p < \infty$. We say that $T \in \mathcal{L}(L_p(Q))$ satisfies the kernel estimate (KE_{Tr}) if there exists a measurable function $K : Q \times \Omega \to \mathbb{C}$ such that*

$$(Tf)(t,x) = \int_Q K(t-s,x,y) f(s,y)\ \mathrm{d}(s,y), \quad (t,x) \notin \operatorname{supp} f,\ \text{a.a. } (t,x),$$

for $f \in L_\infty(Q)$ and there exist constants $C, c > 0$ such that

$$|K(t,x,y)| \le C t^{-N-2} \exp\left(-c\frac{|x-y|^2}{t}\right), \quad 0 < t \le \tau,\ \text{a.a. } x, y \in \Omega. \tag{29}$$

If T satisfies the kernel estimate (KE_{Tr}) we set

$$Q_{t,x}^\epsilon := \{(s,y) \in Q :\ \max\{|t-s|^{\frac{1}{2}},\ |x-y|\} \le \epsilon\}$$

and

$$k_\epsilon(t,s,x,y) := K(t-s,x,y)\chi_{(Q_{t,x}^\epsilon)^c}(s,y), \quad (s,x),(t,y) \in Q,$$

where K denotes the kernel of T. Then for any $\epsilon > 0$ the truncated operator T_ϵ, given by

$$(T_\epsilon f)(t,x) := \int_Q k_\epsilon(t,s,x,y) f(s,y)\, \mathrm{d}(s,y), \quad (t,x) \in Q, \tag{30}$$

is well defined.

THEOREM A.2. *Let $1 < p < \infty$. Assume that $T \in \mathcal{L}(L_p(Q))$ satisfies the kernel estimate (KE_{Tr}). Then the family of the truncated operators $\left(T_\epsilon\right)_{\epsilon>0}$ is uniformly bounded in $\mathcal{L}(L_p(Q))$.*

Proof. Denote the kernel of T by K. Extending K by 0 outside $Q \times \Omega$, we restrict ourselves to the case $Q = \mathbb{R}_+ \times \mathbb{R}^N$. Since the rational numbers are dense in $\mathbb{R}$, there exists $\{(t_i, x_i)\}_{i\in\mathbb{N}}$ such that

$$Q = \bigcup_{i\in\mathbb{N}} Q^{\epsilon/8}_{t_i,x_i}.$$

We choose a maximal disjoint subset $\{Q^{\epsilon/8}_{t_{i_j},x_{i_j}}\}_{j\in\mathbb{N}}$ of $\{Q^{\epsilon/8}_{t_i,x_i}\}_{i\in\mathbb{N}}$. This implies

$$\bigcup_{j\in\mathbb{N}} Q^{\epsilon/4}_{t_{i_k},x_{i_k}} = Q.$$

For $\tilde{T}_\epsilon := T - T_\epsilon$ we show that there exists $C > 0$ such that

$$\left\| \chi_{Q^{\epsilon/4}_{t_{i_j},x_{i_j}}} \tilde{T}_\epsilon f \right\| L_p(Q) \le C \left\| \chi_{Q^{2\epsilon}_{t_{i_j},x_{i_j}}} f \right\| L_p(Q), \quad f \in L_p(Q),\ j \in \mathbb{N},\ \epsilon > 0. \tag{31}$$

Let $f \in L_p(Q)$. Note that

$$(\tilde{T}_\epsilon f)(t,x) \equiv 0 \qquad \text{if } \operatorname{supp} f \subset \left(Q^\epsilon_{t,x}\right)^c, \tag{32}$$

$$(\tilde{T}_\epsilon f)(t,x) = (Tf)(t,x) \qquad \text{if } \operatorname{supp} f \subset Q^\epsilon_{t,x}, \tag{33}$$

for a.a. $(t,x) \in Q$. Following [Ste93, Chapter I.7], we write

$$\begin{aligned}\left(\chi_{Q^{\epsilon/4}_{t_{i_j},x_{i_j}}} \tilde{T}_\epsilon f\right)(t,x) &= \left(\chi_{Q^{\epsilon/4}_{t_{i_j},x_{i_j}}} \tilde{T}_\epsilon \chi_{Q^{\epsilon/2}_{t_{i_j},x_{i_j}}} f\right)(t,x) + \left(\chi_{Q^{\epsilon/4}_{t_{i_j},x_{i_j}}} \tilde{T}_\epsilon \chi_{(Q^{2\epsilon}_{t_{i_j},x_{i_j}})^c} f\right)(t,x) \\ &\quad + \left(\chi_{Q^{\epsilon/4}_{t_{i_j},x_{i_j}}} \tilde{T}_\epsilon \left(\chi_{Q^{2\epsilon}_{t_{i_j},x_{i_j}}} - \chi_{Q^{\epsilon/2}_{t_{i_j},x_{i_j}}}\right) f\right)(t,x) \\ &=: I^\epsilon_{j,1}(t,x) + I^\epsilon_{j,2}(t,x) + I^\epsilon_{j,3}(t,x), \quad \text{a.a. } (t,x) \in Q,\ j \in \mathbb{N},\ \epsilon > 0.\end{aligned}$$

By (33), we obtain

$$\begin{aligned}\|I^\epsilon_{j,1}\|_{L_p(Q)} &\le \left\| \tilde{T} \chi_{Q^{\epsilon/2}_{t_{i_j},x_{i_j}}} f \right\| L_p(Q) \le \|T\|_{\mathcal{L}(L_p(Q))} \left\| \chi_{Q^{\epsilon/2}_{t_{i_j},x_{i_j}}} f \right\| L_p(Q) \\ &\le C \left\| \chi_{Q^{2\epsilon}_{t_{i_j},x_{i_j}}} f \right\| L_p(Q), \quad f \in L_p(Q),\ j \in \mathbb{N},\ \epsilon > 0.\end{aligned}$$

Since $\operatorname{supp} \chi_{(Q^{2\epsilon}_{t_{i_j},x_{i_j}})^c} f \subset (Q^{2\epsilon}_{t_{i_j},x_{i_j}})^c \subset (Q^\epsilon_{t_{i_j},x_{i_j}})^c$, it follows by (32) that $I^\epsilon_{j,2}(t,x) = 0,\ (t,x) \in Q,\ j \in \mathbb{N},\ \epsilon > 0$.

We use the representation (30) and the kernel estimate (KE_{Tr}) to estimate $\|I^\epsilon_{j,3}\|_{L_p(Q)}$. By definition of $Q^\epsilon_{t,x}$, there exists $C>0$, independent of $j\in\mathbb{N}$ and ϵ, such that

$$|K(t-s,x,y)|\le C\left(\frac{\epsilon}{4}\right)^{-N-2},\quad (s,y)\in Q^{2\epsilon}_{t_{i_j},x_{i_j}}\setminus Q^{\epsilon/2}_{t_{i_j},x_{i_j}}, (t,x)\in Q^{\epsilon/4}_{t_{i_j},x_{i_j}}.$$

Since $\operatorname{supp}\chi_{Q^{2\epsilon}_{t_{i_j},x_{i_j}}\setminus Q^{\epsilon/2}_{t_{i_j},x_{i_j}}} f\subset Q^{2\epsilon}_{t_{i_j},x_{i_j}}$, we obtain

$$\begin{aligned}\|I^\epsilon_{j,3}\|_{L_p(Q)}&\le \left|Q^{\epsilon/4}_{t_{i_j},x_{i_j}}\right|^{\frac1p}\|I^\epsilon_{j,3}\|_{L_\infty(Q)}\\&\le C\left|Q^{\epsilon/4}_{t_{i_j},x_{i_j}}\right|^{\frac1p}\left|Q^{2\epsilon}_{t_{i_j},x_{i_j}}\right|^{1-\frac1p}\epsilon^{-N-2}\left\|\chi_{Q^{2\epsilon}_{t_{i_j},x_{i_j}}}f\right\|L_p(Q)\\&\le C\left\|\chi_{Q^{2\epsilon}_{t_{i_j},x_{i_j}}}f\right\|L_p(Q),\quad f\in L_p(Q),\ j\in\mathbb{N},\ \epsilon>0.\end{aligned}$$

Therefore, inequality (31) is proved.

We finally obtain

$$\|\tilde T_\epsilon f\|^p_{L_p(Q)}\le C\sum_{j\in\mathbb{N}}\|\tilde T_\epsilon f\|^p_{L_p(Q^{\epsilon/4}_{t_{i_j},x_{i_j}})}\le C\sum_{j\in\mathbb{N}}\|f\|^p_{L_p(Q^{2\epsilon}_{t_{i_j},x_{i_j}})}.$$

To conclude the proof, we will show that no $(t,x)\in Q$ belongs to more than $M\in\mathbb{N}$ of the $Q^{2\epsilon}_{t_{i_j},x_{i_j}}$, where M does not depend on ϵ. This would imply

$$\sum_{j\in\mathbb{N}}\|f\|^p_{L_p(Q^{2\epsilon}_{t_{i_j},x_{i_j}})}\le M\|f\|^p_{L_p(Q)}.$$

Let $(t,x)\in Q$. Since $Q^{2\epsilon}_{t_{i_j},x_{i_j}}\subset Q^{4\epsilon}_{t,x}$ for all (t_{i_j},x_{i_j}) with $(t,x)\in Q^{2\epsilon}_{t_{i_j},x_{i_j}}$, it suffices to estimate the maximal number of $Q^{\epsilon/8}_{t_{i_j},x_{i_j}}$ in $Q^{4\epsilon}_{t,x}$, independent of $(t,x)\in Q$ and ϵ. Now, the maximal number of $Q^{\epsilon/8}_{t_{i_j},x_{i_j}}$ in $Q^{4\epsilon}_{t,x}$ is bounded by

$$\frac{|Q^{4\epsilon}_{t,x}|}{|Q^{\epsilon/8}_{t,x}|}=\frac{(4\epsilon)^{N+2}}{(\frac{\epsilon}{8})^{N+2}}=32^{N+2},\quad (t,x)\in Q,\ \epsilon>0,$$

since the $Q^{\epsilon/8}_{t_{i_j},x_{i_j}}$ are mutually disjoint. The proof is complete. ∎

Appendix B. Kernel estimates of analytic semigroups. Analytic semigroups satisfying a heat kernel estimate allow us to prove estimates for time derivatives of their kernels as well. The proof of the following lemma uses techniques due to E. B. Davies (see [Dav97]).

LEMMA B.1. *Let $(T(t))_{t\ge0}$ satisfy (KE_{Max}). Then*

$$|\partial_t^k\partial_1^\alpha\partial_2^\beta K(t,x,y)|\le Ct^{-\frac{N+2k+|\alpha|+|\beta|}{2}}\exp\left(-c\frac{|x-y|^2}{t}\right),\quad 0<t\le T,\ x,y\in\Omega,$$

whenever $0\le k\le1, |\alpha|=0, |\beta|\le2$ or $0\le k\le1, |\alpha|\le2, |\beta|=0$.

Proof. Writing $D_1^\alpha D_2^\beta T(z) = (D_1^\alpha D_2^\beta T(\operatorname{Re}\frac{z}{2}))T(z - \operatorname{Re}\frac{z}{2})$, we obtain

$$\begin{aligned}\|D_1^\alpha D_2^\beta T(z)\|_{\mathcal{L}(L_1(\Omega),L_\infty(\Omega))} &\le C(\operatorname{Re} z)^{-\frac{N+|\alpha|+|\beta|}{2}} \|T(z - \operatorname{Re}\tfrac{z}{2})\|_{\mathcal{L}(L_1(\Omega))} \\ &\le C(\operatorname{Re} z)^{-\frac{N+|\alpha|+|\beta|}{2}}\end{aligned}$$

for $z \in \Sigma_{\theta,2T} := \{z \in \mathbb{C} : |\arg z| < \theta,\ |z| < 2T\}$ and some $\theta \in (0, \frac{\pi}{2})$. Thus $D_1^\alpha D_2^\beta T(z)$ is an integral operator for $z \in \Sigma_{\theta,2T}$. Since $D_1^\alpha D_2^\beta T : \Sigma_{\theta,2T} \to \mathcal{L}(L_2(\Omega))$ is analytic, by [AB94, Theorem 3.1], there exists $K^{\alpha,\beta}(\cdot, x, y) : \Sigma_{\theta,2T} \to \mathbb{C}$, analytic for $x, y \in \Omega$, such that $K^{\alpha,\beta}(z, \cdot, \cdot)$ is the kernel of $D_1^\alpha D_2^\beta T(z)$. Moreover, by [DR96, Proposition 3.3], which is a variant of [Dav97, Theorem 4], we obtain

$$|K^{\alpha,\beta}(z, x, y)| \le C(\operatorname{Re} z)^{-\frac{N+|\alpha|+|\beta|}{2}} \exp\left(-c\frac{|x-y|^2}{|z|}\right), \quad z \in \Sigma_{\theta,T},\ x, y \in \Omega. \tag{34}$$

Choosing $r = \min\{\frac{1}{2}, \tan\theta\}$, by Cauchy's theorem, we have

$$\partial_t K^{\alpha,\beta}(t, x, y) = \frac{1}{2\pi i} \int_{B(t,rt)} \frac{K^{\alpha,\beta}(z, x, y)}{(z-t)^2}\, \mathrm{d}z, \quad 0 < t < T,$$

which implies (see [Dav97, Theorem 3])

$$\partial_t K^{\alpha,\beta}(t, x, y)| \le Ct^{-\frac{N+|\alpha|+|\beta|+2}{2}} \exp\left(-c\frac{|x-y|^2}{t}\right), \quad z \in \Sigma_{\theta,T},\ x, y \in \Omega.$$

Since $\partial_t K^{\alpha,\beta}(t, \cdot, \cdot)$ is the kernel of $\frac{d}{dt}T(t)$, the proof is complete. ∎

Acknowledgments. The author would like to thank Matthias Hieber for many discussions and suggestions to improve this paper. Very special thanks go to Stig Larsson for the idea for the present paper which was born during a research visit in Gothenburg.

OPTIMIZED SCHWARZ METHODS*

MARTIN J. GANDER†

Abstract. Optimized Schwarz methods are a new class of Schwarz methods with greatly enhanced convergence properties. They converge uniformly faster than classical Schwarz methods and their convergence rates dare asymptotically much better than the convergence rates of classical Schwarz methods if the overlap is of the order of the mesh parameter, which is often the case in practical applications. They achieve this performance by using new transmission conditions between subdomains which greatly enhance the information exchange between subdomains and are motivated by the physics of the underlying problem. We analyze in this paper these new methods for symmetric positive definite problems and show their relation to other modern domain decomposition methods like the new Finite Element Tearing and Interconnect (FETI) variants.

Key words. optimized Schwarz methods, optimized transmission conditions, domain decomposition, parallel preconditioning

1. Introduction.

The convergence properties of the classical Schwarz methods are well understood for a wide variety of problems; see, for example, the books [37], [35] or the survey articles [4], [40], [41] and references therein. Over the last decade, people have looked at different transmission conditions for the classical Schwarz method. There were three main motivations: the first motivation for different transmission conditions came from the nonoverlapping variant of the Schwarz method proposed by Lions, since without overlap the classical Schwarz method does not converge. Lions proposed to use Robin conditions to obtain a convergent algorithm in [31]. At the end in his paper, we find the following remark: "First of all, it is possible to replace the constants in the Robin conditions by two proportional functions on the interface, or even by local or nonlocal operators." Lions then gives a simple example in one dimension and shows that the optimal choice for the parameters in the Robin transmission conditions of the algorithm are constants in that case. In higher dimensions, however, the optimal choice involves a nonlocal transmission operator, as was shown for a two-dimensional convection diffusion problem by Charton, Nataf, and Rogier in [5], where a parabolic factorization of the operator was used to derive the optimal transmission conditions. Since nonlocal operators are not convenient to implement and costly ("ils se prêtent peu au calcul numérique" [5]), the authors propose for the convection dominated convection-diffusion problem to expand the symbols of the nonlocal operators in the small viscosity parameter to obtain local approximations. A different approximation using a Taylor expansion in the frequency parameter to obtain local transmission conditions for the convection diffusion equation is proposed in [33]; see also [34] and [32]. For symmetric coercive problems, a formulation of the nonoverlapping Schwarz method with Robin transmission conditions which avoids the explicit use of normal derivatives was introduced independently in [7], and convergence of the resulting algorithm was proved using energy estimates. A first optimization of the

transmission conditions for the performance of the algorithm was done by Japhet in [26] for convection diffusion problems, where one coefficient in a second order transmission condition was optimized, which led to the first optimized Schwarz method in this context. This approach was further developped and refined in [29], [27], and [28] for convection diffusion problems.

The second motivation for changing the transmission conditions came from acoustics. For problems of Helmholtz type, the classical Schwarz algorithm is not convergent, even with overlap. Després therefore proposed in [8] to use radiation conditions instead for the Helmholtz equation and proved convergence of a nonoverlapping variant of the Schwarz algorithm with these transmission conditions using energy estimates; see also [9]. The radiation conditions used were again Robin conditions, and the same conditions were also used in an overlapping context in [3]. Higher order local transmission conditions for the Helmholtz equation were introduced in [6] and a first attempt was made to optimize the free parameter in the transmission conditions for the performance of the algorithm, leading to the first optimized Schwarz method without overlap for the Helmholtz equation. The optimization problem for the Robin transmission conditions was then completely solved for this case in [22] and a simple strategy to optimize the second order transmission conditions was also presented. For a complete optimization of the second order transmission conditions for Helmholtz problems, see [14] for the case without overlap and [21] for the case with overlap.

The third motivation was that the convergence rate of the classical Schwarz method is rather slow and very much dependent on the size of the overlap. In a short note on nonlinear problems [24], Hagstrom, Tewarson, and Jazcilevich introduced Robin transmission conditions between subdomains and suggested, "Indeed, we advocate the use of nonlocal conditions." Later and independently, Tang introduced in [39] the generalized Schwarz alternating method, which uses a weighted average of Dirichlet and Neumann conditions at the interfaces, which is equivalent to a Robin condition. Numerically, optimal values for the weighting parameter were determined, and it was shown that a good choice of the parameter leads to a significant speedup of the algorithm. The main difficulty remaining in this approach is the determination of these parameters on the interfaces, like for successive overrelaxation (SOR) methods. Even stronger coupling was proposed in [38], where the authors introduced the overdetermined Schwarz algorithm, which enforces the coupling not only on the interfaces but also in the overlap itself, in so-called artificial boundary layers, and the relaxation parameter is now a function depending on space, as proposed earlier by Lions [31]. But the link with absorbing boundary conditions was only made later in [10], where an overlapping version of the Schwarz algorithm for Laplace's equation was analyzed with Robin and second order transmission conditions and a first attempt was made to determine asymptotically optimal parameters. In the waveform relaxation community, a link made with Schwarz methods in [23] opened up the way for better transmission conditions in the Schwarz waveform relaxation algorithms; see [19]. This led to optimized Schwarz algorithms for evolution problems, where one can clearly see that the optimal transmission conditions are absorbing boundary conditions. For the case of the wave equation with discontinuous coefficients, a nonoverlapping optimized Schwarz method is introduced and analyzed in detail at both the continuous and the discrete level in [20]. For the heat equation, see [17].

Optimized Schwarz methods have several key features:

1. They converge necessarily faster than classical Schwarz methods, at the same cost per iteration.

2. There are simple optimization procedures to determine the best parameters to be used in the transmission conditions, sometimes even closed formulas, depending on the problem solved.
3. Classical Schwarz implementations need only a small change in the implementation, in the information exchange routine, to benefit from the additional performance.
4. Optimized Schwarz methods can be used with or without overlap.

We present here a complete analysis of optimized Schwarz methods for a symmetric positive definite model problem and analyze in detail the optimization problems and the asymptotic performance of different approximations to the optimal transmission conditions. We restrict our analysis to the simple case of two subdomains, because optimized Schwarz method are greatly enhancing the local coupling between subdomains. Once optimized coupling conditions are found, they can be used in the general context of many subdomains, as we show with numerical examples at the end (see also [22]). As for classical Schwarz methods, a coarse grid is necessary as soon as many subdomains are used, if a convergence rate independent of the number of subdomains is desired, but we do not consider this issue here.

2. The classical Schwarz algorithm for a model problem. We use throughout the paper the model problem

$$\mathcal{L}(u) = (\eta - \Delta)(u) = f \quad \text{on } \Omega = \mathbb{R}^2,\ \eta > 0, \tag{2.1}$$

where we require the solution to decay at infinity. To introduce the ideas behind optimized Schwarz methods, we start by analyzing a parallel variant of the classical alternating Schwarz method introduced by Lions [30], applied to the model problem (2.1). We decompose the domain Ω into the two overlapping subdomains

$$\Omega_1 = (-\infty, L) \times \mathbb{R}, \quad \Omega_2 = (0, \infty) \times \mathbb{R}. \tag{2.2}$$

The Jacobi–Schwarz method for the two subdomains and the model problem is then given by

$$\begin{array}{llll} (\eta - \Delta)u_1^n = f & \text{in } \Omega_1, & (\eta - \Delta)u_2^n = f & \text{in } \Omega_2, \\ u_1^n(L, y) = u_2^{n-1}(L, y), & y \in \mathbb{R}, & u_2^n(0, y) = u_1^{n-1}(0, y), & y \in \mathbb{R}, \end{array} \tag{2.3}$$

and we require the iterates to decay at infinity. By linearity it suffices to consider only the case $f = 0$ and analyze convergence to the zero solution. Our analysis is based on the Fourier transform,

$$\hat{f}(k) = \mathcal{F}(f) := \int_{-\infty}^{\infty} e^{-ikx} f(x)dx, \quad f(x) = \mathcal{F}^{-1}(\hat{f}) := \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{ikx} \hat{f}(k)dk, \quad k \in \mathbb{R}. \tag{2.4}$$

Taking a Fourier transform of the Schwarz algorithm (2.3) in the y direction, and using the property of the Fourier transform that derivatives in y become multiplications by ik, we obtain

$$\begin{array}{rlrl} (\eta + k^2 - \partial_{xx})\hat{u}_1^n = 0, & x < L,\ k \in \mathbb{R}, & (\eta + k^2 - \partial_{xx})\hat{u}_2^n = 0, & x > 0,\ k \in \mathbb{R}, \\ \hat{u}_1^n(L, k) = \hat{u}_2^{n-1}(L, k), & k \in \mathbb{R}, & \hat{u}_2^n(0, k) = \hat{u}_1^{n-1}(0, k), & k \in \mathbb{R}. \end{array} \tag{2.5}$$

Hence subdomain solutions in the Fourier transformed domain are of the form

$$\hat{u}_j^n(x, k) = A_j(k)e^{\lambda_1(k)x} + B_j(k)e^{\lambda_2(k)x}, \quad j = 1, 2, \tag{2.6}$$

where the $\lambda_j(k)$, $j = 1, 2$ satisfy the characteristic equation $\eta - \lambda_j^2 + k^2 = 0$ and hence $\lambda_1(k) = \sqrt{k^2+\eta}$ and $\lambda_2(k) = -\sqrt{k^2+\eta}$. By the condition on the iterates at infinity, we obtain for the subdomain solutions

$$\hat{u}_1^n(x,k) = \hat{u}_2^{n-1}(L,k)e^{\sqrt{k^2+\eta}\,(x-L)}, \qquad \hat{u}_2^n(x,k) = \hat{u}_1^{n-1}(0,k)e^{-\sqrt{k^2+\eta}\,x}.$$

Inserting these solutions into algorithm (2.5), we obtain by induction

$$\hat{u}_1^{2n}(0,k) = \rho_{cla}^n \hat{u}_1^0(0,k), \qquad \hat{u}_2^{2n}(L,k) = \rho_{cla}^n \hat{u}_2^0(L,k), \tag{2.7}$$

where the convergence factor $\rho_{cla}(k,\eta,L)$ of the classical Schwarz algorithm is given by

$$\rho_{cla} = \rho_{cla}(k,L,\eta) := e^{-2\sqrt{k^2+\eta}L} < 1 \quad \forall k \in \mathbb{R}. \tag{2.8}$$

Note that we have chosen here to define the convergence factor over two iterations, which would correspond to one iteration of the Gauss–Seidel–Schwarz method in this two-subdomain case. From (2.8), we see that the iterates converge to zero on the line $x = 0$ and $x = L$. Since with zero boundary conditions the solution vanishes identically, we have shown that the classical Schwarz method converges for all frequencies, provided $\eta > 0$. The convergence factor depends on the problem parameter η, the size of the overlap L, and the frequency parameter k: the top curve in Figure 4.1 shows the dependence of ρ_{cla} on k for an overlap $L = \frac{1}{100}$ and $\eta = 1$. One can see that the Schwarz algorithm is a smoother; it damps high frequencies effectively, whereas for low frequencies the convergence factor is close to one and hence the algorithm is very slow.

3. The optimal Schwarz algorithm. We now introduce the key modification in the classical Schwarz method: new transmission conditions between the subdomains. The new algorithm is given by

$$\begin{array}{cc} (\eta-\Delta)u_1^n = f \quad \text{in } \Omega_1, & (\eta-\Delta)u_2^n = f \quad \text{in } \Omega_2, \\ (\partial_x + \mathcal{S}_1)(u_1^n)(L,\cdot) = (\partial_x + \mathcal{S}_1)(u_2^{n-1})(L,\cdot), & (\partial_x + \mathcal{S}_2)(u_2^n)(0,\cdot) = (\partial_x + \mathcal{S}_2)(u_1^{n-1})(0,\cdot), \end{array} \tag{3.1}$$

where $\mathcal{S}_j$, $j = 1, 2$, are linear operators along the interface in the y direction which we will determine in what follows to get the best possible performance of the new Schwarz algorithm. As for the classical Schwarz method, taking a Fourier transform in the y direction for $f = 0$, we obtain

$$\begin{array}{c} \eta\hat{u}_1^n - \partial_{xx}\hat{u}_1^n + k^2\hat{u}_1^n = 0, \quad x < L,\ k \in \mathbb{R}, \\ (\partial_x + \sigma_1(k))(\hat{u}_1^n)(L,k) = (\partial_x + \sigma_1(k))(\hat{u}_2^{n-1})(L,k), \quad k \in \mathbb{R}, \end{array} \tag{3.2}$$

where $\sigma_1(k)$ denotes the symbol of the operator $\mathcal{S}_1$, and

$$\begin{array}{c} \eta\hat{u}_2^n - \partial_{xx}\hat{u}_2^n + k^2\hat{u}_2^n = 0, \quad x > 0,\ k \in \mathbb{R}, \\ (\partial_x + \sigma_2(k))(\hat{u}_2^n)(0,k) = (\partial_x + \sigma_2(k))(\hat{u}_1^{n-1})(0,k), \quad k \in \mathbb{R}, \end{array} \tag{3.3}$$

where $\sigma_2(k)$ is the symbol of $\mathcal{S}_2$. The solutions on the subdomains are again of the form (2.6), and using the condition on the iterates at infinity, the transmission conditions, and the fact that

$$\frac{\partial\hat{u}_1^n}{\partial x} = \sqrt{k^2+\eta}\,\hat{u}_1^n, \qquad \frac{\partial\hat{u}_2^n}{\partial x} = -\sqrt{k^2+\eta}\,\hat{u}_2^n,$$

we find the subdomain solution in Fourier space to be

$$\hat{u}_1^n(x,k) = \frac{\sigma_1(k) - \sqrt{k^2+\eta}}{\sigma_1(k) + \sqrt{k^2+\eta}} e^{\sqrt{k^2+\eta}(x-L)} \hat{u}_2^{n-1}(L,k),$$
$$\hat{u}_2^n(x,k) = \frac{\sigma_2(k) + \sqrt{k^2+\eta}}{\sigma_2(k) - \sqrt{k^2+\eta}} e^{-\sqrt{k^2+\eta}\,x} \hat{u}_1^{n-1}(0,k).$$

Inserting these solutions into algorithm (3.1), we obtain by induction

$$\hat{u}_1^{2n}(0,k) = \rho_{opt}^n \hat{u}_1^0(0,k), \qquad \hat{u}_2^{2n}(L,k) = \rho_{opt}^n \hat{u}_2^0(L,k), \tag{3.4}$$

where the new convergence factor ρ_{opt} is given by

$$\rho_{opt} = \rho_{opt}(k, L, \eta, \sigma_1, \sigma_2) := \frac{\sigma_1(k) - \sqrt{k^2+\eta}}{\sigma_1(k) + \sqrt{k^2+\eta}} \cdot \frac{\sigma_2(k) + \sqrt{k^2+\eta}}{\sigma_2(k) - \sqrt{k^2+\eta}} e^{-2\sqrt{k^2+\eta}L}. \tag{3.5}$$

The only difference between the new convergence factor ρ_{opt} and the one of the classical Schwarz method, ρ_{cla} given in (2.8), is the factor in front of the exponential. But this factor has a tremendous influence on the performance of the method: choosing for the symbols

$$\sigma_1(k) := \sqrt{k^2+\eta}, \quad \sigma_2(k) := -\sqrt{k^2+\eta}, \tag{3.6}$$

the new convergence factor vanishes identically, $\rho_{opt} \equiv 0$, and the algorithm converges in two iterations, independently of the initial guess, the overlap L, and the problem parameter η. This is an optimal result, since the solution in one subdomain depends on the forcing function f in the other subdomain and hence a first solve is necessary to incorporate the influence of f into the subdomain solution, then one information exchange is performed to give this information to the neighboring subdomain and a second solve on the subdomains incorporates this information into the new subdomain solution. Convergence in less than two steps is not possible. One can also see from (3.6) that the optimal choice depends on the problem. The optimal convergence result for two subdomains in two iterations can be generalized to $J > 2$ subdomains and convergence in J iterations (see, for example, [33] or [16]), provided the subdomains are arranged in a sequence. In addition, with this choice of σ_j, the exponential factor in the convergence factor becomes irrelevant and we can have Schwarz methods without overlap.

To use the optimal choice of σ_j in practice, we need to back-transform the transmission conditions involving σ_1 and σ_2 from the Fourier domain into the physical domain to obtain the transmission operators $\mathcal{S}_1$ and $\mathcal{S}_2$. Hence we need

$$\mathcal{S}_1(u_1^n) = \mathcal{F}_k^{-1}(\sigma_1 \hat{u}_1^n), \qquad \mathcal{S}_2(u_2^n) = \mathcal{F}_k^{-1}(\sigma_2 \hat{u}_2^n), \tag{3.7}$$

and thus for the optimal choice of σ_j we have to evaluate a convolution in each step of the algorithm, because the σ_j contain a square root and thus the optimal $\mathcal{S}_j$ are nonlocal operators, as advocated in [24]. If the symbols σ_j were, however, polynomials in ik, then the operators $\mathcal{S}_j$ would consist of derivatives in y and thus be local operators. We will therefore approximate the optimal choice of σ_j by polynomials in the following sections, which leads to the new class of optimized Schwarz methods.

4. Optimized Schwarz algorithms. We approximate the symbols of the optimal transmission conditions found in (3.6) by polynomial symbols in ik which corresponds to local approximations. We choose polynomials of degree two here,

$$\sigma_1^{app}(k) = p_1 + q_1 k^2, \quad \sigma_2^{app}(k) = -p_2 - q_2 k^2. \tag{4.1}$$

Note that we do not consider a first order term, because the operator of the underlying problem is self-adjoint. Higher order approximations would be possible as well, as long as the subdomain problems remain well posed. With the approximation (4.1), the convergence factor of the optimized Schwarz algorithm becomes

$$\rho = \rho(k, L, \eta, p_1, p_2, q_1, q_2) = \frac{\sqrt{k^2+\eta} - p_1 - q_1 k^2}{\sqrt{k^2+\eta} + p_1 + q_1 k^2} \cdot \frac{\sqrt{k^2+\eta} - p_2 - q_2 k^2}{\sqrt{k^2+\eta} + p_2 + q_2 k^2} e^{-2\sqrt{k^2+\eta}L}. \tag{4.2}$$

THEOREM 4.1. *The optimized Schwarz method* (3.1) *with transmission conditions defined by the symbols* (4.1) *converges for* $p_j > 0$, $q_j \geq 0$, $j = 1, 2$, *faster than the classical Schwarz method* (2.3), $|\rho_{opt}(k)| < |\rho_{cla}(k)|$ *for all* k.

Proof. The only difference between ρ_{cla} in (2.8) and ρ_{opt} in (4.2) is the additional factor in front of the exponential, which satisfies for $p_j > 0$ and $q_j \geq 0$

$$\left| \frac{\sqrt{k^2+\eta} - p_1 - q_1 k^2}{\sqrt{k^2+\eta} + p_1 + q_1 k^2} \cdot \frac{\sqrt{k^2+\eta} - p_2 - q_2 k^2}{\sqrt{k^2+\eta} + p_2 + q_2 k^2} \right| < 1 \quad \forall k,$$

and hence $|\rho(k)| < |\rho_{cla}(k)|$ for all k. ∎

The goal of optimized Schwarz methods is now to choose the free parameters $p_j, q_j \geq 0$ for $j = 1, 2$ to further improve the performance of the method.

4.1. Low-frequency approximations. As we have seen, the classical Schwarz method is effective, due to the overlap, for high frequencies but ineffective for low frequencies. The low frequencies can, however, be treated in the new Schwarz algorithm with the transmission conditions: expanding the symbols $\sigma_j(k)$ of the optimal operators $\mathcal{S}_j$ in a Taylor series, we find

$$\sigma_1(k) = \sqrt{\eta} + \frac{1}{2\sqrt{\eta}} k^2 + O(k^4), \qquad \sigma_2(k) = -\sqrt{\eta} - \frac{1}{2\sqrt{\eta}} k^2 + O(k^4), \tag{4.3}$$

and hence a second order Taylor approximation would lead to the values $p_1 = p_2 = \sqrt{\eta}$, $q_1 = q_2 = \frac{1}{2\sqrt{\eta}}$, whereas a zeroth order approximation could be obtained by setting $q_1 = q_2 = 0$ for the same values of p_j. The corresponding optimized Schwarz methods have the convergence factors

$$\begin{aligned} \rho_{T0}(k, L, \eta) &= \left(\frac{\sqrt{k^2+\eta} - \sqrt{\eta}}{\sqrt{k^2+\eta} + \sqrt{\eta}} \right)^2 e^{-2\sqrt{k^2+\eta}L}, \\ \rho_{T2}(k, L, \eta) &= \left(\frac{\sqrt{k^2+\eta} - \sqrt{\eta} - \frac{1}{2\sqrt{\eta}} k^2}{\sqrt{k^2+\eta} + \sqrt{\eta} + \frac{1}{2\sqrt{\eta}} k^2} \right)^2 e^{-2\sqrt{k^2+\eta}L}, \end{aligned} \tag{4.4}$$

where we used the index $T0$ to denote a Taylor approximation of order zero and $T2$ to denote a Taylor approximation of order two of the optimal symbol in the transmission condition. Figure 4.1 shows on the left the convergence factors obtained with this

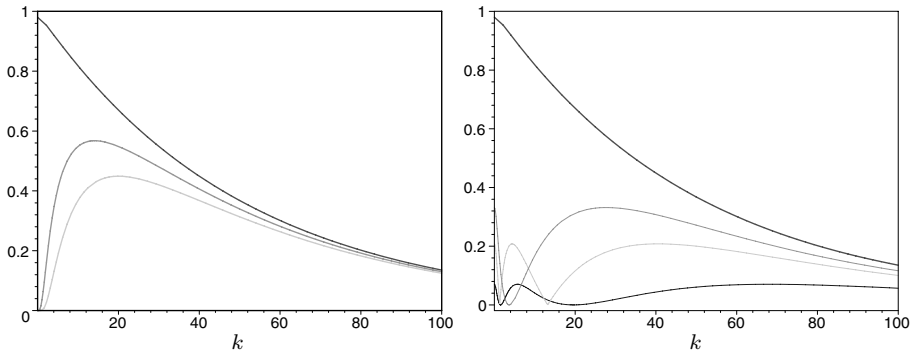

FIG. 4.1. *Convergence factor ρ_{cla} of the classical Schwarz method (top curve) as a function of k, compared on the left to ρ_{T0} (middle curve) and ρ_{T2} (bottom curve) of the optimized Schwarz methods with zeroth and second order transmission conditions, respectively, obtained by Taylor expansion, and on the right compared to the OO0 and OO2 Schwarz methods, and the optimized Schwarz method with two-sided optimized Robin transmission conditions, which lies in between OO0 and OO2.*

choice of transmission conditions for the model problem with two subdomains, overlap $L = \frac{1}{100}$ and problem parameter $\eta = 1$, together with the classical convergence factor ρ_{cla}. First one can clearly see that the optimized Schwarz methods are uniformly better than the classical Schwarz method; in particular the low-frequency behavior is greatly improved. The maximum of the convergence factor of classical Schwarz is about 0.980, whereas the maximum of the convergence factor with zeroth order Taylor condition is 0.568 and the maximum with second order Taylor condition is 0.449 in this example. Hence the classical Schwarz method needs about 28 iterations to obtain the contraction factor of one iteration of the optimized Schwarz method with zeroth order Taylor conditions, and about 40 iterations are needed to obtain the contraction of one iteration of the optimized Schwarz method with second order transmission conditions from Taylor expansion.

As we mentioned earlier, the classical Schwarz method does not converge without overlap: for $L = 0$ we obtain $\rho_{cla}(k, 0, \eta) = 1$ and hence convergence is lost for all modes. Optimized Schwarz methods, however, can be used without overlap, and nonoverlapping Schwarz methods can be of great interest, if the physical properties in the subdomains differ, for example, when there are jumps in the coefficients of the equation as in [20] or the nature of the equations changes, like in the case of coupling of hyperbolic and parabolic problems; see, for example, [18] and references therein. If we set $L = 0$ in the convergence factor (4.4) of the optimized Schwarz method, the exponential term becomes one, but the factor in front remains unchanged, and thus $\rho_{T0}(k, 0, \eta) < 1$ and $\rho_{T2}(k, 0, \eta) < 1$ for all k. In a numerical implementation there is a maximum frequency which can be represented on a grid with grid spacing h. An estimate for this maximum frequency is $k_{\max} = \frac{\pi}{h}$. Hence the slowest convergence for the optimized Schwarz method without overlap and Taylor transmission conditions is obtained for the highest frequency: the method is a rougher as opposed to the smoother the classical Schwarz method is.

In practice, even when using the Schwarz method with overlap, the overlap is often only a few grid cells wide, and thus $L = O(h)$. In that case the convergence factor of the classical Schwarz method deteriorates as well as one refines the mesh and h goes to zero and we have the following comparison theorem.

THEOREM 4.2. *The optimized Schwarz methods with Taylor transmission conditions and overlap $L = h$ have an asymptotically superior performance than the*

classical Schwarz method with the same overlap. As h goes to zero, we have

$$\max_{|k|\le\frac{\pi}{h}} |\rho_{cla}(k,h,\eta)| = 1 - 2\sqrt{\eta}h + O(h^2), \tag{4.5}$$

$$\max_{|k|\le\frac{\pi}{h}} |\rho_{T0}(k,h,\eta)| = 1 - 4\sqrt{2}\eta^{\frac{1}{4}}\sqrt{h} + O(h), \tag{4.6}$$

$$\max_{|k|\le\frac{\pi}{h}} |\rho_{T2}(k,h,\eta)| = 1 - 8\eta^{\frac{1}{4}}\sqrt{h} + O(h). \tag{4.7}$$

Without overlap, the optimized Schwarz methods with Taylor transmission conditions are asymptotically comparable to the classical Schwarz method with overlap $L = h$. As h goes to zero, we have

$$\max_{|k|\le\frac{\pi}{h}} |\rho_{T0}(k,0,\eta)| = 1 - 4\frac{\sqrt{\eta}}{\pi}h + O(h^2), \tag{4.8}$$

$$\max_{|k|\le\frac{\pi}{h}} |\rho_{T2}(k,0,\eta)| = 1 - 8\frac{\sqrt{\eta}}{\pi}h + O(h^2). \tag{4.9}$$

Proof. For the second result it suffices to expand the convergence factors (4.4) for $L = 0$ at $k = k_{\max} = \frac{\pi}{h}$ for h small. Similarly for the classical Schwarz method one expands the convergence factor (2.8) with $L = h$ for h small at $k = 0$. For the optimized Schwarz methods with Taylor transmission conditions and overlap $L = h$, the convergence factors (4.4) attain their maximum in the interior, at

$$\bar{k}_{T0} = \frac{\sqrt{2}\eta^{\frac{1}{4}}}{\sqrt{L}} \quad \text{and} \quad \bar{k}_{T2} = \frac{2\eta^{\frac{1}{4}}}{\sqrt{L}},$$

respectively, as a direct computation shows. Hence with overlap $L = h$, these maxima are in the range of the computational frequencies, since they are smaller than $k_{\max} = \frac{\pi}{h}$ and thus relevant for the convergence factor. Expanding the corresponding convergence factor at these maxima for $L = h$ as h goes to zero leads to the results (4.8) and (4.9). ∎

Hence already for Taylor expansions of the optimal symbols in the transmission conditions the asymptotic performance of the new Schwarz method is better than the one of the classical Schwarz method when the overlap is of the order of the mesh parameter, which is often the case in applications. One can, however, also see that increasing the order of the Taylor approximation does not increase the asymptotic performance further—there is only an initial gain from h to $\sqrt{h}$. This changes with the approach described in the next subsection.

4.2. Uniformly optimized approximations. We now develop an even better choice for the transmission conditions: one can choose the parameters p_j and q_j to optimize the performance of the new Schwarz method, which means minimizing the convergence factor over all frequencies relevant to the problem. For the zeroth order transmission condition we have the min-max problem

$$\min_{p_j\ge 0}\left(\max_{k_{\min}\le k\le k_{\max}}\left|\frac{\sqrt{\eta+k^2}-p_1}{\sqrt{\eta+k^2}+p_1}\right|\left|\frac{\sqrt{\eta+k^2}-p_2}{\sqrt{\eta+k^2}+p_2}\right|e^{-2\sqrt{\eta+k^2}L}\right), \tag{4.10}$$

and for the second order optimized Schwarz method the min-max problem is

$$\min_{p_j,q_j\ge 0}\left(\max_{k_{\min}\le k\le k_{\max}}\left|\frac{\sqrt{\eta+k^2}-p_1-q_1k^2}{\sqrt{\eta+k^2}+p_1+q_1k^2}\right|\left|\frac{\sqrt{\eta+k^2}-p_2-q_2k^2}{\sqrt{\eta+k^2}+p_2+q_2k^2}\right|e^{-2\sqrt{\eta+k^2}L}\right), \tag{4.11}$$

where we have also introduced a lower bound $k_{\min}$ on the frequency range. This is useful for bounded subdomains: if, for example, the subdomains Ω_j were strips of width 1 in the y direction with homogeneous Dirichlet boundary conditions, then the lowest possible frequency on those domains would be $k_{\min} = \pi$, as one can see from a sine expansion. More general, if one uses a coarse grid, which is necessary as soon as one has many subdomains for good performance on elliptic problems, then the highest frequency representable on the coarse grid would be an estimate for $k_{\min}$, since the subdomain iteration does not need to be effective on the coarse grid frequencies.

Since the optimal transmission conditions (3.6) are of the same size with opposite signs, we first analyze the simpler optimization problems when the approximation of the optimal transmission conditions is also of the same size with opposite signs, which means $p_1 = p_2 = p$ and $q_1 = q_2 = q$. In subsection 4.3 we will analyze how much is lost in performance due to this simplifying assumption.

4.2.1. Zeroth order optimized transmission conditions. Using the same zeroth order transmission condition on both sides of the interface, $p_1 = p_2 = p$ and $q_1 = q_2 = 0$, the expression (4.2) of the convergence factor simplifies to

$$\rho_{OO0}(k, L, \eta, p) := \left(\frac{\sqrt{k^2+\eta} - p}{\sqrt{k^2+\eta} + p}\right)^2 e^{-2\sqrt{k^2+\eta}L}. \tag{4.12}$$

To determine the optimal parameter p of the associated optimized Schwarz method (which we call OO0 for "Optimized of Order 0"), we have to solve the min-max problem

$$\min_{p\geq 0}\left(\max_{k_{\min}\leq k\leq k_{\max}} |\rho_{OO0}(k, L, \eta, p)|\right) = \min_{p\geq 0}\left(\max_{k_{\min}\leq k\leq k_{\max}} \left(\frac{\sqrt{\eta+k^2} - p}{\sqrt{\eta+k^2} + p}\right)^2 e^{-2\sqrt{\eta+k^2}L}\right). \tag{4.13}$$

The following Lemma will be needed for several of the results on the min-max problems that arise in the optimization of the new Schwarz methods.

LEMMA 4.3. *Let $f(x,\gamma)$ be a continuously differentiable function, $f : [a,b] \times [c,d] \mapsto \mathbb{R}$, with a unique interior maximum in x at $x^*(\gamma) \in (a,b)$ for each $\gamma \in [c,d]$, $\frac{\partial f}{\partial x}(x^*(\gamma),\gamma) = 0$, and assume that $x^*(\gamma)$ is differentiable and $\frac{\partial f}{\partial \gamma} < 0$ for $x \in [a,b]$, $\gamma \in [c,d]$. Then*

$$\frac{df}{d\gamma}(x^*(\gamma),\gamma) < 0 \quad \forall \gamma \in [c,d].$$

Proof. Since $\frac{\partial f}{\partial x}(x^*(\gamma),\gamma) = 0$ for all $\gamma \in [c,d]$, we have

$$\frac{df}{d\gamma}(x^*(\gamma),\gamma) = \frac{\partial f}{\partial \gamma}(x^*(\gamma),\gamma) + \frac{\partial f}{\partial x}(x^*(\gamma),\gamma)\frac{\partial x^*}{\partial \gamma}(\gamma) = \frac{\partial f}{\partial \gamma}(x^*(\gamma),\gamma) < 0$$

by assumption on the partial derivative with respect to γ. ∎

THEOREM 4.4 (optimal Robin parameter). *For $L > 0$ and $k_{\max} = \infty$, the solution p^* of the min-max problem (4.13) is given by the unique root of the equation*

$$\rho_{OO0}(k_{\min}, L, \eta, p^*) = \rho_{OO0}(\bar{k}(p^*), L, \eta, p^*), \qquad \bar{k}(L,\eta,p) = \frac{\sqrt{L(2p + L(p^2-\eta))}}{L}. \tag{4.14}$$

For $L = 0$ and $k_{\max}$ finite, the optimal parameter p^* is given by

$$p^* = ((k_{\min}^2 + \eta)(k_{\max}^2 + \eta))^{\frac{1}{4}}. \tag{4.15}$$

Proof. The key idea is to use a transformation: the partial derivative of ρ_{OO0} with respect to p is

$$\frac{\partial \rho_{OO0}}{\partial p} = 4\frac{(p - \sqrt{k^2+\eta})\sqrt{k^2+\eta}e^{-2\sqrt{k^2+\eta}L}}{(\sqrt{k^2+\eta}+p)^3},$$

which shows that as long as $p < \sqrt{k_{\min}^2 + \eta}$, increasing p decreases ρ_{OO0} for all $k \in [k_{\min}, \infty)$. Hence one can restrict the range for p in the min-max problem to $p \geq \sqrt{k_{\min}^2 + \eta}$, the solution cannot lie outside this range. This implies that for the new range of p, ρ_{OO0} has a unique zero in $[k_{\min}, \infty)$, namely, at $k = k_1 = \sqrt{p^2 - \eta}$. We can thus transform the min-max problem into a new, equivalent one in the parameter k_1. Defining the function

$$R(k, L, \eta, k_1) := \frac{(\sqrt{k^2+\eta} - \sqrt{k_1^2+\eta})}{\sqrt{k^2+\eta} + \sqrt{k_1^2+\eta}} e^{-\sqrt{k^2+\eta}L}, \tag{4.16}$$

which is negative for $k \in [k_{\min}, k_1)$ and positive for $k > k_1$, the new min-max problem which is equivalent to (4.13) is

$$\min_{k_1 \geq k_{\min}} \left(\max_{k_{\min} \leq k \leq k_{\max}} |R(k, L, \eta, k_1)| \right).$$

Now in the case of overlap, $L > 0$, the derivative with respect to k,

$$\frac{\partial R}{\partial k} = \frac{k e^{-\sqrt{k^2+\eta}L}(2\sqrt{k_1^2+\eta} - Lk^2 + Lk_1^2)}{(\sqrt{k^2+\eta} + \sqrt{k_1^2+\eta})^2\sqrt{k^2+\eta}}$$

shows that the function has a maximum at

$$\bar{k} = \bar{k}(k_1) = \sqrt{\frac{2\sqrt{k_1^2+\eta}}{L} + k_1^2} > k_1.$$

Hence the maximum in the min-max problem can be attained either at $k = k_{\min}$ or at $k = \bar{k}$. Since

$$\frac{\partial R}{\partial k_1} = -2\frac{k_1 e^{-\sqrt{k^2+\eta}L}\sqrt{k^2+\eta}}{(\sqrt{k^2+\eta} + \sqrt{k_1^2+\eta})^2\sqrt{k_1^2+\eta}} < 0, \tag{4.17}$$

the function R decreases monotonically with k_1. For $k_1 = k_{\min}$ we have $0 = |R(k_{\min}, L, \eta, k_{\min})| < R(\bar{k}, L, \eta, k_{\min})$ and for k_1 large, we have $|R(k_{\min}, L, \eta, k_1)| > R(\bar{k}, L, \eta, k_1)$, since in the limit as k_1 goes to infinity, $R(\bar{k}(k_1), L, \eta, k_1)$ goes to zero. By continuity there exists at least one k_1^* such that $-R(k_{\min}, L, \eta, k_1^*) = R(\bar{k}, L, \eta, k_1^*)$. Using now that R decreases monotonically in k_1, we have that $|R(k_{\min}, L, \eta, k_1)|$ increases monotonically with k_1 and by Lemma 4.3 that $R(\bar{k}(k_1), L, \eta, k_1)$ decreases monotonically with k_1. Hence k_1^* is unique and therefore the unique solution of the min-max problem. Back-transforming to the p variable gives the first result of the theorem.

In the case without overlap, $L = 0$, the function R has no interior maximum, hence the maximum can be attained only on the boundary at either $k = k_{\min}$ or at $k = k_{\max}$. Since the sign of the derivative (4.17) remains the same for $L = 0$, the function R decreases monotonically with k_1. For $k_1 = k_{\min}$ we have $0 = |R(k_{\min}, 0, \eta, k_{\min})| < R(k_{\max}, 0, \eta, k_{\min})$ and for $k_1 = k_{\max}$, we have $|R(k_{\min}, L, \eta, k_{\max})| > R(k_{\max}, L, \eta, k_{\max}) = 0$. By continuity there exists at least one k_1^* such that

$$-R(k_{\min}, 0, \eta, k_1^*) = R(k_{\max}, 0, \eta, k_1^*) \tag{4.18}$$

and since R decreases monotonically in k_1, we have that $|R(k_{\min}, L, \eta, k_1)|$ increases monotonically with k_1 and $R(k_{\max}, L, \eta, k_1)$ decreases monotonically with k_1. Hence k_1^* is unique and thus the unique solution of the min-max problem. Solving (4.18) and back-transforming the result to the p variable leads then to the second result of the theorem. ∎

Figure 4.1 shows on the right the convergence factors obtained with the optimized Robin transmission condition for the model problem with overlap $L = \frac{1}{100}$ and $\eta = 1$, comparing the classical Schwarz method and the OO0 Schwarz method. The maximum of the convergence factor of the OO0 Schwarz method is 0.332, which means that about 55 iterations of the classical Schwarz method with convergence factor 0.980 are needed to attain the performance of the OO0 Schwarz method.

THEOREM 4.5 (Robin asymptotics). *The asymptotic performance of the new Schwarz method with optimized Robin transmission conditions and overlap $L = h$, as h goes to zero, is given by*

$$\max_{k_{\min} \le |k| \le \frac{\pi}{h}} |\rho_{OO0}(k, h, \eta, p^*)| = 1 - 4 \cdot 2^{\frac{1}{6}} (k_{\min}^2 + \eta)^{\frac{1}{6}} h^{\frac{1}{3}} + O(h^{\frac{2}{3}}). \tag{4.19}$$

The asymptotic performance without overlap, $L = 0$, is given by

$$\max_{k_{\min} \le |k| \le \frac{\pi}{h}} |\rho_{OO0}(k, 0, \eta, p^*)| = 1 - 4 \frac{(k_{\min}^2 + \eta)^{\frac{1}{4}}}{\sqrt{\pi}} \sqrt{h} + O(h). \tag{4.20}$$

Proof. For the first result, we need to find an asymptotic expansion for the optimal parameter p^* for small h from (4.14). We make the ansatz $p^* = Ch^\alpha$ for $\alpha < 0$, since we know from Theorem 4.4 that the optimal parameter is growing when h diminishes. Inserting this ansatz into (4.14) satisfied by p^* and expanding for small h, we find the leading order terms in the equation to be $4C\sqrt{k_{\min}^2 + \eta} h^\alpha - 4\sqrt{2} C^{\frac{5}{2}} h^{\frac{5}{2}\alpha + \frac{1}{2}}$. Since (4.14) holds for all h, this expression must vanish and hence both the exponents and the coefficients must match, which leads to

$$\alpha = -\frac{1}{3}, \quad C = \frac{(4(k_{\min}^2 + \eta))^{\frac{1}{3}}}{2}$$

and hence the optimal parameter p^* behaves asymptotically like

$$p^* = \frac{(4(k_{\min}^2 + \eta))^{\frac{1}{3}}}{2} h^{-\frac{1}{3}}. \tag{4.21}$$

With this asymptotic behavior of p^*, the interior maximum $\bar{k}$ behaves asymptotically like

$$\bar{k} = (4(k_{\min}^2 + \eta^2)^{\frac{1}{6}} h^{-\frac{2}{3}}, \tag{4.22}$$

which is less than $k_{\max} = \frac{\pi}{h}$ for h small and hence the optimal result given for $k_{\max} = \infty$ in (4.14) is indeed asymptotically the relevant one on the bounded frequency range $|k| \leq k_{\max} = \frac{\pi}{h}$ for $L = O(h)$. Now inserting the asymptotic value of the optimal parameter p^* from (4.21) into the convergence factor (4.12) and expanding at $k = k_{\min}$ leads to (4.19).

For the second result where $L = 0$, the optimal parameter p^* is known in closed form from (4.15) and hence it suffices to insert this p^* into the convergence factor (4.12), to set $k_{\max} = \frac{\pi}{h}$, and to expand the result at $k = k_{\min}$ in a series for small h to find (4.20). ∎

4.2.2. Second order optimized transmission conditions. Using the same second order transmission condition on both sides of the interface, $p_1 = p_2 = p$ and $q_1 = q_2 = q$, the expression (4.2) of the convergence factor simplifies to

$$\rho_{OO2}(k, L, \eta, p, q) := \left(\frac{\sqrt{k^2 + \eta} - p - qk^2}{\sqrt{k^2 + \eta} + p + qk^2} \right)^2 e^{-2\sqrt{k^2+\eta}L}. \tag{4.23}$$

To determine the optimal parameters p and q for the associated Schwarz method (which we call OO2 for "Optimized of Order 2," a term introduced in [25]), we have to solve the min-max problem

$$\begin{aligned} &\min_{p,q \geq 0} \left(\max_{k_{\min} \leq k \leq k_{\max}} |\rho_{OO2}(k, L, \eta, p, q)| \right) \\ &\quad = \min_{p,q \geq 0} \left(\max_{k_{\min} \leq k \leq k_{\max}} \left(\frac{\sqrt{\eta + k^2} - p - qk^2}{\sqrt{\eta + k^2} + p + qk^2} \right)^2 e^{-2\sqrt{\eta+k^2}L} \right). \end{aligned} \tag{4.24}$$

We need a second technical lemma for the analysis of the optimal parameters.

LEMMA 4.6. *Let $R_1(k_1, k_2)$ and $R_2(k_1, k_2)$ be two continuously differentiable functions, $R_j : \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}$, $j = 1, 2$, such that the partial derivatives satisfy*

$$\frac{\partial R_1}{\partial k_1} < 0, \quad \frac{\partial R_1}{\partial k_2} < 0, \quad \frac{\partial R_2}{\partial k_1} < 0, \quad \frac{\partial R_2}{\partial k_2} > 0 \tag{4.25}$$

and assume that there exists a unique differentiable $k_1^*(k_2)$ such that

$$R_1(k_1^*(k_2), k_2) + R_2(k_1^*(k_2), k_2) = 0. \tag{4.26}$$

Then we must have

$$\frac{dR_2}{dk_2}(k_1^*(k_2), k_2) > 0. \tag{4.27}$$

Proof. Using implicit differentiation of (4.26), we find

$$\frac{dk_1^*}{dk_2}(k_2) = -\frac{\frac{\partial R_1}{\partial k_2}(k_1^*(k_2), k_2) + \frac{\partial R_2}{\partial k_2}(k_1^*(k_2), k_2)}{\frac{\partial R_1}{\partial k_1}(k_1^*(k_2), k_2) + \frac{\partial R_2}{\partial k_1}(k_1^*(k_2), k_2)}$$

and inserting this result into the total derivative, we obtain

$$\begin{aligned} \frac{dR_2}{dk_2}(k_1^*(k_2), k_2) &= \frac{\partial R_2}{\partial k_1}(k_1^*(k_2), k_2) \frac{dk_1^*}{dk_2}(k_2) + \frac{\partial R_2}{\partial k_2}(k_1^*(k_2), k_2) \\ &= \frac{-\frac{\partial R_2}{\partial k_1}(k_1^*(k_2), k_2) \frac{\partial R_1}{\partial k_2}(k_1^*(k_2), k_2) + \frac{\partial R_2}{\partial k_1}(k_1^*(k_2), k_2) \frac{\partial R_1}{\partial k_1}(k_1^*(k_2), k_2)}{\frac{\partial R_1}{\partial k_1}(k_1^*(k_2), k_2) + \frac{\partial R_2}{\partial k_1}(k_1^*(k_2), k_2)} \\ &> 0 \end{aligned}$$

using the assumption on the signs of the partial derivatives. ∎

THEOREM 4.7 (optimal second order parameters). *For $L > 0$ and $k_{\max} = \infty$, the solution p^*, q^* of the min-max problem* (4.24) *is given by the unique root of the system of equations*

$$\rho_{OO2}(k_{\min}, L, \eta, p^*, q^*) = \rho_{OO2}(\bar{k}_1, L, \eta, p^*, q^*) = \rho_{OO2}(\bar{k}_2, L, \eta, p^*, q^*), \tag{4.28}$$

where the locations of the maxima $\bar{k}_1$ and $\bar{k}_2$ are given by

$$\bar{k}_{1,2}(L,\eta,p,q) = \frac{1}{q}\sqrt{\frac{L+2q-2Lpq \mp \sqrt{L^2+4Lq-4L^2pq+4q^2-16Lpq^2+16Lq^3\eta+4L^2q^2\eta}}{2L}}. \tag{4.29}$$

For $L = 0$ and $k_{\max}$ finite, the optimal parameters p^* and q^* are given by

$$p^* = \frac{k_{\max}^2\sqrt{k_{\min}^2+\eta}-k_{\min}^2\sqrt{k_{\max}^2+\eta}}{\sqrt{2(k_{\max}^2-k_{\min}^2)}\left(\left(\sqrt{k_{\max}^2+\eta}-\sqrt{k_{\min}^2+\eta}\right)\left((k_{\max}^2+\eta)\sqrt{k_{\min}^2+\eta}-(k_{\min}^2+\eta)\sqrt{k_{\max}^2+\eta}\right)\right)^{\frac{1}{4}}}, \tag{4.30}$$

$$q^* = \frac{\left(\sqrt{k_{\max}^2+\eta}-\sqrt{k_{\min}^2+\eta}\right)^{\frac{3}{4}}}{\sqrt{2(k_{\max}^2-k_{\min}^2)}\left((k_{\max}^2+\eta)\sqrt{k_{\min}^2+\eta}-(k_{\min}^2+\eta)\sqrt{k_{\max}^2+\eta}\right)^{\frac{1}{4}}}.$$

Proof. The argument is again based on a transformation: the partial derivatives of ρ_{OO2} with respect to p and q are

$$\frac{\partial \rho_{OO2}}{\partial p} = 4\sqrt{k^2+\eta}\,\frac{p+qk^2-\sqrt{k^2+\eta}}{(p+qk^2+\sqrt{k^2+\eta})^3}e^{-2\sqrt{k^2+\eta}L}, \quad \frac{\partial \rho_{OO2}}{\partial q} = k^2\frac{\partial \rho_{OO2}}{\partial p}, \tag{4.31}$$

and hence ρ_{OO2} is monotonically decreasing when p and q are decreased for all $k > k_{\min}$ as long as $p + qk^2 > \sqrt{k^2+\eta}$. This implies that at the solution of the min-max problem ρ_{OO2} must have at least one zero $k_1 > k_{\min}$. Then instead of using the parameter p, we can use equivalently the parameter k_1 in the min-max problem by setting $p := \sqrt{k_1+\eta} - qk_1^2$, which leads to the new form of the convergence factor

$$\rho'_{OO2} = \frac{(\sqrt{k_1^2+\eta}-\sqrt{k^2+\eta}+q(k^2-k_1^2))^2}{(\sqrt{k^2+\eta}+\sqrt{k_1^2+\eta}+q(k^2-k_1^2))^2}e^{-2\sqrt{k^2+\eta}L},$$

which has now necessarily a zero at $k_1 > k_{\min}$. If we suppose that k_1 is the only zero at the optimum, we reach again a contradiction, because a partial derivative with respect to q gives

$$\frac{\partial \rho'_{OO2}}{\partial q} = 4\sqrt{k^2+\eta}(k^2-k_1^2)\frac{\sqrt{k_1^2+\eta}-\sqrt{k^2+\eta}+q(k^2-k_1^2)}{(\sqrt{k^2+\eta}+\sqrt{k_1^2+\eta}+q(k^2-k_1^2))^3}e^{-2\sqrt{k^2+\eta}L},$$

where the denominator is positive, since $\sqrt{k_1+\eta} - qk_1^2 = p \geq 0$, and the numerator changes sign only at $k = k_1$ by assumption, which together with the factor $(k^2 - k_1^2)$ in front makes the sign of the derivative negative for all $q > 0$ as long as there is only one zero at k_1. Thus increasing q the convergence factor ρ'_{OO2} can be decreased for all $k > k_{\min}$ as long as there is no second zero. Hence at the optimum, ρ'_{OO2} must have a second zero, without loss of generality at $k_2 \geq k_1 > k_{\min}$. Thus we can use the parameter k_2 instead of q, which leads to the change of variables

$$p = \frac{\sqrt{k_1^2+\eta}k_2^2 - k_1^2\sqrt{k_2^2+\eta}}{k_2^2-k_1^2}, \quad q = \frac{\sqrt{k_2^2+\eta}-\sqrt{k_1^2+\eta}}{k_2^2-k_1^2} \tag{4.32}$$

and the new min-max problem, which is equivalent to (4.24), is

$$\min_{k_{\min}<k_1\le k_2}\left(\max_{k_{\min}\le k\le k_{\max}}|R(k,L,\eta,k_1,k_2)|\right), \tag{4.33}$$

with the new function $R(k,L,\eta,k_1,k_2)$, representing the square root of the convergence factor, given by

$$R(k,L,\eta,k_1,k_2) = \frac{\sqrt{k^2+\eta}(k_2^2-k_1^2)-(\sqrt{k_1^2+\eta}k_2^2-\sqrt{k_2^2+\eta}k_1^2)-(\sqrt{k_2^2+\eta}-\sqrt{k_1^2+\eta})k^2}{\sqrt{k^2+\eta}(k_2^2-k_1^2)+(\sqrt{k_1^2+\eta}k_2^2-\sqrt{k_2^2+\eta}k_1^2)+(\sqrt{k_2^2+\eta}-\sqrt{k_1^2+\eta})k^2}e^{-\sqrt{k^2+\eta}L}. \tag{4.34}$$

Taking the partial derivatives with respect to k_1 and k_2, we find

$$\frac{\partial R}{\partial k_1} = \frac{2k_1(k^2-k_2^2)\sqrt{k^2+\eta}\left(\sqrt{k_2^2+\eta}-\sqrt{k_1^2+\eta}\right)^2}{\sqrt{k_1^2+\eta}\left(\sqrt{k^2+\eta}(k_1^2-k_2^2)+\sqrt{k_1^2+\eta}(k^2-k_2^2)+(k_1^2-k^2)\sqrt{k_2^2+\eta}\right)^2}e^{-\sqrt{k^2+\eta}L}, \tag{4.35}$$

$$\frac{\partial R}{\partial k_2} = \frac{2k_2(k^2-k_1^2)\sqrt{k^2+\eta}\left(\sqrt{k_2^2+\eta}-\sqrt{k_1^2+\eta}\right)^2}{\sqrt{k_2^2+\eta}\left(\sqrt{k^2+\eta}(k_1^2-k_2^2)+\sqrt{k_1^2+\eta}(k^2-k_2^2)+(k_1^2-k^2)\sqrt{k_2^2+\eta}\right)^2}e^{-\sqrt{k^2+\eta}L}, \tag{4.36}$$

which shows that for $k<k_2$, the function R is decreasing when k_1 is increasing and for $k>k_2$ it is increasing with k_1. Similarly for $k<k_1$, the function R is decreasing when k_2 is increasing, and for $k>k_1$ it is increasing with k_2.

Now for $L>0$, $R=(-1+O(\frac{1}{k}))e^{-Lk}$ as k goes to infinity. Hence the maximum in the min-max problem can be attained, by continuity of R and knowing that there are two zeros at $k_1,k_2>k_{\min}$, either at $k_{\min}$, where R is negative, or at $k=\bar{k}_1$ given in (4.29), where R has a maximum, $k_1\le\bar{k}_1\le k_2$, or at $k=\bar{k}_2$ given in (4.29), where R has a negative minimum, $k_2\le\bar{k}_2$. To show that the solution of the min-max problem is indeed when the three are balanced, we first note that for any fixed k_2, there exists a unique $k_1^*=k_1^*(k_2)\in[k_{\min},k_2]$ such that $|R(k_{\min},L,\eta,k_1^*(k_2),k_2)|=R(\bar{k}_1,L,\eta,k_1^*(k_2),k_2)$, because of continuity and $0=|R(k_{\min},L,\eta,k_{\min},k_2)|<R(\bar{k}_1,L,\eta,k_{\min},k_2)$ and $|R(k_{\min},L,\eta,k_2,k_2)|>R(\bar{k}_1,L,\eta,k_2,k_2)=R(k_2,L,\eta,k_2,k_2)=0$, and $|R(k_{\min},L,\eta,k_1,k_2)|$ is monotonically increasing with k_1 by (4.35) and $R(\bar{k}_1,L,\eta,k_1,k_2)$ is monotonically decreasing in k_1 by (4.35) and Lemma 4.3. Hence denoting by $R_1(k_1,k_2):=R(k_{\min},L,\eta,k_1,k_2)$ and $R_2(k_1,k_2):=R(\bar{k}_1,L,\eta,k_1,k_2)$ Lemma 4.6 applies and therefore $|R(k_{\min},L,\eta,k_1^*(k_2),k_2)|=R(\bar{k}_1,L,\eta,k_1^*(k_2),k_2)$ is monotonically increasing with k_2. Now for $k_2=k_{\min}$, we have $k_1^*(k_{\min})=k_{\min}$ and thus $0=|R(k_{\min},L,\eta,k_{\min},k_{\min})|<|R(\bar{k}_2,L,\eta,k_{\min},k_{\min})|$ and for large k_2 we have $|R(k_{\min},L,\eta,k_1^*(k_2),k_2)|>|R(\bar{k}_2,L,\eta,k_1^*(k_2),k_2)|$ (since the right-hand term goes to zero in the limit). Therefore by continuity, Lemma 4.6 for $|R(k_{\min},L,\eta,k_1^*(k_2),k_2)|$ and Lemma 4.3 for $|R(\bar{k}_2,L,\eta,k_1^*(k_2),k_2)|$ (note that $(k_1^*)'\ge 0$), there exists a unique k_2^* where these two expressions are equal, $|R(k_{\min},L,\eta,$

$k_1^*(k_2^*), k_2^*)| = |R(\bar{k}_2, L, \eta, k_1^*(k_2^*), k_2^*)|$, which is the unique solution of the min-max problem. Back-transforming to the p and q variables using (4.32) we obtain the equations for the solution of the min-max problem given in (4.28).

In the case without overlap, $L = 0$, the function R behaves for large k like $-1+O(\frac{1}{k})$ and hence the maximum in the min-max problem for $L = 0$ can be attained either at $k_{\min}$, $k_{\max}$, or at the interior maximum $\bar{k}_1$ which satisfies $k_1 \le \bar{k}_1 \le k_2$ and is given in the p and q variables by

$$\bar{k}_1 = \frac{\sqrt{q(p - 2q\eta)}}{q}.$$

The same argument used for the case $L > 0$ is still valid, and hence there exists a unique solution p^*, q^* of the min-max problem which is characterized by the system of equations

$$\rho_{OO2}(k_{\min}, 0, \eta, p^*, q^*) = \rho_{OO2}(\bar{k}_1, 0, \eta, p^*, q^*) = \rho_{OO2}(k_{\max}, 0, \eta, p^*, q^*). \tag{4.37}$$

This system can be solved in closed form by first solving $\rho_{OO2}(k_{\min}, 0, \eta, p, q^*) = \rho_{OO2}(k_{\max}, 0, \eta, p, q^*)$ for $q^* = q^*(p)$, which leads to

$$q^*(p) = \frac{p(\sqrt{k_{\max}^2 + \eta} - \sqrt{k_{\min}^2 + \eta})}{\sqrt{k_{\min}^2 + \eta}k_{\max}^2 - k_{\min}^2\sqrt{k_{\max}^2 + \eta}}.$$

Inserting this solution into the remaining equation $\rho_{OO2}(k_{\min}, 0, \eta, p^*, q^*(p^*)) = \rho_{OO2}(\bar{k}_1, L, \eta, p^*, q^*(p^*))$ and solving for p^* leads to the closed form solution (4.30) of the min-max problem for $L = 0$. ∎

Figure 4.1 shows on the right the convergence factor obtained with the second order optimized transmission conditions for our model problem with overlap $L = \frac{1}{100}$ and $\eta = 1$, comparing it to the convergence factor of the classical Schwarz method. The maximum of the convergence factor of the new Schwarz method with optimized second order transmission conditions is 0.0704, which means that about 131 iterations of the classical Schwarz method with convergence factor 0.980 are needed to attain the performance of the second order optimized Schwarz method.

THEOREM 4.8 (OO2 asymptotics). *The asymptotic performance of the new Schwarz method with optimized second order transmission conditions and overlap $L = h$, as h goes to zero, is given by*

$$\max_{k_{\min} \le k \le \frac{\pi}{h}} |\rho_{OO2}(k, h, \eta, p^*, q^*)| = 1 - 4 \cdot 2^{\frac{3}{5}}(k_{\min}^2 + \eta)^{\frac{1}{10}} h^{\frac{1}{5}} + O(h^{\frac{2}{5}}). \tag{4.38}$$

The asymptotic performance without overlap, $L = 0$, is for h small given by

$$\max_{k_{\min} \le k \le \frac{\pi}{h}} |\rho_{OO2}(k, 0, \eta, p^*, q^*)| = 1 - 4\frac{\sqrt{2}(k_{\min}^2 + \eta)^{\frac{1}{8}}}{\pi^{\frac{1}{4}}} h^{\frac{1}{4}} + O(h^{\frac{1}{2}}). \tag{4.39}$$

Proof. To obtain the first result, we need to solve the nonlinear equations (4.28) asymptotically in h for the optimal parameters p^* and q^*. We make the ansatz $p = C_1 h^\alpha$ and $q = C_2 h^\beta$, insert this together with $L = h$ into the nonlinear equations (4.28), and expand for small h. The search for the lowest order terms is simplified by the knowledge that $\alpha < 0$ and $\beta > 0$ since p is growing when h is decaying and q is diminishing with h. Expanding for h small, we find from the equation $\rho_{OO2}(k_{\min}, h, \eta, p^*, q^*) = \rho_{OO2}(\bar{k}_1, h, \eta, p^*, q^*)$ the leading order terms

$$-4\sqrt{2}C_1 h^\alpha \sqrt{h} + 8C_2 h^\beta \sqrt{C_1 h^\alpha} C_1 h^\alpha$$

and from the equation $\rho_{OO2}(k_{\min}, h, \eta, p^*, q^*) = \rho_{OO2}(k_2, h, \eta, p^*, q^*)$ the leading order terms

$$-4\sqrt{2}C_1^2 h^{2\alpha}\sqrt{h} + 4\sqrt{k_{\min}^2+\eta}\sqrt{C_2 h^\beta}C_1 h^\alpha.$$

Since the equations hold at the optimum, the leading order terms must match, which leads to a system of equations for the unknown exponents α and β,

$$\frac{3}{2}\alpha + \beta = \alpha + \frac{1}{2}, \quad 2\alpha + \frac{1}{2} = \alpha + \frac{\beta}{2},$$

whose solution is $\alpha = -\frac{1}{5}$ and $\beta = \frac{3}{5}$, and a system of equations for the constants C_1 and C_2, whose solution is

$$C_1 = 2^{-\frac{3}{5}}(k_{\min}^2+\eta)^{\frac{2}{5}}, \quad C_2 = (2(k_{\min}^2+\eta))^{-\frac{1}{5}}.$$

Hence asymptotically the optimal parameters p^* and q^* are

$$p^* = 2^{-\frac{3}{5}}(k_{\min}^2+\eta)^{\frac{2}{5}}h^{-\frac{1}{5}}, \quad q^* = (2(k_{\min}^2+\eta))^{-\frac{1}{5}}h^{\frac{3}{5}}. \tag{4.40}$$

To see that the min-max solution given in (4.38) on the infinite frequency domain $k \in [k_{\min}, \infty)$ is really the relevant one asymptotically on the bounded frequency domain $|k| < k_{\max} = \frac{\pi}{h}$, we must have that the second maximum $\bar{k}_2$ given in (4.29) satisfies asymptotically $\bar{k}_2 \le k_{\max}$. Inserting the asymptotic expressions of p^* and q^* from (4.40) into the expression of $\bar{k}_2$ in (4.29), setting $L = h$ and expanding for h small, we find

$$\bar{k}_2 = \frac{2^{\frac{3}{5}}(k_{\min}^2+\eta)^{\frac{1}{10}}}{h^{\frac{4}{5}}} + O(h^{-\frac{2}{5}}) \tag{4.41}$$

and hence indeed asymptotically $\bar{k}_2 \le k_{\max} = \frac{\pi}{h}$. Inserting now the asymptotically optimal parameters p^* and q^* from (4.40) into the convergence factor ρ_{OO2} and expanding as h goes to zero, we obtain the result (4.38).

For the second result without overlap, we have the closed formulas (4.30) for the optimal parameters p^* and q^*. It suffices therefore to insert them into the convergence factor and to expand it in h for $k_{\max} = \frac{\pi}{h}$ at $k = k_{\min}$ to find the result (4.39). ∎

4.3. A two-sided optimized Robin transmission condition. We now investigate how the simplifying assumption $p_1 = p_2$ and $q_1 = q_2$ in the min-max problem (4.11) affects the performance of the optimized Schwarz methods. We do this only for the case of Robin transmission conditions to illustrate the change. We thus have $q_1 = q_2 = 0$ and the optimization problem (4.10).

THEOREM 4.9 (optimal two-sided Robin conditions). *If there is overlap, $L > 0$, then the optimal two-sided Robin parameters are given by*

$$p_1^* = \frac{1-\sqrt{1+4\eta(q^*)^2-4p^*q^*}}{2q^*}, \quad p_2^* = \frac{1+\sqrt{1+4\eta(q^*)^2-4p^*q^*}}{2q^*}, \tag{4.42}$$

where p^* and q^* are solutions of (4.28) *with L replaced by $2L$. If there is no overlap, $L = 0$, then the optimal two-sided Robin parameters are* (4.42)*, where p^* and q^* are given by* (4.30)*.*

Proof. Multiplying the two factors in the optimization problem (4.10), we obtain the optimization problem

$$\min_{p_j \geq 0} \left(\max_{k_{\min} < k < k_{\max}} \left| \frac{\sqrt{\eta + k^2} - \frac{\eta + p_1 p_2}{p_1 + p_2} - \frac{k^2}{p_1 + p_2}}{\sqrt{\eta + k^2} + \frac{\eta + p_1 p_2}{p_1 + p_2} + \frac{k^2}{p_1 + p_2}} \right| e^{-2\sqrt{\eta + k^2} L} \right) \tag{4.43}$$

and hence in the new parameters

$$p = \frac{\eta + p_1 p_2}{p_1 + p_2}, \quad q = \frac{1}{p_1 + p_2}, \tag{4.44}$$

this optimization problem is equivalent to the optimization problem (4.24) provided L is replaced by $2L$. The solution for this problem is given for $L > 0$ in (4.28) and for $L = 0$ in (4.30). Back-transforming these results using (4.44) concludes the proof. ∎

The preceding theorem shows that one can generate the performance of higher order transmission conditions using lower order transmission conditions which are not equal on both sides. In the case without overlap, one needs to perform two iterations of the two-sided optimized Robin transmission algorithm to attain an error reduction equivalent to the one from one iteration of the optimized second order transmission conditions algorithm. With overlap, two iterations of the algorithm with optimized two-sided Robin transmission conditions is even a bit better than one iteration of the algorithm with second order transmission conditions, since the overlap has been effective twice.

Figure 4.1 shows on the right the convergence factors obtained with the two-sided optimized Robin conditions for our model problem with overlap $L = \frac{1}{100}$ and $\eta = 1$, comparing it to the convergence factor of the classical and the optimized zeroth and second order Schwarz methods. The maximum of the convergence factor of the new Schwarz method with two-sided optimized Robin conditions is 0.208, which means that about 78 iterations of the classical Schwarz method with convergence factor 0.980 are needed to attain the performance of the two-sided optimized Robin Schwarz method.

COROLLARY 4.10. *The asymptotic performance of the two-sided optimized Schwarz method with $L = h$ is*

$$\max_{k_{\min} \leq k \leq \frac{\pi}{h}} |\rho(k, h, \eta, p_1^*, p_2^*)| = 1 - 2 \cdot 2^{\frac{4}{5}} (k_{\min}^2 + \eta)^{\frac{1}{10}} h^{\frac{1}{5}} + O(h^{\frac{2}{5}}). \tag{4.45}$$

Without overlap, $L = 0$, the asymptotic performance is given by

$$\max_{k_{\min} \leq k \leq \frac{\pi}{h}} |\rho(k, 0, \eta, p_1^*, p_2^*)| = 1 - 2 \frac{\sqrt{2} (k_{\min}^2 + \eta)^{\frac{1}{8}}}{\pi^{\frac{1}{4}}} h^{\frac{1}{4}} + O(h^{\frac{1}{2}}). \tag{4.46}$$

Hence asymptotically, the second order optimized algorithm and the two-sided optimized Robin algorithm are equivalent: one can get the same asymptotic performance from Robin transmission conditions that one gets from second order transmission conditions, provided one uses different parameters in the two transmission conditions.

The idea of not using the same parameters on each side can be generalized by not using the same parameter in each iteration: one uses a sequence of transmission conditions with Robin parameters p_i, $i = 1, 2, \ldots, I$, where I is a number of parameters chosen and one cycles through the transmission conditions from 1 to I in the

Schwarz iteration. This adds more degrees of freedom in the optimization problem and leads to Schwarz algorithms that have an arbitrarily weak dependence of the convergence factor on h, even without overlap (see [15]), but at the cost of having to solve subdomain problems with varying transmission conditions per interation.

5. Optimized Schwarz methods compared to Schur and FETI methods. We now investigate what the relation is between optimized Schwarz methods, which can be used without overlap, to other domain decomposition methods without overlap, like the Schur methods and FETI (Finite Element Tearing and Interconnect [13]). To this end we will address two questions:

1. What conditions can one impose to couple subdomain problems ?
2. Which of these conditions are good to build efficient domain decomposition algorithms ?

Although the ideas in this section hold for general second order elliptic problems, we will use our self-adjoint coercive model problem (2.1) to fix ideas.

5.1. Classical coupling conditions between subdomains. There are two classical ways to couple subdomain problems. For the first one, one uses an overlapping decomposition of Ω, say, $\Omega_1 = (-\infty, L)$ and $\Omega_2 = (0, \infty)$ for $L > 0$, and the coupled subproblems are given by

$$\begin{array}{cccc} \mathcal{L}(u_1) = f & \text{in } \Omega_1, & \mathcal{L}(u_2) = f & \text{in } \Omega_2, \\ u_1(L, y) = u_2(L, y), & y \in \mathbb{R}, & u_2(0, y) = u_1(0, y), & y \in \mathbb{R}. \end{array} \tag{5.1}$$

Note that we do not introduce an algorithm to find the solution of the coupled subproblems here; we only define coupled subdomain problems which are equivalent to the original problem. The equivalence can be seen in this case, for example, by studying the associated Schwarz algorithm.

For the second approach, one uses subdomains without overlap, for example, $\Omega_1 = (-\infty, 0)$ and $\Omega_2 = (0, \infty)$, and the coupled subdomain problems are

$$\begin{array}{cccc} \mathcal{L}(u_1) = f & \text{in } \Omega_1, & \mathcal{L}(u_2) = f & \text{in } \Omega_2, \\ u_1(0, y) = u_2(0, y), & y \in \mathbb{R}, & \partial_x u_2(0, y) = \partial_x u_1(0, y), & y \in \mathbb{R}. \end{array} \tag{5.2}$$

Note the key difference: in the decomposition without overlap, both the solution values as well as the normal derivatives are imposed to agree on the interface for this second order problem, whereas in the approach with overlap, only solution values are imposed to agree, but at two different locations, which implies the agreement of normal derivatives.

The classical algorithm to find a solution for the case of an overlapping decomposition is the one given by Schwarz in [36],

$$\begin{array}{cccc} \mathcal{L}(u_1^n) = f & \text{in } \Omega_1, & \mathcal{L}(u_2^n) = f & \text{in } \Omega_2, \\ u_1^n(L, y) = u_2^{n-1}(L, y), & y \in \mathbb{R}, & u_2^n(0, y) = u_1^{n-1}(0, y), & y \in \mathbb{R}, \end{array} \tag{5.3}$$

and we have derived the linear convergence factor of this algorithm in (2.8).

Can a similar iterative method be used for the nonoverlapping decomposition? This would lead, for example, to

$$\begin{array}{cccc} \mathcal{L}(u_1^n) = f & \text{in } \Omega_1, & \mathcal{L}(u_2^n) = f & \text{in } \Omega_2, \\ u_1^n(0, y) = u_2^{n-1}(0, y), & y \in \mathbb{R}, & \partial_x u_2^n(0, y) = \partial_x u_1^{n-1}(0, y), & y \in \mathbb{R}. \end{array} \tag{5.4}$$

In general not, because this algorithm does not converge, as one can see with Fourier analysis. Setting for the convergence analysis $f = 0$ by linearity and taking a Fourier

transform in y with parameter k of (5.4) leads to the transformed iterates

$$\hat{u}_1^n(x,k) = \hat{u}_2^{n-1}(0,k)e^{\sqrt{\eta+k^2}x}, \quad \hat{u}_2^n(x,k) = -\hat{u}_1^{n-1}(0,k)e^{-\sqrt{\eta+k^2}x}.$$

Thus inserting $\hat{u}_2^{n-1}(0,k)$ from the second equation into the first one and evaluating at $x = 0$, we find

$$\hat{u}_1^n(0,k) = -\hat{u}_1^{n-2}(0,k) \quad \text{and similarly} \quad \hat{u}_2^n(0,k) = -\hat{u}_2^{n-2}(0,k).$$

Hence the convergence factor of this algorithm is $\rho = -1$ and thus it does not converge.

A first remedy consists of introducing relaxation parameters γ_j, $j = 1, 2$, which leads to the transmission conditions

$$\begin{aligned} u_1^n(0,y) &= \gamma_1 u_2^{n-1}(0,y) + (1-\gamma_1)u_1^{n-1}(0,y), \\ \partial_x u_2^n(0,y) &= \gamma_2 \partial_x u_1^{n-1}(0,y) + (1-\gamma_2)\partial_x u_2^{n-1}(0,y), \end{aligned} \tag{5.5}$$

for which convergence results have been established. In [1] we find that for the so-called Dirichlet–Neumann method, $\gamma_2 = 1$, there exist γ_1 for which the algorithm converges, and in [35] we find that for the Neumann–Dirichlet method, $\gamma_1 = 1$, there exist γ_2 for which the algorithm converges. For our model problem, we find for the interface system in the Fourier domain

$$\begin{pmatrix} \hat{u}_1^n(0,k) \\ \partial_x \hat{u}_2^n(0,k) \end{pmatrix} = \begin{bmatrix} 1-\gamma_1 & \frac{-\gamma_1}{\sqrt{\eta+k^2}} \\ \gamma_2\sqrt{\eta+k^2} & 1-\gamma_2 \end{bmatrix} \begin{pmatrix} \hat{u}_1^{n-1}(0,k) \\ \partial_x \hat{u}_2^{n-1}(0,k) \end{pmatrix}. \tag{5.6}$$

The asymptotic convergence factor of this matrix iteration is governed by the spectral radius of the 2×2 matrix, which is given by the larger eigenvalue in modulus,

$$\rho = \left| 1 - \frac{1}{2}(\gamma_1+\gamma_2) + \frac{1}{2}\sqrt{(\gamma_1-\gamma_2)^2 - 4\gamma_1\gamma_2} \right|. \tag{5.7}$$

Note that ρ is independent of the frequency parameter k, which implies that the convergence factor is independent of the mesh parameter h if the algorithm is discretized. In the case of the Dirichlet–Neumann algorithm, where $\gamma_2 = 1$, the asymptotic convergence factor for our model problem is

$$\rho = \frac{1}{2}\left| 1 - \gamma_1 + \sqrt{\gamma_1^2 - 6\gamma_1 + 1} \right|,$$

which is less than 1 for $0 < \gamma_1 < 1$. The optimal value which minimizes the convergence factor is $\gamma_1 = 3 - 2\sqrt{2} \approx 0.1716$, for which the convergence factor becomes $\rho \approx 0.4142$. The same results we find by the symmetry of the parameters γ_i also in the case of the Neumann–Dirichlet algorithm, where $\gamma_1 = 1$. But one could also use both relaxation parameters simultaneously to minimize the convergence factor. With both parameters, we can achieve that both eigenvalues vanish simultaneously by setting the term under the square root and the one outside of the square root in (5.7) equal to zero. We find that for the choice

$$\gamma_1 = 1 \pm \frac{1}{\sqrt{2}}, \quad \gamma_2 = 1 \mp \frac{1}{\sqrt{2}},$$

the spectral radius vanishes identically, $\rho \equiv 0$. Hence this method will converge in at most two iterations for any initial guess. (The matrix is not normal; otherwise convergence would be in one iteration, which we know is not possible.)

In a Gauss–Seidel version of this iteration, subdomain Ω_2 would use directly the newest values at the interface from subdomain Ω_1. In that case the relaxed interface iteration can be found after a short calculation to be

$$\begin{pmatrix} \hat{u}_1^n(0,k) \\ \partial_x \hat{u}_2^n(0,k) \end{pmatrix} = \begin{bmatrix} 1-\gamma_1 & \frac{-\gamma_1}{\sqrt{\eta+k^2}} \\ \gamma_2(1-\gamma_1)\sqrt{\eta+k^2} & 1-\gamma_2-\gamma_1\gamma_2 \end{bmatrix} \begin{pmatrix} \hat{u}_1^{n-1}(0,k) \\ \partial_x \hat{u}_2^{n-1}(0,k) \end{pmatrix}. \tag{5.8}$$

As before the asymptotic convergence of this matrix iteration is governed by the spectral radius of the 2×2 matrix and the term depending on the frequency parameter k cancels; the convergence factor is independent of k. In this case, however, both the Dirichlet–Neumann and the Neumann–Dirichlet algorithm can achieve already a convergence factor $\rho = 0$; one parameter suffices. The optimal choice is $\gamma_1 = \frac{1}{2}$ for the Dirichlet–Neumann case, where $\gamma_2 = 1$, and $\gamma_2 = \frac{1}{2}$ for the Neumann–Dirichlet case, where $\gamma_1 = 1$, results found already in [1] and [35]. Unfortunately all these results depend strongly on the symmetry in the problem; otherwise the two symbols depending on the frequency parameter k and containing the square root would not cancel. Hence for a more general situation with uneven domains or variable coefficients, convergence in two steps will not be possible with this approach. The optimal Schwarz method using the exact Dirichlet-to-Neumann map, however, does still converge in two iterations also in these more general cases.

A second remedy, and this is really the classical approach for subdomain problems coupled without overlap, consists of avoiding an iteration first. One keeps the coupled problem and introduces a name for the quantities at the interface,

$$\begin{array}{cc} \mathcal{L}(u_1) = f \quad \text{in } \Omega_1, & \mathcal{L}(u_2) = f \quad \text{in } \Omega_2, \\ u_1(0,y) = u_2(0,y) =: \lambda(y), & \partial_x u_2(0,y) = \partial_x u_1(0,y) =: \lambda_x(y). \end{array} \tag{5.9}$$

The primal Schur method then works as follows: supposing that $\lambda(y)$ is known, one computes $u_1(x,y,\lambda)$ and $u_2(x,y,\lambda)$ and then sets

$$\partial_x u_1(0,y,f,\lambda) - \partial_x u_2(0,y,f,\lambda) = 0,$$

which is a linear equation to determine the interface function λ. Solving this linear problem with a Krylov method requires at each step two subdomain solves with Dirichlet conditions,

$$\mathcal{A}_p\lambda := \partial_x u_1(0,y,0,\lambda) - \partial_x u_2(0,y,0,\lambda) = -\partial_x u_1(0,y,f,0) + \partial_x u_2(0,y,f,0) =: b_p. \tag{5.10}$$

To learn more about the conditioning of the primal Schur complement system $\mathcal{A}_p\lambda = b_p$, we take a Fourier transform of $\mathcal{A}_p\lambda$ to find the symbol of $\mathcal{A}_p$,

$$\hat{\mathcal{A}}_p\hat{\lambda} = \hat{v}_x(0,y,0,\hat{\lambda}) - \hat{w}_x(0,y,0,\hat{\lambda}) = 2\sqrt{\eta+k^2}\hat{\lambda}. \tag{5.11}$$

This symbol is symmetric in k and hence the condition number of the corresponding operator can be estimated using the ratio of the symbol at the maximum and minimum frequencies occurring in a given computation. Estimating the minimum frequency by 0 and the maximum frequency by $k_{\max} = \frac{\pi}{h}$ as before, where h is the mesh parameter, we find the asymptotic condition number for h small to be

$$\mathcal{K}(\mathcal{A}_p) = \frac{\pi}{\sqrt{\eta}h} + O(h). \tag{5.12}$$

Note that the original operator $(\eta - \Delta)u = f$ had a condition number estimate of $O(\frac{1}{h^2})$ and thus the primal Schur method improves the condition number by a square root. On the negative side the matrix vector product is now more expensive, since it involves subdomain solves.

The dual Schur method, which became famous under the name FETI, is similar, although the key feature of a natural coarse space cannot be seen in this simple setting: supposing that λ_x is known, we compute $u_1(x, y, f, \lambda_x)$ and $u_2(x, y, f, \lambda_x)$ and then set

$$u_1(0, y, f, \lambda_x) - u_2(0, y, f, \lambda_x) = 0,$$

which is now a linear equation for λ_x. Solving this linear problem with a Krylov method requires at each step two subdomain solves with Neumann conditions,

$$\mathcal{A}_d\lambda_x := u_1(0, y, 0, \lambda_x) - u_2(0, y, 0, \lambda_x) = -u_1(0, y, f, 0) + u_2(0, y, f, 0) =: b_d. \tag{5.13}$$

The Fourier transform of the dual Schur complement system $\mathcal{A}_d\lambda_x = b_d$ leads to

$$\hat{\mathcal{A}}_d\hat{\lambda}_x = \hat{v}(0, y, 0, \hat{\lambda}_x) - \hat{w}(0, y, 0, \hat{\lambda}_x) = \frac{2}{\sqrt{\eta + k^2}}\hat{\lambda}_x, \tag{5.14}$$

which shows that the operator $\mathcal{A}_d$ has the symbol $\frac{2}{\sqrt{\eta+k^2}}$. This symbol is also symmetric in k and as in the case of the primal Schur complement, we find the condition number for h small to be

$$\mathcal{K}(\mathcal{A}_d) = \frac{\pi}{\sqrt{\eta}h} + O(h). \tag{5.15}$$

Now note that the dual Schur complement with the symbol $\frac{2}{\sqrt{\eta+k^2}}$ is the inverse of the primal Schur complement that had the symbol $2\sqrt{\eta + k^2}$, up to the constant 4, and hence one is the ideal preconditioner for the other. This led to the famous Neumann–Neumann preconditioner for the primal Schur complement, with condition number independent of the mesh parameter [2]. Similarly, one could use a Dirichlet–Dirichlet preconditioner for the dual Schur complement or FETI to obtain a mesh independent domain decomposition method.

But why should one give preference to either the Dirichlet or the Neumann condition when formulating a Schur method? And why should we impose the same type of interface conditions on each subdomain? In the recent FETI-DP method [11], for some parts of the interfaces continuity of the dual variables is imposed, and for other parts continuity of the primal variables. One could go a step further and first assume that both λ and λ_x are known, then solve for $u_1(x, y, f, \lambda)$ and $u_2(x, y, f, \lambda_x)$, for example, and set

$$\begin{aligned} u_1(0, y, f, \lambda) - u_2(0, y, f, \lambda_x) &= 0, \\ \partial_x u_1(0, y, f, \lambda) - \partial_x u_2(0, y, f, \lambda_x) &= 0, \end{aligned}$$

which is now a two-field formulation for the two unknown fields, λ and λ_x. Solving this linear problem with a Krylov method requires at each step one subdomain solve with Dirichlet and one with Neumann conditions,

$$\begin{aligned} \mathcal{A}_{pd}\begin{pmatrix} \lambda \\ \lambda_x \end{pmatrix} &:= \begin{bmatrix} 1 & -u_2(0, y, 0, \cdot) \\ -\partial_x u_1(0, y, 0, \cdot) & 1 \end{bmatrix}\begin{pmatrix} \lambda \\ \lambda_x \end{pmatrix} \\ &= \begin{pmatrix} u_2(0, y, f, 0) \\ \partial_x u_1(0, y, f, 0) \end{pmatrix} =: b_{pd}. \end{aligned} \tag{5.16}$$

Taking a Fourier transform of the operator $\mathcal{A}_{pd}$, we find

$$\hat{\mathcal{A}}_{pd} = \begin{bmatrix} 1 & \frac{1}{\sqrt{\eta+k^2}} \\ -\sqrt{\eta+k^2} & 1 \end{bmatrix}, \tag{5.17}$$

which is precisely the matrix to which we have applied a Richardson iteration trying simply to relax the interface conditions in (5.4), an iteration which did not converge. By applying a Krylov method to solve the problem directly, however, it would converge in two steps, since the eigenvalues are independent of k, there are only two distinct points in the spectrum.

We can also write the coupled subdomain problems with overlap in substructured form. If we give the unknown functions at the interfaces the names $\lambda_0(y)$ and $\lambda_L(y)$, we get

$$\begin{array}{cc} \mathcal{L}(u_1) = f \text{ in } \Omega_1, & \mathcal{L}(u_2) = f \text{ in } \Omega_2, \\ u_1(L,y) = u_2(L,y) \ =: \ \lambda_L(y) & u_2(0,y) = u_1(0,y) \ =: \ \lambda_0(y). \end{array} \tag{5.18}$$

If we assume that both λ_L and λ_0 are known, then we can compute $u_1(x,y,f,\lambda_L)$ and $u_2(x,y,f,\lambda_0)$ and then set

$$\begin{aligned} u_2(0,y,f,\lambda_0) - u_1(0,y,f,\lambda_L) &= 0, \\ -u_2(L,y,f,\lambda_0) + u_1(L,y,f,\lambda_L) &= 0, \end{aligned}$$

which is a linear system of equations for the unknowns λ_0 and λ_L. Solving this linear problem with a Krylov method requires at each step two subdomain solves with Dirichlet conditions,

$$\mathcal{A}_s \begin{pmatrix} \lambda_0 \\ \lambda_L \end{pmatrix} := \begin{bmatrix} 1 & -u_1(0,y,0,\cdot) \\ -u_2(L,y,0,\cdot) & 1 \end{bmatrix} \begin{pmatrix} \lambda_0 \\ \lambda_L \end{pmatrix} = \begin{pmatrix} u_1(0,y,f,0) \\ u_2(L,y,f,0) \end{pmatrix} =: b_s. \tag{5.19}$$

In Fourier the symbol of the operator $\mathcal{A}_s$ is given by

$$\hat{\mathcal{A}}_s = \begin{bmatrix} 1 & -e^{-\sqrt{\eta+k^2}L} \\ -e^{-\sqrt{\eta+k^2}L} & 1 \end{bmatrix}, \tag{5.20}$$

and we see that the operator is symmetric in this case. If one applies a Richardson iteration to this operator, one recovers the classical Schwarz method for which we have seen that it converges independently of the discretization parameter. The eigenvalues in Fourier are $1 \pm e^{-\sqrt{\eta+k^2}L}$, which shows that the eigenvalues are clustering for large k around 1, a very desirable property when a Krylov method is used to solve the corresponding linear system. The condition number of this symmetric operator can be estimated by the ratio of the largest and smallest eigenvalue,

$$\mathcal{K}(\mathcal{A}_s) = \frac{1+e^{-\sqrt{\eta}L}}{1-e^{-\sqrt{\eta}L}}, \tag{5.21}$$

and it is independent of the mesh parameter h, as long as the overlap L is independent of h. For an overlap which depends on h, $L = h$, we have for h small

$$\mathcal{K}(\mathcal{A}_s) = \frac{2}{\sqrt{\eta}h} + O(h) \tag{5.22}$$

as for the primal and dual Schur methods.

5.2. Coupling conditions optimized for the computation. Optimized Schwarz methods bring the overlapping and nonoverlapping strategies together. They do not use either Dirichlet or Neumann conditions, and they work with or without overlap. The fundamental idea is that the coupled problem can be written with any set of conditions that implies the classical coupling conditions. The coupled problems

$$\begin{array}{ll} \mathcal{L}(u_1) = f \quad \text{in } \Omega_1, & \mathcal{L}(u_2) = f \quad \text{in } \Omega_2, \\ (\partial_x + \mathcal{S}_1)(u_1)(L) = (\partial_x + \mathcal{S}_1)(u_2)(L), & (\partial_x + \mathcal{S}_2)(u_2)(0) = (\partial_x + \mathcal{S}_1)(u_1)(0), \end{array} \tag{5.23}$$

are equivalent to the original, unpartitioned problem, as long as the choice of $\mathcal{S}_j$, $j = 1, 2$, leads to well-posed subdomain problems and implies, for $L > 0$, $u_1(0) = u_2(0)$ and $u_1(L) = u_2(L)$, and for $L = 0$, $u_1(0) = u_2(0)$ and $\partial_x u_1(0) = \partial_x u_2(0)$. To write this system in substructured form, we assume again that the interface functions $\lambda_1(y)$ and $\lambda_2(y)$ are known,

$$\begin{aligned} (\partial_x + \mathcal{S}_1)(u_1)(L, y) = (\partial_x + \mathcal{S}_1)(u_2)(L, y) =: \lambda_1(y), \\ (\partial_x + \mathcal{S}_2)(u_2)(0, y) = (\partial_x + \mathcal{S}_1)(u_1)(0, y) =: \lambda_2(y), \end{aligned}$$

solve the subdomain problems, and then set

$$\begin{aligned} -(\partial_x + \mathcal{S}_1)(u_2(0, y, f, \lambda_2)) + \lambda_1 = 0, \\ \lambda_2 - (\partial_x + \mathcal{S}_2)(u_1(L, y, f, \lambda_1)) = 0. \end{aligned}$$

This is again a linear system to be solved for λ_1 and λ_2. Using a Krylov method, at each iteration two problems with the new transmission conditions need to be solved,

$$\begin{aligned} \mathcal{A}\begin{pmatrix} \lambda_1 \\ \lambda_2 \end{pmatrix} &:= \begin{bmatrix} 1 & -(\partial_x + \mathcal{S}_1)(u_2(0, y, 0, \cdot)) \\ -(\partial_x + \mathcal{S}_2)(u_1(L, y, 0, \cdot)) & 1 \end{bmatrix} \begin{pmatrix} \lambda_0 \\ \lambda_L \end{pmatrix} \\ &= \begin{pmatrix} (\partial_x + \mathcal{S}_1)(u_2(0, y, f, 0)) \\ (\partial_x + \mathcal{S}_2)(u_1(L, y, f, 0)) \end{pmatrix} =: b. \end{aligned} \tag{5.24}$$

In the Fourier domain, the symbol of the operator $\mathcal{A}$ becomes for our model problem

$$\hat{\mathcal{A}} = \begin{bmatrix} 1 & -\frac{\sqrt{\eta + k^2} - \sigma_1(k)}{\sqrt{\eta + k^2} - \sigma_2(k)} e^{-\sqrt{\eta + k^2} L} \\ -\frac{\sqrt{\eta + k^2} + \sigma_2(k)}{\sqrt{\eta + k^2} + \sigma_1(k)} e^{-\sqrt{\eta + k^2} L} & 1 \end{bmatrix}. \tag{5.25}$$

For well-posedness of the subdomain problems, we need that $\mathcal{S}_1$ is a positive operator and $\mathcal{S}_2$ a negative one, as one can also see from the denominators in the symbol of the operator $\mathcal{A}$. The iterative optimized Schwarz method is obtained when a Richardson iteration is applied to this system, and we have seen that this iteration converges in two steps, if $= \sigma_2 = -\sigma_1 = \sqrt{\eta + k^2}$, or very fast, if the symbols approximate this choice. If we choose $\sigma_2 = -\sigma_1 > 0$, then the operator becomes symmetric and its condition number equals one for the optimal choice, or it can be made small choosing good approximations. This is the heart of the optimized Schwarz methods: the optimal choice always exists, it is the Dirichlet-to-Neumann map, and good approximations lead to the optimized Schwarz methods with superior performance. The FETI methods have also started to incorporate these ideas; see, for example, the variant FETI-H presented in [12], where the authors state, "The modified Lagrangian formulation presented here can be related to alternative transmission conditions for the subdomain interfaces." FETI-H constructs (5.25) using optimized Robin conditions.

6. Numerical experiments. We perform numerical experiments for our model problem on the unit square, $\Omega = (0,1) \times (0,1)$,

$$\begin{aligned} (\eta - \Delta)(u) &= f \qquad \text{in } \Omega, \\ u &= 0 \qquad \text{on } \partial\Omega. \end{aligned} \tag{6.1}$$

We decompose the unit square Ω into two subdomains $\Omega_1 = (0,\beta) \times (0,1)$ and $\Omega_2 = (\alpha,1) \times (0,1)$, where $0 < \alpha \leq \beta < 1$ and hence the overlap is $L = \beta - \alpha$. Note that we explicitly allow $\alpha = \beta$ such that the method does not have any overlap, $L = 0$. We use a finite difference discretization with the classical five-point discretization for the Laplacian and a uniform mesh with mesh parameter h.

6.1. Overlapping optimized Schwarz methods. Classically the overlap in the Schwarz method is held constant as the mesh is refined to obtain mesh independent convergence factors for the method. The same is true for optimized Schwarz methods because of Theorem 4.1, as iteration counts to reach an error reduction of $1e{-}6$ show in Table 6.1 for a fixed overlap $L = \beta - \alpha = \frac{1}{50}$. We simulate directly the error equations, $f = 0$, and use a random initial guess so that all the frequency components are present. The results show clearly how important transmission conditions are for this algorithm. Note also that while the Krylov method has a big impact on the classical Schwarz method, for the second order optimized Schwarz method the acceleration with the Krylov method does not reduce the iteration count significantly. This situation is well known for multigrid methods, which do not need Krylov acceleration either when applied to a Poisson problem. The Krylov acceleration is then used to improve the performance of the method on more complex problems.

In practical computations, one can often not afford many mesh cells to overlap, so the overlap depends on the mesh parameter h. In the following experiments we choose therefore the overlap $L = \beta - \alpha = h$. Table 6.2 shows the iteration counts for this case. It is interesting to note that the second order optimized Schwarz method without Krylov acceleration is already six times faster than classical Schwarz with Krylov acceleration at high resolution.

In Figure 6.1, we show the number of iterations on a log-log plot so they can be compared to the theoretical asymptotic results. On the top, the Schwarz methods are used as iterative solvers and the numerical results show the asymptotic behavior predicted by the theory. On the bottom, the Schwarz methods are used as preconditioners. This improves the asymptotic performance by a square root, as one can

TABLE 6.2

Number of iterations of the classical Schwarz method compared to the different optimized Schwarz methods with overlap $L = h$ between subdomains.

	Classical	Taylor 0	Taylor 2	Optimized 0	Two-sided optimized 0	Optimized 2

show in ideal situations, since a square root is taken off the condition number of the preconditioned system. This is also visible in our numerical results.

We now investigate how well the continuous analysis predicts the optimal parameters to be used in the numerical setting. To this end we vary the parameter p in the Robin transmission conditions for a fixed problem of mesh size $h = \frac{1}{100}$ and count for each value of p the number of iterations to reach a residual of $1e-6$. The results for both optimized Schwarz used as an iterative solver and as a preconditioner are shown in Figure 6.2 on the top. The analysis predicts very well the optimal parameter, and when the method is used as a preconditioner, the area where the optimum is attained is widened considerably, which shows that the optimized Schwarz method is robust with respect to the optimal parameter. Similar results hold for the second order optimized Schwarz method, as one can see in Figure 6.2 in the middle when the method is used iteratively and on the bottom when used as a preconditioner.

6.2. Nonoverlapping optimized Schwarz methods. Nonoverlapping Schwarz methods are of interest if the physical properties vary from subdomain to subdomain and one has formulated the subdomain decomposition motivated by this fact; see, for example, [20]. They also facilitate the construction of nonmatching grids per subdomain and the formulation of algorithms in that case. We illustrate the performance of the optimized Schwarz methods without overlap, $\alpha = \beta$ or $L = 0$, by choosing for the mesh parameter diminishing values and counting the number of iterations the methods take to reduce the error by a factor $1e-6$. Table 6.3 shows the performance of the different optimized Schwarz methods in that case. Note that the classical Schwarz method is not shown because classical Schwarz does not converge without overlap. Comparing with the performance of the methods with overlap h, one can see that the number of iterations is by a factor 1.5–1.7 higher for the second order optimized Schwarz method, whereas the cost per subdomain is only slightly higher for the method with overlap; there are m more variables in one subdomain for matrices of size m^2. Hence a physical motivation must outweigh the increased cost of a nonoverlapping Schwarz method.

In Figure 6.3 we show the number of iterations on a log-log plot so they can be compared to the theoretical asymptotic factors.

On the left the methods are used as iterative solvers and one can see that again the numerical results show the asymptotic behavior predicted by the analysis. On the right the results are shown when the Schwarz methods are used as preconditioners, and one can see again that Krylov acceleration improves the performance by about a square root.

We finally show in Figure 6.4 how well the analysis predicts the optimization parameters in the nonoverlapping case.

6.3. An application. We now show how a nonoverlapping optimized Schwarz method can be used to compute the temperature distribution in our apartment on Durocher in Montreal. In Figure 6.5, we show on top the floor plan of our apartment with a finite element discretization and a decomposition into the different rooms: on the left is the living room, connected to the kitchen and with a long hallway to the bathroom and bedroom on the right. Insulated walls are shown in blue, the windows on top are shown in black, where we assume -20 degrees Celsius for a regular Montreal winter day, and the doors at the bottom and on the right are also shown in black. They lead to a heated public hallway, at about 15 degrees Celsius. The interfaces are shown in red, and we introduced curved interfaces and nonrectangular domains, so that the Fourier analysis presented in this paper cannot be applied any more. In

the middle in Figure 6.5 we show the first iteration of the optimized Schwarz method with Robin transmission conditions, where one can clearly see the isolated effect of the heaters and warm doors in each subdomain: the iterate is discontinuous. In Figure 6.5 at the bottom we show the final result of the simulation, which is now continuous. The method took 25 iterations to converge to a relative residual of $1e-3$ in the iterative case and 12 iterations when used as a preconditioner, using the optimal parameter $p^* = 2.7207$ from the two-subdomain theory. Refining once more, the method took 32 iterations in the iterative case and 13 in the preconditioned case, with the optimal parameter $p^* = 3.8576$ from the two-subdomain theory. The ratio in the iterative case is $32/25 = 1.28 \approx 2^{1/3} = 1.26$, as predicted by the two-subdomain theory for the simple two-subdomain case with straight interfaces, and in the preconditioned case, the ratio is $13/12 = 1.08 \approx 2^{1/6} = 1.12$. This shows that although the Fourier analysis cannot be applied in the more general case, the results predicted by the theory for

the two-subdomain case are also observed in more practical situations.

The results of this simulation were interesting to us: one can see that while the heaters in the living room on the left and the bedroom on the right are well placed to block the cold from the windows, the heater on the left wall in the bathroom is not effective to keep the room warm, a fact we strongly felt in winter. Also, the kitchen is not heated and stays cold, except when cooking and baking.

7. Conclusion. We introduced the reader to a new class of Schwarz methods, the optimized Schwarz methods. The algorithm is the same as for the classical Schwarz method and it can be used either iteratively or as a preconditioner. The difference is a new type of transmission conditions between subdomains, instead of the classical Dirichlet condition. We analyzed for a symmetric positive definite model problem and two subdomains the influence of the transmission conditions on the convergence factor of the Schwarz algorithm. We showed both analytically and numerically that the optimized Schwarz methods have a greatly improved performance compared to the classical Schwarz method. The number of iterations required to achieve a certain accuracy is by a factor smaller, often more than an order of magnitude. This performance is achieved without an increased cost for the subdomain solves, since the same type of matrix problem has to be solved in the subdomains, and the new subdomain matrices have the same bandwidth as the original ones. We also proved that the optimized Schwarz methods are always faster than the classical Schwarz method and since their implementation is not more difficult than the implementation of a classical Schwarz method, they represent a very attractive alternative. We finally showed in numerical experiments that the results derived for the simple two-subdomain configuration with a straight interface also apply in more complicated situations in practice, where Fourier analysis cannot be applied any more.

L^2-PROJECTED LEAST-SQUARES FINITE ELEMENT METHODS FOR THE STOKES EQUATIONS*

HUO-YUAN DUAN†, PING LIN†, P. SAIKRISHNAN†, AND ROGER C. E. TAN†

Abstract. Two new L^2 least-squares (LS) finite element methods are developed for the velocity-pressure-vorticity first-order system of the Stokes problem with Dirichlet velocity boundary condition. A key feature of these new methods is that a local or almost local L^2 projector is applied to the residual of the momentum equation. Such L^2 projection is always defined onto the linear finite element space, no matter which finite element spaces are used for velocity-pressure-vorticity variables. Consequently, the implementation of this L^2-projected LS method is almost as easy as that of the standard L^2 LS method. More importantly, the former has optimal error estimates in L^2-norm, with respect to both the order of approximation and the required regularity of the exact solution for velocity using equal-order interpolations and for all three variables (velocity, pressure, and vorticity) using unequal-order interpolations. Numerical experiments are given to demonstrate the theoretical results.

Key words. the Stokes equation, velocity-pressure-vorticity least-squares finite element method, L^2 projection, mass-lumping

1. Introduction.

The least-squares (LS) mixed finite element method is widely used in seeking numerical solution of partial differential equations arising from fluid and solid mechanics; cf. [13, 14, 15, 18, 19, 20, 21, 22, 23, 24, 26, 27, 28, 30, 31, 32]. In a broad sense, the LS method minimizes the residual, measured in some Sobolev norms, of a mixed first-order system of partial differential equations. The mixed first-order system is obtained by introducing one or more additional physically important fields such as stress/pressure/vorticity besides displacement/velocity as unknown variables. There are many advantages to LS methods. The LS method may be viewed as a classical Ritz's method of coercive type [29] and is not subject to the so-called inf-sup condition [2, 9]. Its resulting linear system is symmetric positive definite and can be solved by standard iterative methods such as the conjugate gradient method. In addition, the standard finite element spaces can be employed for each unknown variable. Readers may refer to [12, 13] for more details on LS methods. In this paper we shall introduce and study new LS methods for the Stokes problem written as a system of equations of first order, where velocity, pressure, and vorticity appear as unknown variables. This system involves relatively few unknowns and is widely employed in engineering practice.

Let us first review several LS methods developed in the last decade for the velocity-pressure-vorticity Stokes system. The most widely used LS method is the standard L^2 LS method [13, 15], where the LS functional is the squared L^2-norms of the residual of the first-order system. This method is easy to implement and performs very well in many engineering applications (cf. [13, 19, 20, 30, 31]). However, for the important case of Dirichlet velocity boundary condition, this method is not optimal in the usual

†Department of Mathematics, National University of Singapore, 2 Science Drive 2, Singapore 117543 (scidhy@nus.edu.sg, matlinp@nus.edu.sg, matsp@nus.edu.sg, scitance@nus.edu.sg).

sense [16, 17]; for example, for equal-order continuous interpolations, the L^2-error bound for velocity is not optimal with respect to both the order of approximation and the required regularity. In the case of convex polygon, no error estimates are available. Also, no improved error estimates are obtained for unequal-order continuous interpolations (see [33] for some numerical results).

The reason that the standard L^2 LS method suffers from suboptimal error estimates in the case of velocity Dirichlet boundary condition may be the following: the coercivity for vorticity and pressure is measured in L^2-norm, whereas their first-order derivatives having appeared in the term resulting from the momentum equation suggests that the continuity condition cannot be obtained in the same measure, which prevents us from obtaining optimal error estimates. To recover the optimal error estimates one has to do some modifications to that term of the momentum equation.

There have been two important methods which can overcome the difficulty from the term of the momentum equation. One is the Bochev–Gunzburger (BG) method, where a factor h^2 is put in front of the term of the momentum equation. Alternatively, the BG method may be scaled as the one with a factor h^{-2} put in front of terms of the incompressibility condition and of the vorticity equation [18]. The other is the H^{-1} LS method, which may be viewed as a modified version of the BG method by introducing an additional term of the momentum equation, where a preconditioner B_h (or an operator of the finite element solution) for the Dirichlet problem of a second-order elliptic equation is applied [14, 21, 32]. In the BG method the effects from the term of the momentum equation can be eliminated because of the factor h^2, and optimal error estimates can be derived with the use of unequal-order continuous interpolations [16, 18]. In the H^{-1} method, when B_h satisfies a spectral equivalence (see equation (2.15) in [21, p. 941]), the coercivity and the optimal error estimates can be established. These are excellent efforts in achieving optimal error estimates of LS methods. However, there is still room for improvement. The BG method does not give optimal L^2-error estimates for the velocity, excludes the use of linear elements [16, 18, 33], and has a condition number $\mathcal{O}(h^{-4})$. This is due to the fact that it lacks a coercivity uniform in mesh sizes or that in its scaled version the scale factor h^{-2} worsens its continuity condition. The H^{-1} method can provide optimal L^2-error bounds for the velocity, but there is a restriction on B_h (see equation (3.24) in [21, p. 947]). There are few examples of B_h known to satisfy that restriction. Also, due to the fact that B_h is defined onto U_h (the approximating space for the velocity), B_h varies with U_h accordingly. This may complicate implementation issues when U_h is of higher-order elements.

Our new idea presented in the paper is to add an L^2-projected term of the momentum equation to the BG method or to use an L^2 projector to replace the preconditioner in the H^{-1} method. With the L^2 projection term, the uniform coercivity holds (see Theorem 3.1), and the error estimates are optimal (see Theorem 3.3 and Theorem 4.1), for velocity using equal-order interpolations and for all three variables (velocity, pressure, and vorticity) using unequal-order interpolations. Also, the condition number is of $\mathcal{O}(h^{-2})$ (see Corollary 3.2) and the implementation of this L^2-projected LS method is almost as easy as that of the standard L^2 LS method, since the L^2 projection is local or almost local and is always defined onto the linear finite element space, no matter which finite element spaces are used for velocity-pressure-vorticity variables. Note that although the L^2 projection is "fixed" onto the linear element space, this does not cause any consistency problem and does not affect the order of the error estimates.

We provide two methods according to the definitions of L^2 projectors applied to the term of the momentum equation. One is called the local L^2 projection method (I) and the other the mass-lumping L^2 projection method (II). The L^2 projection in method (I) is always element-by-element defined onto the discontinuous linear element space; in method (II) the L^2 projection is always defined by using the mass-lumping technique [1] onto the continuous linear element space. Note that the L^2 projection in method (II) is almost local because the resulting matrix of this L^2 projection is diagonal. Standard equal-order or unequal-order finite elements, with lower-order finite elements for pressure and vorticity enriched with element or edge (face) bubbles or both, are employed for approximating velocity, pressure, and vorticity variables. Note that the role of the bubbles for lower-order elements for pressure and vorticity is to make Assumption (A2) (see (3.35) and (3.36)) hold (cf. Remark 3.2 and Theorem 3.4).

Our L^2 projection plays a critical role (see (3.24)) in the derivation of a uniform coercivity (see (3.6)). All the first-order derivatives of pressure and vorticity appear only in L^2-projected and h^2-weighted terms. Due to Assumption (A2), the errors associated with the L^2-projected term can be made zero (see (3.47)), while the h^2-weighted term is obviously consistent in terms of both the order of approximation and the regularity of the exact solution. Therefore, optimal error estimates can be achieved. Also, an $\mathcal{O}(h^{-2})$ condition number is obtained.

Of course, we may project onto a higher-order element space. But obviously the linear element is simpler and the L^2 projection can be easily implemented. For method (I) we could even consider defining the local L^2 projection onto a piecewise constant space and almost all our techniques of analysis might still work. However, an optimal L^2-error bound for velocity cannot be obtained because the interpolation result of the linear element has to be used in the derivation (see (4.20)).

Finally, we remark that in deriving the L^2-error estimates for the velocity we assume that the domain is a convex polygon as usual [5, 29]. For such a domain some known regularity results for Stokes and elasticity problems (cf. [6, 7, 8, 10]) are used.

The outline of this paper is as follows. In section 2, we recall the first-order system of the velocity-pressure-vorticity Stokes problem and formulate L^2-projected methods. In section 3, we establish coercivity and error bounds and verify an important assumption (Assumption (A2)). In section 4, the L^2-error bound for velocity is obtained. In section 5, numerical results are presented to support our theoretical analysis.

2. Problem formulation.

2.1. First-order system of the Stokes problem. Let $\Omega \subset \mathbb{R}^d$ $(d = 2, 3)$ be a bounded domain with boundary Γ and $\mathbf{f} \in (L^2(\Omega))^d$. We consider the following Stokes problem: Find velocity $\mathbf{u}$ and pressure p such that

$$-\Delta \mathbf{u} + \bigtriangledown p = \mathbf{f}, \quad \bigtriangledown \cdot \mathbf{u} = 0 \quad \text{in } \Omega, \quad \mathbf{u} = \mathbf{0} \quad \text{on } \Gamma. \tag{2.1}$$

Let $\bigtriangledown\times$ denote the curl operator. Introducing the vorticity $\omega = \bigtriangledown \times \mathbf{u} \in (L^2(\Omega))^{2d-3}$ and noting that $-\Delta \mathbf{u} = \bigtriangledown \times \bigtriangledown \times \mathbf{u} - \bigtriangledown \bigtriangledown \cdot \mathbf{u}$ and $\bigtriangledown \cdot \mathbf{u} = 0$, we can write (2.1) as the first-order system

$$\bigtriangledown \times \omega + \bigtriangledown p = \mathbf{f}, \quad \omega = \bigtriangledown \times \mathbf{u}, \quad \bigtriangledown \cdot \mathbf{u} = 0 \quad \text{in } \Omega, \tag{2.2}$$

along with a Dirichlet boundary condition and a pressure mean-zero condition

$$\mathbf{u}_{|\Gamma} = \mathbf{0}, \quad \int_\Omega p = 0. \tag{2.3}$$

Below we shall use the standard Sobolev spaces $H_0^1(D)$ and $H^s(D)$, with norm $\|\cdot\|_{s,D}$ and seminorm $|\cdot|_{s,D}$, where D is some Lipschitz subdomain of Ω; D will be omitted from the notation when $D = \Omega$. We shall use $(\cdot,\cdot)_{0,D}$ for the inner product of $L^2(D)$ $(= H^0(D))$. When $D = \Omega$, $(\cdot,\cdot) := (\cdot,\cdot)_{0,\Omega}$. We shall also define $L_0^2(\Omega) := \{q \in L^2(\Omega); \int_\Omega q = 0\}$. Throughout this paper we always assume that Ω is a Lipschitz polygon (polyhedron in $\mathbb{R}^3$) and that $\mathcal{C}_h$ is a regular triangulation of Ω (tetrahedrons in $\mathbb{R}^3$), with diameters $h_K \le h$ for all triangular elements $K \in \mathcal{C}_h$.

2.2. Local L^2 projection method (I). Introduce

$$Z_h := \{\mathbf{v} \in (L^2(\Omega))^d; \mathbf{v}_{|K} \in (\mathcal{P}_1(K))^d \quad \forall K \in \mathcal{C}_h\}, \tag{2.4}$$

where $\mathcal{P}_1(K)$ denotes the space of linear polynomials on K. For given $\mathbf{g} \in (L^2(\Omega))^d$ we define a function $\breve{R}_h(\mathbf{g}) \in Z_h$ by

$$\int_K \breve{R}_h(\mathbf{g})\,\mathbf{v} = \int_K \mathbf{g}\,\mathbf{v} \quad \forall \mathbf{v} \in (\mathcal{P}_1(K))^d, \quad \forall K \in \mathcal{C}_h. \tag{2.5}$$

Let

$$U_h \subset (H_0^1(\Omega))^d, \quad P_h \subset L_0^2(\Omega), \quad W_h \subset (L^2(\Omega))^{2\,d-3} \tag{2.6}$$

be continuous piecewise polynomial spaces on $\mathcal{C}_h$ for velocity, pressure, and vorticity, respectively. We define an LS functional on $U_h \times P_h \times W_h$ by

$$\begin{aligned}\mathcal{J}_h^I(\mathbf{u},p,\omega;\mathbf{f}) := \|\breve{R}_h(\bigtriangledown\times\omega + \bigtriangledown p - \mathbf{f})\|_0^2 + \sum_{K\in\mathcal{C}_h} h_K^2\,\|\bigtriangledown\times\omega + \bigtriangledown p - \mathbf{f}\|_{0,K}^2 \\ + \|\omega - \bigtriangledown\times\mathbf{u}\|_0^2 + \|\bigtriangledown\cdot\mathbf{u}\|_0^2.\end{aligned} \tag{2.7}$$

We consider a minimization problem: Find $(\mathbf{u}_h, p_h, \omega_h) \in U_h \times P_h \times W_h$ such that

$$\mathcal{J}_h^I(\mathbf{u}_h,p_h,\omega_h;\mathbf{f}) = \inf_{(\mathbf{v}_h,q_h,z_h)\in U_h\times P_h\times W_h} \mathcal{J}_h^I(\mathbf{v}_h,q_h,z_h;\mathbf{f}). \tag{2.8}$$

Taking variations in (2.7) with respect to $(\mathbf{v}_h, q_h, z_h)$, we obtain the weak statement of problem (2.8): Find $(\mathbf{u}_h, p_h, \omega_h) \in U_h \times P_h \times W_h$ such that

(2.9)

$$\left\{\begin{aligned}&\mathcal{L}_h^I((\mathbf{u}_h,p_h,\omega_h);(\mathbf{v}_h,q_h,z_h)) := (\breve{R}_h(\bigtriangledown\times\omega_h + \bigtriangledown p_h), \breve{R}_h(\bigtriangledown\times\ z_h + \bigtriangledown q_h))\\ &\quad + \sum_{K\in\mathcal{C}_h} h_K^2\,(\bigtriangledown\times\omega_h + \bigtriangledown p_h, \bigtriangledown\times z_h + \bigtriangledown q_h)_{0,K}\\ &\quad + (\omega_h - \bigtriangledown\times\mathbf{u}_h, z_h - \bigtriangledown\times\mathbf{v}_h) + (\bigtriangledown\cdot\mathbf{u}_h, \bigtriangledown\cdot\mathbf{v}_h)\\ &= (\mathbf{f}, \breve{R}_h(\bigtriangledown\times z_h + \bigtriangledown q_h)) + \sum_{K\in\mathcal{C}_h} h_K^2\,(\mathbf{f}, \bigtriangledown\times z_h + \bigtriangledown q_h)_{0,K}\end{aligned}\right.$$

holds for all $(\mathbf{v}_h, q_h, z_h) \in U_h \times P_h \times W_h$.

2.3. Mass-lumping L^2 projection method (II). Introduce

$$V_{0,h} := Z_h \cap (H_0^1(\Omega))^d, \tag{2.10}$$

where Z_h is defined in (2.4). Let $(\cdot,\cdot)_h$ denote an inner product in $V_{0,h}$ and the induced norm in $V_{0,h}$ be given by

$$\|\mathbf{v}\|_h := (\mathbf{v},\mathbf{v})_h^{1/2}. \tag{2.11}$$

Remark 2.1. $(\cdot,\cdot)_h$ is usually taken as an approximation of $(\cdot,\cdot)$. For example, when $\mathcal{C}_h$ consists of two-dimensional (2D) triangles, we may take $(\cdot,\cdot)_h$ as the quadrature scheme

$$(u,v)_h := \sum_{K\in\mathcal{C}_h} \frac{\text{area}(K)}{3} \sum_{i=1}^{3} u(i)\, v(i), \tag{2.12}$$

where $i = 1, 2, 3$ denote vertices of the triangle K. In the literature [1], $(\cdot,\cdot)_h$ replacing $(\cdot,\cdot)$ is called *mass-lumping*. The matrix associated with $(\cdot,\cdot)_h$ is diagonal.

For given $w \in (L^2(\Omega))^{2d-3}$ and $p \in L^2(\Omega)$ we define two functions $R_h(\bigtriangledown \times w) \in V_{0,h}$ and $S_h(\bigtriangledown p) \in V_{0,h}$, respectively, by

$$(R_h(\bigtriangledown \times w), \mathbf{v}_h)_h = (w, \bigtriangledown \times \mathbf{v}_h) \quad \forall \mathbf{v}_h \in V_{0,h}, \tag{2.13}$$

$$(S_h(\bigtriangledown p), \mathbf{v}_h)_h = -(p, \bigtriangledown \cdot \mathbf{v}_h) \quad \forall \mathbf{v}_h \in V_{0,h}. \tag{2.14}$$

For given $\mathbf{g} \in (L^2(\Omega))^d$ we define a function $\bar{R}_h(\mathbf{g}) \in V_{0,h}$ by

$$(\bar{R}_h(\mathbf{g}), \mathbf{v}_h)_h = (\mathbf{g}, \mathbf{v}_h) \quad \forall \mathbf{v}_h \in V_{0,h}. \tag{2.15}$$

Remark 2.2. Clearly, R_h, S_h, and $\bar{R}_h$ are all linear operators. In addition, if $w \in (H^1(\Omega))^{2d-3}$ and $p \in H^1(\Omega)$, we have

$$R_h(\bigtriangledown \times w) + S_h(\bigtriangledown p) = \bar{R}_h(\bigtriangledown \times \omega) + \bar{R}_h(\bigtriangledown p) = \bar{R}_h(\bigtriangledown \times w + \bigtriangledown p). \tag{2.16}$$

We consider the case of P_h and W_h possibly being discontinuous or being linear and quadratic continuous elements, and we define an LS functional on $U_h \times P_h \times W_h$:

$$\begin{aligned} \mathcal{J}_h^{II}(\mathbf{u}, p, \omega; \mathbf{f}) := {} & \|R_h(\bigtriangledown \times \omega) + S_h(\bigtriangledown p) - \bar{R}_h(\mathbf{f})\|_h^2 \\ & + \sum_{K\in\mathcal{C}_h} h_K^2 \, \|\bigtriangledown \times \omega + \bigtriangledown p - \mathbf{f}\|_{0,K}^2 \\ & + \sum_{E\in\mathcal{E}_h} h_E \int_E |[p]|^2 + \sum_{E\in\mathcal{E}_h} h_E \int_E |[w]|^2 + \|\omega - \bigtriangledown \times \mathbf{u}\|_0^2 + \|\bigtriangledown \cdot \mathbf{u}\|_0^2, \end{aligned} \tag{2.17}$$

where $\mathcal{E}_h$ denotes the collection of interior edges (faces in $\mathbb{R}^3$), $[p]$ is the jump in p across E, and h_E is the length or diameter of E. With $\mathcal{J}_h^{II}$, in the same way as that for (2.8) and (2.9), we can consider an LS minimization problem and then obtain its weak statement: Find $(\mathbf{u}_h, p_h, \omega_h) \in U_h \times P_h \times W_h$ such that

$$\begin{cases} \mathcal{L}_h^{II}((\mathbf{u}_h, p_h, \omega_h); (\mathbf{v}_h, q_h, z_h)) := (R_h(\bigtriangledown \times \omega_h) + S_h(\bigtriangledown p_h), R_h(\bigtriangledown \times z_h) + S_h(\bigtriangledown q_h))_h \\ \quad + \sum_{K\in\mathcal{C}_h} h_K^2 \, (\bigtriangledown \times \omega_h + \bigtriangledown p_h, \bigtriangledown \times z_h + \bigtriangledown q_h)_{0,K} \\ \quad + \sum_{E\in\mathcal{E}_h} h_E \int_E [\omega_h]\,[z_h] + \sum_{E\in\mathcal{E}_h} h_E \int_E [p_h]\,[q_h] \\ \quad + (\omega_h - \bigtriangledown \times \mathbf{u}_h, z_h - \bigtriangledown \times \mathbf{v}_h) + (\bigtriangledown \cdot \mathbf{u}_h, \bigtriangledown \cdot \mathbf{v}_h) \\ \quad = (\mathbf{f}, R_h(\bigtriangledown \times z_h) + S_h(\bigtriangledown q_h)) + \sum_{K\in\mathcal{C}_h} h_K^2 \, (\mathbf{f}, \bigtriangledown \times z_h + \bigtriangledown q_h)_{0,K} \end{cases} \tag{2.18}$$

holds for all $(\mathbf{v}_h, q_h, z_h) \in U_h \times P_h \times W_h$.

Remark 2.3. Method (I) is simpler than method (II), but the latter applies to lower-order continuous elements and discontinuous elements for pressure and vorticity.

Note that using linear or quadratic elements for pressure and vorticity without the $\breve{R}_h$ term and the h^2 factor, method (I) is the standard L^2 LS method [15] which does not have optimal error estimates. In addition, we remark that without the L^2 projection, our method reduces to the BG method [18], and when replacing the L^2 projector by a preconditioner (or an operator of the finite element solution) for the Dirichlet problem of a second-order elliptic equation, the H^{-1} method [14, 32] is obtained.

3. Coercivity and error bounds in energy norm. We shall give a unified analysis for coercivity and error bounds in energy norm for methods (I) and (II). In what follows, C represents a generic positive constant independent of h and may take different values at different occurrences.

3.1. Coercivity analysis. In this subsection we investigate the coercivity.

PROPOSITION 3.1 (see [2, 11]). *Let Ω be a bounded connected domain with a Lipschitz-continuous boundary Γ. Then*

$$\|\mathbf{v}\|_1^2 \le C\,\{\|\bigtriangledown \times \mathbf{v}\|_0^2 + \|\bigtriangledown \cdot \mathbf{v}\|_0^2\} \quad \forall \mathbf{v} \in (H_0^1(\Omega))^d. \tag{3.1}$$

PROPOSITION 3.2 (see [25]). *Under the assumption on Ω as in Proposition* 3.1*, we have*

$$\inf_{q\in L_0^2(\Omega)} \sup_{\mathbf{0}\neq\mathbf{v}\in(H_0^1(\Omega))^d} \frac{(\bigtriangledown \cdot \mathbf{v}, q)}{\|\mathbf{v}\|_1 \, \|q\|_0} \ge C. \tag{3.2}$$

LEMMA 3.1. *Let X be a given Hilbert space, with inner product $(\cdot,\cdot)_X$ and corresponding norm $\|\cdot\|_X = \sqrt{(\cdot,\cdot)_X}$. For any two elements $A \in X, B \in X$ and for any $\alpha \in \mathbb{R}$, we have*

$$\|A-B\|_X^2 \ge \alpha(1-\alpha/2)\,(\|A\|_X^2 + \|B\|_X^2) - 2\alpha(A,B)_X. \tag{3.3}$$

Proof. Equation (3.3) follows from the sum of the two equations

$$\|A-B\|_X^2 = \|A-\alpha A-B\|_X^2 + \alpha(2-\alpha)\,\|A\|_X^2 - 2\alpha\,(A,B)_X,$$
$$\|A-B\|_X^2 = \|A-B+\alpha B\|_X^2 + \alpha(2-\alpha)\,\|B\|_X^2 - 2\alpha\,(A,B)_X. \qquad \square$$

For the following analysis we recall the well-known Young's inequality

$$|a|\,|b| \le \epsilon\,|a|^2 + \frac{1}{4\,\epsilon}\,|b|^2 \quad \forall a,b \in \mathbb{R}, \quad \forall \epsilon > 0$$

and Green's formulae of integrating by parts

$$(\bigtriangledown \times \mathbf{v}, \phi)_{0,D} - (\mathbf{v}, \bigtriangledown \times \phi)_{0,D} = \int_{\partial\, D} \phi\, \mathbf{v} \times \mathbf{n} \quad \forall \mathbf{v} \in (H^1(D))^d, \phi \in (H^1(D))^{2\,d-3},$$
$$(\bigtriangledown \cdot \mathbf{v}, q)_{0,D} + (\mathbf{v}, \bigtriangledown q)_{0,D} = \int_{\partial D} q\, \mathbf{v} \cdot \mathbf{n} \quad \forall \mathbf{v} \in (H^1(D))^d, q \in H^1(D),$$

where $\mathbf{n}$ denotes the exterior unit normal to $\partial\, D$, and D is a Lipschitz subdomain of Ω. We also introduce a notation

$$|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)}^2 := \sum_{K\in\mathcal{C}_h} h_K^2 \|\bigtriangledown \times \omega + \bigtriangledown p\,\|_{0,K}^2 + \sum_{E\in\mathcal{E}_h} h_E \left(\int_E |[p]|^2 + |[\omega]|^2\right). \tag{3.4}$$

Assumption (A1). There exists $C_1 > 0, C_2 > 0$ independent of h such that

$$C_1 \|\mathbf{v}_h\|_0 \le \|\mathbf{v}_h\|_h \le C_2 \|\mathbf{v}_h\|_0 \quad \forall \mathbf{v}_h \in V_{0,h}. \tag{3.5}$$

Remark 3.1. Taking (2.12) as an example. Assumption (A1) can be easily shown by considering each triangle separately (see also [5, p. 157]).

THEOREM 3.1. *Assuming* (A1) *for method* (II), *let* $\mathcal{J}_h$ *stand for* $\mathcal{J}_h^I$ *or* $\mathcal{J}_h^{II}$. *Then, for all* $(\mathbf{u}, p, \omega) \in U_h \times P_h \times W_h$,

$$\mathcal{J}_h(\mathbf{u}, p, \omega; \mathbf{0}) \ge C \{\|\mathbf{u}\|_1^2 + \|p\|_0^2 + \|\omega\|_0^2\}. \tag{3.6}$$

Proof. We consider method (II) here. The argument remains unchanged for method (I). One needs only to note that, in method (I), $P_h \times W_h$ are continuous and $(\cdot,\cdot)$ is in place of $(\cdot,\cdot)_h$.

In the proof we need only to deal with $\|\omega - \bigtriangledown \times \mathbf{u}\|_0^2$ and $\|R_h(\bigtriangledown \times \omega) + S_h(\bigtriangledown p)\|_h^2$. The proof is divided into three steps. In the first two steps we find lower bounds for $\|\omega - \bigtriangledown \times \mathbf{u}\|_0^2 + \|R_h(\bigtriangledown \times \omega) + S_h(\bigtriangledown p)\|_h^2$. In the last step we use the mesh-dependent terms to obtain (3.6).

Step 1. Let $\alpha > 0$ be a constant to be determined. From Lemma 3.1 we have

$$\|\omega - \bigtriangledown \times \mathbf{u}\|_0^2 \ge \alpha\,(1 - \alpha/2)\,\{\|\bigtriangledown \times \mathbf{u}\|_0^2 + \|\omega\|_0^2\} - 2\,\alpha\,(\omega, \bigtriangledown \times\ \mathbf{u}). \tag{3.7}$$

We take $\tilde{\mathbf{u}} \in V_{0,h}$ as the Clément-interpolant [2, 4] of $\mathbf{u} \in U_h$ and have

$$\left(\sum_{K \in \mathcal{C}_h} h_K^{-2} \|\tilde{\mathbf{u}} - \mathbf{u}\|_{0,K}^2 + \sum_{E \in \mathcal{E}_h} h_E^{-1} \int_E |\tilde{\mathbf{u}} - \mathbf{u}|^2\right)^{1/2} + \|\tilde{\mathbf{u}}\|_1 \le C \|\mathbf{u}\|_1. \tag{3.8}$$

We also have

$$\begin{aligned} -2\,\alpha\,(\omega, \bigtriangledown \times \mathbf{u}) &= -2\,\alpha\,(\omega, \bigtriangledown \times \tilde{\mathbf{u}}) - 2\,\alpha\,(\omega, \bigtriangledown \times (\mathbf{u} - \tilde{\mathbf{u}})) \\ &= -2\,\alpha\,(R_h(\bigtriangledown \times \omega), \tilde{\mathbf{u}})_h - 2\,\alpha\,(\omega, \bigtriangledown \times (\mathbf{u} - \tilde{\mathbf{u}})), \end{aligned} \tag{3.9}$$

and

$$\begin{aligned} &- 2\,\alpha\,(R_h(\bigtriangledown \times \omega), \tilde{\mathbf{u}})_h + \|R_h(\bigtriangledown \times \omega) + S_h(\bigtriangledown p)\|_h^2 \\ &\quad = \|R_h(\bigtriangledown \times \omega) + S_h(\bigtriangledown p) - \alpha\,\tilde{\mathbf{u}}\|_h^2 - \alpha^2 \|\tilde{\mathbf{u}}\|_h^2 + 2\,\alpha\,(S_h(\bigtriangledown p), \tilde{\mathbf{u}})_h, \end{aligned} \tag{3.10}$$

where

$$\begin{aligned} -\alpha^2 \|\tilde{\mathbf{u}}\|_h^2 &\ge -\alpha^2\,C\,\|\tilde{\mathbf{u}}\|_0^2 \qquad \text{(by Assumption (A1))} \\ &\ge -\alpha^2\,C\,\|\mathbf{u}\|_1^2 \qquad \text{(by (3.8))} \\ &\ge -\alpha^2\,C\,\|\bigtriangledown \times \mathbf{u}\|_0^2 - \alpha^2\,C\,\|\bigtriangledown \cdot \mathbf{u}\|_0^2 \qquad \text{(by Proposition 3.1)}, \end{aligned} \tag{3.11}$$

$$\begin{aligned} 2\,\alpha\,(S_h(\bigtriangledown p), \tilde{\mathbf{u}})_h &= -2\,\alpha\,(p, \bigtriangledown \cdot \tilde{\mathbf{u}}) \\ &= -2\,\alpha\,(p, \bigtriangledown \cdot \mathbf{u}) + 2\,\alpha\,(p, \bigtriangledown \cdot (\mathbf{u} - \tilde{\mathbf{u}})), \end{aligned} \tag{3.12}$$

and

$$-2\alpha(p, \bigtriangledown \cdot \mathbf{u}) \ge -\epsilon_1 \|p\|_0^2 - \frac{\alpha^2\,C}{\epsilon_1} \|\bigtriangledown \cdot \mathbf{u}\|_0^2 \tag{3.13}$$

(by Young's inequality). Here $\epsilon_1 > 0$ is a constant to be determined later.

Therefore, summarizing (3.7) and (3.9)–(3.13), we get

$$\begin{cases} \|\omega - \bigtriangledown \times \mathbf{u}\|_0^2 + \|R_h(\bigtriangledown \times \omega) + S_h(\bigtriangledown p)\|_h^2 \\ \geq \alpha(1-\alpha/2)\,\|\omega\|_0^2 + \alpha\,[1-\alpha\,(1/2+C)]\;\|\bigtriangledown \times \mathbf{u}\|_0^2 \\ \quad +2\,\alpha\,\{-(\omega, \bigtriangledown \times (\mathbf{u}-\tilde{\mathbf{u}})) + (p, \bigtriangledown \cdot (\mathbf{u}-\tilde{\mathbf{u}}))\} \\ \quad -\epsilon_1\,\|p\|_0^2 - (\frac{\alpha^2\,C}{\epsilon_1} + \alpha^2\,C)\,\|\bigtriangledown \cdot \mathbf{u}\|_0^2, \end{cases} \tag{3.14}$$

where

$$\begin{cases} 2\,\alpha\,\{-(\omega, \bigtriangledown \times (\mathbf{u}-\tilde{\mathbf{u}})) + (p, \bigtriangledown \cdot (\mathbf{u}-\tilde{\mathbf{u}}))\} \\ \quad = -2\,\alpha \sum\limits_{K\in\mathcal{C}_h} (\bigtriangledown \times \omega + \bigtriangledown p, \mathbf{u}-\tilde{\mathbf{u}})_{0,K} \\ \qquad -2\,\alpha \sum\limits_{E\in\mathcal{E}_h} \int_E [\omega]\,(\mathbf{u}-\tilde{\mathbf{u}}) \times \mathbf{n}_E + 2\,\alpha \sum\limits_{E\in\mathcal{E}_h} \int_E [p]\,(\mathbf{u}-\tilde{\mathbf{u}}) \cdot \mathbf{n}_E, \\ \geq -2\,\alpha\,C\,|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)} \\ \times \Big(\sum\limits_{K\in\mathcal{C}_h} h_K^{-2}\,\|\mathbf{u}-\tilde{\mathbf{u}}\|_{0,K}^2 + \sum\limits_{E\in\mathcal{E}_h} h_E^{-1}\,\int_E\,|\mathbf{u}-\tilde{\mathbf{u}}|^2 \Big)^{1/2} \\ \geq -2\,\alpha\,C\,\|\mathbf{u}\|_1\,|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)} \geq -\alpha^2\,\|\mathbf{u}\|_1^2 - C\,|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)}^2 \\ \geq -\alpha^2\,C\,\|\bigtriangledown \times \mathbf{u}\|_0^2 - \alpha^2\,C\,\|\bigtriangledown \cdot \mathbf{u}\|_0^2 - C\,|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)}^2. \end{cases} \tag{3.15}$$

Thus, (3.14) becomes

$$\begin{cases} \|\omega - \bigtriangledown \times \mathbf{u}\|_0^2 + \|R_h(\bigtriangledown \times \omega) + S_h(\bigtriangledown p)\|_h^2 \\ \geq \alpha(1-\alpha/2)\,\|\omega\|_0^2 + \alpha\,[1-\alpha\,(1/2+2\,C)]\;\|\bigtriangledown \times \mathbf{u}\|_0^2 \\ \quad -\epsilon_1\,\|p\|_0^2 - C\,|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)}^2 - \Big(\frac{\alpha^2\,C}{\epsilon_1} + \alpha^2\,2\,C\Big)\;\|\bigtriangledown \cdot \mathbf{u}\|_0^2. \end{cases} \tag{3.16}$$

Step 2. Let $\beta > 0$ be a constant to be determined. From Proposition 3.2 we can find $\mathbf{v}^* \in (H_0^1(\Omega))^d$ such that

$$(\bigtriangledown \cdot \mathbf{v}^*, p) = \|p\|_0^2, \quad \|\mathbf{v}^*\|_1 \leq C\,\|p\|_0. \tag{3.17}$$

We take $\tilde{\mathbf{v}}^* \in V_{0,h}$ as the Clément-interpolant [2, 4] of $\mathbf{v}^*$ and have

$$\left(\sum_{K\in\mathcal{C}_h} h_K^{-2}\,\|\tilde{\mathbf{v}}^* - \mathbf{v}^*\|_{0,K}^2 + \sum_{E\in\mathcal{E}_h} h_E^{-1} \int_E\,|\tilde{\mathbf{v}}^* - \mathbf{v}^*|^2 \right)^{1/2} + \|\tilde{\mathbf{v}}^*\|_1 \leq C\,\|\mathbf{v}^*\|_1. \tag{3.18}$$

We can write

$$\begin{aligned} \|R_h(\bigtriangledown \times \omega) + S_h(\bigtriangledown p)\|_h^2 &= \|R_h(\bigtriangledown \times \omega) + S_h(\bigtriangledown p) + \beta\,\tilde{\mathbf{v}}^*\|_h^2 \\ &\quad -\beta^2\,\|\tilde{\mathbf{v}}^*\|_h^2 - 2\,\beta\,\{(R_h(\bigtriangledown \times \omega), \tilde{\mathbf{v}}^*)_h + (S_h(\bigtriangledown p), \tilde{\mathbf{v}}^*)_h\}, \end{aligned} \tag{3.19}$$

where

$$-\beta^2\,\|\tilde{\mathbf{v}}^*\|_h^2 \geq -\beta^2\,C\,\|\tilde{\mathbf{v}}^*\|_0^2 \geq -\beta^2\,C\,\|\mathbf{v}^*\|_1^2 \geq -\beta^2\,C\,\|p\|_0^2, \tag{3.20}$$

$$\begin{cases} -2\,\beta\,\{(R_h(\bigtriangledown \times \omega), \tilde{\mathbf{v}}^*)_h + (S_h(\bigtriangledown p), \tilde{\mathbf{v}}^*)_h\} \\ = -2\,\beta\,\{(\omega, \bigtriangledown \times \tilde{\mathbf{v}}^*) - (p, \bigtriangledown \cdot \tilde{\mathbf{v}}^*)\} \\ = 2\,\beta\,(p, \bigtriangledown \cdot \mathbf{v}^*) - 2\,\beta\,(\omega, \bigtriangledown \times \mathbf{v}^*) \\ \quad +2\,\beta\,\{(\omega, \bigtriangledown \times (\mathbf{v}^* - \tilde{\mathbf{v}}^*)) - (p, \bigtriangledown \cdot (\mathbf{v}^* - \tilde{\mathbf{v}}^*))\} \\ = 2\,\beta\,\|p\|_0^2 - 2\,\beta\,(\omega, \bigtriangledown \times \mathbf{v}^*) + 2\,\beta \sum\limits_{K\in\mathcal{C}_h} (\bigtriangledown \times \omega + \bigtriangledown p, \mathbf{v}^* - \tilde{\mathbf{v}}^*)_{0,K} \\ \quad +2\,\beta \sum\limits_{E\in\mathcal{E}_h} \int_E [\omega]\,(\mathbf{v}^* - \tilde{\mathbf{v}}^*) \times \mathbf{n}_E - 2\,\beta \sum\limits_{E\in\mathcal{E}_h} \int_E [p]\,(\mathbf{v}^* - \tilde{\mathbf{v}}^*) \cdot \mathbf{n}_E \end{cases} \tag{3.21}$$

with

(3.22)
$$\begin{cases} 2\,\beta \sum\limits_{K\in\mathcal{C}_h} (\bigtriangledown\times\omega+\bigtriangledown p, \mathbf{v}^*-\tilde{\mathbf{v}}^*)_{0,K} \\ \quad +2\,\beta \sum\limits_{E\in\mathcal{E}_h} \int_E [\omega]\,(\mathbf{v}^*-\tilde{\mathbf{v}}^*)\times\mathbf{n}_E - 2\,\beta \sum\limits_{E\in\mathcal{E}_h}\int_E [p]\,(\mathbf{v}^*-\tilde{\mathbf{v}}^*)\cdot\mathbf{n}_E \\ \geq -2\,\beta\,C\,|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)} \left(\sum\limits_{K\in\mathcal{C}_h} h_K^{-2}\,\|\tilde{\mathbf{v}}^*-\mathbf{v}^*\|_{0,K}^2 + \sum\limits_{E\in\mathcal{E}_h} h_E^{-1}\int_E |\tilde{\mathbf{v}}^*-\mathbf{v}^*|^2\right)^{1/2} \\ \geq -2\,\beta\,C\,|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)}\,\|\mathbf{v}^*\|_1 \\ \geq -2\,\beta\,C\,|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)}\,\|p\|_0 \geq -\beta^2\,\|p\|_0^2 - C\,|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)}^2, \end{cases}$$

and

$$-2\,\beta\,(\omega,\bigtriangledown\times\mathbf{v}^*) \geq -2\,\beta\,C\,\|\omega\|_0\,\|\mathbf{v}^*\|_1 \geq -\epsilon_2\,\|\omega\|_0^2 - \frac{C\,\beta^2}{\epsilon_2}\,\|p\|_0^2. \tag{3.23}$$

Here $\epsilon_2>0$ is also a constant to be determined later.

Summarizing (3.19)–(3.23), we get

$$\begin{aligned} \|R_h(\bigtriangledown\times\omega)+S_h(\bigtriangledown p)\|_h^2 \geq \beta\,&[2-\beta\,(C+1+C/\epsilon_2)]\,\|p\|_0^2 \\ &-\epsilon_2\,\|\omega\|_0^2 - C\,|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)}^2. \end{aligned} \tag{3.24}$$

Step 3. From (3.16) and (3.24), taking

$$0<\alpha<\frac{1}{1/2+2\,C},\quad 0<\epsilon_2<\alpha\,(1-\alpha/2), \tag{3.25}$$

$$0<\beta<\frac{2}{C+1+C/\epsilon_2},\quad 0<\epsilon_1<\beta\,[2-\beta\,(C+1+C/\epsilon_2)]\,, \tag{3.26}$$

we have

$$\begin{cases} \|\omega-\bigtriangledown\times\mathbf{u}\|_0^2 + 2\,\|R_h(\bigtriangledown\times\omega)+S_h(\bigtriangledown p)\|_h^2 \\ \geq [\alpha(1-\alpha/2)-\epsilon_2]\,\|\omega\|_0^2 + \alpha\,[1-\alpha\,(1/2+2\,C)]\,\|\bigtriangledown\times\mathbf{u}\|_0^2 \\ \quad +\{\beta\,[2-\beta\,(C+1+C/\epsilon_2)]-\epsilon_1\}\,\|p\|_0^2 \\ \quad -2\,C\,|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)}^2 - (\frac{\alpha^2\,C}{\epsilon_1}+\alpha^2\,2\,C)\,\|\bigtriangledown\cdot\mathbf{u}\,\|_0^2. \end{cases} \tag{3.27}$$

Now we take positive constants L_i, $i=1,2$, such that

$$L_1>2\,C,\quad L_2>\frac{\alpha^2\,C}{\epsilon_1}+\alpha^2\,2\,C, \tag{3.28}$$

and we have

$$\begin{cases} \max(2,L_1,L_2)\,\mathcal{J}_h^{II}(\mathbf{u},p,\omega;\mathbf{0}) \geq \|\omega-\bigtriangledown\times\mathbf{u}\|_0^2 \\ \quad +2\,\|R_h(\bigtriangledown\times\omega)+S_h(\bigtriangledown p)\|_h^2 + L_1\,|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)}^2 + L_2\,\|\bigtriangledown\cdot\mathbf{u}\|_0^2 \\ \geq [\alpha(1-\alpha/2)-\epsilon_2]\,\|\omega\|_0^2 + \alpha\,[1-\alpha\,(1/2+2\,C)]\,\|\bigtriangledown\times\mathbf{u}\|_0^2 \\ \quad +\{\beta\,[2-\beta\,(C+1+C/\epsilon_2)]-\epsilon_1\}\,\|p\|_0^2 \\ \quad +(L_1-2\,C)\,|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)}^2 + [L_2-(\frac{\alpha^2\,C}{\epsilon_1}+\alpha^2\,2\,C)]\,\|\bigtriangledown\cdot\mathbf{u}\|_0^2 \\ \geq C\{\|\omega\|_0^2+\|p\|_0^2+\|\bigtriangledown\times\mathbf{u}\|_0^2+\|\bigtriangledown\cdot\mathbf{u}\|_0^2+|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)}^2\} \\ \geq C\{\|\mathbf{u}\|_1^2+\|p\|_0^2+\|\omega\|_0^2+|(p,\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)}^2\}. \end{cases} \tag{3.29}$$

Hence, we obtain (3.6) for $\mathcal{J}_h^{II}$. ∎

Using Theorem 3.1 and the Lax–Milgram lemma [3, 5, 29] we can easily obtain the following.

COROLLARY 3.1. *Under the same assumptions as in Theorem* 3.1*, the finite element problems* (2.9) *and* (2.18) *have a unique solution.*

COROLLARY 3.2. *Under the same assumptions as in Theorem* 3.1 *and assuming a quasi-uniform* $\mathcal{C}_h$*, we can conclude that the condition number of the linear system from the finite element problem is* $\mathcal{O}(h^{-2})$.

Proof. We take method (I) as an example. Since $\breve{R}_h$ is an L^2 projector, we have

$$\|\breve{R}_h(\mathbf{g})\|_0 \le C\,\|\mathbf{g}\|_0;$$

then by the inverse estimation [5, 29] we have, for all $(\mathbf{v}_h, q_h, z_h) \in U_h \times P_h \times W_h$,

$$\|\breve{R}_h(\bigtriangledown \times z_h + \bigtriangledown q_h)\|_0 \le C\,\|\bigtriangledown \times z_h + \bigtriangledown q_h\|_0 \le C\,h^{-1}\,\{\|q_h\|_0 + \|z_h\|_0\},$$

and thus

$$\mathcal{L}_h^I((\mathbf{v}_h, q_h, z_h); (\mathbf{v}_h, q_h, z_h)) \le C\,h^{-2}\,\{\|\mathbf{v}_h\|_0^2 + \|q_h\|_0^2 + \|z_h\|_0^2\},$$

which, together with (3.6) and the symmetry of $\mathcal{L}_h^I$, completes the proof. ∎

3.2. Error bounds in energy norm. Since $\mathcal{L}_h$ is symmetric and positive definite (see Theorem 3.1), we introduce a norm $|||\cdot|||$ on $U_h \times P_h \times W_h$ by

$$|||(\mathbf{v}_h, q_h, z_h)|||^2 := \mathcal{L}_h((\mathbf{v}_h, q_h, z_h); (\mathbf{v}_h, q_h, z_h)), \tag{3.30}$$

where $\mathcal{L}_h$ stands for $\mathcal{L}_h^I$ or $\mathcal{L}_h^{II}$. $|||\cdot|||$ will be referred to as *energy norm*. We can also easily show the generalized Cauchy–Schwarz inequality

$$\mathcal{L}_h((\mathbf{u}, p, \omega); (\mathbf{v}, q, z)) \le |||(\mathbf{u}, p, \omega)|||\,|||(\mathbf{v}, q, z)||| \tag{3.31}$$

for all $(\mathbf{u}, p, \omega), (\mathbf{v}, q, z) \in ((H_0^1(\Omega))^d + U_h) \times (H^1(\Omega) + P_h) \times ((H^1(\Omega))^{2\,d-3} + W_h)$. Here $x \in \mathbb{Y} + \mathbb{T}$ means that $x \in \mathbb{Y}$ or $x \in \mathbb{T}$ or $x = y + t$ with $y \in \mathbb{Y}$ and $t \in \mathbb{T}$.

LEMMA 3.2. *Let* $(\mathbf{u}, p, \omega) \in (H^1(\Omega))^d \times H^1(\Omega) \times (H^1(\Omega))^{2d-3}$ *and* $(\mathbf{u}_h, p_h, \omega_h) \in U_h \times P_h \times W_h$ *be the exact and approximate solutions, respectively. Then, for all* $(\mathbf{v}_h, q_h, z_h) \in U_h \times P_h \times W_h$*,*

$$\mathcal{L}_h((\mathbf{u} - \mathbf{u}_h, p - p_h, \omega - \omega_h); (\mathbf{v}_h, q_h, z_h)) = 0. \tag{3.32}$$

Proof. Equation (3.32) can be easily shown, due to (2.2), (2.16), and

$$\begin{aligned}(\mathbf{f}, \breve{R}_h(\bigtriangledown \times z_h + \bigtriangledown q_h)) &= (\breve{R}_h(\mathbf{f}), \breve{R}_h(\bigtriangledown \times z_h + \bigtriangledown q_h)) \\ &= (\breve{R}_h(\bigtriangledown \times \omega + \bigtriangledown p), \breve{R}_h(\bigtriangledown \times z_h + \bigtriangledown q_h)),\end{aligned} \tag{3.33}$$

$$\begin{aligned}&(\mathbf{f}, R_h(\bigtriangledown \times\ z_h) + S_h(\bigtriangledown q_h)) \\ &\quad = (\bar{R}_h(\mathbf{f}), R_h(\bigtriangledown \times\ z_h) + S_h(\bigtriangledown q_h))_h \\ &\quad = (\bar{R}_h(\bigtriangledown \times \omega + \bigtriangledown p), R_h(\bigtriangledown \times\ z_h) + S_h(\bigtriangledown q_h))_h \\ &\quad = (R_h(\bigtriangledown \times \omega) + S_h(\bigtriangledown p), R_h(\bigtriangledown \times\ z_h) + S_h(\bigtriangledown q_h))_h.\end{aligned} \tag{3.34}$$

∎

Assumption (A2). For $\omega \in (H^{l+1}(\Omega))^{2d-3}$ and $p \in H^{m+1}(\Omega) \cap L_0^2(\Omega)$, with $l, m \ge 0$, there exist $\tilde{\omega} \in W_h$ and $\tilde{p} \in P_h$ such that

$$R_h(\bigtriangledown \times (\omega - \tilde{\omega})) + S_h(\bigtriangledown(p - \tilde{p})) = \mathbf{0} \quad \text{(for method (II))} \tag{3.35}$$

or

$$\breve{R}_h(\bigtriangledown \times (\omega - \tilde{\omega}) + \bigtriangledown(p - \tilde{p})) = \mathbf{0} \quad \text{(for method (I))} \tag{3.36}$$

with

$$\|\tilde{\omega} - \omega\|_0 + |(0, \tilde{\omega} - \omega)|_{(\mathcal{C}_h, \mathcal{E}_h)} \leq C\, h^s\, \|\omega\|_s, \quad 1 \leq s \leq l+1 \tag{3.37}$$

and

$$\|\tilde{p} - p\|_0 + |(\tilde{p} - p, 0)|_{(\mathcal{C}_h, \mathcal{E}_h)} \leq C\, h^s\, \|p\|_s, \quad 1 \leq s \leq m+1. \tag{3.38}$$

Remark 3.2. To make Assumption (A2) hold, the approximation spaces for pressure and vorticity are required to have either interior or edge (face) degrees of freedom or both with respect to each element. All standard approximation spaces satisfy this requirement, with lower-order approximation spaces enriched by suitable artificial element bubbles or edge (face) bubbles or both. Here we briefly consider method (II) for 2D problems. Assumption (A2) holds for method (II), using continuous $\mathcal{P}_r$ elements with $r \geq 3$ or discontinuous $\mathcal{P}_r$ elements with $r \geq 0$ or $\mathcal{P}_1^+ (= \mathcal{P}_1 + b_K)$ or $\mathcal{P}_2^+$, where $b_K \in H_0^1(K)$ is a bubble $\lambda_1\lambda_2\lambda_3$ and λ_i is the ith bary-coordinate on a triangle. See Theorem 3.4 for details of the verification of Assumption (A2).

THEOREM 3.2. *Assuming the assumptions of Theorem* 3.1 *and Assumption* (A2)*, let* $(\mathbf{u}, p, \omega) \in (H^1(\Omega))^d \times H^1(\Omega) \times (H^1(\Omega))^{2\,d-3}$ *and* $(\mathbf{u}_h, p_h, \omega_h) \in U_h \times P_h \times W_h$ *be the exact and approximate solutions. We have*

$$|||(\mathbf{u} - \mathbf{u}_h, p - p_h, \omega - \omega_h)||| \leq C\, \Lambda(\tilde{\mathbf{u}} - \mathbf{u}, \tilde{p} - p, \tilde{\omega} - \omega), \tag{3.39}$$

where $\tilde{\mathbf{u}} \in U_h$ *is any given function,* $\tilde{p}$ *and* $\tilde{\omega}$ *come from Assumption* (A2)*, and*

$$\begin{aligned} \Lambda(\tilde{\mathbf{u}} - \mathbf{u}, \tilde{p} - p, \tilde{\omega} - \omega) &:= \|\tilde{\mathbf{u}} - \mathbf{u}\|_1 + \|\tilde{p} - p\|_0 \\ &\quad + \|\tilde{\omega} - \omega\|_0 + |(\tilde{p} - p, \tilde{\omega} - \omega)|_{(\mathcal{C}_h, \mathcal{E}_h)}. \end{aligned} \tag{3.40}$$

We further have

$$\|p - p_h\|_0 + \|\omega - \omega_h\|_0 + \|\mathbf{u} - \mathbf{u}_h\|_1 \leq C\, \Lambda(\tilde{\mathbf{u}} - \mathbf{u}, \tilde{p} - p, \tilde{\omega} - \omega), \tag{3.41}$$

$$|(p - p_h, \omega - \omega_h)|_{(\mathcal{C}_h, \mathcal{E}_h)} \leq C\, \Lambda(\tilde{\mathbf{u}} - \mathbf{u}, \tilde{p} - p, \tilde{\omega} - \omega), \tag{3.42}$$

$$\|R_h(\bigtriangledown \times (\omega - \omega_h)) + S_h(\bigtriangledown(p - p_h))\|_h \leq C\, \Lambda(\tilde{\mathbf{u}} - \mathbf{u}, \tilde{p} - p, \tilde{\omega} - \omega) \tag{3.43}$$

or

$$\|\breve{R}_h(\bigtriangledown \times (\omega - \omega_h) + \bigtriangledown(p - p_h))\|_0 \leq C\, \Lambda(\tilde{\mathbf{u}} - \mathbf{u}, \tilde{p} - p, \tilde{\omega} - \omega). \tag{3.44}$$

Proof. It suffices to show (3.39) with (3.40). From (3.30), Lemma 3.2, and (3.31), we have

$$|||(\tilde{\mathbf{u}} - \mathbf{u}_h, \tilde{p} - p_h, \tilde{\omega} - \omega_h)||| \leq |||(\tilde{\mathbf{u}} - \mathbf{u}, \tilde{p} - p, \tilde{\omega} - \omega)|||. \tag{3.45}$$

Using the triangle inequality, we then get

$$|||(\mathbf{u} - \mathbf{u}_h, p - p_h, \omega - \omega_h)||| \leq C\, |||(\tilde{\mathbf{u}} - \mathbf{u}, \tilde{p} - p, \tilde{\omega} - \omega)|||. \tag{3.46}$$

By Assumption (A2) we have

$$\begin{aligned}|||(\tilde{\mathbf{u}}-\mathbf{u},\tilde{p}-p,\tilde{\omega}-\omega)|||^2 &= \mathcal{L}_h((\tilde{\mathbf{u}}-\mathbf{u},\tilde{p}-p,\tilde{\omega}-\omega);(\tilde{\mathbf{u}}-\mathbf{u},\tilde{p}-p,\tilde{\omega}-\omega))\\ &= |(\tilde{p}-p,\tilde{\omega}-\omega)|^2_{(\mathcal{C}_h,\mathcal{E}_h)} + \|\tilde{\omega}-\omega-\bigtriangledown\times(\tilde{\mathbf{u}}-\mathbf{u})\|_0^2\\ &\quad + \|\bigtriangledown\cdot(\tilde{\mathbf{u}}-\mathbf{u})\|_0^2,\end{aligned} \tag{3.47}$$

which completes the proof. ∎

As a concrete application, we consider the 2D case and state the error estimates for methods (I) and (II) in the following.

THEOREM 3.3. *Assuming the same hypotheses as in Theorem* 3.2*, when employing equal-order continuous interpolation* $\mathcal{P}_r-\mathcal{P}_r-\mathcal{P}_r$ *with* $r\geq 3$ *for methods* (I) *and* (II)*, or for method* (II) *employing* $\mathcal{P}_r-\mathcal{P}_r^+-\mathcal{P}_r^+$ *with* $r=1,2$ *or employing* $\mathcal{P}_r$*(continuous)-*$\mathcal{P}_{r-1}$*(discontinuous)-*$\mathcal{P}_{r-1}$*(discontinuous) with* $r\geq 1$ *for* $(\mathbf{u},p,\omega)\in(H^{r+1}(\Omega))^2\times H^r(\Omega)\times H^r(\Omega)$*, we have*

$$\|\mathbf{u}-\mathbf{u}_h\|_1+\|p-p_h\|_0+\|\omega-\omega_h\|_0\leq C\,h^r\ (\|\mathbf{u}\|_{r+1}+\|p\|_r+\|\omega\|_r). \tag{3.48}$$

When employing unequal-order continuous interpolation $\mathcal{P}_{r+1}-\mathcal{P}_r-\mathcal{P}_r$ *with* $r\geq 3$ *for methods* (I) *and* (II)*, or for method* (II) *employing* $\mathcal{P}_{r+1}-\mathcal{P}_r^+-\mathcal{P}_r^+$ *with* $r=1,2$ *for* $(\mathbf{u},p,\omega)\in(H^{r+2}(\Omega))^2\times H^{r+1}(\Omega)\times H^{r+1}(\Omega)$*, we have*

$$\|\mathbf{u}-\mathbf{u}_h\|_1+\|p-p_h\|_0+\|\omega-\omega_h\|_0\leq C\,h^{r+1}\ (\|\mathbf{u}\|_{r+2}+\|p\|_{r+1}+\|\omega\|_{r+1}). \tag{3.49}$$

Proof. Let U_h be the piecewise $\mathcal{P}_l$ continuous element with $l\geq 1$ and let $\tilde{\mathbf{u}}\in U_h$ be an interpolant of $\mathbf{u}\in(H^k(\Omega))^2$ satisfying (see [2, 3, 5, 29])

$$\|\tilde{\mathbf{u}}-\mathbf{u}\|_1\leq C\,h^{s-1}\,\|\mathbf{u}\|_s,\quad 1\leq s\leq\min(k,l+1). \tag{3.50}$$

From Theorem 3.2 and Assumption (A2) we immediately have (3.48) and (3.49). ∎

Remark 3.3. Note that for lower-order approximation spaces ($r=1,2$), the error estimates for method (I) are not optimal and are the same as those of the standard LS method [16], because Assumption (A2) does not hold. However, we can understand $\mathcal{P}_3$ as the enrichment of $\mathcal{P}_1$ or $\mathcal{P}_2$ with suitable element bubbles and edge bubbles. Denoting $\mathcal{P}_3$ as $\mathcal{P}_1^{\#}$ (the enrichment of $\mathcal{P}_1$) or $\mathcal{P}_2^{\square}$ (the enrichment of $\mathcal{P}_2$), we have (3.48) for method (I) with $r=1$ or $r=2$, using $\mathcal{P}_1-\mathcal{P}_1^{\#}-\mathcal{P}_1^{\#}$ or $\mathcal{P}_2-\mathcal{P}_2^{\square}-\mathcal{P}_2^{\square}$ for $(\mathbf{u},p,\omega)$, and we have (3.49) for method (I) with $r=1$ or $r=2$, using $\mathcal{P}_2-\mathcal{P}_1^{\#}-\mathcal{P}_1^{\#}$ or $\mathcal{P}_3-\mathcal{P}_2^{\square}-\mathcal{P}_2^{\square}$ for $(\mathbf{u},p,\omega)$.

Before closing this section we verify Assumption (A2) using triangular finite elements in a 2D domain. For rectangular elements in a 2D or three-dimensional (3D) domain and tetrahedrons in a 3D domain the verification is similar. In the following we use the $\mathcal{P}_3$ element as an example to show how to verify Assumption (A2).

THEOREM 3.4. *If* $\omega\in H^{l+1}(\Omega)$ *and* $p\in H^{m+1}(\Omega)$*, with* $l,m\geq 0$*, then there exist* $\tilde{p}\in P_h$ *and* $\tilde{\omega}\in W_h$ *such that* (3.35)–(3.38) *hold. Here*

$$W_h:=\{q\in H^1(\Omega);q_{|_K}\in\mathcal{P}_3(K)\ \forall K\in\mathcal{C}_h\},\quad P_h:=W_h\cap L_0^2(\Omega). \tag{3.51}$$

Proof. Consider ω as an example. We shall follow the idea of [2, Lemma A.3, p. 100]. In order to include the less regular case $l=m=0$, we first let $\omega^0\in W_h$ be

an interpolation which satisfies [2, p. 111]

$$\|\omega-\omega^0\|_0+\Big(\sum_{K\in\mathcal{C}_h} h_K^2\,|\omega-\omega^0|_{1,K}^2\Big)^{1/2}\le C\,h^s\,\|\omega\|_s \tag{3.52}$$

and

$$\Big(\sum_{K\in\mathcal{C}_h} h_K^{-2}\,\|\omega-\omega^0\|_{0,K}^2\Big)^{1/2}+|\omega-\omega^0|_1\le C\,h^{s-1}\,\|\omega\|_s, \tag{3.53}$$

where $1\le s\le \min(4,l+1)$. We then define $\tilde{\omega}\in W_h$ in (3.54)–(3.56):

$$\tilde{\omega}(i)=\omega^0(i),\quad 1\le i\le 3\quad \forall K\in\mathcal{C}_h, \tag{3.54}$$

$$\int_E(\tilde{\omega}-\omega)\,v=0\quad \forall v\in\mathcal{P}_1(E)\quad \forall E\in\partial K\quad \forall K\in\mathcal{C}_h, \tag{3.55}$$

where $\mathcal{P}_1(E)$ is the space of linear polynomials on E,

$$\int_K(\tilde{\omega}-\omega)=0\quad \forall K\in\mathcal{C}_h. \tag{3.56}$$

We show that

$$\breve{R}_h(\bigtriangledown\times(\tilde{\omega}-\omega))=\mathbf{0},\quad R_h(\bigtriangledown\times(\tilde{\omega}-\omega))=\mathbf{0}. \tag{3.57}$$

In fact, from the definition (2.5) of $\breve{R}_h$, (3.55), and (3.56) we have

$$\begin{aligned}\int_K \breve{R}_h(\bigtriangledown\times(\omega-\tilde{\omega}))\,\mathbf{v}&=\int_K\bigtriangledown\times(\omega-\tilde{\omega})\,\mathbf{v}\\&=\int_K(\omega-\tilde{\omega})\;\bigtriangledown\times\mathbf{v}-\sum_{E\in\partial K}\int_E(\omega-\tilde{\omega})\,\mathbf{v}\times\mathbf{n}_E\\&=0\quad\forall\mathbf{v}\in(\mathcal{P}_1(K))^2,\quad\forall K\in\mathcal{C}_h,\end{aligned} \tag{3.58}$$

where we have used the fact that $\bigtriangledown\times\mathbf{v}_{|_K}\in\mathcal{P}_0(K)$, $\mathbf{v}\times\mathbf{n}_E|_E\in\mathcal{P}_1(E)$, since $\mathbf{v}_{|_K}\in(\mathcal{P}_1(K))^2$. It follows that $\breve{R}_h(\bigtriangledown\times(\tilde{\omega}-\omega))=\mathbf{0}$. Similarly, since $V_{0,h}$ is a piecewise linear polynomial space and

$$(R_h(\bigtriangledown\times(\omega-\tilde{\omega})),\mathbf{v})_h=(\omega-\tilde{\omega},\bigtriangledown\times\mathbf{v})=\sum_{K\in\mathcal{C}_h}(\omega-\tilde{\omega},\bigtriangledown\times\mathbf{v})_{0,K}=0\quad\forall\mathbf{v}\in V_{0,h},$$

we have $R_h(\bigtriangledown\times(\tilde{\omega}-\omega))=\mathbf{0}$. The approximation property (3.37) follows the standard routine and (3.52)–(3.56); cf. [2, Lemma A.4, p. 101 or pp. 136–138] for a similar argument. Similarly, we can construct $\tilde{p}\in P_h$, satisfying similar properties as $\tilde{\omega}$. We proceed as follows: first let $\bar{p}$ be constructed as above, and then let $\tilde{p}=\bar{p}-\frac{1}{|\Omega|}\int_\Omega\bar{p}=\bar{p}-\frac{1}{|\Omega|}\int_\Omega(\bar{p}-p)$, because of $\int_\Omega p=0$. ∎

Remark 3.4. Methods (I) and (II) and their analysis cover nonaffine families of finite elements such as quads and hexes. In the analysis, only the verification of Assumption (A2) may involve the mapping. In the case of nonaffine mapping families, such verification can be done on the reference element through the mapping. We

consider 2D quadrilaterals. Let F_K denote the mapping from the reference element $\hat{K}$ to K, which associates the function q defined on K with the function $\hat{q}$ defined on $\hat{K}$ by $q = \hat{q} \circ F_K^{-1}$. We define $Z_h = \{\mathbf{v} \in (L^2(\Omega))^2; \mathbf{v}|_K \circ F_K \in (Q_1(\hat{K}))^2 \ \forall K \in \mathcal{C}_h\}$, with $Q_r(\hat{K})$, $r \geq 1$, being the standard element [3, 5, 29]. As approximating spaces of the pressure and vorticity, for example, we take $P_h = W_h = \{q \in H^1(\Omega); q|_K \circ F_K \in Q_4(\hat{K}) \ \forall K \in \mathcal{C}_h\}$ for method (I) and $P_h = W_h = \{q \in H^1(\Omega); q|_K \circ F_K \in Q_1(\hat{K}) + \hat{b}\, Q_2^-(\hat{K}) \ \forall K \in \mathcal{C}_h\}$ for method (II), where $\hat{b}$ is a bubble on $\hat{K}$ and $Q_2^-(\hat{K})$ is the standard reduced biquadratic element. We can easily verify Assumption (A2) through F_K by following the argument in Theorem 3.4 and the interpolation theory in [2, p. 108].

4. L^2-error bound.

In this section we establish the L^2-error bound for velocity.

4.1. Additional assumptions.

We first make a few more assumptions.

Assumption (A3). For all $\mathbf{u}_h, \mathbf{v}_h \in V_{0,h}$, there holds

$$|(\mathbf{u}_h, \mathbf{v}_h) - (\mathbf{u}_h, \mathbf{v}_h)_h| \leq C\, h\, \|\mathbf{u}_h\|_1\, \|\mathbf{v}_h\|_0. \tag{4.1}$$

Remark 4.1. Taking (2.12) as an example, Assumption (A3) holds (see [1, 3, 29]).

LEMMA 4.1. *Let Assumptions* (A1) *and* (A3) *hold. For any given* $\mathbf{u} \in V_{0,h}$, *we have*

$$\|\mathbf{u} - \bar{R}_h(\mathbf{u})\|_h \leq C\, h\, \|\mathbf{u}\|_1. \tag{4.2}$$

Proof. By Assumptions (A1) and (A3) and (2.15) we have (4.2), since

$$\begin{aligned} \|\bar{R}_h(\mathbf{u}) - \mathbf{u}\|_h^2 &= (\bar{R}_h(\mathbf{u}) - \mathbf{u}, \bar{R}_h(\mathbf{u}) - \mathbf{u})_h \\ &= (\bar{R}_h(\mathbf{u}), \bar{R}_h(\mathbf{u}) - \mathbf{u})_h - (\mathbf{u}, \bar{R}_h(\mathbf{u}) - \mathbf{u})_h \\ &= (\mathbf{u}, \bar{R}_h(\mathbf{u}) - \mathbf{u}) - (\mathbf{u}, \bar{R}_h(\mathbf{u}) - \mathbf{u})_h \\ &\leq C\, h\, \|\mathbf{u}\|_1\, \|\bar{R}_h(\mathbf{u}) - \mathbf{u}\|_0 \leq C\, h\, \|\mathbf{u}\|_1\, \|\bar{R}_h(\mathbf{u}) - \mathbf{u}\|_h. \end{aligned} \tag{4.3}$$

∎

Assumption (A4). For any given $\mathbf{f} \in (L^2(\Omega))^d$ and $\mathbf{v} \in (H^2(\Omega) \cap H_0^1(\Omega))^d$, the problem

$$-\Delta\, \mathbf{u} + \bigtriangledown\, p = \mathbf{f}, \quad \bigtriangledown \cdot\, \mathbf{u} = \bigtriangledown \cdot\, \mathbf{v} \quad \text{in } \Omega, \quad \mathbf{u} = \mathbf{0} \quad \text{on } \Gamma \tag{4.4}$$

has a solution $(\mathbf{u}, p)$ satisfying

$$\|\mathbf{u}\|_2 + \|p\|_1 \leq C\, \{\|\mathbf{f}\|_0 + \|\bigtriangledown \cdot \mathbf{v}\|_1\}. \tag{4.5}$$

PROPOSITION 4.1. *For a convex polygon, Assumption* (A4) *holds.*

Proof. From [6, 8] we know that for $\mathbf{v} \in (H^2(\Omega) \cap H_0^1(\Omega))^2$ we can find a $\mathbf{z} \in (H^2(\Omega) \cap H_0^1(\Omega))^2$ such that

$$\bigtriangledown \cdot\, \mathbf{z} = \bigtriangledown \cdot\, \mathbf{v}, \quad \|\mathbf{z}\|_2 \leq C\, \|\bigtriangledown \cdot \mathbf{v}\|_1. \tag{4.6}$$

We then consider the Stokes problem

$$-\Delta\, \mathbf{w} + \bigtriangledown\, p = \mathbf{f} + \Delta\, \mathbf{z}, \quad \bigtriangledown \cdot\, \mathbf{w} = 0 \quad \text{in } \Omega, \quad \mathbf{w} = \mathbf{0} \quad \text{on } \Gamma. \tag{4.7}$$

From [2, 7] we know that the problem (4.7) has a solution $(\mathbf{w}, p)$ satisfying

$$\|\mathbf{w}\|_2 + \|p\|_1 \leq C\, \{\|\mathbf{f}\|_0 + \|\Delta\, \mathbf{z}\|_0\} \leq C\, \{\|\mathbf{f}\|_0 + \|\bigtriangledown \cdot \mathbf{v}\|_1\}. \tag{4.8}$$

We therefore define

$$\mathbf{u} := \mathbf{z} + \mathbf{w}. \tag{4.9}$$

Clearly, such $(\mathbf{u}, p)$ satisfies (4.4) and (4.5). ∎

Assumption (A5). For any given $\mathbf{f} \in (L^2(\Omega))^d$ and for all $\lambda \geq 0$, the elasticity problem

$$-\Delta\, \mathbf{u} - \lambda\, \bigtriangledown \bigtriangledown \cdot\, \mathbf{u} = \mathbf{f} \quad \text{in } \Omega, \quad \mathbf{u} = \mathbf{0} \quad \text{on } \Gamma \tag{4.10}$$

has a solution $\mathbf{u}$ satisfying

$$\|\mathbf{u}\|_2 + \lambda\, \|\bigtriangledown \cdot\, \mathbf{u}\|_1 \leq C\, \|\mathbf{f}\|_0, \tag{4.11}$$

where C is independent of λ.

Remark 4.2. When Ω is a convex polygon in $\mathbb{R}^2$, Assumption (A5) holds (see [6, 10]).

4.2. L^2-error bound for velocity. We can now establish the L^2-error bound.

THEOREM 4.1. *Under the assumptions of Theorem* 3.2 *and Assumptions* (A3)–(A5), *if* $V_{0,h} \subseteq U_h$, *we then have*

$$\|\mathbf{u} - \mathbf{u}_h\|_0 \leq C\, h\, \Lambda, \tag{4.12}$$

where $\Lambda = \Lambda(\tilde{\mathbf{u}} - \mathbf{u}, \tilde{p} - p, \tilde{\omega} - \omega)$ *is defined by* (3.40).

Proof. We consider only method (II). The same argument for method (I) is straightforward. In principle, we follow the Aubin–Nitsche duality technique [29].

We consider the following auxiliary problem: Given $\mathbf{u} - \mathbf{u}_h \in (L^2(\Omega))^d$, find ρ such that

$$-\Delta\, \rho - \lambda\, \bigtriangledown\, \bigtriangledown \cdot\, \rho = \mathbf{u} - \mathbf{u}_h \quad \text{in } \Omega, \quad \rho = \mathbf{0} \quad \text{on } \Gamma, \tag{4.13}$$

which can also be expressed as the mixed form equivalently:

$$-\Delta\, \rho - \bigtriangledown\, \kappa = \mathbf{u} - \mathbf{u}_h, \quad \bigtriangledown \cdot\, \rho - \lambda^{-1}\, \kappa = 0 \quad \text{in } \Omega, \quad \rho = \mathbf{0} \quad \text{on } \Gamma. \tag{4.14}$$

From Assumption (A5) we have

$$\|\rho\|_2 + \|\kappa\|_1 + \lambda\, \|\bigtriangledown \cdot \rho\|_1 \leq C\, \|\mathbf{u} - \mathbf{u}_h\|_0, \tag{4.15}$$

which holds for any $\lambda \geq 0$. We shall take

$$\lambda := \frac{1}{h}. \tag{4.16}$$

Let

$$e_u := \mathbf{u} - \mathbf{u}_h, \quad e_p := p - p_h, \quad e_\omega := \omega - \omega_h. \tag{4.17}$$

From (4.14) we have

$$\begin{aligned} \|e_u\|_0^2 &= (-\Delta\, \rho - \bigtriangledown\, \kappa, e_u) \\ &= (\bigtriangledown \times \bigtriangledown \times \rho - h\, \bigtriangledown\, \kappa, e_u) + (\kappa, \bigtriangledown \cdot\, e_u) \\ &= (\bigtriangledown \times \rho, \bigtriangledown \times e_u) + h\, (\kappa, \bigtriangledown \cdot\, e_u) + (\kappa, \bigtriangledown \cdot\, e_u) \\ &= (e_\omega - \bigtriangledown \times e_u, - \bigtriangledown \times \rho) + (e_\omega, \bigtriangledown \times \rho) \\ &\quad + h\, (\kappa, \bigtriangledown \cdot\, e_u) + (\kappa, \bigtriangledown \cdot\, e_u) \\ &:= I_1 + I_2 + I_3 + I_4, \end{aligned} \tag{4.18}$$

where, by (3.41),

$$I_3 \le |h\,(\kappa, \bigtriangledown \cdot\, e_u)| \le C\ h \|\kappa\|_0 \|e_u\|_1 \le C\,h\,\|\kappa\|_1\,\Lambda. \tag{4.19}$$

Let $\bar\rho \in V_{0,h}$ be such that (see [2, 3, 4, 29])

$$\Big(\sum_{K\in\mathcal{C}_h} h_K^{-2}\,\|\bar\rho-\rho\|_{0,K}^2 + \sum_{E\in\mathcal{E}_h} h_E^{-1}\int_E |\bar\rho-\rho|^2\Big)^{1/2} + \|\bar\rho-\rho\|_1 \le C\,h\,\|\rho\|_2. \tag{4.20}$$

We have

$$I_2 = (e_\omega, \bigtriangledown\times\bar\rho) + (e_\omega, \bigtriangledown\times(\rho-\bar\rho)), \tag{4.21}$$

where, by (3.41) and (4.20),

$$|(e_\omega, \bigtriangledown\times(\rho-\bar\rho))| \le C\|e_\omega\|_0\|\rho-\bar\rho\|_1 \le Ch\,\|\rho\|_2\Lambda, \tag{4.22}$$

$$\begin{aligned}(e_\omega, \bigtriangledown\times\bar\rho) &= (R_h(\bigtriangledown\times e_\omega), \bar\rho)_h\\ &= (R_h(\bigtriangledown\times e_\omega) + S_h(\bigtriangledown e_p), \bar\rho)_h - (S_h(\bigtriangledown e_p), \bar\rho)_h\\ &= (R_h(\bigtriangledown\times e_\omega) + S_h(\bigtriangledown e_p), \bar\rho - \bar R_h(\bar\rho))_h\\ &\quad + (R_h(\bigtriangledown\times e_\omega) + S_h(\bigtriangledown e_p), \bar R_h(\bar\rho))_h\\ &\quad + (e_p, \bigtriangledown\cdot\,(\bar\rho-\rho) + h\,\kappa),\end{aligned} \tag{4.23}$$

and

(4.24)
$$\begin{cases} |(R_h(\bigtriangledown\times e_\omega) + S_h(\bigtriangledown e_p), \bar\rho - \bar R_h(\bar\rho))_h + (e_p, \bigtriangledown\cdot(\bar\rho-\rho) + h\,\kappa)|\\ \le \|R_h(\bigtriangledown\times e_\omega) + S_h(\bigtriangledown e_p)\|_h\,\|\bar\rho - \bar R_h(\bar\rho)\|_h + C\,\|e_p\|_0\,\{\|\bar\rho-\rho\|_1 + h\,\|\kappa\|_0\}\\ \le C\,h\,\{\|\rho\|_2 + \|\kappa\|_1\}\,\Lambda \qquad \text{(by (3.43), Lemma 4.1, (3.41), and (4.20))}.\end{cases}$$

From (4.18), (4.19), and (4.21)–(4.24) we need only to estimate

$$\begin{cases} I_0 := I_1 + I_4 + (R_h(\bigtriangledown\times e_\omega) + S_h(\bigtriangledown e_p), \bar R_h(\bar\rho))_h\\ = (e_\omega - \bigtriangledown\times e_u, -\bigtriangledown\times\rho) + (\kappa, \bigtriangledown\cdot\,e_u)\\ \quad + (R_h(\bigtriangledown\times e_\omega) + S_h(\bigtriangledown e_p), \bar R_h(\bar\rho))_h.\end{cases} \tag{4.25}$$

To do so, we consider an auxiliary problem: Find $(\mathbf{u}^*, p^*)$ such that

$$-\Delta\,\mathbf{u}^* + \bigtriangledown\,p^* = \bar\rho + e_u + h\ \bigtriangledown\ \kappa, \quad \bigtriangledown\cdot\,\mathbf{u}^* = \kappa \quad \text{in } \Omega, \quad \mathbf{u}^* = \mathbf{0} \quad \text{on } \Gamma. \tag{4.26}$$

Since $\kappa = h^{-1}\ \bigtriangledown\cdot\rho = \bigtriangledown\cdot\,(h^{-1}\,\rho)$ and $h^{-1}\,\rho \in (H^2(\Omega)\cap H_0^1(\Omega))^d$, from Assumption (A4), (4.20), and (4.15) we have

$$\|\mathbf{u}^*\|_2 + \|p^*\|_1 \le C\,\{\|\bar\rho\|_0 + \|e_u\|_0 + \|\kappa\|_1\} \le C\,\|e_u\|_0. \tag{4.27}$$

Inserting

$$\bigtriangledown\times\bigtriangledown\times\rho - h\ \bigtriangledown\ \kappa - \bigtriangledown\kappa = e_u \qquad \text{(by the first equation of (4.14))} \tag{4.28}$$

into the first equation of (4.26) we get

$$\bigtriangledown \times (\bigtriangledown \times \mathbf{u}^* - \bigtriangledown \times \rho) + \bigtriangledown p^* = \bar{\rho}. \tag{4.29}$$

Let

$$\phi := \bigtriangledown \times \mathbf{u}^* - \bigtriangledown \times \rho, \tag{4.30}$$

and we have

$$\bigtriangledown \times \phi + \bigtriangledown p^* = \bar{\rho}, \quad \|\phi\|_1 \le C \|e_u\|_0. \tag{4.31}$$

Therefore, noting that

$$\bar{R}_h(\bar{\rho}) = \bar{R}_h(\bigtriangledown \times \phi + \bigtriangledown p^*) = R_h(\bigtriangledown \times \phi) + S_h(\bigtriangledown p^*) \qquad \text{(by (2.16))}, \tag{4.32}$$

we have

$$\begin{cases} I_0 = (e_\omega - \bigtriangledown \times e_u, \phi - \bigtriangledown \times \mathbf{u}^*) + (\bigtriangledown \cdot \mathbf{u}^*, \bigtriangledown \cdot e_u) \\ \quad + (R_h(\bigtriangledown \times e_\omega) + S_h(\bigtriangledown e_p), R_h(\bigtriangledown \times \phi) + S_h(\bigtriangledown p^*))_h \\ \quad = (e_\omega - \bigtriangledown \times e_u, \phi - \tilde{\phi} - \bigtriangledown \times (\mathbf{u}^* - \tilde{\mathbf{u}}^*)) + (\bigtriangledown \cdot (\mathbf{u}^* - \tilde{\mathbf{u}}^*), \bigtriangledown \cdot e_u) \\ \quad + (R_h(\bigtriangledown \times e_\omega) + S_h(\bigtriangledown e_p), R_h(\bigtriangledown \times (\phi - \tilde{\phi})) + S_h(\bigtriangledown (p^* - \tilde{p}^*)))_h \\ \quad + (e_\omega - \bigtriangledown \times e_u, \tilde{\phi} - \bigtriangledown \times \tilde{\mathbf{u}}^*) + (\bigtriangledown \cdot \tilde{\mathbf{u}}^*, \bigtriangledown \cdot e_u) \\ \quad + (R_h(\bigtriangledown \times e_\omega) + S_h(\bigtriangledown e_p), R_h(\bigtriangledown \times \tilde{\phi}) + S_h(\bigtriangledown \tilde{p}^*))_h, \end{cases} \tag{4.33}$$

where we have chosen $(\tilde{\mathbf{u}}^*, \tilde{p}^*, \tilde{\phi}) \in U_h \times P_h \times W_h$ such that $\tilde{\mathbf{u}}^* \in V_{0,h} \subseteq U_h$ and Assumption (A2) is satisfied with $s = 1$:

$$\|\mathbf{u}^* - \tilde{\mathbf{u}}^*\|_0 + h \|\mathbf{u}^* - \tilde{\mathbf{u}}^*\|_1 \le C h^2 \|\mathbf{u}^*\|_2, \tag{4.34}$$

$$R_h(\bigtriangledown \times (\phi - \tilde{\phi})) + S_h(\bigtriangledown (p^* - \tilde{p}^*)) = \mathbf{0}, \tag{4.35}$$

$$\begin{aligned} \|\tilde{\phi} - \phi\|_0 + \|\tilde{p}^* - p^*\|_0 + |(\tilde{p}^* - p^*, \tilde{\phi} - \phi)|_{(\mathcal{C}_h, \mathcal{E}_h)} \\ \le C h \{\|p^*\|_1 + \|\phi\|_1\}. \end{aligned} \tag{4.36}$$

We also have

$$\begin{cases} |(e_\omega - \bigtriangledown \times e_u, \phi - \tilde{\phi} - \bigtriangledown \times (\mathbf{u}^* - \tilde{\mathbf{u}}^*)) + (\bigtriangledown \cdot (\mathbf{u}^* - \tilde{\mathbf{u}}^*), \bigtriangledown \cdot e_u)| \\ \le C h \{\|\mathbf{u}^*\|_2 + \|\phi\|_1\} \Lambda \qquad \text{(by (3.41), (4.36), and (4.34))}, \end{cases} \tag{4.37}$$

$$(R_h(\bigtriangledown \times e_\omega) + S_h(\bigtriangledown e_p), R_h(\bigtriangledown \times (\phi - \tilde{\phi})) + S_h(\bigtriangledown (p^* - \tilde{p}^*)))_h = 0 \tag{4.38}$$

(by (4.35)),

$$\begin{cases} (e_\omega - \bigtriangledown \times e_u, \tilde{\phi} - \bigtriangledown \times \tilde{\mathbf{u}}^*) + (\bigtriangledown \cdot \tilde{\mathbf{u}}^*, \bigtriangledown \cdot e_u) \\ \quad + (R_h(\bigtriangledown \times e_\omega) + S_h(\bigtriangledown e_p), R_h(\bigtriangledown \times \tilde{\phi}) + S_h(\bigtriangledown \tilde{p}^*))_h \\ = \mathcal{L}_h((e_u, e_p, e_\omega); (\tilde{\mathbf{u}}^*, \tilde{p}^*, \tilde{\phi})) \\ \quad - \sum_{K \in \mathcal{C}_h} h_K^2 (\bigtriangledown \times e_\omega + \bigtriangledown e_p, \bigtriangledown \times \tilde{\phi} + \bigtriangledown \tilde{p}^*)_{0,K} \\ \quad - \sum_{E \in \mathcal{E}_h} h_E \int_E [e_\omega] [\tilde{\phi} - \phi] - \sum_{E \in \mathcal{E}_h} h_E \int_E [e_p] [\tilde{p}^* - p^*], \end{cases} \tag{4.39}$$

where we have used the regularity of $\phi \in (H^1(\Omega))^{2d-3}$ and $p^* \in H^1(\Omega)$,

$$\mathcal{L}_h((e_u, e_p, e_\omega); (\tilde{\mathbf{u}}^*, \tilde{p}^*, \tilde{\phi})) = 0 \qquad \text{(by Lemma 3.2)}, \tag{4.40}$$

and

$$\begin{cases} \Big| - \sum\limits_{K\in\mathcal{C}_h} h_K^2 \, (\bigtriangledown \times e_\omega + \bigtriangledown e_p, \bigtriangledown \times \tilde{\phi} + \bigtriangledown \tilde{p}^*)_{0,K} \\ \quad - \sum\limits_{E\in\mathcal{E}_h} h_E \int_E [e_\omega]\,[\tilde{\phi} - \phi] - \sum\limits_{E\in\mathcal{E}_h} h_E \int_E [e_p]\,[\tilde{p}^* - p^*] \Big| \\ \le C\,|(e_p, e_\omega)|_{(\mathcal{C}_h,\mathcal{E}_h)}\,\{|(\tilde{p}^* - p^*, \tilde{\phi} - \phi)|_{(\mathcal{C}_h,\mathcal{E}_h)} + h\,(\|\phi\|_1 + \|p^*\|_1)\} \\ \le C\,h\,\{\|\phi\|_1 + \|p^*\|_1\}\,\Lambda \qquad \text{(by (3.42) and (4.36))}. \end{cases} \tag{4.41}$$

Therefore, summarizing (4.18), (4.19), (4.21)–(4.25), (4.33), and (4.37)–(4.41) and (4.15), (4.27), and (4.31), we finally obtain

$$\begin{aligned} \|e_u\|_0^2 &\le C\,h\,\Lambda\,\{\|\rho\|_2 + \|\kappa\|_1 + \|\mathbf{u}^*\|_2 + \|p^*\|_1 + \|\phi\|_1\} \\ &\le C\,h\,\|e_u\|_0\,\Lambda. \end{aligned} \tag{4.42}$$

This completes the proof. ∎

Remark 4.3. We now clarify the assumptions involved for the two methods. For the two methods the common trivial assumptions are that $\mathcal{C}_h$ is regular and Ω is a Lipschitz convex polygon (polyhedron in $\mathbb{R}^3$) and $V_{0,h} \subseteq U_h$ with (3.50) for U_h. For method (I) the additional assumptions are (A2), (A4), and (A5). For method (II) the additional assumptions are (A1)–(A5).

5. Numerical experiments. In this section we report some numerical experiments to illustrate the theoretical error bounds. We shall consider only method (II) in (2.18), employing continuous $U_h \times P_h \times W_h$, with h_K taken as h and $R_h = S_h = \bar{R}_h$. We shall use the two lower-order elements: $\mathcal{P}_1$-$\mathcal{P}_1^+$-$\mathcal{P}_1^+$ approximation and $\mathcal{P}_2$ -$\mathcal{P}_1^+$-$\mathcal{P}_1^+$ approximation. We take $\Omega := [0,1] \times [0,1]$ and partition it into uniform triangles.

We consider a 2D Stokes problem

$$-\Delta\,\mathbf{u} + \bigtriangledown\, p = \mathbf{f}, \quad \bigtriangledown \cdot\, \mathbf{u} = 0 \quad \text{in } \Omega, \quad \mathbf{u} = \mathbf{0} \quad \text{on } \Gamma. \tag{5.1}$$

We take the example from [17]. The exact solution $(\mathbf{u}, p, \omega)$ of (5.1) is

$$\begin{pmatrix} u_1 \\ u_2 \\ \omega \\ p \end{pmatrix} = \begin{pmatrix} x^2(1-x)^2(2y - 6y^2 + 4y^3) \\ y^2(1-y)^2(-2x + 6x^2 - 4x^3) \\ x^2(1-x)^2(-2 + 12y - 12y^2) + y^2(1-y)^2(-2 + 12x^2 - 12x^2) \\ x^2 + y^2 - \frac{20}{3}xy + x + y \end{pmatrix}.$$

The right-hand side $\mathbf{f}$ is generated by evaluating the equations on the given exact solution. In our experiment we set $p_h(0,0) = 0$ to replace $\int_\Omega p_h = 0$ to ensure the uniqueness. We employ the conjugate gradient method, with the stopping criterion tolerance 10^{-9} and with a zero initial guess, to solve the resulting linear system. We employ the $\mathcal{P}_r - \mathcal{P}_1^+ - \mathcal{P}_1^+$ approximations, $r = 1, 2$. We list the relative errors in L^2- and H^1-norms in Tables 1 and 2 and Tables 3 and 4, respectively.

Tables 1 and 2 show that the relative errors in L^2-norm and H^1-norm for velocity are $\mathcal{O}(h^2)$ and $\mathcal{O}(h)$, respectively, the same as predicted by Theorems 3.3 and 4.1. Tables 1 and 2 show that the relative errors in L^2-norm and H^1-norm for vorticity and pressure are also $\mathcal{O}(h^2)$ and $\mathcal{O}(h)$, respectively, higher than predicted.

$\frac{\|p-p_h\|_1}{\|p\|_1}$	0.528725	0.198494	0.085175

Tables 3 and 4 show that relative errors in L^2- and H^1-norms for velocity are $\mathcal{O}(h^3)$ and $\mathcal{O}(h^2)$, respectively, and also show that the relative errors in L^2- and H^1-norms for vorticity and pressure are $\mathcal{O}(h^2)$ and $\mathcal{O}(h)$, respectively. These are consistent with what was predicted.

DISCONTINUOUS GALERKIN METHODS FOR FRIEDRICHS' SYSTEMS. I. GENERAL THEORY*

A. ERN† AND J.-L. GUERMOND‡

Abstract. This paper presents a unified analysis of discontinuous Galerkin methods to approximate Friedrichs' systems. An abstract set of conditions is identified at the continuous level to guarantee existence and uniqueness of the solution in a subspace of the graph of the differential operator. Then a general discontinuous Galerkin method that weakly enforces boundary conditions and mildly penalizes interface jumps is proposed. All the design constraints of the method are fully stated, and an abstract error analysis in the spirit of Strang's Second Lemma is presented. Finally, the method is formulated locally using element fluxes, and links with other formulations are discussed. Details are given for three examples, namely, advection-reaction equations, advection-diffusion-reaction equations, and the Maxwell equations in the so-called elliptic regime.

Key words. Friedrichs' systems, finite elements, partial differential equations, discontinuous Galerkin method

1. Introduction.

Discontinuous Galerkin (DG) methods were introduced in the 1970s, and their development has since followed two somewhat parallel routes depending on whether the PDE is hyperbolic or elliptic.

For hyperbolic PDEs, the first DG method was introduced by Reed and Hill in 1973 [28] to simulate neutron transport, and the first analysis of DG methods for hyperbolic equations in an already rather general and abstract form was performed by Lesaint and Raviart in 1974 [23, 24]. The analysis was subsequently improved by Johnson, Nävert, and Pitkäranta who established that the optimal order of convergence in the L^2-norm is $p+\frac{1}{2}$ if polynomials of degree p are used [21]. More recently, DG methods for hyperbolic and nearly hyperbolic equations experienced a significant development based on the ideas of numerical fluxes, approximate Riemann solvers, and slope limiters; see, e.g., Cockburn et al. [9] and references therein for a thorough review. This renewed interest in DG methods is stimulated by several factors including the flexibility offered by the use of nonmatching grids and the possibility to use high-order *hp*-adaptive finite element methods; see, e.g., Süli et al. [30].

For elliptic PDEs, DG methods originated from the early work of Nitsche on boundary-penalty methods [25] and the use of interior penalties (IP) to weakly enforce continuity conditions imposed on the solution or its derivatives across the interfaces between adjoining elements; see, e.g., Babuška [4], Babuška and Zlámal [3], Douglas and Dupont [13], Baker [6], Wheeler [31], and Arnold [2]. DG methods for elliptic problems in mixed form were introduced more recently. Initially, a discontinuous approximation was used solely for the primal variable, the flux being still discretized in a conforming fashion; see, e.g., Dawson [11, 12]. Then, a discontinuous approximation

of both the primal variable and its flux has been introduced by Bassi and Rebay [7] and further extended by Cockburn and Shu [10] leading to the so-called local discontinuous Galerkin (LDG) method. Around the same time, Baumann and Oden [8] proposed a nonsymmetric variant of DG for elliptic problems. This method was further developed and analyzed by Oden, Babuška, and Baumann [26] and by Rivière, Wheeler, and Girault [29].

The fact that several DG methods (including IP methods) share common features and can be tackled by similar analysis tools called for a unified analysis. A first important step in that direction has been recently accomplished by Arnold et al. [1] for elliptic equations. It is shown in [1] that it is possible to cast many DG methods for the Poisson equation with homogeneous Dirichlet boundary conditions into a single framework amenable to a unified error analysis. The main idea consists of using the mixed formulation of the Poisson equation to define numerical fluxes and to locally eliminate these fluxes so as to derive a method involving only the primal variable.

The goal of the present paper is to propose a unified analysis of DG methods that goes beyond the traditional hyperbolic/elliptic classification of PDEs by making systematic use of the theory of Friedrichs' systems [17] to formulate DG methods and to perform the convergence analysis. This paper, which concentrates on first-order PDEs, is the first part of a more comprehensive study on DG methods for Friedrichs' systems. The forthcoming second part will deal more specifically with Friedrichs' systems associated with second-order PDEs. Some preliminary results on Friedrichs' systems related to this work can be found in [15, p. 227].

The paper is organized as follows. In section 2 we investigate the well posedness of Friedrichs' systems in graph spaces. Originally, Friedrichs addressed the question of the uniqueness of strong solutions in $\mathfrak{C}^1$ and that of the existence of weak solutions in L^2 [17]. The analysis of Friedrichs' systems in graph spaces has been undertaken by Rauch [27] and more recently by Jensen [20]. The main novelty of the present approach is that we avoid invoking traces at the boundary by introducing a bounded linear operator from the graph space to its dual that satisfies sufficient conditions ensuring well posedness. In section 3 we illustrate the abstract results of section 2 on three important examples of Friedrichs' systems, namely, advection-reaction equations, advection-diffusion-reaction equations, and a simplified version of the Maxwell equations in the so-called elliptic regime. Drawing on earlier ideas by Lesaint and Raviart [23, 24] and Johnson et al. [21], we propose in section 4 a general framework for DG methods. This section contains three main contributions. First, the generic DG method is formulated in terms of a boundary operator enforcing boundary conditions weakly and in terms of an interface operator penalizing the jumps of the solution across the mesh interfaces. Second, the convergence analysis is performed in the spirit of Strang's Second Lemma by using two different norms, namely, a stability norm for which a discrete inf-sup condition holds and an approximability norm ensuring the continuity of the DG bilinear form. All the design constraints to be fulfilled by the boundary and the interface operators for the error analysis to hold are clearly stated. Finally, using integration by parts, the DG method is reinterpreted locally by introducing the concept of element fluxes and element adjoint-fluxes, thus providing a direct link with engineering practice where approximation schemes are often designed by specifying such fluxes. Finally, section 5 reviews various DG approximations for the model problems investigated in section 3. In all the cases, the degrees of freedom in the design of the DG method are underlined.

2. Friedrichs' systems. The goal of this section is to reformulate Friedrichs' theory by giving special care to the meaning of the boundary conditions. The main results of this section are Theorems 2.5 and 2.8. Theorem 2.8 will be the starting point of the DG method developed in section 4.

2.1. The setting. Let Ω be a bounded, open, and connected Lipschitz domain in $\mathbb{R}^d$. We denote by $\mathfrak{D}(\Omega)$ the space of $\mathfrak{C}^\infty$ functions that are compactly supported in Ω. Let m be a positive integer. Let $\mathcal{K}$ and $\{\mathcal{A}^k\}_{1\le k\le d}$ be $(d+1)$ functions on Ω with values in $\mathbb{R}^{m,m}$. Following Friedrichs [17], we assume that

$$\text{(A1)} \qquad \mathcal{K} \in [L^\infty(\Omega)]^{m,m},$$

$$\text{(A2)} \qquad \forall k \in \{1,\dots,d\},\ \mathcal{A}^k \in [L^\infty(\Omega)]^{m,m} \quad \text{and} \quad \sum_{k=1}^d \partial_k \mathcal{A}^k \in [L^\infty(\Omega)]^{m,m},$$

$$\text{(A3)} \qquad \forall k \in \{1,\dots,d\},\ \mathcal{A}^k = (\mathcal{A}^k)^t \ \text{ a.e. in } \Omega,$$

$$\text{(A4)} \qquad \mathcal{Z} := \mathcal{K} + \mathcal{K}^t - \sum_{k=1}^d \partial_k \mathcal{A}^k \ge 2\mu_0 \mathcal{I}_m \ \text{ a.e. on } \Omega,$$

where $\mathcal{I}_m$ is the identity matrix in $\mathbb{R}^{m,m}$. Set $L = [L^2(\Omega)]^m$. We say that a function u in L has an A-weak derivative in L if the linear form

$$[\mathfrak{D}(\Omega)]^m \ni \varphi \longmapsto -\int_\Omega \sum_{k=1}^d u^t \partial_k(\mathcal{A}^k \varphi) \in \mathbb{R}, \tag{2.1}$$

is bounded on L, and we denote by Au the function in L that can be associated with the above linear form by means of the Riesz representation theorem. Clearly, if u is smooth enough, e.g., $u \in [\mathfrak{C}^1(\Omega)]^m$,

$$Au = \sum_{k=1}^d \mathcal{A}^k \partial_k u. \tag{2.2}$$

Define the graph space

$$W = \{w \in L;\ Aw \in L\}, \tag{2.3}$$

and equip W with the graph norm

$$\|w\|_W = \|Aw\|_L + \|w\|_L, \tag{2.4}$$

and the associated scalar product. W is a Hilbert space. Indeed, let v_n be a Cauchy sequence in W; i.e., v_n and Av_n are Cauchy sequences in L. Let v and w be the corresponding limits in L. Let $\varphi \in [\mathfrak{D}(\Omega)]^m$. Then, using the symmetry of $\mathcal{A}^k$ and an integration by parts yields

$$\int_\Omega \sum_{k=1}^d v^t \partial_k(\mathcal{A}^k\varphi) \leftarrow \int_\Omega \sum_{k=1}^d v_n^t \partial_k(\mathcal{A}^k\varphi) = -\int_\Omega \varphi^t A v_n \to -\int_\Omega \varphi^t w,$$

which means that v has an A-weak derivative in L and $Av = w$. Since $[\mathcal{D}(\Omega)]^m \subset W$ and $[\mathcal{D}(\Omega)]^m$ is dense in L, W is dense in L; as a result, we shall henceforth use L as a pivot space, i.e., $W \subset L \equiv L' \subset W'$. Note that owing to (A2), $[H^1(\Omega)]^m$ is a subspace of W.

Let $K \in \mathcal{L}(L;L)$ be defined such that $K : L \ni v \mapsto \mathcal{K}v \in L$ and set

$$T = A + K. \tag{2.5}$$

Then, $T \in \mathcal{L}(W;L)$. Let $K^* \in \mathcal{L}(L;L)$ be the adjoint operator of K, i.e., for all $v \in L$, $K^*v = \mathcal{K}^t v$. Let $\tilde{T} \in \mathcal{L}(W;L)$ be the formal adjoint of T,

$$\tilde{T}w = -\sum_{k=1}^{d} \partial_k(\mathcal{A}^k w) + K^* w \quad \forall w \in W. \tag{2.6}$$

In this definition $\sum_{k=1}^{d} \partial_k(\mathcal{A}^k w)$ is understood in the weak sense. It can easily be verified that this weak derivative exists in L whenever w is in W. Moreover, the usual rule for differentiating products applies. In particular, upon introducing the operator $\nabla\cdot A \in \mathcal{L}(L;L)$ such that $(\nabla\cdot A)w = (\sum_{k=1}^{d} \partial_k \mathcal{A}^k)w$ for all $w \in L$, the following holds

$$\forall w \in W, \quad Tw + \tilde{T}w = (K + K^* - \nabla\cdot A)\, w. \tag{2.7}$$

Observe that (A4) means that

$$\forall w \in W, \quad (Tw, w)_L + (w, \tilde{T}w)_L \geq 2\mu_0 \|w\|_L^2. \tag{2.8}$$

DEFINITION 2.1. *Let $D \in \mathcal{L}(W;W')$ be the operator such that*

$$\forall (u,v) \in W \times W, \quad \langle Du, v\rangle_{W',W} = (Tu, v)_L - (u, \tilde{T}v)_L. \tag{2.9}$$

This definition makes sense since both T and $\tilde{T}$ are in $\mathcal{L}(W;L)$. Note that D is a boundary operator in the sense that $[\mathfrak{D}(\Omega)]^m \subset \mathrm{Ker}(D)$; see also Remark 2.1. A more precise result (see [14]) is that $\mathrm{Ker}(D) = W_0$ and $\mathrm{Im}(D) = W_0^\perp$, where W_0 is the closure of $[\mathfrak{D}(\Omega)]^m$ in W and for any subset $E \subset W'$ we denote by $E^\perp$ the polar set of E, i.e., the set of the continuous linear forms in $W'' \equiv W$ that are zero on E.

LEMMA 2.2. *The operator D is self-adjoint.*

Proof. Let $(u,v) \in W \times W$ and set $Z = K + K^* - \nabla\cdot A$. A straightforward calculation yields

$$\begin{aligned}\langle Du, v\rangle_{W',W} - \langle Dv, u\rangle_{W',W} &= (Tu, v)_L - (u, \tilde{T}v)_L - (Tv, u)_L + (v, \tilde{T}u)_L \\ &= (Zu, v)_L - (u, Zv)_L = 0,\end{aligned}$$

since Z is self-adjoint. ∎

Remark 2.1. Let $n = (n_1, \ldots, n_d)^t$ be the unit outward normal to $\partial\Omega$. The usual way of presenting Friedrichs' systems consists of assuming that the fields $\{\mathcal{A}^k\}_{1\leq k\leq d}$ are smooth enough so that the matrix $\mathcal{D} = \sum_{k=1}^{d} n_k \mathcal{A}^k$ is meaningful at the boundary. Then, the operator D can be represented as follows

$$\langle Du, v\rangle_{W',W} = \int_{\partial\Omega} \sum_{k=1}^{d} v^t n_k \mathcal{A}^k u = \int_{\partial\Omega} v^t \mathcal{D} u,$$

whenever u and v are smooth functions. Provided $[\mathfrak{C}^1(\overline{\Omega})]^m$ is dense in $[H^1(\Omega)]^m$ and in W, it can be shown that $\mathcal{D}u \in [H^{-\frac{1}{2}}(\partial\Omega)]^m$. Further characterization and regularity results on $\mathcal{D}u$ can be found in [27] and in [20].

2.2. The well posedness result. Consider the following problem: For f in L, seek $u \in W$ such that $Tu = f$. In general, boundary conditions must be enforced for this problem to be well posed. In other words, one must find a closed subspace V of W such that the restricted operator $T : V \to L$ is an isomorphism.

The key hypothesis introduced by Friedrichs to select boundary conditions consists of assuming that there exists a matrix-valued field at the boundary, say, $\mathcal{M} : \partial\Omega \longrightarrow \mathbb{R}^{m,m}$, such that a.e. on $\partial\Omega$,

$$\mathcal{M} \text{ is positive, i.e., } (\mathcal{M}\xi, \xi)_{\mathbb{R}^m} \geq 0 \text{ for all } \xi \text{ in } \mathbb{R}^m, \tag{2.10}$$

$$\mathbb{R}^m = \mathrm{Ker}(\mathcal{D} - \mathcal{M}) + \mathrm{Ker}(\mathcal{D} + \mathcal{M}), \tag{2.11}$$

where $\mathcal{D}$ is defined in Remark 2.1. Then, it is possible to prove uniqueness of the so-called strong solution $u \in [\mathfrak{C}^1(\overline{\Omega})]^m$ of the PDE system $Tu = f$ supplemented with the boundary condition $(\mathcal{D} - \mathcal{M})u|_{\partial\Omega} = 0$. Moreover, it is also possible to prove existence of a weak solution in L, namely, of a function $u \in L$ such that the relation $(u, \tilde{T}v)_L = (f, v)_L$ holds for all $v \in [\mathfrak{C}^1(\overline{\Omega})]^m$ such that $(\mathcal{D} + \mathcal{M}^t)v|_{\partial\Omega} = 0$; see [27]. In this paper, we want to investigate the bijectivity of T in a subspace V of the graph W, and it is not possible to set $V = \{v \in W;\, (\mathcal{D} - \mathcal{M})v|_{\partial\Omega} = 0\}$ since the meaning of traces is not clear.

To overcome this difficulty, we modify Friedrichs' hypothesis by the following assumption: there exists an operator $M \in \mathcal{L}(W; W')$ such that

$$M \text{ is positive, i.e., } \langle Mw, w\rangle_{W',W} \geq 0 \text{ for all } w \text{ in } W, \tag{M1}$$

$$W = \mathrm{Ker}(D - M) + \mathrm{Ker}(D + M). \tag{M2}$$

Let $M^* \in \mathcal{L}(W; W')$ be the adjoint operator of M, i.e., for all $(u, v) \in W \times W$, $\langle M^*u, v\rangle_{W',W} = \langle Mv, u\rangle_{W',W}$. Then, one can prove (see [14]) that (M1)–(M2) imply that $\mathrm{Ker}(D) = \mathrm{Ker}(M)$, $\mathrm{Im}(D) = \mathrm{Im}(M)$, and

$$W = \mathrm{Ker}(D - M^*) + \mathrm{Ker}(D + M^*). \tag{2.12}$$

Since $\mathrm{Ker}(D) = \mathrm{Ker}(M)$, M is a boundary operator. Set

$$V = \mathrm{Ker}(D - M) \qquad \text{and} \qquad V^* = \mathrm{Ker}(D + M^*), \tag{2.13}$$

and equip V and V^* with the graph norm (2.4). The following result is proven in [14].

LEMMA 2.3. *Assume* (M1)–(M2). *Then,*

$$D(V)^\perp = V^* \qquad \text{and} \qquad D(V^*)^\perp = V. \tag{2.14}$$

LEMMA 2.4. *Assume* (A1)–(A4) *and* (M1)–(M2). *Then, T is L-coercive on V and $\tilde{T}$ is L-coercive on V^*.*

Proof. Using (2.8) and (2.9) yields

$$(Tw, w)_L \geq \mu_0\|w\|_L^2 + \frac{1}{2}\langle Dw, w\rangle_{W',W},$$
$$(\tilde{T}w, w)_L \geq \mu_0\|w\|_L^2 - \frac{1}{2}\langle Dw, w\rangle_{W',W}.$$

Use (2.13) and (M1) to conclude. ∎

THEOREM 2.5. *Assume* (A1)–(A4) *and* (M1)–(M2). *Let V and V^* be defined in* (2.13). *Then,*

(i) *$T : V \to L$ is an isomorphism.*

(ii) *$\tilde{T} : V^* \to L$ is an isomorphism.*

Proof. We only prove (i) since the proof of (ii) is similar.

(1) Owing to (2.13), V is closed in W; hence, V is a Hilbert space. As a result, showing that $T : V \to L$ is an isomorphism amounts to proving statement (ii) in Theorem 2.6 below with $L \equiv L'$.

(2) Proof of (2.15). Let $u \in V$. Observe that $\sup_{v\in L\setminus\{0\}} \frac{(Tu,v)_L}{\|v\|_L} = \|Tu\|_L$. Lemma 2.4 implies $\|Tu\|_L \geq \mu_0\|u\|_L$. Furthermore,

$$\|Tu\|_L \geq \|Au\|_L - \|K\|_{\mathcal{L}(L;L)}\|u\|_L \geq \|Au\|_L - \frac{\|K\|_{\mathcal{L}(L;L)}}{\mu_0}\|Tu\|_L.$$

This readily yields $\|Au\|_L \leq c\|Tu\|_L$ and thus $\|u\|_W \leq c\|Tu\|_L$.

(3) Proof of (2.16). Assume that $v \in L$ is such that $(Tu, v)_L = 0$ for all $u \in V$. Since $[\mathfrak{D}(\Omega)]^m \subset V$, a standard distribution argument shows that $\tilde{T}v = 0$ in $[\mathfrak{D}'(\Omega)]^m$. Still in the distribution sense, this means that $\sum_{k=1}^d \mathcal{A}^k\partial_k v = K^*v - (\nabla\cdot A)v$. Since the right-hand side is a bounded linear functional on L, v has an A-weak derivative in L, i.e., $v \in W$. As a result, $\langle Du, v\rangle_{W',W} = 0$ for all $u \in V$, i.e., $v \in D(V)^\perp$. Owing to Lemma 2.3, $v \in V^*$. Finally, since $(\tilde{T}v, v)_L = 0$ and $v \in V^*$, Lemma 2.4 implies that v is zero. ∎

THEOREM 2.6 (Banach–Nečas–Babuška (BNB)). *Let V, L be two Banach spaces, and denote by $\langle\cdot,\cdot\rangle_{L',L}$ the duality pairing between L' and L. The following statements are equivalent:*

(i) *$T \in \mathcal{L}(V; L)$ is bijective.*

(ii) *There exists a constant $\alpha > 0$ such that*

$$\forall u \in V, \quad \sup_{v\in L'\setminus\{0\}} \frac{\langle v, Tu\rangle_{L',L}}{\|v\|_{L'}} \geq \alpha\|u\|_V, \tag{2.15}$$

$$\forall v \in L', \quad (\langle v, Tu\rangle_{L',L} = 0 \ \forall u \in V) \implies (v = 0). \tag{2.16}$$

As an immediate consequence of Theorem 2.5, the following problems are well posed: For f in L,

$$\text{seek } u \in V \text{ such that } Tu = f, \tag{2.17}$$

$$\text{seek } u^* \in V^* \text{ such that } \tilde{T}u^* = f. \tag{2.18}$$

Remark 2.2. To guarantee that $T : V \to L$ and $\tilde{T} : V^* \to L$ are isomorphisms, it is also possible to specify assumptions on the spaces V and V^* without using the boundary operator M. Introduce the cones $C^\pm = \{w \in W;\ \pm\langle Dw, w\rangle_{W',W} \geq 0\}$. Then, under the following assumptions:

$$V \subset C^+ \text{ and } V^* \subset C^-, \tag{V1}$$

$$V^* = D(V)^\perp \text{ and } V = D(V^*)^\perp, \tag{V2}$$

$T : V \to L$ and $\tilde{T} : V^* \to L$ are isomorphisms [14]. This way of introducing Friedrichs' systems seems to be new. We think that assumptions (V1)–(V2) are more natural than (M1)–(M2) since they do not involve the somewhat ad hoc operator M.

2.3. Boundary conditions weakly enforced. As we have in mind to solve (2.17) by means of DG methods with the boundary conditions weakly enforced, we

now propose alternative formulations of (2.17) and (2.18). Define the bilinear forms

$$a(u,v) = (Tu,v)_L + \frac{1}{2}\langle (M-D)u, v\rangle_{W',W}, \tag{2.19}$$

$$a^*(u,v) = (\tilde{T}u,v)_L + \frac{1}{2}\langle (M^*+D)u, v\rangle_{W',W}. \tag{2.20}$$

It is clear that a and a^* are in $\mathcal{L}(W\times W;\mathbb{R})$. A remarkable property is the following lemma.

LEMMA 2.7. *Under assumption* (A4)*, the following holds for all* $w\in W$*,*

$$a(w,w) \geq \mu_0\|w\|_L^2 + \frac{1}{2}\langle Mw, w\rangle_{W',W}, \tag{2.21}$$

$$a^*(w,w) \geq \mu_0\|w\|_L^2 + \frac{1}{2}\langle Mw, w\rangle_{W',W}. \tag{2.22}$$

As a result, a and a^* are L-coercive on W whenever (A4) *and* (M1) *hold.*

Proof. Let $w\in W$. Owing to (2.9),

$$\begin{aligned} a(w,w) &= (Tw,w)_L - \frac{1}{2}\langle Dw, w\rangle_{W',W} + \frac{1}{2}\langle Mw, w\rangle_{W',W} \\ &= \frac{1}{2}((T+\tilde{T})w, w)_L + \frac{1}{2}\langle Mw, w\rangle_{W',W}. \end{aligned}$$

Hence, (2.21) follows from (2.8). The proof of (2.22) is similar. ∎

Consider the following problems: For $f\in L$,

$$\text{seek } u\in W \text{ such that } a(u,v) = (f,v)_L \ \forall v\in W, \tag{2.23}$$

$$\text{seek } u^*\in W \text{ such that } a^*(u^*,v) = (f,v)_L \ \forall v\in W. \tag{2.24}$$

THEOREM 2.8. *Assume* (A1)–(A4) *and* (M1)–(M2)*. Then,*

(i) *There is a unique solution to* (2.23) *and this solution solves* (2.17)*;*

(ii) *There is a unique solution to* (2.24) *and this solution solves* (2.18).

Owing to Theorem 2.5, there is a unique $u\in V$ solving $Tu=f$. Moreover, since u is in V, $(D-M)u=0$. Hence, $a(u,v)=(f,v)_L$ for all $v\in W$, i.e., u solves (2.23). In addition, since a is L-coercive on W owing to Lemma 2.7, it is clear that the solution to (2.23) is unique. This proves statement (i). The proof of the second statement is similar. ∎

Remark 2.3. Neither the bilinear form a nor the bilinear form a^* induce an isomorphism between W and W'. In particular, there is no guarantee that (2.23) or (2.24) has a solution if the right-hand side is replaced by $\langle f, v\rangle_{W',W}$ whenever $f\in W'$.

3. Examples. This section discusses admissible boundary conditions for three important examples of Friedrichs' systems: advection-reaction equations, advection-diffusion-reaction equations, and a simplified version of the Maxwell equations in the elliptic regime. We stress the fact that the existence of an operator $M\in\mathcal{L}(W;W')$ such that (M1)–(M2) hold provides sufficient conditions for well posedness. Although the existence of $M\in\mathcal{L}(W;W')$ may not be granted in all cases (this is reflected, for instance, in the necessity to make assumption (H2) to treat advection–reaction equations; see section 3.1), the formalism appears to be general enough to treat advection-diffusion-reaction equations, and Maxwell's equations in the elliptic regime; see sections 3.2 and 3.3.

3.1. Advection-reaction. Let β be a vector field in $\mathbb{R}^d$, assume $\beta \in [L^\infty(\Omega)]^d$, $\nabla\cdot\beta \in L^\infty(\Omega)$, and define

$$\partial\Omega^\pm = \{x \in \partial\Omega;\ \pm\beta(x)\cdot n(x) > 0\}, \tag{3.1}$$

as well as $\partial\Omega^0 = \partial\Omega\backslash(\overline{\partial\Omega^-} \cup \overline{\partial\Omega^+})$; $\partial\Omega^-$ is the inflow boundary, $\partial\Omega^+$ the outflow boundary, and $\partial\Omega^0$ the interior of the set $\{x \in \partial\Omega;\ \beta(x)\cdot n(x) = 0\}$.

Let μ be a function in $L^\infty(\Omega)$ such that

$$\mu(x) - \frac{1}{2}\nabla\cdot\beta(x) \geq \mu_0 > 0 \quad \text{a.e. in } \Omega, \tag{3.2}$$

and consider the advection-reaction equation

$$\mu u + \beta\cdot\nabla u = f. \tag{3.3}$$

This PDE falls into the category studied above by setting $Kv = \mu v$ for all $v \in L^2(\Omega)$, and $\mathcal{A}^k = \beta^k$ for $k \in \{1, \ldots, d\}$. It is clear that (A1)–(A4) hold with $m = 1$. The graph space is $W = \{w \in L^2(\Omega);\ \beta\cdot\nabla w \in L^2(\Omega)\}$.

Henceforth, we assume that

(H1) $\mathfrak{C}_0^1(\mathbb{R}^d)$ is dense in W,

(H2) $\partial\Omega^-$ and $\partial\Omega^+$ are well separated, i.e., $\operatorname{dist}(\partial\Omega^-, \partial\Omega^+) > 0$.

Hypothesis (H1) is a regularity assumption on Ω. It can be shown to hold by using Friedrichs' mollifier whenever Ω and β are smooth. Let $L^2(\partial\Omega; |\beta\cdot n|)$ be the space of real-valued functions that are square integrable with respect to the measure $|\beta\cdot n|\,\mathrm{d}x$ where $\mathrm{d}x$ is the Lebesgue measure on $\partial\Omega$.

LEMMA 3.1. *Provided* (H1)–(H2) *hold,*

(i) *The trace operator* $\gamma : \mathfrak{C}_0^1(\mathbb{R}^d) \ni v \longrightarrow v \in L^2(\partial\Omega; |\beta\cdot n|)$ *extends uniquely to a continuous operator on* W*;*

(ii) *The operator* D *has the following representation: for all* $u, v \in W$*,*

$$\langle Du, v\rangle_{W',W} = \int_{\partial\Omega} uv(\beta\cdot n). \tag{3.4}$$

Proof. Since $\partial\Omega^-$ and $\partial\Omega^+$ are well separated, there are two nonnegative functions ψ^- and ψ^+ in $\mathfrak{C}_0^1(\mathbb{R}^d)$ such that

$$\psi^- + \psi^+ = 1 \ \text{ on } \overline{\Omega}, \qquad \psi^-|_{\partial\Omega^+} = 0, \qquad \psi^+|_{\partial\Omega^-} = 0. \tag{3.5}$$

Let u be a function in $\mathfrak{C}_0^1(\mathbb{R}^d)$. Then,

$$\begin{aligned}\int_{\partial\Omega} u^2|\beta\cdot n| &= \int_{\partial\Omega} u^2(\psi^- + \psi^+)|\beta\cdot n| = \int_{\partial\Omega^-\cup\partial\Omega^0} u^2\psi^-|\beta\cdot n| + \int_{\partial\Omega^+\cup\partial\Omega^0} u^2\psi^+|\beta\cdot n| \\ &= -\int_{\partial\Omega} u^2\psi^-(\beta\cdot n) + \int_{\partial\Omega} u^2\psi^+(\beta\cdot n) = -\int_\Omega \nabla\cdot(u^2\psi^-\beta) + \int_\Omega \nabla\cdot(u^2\psi^+\beta).\end{aligned}$$

Hence, $0 \leq \int_{\partial\Omega} u^2|\beta\cdot n| \leq c(\psi^+, \psi^-)\|u\|_W^2$. Statement (i) follows from the density of $\mathfrak{C}_0^1(\mathbb{R}^d)$ in W. The proof of (ii) is an immediate consequence of the existence of traces in $L^2(\partial\Omega; |\beta\cdot n|)$. ∎

To specify boundary conditions, define for $u, v \in W$,

$$\langle Mu, v\rangle_{W',W} = \int_{\partial\Omega} uv|\beta\cdot n|. \tag{3.6}$$

LEMMA 3.2. *Let $M \in \mathcal{L}(W;W')$ be defined in* (3.6). *Then,*
(i) (M1)–(M2) *hold;*
(ii) $V = \{v \in W;\, v|_{\partial\Omega^-} = 0\}$ *and* $V^* = \{v \in W;\, v|_{\partial\Omega^+} = 0\}$.

Proof of (i). (M1) directly results from (3.6). Let ψ^+, ψ^- be the partition of unity introduced in (3.5). Let $w \in W$ and write $w = \psi^+ w + \psi^- w$. It is clear that $\psi^+ w \in \mathrm{Ker}(D-M)$ since for all $v \in W$, $\langle (D-M)\psi^+ w, v\rangle_{W',W} = \int_{\partial\Omega^+} \psi^+ vw(\beta\cdot n - |\beta\cdot n|) = 0$. Similarly, $\psi^- w \in \mathrm{Ker}(D+M)$. Hence, (M2) holds.

Proof of (ii). Let $v \in \mathrm{Ker}(D-M)$. Then, for all $w \in W$, $-2\int_{\partial\Omega^-} |\beta\cdot n| vw = 0$. Take $w = v$ to infer $v|_{\partial\Omega^-} = 0$; thus, $\mathrm{Ker}(D-M) \subset V$. Conversely, if $v|_{\partial\Omega^-} = 0$, it is clear that for all $w \in W$, $\langle (D-M)v, w\rangle_{W',W} = -2\int_{\partial\Omega^-} |\beta\cdot n| vw = 0$, i.e., $v \in \mathrm{Ker}(D-M)$. Proceed similarly to prove that $V^* = \{v \in W;\, v|_{\partial\Omega^+} = 0\}$. ∎

3.2. Advection-diffusion-reaction equations. Let $\beta : \Omega \longrightarrow \mathbb{R}^d$ be a vector field such that $\beta \in [L^\infty(\Omega)]^d$ and $\nabla\cdot\beta \in L^\infty(\Omega)$. Let μ be a function in $L^\infty(\Omega)$ such that (3.2) holds, and consider the advection-diffusion-reaction equation

$$-\Delta u + \beta\cdot\nabla u + \mu u = f. \tag{3.7}$$

This equation can be written as a system of first-order PDEs in the form

$$\begin{cases} \sigma + \nabla u = 0, \\ \mu u + \nabla\cdot\sigma + \beta\cdot\nabla u = f. \end{cases} \tag{3.8}$$

The above differential operator can be cast into the form of a Friedrichs' operator by setting $K(\sigma,u) = (\sigma,\mu u)$ for all $(\sigma,u) \in [L^2(\Omega)]^{d+1}$, and for $k \in \{1,\dots,d\}$,

$$\mathcal{A}^k = \left[\begin{array}{c:c} 0 & e^k \\ \hdashline (e^k)^t & \beta^k \end{array}\right], \tag{3.9}$$

where e^k is the kth vector in the canonical basis of $\mathbb{R}^d$. It is clear that hypotheses (A1)–(A4) hold with $m = d+1$. Upon observing the norm equivalence

$$\begin{aligned} c_1(\|\nabla u\|_{L^2(\Omega)} + \|\nabla\cdot\sigma\|_{L^2(\Omega)}) \le \|\nabla u\|_{L^2(\Omega)} + \|\beta\cdot\nabla u + \nabla\cdot\sigma\|_{L^2(\Omega)} \\ \le c_2(\|\nabla u\|_{L^2(\Omega)} + \|\nabla\cdot\sigma\|_{L^2(\Omega)}), \end{aligned}$$

it is inferred that the graph space is $W = H(\mathrm{div};\Omega)\times H^1(\Omega)$. Moreover, the boundary operator D is such that for all $(\sigma,u),(\tau,v) \in W$,

$$\langle D(\sigma,u),(\tau,v)\rangle_{W',W} = \langle \sigma\cdot n, v\rangle_{-\frac12,\frac12} + \langle \tau\cdot n, u\rangle_{-\frac12,\frac12} + \int_{\partial\Omega} (\beta\cdot n)uv, \tag{3.10}$$

where $\langle , \rangle_{-\frac12,\frac12}$ denotes the duality pairing between $H^{-\frac12}(\partial\Omega)$ and $H^{\frac12}(\partial\Omega)$. Note that (3.10) makes sense since functions in $H^1(\Omega)$ have traces in $H^{\frac12}(\partial\Omega)$ and vector fields in $H(\mathrm{div};\Omega)$ have normal traces in $H^{-\frac12}(\partial\Omega)$.

3.2.1. Dirichlet boundary conditions. A suitable operator M to weakly enforce Dirichlet boundary conditions is such that for all $(\sigma,u),(\tau,v) \in W$,

$$\langle M(\sigma,u),(\tau,v)\rangle_{W',W} = \langle \sigma\cdot n, v\rangle_{-\frac12,\frac12} - \langle \tau\cdot n, u\rangle_{-\frac12,\frac12}. \tag{3.11}$$

LEMMA 3.3. *Let $M \in \mathcal{L}(W;W')$ be defined in* (3.11)*. Then,*
(i) (M1)–(M2) *hold;*
(ii) $V = V^* = \{(\sigma,u) \in W;\, u|_{\partial\Omega} = 0\}$.

Proof of (i). (M1) clearly holds since $M + M^* = 0$. Let $w = (\sigma,u) \in W$ and write $w = w^+ + w^-$ with $w^+ = (-\frac{1}{2}\beta u, u)$ and $w^- = (\sigma + \frac{1}{2}\beta u, 0)$. By assumption on β, the vector-valued field βu is in $H(\mathrm{div};\Omega)$ if $u \in H^1(\Omega)$; hence, $w^\pm$ are in W. Moreover, a straightforward calculation shows that $w^\pm \in \mathrm{Ker}(D \pm M)$. Hence, (M2) holds.

Proof of (ii). The identity $V = V^*$ results from the fact that $M + M^* = 0$. Moreover, observe that for all $(\sigma,u),(\tau,v) \in W$,

$$\langle (D-M)(\sigma,u),(\tau,v)\rangle_{W',W} = 2\langle \tau{\cdot}n, u\rangle_{-\frac{1}{2},\frac{1}{2}} + \int_{\partial\Omega} (\beta{\cdot}n)uv.$$

Let $(\sigma,u) \in \mathrm{Ker}(D-M)$. Let $\gamma \in H^{-\frac{1}{2}}(\partial\Omega)$. There exists $\tau \in H(\mathrm{div};\Omega)$ such that $\tau{\cdot}n = \gamma$ in $H^{-\frac{1}{2}}(\partial\Omega)$. Then, using $(\tau,0)$ in the above equation yields $\langle \gamma, u\rangle_{-\frac{1}{2},\frac{1}{2}} = 0$. Since γ is arbitrary, this implies $u|_{\partial\Omega} = 0$. Hence, $V \subset \{(\sigma,u) \in W;\, u|_{\partial\Omega} = 0\}$. Conversely, let $(\sigma,u) \in W$ be such that $u|_{\partial\Omega} = 0$. Then, the above equation shows that $(\sigma,u) \in \mathrm{Ker}(D-M) = V$. ∎

Remark 3.1. The choice of the operator M to enforce homogeneous Dirichlet boundary conditions is not unique. For instance, one can take $\langle M(\sigma,u),(\tau,v)\rangle_{W',W} = \langle \sigma{\cdot}n, v\rangle_{-\frac{1}{2},\frac{1}{2}} - \langle \tau{\cdot}n, u\rangle_{-\frac{1}{2},\frac{1}{2}} + \int_{\partial\Omega} \varsigma uv$, where ς is a nonnegative real number.

3.2.2. Neumann and Robin boundary conditions. Let $\varrho \in L^\infty(\partial\Omega)$ be such that $2\varrho + \beta{\cdot}n \geq 0$ a.e. on $\partial\Omega$. Neumann and Robin boundary conditions are treated simultaneously, the choice $\varrho = 0$ yielding a Neumann boundary condition (in this case, $\beta{\cdot}n \geq 0$ a.e. on $\partial\Omega$ corresponding to an outflow boundary). A suitable operator M to weakly enforce Neumann or Robin boundary conditions is such that for all $(\sigma,u),(\tau,v) \in W$,

$$\langle M(\sigma,u),(\tau,v)\rangle_{W',W} = \langle \tau{\cdot}n, u\rangle_{-\frac{1}{2},\frac{1}{2}} - \langle \sigma{\cdot}n, v\rangle_{-\frac{1}{2},\frac{1}{2}} + \int_{\partial\Omega} (2\varrho + \beta{\cdot}n)uv. \tag{3.12}$$

LEMMA 3.4. *Let $M \in \mathcal{L}(W;W')$ be defined in* (3.12)*. Then,*
(i) (M1)–(M2) *hold;*
(ii) $V = \{(\sigma,u) \in W;\, \sigma{\cdot}n = \varrho u|_{\partial\Omega}\}$ *and* $V^* = \{(\sigma,u) \in W;\, \sigma{\cdot}n = -(\varrho + \beta{\cdot}n)u|_{\partial\Omega}\}$.

Proof. (M1) holds since $2\varrho + \beta{\cdot}n \geq 0$ a.e. on $\partial\Omega$. Furthermore, observe that

$$\begin{aligned}
\langle (D-M)(\sigma,u),(\tau,v)\rangle_{W',W} &= 2\langle \sigma{\cdot}n, v\rangle_{-\frac{1}{2},\frac{1}{2}} - 2\textstyle\int_{\partial\Omega} \varrho uv,\\
\langle (D+M)(\sigma,u),(\tau,v)\rangle_{W',W} &= 2\langle \tau{\cdot}n, u\rangle_{-\frac{1}{2},\frac{1}{2}} + 2\textstyle\int_{\partial\Omega} (\varrho + \beta{\cdot}n)uv,\\
\langle (D+M^*)(\sigma,u),(\tau,v)\rangle_{W',W} &= 2\langle \sigma{\cdot}n, v\rangle_{-\frac{1}{2},\frac{1}{2}} + 2\textstyle\int_{\partial\Omega} (\varrho + \beta{\cdot}n)uv.
\end{aligned}$$

Let $w = (\sigma,u) \in W$. Since $\varrho u|_{\partial\Omega} \in H^{-\frac{1}{2}}(\partial\Omega)$, there is $\sigma_0 \in H(\mathrm{div};\Omega)$ such that $\sigma_0{\cdot}n = \varrho u|_{\partial\Omega}$. Then, setting $w^+ = (\sigma - \sigma_0, 0)$ and $w^- = (\sigma_0, u)$, it is easily verified that $w^\pm \in \mathrm{Ker}(D \pm M)$ and, hence, (M2) holds. Finally, proceed as in the proof of Lemma 3.3 to prove (ii). ∎

3.3. Maxwell's equations in the elliptic regime. We close this series of examples by considering a simplified form of Maxwell's equations in $\mathbb{R}^3$ in the elliptic regime, i.e., when displacement currents are negligible. Let σ and μ be two positive functions in $L^\infty(\Omega)$ uniformly bounded away from zero. Consider the following

problem

$$\begin{cases} \mu H + \nabla\times E = f, \\ \sigma E - \nabla\times H = g. \end{cases} \tag{3.13}$$

This problem can be cast into the form of a Friedrichs' system by setting $K(H,E) = (\mu H, \sigma E)$ for all $(H,E) \in [L^2(\Omega)]^3 \times [L^2(\Omega)]^3$ and for $k \in \{1,2,3\}$,

$$\mathcal{A}^k = \left[\begin{array}{c:c} 0 & \mathcal{R}^k \\ \hdashline (\mathcal{R}^k)^t & 0 \end{array}\right]. \tag{3.14}$$

The entries of the matrices $\mathcal{R}^k \in \mathbb{R}^{3,3}$ are those of the Levi–Civita permutation tensor, i.e., $\mathcal{R}^k_{ij} = \epsilon_{ikj}$ for $1 \le i,j,k \le 3$. Hypotheses (A1)–(A4) hold with $m = 6$. The graph space is $W = H(\mathrm{curl};\Omega)\times H(\mathrm{curl};\Omega)$, and the boundary operator D is such that for all $(H,E),(h,e) \in W$,

$$\begin{aligned} \langle D(H,E),(h,e)\rangle_{W',W} = {} & (\nabla\times E, h)_{[L^2(\Omega)]^3} - (E, \nabla\times h)_{[L^2(\Omega)]^3} \\ & + (H, \nabla\times e)_{[L^2(\Omega)]^3} - (\nabla\times H, e)_{[L^2(\Omega)]^3}. \end{aligned} \tag{3.15}$$

When H and E are smooth the above duality product can be interpreted as the boundary integral $\int_{\partial\Omega}(n\times E)\cdot h + (n\times e)\cdot H$.

Let us now define acceptable boundary conditions for (3.13). One possibility (among many others) consists of setting for all $(H,E),(h,e) \in W$,

$$\begin{aligned} \langle M(H,E),(h,e)\rangle_{W',W} = {} & -(\nabla\times E, h)_{[L^2(\Omega)]^3} + (E, \nabla\times h)_{[L^2(\Omega)]^3} \\ & + (H, \nabla\times e)_{[L^2(\Omega)]^3} - (\nabla\times H, e)_{[L^2(\Omega)]^3}. \end{aligned} \tag{3.16}$$

LEMMA 3.5. *Let M be defined in* (3.16). *Then,*

(i) (M1)–(M2) *hold;*

(ii) $V = V^* = \{(H,E) \in W;\ (E\times n)|_{\partial\Omega} = 0\}$.

Proof of (i). Observe that $M + M^* = 0$; hence, M is positive. Let $w = (H,E) \in W$. Write $w = w^+ + w^-$ with $w^+ = (0,E)$ and $w^- = (H,0)$. One easily verifies that $w^\pm \in \mathrm{Ker}(D \pm M)$, i.e., (M2) holds.

Proof of (ii). The identity $V = V^*$ results from the fact that $M + M^* = 0$. Let $(H,E) \in \mathrm{Ker}(D - M)$. Then, for all $(h,e) \in W$,

$$\langle (D-M)(H,E),(h,e)\rangle_{W',W} = 2(\nabla\times E, h)_{[L^2(\Omega)]^3} - 2(E, \nabla\times h)_{[L^2(\Omega)]^3} = 0.$$

Since vector fields in $H(\mathrm{curl};\Omega)$ have tangential traces in $[H^{-\frac12}(\partial\Omega)]^3$, we infer that for all $h \in [H^1(\Omega)]^3$, $\langle (E\times n), h\rangle_{-\frac12,\frac12} = 0$. Since h is arbitrary and the traces of vector fields in $[H^1(\Omega)]^3$ span $[H^{\frac12}(\partial\Omega)]^3$, we conclude that $(E\times n)|_{\partial\Omega} = 0$. Conversely, let $(H,E) \in W$ be such that $(E\times n)|_{\partial\Omega} = 0$. Then, it is clear that $\langle (D-M)(H,E),(h,e)\rangle_{W',W} = 0$ for all $h \in [H^1(\Omega)]^3$ and all $e \in H(\mathrm{curl};\Omega)$. Since $[H^1(\Omega)]^3$ is dense in $H(\mathrm{curl};\Omega)$ and both D and M are in $\mathcal{L}(W;W')$, it follows that $(H,E) \in \mathrm{Ker}(D-M)$. ∎

4. Discontinuous Galerkin. The goal of this section is to introduce a generic DG method to approximate the abstract problem (2.23). The fact that the boundary conditions are enforced weakly through the boundary operator M is a key to the theory. The discrete problem is stated in (4.12)–(4.13). The design constraints of the method are (DG1) to (DG8). The main convergence result is stated in Theorem 4.6.

4.1. The discrete setting. Let $\{\mathcal{T}_h\}_{h>0}$ be a family of meshes of Ω. The meshes are assumed to be affine to avoid unnecessary technicalities, i.e., Ω is assumed to be a polyhedron. However, we do not make any assumption on the matching of element interfaces.

Let p be a nonnegative integer. Define

$$W_h = \{v_h \in [L^2(\Omega)]^m;\, \forall K \in \mathcal{T}_h,\, v_h|_K \in [\mathbb{P}_p]^m\}, \tag{4.1}$$

$$W(h) = [H^1(\Omega)]^m + W_h. \tag{4.2}$$

We denote by $\mathcal{F}_h^{\mathrm{i}}$ the set of interior faces (or interfaces), i.e., $F \in \mathcal{F}_h^{\mathrm{i}}$ if F is a $(d-1)$-manifold and there are $K_1(F)$, $K_2(F) \in \mathcal{T}_h$ such that $F = K_1(F) \cap K_2(F)$. We denote by $\mathcal{F}_h^{\partial}$ the set of the faces that separate the mesh from the exterior of Ω, i.e., $F \in \mathcal{F}_h^{\partial}$ if F is a $(d-1)$-manifold and there is $K(F) \in \mathcal{T}_h$ such that $F = K(F) \cap \partial\Omega$. Finally, we set $\mathcal{F}_h = \mathcal{F}_h^{\mathrm{i}} \cup \mathcal{F}_h^{\partial}$. Since every function v in $W(h)$ has a (possibly two-valued) trace almost everywhere on $F \in \mathcal{F}_h^{\mathrm{i}}$, it is meaningful to set

$$v^1(x) = \lim_{\substack{y \to x \\ y \in K_1(F)}} v(y), \qquad v^2(x) = \lim_{\substack{y \to x \\ y \in K_2(F)}} v(y), \qquad \text{for a.e. } x \in F, \tag{4.3}$$

$$[\![v]\!] = v^1 - v^2, \qquad \{v\} = \frac{1}{2}(v^1 + v^2), \qquad \text{a.e. on } F. \tag{4.4}$$

The arbitrariness in the choice of $K_1(F)$ and $K_2(F)$ could be avoided by choosing an intrinsic notation that would, however, unnecessarily complicate the presentation. For instance, we could have chosen to set $[\![v]\!] = v^1 \otimes n^1 + v^2 \otimes n^2$ where n^1, n^2 are the unit outward normals of $K_1(F)$ and $K_2(F)$, respectively. Although having to choose $K_1(F)$ and $K_2(F)$ may seem cumbersome, nothing that is said hereafter depends on the choice that is made.

For any measurable subset of Ω or $\mathcal{F}_h$, say E, $(\cdot,\cdot)_{L,E}$ denotes the scalar product induced by $[L^2(\Omega)]^m$ or $[L^2(\mathcal{F}_h)]^m$ on E, respectively, and $\|\cdot\|_{L,E}$ the associated norm. Similarly, $\|\cdot\|_{L^d,E}$ denotes the norm induced by $[L^2(\Omega)]^{m\times d}$ or $[L^2(\mathcal{F}_h)]^{m\times d}$ on E. For $K \in \mathcal{T}_h$ (resp., $F \in \mathcal{F}_h$), h_K (resp., h_F) denotes the diameter of K (resp., F).

The mesh family $\{\mathcal{T}_h\}_{h>0}$ is assumed to be shape-regular so that there is a constant c, independent of $h = \max_{K\in\mathcal{T}_h} h_K$, such that for all $v_h \in W_h$ and for all $K \in \mathcal{T}_h$,

$$\|\nabla v_h\|_{L^d,K} \le c\, h_K^{-1} \|v_h\|_{L,K}, \tag{4.5}$$

$$\|v_h\|_{L,F} \le c\, h_K^{-\frac{1}{2}} \|v_h\|_{L,K} \quad \forall F \subset \partial K. \tag{4.6}$$

4.2. Boundary operators. Henceforth we denote $\mathcal{D}_{\partial\Omega} = \sum_{k=1}^d n_k \mathcal{A}^k$ and we assume that the boundary operator M is associated with a matrix-valued field $\mathcal{M} : \partial\Omega \longrightarrow \mathbb{R}^{m,m}$. Hence, for all functions u, v smooth enough (e.g., $u, v \in [H^1(\Omega)]^m$), the following holds:

$$\langle Du, v\rangle_{W',W} = \int_{\partial\Omega} v^t \mathcal{D}_{\partial\Omega} u, \qquad \langle Mu, v\rangle_{W',W} = \int_{\partial\Omega} v^t \mathcal{M} u. \tag{4.7}$$

To enforce boundary conditions weakly, we introduce for all $F \in \mathcal{F}_h^{\partial}$ a linear operator $M_F \in \mathcal{L}([L^2(F)]^m; [L^2(F)]^m)$. The design of the boundary operators $\{M_F\}_{F\in\mathcal{F}_h^{\partial}}$

must comply with the following conditions: For all $F \in \mathcal{F}_h^\partial$ and for all $v, w \in [L^2(F)]^m$,

(DG1) $(M_F(v), v)_{L,F} \geq 0,$

(DG2) $(\mathcal{M}v = \mathcal{D}_{\partial\Omega}v) \implies (M_F(v) = \mathcal{D}_{\partial\Omega}v),$

(DG3) $|(M_F(v) - \mathcal{D}_{\partial\Omega}v, w)_{L,F}| \leq c|v|_{M,F}\|w\|_{L,F},$

(DG4) $|(M_F(v) + \mathcal{D}_{\partial\Omega}v, w)_{L,F}| \leq c\|v\|_{L,F}|w|_{M,F},$

where c is a mesh-independent constant and where we have introduced for all $v \in W(h)$ the following seminorms:

$$|v|_M^2 = \sum_{F\in\mathcal{F}_h^\partial} |v|_{M,F}^2 \qquad \text{with} \qquad |v|_{M,F}^2 = (M_F(v), v)_{L,F}. \tag{4.8}$$

Remark 4.1.

(i) Examples of boundary operators M_F are presented in section 5 for all the model problems introduced in section 3.

(ii) Assumption (DG2) is a consistency assumption while assumptions (DG3) and (DG4) are related to the stability and continuity of the discrete bilinear form; see the analysis in section 4.5.

4.3. Interface operators. For $K \in \mathcal{T}_h$, define the matrix-valued field $\mathcal{D}_{\partial K} : \partial K \to \mathbb{R}^{m,m}$ as

$$\mathcal{D}_{\partial K}(x) = \sum_{k=1}^{d} n_{K,k}\mathcal{A}^k(x) \quad \text{a.e. on } \partial K, \tag{4.9}$$

where $n_K = (n_{K,1}, \ldots, n_{K,d})^t$ is the unit outward normal to K on ∂K. Note that this definition is compatible with that of $\mathcal{D}_{\partial\Omega}$ in (4.7) if $\partial K \cap \partial\Omega \neq \emptyset$. Moreover, observe that for all u, v in $W(h)$ and for all $K \in \mathcal{T}_h$,

$$(\mathcal{D}_{\partial K}u, v)_{L,\partial K} = (Tu, v)_{L,K} - (u, \tilde{T}v)_{L,K}. \tag{4.10}$$

We denote by $\mathcal{D}$ the matrix-valued field defined on $\mathcal{F}_h = \mathcal{F}_h^{\mathrm{i}} \cup \mathcal{F}_h^\partial$ as follows. On $\mathcal{F}_h^\partial$, $\mathcal{D}$ is single-valued and coincides with $\mathcal{D}_{\partial\Omega}$. On $\mathcal{F}_h^{\mathrm{i}}$, $\mathcal{D}$ is two-valued and for all $F \in \mathcal{F}_h^{\mathrm{i}}$, its two values are $\mathcal{D}_{\partial K_1(F)}$ and $\mathcal{D}_{\partial K_2(F)}$. Note that $\{\mathcal{D}\} = 0$ a.e. on $\mathcal{F}_h^{\mathrm{i}}$.

To control the jumps of functions in W_h across mesh interfaces, we introduce for all $F \in \mathcal{F}_h^{\mathrm{i}}$ a linear operator $S_F \in \mathcal{L}([L^2(F)]^m; [L^2(F)]^m)$. The analysis below will show that the design of the interface operators $\{S_F\}_{F\in\mathcal{F}_h^{\mathrm{i}}}$ must comply with the following conditions. For all $F \in \mathcal{F}_h^{\mathrm{i}}$ and for all $v, w \in [L^2(F)]^m$,

(DG5) $(S_F(v), v)_{L,F} \geq 0,$

(DG6) $\|S_F(v)\|_{L,F} \leq c\|v\|_{L,F},$

(DG7) $|(S_F(v), w)_{L,F}| \leq c|v|_{S,F}|w|_{S,F},$

(DG8) $|(\mathcal{D}_{\partial K(F)}v, w)_{L,F}| \leq c|v|_{S,F}\|w\|_{L,F},$

where c is a mesh-independent constant, $K(F)$ denotes any of the two elements sharing F and $\partial K(F)$ its boundary, and where we have introduced for all $v \in W(h)$ the following seminorms:

$$|v|_S^2 = \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} |v|_{S,F}^2 \qquad \text{with} \qquad |v|_{S,F}^2 = (S_F(v), v)_{L,F}. \tag{4.11}$$

Remark 4.2.

(i) Examples of interface operators S_F are presented in section 5 for all the model problems introduced in section 3.

(ii) Since S_F is positive, a sufficient condition for (DG7) to hold with $c = 1$ is S_F be self-adjoint.

4.4. The discrete problem. We now turn our attention to the construction of a discrete counterpart of (2.23). To this end we introduce the bilinear form a_h such that for all v, w in $W(h)$,

$$\begin{aligned} a_h(v,w) = &\sum_{K\in\mathcal{T}_h} (Tv,w)_{L,K} + \sum_{F\in\mathcal{F}_h^\partial} \frac{1}{2}(M_F(v) - \mathcal{D}v, w)_{L,F} \\ &- \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} 2(\{\mathcal{D}v\},\{w\})_{L,F} + \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} (S_F([\![v]\!]),[\![w]\!])_{L,F}. \end{aligned} \tag{4.12}$$

Then, we construct an approximate solution to (2.23) as follows. For $f \in L$,

$$\begin{cases} \text{seek } u_h \in W_h \text{ such that} \\ a_h(u_h, v_h) = (f, v_h)_L \quad \forall v_h \in W_h. \end{cases} \tag{4.13}$$

Remark 4.3. In the definition of a_h, the second term weakly enforces the boundary conditions. The purpose of the third term is to ensure that a coercivity property holds, see Lemma 4.1. The last term controls the jump of the discrete solution across interfaces. Some user-dependent arbitrariness appears in the second and fourth term through the definition of the operators M_F and S_F. The design constraints on M_F and S_F are (DG1)–(DG4) and (DG5)–(DG8), respectively.

4.5. Convergence analysis. To perform the error analysis we introduce the following discrete norms on $W(h)$,

$$\|v\|_{h,A}^2 = \|v\|_L^2 + |v|_J^2 + |v|_M^2 + \sum_{K\in\mathcal{T}_h} h_K \|Av\|_{L,K}^2, \tag{4.14}$$

$$\|v\|_{h,\frac{1}{2}}^2 = \|v\|_{h,A}^2 + \sum_{K\in\mathcal{T}_h} [h_K^{-1}\|v\|_{L,K}^2 + \|v\|_{L,\partial K}^2], \tag{4.15}$$

where we have introduced the jump seminorms

$$|v|_J^2 = \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} |v|_{J,F}^2 \qquad \text{with} \qquad |v|_{J,F} = |[\![v]\!]|_{S,F}. \tag{4.16}$$

The norm $\|\cdot\|_{h,A}$ is used to measure the approximation error, and the norm $\|\cdot\|_{h,\frac{1}{2}}$ serves to measure the interpolation properties of the discrete space W_h.

Throughout this section, we assume that:

- Problem (2.23) is well-posed.
- The mesh family $\{\mathcal{T}_h\}_{h>0}$ is shape-regular so that (4.5) and (4.6) hold.
- The design assumptions (DG1)–(DG8) on M_F and S_F hold.
- For all $k \in \{1,\dots,d\}$, $\mathcal{A}^k \in [\mathfrak{C}^{0,\frac{1}{2}}(\overline{\Omega})]^{m,m}$.

LEMMA 4.1 (L-coercivity). *For all h and for all v in $W(h)$,*

$$a_h(v,v) \geq \mu_0 \|v\|_L^2 + |v|_J^2 + \frac{1}{2}|v|_M^2. \tag{4.17}$$

Proof. Let v in $W(h)$. Using (4.10) and summing over the mesh elements yields

$$\sum_{F\in\mathcal{F}_h^\partial}\frac{1}{2}(\mathcal{D}v,v)_{L,F}+\sum_{F\in\mathcal{F}_h^{\mathrm{i}}}\int_F\left\{v^t\mathcal{D}v\right\}=\frac{1}{2}\sum_{K\in\mathcal{T}_h}[(Tv,v)_{L,K}-(v,\tilde{T}v)_{L,K}].$$

Subtracting this equation from (4.12) and using the fact that $\{v^t\mathcal{D}v\}=2\{v^t\}\{\mathcal{D}v\}$ leads to

$$a_h(v,v)=\frac{1}{2}\sum_{K\in\mathcal{T}_h}\Big[(Tv,v)_{L,K}+(v,\tilde{T}v)_{L,K}\Big]+|v|_J^2+\frac{1}{2}|v|_M^2.$$

Then, the desired result follows using (A4). ∎

LEMMA 4.2. *There is $c>0$, independent of h, such that for all F in $\mathcal{F}_h^{\mathrm{i}}$ and for all $v,w\in W(h)$,*

$$|(S_F([\![v]\!]),[\![w]\!])_{L,F}|+|(\{\mathcal{D}v\},\{w\})_{L,F}|\le c|v|_{J,F}(\|\{w\}\|_{L,F}+\|[\![w]\!]\|_{L,F}). \tag{4.18}$$

Proof.

(1) Owing to (DG7), $(S_F([\![v]\!]),[\![w]\!])_{L,F}\le c|v|_{J,F}|w|_{J,F}$, and owing to (DG6), $|w|_{J,F}\le c\|[\![w]\!]\|_{L,F}$. Hence, $(S_F([\![v]\!]),[\![w]\!])_{L,F}\le c|v|_{J,F}\|[\![w]\!]\|_{L,F}$.

(2) Let $K_1(F)$ and $K_2(F)$ be the two mesh elements such that $F=K_1(F)\cap K_2(F)$. Then, $2\{\mathcal{D}v\}=\mathcal{D}_{K_1(F)}[\![v]\!]$ since $\{\mathcal{D}\}=0$. Using (DG8) yields

$$|(\{\mathcal{D}v\},\{w\})_{L,F}|=|(\mathcal{D}_{K_1(F)}[\![v]\!],\{w\})_{L,F}|\le c|v|_{J,F}\|\{w\}\|_{L,F}.$$

The proof is complete. ∎

LEMMA 4.3 (stability). *There is $c>0$, independent of h, such that*

$$\inf_{v_h\in W_h\setminus\{0\}}\sup_{w_h\in W_h\setminus\{0\}}\frac{a_h(v_h,w_h)}{\|v_h\|_{h,A}\|w_h\|_{h,A}}\ge c. \tag{4.19}$$

Proof.

(1) Let v_h be an arbitrary element in W_h. Let $K\in\mathcal{T}_h$. Denote by $\overline{\mathcal{A}_K^k}$ the mean-value of $\mathcal{A}^k$ on K; then,

$$\|\mathcal{A}^k-\overline{\mathcal{A}_K^k}\|_{[L^\infty(K)]^{m,m}}\le\|\mathcal{A}^k\|_{[\mathfrak{C}^{0,\frac{1}{2}}(\overline{\Omega})]^{m,m}}h_K^{\frac{1}{2}}. \tag{4.20}$$

Set $\overline{A}_Kv_h=\sum_{k=1}^d\overline{\mathcal{A}_K^k}\partial_kv_h$ and $\pi_h=\sum_{K\in\mathcal{T}_h}h_K\overline{A}_Kv_h$. Clearly, $\pi_h\in W_h$. Using (4.20), together with the inverse inequalities (4.5) and (4.6), leads to

$$\begin{cases}\|\overline{A}_Kv_h\|_{L,F}\le c\,h_K^{-\frac{1}{2}}\|\overline{A}_Kv_h\|_{L,K} & \text{if } F\in\mathcal{F}_h^\partial,\\ \|\left\{\overline{A}_Kv_h\right\}\|_{L,F}+\|[\![\overline{A}_Kv_h]\!]\|_{L,F}\le c\,h_K^{-\frac{1}{2}}\|\overline{A}_Kv_h\|_{L,K_1\cup K_2} & \text{if } F\in\mathcal{F}_h^{\mathrm{i}},\end{cases} \tag{4.21}$$

$$\|\overline{A}_Kv_h\|_{L,K}\le c\,\min(\|Av_h\|_{L,K}+h_K^{-\frac{1}{2}}\|v_h\|_{L,K},h_K^{-1}\|v_h\|_{L,K}). \tag{4.22}$$

Note that (4.22) implies $\|\pi_h\|_L \le c\|v_h\|_L$. From the definition of a_h it follows that

$$\begin{aligned}\sum_{K\in\mathcal{T}_h} h_K\|Av_h\|_{L,K}^2 &= a_h(v_h,\pi_h) - (Kv_h,\pi_h)_L - \sum_{F\in\mathcal{F}_h^\partial}\frac{1}{2}(M_F(v_h)-\mathcal{D}v_h,\pi_h)_{L,F}\\ &\quad+\sum_{F\in\mathcal{F}_h^{\mathrm{i}}}\left[2(\{\mathcal{D}v_h\},\{\pi_h\})_{L,F}-(S_F([\![v_h]\!]),[\![\pi_h]\!])_{L,F}\right]\\ &\quad+\sum_{K\in\mathcal{T}_h} h_K(Av_h,(A-\overline{A}_K)v_h)_{L,K}\\ &= a_h(v_h,\pi_h)+R_1+R_2+R_3+R_4,\end{aligned}$$

where R_1, R_2, R_3, and R_4 denote the second, third, fourth, and fifth term in the right-hand side of the above equation, respectively. Each of these terms is bounded from above as follows. Using (4.22) yields $\|\pi_h\|_L \le c\|v_h\|_L$ and hence,

$$|R_1| \le c\|v_h\|_L\|\pi_h\|_L \le c\|v_h\|_L^2.$$

Using (DG3) together with (4.21) and (4.22) leads to

$$\begin{aligned}|R_2| &\le \sum_{F\in\mathcal{F}_h^\partial}\left[c_\gamma(M_F(v_h),v_h)_{L,F}+\gamma\|\pi_h\|_{L,F}^2\right]\\ &\le c(\|v_h\|_L^2+|v_h|_M^2)+\gamma\sum_{K\in\mathcal{T}_h} h_K\|Av_h\|_{L,K}^2,\end{aligned}$$

where $\gamma>0$ can be chosen as small as needed. For the third term, use Lemma 4.2, together with inequalities (4.21) and (4.22), as follows:

$$\begin{aligned}|R_3| &\le \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} c_\gamma|v_h|_{J,F}^2+\gamma\sum_{K\in\mathcal{T}_h} h_K\|\overline{A}_Kv_h\|_{L,K}^2\\ &\le c(\|v_h\|_L^2+|v_h|_J^2)+\gamma\sum_{K\in\mathcal{T}_h} h_K\|Av_h\|_{L,K}^2.\end{aligned}$$

For the last term, (4.5) and (4.20) yield

$$\begin{aligned}|R_4| &\le \sum_{K\in\mathcal{T}_h} h_K\|Av_h\|_{L,K}ch_K^{\frac12}\|\nabla v_h\|_{L^d,K}\\ &\le c\sum_{K\in\mathcal{T}_h} h_K^{\frac12}\|Av_h\|_{L,K}\|v_h\|_{L,K} \le c\|v_h\|_L^2+\gamma\sum_{K\in\mathcal{T}_h} h_K\|Av_h\|_{L,K}^2.\end{aligned}$$

Using the above four bounds, $\gamma=\frac16$, and Lemma 4.1 leads to

$$\frac12\sum_{K\in\mathcal{T}_h} h_K\|Av_h\|_{L,K}^2 \le a_h(v_h,\pi_h)+c\,a_h(v_h,v_h). \tag{4.23}$$

(2) Let us now prove that $\|\pi_h\|_{h,A} \le c\,\|v_h\|_{h,A}$. We have already seen that $\|\pi_h\|_L \le c\|v_h\|_L$. Using (4.5), together with inequalities (4.20) and (4.22), leads to

$$\sum_{K\in\mathcal{T}_h} h_K\|A\pi_h\|_{L,K}^2 \le c\sum_{K\in\mathcal{T}_h} h_K^{-1}\|\pi_h\|_{L,K}^2 \le c\sum_{K\in\mathcal{T}_h}[h_K\|Av_h\|_{L,K}^2+\|v_h\|_{L,K}^2].$$

Moreover, the inverse inequality (4.6), assumption (DG6), and inequalities (4.21) and (4.22) yield

$$|\pi_h|_J^2 = \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} |\pi_h|_{J,F}^2 \le c \sum_{K\in\mathcal{T}_h} h_K^{-1}\|\pi_h\|_{L,K}^2 \le c \sum_{K\in\mathcal{T}_h} [h_K\|Av_h\|_{L,K}^2 + \|v_h\|_{L,K}^2].$$

Proceed similarly to control $|\pi_h|_M$. In conclusion,

$$\|\pi_h\|_{h,A} \le c\,\|v_h\|_{h,A}. \tag{4.24}$$

(3) Owing to (4.17) and (4.23), there is $c_1 > 0$ such that

$$\|v_h\|_{h,A}^2 \le c_1 a_h(v_h, v_h) + a_h(v_h, \pi_h) = a_h(v_h, \pi_h + c_1 v_h).$$

Then, setting $w_h = \pi_h + c_1 v_h$ and using (4.24) yields

$$\|v_h\|_{h,A}\|w_h\|_{h,A} \le c\,\|v_h\|_{h,A}^2 \le c\,a_h(v_h, w_h).$$

The conclusion is straightforward. ∎

Remark 4.4. Note that (4.5) and (4.17) readily imply coercivity in the weaker norm $\|v\|_{h,A^-}^2 = \|v\|_L^2 + |v|_J^2 + |v|_M^2 + \sum_{K\in\mathcal{T}_h} h_K^2\|Av\|_{L,K}^2$, but this property is not sufficient to prove an optimal convergence rate in the broken graph norm; see (4.32).

LEMMA 4.4 (continuity). *There is c, independent of h, such that*

$$\forall (v,w) \in W(h)\times W(h), \quad a_h(v,w) \le c\,\|v\|_{h,\frac12}\|w\|_{h,A}. \tag{4.25}$$

Proof. The general principle of the proof is to integrate by parts $a_h(v,w)$ by making use of the formal adjoint $\tilde{T}$. Observing that

$$\sum_{K\in\mathcal{T}_h} [(Tv,w)_{L,K} - (v,\tilde{T}w)_{L,K}] = \sum_{F\in\mathcal{F}_h^{\partial}} (\mathcal{D}v,w)_{L,F} + \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} \int_F 2\left\{w^t\mathcal{D}v\right\},$$

and $2\{w^t\mathcal{D}v\} = 2\{w^t\}\{\mathcal{D}v\} + \frac12[\![w^t]\!][\![\mathcal{D}v]\!]$, it is clear that

$$\begin{aligned} a_h(v,w) = {} & \sum_{K\in\mathcal{T}_h} (v,\tilde{T}w)_{L,K} + \sum_{F\in\mathcal{F}_h^{\partial}} \frac12 (M_F(v) + \mathcal{D}v, w)_{L,F} \\ & + \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} \frac12 ([\![\mathcal{D}v]\!], [\![w]\!])_{L,F} + \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} (S_F([\![v]\!]), [\![w]\!])_{L,F}. \end{aligned} \tag{4.26}$$

Let R_1 to R_4 be the four terms in the right-hand side. Using the Cauchy–Schwarz inequality yields

$$|R_1| \le c \sum_{K\in\mathcal{T}_h} \|v\|_{L,K}(\|w\|_{L,K} + \|Aw\|_{L,K}) \le c\|v\|_{h,\frac12}\|w\|_{h,A}.$$

Use (DG4) together with the Cauchy–Schwarz inequality to infer

$$|R_2| \le c \sum_{F\in\mathcal{F}_h^{\partial}} \|v\|_{L,F}|w|_{M,F} \le c\|v\|_{h,\frac12}\|w\|_{h,A}.$$

For the third and fourth term, use (DG6) and (DG7), together with the fact that $[\![\mathcal{D}v]\!] = 2\mathcal{D}_{\partial K_1(F)}\{v\}$, to obtain

$$|R_3| + |R_4| \le c \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} (\|\{v\}\|_{L,F} + \|[\![v]\!]\|_{L,F})|w|_{J,F} \le c\|v\|_{h,\frac12}\|w\|_{h,A}.$$

The result follows easily. ∎

LEMMA 4.5 (consistency). *Let u solve* (2.23) *and let u_h solve* (4.13). *If $u \in [H^1(\Omega)]^m$, then,*

$$\forall v_h \in W_h, \quad a_h(u - u_h, v_h) = 0. \tag{4.27}$$

Proof. Since $u \in [H^1(\Omega)]^m$ solves (2.23), $\mathcal{M}u = \mathcal{D}u$ a.e. on $\partial\Omega$ and $Tu = f$ in L. Assumption (DG2) yields $M_F(u|_F) = \mathcal{D}u|_F$ for all $F \in \mathcal{F}_h^{\partial}$. Moreover, $u \in [H^1(\Omega)]^m$ implies that $\{\mathcal{D}u\} = 0$ and $[\![u]\!] = 0$ a.e. on $\mathcal{F}_h^{\mathrm{i}}$. As a result,

$$\forall v_h \in W_h, \quad a_h(u, v_h) = (Tu, v_h)_L = (f, v_h)_L = a_h(u_h, v_h).$$

The conclusion follows readily. ∎

THEOREM 4.6 (convergence). *Let u solve* (2.23) *and let u_h solve* (4.13). *Assume that $u \in [H^1(\Omega)]^m$. Then, there is c, independent of h, such that*

$$\|u - u_h\|_{h,A} \le c \inf_{v_h\in W_h} \|u - v_h\|_{h,\frac12}. \tag{4.28}$$

Proof. Simple application of Strang's Second Lemma; see, e.g., [15, p. 94]. Let $v_h \in W_h$. Owing to Lemmas 4.3, 4.4, and 4.5,

$$\begin{aligned}\|v_h - u_h\|_{h,A} &\le c \sup_{w_h\in W_h\setminus\{0\}} \frac{a_h(v_h - u_h, w_h)}{\|w_h\|_{h,A}} \\ &\le c \sup_{w_h\in W_h\setminus\{0\}} \frac{a_h(v_h - u, w_h)}{\|w_h\|_{h,A}} \le c\,\|u - v_h\|_{h,\frac12}.\end{aligned}$$

Conclude using the triangle inequality. ∎

Owing to the definition of W_h, and the regularity of the mesh family $\{\mathcal{T}_h\}_{h>0}$, the following interpolation property holds. There is c, independent of h, such that for all $v \in [H^{p+1}(\Omega)]^m$, there is $v_h \in W_h$ satisfying

$$\|v - v_h\|_{h,\frac12} \le c h^{p+\frac12}\|v\|_{[H^{p+1}(\Omega)]^m}. \tag{4.29}$$

COROLLARY 4.7. *If u is in $[H^{p+1}(\Omega)]^m$, there is c, independent of h, such that*

$$\|u - u_h\|_{h,A} \le c\,h^{p+\frac12}\|u\|_{[H^{p+1}(\Omega)]^m}. \tag{4.30}$$

In particular,

$$\|u - u_h\|_L \le c\,h^{p+\frac12}\|u\|_{[H^{p+1}(\Omega)]^m}, \tag{4.31}$$

and if the mesh family $\{\mathcal{T}_h\}_{h>0}$ is quasi-uniform,

$$\left(\sum_{K\in\mathcal{T}_h} \|A(u - u_h)\|_{L,K}^2\right)^{\frac12} \le c\,h^p\|u\|_{[H^{p+1}(\Omega)]^m}. \tag{4.32}$$

The above estimates show that, provided the exact solution is smooth enough, the method yields optimal order convergence in the broken graph norm and $(p+\frac12)$-order convergence in the L-norm.

Remark 4.5. The estimates (4.30) to (4.32) are identical to those that can be obtained by other stabilization methods like GaLS [5, 19, 21] or subgrid viscosity [18] and many other methods.

Finally, when the exact solution is not smooth enough to be in $[H^1(\Omega)]^m$ but only in the graph space W, we use a density argument to infer the convergence of the DG approximation in the L-norm.

COROLLARY 4.8. *Let u solve* (2.23) *and let u_h solve* (4.13). *Assume that $[H^1(\Omega)]^m \cap V$ is dense in V. Then,*

$$\lim_{h\to 0} \|u - u_h\|_L = 0. \tag{4.33}$$

Proof. Let $\epsilon > 0$. There is $u_\epsilon \in [H^1(\Omega)]^m \cap V$ such that $\|u - u_\epsilon\|_W \le \frac{\epsilon}{2}$. Let $u_{\epsilon h}$ be the unique solution in W_h such that $a_h(u_{\epsilon h}, v_h) = (Tu_\epsilon, v_h)_L$ for all $v_h \in W_h$. From the regularity of u_ϵ together with Theorem 4.6 and Corollary 4.7 applied with $p = 0$, it is inferred that $\lim_{h\to 0} \|u_{\epsilon h} - u_\epsilon\|_{h,A} = 0$. Furthermore, using the discrete inf-sup condition (4.19) yields

$$\begin{aligned}\|u_{\epsilon h} - u_h\|_L &\le \sup_{v_h\in W_h\setminus\{0\}} \frac{a_h(u_{\epsilon h}, v_h) - a_h(u_h, v_h)}{\|v_h\|_{h,A}} = \sup_{v_h\in W_h\setminus\{0\}} \frac{(T(u_\epsilon - u), v_h)_L}{\|v_h\|_{h,A}} \\ &\le \|T(u_\epsilon - u)\|_L \sup_{v_h\in W_h\setminus\{0\}} \frac{\|v_h\|_L}{\|v_h\|_{h,A}} \le \|u - u_\epsilon\|_W \le \frac{\epsilon}{2},\end{aligned}$$

where we have used the fact that for all $v_h \in W_h$, $a_h(u_h, v_h) = (Tu, v_h)_L$. Finally, using the triangle inequality

$$\|u - u_h\|_L \le \|u - u_\epsilon\|_L + \|u_\epsilon - u_{\epsilon h}\|_L + \|u_{\epsilon h} - u_h\|_L,$$

it is deduced that $\limsup_{h\to 0} \|u - u_h\|_L \le \epsilon$. ∎

4.6. Localization, fluxes, and adjoint-fluxes. The purpose of this section is to discuss briefly some equivalent formulations of the discrete problem (4.13) in order to emphasize the link with other formalisms derived previously for DG methods, namely that of Lesaint and Raviart [23, 24] and Johnson et al. [21, 22] for Friedrichs' systems. To this end, we rewrite the bilinear form (4.12) in various equivalent ways and introduce the concept of element fluxes and that of element adjoint-fluxes.

Let $K \in \mathcal{T}_h$. Define the operator $M^{\mathrm{L}}_{\partial K} \in \mathcal{L}([L^2(\partial K)]^m; [L^2(\partial K)]^m)$ as follows. For $v \in [L^2(\partial K)]^m$ and a face $F \subset \partial K$, set

$$M^{\mathrm{L}}_{\partial K}(v)|_F = \begin{cases} M_F(v|_F) & \text{if } F \in \mathcal{F}_h^\partial, \\ 2S_F(v|_F) & \text{if } F \in \mathcal{F}_h^{\mathrm{i}}. \end{cases} \tag{4.34}$$

Furthermore, for $v \in W(h)$ and $x \in \partial K$, set

$$v^i(x) = \lim_{\substack{y\to x \\ y\in K}} v(y), \qquad v^e(x) = \lim_{\substack{y\to x \\ y\notin K}} v(y), \tag{4.35}$$

$$[\![v]\!]_{\partial K}(x) = v^i(x) - v^e(x), \qquad \{v\}_{\partial K}(x) = \frac{1}{2}(v^i(x) + v^e(x)), \tag{4.36}$$

with $v^e(x) = 0$ if $x \in \partial\Omega$. Then, a straightforward calculation shows that the bilinear

form a_h defined in (4.12) can be rewritten as follows:

$$a_h(u,v) = \sum_{K\in\mathcal{T}_h} (Tu,v)_{L,K} + \sum_{K\in\mathcal{T}_h} \frac{1}{2}(M^{\mathrm{L}}_{\partial K}([\![u]\!]_{\partial K}) - \mathcal{D}_{\partial K}[\![u]\!]_{\partial K}, v^i)_{L,\partial K} \tag{4.37}$$

$$= \sum_{K\in\mathcal{T}_h} (u,\tilde{T}v)_{L,K} + \sum_{K\in\mathcal{T}_h} \frac{1}{2}(M^{\mathrm{L}}_{\partial K}([\![u]\!]_{\partial K}) + 2\mathcal{D}_{\partial K}\{u\}_{\partial K}, v^i)_{L,\partial K}. \tag{4.38}$$

The bilinear form (4.37) is that analyzed by Lesaint and Raviart [24, 23] and further investigated by Johnson et al. [21] in the particular case where the operator $M^{\mathrm{L}}_{\partial K}$ is defined pointwise using a matrix-valued field on ∂K; see section 5.1 for further discussion.

DEFINITION 4.9. *Let $K \in \mathcal{T}_h$ and let $v \in W(h)$. The* element flux *of v on ∂K, say $\phi_{\partial K}(v) \in [L^2(\partial K)]^m$, is defined on a face $F \subset \partial K$ by*

$$\phi_{\partial K}(v)|_F = \begin{cases} \frac{1}{2}M_F(v|_F) + \frac{1}{2}\mathcal{D}_{\partial\Omega}v & \text{if } F \subset \partial K^{\partial}, \\ S_F([\![v]\!]_{\partial K}|_F) + \mathcal{D}_{\partial K}\{v\}_{\partial K} & \text{if } F \subset \partial K^{\mathrm{i}}, \end{cases} \tag{4.39}$$

where ∂K^{i} denotes that part of ∂K that lies in Ω and ∂K^{∂} denotes that part of ∂K that lies on $\partial\Omega$. Likewise, the element adjoint-flux *of v on ∂K, say, $\tilde{\phi}_{\partial K}(v) \in [L^2(\partial K)]^m$, is defined on a face $F \subset \partial K$ by*

$$\tilde{\phi}_{\partial K}(v)|_F = \begin{cases} \frac{1}{2}M_F(v|_F) - \frac{1}{2}\mathcal{D}_{\partial\Omega}v & \text{if } F \subset \partial K^{\partial}, \\ S_F([\![v]\!]_{\partial K}|_F) - \frac{1}{2}\mathcal{D}_{\partial K}[\![v]\!]_{\partial K} & \text{if } F \subset \partial K^{\mathrm{i}}. \end{cases} \tag{4.40}$$

The relevance of the notion of flux and adjoint-flux is clarified by the following proposition.

PROPOSITION 4.10. *The discrete problem* (4.13) *is equivalent to each of the following two local formulations.*

$$\begin{cases} \text{Seek } u_h \in W_h \text{ such that } \forall K \in \mathcal{T}_h \text{ and } \forall v_h \in [\mathbb{P}_p(K)]^m, \\ (u_h, \tilde{T}v_h)_{L,K} + (\phi_{\partial K}(u_h), v_h)_{L,\partial K} = (f, v_h)_{L,K}. \end{cases} \tag{4.41}$$

$$\begin{cases} \text{Seek } u_h \in W_h \text{ such that } \forall K \in \mathcal{T}_h \text{ and } \forall v_h \in [\mathbb{P}_p(K)]^m, \\ (Tu_h, v_h)_{L,K} + (\tilde{\phi}_{\partial K}(u_h), v_h)_{L,\partial K} = (f, v_h)_{L,K}. \end{cases} \tag{4.42}$$

Proof. Localize the test functions in (4.13) to the mesh elements and use the fact that $\phi_{\partial K}(v)|_F = \frac{1}{2}M^{\mathrm{L}}_{\partial K}([\![v]\!]_{\partial K}) + \mathcal{D}_{\partial K}\{v\}_{\partial K}$ and $\tilde{\phi}_{\partial K}(v)|_F = \frac{1}{2}M^{\mathrm{L}}_{\partial K}([\![v]\!]_{\partial K}) - \frac{1}{2}\mathcal{D}_{\partial K}[\![v]\!]_{\partial K}$. ∎

Let v be a function in $W(h)$. We define the *interface fluxes* (resp., *interface adjoint-fluxes*) of v, say, $\phi^{\mathrm{i}}(v)$, (resp., say, $\tilde{\phi}^{\mathrm{i}}(v)$), to be the two-valued function defined on $\mathcal{F}^{\mathrm{i}}_h$ that collects all the element fluxes (resp., adjoint-fluxes) of v on the interior faces. Likewise we define the *boundary fluxes* (resp., *boundary adjoint-fluxes*) of v, say, $\phi^{\partial}(v)$, (resp., say, $\tilde{\phi}^{\partial}(v)$), to be the single-valued function defined on $\mathcal{F}^{\partial}_h$ that collects all the element fluxes (resp., adjoint-fluxes) of v on the boundary faces.

Remark 4.6.

(i) The link between DG methods and the concept of element fluxes has been explored recently by Arnold et al. [1] for the Poisson equation (in [1], the terminology "numerical fluxes" is employed instead).

(ii) In engineering practice, approximation schemes such as (4.41) are often designed by a priori specifying the element fluxes. The above analysis then provides a practical means to assess the stability and convergence properties of the scheme. Indeed, once the element fluxes are given, the boundary operators M_F and the interface operators S_F can be directly retrieved from (4.39). Then, properties (DG1)–(DG8) provide sufficient conditions to analyze the scheme.

(iii) The interface fluxes are such that $\{\phi^{\mathrm{i}}(v)\} = 0$ a.e. on $\mathcal{F}_h^{\mathrm{i}}$. Approximation schemes where the interface fluxes satisfy this property are often termed *conservative*. Note that the concept of conservativity as such does not play any role in the present analysis of the method, although it can play a role when deriving improved L^2-error estimates by using the Aubin–Nitsche lemma; see, e.g., Arnold et al. [1] and the second part of this work [16].

(iv) The following relation links the element fluxes and the element adjoint-fluxes

$$\phi_{\partial K}(v) - \tilde{\phi}_{\partial K}(v) = \mathcal{D}_{\partial K} v^i. \tag{4.43}$$

In particular, the element adjoint-fluxes are not conservative.

(v) Both the element fluxes and the element adjoint-fluxes are associated with the operator T, i.e., they are derived from a DG discretization of (2.23). It is also possible to design a DG discretization of the adjoint problem (2.24) involving the operator $\tilde{T}$ and the bilinear form a^*. This would lead to two new families of fluxes, the element fluxes for $\tilde{T}$ and the element adjoint-fluxes for $\tilde{T}$. It should be noted that the element adjoint-fluxes for T are not the element fluxes for $\tilde{T}$. In particular, the former are not conservative whereas the latter are conservative.

5. Applications. This section shows how the conditions (DG1)–(DG8) can be used to design DG approximations of the model problems introduced in section 3.

5.1. Pointwise boundary and interface operators. For ease of presentation, the boundary and interface operators discussed in this section are constructed from matrix-valued fields defined on all the mesh faces. This simpler construction is sufficient to recover several DG methods considered in the literature. Examples where a more general form for the boundary and interface operators is needed will be presented in a forthcoming work [16].

For all $F \in \mathcal{F}_h^{\partial}$, let $\mathcal{M}_F$ be a matrix-valued field such that for all $\xi, \zeta \in \mathbb{R}^m$,

(DG1a) $\mathcal{M}_F$ is positive,

(DG2a) $\mathrm{Ker}(\mathcal{M} - \mathcal{D}_{\partial\Omega}) \subset \mathrm{Ker}(\mathcal{M}_F - \mathcal{D}_{\partial\Omega})$,

(DG3a) $|\zeta^t(\mathcal{M}_F - \mathcal{D}_{\partial\Omega})\xi| \le c(\xi^t \mathcal{M}_F \xi)^{\frac{1}{2}} \|\zeta\|_{\mathbb{R}^m}$,

(DG4a) $|\zeta^t(\mathcal{M}_F + \mathcal{D}_{\partial\Omega})\xi| \le c(\zeta^t \mathcal{M}_F \zeta)^{\frac{1}{2}} \|\xi\|_{\mathbb{R}^m}$,

where $\|\cdot\|_{\mathbb{R}^m}$ denotes the Euclidean norm in $\mathbb{R}^m$. Similarly, for all $F \in \mathcal{F}_h^{\mathrm{i}}$, let $\mathcal{S}_F$ be a matrix-valued field such that for all $\xi, \zeta \in \mathbb{R}^m$,

(DG5a) $\mathcal{S}_F$ is positive,

(DG6a) $\mathcal{S}_F$ is uniformly bounded,

(DG7a) $|\zeta^t \mathcal{S}_F \xi| \le c(\xi^t \mathcal{S}_F \xi)^{\frac{1}{2}} (\zeta^t \mathcal{S}_F \zeta)^{\frac{1}{2}}$,

(DG8a) $|\zeta^t \mathcal{D} \xi| \le c(\xi^t \mathcal{S}_F \xi)^{\frac{1}{2}} \|\zeta\|_{\mathbb{R}^m}$.

A straightforward verification yields the following proposition.

PROPOSITION 5.1. *For all* $F \in \mathcal{F}_h^\partial$, *define* $M_F : [L^2(F)]^m \ni v \mapsto \mathcal{M}_F|_F v \in [L^2(F)]^m$, *and for all* $F \in \mathcal{F}_h^{\mathrm{i}}$, *define* $S_F : [L^2(F)]^m \ni v \mapsto \mathcal{S}_F|_F v \in [L^2(F)]^m$. *Then,* (DG1)–(DG8) *hold.*

Remark 5.1.

(i) Whenever the matrix-valued field $\mathcal{M}$ defined in (4.7) satisfies (DG3a)–(DG4a), one simply sets $\mathcal{M}_F = \mathcal{M}$; otherwise, it is necessary to strengthen $\mathcal{M}$. This last situation occurs, for instance, when approximating advection-diffusion-reaction problems and the Maxwell equations in the elliptic regime; see sections 5.3 and 5.4.

(ii) One possible way of constructing $\mathcal{S}_F$ follows. Since $\mathcal{D}$ is symmetric, $\mathcal{D}$ is diagonalizable; hence, the absolute value of $\mathcal{D}$, say, $|\mathcal{D}|$, can be defined. Moreover, observing that $|\mathcal{D}|$ is single-valued on $\mathcal{F}_h^{\mathrm{i}}$, one can set $\mathcal{S}_F = |\mathcal{D}|$.

5.2. Advection-reaction. Consider the advection-reaction problem introduced in section 3.1. Assume that all the faces in $\mathcal{F}_h^\partial$ are in $\partial\Omega^-$, in $\partial\Omega^+$, or in $\partial\Omega \setminus (\partial\Omega^- \cup \partial\Omega^+)$. The integral representation (4.7) holds with

$$\mathcal{D}_{\partial\Omega} = \beta{\cdot}n \qquad \text{and} \qquad \mathcal{M} = |\beta{\cdot}n|. \tag{5.1}$$

Let $\alpha > 0$ (this design parameter can vary from face to face) and for all $F \in \mathcal{F}_h$, set

$$\mathcal{M}_F = \mathcal{M} = |\beta{\cdot}n| \qquad \text{and} \qquad \mathcal{S}_F = \alpha|\beta{\cdot}n_F|, \tag{5.2}$$

where n_F is a unit normal vector to F (its orientation is clearly irrelevant). It is straightforward to verify the following proposition.

PROPOSITION 5.2. *Properties* (DG1a)–(DG8a) *hold.*

Remark 5.2. The specific value $\alpha = \frac{1}{2}$ has received considerable attention in the literature. When working with the local formulation (4.42), the interface and boundary fluxes are given by

$$\begin{aligned}\tilde{\phi}^{\mathrm{i}}(u_h)|_{\partial K} &= \left(\alpha|\beta{\cdot}n_K| - \frac{1}{2}\beta{\cdot}n_K\right)[\![u_h]\!]_{\partial K},\\ \tilde{\phi}^{\partial}(u_h) &= -|\beta{\cdot}n|u_h 1_{\partial\Omega^-},\end{aligned}$$

where $1_{\partial\Omega^-}$ denotes the characteristic function of $\partial\Omega^-$. Setting $\alpha = \frac{1}{2}$, one obtains the DG method analyzed by Lesaint and Raviart [24, 23]; in this case the interface adjoint-flux $\tilde{\phi}^{\mathrm{i}}$ is nonzero only on that part of the boundary ∂K where $\beta{\cdot}n_K < 0$. Similarly, when working with the local formulation (4.41), the interface and boundary fluxes are given by

$$\begin{aligned}\phi^{\mathrm{i}}(u_h)|_{\partial K} &= (\beta{\cdot}n_K)\{u_h\} + \alpha|\beta{\cdot}n_K|[\![u_h]\!]_{\partial K},\\ \phi^{\partial}(u_h) &= |\beta{\cdot}n|u_h 1_{\partial\Omega^+},\end{aligned}$$

where $1_{\partial\Omega^+}$ denotes the characteristic function of $\partial\Omega^+$. Setting $\alpha = \frac{1}{2}$ leads to $\phi^{\mathrm{i}}(u_h)|_{\partial K} = (\beta{\cdot}n_K)u_h^\uparrow$, where $u_h^\uparrow = u_h^i$ if $\beta{\cdot}n_K > 0$ and $u_h^\uparrow = u_h^e$ otherwise, i.e., the well-known upwind flux is recovered as a particular case of the above analysis which is valid for any $\alpha > 0$. This coincidence has led many authors to believe that DG methods are methods of choice to solve hyperbolic problems. Actually DG methods, as presented herein, are tailored to solve symmetric positive systems of first-order PDEs, and as pointed out by Friedrichs, the notion of symmetric systems goes beyond the hyperbolic/elliptic traditional classification of PDEs. Moreover, the presence of the user-dependent interface operator S_F (see (DG5)–(DG8)) points to

the fact that DG methods are merely stabilization techniques. This fact is even clearer when one realizes that the error estimates (4.30)–(4.32) are identical to those that can be obtained by using other stabilization techniques like GaLS (also sometimes called streamline diffusion) [5, 19, 21] or subgrid viscosity [18] methods.

5.3. Advection-diffusion-reaction. Consider the advection-diffusion-reaction problem introduced in section 3.2. The integral representation (4.7) for D holds with

$$\mathcal{D}_{\partial\Omega} = \left[\begin{array}{c:c} 0 & n \\ \hdashline n^t & \beta\cdot n \end{array}\right]. \tag{5.3}$$

To simplify, we assume that the parameters β and μ are of order 1, i.e., we hide the dependency on these coefficients in the constants. Special cases such as advection-dominated problems go beyond the scope of the present work. We begin with the interface operator since its design is independent of the boundary conditions imposed. Let $\alpha > 0$, $\eta > 0$, and $\delta \in \mathbb{R}^d$. For all $F \in \mathcal{F}_h^{\mathrm{i}}$, define

$$\mathcal{S}_F = \left[\begin{array}{c:c} \alpha n_F\otimes n_F & (\delta\cdot n_F)n_F \\ \hdashline -(\delta\cdot n_F)n_F^t & \eta \end{array}\right]. \tag{5.4}$$

PROPOSITION 5.3. *Properties* (DG5a)–(DG8a) *hold.*

Proof. For $\xi \in \mathbb{R}^{d+1}$, denote by $\xi = (\xi_\sigma, \xi_u)$ its decomposition in $\mathbb{R}^d \times \mathbb{R}$ and use a similar notation for $\zeta = (\zeta_\sigma, \zeta_u) \in \mathbb{R}^{d+1}$. The field $\mathcal{S}_F$ is clearly positive and bounded, i.e., (DG5a) and (DG6a) hold. Moreover, for ξ, $\zeta \in \mathbb{R}^{d+1}$,

$$\zeta^t\mathcal{S}_F\xi = \alpha(\xi_\sigma\cdot n)(\zeta_\sigma\cdot n) + (\delta\cdot n)(\zeta_\sigma\cdot n)\xi_u - (\delta\cdot n)(\xi_\sigma\cdot n)\zeta_u + \eta\xi_u\zeta_u,$$

and $\xi^t\mathcal{S}_F\xi = \alpha(\xi_\sigma\cdot n)^2 + \eta\xi_u^2$, when (DG7a) is readily deduced. Finally, since

$$\zeta^t\mathcal{D}_{\partial K}\xi = (\xi_\sigma\cdot n_K)\zeta_u + (\zeta_\sigma\cdot n_K)\xi_u + (\beta\cdot n_K)\xi_u\zeta_u,$$

(DG8a) holds. ∎

Remark 5.3.

(i) We stress the fact that the above DG method yields $(p+\frac{1}{2})$-order estimates in the L-norm for both u_h and σ_h.

(ii) The σ- and u-component of the interface fluxes are given by

$$\begin{aligned}\phi^{\sigma,\mathrm{i}}(\sigma_h,u_h)|_{\partial K} &= (\{u_h\} + \alpha n_K\cdot[\![\sigma_h]\!]_{\partial K} + (\delta\cdot n_K)[\![u_h]\!]_{\partial K})n_K,\\ \phi^{u,\mathrm{i}}(\sigma_h,u_h)|_{\partial K} &= n_K\cdot\{\sigma_h\} - (\delta\cdot n_K)n_K\cdot[\![\sigma_h]\!]_{\partial K} + \eta[\![u_h]\!]_{\partial K} + \beta\cdot n_K\{u_h\}.\end{aligned}$$

Owing to the fact that $\alpha \neq 0$, the local formulation (4.41) or (4.42) cannot be used to derive a local reconstruction formula where $\sigma_h|_K$ is expressed solely in terms of u_h. To this end, the coefficient α has to be set to zero, and this requires a nontrivial modification of the analysis that will be reported in [16]. With this modification, the DG approximation does no longer yield a $(p+\frac{1}{2})$-order estimate for σ_h in the L-norm.

(iii) The design parameters α, δ, and η can vary from face to face. In particular, one can take δ to be any bounded vector-valued field on $\mathcal{F}_h^{\mathrm{i}}$; $\delta = 0$ is a suitable choice. Other particular choices lead to DG methods already reported in the literature for advection-diffusion-reaction problems. A more detailed discussion, including a comparison with methods where the unknown $\sigma_h|_K$ is eliminated locally, is postponed to [16].

5.3.1. Dirichlet boundary conditions. The integral representation (4.7) of the boundary operator M defined in (3.11) holds with

$$\mathcal{M} = \left[\begin{array}{c:c} 0 & -n \\ \hdashline n^t & 0 \end{array}\right]. \tag{5.5}$$

Let $\varsigma > 0$ (this design parameter can vary from face to face). For all $F \in \mathcal{F}_h^\partial$, define

$$\mathcal{M}_F = \left[\begin{array}{c:c} 0 & -n \\ \hdashline n^t & \varsigma \end{array}\right]. \tag{5.6}$$

It is straightforward to verify the following proposition.

PROPOSITION 5.4. *Properties* (DG1a)–(DG4a) *hold.*

Remark 5.4. Observe that setting $\mathcal{M}_F = \mathcal{M}$ is not adequate here since with this choice (DG3a) does not hold.

5.3.2. Neumann and Robin boundary conditions. The integral representation (4.7) of the boundary operator M defined in (3.12) holds with

$$\mathcal{M} = \left[\begin{array}{c:c} 0 & n \\ \hdashline -n^t & 2\varrho + \beta{\cdot}n \end{array}\right]. \tag{5.7}$$

Consider first Neumann boundary conditions, i.e., $\varrho = 0$. Let $\lambda > 0$ (this design parameter can vary from face to face). For all $F \in \mathcal{F}_h^\partial$, define

$$\mathcal{M}_F = \left[\begin{array}{c:c} \lambda n{\otimes}n & n \\ \hdashline -n^t & 0 \end{array}\right]. \tag{5.8}$$

It is straightforward to verify the following proposition.

PROPOSITION 5.5. *Properties* (DG1a)–(DG4a) *hold.*

Consider next Robin boundary conditions and assume that $\varrho + \min(\beta{\cdot}n, 0) \geq 0$ (this assumption is not restrictive since Robin boundary conditions are often enforced on inflow boundaries by setting $\varrho = -\beta{\cdot}n$). Let $\lambda \in]0, \frac{1}{\rho}[$ ($\lambda \in]0, +\infty)$ if $\varrho = 0$), $\theta = 1 - \lambda\varrho$, and $\alpha = -\lambda\varrho^2$. For all $F \in \mathcal{F}_h^\partial$, define

$$\mathcal{M}_F = \left[\begin{array}{c:c} \lambda n{\otimes}n & \theta n \\ \hdashline -\theta n^t & 2\varrho + \beta{\cdot}n + \alpha \end{array}\right]. \tag{5.9}$$

PROPOSITION 5.6. *Properties* (DG1a)–(DG4a) *hold.*

Proof. Since $\varrho + \beta{\cdot}n \geq 0$ by assumption and since $\varrho + \alpha > 0$ by construction, it is inferred that for all $\xi \in \mathbb{R}^{d+1}$, $\xi^t \mathcal{M}_F \xi \geq c((\xi_\sigma{\cdot}n)^2 + \xi_u^2)$ with $c > 0$. The rest of the proof is straightforward. ∎

Remark 5.5. The bilinear forms $(u, v) \longmapsto \int_{\partial\Omega} v^t \mathcal{M}_F u$ considered above cannot be extended to $W \times W$ due to the presence of the upper-left block in $\mathcal{M}_F$. The difficulty stems from the fact that vector fields in $H(\mathrm{div}; \Omega)$ may not have normal traces in $L^2(\partial\Omega)$. As a consequence, the approximate method is meaningful only if the exact solution is smooth enough; see the definition of $W(h)$ in (4.2).

5.4. Maxwell's equations in the elliptic regime. We close this series of applications with Maxwell's equations in the elliptic regime; see section 3.3. The integral representation (4.7) holds with the $\mathbb{R}^{6,6}$-valued fields

$$\mathcal{D}_{\partial\Omega} = \left[\begin{array}{c:c} 0 & \mathcal{N} \\ \hdashline \mathcal{N}^t & 0 \end{array}\right] \qquad \text{and} \qquad \mathcal{M} = \left[\begin{array}{c:c} 0 & -\mathcal{N} \\ \hdashline \mathcal{N}^t & 0 \end{array}\right], \tag{5.10}$$

where $\mathcal{N} = \sum_{k=1}^{3} n_k \mathcal{R}^k \in \mathbb{R}^{3,3}$ and $n = (n_1, n_2, n_3)^t$ is the unit outward normal to Ω on $\partial\Omega$. Observe that $\mathcal{N}\xi = n \times \xi$ for all $\xi \in \mathbb{R}^3$.

Let $\varsigma > 0$, $\alpha_1 > 0$, and $\alpha_2 > 0$ (these design parameters can vary from face to face) and set

$$\mathcal{M}_F = \left[\begin{array}{c:c} 0 & -\mathcal{N} \\ \hdashline \mathcal{N}^t & \varsigma \mathcal{N}^t \mathcal{N} \end{array}\right] \qquad \text{and} \qquad \mathcal{S}_F = \left[\begin{array}{c:c} \alpha_1 \mathcal{N}_F^t \mathcal{N}_F & 0 \\ \hdashline 0 & \alpha_2 \mathcal{N}_F^t \mathcal{N}_F \end{array}\right], \tag{5.11}$$

where $\mathcal{N}_F$ is defined as $\mathcal{N}$ by replacing n by n_F. It is straightforward to verify the following proposition.

MULTISTEP METHODS FOR SDES AND THEIR APPLICATION TO PROBLEMS WITH SMALL NOISE*

EVELYN BUCKWAR† AND RENATE WINKLER†

Abstract. In this article the numerical approximation of solutions of Itô stochastic differential equations is considered, in particular for equations with a small parameter ϵ in the noise coefficient. We construct stochastic linear multistep methods and develop the fundamental numerical analysis concerning their mean-square consistency, numerical stability in the mean-square sense and mean-square convergence. For the special case of two-step Maruyama schemes we derive conditions guaranteeing their mean-square consistency. Further, for the small noise case we obtain expansions of the local error in terms of the step size and the small parameter ϵ. Simulation results using several explicit and implicit stochastic linear k-step schemes, $k = 1,\ 2$, illustrate the theoretical findings.

Key words. stochastic linear multistep method, mean-square convergence, mean-square numerical stability, mean-square consistency, small noise, two-step Maruyama methods

1. Introduction.

We consider Itô stochastic differential equations (SDEs) of the form

$$X(s)\Big|_{t_0}^{t} = \int_{t_0}^{t} f(X(s),s)\,\mathrm{d}s + \int_{t_0}^{t} G(X(s),s)\,\mathrm{d}W(s), \quad X(t_0) = X_0, \tag{1.1}$$

for $t \in \mathcal{J}$, where $\mathcal{J} = [t_0, T]$. The drift and diffusion functions are given as $f : \mathbb{R}^n \times \mathcal{J} \to \mathbb{R}^n$, $G = (g_1, \ldots, g_m) : \mathbb{R}^n \times \mathcal{J} \to \mathbb{R}^{n\times m}$, respectively. The process W is an m-dimensional Wiener process on the given probability space $(\Omega, \mathcal{F}, \mathbb{P})$ with a filtration $(\mathcal{F}_t)_{t\in\mathcal{J}}$, and X_0 is a given $\mathcal{F}_{t_0}$-measurable initial value, independent of the Wiener process and with finite second moment. We assume that there exists a pathwise unique strong solution $X(\cdot)$ of (1.1).

The aim of this article is to analyze the mean-square convergence properties of, in general, drift-implicit linear multistep methods (LMMs) for the approximation of the solution of (1.1). An advantage LMMs have in deterministic numerics is that they require less evaluations of the right-hand side in comparison with Runge–Kutta schemes with the same order of convergence which makes them often preferable for problems with an expensive right-hand side. We recall that in the deterministic case a high order of convergence is always based on sufficient smoothness of the solution of the differential equation. In contrast, the solution of an SDE is not smooth in the ordinary sense and a high order of convergence is achievable only by including more information on the driving Wiener process, i.e., a sufficient number of multiple stochastic integrals. In the case of general systems of SDEs, some of these integrals are difficult to simulate; in several special settings, such as additive or diagonal noise, the situation is less difficult. Our interest in stochastic linear multistep methods (SLMMs)

stems from applications with small noise in circuit simulation [11, 12, 25, 30, 31], where especially the backward differentiation formulae (BDF) have proven valuable in the deterministic case. An application in the geosciences has been reported in [13].

Stochastic two-step methods already appear in [24] (methods of order 3/2 for equations with additive noise), in [18], and in the recent book [22]. In [2, 3], two-step methods for Itô SDEs are analyzed. Stochastic versions of Adams methods for order up to 5 have been implemented and tested for SDEs with additive noise in [11]. Consistency of SLMMs for Stratonovich SDEs has been considered in [5]; in addition stochastic Adams methods have been implemented as predictor-corrector schemes and tested. A stochastic version of Adams–Bashforth methods, which involves higher order multiple Wiener integrals, is considered in [13]. For small noise SDEs the authors considered SLMMs incorporating mixed classical stochastic integrals in [7].

The current article provides a unified treatment of the mean-square convergence analysis of a general class of SLMMs. This class generalizes all deterministic multistep schemes as well as all Itô schemes considered in the papers cited above. We aim at understanding when and why these schemes converge in the mean-square sense. This includes understanding the relation between local and global errors. To this end we introduce the fundamental notions of mean-square consistency, stability and convergence. The fundamental results in this respect are Theorems 3.2 and 3.3.

As an application of this result, we recapture some of the properties of deterministic LMMs for SDEs with small noise, i.e., SDEs that can be written in the form

$$X(s)\Big|_{t_0}^{t} = \int_{t_0}^{t} f(X(s),s)\,\mathrm{d}s + \int_{t_0}^{t} \epsilon \hat{G}(X(s),s)\,\mathrm{d}W(s), \quad t \in \mathcal{J}, \quad X(t_0) = X_0, \tag{1.2}$$

where $\epsilon \ll 1$ is a small parameter, and $\hat{G} = (\hat{g}_1, \ldots, \hat{g}_m) : \mathbb{R}^n \times \mathcal{J} \to \mathbb{R}^{n\times m}$ and its derivatives are assumed to have moderate values. For this we will derive expansions of the error in terms of the small parameter ϵ and the step size, as has been done for one-step methods in [21]. Then the small diffusion term makes it unnecessary to use high order multiple stochastic integrals, and Wiener increments will be sufficient if the step-size is not too small.

In section 2 we introduce the class of SLMMs considered and provide necessary definitions and useful facts. In section 3 we consider the solvability of the discrete system and the boundedness of the iterates. We then establish two fundamental results, the first one concerns the relation between mean-square numerical stability of the SLMM and Dahlquist's root condition, and the second one concerns the relation between mean-square convergence, mean-square numerical stability, and mean-square consistency of the SLMM. This mirrors the results and the essential role of zero-stability in the deterministic analysis of discretization schemes, see, e.g., [10, 15, 17, 19]. In section 4 we consider two-step Maruyama methods and give conditions for their mean-square consistency. These conditions allow determining the parameters for the stochastic part from the parameters of the deterministic scheme and reduce to those of the underlying deterministic schemes when there is no noise. We then apply the two-step Maruyama methods to the SDE with small noise (1.2) and derive expansions of the local error in a manner similar to that in [21]. In section 5 we provide illustrative examples. The appendix contains the proof of Theorem 3.2.

2. Definitions and preliminary results. We denote by $|\cdot|$ the Euclidian norm in $\mathbb{R}^n$ and by $\|\cdot\|$ the corresponding induced matrix norm. The mean-square norm of a vector-valued square-integrable random variable $Z \in L_2(\Omega, \mathbb{R}^n)$, with $\mathbb{E}$

the expectation with respect to $\mathbb{P}$, will be denoted by

$$\|Z\|_{L_2} := (\mathbb{E}|Z|^2)^{1/2} .$$

We define a deterministic grid on $\mathcal{J}$ as $t_0 < t_1 < \cdots < t_N = T$ with (for simplicity) a constant step-size $h := T/N$ and $t_\ell = t_0 + \ell \cdot h,\ \ell = 0, \ldots, N$. We consider a stochastic linear k-step method, which for $\ell = k, \ldots, N$, takes the form

$$\sum_{j=0}^{k} \alpha_j\ X_{\ell-j} = h \sum_{j=0}^{k} \beta_j\ f(X_{\ell-j}, t_{\ell-j}) + \sum_{j=1}^{k} \Gamma_j(X_{\ell-j}, t_{\ell-j})\ I^{t_{\ell-j}, t_{\ell-j+1}}. \tag{2.1}$$

We set $\alpha_0 = 1$. We require given initial values $X_0, \ldots, X_{k-1} \in L_2(\Omega, \mathbb{R}^n)$ such that X_ℓ is $\mathcal{F}_{t_\ell}$-measurable for $\ell = 0 \ldots, k-1$. As in the deterministic case, usually only $X_0 = X(t_0)$ is given by the initial value problem and the values $X_1, \ldots, X_{k-1}$ need to be computed numerically. This can be done by suitable one-step methods, where one has to be careful to achieve the desired accuracy. Every diffusion term $\Gamma_j(x,t)\ I^{t,t+h}$ is a finite sum of terms, each containing an appropriate function $\mathcal{G}$ of x and t multiplied by a multiple Wiener integral over $[t, t+h]$, i.e., it takes the general form

$$\Gamma_j(x,t)\ I^{t,t+h} = \sum_{r=1}^{m} \mathcal{G}_j^r(x,t)\ I_r^{t,t+h} + \sum_{\substack{r_1, r_2 = 0 \\ r_1 + r_2 > 0}}^{m} \mathcal{G}_j^{r_1, r_2}(x,t)\ I_{r_1,r_2}^{t,t+h} + \ldots\ .$$

A general multiple Wiener integral is given by

$$I_{r_1, r_2, \ldots, r_j}^{t,t+h}(y) = \int_t^{t+h} \int_t^{s_1} \ldots \int_t^{s_{j-1}} y(X(s_j), s_j)\ \mathrm{d}W_{r_1}(s_j) \ldots\ \mathrm{d}W_{r_j}(s_1), \tag{2.2}$$

where $r_i \in \{0, 1, \ldots, m\}$ and $\mathrm{d}W_0(s) = \mathrm{d}s$. If $y \equiv 1$ we write $I_{r_1, r_2, \ldots, r_j}^{t,t+h}$. Note that the integral $I_r^{t,t+h}$ is simply the increment $W_r(t+h) - W_r(t)$ of the scalar Wiener process W_r. The term $I^{t,t+h}$ denotes the collection of multiple Wiener integrals associated with the interval $[t, t+h]$. We emphasize that an explicit discretization is used for the diffusion term. For $\beta_0 = 0$, the SLMM (2.1) is explicit; otherwise it is drift-implicit. We give two examples of two-step methods.

Example 2.1. The first is a stochastic variant of the implicit two-step backward differentiation formula (BDF) method, which we term the BDF2-Maruyama method. For $\ell = 2, \ldots, N$, it takes the form

$$\begin{aligned} X_\ell - \frac{4}{3} X_{\ell-1} + \frac{1}{3} X_{\ell-2} = h\ \frac{2}{3} f(X_\ell, t_\ell) \\ + \sum_{r=1}^{m} g_r(X_{\ell-1}, t_{\ell-1})\ I_r^{t_{\ell-1}, t_\ell} - \frac{1}{3} \sum_{r=1}^{m} g_r(X_{\ell-2}, t_{\ell-2})\ I_r^{t_{\ell-2}, t_{\ell-1}}. \end{aligned}$$

Here one has $\alpha_0 = 1,\ \alpha_1 = -\frac{4}{3},\ \alpha_2 = \frac{1}{3},\ \beta_0 = \frac{2}{3},\ \beta_1 = \beta_2 = 0$, and

$$\Gamma_1(x,t)\ I^{t,t+h} = \sum_{r=1}^{m} g_r(x,t)\ I_r^{t,t+h}, \qquad \Gamma_2(x,t)\ I^{t,t+h} = -\frac{1}{3} \sum_{r=1}^{m} g_r(x,t)\ I_r^{t,t+h}.$$

Example 2.2. The second example is a Milstein variant of the two-step Adams–Bashforth method (we refer to [28, 29] for possibilities to simulate the double Wiener

integrals if the SDE is not of a type that allows simplifications in their simulation):

$$X_\ell - X_{\ell-1} = h\ \left(\frac{3}{2}f(X_{\ell-1},t_{\ell-1}) - \frac{1}{2}f(X_{\ell-2},t_{\ell-2})\right) + \sum_{r=1}^{m} g_r(X_{\ell-1},t_{\ell-1})\ I_r^{t_{\ell-1},t_\ell} + \sum_{q,r=1}^{m} (g_q)'_x g_r(X(t_{\ell-1}),t_{\ell-1})\ I_{q,r}^{t_{\ell-1},t_\ell}.$$

For this method one has $\alpha_0 = 1,\ \alpha_1 = -1,\ \alpha_2 = 0,\ \beta_0 = 0,\ \beta_1 = \frac{3}{2},\ \beta_2 = -\frac{1}{2}$ and

$$\Gamma_2(x,t)\ I^{t,t+h} \equiv 0, \quad \Gamma_1(x,t)\ I^{t,t+h} = \sum_{r=1}^{m} g_r(x,t)\ I_r^{t,t+h} + \sum_{q,r=1}^{m} (g_q)'_x g_r(x,t)\ I_{q,r}^{t,t+h}.$$

A further example of a stochastic Adams–Bashforth method, which is covered by the general form of (2.1), is studied in [13].

We will consider mean-square convergence of SLMMs in the sense discussed by Milstein and others [1, 24, 22, 30]. Note that in the literature the term *strong* convergence is sometimes used synonymously for our expression *mean-square* convergence.

DEFINITION 2.3. *We call the SLMM* (2.1) *for the approximation of the solution of the SDE* (1.1) *mean-square convergent if the global error* $X(t_\ell) - X_\ell$ *satisfies*

$$\max_{\ell=1,\dots,N} \|X(t_\ell) - X_\ell\|_{L_2} \to 0 \ \text{as}\ h \to 0$$

We say it is mean-square convergent with order γ $(\gamma > 0)$ *if the global error satisfies*

$$\max_{\ell=1,\dots,N} \|X(t_\ell) - X_\ell\|_{L_2} \le C \cdot h^\gamma,$$

with constant $C > 0$ *which is independent of the step size* h.

In the following we will define what we understand by local errors. We would like to point out that for the analysis of one-step schemes essentially two different but related concepts are used in the literature. In the first one the local error is defined as the defect that is obtained when the exact solution values are inserted into the numerical scheme. In the second one the local error is defined as the difference after one step of the exact and the numerical solution started at an arbitrary deterministic value. These concepts differ in the way the error is transported to the end of the integration interval, in the first via the numerical method, in the second via the exact solution. The second definition has been used in the fundamental work of Milstein in [23, 24], where for the first time the relation between local and global errors of one-step methods for SDEs has been clarified. However, only the first definition extends easily to multistep methods; hence we will use it here. For comparison of these principles in the deterministic setting see [16, Chapters II.3, III.4].

DEFINITION 2.4. *We define the local error of the SLMM* (2.1) *for the approximation of the solution of the SDE* (1.1)*, for* $\ell = k, \dots, N$*, as*

(2.3)
$$L_\ell := \sum_{j=0}^{k} \alpha_j X(t_{\ell-j}) - h\sum_{j=0}^{k} \beta_j f(X(t_{\ell-j}),t_{\ell-j}) - \sum_{j=1}^{k} \Gamma_j(X(t_{\ell-j}),t_{\ell-j})\ I^{t_{\ell-j},t_{\ell-j+1}}.$$

We aim to conclude mean-square convergence from local properties of the SLMM by means of numerical stability in the mean-square sense. Numerical stability concerns

the influence of perturbations of the right-hand side of the discrete scheme on the global solution of that discrete scheme. Sources of perturbations may be the local error, round-off errors or defects in the approximate solution of implicit schemes. The mean-square stability estimate of the global error is based on the mean-square norm *and* on the conditional mean of the perturbations. In the case of one-step schemes this appears, e.g., in [1, 30]; we refer in particular to the discussion in [24, Chapter 1.4]. We remark that in the case of k-step schemes the conditional mean has to be taken with respect to the σ-algebra $\mathcal{F}_{t_{\ell-k}}$.

In our analysis we thus consider the following discrete system, the perturbed form of (2.1), for $\ell = k, \dots, N$,

$$\sum_{j=0}^{k} \alpha_j \tilde{X}_{\ell-j} = h \sum_{j=0}^{k} \beta_j f(\tilde{X}_{\ell-j}, t_{\ell-j}) + \sum_{j=1}^{k} \Gamma_j(\tilde{X}_{\ell-j}, t_{\ell-j})\, I^{t_{\ell-j},t_{\ell-j+1}} + D_\ell, \tag{2.4}$$

with initial values $\tilde{X}_\ell = X_\ell + D_\ell,\ \ell = 0, \dots, k-1$. We suppose that the perturbations D_ℓ are $\mathcal{F}_{t_\ell}$-measurable and that $D_\ell \in L_2(\Omega, \mathbb{R}^n)$.

Remark 2.5. It is useful to represent the perturbations in the form

$$D_\ell = R_\ell + S_\ell =: R_\ell + \sum_{j=1}^{k} S_{j,\ell-j+1}, \quad \ell = k, \dots, N, \tag{2.5}$$

where each $S_{j,\ell}$ is $\mathcal{F}_{t_\ell}$-measurable with $\mathbb{E}(S_{j,\ell}|\mathcal{F}_{t_{\ell-1}}) = 0$. The representation (2.5) is not unique. One extreme possibility is $R_\ell = D_\ell,\ S_\ell = 0$; another, more useful one, is given by

$$\begin{aligned} R^*_\ell &= \mathbb{E}(D_\ell|\mathcal{F}_{t_{\ell-k}}), \qquad S^*_\ell = D_\ell - R^*_\ell, \\ S^*_{j,\ell-j+1} &= \mathbb{E}(D_\ell - R^*_\ell - \textstyle\sum_{i=j+1}^{k} S^*_{i,\ell-i+1}|\mathcal{F}_{t_{\ell-j+1}}), \quad j = k, k-1, \dots, 1\ . \end{aligned} \tag{2.6}$$

This construction guarantees the required measurability conditions in (2.5). We also note that this decomposition is orthogonal in $L_2(\Omega)$, i.e.,

$$\|D_\ell\|^2_{L_2} = \|R^*_\ell\|^2_{L_2} + \sum_{j=1}^{k} \|S^*_{j,\ell-j+1}\|^2_{L_2}. \tag{2.7}$$

As an example one obtains for $k = 3$,

$$\begin{aligned} R^*_\ell &= \mathbb{E}(D_\ell|\mathcal{F}_{t_{\ell-3}}) \\ S^*_{3,\ell-2} &= \mathbb{E}(D_\ell - R^*_\ell|\mathcal{F}_{t_{\ell-2}}) \\ S^*_{2,\ell-1} &= \mathbb{E}(D_\ell - R^*_\ell - S^*_{3,\ell-2}|\mathcal{F}_{t_{\ell-1}}) \\ S^*_{1,\ell} &= D_\ell - R^*_\ell - S^*_{3,\ell-2} - S^*_{2,\ell-1}. \end{aligned}$$

Here, in the hypothetical case that $D_\ell = c_0 I_r^{t_{\ell-1},t_\ell} + c_1 I_r^{t_{\ell-2},t_{\ell-1}} + c_2 I_r^{t_{\ell-3},t_{\ell-2}} + c_3$, we have $R^*_\ell = c_3,\ S^*_{3,\ell-2} = c_2 I_r^{t_{\ell-3},t_{\ell-2}},\ S^*_{2,\ell-1} = c_1 I_r^{t_{\ell-2},t_{\ell-1}},\ S^*_{1,\ell} = c_0 I_r^{t_{\ell-1},t_\ell}$.

Now we give the precise definition of mean-square stability and consistency that we consider in this paper.

DEFINITION 2.6. *We call the SLMM* (2.1) ***numerically stable in the mean-square sense*** *if there exist constants $h_0 > 0$ and $S > 0$ such that for all step sizes*

$h < h_0$ and for all $\mathcal{F}_{t_\ell}$-measurable perturbations $D_\ell \in L_2(\Omega, \mathbb{R}^n)$ $(\ell = 0, \dots, N)$ and all their representations (2.5)*, the following inequality holds*

(2.8)
$$\max_{\ell=0,\dots,N} \|X_\ell - \tilde{X}_\ell\|_{L_2} \le S \left\{ \max_{\ell=0,\dots,k-1} \|D_\ell\|_{L_2} + \max_{\ell=k,\dots,N} \left(\frac{\|R_\ell\|_{L_2}}{h} + \frac{\|S_\ell\|_{L_2}}{h^{1/2}} \right) \right\},$$

where $(X_\ell)_{\ell=1}^N$ and $(\tilde{X}_\ell)_{\ell=1}^N$ are the solutions of the SLMM (2.1) *and the perturbed discrete system* (2.4)*, respectively.*

We refer to S as the stability constant and to (2.8) as the stability inequality.

DEFINITION 2.7. *We call the SLMM* (2.1) *for the approximation of the solution of the SDE* (1.1) *mean-square consistent if the local error L_ℓ satisfies*

$$h^{-1} \, \|\mathbb{E}(L_\ell | \mathcal{F}_{t_{\ell-k}})\|_{L_2} \to 0 \text{ for } h \to 0 \quad \text{and} \quad h^{-1/2} \, \|L_\ell\|_{L_2} \to 0 \text{ for } h \to 0.$$

We call the SLMM (2.1) *for the approximation of the solution of the SDE* (1.1) *mean-square consistent of order $\gamma (\gamma > 0)$ if the local error L_ℓ satisfies*

$$\|\mathbb{E}(L_\ell | \mathcal{F}_{t_{\ell-k}})\|_{L_2} \le \bar{c} \cdot h^{\gamma+1} \quad \text{and} \quad \|L_\ell\|_{L_2} \le c \cdot h^{\gamma+\frac{1}{2}}, \quad \ell = k, \dots, N,$$

with constants $c\,, \bar{c} > 0$ only depending on the SDE and its solution.

We remind the reader that consistency is only concerned with the local error. In the case that we disregard other sources of errors in (2.4), we only have to deal with perturbations $D_\ell = L_\ell$.

LEMMA 2.8. *The SLMM* (2.1) *is mean-square consistent of order γ if*

$$\|R_\ell\|_{L_2} \le \bar{c} \cdot h^{\gamma+1} \quad \text{and} \quad \|S_\ell\|_{L_2} \le c \cdot h^{\gamma+\frac{1}{2}}, \quad \ell = k, \dots, N$$

for any representation (2.5) *of the local error $D_\ell = L_\ell$. The SLMM* (2.1) *is mean-square consistent of order γ if and only if*

$$\|R_\ell^*\|_{L_2} \le \bar{c} \cdot h^{\gamma+1} \quad \text{and} \quad \|S_\ell^*\|_{L_2} \le c \cdot h^{\gamma+\frac{1}{2}}, \quad \ell = k, \dots, N,$$

where the representation (2.6) *is chosen for the local error $D_\ell = L_\ell$.*

Proof. First, let $L_\ell = R_\ell + S_\ell =: R_\ell + \sum_{j=1}^k S_{j,\ell-j+1}$ be a representation (2.5) with $\|R_\ell\|_{L_2} \le \bar{c} \cdot h^{\gamma+1}$, and $\|S_\ell\|_{L_2} \le c \cdot h^{\gamma+\frac{1}{2}}, \quad \ell = k, \dots, N$. By the conditions $\mathbb{E}(S_{j,\ell} | \mathcal{F}_{t_{\ell-1}}) = 0$ we conclude

$$\|\mathbb{E}(L_\ell | \mathcal{F}_{t_{\ell-k}})\|_{L_2} = \|\mathbb{E}(R_\ell | \mathcal{F}_{t_{\ell-k}})\|_{L_2} \le \|R_\ell\|_{L_2} \le \bar{c} \cdot h^{\gamma+1}.$$

Further, we have, for $h \le 1$,

$$\|L_\ell\|_{L_2} = \|R_\ell + S_\ell\|_{L_2} \le \|R_\ell\|_{L_2} + \|S_\ell\|_{L_2} \le \bar{c} \cdot h^{\gamma+1} + c \cdot h^{\gamma+\frac{1}{2}} \le (\bar{c} + c) \cdot h^{\gamma+\frac{1}{2}}.$$

Second, let the SLMM (2.1) be mean-square consistent of order γ, i.e., $\|\mathbb{E}(L_\ell | \mathcal{F}_{t_{\ell-k}})\|_{L_2}$ $\le \bar{c} \cdot h^{\gamma+1}$, and $\|L_\ell\|_{L_2} \le c \cdot h^{\gamma+\frac{1}{2}}, \quad \ell = k, \dots, N$. Because of $R_\ell^* = \mathbb{E}(L_\ell | \mathcal{F}_{t_{\ell-k}})$, we then, obviously, have $\|R_\ell^*\|_{L_2} \le \bar{c} \cdot h^{\gamma+1}$, and, further

$$\|S_\ell^*\|_{L_2} = \|L_\ell\|_{L_2} - \|R_\ell^*\|_{L_2} \le \|L_\ell\|_{L_2} \le c \cdot h^{\gamma+\frac{1}{2}}. \qquad \square$$

For further reference we state the following definitions and results.

DEFINITION 2.9. *A function $f : \mathbb{R}^n \times \mathcal{J} \to \mathbb{R}^n$ satisfies a uniform Lipschitz condition with respect to x if there exists a positive constant L_f such that*

$$|f(x,t) - f(y,t)| \le L_f|x-y| \quad \forall x, y \in \mathbb{R}^n, t \in \mathcal{J}. \tag{2.9}$$

A function $\Gamma : \mathbb{R}^n \times \mathcal{J} \to \mathbb{R}^{n\times m_\Gamma}$ satisfies a uniform Lipschitz condition with respect to x if there exists a positive constant L_Γ such that

$$\|\Gamma(x,t) - \Gamma(y,t)\| \le L_\Gamma|x-y| \quad \forall x, y \in \mathbb{R}^n, t \in \mathcal{J}. \tag{2.10}$$

Let $C^{s,s-1}$ denote the class of all functions from $\mathbb{R}^n \times \mathcal{J}$ to $\mathbb{R}^n$ having continuous partial derivatives up to order $s-1$ and, in addition, continuous partial derivatives of order s with respect to the first variable.

Let C^K denote the class of functions y from $\mathbb{R}^n \times \mathcal{J}$ to $\mathbb{R}^n$ that satisfy a linear growth condition in the form

$$|y(x,t)| \le K(1+|x|^2)^{\frac{1}{2}} \quad \forall x \in \mathbb{R}^n, t \in \mathcal{J}. \tag{2.11}$$

DEFINITION 2.10. *The characteristic polynomial of* (2.1) *is given by*

$$\rho(\zeta) = \alpha_0\,\zeta^k + \alpha_1\zeta^{k-1} + \cdots + \alpha_k. \tag{2.12}$$

The SLMM (2.1) *is said to fulfill Dahlquist's root condition if*

(i) *the roots of $\rho(\zeta)$ lie on or within the unit circle;*

(ii) *the roots on the unit circle are simple.*

LEMMA 2.11 (A discrete version of Gronwall's lemma). *Let a_ℓ, $\ell = 1, \ldots, N$, and C_1, C_2 be nonnegative real numbers and assume that the inequalities*

$$a_\ell \le C_1 + C_2\frac{1}{N}\sum_{i=1}^{\ell-1} a_i, \quad \ell = 1, \ldots, N,$$

are valid. Then we have $\max_{\ell=1,\ldots,N} a_\ell \le C_1 \exp(C_2)$.

To estimate the multiple integrals (2.2) we will use the following lemma (cf. Lemmas 2.1 and 2.2 in [24]).

LEMMA 2.12. *For any function y belonging to the class C^K, and any $t \in \mathcal{J}$, $h > 0$, such that $t+h \in \mathcal{J}$, we have that*

$$\mathbb{E}(I^{t,t+h}_{r_1\ldots r_j}(y)|\mathcal{F}_t) = 0 \quad \text{if } r_i \ne 0 \quad \text{for some } i \in \{1, \ldots, j\}, \tag{2.13}$$

$$\|\mathbb{E}(I^{t,t+h}_{r_1,\ldots,r_j}(y)|\mathcal{F}_t)\|_{L_2} \le \|I^{t,t+h}_{r_1,\ldots,r_j}(y)\|_{L_2} = \mathcal{O}(h^{l_1+l_2/2}), \tag{2.14}$$

where l_1 is the number of zero indices r_i, and l_2 the number of nonzero indices r_i.

3. Global properties of stochastic LMMs. In this section we will first establish the solvability of the recurrence equations (2.4) (and thus of (2.1)), then we will discuss numerical stability and mean-square convergence of the SLMM (2.1). The former characterizes the robustness of a numerical scheme with respect to small perturbations such as rounding errors. As a property of the numerical scheme alone, it is not a priori giving evidence on the approximation power of the scheme (which may very well approximate a different problem than intended). However, numerical stability and consistency together yield convergence of the numerical solution to the exact solution. In order to distinguish this stability concept from others, it is sometimes called zero-stability or, in honor of Dahlquist, also D-stability. It should not

be mistaken for properties like asymptotic stability, which guarantee that for fixed step sizes (and long or unbounded time intervals) qualitative properties of the exact solutions like damping behavior in dissipative systems are preserved by the discrete approximations. For further discussions we refer the reader to the deterministic literature (see, e.g., [10, 19, 20]). In the stochastic literature mean-square numerical stability for one-step schemes has been considered in [1, 3, 4, 14, 27, 30]. In the first four of these works only perturbations in the initial data have been treated.

We now turn to the solvability of the recurrence equations. If in (2.1) and (2.4) the parameter $\beta_0 = 0$, the discrete systems are explicit and every iterate $\tilde{X}_\ell$, $\ell \geq k$, can be obtained explicitly for given $I^{t_\ell, t_{\ell+1}}$, i.e., the recurrence equations (2.1) and (2.4) obviously have unique solutions. In the case of implicit systems we need to consider the solvability of the systems of nonlinear equations (2.1) and (2.4). In addition, we have to verify that the mean-square norm of the iterates exists. (The straightforward extension to fully implicit systems would serve as an example where the mean-square norm of the iterates does not exist.)

THEOREM 3.1. *Suppose that $\beta_0 \neq 0$ and the drift-coefficient f satisfies* (2.9) *and assume that $2\,h\,\beta_0\,L_f < 1$. Then the perturbed discrete scheme* (2.4) *and, in consequence, the SLMM* (2.1) *have a unique solution. If, in addition, the coefficients Γ_j satisfy* (2.10)*, then the mean-square norm of the iterates exists.*

Proof. The proof of the existence of unique solutions of the perturbed discrete system (2.4) (and thus of (2.1)) follows the line of proofs used in the deterministic analysis of multistep schemes. The idea is to express (2.4) as

$$\tilde{X}_\ell = h\beta_0 f(\tilde{X}_\ell, t_\ell) + \tilde{B}_\ell \,, \tag{3.1}$$

where

$$\tilde{B}_\ell := -\sum_{j=1}^{k} \alpha_j \tilde{X}_{\ell-j} + h\sum_{j=1}^{k} \beta_j f(\tilde{X}_{\ell-j}, t_{\ell-j}) + \sum_{j=1}^{k} \Gamma_j(X_{\ell-j}, t_{\ell-j})\; I^{t_{\ell-j}, t_{\ell-j+1}} + \tilde{D}_\ell$$

is a known $\mathcal{F}_{t_\ell}$ -measurable random variable, when we suppose that $\tilde{X}_{\ell-j}$ are known $\mathcal{F}_{t_{\ell-j}}$-measurable random variables for $j = 1, \ldots, k$. We can then view (2.4) as a fixed-point equation in x,

$$x = h\beta_0 f(x, t_\ell) + b_\ell$$

and apply the contraction mapping principle. We refer, e.g., to [15, Thm. 6.1.1] for more details.

It remains to be shown that the second moments of the iterates exist. We start from the assumption $\mathbb{E}|\tilde{X}_{\ell-j}|^2 < \infty$, $j = 1, \ldots, k$ on the initial values. Recursively, we conclude that $\mathbb{E}|\tilde{X}_\ell|^2 < \infty$, $\ell = k, \ldots, N$ by comparing $\tilde{X}_\ell$ with the solution of the fixed-point equation (3.1) for $\tilde{B}_\ell = 0$, i.e., with the solution of the deterministic implicit equation $x = h\beta_0 f(x, t_\ell)$, and applying Lipschitz continuity arguments. For more details we refer to [30, Thm. 5]. □

We now formulate our main theorem on numerical stability. The proof is given in the appendix.

THEOREM 3.2. *The stochastic linear multistep method* (2.1) *is numerically stable in the mean-square sense for every continuous f and Γ_j satisfying* (2.9) *and* (2.10)*, respectively, if and only if its characteristic polynomial $\rho(\zeta)$* (2.12) *satisfies Dahlquist's root condition given in Definition* 2.10*.*

With the powerful notion of numerical stability in the mean-square sense, together with mean-square consistency, the mean-square convergence follows almost immediately.

THEOREM 3.3. *A mean-square consistent SLMM* (2.1) *for the approximation of the solution of SDE* (1.1) *is mean-square convergent for all continuous* f *and* Γ_j *satisfying* (2.9) *and* (2.10)*, respectively, if and only if it is numerically stable in the mean-square sense. If, in addition, it is mean-square consistent with order* $\gamma > 0$*, then the SLMM* (2.1) *is mean-square convergent with order* γ*.*

Proof. First, let us assume that the mean-square consistent numerical method (2.1) is mean-square convergent. Then the necessity of stability can essentially be proved as in the deterministic case. Set $f \equiv 0,\ \Gamma_j \equiv 0,\ X_0 = 0$. Then (2.1) reduces to $\sum_{j=1}^{k} \alpha_j X_{\ell-j} = 0,\ l = k, k+1, \ldots$, a deterministic homogeneous difference equation, and stability follows by standard arguments, see, e.g., [15].

Second, let us assume that the numerical method (2.1) is mean-square stable and consistent with order $\gamma > 0$. Then mean-square convergence with order γ follows by applying the stability estimate (2.8) to $\{\tilde{X}_\ell := X(t_\ell)\}$ related to the perturbations $\{D_\ell := L_\ell = R^*_\ell + S^*_\ell\}$. ∎

4. Two-step Maruyama schemes. In this section we consider linear two-step Maruyama schemes; thus, we have for $\ell = 2, \ldots, N$

$$\sum_{j=0}^{2} \alpha_j X_{\ell-j} = h \sum_{j=0}^{2} \beta_j f(X_{\ell-j}, t_{\ell-j}) + \sum_{j=1}^{2} \gamma_j \sum_{r=1}^{m} g_r(X_{\ell-j}, t_{\ell-j})\ I_r^{t_{\ell-j}, t_{\ell-j+1}}. \tag{4.1}$$

For drift and diffusion coefficients $f,\ g_1, \ldots, g_m$, which are continuous and satisfy (2.9), Theorem 3.2 applies and the two-step scheme (4.1) is mean-square stable if the coefficients $\alpha_0,\ \alpha_1,\ \alpha_2$ satisfy Dahlquist's root condition. If, additionally, the scheme is mean-square consistent of order γ, which in general requires more smoothness of the coefficient functions, then the scheme (4.1) is mean-square convergent of that order. Thus we will be concerned with mean-square consistency of the above scheme and derive order conditions in terms of the coefficients $\alpha_0, \alpha_1, \alpha_2, \beta_0, \beta_1, \beta_2, \gamma_1, \gamma_2$. In general, the mean-square order of convergence will be only $\frac{1}{2}$, since the only information about the driving noise process that the Maruyama-type schemes include are the Wiener increments. We note that the simple Euler–Maruyama method would suffice to obtain the same order of convergence. However, convergence is an asymptotic property, i.e., it holds for $h \to 0$ and a result concerning the order of convergence may not provide sufficient information about the size of the actual error that arises for reasonable choices of the step size. In particular when one considers equations with a small noise term as in (1.2), one may find that the influence of the noise is not dominant and properties of the methods in the deterministic setting are recovered to a certain extent.

From the deterministic theory we know that for linear k-step methods

$$\sum_{j=0}^{k} \alpha_j\, x_{\ell-j} = h \sum_{j=0}^{k} \beta_j\, f(x_{\ell-j}, t_{\ell-j}), \quad \text{applied to } x'(t) = f(x(t), t),$$

the local error is of order $p+1$ for sufficiently smooth functions f if

$$\sum_{j=0}^{k} \alpha_j = 0 \quad \text{and} \quad \sum_{j=0}^{k} \alpha_j (k-j)^q = q \sum_{j=0}^{k} \beta_j (k-j)^{q-1} \quad \text{for } q = 1, \ldots, p.$$

In the first part of this section we derive consistency conditions for the two-step scheme (4.1) applied to the general SDE (1.1). We establish a representation of the local error L_ℓ in terms of certain multiple stochastic integrals obtained by the Itô–Taylor expansion. It turns out that consistency is guaranteed under the above conditions for deterministic order 1 and additional conditions that determine the method parameters γ_1 and γ_2.

In the second part of this section we consider the application of the scheme (4.1) in the case that the noise is small. The smallness of the noise is measured by means of the parameter ϵ in the diffusion coefficient $G(x,t) = \epsilon\hat{G}(x,t)$. We emphasize that the numerical schemes include only values of G, the explicit dependence of the diffusion coefficient on the parameter ϵ is used only for a discussion of the errors. We follow the ideas of [21] and develop the local error in powers of the step size h and the small parameter ϵ. The expansion yields the deterministic conditions for order 2, and we discuss for which choices of ϵ and h the stochastic component in the error estimates becomes small compared to these order-2 terms.

4.1. Two-step schemes for general SDEs. To analyze the local error L_ℓ of the scheme (4.1) for the SDE (1.1) and to achieve a suitable representation (2.5) we will derive appropriate Itô–Taylor expansions, where we take special care to separate the stochastic integrals over the different subintervals of integration. We introduce operators Λ_0 and Λ_r, $r = 1, \dots, m$, defined on $C^{2,1}$ and $C^{1,0}$, respectively, by

$$\Lambda_0 y = y'_t + y'_x f + \frac{1}{2}\sum_{r=1}^{m} y''_{xx}[g_r, g_r]\ , \quad \Lambda_r y = y'_x g_r\ ,\ r = 1, \dots, m \tag{4.2}$$

and remind the reader of the notation for multiple Wiener integrals (2.2). Using these operators the Itô formula for a function y in $C^{2,1}$ and the solution X of (1.1) reads

$$y(X(t),t) = y(X(t_0),t_0) + I_0^{t_0,t}(\Lambda_0 y) + \sum_{r=1}^{m} I_r^{t_0,t}(\Lambda_r y), \quad t \in \mathcal{J}. \tag{4.3}$$

Applying the Itô formula (4.3) on the corresponding intervals to the drift coefficient f as well as to the diffusion coefficients g_r yields for $s \in [t_{\ell-j}, t_{\ell-j+1}]$, $j = 1, 2$

$$f(X(s),s) = f(X(t_{\ell-j}),t_{\ell-j}) + I_0^{t_{\ell-j},s}(\Lambda_0 f) + \sum_{r=1}^{m} I_r^{t_{\ell-j},s}(\Lambda_r f), \tag{4.4}$$

$$g_r(X(s),s) = g_r(X(t_{\ell-j}),t_{\ell-j}) + I_0^{t_{\ell-j},s}(\Lambda_0 g_r) + \sum_{q=1}^{m} I_q^{t_{\ell-j},s}(\Lambda_q g_r). \tag{4.5}$$

We trace back the values of the drift coefficient to the point $t_{\ell-2}$ to obtain

$$f(X(t_{\ell-1}),t_{\ell-1}) = f(X(t_{\ell-2}),t_{\ell-2}) + I_0^{t_{\ell-2},t_{\ell-1}}(\Lambda_0 f) + \sum_{r=1}^{m} I_r^{t_{\ell-2},t_{\ell-1}}(\Lambda_r f), \tag{4.6}$$

$$\begin{aligned} f(X(t_\ell),t_\ell) = {} & f(X(t_{\ell-2}),t_{\ell-2}) + I_0^{t_{\ell-2},t_{\ell-1}}(\Lambda_0 f) + I_0^{t_{\ell-1},t_\ell}(\Lambda_0 f) \\ & + \sum_{r=1}^{m} I_r^{t_{\ell-2},t_{\ell-1}}(\Lambda_r f) + \sum_{r=1}^{m} I_r^{t_{\ell-1},t_\ell}(\Lambda_r f). \end{aligned} \tag{4.7}$$

For the general SDE (1.1) we have the following result.

LEMMA 4.1. *Assume that the coefficients* $f,\ g_r, r = 1,\dots,m$ *of the SDE* (1.1) *belong to the class* $C^{2,1}$ *with* $\Lambda_0 f, \Lambda_0 g_r, \Lambda_r f, \Lambda_q g_r \in C^K$ *for* $r,q = 1,\dots,m$. *Then the local error* (2.3) *of the stochastic two-step scheme* (4.1) *allows the representation*

$$L_\ell = R_\ell^\circ + S_{1,\ell}^\circ + S_{2,\ell-1}^\circ, \quad \ell = 2,\dots,N, \tag{4.8}$$

where $R_\ell^\circ, S_{j,\ell}^\circ, j = 1,2$ *are* $\mathcal{F}_{t_\ell}$*-measurable with* $\mathbb{E}(S_{j,\ell}^\circ|\mathcal{F}_{t_{\ell-1}}) = 0$ *and*

$$\begin{aligned}
R_\ell^\circ &= \left[\sum_{j=0}^{2}\alpha_j\right] X(t_{\ell-2}) + \left[2\alpha_0 + \alpha_1 - \sum_{j=0}^{2}\beta_j\right] hf(X(t_{\ell-2}),t_{\ell-2}) + \tilde{R}_\ell^\circ,\\
S_{1,\ell}^\circ &= \Big[\alpha_0 - \gamma_1\Big]\sum_{r=1}^{m} g_r(X(t_{\ell-1}),t_{\ell-1})I_r^{t_{\ell-1},t_\ell} + \tilde{S}_{1,\ell}^\circ,\\
S_{2,\ell-1}^\circ &= \Big[(\alpha_0+\alpha_1) - \gamma_2\Big]\sum_{r=1}^{m} g_r(X(t_{\ell-2}),t_{\ell-2})I_r^{t_{\ell-2},t_{\ell-1}} + \tilde{S}_{2,\ell-1}^\circ
\end{aligned}$$

with

$$\|\tilde{R}_\ell^\circ\|_{L_2} = O(h^2), \quad \|\tilde{S}_{1,\ell}^\circ\|_{L_2} = O(h), \quad \|\tilde{S}_{2,\ell-1}^\circ\|_{L_2} = O(h). \tag{4.9}$$

COROLLARY 4.2. *Let the coefficients* $f,\ g_r,\ r = 1,\dots,m$, *of the SDE* (1.1) *satisfy the assumptions of Lemma* 4.1 *and suppose they are Lipschitz continuous with respect to their first variable. Let the coefficients of the stochastic linear two-step scheme* (4.1) *satisfy Dahlquist's root condition and the consistency conditions*

$$\sum_{j=0}^{2}\alpha_j = 0, \quad 2\alpha_0 + \alpha_1 = \sum_{j=0}^{2}\beta_j, \quad \alpha_0 = \gamma_1, \quad \alpha_0 + \alpha_1 = \gamma_2. \tag{4.10}$$

Then the global error of the scheme (4.1) *applied to* (1.1) *allows the expansion*

$$\max_{\ell=2,\dots,N}\|X(t_\ell) - X_\ell\|_{L_2} = \mathcal{O}(h^{1/2}) + \mathcal{O}(\max_{\ell=0,1}\|X(t_\ell) - X_\ell\|_{L_2})\ .$$

Proof of Corollary 4.2. By Lemma 4.1 we have the representation (4.8) for the local error. Applying the consistency conditions (4.10) yields

$$R_\ell^\circ = \tilde{R}_\ell^\circ, \quad S_{1,\ell}^\circ = \tilde{S}_{1,\ell}^\circ, \quad S_{2,\ell-1}^\circ = \tilde{S}_{2,\ell-1}^\circ, \quad \ell = 2,\dots,N.$$

As the scheme (4.1) satisfies Dahlquist's root condition, it is numerically stable in the mean-square sense. Now the assertion follows from the estimates (4.9) by means of the stability inequality. ∎

Proof of Lemma 4.1. To derive a representation of the local error in the form (4.8) we evaluate and resume the deterministic parts at the point $(X(t_{\ell-2}),t_{\ell-2})$ and separate the stochastic terms carefully over the different subintervals $[t_{\ell-2},t_{\ell-1}]$ and $[t_{\ell-1},t_\ell]$. This ensures the independence of the random variables. It does make the calculations more messy, though. By rewriting

$$\sum_{j=0}^{2}\alpha_j X(t_{\ell-j}) = \alpha_0\big(X(t_\ell) - X(t_{\ell-1})\big) + (\alpha_0+\alpha_1)\big(X(t_{\ell-1}) - X(t_{\ell-2})\big) + \big(\sum_{j=0}^{2}\alpha_j\big)X(t_{\ell-2}),$$

we can express the local error (2.3) as

$$L_\ell = \alpha_0\big(X(t_\ell) - X(t_{\ell-1})\big) + (\alpha_0+\alpha_1)\big(X(t_{\ell-1}) - X(t_{\ell-2})\big) + \sum_{j=0}^{2}\alpha_j X(t_{\ell-2})$$
$$-h\sum_{j=0}^{2}\beta_j f(X(t_{\ell-j}),t_{\ell-j}) - \sum_{j=1}^{2}\gamma_j\sum_{r=1}^{m} g_r(X(t_{\ell-j}),t_{\ell-j})I_r^{t_{\ell-j},t_{\ell-j+1}}.$$

The SDE (1.1) implies the identities

$$X(t_{\ell-1}) - X(t_{\ell-2}) = hf(X(t_{\ell-2}),t_{\ell-2}) + I_{00}^{t_{\ell-2},t_{\ell-1}}(\Lambda_0 f) + \sum_{r=1}^{m} I_{r0}^{t_{\ell-2}t_{\ell-1}}(\Lambda_r f)$$
$$+\sum_{r=1}^{m} g_r(X(t_{\ell-2}),t_{\ell-2})I_r^{t_{\ell-2},t_{\ell-1}} + \sum_{r=1}^{m} I_{0r}^{t_{\ell-2},t_{\ell-1}}(\Lambda_0 g_r) + \sum_{r,q=1}^{m} I_{qr}^{t_{\ell-2},t_{\ell-1}}(\Lambda_q g_r),$$

and, additionally using (4.6),

$$X(t_\ell) - X(t_{\ell-1}) = h\big\{f(X(t_{\ell-2}),t_{\ell-2}) + I_0^{t_{\ell-2},t_{\ell-1}}(\Lambda_0 f) + \sum_{r=1}^{m} I_r^{t_{\ell-2},t_{\ell-1}}(\Lambda_r f)\big\}$$
$$+I_{00}^{t_{\ell-1},t_\ell}(\Lambda_0 f) + \sum_{r=1}^{m} I_{r0}^{t_{\ell-1}t_\ell}(\Lambda_r f) + \sum_{r=1}^{m} g_r(X(t_{\ell-1}),t_{\ell-1})I_r^{t_{\ell-1},t_\ell}$$
$$+\sum_{r=1}^{m} I_{0r}^{t_{\ell-1},t_\ell}(\Lambda_0 g_r) + \sum_{r,q=1}^{m} I_{qr}^{t_{\ell-1},t_\ell}(\Lambda_q g_r).$$

Inserting this and the expansions (4.6, 4.7) into the local error formula and reordering the terms, yields

$$L_\ell = \left[\sum_{j=0}^{2}\alpha_j\right] X(t_{\ell-2}) + \left[2\alpha_0+\alpha_1-\sum_{j=0}^{2}\beta_j\right] hf(X(t_{\ell-2}),t_{\ell-2}) + \tilde{R}_\ell^\circ$$
$$+\Big[\alpha_0-\gamma_1\Big]\sum_{r=1}^{m} g_r(X(t_{\ell-1}),t_{\ell-1})I_r^{t_{\ell-1},t_\ell} + \tilde{S}_{1,\ell}^\circ$$
$$+\Big[(\alpha_0+\alpha_1)-\gamma_2\Big]\sum_{r=1}^{m} g_r(X(t_{\ell-2}),t_{\ell-2})I_r^{t_{\ell-2},t_{\ell-1}} + \tilde{S}_{2,\ell-1}^\circ,$$

where

$$\tilde{R}_\ell^\circ = \alpha_0\big\{hI_0^{t_{\ell-2},t_{\ell-1}}(\Lambda_0 f) + I_{00}^{t_{\ell-1},t_\ell}(\Lambda_0 f)\big\} + (\alpha_0+\alpha_1)I_{00}^{t_{\ell-2},t_{\ell-1}}(\Lambda_0 f)$$
$$-h\beta_0\big\{I_0^{t_{\ell-2},t_{\ell-1}}(\Lambda_0 f) + I_0^{t_{\ell-1},t_\ell}(\Lambda_0 f)\big\} - h\beta_1 I_0^{t_{\ell-2},t_{\ell-1}}(\Lambda_0 f), \tag{4.11}$$

$$\tilde{S}_{1,\ell}^\circ = \sum_{r=1}^{m}\Big(\alpha_0 I_{r0}^{t_{\ell-1},t_\ell}(\Lambda_r f) - h\beta_0 I_r^{t_{\ell-1},t_\ell}(\Lambda_r f)\Big) + \alpha_0\sum_{r=1}^{m} I_{0r}^{t_{\ell-1},t_\ell}(\Lambda_0 g_r)$$
$$+\alpha_0\sum_{r,q=1}^{m} I_{qr}^{t_{\ell-1},t_\ell}(\Lambda_q g_r)), \tag{4.12}$$

$$\tilde{S}^{\circ}_{2,\ell-1} = h(\alpha_0-\beta_0-\beta_1)\sum_{r=1}^{m} I_r^{t_{\ell-2},t_{\ell-1}}(\Lambda_r f) + (\alpha_0+\alpha_1)\sum_{r=1}^{m} I_{r0}^{t_{\ell-2},t_{\ell-1}}(\Lambda_r f)$$

$$+(\alpha_0+\alpha_1)\sum_{r=1}^{m} I_{0r}^{t_{\ell-2},t_{\ell-1}}(\Lambda_0 g_r) + (\alpha_0+\alpha_1)\sum_{r,q=1}^{m} I_{qr}^{t_{\ell-2},t_{\ell-1}}(\Lambda_q g_r). \tag{4.13}$$

Finally, the estimates (4.9) are derived by means of Lemma 2.12, where the last terms in (4.12) and (4.13) determine the order $\mathcal{O}(h)$. ∎

4.2. Two-step schemes for small noise SDEs. For the numerical integration of ODEs two-step schemes of order 2 or higher are particularly interesting. They offer a high order of convergence for low computational cost per step. In this section we discuss the special case of small noise SDEs (1.2) where the parameter ϵ in the diffusion coefficients $g_r = \epsilon\hat{g}_r,\ r = 1,\dots,m$ measures the smallness of the noise. Lemma 4.1 provides a representation for the local error (2.3) of the stochastic linear two-step scheme (4.1) applied to (1.2). Starting from this expression we will further analyze the local error by expanding the term $\Lambda_0 f$ appearing in $\tilde{R}^{\circ}_{\ell}$ (4.11). Naturally, this requires more smoothness of the coefficients. A sufficient condition would be $\Lambda_0 f \in C^{2,1}$, for which, in general, one needs the existence of fourth order derivatives of f with respect to x. However, for small noise SDEs, the term $f'_x f + f'_t$ dominates $\Lambda_0 f$. This allows weakening the smoothness assumptions again. The expansion of $\Lambda_0 f$ also yields additional multiple Itô integrals whose conditional expectation vanishes. By moving these terms from $\tilde{R}^{\circ}_{\ell}$ into the stochastic parts of the representation of the local error we achieve better estimates. With this analysis we are able to prove that some of the potential of deterministic two-step schemes can be recovered in the special case of small noise SDEs.

To be able to exploit the effect of the small parameter ϵ in the expansions of the local error we introduce operators $\Lambda_0^f, \hat{\Lambda}_0$ and $\hat{\Lambda}_r,\ r = 1,\dots,m$ defined on $C^{2,1}$ and $C^{1,0}$, respectively, by

$$\Lambda_0^f y := y'_t + y'_x f, \quad \hat{\Lambda}_0 y := \frac{1}{2}\sum_{r=1}^{m} y''_{xx}[\hat{g}_r,\hat{g}_r], \quad \hat{\Lambda}_r y := y'_x \hat{g}_r\ . \tag{4.14}$$

In terms of the original definition (4.2) we have

$$\Lambda_0 y = \Lambda_0^f y + \epsilon^2 \hat{\Lambda}_0 y \quad \text{and} \quad \Lambda_r y = \epsilon\hat{\Lambda}_r y. \tag{4.15}$$

LEMMA 4.3. *Assume that the coefficients $f, \hat{g}_r, r = 1,\dots,m$ of the small noise SDE* (1.2)*, as well as $\Lambda_0^f f = f'_x f + f'_t$ belong to the class $C^{2,1}$ with $\Lambda_0 f, \Lambda_0\hat{g}_r, \hat{\Lambda}_r f$, $\hat{\Lambda}_q\hat{g}_r, \Lambda_0\Lambda_0^f f,\ \hat{\Lambda}_r\Lambda_0^f f \in C^K$ for $r,q = 1,\dots,m$. Let the stochastic two-step scheme* (4.1) *satisfy the consistency conditions* (4.10)*. Then the local error* (2.3) *of the method* (4.1) *for the small noise SDE* (1.2) *allows the representation*

$$L_\ell = R^{\diamond}_{\ell} + S^{\diamond}_{1,\ell} + S^{\diamond}_{2,\ell-1}, \quad \ell = 2,\dots,N, \tag{4.16}$$

where $R^{\diamond}_{\ell}, S^{\diamond}_{j,\ell}, j = 1,2$ are $\mathcal{F}_{t_\ell}$-measurable with $\mathbb{E}(S^{\diamond}_{j,\ell}|\mathcal{F}_{t_{\ell-1}}) = 0$, and

$$R^{\diamond}_{\ell} = \Big[(4\alpha_0+\alpha_1) - (4\beta_0+2\beta_1)\Big]\frac{h^2}{2}(f'_t + f'_x f)(X(t_{\ell-2}),t_{\ell-2}) + \tilde{R}^{\diamond}_{\ell},$$
$$S^{\diamond}_{1,\ell} = \tilde{S}^{\circ}_{1,\ell} + \tilde{S}^{\diamond}_{1,\ell},$$
$$S^{\diamond}_{2,\ell-1} = \tilde{S}^{\circ}_{2,\ell-1} + \tilde{S}^{\diamond}_{2,\ell-1},$$

where

$$\|\tilde{R}_\ell^\diamond\|_{L_2} = O(h^3 + \epsilon^2 h^2), \quad \|\tilde{S}_{1,\ell}^\diamond\|_{L_2} = O(\epsilon h^{5/2}), \quad \|\tilde{S}_{2,\ell-1}^\diamond\|_{L_2} = O(\epsilon h^{5/2}). \tag{4.17}$$

The terms $\tilde{S}_{1,\ell}^\circ, \tilde{S}_{2,\ell-1}^\circ$ *are given by* (4.12, 4.13) *in the proof of Lemma* 4.1 *and satisfy here*

$$\|\tilde{S}_{1,\ell}^\circ\|_{L_2} = \mathcal{O}(\epsilon^2 h + \epsilon h^{3/2}), \quad \|\tilde{S}_{2,\ell}^\circ\|_{L_2} = \mathcal{O}(\epsilon^2 h + \epsilon h^{3/2}). \tag{4.18}$$

Proof. We have from Lemma 4.1, if the consistency conditions (4.10) are satisfied, the representation

$$L_\ell = \tilde{R}_\ell^\circ + \tilde{S}_{1,\ell}^\circ + \tilde{S}_{2,\ell-1}^\circ, \quad \ell = 2, \dots, N,$$

where $\tilde{R}_\ell^\circ$, $\tilde{S}_{1,\ell}^\circ$, $\tilde{S}_{2,\ell-1}^\circ$ are given by (4.11, 4.12, 4.13). Splitting $\Lambda_0 f = \Lambda_0^f f + \epsilon^2 \hat{\Lambda}_0 f$ immediately yields $\tilde{R}_\ell^\circ = \tilde{R}_\ell^{\circ f} + \epsilon^2 \hat{R}_\ell^\circ$ with

$$\begin{aligned} \tilde{R}_\ell^{\circ f} &:= (\alpha_0 - \beta_0 - \beta_1) h I_0^{t_{\ell-2}, t_{\ell-1}}(\Lambda_0^f f) + (\alpha_0 + \alpha_1) I_{00}^{t_{\ell-2}, t_{\ell-1}}(\Lambda_0^f f) \\ &\quad + \alpha_0 I_{00}^{t_{\ell-1}, t_\ell}(\Lambda_0^f f) - h\beta_0 I_0^{t_{\ell-1}, t_\ell}(\Lambda_0^f f) \end{aligned} \tag{4.19}$$

$$\begin{aligned} \hat{R}_\ell^{\circ} &:= (\alpha_0 - \beta_0 - \beta_1) h I_0^{t_{\ell-2}, t_{\ell-1}}(\hat{\Lambda}_0 f) + (\alpha_0 + \alpha_1) I_{00}^{t_{\ell-2}, t_{\ell-1}}(\hat{\Lambda}_0 f) \\ &\quad + \alpha_0 I_{00}^{t_{\ell-1}, t_\ell}(\hat{\Lambda}_0 f) - h\beta_0 I_0^{t_{\ell-1}, t_\ell}(\hat{\Lambda}_0 f). \end{aligned} \tag{4.20}$$

We note that (4.20) appears with the factor ϵ^2 in the local error representation, thus yielding the $\mathcal{O}(\epsilon^2 h^2)$ term in the estimate of $\|\tilde{R}_\ell^\diamond\|_{L_2}$ in (4.17). We concentrate on developing $\tilde{R}_\ell^{\circ f}$ in more detail. Applying the Itô formula (4.3) to $\Lambda_0^f f(X(s), s)$ for $s \in [t_{\ell-2}, t_{\ell-1}]$ and integrating yields $I_0^{t_{\ell-2}, s}(\Lambda_0^f f) = (s - t_{\ell-2})\Lambda_0^f f(X(t_{\ell-2}), t_{\ell-2}) + I_{00}^{t_{\ell-2}, s}(\Lambda_0 \Lambda_0^f f) + \epsilon \sum_{r=1}^m I_{r0}^{t_{\ell-2}, s}(\hat{\Lambda}_r \Lambda_0^f f)$.

For $s = t_{\ell-1}$ we obtain an expression for the first integral in (4.19) . Integrating again we have for the second integral in (4.19) $I_{00}^{t_{\ell-2}, t_{\ell-1}}(\Lambda_0^f f) = \frac{h^2}{2}\Lambda_0^f f(X(t_{\ell-2}), t_{\ell-2}) + I_{000}^{t_{\ell-2}, t_{\ell-1}}(\Lambda_0 \Lambda_0^f f) + \epsilon \sum_{r=1}^m I_{r00}^{t_{\ell-2}, t_{\ell-1}}(\hat{\Lambda}_r \Lambda_0^f f)$.

Both the other integrals are over the interval $[t_{\ell-1}, t_\ell]$. In the analogous expressions for these the term $\Lambda_0^f f(X(t_{\ell-1}), t_{\ell-1})$ must be substituted by $\Lambda_0^f f(X(t_{\ell-1}), t_{\ell-1}) = \Lambda_0^f f(X(t_{\ell-2}), t_{\ell-2}) + I_0^{t_{\ell-2}, t_{\ell-1}}(\Lambda_0 \Lambda_0^f f) + \epsilon \sum_{r=1}^m I_r^{t_{\ell-2}, t_{\ell-1}}(\Lambda_r \Lambda_0^f f)$.

Then we obtain from (4.19)

$$\tilde{R}_\ell^{\circ f} = \Big[(4\alpha_0 + \alpha_1) - (4\beta_0 + 2\beta_1)\Big] \frac{h^2}{2} \Lambda_0^f f(X(t_{\ell-2}), t_{\ell-2}) + \tilde{R}_\ell^{\diamond f} + \tilde{S}_{1,\ell}^\diamond + \tilde{S}_{2,\ell}^\diamond,$$

where

$$\begin{aligned}
\tilde{R}_\ell^{\diamond f} &= (\alpha_0 - 2\beta_0)\frac{h^2}{2} I_0^{t_{\ell-2},t_{\ell-1}}(\Lambda_0\Lambda_0^f f) \\
&\quad + (\alpha_0 - \beta_0 - \beta_1) h I_{00}^{t_{\ell-2},t_{\ell-1}}(\Lambda_0\Lambda_0^f f) - \beta_0 h I_{00}^{t_{\ell-1},t_\ell}(\Lambda_0\Lambda_0^f f) \\
&\quad + (\alpha_0 + \alpha_1) I_{000}^{t_{\ell-2},t_{\ell-1}}(\Lambda_0\Lambda_0^f f) + \alpha_0 I_{000}^{t_{\ell-1},t_\ell}(\Lambda_0\Lambda_0^f f), \\
\tilde{S}_{1,\ell}^{\diamond} &= \alpha_0\epsilon \sum_{r=1}^m I_{r00}^{t_{\ell-1},t_\ell}(\hat{\Lambda}_r\Lambda_0^f f) - h\beta_0\epsilon \sum_{r=1}^m I_{r0}^{t_{\ell-1},t_\ell}(\hat{\Lambda}_r\Lambda_0^f f), \\
\tilde{S}_{2,\ell}^{\diamond} &= (\alpha_0 - 2\beta_0)\frac{h^2}{2}\epsilon \sum_{r=1}^m I_r^{t_{\ell-2},t_{\ell-1}}(\hat{\Lambda}_r\Lambda_0^f f) + (\alpha_0 - \beta_0 - \beta_1) h\epsilon \sum_{r=1}^m I_{r0}^{t_{\ell-2},t_{\ell-1}}(\hat{\Lambda}_r\Lambda_0^f f) \\
&\quad + (\alpha_0 + \alpha_1)\epsilon \sum_{r=1}^m I_{r00}^{t_{\ell-2},t_{\ell-1}}(\hat{\Lambda}_r\Lambda_0^f f).
\end{aligned}$$

We arrive at $\tilde{R}_\ell^{\diamond} = \tilde{R}_\ell^{\diamond f} + \epsilon^2 \hat{R}_\ell^{\circ}$. Finally, the estimates (4.17) are derived by means of Lemma 2.12. ∎

COROLLARY 4.4. *Let the coefficients* f, $\hat{g}_r$, $r = 1, \dots, m$, *of the SDE* (1.2) *satisfy the assumptions of Lemma* 4.3 *and suppose they are Lipschitz continuous with respect to their first variable. Let the coefficients of the stochastic linear two-step scheme* (4.1) *satisfy Dahlquist's root condition and the consistency conditions* (4.10) *and*

$$(4\alpha_0 + \alpha_1) - (4\beta_0 + 2\beta_1) = 0. \tag{4.21}$$

Then the global error of the scheme (4.1) *applied to* (1.2) *allows the expansion*

$$\max_{\ell=2,\dots,N} \|X(t_\ell) - X_\ell\|_{L_2} = \mathcal{O}(h^2 + \epsilon h + \epsilon^2 h^{1/2}) + \mathcal{O}(\max_{\ell=0,1} \|X(t_\ell) - X_\ell\|_{L_2}) .$$

Proof. Lemma 4.3 stated the representation (4.16) for the local error. Applying the consistency condition (4.21) yields $R_\ell^{\diamond} = \tilde{R}_\ell^{\diamond}$ and by (4.17) we have $\|R_\ell^{\diamond}\|_{L_2} = \mathcal{O}(h^3 + \epsilon^2 h^2)$. The stochastic terms $S_{1,\ell}^{\diamond}$, $S_{2,\ell-1}^{\diamond}$ are dominated by $\tilde{S}_{1,\ell}^{\circ}$, $\tilde{S}_{2,\ell-1}^{\circ}$ and thus are of order of magnitude $\mathcal{O}(\epsilon^2 h + \epsilon h^{3/2})$. As the scheme (4.1) satisfies Dahlquist's root condition, it is numerically stable in the mean-square sense. Applying the stability inequality (2.8) to the representation (4.16) of the local error yields the assertion. ∎

Remark 4.5. We note that $R_\ell^{\diamond}$ is responsible for the $\mathcal{O}(h^2)$ term in the expansion of the global error. In the limit $\epsilon \to 0$ this is the only remaining term. It reflects the convergence properties of the scheme in the deterministic setting. On the other hand, for asymptotically small step sizes $h \to 0$ and fixed parameter ϵ, even if it is small, the term of order $\mathcal{O}(\epsilon^2 h^{1/2})$ causes the low order $\frac{1}{2}$ of convergence. The question arises for which choices of ϵ and h the schemes still show the order 2 behavior. Thus we are interested in when the term $\mathcal{O}(h^2)$ dominates the term $\mathcal{O}(\epsilon h + \epsilon^2 h^{1/2})$. Clearly both these terms depend on the actual coefficients $f, \hat{g}_r, r = 1, \dots, m$, of the SDE (1.2) and their derivatives. Assuming moderate function values, the term $\mathcal{O}(h^2)$ dominates $\mathcal{O}(\epsilon h + \epsilon^2 h^{1/2})$, if $h^2 \gg \epsilon^2 h^{1/2}$, i.e., $h \gg \epsilon^{4/3}$, and $h^2 \gg \epsilon h$, i.e., $h \gg \epsilon$. Obviously, in general, the second condition is stronger. Summarizing, we can expect order 2 behavior if $h \gg \epsilon$.

However, even if the chosen step size does not satisfy this condition for a given ϵ, schemes satisfying the consistency condition (4.21) often show a better performance

TABLE 5.1
Coefficients of two-step schemes.

Method	α_0	α_1	α_2	β_0	β_1	β_2	γ_1	γ_2
Unstable method	1	-3	2	0	1/2	$-3/2$	1	-2
Explicit Euler	1	-1	0	0	1	0	1	0
Implicit Euler	1	-1	0	1	0	0	1	0
Trapezoidal rule	1	-1	0	1/2	1/2	0	1	0
BDF 2	1	$-4/3$	1/3	2/3	0	0	1	$-1/3$
Adams–Bashforth 2	1	-1	0	0	3/2	$-1/2$	1	0
Adams–Moulton 2	1	-1	0	5/12	8/12	$-1/12$	1	0
Milne–Simpson	1	0	-1	1/3	4/3	1/3	1	1

than other schemes. The reason is that their error is dominated by $\mathcal{O}(\epsilon h)$ instead of $\mathcal{O}(\epsilon^2 h^{1/2})$, resulting in an order 1 behavior with the small parameter ϵ in the error constant. Again assuming moderate function values, one may expect this for $\epsilon h \gg \epsilon^2 h^{1/2}$, i.e., $h \gg \epsilon^2$.

5. Test results. We report results for several explicit and implicit stochastic linear k-step schemes for $k = 1, 2$, applied to two examples of SDEs. Table 5.1 summarizes the methods we have implemented and tested. All methods, including the one-step schemes, satisfy the consistency conditions (4.10) and all methods, excluding the Euler schemes, satisfy the consistency condition (4.21). Further, all methods, exept the first one, are zero-stable. The Milne–Simpson method is the only linear two-step method with deterministic order of convergence 4. However, its characteristic polynomial possesses the second root $\alpha_2 = -1$ on the unit circle which easily causes weak instabilities in the integration of decaying solutions, such that this scheme is generally not recommended.

The first example is the simple bilinear scalar SDE

$$X(t) = 1 + \int_0^t \alpha X(s)\, \mathrm{d}s + \int_0^t \beta X(s)\, \mathrm{d}W(s), \quad t \in [0,1] \tag{5.1}$$

with coefficients $f(x,t) := \alpha x$, $G(x,t) = (g(x,t)) = (\beta x)$, parameters $\alpha, \beta \in \mathbb{R}$, and a scalar Wiener process W. This example has the advantage that an explicit solution is available to compare with the numerical approximations. This solution is given by the geometric Brownian motion $X(t) = \exp\big((\alpha - \frac{1}{2}\beta^2)t + \beta W(t)\big)$.

The second example is a two-dimensional system of SDEs which is taken from [8, 9, Problem P1], where it is given in Stratonovich notation. For the purpose of using it as a test equation for small noise SDEs in the form (1.2) we have transformed

it into Itô notation and included a parameter ϵ. We arrive at

$$
\begin{aligned}
(5.2)\quad X(t) &= X(0) + \int_0^t FX(s)\,\mathrm{d}s + \int_0^t G_1 X(s)\,\mathrm{d}W_1(s) + \int_0^t G_2 X(s)\,\mathrm{d}W_2(s),\\
F &= \begin{pmatrix} -0.9 & 0 \\ 0.25 & -0.5 \end{pmatrix} + \frac{\epsilon^2}{2}\begin{pmatrix} 0.75^2+0.9^2 & 0 \\ 0 & 0.75^2+0.9^2 \end{pmatrix},\\
G_1 &= \epsilon\begin{pmatrix} 0.75 & 0 \\ 0 & -0.75 \end{pmatrix}, \quad G_2 = \epsilon\begin{pmatrix} 0 & 0.9 \\ 0.9 & 0 \end{pmatrix}, \quad t \in [0,2]\,.
\end{aligned}
$$

The above system is fully noncommutative, i.e., $[F, G_1]$, $[F, G_2]$, $[G_1, G_2]$ are all nonzero, where $[A, B] = AB - BA$ for matrices A, B. Here we cannot use an explicit formula for the solution of the system; thus we have computed a "reference solution" with the trapezoidal rule on a very fine grid by using 262144 steps.

Results for another example, a scalar SDE with polynomial drift and diffusion coefficients, are reported in [6].

In our experiments we have investigated the relation between step size h and achieved accuracy for several choices of parameters for the two test examples. The accuracy is measured as the maximum approximate L_2-norm of the global errors in the time interval $[0, 1]$ and $[0, 2]$, respectively:

$$
\max_{\ell=1,\dots,N}\left(\frac{1}{M}\sum_{j=1}^{M}|X(t_\ell,\omega_j) - X_\ell(\omega_j)|^2\right)^{1/2} \approx \max_{\ell=1,\dots,N}\|X(t_\ell) - X_\ell\|_{L_2},
$$

where N denotes the number of steps and M the number of computed paths. In our computations we used $M = 100$, unless specified otherwise.

The results are presented as figures, where we have plotted the achieved accuracy versus the step sizes in logarithmic scale with base 10. Then the slope of the resulting lines corresponds to the observed order of the schemes. Lines with slopes 0.5, 1, 2, 3 are provided in some figures to enable comparisons with convergence of these orders.

Our first test concerned the effect of applying a method which is not numerically stable in the mean-square sense, i.e., the coefficients of the method do not satisfy Dahlquist's root condition. For the method considered (the parameters are given in the first row of Table 5.1), one of the roots of the characteristic polynomial ρ (2.12) is 2. Figure 1 shows the behavior of the error of this method applied to the SDE (5.1) with $\alpha = -1$, $\beta = 0.01$, when the step size decreases. We note that the scale is logarithmic!

Next we report results for the other methods listed in Table 5.1, applied to the simple linear SDE (5.1). To start off the integration with the two-step schemes we needed a second starting value X_1. In this example we used the exact solution value $X(t_1)$, thus avoiding introducing additional errors. In computational practice, the starting value X_1 could be computed, e.g., by means of the trapezoidal rule. Then the error structure of the two-step Maruyama schemes is maintained. For reasons of space restriction we present only results for one set of parameters, $\alpha = -1$ and $\beta = 0.01$, where β takes the role of the parameter ϵ. The results are given in Figure 2 and illustrate the observations made in Remark 4.5 very well. We see that the error of the other schemes is smaller than that of the Euler schemes. Their error appears to be of the size $\max(c_1\beta^2 h^{\frac{1}{2}}, c_2\beta h, c_3 h^2)$, c_3 being an error constant particular to the scheme. The constants c_1, c_2 appear to coincide for the considered schemes.

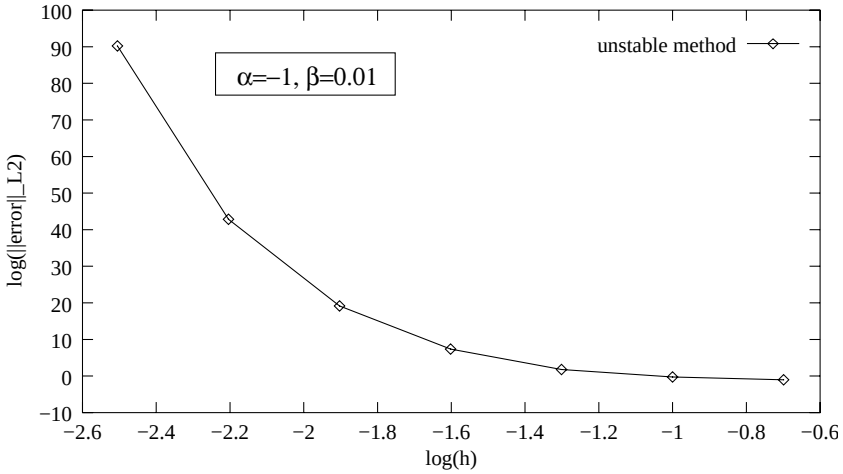

FIG. 1. *Simulation results for the SDE* (5.1) *with the unstable scheme.*

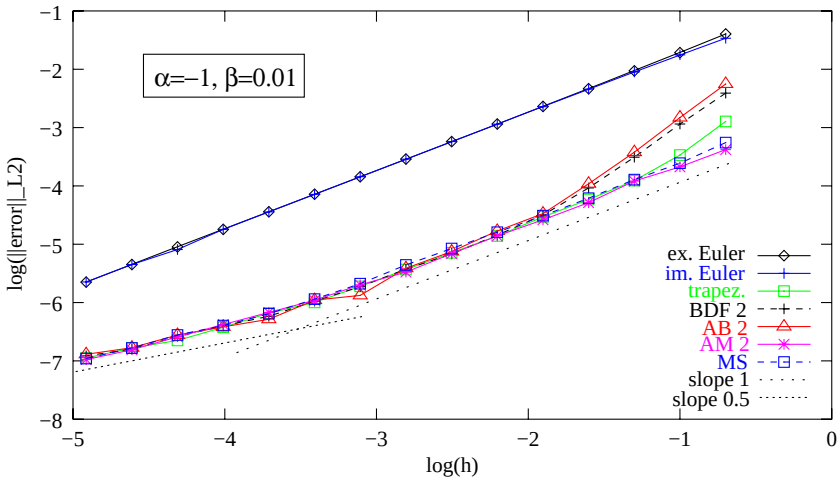

FIG. 2. *Simulation results for the SDE* (5.1) *with the stable schemes of Table* 5.1.

Results of experiments with several methods of Table 5.1 applied to the second example (5.2) are presented in Figures 3 to 5. The second starting value X_1 has been taken as the corresponding value of the reference solution, which amounts to a computation by the trapezoidal rule with very small step sizes. In Figures 3 and 4 we show simulation results with the parameter $\epsilon = 10^{-4}, 10^{-2}$. Again we have plotted the achieved accuracy versus the step size in logarithmic scale. The results are qualitatively the same as for the simple example above. The error of the Euler schemes is larger than that of the other schemes and the error of the schemes with deterministic order 2 (trapezoidal rule, Adams–Bashforth2 and BDF2) appears to be of the size $\max(c_1\beta^2 h^{\frac{1}{2}}, c_2\beta h, c_3 h^2)$, whereas for the Adams–Moulton2 with deterministic order 3 one even observes errors of the size $\max(c_1\beta^2 h^{\frac{1}{2}}, c_2\beta h, c_4 h^3)$.

Figure 5 relates to the case where the parameter in the diffusion coefficient is not small. Here the order $h^{1/2}$ term dominates the error for all chosen step sizes.

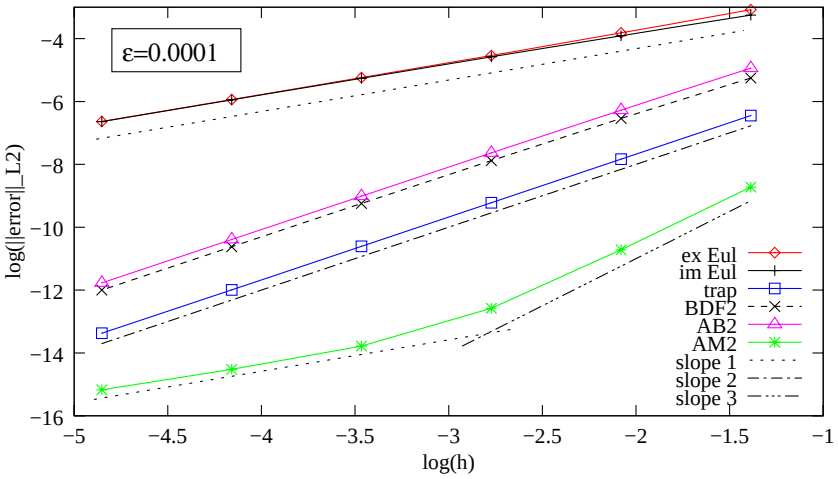

FIG. 3. *Simulation results for the SDE* (5.2), $\epsilon = 10^{-4}$, *with schemes of Table* 5.1.

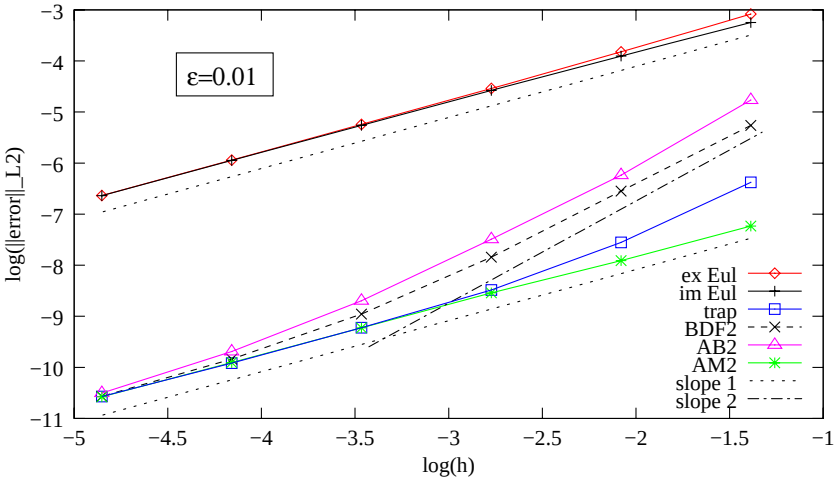

FIG. 4. *Simulation results for the SDE* (5.2), $\epsilon = 10^{-2}$, *with schemes of Table* 5.1.

Furthermore, due to the larger noise the statistical error in the approximation is more visible, which we partly compensated by using 500 paths instead of only 100. In this case one can clearly see that the Euler schemes perform as well as the other schemes and investing the higher effort for the two-step schemes does not pay.

Appendix A. Proof of Theorem 3.2.

Proof. **Necessity:** This part can be proved as in the deterministic case, i.e., we take the equation $X'(t) = 0$, then f and Γ_j satisfy obviously (2.9) and (2.10). We then follow in principle the proof of [15, Thm. 6.3.3].

Sufficiency: Since the SLMM (2.1) contains the stochastic part related to the Γ_j, we cannot rely on the theory of difference equations and the representations of their solutions. Instead, we will follow the route of rewriting the k-step recurrence equation as a one-step recurrence equation in a higher dimensional space (see, e.g., [16, Chap. III.4][26, Chap. 8.2.1]).

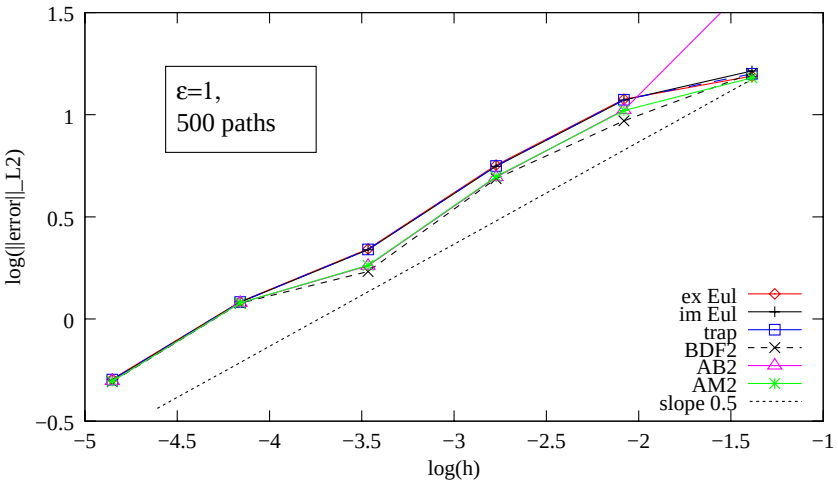

FIG. 5. *Simulation results for the SDE* (5.2), $\epsilon = 1$, *with schemes of Table* 5.1.

For X_ℓ and $\tilde{X}_\ell$ being the solutions of (2.1) and (2.4), respectively, let the n-dimensional vector E_ℓ be defined as the difference $X_\ell - \tilde{X}_\ell$. We have with $E_0, \dots, E_{k-1} \in L_2(\Omega, \mathbb{R}^n)$ for $\ell = k, \dots, N$, the recursion

$$E_\ell = -\sum_{j=1}^{k} \alpha_j \; E_{\ell-j} + \underbrace{h \sum_{j=0}^{k} \beta_j \; \Delta f_{\ell-j}}_{=:\Delta\phi^\ell} + \underbrace{\sum_{j=1}^{k} \Delta\Gamma_{j,\ell-j} \; I^{t_{\ell-j},t_{\ell-j+1}}}_{=:\Delta\psi^\ell} - D_\ell, \tag{A.1}$$

where

$$\Delta f_{\ell-j} := f(X_{\ell-j}, t_{\ell-j}) - f(\tilde{X}_{\ell-j}, t_{\ell-j})$$
$$\Delta\Gamma_{j,\ell-j} := \Gamma_j(X_{\ell-j}, t_{\ell-j}) - \Gamma_j(\tilde{X}_{\ell-j}, t_{\ell-j}).$$

We rearrange this k-step recursion in the space $L_2(\Omega, \mathbb{R}^n)$ to a one-step recursion in $L_2(\Omega, \mathbb{R}^{k\times n})$. Together with the trivial identities $E_{\ell-1} = E_{\ell-1}, \; \dots \; E_{\ell-k+1} = E_{\ell-k+1}$ we obtain

$$\underbrace{\begin{pmatrix} E_\ell \\ E_{\ell-1} \\ \vdots \\ E_{\ell-k+1} \end{pmatrix}}_{=:\,\mathcal{E}_\ell} = \underbrace{\begin{pmatrix} -\alpha_1 I & \cdots & \cdots & -\alpha_k I \\ I & 0 & & \\ & \ddots & \ddots & \\ & & I & 0 \end{pmatrix}}_{=:\,\mathcal{A}} \underbrace{\begin{pmatrix} E_{\ell-1} \\ E_{\ell-2} \\ \vdots \\ E_{\ell-k} \end{pmatrix}}_{=:\,\mathcal{E}_{\ell-1}} + \underbrace{\begin{pmatrix} \Delta\phi^\ell \\ 0 \\ \vdots \\ 0 \end{pmatrix}}_{=:\,\Delta\Phi_\ell} + \underbrace{\begin{pmatrix} \Delta\psi^\ell \\ 0 \\ \vdots \\ 0 \end{pmatrix}}_{=:\,\Delta\Psi_\ell} + \underbrace{\begin{pmatrix} -D_\ell \\ 0 \\ \vdots \\ 0 \end{pmatrix}}_{=:\,\mathcal{D}_\ell}$$

or, in compact form,

$$\mathcal{E}_\ell = \mathcal{A}\mathcal{E}_{\ell-1} + \Delta\Phi_\ell + \Delta\Psi_\ell + \mathcal{D}_\ell \;, \; \ell = k, \dots, N \text{ and } \mathcal{E}_{k-1} = (-D_{k-1}, -D_{k-2}, \dots, -D_0)^T,$$

where $\mathcal{E}_\ell \in L_2(\Omega, \mathbb{R}^{k\times n}), \; \ell = k-1, k, \dots, N$. The vector $\mathcal{E}_{k-1}$ consists of the perturbations to the initial values. We now trace back the recursion in $\mathcal{E}_\ell$ to the initial

vector $\mathcal{E}_{k-1}$. For $\ell = k, \dots, N$ we have

$$\begin{aligned}
\mathcal{E}_\ell &= \mathcal{A}\mathcal{E}_{\ell-1} + \Delta\Phi_\ell + \Delta\Psi_\ell + \mathcal{D}_\ell \\
&= \mathcal{A}(\mathcal{A}\mathcal{E}_{\ell-2} + \Delta\Phi_{\ell-1} + \Delta\Psi_{\ell-1} + \mathcal{D}_{\ell-1}) + \Delta\Phi_\ell + \Delta\Psi_\ell + \mathcal{D}_\ell \\
&= \mathcal{A}^2\mathcal{E}_{\ell-2} + (\Delta\Phi_\ell + \mathcal{A}\Delta\Phi_{\ell-1}) + (\Delta\Psi_\ell + \mathcal{A}\Delta\Psi_{\ell-1}) + (\mathcal{D}_\ell + \mathcal{A}\mathcal{D}_{\ell-1}) \\
&\;\;\vdots \\
&= \mathcal{A}^{\ell-k+1}\mathcal{E}_{k-1} + \sum_{i=0}^{\ell-k} \mathcal{A}^i \Delta\Phi_{\ell-i} + \sum_{i=0}^{\ell-k} \mathcal{A}^i \Delta\Psi_{\ell-i} + \sum_{i=0}^{\ell-k} \mathcal{A}^i \mathcal{D}_{\ell-i} \\
&= \mathcal{A}^{\ell-k+1}\mathcal{E}_{k-1} + \sum_{i=k}^{\ell} \mathcal{A}^{\ell-i} \Delta\Phi_i + \sum_{i=k}^{\ell} \mathcal{A}^{\ell-i} \Delta\Psi_i + \sum_{i=k}^{\ell} \mathcal{A}^{\ell-i} \mathcal{D}_i \,.
\end{aligned}$$

A crucial point for the subsequent calculations is to find a scalar product inducing a matrix norm such that this norm of the matrix $\mathcal{A}$ is less than or equal to 1 (see, e.g., [16, Chap. III.4, Lemma 4.4]. This is possible if the eigenvalues of the Frobenius matrix $\mathcal{A}$ lie inside the unit circle of the complex plane and are simple if their modulus is equal to 1. The eigenvalues of $\mathcal{A}$ are the roots of the characteristic polynomial ρ (2.12) and due to the assumption that Dahlquist's root condition is satisfied they have the required property. Then there exists a nonsingular matrix $\mathcal{C}$ with a block structure like $\mathcal{A}$ such that $\|\mathcal{C}^{-1}\mathcal{A}\mathcal{C}\|_2 \le 1$, where $\|\cdot\|_2$ denotes the spectral matrix norm that is induced by the Euclidian vector norm in $\mathbb{R}^{k\times n}$. We can thus choose a scalar product for $\mathcal{X}, \mathcal{Y} \in \mathbb{R}^{k\times n}$ as

$$\langle \mathcal{X}, \mathcal{Y} \rangle_* := \langle \mathcal{C}^{-1}\mathcal{X}, \mathcal{C}^{-1}\mathcal{Y} \rangle_2$$

and then have $|.|_*$ as the induced vector norm on $\mathbb{R}^{k\times n}$ and $\|\cdot\|_*$ as the induced matrix norm with $\|\mathcal{A}\|_* = \|\mathcal{C}^{-1}\mathcal{A}\mathcal{C}\|_2 \le 1$. We also have

$$\langle \mathcal{X}, \mathcal{Y} \rangle_* = \mathcal{X}^T \mathcal{C}^{-T}\mathcal{C}^{-1}\mathcal{Y} = \mathcal{X}^T \mathcal{C}^* \mathcal{Y} \quad \text{with} \quad \mathcal{C}^* = \mathcal{C}^{-T}\mathcal{C}^{-1} = (c^*_{ij} I_n)_{i,j=1,\dots,k}.$$

Due to the norm equivalence there are constants $c^*, c_* > 0$ such that

$$|\mathcal{X}|_2^2 \le c^* |\mathcal{X}|_*^2 \quad \text{and} \quad |\mathcal{X}|_*^2 \le c_* |\mathcal{X}|_\infty^2 \quad \forall \mathcal{X} \in \mathbb{R}^{k\times n} \,,$$

where $|\mathcal{X}|_2^2 = \sum_{j=1,\dots,k} |x_j|^2$, $|\mathcal{X}|_\infty = \max_{j=1,\dots,k} |x_j|$ for $\mathcal{X} = (x_1^T, \dots, x_k^T)^T$. For the special vectors $\mathcal{X} = (x^T, 0, \dots, 0)^T$ and $\mathcal{Y} = (y^T, 0, \dots, 0)^T$ with $\mathcal{X}, \mathcal{Y} \in \mathbb{R}^{k\times n}$ and $x, y \in \mathbb{R}^n$, one has $\langle \mathcal{X}, \mathcal{Y} \rangle_* = c^*_{11} \langle x, y \rangle_2 = c^*_{11} x^T y$, where c^*_{11} is given by the matrix $\mathcal{C}^*$.

We now apply $|.|_*^2$ to estimate $|\mathcal{E}_\ell|_*^2$ and, later, $\mathbb{E}|\mathcal{E}_\ell|_*^2$. We start with

$$|\mathcal{E}_\ell|_*^2 \le 4 \left\{ \underbrace{|\mathcal{A}^{\ell-k+1}\mathcal{E}_{k-1}|_*^2}_{(1)} + \underbrace{|\sum_{i=k}^{\ell} \mathcal{A}^{\ell-i}\Delta\Phi_i|_*^2}_{(2)} + \underbrace{|\sum_{i=k}^{\ell} \mathcal{A}^{\ell-i}\Delta\Psi_i|_*^2}_{(3)} + \underbrace{|\sum_{i=k}^{\ell} \mathcal{A}^{\ell-i}\mathcal{D}_i|_*^2}_{(4)} \right\}.$$

For the term labeled (1) we have $|\mathcal{A}^{\ell-k+1}\mathcal{E}_{k-1}|_*^2 \le |\mathcal{E}_{k-1}|_*^2$, and thus

$$\mathbb{E}|\mathcal{A}^{\ell-k+1}\mathcal{E}_{k-1}|_*^2 \le \mathbb{E}|\mathcal{E}_{k-1}|_*^2 \,. \tag{A.2}$$

For the term labeled (2) we have

$$\left|\sum_{i=k}^{\ell}\mathcal{A}^{\ell-i}\Delta\Phi_i\right|_*^2 \le (\ell-k+1)\sum_{i=k}^{\ell}|\mathcal{A}^{\ell-i}\Delta\Phi_i|_*^2 \;\le\; N\sum_{i=k}^{\ell}|\Delta\Phi_i|_*^2 = \frac{T}{h}c_{11}^*\sum_{i=k}^{\ell}|\Delta\phi^i|^2$$
$$\le h\ T\ c_{11}^*\ (k{+}1)\sum_{i=k}^{\ell}\sum_{j=0}^{k}|\beta_j\ \Delta f_{i-j}|^2 \le h\ T\ c_{11}^*\ (k{+}1)\ L_f^2\sum_{i=k}^{\ell}\sum_{j=0}^{k}\beta_j^2\ |E_{i-j}|^2$$
$$\le h\ T\ c_{11}^*\ (k{+}1)\ L_f^2\left\{\beta_0^2\ |E_\ell|^2+\sum_{i=k}^{\ell}\left\{\beta_0^2\ |E_{i-1}|^2+\sum_{j=1}^{k}\beta_j^2\ |E_{i-j}|^2\right\}\right\}$$
$$\le h\ T\ c_{11}^*\ (k{+}1)\ L_f^2\left\{c^*\ \beta_0^2\ |\mathcal{E}_\ell|_*^2+C_\beta\ c^*\sum_{i=k-1}^{\ell-1}|\mathcal{E}_i|_*^2\right\},$$

where $C_\beta = 2\ \max_{j=0,\dots,k}\beta_j$. Hence,

$$\text{(A.3)}\quad \mathbb{E}|\sum_{i=k}^{\ell}\mathcal{A}^{\ell-i}\Delta\Phi_i|_*^2 \le h\ T\ c_{11}^*\ (k{+}1)\ L_f^2\ \left\{c^*\ \beta_0^2\ \mathbb{E}|\mathcal{E}_\ell|_*^2+C_\beta\ c^*\sum_{i=k-1}^{\ell-1}\mathbb{E}|\mathcal{E}_i|_*^2\right\}.$$

We will now treat the term labeled (3). For that purpose we introduce the notation $\Delta\Psi_{j,i-j} := ((\Delta\Gamma_{j,i-j}I^{t_{i-j},t_{i-j+1}})^T,0,\dots,0)^T$. Using this we can write

$$\Delta\Psi_i = ((\Delta\psi^i)^T,0,\dots,0)^T = \left(\left(\sum_{j=1}^{k}\Delta\Gamma_{j,i-j}\ I^{t_{i-j},t_{i-j+1}}\right)^T,0,\dots,0\right)^T = \sum_{j=1}^{k}\Delta\Psi_{j,i-j}$$

and

$$\left|\sum_{i=k}^{\ell}\mathcal{A}^{\ell-i}\Delta\Psi_i\right|_*^2 \;=\; \left|\sum_{i=k}^{\ell}\mathcal{A}^{\ell-i}\sum_{j=1}^{k}\Delta\Psi_{j,i-j}\right|_*^2.$$

Every $\Delta\Psi_{j,i-j}$ is $\mathcal{F}_{t_{i-j+1}}$-measurable and $\mathbb{E}(\Delta\Psi_{j,i-j}|\mathcal{F}_{t_{i-j}}) = 0$. We can now reorder the last term above such that we have a sum of terms where each term contains all multiple Wiener integrals over just one subinterval. The expectation of

products of terms from different subintervals vanishes; hence we obtain

$$
\begin{aligned}
&\mathbb{E}\left|\sum_{i=k}^{\ell}\mathcal{A}^{\ell-i}\Delta\Psi_i\right|_*^2\\
&=\mathbb{E}|\mathcal{A}^{\ell-k}\Delta\Psi_{k,0}|_*^2\\
&\quad+\mathbb{E}|\mathcal{A}^{\ell-k-1}\Delta\Psi_{k,1}+\mathcal{A}^{\ell-k}\Delta\Psi_{k-1,1}|_*^2\\
&\quad\vdots\\
&\quad\quad+\mathbb{E}|\mathcal{A}^{\ell-2k+1}\Delta\Psi_{k,k-1}+\mathcal{A}^{\ell-2k+2}\Delta\Psi_{k-1,k-1}+\ldots+\mathcal{A}^{\ell-k}\Delta\Psi_{1,k-1}|_*^2\\
&\quad\quad\vdots\\
&\quad\quad+\mathbb{E}|\mathcal{A}^{0}\Delta\Psi_{k,\ell-k}+\mathcal{A}^{1}\Delta\Psi_{k-1,\ell-k}+\ldots+\mathcal{A}^{k-1}\Delta\Psi_{1,\ell-k}|_*^2\\
&\quad\vdots\\
&\quad+\mathbb{E}|\mathcal{A}^{0}\Delta\Psi_{2,\ell-2}+\mathcal{A}^{1}\Delta\Psi_{1,\ell-2}|_*^2\\
&\quad+\mathbb{E}|\mathcal{A}^{0}\Delta\Psi_{1,\ell-1}|_*^2\\
&\le k\sum_{i=k}^{\ell}\sum_{j=1}^{k}\mathbb{E}|\Delta\Psi_{j,i-j}|_*^2 \qquad \le k\ c_{11}^*\sum_{i=k}^{\ell}\sum_{j=1}^{k}\mathbb{E}\|\Delta\Gamma_{j,i-j}\|^2\ \mathbb{E}|I^{t_{i-j},t_{i-j+1}}|^2\\
&\le h\ k\ c_{11}^*\ L_\Gamma^2\sum_{i=k}^{\ell}\sum_{j=1}^{k}\mathbb{E}|E_{i-j}|^2 \ \le\ h\ k\ c_{11}^*\ L_\Gamma^2\ c^*\sum_{i=k}^{\ell}|\mathcal{E}_{i-1}|_*^2.
\end{aligned}
$$

Thus, for the term labeled (3), we obtain

$$
\mathbb{E}|\sum_{i=k}^{\ell}\mathcal{A}^{\ell-i}\Delta\Psi_i|_*^2\le\ h\ k\ c_{11}^*\ L_\Gamma^2\ c^*\sum_{i=k-1}^{\ell-1}|\mathcal{E}_i|_*^2. \tag{A.4}
$$

We will, for a shorter notation, deal with the term labeled (4), i.e., the perturbations D_i in $\mathcal{D}_i$, after obtaining an intermediate result. Using (A.2), (A.3), and (A.4), and setting $L_0:=L_f^2\ (k+1)\ c_{11}^*\ T\ c^*\ \beta_0^2$ and $L:=L_f^2\ (k+1)\ c_{11}^*\ T\ c_\beta^*\ +\ L_\Gamma^2\ k\ c_{11}^*\ c^*$, we have now arrived at

$$
\mathbb{E}|\mathcal{E}_\ell|_*^2\le 4\left\{\mathbb{E}|\mathcal{E}_{k-1}|_*^2+hL_0\mathbb{E}|\mathcal{E}_\ell|^2+hL\sum_{i=k-1}^{\ell-1}\mathbb{E}|\mathcal{E}_i|_*^2+\mathbb{E}|\sum_{i=k}^{\ell}\mathcal{A}^{\ell-i}\mathcal{D}_i|_*^2\right\},\ \ell=k,\ldots,N.
$$

If necessary, we choose a bound h^0 on the step size such that $4\ h\ L_0<\frac{1}{2}$ holds for all $h<h^0$ and conclude that

$$
\mathbb{E}|\mathcal{E}_\ell|_*^2\le 8\ \mathbb{E}|\mathcal{E}_{k-1}|_*^2+8\ \mathbb{E}\left|\sum_{i=k}^{\ell}\mathcal{A}^{\ell-i}\mathcal{D}_i\right|_*^2+8\ L\ T\ \frac{1}{N}\sum_{i=k-1}^{\ell-1}\mathbb{E}|\mathcal{E}_i|_*^2.
$$

We now apply Lemma 2.11 with $a_\ell:=0,\ \ell=1,\ldots,k-2$, and $a_\ell:=\mathbb{E}|\mathcal{E}_\ell|_*^2,\ \ell=k-1,\ldots,N$, and obtain the intermediate result

$$
\max_{\ell=k-1,\ldots,N}\mathbb{E}|\mathcal{E}_\ell|_*^2\le\hat{S}\left\{\mathbb{E}|\mathcal{E}_{k-1}|_*^2+\max_{\ell=k,\ldots,N}\mathbb{E}\left|\sum_{i=k}^{\ell}\mathcal{A}^{\ell-i}\mathcal{D}_i\right|_*^2\right\},\ \hat{S}:=8\exp(8LT)\ . \tag{A.5}
$$

It remains to deal with the term labeled (4), i.e., the perturbations D_i in $\mathcal{D}_i$. We decompose D_i, and, analogously, $\mathcal{D}_i$, into $D_i = R_i + S_i = R_i + \sum_{j=1}^{k} S_{j,i-j+1}$, $\mathcal{D}_i = \mathcal{R}_i + \mathcal{S}_i = \mathcal{R}_i + \sum_{j=1}^{k} \mathcal{S}_{j,i-j+1}$, where $S_{j,i-j+1}$ is $\mathcal{F}_{t_{i-j+1}}$-measurable with $\mathbb{E}(S_{j,i-j+1}|\mathcal{F}_{t_{i-j}}) = 0$ for $i = k, \dots, N$ and $j = 1, \dots, k$. Then $\mathbb{E}\langle \mathcal{A}^{\ell_1}\mathcal{S}_{j_1,i_1}, \mathcal{A}^{\ell_2}\mathcal{S}_{j_2,i_2}\rangle_* = 0$ for $i_1 \neq i_2$, and by similar computations as above, we obtain

$$\mathbb{E}\left|\sum_{i=k}^{\ell} \mathcal{A}^{\ell-i}\mathcal{D}_i\right|_*^2 \leq 2\,(\ell-k+1)\sum_{i=k}^{\ell}\mathbb{E}|\mathcal{A}^{\ell-i}\mathcal{R}_i|_*^2 + 2\,k\,\sum_{i=k}^{\ell}\sum_{j=1}^{k}\mathbb{E}|\mathcal{A}^{\ell-i}\mathcal{S}_{j,i-j+1}|_*^2$$
$$\leq 2\sum_{i=k}^{\ell}\left(\frac{T}{h}\,\mathbb{E}|\mathcal{R}_i|_*^2 + k\sum_{j=1}^{k}\mathbb{E}|\mathcal{S}_{j,i-j+1}|_*^2\right).$$

Inserting this into the intermediate result (A.5) we obtain

$$\max_{\ell=k-1,\dots,N}\mathbb{E}|\mathcal{E}_\ell|_*^2 \leq \hat{S}\left\{\mathbb{E}|\mathcal{E}_{k-1}|_*^2 + 2\sum_{i=k}^{\ell}\left(\frac{T}{h}\,\mathbb{E}|\mathcal{R}_i|_*^2 + k\sum_{j=1}^{k}\mathbb{E}|\mathcal{S}_{j,i-j+1}|_*^2\right)\right\},$$

and

$$\max_{\ell=k-1,\dots,N}\mathbb{E}|E_\ell|^2 \leq c^*\hat{S}\left\{c_*\max_{\ell=0,\dots,k-1}\mathbb{E}|E_\ell|^2 + 2\,c_{11}^*\max_{\ell=k,\dots,N}\left(\frac{T^2}{h^2}\mathbb{E}|R_\ell|^2 + \frac{kT}{h}\sum_{j=1}^{k}\mathbb{E}|S_{j,\ell-j+1}|^2\right)\right\}.$$

Taking the square root yields the final estimate

$$\max_{\ell=k-1,\dots,N}\|E_\ell\|_{L_2}$$
$$\leq \sqrt{c^*\hat{S}}\left\{\sqrt{c_*}\max_{\ell=0,\dots,k-1}\|E_\ell\|_{L_2} + \sqrt{2c_{11}^*}\max_{\ell=1,\dots,N}\left(\frac{T}{h}\|R_\ell\|_{L_2} + \sqrt{\frac{kT}{h}\sum_{j=1}^{k}\|S_{j,\ell-j+1}\|_{L_2}^2}\right)\right\}$$
$$\leq S\left\{\max_{\ell=0,\dots,k-1}\|E_\ell\|_{L_2} + \max_{\ell=1,\dots,N}\left(\frac{\|R_\ell\|_{L_2}}{h} + \frac{\sqrt{\sum_{j=1}^{k}\|S_{j,\ell-j+1}\|_{L_2}^2}}{\sqrt{h}}\right)\right\},$$

which completes the proof. □

ON A LINEARIZED BACKWARD EULER METHOD FOR THE EQUATIONS OF MOTION OF OLDROYD FLUIDS OF ORDER ONE*

AMIYA K. PANI†, JIN YUN YUAN‡, AND PEDRO D. DAMÁZIO‡§

Abstract. In this paper, a linearized backward Euler method is discussed for the equations of motion arising in the Oldroyd model of viscoelastic fluids. Some new a priori bounds are obtained for the solution under realistically assumed conditions on the data. Further, the exponential decay properties for the exact as well as the discrete solutions are established. Finally, a priori error estimates in $\mathbf{H}^1$ and $\mathbf{L}^2$-norms are derived for the the discrete problem which are valid uniformly for all time $t > 0$.

Key words. viscoelastic fluids, Oldroyd model, a priori bounds, exponential decay, linearized backward Euler method, uniform convergence in time

1. Introduction.

The motion of an incompressible fluid in a bounded domain Ω in $\mathbb{R}^2$ is described by the system of partial differential equations

$$\frac{\partial \mathbf{u}}{\partial t} + \mathbf{u} \cdot \nabla \mathbf{u} - \nabla \cdot \boldsymbol{\sigma} + \nabla p = \mathbf{F}(x,t), \quad x \in \Omega, \ t > 0,$$

$$\nabla \cdot \mathbf{u} = 0, \quad x \in \Omega, \ t > 0,$$

with appropriate initial and boundary conditions. Here, $\boldsymbol{\sigma} = (\boldsymbol{\sigma}_{ik})$ denotes the stress tensor with $tr\boldsymbol{\sigma} = 0$, $\mathbf{u}$ represents the velocity vector, p is the pressure of the fluid, and $\mathbf{F}$ is the external force. The defining relation between the stress tensor $\boldsymbol{\sigma}$ and the rate of deformation tensor $\mathbf{D} = (\mathbf{D}_{ik}) = \frac{1}{2}(\mathbf{u}_{ix_k} + \mathbf{u}_{kx_i})$, called the equation of state or sometimes the rheological equation, in fact, establishes the type of fluids under consideration. When $\boldsymbol{\sigma} = 2\nu\mathbf{D}$ (using Newton's law) with ν the kinematic coefficient of viscosity, we obtain Newton's model of incompressible viscous fluid and the corresponding system is widely known as Navier–Stokes equations. This has been a basic model for describing the flow at moderate velocities of the majority of the incompressible viscous fluids encountered in practice. However, there are many fluids with complex microstructure, such as biological fluids, polymeric fluids, suspensions, and liquid crystals, which are used in the current industrial processes and show (nonlinear) viscoelastic behavior that cannot be described by the classical linear viscous Newtonian models. The deparature from the Navier–Stokes behavior manifests itself in a variety of ways, such as non-Newtonian viscosity, stress relaxation, and nonlinear creeping. The model of rate type such as Oldroyd fluids (see [4], [23], [32]) can predict the stress relaxation as well as the retardation of deformation and, therefore,

§Isaac Newton Institute for Mathematical Sciences Preprint Series NI03028-CPD, Cambridge, UK.

have become popular for describing polymeric suspension. In order to model the behavior of a dilute polymer solution in a Newtonian solvent, the extra stress tensor is often split into two components: a viscoelastic one and a purely viscous one. So the Oldroyd fluids of order one as it is known in the Russian literature (see [23], [2], [18]) are described by the defining relation

$$\left(1+\lambda\frac{\partial}{\partial t}\right)\boldsymbol{\sigma}=2\nu\left(1+\kappa\nu^{-1}\frac{\partial}{\partial t}\right)\mathbf{D},$$

where λ, ν, κ are positive constants with $(\nu-\kappa\lambda^{-1})>0$. Here, ν denotes the kinematic viscocity, λ is the relaxation time, and κ represents the retardation time. In the form of an integral equation, we write the above defining relation as

$$\begin{aligned}\boldsymbol{\sigma}(x,t)&=2\kappa\lambda^{-1}\mathbf{D}(x,t)+2\lambda^{-1}(\nu-\kappa\lambda^{-1})\int_0^t\exp(-\lambda^{-1}(t-\tau))\mathbf{D}(x,\tau)\,d\tau\\&\quad+(\boldsymbol{\sigma}(x,0)-2\kappa\lambda^{-1}\mathbf{D}(x,0))\exp(-\lambda^{-1}t).\end{aligned}$$

Now the equation of motion of the Oldroyd fluids of order one can be described most naturally by the system of integrodifferential equations

$$\frac{\partial\mathbf{u}}{\partial t}+\mathbf{u}\cdot\nabla\mathbf{u}-\mu\Delta\mathbf{u}-\int_0^t\beta(t-\tau)\Delta\mathbf{u}(x,\tau)\,d\tau+\nabla p=\mathbf{f},\ \ x\in\Omega,\ t>0, \tag{1.1}$$

and incompressibility condition

$$\nabla\cdot\mathbf{u}=0,\ \ x\in\Omega,\, t>0, \tag{1.2}$$

with initial and boundary conditions

$$\mathbf{u}(x,0)=\mathbf{u}_0,\quad x\in\Omega,\quad\text{and}\quad\mathbf{u}(x,t)=0,\quad x\in\partial\Omega,\quad t\geq 0. \tag{1.3}$$

Here, Ω is a bounded domain in two-dimensional Euclidean space $\mathbb{R}^2$ with smooth boundary $\partial\Omega$, $\mu=\kappa\lambda^{-1}>0$ and the kernel $\beta(t)=\gamma\exp(-\delta t)$, where $\gamma=\lambda^{-1}(\nu-\kappa\lambda^{-1})$ and $\delta=\lambda^{-1}$. For details of the physical background and its mathematical modeling, see [4], [17], [23], [24], and [32].

Throughout this paper, we shall assume that $\mu=1$ and the nonhomogeneous term $\mathbf{f}=0$. In fact, assuming conservative force, the function $\mathbf{f}$ can be absorbed in the pressure term.

As in Temam [28], we recast the above problem (1.1)–(1.3) as an abstract evolution equation in an appropriate function space setting. Let us denote by $H^m(\Omega)$ the standard Hilbert–Sobolev space and by $\|\cdot\|_m$ the norm defined on it. When $m=0$, we call $H^0(\Omega)$ as the space of square integrable functions $L^2(\Omega)$ with the usual norm $\|\cdot\|$ and inner product $(\cdot,\cdot)$. Further, let $H_0^1(\Omega)$ be the completion of $C_0^\infty(\Omega)$ with respect to $H^1(\Omega)$-norm. In fact, the seminorm $\|\nabla\phi\|$ on $H_0^1(\Omega)$ is a norm and is equivalent to H^1-norm. We also use the following function spaces for the vector valued functions.

Define

$$\mathbf{D}(\Omega):=\{\boldsymbol{\phi}\in(C_0^\infty(\Omega))^2:\ \ \nabla\cdot\boldsymbol{\phi}=0\ \text{ in }\Omega\},$$

$$\mathbf{H}:=\text{the closure of }\mathbf{D}(\Omega)\text{ in }\ (L^2(\Omega))^2-\text{space},$$

and

$$\mathbf{V}:=\text{the closure of }\mathbf{D}(\Omega)\text{ in }\ (H_0^1(\Omega))^2-\text{space}.$$

Note that under some smoothness assumptions on the boundary $\partial\Omega$, it is possible to characterize $\mathbf{V}$ as

$$\mathbf{V} := \{\boldsymbol{\phi} \in (H_0^1)^2 : \quad \nabla \cdot \boldsymbol{\phi} = 0 \ \text{ in } \ \Omega\}.$$

The spaces of vector functions are indicated by boldface letters, for instance, $\mathbf{H}_0^1 = (H_0^1(\Omega))^2$. The inner product on $\mathbf{H}_0^1$ is denoted by

$$(\nabla\boldsymbol{\phi}, \nabla\mathbf{w}) = \sum_{i=1}^{2} (\nabla\phi_i, \nabla w_i)$$

and the norm by

$$\|\nabla\boldsymbol{\phi}\| = \left(\sum_{i=1}^{2} \|\nabla\phi_i\|^2\right)^{\frac{1}{2}}.$$

Using the Poincaré inequality, it can be shown that the norm on $\mathbf{H}_0^1$ is equivalent to $\mathbf{H}^1 = (H^1(\Omega))^2$- norm. Let $\mathbf{P}$ denote the orthogonal projection of $\mathbf{L}^2(\Omega)$ $(= (L^2(\Omega))^2)$ onto $\mathbf{H}$. Now the orthogonal complement $\mathbf{V}^\perp$ of $\mathbf{V}$ in $\mathbf{L}^2(\Omega)$ consists of functions $\boldsymbol{\phi}$ such that $\boldsymbol{\phi} = \nabla p$ for some $p \in H^1(\Omega)/\mathbb{R}$. We define the Stokes operator $A\mathbf{v} = -\mathbf{P}\Delta\mathbf{v}, \quad \mathbf{v} \in D(A) = \mathbf{H}^2 \bigcap \mathbf{V}$. The Stokes operator is a closed linear self-adjoint and positive operator on $\mathbf{H}$ with densely defined domain $D(A)$ in $\mathbf{H}$. Note that its inverse is compact in $\mathbf{H}$; see [28]. Moreover, we set the sth power of A as A^s for every $s \in \mathbb{R}$. For $0 \le s \le 2$, $D(A^{s/2})$ is a Hilbert space with the inner product $(A^{s/2}\mathbf{v}, A^{s/2}\mathbf{w})$ and norm $\|A^{s/2}\mathbf{v}\| := (A^{s/2}\mathbf{v}, A^{s/2}\mathbf{v})^{1/2}$. For $\mathbf{v} \in D(A^{s/2}), \ \ 0 \le s \le 2$, we note that $\|\mathbf{v}\|_s$ and $\|A^{s/2}\mathbf{v}\|$ are equivalent. We also define a bilinear operator $B(\mathbf{u}, \mathbf{v}) = \mathbf{P}((\mathbf{u} \cdot \nabla)\mathbf{v}), \ \mathbf{u}, \mathbf{v} \in \mathbf{V}$.

With the notations described above, we now rewrite the problem (1.1)–(1.3) in its abstract form as follows.

Find $\mathbf{u}(t) \in D(A)$ such that for $t \ge 0$

$$\frac{d\mathbf{u}}{dt}(t) + A\mathbf{u}(t) + B(\mathbf{u}(t), \mathbf{u}(t)) + \int_0^t \beta(t-s)A\mathbf{u}(s)\,ds = 0, \quad t > 0, \tag{1.4}$$
$$\mathbf{u}(0) = \mathbf{u}_0.$$

In an Oldroyd fluid, the stresses after instantaneous cessation of the motion decay like $\exp(-\lambda^{-1}t)$, while the velocities of the flow after instantaneous removal of the stresses die out like $\exp(-\kappa^{-1}t)$. Therefore, it is of interest to discuss the exponential decay property of the solution of (1.4), and we derive these results in section 2. For some related studies in the decay of solution of the linear parabolic equations with memory, see [30] and [3].

The main focus of this paper is to discuss the linearized backward Euler method for time discretization of the system of equations (1.4). For the temporal discretization of the above abstract problem (1.4), let k denote the time step and $t_n = nk$. For smooth function ϕ defined on $[0, \infty)$, set $\phi^n = \phi(t_n)$ and $\bar{\partial}_t\phi^n = (\phi^n - \phi^{n-1})/k$. For the integral term, we apply the right rectangle rule as

$$q^n(\phi) = k\sum_{j=1}^{n} \beta_{n-j}\phi^j \approx \int_0^{t_n} \beta(t_n - s)\phi(s)\,ds, \tag{1.5}$$

where $\beta_{n-j} = \beta(t_n - t_j)$.

Now the linearized version of the backward Euler method applied to the problem (1.4) determines a sequence of functions $\{\mathbf{U}^n\}_{n\geq 0} \subset D(A)$ as solutions of

$$\bar{\partial}_t \mathbf{U}^n + A\mathbf{U}^n + B(\mathbf{U}^{n-1}, \mathbf{U}^n) + q^n(A\mathbf{U}) = 0, \quad n > 0, \tag{1.6}$$
$$\mathbf{U}^0 = \mathbf{u}_0.$$

The main objective of this paper is to derive the following result.

THEOREM 1. *Let $\mathbf{u}_0 \in D(A)$ and let $\mathbf{U}^n$ satisfy* (1.6). *Then there is a positive constant C independent of k but that may depend on $\|\mathbf{u}_0\|_2$ and Ω such that for some $k_0 > 0$ with $0 < k < k_0$ and for positive α with $0 < \alpha < \min(\delta, \lambda_1)$*

$$\|\mathbf{u}(t_n) - \mathbf{U}^n\|_1 \leq C(\|\mathbf{u}_0\|_2) e^{-\alpha t_n} k \left(t_n^{-1/2} + \log \frac{1}{k} \right),$$

where λ_1 is the least eigenvalue of the Stokes operator A.

Once Theorem 1 is proved, the proof of the following theorem becomes routine work. However, we shall indicate only the major steps without proving it in detail in the end of section 3.

THEOREM 2. *Under the assumptions of Theorem* 1, *there is a positive constant C independent of k but that may depend on $\|\mathbf{u}_0\|_2$ and Ω such that for some $k_0 > 0$ with $0 < k < k_0$ and $0 < \alpha < \min(\delta, \lambda_1)$*

$$\|\mathbf{u}(t_n) - \mathbf{U}^n\| \leq C(\|\mathbf{u}_0\|_2) e^{-\alpha t_n} k.$$

Based on the analysis of Ladyzenskaya [20] for the solvability of the Navier–Stokes equations, Oskolkov [24] proved the global existence of unique "almost" classical solutions in finite time interval for the initial and boundary value problem (1.1)–(1.3). The invesigations on solvability were further continued by the coworkers of Oskolkov [19] and Agranovich and Sobolevskii [1] under various sufficient conditions. In these articles, the regularity results are proved which are, in principle, based on some nonlocal compatibility conditions for the data at $t = 0$. Note that these compatibility conditions are either hard to verify or difficult to meet in practice. In case of Navier–Stokes equations, we refer to Heywood and Rannacher [14] for a similar kind of nonlocal conditions. In the present article, we have obtain some new a priori bounds for the solutions of (1.4) under realistically assumed conditions on the initial data. Recently, Sobolevskii [27] discussed the long-time behavior of solution under some stabilizing conditions on the nonhomogeneous forcing function using a combination of energy arguments and semigroup theoretic approach. When the forcing function is zero, we have derived, in sections 2 and 3, the exponential decay properties for the exact solution as well as for the discrete solution using only energy arguments.

For earlier works on the numerical approximations to the solutions of the problem (1.1)–(1.3), see [2] and [5]. While Akhmatov and Oskolkov [2] applied a finite difference scheme to the equation of motion arising in the Oldroyd model, Cannon et al. [5] analyzed a modified nonlinear Galerkin scheme for a periodic problem using spectral Galerkin procedure and discussed the rates of convergence for the semidiscrete approximations. Recently, Pani and Yuan [26] and He et al. [12] applied finite element methods to discretize the spatial variables and derived optimal error estimates for the problems (1.1)–(1.3) without using nonlocal compatibility conditions. In all these pappers [5], [26], [12], only semidiscrete approximations are discussed keeping the time variable continuous. In this article, we have proposed and analyzed a time discretization scheme based on linearized modification of the backward Euler

method. Note that the results on higher order time discretization can easily be proved under the assumption that the exact solutions are sufficiently smooth when t is near 0. These regularity results as we have mentioned earlier entail nonlocal compatibility conditions for the initial data which cannot be verified in practice. Recently, in the context of Oldroyd B fluid, which is a generalization of Oldroyd fluid of order one, a second order Crank–Nicolson scheme [8] is used for the temporal discetization in conjuction with the finite element methods for spatial discretization under regularity requirements on the solutions which cannot be realistically assumed. Therefore, an attempt has been made in this paper to discuss the error estimates for the linearized modified backward Euler scheme (1.6) applied to (1.4) under realistically assumed conditions on the initial data. Finally, in section 4, we conclude with a summary and possible extensions.

The approach of the present article is influenced by the earlier results of Fujita and Mizutani [10], Thomée [29], and references therein on the approximation of semigroups for the parabolic problems; Okamoto [22] on the spatial discretization and Geveci [11] on the time discretization of the Navier–Stokes equations; and Thomée and Zhang [31] for the time discretization of the linear parabolic integrodifferential equations with nonsmooth initial data.

2. Some a priori estimates. For our future use, we make use of the positive definite property (see [21], for a definition) of the kernel β of the integral operator in (1.1). This can be seen as a consequence of the following lemma. For a proof, see Sobolevskii [27, p. 1601] and McLean and Thomeé [21].

LEMMA 3. *For arbitrary $\alpha > 0$, $t^* > 0$, and $\phi \in L^2(0, t^*)$, the following positive definite property holds:*

$$\int_0^{t^*} \left(\int_0^t \exp\left[-\alpha(t-s)\right] \phi(s)\, ds \right) \phi(t)\, dt \geq 0.$$

Since $\beta(t) = \gamma e^{-\delta t}$ with $\gamma > 0$, therefore, the above result is true for $\beta(t)$.

Below, we discuss some a priori bounds for the solution $\mathbf{u}$ of (1.4).

LEMMA 4. *Let $0 < \alpha < \min(\delta, \lambda_1)$ and $\mathbf{u}_0 \in \mathbf{L}^2(\Omega)$. Then, the following estimate holds:*

$$\|\mathbf{u}(t)\| \leq e^{-\alpha t} \|\mathbf{u}_0\|, \ t > 0.$$

Moreover,

$$2\left(1 - \frac{\alpha}{\lambda_1}\right) \int_0^t e^{2\alpha\tau} \|A^{1/2}\mathbf{u}(\tau)\|^2 d\tau \leq \|\mathbf{u}_0\|^2.$$

Proof. Setting $\hat{\mathbf{u}}(t) = e^{\alpha t}\mathbf{u}(t)$ for some $\alpha > 0$, we rewrite (1.4) as

$$\frac{d}{dt}\hat{\mathbf{u}} - \alpha\hat{\mathbf{u}} + e^{-\alpha t} B(\hat{\mathbf{u}}, \hat{\mathbf{u}}) + A\hat{\mathbf{u}} + \int_0^t \beta(t-\tau) e^{\alpha(t-\tau)} A\hat{\mathbf{u}}(\tau)\, d\tau = 0. \tag{2.1}$$

Form L^2-inner product between (2.1) and $\hat{\mathbf{u}}$. Note that $(B(\hat{\mathbf{u}}, \hat{\mathbf{u}}), \hat{\mathbf{u}}) = 0$, $(A\mathbf{u}, \mathbf{v}) = (A^{\frac{1}{2}}\mathbf{u}, A^{1/2}\mathbf{v})$, and $\|\hat{\mathbf{u}}\|^2 \leq \lambda_1^{-1} \|A^{1/2}\hat{\mathbf{u}}\|^2$, where λ_1 is the least eigenvalue of the Stokes operator A. Then

$$\begin{aligned} &\frac{d}{dt}\|\hat{\mathbf{u}}\|^2 + 2\left(1 - \frac{\alpha}{\lambda_1}\right) \|A^{1/2}\hat{\mathbf{u}}\|^2 \\ &\qquad + 2\int_0^t \beta(t-\tau) e^{\alpha(t-\tau)} (A^{1/2}\hat{\mathbf{u}}(\tau), A^{1/2}\hat{\mathbf{u}}(\tau)) d\tau \leq 0. \end{aligned} \tag{2.2}$$

After integrating (2.2) with respect to time, the third term becomes nonnegative, since $\delta > \alpha$, and the second term on the left-hand side of (2.2) is also nonnegative if $\alpha < \lambda_1$. With $0 < \alpha < \min(\delta, \lambda_1)$, we find that

$$\|\hat{\mathbf{u}}\| \le \|\mathbf{u}_0\|.$$

Moreover,

$$2\left(1 - \frac{\alpha}{\lambda_1}\right) \int_0^t e^{2\alpha\tau} \|A^{1/2}\mathbf{u}(\tau)\|^2 d\tau \le \|\mathbf{u}_0\|^2.$$

This completes the rest of the proof. ∎

LEMMA 5. *Under the hypothesis of Lemma* 4*, the solution* $\mathbf{u}$ *of* (1.4) *satisfies*

$$\|A^{1/2}\mathbf{u}(t)\|^2 + e^{-2\alpha t} \int_0^t e^{2\alpha\tau} \|A\mathbf{u}(\tau)\|^2 \, d\tau \le C(\|A^{1/2}u_0\|)e^{-2\alpha t}.$$

Proof. Forming L^2-inner product between (2.1) and $A\hat{\mathbf{u}}$, we obtain

$$(\hat{\mathbf{u}}_t, A\hat{\mathbf{u}}) + \|A\hat{\mathbf{u}}\|^2 + \int_0^t \beta(t-\tau)e^{\alpha(t-\tau)}(A\hat{\mathbf{u}}(\tau), A\hat{\mathbf{u}})\, d\tau = \alpha(\hat{\mathbf{u}}, A\hat{\mathbf{u}}) - e^{-\alpha t}(B(\hat{\mathbf{u}}, \hat{\mathbf{u}}), A\hat{\mathbf{u}}). \tag{2.3}$$

Note that

$$(\hat{\mathbf{u}}_t, A\hat{\mathbf{u}}) = \frac{1}{2}\frac{d}{dt}\|A^{1/2}\hat{\mathbf{u}}\|^2.$$

On integration of (2.3) with respect to time and using Lemma 3 along with the definition of β, it follows for $0 < \alpha \le \delta$ that

$$\begin{aligned} \|A^{1/2}\hat{\mathbf{u}}(t)\|^2 + 2\int_0^t \|A\hat{\mathbf{u}}(\tau)\|^2 \, d\tau &\le \|A^{1/2}\mathbf{u}_0\|^2 + 2\alpha \int_0^t (\hat{\mathbf{u}}, A\hat{\mathbf{u}})\, d\tau \\ &\quad - 2\int_0^t e^{-\alpha\tau}(B(\hat{\mathbf{u}}, \hat{\mathbf{u}}), A\hat{\mathbf{u}})\, d\tau \\ &= \|A^{1/2}\mathbf{u}_0\|^2 + I_1 + I_2. \end{aligned} \tag{2.4}$$

To estimate $|I_1|$, we apply the Poincaré inequality and Cauchy–Schwarz inequality with $ab \le \frac{1}{2\epsilon}a^2 + \frac{\epsilon}{2}b^2$, $a, b \ge 0$, $\epsilon > 0$. Then the use of Lemma 4 yields

$$\begin{aligned} |I_1| &\le C(\alpha, \lambda_1, \epsilon) \int_0^t \|A^{1/2}\hat{\mathbf{u}}(\tau)\|^2 \, d\tau + \epsilon \int_0^t \|A\hat{\mathbf{u}}(\tau)\|^2 \, d\tau \\ &\le C(\alpha, \lambda_1, \epsilon)\|\mathbf{u}_0\|^2 + \epsilon \int_0^t \|A\hat{\mathbf{u}}(\tau)\|^2 \, d\tau. \end{aligned} \tag{2.5}$$

For the estimation of I_2, we apply Hölder's inequality repeatedly with the form of the Sobolev inequality (see Temam [28])

$$\|\boldsymbol{\phi}\|_{L^4(\Omega)} \le C\|\boldsymbol{\phi}\|^{\frac{1}{2}} \, \|A^{1/2}\boldsymbol{\phi}\|^{\frac{1}{2}}, \quad \boldsymbol{\phi} \in \mathbf{H}^1(\Omega),$$

to obtain

$$\begin{aligned} |(B(\hat{\mathbf{u}}, \hat{\mathbf{u}}), A\hat{\mathbf{u}})| &\le \|B(\hat{\mathbf{u}}, \hat{\mathbf{u}})\|\|A\hat{\mathbf{u}}\| \\ &\le C\|\hat{\mathbf{u}}\|^{\frac{1}{2}}\|A^{1/2}\hat{\mathbf{u}}\|\|A\hat{\mathbf{u}}\|^{\frac{3}{2}}. \end{aligned}$$

Thus,

$$|I_2| \le C \int_0^t e^{-\alpha\tau} \|\hat{\mathbf{u}}\|^{\frac{1}{2}} \|A^{1/2}\hat{\mathbf{u}}\| \, \|A\hat{\mathbf{u}}\|^{\frac{3}{2}} \, d\tau.$$

An application of Young's inequality $ab \le \frac{a^p}{\epsilon^{p/q}} + \frac{\epsilon b^q}{q}$, $a, b \ge 0$, $\epsilon > 0$, and $\frac{1}{p} + \frac{1}{q} = 1$ with $p = 4$ and $q = \frac{4}{3}$ yields

$$|I_2| \le C(\epsilon) \int_0^t e^{-4\alpha\tau} \|\hat{\mathbf{u}}\|^2 \|A^{1/2}\hat{\mathbf{u}}\|^4 \, d\tau + \epsilon \int_0^t \|A\hat{\mathbf{u}}\|^2 \, d\tau. \tag{2.6}$$

Substituting (2.5)–(2.6) in (2.4), and using $\epsilon = \frac{1}{2}$, we find that

$$\|A^{1/2}\hat{\mathbf{u}}(t)\|^2 + \int_0^t \|A\hat{\mathbf{u}}(\tau)\|^2 \, d\tau \le C(\alpha, \lambda_1, \|A^{1/2}\mathbf{u}_0\|) + C \int_0^t e^{-4\alpha\tau} \|\hat{\mathbf{u}}\|^2 \|A^{1/2}\hat{\mathbf{u}}\|^4 \, d\tau.$$

An application of Gronwall's lemma yields

$$\|A^{1/2}\hat{\mathbf{u}}(t)\|^2 + \int_0^t \|A\hat{\mathbf{u}}(\tau)\|^2 \, d\tau \le C(\alpha, \lambda_1, \|A^{1/2}\mathbf{u}_0\|) \exp\left\{ C \int_0^t e^{-4\alpha\tau} \|\hat{\mathbf{u}}\|^2 \|A^{1/2}\hat{\mathbf{u}}\|^2 \, d\tau \right\}.$$

Using the a priori bounds in Lemma 4 for $0 < \alpha < \min(\delta, \lambda_1)$, we obtain the desired result. This completes the proof. □

Remark 1. Based on the Faedo–Galerkin method and the a priori bounds derived in the above two lemmas, it is possible to prove the existence of global strong solutions to the problem (1.1)–(1.3). For a similar analysis in the case of Navier–Stokes equations, see Heywood [13], Temam [28], and Ladyzenskaya [20]. Since the analysis is quite standard, we state without proof the global existence theorem [25].

THEOREM 6. *Assume that* $\mathbf{u}_0 \in D(A)$. *Then for any given time* $T > 0$ *with* $0 < T \le \infty$, *there exists a unique strong solution* $\mathbf{u}$ *of* (1.4) *satisfying*

$$\mathbf{u} \in L^2(0, T; D(A)) \cap L^\infty(0, T; \mathbf{V}) \cap H^1(0, T; \mathbf{H}),$$

and the initial condition in the sense that

$$\|A^{1/2}(\mathbf{u}(t) - \mathbf{u}_0)\| \longrightarrow 0, \quad \text{as } t \longrightarrow 0.$$

Recently, Cannon et al. [5] proved existence of a global weak solution $\mathbf{u}$ satisfying

$$\mathbf{u} \in L^\infty(0, T; \mathbf{H}) \cap L^2(0, T; \mathbf{V}), \quad T > 0,$$

for a periodic problem, under the assumption that the forcing function $\mathbf{f} \in L^\infty(0, \infty; \mathbf{L}^2)$ and $\mathbf{u}_0 \in \mathbf{H}$. It is easy to extend our analysis to (1.1)–(1.3) with periodic boundary conditions and $\mathbf{f} = 0$.

Below, we derive some new regularity results without nonlocal assumptions on the data.

LEMMA 7. *Under the assumptions of Lemma* 4, *there is a positive constant* C *such that*

$$\|A\mathbf{u}(t)\| + \|\mathbf{u}_t\| \le C(\|A\mathbf{u}_0\|)e^{-\alpha t}, \quad t > 0, \tag{2.7}$$

and

$$\left(\int_0^t e^{2\alpha s} \|A^{1/2}\mathbf{u}_t(s)\|^2 \, ds \right)^{1/2} \le C(\|A\mathbf{u}_0\|). \tag{2.8}$$

Further, the following estimate holds:

$$\|A^{1/2}\mathbf{u}_t(t)\| + \left(\sigma(t)\int_0^t \sigma(s)\|A\mathbf{u}_t(s)\|^2\,ds\right)^{1/2} \le \frac{C(\|A\mathbf{u}_0\|)}{(\tau^*(t))^{1/2}}e^{-\alpha t}, \quad t>0, \tag{2.9}$$

where $\sigma(t)=\tau^*(t)e^{2\alpha t}$ *and* $\tau^*(t)=\min(t,1)$.

Proof. From (2.1), we obtain

$$e^{\alpha t}\|\mathbf{u}_t\| \le \|A\hat{\mathbf{u}}\| + e^{-\alpha t}\|B(\hat{\mathbf{u}},\hat{\mathbf{u}})\| + \int_0^t \beta(t-s)e^{\alpha(t-s)}\|A\hat{\mathbf{u}}(s)\|\,ds. \tag{2.10}$$

Using the form of B and the Sobolev inequality, it follows that

$$\begin{aligned}\|B(\hat{\mathbf{u}},\hat{\mathbf{u}})\| &\le C\|\hat{\mathbf{u}}\|^{\frac{1}{2}}\|A^{1/2}\hat{\mathbf{u}}\|\|A\hat{\mathbf{u}}\|^{\frac{1}{2}}\\ &\le C\|\hat{\mathbf{u}}\|\|A^{1/2}\hat{\mathbf{u}}\|^2 + C\|A\hat{\mathbf{u}}\|.\end{aligned} \tag{2.11}$$

On squaring (2.10) and integrating with respect to time, we find from (2.11) that

$$\begin{aligned}\int_0^t e^{2\alpha s}\|\mathbf{u}_t\|^2\,ds \le C\Bigg[&\int_0^t \|A\hat{\mathbf{u}}\|^2\,ds + \int_0^t e^{-2\alpha s}\|\hat{\mathbf{u}}\|^2\|A^{1/2}\hat{\mathbf{u}}\|^4\,ds\\ &+ \int_0^t \Big(\int_0^s \beta(s-\tau)e^{\alpha(s-\tau)}\|A\hat{\mathbf{u}}(\tau)\|\,d\tau\Big)^2 ds\Bigg].\end{aligned} \tag{2.12}$$

For the last term on the right-hand side of (2.12), use the form of β and Hölder's inequality to obtain

$$\begin{aligned}I &= \int_0^t \left(\int_0^s \beta(s-\tau)e^{\alpha(s-\tau)}\|A\hat{\mathbf{u}}(\tau)\|\,d\tau\right)^2 ds\\ &= \gamma^2\int_0^t \left(\int_0^s e^{-(\delta-\alpha)(s-\tau)}\|A\hat{\mathbf{u}}(\tau)\|\,d\tau\right)^2 ds\\ &\le \gamma^2\int_0^t \left(\int_0^s e^{-(\delta-\alpha)(s-\tau)}\,d\tau\right)\left(\int_0^s e^{-(\delta-\alpha)(s-\tau)}\|A\hat{\mathbf{u}}(\tau)\|^2\,d\tau\right) ds\\ &\le \frac{\gamma^2}{\delta-\alpha}\int_0^t \left(\int_0^s e^{-(\delta-\alpha)(s-\tau)}\|A\hat{\mathbf{u}}\|^2\,d\tau\right) ds.\end{aligned}$$

Using a change of variable, we find that

$$I \le \frac{\gamma^2}{\delta-\alpha}\int_0^t \left(\int_0^s e^{-(\delta-\alpha)\tau}\|A\hat{\mathbf{u}}(s-\tau)\|^2\,d\tau\right) ds.$$

Now a change in the order of integration yields

$$\begin{aligned}I &\le \frac{\gamma^2}{\delta-\alpha}\int_0^t e^{-(\delta-\alpha)\tau}\left(\int_\tau^t \|A\hat{\mathbf{u}}(s-\tau)\|^2\,ds\right)d\tau\\ &\le \frac{\gamma^2}{(\delta-\alpha)^2}\int_0^t e^{-(\delta-\alpha)(t-\tau)}\left(\int_0^t \|A\hat{\mathbf{u}}\|^2\,ds\right)d\tau,\end{aligned}$$

and hence,

$$I \le \left(\frac{\gamma}{\delta-\alpha}\right)^2\int_0^t \|A\hat{\mathbf{u}}(s)\|^2\,ds. \tag{2.13}$$

Using (2.13) in (2.12), we arrive at

$$\int_0^t e^{2\alpha s}\|\mathbf{u}_t\|^2\,ds \le C\left[\int_0^t \|A\hat{\mathbf{u}}\|^2\,ds + \int_0^t e^{-2\alpha s}\|\hat{\mathbf{u}}\|^2\|A^{1/2}\hat{\mathbf{u}}\|^4\,ds\right] \le C(\|A^{1/2}\mathbf{u}_0\|). \tag{2.14}$$

Differentiate (1.4) with respect to time, and integrate by parts with respect to the temporal variable for the integral term to obtain

$$\mathbf{u}_{tt} + A\mathbf{u}_t + \int_0^t \beta(t-s)A\mathbf{u}_s(s)\,ds = -(B(\mathbf{u}_t,\mathbf{u}) + B(\mathbf{u},\mathbf{u}_t)) - \beta(t)A\mathbf{u}_0. \tag{2.15}$$

Forming an inner product between (2.15) and $e^{2\alpha t}\mathbf{u}_t$, we arrive at

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\|e^{\alpha t}\mathbf{u}_t\|^2 + e^{2\alpha t}\|A^{1/2}\mathbf{u}_t\|^2 + \int_0^t \beta(t-s)e^{\alpha(t-s)}(A^{1/2}e^{\alpha s}\mathbf{u}_s, A^{1/2}e^{\alpha t}\mathbf{u}_t)\,ds\\ &\qquad = \alpha\|e^{\alpha t}\mathbf{u}_t\|^2 - e^{2\alpha t}\left((B(\mathbf{u}_t,\mathbf{u}) + B(\mathbf{u},\mathbf{u}_t),\mathbf{u}_t) - \beta(t)(A\mathbf{u}_0,\mathbf{u}_t)\right).\end{aligned} \tag{2.16}$$

Note that $(B(\hat{\mathbf{u}}, e^{\alpha t}\mathbf{u}_t), e^{\alpha t}\mathbf{u}_t) = 0$. Thus, it follows after integration of (2.16) with respect to time and using the positivity property of the kernel, i.e., Lemma 3 that

$$\begin{aligned}&e^{2\alpha t}\|\mathbf{u}_t\|^2 + 2\int_0^t e^{2\alpha s}\|A^{1/2}\mathbf{u}_t\|^2\,ds \le \|\mathbf{u}_t(0)\|^2 + 2\alpha\int_0^t e^{2\alpha s}\|\mathbf{u}_t\|^2\,ds\\ &\qquad + 2\int_0^t e^{-\alpha s}|B(e^{\alpha s}\hat{\mathbf{u}}_t,\hat{\mathbf{u}}), e^{\alpha s}\mathbf{u}_t)|\,ds + 2\gamma\|A\mathbf{u}_0\|\int_0^t e^{-(\delta-\alpha)s}\|e^{\alpha s}\mathbf{u}_t\|\,ds.\end{aligned} \tag{2.17}$$

The last term on the right-hand side of (2.17) is bounded by

$$\le C(\alpha,\delta,\gamma)\left[\|A\mathbf{u}_0\|^2 + \int_0^t e^{2\alpha s}\|\mathbf{u}_t\|^2\,ds\right]. \tag{2.18}$$

For the second term on the right-hand side of (2.17), we note with the help of Sobolev inequality that

$$\begin{aligned}2\int_0^t e^{-\alpha s}|(B(e^{\alpha s}\hat{\mathbf{u}}_t,\hat{\mathbf{u}}), e^{\alpha s}\mathbf{u}_t)|\,ds &\le C\sup_{0\le s\le t}\|A^{1/2}\hat{\mathbf{u}}(s)\|^4\int_0^t e^{-4\alpha s}(e^{2\alpha s}\|\mathbf{u}_t\|^2)\,ds\\ &\quad + \int_0^t e^{2\alpha s}\|A^{1/2}\mathbf{u}_t\|^2\,ds.\end{aligned} \tag{2.19}$$

On substitution of (2.18)–(2.19) in (2.17) and using Lemmas 4 and 5, we obtain

$$\begin{aligned}&e^{2\alpha t}\|\mathbf{u}_t\|^2 + \int_0^t e^{2\alpha s}\|A^{1/2}\mathbf{u}_t\|^2\,ds\\ &\qquad \le C(\delta,\alpha)\left[\|\mathbf{u}_t(0)\|^2 + \|A\mathbf{u}_0\|^2 + \int_0^t e^{2\alpha s}\|\mathbf{u}_t\|^2\,ds\right].\end{aligned} \tag{2.20}$$

From the main equation (1.4), we have at $t = 0$, $\|\mathbf{u}_t(0)\| \le C(\|A\mathbf{u}_0\|)$, and hence, using (2.14) we find that

$$\|\mathbf{u}_t\|^2 + e^{-2\alpha t}\int_0^t e^{2\alpha s}\|A^{1/2}\mathbf{u}_t(s)\|^2\,ds \le C(\|A\mathbf{u}_0\|)e^{-2\alpha t}. \tag{2.21}$$

To estimate $\|A\mathbf{u}(t)\|$, we now form an inner product between (2.1) and $A\hat{\mathbf{u}}(t)$ to obtain

$$\|A\hat{\mathbf{u}}\|^2 \le e^{\alpha t}\|\mathbf{u}_t\|\|A\hat{\mathbf{u}}\| + e^{-\alpha t}|(B(\hat{\mathbf{u}},\hat{\mathbf{u}}),A\hat{\mathbf{u}})| + \alpha\|\hat{\mathbf{u}}\|\|A\hat{\mathbf{u}}\| + \int_0^t \beta(t-s)e^{\alpha(t-s)}\|A\hat{\mathbf{u}}(s)\|\|A\hat{\mathbf{u}}(t)\|\,ds. \tag{2.22}$$

The first three terms on the right-hand side of (2.22) are bounded by

$$\le C(\epsilon)[\|\hat{\mathbf{u}}\|^2 + e^{2\alpha t}\|\mathbf{u}_t\|^2 + e^{-4\alpha t}\|\hat{\mathbf{u}}\|^2\|A^{1/2}\hat{\mathbf{u}}\|^4] + \epsilon\|A\hat{\mathbf{u}}\|^2.$$

For the last term on the right-hand side of (2.22), we have applied the Hölder's inequality with Sobolev inequality. Then the last term is bounded by

$$C(\gamma,\delta,\alpha,\epsilon)\int_0^t e^{2\alpha\tau}\|A\mathbf{u}(\tau)\|^2\,d\tau + \epsilon\|A\hat{\mathbf{u}}\|^2.$$

Note that we have used $e^{-2(\delta-\alpha)(t-s)} \le 1$. On substituting in (2.22), we choose $\epsilon = \frac{1}{4}$. An appeal to Lemmas 4 and 5 with the estimate (2.21) yields

$$\|A\hat{\mathbf{u}}\|^2 \le C(\|A\mathbf{u}_0\|),$$

and thus we complete the proof of (2.7)–(2.8).

In order to derive (2.9), we now differentiate (1.4) with respect to time and then form an inner product with $\sigma(t)A\mathbf{u}_t$, where $\sigma(t) = \tau^*(t)e^{2\alpha t}$, to obtain

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}(\sigma(t)\|A^{1/2}\mathbf{u}_t\|^2) + \sigma(t)\|A\mathbf{u}_t\|^2 &= -\sigma(t)(A\mathbf{u},A\mathbf{u}_t) + \frac{1}{2}\sigma_t\|A^{1/2}\mathbf{u}_t\|^2\\ -\sigma(t)\int_0^t \beta_t(t-s)(A\mathbf{u}(s),A\mathbf{u}_t(t))\,ds &- \tau^*(t)e^{-\alpha t}\big(B(e^{\alpha t}\mathbf{u}_t,\hat{\mathbf{u}})\\ + B(\hat{\mathbf{u}},e^{\alpha t}\mathbf{u}_t),e^{\alpha t}A\mathbf{u}_t\big) &= I_1 + I_2 + I_3 + I_4.\end{aligned} \tag{2.23}$$

For I_1, we use Young's inequality to arrive at

$$|I_1| \le \frac{\gamma^2}{2\epsilon}\tau^*(t)\|A\hat{\mathbf{u}}\|^2 + \frac{\epsilon}{2}\sigma(t)\|A\mathbf{u}_t\|^2. \tag{2.24}$$

Since $\sigma_t = \tau_t^* e^{2\alpha t} + 2\alpha\tau^* e^{2\alpha t}$ with $\tau^*,\ \tau_t^* \le 1$, we obtain

$$|I_2| \le C(\alpha)e^{2\alpha t}\|A^{1/2}\mathbf{u}_t\|^2. \tag{2.25}$$

To estimate I_4, a use of Sobolev inequality with Young's inequality yields

$$|I_4| \le C(\epsilon)e^{2\alpha t}\|A^{1/2}\mathbf{u}_t\|^2(\|A^{1/2}\hat{\mathbf{u}}\|\|A\hat{\mathbf{u}}\| + \|A^{1/2}\hat{\mathbf{u}}\|^2) + \epsilon\sigma(t)\|A\mathbf{u}_t\|^2. \tag{2.26}$$

Since $\beta_t(t-s) = -\frac{1}{\delta}\beta(t-s)$, we obtain a bound for I_3 as

$$|I_3| \le \frac{\gamma^2}{2\epsilon\delta^2}\tau^*\left(\int_0^t e^{-(\delta-\alpha)(t-s)}\|A\hat{\mathbf{u}}(s)\|\,ds\right)^2 + \frac{\epsilon}{2}\sigma(t)\|A\mathbf{u}_t\|^2, \tag{2.27}$$

and hence, integrating with respect to time and using the estimate (2.3) for I term, we find that

$$\begin{aligned}\int_0^t |I_3|\,ds &\le \frac{\gamma^2}{2\epsilon\delta^2}\tau^* I + \frac{\epsilon}{2}\int_0^t \sigma(s)\|A\mathbf{u}_t\|^2\,ds\\ &\le C(\gamma,\delta,\alpha,\epsilon)\tau^*(t)\int_0^t \|A\hat{\mathbf{u}}(s)\|^2\,ds + \frac{\epsilon}{2}\int_0^t \sigma(s)\|A\mathbf{u}_t(s)\|^2\,ds.\end{aligned} \tag{2.28}$$

Multiply (2.23) by 2 and integrate with respect to time. Substitute (2.24)–(2.28) in (2.23). With $\epsilon = \frac{1}{4}$, it now follows that

$$\sigma(t)\|A^{1/2}\mathbf{u}_t\|^2 + \int_0^t \sigma(s)\|A\mathbf{u}_t(s)\|^2\,ds \le C(\gamma,\delta,\alpha)\left[\tau^* \int_0^t \|A\hat{\mathbf{u}}(s)\|^2\,ds + \int_0^t e^{2\alpha s}\|A^{1/2}\mathbf{u}_t\|^2(\|A^{1/2}\hat{\mathbf{u}}\|\|A\hat{\mathbf{u}}\| + \|A^{1/2}\hat{\mathbf{u}}\|^4)\,ds\right] + \int_0^t e^{2\alpha s}\|A^{1/2}\mathbf{u}_t(s)\|^2\,ds. \tag{2.29}$$

Using Lemmas 4 and 5 and the estimates (2.7) and (2.8) in (2.29), we obtain the required result (2.9), and this completes the rest of the proof. □

Remark 2. The estimate for $\|A^{1/2}\mathbf{u}_t\|$ shows the singular behavior near $t = 0$ and also indicates the exponential decay property as $t \longrightarrow \infty$. In Lemma 7, the regularity results are derived without any nonlocal compatibility conditions.

3. Decay properties for the discrete solution and error estimates. In this section, we discuss the decay properties for the solution of the linearized backward Euler method. Finally, we derive a priori bounds for the error in H^1-norm and present briefly the error estimate in L^2-norm.

The right-hand rectangle rule q^n which is used to discretize the integral in (1.4) is positive in the sense that

$$k\sum_{n=1}^{J} q^n(\phi)\phi^n \ge 0 \quad \forall \phi = (\phi^1,\ldots,\phi^J)^T.$$

For a proof, we refer to McLean and Thomée [21, pp. 40–42]. Moreover, the following Lemma is easy to prove using the line of proof of [21].

LEMMA 8. *For any $\alpha \ge 0$, $J > 0$, and sequence $\{\phi^n\}_{n=1}^{\infty}$, the following positivity property holds:*

$$k^2\sum_{n=1}^{J}\left(\sum_{j=1}^{n} e^{-\alpha(t_n - t_j)}\phi^j\right)\phi^n \ge 0.$$

LEMMA 9. *With $0 < \alpha < \min(\delta,\ \lambda_1)$, choose $k_0 > 0$ small so that for $0 < k \le k_0$*

$$(\lambda_1 k + 1) > e^{\alpha k}.$$

Then the discrete solution $\mathbf{U}^J$, $J \ge 1$ of (1.6) is exponentially stable in the following sense:

$$\|\mathbf{U}^J\| + e^{-\alpha t_J}\left(k\sum_{n=1}^{J}\|A^{1/2}\hat{\mathbf{U}}^n\|^2\right)^{1/2} \le C(\lambda_1,\alpha)\,\|\mathbf{U}^0\|e^{-\alpha t_J}, \quad J \ge 1, \tag{3.1}$$

and

$$\|A^{1/2}\mathbf{U}^J\| \le C(\lambda_1,\alpha,\|A^{1/2}\mathbf{U}^0\|)e^{-\alpha t_J}, \quad J \ge 1. \tag{3.2}$$

Proof. Setting $\hat{\mathbf{U}}^n = e^{\alpha t_n}\mathbf{U}^n$, we rewrite (1.6) as

$$e^{\alpha t_n}\bar{\partial}_t\mathbf{U}^n + A\hat{\mathbf{U}}^n + e^{-\alpha t_{n-1}}B(\hat{\mathbf{U}}^{n-1},\hat{\mathbf{U}}^n) + e^{\alpha t_n}q^n(A\mathbf{U}) = 0.$$

Note that

$$e^{\alpha t_n}\bar{\partial}_t \mathbf{U}^n = e^{\alpha k}\bar{\partial}_t \hat{\mathbf{U}}^n - \left(\frac{e^{\alpha k}-1}{k}\right)\hat{\mathbf{U}}^n.$$

On substitution and then multiplying the resulting equation by $e^{-\alpha k}$, we obtain

$$\bar{\partial}_t \hat{\mathbf{U}}^n - \left(\frac{1-e^{-\alpha k}}{k}\right)\hat{\mathbf{U}}^n + e^{-\alpha k}A\hat{\mathbf{U}}^n + e^{-\alpha t_n}B(\hat{\mathbf{U}}^{n-1},\hat{\mathbf{U}}^n) + \gamma e^{-\alpha k}k\sum_{j=1}^{n} e^{-(\delta-\alpha)(t_n-t_j)}A\hat{\mathbf{U}}^j = 0. \tag{3.3}$$

Forming an inner product between (3.3) and $\hat{\mathbf{U}}^n$, use

$$(B(\hat{\mathbf{U}}^{n-1},\hat{\mathbf{U}}^n),\hat{\mathbf{U}}^n) = 0, \quad \|\hat{\mathbf{U}}^n\|^2 \le \frac{1}{\lambda_1}\|A^{1/2}\hat{\mathbf{U}}^n\|^2, \quad \text{and} \quad (\bar{\partial}_t\hat{\mathbf{U}}^n,\hat{\mathbf{U}}^n) \ge \frac{1}{2}\bar{\partial}_t\|\hat{\mathbf{U}}^n\|^2$$

to obtain

$$\frac{1}{2}\bar{\partial}_t\|\hat{\mathbf{U}}^n\|^2 + \left(e^{-\alpha k} - \left(\frac{1-e^{-\alpha k}}{k}\right)\lambda_1^{-1}\right)\|A^{1/2}\hat{\mathbf{U}}^n\|^2 + \gamma e^{-\alpha k}k\sum_{j=1}^{n} e^{-(\delta-\alpha)(t_n-t_j)}(A^{1/2}\hat{\mathbf{U}}^j, A^{1/2}\hat{\mathbf{U}}^n) \le 0. \tag{3.4}$$

With $0<\alpha<\min(\lambda_1,\delta)$, choose $0<k_0$ such that for $0<k<k_0$

$$(\lambda_1 k+1) \ge e^{\alpha k}.$$

Then for $0<k\le k_0$, the coefficient of the second term on the left-hand side of (3.4), $\left(e^{-\alpha k} - (\frac{1-e^{-\alpha k}}{k})\lambda_1^{-1}\right)$, becomes positive. Multiplying (3.4) by $2k$ and summing from $n=1$ to J, the last term becomes nonnegative by Lemma 8 and thus we obtain the estimate (3.1).

For the estimate (3.2), we form an inner product between (3.3) and $A\hat{\mathbf{U}}^n$ and observe that

$$(\bar{\partial}_t\hat{\mathbf{U}}^n, A\hat{\mathbf{U}}^n) = (\bar{\partial}_t A^{1/2}\hat{\mathbf{U}}^n, A^{1/2}\hat{\mathbf{U}}^n) \ge \frac{1}{2}\bar{\partial}_t\|A^{1/2}\hat{\mathbf{U}}^n\|^2.$$

Altogether, we find that

$$\frac{1}{2}\bar{\partial}_t\|A^{1/2}\hat{\mathbf{U}}^n\|^2 + e^{-\alpha k}\|A\hat{\mathbf{U}}^n\|^2 + \gamma e^{-\alpha k}k\sum_{j=1}^{n} e^{-(\delta-\alpha)(t_n-t_j)}(A\hat{\mathbf{U}}^j, A\hat{\mathbf{U}}^n) \le \left(\frac{1-e^{-\alpha k}}{k}\right)(\hat{\mathbf{U}}^n, A\hat{\mathbf{U}}^n) - e^{-\alpha t_n}(B(\hat{\mathbf{U}}^{n-1},\hat{\mathbf{U}}^n), A\hat{\mathbf{U}}^n). \tag{3.5}$$

Multiplying (3.5) by $2k$ and summing from $n=1$ to J, the third term on the left-hand side becomes nonnegative by applying Lemma 8 as $0<\alpha<\delta$. Then, we obtain

$$\begin{aligned}\|A^{1/2}\hat{\mathbf{U}}^J\|^2 + 2ke^{-\alpha k}\sum_{n=1}^{J}\|A\hat{\mathbf{U}}^n\|^2 &\le \|A^{1/2}\mathbf{U}^0\|^2 + 2(1-e^{-\alpha k})k\sum_{n=1}^{J}|(\hat{\mathbf{U}}^n, A\hat{\mathbf{U}}^n)| \\ &\quad + 2e^{-\alpha k}k\sum_{n=1}^{J} e^{-\alpha t_{n-1}}|(B(\hat{\mathbf{U}}^{n-1},\hat{\mathbf{U}}^{n-1}), A\hat{\mathbf{U}}^n)| \\ &\le \|A^{1/2}\mathbf{U}^0\|^2 + I_1 + I_2.\end{aligned} \tag{3.6}$$

To estimate I_1, we have by the mean value theorem $\frac{1-e^{-\alpha k}}{k} = \alpha e^{-\alpha k^*}$ for some $0 < k^* < k$, and hence, using (3.1), we find that

$$|I_1| \le 2\alpha e^{-\alpha k^*} k \sum_{n=1}^{J} \|A^{1/2}\hat{\mathbf{U}}^n\|^2 \le C(\lambda_1, \alpha)\|\mathbf{U}^0\|^2.$$

For I_2, a repeated use of Hölder's inequality with Sobolev inequality yields

$$e^{-\alpha t_{n-1}}|(B(\hat{\mathbf{U}}^{n-1}, \hat{\mathbf{U}}^n), A\hat{\mathbf{U}}^n)| \le Ce^{-\alpha t_{n-1}}\|\hat{\mathbf{U}}^{n-1}\|^{1/2}\|A^{1/2}\hat{\mathbf{U}}^{n-1}\|^{1/2} \|A^{1/2}\hat{\mathbf{U}}^n\|^{1/2}\|A\hat{\mathbf{U}}^n\|^{3/2}.$$

By an application of Young's inequality, it follows that

$$|I_2| \le Cke^{-\alpha k}\sum_{n=1}^{J} e^{-4\alpha t_{n-1}}(\|\hat{\mathbf{U}}^{n-1}\|^2\|A^{1/2}\hat{\mathbf{U}}^{n-1}\|^2)\|A^{1/2}\hat{\mathbf{U}}^n\|^2 + ke^{-\alpha k}\sum_{n=1}^{J}\|A\hat{\mathbf{U}}^n\|^2.$$

Using the estimate $\|\hat{\mathbf{U}}^{n-1}\|$ and

$$k\|A^{1/2}\hat{\mathbf{U}}^{J-1}\|^2 \le k\sum_{n=1}^{J}\|A^{1/2}\hat{\mathbf{U}}^n\|^2,$$

we easily find that from (3.1)

$$|I_2| \le C(\lambda,\alpha)\|\mathbf{U}^0\|^2 ke^{-\alpha k}\sum_{n=1}^{J-1} e^{-4\alpha t_{n-1}}\|A^{1/2}\hat{\mathbf{U}}^{n-1}\|^2\|A^{1/2}\hat{\mathbf{U}}^n\|^2 + C\|\mathbf{U}^0\|^4 e^{-\alpha k}e^{-4\alpha t_{J-1}}\ \|A^{1/2}\hat{\mathbf{U}}^J\|^2 + ke^{-\alpha k}\sum_{n=1}^{J}\|A\hat{\mathbf{U}}^n\|^2.$$

Now substitute the estimates of I_1 and I_2 in (3.6). For small k, we note that $(1 - C\|\mathbf{U}^0\|^4 e^{-4\alpha k})$ can be made positive. Then apply discrete Gronwall's lemma with estimate (3.1) to complete the rest of the proof. ∎

3.1. Error analysis. Now we are ready to discuss the proof of our main result that is the proof of Theorem 1.

Let ε^n be the quadrature error associated with the quadrature rule (1.5) and for $\phi \in C^1[0, t_n]$, let it be given by

$$\varepsilon^n(\phi) := \int_0^{t_n} \beta(t_n - s)\phi(s)\, ds - q^n(\phi).$$

Note that the quadrature error ε^n satisfies

$$|\varepsilon^n(\phi)| \le Ck\int_0^{t_n}\left|\frac{\partial}{\partial s}\left(\beta(t_n - s)\phi(s)\right)\right| ds \le Ck\int_0^{t_n}\left(|\beta_s(t_n - s)|\ |\phi(s)| + |\beta(t_n - s)|\ |\phi_s(s)|\right) ds. \tag{3.7}$$

For the proof of the main Theorem, we appeal to the semigroup theoretic approach; see Thomée [29], Fujita and Kato [9], and Okamoto [22]. It is well known that the Stoke's operator $-A$ generates an analytic semigroup, say, $E(t),\ t>0$ on $\mathbf{H}$; see [28] or [9]. Moreover, the following estimates are also satisfied:

$$\|A^r E(t)\| \le Ct^{-r}e^{-\lambda_1 t}, \quad t>0, \quad r>0, \tag{3.8}$$

and for $r \in (0,1]$, and $\mathbf{v} \in D(A^r)$, the domain of A^r,

$$\|(E(t)-I)\mathbf{v}\| \le C_r t^r \|A^r \mathbf{v}\|, \quad t>0, \tag{3.9}$$

where C_r is a positive constant. For a proof, see [6, p. 383]. Further, we use the discrete semigroup E_k, which is given by

$$E_k = (I+kA)^{-1}.$$

Using spectral representation of A [29], the following estimate is easy to derive:

$$\|A^r E_k^n\| \le Ct_n^{-r}e^{-\lambda_1 t_n}, \quad t_n>0, \quad 0<r\le 1. \tag{3.10}$$

Now, using Duhamel's principle, (1.4) is written in an equivalent form as

$$\mathbf{u}(t) = E(t)\mathbf{u}_0 - \int_0^t E(t-s)\tilde{A}\mathbf{u}(s)\,ds - \int_0^t E(t-s)B(\mathbf{u}(s),\mathbf{u}(s))\,ds,$$

where for simplicity of symbol, we denote

$$\tilde{A}\mathbf{u}(t) = \int_0^t \beta(t-\tau)A\mathbf{u}(\tau)\,d\tau.$$

Similarly, using discrete semigroup $E_k = (I+kA)^{-1}$, we rewrite (1.6) as

$$\mathbf{U}^n = E_k^n\mathbf{u}_0 - \sum_{j=1}^n kE_k^{n-j+1}q^j(A\mathbf{U}) - \sum_{j=1}^n kE_k^{n-j+1}B(\mathbf{U}^{j-1},\mathbf{U}^j).$$

Proof of Theorem 1. Note that the error $\mathbf{e}^n := \mathbf{u}(t_n) - \mathbf{U}^n$ is written in the form

$$\begin{aligned}\mathbf{e}^n &= (E(t_n)-E_k^n)\,\mathbf{u}_0 - \left(\int_0^{t_n} E(t_n-s)\tilde{A}\mathbf{u}(s)\,ds - \sum_{j=1}^n kE_k^{n-j+1}q^j(A\mathbf{U})\right)\\ &\quad - \left(\int_0^{t_n} E(t_n-s)B(\mathbf{u}(s),\mathbf{u}(s))\,ds - \sum_{j=1}^n kE_k^{n-j+1}B(\mathbf{U}^{j-1},\mathbf{U}^j)\right)\\ &= I_1^n - I_2^n - I_3^n.\end{aligned} \tag{3.11}$$

Since $F_k^n := (E(t_n)-E_k^n)$ denotes the error operator for the purely parabolic problem, then following Thomée [29], we estimate $A^{1/2}I_1^n$ as

$$\|A^{1/2}I_1^n\| = \|A^{1/2}F_k^n\mathbf{u}_0\| \le C(\|A\mathbf{u}_0\|,\Omega)\frac{e^{-\alpha t_n}}{t_n^{1/2}}k. \tag{3.12}$$

In order to estimate $\|A^{1/2}I_2^n\|$, i.e., the memory term, we first rewrite I_2^n as

$$
\begin{aligned}
I_2^n &= \left(\int_0^{t_n} E(t_n - s) \left(\tilde{A}\mathbf{u}(s) - \tilde{A}\mathbf{u}(t_n) \right) ds - \sum_{j=1}^{n} kE_k^{n-j+1} \left(q^j(A\mathbf{u}) - \tilde{A}\mathbf{u}(t_n) \right) \right) \\
&+ \left(\int_0^{t_n} E(t_n - s)\, ds - \sum_{j=1}^{n} kE_k^{n-j+1} \right) \tilde{A}\mathbf{u}(t_n) \qquad (3.13) \\
&+ \sum_{j=1}^{n} kE_k^{n-j+1} q^j(A\mathbf{e}) = I_{2,1}^n + I_{2,2}^n + I_{2,3}^n.
\end{aligned}
$$

For $I_{2,2}^n$, we obtain using the semigroup property

$$
\int_0^{t_n} E(t_n - s) - \sum_{j=1}^{n} kE_k^{n-j+1} = -F_k^n A^{-1},
$$

and hence, using the definition of β, we arrive at

$$
\begin{aligned}
\|A^{1/2}I_{2,2}^n\| &= \|A^{1/2}F_k^n A^{-1}\tilde{A}\mathbf{u}(t_n)\| \\
&\le Ck \frac{e^{-\lambda_1 t_n}}{t_n^{1/2}} e^{-\alpha t_n} \| \int_0^{t_n} e^{-(\delta-\alpha)(t_n-\tau)} A\hat{\mathbf{u}}(\tau)\, d\tau \| \\
&\le Ck \frac{e^{-\lambda_1 t_n}}{t_n^{1/2}} e^{-\alpha t_n} \left(\int_0^{t_n} \|A\hat{\mathbf{u}}(\tau)\|^2\, d\tau \right)^{1/2}.
\end{aligned}
$$

An application of Lemma 5 yields for $0 < \alpha < \min(\lambda_1, \delta,)$

$$
\|A^{1/2}I_{2,2}^n\| \le C(\|A^{1/2}\mathbf{u}_0\|) k \frac{e^{-\alpha t_n}}{t_n^{1/2}}.
$$

For estimating $I_{2,3}^n$, we first use the change of variable and then the change of summation to obtain

$$
\begin{aligned}
A^{1/2}I_{2,3}^n &= \sum_{j=0}^{n-1} kAE_k^{n-j} A^{-1/2} \sum_{i=1}^{j+1} k\beta_{j+1-i} A\mathbf{e}^i = \sum_{j=0}^{n-1} kAE_k^{n-j} \sum_{i=0}^{j} k\beta_{j-i} A^{1/2}\mathbf{e}^{i+1} \\
&= k \sum_{i=0}^{n-1} \left(\sum_{j=i}^{n-1} k\beta_{j-i} AE_k^{n-j} \right) A^{1/2}\mathbf{e}^{i+1} \\
&= k \sum_{i=0}^{n-1} \left(\sum_{j=i}^{n-1} k\beta_{n-i} AE_k^{n-j} \right) A^{1/2}\mathbf{e}^{i+1} \\
&\quad - k \sum_{i=0}^{n-1} \left(\sum_{j=i}^{n-1} k(\beta_{n-i} - \beta_{j-i}) AE_k^{n-j} \right) A^{1/2}\mathbf{e}^{i+1}.
\end{aligned}
$$

For the first term on the right-hand side of $A^{1/2}I_{2,3}^n$, we have from the spectral property of the Stoke's operator and $r(\lambda) = (1+\lambda)^{-1}$:

$$\left\| k\sum_{j=i}^{n-1} AE_k^{n-j} \right\| = \sup_{\lambda\in Sp(A)} \left| \sum_{j=i}^{n-1} k\lambda r(k\lambda)^{n-j} \right| \le \sup_{\lambda>0} \sum_{j=i}^{n-1} \lambda r(\lambda)^{n-j}$$
$$\le \sup_{\lambda>0} \frac{\lambda r(\lambda)}{1-r(\lambda)} = 1,$$

where $Sp(A)$ is the spectrum of the Stokes operator A. For the second term on the right-hand side of $A^{1/2}I_{2,3}^n$, we use the smoothing property (3.8) of E_k^n, and therefore we obtain

$$\begin{aligned}
&\|A^{1/2}I_{2,3}^n\| \\
&\le \gamma k\sum_{i=0}^{n-1} e^{-\delta(t_n-t_i)} \left\| k\sum_{j=i}^{n-1} AE_k^{n-j} \right\| \ \|A^{1/2}\mathbf{e}^{i+1}\| \\
&+\gamma k\sum_{i=0}^{n-1} \left(\sum_{j=i}^{n-1} k|(e^{-\delta t_{n-i}} - e^{-\delta t_{j-i}})| \ \|AE_k^{n-j}\| \right) \|A^{1/2}\mathbf{e}^{i+1}\| \\
&\le Cke^{-\alpha t_n} \sum_{i=0}^{n-1} e^{\alpha t_i} \|A^{1/2}\mathbf{e}^{i+1}\| \\
&+Cke^{-\alpha t_n} \sum_{i=0}^{n-1} e^{\alpha t_i} \left(\sum_{j=i}^{n-1} ke^{-(\delta-\alpha)(t_j-t_i)} \frac{e^{-\delta(t_n-t_j)}-1}{(t_n-t_j)} e^{-(\lambda_1-\alpha)(t_n-t_j)} \right) \|A^{1/2}\mathbf{e}^{i+1}\|.
\end{aligned}$$

Using the meanvalue property of the exponential function, we find that

$$\left(\sum_{j=i}^{n-1} ke^{-(\delta-\alpha)(t_j-t_i)} \frac{e^{-\delta(t_n-t_j)}-1}{(t_n-t_j)} e^{-(\lambda_1-\alpha)(t_n-t_j)} \right) \le C,$$

and hence we arrive at

$$\|A^{1/2}I_{2,3}^n\| \le Ce^{-\alpha t_n}e^{-\alpha k}k\sum_{i=0}^{n} e^{\alpha t_i}\|A^{1/2}\mathbf{e}^i\|.$$

Now for the term $I_{2,1}^n$, we first rewrite it as

$$\begin{aligned}
I_{2,1}^n &= \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} (E(t_n-s) - E(t_{n-j+1})) \left(\tilde{A}\mathbf{u}(s) - \tilde{A}\mathbf{u}(t_n) \right) ds \\
&+ \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} E(t_{n-j+1}) \left(\tilde{A}\mathbf{u}(s) - \tilde{A}\mathbf{u}(t_j) \right) ds \\
&+ \sum_{j=1}^{n} kF_k^{n-j+1} \left(\tilde{A}\mathbf{u}(t_j) - \tilde{A}\mathbf{u}(t_n) \right) + \sum_{j=1}^{n} kE_k^{n-j+1}\varepsilon^j(A\mathbf{u}) \\
&= M_1^n + M_2^n + M_3^n + M_4^n.
\end{aligned}$$

For M_1^n, we write it as

$$A^{1/2}M_1^n = \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} A^{3/2}E(t_n - s)A^{-1}\left(I - E(s - t_{j-1})\right)\left(\tilde{A}\mathbf{u}(s) - \tilde{A}\mathbf{u}(t_n)\right) ds.$$

Thus, using (3.8)–(3.9), we obtain

$$\begin{aligned}\|A^{1/2}M_1^n\| &\le \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \|A^{3/2}E(t_n - s)\|\,\|A^{-1}\left(I - E(s - t_{j-1})\right)\left(\tilde{A}\mathbf{u}(s) - \tilde{A}\mathbf{u}(t_n)\right)\| ds \\ &\le Ck \int_0^{t_n} \frac{e^{-\lambda_1(t_n - s)}}{(t_n - s)^{3/2}} \|\tilde{A}\mathbf{u}(s) - \tilde{A}\mathbf{u}(t_n)\| ds.\end{aligned}$$

In order to estimate $\|\tilde{A}\mathbf{u}(s) - \tilde{A}\mathbf{u}(t_n)\|$, we note that

$$\tilde{A}\mathbf{u}(s) - \tilde{A}\mathbf{u}(t_n) = \int_0^s \left(\beta(s - \tau) - \beta(t_n - \tau)\right) A\mathbf{u}(\tau)\, d\tau - \int_s^{t_n} \beta(t_n - \tau)A\mathbf{u}(\tau)\, d\tau,$$

and hence, using the definition of β, the mean value theorem, $0 < \alpha < \min(\lambda_1, \delta)$, and Lemma 7, we now obtain

$$\begin{aligned}\|\tilde{A}\mathbf{u}(s) - \tilde{A}\mathbf{u}(t_n)\| &\le \gamma e^{-\delta s}\left(1 - e^{-\delta(t_n - s)}\right) \int_0^s e^{\delta\tau}\|A\mathbf{u}(\tau)\| d\tau \\ &\quad + \gamma \int_s^{t_n} e^{-\delta(t_n - \tau)}\|A\mathbf{u}(\tau)\| d\tau \\ &\le \delta\gamma(t_n - s)e^{-\alpha s}e^{-\delta s^*} \int_0^s e^{-(\delta - \alpha)(s - \tau)}\|e^{\alpha\tau}A\mathbf{u}(\tau)\| d\tau \\ &\quad + C(\|A\mathbf{u}_0\|, \gamma) \int_s^{t_n} e^{-\delta(t_n - \tau)}e^{-\alpha\tau} d\tau \\ &\le \delta\gamma(t_n - s)e^{-\alpha s}\left(\int_0^s e^{-2(\delta - \alpha)(s - \tau)} d\tau\right)^{1/2}\left(\int_0^s e^{2\alpha\tau}\|A\mathbf{u}(\tau)\|^2 d\tau\right)^{1/2} \\ &\quad + C(\|A\mathbf{u}_0\|, \gamma)(t_n - s)e^{-\alpha s}.\end{aligned}$$

Using Lemma 5 and the boundedness of

$$\int_0^s e^{-2(\delta - \alpha)(s - \tau)} d\tau \le \frac{1}{2(\delta - \alpha)},$$

we arrive at

$$\|\tilde{A}\mathbf{u}(s) - \tilde{A}\mathbf{u}(t_n)\| \le C(\|A\mathbf{u}_0\|)(t_n - s)e^{-\alpha s}.$$

Therefore,

$$\begin{aligned}\|A^{1/2}M_1^n\| &\le C(\|A\mathbf{u}_0\|)ke^{-\alpha t_n} \int_0^{t_n} \frac{e^{-(\lambda_1 - \alpha)(t_n - s)}}{(t_n - s)^{1/2}} ds \\ &\le C(\|A\mathbf{u}_0\|)ke^{-\alpha t_n} \int_0^{t_n} \frac{e^{-(\lambda_1 - \alpha)\tau}}{\tau^{1/2}} d\tau \\ &\le C(\|A\mathbf{u}_0\|)ke^{-\alpha t_n} \int_0^{\infty} \frac{e^{-(\lambda_1 - \alpha)\tau}}{\tau^{1/2}} d\tau \le C(\|A\mathbf{u}_0\|)ke^{-\alpha t_n}.\end{aligned}$$

To estimate M_2^n, we use the definition of $\tilde{A}$ and the property (3.8) to find that

$$\begin{aligned}\|A^{1/2}M_2^n\| &\le \sum_{j=1}^{n}\int_{t_{j-1}}^{t_j}\|A^{1/2}E(t_{n-j+1})\|\|\tilde{A}\mathbf{u}(s)-\tilde{A}\mathbf{u}(t_j)\|\,ds\\ &\le C\sum_{j=1}^{n}\int_{t_{j-1}}^{t_j}\frac{e^{-\lambda_1(t_n-t_{j-1})}}{(t_n-t_{j-1})^{1/2}}\|\tilde{A}\mathbf{u}(s)-\tilde{A}\mathbf{u}(t_j)\|\,ds.\end{aligned}$$

Since

$$\|\tilde{A}\mathbf{u}(s)-\tilde{A}\mathbf{u}(t_j)\| \le C(\|A\mathbf{u}_0\|)(t_j-s)e^{-\alpha s} \le C(\|A\mathbf{u}_0\|)ke^{-\alpha s},$$

we now obtain

$$\begin{aligned}\|A^{1/2}M_2^n\| &\le C(\|A\mathbf{u}_0\|)ke^{-\alpha t_n}\sum_{j=1}^{n}\frac{e^{-(\lambda_1-\alpha)(t_n-t_{j-1})}}{(t_n-t_{j-1})^{1/2}}\left(e^{\alpha t_{j-1}}\int_{t_{j-1}}^{t_j}e^{-\alpha s}\,ds\right)\\ &\le C(\|A\mathbf{u}_0\|)ke^{-\alpha t_n}\left(k\sum_{j=1}^{n}\frac{e^{-(\lambda_1-\alpha)(t_n-t_{j-1})}}{(t_n-t_{j-1})^{1/2}}\right)\\ &\le C(\|A\mathbf{u}_0\|)ke^{-\alpha t_n}.\end{aligned}$$

Note that we have used the boundedness of the summation term within the bracket.

In order to estimate M_3^n, we use the property of F_k^n and obtain

$$\|A^{1/2}M_3^n\| \le Ck^2\sum_{j=1}^{n}\frac{e^{-\lambda_1(t_n-t_{j-1})}}{(t_n-t_{j-1})^{3/2}}\|\tilde{A}\mathbf{u}(t_j)-\tilde{A}\mathbf{u}(t_n)\|.$$

As in the estimate of $\|A^{1/2}M_1^n\|$, we now find that

$$\begin{aligned}\|A^{1/2}M_3^n\| &\le C(\|A\mathbf{u}_0\|)ke^{-\alpha t_n}e^{-\alpha k}\left(k\sum_{j=1}^{n}\frac{e^{-(\lambda_1-\alpha)(t_n-t_{j-1})}}{(t_n-t_{j-1})^{1/2}}\right)\\ &\le C(\|A\mathbf{u}_0\|)ke^{-\alpha t_n}.\end{aligned}$$

Finally for M_4^n, we note that

$$\|A^{1/2}M_4^n\| \le \sum_{j=1}^{n}k\|AE_k^{n-j+1}\|\,\|\varepsilon^j(A^{1/2}\mathbf{u})\|.$$

Using (3.8), we obtain

$$\|A^{1/2}M_4^n\| \le \sum_{j=1}^{n}k\frac{e^{-\lambda_1(t_n-t_{j-1})}}{(t_n-t_{j-1})}\|\varepsilon^j(A\mathbf{u})\|.$$

To complete the estimate, we use (3.7) to compute the quadrature error $\|\varepsilon^j(A\mathbf{u})\|$ as

$$\|\varepsilon^j(A\mathbf{u})\| \le Ck\int_0^{t_j}\left(|\beta_s(t_j-s)\|A^{1/2}\mathbf{u}(s)\| + |\beta(t_j-s)|\|A^{1/2}\mathbf{u}_s(s)\|\right)ds,$$

and hence we find from Lemma 6 that

$$\begin{aligned}\|\varepsilon^j(A\mathbf{u})\| &\le C(\|A\mathbf{u}_0\|)ke^{-\alpha t_j}\int_0^{t_j} e^{-(\delta-\alpha)(t_j-s)}\,ds\\ &\quad + Cke^{-\alpha t_j}\left(\int_0^{t_j} e^{-2(\delta-\alpha)(t_j-s)}\,ds\right)^{1/2}\left(\int_0^{t_j} e^{2\alpha s}\|A^{1/2}\mathbf{u}_s(s)\|^2\,ds\right)^{1/2}\\ &\le C(\|A\mathbf{u}_0\|)ke^{-\alpha t_j}.\end{aligned}$$

Thus, we arrive at

$$\begin{aligned}\|A^{1/2}M_4^n\| &\le C(\|A\mathbf{u}_0\|)ke^{-\alpha t_n}e^{-\alpha k}\left(k\sum_{j=1}^{n}\frac{e^{-(\lambda_1-\alpha)(t_n-t_{j-1})}}{(t_{n-j+1})}\right)\\ &\le C(\|A\mathbf{u}_0\|)ke^{-\alpha t_n}e^{-\alpha k}\left(k\sum_{j=1}^{n}\frac{1}{(t_{n-j+1})}\right)\\ &\le C(\|A\mathbf{u}_0\|)k\left(\log\frac{1}{k}\right)e^{-\alpha t_n}.\end{aligned}$$

All together, we therefore obtain

$$\begin{aligned}\|A^{1/2}I_2^n\| &\le C(\|A\mathbf{u}_0\|)e^{-\alpha t_n}k\left(1+\log\frac{1}{k}\right)+C(\|A^{1/2}\mathbf{u}_0\|)\frac{e^{-\alpha t_n}}{t_n^{1/2}}k\\ &\quad + Ce^{-\alpha t_n}k\sum_{i=0}^{n-1}e^{\alpha t_i}\|A^{1/2}\mathbf{e}^i\| + Cke^{-\alpha k}\|A^{1/2}\mathbf{e}^n\|.\end{aligned}\tag{3.14}$$

Finally, in order to estimate I_3^n involving the nonlinear term, we may split it as in Geveci [11] and apply Hölder's inequality, Sobolev imbedding theorem with Sobolev inequality. Lastly, with the help of Lemmas 4, 5, 7, and 9, we obtain

$$\begin{aligned}\|A^{1/2}I_3^n\| &\le C(\|A\mathbf{u}_0\|)\frac{e^{-\alpha t_n}}{t_n^{1/2}}k + C(\|A^{1/2}u_0\|)e^{-\alpha t_n}k^{1/4}\|A^{1/2}\mathbf{e}^n\|\\ &\quad + Ce^{-\alpha t_n}k\sum_{i=0}^{n-1}\frac{e^{\alpha t_i}}{(t_n-t_i)^{3/4}}\|A^{1/2}\mathbf{e}^i\|.\end{aligned}\tag{3.15}$$

On substituting (3.12), (3.14), and (3.15) in (3.9), we obtain, for sufficiently small k,

$$\begin{aligned}e^{\alpha t_n}\|A^{1/2}\mathbf{e}^n\| &\le C(\|A\mathbf{u}_0\|)\left[k\left(t_n^{-1/2}+\log\frac{1}{k}\right)\right.\\ &\quad \left. +\ k\sum_{i=0}^{n-1}\left(\frac{1}{(t_n-t_i)^{3/4}}+1\right)e^{\alpha t_i}\|A^{1/2}\mathbf{e}^i\|\right].\end{aligned}\tag{3.16}$$

Using the generalized discrete Gronwall's lemma (see Lemma 7.1 in [7]) and the arguments of Okamoto [22, p. 635], we complete the rest of the proof. □

The convergence in $\mathbf{L}^2$-norm now becomes a routine work. However, we indicate, below, only the major steps in the proof for achieving this result.

Proof of Theorem 2. From (3.9), the error e^n satisfies

$$\mathbf{e}^n = I_1^n - I_2^n - I_3^n.$$

Since a straightforward modification of $\mathbf{H}^1$-estimates of Geveci [11] yields the $\mathbf{L}^2$-estimates of I_1^n and I_3^n, it remains to estimate $\|I_2^n\|$. Note that the $\mathbf{L}^2$-estimates of $I_{2.2}^n$ and $I_{2,3}^n$ in (3.13) follow easily as

$$\begin{aligned}\|I_{2,2}^n\| &= \|F_k^n A^{-1}\tilde{A}\mathbf{u}(t_n)\| \\ &\le Cke^{-\lambda_1 t_n}\|\int_0^{t_n}\beta(t_n-s)A\mathbf{u}(s)\,ds\| \\ &\le Cke^{-\alpha t_n}\left(\int_0^{t_n}\|A\mathbf{u}(s)\|^2\,ds\right)^{1/2} \le C(\|A^{1/2}\mathbf{u}_0\|)ke^{-\alpha t_n}\end{aligned}$$

and

$$\|I_{2,3}^n\| = \|k\sum_{j=0}^{n-1}AE_k^{n-j}\sum_{i=0}^{j}k\beta_{j-i}\mathbf{e}^{i+1}\|.$$

We repeat the analysis for estimating $A^{1/2}I_{2,3}^n$ in Theorem 1, but now $\mathbf{e}^{i+1}$ is made free of $A^{1/2}$. Thus, we obtain

$$\|I_{2,3}^n\| \le Ce^{-\alpha t_n}k\sum_{i=0}^{n-1}e^{\alpha t_i}\|\mathbf{e}^i\| + Ck\|\mathbf{e}^n\|.$$

In order to estimate $I_{2,1}^n$, it is a routine matter to derive the estimates of $\|M_1^n\|$, $\|M_2^n\|$, and $\|M_3^n\|$. To complete the rest of the proof, we therefore need an estimate for $\|M_4^n\|$. Note that

$$\begin{aligned}\|M_4^n\| &\le \sum_{j=1}^{n}k\|A^{1/2}E_k^{n-j+1}\|\,\|\varepsilon^j(A^{1/2}\mathbf{u})\| \\ &\le Ck\sum_{j=1}^{n}\frac{e^{-\lambda_1(t_n-t_{j-1})}}{(t_n-t_{j-1})^{1/2}}\|\varepsilon^j(A^{1/2}\mathbf{u})\|.\end{aligned}$$

Using the estimate of $\|\varepsilon^j(A^{1/2}\mathbf{u})\|$ as in the proof of Theorem 1, we now obtain

$$\begin{aligned}\|M_4^n\| &\le C(\|A\mathbf{u}_0\|)ke^{-\alpha t_n}\left(k\sum_{j=1}^{n}\frac{e^{-(\lambda_1-\alpha)(t_n-t_{j-1})}}{(t_n-t_{j-1})^{1/2}}\right) \\ &\le C(\|A\mathbf{u}_0\|)ke^{-\alpha t_n}.\end{aligned}$$

Note that the summation in the bracket is bounded by a constant which is independent of k. This completes the rest of the proof. □

4. Conclusion. In this paper, we have proved new regularity results for the solutions which are valid for all time $t > 0$ without nonlocal compatibility conditions for the data and established the exponential decay property for the exact solution. Further, we have derived optimal error estimates in $\mathbf{H}^1$ and $\mathbf{L}^2$-norms for the linearized backward Euler scheme under realistically assumed conditions on the initial data. Here, the analysis is not complete as at each time level, we have still to solve an infinite dimensional problem. However, we can easily derive the error estimates for a completely discrete scheme by combining the present analysis with the semidiscrete

results obtained in [26]. Since the problem (1.1)–(1.3) can be thought of as an integral perturbation of the Navier–Stokes equations, we would like to investigate *how far the results on finite element analysis combined with higher order time discretizations of the Navier–Stokes equations* [15], [16], [22] *can be carried over to the present case.* We shall pursue this in future. Finally, we note that we have discussd our results only for the two-dimensional problem and we can easily generalize the analysis of this paper to the problem in three-dimensional bounded domain under smallness conditions on the initial data.

SPECTRAL DISCRETIZATION OF THE VORTICITY, VELOCITY, AND PRESSURE FORMULATION OF THE STOKES PROBLEM*

CHRISTINE BERNARDI† AND NEJMEDDINE CHORFI‡

Abstract. We consider the Stokes problem in a square or a cube provided with nonstandard boundary conditions which involve the normal component of the velocity and the tangential components of the vorticity. We write a variational formulation of this problem with three independent unknowns: the vorticity, the velocity, and the pressure. Next, we propose a discretization by spectral methods which relies on this formulation and, since it leads to an inf-sup condition on the pressure in a natural way, we prove optimal error estimates for the three unknowns. We present numerical experiments which are in perfect coherence with the analysis.

Key words. Stokes problem, vorticity-velocity-pressure formulation, spectral method

AMS subject classifications. 65N35, 35Q30

1. Introduction.

We consider the Stokes problem in a two- or three-dimensional bounded domain when provided with boundary conditions on the normal component of the velocity and the vorticity in dimension 2 and on the normal component of the velocity and the tangential components of the vorticity in dimension 3. The well-posedness of this problem is first proved in the pioneering paper [6]; however, the formulation that is considered in this work deals with the velocity and the pressure as only unknowns and requires the convexity or some regularity of the domain. As first proposed in [18] and [26] (see also [19] and [1]), this problem admits an equivalent variational formulation where the unknowns are the vorticity, the velocity, and the pressure. This formulation involves the domains of the divergence and curl operators, as first suggested in [25]. We also refer the reader to [21] for a different formulation where the unknowns are the vorticity, the vector potential, and the pressure and to [20] for a comparison between different formulations. The aim of this paper is to propose and analyze a discrete problem which relies on the vorticity, velocity, and pressure formulation and is constructed by spectral methods.

Indeed, it seems that the numerical analysis of discretizations relying on this formulation has been performed only for finite element methods; see [26], [2], and [11]. We refer the reader to [8] for the analysis of a spectral discretization of the same problem relying on the velocity and pressure formulation. However, the formulation that we consider here leads naturally to a more accurate approximation of the pressure. One of the difficulties in the discretization consists in handling both the two- and three-dimensional cases. Indeed, the vorticity is a scalar function in dimension 2 and can be approximated in a standard polynomial space while it is a vector field in dimension 3: This requires the introduction of appropriate polynomial spaces which are the spectral analogues of Nédélec's finite elements; see [24]. The discretization that we propose takes into account these considerations, and its numerical analysis leads to optimal

error estimates on the three unknowns. This is the main advantage of this formulation since, in most usual spectral discretizations of the Stokes problem, a lack of optimality appears in the estimate concerning the pressure; see [13, sects. 24–26], and [14] for a possible but less natural improvement. We present numerical experiments which confirm the optimality of the discretization and its efficiency for the Stokes problem provided with this type of boundary condition, both in the two- and three-dimensional situations.

The extension of this study to the case of the nonlinear Navier–Stokes equations is presently under consideration. The main difficulty here is the choice of variational spaces in order to preserve the compactness of the nonlinear term. We also intend to treat more complex geometries by using a spectral element discretization.

An outline of the paper is as follows.

- In section 2, we write the variational formulation of the problem in the case of homogeneous boundary conditions.
- Section 3 is devoted to the description of the spectral discrete problem. We also prove its well-posedness.
- Optimal error estimates are derived in section 4.
- The extension to the case of nonhomogeneous boundary conditions on the velocity is explained in section 5.
- In section 6, we present some numerical experiments which turn out to be in good agreement with the analysis.

2. The velocity, vorticity, and pressure formulation. Let Ω be a bounded connected domain in $\mathbb{R}^d$, $d = 2$ or 3, with a Lipschitz-continuous boundary $\partial\Omega$. We assume for simplicity that Ω is simply connected and has a connected boundary. The generic point in Ω is denoted by $\boldsymbol{x} = (x, y)$ or $\boldsymbol{x} = (x, y, z)$ according to the dimension d. We introduce the unit outward normal vector $\boldsymbol{n}$ to Ω on $\partial\Omega$ and consider the Stokes problem

$$\begin{cases} -\nu\,\Delta\boldsymbol{u} + \mathbf{grad}\,p = \boldsymbol{f} & \text{in } \Omega, \\ \operatorname{div}\boldsymbol{u} = 0 & \text{in } \Omega, \\ \boldsymbol{u}\cdot\boldsymbol{n} = 0 & \text{on } \partial\Omega, \\ \gamma_t(\mathbf{curl}\,\boldsymbol{u}) = \boldsymbol{0} & \text{on } \partial\Omega. \end{cases} \tag{2.1}$$

To make precise the sense of the operator γ_t, we recall the following.

- In dimension $d = 2$, for any vector field $\boldsymbol{v}$ with components v_x and v_y, $\mathbf{curl}\,\boldsymbol{v}$ stands for the scalar function $\partial_x v_y - \partial_y v_x$, so that the operator γ_t is the trace operator on $\partial\Omega$.
- In dimension $d = 3$, for any vector field $\boldsymbol{v}$ with components v_x, v_y, and v_z, $\mathbf{curl}\,\boldsymbol{v}$ stands for the vector field with components $\partial_y v_z - \partial_z v_y$, $\partial_z v_x - \partial_x v_z$, and $\partial_x v_y - \partial_y v_x$, and the operator γ_t is the tangential trace operator on $\partial\Omega$, defined by $\gamma_t(\boldsymbol{w}) = \boldsymbol{w}\times\boldsymbol{n}$.

Of course, the operator γ_t is only defined on smooth enough functions as will be made precise later on.

In system (2.1), the unknowns are the velocity $\boldsymbol{u}$ and the pressure p, while the data $\boldsymbol{f}$ represents a density of body forces. The viscosity ν is a positive constant. To go further, we introduce the vorticity $\boldsymbol{\omega} = \mathbf{curl}\,\boldsymbol{u}$ and observe that system (2.1) is

fully equivalent to

$$\text{(2.2)}\qquad \begin{cases} \nu\,\mathbf{curl}\,\boldsymbol{\omega} + \mathbf{grad}\,p = \boldsymbol{f} & \text{in } \Omega, \\ \operatorname{div}\boldsymbol{u} = 0 & \text{in } \Omega, \\ \boldsymbol{\omega} = \mathbf{curl}\,\boldsymbol{u} & \text{in } \Omega, \\ \boldsymbol{u}\cdot\boldsymbol{n} = 0 & \text{on } \partial\Omega, \\ \gamma_t(\boldsymbol{\omega}) = \boldsymbol{0} & \text{on } \partial\Omega. \end{cases}$$

Note that the operator **curl** in the first line of this system coincides with the previous one in dimension $d = 3$ while, in dimension $d = 2$, it is applied to scalar functions $\boldsymbol{\varphi}$: $\mathbf{curl}\,\boldsymbol{\varphi}$ here denotes the vector field with components $\partial_y\boldsymbol{\varphi}$ and $-\partial_x\boldsymbol{\varphi}$.

In order to write the variational formulation of problem (2.2), we consider the full scale of Sobolev spaces $H^s(\Omega)$. As usual, we denote by $L^2_0(\Omega)$ the space of functions in $L^2(\Omega)$ with a null integral on Ω. Let also $\mathcal{D}(\Omega)$ be the space of infinitely differentiable functions with a compact support in Ω. We introduce the domain $H(\operatorname{div},\Omega)$ of the divergence operator, namely

$$\text{(2.3)}\qquad H(\operatorname{div},\Omega) = \big\{\boldsymbol{v}\in L^2(\Omega)^d;\ \operatorname{div}\boldsymbol{v}\in L^2(\Omega)\big\}.$$

A consequence of the Stokes formula, valid for smooth enough vector fields $\boldsymbol{v}$ and scalar function φ,

$$\text{(2.4)}\qquad \int_\Omega (\operatorname{div}\boldsymbol{v})(\boldsymbol{x})\varphi(\boldsymbol{x})\,d\boldsymbol{x} = -\int_\Omega \boldsymbol{v}(\boldsymbol{x})\cdot(\mathbf{grad}\,\varphi)(\boldsymbol{x})\,d\boldsymbol{x} + \int_{\partial\Omega}(\boldsymbol{v}\cdot\boldsymbol{n})(\boldsymbol{\tau})\varphi(\boldsymbol{\tau})\,d\boldsymbol{\tau},$$

is that the normal trace operator $\boldsymbol{v}\mapsto\boldsymbol{v}\cdot\boldsymbol{n}$ can be defined from $H(\operatorname{div},\Omega)$ into $H^{-\frac12}(\partial\Omega)$. This leads us to introduce its kernel

$$\text{(2.5)}\qquad H_0(\operatorname{div},\Omega) = \big\{\boldsymbol{v}\in H(\operatorname{div},\Omega);\ \boldsymbol{v}\cdot\boldsymbol{n} = 0 \text{ on } \partial\Omega\big\}.$$

Similarly, we introduce the domain of the **curl** operator

$$\text{(2.6)}\qquad H(\mathbf{curl},\Omega) = \big\{\boldsymbol{\vartheta}\in L^2(\Omega)^{\frac{d(d-1)}{2}};\ \mathbf{curl}\,\boldsymbol{\vartheta}\in L^2(\Omega)^d\big\}.$$

The Stokes formula here reads, for smooth enough functions $\boldsymbol{\vartheta}$ in $L^2(\Omega)^{\frac{d(d-1)}{2}}$ and $\boldsymbol{v}$ in $L^2(\Omega)^d$,

$$\text{(2.7)}\qquad \int_\Omega (\mathbf{curl}\,\boldsymbol{\vartheta})(\boldsymbol{x})\cdot\boldsymbol{v}(\boldsymbol{x})\,d\boldsymbol{x} = \int_\Omega \boldsymbol{\vartheta}(\boldsymbol{x})\cdot(\mathbf{curl}\,\boldsymbol{v})(\boldsymbol{x})\,d\boldsymbol{x} - \int_{\partial\Omega}\gamma_t(\boldsymbol{\vartheta})(\boldsymbol{\tau})\cdot\tilde\gamma_t(\boldsymbol{v})(\boldsymbol{\tau})\,d\boldsymbol{\tau},$$

where $\tilde\gamma_t(\boldsymbol{v})$ is equal to $\boldsymbol{v}$ in dimension $d = 3$ and to $v_yn_x - v_xn_y$ in dimension $d = 2$. This allows us to define the kernel

$$\text{(2.8)}\qquad H_0(\mathbf{curl},\Omega) = \big\{\boldsymbol{\vartheta}\in H(\mathbf{curl},\Omega);\ \gamma_t(\boldsymbol{\vartheta}) = \boldsymbol{0} \text{ on } \partial\Omega\big\}.$$

Remark 2.1. Note that the spaces $H(\mathbf{curl},\Omega)$ and $H_0(\mathbf{curl},\Omega)$ coincide with the spaces $H^1(\Omega)$ and $H^1_0(\Omega)$ in dimension $d = 2$, so that their approximation relies on more standard discrete spaces than in dimension $d = 3$.

We now consider the following variational problem:
Find $(\boldsymbol{\omega}, \boldsymbol{u}, p)$ *in* $H_0(\mathbf{curl}, \Omega) \times H_0(\mathrm{div}, \Omega) \times L^2_0(\Omega)$ *such that*

$$\begin{aligned} &\forall \boldsymbol{v} \in H_0(\mathrm{div}, \Omega), && a(\boldsymbol{\omega}, \boldsymbol{u}; \boldsymbol{v}) + b(\boldsymbol{v}, p) = \langle \boldsymbol{f}, \boldsymbol{v} \rangle, \\ &\forall q \in L^2_0(\Omega), && b(\boldsymbol{u}, q) = 0, \\ &\forall \boldsymbol{\vartheta} \in H_0(\mathbf{curl}, \Omega), && c(\boldsymbol{\omega}, \boldsymbol{u}; \boldsymbol{\vartheta}) = 0, \end{aligned} \tag{2.9}$$

where $\langle \cdot, \cdot \rangle$ denotes the duality pairing between $H_0(\mathrm{div}, \Omega)$ and its dual space. The bilinear forms $a(\cdot, \cdot; \cdot)$, $b(\cdot, \cdot)$, and $c(\cdot, \cdot; \cdot)$ are defined by

$$\begin{aligned} a(\boldsymbol{\omega}, \boldsymbol{u}; \boldsymbol{v}) = \nu \int_\Omega (\mathbf{curl}\, \boldsymbol{\omega})(\boldsymbol{x}) \cdot \boldsymbol{v}(\boldsymbol{x})\, d\boldsymbol{x}, \quad b(\boldsymbol{v}, q) = -\int_\Omega (\mathrm{div}\, \boldsymbol{v})(\boldsymbol{x}) q(\boldsymbol{x})\, d\boldsymbol{x}, \\ c(\boldsymbol{\omega}, \boldsymbol{u}; \boldsymbol{\varphi}) = \int_\Omega \boldsymbol{\omega}(\boldsymbol{x}) \cdot \boldsymbol{\varphi}(\boldsymbol{x})\, d\boldsymbol{x} - \int_\Omega \boldsymbol{u}(\boldsymbol{x}) \cdot (\mathbf{curl}\, \boldsymbol{\varphi})(\boldsymbol{x})\, d\boldsymbol{x}. \end{aligned} \tag{2.10}$$

It can be noted that the boundary conditions that appear in (2.2) are treated as essential ones in (2.9). So a direct consequence of the density of $\mathcal{D}(\Omega)^d$ in $H_0(\mathrm{div}, \Omega)$ and of $\mathcal{D}(\Omega)^{\frac{d(d-1)}{2}}$ in $H_0(\mathbf{curl}, \Omega)$ (see [22, Chap. I, sect. 2]) is the following statement.

PROPOSITION 2.2. *Problems* (2.2) *and* (2.9) *are equivalent, in the sense that any triple* $(\boldsymbol{\omega}, \boldsymbol{u}, p)$ *in* $H(\mathbf{curl}, \Omega) \times H(\mathrm{div}, \Omega) \times L^2_0(\Omega)$ *is a solution of problem* (2.2) *if and only if it is a solution of problem* (2.9).

We briefly recall from [26] (see also [11, sect. 3]) the main arguments for the analysis of problem (2.9), in view of their discrete analogues. Let V be the kernel

$$V = \big\{ \boldsymbol{v} \in H_0(\mathrm{div}, \Omega);\ \forall q \in L^2_0(\Omega),\ b(\boldsymbol{v}, q) = 0 \big\}. \tag{2.11}$$

Since the divergence of any function in $H_0(\mathrm{div}, \Omega)$ belongs to $L^2_0(\Omega)$, it is readily checked that V coincides with the space of divergence-free functions in $H_0(\mathrm{div}, \Omega)$. We also introduce the kernel

$$\mathcal{W} = \big\{ (\boldsymbol{\vartheta}, \boldsymbol{v}) \in H_0(\mathbf{curl}, \Omega) \times V;\ \forall \boldsymbol{\varphi} \in H_0(\mathbf{curl}, \Omega),\ c(\boldsymbol{\vartheta}, \boldsymbol{v}; \boldsymbol{\varphi}) = 0 \big\}. \tag{2.12}$$

As can easily be derived from the previously quoted density result, $\mathcal{W}$ coincides with the space of pairs $(\boldsymbol{\vartheta}, \boldsymbol{v})$ in $H_0(\mathbf{curl}, \Omega) \times V$ such that $\boldsymbol{\vartheta}$ is equal to $\mathbf{curl}\, \boldsymbol{v}$ in the distribution sense. Moreover, it follows from the continuity properties of the forms $b(\cdot, \cdot)$ and $c(\cdot, \cdot; \cdot)$ that both V and $\mathcal{W}$ are Hilbert spaces.

We observe that, for any solution $(\boldsymbol{\omega}, \boldsymbol{u}, p)$ of problem (2.9), the pair $(\boldsymbol{\omega}, \boldsymbol{u})$ is a solution of the following reduced problem:
Find $(\boldsymbol{\omega}, \boldsymbol{u})$ *in* $\mathcal{W}$ *such that*

$$\forall \boldsymbol{v} \in V, \quad a(\boldsymbol{\omega}, \boldsymbol{u}; \boldsymbol{v}) = \langle \boldsymbol{f}, \boldsymbol{v} \rangle. \tag{2.13}$$

So we first investigate its well-posedness.

LEMMA 2.3. *There exists a positive constant* α *such that the form* $a(\cdot, \cdot; \cdot)$ *satisfies*

$$\begin{aligned} &\forall \boldsymbol{v} \in V \setminus \{0\}, \quad \sup_{(\boldsymbol{\omega}, \boldsymbol{u}) \in \mathcal{W}} a(\boldsymbol{\omega}, \boldsymbol{u}; \boldsymbol{v}) > 0, \\ &\forall (\boldsymbol{\omega}, \boldsymbol{u}) \in \mathcal{W}, \quad \sup_{\boldsymbol{v} \in V} \frac{a(\boldsymbol{\omega}, \boldsymbol{u}; \boldsymbol{v})}{\|\boldsymbol{v}\|_{L^2(\Omega)^d}} \geq \alpha \big(\|\boldsymbol{\omega}\|_{H(\mathbf{curl}, \Omega)} + \|\boldsymbol{u}\|_{L^2(\Omega)^d} \big). \end{aligned} \tag{2.14}$$

Proof. It is performed in two steps, only in the case $d = 3$ for brevity.

(1) Let $\boldsymbol{v}$ be a function in V such that $a(\boldsymbol{\omega}, \boldsymbol{u}; \boldsymbol{v})$ cancels for all $(\boldsymbol{\omega}, \boldsymbol{u})$ in $\mathcal{W}$. Since Ω is simply connected, and $\boldsymbol{v}$ is divergence-free and satisfies $\boldsymbol{v} \cdot \boldsymbol{n} = 0$ on $\partial\Omega$, it follows from [3, Thm. 3.17] that there exists a divergence-free function $\boldsymbol{\psi}$ in $H_0(\mathbf{curl}, \Omega)$ such that $\boldsymbol{v}$ is equal to $\mathbf{curl}\, \boldsymbol{\psi}$. Similarly, since Ω has a connected boundary and $\boldsymbol{\psi}$ is divergence-free, it follows from [3, Thm. 3.12] that there exists a function $\boldsymbol{z}$ in V such that $\boldsymbol{\psi}$ is equal to $\mathbf{curl}\, \boldsymbol{z}$. So the pair $(\boldsymbol{\psi}, \boldsymbol{z})$ belongs to $\mathcal{W}$. Taking $(\boldsymbol{\omega}, \boldsymbol{u})$ equal to $(\boldsymbol{\psi}, \boldsymbol{z})$ thus yields that $\boldsymbol{v}$ is zero, whence the first part of (2.14).

(2) For any $(\boldsymbol{\omega}, \boldsymbol{u})$ in $\mathcal{W}$, we observe that the function $\boldsymbol{v} = \mathbf{curl}\, \boldsymbol{\omega} + \boldsymbol{u}$ belongs to V. With this choice, we have

$$a(\boldsymbol{\omega}, \boldsymbol{u}; \boldsymbol{v}) = \nu \, \|\mathbf{curl}\, \boldsymbol{\omega}\|^2_{L^2(\Omega)^d} + \nu \int_\Omega (\mathbf{curl}\, \boldsymbol{\omega})(\boldsymbol{x}) \cdot \boldsymbol{u}(\boldsymbol{x}) \, d\boldsymbol{x}.$$

Since $\boldsymbol{\omega}$ is equal to $\mathbf{curl}\, \boldsymbol{u}$, we obtain by integrating by parts

$$a(\boldsymbol{\omega}, \boldsymbol{u}; \boldsymbol{v}) = \nu \, \|\mathbf{curl}\, \boldsymbol{\omega}\|^2_{L^2(\Omega)^d} + \frac{\nu}{2} \, \|\boldsymbol{\omega}\|^2_{L^2(\Omega)^{\frac{d(d-1)}{2}}} + \frac{\nu}{2} \, \|\mathbf{curl}\, \boldsymbol{u}\|^2_{L^2(\Omega)^{\frac{d(d-1)}{2}}}.$$

Next, using [3, Cor. 3.16] yields that, since Ω is simply connected,

$$\forall \boldsymbol{w} \in V, \quad \|\boldsymbol{w}\|_{L^2(\Omega)^d} \le c \, \|\mathbf{curl}\, \boldsymbol{w}\|_{L^2(\Omega)^{\frac{d(d-1)}{2}}}. \tag{2.15}$$

Inserting this inequality applied to $\boldsymbol{u}$ into the previous line gives

$$a(\boldsymbol{\omega}, \boldsymbol{u}; \boldsymbol{v}) \ge \frac{\nu}{2} \, \|\boldsymbol{\omega}\|^2_{H(\mathbf{curl}, \Omega)} + \frac{\nu}{2c^2} \, \|\boldsymbol{u}\|^2_{L^2(\Omega)^d}.$$

This, combined with the bound

$$\|\boldsymbol{v}\|_{L^2(\Omega)^d} \le \sqrt{2} \, \big(\|\mathbf{curl}\, \boldsymbol{\omega}\|^2_{L^2(\Omega)^d} + \|\boldsymbol{u}\|^2_{L^2(\Omega)^d} \big)^{\frac{1}{2}},$$

leads to the inf-sup condition in (2.14).

The next result is now a direct consequence of (2.14); see [22, Chap. I, Lem. 4.1].

COROLLARY 2.4. *For any data $\boldsymbol{f}$ in the dual space of $H_0(\mathrm{div}, \Omega)$, problem* (2.13) *has a unique solution $(\boldsymbol{\omega}, \boldsymbol{u})$ in $\mathcal{W}$. Moreover, this solution satisfies:*

$$\|\boldsymbol{\omega}\|_{H(\mathbf{curl}, \Omega)} + \|\boldsymbol{u}\|_{L^2(\Omega)^d} \le c \, \|\boldsymbol{f}\|_{H_0(\mathrm{div}, \Omega)'}. \tag{2.16}$$

We recall the inf-sup condition, which is easily derived by taking $\boldsymbol{v}$ equal to $\mathbf{grad}\, \mu$, where μ is the unique solution in $H^1(\Omega) \cap L^2_0(\Omega)$ of the Laplace equation with data q and zero Neumann boundary condition:

$$\forall q \in L^2_0(\Omega), \quad \sup_{\boldsymbol{v} \in H_0(\mathrm{div}, \Omega)} \frac{b(\boldsymbol{v}, q)}{\|\boldsymbol{v}\|_{H(\mathrm{div}, \Omega)}} \ge \beta \, \|q\|_{L^2(\Omega)}, \tag{2.17}$$

where β is a positive constant. We are now in a position to prove the main result of this section.

THEOREM 2.5. *For any data $\boldsymbol{f}$ in the dual space of $H_0(\mathrm{div}, \Omega)$, problem* (2.9) *has a unique solution $(\boldsymbol{\omega}, \boldsymbol{u}, p)$ in $H_0(\mathbf{curl}, \Omega) \times H_0(\mathrm{div}, \Omega) \times L^2_0(\Omega)$. Moreover, this solution satisfies:*

$$\|\boldsymbol{\omega}\|_{H(\mathbf{curl}, \Omega)} + \|\boldsymbol{u}\|_{H(\mathrm{div}, \Omega)} + \|p\|_{L^2(\Omega)} \le c \, \|\boldsymbol{f}\|_{H_0(\mathrm{div}, \Omega)'}. \tag{2.18}$$

Proof. We prove separately the existence and the uniqueness.

(1) With any data $\boldsymbol{f}$ in $H_0(\mathrm{div},\Omega)'$, we associate the unique solution $(\boldsymbol{\omega},\boldsymbol{u})$ of problem (2.13) by applying Corollary 2.4. It follows from the definition of V and $\mathcal{W}$ that the second and third lines in (2.9) are satisfied by this solution. Moreover, since the norms $\|\cdot\|_{L^2(\Omega)^d}$ and $\|\cdot\|_{H(\mathrm{div},\Omega)}$ coincide on V, this solution satisfies the first part of (2.18). On the other hand, the pressure p must now satisfy

$$\forall \boldsymbol{v} \in H_0(\mathrm{div},\Omega), \quad b(\boldsymbol{v},p) = \langle \boldsymbol{f},\boldsymbol{v}\rangle - a(\boldsymbol{\omega},\boldsymbol{u};\boldsymbol{v}).$$

Since the right-hand side of the previous line vanishes for all $\boldsymbol{v}$ in V (see (2.13)), the existence of a solution p of this equation in $L^2_0(\Omega)$, together with the second part of (2.18), is a consequence of condition (2.17); again see [22, Chap. I, Lem. 4.1].

(2) Let $(\boldsymbol{\omega},\boldsymbol{u},p)$ be a solution of (2.9) with data $\boldsymbol{f}$ equal to zero. Then $(\boldsymbol{\omega},\boldsymbol{u})$ is a solution of (2.13) with $\boldsymbol{f}=\boldsymbol{0}$, so that it is zero thanks to Corollary 2.4. Then the pressure p satisfies

$$\forall \boldsymbol{v} \in H_0(\mathrm{div},\Omega), \quad b(\boldsymbol{v},p) = 0,$$

so that it is zero due to the inf-sup condition (2.17). This yields the uniqueness of the solution of (2.9).

We refer the reader to [10] for the characterization of the dual space of $H_0(\mathrm{div},\Omega)$ to which the data $\boldsymbol{f}$ must belong. To conclude, we state some regularity properties of the solution of problem (2.9) which can easily be derived from [3, sect. 2], [16], and [17].

PROPOSITION 2.6. *The mapping $\boldsymbol{f} \mapsto (\boldsymbol{\omega},\boldsymbol{u},p)$, where $(\boldsymbol{\omega},\boldsymbol{u},p)$ is the solution of problem* (2.9) *with data $\boldsymbol{f}$, is continuous from $H^{\max\{0,s-1\}}(\Omega)^d$ into $H^s(\Omega)^{\frac{d(d-1)}{2}} \times H^s(\Omega)^d \times H^s(\Omega)$ for*

(i) *all $s \le \frac{1}{2}$ in the general case,*
(ii) *all $s \le 1$ when Ω is convex,*
(iii) *all $s < \frac{\pi}{\omega}$ in dimension $d=2$ when Ω is a polygon with largest angle equal to ω.*

Moreover, when the data $\boldsymbol{f}$ belongs to $L^2(\Omega)^d$, the pressure p belongs to $H^1(\Omega)$, together with the vorticity $\boldsymbol{\omega}$ in dimension $d=2$.

We refer the reader to [16] and [17] for more details about the previous statement. These properties seem weaker than the corresponding ones for the Stokes problem with Dirichlet boundary conditions on the velocity. But they are the appropriate ones for proving the convergence of the discretization.

3. The spectral discrete problem. From now on, we assume that Ω is the square or cube $]-1,1[^d$, $d=2$ or 3. The discrete spaces are constructed from the finite elements proposed by Nédélec on cubic three-dimensional meshes; see [24, sect. 2]. In order to describe them and for any triple (ℓ,m,n) of nonnegative integers, we introduce

- in dimension $d=2$, the space $\mathbb{P}_{\ell,m}(\Omega)$ of restrictions to Ω of polynomials with degree $\le \ell$ with respect to x and $\le m$ with respect to y,
- in dimension $d=3$, the space $\mathbb{P}_{\ell,m,n}(\Omega)$ of restrictions to Ω of polynomials with degree $\le \ell$ with respect to x, $\le m$ with respect to y, and $\le n$ with respect to z.

When ℓ and m are equal to n, these spaces are simply denoted by $\mathbb{P}_n(\Omega)$.

Let N be an integer ≥ 2. The space $\mathbb{D}_N$ which approximates $H_0(\mathrm{div},\Omega)$ is defined

by

(3.1)
$$\mathbb{D}_N = H_0(\mathrm{div},\Omega) \cap \begin{cases} \mathbb{P}_{N,N-1}(\Omega) \times \mathbb{P}_{N-1,N}(\Omega) & \text{if } d=2, \\ \mathbb{P}_{N,N-1,N-1}(\Omega) \times \mathbb{P}_{N-1,N,N-1}(\Omega) \times \mathbb{P}_{N-1,N-1,N}(\Omega) & \\ & \text{if } d=3. \end{cases}$$

In contrast, the space $\mathbb{C}_N$ which approximates $H_0(\mathbf{curl},\Omega)$ is rather different according to the dimension, for the reasons explained in Remark 2.1; it is defined by

(3.2)
$$\mathbb{C}_N = \begin{cases} H_0^1(\Omega) \cap \mathbb{P}_N(\Omega) & \text{if } d=2, \\ H_0(\mathbf{curl},\Omega) \cap \big(\mathbb{P}_{N-1,N,N}(\Omega) \times \mathbb{P}_{N,N-1,N}(\Omega) \times \mathbb{P}_{N,N,N-1}(\Omega)\big) & \text{if } d=3. \end{cases}$$

Finally, for the approximation of $L_0^2(\Omega)$, we consider the space $\mathbb{M}_N$:

$$\mathbb{M}_N = L_0^2(\Omega) \cap \mathbb{P}_{N-1}(\Omega). \tag{3.3}$$

Setting $\xi_0 = -1$ and $\xi_N = 1$, we introduce the $N-1$ nodes ξ_j, $1 \le j \le N-1$, and the $N+1$ weights ρ_j, $0 \le j \le N$, of the Gauss–Lobatto quadrature formula. Denoting by $\mathbb{P}_n(-1,1)$ the space of restrictions to $[-1,1]$ of polynomials with degree $\le n$, we recall that the following equality holds:

$$\forall \Phi \in \mathbb{P}_{2N-1}(-1,1), \quad \int_{-1}^{1} \Phi(\zeta)\, d\zeta = \sum_{j=0}^{N} \Phi(\xi_j)\, \rho_j. \tag{3.4}$$

We also recall [13, form. (13.20)] the property, which is useful in what follows,

$$\forall \varphi_N \in \mathbb{P}_N(-1,1), \quad \|\varphi_N\|^2_{L^2(-1,1)} \le \sum_{j=0}^{N} \varphi_N^2(\xi_j)\, \rho_j \le 3\, \|\varphi_N\|^2_{L^2(-1,1)}. \tag{3.5}$$

Relying on this formula, we introduce the discrete product, defined on continuous functions u and v by

$$(u,v)_N = \begin{cases} \sum_{i=0}^{N} \sum_{j=0}^{N} u(\xi_i,\xi_j) v(\xi_i,\xi_j)\, \rho_i \rho_j & \text{if } d=2, \\ \sum_{i=0}^{N} \sum_{j=0}^{N} \sum_{k=0}^{N} u(\xi_i,\xi_j,\xi_k) v(\xi_i,\xi_j,\xi_k)\, \rho_i \rho_j \rho_k & \text{if } d=3. \end{cases} \tag{3.6}$$

It follows from (3.5) that it is a scalar product on $\mathbb{P}_N(\Omega)$. Finally, let $\mathcal{I}_N$ denote the Lagrange interpolation operator at the nodes (ξ_i,ξ_j), $0 \le i,j \le N$, in dimension $d=2$ and at the nodes (ξ_i,ξ_j,ξ_k), $0 \le i,j,k \le N$, in dimension $d=3$, with values in $\mathbb{P}_N(\Omega)$.

From now on, we assume that the data $\boldsymbol{f}$ are continuous on $\overline{\Omega}$. The discrete problem is constructed from (2.9) by using the Galerkin method combined with numerical integration. It reads as follows:

Find $(\boldsymbol{\omega}_N, \boldsymbol{u}_N, p_N)$ *in* $\mathbb{C}_N \times \mathbb{D}_N \times \mathbb{M}_N$ *such that*

$$\begin{aligned} &\forall \boldsymbol{v}_N \in \mathbb{D}_N, \quad a_N(\boldsymbol{\omega}_N, \boldsymbol{u}_N; \boldsymbol{v}_N) + b_N(\boldsymbol{v}_N, p_N) = (\boldsymbol{f}, \boldsymbol{v}_N)_N, \\ &\forall q_N \in \mathbb{M}_N, \quad b_N(\boldsymbol{u}_N, q_N) = 0, \\ &\forall \boldsymbol{\vartheta}_N \in \mathbb{C}_N, \quad c_N(\boldsymbol{\omega}_N, \boldsymbol{u}_N; \boldsymbol{\vartheta}_N) = 0, \end{aligned} \tag{3.7}$$

where the bilinear forms $a_N(\cdot,\cdot;\cdot)$, $b_N(\cdot,\cdot)$, and $c_N(\cdot,\cdot;\cdot)$ are defined by

$$
\begin{aligned}
&a_N(\boldsymbol{\omega}_N,\boldsymbol{u}_N;\boldsymbol{v}_N)=\nu\,(\mathbf{curl}\,\boldsymbol{\omega}_N,\boldsymbol{v}_N)_N,\quad b_N(\boldsymbol{v}_N,q_N)=-(\operatorname{div}\boldsymbol{v}_N,q_N)_N,\\
&c_N(\boldsymbol{\omega}_N,\boldsymbol{u}_N;\boldsymbol{\varphi}_N)=(\boldsymbol{\omega}_N,\boldsymbol{\varphi}_N)_N-(\boldsymbol{u}_N,\mathbf{curl}\,\boldsymbol{\varphi}_N)_N.
\end{aligned}
\tag{3.8}
$$

It follows from (3.5) combined with Cauchy–Schwarz inequalities that the forms $a_N(\cdot,\cdot;\cdot)$, $b_N(\cdot,\cdot)$, and $c_N(\cdot,\cdot;\cdot)$ are continuous on $\big(\mathbb{C}_N\times\mathbb{D}_N\big)\times\mathbb{D}_N$, $\mathbb{D}_N\times\mathbb{M}_N$, and $\big(\mathbb{C}_N\times\mathbb{D}_N\big)\times\mathbb{C}_N$, respectively, with norms bounded independently of N. Moreover, as a consequence of the exactness property (3.4), the forms $b(\cdot,\cdot)$ and $b_N(\cdot,\cdot)$ coincide on $\mathbb{D}_N\times\mathbb{M}_N$.

The somewhat complex choice of the discrete spaces is justified by the following lemma (its finite element analogue is well known; see [24]).

LEMMA 3.1. *The range of $\mathbb{D}_N$ by the divergence operator is contained in $\mathbb{M}_N$. The range of $\mathbb{C}_N$ by the curl operator is contained in $\mathbb{D}_N$.*

Proof. For any $\boldsymbol{v}_N$ in $\mathbb{D}_N$, $\operatorname{div}\boldsymbol{v}_N$ belongs to $\mathbb{P}_{N-1}(\Omega)$ and the fact that it has a zero integral is derived from the property $\boldsymbol{v}_N\cdot\boldsymbol{n}=0$ on $\partial\Omega$ together with the Stokes formula. This yields the first part of the lemma. Similarly, for any $\boldsymbol{\vartheta}_N$ in $\mathbb{C}_N$, each component of $\mathbf{curl}\,\boldsymbol{\vartheta}_N$ is a polynomial of the right degree and the boundary conditions $\gamma_t(\boldsymbol{\vartheta}_N)=0$ on $\partial\Omega$ imply that $\mathbf{curl}\,\boldsymbol{\vartheta}_N\cdot\boldsymbol{n}$ vanishes on $\partial\Omega$, which concludes the proof.

In analogy with the continuous case, in order to investigate the properties of problem (3.7), we introduce the kernel

$$
V_N=\big\{\boldsymbol{v}_N\in\mathbb{D}_N;\ \forall q_N\in\mathbb{M}_N,\ b_N(\boldsymbol{v}_N,q_N)=0\big\}.
\tag{3.9}
$$

The following result is easily derived from Lemma 3.1 by taking q_N equal to $\operatorname{div}\boldsymbol{v}_N$ in the previous line.

COROLLARY 3.2. *The kernel V_N is the space of divergence-free polynomials in $\mathbb{D}_N$; i.e., it coincides with $\mathbb{D}_N\cap V$.*

We now introduce the kernel

$$
\mathcal{W}_N=\big\{(\boldsymbol{\vartheta}_N,\boldsymbol{v}_N)\in\mathbb{C}_N\times V_N;\ \forall\boldsymbol{\varphi}_N\in\mathbb{C}_N,\ c_N(\boldsymbol{\vartheta}_N,\boldsymbol{v}_N;\boldsymbol{\varphi}_N)=0\big\},
\tag{3.10}
$$

and we consider the following reduced discrete problem:

Find $(\boldsymbol{\omega}_N,\boldsymbol{u}_N)$ in $\mathcal{W}_N$ such that

$$
\forall\boldsymbol{v}_N\in V_N,\quad a_N(\boldsymbol{\omega}_N,\boldsymbol{u}_N;\boldsymbol{v}_N)=(\boldsymbol{f},\boldsymbol{v}_N)_N.
\tag{3.11}
$$

We must now establish the analogues of (2.14) for the form $a_N(\cdot,\cdot;\cdot)$ on the discrete spaces. This requires several preliminary lemmas. We refer the reader to among others [15, Thm. 2.1] and [23] for analogous results in the finite element case.

LEMMA 3.3. *The kernel of the curl operator in $\mathbb{C}_N$ is reduced to $\{0\}$ in dimension $d=2$ and equal to the range of $H_0^1(\Omega)\cap\mathbb{P}_N(\Omega)$ by the gradient operator in dimension $d=3$.*

Proof. Since the lemma is obvious in dimension $d=2$, we prove it only in dimension $d=3$. Let $\boldsymbol{\vartheta}_N$ be a curl-free polynomial in $\mathbb{C}_N$. Using [22, Chap. I, Thm. 2.9] yields that it is the gradient of a function μ. It follows from the identity $\boldsymbol{\vartheta}_N=\mathbf{grad}\,\mu$ that μ belongs to $\mathbb{P}_N(\Omega)$. Moreover, the two tangential derivatives of μ vanish on all faces of Ω: Indeed, for instance on the faces contained in the planes $x=\pm1$, the second and third components of $\boldsymbol{\vartheta}_N$ are equal to zero thanks to the definition of $\mathbb{C}_N$, so that $\partial_y\mu$ and $\partial_z\mu$ vanish. So μ is constant on $\partial\Omega$ and, since it is

defined up to an additive constant, it can be taken equal to zero on $\partial\Omega$. The converse imbedding is readily checked.

The next lemma makes the second part of Lemma 3.1 more precise.

LEMMA 3.4. *The range of $\mathbb{C}_N$ by the curl operator is equal to V_N.*

Proof. Let $\boldsymbol{v}_N$ be any polynomial in V_N. We treat only the more complex case of dimension $d = 3$. Denoting the components of $\boldsymbol{v}_N$ by v_{Nx}, v_{Ny}, and v_{Nz}, we first define a function $\boldsymbol{\psi}_N = (\psi_{Nx}, \psi_{Ny}, \psi_{Nz})$ by

(3.12)
$$\psi_{Nx}(x,y,z) = \int_{-1}^{z} v_{Ny}(x,y,\zeta)\,d\zeta,$$
$$\psi_{Ny}(x,y,z) = -\int_{-1}^{z} v_{Nx}(x,y,\zeta)\,d\zeta, \quad \psi_{Nz} = 0.$$

The first two components of $\boldsymbol{\psi}_N$ belong to $\mathbb{P}_{N-1,N,N}(\Omega)$ and $\mathbb{P}_{N,N-1,N}(\Omega)$, respectively. This function is such that the first two components of its curl are equal to v_{Nx} and v_{Ny}. Moreover, since $\boldsymbol{v}_N$ belongs to V_N. we have

$$(\partial_x\psi_{Ny} - \partial_y\psi_{Nx})(x,y,z) = -\int_{-1}^{z} (\partial_x v_{Nx} + \partial_y v_{Ny})(x,y,\zeta)\,d\zeta$$
$$= \int_{-1}^{z} (\partial_z v_{Nz})(x,y,\zeta)\,d\zeta = v_{Nz}(x,y,z).$$

So $\mathbf{curl}\,\boldsymbol{\psi}_N$ is equal to $\boldsymbol{v}_N$. Moreover, it is readily checked that $\gamma_t(\boldsymbol{\psi}_N)$ vanishes on all faces of Ω but on the face Γ is contained in the plane $z = 1$. In a second step, we look for a function μ_N in $\mathbb{P}_N(\Omega)$ such that $\gamma_t(\mathbf{grad}\,\mu_N)$ is equal to zero on $\partial\Omega\setminus\Gamma$ and to $\gamma_t(\boldsymbol{\psi}_N)$ on Γ. Denoting by g_{Nx} and g_{Ny} the functions defined on Γ by

$$g_{Nx}(x,y) = \int_{-1}^{1} v_{Ny}(x,y,\zeta)\,d\zeta, \quad g_{Ny}(x,y) = -\int_{-1}^{1} v_{Nx}(x,y,\zeta)\,d\zeta,$$

we observe that the function $\boldsymbol{g}_N = (g_{Nx}, g_{Ny})$ belongs to $\mathbb{P}_{N-1,N}(\Gamma)\times\mathbb{P}_{N,N-1}(\Gamma)$, with obvious notation for these new spaces, has its tangential component equal to zero on the four edges of Γ, and satisfies, for the same reasons as previously,

$$(\partial_x g_{Ny} - \partial_y g_{Nx})(x,y) = \int_{-1}^{1} (\partial_z v_{Nz})(x,y,\zeta)\,d\zeta = 0.$$

Again applying [22, Chap. I, Thm. 2.9] yields that $\boldsymbol{g}_N$ is the tangential gradient of a function k_N^g, which is defined up to an additive constant. When choosing this constant such that $k_N^g(-1,-1)$ is zero, we easily derive that k_N^g belongs to $H_0^1(\Gamma)\cap\mathbb{P}_N(\Gamma)$. Then, using an appropriate lifting operator of polynomial traces as proposed in [9, Chap. II, Thm. 4.1], we derive the existence of a μ_N in $\mathbb{P}_N(\Omega)$ equal to 0 on $\partial\Omega\setminus\Gamma$ and to k_N^g on Γ. The function $\boldsymbol{\psi}_N - \mathbf{grad}\,\mu_N$ now belongs to $\mathbb{C}_N$ and has its curl equal to $\boldsymbol{v}_N$, whence the desired result.

It follows from Lemmas 3.3 and 3.4 that, for any function $\boldsymbol{v}_N$ in V_N, there exists a unique function $\boldsymbol{\psi}_N^*$ in $\mathbb{C}_N$ such that $\mathbf{curl}\,\boldsymbol{\psi}_N^*$ is equal to $\boldsymbol{v}_N$ and which, moreover, satisfies in dimension $d = 3$

$$\forall\mu_N \in H_0^1(\Omega)\cap\mathbb{P}_N(\Omega), \quad (\boldsymbol{\psi}_N^*, \mathbf{grad}\,\mu_N)_N = 0. \tag{3.13}$$

Let A_N be the operator defined from V_N into $\mathbb{C}_N$ by $A_N(\boldsymbol{v}_N) = \boldsymbol{\psi}_N^*$.

LEMMA 3.5. *There exists a constant c independent of N such that the following inequality holds:*

$$\forall \boldsymbol{v}_N \in V_N, \quad \|A_N(\boldsymbol{v}_N)\|_{H(\mathbf{curl},\Omega)} \leq c\,\|\boldsymbol{v}_N\|_{L^2(\Omega)^d}. \tag{3.14}$$

Proof. Since $\mathbf{curl}\, A_N(\boldsymbol{v}_N)$ is equal to $\boldsymbol{v}_N$, it suffices to bound $\|A_N(\boldsymbol{v}_N)\|_{L^2(\Omega)^{\frac{d(d-1)}{2}}}$. There also, we consider only the case $d = 3$. The function $\boldsymbol{\psi}_N$ defined in (3.12) obviously satisfies

$$\|\boldsymbol{\psi}_N\|_{L^2(\Omega)^3} \leq 2\,\|\boldsymbol{v}_N\|_{L^2(\Omega)^3}. \tag{3.15}$$

For the same reason, the function k_N^g introduced in the proof of Lemma 3.4 satisfies, thanks to the Poincaré–Friedrichs inequality,

$$\|k_N^g\|_{H^1(\Gamma)} \leq c\,\|\boldsymbol{g}_N\|_{L^2(\Gamma)^2} \leq c\sqrt{2}\|\boldsymbol{v}_N\|_{L^2(\Omega)^3}.$$

Thus applying [9, Chap. II, Thm. 4.1] leads to the estimate

$$\|\mathbf{grad}\,\mu_N\|_{L^2(\Omega)^3} \leq c\,\|k_N^g\|_{H^1(\Gamma)},$$

whence

$$\|\mathbf{grad}\,\mu_N\|_{L^2(\Omega)^3} \leq c'\,\|\boldsymbol{v}_N\|_{L^2(\Omega)^3}. \tag{3.16}$$

Finally, the Lax–Milgram lemma combined with (3.5) and the Poincaré–Friedrichs inequality yields that there exists a unique $\tilde{\mu}_N$ in $H_0^1(\Omega) \cap \mathbb{P}_N(\Omega)$ such that

$$\forall \rho_N \in H_0^1(\Omega) \cap \mathbb{P}_N(\Omega), \quad (\mathbf{grad}\,\tilde{\mu}_N, \mathbf{grad}\,\rho_N)_N = (\boldsymbol{\psi}_N - \mathbf{grad}\,\mu_N, \mathbf{grad}\,\rho_N)_N.$$

Moreover, this function satisfies

$$\|\mathbf{grad}\,\tilde{\mu}_N\|_{L^2(\Omega)^3} \leq 3^{\frac{3}{2}}\,(\|\boldsymbol{\psi}_N\|_{L^2(\Omega)^3} + \|\mathbf{grad}\,\mu_N\|_{L^2(\Omega)^3}). \tag{3.17}$$

The choice of $\tilde{\mu}_N$ yields that the function $\boldsymbol{\psi}_N - \mathbf{grad}\,\mu_N - \mathbf{grad}\,\tilde{\mu}_N$ is equal to $A_N(\boldsymbol{v}_N)$, so that the desired estimate follows from (3.15) to (3.17).

We are now in a position to prove successively the two analogues of (2.14).

LEMMA 3.6. *The form $a_N(\cdot,\cdot;\cdot)$ satisfies the following positivity property:*

$$\forall \boldsymbol{v}_N \in V_N \setminus \{0\}, \quad \sup_{(\boldsymbol{\omega}_N, \boldsymbol{u}_N) \in \mathcal{W}_N} a_N(\boldsymbol{\omega}_N, \boldsymbol{u}_N; \boldsymbol{v}_N) > 0. \tag{3.18}$$

Proof. Let $\boldsymbol{v}_N$ be a polynomial in V_N such that $a_N(\boldsymbol{\omega}_N, \boldsymbol{u}_N; \boldsymbol{v}_N)$ vanishes for all pairs $(\boldsymbol{\omega}_N, \boldsymbol{u}_N)$ in $\mathcal{W}_N$. We set $\boldsymbol{\vartheta}_N = A_N(\boldsymbol{v}_N)$ and consider the equation:

Find $\boldsymbol{z}_N$ in V_N such that

$$\forall \boldsymbol{w}_N \in V_N, \quad (\boldsymbol{z}_N, \boldsymbol{w}_N)_N = (\boldsymbol{\vartheta}_N, A_N(\boldsymbol{w}_N))_N. \tag{3.19}$$

Since the norms $\|\cdot\|_{H(\mathrm{div},\Omega)}$ and $\|\cdot\|_{L^2(\Omega)^3}$ are equal on V_N, it follows from (3.5) that the bilinear form in the left-hand side is elliptic on V_N, so that this problem has a unique solution $\boldsymbol{z}_N$. Moreover, this function satisfies for any $\boldsymbol{\varphi}_N$ in $\mathbb{C}_N$

$$(\boldsymbol{z}_N, \mathbf{curl}\,\boldsymbol{\varphi}_N)_N = \big(\boldsymbol{\vartheta}_N, A_N(\mathbf{curl}\,\boldsymbol{\varphi}_N)\big)_N.$$

Note that $A_N(\mathbf{curl}\,\boldsymbol{\varphi}_N)$ is the sum of $\boldsymbol{\varphi}_N$ and of the gradient of a function μ_N in $H^1_0(\Omega)\cap\mathbb{P}_N(\Omega)$. Then it follows from the choice of $\boldsymbol{\vartheta}_N$ (see (3.13)) that

$$(\boldsymbol{z}_N,\mathbf{curl}\,\boldsymbol{\varphi}_N)_N=(\boldsymbol{\vartheta}_N,\boldsymbol{\varphi}_N)_N.$$

So the pair $(\boldsymbol{\vartheta}_N,\boldsymbol{z}_N)$ belongs to $\mathcal{W}_N$ and taking $(\boldsymbol{\omega}_N,\boldsymbol{u}_N)$ equal to $(\boldsymbol{\vartheta}_N,\boldsymbol{z}_N)$ yields, thanks to (3.5), that $\boldsymbol{v}_N=\mathbf{curl}\,\boldsymbol{\vartheta}_N$ is zero, which concludes the proof.

LEMMA 3.7. *There exists a positive constant α_* independent of N such that the form $a_N(\cdot,\cdot;\cdot)$ satisfies the following inf-sup condition:*

$$\forall(\boldsymbol{\omega}_N,\boldsymbol{u}_N)\in\mathcal{W}_N,\qquad \sup_{\boldsymbol{v}_N\in V_N}\frac{a_N(\boldsymbol{\omega}_N,\boldsymbol{u}_N;\boldsymbol{v}_N)}{\|\boldsymbol{v}_N\|_{L^2(\Omega)^d}}\geq\alpha_*\left(\|\boldsymbol{\omega}_N\|_{H(\mathbf{curl},\Omega)}+\|\boldsymbol{u}_N\|_{L^2(\Omega)^d}\right). \tag{3.20}$$

Proof. For any $(\boldsymbol{\omega}_N,\boldsymbol{u}_N)$ in $\mathcal{W}_N$, we set $\boldsymbol{v}_N=\boldsymbol{u}_N+\mathbf{curl}\,\boldsymbol{\omega}_N$. Thanks to the definition of $\mathcal{W}_N$, this gives

$$a_N(\boldsymbol{\omega}_N,\boldsymbol{u}_N;\boldsymbol{v}_N)\geq\nu\,\|\boldsymbol{\omega}_N\|^2_{H(\mathbf{curl},\Omega)}.$$

On the other hand, again using the definition of $\mathcal{W}_N$ and (3.5), we write

$$\begin{aligned}\|\boldsymbol{u}_N\|^2_{L^2(\Omega)^d}\leq\big(\boldsymbol{u}_N,\mathbf{curl}\,A_N(\boldsymbol{u}_N)\big)_N&=\big(\boldsymbol{\omega}_N,A_N(\boldsymbol{u}_N)\big)_N\\&\leq 3^d\,\|\boldsymbol{\omega}_N\|_{L^2(\Omega)^{\frac{d(d-1)}{2}}}\,\|A_N(\boldsymbol{u}_N)\|_{L^2(\Omega)^{\frac{d(d-1)}{2}}}.\end{aligned}$$

So by using Lemma 3.5 we obtain

$$\|\boldsymbol{u}_N\|_{L^2(\Omega)^d}\leq 3^d\,c\,\|\boldsymbol{\omega}_N\|_{L^2(\Omega)^{\frac{d(d-1)}{2}}}.$$

By combining these two inequalities and noting that

$$\|\boldsymbol{v}_N\|_{L^2(\Omega)^d}\leq\sqrt{2}\left(\|\boldsymbol{\omega}_N\|^2_{H(\mathbf{curl},\Omega)}+\|\boldsymbol{u}_N\|^2_{L^2(\Omega)^d}\right)^{\frac12},$$

we derive the desired inf-sup condition.

The following result is a direct consequence of Lemmas 3.6 and 3.7; see [22, Chap. I, Lem. 4.1]. Note also from (3.5) that if $\mathcal{I}_N$ denotes the Lagrange interpolation operator introduced at the beginning of this section, the following property holds for any $\boldsymbol{v}_N$ in $\mathbb{D}_N$ (note that this requires the continuity of $\boldsymbol{f}$):

$$(\boldsymbol{f},\boldsymbol{v}_N)_N=(\mathcal{I}_N\boldsymbol{f},\boldsymbol{v}_N)_N\leq 3^d\,\|\mathcal{I}_N\boldsymbol{f}\|_{L^2(\Omega)^d}\|\boldsymbol{v}_N\|_{L^2(\Omega)^d}.$$

COROLLARY 3.8. *For any data $\boldsymbol{f}$ continuous on $\overline{\Omega}$, problem* (3.11) *has a unique solution $(\boldsymbol{\omega}_N,\boldsymbol{u}_N)$ in $\mathcal{W}_N$. Moreover, this solution satisfies for a constant c independent of N:*

$$\|\boldsymbol{\omega}_N\|_{H(\mathbf{curl},\Omega)}+\|\boldsymbol{u}_N\|_{L^2(\Omega)^d}\leq c\,\|\mathcal{I}_N\boldsymbol{f}\|_{L^2(\Omega)^d}. \tag{3.21}$$

To go further, we now state an inf-sup condition on the form $b_N(\cdot,\cdot)$. We refer the reader to [4, Lem. 3.1] for the main arguments of the proof in a slightly different case (and to [5] and [13, Thm. 24.6] for the basic ideas).

LEMMA 3.9. *There exists a positive constant β_* independent of N such that the form $b_N(\cdot,\cdot)$ satisfies the following inf-sup condition:*

$$\forall q_N \in \mathbb{M}_N, \quad \sup_{\boldsymbol{v}_N \in \mathbb{D}_N} \frac{b_N(\boldsymbol{v}_N, q_N)}{\|\boldsymbol{v}_N\|_{H(\mathrm{div},\Omega)}} \geq \beta_* \, \|q_N\|_{L^2(\Omega)}. \tag{3.22}$$

Note that Lemma 3.9 makes the first part of Lemma 3.1 more precise: Indeed, it implies that the range of $\mathbb{D}_N$ by the divergence operator is equal to $\mathbb{M}_N$. We skip the proof of the next theorem since it relies on exactly the same arguments as Theorem 2.5 with Corollary 2.4 replaced by Corollary 3.8 and (2.17) replaced by (3.22).

THEOREM 3.10. *For any data $\boldsymbol{f}$ continuous on $\overline{\Omega}$, problem* (3.7) *has a unique solution $(\boldsymbol{\omega}_N, \boldsymbol{u}_N, p_N)$ in $\mathbb{C}_N \times \mathbb{D}_N \times \mathbb{M}_N$. Moreover, this solution satisfies for a constant c independent of N:*

$$\|\boldsymbol{\omega}_N\|_{H(\mathbf{curl},\Omega)} + \|\boldsymbol{u}_N\|_{H(\mathrm{div},\Omega)} + \|p_N\|_{L^2(\Omega)} \leq c \, \|\mathcal{I}_N \boldsymbol{f}\|_{L^2(\Omega)^d}. \tag{3.23}$$

4. Error estimates. We now wish to derive the error estimates between the solution $(\boldsymbol{\omega}, \boldsymbol{u}, p)$ of problem (2.9) and the solution $(\boldsymbol{\omega}_N, \boldsymbol{u}_N, p_N)$ of problem (3.7). The proof is rather technical and requires several lemmas. In all that follows, c stands for a generic constant which can vary from one line to the next one but is always independent of N.

LEMMA 4.1. *The following estimate holds for the error between the solution $(\boldsymbol{\omega}, \boldsymbol{u}, p)$ of problem* (2.9) *and the solution $(\boldsymbol{\omega}_N, \boldsymbol{u}_N, p_N)$ of problem* (3.7)*:*

$$\begin{aligned} &\|\boldsymbol{\omega} - \boldsymbol{\omega}_N\|_{H(\mathbf{curl},\Omega)} + \|\boldsymbol{u} - \boldsymbol{u}_N\|_{H(\mathrm{div},\Omega)} \\ &\qquad \leq c \inf_{(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N) \in \mathcal{W}_N} \Big(\|\boldsymbol{\omega} - \boldsymbol{\vartheta}_N\|_{H(\mathbf{curl},\Omega)} + \|\boldsymbol{u} - \boldsymbol{w}_N\|_{L^2(\Omega)^d} \\ &\qquad\qquad + E_N^{\boldsymbol{f}} + E_N^a(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N) \Big), \end{aligned} \tag{4.1}$$

where the quantities $E_N^{\boldsymbol{f}}$ and $E_N^a(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N)$ are defined by

$$\begin{aligned} E_N^{\boldsymbol{f}} &= \sup_{\boldsymbol{v}_N \in \mathbb{D}_N} \frac{\langle \boldsymbol{f}, \boldsymbol{v}_N \rangle - (\boldsymbol{f}, \boldsymbol{v}_N)_N}{\|\boldsymbol{v}_N\|_{L^2(\Omega)^d}}, \\ E_N^a(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N) &= \sup_{\boldsymbol{v}_N \in \mathbb{D}_N} \frac{(a - a_N)(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N; \boldsymbol{v}_N)}{\|\boldsymbol{v}_N\|_{L^2(\Omega)^d}}. \end{aligned} \tag{4.2}$$

Proof. Let $(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N)$ be an approximation of $(\boldsymbol{\omega}, \boldsymbol{u})$ in $\mathcal{W}_N$. By using (3.11), we have, for all $\boldsymbol{v}_N$ in V_N,

$$a_N(\boldsymbol{\omega}_N - \boldsymbol{\vartheta}_N, \boldsymbol{u}_N - \boldsymbol{w}_N; \boldsymbol{v}_N) = (\boldsymbol{f}, \boldsymbol{v}_N)_N - a_N(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N; \boldsymbol{v}_N).$$

Then using problem (2.13) (we recall that V_N is contained in V) leads to

$$\begin{aligned} a_N(\boldsymbol{\omega}_N - \boldsymbol{\vartheta}_N, \boldsymbol{u}_N - \boldsymbol{w}_N; \boldsymbol{v}_N) = (\boldsymbol{f}, \boldsymbol{v}_N)_N - \langle \boldsymbol{f}, \boldsymbol{v}_N \rangle + a(\boldsymbol{\omega} - \boldsymbol{\vartheta}_N, \boldsymbol{u} - \boldsymbol{w}_N; \boldsymbol{v}_N) \\ + (a - a_N)(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N; \boldsymbol{v}_N). \end{aligned}$$

By combining this identity with the inf-sup condition (3.20), we derive

$$\begin{aligned} &\|\boldsymbol{\omega}_N - \boldsymbol{\vartheta}_N\|_{H(\mathbf{curl},\Omega)} + \|\boldsymbol{u}_N - \boldsymbol{w}_N\|_{L^2(\Omega)^d} \\ &\qquad \leq c \big(\|\mathbf{curl}\,(\boldsymbol{\omega} - \boldsymbol{\vartheta}_N)\|_{L^2(\Omega)^d} + E_N^{\boldsymbol{f}} + E_N^a(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N) \big). \end{aligned}$$

We conclude thanks to a triangle inequality, by noting that both $\boldsymbol{u}$ and $\boldsymbol{u}_N$ are exactly divergence-free.

LEMMA 4.2. *The following estimate holds for the error between the solution* $(\boldsymbol{\omega}, \boldsymbol{u}, p)$ *of problem* (2.9) *and the solution* $(\boldsymbol{\omega}_N, \boldsymbol{u}_N, p_N)$ *of problem* (3.7)*:*

(4.3)
$$\begin{aligned}\|p - p_N\|_{L^2(\Omega)} \le\ & c \inf_{q_N \in \mathbb{M}_N} \|p - q_N\|_{L^2(\Omega)} \\ & + c \inf_{(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N) \in \mathcal{W}_N} \Big(\|\boldsymbol{\omega} - \boldsymbol{\vartheta}_N\|_{H(\mathbf{curl},\Omega)} + \|\boldsymbol{u} - \boldsymbol{w}_N\|_{L^2(\Omega)^d} \\ & \qquad + E_N^{\boldsymbol{f}} + E_N^a(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N) \Big),\end{aligned}$$

where the quantities $E_N^{\boldsymbol{f}}$ *and* $E_N^a(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N)$ *are defined in* (4.2).

Proof. It follows from problems (2.9) and (3.7) (note also that $b(\cdot,\cdot)$ and $b_N(\cdot,\cdot)$ coincide on $\mathbb{D}_N \times \mathbb{M}_N$) that, for any $\boldsymbol{v}_N$ in $\mathbb{D}_N$ and q_N in $\mathbb{M}_N$,

$$\begin{aligned}b_N(\boldsymbol{v}_N, p_N - q_N) = (\boldsymbol{f}, \boldsymbol{v}_N)_N - \langle \boldsymbol{f}, \boldsymbol{v}_N \rangle + a(\boldsymbol{\omega} - \boldsymbol{\omega}_N, \boldsymbol{u} - \boldsymbol{u}_N; \boldsymbol{v}_N) \\ + (a - a_N)(\boldsymbol{\omega}_N, \boldsymbol{u}_N; \boldsymbol{v}_N) + b(\boldsymbol{v}_N, p - q_N).\end{aligned}$$

Moreover, we use the identity

$$(a - a_N)(\boldsymbol{\omega}_N, \boldsymbol{u}_N; \boldsymbol{v}_N) = (a - a_N)(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N; \boldsymbol{v}_N) + (a - a_N)(\boldsymbol{\omega}_N - \boldsymbol{\vartheta}_N, \boldsymbol{u}_N - \boldsymbol{w}_N; \boldsymbol{v}_N).$$

Combining the inf-sup condition (3.22) with Lemma 4.1 and a triangle inequality leads to (4.3).

In order to evaluate the distance from $(\boldsymbol{\omega}, \boldsymbol{u})$ to $\mathcal{W}_N$, we now prove an inf-sup condition on the form $c_N(\cdot,\cdot;\cdot)$.

LEMMA 4.3. *There exists a positive constant* γ_* *independent of* N *such that the form* $c_N(\cdot,\cdot;\cdot)$ *satisfies the following inf-sup condition:*

(4.4)
$$\forall \boldsymbol{\varphi}_N \in \mathbb{C}_N, \qquad \sup_{(\boldsymbol{\omega}_N, \boldsymbol{u}_N) \in \mathbb{C}_N \times V_N} \frac{c_N(\boldsymbol{\omega}_N, \boldsymbol{u}_N; \boldsymbol{\varphi}_N)}{\|\boldsymbol{\omega}_N\|_{H(\mathbf{curl},\Omega)} + \|\boldsymbol{u}_N\|_{L^2(\Omega)^d}} \ge \gamma_* \|\boldsymbol{\varphi}_N\|_{H(\mathbf{curl},\Omega)}.$$

Proof. For any $\boldsymbol{\varphi}_N$ in $\mathbb{C}_N$, we take $(\boldsymbol{\omega}_N, \boldsymbol{u}_N)$ equal to $(\boldsymbol{\varphi}_N, -\mathbf{curl}\, \boldsymbol{\varphi}_N)$ and note that it belongs to $\mathbb{C}_N \times V_N$; see Lemma 3.1. Next, we derive from (3.5) that

$$c_N(\boldsymbol{\omega}_N, \boldsymbol{u}_N; \boldsymbol{\varphi}_N) = (\boldsymbol{\varphi}_N, \boldsymbol{\varphi}_N)_N + (\mathbf{curl}\, \boldsymbol{\varphi}_N, \mathbf{curl}\, \boldsymbol{\varphi}_N)_N \ge \|\boldsymbol{\varphi}_N\|^2_{H(\mathbf{curl},\Omega)}.$$

On the other hand, we have

$$\|\boldsymbol{\omega}_N\|_{H(\mathbf{curl},\Omega)} + \|\boldsymbol{u}_N\|_{L^2(\Omega)^d} \le 2 \|\boldsymbol{\varphi}_N\|_{H(\mathbf{curl},\Omega)},$$

which leads to the desired inf-sup condition.

COROLLARY 4.4. *The following estimate holds:*

(4.5)
$$\begin{aligned}&\inf_{(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N) \in \mathcal{W}_N} \Big(\|\boldsymbol{\omega} - \boldsymbol{\vartheta}_N\|_{H(\mathbf{curl},\Omega)} + \|\boldsymbol{u} - \boldsymbol{w}_N\|_{L^2(\Omega)^d} \Big) \\ &\qquad \le c \inf_{\boldsymbol{\zeta}_N \in \mathbb{C}_N} \inf_{\boldsymbol{z}_N \in V_N} \Big(\|\boldsymbol{\omega} - \boldsymbol{\zeta}_N\|_{H(\mathbf{curl},\Omega)} + \|\boldsymbol{u} - \boldsymbol{z}_N\|_{L^2(\Omega)^d} + E_N^c(\boldsymbol{\zeta}_N, \boldsymbol{z}_N) \Big),\end{aligned}$$

where the quantity $E_N^c(\boldsymbol{\zeta}_N, \boldsymbol{z}_N)$ *is defined by*

$$E_N^c(\boldsymbol{\zeta}_N, \boldsymbol{z}_N) = \sup_{\boldsymbol{\varphi}_N \in \mathbb{C}_N} \frac{(c - c_N)(\boldsymbol{\zeta}_N, \boldsymbol{z}_N; \boldsymbol{\varphi}_N)}{\|\boldsymbol{\varphi}_N\|_{H(\mathbf{curl},\Omega)}}. \tag{4.6}$$

Proof. For any $(\boldsymbol{\zeta}_N, \boldsymbol{z}_N)$ in $\mathbb{C}_N \times V_N$, we derive from the inf-sup condition (4.4) the existence of a pair $(\tilde{\boldsymbol{\zeta}}_N, \tilde{\boldsymbol{z}}_N)$ also in $\mathbb{C}_N \times V_N$ which satisfies, for all $\boldsymbol{\varphi}_N$ in $\mathbb{C}_N$,

$$c_N(\tilde{\boldsymbol{\zeta}}_N, \tilde{\boldsymbol{z}}_N; \boldsymbol{\varphi}_N) = c_N(\boldsymbol{\zeta}_N, \boldsymbol{z}_N; \boldsymbol{\varphi}_N),$$

and, moreover,

$$\|\tilde{\boldsymbol{\zeta}}_N\|_{H(\mathbf{curl},\Omega)} + \|\tilde{\boldsymbol{z}}_N\|_{L^2(\Omega)^d} \le (\gamma_*)^{-1} \sup_{\boldsymbol{\varphi}_N \in \mathbb{C}_N} \frac{c_N(\boldsymbol{\zeta}_N, \boldsymbol{z}_N; \boldsymbol{\varphi}_N)}{\|\boldsymbol{\varphi}_N\|_{H(\mathbf{curl},\Omega)}}.$$

We also note that

$$c_N(\boldsymbol{\zeta}_N, \boldsymbol{z}_N; \boldsymbol{\varphi}_N) = -c(\boldsymbol{\omega} - \boldsymbol{\zeta}_N, \boldsymbol{u} - \boldsymbol{z}_N; \boldsymbol{\varphi}_N) - (c - c_N)(\boldsymbol{\zeta}_N, \boldsymbol{z}_N; \boldsymbol{\varphi}_N).$$

Since the pair $(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N)$ with $\boldsymbol{\vartheta}_N = \boldsymbol{\zeta}_N - \tilde{\boldsymbol{\zeta}}_N$ and $\boldsymbol{w}_N = \boldsymbol{z}_N - \tilde{\boldsymbol{z}}_N$ belongs to $\mathcal{W}_N$, the desired estimate is easily derived from the two previous lines.

Remark 4.5. The same argument as in the previous proof, combined with the inf-sup condition (3.22), leads to the estimate

$$\inf_{\boldsymbol{z}_N \in V_N} \|\boldsymbol{u} - \boldsymbol{z}_N\|_{L^2(\Omega)^d} \le c \inf_{\boldsymbol{v}_N \in \mathbb{D}_N} \|\boldsymbol{u} - \boldsymbol{v}_N\|_{H(\mathrm{div},\Omega)}. \tag{4.7}$$

However, we prefer to avoid dealing with the approximation error in the $H(\mathrm{div},\Omega)$-norm and directly estimate the distance from $\boldsymbol{u}$ to V_N.

By combining Lemmas 4.1 and 4.2 and Corollary 4.4, we observe that the full error

$$\|\boldsymbol{\omega} - \boldsymbol{\omega}_N\|_{H(\mathbf{curl},\Omega)} + \|\boldsymbol{u} - \boldsymbol{u}_N\|_{H(\mathrm{div},\Omega)} + \|p - p_N\|_{L^2(\Omega)}$$

is bounded by the sum of the three terms of approximation error,

$$\inf_{\boldsymbol{\zeta}_N \in \mathbb{C}_N} \|\boldsymbol{\omega} - \boldsymbol{\zeta}_N\|_{H(\mathbf{curl},\Omega)}, \qquad \inf_{\boldsymbol{z}_N \in V_N} \|\boldsymbol{u} - \boldsymbol{z}_N\|_{L^2(\Omega)^d}, \qquad \inf_{q_N \in \mathbb{M}_N} \|p - q_N\|_{L^2(\Omega)},$$

plus the three quantities $E_N^{\boldsymbol{f}}$, $E_N^a(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N)$, and $E_N^c(\boldsymbol{\zeta}_N, \boldsymbol{z}_N)$ which are issued from numerical integration.

In order to estimate these last ones, we introduce the orthogonal projection operator Π_{N-1} from $L^2(\Omega)$ onto $\mathbb{P}_{N-1}(\Omega)$. Indeed, we derive from (3.4) that, for any $\boldsymbol{v}_N$ in $\mathbb{D}_N$,

$$\begin{aligned}\langle \boldsymbol{f}, \boldsymbol{v}_N\rangle - (\boldsymbol{f}, \boldsymbol{v}_N)_N &= \langle \boldsymbol{f} - \Pi_{N-1}\boldsymbol{f}, \boldsymbol{v}_N\rangle - (\boldsymbol{f} - \Pi_{N-1}\boldsymbol{f}, \boldsymbol{v}_N)_N \\ &= \langle \boldsymbol{f} - \Pi_{N-1}\boldsymbol{f}, \boldsymbol{v}_N\rangle - (\mathcal{I}_N\boldsymbol{f} - \Pi_{N-1}\boldsymbol{f}, \boldsymbol{v}_N)_N,\end{aligned}$$

so that, owing to (3.5),

$$E_N^{\boldsymbol{f}} \le (1 + 3^d)\,\|\boldsymbol{f} - \Pi_{N-1}\boldsymbol{f}\|_{L^2(\Omega)^d} + 3^d\,\|\boldsymbol{f} - \mathcal{I}_N\boldsymbol{f}\|_{L^2(\Omega)^d}. \tag{4.8}$$

Similarly, we have, for any $\boldsymbol{v}_N$ in $\mathbb{D}_N$,

$$\begin{aligned}(a - a_N)(\boldsymbol{\vartheta}_N, \boldsymbol{z}_N; \boldsymbol{v}_N) = \nu \int_\Omega \big(\mathbf{curl}\,\boldsymbol{\vartheta}_N - \Pi_{N-1}(\mathbf{curl}\,\boldsymbol{\omega})\big)(\boldsymbol{x}) \cdot \boldsymbol{z}_N(\boldsymbol{x})\,d\boldsymbol{x} \\ - \nu\,\big(\mathbf{curl}\,\boldsymbol{\vartheta}_N - \Pi_{N-1}(\mathbf{curl}\,\boldsymbol{\omega}), \boldsymbol{z}_N\big)_N,\end{aligned}$$

so that

(4.9)
$$E_N^a(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N) \leq (1+3^d)\left(\|\mathbf{curl}\,(\boldsymbol{\omega}-\boldsymbol{\vartheta}_N)\|_{L^2(\Omega)^d} + \|\mathbf{curl}\,\boldsymbol{\omega} - \Pi_{N-1}(\mathbf{curl}\,\boldsymbol{\omega})\|_{L^2(\Omega)^d}\right).$$

Note that a bound for the quantity $\|\mathbf{curl}\,(\boldsymbol{\omega}-\boldsymbol{\vartheta}_N)\|_{L^2(\Omega)^d}$ is provided by Corollary 4.4. Finally, the same arguments lead to

(4.10)
$$E_N^c(\boldsymbol{\zeta}_N, \boldsymbol{z}_N) \leq (1+3^d)\left(\|\boldsymbol{\omega}-\boldsymbol{\zeta}_N\|_{L^2(\Omega)^{\frac{d(d-1)}{2}}} + \|\boldsymbol{\omega}-\Pi_{N-1}\boldsymbol{\omega}\|_{L^2(\Omega)^{\frac{d(d-1)}{2}}} + \|\boldsymbol{u}-\boldsymbol{z}_N\|_{L^2(\Omega)^d} + \|\boldsymbol{u}-\Pi_{N-1}\boldsymbol{u}\|_{L^2(\Omega)^d}\right).$$

We now recall from [13, Thms. 7.1 and 14.2] the approximation properties of the operators Π_{N-1} and $\mathcal{I}_N$: For any function g in $H^s(\Omega)$, $s \geq 0$,

$$\|g - \Pi_{N-1} g\|_{L^2(\Omega)} \leq c\, N^{-s}\, \|g\|_{H^s(\Omega)}, \tag{4.11}$$

and, for any function g in $H^s(\Omega)$, $s > \frac{d}{2}$,

$$\|g - \mathcal{I}_N g\|_{L^2(\Omega)} \leq c\, N^{-s}\, \|g\|_{H^s(\Omega)}. \tag{4.12}$$

Estimates (4.11) and (4.12), when applied to each component of $\boldsymbol{f}$ and combined with (4.8), lead to the desired bound for $E_N^{\boldsymbol{f}}$. When combined with (4.9) and (4.10), they allow us to reduce the evaluation of $E_N^a(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N)$ and $E_N^c(\boldsymbol{\zeta}_N, \boldsymbol{z}_N)$ to a bound for the approximation error.

The approximation error for the pressure can also be estimated from (4.11). To go further we recall the following:

• In dimension $d = 2$, the orthogonal projection operator $\Pi_N^{1,0}$ from $H_0^1(\Omega)$ onto $\mathbb{C}_N$ satisfies, for all functions $\boldsymbol{\varphi}$ in $H^s(\Omega) \cap H_0^1(\Omega)$, $s \geq 1$,

$$\|\boldsymbol{\varphi} - \Pi_N^{1,0}\boldsymbol{\varphi}\|_{L^2(\Omega)} + N^{-1}\,|\boldsymbol{\varphi} - \Pi_N^{1,0}\boldsymbol{\varphi}|_{H^1(\Omega)} \leq c\, N^{-s}\, \|\boldsymbol{\varphi}\|_{H^s(\Omega)}. \tag{4.13}$$

• In dimension $d = 3$, a spectral analogue $\mathcal{R}_N$ of the Nédélec operator [24, sect. 2] has been constructed in [7, sect. 4]. It maps smooth functions in $H_0(\mathbf{curl}, \Omega)$ onto $\mathbb{C}_N$ and satisfies, for all functions $\boldsymbol{\varphi}$ in $H^s(\Omega)^3 \cap H_0(\mathbf{curl}, \Omega)$, $s \geq 2$,

$$\|\boldsymbol{\varphi} - \mathcal{R}_N\boldsymbol{\varphi}\|_{L^2(\Omega)^3} \leq c\, N^{-s}\, \|\boldsymbol{\varphi}\|_{H^s(\Omega)^3}, \tag{4.14}$$

and, for all functions $\boldsymbol{\varphi}$ in $H_0(\mathbf{curl}, \Omega)$ such that $\mathbf{curl}\,\boldsymbol{\varphi}$ belongs to $H^s(\Omega)^3$, $s \geq 1$,

$$\|\mathbf{curl}\,(\boldsymbol{\varphi} - \mathcal{R}_N\boldsymbol{\varphi})\|_{L^2(\Omega)^3} \leq c\, N^{-s}\, \|\mathbf{curl}\,\boldsymbol{\varphi}\|_{H^s(\Omega)^3}. \tag{4.15}$$

Applying these estimates leads to a bound for the approximation error on $\boldsymbol{\omega}$. Moreover, since the velocity $\boldsymbol{u}$ is divergence-free and has a zero normal trace on $\partial\Omega$, it is equal to $\mathbf{curl}\,\boldsymbol{\psi}$ for a function $\boldsymbol{\psi}$ in $H_0(\mathbf{curl}, \Omega)$. Thus, thanks to Lemma 3.1, its best approximation in V_N can be bounded from (4.13) or (4.15).

To state the final estimate, we introduce the scale of spaces, for $s \geq 0$,

$$H^s(\mathbf{curl}, \Omega) = \left\{\boldsymbol{\varphi} \in H^s(\Omega)^{\frac{d(d-1)}{2}};\ \mathbf{curl}\,\boldsymbol{\varphi} \in H^s(\Omega)^d\right\}. \tag{4.16}$$

Note that this space coincides with $H^{s+1}(\Omega)$ in dimension $d = 2$.

THEOREM 4.6. *Assume that the data* $\boldsymbol{f}$ *belong to* $H^\sigma(\Omega)^d$ *for a real number* $\sigma > \frac{d}{2}$ *and that the solution* $(\boldsymbol{\omega}, \boldsymbol{u}, p)$ *of problem* (2.9) *belongs to* $H^s(\mathbf{curl}, \Omega) \times H^s(\Omega)^d \times H^s(\Omega)$ *for a real number* $s \geq d-1$. *Then the following error estimate holds between this solution and the solution* $(\boldsymbol{\omega}_N, \boldsymbol{u}_N, p_N)$ *of problem* (3.7)*:*

(4.17)
$$\begin{aligned}\|\boldsymbol{\omega} - \boldsymbol{\omega}_N\|_{H(\mathbf{curl},\Omega)} + \|\boldsymbol{u} - \boldsymbol{u}_N\|_{H(\mathrm{div},\Omega)} + \|p - p_N\|_{L^2(\Omega)} \\ \leq c\left(N^{-s}\left(\|\boldsymbol{\omega}\|_{H^s(\mathbf{curl},\Omega)} + \|\boldsymbol{u}\|_{H^s(\Omega)^d} + \|p\|_{H^s(\Omega)}\right) + N^{-\sigma}\,\|\boldsymbol{f}\|_{H^\sigma(\Omega)^d}\right).\end{aligned}$$

Estimate (4.17) is fully optimal, which is especially interesting as far as the pressure is concerned since this optimality is not obtained for most spectral discretizations of the Stokes problem.

The regularity which is required ($s \geq d-1$) concerns only the vorticity $\boldsymbol{\omega}$ and seems reasonable at least in the case of a square. Moreover, it follows from [16] and [17] that both $\boldsymbol{\omega}$ and $\boldsymbol{u}$ can be written as a sum of a regular part and the gradient of a linear combination of the singular functions associated with the Laplace operator. These two terms can be approximated separately and, as usual in spectral methods [12], the approximation of the singular part is better than can be hoped from the general theory. This leads to the following result, where, in dimension $d = 2$, σ_Ω is equal to $4 - \varepsilon$ for any $\varepsilon > 0$.

COROLLARY 4.7. *Assume that the data* $\boldsymbol{f}$ *belong to* $H^\sigma(\Omega)^d$ *for a real number* $\sigma > \frac{d}{2}$. *Then the following error estimate holds between the solution* $(\boldsymbol{\omega}, \boldsymbol{u}, p)$ *of problem* (2.9) *and the solution* $(\boldsymbol{\omega}_N, \boldsymbol{u}_N, p_N)$ *of problem* (3.7)*:*

$$\begin{aligned}\|\boldsymbol{\omega} - \boldsymbol{\omega}_N\|_{H(\mathbf{curl},\Omega)} + \|\boldsymbol{u} - \boldsymbol{u}_N\|_{H(\mathrm{div},\Omega)} + \|p - p_N\|_{L^2(\Omega)} \\ \leq c\,N^{-\min\{\sigma,\sigma_\Omega\}}\,\|\boldsymbol{f}\|_{H^\sigma(\Omega)^d},\end{aligned} \tag{4.18}$$

where σ_Ω *is a real number* ≥ 1 *depending only on* Ω.

5. Case of nonhomogeneous boundary conditions. We briefly explain how the results of the previous sections can be extended to the problem

$$\begin{cases}\nu\,\mathbf{curl}\,\boldsymbol{\omega} + \mathbf{grad}\,p = \boldsymbol{f} & \text{in } \Omega,\\ \mathrm{div}\,\boldsymbol{u} = 0 & \text{in } \Omega,\\ \boldsymbol{\omega} = \mathbf{curl}\,\boldsymbol{u} & \text{in } \Omega,\\ \boldsymbol{u}\cdot\boldsymbol{n} = g & \text{on } \partial\Omega,\\ \gamma_t(\boldsymbol{\omega}) = \boldsymbol{0} & \text{on } \partial\Omega,\end{cases} \tag{5.1}$$

where the function g belongs to $H^{-\frac{1}{2}}(\partial\Omega)$ and satisfies the compatibility condition (here $\langle\cdot,\cdot\rangle_{\partial\Omega}$ obviously denotes the duality pairing between $H^{-\frac{1}{2}}(\partial\Omega)$ and $H^{\frac{1}{2}}(\partial\Omega)$)

$$\langle g, 1\rangle_{\partial\Omega} = 0. \tag{5.2}$$

We consider the following variational problem:
Find $(\boldsymbol{\omega}, \boldsymbol{u}, p)$ *in* $H_0(\mathbf{curl}, \Omega) \times H(\mathrm{div}, \Omega) \times L^2_0(\Omega)$ *such that*

$$\boldsymbol{u}\cdot\boldsymbol{n} = g \quad \text{on } \partial\Omega \tag{5.3}$$

and that

$$\begin{aligned}&\forall \boldsymbol{v} \in H_0(\mathrm{div}, \Omega), && a(\boldsymbol{\omega}, \boldsymbol{u}; \boldsymbol{v}) + b(\boldsymbol{v}, p) = \langle \boldsymbol{f}, \boldsymbol{v}\rangle,\\ &\forall q \in L^2_0(\Omega), && b(\boldsymbol{u}, q) = 0,\\ &\forall \boldsymbol{\vartheta} \in H_0(\mathbf{curl}, \Omega), && c(\boldsymbol{\omega}, \boldsymbol{u}; \boldsymbol{\vartheta}) = 0.\end{aligned} \tag{5.4}$$

Thanks to the arguments given in section 2, it can be checked that problems (5.1) and (5.3)–(5.4) are equivalent, in the sense made precise in Proposition 2.2. To prove the well-posedness of problem (5.3)–(5.4), we need a lifting of the boundary condition (5.3).

LEMMA 5.1. *For any g in $H^{-\frac{1}{2}}(\partial\Omega)$ satisfying* (5.2)*, there exists a divergence-free and curl-free function $\boldsymbol{u}_b$ in $L^2(\Omega)^d$ such that $\boldsymbol{u}_b \cdot \boldsymbol{n}$ is equal to g on $\partial\Omega$. Moreover, this function satisfies*

$$\|\boldsymbol{u}_b\|_{H(\mathrm{div},\Omega)} \leq c\,\|g\|_{H^{-\frac{1}{2}}(\partial\Omega)}. \tag{5.5}$$

Proof. The following variational problem,
Find μ in $H^1(\Omega) \cap L^2_0(\Omega)$ such that

$$\forall \rho \in H^1(\Omega) \cap L^2_0(\Omega), \quad \int_\Omega \mathbf{grad}\,\mu \cdot \mathbf{grad}\,\rho\, d\boldsymbol{x} = \langle g, \rho\rangle_{\partial\Omega},$$

admits a unique solution μ which satisfies

$$|\mu|_{H^1(\Omega)} \leq c\,\|g\|_{H^{-\frac{1}{2}}(\partial\Omega)}.$$

Then the function $\boldsymbol{u}_b = \mathbf{grad}\,\mu$ satisfies all the properties stated in the lemma.

THEOREM 5.2. *For any data $\boldsymbol{f}$ in the dual space of $H_0(\mathrm{div},\Omega)$ and g in $H^{-\frac{1}{2}}(\partial\Omega)$ satisfying* (5.2)*, problem* (5.3)–(5.4) *has a unique solution $(\boldsymbol{\omega},\boldsymbol{u},p)$ in $H_0(\mathbf{curl},\Omega) \times H(\mathrm{div},\Omega) \times L^2_0(\Omega)$. Moreover, this solution satisfies*

$$\|\boldsymbol{\omega}\|_{H(\mathbf{curl},\Omega)} + \|\boldsymbol{u}\|_{H(\mathrm{div},\Omega)} + \|p\|_{L^2(\Omega)} \leq c\,\big(\|\boldsymbol{f}\|_{H_0(\mathrm{div},\Omega)'} + \|g\|_{H^{-\frac{1}{2}}(\partial\Omega)}\big). \tag{5.6}$$

Proof. Using the function $\boldsymbol{u}_b$ introduced in Lemma 5.1 and setting $\boldsymbol{u}_0 = \boldsymbol{u} - \boldsymbol{u}_b$, we note that $(\boldsymbol{\omega},\boldsymbol{u},p)$ is a solution of problem (5.3)–(5.4) if and only if $(\boldsymbol{\omega},\boldsymbol{u}_0,p)$ is a solution of a problem similar to (2.9). So the existence and uniqueness of $(\boldsymbol{\omega},\boldsymbol{u},p)$ follow from Theorem 2.5, and estimate (5.6) is derived by combining (2.18) and (5.5).

In order to write the discrete problem, we introduce the space

$$\overline{\mathbb{D}}_N = \begin{cases} \mathbb{P}_{N,N-1}(\Omega) \times \mathbb{P}_{N-1,N}(\Omega) & \text{if } d = 2, \\ \mathbb{P}_{N,N-1,N-1}(\Omega) \times \mathbb{P}_{N-1,N,N-1}(\Omega) \times \mathbb{P}_{N-1,N-1,N}(\Omega) & \text{if } d = 3. \end{cases} \tag{5.7}$$

Assuming that the function g belongs to $L^2(\partial\Omega)$, we define an approximation g_N of g as follows: On each edge ($d = 2$) or face ($d = 3$) Γ_r of Ω, $1 \leq r \leq 2d$, $g_{N|\Gamma_r}$ is equal to the image of $g_{|\Gamma_r}$ by the orthogonal projection operator from $L^2(\Gamma_r)$ onto $\mathbb{P}_{N-1}(\Gamma_r)$. Then we consider the following problem:

Find $(\boldsymbol{\omega}_N,\boldsymbol{u}_N,p_N)$ in $\mathbb{C}_N \times \overline{\mathbb{D}}_N \times \mathbb{M}_N$ such that

$$\boldsymbol{u}_N \cdot \boldsymbol{n} = g_N \quad \text{on } \partial\Omega \tag{5.8}$$

and that

$$\begin{aligned} &\forall \boldsymbol{v}_N \in \mathbb{D}_N, \quad a_N(\boldsymbol{\omega}_N,\boldsymbol{u}_N;v_N) + b_N(\boldsymbol{v}_N,p_N) = (\boldsymbol{f},\boldsymbol{v}_N)_N, \\ &\forall q \in \mathbb{M}_N, \quad b_N(\boldsymbol{u}_N,q_N) = 0, \\ &\forall \boldsymbol{\vartheta}_N \in \mathbb{C}_N, \quad c_N(\boldsymbol{\omega}_N,\boldsymbol{u}_N;\boldsymbol{\vartheta}_N) = 0. \end{aligned} \tag{5.9}$$

Remark 5.3. The choice of g_N as the discrete boundary condition is justified at least in a first step by the following reasons:

(i) The normal trace operator on each Γ_r, $1 \le r \le 2d$, maps $\overline{\mathbb{D}}_N$ onto $\mathbb{P}_{N-1}(\Gamma_r)$, so that each $g_{N|\Gamma_r}$ belongs to the right space.

(ii) In dimension $d = 2$, on two adjacent edges (i.e., that share a vertex), the normal trace operator involves different components of any function in $H(\mathrm{div}, \Omega)$, so that g_N does not have to satisfy any compatibility conditions at the common vertex. The same remark holds in dimension $d = 3$ for two adjacent faces (i.e., that share an edge).

(iii) Property (5.2) is still satisfied with g replaced by g_N, which is essential since we intend to work with exactly divergence-free discrete velocities.
Moreover, the computation of g_N is not too expensive.

THEOREM 5.4. *For any data $\boldsymbol{f}$ continuous on $\overline{\Omega}$ and g in $L^2(\partial\Omega)$ satisfying* (5.2)*, problem* (5.8)–(5.9) *has a unique solution $(\boldsymbol{\omega}_N, \boldsymbol{u}_N, p_N)$ in $\mathbb{C}_N \times \overline{\mathbb{D}}_N \times \mathbb{M}_N$.*

Proof. It is readily checked that problem (5.8)–(5.9) can be written as a square linear system. Moreover, it follows from Theorem 3.10 that the unique solution of this problem when the data $\boldsymbol{f}$ and g_N are zero is $(\mathbf{0}, \mathbf{0}, 0)$. This yields the existence and uniqueness property.

We briefly recall the arguments that can be used in order to derive the same error estimates as in section 4.

(1) It follows from [7, sect. 4] that, in dimension $d = 3$, an extension $\overline{\mathcal{R}}_N$ of the operator $\mathcal{R}_N$ introduced in section 4 can be constructed such that estimate (4.15) still holds but now for $s \ge \frac{3}{2}$ and that, for any smooth enough function $\boldsymbol{\varphi}$, the normal traces of $\mathbf{curl}\,(\overline{\mathcal{R}}_N\boldsymbol{\varphi})$ on each Γ_r coincides with the images of the normal traces of $\mathbf{curl}\,\boldsymbol{\varphi}$ by the projection operator from $L^2(\Gamma_r)$ onto $\mathbb{P}_{N-1}(\Gamma_r)$. A similar operator can obviously be constructed in dimension $d = 2$.

(2) Since the velocity $\boldsymbol{u}$ is divergence-free and thanks to (5.2), there exists a function $\boldsymbol{\psi}$ such that $\mathbf{curl}\,\boldsymbol{\psi} = \boldsymbol{u}$. Then the function $\boldsymbol{z}_N = \mathbf{curl}\,(\overline{\mathcal{R}}_N\boldsymbol{\psi})$ belongs to $\mathbb{D}_N$, is divergence-free, and has its normal trace equal to g_N on $\partial\Omega$. Moreover, the distance of $\boldsymbol{u}$ to $\boldsymbol{z}_N$ in $L^2(\Omega)^d$ can easily be evaluated from (4.15).

(3) Let $\overline{V}_N$ denote the space of divergence-free functions in $\overline{\mathbb{D}}_N$. Thanks to Lemma 4.3 (see also the proof of Corollary 4.4), for the previous function $\boldsymbol{z}_N$ and any $\boldsymbol{\zeta}_N$ in $\mathbb{C}_N$, there exists a $(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N)$ in $\mathbb{C}_N \times \overline{V}_N$ such that the pair $(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N)$ satisfies (4.5), the normal traces of $\boldsymbol{w}_N$ and $\boldsymbol{z}_N$ coincide on $\partial\Omega$, and, moreover,

$$\forall \boldsymbol{\varphi}_N \in \mathbb{C}_N,\ c_N(\boldsymbol{\vartheta}_N, \boldsymbol{w}_N; \boldsymbol{\varphi}_N) = 0.$$

(4) The pair $(\boldsymbol{\omega}_N - \boldsymbol{\vartheta}_N, \boldsymbol{u}_N - \boldsymbol{z}_N)$ now belongs to $\mathcal{W}_N$. So exactly the same arguments as in the proof of Lemma 4.1 lead to estimate (4.1).

THEOREM 5.5. *If the assumptions of Theorem* 4.6 *hold and the data g satisfies condition* (5.2) *and is such that each $g_{|\Gamma_r}$, $1 \le r \le 2d$, belongs to $H^\tau(\Gamma_r)$ for a nonnegative real number τ, the following error estimate holds between the solution $(\boldsymbol{\omega}, \boldsymbol{u}, p)$ of problem* (5.3)–(5.4) *and the solution $(\boldsymbol{\omega}_N, \boldsymbol{u}_N, p_N)$ of problem* (5.8)–(5.9)*:*

(5.10)
$$\begin{aligned}\|\boldsymbol{\omega} - \boldsymbol{\omega}_N\|_{H(\mathbf{curl},\Omega)} + \|\boldsymbol{u} - \boldsymbol{u}_N\|_{H(\mathrm{div},\Omega)} + \|p - p_N\|_{L^2(\Omega)} \\ \le c\Big(N^{-s}\left(\|\boldsymbol{\omega}\|_{H^s(\mathbf{curl},\Omega)} + \|\boldsymbol{u}\|_{H^s(\Omega)^d} + \|p\|_{H^s(\Omega)}\right) \\ + N^{-\sigma}\,\|\boldsymbol{f}\|_{H^\sigma(\Omega)^d} + N^{-\tau-\frac{1}{2}}\sum_{r=1}^{2d}\|g\|_{H^\tau(\Gamma_r)}\Big).\end{aligned}$$

COROLLARY 5.6. *Assume that the data $(\boldsymbol{f}, g)$ belong to $H^\sigma(\Omega)^d \times H^{\sigma-\frac{1}{2}}(\partial\Omega)$ for a real number $\sigma > \frac{d}{2}$ and that condition* (5.2) *is satisfied. Then the following error*

estimate holds between the solution $(\boldsymbol{\omega}, \boldsymbol{u}, p)$ *of problem* (5.3)–(5.4) *and the solution* $(\boldsymbol{\omega}_N, \boldsymbol{u}_N, p_N)$ *of problem* (5.8)–(5.9) *for the same real number* σ_Ω *as in Corollary* 4.7*:*

$$\begin{aligned}\|\boldsymbol{\omega}-\boldsymbol{\omega}_N\|_{H(\mathbf{curl},\Omega)}+\|\boldsymbol{u}-\boldsymbol{u}_N\|_{H(\mathrm{div},\Omega)}+\|p-p_N\|_{L^2(\Omega)}&\\ \le c\,N^{-\min\{\sigma,\sigma_\Omega\}}\left(\|\boldsymbol{f}\|_{H^\sigma(\Omega)^d}+\|g\|_{H^{\sigma-\frac12}(\partial\Omega)}\right).&\end{aligned}\tag{5.11}$$

6. Some numerical experiments. Before presenting the numerical experiments, we briefly describe how problem (3.7) is implemented. Let φ_j, $0 \le j \le N$, denote the Lagrange polynomials in $\mathbb{P}_N(-1,1)$ associated with the nodes ξ_j. We fix an integer j_* between 0 and N (usually equal to the integer part of $\frac{N}{2}$), define J^* as the set $\{0,\dots,N\}\setminus\{j^*\}$, and set

$$\varphi_j^*(\zeta)=\varphi_j(\zeta)\,\frac{\xi_j-\xi_{j^*}}{\zeta-\xi_{j^*}},\quad j\in J^*.\tag{6.1}$$

Then the unknowns $\boldsymbol{\omega}_N$ and $\boldsymbol{u}_N$ and a pseudopressure $\tilde{p}_N$ admit the expansions, in dimension $d=2$ for simplicity,

$$\begin{aligned}\boldsymbol{\omega}_N(x,y)&=\sum_{i=1}^{N-1}\sum_{j=1}^{N-1}\omega_{ij}\,\varphi_i(x)\varphi_j(y),\\ u_{Nx}(x,y)&=\sum_{i=1}^{N-1}\sum_{j\in J^*}u^x_{ij}\,\varphi_i(x)\varphi_j^*(y),\quad u_{Ny}(x,y)=\sum_{i\in J^*}\sum_{j=1}^{N-1}u^y_{ij}\,\varphi_i^*(x)\varphi_j(y),\\ \tilde{p}_N(x,y)&=\sum_{i\in J^*,j\in J^*,(i,j)\neq(0,0)}p_{ij}\,\varphi_i^*(x)\varphi_j^*(y).\end{aligned}$$

The function $\tilde{p}_N$ vanishes in $(-1,-1)$ but no longer belongs to $L^2_0(\Omega)$; however, the real pressure p_N can easily be recovered in a postprocessing step, thanks to the formula

$$p_N(x,y)=\tilde{p}_N(x,y)-\frac{1}{2^d}\,(\tilde{p}_N,1)_N.\tag{6.2}$$

We denote by $\Omega^\diamond$, U, and P the vectors made of these coefficients. Their dimensions are equal to $\frac{d(d-1)}{2}\,N^{d-2}(N-1)^2$, $d\,N^{d-1}(N-1)$, and N^d-1, respectively. Problem (3.7) can thus be written equivalently as the square linear system

$$\begin{pmatrix}A & 0 & B\\ 0 & B^T & 0\\ C_{\boldsymbol{\omega}} & C_{\boldsymbol{u}} & 0\end{pmatrix}\begin{pmatrix}\Omega^\diamond\\ U\\ P\end{pmatrix}=\begin{pmatrix}F\\ 0\\ 0\end{pmatrix},\tag{6.3}$$

where B^T denotes the transposed matrix of B. The global matrix is not symmetric, even if the subblocks $\left(\begin{smallmatrix}0 & B\\ B^T & 0\end{smallmatrix}\right)$ and $C_{\boldsymbol{\omega}}$ are symmetric. Note that, up to the multiplicative constant $-\nu^{-1}$, the matrix $C_{\boldsymbol{u}}$ coincides with A^T. The system is very similar in the case of nonhomogeneous boundary conditions, except that a further vector $-\tilde{B}^TG$ appears in the second line of the right-hand side.

In what follows, system (6.3) is solved via the GMRES method, so that it has not to be assembled. As a preconditioner, we use the matrix issued from an incomplete LU factorization of the global matrix in (6.3). Moreover, as standard in spectral methods, it follows from the tensorization properties of the polynomial spaces that each product of this matrix by a vector is realized with $c\,N^{d+1}$ operations, which highly reduces the cost of the inversion.

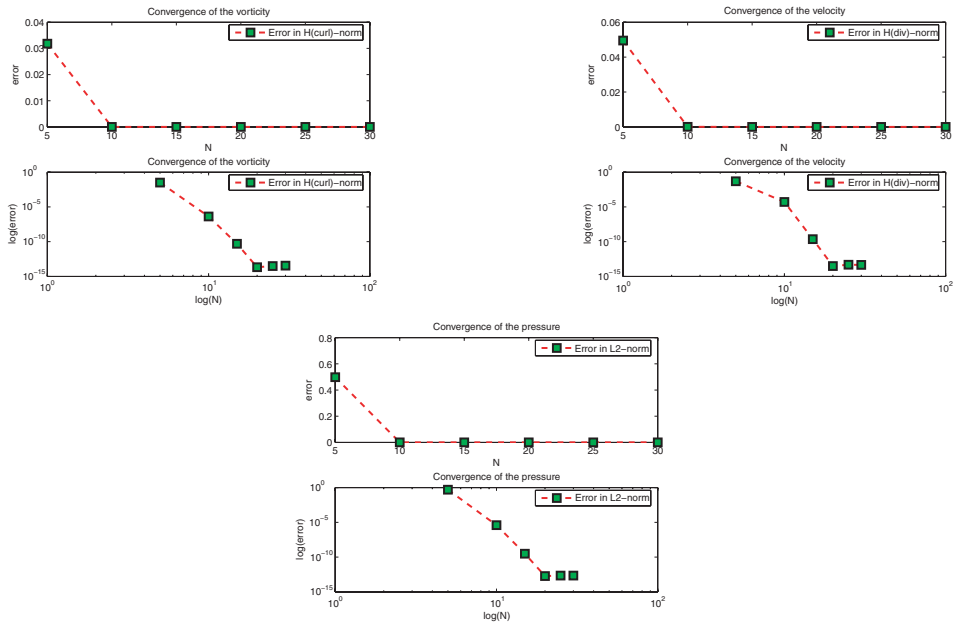

FIG. 1. *Error curves for the solution defined from* (6.4).

Two-dimensional experiments. We first work in the square $\Omega =]-1,1[^2$, with $\nu = 1$. We consider a given solution constructed thanks to the formulas $\boldsymbol{u} = \mathbf{curl}\,\psi$ and $\boldsymbol{\omega} = \mathbf{curl}\,\boldsymbol{u}$ in the two situations

(i) of functions ψ and p of class $\mathcal{C}^\infty$, defined by

$$\psi(x,y) = \sin(\pi x)\sin(\pi y), \quad p(x,y) = xy, \tag{6.4}$$

and

(ii) of functions ψ and p of limited regularity, defined by

$$\psi(x,y) = (1-x^2)^3(1-y^2)^{\frac{7}{2}}, \quad p(x,y) = x(1-x^2)^{\frac{3}{2}}(1+y^2)^{-\frac{1}{2}}. \tag{6.5}$$

Figure 1 for the solution issued from (6.4) and Figure 2 for the solution issued from (6.5) present the convergence curves of the relative errors on $\boldsymbol{\omega}$, $\boldsymbol{u}$, and p in the corresponding norms, both in standard and logarithmic scales, for N varying from 5 to 30.

In Figure 1, the convergence is exponential and the three errors are smaller than 10^{-10} from $N = 15$. The convergence is, of course, slower in Figure 2. It can be noted that the vorticity and the pressure have the same regularity near the edges of Ω contained in the lines $x = \pm 1$ (they behave like $(1-x^2)^{\frac{3}{2}}$) and that the error slopes are the same.

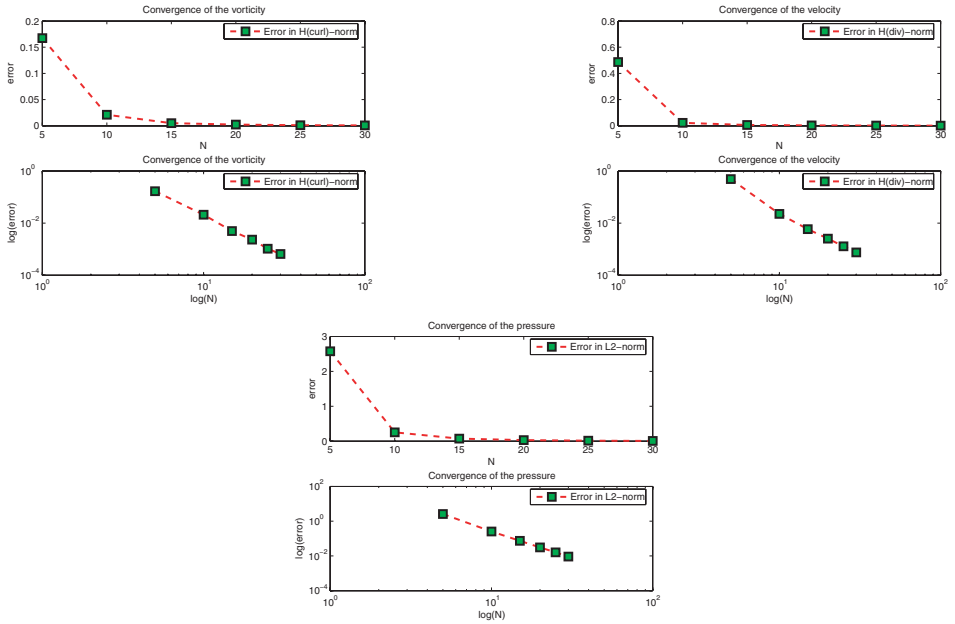

FIG. 2. *Error curves for the solution defined from* (6.5).

Figure 3 presents, from left to right and top to bottom, the values of the vorticity of the two components of the velocity and of the pressure corresponding to the data $\boldsymbol{f} = (f_x, f_y)$, with

$$f_x = 0, \quad f_y = xy^2, \tag{6.6}$$

in the case $g = 0$ of homogeneous boundary conditions, obtained with $N = 40$.

Figure 4 presents, from left to right and top to bottom, the values of the vorticity of the two components of the velocity and of the pressure corresponding to the data $\boldsymbol{f} = (f_x, f_y)$, given in (6.6) and with g given by

$$g(-1, y) = -(1 - y^2)^{\frac{3}{2}}, \qquad g(1, y) = (1 - y^2)^{\frac{3}{2}}, \qquad g(x, \pm 1) = 0, \tag{6.7}$$

obtained with $N = 40$. It can be noted that the vorticity $\boldsymbol{\omega}_N$ and pressure p_N are nearly the same in Figures 3 and 4.

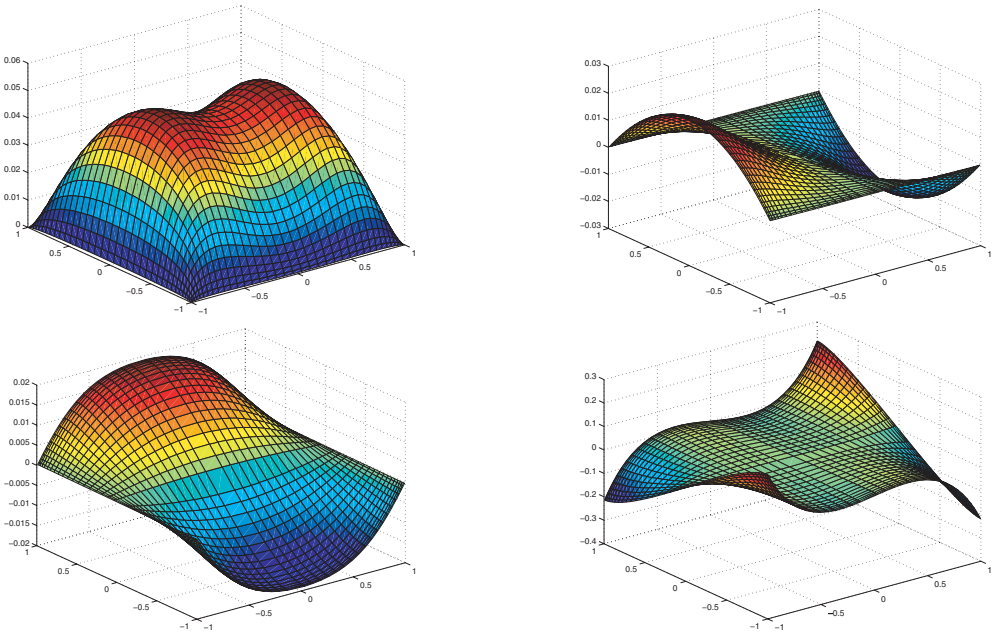

FIG. 3. *The solution* $(\boldsymbol{\omega}, u_x, u_y, p)$ *for the data* $\boldsymbol{f}$ *defined in* (6.6) *and* $g = 0$.

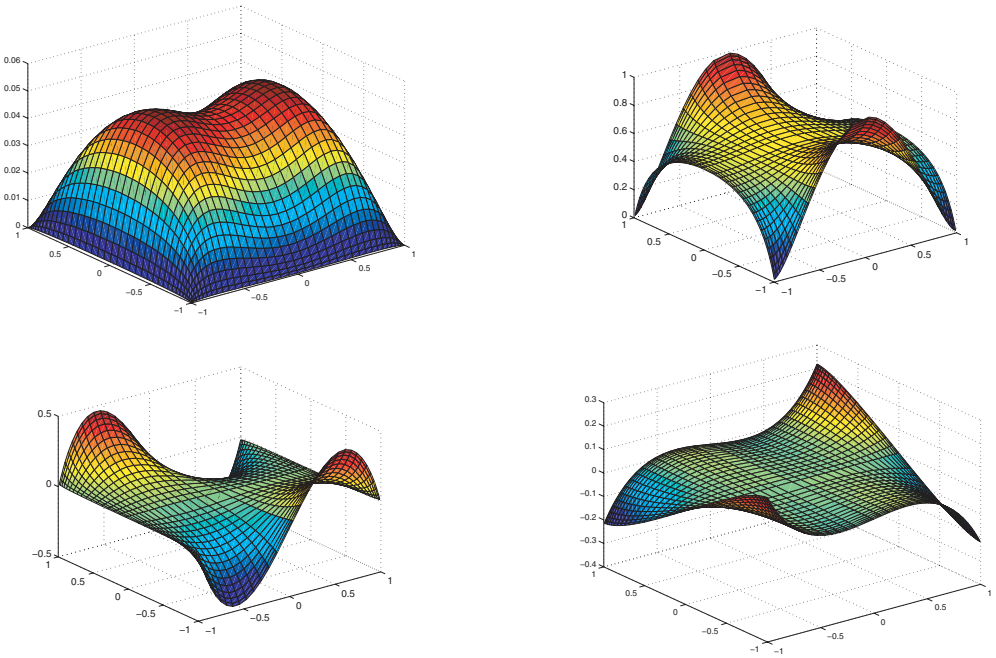

FIG. 4. *The solution* $(\boldsymbol{\omega}, u_x, u_y, p)$ *for the data* $(\boldsymbol{f}, g)$ *defined in* (6.6)–(6.7).

Three-dimensional experiments. We now work in the cube $\Omega =]-1, 1[^3$, with $\nu = 1$ and always in the case $g = 0$ of homogeneous boundary conditions. We consider a given solution constructed thanks to the formulas $\boldsymbol{u} = \mathbf{curl}\,\boldsymbol{\psi}$ and $\boldsymbol{\omega} = \mathbf{curl}\,\boldsymbol{u}$, with

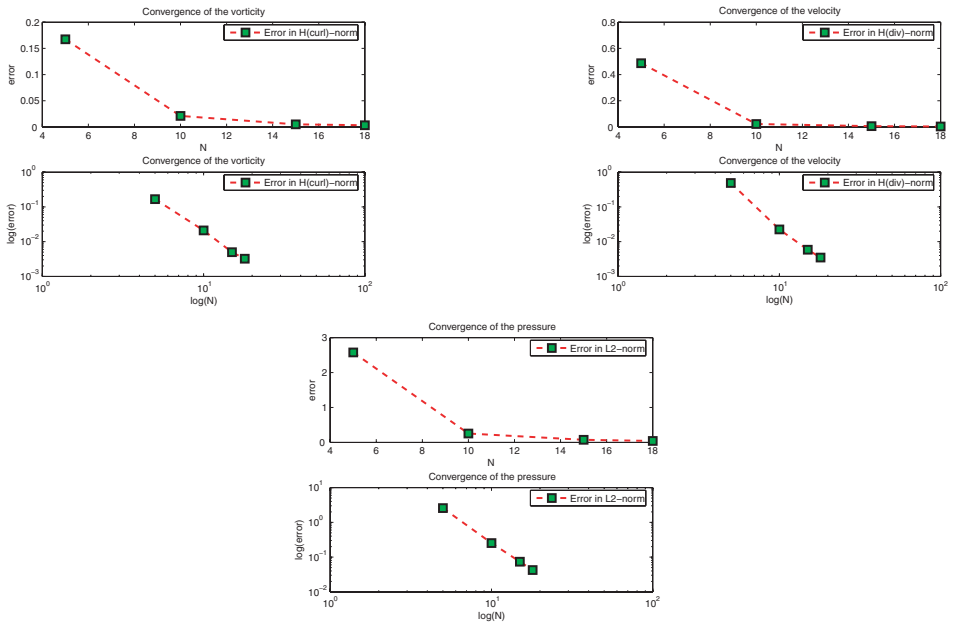

FIG. 5. *Error curves for the solution defined from* (6.8).

$\boldsymbol{\psi} = (\psi_x, \psi_y, \psi_z)$ and p defined by

$$
\begin{aligned}
&\psi_x(x,y,z) = (1-y^2)^3(1-z^2)^{\frac{7}{2}}, \quad \psi_y(x,y,z) = (1-x^2)^{\frac{7}{2}}(1-z^2)^3,\\
&\psi_z(x,y,z) = (1-x^2)^3(1-y^2)^{\frac{7}{2}}, \quad p(x,y,z) = \frac{x(1-x^2)^{\frac{3}{2}}}{(1+y^2)^{\frac{1}{2}}(1+z^2)^{\frac{1}{2}}}.
\end{aligned} \tag{6.8}
$$

Figure 5 presents the convergence curves of the relative errors on $\boldsymbol{\omega}$, $\boldsymbol{u}$, and p, both in standard and logarithmic scales, for N varying from 5 to 18. It can be noted that the regularity of the solution is the same as for the two-dimensional solution defined from (6.5) and that the slopes of the error are very similar to those in Figure 2. We do not present the convergence curves for a solution of class $\mathcal{C}^\infty$ since they are exactly the same as in Figure 1.

Figure 6 presents, from left to right and top to bottom, the curves of isovalues in the plane $x = 0$ of the three components of the vorticity and the velocity and of the pressure corresponding to the data $\boldsymbol{f} = (f_x, f_y, f_z)$, with

$$
f_x = x, \qquad f_y = 0, \qquad f_z = yz^2, \tag{6.9}
$$

obtained with $N = 18$.

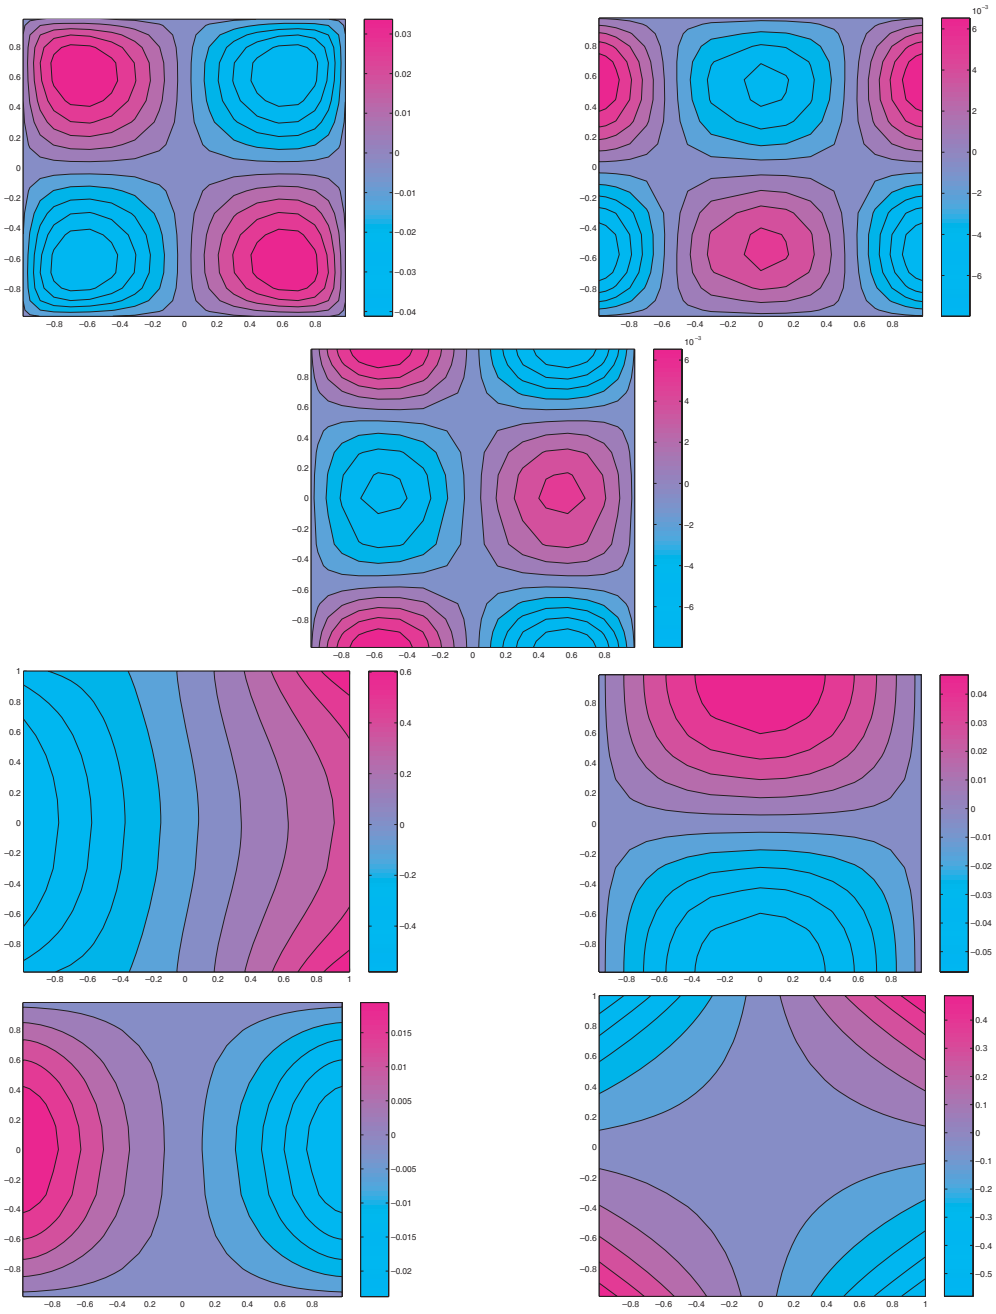

FIG. 6. *The solution* $(\omega_x, \omega_y, \omega_z, u_x, u_y, u_z, p)$ *for the data* $\boldsymbol{f}$ *defined in* (6.9).

As a conclusion, both two- and three-dimensional experiments are in perfect agreement with the error estimates derived in sections 4 and 5 and bring to light the efficiency of the spectral discretization for this type of problem.

A FOURTH-ORDER COMMUTATOR-FREE EXPONENTIAL INTEGRATOR FOR NONAUTONOMOUS DIFFERENTIAL EQUATIONS*

MECHTHILD THALHAMMER†

Abstract. In the present work, we study the convergence behavior of commutator-free exponential integrators for abstract nonautonomous evolution equations

$$u'(t) = A(t)u(t), \qquad 0 < t \le T.$$

In particular, we focus on a fourth-order scheme that relies on the composition of two exponentials involving the values of the linear operator family A at the Gaussian nodes

$$u_1 = \mathrm{e}^{h(a_2A_1+a_1A_2)}\,\mathrm{e}^{h(a_1A_1+a_2A_2)}\,u_0, \quad a_i = \tfrac{1}{4} \pm \tfrac{\sqrt{3}}{6}, \quad c_i = \tfrac{1}{2} \mp \tfrac{\sqrt{3}}{6}, \quad A_i = A(c_ih), \quad i = 1, 2.$$

We prove that the numerical scheme is stable and derive an error estimate with respect to the norm of the underlying Banach space. The theoretically expected order reduction is illustrated by a numerical example for a parabolic initial-boundary value problem subject to a homogeneous Dirichlet boundary condition.

Key words. exponential integrators, commutator-free methods, nonautonomous differential equations, parabolic evolution equations, stability, convergence

1. Introduction. In the present paper, we consider a nonautonomous differential equation involving a time-dependent linear operator A

$$u'(t) = A(t)u(t), \quad 0 < t \le T, \qquad u(0) \text{ given.} \tag{1.1}$$

Our setting includes parabolic initial-boundary value problems that take the form (1.1) when written as an abstract initial value problem on a Banach space. The objective of this work is to analyze the error behavior of the fourth-order commutator-free exponential integrator

$$\begin{aligned} u_1 &= \mathrm{e}^{h(a_2A_1+a_1A_2)}\,\mathrm{e}^{h(a_1A_1+a_2A_2)}\,u_0, \\ a_i &= \tfrac{1}{4} \pm \tfrac{\sqrt{3}}{6}, \quad c_i = \tfrac{1}{2} \mp \tfrac{\sqrt{3}}{6}, \quad A_i = A(c_ih), \qquad i = 1, 2, \end{aligned} \tag{1.2}$$

to explain the substantial order reduction for problems of parabolic type. For that purpose, we derive a representation for the defect of (1.2) which remains valid within the framework of sectorial operators and analytic semigroups. In situations where $A(t)$ is a bounded linear operator, the Campbell–Baker–Hausdorff formula is a powerful tool for the error analysis of (1.2) and higher-order schemes, respectively. However, it is problematic to justify its validity in the context of parabolic evolution equations.

Therefore, in this paper, we follow a different approach based on the variation-of-constants formula.

Numerical schemes that involve the evaluation of the exponential and related functions were proposed in the middle of the past century; for a historical review, see [24]. At present, a variety of works confirms the renewed interest in such exponential integrators; as a small selection, we mention the recent works [5, 8, 14, 16, 19, 20] and refer to the references given therein. A reason for these research activities are advances in the computation of the product of a matrix exponential with a vector; see, for instance, [10, 15, 25]. As a consequence, numerical integrators based on the Magnus expansion [23] and related method classes [2, 3, 6, 7, 17, 21] are practicable in the numerical solution of nonautonomous stiff differential equations; see also [11, 12, 30] and references cited therein.

The excellent error behavior of interpolatory Magnus integrators for time-dependent Schrödinger equations is explained in Hochbruck and Lubich [14]. There, it is proved that the exponential midpoint rule applied to ordinary differential equations (1.1)

$$u_1 = \mathrm{e}^{hA_1}\, u_0, \qquad A_1 = A\big(\tfrac{h}{2}\big), \tag{1.3}$$

is convergent of order 2 without any restriction on the size of $h\big\|A(t)\big\|$. Moreover, under a mild stepsize restriction, a fourth-order error bound is valid for the Magnus integrator

$$u_1 = \mathrm{e}^{ha_1(A_1+A_2)+h^2a_2[A_2,A_1]}\, u_0,$$
$$a_1 = \tfrac{1}{2}, \quad a_2 = \tfrac{\sqrt{3}}{12}, \quad c_i = \tfrac{1}{2} \mp \tfrac{\sqrt{3}}{6}, \quad A_i = A(c_i h), \qquad i = 1, 2,$$

where $[A_1, A_2] = A_1A_2 - A_2A_1$ denotes the matrix commutator. In [11], we considered the numerical scheme (1.3) in the context of parabolic evolution equations and showed that the full convergence order 2 is obtained when the error is measured in the norm of the underlying Banach space, provided that the data and the exact solution of (1.1) are sufficiently smooth in time.

The purpose of the present work is to investigate the convergence properties of higher-order methods for linear nonautonomous parabolic problems (1.1). Provided that the time-dependent sectorial operator $A(t)$ is Hölder-continuous with respect to t, it is ensured that any linear operator defined through $B = \alpha A(\xi_1) + (1-\alpha)A(\xi_2)$ with $\alpha, \xi_1, \xi_2 \in \mathbb{R}$ generates an analytic semigroup $\big(\mathrm{e}^{tB}\big)_{t\geq 0}$, that is, numerical schemes such as (1.2) remain well defined for abstract evolution equations (1.1). For that reason, we focus on commutator-free exponential integrators that rely on the composition of exponentials involving linear combinations of values of A. We show that the fourth-order scheme (1.2) is stable; however, unless the operator familiy A fulfills unnatural requirements, a substantial order reduction is encountered. For instance, for one-dimensional initial-boundary value problems subject to a homogeneous Dirichlet boundary condition, the order of convergence with respect to a discrete L^p-norm is $2 + \kappa$, where $0 \leq \kappa < (2p)^{-1}$, in general.

The present work is organized as follows. In section 2, we first state the fundamental hypotheses on the nonautonomous evolution equation (1.1). The considered commutator-free exponential integration scheme is then introduced in section 3. The numerical approximation is based on the composition of two exponentials that involve the values of A at certain nodal points. Sections 4 and 5 are concerned with a stability and convergence analysis for parabolic problems. In section 5.1, we derive

an expansion of the numerical solution defect which remains well defined for abstract differential equations (1.1) involving an unbounded linear operator $A(t)$, provided that the data and the exact solution of the problem are sufficiently many times differentiable with respect to time. The main result, a convergence estimate for the fourth-order scheme (1.2), is given in section 5.2. Important tools for its proof are the stability bound and the representation of the defect derived before. Section 6 is devoted to a numerical example that illustrates the expected order reduction.

2. Parabolic problems. Henceforth, we denote by $(X, \|\cdot\|_X)$ the underlying Banach space. Our basic requirements on the unbounded linear operator family A defining the right-hand side of the differential equation in (1.1) are that of [11, 30]. For a detailed treatise of time-dependent evolution equations we refer to [22, 29]. The monographs [13, 27] delve into the theory of sectorial operators and analytic semigroups.

HYPOTHESIS 1. *We assume that the densly defined and closed linear operator $A(t) : D \subset X \to X$ is uniformly sectorial for $0 \le t \le T$. Thus, there exist constants $a \in \mathbb{R}$, $0 < \phi < \frac{\pi}{2}$, and $M > 0$ such that for all $0 \le t \le T$ the resolvent of $A(t)$ satisfies the condition*

$$\left\| \big(\lambda I - A(t)\big)^{-1} \right\|_{X \leftarrow X} \le \frac{M}{|\lambda - a|} \tag{2.1}$$

for any complex number $\lambda \notin S_\phi(a) = \big\{\lambda \in \mathbb{C} : |\arg(a - \lambda)| \le \phi\big\} \cup \{a\}$. The graph norm of $A(t)$ and the norm in D fulfill the following relation with a constant $K > 0$:

$$K^{-1}\|x\|_D \le \|x\|_X + \big\|A(t)x\big\|_X \le K\|x\|_D, \qquad x \in D, \qquad 0 \le t \le T.$$

Moreover, it holds $A \in \mathscr{C}^\vartheta\big([0,T], L(D,X)\big)$ for some $0 < \vartheta \le 1$, i.e., the bound

$$\big\|A(t) - A(s)\big\|_{X \leftarrow D} \le L(t-s)^\vartheta, \qquad 0 \le s \le t \le T, \tag{2.2}$$

is valid with a constant $L > 0$.

For any $0 \le s \le T$ the sectorial operator $\Omega = A(s)$ generates an analytic semigroup $\big(\mathrm{e}^{t\Omega}\big)_{t \ge 0}$ on X which is defined by means of the integral formula of Cauchy

$$\mathrm{e}^{t\Omega} = \frac{1}{2\pi \mathrm{i}} \int_\Gamma \mathrm{e}^\lambda \big(\lambda I - t\Omega\big)^{-1} \,\mathrm{d}\lambda, \quad t > 0, \qquad \mathrm{e}^{t\Omega} = I, \quad t = 0. \tag{2.3}$$

Here, Γ denotes a path that surrounds the spectrum of Ω.

Henceforth, for $0 < \mu < 1$, we denote by X_μ some intermediate space between the Banach spaces $D = X_1$ and $X = X_0$ such that the norm in X_μ satisfies the bound $\|x\|_{X_\mu} \le K\|x\|_D^\mu \|x\|_X^{1-\mu}$ with a constant $K > 0$ for all elements $x \in D$. Examples for intermediate spaces are real interpolation spaces (see Lunardi [22]) or fractional power spaces (see Henry [13]). Then, for all $0 \le \mu \le \nu \le 1$ and integers $k \ge 0$ the following bound is valid:

$$\big\|t^{k+\nu-\mu}\, \Omega^k\, \mathrm{e}^{t\Omega}\big\|_{X_\nu \leftarrow X_\mu} \le M, \qquad 0 \le t \le T, \tag{2.4}$$

with a constant $M > 0$. As a consequence, the linear operator φ_m which is given by

$$\varphi_m(t\Omega) = \frac{1}{(m-1)!\, t^m} \int_0^t \mathrm{e}^{(t-\tau)\Omega}\, \tau^{m-1} \mathrm{d}\tau, \quad t > 0, \qquad \varphi_m(0) = \frac{1}{(m-1)!}\, I, \tag{2.5a}$$

for integers $m \geq 1$, remains bounded on X_μ for any $0 \leq t \leq T$ and $0 \leq \mu \leq 1$. In the subsequent sections, we make use of the identities

$$\mathrm{e}^{t\Omega} = I + t\Omega\,\varphi_1(t\Omega), \qquad \varphi_{m-1}(t\Omega) = \frac{1}{(m-1)!}\,I + t\Omega\,\varphi_m(t\Omega), \quad m \geq 1. \tag{2.5b}$$

Furthermore, it is substantial that the relation

$$\varphi_m(t\Omega) - \varphi_m(0) = t\Omega\,\chi(t\Omega) \tag{2.5c}$$

holds with a linear operator $\chi(t\Omega)$ that is bounded on X_μ; see [13, 22] and also [11, 30].

3. Commutator-free exponential integrator. In this section, we introduce an integration method for linear nonautonomous parabolic problems (1.1) which relies on the composition of two exponentials. We note that the considered scheme is an example of a *Crouch–Grossman method* [9].

For a constant stepsize $h > 0$ the associated grid points are denoted by $t_j = jh$ for $j \geq 0$. The numerical approximation $u_{n+1} \approx u(t_{n+1})$ to the true solution of (1.1) is given by the recurrence formula

$$u_{n+1} = \mathrm{e}^{\widetilde{\zeta} h C_n}\,\mathrm{e}^{\zeta h B_n}\,u_n, \qquad n \geq 0. \tag{3.1a}$$

Here, we employ the following abbreviations:

$$\begin{aligned} A_{ni} &= A(t_n + c_i h), \qquad i = 1, 2, \\ B_n &= \alpha A_{n1} + \beta A_{n2}, \qquad C_n = \gamma A_{n1} + \delta A_{n2}. \end{aligned} \tag{3.1b}$$

Throughout, we assume that the nodal points $\zeta, \widetilde{\zeta}, c_1, c_2 \in \mathbb{R}$ and the coefficients $\alpha, \beta, \gamma, \delta \in \mathbb{R}$ satisfy

$$0 < \zeta < 1, \qquad \widetilde{\zeta} = 1 - \zeta, \qquad 0 \leq c_1 \leq c_2 \leq 1, \qquad \alpha + \beta = 1, \qquad \gamma + \delta = 1. \tag{3.1c}$$

The following remark shows that relation (3.1a) remains well defined within the analytical framework of section 2.

Remark 1. Under the assumptions of Hypothesis 1, the linear operator

$$\alpha A_{n1} + (1-\alpha) A_{n2} = A_{n2} + \alpha\big(A_{n1} - A_{n2}\big), \qquad \alpha \in \mathbb{R},$$

is sectorial; see also [13, Theorem 1.3.2]. Therefore, the commutator-free exponential integrator (3.1) is well defined for abstract evolution equations (1.1).

4. Stability. The stability properties of the commutator-free exponential integrator (3.1) are determined by the behavior of the evolution operator

$$\prod_{i=m}^{n} \mathrm{e}^{\widetilde{\zeta} h C_i}\,\mathrm{e}^{\zeta h B_i} = \mathrm{e}^{\widetilde{\zeta} h C_n}\,\mathrm{e}^{\zeta h B_n}\,\mathrm{e}^{\widetilde{\zeta} h C_{n-1}}\,\mathrm{e}^{\zeta h B_{n-1}}\,\cdots\,\mathrm{e}^{\widetilde{\zeta} h C_m}\,\mathrm{e}^{\zeta h B_m}, \tag{4.1}$$

where $n \geq m \geq 0$. The following result implies that the numerical solution u_n remains bounded for arbitrarily chosen stepsizes $h > 0$ as long as $nh \leq T$.

THEOREM 1 (stability). *Under the requirements of Hypothesis* 1 *on* A*, the discrete evolution operator* (4.1) *fulfills the bound*

$$\left\| \prod_{i=m}^{n} \mathrm{e}^{\widetilde{\zeta} h C_i}\,\mathrm{e}^{\zeta h B_i} \right\|_{X \leftarrow X} \leq M, \qquad 0 \leq mh \leq nh \leq T,$$

with a constant $M > 0$ that does not depend on n and h.

Proof. As in our preceeding works [11, 30], the proof of the above stability result relies on the telescopic identity and the integral formula of Cauchy. In the present situation, it is useful to compare the discrete evolution operator (4.1) with the linear operator

$$\prod_{i=m}^{n} \mathrm{e}^{\widetilde{\zeta} h A_{m2}} \, \mathrm{e}^{\zeta h A_{m2}} = \prod_{i=m}^{n} \mathrm{e}^{h A_{m2}} = \mathrm{e}^{(t_{n+1}-t_m) A_{m2}},$$

which satisfies the well-known bound

$$\left\| \mathrm{e}^{(t_{n+1}-t_m) A_{m2}} \right\|_{X \leftarrow X} + \left\| (t_{n+1} - t_m) \, A_{m2} \, \mathrm{e}^{(t_{n+1}-t_m) A_{m2}} \right\|_{X \leftarrow X} \leq C$$

for $0 \leq t_m \leq t_n \leq T$. Therefore, it suffices to estimate the difference

$$\begin{aligned}
\Delta_m^n &= \prod_{i=m}^{n} \mathrm{e}^{\widetilde{\zeta} h C_i} \, \mathrm{e}^{\zeta h B_i} - \mathrm{e}^{(t_{n+1}-t_m) A_{m2}} \\
&= \sum_{j=m}^{n-1} \Delta_{j+1}^n \Big(\mathrm{e}^{\widetilde{\zeta} h C_j} \, \mathrm{e}^{\zeta h B_j} - \mathrm{e}^{h A_{m2}} \Big) \mathrm{e}^{(t_j - t_m) A_{m2}} \\
&\qquad + \sum_{j=m}^{n} \mathrm{e}^{(t_{n+1}-t_{j+1}) A_{m2}} \Big(\mathrm{e}^{\widetilde{\zeta} h C_j} \, \mathrm{e}^{\zeta h B_j} - \mathrm{e}^{h A_{m2}} \Big) \mathrm{e}^{(t_j - t_m) A_{m2}}.
\end{aligned}$$

For this purpose, it is notable that the following relation holds true:

$$\mathrm{e}^{\widetilde{\zeta} h C_j} \mathrm{e}^{\zeta h B_j} - \mathrm{e}^{h A_{m2}} = \Big(\mathrm{e}^{\widetilde{\zeta} h C_j} - \mathrm{e}^{\widetilde{\zeta} h A_{m2}} \Big) \, \mathrm{e}^{\zeta h B_j} + \mathrm{e}^{\widetilde{\zeta} h A_{m2}} \Big(\mathrm{e}^{\zeta h B_j} - \mathrm{e}^{\zeta h A_{m2}} \Big).$$

By means of the integral formula of Cauchy, the resolvent identity

$$(\lambda I - \Omega_1)^{-1} - (\lambda I - \Omega_2)^{-1} = (\lambda I - \Omega_1)^{-1} (\Omega_1 - \Omega_2) (\lambda I - \Omega_2)^{-1},$$

and the relations given in (3.1), we receive

$$\begin{aligned}
&\Big(\mathrm{e}^{\widetilde{\zeta} h C_j} \, \mathrm{e}^{\zeta h B_j} - \mathrm{e}^{h A_{m2}} \Big) \, \mathrm{e}^{(t_j - t_m) A_{m2}} \\
&\quad = \frac{\widetilde{\zeta} h}{2\pi \mathrm{i}} \int_\Gamma \mathrm{e}^{\lambda} \, (\lambda - \widetilde{\zeta} h C_j)^{-1} \big(\gamma (A_{j1} - A_{j2}) + A_{j2} - A_{m2} \big) \\
&\qquad\qquad \times (\lambda - \widetilde{\zeta} h A_{m2})^{-1} \, \mathrm{e}^{\zeta h B_j} \, \mathrm{e}^{(t_j - t_m) A_{m2}} \, \mathrm{d}\lambda \\
&\qquad + \frac{\zeta h}{2\pi \mathrm{i}} \int_\Gamma \mathrm{e}^{\lambda} \, \mathrm{e}^{\widetilde{\zeta} h A_{m2}} \, (\lambda - \zeta h B_j)^{-1} \big(\alpha (A_{j1} - A_{j2}) + A_{j2} - A_{m2} \big) \\
&\qquad\qquad \times (\lambda - \zeta h A_{m2})^{-1} \, \mathrm{e}^{(t_j - t_m) A_{m2}} \, \mathrm{d}\lambda.
\end{aligned}$$

With the help of the resolvent bound (2.1), the Hölder estimate (2.2) for A, and (2.4) it thus follows

$$\begin{aligned}
\left\| \Big(\mathrm{e}^{\widetilde{\zeta} h C_j} \, \mathrm{e}^{\zeta h B_j} - \mathrm{e}^{h A_{m2}} \Big) \, \mathrm{e}^{(t_j - t_m) A_{m2}} \right\|_{X \leftarrow X} &\leq M h^{\vartheta}, \qquad j = m, \\
\left\| \Big(\mathrm{e}^{\widetilde{\zeta} h C_j} \, \mathrm{e}^{\zeta h B_j} - \mathrm{e}^{h A_{m2}} \Big) \, \mathrm{e}^{(t_j - t_m) A_{m2}} \right\|_{X \leftarrow X} &\leq M h (t_j - t_m)^{-1+\vartheta}, \qquad j > m.
\end{aligned}$$

Consequently, a further application of (2.4) together with a Gronwall-type inequality with a weakly singular kernel (see also [4, 26]) yields the desired stability bound. ∎

5. Convergence. In this section, we analyze the convergence behavior of the considered commutator-free exponential integrator for parabolic problems (1.1). As a first step, we next derive a useful relation for the defect of (3.1) by means of a suitable linearization of the differential equation and an application of the variation-of-constants formula. Similar techniques have been used in the study of exponential splitting methods; see [1, 18, 28] and references therein. The following considerations also explain the definition of the numerical method.

5.1. Expansion of the defect. Replacing in (3.1) the numerical by the exact solution values defines the defect of the method

$$u(t_{n+1}) = \mathrm{e}^{\widetilde{\zeta} h C_n}\, \mathrm{e}^{\zeta h B_n}\, u(t_n) + d_{n+1}, \qquad n \geq 0. \tag{5.1}$$

Our basic approach is to consider the initial value problem (1.1) on the subinterval $[t_n, t_{n+1}]$ and to derive an analogous relation to (3.1a) for the exact solution values. For that purpose, we set

$$G_n(t) = \big(A(t) - B_n\big)u(t), \qquad H_n(t) = \big(A(t) - C_n\big)u(t). \tag{5.2}$$

On the one hand, rewriting the right-hand side of the differential equation in (1.1) as $u'(t) = B_n u(t) + G_n(t)$ and applying the variation-of-constants formula (see [22]) yields the following relation for the solution value at time $t_n + \zeta h$:

$$u(t_n + \zeta h) = \mathrm{e}^{\zeta h B_n}\, u(t_n) + \int_0^{\zeta h} \mathrm{e}^{(\zeta h - \tau) B_n}\, G_n(t_n + \tau)\, \mathrm{d}\tau.$$

On the other hand, by linearizing (1.1) around C_n and inserting the above representation for $u(t_n + \zeta h)$, we further obtain

$$\begin{aligned} u(t_{n+1}) = \mathrm{e}^{\widetilde{\zeta} h C_n}\, \mathrm{e}^{\zeta h B_n}\, u(t_n) + \mathrm{e}^{\widetilde{\zeta} h C_n} \int_0^{\zeta h} \mathrm{e}^{(\zeta h - \tau) B_n}\, G_n(t_n + \tau)\, \mathrm{d}\tau \\ + \int_0^{\widetilde{\zeta} h} \mathrm{e}^{(\widetilde{\zeta} h - \tau) C_n}\, H_n(t_n + \zeta h + \tau)\, \mathrm{d}\tau. \end{aligned}$$

Consequently, the defect of the numerical method (3.1) equals

$$d_{n+1} = \mathrm{e}^{\widetilde{\zeta} h C_n} \int_0^{\zeta h} \mathrm{e}^{(\zeta h - \tau) B_n}\, G_n(t_n + \tau)\, \mathrm{d}\tau + \int_0^{\widetilde{\zeta} h} \mathrm{e}^{(\widetilde{\zeta} h - \tau) C_n}\, H_n(t_n + \zeta h + \tau)\, \mathrm{d}\tau. \tag{5.3}$$

In order to derive a suitable expansion of d_{n+1}, it is useful to introduce some additional notation.

The time derivatives of the linear operator A and the exact solution u of (1.1) at time t_n are denoted by

$$A_n^{(i)} = A^{(i)}(t_n), \quad i \geq 0, \qquad \widehat{u}_n^{(j)} = u^{(j)}(t_n), \quad j \geq 0. \tag{5.4a}$$

For the coefficients of the numerical scheme, we define

$$\mu_i = \alpha c_1^i + \beta c_2^i, \qquad \nu_i = \gamma c_1^i + \delta c_2^i, \qquad i = 1, 2, 3; \tag{5.4b}$$

see (3.1). We note that for a sufficiently differentiable function $f : [t_n, t_{n+1}] \to X$ a Taylor series expansion yields

$$
\begin{aligned}
f(t_n+\tau) &= \sum_{i=0}^{m} \frac{\tau^i}{i!}\, f_n^{(i)} + R\big(\tau^{m+1}, f^{(m+1)}\big), \qquad 0 \le \tau \le h,\\
R\big(\tau^{m+1}, f^{(m+1)}\big) &= \frac{1}{m!}\,\tau^{m+1} \int_0^1 (1-\sigma)^m f^{(m+1)}(t_n+\sigma\tau)\,\mathrm{d}\sigma,
\end{aligned}
\tag{5.5}
$$

where $f_n^{(i)} = f^{(i)}(t_n)$. Thus, provided that the quantity

$$
\big\|f^{(m+1)}\big\|_{X,\infty} = \max_{t_n \le t \le t_{n+1}} \big\|f^{(m+1)}(t)\big\|_X
$$

is well defined, the remainder fulfills

$$
\big\|R\big(\tau^{m+1}, f^{(m+1)}\big)\big\|_X \le M h^{m+1} \big\|f^{(m+1)}\big\|_{X,\infty}, \qquad 0 \le \tau \le h,
$$

with some constant $M > 0$. Terms that satisfy an estimate of this form are henceforth denoted by $\mathscr{R}\big(h^{m+1}, f^{(m+1)}\big)$. In particular, the abbrevitation $\mathscr{R}\big(h^k, A^{(i)}\, u^{(j)}\big)$ signifies that the bound

$$
\big\|\mathscr{R}\big(h^k, A^{(i)}\, u^{(j)}\big)\big\|_X \le M h^k \max_{t_n \le s,t \le t_{n+1}} \big\|A^{(i)}(s)\, u^{(j)}(t)\big\|_{X,\infty}
$$

holds true.

Provided that the involved derivatives of A and u are well defined, the following representation is valid for the defect d_{n+1} given by (5.1). We recall formula (2.5a) for the linear operator φ_m.

LEMMA 1. *The numerical solution defect of* (3.1) *fulfills the relation*

$$
\begin{aligned}
d_{n+1} = \sum_{(i,j)\in\mathscr{J}} & h^{i+j+1}\, \Phi_{ij}\, A_n^{(i)} \widehat{u}_n^{(j)} + \mathscr{R}\big(h^5, A^{(4)} u\big)\\
& + \mathscr{R}\big(h^5, A''' u'\big) + \mathscr{R}\big(h^5, A'' u''\big) + \mathscr{R}\big(h^5, A' u'''\big),
\end{aligned}
$$

where $\Phi_{ij} = \Phi_{ij}(hB_n, hC_n)$ *is defined through*

$$
\begin{aligned}
\Phi_{ij} = \frac{1}{i!j!} \Big\{ & \zeta^{j+1} \mathrm{e}^{\widetilde{\zeta} hC_n} \Big((i+j)!\, \zeta^i \varphi_{i+j+1}(\zeta hB_n) - j!\, \mu_i \varphi_{j+1}(\zeta hB_n) \Big)\\
& + \sum_{\ell=j+1}^{i+j} \ell!\, \tbinom{i+j}{\ell} \zeta^{i+j-\ell} \widetilde{\zeta}^{\ell+1} \varphi_{\ell+1}(\widetilde{\zeta} hC_n)\\
& + \sum_{\ell=0}^{j} \ell!\, \zeta^{j-\ell} \widetilde{\zeta}^{\ell+1} \Big(\tbinom{i+j}{\ell} \zeta^i - \nu_i \tbinom{j}{\ell} \Big) \varphi_{\ell+1}(\widetilde{\zeta} hC_n) \Big\}
\end{aligned}
$$

and $\mathscr{J} = \big\{(1,0),(2,0),(1,1),(3,0),(2,1),(1,2)\big\}$.

Proof. We first derive a useful relation for the maps G_n and H_n defined in (5.2). With the help of (5.5), by combining the expansions

$$
\begin{aligned}
A(t_n+\tau) - B_n &= \sum_{i=0}^{3} \frac{1}{i!} \big(\tau^i - \mu_i h^i\big) A_n^{(i)} + \mathscr{R}\big(h^4, A^{(4)}\big),\\
u(t_n+\tau) &= \sum_{j=0}^{2} \frac{1}{j!}\, \tau^j \widehat{u}_n^{(j)} + R\big(\tau^3, u^{(3)}\big),
\end{aligned}
$$

we receive the following representation:

$$G_n(t_n+\tau) = \sum_{(i,j)\in\mathscr{J}} \frac{1}{i!j!}\big(\tau^i - \mu_i h^i\big)\tau^j A_n^{(i)}\widehat{u}_n^{(j)} + \mathscr{R}\big(h^4\big), \tag{5.6a}$$

$$\mathscr{R}\big(h^4\big) = \mathscr{R}\big(h^4, A^{(4)}u\big) + \mathscr{R}\big(h^4, A'''u'\big) + \mathscr{R}\big(h^4, A''u''\big) + \mathscr{R}\big(h^4, A'u'''\big);$$

see also (3.1b)–(3.1c) and (5.4). Similarly, it follows

$$H_n(t_n+\zeta h+\tau) = \sum_{(i,j)\in\mathscr{J}} \frac{1}{i!j!}\big((\zeta h+\tau)^i - \nu_i h^i\big)(\zeta h+\tau)^j A_n^{(i)}\widehat{u}_n^{(j)} + \mathscr{R}\big(h^4\big). \tag{5.6b}$$

We next insert the above expansions (5.6) into (5.3) and express the resulting integrals by means of (2.5a). Altogether, this yields the given result. ∎

In the situation of Section 2, a reasonable smoothness assumption on (1.1) is that the linear operator A and the exact solution u are sufficiently differentiable with respect to the variable t. Precisely, we suppose $A^{(4)}(t)$ and $u^{(4)}(t)$ to be bounded in the underlying Banach space X for all $0 \le t \le T$. The following remark states that then the expansion of Lemma 1 is well-defined. However, unless the exact solution satisfies additional (unnatural) requirements such as $A'(t)u(t) \in D$ for $0 \le t \le T$, in general, it is not possible to further expand the defect.

Remark 2. Provided that $u'(t) \in X$ it follows from the differential equation in (1.1) that $A(t)u(t) \in X$ and therefore $u(t) \in D$ for $0 \le t \le T$. Differentiating (1.1) with respect to the variable t implies $A(t)u'(t) = u''(t) - A'(t)u(t) \in X$, and, as a consequence, $u'(t) \in D$ for any $0 \le t \le T$. Similarly, it follows $u^{(j-1)}(t) \in D$ if $u^{(j)}(t) \in X$ for $0 \le t \le T$ and $j = 3, 4$. Thus, under the regularity requirements $A \in \mathscr{C}^4\big([0,T], L(D,X)\big)$ and $u \in \mathscr{C}^4\big([0,T], X\big)$, the representation of the defect given in Lemma 1 is well defined.

5.2. Error estimate. With the help of the stability estimate and the expansion of the defect given in sections 4 and 5.1, we are able to prove the following convergence result.

THEOREM 2 (convergence). *Assume that the requirements of Hypothesis* 1 *are fulfilled and that further* $A \in \mathscr{C}^4\big([0,T], L(D,X)\big)$ *and* $u \in \mathscr{C}^4\big([0,T], X\big)$. *Then, provided that* $A^{(i)}(t)\,u^{(j)}(t)$ *belongs to the intermediate space* X_κ *with* $0 \le \kappa < 1$ *for* $0 \le t \le T$ *and* $(i,j) \in \big\{(1,0),(2,0),(1,1)\big\}$, *the fourth-order commutator-free exponential integrator* (1.2) *satisfies the error estimate*

$$\|u_n - u(t_n)\|_X \le C\Big(\big\|u_0 - u(0)\big\|_X + h^{2+\kappa}\big(1 + |\log h|\big)\Big), \qquad 0 \le t_n \le T,$$

with some constant $C > 0$ *independent of* n *and* h.

Proof. In order to obtain a suitable relation for the global error $e_n = u_n - u(t_n)$, we first resolve the recurrence formula (3.1a) for the numerical approximation

$$u_n = \prod_{i=0}^{n-1} \mathrm{e}^{\widetilde{\zeta}hC_i}\,\mathrm{e}^{\zeta hB_i}\,u_0, \qquad n \ge 0.$$

Furthermore, by using (5.1), we receive $e_n = e_n^{(1)} + e_n^{(2)}$ with

$$e_n^{(1)} = \prod_{i=0}^{n-1} \mathrm{e}^{\widetilde{\zeta}hC_i}\,\mathrm{e}^{\zeta hB_i}\big(u_0 - u(0)\big), \qquad e_n^{(2)} = -\sum_{j=0}^{n-1}\prod_{i=j+1}^{n-1} \mathrm{e}^{\widetilde{\zeta}hC_i}\,\mathrm{e}^{\zeta hB_i}\,d_{j+1}. \tag{5.7}$$

We next estimate the terms in (5.7) with respect to the norm of the underlying Banach space X. An application of Theorem 1 shows that the first term is bounded by a constant times the error of the initial value

$$\big\|e_n^{(1)}\big\|_X \le \left\|\prod_{i=0}^{n-1} \mathrm{e}^{\widetilde{\zeta} hC_i}\, \mathrm{e}^{\zeta hB_i}\right\|_{X\leftarrow X} \|u_0 - u(0)\|_X \le C\|u_0 - u(0)\|_X.$$

For estimating the second term $e_n^{(2)}$, we employ the representation of the defect given in Lemma 1. Making use of the fact that the sums involving the remainder and the terms where $i + j \ge 3$ are bounded by constant times h^3, we receive

$$\begin{aligned}\big\|e_n^{(2)}\big\|_X \le\ & h^2 \sum_{j=0}^{n-1} \left\|\prod_{i=j+1}^{n-1} \mathrm{e}^{\widetilde{\zeta} hC_i}\, \mathrm{e}^{\zeta hB_i}\, \Phi_{10}(hB_j, hC_j)\right\|_{X\leftarrow X_\kappa} \big\|A_j' \widehat{u}_j\big\|_{X_\kappa} \\ &+ h^3 \sum_{j=0}^{n-1} \left\|\prod_{i=j+1}^{n-1} \mathrm{e}^{\widetilde{\zeta} hC_i}\, \mathrm{e}^{\zeta hB_i}\, \Phi_{20}(hB_j, hC_j)\right\|_{X\leftarrow X_\kappa} \big\|A_j'' \widehat{u}_j\big\|_{X_\kappa} \\ &+ h^3 \sum_{j=0}^{n-1} \left\|\prod_{i=j+1}^{n-1} \mathrm{e}^{\widetilde{\zeta} hC_i}\, \mathrm{e}^{\zeta hB_i}\, \Phi_{11}(hB_j, hC_j)\right\|_{X\leftarrow X_\kappa} \big\|A_j' \widehat{u}_j'\big\|_{X_\kappa} \\ &+ Ch^3.\end{aligned} \tag{5.8}$$

We note that the coefficients of the fourth-order scheme (1.2) satisfy the conditions

$$\begin{aligned}\Phi_{20}(0,0) &= \tfrac{1}{2}\Big\{\zeta\big(\tfrac{1}{3}\,\zeta^2 - \mu_2\big) + \widetilde{\zeta}\Big(\tfrac{1}{3}\,\widetilde{\zeta}^2 + \zeta\widetilde{\zeta} + \zeta^2 - \nu_2\Big)\Big\} = 0, \\ \Phi_{11}(0,0) &= \zeta^2\big(\tfrac{1}{3}\,\zeta - \tfrac{1}{2}\,\mu_1\big) + \widetilde{\zeta}\Big(\tfrac{1}{3}\,\widetilde{\zeta}^2 + \tfrac{1}{2}\,\widetilde{\zeta}(2\zeta - \nu_1) + \zeta(\zeta - \nu_1)\Big) = 0.\end{aligned} \tag{5.9a}$$

Therefore, similar arguments as in the proof of Theorem 1 show the refined bounds

$$\begin{aligned}\left\|\prod_{i=j+1}^{n-1} \mathrm{e}^{\widetilde{\zeta} hC_i}\, \mathrm{e}^{\zeta hB_i}\, \Phi_{20}(hB_j, hC_j)\right\|_{X\leftarrow X_\kappa} &\le Mh(t_n - t_j)^{-1+\kappa}, \\ \left\|\prod_{i=j+1}^{n-1} \mathrm{e}^{\widetilde{\zeta} hC_i}\, \mathrm{e}^{\zeta hB_i}\, \Phi_{11}(hB_j, hC_j)\right\|_{X\leftarrow X_\kappa} &\le Mh(t_n - t_j)^{-1+\kappa};\end{aligned}$$

see also (2.4) and (2.5c). In relation (5.8), it remains to estimate the sum involving Φ_{10}. For that purpose, we apply (2.5b) together with suitable Taylor expansions of B_j and C_j. Moreover, the coefficients of (1.2) fulfill

$$\begin{aligned}\Phi_{10}(0,0) &= \zeta\big(\tfrac{1}{2}\,\zeta - \mu_1\big) + \tfrac{1}{2}\,\widetilde{\zeta}^2 + \widetilde{\zeta}(\zeta - \nu_1) = 0, \\ \Psi_{10}(0,0) &= \zeta^2\big(\tfrac{1}{6}\,\zeta - \tfrac{1}{2}\,\mu_1\big) + \widetilde{\zeta}\Big(\tfrac{1}{6}\,\widetilde{\zeta}^2 + \tfrac{1}{2}\,\widetilde{\zeta}(\zeta - \nu_1) + \zeta\big(\tfrac{1}{2}\,\zeta - \mu_1\big)\Big) = 0.\end{aligned} \tag{5.9b}$$

As a consequence, we finally obtain the refined estimate

$$\left\|\prod_{i=j+1}^{n-1} \mathrm{e}^{\widetilde{\zeta} hC_i}\, \mathrm{e}^{\zeta hB_i}\, \Phi_{10}(hB_j, hC_j)\right\|_{X\leftarrow X_\kappa} \le Mh^{1+\kappa}\big(1 + |\log h| + (t_{n+1} - t_m)^{-1}\big).$$

Altogether, this implies

$$\begin{aligned}\big\|e_n^{(2)}\big\|_X &\le Ch^{3+\kappa}\sum_{j=0}^{n-1}\big(1+|\log h|+(t_n-t_j)^{-1}\big)\\ &\quad + Ch^4\sum_{j=0}^{n-1}(t_n-t_j)^{-1+\kappa}+Ch^3 \le Ch^{2+\kappa}\big(1+|\log h|\big),\end{aligned}$$

which proves the given error estimate. □

Remark 3. Going over the proof of Theorem 2 shows that the essential conditions for a fractional convergence order of $2+\kappa$ are (5.9). We note that the conditions for a classical convergence order 3 are equivalent to the relations in (5.9). However, it is not possible to construct a commutator-free exponential integrator of classical order 3 that is based on the evaluation of one exponential only, that is, the validity of relation (5.9) implies $0<\zeta<1$ in (3.1).

6. Numerical example. In this section, we illustrate the error estimate of Theorem 2 by a numerical example for a parabolic initial boundary value problem subject to a homogeneous Dirichlet boundary condition. We start with a brief discussion of the considered time integration schemes. For notational simplicity, we give only the first step and denote $A_i = A(c_i h)$.

Method 1. For parabolic problems (1.1), it follows from the error estimate given in our previous work [11] that the exponential midpoint rule

$$u_1 = \mathrm{e}^{hA_1}\,u_0, \qquad c_1 = \tfrac{1}{2},$$

is convergent of order 2 with respect to the norm of the underlying Banach space.

Method 2. The commutator-free exponential integration scheme

$$\begin{gathered}u_1 = \mathrm{e}^{(1-\zeta)h(a_1A_1+(1-a_1)A_2)}\,\mathrm{e}^{\zeta hA_1}\,u_0,\\ \zeta = \tfrac{\sqrt{3}}{3}, \qquad a_1 = \tfrac{1}{4}-\tfrac{\sqrt{3}}{4}, \qquad c_i = \tfrac{1}{2}\mp\tfrac{\sqrt{3}}{6}, \qquad i=1,2,\end{gathered}$$

has a classical convergence order 3.

Method 3. The numerical method

$$u_1 = \mathrm{e}^{h(a_2A_1+a_1A_2)}\,\mathrm{e}^{h(a_1A_1+a_2A_2)}\,u_0, \qquad a_i = \tfrac{1}{4}\pm\tfrac{\sqrt{3}}{6}, \qquad c_i = \tfrac{1}{2}\mp\tfrac{\sqrt{3}}{6}, \qquad i=1,2,$$

is the unique scheme of the form (3.1) that satisfies the conditions for a classical convergence order 4; see also (1.2).

In the numerical example, as an illustration, the fourth-order commutator-free exponential integrator given before is compared with a fourth-order interpolatory Magnus integrator. To explain the stability and error behavior of this method for parabolic problems is beyond the purpose of the present work.

Method 4. The fourth-order interpolatory Magnus integrator

$$u_1 = \mathrm{e}^{ha_1(A_1+A_2)+h^2a_2[A_2,A_1]}\,u_0, \qquad a_1 = \tfrac{1}{2}, \qquad a_2 = \tfrac{\sqrt{3}}{12},$$

requires the evaluation of the linear operator $\big[A_2,A_1\big] = A_2A_1 - A_1A_2$.

We consider a one-dimensional initial boundary value problem for a real-valued function $U : [0,1] \times [0,T] \to \mathbb{R} : (x,t) \mapsto U(x,t)$ comprising the partial differential equation

$$\partial_t U(x,t) = \mathscr{A}(x,t)\, U(x,t), \qquad 0 < x < 1, \quad 0 < t \le T, \tag{6.1a}$$

subject to a homogeneous Dirichlet boundary condition and an initial condition

$$U(0,t) = 0 = U(1,t), \quad 0 \le t \le T, \qquad U(x,0) = U_0(x), \quad 0 \le x \le 1. \tag{6.1b}$$

The differential equation involves a second-order differential operator

$$\mathscr{A}(x,t) = \alpha(x,t)\, \partial_x^2 + \beta(x,t)\, \partial_x + \gamma(x,t) \tag{6.1c}$$

which we assume to satisfy the condition of strong ellipticity. We further suppose that the space and time-dependent coefficients α, β, and γ fulfill suitable regularity and boundedness requirements. For $v \in \mathscr{C}_0^\infty(0,1)$ we define $u(t)$ and $A(t)$ through $\big(u(t)\big)(x) = U(x,t)$ and $\big(A(t)v\big)(x) = \mathscr{A}(x,t)v(x)$. Then, problem (6.1) can be cast into the abstract framework of section 2 for

$$X = L^p(0,1), \qquad D = W^{p,2}(0,1) \cap W_0^{p,1}(0,1), \qquad 1 < p < \infty;$$

see [11] and references therein. In view of the numerical experiment, we choose

$$\alpha(x,t) = \mathrm{e}^{x-t}, \qquad \beta(x,t) = xt, \qquad \gamma(x,t) = x^2\big(1 + \mathrm{e}^t\big).$$

The admissible values of κ in Theorem 2 are $0 \le \kappa < (2p)^{-1}$. Thus, the expected fractional convergence order in $X = L^p(0,1)$ is $2 + \kappa$, where $\kappa < (2p)^{-1}$.

TABLE 6.3

In the numerical experiment, we discretize the problem in space by symmetric finite differences of grid length $\Delta x = (M+1)^{-1}$. In time, we apply the exponential integrators given above with stepsize $h = 2^{-i}$ for $1 \le i \le 5$ and integrate the problem up to time $T = 1$. A reference solution is determined for a temporal stepsize $h = 2^{-10}$. The numerical temporal order of convergence with respect to a discrete L^p-norm is determined in a standard way from the numerical solution values. The obtained numbers for $p = 2$ and the limiting cases $p = 1$ and $p = \infty$ are displayed in Tables 6.1, 6.2, and 6.3. The convergence order 2 for the exponential midpoint rule (Method 1) is explained by a convergence result proved in [11]. For the commutator-free exponential integrators of classical order 3 (Method 2) and classical order 4 (Method 3), respectively, the values of approximately $2 + (2p)^{-1}$ are in accordance with the convergence orders predicted by Theorem 2.

7. Conclusions. In the present work, we studied the convergence properties of a commutator-free exponential integrator that relies on the composition of two exponentials for parabolic initial value problems of the form (1.1). In particular, we focused on the fourth-order scheme (1.2), which is based on the Gaussian nodes. We showed that the exponential integration scheme remains stable for arbitrarily large stepsizes. But, it is seen from the theoretical investigations and as well in a numerical experiment that a substantial order reduction occurs, in general. For instance, for one-dimensional parabolic initial-boundary value problems under a homogeneous Dirichlet boundary condition a fractional convergence order of at most $2 + (2p)^{-1}$ can be expected in the norm of the function space L^p. The order reduction is explained by the fact that even if the exact solution of the initial boundary value problem belongs to the domain of the differential operator and further is temporally smooth, it in general does not fulfill additional boundary conditions, that is, combinations of the form $A(s)A(t)u(t)$ are not well defined for all $0 \le s, t \le T$.

For that reason, concerning the derivation of high-order exponential integrators for nonautonomous parabolic problems, it seems more promising to employ a suitable linearization and to base the numerical schemes on explicit exponential methods of Runge–Kutta or multistep type. Also, the error analysis for nonautonomous parabolic equations is of theoretical value as it gives insight into how to construct and study numerical methods for quasi-linear equations which are of particular interest in view of practical applications. For example, quasi-linear parabolic problems are used in the modeling of diffusion processes with state-dependent diffusitivity and arise in the study of fluids in porous media, see [12]. We intend to investigate this approach in a future work.

Acknowledgments. I am grateful to Jitse Niesen. His talk and interest at MaGIC 2005 motivated me to finish this work. I thank Alexander Ostermann for inspiring discussions on exponential integrators.

ROBUST EIGENVALUE COMPUTATION FOR SMOOTHING OPERATORS*

RADU ALEXANDRU TODOR†

Abstract. Robust quasi-relative Galerkin discretization error estimates are derived for the eigenvalue problem associated to a nonnegative compact operator $\mathcal{K}$ acting in a Hilbert space. Trace discretization error estimates for arbitrarily small positive powers of $\mathcal{K}$ are obtained as a consequence. Coupled with bounds on eigenfunction oscillations, the results are then applied to the case of an integral operator with (piecewise) smooth kernel K on a bounded domain and in the context of the h finite element method.

Key words. eigenvalue computation, Galerkin FEM, integral operator

AMS subject classifications. 45C05, 65N30, 47G10

DOI. 10.1137/040616449

1. Introduction.

We consider a bounded domain $D \subset \mathbb{R}^d$ and a symmetric kernel $K \in L^2(D \times D)$ defining a symmetric, nonnegative compact integral operator

$$\mathcal{K} : L^2(D) \to L^2(D), \qquad (\mathcal{K}u)(x) = \int_D K(x,x')u(x')\,dx' \quad \lambda\text{-a.e. } x \in D, \tag{1.1}$$

and for all $u \in L^2(D)$, where λ denotes here the Lebesgue measure. Such operators arise frequently in statistics and the theory of random fields as covariance operators (a typical example is given by the Gaussian kernel $K(x,x') = \exp(-|x-x'|^2)$; see [11] for further examples) and the computation of their spectral decomposition (eigenelements) is relevant for many applications, of which we mention here only the random field representation via the Karhunen–Loève expansion (see, e.g., [8]). This in turn has an important impact on the accuracy of all practical algorithms based on the Karhunen–Loève expansion of a random field, like, e.g., solving PDEs with stochastic data via polynomial chaos and stochastic Galerkin method. See [4] and the references therein for details and further examples.

1.1. Problem formulation.

The eigenvalue computation for the integral operator $\mathcal{K}$ given by (1.1) using the Galerkin method applied with a finite element space family $\mathcal{S} := (S_\hbar)_{\hbar\in\mathfrak{H}} \subset L^2(D)$ ($\hbar \in \mathfrak{H}$ stands here and in the following for the discretization parameter) consists in solving the discrete variational problem of finding $(\lambda_{\hbar,m}, \phi_{\hbar,m})_{m\in\mathbb{N}_+} \subset \mathbb{R} \times S_\hbar$ such that $\|\phi_{\hbar,m}\|_{L^2(D)} = 1\ \forall m \in \mathbb{N}_+$ and

$$\int_D \int_D K(x,x')\phi_{\hbar,m}(x')\psi(x)\,dx'dx = \lambda_{\hbar,m} \int_D \phi_{\hbar,m}(x)\psi(x)\,dx \quad \forall \psi \in S_\hbar. \tag{1.2}$$

Equation (1.2) shows that $(\lambda_{\hbar,m}, \phi_{\hbar,m})_{m\in\mathbb{N}_+}$ is nothing but the eigenvalue sequence of the nonnegative compact operator $\mathcal{K}_\hbar := P_\hbar \mathcal{K} P_\hbar$ in $L^2(D)$, where $P_\hbar$ denotes the $L^2(D)$ orthogonal projection onto $S_\hbar$.

The discretization error analysis of the eigenvalue problem (1.2) in the presence of a Galerkin scheme follows in general from abstract results on compact operators in Hilbert spaces. (See, e.g., [7], [3], [2], [5], or [9] for similar results in Banach spaces.) Denoting by $(\lambda_m, \phi_m)_{m\in\mathbb{N}_+}/(\lambda_{\hbar,m}, \phi_{\hbar,m})_{m\in\mathbb{N}_+}$ the exact/discrete eigenelements of $\mathcal{K}$, the uniform error estimates obtained in an abstract setting in [12], [7] apply

$$0 \leq \lambda_m - \lambda_{\hbar,m} \leq \|(I-P_\hbar)\mathcal{K}(I-P_\hbar)\|_{\mathcal{B}(L^2(D))} \quad \forall m \in \mathbb{N}_+, \forall \hbar \in \mathfrak{H}. \tag{1.3}$$

On the other hand, due to the positivity of $\mathcal{K}$, it trivially holds

$$0 \leq \lambda_m - \lambda_{\hbar,m} \leq \lambda_m \quad \forall m \in \mathbb{N}_+, \forall \hbar \in \mathfrak{H}. \tag{1.4}$$

While (1.3) describes the exact error asymptotics w.r.t. $\hbar$, (1.4) retains the correct scaling with λ_m. In fact, (1.3) and (1.4) are to some extent (but not fully) generalized by the following exact error representation formula (see [12], [3])

$$0 \leq \lambda_m - \lambda_{\hbar,m} = c_{\hbar,m}\|(I-P_\hbar)E^{\mathcal{K}}_{\{\lambda_m\}}\phi_{\hbar,m}\|^2_{L^2(D)}\lambda_m \quad \forall m \in \mathbb{N}_+, \forall \hbar \in \mathfrak{H}, \tag{1.5}$$

where $E^{\mathcal{K}}_A$ denotes the spectral projector of $\mathcal{K}$ onto the Borel set $A \subset \mathbb{R}$ and

$$\forall m \in \mathbb{N}_+ \quad c_{\hbar,m} \to 1 \quad \text{ as } S_\hbar \nearrow L^2(D),$$

that is, as the finite element space $S_\hbar$ gets refined.

However, (1.5) has a rather strong *asymptotic* character: for a fixed $m \in \mathbb{N}_+$, (1.5) becomes sharper than (1.4) and (1.3) only for fine enough finite element spaces depending on m ($\hbar \in \mathfrak{H}_m \subset \mathfrak{H}$) and in fact on the size of the spectrum gap around λ_m. The *estimated* constant $c_{\hbar,m}$ scales unfavorably with m (for rough finite element spaces), as the inverse of the spectrum gap size around λ_m. Consequently, the smaller the gap, the larger the estimated preasymptotic domain $\mathfrak{H}_m$ (that is, the set of those $\hbar \in \mathfrak{H}$ where (1.3), (1.4) are sharper than (1.5)).

1.2. Main results. The purpose of this work is to provide *robust* eigenvalue convergence rates of the type (1.5) for the particular case under consideration, that of an integral operator with smooth kernel, if standard finite element spaces corresponding to the h version of FEM are employed. The main result reads as follows.

THEOREM 1.1. *Let $\mathcal{K}$ be the integral operator* (1.1) *with (piecewise, in the sense of Definition* 3.1*) smooth kernel K and let $\mathcal{T} = (T_h)_{h>0}$ be a regular triangulation of D with meshwidth h. Setting $\hbar := h$ and defining, for $p \in \mathbb{N}_+$, $S_\hbar$ to be the space of discontinuous piecewise polynomials of degree $p-1$ on T_h, we have that for any $s > 0$ there exists $c_{K,\mathcal{T},p,s} > 0$ such that*

$$0 \leq \lambda_m - \lambda_{\hbar,m} \leq c_{K,\mathcal{T},p,s}(h^{2p}\lambda_m^{1-s} + h^{4p}\lambda_m^{-2s}) \quad \forall m \in \mathbb{N}_+, \forall h > 0 \tag{1.6}$$

and

$$0 \leq \lambda_m - \lambda_{\hbar,m} \leq c_{K,\mathcal{T},p,s}h^{2p}\lambda_m^{1/2-s} \quad \forall m \in \mathbb{N}_+, \forall h > 0. \tag{1.7}$$

Note that (1.7) follows by interpolation with logarithmic weight $1/2$ between (1.4) and the second term in the upper bound (1.6). Comparing (1.7) to (1.5), we see that (1.7) retains the correct asymptotic behaviour w.r.t. $\hbar$ and trades a factor $\lambda_m^{1/2}$ for robustness in $m \in \mathbb{N}_+$.

The proof of Theorem 1.1 is based on the following abstract error estimate we prove for a symmetric nonnegative compact operator $\mathcal{K}$ acting in a separable Hilbert

space $(H, \langle\cdot,\cdot\rangle_H)$. Concerning notations, $\mathcal{B}(H)$ denotes throughout this work the space of bounded linear operators acting in the separable Hilbert space $(H, \langle,\rangle_H)$, and we occasionally use traditional subscripts (e.g., $\mathcal{B}_\infty$, $\mathcal{B}_p$, $\mathcal{B}_{\mathrm{sym}}$) for spaces of operators with additional properties (compactness, compactness and ℓ_p summability of the eigenvalue sequence for $p > 0$, symmetry). Further, generic constants are denoted by c and all the variables on which they depend are included as subscripts.

PROPOSITION 1.2. *Let $\mathcal{K} \in \mathcal{B}(H)$ be a nonnegative compact operator with eigenelements $(\lambda_m, \phi_m)_{m\in\mathbb{N}_+}$ and let $\mathcal{S} := (S_\hbar)_{\hbar\in\mathfrak{H}} \subset H$ be a finite element space family. Then the following estimate holds:*

$$0 \le \lambda_m - \lambda_{\hbar,m} \le c_m \Psi(m,\hbar)^2 \lambda_m + c_{\mathcal{K},m} \Psi(m,\hbar)^4 \quad \forall m \in \mathbb{N}_+, \forall \hbar \in \mathfrak{H}, \tag{1.8}$$

where

$$\begin{aligned} \Phi(m,\hbar) &:= \|(I - P_\hbar)\phi_m\|_H, \\ \Psi(m,\hbar) &:= \max_{1\le j\le m} \Phi(j,\hbar), \end{aligned} \tag{1.9}$$

and

$$c_m := m^{3/2} + m, \quad c_{\mathcal{K},m} := m \sum_{j=1}^{m} \lambda_j.$$

Here $(\lambda_{\hbar,m})_{m\in\mathbb{N}_+}$ are the eigenvalues of $\mathcal{K}_\hbar := P_\hbar \mathcal{K} P_\hbar$.

Remark 1.3. In general (i.e., for standard finite element spaces), one expects the maximum in (1.9) to be attained for $j = m$, that is, $\Psi(m,\hbar) = \Phi(m,\hbar)$ for all $m \in \mathbb{N}_+$. This is essentially due to the increasing difficulty of approximating high frequency eigenfunctions, as $m \to \infty$ (or, equivalently, to the larger size of the estimated preasymptotic range $\mathfrak{H}_m$ as compared to $\mathfrak{H}_j$, for $j < m$).

Remark 1.4. Note that the first term on the right-hand side of (1.8) corresponds for any fixed $m \in \mathbb{N}_+$ to the correct asymptotics of (1.5) w.r.t. $\hbar$, whereas the second (corrector) gives a size estimate of the preasymptotic range,

$$\mathfrak{H}_m \subseteq \{\hbar \in \mathfrak{H} \mid \Psi(m,\hbar)^2 \ge \lambda_m / c_{\mathcal{K},m}\}.$$

The application of Proposition 1.2 to the case of the integral operator (1.1) and in the context of standard h FEM is then discussed in the second part of this work. Using the Gagliardo–Nirenberg inequalities (see, e.g., [1]) to bound eigenfunction oscillations and the standard h FEM error estimate, we prove the following upper bound on the functional Ψ.

THEOREM 1.5. *Let $\mathcal{K}$ be the integral operator* (1.1) *with (piecewise, in the sense of Definition* 3.1*) smooth kernel K and let $\mathcal{T} = (T_h)_{h>0}$ be a regular triangulation of D with meshwidth h. Setting $\hbar := h$ and defining $S_\hbar$ to be the space of discontinuous piecewise polynomials of degree $p - 1 \in \mathbb{N}$ on T_h, we have that for any $s > 0$ there exists $c_{K,\mathcal{T},p,s} > 0$ such that*

$$\Phi(m,\hbar) \le \Psi(m,\hbar) \le c_{K,\mathcal{T},p,s} \lambda_m^{-s} h^p \quad \forall m \in \mathbb{N}_+, \forall h > 0. \tag{1.10}$$

Further applications of Proposition 1.2 to the case of an operator $\mathcal{K}$ with a weaker/stronger smoothing effect (corresponding to finite Sobolev/analytic regularity of K), in the context of the h/p FEM, respectively, as well as similar estimates for eigenspaces (known to be more sensitive to perturbations than the eigenvalues) will be addressed in a forthcoming paper.

The article proceeds as follows. We devote section 2 to a proof of Proposition 1.2 and to its consequences (e.g., robust eigenvalue convergence rates for arbitrarily small positive powers of $\mathcal{K}$). We then discuss, as an application, the case of an integral operator in section 3. Proposition 1.2 takes a particularly simple form in this case, due to explicit control of eigenvalue decay and eigenfunction oscillations. Eigenvalue decay rates (in terms of the kernel regularity) are standard and briefly reviewed in section 3.1. Eigenfunction oscillations for smooth kernels are investigated in section 3.2 and shown (see Theorem 1.5) to be significantly milder than the eigenvalue decay rate.

2. Robust eigenvalue error estimates. Here we prove the main abstract discretization error estimate (1.8) and then discuss its optimality plus some direct consequences.

2.1. Abstract estimate. The main tool for the proof of Proposition 1.2, as formulated in the introduction, will be the minimax principle.

Proof of Proposition 1.2. First we note that the lower bound 0 for $\lambda_m - \lambda_{\hbar,m}$ follows trivially from the minimax principle. To check the upper bound, we fix $m \in \mathbb{N}_+$ and $\hbar \in \mathfrak{H}$ and write, using again the minimax principle,

$$\begin{aligned} \lambda_{\hbar,m} &= \max_{\substack{U\subset H\\ \dim U\geq m}} \min_{\substack{\phi\in U\\ \|\phi\|_H=1}} \langle \mathcal{K}_\hbar\phi,\phi\rangle_H \\ &= \max_{\substack{U\subset H\\ \dim U\geq m}} \min_{\substack{\phi\in U\\ \|\phi\|_H=1}} \left\{\langle \mathcal{K}\phi,\phi\rangle_H + \langle(\mathcal{K}_\hbar-\mathcal{K})\phi,\phi\rangle_H\right\}. \end{aligned} \tag{2.1}$$

The identity

$$P_\hbar\mathcal{K}P_\hbar - \mathcal{K} = -(I-P_\hbar)\mathcal{K} - \mathcal{K}(I-P_\hbar) + (I-P_\hbar)\mathcal{K}(I-P_\hbar)$$

and the fact that $\mathcal{K}$ is nonnegative ensure then

$$\langle(\mathcal{K}_\hbar-\mathcal{K})\phi,\phi\rangle_H \geq -2|\langle\mathcal{K}\phi,(I-P_\hbar)\phi\rangle_H| \quad \forall\phi\in H. \tag{2.2}$$

Using (2.2) in (2.1) we obtain

$$\begin{aligned} \lambda_{\hbar,m} &\geq \max_{\substack{U\subset H\\ \dim U\geq m}} \min_{\substack{\phi\in U\\ \|\phi\|_H=1}} \left\{\langle \mathcal{K}\phi,\phi\rangle_H - 2|\langle\mathcal{K}\phi,(I-P_\hbar)\phi\rangle_H|\right\} \\ &\geq \max_{\substack{U\subset H\\ \dim U\geq m}} \min_{\substack{\phi\in U\\ \|\phi\|_H=1}} \left\{\langle \mathcal{K}\phi,\phi\rangle_H - 2\|(I-P_\hbar)\mathcal{K}\phi\|_H\|(I-P_\hbar)\phi\|_H\right\}. \end{aligned} \tag{2.3}$$

At this stage we choose U to be the subspace of H spanned by the first m eigenfunctions $\phi_1,\phi_2,\ldots,\phi_m$ of $\mathcal{K}$. Expanding $\phi = \sum_{j=1}^m \alpha_j\phi_j$ with $\alpha_j\in\mathbb{C}$ and using definition (1.9) we obtain

$$\|(I-P_\hbar)\mathcal{K}\phi\|_H \leq \sum_{j=1}^m |\alpha_j|\lambda_j\Phi(j,\hbar) \leq \Psi(m,\hbar)\sum_{j=1}^m|\alpha_j|\lambda_j. \tag{2.4}$$

On the other hand,

$$\|(I-P_\hbar)\phi\|_H \leq \sum_{j=1}^m|\alpha_j|\Phi(j,\hbar) \leq \left(\sum_{j=1}^m\Phi(j,\hbar)^2\right)^{1/2} \leq \sqrt{m}\Psi(m,\hbar). \tag{2.5}$$

From (2.3), (2.4), (2.5) we obtain

$$\lambda_{\hbar,m} \geq \min_{\sum_{j=1}^m |\alpha_j|^2=1} \left\{ \sum_{j=1}^m \lambda_j |\alpha_j|^2 - 2\sqrt{m}\Psi(m,\hbar)^2 \sum_{j=1}^m \lambda_j |\alpha_j| \right\}. \tag{2.6}$$

Setting $\varepsilon := \sqrt{m}\Psi(m,\hbar)^2$, we distinguish two cases, as follows.

If $\varepsilon \geq 1/\sqrt{m}$, then it holds

$$\lambda_{\hbar,m} \geq 0 \geq \lambda_m - m\Psi(m,\hbar)^2\lambda_m,$$

which is in fact a stronger estimate than (1.8).

Otherwise $\varepsilon < 1/\sqrt{m}$ and we apply Lemma 2.1 below to obtain from (2.6)

$$\lambda_{\hbar,m} \geq \lambda_m - (m^{3/2}+m)\Psi(m,\hbar)^2\lambda_m - c_{\mathcal{K},m}\Psi(m,\hbar)^4$$

with $c_{\mathcal{K},m} = m\sum_{j=1}^m \lambda_j$, which concludes the proof. ∎

LEMMA 2.1. *If $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_m \geq 0$ is a nonincreasing sequence of nonnegative real numbers and $\varepsilon \in [0, 1/\sqrt{m}[$, then*

$$\min_{\sum_{j=1}^m t_j^2=1} \sum_{j=1}^m \lambda_j(t_j^2 - 2\varepsilon t_j) \geq (1-\varepsilon(m+\sqrt{m}))\lambda_m - \varepsilon^2 \sum_{j=1}^m \lambda_j. \tag{2.7}$$

Proof. Obviously, the minimum on the left-hand side (l.h.s.) of (2.7) is attained at a location $\tilde{t} := (\tilde{t}_1, \tilde{t}_2, \ldots, \tilde{t}_m)$ on the unit m dimensional sphere, with nonnegative coordinates. Using Lagrange multipliers for $f, g : \mathbb{R}^m \to \mathbb{R}$ given by

$$f(t) := \sum_{j=1}^m \lambda_j(t_j^2 - 2\varepsilon t_j) \quad \text{and} \quad g(t) := \sum_{j=1}^m t_j^2 - 1 \quad \forall t = (t_1, t_2, \ldots, t_m) \in \mathbb{R}^m,$$

we obtain the existence of a real $\lambda \neq 0$ such that for the location $\tilde{t}$ of the minimum of f restricted to $g^{-1}(\{0\})$ it holds $\nabla f - \lambda \nabla g = 0$, that is,

$$\tilde{t}_j = \frac{\varepsilon\lambda_j}{\lambda_j - \lambda} \quad \forall 1 \leq j \leq m. \tag{2.8}$$

Imposing $g(\tilde{t}) = 0$ we obtain that λ solves the equation

$$\sum_{j=1}^m \frac{\lambda_j^2}{(\lambda_j - \lambda)^2} = \frac{1}{\varepsilon^2}. \tag{2.9}$$

In order to estimate λ, we first remark that $\tilde{t}_j \geq 0$ $\forall 1 \leq j \leq m$ implies that λ is the unique solution of (2.9) situated in the interval $]-\infty, \lambda_m[$. Further, the condition $0 \leq \varepsilon < 1/\sqrt{m}$ ensures the positivity of λ, so that $\lambda \in]0, \lambda_m[$. As a consequence, the mth term of the sum in (2.9) is the largest one, which then implies

$$\frac{\lambda_m^2}{(\lambda_m - \lambda)^2} \leq \frac{1}{\varepsilon^2} \leq \frac{m\lambda_m^2}{(\lambda_m - \lambda)^2}$$

or, equivalently,

$$\lambda_m - \sqrt{m}\varepsilon\lambda_m \leq \lambda \leq \lambda_m - \varepsilon\lambda_m. \tag{2.10}$$

Computing f at $\tilde{t}$ given by (2.8) then yields

$$\begin{aligned}\min_{\substack{t\in\mathbb{R}^m\\ g(t)=0}} f(t) = f(\tilde{t}) &= \lambda - \varepsilon^2 \sum_{1\le j\le m} \frac{\lambda_j^2}{\lambda_j-\lambda}\\ &= \lambda - \varepsilon^2\left(m\lambda + \sum_{j=1}^m \lambda_j + \lambda^2 \sum_{j=1}^m \frac{1}{\lambda_j-\lambda}\right)\\ &\overset{(2.10)}{\ge} (1-\varepsilon^2 m)\lambda - \varepsilon^2\sum_{j=1}^m \lambda_j - \varepsilon m\lambda^2/\lambda_m\\ &\overset{(2.10)}{\ge} (1-\varepsilon m)\lambda - \varepsilon^2\sum_{j=1}^m \lambda_j \overset{(2.10)}{\ge} (1-\varepsilon(m+\sqrt{m}))\lambda_m - \varepsilon^2\sum_{j=1}^m \lambda_j,\end{aligned}$$

which concludes the proof. □

Some comments on the optimality of the estimate (1.8) in Proposition 1.2 are now in order.

Remark 2.2. If $\lambda_1 = \lambda_2 = \cdots = \lambda_m$, then the minimum in (2.7) can be explicitly computed and equals $(1-2\sqrt{m}\varepsilon)\lambda_m$. The lower bound in (2.7) is therefore in this case suboptimal, due to the $O(\varepsilon^2)$ term. However, this is a rather special case, since in general the eigenvalue sequence is not constant, unless $\mathcal{K} = 0$.

We argue in the following that although sharper estimates for $c_m, c_{\mathcal{K},m}$ in (1.8) can be obtained, the upper bound (1.8) obtained through (2.3) is qualitatively optimal, (and serves our purpose of proving Theorem 1.1), in the sense that the second term on the right-hand side (r.h.s.) of (1.8) does not scale with (any positive power of) λ_m. A careful analysis of the proof presented in this section reveals that its main weakness lies in the use of the Cauchy–Schwarz inequality twice, to obtain (2.3) and (2.5).

Remark 2.3. Improving on (2.3) seems to be the key point in obtaining a qualitatively better eigenvalue error estimate, but this requires further favorable properties (e.g., diagonal dominance) of the matrix

$$(\langle\phi_j, (I-P_\hbar)\phi_{j'}\rangle_H)_{1\le j,j'\le m}.$$

Remark 2.4. Improving on (2.5) by using, e.g., $\|(I-P_\hbar)\phi\|_H \le \Psi(m,\hbar)\sum_{j=1}^m |\alpha_j|$ leads to a sharper eigenvalue error estimate via the (more difficult) minimization problem

$$\lambda_{\hbar,m} \ge \lambda := \min_{\sum_{j=1}^m |\alpha_j|^2=1} \left\{\sum_{j=1}^m \lambda_j|\alpha_j|^2 - 2\Psi(m,\hbar)^2 \sum_{j=1}^m \lambda_j|\alpha_j| \sum_{j=1}^m |\alpha_j|\right\}. \tag{2.11}$$

Choosing, for $m \ge 2$, $\alpha_2 = \alpha_3 = \cdots = \alpha_{m-1} = 0$, we have

$$\lambda \le \tilde{\lambda} := \min_{t_1^2+t_m^2=1} \left\{\lambda_1(1-2\varepsilon)t_1^2 + \lambda_m(1-2\varepsilon)t_m^2 - 2\varepsilon(\lambda_1+\lambda_m)t_1t_m\right\} \tag{2.12}$$

with $\varepsilon := \Psi(m,\hbar)^2$.

From Lemma 2.5 below it follows that if $\lambda_m < \lambda_1$ and $0 \le \varepsilon \le \min\{1/2, \lambda_1\} \le \sqrt{2}(\lambda_1-\lambda_m)$ (which both hold for m large enough depending on $\mathcal{K}$), then $\tilde{\lambda}$ satisfies, with some $c \in [1/2, 1]$,

$$\tilde{\lambda} = (1-2\varepsilon)\lambda_m - c\varepsilon^2\frac{(\lambda_1+\lambda_m)^2}{(1-2\varepsilon)(\lambda_1-\lambda_m)}.$$

We conclude that if $(\lambda_j)_{1\le j\le m}$ is not a constant sequence (and this is always the case for the eigenvalue sequence of a compact operator if m is large enough), then the minimization problem (2.11) leads to an estimate qualitatively similar to (1.8). (The term containing $\Psi(m,\hbar)^4$ does not scale with λ_m but with a constant bounded away from 0.)

LEMMA 2.5. *If $0<\beta<\alpha$ and $0\le\gamma\le\sqrt{2}(\alpha-\beta)$, then*

$$\min_{x^2+y^2=1}\{\alpha x^2+\beta y^2-2\gamma xy\}=\beta-\frac{2\gamma^2}{\alpha-\beta+\sqrt{(\alpha-\beta)^2+4\gamma^2}} \tag{2.13}$$

$$\in\left[\beta-\frac{\gamma^2}{\alpha-\beta},\beta-\frac{1}{2}\frac{\gamma^2}{\alpha-\beta}\right]. \tag{2.14}$$

Proof. Note first that (2.14) follows from (2.13) using the assumption on γ. It remains to check (2.13). To this end, we note first that for the location $(\tilde{x},\tilde{y})$ of the minimum in (2.13) and the Lagrange multiplier $\lambda\in\mathbb{R}$ it holds

$$\begin{cases}(\alpha-\lambda)\tilde{x} &= \gamma\tilde{y},\\ (\beta-\lambda)\tilde{y} &= \gamma\tilde{x},\end{cases} \tag{2.15}$$

from which we obtain (assuming also without loss of generality $\tilde{x},\tilde{y}>0$) that $\lambda\in\,]-\infty,\beta]$ solves $(\alpha-\lambda)(\beta-\lambda)=\gamma^2$, that is, λ equals the r.h.s. of (2.13). The system (2.15) has then the solution

$$\tilde{x}=\left(\frac{\beta-\lambda}{\alpha+\beta-2\lambda}\right)^{1/2},\quad \tilde{y}=\left(\frac{\alpha-\lambda}{\alpha+\beta-2\lambda}\right)^{1/2}.$$

Upon inserting these values into the quadratic form (2.13) we obtain that the minimum we look for equals λ, which concludes the proof. ∎

Proposition 1.2 takes a particularly simple form if the operator $\mathcal{K}$ satisfies the following conditions.

ASSUMPTION 2.6. *$\mathcal{K}\in\cap_{p>0}\mathcal{B}_p(H)$ is nonnegative and for any $s>0$ there exists $c_{\mathcal{K},\mathcal{S},s}>0$ such that*

$$\Phi(m,\hbar)=\|(I-P_\hbar)\phi_m\|_H\le c_{\mathcal{K},\mathcal{S},s}\lambda_m^{-s}\Upsilon(\hbar)\quad\forall m\in\mathbb{N}_+,\forall\hbar\in\mathfrak{H}, \tag{2.16}$$

where the functional $\Upsilon:\mathfrak{H}\to\mathbb{R}$ describes the approximation property *of the finite element space family $\mathcal{S}$.*

Keeping in mind the standard h FEM error estimate, we note that (2.16) can be viewed as a combination of *good $\mathcal{K}$-eigenfunction approximability* through the finite elements in $\mathcal{S}$ and a *mild eigenfunction oscillation* condition. We have the next theorem.

THEOREM 2.7. *If Assumption* 2.6 *is satisfied, then for any $s>0$ there exists a constant $c_{\mathcal{K},\mathcal{S},s}>0$ such that*

$$0\le\lambda_m-\lambda_{\hbar,m}\le c_{\mathcal{K},\mathcal{S},s}(\Upsilon(\hbar)^2\lambda_m^{1-s}+\Upsilon(\hbar)^4\lambda_m^{-2s})\quad\forall m\in\mathbb{N}_+,\forall\hbar\in\mathfrak{H}, \tag{2.17}$$

where $(\lambda_m)_{m\in\mathbb{N}_+}$ and $(\lambda_{\hbar,m})_{m\in\mathbb{N}_+}$ are the eigenvalue sequences of $\mathcal{K}$ and $P_\hbar\mathcal{K}P_\hbar$, respectively.

Proof. Condition (2.16) ensures that

$$\Psi(m,\hbar)\le c_{\mathcal{K},\mathcal{S},s}\Upsilon(\hbar)\lambda_m^{-s}\quad\forall m\in\mathbb{N}_+,\forall\hbar\in\mathfrak{H},\forall s>0,$$

whereas $\mathcal{K} \in \cap_{p>0}\mathcal{B}_p(H)$ gives

$$c_m = m^{3/2} + m \leq c_{\mathcal{K},s}\lambda_m^{-s}, \quad c_{\mathcal{K},m} = m\sum_{j=1}^{m}\lambda_j \leq c_{\mathcal{K},s}\lambda_m^{-s} \quad \forall m \in \mathbb{N}_+, \forall s > 0,$$

which concludes the proof via (1.8). ∎

COROLLARY 2.8. *If Assumption* 2.6 *is satisfied, then for any* $s > 0$ *there exists a constant* $c_{\mathcal{K},\mathcal{S},s} > 0$ *such that*

$$0 \leq \lambda_m - \lambda_{\hbar,m} \leq c_{\mathcal{K},\mathcal{S},s}(\Upsilon(\hbar)^2\lambda_m^{1-s} + \Upsilon(\hbar)^{4\alpha}\lambda_m^{1-\alpha-2s\alpha}) \tag{2.18}$$

$\forall m \in \mathbb{N}_+, \forall \hbar \in \mathfrak{H}, \forall \alpha \in [0,1]$, *where* $(\lambda_m)_{m\in\mathbb{N}_+}$ *and* $(\lambda_{\hbar,m})_{m\in\mathbb{N}_+}$ *are the eigenvalue sequences of* $\mathcal{K}$ *and* $P_\hbar\mathcal{K}P_\hbar$ *respectively. In particular* ($\alpha = 1/2$)

$$0 \leq \lambda_m - \lambda_{\hbar,m} \leq c_{\mathcal{K},\mathcal{S},s}\Upsilon(\hbar)^2\lambda_m^{1/2-s} \quad \forall m \in \mathbb{N}_+, \forall \hbar \in \mathfrak{H}. \tag{2.19}$$

Proof. The desired estimate (2.18) follows immediately by interpolation with logarithmic weight α between the second term in the upper bound (2.17) and the trivial estimate $0 \leq \lambda_m - \lambda_{\hbar,m} \leq \lambda_m$, via the inequality $\min\{x, y+z\} \leq y + x^\alpha z^{1-\alpha}$ $\forall x, y, z \geq 0$. ∎

We note next that in contrast to (2.19), the trace discretization error retains the correct scaling factor (λ_m and not $\lambda_m^{1/2}$), in the following sense.

THEOREM 2.9. *If Assumption* 2.6 *is satisfied, then for any* $0 < s < 1$ *there exists a constant* $c_{\mathcal{K},\mathcal{S},s} > 0$ *such that*

$$0 \leq \text{Tr } \mathcal{K} - \text{Tr } P_\hbar\mathcal{K}P_\hbar \leq c_{\mathcal{K},\mathcal{S},s}\Upsilon(\hbar)^2\sum_{m\in\mathbb{N}_+}\lambda_m^{1-s} \quad \forall \hbar \in \mathfrak{H}. \tag{2.20}$$

Proof. The lower bound follows trivially from $\lambda_{\hbar,m} \leq \lambda_m$ $\forall m \in \mathbb{N}_+$.

Further, the identity

$$\mathcal{K} - P_\hbar\mathcal{K}P_\hbar = (I - P_\hbar)\mathcal{K} + \mathcal{K}(I - P_\hbar) - (I - P_\hbar)\mathcal{K}(I - P_\hbar)$$

and the fact that $\mathcal{K}$ is nonnegative ensure

$$\langle(\mathcal{K} - P_\hbar\mathcal{K}P_\hbar)\phi, \phi\rangle_H \leq 2|\langle\mathcal{K}\phi, (I - P_\hbar)\phi\rangle_H| \quad \forall \phi \in H. \tag{2.21}$$

Using (2.21) and Assumption 2.6 it follows

$$\begin{aligned}\text{Tr } \mathcal{K} - \text{Tr } P_\hbar\mathcal{K}P_\hbar &= \sum_{m=1}^{\infty}\langle(\mathcal{K} - P_\hbar\mathcal{K}P_\hbar)\phi_m, \phi_m\rangle_H \leq 2\sum_{m=1}^{\infty}|\langle\mathcal{K}\phi_m, (I - P_\hbar)\phi_m\rangle_H| \\ &\leq 2\sum_{m=1}^{\infty}\lambda_m\|(I - P_\hbar)\phi_m\|_H^2 \leq c_{\mathcal{K},\mathcal{S},s}\Upsilon(\hbar)^2\sum_{m=1}^{\infty}\lambda_m^{1-s},\end{aligned}$$

and the proof is concluded. ∎

2.2. $\mathcal{K}^\delta$ spectrum approximation. For a given $\delta > 0$, a simple argument based on the Lipschitz continuity of

$$]0,\infty[\ni x \to x^\delta \in]0,\infty[$$

shows that the computed eigenvalues of $\mathcal{K}^\delta$, namely, $(\lambda^\delta_{\hbar,m})_{m\in\mathbb{N}_+}$, are good approximations of the exact eigenvalues $(\lambda^\delta_m)_{m\in\mathbb{N}_+}$ of $\mathcal{K}^\delta$.

THEOREM 2.10. *If Assumption* 2.6 *is satisfied, then for any* $0 \le \alpha < \delta \le 1$,

$$0 \le \sum_{m=1}^{\infty} (\lambda^\delta_m - \lambda^\delta_{\hbar,m}) \le c_{K,\mathcal{S},\alpha,\delta} \max\{\Upsilon(\hbar)^2, \Upsilon(\hbar)^{4\alpha}\} \quad \forall \hbar \in \mathfrak{H}. \tag{2.22}$$

Proof. From the Lipschitz condition

$$\lambda^\delta_m - \lambda^\delta_{\hbar,m} \le \lambda_m^{\delta-1}(\lambda_m - \lambda_{\hbar,m})$$

and (2.17) we obtain that for any $s > 0$ there exists a constant $c_{K,\mathcal{S},s} > 0$ such that

$$0 \le \lambda^\delta_m - \lambda^\delta_{\hbar,m} \le c_{K,\mathcal{S},s}(\Upsilon(\hbar)^2 \lambda_m^{\delta-s} + \Upsilon(\hbar)^4 \lambda_m^{\delta-1-2s}) \tag{2.23}$$

$\forall m \in \mathbb{N}_+, \forall \hbar \in \mathfrak{H}$. Interpolation with logarithmic weight $\alpha \in [0, \delta[$ between the second term in the r.h.s. of (2.23) and the trivial estimate $\lambda^\delta_m - \lambda^\delta_{\hbar,m} \le \lambda^\delta_m$ yields

$$0 \le \lambda^\delta_m - \lambda^\delta_{\hbar,m} \le c_{K,\mathcal{S},s}(\Upsilon(\hbar)^2 \lambda_m^{\delta-s} + \Upsilon(\hbar)^{4\alpha} \lambda_m^{\delta-(1+2s)\alpha}). \tag{2.24}$$

Choosing $s > 0$ small enough to ensure $(1 + 2s)\alpha < \delta$ and summing (2.24) over $m \in \mathbb{N}_+$ we obtain (2.22). ∎

3. Application to integral operators. We check the validity of Assumption 2.6 in the case of an integral operator $\mathcal{K}$ with piecewise smooth kernel K, if standard h FEM is used to construct the finite element space family $\mathcal{S}$. We begin with a review of eigenvalue decay rates in terms of the kernel regularity, which are immediately seen to ensure $\mathcal{K} \in \cap_{p>0}\mathcal{B}_p(H)$. We then show that (2.16) is a consequence of standard h FEM error estimates and Gagliardo–Nirenberg inequalities ensuring mild eigenfunction oscillations for $\mathcal{K}$.

3.1. Eigenvalue decay. The results we present in this section are standard (see, e.g., [6], [10]), following from the abstract theory of Weyl/approximation/entropy numbers via approximation of K by discrete, finite rank (separable w.r.t. (x, x')) kernels. Roughly speaking, the smoother the kernel the faster the eigenvalue decay, with finite Sobolev regularity implying algebraic decay and analyticity giving rise to quasi-exponential decay.

Remarkably, all these results hold for piecewise regular kernels on product subdomains of D, in the sense of Definition 3.1. Note that general piecewise regularity allowing singularities on the diagonal set of $D \times D$ ensure in general only a slower eigenvalue decay. (See, e.g., [6] and [4] for examples with known exact eigenelements.)

DEFINITION 3.1. *If D is a bounded domain in $\mathbb{R}^d$ and $p, q \in [0, \infty[$, a measurable function $K : D \times D \to \mathbb{R}$ is said to be piecewise $H^{p,q}$ on $D \times D$ if there exists a finite family $\mathcal{D} = (D_j)_{j\in\mathcal{J}}$ of subdomains of D such that*

i. $D_j \cap D_{j'} = \emptyset \quad \forall j, j' \in \mathcal{J}$ *with* $j \ne j'$,
ii. $D \setminus \bigcup_{j\in\mathcal{J}} D_j$ *is a null set in* $\mathbb{R}^d$,
iii. $\overline{D} \subset \bigcup_{j\in\mathcal{J}} \overline{D_j}$,
iv. $K|_{D_j \times D_{j'}} \in H^{p,q}(D_j \times D_{j'}) := H^p(D_j) \otimes H^q(D_{j'}) \quad \forall j, j' \in \mathcal{J}$.

We denote by $H^{p,q}_{\mathcal{D}}(D^2)$ the space of piecewise $H^{p,q}$ functions on $D \times D$ in the sense given above.

Moreover, if there exists also a finite family $\mathcal{G} = (G_j)_{j\in\mathcal{J}}$ *of open sets in* $\mathbb{R}^d$ *such that*

v. $\overline{D_j} \subset G_j \quad \forall j \in \mathcal{J}$,

vi. $K|_{D_j\times D_{j'}}$ *has an* $H^{p,q}$ *continuation to* $G_j \times G_{j'} \quad \forall j, j' \in \mathcal{J}$,

then we say that K *is piecewise* $H^{p,q}$ *on a covering of* $D \times D$ *and we denote by* $H^{p,q}_{\mathcal{D},\mathcal{G}}(D^2)$ *the corresponding space.*

Similarly we introduce spaces of piecewise regular functions defined on D*, which we denote by* $H^p_{\mathcal{D}}(D)$*,* $H^p_{\mathcal{D},\mathcal{G}}(D)$*, etc.*

For kernels with finite Sobolev regularity the next proposition holds.

PROPOSITION 3.2. *Let* $D \subset \mathbb{R}^d$ *be a bounded domain and* $K \in L^2(D \times D)$ *be a symmetric kernel defining a compact nonnegative integral operator* $\mathcal{K}$ *via* (1.1)*. If* $K \in H^{p,0}_{\mathcal{D},\mathcal{G}}(D^2)$ *for some* $p \in [0, \infty[$*, then there exists a constant* $c_K > 0$ *such that*

$$0 \le \lambda_m \le c_K m^{-p/d} \quad \forall m \in \mathbb{N}_+. \tag{3.1}$$

COROLLARY 3.3. *Let* $D \subset \mathbb{R}^d$ *be a bounded domain and* $K \in L^2(D \times D)$ *be a symmetric kernel defining a compact nonnegative integral operator* $\mathcal{K}$ *via* (1.1)*. If* K *is piecewise smooth (i.e., piecewise* $H^{p,q}_{\mathcal{D},\mathcal{G}}(D^2)$ $\forall p, q \in [0, \infty[$*) on a covering of* $D \times D$ *and* $(\lambda_m)_{m\in\mathbb{N}_+}$ *denotes the eigenvalue sequence of* $\mathcal{K}$*, then for any* $s > 0$ *there exists a constant* $c_{K,s} > 0$ *such that*

$$0 \le \lambda_m \le c_{K,s} m^{-s} \quad \forall m \in \mathbb{N}_+ \tag{3.2}$$

so that $\mathcal{K} \in \cap_{p>0}\mathcal{B}_p(L^2(D))$.

Example 3.4. One is often interested in Gaussian kernels of the form

$$K(x, x') := \sigma^2 \exp(-|x - x'|^2/(\gamma^2\Lambda^2)) \quad \forall (x, x') \in D \times D, \tag{3.3}$$

where $\sigma, \gamma > 0$ are real parameters (standard deviation, correlation length) and Λ is the diameter of the domain D. K given by (3.3) has an entire continuation to $\mathbb{C}^d$ and defines a nonnegative compact operator via (1.1).

Note that for piecewise analytic kernels the next proposition holds.

PROPOSITION 3.5. *Let* $K \in L^2(D\times D)$ *be a symmetric kernel defining a compact nonnegative integral operator via* (1.1)*. If* $K \in \mathcal{A}_{\mathcal{D},\mathcal{G}}(D^2)$ *(defined analogously to* $H^{p,q}_{\mathcal{D},\mathcal{G}}$*) and* $(\lambda_m)_{m\in\mathbb{N}_+}$ *denotes the eigenvalue sequence of* $\mathcal{K}$*, then there exist constants* $c_{1,K}, c_{2,K} > 0$ *such that*

$$0 \le \lambda_m \le c_{1,K} e^{-c_{2,K} m^{1/d}} \quad \forall m \in \mathbb{N}_+. \tag{3.4}$$

Since K given by (3.3) admits an analytic continuation to the whole complex space $\mathbb{C}^d \times \mathbb{C}^d$, the eigenvalue decay is in this case even faster than in (3.4).

PROPOSITION 3.6. *If* $K \in L^2(D \times D)$ *is given by* (3.3)*, then for the eigenvalue sequence* $(\lambda_m)_{m\in\mathbb{N}_+}$ *of* $\mathcal{K}$ *defined by* (1.1) *it holds*

$$0 \le \lambda_m \le c_{\sigma,\gamma,D} \frac{(1/\gamma\Lambda)^{m^{1/d}}}{\Gamma(m^{1/d}/2)} \quad \forall m \in \mathbb{N}_+. \tag{3.5}$$

3.2. Eigenfunction oscillations. We show next that the piecewise smoothness assumption on the kernel allows also a good control of the eigenfunctions and their derivatives in the $L^\infty(D)$ norm. Roughly speaking, the eigenfunctions are shown to be bounded from above, asymptotically as $m \to \infty$, by any negative power of the

corresponding eigenvalue. In other words, the eigenfunction oscillations are much weaker than the eigenvalue decay rate.

First we note that piecewise regularity of eigenfunctions follows from that of the kernel K.

PROPOSITION 3.7. *If $K \in H^{p,q}_{\mathcal{D},\mathcal{G}}(D^2)$, then the eigenfunctions of $\mathcal{K}$ given by* (1.1) *corresponding to nontrivial eigenvalues belong to $H^p_{\mathcal{D},\mathcal{G}}(D)$.*

Proof. The conclusion follows at once from the eigenvalue equation

$$\phi_m(x) = \frac{1}{\lambda_m} \sum_{j' \in \mathcal{J}} \int_{D_{j'}} K(x,x')\phi_m(x')\,dx' \quad \forall x \in D_j, \tag{3.6}$$

which can be naturally extended to G_j by replacing K by its $H^{p,q}$ continuation on $G_j \times G_{j'}$. ∎

Remark 3.8. *Similarly, if $K \in H^{p,q}_{\mathcal{D}}(D^2)$, then the eigenfunctions of $\mathcal{K}$ corresponding to nontrivial eigenvalues belong to $H^p_{\mathcal{D}}(D)$.*

The following result due to Ehrling–Nirenberg–Gagliardo (see [1, Theorem 4.14]) is essential for our analysis.

THEOREM 3.9. *Let $D \subset \mathbb{R}^d$ be a bounded domain having the uniform cone property and $\varepsilon_0 \in (0,\infty)$, $n \in \mathbb{N}$, $p \in [1,\infty)$. Then there exists $c_{\varepsilon_0,n,p,D} > 0$ such that for any $\varepsilon \in (0,\varepsilon_0]$, $l \in \{0,1,\dots,n-1\}$ and $u \in W^{n,p}(D)$,*

$$|u|_{l,p} \le c_{\varepsilon_0,n,p,D} \left\{ \varepsilon |u|_{n,p} + \varepsilon^{-l/(n-l)} |u|_{0,p} \right\}, \tag{3.7}$$

where

$$|u|^p_{l,p} := \int_D \sum_{|\alpha|=l} |\partial^\alpha u(x)|^p \,dx.$$

PROPOSITION 3.10. *For $D \subset \mathbb{R}^d$ a bounded domain and K piecewise smooth on $D \times D$ such that the domains D_j in Definition* 3.1 *all have the uniform cone property, we denote by $(\lambda_m,\phi_m)_{m\in\mathbb{N}_+}$ the eigenelements of the associated integral operator $\mathcal{K}$ via* (1.1)*, such that $\|\phi_m\|_{L^2(D)} = 1$ $\forall m \in \mathbb{N}_+$. Then for any $s > 0$ and any multiindex $\alpha \in \mathbb{N}^d$ there exists $c_{K,s,\alpha} > 0$ such that*

$$\|\partial^\alpha \phi_m\|_{L^\infty(D_j)} \le c_{K,s,\alpha} \, |\lambda_m|^{-s} \quad \forall m \in \mathbb{N}_+, \forall j \in \mathcal{J}. \tag{3.8}$$

Proof. We first note that the eigenvalue equation (3.6) implies (by differentiating and applying the Cauchy–Schwarz inequality to estimate the resulting integrals) for any $\alpha \in \mathbb{N}^d$ the existence of a constant $c_{K,\alpha} > 0$ such that

$$\|\partial^\alpha \phi_m\|_{L^\infty(D_j)} \le \; c_{K,\alpha} |\lambda_m|^{-1} \quad \forall m \in \mathbb{N}_+, \forall j \in \mathcal{J}. \tag{3.9}$$

We apply now Theorem 3.9 on D_j with $p = 2$, $\varepsilon_0 := \max_{m\in\mathbb{N}_+} |\lambda_m|$ and choose in (3.7) $\varepsilon = \lambda_m$, $u = \phi_m$ for an arbitrary $m \in \mathbb{N}_+$ (we assume w.l.o.g. $\lambda_m \neq 0$). It follows that for any $n \in \mathbb{N}$ there exists $c_{\varepsilon_0,n,D_j} > 0$ such that for all $l \in \{0,1,\dots,n-1\}$

$$\begin{aligned} |\phi_m|_{D_j,l,2} &\le c_{\varepsilon_0,n,D_j} \left\{ \lambda_m |\phi_m|_{D_j,n,2} + \lambda_m^{-l/(n-l)} |\phi_m|_{D_j,0,2} \right\} \\ &\le c_{\varepsilon_0,n,D_j,K} \left\{ 1 + \lambda_m^{-l/(n-l)} \right\} \le c_{\varepsilon_0,n,D_j,K} \lambda_m^{-l/(n-l)}, \end{aligned} \tag{3.10}$$

due to (3.9).

Now, for any $s > 0$ and $\alpha \in \mathbb{N}^d$ we choose $l = \lceil d/2 \rceil + |\alpha|$ and $n > l$ such that $l/(n-l) < s$. From (3.10) and the Sobolev embedding theorems we deduce then

$$\begin{aligned}\|\partial^\alpha \phi_m\|_{L^\infty(D_j)} &\le c_{\alpha,D_j}\|\phi_m\|_{H^l(D_j)} \le c_{\alpha,D_j}\sum_{k=0}^{l}|\phi_m|_{D_j,k,2}\\ &\le c_{\varepsilon_0,n,D_j,K,\alpha}\sum_{k=0}^{l}\lambda_m^{-k/(n-k)}\\ &\le c_{\varepsilon_0,n,D_j,K,\alpha}\lambda_m^{-l/(n-l)} \le c_{\varepsilon_0,n,D_j,K,\alpha}\lambda_m^{-s}\end{aligned}$$

$\forall m \in \mathbb{N}_+$, and the proof is concluded. ∎

Remark 3.11. Under the regularity assumptions of Proposition 3.10 the estimate (3.8) is optimal in the sense that for any α it fails to hold with $s = 0$. This can be seen, e.g., on $D :=]0,1[$ by taking $K := \sum_{m\ge1}\lambda_m\,\phi_m \otimes \phi_m$ with

$$\lambda_m := e^{-m}, \quad \phi_m(x) := m\phi(m^2x - m) \quad \forall x \in]0,1[, \forall m \in \mathbb{N}_+,$$

where $\phi \in C_0^\infty(]0,1[)$ satisfies $\|\phi\|_{L^2(]0,1[)} = 1$.

Remark 3.12. It can be shown that further assumptions, like stationarity of the kernel, i.e., $K(x,x') = k(x-x')$ for some $k : \mathbb{R}^d \to \mathbb{R}$, lead to the uniform L^∞ boundedness of the eigenfunctions (but not of their derivatives).

Remark 3.13. If K is not piecewise smooth in the sense of Definition 3.1 (for instance, if the singularities of K lie on the diagonal set of $D \times D$, as it is the case for some usual stationary kernels like, e.g., $K(x,x') = k(x-x') = \exp(-|x-x'|^{1+\delta})$ with $0 \le \delta < 1$), then estimates of type (3.8) hold true only for $s > c_k > 0$, where the constant $c_k \in]0,1]$ depends on the Sobolev regularity of k in $\mathbb{R}^d$. (See also [4] for such examples with known exact eigenelements.)

3.3. *h* FEM. For the integral operator (1.1) with smooth kernel K we can check now the validity of Assumption 2.6, if the standard h FEM is used to construct the finite element space family $\mathcal{S}$. For a fixed $p \in \mathbb{N}_+$ and with $\hbar := h \in]0,\infty]$ we define $S_\hbar = S_h := S_h^p$ to be the space of discontinuous piecewise polynomials of total degree at most $p-1$ on a regular mesh T_h in $\overline{D}$ of width h and subordinate to $\mathcal{D}$, i.e., to the covering $(\overline{D_j})_{j\in\mathcal{J}}$. With this choice the next proposition holds.

PROPOSITION 3.14. *If $K \in L^2(D\times D)$ is piecewise smooth on a covering of $D \times D$, defining a compact nonnegative integral operator $\mathcal{K}$ via* (1.1) *and $p \in \mathbb{N}_+$, $S_\hbar = S_h^p$ $\forall \hbar = h \in]0,\infty]$, then Assumption* 2.6 *holds with $\Upsilon(\hbar) := h^p$.*

Proof. The fast eigenvalue decay has been established in Corollary 3.3, so that we only have to check (2.16). To this end, we note that the standard h FEM approximation property holds for S_h,

$$\|\phi - P_\hbar\phi\|_{L^2(D)} \le c_{p,\mathcal{D}}h^p|\phi|_p \quad \forall h > 0,\, \forall \phi \in H^p_{\mathcal{D}}(D), \tag{3.11}$$

where

$$|\phi|_p^2 := \sum_{j\in\mathcal{J}}\sum_{|\alpha|=p}\|\partial^\alpha\phi\|^2_{L^2(D_j)} \quad \forall \phi \in H^p_{\mathcal{D}}(D).$$

The conclusion follows then by applying (3.11) to $\phi := \phi_m \in H^p_{\mathcal{D}}(D)$ (in view of Remark 3.8), and using Proposition 3.10 to estimate $|\phi_m|_p$ in terms of a given $s > 0$ and λ_m. ∎

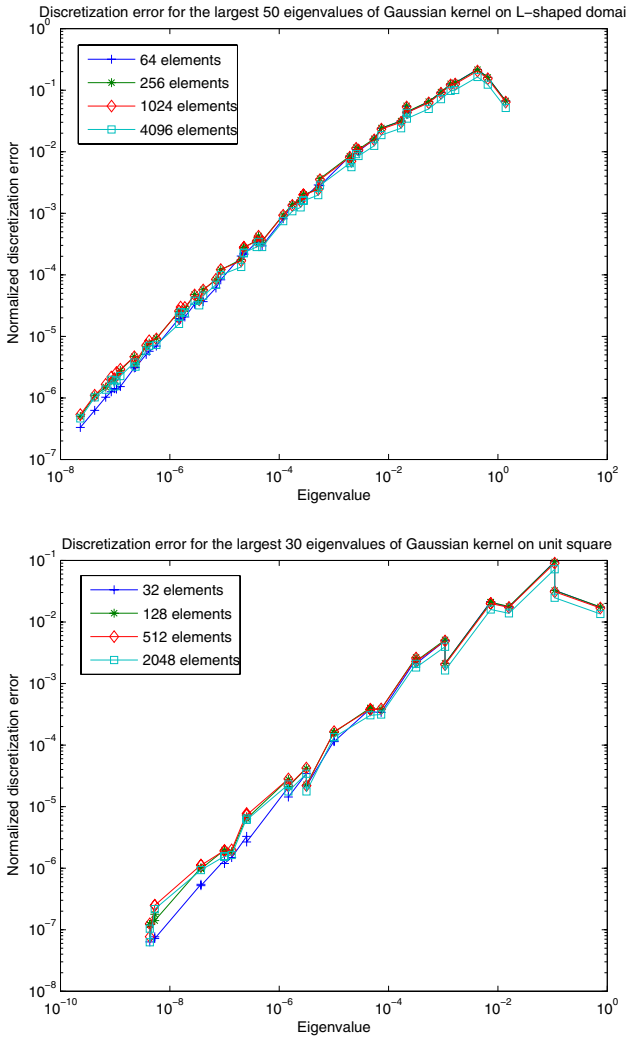

FIG. 1. *Eigenvalue discretization error for Gaussian kernel* $K(x,x') = \exp(-|x-x'|^2)$ *on two-dimensional L-shaped domain (top) and unit square (bottom).*

Theorem 1.5 is now just a reformulation of Proposition 3.14, whereas Theorem 1.1 follows directly from the main abstract result, Theorem 2.7.

Remark 3.15. For the h FEM applied to the integral operator (1.1) with piecewise smooth kernel, (2.22) becomes

$$0 \leq \sum_{m=1}^{\infty} (\lambda_m^{\delta} - \lambda_{h,m}^{\delta}) \leq c_{K,\mathcal{S},\alpha,\delta} h^{p \min\{2,4\alpha\}} \quad \forall h \in]0,1], \forall \alpha < \delta.$$

3.4. Numerical tests. The results of the eigenvalues computation for the case of a Gaussian kernel $K(x,x') = \exp(-|x-x'|^2)$ on an L-shaped domain and on the unit square, respectively, are presented in Figure 1. In both cases we employ piecewise constant elements on a regular mesh, at discretization levels 2, 3, 4, and

5 (corresponding to 64, 256, 1024, and 4096 elements for the L-shaped and to 32, 128, 512, and 2048 elements for the unit square, respectively). We use the results of an overkill computation on level 6 (with 16384 and 8192 elements, respectively) as exact eigenvalues. In Figure 1 we plot the normalized (w.r.t. meshwidth h) discretization error $(\lambda_m - \lambda_{m,\hbar})/h^2$ versus the corresponding eigenvalue λ_m for the first 50 eigenvalues ($m = 1, 2, \ldots, 50$) in the case of the L-shaped domain and the first 30 eigenvalues for the unit square. Note that the separability of the Gaussian kernel on the unit square ensures the existence of multiple eigenvalues. In both cases the slope of the resulting curve appears to be close to 1, validating thus the theoretical result (Theorem 1.1), which predicted a slope of at least 1/2. Moreover, Figure 1 and the exact error representation formula (1.5) suggest the following question.

OPEN QUESTION 3.16. *Is it true that in the case of an analytic (or just smooth) kernel K, the curve slopes in Figure* 1 *come arbitrarily close to* 1*? More precisely, does the estimate stronger than* (1.7)*,*

$$0 \leq \lambda_m - \lambda_{\hbar,m} \leq c_{K,\mathcal{T},p,s} h^{2p} \lambda_m^{1-s} \quad \forall m \in \mathbb{N}_+, \forall h > 0, \forall s > 0, \tag{3.12}$$

hold under the assumptions of Theorem 1.1*?*

Acknowledgments. The author would like to thank Prof. Christoph Schwab of ETH Zürich for helpful discussions during the preparation of this article as well as Dr. Gregor Schmidlin for providing the software and assistance with the eigenvalue computation.

CONVERGENT DIFFERENCE SCHEMES FOR DEGENERATE ELLIPTIC AND PARABOLIC EQUATIONS: HAMILTON–JACOBI EQUATIONS AND FREE BOUNDARY PROBLEMS*

ADAM M. OBERMAN†

Abstract. Convergent numerical schemes for degenerate elliptic partial differential equations are constructed and implemented. Simple conditions are identified which ensure that nonlinear finite difference schemes are monotone and nonexpansive in the maximum norm. Explicit schemes endowed with an explicit CFL condition are built for time-dependent equations and are used to solve stationary equations iteratively. Explicit and implicit formulations of monotonicity for first- and second-order equations are unified. Bounds on orders of accuracy are established. An example of a scheme which is stable, but nonmonotone and nonconvergent, is presented. Schemes for Hamilton–Jacobi equations, obstacle problems, one-phase free boundary problems, and stochastic games are built and computational results are presented.

Key words. finite difference schemes, partial differential equations, monotone schemes, viscosity solution, Hamilton–Jabobi equation, free boundary problems

1. Introduction.

We devise practical techniques for building convergent numerical schemes for a class of nonlinear partial differential equations. This is the class of *degenerate elliptic* (in the sense of Crandall, Ishii, and Lions [11]) partial differential equations, for which unique viscosity solutions exist. The class includes Hamilton–Jacobi equations, which are nonlinear first-order equations; elliptic equations which may be degenerate; and fully nonlinear second-order equations. It also includes free boundary problems and the equation for the value function from control and game theory.

The approximation theory developed by Barles and Souganidis [5] provides the following criteria for the convergence of approximation schemes: monotone, consistent, and stable schemes converge to the unique viscosity solution of a degenerate elliptic equation. Despite the clear requirements of the theory, building monotone schemes remains a challenge for many important equations. The finite difference method is the natural method for building monotone schemes, but conditions which ensure monotonicity are different for first- and second-order equations, and for explicit and implicit schemes.

For linear elliptic equations, Motzkin and Wasow [28] introduced the notion that a scheme is of "positive type." These linear schemes respect the discrete maximum principle. This formulation of monotonicity was further studied in [7] and later generalized to nonlinear elliptic equations by Kuo and Trudinger [23, 24, 25, 26]. Related notions for linear parabolic equations have been studied [1, 21, 35].

For conservation laws, monotonicity[1] is associated with entropy solutions. In this setting, monotone schemes are contractions in ℓ^1 [13] and are at most first-order accurate [18]. Higher-order accuracy is achieved by essentially nonoscillatory (ENO) or weighted ENO (WENO) schemes [19], which are not monotone: they selectively use high-order (nonmonotone) interpolation in smooth regions of the solution and monotone schemes in nonsmooth regions.

For Hamilton–Jacobi equations, monotonicity is necessary for convergence. Early numerical papers studied explicit schemes for time-dependent equations on uniform grids [10, 33]. A number of methods have since been developed, which include fast marching [32], fast sweeping [34], semi-Lagrangian [16], central [27], and ENO [31].

For certain second-order equations, which include fully nonlinear equations and degenerate linear elliptic equations, monotonicity is necessary for convergence. An early result of Motzkin and Wasow illustrated difficulties associated with monotone schemes: even for linear elliptic equations, in general it is not possible to build monotone schemes using a narrow stencil [28]. Very large stencil schemes for quasi-linear equations were studied by Crandall and Lions [12]. Wide stencil schemes have been used to solve certain degenerate second-order equations [29, 30].

We identify a class of nonlinear finite difference schemes which we call *degenerate elliptic*. Degenerate elliptic schemes are monotone. They also enjoy a strong form of stability: they are nonexpansive in the maximum norm. The class includes implicit or explicit schemes for first- or second-order equations on structured or unstructured grids.

Degenerate elliptic schemes are built in simple ways from building blocks consisting of schemes for basic equations. They begin with an implicit scheme for the spatial part of the equation. This scheme may then be extended to an explicit scheme for the time-dependent equation, or equivalently, to an iterative method for the stationary equation. The explicit scheme is endowed with a nonlinear CFL condition which is easily calculated.

A guiding principle of this work is that, in order to build effective numerical schemes, it is essential to have a thorough understanding of the underlying equations. In this manner, schemes can be built that inherit desirable properties from the equations.

THEOREM 1. *The solution operator of a degenerate elliptic partial differential equation is monotone and nonexpansive in the maximum norm, provided mild analytic conditions hold so that it is well defined.*

THEOREM 2. *The solution operator of a degenerate elliptic finite difference scheme is monotone and nonexpansive in the maximum norm, provided mild analytic conditions hold so that it is well defined.*

THEOREM 3. *A scheme is monotone and nonexpansive in the ℓ^∞ norm if and only if it is degenerate elliptic.*

Remark 1. Monotonicity by itself does not ensure stability. For example, $u_j^{n+1} = 2u_j^n$ is unstable; examples with worse growth rates are easily constructed.

While degenerate ellipticity is stronger than monotonicity for abstract schemes, the condition occurs naturally for schemes built using the finite difference method; see section 2.3. For these schemes, the two conditions are equivalent.

Remark 2. Theorem 3 recalls a theorem from [14], which states that monotonicity is equivalent to nonexpansivity in ℓ^∞, for mappings which are invariant under

[1]Not to be confused with "monotonicity preserving," which means that increasing functions on the line remain increasing.

translation by a constant.

THEOREM 4. *The accuracy of a monotone finite difference scheme is at most first order for first-order equations and at most second order for second-order equations.*

Remark 3. Useful numerical solutions can be obtained with first- or second-order schemes. Despite the fact that singularities occur, the accuracy requirements are not as high in this setting are they are for conservation laws.

Contents. Section 1.1 demonstrates the equivalence of the explicit and implicit formulations of monotonicity. Section 1.2 contains basic examples to illustrate the definitions. Section 1.3 contains an example which shows monotonicity is necessary for convergence.

Section 2 is the bulk of the theory. Section 2.1 summarizes relevant aspects of degenerate elliptic equations. Section 2.2 defines the class of degenerate elliptic *equations*, followed by section 2.3, which defines the class of degenerate elliptic *schemes*. Section 2.4 provides the nonlinear CFL-type condition for explicit schemes. Section 2.5 establishes properties of the solution operator. Section 2.6 contains proofs of Theorems 1, 2, 3, and 4.

A technique is developed in section 3 to build schemes for complicated equations using building blocks consisting of schemes for simpler equations. This technique is used to build schemes for various equations, including Hamilton–Jacobi equations, obstacle problems, one-phase free boundary problems, and stochastic games. In section 4 computational results are presented.

1.1. Equivalent formulations of monotonicity. In its most general formulation, monotonicity means that the comparison principle holds. This global property was used in [5] to prove convergence of nondiscrete approximation schemes.

For the purpose of building schemes, it is useful to have an easily verified local condition which guarantees monotonicity. The condition comes in two forms. The explicit formulation, usually seen for time-dependent equations, is

$$u_i = H^i\left(u|_{j=N(i)}\right), \tag{1}$$

where $N(i)$ is the list of neighbors of u_i. For example, it appears as $u_i^{n+1} = H(u_{j-1}^n, u_j^n, u_{j+1}^n)$ in the case of three-point explicit schemes [10]. The explicit formulation (1) is monotone if H^i is a nondecreasing function of each variable. The implicit formulation, usually seen for stationary elliptic equations, is

$$F^i\left(u_i, u|_{j=N(i)}\right) = 0. \tag{2}$$

For example, linear schemes $\sum_{i=0}^n a_i u(x+idx)$ are monotone (of "positive type") if $a_0 \geq 0$ and $a_i \leq 0$ for $i \neq 0$ [28]. For nonlinear equations, schemes are monotone if F^i is nondecreasing in the first variable and nonincreasing in the remaining variables [24].

Remark 4. The two formulations are formally equivalent. To put the explicit form into an implicit form is trivial. To go from the implicit form to the explicit form, differentiate implicitly to obtain $D_{u_i}F^i du_i + \sum_{j=N(i)} D_{u_j}F^i du_j = 0$. Fixing all but neighbor u_k, we obtain $du_i/du_k = -D_{u_k}F^i/D_{u_i}F^i \geq 0$. Use the implicit function theorem to solve for u_i as a nondecreasing function of the neighbors.

1.2. Illustration of the definitions. Consider the standard centered difference scheme for $-u_{xx}$, $(u_i - u_{i-1} + u_i - u_{i+1})/dx^2$. The scheme is degenerate elliptic, since, as in Definition 2, it is a nondecreasing function of the differences between the reference variable and its neighbors, $u_i - u_{i-1}$ and $u_i - u_{i+1}$. Solving for u_i gives

$u_i = \frac{1}{2}(u_{i+1} + u_{i-1})$. This puts the scheme in the explicit form of monotonicity, since the righthand side is a nondecreasing function of its arguments.

The implicit Euler scheme for the heat equation, $u_t - u_{xx} = 0$, is also degenerate elliptic,

$$\frac{1}{dt}(u_i^n - u_i^{n-1}) + \frac{1}{dx^2}\left(u_i^n - u_{i-1}^n + u_i^n - u_{i+1}^n\right) = 0.$$

On the other hand, the explicit Euler scheme,

$$u_i^n = (1 - 2dt/dx^2)u_i^{n-1} + (dt/dx^2)(u_{i-1}^{n-1} + u_{i+1}^{n-1}),$$

is monotone if and only if $0 \le dt \le dx^2/2$. In this case, the scheme is also degenerate elliptic,

$$\left(1 - 2dt/dx^2\right)\left(u_i^n - u_i^{n-1}\right) + dt/dx^2(u_i^n - u_{i-1}^{n-1} + u_i^n - u_{i+1}^{n-1}) = 0.$$

Remark 5. The restriction on the time step coincides with the usual CFL condition [9], which is a condition for stability in ℓ^2. In general, these conditions do not coincide.

Remark 6. The example generalizes naturally to nonlinear schemes. As an exercise for the reader, repeat the example with $|u_x|$ instead of $-u_{xx}$. Use the discretization $\max\{u_i - u_{i-1}, u_i - u_{i+1}, 0\}/dx$. The resulting nonlinear CFL condition is $0 \le dt \le dx$.

1.3. A stable but nonconvergent scheme. In this section, we give an example of a difference scheme which is stable but nonmonotone and nonconvergent. The example involves the linear, but degenerate, second-order elliptic equation,

$$-(u_{xx} + 2u_{xy} + u_{yy}) = -\frac{d^2u}{dv^2} = 0, \qquad v = (1,1),$$

along with Dirichlet boundary conditions on the unit square. Continuous functions of the form $f(x - y)$, whose level sets are straight lines in the direction of v, are viscosity solutions. The equation is degenerate: it has a zero eigenvalue in the direction perpendicular to v.

Two discretizations. We present two consistent, second-order accurate difference schemes on a uniform grid with spacing h. For the first scheme, simply use the centered second difference in the diagonal direction,

$$\frac{1}{h^2}\left(u(x+h, y+h) - 2u(x,y) + u(x-h, y-h)\right).$$

For the second scheme, use centered differences for u_{xx} and u_{yy}, and a symmetric centered difference for u_{xy}, to obtain

$$\begin{aligned}\frac{1}{h^2}\big(&2u(x+h,y) + 2u(x,y+h) + 2u(x-h,y) + 2u(x,y-h)\\ &- 6u(x,y) - u(x+h,y-h) - u(x-h,y+h)\big).\end{aligned}$$

The first scheme is degenerate elliptic. The second scheme is not, since the coefficients of the values at grid points $(x+h, y-h)$ and $(x-h, y+h)$ are negative.

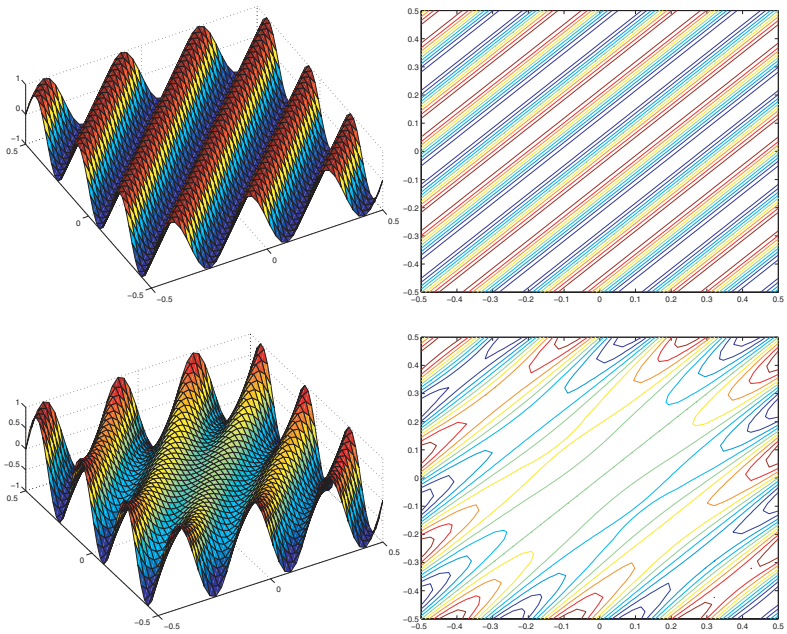

FIG. 1. *Solution and level sets, computed using the first (top) and second (bottom) scheme.*

Numerical experiments. The first scheme converges. The second scheme gives errors of a size comparable to the data, independent of the grid spacing. The solutions were found by an explicit, stable iteration scheme. Computational results using Dirichlet boundary values $\sin(6\pi(x-y))$ are presented in Figure 1. Note that the level sets fail to be straight lines for the second scheme.

Stability analysis. We verify stability in ℓ^2 directly. Consider for the sake of analysis a periodic, 2×2 grid. The grid functions

$$v_1 = \begin{pmatrix} + & + \\ + & + \end{pmatrix}, \qquad v_2 = \begin{pmatrix} + & - \\ + & - \end{pmatrix}, \qquad v_3 = \begin{pmatrix} + & + \\ - & - \end{pmatrix}, \qquad v_4 = \begin{pmatrix} + & - \\ - & + \end{pmatrix},$$

which consist of horizontal, vertical, and diagonal stripes, form a simultaneous set of eigenvectors for the schemes, with eigenvalues $\{0, -4, -4, 0\}$ and $\{0, -4, -4, -8\}$, respectively. Thus the operators are stable. The explicit scheme with time step dt corresponds to adding the identity to dt times the linear map, so it has the same eigenvectors, with eigenvalues $\lambda \mapsto 1 + dt\lambda$. Taking $dt \leq 1/2, 1/4$, respectively, gives a scheme with eigenvalues in the unit circle, and that is thus stable in ℓ^2.

Conclusion. Despite the stability of the second scheme, it is nonconvergent. For this equation, monotonicity is necessary for convergence. We offer a heuristic explanation: while the equation is sensitive to data only in the diagonal direction, the second scheme uses data from grid points in other directions.

2. Theory.

2.1. Viscosity solutions.

We have endeavored to make this article accessible to readers who are not familiar with the theory of viscosity solutions. The standard reference is [11]. An introduction to the first-order case, with applications to

control theory, is [15]. A readable introductory article with valuable exercises is the contribution by Crandall [3]. The complete first-order theory can be found in [2, 4].

Viscosity solutions are weak solutions defined for the class of degenerate elliptic and parabolic equations. In this class, under mild analytic assumptions [20], there exist unique viscosity solutions. These solutions are stable in the maximum norm under perturbations: a perturbation to the data of size ϵ results in an error in the solution of size at most ϵ. Solutions are also stable under perturbations of the *equation*, as long as the resulting equation is still in the class. For example, adding ϵ times the Laplacian regularizes the equation (this is where the term *viscosity solutions* comes from). It is also common to add ϵ time u to the equation. In addition, replacing the equation with a finite difference approximation is a valid perturbation, as long as the approximation is monotone [5]. In this case, ϵ may represent the grid spacing.

Remark 7 (nonsmooth functions). Although solutions need not be smooth (or even differentiable), the definition of viscosity solutions requires only verifying inequalities for smooth test functions. In particular, when verifying consistency for numerical schemes, we may work freely with smooth functions.

2.2. Degenerate elliptic equations. Let Ω be a domain in $\mathbb{R}^n$, Du and D^2u denote the gradient and Hessian of u, respectively, and $F(x, r, p, X)$ be a continuous real valued function defined on $\Omega \times \mathbb{R} \times \mathbb{R}^n \times \mathbb{S}^n$, with $\mathbb{S}^n$ being the space of symmetric $n \times n$ matrices. Write $F[u](x) \equiv F(x, u(x), Du(x), D^2u(x))$. Consider the nonlinear, degenerate elliptic partial differential equation with Dirichlet boundary conditions,

$$\begin{cases} F[u](x) = 0 & \text{for } x \text{ in } \Omega, \\ u(x) = g(x) & \text{for } x \text{ on } \partial\Omega, \end{cases}$$

or the initial-boundary value problem for the degenerate parabolic partial differential equation,

$$\begin{cases} u_t(t,x) = -F[u](t,x) & \text{for } (t,x) \text{ in } \Omega \equiv [0,t) \times \Omega, \\ u(t,x) = g(t,x) & \text{for } (t,x) \text{ on } \partial\Omega \equiv \{t=0\} \times \Omega \cup [0,t) \times \partial\Omega. \end{cases}$$

In both cases, $\partial\Omega$ is the correct set on which boundary conditions are set for the equation, not the topological boundary.

Definition 1. *The equation F is* degenerate elliptic *if*

$$F(x, r, p, X) \le F(x, s, p, Y) \text{ whenever } r \le s \text{ and } Y \le X,$$

where $Y \le X$ means that $Y - X$ is a nonnegative definite symmetric matrix.

Example. The obstacle problem, $\min(-u_{xx}, u - g(x)) = 0$, is degenerate elliptic. The Hamilton–Jacobi equation, $u_t - |u_x| = 0$, is degenerate parabolic.

Given a degenerate elliptic equation, F, consider the solution mapping, S, which takes continuous boundary data, g, to the continuous solution, u, assuming it is well-defined. We say that S is *monotone* if for all continuous functions g, h on $\partial\Omega$,

$$g(x) \le h(x) \text{ for all } x \in \partial\Omega \text{ implies } S(g)(x) \le S(h)(x) \text{ for all } x \in \Omega. \tag{3}$$

Likewise, the solution mapping is nonexpansive in the maximum norm if

$$\max_{x\in\Omega} |S(g)(x) - S(h)(x)| \le \max_{x\in\partial\Omega} |g(x) - h(x)|. \tag{4}$$

These conditions generalize the maximum principle, with equivalence when constants (or zero) are solutions.

2.3. Degenerate elliptic schemes. We begin with the definition of a finite difference scheme on an unstructured grid. We regard a scheme as an *equation* which holds at each grid point, and thereby study monotonicity and stability properties of the solution operator.

For the purpose of convergence, we implicitly assume the existence of an interpolation operator, which takes grid functions to functions on the domain. We also require a sequence of grids indexed by a small parameter. Typically, the small parameter is dx, the maximum distance between neighboring grid points, but we might want to allow for $d\theta$, the directional resolution [29, 30]. The interpolation operator and the sequence of approximations puts us in the framework of the convergence theory in [5].

Define an unstructured grid on the domain Ω as a directed graph consisting of a set of points, $x_i \in \Omega, i = 1, \ldots, N$, each endowed with a list of neighbors, $N(i)$. A *grid function* is a real valued function defined on the grid, with values $u_i = u(x_i)$. The scheme is represented at each grid point by an equation of the form

$$F^i[u] \equiv F^i\left(u_i, \left.\frac{u_i - u_j}{|x_i - x_j|}\right|_{j=N(i)}\right), \quad i = 1, \ldots, N. \tag{5}$$

A finite difference scheme is local: it depends only on the value at the reference points, and on the first-order approximations to the derivatives in the direction of the neighbors. Higher-order approximations are obtained by taking linear combinations of the first-order derivatives.

From now on, we suppress the explicit dependence on $|x_i - x_j|$ and write

$$F^i[u] \equiv F^i\left(u_i, u_i - u_j|_{j=N(i)}\right) \equiv F^i(u_i, u_i - u_j),$$

where u_j is shorthand for the list of neighbors $u_j|_{j=N(i)}$.

A *boundary* point is a grid point with no neighbors. Dirichlet boundary conditions are imposed at boundary points by setting $F^i[u] = u_i - g(x_i)$. A *solution* is a grid function which satisfies $F[u] = 0$. If, for arbitrary boundary data g, there exists a unique solution u, we write $u = S(g)$ for the *solution operator*. We regard the solution operator as a mapping from the Dirichlet data on the boundary points to grid functions.

We now define degenerate elliptic schemes.

DEFINITION 2. *The scheme F is* degenerate elliptic *if each component F^i is nondecreasing in each variable.*

Remark 8. We emphasize that the scheme is a nondecreasing function of u_i and the differences $u_i - u_j$.

2.4. The nonlinear CFL condition. Write $\|x\|_\infty$ for the maximum norm, $\max_i |x_i|$.

While schemes may be nonlinear and nondifferentiable, we assume that they are globally Lipschitz continuous, with constant K. The resulting restriction on the time step is simply that $dt \leq K^{-1}$. We can also allow for schemes which are only locally Lipschitz continuous by allowing for the time step to depend on the data, $dt = K(u)^{-1}$. Higher-order time-stepping methods which still maintain monotonicity and nonexpansivity may also be used [17].

DEFINITION 3 (Lipschitz continuity). *The finite difference scheme, F, is Lipschitz continuous if there is a constant K such that for all $i = 1, \ldots, N$, $x, y \in \mathbb{R}^{|N(i)|+1}$,*

$$|F^i(x) - F^i(y)| \leq K\|x - y\|_\infty. \tag{6}$$

DEFINITION 4 (the explicit Euler map). *For $\rho > 0$, define $S_\rho : \mathbb{R}^N \to \mathbb{R}^N$ by*

$$S_\rho(u) = u - \rho F[u]. \tag{7}$$

This map is the explicit Euler discretization, with time step ρ, of the ordinary differential equation $du/dt + F[u] = 0$.

DEFINITION 5 (nonlinear CFL condition). *Let F be a Lipschitz continuous, degenerate elliptic scheme, with Lipschitz constant K. The nonlinear CFL condition for the Euler map S_ρ is*

$$\rho \leq \frac{1}{K}. \tag{CFL}$$

2.5. Existence, uniqueness, and comparison for schemes. Given $u, v \in \mathbb{R}^N$, define $u \vee v = \max(u, v), u^+ = \max(u, 0)$, $u^- = \min(u, 0)$, componentwise and define $u \leq v$ to mean $u_i \leq v_i$ for $i = 1, \ldots, N$

DEFINITION 6 (proper schemes). *The finite difference scheme is* proper *if there exists $\delta > 0$ such that for $i = 1, \ldots, N$ and for all $x \in \mathbb{R}^{|N(i)|}$ and $x_0, y_0 \in \mathbb{R}$,*

$$x_0 \leq y_0 \text{ implies that } F^i(x_0, x) - F^i(y_0, x) \leq \delta(x_0 - y_0). \tag{8}$$

Remark 9. If a scheme is not proper, we can consider instead $F[u] + \epsilon u$. By taking ϵ to be small enough (for example, smaller than the discretization error), we can assume the scheme is proper without any loss of generality.

Remark 10. This property is introduced to simplify the existence proof. It can be relaxed for the proof of comparison. An alternative approach would be to generalize the "marching to the boundary" argument of [28].

THEOREM 5 (comparison of sub- and supersolutions). *Let F be a proper, degenerate elliptic finite difference scheme. If $F[u] \leq F[v]$, then $u \leq v$. In particular, solutions are unique.*

Proof. Suppose $u \not\leq v$ and let i be an index for which

$$u_i - v_i = \max_{j=1,\ldots,N} \{u_j - v_j\} > 0, \tag{i}$$

so that

$$u_i - u_j \geq v_i - v_j, \quad j = 1, \ldots, N. \tag{ii}$$

(See Figure 2.) Then we obtain a contradiction as follows:

$$\begin{aligned} F[u]^i = F^i(u_i, u_i - u_j) &\geq F^i(u_i, v_i - v_j) && \text{by (ii) and Definition 2,} \\ &> F^i(v_i, v_i - v_j) = F[v]^i && \text{by (i) and (8).} \end{aligned}$$

Uniqueness follows, since if u, v are solutions, then $F[u] = F[v] = 0$, so $u \geq v$ and $u \leq v$, and thus $u = v$. ∎

The next result combines the Lipschitz continuity property with the degenerate elliptic property of the scheme to give an ordered Lipschitz continuity property.

LEMMA 1 (ordered Lipschitz continuity property). *Let F be a Lipschitz continuous, degenerate elliptic scheme, with Lipschitz constant K. Then for all $i = 1, \ldots, N$ and $x, y \in \mathbb{R}^{|N(i)|+1}$,*

$$-K\|(x - y)^-\|_\infty \leq F^i(x) - F^i(y) \leq K\|(x - y)^+\|_\infty. \tag{9}$$

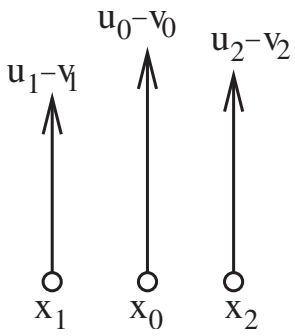

FIG. 2. *Discrete local maximum of* $u_i - v_i$ *at* $i = 0$.

Proof. Given x, y, use Definition 2 and (6) to compute

$$F(x) - F(y) \le F(x \vee y) - F(y) \le K\|x \vee y - y\|_\infty = K\|(x-y)^+\|_\infty.$$

The other inequality is similar. ∎

THEOREM 6 (the Euler map is monotone). *Let F be a Lipschitz continuous, degenerate elliptic scheme. Then the Euler map* (7) *is monotone provided (CFL) holds.*

Proof. Suppose $u \le v$. Compute for an arbitrary index i,

$$\begin{aligned} S^i_\rho(u) - S^i_\rho(v) &= u_i - v_i + \rho\left(F^i(v_i, v_i - v_j) - F^i(u_i, u_i - u_j)\right) \\ &\le u_i - v_i + \rho K\|(v_i - u_i, v_i - u_i + u_j - v_j)^+\|_\infty \quad \text{by (9)} \\ &\le (1 - \rho K)(u_i - v_i) \quad \text{since } u \le v \\ &\le 0 \quad \text{by (CFL).} \end{aligned}$$ ∎

THEOREM 7 (the Euler map is a contraction). *Let F be a Lipschitz continuous, degenerate elliptic scheme. Then the Euler map* (7) *is a contraction in $\mathbb{R}^N$ equipped with the maximum norm, provided* (CFL) *holds. If, in addition, F is proper, and strict inequality holds in* (CFL)*, then the Euler map is a strict contraction.*

Proof. We will show that

$$\|S_\rho(u) - S_\rho(v)\|_\infty \le r\|u - v\|_\infty \tag{i}$$

for $r = \max(1 - \rho\delta, \rho K)$. We assume without loss of generality that $\rho\delta, \rho K < 1/2$.

We proceed to find upper and lower bounds on $S^k_\rho(u) - S^k_\rho(v)$ for an arbitrary index k. The lower bound will follow easily, while the upper bound will rely on careful application of the ordered Lipschitz continuity property.

1. Assume $u_k \ge v_k$. The alternative will follow by a similar argument.
2. For the lower bound, use (9) in the definition of the Euler map (7) to obtain

$$\begin{aligned} S^k_\rho(u) - S^k_\rho(v) &\ge u_k - v_k - \rho K\| \left(u_k - v_k, u_k - v_k - (u_j - v_j)\right)^- \|_\infty \\ &\ge -\rho K\|u - v\|_\infty, \end{aligned} \tag{ii}$$

since $u_k \ge v_k$.

3. For the upper bound, add and subtract $\rho F^k(v_k, u_k - u_j)$ to $S^k_\rho(u) - S^k_\rho(v)$,

$$\begin{aligned} S^k_\rho(u) - S^k_\rho(v) = u_k - v_k - \rho\left(F^k(u_k, u_k - u_j) - F^k(v_k, u_k - u_j)\right) \\ + \rho\left(F^k(v_k, v_k - v_j) - F^k(v_k, u_k - u_j)\right). \end{aligned} \tag{iii}$$

Use (8) to estimate the second to last term in (iii),

$$-\left(F^k\left(u_k, u_k - u_j\right) - F^k(v_k, u_k - u_j)\right) \leq -\delta(u_k - v_k). \tag{iv}$$

Next use (9) to estimate the last term in (iii),

$$\begin{aligned} F^k\left(v_k, v_k - v_j\right) - F^k(v_k, u_k - u_j) &\leq K\|((u_j - v_j) - (u_k - v_k))^+\|_\infty, \\ &\leq K\left(\|u - v\|_\infty - (u_k - v_k)\right), \end{aligned} \tag{v}$$

since $u_k \geq v_k$. Combining (iv) and (v) gives

$$\begin{aligned} S^k_\rho(u) - S^k_\rho(v) &\leq (1 - \rho\delta - \rho K)(u_k - v_k) + \rho K\|u - v\|_\infty \\ &\leq (1 - \rho\delta - \rho K)\|u - v\|_\infty + \rho K\|u - v\|_\infty \\ &\leq (1 - \rho\delta)\|u - v\|_\infty. \end{aligned} \tag{vi}$$

4. Combining (ii) and (vi) gives (i) as desired. ∎

THEOREM 8. *A proper, Lipschitz continuous degenerate elliptic scheme has a unique solution. The iterates of the Euler map converge to the solution for arbitrary initial data, provided strict inequality holds in* (CFL).

Proof. By Theorem 7, S_ρ is a strict contraction on $\mathbb{R}^N$, equipped with the maximum norm. Thus by Banach's fixed point theorem, iterates of S_ρ converges to a unique fixed point from arbitrary initial data. Such a fixed point is a solution. ∎

Remark 11. Since the error tolerance is on the order of the spatial discretization error, the number of iterations need not be prohibitive. Experimentally, the number of iterations is on the order of the diameter of the graph, when the time step is optimal.

2.6. Proofs. We begin by establishing a link between the degenerate ellipticity condition and the comparison principle.

LEMMA 2 (exercise in [3]). *The function $F(x, r, p, X)$ is degenerate elliptic if and only if whenever x is a nonnegative local maximum of $u - v$, for $u, v \in C^2$, $F[u](x) \geq F[v](x)$.*

Proof. If x is a local maximum, $u \geq v$, $Dv = Du$, and $D^2u \leq D^2v$, at x. Then $F(x, u, Du, D^2u) = F(x, u, Dv, D^2u) \geq F(x, v, Dv, D^2u) \geq F(x, v, Dv, D^2v)$. ∎

LEMMA 3. *The scheme F is degenerate elliptic if and only if whenever x_i is a nonnegative maximum of $u - v$, for u, v grid functions, $F^i[u] \geq F^i[v]$.*

Proof. Let i be an index for which $u_i - v_i = \max_{j=1,\ldots,N}\{u_j - v_j\} \geq 0$, so that $u_i - u_j \geq v_i - v_j$, $j = 1, \ldots, N$. Then $F^i[u] = F^i\left(u_i, u_i - u_j\right) \geq F^i\left(v_i, u_i - u_j\right) \geq F^i\left(v_i, v_i - v_j\right) = F^i[v]$. ∎

Proof of Theorem 1. The proof is formal, but can be made rigorous. Let $\epsilon > 0$, set $F^\epsilon[u] = F[u] + \epsilon u$, and let S^ϵ be the corresponding solution operator. Let $u^\epsilon = S^\epsilon(g), v^\epsilon = S^\epsilon(h)$. If x is a strict local max of $u^\epsilon - v^\epsilon$, then as in Lemma 2, $F^\epsilon[u](x) > F^\epsilon[v](x)$, which contradicts $F^\epsilon[u] = F^\epsilon[v] = 0$. So the maximum of $u^\epsilon - v^\epsilon$ occurs on the boundary. Likewise, the minimum of $u^\epsilon - v^\epsilon$ occurs on the boundary. Stability of viscosity solutions implies that $u^\epsilon \to u, v^\epsilon \to v$, and thus sending $\epsilon \to 0$ allows the same conclusions to hold for u, v. Thus (4) follows; assuming $g \leq h$ gives (3). ∎

Proof of Theorem 2. We can assume without loss of generality that F is proper. Then as in Lemma 3, we can show that the max and min of $S(g), S(h)$ occur on the boundary. The conclusion follows as in the proof of Theorem 1. □

Proof of Theorem 3. We have already shown that degenerate elliptic schemes are monotone and nonexpansive. Now, suppose a scheme given in explicit form (1) is monotone and nonexpansive. Then H^i is a nondecreasing function for each i. Nonexpansivity means

$$|H^i(x) - H^i(y)| \le \|x - y\|_\infty$$

for all x, y. Estimate $|H^i(x) - H^i(y)| \le \|DH^i\|_1 \|x - y\|_\infty$. Since equality may hold for some x, y, we require $\|DH^i\|_1 \le 1$. Locally define $F^i = (1 - \sum_{j=N(i)} D_j H^i)u_i + \sum_{j=N(i)} D_j H^i(u_i - u_j)$. Applying the implicit function theorem gives F^i in the required form. □

Remark 12. The linear scheme $u^{n+1} = Mu^n$ is monotone if and only if $m_{ij} \ge 0$ and nonexpansive in the ℓ^∞ norm if and only if $\sum_j |m_{ij}| \le 1$ for each i. The differentiable scheme, $u^{n+1} = F(u^n)$, is monotone (respectively, nonexpansive) if the gradient $DF(u)$ is monotone (nonexpansive) for every u. In the linear case, nonexpansivity in ℓ^∞ does not imply nonexpansivity in ℓ^2, or in ℓ^1, as simple examples illustrate.

Accuracy. Given the equation $F(x, u(x), Du(x), D^2u(x))$ and the scheme $F^i(u_i, u_i - u_j|_{j=N(i)})$, fix $x = x_i$ and set $h_j = |x_i - x_j|$, $j = N(i)$. Assume the h_j are of the same order so that the expression $O(h)$ is meaningful. The order of accuracy of the scheme is the best possible number r in the expression

$$F(x_i, u(x_i), Du(x_i), D^2u(x_i)) - F^i(u(x_i), u(x_i) - u(x_j)|_{j=N(i)}) = O(h^r),$$

over all functions u which have all derivatives defined in a neighborhood of x_i.

Proof of Theorem 4. It is sufficient to show that higher-order accuracy is impossible for functions of a particular form. By considering functions of the form $u(x) = g(n \cdot x)$, where n is a direction vector, we reduce to an equation in one space dimension. Considering functions with constant values $u(x_i)$ and constant first or second derivatives further reduces the equation to the form $H(u_x)$ or $H(u_{xx})$. While some reductions yield trivial equations, any nontrivial equation will give a nontrivial reduction for some choice of the direction n, $u(x_i)$, and the derivatives.

Redefine $h_j = x_j - x_i$, and expand u in Taylor series, $u(x_j) = \sum_{k=0}^\infty \frac{h_j^k}{k!} \frac{\partial^k u}{\partial x^k}(x_i)$. Apply the series to each u_j in the expression for $F^i[u]$, dropping the u_i dependence to give

$$\text{(i)} \qquad F^i[u] = F^i\left(- \sum_{k=1}^\infty \frac{h_j^k}{k!} \frac{\partial^k u}{\partial x^k}(x_i) \Big|_{j=N(i)} \right).$$

Consider first the case when both the scheme and the equation are linear. Write $F^i[u] = \sum_{j=1}^{|N(i)|} a_j(u_i - u_j)$, $a_j > 0$, and insert the Taylor expansion into (i) to obtain $-\sum_{j=1}^{|N(i)|} \sum_{k=1}^\infty \frac{a_j h_j^k}{k!} \frac{\partial^k u}{\partial x^k}(x_i)$. Observe that the coefficients of $\partial^k u/\partial x^k$ have the same sign for even values of k, and thus no cancellation is possible. In addition, the coefficients are homogeneous of order k in h. After dividing by the leading coefficient, a scheme for u_x will have a nonzero coefficient of u_{xx} of $O(h)$, and a scheme for u_{xx} will have a nonzero coefficient of u_{xxxx} of $O(h^2)$.

We now treat the general case. Since F is nondecreasing, there is still no cancellation among the terms with even values of k. An expression containing u_x to $O(1)$ appears with a u_{xx} term of $O(h)$, and similarly u_{xx} appears with a u_{xxxx} term of $O(h^2)$. Since the higher derivatives do not appear at all in the expression for H, the error is $O(h)$ and $O(h^2)$ for the first-order and second-order equations, respectively. □

3. Building elliptic schemes. In this section we construct examples of degenerate elliptic schemes. Using simple schemes as building blocks, we build schemes for nontrivial equations. We begin with parallel observations for equations and schemes which, when taken together, give a technique for building schemes.

Many types of operations (addition, min, max, nondecreasing transformations) may be used to combine schemes. On the other hand, selection criteria ("if" statements) generally do not preserve ordering properties and must be used with care.

Observation 1 (see [11, p. 8]). Let $g : \mathbb{R}^2 \to \mathbb{R}$ be a nondecreasing function. If F_1 and F_2 are degenerate elliptic functions, then so is $F = g(F_1, F_2)$.

Observation 2. Let $g : \mathbb{R}^2 \to \mathbb{R}$ be a nondecreasing function. If F_1 and F_2 are degenerate elliptic finite difference schemes, then so is $F = g(F_1, F_2)$.

Example (order preserving operations). The constant scheme $F[u] = u - g$ is degenerate elliptic. If F, F_1, F_2 are degenerate elliptic, then so are $F^+ = \max(F, 0)$, and $F^- = \min(F, 0)$ as well as $\min(F_1, F_2), \max(F_1, F_2)$, and $aF_1 + bF_2$ for $a, b \in \mathbb{R}^N, a, b \geq 0$.

Example ("if" statements). If $F_1[u], F_2[u]$ are degenerate elliptic, and $G[u]$ is an equation, then

$$F[u] = \begin{cases} F_2[u] = 0 & \text{if } G[u] > 0, \\ F_1[u] = 0 & \text{otherwise} \end{cases}$$

is not usually degenerate elliptic. If, however, G is degenerate elliptic, and $F_2[u] \geq F_1[u]$ for all u, then F is degenerate elliptic. This follows by using Lemma 3. If $u - v$ has a nonnegative local max at i, then $G^i[u] \geq G^i[v]$, and thus $F^i[u] \geq F^i[v]$.

Example (distance function and eikonal equation). Starting from the upwind schemes $u_x = (u_j - u_{j-1})/dx$ and $-u_x = (u_j - u_{j+1})/dx$, which are degenerate elliptic, write $|u_x| = \max(u_x, -u_x)$, $-|u_x| = \min(u_x, -u_x)$ and apply the observations to build the schemes

$$|u_x| = \frac{1}{dx} \max\left(u_j - u_{j-1}, u_j - u_{j+1}, 0\right), \quad -|u_x| = \frac{1}{dx} \min\left(u_j - u_{j-1}, u_j - u_{j+1}, 0\right),$$

accurate to $O(dx)$. Next write $u_x^2 = |u_x|^2$ to obtain the scheme

$$u_x^2 = \frac{1}{dx^2} \max\left(u_j - u_{j-1}, u_j - u_{j+1}, 0\right)^2,$$

which is accurate to $O(dx)$. Schemes for $|Du|$ and $|Du|^p$ in higher dimensions are easily built.

Example (obstacle problems). Let F_1 be a degenerate elliptic scheme for $F[u]$. The obstacle problem

$$\min(F[u], u - g(x)) = 0$$

is degenerate elliptic, and the scheme $\min(F_1, u - g)$, is consistent and degenerate elliptic. This example can be generalized to double obstacle problems.

Example (finite maxima and minima of schemes [5]). A degenerate elliptic scheme for $\min_{\gamma\in\Gamma}\max_{\beta\in B}\{F_{\gamma\beta}\}$, where the index sets are finite, can be built from schemes for each $F_{\gamma\beta}$ by taking the corresponding finite minima and maxima over the schemes.

Example (nonlinear one-dimensional equations). The degenerate elliptic equation $F(x,u_{xx})$ is nonincreasing in u_{xx}, and thus the scheme $F^i[u]=F(x_i,(2u_i-u_{i+1}-u_{i-1})/dx^2)$ is degenerate elliptic. If $H(x,u_x)$ is increasing in u_x, then the scheme $F^i[u]=H(x_i,(u_i-u_{i-1})/dx)$ is also degenerate elliptic. Likewise, if $H(x,u_x)$ is decreasing in u_x, then $F^i[u]=H(x_i,(u_i-u_{i+1})/dx)$ is degenerate elliptic. Simply combining the previous two schemes with an if statement will not yield a degenerate elliptic scheme for general H.

Example (one-phase free boundary problems). Consider

$$\begin{cases} F[u]=0 & \text{in } \{u>0\},\\ H(x,Du)=0 & \text{on } \partial\{u=0\}, \end{cases}$$

where $F[u]=F(x,Du,D^2u)$ is degenerate elliptic. Time-dependent versions may also be considered. This one-phase free boundary problem (see [8, 22] for examples) is degenerate elliptic when the boundary condition is interpreted in the viscosity sense,

$$\min(F,H)\le 0 \text{ and } \max(F,H)\ge 0 \quad \text{on } \partial\{u=0\}.$$

Eliminate the free boundary by extending to a computational domain large enough to contain $\{u=0\}$, and consider instead

$$\begin{cases} F[u]=0 & \text{in } \{u>0\},\\ \min(F[u],H(x,Du))=0 & \text{on } \{u\le 0\}. \end{cases}$$

Given F_1,F_2, degenerate elliptic schemes for F and H, respectively, the following scheme is consistent and degenerate elliptic:

$$F^i[u]=\begin{cases} F_1^i[u] & \text{if } u_i>0,\\ \min(F_1^i[u],F_2^i[u]) & \text{if } u_i\le 0. \end{cases}$$

4. Computations.

Example (front propagation). For $u_t=|u_x|$, (CFL) gives $\rho\le dx$. Setting $\rho=dx$ gives the exact solution for piecewise linear initial data. For $|u_x|^2$, the function $F(x,y,0)=\max(x,y,0)^2$ is locally, but not globally, Lipschitz, with constant $K=\max(x,y,0)$. (Simply differentiating overestimates the constant by a factor of 2.) This leads to $dt\le dx^2/\max_j\{|u_j-u_{j-1}|\}$. The solution was computed using sinusoidal initial data and periodic boundary conditions, with 500 grid points. The solutions are displayed in Figure 3.

Homogenization of Hamilton–Jacobi equations. Next we consider one- and two-dimensional nonconvex Hamilton–Jacobi homogenization problems. The problem involves solve $H(x,Du)=\overline{H}$, for the function u and the constant $\overline{H}$, using periodic boundary conditions. The value $\overline{H}$ is unique, although the function u is not. The solution can be obtained by solving the time-dependent problem $u_t=H(x,Du)$ for a long time, because (see [6]) $u_t\to\overline{H}, u(t,\cdot)\to u+\overline{H}t$ as $t\to\infty$.

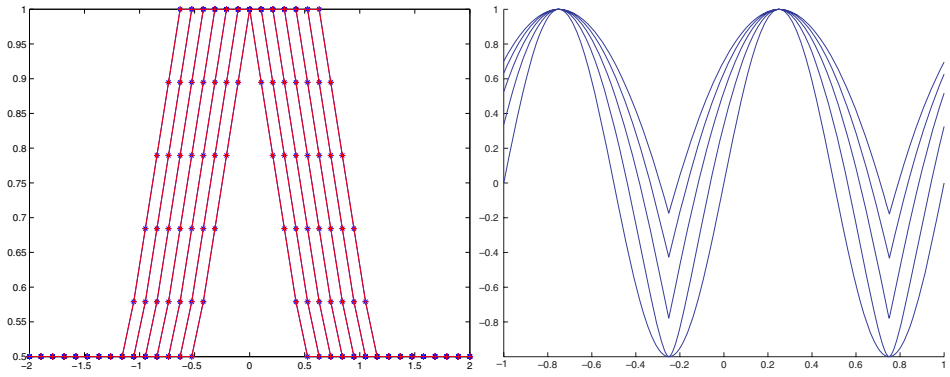

FIG. 3. *Snapshots of the solution of* $u_t = |u_x|$, *and* $u_t = |u_x|^2$.

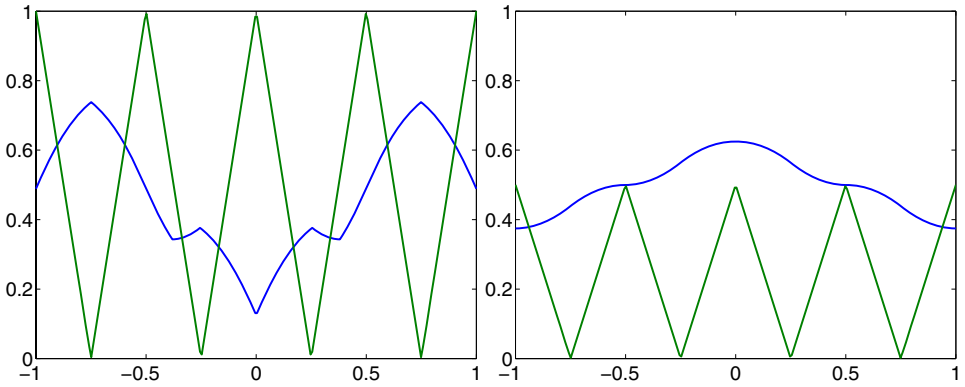

FIG. 4. *Solutions* u *plotted with the zig-zag functions.*

Example (one-dimensional nonconvex Hamilton–Jacobi equation). Set $H(x, u_x) = \max(|u_x|, 1 - |u_x|) + f(x)$, where $f(x)$ is periodic on $[-1, 1]$. With $f(x)$ the "zigzag" function $f(x) = 2|2x \pmod 1 - .5|$, we found $\overline{H} \approx .48$. The solutions were also computed with $f(x) = |2x \pmod 1 - .5|$. The solutions, along with the functions $f(x)$, are displayed in Figure 4, plotted so that the average of the solution is $\overline{H}$. In the second case, with the hindsight afforded by the numerical solution, we found an exact piecewise quadratic solution, with $\overline{H}(u) = .5$. Modifying the solution by reflecting the portion between $-.5$ and $.5$ (where $u_x = 0$) in the line $y = .5$ gives another solution with $\overline{H} = .5$.

Example (two-dimensional nonconvex Hamilton–Jacobi equation). Set $H(u_x, u_y) = u_x^2 - u_y^2$ in a periodic domain, with periodic boundary conditions. With initial data $\sin(x)\sin(y)$, a nontrivial steady solution was computed, shown in Figure 5. Examination of the numerical solution reveals an exact solution, which is piecewise quadratic, with u_x, u_y as piecewise linear functions with slopes ± 1.

Free boundary problems.

Example (two-dimensional double obstacle problem). We have the equation

$$-\max\left(u - h, \min\left(u_{xx} + u_{yy}, u - g\right)\right) = 0,$$

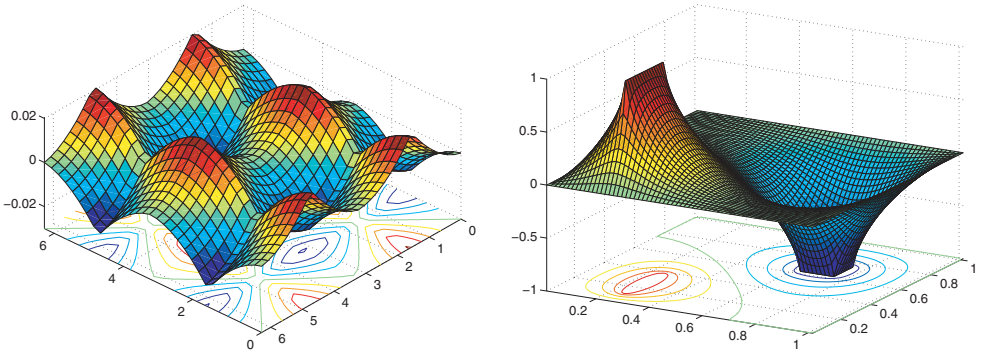

FIG. 5. *Piecewise quadratic solution of* $u_x^2 - u_y^2 = 0$*, solution of the double obstacle problem.*

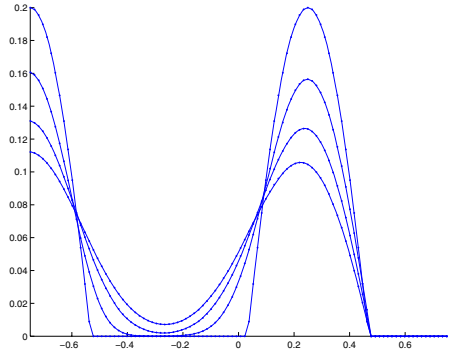

FIG. 6. *Snapshots in time of the solution to the Stefan problem. Two bumps move together and merge.*

where the obstacle functions h, g are characteristic functions of a square and a line on different parts of the domain. The solution is displayed in Figure 5.

Example. The one-phase Stefan problem

$$\begin{cases} u_t - \Delta u = 0 & \text{in } \{u > 0\}, \\ u_t - |Du|^2 = 0 & \text{on } \partial\{u = 0\} \end{cases}$$

is solved in one dimension with sinusoidal initial data. Snapshots of the solution are shown in Figure 6.

Example (a nonconvex, fully nonlinear second-order equation). The fully nonlinear, uniformly elliptic second-order equation $-\max(\min(L^1u, L^2u)L^3u) + 1 = 0$, where $L^1u = u_{xx} + u_{yy}$, $L^2u = \frac{1}{2}u_{xx} + 2u_{yy}$, $L^3u = \frac{1}{2}u_{xx} + u_{yy}$, is solved in the unit square with Dirichlet boundary values $\frac{1}{2}\max(\min(x^2+y^2, \frac{1}{2}x^2+2y^2), \frac{1}{2}x^2+y^2)$. The solution is displayed in Figure 7. The boundary shown is composed of two parts: the dotted lines correspond to the boundary of the set $\{L^1u \le L^2u\}$. The heavy lines correspond to the boundary of the set $L^3u \ge \min(L^1u, L^2u)$.

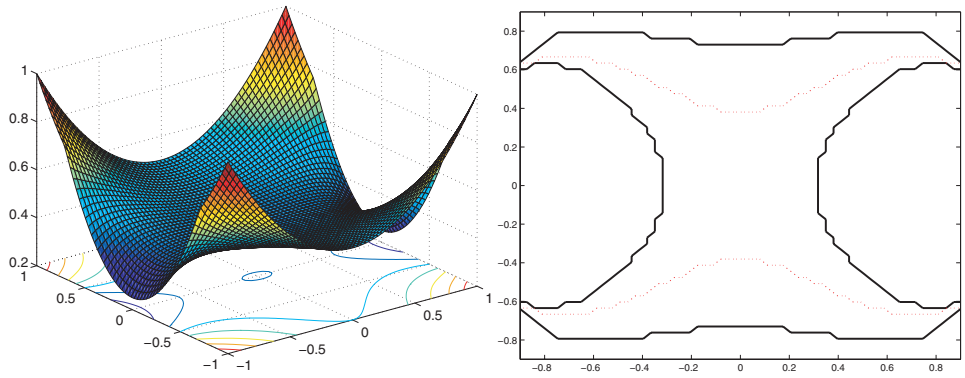

FIG. 7. *Solution and free boundary for the fully nonlinear second-order equation* $-\max(\min(L^1u, L^2u)L^3u) + 1 = 0$.

Acknowledgments. It is a pleasure to acknowledge many valuable discussions with P. E. Souganidis. I am grateful to Ward E. Cheney for writing advice, and to the University of Texas at Austin for its hospitality during the course of this work.

NUMERICAL CUBATURE USING ERROR-CORRECTING CODES*

GREG KUPERBERG†

Dedicated to Włodzimierz and Krystyna Kuperberg on the occasion of their 40th anniversary

Abstract. We present a construction for improving numerical cubature formulas with equal weights and a convolution structure, in particular equal-weight product formulas, using linear error-correcting codes. The construction is most effective in low degree with extended BCH codes. Using it, we obtain several sequences of explicit, positive, interior cubature formulas with good asymptotics for each fixed degree t as the dimension $n \to \infty$. Using a special quadrature formula for the interval [G. Kuperberg, *Adv. in Appl. Math.*, 34 (2005), pp. 853–870, arXiv:math.PR/0408360], we obtain an equal-weight t-cubature formula on the n-cube with $O(n^{\lfloor t/2 \rfloor})$ points, which is within a constant of the Stroud lower bound. We also obtain t-cubature formulas on the n-sphere, n-ball, and Gaussian $\mathbb{R}^n$ with $O(n^{t-2})$ points when t is odd. When μ is spherically symmetric and $t = 5$, we obtain $O(n^2)$ points. For each $t \geq 4$, we also obtain explicit, positive, interior formulas for the n-simplex with $O(n^{t-1})$ points; for $t = 3$, we obtain $O(n)$ points. These constructions asymptotically improve the nonconstructive Tchakaloff bound.

Some related results were recently found independently by Victoir [*SIAM J. Numer. Anal.*, 42 (2004), pp. 209–227], who also noted that the basic construction more directly uses orthogonal arrays.

Key words. cubature formulas, orthogonal arrays, error-correcting codes

1. General results.

Let μ be a normalized measure on $\mathbb{R}^n$ with finite moments. A *cubature formula of degree* t, or t-cubature formula, for μ is a set of points $F = \{\vec{p}_a\} \subset \mathbb{R}^n$ and a weight function $\vec{p}_a \mapsto w_a \in \mathbb{R}$ such that

$$\int P(\vec{x}) d\mu = P(F) = \sum_{a=1}^{N} w_a P(\vec{p}_a)$$

for polynomials P of degree at most t. (If $n = 1$, then F is also called a *quadrature formula*.) The formula F is *equal-weight* if the w_a are all equal; it is *positive* if $w_a > 0$ for all a; and otherwise it is *negative*. Let X be the support of μ. The formula F is *interior* if every point $\vec{p}_a$ is in the interior of X; it is *boundary* if every $\vec{p}_a$ is in X and some $\vec{p}_a \in \partial X$; and otherwise it is *exterior*. These properties of cubature formulas are often abbreviated. For example, PI means positive and interior and EB means equal-weight and boundary. (Exterior formulas are denoted "O," for outside.) An equal-weight formula is abbreviated "E" and is also called a (geometric) *t-design* or a *Chebyshev-type formula*.

The main use of a cubature formula is to numerically integrate a function f which is approximately a polynomial. In this application, formulas with many points or nonexplicit points are impractical; exterior formulas are ill-founded if f is defined only on X; and formulas with large negative weights are ill-conditioned on the class

†Department of Mathematics, University of California, Davis, CA 95616 (greg@math.ucdavis.edu).

of continuous functions [20, Chap. 1]. Thus PI formulas with few points are the best kind.

By Tchakaloff's theorem [20, p. 61], every measure μ on $\mathbb{R}^n$ has a PI t-cubature formula with at most $\binom{n+t}{t}$ points, the same as the dimension of the vector space of relevant polynomials, $\mathbb{R}[\vec{x}]_{\le t}$. (If ∂X has nonzero measure, it may be only a PB formula.) Tchakaloff's theorem has a short proof, but it is computationally nonconstructive. Many known formulas with n small, or with n large and $t \le 2$, are better than the Tchakaloff bound [20, 4]. But if n is large, $t \ge 3$, and μ is reasonably natural, most explicit formulas in the existing literature either are negative, are exterior, or have exponentially many points.

In this article we present a new method to thin equal-weight cubature formulas with a convolution structure, in particular product formulas for product measures. (By *thinning* a formula, we mean removing some of its points without reducing its cubature degree.) The thinned formulas are efficient in high dimensions and low degree. The method also applies to some nonproduct measures that are related to product measures, in particular spheres and simplices with uniform measure. Victoir [21] independently obtained the basic construction when $q = 2$ (where q is the prime power parameter in Theorem 1.1), together with some other generalizations not considered by this author. However, many of our asymptotic bounds and derived constructions are new.

If F and G are two cubature formulas, we define their *convolution* $F * G$ to be their sum as sets, $F + G$. The weight w_a of $\vec{p}_a$ in $F * G$ is given by a product rule:

$$w_a = \sum_{\substack{\vec{p}_a = \vec{p}_b + \vec{p}_c \\ \vec{p}_b \in F, \vec{p}_c \in G}} w_b w_c.$$

Convolution of cubature formulas is related to convolution of measures in two ways: First, it is convolution of measures if cubature formulas are interpreted as atomic measures. Second, if F is a t-cubature formula for μ and G is a t-cubature formula for ν, then $F * G$ is a t-cubature formula for $\mu * \nu$. In particular, product formulas and product measures are convolutions in independent directions.

We also recall some basic facts from coding theory. For each prime power q, there is a unique finite field $\mathbb{F}_q$ with q elements. A *linear error-correcting code* of length ℓ, dimension k, and distance t over $\mathbb{F}_q$ is a k-dimensional vector subspace of $\mathbb{F}_q^\ell$ such that each nonzero vector has at least t nonzero coordinates. It is also called an $[\ell, k, t]_q$ code. A code C is a *zero-sum code* if the coordinates of every $\vec{a} \in C$ sum to 0.

THEOREM 1.1. *Let t, n, and ℓ be positive integers, let q be a prime power, and let μ be a measure on $\mathbb{R}^n$. For each $1 \le i \le \ell$, let F_i be an equal-weight formula with q elements such that the convolution*

$$F = F_1 * F_2 * \cdots * F_\ell$$

is a t-cubature formula for μ. Then an $[\ell, k, t+1]_q$ code C yields a thinning $G \subset F$ with $q^{\ell-k}$ points. In addition, if each F_i is centrally symmetric, t is odd, and either q is odd or C is a zero-sum code, then C need only be an $[\ell, k, t]_q$ code.

Theorem 1.1 can be strengthened further using the notion of an orthogonal array [9]. Linear error-correcting codes are dual to linear orthogonal arrays, and the proof actually uses orthogonal arrays rather than codes. In some cases nonlinear orthogonal arrays are slightly better than linear ones. See sections 2 and 4.

The most effective case of Theorem 1.1 is in the asymptotic limit $n \to \infty$ with t and q fixed. Recall that a function $f(n)$ is *quasi-linear* if $f(n) = O((\log n)^\alpha n)$ for some

α. Quasi linearity is also written $f(n) = \widetilde{O}(n)$. Say that a family $\{F\}$ of cubature formulas is quasi-linear (abbreviated "QL") if the points and weights of each F can be generated in quasi-linear time in the length of the output.

THEOREM 1.2. *Assume all variables as in Theorem* 1.1. *Then G can have $O(\ell^\alpha)$ points (with the constant depending only on q), where*

$$\alpha = t - 1 - \left\lfloor \frac{t-1}{q} \right\rfloor.$$

If each G is centrally symmetric and t is odd, then

$$\alpha = t - 2 - \left\lfloor \frac{t-2}{q} \right\rfloor.$$

Moreover, G is quasi-linear as $\ell \to \infty$, assuming precomputation of each F_i.

We can make some comparisons between Theorem 1.2 and other asymptotic bounds. To properly state these other bounds, we recall that a function $f(n)$ is of class $\Omega(g(n))$ if $f(n) \geq Cg(n)$ for some constant C (the reverse of $O(g(n))$) and that $f(n)$ is $\Theta(g(n))$ if it is both $O(g(n))$ and $\Omega(g(n))$.

If μ is an m-fold product with $m \propto n$, then we can take $\ell \propto n$ in Theorem 1.2, so that $O(\ell^\alpha) = O(n^\alpha)$. In comparison, the Tchakaloff upper bound is $O(n^t)$ points, or it is $O(n^{t-1})$ points when t is odd and μ is centrally symmetric (section 4). Thus Theorem 1.2 is asymptotically better than Tchakaloff's theorem for all such product measures. Tchakaloff's theorem also does not guarantee equal weights.

Another comparison is with the cardinality of exact determination. A t-cubature formula F is *overdetermined*, *underdetermined*, or *exactly determined* if the parameters of its points provide fewer, more, or the same number of degrees of freedom, respectively, as the constraints imposed by integrating all polynomials of degree t. The cardinality of exact determination is $\Theta(n^{t-1})$ for general μ and $\Theta(n^{t-2})$ when t is odd and μ is centrally symmetric. Thus for product measures, the formulas in Theorem 1.2 are asymptotically exactly determined (up to a constant factor that depends on t) when q is large. But when $q < t-1$, or $q < t-2$ in the odd and centrally symmetric case, they are asymptotically overdetermined.

A third comparison is with the Stroud lower bound: Any t-cubature formula in n dimensions, not necessarily interior or positive, requires $\Omega(n^{\lfloor t/2 \rfloor})$ points. Theorem 1.2 achieves the Stroud bound (up to a constant factor) when $q = 2$.

A final comparison is with an interesting thinning construction of Novak and Ritter for products of quadrature formulas [16]. (It is similar to an earlier construction due to Grundmann and Möller for the n-simplex [6].) They produce t-cubature formulas with $O(n^{\lfloor t/2 \rfloor})$ points, which is within a constant factor of the Stroud bound and better than Theorem 1.2 when $q > 2$. Crucially, their formulas are not positive, although they can be made interior. They also require that the factors of μ be 1-dimensional. The Novak–Ritter construction does generalize to convolutions, as long as each factor formula has collinear points.

Theorem 1.2 can be used to construct interesting cubature formulas for several infinite sequences of regions and measures considered by Stroud [20, Chaps. 7 and 8].

THEOREM 1.3. *For any t:*

1. *the n-cube C_n with uniform measure has a QLEI t-cubature formula with $O(n^{\lfloor t/2 \rfloor})$ points;*
2. *the cubical shell $C_n - rC_n$ has a QLEI t-cubature formula with $O(n^{\lfloor t/2 \rfloor + 1})$ points.*

For any odd $t \geq 3$,

1. *$\mathbb{R}^n$ with Gaussian weight function has a QLEI t-cubature formula with $O(n^{t-2})$ points;*
2. *any spherically symmetric measure on $\mathbb{R}^n$ has a QLPI t-cubature formula with $O(n^{t-2})$ points, which includes the n-ball B_n, the spherical shell $B_n - rB_n$, and the $(n-1)$-sphere S^{n-1} with uniform measure and $\mathbb{R}^n$ with radial exponential weight function $\exp(-||\vec{x}||_2)$.*

For any $t \geq 2$,

1. *the n-simplex Δ_n has a QLPI t-cubature formula with $O(n^{t-1})$ points;*
2. *the n-cross-polytope C_n^* with uniform measure has a QLPI t-cubature formula with $O(n^{\lfloor 3t/2 \rfloor - 1})$ points.*

All cases of Theorem 1.3 other than the cross polytope C_n^* improve the Tchakaloff bound. On the other hand, the construction for the cube C_n matches the Stroud bound up to a constant factor. We admit that this t-dependent factor is very generous when t is large: For each $t = 2s+1$, it approaches $2 \cdot s^s \cdot s!$ as $n \to \infty$ in the favorable case $n = 2^m$. By contrast, the Novak–Ritter formulas use only 2^s more points than the Stroud bound as $n \to \infty$.

Theorem 1.3 partially solves a problem of Stroud [20, p. 18]: Are there PI 5-cubature formulas for C_n, B_n, or Δ_n with $O(n^2)$ or $O(n^3)$ points? Theorem 1.3 provides QLPI 5-cubature formulas with $O(n^2)$ points for C_n, $O(n^3)$ points for B_n, and $O(n^4)$ points for Δ_n. In section 3, we will establish a special QLPI 5-cubature formula for B_n with $O(n^2)$ points and QLPB and QLPI 3-cubature formulas for Δ_n with $O(n)$ points. Thus the only remaining case of Stroud's question is the n-simplex in degree 4 or 5.

REMARK 1. *The formula in Theorem* 1.3 *for S^{n-1} is technically a QLPB formula if we take the definition of boundary in general topology. However, we take boundary in the sense of geometric topology, so that Theorem* 1.3 *is correct as stated.*

2. Proofs. *Proof of Theorem* 1.1. First, identify an affinely independent set of q points in $\mathbb{R}^{q-1}$ with the finite field $\mathbb{F}_q$. For each $1 \leq i \leq \ell$, choose a linear map $\pi_i : \mathbb{R}^q \to \mathbb{R}^n$ that sends $\mathbb{F}_q$ to F_i and define $\pi : \mathbb{R}^{(q-1)\ell} \to \mathbb{R}^n$ to be their direct sum:

$$\pi = \pi_1 \oplus \pi_2 \oplus \cdots \oplus \pi_\ell.$$

Because $F_1 * F_2 * \cdots * F_\ell$ is a t-design for the measure μ on $\mathbb{R}^n$, the identity

$$\int P(\vec{x}) d\mu = \frac{1}{q^\ell} \sum_{\vec{p} \in \mathbb{F}_q^\ell} P(\pi(\vec{p}))$$

holds for any polynomial P of degree at most t on $\mathbb{R}^n$. Now suppose that we thin the set $F = \pi(\mathbb{F}_q^\ell)$ to a set $G = \pi(A)$ for some set $A \subset \mathbb{F}_q^\ell$. Since π is linear, if we want G to be a t-cubature formula for μ as F is, it suffices that

$$\frac{1}{q^\ell} \sum_{\vec{p} \in \mathbb{F}_q^\ell} P(\vec{p}) = \frac{1}{|A|} \sum_{\vec{p} \in A} P(\vec{p}) \tag{2.1}$$

for any polynomial P on $\mathbb{R}^{(q-1)\ell}$ of degree at most t. If P is a monomial, then as a function on $\mathbb{F}_q^\ell$, it depends on at most t coordinates. Conversely, any function on $\mathbb{F}_q^\ell$ that depends on at most t coordinates is realized by a polynomial of degree at most t. It follows that (2.1) is equivalent to the statistical property that the projection of

A onto any t of the I coordinates of $\mathbb{F}_q^\ell$ is constant-to-1. Such a set A is called an *orthogonal array* of strength t.

If C is an $[\ell, k, t+1]_q$ code, then the dual space C^* (in the sense of linear algebra over $\mathbb{F}_q$) is a linear orthogonal array of strength t. Since C has dimension k, C^* has dimension $\ell - k$ and therefore has $q^{\ell-k}$ points. Thus we can let $G = \pi(C^*)$.

The refinement when t is odd and each F_i is centrally symmetric is as follows. If q is odd, we replace $\mathbb{R}^{q-1}$ by $\mathbb{R}^{(q-1)/2}$, and we position $\mathbb{F}_q$ as a centrally symmetric set that does not lie in a hyperplane. (In other words, the points of $\mathbb{F}_q$ are the vertices of an affinely regular cross polytope, plus the origin.) We further demand that negation in $\mathbb{F}_q$ coincides with negation in $\mathbb{R}^{(q-1)/2}$. Then any centrally symmetric subset $A \subset \mathbb{F}_q^\ell$ is centrally symmetric in $\mathbb{R}^{(q-1)\ell/2}$. In this case both sides of (2.1) vanish when P is an odd polynomial. Thus A need only be an orthogonal array of strength $t-1$. In particular, this is so if $A = C^*$, because C^* is a vector space over $\mathbb{F}_q$ and vector spaces are centrally symmetric sets.

Finally, if t is odd, q is even, and C is a zero-sum code, then C^* contains the vector $(1, 1, \ldots, 1)$ and therefore is invariant under addition by this vector. In this case we replace $\mathbb{R}^{q-1}$ in the general construction by $\mathbb{R}^{q/2}$ and realize $\mathbb{F}_q$ as a centrally symmetric set (the vertices of a regular cross polytope). We further demand that adding 1 in $\mathbb{F}_q$ coincides with negation in $\mathbb{R}^{q/2}$. Then once again C^* is centrally symmetric and need only be an orthogonal array of strength $t-1$. □

The following lemma establishes Theorem 1.2 as a corollary of Theorem 1.1.

LEMMA 2.1. *Let q be a prime power, let $m, t \in \mathbb{Z}_{\geq 0}$, and let*

$$\alpha = t - 1 - \left\lfloor \frac{t-1}{q} \right\rfloor.$$

Then there is a $[q^m, k, u]_q$ zero-sum code C with

$$u \geq t+1, \qquad k \geq q^m - m\alpha - 1.$$

The code in Lemma 2.1 is called an (extended, narrow-sense) *BCH code* [14, 3, 1, 10]. We will use the duals of BCH codes to thin cubature formulas. As it happens, the dual of a BCH code of this type is another BCH of the same type.

Proof. It is easier to define the dual code C^* and show that it is an orthogonal array. Since it is a linear space, it suffices to show that every coordinate projection $\pi_I : C^* \to \mathbb{F}_q^I$ with $|I| \leq t$ is onto. There is an important $\mathbb{F}_q$-linear function

$$\mathrm{Tr}_q : \mathbb{F}_{q^m} \to \mathbb{F}_q$$

called the *trace*. (It is analogous to the taking the real part of a complex number.) First, we interpret $\mathbb{F}_q^{q^m}$ as the space of all functions from $\mathbb{F}_{q^m}$ to $\mathbb{F}_q$. We define C^* as the set of all functions

$$f : \mathbb{F}_{q^m} \to \mathbb{F}_q, \qquad f(x) = \mathrm{Tr}_q(P(x)),$$

where P is a polynomial of degree at most $t-1$. If $I \subseteq \mathbb{F}_{q^m}$ and $|I| \leq t$, the polynomial P can achieve any desired values on I by Lagrange interpolation. Thus the distance of C is at least $t+1$.

The space of polynomials of degree $t-1$ on $\mathbb{F}_{q^m}$ has $\mathbb{F}_{q^m}$-dimension t, and therefore $\mathbb{F}_q$-dimension mt. But taking the trace reduces the dimension in two ways. To give

an explicit example, suppose that $q = 2$, $t = 3$, and m is arbitrary. Then C^* is the set of all

$$f(x) = \mathrm{Tr}_2(ax^2 + bx + c).$$

The apparent dimension of C^* is $3m$. But f depends only on the trace of c, so c contributes 1 rather than m to the dimension of C^*. Moreover, $\mathrm{Tr}_2(bx) = \mathrm{Tr}_2(b^2x^2)$, so the linear term can be removed from f, with the conclusion that

$$\dim C^* \leq m + 1.$$

In general, the constant term of P contributes 1 to the dimension and the other $t-1$ terms contribute m each, except that $\lfloor \frac{t-1}{q} \rfloor$ terms are superfluous by the Frobenius automorphism $x \mapsto x^q$. Thus

$$\dim C^* \leq m\alpha + 1,$$

as desired.

Since constants are polynomials of degree 0, C^* contains constant vectors. Therefore C is a zero-sum code. □

On the face of it, Lemma 2.1 establishes Theorem 1.2 only when $\ell = q^m$. If $q^{m-1} < \ell < q^m$, we can project a BCH code from $\mathbb{F}_q^{q^m}$ to $\mathbb{F}_q^n$. This preserves the $O(t^\alpha)$ bound at the expense of worsening the constant factor. If ℓ is not much more than q^{m-1}, we can slightly improve the projected code with a projection that annihilates up to $\alpha - 1$ independent vectors in C^*. (See Theorem 3.1 for an example.)

REMARK 2. *The inequalities for u and k in Lemma* 2.1 *become sharp as $m \to \infty$.*

Proof of Theorem 1.3. The simplest case to consider is with uniform measure and $\mathbb{R}^n$ with Gaussian weight function. This fits Theorem 1.2 with $\ell = n$, provided that for each t we find an EI, centrally symmetric t-quadrature formula with Gaussian weight and with q points for some prime power q. Since we assume no upper bound on q, the very general Seymour–Zaslavsky theorem [18] establishes the existence of such formulas. (The proof of the theorem, but not the statement, shows that there is a Q such that we can take any $q \geq Q$. In particular we can take $q = 2^k$. We can then symmetrize the formula by taking the multiset union of it and its reflection.) On the other hand, since q is large, $\lfloor (t-2)/q \rfloor = 0$. Thus Theorem 1.2 produces formulas with $O(n^{t-2})$ points.

We will need the same construction for the orthant $\mathbb{R}^n_{\geq 0}$ with exponential weight function $\exp(-||\vec{x}||_1)$. This measure does not have central symmetry, and the end result is formulas with $O(n^{t-1})$ points, again with $\ell = n$.

The next simplest case is the n-simplex Δ_n. Recall that Δ_n has barycentric coordinates

$$x_0 + x_1 + \cdots + x_n = 1$$

which realize it as a subset of the orthant $\mathbb{R}^{n+1}_{\geq 0}$. If $P(\vec{x})$ is a polynomial of degree t on Δ_n, then it can be *homogenized*: it can be expressed as a homogeneous polynomial of degree t by attaching a factor of $\left(\sum_i x_i\right)^{t-s}$ to each term of degree s. In this case

$$\int_{\Delta_n} P(\vec{x}) d\vec{x} = \frac{1}{(n+t)!} \int_{\mathbb{R}^{n+1}_{\geq 0}} P(\vec{x}) \exp(-||\vec{x}||_1) d\vec{x}.$$

Therefore we can project any nonexterior cubature formula for $\mathbb{R}^{n+1}_{\geq 0}$ radially onto Δ_n without loss of degree, although the weights change. (If the origin happens to

be a cubature point, discard it.) In particular, we can project the cubature formulas provided by Theorem 1.2 as explained previously. The formulas still have $O(n^{t-1})$ points, although the weights are no longer equal.

The same argument works for the sphere $S^{n-1} \subset \mathbb{R}^n$ for centrally symmetric formulas. Every polynomial P on S^{n-1} can be expressed as $P_S + P_A$, where P_S is centrally symmetric and P_A is centrally antisymmetric. The integral of P_A vanishes, as does its sum with respect to any centrally symmetric formula. Meanwhile every term of P_S has even degree, so it can be expressed as a homogeneous polynomial on $\mathbb{R}^n$ using the equation

$$x_1^2 + \cdots + x_n^2 = 1$$

for the unit sphere. Then

$$\int_{S^{n-1}} P(\vec{x}) d\Omega = \frac{2}{(\frac{n+t}{2} - 1)!} \int_{\mathbb{R}^n} P(\vec{x}) \exp(-||\vec{x}||_2^2) d\vec{x},$$

where Ω is usual surface volume on S^{n-1}. Again, any centrally symmetric cubature formula can be radially projected and the weights can be adjusted.

Formulas for the ball B_n and the spherical shell $B_n - rB_n$ can be derived from formulas for the sphere S^{n-1} using radial separation of variables [20, Thm. 2.8]. The result is a product formula where the radial factor can be Gaussian quadrature. The number of points in this factor does not increase with dimension.

The cross-polytope C_n^* is the union of 2^n simplices. Thus we can obtain formulas for C_n^* by repeating formulas for Δ_n. In degree t, we do not need all 2^n copies; instead we can repeat it in the pattern of the BCH code over $\mathbb{F}_2$ defined by polynomials of degree $t-1$ over $\mathbb{F}_{2^m}$. Such a code has $O(n^{\lfloor t/2 \rfloor})$ vectors and the formula for Δ_n has $O(n^{t-1})$ points, so the total is $O(n^{\lfloor 3t/2 \rfloor - 1})$ points.

The n-cube $C_n = [-1, 1]^n$ is in some ways the most interesting case. As in the Gaussian case, it is a straight application of Theorem 1.2 using an equal-weight quadrature formula. But in this case we will carefully choose the quadrature formula on $[-1, 1]$ to itself be a convolution of $s = \lfloor t/2 \rfloor$ formulas with two points. For example, the Chebyshev 5-quadrature formula has points at

$$\pm\sqrt{\frac{5+\sqrt{5}}{30}} \pm \sqrt{\frac{5-\sqrt{5}}{30}}.$$

This is evidently a convolution, as is any centrally symmetric, equal-weight formula with four points. Elsewhere [13] we show that the 2^s points

$$\pm z_1 \pm z_2 \pm \cdots \pm z_s$$

form a Chebyshev-type $(2s+1)$-quadrature formula for $[-1, 1]$ with constant weight if and only if the z_i's are the roots of the polynomial

$$Q(x) = x^s - \frac{x^{s-1}}{3} + \frac{x^{s-2}}{45} - \cdots + \frac{(-1)^s}{1 \cdot 3 \cdot 15 \cdots (4^s - 1)}.$$

We also show that all roots of Q are real and that the resulting quadrature formula is interior. The n-fold product power of this formula is thus a convolution of sn pairs of points, so we can apply Theorem 1.2 with $\ell = sn$ and $q = 2$.

Finally, the $O(n^{\lfloor t/2 \rfloor})$ formula for the n-cube C_n yields a $O(n^{\lfloor t/2 \rfloor + 1})$ formula for the cube surface ∂C_n just by repeating the formula for C_{n-1} on each facet of C_n. Then radial separation of variables produces a product formula for the cubical shell $C_n - rC_n$ which also has $O(n^{\lfloor t/2 \rfloor + 1})$ points. □

3. Special constructions and examples. In this section we will consider some examples and special constructions with concern for constant factors. For this purpose, we spell out more precisely the notion of an orthogonal array. Let A be a finite set. If a subset $T \subset A^n$ has the property that its projection $T \to A^I$ is a constant-to-1 map for every $|I| \le t$, then T is an *orthogonal array* of strength t, or an $\mathrm{OA}(|T|, n, |A|, t)$ [9]. If $A = \mathbb{F}_q$ and $T = C^*$ is the dual of an $[n, k, t]_q$ code, then T is an $\mathrm{OA}(q^{n-k}, n, q, t-1)$. We will also say that T is an $[n, n-k, t^*]_q$ to refer to its linear structure and indicate its dual distance.

If $|A| = q$ is a prime power and t is fixed, then BCH codes are the best presently known $\mathbb{F}_q$-linear orthogonal arrays in the limit $n \to \infty$. But a few nonlinear arrays are slightly better.

A *Hadamard matrix* of order n is an $n \times n$ matrix with entries ± 1 and with orthogonal rows (and therefore orthogonal columns). It is easy to show that a Hadamard matrix is equivalent to an $\mathrm{OA}(2n, n, 2, 3)$. A $[2^m, m+1, 4^*]_2$ BCH code, which is also called a first-order Reed–Muller code, yields a Hadamard matrix of order 2^m. But there are also Hadamard matrices for other values of n, for example when $n-1$ is prime and 4 divides n. The Hadamard conjecture asserts that there is a Hadamard matrix of every order n divisible by 4.

For any even $m \ge 4$, there is a Kerdock code which is a nonlinear $\mathrm{OA}(2^{2m}, 2^m, 2, 5)$. It has half as many points as the corresponding $[2^m, 2m+1, 6^*]_2$ BCH code [9, 8, 11]. For any even $m \ge 6$, there is a Delsarte–Goethals code which is a nonlinear $\mathrm{OA}(2^{3m-2}, 2^m, 2, 7)$ [5]. It has one-fourth as many points as the corresponding $[2^m, 3m+1, 8^*]_2$ BCH code.

The following result comes from thinning some cubature formulas of Stroud, some of whose points have a product structure.

THEOREM 3.1. *Let $n \ge 6$, and let*

$$k = \begin{cases} 4m, & 2^{2m-1} < n \le 2^{2m}, \\ 4m+2, & 2^{2m} < n \le 2^{2m} + 2^m, \\ 4m+3, & 2^{2m} + 2^m < n \le 2^{2m+1}. \end{cases}$$

Then the sphere S^{n-1}, $\mathbb{R}^n$ with Gaussian measure, and the ball B_n admit QLPI 5-cubature formulas with $2^k + 2n$ points.

Proof. The formulas S_n:5-3, U_n:5-2, and $E_n^{r^2}$:5-3 listed in Stroud [20, pp. 270, 294, and 317] have $2^n + 2n$ points with 2^n of them lying on the vertices of a cube. These 2^n points can be thinned to either the $[2^{2m+1}, 4m+3, 6^*]_2$ BCH code or the Kerdock $\mathrm{OA}(2^{4m}, 2^{2m}, 2, 5)$ and then projected down to n dimensions.

If $2^{2m} < n \le 2^{2m} + 2^m$, then the $[2^{2m+1}, 4m+3, 6^*]_2$ BCH code can be reduced in half by carefully choosing the projection. The code has a vector of weight $2^{2m} - 2^m$, so when n is only slightly larger than 2^{2m}, we can choose a projection that annihilates this vector.

In each of the three cases, the result is a formula with $2^k + 2n$ points. ∎

Actually, Theorem 3.1 is not quite optimal, because it uses a convenient set of good distance-6 linear codes and nonlinear strength-5 orthogonal arrays rather than the best ones presently known. A complicated map of the best presently known linear codes over $\mathbb{F}_2$ of length $n \le 256$ is provided by the "best codes" functions in Magma [22]. Undoubtedly this map could be augmented by nonlinear orthogonal arrays, but we know of no effort to do so. When n is a power of 2, Kerdock and BCH codes are the best presently known choices.

Victoir [21] also established Theorem 3.1 (with BCH codes). If $n = 2^m$ and Stroud's formulas for S^{n-1} is thinned using a BCH code, it then has equal weights and is therefore a 5-design. Interestingly, in this case it has a transitive symmetry group and was previously found by Calderbank et al. [2]. Similar constructions were found by König [12], by Sidelnikov [19], and by Schechtman, interpreting the work of Hajela [7].

We can obtain a good 3-cubature formula for the cube C_n by a straightforward application of Theorem 1.2 using the 2-point Gaussian quadrature formula for the interval $[-1, 1]$. Thinning the product formula using a BCH code yields a 2^{j+1}-point formula when $2^{j-1} < n \le 2^j$. When $n = 2^j$, or more generally whenever there is a Hadamard matrix of order n, the product formula can be thinned to the $2n$ vertices of a certain regular cross-polytope inside C_n. A formula due to Stroud, C_n:3-1 (see [20, p. 230]), also uses the vertices of a regular cross-polytope but not the same one.

We can obtain a 3-cubature formula with $O(n)$ points for Δ_{n-1} with a similar construction. Using known Hadamard matrices, the formula has $3n + o(n)$ points; if the Hadamard conjecture holds, it has between $3n - 1$ and $3n + 5$ points. First, the positive ray $\mathbb{R}_{\ge 0}$ with exponential weight has an equal-weight 2-quadrature formula with points at 0 and 2. If we apply Theorem 1.1 to this formula and a Hadamard matrix of order n, the result is a $2n$-point formula F on $\mathbb{R}^n_{\ge 0}$ which also has degree 2. However, if our interest is integration on Δ_{n-1}, we need only consider homogeneous polynomials on $\mathbb{R}^n_{\ge 0}$. The formula F correctly integrates every degree 3 monomial other than x_i^3. We can fix F for these monomials, without changing its sum for $x_i^2 x_j$ or $x_i x_j x_k$, by adding a point at $(1, 0, 0, \dots)$ (and permutations) with weight 2.

The projected formula on Δ_{n-1} consists of these points and weights in barycentric coordinates:

$$\begin{array}{cc} (1, 0, 0, \dots, 0)_S, & \frac{2}{n(n+1)(n+2)}, \\ (\frac{2}{n}, \frac{2}{n}, \dots, \frac{2}{n}, 0, 0, \dots, 0)_H, & \frac{n}{2(n+1)(n+2)}, \\ (\frac{1}{n}, \frac{1}{n}, \dots, \frac{1}{n}), & \frac{4n}{(n+1)(n+2)}. \end{array}$$

The subscript S denotes full symmetrization, as in Stroud's notation. The subscript H denotes symmetrization in the pattern of a Hadamard design. (See section 4.) This produces a formula with $3n-1$ points, provided that there exists a Hadamard matrix of order n. When there is none, we can use a Hadamard matrix of order $\ell > n$. The formula on $\Delta_{\ell-1}$ with $3\ell - 1$ points can be projected onto Δ_{n-1}, as in the proof of Theorem 1.3. We can take $\ell = n + o(n)$ by letting $\ell - 1$ be the first prime after n which is 3 mod 4. If the Hadamard conjecture holds, we can take $\ell = 4\lceil n/4 \rceil$.

Stroud asked for a practical, PI 5-cubature formula for C_{100}. Following Theorem 1.3, we can find one by thinning the product formula coming from the 4-point Chebyshev quadrature on $[-1, 1]$. This product formula is the convolution of 200 pairs of points, so we can thin it using the Kerdock $\mathrm{OA}(2^{16}, 2^8, 2, 5)$, projected to 200 dimensions. The cubature formula therefore has $2^{16} = 65536$ points, which would have been fairly practical even in 1971 when Stroud asked the question. (The Kerdock code used here was discovered shortly afterward [11], but the BCH codes were known in 1959 [1, 10].)

Victoir [21] found another thinning of the same Chebyshev product formula with $4^{12} = 16777216$ points, which the author tied in the first version of this paper.

Note that the Chebyshev–Kerdock 5-cubature formula for C_{100} is overdetermined. The threshold of exact determination for centrally symmetric 5-cubature formulas on

C_{100} is 87651 points. Meanwhile the centrally symmetric Tchakaloff bound is 8852652 points, while the Stroud lower bound is 5050 points.

Finally, Schürer [17] compared the numerical accuracy of various cubature and quasi-Monte Carlo methods for the integration of various test functions defined on C_n with $2 \leq n \leq 100$. He assumed a more modern limit of 2^{25} evaluations of the integrand. For much of this test regime we can suggest the following cubature formulas: Start with the power of the convolutional 7-quadrature formula [13] for $[-1, 1]$, whose points are approximately at

$$\pm.500128 \pm .243941 \pm .153942.$$

Then thin the n-fold product power of this formula using a Delsarte–Goethals code. The result is an EI 7-cubature formula with at most 2^{23} points up to dimension $\lfloor 256/3 \rfloor = 85$.

4. Other comments. Victoir [21] proposes thinning symmetric cubature formulas rather than product or convolution formulas. The enabling result of symmetric cubature formulas is Sobolev's theorem: If a linear action of a finite group G preserves μ, then a cubature formula consisting of orbits of G need only be checked for G-invariant polynomials. Victoir extends Sobolev's theorem with a G-invariant generalization of Tchakaloff's theorem: A PI cubature formula needs only as many orbits as the dimension of $\mathbb{R}[\vec{x}]^G_{\leq t}$, the space of G-invariant polynomials of degree at most t. One important special case is when G is the 2-element central symmetry group. If μ is a measure on $\mathbb{R}^n$ with central symmetry and t is odd, the bound from this version of Tchakaloff's theorem is $O(n^{t-1})$ points.

Even if a cubature formula F uses very few orbits of G, some of the orbits might be very large. Victoir proposes thinning each large orbit separately. He notes that this can be done using linear programming, among other methods; linear programming on a set of G-orbits should be much easier than general numerical methods to find positive cubature formulas for μ. If $G = (\mathbb{Z}/2)^n$ is the group of independent sign changes of all n coordinates, then an orbit of Gq can be identified with $\mathbb{F}_2^k$ for some $k \leq n$. In this case Victoir found the constructions of Theorems 1.1 and 1.2. (In the case of 5-cubature on C_n, he found a special construction with $O(n^3)$ points with elements of both Theorem 1.1 and the n-cube case of Theorem 1.3.)

If G is the group of coordinate permutations, then an orbit whose points have two distinct coordinates can be identified with the set of k-subsets of an n-set. A geometric t-design T within this orbit is also a traditional combinatorial t-design, or an $(n, k, t) - \lambda$ design. Namely, T is a collection of blocks of size k in a set of n such that each t-subset is contained in exactly λ blocks. In particular, an $(n, \frac{n}{2}, 3) - \frac{n}{4}$ design is called a *Hadamard design*, because it comes from the rows of a Hadamard matrix.

These constructions motivate the notion of a weighted orthogonal array. We define it as a finite set A and a measure μ on A^n that projects to uniform measure on each A^I with $|I| \leq t$. More generally, μ might project to σ^n for some reference measure σ on S. Such arrays could improve of Theorem 1.1; the factor formulas would not need to have equal weights.

Finally, cubature formulas coming from Theorem 1.1 could be viewed as quasi-Monte Carlo methods. They are similar to some constructions of (t, m, s)-nets, which are quasi-Monte Carlo methods first defined and largely developed by Niederreiter [15]. Nonetheless, PI cubature formulas and discrepancy-based quasi-Monte Carlo methods are thought to have complementary advantages [17]. We believe that the

improved asymptotics presented here could change the standing of cubature among numerical methods for integration.

Acknowledgments. The author would like to thank Hermann König, Eric Rains, and Hong Xiao for useful discussions. The author is also indebted to the late Arthur Stroud for his excellent introduction to the cubature problem.

NUMERICAL CUBATURE FROM ARCHIMEDES' HAT-BOX THEOREM*

GREG KUPERBERG†

Dedicated to Krystyna Kuperberg on the occasion of her 60th birthday

Abstract. Archimedes' hat-box theorem states that uniform measure on a sphere projects to uniform measure on an interval. This fact can be used to derive Simpson's rule. We present various constructions of, and lower bounds for, numerical cubature formulas using moment maps as a generalization of Archimedes' theorem. We realize some well-known cubature formulas on simplices as projections of spherical designs. We combine cubature formulas on simplices and tori to make new formulas on spheres. In particular, S^n admits a 7-cubature formula (and sometimes a 7-design) with $O(n^4)$ points. We establish a local lower bound on the density of a positive interior cubature formula on a simplex using the moment map.

Along the way we establish other quadrature and cubature results of independent interest. For each t, we construct a lattice trigonometric $(2t+1)$-cubature formula in n dimensions with $O(n^t)$ points. We derive a variant of the Möller lower bound using vector bundles. And we show that Gaussian quadrature is very sharply locally optimal among positive quadrature formulas.

Key words. cubature formulas, moment maps, projective space, lattices

1. Introduction.

Let μ be a measure on $\mathbb{R}^n$ with finite moments. A *cubature formula of degree t* for μ is a set of points $F = \{\vec{p}_a\} \subset \mathbb{R}^n$ and a weight function $\vec{p}_a \mapsto w_a \in \mathbb{R}$ such that

$$\int P(\vec{x}) d\mu = P(F) \stackrel{\text{def}}{=} \sum_{a=1}^{N} w_a P(\vec{p}_a)$$

for polynomials P of degree at most t. (If $n = 1$, then F is also called a *quadrature formula*.) The formula F is *equal-weight* if all w_a are equal, *positive* if all w_a are positive, and *negative* if at least one w_a is negative. Let X be the support of μ. The formula $\mathbb{F}$ is *interior* if every point $\vec{p}_a$ is in the interior of X; it is *boundary* if every $\vec{p}_a$ is in X and some $\vec{p}_a$ is in ∂X; and otherwise it is *exterior*. We will mainly consider positive interior (PI) and positive boundary (PB) cubature formulas, and we will also assume that μ is normalized so that total measure is 1. PI formulas are the most useful in numerical analysis [30, Chap. 1]. This application also motivates the main question of cubature formulas, which is to determine how many points are needed for a given formula and a given degree t. Equal-weight formulas that are either interior or boundary (EI or EB) are important for other applications, in which context they are also called *t-designs*.

Our starting point is to use Archimedes' hat-box theorem [2] to relate quadrature on the interval $[-1, 1]$ and cubature on the unit sphere S^2, both with uniform measure. (Lest the reader be misled, this starting point is much simpler and easier than the generalizations that will eventually follow.) Archimedes' theorem says that the orthogonal projection π from S^2 to the z coordinate preserves normalized uniform

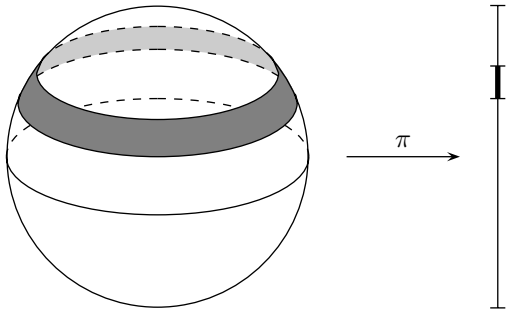

FIG. 1. *Archimedes' hat-box theorem.*

measure. In plainer terms, for any interval $I \subset [a, b]$ or other measurable set, the area of $\pi^{-1}(I)$ is proportional to the length of I; see Figure 1. (It is called the hat-box theorem because the surface area of a hemispherical hat equals the area of the side of a cylindrical box containing it.) Therefore if F is a t-cubature formula on S^2, its projection $\pi(F)$ is a t-cubature formula on $[-1, 1]$.

The 2-sphere S^2 has five especially nice cubature formulas given by the vertices of the Platonic solids. Their cubature properties follow purely from a symmetry argument of Sobolev [27]. Suppose that G is the group of common symmetries of a putative cubature formula F and its measure μ. If $P(\vec{x})$ is a polynomial and $P_G(\vec{x})$ is the average of its G-orbit, then

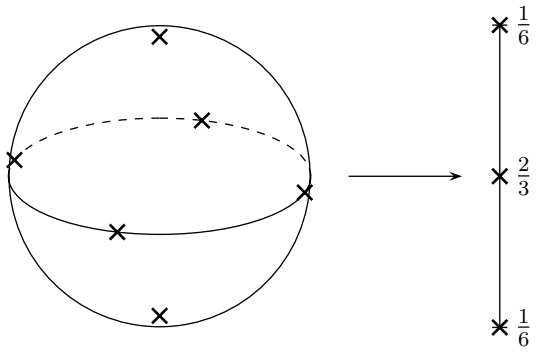
$$\int P_G(\vec{x}) d\mu = \int P(\vec{x}) d\mu, \qquad P_G(F) = P(F).$$

Therefore it suffices to check F for G-invariant polynomials. In particular, if every G-invariant polynomial of degree $\leq t$ is constant, then any G-orbit is a t-design.

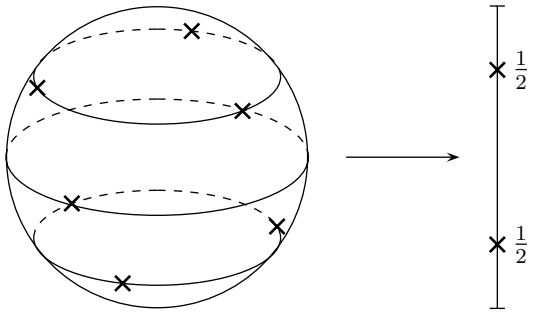
By Sobolev's theorem, the vertices of a regular octahedron form a 3-design on S^2. If we project this formula using Archimedes' theorem, the result is Simpson's rule. Another projection of the same six points yields 2-point Gauss–Legendre quadrature. Figure 2 shows both projections. The eight vertices of a cube are also a 3-design. One projection is again 2-point Gauss–Legendre quadrature; another is Simpson's $\frac{3}{8}$ rule. Finally the twelve vertices of a regular icosahedron form a 5-design by symmetry. One projection of these twelve points is 4-point Gauss–Lobatto quadrature.

The rest of this article applies toric moment maps, which generalize Archimedes' theorem to higher dimensions, to the cubature problem. Section 2 shows that several well-known quadrature formulas on the interval and cubature formulas on simplices are projections of higher-dimensional symmetric formulas. Section 4 combines formulas on tori with formulas on simplices and moment maps to make formulas on spheres and projective spaces. In particular, it constructs a PI 7-cubature formula on the sphere S^n with $O(n^4)$ points. Finally, section 6 uses moment maps to establish a local lower bound for the density of points in any PI cubature formula on a simplex. A similar lower bound holds for an arbitrary simple convex polytope.

Along the way we establish some other quadrature and cubature results that are not derived from moment maps but are of independent interest. Section 3 establishes new lattice cubature formulas on tori that are similar to cubature formulas based on error-correcting codes [18]. In particular, it constructs for each t a trigonometric



(a) Simpson's rule



(b) 2-point Gauss-Legendre rule

FIG. 2. *Two projections of the octahedron rule.*

$(2t+1)$-cubature formula on $[0, 2\pi)^n$ of lattice type with $O(n^t)$ points. This improves a construction of Cools, Novak, and Ritter with $O(n^{2t})$ points and negative weights [5], and agrees up to a t-dependent constant factor with the Stroud-type lower bound [20, 22, 31]. Section 5 presents a refinement of this well-known lower bound in odd degree. It is similar to the Möller bound [19] but applies to some new cases. Section 6 also establishes that Gaussian quadrature is very sharply locally optimal among all positive quadrature formulas (Theorem 6.3). This bound might be previously known, since Gaussian quadrature has been widely studied, but the author could not find it in the literature.

2. Projection constructions. The immediate higher-dimensional generalization of Archimedes' theorem replaces the sphere S^2 by the complex manifold $\mathbb{C}P^n$. This manifold has a natural metric and a natural real algebraic structure. Concretely, assume that the projective coordinates $(z_0 : z_1 : \cdots : z_n)$ of $\mathbb{C}P^n$ are normalized so that

$$|z_0|^2 + |z_1|^2 + \cdots + |z_n|^2 = 1.$$

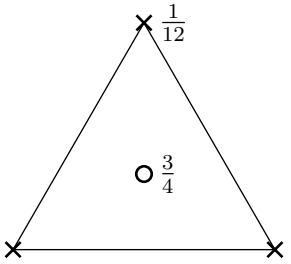


FIG. 3. *A 2-dimensional generalization of Simpson's rule.*

Then the coordinates $z_k\overline{z}_j$ together embed $\mathbb{C}P^n$ into $\mathbb{C}^{(n+1)^2}$ as a real algebraic variety (with $\mathbb{C}^{(n+1)^2}$ interpreted as a $2(n+1)^2$-dimensional real vector space) and a Riemannian manifold. This embedding is familiar in quantum mechanics as the density matrix (or density operator) formalism [21, sect. 2.4]. The induced metric is called the Fubini–Study metric. Since the metric yields a measure on $\mathbb{C}P^n$, and since it is a real algebraic variety, we can consider cubature formulas on it.

There is a projection $\pi : \mathbb{C}P^n \to \Delta_n$ to the n-simplex given by

$$\pi(z_0 : z_1 : \cdots : z_n) = (|z_0|^2, |z_1|^2, \ldots, |z_n|^2),$$

using normalized coordinates for $\mathbb{C}P^n$ and barycentric coordinates for Δ_n. It is linear and preserves normalized measure. In more abstract terms, π has these properties because $\mathbb{C}P^n$ is a projective toric variety and π is its moment map. Archimedes' theorem is a description of the moment map of $\mathbb{C}P^1 \cong S^2$. Thus, if F is an interior t-cubature formula on $\mathbb{C}P^n$, then $\pi(F)$ is a t-cubature formula on Δ_n.

Ivanović [13] and Wootters and Fields [34] defined one interesting family of 2-designs on $\mathbb{C}P^{q-1}$ for $q = p^k$ a prime power. If p is odd, then the 2-design is the orbit of a standard basis vector e_k in the group generated by cyclic permutation and linear operators of the form

$$L(e_k) = \omega^{\mathrm{Tr}_p(ak^2+bk+c)} e_k,$$

where ω is a pth root of unity and Tr_p is the $\mathbb{F}_p$ trace function on $\mathbb{F}_q$. The construction is more complicated when $p = 2$. In either case, the standard basis projects to the vertices of Δ_{q-1}, and the other q^2 vectors project to the center. The result is a standard degree 2 generalization of Simpson's rule for Δ_{q-1}, shown in Figure 3 when $q = 3$.

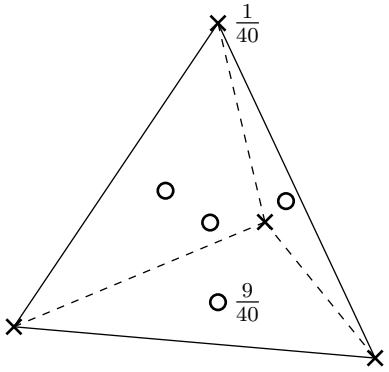
Other interesting designs and cubature formulas on $\mathbb{C}P^{n-1}$ come from designs and formulas on S^{2n-1}. The generalized Hopf fibration

$$h : S^{2n-1} \to \mathbb{C}P^{n-1}$$

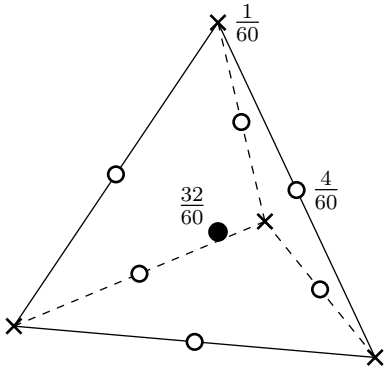
is a quadratic, volume-preserving map from S^{2n-1} to $\mathbb{C}P^{n-1}$. Namely, if we place S^{2n-1} in $\mathbb{C}^n$, h takes each point to the complex line containing it. The map h projects a $2t$- or $2t+1$-cubature formula on S^{2n-1} to a t-cubature formula on $\mathbb{C}P^{n-1}$.

One interesting example is the 240 roots of the E_8 root system, which are a 7-design as well as the solution to the sphere kissing problem in $\mathbb{R}^8$ [4, sect. 14.2]. The root system has two natural positions in $\mathbb{C}^4$. In the first position, it is generated from the two points

$$(1, 1, 1, 0), \qquad (1 - \omega, 0, 0, 0)$$



(a) 8 points



(b) 11 points

FIG. 4. 3-*cubature formulas on* Δ_3 *from the* E_8 *root system.*

by freely permuting the first three coordinates, applying the map $(a, b, c, d) \mapsto (d, a, -b, c)$, and multiplying any one coordinate by ω, a cube root of unity. In the second position, it is generated from the three points

$$(1, 1, 1, 1), \qquad (2, 0, 0, 0), \qquad (1 + i, 1 + i, 0, 0)$$

by freely permuting the four coordinates and multiplying any two coordinates by i. These two positions respectively exhibit the Eisenstein and Gaussian lattice structures of the E_8 lattice. The Hopf fibration sends the Eisenstein position of the root system to a 40-point 3-design in $\mathbb{C}P^3$ and the Gaussian position to a 60-point 3-design. Then the moment map projects these two 3-designs to 3-cubature formulas for the tetrahedron Δ_3 that appear in Abramowitz and Stegun [1, p. 895]. They have 8 and 11 points, respectively, and are shown in Figure 4.

The composition $\pi \circ h$ of the moment map and the Hopf fibration is a torus fibration $\tau_2 : \mathbb{R}^{2n} \to \Delta_{n-1}$ that does not fully depend on the complex structure $\mathbb{R}^{2n} = \mathbb{C}^n$ but only on the decomposition of $\mathbb{R}^{2n}$ into n orthogonal planes. Explicitly, the map is

$$\tau_2(x_1, \ldots, x_{2n}) = (x_1^2 + x_2^2, x_3^2 + x_4^2, \ldots, x_{2n-1}^2 + x_{2n}^2).$$

This projection is analogous to a map $\tau_1 : S^{n-1} \to \Delta_{n-1}$ defined by Xu [35]:

$$\tau_1(x_1, \ldots, x_n) = (x_1^2, \ldots, x_n^2).$$

The Xu map does not preserve uniform measure. Rather, it takes uniform measure on the sphere to the measure with weight function

$$w_1(\vec{y}) = \frac{2^n \pi^{n/2}}{\frac{n}{2}! n \sqrt{y_0 y_1 y_2 \cdots y_{n-1}}}$$

in barycentric coordinates.

In the case of the E_8 root system, one interesting set of orthogonal planes are the four eigenplanes of the abelian subgroup of $\mathrm{Aut}(E_8)$ of the form $C_5 \times C_5$. Rains [25] has computed the corresponding 3-cubature formula on Δ_3 using Magma [37]. In barycentric coordinates on Δ_3, its points and weights are the orbits of the two weighted points

$$\begin{aligned} \vec{p}_1 &= \frac{1}{10}(0, 0, 5 - \sqrt{5}, 5 + \sqrt{5}), \qquad & w_1 &= \frac{1}{24}, \\ \vec{p}_2 &= \frac{1}{10}(2, 2, 3 + \sqrt{5}, 3 - \sqrt{5}), \qquad & w_2 &= \frac{5}{24}, \end{aligned}$$

under the action of the coordinate permutations (34) and (13), (24). In particular, it has eight points. In conclusion, at least three interesting 3-cubature formulas for Δ_3 arise as projections of E_8 root system. The root system model explains the simple rational values of the weights.

The E_8 lattice is one of four widely studied and highly symmetric lattices in low dimensions; the other three are the Coxeter–Todd lattice K_{12} in $\mathbb{R}^{12}$, the Barnes–Wall lattice Λ_{16} in $\mathbb{R}^{16}$, and the Leech lattice Λ_{24} in $\mathbb{R}^{24}$ [4, Chap. 4]. In each case, the set of short vectors has transitive symmetry, and in each case, Sobolev's theorem establishes its degree as a spherical design.

The 756 short vectors of K_{12} form a 7-design on S^{11}. In one of its several presentations as an Eisenstein lattice in $\mathbb{C}^6$ (the "3-base" presentation [4, sect. 7.8]), the short vectors are generated from the two points

$$(1, 1, 1, 1, 1, 1), \qquad (1 - \omega, \omega - 1, 0, 0, 0, 0)$$

by freely permuting coordinates, multiplying the coordinates by powers of ω whose exponents sum to 0, and negating all coordinates. The projection τ_2 sends these points to a 16-point 3-cubature formula on Δ_5 generated from the points

$$\begin{aligned} \vec{p}_1 &= \frac{1}{2}(1, 1, 0, 0, 0, 0), \qquad & w_1 &= \frac{1}{42}, \\ \vec{p}_2 &= \frac{1}{6}(1, 1, 1, 1, 1, 1), \qquad & w_2 &= \frac{27}{42}, \end{aligned}$$

by freely permuting coordinates. This formula was found by Stroud [29, 30].

The 4320 short vectors of Λ_{16} form a 7-design on S^{15}. In its simplest position (which exhibits its Gaussian lattice structure), the short vectors are generated from the two vectors

$$\begin{gathered} (1, 1, 1, 1, 1, 1, 1, 1, 0, 0, 0, 0, 0, 0, 0, 0), \\ (2, 2, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0) \end{gathered}$$

by permuting coordinates under the group $\mathrm{GL}(4,2) \ltimes (\mathbb{Z}/2)^4$ of affine automorphisms of $(\mathbb{Z}/2)^4$, together with sign changes that keep the coordinate sums divisible by 4. The projection τ_2 sends these points to a 51-point 3-cubature formula on Δ_7 generated from the points

$$\begin{aligned}
\vec{p}_1 &= (1,0,0,0,0,0,0,0), & w_1 &= \frac{1}{1080},\\
\vec{p}_2 &= \frac{1}{2}(1,1,0,0,0,0,0,0), & w_2 &= \frac{1}{270},\\
\vec{p}_3 &= \frac{1}{4}(1,1,1,1,0,0,0,0), & w_3 &= \frac{4}{135},\\
\vec{p}_4 &= \frac{1}{8}(1,1,1,1,1,1,1,1), & w_4 &= \frac{64}{135},
\end{aligned}$$

under the action of the affine group $\mathrm{GL}(3,2) \ltimes (\mathbb{Z}/2)^3$. This is not an optimal PI 3-cubature formula, because the orbit of $\vec{p}_2$ can be eliminated, leaving only 23 points. But it does have a novel property: Instead of full symmetrization, the orbit of $\vec{p}_3$ is in the pattern of the (8, 4, 3) Steiner system. This is as good as full symmetrization for 3-cubature, because any monomial of degree 3 involves at most three coordinates. The structure of this Barnes–Wall projection led the author to relate cubature to combinatorial t-designs and orthogonal arrays [18].

The above position of Λ_{16} is compatible with its Gaussian lattice structure. Rains found another interesting position which is compatible with an Eisenstein lattice structure. The corresponding 3-cubature formula on Δ_7 has 50 points. They are generated from

$$\begin{aligned}
\vec{p}_1 &= (1,0,0,0,0,0,0,0), & w_1 &= \frac{1}{720},\\
\vec{p}_2 &= \frac{1}{4}(1,1,1,1,0,0,0,0), & w_2 &= \frac{1}{90},\\
\vec{p}_3 &= \frac{1}{3}(1,1,0,0,1,0,0,0), & w_3 &= \frac{1}{80},\\
\vec{p}_4 &= \frac{1}{12}(4,0,4,0,1,1,3,3), & w_4 &= \frac{1}{60},\\
\vec{p}_5 &= \frac{1}{12}(4,0,4,0,1,1,1,1), & w_5 &= \frac{1}{40},\\
\vec{p}_6 &= \frac{1}{12}(3,1,3,1,1,1,1,1), & w_6 &= \frac{1}{30},\\
\vec{p}_7 &= \frac{1}{12}(3,1,1,1,1,1,3,1), & w_7 &= \frac{1}{30},
\end{aligned}$$

by the coordinate permutations (12), (13), (24), (57), (68) and (15), (26), (37), (48).

The 196560 short vectors of the Leech lattice form an 11-design on S^{23}. The lattice has a space Eisenstein lattice structure, which Conway and Sloane call the *complex Leech lattice* [4, sect. 7.8]. The complex basis that they give leads to a 5-cubature

formula on Δ_{11} generated by the points

$$\begin{aligned}
\vec{p}_1 &= \frac{1}{2}(1,1,0,0,0,0,0,0,0,0,0,0), & w_1 &= \frac{1}{10920},\\
\vec{p}_2 &= \frac{1}{6}(1,1,1,1,1,1,0,0,0,0,0,0), & w_2 &= \frac{9}{3640},\\
\vec{p}_3 &= \frac{1}{18}(7,1,1,1,1,1,1,1,1,1,1,1), & w_3 &= \frac{27}{1820},\\
\vec{p}_4 &= \frac{1}{18}(4,4,1,1,1,1,1,1,1,1,1,1), & w_4 &= \frac{27}{3640},
\end{aligned}$$

by the action of the Mathieu group M_{12}. In other words, the coordinates of $\vec{p}_2$ are permuted in the pattern of the (12, 6, 5) Steiner system, and the points of the other coordinate are permuted freely. The total is 276 points. Another interesting basis of the plane consists of the mutual eigenplanes of the $(\mathbb{Z}/5)^3$ subgroup of the isometry group of the Leech lattice. Rains has computed that the corresponding 5-cubature formula on Δ_{11} has 498 points, consisting of 22 orbits of the surviving coordinate permutations. However, since none of the Barnes–Wall formulas on Δ_7 is optimal, it is not clear that the smaller of these formulas is either.

3. Torus constructions. The constructions in the next section depend on an auxiliary case that generally works out better than cubature on S^n, $\mathbb{C}P^n$, and Δ_n, namely cubature on algebraic tori. There is a developed theory for a special case of this problem known as trigonometric cubature [6, 7]. We will describe a more general class of problems, with one new result for the classic trigonometric cubature problem (Theorem 3.3).

Consider a torus group $T \cong (S^1)^n$ together with a faithful linear action on some real vector space $V \cong \mathbb{R}^N$. Then we can identify T with any faithful orbit O to give it a real algebraic structure. Since T is a compact group, it also comes with Haar measure (i.e., uniform measure). Given both structures, we can then consider cubature formulas for T. If a cubature formula F is a t-design and forms a subgroup of T, then it is called a *lattice formula* or an *additive t-design*.

PROPOSITION 3.1. *The lattice cubature problem on T is equivalent to a lattice packing problem as follows:*

1. *The real algebraic structure on T does not depend on the orbit O or the base point chosen on O. The ring of polynomials on T is the same as the character ring $R(T)$.*
2. *Every character $\chi : T \to \mathbb{C}$ is homogeneous as a polynomial on T. Its degree defines a norm on $\widehat{T}$, the character group of T. The norm is generated by unit steps corresponding to the characters that appear in $V \otimes \mathbb{C}$.*
3. *The characters that are constant on a subgroup $F \subset T$ form a sublattice $\widehat{F} \subseteq \widehat{T}$. This correspondence is a bijection between finite subgroups and sublattices such that $|F| = [\widehat{T} : \widehat{F}]$.*
4. *The subgroup F is a t-design if and only if $\widehat{F}$ has minimum distance $d = t+1$.*

The proof of Proposition 3.1 is lengthy but routine and can be left as an exercise for the reader. It is essentially established in the literature when $T = T(\mathrm{SO}(2n))$ acts on $\mathbb{R}^{2n}$ by separate rotations in n orthogonal planes. This case is equivalent to the (cubic) trigonometric cubature problem, defined as cubature formulas on the n-cube $[0, 2\pi)^n$, which are exact for trigonometric polynomials of degree t [7]. All of the arguments generalize without change.

When $T = T(\mathrm{SO}(2n))$, $\widehat{T}$ is naturally identified with $\mathbb{Z}^n$, and its norm is the ℓ_1

or taxicab norm. Another torus of interest to us is $T = T(\mathrm{PSU}(n+1))$, the group of diagonal unitary matrices with determinant 1 modulo its center. It acts on $\mathbb{C}^{(n+1)^2}$, interpreted as the space of $(n+1) \times (n+1)$ complex matrices, by conjugation. In this case $\widehat{T} = A_n$, the root lattice of $\mathrm{PSU}(n+1)$, and its norm is defined by taking the roots of A_n as unit steps.

THEOREM 3.2. *Given a real algebraic torus T of dimension n, let $K \subset \widehat{T} \otimes \mathbb{R}$ be the real convex hull of the unit steps in $\widehat{T}$. Let $\delta_L(K)$ be the lattice packing density of K, and let $\operatorname{Vol} K$ be the volume of K normalized by $\widehat{T}$. Let $t \geq 0$ and let $d = t+1$. Then the best additive t-design F on T has at least*

$$\frac{d^n(\operatorname{Vol} K)}{2^n \delta_L(K)} \leq |F| \leq \frac{d^n(\operatorname{Vol} K)}{2^n \delta_L(K)}(1 + O(t^{-1}))$$

points.

Theorem 3.2 has been noted independently by several people for trigonometric cubature, but may originally be due to Frolov [11]. In outline, a lattice $\widehat{F} \subset \widehat{T}$ with minimum distance d produces a packing of the dilated body $\frac{d}{2}K$. The packing density $\delta_L(K)$ then yields a lower bound on the index of $\widehat{F}$. On the other hand, if Λ is the center lattice of the best packing of K, then when t is large, $\frac{d}{2}\Lambda$ can be approximated by a sublattice of $\widehat{T}$. This establishes the upper bound.

Note also that the best Λ has rational coordinates relative to $\widehat{T}$ (or they can be made rational if Λ is not unique), because K is a rational polytope. Thus there exist special distances d such that the best F has exactly

$$\frac{d^n(\operatorname{Vol} K)}{2^n \delta_L(K)}$$

points. Also if some d achieves exactitude, then so does kd for every $k > 1$.

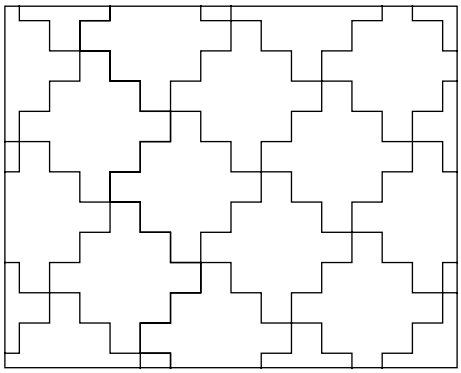
If $T = T(\mathrm{SO}(2n))$ is the standard cubic n-torus, then K is the n-cross polytope C_n^*. For example, Minkowski established that the lattice packing density of the regular octahedron C_3^* is $\frac{18}{19}$. Thus there exists an additive 5-design on $T(\mathrm{SO}(6))$ with 38 points [11, 23].

Since C_2^* is a square, its packing density is 1. Noskov [23] found the best discrete approximation to this packing for every distance d to obtain lattice rules for $T(\mathrm{SO}(4))$. If $d = 2s$, then the best approximation is exact and there is a $(2s-1)$-design with $2s^2$ points. If $d = 2s+1$, then the best approximation corresponds to the tiling of $\mathbb{Z}^2$ by the discrete ℓ_1 ball of radius s, or the tiling of the plane $\mathbb{R}^2$ by certain Aztec diamonds, as shown in Figure 5(a). The ball and the corresponding $2s$-design have $s^2 + (s+1)^2$ points.

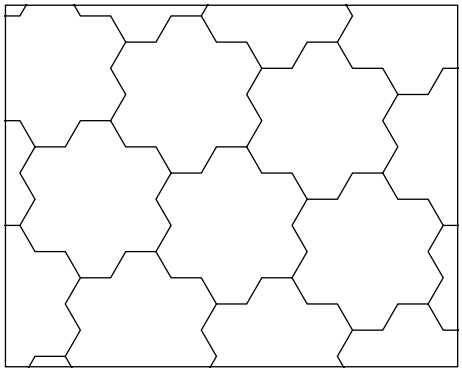
Noskov's designs have a counterpart for $T(\mathrm{PSU}(3))$, where $T(\widehat{\mathrm{PSU}(3)}) = A_2$ is the triangular lattice. If we identify A_2 with the Eisenstein integers $\mathbb{Z}[\omega]$, then the highest-density lattice with minimum distance d is the ideal generated by

$$\left\lfloor \frac{d}{2} \right\rfloor - \omega \left\lfloor \frac{d+1}{2} \right\rfloor.$$

When $d = 2s$, the dual $(d-1)$-design has $3s^2$ points and exactly matches the tiling of the plane by regular hexagons. When $d = 2s+1$, it has $3s^2 + 3s + 1$ points and corresponds to a tiling of the plane by the hexagonal polyhex of order s (an "Afghan hexagon"), as shown in Figure 5(b).



(a) Aztec diamonds for $T(\mathrm{SO}(4))$.



(b) Afghan hexagons for $T(\mathrm{PSU}(3))$.

FIG. 5. *Polyomino and polyhex tilings that lead to lattice rules.*

THEOREM 3.3. *Let $t \geq 0$. The torus $T(\mathrm{SO}(2n))$ has a $(2t+1)$-design with $O(n^t)$ points. More precisely it has a $2t$-design with $(2n)^t(1+o(1))$ points as $n \to \infty$ and a $(2t+1)$-design with twice as many points. The torus $T(\mathrm{PSU}(n+1))$ has a t-design with $n^t(1+o(1))$ points as $n \to \infty$.*

Remark 3.1. Theorem 3.3 can be compared with a prior result by Cools, Novak, and Ritter [5], who obtained negative interior (NI) t-cubature formulas for $T(\mathrm{SO}(2n))$ with $O(n^t)$ points. Another comparison is with the lower bound due to Stroud [31], Noskov [22], and Mysovskikh [20] for trigonometric $2t$-cubature:

$$|F| \geq \frac{(2n)^t(1-o(1))}{t!}.$$

The Möller bound applies to trigonometric $(2t+1)$-cubature in its interpretation as cubature on $T(\mathrm{SO}(2n))$ because it is a centrally symmetric algebraic variety. It yields the inequality

$$|F| \geq \frac{2(2n)^t(1-o(1))}{t!}.$$

Section 5 establishes an analogous lower bound for t-cubature on $T(\mathrm{PSU}(n))$ (Corollary 5.4):

$$|F| \geq \frac{n^t(1-o(1))}{\lceil t/2 \rceil! \lfloor t/2 \rfloor!}.$$

Thus for each t, Theorem 3.3 is asymptotically optimal to within a constant factor, even though the lower bounds do not require that F be positive or interior.

Proof. By Proposition 3.1, our task is to find suitable lattices in $\mathbb{Z}^n = T(\widehat{\mathrm{SO}(2n)})$ and $A_n = T(\widehat{\mathrm{PSU}(n+1)})$. Our task is fulfilled by Craig lattices [4, sect. 8.6] in A_n and skew analogues of Craig lattices in $\mathbb{Z}^n$. We describe the A_n case first.

We can model A_n as the set of points in $\mathbb{Z}^{n+1}$ with zero coordinate sum. Let $p \geq n+1$ be prime, and index the standard basis $\{\vec{e}_a\}$ of $\mathbb{Z}^{n+1}$ by some subset $N \subset \mathbb{Z}/p$. Let $p > t > 0$, and define a linear map $\phi : \mathbb{Z}^{n+1} \to (\mathbb{Z}/p)^t$ by

$$\phi(\vec{e}_a) = (a, a^2, \dots, a^t).$$

We define the lattice

$$\Lambda^{(t)}(A_n) = \ker \phi \cap A_n.$$

Plainly the index of $\Lambda^{(t)}(A_n)$ is at most $p^t = n^t(1+o(1))$. (If n is large and $p \approx n$, it is p^t, because any lower power of p would violate the Stroud-type bound.)

We claim that the distance of $\Lambda^{(t)}(A_n)$ is $t+1$. To show this, we will show that ϕ is injective on the simplex $\Delta_n^{(t)} \subset \mathbb{Z}_{\geq 0}^{n+1}$ of nonnegative vectors with coordinate sum t. A vector $\vec{x} \in A_n$ with root-step length at most t can be expressed as the difference of two vectors in $\Delta_n^{(t)}$; therefore injectivity shows that none of these vectors lie in $\Lambda^{(t)}(A_n)$.

We can interpret a vector $\vec{x} \in \Delta_n^{(t)}$ as a multiset of S over the set $\{0, \dots, n\}$ with $|S| = t$: if

$$\vec{x} = \sum_a m_a \vec{e}_a,$$

then m_a is the multiplicity of $a \in S$. In this interpretation, $\phi(\vec{x})$ is the list of power sums

$$\sum_{a \in S} a^k$$

for $1 \leq k \leq t$. By standard inversion formulas [28], these power sums determine the elementary symmetric functions of the elements of S when $p > t$, which are the coefficients of the polynomial

$$\prod_{a \in S} (x - a).$$

Thus $\phi(\vec{x})$ determines S as a multiset and the vector $\vec{x}$, and it is injective on $\Delta_n^{(t)}$.

For $\mathbb{Z}^n$ (with the ℓ_1 norm), let $p > 2n$ be prime. Index the standard basis $\{\vec{e}_a\}$ of $\mathbb{Z}^n$ by some subset $N \subset \mathbb{Z}/p$ such that N is disjoint from $-N$. Define $\phi : \mathbb{Z}^n \to (\mathbb{Z}/p)^t$ by

$$\widehat{\phi}(\vec{e}_a) = (a, a^3, a^5, \dots, a^{2t-1}),$$

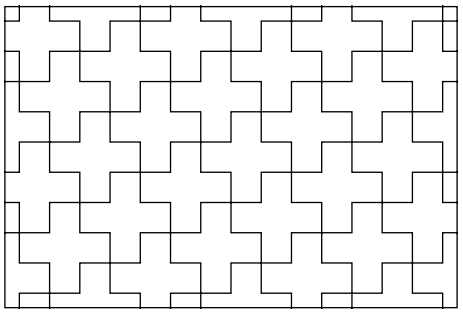


FIG. 6. *A Hamming-like "plus" tiling.*

and define

$$\Lambda^{(t)}(\mathbb{Z}^n) = \ker \widehat{\phi}.$$

Then the index of $\Lambda^{(t)}(\mathbb{Z}_n)$ is again at most (and usually exactly) $p^t = n^1(1 + o(1))$. Its distance property can be explained by embedding $\mathbb{Z}^n$ isometrically into A_{2n} using the map

$$\alpha : \vec{e}_a \mapsto \vec{e}_a - \vec{e}_{-a}.$$

Then

$$\Lambda^{(t)}(\mathbb{Z}^n) = \alpha^{-1}(\Lambda^{(2t)}(A_n)).$$

Since $\Lambda^{(2t)}(A_n)$ has distance at least $2t + 1$, so does $\Lambda^{(t)}(\mathbb{Z}^n)$. We can boost the distance to $2t + 2$ by passing to its even-sum sublattice. □

Remark 3.2. When $t = 1$, the number p in the proof of Theorem 3.3 need not be prime, and the lattices $\Lambda^{(1)}(\mathbb{Z}_n)$ and $\Lambda^{(1)}(A_n)$ produce lattice tilings of the ball of ℓ_1-radius 1 in $\mathbb{Z}^n$ and the combinatorial simplex $\Lambda^{(1)}$ in A_n. For example, when $n = 2$, these tilings are equivalent to familiar tilings of the plus pentomino (Figure 6) and the triangle trihex. The plus tiling resembles combinatorial tilings coming from Hamming codes [4, sect. 3.2]. More generally, Craig lattices resemble low-distance BCH codes. This resemblance is what led the author to Theorem 3.3.

4. Fibration constructions. The projection construction in section 2, while instructive, is backwards in a sense: It is harder to make t-cubature formulas for $\mathbb{C}P^{n-1}$ and S^{2n-1} than for Δ_{n-1} for most values of n and t. In this section we will use the same projections to lift cubature formulas to spheres and projective spaces from simplices. The construction also requires the definition and construction of cubature formulas on tori from section 3.

THEOREM 4.1. *Let $\alpha : X \to Y$ be one of the three projections h, π, or τ_2, and let T be a generic fiber. Let $s = 2t+1$ when $X = S^{2n-1}$ and $s = t$ when $X = \mathbb{C}P^{n-1}$. Given an interior (or boundary) t-cubature formula F for Y and an interior s-cubature formula F_T for T, there is a twisted product s-cubature formula $F_X = F_T \ltimes F_Y$ for X. It satisfies $|F_X| = |F_T|\ |F_Y|$ and it inherits positivity from its factors. In the boundary case, $|F_X| \le |F_T|\ |F_Y|$.*

Note that in the three cases, T is isomorphic to S^1, $T(\mathrm{SO}(2n))$, and $T(\mathrm{PSU}(n))$, respectively.

Proof. Let σ_Y be the discrete measure on Y corresponding to the cubature formula F_Y, and let $\sigma_X = \alpha^*(\sigma_Y)$ be the pull-back of σ_Y to X. In other words, for each point p of weight w in F_Y, σ_X has a term consisting of uniform measure on the torus fiber $\alpha^{-1}(p)$. Also let μ_X and μ_Y be normalized uniform measure on X and Y.

We claim that

$$\int_X P(\vec{x})d\mu_X = \int_X P(\vec{x})d\sigma_X$$

for any polynomial of P of degree s; in other words μ_X and σ_X are *s-cubature equivalent* [18]. If we assume the natural group structure on T, then T acts on X in each of the three cases with Y as the set of orbits. Then

$$\int_X P(\vec{x})d\sigma_X = \int_X P_T(\vec{x})d\sigma_X, \qquad \int_X P(\vec{x})d\mu_X = \int_X P_T(\vec{x})d\mu_X,$$

where P_T is the average of P with respect to the action of T. The polynomial P_T then descends to a polynomial P_Y on Y of degree t, and

$$\int_X P_T(\vec{x})d\sigma_X = P(F_Y), \qquad \int_X P_T(\vec{x})d\mu_X = \int_Y P_Y(\vec{y})d\mu_Y$$

because α preserves measure.

The measure σ_X evidently has a twisted product s-cubature formula $F_X = F_T \ltimes F_Y$ given by replacing each fiber by a copy of F_T. (A singular fiber corresponding to a boundary point of T can be replaced by a projection of F_T.) Since μ_X and σ_X are s-cubature equivalent, F_X is a cubature formula for μ_X as well. □

Remark 4.1. The proof of Theorem 4.1 is analogous to that of Sobolev's theorem with the finite group G replaced by the torus T. Indeed, the argument works for any compact group.

The simplest case of Theorem 4.1 is the Hopf map h. In this case the theorem says that a t-cubature formula F on $\mathbb{C}P^{n-1}$ lifts to a $(2t+1)$-cubature formula F' on S^{2n-1} with $(2t+2)|F|$ points. This relation was also observed by König [16].

Corollary 4.2. *The n-sphere S^n has a 7-cubature formula with $O(n^4)$ points for all n, more precisely $4n^4(1+o(1))$ points. The 3-sphere S^3 has a $(2s+1)$-cubature formula with*

$$|F| = \begin{cases} (s+1)(s^2+3), & s \text{ odd}, \\ (s+1)(s^2+s+2), & s \text{ even}, \end{cases}$$

points.

Proof. The simplex Δ_n has a 3-cubature formula with $O(n)$ points [18] constructed using Hadamard designs. This can be combined with the 7-design on $T(\mathrm{SO}(2n))$ with $O(n^3)$ points provided by Theorem 3.3, for a total of $O(n^4)$ points. More precisely, the formula on Δ_n has points at the corners, each of which lifts to $O(n)$ points; a point in the center, which lifts to $O(n^3)$ points; and $2n+o(n)$ points on $\lfloor n/2 \rfloor$-dimensional faces, each of which lift to $2n^3(1+o(1))$ points. Only the last family of points is significant, and it comprises $4n^4(1+o(1))$ points.

Noskov's formulas from section 3 include a $(2s+1)$-design on the square torus $T(\mathrm{SO}(4))$ with $2(s+1)^2$ points. When s is odd, this can be combined with the Gauss–Lobatto s-quadrature formula on the interval Δ_2 with $\frac{s+3}{2}$ points. Two of the fibers are circles and can be replaced by $2(s+1)$ points instead of $2(s+1)^2$ points.

The total is then $(s+1)(s^2+3)$ points. When s is even, it can be combined with the Gauss–Radau s-quadrature formula with $\frac{s+2}{2}$ points. In this case one fiber is a circle. □

Remark 4.2. The first part of Corollary 4.2 actually yields a 7-design on S^{n-1} with $O(n^6)$ points whenever there is a Hadamard matrix of order n. In this case the weights of the 3-cubature formulas on Δ_{n-1} are $\frac{2}{n(n+1)(n+2)}$ at the corners, $\frac{n}{2(n+1)(n+2)}$ at the faces, and $\frac{4n}{(n+1)(n+2)}$ at the center. Thus the weights are all commensurable up to a factor of $2n^2$ (note that n is even), and the cubature formula can be interpreted as a 7-design with this multiplicity factor. Moreover, copies of the lattice formulas on the torus fibers can be shifted to make the design multiplicity-free. Better yet, the design need have only $O(n^4)$ points if, for example, $n = 4 \cdot 7^k$. In this case the prime p used in the proof of Theorem 3.3 can be replaced by the prime power 7^{k+1}. The number of points on each fiber then compensates for all but a bounded part of the factor of $2n^2$ in the weights.

The previous best construction of 7-designs on S^{n-1} is due to Sidelnikov [26] and requires $O(2^{k(k+1)/2})$ points when $n = 2^k$.

A useful variant of Theorem 4.1 involves the moment map $\tau_2 : \mathbb{R}^{2n} \to \mathbb{R}^n$ defined by the same formula as $\tau_2 : S^{2n-1} \to \Delta_{n-1}$, namely,

$$\tau_2(x_1, \ldots, x_{2n}) = (x_1^2 + x_2^2, x_3^2 + x_4^2, \ldots, x_{2n-1}^2 + x_{2n}^2).$$

This τ_2 takes uniform measure on the ball B_n to uniform measure on the simplex

$$\Delta_n' = \Big\{ \vec{x} | x_k \geq 0, \sum x_k \leq 1 \Big\}.$$

When $n = 2$, Noskov's formulas together with some ad hoc cubature formulas for the triangle yield some economical formulas for the 4-ball B_4. For example, there is a PB 3-cubature formula on the triangle $x, y \geq 0,\ x + y \leq 1$ with points and weights generated from

$$\vec{p}_1 = \left(\frac{2}{5}, \frac{2}{5}\right), \qquad w_1 = \frac{25}{48},$$
$$\vec{p}_2 = \left(\frac{161 + 17\sqrt{14}}{1344}, 0\right), \qquad w_2 = \frac{16 - 2\sqrt{14}}{25}$$

by switching the coordinates and negating $\sqrt{14}$. This formula lifts to 1 generic fiber in B_4, which can be replaced with 32 points and 4 singular fibers, which are circles and can be replaced with 8 points each. The result is a PI 7-cubature formula on B_4 with 64 points.

Wandzura and Xiao [33] found competitive PI s-cubature formulas for s up to 30; Figure 7 shows one example. Most of these yield competitive PI $(2s+1)$-cubature formulas on B_4 and S^5. The formulas could probably be improved further with a search on the triangle that favors nodes on the edges.

The map $\tau_2 : \mathbb{R}^{2n} \to \mathbb{R}^n$ also takes Gaussian measure on $\mathbb{R}^{2n}$ to exponential measure on $\mathbb{R}^n_+$. For example, there is a PB exponential 4-cubature formula on $\mathbb{R}^2_+$ with points and weights generated from

$$\vec{p}_1 \approx (1.50766353, 1.50766353), \qquad w_1 \approx 0.354104443,$$
$$\vec{p}_2 \approx (6.29508677, 1.76717584), \qquad w_2 \approx 0.00876905581,$$
$$\vec{p}_3 \approx (0.285606152, 0), \qquad w_3 \approx 0.556110610,$$
$$\vec{p}_4 \approx (3.27491992, 0), \qquad w_4 \approx 0.0722468398$$

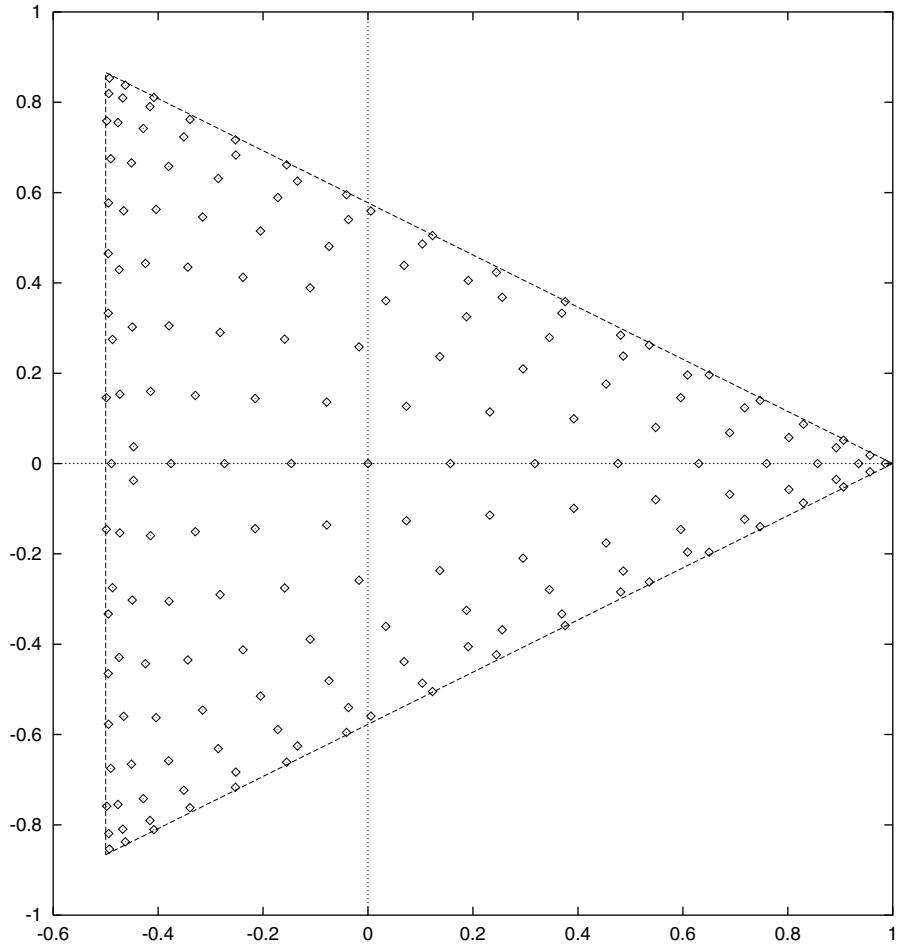

FIG. 7. *A* 175*-point* 30*-cubature formula found by Wandzura and Xiao* [33].

by switching the coordinates. It lifts to 3 generic fibers with 50 points each and 4 singular fibers with 10 points each. The result is a positive Gaussian 7-cubature formula on $\mathbb{R}^4$ with 190 points.

5. An algebraic lower bound. Let X be the Zariski closure of the support of a measure μ on $\mathbb{R}^n$, and let A be the ring of polynomial functions on X. (Recall that the *Zariski closure* of a set S, or closure in the Zariski topology, is the smallest algebraic variety containing S.) In other words, A is the quotient of $\mathbb{R}[\vec{x}\,]$ by the ideal I_X of polynomials that vanish on X. The ring A has a degree filtration coming from the degree filtration of $\mathbb{R}[\vec{x}\,]$. Stroud [31, 30] established an important lower bound on an arbitrary $2t$-cubature formula F for μ (not necessarily positive or interior), as follows.

THEOREM 5.1 (after Stroud). *If F is a $2t$-cubature formula for μ, then*

$$|F| \geq \dim A_{\leq t}.$$

Noskov [22] and Mysovskikh [20] observed that this applies to trigonometric cu-

bature by taking $X = T(\mathrm{SO}(2n))$. (According to Möller [19], the bound was also noted independently in special cases by other authors, e.g., Radon.)

Proof. Define a bilinear form

$$b : A_{\leq t} \times A_{\leq t} \to \mathbb{R}$$

by

$$b(P, Q) = \int_X P(\vec{x})Q(\vec{x})d\mu.$$

The form b is positive-definite because the integrand of $b(P, P)$ is nonnegative; moreover, if the integrand vanishes on X, then $P = 0$ as an element of A. Therefore b is nondegenerate, and its rank is $\dim A_{\leq t}$. On the other hand, the integrand lies in $A_{\leq 2t}$, so a $2t$-cubature formula F leads to the formula

$$b(P, Q) = \sum w_k P(\vec{p}_k)Q(\vec{p}_k).$$

This formula realizes b as a sum of $|F|$ rank 1 forms. Therefore $|F|$ is at least the rank of b, as desired. ∎

An interesting scholium of the proof of Theorem 5.1 is that if F is a $2t$-cubature formula, then its points suffice to interpolate polynomials on X of degree t.

It is curiously difficult to improve the Stroud bound for odd-degree cubature. However, the inference that lower bounds improve mainly in even degrees is not consistent with the Hopf fibrations

$$h : S^{2n+1} \to \mathbb{C}P^n, \qquad h : T(\mathrm{SO}(2n + 2)) \to T(\mathrm{PSU}(n + 1)).$$

On the one hand, these maps are quadratic and double the degree of cubature in passing from the target to the domain; in particular, they do not preserve odd and even. On the other hand, sections 2 and 4 together show that cubature in the domain and target are comparably difficult when $n \gg t$.

The Hopf fibration example suggests a generalization of Stroud's theorem involving group actions and degree doubling.

THEOREM 5.2. *Let μ be a measure on $\mathbb{R}^n$, and let X be the Zariski closure of its support. Let $Y \subset \mathbb{R}^k$ be another affine real algebraic variety on which a compact group G acts. Let A and B be the rings of complex-valued polynomials on X and Y, and suppose that there is a ring isomorphism*

$$A \xrightarrow{\cong} \mathrm{Inv}_G(B)$$

that doubles the filtration degree of A. Let V be a unitary representation of G, and define the filtered vector space

$$M = \mathrm{Inv}_G(B \otimes V).$$

If F is a t-cubature formula for μ, then

$$|F| \geq \frac{\dim M_{\leq t}}{\dim V}.$$

We will always take Y to be the coordinate ring of another algebraic variety Y, which is a principal G-bundle over X, such that the bundle projection $\alpha : Y \to X$

is quadratic. The A-module M can then be understood as the space of polynomial sections of a vector bundle E over X with fiber V. The sections in $M_{\le t}$ then behave like polynomials elements of A, except that their degrees are half-integers. If $Y = X$ and G is trivial, then E is the trivial line bundle and Theorem 5.2 reduces to Theorem 5.1. The hypotheses of Theorem 5.2 have been chosen so that the proof of Theorem 5.1 generalizes to the case when E is not trivial.

Proof. The vector space M (which is naturally an A-module) has an A-valued Hermitian inner product a induced by the Hermitian inner product on V. More precisely, let $\overline{V}$ be the representation conjugate to V and let

$$\overline{M} = \mathrm{Inv}_G(\overline{V} \otimes B)$$

be the corresponding conjugate of M. (Note that A and B are both self-conjugate by hypothesis.) Let

$$\varepsilon : V \otimes \overline{V} \longrightarrow \mathbb{C}$$

be the linearization of the standard Hermitian inner product on V, and let

$$m : B \otimes B \longrightarrow B$$

be the linearization of multiplication on B. Let a' be the composition

$$B \otimes V \otimes \overline{V} \otimes B \xrightarrow{I \otimes \varepsilon \otimes I} B \otimes B \xrightarrow{m} B.$$

We can restrict the domain to

$$M \otimes \overline{M} = \mathrm{Inv}_G(B \otimes V) \otimes \mathrm{Inv}_G(\overline{V} \otimes B).$$

Since the restricted domain is G-invariant, we can then restrict the target to A. Let a be this restriction of a'. Although given as a linear map on $M \otimes \overline{M}$, it can be reinterpreted as a Hermitian inner product on M. In more geometric terms, if M comes from a bundle E over X with fiber V, then $a(f, g)$ is the pointwise inner product of two sections f and g of E.

Note that a is positive-definite in the sense that

$$a(f, f)(\vec{x}) \ge 0$$

for all $\vec{x} \in X$, and if $a(f, f) = 0$, then $f = 0 \in M$. The rest of the proof follows that of Theorem 5.1: Define a complex-valued Hermitian inner product b on $M_{\le t}$ by

$$b(f, g) = \int_X a(f(\vec{x}), g(\vec{x}))d\mu.$$

Then b is also positive-definite, because a is positive-definite and μ is Zariski-dense in X. Thus, b has rank $\dim M_{\le t}$. A cubature formula F realizes b as a sum of $|F|$ terms of rank at most $\dim V$. □

We state the following three special cases of Theorem 5.2 as corollaries.

Corollary 5.3. *If $|F|$ is a $(2t+1)$-cubature formula on $\mathbb{C}P^n$, then*

$$|F| \ge \binom{n+t}{n}\binom{n+t+1}{n}.$$

Proof. Let Y be S^{2n+1}, let G be $S^1 \subset \mathbb{C}$, and let G act by complex rotation on $\mathbb{C}^{n+1} \supset S^{2n+1}$. The bundle projection $\alpha : Y \to X$ is the Hopf map h. Let $V = L_1$ be the tautological representation of S^1, so that E is the tautological line bundle on $\mathbb{C}P^n$. The space $M_{\leq 2t+1}$ is explicitly realized as the space of homogeneous polynomials in $\vec{z}$ and $\overline{\vec{z}}$ of bidegree $(t+1, t)$. The result follows by noting that

$$\dim M_{\leq 2t+1} = \binom{n+t}{n}\binom{n+t+1}{n}$$

and that $\dim L_1 = 1$. ∎

COROLLARY 5.4. *If $|F|$ is a t-cubature formula on $T(\mathrm{PSU}(n+1))$, then*

$$|F| \geq \frac{n^t(1-o(1))}{\lceil t/2 \rceil! \lfloor t/2 \rfloor!}$$

uniformly as $n \to \infty$.

Proof. Let Y be the torus $T(\mathrm{SO}(2n+2))$, and let $G = S^1$ again act by complex rotation in $\mathbb{C}^{n+1}$. In this case $M_{\leq 2t+1}$ is spanned by the space of monomials in $\vec{z}$ and $\overline{\vec{z}}$ of bidegree $(s+1, s)$ with $s \leq t$ and with the relation

$$z_k \overline{z}_k = 1$$

for all k. Its dimension is the number of points in the Minkowski difference

$$\Delta_n^{(t+1)} - \Delta_n^{(t)},$$

where $\Delta_n^{(t)}$ is the discrete simplex defined in the proof of Theorem 3.3. This is very similar to Theorem 5.1 for $2t$-cubature, because

$$\dim A_{\leq t} = |\Delta_n^{(t)} - \Delta_n^{(t)}|.$$

There is no concise formula for either number, but there is a concise estimate for fixed t in the limit $n \to \infty$. If E is either the trivial bundle when t is even or the bundle L_1 (restricted from $\mathbb{C}P^n$) when t is odd, then

$$\dim M_{\leq t} \approx \binom{n+1}{\lceil t/2 \rceil, \lfloor t/2 \rfloor, n+1-t} \approx \frac{n^t}{\lceil t/2 \rceil! \lfloor t/2 \rfloor!}$$

as $n \to \infty$, as desired. ∎

Remark 5.1. When F is a lattice formula, Corollary 5.4 is equivalent to Minkowski's classic upper bound on the density $\widehat{F}$ as a lattice packing of the discrete simplex $\Delta_n^{(t)}$. This and the fact that the Hopf fibration is quadratic led the author to Theorem 5.2.

COROLLARY 5.5. *If μ is a Zariski-dense measure on S^n and F is a $(2t+1)$-cubature formula for μ, then*

$$|F| \geq 2\binom{n+t}{t}.$$

Remark 5.2. Corollary 5.5 matches the Möller bound [19] for cubature on S^n, but it is more general because the measure μ need not be centrally symmetric.

Proof. The idea is to let $Y = \mathrm{Spin}(n+1)$ and $G = \mathrm{Spin}(n)$, where $\mathrm{Spin}(n)$ is the connected double cover of the Lie group $\mathrm{SO}(n)$. Then

$$X = \mathrm{Spin}(n+1)/\mathrm{Spin}(n) = \mathrm{SO}(n+1)/\mathrm{SO}(n) = S^n.$$

Our choice for the representation V is the spinor representation of $\mathrm{Spin}(n)$ when n is odd and a semispinor representation when n is even. The rest of the argument is a review of standard but nontrivial representation theory. We will borrow some specific calculations from Koike [15]. For an introduction to representation theory of Lie groups, see Varadarajan [32] or Fulton and Harris [12].

We divide the argument into steps. It is convenient to postpone the cases with $n \leq 3$ because of notational discrepancies.

1. If G is a compact, connected, and simply connected Lie group of rank n, then it has an irreducible unitary representation V (an irrep) for every list of nonnegative integers $(a_1, a_2, \ldots, a_n)$. The list is usually expressed in the vector form
$$\vec{\lambda} = a_1\vec{\lambda}_1 + a_2\vec{\lambda}_2 + \cdots + a_n\vec{\lambda}_n,$$
where $\vec{\lambda}$ is called the highest weight of V. The standard notation for this V is $V(\vec{\lambda})$.

   Both $\mathrm{Spin}(2n)$ and $\mathrm{Spin}(2n+1)$ are compact, connected, simply connected and have rank n when $n \geq 1$, except that $\mathrm{Spin}(2)$ is not simply connected. We will denote the irrep $V(\vec{\lambda})$ of $\mathrm{Spin}(n)$ by $V(n, \vec{\lambda})$.
2. When $n \geq 4$, the representation $V(n+1, t\vec{\lambda}_1)$ is realized as the space A_t of harmonic polynomials of degree t on S^n. The representation $V(2n+1, \vec{\lambda}_n)$ is the spinor representation of $\mathrm{Spin}(2n+1)$, and its dimension is 2^n. The representations $V(2n, \vec{\lambda}_{n-1})$ and $V(2n, \vec{\lambda}_n)$ are the semispinor representations of $\mathrm{Spin}(2n)$, and the dimension of each is 2^{n-1}.
3. The matrix entries of $V(n, \vec{\lambda})$ for all $\vec{\lambda}$ can be viewed as polynomials on $\mathrm{Spin}(n)$. (Indeed, this works for any compact Lie group.) Their span forms a ring which is generated by the entries of $V(n, \vec{\lambda}_k)$ for all k. We can define a degree filtration by giving every matrix entry of every $V(n, \vec{\lambda}_k)$ degree 2, except for spinor or semispinor representations, which are given degree 1.
4. For any irrep $V(n, \vec{\lambda})$, we can define a representation
$$M(n, \vec{\lambda}) = \mathrm{Ind}_{\mathrm{Spin}(n)}^{\mathrm{Spin}(n+1)} V(n, \vec{\lambda}).$$
There is more than one way to define representation induction in this context. One way is in terms of the algebraic structure in the previous step. In this case, $M(n, \vec{0})$ is the subring of polynomials on $\mathrm{Spin}(n+1)$ which are constant on left cosets of $\mathrm{Spin}(n)$, or in other words the ring of polynomials on
$$S^n = \mathrm{Spin}(n+1)/\mathrm{Spin}(n).$$
Each $M(n, \vec{\lambda})$ is not only a representation of $\mathrm{Spin}(n+1)$, but also a filtered module over $M(n, \vec{0})$. To apply Theorem 5.2, we let
$$M = M(n, \vec{\lambda}), \qquad A = M(n, \vec{0}), \qquad V = V(n, \vec{\lambda}).$$
5. The structure of $M(n, \vec{\lambda})$ can be computed by branching formulas for the restriction of an irrep of $\mathrm{Spin}(n+1)$ to $\mathrm{Spin}(n)$, together with induction-restriction duality. Induction-restriction duality says in general that if H is a subgroup of G, V is a unitary irrep of G, and W is a unitary irrep of H, then the number of times that W appears in the restriction $\mathrm{Res}_G^H V$ equals the number of times that V appears in the induced representation $\mathrm{Ind}_H^G W$.

The restriction formulas were computed by Koike [15, Thms. 11.2 and 11.3]. When $\vec{\lambda} = \vec{\lambda}_n$, Koike's formulas together with the degree filtrations yield the decompositions

$$M(2n, \vec{\lambda}_n)_{\le 2t+1} \cong \bigoplus_{s \le t} V(2n+1, s\vec{\lambda}_1 + \vec{\lambda}_n)$$

and

$$M(2n-1, \vec{\lambda}_n)_{\le 2t+1} \cong \bigoplus_{0 \le s \le t} \big(V(2n, s\vec{\lambda}_1 + \vec{\lambda}_{n-1}) \oplus V(2n, s\vec{\lambda}_1 + \vec{\lambda}_n)\big).$$

6. By the Weyl dimension formula,

$$\begin{aligned}
\dim V(2n+1, s\vec{\lambda}_1 + \vec{\lambda}_n) &= 2^n \binom{2n-1+s}{s}, \\
\dim V(2n, s\vec{\lambda}_1 + \vec{\lambda}_n) &= 2^{n-1} \binom{2n-2+s}{s}, \\
\dim V(2n, s\vec{\lambda}_1 + \vec{\lambda}_{n-1}) &= 2^{n-1} \binom{2n-2+s}{s}.
\end{aligned}$$

Combining the dimension formulas with the decomposition of $M(n, \vec{\lambda})_{\le 2t+1}$ yields

$$\begin{aligned}
|F| &\ge \frac{\dim M(n, \vec{\lambda})_{\le 2t+1}}{\dim V} \\
&= \sum_{0 \le s \le t} 2\binom{n-1+s}{s} = 2\binom{n+t}{t}.
\end{aligned}$$

This completes the proof of the result when $n \ge 4$.

The proof for $n \ge 3$ is not really different, but the notation for the representations changes because the groups involved have a simplified structure. Nonetheless, both Spin(1) and Spin(3) have a spinorial representation V, while Spin(2) has two semispinorial representations, and either one can be called V. In each case, A is the ring of polynomials on S^n with doubled degrees, the elements of V have degree 1, and

$$M = \operatorname{Ind}_{\mathrm{Spin}(n)}^{\mathrm{Spin}(n+1)} V.$$

The notation for the calculations changes, but the final answer is the same. ∎

Remark 5.3. The $n = 2$ case of Corollary 5.5 coincides with the $n = 1$ case of Corollary 5.3, and so does the proof. This was the original inspiration for Corollary 5.5.

6. A local lower bound. Our final application of moment maps is to help establish a local lower bound on the density of points of a PI or PB cubature formula on the simplex Δ_n. The bound was originally inspired by PI cubature formulas due to Wandzura and Xiao [33], which were found by simulated annealing. As in the example shown in Figure 7, the points in these formulas accumulate transversely at the edges of the triangle. Another related result is that the limiting density of the points of Gauss–Legendre quadrature (i.e., the zeros of Legendre polynomials) is $\frac{1}{\pi\sqrt{1-x^2}}$ [8].

This density can be interpreted as the linear projection of uniform measure on a circle, which is related to Archimedes' moment map (see Figure 9 below).

Theorem 6.1 and Corollary 6.2 establish a lower bound on the limiting density of any sequence of PI and PB formulas on Δ_n that generalizes the limiting density of Legendre zeros. Moreover, if the local density is high in certain regions, in particular near the vertices of Δ_n, then the weights there must be low. By this reasoning, Theorem 6.3 and Corollary 6.4 establish that a t-design on Δ_n requires many more points than an efficient t-cubature formula does as $t \to \infty$ (namely, $O(t^{2n})$ points versus $O(t^n)$ points). Along the way, Theorem 6.3 establishes that Gaussian quadrature for an arbitrary weight function is very sharply locally optimal among all positive quadrature formulas. Finally Scholium 6.5 generalizes the results for uniform measure on Δ_n to uniform measure on an arbitrary simple convex polytope.

THEOREM 6.1. *A PI or PB $2t-1$-cubature formula F on the simplex Δ_n is an ε-net with respect to the metric*

$$ds^2 = \frac{dx_0^2}{2x_0} + \frac{dx_1^2}{2x_1} + \cdots + \frac{dx_n^2}{2x_n}$$

in barycentric coordinates, where $\cos 2\varepsilon$ is the highest zero of the Jacobi polynomial $P_t^{(n-1,0)}(x)$.

In the proof and later, we will abbreviate $(n-1,0)$ as "#" in superscripts.

Proof. The idea of the proof is to find, for each $\vec{p} \in \Delta_n$ and each $\varepsilon' > \varepsilon$, a P of degree $2t-1$ on Δ_n such that

$$\int_{\Delta_n} P(\vec{x}) d\vec{x} > 0$$

but $P(\vec{x}) > 0$ only when $\vec{x} \in \Delta_n$ is in the ε'-ball $B_{\varepsilon'}(\vec{p})$ around $\vec{p}$. We can call this ball the *positive island* of $P(\vec{x})$; see Figure 8. The existence of such a polynomial P forces F to have an evaluation point in $B_\varepsilon(\vec{p})$, for otherwise $P(F) \le 0$.

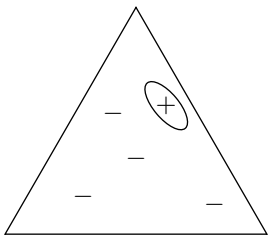

FIG. 8. *A polynomial on Δ_n with a small positive island.*

We first claim that the stated metric is the distance between fibers of the moment map π with respect to the Fubini–Study metric on $\mathbb{C}P^n$. To see this it suffices to check the following: The real locus $\mathbb{R}P^n \subset \mathbb{C}P^n$ is perpendicular to the fibers of π and meets each generic fiber 2^n times. Indeed, π is a bijection on the orthant $\mathbb{R}P^n_{\ge 0}$ with non-negative projective coordinates. Moreover, $\mathbb{R}P^n_{\ge 0}$ is isometric to the orthant $S^n_{\ge 0}$ of a unit n-sphere, and the restriction of π agrees with the restriction of the Xu map τ_1. The metric ds^2 on Δ_n is exactly the push-forward of the standard metric on $S^n_{\ge 0}$ under τ_1. See Figure 9 for an example.

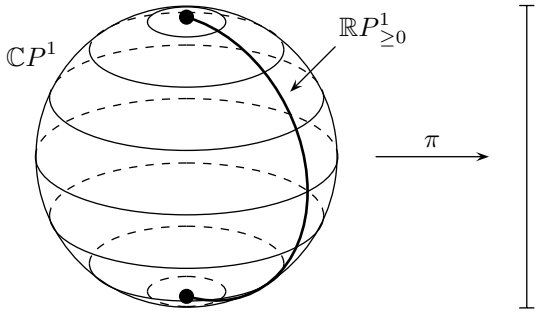

FIG. 9. *The moment map π restricts to the Xu map τ_1.*

Consider the linear projection $\alpha : \Delta_n \to [-1, 1]$ given by

$$\alpha(\vec{x}) = 2x_0 - 1. \tag{1}$$

The map α sends uniform measure on $\mathbb{C}P^n$ to the measure

$$\mu(x) = n2^{1-n}(1-x)^{n-1}.$$

The tth orthogonal polynomial with respect to this measure μ is the Jacobi polynomial $P_t^{\#} = P_t^{(n-1,0)}$. Let $p_t^{\#}$ be its highest zero.

Define a polynomial $Q_\delta : \mathbb{C}P^n \to \mathbb{R}$ by

$$Q_\delta(\vec{z}) = Q_\delta(x) = \frac{P_t^{\#}(x)^2(x - p_t^{\#} + \delta)}{(x - p_t^{\#})^2}, \tag{2}$$

where $x = \alpha(\pi(\vec{z}))$ and $\delta > 0$. It has degree $2t - 1$ as a polynomial in x, as well as a polynomial on $\mathbb{C}P^n$. Moreover, Q_δ vanishes at the zeros of $P_t^{\#}$, except at the highest zero, at which its value is positive. Therefore by Gaussian quadrature (!) with respect to the measure μ,

$$\int_{\mathbb{C}P^n} Q_\delta(\vec{z})d\vec{z} = \int_{-1}^{1} Q_\delta(x)d\mu > 0.$$

At the same time, Q is nonpositive outside of the region

$$x > p_t^{\#} - \delta.$$

This region corresponds to the ball of radius ε' around $(1 : 0 : 0 : \cdots : 0)$, with

$$2(\cos\varepsilon')^2 - 1 = \cos 2\varepsilon' = p_t^{\#} - \delta.$$

This can be confirmed by comparing with the orthant $\mathbb{R}P^n_{\geq 0}$ mentioned previously. Note that $\varepsilon' \to \varepsilon$ as $\delta \to 0$.

Given $\vec{q} \in \mathbb{C}P^n$, define $Q_{\delta,\vec{q}}$ by rotating Q_δ by some isometry of $\mathbb{C}P^n$ that takes $(1 : 0 : 0 : \cdots : 0)$ to $\vec{q}$. Define $Q^T_{\delta,\vec{p}} : \Delta_n \to \mathbb{R}$, where $\vec{p} = \pi(\vec{q})$, by averaging Q over torus fibers:

$$Q^T_{\delta,\vec{p}}(\vec{x}) = \frac{1}{|\pi^{-1}(\vec{x})|} \int_{\pi^{-1}(\vec{x})} Q_{\delta,\vec{p}}(\vec{z})d\vec{z}.$$

Then

$$\int_{\Delta_n} Q^T_{\delta,\vec{p}}(\vec{x})d\vec{x} = \int_{\mathbb{C}P^n} Q_{\delta,\vec{p}}(\vec{z})d\vec{z} > 0,$$

and $Q^T_{\delta,\vec{p}}$ is nonpositive outside of the ball of radius ε' around $\vec{p} = \pi(\vec{q})$ in the induced metric on Δ_n. Thus, $Q^T_{\delta,\vec{p}}$ has the desired properties. □

Remark 6.1. A somewhat weaker version of Theorem 6.1 holds when F is positive and exterior, but with real evaluation points. Polynomials similar to Q^T_δ can be constructed directly as products of factors that vanish on quadratic surfaces in $\mathbb{R}^n \supset \Delta_n$, with only one unsquared factor that vanishes on the boundary of $B_{\varepsilon'}(\vec{p})$. As it happens, the boundary of $B_{\varepsilon'}(\vec{p})$ is a quadratic surface. We did not refine this sketched argument into a proof with explicit estimates.

COROLLARY 6.2. *Any sequence of PI or PB t-cubature formulas on Δ_n has limiting point density $\Omega(t^n \prod_k x_k^{-1/2})$, where $\vec{x} \in \Delta_n$ is fixed and given in barycentric coordinates, and $t \to \infty$.*

Proof. The corollary follows from computing the volume form corresponding to the metric ds^2 in the statement of Theorem 6.1 and estimating the covering radius ε. The asymptotic behavior of zeros of Jacobi polynomials is given in Abramowitz and Stegun [1, p. 787]. The key step in the estimate is the limit

$$\lim_{t\to\infty} \frac{P_t^{(a,b)}(\cos\frac{\theta}{t})}{P_t^{(a,b)}(1)} = 2^a \theta^{-a} a! J_a(\theta), \tag{3}$$

where $J_a(z)$ is the ordinary Bessel function of the first kind. Convergence to the limit is analytic in θ. Thus

$$\lim_{t\to\infty} t\theta^{(a,b)}_{t,t+1-k} = j_{a,k}$$

for every fixed k, where $\cos\theta^{(a,b)}_{t,k}/t$ is the kth zero of $P_t^{(a,b)}(x)$ and $j_{a,k}$ is the kth zero of $J_a(x)$. The estimate can be established directly in our geometry by noting that $P_t^{\#}(2|z_0|^2 - 1)$ is a harmonic function on $\mathbb{C}P^n$. The harmonic equation on $\mathbb{C}P^n$ is then locally approximated by the harmonic (or Helmholtz) equation on $\mathbb{R}^{2n}$, whose radial solutions are derived from Bessel functions.

In our case,

$$\cos 2\varepsilon = \cos\frac{\theta^{\#}_{t,t}}{t}$$

for $(2t-1)$ cubature. Thus

$$\varepsilon = \frac{j_{n-1,1}}{2t}(1 + o(1)) = \Theta(t^{-1}),$$

which is also $\Theta(t^{-1})$ for t-cubature. □

THEOREM 6.3. *Let μ be an arbitrary normalized measure on $\mathbb{R}$ whose support has at least $2t$ points. Let $p_1, \ldots, p_t$ and $w_1, \ldots, w_t$ be the points and weights of Gaussian t-quadrature for the measure μ. Let F be a positive t-quadrature formula for μ. Then for each $1 \le k \le t$, F has at least one point in the half-open interval $(p_{k-1}, p_k]$, where $p_0 = -\infty$. Moreover, the total weight of all points in $(-\infty, p_1]$ is at most w_1, with equality if and only if F is the Gaussian quadrature formula.*

Note that Theorem 6.3 is further sharpened by symmetry: F must also have at least one point in each half-open interval $[p_k, p_{k+1})$, with $p_{t+1} = \infty$, and its total weight in $[p_t, \infty)$ is at most w_t.

Proof. Let $\phi_t(x)$ be the tth orthonormal polynomial with respect to μ (with either sign), and let A_t be the leading coefficient of $\phi_t(x)$. If $k = 1$, let

$$P(x) = \frac{\phi_t(x)^2(p_1 + \delta_1 - x)}{(x - p_1)^2}$$

with $\delta_1 > 0$. If $k > 1$, let

$$P(x) = \frac{\phi_t(x)^2(x - p_{k-1} - \delta_0)(p_k + \delta_1 - x)}{(x - p_{k-1})^2(x - p_k)^2}$$

with $\delta_1 \gg \delta_0 > 0$. In both cases,

$$\int_{\mathbb{R}} P(x)d\mu > 0$$

by Gaussian quadrature, while P is positive only on the interval $(p_{k-1} + \delta_0, p_k + \delta_1)$. Therefore F has at least one point in this interval. Since F has only finitely many points, the limit $\delta_1 \to 0$ establishes that F has a point in $(p_{k-1}, p_k]$.

For the second claim, let

$$P(x) = \frac{\phi_t(x)^2}{(x - p_1)^2}.$$

Then by Gaussian quadrature,

$$\int_{\mathbb{R}} P(x)d\mu = w_1 P(p_1).$$

Let $q_1, \ldots, q_k$ be the points of F which are at most p_1, and let $v_1, \ldots, v_k$ be their weights. Then

$$\int_{\mathbb{R}} P(x)d\mu = P(F) \geq \sum_{j=1}^{k} w_j P(q_j) \geq P(p_1) \sum_{j=1}^{k} w_j.$$

The first inequality holds because P is nonnegative, the second because P decreases on $(-\infty, p_1]$. ∎

COROLLARY 6.4. *The least weight of any positive t-cubature formula on Δ_n (with uniform measure) is $O(t^{-2n})$, uniformly in t. Any t-design on Δ_n has $\Omega(t^{2n})$ points.*

Proof. If F is a t-cubature formula on Δ_n, the map α (see (1)) sends it to a t-quadrature formula $\alpha(F)$ on $[-1, 1]$ with Jacobi-polynomial measure. If F is positive, then the least weight of $\alpha(F)$ is at least that of F. On the other hand, Theorem 6.3 establishes that the least weight $\alpha(F)$ is at least the last Christoffel weight w_t.

The first claim follows by estimating this weight. One of the standard formulas for the general Christoffel weight w_k is

$$w_k = -\frac{A_{t+1}||\phi_t(x)||_\mu^2}{A_t \phi_t'(p_k)\phi_{t+1}(p_k)},$$

where $\phi_t(x)$ is the tth orthogonal polynomial, A_t is its leading coefficient, and p_k is its kth root. In our case, $\phi_t = P_t^\#$, $p_k = p_{t,k}^\#$, and $k = t$. We compute

$$\|P_t^\#\|_\mu^2 = \frac{n}{2t+n} = \Theta(t^{-1}),$$
$$A_t = 2^{-t}\binom{n-1+2t}{t} = \Theta(2^t).$$

To estimate $(P_t^\#)'(p_{t,t}^\#)$ and $P_{t+1}^\#(p_{t,t}^\#)$, we again appeal to the limit in (3). Differentiating both sides by θ, we obtain

$$\lim_{t\to\infty} -\frac{(P_t^\#)'(\cos\theta/t)(\sin\theta/t)}{tP_t^\#(1)} = -a2^a\theta^{-a}a!J_a'(\theta).$$

Note that $P_t^\#(1) = \binom{t+n-1}{t} = \Theta(t^{n-1})$. For a fixed value of θ, the various parts of the limit yield

$$(P_t^\#)'\left(\cos\frac{\theta}{t}\right) = \Theta(t^{n+1}).$$

By the same token

$$(P_t^\#)'\left(\cos\frac{\theta_t}{t}\right) = \Theta(t^{n+1})$$

when θ_t approaches a fixed value of θ, as is the case when $\theta_t = \theta_{t,t}^\#$ is given by

$$p_{t,t}^\# = \cos\frac{\theta_{t,t}^\#}{t}.$$

By a similar calculation,

$$(P_{t+1}^\#)(p_{t,t}^\#) = \Theta(t^{n-2}).$$

The conclusion is that

$$w_t = \Theta(t^{2n}),$$

as desired. □

SCHOLIUM 6.5. *Let $K \subset \mathbb{R}^n$ be a convex n-polytope with N facets. Let F be a t-cubature formula on K with uniform measure. If F is PI or PB and if K is simple, then F is an ε-net with respect to the metric*

$$ds^2 = \frac{dx_0^2}{x_1} + \frac{dx_2^2}{x_2} + \cdots + \frac{dx_N^2}{x_N},$$

where $\varepsilon = O(1/t)$. If F is positive, then its least weight is $O(t^{-2n})$. If it is a t-design, then it has at least $O(t^{2n})$ points.

Proof sketch. The proof of Theorem 6.1 retains its strength if $K \subseteq \Delta_n$ and we pass from Δ_n to K, provided that the positive island of the polynomial $Q_{\delta,\vec{p}}^T$ lies within K. In this case

$$\int_K Q_{\delta,\vec{p}}^T(\vec{x})d\vec{x} \geq \int_{\Delta_n} Q_{\delta,\vec{p}}^T(\vec{x})d\vec{x} > 0.$$

In order to properly position $Q^T_{\delta,\vec{p}}$ for all $\vec{p} \in K$, we need several embeddings of K into Δ_n. For each vertex $\vec{x} \in K$, choose a linear embedding L that sends $\vec{x}$ to some vertex of Δ_n, and that sends the facets incident to $\vec{x}$ to facets of Δ_n. (Equivalently, for each vertex $\vec{x} \in K$, choose a simplex $L^{-1}(\Delta_n) \supseteq K$ whose facets include all facets of K that meet at $\vec{x}$. See Figure 10.) Then there exists a finite set of L such that the positive islands of polynomials of the form $Q^T_{\delta,vq} \circ L$ together cover K. The formula F must have a point in each island, which establishes that F is an ε-net.

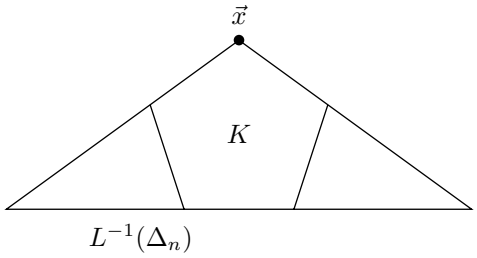

FIG. 10. *A simplex $L^{-1}(\Delta_n)$ whose facets contain facets of K that meet at $\vec{x}$.*

Similarly, the proofs of Theorem 6.3 and Corollary 6.4 retain their strength if a uniform measure on K projects by a map α to a measure ν on $[-1, 1]$ which is dominated by

$$\mu(x) = 2^{-n} n (1 - x)^{n-1}$$

and which agrees with μ in a neighborhood of 1. (Of course, μ cannot dominate ν if ν is normalized, so this condition on ν must be dropped.) In this case

$$\int_{\mathbb{R}} P(x) d\nu \geq \int_{\mathbb{R}} P(x) d\mu > 0$$

for the first half of Theorem 6.3 for the interval $(-\infty,\ p_1)$, while

$$\int_{\mathbb{R}} P(x) d\nu \leq \int_{\mathbb{R}} P(x) d\mu$$

for the second half of Theorem 6.3. A suitable projection α can be realized by positioning K in Δ_n so that it touches the vertex $x_0 = 1$, and then restricting the usual map α to K. □

7. Other comments. In this article we have studied the toric moment map on $\mathbb{C}P^n$ and on $\mathbb{C}^n$ restricted to S^{2n-1} (which can be interpreted as the level surface of an invariant Hamiltonian on $\mathbb{C}^n$) as it applies to the cubature problem. Many of the constructions apply equally well to arbitrary toric varieties. To begin with, every complex projective variety X inherits both a metric and an affine real structure from $\mathbb{C}P^n$. If X is toric, it also has a volume-preserving moment map whose image is a centrally symmetric polytope. However, the variety X rarely has much more symmetry than its moment map image.

The duality between toric cubature (particularly trigonometric cubature) and lattice packings explored in section 3 suggests a different limit of the cubature problem. Let $K \subset \mathbb{R}^n$ be a centrally symmetric convex body. For simplicity let $F = \{\vec{p}_a\}$ be a periodic discrete subset of $\mathbb{R}^n$ with a periodic weight function $\vec{p}_a \mapsto w_a$. Since

it is periodic, it has a well-defined Fourier transform $\widehat{F}$. In this setting, F is a Fourier K-cubature formula if and only if $\widehat{F}$ is disjoint from the interior of K. The (continuous) Fourier cubature problem is to minimize the density of F among all K-cubature formulas or all positive K-cubature formulas. If F is a lattice with equal weights, then $\widehat{F}$ has the same property, and the Fourier K-cubature problem reduces to finding the best lattice packing of K. It would be interesting to find examples of nonlattice formulas that are better than the best lattice formula.

We conjecture that a version of Corollary 5.5 holds, using Theorem 5.2 and the same spinor bundles, for any centrally symmetric subvariety $X \subset S^n$. That is, we conjecture Möller's bound for these varieties, even when the measure μ is not centrally symmetric.

Theorem 6.1 shows why some tempting approaches to constructing efficient PI or PB formulas on the simplex Δ_n, even the triangle Δ_2, are bound to fail. For example, if the points of a putative cubature formula F are fixed in advance, the question of whether it admits nonnegative weights for t-cubature reduces to linear programming. But if the points are arranged in some lattice with spacing $1/k$, Theorem 6.1 shows that the weights can only be nonnegative if $k = \Omega(t^2)$, so that $|F| = \Omega(t^{2n})$.

We believe that the requirement that K be simple in Scholium 6.5 is not essential. More generally we conjecture that similar results hold if K is not convex. We also conjecture that the bounds in Theorem 6.1 and Scholium 6.5 are sharp to within a constant factor. The cubature formulas found by Wandzura and Xiao support this conjecture, at least when $K = \Delta_n$.

The proof of Theorem 6.1 was partly inspired by the linear programming method for bounding kissing numbers, t-designs, and sphere packings [3, 9, 10, 14, 24]. Xu observed that the method for t-designs also yields bounds on PI t-cubature [36]. In fact, it yields an upper bound on the ℓ_2 norm of the weights of a PI t-cubature formula, which implies a lower bound on the number of points. We conjecture that linear programming methods could be used to improve the constants in Theorem 6.1.

Krylov [17] established that if $\{F_t\}$ is a sequence of interior t-cubature formulas for a measure μ, then $\{f(F_t)\}$ converges to $\int_X f(\vec{x})d\mu$ for every continuous f if and only if the ℓ_1 norm of the weights of F_t is bounded as $t \to \infty$. We conjecture then that Theorem 6.1 still holds, assuming a bound on the ℓ_1 norm of the coefficients of F instead of assuming that F is positive.

Acknowledgments. The author would like to thank Yael Karshon, Włodzimierz Kuperberg, Thomas Strohmer, and Hong Xiao for useful discussions. The author would especially like to thank Noam Elkies and Eric Rains, who obtained some of the examples and provided many other useful comments.

HOW DATA DEPENDENT IS A NONLINEAR SUBDIVISION SCHEME? A CASE STUDY BASED ON CONVEXITY PRESERVING SUBDIVISION*

THOMAS POK-YIN YU†

This paper is dedicated to the memory of Wong Suk Ling (1935–2004)

Abstract. The regularity of the limit function of a linear subdivision scheme is essentially irrelevant to the initial data. How data dependent, then, is the regularity of the limit of a nonlinear subdivision scheme? The answer is the most obvious—*it depends*. In this paper, we prove that the nonlinear convexity preserving subdivision scheme developed independently by Floater and Micchelli [M. S. Floater and C. A. Micchelli, *Approximation Theory*, Marcel Dekker, New York, 1998, pp. 209–224] and Kuijt and van Damme [F. Kuijt and R. van Damme, *Constr. Approx.*, 14 (1998), pp. 609–630] exhibits a rather strong nonlinear, data-dependent, behavior: For any $\nu \in (1, 2)$, there exists initial convex data such that the critical Hölder regularity of the limit curve is exactly ν. We also show that the limit function of any initial data always has Hölder regularity less than 2, unless if restricted to a subset of the domain at which the initial data is sampled from the convex branch of a rational polynomial of degree 2 over degree 1.

This result stands in contrast to what is reported in several recent publications on nonlinear subdivision schemes [I. Ur Rahman, I. Drori, V. C. Stodden, D. L. Donoho, and P. Schröder, *SIAM J. Multiscale Modeling and Simulation*, submitted, 2005; G. Xie and T. P.-Y. Yu, *Constr. Approx.*, 22 (2005), pp. 219–254; G. Xie and T. P.-Y. Yu, *Advances in Constructive Approximation*, 2004, pp. 519–533; I. Daubechies, O. Runborg, and W. Sweldens, *Constr. Approx.*, 3 (2004), pp. 399–463; T. P.-Y. Yu, *Cutting corners on the sphere*, preprint available at http://www.rpi.edu/∼yut/Papers/CuttingCorners.pdf, 2005], in which various families of nonlinear subdivision schemes are either proved or empirically observed to have rather weak nonlinearity in the sense that they produce limit curves with smoothness insensitive to initial data.

Key words. subdivision/refinement scheme, nonlinear subdivision scheme, convexity preserving subdivision, Hölder regularity, homogeneous map, real projective plane

1. Introduction.

Subdivision is a method for taking coarsely described data and recursively generating (typically smooth) data at finer and finer resolution. It can be used to rapidly generate curves and surfaces with built-in multiple level-of-details. Linear subdivision in the regular grid setting is also well known to be connected to wavelet construction via the MRA framework due to Mallat and Meyer; and this connection had been explored and exploited in various nonlinear settings [8, 17, 2, 18, 5] to construct various nonlinear "wavelet" transforms. Despite the interest in both wavelets and computer-aided geometric design, there has been little theory on nonlinear subdivision schemes.

In recent years, it was either observed empirically or proved that certain nonlinear subdivision schemes exhibit the following *weakly nonlinear* property: for "most" initial data, the limit curve produced by the nonlinear subdivision scheme has a critical

†Department of Mathematics, Drexel University, 3141 Chestnut Street, 206 Korman Center, Philadelphia, PA 19104 (yut@drexel.edu).

Hölder regularity exactly the same as that produced by a related linear subdivision scheme. Notable examples include (i) median- and p-mean-interpolating subdivision schemes [21, 20, 8, 17, 16], (ii) refinement schemes of manifold-valued data [18, 19, 22], and (iii) refinement schemes arising from normal multiresolution analysis [5]. A conceptually related discovery is reported in [3], where it is shown that an irregular grid variant of Dubuc's 4-point interpolatory subdivision scheme [9] has the exact same critical Hölder regularity as that in the regular grid setting, so long as the irregularity of the successively refined grids is somehow controlled; and it is conjectured [3, 23] that a similar phenomenon holds for a wilder class of irregular grid subdivision schemes.

Since the regularity of the limit function of a linear subdivision scheme is essentially irrelevant to the initial data, the aforementioned weakly nonlinear subdivision schemes share the same property of data-independence.

In this paper, we show that the nonlinear convexity preserving subdivision scheme (2.1) by [14, 12] produces limit curves with critical Hölder exponents quite heavily dependent on the initial data, unlike the behavior of a linear or weakly nonlinear subdivision scheme. Note that the convexity preserving subdivision scheme when applied to strictly convex data is simply based on the harmonic mean and, similar to the aforementioned weakly nonlinear schemes, may *not* occur to be data dependent at first glance. There exist nonlinear refinement schemes that are more data adaptive in appearance, e.g., the edge adapted or ENO refinement schemes in [2, 7].

While this paper is intended to be self-contained, the proof of our main result (Theorem 2.1) uses a key idea from [21], which is described by the commutative diagram in Figure 1.

We reiterate the lame statement that a lot is known about linear subdivision, but little is known about their nonlinear counterparts; there are currently many unsolved open questions in the nonlinear subdivision literature; see the nonexhaustive list: [18, 19, 5, 21, 20, 8, 17, 13, 16, 15, 14, 12, 2, 22]. Subdivision schemes in various geometric and nonlinear settings are of recent practical interest because of their natural connection with multiscale representations of different data types.

2. Convexity preserving subdivision. In [14, 12], the following nonlinear subdivision scheme is introduced: $f_{j+1} = Sf_j$, where $S : \ell(\mathbb{Z}) \to \ell(\mathbb{Z})$ is defined by

$$f_{j+1,2k} = f_{j,k}, \quad f_{j+1,2k+1} = \frac{f_{j,k} + f_{j,k+1}}{2} - \frac{1}{8} H\big((\triangle^2 f_j)_{k-1}, (\triangle^2 f_j)_k\big). \tag{2.1}$$

Here Δ is a forward difference operator, and $H(\cdot,\cdot)$ denotes harmonic mean, i.e., $H(a,b) = 2ab/(a+b)$ if $ab > 0$, and we define $H(a,b) = 0$ if $ab \leqslant 0$.

It is helpful to bear in mind the linear counterpart of (2.1) based on replacing the nonlinear harmonic mean by the linear arithmetic mean:

$$\begin{aligned} f_{j+1,2k} = f_{j,k}, \quad f_{j+1,2k+1} &= \frac{f_{j,k} + f_{j,k+1}}{2} - \frac{1}{8}\text{Average}\big((\triangle^2 f_j)_{k-1}, (\triangle^2 f_j)_k\big) \\ &= \frac{9}{16}(f_{j,k} + f_{j,k+1}) - \frac{1}{16}(f_{j,k-1} + f_{j,k+2}). \end{aligned} \tag{2.2}$$

This is the well-known subdivision scheme by Dubuc [9]; we denote its subdivision operator by $\overline{S} : \ell(\mathbb{Z}) \to \ell(\mathbb{Z})$.

For $r = 1, 2$, there exist (nonlinear) subdivision operators $S^{[r]}$ such that

$$S^{[r]} \circ \Delta^r = \Delta^r \circ S. \tag{2.3}$$

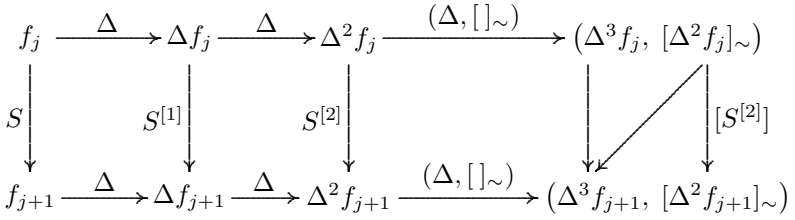

FIG. 1. *Commutation relations for S.*

In particular, $S^{[2]}\Delta^2 v = \Delta^2 S v$; if we write $w = \Delta^2 v$, we have

$$\begin{aligned}\big(S^{[2]}w\big)_{2k} = (\Delta^2 Sv)_{2k} &= (Sv)_{2k} - 2(Sv)_{2k+1} + (Sv)_{2k+2}\\ &= v_k - 2[\frac{v_k + v_{k+1}}{2} - \frac{1}{8}H\big((\triangle^2 v)_{k-1}, (\triangle^2 v)_k\big)] + v_{k+1}\\ &= \frac{1}{4}H(w_{k-1}, w_k),\end{aligned} \tag{2.4}$$

$$\begin{aligned}\big(S^{[2]}w\big)_{2k+1} = (\Delta^2 Sv)_{2k+1} &= (Sv)_{2k+1} - 2(Sv)_{2k+2} + (Sv)_{2k+3}\\ &= \frac{v_k + v_{k+1}}{2} - \frac{1}{8}H\big((\triangle^2 v)_{k-1}, (\triangle^2 v)_k\big) - 2v_{k+1}\\ &\quad + \frac{v_{k+1} + v_{k+2}}{2} - \frac{1}{8}H\big((\triangle^2 v)_k, (\triangle^2 v)_{k+1}\big)\\ &= \frac{w_k}{2} - \frac{1}{8}[H(w_{k-1}, w_k) + H(w_k, w_{k+1})].\end{aligned} \tag{2.5}$$

As a comparison, there exist linear subdivision operators $\overline{S}^{[r]}$, $r = 1, 2, 3, 4$, such that $\overline{S}^{[r]} \circ \Delta^r = \Delta^r \circ \overline{S}$.

It is easy to check, using (2.4)–(2.5), that $S^{[2]}$ is positivity preserving; consequently $S^{[1]}$ is monotonicity preserving and S is convexity preserving. These properties of S are *not* shared by its linear counterpart $\overline{S}$. More in-depth discussions of the relationships among convexity preservation, nonlinear means, and rational interpolation can be found in [14, 12, 11]. We shall later use the fact that S reproduces rational polynomials of degree 2 over degree 1.

We denote by $\mathbb{R}_+$ the set of positive real numbers, and let $\ell_+(\mathbb{Z}) := \{v \mid v : \mathbb{Z} \to \mathbb{R}_+\}$ and $\ell_+^\infty(\mathbb{Z}) := \ell_+(\mathbb{Z}) \cap \ell^\infty(\mathbb{Z})$. By the positivity preserving and locality properties of $S^{[2]}$, we can view it as operators on either $\ell_+(\mathbb{Z})$ or $\ell_+^\infty(\mathbb{Z})$.

By (2.4)–(2.5), we have

$$(S^{[2]}w)_{2k,2k+1,2k+2} = D(w_{k-1}, w_k, w_{k+1}), \tag{2.6}$$

where the nonlinear map $D : \mathbb{R}^3 \to \mathbb{R}^3$ is given by

$$D(w_1, w_2, w_3) = \left(\frac{H(w_1, w_2)}{4},\ \frac{w_2}{2} - \frac{1}{8}\big(H(w_1, w_2) + H(w_2, w_3)\big),\ \frac{H(w_2, w_3)}{4}\right). \tag{2.7}$$

Since D is homogeneous (i.e., $D(\lambda w) = \lambda D(w)$ for all $\lambda \in \mathbb{R}$ and $w \in \mathbb{R}^3$), it induces a quotient map $\pi : \mathbb{P}(\mathbb{R}^3) \to \mathbb{P}(\mathbb{R}^3)$ via the formula $\pi([x]_\sim) = [Dx]_\sim$. Here if V is a real vector space, $\mathbb{P}(V) := V/\sim := \{[v]_\sim : v \in V\}$, where $\sim$ is the equivalence relation defined by $v \sim v' \iff \exists\, c \neq 0$ such that $v = cv'$.

Since D leaves $\mathbb{R}^3_+$ invariant, so does π to $\{[v]_\sim : v \in \mathbb{R}^3_+\}$. Clearly $\{[v]_\sim : v \in \mathbb{R}^3_+\}$ can be identified with $\mathbb{R}^2_+$ by pairing $[x, 1, y]^T_\sim$ with (x, y) (here $x, y > 0$.) Viewing π as a map on $\mathbb{R}^2_+$ under this identification, we have, by (2.7),

$$\pi(x, y) = \left(\frac{2x(1+y)}{2+x+y} \, , \, \frac{2y(1+x)}{2+x+y} \right). \tag{2.8}$$

We have the following facts pertaining to this map:

[P1] (x, x) is a fixed point of π for any $x > 0$.

[P2] For any $x, y > 0$, there is a unique $\overline{x} > 0$ such that $\lim_{n\to\infty} \pi^n(x, y) = (\overline{x}, \overline{x})$.
Proof. [P1] takes care of the case of $x = y$. Assume $x > y$; the other case is symmetrical. The observation that

$$1 < \frac{xy + x}{xy + y} = \frac{\pi(x, y)_1}{\pi(x, y)_2} = \frac{x}{y} \frac{1+y}{1+x} < \frac{x}{y} \tag{2.9}$$

implies that as n increases the first component of $\pi^n(x, y)$ decreases monotonically to a limit value $\overline{x}$, whereas the second component of $\pi^n(x, y)$ increases monotonically to the same value. □

[P3] For any $0 < a < b$, π leaves the square $R := [a, b] \times [a, b]$ invariant, i.e., $\pi(R) \subseteq R$.
Proof. Let $(x, y) \in R$. Without loss of generality, assume $x \geqslant y$. We seek to show that $(x', y') := \pi(x, y)$ continues to belong to R. By (2.9), we have (i) $x' \leqslant x$, (ii) $y' \geqslant y$, and (iii) $x' \geqslant y'$. Assume the contrary that $(x', y') \notin R$; then either $x' < a$ or $y' > b$. If $x' < a$, then $y' < a$ by (iii), so $y < a$ by (ii), contradicting the assumption that $(x, y) \in R$. A similar contradiction can be generated if $y' > b$. □

The following is a more quantitative version of [P2], and is due to Güntürk.

[P4] $L(x, y) := xy/(2 + x + y)$ is invariant under π, i.e., $L(\pi(x, y)) = L(x, y)$. Therefore, for any $(x', y') \in \mathbb{R}^2_+$, the orbit $\{\pi^n(x', y'), : n = 0, 1, 2, \ldots\}$ lies on the level curve $C = \{(x, y) : L(x, y) = x'y'/(2 + x' + y')\}$ and converges (in a monotonic fashion as described in [P2]) to the limit point $(\overline{x}, \overline{x})$, where $\overline{x}$ is the positive root of the quadratic equation $L(\overline{x}, \overline{x}) = x'y'/(2 + x' + y')$. In Lemma 2.5 we show that the curve $xy/(2 + x + y) = 1/4$ corresponds exactly to data sampled from rational polynomials of degree 2 over degree 1.

Let $\Delta : \ell(\mathbb{Z}) \to \ell(\mathbb{Z})$ or $\mathbb{R}^N \to \mathbb{R}^{N-1}$ $(N \geqslant 2)$ be the forward differencing operator defined by $(\Delta m)_i = m_{i+1} - m_i$. Let

$$\Delta^1 := \Delta, \qquad \Delta^{r+1} := \Delta \circ \Delta^r.$$

(Clearly we are abusing notation when Δ acts on finite vectors. In this case Δ^r maps $\mathbb{R}^N$ to $\mathbb{R}^{N-r}$ for $N \geqslant r + 1$.)

Next we consider the *shrinking factor*: for $(x, y) \neq (1, 1)$, define

$$\begin{aligned} s(x, y) &:= \frac{\|\Delta D([x, 1, y])\|_\infty}{\|\Delta[x, 1, y]\|_\infty} \\ &= \frac{\max\left(\left|\tfrac{1}{2} - \tfrac{3}{8}H(1, x) - \tfrac{1}{8}H(1, y)\right|, \left|\tfrac{1}{2} - \tfrac{1}{8}H(1, x) - \tfrac{3}{8}H(1, y)\right| \right)}{\max(|1 - x|, |1 - y|)}. \end{aligned} \tag{2.10}$$

We define $s(1, 1) = 1/4$ in order to make $s(x, x) = [2(1 + x)]^{-1}$ continuous on $x > 0$. It is elementary to verify the following:

[S1] $s(x,y) \in (0,1/2)$ for $(x,y) \in \mathbb{R}^2_+$.

[S2] $s(x,y)$ is discontinuous at (and only at) $(x,y) = (1,1)$. In a small neighborhood of $(1,1)$, $s(x,y)$ ranges from a little below $1/8$ to a little above $1/4$; precisely one can check that

$$\lim_{\varepsilon\to 0} \inf_{\|(x,y)-(1,1)\|<\varepsilon} s(x,y) = \frac{1}{8} = \lim_{\substack{(x,y)\to(1,1)\\ xy/(2+x+y)=1/4}} s(x,y), \tag{2.11}$$

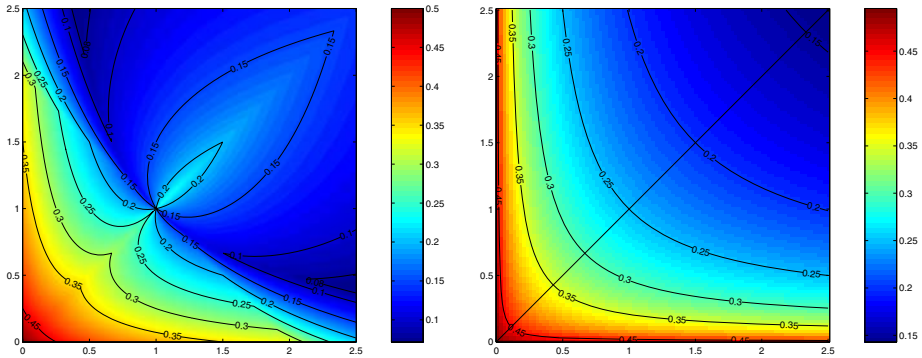
$$\lim_{\varepsilon\to 0} \sup_{\|(x,y)-(1,1)\|<\varepsilon} s(x,y) = \frac{1}{4} = \lim_{\substack{(x,y)\to(1,1)\\ x=y}} s(x,y).$$

See Figure 2. Warning: The 0.25-contour in Figure 2(b), which is exactly the curve $xy/(2+x+y) = 1/4$, can be misleading due to the discontinuity at (1,1): if (x_0,y_0) is any point on this curve not equal to $(1,1)$, then $\lim_{n\to\infty} s(\pi^n(x_0,y_0)) = 1/8 \neq s(\lim_{n\to\infty}\pi^n(x_0,y_0)) = 1/4$.

[S3] $s(x,y) \leqslant s(\pi(x,y))$ with equality holds iff $x = y$.

See also Figure 2. Combining [S3] with [P3] and that $s(x,x)$ is decreasing in x, we have

$$\sup_{\theta\in[a,b]\times[a,b]} s(\theta) = s(a,a) = [2(1+a)]^{-1}. \tag{2.12}$$



(a) (b)

FIG. 2. (a) *Shrinking factor* $s(x,y)$. (b) *Asymptotic shrinking factor* $s(\lim_{n\to\infty}\pi^n(x,y))$.

Let M, N be integers, $M < N$. It is well known in approximation theory (see, e.g., [1, 6]) that for $f \in C([M,N])$, for $\alpha > 0$, we have

$$\begin{aligned} f \in \operatorname{Lip}\alpha \quad &\Longleftrightarrow \quad \exists\, r \in \mathbb{Z}_+,\ r > \alpha, \text{ s.t. } \max_{2^j M\leqslant k\leqslant 2^j N-r} |(\Delta^r f_j)_k| = O(2^{-j\alpha}) \\ &\Longleftrightarrow \quad \forall\, r \in \mathbb{Z}_+,\ r > \alpha, \ \max_{2^j M\leqslant k\leqslant 2^j N-r} |(\Delta^r f_j)_k| = O(2^{-j\alpha}), \end{aligned} \tag{2.13}$$

where f_j is the (length $2^j(N-M)+1$) sequence $(f_j)_k = f(2^{-j}k)$. This equivalence implies that the critical Hölder regularity exponent of f can be determined from the exact asymptotic decay rate of $\max_{2^j M\leqslant k\leqslant 2^j N-r} |(\Delta^r f_j)_k|$ for a large enough differencing order r, i.e.,

$$\sup\{\alpha : f \in \operatorname{Lip}\alpha\} = \sup\Big\{\alpha : \max_{2^j M\leqslant k\leqslant 2^j N-r} |(\Delta^r f_j)_k| = O(2^{-j\alpha})\Big\}. \tag{2.14}$$

For continuous functions defined on the whole real line instead of a compact interval, the equivalence in (2.13) with $M = -\infty$ and $N = +\infty$ holds if we assume that f is bounded. For a (possibly unbounded) continuous function $f : \mathbb{R} \to \mathbb{R}$, we say $f \in \text{Lip } \alpha$ if $f|_{[M,N]} \in \text{Lip } \alpha$ for any $M < N$. Then, under the assumption that there exists $r > \alpha$, $r \in \mathbb{Z}_+$ such that $\Delta^r f_j \in \ell^\infty$ for all j, we have

$$f \in \text{Lip } \alpha \quad \Longleftrightarrow \quad \max_{k\in\mathbb{Z}} |(\Delta^r f_j)_k| = O(2^{-j\alpha}).$$

Remark. Since S is (point-)interpolatory, the subdivision data $S^j f_0$ is exactly the limit function f sampled on the grid $2^{-j}\mathbb{Z}$, so the above result is directly applicable to analyzing the smoothness of f. For other subdivision schemes, linear or nonlinear, more subtle arguments related to stability are needed; see [21, section 3] and the references therein.

As suggested by Figure 1, we shall use $r = 3$ (i.e., third order differences) to analyze the limit functions generated by the nonlinear convexity preserving scheme S.

An essential fact based on the locality property of S is that if we specify the initial data $f_{0,k}$ at the integers $k = M - 2, \ldots, N + 2$, then the limit function restricted to the interval $[M, N]$ is uniquely determined. For $v \in \ell(\mathbb{Z})$, we denote by $S^\infty v$ or $f_v : \mathbb{R} \to \mathbb{R}$ the limit function; it is shown in [14] that f_v is C^1 smooth for arbitrary *strictly convex* initial data v, i.e., $\Delta^2 v \in \ell_+(\mathbb{Z})$.

Remark. Property [S1] already says that $\|\Delta^3 S^j v\|_\infty = O((1/2)^j)$ if $\Delta^2 v \in \ell_+^\infty(\mathbb{Z})$. With a refined argument, one can prove that

$$\|\Delta^3 S^j v\|_\infty = O((1/2 + \epsilon)^j)$$

for an $\epsilon > 0$ dependent on v and can be arbitrarily small. This, in turn, implies the above-mentioned C^1 result in [14].

Our main result is the following theorem.

THEOREM 2.1. *Let $v \in \ell(\mathbb{Z})$ be such that $(\Delta^2 v)_{i-1} = (\Delta^2 v)_{i+1}$ and $(\Delta^2 v)_i > 0$ for all i. Assume*

$$\mu := \frac{(\Delta^2 v)_{2i}}{(\Delta^2 v)_{2i-1}} \in (0, 1). \tag{2.15}$$

(In particular, $\Delta^2 v \in \ell_+^\infty(\mathbb{Z})$ and is a 2-periodic sequence.) Then

$$\sup\{\alpha : f_v \in \text{Lip } \alpha\} = \log_2 2(1 + \mu). \tag{2.16}$$

Therefore, by adjusting the value $\mu \in (0, 1)$, one can construct strictly convex initial data v such that the limit function f_v has a critical Hölder exponent equal to **any** *value in $(1, 2)$.*

Proof. Write $f_j := S^j v \in \ell(\mathbb{Z})$. As $r := 3 > 2 > \log_2 2(1 + \mu)$, it suffices to use $r = 3$ in (2.14) and prove

$$\|\Delta^3 f_j\|_\infty \asymp [2(1 + \mu)]^{-j}, \quad j \to \infty. \tag{2.17}$$

Note that $s(x, x) = [2(1+x)]^{-1}$ according to (2.10). The key point here is to relate the decay rate of $\|\Delta^3 f_j\|_\infty$ to the maps $\pi : \mathbb{R}_+^2 \to \mathbb{R}_+^2$ and $s : \mathbb{R}_+^2 \to (0, 1/2)$ introduced in (2.8) and (2.10).

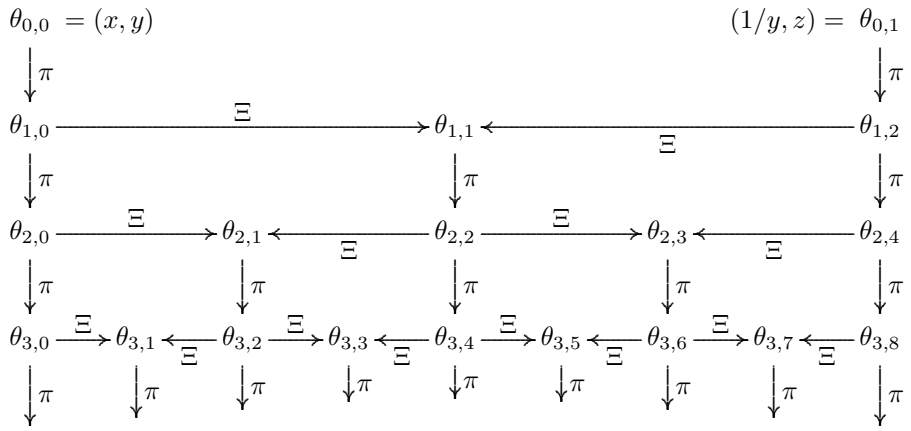


FIG. 3. *Recursive definition of* $\theta_{j,k}$.

(1°) Recall that $\Delta^2 f_j = (S^{[2]})^j w$, where $w := \Delta^2 v$. Recall also that the map $D : \mathbb{R}^3 \to \mathbb{R}^3$ in (2.7) describes the operator $S^{[2]}$ via (2.6). Now, if we write

$$\begin{aligned} \mathbb{R}^3_+ \ni w_{j,k} &:= \big((S^{[2]})^j w\big)_{k-2,\,k-1,\,k} \\ &= \big((\Delta^2 f_j)_{k-2}, (\Delta^2 f_j)_{k-1}, (\Delta^2 f_j)_k\big), \quad k = 0, \dots, 2^j, \end{aligned} \tag{2.18}$$

then, by virtue of (2.6) we have

$$\begin{aligned} w_{j+1,2k} &= D(w_{j,k}), \quad k = 0, \dots, 2^j, \\ w_{j+1,2k+1} &= \big[(w_{j+1,2k})_2, (w_{j+1,2k})_3 = (w_{j+1,2k+2})_1, (w_{j+1,2k+2})_2\big]^T, \\ &\qquad k = 0, \dots, 2^j - 1. \end{aligned} \tag{2.19}$$

Define $\theta_{j,k} = ((w_{j,k})_1, (w_{j,k})_3)/(w_{j,k})_2 \in \mathbb{R}^2_+$. Then (2.19) gives

$$\begin{aligned} \theta_{j+1,2k} &= \pi(\theta_{j,k}), \quad k = 0, \dots, 2^j, \\ \theta_{j+1,2k+1} &= \Xi(\theta_{j+1,2k}, \theta_{j+1,2k+2}), \quad k = 0, \dots, 2^j - 1, \end{aligned} \tag{2.20}$$

where $\Xi : \mathbb{R}^2_+ \times \mathbb{R}^2_+ \to \mathbb{R}^2_+$, $\Xi\big((x, y), (x', y')\big) = (1/y, 1/x')$. (See Figure 3.)

(2°) Under these notations, the assumption (2.15) of the theorem is equivalent to saying

$$\theta_{0,0} = (\mu, \mu) \text{ and } \theta_{0,1} = (1/\mu, 1/\mu), \tag{2.21}$$

and (2.17) is, by symmetry of the data and the subdivision scheme, equivalent to

$$\max_{k=0,\dots,2^j} ||\Delta w_{j,k}||_\infty \asymp [2(1+\mu)]^{-j}, \quad j \to \infty. \tag{2.22}$$

By the overlapping properties of $w_{j,k}$'s (recall (2.18)) we do not need to use all the spatial indices k for a given scale j, and (2.22) is equivalent to

$$\max_{k=0,\dots,2^j} ||\Delta w_{j+1,2k}||_\infty \asymp [2(1+\mu)]^{-(j+1)}, \quad j \to \infty. \tag{2.23}$$

Let $R_\mu := [\mu, 1/\mu] \times [\mu, 1/\mu]$. It is clear that $\Xi(\theta, \theta') \in R_\mu$ if $\theta, \theta' \in R_\mu$, together with property [P3] ($\pi(R_\mu) \subset R_\mu$). We conclude that

$$\theta_{j,k} \in R_\mu \qquad \forall\, j, k. \tag{2.24}$$

So by (2.12), we upper bound all the shrinking factors as

$$s(\theta_{j,k}) \leqslant s(\mu,\mu) = [2(1+\mu)]^{-1} \qquad \forall\, j,k. \tag{2.25}$$

Notice also that

$$\theta_{j,0} = (\mu,\mu) \qquad \forall\, j \geqslant 0. \tag{2.26}$$

Since

$$||\Delta w_{j+1,2k}||_\infty = s(\theta_{j,k})||\Delta w_{j,k}||_\infty,$$

together with (2.25) we have

$$\max_{k=0,\dots,2^j} ||\Delta w_{j+1,2k}||_\infty = O([2(1+\mu)]^{-(j+1)}). \tag{2.27}$$

On the other hand $\max_{k=0,\dots,2^j} ||\Delta w_{j+1,2k}||_\infty = \Omega([2(1+\mu)]^{-(j+1)})$ since

$$\max_k ||\Delta w_{j,k}||_\infty \geqslant ||\Delta w_{j,0}||_\infty = ||\Delta w_{0,0}||_\infty \prod_{l=1}^{j} s(\theta_{l,0}) \overset{(2.26)}{=} ||\Delta w_{0,0}||_\infty\, s(\mu,\mu)^j.$$

So we have proved (2.17). □

In contrast to the nonlinear S, it is well known that for Dubuc's scheme $\overline{S}$,

$$\sup\{\nu : \overline{S}^\infty v \in \operatorname{Lip}\nu\} = \begin{cases} 2 & \text{if } v \in \ell(\mathbb{Z})\backslash\Pi_3|_{\mathbb{Z}}, \\ \infty & \text{if } v \in \Pi_3|_{\mathbb{Z}}. \end{cases} \tag{2.28}$$

In other words, except for initial data sampled from a polynomial of degree 3 or lower, the critical Hölder regularity of the limit curve is 2.[1] This is characteristic of linear subdivision schemes and of the weakly nonlinear schemes mentioned in section 1.

Note. Both (2.16) and (2.17) are not true if $\mu = 1$. When $\mu = 1$, $\Delta^2 v$ is a constant sequence. By (2.4)–(2.5), $\Delta^2 f_j = (1/4)^j \Delta^2 v$, so $\Delta^3 f_j$ is the zero sequence for all j. In this case, the limit function f_v is a quadratic polynomial, which is infinitely smooth.

For general initial strictly convex data, we have the following theorem.

THEOREM 2.2. *Let $w = \Delta^2 v \in \ell_+(\mathbb{Z})$ and $k \in \mathbb{Z}$. Write*

$$x = \frac{w_{k-2}}{w_{k-1}}, \quad y = \frac{w_k}{w_{k-1}}, \quad z = \frac{w_{k+1}}{w_k}.$$

1. *If $\frac{x\,y}{2+x+y} = \frac{1}{4} = \frac{(1/y)\,z}{2+(1/y)+z}$, then $S^\infty v|_{[k,k+1]}$ is a rational polynomial and is C^∞.*
2. *Otherwise, for any $\varepsilon > 0$,*

$$\sup\{\alpha : S^\infty v|_{[k-\varepsilon,k+1+\varepsilon]} \in \operatorname{Lip}\alpha\} < 2.$$

To prove this result we need the following facts pertaining to rational functions.

Remark 2.3. If $R(t) = (at^2+bt+c)/(t-d)$, then $R''(t) = 2(ad^2+bd+c)/(t-d)^3$. This means R is convex on one side of the pole $t = d$ if and only if it is concave on the other side. We refer to the open subset of $\mathbb{R}$ ($\{t : t > d\}$ or $\{t : t < d\}$) at which

[1] More precisely: f_v satisfies $|f_v'(x+t) - f_v'(x)| = O(t\log(1/t))$ and this bound cannot be improved unless for data sampled from a cubic polynomial.

$R''(t) \geqslant 0$ is the *convex branch* of R. If $R(t) = at^2 + bt + c$, its convex branch is defined to be the whole of $\mathbb{R}$ when $a \geqslant 0$, and $\emptyset$ otherwise.

Remark 2.4. Let $t_0 < t_1 < \cdots < t_{n+1}$, and $f_0, f_1, \ldots, f_{n+1} \in \mathbb{R}$. Let $[t_i, \ldots, t_k]f$ be the divided difference of $f_i, \ldots, f_k$ at $t_i, \ldots, t_k$, defined, recursively, by

$$[t_\ell]f := f_\ell, \quad [t_\ell, \ldots, t_{\ell+n}]f := \frac{[t_{\ell+1}, \ldots, t_{\ell+n}]f - [t_\ell, \ldots, t_{\ell+n-1}]f}{t_{\ell+n} - t_\ell} \quad \text{if } n \geqslant 1.$$

If $D_i := [t_i, t_{i+1}, \ldots, t_{i+n}]f$, $i = 0, 1$, are such that $D_0 D_1 > 0$, then there is a unique rational polynomial $R(t)$ of degree n over degree 1 that interpolates f_i at t_i; moreover,

$$R(t) = \frac{D_1 \cdot (t_{n+1} - t)p_0(t) + D_0 \cdot (t - t_0)p_1(t)}{D_1 \cdot (t_{n+1} - t) + D_0 \cdot (t - t_0)}, \tag{2.29}$$

where p_i is the unique Lagrange interpolant of $f_i, \ldots, f_{i+n}$ at $t_i, \ldots, t_{i+n}$, $i = 0, 1$. Recall also Newton's formula

$$p_i(t) = \sum_{k=i}^{i+n} [t_k, \ldots, t_{i+n}]f \prod_{\ell=k+1}^{i+n} (t - t_\ell). \tag{2.30}$$

Note that the numerator of $R(t)$ is a polynomial of degree n or lower: by (2.30) the coefficient of t^n in p_i is D_i, so the coefficient of t^{n+1} in the numerator of $R(t)$ is $D_1 D_0 - D_0 D_1 = 0$. The denominator of $R(t)$ is a constant when $D_0 = D_1$.

Note. When $D_0 \neq D_1$, the rational function (2.29) has a pole at $d = (t_0 D_0 - t_{n+1} D_1)/(D_0 - D_1)$. The condition $D_0 D_1 > 0$ guarantees that $d \neq t_i$, $i = 0, \ldots, n+1$, as $D_1(t_{n+1} - t_i) + D_0(t_i - t_0)$ is positive (resp., negative) if both D_i are positive (resp., negative). However, an example would show that in general there is *no* guarantee that d must stay outside the interval $[t_0, t_{n+1}]$. This last comment adds to the subtlety of the next lemma.

LEMMA 2.5. *Let $f_0, f_1, \ldots, f_4$ be such that $w_i := f_{i+2} - 2f_{i+1} + f_i > 0$ for $i = 0, 1, 2$. Set $x = w_0/w_1$ and $y = w_2/w_1$. Let $\overline{t} \in \mathbb{R}$ and $h > 0$.*

Then there exists a (unique) rational function $R(t) = (at^2 + bt + c)/(t - d)$ such that $R(\overline{t} + ih) = f_i$ for $i = 0, \ldots, 4$ and $[\overline{t}, \overline{t} + 4h] \subset$ (convex branch of R) if and only if

$$\frac{x\, y}{2 + x + y} = \frac{1}{4}. \tag{2.31}$$

Proof. Without loss of generality, we can assume $\overline{t} = 0$ and $h = 1$.

If $f_i = (a(i)^2 + b(i) + c)/(i - d)$, $i = 0, 1, 2, 3, 4$, then $x = (f_2 - 2f_1 + f_0)/(f_3 - 2f_2 + f_1) = (-3 + d)/d$, $y = (f_4 - 2f_3 + f_2)/(f_3 - 2f_2 + f_1) = (-1 + d)/(-4 + d)$. One can then verify (2.31) immediately. Notice that the assumption $[\overline{t}, \overline{t} + 4h] \subset$ (convex branch of R) is the same as saying $d < 0$ or $d > 4$, so there is no worry of division by zero in the definitions of f_i's.

To prove the converse, let

$$D_i := [i, i+1, i+2, i+3]f = (w_{i+1} - w_i)/6, \quad i = 0, 1. \tag{2.32}$$

(We use the divided difference notation as mentioned in Remark 2.4.) Since $D_0 D_1 = (w_1 - w_0)(w_2 - w_1)/36$, $D_0 D_1 > 0$ follows from (2.31) according to the following calculation: $(w_1 - w_0)(w_2 - w_1) = w_1(1 - x)(y - 1) = w_1(1 - x)((2 + x)/(4x - 1) - 1) = 3w_1(1 - x)^2/(4x - 1) > 0$. (Notice that (2.31) implies that $x, y > 1/4$.)

Knowing $D_0D_1 > 0$, Remark 2.4 then applies: The unique rational polynomial of degree 3 over degree 1 that interpolates $f_0, \dots, f_4$ at $0, \dots, 4$ is given by

$$R(x) = \frac{D_1(4-t)p_0(t) + D_0 t p_1(t)}{D_1(4-t) + D_0 t}. \tag{2.33}$$

The goal here is to the show that the numerator of the right-hand side of (2.33) is in fact a polynomial of degree 2 or lower, and also to prove that the pole of R is outside of the interval $[0, 4]$.

The coefficient of t^3 in the numerator of $R(x)$ is

$$\begin{aligned} & D_1(4\,(\text{coeff. of } t^3 \text{ in } p_0) - (\text{coeff. of } t^2 \text{ in } p_0)) + D_0(\text{coeff. of } t^2 \text{ in } p_1) \\ = \;& D_1(4D_0 - (w_1/2 - 6D_0)) + D_0(w_2/2 - 9D_1) \\ \overset{(2.32)}{=} \;& 36w_1(2 + x + y - 4xy) \overset{(2.31)}{=} 0. \end{aligned}$$

The denominator is constant if $D_0 = D_1$; in this case $x = y = 1$ under the condition (2.31). Otherwise, R has its pole at

$$d = \frac{4D_1}{D_1 - D_0} = \frac{4(y-1)}{x+y-2} \overset{(2.31)}{=} \frac{3}{1-x},$$

which stays out of the interval $[0, 4]$ since (2.31) also implies $x > 1/4$. ∎

Proof of Theorem 2.2. Without loss of generality, assume $k = 0$.

(1°) If $\frac{x\,y}{2+x+y} = \frac{1}{4} = \frac{(1/y)\,z}{2+(1/y)+z}$, then, by Lemma 2.5, there exists a unique rational polynomial $R(t)$ of degree 2 over degree 1 such that $f_i = R(i)$, $i = -2, \dots, 3$. It is known from [12] that the subdivision scheme reproduces R on $[0, 1]$, i.e., $S^\infty v|_{[0,1]} = R$. The pole of R is outside the interval $[-2, 3]$. So R is certainly C^∞ on $[0, 1]$.

(2°) To prove the second part of the theorem, we need to first recall the basic setup in part (1°) of the proof of Theorem 2.1. If we define $\theta_{j,k}$ $k = 0, \dots, 2^j$ according to (2.20) with

$$\theta_{0,0} = (x, y), \quad \theta_{0,1} = (1/y, z).$$

(Recall also Figure 3.) We write $C := \{(x, y) \in \mathbb{R}^2_+ : xy/(2 + x + y) = 1/4\}$, $C^+ := \{(x, y) \in \mathbb{R}^2_+ : xy/(2+x+y) > 1/4\}$, and $C^- := \{(x, y) \in \mathbb{R}^2_+ : xy/(2+x+y) < 1/4\}$. Note that $C^+ \supset (1, \infty)^2$ and $C^- \supset (0, 1)^2$.

To prove the theorem, we claim that it suffices to show that

$$\exists\, \overline{j}, \overline{k} \;\text{ s.t. }\; \theta_{\overline{j},\overline{k}} \in C^-. \tag{2.34}$$

By properties [P2] and [P4] of π and the identity $s(x, x) = [2(1 + x)]^{-1}$, (2.34) is equivalent to saying

$$\lim_{n\to\infty} s(\pi^n(\theta_{\overline{j},\overline{k}})) = s^* > 1/4. \tag{2.35}$$

Now, recall from part (1°) of the proof of Theorem 2.1 that

$$s(\theta_{j,k}) = \frac{\max\left(|(\Delta^3 f_{j+1})_{2k-2}|, |(\Delta^3 f_{j+1})_{2k-1}|\right)}{\max\left(|(\Delta^3 f_j)_{k-2}|, |(\Delta^3 f_j)_{k-1}|\right)} \tag{2.36}$$

and

$$\theta_{j,k} = \left(\frac{(\Delta^2 f_j)_{k-2}}{(\Delta^2 f_j)_{k-1}}, \frac{(\Delta^2 f_j)_k}{(\Delta^2 f_j)_{k-1}}\right).$$

If $\theta_{j,k} \in C^-$, then at least one of its two components is strictly less than one, which in turn implies that the denominator of (2.36) is nonzero. So altogether (2.35) implies that

$$\max_{-2 \leqslant k < 2^j} |(\Delta^3 f_j)_k| = \Omega(s_-^j)$$

for any $s_- \in (1/4, s^*)$. Consequently, for any $\varepsilon > 0$, $S^\infty v|_{[-\varepsilon, 1+\varepsilon]}$ has Hölder regularity strictly less than 2.

(3°) So it remains to prove (2.34) under the assumption that either $(x, y) \notin C$ or $(1/y, z) \notin C$.

There is nothing to prove if $(x, y) \in C^-$ or $(1/y, z) \in C^-$. So we can assume without loss of generality that

$$\theta_{0,0} = (x, y) \in C^+ \quad \text{and} \quad \theta_{0,1} = (1/y, z) \in C \cup C^+.$$

As a warmup, let us first consider the case $y = 1$. If $y = 1$, then $1/y = 1$, $z \geqslant 1$ and $x > 1$. But then $\theta_{1,0} = \pi((> 1, 1)) = (> 1, > 1)$, and $\theta_{1,2} = \pi((1, \geqslant 1)) = (\geqslant 1, \geqslant 1)$, so

$$\theta_{1,1} = \Xi(\theta_{1,0}, \theta_{1,2}) = \left(\frac{1}{> 1}, \frac{1}{\geqslant 1} \right) = \big(< 1, \leqslant 1 \big) \in C^-,$$

and we are done with the special case $y = 1$.

We now consider the case $y < 1$; the case of $y > 1$ is similar.

Assume the contrary that no $\theta_{j,k} \in C^-$.

If $y < 1$, then $x > 1$, and $1/y > 1$, so we have

$$\theta_{0,0} = (> 1, < 1), \quad \theta_{0,1} = (> 1, *). \tag{2.37}$$

We know that $\theta_{1,0} = (> 1, *)$, $\theta_{1,2} = (> 1, *)$. Observe that $\theta_{1,0} = (> 1, < 1)$, otherwise $\theta_{1,0} = (> 1, \geqslant 1)$ and

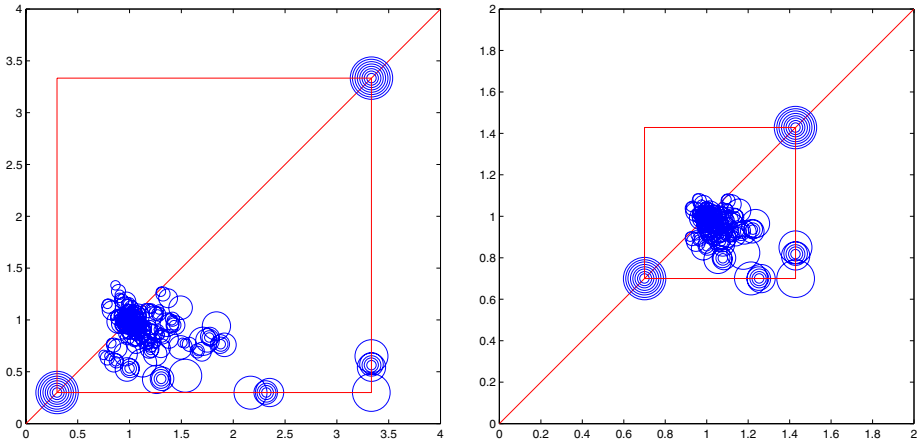
$$\theta_{1,1} = \Xi(\theta_{1,0}, \theta_{1,2}) = \big(1/(\geqslant 1), 1/(> 1) \big) = (\leqslant 1, < 1) \in C^-,$$

violating our assumption. So we now have $\theta_{1,0} = (> 1, < 1)$, $\theta_{1,1} = (> 1, *)$. This brings us back to the same situation as in scale $j = 0$ (recall (2.37)); this means, by induction,

$$\theta_{n,0} = (> 1, < 1), \quad \theta_{n,1} = (> 1, *) \quad \forall\, n.$$

But this contradicts the fact that $\lim_{n\to\infty} \theta_{n,0} = \lim_{n\to\infty} \pi^n(\theta_{0,0}) = (c, c)$, $c > 1$. This completes the proof of the theorem. □

Remark. If $\theta_{0,0}, \theta_{0,1} \in C$, then all $\theta_{j,k}$'s lie on C as well, and are near $(1, 1)$ for j large enough. So, by (2.11), the shrinking factors $s(\theta_{j,k})$ are close to $1/8$ for large j, so $\|\Delta^3 f_j\|_\infty$ decays essentially like $(1/8)^j = 2^{-3j}$. In this very case, we can only say that the critical Hölder regularity is no less than 3, but third order differences may be too "underpower" to determine the optimal Hölder regularity. In other words, the critical smoothness can be higher than 3, and this is exactly the case: Part 1 of Theorem 2.2 says that the smoothness is ∞ ($\gg 3$!).



(a) $x = 0.3$ (b) $x = 0.7$

FIG. 4. *For each $\theta_{j,k} \in \mathbb{R}^2_+$ defined by* (2.20)*, a circle with center $\theta_{j,k}$ and radius which decreases linearly with j is drawn. Notice that $\theta_{j,k}$ tends to cluster at* $(1, 1)$.

3. Observations. For linear subdivision schemes, it is typical that the local Hölder exponents at dyadic irrationals are higher than the global critical Hölder regularity; see [4, section 4]. (Here we assume that the subdivision scheme is binary.) A similar property holds for the nonlinear convexity preserving scheme in this paper, except that it can be more easily explained than those linear examples in [4, section 4]: While Theorem 2.2 says that the global regularity of the limit function f_v for any initial data v is less than 2, a classical result of Alexsandrov (see, e.g., [10]) asserts that f_v, being a convex function on $\mathbb{R}$, must be twice differentiable almost everywhere. (This also partly explains the observed clustering of $\theta_{j,k}$ about $(1, 1)$ for arbitrary initial configuration $x, y, z > 0$ (see, e.g., Figure 4)—a fact that seems difficult to explain by elementary means.)

Acknowledgment. The author thanks Sinan Güntürk for discussions on dynamical systems.

A POSTERIORI ERROR ESTIMATIONS OF SOME CELL CENTERED FINITE VOLUME METHODS FOR DIFFUSION-CONVECTION-REACTION PROBLEMS*

SERGE NICAISE†

Abstract. This paper presents an a posteriori residual error estimator for diffusion-convection-reaction problems approximated by some cell centered finite volume methods on isotropic or anisotropic meshes in $\mathbb{R}^d$, $d = 2$ or 3. For that purpose we built a reconstructed approximation, which is an appropriate interpolant of the finite volume solution. The error is then the difference between the exact solution and this interpolant. The residual error estimator is based on the jump of the normal derivative of the interpolant. We then prove the equivalence between the energy norm of the error and the residual error estimator. Some numerical tests confirm our theoretical results.

Key words. finite volume method, cell centered method, a posteriori error estimates

1. Introduction. The finite volume method is a well-adapted method for the discretization of various partial differential equations and is largely used by engineers [31]. The mathematical analysis of the method has started only recently. Existence and uniqueness results as well as a priori error estimates are now available for quite a large class of problems; see [10] and the references cited there. For finite element methods, a posteriori error estimates are now well understood for a large class of equations; see, for instance, [34]. On the other hand, for finite volume methods, such estimates are not well developed and up to now only a few such results had been obtained. Let us quote [14, 29, 1, 12, 13] for cell centered finite volume methods, [23, 25, 33, 30] for vertex centered methods, and [4, 5, 21, 22, 20] for finite volume element methods.

Recently we obtained a posteriori error estimates of residual type for some cell centered finite volume methods for the Laplace equation in a bounded domain of $\mathbb{R}^d, d = 2$ or 3 [27, 26]. This estimator is based on the use of a reconstructed approximation, namely, an interpolant of Morley type of the finite volume solution. The first goal of the present paper is to extend the previous analysis to diffusion-convection-reaction problems that eventually develop boundary or interior layers. As for the Laplace equation, this requires the introduction of an interpolant, also of Morley type, of the finite volume solution possessing the desired conservation properties. For that purpose, we introduce new finite elements with appropriate degrees of freedom. In contrast with [27, 26] our interpolant is in $H^1(\Omega)$, and therefore the residual error estimator is naturally based on the jump of normal derivatives of the interpolant of the solution. We finally show the equivalence between the energy norm of the error and the residual error estimator. The proof of the upper error bound uses a quasi-orthogonality relation based on the conservation properties of the interpolant. The

proof of the lower error bound is more standard and simply uses some Green formulas and inverse inequalities as for finite element methods [34, 36, 15, 19].

In certain situations the solution of the diffusion-convection-reaction problem exhibits strong directional features. For instance, if the Peclet number (see below) is large, then boundary or interior layers may occur. Other examples are edge singularities appearing along concave edges in three-dimensional domains. In these cases the use of anisotropic meshes is recommended. Such meshes consist of elements in which the aspect ratio can be very large. Our second goal is to present a residual error estimate valid for anisotropic meshes satisfying minimal assumptions (contrary to the case of a standard residual error estimate for finite element methods; see [15, 16, 18]). This estimate is such that the size of the constant appearing in the upper bound is independent of the coefficients of the operator, while the size of the constant appearing in the lower bound is explicitly given with respect to the coefficients of the operator. These facts are further confirmed numerically.

In contrast with standard practice [35, 19], we do not assume a strong coerciveness assumption (see below), and therefore our residual a posteriori analysis differs from [35, 19].

The outline of the paper is as follows: In section 2 we describe the so-called "cell centered" method for the diffusion-convection-reaction model problem on a triangulation of the domain consisting of triangles, rectangles, or tetrahedra. Some inverse inequalities are recalled in section 3, where we give some further useful interpolation error estimates. Section 4 is devoted to the introduction of some new finite elements (of Morley type) used later on. In section 5 we introduce the Morley interpolant of the approximate solution and prove its main properties. The upper and lower error bounds are then deduced in section 6. The upper error bound is based on the properties of the Morley interpolant, while the lower error bound is proved in a quite standard way. Finally, section 7 is devoted to numerical tests that confirm our theoretical considerations.

2. Discretization of the diffusion-convection-reaction equation. Let Ω be a bounded open subset of $\mathbb{R}^d$, $d = 2$ or 3, with a polygonal ($d = 2$) or polyhedral ($d = 3$) boundary Γ.

We consider the following standard elliptic problem: For $f \in L^2(\Omega)$ let u be the solution of

$$\begin{cases} Au := \operatorname{div}(-\varepsilon\nabla u + \mathbf{v}u) + bu & = f \quad \text{in} \quad \Omega, \\ u & = 0 \quad \text{on} \quad \Gamma, \end{cases} \tag{2.1}$$

where ε is a fixed positive constant, $\mathbf{v}$ a fixed vector function assumed to be sufficiently regular, namely $\mathbf{v} \in C^1(\bar{\Omega}, \mathbb{R}^d)$, and $b \in L^\infty(\Omega, \mathbb{R})$ is a fixed function. This problem is a linearized diffusion-convection-reaction problem appearing in many physical models. In the case of a large Peclet number $Pe \equiv \varepsilon^{-1}\|\mathbf{v}\|_\infty$ and/or large number $\Gamma \equiv \varepsilon^{-1}\|\operatorname{div}\mathbf{v} + b\|_\infty$, the problem is singularly perturbed and the solution may generate sharp boundary or interior layers, where the solution of the limit problem (corresponding to $\varepsilon = 0$) is not smooth or does not satisfy the Dirichlet boundary condition.

In this paper we further assume that

$$\frac{1}{2}\operatorname{div}\mathbf{v} + b \geq 0.$$

This assumption guarantees that there exists a unique weak solution $u \in H_0^1(\Omega)$ of problem (2.1), i.e., satisfying

$$\int_\Omega (\varepsilon \nabla u \cdot \nabla v + \operatorname{div}(\mathbf{v}u)v + buv)\,dx = \int_\Omega fv\,dx \quad \forall v \in H_0^1(\Omega). \tag{2.2}$$

Moreover this solution satisfies

$$|||u||| \lesssim \|f\|, \tag{2.3}$$

where $|||\cdot|||$ is the natural energy norm defined by

$$|||u|||^2 := \int_\Omega \left(\varepsilon|\nabla u|^2 + \left(\frac{1}{2}\operatorname{div}\mathbf{v} + b\right)|u|^2\right).$$

This norm slightly differs from the one used in [35, 19] since in those papers the authors assume that the strong coercivity assumption

$$\frac{1}{2}\operatorname{div}\mathbf{v}(x) + b(x) \geq c_0 > 0 \quad \forall x \in \Omega,$$

holds. This condition excludes the study of convection-diffusion equations (2.1) with $b = 0$ and $\operatorname{div}\mathbf{v} = 0$ that we want to consider here. Therefore their residual a posteriori analysis slightly differs from the one presented here.

As usual, we denote by $L^2(.)$ the Lebesgue spaces and by $H^s(.)$, $s \geq 0$, the standard Sobolev spaces. The usual norm and seminorm of $H^s(D)$ are denoted by $\|\cdot\|_{s,D}$ and $|\cdot|_{s,D}$. For the sake of brevity the $L^2(D)$-norm will be denoted by $\|\cdot\|_D$, and in the case when $D = \Omega$, we will drop the index Ω. The space $H_0^1(\Omega)$ is defined, as usual, by $H_0^1(\Omega) := \{v \in H^1(\Omega) : v = 0 \text{ on } \Gamma\}$. In what follows, the symbol $|\cdot|$ will denote either the Euclidean norm in $\mathbb{R}^d$, $d = 2$ or 3, or the length of a line segment, or the measure of a domain of $\mathbb{R}^d$. Finally, the notation $a \lesssim b$ means here and below that there exists a positive constant C independent of a and b (of the meshsize of the triangulation, as well as the diffusion constant ε) such that $a \leq C\ b$. The notation $a \sim b$ means that $a \lesssim b$ and $b \lesssim a$ hold simultaneously.

2.1. Discretization of the domain. To approximate problem (2.1) by a finite volume scheme we fix a mesh T_h of Ω that satisfies the usual conformity conditions; cf. [6, Chap. 2]. In two dimensions we assume that all elements of T_h are triangles or rectangles, while in three dimensions the mesh is made up of tetrahedra only. For $K \in T_h$ we denote by h_K the diameter of K, and $h = \max_{K\in T_h} h_K$.

We define E_h as the set of edges ($d = 2$) or faces ($d = 3$) of the triangulation, $E_h^{int} = \{E \in E_h / E \subset \Omega\}$ as the set of interior edges/faces of T_h, and $E_h^{ext} = E_h \setminus E_h^{int}$ as the set of exterior edges/faces of T_h.

For an edge E of a two-dimensional element K we introduce $n_{K,E} = (n_x, n_y)$, which is the unit outward normal vector to K along E. Similarly, for a face E of a tetrahedron K let $n_{K,E} = (n_x, n_y, n_z)$ be the unit outward normal vector to K on E. Furthermore, for each edge/face E we fix one of the two normal vectors and denote it by n_E.

The jump of some function v across an edge/face E at a point $y \in E$ is defined as

$$[\![v(y)]\!]_E := \begin{cases} \lim_{\alpha\to+0} v(y + \alpha n_E) - v(y - \alpha n_E) & \forall E \in E_h^{int}, \\ v(y) & \forall E \in E_h^{ext}. \end{cases}$$

Finally, we will need local subdomains (also called patches). As usual, let ω_K be the union of all elements having a common edge/face with K. Similarly, let ω_E be the union of both elements having E as an edge/face.

2.2. The finite volume scheme. Integrating (2.1) on a control volume K and using the divergence formula, we obtain

$$\sum_{E\in E_K}\int_E(-\varepsilon\nabla u+\mathbf{v}u)\cdot n_{K,E}\,ds+\int_K bu\,dx=\int_K f(x)\,dx\quad\forall K\in T_h, \tag{2.4}$$

where E_K is the set of edges/faces of K. The continuous diffusion flux $-\varepsilon\nabla u\cdot n_{K,E}$ is approximated using finite differences and the principle of conservation of flux, the expression $\mathbf{v}u\cdot n_{K,E}$ is approximated by a first order upwind scheme, and the reaction term $\int_K bu$ by a simple quadrature formula (see [10]). These approximations lead to the following system: Find $u_h:=(u_K)_{K\in T_h}$ (u_K being the approximation of $u(x_K)$ for $K\in T_h$ with x_K being the "center" of the box K) that is a solution of

$$\sum_{E\in E_K}\left(-\varepsilon F^D_{K,E}(u_h)+v_{K,E}F^C_E(u_h)\right)+\beta_K F^R_K(u_h)=\int_K f(x)\,dx\quad\forall K\in T_h, \tag{2.5}$$

where $v_{K,E}=\mathcal{M}_E(\mathbf{v}\cdot n_{K,E})$, $\beta_K=\mathcal{M}_K b$; $\mathcal{M}_K g$ and $\mathcal{M}_E g$ denote the mean of g on K and E, respectively, i.e.,

$$\mathcal{M}_K g=\frac{1}{|K|}\int_K g(x)\,dx\quad\forall K\in T_h,\quad \mathcal{M}_E g=\frac{1}{|E|}\int_E g(x)\,d\sigma(x)\quad\forall E\in E_h,$$

while the quantities $F^C_E(u_h)$ and $F^R_K(u_h)$ are defined as

$$F^C_E(u_h):=|E|u_{E,+}, \tag{2.6}$$

where for $E\in E_h^{int}$, $u_{E,+}=u_{K_{E,+}}$, with $K_{E,+}$ being the upstream control volume, i.e., $v_{K_{E,+},E}\geq 0$, while for $E\in\bar K\cap\Gamma$, $u_{E,+}=u_K$ if $v_{K,E}\geq 0$, and $u_{E,+}=0$ otherwise. Similarly,

$$F^R_K(u_h)=|K|u_K.$$

For our purposes, we do not need the exact form of $F^D_{K,E}(u_h)$, but the principle of conservation of flux is required:

$$F^D_{K,E}(u_h)=-F^D_{L,E}(u_h)\text{ for }E=\bar K\cap\bar L.$$

If the mesh T_h is admissible in the sense of [10, Def. 9.1], i.e., satisfies standard orthogonality conditions (see Figure 2.1), then the numerical diffusion flux is defined by

$$F^D_{K,E}(u_h):=\begin{cases}\frac{|E|}{d_E}(u_L-u_K) & \text{if } E=\overline{K}\cap\overline{L},\\ -\frac{|E|}{d_E}u_K & \text{if } E\subset\overline{K}\cap\partial\Omega,\end{cases} \tag{2.7}$$

when $d_E=d(x_K,x_L)$ if $E=\overline{K}\cap\overline{L}$, with $K,L\in T_h$ and $d_E=d(x_K,\Gamma)$ if $E=\partial K\cap\Gamma$. For general meshes, a possible choice for $F^D_{K,E}(u_h)$ is proposed in [7, 8] using the diamond cell method.

For a restricted admissible mesh in the sense of [10, Def. 9.4], if $F^D_{K,E}(u_h)$ is given by (2.7), then system (2.5) is well defined as proved in [9]; see also [10] in the particular case when $\operatorname{div}\mathbf{v}\geq 0$ and b a positive constant. For a general mesh, as is the case here, we simply assume that system (2.5) has a unique solution.

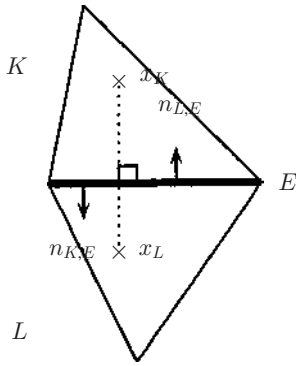

FIG. 2.1. *The standard orthogonality condition.*

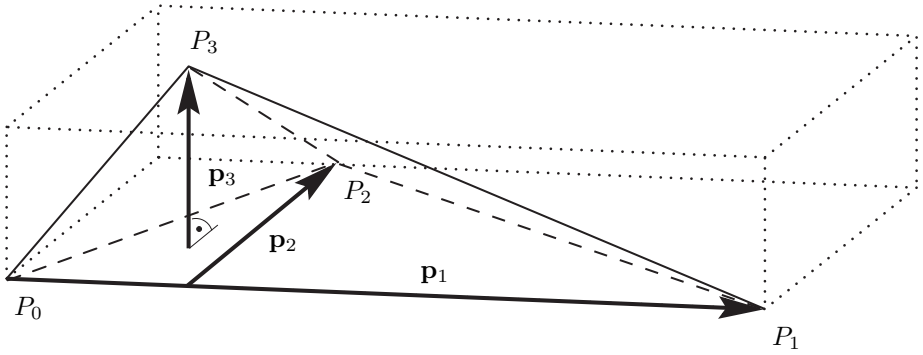

FIG. 2.2. *Notation of tetrahedron K.*

2.3. Some anisotropic quantities. As explained in the introduction, anisotropic discretizations can be very advantageous or, in certain situations, even mandatory. More information and arguments concerning anisotropy can be found in [2, 15].

In this subsection we introduce and describe anisotropic quantities and present their basic properties.

We start with an arbitrary (anisotropic) tetrahedron $K \in T_h$. We enumerate its vertices so that P_0P_1 is the longest edge, $\text{meas}_2(\triangle P_0P_1P_2) \geq \text{meas}_2(\triangle P_0P_1P_3)$, and $\text{meas}_1(P_1P_2) \geq \text{meas}_1(P_0P_2)$. Further, we introduce three orthogonal vectors $\mathbf{p}_{i,K}$ of length $h_{i,K} := |\mathbf{p}_{i,K}|$, as described in Figure 2.2.

The minimal element size is particularly important; thus define

$$h_{min,K} := h_{3,K}.$$

The three main anisotropic directions $\mathbf{p}_{i,K}$ play an important role in several proofs. They span the orthogonal matrix

$$C_K := (\mathbf{p}_{1,K}, \mathbf{p}_{2,K}, \mathbf{p}_{3,K}) \in \mathbb{R}^{3\times 3}.$$

This matrix may be considered as a transformation matrix which defines implicitly the *reference element* $\hat{K}$ via $\hat{K} := C_K^{-1}(K - \vec{P}_0)$; cf. Figure 2.3. In order to facilitate the understanding of this mapping, the circumscribing box of K has been drawn in Figure 2.2. This box is mapped onto the unit cube given in Figure 2.3. Note in particular that the reference element $\hat{K}$ is of size $\mathcal{O}(1)$.

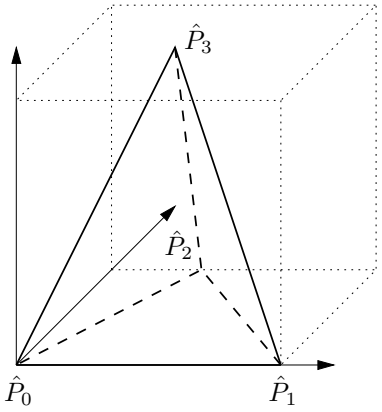

FIG. 2.3. *Reference tetrahedron* $\hat{K}$.

In two dimensions the notation is similar. For a triangle K the enumeration is as in the bottom triangle $P_0P_1P_2$ of Figure 2.2. For a rectangle K we simply take P_0P_1 as the longest edge of K, P_0P_2 as the edge perpendicular to P_0P_1, and simply take $\mathbf{p}_{1,K} = P_0P_1$, $\mathbf{p}_{2,K} = P_0P_2$. In both cases, $h_{min,K} := h_{2,K}$, and C_K becomes a 2×2 matrix.

For an edge/face E of an element K, introduce the height $h_{E,K} = \frac{|K|}{|E|}$.

3. Analytical tools.

3.1. Bubble functions, extension operator, and inverse inequalities. For our further analysis we require standard bubble functions and extension operators that satisfy certain properties recalled here for the sake of completeness.

We need two types of bubble functions, namely, b_K and b_E associated with an element K and an edge E, respectively. For a triangle or a tetrahedron K, denoting by $\lambda_{a_i^K}$, $i = 1, \ldots, d+1$, the barycentric coordinates of K and by $a_i^E, i = 1, \ldots, d$, the vertices of the edge/face $E \subset \partial K$ we recall that

$$b_K = \prod_{i=1}^{d+1} \lambda_{a_i^K} \text{ and } b_E = \prod_{i=1}^{d} \lambda_{a_i^E}.$$

For a rectangle K, we enumerate its vertices in a clockwise sense here. Denoting by $\lambda_{a_i^K}$, $i = 1, \ldots, 4$, the barycentric coordinates of K, namely, $\lambda_{a_i^K}$ is the unique element in $\mathbb{Q}_1(K)$ such that $\lambda_{a_i^K}(a_j^K) = \delta_{i,j}$, we recall that

$$b_K = \lambda_{a_1^K}\lambda_{a_3^K} \text{ and } b_E = \lambda_{a_1^K}(\lambda_{a_2^K} + \lambda_{a_3^K})$$

if the endpoints of the edge E are a_1^K and a_2^K.

We note that

$$b_K = 0 \text{ on } \partial K, \qquad b_E = 0 \text{ on } \partial\omega_E, \qquad \|b_K\|_{\infty,K} = \|b_E\|_{\infty,\omega_E} \sim 1.$$

In two dimensions for an edge $E \subset \partial K$, using temporarily the local coordinates system (x, y) such that E is included in the x-axis, the extension $\mathrm{F}_{\mathrm{ext}}(v_E)$ of $v_E \in C(E)$ to K is defined by $\mathrm{F}_{\mathrm{ext}}(v_E)(x, y) = v_E(x)$. We proceed similarly in three dimensions.

Now we may recall the so-called inverse inequalities that are proved using classical scaling techniques (cf. [34] for the isotropic case and [15] for the anisotropic case).

LEMMA 3.1 (inverse inequalities). *Let $v_K \in \mathbb{P}_{k_0}(K)$ and $v_E \in \mathbb{P}_{k_1}(E)$ for some nonnegative integers k_0 and k_1. Then the following inequalities hold, with the constants in the inequalities depending on the polynomial degrees k_0 or k_1 but not on K, E or v_K, v_E:*

$$\|v_K b_K^{1/2}\|_K \sim \|v_K\|_K, \tag{3.1}$$

$$\|\nabla(v_K b_K)\|_K \lesssim h_{min,K}^{-1}\|v_K\|_K, \tag{3.2}$$

$$\|v_E b_E^{1/2}\|_E \sim \|v_E\|_E, \tag{3.3}$$

$$\|\mathrm{F}_{\mathrm{ext}}(v_E) b_E\|_K \lesssim h_{E,K}^{1/2}\|v_E\|_E, \tag{3.4}$$

$$\|\nabla(\mathrm{F}_{\mathrm{ext}}(v_E) b_E)\|_K \lesssim h_{E,K}^{1/2} h_{min,K}^{-1}\|v_E\|_E. \tag{3.5}$$

3.2. Anisotropic interpolation error estimates. In order to obtain an accurate discrete solution u_h, it is obviously helpful to align the elements of the mesh according to the anisotropy of the solution. It turns out that this intuitive alignment is also necessary to prove sharp upper error bounds. In particular the proof employs specific interpolation error estimates. However, these interpolation estimates do not hold for general meshes; instead the mesh has to have the aforementioned anisotropic alignment with the function to be interpolated.

In order to quantify this alignment, we introduce a so-called alignment measure $m_1(v, T_h)$ which was originally introduced in [16].

DEFINITION 3.2 (alignment measure). *Let $v \in H^1(\Omega)$, and $\mathcal{F} = \{T_h\}$ be a family of triangulations of Ω. Define the* alignment measure *$m_1 : H^1(\Omega) \times \mathcal{F} \mapsto \mathbb{R}$ by*

$$m_1(v, T_h) := \left(\sum_{K \in T_h} h_{min,K}^{-2} \|C_K^\top \nabla v\|_K^2 \right)^{1/2} \Big/ \|\nabla v\|. \tag{3.6}$$

By definition one has $m_1(v, T_h) \geq 1$. For arbitrary isotropic meshes one obtains that $m_1(v, T_h) \sim 1$. The same is achieved for anisotropic meshes T_h that are aligned with the anisotropic function v. Therefore the alignment measure is not an obstacle for reliable error estimation.

Since the focus of our work is a posteriori error estimation, we refer to [17, 16] for discussions concerning this alignment measure.

LEMMA 3.3 (local interpolation error bounds). *Let $v \in H_0^1(\Omega)$; then,*

$$\|v - \mathcal{M}_K v\|_K \lesssim \|C_K^\top \nabla v\|_K \qquad \forall K \in T_h, \tag{3.7}$$

$$h_{E,K}\|v - \mathcal{M}_E v\|_E^2 \lesssim \|C_K^\top \nabla v\|_K^2 \qquad \forall E \in E_K, K \in T_h. \tag{3.8}$$

Proof. The first inequality (3.7) has been proved in [16, Lemma 4]. The same scaling argument and the compact embedding of $H^1(\hat{K})$ into $L^2(\hat{E})$ yield the second estimate. ∎

LEMMA 3.4 (global interpolation error bounds). *Let $v \in H^1(\Omega)$; then,*

$$\sum_{K \in T_h} h_{min,K}^{-2}\|v - \mathcal{M}_K v\|_K^2 \lesssim m_1(v, T_h)^2 \|\nabla v\|^2, \tag{3.9}$$

$$\sum_{K \in T_h} \sum_{E \in E_K \cap E_h^{int}} h_{E,K} h_{min,K}^{-2}\|v - \mathcal{M}_E v\|_E^2 \lesssim m_1(v, T_h)^2 \|\nabla v\|^2. \tag{3.10}$$

Proof. These are direct consequences of the previous lemma and the definition of the alignment measure. ∎

For further analysis of our estimator, we need specific interpolation estimates related to the diffusion-convection-reaction problem [36, 18, 19]. Namely, the error estimates have to be related to the energy norm $|||\cdot|||$ and a local quantity relying on the local meshsize and the local behavior of the functions involved in the operator. This quantity is defined by

$$\alpha_K := \min\{c_K^{-1/2}, \varepsilon^{-1/2} h_{min,K}\},$$

where we set

$$c_K = \min_{x\in K}\left(\frac{1}{2}\operatorname{div}\mathbf{v}(x) + b(x)\right).$$

Here we use the convention that if $c_K = 0$, then the minimum is the second term, namely, $\alpha_K := \varepsilon^{-1/2} h_{min,K}$.

We are now able to prove the following error estimate (compare with Lemma 3.9 of [18]).

LEMMA 3.5 (global interpolation error bounds). *Let $v \in H_0^1(\Omega)$. Then we have*

$$\sum_{K\in T_h} \alpha_K^{-2}\|v - \mathcal{M}_K v\|_K^2 \lesssim m_1(v,T_h)^2 |||v|||^2, \tag{3.11}$$

$$\varepsilon^{1/2}\sum_{K\in T_h}\alpha_K^{-1}\sum_{E\in E_K\cap E_h^{int}}\|v - \mathcal{M}_E v\|_E^2 \lesssim m_1(v,T_h)^2 |||v|||^2. \tag{3.12}$$

Proof. For the first estimate, we split up its left-hand side as follows:

$$\begin{aligned}\sum_{K\in T_h}\alpha_K^{-2}\|v - \mathcal{M}_K v\|_K^2 = &\sum_{K\in T_h:\varepsilon h_{min,K}^{-2}\le c_K} c_K\|v - \mathcal{M}_K v\|_K^2\\ &+ \sum_{K\in T_h:\varepsilon h_{min,K}^{-2} > c_K}\varepsilon h_{min,K}^{-2}\|v - \mathcal{M}_K v\|_K^2.\end{aligned}$$

By the definition of c_K and estimate (3.9), we conclude that

$$\begin{aligned}\sum_{K\in T_h}\alpha_K^{-2}\|v - \mathcal{M}_K v\|_K^2 &\lesssim \|\left(\frac{1}{2}\operatorname{div}\mathbf{v} + b\right)^{1/2} v\|^2 + \varepsilon m_1(v,T_h)^2\|\nabla v\|^2\\ &\lesssim m_1(v,T_h)^2|||v|||^2.\end{aligned}$$

For the second estimate, we first use the same splitting

$$\begin{aligned}\sum_{K\in T_h}\sum_{E\in E_K\cap E_h^{int}}\alpha_K^{-1}\|v - \mathcal{M}_E v\|_E^2 = &\sum_{\substack{K\in T_h:\\ \varepsilon h_{min,K}^{-2}\le c_K}}\sum_{E\in E_K\cap E_h^{int}}\alpha_K^{-1}\|v - \mathcal{M}_E v\|_E^2\\ &+ \sum_{\substack{K\in T_h:\\ \varepsilon h_{min,K}^{-2} > c_K}}\sum_{E\in E_K\cap E_h^{int}}\alpha_K^{-1}\|v - \mathcal{M}_E v\|_E^2.\end{aligned}$$

As before, this leads to

$$\varepsilon^{1/2}\sum_{K\in T_h}\sum_{E\in E_K\cap E_h^{int}}\alpha_K^{-1}\|v-\mathcal{M}_E v\|_E^2 \lesssim \varepsilon^{1/2}\sum_{\substack{K\in T_h:\\ \varepsilon h_{min,K}^{-2}\le c_K}} c_K^{1/2}\sum_{E\in E_K\cap E_h^{int}}\|v\|_E^2$$
$$+\varepsilon\sum_{\substack{K\in T_h:\\ \varepsilon h_{min,K}^{-2}> c_K}} h_{min,K}^{-1}\sum_{E\in E_K\cap E_h^{int}}\|v-\mathcal{M}_E v\|_E^2.$$

Using the estimate $h_{min,K}\lesssim h_{E,K}$ proved in Lemma 3.1 of [18] and the estimate (3.10), we obtain

$$\varepsilon^{1/2}\sum_{K\in T_h}\sum_{E\in E_K\cap E_h^{int}}\alpha_K^{-1}\|v-\mathcal{M}_E v\|_E^2 \lesssim \sum_{\substack{K\in T_h:\\ \varepsilon h_{min,K}^{-2}\le c_K}}\varepsilon^{1/2}c_K^{1/2}\sum_{E\in E_K\cap E_h^{int}}\|v\|_E^2 + \varepsilon m_1(v,T_h)^2\|\nabla v\|^2. \tag{3.13}$$

For the first term of this right-hand side, using the trace inequality (see, for instance, Lemma 2.4 of [15] or Lemma 3.5 of [18])

$$\|v\|_E^2\lesssim h_{E,K}^{-1}\|v\|_K(\|v\|_K+\|C_K^\top\nabla v\|_K),$$

we may write

$$\sum_{\substack{K\in T_h:\\ \varepsilon h_{min,K}^{-2}\le c_K}}\varepsilon^{1/2}c_K^{1/2}\sum_{E\in E_K\cap E_h^{int}}\|v\|_E^2\lesssim\sum_{\substack{K\in T_h:\\ \varepsilon h_{min,K}^{-2}\le c_K}}\varepsilon^{1/2}c_K^{1/2}h_{E,K}^{-1}(\|v\|_K^2+\|v\|_K\|C_K^\top\nabla v\|_K). \tag{3.14}$$

Fix for a moment an element K such that $\varepsilon h_{min,K}^{-2}\le c_K$. Using the property $h_{min,K}\lesssim h_{E,K}$ and Young's inequality with a parameter $\eta_K>0$, we may write

$$\varepsilon^{1/2}c_K^{1/2}h_{E,K}^{-1}(\|v\|_K^2+\|v\|_K\|C_K^\top\nabla v\|_K)\lesssim\varepsilon^{1/2}c_K^{1/2}h_{min,K}^{-1}\|v\|_K^2 + \frac{\varepsilon^{1/2}c_K^{1/2}}{2\eta_K}\|v\|_K^2+\frac{\varepsilon^{1/2}c_K^{1/2}h_{min,K}^{-2}\eta_K}{2}\|C_K^\top\nabla v\|_K^2.$$

Since $\varepsilon^{1/2}h_{min,K}^{-1}\le c_K^{1/2}$, the first term has the correct factor, namely,

$$\varepsilon^{1/2}c_K^{1/2}h_{E,K}^{-1}(\|v\|_K^2+\|v\|_K\|C_K^\top\nabla v\|_K) \lesssim c_K\|v\|_K^2+\frac{\varepsilon^{1/2}c_K^{1/2}}{2\eta_K}\|v\|_K^2+\frac{\varepsilon^{1/2}c_K^{1/2}h_{min,K}^{-2}\eta_K}{2}\|C_K^\top\nabla v\|_K^2.$$

For the last two terms we choose $\eta_K=\frac{\varepsilon^{1/2}}{c_K^{1/2}}$ which yields

$$\varepsilon^{1/2}c_K^{1/2}h_{E,K}^{-1}(\|v\|_K^2+\|v\|_K\|C_K^\top\nabla v\|_K)\lesssim c_K\|v\|_K^2+\varepsilon h_{min,K}^{-2}\|C_K^\top\nabla v\|_K^2.$$

This estimate in (3.14) leads to

$$\sum_{\substack{K\in T_h:\\ \varepsilon h_{min,K}^{-2}\le c_K}}\varepsilon^{1/2}c_K^{1/2}\sum_{E\in E_K\cap E_h^{int}}\|v\|_E^2\lesssim\sum_{K\in T_h}(c_K\|v\|_K^2+\varepsilon h_{min,K}^{-2}\|C_K^\top\nabla v\|_K^2) \lesssim m_1(v,T_h)^2|||v|||^2.$$

Inserting this estimate in (3.13) we arrive at (3.12). ∎

4. Some finite elements of Morley type. For our further analysis, we need a continuous interpolant p satisfying

$$\int_E \frac{\partial p}{\partial n_{K,E}}\, ds = F^D_{K,E}(u_h) \qquad \forall E \in E_K, \tag{4.1}$$

$$\int_E \mathbf{v}\cdot n_{K,E} p\, ds = v_{K,E} F^C_{K,E}(u_h) \qquad \forall E \in E_K, \tag{4.2}$$

$$\int_K bp = \beta_K F^R_K(u_h) \tag{4.3}$$

for any $K \in T_h$. This means that we need to use C^0-finite elements having as degrees of freedom the three left-hand sides above. Since these left-hand sides clearly depend on the restriction of $\mathbf{v}$ and b on K, the finite elements depend on these restrictions. The interpolant's construction is quite complicated and could be expansive from a computational point of view. Such elements are even not unique. We therefore build them in a generic way and also give simpler elements in the case of constant coefficients.

4.1. Convection-diffusion elements for constant coefficients. For a convection-diffusion problem with constant coefficients (i.e., for $b = 0$ and $\mathbf{v} \in \mathbb{R}^d, \mathbf{v} \neq 0$) we need an interpolant p satisfying only (4.1) and (4.2). In this case we need finite elements having as degrees of freedom the mean of p and the normal derivative of p on each edge. Therefore we need a kind of Morley element [24, 6]. In two dimensions we modify the element of Nilssen, Tai, and Winther [28] and extend this new element to rectangles and to tetrahedra.

4.1.1. Triangles. Here K is a (nondegenerate) triangle with vertices a_i^K, $i = 1, 2, N_f := 3$.

Now, inspired by [28, sect. 4], we take

$$\begin{aligned} &P_K = \mathbb{P}_2(K) \oplus \mathbb{P}_1(K) b_K = \{q + p b_K : q \in \mathbb{P}_2(K), p \in \mathbb{P}_1(K)\}, \\ &\Sigma_K = \{p(a_i^K)\}_{i=1,\dots,N_f} \cup \left\{\int_E p\, ds\right\}_{E\in E_K} \cup \left\{\int_E \frac{\partial p}{\partial n_{K,E}}\, ds\right\}_{E\in E_K}. \end{aligned} \tag{4.4}$$

LEMMA 4.1. *The above triple (K, P_K, Σ_K) is a C^0-finite element.*

Proof. It suffices to show that $w \in P_K$ satisfying

$$l(w) = 0 \quad \forall l \in \Sigma_K \tag{4.5}$$

is equal to zero. But w is of the form $w = q + p b_K$ with $q \in \mathbb{P}_2(K), p \in \mathbb{P}_1(K)$, and since b_K is identically equal to zero on the edges $E \in E_K$, the conditions $w(a_i^K) = \int_E w\, ds = 0$ are equivalent to

$$q(a_i^K) = \int_E q\, ds = 0.$$

Since the restriction of q to E is of degree 2, these conditions imply that $q_{|E} \equiv 0$ for all $E \in E_K$ and consequently $q \equiv 0$.

The conclusion follows from Lemma 4.1 of [28] since it is proved there that $w = p b_K$ with $p \in \mathbb{P}_1(K)$ satisfying $\int_E \frac{\partial w}{\partial n_{K,E}}\, ds = 0$ for all $E \in E_K$ is identically equal to zero.

The continuity of the element follows from the first part of the proof. ∎

4.1.2. Rectangles. Here K is a (nondegenerate) rectangle with vertices a_i^K, $i = 1, \dots, N_f := 4$ with edges parallel to the axes. Now we take

$$P_K = \{q + pb_K : q \in \mathbb{Q}_2(K), p(x,y) = \alpha x + \beta y + \gamma y^2, \alpha, \beta, \gamma \in \mathbb{R}\}.$$

As before, the degrees of freedom are defined by (4.4).

LEMMA 4.2. *The above triple (K, P_K, Σ_K) is a C^0-finite element.*

Proof. By an affine transformation, it suffices to show the result on the reference element $\hat{K} = (0,1)^2$. For the sake of brevity we will omit the sign $\hat{}$. As $\dim P_K = \operatorname{card} \Sigma_K$, it suffices to show that $w \in P_K$ satisfying (4.5) is equal to zero. But w is of the form $w = q + pb_K$ with $q \in \mathbb{Q}_2(K)$ and p of the form $p(x,y) = \alpha x + \beta y + \gamma y^2, \alpha, \beta, \gamma \in \mathbb{R}$. Since b_K is identically equal to zero on the edges $E \in E_K$, the conditions $w(a_i^K) = \int_E w\, ds = 0$ are equivalent to

$$q(a_i^K) = \int_E q\, ds = 0.$$

Since the restriction of q to E is of degree 2, these conditions imply, as before, that $q_{|E} \equiv 0$ for all $E \in E_K$. Fix the basis $\{\lambda_i(x)\lambda_j(y)\}_{0 \le i,j \le 2}$ of $\mathbb{Q}_2(K)$, where $\lambda_i \in \mathbb{P}_2(0,1)$ satisfy $\lambda_i(x_j) = \delta_{ij}$, where $x_i = \frac{i}{2}, i = 0, 1, 2$. Writing q in this basis, we observe that the property $q_{|E} \equiv 0$ for all $E \in E_K$ implies that $q(x,y) = \delta\lambda_1(x)\lambda_1(y) = \delta b_K(x,y)$ for some $\delta \in \mathbb{R}$.

Returning to w, we conclude that

$$w(x,y) = (\delta + \alpha x + \beta y + \gamma y^2) b_K(x,y).$$

Now, one readily sees that the remainding condition $\int_E \frac{\partial w}{\partial n_{K,E}}\, ds = 0$ for all $E \in E_K$ is equivalent to a homogeneous 4×4 linear system in $\alpha, \beta, \gamma, \delta$ whose unique solution is $\alpha = \beta = \gamma = \delta = 0$. Therefore w is identically equal to zero. ∎

4.1.3. Tetrahedra. Here K is a (nondegenerate) tetrahedron with vertices a_i^K, $i = 1, 2, 3, N_f := 4$.

Inspired by the above triangular example, we choose Σ_K defined by (4.4) and

$$P_K = \left\{ q + pb_K + \sum_{E \in E_K} \alpha_E b_E : p, q \in \mathbb{P}_1(K), \alpha_E \in \mathbb{R} \right\}.$$

As before, we can prove that the above triple (K, P_K, Σ_K) is a C^0-finite element.

4.2. Diffusion-convection-reaction elements for constant coefficients. We build our finite elements by slightly modifying the elements from the previous subsection.

4.2.1. Triangles. We take

$$\begin{aligned} P_K &= \{q + (p + \alpha b_K) b_K : q \in \mathbb{P}_2(K), p \in \mathbb{P}_1(K), \alpha \in \mathbb{R}\}, \\ \Sigma_K &= \{p(a_i^K)\}_{i=1,\dots,N_f} \cup \left\{ \int_K p \right\} \cup \left\{ \int_E p\, ds \right\}_{E \in E_K} \cup \left\{ \int_E \frac{\partial p}{\partial n_{K,E}}\, ds \right\}_{E \in E_K}. \end{aligned} \tag{4.6}$$

LEMMA 4.3. *The above triple (K, P_K, Σ_K) is a C^0-finite element.*

Proof. It suffices to show that $w \in P_K$ satisfying (4.5) is equal to zero. Here w is of the form $w = q + (p + \alpha b_K) b_K$ with $q \in \mathbb{P}_2(K), p \in \mathbb{P}_1(K)$, and $\alpha \in \mathbb{R}$. As in Lemma 4.1, the conditions $w(a_i^K) = \int_E w\, ds = 0$ imply that $q \equiv 0$.

Next, we consider the condition

$$\int_E \frac{\partial w}{\partial n_{K,E}}\, ds = 0 \qquad \forall E \in E_K,$$

which is reduced to

$$\int_E \frac{\partial (pb_K)}{\partial n_{K,E}}\, ds = 0 \qquad \forall E \in E_K.$$

Thanks to Lemma 4.1 of [28], p is identically equal to zero.

Finally, the condition $\int_K w$ becomes $\alpha \int_K b_K^2 = 0$, which leads to the conclusion. ∎

4.2.2. Rectangles. In the setting of subsection 4.1.2, we take Σ_K defined by (4.6) and

$$P_K = \{q + pb_K : q \in \mathbb{Q}_2(K), p(x,y) = \alpha x + \beta y + \gamma x^2 + \delta y^2, \alpha, \beta, \gamma, \delta \in \mathbb{R}\}.$$

Arguments similar to those used in the proof of Lemma 4.2 allow one to show that the above triple (K, P_K, Σ_K) is a C^0-finite element.

4.2.3. Tetrahedra. Inspired by the above triangular example and the tetrahedral example from subsection 4.1, we choose Σ_K defined by (4.6) and

$$P_K = \left\{ q + pb_K + \alpha b_K^2 + \sum_{E \in E_K} \alpha_E b_E : p, q \in \mathbb{P}_1(K), \alpha_E, \alpha \in \mathbb{R} \right\}.$$

As before, the above triple (K, P_K, Σ_K) is a C^0-finite element.

4.3. Reaction-diffusion elements for constant coefficients. If we consider only reaction-diffusion equations (i.e., $\mathbf{v} = 0$), we may restrict ourselves to an interpolant p satisfying (4.1) and (4.3). Therefore we need to use finite elements having as degrees of freedom the left-hand side of (4.1) and the mean on K. Again we need to slightly modify the previous elements.

4.3.1. Triangles or tetrahedra. We take

$$\begin{aligned} P_K &= \{q + (p + \alpha b_K) b_K : q \in \mathbb{P}_1(K), p \in \mathbb{P}_1(K), \alpha \in \mathbb{R}\}, \\ \Sigma_K &= \{p(a_i^K)\}_{i=1,\dots,N_f} \cup \left\{ \int_K p \right\} \cup \left\{ \int_E \frac{\partial p}{\partial n_{K,E}}\, ds \right\}_{E \in E_K}. \end{aligned} \tag{4.7}$$

LEMMA 4.4. *The above triple (K, P_K, Σ_K) is a C^0-finite element.*

Proof. As usual, it suffices to show that $w \in P_K$ satisfying (4.5) is equal to zero. Here w is of the form $w = q + (p + \alpha b_K) b_K$ with $q \in \mathbb{P}_1(K), p \in \mathbb{P}_1(K)$, and $\alpha \in \mathbb{R}$. As in Lemma 4.1, the conditions $w(a_i^K) = 0$ imply that $q \equiv 0$ since q is of degree at most 1. The remainder of the proof is the same as the one of Lemma 4.3. ∎

4.3.2. Rectangles. In the setting of subsection 4.1.2, we take Σ_K defined by (4.7) and

$$P_K = \{q + pb_K : q \in \mathbb{Q}_1(K), p(x,y) = \eta + \alpha x + \beta y + \gamma x^2 + \delta y^2, \alpha, \beta, \gamma, \delta, \eta \in \mathbb{R}\}.$$

Arguments similar to those used in the proof of Lemma 4.2 allow one to show that the triple (K, P_K, Σ_K) is a C^0-finite element.

4.4. General case.

4.4.1. Triangles or tetrahedra. Inspired by the previous examples, we take

$$P_K^{\mathbf{v},b} = \Big\{ q_0 + \sum_{E\in E_K} \alpha_E \tilde{v}_{K,E} b_E b_K + \Big(\sum_{E\in E_K} \beta_E b_E + \gamma b_K \Big) b_K : q_0 \in \mathbb{P}_1(K), \alpha_E, \beta_E, \gamma \in \mathbb{R} \Big\}, \tag{4.8}$$

$$\Sigma_K^{\mathbf{v},b} = \{p(a_i^K)\}_{i=1,\dots,N_f} \cup \Big\{ \int_E \mathbf{v}\cdot n_{K,E} p\, ds \Big\}_{E\in E_K} \cup \Big\{ \int_E \frac{\partial p}{\partial n_{K,E}}\, ds \Big\}_{E\in E_K} \cup \Big\{ \int_K bp \Big\}, \tag{4.9}$$

where $\tilde{v}_{K,E}$ is any extension from E to K of the function $\mathbf{v}\cdot n_{K,E}$ such that $\tilde{v}_{K,E} \equiv 0$ if $\mathbf{v}\cdot n_{K,E} \equiv 0$ on E. Here there is a slight abuse of notation in the sense that the degree of freedom $\int_E \mathbf{v}\cdot n_{K,E} p\, ds$ (or $\int_K bp$) disappears if $\mathbf{v}\cdot n_{K,E} \equiv 0$ on E (or $b \equiv 0$).

As before, we can prove that the triple $(K, P_K^{\mathbf{v},b}, \Sigma_K^{\mathbf{v},b})$ is a C^0-finite element.

4.4.2. Rectangles. Now we take $P_K^{\mathbf{v},b}$ defined by (4.8), but with q_0 in $\mathbb{Q}_1(K)$ and $\Sigma_K^{\mathbf{v},b}$ defined by (4.9). Again this triple $(K, P_K^{\mathbf{v},b}, \Sigma_K^{\mathbf{v},b})$ is a C^0-finite element.

5. The Morley interpolant.

5.1. Definition. For any $K \in T_h$, we fix a C^0-finite element $(K, P_K^{\mathbf{v},b}, \Sigma_K^{\mathbf{v},b})$ such that

$$\Big\{ \int_E \mathbf{v}\cdot n_{K,E} p\, ds \Big\}_{E\in E_K} \cup \Big\{ \int_E \frac{\partial p}{\partial n_{K,E}}\, ds \Big\}_{E\in E_K} \cup \Big\{ \int_K bp \Big\} \subset \Sigma_K^{\mathbf{v},b}.$$

We refer to the previous section for its existence.

We now introduce the finite element space:

$$V_h := \Big\{ v_h \in H_0^1(\Omega) : v_{h|K} \in P_K^{\mathbf{v},b} \quad \forall K \in T_h, \int_E \frac{\partial v_{h|K}}{\partial n_E}\, ds = \int_E \frac{\partial v_{h|K}}{\partial n_E}\, ds \qquad \forall E \in E_h, K, L \in T_h : E = K \cap L \Big\}.$$

DEFINITION 5.1. *For $u_h = (u_K)_{K\in T_h}$ we define its interpolant (of Morley type) $I_M u_h$ as the unique element v_h in V_h satisfying*

$$\int_E \frac{\partial v_{h|K}}{\partial n_{K,E}}\, ds = F_{K,E}^D(u_h) \quad \forall E \in E_K, K \in T_h, \tag{5.1}$$

$$\int_E \mathbf{v}\cdot n_{K,E} v_h\, ds = v_{K,E} F_E^C(u_h) \quad \forall E \in E_h^{int}, \tag{5.2}$$

$$\int_K b v_h\, dx = \beta_K F_K^R(u_h) \quad \forall K \in T_h. \tag{5.3}$$

5.2. Some useful properties. The key point of our a posteriori analysis is the following basic property of the Morley interpolant.

LEMMA 5.2. *If u_h is solution of* (2.5), *then $I_M u_h$ satisfies*

$$\int_K (A(I_M u_h) - f)\, dx = 0 \quad \forall K \in T_h. \tag{5.4}$$

Proof. By Green's formula we have

$$\begin{aligned}\int_K A(I_M u_h)\, dx &= \int_K (\operatorname{div}(-\varepsilon \nabla I_M u_h + \mathbf{v} I_M u_h) + b I_M u_h)\, dx \\ &= \sum_{E \in E_K} \int_E \left(-\varepsilon \frac{\partial (I_M u_h)}{\partial n_{K,E}} + \mathbf{v} \cdot n_{K,E} I_M u_h\right) ds + \int_K b I_M u_h\, dx.\end{aligned}$$

Using the properties (5.1), (5.2), and (5.3) satisfied by $I_M u_h$ we obtain

$$\int_K A(I_M u_h)\, dx = \sum_{E \in E_K} \left(-\varepsilon F^D_{K,E}(u_h) + v_{K,E} F^C_E(u_h)\right) + \beta_K F^R_K(u_h)$$

and we conclude by using (2.5). ∎

Now we prove a quasi-orthogonality relation that will be used for the upper error bound. We first define the gradient jump of $I_M u_h$ in the normal direction by

$$J_{E,n}(u_h) = \varepsilon \left[\left[\left(\frac{\partial}{\partial n_E}\right)(I_M u_h)\right]\right]_E \quad \forall E \in E_h^{int}.$$

LEMMA 5.3. *If u is a solution of* (2.2) *and u_h is a solution of* (2.5), *then for any $\chi \in H^1_0(\Omega)$, setting $e = u - I_M u_h$, we have that*

$$\begin{aligned}\int_\Omega (\varepsilon \nabla e \cdot \nabla \chi + (\operatorname{div}(\mathbf{v} e) + be)\chi)\, dx &= \sum_{K \in T_h} \int_K (f - A(I_M u_h))(\chi - \mathcal{M}_K \chi)\, dx \\ &\quad + \sum_{E \in E_h^{int}} \int_E J_{E,n}(u_h)(\chi - \mathcal{M}_E \chi)\, ds.\end{aligned} \tag{5.5}$$

Proof. For the sake of brevity denote the left-hand side of (5.5) by $I_1(\chi)$. By (2.2) and using Green's formula on each element K we obtain

$$I_1(\chi) = \int_\Omega f\chi\, dx - \sum_{K \in T_h} \int_K A(I_M u_h)\chi\, dx - \sum_{K \in T_h} \int_{\partial K} \varepsilon \frac{\partial (I_M u_h)}{\partial n_K} \chi\, ds.$$

The continuity of $I_M u_h$ and of χ across the edges/faces (in the sense of trace) and the fact that $\chi = 0$ on Γ lead to

$$I_1(\chi) = \sum_{K \in T_h} \int_K (f - A(I_M u_h))\chi\, dx + \sum_{E \in E_h^{int}} \int_E J_{E,n}(u_h)\chi\, ds.$$

Using the identity (5.4) we arrive at

$$I_1(\chi) = \sum_{K \in T_h} \int_K (f - A(I_M u_h))(\chi - \mathcal{M}_K \chi)\, dx + \sum_{E \in E_h^{int}} \int_E J_{E,n}(u_h)\chi\, ds.$$

The conclusion now follows from the fact that

$$\int_E J_{E,n}(u_h)\,ds = 0 \quad \forall E \in E_h^{int},$$

which is due to (5.1) and the principle of conservation of flux: $F_{K,E}^D(u_h) = -F_{L,E}^D(u_h)$ if $E = K \cap L$, $K, L \in T_h$. ∎

COROLLARY 5.4. *Let the assumptions of Lemma* 5.3 *be satisfied. Then, the following estimate holds:*

$$|I_1(\chi)| \lesssim \Big\{ \sum_{K\in T_h} \Big(\alpha_K^2 \|f - A(I_M u_h)\|_K^2 + \varepsilon^{-1/2}\alpha_K \sum_{E\in E_K\cap E_h^{int}} \|J_{E,n}(u_h)\|_E^2 \Big) \Big\}^{1/2} m_1(\chi, T_h)|||\chi|||. \tag{5.6}$$

Proof. The identity (5.5) and the Cauchy–Schwarz inequality yield

$$|I_1(\chi)| \lesssim \sum_{K\in T_h} \|f - A(I_M u_h)\|_K \|\chi - \mathcal{M}_K\chi\|_K + \sum_{K\in T_h} \sum_{E\in E_K\cap E_h^{int}} \|J_{E,n}(u_h)\|_E \|\chi - \mathcal{M}_E\chi\|_E.$$

The discrete Cauchy–Schwarz inequality then leads to

$$\begin{aligned} |I_1(\chi)| \lesssim{}& \Big(\sum_{K\in T_h} \alpha_K^2 \|f - A(I_M u_h)\|_K^2 \Big)^{1/2} \Big(\sum_{K\in T_h} \alpha_K^{-2} \|\chi - \mathcal{M}_K\chi\|_K^2 \Big)^{1/2} \\ &+ \Big(\sum_{K\in T_h} \varepsilon^{-1/2}\alpha_K \sum_{E\in E_K\cap E_h^{int}} \|J_{E,n}(u_h)\|_E^2 \Big)^{1/2} \\ &\cdot \Big(\sum_{K\in T_h} \varepsilon^{1/2}\alpha_K^{-1} \sum_{E\in E_K\cap E_h^{int}} \|\chi - \mathcal{M}_E\chi\|_E^2 \Big)^{1/2}. \end{aligned}$$

We conclude by applying Lemma 3.5. ∎

Remark 5.5. The fundamental properties above are based only on the definition of the scheme (2.5), on the continuity of the interpolant, and on the interpolation properties (5.1), (5.2), and (5.3). Therefore our further analysis is valid for any finite element $(K, P_K^{\mathbf{v},b}, \Sigma_K^{\mathbf{v},b})$ such that the associated interpolant satisfies these properties. But the finite element and the definition of the interpolant should be appropriately chosen in order to guarantee the convergence of $I_M u_h$ to the exact solution u. This convergence analysis is yet to be performed but, in any case, it is outside the scope of this paper.

6. Error estimators.

6.1. Residual error estimators. The exact element residual is defined by $R_K := f - A(I_M u_h)$ on K. As usual, this exact residual is replaced by a certain finite-dimensional approximation $r_K \in \mathbb{P}_k(K)$ called an approximate element residual.

DEFINITION 6.1 (residual error estimator). *The local and global residual error estimators are defined by*

$$\eta_K^2 := \alpha_K^2 \|r_K\|_K^2 + \varepsilon^{-1/2}\alpha_K \sum_{E\in E_K\cap E_h^{int}} \|J_{E,n}(u_h)\|_E^2, \qquad \eta^2 := \sum_{K\in T_h} \eta_K^2.$$

The local and global approximation terms are defined by

$$\zeta_K^2 := \alpha_K^2 \sum_{K' \subset \omega_K} \|R_{K'} - r_{K'}\|_{K'}^2, \qquad \zeta^2 := \sum_{K \in T_h} \zeta_K^2.$$

6.2. Upper error bound.

THEOREM 6.2. *Let u be a solution of (2.2) and u_h a solution of (2.5), and denote the error by $e := u - I_M u_h$. Then the error is bounded as follows:*

$$|||e||| \lesssim m_1(e, T_h)(\eta + \zeta). \tag{6.1}$$

Proof. As e belongs to $H_0^1(\Omega)$, Green's formula yields

$$\int_\Omega (\mathrm{div}\,(\mathbf{v}e)e + b|e|^2)\,dx = \int_\Omega \left(\frac{1}{2}\mathrm{div}\,\mathbf{v} + b\right)|e|^2\,dx.$$

Therefore we have

$$|||e|||^2 = \int_\Omega (\varepsilon \nabla e \cdot \nabla e + (\mathrm{div}\,(\mathbf{v}e) + be)e)\,dx,$$

or equivalently, with the notation from Lemma 5.3,

$$|||e|||^2 = I_1(e).$$

The conclusion immediately follows from estimate (5.6). ∎

6.3. Lower error bound.

THEOREM 6.3. *Assume that there exists $\delta_1 > 2$ and $\delta_2 \in [3/2, 2)$ such that*

$$\begin{cases} -\mathrm{div}\,\mathbf{v} \le \delta_1 b & \text{in } \{x \in \Omega : \mathrm{div}\,\mathbf{v}(x) > 0\}, \\ -\mathrm{div}\,\mathbf{v} \le \delta_2 b & \text{in } \{x \in \Omega : \mathrm{div}\,\mathbf{v}(x) < 0\}. \end{cases} \tag{6.2}$$

Then for all elements K, the following local lower error bound holds:

$$\eta_K \lesssim (1 + Pe_{\omega_K} + \Gamma_{\omega_K})|||e|||_{\omega_K} + \zeta_K, \tag{6.3}$$

where $|||e|||_\omega^2 := \int_\omega (\varepsilon|\nabla e|^2 + (\frac{1}{2}\mathrm{div}\,\mathbf{v} + b)|e|^2)$; $Pe_{\omega_K} = \max_{K' \subset \omega_K} Pe_{K'}$ is the local patch Peclet number, with the local mesh Peclet number being defined as usual by

$$Pe_K = \varepsilon^{-1}\|\mathbf{v}\|_{\infty,K} h_{min,K};$$

see [11, 2, 19] *for anisotropic meshes and* [32, 35] *for isotropic meshes. The element-wise quantity Γ_{ω_K} is defined similarly; namely, $\Gamma_{\omega_K} = \max_{K' \subset \omega_K} \Gamma_{K'}$, where (cf.* [3, 2])

$$\Gamma_K = \max\{1, \alpha_K \|b + \mathrm{div}\,\mathbf{v}\|_{\infty,K}^{1/2}\}.$$

Proof. Since $b + \frac{1}{2}\mathrm{div}\,\mathbf{v} \ge 0$, we readily see that (6.2) is equivalent to

$$|b + \mathrm{div}\,\mathbf{v}| \le \gamma\left(b + \frac{1}{2}\mathrm{div}\,\mathbf{v}\right) \text{ in } \Omega, \tag{6.4}$$

with $\gamma = 2\max\{\frac{\delta_1 - 1}{\delta_1 - 2}, \frac{\delta_2 - 1}{2 - \delta_2}\} > 0$.

Element residual. For a fixed element K define $w_K = r_K b_K$, which belongs to $H_0^1(\Omega)$. From the definition of R_K we have

$$\begin{aligned}\int_K r_K w_K &= \int_K (r_K - R_K) w_K + \int_K R_K w_K = \int_K (r_K - R_K) w_K + \int_K A(u - I_M u_h) w_K \\ &= \int_K (r_K - R_K) w_K + \int_K (\operatorname{div}(\mathbf{v}e) + be) w_K - \int_K \operatorname{div}(\varepsilon \nabla e) w_K.\end{aligned}$$

Integrating by parts in that last term we obtain

$$\int_K r_K w_K = \int_K (r_K - R_K) w_K + \int_K \left(\varepsilon \nabla e \cdot \nabla w_K + (\operatorname{div}(\mathbf{v}e) + be) w_K\right).$$

Leibniz's rule and the Cauchy–Schwarz inequality yield

$$\begin{aligned}\int_K r_K w_K = \|r_K - R_K\|_K \|w_K\|_K &+ (\varepsilon \|\nabla w_K\|_K + \|\mathbf{v}\|_{\infty,K} \|w_K\|_K) \|\nabla e\|_K \\ &+ \|(\operatorname{div} \mathbf{v} + b) e\|_K \|w_K\|_K.\end{aligned}$$

Using property (6.4), we obtain

$$\begin{aligned}\int_K r_K w_K \le \|r_K - R_K\|_K \|w_K\|_K &+ (\varepsilon \|\nabla w_K\|_K + \|\mathbf{v}\|_{\infty,K} \|w_K\|_K) \|\nabla e\|_K \\ &+ \gamma^{1/2} \|\operatorname{div} \mathbf{v} + b\|_{\infty,K}^{1/2} \left\| \left(\frac{1}{2} \operatorname{div} \mathbf{v} + b\right)^{1/2} e \right\|_K \|w_K\|_K.\end{aligned}$$

By the inverse inequalities (3.1), (3.2) we get

$$\begin{aligned}\alpha_K \|r_K\|_K \lesssim \xi_K &+ \alpha_K (\varepsilon h_{min,K}^{-1} + \|\mathbf{v}\|_{\infty,K}) \|\nabla e\|_K \\ &+ \alpha_K \|\operatorname{div} \mathbf{v} + b\|_{\infty,K}^{1/2} \left\| \left(\frac{1}{2} \operatorname{div} \mathbf{v} + b\right)^{1/2} e \right\|_K.\end{aligned}$$

Using the property $\alpha_K \le \varepsilon^{-1/2} h_{min,K}$, we conclude that

$$\alpha_K \|r_K\|_K \lesssim (1 + Pe_K + \Gamma_K) |||e|||_K + \zeta_K. \tag{6.5}$$

Normal jump. Fix an arbitrary edge/face $E \in E_h^{int}$. Recall that $J_{E,n}(u_h) \in \mathbb{P}_k(E)$ for some $k \in \mathbb{N}$ and let

$$w_E := \mathrm{F}_{\mathrm{ext}}(J_{E,n}(u_h)) b_{E,\gamma_{E,K}} \text{ on } K_{E,\gamma_{E,K}} \subset K \subset \omega_E,$$

where $K_{E,\gamma_{E,K}}$ is the squeezed element associated with K (defined in [36, 15, 19] for triangles and tetrahedra and easily extended to rectangles; we do not go into detail here, though we note that the main properties of $K_{E,\gamma_{E,K}}$ are that it be included in K to have E as edge/face and be of height $\sim \gamma_{E,K} h_{E,K}$) and the parameter $\gamma_{E,K}$ is fixed and is equal to

$$\gamma_{E,K} = \min\left\{1, \frac{h_{min,K}}{h_{E,K}}, \frac{\varepsilon^{1/2}}{c_K^{1/2} h_{E,K}}\right\}.$$

Here the function $b_{E,\gamma_{E,K}}$ is the edge/face bubble associated with E in $K_{E,\gamma_{E,K}}$.

The difference with the choice made in [19] relies on the factor c_K.

By elementwise partial integration we get

$$\int_E J_{E,n}(u_h)w_E = -\varepsilon \sum_{K\subset\omega_E}\int_{\partial K}\frac{\partial e}{\partial n_K}w_E = -\sum_{K\subset\omega_E}\int_K (\varepsilon\nabla e\nabla w_E + \operatorname{div}(\varepsilon\nabla e)w_E)$$
$$= \sum_{K\subset\omega_E}\int_K (-\varepsilon\nabla e\nabla w_E + Aew_E - (\operatorname{div}(\mathbf{v}e) + be)w_E).$$

By Leibniz's rule, the Cauchy–Schwarz inequality, and condition (6.4) we obtain

$$\int_E J_{E,n}(u_h)w_E \lesssim \sum_{K\subset\omega_E}\Big(\|R_K\|_K\|w_E\|_K + (\varepsilon\|\nabla w_E\|_K + \|\mathbf{v}\|_{\infty,K}\|w_E\|_K)\|\nabla e\|_K$$
$$+ \|\operatorname{div}\mathbf{v} + b\|_{\infty,K}^{1/2}\|\Big(\frac{1}{2}\operatorname{div}\mathbf{v} + b\Big)^{1/2}e\|_K\|w_E\|_K\Big).$$

The inverse inequalities from Lemma 2 of [19] (see our Lemma 3.1 and the above properties of $K_{E,\gamma_{E,K}}$) in the previous estimate lead to

$$\|J_{E,n}(u_h)\|_E \lesssim \sum_{K\subset\omega_E}\gamma_{E,K}^{1/2}h_{E,K}^{1/2}[(\varepsilon\min\{\gamma_{E,K}h_{E,K}, h_{min,K}\}^{-1} + \|\mathbf{v}\|_{\infty,K})\|\nabla e\|_K$$
$$+ \|\operatorname{div}\mathbf{v} + b\|_{\infty,K}^{1/2}\|\Big(\frac{1}{2}\operatorname{div}\mathbf{v} + b\Big)^{1/2}e\|_K + \|R_K\|_K].$$

Multiplying this estimate by $\varepsilon^{-1/4}\alpha_K^{1/2}$ and using the definition of $\gamma_{E,K}$ we arrive at

(6.6)
$$\varepsilon^{-1/4}\alpha_K^{1/2}\|J_{E,n}(u_h)\|_E \lesssim (1 + Pe_{\omega_E})\varepsilon^{1/2}\|\nabla e\|_{\omega_E} + \Gamma_{\omega_E}\|\Big(\frac{1}{2}\operatorname{div}\mathbf{v} + b\Big)^{1/2}e\|_{\omega_E} + \zeta_K.$$

The conclusion follows from estimates (6.5) and (6.6). □

Remark 6.4. Condition (6.2) is not restrictive since it is satisfied in the so-called convection-dominated case $b + \frac{1}{2}\operatorname{div}\mathbf{v} \geq c_0 > 0$ in Ω. It also holds if $\operatorname{div}\mathbf{v} + b \geq 0$ and $b \geq 0$ (a.e.) in Ω.

7. Numerical results. In this section we present two examples that illustrate the efficiency and reliability of our estimator and show that our estimator is appropriate for adaptivity. Additionally, for both examples we provide the order of convergence of the error $|||u - I_M u_h|||$. In both cases the order is approximately h, which confirms that $I_M u_h$ is a good approximation to u. The first and second examples concern problems with solutions which exhibit boundary layers and for which the use of anisotropic meshes is recommended. The third example even treats the case when the meshes are not fully aligned with the solution. Finally, for a convection-diffusion problem we present two sequences of meshes obtained by an adaptive process. As the meshes are refined in the region of large variation of the solutions we can verify the reliability of our estimator.

For both examples we investigate the main theoretical results which are the upper and lower error bounds. In order to present the inequalities (6.1) and (6.3) appropriately, we consider the ratios

$$q_{up} := \frac{|||u - I_M u_h|||}{\eta + \xi}, \qquad q_{low} := \max_{K\in T_h}\frac{\eta_K}{(1 + Pe_{\omega_K} + \Gamma_{\omega_K})|||e|||_{\omega_K} + \zeta_K}$$

as a function of the degrees of freedom. The first ratio q_{up} is frequently referred to as the effectivity index. It measures the reliability of the estimator and is related to the global upper bound on the error. The second ratio is related to the local lower error bound and measures the efficiency of the estimator. From our theoretical considerations, both ratios should be bounded from above, which is confirmed below experimentally. Hence our estimator is reliable and efficient.

7.1. A reaction-diffusion problem (Test 1). As a particular problem, in (2.1) we take $\mathbf{v} = (0,0)^\top$ and $b = 1$ in the unit square; i.e., we consider

$$-\varepsilon\ \Delta u\ +\ u =\ 0 \quad \text{in} \quad \Omega = (0,1)^2.$$

We prescribe the exact solution to be

$$u(x,y) = \exp\left(-x/\sqrt{\varepsilon}\right),$$

with the Dirichlet boundary datum being fixed accordingly. This solution exhibits an exponential boundary layer of width $O(\sqrt{\varepsilon}|\ln\varepsilon|)$ along the y-axis.

To approximate the solution to this problem appropriately we use anisotropic meshes. Each mesh is the tensor product of a Shishkin-type mesh in the x-direction and a uniform mesh in the y-direction, both with n subintervals. More precisely we fix the transition point $\tau := \min\{1/2, \sqrt{\varepsilon}|\ln\varepsilon|\}$ and define the rectangular mesh of nodes (x_i, y_j), $0 \le i,j \le n$, with (n is assumed to be even)

$$\begin{aligned} &x_i = i2\tau h \text{ for } 0 \le i \le n/2,\\ &x_i = \tau + (2i-n)(1-\tau)h \text{ for } n/2 \le i \le n,\\ &y_j = jh \text{ for } 0 \le j \le n, \end{aligned}$$

where the meshsize h is equal to $1/n$. Such a mesh is illustrated in Figure 7.1 (left) for $h = 1/8$ and $\tau \approx 0.25$.

For each triangulation, we compute the finite volume approximation u_h as a solution to (2.5), and then compute its interpolant $I_M u_h$ using the finite element of subsection 4.3.2 (with the values of $I_M u_h$ at any interior node a being fixed by $I_M u_h(a) = \frac{1}{4}\sum_{a\in K} u_K$). Figure 7.2 presents the energy norm $|||u - I_M u_h|||$ with respect to n for different values of ε. The rate of convergence is approximately h, which confirms that $I_M u_h$ converges quite well to u.

Now we investigate the upper and lower error bounds. According to previous results on finite element methods [15, 19], the meshes are appropriately chosen to resolve the boundary layer, and consequently the alignment measure $m_1(e, T_h)$ should be moderated. Figure 7.3 presents the values of q_{up} (top) and of q_{low} (bottom) with respect to n for different values of ε. We observe that q_{up} is bounded from above by 0.15 and that q_{low} is bounded from above by 0.5.

7.2. Convection-diffusion problems (Test 2). Here we consider the convection-diffusion problem

$$-\varepsilon\ \Delta u\ +\ \operatorname{div}(\mathbf{v}u) =\ 0 \text{ in } \ \Omega = (0,1)^2, \tag{7.1}$$

where $\mathbf{v}$ is either $(-1,0)^\top$ or $(-1,-1)^\top$. We prescribe the exact solution to be, respectively,

$$u(x,y) = \exp\left(-x/\varepsilon\right) \text{ or } u(x,y) = \exp\left(-(x+y)/\varepsilon\right),$$

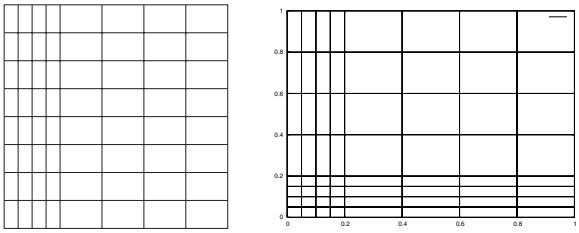

FIG. 7.1. *Shishkin-type meshes on the unit square with* $n = 8$.

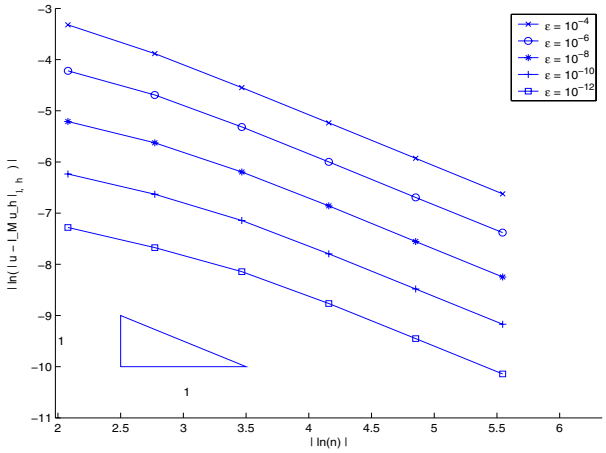

FIG. 7.2. *Illustration of the convergence of* $\|\nabla_h(u - I_M u_h)\|$ *for Test* 1.

with the Dirichlet boundary datum being fixed accordingly. In the first case the solution exhibits an exponential boundary layer of width $O(\varepsilon|\ln\varepsilon|)$ along the y-axis, while in the second case, two exponential boundary layers appear along the x and y axes. Therefore these problems are approximated using similar anisotropic meshes as before with the transition point $\tau := \min\{1/2, \varepsilon|\ln\varepsilon|\}$ (with the tensor product of two Shishkin type meshes in the second case; see Figure 7.1 (right)). Once we have computed the finite volume approximation u_h, solution of (2.5), we compute its interpolant $I_M u_h$ using the finite element of subsection 4.1.2 and the same values at the nodes as before.

Figure 7.4 shows the energy norm $|||u - I_M u_h|||$ with respect to n for different values of ε and confirms a rate of convergence of approximately h.

As before, the meshes are appropriately chosen so the alignment measure $m_1(e, T_h)$ should be moderated. The values of q_{up} and of q_{low} with respect to n for different values of ε are plotted in Figures 7.5 and 7.6. Here we observe similar values for both examples; moreover we see that q_{up} is bounded from above by 0.1 and that q_{low} is approximately 2.2.

7.3. Meshes not aligned with the solutions (Test 3). Here we consider the convection-diffusion problem (7.1) with $\mathbf{v} = (-\cos\theta, \sin\theta)^\top$, with $\theta = 0, 0.1\pi$, and 0.2π, and its prescribed solution given by

$$u(x, y) = \exp\left((-\cos\theta x + \sin\theta y)/\varepsilon\right)$$

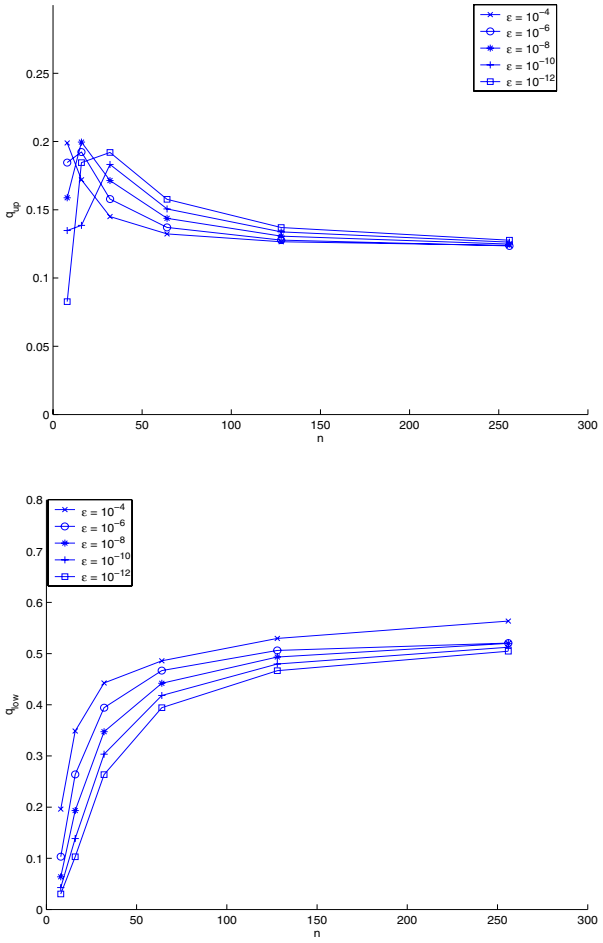

FIG. 7.3. q_{up} *(top) and* q_{low} *(bottom) with respect to* n *for Test* 1.

and $\varepsilon = 0.05$. This solution has a layer along the line $-\cos\theta x + \sin\theta y = 0$ (the case $\theta = 0$ corresponds to the case of the previous subsection but is presented in order to compare the different results). Here we take the sequence of meshes from subsection 7.1 with the transition point $\tau = 4\varepsilon = 0.2$. This means that for $\theta = 0.1\pi$ and 0.2π, the meshes are not fully aligned with the solution and are less and less aligned as θ increases. Nevertheless the convergence rate is h according to Figure 7.7. Moreover the values of q_{up} and q_{low} with respect to n for the different values of θ are plotted in Figures 7.8, where we see that q_{up} varies between 0.1 and 0.14 and that q_{low} is bounded from above by 2.75. From this figure, we further remark that the effectivity index q_{up} grows as θ increases, implying that the matching function $m_1(e, T_h)$ grows as well. This phenomenon was expected since the meshes are less and less aligned as θ increases.

7.4. An adaptive algorithm (Test 4). In view of the upper bound (6.1), we use the following (standard) adaptive process: Starting from an initial mesh T_{h_0}, we

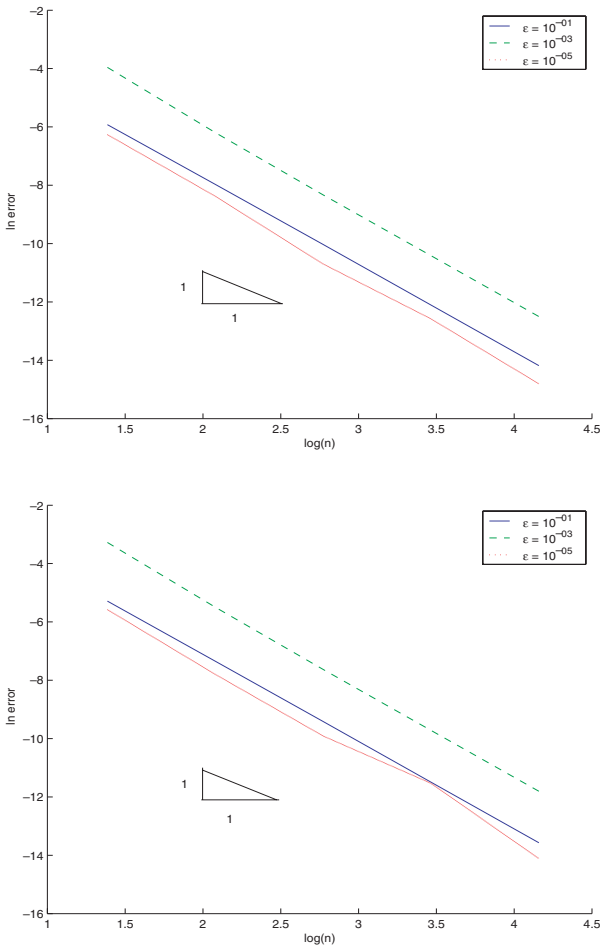

FIG. 7.4. *Illustration of the convergence of* $\|\nabla_h(u - I_M u_h)\|$ *for Test* 2 *for* $\mathbf{v} = (-1, 0)^\top$ (*top*) *and for* $\mathbf{v} = (-1, -1)^\top$ (*bottom*).

mark the elements K for which

$$\eta_K > c \max_{K'} \eta_{K'},$$

for a chosen constant $c \in (0, 1)$. All marked elements are divided into four subelements (standard regular refinement rule), with the other elements being subdivided only to guarantee the conformity of the new mesh. We refine the meshes up to the requested accuracy.

We test this adaptive algorithm for the convection-diffusion problem (7.1) with $\mathbf{v} = (1, 1)^\top$ and the prescribed solution given by

$$u(x, y) = \exp\left(-100((x - 0.5)^2 + (y - 0.5)^2)\right),$$

with the right-hand side and the boundary datum being fixed accordingly. This exact solution is a Gaussian function whose center is the point $(0.5, 0.5)$. For this example we use either meshes consisting of rectangles satisfying the admissibility condition or

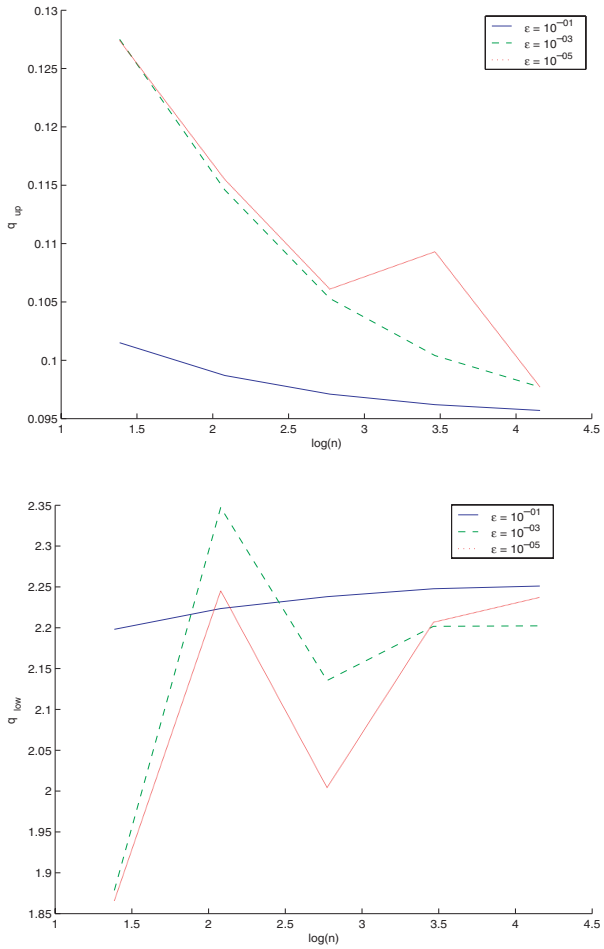

FIG. 7.5. *q_{up} (top) and q_{low} (bottom) with respect to n for Test 2 for* $\mathbf{v} = (-1, 0)^\top$.

meshes consisting of triangles that do not satisfy the admissibility condition (in which case we use the diamond cell technique; see subsection 2.2). The Morley interpolant is computed using the finite elements from subsection 4.1.2 or 4.1.1. The meshes obtained after four iterations are shown in Figure 7.9. In the case of rectangular meshes, anisotropic meshes appear due to the admissibility condition, but this does not affect the convergence of our adaptive process. This also underlines the incompatibility between standard refinement rules and this admissibility condition. From this figure, we can conclude that the meshes are refined in the region of large variation of the solution. Again this confirms the reliability of our estimator.

Figure 7.10 shows the energy norm $|||u - I_M u_h|||$ with respect to the degrees of freedom for the adaptive algorithm in comparison with uniformly refined meshes. In both cases, we see that the adaptive algorithm gives rise to better error bounds and to convergence in h.

The values of q_{up} and q_{low} with respect to the degrees of freedom are plotted in Figures 7.11 and 7.12 and are compared with uniformly refined meshes. There we observe that q_{up} is bounded from above by 0.1 and that q_{low} is bounded from above

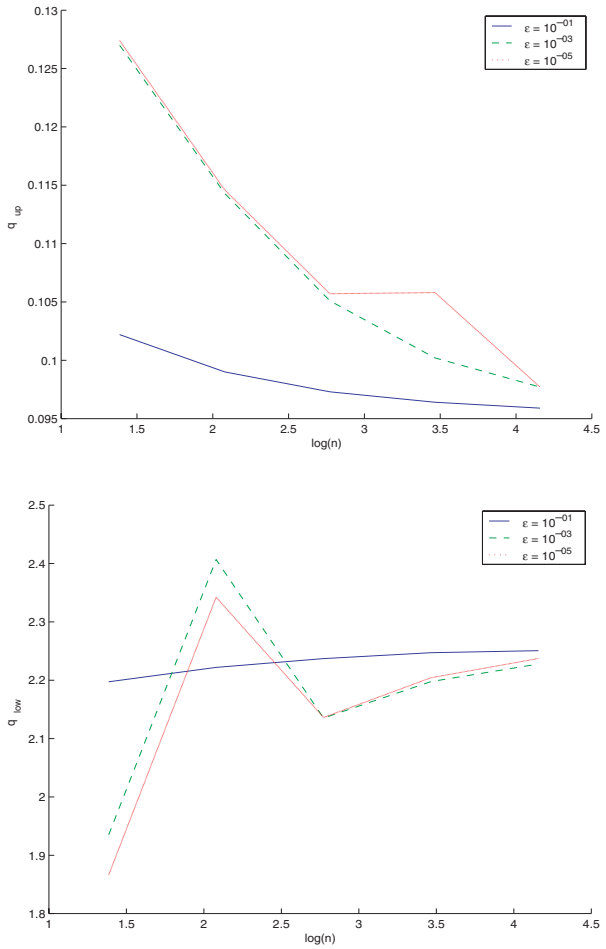

FIG. 7.6. q_{up} *(top) and* q_{low} *(bottom) with respect to* n *for Test* 2 *for* $\mathbf{v} = (-1,-1)^\top$.

by 1.42 (resp., 3.5). From these figures, we can say that the different values of q_{up} remain similar for adaptive meshes and for uniformly refined meshes, while the values of q_{low} have a different behavior but stay in a relatively small range of variations. For rectangular meshes, uniform meshes lead to smallest values of q_{low}, probably due to the overrefinement of adaptive meshes, while the converse holds for triangular meshes because adaptive triangular meshes fit the solution well.

8. Conclusions. We have proposed and rigorously analyzed a new a posteriori error estimate for a cell centered finite volume approximation of diffusion-convection-reaction equations. We have shown that this estimate is reliable and efficient. This estimate is based on the construction of an appropriate interpolant of Morley type. Some numerical experiments confirm our theoretical predictions.

Acknowledgment. I am very grateful to Karim Djadel (Cermics, ENPC, France), who made the numerical experiments presented in section 7.

DISCRETE COMPACTNESS FOR THE *hp* VERSION OF RECTANGULAR EDGE FINITE ELEMENTS*

DANIELE BOFFI†, MARTIN COSTABEL‡, MONIQUE DAUGE‡, AND LESZEK DEMKOWICZ§

Abstract. Discretization of Maxwell eigenvalue problems with edge finite elements involves a simultaneous use of two discrete subspaces of H^1 and $\mathbf{H}(\mathrm{curl})$, reproducing the exact sequence condition. Kikuchi's discrete compactness property, along with appropriate approximability conditions, implies the convergence of discrete eigenpairs to the exact ones. In this paper we prove the discrete compactness property for the edge element approximation of Maxwell's eigenpairs on general *hp* adaptive rectangular meshes. Hanging nodes, yielding 1-irregular meshes, are covered, and the order of the used elements can vary from one rectangle to another, thus allowing for a real *hp* adaptivity. As a particular case, our analysis covers the convergence result for the *p*-method.

Key words. Maxwell equations, *hp* finite elements, discrete compactness, edge elements, eigenvalue approximation

1. Introduction.

The importance of the exact sequence

$$H^1 \xrightarrow{\mathbf{grad}} \mathbf{H}(\mathrm{curl}) \xrightarrow{\mathbf{curl}} \mathbf{H}(\mathrm{div}) \xrightarrow{\mathrm{div}} L^2$$

has been recognized in the analysis of Maxwell equations [2, 12, 13]. In two space dimensions the sequence reduces to

$$H^1 \xrightarrow{\mathbf{grad}} \mathbf{H}(\mathrm{curl}) \xrightarrow{\mathrm{curl}} L^2.$$

In this paper we shall deal with the two-dimensional (2D) case.

The fundamental idea behind the construction of *edge elements* is based on the reproduction of the sequence at the discrete level. This idea had been also successfully exploited in the framework of mixed finite elements for elliptic problems, where it is also known as *commuting diagram property* [34].

Thus, we shall consider discrete subspaces of H^1 and $\mathbf{H}(\mathrm{curl})$ forming part of the discrete exact sequence. It is in this context that Kikuchi [35] introduced the fundamental notion of the *discrete compactness property* which, along with appropriate approximability properties, guarantees the convergence of discrete Maxwell eigenvalues to the exact ones. We also refer the reader to the book [17] for a definition corresponding to discrete compactness in an abstract setting. In another important contribution Caorsi, Fernandes, and Raffetto [16] have demonstrated that the discrete compactness

property is not only a sufficient but also a necessary condition for the convergence of Maxwell eigenvalues without the appearance of any spurious mode.

Let us recall that the difficulty related with the Maxwell curl curl operator is the lack of ellipticity manifested by the presence of the infinite dimensional kernel formed by the gradients. Nevertheless, the Maxwell problem is well posed as soon as the divergence-free constraint is imposed. With this constraint, the Maxwell problem recovers ellipticity properties due to the compact embedding of $\mathbf{H}_0(\mathrm{curl}) \cap \mathbf{H}(\mathrm{div})$ into L^2. The discrete compactness is the correct discrete analogue of the above compact embedding.

For the sake of clarity let us give the definition of discrete compactness property. As with the usual approximability properties, it is related to a sequence of discrete spaces. Let $(\mathbf{X}_n)_n$ be a sequence of finite dimensional subspaces of $\mathbf{H}_0(\mathrm{curl})$ and $(\mathbb{Q}_n)_n$ a related sequence of subspaces of H^1. We say that the sequence $(\mathbb{Q}_n, \mathbf{X}_n)_n$ has the discrete compactness property if the following holds:

Any sequence $\mathbf{u}_n \in \mathbf{X}_n$ of *discrete divergence-free* fields, i.e., satisfying

$$(\mathbf{u}_n, \mathbf{grad}\, \phi_n) = 0 \quad \forall \phi_n \in \mathbb{Q}_n$$

and uniformly bounded in $\mathbf{H}(\mathrm{curl})$, has a subsequence converging in L^2.

The discrete compactness property has been extensively studied in the framework of the h version of edge finite elements, where it is well known to hold true for a variety of edge finite elements on quite general 2D and three-dimensional (3D) meshes (see the review papers [19, 33], the book [38], and the references therein, among which we recall in particular [6, 7, 9, 14, 16, 35, 39]), but it has not been widely investigated for the p and hp version yet. On the other hand, electromagnetic devices very often involve complicated geometries, which in particular may be neither smooth nor convex. The analysis of the singularities arising from reentrant corners or edges and from material discontinuities (see [18, 20]) shows that such situations are to be handled with care. When using edge elements, one might want to locally adapt the meshsize h and the approximation order p, which can possibly vary from one element to another within the same mesh. Such an *hp strategy* is an excellent way to get accurate results (an *exponential convergence* is expected and observed) when even severe singularities are present (see [23, 42] for examples of hp finite element (FE) implementations).

In [8], the analysis of the discrete compactness property for triangular hp finite elements has been tackled, but the proof of the main result relied on a conjectured L^2 estimate which had only been demonstrated numerically. Even for the pure p method, there is no result in this direction available in the literature. In [37] the p version of edge elements has been considered, but the proved results do not apply to eigenvalue approximations.

In this paper, we consider the 2D case of rectangular elements. A rigorous proof of the discrete compactness property is provided for edge elements of the first Nédélec family. Our hypotheses allow for a complete hp refinement, including the presence of hanging nodes. The pure p version of edge elements, being a subset of our setting, is naturally covered by our analysis. The same proof applies to meshes of quadrilaterals obtained by affine transformation from the reference square (i.e., parallelograms) and, more generally, to meshes obtained using the so-called *algebraic mesh generators*.

The case of unstructured quadrilateral meshes presents some issues: It is known that the h version of standard edge elements does not provide optimal results in this case, and even in the lowest order case there is no convergence at all; see [3].

Nevertheless, the results of [31] show that the discrete compactness property holds in the framework of the h version for the modified family of edge elements proposed and analyzed in [3]; another, simpler modification has been proposed and analyzed in [11]. But the validity of the discrete compactness property for the p and hp versions of edge elements remains an open problem in the situation of unstructured meshes.

Our presentation starts with the pure p method on a single square element, which is analyzed in section 3 after the introduction of some preliminary notation in section 2. We consider, in particular, full tensor polynomials (the second Nédélec family of edge elements; see [41]) and standard edge element of the first Nédélec family (see [40]). We show that standard edge elements provide convergent approximation, while the second Nédélec family presents several spurious eigenpairs (more precisely, some discrete eigenvalues come with wrong multiplicity). We then present in section 4 the general hp theory which relies on an L^2 estimate which is proved thanks to the evaluation of an inf-sup constant on the reference element (section 4.3). We make use of the hp edge element spaces presented in [42], which generalize the first family of Nédélec finite elements.

We conclude our paper in section 5, where we recall the consequences of the discrete compactness property on the eigenvalue approximation by a Galerkin method: As a result, the kth nonzero eigenvalue of the Galerkin discretization converges to the kth nonzero Maxwell eigenvalue. We discuss the possibility of proving an exponential convergence rate, such as the one obtained in [22] for the discretization of the Maxwell problem by the weighted regularization method. We then finally comment on the extension of our proofs to the situation of general curvilinear polygons, with meshes obtained using algebraic mesh generators.

2. Preliminary notions and notation.

2.1. Polynomial spaces on the reference square. The square is defined as $\Sigma := I^2$, where I is the interval $(-1, 1)$. We denote the coordinates by $\mathbf{x} = (x, y)$. The outward unit normal vector on the boundary $\partial\Sigma$ is $\mathbf{n}$.

Everywhere p denotes an integer $p \geq 1$. The space of polynomials of degree $\leq p$ on I is denoted by $\mathbb{P}^p(I)$, and its subspace of polynomials φ with zero traces, $\varphi(\pm 1) = 0$, is denoted by $\mathbb{P}^p_0(I)$.

On the square, let $\mathbb{Q}^{p,q}(\Sigma)$ be the space of polynomials of separate degrees p and q in x and y, respectively. This can be expressed as

$$\mathbb{Q}^{p,q}(\Sigma) = \mathbb{P}^p(I) \otimes \mathbb{P}^q(I).$$

Symbol $\mathbb{Q}^p$ will be used for isotropic spaces, $\mathbb{Q}^p = \mathbb{Q}^{p,p}$, and $\mathbb{Q}^p_0$ will denote the polynomials with zero traces, $\mathbb{Q}^p_0 = \mathbb{P}^p_0 \otimes \mathbb{P}^p_0$.

We will study in the following two families of polynomial spaces for the electric field $\mathbf{u} = (u_1, u_2)$ on the square Σ.

2.1.1. Full tensor product spaces. $\mathbf{Q}^p(\Sigma)$ denotes the full space $\mathbb{Q}^p(\Sigma) \times \mathbb{Q}^p(\Sigma)$. This is the space of Lagrange nodal elements on the square and, with appropriate degrees of freedom, this also forms the *second Nédélec family* of edge elements.

We denote by $\mathbf{Q}^p_{\mathsf{N}}(\Sigma)$ its subspace of the fields $\mathbf{u}$ satisfying the perfect electric conductor boundary condition $\mathbf{u} \times \mathbf{n} = 0$ on $\partial\Sigma$. We have

$$\mathbf{Q}^p_{\mathsf{N}}(\Sigma) = \big[\mathbb{P}^p(I) \otimes \mathbb{P}^p_0(I)\big] \times \big[\mathbb{P}^p_0(I) \otimes \mathbb{P}^p(I)\big]. \tag{1}$$

2.1.2. Classical edge elements. $\mathbf{N}^p(\Sigma)$ denotes the space $\mathbb{Q}^{p-1,p}(\Sigma) \times \mathbb{Q}^{p,p-1}(\Sigma)$ which allows the commuting diagram property with the operator **grad** from the space of scalar polynomials $\mathbb{Q}^p(\Sigma)$. These edge element spaces are also known as the *first Nédélec family* of edge elements. For simplicity, we shall refer to the spaces of this section as standard (Nédélec) edge elements. We denote by $\mathbf{N}^p_{\mathsf{N}}(\Sigma)$ the subspace of fields satisfying the electric boundary condition:

$$\mathbf{N}^p_{\mathsf{N}}(\Sigma) = \left[\mathbb{P}^{p-1}(I) \otimes \mathbb{P}^p_0(I)\right] \times \left[\mathbb{P}^p_0(I) \otimes \mathbb{P}^{p-1}(I)\right]. \tag{2}$$

2.2. Maxwell spectrum in the square. In section 3 we shall describe in terms of one-dimensional (1D) problems the Maxwell spectrum computed with the spaces $\mathbf{Q}^p_{\mathsf{N}}(\Sigma)$ and $\mathbf{N}^p_{\mathsf{N}}(\Sigma)$.

We first recall the definition of the standard continuous spaces associated with Maxwell equations on a domain Ω: $\mathbf{H}(\mathrm{curl}, \Omega)$ is the space of $L^2(\Omega)$ fields with curl in $L^2(\Omega)$, while $\mathbf{H}_0(\mathrm{curl}, \Omega)$ is the subspace of $\mathbf{H}(\mathrm{curl}, \Omega)$ with perfect electric boundary conditions; $\mathbf{H}(\mathrm{div}, \Omega)$ is the space of $L^2(\Omega)$ fields with divergence in $L^2(\Omega)$.

Let us describe the Maxwell spectrum in the continuous space

$$\mathbf{X}_{\mathsf{N}}(\Sigma) := \mathbf{H}_0(\mathrm{curl}, \Sigma) \cap \mathbf{H}(\mathrm{div}, \Sigma),$$

i.e., the eigenpairs $(\lambda, \mathbf{u})$ with $\mathbf{u} \neq 0$ such that

$$\mathbf{u} \in \mathbf{X}_{\mathsf{N}}(\Sigma) : \int_\Sigma \mathrm{curl}\,\mathbf{u}\ \mathrm{curl}\,\mathbf{v}\, d\mathbf{x} = \lambda \int_\Sigma \mathbf{u} \cdot \mathbf{v}\, d\mathbf{x} \quad \forall \mathbf{v} \in \mathbf{X}_{\mathsf{N}}(\Sigma). \tag{3}$$

2.2.1. The kernel. For $\lambda = 0$, we have the whole space $\mathbf{grad}\, H^1_0(\Sigma)$ of kernel elements.

2.2.2. The genuine Maxwell spectrum. The whole nonzero spectrum corresponds to eigenvectors of the form $\mathbf{u} = \mathbf{curl}\,\varphi$ with φ the nonconstant eigenvector of the Neumann problem on Σ. Let $(\psi_j)_{j\geq 0}$ be the basis of the Neumann eigenvectors on the interval I; they are associated with the eigenvalues $j^2\pi^2/4$. Then the Maxwell spectrum on Σ is

$$\lambda_{j,k} = (j^2 + k^2)\pi^2/4, \quad \mathbf{u}_{j,k}(x, y) = (\psi_j(x)\psi'_k(y), -\psi'_j(x)\psi_k(y)), \quad j + k \geq 1. \tag{4}$$

For comparison purposes, it is convenient to split the whole spectrum into the three following parts:

(a) the kernel;

(b) the nonzero Neumann eigenvalues $j^2\pi^2/4$ associated with the two eigenvectors

$$(0, -\psi'_j(x)) \quad \text{and} \quad (\psi'_j(y), 0);$$

(c) the sum of two nonzero Neumann eigenvalues $(j^2 + k^2)\pi^2/4$ with the eigenvectors $\mathbf{u}_{j,k}$ (and $\mathbf{u}_{k,j}$ if $j \neq k$).

Remark 1. For all nonconstant Neumann eigenvectors ψ_j (i.e., for $j \geq 1$), ψ'_j is a Dirichlet eigenvector associated with the eigenvalue $j^2\pi^2/4$. Let us denote $\varphi_j := -\psi'_j$. Then $(j^2\pi^2/4)\psi_j = -\psi''_j = \varphi'_j$, and we can see that eigenvectors associated with part (c) of the spectrum can be written as

$$\left(\frac{1}{j^2}\,\varphi'_j(x)\varphi_k(y), -\frac{1}{k^2}\,\varphi_j(x)\varphi'_k(y)\right). \tag{5}$$

3. Approximation of Maxwell's spectrum in a square by the *p* method. In this section we characterize explicitly the Maxwell spectrum on the square computed with the full polynomial space $\mathbf{Q}^p_{\mathsf{N}}(\Sigma)$ and with the Nédélec edge element space $\mathbf{N}^p_{\mathsf{N}}(\Sigma)$.

In contrast with (4), where the 1D generators are the *Neumann* eigenvectors on the interval, at the discrete level we will show that the 1D generators are the *Dirichlet* discrete eigenvectors: for $p \geq 2$, we consider the eigenpairs (λ, β) with $\beta \neq 0$ such that

$$\beta \in \mathbb{P}^p_0(I) : \int_I \beta' w' \, dx = \lambda \int_I \beta w \, dx \quad \forall w \in \mathbb{P}^p_0(I). \tag{6}$$

The dimension of $\mathbb{P}^p_0(I)$ is $p-1$; for $j = 1, \ldots, p-1$, let $(\lambda_j^{[p]}, \beta_j^{[p]})$ be an eigenpair basis of (6) satisfying

$$\lambda_1^{[p]} < \lambda_2^{[p]} < \cdots < \lambda_{p-1}^{[p]}.$$

For each j, $\lambda_j^{[p]}$ tends exponentially to $j^2\pi^2/4$ as $p \to \infty$. This follows from the standard convergence analysis for elliptic eigenvalue problems [5] and best approximation properties of the p-version of the finite element method (FEM); see [43, Chapter 3].

We are going to describe the Maxwell spectrum in $\mathbf{Q}^p_{\mathsf{N}}(\Sigma)$, i.e., the eigenpairs $(\lambda, \mathbf{u})$ such that

$$\mathbf{u} \in \mathbf{Q}^p_{\mathsf{N}}(\Sigma) : \quad \int_\Sigma \operatorname{curl} \mathbf{u} \operatorname{curl} \mathbf{v} \, d\mathbf{x} = \lambda \int_\Sigma \mathbf{u} \cdot \mathbf{v} \, d\mathbf{x} \quad \forall \mathbf{v} \in \mathbf{Q}^p_{\mathsf{N}}(\Sigma). \tag{7}$$

THEOREM 1. *The whole Maxwell spectrum* (7) *in* $\mathbf{Q}^p_{\mathsf{N}}(\Sigma)$ *can be split into four parts:*

(a) *the kernel:* $\lambda = 0$ *and* $\mathbf{u} \in \mathbf{grad}(\mathbb{P}^p_0 \otimes \mathbb{P}^p_0)$*;*

(b) *the Dirichlet discrete eigenvalues* $\lambda_j^{[p]}$ *associated with the two eigenvectors*

$$(0, -\beta_j^{[p]}(x)) \quad \textit{and} \quad (\beta_j^{[p]}(y), 0), \quad j = 1, \ldots, p-1; \tag{8}$$

(c) *the sum of two Dirichlet discrete eigenvalues* $\lambda_j^{[p]} + \lambda_k^{[p]}$ *with the eigenvectors*

$$(\lambda_j^{[p]} \beta_k^{[p]\prime}(x) \beta_j^{[p]}(y), -\lambda_k^{[p]} \beta_k^{[p]}(x) \beta_j^{[p]\prime}(y)), \quad 1 \leq j, k \leq p-1; \tag{9}$$

(d) *the Dirichlet discrete eigenvalues* $\lambda_j^{[p]}$ *associated with two* spurious *eigenvectors*

$$(0, -\beta_j^{[p]}(x) L_p(y)) \quad \textit{and} \quad (L_p(x) \beta_j^{[p]}(y), 0), \tag{10}$$

where L_p *denotes the Legendre polynomial of degree* p*.*

Remark 2. Note that formula (5) transforms into $(j^2 \varphi_k'(x) \varphi_j(y), -k^2 \varphi_k(x) \varphi_j'(y))$ by swapping j and k and multiplying by $j^2 k^2$. The similarity with formula (9) is now obvious.

Remark 3. The previous theorem shows that the space $\mathbf{Q}^p_{\mathsf{N}}(\Sigma)$ is not suited for the computation of Maxwell's eigenvalues. Indeed, the discrete eigenvalues described in part (d) are redundant, providing a wrong multiplicity to the correct eigenvalues described in part (b). Moreover, the discrete eigenvectors of part (d) do not approximate any physical eigenfunction. The fact that the second Nédélec family produces

spurious modes in the h-version of the FEM has been documented in the literature; see, e.g., [29, 30].

Proof. Let us first check the dimensions of the spaces described in the four above cases:

(a) $(p-1)^2$.
(b) $2(p-1)$.
(c) $(p-1)^2$.
(d) $2(p-1)$.

The sum is $2(p-1)(p+1)$, which is the dimension of $\mathbf{Q}^p_{\mathsf{N}}(\Sigma)$ (see (1)).

It remains to check that the proposed pairs are eigenpairs of (7).

Case (a). The scalar polynomial space $\mathbb{P}^p_0 \otimes \mathbb{P}^p_0$ is contained in $H^1_0(\Sigma)$; therefore all elements of $\mathbf{grad}(\mathbb{P}^p_0 \otimes \mathbb{P}^p_0)$ belong to the kernel.

For the remaining part of the proof, since p is fixed, let us drop the exponent $[p]$ in the notation of the discrete 1D Dirichlet eigenpairs. By integration by parts we note that the discrete eigenpairs (λ_j, β_j) satisfy

$$\int_I (\beta_j'' + \lambda_j \beta_j)\, w\, dx = 0 \quad \forall w \in \mathbb{P}^p_0(I). \tag{11}$$

On the other hand, again by integration by parts, we obtain that $(\lambda, \mathbf{u})$ is an eigenpair in $\mathbf{Q}^p_{\mathsf{N}}(\Sigma)$ if and only if

$$\mathbf{u} \in \mathbf{Q}^p_{\mathsf{N}}(\Sigma) : \int_\Sigma (\mathbf{curl}\,\mathrm{curl}\,\mathbf{u} - \lambda \mathbf{u}) \cdot \mathbf{v}\, d\mathbf{x} = 0 \quad \forall \mathbf{v} \in \mathbf{Q}^p_{\mathsf{N}}(\Sigma). \tag{12}$$

It is clear that all proposed eigenvectors in (b), (c), and (d) belong to $\mathbf{Q}^p_{\mathsf{N}}(\Sigma)$. It remains to compute $\mathbf{curl}\,\mathrm{curl}\,\mathbf{u} - \lambda\mathbf{u}$ in each case and to check (12).

Case (b). For $\lambda = \lambda_j$ and $\mathbf{u} = (0, -\beta_j(x))$, the two components of $\mathbf{curl}\,\mathrm{curl}\,\mathbf{u} - \lambda\mathbf{u}$ are

$$0 \quad \text{and} \quad \beta_j''(x) + \lambda_j \beta_j(x).$$

Then relation (11) yields (12), and the same argument applies to the other vector $(\beta_j(y), 0)$.

Case (c). For $\lambda = \lambda_j + \lambda_k$ and $\mathbf{u}$ given by (9), we have

$$\mathrm{curl}\,\mathbf{u} = (\lambda_j + \lambda_k)\beta_k'(x)\beta_j'(y)$$

and the two components of $\mathbf{curl}\,\mathrm{curl}\,\mathbf{u} - \lambda\mathbf{u}$ are

$$\begin{aligned} &-(\lambda_j + \lambda_k)\beta_k'(x)\beta_j''(y) - (\lambda_j + \lambda_k)\lambda_j \beta_k'(x)\beta_j(y) \\ &+ (\lambda_j + \lambda_k)\beta_k''(x)\beta_j'(y) + (\lambda_j + \lambda_k)\lambda_k \beta_k(x)\beta_j'(y) \end{aligned}$$

which can be written as

$$\begin{aligned} &-(\lambda_j + \lambda_k)\beta_k'(x)\big\{\beta_j''(y) + \lambda_j\beta_j(y)\big\} \\ &+ (\lambda_j + \lambda_k)\beta_j'(y)\big\{\beta_k''(x) + \lambda_k\beta_k(x)\big\}. \end{aligned}$$

Then relation (11) yields (12).

Case (d). For $\lambda = \lambda_j$ and $\mathbf{u} = (0, -\beta_j(x)L_p(y))$, the two components of $\mathbf{curl}\,\mathrm{curl}\,\mathbf{u} - \lambda\mathbf{u}$ are

$$-\beta_j'(x)L_p'(y) \quad \text{and} \quad \beta_j''(x)L_p(y) + \lambda_j\beta_j(x)L_p(y).$$

The second component is orthogonal to any element of $\mathbb{P}_0^p(I) \otimes \mathbb{P}^p(I)$ (see (1) and (11)). It remains to check that the first component is orthogonal to $\mathbb{P}^p(I) \otimes \mathbb{P}_0^p(I)$, i.e.,

$$\int_\Sigma v_j'(x) L_p'(y) w(x) v(y)\, dxdy = 0 \quad \forall w \in \mathbb{P}^p(I), \quad \forall v \in \mathbb{P}_0^p(I). \tag{13}$$

It is sufficient to prove that $\int_I L_p'(y) v(y)\, dy = 0$ for all $v \in \mathbb{P}_0^p(I)$: such a v is given by $(1-y^2)\varphi(y)$ with $\varphi \in \mathbb{P}^{p-2}(I)$. Since the polynomials L_k' are orthogonal on I with respect to the measure $(1-y^2)\, dy$ and since the degree of L_j' is $j-1$, we obtain that

$$\int_I L_p'(y)\varphi(y)(1-y^2)\, dy = 0 \quad \forall \varphi \in \mathbb{P}^{p-2}(I),$$

hence (13). ∎

The next theorem characterizes the Maxwell spectrum in $\mathbf{N}_{\mathsf{N}}^p(\Sigma)$, i.e., the eigenpairs $(\lambda, \mathbf{u})$ such that

$$\mathbf{u} \in \mathbf{N}_{\mathsf{N}}^p(\Sigma) : \quad \int_\Sigma \operatorname{curl} \mathbf{u} \operatorname{curl} \mathbf{v}\, d\mathbf{x} = \lambda \int_\Sigma \mathbf{u} \cdot \mathbf{v}\, d\mathbf{x} \quad \forall \mathbf{v} \in \mathbf{N}_{\mathsf{N}}^p(\Sigma). \tag{14}$$

THEOREM 2. *The three first parts* (a), (b), *and* (c) *of the discrete spectrum described in Theorem* 1 *are the whole discrete Maxwell spectrum computed by the edge element space* $\mathbf{N}_{\mathsf{N}}^p(\Sigma)$.

Proof. We can see that the eigenvectors of parts (a), (b), and (c) all belong to the smaller space $\mathbf{N}_{\mathsf{N}}^p(\Sigma)$. Therefore they are also eigenvectors in this space. We see that the sum of the dimensions of the corresponding eigenspaces is $(p-1)^2 + 2(p-1) + (p-1)^2$, which is equal to $2(p-1)p$, the dimension of $\mathbf{N}_{\mathsf{N}}^p(\Sigma)$ (see (2)). ∎

The conclusion arising from Theorems 1 and 2 is that the space $\mathbf{N}_{\mathsf{N}}^p(\Sigma)$ is to be preferred with respect to $\mathbf{Q}_{\mathsf{N}}^p(\Sigma)$ for the computation of Maxwell's eigenpairs. Indeed, the latter space does not provide correct approximation of the spectrum (see Remark 3).

4. Approximation of Maxwell's spectrum by *hp* rectangular finite elements. In this section we extend the results about the space $\mathbf{N}_{\mathsf{N}}^p(\Sigma)$ to the more involved situation of *hp* refinements, which provides realistic applications to a class of polygonal domains. The structure of this section is as follows. First, we define the FE spaces we are dealing with and make precise the assumptions on the mesh. Then, after establishing an L^2-stability result (see section 4.3), we prove the discrete compactness property which implies the convergence of eigenvalues/eigenvectors. Our proof clearly implies that the discrete compactness property also holds true for the pure p method on a conforming rectangular mesh (i.e., without hanging node) with the standard edge elements of the first Nédélec family.

4.1. De Rham diagram for a variable order quad element. Let $\Sigma = I \times I$ be the master square element. A feature of edge elements is their embedding in a *commuting de Rham diagram* of type (15) relating two exact sequences of spaces on both continuous and discrete levels. We refer the reader to [14, 33] for a systematic description of the standard discrete de Rham diagram of any degree, where the interpolation operators are based on nodal values, edge moments, and volume moments. In view of the construction *hp* finite elements, another class of commuting de Rham diagram has been introduced [26], relying on the so-called *projection-based interpolants*, which

allow variable orders on distinct elements of the same mesh, while preserving the commuting property.

We start by introducing this latter version of the de Rham diagram, involving discrete spaces and interpolation operators on Σ, according to

$$
\begin{array}{ccccccccc}
\mathbb{R} & \longrightarrow & H^{1+\varepsilon}(\Sigma) & \overset{\mathbf{grad}}{\longrightarrow} & \mathbf{H}^{\varepsilon}(\Sigma)\cap\mathbf{H}(\mathrm{curl},\Sigma) & \overset{\mathrm{curl}}{\longrightarrow} & L^2(\Sigma) & \longrightarrow & \mathbf{0} \\
\Big\downarrow id & & \Big\downarrow \Pi & & \Big\downarrow \Pi^{\mathrm{curl}} & & \Big\downarrow \mathrm{P} & & \\
\mathbb{R} & \longrightarrow & \mathbb{Q}^{p|\,p_e}(\Sigma) & \overset{\mathbf{grad}}{\longrightarrow} & \mathbf{N}^{p|\,p_e-1}(\Sigma) & \overset{\mathrm{curl}}{\longrightarrow} & \mathbb{Q}^{p-1}(\Sigma) & \longrightarrow & \mathbf{0}.
\end{array}
\tag{15}
$$

Index p specifies the order in both variables which, for the sake of simplicity of this presentation, we assume to be identical, $\mathbb{Q}^p(\Sigma) = \mathbb{Q}^{p,p}(\Sigma) = \mathbb{P}^p(I)\otimes\mathbb{P}^p(I)$, and with every edge e of the master element, we associate the corresponding order p_e, $e = 1,\dots,4$ (with standard, counterclockwise enumeration of edges), that satisfies the condition

$$
p_e \le p, \quad e = 1,\dots,4. \tag{16}
$$

The polynomial spaces present in the diagram are defined as follows.

- $\mathbb{Q}^{p|\,p_e}(\Sigma)$—the subspace of $\mathbb{Q}^p(\Sigma)$, consisting of polynomials whose traces on edges e reduce to (possibly lower) order p_e, $e = 1,\dots,4$.
- $\mathbf{N}^{p|\,p_e}(\Sigma)$—the subspace of $\mathbf{N}^p(\Sigma)$ (cf. section 2.1.2) of vector-valued polynomials with traces of their tangential components on edges e of (possibly lower) order p_e:

$$
\mathbf{N}^{p|\,p_e}(\Sigma) = \{\mathbf{u}\in\mathbf{N}^p(\Sigma) : u_t|_e := (\mathbf{n}\times\mathbf{u})|_e \in \mathbb{P}^{p_e}(e)\ \forall e\}, \tag{17}
$$

  where $\mathbf{n}$ is the outward unit normal vector.

In particular, $\mathbb{Q}^{p|\,-1}$ provides an alternative notation for the subspace $\mathbb{Q}_0^p$ of polynomials vanishing on the boundary of the element, and $\mathbf{N}^{p|\,-1} = \mathbf{N}_{\mathsf{N}}^p$ stands for the subspace of vector-valued polynomials from the first Nédélec family whose tangential component traces on the boundary are equal to zero. The assumption that edge orders p_e should not exceed corresponding components of order p is realized in practice by implementing the *minimum rule* that sets an edge order p_e to the minimum of orders p corresponding to the adjacent elements.

4.1.1. H^1-conforming projection-based interpolation. Let $\mathbb{P}_0^p(I)$ denote the space of polynomials of degree $\le p$, defined on the interval $I = (-1,1)$ with zero traces at the endpoints. Let $\phi_1(x) = (1-x)/2$, $\phi_2(x) = (x+1)/2$ be the standard 1D linear shape functions. Space $\mathbb{Q}^{p|\,p_e}(\Sigma)$ admits a natural decomposition into vertex bilinear shape functions, edge bubbles, and element bubbles:

$$
\begin{aligned}
\mathbb{Q}^{p|\,p_e}(\Sigma) = {} & \big\{\mathbb{P}^1(I)\otimes\mathbb{P}^1(I)\big\} \\
& \oplus \big\{(\mathbb{P}_0^{p_1}(I)\otimes\mathbb{R}\phi_1)\oplus(\mathbb{R}\phi_2\otimes\mathbb{P}_0^{p_2}(I))\oplus(\mathbb{P}_0^{p_3}(I)\otimes\mathbb{R}\phi_2)\oplus(\mathbb{R}\phi_1\otimes\mathbb{P}_0^{p_4}(I))\big\} \\
& \oplus \big\{\mathbb{P}_0^p(I)\otimes\mathbb{P}_0^p(I)\big\}.
\end{aligned}
\tag{18}
$$

We will alternatively speak of edge bubbles for functions defined on a particular edge (and zero at its ends) or for their extensions to the whole element (and zero on the

other edges). The linear extensions are natural but not essential in the forthcoming discussion. For a particular edge, the corresponding edge bubbles must vanish on the remaining edges and must "live" in the FE space. Similarly, the shape function for a vertex node must vanish at the remaining vertices, and it must be in the FE space; the fact that it is constructed using bilinear functions is secondary.

Given a function $u \in H^{1+\varepsilon}(\Sigma)$, we define its interpolant, $u_p = \Pi u$, as a sum of three contributions,

$$u_p = u_1 + \underbrace{\sum_e u_{2,e,p}}_{u_{2,p}} + u_{3,p}. \tag{19}$$

Interpolation at vertices. Vertex interpolant u_1 interpolates function u at vertices,

$$u_1(a) = u(a) \quad \text{for each vertex } a.$$

The simplest choice of an extension of the vertex values is provided by the bilinear function, but the ultimate value of the interpolant is independent of the choice of the extension as long as the extension "lives" in the FE space.

Projection on edges. We subtract the vertex interpolant u_1 from u and project the difference $u - u_1$, over each edge e, onto the space of edge bubbles,

$$|u - u_1 - u_{2,e,p}|_{1/2,e} \to \min.$$

The projection is done in an $H^{1/2}(e)$ seminorm, and it is equivalent to the solution of a small linear system,

$$\begin{aligned} &\textit{Find edge bubble } u_{2,e,p} \in \mathbb{P}_0^{p_e}(e) \textit{ such that} \\ &(u - u_1 - u_{2,e,p}\,, \phi)_{1/2,e} = 0, \quad \textit{for each edge bubble } \phi \in \mathbb{P}_0^{p_e}(e), \end{aligned}$$

where $(\cdot,\cdot)_{1/2,e}$ denotes the inner product corresponding to edge seminorm $|\cdot|_{1/2,e}$.

Projection on the element. We extend each edge bubble $u_{2,e,p}$ to the whole element. Again, the most natural extension is provided by the element shape functions and corresponds to decomposition (19). We subtract then the total edge interpolant $u_{2,p} = \sum_e u_{2,e,p}$ from the difference $u - u_1$ and project the resulting difference on the element bubbles,

$$|u - u_1 - u_{2,p} - u_{3,p}|_{1,\Sigma} \to \min.$$

Again, the projection is equivalent to a local Dirichlet problem on the element,

$$\begin{aligned} &\textit{Find element bubble } u_{3,p} \in \mathbb{Q}_0^p(\Sigma) \textit{ such that} \\ &(u - u_1 - u_{2,p} - u_{3,p}, \phi)_{1,\Sigma} = 0, \quad \textit{for each element bubble } \phi \in \mathbb{Q}_0^p(\Sigma), \end{aligned}$$

where $(\cdot,\cdot)_{1,\Sigma}$ denotes the H_0^1-inner product.

The interpolation is thus equivalent to the solution of a sequence of local (approximate) Dirichlet problems. We first interpolate at the vertices and then, with the vertex values providing Dirichlet conditions, solve the edge Dirichlet problems. Finally, we use the vertex and edge interpolants to set up the Dirichlet boundary conditions and solve the final Dirichlet problem on the whole element. Remember that it does not matter in which way we construct lifts of the approximate Dirichlet data; the ultimate interpolant is unique. In each of the three steps, we determine a part of the interpolant corresponding to the decomposition (18).

4.1.2. H(curl)-conforming projection-based interpolation. A similar decomposition into edge functions and element bubbles can be constructed for the space $\mathbf{N}^{p|\,p_e-1}(\Sigma)$,

$$\begin{aligned}\mathbf{N}^{p|\,p_e-1}(\Sigma) = \big\{ \big[(\mathbb{P}^{p_1-1}(I)\otimes\mathbb{R}\phi_1)\times\{0\}\big] \oplus \big[\{0\}\times(\mathbb{R}\phi_2\otimes\mathbb{P}^{p_2-1}(I))\big] \\ \oplus \big[(\mathbb{P}^{p_3-1}(I)\otimes\mathbb{R}\phi_2)\times\{0\}\big] \oplus \big[\{0\}\times(\mathbb{R}\phi_1\otimes\mathbb{P}^{p_4-1}(I))\big]\big\} \\ \oplus \big\{ \big[(\mathbb{P}^{p-1}\otimes\mathbb{P}_0^p)(\Sigma)\times\{0\}\big] \oplus \big[\{0\}\times(\mathbb{P}_0^p\otimes\mathbb{P}^{p-1})(\Sigma)\big]\big\}.\end{aligned} \tag{20}$$

Given a vector-valued function $\mathbf{u}\in\mathbf{H}^{\varepsilon}(\mathrm{curl},\Sigma)$, we define its interpolant $\mathbf{u}_p=\Pi^{\mathrm{curl}}\mathbf{u}$ as a sum of two contributions,

$$\mathbf{u}_p = \underbrace{\sum_e \mathbf{u}_{2,e,p}}_{\mathbf{u}_{2,p}} + \mathbf{u}_{3,p}.$$

Edge projections. For each edge e, let $v_t=\mathbf{n}\times\mathbf{v}$ denote the (scalar-valued) tangential component[1] of a field $\mathbf{v}$ on e. We project the tangential component u_t of function $\mathbf{u}$ onto the scalar edge functions,

$$\|u_t - u_{2,e,p,t}\|_{-1/2,e}\to\min.$$

Here the norm $\|\cdot\|_{-1/2,e}$ denotes the norm in the dual space

$$H^{-1/2}(e) = (H_{00}^{1/2}(e))';$$

see, e.g., [36]. We then define the vector edge function $\mathbf{u}_{2,e,p}$ as the tangent vector field on e such that $u_{2,e,p,t}=\mathbf{n}\times\mathbf{u}_{2,e,p}$. The projection problem is equivalent to the variational problem

Find the tangential component $u_{2,e,p,t}\in\mathbb{P}^{p_e-1}(e)$ *of the edge function* $\mathbf{u}_{2,e,p}$ *s. t.*
$(u_t-u_{2,e,p,t},\phi)_{-1/2,e}=0$, *for each edge function* $\phi\in\mathbb{P}^{p_e-1}(e)$,

with $(\cdot,\cdot)_{-1/2,e}$ denoting the inner product corresponding to norm $\|\cdot\|_{-1/2,e}$. Notice that for a constant function ϕ, the inner product reduces to L^2-product, and the equation above incorporates in particular the edge average condition

$$\int_e (u_t - u_{2,e,p,t})\,ds = 0.$$

Element projection. We extend each individual edge function $\mathbf{u}_{2,e,p}$ to the whole element using the edge shape functions according to the splitting (20), sum it up, $\mathbf{u}_{2,p}=\sum_e \mathbf{u}_{2,e,p}$, and subtract the difference from function $\mathbf{u}$. We then solve a local projection problem,

$$\|\,\mathrm{curl}(\mathbf{u}-\mathbf{u}_{2,p}-\mathbf{u}_{3,p})\|_{0,\Sigma}\to\min,$$

subjected to the additional constraint,

$$(\mathbf{u}-\mathbf{u}_{2,p}-\mathbf{u}_{3,p},\mathbf{grad}\,\phi)=0,\quad \text{for each element scalar bubble } \phi.$$

[1]More precisely, using the 3D notation, we have $v_t=(\mathbf{n}\times\mathbf{v})\cdot\mathbf{e}_z$, where $\mathbf{e}_z$ is the unit vector orthogonal to the 2D plane.

The constrained projection problem is equivalent to a Dirichlet mixed problem:

Find element bubble $\mathbf{u}_{3,p}$ and Lagrange multiplier ψ such that

(21)
$$\begin{cases} (\operatorname{curl}(\mathbf{u}-\mathbf{u}_{2,p}-\mathbf{u}_{3,p}),\operatorname{curl}\mathbf{v})+(\mathbf{grad}\,\psi,\mathbf{v})=0 & \text{for every element vector bubble } \mathbf{v},\\ (\mathbf{u}-\mathbf{u}_{2,p}-\mathbf{u}_{3,p},\mathbf{grad}\,\phi)=0 & \text{for every element scalar bubble } \phi. \end{cases}$$

Here the Lagrange multiplier ψ lives in the space of scalar bubbles. Since $\mathbf{grad}\,\psi$ is a vector bubble, the multiplier is identically equal to zero and, for this reason, is sometimes called the *hidden variable*.

Remark 4. In [24], the edge contributions $\mathbf{u}_{2,e,p}$ were split into the Whitney interpolant with constant tangential component and a higher order edge bubble. Also, the choice of "edge" norms in the presentation above is consistent with the latest 3D results (see [25]), and it is slightly different from those used in [24].

Finally, P is the L^2-projection from $L^2(\Sigma)$ onto $\mathbb{Q}^{p-1}(\Sigma)$. With this, we have the following result.

THEOREM 3. *If the edge seminorm $|u|_{1/2,e}$ is selected in such a way that*

$$|u|_{1/2,e}=\left\|\frac{\partial u}{\partial s}\right\|_{-1/2,e},$$

then the de Rham diagram (15) *commutes.*

Proof. The tangential derivative ∂_s is an isomorphism from $H^{1/2}(e)/\mathbb{R}$ onto $H^{-1/2}(e)$ (see [32, p. 31]). By the Bramble–Hilbert lemma, the norm in the quotient space $H^{1/2}(e)/\mathbb{R}$ is equivalent to the standard $|u|_{1/2,e}$-seminorm. Consequently, $\|\partial_s u\|_{-1/2,e}$ defines a seminorm on $H^{1/2}(e)$, equivalent to the standard seminorm.

The commuting projection-based interpolation operators considered in [26] use different projections on edges based on the H^1-seminorm for operator Π and the L^2-norm for operator Π^{curl}. The proof from [26] carries over to the case being presented without any modification, provided the H^1-seminorm is traded for the $H^{1/2}$-seminorm, and the L^2-norm is traded for the $H^{-1/2}$-norm. ∎

4.2. De Rham diagram for *hp* meshes. In this section we consider a polygonal domain Ω with sides parallel to the axes, covered by rectangular meshes aligned along the same axes. Of course, by a global affine transformation, our result generalizes to the situation of nonperpendicular axes.

If we fix a conforming mesh (i.e., such that the intersection of any two distinct elements $\overline{K}$ is either empty or a vertex or a full edge) and consider on each K the mapped spaces $\mathbb{Q}^{p|\,p}(K)$, $\mathbf{N}^{p|\,p-1}(K)$, and $\mathbb{Q}^{p-1}(K)$ with the same p, we can define on the whole domain Ω the corresponding H^1-, $\mathbf{H}(\mathrm{curl})$-, and L^2-conforming discrete spaces Q_p, $\mathbf{X}_p$, and S_p, and the projection-based interpolation is done element by element. The elements are said to be *unconstrained* in this case. Then it is clear that the commutativity properties (15) of the projection-based interpolation operators are still valid on the whole domain Ω. Besides, we note that in this case the discrete spaces coincide with those of the standard p-extension of the edge elements [37, 40].

The adaptation to *hp* meshes containing local refinements, therefore hanging nodes, and variable degrees are by no means obvious.

For the sake of simplicity of the presentation, we shall restrict ourselves to 1-irregular *hp* meshes corresponding to isotropic refinements only and consisting of square elements. Beginning with a standard regular mesh consisting of square elements of the same size, we allow for breaking each element into four elements with the

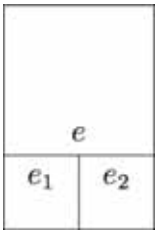

FIG. 1. *Constrained approximation.*

restriction that an element cannot share an edge with more than two small neighbors—the classical "two to one" rule. In other words, the *generation level* for two neighboring elements cannot differ by more than one. The order of elements can be modified locally, element by element, with the *minimum rule* being enforced—the order for an edge is set to the minimum of orders for all adjacent elements. Finally, since for meshes with hanging nodes the projections cannot be done on an element level—the resulting interpolants will no longer be conforming—the global conformity is maintained by means of the *constrained approximation*; see [23, 42].

The situation is illustrated in Figure 1. For a function u defined on "big" edge e, the corresponding "big edge" interpolant is a polynomial defined on the whole edge, whereas the interpolants determined on the small edges e_1, e_2 result in a piecewise interpolant that, in general, is different.

A natural idea is to utilize the constrained approximation concepts. First, do the projections on the big edges and then define the corresponding small edges interpolants by enforcing the global conformity requirements. The resulting interpolants will indeed be globally conforming, but we then lose the commutativity properties. This can be seen by considering the lowest order elements. The last space in the diagram then reduces to piecewise constants and the commutativity property requires that

$$\int_{\partial K} (u_{p,t} - u_t)\, ds = \int_K \operatorname{curl}(\mathbf{u}_p - \mathbf{u})\, d\mathbf{x} = 0$$

for each element K in the mesh. For regular meshes, the condition follows from the edge averaging. In the presence of hanging nodes, however, the condition may not be satisfied. Going back to the situation illustrated in Figure 1, enforcing the averaging condition on "big" edge e *does not imply* the same condition for the restrictions of the original function and its projection on the small edge e_1. Consequently, the condition above is violated for the small element, and the commutativity fails.

A remedy to the problem is to perform the interpolation on groups of elements. The whole mesh is split into *polygonal patches* consisting of single elements or *element clusters* (of minimum size) in such a way that all vertices of the polygonal patches are unconstrained. The decomposition is illustrated with the classical example of the L-shaped domain and h-refinements aimed at resolving the corner singularity shown in Figure 2.

All clusters in this example coincide with either a single element (the white elements) or three elements forming an L-shaped patch (such clusters are indicated in the picture with a grey or black shading). In general, the 1-irregularity rule limits the number of possible cluster shapes to four cases only: clusters of a single, two, three, or four small elements. Our convention is to call patch, denoted by P, the

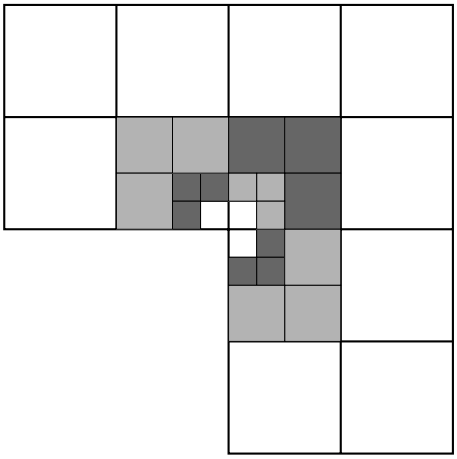

FIG. 2. *Decomposition of a* 1*-irregular mesh into clusters.*

FIG. 3. *L-shaped cluster and patch.*

union of the cluster elements K together with the interior edges. In our example, the L-shaped patches are the union of three squares and two interior edges; see Figure 3. Such patches have six distinct (exterior) edges. Edges of a patch always coincide with either a single element edge or two "small" edges adjacent to a big one.

The space $\mathbb{Q}^{p|\,p_e}(P)$ on the patch is the subspace of continuous functions on P, which are $\mathbb{Q}^p$ on each element K of the cluster, and whose restriction on e belongs to $\mathbb{Q}^{p_e}(e)$ for each edge of the patch. The space $\mathbf{N}^{p|\,p_e-1}(P)$ is defined correspondingly as the subspace of $\mathbf{H}(\mathrm{curl})$ fields on P, which are in $\mathbf{N}^p$ on each element K, and whose tangential restriction on e belongs to $\mathbb{Q}^{p_e}(e)$.

The definition of projection-based interpolation extends now naturally to the patch P: We list only the main steps. The vertices are the corners of P, and we check that there exists a continuous piecewise bilinear vertex interpolant $u_1 \in \mathbb{Q}^{1|\,1}(P)$. The edge bubbles $u_{2,e,p}$ are related with patch edges (and no longer with element edges) and are polynomial on the whole patch edge. These bubbles can be extended inside P as elements of $\mathbb{Q}^{p|\,p_e}(P)$. The patch bubbles $u_{3,p}$ are the functions in the FE space $\mathbb{Q}^{p|\,p_e}(P)$ with zero traces on the patch boundary ∂P.

Similarly we define the edge functions $\mathbf{u}_{2,e,p}$ as vector polynomials on the whole patch edge, tangential to the edge. They can be extended in $\mathbf{N}^{p|\,p_e-1}(P)$. The patch bubbles $\mathbf{u}_{3,p}$ are the elements of $\mathbb{Q}^{p|\,p_e}(P)$ with zero tangential traces on the patch boundary ∂P. The patch bubbles are, therefore, no longer polynomials but *piecewise polynomials* only.

Thus, by the same procedure as before we define the projection operators

$$\Pi = \Pi_P, \quad \Pi^{\mathrm{curl}} = \Pi_P^{\mathrm{curl}}, \quad \text{and} \quad \mathrm{P} = \mathrm{P}_P \tag{22}$$

and obtain a commutative scheme like (15).

Once the interpolation is done on the patches, we regain both the global conformity and commutativity of the interpolation operators on the whole *hp* mesh:

$$\begin{array}{ccccccccc}
\mathbb{R} & \longrightarrow & H^{1+\varepsilon}(\Omega) & \stackrel{\mathbf{grad}}{\longrightarrow} & \mathbf{H}^{\varepsilon}(\Omega)\cap\mathbf{H}(\mathrm{curl},\Omega) & \stackrel{\mathrm{curl}}{\longrightarrow} & L^2(\Omega) & \longrightarrow & \mathbf{0} \\
\downarrow id & & \downarrow \Pi & & \downarrow \Pi^{\mathrm{curl}} & & \downarrow \mathrm{P} & & \\
\mathbb{R} & \longrightarrow & Q_{hp} & \stackrel{\mathbf{grad}}{\longrightarrow} & \mathbf{X}_{hp} & \stackrel{\mathrm{curl}}{\longrightarrow} & S_{hp} & \longrightarrow & \mathbf{0}.
\end{array}$$

Here Q_{hp}, $\mathbf{X}_{hp}$, and S_{hp} denote FE spaces defined on the common domain Ω, corresponding to the H^1-, $\mathbf{H}(\mathrm{curl})$-, and L^2-conforming discretizations, done patch by patch.

4.3. A stability result in L^2. We begin by recalling the inclusion of polynomial spaces,

$$\mathbb{Q}_0^p(\Sigma) \stackrel{\mathbf{grad}}{\longrightarrow} \mathbf{N}_{\mathsf{N}}^p(\Sigma).$$

Here

$$\begin{aligned}
&\mathbb{Q}_0^p(\Sigma) = \mathbb{P}_0^p(I)\otimes\mathbb{P}_0^p(I),\\
&\mathbf{N}_{\mathsf{N}}^p(\Sigma) = [\mathbb{P}^{p-1}(I)\otimes\mathbb{P}_0^p(I)]\times[\mathbb{P}_0^p(I)\otimes\mathbb{P}^{p-1}(I)].
\end{aligned}$$

In this section, we will omit the mention of Σ and I for the spaces $\mathbb{Q}^p$, $\mathbf{N}^p$, and $\mathbb{P}^p$, respectively. We shall denote the L^2-norm on I or Σ by $\|\cdot\|$, with the corresponding L^2-product denoted by $(\cdot,\cdot)$. We hope that the similarity of the latter with the notation for vector components will not lead to confusion.

THEOREM 4. *The following stability condition holds:*

$$\inf_{\mathbf{q}\in\mathbf{N}_{\mathsf{N}}^p}\ \sup_{\mathbf{s}\in\mathbf{grad}\,\mathbb{Q}_0^p\oplus\mathbf{curl}\,\mathrm{curl}\,\mathbf{N}_{\mathsf{N}}^p}\frac{(\mathbf{q},\mathbf{s})}{\|\mathbf{q}\|\,\|\mathbf{s}\|} = C_p, \tag{23}$$

where

$$C_p = \left(\frac{2(2p+1)}{(p+1)(p+2)}\right)^{1/2} = O(p^{-1/2}). \tag{24}$$

The proof of Theorem 4 relies on two lemmas.

LEMMA 5. *Let $a_i>0$, $b_i>0$, $i=1,\dots,n$. Then for any real $v_1,\dots,v_n$*

$$\sup_{u_1,\dots,u_n}\frac{|\sum_{i=1}^n a_iu_iv_i|}{(\sum_{i=1}^n b_iu_i^2)^{1/2}} = \left(\sum_{i=1}^n\frac{a_i^2}{b_i}v_i^2\right)^{1/2}.$$

Proof. Use the Cauchy–Schwarz inequality for the discrete l^2-product and the representation,

$$\sum_{i=1}^n a_iu_iv_i = \sum_{i=1}^n\frac{a_i}{b_i^{1/2}}v_i\,b_i^{1/2}u_i. \qquad \square$$

We recall that (λ_i, β_i), $i = 1, \dots, p-1$, and denote the discrete eigenpairs of the 1D Laplace operator defined in (6) (we omit the exponent $[p]$ for simplicity). The eigenvectors are normalized to satisfy $(\beta_i, \beta_j) = \delta_{ij}$.

LEMMA 6. *The following inequality holds:*

$$\left(\sum_{i=1}^{p-1} \lambda_i^2 v_i^2\right)^{1/2} \geq C_p \left\| \sum_{i=1}^{p-1} v_i \beta_i'' \right\| \quad \forall \mathbf{v} = (v_1, \dots, v_{p-1}) \in \mathbb{R}^{p-1},$$

where C_p is defined in (24).

Proof. It was proved in [8] that the constant

$$C_p = \inf_{u \in \mathbb{P}_0^p} \sup_{f \in \mathbb{P}^{p-2}} \frac{(u,f)}{\|u\|\|f\|} = \inf_{u \in \mathbb{P}_0^p} \sup_{v \in \mathbb{P}_0^p} \frac{(u,v'')}{\|u\|\|v''\|}$$
$$= \inf_{u \in \mathbb{P}_0^p} \sup_{v \in \mathbb{P}_0^p} \frac{(u',v')}{\|u\|\|v''\|} = \inf_{v \in \mathbb{P}_0^p} \sup_{u \in \mathbb{P}_0^p} \frac{(u',v')}{\|u\|\|v''\|}$$

is given by formula (24). Consequently,

$$\sup_{u \in \mathbb{P}_0^p} \frac{(u',v')}{\|u\|} \geq C_p \|v''\| \quad \forall v \in \mathbb{P}_0^p.$$

If we now define

$$u = \sum_{i=1}^{p-1} u_i \beta_i, \quad v = \sum_{i=1}^{p-1} v_i \beta_i,$$

then

$$(u', v') = \sum_{i=1}^{p-1} \lambda_i u_i v_i \qquad \text{and} \qquad \|u\| = \left(\sum_{i=1}^{p-1} u_i^2\right)^{1/2}.$$

Apply Lemma 5 to finish the proof. ∎

Proof of Theorem 4. *Step* 1. Let α_i, $i = 0, \dots, p-1$ be a basis for $\mathbb{P}^{p-1}$ defined as follows:

$$\alpha_i = \begin{cases} 1/\sqrt{2}, & i = 0, \\ \beta_i', & i = 1, \dots, p-1. \end{cases}$$

Polynomials α_i are orthogonal and satisfy

$$\|\alpha_0\|^2 = 1, \quad \|\alpha_i\|^2 = \lambda_i, \ i = 1, \dots, p-1.$$

Any element $\mathbf{q} \in \mathbf{N}_{\mathsf{N}}^p$ can be represented in the form

$$\mathbf{q} = \left(\sum_{i=0}^{p-1} \sum_{j=1}^{p-1} q_{1,ij} \alpha_i \beta_j, \sum_{i=1}^{p-1} \sum_{j=0}^{p-1} q_{2,ij} \beta_i \alpha_j \right). \tag{25}$$

Here and in what follows, we assume that in a tensor product $\alpha\beta$, the first function is always a function of x, and the second is a function of y, i.e., $\alpha\beta = \alpha(x)\beta(y)$.

A direct calculation shows that

$$
\begin{aligned}
&\mathbf{curl}\,\mathrm{curl}\,\mathbf{q}\\
&= \left(\sum_{i=1}^{p-1}\sum_{j=0}^{p-1} q_{2,ij}\beta_i'\alpha_j' - \sum_{i=0}^{p-1}\sum_{j=1}^{p-1} q_{1,ij}\alpha_i\beta_j'', \quad -\sum_{i=1}^{p-1}\sum_{j=0}^{p-1} q_{2,ij}\beta_i''\alpha_j + \sum_{i=0}^{p-1}\sum_{j=1}^{p-1} q_{1,ij}\alpha_i'\beta_j' \right)\\
&= \left(\sum_{i=1}^{p-1}\sum_{j=1}^{p-1} q_{2,ij}\beta_i'\beta_j'' - \sum_{i=0}^{p-1}\sum_{j=1}^{p-1} q_{1,ij}\alpha_i\beta_j'', \quad -\sum_{i=1}^{p-1}\sum_{j=0}^{p-1} q_{2,ij}\beta_i''\alpha_j + \sum_{i=1}^{p-1}\sum_{j=1}^{p-1} q_{1,ij}\beta_i''\beta_j' \right)\\
&= \Bigg(-\sum_{j=1}^{p-1} q_{1,0j}\alpha_0\beta_j'' + \sum_{i=1}^{p-1}\sum_{j=1}^{p-1}(q_{2,ij}-q_{1,ij})\beta_i'\beta_j'',\\
&\qquad -\sum_{i=1}^{p-1} q_{2,i0}\beta_i''\alpha_0 - \sum_{i=1}^{p-1}\sum_{j=1}^{p-1}(q_{2,ij}-q_{1,ij})\beta_i''\beta_j' \Bigg).
\end{aligned}
$$

Hence, any element $\mathbf{s} \in \mathbf{curl}\,\mathrm{curl}\,\mathbf{N}_{\mathsf{N}}^p$ can be represented in the form

$$
\mathbf{s} = \left(\sum_{j=1}^{p-1} s_{0j}\alpha_0\beta_j'' + \sum_{i=1}^{p-1}\sum_{j=1}^{p-1} s_{ij}\beta_i'\beta_j'', \quad \sum_{i=1}^{p-1} s_{i0}\beta_i''\alpha_0 - \sum_{i=1}^{p-1}\sum_{j=1}^{p-1} s_{ij}\beta_i''\beta_j' \right).
$$

Let $\mathbf{q} \in \mathbf{N}_{\mathsf{N}}^p$ be discrete divergence-free, i.e.,

$$
(\mathbf{q}, \mathbf{grad}\, w) = 0 \quad \forall w \in \mathbb{Q}_0^p.
$$

Selecting $w = \beta_k\beta_l$, $k,l = 1,\dots,p-1$, we conclude that coefficients $q_{1,ij}, q_{2,ij}$ in representation (25) must satisfy the identity

$$
q_{1,kl}\lambda_k + q_{2,kl}\lambda_l = 0.
$$

This leads to the following formulas for the norm of a discrete divergence-free vector and the L^2-product of such a vector with $\mathbf{s} \in \mathbf{curl}\,\mathrm{curl}\,\mathbf{N}_{\mathsf{N}}^p$:

$$
\begin{aligned}
\|\mathbf{q}\|^2 &= \sum_{j=1}^{p-1} q_{1,0j}^2 + \sum_{i=1}^{p-1} q_{2.i0}^2 + \sum_{i=1}^{p-1}\sum_{j=1}^{p-1}\left(\frac{\lambda_i^2}{\lambda_j} + \lambda_i\right) q_{1,ij}^2,\\
(\mathbf{q},\mathbf{s}) &= -\sum_{j=1}^{p-1} q_{1,0j}s_{0j}\lambda_j - \sum_{i=1}^{p-1} q_{2,i0}s_{i0}\lambda_i - \sum_{i=1}^{p-1}\sum_{j=1}^{p-1} q_{1,ij}s_{ij}(\lambda_i\lambda_j + \lambda_i^2).
\end{aligned}
$$

Applying Lemma 5 we get

$$
\sup_{\substack{\mathbf{q}\in\mathbf{N}_{\mathsf{N}}^p\\ (\mathbf{q},\mathbf{grad}\,w)=0\ \forall w\in\mathbb{Q}_0^p}} \frac{(\mathbf{q},\mathbf{s})}{\|\mathbf{q}\|} = \sum_{j=1}^{p-1}\lambda_j^2 s_{0j}^2 + \sum_{i=1}^{p-1}\lambda_i^2 s_{i0}^2 + \sum_{i=1}^{p-1}\sum_{j=1}^{p-1}(\lambda_i^2\lambda_j + \lambda_i\lambda_j^2)s_{ij}^2.
$$

Finally, the norm of $\mathbf{s} \in \mathbf{curl}\,\mathrm{curl}\,\mathbf{N}_{\mathsf{N}}^p$ can be represented in the form

$$
\|\mathbf{s}\|^2 = \left\|\sum_{j=1}^{p-1} s_{0j}\beta_j''\right\|^2 + \left\|\sum_{i=1}^{p-1} s_{i0}\beta_i''\right\|^2 + \sum_{i=1}^{p-1}\lambda_i\left\|\sum_{j=1}^{p-1} s_{ij}\beta_j''\right\|^2 + \sum_{j=1}^{p-1}\lambda_j\left\|\sum_{i=1}^{p-1} s_{ij}\beta_i''\right\|^2.
$$

By Lemma 6 we have

$$\sum_{j=1}^{p-1}\lambda_j^2 s_{0j}^2 \geq C_p^2 \left\| \sum_{j=1}^{p-1} s_{0j}\beta_j'' \right\|^2,$$
$$\sum_{i=1}^{p-1}\lambda_i^2 s_{i0}^2 \geq C_p^2 \left\| \sum_{i=1}^{p-1} s_{i0}\beta_i'' \right\|^2,$$
$$\lambda_i \sum_{j=1}^{p-1}\lambda_j^2 s_{ij}^2 \geq \lambda_i C_p^2 \left\| \sum_{j=1}^{p-1} s_{ij}\beta_j'' \right\|^2,$$
$$\lambda_j \sum_{i=1}^{p-1}\lambda_i^2 s_{ij}^2 \geq \lambda_j C_p^2 \left\| \sum_{i=1}^{p-1} s_{ij}\beta_i'' \right\|^2.$$

Summing up all the inequalities, we get

$$\sup_{\substack{\mathbf{q}\in \mathbf{N}_{\mathsf{N}}^p \\ (\mathbf{q},\,\mathbf{grad}\, w)=0 \ \forall w\in\mathbb{Q}_0^p}} \frac{(\mathbf{q},\mathbf{s})}{\|\mathbf{q}\|} \ \geq\ C_p\|\mathbf{s}\|,$$

or, equivalently, using the equality of inf-sup constants for a bilinear form and its adjoint, we get

$$\inf_{\substack{\mathbf{q}\in \mathbf{N}_{\mathsf{N}}^p \\ (\mathbf{q},\,\mathbf{grad}\, w)=0 \ \forall w\in\mathbb{Q}_0^p}} \sup_{\mathbf{s}\in \mathbf{curl}\,\mathrm{curl}\,\mathbf{N}_{\mathsf{N}}^p} \frac{(\mathbf{q},\mathbf{s})}{\|\mathbf{q}\|\|\mathbf{s}\|} \ \geq\ C_p. \tag{26}$$

Step 2. Use discrete Helmholtz decomposition,

$$\mathbf{q} = \mathbf{q}_0 + \mathbf{grad}\,\phi, \quad (\mathbf{q}_0, \mathbf{grad}\, w) = 0 \quad \forall w\in\mathbb{Q}_0^p, \quad \phi\in\mathbb{Q}_0^p,$$

to extend inequality (26) to arbitrary $\mathbf{q}\in\mathbf{N}_{\mathsf{N}}^p$ and $\mathbf{s}\in\mathbf{grad}\,\mathbb{Q}_0^p \oplus \mathbf{curl}\,\mathrm{curl}\,\mathbf{N}_{\mathsf{N}}^p$.

Step 3. The *equality* in (23) follows, e.g., from the fact that for $\mathbf{q}$ coinciding with eigenvectors from part (b) of the spectrum (see (8)), the 2D inf-sup condition reduces to its 1D counterpart. ∎

The consequence of Theorem 4 is the following L^2-stability result in p-version.

THEOREM 7. *Let* $\mathbf{u}_3\in\mathbf{H}^{\varepsilon}(\Sigma)\cap\mathbf{H}_0(\mathrm{curl},\Sigma)$ *be a divergence-free bubble function on* Σ. *Let* $\mathbf{u}_{3,p}$ *be the projection* $\Pi^{\mathrm{curl}}\mathbf{u}_3$. *Then* $\mathbf{u}_{3,p}$ *is discrete divergence-free and there holds*

$$\|\mathbf{u}_3-\mathbf{u}_{3,p}\|_{0,\Sigma} \leq Cp^{1/2} \inf_{\mathbf{q}_p\in\mathbf{N}_{\mathsf{N}}^p} \|\mathbf{u}_3-\mathbf{q}_p\|_{0,\Sigma}. \tag{27}$$

Proof. Let $\mathbf{q}_p$ be any element of $\mathbf{N}_{\mathsf{N}}^p$. Since

$$(\Pi^{\mathrm{curl}}\mathbf{u}_3, \mathbf{grad}\,\mathbf{q}_p) = (\mathbf{u}_3, \Pi^{\mathrm{curl}}\,\mathbf{grad}\,\mathbf{q}_p) = (\mathbf{u}_3, \mathbf{grad}\,\Pi\mathbf{q}_p),$$

we obtain that $\mathbf{u}_{3,p}$ is discrete divergence-free.

By Theorem 4, there exists $\mathbf{s}\in\mathbf{grad}\,\mathbb{Q}_0^p\oplus\mathbf{curl}\,\mathrm{curl}\,\mathbf{N}_{\mathsf{N}}^p$ so that

$$C_p\|\mathbf{u}_{3,p}-\mathbf{q}_p\|\,\|\mathbf{s}\| \leq (\mathbf{u}_{3,p}-\mathbf{q}_p,\mathbf{s}).$$

Any $\mathbf{s} \in \mathbf{grad}\, \mathbb{Q}_0^p \oplus \mathbf{curl}\, \mathrm{curl}\, \mathbf{N}_{\mathsf{N}}^p$ being orthogonal to $\mathbf{u}_3 - \mathbf{u}_{3,p}$ we get

$$C_p \|\mathbf{u}_{3,p} - \mathbf{q}_p\| \, \|\mathbf{s}\| \leq (\mathbf{u}_3 - \mathbf{q}_p, \mathbf{s}) \leq \|\mathbf{u}_3 - \mathbf{q}_p\| \, \|\mathbf{s}\|.$$

By the triangle inequality we deduce (27). ∎

The best approximation error in the L^2-norm by polynomials in $\mathbf{N}_{\mathsf{N}}^p$ behaves as p^{-1} for fields in H^1 satisfying the boundary conditions of $\mathbf{H}_0(\mathrm{curl})$.

LEMMA 8. *Let $\mathbf{u}_3 \in \mathbf{H}^1(\Sigma) \cap \mathbf{H}_0(\mathrm{curl}, \Sigma)$ be a general bubble function on Σ. There exists $\mathbf{q}_p \in \mathbf{N}_{\mathsf{N}}^p(\Sigma)$ such that*

$$\|\mathbf{u}_3 - \mathbf{q}_p\|_{0,\Sigma} \leq C p^{-1} \|\mathbf{u}_3\|_{1,\Sigma}. \tag{28}$$

Proof. Let u_x and u_y be the two components of $\mathbf{u}_3$. We note that u_x belongs to $L^2(I, H_0^1(I)) \cap H^1(I, L^2(I))$. We take as interpolant for u_x the function $\pi_x^{p-1,0} \otimes \pi_y^{p,1}(u_x)$, where $\pi^{p,0}$ and $\pi^{p,1}$ are the 1D standard projection operators used in spectral and p methods: $\pi^{p,0}$ is the L^2 orthogonal projection on $\mathbb{P}^p(I)$ and $\pi^{p,1}$ is defined as

$$\pi^{p,1}(u)(t) = \int_{-1}^{t} \pi^{p-1,0}(u')(s)\, ds.$$

Both $\pi^{p,0}$ and $\pi^{p,1}$ satisfy the L^2-H^1 error estimate with a factor p^{-1}; see, for instance, [43, Chapter 3]. Moreover, $\pi^{p,0}$ is stable in L^2 and $\pi^{p,1}$ in H^1. The proof of the estimate for $\|u_x - \pi_x^{p-1,0} \otimes \pi_y^{p,1}(u_x)\|_{0,\Sigma}$ then follows. The situation for the second component is similar. ∎

4.4. Discrete compactness. In this section we prove the discrete compactness property for edge finite elements on 1-irregular *hp* square meshes. The discrete compactness property, stated in Theorem 11, is known to be sufficient and in a sense necessary for the good approximation of eigenvalues/eigenvectors (see, for instance, [7, 16, 33, 39]).

For our proof we need L^2 estimates for $\mathbf{u} - \Pi^{\mathrm{curl}}\mathbf{u}$ for divergence-free fields $\mathbf{u}$ on any unconstrained element K (Lemma 9) or any patch P (Lemma 10).

LEMMA 9. *Let K be an unconstrained square element of size $h = h_K$, and let p be the minimum among p_K and $\{p_e,\ e = 1, \ldots, 4\}$. Let $\mathbf{u} \in \mathbf{H}^r(K)$, $0 < r < 1/2$, $\mathrm{curl}\, \mathbf{u} \in L^2(K)$, $\mathrm{div}\, \mathbf{u} = 0$. For every $\varepsilon > 0$, there exists a constant $C > 0$, dependent upon ε but independent of the element and function $\mathbf{u}$, such that*

$$\|\mathbf{u} - \Pi_K^{\mathrm{curl}}\mathbf{u}\| \leq C \left(\frac{h}{p}\right)^{(r-\varepsilon)} (\|\mathbf{u}\|_{r,K} + \|\mathrm{curl}\, \mathbf{u}\|_{0,K}).$$

Here Π_K^{curl} is the projection-based interpolation on K transported from Π^{curl} in (15).

Proof. Step 1. *p-estimate on the master element.* Assume first that $K = \Sigma$ is the master square element. It follows from the integration by parts formula

$$\int_K (\mathrm{curl}\, \mathbf{u})\phi \, d\mathbf{x} = \int_K \mathbf{u} \cdot \mathbf{curl}\, \phi \, d\mathbf{x} + \int_{\partial K} u_t \phi \, ds$$

that the tangential component u_t lives in $H^{-1/2+r}(\partial K)$ and

$$\|u_t\|_{-1/2+r,\partial K} \leq C(\|\mathbf{u}\|_{r,K} + \|\mathrm{curl}\, \mathbf{u}\|_{0,K}),$$

with C denoting a generic constant depending upon the master element only. We decompose function $\mathbf{u}$ into three contributions

$$\mathbf{u} = \mathbf{u}_1 + \mathbf{grad}\, q + \mathbf{u}_3. \tag{29}$$

The terms are constructed as follows.

- $\mathbf{u}_1$ is the lowest degree Whitney interpolant, which means that $\mathbf{u}_1 \in \mathbf{N}^{1|\,0}(K)$, $\operatorname{div} \mathbf{u}_1 = 0$, and the tangential traces of $\mathbf{u}_1$ are the mean values of those of $\mathbf{u}$ on each edge of K.
- Potential q is obtained by integrating tangential component $u_t - u_{1t}$ along the element boundary, starting from any of its vertex nodes. Potential q vanishes at all vertex nodes and

  $$\|q\|_{1/2+r,\partial K} \leq C\|u_t - u_{1t}\|_{-1/2+r,\partial K}.$$

  As the Whitney interpolant depends continuously upon the tangential component u_t itself and it lives in a finite dimensional space, by the standard finite dimensionality argument we conclude that the norm of potential q is controlled by the norm of $\mathbf{u}$ alone:

  $$\begin{aligned}\|q\|_{1/2+r,\partial K} &\leq C\|u_t\|_{-1/2+r,\partial K}\\ &\leq C(\|\mathbf{u}\|_{r,K} + \|\operatorname{curl}\mathbf{u}\|_{0,K}).\end{aligned}$$

  We then extend potential q to the rest of the element using a harmonic (minimum energy) extension. Consequently,

  $$\|q\|_{1+r,K} \leq (\|\mathbf{u}\|_{r,K} + \|\operatorname{curl}\mathbf{u}\|_{0,K}).$$

- $\mathbf{u}_3$ is the residual bubble function: $\mathbf{n}\times\mathbf{u}_3 = 0$ on the boundary ∂K, and

  $$\operatorname{curl}\mathbf{u}_3 = \operatorname{curl}(\mathbf{u}-\mathbf{u}_1), \quad \operatorname{div}\mathbf{u}_3 = \operatorname{div}(\mathbf{u}-\mathbf{u}_1) = 0.$$

  It follows that $\mathbf{u}_3 \in \mathbf{H}^1(K)$ and

  $$\|\mathbf{u}_3\|_{1,K} \leq C\|\operatorname{curl}(\mathbf{u}-\mathbf{u}_1)\|_{0,K} \leq C\|\operatorname{curl}\mathbf{u}\|_{0,K}.$$

We use a similar decomposition for the projection-based interpolant $\Pi_K^{\mathrm{curl}}\mathbf{u}$ of $\mathbf{u}$,

$$\Pi_K^{\mathrm{curl}}\mathbf{u} = \mathbf{u}_1 + \mathbf{grad}\, q_p + \mathbf{u}_{p,3},$$

with the same Whitney interpolant $\mathbf{u}_1$ and $q_p = \Pi_K q$. Thus q_p is only a discrete harmonic function, and $\mathbf{u}_{p,3}$ is only discrete divergence-free. Obviously,

$$\mathbf{u} - \Pi_K^{\mathrm{curl}}\mathbf{u} = \mathbf{grad}(q - q_p) + \mathbf{u}_3 - \mathbf{u}_{p,3}.$$

The first term then admits the estimate (see [24])

$$\begin{aligned}\|\mathbf{grad}(q-q_p)\|_{0,K} &\leq Cp^{-(r-\varepsilon)}\|q\|_{1+r,K}\\ &\leq Cp^{-(r-\varepsilon)}(\|\mathbf{u}\|_{r,K} + \|\operatorname{curl}\mathbf{u}\|_{0,K}).\end{aligned} \tag{30}$$

The estimate of the second term is made possible by Theorem 7: there holds

$$\|\mathbf{u}_3 - \mathbf{u}_{3,p}\|_{0,K} \leq Cp^{1/2} \inf_{\mathbf{F}_{3,p}\in\mathbf{N}_{\mathsf{N}}^p} \|\mathbf{u}_3 - \mathbf{F}_{3,p}\|_{0,K}.$$

The approximation result (28) then gives

$$\begin{aligned}\|\mathbf{u}_3 - \mathbf{u}_{3,p}\|_{0,K} &\le Cp^{-1/2}\|\mathbf{u}_3\|_{1,K} \\ &\le Cp^{-1/2}(\|\mathbf{u}\|_{r,K} + \|\operatorname{curl}\mathbf{u}\|_{0,K}).\end{aligned} \tag{31}$$

Combining (30) and (31), we get the final estimate for the master element,

$$\|\mathbf{u} - \Pi_K^{\mathrm{curl}}\mathbf{u}\|_{0,K} \le Cp^{-(r-\varepsilon)}(\|\mathbf{u}\|_{r,K} + \|\operatorname{curl}\mathbf{u}\|_{0,K}).$$

Step 2. *Scaling argument.* Let K be an arbitrary (unconstrained) square element, and let

$$\Sigma = \hat{K} \ni \boldsymbol{\xi} \to \mathbf{x} \in K$$

be the homothetic transformation from the master element Σ onto K. Recalling the transformation for $\mathbf{H}(\mathrm{curl})$-conforming elements,

$$\hat{\mathbf{u}}(\boldsymbol{\xi}) = \mathbf{u}(\mathbf{x})h,$$

where $h = h_K$ is the element size, we follow the standard scaling argument and Step 1 result to obtain

$$\begin{aligned}\|\mathbf{u} - \Pi_K^{\mathrm{curl}}\mathbf{u}\|_{0,K} &= \|\hat{\mathbf{u}} - \Pi^{\mathrm{curl}}\hat{\mathbf{u}}\|_{0,\Sigma} \\ &\le Cp^{-(r-\varepsilon)}(\|\hat{\mathbf{u}}\|_{r,\Sigma} + \|\operatorname{curl}\hat{\mathbf{u}}\|_{0,\Sigma}).\end{aligned}$$

However, the (projection-based) interpolation reproduces polynomials and, by the Bramble–Hilbert argument and standard interpolation arguments, we get

$$\begin{aligned}\|\mathbf{u} - \mathbf{u}_p\|_{0,K} &\le Cp^{-(r-\varepsilon)}(|\hat{\mathbf{u}}|_{r,\Sigma} + \|\operatorname{curl}\hat{\mathbf{u}}\|_{0,\Sigma}) \\ &\le C\left(\frac{h}{p}\right)^{(r-\varepsilon)}(|\mathbf{u}|_{r,K} + \|\operatorname{curl}\mathbf{u}\|_{0,K}).\end{aligned}$$

This finishes the proof. ∎

We have an analogous but slightly different result for element patches.

LEMMA 10. *Let P be a patch of two, three, or four square elements of the same size, forming a rectangle, an L-shaped domain, and a square, respectively; cf. section* 4.2. *Let p denote the minimum order of all elements and edges constituting the patch. Let h denote the size of the elements forming the patch. Let $\mathbf{u} \in \mathbf{H}^r(P)$, $0 < r < 1/2$, $\operatorname{curl}\mathbf{u} \in L^2(P)$, $\operatorname{div}\mathbf{u} = 0$. There exist constant $C > 0$, independent of the element and function $\mathbf{u}$, and constant r_P, $0 < r_P < r$, such that*

$$\|\mathbf{u} - \Pi_P^{\mathrm{curl}}\mathbf{u}\|_{0,P} \le C\left(\frac{h}{p}\right)^{r_P}(\|\mathbf{u}\|_{r,P} + \|\operatorname{curl}\mathbf{u}\|_{0,P}).$$

By $\Pi_P^{\mathrm{curl}}\mathbf{u}$ we understand the projection-based interpolation (22) *done on the patch.*

Proof. The reasoning follows the same lines as for the preceding lemma. We revisit the main steps and point out the differences.

- $\mathbf{u}_1$ plays on the patch P a similar (but weaker) role as the lowest degree Whitney interpolant on K: $\mathbf{u}_1 \in \mathbf{N}^{1|\,0}(P)$, $\operatorname{div}\mathbf{u}_1 = 0$ in P, and $\mathbf{u}_1$ compensates for the mean value of the tangential trace of $\mathbf{u}$ on the whole boundary ∂P:

$$\int_{\partial P} \mathbf{n} \times (\mathbf{u} - \mathbf{u}_1)\, ds = 0.$$

  For $\mathbf{u}_1$ we may take a field of the form $\gamma\mathbf{e}|_P$, where $\mathbf{e}$ is any nonzero element of $\mathbf{N}^{1|\,0}(\hat{P})$ on the convex hull $\hat{P}$ of P, and γ is a suitable constant.

- The potential q is still obtained by first integrating $u_t - u_{1t}$ along ∂P. Now it does not vanish at the corners, but we still have $q \in H^{1/2+r}(\partial P)$, so we can take its harmonic extension in P to find $q \in H^{1+r}(P)$.
- We still have a decomposition like (29), $\mathbf{u} = \mathbf{u}_1 + \mathbf{grad}\, q + \mathbf{u}_3$, with a divergence-free patch bubble function $\mathbf{u}_3$. But for the L-shaped patches, $\mathbf{u}_3$ is no longer an $\mathbf{H}^1$-function; however, $\mathbf{u}_3$ belongs to $\mathbf{H}^{1/2+r_P}(P)$, with $r_P > 0$ (here r_P is any constant $< \frac{1}{6}$) [18].
- At the discrete level, we have $\Pi_P^{\mathrm{curl}}\mathbf{u} = \mathbf{u}_1 + \mathbf{grad}(\Pi_P q) + \mathbf{u}_{3,p}$. The estimate corresponding to (30), $\|\mathbf{grad}(q - \Pi_P q)\|_{0,P}$, does not follow directly from element estimates, but it can be obtained extending arguments from [24]. Alternatively, the H^1 patch interpolant $\Pi_P q$ can be seen as the Galerkin approximation to the solution of the Laplace equation on the patch, with Dirichlet boundary conditions and right approximation of Dirichlet data (in the $H^{1/2}$-norm). The corresponding estimates can be found in [43].
- The bound on $\|\mathbf{u}_3 - \mathbf{u}_{3,p}\|_{0,P}$ corresponding to (31) does not follow directly from the L^2-stability result for a single element. Instead, we proceed by comparing the patch interpolant $\mathbf{u}_{3,p} = \Pi_P^{\mathrm{curl}}\mathbf{u}_3$ with the union of interpolants $\Pi_K^{\mathrm{curl}}\mathbf{u}_3$ corresponding to elements K contributing to the patch, denoted by $\mathbf{v}_{3,p}$:

$$\mathbf{v}_{3,p}\big|_K = \Pi_K^{\mathrm{curl}}\mathbf{u}_3 \quad \forall K \subset P.$$

  Both operators Π_P^{curl} and $(\Pi_K^{\mathrm{curl}})_{K\subset P}$, acting from $\mathbf{H}_0(\mathrm{curl}, P)\cap\mathbf{H}^{\varepsilon}(P)$, satisfy the commutativity property for the de Rham diagram. The L^2-projections of $\mathrm{curl}\,\mathbf{u}$ done on the whole patch or elementwise are identical. Consequently,

$$\mathrm{curl}\,\mathbf{u}_{3,p} = \mathrm{curl}\,\mathbf{v}_{3,p},$$

  and the two functions may differ only by a gradient of potential ϕ that is zero on the patch boundary ∂P and lives in the patch FE space. It follows from the fact that $\mathbf{u}_{3,p}$ is discrete divergence-free that

$$\begin{aligned}\|\mathbf{u}_3 - \mathbf{u}_{3,p}\|_{0,P} &\le \inf_{\phi} \|\mathbf{u}_3 - \mathbf{u}_{3,p} - \mathbf{grad}\,\phi\|_{0,P}\\ &\le \|\mathbf{u}_3 - \mathbf{v}_{3,p}\|_{0,P}.\end{aligned}$$

  Coming back to the definition of $\mathbf{v}_{3,p}$, we finally obtain

$$\|\mathbf{u}_3 - \mathbf{u}_{3,p}\|_{0,P} \le \sum_{K\subset P} \|\mathbf{u}_3 - \Pi_K^{\mathrm{curl}}\mathbf{u}_3\|_{0,P}.$$

  The estimation can now be done elementwise on each unconstrained element $K \subset P$ utilizing Lemma 9 for $\mathbf{u} := \mathbf{u}_3|_K$, noting that $\mathrm{div}\,\mathbf{u}_3|_K = 0$. ∎

We are ready now to formulate and prove our final result.

THEOREM 11. *Starting with a regular mesh on Ω we perform consecutive hp-refinements, enforcing the 1-irregularity and minimum rules, constructing meshes $\mathfrak{M}_{hp}$. We assume that*

$$\max_{K\in\mathfrak{M}_{hp}} \frac{h_K}{p_K} \to 0. \tag{32}$$

Let $\mathbf{u}_{hp} \in \mathbf{X}_{hp}$ be an arbitrary sequence of FE functions on $\mathfrak{M}_{hp}$, such that $\mathbf{u}_{hp}\times\mathbf{n} = 0$ on $\partial\Omega$. We assume that the functions $\mathbf{u}_{hp}$ are discrete divergence-free, *i.e.,*

$$(\mathbf{u}_{hp}, \mathbf{grad}\,\phi_{hp}) = 0 \quad \forall \phi_{hp} \in \mathbb{Q}_{hp}.$$

We also assume that the $\mathbf{u}_{hp}$ *are uniformly bounded in the space* $\mathbf{H}(\mathrm{curl},\Omega)$*:*

$$\|\operatorname{curl}\mathbf{u}_{hp}\| \le 1.$$

Then there exists a subsequence $\mathbf{u}_{hp}$*, (denoted with the same symbol) converging strongly in* $L^2(\Omega)$ *to a limit*[2] $\mathbf{u}$*:*

$$\|\mathbf{u}_{hp}-\mathbf{u}\| \to 0.$$

Proof. Step 1. Following Kikuchi's reasoning (see [35]), we introduce a sequence of divergence-free functions $\mathbf{u}^{hp}$, satisfying the same essential boundary conditions, such that

$$\operatorname{curl}\mathbf{u}^{hp} = \operatorname{curl}\mathbf{u}_{hp}, \quad (\mathbf{u}^{hp},\, \mathbf{grad}\,\phi) = 0 \quad \forall \phi \in H^1_0(\Omega).$$

We have

$$\mathbf{u}_{hp} = \mathbf{u}^{hp} + \mathbf{grad}\, q^{hp}, \tag{33}$$

where q^{hp} is the solution to

$$\begin{aligned} &q^{hp} \in H^1_0(\Omega)\\ &(\mathbf{grad}\, q^{hp},\, \mathbf{grad}\,\phi) = (\mathbf{u}_{hp},\, \mathbf{grad}\,\phi) \quad \forall \phi \in H^1_0(\Omega). \end{aligned}$$

It follows from the regularity results of [18] that

$$\mathbf{u}^{hp} \in \mathbf{H}^r(\Omega), \quad r>0,$$

with a uniform bound on the $\mathbf{H}^r$ norm,

$$\|\mathbf{u}^{hp}\|_{\mathbf{H}^r(\Omega)} \le C.$$

By a standard compactness argument, there exists a subsequence $\mathbf{u}^{hp}$ converging strongly in $L^2(\Omega)$ to a limit $\mathbf{u}$. We are going to prove that $\mathbf{grad}\, q^{hp} \to 0$, and thus obtain that $\mathbf{u}_{hp}$ converges to the same limit $\mathbf{u}$.

Step 2. Applying the interpolation operator to both sides of the equation, and using the commutativity of interpolation and the fact that the interpolation preserves FE spaces, we get

$$\mathbf{u}_{hp} = \Pi^{\mathrm{curl}}\mathbf{u}^{hp} + \mathbf{grad}\,\Pi q^{hp}. \tag{34}$$

Subtracting (34) from (33) we get

$$-\mathbf{grad}(q^{hp} - \Pi q^{hp}) = \mathbf{u}^{hp} - \Pi^{\mathrm{curl}}\mathbf{u}^{hp}\,.$$

It follows from (33) that $\mathbf{grad}\, q^{hp}$ is orthogonal to all discrete gradients. Consequently,

$$\|\mathbf{grad}\, q^{hp}\| = \inf_{q_{hp}\in Q_{hp}} \|\mathbf{grad}(q^{hp}-q_{hp})\| \le \|\mathbf{grad}(q^{hp}-\Pi q^{hp})\| = \|\mathbf{u}^{hp} - \Pi^{\mathrm{curl}}\mathbf{u}^{hp}\|.$$

It is sufficient, therefore, to prove that the interpolation error of functions $\mathbf{u}^{hp}$ converges uniformly to zero.

[2] Notice that the limit satisfies $\|\operatorname{curl}\mathbf{u}\| \le 1$ and that $\mathbf{u}$ is divergence-free.

Step 3. Applying Lemmas 9 and 10, we obtain

$$\|\mathbf{u}^{hp} - \Pi^{\mathrm{curl}}\mathbf{u}^{hp}\|^2_{0,\Omega} = \sum_P \|\mathbf{u}^{hp} - \Pi^{\mathrm{curl}}\mathbf{u}^{hp}\|^2_{0,P}$$
$$\leq C \sum_P \left(\frac{h_P}{p_P}\right)^{2r_P} (\|\mathbf{u}^{hp}\|_{r,P} + \|\operatorname{curl}\mathbf{u}^{hp}\|_{0,P})^2.$$

Here r is the global regularity constant and $r_P < r$ denote the patch constants discussed in Lemma 10 (we also consider unconstrained elements K as one-element patches and, applying Lemma 9, take r_P as any number between 0 and r in this case). As r_P depends only upon the shape of the patch and the number of different patches is finite, the L^2-interpolation error must converge to zero if the maximum ratio of patch size and (minimum) order converges to zero,

$$\max_P \frac{h_P}{p_P} \to 0.$$

Notice, finally, that the 1-irregularity and max rules imply that the last condition follows from assumption (32). ∎

Remark 5. Examining our proof, we see that we have proved the following property: There exists a sequence δ_{hp} converging to 0 such that

(35) $\forall \mathbf{u}_{hp} \in \mathbf{X}_{hp}$, discrete divergence-free,
$\exists \mathbf{u}^{hp} \in \mathbf{H}_0(\mathrm{curl},\Omega)$ with $\operatorname{div}\mathbf{u}^{hp} = 0$: $\|\mathbf{u}^{hp} - \mathbf{u}_{hp}\| \leq C\delta_{hp}(\|\mathbf{u}_{hp}\| + \|\operatorname{curl}\mathbf{u}_{hp}\|)$.

Here $C > 0$ does not depend on $\mathbf{u}_{hp}$. Condition (35) implies the discrete compactness property; cf. [6, 7]. It also implies the quasi optimality of the discrete electric Maxwell problems for any fixed frequency which is not an eigenfrequency of the continuous problem; see [10, 15, 27].

5. Conclusions. Relying on our main result, Theorem 11, and on [16], we can conclude the convergence of eigenvalue approximation along the following lines.

Let Ω be a simply connected polygonal domain with sides parallel to the coordinate axes. We consider the Maxwell eigenvalue problem on Ω:

(36) Find $\mathbf{u} \in \mathbf{H}(\mathrm{curl},\Omega), \mathbf{u} \neq 0$, and $\lambda \neq 0$:
$$\int_\Omega \operatorname{curl}\mathbf{u}\, \operatorname{curl}\mathbf{v}\, d\mathbf{x} = \lambda \int_\Omega \mathbf{u}\cdot\mathbf{v}\, d\mathbf{x} \quad \forall \mathbf{v} \in \mathbf{H}(\mathrm{curl},\Omega).$$

The condition $\lambda \neq 0$ implies that eigenvectors $\mathbf{u}$ are divergence-free. The converse is also true since Ω is simply connected. The eigenvalues λ have a finite multiplicity and form an increasing sequence of positive numbers without accumulation point. We denote by $\lambda^1 \leq \lambda^2 \leq \cdots \leq \lambda^k \leq \cdots$ the sequence of eigenvalues with repetition according to their multiplicities.

We choose a sequence of *hp* FE spaces $\mathbf{X}_{hp}$ satisfying the assumptions of Theorem 11 and define the approximated problems by the following problem:

(37) Find $\mathbf{u}_{hp} \in \mathbf{X}_{hp}, \mathbf{u}_{hp} \neq 0$, and $\lambda_{hp} \neq 0$:
$$\int_\Omega \operatorname{curl}\mathbf{u}_{hp}\, \operatorname{curl}\mathbf{v}_{hp}\, d\mathbf{x} = \lambda_{hp} \int_\Omega \mathbf{u}_{hp}\cdot\mathbf{v}_{hp}\, d\mathbf{x} \quad \forall \mathbf{v}_{hp} \in \mathbf{X}_{hp}.$$

The discrete eigenvectors $\mathbf{u}_{hp}$ are discrete divergence-free. We denote by $\lambda_{hp}^1 \le \lambda_{hp}^2 \le \cdots \le \lambda_{hp}^k \le \cdots$ the sequence of eigenvalues with repetition according to their multiplicities.

Assumption (32) guarantees that the conditions (CAS) (approximation in $\mathbf{H}(\mathrm{curl}, \Omega)$) and (CDK) (approximation in the kernel of the curl operator) of [16] are satisfied. Theorem 11 yields condition (DCP) of discrete compactness. Thus [16, Theorem 6.9] yields that the sequence of problems (37) is a *spurious-free spectrally correct* approximation of problem (36). As a consequence, we have

$$\forall k \ge 1, \quad \lambda_{hp}^k \longrightarrow \lambda^k \quad \text{as} \quad \max_{K \in \mathfrak{M}_{hp}} \frac{h_K}{p_K} \to 0. \tag{38}$$

Let us recall that the spectral correctness alone would provide a weaker statement, according to which the correct numbering of discrete eigenvalues which ensures (38) should be done by discarding *small* eigenvalues (and not only *zero* eigenvalues). "Small" means that the maximal size ε_{hp} of the discarded ones tends to zero as h_K/p_K tends to zero. The consequence of the spurious-free property is that ε_{hp} is equal to zero.

According to [16, Theorem 6.11] the three conditions (CAS), (CDK), and (DCP) imply condition (CHN) too. Condition (CHN) is the one which allows the application of the theory of [28]; see also [16, Remark 4.11]. This implies, for example, that if λ^k is a simple eigenvalue, there holds the estimate

$$|\lambda^k - \lambda_{hp}^k| \le C_k \left(\min_{\mathbf{v}_{hp} \in \mathbf{X}_{hp}} \|\mathbf{u}^k - \mathbf{v}_{hp}\|_{\mathbf{H}(\mathrm{curl},\Omega)} \right)^2. \tag{39}$$

Here $\mathbf{u}^k$ is a normalized eigenvector associated with λ^k. Less sharp estimates can be deduced by this argument in the case of multiple eigenvalues.

In [21, 22], it is proved that the regularity of the eigenvectors $\mathbf{u}^k$ can be described in terms of weighted analytic spaces (close to the countably normed spaced of [4]), via a decomposition $\nabla\varphi^k + \mathbf{w}^k$ where the potential φ^k concentrates the strongest singularities. Combining this with the approximation result proved in [1] for Raviart–Thomas elements, it is possible to deduce an exponential estimate in our case:

$$|\lambda^k - \lambda_{hp}^k| \le C_k \, e^{-b_k N^{1/3}}, \quad b_k > 0. \tag{40}$$

Here N is the dimension of $\mathbf{X}_{hp}$. Note that $N^{1/3}$ is a $\mathcal{O}(p)$.

Our final comment concerns the validity of our result for meshes obtained using the so-called algebraic mesh generators. This is the case when the actual physical domain is partitioned into a finite number of (possibly curvilinear) quadrilaterals, each of them being the image of a reference unit square through a smooth map. The maps are compatible in the sense that parametrizations for two quadrilaterals adjacent to a common edge provide an identical parametrization for the edge. The original Maxwell problem can then be restated on a collection of reference square domains with appropriate interface conditions and modified material properties resulting from the change of coordinates. According to the result of Caorsi, Fernandes, and Raffetto [16], the discrete compactness property for constant material data implies the corresponding discrete compactness property for the case of general, possibly anisotropic, material data. As the discretization in the original domain with parametric, exact geometry elements is equivalent to the discretization of the modified problem on the reference

squares using square elements discussed in this paper, our analysis applies to such a case as well. We emphasize that the situation is essentially different when unstructured mesh generators are used, and the geometry of individual quadrilateral elements is no longer controlled by global (and sufficiently smooth) maps; cf. [3].

OPTIMALITY OF MULTILEVEL PRECONDITIONERS FOR LOCAL MESH REFINEMENT IN THREE DIMENSIONS*

BURAK AKSOYLU†‡ AND MICHAEL HOLST§

Abstract. In this article, we establish optimality of the Bramble–Pasciak–Xu (BPX) norm equivalence and optimality of the wavelet modified (or *stabilized*) hierarchical basis (WHB) preconditioner in the setting of local 3D mesh refinement. In the analysis of WHB methods, a critical first step is to establish the optimality of BPX norm equivalence for the refinement procedures under consideration. While the available optimality results for the BPX norm have been constructed primarily in the setting of uniformly refined meshes, a notable exception is the local 2D red-green result due to Dahmen and Kunoth. The purpose of this article is to extend this original 2D optimality result to the local 3D red-green refinement procedure introduced by Bornemann, Erdmann, and Kornhuber, and then to use this result to extend the WHB optimality results from the quasi-uniform setting to local 2D and 3D red-green refinement scenarios. The BPX extension is reduced to establishing that locally enriched finite element subspaces allow for the construction of a scaled basis which is formally Riesz stable. This construction turns out to rest not only on the shape regularity of the refined elements, but also critically on a number of geometrical properties we establish between neighboring simplices produced by the Bornemann–Erdmann–Kornhuber (BEK) refinement procedure. It is possible to show that the number of degrees of freedom used for smoothing is bounded by a constant times the number of degrees of freedom introduced at that level of refinement, indicating that a practical, implementable version of the resulting BPX preconditioner for the BEK refinement setting has provably optimal (linear) computational complexity per iteration. An interesting implication of the optimality of the WHB preconditioner is the a priori H^1-stability of the L_2-projection. The existing a posteriori approaches in the literature dictate a reconstruction of the mesh if such conditions cannot be satisfied. The theoretical framework employed supports arbitrary spatial dimension $d \geq 1$ and requires no coefficient smoothness assumptions beyond those required for well-posedness in H^1.

Key words. finite element approximation theory, multilevel preconditioning, BPX, hierarchical bases, wavelets, three dimensions, local mesh refinement, red-green refinement

1. Introduction.

In this article, we analyze the impact of local mesh refinement on the stability of multilevel finite element spaces and on optimality (linear space and time complexity) of multilevel preconditioners. Adaptive refinement techniques have become a crucial tool for many applications, and access to optimal or near-optimal multilevel preconditioners for locally refined mesh situations is of primary concern to computational scientists. The preconditioners which can be expected to have somewhat favorable space and time complexity in such local refinement scenarios are the hierarchical basis (HB) method [9], the Bramble–Pasciak–Xu (BPX)

preconditioner [16], and the wavelet modified (or stabilized) hierarchical basis (WHB) method [35]. While there are optimality results for both the BPX and WHB preconditioners in the literature, these are primarily for quasi-uniform meshes and/or two space dimensions (with some exceptions noted below). In particular, there are few hard results in the literature on the optimality of these methods for various realistic local mesh refinement hierarchies, especially in three space dimensions. In this article, the first in a series of two articles [2] on local refinement and multilevel preconditioners, we first assemble optimality results for the BPX norm equivalence in local refinement scenarios in three spatial dimensions. Building on the extended BPX results, we then develop optimality results for the WHB method in local refinement settings. The material forming this series is based on the first author's Ph.D. dissertation [1]; a comprehensive presentation of this article can be found in [3, 4, 5, 6].

Through some topological or geometrical abstraction, if local refinement is extended to d spatial dimensions, then the main results are valid for any dimension $d \geq 1$ and for nonsmooth PDE coefficients $p \in L_\infty(\Omega)$. Throughout this article, we consider primarily the $d = 3$ case. But, when the abstraction to generic d is clear, we simply state the argument by using this generic d.

The problem class we focus on here is linear second order PDEs of the form

$$-\nabla \cdot (p\ \nabla u) + q\ u = f, \quad u = 0 \ \text{ on } \partial\Omega. \tag{1.1}$$

Here, $f \in L_2(\Omega)$, $p, q \in L_\infty(\Omega)$, $p : \Omega \to L(\mathbb{R}^d, \mathbb{R}^d)$, $q : \Omega \to \mathbb{R}$, where p is a symmetric positive definite matrix function and q is a nonnegative function. Let $\mathcal{T}_0$ be a shape regular and quasi-uniform initial partition of Ω into a finite number of d simplices, and generate $\mathcal{T}_1, \mathcal{T}_2, \ldots$ by refining the initial partition using red-green local refinement strategies in $d = 3$ spatial dimensions. Denote by $\mathcal{S}_j$ the simplicial linear C^0 finite element space corresponding to $\mathcal{T}_j$ equipped with zero boundary values. The set of nodal basis functions for $\mathcal{S}_j$ is denoted by $\Phi^{(j)} = \{\phi_i^{(j)}\}_{i=1}^{N_j}$, where $N_j = \dim\ \mathcal{S}_j$ is equal to the number of interior nodes in $\mathcal{T}_j$, representing the number of degrees of freedom (DOF) in the discrete space. Successively refined finite element spaces will form the following nested sequence:

$$\mathcal{S}_0 \subset \mathcal{S}_1 \subset \cdots \subset \mathcal{S}_j \subset \cdots \subset H_0^1(\Omega).$$

Let the bilinear form and the functional associated with the weak formulation of (1.1) be denoted as

$$a(u, v) = \int_\Omega p\ \nabla u \cdot \nabla v + q\ u\ v\ dx, \quad b(v) = \int_\Omega f\ v\ dx, \quad u, v \in H_0^1(\Omega).$$

We consider primarily the following Galerkin formulation: Find $u \in \mathcal{S}_j$, such that

$$a(u, v) = b(v) \quad \forall v \in \mathcal{S}_j. \tag{1.2}$$

The finite element approximation in $\mathcal{S}_j$ has the form $u^{(j)} = \sum_{i=1}^{N_j} u_i \phi_i^{(j)}$, where $u = (u_1, \ldots, u_{N_j})^T$ denotes the coefficients of $u^{(j)}$ with respect to $\Phi^{(j)}$. The resulting *discretization operator* $A^{(j)} = \{a(\phi_k^{(j)}, \phi_l^{(j)})\}_{k,l=1}^{N_j}$ must be inverted numerically to determine the coefficients u from the linear system

$$A^{(j)} u = F^{(j)}, \tag{1.3}$$

where $F^{(j)} = \{b(\phi_l^{(j)})\}_{l=1}^{N_j}$. Our task is to solve (1.3) with optimal (linear) complexity in both storage and computation, where the finite element spaces $\mathcal{S}_j$ are built on locally refined meshes.

Optimality of the BPX norm equivalence with generic local refinement was shown by Bramble and Pasciak in [14], where the impact of the local smoother and the local projection operator on the estimates was carefully analyzed. The two primary results on optimality of the BPX norm equivalence in the local refinement settings are due to Dahmen and Kunoth [19] and Bornemann and Yserentant [12]. Both works consider only two space dimensions, and in particular, the refinement strategies analyzed are restricted to 2D red-green refinement and 2D red refinement, respectively. In this paper, we extend the framework developed in [19] to a practical, implementable 3D local red-green refinement procedure introduced by Bornemann, Erdmann, and Kornhuber [11]. We will refer to this as the BEK refinement procedure.

HB methods [9, 7, 37] are particularly attractive in the local refinement setting because (by construction) each iteration has linear (optimal) computational and storage complexity. Unfortunately, the resulting preconditioner is not optimal due to condition number growth: in two dimensions the growth is slow, and the method is quite effective (nearly optimal), but in three dimensions the condition number grows much more rapidly with the number of unknowns [26]. To address this instability, one can employ L_2-orthonormal wavelets in place of the HB, giving rise to an optimal preconditioner [23]. However, the complicated nature of traditional wavelet bases, in particular the nonlocal support of the basis functions and problematic treatment of boundary conditions, severely limits computational feasibility. WHB methods have been developed [34, 35] as an alternative, and they can be interpreted as a wavelet modification (or *stabilization*) of the HB. These methods have been shown to optimally stabilize the condition number of the systems arising from HB methods on quasi-uniform meshes, in both two and three space dimensions, and retain a comparable cost per iteration.

There are two main results and one secondary result in this article. The main results establish the optimality of the BPX norm equivalence and also optimality of the WHB preconditioner—as well as optimal computational complexity per iteration—for the resulting locally refined 3D finite element hierarchy. Both the BPX and WHB preconditioners under consideration are additive Schwarz preconditioners. The BPX analysis here relies heavily on the techniques of the Dahmen–Kunoth [19] framework and can be seen as an extension to three spatial dimensions, with the realistic BEK refinement procedure [11] being the application of interest. The WHB framework relies on the optimality of the BPX norm equivalence. Hence, the WHB results are established after the BPX results.

The secondary result is the H^1-stability of L_2-projection onto finite element spaces built through the BEK local refinement procedure. This is currently under intensive study in the finite element community due to its relationship to multilevel preconditioning. The existing theoretical results, due primarily to Carstensen [18] and Bramble, Pasciak, and Steinbach [15] involve a posteriori verification of somewhat complicated mesh conditions after local refinement has taken place. If such mesh conditions are not satisfied, one has to redefine the mesh. However, an interesting consequence of the BPX optimality results for locally refined 2D and 3D meshes established here is H^1-stability of L_2-projection restricted to the same locally enriched finite element spaces. This result appears to be the first a priori H^1-stability result for L_2-projection on finite element spaces produced by practical and easily implementable 2D and 3D local refinement procedures.

Outline of the paper. In section 2, we introduce some basic approximation theory tools used in the analysis such as Besov spaces and Bernstein inequalities. The framework for the main norm equivalence is also established here. In section 3,

we list the BEK refinement conditions. We give several theorems about the generation and size relations of the neighboring simplices, thereby establishing local (patchwise) quasi uniformity. This gives rise to an L_2-stable Riesz basis in section 3.1; one can then establish the Bernstein inequality.

In section 4, we explicitly give an upper bound for the nodes introduced in the refinement region. This implies that one application of the BPX preconditioner to a function has linear (optimal) computational complexity. In section 5, we use the geometrical results from section 3 to extend the 2D Dahmen–Kunoth results to the 3D BEK refinement procedure by establishing the desired norm equivalence. While it is not possible to establish a Jackson inequality due to the nature of local adaptivity, in section 6 the remaining inequality in the norm equivalence is handled directly using approximation theory tools, as in the original work [19]. In section 7, we introduce the WHB preconditioner as well as the operator used in its definition. In section 8, we state the fundamental assumption for establishing basis stability and set up the main theoretical results for the WHB framework, namely, optimality of the WHB preconditioner in the 2D and 3D local red-green refinements. The results in section 8 rest completely on the BPX results in section 5 and on the Bernstein inequalities, the latter of which rest on the geometrical results established in section 3. The first a priori H^1-stability result for L_2-projection on the finite element spaces produced is established in section 9. We conclude in section 10.

2. Preliminaries and the main norm equivalence. The basic restriction on the refinement procedure is that it remains *nested*. In other words, tetrahedra of level j which are not candidates for further refinement will never be touched in the future. Let Ω_j denote the refinement region, namely, the union of the supports of basis functions which are introduced at level j. Due to nested refinement, $\Omega_j \subset \Omega_{j-1}$, the following hierarchy holds:

$$\Omega_J \subset \Omega_{J-1} \subset \cdots \subset \Omega_0 = \Omega. \tag{2.1}$$

In the local refinement setting, in order to maintain optimal computational complexity, the smoother is restricted to a local space $\tilde{\mathcal{S}}_j$, typically

$$\mathcal{S}_j^f \subseteq \tilde{\mathcal{S}}_j \subset \mathcal{S}_j, \tag{2.2}$$

where $\mathcal{S}_j^f := (I_j - I_{j-1})\ \mathcal{S}_j$ and $I_j : L_2(\Omega) \to \mathcal{S}_j$ denotes the finite element interpolation operator. DOF corresponding to $\mathcal{S}_j^f$ and $\tilde{\mathcal{S}}_j$ will be denoted by $\mathcal{N}_j^f$ and $\tilde{\mathcal{N}}_j$, respectively, where f stands for *fine*. Equation (2.2) indicates that $\mathcal{N}_j^f \subseteq \tilde{\mathcal{N}}_j$; typically, $\tilde{\mathcal{N}}_j$ consists of fine DOF and their corresponding coarse fathers.

The BPX preconditioner (also known as the parallelized or additive multigrid) is defined as follows:

$$Xu := \sum_{j=0}^{J} 2^{j(d-2)} \sum_{i \in \tilde{\mathcal{N}}_j} (u, \phi_i^{(j)}) \phi_i^{(j)}. \tag{2.3}$$

Success of the BPX preconditioner in locally refined regimes relies on the fact that the BPX smoother acts on a local space as in (2.2). As mentioned above, it acts on a slightly bigger set than fine DOF (examples of these are given in [13]). The choice of such a set is crucial because computational cost per iteration will eventually determine the overall computational complexity of the method. Hence, in section 4

we show that the overall computational cost of the smoother is $O(N)$, meaning that the BPX preconditioner is optimal per iteration. We would like to emphasize that one of the main goals of this paper, as in the earlier works of Dahmen and Kunoth [19] and Bornemann and Yserentant [12] in the purely 2D case, is to establish the optimality of the BPX norm equivalence,

$$c_1 \sum_{j=0}^{J} 2^{2j} \|(Q_j - Q_{j-1})u\|_{L_2}^2 \leq \|u\|_{H^1}^2 \leq c_2 \sum_{j=0}^{J} 2^{2j} \|(Q_j - Q_{j-1})u\|_{L_2}^2, \tag{2.4}$$

where Q_j is the L_2-projection. We note that in the uniform refinement setting, it is straightforward to link the BPX norm equivalence to the optimality of the BPX preconditioner,

$$c_1(Xu, u) \leq \|u\|_{H^1}^2 \leq c_2(Xu, u),$$

due to the projector relationships between the Q_j operators. However, in the local refinement scenario the precise link between the norm equivalence and the preconditioner is more subtle and essentially remains open.

The rest of this section is dedicated to setting up the framework to establish the main norm equivalence (2.4), which will be formalized in Theorem 2.1 at the end of this section. We borrow several tools from approximation theory, including the modulus of smoothness, $\omega_k(f, t, \Omega)_p$, which is a finer scale of smoothness than differentiability. It is a central tool in the analysis here and it naturally gives rise to the notion of *Besov spaces*. For further details and definitions, see [19, 29]. Besov spaces are defined to be the collection of functions $f \in L_p(\Omega)$ with a finite Besov norm defined as

$$\|f\|_{B^s_{p,q}(\Omega)}^q := \|f\|_{L_p(\Omega)}^q + |f|_{B^s_{p,q}(\Omega)}^q,$$

where the seminorm is given by

$$|f|_{B^s_{p,q}(\Omega)} := \|\{2^{sj}\omega_k(f, 2^{-j}, \Omega)_p\}_{j\in\mathbb{N}_0}\|_{l_q},$$

with k any fixed integer larger than s.

Besov spaces become the primary function space setting in the analysis by realizing Sobolev spaces as Besov spaces:

$$H^s(\Omega) \cong B^s_{2,2}(\Omega), \quad s > 0.$$

The primary motivation for employing the Besov space stems from the fact that the characterization of functions which have a given upper bound for the error of approximation sometimes calls for a finer scale of smoothness than that provided by Sobolev classes functions.

The Bernstein inequality is defined as

$$\omega_{k+1}(u, t)_p \leq c\ (\min\{1, t2^J\})^\beta \|u\|_{L_p}, \quad u \in \mathcal{S}_j, \quad j = 0, \ldots, J, \tag{2.5}$$

where c is independent of u and j. Usually $k =$ degree of the element, and in the case of linear finite elements, $k = 1$. Here β is determined by the global smoothness of the approximation space as well as p. For C^r finite elements, $\beta = \min\{1 + r + \frac{1}{p}, k + 1\}$.

Let θ_J be defined as

$$\theta_{j,J} := \sup_{u \in \mathcal{S}_J} \frac{\|u - Q_j u\|_{L_2}}{\omega_2(u, 2^{-j})_2}, \quad \theta_J := \max\{1, \theta_{j,J} : j = 0, \ldots, J\}. \tag{2.6}$$

Following [19] we have the following theorem.

THEOREM 2.1. *Suppose the Bernstein inequality* (2.5) *holds for some real number* $\beta > 1$. *Then, for each* $0 < s < \min\{\beta, 2\}$, *there exist constants* $0 < c_1,\ c_2 < \infty$ *independent of* $u \in \mathcal{S}_J,\ J = 0, 1, \ldots,$ *such that the following norm equivalence holds:*

$$\frac{c_1}{\theta_J^2} \sum_{j=0}^{J} 2^{2j} \|(Q_j - Q_{j-1})u\|_{L_2}^2 \le \|u\|_{H^1}^2 \le c_2 \sum_{j=0}^{J} 2^{2j} \|(Q_j - Q_{j-1})u\|_{L_2}^2, \quad u \in \mathcal{S}_J. \tag{2.7}$$

Proof. See [19, Thm. 4.1]. ∎

We would like to elaborate on the difficulties one faces within the local refinement framework. In order for the Bernstein inequality to hold, one needs to establish that the underlying basis is an L_2-stable Riesz basis as in (3.8). This crucial property heavily depends on local quasi uniformity of the mesh. Hence, the Bernstein inequality is established in section 5 through local quasi uniformity and L_2-stability of the basis in the Riesz sense.

A Jackson-type inequality cannot hold in a local refinement setting. This poses a major difficulty in the analysis because one has to calculate θ_J directly. The missing crucial piece of the optimal norm equivalence in (2.7), namely, $\theta_J = O(1)$ as $J \to \infty$, will be shown in (6.12) and as a result (2.4) will hold. This required the operator $\tilde{Q}_j$ to be bounded locally and to fix polynomials of degree 1 as will be shown in section 6.

3. The BEK refinement procedure. Our interest is in showing optimality of the BPX norm equivalence for the local 3D red-green refinement introduced by Bornemann, Erdmann, and Kornhuber [11]. This 3D red-green refinement is practical and easy to implement; numerical experiments were presented in [11]. A similar refinement procedure was analyzed by Bey [10]; in particular, the same green closure strategy was used in both papers. While these refinement procedures are known to be asymptotically nondegenerate (and thus produce shape regular simplices at every level of refinement), shape regularity is insufficient for constructing a stable Riesz basis for finite element spaces on locally adapted meshes. To construct a stable Riesz basis we will need to establish patchwise quasi uniformity as in [19]; as a result, d-vertex adjacency relationships that are independent of the shape regularity of the elements must be established between neighboring tetrahedra as done in [19] for triangles.

We first list a number of geometric assumptions concerning the underlying mesh. Let $\Omega \subset \mathbb{R}^3$ be a polyhedral domain. We assume that the triangulation $\mathcal{T}_j$ of Ω at level j is a collection of tetrahedra with mutually disjoint interiors which cover $\Omega = \bigcup_{\tau \in \mathcal{T}_j} \tau$. We want to generate successive refinements $\mathcal{T}_0, \mathcal{T}_1, \ldots$ which satisfy the following conditions.

Assumption 3.1 (*nestedness*). Each tetrahedron (son) $\tau \in \mathcal{T}_j$ is covered by exactly one tetrahedron (father) $\tau' \in \mathcal{T}_{j-1}$, and any corner of τ is either a corner or an edge midpoint of τ'.

Assumption 3.2 (*conformity*). The intersection of any two tetrahedra $\tau, \tau' \in \mathcal{T}_j$ is either empty, a common vertex, a common edge, or a common face.

Assumption 3.3 (*nondegeneracy*). The interior angles of all tetrahedra in the refinement sequence $\mathcal{T}_0, \mathcal{T}_1, \ldots$ are bounded away from zero.

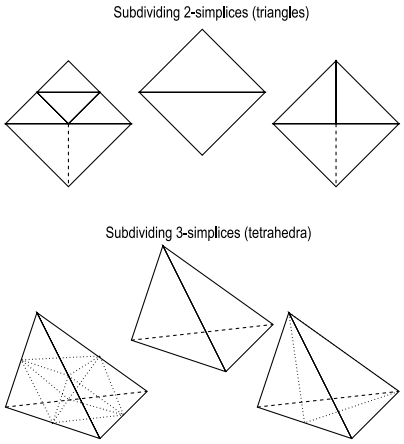

FIG. 3.1.

A regular (red) refinement subdivides a tetrahedron τ into eight equal volume subtetrahedra. We connect the edges of each face as in 2D regular refinement. We then cut off four subtetrahedra at the corners which are congruent to τ. An octahedron with three parallelograms remains in the interior. Cutting the octahedron along the two faces of these parallelograms, we obtain four more subtetrahedra which are not necessarily congruent to τ. We choose the diagonal of the parallelogram so that the successive refinements always preserve nondegeneracy [1, 10, 27, 38]. A sketch of regular refinement (octasection and quadrasection in three and two dimensions, respectively) as well as bisection is given in Figure 3.1.

If a tetrahedron is marked for regular refinement, the resulting triangulation violates conformity Assumption 3.2. Nonconformity is then remedied by irregular (green) refinement. In three dimensions, there are altogether $2^6 = 64$ possible edge refinements, of which 62 are irregular. One must pay extra attention to irregular refinement in the implementation due to the large number of possible nonconforming configurations. Bey [10] gives a methodical way of handling irregular cases. Using symmetry arguments, the 62 irregular cases can be divided into nine different types. To ensure that the interior angles remain bounded away from zero, we enforce the following additional conditions. (Identical assumptions were made in [19] for their 2D refinement analogue.)

Assumption 3.4. Irregular tetrahedra are not refined further.

Assumption 3.5. Only tetrahedra $\tau \in \mathcal{T}_j$ with $L(\tau) = j$ are refined for the construction of $\mathcal{T}_{j+1}$, where $L(\tau) = \min\{j : \tau \in \mathcal{T}_j\}$ denotes the level of τ.

One should note that the restrictive character of Assumptions 3.4 and 3.5 can be eliminated by a modification on the sequence of the tetrahedralizations [10]. On the other hand, it is straightforward to enforce both assumptions in a typical local refinement algorithm by minor modifications of the supporting datastructures for tetrahedral elements (cf. [22]). In any event, the proof technique (see (6.8) and (6.9)) requires both assumptions hold. The last refinement condition enforced for the possible 62 irregularly refined tetrahedra is stated as the following.

Assumption 3.6. If three or more edges are refined and do not belong to a common face, then the tetrahedron is refined regularly.

We note that the d-vertex adjacency generation bound for simplices in $\mathbb{R}^d$ which are adjacent at d vertices *is the primary result required in the support of a basis func-*

tion so that Assumption 3.6 *holds, and depends critically on the particular details of the local refinement procedure rather than on shape regularity of the elements.* The generation bound for simplices which are adjacent at $d-1, d-2, \ldots$ vertices follows by using the shape regularity and the generation bound established for d-vertex adjacency. We provide rigorous generation bounds for all the adjacency types mentioned in the lemmas to follow when $d = 3$. The 2D version appeared in [19]; the 3D extension is described below.

LEMMA 3.1. *Let τ and τ' be two tetrahedra in $\mathcal{T}_j$ sharing a common face f. Then*

$$|L(\tau) - L(\tau')| \leq 1. \tag{3.1}$$

Proof. If $L(\tau) = L(\tau')$, then $0 \leq 1$, and there is nothing to show. Without loss of generality, assume that $L(\tau) < L(\tau')$. The proof requires a detailed and systematic analysis. To show the line of reasoning, we first list as follows the facts used in the proof:

1. $L(\tau') \leq j$ because by assumption $\tau' \in \mathcal{T}_j$. Then $L(\tau) < j$.
2. By assumption $\tau \in \mathcal{T}_j$, meaning that τ was never refined from level $L(\tau)$, in which it was born, to level j.
3. Let τ'' be the father of τ'. Then $L(\tau'') = L(\tau') - 1 < j$.
4. $L(\tau) < L(\tau')$ by assumption, implying $L(\tau) \leq L(\tau'')$.
5. By (2), τ belongs to all the triangulations from $L(\tau)$ to j, in particular $\tau \in \mathcal{T}_{L(\tau'')}$, where by fact 3 $L(\tau'') < j$.

f is the common face of τ and τ' on level j. By fact 5 both $\tau,\ \tau'' \in \mathcal{T}_{L(\tau'')}$. Then, Assumption 3.2 implies that f must still be the common face of τ and τ''. Hence, τ' must have been irregular.

On the other hand, $L(\tau) \leq L(\tau') - 1 = L(\tau'')$. Next, we proceed by eliminating the possibility that $L(\tau) < L(\tau'')$. If so, we repeat the above reasoning, and τ'' becomes irregular. τ'' is already the father of the irregular τ', contradicting Assumption 3.4 for level $L(\tau'')$. Hence, $L(\tau) = L(\tau'') = L(\tau') - 1$ concludes the proof. ∎

By Assumptions 3.4 and 3.5, every tetrahedron at any $\mathcal{T}_j$ is geometrically similar to some tetrahedron in $\mathcal{T}_0$ or to a tetrahedron arising from an irregular refinement of some tetrahedron in $\mathcal{T}_0$. Then, there exist absolute constants $c_1,\ c_2$ such that

$$c_1 \operatorname{diam}(\bar{\tau})\ 2^{-L(\tau)} \leq \operatorname{diam}(\tau) \leq c_2 \operatorname{diam}(\bar{\tau})\ 2^{-L(\tau)}, \tag{3.2}$$

where $\bar{\tau}$ is the father of τ in the initial mesh. The lemma below follows by shape regularity and (3.1).

LEMMA 3.2. *Let τ, τ' and ζ, ζ' be the tetrahedra in $\mathcal{T}_j$ sharing a common edge (two vertices) and a common vertex, respectively. Then there exist finite numbers V and E depending on the shape regularity such that*

$$|L(\tau) - L(\tau')| \leq V, \tag{3.3}$$

$$|L(\zeta) - L(\zeta')| \leq E. \tag{3.4}$$

Consequently, simplices in the support of a basis function are comparable in size as indicated in (3.5). This is usually called *patchwise quasi uniformity*. Furthermore, it was shown in [1] that patchwise quasi uniformity (3.5) holds for 3D marked tetrahedron bisection introduced by Liu and Joe [24] and for 2D newest vertex bisection introduced by Sewell [30] and Mitchell [25]. Due to the restrictive nature of the proof technique (see (6.8) and (6.9)), we focus on refinement procedures which obey Assumptions 3.4 and 3.5. However, due to the strong geometrical results available for

purely bisection-based local refinement procedures, it should be possible to establish the main results of this paper for purely bisection-based strategies.

LEMMA 3.3. *There is a constant depending on the shape regularity of $\mathcal{T}_j$ and the quasi uniformity of $\mathcal{T}_0$, such that*

$$\frac{\operatorname{diam}(\tau)}{\operatorname{diam}(\tau')} \le c \quad \forall \tau, \tau' \in \mathcal{T}_j, \quad \tau \cap \tau' \neq \emptyset. \tag{3.5}$$

Proof. τ and τ' are either face-adjacent (d vertices), edge-adjacent ($d-1$ vertices), or vertex-adjacent, and are handled by (3.1), (3.4), (3.3), respectively. Therefore we have

$$\begin{aligned}\frac{\operatorname{diam}(\tau)}{\operatorname{diam}(\tau')} &\le c\ 2^{|L(\tau)-L(\tau')|}\ \frac{\operatorname{diam}(\bar{\tau})}{\operatorname{diam}(\bar{\tau}')} \quad \text{(by (3.2))} \\ &\le c\ 2^{\max\{1,E,V\}}\ \gamma^{(0)} \quad \text{(by (3.1), (3.4), (3.3) and quasi uniformity of } \mathcal{T}_0). \ \square\end{aligned}$$

3.1. L_2-stable Riesz basis. Since patchwise quasi uniformity is established by (3.5), we can now take the first step in establishing the norm equivalence in section 5. In other words, our motivation is to form a stable basis in the following sense [29]:

$$\left\| \sum_{x_i \in \mathcal{N}_j} u_i \phi_i^{(j)} \right\|_{L_2(\Omega)} \eqsim \|\{\text{volume}^{1/2}(\text{supp } \phi_i^{(j)})\ u_i\}_{x_i \in \mathcal{N}_j}\|_{l_2}. \tag{3.6}$$

The basis stability (3.6) will then guarantee that the Bernstein inequality (2.5) holds. For a stable basis, functions with small supports have to be augmented by an appropriate scaling so that $\|\phi_i^{(j)}\|_{L_2(\Omega)}$ remains roughly the same for all basis functions. This is reflected in volume(supp $\phi_i^{(j)}$) by defining

$$L_{j,i} = \min\{L(\tau) : \tau \in \mathcal{T}_j,\ x_i \in \tau\}. \tag{3.7}$$

Then

$$\text{volume}(\text{supp } \phi_i^{(j)}) \eqsim 2^{-dL_{j,i}}.$$

We prefer to use an equivalent notion of basis stability; a basis is called an *L_2-stable Riesz basis* if

$$\left\| \sum_{x_i \in \mathcal{N}_j} \hat{u}_i \hat{\phi}_i^{(j)} \right\|_{L_2(\Omega)} \eqsim \|\{\hat{u}_i\}_{x_i \in \mathcal{N}_j}\|_{l_2}, \tag{3.8}$$

where $\hat{\phi}_i^{(j)}$ denotes the scaled basis, and the relationship between (3.6) and (3.8) is given as follows:

$$\hat{\phi}_i^{(j)} = 2^{d/2L_{j,i}}\ \phi_i^{(j)}, \quad \hat{u}_i = 2^{-d/2L_{j,i}}\ u_i, \quad x_i \in \mathcal{N}_j. \tag{3.9}$$

Then (3.8) forms the sufficient condition to establish the Bernstein inequality (2.5). This crucial property helps us to prove Theorem 8.2.

Remark 3.1. The analysis is done purely with basis functions, completely independent of the underlying mesh geometry. Furthermore, our construction works for any d-dimensional setting with the scaling (3.9). However, it is not clear how to define face-adjacency relations for $d > 3$. If such relations can be defined through some topological or geometrical abstraction, then our framework naturally extends to d-dimensional local refinement strategies, and hence the optimality of the BPX and WHB preconditioners can be guaranteed in $\mathbb{R}^d$, $d \ge 1$. One such generalization was given by Brandts, Korotov, and Krizek in [17]; also see the references therein.

4. Local smoothing computational complexity. In [11], the smoother is chosen to act on the local space

$$\tilde{\mathcal{S}}_j = \text{span}\left[\bigcup\{\phi_i^{(j)}\}_{i=N_{j-1}+1}^{N_j}\bigcup\{\phi_i^{(j)} \neq \phi_i^{(j-1)}\}_{i=1}^{N_{j-1}}\right].$$

Other choices for $\tilde{\mathcal{N}}_j$ are also possible, e.g., DOF which intersect the refinement region Ω_j [2, 14]. The only restriction is that $\tilde{\mathcal{N}}_j \subset \Omega_j$. For this particular choice, $\tilde{\mathcal{N}}_j = \{i = N_{j-1}+1,\ldots,N_j\}\bigcup\{i : \phi_i^{(j)} \neq \phi_i^{(j-1)}, \quad i = 1,\ldots,N_{j-1}\}$, the following result from [11] establishes a bound for the number of nodes used for smoothing (those created in Ω_j by the BEK procedure) so that the BPX preconditioner has provably optimal (linear) computational complexity per iteration.

LEMMA 4.1. *The total number of nodes used for smoothing satisfies the bound*

$$\sum_{j=0}^{J} \tilde{N}_j \leq \frac{5}{3}N_J - \frac{2}{3}N_0. \tag{4.1}$$

Proof. See [11, Lem. 1]. ∎

A similar result for 2D red-green refinement was given by Oswald [29, p. 95]. In the general case of local smoothing operators, which involve smoothing over newly created basis functions plus some additional sets of local neighboring basis functions, one can extend the arguments from [11] and [29] using shape regularity.

5. Establishing optimality of the BPX norm equivalence. In this section, we extend the Dahmen–Kunoth framework to three spatial dimensions; the extension closely follows the original work [19]. However, the general case for $d \geq 1$ spatial dimensions is not in the literature, and therefore we present it below.

For linear g, the element mass matrix gives rise to the following useful formula:

$$\|g\|_{L_2(\tau)}^2 = \frac{\text{volume}(\tau)}{(d+1)(d+2)}\left(\sum_{i=1}^{d+1} g(x_i)^2 + \left[\sum_{i=1}^{d+1} g(x_i)\right]^2\right), \tag{5.1}$$

where $i = 1,\ldots,d+1$ and x_i is a vertex of τ, $d = 2, 3$. In view of (5.1), we have that

$$\|\hat{\phi}_i^{(j)}\|_{L_2(\Omega)}^2 = 2^{dL_{j,i}}\ \frac{\text{volume}(\text{supp}\ \hat{\phi}_i^{(j)})}{(d+1)(d+2)}.$$

Since the min in (3.7) is attained, there exists at least one $\tau \in \text{supp}\ \hat{\phi}_i^{(j)}$ such that $L(\tau) = L_{j,i}$. By (3.2) we have

$$2^{L_{j,i}} \eqsim \frac{\text{diam}(\tau)}{\text{diam}(\bar{\tau})}. \tag{5.2}$$

Also,

$$\text{volume}(\text{supp}\ \hat{\phi}_i^{(j)}) \eqsim \sum_{i=1}^{E} \text{diam}^d(\tau_i), \quad \tau_i \in \text{supp}\ \hat{\phi}_i^{(j)}. \tag{5.3}$$

By (3.5), we have

$$\text{diam}(\tau_i) \eqsim \text{diam}(\tau). \tag{5.4}$$

Combining (5.3) and (5.4), we conclude that

$$\text{volume}(\text{supp } \hat{\phi}_i^{(j)}) \eqsim E \text{ diam}^d(\tau). \tag{5.5}$$

Finally, (5.2) and (5.5) yield

$$2^{dL_{j,i}} \text{volume}(\text{supp } \hat{\phi}_i^{(j)}) \eqsim E \frac{1}{\text{diam}^d(\bar{\tau})}.$$

E is a uniformly bounded constant by shape regularity. One can view the size of any tetrahedron in $\mathcal{T}_0$, in particular of size $\bar{\tau}$, as a constant. The reason is the following: Assumptions 3.4 and 3.5 force every tetrahedron at any $\mathcal{T}_j$ to be geometrically similar to some tetrahedron in $\mathcal{T}_0$ or to a tetrahedron arising from an irregular refinement of some tetrahedron in $\mathcal{T}_0$, and hence to some tetrahedron of a fixed finite collection. Combining the two arguments above, we have established that

$$\|\hat{\phi}_i^{(j)}\|_{L_2(\Omega)} \eqsim 1, \quad x_i \in \mathcal{N}_j. \tag{5.6}$$

Let $g = \sum_{x_i \in \mathcal{N}_j} \hat{u}_i \hat{\phi}_i^{(j)} \in \mathcal{S}_j$. For any $\tau \in \mathcal{T}_j$ we have that

$$\|g\|^2_{L_2(\tau)} \leq c \sum_{x_i \in \mathcal{N}_{j,\tau}} |\hat{u}_i|^2 \|\hat{\phi}_i^{(j)}\|^2_{L_2(\Omega)}, \tag{5.7}$$

where $\mathcal{N}_{j,\tau} = \{x_i \in \mathcal{N}_j : x_i \in \tau\}$, which is uniformly bounded in $\tau \in \mathcal{T}_j$ and $j \in \mathbb{N}_0$. By the scaling (3.9), we get equality in the estimate below. The inequality is a standard inverse inequality, where one bounds $g(x_i)$ using formula (5.1) and by handling the volume in the formula by (3.2):

$$|\hat{u}_i|^2 = 2^{-dL_{j,i}} |g(x_i)|^2 \leq c\, 2^{-dL_{j,i}} 2^{dL_{j,i}} \|g\|^2_{L_2(\tau)}. \tag{5.8}$$

Now, we are ready to establish that our basis is an L_2-stable Riesz basis as in (3.8). This is achieved by simply summing up over $\tau \in \mathcal{T}_j$ in (5.7) and (5.8) and using (5.6). L_2-stability in the Riesz sense allows us to establish the Bernstein inequality (2.5).

LEMMA 5.1. *For the scaled basis* (3.9), *the Bernstein inequality* (2.5) *holds for* $\beta = 3/2$.

Proof. Equation (5.6) with (5.7) and (5.8) asserts that the scaled basis (3.9) is stable in the sense of (3.8). Hence, (2.5) holds by [29, Thm. 4]. Note that the proof actually works independently of the spatial dimension. ∎

6. Lower bound in the norm equivalence. The Jackson inequality for Besov spaces is defined as follows:

$$\inf_{g \in \mathcal{S}_J} \|f - g\|_{L_p} \leq c\, \omega_\alpha(f, 2^{-J})_p, \quad f \in L_p(\Omega), \tag{6.1}$$

where c is a constant independent of f and J, and α is an integer. In the uniform refinement setting, (6.1) is used to obtain the lower bound in (2.7). However, in the local refinement setting, (6.1) holds only for functions whose singularities are somehow well captured by the mesh geometry. For instance, if a mesh is designed to pick up the singularity at $x = 0$ of $y = 1/x$, then on the same mesh we will not be able to recover a singularity at $x = 1$ of $y = 1/(x-1)$. Hence, the Jackson inequality (6.1) cannot hold in a general setting, i.e., for $f \in W_p^k$. In order to get the lower bound in (2.7), we focus on estimating θ_J directly, as in [19] for the 2D setting.

To begin, we borrow the quasi-interpolant construction from [19], extending it to the 3D setting. Let $\tau \in \mathcal{T}_j$ be a tetrahedron with vertices x_1, x_2, x_3, x_4. Clearly the restrictions of $\hat{\phi}_i^{(j)}$ to τ are linearly independent over τ, where $x_i \in \{x_1, x_2, x_3, x_4\}$. Then, there exists a unique set of linear polynomials $\psi_1^\tau, \psi_2^\tau, \psi_3^\tau, \psi_4^\tau$ such that

$$\int_\tau \hat{\phi}_k^{(j)}(x,y,z)\psi_l^\tau(x,y,z)dxdydz = \delta_{kl}, \quad x_k, x_l \in \{x_1, x_2, x_3, x_4\}. \tag{6.2}$$

For $x_i \in \mathcal{N}_j$ and $\tau \in \mathcal{T}_j$, define a function for $x_i \in \tau$,

$$M_i^{(j)}(x,y,z) = \begin{cases} \frac{1}{E_i}\psi_i^\tau(x,y,z), & (x,y,z) \in \tau, \\ 0, & (x,y,z) \notin \text{supp } \hat{\phi}_i^{(j)}, \end{cases} \tag{6.3}$$

where E_i is the number of tetrahedra in $\mathcal{T}_j$ in supp $\hat{\phi}_i^{(j)}$. By (6.2) and (6.3), we obtain

$$(M_k^{(j)}, \hat{\phi}_l^{(j)}) = \int_\Omega M_k^{(j)}(x,y,z)\hat{\phi}_l(x,y,z)\ dxdydz = \delta_{kl}, \quad x_k, x_l \in \mathcal{N}_j. \tag{6.4}$$

We can now define a quasi interpolant, and in fact a *projection* onto $\mathcal{S}_j$, such that

$$(\tilde{Q}_j f)(x,y,z) = \sum_{x_i \in \mathcal{N}_j} (f, M_i^{(j)})\hat{\phi}_i^{(j)}(x,y,z). \tag{6.5}$$

As remarked earlier, due to (6.3) the slice operator term $\tilde{Q}_j - \tilde{Q}_{j-1}$ will vanish outside the refined set Ω_j defined in (2.1). One can easily observe by (5.6) and (6.4) that

$$\|M_i^{(j)}\|_{L_2(\Omega)} \eqsim 1, \quad x_i \in \mathcal{N}_j,\ j \in \mathbb{N}_0. \tag{6.6}$$

Letting $\Omega_{j,\tau} = \bigcup\{\tau' \in \mathcal{T}_j :\ \tau \cap \tau' \neq \emptyset\}$, we can conclude from (5.6) and (6.6) that

$$\|\tilde{Q}_j f\|_{L_2(\tau)} = \| \sum_{x_k \in \mathcal{N}_{j,\tau}} (f, M_l^{(j)})\hat{\phi}_k^{(j)}\|_{L_2(\tau)} \leq c\|f\|_{L_2(\Omega_{j,\tau})}. \tag{6.7}$$

We define now a subset of the triangulation where the refinement activity stops, meaning that all tetrahedra in $\mathcal{T}_j^*,\ j \leq m$ also belong to $\mathcal{T}_m$:

$$\mathcal{T}_j^* = \{\tau \in \mathcal{T}_j :\ L(\tau) < j,\ \Omega_{j,\tau} \cap \tau' = \emptyset\ \forall \tau' \in \mathcal{T}_j \text{ with } L(\tau') = j\}. \tag{6.8}$$

Due to the local support of the dual basis functions $M_i^{(j)}$ and the fact that $\tilde{Q}_j$ is a projection, one gets for $g \in \mathcal{S}_J$,

$$\|g - \tilde{Q}_j g\|_{L_2(\tau)} = 0, \quad \tau \in \mathcal{T}_j^*. \tag{6.9}$$

Since $\tilde{Q}_j$ is a projection onto linear finite element space, it fixes polynomials of degree at most 1 (i.e., $\Pi_1(\mathbb{R}^3)$). Using this fact and (6.7), we arrive at

$$\begin{aligned} \|g - \tilde{Q}_j g\|_{L_2(\tau)} &\leq \|g - P\|_{L_2(\tau)} + \|\tilde{Q}_j(P - g)\|_{L_2(\tau)} \\ &\leq c\ \|g - P\|_{L_2(\Omega_{j,\tau})}, \quad \tau \in \mathcal{T}_j \setminus \mathcal{T}_j^*. \end{aligned} \tag{6.10}$$

We would like to bound the right-hand side of (6.10) in terms of a modulus of smoothness in order to reach a Jackson-type inequality. Following [19], we utilize a modified modulus of smoothness for $f \in L_p(\Omega)$,

$$\tilde{\omega}_k(f,t,\Omega)_p^p = t^{-s} \int_{[-t,t]^s} \|\Delta_h^k f\|_{L_p(\Omega_{k,h})}^p\ dh.$$

The two moduli of smoothness can be shown to be equivalent:

$$\tilde{\omega}_{k+1}(f,t,\Omega)_p \eqsim \omega_{k+1}(f,t,\Omega)_p.$$

The equivalence in the one-dimensional setting can be found in [20, Lem. 5.1].

For τ a simplex in $\mathbb{R}^d$ and $t = \operatorname{diam}(\tau)$, a Whitney estimate shows that [21, 28, 33]

$$\inf_{P\in\Pi_k(\mathbb{R}^d)} \|f-P\|_{L_p(\tau)} \le c\tilde{\omega}_{k+1}(f,t,\tau)_p, \tag{6.11}$$

where c depends only on the smallest angle of τ but not on f and t. The reason why $\tilde{Q}_j$ works well for tetrahedralization in three dimensions is the fact that the Whitney estimate (6.11) remains valid for any spatial dimension. $\mathcal{T}_j \setminus \mathcal{T}_j^*$ is the part of the tetrahedralization $\mathcal{T}_j$, where refinement is active at every level. Then, in view of (3.5),

$$\operatorname{diam}(\Omega_{j,\tau}) \eqsim 2^{-j}, \quad \tau \in \mathcal{T}_j \setminus \mathcal{T}_j^*.$$

Taking the inf over $P \in \Pi_1(\mathbb{R}^3)$ in (6.10) and using the Whitney estimate (6.11), we conclude that

$$\|g - \tilde{Q}_j g\|_{L_2(\tau)} \le c\tilde{\omega}_2(g, 2^{-j}, \Omega_{j,\tau})_2.$$

Recalling (6.9) and summing over $\tau \in \mathcal{T}_j \setminus \mathcal{T}_j^*$ gives rise to

$$\|g - \tilde{Q}_j g\|_{L_2(\Omega)} \le c\tilde{\omega}_2(g, 2^{-j}, \Omega)_2 \le \tilde{c}\ \omega_2(g, 2^{-j}, \Omega)_2,$$

where we have switched from the modified modulus of smoothness to the standard one. Since Q_j is an orthogonal projection, we have the following:

$$\|g - Q_j g\| \le \|g - \tilde{Q}_j g\|.$$

Using the above inequality with (2.6), one then has

$$v_J = O(1), \quad J \to \infty. \tag{6.12}$$

7. The WHB preconditioner. In local refinement, HB methods enjoy an optimal complexity of $O(N_j - N_{j-1})$ per iteration per level (resulting in $O(N_J)$ overall complexity per iteration) by using only DOF corresponding to $\mathcal{S}_j^f$. However, HB methods suffer from suboptimal iteration counts or, equivalently, suboptimal condition numbers. The BPX decomposition $\mathcal{S}_j = \mathcal{S}_{j-1} \oplus (Q_j - Q_{j-1})\mathcal{S}_j$ gives rise to basis functions which are not locally supported, but they decay rapidly outside a local support region. This allows for locally supported approximations; in addition, the WHB methods [34, 35, 36] can be viewed as an approximation of the wavelet basis stemming from the BPX decomposition [23]. A similar wavelet-like multilevel decomposition approach was taken in [32], where the orthogonal decomposition is formed by a discrete L_2-equivalent inner product. This approach utilizes the same BPX two-level decomposition [31, 32]. The WHB preconditioner is defined as follows:

$$Hu := \sum_{j=0}^{J} 2^{j(d-2)} \sum_{i\in\mathcal{N}_j^f} (u, \psi_i^{(j)})\psi_i^{(j)}, \tag{7.1}$$

where $\psi_i^{(j)} = (\tilde{Q}_j - \tilde{Q}_{j-1})\phi_i^{(j)}$. The WHB preconditioner uses the modified basis (whereas the BPX preconditioner uses the standard nodal basis) where the projection

operator used is defined as in (7.5). In the WHB setting, these operators are chosen to satisfy the following three properties [5]:

$$\tilde{Q}_j \mid_{\mathcal{S}_j} = I, \tag{7.2}$$

$$\tilde{Q}_j \tilde{Q}_k = \tilde{Q}_{\min\{j,k\}}, \tag{7.3}$$

$$\|(\tilde{Q}_j - \tilde{Q}_{j-1})u^{(j)}\|_{L_2} \eqsim \|u^{(j)}\|_{L_2}, \quad u^{(j)} \in (I_j - I_{j-1})\mathcal{S}_j. \tag{7.4}$$

As indicated in (2.2), the WHB smoother acts on only the fine DOF, i.e., $\mathcal{N}_j^f$, and hence is an approximation to a fine-fine discretization operator $A_{ff}^{(j)} : \mathcal{S}_j^f \to \mathcal{S}_j^f$, where $\mathcal{S}_j^f := (\tilde{Q}_j - \tilde{Q}_{j-1})\mathcal{S}_j$ and f stands for fine. On the other hand, the BPX smoother acts on a slightly bigger set than fine DOF, typically $\mathcal{N}_j^f \subseteq \tilde{\mathcal{N}}_j$, the union of fine DOF and their corresponding coarse fathers.

The WHB preconditioner introduced in [34, 35] is, in some sense, the best of both worlds. While the condition number of the HB preconditioner is stabilized by inserting Q_j into the definition of $\tilde{Q}_j$, somehow employing the operators $I_j - I_{j-1}$ at the same time guarantees optimal computational and storage cost per iteration. The operators which will be seen to meet both goals at the same time are

$$\tilde{Q}_k = \prod_{j=k}^{J-1} I_j + Q_j^a(I_{j+1} - I_j), \tag{7.5}$$

with $\tilde{Q}_J = I$. The exact L_2-projection Q_j is replaced with a computationally feasible approximation $Q_j^a : L_2 \to \mathcal{S}_j$. To control the approximation quality of Q_j^a, a small fixed tolerance γ is introduced:

$$\|(Q_j^a - Q_j)u\|_{L_2} \leq \gamma \|Q_j u\|_{L_2} \quad \forall u \in L_2(\Omega). \tag{7.6}$$

In the limiting case $\gamma = 0$, $\tilde{Q}_k$ reduces to the exact L_2-projection on $\mathcal{S}_J$ by (7.2):

$$\tilde{Q}_k = Q_k I_{k+1} Q_{k+1} \cdots I_{J-1} Q_{J-1} I_J = Q_k Q_{k+1} \cdots Q_{J-1} = Q_k.$$

Following [34, 35], the properties (7.2), (7.3), and (7.4) can be verified for $\tilde{Q}_k$ as follows:

• Property (7.2): Let $u^{(k)} \in \mathcal{S}_k$. Since $(I_{j+1} - I_j)u^{(k)} = 0$ and $I_j u^{(k)} = u^{(k)}$ for $k \leq j$, then $[I_j + Q_j^a(I_{j+1} - I_j)](u^{(k)}) = u^{(k)}$, verifying (7.2) for $\tilde{Q}_k$. It also implies

$$\tilde{Q}_k^2 = \tilde{Q}_k. \tag{7.7}$$

• Property (7.3): Let $k \leq l$; then by (7.7)

$$\tilde{Q}_k \tilde{Q}_l = [(I_k + Q_k^a(I_{k+1} - I_k)) \cdots (I_{l-1} + Q_{l-1}^a(I_l - I_{l-1}))\ \tilde{Q}_l]\tilde{Q}_l = \tilde{Q}_k. \tag{7.8}$$

Since $\tilde{Q}_k u \in \mathcal{S}_k$ and $\mathcal{S}_k \subset \mathcal{S}_l$, then by (7.2) we have

$$\tilde{Q}_l(\tilde{Q}_k u) = \tilde{Q}_k u. \tag{7.9}$$

Finally, (7.3) then follows from (7.8) and (7.9).

• Property (7.4): This is an implication of Lemma 7.1.

For an overview, we list the corresponding slice spaces for the preconditioners of interest:

HB:	$\mathcal{S}_j^f$	$=$	$(I_j - I_{j-1})\mathcal{S}_j$,
BPX:	$\mathcal{S}_j^f$	$=$	$(Q_j - Q_{j-1})\mathcal{S}_j$,
WHB:	$\mathcal{S}_j^f$	$=$	$(\tilde{Q}_j - \tilde{Q}_{j-1})\mathcal{S}_j = (I - Q_{j-1}^a)(I_j - I_{j-1})\mathcal{S}_j$, where $\tilde{Q}_j$ is given in (7.5).

The WHB smoother acts only on the fine DOF. Then, in the generic multilevel preconditioner notation, the WHB preconditioner can be written in the following form:

$$Bu := \sum_{j=0}^{J} B_{ff}^{(j)^{-1}} (\tilde{Q}_j - \tilde{Q}_{j-1})u. \tag{7.10}$$

B_{ff} is chosen to be a spectrally equivalent operator to fine-fine discretization operator $A_{ff}^{(j)}$. Since the smoother and property (7.4) both rely on a well-conditioned $A_{ff}^{(j)}$, we discuss this next.

7.1. Well-conditioned $A_{ff}^{(j)}$. The lemma below is essential to extend the existing results for quasi-uniform meshes (see [34, Lem. 6.1] or [35, Lem. 2]) to the locally refined ones. $\mathcal{S}_j^{(f)} = (I_j - I_{j-1})\mathcal{S}_j$ denotes the HB slice space.

LEMMA 7.1. *Let $\mathcal{T}_j$ be constructed by the local refinements under consideration. Let $\mathcal{S}_j^f = (I - \tilde{Q}_{j-1})\mathcal{S}_j^{(f)}$ be the modified hierarchical subspace, where $\tilde{Q}_{j-1}$ is any L_2-bounded operator. Then, there are constants c_1 and c_2 independent of j such that*

$$c_1 \|\phi^f\|_X^2 \le \|\psi^f\|_X^2 \le c_2 \|\phi^f\|_X^2, \quad X = H^1, L_2, \tag{7.11}$$

holds for any $\psi^f = (I - \tilde{Q}_{j-1})\phi^f \in \mathcal{S}_j^f$ with $\phi^f \in \mathcal{S}_j^{(f)}$.

Proof. The Cauchy–Schwarz like inequality [8] is central to the proof: There exists $\delta \in (0,1)$ independent of the mesh size or level j such that

$$(1-\delta^2)(\nabla\phi^f, \nabla\phi^f) \le (\nabla(\phi^c + \phi^f), \nabla(\phi^c + \phi^f)) \quad \forall \phi^c \in \mathcal{S}_{j-1}, \phi^f \in \mathcal{S}_j^{(f)}, \tag{7.12}$$

$$(1-\delta^2)\|\phi^f\|_{L_2}^2 \le c|\phi^c + \phi^f|_{H^1}^2 \quad \text{(by the Poincaré inequality and (7.12))}. \tag{7.13}$$

Combining (7.12) and (7.13), we get $(1-\delta^2)\|\phi^f\|_{H^1}^2 \le \|\phi^c + \phi^f\|_{H^1}^2$. Choosing $\phi^c = -\tilde{Q}_{j-1}\phi^f$, we get the lower bound $(1-\delta^2)\|\phi^f\|_{H^1}^2 \le \|\psi^f\|_{H^1}^2$.

Let Ω_j^f denote the support of basis functions corresponding to $\mathcal{N}_j^f$. Due to nested refinement, triangulation on Ω_j^f is quasi uniform. One can analogously introduce a triangulation hierarchy, where all the simplices are exposed to uniform refinement: $\mathcal{T}_j^f := \{\tau \in \mathcal{T}_j : L(\tau) = j\} = \mathcal{T}_j|_{\Omega_j^f}$. Hence, $\mathcal{T}_j^f$ becomes a quasi-uniform tetrahedralization and the inverse inequality holds for $\mathcal{S}_j^f$. The upper bound is derived by using a father-son size relation, the inverse inequalities, and L_2-boundedness of $\tilde{Q}_{j-1}$. Hence, one gets

$$\|\psi^f\|_{H^1}^2 \le c_0 2^{2j} \|\psi^f\|_{L_2}^2 \le c_0 2^{2j} \left(1 + \|\tilde{Q}_{j-1}\|_{L_2}\right)^2 \|\phi^f\|_{L_2}^2 \le c 2^{2j} \|\phi^f\|_{L_2}^2.$$

The slice space $\mathcal{S}_j^{(f)}$ is oscillatory. Then there exists c such that $\|\phi^f\|_{L_2}^2 \le c 2^{-2j} \|\phi^f\|_{H^1}^2$. Hence, $\|\psi^f\|_{H^1}^2 \le c\|\phi^f\|_{H^1}^2$. The case for $X = L_2$ can be established similarly. ∎

Using the above tools, one can establish that $A_{ff}^{(j)}$ is well conditioned. Namely,

$$c_1 2^{2j} \leq \lambda_{j,\min}^f \leq \lambda_{j,\max}^f \leq c_2 2^{2j}, \tag{7.14}$$

where $\lambda_{j,\min}^f$ and $\lambda_{j,\max}^f$ are the smallest and largest eigenvalues of $A_{ff}^{(j)}$, and both c_1 and c_2 are independent of j. For details see [34, Lem. 4.3] or [35, Lem. 3].

8. The fundamental assumption and WHB optimality. As in the BPX splitting, the main ingredient in the WHB splitting is the L_2-projection. Hence, the stability of the BPX splitting is still important in the WHB splitting. The lower bound in the BPX norm equivalence is the *fundamental assumption* for the WHB preconditioner. Utilizing a local projection $\tilde{Q}_j$, the BPX lower bound was verified earlier for 3D a local red-green (BEK) refinement procedure. The same result easily holds for the projection Q_j. Dahmen and Kunoth [19] verified a BPX lower bound for the 2D red-green refinement procedures.

Before getting to the stability result we remark that the existing perturbation analysis of WHB is one of the primary insights in [34, 35]. Although not observed in [34, 35], the result does not require substantial modification for locally refined meshes. Let $e_j := (\tilde{Q}_j - Q_j)u$ be the error; then the following holds.

LEMMA 8.1. *Let γ be as in* (7.6). *There exists an absolute c satisfying*

$$\sum_{j=0}^{J} 2^{2j} \|e_j\|_{L_2}^2 \leq c\gamma^2 \sum_{j=0}^{J} 2^{2j} \|(Q_j - Q_{j-1})u\|_{L_2}^2 \quad \forall u \in \mathcal{S}_J. \tag{8.1}$$

Proof. See [34, Lem. 5.1] or [35, Lem. 1]. ∎

We arrive now at the primary result, which indicates that the WHB slice norm is optimal in the class of locally refined meshes under consideration.

THEOREM 8.2. *If there exists sufficiently small γ_0 such that* (7.6) *is satisfied for $\gamma \in [0, \gamma_0)$, then*

$$\|u\|_{\text{WHB}}^2 = \sum_{j=0}^{J} 2^{2j} \|(\tilde{Q}_j - \tilde{Q}_{j-1})u\|_{L_2}^2 \eqsim \|u\|_{H^1}^2, \quad u \in \mathcal{S}_J. \tag{8.2}$$

Proof. Observe that

$$\begin{aligned} (\tilde{Q}_j - \tilde{Q}_{j-1})u &= (\tilde{Q}_j - Q_j)u - (\tilde{Q}_{j-1} - Q_{j-1})u + (Q_j - Q_{j-1})u \\ &= e_j - e_{j-1} + (Q_j - Q_{j-1})u. \end{aligned} \tag{8.3}$$

This gives

$$\begin{aligned} \sum_{j=0}^{J} 2^{2j} \|(\tilde{Q}_j - \tilde{Q}_{j-1})u\|_{L_2}^2 &\leq c \sum_{j=0}^{J} 2^{2j} \|(Q_j - Q_{j-1})u\|_{L_2}^2 + c \sum_{j=0}^{J} 2^{2j} \|e_j\|_{L_2}^2 \\ &\leq c(1+\gamma^2) \sum_{j=0}^{J} 2^{2j} \|(Q_j - Q_{j-1})u\|_{L_2}^2 \quad \text{(using (8.1))} \\ &\leq c\|u\|_{H^1}^2. \end{aligned}$$

Let us now proceed with the upper bound. The Bernstein inequality (2.5) holds for $\mathcal{S}_j$ [1, 19] for the local refinement procedures. Hence, we are going to utilize an inequality

involving the Besov norm $\|\cdot\|_{B^1_{2,2}}$ which naturally fits into our framework when the moduli of smoothness is considered in (2.5). The following important inequality holds, provided that (2.5) holds [29, p. 39]:

$$\|u\|^2_{B^1_{2,2}} \leq c \sum_{j=0}^{J} 2^{2j} \|u^{(j)}\|^2_{L_2} \tag{8.4}$$

for any decomposition such that $u = \sum_{j=0}^{J} u^{(j)}$, $u^{(j)} \in \mathcal{S}_j$, in particular for $u^{(j)} = (\tilde{Q}_j - \tilde{Q}_{j-1})u$. Then the upper bound holds due to $H^1(\Omega) \cong B^1_{2,2}(\Omega)$. ∎

Remark 8.1. The following equivalence is used for the upper bound in the proof of Theorem 8.2 on uniformly refined meshes [35, Lem. 4]:

$$c_1 \|u\|^2_{H^1} \leq \inf_{\substack{u=\sum_{j=0}^{J} u^{(j)}, \\ u^{(j)} \in \mathcal{S}_j}} \sum_{j=0}^{J} 2^{2j} \|u^{(j)}\|^2_{L_2} \leq c_2 \|u\|^2_{H^1}.$$

Let us emphasize that the left-hand side holds in the presence of the Bernstein inequality (2.5), and the right-hand side holds in the simultaneous presence of Bernstein and Jackson inequalities. However, the Jackson inequality cannot hold under local refinement procedures (cf. the counterexample in section 6). That is why we can utilize only the left-hand side of the above equivalence as in (8.4).

Now, we have all the required estimates at our disposal for establishing the optimality of WHB preconditioner for 2D and 3D red-green refinement procedures for $p \in L_\infty(\Omega)$. We would like to emphasize that our framework supports any spatial dimension $d \geq 1$, provided that the necessary geometrical abstractions are in place.

THEOREM 8.3. *If a BPX lower bound holds and if there exists sufficiently small* γ_0 *such that* (7.6) *is satisfied for* $\gamma \in (0, \gamma_0)$, *then for* B *in* (7.10),

$$(Bu, u) \eqsim \|u\|^2_{H^1}.$$

Proof. $B^{(j)}_{ff}$ is spectrally equivalent to $A^{(j)}_{ff}$. Since $A^{(j)}_{ff}$ is a well-conditioned matrix, by using (7.14) it is spectrally equivalent to $2^{2j} I$. The result follows from Theorem 8.2. ∎

An extension to a multiplicative WHB preconditioner is also possible under additional assumptions. These results will not be reported here.

9. H^1-stable L_2-projection. The involvement of $\tilde{Q}_j$ in the multilevel decomposition makes it the most crucial element in the stabilization. We then come to the central question, Which choice of $\tilde{Q}_j$ can provide an optimal preconditioner? The following theorem sets a guideline for picking $\tilde{Q}_j$. It shows that H^1-stability of $\tilde{Q}_j$ is actually a *necessary condition* for obtaining an optimal preconditioner.

THEOREM 9.1 (see [34, 35]). *If* $\tilde{Q}_j$ *induces an optimal preconditioner, namely for* $u \in \mathcal{S}_J$, $\sum_{j=0}^{J} 2^{2j} \|(\tilde{Q}_j - \tilde{Q}_{j-1})u\|^2_{L_2} \eqsim \|u\|^2_{H^1}$, *then there exists an absolute constant* c *such that*

$$\|\tilde{Q}_k u\|_{H^1} \leq c \, \|u\|_{H^1} \quad \forall k \leq J.$$

Proof. Using the multilevel decomposition and (7.3), we get $\tilde{Q}_k u = \sum_{j=0}^{k} (\tilde{Q}_j - \tilde{Q}_{j-1})u$. Since $\tilde{Q}_j$ induces an optimal preconditioner, there exist two absolute

constants σ_1 and σ_2:

$$\sigma_1 \|u\|_{H^1}^2 \leq \sum_{j=0}^{J} 2^{2j} \|(\tilde{Q}_j - \tilde{Q}_{j-1})u\|_{L_2}^2 \leq \sigma_2 \|u\|_{H^1}^2 \quad \forall u \in \mathcal{S}_J. \tag{9.1}$$

Using (9.1) for $\tilde{Q}_k u$, we get

$$\|\tilde{Q}_k u\|_{H^1}^2 \leq \frac{1}{\sigma_1} \sum_{j=0}^{k} 2^{2j} \|(\tilde{Q}_j - \tilde{Q}_{j-1})u\|_{L_2}^2 \leq \frac{1}{\sigma_1} \sum_{j=0}^{J} 2^{2j} \|(\tilde{Q}_j - \tilde{Q}_{j-1})u\|_{L_2}^2 \leq \frac{\sigma_2}{\sigma_1} \|u\|_{H^1}^2. \qquad \square$$

As a consequence of Theorem 9.1 we have the following corollary.

COROLLARY 9.2. *L_2-projection restricted to $\mathcal{S}_j$, $Q_j|_{\mathcal{S}_j} : L_2 \to \mathcal{S}_j$ is H^1-stable on $2D$ and $3D$ locally refined meshes by red-green refinement procedures.*

Proof. Optimality of the BPX norm equivalence on the above locally refined meshes was already established. Application of Theorem 9.1 with Q_j proves the result. Alternatively, the same result can be obtained through Theorem 9.1 applied to the WHB framework. Theorem 8.2 will establish the optimality of the WHB preconditioner for the local refinement procedures. Hence, the operator $\tilde{Q}_j$ restricted to $\mathcal{S}_j$ is H^1-stable. Since $\tilde{Q}_j$ is none other than Q_j in the limiting case, we can also conclude the H^1-stability of the L_2-projection. $\square$

Our stability result appears to be the first a priori H^1-stability for the L_2-projection on these classes of locally refined meshes. H^1-stability of L_2-projection is guaranteed for the subset $\mathcal{S}_j$ of $L_2(\Omega)$, but not for all of $L_2(\Omega)$. This problem is currently undergoing intensive study in the finite element and approximation theory communities. The existing theoretical results, mainly those in [15, 18], involve a posteriori verification of somewhat complicated mesh conditions after refinement has taken place. If such mesh conditions are not satisfied, one has to redefine the mesh. The mesh conditions mentioned require that the simplex sizes do not change drastically between regions of refinement. In this context, quasi uniformity in the support of a basis function becomes crucial. This type of local quasi uniformity is usually called *patchwise quasi uniformity*. Local quasi uniformity requires neighbor generation relations as in (3.1), neighbor size relations, and shape regularity of the mesh. It was shown in [1] that patchwise quasi uniformity holds also for 3D marked tetrahedron bisection [24] and for 2D newest vertex bisection [25, 30]. These are promising refinement procedures for which H^1-stability of the L_2-projection can be established.

10. Conclusion. In this article, we examined the Bramble–Pasciak–Xu (BPX) norm equivalence in the setting of local 3D mesh refinement. In particular, we extended the 2D optimality result for BPX due to Dahmen and Kunoth to the local 3D red-green refinement procedure introduced by Bornemann, Erdmann, and Kornhuber (BEK procedure). The extension involved establishing that the locally enriched finite element subspaces produced by the BEK procedure allow for the construction of a scaled basis which is formally Riesz stable. This in turn rested entirely on establishing a number of geometrical relationships between neighboring simplices produced by the local refinement algorithms. We remark again that shape regularity of the elements produced by the refinement procedure is insufficient to construct a stable Riesz basis for finite element spaces on locally adapted meshes. The d-vertex adjacency generation bound for simplices in $\mathbb{R}^d$ is the primary result required to establish patchwise quasi uniformity for stable Riesz basis construction, and this result depends critically

on the particular details of the local refinement procedure rather than on shape regularity of the elements. We also noted in section 3 that these geometrical properties have been established in [1] for purely bisection-based refinement procedures that have been shown to be asymptotically nondegenerate, and therefore also allow for the construction of a stable Riesz basis.

We also examined the wavelet modified hierarchical basis (WHB) methods of Vassilevski and Wang and extended their original quasi-uniformity-based framework and results to local 2D and 3D red-green refinement scenarios. A critical step in the extension involved establishing the optimality of the BPX norm equivalence for the local refinement procedures under consideration, as established in the first part of this article. With the local refinement extension of the WHB analysis framework presented here, we established the optimality of the WHB preconditioner on locally refined meshes in both two and three dimensions under the minimal regularity assumptions required for well-posedness. An interesting implication of the optimality of WHB preconditioner was the a priori H^1-stability of the L_2-projection. Existing a posteriori approaches in the literature dictate a reconstruction of the mesh if such conditions cannot be satisfied.

The theoretical framework established here supports arbitrary spatial dimension $d \geq 1$, and therefore allows for extension of the optimality results, the H^1-stability of L_2-projection results, and the various supporting results to arbitrary $d \geq 1$. We indicated clearly which geometrical properties must be re-established to show BPX optimality for spatial dimension $d \geq 4$. All of the results here require no smoothness assumptions on the PDE coefficients beyond those required for well-posedness in H^1.

To address the practical computational complexity of implementable versions of the BPX and WHB preconditioners, we indicated how the number of degrees of freedom (DOF) used for the smoothing step can be shown to be bounded by a constant times the number of DOF introduced at that level of refinement. This indicates that practical implementable versions of the BPX and WHB preconditioners for the local 3D refinement setting considered here have provably optimal (linear) computational complexity per iteration. A detailed analysis of both the storage and per-iteration computational complexity questions arising with BPX and WHB implementations can be found in the second article in our series [2].

Acknowledgments. The authors thank R. Bank, P. Vassilevski, and J. Xu for many enlightening discussions.

ON THE EVALUATION OF HIGHLY OSCILLATORY INTEGRALS BY ANALYTIC CONTINUATION*

DAAN HUYBRECHS† AND STEFAN VANDEWALLE†

Abstract. We consider the integration of one-dimensional highly oscillatory functions. Based on analytic continuation, rapidly converging quadrature rules are derived for a general class of oscillatory integrals with an analytic integrand. The accuracy of the quadrature increases both for the case of a fixed number of points and increasing frequency, and for the case of an increasing number of points and fixed frequency. These results are then used to obtain quadrature rules for more general oscillatory integrals, i.e., for functions that exhibit some smoothness but that are not analytic. The approach described in this paper is related to the steepest descent method, but it does not employ asymptotic expansions. It can be used for small or moderate frequencies as well as for very high frequencies. The approach is compared with the oscillatory integration techniques recently developed by Iserles and Nørsett.

Key words. oscillatory functions, steepest descent method, numerical quadrature

1. Introduction.

Consider the oscillatory integral

$$I := \int_a^b f(x) e^{i\omega g(x)} \, \mathrm{d}x \tag{1.1}$$

with $\omega > 0$ and with $f(x)$ and $g(x)$ smooth functions. Integrals of this form abound in mathematical models and computational algorithms for oscillatory phenomena in science and engineering. Recently, much progress has been made in numerical quadrature techniques for (1.1). Methods have been devised that compute an accurate approximation to the value of the integral with low computational complexity and with a number of operations that actually decreases as ω increases to infinity [12, 13, 14, 15, 16, 17, 18]. This is in contrast to most classical integration approaches, based on polynomial interpolation, that rapidly deteriorate in the presence of strong oscillations. In order to appreciate the inner workings of these methods, one should understand the asymptotic behavior of the oscillatory integral (1.1) for large values of the parameter ω.

The value of I at large frequencies depends on the behavior of the smooth functions f and g near the endpoints a and b, and near the so-called stationary points. The latter are the solutions to the equation $g'(x) = 0$ on $[a, b]$; they represent points in which the integrand locally does not oscillate. An intuitive justification of this property may be that, away from the endpoints and the stationary points, the oscillations of the integrand increasingly cancel out. Mathematically, the property is reflected in the asymptotic expansion of I. We say that a stationary point ξ has order r if $g^{(j)}(\xi) = 0$, $j = 1, \ldots, r$, but $g^{(r+1)}(\xi) \neq 0$; i.e., the first r derivatives of the

oscillator vanish. Assuming one stationary point ξ of order r in the interval $[a, b]$, the asymptotic expansion of (1.1) has the form

$$I \sim \sum_{j=0}^{\infty} \frac{a_j}{\omega^{(j+1)/(r+1)}}, \tag{1.2}$$

where the coefficients a_j depend only on a finite number of function values and derivatives of f and g at the critical points a, b, and ξ [20]. The coefficients are in general not easily obtained, although the leading order coefficient a_0 is given by the method of stationary phase. Still, the mere existence of the asymptotic expansion reveals a lot of information about I. For example, an immediate consequence is that $|I| = O(\omega^{-1/(r+1)})$.

A first efficient method is to simply truncate the asymptotic expansion (1.2) after a finite number of terms. By construction, the truncation error decays as a power of $1/\omega$. This *asymptotic method* was described by Iserles and Nørsett in [14]. The problem of the unknown coefficients in the presence of stationary points is solved by constructing a uniform asymptotic expansion, based on factoring out the moment $\mu_0 = \int_a^b e^{i\omega g(x)}\,\mathrm{d}x$, or similar higher order moments. The coefficients in this expansion can be computed explicitly if the moments themselves are known a priori. A disadvantage of such an approach is that the error of an asymptotic expansion is essentially uncontrollable, since asymptotic expansions tend to diverge. This is especially true for smaller frequencies.

A second approach, proposed also in [14], is to extend Filon's method for oscillatory integrals (see [9, 5]) by considering Hermite interpolation of f. The result is a quadrature rule for I with a classical form, involving function values and derivatives of f. The error of this approach is controllable and may be very small. A disadvantage is that the weights of the rule are given by oscillatory integrals themselves, and they cannot always be explicitly computed. We will revisit *Filon-type methods* in section 6.

An entirely different approach was proposed by Levin in [17]. If the indefinite integral is written as $F(x)e^{i\omega g(x)}$, then we immediately have $I = F(b)e^{i\omega g(b)} - F(a)e^{i\omega g(a)}$. It was observed in [17] that $F(x)$ is a smooth function in the absence of stationary points. Moreover, it satisfies the nonoscillatory differential equation

$$F'(x) + i\omega F(x)g'(x) = f(x). \tag{1.3}$$

This system can be solved for $F(x)$ by collocation. The method was generalized in [7, 8] to more general oscillatory functions that satisfy a linear ordinary differential equation; for example, Bessel functions. The accuracy of the methods improves with ω if the boundary points are included in the collocation. Recently, it was shown in [18] that collocating also the derivatives of f in the endpoints can arbitrarily increase the order of accuracy as a function of $1/\omega$. In some cases, the order can also be increased by adding internal points. This *Levin-type method* allows for an accurate evaluation of the integral, without the need for moments. The accuracy is increased simply by solving the differential equation more accurately.

For the particular case of an oscillating factor of the form $\cos(\omega x)$ or $\sin(\omega x)$, specialized quadrature rules using first order derivatives were developed in [16]. An *exponentially fitting quadrature rule* with n points has an error of order ω^{-n}. The weights depend on ω and converge to zero.

The approach taken in this paper achieves a similar high convergence rate as a function of ω. We will show that it solves some of the problems of the other methods

and introduces some peculiarities of its own, thus adding to the spectrum of available approaches that appear to complement each other. For example, we present a case that exhibits a significantly faster convergence rate for increasing ω. The method we describe for approximating (1.1) depends on two simple observations. First, the oscillatory function $e^{i\omega g(x)}$ decays exponentially fast for a complex $g(x)$ along a path with a growing imaginary part. Second, the oscillatory function $e^{i\omega g(x)}$ does *not* oscillate for complex $g(x)$ along a path with fixed real part. These observations are exploited numerically in combination with a corollary to Cauchy's theorem; i.e., the value of a line integral of an analytic function along a path between two points in the complex plane does not depend on the exact path taken (see, e.g., [11]). The same observations also provide the foundation for the steepest descent method [1, 2]. In that method, an asymptotic expansion of the form (1.2) is developed for I. The method was used already by Cauchy and Riemann and developed further by Debye [6]. Methods in the complex plane have since been considered for oscillatory integrals several times in specific applications and for Laplace transforms (see, e.g., [21, 4, 3]). We will present a rather general implementation of the steepest descent method that is also valid for small values of ω. We prove convergence estimates of the numerical scheme as a function of the frequency, and we extend the method to functions f and g that are not analytic. A quadrature rule is proposed that has the same order of accuracy as the Filon-type method. The implementation is entirely numerical; hence we shall refer to the method as the *numerical steepest descent method*.

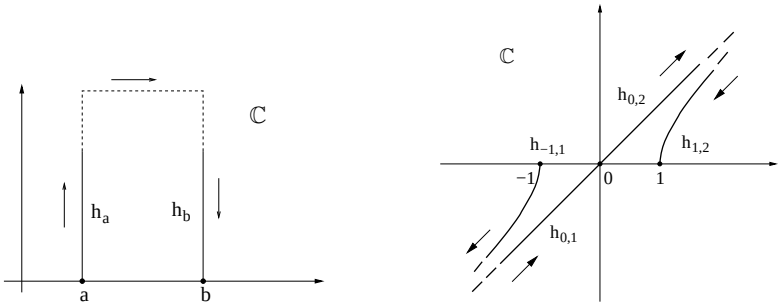
We start this paper in section 2 with some practical and motivating examples that illustrate most of the theory described later. In section 3 we describe and analyze the idealized setting that gives the best possible convergence. It is shown that a suitable n-point quadrature rule in that setting leads to a convergence of $O(\omega^{-2n-1})$. This setting comes with the most restrictions but still covers many important applications. The first requirement is that the functions f and g in (1.1) be analytic in an (infinitely) large region of the complex plane containing the integration interval $[a, b]$. Further, it is assumed that there are no stationary points in $[a, b]$ and that the equation $g(x) = c$ should be "easily solvable." This rather vague description will be made more precise further on. We then proceed by relaxing the requirements one by one until a more generally applicable method is obtained. This increase in generality will, at times, come with a loss in convergence rate. In section 4 we will allow stationary points. We relax the "easy solvability" requirement in section 5. We drop the requirement that f and g should be analytic in sections 6 and 7, respectively. Some final remarks conclude the paper in section 8.

2. Some motivating examples. Consider the following integral, which frequently appears in Fourier analysis applications:

$$\int_a^b f(x)e^{i\omega x}\,\mathrm{d}x. \tag{2.1}$$

This integral has the form of (1.1) with $g(x) = x$. The integrand is highly oscillatory along the real axis if ω is sufficiently large. An important observation is that the function $e^{i\omega x}$ decays rapidly for complex values of x with a positive imaginary part, since $e^{i\omega x} = e^{-\omega \Im x} e^{i\omega \Re x}$. The speed of the decay actually grows as the frequency parameter ω increases. Additionally, the function $e^{i\omega x}$ does not oscillate if the real part of the argument x remains fixed.

Based on these observations, integral (2.1) can be reformulated in such a way that the difficulty—the highly oscillatory nature—is removed. To that end, the integration



(a) $g(x) = x$ (b) $g(x) = x^2$

FIG. 2.1. *Illustration of the integration paths for $g(x) = x$ and $g(x) = x^2$.*

on interval $[a, b]$ is replaced with a path in the complex plane, as illustrated in the left panel of Figure 2.1. The first, vertical part of the path is of the form $z = h_a(p) := a+ip$ for $p \in [0, P]$. The second part is horizontal and connects the points $h_a(P) := a + iP$ to the point $h_b(P) := b + iP$. Finally, the third part connects $h_b(P)$ to b with the vertical path $z = h_b(p)$ for $p \in [0, P]$. Now assume that f is analytic and that f itself does not grow exponentially large in the complex plane. Letting P go to infinity, and using paths parameterized by $h_a(p)$ and $h_b(p)$, for $p \in [0, \infty)$, we can write (2.1) as

$$\int_a^b f(x)e^{i\omega x}\,\mathrm{d}x = e^{i\omega a}\int_0^\infty f(a+ip)e^{-\omega p}\,\mathrm{d}p - e^{i\omega b}\int_0^\infty f(b+ip)e^{-\omega p}\,\mathrm{d}p. \tag{2.2}$$

The integral along the path that connects the endpoints of $h_a(P)$ and $h_b(P)$ vanishes for $P = \infty$ and can therefore be discarded. Both integrals in the right-hand side of (2.2) are well behaved. They can be evaluated efficiently by standard numerical integration techniques, e.g., by Gauss–Laguerre integration [5]. It can be expected from (2.2) that the accuracy of any numerical integration scheme will increase with increasing ω, thanks to the faster decay of the integrand. This expectation will be confirmed both theoretically and numerically in the subsequent sections. One also sees that, asymptotically, the behavior of f around $x = a$ and $x = b$ completely determines the value of (2.1).

Next, we consider the function $g(x) = x^2$ and the corresponding integral

$$\int_{-1}^{1} f(x)e^{i\omega x^2}\,\mathrm{d}x. \tag{2.3}$$

Again, we can remove the integration difficulty by a careful selection of an integration path in the complex plane. The path is drawn in the right panel of Figure 2.1. The following notation is used for the parameterization: $h_{xj}(p) = (-1)^j\sqrt{x^2 + ip}$. Integrating along any such path for $p \in [0, \infty)$ leads to an integrand with the desired decay properties, since $e^{i\omega h_{xj}(p)^2} = e^{i\omega x^2}e^{-\omega p}$. One can see that, for general g, a similar result is obtained if the path satisfies $g(h_x(p)) = g(x) + ip$. This path can be found by using the inverse of g, if it exists, i.e., $h_x(p) = g^{-1}(g(x) + ip)$. Returning to the example function $g(x) = x^2$, however, we note that the inverse of $y = g(x)$ is multivalued: we have $x = -\sqrt{y}$ corresponding to the restriction $g_1 := g|_{[-1,0]}$, and

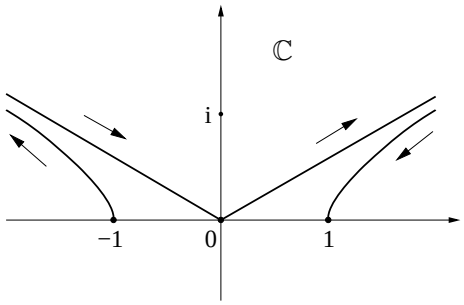


FIG. 2.2. *Illustration of the integration path for* $g(x) = x^3$.

$x = \sqrt{y}$ corresponding to $g_2 := g|_{[0,1]}$. The paths leaving -1 and arriving at 1 are uniquely determined by the requirement that $h_{xj}(0) = x$. Hence,

$$h_{-1,1}(p) = -\sqrt{1+ip} \quad \text{and} \quad h_{1,2}(p) = \sqrt{1+ip}.$$

Contrary to the first example, the integral along the path that connects the limiting endpoints of $h_{-1,1}(p)$ and $h_{1,2}(p)$ cannot be discarded. Since $h_{-1,1}(p)$ and $h_{1,2}(p)$ have opposite signs, any connecting path should cross the real axis. Additionally we require the connecting path to be such that the integrand along the path is nonoscillatory. The solution is to pass explicitly through the point $x = 0$ via two new paths

$$h_{0,1}(p) = -\sqrt{ip} \quad \text{and} \quad h_{0,2}(p) = \sqrt{ip}.$$

The point $x = 0$ is such that the paths corresponding to the two inverses coincide at $x = 0$. We can now rewrite (2.3) as

$$\begin{aligned}\int_{-1}^{1} f(x)e^{i\omega x^2}\mathrm{d}x =& e^{i\omega}\int_0^\infty f(h_{-1,1}(p))e^{-\omega p}h'_{-1,1}(p)\mathrm{d}p - \int_0^\infty f(h_{0,1}(p))e^{-\omega p}h'_{0,1}(p)\mathrm{d}p \\ &+ \int_0^\infty f(h_{0,2}(p))e^{-\omega p}h'_{0,2}(p)\mathrm{d}p - e^{i\omega}\int_0^\infty f(h_{1,2}(p))e^{-\omega p}h'_{1,2}(p)\mathrm{d}p.\end{aligned}$$

These four integrals are well behaved, although the derivatives $h'_{0,1}(p)$ and $h'_{0,2}(p)$ introduce a weak singularity of the form $1/\sqrt{p}$ for $p \to 0$. The integrands do not oscillate, and their decay is exponentially fast.

Note that $\xi = 0$ is a stationary point because $g'(\xi) = 0$. More general stationary points, where also higher order derivatives of g vanish, are handled in a similar way. Consider, e.g., $g(x) = x^3$ and its inverse $g^{-1}(y) = \sqrt[3]{y}$. The cubic root has three branches in the complex plane, and the optimal path $h_x(p) = g^{-1}(g(x) + ip)$ at the point x is found by taking the branch corresponding to the inverse of g that is valid at x, i.e., for which $h_x(0) = x$. At $\xi = 0$, we have that $g'(\xi) = g''(\xi) = 0$ and the three branches coincide. For this example, integral (1.1) can again be decomposed into four contributions, each of which corresponds to a nonoscillating integral. The integration path is drawn in Figure 2.2.

3. The ideal case: Analytic integrand and no stationary points.

3.1. An approximate decomposition of the oscillatory integral. The ideal setting for our approach has three conditions: both f and g are analytic functions, there are no stationary points in the integration interval $[a, b]$ (i.e., $g'(x) \neq 0$),

and the equation $g(x) = z$ is easily solvable, preferably by analytical means. None of these conditions is crucial in order to obtain a convergent quadrature method, as we will relax all conditions later on. But, the ideal case leads to the highest convergence rate among all cases described and is most suited to demonstrate our approach: the problem of evaluating (1.1) can be transformed into the problem of integrating two integrals on $[0, \infty)$ with a smooth integrand that does not oscillate and that decays exponentially fast. This will be proved in this section in Theorem 3.3. First, we give a basic lemma for the approximation of an integral with an integrand that becomes small in some region S of the complex plane.

LEMMA 3.1. *Assume u is analytic in a simply connected complex region $D \subset \mathbb{C}$ with $[a, b] \subset D$, and there exists a bounded and connected region $S \subset D$ such that $|u(z)| \leq \epsilon \ \forall z \in S$. If the shortest distance between any two points p and q of S along a curve that lies in S can be bounded from above by a constant $M > 0$, then there exists a function $F(x)$, $x \in [a, b]$, such that the integral of u can be approximated by*

$$\int_a^x u(z)\,\mathrm{d}z \approx F(a) - F(x) \tag{3.1}$$

with an error e that satisfies $|e| \leq M\epsilon$. The function F is of the form

$$F(x) = \int_{\Gamma_x} u(z)\,\mathrm{d}z \tag{3.2}$$

with Γ_x any path in D that starts at x and ends in S.

Proof. Let Γ_x be a curve in D from x to an arbitrary point in S, denoted by $q(x)$, and Γ_a a curve in D from a to $q(a) \in S$. Choose κ as the shortest path in S that connects $q(a)$ and $q(x)$. Since u is analytic in D, the integration path between a and x may be chosen as the concatenation of Γ_a, κ, and $-\Gamma_x$. The integral is written as

$$\int_a^x u(z)\,\mathrm{d}z = F(a) + \int_\kappa u(z)\,\mathrm{d}z - F(x) \quad \text{with} \quad \left| \int_\kappa u(z)\,\mathrm{d}z \right| \leq M\epsilon.$$

This proves the result. ∎

Note that F is not completely determined by the conditions of this lemma. In particular, the endpoint $q(x)$ of Γ_x may be an arbitrary function of x.

If g is analytic, then the oscillating function $e^{i\omega g(x)}$ in the integrand of (1.1) is also analytic as a function of x. This function is small in absolute value if

$$|e^{i\omega g(x)}| \leq \epsilon \iff e^{-\omega \Im g(x)} \leq \epsilon \iff \Im g(x) \geq \frac{-\log(\epsilon)}{\omega}.$$

Hence, if the inverse of g exists, we can find a suitable region S that is required for Lemma 3.1 with points given by $g^{-1}(c + id)$ for $d \geq d_0 := \frac{-\log(\epsilon)}{\omega}$. Note that, in general, the inverse of an analytic function may be multivalued. Each single-valued branch of the inverse has branch points that are located at the points ξ where $g'(\xi) = 0$, and it is discontinuous across branch cuts that extend from one branch point to another, or from a branch point to infinity. By explicitly excluding the presence of branch points locally, a single-valued branch of the inverse can be found that is analytic in a neighborhood of $[a, b]$. We can then characterize the error of the decomposition given in Lemma 3.1 for the particular case of integral (1.1) as a function of ω.

THEOREM 3.2. *Assume f and g are analytic in a bounded and open complex neighborhood D of $[a,b]$, and assume $g'(z) \neq 0$, $z \in D$. Then there exists an approximation of the form* (3.1) *for* (1.1)*, with an error that has order $O(e^{-\omega d_0})$ as a function of ω for a real constant $d_0 > 0$.*

Proof. Define $S := \{z : \Im g(z) \geq d_0\} \cap D$ with $d_0 > 0$. A positive constant d_0 can always be found such that S is nonempty because g is analytic. In order to prove this, consider a point $x \in [a,b]$. Since g is analytic at x, the equation $g(z) = g(x) + id_0$ always has a solution z for sufficiently small $d_0 > 0$ [11]. Additionally, d_0 can be chosen small enough such that $z \in D$, because D contains an open neighborhood of x. The necessary geometrical conditions on S required by Lemma 3.1 follow from the continuity properties of g. We have

$$\forall x \in S : |f(x)e^{i\omega g(x)}| \leq |f(x)|e^{-\omega d_0}.$$

Since S is finite (because D is bounded), there exists a constant $C > 0$ such that $|f(x)| \leq C$, $x \in S$. The result is established by Lemma 3.1 with $u(x) = f(x)e^{i\omega g(x)}$ and $\epsilon = Ce^{-\omega d_0}$. ∎

Theorem 3.2 shows that the error in the approximation $I \approx F(a) - F(b)$ for (1.1) decays exponentially fast as the frequency parameter ω increases. It requires only that f and g are analytic in a finite neighborhood of $[a,b]$. The function F is given by an integral along a curve that originates in x, and it leads to a point z such that $g(z)$ has a positive imaginary part. The result follows from the exponential decay of the integrand, which is the first of the two observations about the integrand made in the introduction.

3.2. An exact decomposition of the oscillatory integral. Next, we will take the second observation into account: $e^{i\omega g(x)}$ does not oscillate along a path where $g(x)$ has a fixed real part. This will lead to a particularly useful choice for the path Γ_x in definition (3.2) of F.

Let $h_x(p)$ be a parameterization for Γ_x, $p \in [0,P]$; then we find a suitable path as the solution to

$$g(h_x(p)) = g(x) + ip, \quad x \in [a,b].$$

If the inverse of g exists, we have the unique solution $h_x(p) = g^{-1}(g(x) + ip)$. The path $h_x(p)$ is also called the path of steepest descent [1, 2]. This can be understood as follows. Define $k(x,y) := ig(z) = u(x,y) + iv(x,y)$, with $z = x + iy$. Then we have $e^{i\omega g(z)} = e^{\omega k(x,y)}$. It can be shown that the path is such that $v(x,y) = v(x_0,y_0)$ is constant and that the descent of $u(x,y)$ is maximal. In particular, the direction of steepest descent coincides with $-\nabla u$ at each point $z = x + iy$.

Using this path in the definition of F, the decomposition for (1.1) becomes

$$\begin{aligned}\int_a^x f(z)e^{i\omega g(z)}\,\mathrm{d}z &\approx F(a) - F(x)\\ &= e^{i\omega g(a)}\int_0^P f(h_a(p))e^{-\omega p}h_a'(p)\,\mathrm{d}p - e^{i\omega g(x)}\int_0^P f(h_x(p))e^{-\omega p}h_x'(p)\,\mathrm{d}p.\end{aligned}$$

The integrands in the right-hand side do not oscillate, and they decay exponentially fast as the integration parameter p or the frequency parameter ω increases.

In the following theorem, we will consider the limit case $P \to \infty$ in which the error of the approximation vanishes. This will require stronger analyticity conditions for

both f and g. Additionally, the function f can no longer be assumed to be bounded. The result of the theorem will hold if f does not grow faster than polynomially in the complex plane along the suggested integration path.

THEOREM 3.3. *Assume that the functions f and g are analytic in a simply connected and sufficiently (infinitely) large complex region D containing the interval $[a,b]$, and that the inverse of g exists on D. If the following conditions hold in D:*

$$\exists m \in \mathbb{N} : |f(z)| = O(|z|^m), \tag{3.3}$$

$$\exists \omega_0 \in \mathbb{R} : |g^{-1}(z)| = O(e^{\omega_0 |z|}), \quad |z| \to \infty, \tag{3.4}$$

then there exists a function $F(x)$ for $x \in [a,b]$ such that

$$\int_a^x f(z) e^{i\omega g(z)} \, \mathrm{d}z = F(a) - F(x) \qquad \forall \omega > (m+1)\omega_0, \tag{3.5}$$

where $F(x)$ is of the form

$$F(x) := \int_{\Gamma_x} f(z) e^{i\omega g(z)} \, \mathrm{d}z, \tag{3.6}$$

with Γ_x a path that starts at x. A parameterization $h_x(p)$, $p \in [0,\infty)$, for Γ_x exists such that the integrand of (3.6) *is $O(e^{-\omega p})$.*

Proof. We will use $u(z)$ to denote the integrand of (1.1). Using the fact that $|u(z)| = |f(z)e^{i\omega g(z)}| = |f(z)|e^{-\omega \Im g(z)}$, and conditions (3.3) and (3.4), we can state

$$c + id \in D \Rightarrow |u(g^{-1}(c+id))| = O(e^{(m\omega_0 - \omega)d}), \quad d \to \infty. \tag{3.7}$$

If $\omega > m\omega_0$, then (3.7) characterizes the exponential decay of the integrand in the complex plane. We will now choose an integration path from the point a to the region where the integrand becomes small and from that region back to the point $x \in [a,b]$. We will show that the contribution along the line that connects both paths can be discarded. This will establish the existence of Γ_a and Γ_x in (3.6) and the independence of Γ_a and Γ_x.

Assume an integration path for I that consists of three connected parts, parameterized as $h_a(p)$ and $h_x(p)$ with $p \in [0,P]$, and $\kappa(p)$ with $p \in [a,x]$. The parameterizations can be chosen differentiable and satisfy $h_a(0) = a$, $h_x(0) = x$, $h_a(P) = \kappa(a)$, and $h_x(P) = \kappa(x)$. We have

$$\begin{aligned} \int_a^x u(z) \, \mathrm{d}z = &\int_0^P u(h_a(p)) h_a'(p) \, \mathrm{d}p + \int_a^x u(\kappa(p)) \kappa'(p) \, \mathrm{d}p \\ &- \int_0^P u(h_x(p)) h_x'(p) \, \mathrm{d}p. \end{aligned} \tag{3.8}$$

Since the inverse function g^{-1} exists, we can choose the points $h_a(P)$ and $h_x(P)$ as follows: $h_a(P) = g^{-1}(g(a) + iP)$ and $h_x(P) = g^{-1}(g(x) + iP)$. Hence, by (3.7),

$$|u(h_a(P))| = O(e^{(m\omega_0 - \omega)P}) \quad \text{and} \quad |u(h_x(P))| = O(e^{(m\omega_0 - \omega)P}).$$

We will now show that, as $P \to \infty$, the second integral vanishes. Equation (3.8) is then of the form (3.5), with Γ_a and Γ_x parameterized by $h_a(p)$ and $h_x(p)$, respectively, with $p \in [0,\infty)$. The contribution of the integral along $\kappa(p)$ is bounded by

$$\left| \int_a^x u(\kappa(p)) \kappa'(p) \, \mathrm{d}p \right| \leq \max_{p \in [a,x]} |u(\kappa(p))| \max_{p \in [a,x]} |\kappa'(p)| \, |x - a|. \tag{3.9}$$

Defining the path $\kappa(p) := g^{-1}(g(p)+iP)$, we have by (3.7) that $|u(\kappa(p))| = O(e^{(m\omega_0-\omega)P})$, $p \in [a, x]$. We can write the second factor in the bound (3.9) as

$$\kappa'(p) = \frac{\partial g^{-1}}{\partial y}(g(p) + iP)\frac{\mathrm{d}g}{\mathrm{d}p}(p).$$

The derivative of $g(p)$ with respect to p is bounded on $[a, b]$ because g is analytic. The factor $\frac{\partial g^{-1}}{\partial y}(g(p) + iP)$ is bounded by $O(e^{\omega_0 P})$. Combining the asymptotic behavior of the factors in (3.9), the second term in (3.8) vanishes for $P \to \infty$ and $\forall\ x \in [a, b]$ if $\omega > (m + 1)\omega_0$. This proves the result. ∎

Remark 3.4. Note that f and g should be analytic in a simply connected region D that contains the paths h_a, h_b, and $\kappa(p)$ in order to apply Cauchy's theorem. The unique existence of the inverse of g is a necessary condition: if $g'(z) = 0$ with $z \in D$, then the point z is a branch point of the inverse function. The path $\kappa(p)$ may cross the branch cut that originates at z, and Cauchy's theorem cannot be applied.

Remark 3.5. Conditions (3.3) and (3.4) are sufficient but not necessary. For example, the limit case also applies when $f(x) = e^x$ and $g(x) = x$. If, however, $f(x) = e^{-x^2}$ and $g(x) = x$, the integrand always diverges at infinity along the steepest descent path, regardless of the size of ω. In that case, the path should be truncated at a finite distance from the real axis. The accuracy of the decomposition is then described by Theorem 3.2; i.e., the error decays exponentially fast.

3.3. Evaluation of $F(x)$ by Gauss–Laguerre quadrature. Next, we consider the evaluation of $F(x)$ as defined by (3.6). The parameterization of the path $h_x(p)$ is such that it solves the equation

$$g(h_x(p)) = g(x) + ip. \tag{3.10}$$

The integrand of (1.1) along this path is nonoscillatory and exponentially decaying,

$$f(h_x(p))e^{i\omega g(h_x(p))} = f(h_x(p))e^{i\omega g(x)}e^{-\omega p}.$$

In the simplest, yet important, case $g(x) := x$ the suggested path is $h_x(p) = x + ip$.

An efficient approach for infinite integrals with an exponentially decaying integrand is Gauss–Laguerre quadrature [5]. Laguerre polynomials are orthogonal with respect to e^{-x} on $[0, \infty]$. A Gauss–Laguerre rule with n points is exact for polynomials up to degree $2n - 1$. The integral $F(x)$ with the suggested path can be written as

$$\begin{aligned} F(x) &= \int_0^\infty f(h_x(p))e^{i\omega(g(x)+ip)}h_x'(p)\,\mathrm{d}p = e^{i\omega g(x)}\int_0^\infty f(h_x(p))h_x'(p)e^{-\omega p}\,\mathrm{d}p \\ &= \frac{e^{i\omega g(x)}}{\omega}\int_0^\infty f\left(h_x\left(\frac{q}{\omega}\right)\right)h_x'\left(\frac{q}{\omega}\right)e^{-q}\,\mathrm{d}q, \end{aligned}$$

with $q = \omega p$ in the last expression. Applying a Gauss–Laguerre quadrature rule with n points x_i and weights w_i yields a quadrature rule

$$F(x) \approx Q_F[f, g, h_x] := \frac{e^{i\omega g(x)}}{\omega}\sum_{i=1}^{n} w_i f\left(h_x\left(\frac{x_i}{\omega}\right)\right)h_x'\left(\frac{x_i}{\omega}\right). \tag{3.11}$$

The rule requires the evaluation of f in a complex neighborhood of x.

THEOREM 3.6. *Assume functions f and g satisfy the conditions of Theorem* 3.3. *Let I be approximated by the quadrature formula*

$$I \approx Q[f,g] := Q_F[f,g,h_a] - Q_F[f,g,h_b], \tag{3.12}$$

where Q_F is evaluated by an n-point Gauss–Laguerre quadrature rule as specified in (3.11). *Then the quadrature error behaves asymptotically as $O(\omega^{-2n-1})$.*

Proof. A formula for the error of the n-point Gauss–Laguerre quadrature rule applied to the integral $\int_0^\infty f(x)e^{-x}\mathrm{d}x$ is given by [5]

$$E = \frac{(n!)^2}{(2n)!} f^{(2n)}(\zeta), \quad \zeta \in [0,\infty).$$

Using this formula, one can derive an expression for the error $E := F(a) - Q_F[f,g,h_a]$:

$$\begin{aligned} E &= \frac{e^{i\omega g(a)}}{\omega} \frac{(n!)^2}{(2n)!} \left. \frac{\mathrm{d}^{2n}(f(h_a(q/\omega))h_a'(q/\omega))}{\mathrm{d}q^{2n}} \right|_{q=\zeta} \\ &= \frac{e^{i\omega g(a)}}{\omega^{2n+1}} \frac{(n!)^2}{(2n)!} \left. \frac{\mathrm{d}^{2n}(f(h_a(q))h_a'(q))}{\mathrm{d}q^{2n}} \right|_{q=\zeta/\omega} \end{aligned} \tag{3.13}$$

with $\zeta \in \mathbb{C}$. The error behaves asymptotically as $O(\omega^{-2n-1})$. The absolute error for the approximation to (1.1) is composed of two contributions of the form (3.13), and, hence, has the same high order of convergence. ∎

Remark 3.7. The decomposition $I = F(a) - F(b)$ is of a similar type as the decomposition of I in [14] based on asymptotic expansions. There, the terms in the expansions are given by a combination of f, g, and their derivatives, evaluated in the points a and b. Yet, the numerical properties of our approach are different: the convergence rate $O(\omega^{-2n-1})$ when using an n-point quadrature rule for both $Q_F[f,g,h_a]$ and $Q_F[f,g,h_b]$ should be compared to the rate $O(\omega^{-n-1})$ when using an n-term asymptotic expansion of I evaluated in a and b.

Example 3.8. We end this section with a numerical example to illustrate the sharpness of our convergence result. The absolute error for different values of ω and of n is given in Table 3.1 for the functions $g(x) = x$ and $f(x) = 1/(1+x)$ on $[0,1]$. The parameterization for Γ_x is given by $h_x(p) = g(x) + ip$. The behavior as a function of ω follows the theory until machine precision is reached. The relative error scales only slightly worse, since $|I| = O(\omega^{-1})$.

One should note that decomposition (3.5) is exact for all positive values of the parameter $\omega > (m+1)\omega_0 > 0$. The conditions from Theorem 3.3 yield the minimal frequency parameter $(m+1)\omega_0$. The method itself is therefore not asymptotic—only

TABLE 3.1

Absolute error of the approximation of I by $Q_F[f,g,h_a] - Q_F[f,g,h_b]$ with n quadrature points for the functions $f(x) = 1/(1+x)$ and $g(x) = x$ on $[0,1]$. The last row shows the value of $\log_2(e_{40}/e_{80})$: this value should approximate $2n+1$.

$\omega \setminus n$	1	2	3	4	5
10	$1.0E-3$	$3.1E-5$	$1.9E-6$	$1.7E-7$	$2.1E-8$
20	$1.2E-4$	$1.1E-6$	$2.3E-8$	$7.5E-10$	$3.2E-11$
40	$1.7E-5$	$3.9E-8$	$2.1E-10$	$2.0E-12$	$2.8E-14$
80	$2.0E-6$	$1.2E-9$	$1.7E-12$	$4.2E-15$	$1.6E-17$
Rate	3.1	5.0	6.9	8.9	10.8

the convergence estimate is. Table 3.1 shows an absolute error of $2.1E-8$ (relative error $1.4E-7$) for $\omega = 10$ with a number of quadrature points as small as $n = 5$. The corresponding integral is not highly oscillatory at all. In order to achieve the same absolute error with standard Gaussian quadrature on $[0, 1]$, we had to choose a rule with 10 points. Considering the fact that we evaluate both $Q_F[f, g, h_a]$ and $Q_F[f, g, h_b]$ with $n = 5$ points, the amount of work is the same. Thus, even at relatively low frequencies, our approach is competitive with conventional quadrature on the real axis. For higher frequencies, obviously, the new approach may be many orders of magnitude faster.

4. The case of stationary points.

4.1. A new decomposition for the oscillatory integral. At a stationary point ξ, the derivative of g vanishes and the integrand $f(x)e^{i\omega g(x)}$ does not oscillate, at least locally. The contribution of the integrand and its derivatives at ξ can therefore not be neglected. The theorems of section 3 do not apply, because the inverse of g does not exist uniquely due to the branch point at ξ.

In order to illustrate the problem, consider the following situation. Assume that the equation $g'(x) = 0$ has one solution ξ and $\xi \in [a, b]$. Now define the restrictions

$$g_1 := g|_{[a,\xi]} \quad \text{and} \quad g_2 := g|_{[\xi,b]} \tag{4.1}$$

of g on the intervals $[a, \xi]$ and $[\xi, b]$, respectively. Then the unique inverse of g on $[a, b]$ does not exist, but a single-valued branch g_1^{-1} can be found that satisfies $g_1^{-1}(g_1(x)) = x$, $x \in [a, \xi]$. This branch is analytic everywhere except at the point ξ and along a branch cut that can be chosen arbitrarily but that always originates at ξ. Similarly, a single-valued branch g_2^{-1} exists that satisfies $g_2^{-1}(g_2(x)) = x$, $x \in [\xi, b]$. Both branches satisfy $g(g_i^{-1}(z)) = z$, $i = 1, 2$, in their domain of analyticity. The integrand is small in the region S_1 with points of the form $g_1^{-1}(c+id)$, $d \geq d_0$, or in the region S_2 with points of the form $g_2^{-1}(c + id)$, $d \geq d_0$. It is easy to see that S_1 and S_2 are not connected: applying g on both sides of the equality $g_1^{-1}(y) = g_2^{-1}(z)$ leads to $y = z$, which is only possible if $z = \xi \notin S_1, S_2$. The path (3.10) that solves $g(h_x(p)) = g(x) + ip$, as suggested in section 3, leads to a path in S_1 for a and to a path in S_2 for b.

The solution is therefore to split the integration interval into the two subintervals $[a, \xi]$ and $[\xi, b]$. This procedure can be repeated for any number of stationary points. The analogues of Theorems 3.2 and 3.3 can be stated as follows.

THEOREM 4.1. *Assume that the functions f and g are analytic in a bounded and open complex neighborhood D of $[a, b]$. If the equation $g'(x) = 0$ has only one solution ξ in D and $\xi \in (a, b)$, then there exist functions $F_j(x)$, $j = 1, 2$, such that*

$$\int_s^t f(z)e^{i\omega g(z)}\,\mathrm{d}z = F_1(s) - F_1(\xi) + F_2(\xi) - F_2(t) + O(e^{-\omega d_0}), \quad d_0 > 0,$$

for $s \in [a, \xi]$ and $t \in [\xi, b]$, where $F_j(x)$ is of the form

$$F_j(x) := \int_{\Gamma_{x,j}} f(z)e^{i\omega g(z)}\,\mathrm{d}z \tag{4.2}$$

with $\Gamma_{x,j}$ a path that starts at x.

Proof. Define $g_2(x)$ as in (4.1). A decomposition for $\int_\xi^t f(x)e^{i\omega g_2(x)}\,\mathrm{d}x$ can be found using the proof of Theorem 3.2 with two modifications. First, the equation $g(z) = g(x) + id_0$ now has at least two solutions locally around $x = \xi$. We choose

the solution that corresponds to the single-valued branch g_2^{-1} of the inverse of g that satisfies $g_2^{-1}(g(x)) = x$, $x \in [\xi, b]$. The branch cut can always be chosen such that it does not prevent us from applying Cauchy's theorem. Second, the set S in the proof is now defined as $S := \{z : \Im g(z) \geq d_0 \text{ and } g_2^{-1}(g(z)) = z\} \cap D$; i.e., the set is restricted to one connected part of D, where the integrand is small, as opposed to the set of all points, where the integrand is small. The latter set would not be connected in this case. With these modifications, the proof shows the existence of F_2 such that

$$\int_\xi^t f(z)e^{i\omega g_2(z)}\,\mathrm{d}z = F_2(\xi) - F_2(t) + O(e^{-\omega d_0}).$$

The same reasoning can be applied in order to find a decomposition on the interval $[a, \xi]$. This leads to the result. ∎

The next theorem is the limit case of Theorem 4.1, where the error vanishes. The notation g_1^{-1} denotes a branch of the multivalued inverse of g that satisfies $g_1^{-1}(g_1(x)) = x$, $x \in [a, \xi]$. The notation g_2^{-1} is similar.

THEOREM 4.2. *Assume that the functions f and g are analytic in a simply connected and sufficiently (infinitely) large complex region D containing the interval $[a, b]$. Assume further that the equation $g'(x) = 0$ has only one solution ξ in D and $\xi \in (a, b)$. Define g_1 and g_2 as in* (4.1)*. If the following conditions hold:*

$$\begin{aligned}&\exists m \in \mathbb{N} : |f(z)| = O(|z|^m),\\ &\exists \omega_0 \in \mathbb{R} : |g_1^{-1}(z)| = O(e^{\omega_0|z|}) \text{ and } |g_2^{-1}(z)| = O(e^{\omega_0|z|}), \quad |z| \to \infty,\end{aligned}$$

then there exist functions $F_j(x)$, $j = 1, 2$, of the form (4.2) *such that*

$$\int_s^t f(z)e^{i\omega g(z)}\,\mathrm{d}z = F_1(s) - F_1(\xi) + F_2(\xi) - F_2(t) \quad \forall \omega > (m+1)\omega_0 \tag{4.3}$$

for $s \in [a, \xi]$ and $t \in [\xi, b]$. A parameterization $h_{\xi,j}(p)$, $p \in [0, \infty)$, for $\Gamma_{x,j}$ exists such that the integrand of (4.2) *is $O(e^{-\omega p})$.*

Theorems 4.1 and 4.2 are easily extended to the case when $\xi = a$ (or $\xi = b$) by discarding the two terms $F_1(a) - F_1(\xi)$ (or $F_2(\xi) - F_2(b)$).

Example 4.3. We consider the function $g(x) = (x - 1/2)^2$ with a stationary point at $\xi = 1/2$. The inverse of g, i.e., $g^{-1}(y) = 1/2 \pm \sqrt{y}$, is a two-valued function. One branch is valid on the interval $[0, \xi]$, the other on $[\xi, 1]$. The paths suggested by (3.10) on $[0, \xi]$ that originate at the points 0 and ξ, respectively, are given by

$$h_{0,1}(p) = 1/2 - \sqrt{1/4 + ip} \quad \text{and} \quad h_{\xi,1}(p) = 1/2 - \sqrt{ip}.$$

The paths on $[\xi, 1]$ for the points $1/2$ and 1 are parameterized by

$$h_{\xi,2}(p) = 1/2 + \sqrt{ip} \quad \text{and} \quad h_{1,2}(p) = 1/2 + \sqrt{1/4 + ip}.$$

These paths correspond to the two inverse functions. We have found the decomposition $I = F_1(a) - F_1(\xi) + F_2(\xi) - F_2(b)$.

Note that the paths $h_{\xi,1}$ and $h_{\xi,2}$ that originate in the point ξ introduce a numerical problem. Their derivatives, which appear in the integrand of the line integral, behave like $1/\sqrt{p}$, $p \to 0$, at ξ. This weak singularity is integrable but prevents convergence of the Gauss–Laguerre quadrature rules. We will require a new method to evaluate $F_j(\xi)$.

4.2. The evaluation of $F_j(x)$ by generalized Gauss–Laguerre quadrature. The previous example showed a numerical problem for the evaluation of $F_j(x)$ by numerical quadrature: the integrand of $F_j(\xi)$ along the path suggested by (3.10) becomes weakly singular at the stationary point ξ. A similar singularity occurs if higher order derivatives of $g(\xi)$ also vanish. Assume that $g^{(k)}(\xi) = 0$, $k = 1, \ldots, r$. The Taylor expansion of g is then

$$g(x) = g(\xi) + 0 + \cdots + 0 + g^{(r+l)}(\xi)\frac{(x-\xi)^{r+1}}{(r+1)!} + O((x-\xi)^{l+2}).$$

The path $h_{\xi,j}(p)$ solves the equation $g(h_{\xi,j}(p)) = g(\xi) + ip$. Its behavior at $p = 0$ is

$$h_{\xi,j}(p) \sim \xi + \sqrt[r+1]{\frac{(r+1)!\,p}{g^{(r+1)}(\xi)}}\,i. \tag{4.4}$$

The derivative has a singularity of the form $p^{\frac{1}{r+1}-1}$, $p \to 0$.

Fortunately, these types of singularities can be handled efficiently by generalized Gauss–Laguerre quadrature. Generalized Laguerre polynomials are orthogonal with respect to the weight function $x^\alpha e^{-x}$, $\alpha > -1$ [5]. Function $F_j(\xi)$ with optimal path $h_{\xi,j}(p)$ is given by

$$F_j(\xi) = \frac{e^{i\omega g(\xi)}}{\omega}\int_0^\infty f\left(h_{\xi,j}\left(\frac{q}{\omega}\right)\right)h'_{\xi,j}\left(\frac{q}{\omega}\right)e^{-q}\,\mathrm{d}q. \tag{4.5}$$

Generalized Gauss–Laguerre quadrature will be used with n points x_i and weights w_i that depend on the value of $\alpha = 1/(r+1) - 1 = -r/(r+1)$. The function $F_j(x)$ is then approximated by

$$Q_F^\alpha[f, g, h_{\xi,j}] := \frac{e^{i\omega g(\xi)}}{\omega}\sum_{i=1}^{n} w_i\, f\left(h_{\xi,j}\left(\frac{x_i}{\omega}\right)\right)h'_{\xi,j}\left(\frac{x_i}{\omega}\right)x_i^{-\alpha}. \tag{4.6}$$

This expression is similar to (3.11) but includes the factor $x_i^{-\alpha}$ to regularize the singularity.

THEOREM 4.4. *Assume functions f and g satisfy the conditions of Theorem* 4.2. *Assume that $g^{(k)}(\xi) = 0$, $k = 1, \ldots, r$, and $g^{(r+1)}(\xi) \neq 0$. Let the function $F_j(\xi)$ be approximated by the quadrature formula*

$$F_j(\xi) \approx Q_F^\alpha[f, g, h_{\xi,j}]$$

with $\alpha = -r/(r+1)$. Then the quadrature error has order $O(\omega^{-2n-1-\alpha})$.

Proof. The error formula for an n-point generalized Gauss–Laguerre quadrature rule is

$$\frac{n!\Gamma(n+\alpha+1)}{(2n)!}f^{(2n)}(\zeta), \quad 0 < \zeta < \infty. \tag{4.7}$$

We can repeat the arguments of the proof of Theorem 3.6. An expression for the error $e := F_j(\xi) - Q_F^\alpha[f, g, h_{\xi,j}]$ can be derived by using (4.7). This leads to

$$\begin{aligned} e &= \frac{e^{i\omega g(\xi)}}{\omega}\frac{n!\Gamma(n+\alpha+1)}{(2n)!}\left.\frac{\mathrm{d}^{2n}(f(h_{\xi,j}(q/\omega))h'_{\xi,j}(q/\omega)q^{-\alpha})}{\mathrm{d}q^{2n}}\right|_{q=\zeta} \\ &= \frac{e^{i\omega g(\xi)}}{\omega^{2n+1}}\frac{n!\Gamma(n+\alpha+1)}{(2n)!}\left.\frac{\mathrm{d}^{2n}(f(h_{\xi,j}(q))h'_{\xi,j}(q)(\omega q)^{-\alpha})}{\mathrm{d}q^{2n}}\right|_{q=\zeta/\omega} \end{aligned}$$

with $\zeta \in \mathbb{C}$. Hence, the error is asymptotically of the order $O(\omega^{-2n-1-\alpha})$. ∎

Remark 4.5. Generalized Gauss–Laguerre quadrature converges rapidly only if the function $v(x)$ in an integrand of the form $v(x)x^\alpha e^{-x}$ has polynomial behavior. Depending on f, the function $f(h_{\xi,j}(p))$ may not resemble a polynomial very well, due to the root in (4.4) for small p. An alternative to generalized Gauss–Laguerre quadrature with $\alpha = -1/2$ is to remove the singularity by the transformation $u = \sqrt{p}$ or $p = u^2$. The same transformation also removes the square root behavior of $h_{\xi,j}(p)$. The integrand after the transformation decays like e^{-u^2}. In that case, variants of the classical Hermite polynomials that are orthogonal with respect to e^{-u^2} on the half-range interval $[0, \infty)$ can be used with corresponding Gaussian quadrature rules as constructed by Gautschi [10]. A similar convergence analysis yields the order $O(\omega^{-n-1})$ in this case.

We can now characterize the approximation of (1.1) in the presence of several stationary points.

THEOREM 4.6. *Assume that f and g are analytic in a sufficiently large region $D \subset \mathbb{C}$ and that the equation $g'(x) = 0$ has l solutions $\xi_i \in (a, b)$. Define $r_i := (\min_{k>1} g^{(k)}(\xi_i) \neq 0) - 1$ and $r := \max_i r_i$. If the conditions of Theorem* 4.2 *are satisfied on each subinterval $[\xi_i, \xi_{i+1}]$, and on $[a, \xi_1]$ and $[\xi_r, b]$, then* (1.1) *can be approximated by*

$$
\begin{aligned}
I \approx Q[f,g] := {} & Q_F[f,g,h_{a,0}] - Q_F^{\alpha_1}[f,g,h_{\xi_1,0}] \\
& + \sum_{i=1}^{l-1} \left(Q_F^{\alpha_i}[f,g,h_{\xi_i,i}] - Q_F^{\alpha_{i+1}}[f,g,h_{\xi_{i+1},i}] \right) \\
& + Q_F^{\alpha_l}[f,g,h_{\xi_l,l}] - Q_F[f,g,h_{b,l}]
\end{aligned} \tag{4.8}
$$

with $\alpha_i = -r_i/(r_i + 1)$, with a quadrature error of the order $O(\omega^{-2n-1/(r+1)})$.

Proof. This follows from a repeated application of the decomposition given by Theorem 4.2 and from the approximation of each term $F_i(x)$ by $Q_F^{\alpha_i}[f, g, h_{x,i}]$ as in Theorem 4.4. ∎

Theorem 4.6 can easily be extended to the case when $g'(a) = 0$ or $g'(b) = 0$. If, e.g., $g'(a) = 0$, we can set $\xi_1 = a$ and use the general decomposition (4.8) with the first two terms left out.

Example 4.7. We return to Example 4.3 of this section in order to illustrate the convergence results. The approximation of (1.1) for the function $g(x) = (x - 1/2)^2$ is given by

$$
Q[f,g] = Q_F[f,g,h_{0,1}] - Q_F^{-1/2}[f,g,h_{1/2,1}] + Q_F^{-1/2}[f,g,h_{1/2,2}] - Q_F[f,g,h_{1,2}].
$$

Theorem 4.6 predicts an error of the order $O(\omega^{-2n-1/2})$. The sharpness of this estimate can be verified by the results in Table 4.1.

4.3. The case of complex stationary points. So far, we have required the stationary point $\xi \in [a, b]$ to be real. But even for functions g that are real valued on the real axis, the equation $g'(x) = 0$ may have complex solutions. The value of $g'(x)$ on $[a, b]$ can become very small if a complex stationary point ξ lies close to the real axis. We may therefore expect that such a point contributes to the value of the integral (1.1). Here, we will not pursue the extension of the theory to the case of complex stationary points in any detail. Instead, we will restrict ourselves to a number of remarks that address some of the relevant issues.

A first observation is that Theorem 4.1 can still be applied if the region D is chosen small enough such that it does not contain ξ. This means that the contribution of

TABLE 4.1
Absolute error of the approximation of I by $Q[f,g]$ using (generalized) Gauss–Laguerre quadrature with $f(x) = 1/(1+x)$ and $g(x) = (x-1/2)^2$ on $[0,1]$. The last row shows the value of $\log_2(e_{80}/e_{160})$: this value should approximate $2n+1/2$.

ξ to the value of I, if any, decays exponentially fast as ω increases. Still, for small values of ω, the error may become prohibitively large if ξ lies close to the real axis.

In order to resolve this problem, one must first know which stationary points can contribute to the error of the approximations of section 4. In general, the question can be answered by inspecting the integration paths. A stationary point contributes if it lies in the interior of the domain bounded by the integration interval on the real axis and the complex integration path (including the limiting connecting part at infinity). In order to obtain an exact decomposition, the integration path should be changed to pass through ξ explicitly. Specifically, the decomposition should include two additional terms for ξ of the form (4.5).

As a final remark, we note that the integral of the form (4.5) has a factor $e^{i\omega g(\xi)}$ with $g(\xi) = c + id$ complex. If $d > 0$, then the contribution decays exponentially as $e^{-\omega d}$. We know from Theorem 4.1 that the error introduced by discarding complex stationary points should decay exponentially. Hence, complex stationary points for which $d \leq 0$ cannot contribute to the value of I.

5. The case when the oscillator is not easily invertible. Theorems 3.3 and 4.2 continue to hold for paths different from the one implicitly defined by (3.10). The value of $F(a)$ does not depend on the path taken, and does not even depend on the limiting endpoint of the path, as long as the imaginary part of $g(x)$ grows infinitely large. We have merely suggested (3.10), which yields a nonoscillatory integrand with exponential decay, as being suitable for Gauss–Laguerre quadrature. Other integration techniques may be applied for other paths with different numerical properties. We will not explore these possibilities in depth here.

We restrict the discussion to an approach that is useful when the inverse function of g is known to exist, but when the suggested path is not easily obtained by analytical means. As ω increases, we see from (3.11) that $Q_F[f,g,h_a]$ requires function values in a complex region around a of diminishing size. Therefore, it is reasonable to assume that approximating the path defined by (3.10) locally around $x = a$ is acceptable. Use of the first order Taylor approximation $g(x) \approx g(a) + g'(a)(x-a)$ to replace the left-hand side of (3.10) leads to the path

$$h_a(p) = a + \frac{ip}{g'(a)}.$$

The second order Taylor approximation leads to the path

$$h_a(p) = a - \frac{g'(a) - \sqrt{g'(a)^2 + 2ipg^{(2)}(a)}}{g^{(2)}(a)}.$$

In the case of stationary points the path can be approximated by using (4.4).

The general expression for the integral along the approximate path is given by

$$F(a) = \int_0^\infty f(h_a(p))e^{i\omega g(h_a(p))}h_a'(p)\,\mathrm{d}p.$$

Computing $F(a)$ by Gauss–Laguerre quadrature yields a numerical approximation with an error given by

$$\begin{aligned} E &= \omega^{-1}\frac{(n!)^2}{(2n)!}\left.\frac{\mathrm{d}^{2n}(f(h_a(q/\omega))e^{i\omega g(h_a(q/\omega))}h_a'(q/\omega)e^q)}{\mathrm{d}q^{2n}}\right|_{q=\zeta} \\ &= \omega^{-2n-1}\frac{(n!)^2}{(2n)!}\left.\frac{\mathrm{d}^{2n}(f(h_a(q))h_a'(q)e^{i\omega g(h_a(q))}e^{\omega q})}{\mathrm{d}q^{2n}}\right|_{q=\zeta/\omega}. \end{aligned}$$

The order of convergence is not necessarily $O(\omega^{-2n-1})$ in this case because the derivative still depends on ω. However, the function $e^{i\omega g(h_a(q))}$ is a good approximation to $e^{i\omega g(a)}e^{-\omega q}$, and we can expect the quadrature to converge. This will be illustrated further on.

The results can be improved to preserve the original convergence rate of $O(\omega^{-2n-1})$ at the cost of a little extra work to determine the optimal path. The optimal path depends only on $g(x)$, and on the interval $[a,b]$, and can therefore be reused for different functions f. The extra computations have to be done once for each combination of $g(x)$ and $[a,b]$.

The Taylor approximation of the path can be used to generate suitable starting values for a Newton–Raphson iteration, which is applied to find the root x of the equation

$$g(x) - g(a) - ip = 0. \tag{5.1}$$

For the set of n (fixed) values for p that are required by the quadrature rule, the iteration yields the points $x = h_a(p)$ on the path. The values of $h_a'(p)$, i.e., $\frac{\mathrm{d}x}{\mathrm{d}p}$, are found by taking the derivative of (5.1) with respect to p,

$$g'(x)\frac{\mathrm{d}x}{\mathrm{d}p} = i.$$

With the Newton–Raphson method, the points on the optimal path and the derivatives at these points can be found to high precision. Since the Taylor approximation is already a good approximation for large ω, the required number of iterations is small.

Example 5.1. We consider the second order Taylor approximation of the path for $f(x) = 1/(1+x)$ and $g(x) = (x^2+x+1)^{1/3}$. The absolute error is shown in Table 5.1. Use of the Newton–Raphson iteration for the same example yields an error of order $O(\omega^{-2n-1})$. This is shown in Table 5.2. The number of iterations per quadrature point varied between 1 and 4.

6. Generalization to a nonanalytic function $f(x)$. If $f(x)$ is not analytic in a complex region surrounding $[a,b]$, then the method presented thus far will not work. If $f(x)$ is piecewise analytic (e.g., piecewise polynomial), the integration can be split into the integrals corresponding to the analytic parts of f. More generally, however, we need to resort to another approach. For a suitable analytic function $\tilde{f}$ that approximates f, we can expect the integral

$$\tilde{I} := \int_a^b \tilde{f}(x)e^{i\omega g(x)}\,\mathrm{d}x$$

to approximate the value of I.

TABLE 5.1
Absolute error of approximation of $F(a) - F(b)$ by Gauss–Laguerre quadrature with $f(x) = 1/(1+x)$ and $g(x) = (x^2+x+1)^{1/3}$ on $[0,1]$ and second order Taylor approximation of the optimal path. The last row shows the value of $\log_2(e_{160}/e_{320})$.

This leads to a *Filon-type method* that was already mentioned in the introduction. Filon's method was extended by Iserles and Nørsett in [14]. Since the value of I depends on the value of f and its derivatives at $x = a$ and $x = b$, they successfully used Hermite interpolation in the points a and b, in the stationary points, and in a few other regular points in the interval $[a, b]$. In [14, Thm. 2.3] it was shown that interpolating $f^{(j)}(x)$ at a and b, $j = 0, \ldots, s-1$, with a polynomial of degree $2s-1$ leads to a quadrature rule with an error of order $O(\omega^{-s-1})$.

Since polynomials are analytic, we can also use the Hermite approximation in our approach. This enables the computation of the weights of the Filon-type quadrature rule for general oscillators. (Note that the complex approach also enables the computation of the moments in the *asymptotic method* of [14].) It does not improve the convergence rate of the method. We can improve on the Filon-type method, however, in a different way. Thanks to the decomposition of (1.1) as $I = F(a) - F(b)$, it is possible to use different approximations around a and b, and, hence, to approximate $F(a)$ and $F(b)$ independently. Since $F(a)$ depends only on the behavior of f around a, the approximating Hermite polynomial can have a much lower degree. In the theorem below, we show that we can obtain a similar accuracy as in [14, Thm. 2.3] with two independently constructed polynomials of degree $s-1$ instead of one polynomial of degree $2s-1$.

THEOREM 6.1. *Assume that f is a smooth function and g is analytic. Let $f_a(x)$ and $f_b(x)$ be the Hermite interpolating polynomials of degree $s-1$ that satisfy*

$$f_a^{(k)}(a) = f^{(k)}(a) \quad \textit{and} \quad f_b^{(k)}(b) = f^{(k)}(b), \quad k = 0, \ldots, s-1.$$

Then the approximation of (1.1) *by*

$$F_{f_a}(a) - F_{f_b}(b) := \int_0^\infty f_a(h_a(p))e^{i\omega g(h_a(p))}h_a'(p)\,\mathrm{d}p - \int_0^\infty f_b(h_b(p))e^{i\omega g(h_b(p))}h_b'(p)\,\mathrm{d}p$$

along the paths $h_a(p)$ *and* $h_b(p)$ *that satisfy* (3.10) *has an error of order* $O(\omega^{-s-1})$.

Proof. First, we consider the approximation with the Hermite interpolating polynomial $\tilde{f}(x)$ of degree $2s-1$ that satisfies $\tilde{f}^{(k)}(a) = f^{(k)}(a)$ and $\tilde{f}^{(k)}(b) = f^{(k)}(b)$, $k = 0, \ldots, s-1$. Since $\tilde{f}$ is analytic, it can be used to approximate (1.1) as $I \approx F_{\tilde{f}}(a) - F_{\tilde{f}}(b)$. This approximation has an error of $O(\omega^{-s-1})$ by [14, Thm. 2.3]. Now consider the approximation of $F_{\tilde{f}}(a)$ by $F_{f_a}(a)$. Since $\tilde{f}(x)$ is a polynomial, we can write $F_{\tilde{f}}(a)$ as

$$F_{\tilde{f}}(a) = \sum_{k=0}^{2s-1} \tilde{f}^{(k)}(a)\frac{\mu_k(a)}{k!}, \tag{6.1}$$

where the $\mu_k(a)$ are the moments of the form

$$\begin{aligned}\mu_k(a) &:= \int_0^\infty (h_a(p)-a)^k e^{i\omega g(h_a(p))}h_a'(p)\,\mathrm{d}p \\ &= \int_0^\infty \frac{e^{i\omega g(a)}}{\omega}(h_a(q/\omega)-a)^k e^{-q}h_a'(q/\omega)\,\mathrm{d}q.\end{aligned} \tag{6.2}$$

Although q goes to infinity, the behavior for small q/ω dominates due to the factor e^{-q} (this follows from Watson's lemma [1]). Since $(h_a(q/\omega)-a) \sim \omega^{-1}$, we see that $\mu_k(a) \sim \omega^{-k-1}$. For $F_{f_a}(a)$, we have

$$F_{f_a}(a) = \sum_{k=0}^{s-1} f_a^{(k)}(a)\frac{\mu_k(a)}{k!}. \tag{6.3}$$

The first discarded moment, $\mu_s(a)$, is of order $O(\omega^{-s-1})$. The approximation of $F_{\tilde{f}}(b)$ by $F_{f_b}(b)$ has an error of the same order. This concludes the proof. ∎

There are two ways to proceed: either $f_a(x)$ can be evaluated explicitly in the quadrature evaluation of $F_{f_a}(a)$, or the moments (6.2) can be precomputed with the previous techniques and used in the summation (6.3). The result is a quadrature rule for integrals of type (1.1) for fixed g, a, and b, and using function values and derivatives of f at a and b. Define $w_{i,1} = \frac{\mu_k(a)}{k!}$ and $w_{i,2} = -\frac{\mu_k(b)}{k!}$. Then

$$I \approx Q_\mu[f] := \sum_{i=0}^{s-1} w_{i,1}f^{(i)}(a) + \sum_{i=0}^{s-1} w_{i,2}f^{(i)}(b) \tag{6.4}$$

is a quadrature rule with an error of order $O(\omega^{-s-1})$. For a fixed frequency, this *localized Filon-type method* is exact for polynomials up to degree $s-1$, while the regular Filon-type method is exact for polynomials up to degree $2s-1$. Hence, the simplified construction comes at a cost; the order of accuracy as a function of ω is the same, but we can expect the coefficient to be much larger.

We can generalize the result to include stationary points. The same reasoning applies, but we need to interpolate more derivatives in order to achieve a similar convergence rate. That rate depends on the smallest value of r for which $g^{(r+1)}(\xi) \neq 0$ with ξ a stationary point.

THEOREM 6.2. *Assume that g is analytic and that $g^{(k)}(\xi) = 0$, $k = 1, \ldots, r$, and $g^{(r+1)}(\xi) \neq 0$. Let f be sufficiently smooth, and let $f_\xi(x)$ be the Hermite interpolating polynomial of degree $s(r+1)-1$ that satisfies*

$$f_\xi^{(k)}(\xi) = f^{(k)}(\xi), \quad j = 0, \ldots, s(r+1)-1.$$

Then the sequence $F_{f_\xi,j}(\xi)$ converges for increasing values of s to a limit with an error of order $O(\omega^{-s-1/(r+1)})$.

Proof. The proof follows essentially the same lines as the proof of Theorem 6.1 and uses the moments $\mu_{k,j}(\xi)$, defined using the path $h_{\xi,j}$,

$$\mu_{k,j}(\xi) := \int_0^\infty \frac{e^{i\omega g(\xi)}}{\omega} \left(h_{\xi,j}\left(\frac{q}{\omega}\right) - \xi \right)^k e^{-q} h'_{\xi,j}\left(\frac{q}{\omega}\right) \mathrm{d}q. \tag{6.5}$$

The derivative of the parameterization $h_{\xi,j}$ in the integrand has an integrable singularity of the form $(q/\omega)^{-r/(r+1)}$ at the stationary point ξ and leads to a factor $\omega^{r/(r+1)}$. By (4.4) we have $(h_{\xi,j}(q/\omega) - \xi) \sim \omega^{-1/(r+1)}$. This makes $\mu_{k,j}(\xi) \sim \omega^{r/(r+1)-k/(r+1)-1} = \omega^{(-k-1)/(r+1)}$. The first discarded moment $\mu_{k,j}(\xi)$ in the sum $F_{f_\xi,j}$ of the form (6.3) has the index $k = s(r+1)$, which leads to the result. ∎

Theorem 6.2 shows only that the value $F_{f_\xi}(\xi)$ converges with a specific rate if more derivatives of f are interpolated. It does not explicitly state that $F_{f_\xi}(\xi)$ can be used in a decomposition to approximate (1.1). The existence of an analytic function $\tilde{f}$ that can be used to approximate the value of (1.1) with an arbitrary accuracy, provided f is smooth enough, was proved in [14, Thm. 3.3] using Hermite interpolation.

Assume there is one stationary point $\xi \in (a, b)$, and $g^{(r+1)}(\xi) \neq 0$. Then we can extend the definition of quadrature rule (6.4) to

$$I \approx Q_\mu[f] := \sum_{i=0}^{s-1} w_{i,1} f^{(i)}(a) + \sum_{i=0}^{s(r+1)-1} w_{i,2} f^{(i)}(\xi) + \sum_{i=0}^{s-1} w_{i,3} f^{(i)}(b), \tag{6.6}$$

with $w_{i,1} = \frac{\mu_k(a)}{k!}$, $w_{i,3} = -\frac{\mu_k(b)}{k!}$, and $w_{i,2} = \frac{-\mu_{k,1}(\xi)+\mu_{k,2}(\xi)}{k!}$. This rule has an absolute error of order $O(\omega^{-s-1/(r+1)})$ and a relative error of order $O(\omega^{-s})$.

Example 6.3. We consider the functions $f(x) = 1/(1+x)$ and $g(x) = (x-1/3)^2$ on $[0, 1]$. Since f is analytic, we could use the previous techniques. However, here we will use only the values of the first few derivatives of f at 0 and 1 and at the stationary point $\xi = 1/3$. The results are shown in Table 6.1 for varying degrees of interpolation. The convergence rate is limited to the convergence rate at the stationary point. According to Theorem 6.2, in order to obtain an error of order $O(\omega^{-s-1/(r+1)})$, we need to interpolate up to the derivative of order $m = s(r+1)-1$. Hence, solving the latter expression for s, we expect a convergence rate of $(m+2)/(r+1)$. The rate is actually higher in the columns with even m, due to the cancellation of the moments at ξ with odd index. For a more general function g there is no exact cancellation, but the difference of the moments at ξ, i.e., $\mu_{k,1}(\xi) - \mu_{k,2}(\xi)$, can have lower order than predicted by Theorem 6.2. This cancellation does not occur if the stationary point ξ is the endpoint of the integration interval.

TABLE 6.1

Absolute error of the approximation of I for $f(x) = 1/(1+x)$ and $g(x) = (x-1/3)^2$ on $[0,1]$. We approximate f by interpolating m derivatives. The last row shows the value of $\log_2(e_{1280}/e_{2560})$: this value should approximate $(m+2)/2$ for odd m and $(m+3)/2$ for even m.

$\omega \setminus m$	0	1	2	3	4

(a) (b)

FIG. 6.1. *A numerical comparison between the regular and localized Filon-type methods and the numerical steepest descent method (Example 6.4).* (a) *Absolute error for four methods.* (b) *The absolute error for numerical steepest descent, scaled by $\omega^{5/2}$.*

Example 6.4. We make a numerical comparison between the regular Filon-type method, the localized Filon-type method, and the numerical steepest descent method for $f(x) = 1/(1+x^2)$ and $g(x) = (x-1/2)^2$ on $[-1,1]$. Filon-type methods for this integral suffer from Runge's phenomenon: the interpolation error for the function f is large [19]. We choose $s = 1$; i.e., we use only function values of f in $\{-1, 1/2, 1\}$ and no derivatives. The order of the Filon-type methods is then $O(\omega^{-3/2})$. We choose $n = 1$ in Theorem 4.6. The order of the numerical steepest descent method is then $O(\omega^{-5/2})$, using four evaluations of f in the complex plane. We also interpolate two additional derivatives at $1/2$ for the Filon-type method: this yields a quadrature rule with five weights and order $O(\omega^{-2})$. The results are illustrated in Figure 6.1.

7. Generalization to a nonanalytic function $g(x)$. If $g(x)$ is piecewise analytic, the integration interval can be split into subintervals, where the function is analytic. Otherwise we can try to approximate $g(x)$ by an analytic function $\tilde{g}(x)$ on $[a,b]$. We should take care to not introduce new stationary points and to make sure that we accurately approximate all stationary points of $g(x)$. Alternatively, we can approximate $g(x)$ locally around the special points, possibly by using different functions for each point. This will turn out to be easier and will yield the same convergence rate.

When $g(x)$ is smooth, it can be approximated arbitrarily well by an analytic function $\tilde{g}(x)$ on $[a,b]$. Hence, there exist analytic $\tilde{g}$ such that the integral

$$\tilde{I} := \int_a^b f(x) e^{i\omega\tilde{g}(x)}\,\mathrm{d}x = \tilde{F}(a) - \tilde{F}(b) \tag{7.1}$$

is arbitrarily close to the value of I. Such function $\tilde{g}$ may be difficult to find, however, and, if found, intractable for numerical purposes. Hermite interpolation in the points a and b is not a solution in this case, as the resulting polynomial may introduce stationary points that the original function g did not have. However, owing to decomposition (7.1), it becomes possible to do Hermite interpolation in a and b separately by different polynomials.

THEOREM 7.1. *Assume that f and $\tilde{g}$ are analytic. Let $g_a(x)$ be the Hermite interpolating polynomial of degree s that satisfies*

$$g_a^{(k)}(a) = \tilde{g}^{(k)}(a), \quad k = 0, \dots, s.$$

Then the approximation of $\tilde{F}(a)$ by $F_{g_a}(a)$ has an error of order $O(\omega^{-s-1})$.

Proof. The error $e := \tilde{F}(a) - F_{g_a}(a)$ can be written as

$$\begin{aligned} e &= \int_0^\infty f(h_a(p))(e^{i\omega\tilde{g}(h_a(p))} - e^{i\omega g_a(h_a(p))})h_a'(p)\,\mathrm{d}p \\ &= \int_0^\infty f(h_a(p))e^{i\omega g_a(h_a(p))}(e^{i\omega(\tilde{g}(h_a(p))-g_a(h_a(p)))} - 1)h_a'(p)\,\mathrm{d}p \\ &= \frac{e^{i\omega g_a(a)}}{\omega}\int_0^\infty f\left(h_a\left(\frac{q}{\omega}\right)\right)e^{-q}(e^{i\omega(\tilde{g}(h_a(\frac{q}{\omega}))-g_a(h_a(\frac{q}{\omega})))} - 1)h_a'\left(\frac{q}{\omega}\right)\mathrm{d}q. \end{aligned} \tag{7.2}$$

The path $h_a(p)$ was chosen as the solution of (3.10) with respect to the approximation $g_a(x)$. Using a Taylor approximation around a, we have

$$\tilde{g}(x) - g_a(x) = (\tilde{g}^{(s+1)}(a) - g_a^{(s+1)}(a))\frac{(x-a)^{s+1}}{(s+1)!} + O((x-a)^{s+2}).$$

Because $h_a(q/\omega) - a \sim \omega^{-1}$, we have

$$e^{i\omega(\tilde{g}(h_a(q/\omega))-g_a(h_a(q/\omega)))} - 1 \sim i\omega(\tilde{g}(h_a(q/\omega)) - g_a(h_a(q/\omega))) \sim \omega^{-s}.$$

The error e is therefore of order $O(\omega^{-s-1})$. ∎

The value of $\tilde{I}$, defined by (7.1), is completely determined by the derivatives of $\tilde{g}$ at a and b. If $\tilde{I} - I$ is small, it follows from Theorem 7.1 that $\tilde{g}$ should satisfy $\tilde{g}^{(j)}(a) = g^{(j)}(a)$ and $\tilde{g}^{(j)}(b) = g^{(j)}(b)$, $j = 0, \dots, s$, for some maximal order s that depends on the smoothness of g. Hence, $\tilde{g}$ need not be explicitly constructed.

At a stationary point ξ, more derivatives are needed. The convergence rate depends on the minimal value of r for which $\tilde{g}^{(r+1)}(\xi) \neq 0$.

THEOREM 7.2. *Assume that f and $\tilde{g}$ are analytic and that $\tilde{g}^{(k)}(\xi) = 0$, $k = 1, \dots, r$, and $\tilde{g}^{(r+1)}(\xi) \neq 0$. Let $g_\xi(x)$ be the Hermite interpolating polynomial of degree $(s+1)(r+1)-1$ that satisfies*

$$g_\xi^{(k)}(\xi) = \tilde{g}^{(k)}(\xi), \quad k = 0, \dots, (s+1)(r+1)-1.$$

Then the approximation of $\tilde{F}_j(\xi)$ by $F_{g_\xi,j}(\xi)$ has an error of order $O(\omega^{-s-1/(r+1)})$.

Proof. The proof follows the same lines as the proof of Theorem 7.1. The difference is that, similar to the situation in the proof of Theorem 6.2, we have $h_{\xi,j}(q/\omega) - \xi \sim \omega^{-1/(r+1)}$ and $h_{\xi,j}'(q/\omega) \sim \omega^{r/(r+1)}$. This leads to

$$e^{i\omega(\tilde{g}(h_{\xi,j}(q/\omega))-g_\xi(h_{\xi,j}(q/\omega)))} - 1 \sim \omega^{-s}.$$

TABLE 7.1

Absolute error of the approximation of $\tilde{F}(a)$ by $F_a(a)$ for $f(x) = 1/(1+x)$ and $g(x) = (x - 1/2)^2(x-2)e^{x^2}$ at $a = 0$. We approximate g by interpolating m derivatives. The last row shows the value of $\log_2(e_{400}/e_{800})$: this value should approximate $m+1$.

$\omega \setminus m$	1	2	3	4
100	$6.1E-5$	$7.6E-7$	$1.3E-8$	$1.9E-10$

Rate	2.0	3.0	4.0	5.0

TABLE 7.2

Absolute error of the approximation of I by $\tilde{I}$ for $f(x) = 1/(1+x)$ and $g(x) = (x-1/2)^2(x-2)e^{x^2}$ on $[0,1]$. We approximate g by interpolating m derivatives. The last row shows the value of $\log_2(e_{400}/e_{800})$: this value should approximate $m/2$ for odd m and $(m+1)/2$ for even m.

$\omega \setminus m$	2	3	4
100	$1.6E-4$	$2.7E-4$	$1.8E-7$
200	$5.5E-5$	$9.8E-6$	$3.2E-8$
400	$2.0E-5$	$3.5E-6$	$5.6E-9$
800	$6.9E-6$	$1.2E-6$	$9.9E-10$
Rate	1.5	1.5	2.5

The error estimate for this case is analogous to (7.2) in the proof of Theorem 7.1. Adding all contributions, it is of order $O(\omega^{-1-s+r/(r+1)}) = O(\omega^{-s-1/(r+1)})$. □

Example 7.3. We illustrate the convergence with two examples. The function $g(x) = (x-1/2)^2(x-2)e^{x^2}$ is approximated by a polynomial of degree m in the endpoints $a = 0$ and $b = 1$, and in the stationary point $\xi = 1/2$. The resulting errors are displayed in Tables 7.1 and 7.2. Table 7.1 shows the error in approximating only $\tilde{F}(a)$. Table 7.2 shows the error of the approximation of I. The latter error is dominated by the error made at the stationary points but follows the theory. As in the last example for a nonanalytic function f, the convergence rate is actually higher for even m because the difference of the terms at ξ in the decomposition of I can have an order lower than predicted by Theorem 7.2. Note that it is not possible to approximate $g(x)$ by a fixed constant since in that case also $e^{i\omega g_a(x)} = e^{i\omega c}$ reduces to a constant. At a stationary point with r vanishing derivatives, the minimal number of derivatives to interpolate is $r+1$.

8. Concluding remarks. We have presented an approach to compute highly oscillatory integrals of the form (1.1). The method is quite general and leads to high order convergence when the frequency increases. The (generalized) Gauss–Laguerre quadrature rules yields the typical Gauss rule convergence exponent of approximately $2n$, but here as a function of $1/\omega$. This is made possible by transforming the integrand into a numerically well behaved one, i.e., one that is not oscillatory and that has exponential decay which becomes faster with increasing ω.

The approach by Iserles and Nørsett has led us to consider the use of Hermite interpolation for functions $f(x)$ that are not analytic. The resulting polynomial is analytic, and this enables the use of our rapidly converging complex approach. Owing to our decomposition of the integral into a sum of a number of functions that each depend only on one point, this approach could be simplified considerably in our setting. Vice versa, the methods developed in this paper may be used to compute generalized moments of the form $\int_0^1 p(x)e^{i\omega g(x)}\mathrm{d}x$ with $p(x)$ a polynomial of low degree. Such

moments are assumed to be available in the approach of Iserles and Nørsett, but an analytical value may not always be available. The details of the latter method can be found in [14].

Acknowledgments. The authors wish to thank Arieh Iserles and Sheehan Olver for many insightful discussions on the topic of oscillatory integrals (suggesting the term *numerical steepest descent* in the process) and to thank the anonymous referees for a number of helpful suggestions and references.

FULLY DISCRETE FINITE ELEMENT APPROXIMATIONS OF THE NAVIER–STOKES–CAHN-HILLIARD DIFFUSE INTERFACE MODEL FOR TWO-PHASE FLUID FLOWS*

XIAOBING FENG†

Abstract. This paper develops and analyzes some fully discrete finite element methods for a parabolic system consisting of the Navier–Stokes equations and the Cahn–Hilliard equation, which arises as a diffuse interface model for the flow of two immiscible and incompressible fluids. In the model the two sets of equations are coupled through an extra phase induced stress term in the Navier–Stokes equations and a fluid induced transport term in the Cahn–Hilliard equation. Fully discrete mixed finite element methods are proposed for approximating the coupled system, it is shown that the proposed numerical methods satisfy a mass conservation law, and a discrete energy law which is analogous to the basic energy law for the phase field model. The convergence of the numerical solutions to the solutions of the phase field model and its sharp interface limit is established by utilizing the discrete energy law. As a by-product, the convergence result also provides a constructive proof of the existence of weak solutions to the Navier–Stokes-Cahn–Hilliard phase field model. Numerical experiments are also presented to validate the theory and to show the effectiveness of the combined phase field and finite element approach.

Key words. two-phase fluids, phase field model, Cahn–Hilliard equation, Navier–Stokes equations, finite element methods

1. Introduction.

Interfacial dynamics in the mixture of different fluids, solids, or gas has been one of the fundamental issues in hydrodynamics and materials science. It plays an increasingly important role in many current scientific, engineering, and industrial applications (cf. [7, 15] and the references therein). In the classical approaches, the interface is usually considered as a free curve/surface that evolves in time along with fluid. The movement of the interface at each time is determined by a set of interfacial balance conditions. In the case of two immiscible incompressible fluids, the dynamics of the fluid mixture is described by the following two-phase Navier–Stokes equations:

$$\mathbf{u}_t - \nu\Delta\mathbf{u} + (\mathbf{u}\cdot\nabla)\mathbf{u} + \nabla p = \mathbf{g} \quad \text{in } \Omega_T \setminus \Gamma_t, \tag{1.1}$$

$$\text{div } \mathbf{u} = 0 \quad \text{in } \Omega_T \setminus \Gamma_t, \tag{1.2}$$

$$[(\nu D(\mathbf{u}) - pI)\mathbf{n}] = \alpha\kappa\mathbf{n} \quad \text{on } \Gamma_t, \tag{1.3}$$

$$[\mathbf{u}] = 0 \quad \text{on } \Gamma_t, \tag{1.4}$$

with a given set of initial and boundary conditions. Here $\Omega \subset \mathbf{R}^d\,(d = 1, 2, 3)$ is a bounded domain, $\Omega_T = \Omega \times (0, T)$, Γ_t denotes the (free) interface at the time t with the normal $\mathbf{n}$ and the mean curvature κ, $\alpha > 0$ is the surface tension constant. $D(\mathbf{u}) = \frac{1}{2}(\nabla\mathbf{u} + (\nabla\mathbf{u})^T)$ denotes the deformation tensor, I is the $d \times d$ identity matrix. $[\mathbf{u}]$ denotes the jump of the $\mathbf{u}$ across the interface Γ_t. Clearly, (1.3) and (1.4) are the

†Department of Mathematics, The University of Tennessee, Knoxville, TN 37996 (xfeng@math.utk.edu).

interfacial conditions for the fluid mixture, which are the mathematical descriptions of the balance of the normal stress and the balance of the movement.

Computationally, the above free interface problem is difficult to solve directly due to the existence of the surface tension on the interface. In addition, during the evolution the fluid interface may experience topological changes such as self-intersection, pinch-off, splitting, and fattening. When that happens, the classical solution of the free interface problem ceases to exist. In such a situation it is delicate and difficult to develop a proper notion of generalized solutions, it becomes even more challenging to compute the generalized solutions when they are defined.

To overcome the difficulties, an alternative approach for solving interface problems is the *diffuse interface (or mean field) theory*, which was originally developed as methodology for modeling and approximating solid-liquid phase transitions in which the effects of surface tension and nonequilibrium thermodynamic behavior may be important at the surface [28, 12, 24]. In the theory, the interface is represented as a thin layer of finite thickness. The method uses an auxiliary function (called phase field function/variable) to indicate the "phase." The phase-field function assumes distinct values in the bulk phases away from the interfacial regions over which the phase function varies smoothly, and the interface itself can be associated with an intermediate contour or level set of the phase function (cf. [32] and the references therein). The diffuse interface models converge to their corresponding sharp interface models as the width of the interfacial layer ε tends to zero.

This is the second paper in a series (cf. [18]) which devotes to finite element numerical analysis of two-phase fluid flows based on the phase field (diffuse interface) approach. In [18] finite element methods were developed and analyzed for the Navier–Stokes-Allen–Cahn phase field model proposed in. The goal of this paper is to carry out a parallel finite element numerical analysis for a mass-conserved diffuse interface model for two-phase fluids proposed in [27, 30], which consists of the Navier–Stokes equations and the Cahn–Hilliard equation. In the model the two sets of equations are coupled through an extra phase induced stress term in the Navier–Stokes equations and a fluid induced transport term in the Cahn–Hilliard equation. We develop and analyze some fully discrete mixed finite element methods for the Navier–Stokes-Cahn–Hilliard phase field model. It is proved that the proposed numerical methods satisfy a mass conservation law, and a discrete energy law which exactly mimics the basic energy law for the phase field model. The convergence of the numerical solutions to the solutions of the phase field model and its sharp interface limit is then established by utilizing the discrete energy law.

It should be noted that the Navier–Stokes-Cahn–Hilliard phase field model (in different forms, see section 2 for more details) for two phase fluids has been studied numerically by several authors [2, 3, 27, 30, 31], among them [27, 30] are most closely related to the current paper. In [27] Jacqmin derived the mathematical model based on physical arguments, and then proposed some finite difference compact schemes for the model. Impressive numerical experiments also were reported in the paper although no convergence analysis was given. In [30], inspired by their early experiences on the nematic liquid crystal flows, Liu and Shen rederived the Navier–Stokes-Cahn–Hilliard phase field model based on the (heuristic) mathematical arguments, and then proposed some Fourier-spectral element methods under the periodic assumptions. *Local-in-time* stability estimates were also established for the proposed Fourier-spectral element methods.

The remainder of this paper is organized as follows. In section 2, we present the mass conserved Navier–Stokes-Cahn–Hilliard phase field model for two-phase fluids

to be studied in this paper. We then demonstrate that various phase field models appeared in [27, 30] are actually mathematically equivalent up to an additive function to the pressure. However, it is shown later in this paper that numerically the phase field model in the potential form is favored since finite element methods based on this form are shown to fulfill a *global-in-time* energy (or stability) estimate which exactly mimics the basic energy law of the differential model. In section 3, we first re-establish the basic energy law (in a slightly different form) associated with the Navier–Stokes-Cahn–Hilliard phase field model, and then derive some additional a priori energy estimates which show explicit dependence on the physical parameters $\varepsilon, \lambda, \gamma$, and ν. In section 4, we propose and analyze a family of fully discrete mixed finite element methods for the phase field model. It is proved that the proposed numerical methods enjoy a discrete energy law which mimics the basic energy law for the differential problem. It is this discrete energy law which paves the way for us to establish the convergence of the fully discrete methods to the phase field model as the mesh sizes $h, \tau \to 0$, and to the sharp interface model (1.1)–(1.4) as the mesh sizes h, τ, and the capillary width ε all tend to zero, provided that the phase field model converges to the sharp interface model. Our main idea is to rewrite the flow equations in the potential form by introducing a new "pressure" $\overline{p} = p + \frac{\lambda}{2}|\nabla\varphi|^2 + \frac{\lambda}{\varepsilon^2}F(\varphi) + \lambda\varphi(\Delta\varphi - \frac{1}{\varepsilon^2}F'(\varphi))$ in the place of the original pressure p. As a by-product, our convergence result also provides a rigorous proof of the existence of weak solutions to the phase field model, which clearly is of interests in itself. Finally, in section 5 we present some numerical experiment results to validate our theoretical results and to show the effectiveness of the combined phase field and finite element approach.

2. The Navier–Stokes-Cahn–Hilliard phase field model. The phase field model for two immiscible and incompressible fluids with comparable densities (which are taken to be 1) and viscosities $\nu > 0$ to be studied in this paper takes the form [30, 3]

$$\mathbf{u}_t - \nu\Delta\mathbf{u} + (\mathbf{u}\cdot\nabla)\mathbf{u} + \nabla p + \lambda\,\mathrm{div}\,(\nabla\varphi\otimes\nabla\varphi) = \mathbf{g} \quad \text{in } \Omega_T, \tag{2.1}$$

$$\varphi_t + \mathbf{u}\cdot\nabla\varphi + \gamma\Delta\big(\Delta\varphi - \frac{1}{\varepsilon^2}f(\varphi)\big) = 0 \quad \text{in } \Omega_T, \tag{2.2}$$

$$\mathrm{div}\ \mathbf{u} = 0 \quad \text{in } \Omega_T. \tag{2.3}$$

To close the system, it will be complemented with the following initial and boundary conditions:

$$\mathbf{u}(\cdot,0) = \mathbf{u}_0^\varepsilon(\cdot), \qquad \varphi(\cdot,0) = \varphi_0^\varepsilon(\cdot), \qquad \text{in } \Omega, \tag{2.4}$$

$$\mathbf{u} = 0, \qquad \frac{\partial\varphi}{\partial\mathbf{n}} = \frac{\partial\Delta\varphi}{\partial\mathbf{n}} = 0, \qquad \text{on } \partial\Omega_T := \partial\Omega\times(0,T]. \tag{2.5}$$

Note that we have suppressed the superscript ε in $(\mathbf{u}^\varepsilon, \varphi^\varepsilon, p^\varepsilon)$ for the notation brevity. Here the vector $\mathbf{u}(x,t) \in \mathbf{R}^d$ and the scalar $p(x,t) \in \mathbf{R}$ denote the velocity and the pressure of the fluid mixture at the space time point (x,t), respectively. The scalar function φ is called a *phase function* and is used to indicate the fluid phases. φ assumes distinct values in the bulk phases away from a thin layer (called the interfacial region) over which φ varies smoothly, and the interface itself can be associated with the zero level set $\{\varphi = 0\}$ of φ ($f(\varphi) = F'(\varphi)$ and $F(\varphi) = \frac{1}{4}(\varphi^2-1)^2$). The positive constants λ, γ, and ε are the surface tension, the elastic relaxation time, and the capillary width (width of the interfacial layer), respectively. $\nabla\varphi\otimes\nabla\varphi$ stands for the $d\times d$ rank-one matrix $(\nabla\varphi)^T\nabla\varphi$ with entries $\varphi_{x_i}\varphi_{x_j}$. We especially note that $\varepsilon << 1$.

Equation (2.1) without the stress term $\lambda \text{div}\,(\nabla\varphi \otimes \nabla\varphi)$ is the Navier–Stokes equations [33] and (2.2) without the convection term $u \cdot \nabla\varphi$ is the Cahn–Hilliard equation [23, 32]. In the literature, the phase equation is always given by (2.2). On the other hand, the flow equations often appear differently in different papers due to how the phase induced force is expressed in the equations. In (2.1), since $\nabla\varphi \otimes \nabla\varphi$ is a phase induced stress tensor (its divergence represents the phase induced force), hence, we may regard (2.1) as the flow equations in the *stress form*. Using the differential identity

$$\text{div}\,(\nabla\varphi \otimes \nabla\varphi) = \Delta\varphi\nabla\varphi + \frac{1}{2}\nabla|\nabla\varphi|^2, \tag{2.6}$$

(2.1) can be rewritten as

$$\mathbf{u}_t - \nu\Delta\mathbf{u} + (\mathbf{u}\cdot\nabla)\mathbf{u} + \nabla\widehat{p} + \lambda\,\Delta\varphi\nabla\varphi = \mathbf{g}, \tag{2.7}$$

where

$$\widehat{p} := p + \frac{\lambda}{2}|\nabla\varphi|^2. \tag{2.8}$$

By introducing the *chemical potential* (cf. [11, 23, 32]),

$$w := -\Delta\varphi + \frac{1}{\varepsilon^2}f(\varphi), \tag{2.9}$$

and noticing the fact that $F'(\varphi) = f(\varphi)$, (2.7) can be rewritten as

$$\mathbf{u}_t - \nu\Delta\mathbf{u} + (\mathbf{u}\cdot\nabla)\mathbf{u} + \nabla\widetilde{p} - \lambda\, w\nabla\varphi = \mathbf{g}, \tag{2.10}$$

where

$$\widetilde{p} := \widehat{p} + \frac{\lambda}{\varepsilon^2}F(\varphi) = p + \frac{\lambda}{2}|\nabla\varphi|^2 + \frac{\lambda}{\varepsilon^2}F(\varphi). \tag{2.11}$$

It was based exactly on $(\mathbf{u}, \widetilde{p}, \varphi, w)$ formulation that convergent finite element methods were successfully developed in [18] for the related Navier–Stokes-Allen–Cahn phase field model of for two-phase fluids.

It is natural to ask if the success of [18] can be extended to the above Navier–Stokes-Cahn–Hilliard phase field model. It turns out (see section 4 for details) that one can show that mixed finite methods based on $(\mathbf{u}, \widetilde{p}, \varphi, w)$ formulation for the Navier–Stokes-Cahn–Hilliard phase field model do satisfy a discrete energy law which mimics the basic energy law associated with the phase field model. However, the numerical solutions may *not* satisfy the mass conservation law

$$\int_\Omega \varphi(x,t)\,dx = \int_\Omega \varphi(x,0)\,dx \qquad \forall t \in [0,T],$$

associated with the Navier–Stokes-Cahn–Hilliard phase field model (2.1)–(2.5).

To overcome the difficulty, we define another new "pressure" $\overline{p}$ as

$$\overline{p} := \widetilde{p} - \lambda\varphi w = p + \frac{\lambda}{2}|\nabla\varphi|^2 + \frac{\lambda}{\varepsilon^2}F(\varphi) + \lambda\varphi\Big(\Delta\varphi - \frac{1}{\varepsilon^2}F'(\varphi)\Big), \tag{2.12}$$

and rewrite (2.10) as

$$\mathbf{u}_t - \nu\Delta\mathbf{u} + (\mathbf{u}\cdot\nabla)\mathbf{u} + \nabla\overline{p} + \lambda\,\varphi\nabla w = \mathbf{g}, \tag{2.13}$$

which it turns out is exactly the flow equations proposed by Jacqmin in [27] using physical arguments. Since the phase induced force is expressed as the gradient of the chemical potential w, we may regard (2.13) as the flow equation in the *potential form*. We also note that with help of the chemical potential w, (2.2) can be rewritten as

$$\varphi_t + \mathbf{u} \cdot \nabla \varphi - \gamma \Delta w = 0. \tag{2.14}$$

Equations (2.9) and (2.14) is known as the mixed (or split) formulation for the Cahn–Hilliard equation (cf. [16, 19, 20]).

In section 4, we shall present some fully discrete mixed finite element methods for the Navier–Stokes-Cahn–Hilliard phase field model based on the $(\mathbf{u}, \overline{p}, \varphi, w)$ formulation, which consists of (2.13), (2.14), (2.3), and (2.9). It is shown that such numerical methods not only satisfy the global-in-time discrete energy law but also fulfill the mass conservation law. We like to emphasize that although the flow equations presented above all are mathematically equivalent, numerical methods based on these equations are often different, and the differences could be significant.

3. A priori energy estimates. The standard space notations are used in this paper; we refer to [1, 33] for their exact definitions. In particular, B^* denotes the dual space of a Banach space B, and $\mathbf{B}$ denotes the vector Banach space B^d. $(\cdot, \cdot)$ is used to denote the standard $L^2(\Omega)$ inner product, $\langle \cdot, \cdot \rangle$ stands for the dual product between $H_0^1(\Omega)$ and $H^{-1}(\Omega)$, and

$$L_0^2(\Omega) = \{q \in L^2(\Omega);\ (q, 1) = 0\},$$

$$\mathbf{V} = \{\mathbf{v} \in \mathbf{H}_0^1(\Omega);\ \text{div } \mathbf{v} = 0 \text{ in } \Omega\},$$

$$\mathbf{H} = \{\mathbf{v} \in \mathbf{L}^2(\Omega);\ \text{div } \mathbf{v} = 0 \text{ in } \Omega \text{ and } \mathbf{v} \cdot \mathbf{n}|_{\partial\Omega} = 0\}.$$

In addition, we use π to denote the L^2-orthogonal projection from $\mathbf{L}^2(\Omega)$ onto $\mathbf{H}$, and $\tilde{\Delta} = \pi\Delta$ to denote the Stokes operator (cf. [33]).

Throughout the paper, unless stated otherwise, c and C will be used to denote generic positive constants which is independent of $\mathbf{u}, p, \varphi$, and ε.

Existence and uniqueness (for $d = 2$) of weak solutions of system (2.1)–(2.3) were heuristically outlined in [30]. A key ingredient of the proof is to establish the basic energy law for the phase field model (see (3.9) below). In this section, we shall first reestablish the basic energy law in a slightly different form. We shall also derive some additional uniform (in ε) a priori estimates, in particular on $\mathbf{u}_t, \varphi_t$, and $\overline{p}$, for weak solutions to the system (2.1)–(2.3), which will be needed in section 4. Special attention will be given to tracing the explicit dependence of the a priori estimates on the capillary width ε, and the parameters λ and γ.

LEMMA 3.1. *Suppose that* $\mathbf{g} \in L^2((0,T); \mathbf{L}^2(\Omega))$*, and the initial values* $\mathbf{u}_0^\varepsilon$ *and* φ_0^ε *satisfy* $|\varphi_0^\varepsilon| \le 1$ *and* $\mathcal{J}_{\varepsilon,\lambda}(\mathbf{u}_0^\varepsilon, \phi_0^\varepsilon) < \infty$*, i.e., the initial energy is bounded, then every regular solution* $(\mathbf{u}, \varphi, p)$ *of system* (2.1)–(2.3) *satisfies the following estimates: for all* $T \in [0, \infty]$

$$\int_\Omega \varphi(x,t)\, dx = \int_\Omega \varphi_0^\varepsilon(x)\, dx \quad \forall t \in (0,T), \tag{3.1}$$

$$\operatorname*{ess\,sup}_{t\in[0,T]} \{\|\mathbf{u}(t)\|_{L^2}^2 + \lambda \|\nabla\varphi(t)\|_{L^2}^2 + \lambda\varepsilon^{-2}(F(\varphi(t)), 1)\} \le C, \tag{3.2}$$

$$\int_0^T \nu \,\|\nabla \mathbf{u}(t)\|_{L^2}^2\, dt + \left\{ \begin{array}{l} \displaystyle\int_0^T \lambda\gamma \,\|\nabla w(t)\|_{L^2}^2 \, dt \\ \displaystyle\int_0^T \lambda\gamma^{-1} \,\|\varphi_t(t) + \mathbf{u}(t)\cdot\nabla\varphi(t)\|_{H^{-1}}^2 \, dt \end{array} \right\} \le C, \tag{3.3}$$

$$\int_0^T \left\{ \|\mathbf{u}_t(t)\|_{V^*}^{\frac{12}{6+d}} + \|\mathbf{u}_t(t)\|_{(V\cap L^\infty)^*}^2 \right\} dt \le C, \tag{3.4}$$

$$\operatorname*{ess\,sup}_{t\in[0,T]} \left\| \int_0^t \overline{p}(s)\, ds \right\|_{L^2} \le C, \tag{3.5}$$

$$\int_0^T \|\varphi_t(t)\|_{H^{-1}}^2 \le C, \tag{3.6}$$

where $\overline{p} = p + \frac{\lambda}{2}|\nabla\varphi|^2 + \frac{\lambda}{\varepsilon^2}F(\varphi)$. *In addition, there holds*

$$\int_0^T \|\Delta\varphi(t)\|_{L^2}^2 \, dt \le C\,\varepsilon^{-2}, \tag{3.7}$$

$$\int_0^T \|\nabla\Delta\varphi\|_{L^2}^2 \, dt \le C\,\varepsilon^{-\frac{6(4+d)}{6-d}}. \tag{3.8}$$

Proof. Testing (2.1) with $\mathbf{u}$, (2.14) with $\lambda\gamma^{-1}\Delta^{-1}(\varphi_t + \mathbf{u}\cdot\nabla\varphi)$ or with w, (2.9) with φ_t, using the differential identity (2.6), and adding the resulting equations yield

$$\frac{d}{dt}\mathcal{J}_{\varepsilon,\lambda}(\mathbf{u},\varphi) + \nu\,\|\nabla\mathbf{u}\|_{L^2}^2 + \left\{ \begin{array}{l} \lambda\gamma\,\|\nabla w\|_{L^2}^2 \\ \nu\gamma^{-1}\,\|\varphi_t + \mathbf{u}\cdot\nabla\varphi\|_{H^{-1}} \end{array} \right\} = \int_\Omega \mathbf{g}\cdot\mathbf{u}\, dx, \tag{3.9}$$

where

$$\mathcal{J}_{\varepsilon,\lambda}(\mathbf{u},\varphi) := \int_\Omega \left[\frac{1}{2}|\mathbf{u}|^2 + \frac{\lambda}{2}|\nabla\varphi|^2 + \frac{\lambda}{\varepsilon^2}F(\varphi) \right] dx. \tag{3.10}$$

The identity (3.9) is known (cf. [27, 30]) as the basic energy law for the system (2.1)–(2.5).

Next, the estimates (3.2) and (3.3) follow easily from integrating (3.9) in t from 0 to T and using the inequality

$$|(\mathbf{g},\mathbf{u})| \le \frac{1}{4}\,\|\mathbf{u}\|_{L^2}^2 + \|\mathbf{g}\|_{L^2}^2.$$

To show (3.4), we test (2.13) with $\mathbf{v}\in\mathbf{V}\cap\mathbf{L}^\infty(\Omega)$ to get

$$\begin{aligned} (\mathbf{u}_t,\mathbf{v}) &= -\nu\,(\nabla\mathbf{u},\nabla\mathbf{v}) - ((\mathbf{u}\cdot\nabla)\mathbf{u},\mathbf{v}) - \lambda\,(\varphi\nabla w,\mathbf{v}) + (\mathbf{g},\mathbf{v}) \\ &\le \nu\,\|\nabla\mathbf{u}\|_{L^2}\,\|\nabla\mathbf{v}\|_{L^2} + \lambda\,\|\nabla w\|_{L^2}\,\|\varphi\|_{L^3}\,\|\mathbf{v}\|_{L^6} + \|\mathbf{g}\|_{L^2}\,\|\mathbf{v}\|_{L^2} \\ &\quad -((\mathbf{u}\cdot\nabla)\mathbf{u},\mathbf{v}). \end{aligned} \tag{3.11}$$

For the last term above we have

$$((\mathbf{u}\cdot\nabla)\mathbf{u},\mathbf{v}) \le C \left\{ \begin{array}{l} \|\nabla\mathbf{u}\|_{L^2}^{\frac{6+d}{6}}\,\|u\|_{L^2}^{\frac{6-d}{6}}\,\|\mathbf{v}\|_{L^6} + \|\nabla\mathbf{u}\|_{L^2}\,\|u\|_{L^2}\,\|\mathbf{v}\|_{L^6}, \\ \|\nabla\mathbf{u}\|_{L^2}\,\|u\|_{L^2}\,\|\mathbf{v}\|_{L^\infty}, \end{array} \right. \tag{3.12}$$

here we have used the interpolation inequality (cf. [1])

$$\|\mathbf{u}\|_{L^3} \le C\,\|\nabla\mathbf{u}\|_{L^2}^{\frac{d}{6}}\,\|\mathbf{u}\|_{L^2}^{\frac{6-d}{d}} + C\,\|\mathbf{u}\|_{L^2}\,. \tag{3.13}$$

Equation (3.4) then follows from combining (3.11), (3.12), (3.13), (3.2), and (3.3).

To verify (3.5), testing (2.13) with $\mathbf{v} \in \mathbf{H}_0^1(\Omega)$ and integrating the resulted equation in t from 0 to $\tau(\le T)$ yield

$$\left(\int_0^\tau p(t)dt, \operatorname{div}\mathbf{v}\right) = (\mathbf{u}(\tau) - \mathbf{u}_0, \mathbf{v}) + \nu\left(\int_0^\tau \nabla\mathbf{u}(t)dt, \nabla\mathbf{v}\right) + \left(\int_0^\tau (\mathbf{u}\cdot\nabla\mathbf{u})(t)dt, \mathbf{v}\right) - \lambda\left(\int_0^\tau (\varphi\nabla w)(t)dt, \mathbf{v}\right).$$

Using the estimates (3.2), (3.3), (3.11)–(3.13), and the Sobolev inequality (cf. [1]) we conclude that

$$\left(\int_0^\tau p(t)dt, \operatorname{div}\mathbf{v}\right) \le C\,\|\mathbf{v}\|_{H^1} \qquad \forall\mathbf{v} \in \mathbf{H}_0^1(\Omega). \tag{3.14}$$

Equation (3.5) then follows from (3.14) and an application of the inf-sup inequality (cf. [33]).

To show (3.6), we first notice that $\nabla w \in L^2(\Omega_T)$ implies that $\Delta w \in L^2((0,T); H^{-1})$. Then (3.6) follows from (2.14), (3.2), (3.3), and the following inequality:

$$\|\mathbf{u}\cdot\nabla\varphi\|_{L^{\frac{6}{5}}} \le \|\mathbf{u}\|_{L^3}\,\|\nabla\varphi\|_{L^2}\,.$$

To show (3.7), testing (2.9) with $\Delta\varphi$ we get

$$\begin{aligned}\|\Delta\varphi\|_{L^2}^2 &= -(w, \Delta\varphi) + \frac{1}{\varepsilon^2}(f(\varphi), \Delta\varphi) \le \|\nabla w\|_{L^2}\,\|\nabla\varphi\|_{L^2} - \frac{1}{\varepsilon^2}(f'(\varphi), |\nabla\varphi|^2)\\ &\le \left(\frac{1}{2} + \frac{1}{\varepsilon^2}\right)\|\nabla\varphi\|_{L^2}^2 + \frac{1}{2}\,\|\nabla w\|_{L^2}^2\,.\end{aligned}$$

Here we have used the fact that $f'(\varphi) = 3\phi^2 - 1$. The assertion then follows from the above inequality, (3.2), and (3.3).

Finally, applying the operator ∇ on both sides of (2.9) yields

$$\nabla\Delta\varphi = -\nabla w + \frac{1}{\varepsilon^2}f'(\varphi)\nabla\varphi = -\nabla w + \frac{3}{\varepsilon^2}\varphi^2\nabla\varphi - \frac{1}{\varepsilon^2}\nabla\varphi,$$

which, (3.2), (3.3), and the interpolation inequality (cf. [1])

$$\|\varphi\|_{L^\infty} \le C\left(\|\Delta\varphi\|_{L^2}^{\frac{d}{2(6-d)}}\,\|\varphi\|_{L^6}^{\frac{3(4-d)}{2(6-d)}} + \|\varphi\|_{L^6}\right)$$

imply that

$$\int_0^T \|\nabla\Delta\varphi\|_{L^2}^2\,dt \le C\big(1 + \varepsilon^{-4-\frac{2d}{6-d}}\big).$$

Hence, (3.8) holds. The proof is complete. ∎

Remark 3.1. (a) Compare with a priori estimates for the Navier–Stokes-Allen–Cahn phase field model obtained in [18], here for the Navier–Stokes-Cahn–Hilliard model we get better uniform estimates for w, $\mathbf{u}_t$, and $\overline{p}$. However, the estimate for φ_t is weaker.

(b) The estimate (3.1) is often known as the mass conservation property of the Cahn–Hilliard equation. It should be noted that this property does not hold for the Navier–Stokes-Allen–Cahn model.

(c) It is well known that no maximum principle holds for the fourth order Cahn–Hilliard equation. Although L^∞-estimate is known [10] for the Cauchy problem of the Cahn–Hilliard equation, to the best of our knowledge, it is not clear if such an estimate still holds for the initial-boundary value problem for the Cahn–Hilliard equation, in particular, with the presence of a flow. Hence, throughout this paper, we do *not* assume any L^∞-estimate for φ.

(d). We emphasize that the constant C in (3.2)–(3.8) is independent of T.

The next lemma derives a priori estimates in higher norms for $(\mathbf{u},\varphi)$ under stronger assumptions on the initial data $(\mathbf{u}_0^\varepsilon,\varphi_0^\varepsilon)$.

LEMMA 3.2. *In addition to the assumptions of Lemma* 3.1*, suppose that* $\mathbf{u}_0^\varepsilon\in\mathbf{V}$*,* $\varphi_0^\varepsilon\in H^2(\Omega)$*, then every regular solution* $(\mathbf{u},\varphi)$ *of problem* (2.1)–(2.3) *satisfies the following estimates: for any* $T\in(0,\infty)$

$$\operatorname*{ess\,sup}_{t\in[0,T]}\|\Delta\varphi(t)\|_{L^2}^2+\gamma\int_0^T\left\|\Delta^2\varphi(s)\right\|_{L^2}^2\,ds\le c_1\varepsilon^{-\frac{2d(18-d)}{d^2-24d+72}},\tag{3.15}$$

$$\int_0^T\left[\,\|\varphi_t(s)+\mathbf{u}(s)\cdot\nabla\varphi(s)\|_{L^2}^2+\gamma^2\,\|\Delta w(s)\|_{L^2}^2\,\right]ds\le c_2\varepsilon^{-\frac{2d(18-d)}{d^2-24d+72}},\tag{3.16}$$

$$\int_0^T\|\varphi_t(s)\|_{L^2}^2\,ds\le c_3\varepsilon^{-\frac{2d(18-d)}{d^2-24d+72}}.\tag{3.17}$$

Moreover, when $d=2$ *there also hold the following additional estimates:*

$$\operatorname*{ess\,sup}_{t\in[0,T]}\|\nabla\mathbf{u}\|_{L^2}^2+\nu\int_0^T\|\Delta\mathbf{u}(s)\|_{L^2}^2\,ds\le c_4\varepsilon^{-\frac{2d(18-d)}{d^2-24d+72}},\tag{3.18}$$

$$\int_0^T\left[\,\|\mathbf{u}_t(s)\|_{L^2}^2+\|\nabla\overline{p}(s)\|_{L^2}^2\,\right]ds\le c_5\varepsilon^{-\frac{2d(18-d)}{d^2-24d+72}}.\tag{3.19}$$

Here $c_j=c_j(u_0,\varphi_0,\nu,g,\lambda,\gamma,T)$ *for* $j=1,2,3,4,5$ *are some positive constants.*

Proof. Testing (2.2) with $\Delta^2\varphi$ and using Young's inequality yields

$$\frac{d}{dt}\|\Delta\varphi\|_{L^2}^2+\gamma\left\|\Delta^2\varphi\right\|_{L^2}^2\le\frac{\gamma}{\varepsilon^4}\|\Delta f(\varphi)\|_{L^2}^2+\frac{1}{\gamma}\|\mathbf{u}\cdot\Delta\varphi\|_{L^2}^2.\tag{3.20}$$

By (3.2) and the interpolation inequality (cf. [1]):

$$\|\nabla\varphi\|_{L^\infty}\le C\left\|\Delta^2\varphi\right\|_{L^2}^{\frac{d}{6}}\|\nabla\varphi\|_{L^2}^{\frac{6-d}{6}}+C\|\nabla\varphi\|_{L^2},$$

we have

$$\begin{aligned}\|\mathbf{u}\cdot\Delta\varphi\|_{L^2}^2&\le\|\mathbf{u}\|_{L^2}^2\|\nabla\phi\|_{L^\infty}^2\\&\le C\left\|\Delta^2\varphi\right\|_{L^2}^{\frac{d}{3}}\|\nabla\varphi\|_{L^2}^{\frac{6-d}{3}}+C\|\nabla\varphi\|_{L^2}^2\\&\le\frac{\gamma}{4}\left\|\Delta^2\varphi\right\|_{L^2}^2+C.\end{aligned}\tag{3.21}$$

To estimate the first term on the right-hand side of (3.20), using the differential identity

$$\Delta f(\varphi) = f'(\varphi)\Delta\varphi + f''(\varphi)|\nabla\varphi|^2,$$

we have

$$\|\Delta f(\varphi)\|_{L^2} \le 3\,\|\varphi\|_{L^\infty}^2\,\|\Delta\varphi\|_{L^2} + 6\,\|\varphi\|_{L^\infty}\,\|\nabla\varphi\|_{L^4}^2\,.$$

The above inequality, (3.2), and the interpolation inequalities (cf. [1])

$$\|\varphi\|_{L^\infty} \le C\left(\left\|\Delta^2\varphi\right\|_{L^2}^{\frac{d}{2(12-d)}}\,\|\varphi\|_{L^6}^{\frac{3(8-d)}{2(12-d)}} + \|\varphi\|_{L^6}\right) \tag{3.22}$$

$$\|\Delta\varphi\|_{L^2} \le C\left(\left\|\Delta^2\varphi\right\|_{L^2}^{\frac{d}{6}}\,\|\nabla\varphi\|_{L^2}^{\frac{6-d}{6}} + \|\nabla\varphi\|_{L^2}\right) \tag{3.23}$$

$$\|\nabla\varphi\|_{L^4} \le C\left(\left\|\Delta^2\varphi\right\|_{L^2}^{\frac{d}{12}}\,\|\nabla\varphi\|_{L^2}^{\frac{12-d}{12}} + \|\nabla\varphi\|_{L^2}\right), \tag{3.24}$$

imply that

$$\|\Delta f(\varphi)\|_{L^2} \le C\Big(\left\|\Delta^2\varphi\right\|_{L^2}^{\frac{d(18-d)}{6(12-d)}} + 1\Big) \le \varepsilon^2\sqrt{\frac{\gamma}{8}}\left\|\Delta^2\varphi\right\|_{L^2} + C\varepsilon^{-\frac{2d(18-d)}{d^2-24d+72}}. \tag{3.25}$$

Now (3.15) follows immediately from combining (3.20), (3.21), and (3.25).

Applying the operator Δ to both sides of (2.9) we get

$$\Delta w = -\Delta^2\varphi + \frac{1}{\varepsilon^2}\Delta f(\varphi).$$

It then follows from the above equation, (3.15), and (3.25) that

$$\int_0^T \|\Delta w(s)\|_{L^2}^2\,ds \le C\varepsilon^{-\frac{2d(18-d)}{d^2-24d+72}},$$

which (2.14) in turn implies that

$$\int_0^T \|\varphi_t(s) + \mathbf{u}(s)\cdot\nabla\varphi(s)\|_{L^2}^2\,ds \le C\varepsilon^{-\frac{2d(18-d)}{d^2-24d+72}}.$$

Hence, (3.16) holds.

Clearly, (3.17) is a trivial consequence of (3.16) and (3.21). To show (3.18), we test (2.13) with $-\Delta\mathbf{u}$ to get

$$\frac{1}{2}\frac{d}{dt}\|\nabla\mathbf{u}\|_{L^2}^2 + \nu\,\|\Delta\mathbf{u}\|_{L^2}^2 = ((\mathbf{u}\cdot\nabla)\mathbf{u}, \Delta\mathbf{u})) + \lambda\big(\varphi\nabla w, \Delta\mathbf{u}\big) - (\mathbf{g}, \Delta\mathbf{u}). \tag{3.26}$$

Using (3.2) and interpolation inequalities, three terms on the right-hand side of (3.26) can be bounded as follows:

$$\begin{aligned}\big|((\mathbf{u}\cdot\nabla)\mathbf{u}, \Delta\mathbf{u})\big| &\le \|\Delta\mathbf{u}\|_{L^2}\,\|\mathbf{u}\|_{L^4}\,\|\nabla\mathbf{u}\|_{L^4} \\ &\le C\,\|\Delta\mathbf{u}\|_{L^2}^{\frac{4+d}{4}}\,\|\mathbf{u}\|_{L^2}^{\frac{4-d}{4}}\,\|\nabla\mathbf{u}\|_{L^2}\,, \qquad \text{(see [33])} \\ &\le \frac{\nu}{4}\,\|\Delta\mathbf{u}\|_{L^2}^2 + C\,\|\nabla\mathbf{u}\|_{L^2}^{2+\frac{2d}{4-d}}\,,\end{aligned} \tag{3.27}$$

$$\begin{aligned}\big|\lambda(\varphi\nabla w, \Delta\mathbf{u})\big| &\le \|\Delta\mathbf{u}\|_{L^2}\,\|\nabla w\|_{L^4}\,\|\phi\|_{L^4} \\ &\le C\,\|\Delta\mathbf{u}\|_{L^2}\left\{\|\Delta w\|_{L^2}^{\frac{d}{4}}\,\|\nabla w\|_{L^2}^{\frac{4-d}{4}} + \|\nabla w\|_{L^2}\right\} \\ &\le \frac{\nu}{4}\,\|\Delta\mathbf{u}\|_{L^2}^2 + C\,\|\Delta w\|_{L^2}^2 + C\,\|\nabla w\|_{L^2}^2\,,\end{aligned} \tag{3.28}$$

$$\big|(\mathbf{g}, \Delta\mathbf{u})\big| \le \frac{\nu}{4}\left\|\Delta^2\mathbf{u}\right\|_{L^2}^2 + C\,\|\mathbf{g}\|_{L^2}^2\,. \tag{3.29}$$

For $d = 2$, (3.18) now follows from applying the Gronwall's inequality to (3.26) after substituting (3.27)–(3.29) into it.

Testing (2.13) with $\mathbf{u}_t$ and utilizing (3.2), (3.28), (3.29), and (3.18) we obtain

$$\int_0^T \|\mathbf{u}_t(s)\|_{L^2}^2 \, ds \le C\,\varepsilon^{-\frac{2d(18-d)}{d^2-24d+72}},$$

which together with (2.13), (3.18), and (3.27) in turn implies that

$$\int_0^T \|\nabla \overline{p}(s)\|_{L^2}^2 \, ds \le C\,\varepsilon^{-\frac{2d(18-d)}{d^2-24d+72}}.$$

Hence, (3.19) holds. The proof is complete. □

Remark 3.2. (a) When $d = 3$, estimates (3.18) and (3.19) only hold local in time as is the case for the Navier–Stokes equations (cf. [33]). In addition, the difficulty of extending these estimates to all times is caused exactly by the nonlinear term $(\mathbf{u}\cdot\nabla)\mathbf{u}$, not by the nonlinear coupling terms.

(b) Unlike the Navier–Stokes-Allen–Cahn model for two-phase fluids (cf. [18]), the higher order norm estimates for the solution of the Navier–Stokes-Cahn–Hilliard model depend on ε^{-1} only *polynomially*, instead of *exponentially*. This important fact may give the possibility to derive a priori error estimates, which depend on ε^{-1} polynomially, for numerical solutions to the Navier–Stokes-Cahn–Hilliard model; see section 4 for further discussions.

4. Fully discrete finite element approximations and convergence analysis. In this section, we shall first give the weak formulation of the problem (2.1)–(2.5) based on the mixed (or split) setting using variables $(\mathbf{u}, \overline{p}, \varphi, w)$. We then introduce a family of fully discrete finite element methods based on this mixed (or split) weak formulation. The implicit Euler time-stepping will be used as a prototype scheme for time discretization and for presenting the idea of our convergence analysis. Essentially, any stable finite element for the Navier–Stokes equations can be used for the spatial discretizations of $\mathbf{u}$ and $\overline{p}$, and any of Ciarlet–Raviart family of mixed elements for the biharmonic operator can be used for the spatial discretizations of φ and w. The highlight of this section is to establish a discrete energy law, which mimics exactly the basic energy law (3.9) for the Navier–Stokes-Cahn–Hilliard phase field model, for the proposed finite element methods. Utilizing this discrete energy law we then show the convergence of the numerical solutions to the weak solution of (2.13), (2.14), (2.3), and (2.9) as $h, \tau \to 0$, and to the solution of its sharp interface model (1.1)–(1.4) as $h, \tau, \varepsilon \to 0$, provided that the phase field model converges to the sharp interface model (cf. Conjecture 4.1).

4.1. Weak formulation. The mixed weak formulation of (2.13), (2.14), (2.3), and (2.9) used in this paper is defined as follows: Find $(\mathbf{u}, \overline{p}, \varphi, w)$ such that

$$\begin{aligned}
&\mathbf{u} \in L^\infty((0,T);\mathbf{L}^2(\Omega)) \cap L^2((0,T);\mathbf{H}_0^1(\Omega)) \cap L^2((0,T);\mathbf{V}^*),\\
&\int_0^t \overline{p}(s)ds \in L^\infty((0,T);L_0^2(\Omega)),\\
&\varphi \in L^\infty((0,T);H^1(\Omega)) \cap H^1((0,T);H^{-1}(\Omega)),\\
&w \in L^2((0,T);H^1(\Omega)),
\end{aligned}$$

and (2.13) holds in the distribution sense. Moreover, for all $(\mathbf{v}, q, \psi, \chi) \in \mathbf{V} \times L_0^2(\Omega) \times H^1(\Omega) \times H^1(\Omega)$ there hold

$$\langle \mathbf{u}_t, \mathbf{v}\rangle + \nu(\nabla \mathbf{u}, \nabla \mathbf{v}) + ((\mathbf{u}\cdot\nabla)\mathbf{u}, \mathbf{v}) + \lambda(\varphi \nabla w, \mathbf{v}) = (\mathbf{g}, \mathbf{v}), \tag{4.1}$$

$$(\text{div } \mathbf{u}, q) = 0, \tag{4.2}$$

$$\langle \varphi_t, \psi\rangle - (\varphi \mathbf{u}, \nabla\psi) + \gamma(\nabla w, \nabla\psi) = 0, \tag{4.3}$$

$$(\nabla\varphi, \nabla\chi) + \frac{1}{\varepsilon^2}(f(\varphi), \chi) = (w, \chi), \tag{4.4}$$

with the initial conditions $\mathbf{u}(0) = \mathbf{u}_0^\varepsilon$ and $\varphi(0) = \varphi_0^\varepsilon$.

Remark 4.1. (a) We note that the second term on the left-hand side of (4.3) is obtained after performing an integration by parts to the coupling term. It turns out this simple step is quite important for the construction of the finite element methods which not only satisfy the discrete energy law but also fulfill the mass conservation law (see Lemma 4.2).

(b) The well-posedness of (4.1)–(4.4) can be proved by the standard techniques such as the Galerkin method using a priori estimates derived in the previous section (cf. [33]). In fact, as a by-product, our convergence result (see section 4.3) also provides an alternative and constructive proof of the existence of weak solutions.

4.2. Formulation of fully discrete finite element method. Let $J_\tau = \{t_m\}_{m=0}^M$ be a quasi-uniform partition of $[0, T]$ of mesh size $\tau := \frac{T}{M}$, and $d_t v^m := (v^m - v^{m-1})/\tau$. Let $\mathcal{T}_h$ be a quasi-uniform "triangulation" of the domain Ω of mesh size $h \in (0, 1)$ and $\overline{\Omega} = \bigcup_{K\in\mathcal{T}_h} \overline{K}$ ($K \in \mathcal{T}_h$ are tetrahedrons in the case $d = 3$). For a nonnegative integer r, let $P_r(K)$ denote the space of polynomials of degree less than or equal to r on K. We introduce the finite element spaces

$$\begin{aligned}
M_h &= \{q_h \in L_0^2(\Omega);\ q_h|_K \in P_0(K)\},\\
\mathbf{X}_h &= \{v_h \in \mathbf{C}^0(\overline{\Omega}) \cap \mathbf{H}_0^1(\Omega);\ \mathbf{v}_h|_K \in \mathbf{P}_2(K)\},\\
\mathbf{V}_h &= \{\mathbf{v}_h \in \mathbf{X}_h;\ (\text{div } \mathbf{v}_h, q_h) = 0 \quad \forall q_h \in M_h\},\\
Y_h &= \{\psi_h \in C^0(\overline{\Omega});\ \psi_h|_K \in P_r(K),\ r \ge 1\}.
\end{aligned}$$

It is well known that [9, 25] the P_2-P_0 mixed finite element space $(\mathbf{X}_h, M_h)$ is a stable pair for the Navier–Stokes equations since it satisfies the inf-sup condition

$$\sup_{\mathbf{v}_h\in\mathbf{X}_h} \frac{(\text{div } \mathbf{v}_h, q_h)}{\|\nabla \mathbf{v}_h\|_{L^2}} \ge c\,\|q_h\|_{L^2} \qquad \forall q_h \in M_h. \tag{4.5}$$

Remark 4.2. The above finite element spaces $(\mathbf{X}_h, M_h)$ are chosen for the convenience of presentation, our convergence analysis in fact holds for *any* stable mixed finite element pairing (X_h, M_h) for the Navier–Stokes equations. In addition, the convergence analysis also holds for stabilized finite element approximations of the Navier–Stokes equations (cf. [9]).

It is also well known [13, 34, 16, 19] that $Y_h \times Y_h$ is a stable pair for the biharmonic operator and there holds the inf-sup condition

$$\sup_{\psi_h\in Y_h} \frac{(\nabla\psi_h, \nabla\chi_h)}{\|\psi_h\|_{H^1}} \ge c\,\|\chi_h\|_{H^1} \qquad \forall \chi_h \in Y_h. \tag{4.6}$$

We now are ready to introduce our fully discrete mixed finite element methods for problem (2.1)–(2.5). Find $\{(\mathbf{u}_h^m, \overline{p}_h^m, \varphi_h^m, w_h)\}_{m=1}^M \in \mathbf{X}_h \times M_h \times Y_h \times Y_h$ such that

for all $(\mathbf{v}_h, q_h, \psi_h, \chi_h) \in \mathbf{X}_h \times M_h \times Y_h \times Y_h$

$$(d_t\mathbf{u}_h^m, \mathbf{v}_h) + \nu\big(\nabla\mathbf{u}_h^m, \nabla\mathbf{v}_h\big) + ((\mathbf{u}_h^m \cdot \nabla)\mathbf{u}_h^m, \mathbf{v}_h) + \frac{1}{2}(\mathbf{u}_h^m \mathrm{div}\ \mathbf{u}_h^m, \mathbf{v}_h) - \big(\overline{p}_h^m, \mathrm{div}\ \mathbf{v}_h\big) + \lambda\big(\varphi_h^m \nabla w_h^m, \mathbf{v}_h\big) = (\mathbf{g}(t_m), \mathbf{v}_h), \tag{4.7}$$

$$\big(\mathrm{div}\ \mathbf{u}_h^m, q_h\big) = 0, \tag{4.8}$$

$$(d_t\varphi_h^m, \psi_h) - \big(\varphi_h^m\mathbf{u}_h^m, \nabla\psi_h\big) + \gamma\big(\nabla w_h^m, \nabla\psi_h\big) = 0, \tag{4.9}$$

$$(\nabla\varphi_h^m, \nabla\chi_h) + \frac{1}{\varepsilon^2}\big(f_h^m, \chi_h\big) = \big(w_h^m, \chi_h\big), \tag{4.10}$$

with the initial conditions $\mathbf{u}_h^0 = \mathbf{u}_{0h}$, and $\varphi_h^0 = \varphi_{0h}$. Here

$$f_h^m = \frac{1}{4}\big\{|\varphi_h^m|^2 + |\varphi_h^{m-1}|^2 - 2\big\}\big\{\varphi_h^m + \varphi_h^{m-1}\big\}, \tag{4.11}$$

Remark 4.3. (a) The f_h^m factor in the above scheme can be replaced by $\widetilde{f}_h^m := (\varphi_h^m)^3 - \varphi_h^{m-1}$. It is not hard to check that the resulted scheme will still satisfy an almost same discrete energy law that (to be given in the next subsection) satisfied by the above scheme, *provided* that a mesh constraint on τ is met (cf. section 3 of [19]).

(b) The solvability of (4.7)–(4.8) can be verified by using a fixed point argument in finite dimensional spaces (cf. [33]) and the discrete energy law to be given in the next subsection.

4.3. Convergence analysis. Since the phase field model couples two sets of well-known equations, the Navier–Stokes equations and the Cahn–Hilliard equation, it should not be hard to derive a priori error estimates for the above fully discrete mixed finite element schemes using the standard techniques as presented in [6, 25, 26, 33] and in [14, 17, 16]. However, since these standard techniques use the Gronwall type arguments at the end, the anticipated error estimates will definitely depend on $\frac{1}{\varepsilon}$ *exponentially*! Such error estimates clearly are not informative and have no practical usefulness for small ε. We refer interested readers to [19, 20] for more discussions in this direction.

One way to overcome this difficulty is to derive better error estimates which only depend on $\frac{1}{\varepsilon}$ *polynomially*, the best situation one can expect. For the Cahn–Hilliard equation, which is (2.2) with $\mathbf{u} = 0$, such error estimates were obtained in [19, 20] using a nonstandard technique. The key idea of this technique is to make use of a spectrum estimate result for the linearized Cahn–Hilliard operator (cf. [4] and the reference therein). In order to adapt this technique for analyzing the scheme (4.1)–(4.4), one needs a similar spectrum estimate result for the linearized operator associated with the coupled system (2.1)–(2.3). Unfortunately, to our knowledge, such a desired spectrum estimate has not been proved in the literature, although it is believed to be true.

In this paper, we shall take a different approach to address the convergence. Instead of proving the convergence by first establishing a rate of convergence (i.e., an error estimate), we shall prove the convergence directly. As expected, the crux of carrying out such a proof is to derive uniform (in ε) a priori estimates for the numerical solutions; in particular, to establish a discrete energy law, which must mimic the basic energy law (3.9). It should be noted that not every numerical method will meet such a criterion. The goal of this subsection is to prove that the fully discrete finite element method proposed in section 4.2 indeed is one exception. We verify our claim in the

next lemma by establishing a discrete counterpart of the basic energy law (3.9) for the numerical scheme (4.7)–(4.8).

LEMMA 4.1. *Let* $(\mathbf{u}_h^m, \overline{p}_h^m, \varphi_h^m, w_h^m)$ *solves* (4.7)–(4.10)*, then there holds that*

$$\mathcal{J}_{\varepsilon,\lambda}(\mathbf{u}_h^\ell, \varphi_h^\ell) + \tau \sum_{m=1}^{\ell} \Big[\frac{\tau}{2} \|d_t \mathbf{u}_h^m\|_{L^2}^2 + \frac{\tau\lambda}{2} \|d_t \nabla \varphi_h^m\|_{L^2}^2 + \nu \|\nabla \mathbf{u}_h^m\|_{L^2}^2 + \lambda\gamma \|\nabla w_h^m\|_{L^2}^2 \Big] = \tau \sum_{m=1}^{\ell} (\mathbf{g}(t_m), \mathbf{u}_h^m) + \mathcal{J}_{\varepsilon,\lambda}(\mathbf{u}_h^0, \varphi_h^0) \tag{4.12}$$

for all $0 \le \ell \le M$*. Here* $\mathcal{J}_{\varepsilon,\lambda}(\cdot,\cdot)$ *is defined by* (3.10)*.*

Proof. The desired estimate (4.12) follows from setting $\mathbf{v}_h = \mathbf{u}_h^m$ in (4.7), $q_h = \overline{p}_h^m$ in (4.8), $\psi_h = w_h^m$ in (4.9), $\chi_h = d_t \varphi_h^m$ in (4.10), adding the resulting equations, using the identities

$$\begin{aligned}
&(d_t \mathbf{u}_h^m, \mathbf{u}_h^m) = \frac{1}{2} \big\{ d_t \|\mathbf{u}_h^m\|_{L^2}^2 + \tau \|d_t \mathbf{u}_h^m\|_{L^2}^2 \big\},\\
&(d_t \nabla \mathbf{u}_h^m, \nabla \mathbf{u}_h^m) = \frac{1}{2} \big\{ d_t \|\nabla \mathbf{u}_h^m\|_{L^2}^2 + \tau \|d_t \nabla \mathbf{u}_h^m\|_{L^2}^2 \big\},\\
&((\mathbf{u}_h^m \cdot \nabla)\mathbf{u}_h^m, \mathbf{u}_h^m) + \frac{1}{2} (\mathbf{u}_h^m \mathrm{div}\ \mathbf{u}_h^m, \mathbf{u}_h^m) = 0,\\
&(d_t \varphi_h^m, f_h^m) = \frac{1}{4} d_t \big\| (\varphi_h^m)^2 - 1 \big\|_{L^2}^2 .
\end{aligned}$$

and applying the operator $\tau \sum_{m=1}^{\ell}$ to the combined equation. ∎

The discrete energy law immediately implies the following uniform (in ε) a priori estimates for $(\mathbf{u}_h^m, \overline{p}_h^m, \varphi_h^m, w_h^m)$.

LEMMA 4.2. *Let* $(\mathbf{u}_h^m, \overline{p}_h^m, \varphi_h^m, w_h^m)$ *solves* (4.7)–(4.10)*, and suppose that* $\mathbf{g} \in L^2((0,T); \mathbf{H}^{-1}(\Omega))$ *and there exists a positive constant* C_0 *such that* $\mathcal{J}_{\varepsilon,\lambda}(\mathbf{u}_0^\varepsilon, \varphi_0^\varepsilon) \le C_0$*, then there hold the following estimates:*

$$\int_\Omega \varphi_h^m \, dx = \int_\Omega \varphi_h^0, \qquad \text{for } m \ge 1, \tag{4.13}$$

$$\max_{0 \le m \le M} \big\{ \|\mathbf{u}_h^m\|_{L^2}^2 + \lambda \|\nabla \varphi_h^m\|_{L^2}^2 + \lambda \varepsilon^{-2} (F(\varphi_h^m), 1) \big\} \le C, \tag{4.14}$$

$$\sum_{m=1}^{M} \big[\big\|\mathbf{u}_h^m - \mathbf{u}_h^{m-1}\big\|_{L^2}^2 + \lambda \big\|\nabla \varphi_h^m - \nabla \varphi_h^{m-1}\big\|_{L^2}^2 \big] \le C, \tag{4.15}$$

$$\tau \sum_{m=1}^{M} \big[\nu \|\nabla \mathbf{u}_h^m\|_{L^2}^2 + \lambda\gamma \|\nabla w_h^m\|_{L^2}^2 \big] \le C, \tag{4.16}$$

$$\tau \sum_{m=1}^{M} \|d_t \mathbf{u}_h^m\|_{\mathbf{V}^*}^{\frac{12}{6+d}} \le C, \tag{4.17}$$

$$\max_{0 \le \ell \le M} \Big\| \tau \sum_{m=1}^{\ell} \overline{p}_h^m \Big\|_{L^2} \le C, \tag{4.18}$$

$$\tau \sum_{m=1}^{M} \|d_t \varphi_h^m\|_{H^{-1}}^2 \le C, \tag{4.19}$$

for some positive constant $C = C(\mathbf{g}, C_0)$*.*

Proof. Equation (4.13) follows from setting $\psi_h = 1$ in (4.9), and (4.14)–(4.19) are the immediate consequences of the discrete energy law (4.12).

To show (4.17), let P_h denote the L^2-projection operator from $\mathbf{L}^2(\Omega)$ to $\mathbf{V}_h$. For any $\mathbf{v} \in \mathbf{V}$ setting $\mathbf{v}_h = P_h\mathbf{v}$ in (4.7), using the stability property of P_h and an inverse inequality (cf. [13, 25]) we get

$$\begin{aligned}(d_t\mathbf{u}_h^m, \mathbf{v}) &= -\nu\big(\nabla\mathbf{u}_h^m, \nabla P_h\mathbf{v}\big) - \lambda\,(\varphi_h^m\nabla w_h^m, P_h\mathbf{v}) - ((\mathbf{u}_h^m\cdot\nabla)\mathbf{u}_h^m, P_h\mathbf{v})\\ &\qquad -\frac{1}{2}\,(\mathbf{u}_h^m \mathrm{div}\ \mathbf{u}_h^m, P_h\mathbf{v}) + (\mathbf{g}, P_h\mathbf{v})\\ &\le c\nu\,\|\nabla\mathbf{u}_h^m\|_{L^2}\,\|\nabla\mathbf{v}\|_{L^2} + \lambda\,\|\nabla w_h^m\|_{L^2}\,\|\varphi_h^m\|_{L^3}\,\|\mathbf{v}\|_{L^6}\\ &\qquad + \|\nabla\mathbf{u}_h^m\|_{L^2}\,\|\mathbf{u}_h^m\|_{L^3}\,\|\mathbf{v}\|_{L^6} + c\,\|\mathbf{g}\|_{H^{-1}}\,\|\nabla\mathbf{v}\|_{L^2}\\ &\le c\big\{\nu\,\|\nabla\mathbf{u}_h^m\|_{L^2} + \lambda\,\|\nabla w_h^m\|_{L^2} + \|\mathbf{g}\|_{H^{-1}}\big\}\,\|\nabla\mathbf{v}\|_{L^2}\\ &\qquad + \|\nabla\mathbf{u}_h^m\|_{L^2}^{\frac{6+d}{6}}\,\|\mathbf{u}_h^m\|_{L^2}^{\frac{6-d}{6}}\,\|\nabla\mathbf{v}\|_{L^2}\,.\end{aligned}$$

It follows from the above estimate and (4.14)–(4.16) that

$$\tau\sum_{m=1}^{M}\|d_t\mathbf{u}_h^m\|_{V^*}^{\frac{12}{6+d}} \le C.$$

Hence, (4.17) holds.

To show (4.18), we apply the operator $\tau\sum_{m=1}^{\ell}$ to (4.7) to get

$$\begin{aligned}\left(\tau\sum_{m=1}^{\ell}\overline{p}_h^m, \mathrm{div}\mathbf{v}_h\right) &= \big(\mathbf{u}_h^\ell - \mathbf{u}_h^0, \mathbf{v}_h\big) + \nu\left(\tau\sum_{m=1}^{\ell}\nabla\mathbf{u}_h^m, \nabla\mathbf{v}_h\right)\\ &\quad + \left(\tau\sum_{m=1}^{\ell}\left[(\mathbf{u}_h^m\cdot\nabla)\mathbf{u}_h^m + \frac{1}{2}\mathbf{u}_h^m\mathrm{div}\mathbf{u}_h^m\right], \mathbf{v}_h\right)\\ &\quad + \lambda\left(\tau\sum_{m=1}^{\ell}\varphi_h^m\nabla w_h^m, \mathbf{v}_h\right) - \left(\tau\sum_{m=1}^{\ell}\mathbf{g}(t_m), \mathbf{v}_h\right).\end{aligned}$$

It then follows from (4.14), (4.16), (3.12), (3.13), and the Sobolev inequality (cf. [1]) that

$$\left(\tau\sum_{m=1}^{\ell}\overline{p}_h^m, \mathrm{div}\mathbf{v}_h\right) \le C\,\|\mathbf{v}_h\|_{H^1} \qquad \forall\mathbf{v}_h \in \mathbf{X}_h. \tag{4.20}$$

Hence, (4.18) is an immediate consequence of (4.20) and the inf-sup inequality (4.5).

Finally, to show (4.19), for any $\psi \in H_0^1(\Omega)$ setting $\psi_h = Q_h\psi$ in (4.9), where Q_h denotes the L^2-projection from $L^2(\Omega)$ to Y_h, and using the stability property of the L^2-projection (cf. [8]) we get

$$\begin{aligned}(d_t\varphi_h^m, \psi) &= -\gamma\,(\nabla w_h^m, \nabla Q_h\psi) - (\mathbf{u}_h^m\cdot\nabla\varphi_h^m, \psi)\\ &\le c\gamma\,\|\nabla w_h^m\|_{L^2}\,\|\nabla\psi\|_{L^2} + \|\mathbf{u}_h^m\cdot\nabla\varphi_h^m\|_{L^{\frac{6}{5}}}\,\|\psi\|_{L^6}\\ &\le c\big\{\gamma\,\|\nabla w_h^m\|_{L^2} + \|\nabla\mathbf{u}_h^m\|_{L^2}\,\|\nabla\varphi_h^m\|_{L^2}\big\}\,\|\nabla\psi\|_{L^2}\,.\end{aligned}$$

Now, (4.19) follows immediately from the above estimate and (4.14)–(4.16). The proof is complete. ∎

Remark 4.4. The property (4.13) says that our numerical methods preserve the mass conservation law of the phase field model (cf. (3.1)). This property will be further validated numerically in section 5. We remark that such a mass conservation law does not hold for the Navier–Stokes-Cahn–Hilliard phase field model, nor does it for its numerical approximations developed in [18].

Let $(\mathbf{U}_{\varepsilon,h,\tau}(x,t), \Phi_{\varepsilon,h,\tau}(x,t))$ denote the piecewise linear interpolation (in t) of the fully discrete solution $\{(\mathbf{u}_h^m, \varphi_h^m)\}$, that is,

$$\mathbf{U}_{\varepsilon,h,\tau}(\cdot,t) := \frac{t-t_{m-1}}{\tau}\mathbf{u}_h^m(\cdot) + \frac{t_m-t}{\tau}\mathbf{u}_h^{m-1}(\cdot) \quad \forall t \in [t_{m-1}, t_m], \tag{4.21}$$

$$\Phi_{\varepsilon,h,\tau}(\cdot,t) := \frac{t-t_{m-1}}{\tau}\varphi_h^m(\cdot) + \frac{t_m-t}{\tau}\varphi_h^{m-1}(\cdot) \quad \forall t \in [t_{m-1}, t_m], \tag{4.22}$$

for $1 \le m \le M$, and let $\overline{P}_{\varepsilon,h,\tau}(x,t)$, $\overline{\mathbf{U}}_{\varepsilon,h,\tau}(x,t)$, $\overline{\Phi}_{\varepsilon,h,\tau}(x,t)$, and $\overline{W}_{\varepsilon,h,\tau}(x,t)$ denote the piecewise constant extensions of $\{\overline{p}_h^m\}$, $\{\mathbf{u}_h^m\}$, $\{\varphi_h^m\}$, and $\{w_h^m\}$, respectively. That is,

$$\overline{P}_{\varepsilon,h,\tau}(\cdot,t) := \overline{p}_h^m \qquad \forall t \in [t_{m-1}, t_m], \quad 1 \le m \le M, \tag{4.23}$$

$$\overline{\mathbf{U}}_{\varepsilon,h,\tau}(\cdot,t) := \mathbf{u}_h^m \qquad \forall t \in [t_{m-1}, t_m], \quad 1 \le m \le M, \tag{4.24}$$

$$\overline{\Phi}_{\varepsilon,h,\tau}(\cdot,t) := \varphi_h^m \qquad \forall t \in [t_{m-1}, t_m], \quad 1 \le m \le M, \tag{4.25}$$

$$\overline{W}_{\varepsilon,h,\tau}(\cdot,t) := w_h^m \qquad \forall t \in [t_{m-1}, t_m], \quad 1 \le m \le M. \tag{4.26}$$

We remark that $\mathbf{U}_{\varepsilon,h,\tau}(x,t)$ and $\Phi_{\varepsilon,h,\tau}(x,t)$ are continuous piecewise polynomial functions in space and time, $\overline{P}_{\varepsilon,h,\tau}(x,t)$, $\overline{\mathbf{U}}_{\varepsilon,h,\tau}(x,t)$, $\overline{\Phi}_{\varepsilon,h,\tau}(x,t)$, and $\overline{W}_{\varepsilon,h,\tau}(x,t)$ are right continuous at the nodes $\{t_m\}$.

The main result of this section is the following convergence theorem.

THEOREM 4.3. *Suppose the assumptions of Lemma* 4.2 *hold. For each fixed* $\varepsilon > 0$, *let* $(\mathbf{u}_*^\varepsilon, \overline{p}_*^\varepsilon, \varphi_*^\varepsilon, w_*^\varepsilon)$ *denote the unique solution of problem* (4.1)–(4.4), *and* $\{(\mathbf{U}_{\varepsilon,h,\tau}, \overline{P}_{\varepsilon,h,\tau}, \Phi_{\varepsilon,h,\tau}, \overline{W}_{\varepsilon,h,\tau})\}$ *be defined as above. Then we have*

$$\lim_{h,\tau\to 0}\Big(\|\mathbf{U}_{\varepsilon,h,\tau} - \mathbf{u}_*^\varepsilon\|_{L^2(L^2)} + \|\Phi_{\varepsilon,h,\tau} - \varphi_*^\varepsilon\|_{L^2(L^2)} + \big\|\overline{W}_{\varepsilon,h,\tau} - w_*^\varepsilon\big\|_{L^2(L^2)} \Big) = 0, \tag{4.27}$$

$$\int_0^t \overline{P}_{\varepsilon,h,\tau}(s) \longrightarrow \int_0^t \overline{p}_*^\varepsilon(s)ds \qquad \text{weakly } \star \text{ in } L^\infty((0,T); L^2(\Omega)). \tag{4.28}$$

Proof. Since the proof is long, we divide it into three steps.

Step 1*: Extracting convergent subsequences.* The estimates of Lemma 4.2 immediately give the following (uniform in h, τ and ε) estimates:

$$\big\|\overline{\mathbf{U}}_{\varepsilon,h,\tau}\big\|_{L^\infty(L^2)} + \sqrt{\lambda}\,\big\|\nabla\overline{\Phi}_{\varepsilon,h,\tau}\big\|_{L^\infty(L^2)} + \varepsilon^{-1}\sqrt{\lambda}\,\Big\|\overline{\Phi}_{\varepsilon,h,\tau}^2 - 1\Big\|_{L^\infty(L^2)} \le C, \tag{4.29}$$

$$\sqrt{\nu}\,\big\|\nabla\overline{\mathbf{U}}_{\varepsilon,h,\tau}\big\|_{L^2(L^2)} + \sqrt{\lambda\gamma}\,\big\|\nabla\overline{W}_{\varepsilon,h,\tau}\big\|_{L^2(L^2)} \le C, \tag{4.30}$$

$$\Big\|\frac{\partial}{\partial t}\mathbf{U}_{\varepsilon,h,\tau}\Big\|_{L^{\frac{12}{6+d}}(V^*)} \le C, \tag{4.31}$$

$$\Big\|\int_0^t \overline{P}_{\varepsilon,h,\tau}(s)ds\Big\|_{L^\infty(L^2)} \le C, \tag{4.32}$$

$$\Big\|\frac{\partial}{\partial t}\Phi_{\varepsilon,h,\tau}\Big\|_{L^2(H^{-1})} \le C. \tag{4.33}$$

Then there exists a convergent subsequence of $\{(\mathbf{U}_{\varepsilon,h,\tau}, \overline{P}_{\varepsilon,h,\tau}, \Phi_{\varepsilon,h,\tau}, \overline{W}_{\varepsilon,h,\tau})\}$ (still denote by the same notation) and a quadruple $(\mathbf{u}^\varepsilon, \overline{p}^\varepsilon, \varphi^\varepsilon, w^\varepsilon)$ such that

$$\begin{aligned}
&\mathbf{u}^\varepsilon \in L^\infty((0,T);\mathbf{L}^2(\Omega)) \cap L^2((0,T);\mathbf{H}_0^1(\Omega)) \cap H^1((0,T);\mathbf{V}^*),\\
&\varphi^\varepsilon \in L^\infty((0,T);H^1(\Omega)) \cap H^1((0,T);\mathbf{H}^{-1}(\Omega)),\\
&\int_0^t \overline{p}^\varepsilon(s)ds \in L^\infty((0,T);L_0^2(\Omega)),\\
&w^\varepsilon \in L^2((0,T);H^1(\Omega)),
\end{aligned}$$

and

$$\overline{\mathbf{U}}_{\varepsilon,h,\tau} \overset{h,\tau\searrow 0}{\longrightarrow} \mathbf{u}^\varepsilon \quad \begin{array}{l}\text{weakly}\star \text{ in } L^\infty((0,T);\mathbf{L}^2(\Omega)),\\ \text{strongly in } L^2((0,T);\mathbf{L}^2(\Omega)),\\ \text{weakly in } L^2((0,T);\mathbf{H}^1(\Omega)),\\ \text{weakly in } H^1((0,T);\mathbf{V}^*),\end{array} \tag{4.34}$$

$$\overline{\Phi}_{\varepsilon,h,\tau} \overset{h,\tau\searrow 0}{\longrightarrow} \varphi^\varepsilon \quad \begin{array}{l}\text{weakly}\star \text{ in } L^\infty((0,T);H^1(\Omega)),\\ \text{strongly in } L^2((0,T);L^2(\Omega)),\\ \text{weakly in } H^1((0,T);H^{-1}(\Omega)),\end{array} \tag{4.35}$$

$$\int_0^t \overline{P}_{\varepsilon,h,\tau}(s)ds \overset{h,\tau\searrow 0}{\longrightarrow} \int_0^t \overline{p}^\varepsilon(s)ds \quad \text{weakly } * \text{ in } L^\infty((0,T);L^2(\Omega)), \tag{4.36}$$

$$\overline{W}_{\varepsilon,h,\tau} \overset{h,\tau\searrow 0}{\longrightarrow} w^\varepsilon \quad \begin{array}{l}\text{weakly in } L^2((0,T);H^1(\Omega)),\\ \text{strongly in } L^2((0,T);L^2(\Omega)).\end{array} \tag{4.37}$$

From (4.15) we also have

$$\begin{aligned}
\big\|\mathbf{U}_{\varepsilon,h,\tau} - \overline{\mathbf{U}}_{\varepsilon,h,\tau}\big\|_{L^2(L^2)}^2 &= \sum_{m=1}^M \big\|\mathbf{u}_h^m - \mathbf{u}_h^{m-1}\big\|_{L^2}^2 \int_{t_{m-1}}^{t_m} \left(\frac{t-t_{m-1}}{\tau}\right)^2 dt\\
&= \frac{\tau}{3}\sum_{m=1}^M \big\|\mathbf{u}_h^m - \mathbf{u}_h^{m-1}\big\|_{L^2}^2 \overset{\tau\searrow 0}{\longrightarrow} 0,\\
\big\|\nabla(\Phi_{\varepsilon,h,\tau} - \overline{\Phi}_{\varepsilon,h,\tau})\big\|_{L^2(L^2)}^2 &= \frac{\tau}{3}\sum_{m=1}^M \big\|\nabla(\varphi_h^m - \phi_h^{m-1})\big\|_{L^2}^2 \overset{\tau\searrow 0}{\longrightarrow} 0.
\end{aligned}$$

Hence, the sequences $\{\mathbf{U}_{\varepsilon,h,\tau}\}$ and $\{\overline{\mathbf{U}}_{\varepsilon,h,\tau}\}$ converge to the same limit as $h,\tau \to 0$, so do the sequences $\{\Phi_{\varepsilon,h,\tau}\}$ and $\{\overline{\Phi}_{\varepsilon,h,\tau}\}$.

Step 2*: Passing to the limit.* We now want to pass to the limit in (4.7)–(4.10) and show that $(\mathbf{u}^\varepsilon, \overline{p}^\varepsilon, \varphi^\varepsilon, w^\varepsilon)$ is a weak solution of problem (4.1)–(4.4) with the initial values $\mathbf{u}^\varepsilon(0) = \mathbf{u}_0^\varepsilon$ and $\varphi^\varepsilon(0) = \varphi_0^\varepsilon$. To the end, we rewrite (4.7)–(4.10) as

$$\begin{aligned}
&((\mathbf{U}_{\varepsilon,h,\tau})_t, \mathbf{v}_h) + \nu\big(\nabla\overline{\mathbf{U}}_{\varepsilon,h,\tau}, \nabla\mathbf{v}_h\big) + \big((\overline{\mathbf{U}}_{\varepsilon,h,\tau}\cdot\nabla)\overline{\mathbf{U}}_{\varepsilon,h,\tau}, \mathbf{v}_h\big)\\
&\qquad + \frac{1}{2}\big(\overline{\mathbf{U}}_{\varepsilon,h,\tau}\mathrm{div}\ \overline{\mathbf{U}}_{\varepsilon,h,\tau}, \mathbf{v}_h\big) + \lambda\big(\overline{\Phi}_{\varepsilon,h,\tau}\nabla\overline{W}_{\varepsilon,h,\tau}, \mathbf{v}_h\big) = (\overline{\mathbf{g}}_\tau, \mathbf{v}_h),
\end{aligned} \tag{4.38}$$

$$\big(\mathrm{div}\ \overline{\mathbf{U}}_{\varepsilon,h,\tau}, q_h\big) = 0, \tag{4.39}$$

$$((\Phi_{\varepsilon,h,\tau})_t, \psi_h) - \big(\overline{\Phi}_{\varepsilon,h,\tau}\overline{\mathbf{U}}_{\varepsilon,h,\tau}, \nabla\psi_h\big) + \gamma\big(\nabla\overline{W}_{\varepsilon,h,\tau}, \nabla\psi_h\big) = 0, \tag{4.40}$$

$$\big(\nabla\overline{\Phi}_{\varepsilon,h,\tau}, \nabla\chi_h\big) + \frac{1}{\varepsilon^2}\big(\overline{f}_{\varepsilon,h,\tau}, \chi_h\big) = \big(\overline{W}_{\varepsilon,h,\tau}, \chi_h\big), \tag{4.41}$$

for $(\mathbf{v}_h, q_h, \psi_h, \chi_h) \in \mathbf{V}_h \times M_h \times Y_h \times Y_h$. Here $\overline{f}_{\varepsilon,h,\tau}$ and $\overline{g}_\tau$ denotes the constant extensions of $\{f_h^m\}$ and $\{\mathbf{g}(t_m)\}$, respectively.

For any $\eta \in C^0[0,T]$, we multiply (4.38)–(4.41) by η, respectively, and integrate the resulting equations in t from 0 to T to get

$$\begin{aligned}(4.42)\quad &\int_0^T \big[((\mathbf{U}_{\varepsilon,h,\tau})_t, \mathbf{v}_h) + \nu\big(\nabla\overline{\mathbf{U}}_{\varepsilon,h,\tau}, \nabla\mathbf{v}_h\big) + \big((\overline{\mathbf{U}}_{\varepsilon,h,\tau}\cdot\nabla)\overline{\mathbf{U}}_{\varepsilon,h,\tau}, \mathbf{v}_h\big)\big]\eta(t)dt \\ &+ \int_0^T \left[\frac{1}{2}\left(\overline{\mathbf{U}}_{\varepsilon,h,\tau}\mathrm{div}\ \overline{\mathbf{U}}_{\varepsilon,h,\tau}, \mathbf{v}_h\right) + \lambda\big(\overline{\Phi}_{\varepsilon,h,\tau}\nabla\overline{W}_{\varepsilon,h,\tau}, \mathbf{v}_h\big)\right]\eta(t)dt \\ &\qquad = \int_0^T (\overline{\mathbf{g}}_\tau, \mathbf{v}_h)\eta(t)dt,\end{aligned}$$

$$(4.43)\quad \int_0^T \big(\mathrm{div}\ \overline{\mathbf{U}}_{\varepsilon,h,\tau}, q_h\big)\eta(t)dt = 0,$$

$$(4.44)\quad \int_0^T \big[((\Phi_{\varepsilon,h,\tau})_t, \psi_h) - \big(\overline{\Phi}_{\varepsilon,h,\tau}\overline{\mathbf{U}}_{\varepsilon,h,\tau}, \nabla\psi_h\big) + \gamma\big(\nabla\overline{W}_{\varepsilon,h,\tau}, \nabla\psi_h\big)\big]\eta(t)dt = 0,$$

$$(4.45)\quad \int_0^T \left[\big(\nabla\overline{\Phi}_{\varepsilon,h,\tau}, \nabla\chi_h\big) + \frac{1}{\varepsilon^2}\left(\overline{f}_{\varepsilon,h,\tau}, \chi_h\right)\right]\eta(t)dt = \int_0^T \left(\overline{W}_{\varepsilon,h,\tau}, \chi_h\right)\eta(t)dt.$$

For any $(\mathbf{v}, q, \psi, \chi) \in \mathbf{V} \times L_0^2(\Omega) \times H^1(\Omega) \times H^1(\Omega)$, let $(\mathbf{v}_h, q_h, \varphi_h, \chi_h) \in \mathbf{V}_h \times M_h \times Y_h \times Y_h$ denote the standard finite element (nodal) interpolations of $(\mathbf{v}, q, \psi, \chi)$ in (4.42)–(4.45). Since

$$\begin{aligned}\mathbf{v}_h &\xrightarrow{h\searrow 0} \mathbf{v} \quad \text{strongly in } \mathbf{H}_0^1(\Omega),\\ q_h &\xrightarrow{h\searrow 0} q \quad \text{strongly in } L_0^2(\Omega),\\ \psi_h &\xrightarrow{h\searrow 0} \psi \quad \text{strongly in } H^1(\Omega),\\ \chi_h &\xrightarrow{h\searrow 0} \chi \quad \text{strongly in } H^1(\Omega),\end{aligned}$$

setting $h, \tau \to 0$ in (4.42)–(4.45) and using(4.34)–(4.37) we get $\mathbf{u}^\varepsilon(0) = \mathbf{u}_0^\varepsilon$, $\varphi^\varepsilon(0) = \varphi_0^\varepsilon$, and

$$\begin{aligned}&\int_0^T \left[\langle \mathbf{u}_t^\varepsilon, \mathbf{v}\rangle + \nu\big(\nabla\mathbf{u}^\varepsilon, \nabla\mathbf{v}\big) + ((\mathbf{u}^\varepsilon\cdot\nabla)\mathbf{u}, \mathbf{v}) + \frac{1}{2}\left(\mathbf{u}^\varepsilon\mathrm{div}\ \mathbf{u}^\varepsilon, \mathbf{v}\right)\right]\eta(t)dt \\ &\qquad + \lambda\int_0^T \big(\varphi^\varepsilon\nabla w^\varepsilon, \mathbf{v}\big)\eta(t)dt = \int_0^T (\mathbf{g}, \mathbf{v})\,\eta(t)dt,\\ &\int_0^T (\mathrm{div}\ \mathbf{u}^\varepsilon, q)\,\eta(t)dt = 0,\\ &\int_0^T \big[\langle\varphi_t, \psi\rangle - \big(\varphi^\varepsilon\mathbf{u}^\varepsilon, \nabla\psi\big) + \gamma\big(\nabla w^\varepsilon, \nabla\psi\big)\big]\eta(t)dt = 0,\\ &\int_0^T \left[(\nabla\varphi^\varepsilon, \nabla\chi) + \frac{1}{\varepsilon^2}\big(f(\varphi^\varepsilon), \chi\big)\right]\eta(t)dt = \int_0^T (w^\varepsilon, \chi)\,\eta(t)dt,\end{aligned}$$

which is equivalent to (4.1)–(4.4) since $C^0[0,T]$ is dense in $L^2(0,T)$. In addition, it is easy see that $(\mathbf{u}^\varepsilon, \overline{p}^\varepsilon, \varphi^\varepsilon, w^\varepsilon)$ satisfies (2.13) in the distribution sense. Hence, $(\mathbf{u}^\varepsilon, \overline{p}^\varepsilon, \varphi^\varepsilon, w^\varepsilon)$ is a weak solution of (4.1)–(4.4).

Step 3*: Finishing up.* We have shown above that $\{(\mathbf{U}_{\varepsilon,h,\tau}, \overline{P}_{\varepsilon,h,\tau}, \Phi_{\varepsilon,h,\tau}, \overline{W}_{\varepsilon,h,\tau})\}$ has a convergent subsequence and its limit $(\mathbf{u}^\varepsilon, \overline{p}^\varepsilon, \varphi^\varepsilon, w^\varepsilon)$ is a weak solution of (4.1)–(4.4). By the uniqueness, we have $\mathbf{u}^\varepsilon = \mathbf{u}^\varepsilon_*, \overline{p}^\varepsilon = \overline{p}^\varepsilon_*, \varphi^\varepsilon = \varphi^\varepsilon_*$, and $w^\varepsilon = w^\varepsilon_*$. Moreover, the proof also implies that the limit of *every* convergent subsequence of $\{(\mathbf{U}_{\varepsilon,h,\tau}, \overline{P}_{\varepsilon,h,\tau}, \Phi_{\varepsilon,h,\tau}, \overline{W}_{\varepsilon,h,\tau})\}$ must be a weak solution of (4.1)–(4.4). Hence, the whole sequence $\{(\mathbf{U}_{\varepsilon,h,\tau}, \overline{P}_{\varepsilon,h,\tau}, \Phi_{\varepsilon,h,\tau}, \overline{W}_{\varepsilon,h,\tau})\}$ converge to the unique weak solution $(\mathbf{u}^\varepsilon_*, \overline{p}^\varepsilon_*, \varphi^\varepsilon_*, w^\varepsilon_*)$. The proof is complete. ∎

Remark 4.5. We remark that since the phase field model (2.13), (2.14), (2.3), and (2.9) contains the Navier–Stokes equations, in general, one cannot expect any better results than those for the Navier–Stokes equations. Hence, the uniqueness assumption on the solution $(\mathbf{u}^\varepsilon_*, \overline{p}^\varepsilon_*, \varphi^\varepsilon_*, w^\varepsilon_*)$ can only be justified when $d = 2$. For the case $d = 3$, it can be shown that (2.13), (2.14), (2.3), and (2.9) has a unique local-in-time classical solution, hence, we assume that the uniqueness is understood local-in-time when $d = 3$. Clearly, without the uniqueness assumption *Step* 3 of the above proof does not stand anymore, hence, the convergence stated in Theorem 4.3 only holds for a subsequence, instead of the whole sequence, of $\{(\mathbf{U}_{\varepsilon,h,\tau}, \overline{P}_{\varepsilon,h,\tau}, \Phi_{\varepsilon,h,\tau}, \overline{W}_{\varepsilon,h,\tau})\}$.

We now recall that the following convergent result was conjectured in [27, 30], and we also believe it should be true.

CONJECTURE 4.1. *Assume that the sharp interface problem* (1.1)–(1.4) *has a unique regular solution* (u_*, p_*)*. Under the assumptions of Theorem* 4.3 *there hold*

$$\lim_{\varepsilon\to 0} \|\mathbf{u}^\varepsilon_* - u_*\|_{L^2(L^2)} = 0, \tag{4.46}$$

$$\int_0^t \overline{p}^\varepsilon_*(s)\,ds \overset{\varepsilon\searrow 0}{\longrightarrow} \int_0^t p_*(s)\,ds \qquad \textit{weakly} * \textit{ in } L^\infty((0,T); L^2(\Omega)), \tag{4.47}$$

$$\varphi^\varepsilon_* \overset{\varepsilon\searrow 0}{\longrightarrow} \pm 1 \qquad \textit{a.e. in } \Omega_t^\pm \times (0,T). \tag{4.48}$$

Here Ω_t^+ *and* Ω_t^- *denote the outside and inside of* Γ_t *in* Ω *at time* t*, respectively.*

An immediate consequence of Theorem 4.3 and Conjecture 4.1 is the following convergence theorem.

THEOREM 4.4. *Under the assumptions of Conjecture* 4.1 *there hold*

$$\lim_{\varepsilon\to 0} \lim_{h,\tau\to 0} \|U_{\varepsilon,h,\tau} - u_*\|_{L^2(L^2)} = 0, \tag{4.49}$$

$$\int_0^t \overline{P}_{\varepsilon,h,\tau}(s)\,ds \overset{\varepsilon\searrow 0}{\longrightarrow} \int_0^t p_*(s)\,ds \qquad \textit{weakly} * \textit{ in } L^\infty((0,T); L^2(\Omega)), \tag{4.50}$$

$$\Phi_{\varepsilon,h,\tau} \overset{\varepsilon,h,\tau\searrow 0}{\longrightarrow} \pm 1 \qquad \textit{a.e. in } \Omega_t^\pm \times (0,T). \tag{4.51}$$

Remark 4.6. (a) The convergence result of Theorem 4.3 essentially guarantees that the numerical solution $(\mathbf{U}_{\varepsilon,h,\tau}, \overline{P}_{\varepsilon,h,\tau}, \Phi_{\varepsilon,h,\tau}, \overline{W}_{\varepsilon,h,\tau})$ enjoys the same kind convergence to the solution $(\mathbf{u}_*, p_*)$ of the sharp interface problem (1.1)–(1.4) as the phase field solution $(\mathbf{u}^\varepsilon_*, \overline{p}^\varepsilon_*, \varphi^\varepsilon_*, w^\varepsilon_*)$ of (2.13), (2.14), (2.3), and (2.9) does.

(b) We remark that the analogue of convergence result (4.50) for the pressure does not hold for the Navier–Stokes-Allen–Cahn model (cf. [18]). However, this result holds for the Navier–Stokes-Cahn–Hilliard model due to the uniform (in ε) estimate (4.18).

5. Numerical experiments. In this section we provide some 2-D numerical experiments to gauge the fully discrete finite element method developed in the previous sections. In addition, our numerical results reveal some interesting features such

as shrinking, splitting, and merging of fluid interfaces governed by the phase field model (2.13), (2.14), (2.3), and (2.9). In all numerical experiments to be given in the following, we choose $\Omega = [-0.4, 0.4]^2$, $\varepsilon = 10^{-2}$, $\nu = 1$, $\lambda = \gamma = 0.1$, $\mathbf{g} = (1, 0)^t$, $u_0^\varepsilon \equiv 0$, while the initial condition for ϕ is specified in each test. Also, in order to resolve the diffuse interface, we use $\tau = 10^{-5}$ and unstructured spatial meshes with the minimum triangle size $h = 10^{-4}$ in all experiments.

Test 1. In this test, we take the following initial condition for φ:

$$\varphi_0^\varepsilon(x) = \tanh\left(\frac{x_1^2}{0.01} + \frac{x_2^2}{0.0225} - 1\right).$$

Note that the zero level set of φ_0^ε, which gives the initial fluid interface, is the ellipse $\frac{x_1^2}{0.01} + \frac{x_2^2}{0.0225} = 1$. Hence, we have the situation of one elliptical fluid bubble inside another fluid.

Figure 5.1 shows snapshots of color and zero-level set plots of the computed phase function ϕ_h^m at six time steps. In the figure, the red color stands for $\phi_h^m = 1$, the blue color stands for $\phi_h^m = -1$, and the black curve represents the zero-level set of the computed phase function. We notice that the elliptical bubble quickly deforms into a circular bubble while the total mass (the integral of ϕ_h^m over Ω) remains constant in time. In the test, we have

$$\int_\Omega \phi_h^m \, dx \equiv 0.54538 \qquad \text{for } m = 1, 2, \ldots, M.$$

The shape and size of the circular bubble remains unchanged, it should eventually be stabilized (i.e., converge to a stationary solution) due to the dissipative mechanism of the phase field model (2.13), (2.14), (2.3), and (2.9) (cf. Lemma 3.1). We also remark that the interface (zero-level set of φ_h^m) movement is very similar to that of the zero-level set of the solution to the Cahn–Hilliard equation (the equation obtained by setting $u \equiv 0$ in (2.2)) (cf. [21, 22]). As expected, here the zero-level set is pushed to the right by the fluid flow (through the convective term $u \cdot \nabla \phi$) while it is approaching the equilibrium state.

Figure 5.2 displays snapshots of the arrow and streamline plots of the computed velocity field u_h^m at six time steps. The black ellipse in the center of each snapshot stands for the initial fluid interface (i.e., the zero-level set of ϕ_0^ε). We notice that fluid vertices are formed shortly after the initial time step, and the vertices become stronger as the time goes on.

Test 2. In this test, the initial profile of the phase function is taken as

$$\varphi_0^\varepsilon(x) = \tanh\left(\frac{1}{\varepsilon}\left(\frac{x_1^2}{0.0064} + \frac{x_2^2}{0.0225} - 1\right)\left(\frac{x_1^2}{0.0225} + \frac{x_2^2}{0.0064} - 1\right)\right).$$

Note that the zero level set of φ_0^ε, which gives the initial fluid interface, is the union of the following two intersecting ellipses: $\frac{x_1^2}{0.0064} + \frac{x_2^2}{0.0225} = 1$ and $\frac{x_1^2}{0.0225} + \frac{x_2^2}{0.0064} = 1$, which enclose four bullethead-like bubbles inside a fluid.

Figure 5.3 shows snapshots of color and zero-level set plots of the computed phase function φ_h^m at fifteen time steps. Again, the red color stands for $\varphi_h^m = 1$, the blue color stands for $\varphi_h^m = -1$, and the black curve represents the zero-level set of the computed phase function. In this test, we see the fluid bubble first splits into four bubbles, they then deform into four circular bubbles, and finally merge to form a

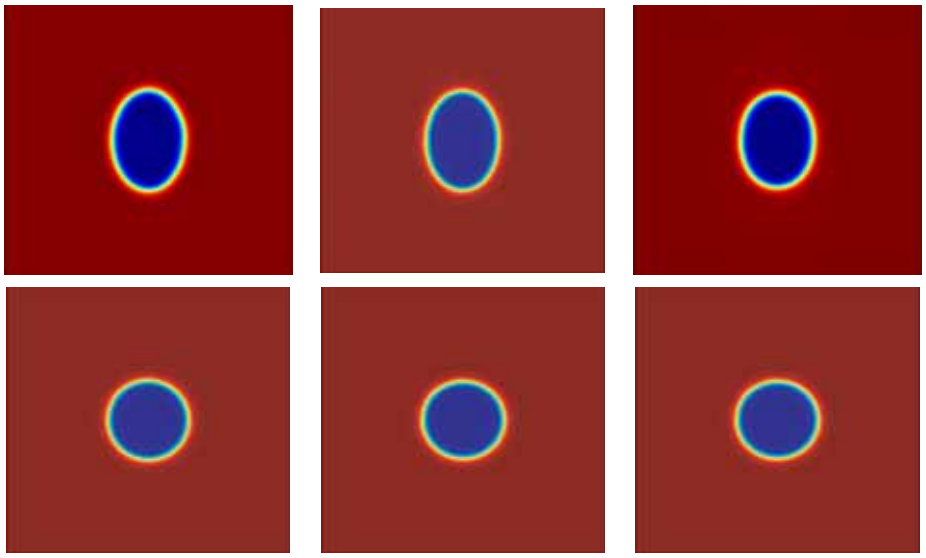

FIG. 5.1. *Color and zero-level set plots of computed phase function* φ_h^m *at* $t_m = 10^{-7}$, $1.1 \times 10^{-6}, 10^{-5}, 10^{-4}, 5 \times 10^{-4}, 10^{-3}$. *The graphs are arranged row-wise.*

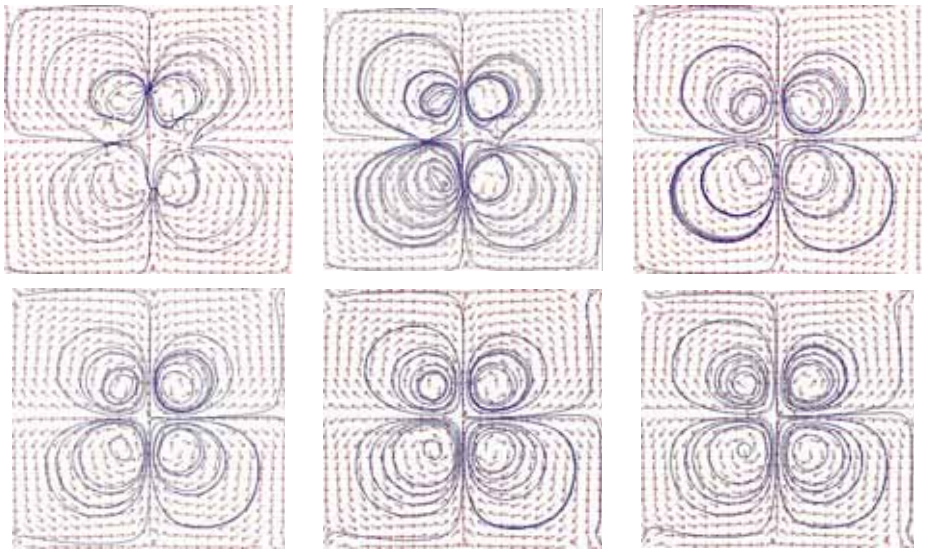

FIG. 5.2. *Arrow and streamline plots of computed velocity field* u_h^m *at* $t_m = 10^{-7}, 1.1 \times 10^{-6}$, $5 \times 10^{-5}, 2 \times 10^{-4}, 5 \times 10^{-4}, 10^{-3}$. *The graphs are arranged row-wise.*

bigger circular bubble which eventually stabilizes. During the evolution, the total mass (the integral of ϕ_h^m over Ω) remains constant in time. In the test, we have

$$\int_\Omega \phi_h^m \, dx \equiv 0.58313 \qquad \text{for } m = 1, 2, \ldots, M.$$

As expected, the interface (zero-level set of φ_h^m) movement is very similar to that of the zero-level set of the solution to the Cahn–Hilliard equation (the equation obtained

by setting $u \equiv 0$ in (2.2)) (cf. [21, 22]), and it is pushed very slowly off the center to the right by the fluid flow (through the convective term $u \cdot \nabla\varphi$). Another noticeable difference is that, unlike the dynamics of the zero-level set of the solution to the Cahn–Hilliard equation, here the four bullethead-like bubbles seem to evolve at slightly different speed and the bottom bubble disappears a couple of time steps earlier than the top one, which in turn is taken a couple of time steps earlier than the left bubble. We think that this phenomenon is caused by the fluid flow through the convective term $u \cdot \nabla\varphi$.

Figure 5.4 displays snapshots of the arrow and streamline plots of the computed velocity field u_h^m at nine time steps. The black ellipses in the center of each snapshot stand for the initial fluid interface (i.e., the zero-level set of φ_0^ε). We notice that fluid vertices are formed shortly after the initial time step, and more vertices are produced as the time goes on.

FAST RECONSTRUCTION METHODS FOR BANDLIMITED FUNCTIONS FROM PERIODIC NONUNIFORM SAMPLING*

THOMAS STROHMER† AND JARED TANNER‡

Abstract. A well-known generalization of Shannon's sampling theorem states that a bandlimited function can be reconstructed from its periodic nonuniformly spaced samples if the effective sampling rate is at least the Nyquist rate. Analogous to Shannon's sampling theorem this generalization requires that an infinite number of samples be available, which, however, is never the case in practice. Most existing reconstruction methods for periodic nonuniform sampling yield very low order (often not even first order) accuracy when only a finite number of samples is given. In this paper we propose a fast, numerically robust, root-exponential accurate reconstruction method. The efficiency and accuracy of the algorithm is obtained by fully exploiting the sampling structure and utilizing localized Fourier analysis. We discuss applications in analog-to-digital conversion where nonuniform periodic sampling arises in various situations. Finally, we demonstrate the performance of our algorithm by numerical examples.

Key words. Shannon's sampling theorem, oversampling, nonuniform periodic sampling, analog-to-digital conversion, Gevrey regularity, uniform interleaved sampling

1. Introduction.

The classical Shannon sampling theorem plays a crucial role in signal processing and communications, indicating how to transfer between analog signals and discrete sequences [26]. Shannon's sampling theorem states that if a function[1] belongs to the space of bandlimited functions B_σ, i.e.,

$$f(t) := \frac{1}{\sqrt{2\pi}} \int_{-\sigma}^{\sigma} e^{2\pi i w t} F(w) dw, \qquad F(w) \in L_0^2[-\sigma, \sigma], \tag{1.1}$$

then it can be recovered exactly from its equidistant samples

$$f(t) \equiv \sum_{k=-\infty}^{\infty} f\left(\frac{k}{2\sigma}\right) \frac{\sin(2\pi\sigma t - \pi k)}{2\pi\sigma t - \pi k} := \sum_{k=-\infty}^{\infty} f\left(\frac{k}{2\sigma}\right) \operatorname{sinc}(2\pi\sigma t - \pi k). \tag{1.2}$$

Shannon's sampling theorem assumes that an infinite number of samples is available, which is of course never true in practice. Truncation of the cardinal series (1.2) results in rather poor approximation of the original bandlimited signal, and the truncation error is of the unacceptable low order of $1/\sqrt{L}$, where L is the number of samples; cf. [26]. In the presence of noise or quantization errors convergence may even break down completely [4]. To avoid these problems in practice, one usually

[1]Throughout this paper we will use lowercase letters to designate functions in the time domain, and uppercase for the Fourier transform of the same function.

resorts to oversampling of the signal, since this gives rise to vastly better convergence rates and as a result greater robustness to noise.

While oversampling is therefore desirable in practice, it is not always easily done in real world applications. For example, consider advanced wireless communication systems, where demand for data rate is steadily increasing, requiring communication systems that use transmission signals with a (baseband) bandwidth in the range of tens of megahertz up to one gigahertz (as in currently developed ultrawideband systems). Such a huge bandwidth necessitates very high sampling rates in the analog-to-digital conversion which puts enormous demands on the analog sampling devices. While it is possible to construct signal acquisition systems that sample a signal even at nanosecond scales with high precision, such devices become increasingly expensive. More specifically, a linear increase in precision of a sampling device often goes hand in hand with a superlinear increase in the costs of constructing such a device.

One possible way to remedy this problem is to combine several analog-to-digital converters (ADCs) with lower sampling rate to obtain one virtual sensor with high sampling rate. We describe this concept in more detail. A standard ADC uniformly (over)samples an analog signal (a continuous-time function) at rate T^{-1}, say, where T is the time between two successive samples. The so obtained discrete-time signal is then subject to quantization, and the quantized signal is further processed by a digital signal processor (DSP). Instead of using one ADC with sampling rate T^{-1} we could run N ADCs in parallel, each operating at the slower rate $(NT)^{-1}$. The sampling instances of the nth ADC are chosen at $\{(kN+n)T\}_{k\in\mathbb{Z}}$, $n=0,\dots,N-1$, so that the combined sampling instances are $\{kT\}_{k\in\mathbb{Z}}$, which is equivalent to the output of one ADC that operates at the N times higher rate T^{-1}.

Many companies such as Maxim (http://www.maxim-ic.com/appnotes.cfm/appnote_number/2094), Agilent Technologies (http://www.agilent.com/labs/news/2003features/fea_adc03.html), and Analog Devices have been developing or are currently developing such time-interleaved ADCs.

To give another concrete current example for the need of time-interleaved ADCs consider the 10 Gigabit Ethernet over copper standard (which is part of the IEEE 802.3 standard; see http://www.ieee802.org). There 4 Cat6 copper pairs are used, so 2.5 Gigabits/sec are transmitted. Since a 12-PAM code with error correction is used, this means the baud rate is about 800 MHz. At least 8 bits precision is necessary. The fastest ADC with the desired precision runs about 1/2 of that. Consequently 2 or 4 time-interleaved ADC channels must be used to achieve the required precision.

While a time-interleaved ADC structure obviously has its merits, it does not come without caveats. The coordination of the N ADCs has to be done with high precision, but in practice timing errors between the individual ADCs result in sampling sets of the form $\{kNT+T_n\}_{k\in\mathbb{Z}}$, where the T_n are distinct random timing shifts. In other words, the combined sampling set does not form a uniform sampling set but consists of nonuniformly shifted unions of uniform sampling points, which is often referred to as *periodic nonuniform sampling* or *bunched sampling* [2, 18]. This poses two problems: (i) How can we estimate the unknown shifts T_n? (ii) How can we reconstruct quickly and stably the original signal from its periodically nonuniformly spaced samples? In this paper we focus on the second question, with shift estimation discussed in [23]. While there are several algorithms in the literature that deal with the reconstruction of bandlimited signals from periodic nonuniform samples (see, e.g., [14, 18, 2, 25, 24, 5, 12, 15, 20]), none of these algorithms provide high order accuracy with respect to truncation error.

Sometimes it can be advantageous to deliberately perform nonuniform periodic sampling in connection with analog-to-digital conversion. For instance, in [20] the use of periodic nonuniform sampling is proposed to avoid noise coupling in a mixed-signal integrated circuit, which contains analog and digital signal processing circuits, as is the case for an ADC. After the analog input signal has been sent through the ADC, the digital output is processed further by a DSP. However, switching of the digital circuits generates noise that can couple into the analog signal path through so-called parasite signal paths. Such noise coupling distorts the analog signal, which degrades the signal-to-noise ratio at the input of the ADC.

To avoid this noise coupling, it is proposed in [20] to have the ADC acquire a group (bunch) of samples at high rate while the digital signal processor is inactive, and allow digital processing of the ADC output during a second phase when the ADC is not sampling. This reduces the noise coupled to the analog signal, since the DSP operates only during the second phase. As the final step, one has to convert the bunched samples to uniformly spaced samples. Practical restrictions in terms of available memory and tolerable time delay imply an upper limit on the number of samples that can be processed during the conversion from bunched to uniform samples. This sampling pattern is obviously a special case of the periodic nonuniform sampling pattern described in the previous paragraph, with the simplification that all $T_n - T_{n-1}$ are (nearly) equal, but with the difficulty that we have a potentially large gap between two clusters of samples. This large gap may cause some instabilities; therefore it is vital to have a numerical reconstruction algorithm that is robust to such large gaps.

In this paper we develop the first method for reconstruction of a bandlimited signal from its periodic nonuniformly spaced samples that achieves root-exponential accuracy from a finite number of samples. The proposed method is numerically robust, and since its computationally most expensive steps consist of fast Fourier transforms (FFTs), it is numerically very efficient.

The paper is organized as follows. In section 2 we review some results on oversampling and localization of functions and their Fourier transforms. The Gevrey class arises as a natural candidate space for compactly supported smooth filter functions in connection with oversampled bandlimited signals. In section 3 we briefly describe how these smooth filters correspond to a localized reconstruction, resulting in a root-exponential accurate, fast algorithm for recovering a bandlimited signal from its uniformly spaced oversampled values. This simple observation is integral for the derivation of the main algorithm for the case of periodic nonuniformly spaced samples; cf. section 4. Numerical simulations that demonstrate the performance of the proposed method are presented in section 5. Finally, section 6 contains our conclusion and an outlook of future research.

2. Oversampling and localization. As mentioned in the introduction, the formulation in (1.2) is unsuitable for practical applications, where only a finite number of samples is available, $\{f(k/2\sigma)\}_{|k|\le L}$. For truncated samples the error, classically referred to as the truncation error, is controlled by the atom's localization

$$\epsilon(t,L,T) := \left| f(t) - \frac{\sqrt{2\pi}}{2\sigma} \sum_{|k|\le L} f\left(\frac{k}{2\sigma}\right) \psi\left(t - \frac{k}{2\sigma}\right) \right| \le \frac{\sqrt{2\pi}}{2\sigma} \cdot \|f\|_{L_\infty} \sum_{|k|>L} \left| \psi\left(t - \frac{k}{2\sigma}\right) \right|. \tag{2.1}$$

In the case of the classical Shannon sampling theorem, the atom, $\psi(\tau) := \mathrm{sinc}(\tau)$, suffers from an unacceptably slow decay, $\lim_{\tau\to\infty} \psi(\tau) \sim 1/\tau$, resulting in a first order convergence rate while moving from the sample boundaries, $\pm L/2\sigma$, to the interior. Moreover, if the samples $f(k/(2\sigma))$ are replaced by noisy samples $f(k/(2\sigma))+\epsilon_k$, then the corresponding approximation via the cardinal series in (1.2) may differ significantly from $f(t)$; cf. [4].

To remedy these problems in applications, one usually introduces oversampling. Sampling a function in the time domain introduces a periodization in the associated Fourier dual space, where sampling rate $T^{-1} = 2\sigma$ corresponds to a 2σ periodization. In (1.2) the reproducing atom (time domain), $\mathrm{sinc}(2\pi\sigma t - \pi k)$, removes the periodization introduced by sampling, through the action of its associated filter (Fourier dual space), $\chi_{[-\sigma,\sigma]}$. For this critical, Nyquist sampling rate, $\mathrm{sinc}(\cdot)$ is the unique atom that can be used to remove the periodization. However, if the bandlimited signal is sampled at a faster rate, $T^{-1} := 2\sigma/r$, where $r < 1$, then the dual space periodization is increased to $2\sigma/r$, allowing a large family of reproducing filters. Specifically, any function satisfying[2]

$$\Psi(w) = \begin{cases} 1, & |w| \le \sigma, \\ 0, & |w| > \sigma(2-r)/r =: \Omega \\ \text{anything} & \text{else} \end{cases} \qquad \Rightarrow \quad \psi \in B_\Omega, \tag{2.2}$$

gives rise to a Shannon-type series expansion

$$f(t) \equiv \sqrt{2\pi}T \sum_{k=-\infty}^{\infty} f\,(kT)\,\psi\,(t-kT)\,. \tag{2.3}$$

For $r = 1$ the above filter reduces to $\chi_{[-\sigma,\sigma]}$ and the classical Shannon's sampling theorem, whereas for $r < 1$ a gap[3] is introduced between σ and $\sigma(2-r)/r$, allowing for a host of other reproducing filters, including those with a high degree of regularity; see Figure 2.1.

Asymptotically the atom's localization is reflected in the filter's smoothness; consequently, the filter's regularity controls the convergence rate of the truncation error (2.1). By constructing infinitely differentiable filters with precise regularity estimates, we obtain root-exponential accuracy for the approximation of a bandlimited signal, as the point to be approximated moves from the sampling boundary, $\pm LT$, to the interior; see subsection 2.1. Unfortunately, unlike classical finite regularity filters, such as the raised cosine, which have a closed form expression for their corresponding atoms, to the authors' knowledge, there is no known infinitely differentiable compactly supported filter whose atom allows an explicit closed form expression. Alternatively to approximating the atoms as proposed in [16, 22], we introduce and analyze a direct Fourier domain implementation that does not adversely affect the high resolution

[2]It has been noted in [11] that the reproducing property is somewhat less strict than as stated in (2.2), in that the filter need not be zero for all $|w| \ge (2-r)/r$. Rather, the reproducing property is satisfied if the filter is one for $|w| \le \sigma$ and zero at the points where the periodic extension of the signal's dual representation is nonzero. However, this added flexibility cannot increase the regularity of the filter or decrease its regularity constants and, as such, cannot improve the asymptotic convergence rate. Although this added flexibility can be used to increase the atom's immediate localization about the origin, it introduces substantial peaks away from the origin [11], decreasing the overall convergence rate.

[3]Filters which are nonzero for $\sigma < |w| < \Omega$ necessarily decrease noise less than the characteristic filter, $\chi_{[-\sigma,\sigma]}$, but the vastly improved convergence rate more than makes up for this modestly lower denoising which is overcome in other ways.

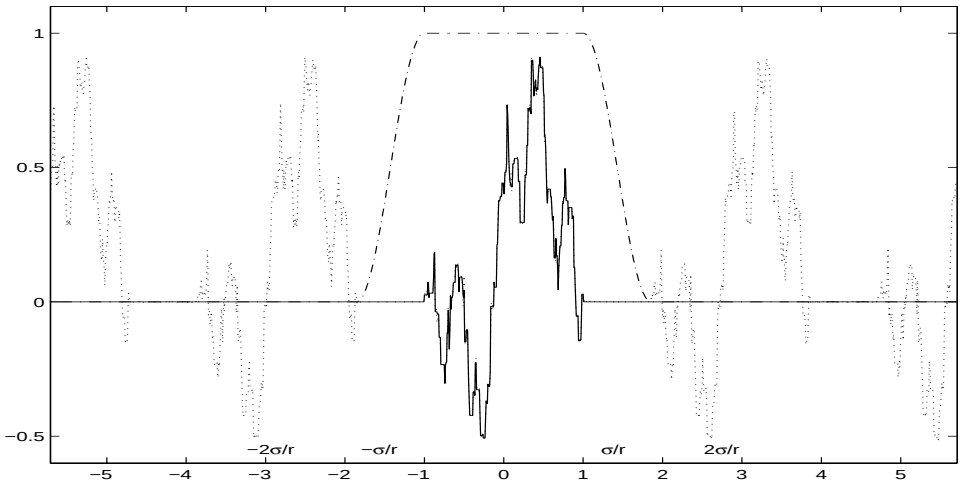

FIG. 2.1. *The signal's dual space representation (solid line) and the signal's periodization due to sampling at the rate, $T^{-1} := 2\sigma/r$, for $r < 1$ (dotted line). With the gap between periodization, a smooth filter (dot-dash line) can be used to remove the periodization introduced by sampling.*

achieved by smooth filters. The time domain localization of an atom, $\psi(\cdot)$, is reflected in the regularity[4] of its corresponding filter, $\Psi(\cdot)$,

$$|\psi(t)| \le (2\pi t)^{-s}\|\Psi\|_{C^s} \cdot \frac{2\Omega}{\sqrt{2\pi}} \quad \forall s, \qquad \psi \in B_\Omega, \tag{2.4}$$

where $\|\Psi\|_{C^s} := \|\Psi^{(s)}\|_{L^\infty}$.

Consequently, combining the bounds in (2.1) and (2.4), convergence is gained at the polynomial rate[5]

$$\epsilon(t, L, T) \le \text{Const} \cdot (LT - |t|)^{1-s}(2\pi)^{-s}\|\Psi\|_{C^s} \cdot \left(\frac{\Omega}{\sigma}\right), \quad s \ge 2, \tag{2.5}$$

as t passes from the boundary, $\pm LT$, to the interior, where $T := r/2\sigma$.

Rather than improving the atom's localization by increasing its corresponding filter's regularity, attempts have been made to construct highly localized atoms by maximizing the atom's local weight, $\int_{-R}^{R}\psi^2(t)dt/\int_{-\infty}^{\infty}\psi^2(t)dt$. However, such approaches have resulted in discontinuous filters [17] and atoms which do not decay globally [11]. A much more successful approach for polynomial order filters is to minimize the filter's regularity constant, $\|\Psi\|_{C^s}$. The classical raised cosine is such a filter [21]:

$$\Psi_{rc}(w) = \begin{cases} 1, & |w| \le \sigma, \\ 0, & |w| > \sigma(2-r)/r, \\ \frac{1}{2}(1 + \cos(\frac{\pi}{2}(\frac{r}{1-r})(\frac{w}{\sigma} - 1)), & \sigma < w < \sigma\frac{2-r}{r}, \\ \frac{1}{2}(1 + \cos(\frac{\pi}{2}(\frac{r}{1-r})(\frac{w}{\sigma} + 1)), & -\sigma > w > -\sigma\frac{2-r}{r}, \end{cases} \tag{2.6}$$

[4]This is achieved by s integrations by parts, where the derivatives are transferred onto the filter.

[5]If the underlying filter possesses $\|\Psi\|_{C^{s+1}} < \infty$, then the bound (2.5) can be tightened by one order of $(LT - |t|)$ to the rate $(LT - |t|)^{-s}$ [9].

where the bounded regularity constants are given explicitly by $\|\Psi\|_{C^1} = \frac{1}{2}(\frac{T}{2(1-r)})$ and $\|\Psi\|_{C^2} = \frac{1}{2}(\frac{T}{2(1-r)})^2$.

When a comparatively small number of sampling points is taken, low regularity constant polynomial order methods give extremely good reconstructions. However, when a larger number of samples is available, atoms with significantly improved asymptotic localization can be achieved by constructing infinitely regular filters, $\Psi \in C_0^\infty$. It should be noted that for infinitely differentiable functions, the optimal bound in (2.4) is not necessarily obtained for large s, as the regularity constant $\|\Psi\|_{C^s}$ grows rapidly in s. Rather, for functions where precise regularity estimates are known, the optimal s can be determined, resulting in an exponential decay without necessarily large constants. These claims will be realized in the numerical experiments presented in section 5, contrary to the assertion in [3], where it is claimed that the increased regularity does not improve numerical convergence. In a direct numerical comparison with the raised cosine filter, our infinitely differentiable filter (2.10) achieves dramatically superior convergence in the interior of the samples, and quantitatively similar errors near the sampling boundaries; see Figure 5.1.

2.1. Localization and Gevrey regularity. To achieve exponential accuracy and satisfy the reproducing condition, (2.2), requires a filter which is infinitely differentiable and compactly supported. The natural space for infinitely differentiable compactly supported functions is the Gevrey class which consists of functions satisfying the smoothness bound

$$\|h\|_{C^s} := \|h^{(s)}\|_{L^\infty} \leq \text{Const} \cdot \frac{(s!)^\alpha}{\eta_h^s} \Longleftrightarrow h \in G^\alpha, \tag{2.7}$$

where η_h is a constant independent of s. Incorporating the regularity information in the localization bound, (2.4), and minimizing over all admissible s, we conclude that Gevrey class filters satisfy a root-exponential localization decay,[6]

$$|\psi(t)| \leq \text{Const} \cdot \sqrt{|t|} \exp(-\alpha(2\pi\eta|t|)^{1/\alpha}), \quad \Psi \in G^\alpha, \tag{2.8}$$

and root-exponential truncation error

$$\epsilon(t, L, T) \leq \text{Const}_{\alpha,\eta} \exp(-(2\pi\eta(LT - |t|))^{1/\alpha}), \tag{2.9}$$

where $\text{Const}_{\alpha,\eta} \sim \eta^{-2} \sum_{l=0}^{q} q!\eta^{l/2}/(q-l)!$, with q the smallest integer greater than or equal to $(3\alpha - 2)/2$.

A similarly localized atom was constructed in [8, 16] by multiplying the sinc function with the inverse Fourier transform of an appropriately dilated G^2 function. Alternatively, such G^α filters can be expressed explicitly in the dual space, such as

$$\Psi_{G2}(w) = \begin{cases} 1, & |w| \leq \sigma, \\ 0, & |w| > \sigma(2-r)/r, \\ \rho\big(\frac{w-\sigma}{\sigma(2-r)/r}\big), & \sigma < w < \sigma\frac{2-r}{r}, \\ \rho\big(\frac{-w-\sigma}{\sigma(2-r)/r}\big), & -\sigma > w > -\sigma\frac{2-r}{r}, \end{cases} \tag{2.10}$$

where $\rho(w) := \exp[\beta(w-1)^{-1}\, e^{-1/w}] \ \in G^2$ [13].

[6] Compact support is inconsistent with analyticity, G^1, so reproducing atoms can at most be in the space G^α, for $\alpha > 1$, excluding true exponential decay, i.e., $\alpha = 1$, as was shown in the classical paper [1]. The Gevrey class of functions is essentially similar to ultradifferentiable functions [19].

Although the filter $\Psi_{G2}(\cdot)$ and the one in [16] result in rapid convergence while approaching the interior, $|t| \leq LT$, their associated atoms lack an explicit construction. As a result, to reconstruct a bandlimited signal at an arbitrary point has required the costly implementation of a quadrature evaluation, or a global approximation of the atom, such as the Padé and Gabor approximations proposed in [16] and [22], respectively. Alternatively, in the next section we introduce and analyze a direct Fourier domain implementation that does not adversely effect the high resolution achieved by smooth filters.

3. Dual space implementation for uniform oversampling. In this section we introduce an implementation which removes the sampling induced periodization through the direct action of the filter in the Fourier dual space. More specifically, if the bandlimited signal is sampled on the mesh $R := \{kT\}_{|k|\leq L}$, with $T := r/2\sigma$ and $r < 1$, we seek to compute an approximation to the signal on the refined mesh $P := \{kT/p\}_{|k|\leq pL}$, where $p \in \mathbb{N}/\{1\}$. This implementation is extremely efficient, as it only requires the FFT of the zero inserted signal, (3.2), and the pointwise multiplication in the dual space.

Define the approximation on the fine mesh as

$$Approx_\psi\ f\left(\frac{qT}{p}\right) := \sum_{|k|\leq L} f(kT)\psi\left[\left(\frac{q}{p}-k\right)T\right]. \tag{3.1}$$

We zero insert the samples from the coarse mesh to the fine mesh

$$f_o(x) := \begin{cases} f(x), & x \in R, \\ 0, & x \in P/R, \end{cases} \tag{3.2}$$

and note that the approximation in (3.1) is a discrete convolution,

$$Approx_\psi\ f(hq) = \sum_{|k|\leq pL} f_o(hk)\psi\left([q-k]\,h\right), \tag{3.3}$$

where $h := T/p$. To transfer the discrete convolution to pointwise multiplication in the dual space, we define the discrete, pseudo-Fourier transforms of a function as

$$\tilde{G}(w_j) := \frac{h}{\sqrt{2\pi}} \sum_{|k|\leq pL} g(hk)\exp(-2\pi i hkw_j), \tag{3.4}$$

$$g(hq) := \frac{\sqrt{2\pi}}{h(2pL+1)} \sum_{|j|\leq pL} \tilde{G}(w_j)\exp(2\pi i hqw_j), \tag{3.5}$$

where $w_j := j/h(2pL+1)$.

In this notation the time domain implementation can be expressed in the Fourier domain,

$$\begin{aligned} Approx_\psi\ f(hq) &= \sum_{|k|\leq pL} f_o(kh)\psi([q-k]h) \\ &= \frac{2\pi}{h^2(2pL+1)} \sum_{|j|\leq pL} \tilde{F}_o(w_j)\tilde{\Psi}(w_j)\exp(2\pi i hw_j q). \end{aligned} \tag{3.6}$$

Although this illustrates an efficient method for computing the approximation on a refined grid without increasing the overall error, it remains necessary to compute the atom in order to determine $\tilde{\Psi}(w_j)$. However, the pseudo-Fourier transform is the spectral projection (truncated Fourier series) of the true Fourier representation,

$$\begin{aligned}\tilde{\Psi}\left(\frac{w_j}{2\pi h}\right) &= \frac{h}{\sqrt{2\pi}}\sum_{|k|\le pL}\psi(hk)\exp(-ikw_j)\\ &= h\int_{-\sigma(2-r)/r}^{\sigma(2-r)/r}\Psi\left(\frac{w}{2\pi h}\right)D_{pL}(2\pi h(w-w_j))dw\\ &= S_{pL}\Psi\left(\frac{w_j}{2\pi h}\right), \qquad (3.7)\end{aligned}$$

where $D_R(x) := \sin((R+1/2)x)/2\pi\sin(x/2)$ is the Dirichlet kernel of order R, and $S_Rf(\cdot)$ is the R term truncated Fourier series projection of $f(\cdot)$, i.e., $S_Rf := D_R * f$. As such, for highly smooth filters, the two Fourier representations are root-exponentially close[7] for all w_j,

$$\begin{aligned}\left|\Psi(w_j)-\tilde{\Psi}(w_j)\right| &= |\Psi(w_j)-S_{pL}\Psi(w_j)|\\ &\le \text{Const}\cdot e^{-\alpha(\eta_\Psi LT)^{1/\alpha}}, \qquad \Psi(\cdot)\in G^\alpha. \qquad (3.8)\end{aligned}$$

The composite error is then composed of the traditional truncation error, (2.1), and the error in replacing the pseudo-Fourier transform with the exact dual space representation of the atom, i.e., the filter. We summarize the above results in the following theorem.

THEOREM 3.1. *Let $f(t)$ be a signal bandlimited to $[-\sigma,\sigma]$, and $\Psi(\cdot)$ a filter in G^α satisfying* (2.2). *From the function's oversampled values on the mesh, $R := \{kT\}_{|k|\le L}$, where $T := r/2\sigma$; its approximation on the fine mesh, $P := \{kh\}_{|k|\le PL}/R$, where $h := r/2\sigma p$ for $p \in \mathbb{N}/\{1\}$, can be computed by pointwise multiplying the pseudo-Fourier transform,* (3.4), *of the signal's zero insertion onto P and the filter, $\Psi(\cdot)$. The resulting error is bounded by*

$$\begin{aligned}&\left|f(hk)-\frac{2\pi}{h^2(2pL+1)}\sum_{|j|\le pL}\tilde{F}_o(w_j)\Psi(w_j)\exp(2\pi ihw_jk)\right|\\ &\le \text{Const}\cdot\frac{p^2L}{\sigma r}\|f\|_{L^\infty}\left(e^{-\alpha(\eta_\Psi LT)^{1/\alpha}}+e^{-\alpha(\eta_\Psi(LT-|t|))^{1/\alpha}}\right)\\ &\le \text{Const}\cdot\frac{p^2L}{\sigma r}\|f\|_{L^\infty}e^{-\alpha(\eta_\Psi(LT-|t|))^{1/\alpha}}.\end{aligned}$$

Remark. Although the approximation of an arbitrary point is not possible by the method put forth in Theorem 3.1, the filter can be modulated to give an approximation on a shifted submesh, $P+s_0 := \{kh+s_0\}_{|k|\le pL}$. This can be seen directly be replacing $\tilde{\Psi}(w_j)$ in (3.6) with its modulation $\tilde{\Psi}(w_j)\exp(2\pi is_0w_j)$ and absorbing the modulation into the exponential, resulting in $Approx_\psi f(hq+s_0)$. An arbitrary point in $|t| \le LT$ can be approximated for a small modulation, $|s_0| \le h/2$, and

[7] This is true for any $p \in \mathbb{N}/\{1\}$ as the trapezoidal quadrature is taken over the support of the filter, $[-\sigma(2-r)/r, \sigma(2-r)/r] \subset [w_{-pL}, w_{pL}]$.

as a result, the difference between the modulated pseudo-filter and the true modulated filter remain exponentially small, only modestly increasing the constant in (3.8). Consequently any point in the interior of the samples, $|t| \leq LT$, can be approximated with the exponential accuracy stated in Theorem 3.1 through the application of the appropriately modulated filter and a zero insertion of $p = 2$.

4. An algorithm for periodic nonuniform sampling. Although uniform oversampling achieves the optimal convergence rate for a given sampling rate, applications exist where for various reasons one is confronted with more general sampling geometries. In this section we devote our attention to the case of periodic nonuniform sampling (bunched sampling), i.e., when multiple uniform undersampled sets are combined to achieve an effective sampling density similar to the uniform sampling case. First order methods exist for the reconstruction of the bandlimited signal from periodic nonuniform sampling [18, 2, 25, 5]. Here we investigate the dual space structure induced by periodic nonuniform sampling, and derive direct high resolution reconstruction methods.

It is well known that for periodic nonuniform sampling a generalization of the cardinal series (1.2) holds by using N atoms in the series expansion (in combination with appropriate coefficients) instead of just one atom. Various essentially equivalent versions of this generalized sampling theorem have been derived, which all revolve around exploiting in the Fourier domain certain periodicities induced by the sampling geometry. Initially we follow a similar path, but unlike other approaches we pay special attention in our derivations to our goal of using highly localized atoms for the reconstruction of the sampled function.

Poisson's summation theorem relates the physical space sampling to the resulting dual space periodization. Specifically, a bandlimited signal, $f \in B_\sigma$, sampled at the rate $T^{-1} := 2\sigma/r$ causes a dual space periodization of $2\sigma/r$. For oversampling, $r < 1$, the signal's dual space representation is separated (Figure 2.1), and the introduced periodization can be removed in one step by applying a smooth filter which satisfies the reproducing condition (2.2). Alternatively, when a signal is undersampled ($r > 1$), the dual space periodizations overlap, and a general signal cannot be reconstructed from those samples alone. More precisely, if a signal is sampled at the points $\{lT + T_n\}_{l\in\mathbb{Z}}$, the dual space representation is given by

$$S_{T_n}(w) := e^{2\pi i T_n w} \sum_{l=-\infty}^{\infty} e^{-2\pi i l T_n T^{-1}} F(w - lT^{-1}). \tag{4.1}$$

If $N \geq \lceil r \rceil$ such undersampled sets are available, then an *effective sampling rate of* $2\sigma N/r$ is obtained and the overlapping can be removed for $|w| \leq \sigma$, allowing the recovery of the bandlimited signal. We now present general conditions, reminiscent of (2.2), for the recovery of a bandlimited signal from its bunched sampling. We then conclude this section with an algorithm for the construction of a family of filters which remove the sampling induced periodization.

For a given value of k, $F(w)$ can be recovered from the N bunched sampling sets of the signal in the interval $I_k := [(-N+k-1)T^{-1}+\sigma, kT^{-1}-\sigma]$ by multiplying each undersampled set's dual space representation, S_{T_n} by an undetermined coefficient, $c_{k,n}$, selected to remove the periodizations for $l = -N + k, \ldots, k - 1$, i.e.,

$$F_k(w) := \sum_{n=1}^{N} c_{k,n} e^{-2\pi i T_n w} S_{T_n}(w) \qquad \text{with } F_k(w) = F(w) \quad \text{for } w \in I_k. \tag{4.2}$$

The coefficients can then be determined by solving the resulting system[8]

$$AR(k)c(k) = e_{N-k+1} \quad \text{with} \quad A_{m,n} := \exp(2\pi i T_n T^{-1} m), \quad m, n = 1, \ldots, N, \tag{4.3}$$

$c(k) = (c_{k,1}\ c_{k,2}\ \cdots\ c_{k,N})^T$, $e_{N-k+1} = \delta_{j,N-k+1}$, and

$$R(k) := \operatorname{diag}(\gamma_1(k)\ \gamma_2(k)\ \cdots\ \gamma_N(k)), \text{where } \gamma_n(k) := \exp(2\pi i T_n T^{-1}(k - N - 1)).$$

Repeating this process for a sufficient set of intervals to cover the bandwidth of the signal, $[-\sigma, \sigma] \subseteq \cup_{j=1}^{\kappa} I_{k_j}$, removes the sampling induced periodization for the bandwidth of interest.[9] However, the overall domain is segmented into κ overlapping intervals which must be spliced together with partitioning functions $\Phi_{k_j}(w)$ constructed appropriately to recover $F(w)$,

$$F(w) = \sum_{j=1}^{\kappa} F_{k_j}(w)\Phi_{k_j}(w), \qquad |w| \le \sigma. \tag{4.4}$$

For partitions which are not dependent on the translates, $\{T_n\}_{n=1}^N$ requires $\Phi_k(w) = 0$ for $w \notin I_k$ and consequently $\sum_{j=1}^{\kappa} \Phi_{k_j}(w) = 1$ for $|w| \le \sigma$. In summary, the signal's dual space representation can be recovered from its bunched sampling if the following conditions on the intervals and partitioning functions are satisfied:

(4.5)

$$[-\sigma, \sigma] \subseteq \cup_{j=1}^{\kappa} I_{k_j}, \qquad \Phi_{k_j}(w) = 0 \ \text{ for } \ w \notin I_{k_j}, \qquad \sum_{j=1}^{\kappa} \Phi_{k_j}(w) = 1 \ \text{ for } |w| \le \sigma.$$

Accordingly, a bandlimited signal's ($f(\cdot) \in B_\sigma$) Fourier transform can be recovered from its overlapping induced periodization by the set of filters $\{\Psi_n(\cdot)\}_{n=1}^N$,

$$\begin{aligned} F(w) &= \sum_{j=1}^{\kappa} \Phi_{k_j}(w) \sum_{n=1}^{N} S_{T_n}(w) c_{k_j,n} e^{-2\pi i T_n w} \\ &= \sum_{n=1}^{N} \left(\sum_{j=1}^{\kappa} c_{n,k_j} \Phi_{k_j}(w) \right) \sum_{l=-\infty}^{\infty} e^{-2\pi i l T_n T^{-1}} F(w - lT^{-1}) \\ &= \sum_{n=1}^{N} \Psi_n(w) \sum_{l=-\infty}^{\infty} e^{-2\pi i l T_n T^{-1}} F(w - lT^{-1}) \\ &= T \sum_{n=1}^{N} \Psi_n(w) \sum_{l=-\infty}^{\infty} f(lT + T_n) e^{-2\pi i w (lT + T_n)}, \end{aligned} \tag{4.6}$$

where the last equality is due to the Poisson summation formula, and the filters are defined as

$$\Psi_n(w) := \sum_{j=1}^{\kappa} c_{k_j,n} \Phi_{k_j}(w), \tag{4.7}$$

[8] The matrix A is of Vandermonde type and is therefore invertible for distinct translates, $\{T_n\}_{n=1}^N$.

[9] The effective oversampling rate $N/r > 1$ guarantees the full set of intervals cover the signal's bandwidth, $[-\sigma, \sigma] \subseteq_{k=1}^{N} I_k$.

with I_{k_j} and Φ_{k_j} selected to satisfy conditions (4.5), and $c_{k_j,n}$ being the solutions of the system (4.3). Note that this N stage filtering is in contrast to the one-step filtering, $F(w) = \Psi(w)\sum_{l=-\infty}^{\infty} F(w-lT^{-1})$, used to remove the periodization induced by uniform oversampling.

Consequently, by taking the inverse Fourier transform of (4.6), the signal can be represented by its bunched samples and translated atoms:

$$f(t) = T\sum_{n=1}^{N}\sum_{l=-\infty}^{\infty} f(lT - T_n)\psi_n(t - (lT + T_n)), \tag{4.8}$$

where ψ_n, the inverse Fourier transform of Ψ_n, is the atom associated with the undersampled set $\{lT-T_n\}_{l\in\mathbb{Z}}$. This is the corresponding generalization of the oversampling representation (2.3) to the case of bunched sampling.

Similar to the case of uniform oversampling, the truncation error for bunched sampling, (4.8), is governed by the atom's localization:

$$\begin{aligned}\epsilon_b(t, L, T) &:= \left| f(t) - T\sum_{n=1}^{N}\sum_{|l|\le L} f\left(lT - T_n\right)\psi_n\left(t - (lT + T_n)\right)\right| \\ &\le T\|f\|_{L_\infty}\sum_{n=1}^{N}\sum_{|l|>L}\left|\psi_n\left(t - (lT + T_n)\right)\right|. \end{aligned} \tag{4.9}$$

In [5] the Nyquist sampling rate $N = r$ was considered, where the interval $|w| \le \sigma$ was necessarily partitioned with characteristic functions, $\Phi_k(w) = \chi_{I_k}$. However, similar to uniform Nyquist sampling the abrupt filtering results in atoms with first order decay, and consequently the convergence rate for truncated sets of samples is first order, making it an impractical method for real world applications.

For smooth G^α filters, the atoms, $\psi_n(t)$, possess root-exponential localization, (2.8), and consequently the truncation error satisfies

$$\epsilon_b(t, L, T) \le \mathrm{Const}_{\alpha,\eta} NT\|A^{-1}\|\|f\|_{L^\infty}\cdot\exp(-\alpha(2\pi\eta((L-1)T - |t|))^{1/\alpha}), \tag{4.10}$$

where $\mathrm{Const}_{\alpha,\eta}$ is as before and $\|A^{-1}\|$ is determined solely by the set of translates, $\{T_n\}_{n=1}^N$.

Remark. (i) The truncation error bound in (4.10) is overly pessimistic in the factor $\|A^{-1}\|$ due to inherent structure in the system of equations $AR(k)c(k) = e_{N-k+1}$. The $(N-k+1)$th row of this system simplifies to $\sum_{n=1}^{N} c_{k,n} = 1$ for each k, imposing the additional structure on the atoms that the sum of the filters is the sum of the partitions,

$$\sum_{n=1}^{N}\Psi_n(w) = \sum_{n=1}^{N}\sum_{j=1}^{\kappa} c_{n,k_j}\Phi_{k_j}(w) = \sum_{j=1}^{\kappa}\Phi_{k_j}(w), \tag{4.11}$$

which is by construction a smooth function satisfying condition (2.2) with a modified bandwidth Ω. Applying the Fourier transform to (4.11), this structure implies that the atoms sum to a fixed function, independent of the set of translates. As a result, even when the translates are such that the matrix A is ill conditioned, a substantial amount of cancellation between the

atoms significantly reduces its effect on the truncation error. To see this more quantitatively, first group those translates that are near one another, say $\{T_n\}_{n\in\lambda}$. Then let x_λ be the overall amount of e_{N-k+1} contained in the space spanned by the associated columns of $AR(k)$. We observe in (4.3) that due to the linear dependence of the columns in $AR(k)$ associated with $n \in \lambda$ the coefficients $\{c_{k,n}\}_{n\in\lambda}$ are often large in magnitude. Nonetheless, the sum of these coefficients is dictated by x_λ, which by construction is order one, not by the individual translates. For this reason, although the individual *atoms* associated with $n \in \lambda$ may have large magnitude, determined by $\{c_{k,n}\}_{n\in\lambda}$ rather than x_λ, their sum will not. Combined with the values of $f(lT - T_n)$ for $n \in \lambda$ being nearly equal results in a substantial amount of cancellation between the associated atoms. To capture the effect of this cancellation quantitatively, rather than pass the absolute value onto each element as in (4.9), the bound can be left as

$$\epsilon_b(t, L, T) \le T \sum_{|l|>L} \left| \sum_{n=1}^{N} f(lT - T_n)\psi_n(t - (lT + T_n)) \right|, \tag{4.12}$$

where for each l, the atoms corresponding to near translates possess substantial cancellation. The numerical example in Figure 5.3 illustrates this effect, where the error near the sampling boundaries does not increase substantially for highly ill conditioned matrices A, but rather roundoff error in the cancellations pollutes the high resolution near the origin.

(ii) To improve the robustness of the proposed method even further we could multiply each uniform sampling set by some weight, similar to the general nonuniform sampling case discussed in [7]. In fact, by introducing properly chosen weights we can obtain estimates for the condition number of A, since the Toeplitz matrix A^*A is of the same form as the Toeplitz matrix appearing in [10]. We leave the details to the reader.

We now turn our attention to constructing intervals and smooth G^α partitioning functions satisfying condition (4.5) where the number of undersampled sets is sufficient to achieve a density similar to oversampling, $N > r$, with an *effective oversampling rate of* $N/r > 1$.

For minimal oversampling, $N = \lceil r \rceil > r$, the recovered regions only overlap with their immediate neighbors, i.e., $I_k \cap I_j = \emptyset$ for $|k-j| > 1$, and the full set of recovered zones $\{I_k\}_{k=1}^N$ is required to cover the interval $[-\sigma, \sigma]$. Moreover, for each I_k there is a subset that is not contained in the other intervals; consequently, the condition $\sum_k \Phi_k(w) = 1$ for $|w| \le \sigma$ implies that the partitioning functions must satisfy

$$\Phi_k(w) = \begin{cases} 1, & w \in [\max(-\sigma, (k-1)T^{-1} - \sigma), \min(\sigma, (-N+k)T^{-1} + \sigma)], \\ 0, & w \notin I_k. \end{cases} \tag{4.13}$$

An example of G^α partitioning functions satisfying conditions (4.13) and $\sum_k \Phi_k(w) = 1$ for $|w| \le \sigma$ is

(4.14)
$$\Phi_{k_1}(w) := \begin{cases} 0, & w \le \sigma + (k_1 - 1)T^{-1}, \\ \rho\left(\frac{-w-\sigma}{-(k_1-1)T^{-1}-2\sigma}\right), & \sigma + (k_1-1)T^{-1} < w < -\sigma, \\ 1, & -\sigma \le w \le \sigma + (k_2-1)T^{-1}, \\ \rho\left(\frac{w-(\sigma+(k_2-1)T^{-1})}{(k_1-k_2+N+1)T^{-1}-2\sigma}\right), & \sigma + (k_2-1)T^{-1} < w < (k_1+N-1)T^{-1} - \sigma, \\ 0, & (k_1+N-1)T^{-1} - \sigma \le w, \end{cases}$$

for the leftmost partition,

(4.15)
$$\Phi_{k_j}(w) := \begin{cases} 0, & w \le \sigma + (k_j-1)T^{-1}, \\ 1 - \rho\left(\frac{w-(\sigma+(k_j-1)T^{-1})}{(k_{j-1}-k_j+N+1)T^{-1}-2\sigma}\right), & \sigma + (k_j-1)T^{-1} < w \\ & \quad < (k_{j-1}+N-1)T^{-1} - \sigma, \\ 1, & (k_{j-1}+N-1)T^{-1} - \sigma \le w \\ & \quad \le \sigma + (k_{j+1}-1)T^{-1}, \\ \rho\left(\frac{w-(\sigma+(k_{j+1}-1)T^{-1})}{(k_j-k_{j+1}+N+1)T^{-1}-2\sigma}\right), & \sigma + (k_{j+1}-1)T^{-1} < w \\ & \quad < (k_{j+1}+1)T^{-1} - \sigma, \\ 0, & (k_{j+1}+1)T^{-1} - \sigma \le w, \end{cases}$$

for interior regions $j = 2, 3, \ldots, \kappa - 1$, and

(4.16)
$$\Phi_{k_\kappa}(w) := \begin{cases} 0, & w \le \sigma + (k_\kappa - 1)T^{-1}, \\ 1 - \rho\left(\frac{w-(\sigma+(k_\kappa-1)T^{-1})}{(k_{\kappa-1}-k_\kappa+N+1)T^{-1}-2\sigma}\right), & \sigma + (k_\kappa-1)T^{-1} < w \\ & \quad < (k_{\kappa-1}+N)T^{-1} - \sigma, \\ 1, & (k_{\kappa-1}+N)T^{-1} - \sigma \le w \le \sigma, \\ \rho\left(\frac{w-\sigma}{(k_\kappa+N)T^{-1}-2\sigma}\right), & \sigma < w < (k_\kappa+N)T^{-1} - \sigma, \\ 0, & (k_\kappa+N)T^{-1} - \sigma \le w, \end{cases}$$

for the rightmost partition, where $k_j := j - N$ for $j = 1, 2, \ldots, N$ and $\rho(\cdot)$ is defined as in (2.10).

For more general effective oversampling rates, $N > r$, the recovered zones I_k often overlap many of their neighbors, and as such constructing the full set of N partitioning functions satisfying $\sum_k \Phi_k(w) = 1$ for $|w| \le \sigma$ becomes substantially more complicated. However, for such higher effective oversampling, a smaller number of partitions, $\kappa \le N$, is required to cover the support of $F(w)$. The ideal subset of intervals and partitioning functions selected through $\{k_j\}_{j=1}^{\kappa}$ possess minimal slope, requiring that the intervals have equal size of internal and boundary overlaps, i.e., $length(I_{k_j} \cap I_{k_{j+1}}) = length(I_{k_1}/[-\sigma, \sigma]) = length(I_{k_\kappa}/[-\sigma, \sigma])$. Combined with the fixed length of I_k the optimal subset for a given κ is selected as $k_j^* := j\frac{N+1}{\kappa+1} - N$ for $j = 1, 2, \ldots \kappa$. The overlap length for κ sets with k_j as defined before is $T^{-1}(1 - r - \frac{\kappa N - 1}{\kappa+1})$. The minimum number of partitions κ necessary to cover the bandwidth

$[-\sigma, \sigma]$ is then determined by requiring the overlap interval to be nonnegative, yielding $\kappa_{min} := \lceil \frac{r}{N+1-r} \rceil$.

For computational purposes using the minimum number of partitions, κ_{min} results in unnecessarily steep partitions. Alternatively, a reasonable balance between simplicity of construction and minimizing the partitions slope is achieved by using the maximum number of partitions subject to the constraint that the intervals only interact with their immediate neighbors, yielding $\kappa^* := \min(N, \lfloor \frac{N+1+r}{N+1-r} \rfloor)$. The above results for bunched sampling are summarized in the following theorem.

THEOREM 4.1. *A bandlimited signal $f \in B_\sigma$ can be expressed in terms of its samples on the $N > \lceil r \rceil$ uniform meshes $\{lT + T_n\}_{l \in \mathbb{Z}}$, where $\{T_n\}_{n=1}^N$ are distinct and $T := r/2\sigma$. Reminiscent of the classical Shannon sampling theorem, the signal is decomposed into the translates of N atoms, $\psi_n(\cdot)$, each of which are associated with a particular uniform sampling mesh,*

$$f(t) = T \sum_{n=1}^{N} \sum_{l=-\infty}^{\infty} f(lT - T_n) \psi_n(t - (lT + T_n)).$$

A particularly simple construction of filters is achieved by solving the system of equations (4.3) *for $k_j^* = round(j \frac{N+1}{\kappa^*+1} - N)$, where $\kappa^* = \min(N, \lfloor \frac{N+1+r}{N+1-r} \rfloor)$. The N filters are then given by*

$$\Psi_n(w) := \sum_{j=1}^{\kappa^*} c_{k_j^*, n} \Phi_{k_j^*}(w),$$

where the coefficient $c_{k_j^*, n}$ are determined by solving (4.3) *for $\{k_j^*\}_{j=1}^{\kappa^*}$, and the partitioning functions are given by* (4.14), (4.15), (4.16).

Before developing a dual space implementation for truncated bunched sampling, we illustrate partitions and representative atoms for bunched samples in the case of minimal oversampling, $N = \lceil r \rceil > r$.

EXAMPLE 1. *The partitions for $r = 2.4$ as expressed in* (4.14), (4.15), (4.16) *for the case $N = \lceil r \rceil > r$ are shown in Figure* 4.1, *where $\rho(w) := \exp[\beta(w-1)^{-1} e^{-1/w}] \in G^2$, with $\beta = e^2/3$. It should be noted that the partitioning does not depend on the translates $\{T_n\}_{n=1}^N$, rather solely on the number of undersampled sets, N.*

The atoms, $\{\psi_n\}_{n=1}^N$, associated with $r = 2.4$, $N = 3$, and random translates $T_n/T = \{-0.4484, 0.3419, -0.0984\}$ are given in Figure 4.2. *This distribution of shifts is near the distribution that would correspond to uniform oversampling, $T_n/T = \{-1/3, 0, 1/3\}$ at the rate $N/r = 1.25$, and as such the atoms for this bunched sampling are qualitatively similar to the atom associated with uniform oversampling at the rate $N/r = 1.25$. Figure* 4.3 *illustrates the atoms for the set of translates $T_n/T = \{-1/3, 0, 10^{-6}\}$, where $\mathrm{cond}(A) = 5.5 \times 10^5$. Having constructed the partitions Φ_k from $\rho(\cdot) \in G^2$, the atoms possess root-exponential localization.*

4.1. Direct dual space implementation for bunched sampling. Just as in the case of the single oversampled set, the approximation of $f(\cdot)$ on the zero inserted grid $\{hq\}_{|q| \le pL}$, where $h = T/p$, can be implemented directly in the dual space. Define

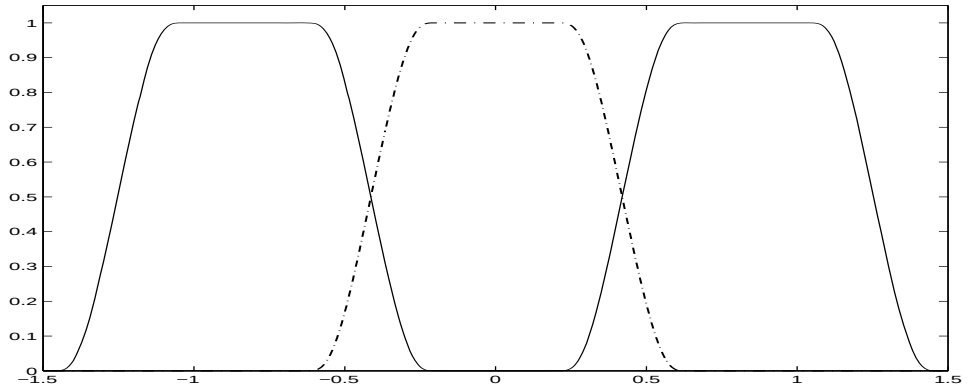

FIG. 4.1. *The partitions for* $r = 2.4$ *and* $N = 3$ *as described in* (4.14), (4.15), (4.16); *the end partitions* Φ_1, Φ_3 *(solid line) and the center partition* Φ_2 *(dot-dashed line).*

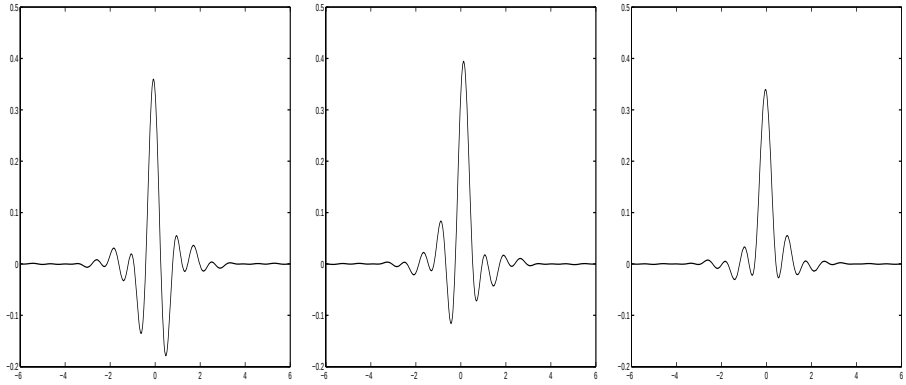

FIG. 4.2. *The atoms* $\{\psi_n\}_{n=1}^N$ *associated with* $r = 2.4$, $N = 3$, *and random translates* $T_n/T = \{-0.4484, 0.3419, -0.0984\}$ *shown from left to right, respectively. The atoms are qualitatively similar due to the low condition number* $\mathrm{cond}(A) = 1.8939$.

the approximation on this mesh from the bunched sampling as

$$Approx_{\psi,B} f(hq) := T \sum_{n=1}^{N} \sum_{|k| \le L} f(kT - T_n)\psi_n(hq - (kT + T_n))$$

$$= T \sum_{n=1}^{N} \sum_{|j| \le pL} f_0(jh - T_n)\psi_n(h(q-j)T_n), \tag{4.17}$$

where $f_0(x)$ is zero unless $x = kT - T_n$ for $k = -L, \ldots, L$. Replacing the point values in (4.17) with their pseudo-Fourier transform, we can express the evaluation in terms

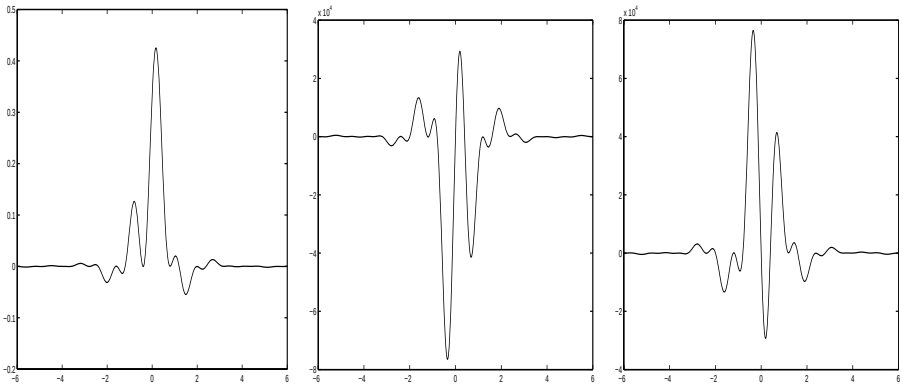

FIG. 4.3. *The atoms* $\{\psi_n\}_{n=1}^N$ *associated with* $r = 2.4$, $N = 3$, *and translates* $T_n/T = \{-1/3, 0, 10^{-6}\}$ *shown from left to right, respectively. The first atom is similar to those in Figure* 4.2, *and although the remaining atoms have significant amplitude, due to the relatively large condition number* $\mathrm{cond}(A) = 5.5 \times 10^5$, *they are nearly the negative of each other, allowing for significant cancellation.*

of the sampling sets pseudo-Fourier transforms,

$$\begin{aligned} Approx_{\psi,B} f(hq) &= T \sum_{n=1}^{N} \sum_{|j|\le pL} f_0(jh - T_n)\psi_n(h(q-j)T_n) \\ &= \frac{2\pi T}{h^2(2pL+1)^2} \sum_{n=1}^{N} \sum_{|j|\le pL} \left(\sum_{|l|\le pL} \tilde{F}_0(w_l) e^{2\pi i w_l (jh - T_n)} \right) \\ &\quad \times \left(\sum_{|k|\le pL} \tilde{\Psi}_n(w_k) e^{2\pi i w_k (h(q-j) - T_n)} \right) \\ &= T\sqrt{2\pi} \sum_{n=1}^{N} \sum_{|l|\le pL} \left(\frac{\sqrt{2\pi}}{h(2pL+1)} \tilde{F}_0(w_l) e^{2\pi i w_l (hq - T_n)} \right) \tilde{\Psi}_n(w_l) e^{-2\pi i T_n w_l}. \end{aligned} \tag{4.18}$$

The last line can be viewed as an algorithm, where first each undersampled set is zero inserted of order p, its pseudo-Fourier transform is computed, and it is multiplied by the appropriately modulated filter, $\tilde{\Psi}_n(\cdot)$, to remove the overlapping periodization. These filtered dual space representations are then summed and their inverse pseudo-Fourier transform computed to achieve an approximation of the bandlimited signal at the set of point $\{hq\}_{|q|\le pL}$. Just as in the case of the uniform oversampled dual space representation it is computationally advantageous to avoid the construction of $\psi_n(\cdot)$ in order to compute $\tilde{\Psi}_n$; rather for a fast algorithm the true filters $\{\Psi_n(\cdot)\}_{n=1}^N$ should be applied directly. Again we note that the atom's pseudo-Fourier transform is the pL order spectral projection of the atom's associated filter, (3.7). As such their difference is exponentially small,

$$\left| \Psi_n(w_l) - \tilde{\Psi}_n(w_l) \right| \le \mathrm{Const} \cdot \|A^{-1}\| e^{-\alpha(\eta_n LT)^{1/\alpha}}, \qquad \Psi_n(\cdot) \in G^\alpha, \tag{4.19}$$

if the zero padding is sufficient to expend the dual axis beyond the support of the filter, $p \ge 2N - r$.

In addition to the usual truncation error, this additional error gives a threshold below which the error does not fall, determined by the condition number of A as dictated by the set of translates. Unlike the truncation error, the structure in A does not result in cancellation to reduce the effects of $\|A^{-1}\|$; however, the bound does not depend on t and is well below the truncation error for all but the most ill conditioned sets of translates. We summarize the above results in the following theorem.

THEOREM 4.2. *Let $f(t) \in B_\sigma$ be sampled at the points $\{kT + T_n\}_{|k|\le L}$ with sampling rate $T^{-1} := 2\sigma/r$ and translate $|T_n| \le T/2$. From $N > r$ such distinct sampling sets, and filters $\{\Psi_n\}_{n=1}^N \in G^\alpha$ constructed as in Theorem* 4.1*, the signal can be approximated on the set $\{kT/N\}_{|k|\le pL}$, with $p \ge 2N - r$, within the bound*

$$|f(t) - Approx_B f(hk)| \le \text{Const}\,\frac{N^2}{\sigma}\|f\|_{L^\infty}\|A^{-1}\| \cdot e^{-\alpha(\eta((L-1)T-|t|))^{1/\alpha}},$$

where $Approx_B f(hk)$ is computed by the following algorithm:

1. *Zero insert each of the uniform sampling sets $\{kT+T_n\}_{|k|\le L}$ to the fine mesh $\{kh + T_n\}_{|k|\le pL}$, where $p \ge 2N - r$ and $h = T/p$, yielding $\{f_{o,n}\}_{n=1}^N$.*
2. *Compute the pseudo-Fourier transform, as defined in* (3.4)*, of each set of zero inserted samples from step* 1*, labeled $\{\tilde{F}_{o,n}(w_l)\}_{n=1}^N$, and pointwise multiply by $\exp(-2\pi i T_n w_l)$, respectively.*
3. *Pointwise multiply each of the pseudo-Fourier transforms from step* 2*, $\tilde{F}_{o,n}(w_l)$, by their corresponding filters, $\Psi_n(w_l)$, and sum over N, yielding an approximation of $F(w)$, $\tilde{F}_A(w_l) := \sum_{n=1}^N e^{-2\pi i T_n w_l}\tilde{F}_{o,n}(w_l)\Psi_n(w_l)$.*
4. *Compute the inverse pseudo-Fourier transform of $\tilde{F}_A$ formed in step* 4*, and multiply by p.*

Similar to the remark following Theorem 4.1, the signal can be recovered on a shifted mesh, $\{kT/N + s_0\}_{|k|\le pL}$, by multiplying $\tilde{F}_A(w_l)$ with $\exp(2\pi i s_0 w_l)$ between steps 3 and 4 of the algorithm in Theorem 4.2.

The direct implementation for uniform oversampling has a computational cost limited by the FFT, proportional to $L\log(L)$, where L is the number of samples used in the reconstruction. For the algorithm described in Theorem 4.2 for bunched sampling, the computational cost is again limited by the overall FFT evaluations. To allow for a direct comparison to the uniform oversampling let each of the N sampling sets contain L/N samples for a similar total number of samples being available for the algorithm. Each of the N FFTs then requires $\frac{L}{N}\log(pL/N)$, where p is the level of zero insertion required to be proportional to the number of sampling sets, $p \approx N$. The overall computational cost for the algorithm in Theorem 4.2 is then $NL\log(L)$, where L is the total number of samples used in the approximation. In principle we also have to take into account the costs for inverting the matrix A in (4.3). Since A is a Vandermonde matrix and A^*A is a Toeplitz matrix, there are plenty of fast standard algorithms for the solution of the system in (4.3) at our disposal. Moreover, in practice N is small compared to L, and thus the computational costs of this step have little impact on the overall complexity of the proposed method. In summary, the bunched sampling algorithm requires an additional factor of N in the total computational cost, when compared to uniform sampling at the same effective sampling rate and number of available samples.

5. Numerical examples. We illustrate the convergence rates and algorithms for the results presented in Theorems 3.1 and 4.2 for characteristic bandlimited signals. For the approximation of an arbitrary bandlimited signal, we form a test signal

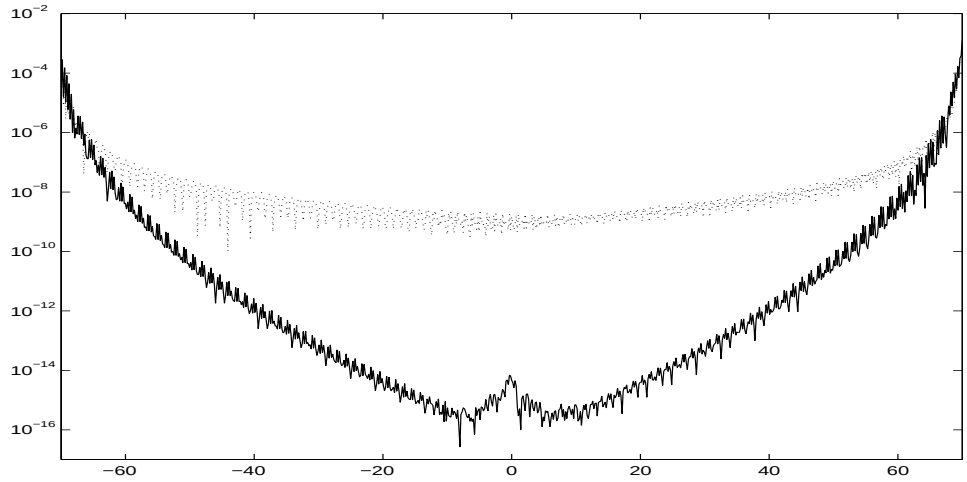

FIG. 5.1. *The error with oversample rate* $r^{-1} = 1.43$ *in recovering the signal in* B_1 *whose real portion is shown in Figure* 2.1. *With the log axis, note the log convergence exhibited by the reconstruction using the raised cosine (dotted line), as compared to the root convergence obtained by the dual space implementation using* Ψ_{G2} *(solid line). The approximations were computed with zero insertion rate* $p = 2$ *on the grid translated by* $s_0 = T/\sqrt{5}$.

whose Fourier transform is composed of one hundred characteristic functions with random complex valued amplitudes normalized to unit l_2 norm, and with random widths and centers, normalized so that the largest magnitude bandwidth is σ. The resulting numerics shown are characteristic of arbitrary complex valued bandlimited signals. The dual space representation, real portion, of such a function can be seen in Figure 2.1. Before illustrating the main results of Theorem 4.2 we briefly contrast the exponential convergence of Gevrey class filters with the polynomial order convergence of classical finite regular filters. To compare representative filters with finite and infinite regularity, we use the canonical raised cosine filter (2.6) and the Gevrey order two filter given in (2.10), respectively; see Figure 5.1.

Much of the success of the raised cosine filter is due to the optimally small first two regularity constants, $\|\Psi\|_{C^s}$ for $s = 1, 2$, which result in rapid initial localization. Infinitely regular filters possess bounded regularity constants for all s, but at the cost of necessarily larger regularity constants for small s. However, a great deal of freedom exists in the selection of G^α regular filters, for example the constant β used in the filter of (2.10). A good approximation of the β which minimizes the first regularity constant in Ψ_{G2} can be obtained by selecting β such that the filter's points of inflection are at the middle of the region connecting zero and one, i.e., $\Psi^{(2)}(\pm\sigma/r) = 0$. As such, for the numerical experiments involving the filter Ψ_{G2}, we use $\beta := \frac{1}{3}e^2$ which satisfies $\rho^{(2)}(\frac{1}{2}) = 0$.

Various properties of Theorem 4.2 are demonstrated in the following numerical examples. First we begin with the simplest case of bunched sampling where only just sufficiently many sampling sets are available for effective oversampling, $N := \lceil r \rceil > r$; in particular for $r = 2.4$ and a random set of well separated translates with corresponding atoms presented in Figure 4.2, and the exponentially small error shown in Figure 5.2. To illustrate the computational robustness, Figure 5.3 shows the error as two sampling sets approach one another, resulting in a poorly conditioned matrix A in system (4.3). However, as noted in the Remark following (4.10), the ill conditioning

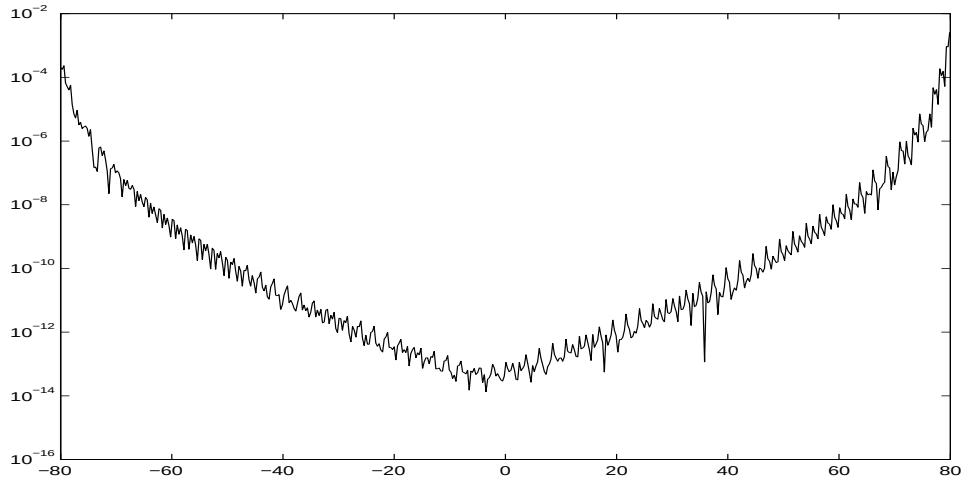

FIG. 5.2. *The error with $N = 3$ undersampled sets with effective sampling rate $N/r = 1.25$ in recovering the signal in B_1 whose real portion is shown in Figure* 2.1. *The translates were $T_n/T = \{-0.4484, -0.0984, 0.3419\}$ with $\mathrm{cond}(A) = 1.8939$ and atoms illustrated in Figure* 4.2.

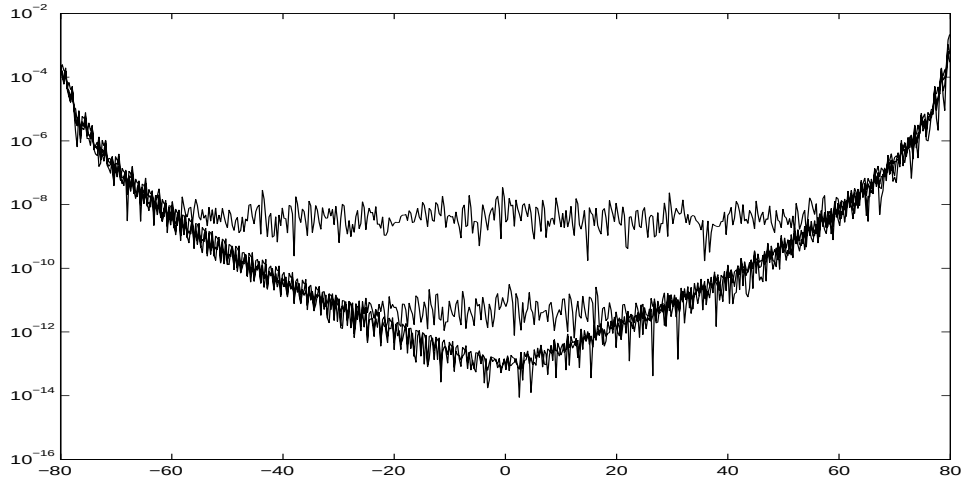

FIG. 5.3. *The error with $N = 3$ undersampled sets and effective sampling rate $N/r = 1.25$ in recovering the signal in B_1 whose real portion is shown in Figure* 2.1. *The translates used, $T_n/T = \{-1/3, 0, 10^{-3j}\}$ for $j = 1, 2, 3$, result in systems* (4.3) *with respective condition numbers $\mathrm{cond}(A) = 5.5 \times 10^{3j-1}$. Note that although the condition number becomes very large, the error near the boundaries does not suffer. Rather, the minimal error is increased due to roundoff errors. The atoms associated with the set of translations, $j = 2$, are shown in Figure* 4.3.

of the matrix does not increase the entire error by the factor $\|A^{-1}\|$ as stated in the pessimistic bound of Theorem 4.2; rather, the ill conditioning results in a rounding error that limits the achievable error for a given precision arithmetic.

A more general example of Theorem 4.2 is shown in Figure 5.4 where $N = 17$ uniform sampling sets with random translates undersampled at the rate $r = 12.4$ are given for an effective sampling rate of $N/r \approx 1.37$. The resulting error is typical for the algorithm of Theorem 4.2 when the system (4.3) has a relatively modest condition

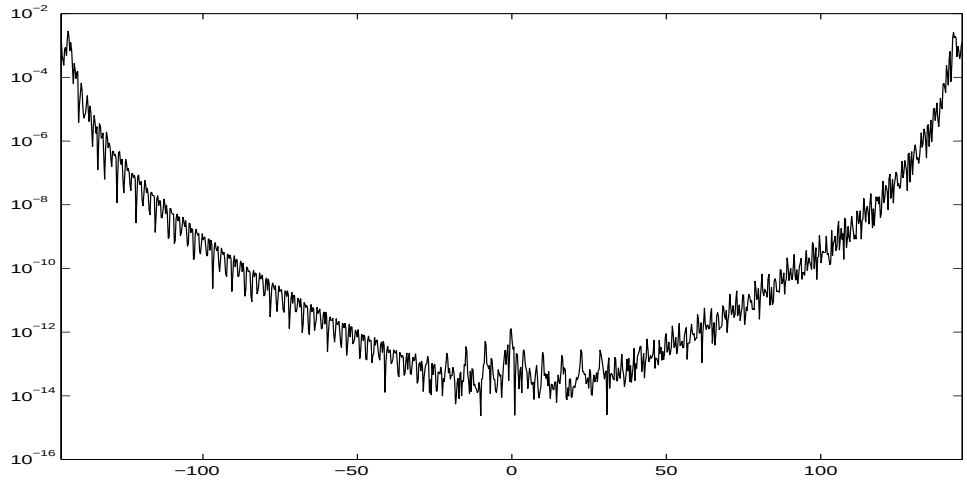

FIG. 5.4. *The error in recovering a random signal in* B_1 *from* $N = 17$ *undersampled sets of random translation with effective sampling rate* $N/r = 1.37$. *The filters were composed of five partitions,* $\kappa^* = 5$, *and the system of the random translates had condition number* $\mathrm{cond}(A) = 1.4 \times 10^4$.

number.

Before concluding the numerical examples we illustrate the algorithm's performance for a particular application discussed in the introduction. Due to feedback interactions between sampling and processing chips in close proximity, it is advantageous to use a sampling structure that includes relatively large sampling gaps, when the signal processing can be applied and not interact with the sampling. However, the introduced sampling gap could potentially introduce stability problems. The extraordinary robustness of the algorithm in Theorem 4.2 overcomes any stability issues, even for relatively large sampling gaps. For example, Figure 5.5 shows the approximation error with eight sets interleaved over a third of the effective sampling rate, i.e., $T_n := T(n/24)$ for $n = 1, 2, \ldots, 8$.

6. Final remarks. We have derived a fast algorithm for reconstructing a bandlimited signal from its periodic nonuniform samples that achieves root-exponential accuracy with respect to the given number of samples. Due to its high accuracy the method can be easily realized in practice via finite impulse response (FIR) filters. Furthermore, since the numerically most expensive steps are FFTs the proposed method lends itself to a simple implementation on standard DSP processors. Furthermore, the high accuracy provided by the algorithms derived in this paper will not be lost in the subsequent reconstruction of the signal from its quantized samples due to the recently developed highly accurate algorithms for recovering a quantized bandlimited signal; cf. [4].

Another application where periodic nonuniform sampling arises is image processing. For instance, in astronomical imaging one is confronted with images that are blurred and notoriously undersampled. The goal is to combine these blurred low-resolution images to one high-resolution image. This problem is also referred to as superresolution; see, e.g., [6]. The low-resolution images contain (blurred, noisy) samples of the high-resolution image where the sampling sets can be thought of as a union of arbitrarily shifted (and/or rotated) uniform sampling sets. One step in reconstruct-

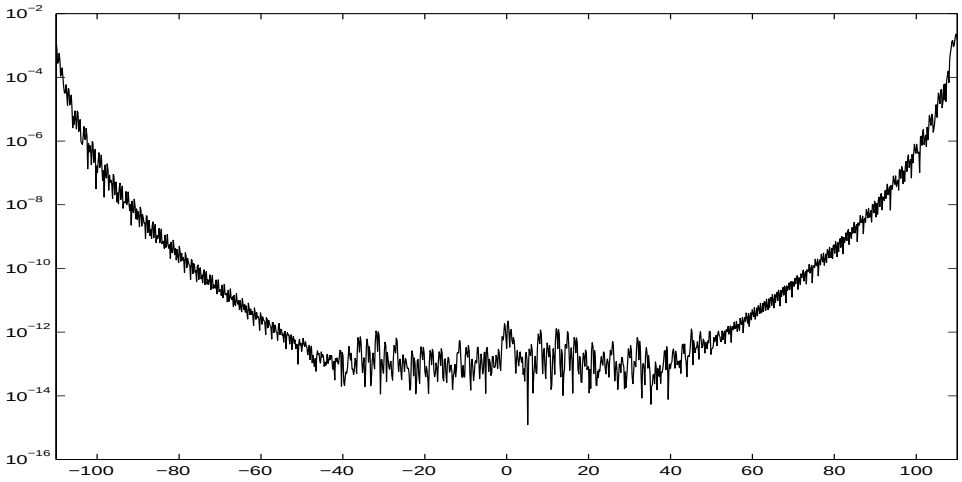

FIG. 5.5. *The error in recovering a random signal in B_1 from $N = 8$ undersampled sets with effective sampling rate $N/r = 1.82$. The filters were composed of two partitions, $\kappa^* = 2$, and the translates, $T_n := T(n/24)$ for $n = 1, 2, \ldots, 8$, had condition number* $\mathrm{cond}(A) = 3.1 \times 10^4$.

ing a high-resolution image is thus the conversion of the periodic nonuniform image samples to a uniform sampling set at a fine sampling grid. In our future research we will address two-dimensional reconstruction algorithms and their effect on deblurring and noise.

Acknowledgment. We are indebted to Professor Bernard Levy for insightful discussions on practical aspects of the research presented in this paper.

C^1 INTERPOLATORY SUBDIVISION WITH SHAPE CONSTRAINTS FOR CURVES*

TOM LYCHE† AND JEAN-LOUIS MERRIEN‡

Abstract. We derive two reformulations of the C^1 Hermite subdivision scheme introduced by Merrien. One where we separate computation of values and derivatives and one based of refinement of a control polygon. We show that the latter leads to a subdivision matrix which is totally positive. Based on this we give algorithms for constructing subdivision curves that preserve positivity, monotonicity, and convexity.

Key words. interpolation, subdivision, corner cutting, total positivity, positivity, monotonicity, convexity

DOI. 10.1137/040621302

1. Introduction. Subdivision is a technique for creating a smooth curve or surface out of a sequence of successive refinements of polygons; or grids see [2]. Subdivision has found applications in areas such as geometric design [6, 16], and in computer games and animation [4]. We consider here the two point Hermite scheme, the HC^1-algorithm, introduced in [11]. We start with values and derivatives at the endpoint of an interval and then compute values and derivatives at the midpoint. Repeating this on each subinterval we obtain in the limit a function with a certain smoothness. The scheme depends on two parameters α and β and it has been shown that the limit function is C^1 for a range C of these parameters. For more references to Hermite subdivision, see [5, 10, 12, 13].

The strong locality of the HC^1-algorithm was used in [13] to construct subdivision curves with shape constraints like positivity, monotonicity, and convexity. A notion of control points, control coefficients, and a Bernstein basis for two subfamilies of the HC^1-interpolant were introduced in [15].

In this paper we continue the study of subdivision with shape constraints initiated in [13, 15]. Before detailing our results let us first describe the shape preserving subdivision process and give an example. Suppose we have values $y_1, \dots, y_n$ and derivatives $y'_1, \dots, y'_n$ at some abscissae $t_1 < t_2 < \cdots < t_n$. With each subinterval $[t_i, t_{i+1}]$ we associate parameters $(\alpha_i, \beta_i) \in C$ chosen so that the HC^1-interpolant using data $(y_i, y'_i, y_{i+1}, y'_{i+1})$ has the required shape on $[t_i, t_{i+1}]$. We then obtain a C^1-function on $[t_1, t_n]$. As an illustration consider the function in Figure 1.1.

This function is defined on the interval $[0, 4]$. It is positive on $[0, 1]$, strictly increasing on $[1, 2]$, constant on $[2, 3]$, and concave on $[3, 4]$. Suppose we want to use subdivision to construct a C^1-approximation to this function with the same shape characteristics and that all we know about the function is the function values $y_1, \dots, y_n$ at some points $t_1 < \cdots < t_n$. We can achieve this with the HC^1-algorithm using only

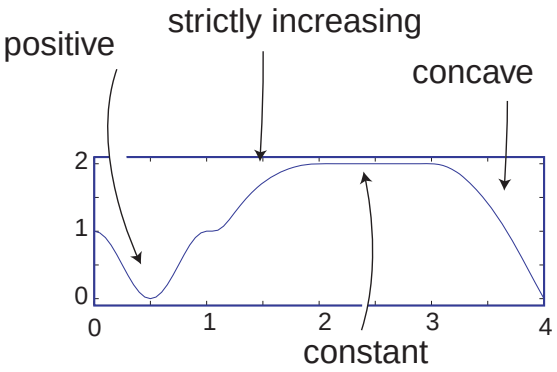

FIG. 1.1. *A given function.*

crude estimates for the derivatives $y'_1, \ldots, y'_n$ as long as the transition points $1, 2, 3$ are among the abscissae and the chosen derivatives are consistent with the required shapes; see section 6 for details. For classical curve based shape preserving algorithms we refer to [7, 8, 9] and references therein.

As for Bézier and spline curves we introduce a control polygon for the HC^1-interpolant. The originality of this family of interpolants is that monotonicity or convexity of the control polygon and of the function are equivalent (see Propositions 5.3 and 5.6). We observe that this is only true in one direction for Bezier or spline curves.

Our paper can be detailed as follows. In section 2, we recall the HC^1-algorithm and some properties which were proved in [13]. We give a new formulation of the HC^1-algorithm where we separate the computation of function values and derivatives. This formulation is useful for proving shape preserving properties and with the aid of this formulation we simplify the proofs of the main results in [13]. The new formulation also shows why the one parameter family given by $\alpha = \beta/(4(1-\beta))$ and $\beta \in [-1, 0)$ considered in [13, 15] really is an extension of the quadratic spline case. We will refer to this family as the *EQS-case* of the HC^1-algorithm. We also give a new domain C for C^1-convergence of the algorithm. In section 3 we use the control points introduced in [15] to reformulate the HC^1-algorithm as a stationary subdivision algorithm called SC^1. The control points depend on a third parameter $\lambda \geq 2$ and we show convergence of the SC^1-algorithm for $(\alpha, \beta) \in C$ and $\lambda \geq 2$. Starting in section 4, we restrict our attention to the EQS-case. By formulating the SC^1-algorithm as a corner cutting scheme we show that the subdivision matrix $\mathbf{S}$ is totally positive. We show this for an extended range of β and λ and also prove the total positivity of the HC^1-Bernstein basis. With this last property, the interpolant inherits shape properties of the control polygon such as nonnegativity, monotonicity, or convexity. In section 5, we give algorithms for interpolation with any of the previous shape constraints. An example based on Figure 1.1 is given in section 6.

We also point out that Proposition 2.1 on one hand and Proposition 3.1 with Theorem 3.4 on the other hand show that we obtain two Lagrange subdivision schemes from the HC^1-Hermite subdivision scheme.

2. The HC^1-algorithm. We recall the univariate version of the Hermite subdivision scheme for C^1 interpolation given by Merrien [11], which we call here HC^1. We start with values $(f(a), p(a))$ and $(f(b), p(b))$ of a function f and of its first derivative

$p = f'$ at the endpoints a, b of a bounded interval $I := [a, b]$ of $\mathbb{R}$. To build f and p on I, we proceed recursively. At step n ($n \geq 0$), let us denote by $\mathcal{P}_n$ the regular partition of I in 2^n subintervals and let us write $h_n := (b-a)/2^n$. If c and d are two consecutive points of $\mathcal{P}_n$, then we compute f and p at the midpoint $(c+d)/2$ according to the following scheme, which depends on two parameters α and β,

$$\begin{aligned} f\left(\frac{c+d}{2}\right) &:= \frac{f(d)+f(c)}{2} + \alpha h_n[p(d)-p(c)], \\ p\left(\frac{c+d}{2}\right) &:= (1-\beta)\frac{f(d)-f(c)}{h_n} + \beta\frac{p(d)+p(c)}{2}. \end{aligned} \tag{2.1}$$

By applying these formulae on ever finer partitions, we define f and p on $\mathcal{P} = \cup\mathcal{P}_n$ which is a dense subset of I. We say that the scheme is C^1-*convergent* if, for any initial data, f and p can be extended from $\mathcal{P}$ to continuous functions on I with $p = f'$. We call f defined either on I or on $\mathcal{P}$ the HC^1-*interpolant* to the data.

The HC^1-algorithm can also be formulated as follows. We start with Hermite data f_0, p_0, f_1, p_1 at the endpoints of a finite interval $[a, b]$ and set $f_0^0 = f_0$, $p_0^0 = p_0$, $f_1^0 = f_1$, and $p_1^0 = p_1$. For $n = 0, 1, 2, \ldots$, $h_n = 2^{-n}(b-a)$, and $k = 0, 1, \ldots, 2^n - 1$

$$f_{2k}^{n+1} := f_k^n, \quad f_{2k+1}^{n+1} := \frac{f_{k+1}^n + f_k^n}{2} + \alpha h_n\big(p_{k+1}^n - p_k^n\big), \tag{2.2}$$

$$p_{2k}^{n+1} := p_k^n, \quad p_{2k+1}^{n+1} := (1-\beta)\frac{f_{k+1}^n - f_k^n}{h_n} + \beta\frac{p_{k+1}^n + p_k^n}{2}, \tag{2.3}$$

and $f_{2^{n+1}}^{n+1} := f_{2^n}^n$, $p_{2^{n+1}}^{n+1} := p_{2^n}^n$. If the scheme is C^1-convergent with limit functions f and p, then

$$f(t_k^n) = f_k^n, \ f'(t_k^n) = p(t_k^n) = p_k^n, \ t_k^n := a + kh_n, \ k = 0, 1, \ldots, 2^n. \tag{2.4}$$

2.1. The vector space of HC^1-interpolants. To each choice of (α, β) there is a vector space

$$VC^1_{\alpha,\beta}(\mathcal{P}) := \{f : \mathcal{P} \to \mathbb{R} : f, p \text{ computed by (2.2)–(2.4)}\}$$

of HC^1-interpolants. If the scheme is C^1-convergent we define

$$VC^1_{\alpha,\beta}(I) := \{f : I \to \mathbb{R} : f|_{\mathcal{P}} \in VC^1_{\alpha,\beta}(\mathcal{P})\}.$$

The HC^1-*Hermite basis functions* $\{\phi_0, \psi_0, \phi_1, \psi_1\}$ are defined by taking as initial data the four unit vectors $e_j = (\delta_{i,j})_{i=1}^4$, respectively. They are always defined on $\mathcal{P}$ and the HC^1-interpolant corresponding to initial data (f_0, p_0, f_1, p_1) can be written $f = f_0\phi_0 + p_0\psi_0 + f_1\phi_1 + p_1\psi_1$. Since the Hermite basis functions are clearly linearly independent on $\mathcal{P}$ they form a basis for $VC^1_{\alpha,\beta}(\mathcal{P})$. Thus $VC^1_{\alpha,\beta}(\mathcal{P})$ and $VC^1_{\alpha,\beta}(I)$ are vector spaces of dimension 4.

Let us denote the HC^1-interpolant to initial data sampled from a function g by $f = Hg$. By induction it is easy to see that for any (α, β) we have $g = Hg$ for all polynomials g of degree at most one, while $g = Hg$ for all quadratic polynomials if and only if $\alpha = -1/8$. We also have $g = Hg$ for all cubic polynomials if and only if $\alpha = -1/8$ and $\beta = -1/2$ and it can be shown that $x^k \neq Hx^k$ for any integer $k \geq 4$. The fact that the scheme reproduces polynomials up to a certain degree can be used to give error bounds; see [13, section 5]. Assume (α, β) are chosen so that the scheme

is C^1-convergent. Then there is a constant $C(\alpha,\beta)$ such that for all intervals $I=[a,b]$ and all $g\in C^k(I)$ we have

$$\|g-Hg\|_{L_\infty(I)}\le C(\alpha,\beta)h^k\|g^{(k)}\|_{L_\infty(I)}, \tag{2.5}$$

where $h:=b-a$ and $k=2$ for most choices of α and β.

Notice some important choices of (α,β):

1. If $\alpha=-1/8$, $\beta=-1/2$, then f is the cubic polynomial known as the Hermite cubic interpolant. For this choice of parameters, (2.5) holds with $k=4$ and $C(\alpha,\beta)=1/384$.
2. If $\alpha=-1/8$, $\beta=-1$, then f is the Hermite quadratic interpolant, i.e., the quadratic C^1 spline interpolant with one knot at the midpoint of the initial interval. In this case (2.5) holds with $k=3$ and $C(\alpha,\beta)=1/96$; see [13].
3. The EQS-case $\alpha=\frac{\beta}{4(1-\beta)}$ with $\beta\in[-1,0)$ is a one parameter extension of the quadratic spline case; it was introduced and studied in [13], see also [15]. In this case (2.5) only holds with $k=2$ and $C(\alpha,\beta)\le 1/48$ unless $\beta=-1$, but as we will see this scheme has important shape preserving properties.

2.2. Direct computation of the function or the derivative. We can reformulate (2.2), (2.3) so that only values of p are involved and similarly for f.

PROPOSITION 2.1. *For $\alpha,\beta\in\mathbb{R}$, the function f and the derivative p of the HC^1-interpolant satisfy the following relations:*
For $n=1,2,\dots$ and $i=0,1,\dots,2^{n-1}-1$,

$$\begin{bmatrix} p_{4i}^{n+1}\\ p_{4i+1}^{n+1}\\ p_{4i+2}^{n+1}\\ p_{4i+3}^{n+1}\end{bmatrix}=\begin{bmatrix} 1 & 0 & 0\\ \mu & 1+\beta/2 & -\nu\\ 0 & 1 & 0\\ -\nu & 1+\beta/2 & \mu\end{bmatrix}\begin{bmatrix} p_{2i}^{n}\\ p_{2i+1}^{n}\\ p_{2i+2}^{n},\end{bmatrix}. \tag{2.6}$$

For $n\ge 2$ and $i=0,1,\dots,2^{n-2}-1$

$$\begin{bmatrix} f_{8i}^{n+1}\\ f_{8i+1}^{n+1}\\ f_{8i+2}^{n+1}\\ f_{8i+3}^{n+1}\\ f_{8i+4}^{n+1}\\ f_{8i+5}^{n+1}\\ f_{8i+6}^{n+1}\\ f_{8i+7}^{n+1}\end{bmatrix}=\frac14\begin{bmatrix} 4 & 0 & 0 & 0 & 0\\ 1+\mu & 2(2-\mu) & \mu+\nu-1 & -2\nu & \nu\\ 0 & 4 & 0 & 0 & 0\\ -\mu & 2(1+\mu) & 2-\mu-\nu & 2\nu & -\nu\\ 0 & 0 & 4 & 0 & 0\\ -\nu & 2\nu & 2-\mu-\nu & 2(1+\mu) & -\mu\\ 0 & 0 & 0 & 4 & 0\\ \nu & -2\nu & \mu+\nu-1 & 2(2-\mu) & 1+\mu\end{bmatrix}\begin{bmatrix} f_{4i}^{n}\\ f_{4i+1}^{n}\\ f_{4i+2}^{n}\\ f_{4i+3}^{n}\\ f_{4i+4}^{n},\end{bmatrix}, \tag{2.7}$$

where $\mu:=-2\alpha(1-\beta)$ and $\nu=\mu+\beta/2$.

Proof. The result is clear for equations corresponding to even subscripts of p and f since the scheme is interpolating. Consider therefore the odd subscript equations. We will use the notation $\Delta p_k^n=p_{k+1}^n-p_k^n$, $\Delta f_k^n=f_{k+1}^n-f_k^n$ and $\Delta^2 f_k^n=\Delta(\Delta f_k^n)=f_{k+2}^n-2f_{k+1}^n+f_k^n$.

Let us start by proving (2.6). Using (2.3) with $k=2i$ and $k=2i+1$

$$\begin{aligned} p_{4i+1}^{n+1}&=(1-\beta)\frac{\Delta f_{2i}^n}{h_n}+\frac{\beta}{2}\big(p_{2i+1}^n+p_{2i}^n\big)\\ p_{4i+3}^{n+1}&=(1-\beta)\frac{\Delta f_{2i+1}^n}{h_n}+\frac{\beta}{2}\big(p_{2i+2}^n+p_{2i+1}^n\big).\end{aligned} \tag{2.8}$$

From (2.2) we obtain

$$\begin{aligned}\frac{\Delta f_{2i}^n}{h_n} &= \frac{\Delta f_i^{n-1}}{h_{n-1}} + 2\alpha\Delta p_i^{n-1},\\ \frac{\Delta f_{2i+1}^n}{h_n} &= \frac{\Delta f_i^{n-1}}{h_{n-1}} - 2\alpha\Delta p_i^{n-1}.\end{aligned} \tag{2.9}$$

The f difference on the right can be eliminated by a reordering of (2.3) with $k = i$ and $n \to n-1$

$$(1-\beta)\frac{\Delta f_i^{n-1}}{h_{n-1}} = p_{2i+1}^n - \frac{\beta}{2}\big(p_{i+1}^{n-1} + p_i^{n-1}\big). \tag{2.10}$$

Combining (2.8)–(2.10), we find

$$\begin{aligned}p_{4i+1}^{n+1} &= p_{2i+1}^n + \frac{\beta}{2}\big(p_{2i+1}^n - p_{i+1}^{n-1}\big) - \mu\Delta p_i^{n-1},\\ p_{4i+3}^{n+1} &= p_{2i+1}^n + \frac{\beta}{2}\big(p_{2i+1}^n - p_i^{n-1}\big) + \mu\Delta p_i^{n-1},\end{aligned}$$

and we obtain (2.6).

In terms of differences (2.6) takes the form

$$\begin{aligned}\Delta p_{4i}^n &= (1-\mu)\Delta p_{2i}^{n-1} - \nu\Delta p_{2i+1}^{n-1},\\ \Delta p_{4i+1}^n &= \mu\Delta p_{2i}^{n-1} + \nu\Delta p_{2i+1}^{n-1},\\ \Delta p_{4i+2}^n &= \nu\Delta p_{2i}^{n-1} + \mu\Delta p_{2i+1}^{n-1},\\ \Delta p_{4i+3}^n &= -\nu\Delta p_{2i}^{n-1} + (1-\mu)\Delta p_{2i+1}^{n-1}.\end{aligned} \tag{2.11}$$

Notice that an equivalent formulation of (2.2) is

$$\Delta^2 f_{2k}^{n+1} = -2\alpha h_n \Delta p_k^n$$

and (2.11) can be written

$$\begin{aligned}2\Delta^2 f_{8i}^{n+1} &= (1-\mu)\Delta^2 f_{4i}^n - \nu\Delta^2 f_{4i+2}^n,\\ 2\Delta^2 f_{8i+2}^{n+1} &= \mu\Delta^2 f_{4i}^n + \nu\Delta^2 f_{4i+2}^n,\\ 2\Delta^2 f_{8i+4}^{n+1} &= \nu\Delta^2 f_{4i}^n + \mu\Delta^2 f_{4i+2}^n,\\ 2\Delta^2 f_{8i+6}^{n+1} &= -\nu\Delta^2 f_{4i}^n + (1-\mu)\Delta^2 f_{4i+2}^n.\end{aligned} \tag{2.12}$$

It remains to extract the values f_{8i+j}^{n+1}, $j = 1, 3, 5, 7$ from the previous formulae to obtain (2.7). □

From (2.6) it follows that the new p-values on level $n+1$ ($n \geq 1$) can be formed by an affine combination of three p values on the previous level n. This can especially be used to simplify the proofs of two results in [13] on monotonicity and convexity of the HC^1-interpolant.

For monotonicity the HC^1-algorithm is applied in [13, section 3] to test data $(f_0, p_0, f_1, p_1) = (0, x, 1, y)$ computing the corresponding HC^1-interpolant f and its derivative p. For fixed (α, β) the authors determine the set of slopes (x, y) giving $p \geq 0$. Theorem 11 in [13] states that if $-1 < \beta < 0$ and $0 > \alpha \geq \beta/(4(1-\beta))$, then

$$M(\alpha,\beta) := \{(x,y) \in \mathbb{R}_+^2 : p \geq 0\} = \{(x,y) \in \mathbb{R}_+^2 : x + y \leq \gamma\} =: T(\gamma),$$

where $\gamma := \frac{2(\beta-1)}{\beta}$ and $\mathbb{R}^2_+ = \{(x,y) \in \mathbb{R} : x > 0,\ y > 0\}$. Note that any point in $\mathbb{R}^2_+$ belongs to $T(\gamma)$ for some $\beta < 0$. Thus we can obtain an increasing interpolant for any nonnegative initial slopes x, y by choosing β suitably close to zero. For arbitrary initial data (f_0, p_0, f_1, p_1) on $[a,b]$ one can use the change of variables $g(t) := \big(f(a + t(b-a)) - f_0\big)/(f_1 - f_0)$ to show that the HC^1-interpolant f is increasing if and only if $\big(p_0/\Delta, p_1/\Delta\big) \in M(\alpha,\beta)$, where $\Delta := (f_1 - f_0)/(b-a)$.

The proof of Theorem 11 follows immediately from (2.6). Indeed for the assumed range of (α,β) the elements in the matrix in (2.6) are all nonnegative. Thus if p is nonnegative on level $n-1$ it is nonnegative on level n. Moreover, if $(x,y) \in T(\gamma)$, then $p((a+b)/2) = 1 - \beta + \beta(x+y)/2 \geq 1 - \beta + \frac{\beta}{2}\frac{2}{\beta}(\beta - 1) = 0$ and the theorem follows. In fact the theorem holds for $-2 \leq \beta < 0$ as long as we have C^1-convergence of the HC^1-interpolant; see the next subsection for convergence results.

For convexity the HC^1-algorithm is applied to the test data $(f_0, p_0, f_1, p_1) = (0, -x, 0, y)$ with $(x,y) \in \mathbb{R}^2_+$. For fixed (α,β) the set of slopes (x,y) giving an increasing p, is determined. Theorem 18 in [13] states that if $-1 \leq \beta < 0$ and $\gamma := (\beta - 2)/\beta$, then

$$C(\alpha,\beta) := \{(x,y) \in \mathbb{R}^2_+ : p \text{ is increasing}\} = \{(x,y) \in \mathbb{R}^2_+ : x/\gamma \leq y \leq x\gamma\} =: C^*(\gamma)$$

if and only if $\alpha = \beta/(4(1-\beta))$. Since any point in $\mathbb{R}^2_+$ belongs to $C^*(\gamma)$ for β sufficiently close to zero, this result implies that we can obtain a convex HC^1-interpolant in the EQS-case by using any nonnegative values (x,y) as initial data. For arbitrary initial data (f_0, p_0, f_1, p_1) on $[a,b]$ with $h = b-a$, one can for convexity use the change of variables $g(t) := f(a+th) - (1-t)f_0 - tf_1$ to show that the HC^1-interpolant f is convex if and only if $h * \big(p_1 - \Delta, \Delta - p_0\big) \in C(\alpha,\beta)$, where as before $\Delta := (f_1 - f_0)/h$.

To prove Theorem 18 we use (2.11). For the given value of α we have $\nu = 0$ and moreover $0 \leq \mu \leq 1$. Thus p is increasing on level n if it is increasing on level $n-1$. Since $-x = \beta(\gamma - 1)x \leq \beta(y-x)/2 = p((a+b)/2) \leq \beta(y - \gamma y)/2 = y$, p is increasing on level 1 and the if part of the theorem follows. The only if part is easy; see [13, p. 293].

In the EQS-case we only need two of the three p-values on the right of (2.6). Moreover, the derivatives will be sampled from a piecewise linear curve.

COROLLARY 2.2. *In the EQS-case* $\alpha = \frac{\beta}{4(1-\beta)}$ *we have*

$$\begin{aligned} p^{n+1}_{4i+1} &= -\frac{\beta}{2}p^n_{2i} + \left(1 + \frac{\beta}{2}\right)p^n_{2i+1}, \\ p^{n+1}_{4i+3} &= \left(1 + \frac{\beta}{2}\right)p^n_{2i+1} - \frac{\beta}{2}p^n_{2i+2}. \end{aligned} \tag{2.13}$$

and

$$\begin{aligned} 4f^{n+1}_{8i+1} &= \left(1 - \frac{\beta}{2}\right)f^n_{4i} + (4+\beta)f^n_{4i+1} - \left(1 + \frac{\beta}{2}\right)f^n_{4i+2} \\ 4f^{n+1}_{8i+3} &= \frac{\beta}{2}f^n_{4i} + (2-\beta)f^n_{4i+1} + \left(2 + \frac{\beta}{2}\right)f^n_{4i+2} \\ 4f^{n+1}_{8i+5} &= \left(2 + \frac{\beta}{2}\right)f^n_{4i+2} + (2-\beta)f^n_{4i+3} + \frac{\beta}{2}f^n_{4i+4} \\ 4f^{n+1}_{8i+7} &= -\left(1 + \frac{\beta}{2}\right)f^n_{4i+2} + (4+\beta)f^n_{4i+3} + \left(1 - \frac{\beta}{2}\right)f^n_{4i+4}. \end{aligned} \tag{2.14}$$

If in addition $\beta \in (-2, 0)$, then there exist

$$a = \tau_0^n < \tau_1^n < \cdots < \tau_{2^n}^n = b, \tag{2.15}$$

with $\tau_{2^{n-1}}^n = \frac{a+b}{2}$ for $n \geq 1$, such that

$$p_i^n = L(\tau_i^n), \quad i = 0, 1, \ldots, 2^n, \quad n = 0, 1, \ldots, \tag{2.16}$$

where L is the piecewise linear curve connecting the three points $(a, p(a))$, $(\frac{a+b}{2}, p(\frac{a+b}{2}))$, $(b, p(b))$.

Proof. If $\alpha = \frac{\beta}{4(1-\beta)}$, then $\mu = -\beta/2$ and (2.13) follows from (2.6). Similarly, we obtain (2.14).

We claim that (2.16) holds with

$$\begin{aligned} \tau_{4i}^{n+1} &= \tau_{2i}^n, \quad \tau_{4i+1}^{n+1} = -\frac{\beta}{2}\tau_{2i}^n + \left(1 + \frac{\beta}{2}\right)\tau_{2i+1}^n, \\ \tau_{4i+2}^{n+1} &= \tau_{2i+1}^n, \quad \tau_{4i+3}^{n+1} = -\frac{\beta}{2}\tau_{2i+2}^n + \left(1 + \frac{\beta}{2}\right)\tau_{2i+1}^n. \end{aligned} \tag{2.17}$$

Since $p_0^n = p(a)$ and $p_{2^n}^n = p(b)$, we have $\tau_0^n = a$ and $\tau_{2^n}^n = b$ for all $n \geq 0$. Moreover, since $p_{2^{n-1}}^n = p(\frac{a+b}{2})$, we see that $\tau_{2^{n-1}}^n = \frac{a+b}{2}$ for all $n \geq 1$. Thus (2.15) will follow from (2.17) since the latter involves convex combinations for $\beta \in (-2, 0)$; (2.17) follows from (2.13) by induction. Suppose (2.16) holds for some n. Since L is linear on the actual segment we obtain

$$p_{4i+1}^{n+1} = -\frac{\beta}{2}L(\tau_{2i}^n) + \left(1 + \frac{\beta}{2}\right)L(\tau_{2i+1}^n) = L(\tau_{4i+1}^{n+1}),$$

where τ_{4i+1}^{n+1} is given by (2.17). The proof of the other τ-relation is similar. ∎

2.3. C^1-convergence. To study convergence we observe that it is enough to consider the interval $[0, 1]$. Indeed, if $I := [a, b]$ and $h := b - a$, defining the initial data $g(u) = f(a + hu)$, $g'(u) = hf'(a + hu)$, for $u \in \{0, 1\}$, the construction of f on $[a, b]$ or g on $[0, 1]$ by (2.1) are equivalent and at step n, $g(u) = f(a + uh)$ and $g'(u) = hf'(a + hu)$ for $u \in \{0, 1/2^n, \ldots, \ell/2^n, \ldots, 1\}$.

In [12] it was shown that if there exist positive constants c, ρ with $\rho < 1$ such that for each integer $n \geq 0$ we have $|\Delta p_i^n| \leq c\rho^n$ for $i = 0, 1, \ldots, 2^n - 1$, where

$$\Delta p_i^n := p\left(\frac{i+1}{2^n}\right) - p\left(\frac{i}{2^n}\right), \quad i = 0, 1, \ldots, 2^n - 1, \tag{2.18}$$

then p has a unique continuous extension to I. Moreover, there is a positive constant c_1 such that for all $(x, y) \in [0, 1]^2$

$$|p(x) - p(y)| \leq c_1 |x - y|^{-\log_2 \rho},$$

i.e., p is Hölder continuous with exponent $-\log_2 \rho$.

Suppose p is continuous and $\lim_{n\to\infty} \max_{0 \leq i < 2^n - 1} |\Delta(f, p)_i^n| = 0$, where

$$\Delta(f, p)_i^n := 2^n \Delta f_i^n - \sigma p_i^n, \quad \sigma p_i^n := \frac{1}{2}\left(p\left(\frac{i+1}{2^n}\right) + p\left(\frac{i}{2^n}\right)\right), \tag{2.19}$$

and $\Delta f_i^n = f\left(\frac{i+1}{2^n}\right) - f\left(\frac{i}{2^n}\right)$. Then [12] f has a unique continuous extension to $I := [0,1]$. Moreover, $f \in C^1([0,1])$ with $f' = p$. From this discussion we have the following lemma.

LEMMA 2.3. *Let* $U_i^n := [\Delta p_i^n, \Delta(f,p)_i^n]^T$ *for* $i = 0,1,\ldots,2^n-1$ *and* $n = 0,1,2,\ldots$. *If we can find a vector norm* $\|\cdot\|$ *on* $\mathbb{R}^2$ *and positive constants* c, ρ *with* $\rho < 1$ *such that*

$$\|U_i^n\| \le c\rho^n,\ i = 0,1,\ldots,2^n-1 \text{ and } n = 0,1,\ldots,$$

then the HC^1*-algorithm is* C^1*-convergent and* $f' = p$ *is Hölder continuous with exponent* $-\log_2 \rho$.

We can now show the following proposition.

PROPOSITION 2.4. *Algorithm* HC^1 *is* C^1*-convergent for* $(\alpha,\beta) \in [-1/8,0) \times [-2,1)$.

Proof. An immediate evaluation gives

$$U_{2i}^{n+1} = \Lambda_1 U_i^n \text{ and } U_{2i+1}^{n+1} = \Lambda_{-1} U_i^n \text{ for } i = 0,1,\ldots,2^n, n = 0,1,\ldots,$$

where

$$\Lambda_\epsilon = \begin{bmatrix} \frac{1}{2} & \epsilon(1-\beta) \\ \epsilon\frac{8\alpha+1}{4} & \frac{1+\beta}{2} \end{bmatrix}, \quad \varepsilon = \pm 1. \tag{2.20}$$

Note that the off-diagonal elements of Λ_ε have the same sign for $\alpha \ge -1/8$ and $\beta \le 1$. We define a vector norm by $\|v\| := \|P^{-1}v\|_2$, where $\|\cdot\|_2$ is the usual Euclidian vector norm and $P := \begin{bmatrix} 2\sqrt{1-\beta} & 0 \\ 0 & \sqrt{8\alpha+1} \end{bmatrix}$. Then $P^{-1}\Lambda_\varepsilon P$ is symmetric and the corresponding matrix operator norm is given by $\|\Lambda_\varepsilon\| := \|P^{-1}\Lambda_\varepsilon P\|_2$, where $\|A\|_2 := \sqrt{\rho(A^TA)}$ is the spectral norm of a matrix A. The eigenvalues of Λ_ε or of $P^{-1}\Lambda_\varepsilon P$ are

$$\lambda_1 = \frac{1}{4}\big(2+\beta+\sqrt{(2-\beta)^2+32\alpha(1-\beta)}\big), \quad \lambda_2 = \frac{1}{4}\big(2+\beta-\sqrt{(2-\beta)^2+32\alpha(1-\beta)}\big).$$

Since $P^{-1}\Lambda_\varepsilon P$ is symmetric the eigenvalues are real with $\lambda_2 < \lambda_1$. Now for $\beta \in [-2,1)$ and $\alpha \in [-1/8,0)$ we find $\lambda_1 < (2+\beta+\sqrt{(2-\beta)^2})/4 = 1$ and $\lambda_2 > (2+\beta-\sqrt{(2-\beta)^2})/4 = \beta/2 \ge -1$. Thus $\rho := \|\Lambda_\varepsilon\| = \max\{|\lambda_1|,|\lambda_2|\} < 1$ for $\varepsilon = \pm 1$ and we have shown that $\max\{\|U_{2i}^{n+1}\|, \|U_{2i+1}^{n+1}\|\} \le \rho\|U_i^n\|$ so that $\|U_i^n\| \le \rho^n\|U_0^0\|$ for $i = 0,1,\ldots,2^n-1$ and $n = 0,1,2,\ldots$. The C^1-convergence for $(\alpha,\beta) \in [-1/8,0)\times[-2,1)$ now follows from Lemma 2.3. ∎

By Proposition 2.4, the HC^1-algorithm converges for $\beta \in [-1,0)$ if $\alpha = \frac{\beta}{4(1-\beta)}$. We can now extend this result.

PROPOSITION 2.5. *If* $\alpha = \frac{\beta}{4(1-\beta)}$, *then the* HC^1*-algorithm is* C^1*-convergent for* $\beta \in (-2,0)$.

Proof. For $\varepsilon = \pm 1$ the matrices Λ_ε in (2.20) take the form

$$\Lambda_\varepsilon = \begin{pmatrix} \frac{1}{2} & \varepsilon(1-\beta) \\ \varepsilon\frac{\beta+1}{4(1-\beta)} & \frac{1+\beta}{2} \end{pmatrix}.$$

Now, for any positive real number θ, we define the norm $\|\cdot\|_\theta$ on $\mathbb{R}^2$ by $\|(x,y)\|_\theta = |x|+\theta|y|$. It is easy to prove that for any matrix $M = (m_{ij}) \in \mathbb{R}^{2\times 2}$, the corresponding matrix operator norm is given by $\|M\|_\theta := \max(|m_{11}| + \theta|m_{21}|, |m_{12}|/\theta + |m_{22}|)$. Choosing $\theta = 2(1-\beta)$ we find $\|\Lambda_1\|_\theta = \|\Lambda_{-1}\|_\theta = 1/2(1+|1+\beta|)$, which is stricly less than one for $-2 < \beta < 0$. Lemma 2.3 now gives the convergence. ∎

We define the convergence region C by

$$C := \{(\alpha,\beta) : \text{ the scheme } HC^1 \text{ is } C^1\text{-convergent}\}. \tag{2.21}$$

We have shown that $[-1/8, 0) \times [-2, 1) \subset C$ and also that $\{(\frac{\beta}{4(1-\beta)}, \beta) : -2 < \beta < 0\} \subset C$.

The function $f' = p$ is Hölder continuous with exponent $-\log_2 \rho$. In the case where $\alpha = \frac{\beta}{4(1-\beta)}$ we have $\|\Lambda_1\|_\theta = \|\Lambda_{-1}\|_\theta = \rho = \rho(\beta) = 1/2(1+|1+\beta|)$ which is piecewise linear with a minimum for $\beta = -1$ and we obtain the best regularity of the interpolant for $\beta = -1$ when f is a quadratic spline.

To illustrate the smoothness properties of a HC^1-interpolant we show the Hermite basis with $\beta = -3/5$ and $\alpha = \frac{\beta}{4(1-\beta)} = -3/32$ in Figure 2.1. The spectral radius of the matrices Λ_ε is $7/10$ and hence the derivatives of the Hermite basis functions are Hölder continuous with exponent $\rho = -\log_2(7/10) \approx 0.5146$.

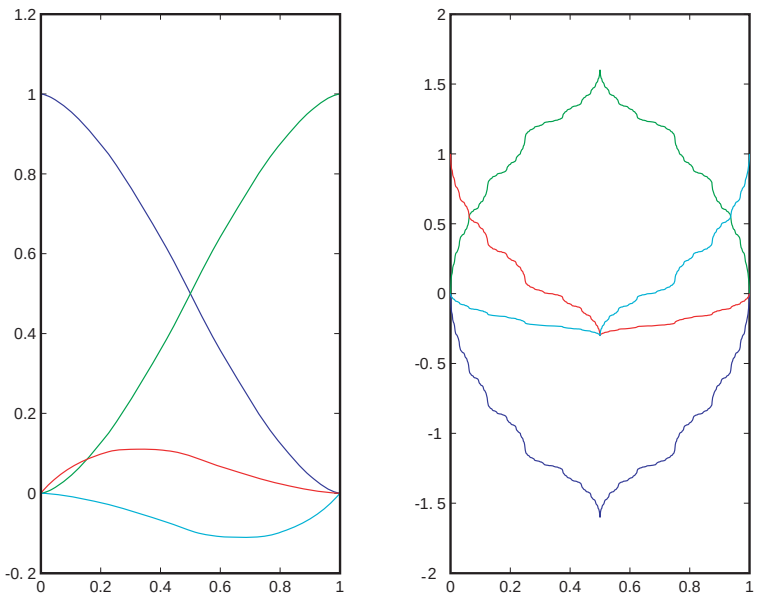

FIG. 2.1. *Hermite basis and derivatives, corresponding to* $\alpha = -3/32$ *and* $\beta = -3/5$.

Remark. The data $f(a), p(a), f(b), p(b)$ can either have real values or vector values in $\mathbb{R}^s$, $s \geq 2$. In this second case, we look for vector continuous functions f and p with $f' = p$ from $I = [a,b]$ to $\mathbb{R}^s$. The C^1-convergence is guaranteed for all (α,β) in the convergence region C since it suffices to study the convergence independently for each component of f and p.

3. Control polygons and subdivision algorithm.

3.1. Control coefficients and control polygons. Suppose we apply the subdivision scheme HC^1 to some real valued data $f(a)$, $p(a)$, $f(b)$, $p(b)$. In order to obtain a geometric formulation of the scheme we define *control coefficients* relative to the interval $[a,b]$ by

$$a_0 = f(a), \quad a_1 = f(a) + \frac{h}{\lambda}p(a), \quad a_2 = f(b) - \frac{h}{\lambda}p(b), \quad a_3 = f(b), \tag{3.1}$$

where $h := b - a$ and $\lambda \geq 2$ is a real number to be chosen. We define the *control points* $(A_0,\ A_1,\ A_2,\ A_3)$ on $[a,b]$ by

$$A_0 = (a, a_0), \quad A_1 = \left(a + \frac{h}{\lambda}, a_1\right), \quad A_2 = \left(b - \frac{h}{\lambda}, a_2\right), \quad A_3 = (b, a_3), \tag{3.2}$$

and the *control polygon* $\{A_0,\ A_1,\ A_2,\ A_3\}$ on $[a,b]$ by connecting the four control points by straight line segments. If f is the HC^1-interpolant, then the parametric curve $(x, f(x))$ with $x \in [a,b]$ passes through A_0 with tangent directions $A_1 - A_0$ and A_3 with tangent direction $A_3 - A_2$; see Figure 3.1.

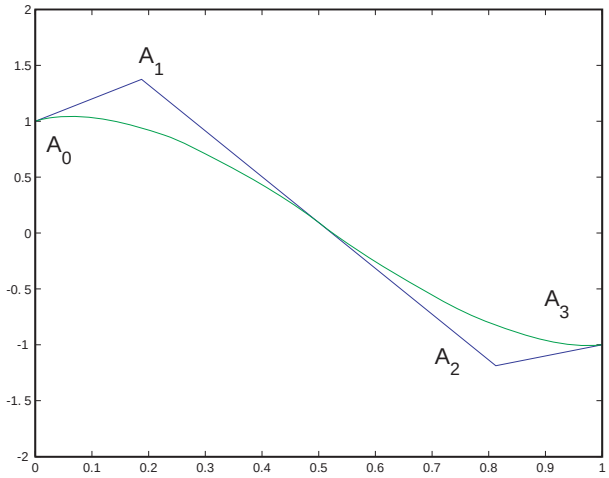

FIG. 3.1. *A HC^1-interpolant and its control polygon, $\beta = -3/5$, $\alpha = -3/32$, $\lambda = 16/3$.*

We can also apply the subdivision scheme HC^1 to vector valued data f_0, p_0, f_1, p_1 in $\mathbb{R}^s$ for some $s \geq 2$. We pick an interval $[a,b]$ and use the HC^1-algorithm on each component of f and p. To obtain a geometric formulation of this process we define control coefficients relative to $[a,b]$ by (3.1) and we define the control points to be the same as the control coefficients. The computed curve interpolates the first and last control coefficient and its tangent direction at a_0 is $a_1 - a_0$, and at a_3 the tangent direction is $a_3 - a_2$.

Note that if 4 points a_0, a_1, a_2, a_3 in $\mathbb{R}^s$ for $s \geq 1$ are given we can think of these as control coefficients of a HC^1-interpolant on some finite interval $[a,b]$ and apply the HC^1-algorithm to the data given by

$$f(a) := a_0,\ p(a) := \frac{\lambda}{h}(a_1 - a_0),\ f(b) := a_3,\ p(b) := \frac{\lambda}{h}(a_3 - a_2), \tag{3.3}$$

where $h := b-a$. We now derive a parameter independent formulation of this scheme. In particular suppose (a_0, a_1, a_2, a_3) are points in $\mathbb{R}^s$ for some $s \geq 1$ which are distinct if $s \geq 2$ and let $[a, b]$ be any finite interval.

Using (3.1) and (3.3) we can compute new control coefficients $(\bar{a}_0, \bar{a}_1, \bar{a}_2, \bar{a}_3)$ for the interval I_1 and new control coefficients $(\bar{a}_3, \bar{a}_4, \bar{a}_5, \bar{a}_6)$ for I_2, and then join them into control coefficients $(\bar{a}_0, \bar{a}_1, \bar{a}_2, \bar{a}_3, \bar{a}_4, \bar{a}_5, \bar{a}_6)$ on $[a, b]$. In the following geometric formulation of the subdivision scheme we do this computation directly without picking an underlying interval $[a, b]$. The proposition is a generalization of [15, Theorem 10].

PROPOSITION 3.1. *Suppose $a_i \in \mathbb{R}^s$ for $i = 0, 1, 2, 3$ and some $s \geq 1$. After one subdivision of the control coefficients (a_0, a_1, a_2, a_3) we obtain new control coefficients $(\bar{a}_0, \bar{a}_1, \bar{a}_2, \bar{a}_3, \bar{a}_4, \bar{a}_5, \bar{a}_6)$ given by*

$$\begin{bmatrix} \bar{a}_0 \\ \bar{a}_1 \\ \bar{a}_2 \\ \bar{a}_3 \\ \bar{a}_4 \\ \bar{a}_5 \\ \bar{a}_6 \end{bmatrix} = \mathbf{S} \begin{bmatrix} a_0 \\ a_1 \\ a_2 \\ a_3 \end{bmatrix} := \frac{1}{4} \begin{bmatrix} 4 & 0 & 0 & 0 \\ 2 & 2 & 0 & 0 \\ \gamma & v-\beta & v+\beta & \delta \\ 2-v & v & v & 2-v \\ \delta & v+\beta & v-\beta & \gamma \\ 0 & 0 & 2 & 2 \\ 0 & 0 & 0 & 4 \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ a_2 \\ a_3 \end{bmatrix}, \tag{3.4}$$

where

$$\begin{aligned} v &= -4\alpha\lambda, \\ \gamma &= 2 - v + (2 + \beta(\lambda - 2))/\lambda, \\ \delta &= 2 - v - (2 + \beta(\lambda - 2))/\lambda. \end{aligned} \tag{3.5}$$

Moreover,

$$\bar{a}_3 = \frac{1}{2}(\bar{a}_2 + \bar{a}_4). \tag{3.6}$$

Proof. Pick any interval $[a, b]$ and let $h := b - a$. By (3.1)

$$\bar{a}_0 = f(a),\ \bar{a}_1 = f(a) + \frac{h}{2\lambda}p(a),\ \bar{a}_2 = f\left(\frac{a+b}{2}\right) - \frac{h}{2\lambda}p\left(\frac{a+b}{2}\right),\ \bar{a}_3 = f\left(\frac{a+b}{2}\right),$$
$$\bar{a}_6 = f(b),\ \bar{a}_5 = f(b) - \frac{h}{2\lambda}p(b),\ \bar{a}_4 = f\left(\frac{a+b}{2}\right) + \frac{h}{2\lambda}p\left(\frac{a+b}{2}\right).$$

From (2.1) and (3.3) we obtain on an interval $[a, b]$ the inverse relations

$$\begin{aligned} f(a) = a_0, \quad p(a) &= \frac{\lambda}{h}(a_1 - a_0), \\ f(b) = a_3, \quad p(b) &= \frac{\lambda}{h}(a_3 - a_2), \\ f\left(\frac{a+b}{2}\right) &= \frac{a_0 + a_3}{2} - \frac{v}{4}(a_3 - a_2 - a_1 + a_0), \\ \frac{h}{2\lambda}p\left(\frac{a+b}{2}\right) &= \frac{1-\beta}{2\lambda}(a_3 - a_0) + \frac{\beta}{4}(a_3 - a_2 + a_1 - a_0), \\ &= \frac{2 + \beta(\lambda - 2)}{\lambda}(a_3 - a_0) + \frac{\beta}{4}(a_1 - a_2). \end{aligned} \tag{3.7}$$

But then we see that $(\bar a_0, \bar a_1, \bar a_2, \bar a_3, \bar a_4, \bar a_5, \bar a_6)^T = \mathbf{S}(a_0, \dots, a_3)^T$, where $\mathbf{S}$ is the matrix in (3.4). Since the sum of rows three and five in the matrix $\mathbf{S}$ equals twice row four the relation (3.6) follows. □

For $s \geq 2$ the control coefficients and control points are the same and the proposition also gives rules for subdividing the control polygon. The following corollary holds in general.

COROLLARY 3.2. *Suppose $(a_0, a_1, a_2, a_3) \in \mathbb{R}^s$ for some $s \geq 1$. After one subdivision of the corresponding control polygon $\{A_0, A_1, A_2, A_3\}$ we obtain a new control polygon $\{\bar A_0, \bar A_1, \bar A_2, \bar A_3, \bar A_4, \bar A_5, \bar A_6\}$ given by*

$$\begin{bmatrix}\bar A_0 & \bar A_1 & \bar A_2 & \bar A_3 & \bar A_4 & \bar A_5 & \bar A_6\end{bmatrix}^T = \mathbf{S}\begin{bmatrix}A_0 & A_1 & A_2 & A_3\end{bmatrix}^T, \tag{3.8}$$

where $\mathbf{S}$ is given by (3.4). *Moreover,*

$$\bar A_3 = \frac{1}{2}(\bar A_2 + \bar A_4), \tag{3.9}$$

which means that these control points always lie on a straight line.

Proof. This has already been shown for $s \geq 2$ and for the control coefficients for $s = 1$. For the control point abscissas we obtain the relation $(a, a + h/(2\lambda), \bar a - h/(2\lambda), \bar a, \bar a + h/(2\lambda), b - h/(2\lambda), d)^T = \mathbf{S}(a, a + h/\lambda, b - h/\lambda, d)^T$, where $\bar a = (a+b)/2$, since the scheme HC^1 reproduces linear functions. Thus (3.8) and (3.9) also holds for $s = 1$. □

3.2. A stationary subdivision algorithm. By applying (3.4), we can reformulate the Hermite subdivision scheme HC^1 as a stationary subdivision scheme working on points in $\mathbb{R}^s$.

Starting with 4 points a_0, a_1, a_2, a_3 in $\mathbb{R}^s$, $s \geq 1$, (α, β) in the convergence region C, and $\lambda \geq 2$, we define Algorithm SC^1 as follows.

At step $n = 0$, we set $a_0^0 = a_0$, $a_1^0 = a_1$, $a_2^0 = a_2$, $a_3^0 = a_3$.

At step $n + 1$, $n \geq 0$, we define

$$\begin{bmatrix} a_{6i}^{n+1} \\ a_{6i+1}^{n+1} \\ a_{6i+2}^{n+1} \\ a_{6i+3}^{n+1} \\ a_{6i+4}^{n+1} \\ a_{6i+5}^{n+1} \end{bmatrix} = \frac{1}{4}\begin{bmatrix} 4 & 0 & 0 & 0 \\ 2 & 2 & 0 & 0 \\ \gamma & v-\beta & v+\beta & \delta \\ 2-v & v & v & 2-v \\ \delta & v+\beta & v-\beta & \gamma \\ 0 & 0 & 2 & 2 \end{bmatrix}\begin{bmatrix} a_{3i}^n \\ a_{3i+1}^n \\ a_{3i+2}^n \\ a_{3i+3}^n \end{bmatrix}, \quad i = 0, 1, \dots, 2^n - 1 \tag{3.10}$$

and $a_{3.2^{n+1}}^{n+1} = a_{3.2^n}^n$. Here v, γ, δ are given by (3.5). The matrix $(s_{\ell,k})_{\ell=0,\dots,5,k=0,\dots,3}$ in (3.10) is formed from the first 6 rows of $\mathbf{S}$ given by (3.4).

LEMMA 3.3. *For all $n \geq 1$ and for all $i = 1, \dots, 2^n - 1$, we have*

$$\begin{aligned} a_{6i}^{n+1} &= a_{3i}^n, \ i = 1, \dots, 2^{n-1}, \\ a_{6i+1}^{n+1} - a_{6i}^{n+1} &= \frac{1}{2}\big(a_{3i+1}^n - a_{3i}^n\big), \ i = 1, \dots, 2^{n-1} - 1, \\ a_{3i+1}^n + a_{3i-1}^n &= 2a_{3i}^n, \ i = 1, \dots, 2^n - 1. \end{aligned} \tag{3.11}$$

Proof. The first two equations follow immediately from (3.10). As in the proof of (3.6) it is clear that

$$a_{6i+2}^{n+1} + a_{6i+4}^{n+1} = 2a_{6i+3}^{n+1}, \quad i = 0, \dots, 2^n - 1, \quad n = 0, 1, \dots,$$

and in particular $a_2^1 + a_4^1 = 2a_3^1$. By (3.11) and induction on n

$$a_{6i+1}^{n+1} + a_{6i-1}^{n+1} = \frac{1}{2}(a_{3i}^n + a_{3i+1}^n) + \frac{1}{2}(a_{3i-1}^n + a_{3i}^n) = 2a_{3i}^n = 2a_{6i}^{n+1}. \qquad \square$$

If we define a_i^0 for $i < 0$ and $i > 3$ in any way, the subdivision scheme can be written $a_\ell^{n+1} = \sum_{k\in\mathbb{Z}} \sigma_{\ell,k} a_k^n$, $\ell \in \mathbb{Z}$, where $\sigma_{6i+\ell,3i+k} = s_{\ell,k}$ for $i \in \mathbb{Z}$, $\ell = 0, \ldots, 5$, $k = 0, \ldots, 3$ and $\sigma_{i,j} = 0$ otherwise. With the definitions recalled in [3], the scheme is *local* since $\sigma_{\ell,k} = 0$ for $|\ell - 2k| > 4$. Since $\sum_{k\in\mathbb{Z}} \sigma_{\ell,k} = 1$, it is *affine* but is not interpolating in a classical sense since we generally have $a_{6i+2}^{n+1} \neq a_{3i+1}^n$.

3.3. Convergence of SC^1. The convergence of the subdivision schemes are usually established by studying the difference sequence. Alternatively convergence follows since SC^1 was derived from HC^1. Here are the details.

THEOREM 3.4. *Let $s \geq 1$ and a_0, a_1, a_2, a_3 be 4 points in $\mathbb{R}^s$. Suppose $\lambda \geq 2$ and that (α, β) is in the convergence region C given by (2.21). We build the sequence of points $\{a_i^n\}_{n\in\mathbb{N}, i=0,\ldots,3.2^n}$ by (3.10). Choose any interval $I := [a, b]$ with $h := b - a > 0$ and define $t_i^n := a + ih_n$, where $h_n := h2^{-n}$ for $n \in \mathbb{N}$ and $i = 0, \ldots, 2^n$. Then, there exists a C^1 function $f : I \to \mathbb{R}^s$ such that for all $n \in \mathbb{N}$:*

$$\begin{aligned} a_{3i}^n &= f(t_i^n), \quad i = 0, \ldots, 2^n, \\ a_{3i+1}^n - a_{3i}^n &= \frac{h_n}{\lambda} f'(t_i^n), \quad i = 0, \ldots, 2^n - 1, \\ a_{3i}^n - a_{3i-1}^n &= \frac{h_n}{\lambda} f'(t_i^n), \quad i = 1, \ldots, 2^n. \end{aligned}$$

For $s \geq 2$, let $A_i^n = a_i^n$, $i = 0, 1, \ldots, 3 \times 2^n$ and for $s = 1$, let $A_{3i}^n = (t_i^n, a_{3i}^n)$, $A_{3i+1}^n = (t_i^n + \frac{h_n}{\lambda}, a_{3i+1}^n)$, $A_{3i+2}^n = (t_{i+1}^n - \frac{h_n}{\lambda}, a_{3i+2}^n)$, $i = 0, 1, \ldots, 2^n - 1$, and $A_{3\times 2^n}^n = (b, a_{3\times 2^n}^n)$.

Then the sequence of polygons $\{A_0^n, \ldots, A_{3\times 2^n}^n\}$ converges to the curve $\{f(t), t \in I\}$.

Proof. We will show that the scheme SC^1 generates sequences $\{f^n\}$ and $\{p^n\}$ of piecewise linear vector functions which interpolate values and derivatives at the points of $\mathcal{P}_n = \{t_0^n, \ldots, t_{2^n}^n\}$.

We define f^n and p^n to be linear on $[t_i^n, t_{i+1}^n]$, $i = 0, \ldots, 2^n - 1$, and to interpolate the following values:

$$\begin{aligned} f^n(t_i^n) = a_{3i}^n, \quad p^n(t_i^n) &= \frac{\lambda}{h_n}(a_{3i+1}^n - a_{3i}^n), \quad i = 0, \ldots, 2^n - 1, \\ f^n(b) = a_{3.2^n}^n, \quad p^n(b) &= \frac{\lambda}{h_n}(a_{3\times 2^n}^n - a_{3\times 2^n-1}^n). \end{aligned} \tag{3.12}$$

Since $t_i^n = t_{2i}^{n+1}$ we find from (3.11) and (3.12)

$$f^{n+1}(t_i^n) = f^n(t_i^n), \quad p^{n+1}(t_i^n) = p^n(t_i^n), \ i = 0, \ldots, 2^n. \tag{3.13}$$

Below we prove that, for $i = 0, \ldots, 2^n - 1$,

$$f^{n+1}(t_{2i+1}^{n+1}) = \frac{f^n(t_{i+1}^n) + f^n(t_i^n)}{2} + \alpha h_n (p^n(t_{i+1}^n) - p^n(t_i^n)), \tag{3.14}$$

$$p^{n+1}(t_{2i+1}^{n+1}) = (1 - \beta)\frac{f^n(t_{i+1}^n) - f^n(t_i^n)}{h_n} + \beta \frac{p^n(t_{i+1}^n) + p^n(t_i^n)}{2}. \tag{3.15}$$

Comparing (3.13), (3.14), and (3.15) with (2.2)–(2.3) we conclude that $f^n = f$ and $p^n = p$ on $\mathcal{P}_n$, where f and p are the functions built on $\cup\mathcal{P}_n$ by HC^1 defined by (2.2)–(2.4) from the initial data $f(a) = a_0$, $p(a) = \frac{\lambda}{h}(a_1 - a_0)$, $f(b) = a_3$, and $p(b) = \frac{\lambda}{h}(a_3 - a_2)$, and then extended to $[a, b]$. So that if $(\alpha, \beta) \in C$, then the sequences f^n and p^n defined from SC^1 by (3.12) converge uniformly to continuous vector functions f and p defined on $[a, b]$. Moreover, $f \in C^1([a, b])$ and $f' = p$.

Now since f' is bounded and $a^n_{3i+1} - a^n_{3i} = \frac{h}{\lambda 2^n} f'(t^n_i)$, $i = 0, \ldots, 2^n - 1$, we deduce that $a^n_{3i+1} - a^n_{3i}$ tends uniformly to 0. We conclude that the sequence of polygons $\{A_0, \ldots, A_{3\times 2^n}\}$ tends to the curve $\{f(t),\, t \in I\}$ since $a^n_{3i} = f(t^n_i)$ for $i = 0, \ldots, 2^n$.

It remains to prove (3.14) and (3.15). Since $\alpha = -v/4\lambda$, for $i = 0, \ldots, 2^n - 1$ and using (3.12) and (3.10),

$$\begin{aligned}
&\frac{1}{2}(f^n(t^n_{i+1}) + f^n(t^n_i)) + \alpha h_n(p^n(t^n_{i+1}) - p^n(t^n_i)) \\
&\quad = \frac{1}{2}(a^n_{3i+3} + a^n_{3i}) - \frac{v}{4}(a^n_{3i+3} - a^n_{3i+2} - a^n_{3i+1} + a^n_{3i}) \\
&\quad = a^{n+1}_{6i+3} = f^{n+1}(t^{n+1}_{2i+1})
\end{aligned}$$

so that (3.14) is proved.

Similarly, for (3.15), let $i \in \{0, \ldots, 2^n - 1\}$. With the definitions of γ and δ in (3.5) we find

$$\begin{aligned}
&\frac{1-\beta}{h_n}(f^n(t^n_{i+1}) - f^n(t^n_i)) + \frac{\beta}{2}(p^n(t^n_{i+1}) + p^n(t^n_i)) \\
&\qquad = \frac{1-\beta}{h_n}(a^n_{3i+3} - a^n_{3i}) + \frac{\beta\lambda}{2h_n}(a^n_{3i+3} - a^n_{3i+2} + a^n_{3i+1} - a^n_{3i}) \\
&\qquad = \frac{\lambda}{h_{n+1}}\left(-\left(\frac{1-\beta}{2\lambda} + \frac{\beta}{4}\right)a^n_{3i} + \frac{\beta}{4}a^n_{3i+1} - \frac{\beta}{4}a^n_{3i+2} + \left(\frac{1-\beta}{2\lambda} + \frac{\beta}{4}\right)a^n_{3i+3}\right) \\
&\qquad = \frac{1}{4}\frac{\lambda}{h_{n+1}}\big((\delta - 2 + v)a^n_{3i} + \beta a^n_{3i+1} - \beta a^n_{3i+2} + (\gamma - 2 + v)a^n_{3i+3}\big) \\
&\qquad = \frac{\lambda}{h_{n+1}}\big(a^{n+1}_{6i+4} - a^{n+1}_{6i+3}\big) = p^{n+1}(t^{n+1}_{2i+1}). \qquad \square
\end{aligned}$$

4. Total positivity and consequences.

4.1. Corner cutting and total positivity of the subdivision matrix. Consider now the subdivision process in the EQS-case when $\alpha = \frac{\beta}{4(1-\beta)}$ with $\beta \in (-2, 0)$. Since $v = -4\alpha\lambda = \frac{\beta}{\beta-1}\lambda$, or $\lambda = \frac{\beta-1}{\beta}v$ we find from (3.5)

$$\gamma = 2 - v + \frac{2 + \beta\lambda - 2\beta}{\lambda} = 2 - v + \frac{2 + (\beta-1)v - 2\beta}{(\beta-1)v}\beta = \frac{(2-v)(v-\beta)}{v},$$

and similarly

$$\delta = \frac{(2-v)(v+\beta)}{v}.$$

Thus the subdivision matrix (3.4) can be written

$$\mathbf{S} = \frac{1}{4}\begin{bmatrix} 4 & 0 & 0 & 0 \\ 2 & 2 & 0 & 0 \\ \frac{(2-v)(v-\beta)}{v} & v-\beta & v+\beta & \frac{(2-v)(v+\beta)}{v} \\ 2-v & v & v & 2-v \\ \frac{(2-v)(v+\beta)}{v} & v+\beta & v-\beta & \frac{(2-v)(v-\beta)}{v} \\ 0 & 0 & 2 & 2 \\ 0 & 0 & 0 & 4 \end{bmatrix}. \tag{4.1}$$

In this case, as soon as $1 \le v \le 2$ and $v \ge -\beta$, we can compute the subdivided control points

$$(\bar{A}_0, \bar{A}_1, \bar{A}_2, \bar{A}_3, \bar{A}_4, \bar{A}_5, \bar{A}_6)^T = \mathbf{S}(A_0, A_1, A_2, A_3)^T$$

by successive convex combinations starting with the polygon defined by (A_0, A_1, A_2, A_3). With 2 intermediate quantities B and C we have (see Figure 4.1)

$$\begin{aligned} &\bar{A}_0 = A_0, \quad \bar{A}_1 = \frac{1}{2}A_0 + \frac{1}{2}A_1, \quad \bar{A}_5 = \frac{1}{2}A_2 + \frac{1}{2}A_3, \quad \bar{A}_6 = A_3, \\ &B = (1 - \frac{v}{2})A_0 + \frac{v}{2}A_1, \\ &C = (1 - \frac{v}{2})A_3 + \frac{v}{2}A_2, \\ &\bar{A}_2 = \frac{v-\beta}{2v}B + \frac{v+\beta}{2v}C, \\ &\bar{A}_4 = \frac{v+\beta}{2v}B + \frac{v-\beta}{2v}C, \\ &\bar{A}_3 = \frac{1}{2}\bar{A}_2 + \frac{1}{2}\bar{A}_4. \end{aligned} \tag{4.2}$$

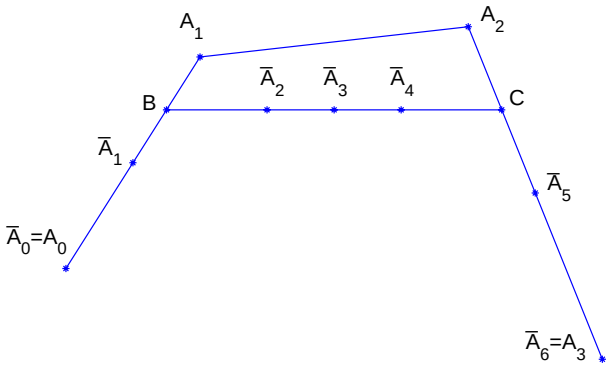

FIG. 4.1. *Corner cutting with* $\alpha = -3/32$, $\beta = -3/5$ *and* $v = 1.5$.

For $v = 2$ we obtain $B = A_1$ and $C = A_2$. The value of λ corresponding to $v = 2$ was considered in [15, Theorem 10], where formulae similar to (4.2) were given.

The equations (4.2) can be formulated as a corner cutting scheme in the following way. We start with the polygon $\{A_0, A_1, A_2, A_3\}$ and then either cut one of the previous corners or break an edge in the following sequence of convex combinations:

1. $B = (1-\frac{v}{2})A_0 + \frac{v}{2}A_1$ (replace A_1 by B to obtain $\{A_0, B, A_2, A_3\}$).
2. $C = (1-\frac{v}{2})A_3 + \frac{v}{2}A_2$ (replace A_2 by C to obtain $\{A_0, B, C, A_3\}$).
3. $\bar{A}_1 = (1-\frac{1}{v})A_0 + \frac{1}{v}B$ (break $[A_0, B]$ to obtain $\{A_0, \bar{A}_1, B, C, A_3\}$).
4. $\bar{A}_5 = \frac{1}{v}C + (1-\frac{1}{v})A_3$ (break $[C, A_3]$ to obtain $\{A_0, \bar{A}_1, B, C, \bar{A}_5, A_3\}$).
5. $\bar{A}_2 = \frac{v-\beta}{2v}B + \frac{v+\beta}{2v}C$ (replace B by $\bar{A}_2$ to obtain $\{A_0, \bar{A}_1, \bar{A}_2, C, \bar{A}_5, A_3\}$).
6. $\bar{A}_4 = \frac{v+\beta}{v-\beta}\bar{A}_2 - \frac{2\beta}{v-\beta}C$ (replace C by $\bar{A}_4$ to obtain $\{A_0, \bar{A}_1, \bar{A}_2, \bar{A}_4, \bar{A}_5, A_3\}$).
7. $\bar{A}_3 = (\bar{A}_2 + \bar{A}_4)/2$ (break $[\bar{A}_2, \bar{A}_4]$ to obtain $\{A_0, \bar{A}_1, \bar{A}_2, \bar{A}_3, \bar{A}_4, \bar{A}_5, A_3\}$).

Since $\bar{A}_0 = A_0$ and $\bar{A}_6 = A_3$ we have obtained the subdivided polygon $\{\bar{A}_0, \bar{A}_1, \bar{A}_2, \bar{A}_3, \bar{A}_4, \bar{A}_5, \bar{A}_6\}$ by carrying out a sequence of simple corner cuts (see, for example, [14, 8]) on the polygon defined by $\{A_0, A_1, A_2, A_3\}$.

We recall that a matrix is totally positive if all minors are nonnegative [1]. Then we obtain the following theorem.

THEOREM 4.1. *Suppose* $-2 < \beta < 0$, $1 \le v := \frac{\lambda\beta}{\beta-1} \le 2$, *and* $\lambda \ge 1-\beta$. *Then the matrix* $\mathbf{S}$ *given by* (4.1) *is totally positive. For each* $v \notin [1,2]$ *there is a* $\beta \in [-1,0[$ *such that* $\mathbf{S}$ *is not totally positive.*

Proof. The sequence of simple corner cuts corresponds to a factorization of $\mathbf{S}$ into a product of 7 matrices as follows:

$$\mathbf{S} = \begin{bmatrix} 1&0&0&0&0&0\\ 0&1&0&0&0&0\\ 0&0&1&0&0&0\\ 0&0&\frac{1}{2}&\frac{1}{2}&0&0\\ 0&0&0&1&0&0\\ 0&0&0&0&1&0\\ 0&0&0&0&0&1 \end{bmatrix} \begin{bmatrix} 1&0&0&0&0&0\\ 0&1&0&0&0&0\\ 0&0&1&0&0&0\\ 0&0&\frac{v+\beta}{v-\beta}&\frac{-2\beta}{v-\beta}&0&0\\ 0&0&0&0&1&0\\ 0&0&0&0&0&1 \end{bmatrix} \begin{bmatrix} 1&0&0&0&0&0\\ 0&1&0&0&0&0\\ 0&0&\frac{v-\beta}{2v}&\frac{v+\beta}{2v}&0&0\\ 0&0&0&1&0&0\\ 0&0&0&0&1&0\\ 0&0&0&0&0&1 \end{bmatrix}$$

$$\begin{bmatrix} 1&0&0&0&0\\ 0&1&0&0&0\\ 0&0&1&0&0\\ 0&0&0&1&0\\ 0&0&0&\frac{1}{v}&1-\frac{1}{v}\\ 0&0&0&0&1 \end{bmatrix} \begin{bmatrix} 1&0&0&0\\ 1-\frac{1}{v}&\frac{1}{v}&0&0\\ 0&1&0&0\\ 0&0&1&0\\ 0&0&0&1 \end{bmatrix} \begin{bmatrix} 1&0&0&0\\ 0&1&0&0\\ 0&0&\frac{v}{2}&1-\frac{v}{2}\\ 0&0&0&1 \end{bmatrix} \begin{bmatrix} 1&0&0&0\\ 1-\frac{v}{2}&\frac{v}{2}&0&0\\ 0&0&1&0\\ 0&0&0&1 \end{bmatrix}.$$

Since these matrices are bidiagonal and the entries are nonnegative for the indicated values of the parameters it is well known that each of the 7 matrices are totaly positive (see, for example, [8]). Since a product of totally positive matrices is totally positive we conclude that $\mathbf{S}$ is totally positive.

If $v \notin [1,2]$, then we can find $\beta \in [-1,0)$ such that $\mathbf{S}$ has at least one negative entry. Hence $\mathbf{S}$ is not totally positive for these v, β. ∎

4.2. The HC^1-Bernstein basis. Let a, b be 2 real numbers with $a < b$ and let us define $h := b - a$. Recall that the HC^1-Hermite basis $\{\phi_0, \psi_0, \phi_1, \psi_1\}$ on $I := [a, b]$ forms a basis for the space $VC^1_{\alpha,\beta}(I)$ of all possible HC^1 interpolants on I. The *HC^1-Bernstein basis* $\{b_0, b_1, b_2, b_3\}$ on I are defined as in [15] from the Hermite basis on I by

$$b_0 := \phi_0 - \frac{\lambda}{h}\psi_0, \quad b_1 := \frac{\lambda}{h}\psi_0, \quad b_2 := -\frac{\lambda}{h}\psi_1, \quad b_3 := \phi_1 + \frac{\lambda}{h}\psi_1, \tag{4.3}$$

where $\lambda \ge 2$ is the parameter used to define the control points; see Figure 4.2. These functions are clearly linearly independent and so they form a basis for $VC^1_{\alpha,\beta}(I)$. The

coefficients in terms of this basis are the control coefficients of f. This follows since

$$f := f(a)\phi_0 + p(a)\psi_0 + f(b)\phi_1 + p(b)\psi_1, \quad \Leftrightarrow \quad f = a_0 b_0 + a_1 b_1 + a_2 b_2 + a_3 b_3,$$

where a_0, a_1, a_2, a_3 are the control coefficients of f on I given by (3.1).

We note that $b_j(0) = \delta_{j,0}$ and $b_j(1) = \delta_{j,3}$.

For certain values of the parameters the HC^1-Benstein basis is totally positive.

THEOREM 4.2. *Suppose* $-2 < \beta < 0$, $1 \le v := \frac{\lambda\beta}{\beta - 1} \le 2$, *and* $\lambda \ge 1 - \beta$. *Then the* HC^1*-Bernstein basis is totally positive.*

Proof. It is enough to prove the result for the interval $[0, 1]$. Consider for some integers n, k with $n \ge 0$ and $0 \le k \le 2^n - 1$ the interval $I_k^n := [k/2^n, (k+1)/2^n]$.

On I_k^n the HC^1-Hermite basis $\{\phi_{0,k}^n, \psi_{0,k}^n, \phi_{1,k}^n, \psi_{1,k}^n\}$ can be expressed as

$$\begin{aligned} \phi_{0,k}^n(t) &= \phi_0(2^n t - k), \quad \psi_{0,k}^n(t) = 2^{-n}\psi_0(2^n t - k), \\ \phi_{1,k}^n(t) &= \phi_1(2^n t - k), \quad \psi_{1,k}^n(t) = 2^{-n}\psi_1(2^n t - k), \end{aligned}$$

where $\{\phi_0, \psi_0, \phi_1, \psi_1\}$ is the HC^1-Hermite basis on $[0, 1]$. From (4.3) with $h := 2^{-n}$, it then follows that the HC^1-Bernstein basis $\{b_{4k}^n, b_{4k+1}^n, b_{4k+2}^n, b_{4k+3}^n\}$ on I_k^n can be expressed in terms of the HC^1-Bernstein basis $\{b_0, b_1, b_2, b_3\}$ on $[0, 1]$ as

$$b_{4k+j}^n(t) = \begin{cases} b_j(2^n t - k), & \text{if } t \in I_k^n \text{ and } j = 0, 1, 2, 3 \\ 0 & \text{otherwise.} \end{cases} \tag{4.4}$$

We note that

$$b_{4k+j}^n(k/2^n) = \delta_{j,0}, \quad b_{4k+j}^n((k+1)/2^n) = \delta_{j,3} \quad \text{for} \quad j = 0, 1, 2, 3. \tag{4.5}$$

Let $f \in C^1[0, 1]$ be a HC^1-interpolant to some initial data. We can then write

$$f = \sum_{i=0}^{m} a_i^n b_i^n,$$

where $m := 4 \times 2^n - 1$ and where for $k = 0, \ldots, 2^n - 1$ the numbers a_{4k}^n, a_{4k+1}^n, a_{4k+2}^n, a_{4k+3}^n are the control points of f on I_k^n. In vector form, we have $f = b^n a^n$, where $b^n = (b_0^n, \ldots, b_m^n)$ is a row vector and $a^n = (a_0^n, \ldots, a_m^n)^T$ a column vector. Note that b^n is a vector of linearly independent functions on $[0, 1]$. They span a space containing $VC_{\alpha,\beta}^1[0, 1]$ as a 4-dimensional subspace. On level $n + 1$ we have $f = b^{n+1}a^{n+1}$, where from Proposition 3.1 it follows that $a^{n+1} = \mathbf{A}_n a^n$ for some matrix $\mathbf{A}_n$. The matrix $\mathbf{A}_n$ is a block diagonal with 2^n diagonal blocks $\hat{\mathbf{S}}$ of order 8×4. Indeed, $\hat{\mathbf{S}}$ is obtained from the matrix $\mathbf{S}$ in (3.4) by adding a copy of row 4 as a new row 5. But then $f = b^{n+1}a^{n+1} = b^{n+1}\mathbf{A}_n a^n = b^n a^n$ and by linear independence, it follows that $b^n = b^{n+1}\mathbf{A}_n$. Thus we obtain

$$b^0 = b^n \mathbf{A}_{n-1} \cdots \mathbf{A}_0, \quad n \ge 1. \tag{4.6}$$

For distinct points $y_0, \ldots, y_p$ and functions $f_0, \ldots, f_q$ defined on the y's, we use the standard notation

$$M \begin{bmatrix} y_0, \ldots, y_p \\ f_0, \ldots, f_q \end{bmatrix} := \begin{bmatrix} f_0(y_0) & \cdots & f_q(y_0) \\ \vdots & & \vdots \\ f_0(y_p) & \cdots & f_q(y_p) \end{bmatrix}$$

for a collocation matrix of order $(p+1)\times(q+1)$. In order to show total positivity of $b=b^0$ we choose $0\le x_0<x_1<x_2<x_3\le 1$ and consider the collocation matrix $M\begin{bmatrix}x_0,x_1,x_2,x_3\\ b_0,b_1,b_2,b_3\end{bmatrix}$. From (4.6) we immediatly obtain

$$M\begin{bmatrix}x_0,\dots,x_3\\ b_0,\dots,b_3\end{bmatrix}=M\begin{bmatrix}x_0,\dots,x_3\\ b_0^n,\dots,b_m^n\end{bmatrix}\mathbf{A}_{n-1}\cdots\mathbf{A}_0,\quad n\ge 1. \tag{4.7}$$

Since the matrix $\mathbf{S}$ is totally positive, it follows that $\hat{\mathbf{S}}$ and hence each $\mathbf{A}_k$ is totally positive. We now show that the first matrix on the right of (4.7) is totally positive provided $x_j\in\mathcal{P}_n$ for $j=0,1,2,3$. For this, with $m=2^{n-1}-1$, we consider the bigger matrix

$$\mathbf{B}=M\begin{bmatrix}y_0,\dots,y_{m+1}\\ b_0^n,\dots,b_m^n\end{bmatrix}$$

using all points $y_i=i/2^n$, $i=0,1,\dots,2^n$ in $\mathcal{P}_n$. From (4.5) it follows that $b_{4k-1}(y_k)=1$ for $k=1,\dots,2^n$, $b_{4k}(y_k)=1$ for $k=0,\dots,2^n-1$ and $b_i^n(y_j)=0$ otherwise. Thus the columns of $\mathbf{B}$ have the following form:

$$\mathbf{B}=[e_1,0,0,e_2,e_2,0,0,e_3,e_3,0,0,e_4\dots,e_m,0,0,e_{m+1}],$$

where $e_j=(\delta_{i,j})_{i=0}^m$ is the jth unit vector in $\mathbb{R}^{m+1}$. From this explicit form we see that $\mathbf{B}$ is totally positive since each nonzero minor must be the determinant of the identity matrix. But then all matrices on the right in (4.7) are totally positive and we conclude that $M\begin{bmatrix}x_0,\dots,x_3\\ b_0,\dots,b_3\end{bmatrix}$ is totally positive provided $x_j\in\mathcal{P}_n$ for $j=0,1,2,3$. Since $\cup\mathcal{P}_n$ is dense in $[0,1]$ we conclude that the HC^1-Bernstein basis is totally positive. ∎

COROLLARY 4.3. *For $p\ge 0$ and $m=4\cdot 2^p-1$, the basis $b^p=(b_0^p,\dots,b_m^p)$ for the space span(b^p) is totally positive on $[0,1]$.*

Proof. Instead of (4.6) we use for $n>p$ the equation

$$b^p=b^n\mathbf{A}_{n-1}\cdots\mathbf{A}_p.$$

The argument now proceeds as in the proof of Theorem 4.2 replacing $x_0,\dots,x_3$ by suitable $x_0,\dots,x_m$. ∎

It is well known that total positivity of the HC^1-Bernstein basis on $[0,1]$ implies that the HC^1-interpolant f inherits properties of the control polygon P^0 defined by $\{a_0,a_1,a_2,a_3\}$; see, for example, [8]. In particular if P_0 is positive (monotone, convex) then f is positive (monotone, convex). We can use this to generalize Theorem 4 in [15].

COROLLARY 4.4. *Let b_0,b_1,b_2,b_3 be the HC^1-Bernstein basis on $[0,1]$ given by (4.3) with $\lambda=v(\beta-1)/\beta>2$. Suppose also that $\alpha=\frac{\beta}{4(1-\beta)}$, $-1\le\beta<0$, and $1\le v\le 2$. Then*

1. *b_0 is nonnegative, decreasing, and convex on $[0,1]$. If $v=2$, then $b_0(t)=0$ for $t\in[1/2,1]$.*
2. *b_1 is nonnegative and concave on $[0,1/2]$ and nonnegative, decreasing, and convex on $[1/2,1]$.*
3. *b_2 is nonnegative, increasing, and convex on $[0,1/2]$ and nonnegative and concave on $[1/2,1]$.*
4. *b_3 is nonnegative, increasing, and convex on $[0,1]$. If $v=2$, then $b_3(t)=0$ for $t\in[0,1/2]$.*

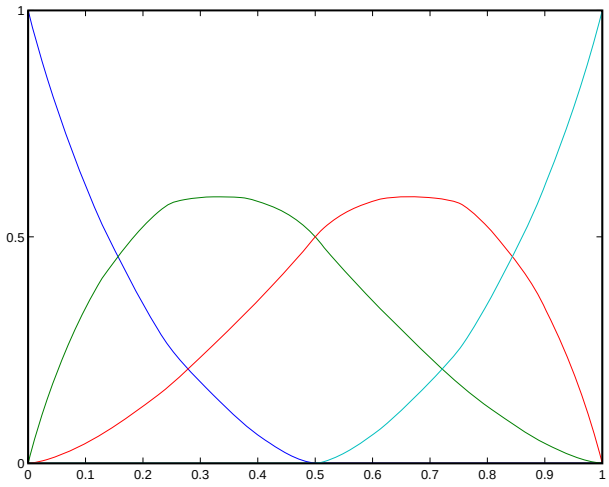

FIG. 4.2. *Bernstein basis,* $\beta = -3/5$, $\alpha = -3/32$, $\lambda = 16/3$.

5. $\sum_{j=0}^{3} b_j(t) = 1$ *for* $t \in [0,1]$.

Proof. From (4.3) it follows that the control points of the function b_j is the jth unit vector e_{j+1} for $j = 0,1,2,3$. Thus nonnegativity of b_j follows from the nonnegativity of e_{j+1} for $j = 0,1,2,3$. Moreover, the monotonicity and convexity properties of b_0 and b_3 follow. For the remaining properties of b_1 and b_2, we carry out one subdivision, then the proof is similar.

The refined points are given as the columns of the matrix $\mathbf{S}$ given by (4.1). When $v = 2$ the first column is given by $[1, 1/2, 0, 0, 0, 0, 0]$. Since the last four entries are zero it follows that $b_0(t) = 0$ for $t \in [1/2, 1]$. Similarly $b_3(t) = 0$ for $t \in [0, 1/2]$.

The interpolation of the constant function $f = 1$ with $p = f' = 0$ gives $a_0 = a_1 = a_2 = a_3 = 1$ in (3.1) so that 5. holds. ∎

5. Algorithms for local shape constraints. We base shape preserving algorithms on the extended quadratic spline case given by $\alpha = \frac{\beta}{4(1-\beta)}$. The control point subdivision matrix for this case is given by (4.1), where we have both β and λ as free parameters. The matrix simplifies when $v = \frac{\beta\lambda}{\beta - 1} = 2$ and we will use this one parameter family of schemes in our algorithms. Using the parameter λ to control the shape we thus have

$$\alpha = \frac{\beta}{4(1-\beta)} = -\frac{1}{2\lambda}, \quad \beta = \frac{2}{2-\lambda}. \tag{5.1}$$

We restrict our attention to $\lambda \geq 4$. We then have $\beta \in [-1, 0)$ and both algorithms HC^1 and SC^1 are convergent. In the limit when $n \to \infty$ we obtain a function $f \in C^1(I)$. This function is the quadratic spline interpolant with a knot at the midpoint of I when $\lambda = 4$, while $p = f'$ is Hölder continuous on I with exponent

$$\log_2\left(1 + \frac{1}{\lambda - 3}\right) \approx \frac{1.44}{\lambda - 3}, \quad \lambda \to \infty.$$

Thus the derivative becomes less regular when λ increases, but it is always C^1.

Given $s \geq 1$, points $a_j^0 = a_j \in \mathbb{R}^s$ for $j = 0,1,2,3$, and $\lambda \geq 4$, the following algorithm computes sequences $\{a^n\}$ of control coefficients $a^n = (a_0^n, a_1^n, \ldots, a_{3\times 2^n}^n)$ in $\mathbb{R}^s$.

ALGORITHM 5.1 (CC^1).

1. $\beta = 2/(2-\lambda)$.
2. *For* $n = 0, 1, 2, 3, \ldots,$
   For $i = 0, 1, \ldots 2^n - 1,$
   (a) $a_{6i}^{n+1} = a_{3i}^n,$
   (b) $a_{6i+1}^{n+1} = \frac{1}{2}(a_{3i}^n + a_{3i+1}^n),$
   (c) $a_{6i+2}^{n+1} = (\frac{1}{2} - \frac{\beta}{4})a_{3i+1}^n + (\frac{1}{2} + \frac{\beta}{4})a_{3i+2}^n,$
   (d) $a_{6i+3}^{n+1} = \frac{1}{2}(a_{3i+1}^n + a_{3i+2}^n),$
   (e) $a_{6i+4}^{n+1} = (\frac{1}{2} + \frac{\beta}{4})a_{3i+1}^n + (\frac{1}{2} - \frac{\beta}{4})a_{3i+2}^n,$
   (f) $a_{6i+5}^{n+1} = \frac{1}{2}(a_{3i+2}^n + a_{3i+3}^n),$
   $a_{3\cdot 2^{n+1}} = a_{3\cdot 2^n}.$

The control points corresponding to the computed control coefficients converges to a C^1-curve. More specifically, pick any finite closed interval $[a, b]$ and define $h_n := (b-a)/2^n$ and $t_k^n := a + kh_n$ for $k = 0, \ldots, 2^n$, $n \geq 0$. By Theorem 3.4 the computed control points converge uniformly to a C^1-curve $f : [a, b] \to \mathbb{R}^s$. Moreover,

$$
\begin{aligned}
a_{3i}^n &= f(t_i^n), \quad i = 0, \ldots, 2^n, \\
a_{3i+1}^n - a_{3i}^n &= \frac{h_n}{\lambda} f'(t_i^n), \quad i = 0, \ldots, 2^n - 1, \\
a_{3i}^n - a_{3i-1}^n &= \frac{h_n}{\lambda} f'(t_i^n), \quad i = 1, \ldots, 2^n.
\end{aligned}
$$

We now discuss shape preservation in the scalar case $s = 1$ in more detail. We start by noting that if the initial control polygon is nonnegative (respectively, increasing, convex) on an interval $I = [a, b]$, then the HC^1-interpolant computed in Algorithm 5.1 will be nonnegative (respectively, increasing, convex) on the same interval I. This follows from the total positivity of the Bernstein basis. In addition to total positivity the main tool will be Corollary 2.2 which says that the p-values of the interpolant are located on the piecewise linear curve connecting the three points $(a, p(a))$, $(\frac{a+b}{2}, p(\frac{a+b}{2}))$, $(b, p(b))$.

5.1. Nonnegative interpolants. We already remarked that if the initial control coefficients are nonnegative, then the HC^1-interpolant will be nonnegative. Notice that the converse is false. For example, the HC^1-interpolant to the function f given on $[0, 1]$ by $f(x) := 16(x - 1/4)^2$ and using $\lambda = 4$ is f itself. Note that f is nonnegative, but the initial control coefficient $a_1 = -1$ is negative.

To give an algorithm for constructing a nonnegative interpolant we assume that

$$
f(a) \geq 0, \ f(b) \geq 0, \ p(a) \geq 0 \text{ if } f(a) = 0, \text{ and } p(b) \leq 0 \text{ if } f(b) = 0. \tag{5.2}
$$

Under these weak assumptions nonnegative initial control coefficients $a_0, \ldots, a_3$ can always be obtained by choosing λ sufficiently large. Indeed, since $a_0 = f(a) \geq 0$ and $a_3 = f(b) \geq 0$ we only need to make sure that $a_1 = f(a) + hp(a)/\lambda \geq 0$ and $a_2 = f(b) - hp(b)/\lambda \geq 0$. If $f(a) = 0$, then $p(a) \geq 0$ and $a_1 \geq 0$ whenever $\lambda > 0$. Similarly $a_2 \geq 0$ if $f(b) = 0$. But then we can choose $\lambda = 4$ except possibly in the two cases $f(a) > 0$, $p(a) < 0$ and $f(b) > 0$, $p(b) > 0$. If (5.2) holds, then the following algorithm will compute a nonnegative HC^1-interpolant on $[a, b]$.

ALGORITHM 5.2 (nonnegative interpolant).

1. *Compute* λ*:*
   (a) $\lambda = 4$,
   (b) *if* $(f(a) > 0)$ *and* $(p(a) < 0)$, *then* $\lambda = \max(\lambda, -hp(a)/f(a))$,

(c) *if* $(f(b) > 0)$ *and* $(p(b) > 0)$, *then* $\lambda = \max(\lambda, hp(b)/f(b))$.

2. *Compute initial control coefficients using* (3.1).
3. *Apply Algorithm* 5.1 *or Algorithm* HC^1 *with* $\alpha = -\frac{1}{2\lambda}$, $\beta = \frac{2}{2-\lambda}$.

5.2. Monotone interpolants. The monotonicity of the HC^1-interpolant is completely determined by the monotonicity of the initial control polygon. If f is decreasing, then $-f$ is increasing and we restrict our discussion to increasing interpolants.

PROPOSITION 5.3. *Suppose that the parameters are chosen according to* (5.1). *Then the* HC^1*-interpolant* f *is nondecreasing on an interval* $I = [a, b]$ *if and only if the control polygon on* I *is nondecreasing.*

Proof. By Theorem 4.2 the Bernstein basis is totally positive and it follows that the HC^1-interpolant is nondecreasing if the control polygon is nondecreasing; see [8]. Conversely, suppose the HC^1-interpolant f is nondecreasing. Since $\beta = 2/(2-\lambda)$, we obtain from (2.1)

$$p\left(\frac{a+b}{2}\right) = \frac{1}{\lambda - 2}\left(\lambda \frac{f(b) - f(a)}{h} - (p(a) + p(b))\right). \tag{5.3}$$

From (3.1), we then find

$$a_1 - a_0 = \frac{h}{\lambda}p(a), \quad a_2 - a_1 = \frac{\lambda - 2}{\lambda}hp\left(\frac{a+b}{2}\right), \quad a_3 - a_2 = \frac{h}{\lambda}p(b). \tag{5.4}$$

Now $p \geq 0$ at all points if f is nondecreasing. It follows that the control coefficients, and hence the control polygon is nondecreasing. □

Consider next the case of a strictly increasing interpolant.

PROPOSITION 5.4. *Suppose that the parameters are chosen according to* (5.1) *and that the* HC^1*-interpolant* f *is nondecreasing on an interval* $I = [a, b]$. *Then* f *is strictly increasing on* $[a, b]$ *if and only if the two middle control coefficients on* I *satisfy* $a_2 > a_1$.

Proof. Since f is nondecreasing, we have $p(a) \geq 0$, $p(\frac{a+b}{2}) \geq 0$ and $p(b) \geq 0$. By Corollary 2.2, it follows that f is strictly increasing on $[a, b]$ if and only if $p(\frac{a+b}{2}) > 0$. By (5.4), this happens if and only if $a_2 > a_1$. □

To give an algorithm to construct a nondecreasing interpolant we assume that

$$f(a) \leq f(b),\ p(a) \geq 0,\ p(b) \geq 0 \text{ and } p(a) = p(b) = 0 \text{ if } f(a) = f(b). \tag{5.5}$$

In the latter case the HC^1-interpolant is constant and we can set $\lambda = 4$.

Suppose $f(b) > f(a)$. With $h := b - a$ we then have

$$a_0 = f(a) \leq a_1 = f(a) + \frac{h}{\lambda}p(a) \leq a_2 = f(b) - \frac{h}{\lambda}p(b) \leq a_3 = f(b)$$

provided

$$a_2 - a_1 = f(b) - f(a) - \frac{h}{\lambda}\big(p(b) + p(a)\big) \geq 0$$

or

$$\lambda \geq \frac{(p(a) + p(b))h}{f(b) - f(a)}. \tag{5.6}$$

If (5.5) holds, then the following algorithm will compute a nondecreasing HC^1-interpolant on $[a,b]$. It will be strictly increasing if $f(b) > f(a)$ and (5.6) holds with strict inequality.

ALGORITHM 5.5 (nondecreasing or strictly increasing interpolant).

1. *Compute* λ*:*
   (a) $\lambda = 4$,
   (b) *If* $f(a) < f(b)$*, then*
      (i.) $\lambda_1 \geq \frac{(p(a)+p(b))h}{f(b)-f(a)}$,
      (ii.) $\lambda = \max(4, \lambda_1)$.
2. *Compute initial control coefficients using* (3.1).
3. *Apply Algorithm* 5.1 *or Algorithm* HC^1 *with* $\alpha = -\frac{1}{2\lambda}$, $\beta = \frac{2}{2-\lambda}$.

Note that if the initial control points are located on a straight line then the HC^1-interpolant is the line segment connecting the first and last control point. For if the initial control points are located on a straight line, then

$$\frac{\lambda}{h}(a_1 - a_0) = \frac{\lambda}{(\lambda-2)h}(a_2 - a_1) = \frac{\lambda}{h}(a_3 - a_2)$$

and by (5.4) the three slopes $p(a), p(\frac{a+b}{2}), p(b)$ are all equal. By Corollary 2.2, all slopes are equal and the function f is a straight line.

In Figure 5.1 we interpolate three sets of data on $[0,1]$. In all cases $f(0) = -1$ and $f(1) = 1$. In the first case, with $p(0) = 3$ and $p(1) = 4$ we find $\frac{p(0)+p(1)}{f(1)-f(0)} = 7/2 < 4$. Suppose in Algorithm 5.5 we choose $7/2 \leq \lambda_1 \leq 4$ in statement (b)(i). and apply Algorithm 5.1 with $\lambda = 4$. Then the HC^1-interpolant is the quadratic spline and it is strictly increasing since $\lambda > 7/2$. In the two other cases we use $p(0) = 8$ and $p(1) = 4$ giving $\frac{p(0)+p(1)}{f(1)-f(0)} = 6$. With $\lambda = 6$ we have $p(1/2) = 0$ and the interpolant is increasing, but not strictly increasing. We obtain a strictly increasing interpolant by using $\lambda = 10$. Note that choosing a bigger λ decreases the regularity of the interpolant. In both cases the first derivative is Hölder continuous, but the exponent is $\log_2(4/3) \approx 0.415$ when $\lambda = 6$ and $\log_2(4/3) \approx 0.193$ when $\lambda = 10$.

5.3. Convex interpolants. The convexity of the HC^1-interpolant is also completely determined by the convexity of the initial control polygon.

PROPOSITION 5.6. *Suppose that the parameters are chosen according to* (5.1). *Then* f *is convex (concave) on an interval* $I = [a,b]$ *if and only if the control polygon on* I *is convex (concave).*

Proof. Again by total positivity of the Bernstein basis the HC^1-interpolant is convex (concave) if the control polygon is convex (concave); see [8]. Conversely, suppose the HC^1-interpolant f is convex (concave). Now the control polygon is convex if and only if the conditions

$$\frac{a_1 - a_0}{h/\lambda} \leq \frac{a_2 - a_1}{h - 2h/\lambda} \leq \frac{a_3 - a_2}{h/\lambda}$$

hold. But from (5.4) we find

$$\frac{a_1 - a_0}{h/\lambda} = p(a), \quad \frac{a_2 - a_1}{h - 2h/\lambda} = p(\frac{a+b}{2}), \quad \frac{a_3 - a_2}{h/\lambda} = p(b).$$

Since f is convex (concave) the function p is nondecreasing (nonincreasing) and hence the control polygon is convex (concave). ∎

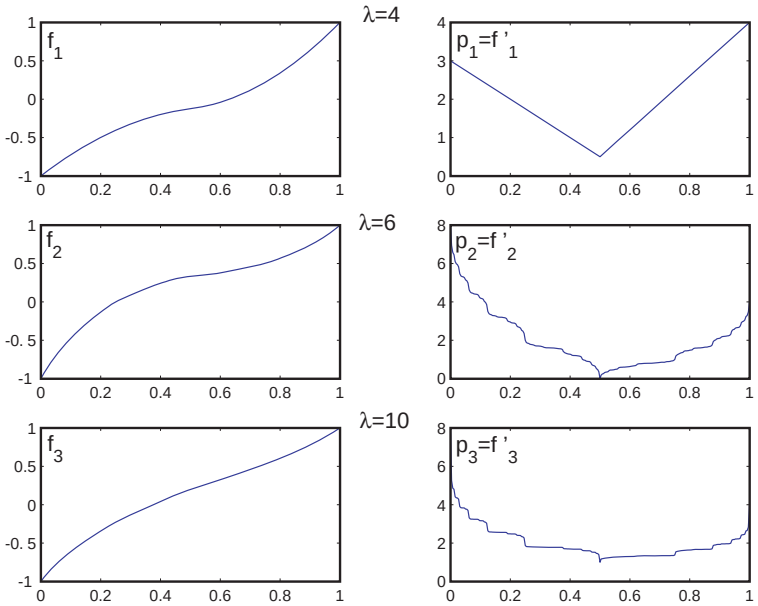

FIG. 5.1. *Monotone interpolants.*

To give an algorithm for constructing a convex (concave) HC^1-interpolant on an interval $I = [a, b]$ we first assume that

$$p(a) < \frac{f(b) - f(a)}{h} < p(b) \quad \big(p(a) > \frac{f(b) - f(a)}{h} > p(b)\big), \tag{5.7}$$

where $h := b - a$. We define

$$\lambda_1 := \frac{p(b) - p(a)}{p(b) - \frac{f(b)-f(a)}{h}}, \quad \lambda_2 := \frac{p(b) - p(a)}{\frac{f(b)-f(a)}{h} - p(a)} \tag{5.8}$$

and note that the tangents

$$t_c(x) := f(a) + (x - a)p(a), \quad t_d(x) := f(b) + (x - b)p(b)$$

of f at a and b intersect at the point $(\bar{x}, \bar{y})$ given by

$$\frac{\bar{x} - a}{h} = \frac{1}{\lambda_1}, \quad \text{and} \quad \frac{b - \bar{x}}{h} = \frac{1}{\lambda_2}.$$

Moreover, the hypothesis (5.7) is equivalent to $a < \bar{x} < b$.

Under the assumption

$$p(a) \le \frac{f(b) - f(a)}{h} \le p(b) \quad \big(p(a) \ge \frac{f(b) - f(a)}{h} \ge p(b)\big), \tag{5.9}$$

the following algorithm will compute a convex (concave) interpolant.

ALGORITHM 5.7 (convex or concave interpolant).

1. (a) *If* $p(a) = \frac{f(b)-f(a)}{h} \ne p(b)$, *choose* $\lambda \ge \max(4, \lambda_1)$,
   (b) *If* $p(a) \ne \frac{f(b)-f(a)}{h} = p(b)$, *choose* $\lambda \ge \max(4, \lambda_2)$,

(c) *If* $p(a) \neq \frac{f(b)-f(a)}{h} \neq p(b)$, *choose* $\lambda \geq \max(4, \lambda_1, \lambda_2)$.

2. *Compute initial control points using* (3.1).
3. *Apply Algorithm* 5.1 *or Algorithm* HC^1 *with* $\alpha = -\frac{1}{2\lambda}$, $\beta = \frac{2}{2-\lambda}$.

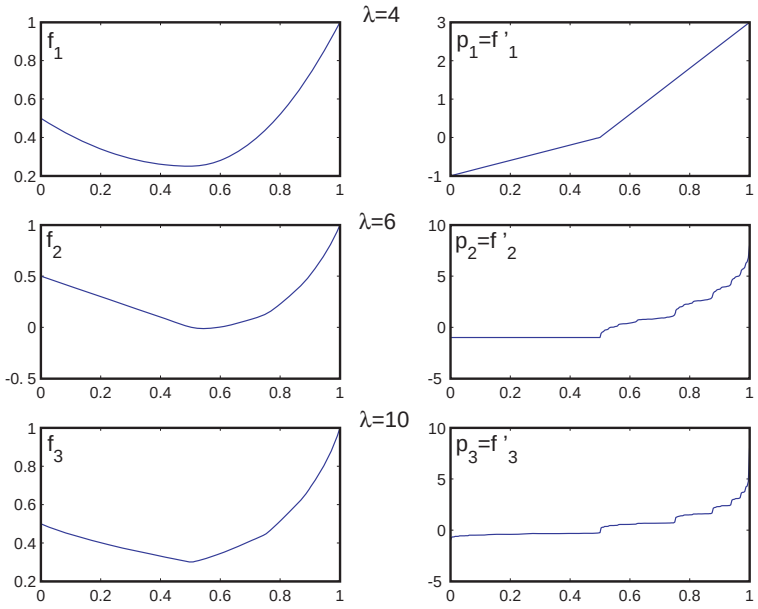

FIG. 5.2. *Convex interpolants.*

In Figure 5.2, we have interpolated three sets of data on $[0, 1]$. In all cases $f(0) = 0.5$ and $f(1) = 1$.

In the first case, $p(0) = -1$ and $p(1) = 3$ so that $\lambda_1 = 8/5$ and $\lambda_2 = 8/3$. Then $\max(4, \lambda_1, \lambda_2) = 4$ and we have chosen $\lambda = 4$. In this case, the interpolant is the quadratic spline.

In the two other cases $p(0) = -1$ and $p(1) = 8$ so that $\lambda_1 = 18/5$ and $\lambda_2 = 6$. Then $\max(4, \lambda_1, \lambda_2) = 6$. With $\lambda = 6$ we have $p = -1$ on $[0, 1/2]$, while we obtain a strictly convex interpolant by using $\lambda = 10$. Recall that choosing a bigger λ decreases the regularity of the interpolant.

6. Example. Given data (t_i, y_i, y_i') for $i = 1, \ldots, n$, where $t_1 < \cdots < t_n$ and the y's are real numbers, we look for a function $f \in C^1([t_1, t_n])$ that satisfies

$$f(t_i) = y_i, \;\; f'(t_i) = y_i' \;\; \text{for } i = 1, \ldots, n. \tag{6.1}$$

In addition we would like f to be positive, monotone, linear, or convex on some or all of the subintervals $I_i = [t_i, t_{i+1}], i = 1, \ldots, n-1$. We assume that

(P) (5.2) holds for the subintervals where we want nonnegativity or positivity,
(M) (5.5) holds for the subintervals where we want a nondecreasing or a strictly increasing interpolant,
(L) $y_i' = y_{i+1}' = \frac{y_{i+1}-y_i}{t_{i+1}-t_i}$ for the subintervals where the interpolant should be linear,
(C) (5.9) holds for the subintervals where the interpolant should be convex or concave.

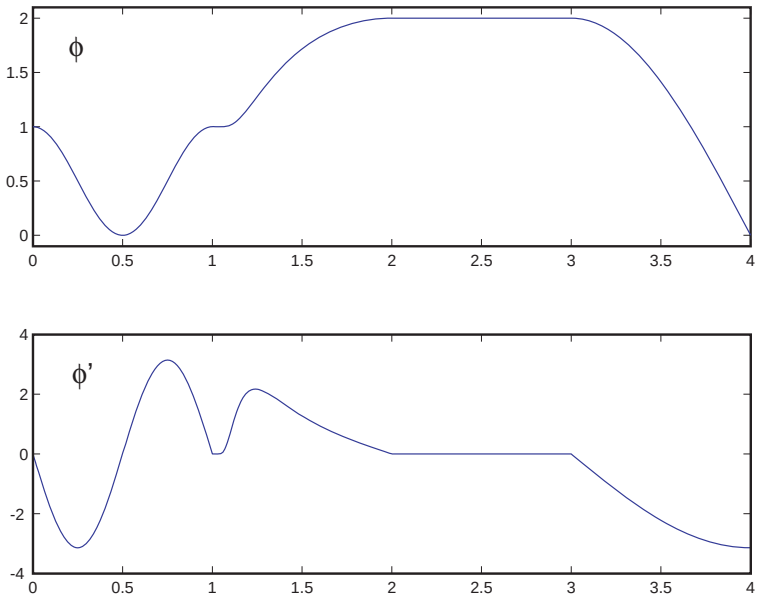

FIG. 5.3. *The function ϕ and its derivative.*

We also require that the given data is consistent with these shape requirements. We can compute f locally by applying the HC^1-algorithm with parameters given by (5.1) on each subinterval $I_i = [t_i, t_{i+1}]$, $i = 1, \ldots, n-1$ using initial data $f(t_i) = y_i$, $f(t_{i+1}) = y_{i+1}$, $p(t_i) = y'_i$, and $p(t_{i+1}) = y'_{i+1}$. We obtain C^1-convergence and the desired shape locally by choosing the parameter λ_i for the interval I_i sufficiently large.

Consider now (6.1) for the example illustrated in Figure 1.1. The data are sampled from the function $\phi \in C^1([0,4])$ given by

$$\phi(t) = \begin{cases} \frac{1}{2}\sin(2\pi t + \pi/2) + \frac{1}{2}, & 0 \le t \le 1, \\ 1 + \exp(-\frac{1}{1-(t-2)^2} + 1), & 1 < t \le 2, \\ 2, & 2 < t \le 3, \\ 2\cos(\pi \frac{t-3}{2}), & 3 \le t \le 4. \end{cases} \tag{6.2}$$

The function and its first derivative are displayed in Figure 5.3 and it can be shown that ϕ is positive on $[0,1]$, strictly increasing on $[1,2]$, constant on $[2,3]$, and concave on $[3,4]$; given n and let $(t_1, \ldots, t_n)$ be a partition of $[0,4]$. The points $(t_2, \ldots, t_{n-1})$ are chosen randomly except that $1, 2, 3$, are among them. In the example, we used $t_1 = 0$, $t_{n_1} = t_5 = 1$, $t_{n_2} = t_9 = 2$, $t_{n_3} = t_{13} = 3$, and $t_n = t_{17} = 4$. We want an interpolant f which is positive on $[t_1, t_{n_1}] = [0,1]$, strictly increasing on $[t_{n_1}, t_{n_2}] = [1,2]$, constant on $[t_{n_2}, t_{n_3} = [2,3]$, and concave on $[t_{n_3}, t_n] = [3,4]$.

In the first test we use $y_i = \phi(t_i)$ and exact derivatives $y'_i = \phi'(t_i), i = 1, \ldots, n$. In this case all λ's become equal to 4 and the quadratic spline interpolant f_1 does the job. Plots of this function and its first derivative are shown in Figure 6.1. The first derivative appears continuous and piecewise linear.

For the second test shown in Figure 6.2, we kept the previous data t_i and $y_i = \phi(t_i)$ for $i = 1, \ldots, n = 17$, but we used inexact derivatives given by crosses in the lower part of the figure. However, the derivatives were chosen so that the relevant requirement (P), (M), (L), and (C) above are satisfied on each subinterval $[t_i, t_{i+1}]$. We obtain

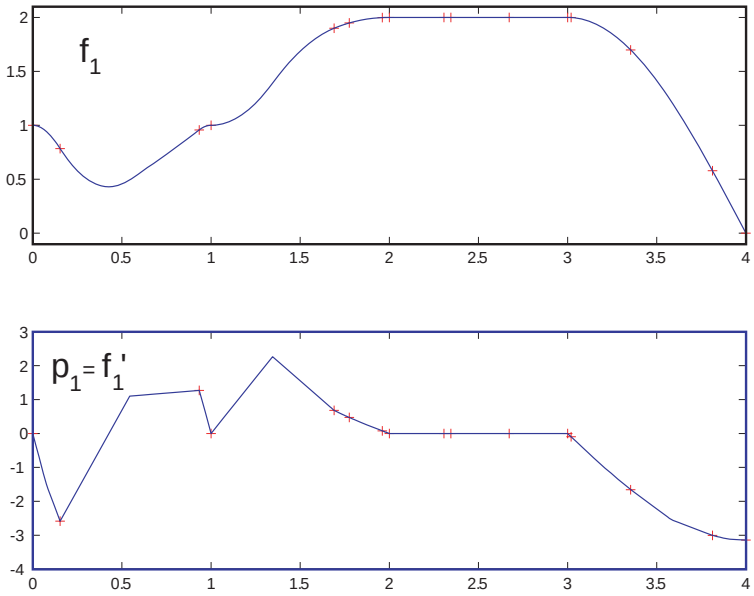

FIG. 6.1. *Interpolation with exact derivatives.*

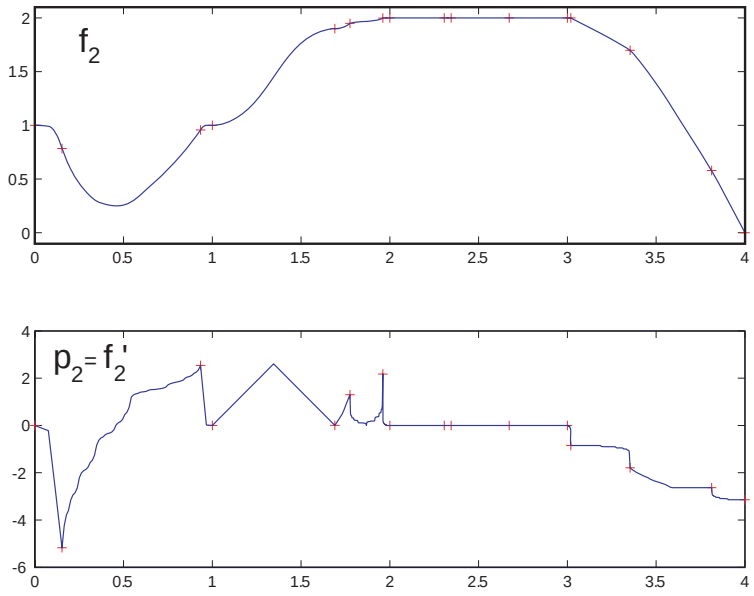

FIG. 6.2. *Interpolation with modified derivatives.*

a C^1-interpolant f_2 satisfying the required shape constraints. The computed values of λ_i are successively $(4, 5.1425, 4, 4, 4, 12.8631, 55.8239, 4, 4, 4, 4, 17.6767, 20.0216, 4.4087, 11.3544)$. These are the smallest values on each interval. Any larger value of λ_i is possible without losing the shape, but then the curve is less regular (smaller Hölder exponent) on the corresponding interval. This example shows that we can obtain a desired shape even with more or less random derivative values.

7. Conclusion. We have shown that the Hermite subdivision scheme introduced by Merrien in 1992 [11] has many desirable properties. It gives a C^1 limit curve for a wide range of parameters. A one parameter subfamily called the extended quadratic spline-scheme is particularly interesting. This family can be formulated as a scheme, the SC^1 algorithm, with a totally positive subdivision matrix. When applied in a piecewise fashion its local nature makes it easy to control the final shape of the subdivision curve. In many cases a desired shape can be obtained even without accurate derivative estimates.

The SC^1 algorithm can also be used in the parametric case, but a discussion of this will be deferred to a future paper. We also defer the construction of interpolating C^1 surfaces with shape preserving properties.

ASYMPTOTIC EXPANSIONS AND RICHARDSON EXTRAPOLATION OF APPROXIMATE SOLUTIONS FOR SECOND ORDER ELLIPTIC PROBLEMS ON RECTANGULAR DOMAINS BY MIXED FINITE ELEMENT METHODS*

GRAEME FAIRWEATHER†, QUN LIN‡, YANPING LIN§, JUNPING WANG¶, AND SHUHUA ZHANG‖

Abstract. In this paper asymptotic error expansions for mixed finite element approximations of general second order elliptic problems are derived under rectangular meshes, and the Richardson extrapolation is applied to improve the accuracy of the approximations by two different schemes with the help of an interpolation postprocessing technique. The results of this paper provide new asymptotic expansions and new approximate solutions which are one-order and a half-order higher in accuracy than those obtained in [J. Wang, *Math Comp.*, 56 (1991), pp. 477–503] and [H. Chen, R. E. Ewing, and R. Lazarov, *Asymptotic Error Expansion for the Lowest Order Raviart–Thomas Rectangular Mixed Finite Elements*, Technical report ISC-97-01, 1997], respectively. As a by-product, we illustrate that all the approximations of higher accuracy can be used to form a class of a posteriori error estimators for the mixed finite element method.

Key words. second order elliptic problems, mixed finite element methods, asymptotic expansions, interpolation postprocessing, a posteriori error estimators

1. Introduction.

We are concerned with approximate solutions for the following system of linear equations:

$$\mathbf{u} = -A\nabla p, \quad \nabla \cdot \mathbf{u} + cp = f \quad \text{in } \Omega \tag{1.1}$$

subject to the Neumann boundary condition

$$\nabla p \cdot \mathbf{n} = 0 \quad \text{on } \Gamma. \tag{1.2}$$

Here ∇ is the gradient operator; $\Omega \subset \mathbf{R}^2$ is a rectangular domain; $\mathbf{n}$ indicates the outward unit normal vector along Γ; and $A = (a_{ij})_{2\times 2}$ is a positive definite matrix uniformly in Ω. Mixed finite element methods [4] shall be employed to discretize the system (1.1).

There is extensive literature on the numerical methods for problem (1.1)–(1.2). For example, see [5, 9, 18, 26] and the references therein for mixed finite element methods, finite element methods, and finite difference methods.

Our objective in this paper is to present an analysis for the Richardson extrapolation of two different forms for the mixed finite element approximations. It is well known that the extrapolation method, which was established by Richardson in 1926, is an efficient procedure for increasing the accuracy of approximation of many problems in numerical analysis. The effectiveness of this technique relies heavily on the existence of an asymptotic expansion for the error. The application of this approach in finite difference methods can be found in the book of Marchuk and Shaidurov [26]. Also, this technique has been well demonstrated in its applications to the finite element and the mixed finite element methods for elliptic partial differential equations [2, 9, 10, 18, 28, 29], parabolic partial differential equations [15], Sobolev- and viscoelasticity-type equations [19], partial integro-differential equations [18, 20, 21], Fredholm and Volterra integral equations of the second kind [23, 6], and Volterra integro-differential equations [24, 32], and to boundary element methods and collocation methods in [31] and [17], respectively. Recently, multiparameter parallel algorithms have been considered to accelerate its computational speed [33].

In [28, 29] Richardson extrapolation methods of mixed finite elements have been investigated for a special case of the problem (1.1)–(1.2): Seek $u \in H^1(\Omega)$ such that

$$\begin{aligned} -\mathrm{div}(\beta(\mathbf{x})\nabla u(\mathbf{x})) &= f(\mathbf{x}) \qquad \text{in } \Omega, \\ \beta(\mathbf{x})\nabla u \cdot \mathbf{n} &= 0 \qquad\quad \text{on } \Gamma, \end{aligned} \tag{1.3}$$

where $\beta(\mathbf{x})$ is a positive, continuous function on the closure of the rectangular domain Ω, and the approximate solution of accuracy $O(h^3|\log h|)$ in the L^∞-norm has been obtained for the lowest triangular and rectangular elements, respectively.

In particular, when $\beta(\mathbf{x}) = 1$ in (1.3), Chen, Ewing, and Lazarov [10] obtained an asymptotic error expansion of the lowest order Raviart–Thomas rectangular mixed finite elements for the velocity, such that an approximate solution of accuracy $O(h^{3+1/2})$ was gained by the Richardson extrapolation method.

To our best knowledge, there is no analysis for the Richardson extrapolation in mixed finite element methods for the problem (1.1)–(1.2) because $A(\mathbf{x})$ is a full matrix, such that the high accuracy analysis of mixed finite elements and finite elements, such as Richardson extrapolation and superconvergence, is much more difficult than the case (1.3). In this paper, we employ the sharp integral estimates, which were first proposed by Lin in 1990 (see, for example, [18, 19]), to establish an asymptotic expansion for the error between the mixed finite element solution and the corresponding interpolation function of the exact solution to (1.1). These analysis techniques are quite different from those used in [10] and [28]. Furthermore, by virtue of an interpolation postprocessing method we will obtain an asymptotic expansion of the error in a mixed finite element solution, so that the Richardson extrapolation of two different types can be applied to yield mixed finite element approximations of accuracy $O(h^4)$ in the L^2-norm which are a half-order higher than those obtained in [10]. In another paper, we will demonstrate that our new method in this paper can also provide the approximations of accuracy $O(h^4|\log h|)$ in the L^∞-norm which are one-order higher than those gained in [28]. In addition, based on the high accuracy approximations, a class of a posteriori error estimators are constructed for this mixed finite element

method. Also, other types of superconvergence and a posteriori estimates have been obtained; see, for example, [1, 3, 7, 8, 16, 25, 27, 30], where the authors studied these problems on mixed finite element methods for optimal control, quadratic control, and elliptic problems by using conforming and nonconforming elements via structured and unstructured meshes.

This paper is organized in the following way. In section 2, we give the approximate subspace and the variational formula for the problem (1.1)–(1.2) as well as the Raviart–Thomas projection. The asymptotic expansion for the Raviart–Thomas projection is derived in section 3. Section 4 is devoted to investigating the asymptotic expansion of the error between the mixed finite element solution and the Raviart–Thomas projection of the exact solution to (1.1)–(1.2), on the basis of which the asymptotic expansion of the mixed finite element approximation is demonstrated by an interpolation postprocessing method. Hence, the Richardson extrapolation of two schemes can be used to improve the mixed finite element solution. Moreover, in this section suggestions are presented on how to form a posteriori error estimators by those approximations with high convergence rates.

2. The mixed finite element method. In this section we first formulate the mixed finite element method for the second order elliptic partial differential equation (1.1)–(1.2).

Let

$$W := L^2(\Omega) \quad \text{and} \quad \mathbf{V} := H(\mathrm{div}, \Omega) = \left\{ \mathbf{v} \in (L^2(\Omega))^2 : \ \nabla \cdot \mathbf{v} \in L^2(\Omega) \right\}$$

be the standard L^2-space on Ω with norm $\|\cdot\|_0$ and the Hilbert space equipped with the norm

$$\|\mathbf{v}\|_{\mathbf{V}} := \left(\|\mathbf{v}\|_0^2 + \|\nabla \cdot \mathbf{v}\|_0^2 \right)^{\frac{1}{2}},$$

respectively. In addition, set

$$\mathbf{V}_0 := \{ \mathbf{v} \in \mathbf{V} : \ \ \mathbf{v} \cdot \mathbf{n} = 0, \ \ \mathbf{x} \in \Gamma \}.$$

Using Green's formula and the boundary condition $\mathbf{v} \cdot \mathbf{n} = 0$, one finds

$$(\nabla p, \mathbf{v}) = -(\nabla \cdot \mathbf{v}, p) \tag{2.1}$$

for all $\mathbf{v} \in \mathbf{V}_0$. Moreover, from (1.1) and (1.2) we know that the vector-valued function $\mathbf{u}$ satisfies

$$\mathbf{u}(\mathbf{x}) \cdot \mathbf{n}(\mathbf{x}) = 0 \quad \text{on} \quad \Gamma. \tag{2.2}$$

Thus, noticing (2.1) and (2.2), the weak mixed formulation for the problem (1.1)–(1.2) is to seek $(p, \mathbf{u}) \in W \times \mathbf{V}_0$ such that

$$\begin{aligned} &a(\mathbf{u}, \mathbf{v}) - (\nabla \cdot \mathbf{v}, p) = 0 && \forall\, \mathbf{v} \in \mathbf{V}_0, \\ &(\nabla \cdot \mathbf{u}, w) + (cp, w) = (f, w) && \forall\, w \in W, \end{aligned} \tag{2.3}$$

where $a(\cdot,\cdot)$ is a bilinear form defined by

$$a(\mathbf{u},\mathbf{v}) = \int_\Omega A^{-1}\mathbf{u}\cdot\mathbf{v}d\Omega,$$

and $(\cdot,\cdot)$ denotes the standard L^2-inner product.

Let $\mathcal{T}_{h_1,h_2}$ be a finite element partition of Ω into uniform rectangles and $\mathbf{V}_{h_1,h_2}\times W_{h_1,h_2}\subset\mathbf{V}\times W$ denote a pair of finite element spaces satisfying the Babuška–Brezzi condition, where h_1 and h_2 are the mesh sizes in the x- and y-axis, respectively. Even if there are now several choices for $\mathbf{V}_{h_1,h_2}$ and W_{h_1,h_2}, here we will consider only the Raviart–Thomas space of the lowest order; i.e.,

$$\begin{aligned}\mathbf{V}_{h_1,h_2} &:= \{\mathbf{v}_{h_1,h_2}\in\mathbf{V}:\ \ \mathbf{v}_{h_1,h_2}|_e\in Q_{1,0}(e)\times Q_{0,1}(e),\ \ e\in\mathcal{T}_{h_1,h_2}\},\\ W_{h_1,h_2} &:= \{w_{h_1,h_2}\in W:\ \ w_{h_1,h_2}|_e\in Q_{0,0}(e),\ \ e\in\mathcal{T}_{h_1,h_2}\},\end{aligned}\tag{2.4}$$

where $Q_{m,n}(e)$ indicates the space of polynomials of degree no more than m and n in x and y on e, respectively. Following the steps of the paper, the extension to other stable rectangular element spaces can be also made. Hence, the corresponding discrete mixed finite element version of (2.3) seeks a pair $(p_{h_1,h_2},\mathbf{u}_{h_1,h_2})\in W_{h_1,h_2}\times\mathbf{V}_{0,h_1,h_2}\subset W\times\mathbf{V}_0$ such that

$$\begin{aligned}&a(\mathbf{u}_{h_1,h_2},\mathbf{v})-(\nabla\cdot\mathbf{v},p_{h_1,h_2})=0 &&\forall\ \mathbf{v}\in\mathbf{V}_{0,h_1,h_2},\\ &(\nabla\cdot\mathbf{u}_{h_1,h_2},w)+(cp_{h_1,h_2},w)=(f,w) &&\forall\ w\in W_{h_1,h_2}.\end{aligned}\tag{2.5}$$

Moreover, from (2.3) and (2.5) one derives the following mixed finite element error equation:

$$\begin{aligned}&a(\mathbf{u}-\mathbf{u}_{h_1,h_2},\mathbf{v})-(\nabla\cdot\mathbf{v},p-p_{h_1,h_2})=0 &&\forall\ \mathbf{v}\in\mathbf{V}_{0,h_1,h_2},\\ &(\nabla\cdot(\mathbf{u}-\mathbf{u}_{h_1,h_2}),w)+(c(p-p_{h_1,h_2}),w)=0 &&\forall\ w\in W_{h_1,h_2}.\end{aligned}\tag{2.6}$$

Let us recall that the Raviart–Thomas projection

$$\Pi^0_{h_1,h_2}\times P^0_{h_1,h_2}:\ \ \mathbf{V}\times W\to\mathbf{V}_{0,h_1,h_2}\times W_{h_1,h_2}$$

is defined by the following conditions:

$$\begin{aligned}&\int_{s_i}(\mathbf{u}-\Pi^0_{h_1,h_2}\mathbf{u})\cdot\mathbf{n}_i ds=0,\quad i=1,2,3,4,\\ &\int_e(p-P^0_{h_1,h_2}p)de=0,\end{aligned}\tag{2.7}$$

where s_i $(i=1,2,3,4)$ are the four edges of the rectangle e and $\mathbf{n}_i$ is the outward normal direction on s_i (see the left-hand side of Figure 2.1).

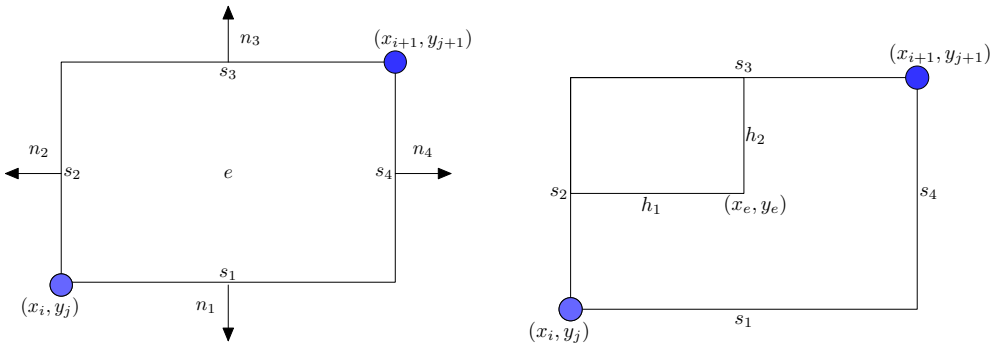

FIG. 2.1. *The rectangular element e and its four edges.*

This projection enjoys the following properties [11]:
(i) $P^0_{h_1,h_2}$ is the local $L^2(\Omega)$ projection;
(ii) $\Pi^0_{h_1,h_2}$ and $P^0_{h_1,h_2}$ satisfy

$$\begin{aligned} &(\nabla \cdot (\mathbf{u} - \Pi^0_{h_1,h_2}\mathbf{u}), w) = 0, \quad && w \in W_{h_1,h_2}, \\ &(\nabla \cdot \mathbf{v}, p - P^0_{h_1,h_2} p) = 0, && \mathbf{v} \in \mathbf{V}_{h_1,h_2}; \end{aligned} \tag{2.8}$$

(iii) the following approximation properties hold:

$$\begin{aligned} &||\mathbf{u} - \Pi^0_{h_1,h_2}\mathbf{u}||_0 \le Ch||\mathbf{u}||_1, \\ &||\nabla \cdot (\mathbf{u} - \Pi^0_{h_1,h_2}\mathbf{u})||_{-s} \le Ch^{1+s}||\nabla \cdot \mathbf{u}||_1, && 0 \le s \le 1, \\ &||p - P^0_{h_1,h_2} p||_{-s} \le Ch^{1+s}||p||_1, && 0 \le s \le 1, \end{aligned} \tag{2.9}$$

where $h := \max\{h_1, h_2\}$.

3. The asymptotic expansion. The aim of this section is to give an asymptotic error expansion for the Raviart–Thomas projection. To this end, we first introduce some notation for future use.

For any element $e \in \mathcal{T}_{h_1,h_2}$, let (x_e, y_e) stand for the center of e and let $2h_1$ and $2h_2$ stand for the side lengths of e in the x- and y-direction, respectively. Define two error functions for x and y as follows [18, 19]:

$$E(x) := \frac{1}{2}[(x - x_e)^2 - h_1^2] \quad \text{and} \quad F(y) := \frac{1}{2}[(y - y_e)^2 - h_2^2].$$

Then, we have

$$(E^m)^{(r)}|_{s_i} = 0 \ (i = 2, 4) \ \text{ and } \ (F^m)^{(r)}|_{s_i} = 0 \ (i = 1, 3) \ \text{ when } \ r \le m - 1, \tag{3.1}$$

where s_2, s_4 and s_1, s_3 are the sides of e parallel to the y-axis and x-axis, respectively (see the right-hand side of Figure 2.1).

In addition, it is easy to check that

$$
\begin{aligned}
&E = \frac{1}{6}(E^2)_{xx} - \frac{1}{3}h_1^2, && F = \frac{1}{6}(F^2)_{yy} - \frac{1}{3}h_2^2,\\
&(x-x_e)^2 = \frac{1}{3}(E^2)_{xx} + \frac{1}{3}h_1^2, && (y-y_e)^2 = \frac{1}{3}(F^2)_{yy} + \frac{1}{3}h_2^2,\\
&x - x_e = \frac{1}{6}(E^2)_{xxx}, && y - y_e = \frac{1}{6}(F^2)_{yyy},\\
&E^2 = \frac{1}{420}(E^4)_{xxxx} - \frac{2}{21}h_1^2(E^2)_{xx} + \frac{2}{15}h_1^4,\\
&F^2 = \frac{1}{420}(F^4)_{yyyy} - \frac{2}{21}h_2^2(F^2)_{yy} + \frac{2}{15}h_2^4,
\end{aligned}
\tag{3.2}
$$

where $f_{xx} = \frac{\partial^2 f}{\partial x^2}$, $f_{xxx} = \frac{\partial^3 f}{\partial x^3}$, and so on.

We are now in a position to derive an asymptotic expansion for the error of the Raviart–Thomas projection in the Raviart–Thomas space of the lowest order.

THEOREM 3.1. *Assume that* $\mathbf{u} \in \mathbf{V} \cap (H^4(\Omega))^2$ *and* $\alpha_{ij} \in H^4(\Omega)$ $(1 \le i, j \le 2)$. *Then we have*

$$
\begin{aligned}
(\alpha \cdot (\mathbf{u} - \Pi^0_{h_1,h_2}\mathbf{u}), \mathbf{v}) = &-\frac{h_1^2}{3}\int_\Omega [\alpha_{11}(u_1)_{xx} + \alpha_{12}(u_2)_{xx}]v_1 d\Omega\\
&+ \frac{h_1^2}{3}\int_\Omega [(\alpha_{22})_x(u_2)_x - \alpha_{21}(u_1)_{xx}]v_2 d\Omega\\
&+ \frac{h_2^2}{3}\int_\Omega [(\alpha_{11})_y(u_1)_y - \alpha_{12}(u_2)_{yy}]v_1 d\Omega\\
&- \frac{h_2^2}{3}\int_\Omega [\alpha_{22}(u_2)_{yy} + \alpha_{21}(u_1)_{yy}]v_2 d\Omega\\
&+ O(h^4)||\mathbf{u}||_4||\mathbf{v}||_0, \quad \mathbf{v} \in \mathbf{V}_{0,h_1,h_2},
\end{aligned}
$$

where u_1, u_2 *and* v_1, v_2 *are the first components and the second components of the vector-valued functions* $\mathbf{u}$ *and* $\mathbf{v}$, *respectively, and* $\alpha = (\alpha_{ij})_{2\times 2}$ *is the inverse of the matrix* $A : \alpha = A^{-1}$.

Proof. Set

$$
\begin{aligned}
&(\alpha \cdot (\mathbf{u} - \Pi^0_{h_1,h_2}\mathbf{u}), \mathbf{v})\\
&= \sum_{e\in\mathcal{T}_{h_1,h_2}} \int_e [\alpha_{11}(u_1 - \Pi^0_{1,h_1,h_2}u_1) + \alpha_{12}(u_2 - \Pi^0_{2,h_1,h_2}u_2)]v_1 de\\
&\quad + \sum_{e\in\mathcal{T}_{h_1,h_2}} \int_e [\alpha_{21}(u_1 - \Pi^0_{1,h_1,h_2}u_1) + \alpha_{22}(u_2 - \Pi^0_{2,h_1,h_2}u_2)]v_2 de\\
&:= \sum_{e\in\mathcal{T}_{h_1,h_2}} (I + II).
\end{aligned}
\tag{3.3}
$$

Since the treatment for II is the same as that for I, we deal only with I in Lemmas 3.2 and 3.3. ∎

LEMMA 3.2. *We have under the conditions of Theorem* 3.1 *that*

$$\int_\Omega \alpha_{11}(u_1 - \Pi^0_{1,h_1,h_2}u_1)v_1 d\Omega = -\frac{h_1^2}{3}\int_\Omega \alpha_{11}(u_1)_{xx}v_1 d\Omega + \frac{h_2^2}{3}\int_\Omega (\alpha_{11})_y(u_1)_y v_1 d\Omega + O(h^4)||u_1||_4||v_1||_0.$$

Proof. Denoting the first term of I in (3.3) by I_1, we obtain from the Taylor expansion of α_{11} and (2.9) that

$$\begin{aligned} I_1 &= \int_e [\alpha_{11}(x,y_e) + (y-y_e)(\alpha_{11})_y(x,y_e)](u_1 - \Pi^0_{1,h_1,h_2}u_1)v_1 de \\ &+ \frac{1}{2}\int_e (y-y_e)^2(\alpha_{11})_{yy}(x,y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)v_1 de + O(h^4)||u_1||_{1,e}||v_1||_{0,e} \\ &:= I_{11} + I_{12} + I_{13} + O(h^4)||u_1||_{1,e}||v_1||_{0,e}. \end{aligned} \tag{3.4}$$

Next we shall deal with I_{11}, I_{12}, and I_{13}, respectively.

It follows from the Taylor expansion of v_1 that

$$\begin{aligned} I_{11} &= \int_e \alpha_{11}(x,y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)[v_1(x_e,y) + (x-x_e)(v_1)_x]de \\ &:= I_{111} + I_{112}. \end{aligned} \tag{3.5}$$

From (2.7) we find that

$$\int_{s_i} (u_1 - \Pi^0_{1,h_1,h_2}u_1)ds = 0, \quad i = 2,4,$$

where s_2 and s_4 are the two sides of e parallel to the y-axis. Thus, we further obtain for I_{111} according to the definition of the error function $E(x)$ and integration by parts as well as (3.1) that

$$\begin{aligned} I_{111} &= \int_e \alpha_{11}(x,y_e)E_{xx}(u_1 - \Pi^0_{1,h_1,h_2}u_1)v_1(x_e,y)de \\ &= \int_e E[\alpha_{11}(x,y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)]_{xx}v_1(x_e,y)de \\ &= \int_e E[(u_1)_{xx}\alpha_{11}(x,y_e) + 2(u_1 - \Pi^0_{1,h_1,h_2}u_1)_x(\alpha_{11})_x(x,y_e)]v_1(x_e,y)de \\ &+ \int_e E(u_1 - \Pi^0_{1,h_1,h_2}u_1)(\alpha_{11})_{xx}(x,y_e)v_1(x_e,y)de \\ &:= I^1_{111} + I^2_{111} + I^3_{111}. \end{aligned} \tag{3.6}$$

For I^1_{111} it follows from (3.2), integration by parts, and the Taylor expansion of $\alpha_{11}(x,y_e)$,

$$\alpha_{11}(x,y_e) = \alpha_{11}(x,y) - F_y(\alpha_{11})_y(x,\xi_1),$$

where ξ_1 is between y_e and y, that

$$\begin{aligned}
I^1_{111} &= \frac{1}{6}\int_e (E^2)_{xx}(u_1)_{xx}\alpha_{11}(x,y_e)v_1(x_e,y)de - \frac{h_1^2}{3}\int_e (u_1)_{xx}\alpha_{11}(x,y_e)v_1(x_e,y)de \\
&= \frac{1}{6}\int_e E^2[(u_1)_{xx}\alpha_{11}(x,y_e)]_{xx}v_1(x_e,y)de - \frac{h_1^2}{3}\int_e (u_1)_{xx}\alpha_{11}v_1(x_e,y)de \\
&\quad - \frac{h_1^2}{3}\int_e (u_1)_{xx}F(\alpha_{11})_y(x,\xi_1)v_1(x_e,y)de \\
&= O(h^4)||u_1||_{4,e}||v_1||_{0,e} - \frac{h_1^2}{3}\int_e (u_1)_{xx}\alpha_{11}v_1(x_e,y)de \\
&= -\frac{h_1^2}{3}\int_e (u_1)_{xx}\alpha_{11}v_1(x,y)de - \frac{h_1^2}{3}\int_e E[(u_1)_{xx}\alpha_{11}]_x(v_1)_x de \\
&\quad + O(h^4)||u_1||_{4,e}||v_1||_{0,e} \\
&= -\frac{h_1^2}{3}\int_e \alpha_{11}(u_1)_{xx}v_1 de + \frac{h_1^4}{9}\int_e [(u_1)_{xx}\alpha_{11}]_x(v_1)_x de \\
&\quad - \frac{h_1^2}{18}\int_e (E^2)_{xx}[(u_1)_{xx}\alpha_{11}]_x(v_1)_x de + O(h^4)||u_1||_{4,e}||v_1||_{0,e} \\
&= -\frac{h_1^2}{3}\int_e \alpha_{11}(u_1)_{xx}v_1 de + \frac{h_1^4}{9}\left(\int_{s_4} - \int_{s_2}\right)[(u_1)_{xx}\alpha_{11}]_x v_1 ds \\
&\quad + O(h^4)||u_1||_{4,e}||v_1||_{0,e}. \qquad (3.7)
\end{aligned}$$

Here we have used (3.1) and the standard inverse inequality for finite element functions,

$$h||v_1||_{1,e} \le C||v_1||_{0,e}.$$

Similarly, we have for I^2_{111} by (3.2), integration by parts, and the finite element inverse inequality as well as (2.7) that

$$\begin{aligned}
I^2_{111} &= -\frac{2}{3}h_1^2\int_e (u_1 - \Pi^0_{1,h_1,h_2}u_1)_x(\alpha_{11})_x(x,y_e)v_1(x_e,y)de \\
&\quad + \frac{1}{3}\int_e (E^2)_{xx}(u_1 - \Pi^0_{1,h_1,h_2}u_1)_x(\alpha_{11})_x(x,y_e)v_1(x,y_e)de \\
&= -\frac{2}{3}h_1^2\left(\int_{s_4} - \int_{s_2}\right)(u_1 - \Pi^0_{1,h_1,h_2}u_1)(\alpha_{11})_x(x,y_e)v_1(x_e,y)ds \\
&\quad + \frac{2}{3}h_1^2\int_e (u_1 - \Pi^0_{1,h_1,h_2}u_1)(\alpha_{11})_{xx}(x,y_e)v_1 de + O(h_1^4)||u_1||_{3,e}||v_1||_{0,e} \qquad (3.8) \\
&= \frac{2}{3}h_1^2\int_e E_{xx}(u_1 - \Pi^0_{1,h_1,h_2}u_1)(\alpha_{11})_{xx}(x,y_e)v_1(x_e,y)de \\
&\quad + O(h_1^4)||u_1||_{3,e}||v_1||_{0,e} \\
&= O(h_1^4)||u_1||_{3,e}||v_1||_{0,e}.
\end{aligned}$$

Also, we obtain for I^3_{111} that

$$I^3_{111} = O(h_1^4)||u_1||_{2,e}||v_1||_{0,e}. \tag{3.9}$$

Thus, combining (3.7)–(3.9) with (3.6) yields

$$\begin{aligned} I_{111} = &-\frac{h_1^2}{3}\int_e \alpha_{11}(u_1)_{xx}v_1 de + \frac{h_1^4}{9}\left(\int_{s_4} - \int_{s_2}\right)[(u_1)_{xx}\alpha_{11}]_x v_1 ds \\ &+ O(h^4)||u_1||_{4,e}||v_1||_{0,e}. \end{aligned} \tag{3.10}$$

Next we turn our attention to I_{112} in (3.5).

Again, it follows from (3.2), integration by parts, and (2.7) that

$$\begin{aligned} I_{112} &= \frac{1}{6}\int_e (E^2)_{xxx}\alpha_{11}(x,y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)(v_1)_x de \\ &= -\frac{1}{6}\int_e E^2[\alpha_{11}(x,y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)]_{xxx}(v_1)_x de \\ &= -\frac{1}{6}\int_e \left[\frac{2}{15}h_1^4 + \frac{1}{420}(E^4)_{xxxx}\right]\left[\alpha_{11}(x,y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)\right]_{xxx}(v_1)_x de \\ &\quad + \frac{1}{3}\int_e \frac{1}{21}h_1^2(E^2)_{xx}\left[\alpha_{11}(x,y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)\right]_{xxx}(v_1)_x de \\ &= -\frac{h_1^4}{45}\int_e [\alpha_{11}(x,y_e)(u_1)_{xxx} + 3(\alpha_{11})_x(x,y_e)(u_1)_{xx}](v_1)_x de \\ &\quad - \frac{h_1^4}{45}\int_e 3(\alpha_{11})_{xx}(x,y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)_x(v_1)_x de \\ &\quad - \frac{h_1^4}{45}\int_e (\alpha_{11})_{xxx}(x,y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)(v_1)_x de \\ &\quad + O(h_1^4)||u_1||_{4,e}||v_1||_{0,e}. \end{aligned}$$

For the second and third terms of I_{112}, we have from the Cauchy–Schwartz inequality, (2.9), and the inverse estimate for finite element functions that

$$\begin{aligned} &\left|-\frac{h_1^4}{45}\int_e [3(\alpha_{11})_{xx}(x,y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)_x \right. \\ &\qquad \left. + (\alpha_{11})_{xxx}(x,y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)](v_1)_x de\right| \\ &\le Ch_1^4(||u_1 - \Pi^0_{1,h_1,h_2}u_1||_{1,e} + ||u_1 - \Pi^0_{1,h_1,h_2}u_1||_{0,e})||v_1||_{1,e} \\ &\le Ch_1^4(Ch_1||u_1||_{2,e} + Ch_1||u_1||_{1,e})||v_1||_{1,e} \\ &\le Ch_1^5||u_1||_{2,e}||v_1||_{1,e} \le Ch_1^4||u_1||_{2,e}||v_1||_{0,e}, \end{aligned}$$

which yields

$$I_{112} = -\frac{h_1^4}{45}\int_e [\alpha_{11}(x,y_e)(u_1)_{xxx}+3(\alpha_{11})_x(x,y_e)(u_1)_{xx}](v_1)_x de+O(h_1^4)||u_1||_{4,e}||v_1||_{0,e}.$$

Furthermore, we know from the Taylor expansions of $\alpha_{11}(x,y_e)$ and $(\alpha_{11})_x(x,y_e)$,

$$\alpha_{11}(x,y_e) = \alpha_{11}(x,y) + O(h_2), \quad (\alpha_{11})_x(x,y_e) = (\alpha_{11})_x(x,y) + O(h_2),$$

and the inverse inequality for finite element functions that

$$\begin{aligned} I_{112} =& -\frac{h_1^4}{45}\int_e [\alpha_{11}(x,y)(u_1)_{xxx} + 3(\alpha_{11})_x(x,y)(u_1)_{xx}](v_1)_x de \\ & -\frac{h_1^4}{45}\int_e [O(h_2)(u_1)_{xxx} + 3O(h_2)(u_1)_{xx}](v_1)_x de + O(h_1^4)||u_1||_{4,e}||v_1||_{0,e} \\ =& -\frac{h_1^4}{45}\int_e [\alpha_{11}(u_1)_{xxx} + 3(\alpha_{11})_x(u_1)_{xx}](v_1)_x de + O(h_1^4)||u_1||_{4,e}||v_1||_{0,e}. \end{aligned}$$

This, together with integration by parts with respect to the variable x, implies

$$\begin{aligned} & I_{112} \\ =& -\frac{h_1^4}{45}\left(\int_{s_4} - \int_{s_2}\right)[\alpha_{11}(u_1)_{xxx} + 3(\alpha_{11})_x(u_1)_{xx}]v_1 ds \\ & + \frac{h_1^4}{45}\int_e [\alpha_{11}(u_1)_{xxx} + 3(\alpha_{11})_x(u_1)_{xx}]_x v_1 de + O(h_1^4)||u_1||_{4,e}||v_1||_{0,e} \\ =& -\frac{h_1^4}{45}\left(\int_{s_4} - \int_{s_2}\right)[\alpha_{11}(u_1)_{xxx} + 3(\alpha_{11})_x(u_1)_{xx}]v_1 ds + O(h_1^4)||u_1||_{4,e}||v_1||_{0,e}. \end{aligned}$$

Thus, by means of (3.5) and (3.10), we have

$$\begin{aligned} I_{11} =& -\frac{h_1^2}{3}\int_e \alpha_{11}(u_1)_{xx}v_1 de + \frac{h_1^2}{9}\left(\int_{s_4} - \int_{s_2}\right)[\alpha_{11}(u_1)_{xx}]_x v_1 ds \\ & - \frac{h_1^4}{45}\left(\int_{s_4} - \int_{s_2}\right)[\alpha_{11}(u_1)_{xxx} + 3(\alpha_{11})_x(u_1)_{xx}]v_1 ds \\ & + O(h^4)||u_1||_{4,e}||v_1||_{0,e}. \end{aligned} \tag{3.11}$$

We shall handle I_{12} in (3.4) as follows.

Noticing $v_1|_e \in Q_{1,0}(e)$ and (3.1), we get from the definition of the error function $F(y)$ and integration by parts as well as (3.2) that

$$\begin{aligned} I_{12} =& -\int_e F(\alpha_{11})_y(x,y_e)(u_1)_y v_1 de \\ =& \frac{h_2^2}{3}\int_e (\alpha_{11})_y(x,y_e)(u_1)_y v_1 de + O(h_2^4)||u_1||_{3,e}||v_1||_{0,e}. \end{aligned}$$

Therefore, it follows from the Taylor expansion of $(\alpha_{11})_y(x, y_e)$,

$$(\alpha_{11})_y(x, y_e) = (\alpha_{11})_y(x, y) + (y_e - y)(\alpha_{11})_{yy}(x, y) + O(h_2^2),$$

integration by parts, and (3.1) that

$$\begin{aligned} I_{12} &= \frac{h_2^2}{3}\int_e (\alpha_{11})_y (u_1)_y v_1 de - \frac{h_2^2}{3}\int_e F_y (\alpha_{11})_{yy}(u_1)_y v_1 de \\ &\quad + O(h_2^4)||u_1||_{3,e}||v_1||_{0,e} \\ &= \frac{h_2^2}{3}\int_e (\alpha_{11})_y (u_1)_y v_1 de - \frac{h_2^2}{3}\left(\int_{s_3} - \int_{s_1}\right) F(\alpha_{11})_{yy}(u_1)_y v_1 ds \\ &\quad + \frac{h_2^2}{3}\int_e F[(\alpha_{11})_{yy}(u_1)_y]_y v_1 de + O(h_2^4)||u_1||_{3,e}||v_1||_{0,e} \\ &= \frac{h_2^2}{3}\int_e (\alpha_{11})_y (u_1)_y v_1 de + O(h_2^4)||u_1||_{3,e}||v_1||_{0,e}. \end{aligned} \tag{3.12}$$

As to I_{13}, one can find from (3.2), the Taylor expansion of v_1,

$$v_1(x, y) = v_1(x_e, y) + (x - x_e)(v_1)_x,$$

and integration by parts that

$$\begin{aligned} I_{13} &= \frac{h_2^2}{6}\int_e (\alpha_{11})_{yy}(x, y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)v_1(x_e, y) de \\ &\quad + \frac{h_2^2}{6}\int_e (\alpha_{11})_{yy}(x, y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)(x - x_e)(v_1)_x de \\ &\quad + \frac{1}{6}\int_e (F^2)_{yy}(\alpha_{11})_{yy}(x, y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)v_1 de \\ &:= I_{13}^1 + I_{13}^2 + O(h_2^4)||u_1||_{2,e}||v_1||_{0,e}. \end{aligned} \tag{3.13}$$

It follows from (2.7), (3.1), and integration by parts that

$$\begin{aligned} I_{13}^1 &= \frac{h_2^2}{6}\int_e E_{xx}(\alpha_{11})_{yy}(x, y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)v_1(x_e, y) de \\ &= \frac{h_2^2}{6}\left(\int_{s_4} - \int_{s_2}\right) E_x(\alpha_{11})_{yy}(x, y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)v_1(x_e, y) ds \\ &\quad - \frac{h_2^2}{6}\int_e E_x[(\alpha_{11})_{yy}(x, y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)]_x v_1(x_e, y) de \\ &= -\frac{h_2^2}{6}\int_e E_x[(\alpha_{11})_{yy}(x, y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)]_x v_1(x_e, y) de \\ &= \frac{h_2^2}{6}\int_e E[(\alpha_{11})_{yy}(x, y_e)(u_1 - \Pi^0_{1,h_1,h_2}u_1)]_{xx} v_1(x_e, y) de \\ &= O(h^4)||u_1||_{2,e}||v_1||_{0,e}. \end{aligned} \tag{3.14}$$

Analogously, we have via (2.7), (3.1)–(3.2), and integration by parts as well as the finite element inverse inequality that

$$\begin{aligned} I_{13}^2 &= \frac{h_2^2}{36}\int_e (E^2)_{xxx}(\alpha_{11})_{yy}(x,y_e)(u_1-\Pi^0_{1,h_1,h_2}u_1)(v_1)_x de \\ &= \frac{h_2^2}{36}\int_e (E^2)_x[(\alpha_{11})_{yy}(x,y_e)(u_1-\Pi^0_{1,h_1,h_2}u_1)]_{xx}(v_1)_x de \\ &= O(h^4)||u_1||_{2,e}||v_1||_{0,e}, \end{aligned}$$

which, together with (3.13) and (3.14), implies

$$I_{13} = O(h^4)||u_1||_{2,e}||v_1||_{0,e}. \tag{3.15}$$

Finally, combining (3.11), (3.12), and (3.15) with (3.4) results in

$$\begin{aligned} I_1 = &-\frac{h_1^2}{3}\int_e \alpha_{11}(u_1)_{xx}v_1 de + \frac{h_2^2}{3}\int_e (\alpha_{11})_y(u_1)_y v_1 de \\ &+ \frac{h_1^4}{45}\left(\int_{s_4} - \int_{s_2}\right)[4\alpha_{11}(u_1)_{xxx} + 2(\alpha_{11})_x(u_1)_{xx}]v_1 ds \\ &+ O(h^4)||u_1||_{4,e}||v_1||_{0,e}. \end{aligned}$$

The line integrals in the above can be canceled if we sum up I_1 over all the elements $e \in \mathcal{T}_{h_1,h_2}$. In fact, the integral on s_2 will be canceled from a similar contribution from the element to the immediate left of the element e if s_2 is an interior edge. In the case that s_2 is a boundary edge, the trace of v_1 on s_2 is vanishing. To summarize, we have obtained the expansion stated in Lemma 3.2 □

LEMMA 3.3. *Assume that the conditions of Theorem* 3.1 *hold. Then, there exists the following asymptotic expansion:*

$$\begin{aligned} \int_\Omega \alpha_{12}(u_2-\Pi^0_{2,h_1,h_2}u_2)v_1 d\Omega = &-\frac{h_1^2}{3}\int_\Omega \alpha_{12}(u_2)_{xx}v_1 d\Omega - \frac{h_2^2}{3}\int_\Omega \alpha_{12}(u_2)_{yy}v_1 d\Omega \\ &+ O(h^4)||u_2||_4||v_1||_0. \end{aligned}$$

Proof. By letting I_2 stand for the second term of I in (3.3), one finds from the Taylor expansion of v_1 with respect to x_e that

$$\begin{aligned} I_2 &= \int_e \alpha_{12}(u_2-\Pi^0_{2,h_1,h_2}u_2)[v_1(x_e,y) + (v_1)_x(x-x_e)]de \\ &:= I_{21} + I_{22}. \end{aligned} \tag{3.16}$$

For I_{21} we derive from the Taylor expansion of α_{12} with respect to x_e and (2.9) that

$$\begin{aligned} I_{21} = &\int_e [\alpha_{12}(x_e,y) + (x-x_e)(\alpha_{12})_x(x_e,y)](u_2-\Pi^0_{2,h_1,h_2}u_2)v_1(x_e,y)de \\ &+ \frac{1}{2}\int_e (x-x_e)^2(\alpha_{12})_{xx}(x_e,y)(u_2-\Pi^0_{2,h_1,h_2}u_2)v_1(x_e,y)de \\ &+ O(h^4)||u_2||_{2,e}||v_1||_{0,e} := I_{211} + I_{212} + I_{213} + O(h^4)||u_2||_{2,e}||v_1||_{0,e}. \end{aligned} \tag{3.17}$$

Next we shall estimate I_{211}, I_{212}, and I_{213}, respectively.

Similar to I_{111} we have by means of (2.7), (3.1)–(3.2), and integration by parts that

(3.18)
$$\begin{aligned} I_{211} &= \int_e F[\alpha_{12}(x_e,y)(u_2-\Pi^0_{2,h_1,h_2}u_2)]_{yy}v_1(x_e,y)de \\ &= -\frac{h_2^2}{3}\int_e [\alpha_{12}(x_e,y)(u_2)_{yy}+2(\alpha_{12})_y(x_e,y)(u_2-\Pi^0_{2,h_1,h_2}u_2)_y]v_1(x_e,y)de \\ &\quad -\frac{h_2^2}{3}\int_e (\alpha_{12})_{yy}(x_e,y)(u_2-\Pi^0_{2,h_1,h_2}u_2)v_1(x_e,y)de + O(h_2^4)||u_2||_{4,e}||v_1||_{0,e} \\ &:= I^1_{211}+I^2_{211}+I^3_{211}+O(h_2^4)||u_2||_{4,e}||v_1||_{0,e}. \end{aligned}$$

From the Taylor expansion of $\alpha_{12}(x_e,y)$ we know that there exists ξ_2 between x_e and x such that

$$\alpha_{12}(x_e,y)=\alpha_{12}(x,y)-E_x(\alpha_{12})_x(\xi_2,y),$$

which, together with the Taylor expansion of $v_1(x_e,y)$ and (3.2), leads to

$$\begin{aligned} I^1_{211} &= -\frac{h_2^2}{3}\int_e \alpha_{12}(u_2)_{yy}v_1de+\frac{h_2^2}{3}\int_e \alpha_{12}(u_2)_{yy}E_x(v_1)_xde \\ &\quad -\frac{h_2^2}{3}\int_e E[(\alpha_{12})_x(\xi_2,y)(u_2)_{yy}]_xv_1(x_e,y)de \\ &= -\frac{h_2^2}{3}\int_e \alpha_{12}(u_2)_{yy}v_1de-\frac{h_2^2}{3}\int_e E[\alpha_{12}(u_2)_{yy}]_x(v_1)_xde \\ &\quad +O(h^4)||u_2||_{3,e}||v_1||_{0,e} \\ &= -\frac{h_2^2}{3}\int_e \alpha_{12}(u_2)_{yy}v_1de+\frac{(h_2h_1)^2}{9}\left(\int_{s_4}-\int_{s_2}\right)[\alpha_{12}(u_2)_{yy}]_xv_1ds \\ &\quad -\frac{(h_2h_1)^2}{9}\int_e[\alpha_{12}(u_2)_{yy}]_{xx}v_1de+\frac{h_2^2}{18}\int_e(E^2)_x[\alpha_{12}(u_2)_{yy}]_{xx}(v_1)_xde \\ &\quad +O(h^4)||u_2||_{3,e}||v_1||_{0,e} \\ &= -\frac{h_2^2}{3}\int_e \alpha_{12}(u_2)_{yy}v_1de+\frac{(h_2h_1)^2}{9}\left(\int_{s_4}-\int_{s_2}\right)[\alpha_{12}(u_2)_{yy}]_xv_1ds \\ &\quad +O(h^4)||u_2||_{4,e}||v_1||_{0,e}. \end{aligned} \tag{3.19}$$

For u_2, we have by (2.7) that

$$\int_{s_i}(u_2-\Pi^0_{2,h_1,h_2}u_2)ds=0,\quad i=1,3,$$

where s_1 and s_3 are the two sides of e parallel to the x-axis. Thus, analogous to I^2_{111} we can also obtain via integration by parts with respect to y and (3.2) that

$$I^2_{211}=O(h_2^4)||u_2||_{2,e}||v_1||_{0,e}. \tag{3.20}$$

Similarly, we have

$$I_{211}^3 = O(h_2^4)||u_2||_{2,e}||v_1||_{0,e},$$

which, together with (3.18)–(3.20), implies

$$\begin{aligned} I_{211} &= -\frac{h_2^2}{3}\int_e \alpha_{12}(u_2)_{yy}v_1 de + \frac{(h_2h_1)^2}{9}\left(\int_{s_4} - \int_{s_2}\right)[\alpha_{12}(u_2)_{yy}]_x v_1 ds \\ &\quad + O(h^4)||u_2||_{4,e}||v_1||_{0,e}. \end{aligned} \tag{3.21}$$

Also, we can obtain from integration by parts and (3.2) that

$$\begin{aligned} I_{212} &= -\int_e E(\alpha_{12})_x(x_e,y)(u_2)_x v_1(x_e,y)de \\ &= \frac{h_1^2}{3}\int_e [(\alpha_{12})_x + (x_e - x)(\alpha_{12})_{xx}](u_2)_x v_1(x_e,y)de \\ &\quad + O(h_1^4)||u_2||_{3,e}||v_1||_{0,e} \\ &= \frac{h_1^2}{3}\int_e (\alpha_{12})_x(u_2)_x v_1 de - \frac{h_1^2}{3}\int_e E_x(\alpha_{12})_x(u_2)_x(v_1)_x de \\ &\quad + O(h_1^4)||u_2||_{3,e}||v_1||_{0,e} \\ &= \frac{h_1^2}{3}\int_e (\alpha_{12})_x(u_2)_x v_1 de - \frac{h_1^4}{9}\int_e [(\alpha_{12})_x(u_2)_x]_x(v_1)_x de \\ &\quad + \frac{h_1^2}{18}\int_e (E^2)_{xx}[(\alpha_{12})_x(u_2)_x]_x(v_1)_x de + O(h_1^4)||u_2||_{3,e}||v_1||_{0,e} \\ &= \frac{h_1^2}{3}\int_e (\alpha_{12})_x(u_2)_x v_1 de - \frac{h_1^4}{9}\left(\int_{s_4} - \int_{s_2}\right)[(\alpha_{12})_x(u_2)_x]_x v_1 ds \\ &\quad + O(h_1^4)||u_2||_{3,e}||v_1||_{0,e}. \end{aligned} \tag{3.22}$$

Using a similar argument, we obtain

$$\begin{aligned} I_{213} &= \frac{h_1^2}{6}\int_e (\alpha_{12})_{xx}(x_e,y)(u_2 - \Pi^0_{2,h_1,h_2}u_2)v_1(x_e,y)de \\ &\quad + \frac{1}{6}\int_e (E^2)_{xx}(\alpha_{12})_{xx}(x_e,y)(u_2 - \Pi^0_{2,h_1,h_2}u_2)v_1(x_e,y)de \\ &= \frac{h_1^2}{6}\int_e F_{yy}(\alpha_{12})_{xx}(x_e,y)(u_2 - \Pi^0_{2,h_1,h_2}u_2)v_1(x_e,y)de \\ &\qquad + O(h_1^4)||u_2||_{2,e}||v_1||_{0,e} \\ &= \frac{h_1^2}{6}\int_e F[(\alpha_{12})_{xx}(x_e,y)(u_2 - \Pi^0_{2,h_1,h_2}u_2)]_{yy}v_1(x_e,y)de \\ &\qquad + O(h_1^4)||u_2||_{2,e}||v_1||_{0,e} \\ &= O(h^4)||u_2||_{2,e}||v_1||_{0,e}. \end{aligned} \tag{3.23}$$

Combining (3.21)–(3.23) with (3.17) implies

$$
\begin{aligned}
I_{21} &= \frac{h_1^2}{3}\int_e (\alpha_{12})_x (u_2)_x v_1 de - \frac{h_2^2}{3}\int_e \alpha_{12}(u_2)_{yy} v_1 de \\
&\quad - \frac{h_1^4}{9}\left(\int_{s_4} - \int_{s_2}\right)[(\alpha_{12})_x (u_2)_x]_x v_1 ds \\
&\quad + \frac{(h_1 h_2)^2}{9}\left(\int_{s_4} - \int_{s_2}\right)[\alpha_{12}(u_2)_{yy}]_x v_1 ds \\
&\quad + O(h^4)||u_2||_{4,e}||v_1||_{0,e}.
\end{aligned} \tag{3.24}
$$

It remains to deal with I_{22} in (3.16). To this end, we notice that from the Taylor expansion for α_{12} we have

$$
\begin{aligned}
&I_{22} \\
&= \int_e [\alpha_{12}(x_e, y) + (x - x_e)(\alpha_{12})_x (x_e, y)](u_2 - \Pi^0_{2,h_1,h_2} u_2)(x - x_e)(v_1)_x de \\
&\quad + \frac{1}{2}\int_e (x - x_e)^2 (\alpha_{12})_{xx}(x_e, y)(u_2 - \Pi^0_{2,h_1,h_2} u_2)(x - x_e)(v_1)_x de \\
&\quad + O(h_1^4)||u_2||_{1,e}||v_1||_{0,e} := I_{221} + I_{222} + I_{223} + O(h_1^4)||u_2||_{1,e}||v_1||_{0,e}.
\end{aligned} \tag{3.25}
$$

The above terms can be estimated as follows. First, we have

$$
\begin{aligned}
&I_{221} \\
&= -\int_e E\alpha_{12}(x_e, y)(u_2)_x (v_1)_x de \\
&= \frac{h_1^2}{3}\int_e \alpha_{12}(u_2)_x (v_1)_x de - \frac{h_1^2}{3}\int_e E_x \alpha_{12}(\xi_3, y)(u_2)_x (v_1)_x de \\
&\quad - \frac{1}{6}\int_e E^2 \alpha_{12}(x_e, y)(u_2)_{xxx}(v_1)_x de \\
&= \frac{h_1^2}{3}\left(\int_{s_4} - \int_{s_2}\right)\alpha_{12}(u_2)_x v_1 ds - \frac{h_1^2}{3}\int_e [\alpha_{12}(u_2)_x]_x v_1 de \\
&\quad + \frac{h_1^2}{3}\int_e E[\alpha_{12}(\xi_3, y)(u_2)_x]_x (v_1)_x de \\
&\quad - \frac{1}{6}\int_e \left[\frac{1}{420}(E^4)_{xxxx} - \frac{2}{21}h_1^2 (E^2)_{xx} + \frac{2}{15}h_1^4\right]\alpha_{12}(x_e, y)(u_2)_{xxx}(v_1)_x de \\
&= -\frac{h_1^2}{3}\int_e [\alpha_{12}(u_2)_x]_x v_1 de + \frac{h_1^2}{3}\left(\int_{s_4} - \int_{s_2}\right)\alpha_{12}(u_2)_x v_1 ds \\
&\quad - \frac{h_1^4}{9}\left(\int_{s_4} - \int_{s_2}\right)[\alpha_{12}(u_2)_x]_x v_1 ds - \frac{h_1^4}{45}\left(\int_{s_4} - \int_{s_2}\right)\alpha_{12}(u_2)_{xxx} v_1 ds \\
&\quad + O(h_1^4)||u_2||_{4,e}||v_1||_{0,e},
\end{aligned} \tag{3.26}
$$

where ξ_3 is between x_e and x. Also, we have

$$
\begin{aligned}
I_{222} &= \frac{h_1^2}{3}\int_e F_{yy}(\alpha_{12})_x(x_e,y)(u_2-\Pi^0_{2,h_1,h_2}u_2)(v_1)_x de \\
&\quad + \frac{1}{3}\int_e E^2(\alpha_{12})_x(x_e,y)(u_2)_{xx}(v_1)_x de \\
&= \frac{h_1^2}{3}\left(\int_{s_3}-\int_{s_1}\right) F_y(\alpha_{12})_x(x_e,y)(u_2-\Pi^0_{2,h_1,h_2}u_2)(v_1)_x ds \\
&\quad - \frac{h_1^2}{3}\int_e F_y[(\alpha_{12})_x(x_e,y)(u_2-\Pi^0_{2,h_1,h_2}u_2)]_y(v_1)_x de \\
&\quad + \frac{1}{3}\int_e \left[\frac{2}{15}h_1^4+\frac{1}{420}(E^4)_{xxxx}-\frac{2}{21}h_1^2(E^2)_{xx}\right](\alpha_{12})_x(x_e,y)(u_2)_{xx}(v_1)_x de \qquad (3.27)\\
&= -\frac{(h_1h_2)^2}{9}\int_e (\alpha_{12})_x(u_2)_{yy}(v_1)_x de \\
&\quad - \frac{2(h_1h_2)^2}{9}\left(\int_{s_3}-\int_{s_1}\right)(\alpha_{12})_{xy}(x_e,y)(u_2-\Pi^0_{2,h_1,h_2}u_2)(v_1)_x ds \\
&\quad + \frac{2}{45}h_1^4\left(\int_{s_4}-\int_{s_2}\right)(\alpha_{12})_x(u_2)_{xx}v_1 ds + O(h_1^4)||u_2||_{3,e}||v_1||_{0,e} \\
&= -\frac{(h_1h_2)^2}{9}\left(\int_{s_4}-\int_{s_2}\right)(\alpha_{12})_x(u_2)_{yy}v_1 ds \\
&\quad + \frac{2}{45}h_1^4\left(\int_{s_4}-\int_{s_2}\right)(\alpha_{12})_x(u_2)_{xx}v_1 ds + O(h_1^4)||u_2||_{3,e}||v_1||_{0,e}.
\end{aligned}
$$

Since

$$(x-x_e)^3 = \frac{1}{15}(E^3)_{xxx}+\frac{9}{15}h_1^2E_x,$$

we have

$$
\begin{aligned}
I_{223} &= -\frac{3h_1^2}{10}\int_e E(\alpha_{12})_{xx}(x_e,y)(u_2)_x(v_1)_x de + O(h_1^4)||u_2||_{2,e}||v_1||_{0,e} \\
&= \frac{h_1^4}{10}\int_e (\alpha_{12})_{xx}(u_2)_x(v_1)_x de + O(h_1^4)||u_2||_{2,e}||v_1||_{0,e} \\
&= \frac{h_1^4}{10}\left(\int_{s_4}-\int_{s_2}\right)(\alpha_{12})_{xx}(u_2)_x v_1 ds + O(h_1^4)||u_2||_{2,e}||v_1||_{0,e},
\end{aligned}
$$

which, together with (3.25)–(3.27), leads to

$$
\begin{aligned}
I_{22} = &-\frac{h_1^2}{3}\int_e [\alpha_{12}(u_2)_x]_x v_1 de + \frac{h_1^2}{3}\left(\int_{s_4} - \int_{s_2}\right)\alpha_{12}(u_2)_x v_1 ds \\
&- \frac{h_1^4}{9}\left(\int_{s_4} - \int_{s_2}\right)[\alpha_{12}(u_2)_x]_x v_1 ds - \frac{h_1^4}{45}\left(\int_{s_4} - \int_{s_2}\right)\alpha_{12}(u_2)_{xxx} v_1 ds \\
&- \frac{(h_1 h_2)^2}{9}\left(\int_{s_4} - \int_{s_2}\right)(\alpha_{12})_x (u_2)_{yy} v_1 ds \\
&+ \frac{2h_1^4}{45}\left(\int_{s_4} - \int_{s_2}\right)(\alpha_{12})_x (u_2)_{xx} v_1 ds \\
&+ \frac{h_1^4}{10}\left(\int_{s_4} - \int_{s_2}\right)(\alpha_{12})_{xx} (u_2)_x v_1 ds + O(h^4)||u_2||_{4,e}||v_1||_{0,e}.
\end{aligned} \tag{3.28}
$$

Hence, combining (3.24) and (3.28) with (3.16) gives rise to

$$
\begin{aligned}
I_2 = &-\frac{h_1^2}{3}\int_e \alpha_{12}(u_2)_{xx} v_1 de - \frac{h_2^2}{3}\int_e \alpha_{12}(u_2)_{yy} v_1 de \\
&+ \frac{h_1^2}{3}\left(\int_{s_4} - \int_{s_2}\right)\alpha_{12}(u_2)_x v_1 ds \\
&- \frac{h_1^4}{9}\left(\int_{s_4} - \int_{s_2}\right)\left\{[(\alpha_{12})_x (u_2)_x]_x + [\alpha_{12}(u_2)_x]_x + \frac{1}{5}\alpha_{12}(u_2)_{xxx}\right\} v_1 ds \\
&+ \frac{h_1^4}{5}\left(\int_{s_4} - \int_{s_2}\right)\left[\frac{2}{9}(\alpha_{12})_x (u_2)_{xx} + \frac{1}{2}(\alpha_{12})_{xx}(u_2)_x\right] v_1 ds \\
&+ \frac{(h_1 h_2)^2}{9}\left(\int_{s_4} - \int_{s_2}\right)\alpha_{12}(u_2)_{yyx} v_1 ds + O(h^4)||u_2||_{4,e}||v_1||_{0,e}.
\end{aligned}
$$

Furthermore, summing up I_2 over all the elements $e \in \mathcal{T}_{h,k}$, we can obtain the desired result. ∎

THEOREM 3.4. *Assume that p, $c \in H^3(\Omega)$. Then we have the following asymptotic expansion:*

$$
(c(p - P^0_{h_1,h_2}p), w) = \frac{h_1^2}{3}\int_\Omega c_x p_x w d\Omega + \frac{h_2^2}{3}\int_\Omega c_y p_y w d\Omega + O(h^4)||p||_3||w||_0, \quad w \in W_{h_1,h_2}.
$$

Proof. It follows from (2.7), (2.9), and the Taylor expansion of $c(x, y)$ at x_e that

$$
\begin{aligned}
&\int_e c(x,y)(p - P^0_{h_1,h_2}p) w de \\
&= \int_e [c(x_e, y) + c_x(x_e, y)(x - x_e)](p - P^0_{h_1,h_2}p) w de \\
&\quad + \frac{1}{2}\int_e (x - x_e)^2 c_{xx}(x_e, y)(p - P^0_{h_1,h_2}p) w de + O(h_1^4)||p||_{1,e}||w||_{0,e} \\
&:= III_1 + III_2 + III_3 + O(h_1^4)||p||_{1,e}||w||_{0,e}.
\end{aligned} \tag{3.29}
$$

For III_1 we know from (2.7), (2.9), (3.1)–(3.2), integration by parts, and the Taylor expansion of $c(x_e, y)$ with respect to y_e that

$$\begin{aligned}
III_1 &= \int_e [c(x_e, y_e) + (y - y_e)c_y(x_e, y_e)](p - P^0_{h_1,h_2}p)wde \\
&\quad + \frac{1}{2}\int_e (y - y_e)^2 c_{yy}(x_e, y_e)(p - P^0_{h_1,h_2}p)wde + O(h_2^4)||p||_{1,e}||w||_{0,e} \\
&= -\int_e F c_y(x_e, y_e)p_y wde + \frac{h_2^2}{6}\int_e c_{yy}(x_e, y_e)(p - P^0_{h_1,h_2}p)wde \\
&\quad + \frac{1}{6}\int_e (F^2)_{yy}c_{yy}(x_e, y_e)(p - P^0_{h_1,h_2}p)wde + O(h_2^4)||p||_{1,e}||w||_{0,e} \\
&= \frac{h_2^2}{3}\int_e c_y(x_e, y_e)p_y wde - \frac{1}{6}\int_e (F^2)_{yy}c_y(x_e, y_e)p_y wde + O(h_2^4)||p||_{2,e}||w||_{0,e} \\
&= \frac{h_2^2}{3}\int_e c_y p_y wde - \frac{h_2^2}{3}\int_e E_x c_{yx}p_y wde \\
&\quad - \frac{h_2^2}{3}\int_e F_y c_{yy}p_y wde + O(h_2^4)||p||_{3,e}||w||_{0,e} \\
&= \frac{h_2^2}{3}\int_e c_y u_y wde + O(h^4)||p||_{3,e}||w||_{0,e}. \qquad (3.30)
\end{aligned}$$

We can also get for III_2 that

$$\begin{aligned}
III_2 &= -\int_e E c_x(x_e, y)p_x wde \\
&= \frac{h_1^2}{3}\int_e (c_x - E_x c_x)p_x wde + O(h_1^4)||p||_{3,e}||w||_{0,e} \qquad (3.31) \\
&= \frac{h_1^2}{3}\int_e c_x p_x wde + O(h_1^4)||p||_{3,e}||w||_{0,e}.
\end{aligned}$$

Analogously, we have

$$\begin{aligned}
III_3 &= \frac{h_1^2}{6}\int_e c_{xx}(x_e, y)(p - P^0_{h_1,h_2}p)wde + \frac{1}{6}\int_e c_{xx}(x_e, y)(E^2)_{xx}(p - P^0_{h_1,h_2}p)wde \\
&= \frac{h_1^2}{6}\int_e c_{xxy}(x_e, y_e)F_y(p - P^0_{h_1,h_2}p)wde + O(h_1^4)||p||_{2,e}||w||_{0,e} \\
&= O(h^4)||p||_{2,e}||w||_{0,e},
\end{aligned}$$

which, together with (3.29)–(3.31), implies

$$\int_e c(p - P^0_{h_1,h_2}p)wde = \frac{h_1^2}{3}\int_e c_x p_x wde + \frac{h_2^2}{3}\int_e c_y p_y wde + O(h^4)||p||_{3,e}||w||_{0,e}.$$

Thus,

$$\int_\Omega c(p - P^0_{h_1,h_2}p)wd\Omega = \frac{h_1^2}{3}\int_\Omega c_x p_x w d\Omega + \frac{h_2^2}{3}\int_\Omega c_y p_y w d\Omega + O(h^4)||p||_3||w||_0. \qquad \square$$

From Theorems 3.1 and 3.4 we immediately obtain the following corollaries.

COROLLARY 3.5. *If* $\mathbf{u} \in \mathbf{V}\bigcap(H^2(\Omega))^2$ *and* $\alpha_{ij} \in H^2(\Omega)$ $(1 \le i, j \le 2)$, *we have*

$$|(\alpha \cdot (\mathbf{u} - \Pi^0_{h_1,h_2}\mathbf{u}), \mathbf{v})| \le Ch^2||\mathbf{u}||_2||\mathbf{v}||_0, \quad \mathbf{v} \in \mathbf{V}_{0,h_1,h_2}.$$

COROLLARY 3.6. *If* p, $c \in H^1(\Omega)$, *we have*

$$|(c(p - P^0_{h_1,h_2}p), w)| \le Ch^2||p||_1||w||_0, \quad w \in W_{h_1,h_2}.$$

4. The global Richardson extrapolation. In this section we turn to the asymptotic expansions between the mixed finite element solution and the interpolant of the exact solution of the problem (1.1)–(1.2), from which asymptotic expansions between the exact solution and the postprocessed mixed finite element solution by interpolation are further obtained. The Richardson extrapolations of two different schemes will be performed to generate high order approximations to the exact solution of (1.1)–(1.2). First, we recall from [13, 14] the following lemma.

LEMMA 4.1. *Assume that the matrix* A *is positive definite. Then, the norms* $||\mathbf{u}||_0^2 := (\mathbf{u}, \mathbf{u})$ *and* $||\mathbf{u}||_{A^{-1}}^2 := (A^{-1}\mathbf{u}, \mathbf{u})$ *are equivalent.*

4.1. The global Richardson extrapolation in two directions. We first discuss the extrapolation method of mixed finite element approximation for (1.1)–(1.2) in both the x and y directions as follows.

THEOREM 4.2. *Suppose that* $(p, \mathbf{u})$ *and* $(p_{h_1,h_2}, \mathbf{u}_{h_1,h_2})$ *are the exact solution of* (2.3) *and its mixed finite element solution, respectively. Then we have the following asymptotic expansions under the conditions that* p, $c \in H^3(\Omega)$, $\mathbf{u} \in \mathbf{V} \cap (H^4(\Omega))^2$, *and* $\alpha_{ij} \in H^4(\Omega)$ $(1 \le i, j \le 2)$*:*

$$p_{h_1,h_2} - P^0_{h_1,h_2}p = h^2\xi_{h_1,h_2} + r_{h_1,h_2}, \qquad ||r_{h_1,h_2}||_0 \le Ch^4,$$

$$\mathbf{u}_{h_1,h_2} - \Pi^0_{h_1,h_2}\mathbf{u} = h^2\eta_{h_1,h_2} + \mathbf{r}_{h_1,h_2}, \quad ||\mathbf{r}_{h_1,h_2}||_{\mathbf{V}} \le Ch^4,$$

where $(\xi_{h_1,h_2}, \eta_{h_1,h_2}) \in W_{h_1,h_2} \times \mathbf{V}_{0,h_1,h_2}$ *and* $P^0_{h_1,h_2} \times \Pi^0_{h_1,h_2} : W \times \mathbf{V}_0 \to W_{h_1,h_2} \times \mathbf{V}_{0,h_1,h_2}$ *is the Raviart–Thomas projection operator.*

Proof. Let

$$\rho_{h_1,h_2} := p_{h_1,h_2} - P^0_{h_1,h_2}p, \quad \theta_{h_1,h_2} := \mathbf{u}_{h_1,h_2} - \Pi^0_{h_1,h_2}\mathbf{u}.$$

Then, it follows from (2.6) and (2.8) that

$$\begin{aligned}
&(\alpha\theta_{h_1,h_2}, \mathbf{v}) - (\rho_{h_1,h_2}, \nabla \cdot \mathbf{v}) = (\alpha(\mathbf{u} - \Pi^0_{h_1,h_2}\mathbf{u}), \mathbf{v}), \qquad \mathbf{v} \in \mathbf{V}_{0,h_1,h_2}, \\
&(\nabla \cdot \theta_{h_1,h_2}, w) + (c\rho_{h_1,h_2}, w) = (c(p - P^0_{h_1,h_2}p), w), \qquad w \in W_{h_1,h_2},
\end{aligned} \tag{4.1}$$

where $\alpha = A^{-1}$. From Theorems 3.1 and 3.4 we derive that

$$
\begin{aligned}
&(\alpha(\mathbf{u} - \Pi^0_{h_1,h_2}\mathbf{u}), \mathbf{v}) = h^2 L_{h_1,h_2}(\mathbf{v}) + O(h^4)||\mathbf{v}||_0, \quad \mathbf{v} \in \mathbf{V}_{0,h_1,h_2},\\
&(c(p - P^0_{h_1,h_2}p), w) = h^2 G_{h_1,h_2}(w) + O(h^4)||w||_0, \quad w \in W_{h_1,h_2},
\end{aligned} \tag{4.2}
$$

where

$$
\begin{aligned}
G_{h_1,h_2}(\phi) &= \frac{1}{3}\left(\frac{h_1}{h}\right)^2 \int_\Omega c_x p_x \phi d\Omega + \frac{1}{3}\left(\frac{h_2}{h}\right)^2 \int_\Omega c_y p_y \phi d\Omega,\\
L_{h_1,h_2}(\psi) &= -\frac{1}{3}\left(\frac{h_1}{h}\right)^2 \int_\Omega [\alpha_{11}(u_1)_{xx} + \alpha_{12}(u_2)_{xx}]\psi_1 d\Omega\\
&\quad + \frac{1}{3}\left(\frac{h_1}{h}\right)^2 \int_\Omega [(\alpha_{22})_x (u_2)_x - \alpha_{21}(u_1)_{xx}]\psi_2 d\Omega\\
&\quad + \frac{1}{3}\left(\frac{h_2}{h}\right)^2 \int_\Omega [(\alpha_{11})_y (u_1)_y - \alpha_{12}(u_2)_{yy}]\psi_1 d\Omega\\
&\quad - \frac{1}{3}\left(\frac{h_2}{h}\right)^2 \int_\Omega [\alpha_{22}(u_2)_{yy} + \alpha_{21}(u_1)_{yy}]\psi_2 d\Omega.
\end{aligned}
$$

Here, $\psi = (\psi_1, \psi_2)$ is a vector-valued function. Obviously,

$$
L_{h_1/2,h_2/2}(\psi) = L_{h_1,h_2}(\psi) \quad \text{and} \quad G_{h_1/2,h_2/2}(\phi) = G_{h_1,h_2}(\phi). \tag{4.3}
$$

Let $(\xi, \eta) \in W \times \mathbf{V}_0$ and $(\xi_{h_1,h_2}, \eta_{h_1,h_2}) \in W_{h_1,h_2} \times \mathbf{V}_{0,h_1,h_2}$ be the exact solution and the mixed finite element solution, respectively, of the following auxiliary problem:

$$
\begin{aligned}
&(\alpha\eta, \mathbf{v}) - (\xi, \nabla \cdot \mathbf{v}) = L_{h_1,h_2}(\mathbf{v}), \qquad \mathbf{v} \in \mathbf{V}_0,\\
&(\nabla \cdot \eta, w) + (c\xi, w) = G_{h_1,h_2}(w), \qquad w \in W.
\end{aligned} \tag{4.4}
$$

Then, from (4.1), (4.2), and (4.4) one finds that

$$
\begin{aligned}
&(\alpha(\theta_{h_1,h_2} - h^2\eta_{h_1,h_2}), \mathbf{v}) - (\rho_{h_1,h_2} - h^2\xi_{h_1,h_2}, \nabla \cdot \mathbf{v}) = O(h^4)||\mathbf{v}||_0, \qquad \mathbf{v} \in \mathbf{V}_{0,h_1,h_2},\\
&(\nabla \cdot (\theta_{h_1,h_2} - h^2\eta_{h_1,h_2}), w) + (c(\rho_{h_1,h_2} - h^2\xi_{h_1,h_2}), w) = O(h^4)||w||_0, \quad w \in W_{h_1,h_2}.
\end{aligned}
$$

Set

$$
\theta^*_{h_1,h_2} := \theta_{h_1,h_2} - h^2\eta_{h_1,h_2} \quad \text{and} \quad \rho^*_{h_1,h_2} := \rho_{h_1,h_2} - h^2\xi_{h_1,h_2}.
$$

Thus, we have

$$
\begin{aligned}
&(\alpha\theta^*_{h_1,h_2}, \mathbf{v}) - (\rho^*_{h_1,h_2}, \nabla \cdot \mathbf{v}) = O(h^4)||\mathbf{v}||_0, \quad \mathbf{v} \in \mathbf{V}_{0,h_1,h_2},\\
&(\nabla \cdot \theta^*_{h_1,h_2}, w) + (c\rho^*_{h_1,h_2}, w) = O(h^4)||w||_0, \quad w \in W_{h_1,h_2},
\end{aligned} \tag{4.5}
$$

which implies by using the standard stability argument [5] that

$$||\theta^*_{h_1,h_2}||_{\mathbf{V}} + ||\rho^*_{h_1,h_2}||_0 \leq C\left(\sup_{\mathbf{v}\in\mathbf{V}_{0,h_1,h_2}} \frac{|O(h^4)|\,||\mathbf{v}||_0}{||\mathbf{v}||_{\mathbf{V}}} + \sup_{w\in W_{h,k}} \frac{|O(h^4)|\,||w||_0}{||w||_0}\right)$$

$$\leq Ch^4.$$

Thus, the proof of Theorem 4.2 is complete. □

Remark 4.1. In another paper we will discuss asymptotic expansions in L^∞-norm that are similar to those in Theorem 4.2 above.

Following the procedure for Theorem 4.2 and utilizing Corollaries 3.5 and 3.6 we can also prove the following result.

LEMMA 4.3. *If* $(\xi,\eta)\in W\times\mathbf{V}_0$ *and* $(\xi_{h_1,h_2},\eta_{h_1,h_2})\in W_{h_1,h_2}\times\mathbf{V}_{0,h_1,h_2}$ *are the variational solution and the mixed finite element solution of* (4.4)*, respectively, then we have the superconvergent estimate*

$$||\xi_{h_1,h_2} - P^0_{h_1,h_2}\xi||_0 + ||\eta_{h_1,h_2} - \Pi^0_{h_1,h_2}\eta||_{\mathbf{V}} \leq Ch^2(||\xi||_1 + ||\eta||_2).$$

Now we use the interpolation postprocessing technique to get a global extrapolation approximation of high accuracy for the pressure and the velocity fields. Analogous to [18, 13, 14] we need to define two postprocessing interpolation operators $\Pi^3_{4h_1,4h_2}$ and $P^3_{4h_1,4h_2}$ to satisfy

$$\begin{aligned}
&\Pi^3_{4h_1,4h_2}\Pi^0_{h_1,h_2} = \Pi^3_{4h_1,4h_2},\\
&||\Pi^3_{4h_1,4h_2}\mathbf{v}||_0 \leq C||\mathbf{v}||_0 \qquad &&\forall\mathbf{v}\in\mathbf{V}_{0,h_1,h_2},\\
&||\Pi^3_{4h_1,4h_2}\mathbf{u}-\mathbf{u}||_0 \leq Ch^4||\mathbf{u}||_4 \qquad &&\forall\mathbf{u}\in(H^4(\Omega))^2,\\
&P^3_{4h_1,4h_2}P^0_{h_1,h_2} = P^3_{4h_1,4h_2},\\
&||P^3_{4h_1,4h_2}w||_0 \leq C||w||_0 \qquad &&\forall w\in W_{h_1,h_2},\\
&||P^3_{4h_1,4h_2}p-p||_0 \leq Ch^4||p||_4 \qquad &&\forall p\in H^4(\Omega).
\end{aligned} \tag{4.6}$$

To this end, assume that the rectangular partition $\mathcal{T}_{h_1,h_2}$ has been obtained from $\mathcal{T}_{4h_1,4h_2}$ with mesh size $4h$ by subdividing each element of $\mathcal{T}_{4h_1,4h_2}$ into sixteen small congruent rectangles. Let $\tau := \bigcup_{i=1}^{16} e_i$ with $e_i\in\mathcal{T}_{h_1,h_2}$. We define two projection operators $\Pi^3_{4h_1,4h_2}$ and $P^3_{4h_1,4h_2}$ associated with $\mathcal{T}_{4h_1,4h_2}$ of degree at most 3 in x and y on τ, respectively, according to the following conditions:

$$\begin{aligned}
&\Pi^3_{4h_1,4h_2}\mathbf{u}|_\tau \in Q_{4,3}(\tau)\times Q_{3,4}(\tau), \qquad &&P^3_{4h_1,4h_2}u|_\tau \in Q_{3,3}(\tau),\\
&\int_{s_i}(\mathbf{u}-\Pi^3_{4h_1,4h_2}\mathbf{u})\cdot\mathbf{n}ds = 0, \qquad &&i=1,2,\ldots,40, \text{ and}\\
&\int_{e_i}(p-P^3_{4h_1,4h_2}p) = 0, \qquad &&i=1,2,\ldots,16,
\end{aligned} \tag{4.7}$$

where s_i $(i=1,2,\ldots,40)$ is one of the forty sides of the sixteen small elements e_i $(i=1,2,\ldots,16)$. It is easy to check that the two operators $\Pi^3_{4h_1,4h_2}$ and $P^3_{4h_1,4h_2}$ defined by (4.7) satisfy the properties described in (4.6).

THEOREM 4.4. *We have under the conditions of Theorem* 4.2 *that*

$$P^3_{4h_1,4h_2}p_{h_1,h_2} - p = h^2\xi + r^*_{h_1,h_2}, \quad ||r^*_{h_1,h_2}||_0 \le Ch^4,$$

$$\Pi^3_{4h_1,4h_2}\mathbf{u}_{h_1,h_2} - \mathbf{u} = h^2\eta + \mathbf{r}^*_{h_1,h_2}, \quad ||\mathbf{r}^*_{h_1,h_2}||_0 \le Ch^4,$$

where $(\xi,\eta) \in W \times \mathbf{V}_0$ *is the variational solution of* (4.4).

Proof. Let

$$\overline{r}_{h_1,h_2} := p_{h_1,h_2} - P^0_{h_1,h_2}p - h^2P^0_{h_1,h_2}\xi.$$

Then, it follows from Theorem 4.2 and Lemma 4.3 that

$$||\overline{r}_{h_1,h_2}||_0 \le Ch^4.$$

Thus, we find from (4.6) that

$$\begin{aligned}
&P^3_{4h_1,4h_2}p_{h_1,h_2} - p \\
&= P^3_{4h_1,4h_2}(p_{h_1,h_2} - P^0_{h_1,h_2}p) + (P^3_{4h_1,4h_2}p - p) \\
&= P^3_{4h_1,4h_2}(h^2P^0_{h_1,h_2}\xi + \overline{r}_{h_1,h_2}) + (P^3_{4h_1,4h_2}p - p) \\
&= h^2P^3_{4h_1,4h_2}\xi + P^3_{4h_1,4h_2}\overline{r}_{h_1,h_2} + (P^3_{4h_1,4h_2}p - p) \\
&= h^2\xi + h^2(P^3_{4h_1,4h_2}\xi - \xi) + P^3_{4h_1,4h_2}\overline{r}_{h_1,h_2} + (P^3_{4h_1,4h_2}p - p) \\
&= h^2\xi + r^*_{h_1,h_2},
\end{aligned}$$

where

$$r^*_{h_1,h_2} := h^2(P^3_{4h_1,4h_2}\xi - \xi) + P^3_{4h_1,4h_2}\overline{r}_{h_1,h_2} + (P^3_{4h_1,4h_2}p - p)$$

with $||r^*_{h_1,h_2}||_0 \le Ch^4$.

Analogously, we can also get the second equality in the theorem. ∎

Theorem 4.4 guarantees that we can use low order mixed finite element solutions to generate high order approximations by the Richardson extrapolation. And thus, we employ, in addition to $W_{h_1,h_2} \times \mathbf{V}_{0,h_1,h_2}$, the Raviart–Thomas mixed finite element space $W_{h_1/2,h_2/2} \times \mathbf{V}_{0,h_1/2,h_2/2}$ of the lowest order gained by subdividing each element $e_i \in \mathcal{T}_{h_1,h_2}$ into four small congruent elements $\hat{e}_{i,j} \in \mathcal{T}_{h_1/2,h_2/2}$ $(j = 1,2,3,4)$. Denote by $(p_{h_1/2,h_2/2}, \mathbf{u}_{h_1/2,h_2/2}) \in W_{h_1/2,h_2/2} \times \mathbf{V}_{0,h_1/2,h_2/2}$ and $P^3_{2h_1,2h_2} \times \Pi^3_{2h_1,2h_2}$ the mixed finite element approximation and the Raviart–Thomas projection of degree at most 3 in x and y with respect to this new partition. From Theorem 4.4 we know under the L^2-norm that

$$P^3_{2h_1,2h_2}p_{h_1/2,h_2/2} - p = \left(\frac{h}{2}\right)^2 \xi + O(h^4),$$

which produces by applying the Richardson extrapolation that under the L^2-norm

$$\frac{4P^3_{2h_1,2h_2}p_{h_1/2,h_2/2} - P^3_{4h_1,4h_2}p_{h_1,h_2}}{3} = p + O(h^4). \tag{4.8}$$

Similarly, we have under the L^2-norm that

$$\frac{4\Pi^3_{2h_1,2h_2}\mathbf{u}_{h_1/2,h_2/2} - \Pi^3_{4h_1,4h_2}\mathbf{u}_{h_1,h_2}}{3} = \mathbf{u} + O(h^4). \tag{4.9}$$

It is very important for a mixed finite element method to have a computable a posteriori error estimator such that we can assess the accuracy of the approximate solutions by means of the error estimator in applications. The superconvergent approximations generated above in (4.8) and (4.9) can be used naturally to produce efficient a posteriori error estimators. In fact, we have by the same way as in Theorem 5.3 in [13] that the following theorem holds.

THEOREM 4.5. *Under the assumptions of Theorem* 4.4*, we have*

$$\begin{aligned} &||p - P^3_{2h_1,2h_2}p_{h_1/2,h_2/2}||_0 \\ &\quad = \frac{1}{3}||P^3_{2h_1,2h_2}p_{h_1/2,h_2/2} - P^3_{4h_1,4h_2}p_{h_1,h_2}||_0 + O(h^4), \end{aligned} \tag{4.10}$$

$$\begin{aligned} &||\mathbf{u} - \Pi^3_{2h_1,2h_2}\mathbf{u}_{h_1/2,h_2/2}||_0 \\ &\quad = \frac{1}{3}||\Pi^3_{2h_1,2h_2}\mathbf{u}_{h_1/2,h_2/2} - \Pi^3_{4h_1,4h_2}\mathbf{u}_{h_1,h_2}||_0 + O(h^4). \end{aligned} \tag{4.11}$$

In addition, if there exist positive constants C_1, C_2 *and* ϵ_1, $\epsilon_2 \in (0,1)$ *such that*

$$||p - P^3_{2h_1,2h_2}p_{h_1/2,h_2/2}||_0 \geq C_1 h^{4-\epsilon_1}, \tag{4.12}$$

$$||\mathbf{u} - \Pi^3_{2h_1,2h_2}\mathbf{u}_{h_1/2,h_2/2}||_0 \geq C_2 h^{4-\epsilon_2}, \tag{4.13}$$

then we have

$$\lim_{h\to 0} \frac{3||p - P^3_{2h_1,2h_2}p_{h_1/2,h_2/2}||_0}{||P^3_{2h_1,2h_2}p_{h_1/2,h_2/2} - P^3_{4h_1,4h_2}p_{h_1,h_2}||_0} = 1, \tag{4.14}$$

$$\lim_{h\to 0} \frac{3||\mathbf{u} - \Pi^3_{2h_1,2h_2}\mathbf{u}_{h_1/2,h_2/2}||_0}{||\Pi^3_{2h_1,2h_2}\mathbf{u}_{h_1/2,h_2/2} - \Pi^3_{4h_1,4h_2}\mathbf{u}_{h_1,h_2}||_0} = 1. \tag{4.15}$$

From (4.10) we see that the computable error estimator $\frac{1}{3}||P^3_{2h_1,2h_2}p_{h_1/2,h_2/2} - P^3_{4h_1,4h_2}p_{h_1,h_2}||_0$ is the principal part of the error $||p - P^3_{2h_1,2h_2}p_{h_1/2,h_2/2}||_0$, and can be used as an a posteriori error indicator to assess the accuracy of the pressure error $||p - P^3_{2h_1,2h_2}p_{h_1/2,h_2/2}||_0$. Meanwhile, the condition (4.12) seems to be a reasonable assumption because $O(h^2)$ is the optimal convergence rate of $||p - P^3_{2h_1,2h_2}p_{h_1/2,h_2/2}||_0$ according to Theorem 4.4. Also, it can be further seen from (4.14) that the a posteriori error estimator $\frac{1}{3}||P^3_{2h_1,2h_2}p_{h_1/2,h_2/2} - P^3_{4h_1,4h_2}p_{h_1,h_2}||_0$ is quite reliable. The same comments are also valid for (4.11), (4.13), and (4.15).

4.2. The global Richardson extrapolation in one direction. The approach introduced in the last subsection has a limitation in that it requires a global and uniform refinement in both the x- and y-directions, and hence, it wastes computing time and memory. To overcome this shortcoming, here we propose an extrapolation method of a partial refinement [18], in which the meshes are refined just in either the x- or y-direction. Thus, this method is more efficient and is also more suitable for parallel computations.

THEOREM 4.6. *Under the conditions of Theorem* 4.4 *we have*

$$p_{h_1,h_2} - P^0_{h_1,h_2}p = h_1^2\xi^1_{h_1,h_2} + h_2^2\xi^2_{h_1,h_2} + \hat{r}_{h_1,h_2}, \qquad ||\hat{r}_{h_1,h_2}||_0 \le Ch^4,$$

$$\mathbf{u}_{h_1,h_2} - \Pi^0_{h_1,h_2}\mathbf{u} = h_1^2\eta^1_{h_1,h_2} + h_2^2\eta^2_{h_1,h_2} + \hat{\mathbf{r}}_{h_1,h_2}, \qquad ||\hat{\mathbf{r}}_{h_1,h_2}||_0 \le Ch^4,$$

where $(\xi^1_{h_1,h_2}, \eta^1_{h_1,h_2})$, $(\xi^2_{h_1,h_2}, \eta^2_{h_1,h_2}) \in W_{h_1,h_2} \times \mathbf{V}_{0,h_1,h_2}$.

Proof. Let (ξ^1, η^1), $(\xi^2, \eta^2) \in W \times \mathbf{V}_0$ and $(\xi^1_{h_1,h_2}, \eta^1_{h_1,h_2})$, $(\xi^2_{h_1,h_2}, \eta^2_{h_1,h_2}) \in W_{h_1,h_2} \times \mathbf{V}_{0,h_1,h_2}$ be the exact solutions and the mixed finite element solutions, respectively, of the following two auxiliary variational problems:

$$\begin{aligned} &(\alpha\eta^1, \mathbf{v}) - (\xi^1, \nabla\cdot\mathbf{v}) = L_1(\mathbf{v}), \quad \mathbf{v} \in \mathbf{V}_0, \\ &(\nabla\cdot\eta^1, w) + (c\xi^1, w) = L_3(w), \quad w \in W, \end{aligned} \tag{4.16}$$

and

$$\begin{aligned} &(\alpha\eta^2, \mathbf{v}) - (\xi^2, \nabla\cdot\mathbf{v}) = L_2(\mathbf{v}), \quad \mathbf{v} \in \mathbf{V}_0, \\ &(\nabla\cdot\eta^2, w) + (c\xi^2, w) = L_4(w), \quad w \in W, \end{aligned} \tag{4.17}$$

where

$$\begin{aligned} L_1(\mathbf{v}) &= -\frac{1}{3}\int_\Omega [\alpha_{11}(u_1)_{xx} + \alpha_{12}(u_2)_{xx}]v_1 d\Omega \\ &\quad + \frac{1}{3}\int_\Omega [(\alpha_{22})_x(u_2)_x - \alpha_{21}(u_1)_{xx}]v_2 d\Omega, \\ L_2(\mathbf{v}) &= \frac{1}{3}\int_\Omega [(\alpha_{11})_y(u_1)_y - \alpha_{12}(u_2)_{yy}]v_1 d\Omega \\ &\quad - \frac{1}{3}\int_\Omega [\alpha_{22}(u_2)_{yy} + \alpha_{21}(u_1)_{yy}]v_2 d\Omega, \\ L_3(w) &= \frac{1}{3}\int_\Omega c_x p_x w d\Omega, \quad L_4(w) = \frac{1}{3}\int_\Omega c_y p_y w d\Omega. \end{aligned}$$

Then, it follows from (4.1) and Theorems 3.1 and 3.4 that

$$\begin{aligned}&(\alpha\theta_{h_1,h_2},\mathbf{v})-(\rho_{h_1,h_2},\nabla\cdot\mathbf{v})=h_1^2L_1(\mathbf{v})+h_2^2L_2(\mathbf{v})+O(h^4)||\mathbf{v}||_0,\quad \mathbf{v}\in\mathbf{V}_{0,h_1,h_2},\\&(\nabla\cdot\theta_{h_1,h_2},w)+(c\rho_{h_1,h_2},w)=h_1^2L_3(w)+h_2^2L_4(w)+O(h^4)||w||_0,\quad w\in W_{h_1,h_2}.\end{aligned}\tag{4.18}$$

Set

$$\hat{\theta}_{h_1,h_2}:=\theta_{h_1,h_2}-h_1^2\eta^1_{h_1,h_2}-h_2^2\eta^2_{h_1,h_2},\quad \hat{\rho}_{h_1,h_2}:=\rho_{h_1,h_2}-h_1^2\xi^1_{h_1,h_2}-h_2^2\xi^2_{h_1,h_2}.$$

Thus, we know from (4.16)-(4.18) that

$$\begin{aligned}&(\alpha\hat{\theta}_{h_1,h_2},\mathbf{v})-(\hat{\rho}_{h,k},\nabla\cdot\mathbf{v})=O(h^4)||\mathbf{v}||_0,\quad \mathbf{v}\in\mathbf{V}_{0,h,k},\\&(\nabla\cdot\hat{\theta}_{h,k},w)+(c\hat{\rho}_{h,k},w)=O(h^4)||w||_0,\qquad w\in W_{h,k}.\end{aligned}\tag{4.19}$$

Following the steps for the estimates of $\theta^*_{h_1,h_2}$ and $\rho^*_{h_1,h_2}$ in the proof of Theorem 4.2 yields by means of (4.19) that

$$||\hat{\rho}_{h_1,h_2}||_0\le Ch^4\quad\text{and}\quad||\hat{\theta}_{h_1,h_2}||_0\le Ch^4.\qquad\square$$

By the same argument as that for Theorem 4.4, we can establish the following result.

THEOREM 4.7. *We have under the conditions of Theorem* 4.6 *that*

$$\begin{aligned}&P^3_{4h_1,4h_2}p_{h_1,h_2}-p=h_1^2\xi^1+h_2^2\xi^2+\tilde{r}_{h_1,h_2},\qquad ||\tilde{r}_{h_1,h_2}||_0\le Ch^4,\\&\Pi^3_{4h_1,4h_2}\mathbf{u}_{h_1,h_2}-\mathbf{u}=h_1^2\eta^1+h_2^2\eta^2+\tilde{\mathbf{r}}_{h_1,h_2},\qquad ||\tilde{\mathbf{r}}_{h_1,h_2}||_0\le Ch^4,\end{aligned}$$

where (ξ^1,η^1), $(\xi^2,\eta^2)\in W\times\mathbf{V}_0$.

From Theorem 4.7 one can obtain the following unidirectional Richardson extrapolation results under the L^2-norm:

$$\begin{aligned}&\frac{4(\Pi^3_{2h_1,4h_2}\mathbf{u}_{h_1/2,h_2}+\Pi^3_{4h_1,2h_2}\mathbf{u}_{h_1,h_2/2})-5\Pi^3_{4h_1,4h_2}\mathbf{u}_{h_1,h_2}}{3}=\mathbf{u}+O(h^4),\\&\frac{4(P^3_{2h_1,4h_2}p_{h_1/2,h_2}+P^3_{4h_1,2h_2}p_{h_1,h_2/2})-5P^3_{4h_1,4h_2}p_{h_1,h_2}}{3}=p+O(h^4),\end{aligned}\tag{4.20}$$

where $(p_{h_1/2,h_2},\mathbf{u}_{h_1/2,h_2})$, $(p_{h_1,h_2/2},\mathbf{u}_{h_1,h_2/2})$, and $(p_{h_1,h_2},\mathbf{u}_{h_1,h_2})$ are the mixed finite element solutions corresponding to the meshes $\mathcal{T}_{h_1/2,h_2}$, $\mathcal{T}_{h_1,h_2/2}$, and $\mathcal{T}_{h_1,h_2}$, respectively, and $\mathcal{T}_{h_1/2,h_2}$ as well as $\mathcal{T}_{h_1,h_2/2}$ are gained by subdividing each element of $\mathcal{T}_{h_1,h_2}$ into two small congruent rectangles in the x-direction and y-direction, respectively.

In order to fulfill the Richardson extrapolation, in (4.8) and (4.9) we have to compute $p_{h_1/2,h_2/2}$, $\mathbf{u}_{h_1/2,h_2/2}$, and p_{h_1,h_2}, $\mathbf{u}_{h_1,h_2}$ in advance. The numbers of the unknown variables for $p_{h_1/2,h_2/2}$ (or $\mathbf{u}_{h_1/2,h_2/2}$), and p_{h_1,h_2} (or $\mathbf{u}_{h_1,h_2}$) are $O(4h^{-2})$ and $O(h^{-2})$, respectively. However, in (4.20) we need only compute $p_{h_1/2,h_2}$, $p_{h_1,h_2/2}$, p_{h_1,h_2} and $\mathbf{u}_{h_1/2,h_2}$, $\mathbf{u}_{h_1,h_2/2}$, $\mathbf{u}_{h_1,h_2}$. The numbers of the unknown variables for $p_{h_1/2,h_2}$ (or $\mathbf{u}_{h_1/2,h_2}$), $p_{h_1,h_2/2}$ (or $\mathbf{u}_{h_1,h_2/2}$), and p_{h_1,h_2} (or $\mathbf{u}_{h_1,h_2}$) are $O(2h^{-2})$, $O(2h^{-2})$, and

$O(h^{-2})$, respectively. Generally speaking, the scale of computing $p_{h_1/2,h_2}$ (or $p_{h_1,h_2/2}$) and $\mathbf{u}_{h_1/2,h_2}$ (or $\mathbf{u}_{h_1,h_2/2}$) is smaller than that of computing $p_{h_1/2,h_2/2}$ and $\mathbf{u}_{h_1/2,h_2/2}$. Hence, the computation and storage can be saved. In addition, compared with (4.8) and (4.9), (4.20) is easy to compute in a parallel manner, so that this method is more efficient than the normal method described in (4.8) and (4.9), especially for three-dimensional problems.

Similarly to (4.8) and (4.9), we can also construct a posteriori error estimators by virtue of (4.20).

THEOREM 4.8. *Under the conditions of Theorem* 4.7 *we have*

$$\begin{aligned}
&||p - P^3_{2h_1,4h_2}p_{h_1/2,h_2}||_0\\
&\quad = \frac{1}{3}||P^3_{2h_1,4h_2}p_{h_1/2,h_2} + 4P^3_{4h_1,2h_2}p_{h_1,h_2/2} - 5P^3_{4h_1,4h_2}p_{h_1,h_2}||_0 + O(h^4),\\
&\qquad ||\mathbf{u} - \Pi^3_{2h_1,4h_2}\mathbf{u}_{h_1/2,h_2}||_0\\
&\quad = \frac{1}{3}||\Pi^3_{2h_1,4h_2}\mathbf{u}_{h_1/2,h_2} + 4\Pi^3_{4h_1,2h_2}\mathbf{u}_{h_1,h_2/2} - 5\Pi^3_{4h_1,4h_2}\mathbf{u}_{h_1,h_2}||_0 + O(h^4),\\
&\qquad ||p - P^3_{4h_1,2h_2}p_{h_1,h_2/2}||_0\\
&\quad = \frac{1}{3}||4P^3_{2h_1,4h_2}p_{h_1/2,h_2} + P^3_{4h_1,2h_2}p_{h_1,h_2/2} - 5P^3_{4h_1,4h_2}p_{h_1,h_2}||_0 + O(h^4),\\
&\qquad ||\mathbf{u} - \Pi^3_{4h_1,2h_2}\mathbf{u}_{h_1,h_2/2}||_0\\
&\quad = \frac{1}{3}||4\Pi^3_{2h_1,4h_2}\mathbf{u}_{h_1/2,h_2} + \Pi^3_{4h_1,2h_2}\mathbf{u}_{h_1,h_2/2} - 5\Pi^3_{4h_1,4h_2}\mathbf{u}_{h_1,h_2}||_0 + O(h^4).
\end{aligned}$$

Moreover, if there exist positive constants C_1, C_2, C_3, C_4 *and* ϵ_1, ϵ_2, ϵ_3, $\epsilon_4 \in (0,1)$ *such that*

$$||p - P^3_{2h_1,4h_2}p_{h_1/2,h_2}||_0 \geq C_1h^{4-\epsilon_1},$$

$$||\mathbf{u} - \Pi^3_{2h_1,4h_2}\mathbf{u}_{h_1/2,h_2}||_0 \geq C_2h^{4-\epsilon_2},$$

$$||p - P^3_{4h_1,2h_2}p_{h_1,h_2/2}||_0 \geq C_3h^{4-\epsilon_3},$$

$$||\mathbf{u} - \Pi^3_{4h_1,2h_2}\mathbf{u}_{h_1,h_2/2}||_0 \geq C_4h^{4-\epsilon_4},$$

then we have

$$\lim_{h\to 0}\frac{3||p - P^3_{2h_1,4h_2}p_{h_1/2,h_2}||_0}{||P^3_{2h_1,4h_2}p_{h_1/2,h_2} + 4P^3_{4h_1,2h_2}p_{h_1,h_2/2} - 5P^3_{4h_1,4h_2}p_{h_1,h_2}||_0} = 1,$$

$$\lim_{h\to 0}\frac{3||\mathbf{u} - \Pi^3_{2h_1,4h_2}\mathbf{u}_{h_1/2,h_2}||_0}{||\Pi^3_{2h_1,4h_2}\mathbf{u}_{h_1/2,h_2} + 4\Pi^3_{4h_1,2h_2}\mathbf{u}_{h_1,h_2/2} - 5\Pi_{4h_1,4h_2}\mathbf{u}_{h_1,h_2}||_0} = 1,$$

$$\lim_{h\to 0}\frac{3||p - P^3_{4h_1,2h_2}p_{h_1,h_2/2}||_0}{||4P^3_{2h_1,4h_2}p_{h_1/2,h_2} + P^3_{4h_1,2h_2}p_{h_1,h_2/2} - 5P^3_{4h_1,4h_2}p_{h_1,h_2}||_0} = 1,$$

$$\lim_{h\to 0}\frac{3||\mathbf{u} - \Pi^3_{4h_1,2h_2}\mathbf{u}_{h_1,h_2/2}||_0}{||4\Pi^3_{2h_1,4h_2}\mathbf{u}_{h_1/2,h_2} + \Pi^3_{4h_1,2h_2}\mathbf{u}_{h_1,h_2/2} - 5\Pi^3_{4h_1,4h_2}\mathbf{u}_{h_1,h_2}||_0} = 1.$$

Acknowledgments. The authors would like to thank Professor Michal Křížek for his many helpful suggestions during the preparation of the paper, Professor Raytcho Lazarov for the reference on his early work [10], and the anonymous referees' comments and suggestions, which improved the presentation.

SUBGRID UPSCALING AND MIXED MULTISCALE FINITE ELEMENTS*

TODD ARBOGAST† AND KIRSTEN J. BOYD‡

Abstract. Second order elliptic problems in divergence form with a highly varying leading order coefficient on the scale ϵ can be approximated on coarse meshes of spacing $H \gg \epsilon$ only if one uses special techniques. The mixed variational multiscale method, also called subgrid upscaling, can be used, and this method is extended to allow oversampling of the local subgrid problems. The method is shown to be equivalent to the multiscale finite element method when one uses the lowest order Raviart–Thomas spaces and provided that there are no fine scale components in the source function f. In the periodic setting, a multiscale error analysis based on homogenization theory of the more general subgrid upscaling method shows that the error is $O(\epsilon+H^m+\sqrt{\epsilon/H})$, where $m = 1$. Moreover, $m = 2$ if one uses the second order Brezzi–Douglas–Marini or Brezzi–Douglas–Durán–Fortin spaces and no oversampling. The error bounding constant depends only on the H^{m-1}-norm of f and so is independent of small scales when $m = 1$. When oversampling is not used, a superconvergence result for the pressure approximation is shown.

Key words. mixed method, multiscale finite element, subgrid upscaling, variational multiscale

1. Introduction.

Many physical problems can be modeled by a second order elliptic partial differential equation in space. In many cases, the coefficients of the equation are highly heterogeneous, which induces fine scale variability in the solution. Thus the difficulty in approximating the solution on a coarse finite element mesh $\mathcal{T}_H$ is that the solution is not fully resolved on this scale. Traditional finite element analysis fails, and we require some multiscale approximation techniques.

Babuška and Osborn [10, 9] proposed using special finite elements to approximate the solution. Hughes et al. [23, 24] (see also [13]) developed a more formal framework, which they called the variational multiscale method. A mixed variant, described as *subgrid upscaling,* was developed by Arbogast et al. [7, 3, 4, 6, 5]. Hou and Wu [21] and Hou, Wu, and Cai [22] took a more direct approach and simply proposed finding a special finite element basis by solving the problem locally. They called this approach the multiscale finite element method. A mixed form was developed later by Chen and Hou [17].

To be more precise, consider a connected, convex polygonal domain $\Omega \subseteq \mathbb{R}^d$, where $d = 2$ or 3, and a second order, uniformly positive-definite symmetric tensor a, so that both a and a^{-1} are uniformly elliptic and uniformly bounded. Suppose we are also given vectors $\mathbf{b}$ and $\mathbf{v}_g$. For a set S, let ν^S be the outward unit normal to ∂S, and define the function g on $\partial\Omega$ by $g = \mathbf{v}_g \cdot \nu$, where $\nu = \nu^\Omega$. The problem under

consideration is to find $\mathbf{u}$ and p such that

$$\nabla \cdot \mathbf{u} = f \quad \text{in } \Omega, \tag{1.1}$$

$$\mathbf{u} = -a(\nabla p - \mathbf{b}) \quad \text{in } \Omega, \tag{1.2}$$

$$\mathbf{u} \cdot \nu = g \quad \text{on } \partial\Omega. \tag{1.3}$$

The above system of two first order differential equations is described as a *mixed* formulation, and it is preferable to a single second order differential equation for p because it allows one to enforce the conservation property for the flux (1.1) locally [16]. An example governed by this system is fluid flow in porous media, where the permeability (divided by fluid viscosity) a can vary by many orders of magnitude over a small spatial displacement, $\mathbf{u}$ is the Darcy velocity, p is the fluid pressure, and f models sources and sinks, i.e., wells, which themselves may be quite small scale features in the problem.

To approximate the velocity $\mathbf{u}$ and pressure p on the coarse mesh $\mathcal{T}_H$ requires meeting two competing objectives. First, the approximating spaces must be rich enough to follow the variability in the solution. While a fully fine scale approximating space fulfills this objective, it is not computationally efficient. The second objective is to somehow reduce the problem to the size and complexity of an ordinary coarse scale approximation. The natural approach is to simplify the representation of the solution on the coarse element edges in two dimensions, or faces in three dimensions.

In the variational point of view taken by Arbogast et al., the solution space is decomposed into coarse and fine scale components. This also splits the trial space, and therefore the equations, into coarse and fine scale parts. The fine scale equations are local, and thus solvable, and allow one to compute the fine scale part of the solution from the coarse scale part. The problem then reduces to solving a coarse scale problem for the coarse part of the solution. Any of the usual mixed finite element spaces can be used on the coarse scale. To obtain good approximation on the coarse element edges or faces in this context, it was found that one should use at least second order accurate velocities on the coarse scale.

The multiscale finite element approach of Hou, Wu, and Cai is based on using the lowest order Raviart–Thomas (RT0) spaces [27] on the coarse scale. One modifies the usual coarse basis to incorporate the microstructure in a by solving the system (1.1)–(1.2) locally. This produces finite elements that vary much like the solution itself. One simply solves a coarse mesh mixed finite element method using these perturbed elements. However, because the RT0 spaces are only first order accurate, they do not give good approximation on the coarse element boundaries. To alleviate this problem, Hou, Wu, and Cai propose an oversampling technique, in which they modify each local basis function by sampling the microstructure over a domain larger than its support. This induces variability in the velocity across coarse element edges or faces and improves the quality of the solution. Several interesting and important advances in the design of the mixed multiscale finite elements have been proposed by Aarnes [1] and Aarnes, Krogstad, and Lie [2].

In this paper, we obtain a connection between the two frameworks. Even though they appear very different, we show that they are in fact equivalent under mild restrictions. We first extend the subgrid upscaling approach to allow oversampling. Then the two frameworks are equivalent provided that one uses the RT0 spaces, and provided that there are no fine scale components in f. This last is a subtle point, but important in porous media applications, since wells are so small in two of their three dimensions. The variational framework picks up additional terms related to fine scale

components of the wells that are overlooked in the multiscale finite element approach, since the latter emphasizes only heterogeneity in a (unless perhaps one supplements the finite element space with special well elements).

We also show that the multiscale error analysis of Chen and Hou [17] extends to the variational multiscale framework. In this analysis, one considers $a(x)$ to be locally periodic of period ϵ; that is, the scale of the heterogeneity is well defined as ϵ. In the case considered in [17], RT0 on simplices, our results are similar and give an $O(\epsilon + H + \sqrt{\epsilon/H})$ error bound, wherein the bounding constant depends on Sobolev norms of the smooth homogenized solution but not on the solution itself. Moreover, the proof is elucidated by the application of variational upscaling ideas and results in improved error estimates with regard to f, requiring its L^2-norm to be bounded rather than its H^1-norm. When oversampling is not used, we obtain error bounds of $O(\epsilon + H^m + \sqrt{\epsilon/H})$ for RT0 on nonsimplicial elements ($m = 1$) and the second order accurate ($m \le 2$) Brezzi–Douglas–Marini (BDM1) [15] spaces in two dimensions or the Brezzi–Douglas–Durán–Fortin (BDDF1) [14] spaces in three dimensions. Furthermore, when oversampling is not used, we obtain an important superconvergence result for the pressure approximation, showing that it is $O\big((\epsilon + H + (\epsilon/H)^{1/d-\eta})(\epsilon + H^m + \sqrt{\epsilon/H})\big)$, where $\eta > 0$ if $d = 2$ and $\eta = 0$ if $d = 3$.

The outline of the paper follows. In section 2, we apply the construction in [5] to obtain equations upscaled to the coarse level. We show that the upscaling correction terms are antidiffusive and nonlocal in character. We also extend the method to allow oversampling. In section 3, we extract the multiscale finite elements that are implicit in the construction and show when the method is equivalent to that of Chen and Hou [17]. In section 4, we discuss the fundamental inf-sup lemma regarding solvability and approximability. In the next section, section 5, we state certain homogenization results that we need for section 6, in which our multiscale convergence result for the velocity is stated and proved. Due to the structure of the inf-sup lemma, the error has two components, the optimal velocity error and an error due to the use of nonconforming spaces. Finally, in section 7, we treat the pressure error and show that it is superconvergent in the multiscale setting.

We close the introduction by recasting (1.1)–(1.3) in variational form. Let

$$H(\mathrm{div};\Omega) = \{\mathbf{v} \in (L^2(\Omega))^d : \nabla \cdot \mathbf{v} \in L^2(\Omega)\}$$

with inner product

$$(\mathbf{v}_1, \mathbf{v}_2)_{H(\mathrm{div};\Omega)} = (\mathbf{v}_1, \mathbf{v}_2)_{(L^2(\Omega))^d} + (\nabla \cdot \mathbf{v}_1, \nabla \cdot \mathbf{v}_2)_{L^2(\Omega)}$$

and norm $\|\mathbf{v}\|_{H(\mathrm{div};\Omega)} = (\mathbf{v}, \mathbf{v})^{1/2}_{H(\mathrm{div};\Omega)}$. We set

$$\mathbf{V} = H_0(\mathrm{div};\Omega) = \{\mathbf{v} \in H(\mathrm{div};\Omega) : \mathbf{v} \cdot \nu = 0 \text{ on } \partial\Omega\}$$

and $W = L^2(\Omega)/\mathbb{R}$ with the $L^2(\Omega)$-norm, so that $\nabla \cdot \mathbf{V} = W$. We wish to find $\mathbf{u} \in \mathbf{V} + \mathbf{v}_g$ and $p \in W$ such that

$$(\nabla \cdot \mathbf{u}, w) = (f, w) \qquad \forall\, w \in W, \tag{1.4}$$

$$(\alpha\mathbf{u}, \mathbf{v}) = (p, \nabla \cdot \mathbf{v}) + (\mathbf{b}, \mathbf{v}) \quad \forall\, \mathbf{v} \in \mathbf{V}, \tag{1.5}$$

where $\alpha = a^{-1}$ and we denote the $L^2(S)$ inner product by $(\cdot,\cdot)_S$ for set S and omit S from the notation when it is Ω. We assume that $a \in (L^\infty(\Omega))^{d\times d}$, $\mathbf{b} \in \big(L^2(\Omega)\big)^d$,

$f \in L^2(\Omega)$, and $\mathbf{v}_g \in H^1(\Omega)$. Provided that we have the compatibility condition

$$\int_\Omega f(x)\,dx = \int_{\partial\Omega} g(x)\,ds,$$

it follows from the standard inf-sup theory of saddle point problems [8, 12, 11, 16, 17] that (1.4)–(1.5) is indeed uniquely solvable.

2. Approximation by the variational multiscale method. Let $\mathcal{T}_H$ be a regular and quasi-uniform partition of Ω into simplices and/or bricks having maximum diameter H, satisfying the condition that the minimum angle of each E is bounded below by some positive constant independent of H. Consider the orthogonal direct sum decomposition

$$W = \bar{W} \oplus W',$$

where the coarse space is

$$\bar{W} = \{\bar{w} \in W : \bar{w} \text{ is constant on each } E \in \mathcal{T}_H\}$$

and the "subgrid" space is the orthogonal complement

$$W' = \bar{W}^\perp = \left\{ w' \in W : \int_E w'(x)\,dx = 0 \ \ \forall\, E \in \mathcal{T}_H \right\}.$$

Following [5], we can find a (nonorthogonal) direct sum decomposition of $\mathbf{V}$ into closed subspaces $\bar{\mathbf{V}}$ and $\mathbf{V}'$ such that

$$\begin{aligned}
&\mathbf{V} = \bar{\mathbf{V}} \oplus \mathbf{V}',\\
&\bar{\mathbf{V}} \subseteq \left\{\bar{\mathbf{v}} \in \mathbf{V} : \nabla\cdot\bar{\mathbf{v}} \in \bar{W}\right\},\\
&\mathbf{V}' = \left\{\mathbf{v}' \in \mathbf{V} : \nabla\cdot\mathbf{v}' \in W' \text{ and } \mathbf{v}'\cdot\nu^E = 0 \text{ on } \partial E \ \ \forall E \in \mathcal{T}_H\right\};
\end{aligned}$$

moreover, $\nabla\cdot\bar{\mathbf{V}} = \bar{W}$ and $\nabla\cdot\mathbf{V}' = W'$. Thus we can uniquely decompose the solution $(\mathbf{u}, p) \in (\mathbf{V} + \mathbf{v}_g) \times W$ of (1.4)–(1.5) as

$$\mathbf{u} = \bar{\mathbf{u}} + \mathbf{u}' + \mathbf{v}_g, \tag{2.1}$$

$$p = \bar{p} + p', \tag{2.2}$$

where $\bar{\mathbf{u}} \in \bar{\mathbf{V}}$, $\mathbf{u}' \in \mathbf{V}'$, $\bar{p} \in \bar{W}$, and $p' \in W'$.

2.1. Subgrid closure operators. By using the above decompositions and restricting the test functions in (1.4)–(1.5) to $(\mathbf{v}', w') \in \mathbf{V}' \times W'$, we obtain the *subgrid equation*

$$(\nabla\cdot\mathbf{u}', w') = (f - \nabla\cdot\mathbf{v}_g, w') \qquad \forall\, w' \in W', \tag{2.3}$$

$$(\alpha(\bar{\mathbf{u}} + \mathbf{u}'), \mathbf{v}') = (p', \nabla\cdot\mathbf{v}') + (\mathbf{b} - \alpha\mathbf{v}_g, \mathbf{v}') \quad \forall\, \mathbf{v}' \in \mathbf{V}', \tag{2.4}$$

where certain terms have vanished due to the orthogonality of $\bar{W}$ and W' and the property that $\nabla\cdot\bar{\mathbf{V}} = \bar{W}$. Note that for our problem, $\bar{p}$ does not appear in the above equation (see [5] for handling the general case).

We now define the *subgrid closure operators* mapping each $\bar{\mathbf{u}} \in \bar{\mathbf{V}}$ to some $\mathbf{u}' \in \mathbf{V}'$ and $p' \in W'$. Each is an affine operator consisting of a linear and a constant part depending on $\bar{\mathbf{u}}$, the coarse part of $\mathbf{u}$, so we write

$$\mathbf{u}' = \mathbf{u}'(\bar{\mathbf{u}}) = \hat{\mathbf{u}}'(\bar{\mathbf{u}}) + \tilde{\mathbf{u}}', \tag{2.5}$$

$$p' = p'(\bar{\mathbf{u}}) = \hat{p}'(\bar{\mathbf{u}}) + \tilde{p}'. \tag{2.6}$$

More generally, for each $\mathbf{v} \in H(\mathrm{div};\Omega)$, by (2.3)–(2.4), $(\hat{\mathbf{u}}'(\mathbf{v}), \hat{p}'(\mathbf{v})) \in \mathbf{V}' \times W'$ is defined by

$$(\nabla \cdot \hat{\mathbf{u}}'(\mathbf{v}), w') = 0 \qquad \forall\, w' \in W', \tag{2.7}$$

$$(\alpha\,(\mathbf{v} + \hat{\mathbf{u}}'(\mathbf{v}))\,, \mathbf{v}') = (\hat{p}'(\mathbf{v}), \nabla \cdot \mathbf{v}') \quad \forall\, \mathbf{v}' \in \mathbf{V}', \tag{2.8}$$

and $(\tilde{\mathbf{u}}', \tilde{p}') \in \mathbf{V}' \times W'$ is defined by

$$(\nabla \cdot \tilde{\mathbf{u}}', w') = (f - \nabla \cdot \mathbf{v}_g, w') \qquad \forall\, w' \in W', \tag{2.9}$$

$$(\alpha\tilde{\mathbf{u}}', \mathbf{v}') = (\tilde{p}', \nabla \cdot \mathbf{v}') + (\mathbf{b} - \alpha\mathbf{v}_g, \mathbf{v}') \quad \forall\, \mathbf{v}' \in \mathbf{V}'. \tag{2.10}$$

These equations are well-posed on each $E \in \mathcal{T}_H$ [5].

For future reference, we note that on each $E \in \mathcal{T}_H$,

$$-a\nabla\hat{p}'(\mathbf{v}) = \mathbf{v} + \hat{\mathbf{u}}'(\mathbf{v}), \tag{2.11}$$

$$-a\nabla\tilde{p}' = \tilde{\mathbf{u}}' - a\mathbf{b} + \mathbf{v}_g, \tag{2.12}$$

because $\mathbf{V}'|_E = H_0(\mathrm{div};E)$ is the full space. Moreover, $W'|_E = L^2(E)/\mathbb{R}$, so

$$\nabla \cdot \hat{\mathbf{u}}'(\mathbf{v}) = 0. \tag{2.13}$$

2.2. The upscaled equation. We now define a vector space $\hat{\mathbf{V}} \subseteq \mathbf{V}$ by

$$\hat{\mathbf{V}} = \left\{\hat{\mathbf{v}} \in \mathbf{V} : \hat{\mathbf{v}} = \bar{\mathbf{v}} + \hat{\mathbf{u}}'(\bar{\mathbf{v}}) \text{ for some } \bar{\mathbf{v}} \in \bar{\mathbf{V}}\right\},$$

restrict the test functions in (1.4)–(1.5) to be in $\hat{\mathbf{V}} \times \bar{W}$, use the various decompositions, and introduce the notation

$$\hat{f} = f - \nabla \cdot \mathbf{v}_g \quad \text{and} \quad \hat{\mathbf{b}} = \mathbf{b} - \alpha(\mathbf{v}_g + \tilde{\mathbf{u}}').$$

Thus we rewrite (1.4)–(1.5) in *upscaled form* as the problem of finding $(\hat{\mathbf{u}}, \bar{p}) \in \hat{\mathbf{V}} \times \bar{W}$ such that

$$(\nabla \cdot \hat{\mathbf{u}}, \bar{w}) = (\hat{f}, \bar{w}) \qquad \forall\, \bar{w} \in \bar{W}, \tag{2.14}$$

$$(\alpha\hat{\mathbf{u}}, \hat{\mathbf{v}}) = (\bar{p}, \nabla \cdot \hat{\mathbf{v}}) + (\hat{\mathbf{b}}, \hat{\mathbf{v}}) \quad \forall\, \hat{\mathbf{v}} \in \hat{\mathbf{V}}, \tag{2.15}$$

where now

$$\mathbf{u} = \bar{\mathbf{u}} + \hat{\mathbf{u}}'(\bar{\mathbf{u}}) + \tilde{\mathbf{u}}' + \mathbf{v}_g = \hat{\mathbf{u}} + \tilde{\mathbf{u}}' + \mathbf{v}_g. \tag{2.16}$$

By [5, Theorem 4.6], the above problem has a unique solution.

2.3. Character of the upscaled operator. With $\mathbf{v}' = \hat{\mathbf{u}}'(\bar{\mathbf{u}})$ in (2.8), we note that

$$(\alpha\hat{\mathbf{u}}'(\bar{\mathbf{u}}), \bar{\mathbf{v}}) = -(\alpha\hat{\mathbf{u}}'(\bar{\mathbf{u}}), \hat{\mathbf{u}}'(\bar{\mathbf{v}})),$$

so (1.5) with $\mathbf{v} = \bar{\mathbf{v}} \in \bar{\mathbf{V}}$ enables us to rewrite the upscaled equation (2.15) as

$$(\alpha\bar{\mathbf{u}}, \bar{\mathbf{v}}) - (\alpha\hat{\mathbf{u}}'(\bar{\mathbf{u}}), \hat{\mathbf{u}}'(\bar{\mathbf{v}})) = (\bar{p}, \nabla \cdot \bar{\mathbf{v}}) + (\hat{\mathbf{b}}, \bar{\mathbf{v}}) \quad \forall\, \bar{\mathbf{v}} \in \bar{\mathbf{V}}. \tag{2.17}$$

Thus the second term on the left-hand side, the primary subscale correction, is purely antidiffusive on the coarse scale, as we should expect. Moreover, there is an affine correction term related to subscales of $\mathbf{b}$, f, and $\mathbf{v}_g$ through $\tilde{\mathbf{u}}'$.

Next let $G_x(y)$ be the Green's function on a coarse element E, defined by

$$\begin{aligned} -\nabla \cdot a\nabla G_x &= \delta_x - 1/|E| \quad \text{in } E, \\ -a\nabla G_x \cdot \nu^E &= 0 \qquad\qquad\quad \text{on } \partial E, \end{aligned}$$

where δ_x is the Dirac mass at $x \in E$ and the average of G_x vanishes, and where vertical bars around a set in $\mathbb{R}^d$ denotes d-dimensional or $(d-1)$-dimensional Lebesgue measure, as appropriate. Then on E,

$$\begin{aligned} p(x) &= (-\nabla \cdot a\nabla G_x + 1/|E|, p)_E \\ &= (a\nabla G_x, \nabla p)_E + \bar{p} \\ &= -(\nabla G_x, \mathbf{u} - a\mathbf{b})_E + \bar{p} \\ &= -(\nabla G_x, \bar{\mathbf{u}} - a\mathbf{b})_E - (\nabla G_x, \mathbf{u}' + \mathbf{v}_g)_E + \bar{p} \\ &= -(\nabla G_x, \bar{\mathbf{u}} - a\mathbf{b})_E + (G_x, \nabla \cdot (\mathbf{u}' + \mathbf{v}_g))_E - (G_x, \mathbf{v}_g \cdot \nu^E)_{\partial E} + \bar{p} \\ &= -(\nabla G_x, \bar{\mathbf{u}} - a\mathbf{b})_E + (G_x, f')_E - (G_x, \mathbf{v}_g \cdot \nu^E)_{\partial E} + \bar{p}, \end{aligned}$$

where f' is defined by the decomposition $f = \bar{f} + f' \in \bar{W} \oplus W'$ and we use that $G_x \in W'$ to replace $(G_x, \nabla \cdot (\mathbf{u}' + \mathbf{v}_g))_E$ by $(G_x, \nabla \cdot \mathbf{u})_E = (G_x, f')$. Now

$$\alpha(x)\mathbf{u}(x) - \mathbf{b} = -\nabla p = (\nabla_x \nabla_y G_x, \bar{\mathbf{u}} - a\mathbf{b})_E - (\nabla_x G_x, f')_E + (\nabla_x G_x, \mathbf{v}_g \cdot \nu^E)_{\partial E},$$

so the diffusive and $\mathbf{b}$ terms of (1.5), tested on the coarse scale, are

$$\begin{aligned} (\alpha\mathbf{u} - \mathbf{b}, \bar{\mathbf{v}})_E = &\int_E \int_E \bar{\mathbf{u}}(y) \cdot \nabla_x \nabla_y G_x(x,y) \cdot \bar{\mathbf{v}}(x)\, dy\, dx \\ &- \int_E \int_E \mathbf{b}(y) \cdot a(y) \nabla_x \nabla_y G_x(x,y) \cdot \bar{\mathbf{v}}(x)\, dy\, dx \\ &- \int_E \int_E f'(y) \nabla_x G_x(x,y) \cdot \bar{\mathbf{v}}(x)\, dy\, dx \\ &+ \int_E \int_{\partial E} \mathbf{v}_g \cdot \nu^E(y) \nabla_x G_x(x,y) \cdot \bar{\mathbf{v}}(x)\, ds(y)\, dx, \end{aligned} \tag{2.18}$$

so the upscaled inverse permeability tensor is a nonlocal operator (confined to E) related to $a(y)\nabla_x \nabla_y G_x(y)$.

2.4. Oversampling. For each element $E \in \mathcal{T}_H$, choose some larger set $E_* \supseteq E$ such that $E_* \subseteq \Omega$, E_* is the same shape as E (i.e., a simplex or brick, again such that the minimum angle is bounded below by some positive constant independent of H and E), and, for some $C > 0$ independent of H and E, $\operatorname{diam}(E_*) \leq C \operatorname{diam}(E)$. Locally on each E_*, recalling the definition of W' and properties of $\mathbf{V}'$, we define function spaces $W'_*(E_*) = L^2(E_*)/\mathbb{R}$ and

$$\mathbf{V}'_*(E_*) = \left\{ \mathbf{v}'_* \in \mathbf{V} : \nabla \cdot \mathbf{v}'_* \in W'_*(E_*) \text{ and } \mathbf{v}'_* \cdot \nu^{E_*} = 0 \text{ on } \partial E_* \right\}. \tag{2.19}$$

By analogy to (2.7)–(2.8), we now define the linear part of the *oversampled* subgrid closure operators mapping any $\mathbf{v} \in \mathbf{V}$ to some $(\hat{\mathbf{u}}'_*(\mathbf{v}), \hat{p}'_*(\mathbf{v})) \in \mathbf{V}'_*(E_*) \times W'_*(E_*)$ defined by

$$(\nabla \cdot \hat{\mathbf{u}}'_*(\mathbf{v}), w'_*)_{E_*} = 0 \qquad \forall\, w'_* \in W'_*(E_*), \tag{2.20}$$

$$\left(\alpha\left(\mathbf{v} + \hat{\mathbf{u}}'_*(\mathbf{v})\right), \mathbf{v}'_*\right)_{E_*} = (\hat{p}'_*(\mathbf{v}), \nabla \cdot \mathbf{v}'_*)_{E_*} \quad \forall\, \mathbf{v}'_* \in \mathbf{V}'_*(E_*). \tag{2.21}$$

Note that if $E_* = E$, then the operators $\hat{\mathbf{u}}'_*(\cdot)$ and $\hat{\mathbf{u}}'(\cdot)$ coincide. We also define the *oversampled* constant parts of the subgrid closure operators corresponding to (2.9)–(2.10) as $(\tilde{\mathbf{u}}'_*, \tilde{p}'_*) \in \mathbf{V}'_*(E_*) \times W'_*(E_*)$ defined by

$$(\nabla \cdot \tilde{\mathbf{u}}'_*, w'_*)_{E_*} = (f - \nabla \cdot \mathbf{v}_g, w'_*)_{E_*} \qquad \forall\, w'_* \in W'_*(E_*), \tag{2.22}$$

$$(\alpha \tilde{\mathbf{u}}'_*, \mathbf{v}'_*)_{E_*} = (\tilde{p}'_*, \nabla \cdot \mathbf{v}'_*)_{E_*} + (\mathbf{b} - \alpha \mathbf{v}_g, \mathbf{v}'_*)_{E_*} \quad \forall\, \mathbf{v}'_* \in \mathbf{V}'_*(E_*). \tag{2.23}$$

Usually we consider these quantities only locally on E, so we need not concern ourselves with the overlap of the E_*'s. Also note that $\nabla \cdot \hat{\mathbf{u}}'_*(\mathbf{v}) = 0$ for all $\mathbf{v} \in \mathbf{V}$.

2.5. Discretization. In practice, we must approximate the solution to the subgrid problems (2.20)–(2.21) and (2.22)–(2.23). Since these problems are small (i.e., localized to E_*), we assume that we can fully resolve the fine scales in these problems on a fine subgrid mesh and thereby obtain a sufficiently accurate approximation (see also [5]). Thus, we will discuss only approximation of the coarse space in this paper, and we assume that the subgrid is solved exactly.

Let $\bar{\mathbf{V}}_H \times \bar{W}_H \subseteq \mathbf{V} \times W$ be the lowest order Raviart–Thomas (RT0) [27] space or the lowest order Brezzi–Douglas–Marini (BDM1) [15] space in two dimensions or the Brezzi–Douglas–Durán–Fortin (BDDF1) [14] space in three dimensions. In each case, the pressure approximation space is the space of piecewise constants, so we have $\bar{W}_H = \bar{W}$. Let $\mathcal{E}_E$ be the analytic extension operator from E to E_*, and define the function space

$$\hat{\mathbf{V}}_{H,*} = \left\{ \hat{\mathbf{v}}_{H,*} : \hat{\mathbf{v}}_{H,*} = \bar{\mathbf{v}}_H + \sum_{E \in \mathcal{T}_H} \hat{\mathbf{u}}'_*(\mathcal{E}_E \bar{\mathbf{v}}_H)|_E \text{ for some } \bar{\mathbf{v}}_H \in \bar{\mathbf{V}}_H \right\}, \tag{2.24}$$

wherein, technically, $\mathcal{E}_E \bar{\mathbf{v}}_H = \mathcal{E}_E(\bar{\mathbf{v}}_H|_E)$. Now $\hat{\mathbf{V}}_{H,*} \subseteq X$, where

$$X = \bigoplus_{E \in \mathcal{T}_H} H(\mathrm{div}; E) \tag{2.25}$$

is a Banach space with the norm $\|\mathbf{v}\|_X = \left(\sum_{E \in \mathcal{T}_H} \|\mathbf{v}\|^2_{H(\mathrm{div};E)} \right)^{1/2}$. Clearly $\mathbf{V} = H_0(\mathrm{div}; \Omega) \subseteq X$, but if $E_* \neq E$ for any $E \in \mathcal{T}_H$, then $\hat{\mathbf{V}}_{H,*} \not\subseteq \mathbf{V}$ and we have a nonconforming finite element space.

We approximate (2.14)–(2.15) by the problem of finding $(\hat{\mathbf{u}}_H, \bar{p}_H) \in \hat{\mathbf{V}}_{H,*} \times \bar{W}_H$ such that

$$\sum_{E \in \mathcal{T}_H} (\nabla \cdot \hat{\mathbf{u}}_H, \bar{w}_H)_E = (\hat{f}, \bar{w}_H) \qquad \forall\, \bar{w}_H \in \bar{W}_H, \tag{2.26}$$

$$(\alpha \hat{\mathbf{u}}_H, \hat{\mathbf{v}}_H) = \sum_{E \in \mathcal{T}_H} (\bar{p}_H, \nabla \cdot \hat{\mathbf{v}}_H)_E + (\hat{\mathbf{b}}_*, \hat{\mathbf{v}}_H) \quad \forall\, \hat{\mathbf{v}}_H \in \hat{\mathbf{V}}_{H,*}, \tag{2.27}$$

where

$$\hat{\mathbf{b}}_* = \mathbf{b} - \alpha \left(\mathbf{v}_g + \sum_{E \in \mathcal{T}_H} \tilde{\mathbf{u}}'_*|_E \right).$$

Define the affine space

$$\mathbf{V}_{H,*} = \hat{\mathbf{V}}_{H,*} + \sum_{E \in \mathcal{T}_H} \tilde{\mathbf{u}}'_*|_E + \mathbf{v}_g \tag{2.28}$$

and the discrete oversampled approximation

$$\mathbf{u} \approx \mathbf{u}_H = \hat{\mathbf{u}}_H + \sum_{E\in\mathcal{T}_H} \tilde{\mathbf{u}}'_*|_E + \mathbf{v}_g \in \mathbf{V}_{H,*}, \tag{2.29}$$

$$p \approx p_H = \bar{p}_H + \sum_{E\in\mathcal{T}_H} \left(\hat{p}'_*(\mathcal{E}_E\bar{\mathbf{u}}_H) + \tilde{p}'_*\right)\big|_E \in W. \tag{2.30}$$

The full approximation satisfies

$$\sum_{E\in\mathcal{T}_H} (\nabla\cdot\mathbf{u}_H, w)_E = (f,w) \qquad \forall\, w\in W, \tag{2.31}$$

$$(\alpha\mathbf{u}_H, \hat{\mathbf{v}}_H) = \sum_{E\in\mathcal{T}_H} (\bar{p}_H, \nabla\cdot\hat{\mathbf{v}}_H)_E + (\mathbf{b},\hat{\mathbf{v}}_H) \quad \forall\, \hat{\mathbf{v}}_H \in \hat{\mathbf{V}}_{H,*}, \tag{2.32}$$

which corresponds to the original system (1.4)–(1.5). The systems (2.26)–(2.27) and (2.31)–(2.32) are equivalent; the former is suitable for computation and the latter for analysis. In section 4, it will be shown using the abstract inf-sup lemma [8, 12, 11, 16, 17] that this problem has a unique solution.

If oversampling is *not* used, this is the same discrete approximation considered in [5], except that there the subgrid operators are also approximated on a finer mesh than $\mathcal{T}_H$. Since our concern in this paper is to relate ϵ, the scale of the heterogeneity, to H, the size of the coarse mesh, we have assumed that the subgrid operators are fully resolved (as was done in [17]).

3. Partial equivalence with the multiscale finite element method. In [17], Chen and Hou give a mixed finite element method for the equations making use of their multiscale finite element basis functions. As we show in this section, their method is fundamentally equivalent to that described in this paper in the case where $\bar{\mathbf{V}}_H$ is the vector variable part of the RT0 space and $\tilde{\mathbf{u}}'$ and $\tilde{p}'$ vanish. Note that from (2.9)–(2.10), $\tilde{\mathbf{u}}'$ and $\tilde{p}'$ vanish exactly when $(f-\nabla\cdot\mathbf{v}_g, w') = 0$ for all $w'\in W'$ and $(\mathbf{b}-\alpha\mathbf{v}_g, \mathbf{v}') = 0$ for all $\mathbf{v}'\in\mathbf{V}'$; that is, the subscales of $f-\nabla\cdot\mathbf{v}_g$ and $\mathbf{b}-\alpha\mathbf{v}_g$ vanish.

Let $E\in\mathcal{T}_H$ be given, and let e_i^E represent the ith edge in two dimensions or face in three dimensions of E. We begin by recalling a standard basis $\{R_i^E\}$ for $\mathrm{RT}_0(E)$, the vector part of the RT0 space [27] on $E\in\mathcal{T}_H$, which satisfies

$$\begin{aligned}
&\nabla\cdot R_i^E = 1/|E| && \text{in } E,\\
&R_i^E = -\nabla\omega_i^E && \text{in } E,\\
&R_i^E\cdot\nu^E = \begin{cases} 1/|e_i^E| & \text{on } e_i^E,\\ 0 & \text{on } e_j^E,\ j\neq i. \end{cases}
\end{aligned}$$

That is, R_i^E is linear, has a constant divergence, and has constant fluxes over the edges or faces of E.

Chen and Hou [17] construct the multiscale finite element space in the following way. Let $\{R_i^{E_*}\}$ be the basis of $\mathrm{RT}_0(E_*)$, the vector part of the RT0 space on E_*, which satisfies

$$R_i^{E_*}\cdot\nu^{E^*} = \begin{cases} 1/|e_i^{E_*}| & \text{on } e_i^{E_*},\\ 0 & \text{on } e_j^{E_*},\ j\neq i, \end{cases}$$

where $e_i^{E_*}$ represents an edge or face of E_*. Since the RT0 basis functions on E_* also span $\mathrm{RT}_0(E)$, there must exist, for each i and j, constants c_{ij}^E such that

$$R_i^E = \sum_j c_{ij}^E R_j^{E_*}|_E.$$

(If $E_* = E$, we simply have $c_{ij}^E = \delta_{ij}$, where δ_{ij} is the Kronecker delta.) Now for each j, let $w_j^{E_*}$ be the unique solution in $L^2(E_*)/\mathbb{R} = W_*'(E_*)$ of the Neumann problem

$$\int_{E_*} a\nabla w_j^{E_*} \cdot \nabla\varphi\,dx = \frac{1}{|E_*|}\int_{E_*} \varphi\,dx - \frac{1}{|e_j^{E_*}|}\int_{e_j^{E_*}} \varphi\,ds \quad \forall \varphi \in H^1(E_*), \tag{3.1}$$

which is equivalent to

$$\nabla\cdot\hat{\psi}_{H,i} = \nabla\cdot R_i^{E_*} \qquad \text{in } E_*, \tag{3.2}$$

$$\hat{\psi}_{H,i} = -a\nabla w_i^{E_*} \qquad \text{in } E_*, \tag{3.3}$$

$$\hat{\psi}_{H,i}\cdot\nu^{E_*} = R_i^{E_*}\cdot\nu^{E_*} \quad \text{on } \partial E_*. \tag{3.4}$$

For each i, set

$$\tilde{w}_i^{E_*} = \sum_j c_{ij}^E w_j^{E_*}.$$

Now let

$$\mathrm{MS}_*(E) = \mathrm{span}\{-a\nabla\tilde{w}_i^{E_*}|_E\}$$

and $\tilde{X}_{H,*} = \{\mathbf{v}\in X : \mathbf{v}|_E \in \mathrm{MS}_*(E) \text{ for all } E\in\mathcal{T}_H\}$. Define

$$\Pi_H : \tilde{X}_{H,*} \to \bigoplus_{E\in\mathcal{T}_H} \mathrm{RT}_0(E)$$

to be the natural projection defined locally for $\mathbf{v}|_E = -\sum_i b_i a\nabla\tilde{w}_i^E$ by $\Pi_H(\mathbf{v})|_E = \sum_i b_i R_i^E$. The *oversampled multiscale finite element* space $\hat{X}_{H,*}\subseteq X$ is then defined by

$$\hat{X}_{H,*} = \big\{\mathbf{v}\in\tilde{X}_{H,*} : \Pi_H\mathbf{v}\in\bar{\mathbf{V}}_H\big\},$$

wherein $\bar{\mathbf{V}}_H$ is RT_0 in this section. Note that again the subgrid problems have been assumed to be solved exactly, since the fine scales can be fully resolved.

To see the equivalence with the construction in this paper, first note that the problems (3.1), i.e., (3.2)–(3.4), and (2.20)–(2.21) are closely related, so that

$$-a\nabla w_j^{E_*} = R_j^{E_*} + \hat{\mathbf{u}}_*'(R_j^{E_*}) = -a\nabla\hat{p}_*'(R_j^{E_*});$$

that is, $w_j^{E_*} = \hat{p}_*'(R_j^{E_*})$. Now clearly $\mathcal{E}_E R_i^E = \sum_j c_{ij}^E R_j^{E_*}$, so

$$\mathcal{E}_E R_i^E + \hat{\mathbf{u}}_*'(\mathcal{E}_E R_i^E) = -a\nabla\hat{p}_*'(\mathcal{E}_E R_i^E) = -\sum_j c_{ij}^E a\nabla\tilde{w}_j^{E_*}.$$

Since the matrix c_{ij}^E is invertible,

$$\mathrm{MS}_*(E) = \mathrm{span}\{R_i^E + \hat{\mathbf{u}}_*'(\mathcal{E}_E R_i^E)|_E\}.$$

Now if $\mathbf{v} \in \tilde{X}_{H,*}$, then $\mathbf{v}|_E = \sum_i b_i\big(R_i^E + \hat{\mathbf{u}}'_*(\mathcal{E}_E R_i^E)|_E\big)$, and so $\Pi_H \mathbf{v}|_E = \sum_i b_i R_i^E$. The condition that $\Pi_H \mathbf{v} \in \bar{\mathbf{V}}_H$ merely says that the local RT0 basis functions fit together globally in $H(\mathrm{div};\Omega)$. Thus $\hat{X}_{H,*}$ is the span of $\bar{\mathbf{v}}_H + \sum_E \hat{\mathbf{u}}'_*(\mathcal{E}_E \bar{\mathbf{v}}_H)|_E$ for $\bar{\mathbf{v}}_H \in \bar{\mathbf{V}}_H$; that is,

$$\hat{X}_{H,*} = \hat{\mathbf{V}}_{H,*},$$

and our construction agrees with that in [17], up to the treatment of $\tilde{\mathbf{u}}'$ and $\tilde{p}'$. Moreover, the mixed multiscale finite element method obtains only $\bar{p}_H \in \bar{W}_H$ (not p_H) from (2.30).

4. Analysis of the saddle point variational problem. In this paper, we use the notation $\|\cdot\|_{j,S}$ for the norm of the Sobolev space $H^j(S)$, and $\|\cdot\|_{j,p,S}$ for the norm of the Sobolev space $W^{j,p}(S)$ when $p \neq 2$. We proceed through a series of lemmas.

LEMMA 4.1. *There exists $C > 0$, independent of ϵ and H, such that for each $E \in \mathcal{T}_H$ and $\mathbf{v} \in \mathbf{V}$,*

$$\|\hat{\mathbf{u}}'_*(\mathbf{v})\|_{0,E_*} + \|\nabla \hat{p}'_*(\mathbf{v})\|_{0,E_*} \leq C\|\mathbf{v}\|_{0,E_*}.$$

Moreover, if $\mathbf{v} \in \mathbf{V}'_*(E_*)$ has vanishing divergence, then $\hat{\mathbf{u}}'_*(\mathbf{v}) = -\mathbf{v}$ and $\hat{p}'_*(\mathbf{v}) = 0$.

Proof. This is the standard energy estimate for the differential system (2.20)–(2.21), and the bound depends only on the ellipticity and continuity constants for a and so is independent of ϵ and H. The final remark is obvious from the definition of the operator. ∎

LEMMA 4.2. *There exists $C > 0$, independent of ϵ and H, such that for any $\hat{\mathbf{v}}_H \in \hat{\mathbf{V}}_{H,*}$, if $\bar{\mathbf{v}}_H \in \bar{\mathbf{V}}_H$ is any element corresponding to $\hat{\mathbf{v}}_H$ in the sense that*

$$\hat{\mathbf{v}}_H = \bar{\mathbf{v}}_H + \sum_{E \in \mathcal{T}_H} \hat{\mathbf{u}}'_*(\mathcal{E}_E \bar{\mathbf{v}}_H)|_E, \tag{4.1}$$

then on any E, $\nabla \cdot \hat{\mathbf{v}}_H|_E = \nabla \cdot \bar{\mathbf{v}}_H|_E$ and

$$\|\hat{\mathbf{v}}_H\|_{H(\mathrm{div};E)} \leq C\|\bar{\mathbf{v}}_H\|_{H(\mathrm{div};E)}.$$

Proof. By the definition (2.24), each $\hat{\mathbf{v}}_H \in \hat{\mathbf{V}}_{H,*}$ has at least one $\bar{\mathbf{v}}_H$ satisfying (4.1). Since the operator norm of $\mathcal{E}_E$ (as applied to low order polynomials and with respect to the $L^2(E)$- and $L^2(E_*)$-norms) is bounded uniformly in E and H under our assumptions on the shape regularity of E and E_*, we have

$$\|\mathcal{E}_E \bar{\mathbf{v}}_H + \hat{\mathbf{u}}'_*(\mathcal{E}_E \bar{\mathbf{v}}_H)\|_{0,E_*} \leq C\|\mathcal{E}_E \bar{\mathbf{v}}_H\|_{0,E_*} \leq C\|\bar{\mathbf{v}}_H\|_{0,E}.$$

Note that $\mathcal{E}_E \bar{\mathbf{v}}_H + \hat{\mathbf{u}}'_*(\mathcal{E}_E \bar{\mathbf{v}}_H)$ agrees with $\hat{\mathbf{v}}_H$ on E, so we have

$$\|\hat{\mathbf{v}}_H\|_{0,E} \leq C\|\bar{\mathbf{v}}_H\|_{0,E}.$$

The above inequality holds for the $H(\mathrm{div};E)$-norm as well, because $\nabla \cdot \hat{\mathbf{u}}'_*(\mathbf{v})$ is identically zero for all $\mathbf{v} \in \mathbf{V}$, which implies $\nabla \cdot \hat{\mathbf{v}}_H = \nabla \cdot \bar{\mathbf{v}}_H$. ∎

LEMMA 4.3. *There exists a constant $\beta > 0$, independent of ϵ and H, such that for any $\bar{q}_H \in \bar{W}_H$, the following inf-sup condition holds:*

$$\sup_{0 \neq \hat{\mathbf{v}}_H \in \hat{\mathbf{V}}_{H,*}} \frac{\sum_{E \in \mathcal{T}_H} (\bar{q}_H, \nabla \cdot \hat{\mathbf{v}}_H)_E}{\|\hat{\mathbf{v}}_H\|_X} \geq \beta \|\bar{q}_H\|_{0,\Omega}.$$

Proof. It is known that the inf-sup condition holds for all the usual mixed finite element spaces, such as $\bar{W}_H \times \bar{\mathbf{V}}_H$. Because $\nabla \cdot \hat{\mathbf{u}}'_*(\cdot) = 0$, and by Lemma 4.2, we have

$$\sup_{0 \neq \hat{\mathbf{v}}_H \in \hat{\mathbf{V}}_{H,*}} \frac{\sum_{E \in \mathcal{T}_H} (\bar{q}_H, \nabla \cdot \hat{\mathbf{v}}_H)_E}{\|\hat{\mathbf{v}}_H\|_X} \geq C \sup_{0 \neq \bar{\mathbf{v}}_H \in \bar{\mathbf{V}}_H} \frac{(\bar{q}_H, \nabla \cdot \bar{\mathbf{v}}_H)}{\|\bar{\mathbf{v}}_H\|_{H(\mathrm{div};\Omega)}} \geq C\bar{\beta} \|\bar{q}_H\|_{0,\Omega},$$

where $\bar{\beta} > 0$ is the inf-sup condition constant for $\bar{W}_H \times \bar{\mathbf{V}}_H$. ∎

To obtain a unique solution of the discrete approximation (2.31)–(2.32) of (1.4)–(1.5), we can now apply the abstract inf-sup theory given in [16], for example. We can also obtain a bound on the approximation error, but it involves the approximation of p in $\bar{W}_H$, which is only first order accurate. This is acceptable for RT0, but suboptimal for the higher order spaces.

THEOREM 4.4. *There exists a unique solution $(\mathbf{u}_H, \bar{p}_H) \in \mathbf{V}_{H,*} \times \bar{W}_H$ to (2.31)–(2.32). Moreover, there exists $C > 0$, independent of ϵ and H, such that if $(\mathbf{u}, p)$ is the solution of (1.4)–(1.5), then*

$$\nabla \cdot \mathbf{u}_H = \nabla \cdot \mathbf{u} = f, \tag{4.2}$$

$$\|\mathbf{u} - \mathbf{u}_H\|_{0,\Omega} \leq C \Bigg\{ \inf_{\mathbf{v}_H \in \mathbf{V}_{H,*}, \nabla \cdot \mathbf{v}_H = \nabla \cdot \mathbf{u}} \|\mathbf{u} - \mathbf{v}_H\|_{0,\Omega} + \sup_{0 \neq \psi_H \in \hat{\mathbf{V}}_{H,*}, \nabla \cdot \psi_H = 0} \frac{|(\alpha \mathbf{u} - \mathbf{b}, \psi_H)|}{\|\psi_H\|_{0,\Omega}} \Bigg\}, \tag{4.3}$$

$$\|\bar{p} - \bar{p}_H\|_{0,\Omega} \leq C \Bigg\{ \|\mathbf{u} - \mathbf{u}_H\|_{0,\Omega} + \sup_{0 \neq \psi_H \in \hat{\mathbf{V}}_{H,*}} \frac{\left| (\alpha \mathbf{u} - \mathbf{b}, \psi_H) - \sum_{E \in \mathcal{T}_H} (p, \nabla \cdot \psi_H)_E \right|}{\|\psi_H\|_X} \Bigg\}. \tag{4.4}$$

Proof. The first equality follows from (2.31). The inf-sup condition of the previous lemma and (2.32) allow us to estimate directly that

$$\begin{aligned}
&\beta \|\bar{p} - \bar{p}_H\|_{0,\Omega} \\
&\quad \leq \sup_{0 \neq \psi_H \in \hat{\mathbf{V}}_{H,*}} \frac{\sum_{E \in \mathcal{T}_H} (\bar{p} - \bar{p}_H, \nabla \cdot \psi_H)_E}{\|\psi_H\|_X} \\
&\quad = \sup_{0 \neq \psi_H \in \hat{\mathbf{V}}_{H,*}} \frac{\sum_{E \in \mathcal{T}_H} \left[(p, \nabla \cdot \psi_H)_E - (\alpha \mathbf{u}_H - \mathbf{b}, \psi_H)_E \right]}{\|\psi_H\|_X} \\
&\quad \leq \sup_{0 \neq \psi_H \in \hat{\mathbf{V}}_{H,*}} \frac{\sum_{E \in \mathcal{T}_H} \left[(p, \nabla \cdot \psi_H)_E - (\alpha \mathbf{u} - \mathbf{b}, \psi_H)_E \right]}{\|\psi_H\|_X} + \|\alpha(\mathbf{u} - \mathbf{u}_H)\|_{0,\Omega},
\end{aligned}$$

and the third result (4.3) follows.

The statement $\mathbf{v}_H \in \mathbf{V}_{H,*}$ such that $\nabla \cdot \mathbf{v}_H = \nabla \cdot \mathbf{u} = \nabla \cdot \mathbf{u}_H$ merely says that $\mathbf{v}_H - \mathbf{u}_H \in \hat{\mathbf{V}}_{H,*}$ and has vanishing divergence. For any such $\mathbf{v}_H$, we compute

$$\begin{aligned}
\|\mathbf{u} - \mathbf{u}_H\|_{0,\Omega} &\le \|\mathbf{u} - \mathbf{v}_H\|_{0,\Omega} + \|\mathbf{v}_H - \mathbf{u}_H\|_{0,\Omega} \\
&\le \|\mathbf{u} - \mathbf{v}_H\|_{0,\Omega} + C \sup_{0 \neq \psi_H \in \hat{\mathbf{V}}_{H,*}, \nabla \cdot \psi_H = 0} \frac{|(\alpha(\mathbf{v}_H - \mathbf{u}_H), \psi_H)|}{\|\psi_H\|_{0,\Omega}} \\
&\le \|\mathbf{u} - \mathbf{v}_H\|_{0,\Omega} + C \Bigg\{ \sup_{0 \neq \psi_H \in \hat{\mathbf{V}}_{H,*}, \nabla \cdot \psi_H = 0} \frac{|(\alpha(\mathbf{u} - \mathbf{u}_H), \psi_H)|}{\|\psi_H\|_{0,\Omega}} \\
&\quad + \sup_{0 \neq \psi_H \in \hat{\mathbf{V}}_{H,*}, \nabla \cdot \psi_H = 0} \frac{|(\alpha(\mathbf{v}_H - \mathbf{u}), \psi_H)|}{\|\psi_H\|_{0,\Omega}} \Bigg\} \\
&\le C \Bigg\{ \|\mathbf{u} - \mathbf{v}_H\|_{0,\Omega} + \sup_{0 \neq \psi_H \in \hat{\mathbf{V}}_{H,*}, \nabla \cdot \psi_H = 0} \frac{|(\alpha \mathbf{u} - \mathbf{b}, \psi_H)|}{\|\psi_H\|_{0,\Omega}} \Bigg\},
\end{aligned}$$

since $(\alpha \mathbf{u}_H, \psi_H) = (\mathbf{b}, \psi_H)$, and the second result (4.4) follows.

Finally, we obtain that the discrete solution must be unique by setting all the data to zero (f, $\mathbf{b}$, $\mathbf{v}_g$, which implies that $\mathbf{u}$ and p also vanish). We then also obtain existence of a solution, since the system has finite dimensions and is square. ∎

5. Some homogenization theory needed for multiscale error analysis. We give a multiscale analysis of the error similar to that given by Hou et al. [22, 17]. This analysis determines the behavior of the error as a function both of H and the scale of the heterogeneity in a, which we denote by ϵ. If $H \sim \epsilon$, the system is well resolved, there is no need for oversampling, and the scheme converges with optimal order of approximation [5]. Thus we tacitly assume the underresolved case where $\epsilon \ll H$. The difficulty, then, with standard approximation theory is that the error is bounded in terms of H and derivatives of the solution. However, we expect that each derivative of the solution is proportional to ϵ^{-1}, and H/ϵ is not small. The two exceptions are given by the standard energy estimates for our problem, which are stated in the following lemma.

LEMMA 5.1. *Let $(\mathbf{u}, p) \in (\mathbf{V} + \mathbf{v}_g) \times W$ be the solution of* (1.4)–(1.5). *Then there is a constant $C > 0$, depending only on the ellipticity bounds for a, such that*

$$\begin{aligned}
&\|\mathbf{u}\|_{0,\Omega} + \|\nabla p\|_{0,\Omega} \le C\big\{\|f - \nabla \cdot \mathbf{v}_g\|_{0,\Omega} + \|\mathbf{v}_g\|_{0,\Omega} + \|\mathbf{b}\|_{0,\Omega}\big\}, \\
&\|\nabla \cdot \mathbf{u}\|_{0,\Omega} = \|f\|_{0,\Omega}.
\end{aligned}$$

In order to quantify the scale of the heterogeneity, we use homogenization theory. Thus we assume that the permeability has "locally periodic" oscillations whose scale is on the order of some $\epsilon > 0$. That is, let $C^1_{\mathrm{per}}(\mathbb{R}^d)$ denote the space of all $C^1(\mathbb{R}^d)$ functions that are periodic with respect to the unit cube $Y \subseteq \mathbb{R}^d$, and assume that $a = a(x, x/\epsilon)$, where for each $i, j = 1, \ldots, d$, $a_{ij}(x, y) \in C^1(\bar{\Omega}; C^1_{\mathrm{per}}(\mathbb{R}^d))$, and a varies slowly in its first argument on a scale resolved by H. Moreover, suppose $\mathbf{B} \in (L^2(D))^d$.

Following Chen and Hou [17], we now review the relevant aspects of homogenization theory. Let $D \subseteq \Omega$ be a Lipschitz domain in $\mathbb{R}^d$ and suppose $F \in L^2(D)$ and $G \in L^2(\partial D)$ satisfy the compatibility condition

$$\int_D F(x)\, dx = \int_{\partial D} G(x)\, ds.$$

For each $\epsilon > 0$, we let $q^\epsilon \in H^1(D)/\mathbb{R}$ be the unique solution of the Neumann problem

$$\int_D a(x, x/\epsilon)\,(\nabla q^\epsilon - \mathbf{B}) \cdot \nabla\varphi\, dx = \int_D F\varphi\, dx - \int_{\partial D} G\varphi\, ds \quad \forall\, \varphi \in H^1(D). \tag{5.1}$$

The homogenized coefficient matrix $a^0(x) = \big(a^0_{ij}(x)\big)_{ij}$ of $a(x, x/\epsilon)$ is given by

$$a^0_{ij}(x) = \frac{1}{|Y|} \sum_{k=1}^{d} \int_Y a_{ik}(x, y) \left(\delta_{kj} - \frac{\partial \chi^j}{\partial y_k}(x, y)\right) dy, \quad x \in \Omega,\ y \in Y, \tag{5.2}$$

where δ_{kj} is the Kronecker delta and $\chi^j(x, y)$ is the Y-periodic (in y) solution of the jth cell problem

$$\sum_{i=1}^{d} \sum_{k=1}^{d} \frac{\partial}{\partial y_i} \left(a_{ik}(x, y) \frac{\partial \chi^j}{\partial y_k}(x, y)\right) = \sum_{i=1}^{d} \frac{\partial}{\partial y_i} a_{ij}(x, y),$$

with $\int_Y \chi^j(x, y)\, dy = 0$. Now, we let $q^0 \in H^1(D)/\mathbb{R}$ be the unique solution of the homogenized counterpart of (5.1), namely,

$$\int_D a^0(x)(\nabla q^0 - \mathbf{B}) \cdot \nabla\varphi\, dx = \int_D F\varphi\, dx - \int_{\partial D} G\varphi\, ds \ \ \forall\, \varphi \in H^1(D). \tag{5.3}$$

In the usual way, we define the first order corrector of q^ϵ by

$$(q^0)^\epsilon_1(x) = q^0(x) - \epsilon \sum_{k=1}^{d} \chi^k(x, x/\epsilon) \left(\frac{\partial q^0}{\partial x_k} - B_k\right). \tag{5.4}$$

Recall that we use the notation $\|\cdot\|_{j,p,S}$ for the norm of the Sobolev space $W^{j,p}(S)$, and simply $\|\cdot\|_{j,S}$ if $p = 2$.

THEOREM 5.2. *Suppose that $q^0 \in H^2(D) \cap W^{1,\infty}(D)$ and $D' \subset D$. Let the fluxes be denoted by*

$$\mathbf{U}^\epsilon = -a_\epsilon(\nabla q^\epsilon - \mathbf{B}) \quad \textit{and} \quad \mathbf{U}^0 = -a^0(\nabla q^0 - \mathbf{B}).$$

There exist a constant C, independent of ϵ, the size of the domains D and D', and the terms $\mathbf{B}$, F, and G, and there exists a boundary corrector $\theta^S_\epsilon \in H^1(S)/\mathbb{R}$, defined below for $S \subset D$ in (5.11)–(5.12) and (5.9)–(5.10), such that

$$\|\nabla[q^\epsilon - (q^0)^\epsilon_1 - \epsilon\theta^D_\epsilon]\|_{0,D} \le C\epsilon \|\nabla q^0 - \mathbf{B}\|_{1,D}, \tag{5.5}$$

$$\|\mathbf{U}^\epsilon - (\mathbf{U}^0 + \epsilon a_\epsilon \nabla\theta^{D'}_\epsilon - \epsilon a_\epsilon \nabla\theta^D_\epsilon + \psi^{D'}_{\mathrm{Sol}})\|_{0,D'} \le C\epsilon \|\nabla q^0 - \mathbf{B}\|_{1,D}, \tag{5.6}$$

where $\psi^{D'}_{\mathrm{Sol}}$ is a solenoidal vector, i.e., $\nabla\cdot\psi^{D'}_{\mathrm{Sol}} = 0$ and $\psi^{D'}_{\mathrm{Sol}}\cdot\nu^{D'} = 0$ on $\partial D'$. Moreover,

$$\|\epsilon\nabla\theta^S_\epsilon\|_{0,S} \le C\big\{\epsilon\|\nabla q^0 - \mathbf{B}\|_{1,S} + \sqrt{\epsilon|\partial S|}\,\|\nabla q^0 - \mathbf{B}\|_{0,\infty,S}\big\}, \tag{5.7}$$

$$\|\epsilon\nabla\theta^S_\epsilon\|_{0,S} \le C\big(\epsilon + H_S^{-1}(\epsilon|\partial S|)^{1/d-\eta}\big)\|\nabla q^0 - \mathbf{B}\|_{1,S}, \tag{5.8}$$

where S is D or D', $H_S = \operatorname{diam}(S)$, and $\eta = 0$ if $d = 3$ and η is any fixed positive number if $d = 2$.

REMARK 5.1. *In [17], it is conjectured, but not proven, that estimate (5.7) can be improved by replacing $\sqrt{\epsilon|\partial S|}$ by $\epsilon\sqrt{|S|}/H_S$ in the oversampled case, i.e., with S*

replaced by $S' \subset S$ on the left-hand side. If this turns out to be the case, the estimates we derive can be correspondingly improved.

In [25], (5.5) and (5.7) were derived in the case where the coefficient $a = a(x)$ is periodic and $\mathbf{B} = 0$. In [17], the proof was elucidated and extended to the case in point, where $a = a(x, x/\epsilon)$ is locally periodic. The proof easily modifies to handle the extra term related to $\mathbf{B}$, and we reproduce it here in brief so that we can extract the estimates (5.6) and (5.8).

Proof. We use the Einstein summation convention for repeated indices, and the more concise notation $\partial_j = \partial/\partial x_j$, and $\partial_j^x = \partial/\partial x_j$ and $\partial_j^y = \partial/\partial y_j$ if we are dealing with a function of (x, y). The key to the proof is to note that

$$a_{ik}^0(x) - a_{\epsilon,ij}(x,y)\big(\delta_{jk} - \partial_j^y \chi^k(x,y)\big) = \partial_j^y A_{ij}^k(x,y), \tag{5.9}$$

where $A_{ij}^k(x,y)$ is skew-symmetric for each k [25, p. 6]. Let us denote

$$\gamma_i(x) = \partial_j\{A_{ij}^k(x, x/\epsilon)\,[\partial_k q^0(x) - B_k(x)]\}, \tag{5.10}$$

so that

$$\partial_j^y A_{ij}^k(x,x/\epsilon)\,(\partial_k q^0 - B_k) = \epsilon\gamma_i - \epsilon\partial_j^x A_{ij}^k(\partial_k q^0 - B_k) - \epsilon A_{ij}^k \partial_j(\partial_k q^0 - B_k).$$

After some manipulation

$$-a_{\epsilon,ij}[\partial_j (q^0)_1^\epsilon - B_j] = -a_{ij}^0(\partial_j q^0 - B_j) + \epsilon\gamma_i + \epsilon\psi_{1,i},$$

where

$$\begin{aligned}\psi_{1,i} = {} & -\partial_j^x A_{ij}^k(\partial_k q^0 - B_k) - A_{ij}^k \partial_j(\partial_k q^0 - B_k) \\ & + a_{\epsilon,ij}\partial_j^x \chi^k(\partial_k q^0 - B_k) + a_{\epsilon,ij}\chi^k \partial_j(\partial_k q^0 - B_k).\end{aligned}$$

Now we let $\theta_\epsilon^S \in H^1(S)/\mathbb{R}$ be defined by

$$\nabla \cdot (a_\epsilon \nabla \theta_\epsilon^S) = 0 \qquad \text{in } S, \tag{5.11}$$

$$a_\epsilon \nabla \theta_\epsilon^S \cdot \nu^S = \gamma \cdot \nu^S \quad \text{on } \partial S, \tag{5.12}$$

so that $\psi_{\mathrm{Sol}}^S = \epsilon(\gamma - a_\epsilon \nabla \theta_\epsilon^S)$ has the requisite properties and

$$-a_\epsilon[\nabla (q^0)_1^\epsilon - \mathbf{B}] = -a^0(\nabla q^0 - \mathbf{B}) + \epsilon a_\epsilon \nabla \theta_\epsilon^S + \psi_{\mathrm{Sol}}^S + \epsilon\psi_1. \tag{5.13}$$

It is now a simple consequence of the governing equations (5.1) and (5.3) and the properties of ψ_{Sol}^D that

$$(a_\epsilon \nabla[q_\epsilon - (q^0)_1^\epsilon - \epsilon\theta_\epsilon^D], \nabla\varphi)_D = \epsilon(\psi_1, \nabla\varphi)_D,$$

and the first result (5.5) follows easily. The second result (5.6) follows from (5.13) and the previous result.

To obtain bounds on the boundary corrector, we use a smooth cut-off function $\zeta_\epsilon(x) \in [0,1]$ with compact support that is one except near ∂S, where it tends to zero in a narrow region of width ϵ with gradient bounded by C/ϵ. Now let

$$\begin{aligned}\gamma_{I,i}(x) &= \partial_j\{A_{ij}^k(x, x/\epsilon)\,[\partial_k q^0(x) - B_k(x)]\zeta_\epsilon(x)\}, \\ \gamma_{B,i}(x) &= \partial_j\{A_{ij}^k(x, x/\epsilon)\,[\partial_k q^0(x) - B_k(x)][1 - \zeta_\epsilon(x)]\}\end{aligned}$$

(i.e., $\gamma = \gamma_B + \gamma_I$), and note that (5.11)–(5.12) imply that

$$\|\nabla\theta_\epsilon\|_{0,S} \le C\|\gamma_B\|_{0,S},$$

since γ_B is divergence free. Finally,

$$\begin{aligned}
\epsilon\|\gamma_{B,i}\|_{0,S} &= \epsilon\|\partial_j\{A^k_{ij}[\partial_k q^0 - B_k][1-\zeta_\epsilon]\}\|_{0,S} \\
&\le \epsilon\|\partial^x_j A^k_{ij}[\partial_k q^0 - B_k][1-\zeta_\epsilon]\|_{0,S} + \epsilon\|A^k_{ij}\partial_j[\partial_k q^0 - B_k][1-\zeta_\epsilon]\|_{0,S} \\
&\quad + \epsilon\|A^k_{ij}[\partial_k q^0 - B_k]\partial_j[1-\zeta_\epsilon]\|_{0,S} + \|\partial^y_j A^k_{ij}[\partial_k q^0 - B_k][1-\zeta_\epsilon]\|_{0,S} \\
&\le C\big\{\epsilon\|\nabla q^0 - \mathbf{B}\|_{1,S} + \|\nabla q^0 - \mathbf{B}\|_{0,S^\zeta_\epsilon}\big\},
\end{aligned}$$

where S^ζ_ϵ is the support of $1-\zeta_\epsilon$. Since the measure of S^ζ_ϵ is proportional to $\epsilon|\partial S|$, we have

$$\|\nabla q^0 - \mathbf{B}\|_{0,S^\zeta_\epsilon} \le \sqrt{\big|S^\zeta_\epsilon\big|}\,\|\nabla q^0 - \mathbf{B}\|_{0,\infty,S} \le C\sqrt{\epsilon|\partial S|}\,\|\nabla q^0 - \mathbf{B}\|_{0,\infty,S},$$

and (5.7) follows. To show (5.8), we instead use Hölder's inequality with $r = d/(d-2)$ (or large but finite if $d = 2$) and the Sobolev imbedding theorem to show that

$$\begin{aligned}
\|\nabla q^0 - \mathbf{B}\|_{0,S^\zeta_\epsilon} &\le C(\epsilon|\partial S|)^{(r-1)/2r}\|\nabla q^0 - \mathbf{B}\|_{0,2r,S^\zeta_\epsilon} \\
&\le CH_S^{-1}(\epsilon|\partial S|)^{1/d-\eta}\|\nabla q^0 - \mathbf{B}\|_{1,S},
\end{aligned}$$

wherein $\eta = 0$ if $d = 3$ and $\eta > 0$ if $d = 2$ (the factor H_S^{-1} comes from a scaling argument on the size of the domain S). The proof is complete. ∎

We will apply Theorem 5.2 several times, with D being one of Ω, E, or E_*. Since these are convex polygonal domains, the hypothesis $q^0 \in H^2(D) \cap W^{1,\infty}(D)$ will hold provided that, for some $r > d$, $F \in L^r(D)$ and $G = \mathbf{v}_g \cdot \nu^D$ on ∂D for some $\mathbf{v}_g \in (W^{1,r}(D))^d$ [17, 20, 26].

6. Multiscale estimation of the errors. In this section, we estimate the terms in the basic estimates of Theorem 4.4 for the velocity and pressure errors. We obtain the following estimates which isolate the dependence on both H and ϵ.

THEOREM 6.1. *For each $\epsilon > 0$, let $(\mathbf{u}^\epsilon, p^\epsilon) \in (\mathbf{V}+\mathbf{v}_g)\times W$ be the solution of* (1.4)–(1.5) *with the coefficient $a_\epsilon = a(x, x/\epsilon)$ and $\alpha_\epsilon = a_\epsilon^{-1}$. Let $(\mathbf{u}^0, p^0) \in (\mathbf{V} + \mathbf{v}_g) \times W$ satisfy* (1.4)–(1.5) *with the homogenized coefficient a^0 defined by* (5.2) *in place of a, and $\alpha^0 = (a^0)^{-1}$. For $H > 0$, let $(\hat{\mathbf{u}}^\epsilon_H, \bar{p}^\epsilon_H) \in \hat{\mathbf{V}}_{H,*} \times \bar{W}_H$ be the solution of the discrete upscaled equation* (2.26)–(2.27), *and define $\mathbf{u}^\epsilon_H$ by* (2.29).

(a) Oversampling. *Assume that the partition $\mathcal{T}_H$ consists only of simplices and $\bar{\mathbf{V}}_H$ is RT0. Then*

$$\begin{aligned}
(6.1)\qquad &\|\mathbf{u}^\epsilon - \mathbf{u}^\epsilon_H\|_{H(\mathrm{div};\Omega)} + \|p^\epsilon - \bar{p}^\epsilon_H\|_{0,\Omega} \\
&\quad\le C\big\{(\epsilon + \sqrt{\epsilon/H} + H)\big[\|f - \nabla\cdot\mathbf{v}_g\|_{0,\Omega} + \|\mathbf{v}_g\|_{0,\Omega} + \|\mathbf{b}\|_{0,\Omega}\big] \\
&\qquad + (\epsilon/H)\,\|\nabla p^0\|_{0,\infty,\Omega} + \sqrt{\epsilon/H}\,\|\nabla p^0 - \mathbf{b}\|_{0,\infty,\Omega} \\
&\qquad + (\epsilon + H)\big[\|\nabla p^0\|_{1,\Omega} + \|\nabla p^0 - \mathbf{b}\|_{1,\Omega}\big] + H\|\mathbf{u}^0 - \mathbf{v}_g\|_{1,\Omega}\big\}.
\end{aligned}$$

If the oversampling conjecture of Chen and Hou [17] *holds (Remark* 5.1*), then $\sqrt{\epsilon/H}$ may be replaced by ϵ/H above.*

(b) Nonoversampling. *Assume that oversampling is* not *used. Let* $m = 1$ *when* $\bar{\mathbf{V}}_H$ *is RT*0 *and* $m = 1$ *or* 2 *when* $\bar{\mathbf{V}}_H$ *is BDM*1 *or BDDF*1. *Then*

$$\begin{aligned}(6.2)\qquad &\|\mathbf{u}^\epsilon - \mathbf{u}_H^\epsilon\|_{H(\mathrm{div};\Omega)} + \|\bar{p}^\epsilon - \bar{p}_H^\epsilon\|_{0,\Omega}\\ &\quad\le C\big\{\epsilon\|\nabla p^0 - \mathbf{b}\|_{1,\Omega} + \sqrt{\epsilon/H}\,\|\nabla p^0 - \mathbf{b}\|_{0,\infty,\Omega}\\ &\qquad + H^m\big(\|\mathbf{u}^0 - \mathbf{v}_g\|_{m,\Omega} + \|f - \nabla\cdot\mathbf{v}_g\|_{m-1,\Omega}\big)\big\}.\end{aligned}$$

Moreover, with $\eta = 0$, *if* $d = 3$, *and* η *any fixed positive number, if* $d = 2$,

$$\begin{aligned}(6.3)\qquad \|\mathbf{u}^\epsilon - \mathbf{u}_H^\epsilon\|_{H(\mathrm{div};\Omega)} &\le C\big\{\big(\epsilon + (\epsilon/H)^{1/d-\eta}\big)\|\nabla p^0 - \mathbf{b}\|_{1,\Omega}\\ &\qquad + H^m\big(\|\mathbf{u}^0 - \mathbf{v}_g\|_{m,\Omega} + \|f - \nabla\cdot\mathbf{v}_g\|_{m-1,\Omega}\big)\big\}.\end{aligned}$$

We remark that (a) is a small improvement over the result in [17, Theorem 2.2]. Assuming the more pessimistic but proven bound on the boundary corrector, and with $\mathbf{v}_g = \mathbf{b} = 0$, this previous result is

$$\begin{aligned}&\|\mathbf{u}^\epsilon - \mathbf{u}_H^\epsilon\|_{H(\mathrm{div};\Omega)} + \|p^\epsilon - \bar{p}_H^\epsilon\|_{0,\Omega}\\ &\quad\le C\big\{(\epsilon + H)\big(\|p^0\|_{2,\Omega} + \|f\|_{1,\Omega} + \|\mathbf{u}^0\|_{H(\mathrm{div};\Omega)}\big)\\ &\qquad + \sqrt{\epsilon/H}\,\big(\|p^0\|_{1,\infty,\Omega} + \|f\|_{0,\Omega} + \|\mathbf{u}^0\|_{H(\mathrm{div};\Omega)}\big)\big\}.\end{aligned}$$

The small improvement is in the norm on f, which as noted in the introduction can have small scale aspects in some applications such as flow in porous media. Result (b) is new for the BDM1 and BDDF1 spaces, and for RT0 with nonsimplicial elements.

Concerning the proof of this theorem, by Theorem 4.4, for (b), we need only to bound the optimal velocity error, which is done in section 6.1. For (a), we need this, the oversampling error, handled in section 6.2, and the following simple estimate for the pressure. Note that in (6.1), we have p^ϵ rather than $\bar{p}^\epsilon$. This is allowed by the estimate

$$\|p - \bar{p}_H\|_{0,\Omega} \le \|p - \bar{p}\|_{0,\Omega} + \|\bar{p} - \bar{p}_H\|_{0,\Omega} \le CH\|\nabla p\|_{0,\Omega} + \|\bar{p} - \bar{p}_H\|_{0,\Omega}$$

and the bound on $\|\nabla p\|_{0,\Omega}$ in Lemma 5.1. We will improve the pressure estimate of (b) in section 7.

6.1. The optimal velocity error. In this subsection, we assume that oversampling may be used, so as to handle cases (a) and (b) of Theorem 6.1 simultaneously. Let $\bar{\pi}_H : \mathbf{V} \cap L^r(\Omega) \to \bar{\mathbf{V}}_H$ (for some $r > 2$) be the standard mixed finite element interpolation operator [27, 18, 15, 14, 16]. It has the property that

$$\nabla\cdot\bar{\pi}_H\mathbf{v} = \mathcal{P}_{\bar{W}_H}\nabla\cdot\mathbf{v} \tag{6.4}$$

for all $\mathbf{v} \in \mathbf{V} \cap L^r(\Omega)$, where $\mathcal{P}_{\bar{W}_H}$ is the L^2-projection onto $\bar{W}_H$. We also have the approximation property

$$\|\mathbf{v} - \bar{\pi}_H\mathbf{v}\|_{0,\Omega} \le CH^m\|\mathbf{v}\|_{m,\Omega}, \tag{6.5}$$

where $m = 1$ when $\bar{\mathbf{V}}_H$ is RT0 and $m = 1$ or 2 when $\bar{\mathbf{V}}_H$ is BDM1 or BDDF1.

We now note a lemma on the difference between nonoversampled and oversampled quantities.

LEMMA 6.2. *If* $E \in \mathcal{T}_H$ *and* $w \in H^1(E_*)$, *then*

$$\nabla\hat{p}_*'(a\nabla w) = -\nabla w \quad \textit{and} \quad \hat{\mathbf{u}}_*'(a\nabla w) = 0. \tag{6.6}$$

In fact, $\hat{p}'_*(a\nabla w) = -w$ *provided* $w \in W'_*(E_*)$. *Moreover, on* E,

$$\nabla \hat{p}'(a\nabla w) = \nabla \hat{p}'_*(a\nabla w)|_E = -\nabla w. \tag{6.7}$$

Proof. We simply observe that (6.6) provides the unique solution to the equations defining the subgrid operator (2.20)–(2.21). The remark for $w \in W'_*(E_*) \cap H^1(E_*)$ is then trivial, since w is correctly normalized. Similar results hold for $\hat{p}'$, so (6.7) follows. ∎

Our main result in this subsection follows.

LEMMA 6.3. *Let*

$$\hat{\mathbf{v}}_H^\epsilon = \bar{\pi}_H(\mathbf{u}^0 - \mathbf{v}_g) + \sum_{E\in\mathcal{T}_H} \hat{\mathbf{u}}'_*(\mathcal{E}_E\bar{\pi}_H(\mathbf{u}^0 - \mathbf{v}_g))|_E \in \hat{\mathbf{V}}_{H,*},$$
$$\mathbf{v}_H^\epsilon = \hat{\mathbf{v}}_H^\epsilon + \sum_{E\in\mathcal{T}_H} \tilde{\mathbf{u}}'_*|_E + \mathbf{v}_g \in \mathbf{V}_{H,*}.$$

Then there is $C > 0$, *independent of* ϵ *and* H, *such that*

$$\begin{aligned}
\nabla\cdot\mathbf{u}^\epsilon &= \nabla\cdot\mathbf{v}_H^\epsilon,\\
\|\mathbf{u}^\epsilon - \mathbf{v}_H^\epsilon\|_{0,\Omega} &\le C\big\{\epsilon\|\nabla p^0 - \mathbf{b}\|_{1,\Omega} + \sqrt{\epsilon/H}\,\|\nabla p^0 - \mathbf{b}\|_{0,\infty,\Omega}\\
&\qquad + H^m\big(\|\mathbf{u}^0 - \mathbf{v}_g\|_{m,\Omega} + \|f - \nabla\cdot\mathbf{v}_g\|_{m-1,\Omega}\big)\big\},\\
\|\mathbf{u}^\epsilon - \mathbf{v}_H^\epsilon\|_{0,\Omega} &\le C\big\{\big(\epsilon + (\epsilon/H)^{1/d-\eta}\big)\|\nabla p^0 - \mathbf{b}\|_{1,\Omega}\\
&\qquad + H^m\big(\|\mathbf{u}^0 - \mathbf{v}_g\|_{m,\Omega} + \|f - \nabla\cdot\mathbf{v}_g\|_{m-1,\Omega}\big)\big\},
\end{aligned}$$

where m *is* 1 *or* 2 *and* $\eta \ge 0$ *as in Theorem* 6.1.

Proof. The divergence result is easy to see from (6.4). For the other result, we work locally on $E_* \supset E \in \mathcal{T}_H$. We have an expansion over E_* similar to the one over E, so on E_* we can write

$$p^\epsilon = \bar{p}_* + \hat{p}'_* + \tilde{p}'_*,$$

where $\bar{p}_*$ is the average of p^ϵ over E_* and $\hat{p}'_*, \tilde{p}'_* \in W'_*(E_*)$ are defined in (2.20)–(2.23) above. (To see this fact, simply consider an expansion as in section 2 on a perturbed coarse mesh containing E_*, and discard the expansion outside E_*.) In fact, we have $\mathbf{u}^\epsilon = \bar{\mathbf{u}}_* + \hat{\mathbf{u}}'_* + \tilde{\mathbf{u}}'_* + \mathbf{v}_g$ and the functional relationship

$$\hat{p}'_* = \hat{p}'_*(\bar{\mathbf{u}}_*) = \hat{p}'_*(\mathbf{u}^\epsilon - \tilde{\mathbf{u}}'_* - \mathbf{v}_g),$$

using Lemma 4.1 to avoid further discussion of $\bar{\mathbf{u}}_*$ and $\hat{\mathbf{u}}'_*$. Thus we have on E that

$$\begin{aligned}
\mathbf{u}^\epsilon &= -a_\epsilon(\nabla p^\epsilon - \mathbf{b})\\
&= -a_\epsilon\nabla\hat{p}'_*(\mathbf{u}^\epsilon - \tilde{\mathbf{u}}'_* - \mathbf{v}_g) - a_\epsilon(\nabla\tilde{p}'_* - \mathbf{b})\\
&= -a_\epsilon[\nabla\hat{p}'_*(\mathbf{u}^\epsilon - \mathbf{u}^0) + \nabla\hat{p}'_*(\mathbf{u}^0 - \mathbf{v}_g) - \nabla\hat{p}'_*(\tilde{\mathbf{u}}'_*)] + \tilde{\mathbf{u}}'_* + \mathbf{v}_g,
\end{aligned}$$

using (2.23) in the last step.

Note that on E,

$$\hat{\mathbf{v}}_H^\epsilon|_E = \bar{\pi}_H(\mathbf{u}^0 - \mathbf{v}_g) + \hat{\mathbf{u}}'_*(\mathcal{E}_E\bar{\pi}_H(\mathbf{u}^0 - \mathbf{v}_g))|_E = -a_\epsilon\nabla\hat{p}'_*(\mathcal{E}_E\bar{\pi}_H(\mathbf{u}^0 - \mathbf{v}_g))|_E, \tag{6.8}$$

so

$$\begin{aligned}\mathbf{u}^\epsilon - \mathbf{v}_H^\epsilon &= \mathbf{u}^\epsilon - (\hat{\mathbf{v}}_H^\epsilon + \tilde{\mathbf{u}}'_* + \mathbf{v}_g)\\ &= -a_\epsilon[\nabla\hat{p}'_*(\mathbf{u}^\epsilon - \mathbf{u}^0) + \nabla\hat{p}'_*(\mathbf{u}^0 - \mathbf{v}_g) - \nabla\hat{p}'_*(\tilde{\mathbf{u}}'_*) - \nabla\hat{p}'_*(\mathcal{E}_E\bar{\pi}_H(\mathbf{u}^0 - \mathbf{v}_g))].\end{aligned}$$

Now we estimate

$$\begin{aligned}\|\mathbf{u}^\epsilon - \mathbf{v}_H^\epsilon\|_{0,E} \le C\{&\|\nabla\hat{p}'_*(\mathbf{u}^\epsilon - \mathbf{u}^0)\|_{0,E} + \|\mathbf{u}^0 - \mathbf{v}_g - \mathcal{E}_E\bar{\pi}_H(\mathbf{u}^0 - \mathbf{v}_g)\|_{0,E_*}\\ &+ \|\nabla\hat{p}'_*(\tilde{\mathbf{u}}'_*)\|_{0,E}\},\end{aligned} \tag{6.9}$$

using Lemma 4.1 again, this time to bound the operator. The second term on the right is bounded as

$$\|\mathbf{u}^0 - \mathbf{v}_g - \mathcal{E}_E\bar{\pi}_H(\mathbf{u}^0 - \mathbf{v}_g)\|_{0,E_*} \le C\,H^m\,\|\mathbf{u}^0 - \mathbf{v}_g\|_{m,E_*},$$

using the approximation property (6.5) of $\bar{\pi}_H$ (actually, a slight extension to E_*, but the approximation result continues to hold since the operator $\mathcal{E}_E\bar{\pi}_H$ preserves low order polynomials).

For the last term on the far right side of (6.9), since $\tilde{\mathbf{u}}'_* \in \mathbf{V}'_*(E_*)$, note that we have the differential system

$$\begin{aligned}-\nabla\cdot a_\epsilon\nabla\hat{p}'_*(\tilde{\mathbf{u}}'_*) &= \mathcal{P}_{W'_*}(f - \nabla\cdot\mathbf{v}_g) \quad \text{in } E_*,\\ -a_\epsilon\nabla\hat{p}'_*(\tilde{\mathbf{u}}'_*)\cdot\nu^{E_*} &= 0 \qquad\qquad\qquad\quad \text{on } \partial E_*,\end{aligned}$$

where $\mathcal{P}_{W'_*}$ is the L^2-projection onto $W'_*(E_*)$. The standard energy estimate is

$$\|\nabla\hat{p}'_*(\tilde{\mathbf{u}}'_*)\|_{0,E_*} \le C\|\mathcal{P}_{W'_*}(f - \nabla\cdot\mathbf{v}_g)\|_{(H^1(E_*))^*} \le C\,H^m\,\|f - \nabla\cdot\mathbf{v}_g\|_{m-1,E_*}, \tag{6.10}$$

where $(H^1(E_*))^*$ is the dual space of $H^1(E_*)$, using standard negative norm estimates for approximation of a function with vanishing average.

Finally, we estimate the first term on the far right side of (6.9), using Theorem 5.2, specifically the expansion in (5.6). By Lemma 4.1 we can introduce the local solenoidal term $\psi_{\mathrm{Sol}}^{E_*}$, so we have

$$\begin{aligned}&\nabla\hat{p}'_*(\mathbf{u}^\epsilon - \mathbf{u}^0)\\ &\quad= \nabla\hat{p}'_*(\mathbf{u}^\epsilon - \mathbf{u}^0 - \epsilon a_\epsilon\nabla\theta_\epsilon^{E_*} + \epsilon a_\epsilon\nabla\theta_\epsilon^{\Omega}) + \epsilon\nabla\hat{p}'_*(a_\epsilon\nabla\theta_\epsilon^{E_*}) - \epsilon\nabla\hat{p}'_*(a_\epsilon\nabla\theta_\epsilon^{\Omega})\\ &\quad= \nabla\hat{p}'_*(\mathbf{u}^\epsilon - \mathbf{u}^0 - \epsilon a_\epsilon\nabla\theta_\epsilon^{E_*} + \epsilon a_\epsilon\nabla\theta_\epsilon^{\Omega} + \psi_{\mathrm{Sol}}^{E_*}) - \epsilon\nabla\theta_\epsilon^{E_*} + \epsilon\nabla\theta_\epsilon^{\Omega},\end{aligned}$$

using Lemma 6.2. Thus Theorem 5.2 gives the two bounds

$$\begin{aligned}&\|\nabla\hat{p}'_*(\mathbf{u}^\epsilon - \mathbf{u}^0)\|_{0,E}\\ &\quad\le C\big\{\epsilon\|\nabla p^0 - \mathbf{b}\|_{1,E_*} + \sqrt{\epsilon|\partial E_*|}\,\|\nabla p^0 - \mathbf{b}\|_{0,\infty,E_*} + \|\epsilon\nabla\theta_\epsilon^{\Omega}\|_{0,E_*}\big\},\\ &\|\nabla\hat{p}'_*(\mathbf{u}^\epsilon - \mathbf{u}^0)\|_{0,E} \le C\big\{\big(\epsilon + H^{-1}(\epsilon|\partial E_*|)^{1/d-\eta}\big)\|\nabla p^0 - \mathbf{b}\|_{1,E_*} + \|\epsilon\nabla\theta_\epsilon^{\Omega}\|_{0,E_*}\big\}\end{aligned}$$

(with the first bound improved if the oversampling conjecture holds).

Combining terms, summing over $E \in \mathcal{T}_H$, and using that the number of overlaps of the E_* are bounded yield

$$\begin{aligned}\|\mathbf{u}^\epsilon - \mathbf{v}_H^\epsilon\|_{0,\Omega} \le C\big\{&\epsilon\|\nabla p^0 - \mathbf{b}\|_{1,\Omega} + \sqrt{\epsilon/H}\,\|\nabla p^0 - \mathbf{b}\|_{0,\infty,\Omega}\\ &+ \|\epsilon\nabla\theta_\epsilon^{\Omega}\|_{0,\Omega} + H^m\left(\|\mathbf{u}^0 - \mathbf{v}_g\|_{m,\Omega} + \|f - \nabla\cdot\mathbf{v}_g\|_{m-1,\Omega}\right)\big\},\end{aligned}$$

wherein $\sqrt{\epsilon/H}\,\|\nabla p^0-\mathbf{b}\|_{0,\infty,\Omega}$ can be replaced by $(\epsilon/H)^{1/d-\eta}\|\nabla p^0-\mathbf{b}\|_{1,\Omega}$. The proof is completed by Theorem 5.2 to bound the global boundary corrector term. ∎

We have an abstract result, analogous to Theorem 5.2, relating $\mathbf{u}^\epsilon$ to a correction of the homogenized solution $\mathbf{u}^0$.

COROLLARY 6.4. *If $\tilde{\mathbf{u}}'_*(\mathbf{u}^0)$ is defined by* (2.22)–(2.23) *with $\mathbf{v}_g$ replaced by $\mathbf{u}^0$, then*

$$\left\|\mathbf{u}^\epsilon-\left(\mathbf{u}^0+\sum_{E\in\mathcal{T}_H}\tilde{\mathbf{u}}'_*(\mathbf{u}^0)|_E\right)\right\|_{0,\Omega}\le C\big\{\epsilon\|\nabla p^0-\mathbf{b}\|_{1,\Omega}+\sqrt{\epsilon/H}\,\|\nabla p^0-\mathbf{b}\|_{0,\infty,\Omega}\big\},$$

$$\left\|\mathbf{u}^\epsilon-\left(\mathbf{u}^0+\sum_{E\in\mathcal{T}_H}\tilde{\mathbf{u}}'_*(\mathbf{u}^0)|_E\right)\right\|_{0,\Omega}\le C\big(\epsilon+(\epsilon/H)^{1/d-\eta}\big)\|\nabla p^0-\mathbf{b}\|_{1,\Omega}.$$

Proof. Simply take $\mathbf{v}_g=\mathbf{u}^0$. Then $\hat{\mathbf{v}}_H^\epsilon=0$, and we can remove the term involving f from the estimate since $\nabla\cdot\mathbf{v}_g=\nabla\cdot\mathbf{u}^0=f$. ∎

6.2. The oversampled nonconforming error. Chen and Hou [17, pp. 559–563] bounded the nonconforming error terms in Theorem 4.4 when $\mathbf{b}=0$. The key features needed in the analysis are (1) that the vector variable of the RT0 spaces, when restricted to an element and multiplied by a constant matrix, is a pure potential (i.e., a gradient of a scalar function), and (2) a vector variable $\bar{\mathbf{v}}_H$ in RT0 satisfies the estimate

$$\|\bar{\mathbf{v}}_H\|_{1,E}\le C\|\bar{\mathbf{v}}_H\|_{H(\mathrm{div};E)} \tag{6.11}$$

(see [17, (4.26)]). These properties hold only for RT0 on simplices.

The extension of their result to nonzero $\mathbf{b}$ is not difficult, and, again using the more pessimistic but proven bound on the homogenization boundary corrector terms (see Remark 5.1), the extended result follows.

LEMMA 6.5. *There is a constant $C>0$, independent of H and ϵ, such that for any $\psi_H\in\hat{\mathbf{V}}_{H,*}$,*

$$\begin{aligned}&\left|(\alpha\mathbf{u}-\mathbf{b},\psi_H)-\sum_{E\in\mathcal{T}_H}(p,\nabla\cdot\psi_H)_E\right|\\&\quad\le C\Big\{(\epsilon+\sqrt{\epsilon/H}+H)\big[\|f-\nabla\cdot\mathbf{v}_g\|_{0,\Omega}+\|\mathbf{v}_g\|_{0,\Omega}+\|\mathbf{b}\|_{0,\Omega}\big]\\&\qquad+(\epsilon+H)\big[\|\nabla p^0\|_{1,\Omega}+\|\nabla p^0-\mathbf{b}\|_{1,\Omega}\big]\\&\qquad+(\epsilon/H)\,\|\nabla p^0\|_{0,\infty,\Omega}+\sqrt{\epsilon/H}\,\|\nabla p^0-\mathbf{b}\|_{0,\infty,\Omega}\Big\}\|\psi_H\|_X.\end{aligned}$$

This completes the proof of Theorem 6.1.

7. Superconvergent multiscale estimation of the pressure error. In this section, we assume that oversampling is not used. In this case, we can significantly improve the estimate of the pressure error over that obtained in Theorem 6.1 above.

THEOREM 7.1. *For each $\epsilon>0$, let $(\mathbf{u}^\epsilon,p^\epsilon)\in(\mathbf{V}+\mathbf{v}_g)\times W$ be the solution of* (1.4)–(1.5)*, with the coefficient $a_\epsilon=a(x,x/\epsilon)$ and $\alpha_\epsilon=a_\epsilon^{-1}$. For each $H>0$, let $(\hat{\mathbf{u}}_H^\epsilon,\bar{p}_H^\epsilon)\in\hat{\mathbf{V}}_H\times\bar{W}_H$ be the solution of the nonoversampled ($E_*=E\ \forall E\in\mathcal{T}_H$) discrete upscaled equation* (2.26)–(2.27)*, and define $(\mathbf{u}_H^\epsilon,p_H^\epsilon)$ by* (2.29)–(2.30)*. Let $m=1$ when $\bar{\mathbf{V}}_H$ is the RT0 space and $m=1$ or 2 when $\bar{\mathbf{V}}_H$ is BDM1 or BDDF1. Assume that the domain Ω is k-regular, in the sense of* (7.3) *below. If $k=2$, then*

$$\|p^\epsilon-p_H^\epsilon\|_{0,\Omega}\le C\big(\epsilon+(\epsilon/H)^{1/d-\eta}+H\big)\|\mathbf{u}^\epsilon-\mathbf{u}_H^\epsilon\|_{0,\Omega},$$

and if $k = 3$, then

$$\|p^\epsilon - p_H^\epsilon\|_{-1,\Omega} \le C\big(\epsilon + (\epsilon/H)^{1/d-\eta} + H^m\big)\|\mathbf{u}^\epsilon - \mathbf{u}_H^\epsilon\|_{0,\Omega}.$$

These results display superconvergence, in that the pressure converges at a rate better that we would normally expect from approximation theory. Combining Theorems 7.1 and 6.1(b), we obtain for $d = 2$ that

$$\|p^\epsilon - p_H^\epsilon\|_{0,\Omega} \le C\big(\epsilon^2 + \epsilon/H + H^{m+1}\big). \tag{7.1}$$

One should compare this estimate to the L^2-estimate of Efendiev, Hou, and Wu [19] for the (nonmixed) multiscale finite element method:

$$\|p^\epsilon - p_H^\epsilon\|_{0,\Omega} \le C\big(\epsilon + \epsilon|\ln h| + (\epsilon/H)^2 + C_\theta \epsilon/H + H^2\big),$$

although numerical results suggest that C_θ is negligible.

Proof. The difference between (1.5) and the conforming, nonoversampled method (2.32) is

$$\big(\alpha(\mathbf{u} - \mathbf{u}_H), \hat{\mathbf{v}}_H\big) = (\bar{p} - \bar{p}_H, \nabla \cdot \bar{\mathbf{v}}_H) \quad \forall\ \hat{\mathbf{v}}_H \in \hat{\mathbf{V}}_H \tag{7.2}$$

(wherein we suppress the superscript ϵ on the solutions and the subscript ϵ on α). For $\varphi \in H^{k-2}(\Omega)$, we construct a test function from the solution $\mathbf{U} \in \mathbf{V}$ to the problem

$$\begin{aligned} \nabla \cdot \mathbf{U} &= \varphi \quad && \text{in } \Omega, \\ \mathbf{U} &= -a\nabla q \quad && \text{in } \Omega, \\ \mathbf{U} \cdot \nu &= 0 \quad && \text{on } \partial\Omega. \end{aligned}$$

This is the same problem as (1.1)–(1.3), with $f = \varphi$, $\mathbf{b} = 0$, and $g = 0$ (i.e., $\mathbf{v}_g = 0$). We solve this problem approximately with the variational multiscale method (2.31)–(2.32) of section 2 for $\mathbf{U}_H = \hat{\mathbf{U}}_H + \tilde{\mathbf{U}}' \in \hat{\mathbf{V}}_H + \tilde{\mathbf{U}}'$. Note that $\nabla \cdot \hat{\mathbf{U}}_H = \bar{\varphi}$, $\tilde{\mathbf{U}}' = -a\nabla\tilde{q}'$, and Theorem 6.1 imply that

$$\|\mathbf{U} - \mathbf{U}_H\|_{0,\Omega} \le C\big\{\big(\epsilon + (\epsilon/H)^{1/d-\eta}\big)\|\nabla q^0\|_{1,\Omega} + H^m\big(\|\mathbf{U}^0\|_{m,\Omega} + \|\varphi\|_{m-1,\Omega}\big)\big\},$$

where $(\mathbf{U}^0, q^0) \in \mathbf{V} \times W$ satisfies the corresponding homogenized problem (i.e., with a^0 replacing a). The k-regularity assumption means that there is some constant $C > 0$, independent of H and ϵ, such that

$$\|\mathbf{U}^0\|_{k-1,\Omega} + \|q^0\|_{k,\Omega} \le C\|\varphi\|_{k-2,\Omega}, \tag{7.3}$$

so

$$\|\mathbf{U} - \mathbf{U}_H\|_{0,\Omega} \le C\big(\epsilon + (\epsilon/H)^{1/d-\eta} + H^m\big)\|\varphi\|_{k-2,\Omega},$$

wherein $m = 1$ if $k = 2$.

Using the test function $\hat{\mathbf{U}}_H \in \hat{\mathbf{V}}_H$ in (7.2), we obtain that

$$\begin{aligned} (\bar{p} - \bar{p}_H, \bar{\varphi}) &= (\bar{p} - \bar{p}_H, \varphi) = \big(\alpha(\mathbf{u} - \mathbf{u}_H), \hat{\mathbf{U}}_H\big) \\ &= \big(\alpha(\mathbf{u} - \mathbf{u}_H), \mathbf{U}_H - \mathbf{U}\big) + \big(\alpha(\mathbf{u} - \mathbf{u}_H), \mathbf{U} - \tilde{\mathbf{U}}'\big). \end{aligned} \tag{7.4}$$

Now, by the divergence theorem,

$$\begin{aligned}\big(\alpha(\mathbf{u}-\mathbf{u}_H),\mathbf{U}-\tilde{\mathbf{U}}'\big) &= -\big(\alpha(\mathbf{u}-\mathbf{u}_H),a\nabla(q-\tilde{p}')\big)\\ &= -\big(\mathbf{u}-\mathbf{u}_H,\nabla(q-\tilde{p}')\big) = \big(\nabla\cdot(\mathbf{u}-\mathbf{u}_H),q-\tilde{p}'\big) = 0,\end{aligned}$$

so

$$\begin{aligned}(\bar{p}-\bar{p}_H,\varphi) &= \big(\alpha(\mathbf{u}-\mathbf{u}_H),\mathbf{U}_H-\mathbf{U}\big)\\ &\le C\|\mathbf{u}-\mathbf{u}_H\|_{0,\Omega}\|\mathbf{U}-\mathbf{U}_H\|_{0,\Omega}\\ &\le C\|\mathbf{u}-\mathbf{u}_H\|_{0,\Omega}\big(\epsilon+(\epsilon/H)^{1/d-\eta}+H^m\big)\|\varphi\|_{k-2,\Omega},\end{aligned}$$

wherein $m=1$ if $k=2$.

Taking $k=2$ and the supremum over $\varphi\in L^2(\Omega)$, we see the estimate

$$\|\bar{p}-\bar{p}_H\|_{0,\Omega}\le C\big(\epsilon+(\epsilon/H)^{1/d-\eta}+H\big)\|\mathbf{u}-\mathbf{u}_H\|_{0,\Omega}.$$

If instead $k=3$ and $\varphi\in H_0^1(\Omega)$, we obtain

$$\|\bar{p}-\bar{p}_H\|_{-1,\Omega}\le C\big(\epsilon+(\epsilon/H)^{1/d-\eta}+H^m\big)\|\mathbf{u}-\mathbf{u}_H\|_{0,\Omega}.$$

Now by Lemma 4.1, we see that

$$\hat{p}'(\bar{\mathbf{u}}-\bar{\mathbf{u}}_H)=\hat{p}'\big(\bar{\mathbf{u}}+\hat{\mathbf{u}}'(\bar{\mathbf{u}})-\bar{\mathbf{u}}_H-\hat{\mathbf{u}}'(\bar{\mathbf{u}}_H)\big)=\hat{p}'(\mathbf{u}-\mathbf{u}_H),$$

so we conclude that

$$\begin{aligned}\|p-p_H\|_{0,\Omega} &\le \|\bar{p}-\bar{p}_H\|_{0,\Omega}+\|\hat{p}'(\mathbf{u}-\mathbf{u}_H)\|_{0,\Omega}\\ &\le \|\bar{p}-\bar{p}_H\|_{0,\Omega}+CH\|\nabla\hat{p}'(\mathbf{u}-\mathbf{u}_H)\|_{0,\Omega}\\ &\le \|\bar{p}-\bar{p}_H\|_{0,\Omega}+CH\|\mathbf{u}-\mathbf{u}_H\|_{0,\Omega}\\ &\le C\big(\epsilon+(\epsilon/H)^{1/d-\eta}+H\big)\|\mathbf{u}-\mathbf{u}_H\|_{0,\Omega},\end{aligned}$$

which is our first estimate. For the negative norm estimate,

$$\|\hat{p}'(\mathbf{u}-\mathbf{u}_H)\|_{-1,\Omega}\le CH^2\|\nabla\hat{p}'(\mathbf{u}-\mathbf{u}_H)\|_{0,\Omega}\le CH^2\|\mathbf{u}-\mathbf{u}_H\|_{0,\Omega},$$

so if $k=3$,

$$\begin{aligned}\|p-p_H\|_{-1,\Omega} &\le \|\bar{p}-\bar{p}_H\|_{-1,\Omega}+\|\hat{p}'(\mathbf{u}-\mathbf{u}_H)\|_{-1,\Omega}\\ &\le C\big(\epsilon+(\epsilon/H)^{1/d-\eta}+H^m\big)\|\mathbf{u}-\mathbf{u}_H\|_{0,\Omega},\end{aligned}$$

completing the proof. ∎

SEMI-IMPLICIT EULER SCHEME FOR GENERALIZED NEWTONIAN FLUIDS*

LARS DIENING†, ANDREAS PROHL‡, AND MICHAEL RŮŽIČKA†

Abstract. Rheological behavior of certain non-Newtonian fluids in engineering sciences is often modeled by power law ansatzes with $p \leq 2$. So far, existing numerical analysis for local strong solutions studies a fully implicit time discretization and find only restricted ranges of admissible p's for corresponding error estimates [A. Prohl and M. Růžička, *SIAM J. Numer. Anal.*, 39 (2001), pp. 214–249]; different nonlinear stabilization strategies which allow a corresponding error analysis for smaller p's are examined in [L. Diening, *Theoretical and Numerical Results for Electrorheological Fluids*, Ph.D. thesis, University of Freiburg, Freiburg, Germany, 2002] and [L. Diening, A. Prohl, and M. Růžička, in *Nonlinear Problems in Mathematical Physics and Related Topics*, II, Kluwer/Plenum, New York, 2002, pp. 89–118]. In the present paper, a semi-implicit time discretization scheme is proposed, and error estimates apply to the extended range $p \in (\frac{3}{2}, 2]$. The key analytical tool is a new Gronwall-type inequality.

Key words. non-Newtonian fluid flow, degenerate parabolic system, time discretization, weak and strong solution, shear-dependent viscosity, error analysis

1. Introduction and main results.

Viscous fluids that cannot be adequately described by the classical linearly viscous fluid model are usually called non-Newtonian fluids. There are many fluids which differ from a Newtonian fluid only in that their viscosity depends on the shear rate, i.e., on the modulus of the symmetric part of the velocity gradient. Such fluids are called *fluids with shear-dependent viscosity* or *generalized Newtonian fluids*. We refer to [2], [4], [10], [12], [14], and [17] for a detailed discussion of the modeling and the engineering relevance of such fluids.

A typical example of a constitutive relation for the extra stress tensor $\mathbf{S}$ of a *generalized Newtonian fluid* is

$$\mathbf{S}(\mathbf{D}) = \mu \left(\kappa + |\mathbf{D}|^2\right)^{\frac{p-2}{2}} \mathbf{D},$$

where $\mu > 0$, $\kappa \geq 0$, and $p \in (1, \infty)$ are some given material constants. Note that in the case $p \in (1, 2)$ the model reflects shear-thinning behavior, while $p \in (2, \infty)$ corresponds to shear-thickening behavior. For $p = 2$ the model reduces to the Newtonian one.

In this paper we abstract from the specific form of the constitutive relation of the extra stress tensor $\mathbf{S}$ but make the following assumptions: We assume that the extra stress tensor $\mathbf{S}$ has *p-structure*; i.e., for the constitutive function $\mathbf{S} : \mathbb{R}^{3\times3}_{\text{sym}} \to \mathbb{R}^{3\times3}_{\text{sym}}$, with $\mathbb{R}^{3\times3}_{\text{sym}} := \{\mathbf{D} \in \mathbb{R}^{3\times3}; \mathbf{D} = \mathbf{D}^\top\}$, there exist $p > 1$ and $C_1, C_2 > 0$ such that for

all $\mathbf{A}, \mathbf{B} \in \mathbb{R}^{3\times 3}_{\mathrm{sym}}$ it holds that

$$\sum_{i,j,k,l=1}^{3} \frac{\partial S_{ij}(\mathbf{A})}{\partial A_{kl}} B_{ij} B_{kl} \geq C_1 \left(1 + |\mathbf{A}|\right)^{p-2} |\mathbf{B}|^2 \tag{1.1}$$

and for all $i, j, k, l = 1, 2, 3$

$$\left| \frac{\partial S_{ij}(\mathbf{A})}{\partial A_{kl}} \right| \leq C_2 \left(1 + |\mathbf{A}|\right)^{p-2}. \tag{1.2}$$

We consider only the case $p \in (1, 2]$, i.e., the shear-thinning and the Newtonian model. Moreover, in our investigation of the governing system for such fluids we restrict ourselves to space-periodic boundary conditions. From the physical point of view this can be viewed only as a model case. However, in the case of Dirichlet boundary conditions in three-dimensional bounded domains, appropriate existence, uniqueness, and regularity results are only partially available. For example, the existence of weak solutions is known for $p > \frac{8}{5}$ (cf. [8], [9], [11], [18]). However, regularity properties of solutions and their uniqueness are known only for $p > \frac{20}{9}$ (cf. [11], [1]), and the results are much weaker than the corresponding ones in the space-periodic case (cf. Proposition 1.1). Moreover, we do not wish to burden the already complicated analysis with further technical difficulties. In fact all the difficulties which appear in the investigation of the continuous problem will also appear in the numerical analysis. Finally, we restrict ourselves to the three-dimensional case.

Now we will state precisely the problem in which we are interested. Let $\Omega = (0, L)^3$, $L \in (0, \infty)$, be a cube in $\mathbb{R}^3$. Let us denote $\Gamma_j = \partial\Omega \cap \{x_j = 0\}$ and $\Gamma_{j+3} = \partial\Omega \cap \{x_j = L\}$ for $j = 1, 2, 3$. For $T \in (0, \infty)$, we denote by Q_T the time-space cylinder $I \times \Omega$, where $I = (0, T)$ is the time interval. Assume that $\mathbf{S}$ satisfies assumptions (1.1), (1.2). For a given external body force $\mathbf{f} : Q_T \to \mathbb{R}^3$ and a given initial velocity $\mathbf{u}_0 : \Omega \to \mathbb{R}^3$ we seek a velocity field $\mathbf{u} = (u_1, u_2, u_3)^\top : Q_T \to \mathbb{R}^3$ and a pressure function $\pi \colon \Omega \to \mathbb{R}$ solving the system

$$\begin{aligned} \partial_t \mathbf{u} - \operatorname{div} \mathbf{S}(\mathbf{D}\mathbf{u}) + [\nabla \mathbf{u}]\mathbf{u} + \nabla \pi &= \mathbf{f} && \text{in } Q_T, \\ \operatorname{div} \mathbf{u} &= 0 && \text{in } Q_T, \\ \mathbf{u}(0) &= \mathbf{u}_0 && \text{on } \Omega, \end{aligned} \tag{1.3}$$

and satisfying the space-periodicity requirements

$$\mathbf{u}\big|_{\Gamma_j} = \mathbf{u}\big|_{\Gamma_{j+3}}, \qquad \nabla \mathbf{u}\big|_{\Gamma_j} = \nabla \mathbf{u}\big|_{\Gamma_{j+3}}, \qquad \pi\big|_{\Gamma_j} = \pi\big|_{\Gamma_{j+3}} \tag{1.4}$$

for $j = 1, 2, 3$. The term $\mathbf{D}\mathbf{u} := \frac{1}{2}(\nabla \mathbf{u} + \nabla \mathbf{u}^\top)$ denotes the symmetric part of the velocity gradient $\nabla \mathbf{u}$. We refer to (1.3), (1.4) as problem (NS_p).

This paper studies the following time discretization of (NS_p).

ALGORITHM 1. Given a time step size $k > 0$ and the corresponding net $I_k = \{t_m\}_{m=0}^{M}$, for $m \geq 1$ and $\mathbf{u}^{m-1}$ given from the previous step, compute an iterate $\mathbf{u}^m$ that solves

$$\begin{aligned} d_t \mathbf{u}^m - \operatorname{div} \mathbf{S}(\mathbf{D}\mathbf{u}^m) + [\nabla \mathbf{u}^m]\mathbf{u}^{m-1} + \nabla \pi^m &= \mathbf{f}(t_m), \\ \operatorname{div} \mathbf{u}^m &= 0, \\ \mathbf{u}^0 &= \mathbf{u}_0 \end{aligned} \tag{NS_p^k}$$

endowed with space-periodic boundary conditions (1.4), where we denote by $d_t\mathbf{u}^m := k^{-1}(\mathbf{u}^m - \mathbf{u}^{m-1})$ the divided difference in time. We assume that $\mathbf{S}$ has p-structure, i.e., it satisfies (1.1) and (1.2).

To our knowledge, numerical analysis for the full model (NS_p) starts with [13, 4], where error estimates for a first order fully implicit space-time discretization of (NS_p) are derived in the context of locally existing strong solutions; new tools had to be developed to efficiently control errors—albeit surprisingly only valid for restricted values of p. This observation motivated nonlinear stabilization strategies in [3, 4] which significantly extended the range of admissible p's. Proper strategies here are to add a q–Laplacian-type operator ($q \geq 2$) to the problem (scaled with the discretization parameter), or substitute p-growth of the underlying functional $\Phi : \mathbb{R} \to \mathbb{R}$ at a numerical threshold by a quadratic one; the motivation for these strategies is to "strengthen" the dissipative mechanism in the scheme for small values of p in relation to the convective term.

The goal of this paper is to show a similar effect for the scheme (NS_p^k) that is due to its semi-implicit character—with no need for additional stabilizing terms. The key step in our analysis is a new lemma of Gronwall-type (see Lemma 3.2). The verified rate of convergence with respect to the step size $k > 0$ will be the same as for the (more expensive) fully implicit stabilized schemes. The range of admissible p's for the derivation of the error estimates and for the existence of strong solutions will even be extended to $p > \frac{3}{2}$.

The existence of *strong* solutions locally in time for large data of the problem (NS_p) is ensured by the following assertion.[1]

PROPOSITION 1.1. *Let* $\mathbf{f} \in L^\infty(I, W^{1,2}(\Omega))$, $\partial_t\mathbf{f} \in L^2(I, L^2(\Omega))$, $\mathbf{u}_0 \in W^{2,2}_{\mathrm{div}}(\Omega)$, *and* $\frac{7}{5} < p \leq 2$. *Then there exists a time interval* $I = (0, T)$, $T > 0$, *and a unique solution* $\mathbf{u}$, π *which satisfies for all* $1 \leq r < 6(p-1)$

$$\begin{aligned} &\mathbf{u} \in C(I, W^{1,r}(\Omega)), \\ &\partial_t\mathbf{u} \in L^\infty(I, L^2(\Omega)) \cap L^p(I, L^{3p}(\Omega)), \\ &\partial_t^2\mathbf{u} \in L^2(I, (W^{1,2}_{\mathrm{div}}(\Omega))^*). \end{aligned} \tag{1.5}$$

The proof of this proposition for $p \in (7/5, 2]$ can be found in [3] and [5] under the additional assumption that $\mathbf{S}$ is given by a potential. However, this fact is never used in these papers, and the result also extends to the situation without a potential (cf. [16] where the case $p \in (3/2, 2]$ is treated under the assumptions (1.1) and (1.2) only). The case $p > 5/3$ is already covered in [10]. In [13] the existence of a weak solution $\mathbf{u}^m \in l^\infty(I_k; L^2(\Omega)) \cap l^p(I_k; W^{1,p}_{\mathrm{div}})$ of the fully implicit time discretization of (NS_p) is proved for $p > 3/2$, but the analysis applies to (NS_p^k) as well with only minor changes. In order to analyze the above algorithm for all $p > 3/2$ we first derive suboptimal convergence rates for the error between the strong solution $\mathbf{u}$ from Proposition 1.1 and the unique weak solution $\mathbf{u}^m$ of the discrete problem (NS_p^k) from Lemma 3.1. In fact, we show with the help of a new Gronwall-type lemma that the following proposition holds.

PROPOSITION 1.2. *Suppose that* $\mathbf{u}_0 \in W^{2,2}(\Omega) \cap W^{1,p}_{\mathrm{div}}$, $\mathbf{f} \in C(I; W^{1,2}(\Omega))$, $\partial_t\mathbf{f} \in C(I; L^2(\Omega))$ *are given. Let* $\mathbf{u}$ *be the strong solution of problem* (NS_p) *for* $p \in (\frac{3}{2}, 2]$ *satisfying* (1.5) *and let* $\mathbf{u}^m$ *be the unique weak solution of problem* (NS_p^k) *satisfying* (3.1) *and* $t_M \leq T$. *Then the following error estimate is valid provided that the time*

[1] We use standard notation for Lebesgue, Sobolev, and Bochner spaces, which will be defined precisely in section 2.

step size k is chosen sufficiently small, i.e., $k \le k_1(p,T)$:

$$\max_{0\le m\le M} \|\mathbf{u}(t_m)-\mathbf{u}^m\|_2^2 + k\sum_{m=0}^{M} \|\nabla(\mathbf{u}(t_m)-\mathbf{u}^m)\|_p^2 \le c_1\, k^{2\beta}\,, \qquad \max_{0\le m\le M} \|\nabla(\mathbf{u}(t_m)-\mathbf{u}^m)\|_p \le 1, \tag{1.6}$$

with $c_1 = c_1(p,T,\mathbf{u}_0,\mathbf{f})$ and

$$\beta := \frac{5p-6}{2p}\,.$$

Then we use this error estimate to show by an induction argument that the weak solution of problem (NS_p^k) is actually a strong one. Namely, we show that the following theorem holds.

THEOREM 1.3. *Let $\mathbf{u}_0$, $\mathbf{f}$, p, $\mathbf{u}$, $\mathbf{u}^m$, T, and t_M be as in Proposition* 1.2. *Then*

$$\max_{1\le m\le M} \|d_t\mathbf{u}^m\|_2^2 + k\sum_{m=1}^{M} \Big(\mathcal{I}_p(\mathbf{u}^m)^{\frac{5p-6}{2-p}} + \mathcal{K}_p(\mathbf{u}^m)\Big) \le c(\mathbf{f},\mathbf{u}_0), \tag{1.7}$$

where $\mathcal{I}_p$ and $\mathcal{K}_p$ are defined below by (2.1) *and* (2.2). *In particular, due to Lemma* 2.3 *for all $1<r<6(p-1)$ we have*

$$\begin{aligned} \mathbf{u}^m &\in l^{\frac{5p-6}{2-p}}(I_k; W^{2,\frac{3p}{p+1}}(\Omega)) \cap l^\infty(I_k; V_r),\\ d_t\mathbf{u}^m &\in l^{\frac{p(5p-6)}{(3p-2)(p-1)}}(I_k; W^{1,\frac{3p}{p+1}}(\Omega)) \cap l^\infty(I_k; L^2(\Omega)). \end{aligned} \tag{1.8}$$

Now using this regularity we can improve the convergence rate from Proposition 1.2 and show that the following theorem holds.

THEOREM 1.4. *Let $\mathbf{u}_0$, $\mathbf{f}$, p, $\mathbf{u}$, $\mathbf{u}^m$, T, and t_M be as in Proposition* 1.2. *Then for all*

$$\alpha < \alpha_0(p) := \frac{5p-6}{4(p-1)},$$

there exists a constant $c_2 = c_2(p,T,\mathbf{u}_0,\mathbf{f},\alpha)$, such that the following error estimate is valid for k chosen sufficiently small, i.e., $k \le k_2(p,T,\alpha)$:

$$\max_{0\le m\le M} \|\mathbf{u}(t_m)-\mathbf{u}^m\|_2^2 + k\sum_{m=0}^{M} \|\nabla(\mathbf{u}(t_m)-\mathbf{u}^m)\|_p^2 \le c_2\, k^{2\alpha}\,. \tag{1.9}$$

REMARK 1.5. *Theorem* 1.4 *improves Theorem* 1.10 *in* [4] *considerably, both with respect to the range of admissible p's and the regularity of the solution $\mathbf{u}^m$. In* [13] *it is proved that for $p \in (\frac{11+\sqrt{21}}{10}, 2] \approx (1.5583, 2]$ estimate* (1.9) *holds. However, note that the discrete solution $\mathbf{u}^m$ in* [4] *is only a weak solution; i.e., only* (3.1) *holds. The regularity of $\mathbf{u}^m$ ensured by Theorem* 1.3 *is proved in* [4] *only for stabilized schemes. For a subsequent analysis of a spatial discretization it is shown in* [13] *that the existence and characterization of strong solutions to (NS_p^k) are essential. For example, uniform a priori bounds in* [13] *in a comparable situation are obtained only for restricted values $p \in (\frac{9}{5}, 2]$. Using the results in this paper one can carry out the*

analysis of the fully discrete system based on (NS_p^k) *along the lines of* [13]. *Within the framework of the DFG–Forschergruppe "Nonlinear Partial Differential Equations: Theoretical and Numerical Analysis" we currently develop a robust and efficient solver for problems with p-structure. Part of the research is a comparison of semi-implicit and fully implicit schemes. However, at the moment results are not yet available.*

The remainder of this paper is organized as follows. Section 2 provides the mathematical setup to study (NS_p^k) and collects the consequences of our assumptions (1.1), (1.2). In section 3 first the existence of weak solutions is verified and then the proof of Proposition 1.2 is given, where Lemma 3.2 is the main tool. Section 4 presents proofs of Theorems 1.3 and 1.4.

2. Notation and technical preliminaries. In this section we fix the notation and collect some useful consequences of the assumptions (1.1), (1.2). Recall that $\Omega = (0,L)^3$, $L \in (0,\infty)$, is a cube in $\mathbb{R}^3$. By $\mathcal{D}(\Omega)$ we denote the space of smooth periodic functions with mean value zero. Let further $p, q > 1$ and $k > 0$. Then $(L^p(\Omega), \|\cdot\|_p)$ (respectively, $(W^{k,p}(\Omega), \|\cdot\|_{k,p})$) is used for the usual Lebesgue (respectively, Sobolev) spaces of periodic functions with mean value zero. We will further make frequent use of spaces of divergence-free functions defined by

$$\mathcal{V} := \big\{\boldsymbol{\psi} \in \mathcal{D}(\Omega) : \operatorname{div} \boldsymbol{\psi} = 0\big\},$$
$$W^{1,p}_{\mathrm{div}} := \text{the closure of } \mathcal{V} \text{ with respect to the } \|\nabla\cdot\|_p\text{-norm}.$$

By $\langle g, h\rangle$ we denote the scalar product $\int_\Omega g(x)\,h(x)\,dx$. For two Banach spaces X_0, X_1 and $\theta \in (0,1)$ the complex interpolation space is $[X_0, X_1]_{[\theta]}$. Moreover, we denote by $L^q(I;X)$ Bochner spaces which are equipped with the norm $\big(\int_I \|\cdot\|_X^q\,ds\big)^{1/q}$. We refer the reader to [7] for more details. We make frequent use of the discrete counterparts of these spaces. Let $I_k = \{t_m\}_{m=0}^M$ be a given net in an interval $I = [0, t_M]$ with a constant time step size $k := t_m - t_{m-1}$. We denote by $d_t\mathbf{u}^m := k^{-1}(\mathbf{u}^m - \mathbf{u}^{m-1})$ the divided difference in time. By $l^p(I_k;X)$ we denote the space of functions $\{\varphi^m\}_{m=0}^M$ with finite norm $\big(k\sum_{m=0}^M \|\varphi^m\|_X^p\big)^{1/p}$. In the case $p=\infty$, functions $\{\varphi^m\}_{m=0}^M$ need to satisfy the bound $\max_{0\le m\le M}\|\varphi^m\|_X < \infty$.

Let us introduce some notation for terms which arise from $\mathbf{S}$ when we test (NS_p) with $-\Delta\mathbf{u}$ or with $\partial_t^2\mathbf{u}$. Namely, for $p > 1$ we set

$$\begin{aligned}\mathcal{I}_p(\mathbf{u}) &= \int_\Omega \big(1+|\mathbf{D}\mathbf{u}|^2\big)^{\frac{p-2}{2}} |\mathbf{D}(\nabla\mathbf{u})|^2\,dx,\\ \mathcal{J}_p(\mathbf{u}) &= \int_\Omega \big(1+|\mathbf{D}\mathbf{u}|^2\big)^{\frac{p-2}{2}} |\mathbf{D}(\partial_t\mathbf{u})|^2\,dx.\end{aligned} \tag{2.1}$$

The discrete analogue for $\mathcal{J}_p(\mathbf{u})$ for a function defined on a net I_k reads as follows:

$$\mathcal{K}_p(\mathbf{u}^m) = \int_\Omega \left(1+\frac{1}{2}|\mathbf{D}\mathbf{u}^m|^2 + \frac{1}{2}|\mathbf{D}\mathbf{u}^{m-1}|^2\right)^{\frac{p-2}{2}} |\mathbf{D}(d_t\mathbf{u}^m)|^2\,dx. \tag{2.2}$$

Let us now summarize some important estimates for $\mathbf{S}$, $\mathcal{I}_p$, $\mathcal{J}_p$, and $\mathcal{K}_p$. The proofs can be found, for example, in [10, Lemmas 5.1.19 and 5.1.35] and [13, Lemma 2.8].

LEMMA 2.1. *Suppose that* Φ *and* $\mathbf{S}$ *satisfy* (1.1), (1.2) *for some* $p > 1$. *Then there are constants* $c_3 = c_3(p)$ *and* $c_4 = c_4(p)$ *such that for all* $\mathbf{A}, \mathbf{B} \in \mathbb{R}^{3\times 3}_{\mathrm{sym}}$

$$\mathbf{S}(\mathbf{A})\cdot\mathbf{A} \ge c_3\big(1+|\mathbf{A}|\big)^{p-2}|\mathbf{A}|^2, \tag{2.3}$$

$$|\mathbf{S}(\mathbf{A})| \le c_4\big(1+|\mathbf{A}|\big)^{p-1}. \tag{2.4}$$

Additionally, we have

$$\big(\mathbf{S}(\mathbf{A})-\mathbf{S}(\mathbf{B})\big)\cdot\big(\mathbf{A}-\mathbf{B}\big)\geq c_3\,\big|\mathbf{A}-\mathbf{B}\big|^2\big(1+|\mathbf{B}|+|\mathbf{A}-\mathbf{B}|\big)^{p-2}, \tag{2.5}$$

$$\big|\mathbf{S}(\mathbf{A})-\mathbf{S}(\mathbf{B})\big|\leq c_4\,|\mathbf{A}-\mathbf{B}|\big(1+|\mathbf{B}|+|\mathbf{A}-\mathbf{B}|\big)^{p-2}. \tag{2.6}$$

REMARK 2.2. *From* (2.5) *it follows that for* $r\in[1,\infty)$ *and* $p\in(1,2]$

$$\begin{aligned}&\int_\Omega(\mathbf{S}(\mathbf{Du})-\mathbf{S}(\mathbf{Dv}))\cdot\mathbf{D}(\mathbf{u}-\mathbf{v})\,dx\\&\quad\geq c_5\,\|\mathbf{Du}-\mathbf{Dv}\|^2_{\frac{2r}{2-p+r}}(1+\|\mathbf{Du}\|_r+\|\mathbf{Du}-\mathbf{Dv}\|_r)^{p-2}.\end{aligned} \tag{2.7}$$

The following lemmas are proved in [4].

LEMMA 2.3. *Let* $\mathbf{u}\in C^1(I;\mathbf{C}^2(\Omega))$ *be a space periodic function with mean value zero and* $p\in(1,2]$. *Then there exists a constant* c *depending only on* Ω *and* p *such that for* $s\in[1,\infty)$

$$\|\nabla\mathbf{u}\|^2_{\frac{6s}{6-3p+s}}+\|\nabla^2\mathbf{u}\|^2_{\frac{2s}{2-p+s}}\leq c\,\mathcal{I}_p(\mathbf{u})\big(1+\|\nabla\mathbf{u}\|_s\big)^{2-p}, \tag{2.8}$$

$$\|\nabla\mathbf{u}\|^p_{3p}+\|\nabla^2\mathbf{u}\|^p_{\frac{3p}{p+1}}\leq c\,(1+\mathcal{I}_p(\mathbf{u})), \tag{2.9}$$

$$\|\partial_t\mathbf{u}\|^2_{\frac{6s}{6-3p+s}}+\|\nabla\partial_t\mathbf{u}\|^2_{\frac{2s}{2-p+s}}\leq c\,\mathcal{J}_p(\mathbf{u})(1+\|\nabla\mathbf{u}\|_s)^{2-p}, \tag{2.10}$$

$$\begin{aligned}\|\partial_t\mathbf{u}\|^p_{3p}+\|\nabla\partial_t\mathbf{u}\|^p_{\frac{3p}{p+1}}&\leq c\,(1+\mathcal{I}_p(\mathbf{u}))^{\frac{2-p}{2}}\mathcal{J}_p(\mathbf{u})^{\frac{p}{2}}\\&\leq c\,(1+\mathcal{I}_p(\mathbf{u})+\mathcal{J}_p(\mathbf{u})).\end{aligned} \tag{2.11}$$

Moreover, for $1\leq r<6(p-1)$ *we have*

$$\sup_{t\in I}\|\nabla\mathbf{u}\|^p_r\leq c\bigg(1+\int_I\mathcal{I}_p(\mathbf{u})^{\frac{5p-6}{2-p}}+\mathcal{J}_p(\mathbf{u})\,dt\bigg). \tag{2.12}$$

LEMMA 2.4. *Let* $\mathbf{u}\in l^\infty(I_k;\mathbf{C}^2(\Omega))$ *be a space-periodic function with mean value zero, and let* $p\in(1,2]$. *Then there exists a constant* c *depending only on* Ω *and* p *such that for* $s\in[1,\infty)$

$$\begin{aligned}&\|d_t\mathbf{u}^m\|^2_{\frac{6s}{6-3p+s}}+\|d_t\nabla\mathbf{u}^m\|^2_{\frac{2s}{2-p+s}}\\&\qquad\leq c\,\mathcal{K}_p(\mathbf{u}^m)(1+\|\nabla\mathbf{u}^m\|_s+\|\nabla\mathbf{u}^{m-1}\|_s)^{2-p},\end{aligned} \tag{2.13}$$

$$\begin{aligned}&\|d_t\mathbf{u}^m\|^p_{3p}+\|d_t\nabla\mathbf{u}^m\|^p_{\frac{3p}{p+1}}\\&\qquad\leq c\,(1+\mathcal{I}_p(\mathbf{u}^m)+\mathcal{I}_p(\mathbf{u}^{m-1}))^{\frac{2-p}{2}}\mathcal{K}_p(\mathbf{u}^m)^{\frac{p}{2}}\end{aligned} \tag{2.14}$$

$$\leq c\,(1+\mathcal{I}_p(\mathbf{u}^m)+\mathcal{I}_p(\mathbf{u}^{m-1})+\mathcal{K}_p(\mathbf{u}^m)). \tag{2.15}$$

Moreover, for $1\leq r<6(p-1)$

$$\max_{1\leq m\leq M}\|\nabla\mathbf{u}^m\|^p_r\leq c(r)\left(1+k\sum_{m=1}^M(\,\mathcal{I}_p(\mathbf{u}^m)^{\frac{5p-6}{2-p}}+\mathcal{I}_p(\mathbf{u}^{m-1})^{\frac{5p-6}{2-p}}+\mathcal{K}_p(\mathbf{u}^m)\,)\right). \tag{2.16}$$

3. Proof of Proposition 1.2. In this section we will present a proof of Proposition 1.2; i.e., we will derive preliminary estimates for the error $\mathbf{u}(t_m) - \mathbf{u}^m$. Before we do so, let us offer a few words on the existence of the solution $\mathbf{u}^m$ to the system (NS_p^k). The strategy employed in the proof of Proposition 1.1 to ensure the existence of strong solutions is not applicable to the discrete system (NS_p^k). However, the existence of *weak* solutions to the fully discrete analogue of problem (NS_p^k) is ensured, e.g., by [13, Lemma 4.1] which we recall here.

LEMMA 3.1. *Let* $\mathbf{u}_0$ *and* $\mathbf{f}$ *be as in Proposition* 1.1*, and let* $p > 3/2$*. Then there exists a unique, weak solution* $\mathbf{u}^m$ *of the problem* (NS_p^k) *satisfying*

$$\max_{0\le m\le M} \|\mathbf{u}^m\|_2^2 + k\sum_{m=0}^{M} \|\mathbf{D}\mathbf{u}^m\|_p^p \le c(\mathbf{f},\mathbf{u}_0), \tag{3.1}$$

whenever $p > 3/2$.

The proof of Lemma 3.1 is based on the fact that each $\mathbf{u}^m$ is just the solution to a stationary Stokes-like problem which is then solved by the techniques developed in [6] and [15]. Lemma 3.1 was originally developed for the fully implicit time discretization, i.e., with convective term $[\nabla\mathbf{u}^m]\mathbf{u}^m$, without the statement for uniqueness. In our case of a semi-implicit time discretization, i.e., with convective term $[\nabla\mathbf{u}^m]\mathbf{u}^{m-1}$, the proof could even be simplified, since the convective term is linear in $\mathbf{u}^m$. The same reason ensures that the solution $\mathbf{u}^m$ for each time step is unique.

Proof of Proposition 1.2. Let us introduce some notation. We set $\mathbf{e}^0 = \mathbf{0}$ and we define for $1 \le m \le M$

$$\mathbf{e}^m := \mathbf{u}(t_m) - \mathbf{u}^m, \qquad \eta^m := \pi(t_m) - \pi^m, \qquad \mathbf{R}^m := d_t\mathbf{u}(t_m) - \partial_t\mathbf{u}(t_m).$$

It has been shown in [13] and [4] under the assumptions (1.5) that $\mathbf{R}^m$ is well defined and satisfies

$$\begin{aligned} \|\mathbf{R}^m\|_{l^2(I_k;(W^{1,2}_{\mathrm{div}}(\Omega))^*)} &\le c\,k\,\|\partial_t^2\mathbf{u}\|_{L^2(I;(W^{1,2}_{\mathrm{div}}(\Omega))^*)},\\ \|\mathbf{R}^m\|_{l^\infty(I_k;L^2(\Omega))} &\le c\,\|\partial_t\mathbf{u}\|_{L^\infty(I;L^2(\Omega))}. \end{aligned}$$

Especially, by (1.5) we have

$$\|\mathbf{R}^m\|_{l^2(I_k;(W^{1,2}_{\mathrm{div}}(\Omega))^*)} \le c\,k, \qquad \|\mathbf{R}^m\|_{l^\infty(I_k;L^2(\Omega))} \le c. \tag{3.2}$$

With this new notation, system (NS_p) reads at time $t_m > 0$ as follows:

$$\begin{aligned} d_t\mathbf{u}(t_m) - \operatorname{div}\mathbf{S}(\mathbf{D}\mathbf{u}(t_m)) + [\nabla\mathbf{u}(t_m)]\mathbf{u}(t_m) + \nabla\pi(t_m) &= \mathbf{f}(t_m) + \mathbf{R}^m,\\ \operatorname{div}\mathbf{u}(t_m) &= 0,\\ \mathbf{u}(0) &= \mathbf{u}_0, \end{aligned}$$

with $1 \le m \le M$. This and (NS_p^k) imply for $1 \le m \le M$ that

$$\begin{aligned} &d_t\mathbf{e}^m - \operatorname{div}(\mathbf{S}(\mathbf{D}\mathbf{u}(t_m)) - \mathbf{S}(\mathbf{D}\mathbf{u}^m)) + \nabla\eta^m\\ &\quad = -k\,[\nabla\mathbf{u}(t_m)]d_t\mathbf{u}(t_m) - [\nabla\mathbf{u}(t_m)]\mathbf{e}^{m-1} - [\nabla\mathbf{e}^m]\mathbf{u}^{m-1} + \mathbf{R}^m,\\ &\operatorname{div}\mathbf{e}^m = 0,\\ &\mathbf{e}^0 = 0. \end{aligned} \tag{3.3}$$

We use the test function $\mathbf{e}^m$ for this system and get

$$\begin{aligned}&\big\langle d_t\mathbf{e}^m,\mathbf{e}^m\big\rangle+\big\langle\mathbf{S}(\mathbf{Du}(t_m))-\mathbf{S}(\mathbf{Du}^m),\mathbf{De}^m\big\rangle\\&\quad\le k\,\big|\big\langle[\nabla\mathbf{u}(t_m)]d_t\mathbf{u}(t_m),\mathbf{e}^m\big\rangle\big|+\big|\big\langle[\nabla\mathbf{u}(t_m)]\mathbf{e}^{m-1},\mathbf{e}^m\big\rangle\big|+\big|\langle\mathbf{R}^m,\mathbf{e}^m\rangle\big|\\&\quad=:K_1^m+K_2^m+K_3^m,\end{aligned}\tag{3.4}$$

where we have used that $\langle\nabla\eta^m,\mathbf{e}^m\rangle=0$ and $\langle[\nabla\mathbf{e}^m]\mathbf{u}^{m-1},\mathbf{e}^m\rangle=0$ since $\operatorname{div}(\mathbf{u}^{m-1})=\operatorname{div}(\mathbf{u}^m)=0$. With $\langle d_t\mathbf{e}^m,\mathbf{e}^m\rangle=\frac12 d_t\|\mathbf{e}^m\|_2^2+\frac{k}{2}\|d_t\mathbf{e}^m\|_2^2$, Remark 2.2, with $r=p$, and Korn's inequality we get

$$\tfrac12 d_t\|\mathbf{e}^m\|_2^2+\frac{c_5\,\|\nabla\mathbf{e}^m\|_p^2}{(1+\|\nabla\mathbf{u}(t_m)\|_p+\|\nabla\mathbf{e}^m\|_p)^{2-p}}\le c\,\big(K_1^m+K_2^m+K_3^m\big).$$

Since $\mathbf{u}\in C(I;W^{1,p}(\Omega))$ by (1.5), this implies the existence of a constant $c_6>0$ such that

$$\tfrac12 d_t\|\mathbf{e}^m\|_2^2+\frac{c_6\,\|\nabla\mathbf{e}^m\|_p^2}{(1+\|\nabla\mathbf{e}^m\|_p)^{2-p}}\le c\,\big(K_1^m+K_2^m+K_3^m\big).\tag{3.5}$$

We will now estimate K_1^m, K_2^m, and K_3^m in such a way that we can apply Lemma 3.2 below with

$$\begin{aligned}a_m&:=\|\mathbf{e}^m\|_2,\\b_m&:=\|\nabla\mathbf{e}^m\|_p,\\r_m&:=c\,\big(\|\mathbf{R}^m\|_{-1,p'}+k\,\|d_t\mathbf{u}(t_m)\|_{\frac{12}{8-3p}}\big),\\\beta&:=\frac{5p-6}{2p}.\end{aligned}\tag{3.6}$$

Let us first show that r_m satisfies (3.14). From the embedding ($p\le2$)

$$\begin{aligned}[l^2(I_k;W^{-1,2}(\Omega)),l^\infty(I_k;L^2(\Omega))]_{[\frac{5p-6}{2p}]}&\hookrightarrow[l^2(I_k;W^{-1,2}(\Omega)),l^\infty(I_k;W^{-1,6}(\Omega))]_{[\frac{5p-6}{2p}]}\\&\hookrightarrow l^{\frac{4p}{5p-6}}(I_k;W^{-1,p'}(\Omega))\\&\hookrightarrow l^2(I_k;W^{-1,p'}(\Omega))\end{aligned}$$

and (3.2) it follows that

$$\begin{aligned}\|\mathbf{R}^m\|_{l^2(I_k;W^{-1,p'}(\Omega))}&\le c\,\|\mathbf{R}^m\|_{[l^2(I_k;W^{-1,2}(\Omega)),l^\infty(I_k,L^2(\Omega))]_{[\frac{5p-6}{2p}]}}\\&\le c\,\|\mathbf{R}^m\|_{l^\infty(I_k;L^2(\Omega))}^{\frac{6-3p}{2p}}\|\mathbf{R}^m\|_{l^2(I_k;W^{1,2}(\Omega)^*)}^{\frac{5p-6}{2p}}\\&\le c\,k^{\frac{5p-6}{2p}}.\end{aligned}\tag{3.7}$$

From $\partial_t\mathbf{u}\in L^\infty(I;L^2(\Omega))$ and $\partial_t\mathbf{u}\in L^p(I;L^{3p}(\Omega))$ it follows by complex interpolation that

$$\partial_t\mathbf{u}\in L^2(I;L^{\frac{12}{8-3p}}(\Omega))=[L^\infty(I;L^2(\Omega)),L^p(I;L^{3p}(\Omega))]_{[\frac{p}{2}]}.$$

We estimate

$$k\sum_{m=1}^M\|d_t\mathbf{u}(t_m)\|_{\frac{12}{8-3p}}^2=k^{-1}\sum_{m=1}^M\left\|\int_{t_{m-1}}^{t_m}\partial_t\mathbf{u}(t)\,dt\right\|_{\frac{12}{8-3p}}^2\le\int_0^{t_M}\|\partial_t\mathbf{u}(t)\|_{\frac{12}{8-3p}}^2\,dt.$$

In particular,

$$\|d_t\mathbf{u}(t_m)\|_{l^2(I_k;L^{\frac{12}{8-3p}}(\Omega))} \le \|\partial_t\mathbf{u}\|_{L^2(I;L^{\frac{12}{8-3p}}(\Omega))} \le c. \tag{3.8}$$

From (3.7) and (3.8) follows

$$\begin{aligned} k\sum_{m=1}^{M} r_m^2 &\le c\left(\|\mathbf{R}^m\|^2_{l^2(I_k;W^{-1,p'}(\Omega))} + k^2\,\|d_t\mathbf{u}(t_m)\|^2_{l^2(I_k;L^{\frac{12}{8-3p}}(\Omega))}\right)\\ &\le c\,k^{\frac{5p-6}{p}} + c\,k^2 \le c\,k^{2\beta}. \end{aligned}$$

This proves (3.14). Let us return to the estimation of K_1^m, K_2^m, and K_3^m. First,

$$K_3^m = \left|\langle \mathbf{R}^m, \mathbf{e}^m\rangle\right| \le \|\mathbf{R}^m\|_{-1,p'}\|\mathbf{e}^m\|_{1,p} \le c\,\|\mathbf{R}^m\|_{-1,p'}\|\nabla\mathbf{e}^m\|_p. \tag{3.9}$$

Second,

$$K_1^m \le k\,\|\nabla\mathbf{u}(t_m)\|_{\frac{12p}{3p^2+8p-12}}\|d_t\mathbf{u}(t_m)\|_{\frac{12}{8-3p}}\|\mathbf{e}^m\|_{\frac{3p}{3-p}}.$$

We use $6(p-1) > \frac{12p}{3p^2+8p-12}$ for all $p \in [\frac{3}{2}, 2]$ and (1.5). Then

$$K_1^m \le ck\,\|d_t\mathbf{u}(t_m)\|_{\frac{12}{8-3p}}\|\nabla\mathbf{e}^m\|_p. \tag{3.10}$$

From (3.9) and (3.10) we deduce

$$K_1^m + K_3^m \le r_m b_m. \tag{3.11}$$

Third,

$$\begin{aligned} K_2^m &= \left|\left\langle [\nabla\mathbf{u}(t_m)]\mathbf{e}^{m-1}, \mathbf{e}^m\right\rangle\right|\\ &\le \|\nabla\mathbf{u}(t_m)\|_3\|\mathbf{e}^m\|_{\frac{p}{p-1}}\|\mathbf{e}^{m-1}\|_{\frac{3p}{3-p}}\\ &\le c\,\|\mathbf{e}^m\|_{\frac{p}{p-1}}\|\nabla\mathbf{e}^{m-1}\|_p, \end{aligned}$$

where we have used that $3 < 6(p-1)$ for all $p \in (\frac{3}{2}, 2]$, and (1.5).[2] Since $p \in (\frac{3}{2}, 2]$ there exists $\theta \in (0,1]$ with $\|\mathbf{e}^m\|_{\frac{p}{p-1}} \le c\,\|\nabla\mathbf{e}^m\|_p^{1-\theta}\|\mathbf{e}^m\|_2^{\theta}$. Thus

$$K_2^m \le c\,\|\nabla\mathbf{e}^{m-1}\|_p\|\nabla\mathbf{e}^m\|_p^{1-\theta}\|\mathbf{e}^m\|_2^{\theta} = c\,b_{m-1}b_m^{1-\theta}a_m^{\theta}. \tag{3.12}$$

Due to the embedding $W_0^{1,p}(\Omega) \hookrightarrow L^2(\Omega)$ it holds that $a_m \le c\,b_m$ which immediately implies

$$K_2^m \le c\,b_{m-1}b_m. \tag{3.13}$$

We combine (3.5), (3.11), (3.12), and (3.13) to obtain

$$\begin{aligned} d_t a_m^2 + c_6(1+b_m)^{p-2}b_m^2 &\le b_m r_m + c\,b_{m-1}b_m,\\ d_t a_m^2 + c_6(1+b_m)^{p-2}b_m^2 &\le b_m r_m + c\,b_{m-1}b_m^{1-\theta}a_m^{\theta}, \end{aligned}$$

[2]Note that this is the crucial estimate which limits the analysis to $p > 3/2$. Since the extra stress tensor $\mathbf{S}$ in problem (NS_p) depends on the symmetric part of the velocity gradient $\mathbf{D}$, the regularity stated in (1.5) is at the present time optimal. Thus the method presented here cannot be extended to smaller values of p.

which proves the validity of (3.15) and (3.16). Overall, we have shown that we can apply Lemma 3.2 below. This ensures the existence of k_3 such that if $0 < k < k_3$, then the error $\mathbf{e}^m$ satisfies

$$\max_{0\le m\le M} \|\nabla \mathbf{e}^m\|_p \le 1,$$

$$\max_{0\le m\le M} \|\mathbf{e}_m\|_2^2 + c_6\, k \sum_{m=0}^{M} \|\nabla \mathbf{e}^m\|_p^2 \le c\, k^{\frac{5p-6}{p}} \exp(c\,T).$$

This proves Proposition 1.2. □

We now state and prove the crucial Lemma 3.2 which is of Gronwall-type.

LEMMA 3.2. *Let $1 < p \le 2$. Let $0 \le a_m, b_m, r_m < \infty$, with $a_0 = b_0 = 0$, and let*

$$k \sum_{m=1}^{M} r_m^2 \le c_7 k^{2\beta}, \tag{3.14}$$

with $\frac{1}{2} < \beta$. Further, let

$$d_t a_m^2 + c_8\,(c_9 + b_m)^{p-2} b_m^2 \le b_m r_m + c_{10}\, b_{m-1} b_m, \tag{3.15}$$

$$d_t a_m^2 + c_8\,(c_9 + b_m)^{p-2} b_m^2 \le b_m r_m + c_{11}\, b_{m-1} b_m^{1-\theta} a_m^{\theta}, \tag{3.16}$$

with $0 < c_8, c_9 \le 1$, $c_{10}, c_{11} \ge 1$, and some $0 < \theta \le 1$. Then there exists $k_4 > 0$, such that if (3.15) and (3.16) hold for $0 < k < k_4 = \min(k_5, k_6)$, then

$$\max_{0\le m\le M} b_m \le 1, \tag{3.17}$$

$$\max_{0\le m\le M} a_m^2 + c_8\, k \sum_{m=0}^{M} b_m^2 \le c_{12} k^{2\beta} \exp(c_{13} k M), \tag{3.18}$$

where

$$c_{12} := 8\, c_7\, c_8^{-1}, \qquad c_{13} := 2 \cdot 8^{\frac{2-\theta}{\theta}}\, c_8^{\frac{\theta-2}{\theta}}\, c_{11}^{\frac{2}{\theta}},$$

$$k_5 := \left(8\, c_8^{-2} \left(c_7 + c_{10}^2\, c_{12} \exp(c_{13} T)\right)\right)^{\frac{-1}{2\beta-1}}, \qquad k_6 := \frac{1}{2}\big(2 \cdot 8^{\frac{2-\theta}{\theta}}\, c_8^{\frac{\theta-2}{\theta}}\, c_{11}^{\frac{2}{\theta}}\big)^{-1}.$$

Proof. We prove (3.17) and (3.18) by induction over M.

Case $M = 0$. Obvious.

Case $(M-1) \mapsto M$. We start with the proof of (3.17). There is nothing to show for $b_M \le 1$ so assume $b_M > 1$. Especially, we have $0 \le b_1, \dots, b_{M-1} \le 1 < b_M$. Summation of (3.15) over $\{1, \dots, M\}$ implies (with $a_0 = 0$)

$$\begin{aligned} a_M^2 + c_8\, k \sum_{m=0}^{M} (c_9 + b_m)^{p-2}\, b_m^2 &\le k \sum_{m=0}^{M} b_m \big(r_m + c_{10} b_{m-1}\big) \\ &\le c_8\, \frac{k}{2} \sum_{m=0}^{M} (c_9 + b_m)^{p-2} b_m^2 + \frac{1}{c_8}\, k \sum_{m=0}^{M} (c_9 + b_m^2)^{2-p} \big(r_m^2 + c_{10}^2 b_{m-1}^2\big). \end{aligned}$$

We absorb the first term of the right-hand side and then neglect all summands on the left-hand side, except for $m = M$:

$$\begin{aligned} c_8\, k\, (c_9 + b_M)^{p-2}\, b_M^2 &\le \frac{2}{c_8} k \sum_{m=0}^{M} (c_9 + b_m^2)^{2-p} \big(r_m^2 + c_{10}^2 b_{m-1}^2\big) \\ &\le \frac{2}{c_8} (c_9 + b_M)^{2-p} k \sum_{m=0}^{M} \big(r_m^2 + c_{10}^2 b_{m-1}^2\big) \\ &\le \frac{2}{c_8} (c_9 + b_M)^{2-p} k^{2\beta} \big(c_7 + c_{10}^2\, c_{12}\, \exp(c_{13}\, kM)\big), \end{aligned}$$

where we have used (3.18) for $0 \le m \le M-1$. With $0 \le c_9 \le 1 < b_M$

$$\begin{aligned} b_M^2 &\le 2 c_8^{-2} (c_9 + b_M)^{2(2-p)} k^{2\beta-1} \big(c_7 + c_{10}^2\, c_{12}\, \exp(c_{13}\, kM)\big) \\ &\le 2 c_8^{-2} b_M^{2(2-p)} 2^{2(2-p)} k^{2\beta-1} \big(c_7 + c_{10}^2\, c_{12}\, \exp(c_{13}\, kM)\big). \end{aligned}$$

In particular, with $1 < p \le 2$

$$1 < b_M^{2(p-1)} \le 8\, k^{2\beta-1}\, c_8^{-2} \big(c_7 + c_{10}^2\, c_{12}\, \exp(c_{13}\, T)\big).$$

If $0 < k < k_5$ with

$$k_5 := \left(8\, c_8^{-2} \left(c_7 + c_{10}^2\, c_{12} \exp(c_{13} T)\right)\right)^{\frac{-1}{2\beta-1}},$$

we get the desired contradiction $1 < 1$. This proves $0 \le b_M \le 1$, i.e., (3.17).

We continue with the proof of (3.18). From (3.16) and Young's inequality we deduce

$$\begin{aligned} d_t a_m^2 + c_8\, (c_9 + b_m)^{p-2} b_m^2 &\le r_m\, b_m + c_{11}\, b_m^{1-\theta} a_m^\theta b_{m-1} \\ &\le c_{11} \big(b_m^{2-\theta} + b_{m-1}^{2-\theta}\big) a_m^\theta + 2\, c_8^{-1}\, r_m^2 + \frac{c_8}{8}\, b_m^2. \end{aligned}$$

Now $b_1, \dots, b_M \le 1$, $0 < c_9 \le 1$, $0 < \theta \le 1$, $c_{11} \ge 1$, and Young's inequality imply

$$\begin{aligned} d_t a_m^2 + \frac{c_8}{2} b_m^2 &\le c_{11} \big(b_m^{2-\theta} + b_{m-1}^{2-\theta}\big) a_m^\theta + 2\, c_8^{-1} r_m^2 + \frac{c_8}{8} b_m^2 \\ &\le \frac{c_8}{8} \big(b_m^2 + b_{m-1}^2\big) + 2 \cdot 8^{\frac{2-\theta}{\theta}}\, c_8^{\frac{\theta-2}{\theta}}\, c_{11}^{\frac{2}{\theta}} a_m^2 + 2\, c_8^{-1} r_m^2. \end{aligned}$$

Taking the sum $m = 1, \dots, M$ with $a_0 = 0$ implies

$$a_M^2 + \frac{c_8}{4} k \sum_{k=1}^{M} b_m^2 \le 2\, c_8^{-1}\, k \sum_{k=1}^{M} r_m^2 + 2 \cdot 8^{\frac{2-\theta}{\theta}}\, c_8^{\frac{\theta-2}{\theta}} c_{11}^{\frac{2}{\theta}}\, k \sum_{k=1}^{M} a_m^2\,.$$

Let $k_6 := \frac{1}{2}\big(2 \cdot 8^{\frac{2-\theta}{\theta}}\, c_8^{\frac{\theta-2}{\theta}} c_{11}^{\frac{2}{\theta}}\big)^{-1}$. Then for $0 < k < k_6$ we absorb $k\, 2 \cdot 8^{\frac{2-\theta}{\theta}}\, c_8^{\frac{\theta-2}{\theta}} c_{11}^{\frac{2}{\theta}} a_M^2 < \frac{1}{2} a_M^2$ on the left-hand side. Thus

$$a_M^2 + \frac{c_8}{2} k \sum_{k=1}^{M} b_m^2 \le \frac{4}{c_8}\, k \sum_{k=1}^{M} r_m^2 + 2 \cdot 8^{\frac{2-\theta}{\theta}}\, c_8^{\frac{\theta-2}{\theta}} c_{11}^{\frac{2}{\theta}}\, k \sum_{k=1}^{M-1} a_m^2.$$

An application of Gronwall's lemma implies

$$a_M^2 + \frac{c_8}{2} k \sum_{m=0}^{M} b_m \le \left(\frac{4}{c_8} k \sum_{m=0}^{M} r_m^2 \right) \exp\left(2 \cdot 8^{\frac{2-\theta}{\theta}} c_8^{\frac{\theta-2}{\theta}} c_{11}^{\frac{2}{\theta}} kM \right)$$
$$\le \frac{4\, c_7}{c_8}\, k^{2\beta} \exp\left(2 \cdot 8^{\frac{2-\theta}{\theta}} c_8^{\frac{\theta-2}{\theta}} c_{11}^{\frac{2}{\theta}}\, kM \right).$$

Let $c_{12} := 8\, c_7\, c_8^{-1}$ and $c_{13} := 2 \cdot 8^{\frac{2-\theta}{\theta}} c_8^{\frac{\theta-2}{\theta}} c_{11}^{\frac{2}{\theta}}$; then

$$a_M^2 + c_8\, k \sum_{m=0}^{M} b_m \le c_{12} k^{2\beta} \exp(c_{13} kM).$$

This proves (3.15). The choice $k_4 := \min(k_5, k_6)$ concludes the lemma. ∎

4. Proof of Theorems 1.3 and 1.4. In this section we will show that the solution $\mathbf{u}^m$ of system (NS_p^k) is not only a weak solution but a strong solution. In particular, we will derive some a priori estimates of second derivatives of $\mathbf{u}^m$ which will be independent of the time step size k (as long as $k \le k_1$). The results of this are summarized in Theorem 1.3.

Before we start with the derivation of the (global in time) a priori estimates of $\mathbf{u}^m$ we will show that each $\mathbf{u}^m$ has some higher regularity in space. This regularity in terms of norms crucially depends on the time step size k and the time step m. Nevertheless, we will need this in order to justify all the calculations later, in particular that all terms involved are finite.

LEMMA 4.1. *Let p, $\mathbf{f}$, and $\mathbf{u}_0$ be as in Theorem* 1.3. *Let $\mathbf{u}^m$ be the weak solution of system (NS_p^k) as in Lemma* 3.1. *Then for all $m \in \{-1, 0, \dots, M\}$ it holds that*

$$k^{-1} \|\nabla \mathbf{u}^m\|_2^2 + \mathcal{I}_p(\mathbf{u}^m) \le c(m, k^{-1}) < \infty. \tag{4.1}$$

Proof. We proceed by induction of m. For each time index m the function $\mathbf{u}^m$ is just the solution of a stationary quasi–Stokes-like system equipped with periodic boundary conditions

$$\begin{aligned} \frac{1}{k}\mathbf{u}^m - \operatorname{div} \mathbf{S}(\mathbf{D}\mathbf{u}^m) + [\nabla \mathbf{u}^m]\mathbf{u}^{m-1} &= \mathbf{f}^m + \frac{1}{k}\mathbf{u}^{m-1}, \\ \operatorname{div} \mathbf{u}^m &= 0. \end{aligned} \tag{4.2}$$

Either by means of the difference quotient method or by a Galerkin approach with eigenfunctions of the Stokes operator, it is possible to justify the formal use of $-\Delta \mathbf{u}^m$ as a test function of (4.2). As in [13] this implies

$$\tfrac{1}{2} d_t \|\nabla \mathbf{u}^m\|_2^2 + C_1\, \mathcal{I}_p(\mathbf{u}^m) \le c(\mathbf{f}) + \int_\Omega |\nabla \mathbf{u}^m|^2\, |\nabla \mathbf{u}^{m-1}|\, dx. \tag{4.3}$$

Here we have used

$$\begin{aligned}\langle -\operatorname{div}\mathbf{S}(\mathbf{D}\mathbf{u}^m), -\Delta\mathbf{u}^m\rangle &= \sum_{i,j,k}\langle \partial_j S_{ij}(\mathbf{D}\mathbf{u}^m), \partial_k^2 u_i^m\rangle\\ &= \sum_{i,j,k}\langle \partial_k S_{ij}(\mathbf{D}\mathbf{u}^m), \partial_j\partial_k u_i^m\rangle\\ &= \sum_{i,j,k,l,m}\big\langle \partial_{ij}\partial_{lm}\Phi(|\mathbf{D}\mathbf{u}^m|)D_{ij}(\partial_k\mathbf{u}^m), D_{ij}(\partial_k\mathbf{u}^m)\big\rangle\\ &\geq C_1\int_\Omega (1+|\mathbf{D}\mathbf{u}^m|^2)^{\frac{p-2}{2}}|\mathbf{D}(\nabla\mathbf{u}^m)|^2\,dx \qquad \text{(by (1.1))}\\ &= C_1\,\mathcal{I}_p(\mathbf{u}^m)\end{aligned}$$

and

$$\begin{aligned}\big\langle [\nabla\mathbf{u}^m]\mathbf{u}^{m-1}, -\Delta\mathbf{u}^m\big\rangle &= \sum_{j,k,l}\big\langle \partial_j u_k^m u_k^{m-1}, \partial_l^2 u_k^m\big\rangle\\ &= \sum_{j,k,l}\big\langle \partial_j u_k^m \partial_l u_j^{m-1}, \partial_l u_k^m\big\rangle + \sum_{j,k,l}\int_\Omega \tfrac{1}{2}\partial_j\big((\partial_j u_k^m)^2\big)u_j^{m-1}\,dx\\ &= \sum_{j,k.l}\big\langle \partial_j u_k^m \partial_l u_j^{m-1}, \partial_l u_k^m\big\rangle \qquad \text{(by } \operatorname{div}\mathbf{u}^{m-1}=0)\\ &\leq \int_\Omega |\nabla\mathbf{u}^m|^2|\nabla\mathbf{u}^{m-1}|\,dx,\end{aligned}$$

where we have frequently used the periodicity. Now, Young's inequality and (2.8) imply

$$\begin{aligned}\int_\Omega |\nabla\mathbf{u}^m|^2|\nabla\mathbf{u}^{m-1}|\,dx &\leq \|\nabla\mathbf{u}^{m-1}\|_{3p}\|\nabla\mathbf{u}^m\|^2_{\frac{6p}{3p-1}}\\ &\leq c\,\|\nabla\mathbf{u}^{m-1}\|_{3p}\|\nabla\mathbf{u}^m\|_p^{\frac{5p-7}{p}}\|\nabla\mathbf{u}^m\|^{\frac{7-3p}{p}}_{\frac{3p}{3-p}}\\ &\leq c_\delta\,\|\nabla\mathbf{u}^{m-1}\|_{3p}^{\frac{2p}{5p-7}}\|\nabla\mathbf{u}^m\|_p^2 + \delta\|\nabla\mathbf{u}^m\|^2_{\frac{3p}{3-p}}\\ &\leq c_\delta\,\|\nabla\mathbf{u}^{m-1}\|_{3p}^{\frac{2p}{5p-7}}\|\nabla\mathbf{u}^m\|_p^2 + \delta\,c\,\|\nabla^2\mathbf{u}^m\|_p^2\\ &\leq c_\delta\,\|\nabla\mathbf{u}^{m-1}\|_{3p}^{\frac{2p}{5p-7}}\|\nabla\mathbf{u}^m\|_p^2 + \delta\,c\,\mathcal{I}_p(\mathbf{u}^m).\end{aligned}$$

We absorb the last term on the left-hand side of (4.3) and get

$$\frac{1}{2}d_t\|\nabla\mathbf{u}^m\|_2^2 + C_1\,\mathcal{I}_p(\mathbf{u}^m) \leq c(\mathbf{f}) + c\,\|\nabla\mathbf{u}^{m-1}\|_{3p}^{\frac{2p}{5p-7}}\|\nabla\mathbf{u}^m\|_p^2.$$

From $\mathcal{I}_p(\mathbf{u}^{m-1})<\infty$, $\|\nabla\mathbf{u}^m\|_2<\infty$, and (2.9) we know that the right-hand side is finite. This proves the lemma. □

Note that estimate (4.1) depends on k^{-1} and m. Nevertheless, it will justify all of the following calculations. We will now get to the proof of Theorem 1.3.

Proof of Theorem 1.3. Let $\mathbf{u}^m$ be the weak solution of Lemma 3.1. We will show that $\mathbf{u}^m$ satisfies (1.7). Unfortunately, the proof of this cannot be reduced to a simple Gronwall argument but is rather subtle. Let q, r be such that $3<q<r<6(p-1)$.

By assumption (1.5) on $\mathbf{u}$ there exists $c_{14} = c_{14}(\mathbf{f}, \mathbf{u}_0) \geq 1$ such that for all M with $kM \leq T$ it holds that

$$\max_{0\leq m\leq M} \|\nabla \mathbf{u}(t_m)\|_p + \max_{0\leq m\leq M} \|\nabla \mathbf{u}(t_m)\|_r \leq c_{14}. \tag{4.4}$$

From Proposition 1.2, it follows that, for $k \leq k_1$, $\max_{0\leq m\leq M} \|\nabla \mathbf{e}^m\|_p \leq 1$ holds. This, together with $c_{14} \geq 1$ and (4.4), implies

$$\max_{0\leq m\leq M} \|\nabla \mathbf{u}^m\|_p \leq 2\, c_{14}. \tag{4.5}$$

We proceed by induction over M with step $M-1 \mapsto M$. Instead of (1.7) we will show step by step that $\mathbf{u}^m$ satisfies

$$\max_{0\leq m\leq M} \|\nabla \mathbf{u}^m\|_2^2 + k \sum_{m=0}^{M} \mathcal{I}_p(\mathbf{u}^m) \leq c_{15} = c_{15}(c_{14}, p), \tag{4.6a}$$

$$\max_{1\leq m\leq M} \|d_t \mathbf{u}^m\|_2^2 + k \sum_{m=1}^{M} \mathcal{K}_p(\mathbf{u}^m) \leq c_{16} = c_{16}(c_{14}, p), \tag{4.6b}$$

$$k \sum_{m=0}^{M} \big(\mathcal{I}_p(\mathbf{u}^m)\big)^{\frac{5p-6}{2-p}} \leq c_{17} = c_{17}(c_{14}, p), \tag{4.6c}$$

$$\max_{0\leq m\leq M} \|\nabla \mathbf{u}^m\|_r \leq c_{18} = c_{18}(c_{14}, p), \tag{4.6d}$$

$$\max_{0\leq m\leq M} \|\nabla \mathbf{u}(t_m) - \nabla \mathbf{u}^m\|_q \leq c_{14}, \tag{4.6e}$$

$$\max_{0\leq m\leq M} \|\nabla \mathbf{u}^m\|_q \leq 2\, c_{14}. \tag{4.6f}$$

Obviously, by $\mathbf{u}(0) = \mathbf{u}^0 = \mathbf{u}_0$ and the assumptions on $\mathbf{u}_0$ and $p \leq 2$, inequalities (4.6) are valid for $M = 0$. Note that due to (2.16) the inequality (4.6f) seems to contain less information than (4.6b) and (4.6c). The point here is that c_{14} is much smaller than c_{17} and is given in advance by (1.5). In the proof of (4.6a), (4.6b), and (4.6e) we will need some smallness of the step size k, which is dependent on c_{14} and c_1. Therefore, we assume $0 < k \leq k_7(c_{14}, c_1, k_1)$, where c_1 and k_1 are from Proposition 1.2. The exact dependence of k_5 on c_{14}, c_1, and k_1 is given later. The proof of (4.6e) will further rely on the error estimates of Proposition 1.2. We will prove (4.6a)–(4.6f) in the same order as stated. Assume in the following that (4.6) holds for $M-1$. From Lemma 4.1 we further know that $\mathbf{u}^m$ has enough regularity to justify the calculations below.

Proof of (4.6a). Using the test function $-\Delta \mathbf{u}^m$ for the system (NS_p^k) we conclude as in the proof of (4.3) in Lemma 4.1 that

$$\begin{aligned} \tfrac{1}{2} d_t \|\nabla \mathbf{u}^m\|_2^2 + C_1\, \mathcal{I}_p(\mathbf{u}^m) &\leq c(\mathbf{f}) + \int_\Omega |\nabla \mathbf{u}^m|^2 |\nabla \mathbf{u}^{m-1}|\, dx \\ &\leq c(\mathbf{f}) + \|\nabla \mathbf{u}^m\|_3^2 \|\nabla \mathbf{u}^{m-1}\|_3. \end{aligned} \tag{4.7}$$

Since $2 < 3 < \frac{3p}{3-p}$, there exists $\theta = \theta(p) \in (0,1)$ with $L^3(\Omega) = [L^2(\Omega), L^{\frac{3p}{3-p}}(\Omega)]_{[\theta]}$.

This and (4.6f) for $M-1$ imply

$$\begin{aligned}\frac{1}{2}d_t\|\nabla\mathbf{u}^m\|_2^2+C_1\,\mathcal{I}_p(\mathbf{u}^m)&\le c(\mathbf{f})+c_{14}\,\|\nabla\mathbf{u}^m\|_3^2\\&\le c(\mathbf{f})+c_{14}\,\|\nabla\mathbf{u}^m\|_2^{2(1-\theta)}\|\nabla\mathbf{u}^m\|_{\frac{3p}{3-p}}^{2\theta}\\&\le c(\mathbf{f})+c(c_{14},p,\varepsilon)\,\|\nabla\mathbf{u}^m\|_2^2+\varepsilon\|\nabla\mathbf{u}^m\|_{\frac{3p}{3-p}}^2,\end{aligned}\tag{4.8}$$

with $\varepsilon>0$. From (2.8) with $s=p$ and (4.5) follows

$$\frac{1}{2}d_t\|\nabla\mathbf{u}^m\|_2^2+C_1\,\mathcal{I}_p(\mathbf{u}^m)\le c(\mathbf{f})+c(c_{14},p,\varepsilon)\,\|\nabla\mathbf{u}^m\|_2^2+\varepsilon\,\mathcal{I}_p(\mathbf{u}^m)\,(1+2\,c_{14})^{2-p}.$$

For small ε we obtain

$$d_t\|\nabla\mathbf{u}^m\|_2^2+C_1\,\mathcal{I}_p(\mathbf{u}^m)\le c(\mathbf{f})+c(c_{14},p)\|\nabla\mathbf{u}^m\|_2^2.\tag{4.9}$$

Now, Gronwall's inequality provides the existence of $k_8=k_8(c_{14},p)$ and $c_{15}=c_{15}(c_{14},p)$ such that (4.6a) holds, provided that $k_7\le k_8$.

Proof of (4.6b). We want to use the test function $d_t\mathbf{u}^M$. In order to give $d_t\mathbf{u}^0$ a meaning we introduce $\mathbf{u}^{-1}$. For that we set for all $\boldsymbol{\varphi}\in\mathcal{V}$

$$\frac{1}{k}\langle\mathbf{u}^0-\mathbf{u}^{-1},\boldsymbol{\varphi}\rangle+\big\langle\mathbf{S}(\mathbf{D}(\mathbf{u}^0)),\mathbf{D}(\boldsymbol{\varphi})\big\rangle+\langle[\nabla\mathbf{u}^0]\mathbf{u}^0,\boldsymbol{\varphi}\rangle=\langle\mathbf{f}(0),\boldsymbol{\varphi}\rangle.$$

Using $\mathbf{u}^0=\mathbf{u}_0$, $p\le 2$, and the assumption on $\mathbf{u}_0$, we obtain

$$\|d_t\mathbf{u}^0\|_2^2\le\|\mathbf{f}(0)\|_2^2+\|[\nabla\mathbf{u}_0]\mathbf{u}_0\|_2^2+\big\|\operatorname{div}\mathbf{S}(\mathbf{D}(\mathbf{u}_0))\big\|_2^2\le c(\mathbf{f},\mathbf{u}_0).\tag{4.10}$$

Now we can take the discrete time derivative of the weak formulation (NS_p^k), use $d_t\mathbf{u}^m$ as a test function, and sum up to obtain

$$\begin{aligned}&\|d_t\mathbf{u}^M\|_2^2+k^{-1}\sum_{m=1}^M\big\langle\mathbf{S}(\mathbf{D}\mathbf{u}^m)-\mathbf{S}(\mathbf{D}\mathbf{u}^{m-1}),\mathbf{D}\mathbf{u}^m-\mathbf{D}\mathbf{u}^{m-1}\big\rangle\\&\quad\le c(\mathbf{f},\mathbf{u}_0)+c\,k\sum_{m=1}^M\big|\big\langle d_t\big([\nabla\mathbf{u}^m]\mathbf{u}^{m-1}\big),d_t\mathbf{u}^m\big\rangle\big|\\&\quad\le c(\mathbf{f},\mathbf{u}_0)+c\,k\sum_{m=1}^M\big|\big\langle[\nabla\mathbf{u}^{m-1}]d_t\mathbf{u}^{m-1},d_t\mathbf{u}^m\big\rangle\big|,\end{aligned}$$

where we used (4.10), $d_t\big([\nabla\mathbf{u}^m]\mathbf{u}^{m-1}\big)=[d_t\nabla\mathbf{u}^m]\mathbf{u}^{m-1}+[\nabla\mathbf{u}^{m-1}]d_t\mathbf{u}^{m-1}$, and $\langle[d_t\nabla\mathbf{u}^m]\mathbf{u}^{m-1},d_t\mathbf{u}^m\rangle=0$ as $\operatorname{div}\mathbf{u}^{m-1}=0$. From (2.5) and the definition of $\mathcal{K}_p$ we deduce

$$\big\langle\mathbf{S}(\mathbf{D}\mathbf{u}^m)-\mathbf{S}(\mathbf{D}\mathbf{u}^{m-1}),\mathbf{D}\mathbf{u}^m-\mathbf{D}\mathbf{u}^{m-1}\big\rangle\ge c\,k^2\,\mathcal{K}_p(\mathbf{u}^m).$$

Overall,

$$\begin{aligned}\|d_t\mathbf{u}^M\|_2^2+k\sum_{m=1}^M\mathcal{K}_p(\mathbf{u}^m)&\le c(\mathbf{f},\mathbf{u}_0)+c\,k\sum_{m=1}^M\big|\big\langle[\nabla\mathbf{u}^{m-1}]d_t\mathbf{u}^{m-1},d_t\mathbf{u}^m\big\rangle\big|\\&\le c(\mathbf{f},\mathbf{u}_0)+c\,k\sum_{m=1}^M\|\nabla\mathbf{u}^{m-1}\|_3\|d_t\mathbf{u}^{m-1}\|_3\|d_t\mathbf{u}^m\|_3.\end{aligned}$$

Thus, by $q > 3$ and (4.6f) for $M-1$ follows

$$\|d_t \mathbf{u}^M\|_2^2 + k \sum_{m=1}^{M} \mathcal{K}_p(\mathbf{u}^m) \le c(\mathbf{f}, \mathbf{u}_0) + c\, c_{14}\, k \sum_{m=1}^{M} \|d_t \mathbf{u}^{m-1}\|_3 \|d_t \mathbf{u}^m\|_3.$$

Analogously to the step from (4.7) to (4.8) we get

$$\|d_t \mathbf{u}^M\|_2^2 + k \sum_{m=1}^{M} \mathcal{K}_p(\mathbf{u}^m) \le c(\mathbf{f}, \mathbf{u}_0) + c(c_{14}, p, \varepsilon)\, k \sum_{m=1}^{M} \big(\|d_t \mathbf{u}^{m-1}\|_2^2 + \|d_t \mathbf{u}^m\|_2^2\big) + \varepsilon\, k \sum_{m=1}^{M} \|d_t \mathbf{u}^m\|_{\frac{3p}{3-p}}^2.$$

From (2.13) with $s = p$ and (4.5) follows

$$\|d_t \mathbf{u}^M\|_2^2 + k \sum_{m=1}^{M} \mathcal{K}_p(\mathbf{u}^m) \le c(\mathbf{f}, \mathbf{u}_0) + c(c_{14}, p, \varepsilon)\, k \sum_{m=1}^{M} \big(\|d_t \mathbf{u}^{m-1}\|_2^2 + \|d_t \mathbf{u}^m\|_2^2\big) + \varepsilon\, k \sum_{m=1}^{M} \mathcal{K}_p(\mathbf{u}^m)\, (1 + 2\, c_{14})^{2-p}.$$

For small ε we obtain

(4.11)
$$\|d_t \mathbf{u}^M\|_2^2 + k \sum_{m=1}^{M} \mathcal{K}_p(\mathbf{u}^m) \le c(\mathbf{f}, \mathbf{u}_0) + c(c_{14}, p, \varepsilon)\, k \sum_{m=1}^{M} \big(\|d_t \mathbf{u}^{m-1}\|_2^2 + \|d_t \mathbf{u}^m\|_2^2\big).$$

Now, Gronwall's inequality provides the existence of $k_9 = k_9(c_{14}, p)$ and $c_{16} = c_{16}(c_{14}, p)$ such that (4.6b) holds, provided that $k_7 \le k_9$.

Proof of (4.6c). As in the proof of (4.6a) we use $-\Delta \mathbf{u}^m$ as a test function. But, instead of retrieving information from the term $\langle d_t \mathbf{u}^m, \Delta \mathbf{u}^m \rangle$ as in the proof of (4.6a), will we estimate it on the right-hand side. In particular, instead of (4.9) we get

$$\begin{aligned} C_1\, \mathcal{I}_p(\mathbf{u}^m) &\le c(\mathbf{f}) + c(c_{14}, p) \|\nabla \mathbf{u}^m\|_2^2 + \big|\langle d_t \mathbf{u}^m, \Delta \mathbf{u}^m \rangle\big| \\ &\le c(\mathbf{f}) + c(c_{14}, p) + \big|\langle d_t \mathbf{u}^m, \Delta \mathbf{u}^m \rangle\big|, \end{aligned} \tag{4.12}$$

where we have used (4.6a). We will proceed as in [4], [16]:

$$\big|\langle d_t \mathbf{u}^m, \Delta \mathbf{u}^m \rangle\big| \le \|d_t \mathbf{u}^m\|_{\frac{3p}{2p-1}} \|\nabla^2 \mathbf{u}^m\|_{\frac{3p}{p+1}} \le c\, \|d_t \mathbf{u}^m\|_{\frac{3p}{2p-1}} \big(1 + \mathcal{I}_p(\mathbf{u}^m)\big)^{\frac{1}{p}},$$

where we used (2.9). With (4.12) we get

$$\big(1 + \mathcal{I}_p(\mathbf{u}^m)\big)^{\frac{p-1}{p}} \le c(c_{14}, p) \big(1 + \|d_t \mathbf{u}^m\|_{\frac{3p}{2p-1}}\big).$$

Now, we interpolate $L^{\frac{3p}{2p-1}}(\Omega)$ between $L^2(\Omega)$ and $L^{3p}(\Omega)$ and use (4.6b) and (2.14) to arrive at

$$\big(1 + \mathcal{I}_p(\mathbf{u}^m)\big)^{\frac{p-1}{p}} \le c(c_{14}, p) \Big(1 + \mathcal{K}_p(\mathbf{u}^m)^{\frac{\lambda}{2}} \big(1 + \mathcal{I}_p(\mathbf{u}^m) + \mathcal{I}_p(\mathbf{u}^{m-1})\big)^{\lambda\, \frac{2-p}{2p}}\Big),$$

with $\lambda = \frac{2-p}{3p-2}$. We raise this inequality to the power γ and apply Young's inequality to get

$$\begin{aligned}
&(1+\mathcal{I}_p(\mathbf{u}^m)\,)^{\gamma\,\frac{p-1}{p}}\\
&\quad\le c(c_{14},p)\left(1+\mathcal{K}_p(\mathbf{u}^m)^{\gamma\,\frac{\lambda}{2}}(1+\mathcal{I}_p(\mathbf{u}^m)+\mathcal{I}_p(\mathbf{u}^{m-1})\,)^{\gamma\,\lambda\,\frac{2-p}{2p}}\right)\\
&\quad\le c(c_{14},p)\left(1+c_\varepsilon\mathcal{K}_p(\mathbf{u}^m)+\varepsilon\big(1+\mathcal{I}_p(\mathbf{u}^m)+\mathcal{I}_p(\mathbf{u}^{m-1})\,\big)^{\frac{2\gamma\,\lambda}{2-\gamma\lambda}\,\frac{2-p}{2p}}\right). \qquad (4.13)
\end{aligned}$$

We now require

$$\gamma\frac{p-1}{p}=\frac{2\gamma\,\lambda}{2-\gamma\lambda}\frac{2-p}{2p},$$

which gives $\gamma=\frac{p}{p-1}\frac{5p-6}{2-p}$. With this γ and with ε sufficiently small we can absorb the last term in (4.13) into the left-hand side after summation over all time steps. Thus, we have derived

$$k\sum_{m=1}^{M}\mathcal{I}_p(\mathbf{u}^m)^{\frac{5p-6}{2-p}}\le c(c_{14},p)\left(1+k\sum_{m=1}^{M}\mathcal{K}_p(\mathbf{u}^m)\right)\le c(c_{14},p),$$

where we have used (4.6b). This proves (4.6c).

Proof of (4.6d). This is a direct consequence of (2.16), (4.6b), and (4.6c).

Proof of (4.6e). From (4.4) and (4.6d) we deduce

$$\max_{0\le m\le M}\|\nabla\mathbf{u}(t_m)-\nabla\mathbf{u}^m\|_r\le c(c_{14},p). \qquad (4.14)$$

On the other hand from (1.6) we know that

$$\max_{0\le m\le M}\|\nabla\mathbf{u}(t_m)-\nabla\mathbf{u}^m\|_p\le c_1\,k^{\frac{4p-6}{2p}}\le c_1\,k^{\frac{2p-3}{p}} \qquad (4.15)$$

for $p\in(\frac{3}{2},2]$. Since $p<q<r$, there exists by interpolation of (4.14) and (4.15) some $k_{10}=k_{10}(p,c_{14})>0$ such that

$$\max_{0\le m\le M}\|\nabla\mathbf{u}(t_m)-\nabla\mathbf{u}^m\|_q\le c_{14}$$

as long as $k\le k_{10}$. This proves (4.6e).

Proof of (4.6f). By (4.4) and $p<q<r$ there follows by interpolation

$$\max_{0\le m\le M}\|\nabla\mathbf{u}(t_m)\|_q\le c_{14}.$$

This and (4.6e) immediately imply (4.6f).

The proof of Theorem 1.3 is complete. □

Based on Theorem 1.3 we can now improve the convergence rate from Proposition 1.2.

Proof of Theorem 1.4. We will proceed as in the proof of Proposition 1.2. However, due to the better regularity properties of $\mathbf{u}^m$ we can extract more information from the second term on the left-hand side in (3.4). Namely, from Remark 2.2, with $r\in(p,6(p-1))$, (1.5), and (1.8) we deduce instead of (3.5)

$$\frac{1}{2}d_t\|\mathbf{e}^m\|_2^2+c_{19}\left(\|\nabla\mathbf{e}^m\|_p^2+\|\nabla\mathbf{e}^m\|^2_{\frac{2r}{2-p+r}}\right)\le c\left(K_1^m+K_2^m+K_3^m\right). \qquad (4.16)$$

Now we set instead of (3.6)

$$
\begin{aligned}
a_m &:= \|\mathbf{e}^m\|_2,\\
\widetilde{b}_m &:= \|\nabla \mathbf{e}^m\|_p + \|\nabla \mathbf{e}^m\|_{\frac{2r}{2-p+r}},\\
\widetilde{r}_m &:= c\left(\|\mathbf{R}^m\|_{-1,(\frac{2r}{2-p+r})'} + k\,\|d_t\mathbf{u}(t_m)\|_{\frac{12}{8-3p}}\right),\\
\beta = \beta(p,r) &:= \frac{2r+3p-6}{2r},
\end{aligned}
\tag{4.17}
$$

and want to use Lemma 3.2 with b_m replaced by $\widetilde{b}_m$ and r_m replaced by $\widetilde{r}_m$. Note that

$$b_m \le \widetilde{b}_m$$

since $r > p$. Thus we can replace in all estimates in the proof of Proposition 1.2 the term b_m by $\widetilde{b}_m$. In order to show that $\widetilde{r}_m$ satisfies (3.14) we use the embedding

$$
\begin{aligned}
&[l^2(I_k;W^{-1,2}(\Omega)), l^\infty(I_k;L^2(\Omega))]_{[\frac{2r+3p-6}{2r}]}\\
&\quad\hookrightarrow [l^2(I_k;W^{-1,2}(\Omega)), l^\infty(I_k;W^{-1,6}(\Omega))]_{[\frac{2r+3p-6}{2r}]}\\
&\quad\hookrightarrow l^{\frac{4r}{2r+3p-6}}(I_k;W^{-1,(\frac{2r}{2-p+r})'}(\Omega))\\
&\quad\hookrightarrow l^2(I_k;W^{-1,(\frac{2r}{2-p+r})'}(\Omega))
\end{aligned}
$$

and (3.2) to show that

$$
\begin{aligned}
\|\mathbf{R}^m\|_{l^2(I_k;W^{-1,p'}(\Omega))} &\le c\,\|\mathbf{R}^m\|_{[l^2(I_k;W^{-1,2}(\Omega)),l^\infty(I_k,L^2(\Omega))]_{[\frac{2r+3p-6}{2r}]}}\\
&\le c\,\|\mathbf{R}^m\|_{l^\infty(I_k;L^2(\Omega))}^{\frac{6-3p}{2r}}\|\mathbf{R}^m\|_{l^2(I_k;W^{1,2}(\Omega)^*)}^{\frac{2r+3p-6}{2r}}\\
&\le c\,k^{\frac{2r+3p-6}{2r}} = c\,k^{\beta(p,r)}.
\end{aligned}
\tag{4.18}
$$

From this and (3.8) follows

$$
\begin{aligned}
k\sum_{m=1}^M \widetilde{r}_m^2 &\le c\left(\|\mathbf{R}^m\|^2_{l^2(I_k;W^{-1,(\frac{2r}{2-p+r})'}(\Omega))} + k^2\,\|d_t\mathbf{u}(t_m)\|^2_{l^2(I_k;L^{\frac{12}{8-3p}}(\Omega))}\right)\\
&\le c\,k^{\frac{2r+3p-6}{r}} + c\,k^2 \le c\,k^{2\beta(p,r)}.
\end{aligned}
$$

This proves (3.14). Thus Lemma 3.2 in particular implies

$$\max_{0\le m\le M}\|\nabla\mathbf{e}^m\|_p \le 1,$$

$$\max_{0\le m\le M}\|\mathbf{e}_m\|_2^2 + c_{19}\,k\sum_{m=0}^M\|\nabla\mathbf{e}^m\|_p^2 \le c\,k^{2\beta(p,r)}\exp(c\,T).$$

Since

$$\lim_{r\to 6(p-1)}\beta(p,r) = \alpha_0(p) = \frac{5p-6}{4(p-1)},$$

the proof of Theorem 1.4 is complete. □

PERFECTLY MATCHED LAYERS FOR TIME-HARMONIC ACOUSTICS IN THE PRESENCE OF A UNIFORM FLOW*

E. BÉCACHE†, A.-S. BONNET-BEN DHIA‡, AND G. LEGENDRE‡§

Abstract. This paper is devoted to the resolution of the time-harmonic linearized Galbrun equation, which models, via a mixed Lagrangian–Eulerian representation, the propagation of acoustic and hydrodynamic perturbations in a given flow of a compressible fluid. We consider here the case of a uniform subsonic flow in an infinite, two-dimensional duct. Using a limiting absorption process, we characterize the outgoing solution radiated by a compactly supported source. Then we propose a Fredholm formulation with perfectly matched absorbing layers for approximating this outgoing solution. The convergence of the approximated solution to the exact one is proved, and error estimates with respect to the parameters of the absorbing layers are derived. Several significant numerical examples are included.

Key words. aeroacoustics, Galbrun's equation, limiting absorption principle, perfectly matched layers, acoustic waveguide, modal decomposition

1. Introduction.

Several industrial applications are concerned with the propagation of acoustic waves in a moving fluid. Aeronautics, for instance, requires accurate simulations of acoustic radiation in the presence of a flow in order to design efficient devices for noise reduction. In this context, most of the numerical simulations consist of solving in the time domain the hyperbolic system of linearized Euler equations using finite difference schemes or, more recently, discontinuous Galerkin methods. The computational domain being necessarily finite, artificial boundary conditions are needed, and the perfectly matched layers (PMLs), introduced by Bérenger [3] in computational electromagnetics, have already been used to this end, raising some specific difficulties related to instabilities [14, 13, 19, 1, 15].

The present work differs from the previous ones as it considers the time-harmonic regime and aims at developing a finite element approach.

We use a model introduced by Galbrun [8, 18], which assumes small perturbations of an isentropic flow of a perfect fluid and whose unknown is the Lagrangian displacement perturbation, expressed in terms of Eulerian variables with respect to the mean flow. It can be viewed as an alternative to the use of the linearized Euler equations, as the perturbations of density, velocity, and pressure can be retrieved from the knowledge of both the the Lagrangian displacement perturbation and the mean flow quantities [18]. The so-called Galbrun equation is a linear partial differential equation of second order in time and space and is well suited to variational approaches. However, its numerical solution by standard (i.e., nodal) finite element methods is subject to difficulties similar to those observed for Maxwell's equations

in electromagnetism. We previously proposed a regularized formulation of the time-harmonic Galbrun equation [5, 16] that allowed the use of nodal finite elements for the discretization of the problem.

The simple case of a uniform subsonic flow in an infinite two-dimensional duct is considered here, but the method should, in its principle, be extended to problems involving arbitrary flows and geometries. The two main difficulties we are confronted with when solving this problem in the time-harmonic regime are the characterization of its outgoing solution and its reduction to a bounded domain. We settle the first difficulty by a classical limiting absorption process and use a PML technique for the latter.

In a previous paper [2], we dealt with PMLs for the convected Helmholtz equation in a waveguide, and two different models of PML were analyzed: the "classical" Bérenger model and a modified model, designed to avoid a possible exponential spatial growth of the solution in the downstream layer (responsible for the instabilities in the time domain). For both models, we proved the well-posedness and convergence of the method. Yet, this last problem being scalar, acoustic waves were the only ones taken into account, whereas one of the difficulties when applying the PML technique in aeroacoustics lies in the appropriate treatment in the layers of the vorticity waves, which are convected downstream of the mean flow. In the present work, we will see that the regularization of Galbrun's equation leads to the addition of a noncompactly supported source term, accounting for the vortical effects of the flow, which will necessitate a proper, nonstandard treatment in the layers based on the modified PML model studied in [2].

The outline is the following. The problem to be solved is introduced in section 2. In section 3, a limiting absorption result is established. The problem with PML is posed and analyzed in section 4, and its convergence is subsequently proved in section 5 via the combined use of vector potentials and scalar modal analysis. Finally, numerical applications are presented in section 6.

2. The physical problem posed in an infinite waveguide. We consider Galbrun's formulation for the propagation of acoustic waves in an infinite, rigid, two-dimensional duct in the presence of a uniform mean flow of subsonic speed v_0. A time-harmonic dependence of the form $\exp(-\mathrm{i}\omega t)$, $\omega > 0$ being the pulsation, is assumed throughout the paper. The displacement perturbation then satisfies the equation and boundary condition

$$\mathrm{D}^2\boldsymbol{u} - \boldsymbol{\nabla}\,(\operatorname{div}\boldsymbol{u}) = \boldsymbol{f} \quad \text{in } \Omega, \tag{2.1}$$

$$\boldsymbol{u}\cdot\boldsymbol{n} = 0 \quad \text{on } \partial\Omega, \tag{2.2}$$

where Ω and $\partial\Omega$ denote, respectively, the infinite duct of height l and its rigid walls (i.e., $\Omega = \{(x_1, x_2) \in \mathbb{R}^2 \ ; \ 0 < x_2 < l\}$) and $\boldsymbol{n}$ is a unit outward normal to $\partial\Omega$. In (2.1), the letter D stands for the time-harmonic material derivative in the subsonic uniform flow, given by $\mathrm{D}\boldsymbol{u} = -\mathrm{i}k\,\boldsymbol{u} + M\,\partial_{x_1}\boldsymbol{u}$, where the scalar $k = \frac{\omega}{c_0}$ is the wave number and the scalar $M = \frac{v_0}{c_0}$ is the Mach number ($0 < M < 1$), c_0 being the sound velocity in the mean flow. Thus, in extended form, (2.1) reads

$$-k^2\,\boldsymbol{u} - 2\mathrm{i}kM\,\partial_{x_1}\boldsymbol{u} + M^2\,\partial_{x_1}^2\boldsymbol{u} - \boldsymbol{\nabla}\,(\operatorname{div}\boldsymbol{u}) = \boldsymbol{f} \quad \text{in } \Omega.$$

Note that the equation resulting from (2.1) when the fluid is at rest (i.e., when $M = 0$) arises in several fluid-structure interaction problems (see, for instance, [12]).

An additional hypothesis is made on the compactly supported source $\boldsymbol{f}$, which is assumed to admit the Helmholtz decomposition $\boldsymbol{f} = \boldsymbol{\nabla} g_a + \mathbf{curl}\, g_h$, where g_a and g_h are also compactly supported. From a physical point of view, the source term $\boldsymbol{f}$ is meant to contain an "acoustic" part g_a, which generates irrotational perturbations (i.e., pressure fluctuations), and a vortical part g_h, which creates hydrodynamic perturbations. Note here that $\mathbf{curl}\, f = \partial_{x_2} f\, \boldsymbol{e_1} - \partial_{x_1} f\, \boldsymbol{e_2}$, where $\boldsymbol{e_1}$ and $\boldsymbol{e_2}$ are the vectors of the canonical basis of $\mathbb{R}^2$, is the vectorial form of the curl operator when applied to scalar functions. We denote by $\operatorname{curl} \boldsymbol{v} = \partial_{x_1} v_2 - \partial_{x_2} v_1$ the dual form of this operator when applied to vector fields.

The source $\boldsymbol{f}$ is also assumed to belong to the space $H(\operatorname{curl}; \Omega)$, which implies some regularity on g_a and g_h ($g_a \in H^1(\Omega)$ and $g_h \in H^2(\Omega)$, for instance).

The problem (2.1)–(2.2) admits an infinite number of solutions as long as an additional condition at infinity is not given. We are interested in the unique solution associated with the time-harmonic regime. In the next section, we characterize this solution through the study of a dissipative problem and the use of the limiting absorption principle [7].

3. Well-posedness—The limiting absorption principle.

3.1. The dissipative problem. A dissipative problem associated with (2.1)–(2.2) is readily obtained by replacing the real wave number k by a complex number $k_\varepsilon = k + \mathrm{i}\varepsilon$, where ε is a positive real number. The physical case then becomes the limiting case in which ε is equal to zero. In what follows, we prove that the unique solution of "finite energy" (that is, which belongs to the space $H^1(\Omega)^2$) of the dissipative problem converges, as ε tends to zero, in the $H^1_{\mathrm{loc}}(\Omega)^2$ sense to a limit, which will be called the "outgoing" solution of (2.1)–(2.2).

3.2. Study of the dissipative problem. We seek a function $\boldsymbol{u}^\varepsilon$ in $H^1(\Omega)^2$ satisfying

$$\mathrm{D}_\varepsilon^2 \boldsymbol{u}^\varepsilon - \boldsymbol{\nabla}\,(\operatorname{div} \boldsymbol{u}^\varepsilon) = \boldsymbol{f} \quad \text{in } \Omega, \tag{3.1}$$

$$\boldsymbol{u}^\varepsilon \cdot \boldsymbol{n} = 0 \quad \text{on } \partial\Omega, \tag{3.2}$$

where $\mathrm{D}_\varepsilon = -\mathrm{i}k_\varepsilon + M\,\partial_{x_1}$. To be able to prove the well-posedness of this problem, it must be regularized, as proposed in [5]. To this end, we introduce the function $\psi^\varepsilon = \operatorname{curl} \boldsymbol{u}^\varepsilon$, belonging to $L^2(\Omega)$, which is a solution to the following ordinary differential equation with constant coefficients (obtained by taking the curl of (3.1)):

$$\mathrm{D}_\varepsilon^2 \psi^\varepsilon = \operatorname{curl} \boldsymbol{f} \quad \text{in } \Omega. \tag{3.3}$$

We first state a preliminary result.

LEMMA 3.1. *Equation* (3.3) *has a unique solution* ψ^ε *in* $L^2(\Omega)$. *This solution vanishes upstream of the support of the source* $\boldsymbol{f}$.

Proof. Introducing the causal Green's function of the differential operator D_ε^2,

$$G_\varepsilon(x_1) = \frac{x_1}{M^2} H(x_1)\, e^{\mathrm{i}\frac{k_\varepsilon}{M} x_1} \quad \forall x_1 \in \mathbb{R},$$

where H denotes the Heaviside function, one can derive the following particular solution to (3.3):

$$\psi^\varepsilon(x_1, x_2) = G_\varepsilon * \operatorname{curl} \boldsymbol{f}(\cdot, x_2)(x_1) = \frac{1}{M^2} \int_{-\infty}^{x_1} (x_1 - z)\, e^{\mathrm{i}\frac{k_\varepsilon}{M}(x_1 - z)} \operatorname{curl} \boldsymbol{f}(z, x_2)\, \mathrm{d}z.$$

We easily verify that this function vanishes upstream of the source and belongs to $L^2(\Omega)$ (see the appendix). Uniqueness of the solution follows from the fact that the solutions to the homogeneous equation $\mathrm{D}_\varepsilon^2\psi = 0$ are of the form

$$(c(x_2) + x_1\, d(x_2))\; e^{\mathrm{i}\frac{k_\varepsilon}{M}\, x_1} \qquad \forall (x_1, x_2) \in \Omega$$

and therefore do not belong to $L^2(\Omega)$, except for the trivial solution $c = d \equiv 0$. ∎

Now, if $\boldsymbol{u}^\varepsilon$ is a solution to (3.1)–(3.2), it clearly satisfies the so-called *regularized* or *augmented* problem

$$\begin{aligned} &\mathrm{D}_\varepsilon^2\boldsymbol{u}^\varepsilon - \boldsymbol{\nabla}\,(\operatorname{div}\boldsymbol{u}^\varepsilon) + \mathbf{curl}\;(\operatorname{curl}\boldsymbol{u}^\varepsilon - \psi^\varepsilon) = \boldsymbol{f} \quad \text{in } \Omega,\\ &\boldsymbol{u}^\varepsilon \cdot \boldsymbol{n} = 0 \quad \text{on } \partial\Omega,\\ &\operatorname{curl}\boldsymbol{u}^\varepsilon = \psi^\varepsilon \quad \text{on } \partial\Omega. \end{aligned} \tag{3.4}$$

Setting $V(\Omega) = \big\{\boldsymbol{v} \in H^1(\Omega)^2 \mid \boldsymbol{v}\cdot\boldsymbol{n} = 0 \text{ on } \partial\Omega\big\}$, a variational formulation of this last problem reads as follows: *find* $\boldsymbol{u}^\varepsilon \in V(\Omega)$ *such that*

$$a_\Omega(k_\varepsilon; \boldsymbol{u}^\varepsilon, \boldsymbol{v}) = \int_\Omega (\boldsymbol{f}\cdot\overline{\boldsymbol{v}} + \psi^\varepsilon(\operatorname{curl}\overline{\boldsymbol{v}}))\;\mathrm{d}\boldsymbol{x} \qquad \forall \boldsymbol{v} \in V(\Omega), \tag{3.5}$$

where the sesquilinear form $a_\Omega(k_\varepsilon;\cdot,\cdot)$ is defined by

$$\begin{aligned} a_\Omega(k_\varepsilon; \boldsymbol{u}, \boldsymbol{v}) = \int_\Omega \big((\operatorname{div}\boldsymbol{u})(\operatorname{div}\overline{\boldsymbol{v}}) + (\operatorname{curl}\boldsymbol{u})(\operatorname{curl}\overline{\boldsymbol{v}}) - M^2\,\partial_{x_1}\boldsymbol{u}\cdot\partial_{x_1}\overline{\boldsymbol{v}}\big)\;\mathrm{d}\boldsymbol{x}\\ + \int_\Omega \big(-{k_\varepsilon}^2\,\boldsymbol{u}\cdot\overline{\boldsymbol{v}} - 2\mathrm{i}k_\varepsilon M\,\partial_{x_1}\boldsymbol{u}\cdot\overline{\boldsymbol{v}}\big)\;\mathrm{d}\boldsymbol{x}. \end{aligned}$$

THEOREM 3.2. *The variational problem* (3.5) *is well-posed.*

Proof. Integrating by parts gives

$$\int_\Omega \partial_{x_1}\boldsymbol{u}\cdot\overline{\boldsymbol{u}}\,\mathrm{d}\boldsymbol{x} = -\int_\Omega \boldsymbol{u}\cdot\partial_{x_1}\overline{\boldsymbol{u}}\,\mathrm{d}\boldsymbol{x} = -\overline{\int_\Omega \partial_{x_1}\boldsymbol{u}\cdot\overline{\boldsymbol{u}}\,\mathrm{d}\boldsymbol{x}} \qquad \forall \boldsymbol{u} \in H^1(\Omega)^2;$$

hence $\int_\Omega \partial_{x_1}\boldsymbol{u}\cdot\overline{\boldsymbol{u}}\,\mathrm{d}\boldsymbol{x} \in \mathrm{i}\mathbb{R}$. We then have

$$\operatorname{Im}\left(-\frac{1}{k_\varepsilon}\,a_\Omega(k_\varepsilon;\boldsymbol{u},\boldsymbol{u})\right) = \int_\Omega \operatorname{Im}(k_\varepsilon)\left(|\boldsymbol{u}|^2 + \frac{|\operatorname{div}\boldsymbol{u}|^2 + |\operatorname{curl}\boldsymbol{u}|^2 - M^2\;|\partial_{x_1}\boldsymbol{u}|^2}{|k_\varepsilon|^2}\right)\mathrm{d}\boldsymbol{x}.$$

Since $M^2 < 1$ and $\operatorname{Im}(k_\varepsilon) > 0$, the sesquilinear form $a_\Omega(k_\varepsilon;\cdot,\cdot)$ is coercive on $H^1(\Omega)^2$, due to Theorem 4.1 of [6]. It is also clear that this form is continuous on the same space. Moreover, estimate (6.2) (see the appendix) allows one to establish the continuity of the antilinear form by simply using the Cauchy–Schwarz inequality. The well-posedness of problem (3.5) is then a consequence of the Lax–Milgram lemma. ∎

By construction, every solution to (3.1)–(3.2) belonging to $H^1(\Omega)$ is a solution to (3.5). The converse statement results from the following theorem.

THEOREM 3.3. *The solution* $\boldsymbol{u}^\varepsilon$ *to problem* (3.5) *is such that* $\operatorname{curl}\boldsymbol{u}^\varepsilon = \psi^\varepsilon$.

Proof. Taking as test function $\boldsymbol{v} = \mathbf{curl}\,\varphi$ with $\varphi \in \big\{\phi \in H^3(\Omega) \mid \phi_{|\partial\Omega} = 0\big\}$, we obtain, after some integration by parts and the use of boundary conditions of problem (3.5), the following orthogonality relation:

$$\int_\Omega (\operatorname{curl}\boldsymbol{u}^\varepsilon - \psi^\varepsilon)\,(\mathcal{H}_{k_\varepsilon,M}\overline{\varphi})\;\mathrm{d}\boldsymbol{x} = 0.$$

Here $\mathcal{H}_{k_\varepsilon,M}$ denotes the operator $\mathrm{D}_\varepsilon^2 - \Delta$. Owing to a density result (Theorem 1.6.2 of [11]), this relation holds for any function φ of $D(\mathcal{H}_{k_\varepsilon,M}) = H^2(\Omega) \cap H_0^1(\Omega)$. To conclude that $\operatorname{curl} \boldsymbol{u}^\varepsilon = \psi^\varepsilon$ in $L^2(\Omega)$, it suffices to show that $\mathcal{H}_{k_\varepsilon,M}$ is surjective from $D(\mathcal{H}_{k_\varepsilon,M})$ to $L^2(\Omega)$. For all φ in $D(\mathcal{H}_{k_\varepsilon,M})$, we have

$$(\mathcal{H}_{k_\varepsilon,M}\varphi,\varphi)_{L^2(\Omega)} = \int_\Omega \left(-{k_\varepsilon}^2\,|\varphi|^2 + 2\mathrm{i}k_\varepsilon M\,\partial_{x_1}\varphi\overline{\varphi} + |\boldsymbol{\nabla}\varphi|^2 - M^2\,\left|\partial_{x_1}\varphi\right|^2\right)\,\mathrm{d}\boldsymbol{x}.$$

Again, we have $\int_\Omega \partial_{x_1}\varphi\overline{\varphi}\,\mathrm{d}\boldsymbol{x} \in \mathrm{i}\mathbb{R}$, and we deduce that

$$\operatorname{Im}\left(-\frac{1}{k_\varepsilon}\,(\mathcal{H}_{k_\varepsilon,M}\varphi,\varphi)_{L^2(\Omega)}\right) = \int_\Omega \operatorname{Im}(k_\varepsilon)\left(|\varphi|^2 + \frac{|\boldsymbol{\nabla}\varphi|^2 - M^2\,\left|\partial_{x_1}\varphi\right|^2}{|k_\varepsilon|^2}\right)\,\mathrm{d}\boldsymbol{x}.$$

The surjectivity of the operator is then a consequence of the Lax–Milgram lemma. ∎

COROLLARY 3.4. *Problem* (3.1)–(3.2) *has a unique solution in* $H^1(\Omega)^2$ *which is the solution to problem* (3.5).

Proof. We choose $\boldsymbol{v} \in \mathscr{D}(\Omega)^2 \subset V(\Omega)$ in the variational formulation (3.5). Integration by parts and Theorem 3.3 imply that the unique solution $\boldsymbol{u}^\varepsilon$ to (3.5) verifies (3.1) in the distributional sense. The boundary condition (3.2) is also satisfied since $\boldsymbol{u}^\varepsilon \in V(\Omega)$. ∎

3.3. Convergence of the dissipative problem. We will prove in this subsection that, if k is not a cut-off wave number for acoustic modes, the solution $\boldsymbol{u}_\varepsilon$ to problem (3.5) converges to a limit $\boldsymbol{u}$ in $H^1_{\mathrm{loc}}(\Omega)^2$ as ε tends to zero. This limit is clearly a solution to (2.1)–(2.2) and, contrary to $\boldsymbol{u}_\varepsilon$, does not belong to $H^1(\Omega)^2$, since it does not decrease at infinity. The proof of convergence is based on a Helmholtz decomposition of the field $\boldsymbol{u}_\varepsilon$ and the use of convergence results for scalar problems.

3.3.1. Use of potentials. Let us consider the following problems: *find* $\varphi_a^\varepsilon \in H^1(\Omega)$ *such that*

$$\begin{aligned} &\mathrm{D}_\varepsilon^2\varphi_a^\varepsilon - \Delta\varphi_a^\varepsilon = g_a \quad \text{in } \Omega,\\ &\partial_{\boldsymbol{n}}\varphi_a^\varepsilon = 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{3.6}$$

and *find* $\varphi_h^\varepsilon \in L^2(\Omega)$ *such that*

$$\mathrm{D}_\varepsilon^2\varphi_h^\varepsilon = g_h \quad \text{in } \Omega. \tag{3.7}$$

Both problems are well-posed. Indeed, problem (3.6) has been studied in [4, Theorem 1], and the regularity of g_a and of the domain Ω imply that its solution φ_a^ε belongs to the space $H^2(\Omega)$. Problem (3.7) was dealt with in Lemma 3.1, the regularity of g_h implying that φ_h^ε is in $H^2(\Omega)$ (see the appendix). It then clearly ensues that the function $\boldsymbol{\nabla}\varphi_a^\varepsilon + \mathbf{curl}\,\varphi_h^\varepsilon$ is a solution to (3.1)–(3.2) (or equivalently to problem (3.5)), since $\boldsymbol{\nabla}\left(\mathrm{D}_\varepsilon^2\varphi_a^\varepsilon - \Delta\varphi_a^\varepsilon\right) + \mathbf{curl}\,\left(\mathrm{D}_\varepsilon^2\varphi_h^\varepsilon\right) = \boldsymbol{\nabla}g_a + \mathbf{curl}\,g_h = \boldsymbol{f}$ in Ω and $\partial_{\boldsymbol{n}}\varphi_a^\varepsilon + \mathbf{curl}\,\varphi_h^\varepsilon \cdot \boldsymbol{n} = 0$ on $\partial\Omega$ (the function g_h being compactly supported, φ_h^ε vanishes on the boundary $\partial\Omega$, which implies that $\mathbf{curl}\,\varphi_h^\varepsilon \cdot \boldsymbol{n} = 0$ on $\partial\Omega$). Hence, the uniqueness of the solution to (3.5) implies that

$$\boldsymbol{u}^\varepsilon = \boldsymbol{\nabla}\varphi_a^\varepsilon + \mathbf{curl}\,\varphi_h^\varepsilon. \tag{3.8}$$

We now prove the convergence of the respective solutions to problems (3.6) and (3.7) as ε tends to zero.

3.3.2. Limit and convergence of the acoustic problem. In order to obtain the limit in $H^2_{\rm loc}(\Omega)$ of φ_a^ε as ε tends to zero, we use some theoretical results previously established in [4] for scalar problems of the same type. First, problem (3.6) is equivalently set in a bounded domain Ω_b, which contains the supports of g_a and g_h and is situated in between the two vertical boundaries $\Sigma_\pm$, respectively located at $x_1 = x_\pm$. To this end, we make use of the Dirichlet-to-Neumann (DtN) operators $T_\pm^{N,\varepsilon} : H^{1/2}(\Sigma_\pm) \to H^{-1/2}(\Sigma_\pm)$ (the superscript N refers here to the Neumann boundary condition in problem (3.11)), defined by $T_\pm^{N,\varepsilon}\phi = \mp \mathrm{i} \sum_{n=0}^{+\infty} \beta_n^{\varepsilon\pm} \, (\phi, \mathrm{C}_n)_{L^2(\Sigma_\pm)} \, \mathrm{C}_n(x_2)$, where

$$\beta_n^{\varepsilon\pm} = \frac{-k_\varepsilon M \pm \sqrt{{k_\varepsilon}^2 - \frac{n^2\pi^2}{l^2}(1-M^2)}}{1-M^2}, \tag{3.9}$$

the square root being defined by $\sqrt{z} = \sqrt{|z|}\, e^{\mathrm{i}\frac{\arg(z)}{2}}$, $0 \le \arg(z) < 2\pi$, and where

$$\mathrm{C}_0(x_2) = \sqrt{\frac{1}{l}} \quad \text{and} \quad \mathrm{C}_n(x_2) = \sqrt{\frac{2}{l}} \cos\Big(\frac{n\pi}{l} x_2\Big) \ \ \forall n \in \mathbb{N}^*. \tag{3.10}$$

An equivalent formulation of problem (3.6) is then as follows: *find* $\varphi_a^\varepsilon \in H^1(\Omega_b)$ *such that*

$$\begin{aligned} &\mathrm{D}_\varepsilon^2 \varphi_a^\varepsilon - \Delta \varphi_a^\varepsilon = g_a \quad \textit{in } \Omega_b, \\ &\partial_{\boldsymbol{n}} \varphi_a^\varepsilon = 0 \quad \textit{on } \partial\Omega \cap \partial\Omega_b, \\ &\partial_{\boldsymbol{n}} \varphi_a^\varepsilon = -T_\pm^{N,\varepsilon} \varphi_a^\varepsilon \quad \textit{on } \Sigma_\pm. \end{aligned} \tag{3.11}$$

We now can formally derive a limiting problem for (3.11). Observe that, because of the definition of the complex square root, one has

$$\lim_{\varepsilon\to 0} \sqrt{{k_\varepsilon}^2 - \frac{n^2\pi^2}{l^2}(1-M^2)} = \begin{cases} \sqrt{k^2 - \dfrac{n^2\pi^2}{l^2}(1-M^2)} \in \mathbb{R}_+ & \text{if } k \ge \dfrac{n\pi}{l}\sqrt{1-M^2}, \\ \mathrm{i}\sqrt{\dfrac{n^2\pi^2}{l^2}(1-M^2) - k^2} \in \mathrm{i}\mathbb{R}_+ & \text{if } k < \dfrac{n\pi}{l}\sqrt{1-M^2}. \end{cases}$$

Hence, the respective limits $\beta_n^\pm \ \forall n \in \mathbb{N}$ of axial wave numbers $\beta_n^{\varepsilon\pm}$ are defined by

$$\beta_n^\pm = \begin{cases} \dfrac{-kM \pm \sqrt{k^2 - \frac{n^2\pi^2}{l^2}(1-M^2)}}{1-M^2} & \text{if } k \ge \dfrac{n\pi}{l}\sqrt{1-M^2}, \\ \dfrac{-kM \pm \mathrm{i}\sqrt{\frac{n^2\pi^2}{l^2}(1-M^2) - k^2}}{1-M^2} & \text{if } k < \dfrac{n\pi}{l}\sqrt{1-M^2}. \end{cases} \tag{3.12}$$

The limiting problem to be considered is then as follows: *find* $\varphi_a \in H^1(\Omega_b)$ *such that*

$$\begin{aligned} &\mathrm{D}^2 \varphi_a - \Delta \varphi_a = g_a \quad \textit{in } \Omega_b, \\ &\partial_{\boldsymbol{n}} \varphi_a = 0 \quad \textit{on } \partial\Omega \cap \partial\Omega_b, \\ &\partial_{\boldsymbol{n}} \varphi_a = -T_\pm^N \varphi_a \quad \textit{on } \Sigma_\pm, \end{aligned} \tag{3.13}$$

with the following obvious definition for the DtN operators $T_\pm^N : H^{1/2}(\Sigma_\pm) \to H^{-1/2}(\Sigma_\pm)$, $T_\pm^N \phi = \mp \mathrm{i} \sum_{n=0}^{+\infty} \beta_n^\pm \, (\phi, \mathrm{C}_n)_{L^2(\Sigma_\pm)} \, \mathrm{C}_n(x_2)$.

THEOREM 3.5. *Problem* (3.13) *is well-posed, except if* $k = k_n$ *for* $n \in \mathbb{N}$, *with* $k_n = \sqrt{1-M^2}\,\frac{n\pi}{l}$.

A proof of this theorem is available in [2, Theorem 2.2]. The scalars k_n, $n \in \mathbb{N}$, are called the cut-off wave numbers of the modes. We are now in a position to prove a convergence result for problem (3.6).

THEOREM 3.6. *If $k \neq k_n$ $\forall n \in \mathbb{N}$, the solution φ_a^ε to problem* (3.6) *tends in $H^2(\Omega_b)$ to φ_a as ε tends to zero, φ_a being the solution to* (3.13).

Proof. Theorem 4 of [4] gives the convergence of φ_a^ε to φ_a in $H^1(\Omega_b)$. We then have $(1-M^2)\,\partial_{x_1}^2\varphi_a^\varepsilon + \partial_{x_2}^2\varphi_a^\varepsilon \underset{\varepsilon\to 0}{\longrightarrow} (1-M^2)\,\partial_{x_1}^2\varphi_a + \partial_{x_2}^2\varphi_a$ in $L^2(\Omega_b)$. The domain Ω_b being convex, we deduce $\varphi_a^\varepsilon \underset{\varepsilon\to 0}{\longrightarrow} \varphi_a$ in $H^2(\Omega_b)$ (see [10]). ∎

3.3.3. Limit and convergence of the hydrodynamic problem. The solution to problem (3.7) is explicitly given by the convolution product $\varphi_h^\varepsilon(x_1,x_2) = G_\varepsilon * g_h(.,x_2)(x_1)\ \forall (x_1,x_2) \in \Omega$, where the kernel G_ε denotes the causal Green's function of the differential operator D_ε^2. Introducing $G(x_1) = \frac{x_1}{M^2} H(x_1)\, e^{\mathrm{i}\frac{k}{M}x_1}\ \forall x_1 \in \mathbb{R}$ as the formal limit of G_ε as ε tends to zero, one can show that G_ε converges to G in $L^2_{\mathrm{loc}}(\mathbb{R})$. Consider now $\varphi_h(x_1,x_2) = G * g_h(.,x_2)(x_1)$, which is a solution to the limiting problem *find $\varphi_h \in L^2_{loc}(\Omega)$ such that*

$$\mathrm{D}^2\varphi_h = g_h \quad \text{in } \Omega. \tag{3.14}$$

One has $|\varphi_h^\varepsilon - \varphi_h| = |(G_\varepsilon - G) * g_h(.,x_2)|\ \forall x_2 \in [0,l]$, and, using the Cauchy–Schwarz inequality,

$$\|\varphi_h^\varepsilon - \varphi_h\|_{L^2(\Omega_b)} \leq \left(\int_{x_-}^{x_+} |G_\varepsilon(z) - G(z)|^2 \,\mathrm{d}z \right)^{1/2} \|g_h\|_{L^2(\Omega)}.$$

The convergence of G_ε to G in $L^2_{\mathrm{loc}}(\Omega)$ implies that φ_h^ε converges to φ_h in $L^2(\Omega_b)$ as ε tends to zero. Since $g_h \in H^2(\Omega)$ and using classical properties of the convolution of distributions, the above estimate is also true in the $H^2(\Omega)$ norm and we deduce the following theorem.

THEOREM 3.7. *The solution φ_h^ε to problem* (3.7) *tends to φ_h in $H^2(\Omega_b)$ as ε tends to zero.*

3.3.4. Conclusion. We finally infer from Theorems 3.6 and 3.7 the following result.

THEOREM 3.8. *If k is not a cut-off wave number, the solution $\boldsymbol{u}^\varepsilon$ to problem* (3.1)–(3.2) *tends to $\boldsymbol{u} = \boldsymbol{\nabla}\varphi_a + \mathbf{curl}\,\varphi_h$ in $H^1(\Omega_b)^2$ as ε tends to zero, where φ_a is the unique solution to* (3.13) *and $\varphi_h(x_1,x_2) = G * g_h(.,x_2)(x_1)$.*

The potential φ_a can be extended via a modal expansion to the whole domain Ω. The field $\boldsymbol{u}$ is therefore also defined in the whole duct Ω, where it obviously satisfies (2.1) and (2.2). From now on, this field will be referred to as the outgoing solution to problem (2.1)–(2.2).

COROLLARY 3.9. *The function $\psi^\varepsilon = \operatorname{curl}\boldsymbol{u}^\varepsilon$ tends to $\operatorname{curl}\boldsymbol{u}$ in $L^2(\Omega_b)$. We set $\psi = \operatorname{curl}\boldsymbol{u}$.*

In the remainder of the paper, we assume that k is not a cut-off wave number:

$$k \neq k_n \quad \forall n \in \mathbb{N}. \tag{3.15}$$

3.3.5. Another characterization of $\boldsymbol{\varphi_h}$. We observe that using the Helmholtz decomposition (3.8) of $\boldsymbol{u}^\varepsilon$ in the regularized problem (3.4) would lead, as $\operatorname{curl}(\mathbf{curl}) = -\Delta$ for a scalar field, to the following problem for the hydrodynamic potential:

find $\varphi_h^\varepsilon \in H^1(\Omega)$ *such that*

$$\begin{aligned} &\mathrm{D}_\varepsilon^2 \varphi_h^\varepsilon - \Delta \varphi_h^\varepsilon = g_h + \psi^\varepsilon \quad \text{in } \Omega, \\ &\varphi_h^\varepsilon = 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{3.16}$$

in place of (3.7). Nevertheless, problems (3.7) and (3.16) are equivalent, since $-\Delta\varphi_h^\varepsilon = \psi^\varepsilon$, but using the latter to find the limit of φ_h^ε as ε tends to zero is less natural and more delicate than what has been proposed in subsection 3.3.3. Even still, we detail this alternative approach here, since it provides another characterization of the potential φ_h, which will prove to be useful in what follows.

Notice that problem (3.16) is very similar to (3.6), except for the homogeneous Dirichlet boundary condition, which replaces the homogeneous Neumann boundary condition of (3.6), and for the right-hand side term, which does not have compact support. To prove the convergence of problem (3.16), we define a similar problem with compactly supported data, which then fits into the previous framework. This leads to the following statement.

LEMMA 3.10. *The limit* φ_h *of the potential* φ_h^ε *has the following two equivalent characterizations:*

1. φ_h *is the unique solution to* (3.14) *which vanishes upstream of the source* g_h.
2. $\varphi_h = \widetilde{\varphi}_h + \chi\zeta$, *where* $\widetilde{\varphi}_h$ *is the unique (outgoing) solution to problem* (3.21) *and* χ *and* ζ *are defined below.*

Proof. We first introduce the function $\psi^{\varepsilon,\infty}$, which coincides with ψ^ε downstream of the support of curl $\boldsymbol{f}$ and is the sum of two functions with separated variables. More precisely, if $\mathrm{supp}(\mathrm{curl}\,\boldsymbol{f}) \subset \{(x_1,x_2) \in \Omega \mid d_- < x_1 < d_+\}$, we have by definition that $\psi^{\varepsilon,\infty}(x_1,x_2) = \psi^\varepsilon(x_1,x_2)$ for $x_1 > d_+$ and, from (6.3), that

$$\psi^{\varepsilon,\infty}(x_1,x_2) = (a_\varepsilon(x_2) + x_1\, b_\varepsilon(x_2))\, e^{\mathrm{i}\frac{k_\varepsilon}{M}x_1} \quad \forall (x_1,x_2) \in \Omega.$$

Notice that $\psi^{\varepsilon,\infty}$ does not generally vanish upstream of the support of the source, contrary to ψ^ε. Taking advantage of the particular form of $\psi^{\varepsilon,\infty}$, one can explicitly determine a function ζ^ε satisfying the problem *find* $\zeta^\varepsilon \in H^1(\Omega)$ *such that*

$$\begin{aligned} &\mathrm{D}_\varepsilon^2 \zeta^\varepsilon - \Delta \zeta^\varepsilon = \psi^{\varepsilon,\infty} \quad \text{in } \Omega, \\ &\zeta^\varepsilon = 0 \quad \text{on } \partial\Omega, \end{aligned}$$

which is sought in the form $\zeta^\varepsilon(x_1,x_2) = (A_\varepsilon(x_2) + x_1\, B_\varepsilon(x_2))\, e^{\mathrm{i}\frac{k_\varepsilon}{M}x_1}\ \forall (x_1,x_2) \in \Omega$. This leads to the solution of the following two problems:

$$\begin{aligned} &-B_\varepsilon''(x_2) + \frac{{k_\varepsilon}^2}{M^2} B_\varepsilon(x_2) = b_\varepsilon(x_2), \\ &B_\varepsilon(0) = B_\varepsilon(l) = 0, \end{aligned} \tag{3.17}$$

$$\begin{aligned} &-A_\varepsilon''(x_2) + \frac{{k_\varepsilon}^2}{M^2} A_\varepsilon(x_2) = 2\mathrm{i}\frac{k_\varepsilon}{M}\, B_\varepsilon(x_2) + a_\varepsilon(x_2), \\ &A_\varepsilon(0) = A_\varepsilon(l) = 0. \end{aligned} \tag{3.18}$$

One can easily prove that problem (3.17) is well-posed in the space $H_0^1([0,l])$ and consequently compute the function B_ε, which allows us in turn to determine A_ε (using the same argument) and finally find the function ζ^ε.

Now using their explicit formulas (see the appendix), one can show that a_ε and b_ε, respectively, tend, as ε tends to zero, to some functions a and b which are related

to $\psi = \operatorname{curl} \boldsymbol{u}$ through the relation $\psi(x_1, x_2) = (a(x_2) + x_1\, b(x_2))\, e^{\mathrm{i}\frac{k}{M}x_1}\ \forall (x_1, x_2) \in]d_+, +\infty[\times[0, l]$. We are then able to compute the respective limits of A_ε and B_ε, denoted A and B, by simply solving similar problems. We have consequently defined a function $\zeta(x_1, x_2) = (A(x_2) + x_1\, B(x_2))\, e^{\mathrm{i}\frac{k}{M}x_1}\ \forall (x_1, x_2) \in \Omega$, which satisfies $\mathrm{D}^2\zeta - \Delta\zeta = \psi\ \forall (x_1, x_2) \in]d_+, +\infty[\times[0, l]$ and which is the limit of ζ^ε as ε tends to zero.

Now, consider a cut-off function $\chi \in C^\infty(\mathbb{R})$ such that $\chi(x_1) = 1$ if $x_1 > d_+$ and vanishing for $x_1 < d_-$. It is easily seen that $\widetilde{\varphi}_h^\varepsilon = \varphi_h^\varepsilon - \chi\zeta^\varepsilon$ satisfies the following problem: *find* $\widetilde{\varphi}_h^\varepsilon \in H^1(\Omega)$ *such that*

$$\begin{aligned} &\mathrm{D}_\varepsilon^2\widetilde{\varphi}_h^\varepsilon - \Delta\widetilde{\varphi}_h^\varepsilon = \widetilde{g}_h^\varepsilon \quad \textit{in } \Omega,\\ &\widetilde{\varphi}_h^\varepsilon = 0 \quad \textit{on } \partial\Omega, \end{aligned}$$

where $\widetilde{g}_h^\varepsilon = g_h + \psi^\varepsilon - \big(\mathrm{D}_\varepsilon^2(\chi\zeta^\varepsilon) - \Delta(\chi\zeta^\varepsilon)\big)$. By construction, $\psi^\varepsilon - \big(\mathrm{D}_\varepsilon^2(\chi\zeta^\varepsilon) - \Delta(\chi\zeta^\varepsilon)\big)$ has a compact support contained in Ω_b, and therefore $\widetilde{g}_h^\varepsilon$ is compactly supported in Ω_b. Using DtN operators, this last problem may equivalently be rewritten as a problem set in Ω_b: *find* $\widetilde{\varphi}_h^\varepsilon \in H^1(\Omega_b)$ *such that*

$$\begin{aligned} &\mathrm{D}_\varepsilon^2\widetilde{\varphi}_h^\varepsilon - \Delta\widetilde{\varphi}_h^\varepsilon = \widetilde{g}_h^\varepsilon \quad \textit{in } \Omega_b,\\ &\widetilde{\varphi}_h^\varepsilon = 0 \quad \textit{on } \partial\Omega \cap \partial\Omega_b,\\ &\partial_{\boldsymbol{n}}\widetilde{\varphi}_h^\varepsilon = -T_\pm^{D,\varepsilon}\widetilde{\varphi}_h^\varepsilon \quad \textit{on } \Sigma_\pm, \end{aligned} \tag{3.19}$$

where the operators $T_\pm^{D,\varepsilon} : H^{1/2}(\Sigma_\pm) \to H^{-1/2}(\Sigma_\pm)$ (the superscript D refers to the Dirichlet boundary condition in (3.19)) are defined by

$$T_\pm^{D,\varepsilon}\phi = \mp\mathrm{i}\sum_{n=1}^{+\infty} \beta_n^{\varepsilon\pm}\ (\phi, \mathrm{S}_n)_{L^2(\Sigma_\pm)}\ \mathrm{S}_n(x_2),$$

the numbers $\beta_n^{\varepsilon\pm}$, $n \in \mathbb{N}^*$, being defined in (3.9) and with

$$\mathrm{S}_n(x_2) = \sqrt{\frac{2}{l}}\ \sin\Big(\frac{n\pi}{l}x_2\Big)\ \ \forall n \in \mathbb{N}^*. \tag{3.20}$$

One can prove that problem (3.19) is well-posed, due to hypothesis (3.15). It is now possible to pass to the limit as ε tends to zero in the same way as previously done for the acoustic potential φ_a^ε and finally show that $\lim_{\varepsilon\to 0}\widetilde{\varphi}_h^\varepsilon = \widetilde{\varphi}_h$ in $H^1(\Omega_b)$, where $\widetilde{\varphi}_h$ is the solution to the following: *find* $\widetilde{\varphi}_h \in H^1(\Omega_b)$ *such that*

$$\begin{aligned} &\mathrm{D}^2\widetilde{\varphi}_h - \Delta\widetilde{\varphi}_h = \widetilde{g}_h \quad \textit{in } \Omega_b,\\ &\widetilde{\varphi}_h = 0 \quad \textit{on } \partial\Omega \cap \partial\Omega_b,\\ &\partial_{\boldsymbol{n}}\widetilde{\varphi}_h = -T_\pm^D\widetilde{\varphi}_h \quad \textit{on } \Sigma_\pm, \end{aligned} \tag{3.21}$$

where $\widetilde{g}_h = g_h + \psi - \big(\mathrm{D}^2(\chi\zeta) - \Delta(\chi\zeta)\big)$, the DtN operators $T_\pm^D : H^{1/2}(\Sigma_\pm) \to H^{-1/2}(\Sigma_\pm)$ being defined by $T_\pm^D\phi = \mp\mathrm{i}\sum_{n=0}^{+\infty}\beta_n^\pm\ (\phi, \mathrm{S}_n)_{L^2(\Sigma_\pm)}\ \mathrm{S}_n(x_2)$.

Using that $\lim_{\varepsilon\to 0}\zeta^\varepsilon = \zeta$, one has $\lim_{\varepsilon\to 0}\varphi_h^\varepsilon = \lim_{\varepsilon\to 0}(\widetilde{\varphi}_h^\varepsilon + \chi\zeta^\varepsilon) = \widetilde{\varphi}_h + \chi\zeta$. By uniqueness of the limit, we conclude that $\varphi_h = \widetilde{\varphi}_h + \chi\zeta$. ∎

4. Setting of the problem with perfectly matched layers. Our goal in this section is to develop a finite element method to compute an approximation of the outgoing solution $\boldsymbol{u}$ to problem (2.1)–(2.2). To do so, we must address two main difficulties. First, this problem is set in an unbounded domain. Second, the operator in Galbrun's equation is not coercive.

As already seen during the study of the dissipative problem, the coerciveness can be restored by applying a regularization technique. On the other hand, we use PMLs (see, for example, [2] and references therein for a presentation of this methodology) in order to truncate the computational domain. A posteriori, the regularization will prove to be necessary not only for the finite element method, but also for the PML method (see subsection 5.5).

In a previous paper [2], we proved the convergence of the solutions to PML formulations of the scalar problem (3.13). Two different models of PMLs were studied: a "classical" one, derived directly from Bérenger's original model, and a modified one, designed to avoid a possible growing of the solution in the downstream layer (due to the presence of the so-called inverse upstream modes). This last property will be useful for the vectorial problem at hand, and the modified PML model (to be recalled in the next subsection) will be the only one considered here.

4.1. The PML formulation. We introduce the bounded domain Ω^L, composed of domain Ω_b and surrounding layers $\Omega^L_\pm$, which are respectively defined by $\Omega^L_- = \{(x_1,x_2)\in\Omega\,|\,x_- - L < x_1 < x_-\}$ and $\Omega^L_+ = \{(x_1,x_2)\in\Omega\,|\,x_+ < x_1 < x_+ + L\}$, the external vertical boundaries of the layers $\Omega^L_\pm$ being respectively denoted by $\Sigma^L_\pm$.

The so-called modified PML model consists of the formal transformation of the differential operator

$$\partial_{x_1} \longrightarrow \alpha(x_1)\,\partial_{x_1} + \mathrm{i}\lambda(x_1) \tag{4.1}$$

in the governing equations of the problem. The complex function α is assumed to be unity in Ω_b and, in order to simplify the study, constant and equal to the complex scalar α^*, satisfying the hypotheses

$$\mathrm{Re}(\alpha^*) > 0, \quad \mathrm{Im}(\alpha^*) < 0 \tag{4.2}$$

in $\Omega\backslash\Omega_b$ (see [2] for a justification), but it can generally depend on the coordinate x_1 in the layers. The function λ is assumed to be zero in Ω_b and to be constant and equal to

$$\lambda^* = -\frac{kM}{1-M^2} \tag{4.3}$$

in $\Omega\backslash\Omega_b$. In Bérenger's model, one has $\lambda\equiv 0$. Note that the results obtained subsequently can be extended to the case of a varying coefficient α^*, as done in [2].

As a consequence of the transformation (4.1), the various modified operators will now be indexed by α and λ.

As seen in section 3, Galbrun's equation must be regularized in order to be numerically solved in a stable fashion by a nodal (i.e., H^1-conforming) finite element method. The PML formulation of the problem is no exception to this rule. Consequently, we introduce a function $\psi_{\alpha,\lambda}$, defined as the unique solution to $\mathrm{D}^2_{\alpha,\lambda}\psi_{\alpha,\lambda} = \mathrm{curl}\,\boldsymbol{f}$ in Ω, which vanishes upstream of the source. One can easily verify that $\psi_{\alpha,\lambda} = \psi$ in Ω_b and that, $\forall (x_1,x_2)\in\Omega_+$,

$$\psi_{\alpha,\lambda}(x_1,x_2) = e^{\mathrm{i}\left(\frac{k}{M}\,x_+ + \left(\frac{k}{M}-\lambda^*\right)\frac{x_1-x_+}{\alpha^*}\right)}\left(a(x_2) + \left(x_+ + \frac{(x_1-x_+)}{\alpha^*}\right)b(x_2)\right).$$

We then set the problem for the approximated displacement field: *find* $\boldsymbol{u}^L\in H^1(\Omega^L)^2$

such that

$$
\begin{aligned}
&\mathrm{D}^2_{\alpha,\lambda}\boldsymbol{u}^L - \boldsymbol{\nabla}_{\alpha,\lambda}\left(\mathrm{div}_{\alpha,\lambda}\,\boldsymbol{u}^L\right) + \mathbf{curl}_{\,\alpha,\lambda}\left(\mathrm{curl}_{\,\alpha,\lambda}\boldsymbol{u}^L - \psi_{\alpha,\lambda}\right) = \boldsymbol{f} \quad \text{in } \Omega^L,\\
&\boldsymbol{u}^L\cdot\boldsymbol{n} = 0 \quad \text{on } \partial\Omega^L,\\
&\mathrm{curl}_{\,\alpha,\lambda}\boldsymbol{u}^L = \psi_{\alpha,\lambda} \quad \text{on } \partial\Omega^L.
\end{aligned}
\tag{4.4}
$$

4.2. Well-posedness. We first establish a variational formulation of problem (4.4): *find* $\boldsymbol{u}^L \in V(\Omega^L) = \left\{\boldsymbol{v}\in H^1(\Omega^L)^2 \mid \boldsymbol{v}\cdot\boldsymbol{n} = 0 \text{ on } \partial\Omega^L\right\}$ *such that*

$$
a_{\Omega^L}(\boldsymbol{u}^L,\boldsymbol{v}) + b_{\Omega^L}(\boldsymbol{u}^L,\boldsymbol{v}) = l_{\Omega^L}(\boldsymbol{v})\ \forall \boldsymbol{v}\in V(\Omega^L),
\tag{4.5}
$$

where

$$
\begin{aligned}
a_{\Omega^L}(\boldsymbol{u},\boldsymbol{v}) &= \int_{\Omega^L}\left(\boldsymbol{u}\cdot\overline{\boldsymbol{v}} + \frac{1}{\alpha}\left(\mathrm{div}_{\alpha,\lambda}\,\boldsymbol{u}\ \mathrm{div}_{\alpha,-\lambda}\,\overline{\boldsymbol{v}} + \mathrm{curl}_{\,\alpha,\lambda}\boldsymbol{u}\,\mathrm{curl}_{\,\alpha,-\lambda}\overline{\boldsymbol{v}}\right)\right.\\
&\qquad\left. - \alpha M^2\,\partial_{x_1}\boldsymbol{u}\cdot\partial_{x_1}\overline{\boldsymbol{v}}\right)\mathrm{d}\boldsymbol{x},\\
b_{\Omega^L}(\boldsymbol{u},\boldsymbol{v}) &= \int_{\Omega^L}\left(\frac{1}{\alpha}\left(-k^2 + 2kM\lambda - M^2\lambda^2 - \alpha\right)\,\boldsymbol{u}\cdot\overline{\boldsymbol{v}} + \left(\mathrm{i}\lambda M^2 - 2\mathrm{i}kM\right)\,\partial_{x_1}\boldsymbol{u}\cdot\overline{\boldsymbol{v}}\right.\\
&\qquad\left. - \mathrm{i}\lambda M^2\,\boldsymbol{u}\cdot\,\partial_{x_1}\overline{\boldsymbol{v}}\right)\mathrm{d}\boldsymbol{x},\\
l_{\Omega^L}(\boldsymbol{v}) &= \int_{\Omega^L}\frac{1}{\alpha}\left(\boldsymbol{f}\cdot\overline{\boldsymbol{v}} + \psi_{\alpha,\lambda}\,\mathrm{curl}_{\,\alpha,-\lambda}\overline{\boldsymbol{v}}\right)\,\mathrm{d}\boldsymbol{x} - \int_{\Sigma^L_{\pm}} M^2\psi_{\alpha,\lambda}\overline{v_2}(\boldsymbol{n}\cdot\boldsymbol{e_1})\,\mathrm{d}\sigma.
\end{aligned}
$$

THEOREM 4.1. *If the assumption* (4.2) *is satisfied, the variational problem* (4.5) *is of Fredholm type.*

Proof. We prove that the sesquilinear form $a_{\Omega^L}(\cdot\,,\cdot)$ defines, via the Riesz representation theorem, an operator which is the sum of an isomorphism and a compact operator on $V(\Omega^L)$. Let us write $a_{\Omega^L}(\cdot\,,\cdot)$ as the sum

$$
a_{\Omega^L}(\boldsymbol{u},\boldsymbol{v}) = a^0_{\Omega^L}(\boldsymbol{u},\boldsymbol{v}) + \lambda\, a^1_{\Omega^L}(\boldsymbol{u},\boldsymbol{v}) + \lambda^2\, a^2_{\Omega^L}(\boldsymbol{u},\boldsymbol{v}),
$$

where the sesquilinear forms $a^i_{\Omega^L}(\cdot\,,\cdot)$, $i = 0,1,2$, are independent of λ. The sesquilinear form $a^0_{\Omega^L}(\cdot\,,\cdot)$ is coercive on $V(\Omega^L)$. Indeed, $\forall\boldsymbol{u}$, $\boldsymbol{v}$ in $V(\Omega^L)$, we have

$$
\int_{\Omega^L}\left(\mathrm{curl}_{\,\alpha,0}\boldsymbol{u}\,\mathrm{curl}_{\,\alpha,0}\overline{\boldsymbol{v}} + \mathrm{div}_{\alpha,0}\,\boldsymbol{u}\ \mathrm{div}_{\alpha,0}\,\overline{\boldsymbol{v}}\right)\,\mathrm{d}\boldsymbol{x} = \int_{\Omega^L}\boldsymbol{\nabla}_{\alpha,0}\boldsymbol{u} : \boldsymbol{\nabla}_{\alpha,0}\overline{\boldsymbol{v}}\,\mathrm{d}\boldsymbol{x},
$$

and due to assumption (4.2), we have $\forall\boldsymbol{u}$ of $V(\Omega^L)$

$$
\begin{aligned}
\mathrm{Re}\left(a^0_{\Omega^L}(\boldsymbol{u},\boldsymbol{u})\right) &= \int_{\Omega^L}\left(|\boldsymbol{u}|^2 + \mathrm{Re}(\alpha)(1-M^2)\,|\partial_{x_1}\boldsymbol{u}|^2 + \mathrm{Re}\left(\frac{1}{\alpha}\right)|\partial_{x_2}\boldsymbol{u}|^2\right)\,\mathrm{d}\boldsymbol{x}\\
&\geq C_\alpha\,\|\boldsymbol{u}\|_{H^1(\Omega^L)^2},
\end{aligned}
$$

with $C_\alpha = \min\left(1-M^2, \mathrm{Re}(\alpha^*)(1-M^2), \mathrm{Re}\left(\frac{1}{\alpha^*}\right)\right)$.

On the other hand, the forms $a^1_{\Omega^L}(\cdot\,,\cdot)$ and $a^2_{\Omega^L}(\cdot\,,\cdot)$ both define a compact operator on $V(\Omega^L)$, due to the compact embedding of $H^1(\Omega^L)$ into $L^2(\Omega^L)$. The same argument is used to show that the bounded operator defined on $H^1(\Omega^L)^2$ by the sesquilinear form $b_{\Omega^L}(\cdot\,,\cdot)$ is compact, which ends the proof. ∎

We now prove the equivalence between the variational formulation (4.5) and the following (strong) problem: *find* $\boldsymbol{u}^L \in H^1(\Omega^L)^2$ *such that*

$$\begin{aligned} &\mathrm{D}^2_{\alpha,\lambda}\boldsymbol{u}^L - \boldsymbol{\nabla}_{\alpha,\lambda}(\mathrm{div}_{\alpha,\lambda}\,\boldsymbol{u}^L) = \boldsymbol{f} \quad \text{in } \Omega^L,\\ &\mathrm{curl}_{\,\alpha,\lambda}\boldsymbol{u}^L = \psi_{\alpha,\lambda} \quad \text{in } \Omega^L,\\ &\boldsymbol{u}^L\cdot\boldsymbol{n} = 0 \quad \text{on } \partial\Omega^L. \end{aligned}$$

LEMMA 4.2. *There exists a strictly positive constant* δ*, depending on* k*,* M*, and* $\theta = \arg(\alpha^*)$*, such that if* $L/|\alpha^*| \geq \delta$*, any solution to variational problem* (4.5) *is such that* $\mathrm{curl}_{\,\alpha,\lambda}\boldsymbol{u}^L = \psi_{\alpha,\lambda}$ *in* Ω^L*.*

Proof. Considering a test function of the form $\boldsymbol{v} = \mathbf{curl}_{\,\overline{\alpha},-\lambda}\phi$ with $\phi \in H^3(\Omega^L)\cap H^1_0(\Omega^L)$ in (4.5), we obtain, after integrating by parts,

$$\begin{aligned}\int_{\Omega^L}\frac{1}{\alpha}\mathrm{curl}_{\,\alpha,\lambda}\boldsymbol{u}^L\left(\mathrm{D}^2_{\alpha,-\lambda}\overline{\phi} - \Delta_{\alpha,-\lambda}\overline{\phi}\right)\mathrm{d}\boldsymbol{x} &= \int_{\Omega^L}\frac{1}{\alpha}\left(\overline{\phi}\,\mathrm{curl}_{\,\alpha,\lambda}\boldsymbol{f} - \psi_{\alpha,\lambda}\Delta\overline{\varphi}\right)\mathrm{d}\boldsymbol{x}\\ &\quad + \int_{\Sigma^L_-\cup\Sigma^L_+}\alpha M^2\psi_{\alpha,\lambda}\partial_{x_1}\overline{\phi}(\boldsymbol{n}\cdot\boldsymbol{e_1})\,\mathrm{d}\sigma.\end{aligned}$$

Knowing that the function $\psi_{\alpha,\lambda}$ satisfies $\mathrm{D}^2_{\alpha,\lambda}\psi_{\alpha,\lambda} = \mathrm{curl}_{\,\alpha,\lambda}\boldsymbol{f}$ in Ω^L, we finally have

$$\int_{\Omega^L}\frac{1}{\alpha}\left(\mathrm{curl}_{\,\alpha,\lambda}\boldsymbol{u}^L - \psi_{\alpha,\lambda}\right)\left(\mathrm{D}^2_{\alpha,-\lambda}\overline{\phi} - \Delta_{\alpha,-\lambda}\overline{\phi}\right)\mathrm{d}\boldsymbol{x} = 0.$$

Owing to a density argument, this equality holds for any function ϕ in $H^2(\Omega^L)\cap H^1_0(\Omega^L)$. Then, if $L/|\alpha^*|$ is large enough, the operator $\mathrm{D}^2_{\alpha,-\lambda}-\Delta_{\alpha,-\lambda}$ is surjective from $H^2(\Omega^L)\cap H^1_0(\Omega^L)$ onto $L^2(\Omega^L)$ (see subsection 5.1), and we deduce that $\mathrm{curl}_{\,\alpha,\lambda}\boldsymbol{u}^L = \psi_{\alpha,\lambda}$ almost everywhere in Ω^L. ∎

We finish this study by an existence and uniqueness result. In addition to hypothesis (3.15) on the wave number k, we now assume that

$$k \neq \frac{n\pi}{l} \quad \forall n \in \mathbb{N}. \tag{4.6}$$

The need for this second assumption will be made clear in the next section.

THEOREM 4.3. *Assume that hypotheses* (4.2) *are satisfied and choice* (4.3) *is made. Then, there exists a strictly positive constant* δ *such that problem* (4.5) *admits a unique solution if* $L/|\alpha^*| \geq \delta$*.*

Proof. The problem being of Fredholm type, proving the existence of its solution amounts to proving uniqueness. Let $\boldsymbol{w} \in H^1(\Omega^L)^2$ denote the difference between two solutions to problem (4.5). It verifies that

$$\begin{aligned} &\mathrm{D}^2_{\alpha,\lambda}\boldsymbol{w} - \boldsymbol{\nabla}_{\alpha,\lambda}(\mathrm{div}_{\alpha,\lambda}\,\boldsymbol{w}) = \boldsymbol{0} \quad \text{in } \Omega^L,\\ &\mathrm{curl}_{\,\alpha,\lambda}\boldsymbol{w} = 0 \quad \text{in } \Omega^L,\\ &\boldsymbol{w}\cdot\boldsymbol{n} = 0 \quad \text{on } \partial\Omega^L. \end{aligned}$$

We then consider the function $\check{\boldsymbol{w}}(x_1,x_2) = \boldsymbol{w}(x_1,x_2)\,e^{\mathrm{i}\lambda x_1}$, so that $\mathrm{curl}_{\,\alpha,0}\check{\boldsymbol{w}} = \mathrm{curl}_{\,\alpha,\lambda}\boldsymbol{w}\,e^{\mathrm{i}\lambda x_1}$, and we use the following result.

THEOREM 4.4. *A function* $\boldsymbol{v}$ *in* $L^2(\Omega^L)^2$ *satisfies* $\mathrm{curl}_{\,\alpha,0}\boldsymbol{v} = 0$ *in* Ω^L *if and only if there exists a function* ϕ *in* $H^1(\Omega^L)$ *such that* $\boldsymbol{v} = \boldsymbol{\nabla}_{\alpha,0}\phi$*. This function is unique up to an additive constant.*

A proof of the above theorem can be obtained by slightly modifying the proof of Theorem 2.9 of [9, Chapter 1].

The field $\check{\boldsymbol{w}}$ then derives from a scalar potential ϕ, which is a solution to

$$\begin{aligned} &\boldsymbol{\nabla}_{\alpha,0}\left(\mathrm{D}^2_{\alpha,0}\phi - \Delta_{\alpha,0}\phi\right) = 0 \quad \text{in } \Omega^L,\\ &\boldsymbol{\nabla}_{\alpha,0}\phi\cdot\boldsymbol{n} = 0 \quad \text{on } \partial\Omega^L; \end{aligned}$$

hence

$$\begin{aligned} &\mathrm{D}^2_{\alpha,0}\phi - \Delta_{\alpha,0}\phi = C \quad \text{in } \Omega^L,\\ &\boldsymbol{\nabla}_{\alpha,0}\phi\cdot\boldsymbol{n} = 0 \quad \text{on } \partial\Omega^L, \end{aligned} \tag{4.7}$$

where C is a complex constant. This last problem is well-posed if $L/|\alpha^*|$ is large enough (this will be proved later; see subsection 5.1). Besides, one can easily verify that $\phi \equiv -\frac{C}{k^2}$ is a solution to system (4.7) and, thus, the unique solution of the problem. As a consequence, one has $\boldsymbol{w} = \boldsymbol{0}$ in Ω^L. ∎

5. Convergence results of PMLs for Galbrun's equation. Our objective is to show that $\boldsymbol{u}^L$, the solution to (4.5), tends to $\boldsymbol{u} = \boldsymbol{\nabla}\varphi_a + \mathbf{curl}\,\varphi_h$ in Ω_b when the ratio $L/|\alpha^*|$ tends to infinity. A natural idea is to introduce two approximate potentials φ_a^L and φ_h^L, which converge, respectively, to φ_a and φ_h and are such that $\boldsymbol{u}^L = \boldsymbol{\nabla}\varphi_a^L + \mathbf{curl}\,\varphi_h^L$.

We now briefly present a sketch of the convergence proof and point out several difficulties that need to be addressed in the analysis as well. Indeed, it appears there is not a unique Helmholtz decomposition for $\boldsymbol{u}^L$, which leaves us with the delicate task of choosing the adequate approximate potentials. Second, the "natural candidates" for these potentials satisfy scalar problems with boundary conditions that are, as we shall see, a priori unusual for PML problems.

Let us characterize the potentials φ_h^L and φ_a^L as the respective solutions to the following scalar problems: *find* $\varphi_h^L \in H^1(\Omega^L)$ *such that*

$$\mathrm{D}^2_{\alpha,\lambda}\varphi_h^L - \Delta_{\alpha,\lambda}\varphi_h^L = g_h + \psi_{\alpha,\lambda} \quad \textit{in } \Omega^L, \tag{5.1a}$$

$$\varphi_h^L = 0 \quad \textit{on } \partial\Omega^L \cap \partial\Omega, \tag{5.1b}$$

$$-\Delta_{\alpha,\lambda}\varphi_h^L = \psi_{\alpha,\lambda} \quad \textit{on } \Sigma_\pm^L, \tag{5.1c}$$

and *find* $\varphi_a^L \in H^1(\Omega^L)$ *such that*

$$\mathrm{D}^2_{\alpha,\lambda}\varphi_a^L - \Delta_{\alpha,\lambda}\varphi_a^L = g_a \quad \textit{in } \Omega^L, \tag{5.2a}$$

$$\boldsymbol{\nabla}_{\alpha,\lambda}\varphi_a^L\cdot\boldsymbol{n} = 0 \quad \textit{on } \partial\Omega^L \cap \partial\Omega, \tag{5.2b}$$

$$\boldsymbol{\nabla}_{\alpha,\lambda}\varphi_a^L\cdot\boldsymbol{n} = -\mathbf{curl}_{\,\alpha,\lambda}\varphi_h^L\cdot\boldsymbol{n} \quad \textit{on } \Sigma_\pm^L. \tag{5.2c}$$

The first step of the proof consists of showing that these two problems are well-posed. The field $\boldsymbol{\nabla}\varphi_a^L + \mathbf{curl}\,\varphi_h^L$ is then clearly a solution to problem (4.4), which establishes that $\boldsymbol{u}^L = \boldsymbol{\nabla}\varphi_a^L + \mathbf{curl}\,\varphi_h^L$. It remains to prove the convergence of the potentials φ_h^L and φ_a^L to their counterparts φ_h and φ_a, using the convergence analysis previously done in [2]. However, problems (5.1) and (5.2) do not exactly enter the framework considered in [2] for three main reasons. First, the boundary condition (5.1c) is nonstandard (from a functional point of view) and nonhomogeneous. Second, the right-hand side term in (5.1a) has a part of its support contained in the PMLs (we nevertheless observe that both this datum and the one in (5.1c) are exponentially decreasing in the layers). Third, the boundary condition (5.2c) is not homogeneous. Note that this last condition links the potential φ_a^L to the tangential trace of $\mathbf{curl}\,\varphi_h^L$

on the boundaries $\Sigma_\pm^L$. Since φ_a satisfies an analogous problem with homogeneous boundary conditions, we expect this trace to tend to zero in order to be able to prove the convergence of the method. As a consequence, we will first investigate the convergence of φ_h^L and then that of φ_a^L.

Before doing so, we first recall and give convergence results for scalar problems of the type of (5.1) and (5.2), but with compactly supported data and homogeneous boundary conditions.

5.1. Convergence results of PMLs for scalar problems. Some straightforward extensions of the results of [2] will be needed in what follows. We do not detail their proofs here, as they are only slight modifications from the ones in the cited reference.

We study the following model problem. Suppose $g \in L^2(\Omega_b)$ is a source with compact support and consider the scalar field φ in $H^1_{\rm loc}(\Omega)$, which satisfies

$$\begin{aligned} &\mathrm{D}^2\varphi - \Delta\varphi = g \quad \text{in } \Omega, \\ &\varphi = 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{5.3}$$

and an additional radiation condition at infinity, which selects the outgoing solution of the problem. As already seen in subsection 3.3.5, this (nonlocal) condition may be expressed through the DtN operators $T_\pm^D$ on $\Sigma_\pm$.

In the following subsections, we give three PML formulations of this model problem, each one of them using a different boundary condition at the end of the layers. One should note that the results obtained here are still valid if a homogeneous Neumann boundary condition is applied on $\partial\Omega$ and, for the sake of brevity, we do not duplicate the statements. Indeed, such a change induces only a modification of the modal basis that appears in the proofs—the sine functions $(\mathrm{S}_n)_{n\in\mathbb{N}^*}$ introduced in (3.20) being replaced by the cosine functions $(\mathrm{C}_n)_{n\in\mathbb{N}}$ defined in (3.10).

5.1.1. Problem A. We first consider a PML formulation of problem (5.3) with a homogeneous Dirichlet boundary condition on $\Sigma_\pm^L$: *find* $\varphi^L \in H^1(\Omega^L)$ *such that*

$$\mathrm{D}^2_{\alpha,\lambda}\varphi^L - \Delta_{\alpha,\lambda}\varphi^L = g \quad \textit{in } \Omega^L, \tag{5.4a}$$

$$\varphi^L = 0 \quad \textit{on } \partial\Omega^L. \tag{5.4b}$$

Equation (5.4a) has to be understood in the distributional sense, so that it implies the following transmission conditions at the interfaces between Ω_b and $\Omega_\pm^L$:

$$\left[\varphi^L\right]_{\Sigma_\pm} = 0 \quad \text{and} \quad \left[\alpha\,\partial_{x_1}\varphi^L + \mathrm{i}\lambda\,\varphi^L\right]_{\Sigma_\pm} = 0. \tag{5.5}$$

In the domain Ω_b, the function φ^L, solution to (5.4), is meant to be an approximation of φ, solution to (5.3).

Adapting the proofs in [2], one can easily show the following lemma.

LEMMA 5.1. *Assume that problem* (5.4) *has a solution. Then, this solution can be written as*

$$\varphi^L(x_1,x_2) = \sum_{n=1}^{+\infty} \left(\varphi^L(x_\pm,.),\mathrm{S}_n\right)_{L^2(\Sigma_\pm)} \Big(A_n^+(\pm L)\, e^{\mathrm{i}\gamma_n^+(x_1-x_\pm)} + A_n^-(\pm L)\, e^{\mathrm{i}\gamma_n^-(x_1-x_\pm)} \Big)\, \mathrm{S}_n(x_2)$$

in the layers $\Omega_\pm^L$, *where* $\gamma_n^\pm = \frac{\beta_n^\pm - \lambda^*}{\alpha^*}$ *and* $A_n^\pm(L) = \mp \frac{e^{\mathrm{i}\beta_n^\mp L/\alpha^*}}{e^{\mathrm{i}\beta_n^+ L/\alpha^*} - e^{\mathrm{i}\beta_n^- L/\alpha^*}}$.

We easily check that the denominators of $(A_n^{\pm}(\pm L))_{n\in\mathbb{N}}$ do not vanish due to assumptions (3.15) and (4.2). We are then able to write exact boundary conditions satisfied by ${\varphi^L}_{|_{\Omega_\pm^L}} = \varphi_\pm^L$ on $\Sigma_\pm$, that is,

$$\partial_{x_1}\varphi_{\pm|_{\Sigma_\pm}}^L = \mathrm{i}\sum_{n=1}^{+\infty}\left(\varphi_\pm^L(x_\pm,.),\mathrm{S}_n\right)_{L^2(\Sigma_\pm)}\left(A_n^+(\pm L)\gamma_n^+ + A_n^-(\pm L)\gamma_n^-\right)\mathrm{S}_n,$$

which in turn yield, using the transmission conditions (5.5),

$$\partial_{x_1}{\varphi_b^L}_{|_{\Sigma_\pm}} = \mathrm{i}\sum_{n=1}^{+\infty}\left(\varphi_b^L(x_\pm,.),\mathrm{S}_n\right)_{L^2(\Sigma_\pm)}\nu_n(\pm L)\,\mathrm{S}_n,$$

where we have set $\nu_n(L) = A_n^+(L)\beta_n^+ + A_n^-(L)\beta_n^- = \beta_n^+ + \frac{\beta_n^- - \beta_n^+}{1-e^{\mathrm{i}(\beta_n^- - \beta_n^+)L/\alpha^*}}$ $\forall n\in\mathbb{N}$. Observe here that these quantities do not depend on the value of λ^*.

Having in mind the comparison between φ^L and φ in Ω_b, we reformulate (5.4) as an equivalent problem posed solely in this domain: *find* $\varphi^L\in H^1(\Omega_b)$ *such that*

$$\begin{aligned}
&\mathrm{D}^2\varphi^L - \Delta\varphi^L = g \quad \text{in } \Omega_b,\\
&\varphi^L = 0 \quad \text{on } \partial\Omega_b\cap\partial\Omega,\\
&\partial_{\boldsymbol{n}}\varphi^L = -T_\pm^L\varphi^L \quad \text{on } \Sigma_\pm,
\end{aligned} \tag{5.6}$$

where the DtN operators $T_\pm^L : H^{1/2}(\Sigma_\pm)\to H^{-1/2}(\Sigma_\pm)$ are defined by $T_\pm^L\phi = \mp\mathrm{i}\sum_{n=1}^{+\infty}\nu_n(\pm L)\ (\phi,\mathrm{S}_n)_{L^2(\Sigma_\pm)}\ \mathrm{S}_n(x_2)$.

On the other hand, problem (5.3) has the following equivalent formulation: *find* $\varphi\in H^1(\Omega_b)$ *such that*

$$\begin{aligned}
&\mathrm{D}^2\varphi - \Delta\varphi = g \quad \text{in } \Omega_b,\\
&\varphi = 0 \quad \text{on } \partial\Omega_b\cap\partial\Omega,\\
&\partial_{\boldsymbol{n}}\varphi = -T_\pm^D\varphi \quad \text{on } \Sigma_\pm.
\end{aligned}$$

Since the scalars $\nu_n(\pm L)$ tend to $\beta_n^\pm$ as $L/|\alpha^*|$ tends to infinity for any integer n, we have the following convergence result (see [2] for a proof).

THEOREM 5.2. *Suppose that assumptions* (3.15) *and* (4.2) *are verified and let* g *in* $L^2(\Omega^L)$ *be compactly supported in* Ω_b. *Then, there exists a strictly positive constant* δ, *depending on* k, M, *and* $\theta = \arg(\alpha^*)$, *such that if* $L/|\alpha^*|\geq\delta$, *problem* (5.4) *is well-posed. Furthermore, the restriction to* Ω_b *of the solution* φ^L *to problem* (5.4) *converges to the restriction of the solution* φ *to problem* (5.3) *as* $L/|\alpha^*|$ *tends to infinity. There also exists a constant* C, *depending on* M *and* k, *such that*

$$\|\varphi-\varphi^L\|_{H^2(\Omega_b)} \leq C\,e^{-\eta\frac{L}{|\alpha^*|}}\|\varphi\|_{H^2(\Omega_b)},$$

with

$$\eta = \frac{2k}{1-M^2}\min\left(-\sin(\theta)\sqrt{1-\frac{{N_0}^2}{{K_0}^2}},\cos(\theta)\sqrt{\frac{(N_0+1)^2}{{K_0}^2}-1}\right), \tag{5.7}$$

where $K_0 = \frac{kl}{\pi\sqrt{1-M^2}}$, N_0 *is the floor of* K_0, *and* $\theta = \arg(\alpha^*)$.

5.1.2. Problem B. We now consider the homogeneous Neumann boundary condition

$$\boldsymbol{\nabla}_{\alpha,\lambda}\varphi^L \cdot \boldsymbol{n} = 0 \quad \text{on } \Sigma_{\pm}^L, \tag{5.8}$$

instead of the previous Dirichlet boundary condition. In this case, the claim of Theorem 5.2 remains true if we furthermore assume that $k \neq \frac{n\pi}{l}$ $\forall n \in \mathbb{N}$. Indeed, the sketch of the proof for the problem at hand is nearly identical to the preceding one, with the following values: $A_n^{\pm}(L) = \mp \frac{\beta_n^{\mp} e^{\mathrm{i}\beta_n^{\mp} L/\alpha^*}}{\beta_n^+ e^{\mathrm{i}\beta_n^+ L/\alpha^*} - \beta_n^- e^{\mathrm{i}\beta_n^- L/\alpha^*}}$ and $\nu_n(L) = \beta_n^+ + \frac{\beta_n^+(\beta_n^- - \beta_n^+)}{\beta_n^+ - \beta_n^- e^{\mathrm{i}(\beta_n^- - \beta_n^+)L/\alpha^*}}$.

Again, one can verify that the scalars $(A_n^{\pm}(L))_{n\in\mathbb{N}}$ are always defined if the assumptions (3.15) and (4.2) are satisfied. Obviously, the scalar $\nu_n(L)$ tends to β_n^+ as $L/|\alpha^*|$ tends to $+\infty$ for any integer n. On the other hand, if there exists an integer j such that $k = \frac{j\pi}{l}$, then the corresponding axial wave number β_j^+ vanishes and the scalar $\nu_j(-L) = \beta_j^- + \frac{\beta_j^-(\beta_j^+ - \beta_j^-)}{\beta_j^- - \beta_j^+ e^{\mathrm{i}(\beta_j^- - \beta_j^+)L/\alpha^*}} = 0$ cannot converge to $\beta_j^- \neq 0$ when $L/|\alpha^*|$ tends to infinity; hence we have the supplementary assumption.

Additionally, the well-posedness of problem (5.4a)–(5.8) in the more general case of a source g with noncompact support and/or if the boundary condition (5.8) is not homogeneous can be proved by means of the Fredholm alternative.

5.1.3. Problem C. We finally consider the following homogeneous condition:

$$\Delta_{\alpha,\lambda}\varphi^L = 0 \quad \text{on } \Sigma_{\pm}^L. \tag{5.9}$$

Theorem 5.2 is still valid. This time, in the proof, we have

$$A_n^{\pm}(L) = \mp \frac{(M\beta_n^{\mp} - k)^2\, e^{\mathrm{i}\beta_n^{\mp} L/\alpha^*}}{(M\beta_n^+ - k)^2\, e^{\mathrm{i}\beta_n^+ L/\alpha^*} - (M\beta_n^- - k)^2\, e^{\mathrm{i}\beta_n^- L/\alpha^*}} \tag{5.10}$$

and $\nu_n(L) = \beta_n^+ + \frac{(M\beta_n^+ - k)^2(\beta_n^- - \beta_n^+)}{(M\beta_n^+ - k)^2 - (M\beta_n^- - k)^2\, e^{\mathrm{i}(\beta_n^- - \beta_n^+)L/\alpha^*}}$.

Contrary to both previous problems, the well-posedness of problem (5.4a)–(5.9) cannot be extended to the case of an arbitrary source term g, since the boundary condition (5.9) does not allow us to write a variational formulation of the problem.

5.2. Well-posedness and convergence analysis for $\boldsymbol{\varphi_h^L}$. Once again, the idea is to deal with an equivalent problem, whose source term is compactly supported and whose boundary conditions are homogeneous, and the approach previously used in subsection 3.3.5 is followed closely. This new problem then permits the construction of the solution via a modal decomposition.

We first introduce the functions $\psi_{\alpha,\lambda}^{\infty}$ such that, $\forall (x_1, x_2) \in \Omega_+^L$,

$$\psi_{\alpha,\lambda}^{\infty}(x_1,x_2) = \begin{cases} (a(x_2) + b(x_2)x_1)\; e^{\mathrm{i}\frac{k}{M}x_1} \;\; \forall (x_1,x_2) \in]d_+, x_+[\times]0,l[, \\ \left(a(x_2) + b(x_2)\left(x_+ + \dfrac{x_1 - x_+}{\alpha^*}\right)\right)\; e^{\mathrm{i}\left(\frac{k}{M}x_+ + \left(\frac{k}{M} - \lambda^*\right)\frac{x_1 - x_+}{\alpha^*}\right)}, \end{cases}$$

and $\zeta_{\alpha,\lambda}$ such that, $\forall (x_1, x_2) \in \Omega_+^L$,

$$\zeta_{\alpha,\lambda}(x_1,x_2) = \begin{cases} (A(x_2) + B(x_2)x_1)\; e^{\mathrm{i}\frac{k}{M}x_1} \;\; \forall (x_1,x_2) \in]d_+, x_+[\times]0,l[, \\ \left(A(x_2) + B(x_2)\left(x_+ + \dfrac{x_1 - x_+}{\alpha^*}\right)\right)\; e^{\mathrm{i}\left(\frac{k}{M}x_+ + \left(\frac{k}{M} - \lambda^*\right)\frac{x_1 - x_+}{\alpha^*}\right)}, \end{cases}$$

the functions a, b, A, and B having been characterized in the subsection 3.3.5. We then set $\varphi_h^L = \widetilde{\varphi}_h^L + \chi\zeta_{\alpha,\lambda}$, where the function $\widetilde{\varphi}_h^L$ satisfies

$$\begin{array}{ll} \mathrm{D}^2_{\alpha,\lambda}\widetilde{\varphi}_h^L - \Delta_{\alpha,\lambda}\widetilde{\varphi}_h^L = \widetilde{g}_h & \text{in } \Omega^L, \\ \widetilde{\varphi}_h^L = 0 \quad \text{on } \partial\Omega^L \cap \partial\Omega, & \\ -\Delta_{\alpha,\lambda}\widetilde{\varphi}_h^L = 0 \quad \text{on } \Sigma_\pm^L. & \end{array}$$

Indeed, the quantity $g_h + \psi_{\alpha,\lambda} - \mathrm{D}^2_{\alpha,\lambda}(\chi\zeta_{\alpha,\lambda}) - \Delta_{\alpha,\lambda}(\chi\zeta_{\alpha,\lambda})$ coincides with $\widetilde{g}_h$, since $\psi_{\alpha,\lambda}$ and $\zeta_{\alpha,\lambda}$, respectively, coincide with ψ and ζ in Ω_b. This last problem is well-posed, owing to the results of subsection 5.1, and we easily deduce the following result.

THEOREM 5.3. *If the ratio $L/|\alpha^*|$ is large enough, problem* (5.1) *has a unique solution which is $\varphi_h^L = \widetilde{\varphi}_h^L + \chi\zeta_{\alpha,\lambda}$. Moreover, the function φ_h^L converges to $\widetilde{\varphi}_h + \chi\zeta = \varphi_h$ in $H^2(\Omega_b)$ as $L/|\alpha^*|$ tends to infinity, and one has the estimate*

$$\left\|\varphi_h - \varphi_h^L\right\|_{H^2(\Omega_b)} \leq C\, e^{-\frac{\eta}{2}\frac{L}{|\alpha^*|}} \left\|\varphi_h\right\|_{H^2(\Omega_b)},$$

where the constant C depends on k and M and η is defined in (5.7).

Proof. In the domain Ω_b, one has $\varphi_h^L - \varphi_h = \widetilde{\varphi}_h^L + \chi\zeta_{\alpha,\lambda} - \widetilde{\varphi}_h - \chi\zeta = \widetilde{\varphi}_h^L - \widetilde{\varphi}_h$. The convergence result then directly follows from subsection 5.1. ∎

COROLLARY 5.4. *Suppose that assumptions* (4.2) *and* (4.3) *hold. Then, the traces $(\mathbf{curl}\,_{\alpha,\lambda}\varphi_h^L \cdot \boldsymbol{n})_{|_{\Sigma_\pm^L}}$ tend to zero in $H^{1/2}(\Sigma_\pm^L)$ as $L/|\alpha^*|$ tends to infinity. More precisely, for $L/|\alpha^*|$ large enough, one has the estimate*

$$\left\|\mathbf{curl}\,_{\alpha,\lambda}\varphi_h^L \cdot \boldsymbol{n}\right\|_{H^{1/2}(\Sigma_\pm^L)} \leq C\left(e^{-\frac{\eta}{2}\frac{L}{|\alpha^*|}}\left\|\varphi_h\right\|_{H^2(\Omega_b)} + e^{\left(\frac{k}{M}-\lambda^*\right)\sin(\theta)\frac{L}{|\alpha^*|}}\left\|g_h\right\|_{L^2(\Omega_b)}\right),$$

where the constant C depends on k and M, η is defined in (5.7), *and θ denotes the argument of α^*.*

Proof. Using a modal decomposition for $\widetilde{\varphi}_h^L$ in the layers $\Omega_\pm^L$, similar to the ones used in the subsection 5.1, one has, on Σ_+^L, for instance, $\forall x_2 \in [0,l]$,

$$\partial_{x_2}\widetilde{\varphi}_h^L(x_+ + L, x_2) = \sum_{n=1}^{+\infty}\left(\widetilde{\varphi}_h^L(x_+,\cdot),\mathrm{S}_n\right)_{L^2([0,l])}\left(A_n^+(L)e^{\mathrm{i}\gamma_n^+ L} + A_n^-(L)e^{\mathrm{i}\gamma_n^- L}\right)\frac{n\pi}{l}\mathrm{C}_n(x_2),$$

the scalars $(A_n^\pm(L))_{n\in\mathbb{N}}$ being defined in (5.10). Setting

$$\tau_n = A_n^+(L)\,e^{\mathrm{i}\gamma_n^+ L} + A_n^-(L)\,e^{\mathrm{i}\gamma_n^- L} = \frac{M(\beta_n^- - \beta_n^+)\,(2k + M(\beta_n^+ + \beta_n^-))\;e^{\mathrm{i}\gamma_n^+ L}}{(M\beta_n^+ - k)^2\,e^{\mathrm{i}(\beta_n^+ - \beta_n^-)\frac{L}{\alpha^*}} - (M\beta_n^- - k)^2} \quad \forall n \in \mathbb{N},$$

we obtain, if $L/|\alpha^*|$ is large enough and after some majorizations,

$$|\tau_n| \leq C\, e^{-\frac{\eta}{2}\frac{L}{|\alpha^*|}} \quad \forall n \in \mathbb{N},$$

the constant η being defined in (5.7). Thus, we have

$$\begin{aligned} \left\|\partial_{x_2}\widetilde{\varphi}_h^L\right\|^2_{H^{1/2}(\Sigma_+^L)} &\leq \sum_{n=1}^{+\infty}\left(1 + \frac{n^2\pi^2}{l^2}\right)^{3/2}|\tau_n|^2\left|\left(\widetilde{\varphi}_h^L(x_+,\cdot),\mathrm{S}_n\right)_{L^2([0,l])}\right|^2 \\ &\leq C\, e^{-\eta\frac{L}{|\alpha^*|}}\left\|\widetilde{\varphi}_h^L\right\|^2_{H^{3/2}(\Sigma_+)}. \end{aligned}$$

We then deduce an estimate of this quantity using the convergence of $\widetilde{\varphi}_h^L$ to $\widetilde{\varphi}_h$ in $H^2(\Omega_b)$ and a trace theorem. On the other hand, one has

$$\|\partial_{x_2}\zeta_{\alpha,\lambda}\|^2_{H^{1/2}(\Sigma_+^L)} \leq \left(\|A\|^2_{H^2([0,l])} + \|B\|^2_{H^2([0,l])}\left|x_+ + \frac{L}{\alpha^*}\right|^2\right) e^{2\left(\frac{k}{M}-\lambda^*\right)\sin(\theta)\frac{L}{|\alpha^*|}}$$
$$\leq C\left(1+\frac{L}{|\alpha^*|}\right)^2 e^{2\left(\frac{k}{M}-\lambda^*\right)\sin(\theta)\frac{L}{|\alpha^*|}}\,\|g_h\|^2_{L^2(\Omega)}.$$

One obviously has similar estimates on Σ_-^L, and thus the announced result is obtained. ∎

We emphasize here that this corollary is valid only for the PML model corresponding to the transformation (4.1) with the choice (4.3) for λ^*. Indeed, every propagative mode, and, more particularly, every inverse upstream mode, has to be damped in the layers in order to prove the claim. This appears to be different from the convergence results previously given in [2] and subsequently extended in subsection 5.1, which are also true for the original Bérenger model (that is, when $\lambda \equiv 0$).

5.3. Well-posedness and convergence analysis for $\boldsymbol{\varphi_a^L}$. Since the analysis in section 5.1 was concerned with PML problems with homogeneous boundary conditions on $\Sigma_\pm^L$, the only difficulty in proving the convergence of problem (5.2) comes from the nonhomogeneous boundary condition (5.2c). Consequently, the scalar field φ_a^L is split in the following manner: $\varphi_a^L = \varphi_a^{L,1} + \varphi_a^{L,2}$, with

$$\begin{aligned} &\mathrm{D}^2_{\alpha,\lambda}\varphi_a^{L,1} - \Delta_{\alpha,\lambda}\varphi_a^{L,1} = g_a \quad \text{in } \Omega^L,\\ &\boldsymbol{\nabla}_{\alpha,\lambda}\varphi_a^{L,1}\cdot\boldsymbol{n} = 0 \quad \text{on } \partial\Omega^L, \end{aligned} \tag{5.11}$$

and

$$\begin{aligned} &\mathrm{D}^2_{\alpha,\lambda}\varphi_a^{L,2} - \Delta_{\alpha,\lambda}\varphi_a^{L,2} = 0 \quad \text{in } \Omega^L,\\ &\boldsymbol{\nabla}_{\alpha,\lambda}\varphi_a^{L,2}\cdot\boldsymbol{n} = 0 \quad \text{on } \partial\Omega^L\cap\partial\Omega,\\ &\boldsymbol{\nabla}_{\alpha,\lambda}\varphi_a^{L,2}\cdot\boldsymbol{n} = -\mathbf{curl}_{\,\alpha,\lambda}\varphi_h^L\cdot\boldsymbol{n} \quad \text{on } \Sigma_\pm^L. \end{aligned} \tag{5.12}$$

As seen in subsection 5.1, both of these problems are well-posed. Moreover, the results of subsection 5.1.2 readily give the convergence of the solution $\varphi_a^{L,1}$ to problem (5.11) to φ_a in $H^2(\Omega_b)$ as the ratio $L/|\alpha^*|$ tends to infinity.

We next prove the following lemma.

LEMMA 5.5. *If the ratio $L/|\alpha^*|$ is large enough, the solution $\varphi_a^{L,2}$ to problem* (5.12) *satisfies the estimate*

$$\left\|\varphi_a^{L,2}\right\|_{H^2(\Omega_b)} \leq C\,e^{-\frac{\eta}{2}\frac{L}{|\alpha^*|}}\left\|\mathbf{curl}_{\,\alpha,\lambda}\varphi_h^L\cdot\boldsymbol{n}\right\|_{H^{1/2}\left(\Sigma_\pm^L\right)},$$

where the constant C depends on k and M and the constant η is defined in (5.7).

Proof. Let us set $q^\pm = -(\mathbf{curl}_{\,\alpha,\lambda}\varphi_h^L\cdot\boldsymbol{n})_{|_{\Sigma_\pm^L}}$. The main tool of the proof is again a modal decomposition. Since the functions $q^\pm$, respectively, belong to $H^{1/2}(\Sigma_\pm^L)$, they can be written as $q^\pm(x_2) = \sum_{n=0}^{+\infty} q_n^\pm\,\mathrm{C}_n(x_2)$ on $\Sigma_\pm^L$, and we have $\|q^\pm\|^2_{H^{1/2}(\Sigma_\pm^L)} = \sum_{n=0}^{+\infty}(1+\frac{n^2\pi^2}{l^2})^{1/2}\,|q_n^\pm|^2$.

We look for a solution to problem (5.12) of the same form,

$$\varphi_a^{L,2}(x_1,x_2) = \sum_{n=0}^{+\infty}\phi_n(x_1)\,\mathrm{C}_n(x_2) \quad \text{in } \Omega^L, \tag{5.13}$$

which yields the following ODEs: $\mathrm{D}^2_{\alpha,\lambda}\phi_n - (\alpha\,\mathrm{d}_{x_1} + \mathrm{i}\lambda)^2\,\phi_n + \frac{n^2\pi^2}{l^2}\phi_n = 0$, $n \in \mathbb{N}$, with boundary conditions $\alpha\,\phi_n{}' + \mathrm{i}\lambda\,\phi_n = \pm q_n^{\pm}$ on $\Sigma_{\pm}^L$ and transmission conditions, between Ω_b and the PMLs, $[\phi_n]_{\Sigma_\pm} = 0$ and $\left[\alpha\,\phi_n{}' + \mathrm{i}\lambda\,\phi_n\right]_{\Sigma_\pm} = 0$.

There are three different zones:

$$\phi_n(x_1) = \begin{cases} A_n^-\,e^{\mathrm{i}\gamma_n^- x_1} + A_n^+\,e^{\mathrm{i}\gamma_n^+ x_1} & \text{if } x_1 \le x_-, \\ B_n^-\,e^{\mathrm{i}\beta_n^-(x_1-x_+)} + B_n^+\,e^{\mathrm{i}\beta_n^+(x_1-x_-)} & \text{if } x_- \le x_1 \le x_+, \\ C_n^-\,e^{\mathrm{i}\gamma_n^- x_1} + C_n^+\,e^{\mathrm{i}\gamma_n^+ x_1} & \text{if } x_1 \ge x_+. \end{cases}$$

Expressing the boundary and transmission conditions gives a 6-by-6 linear system to solve in order to obtain the coefficients $(A_n^{\pm}, B_n^{\pm}, C_n^{\pm})$. After some manipulations, we finally obtain $B_n^- = -\mathrm{i}\frac{q_n^-}{\beta_n^-}\,e^{-\mathrm{i}\gamma_n^- L}\frac{1+z_n^+}{1-z_n^+ z_n^-}$ and $B_n^+ = \mathrm{i}\frac{q_n^+}{\beta_n^+}\,e^{\mathrm{i}\gamma_n^+ L}\frac{1+z_n^-}{1-z_n^+ z_n^-}$, where $z_n^+ = e^{\mathrm{i}\beta_n^+(x_+-x_-)}e^{2\mathrm{i}\gamma_n^+ L}$ and $z_n^- = e^{-\mathrm{i}\beta_n^-(x_+-x_-)}e^{-2\mathrm{i}\gamma_n^- L}$.

Note that, due to assumption (4.6), the scalars $B_n^{\pm}$ are well defined. Using classical properties of propagative and evanescent modes, it is easy to show that, for $L/|\alpha^*|$ sufficiently large, we have $|B_n^{\pm}| \le C\left|\frac{q_n^{\pm}}{\beta_n^{\pm}}\right| e^{\mp \mathrm{Im}(\gamma_n^{\pm})L}$, which yield $|B_n^{\pm}| \le C\left|\frac{q_n^{\pm}}{\beta_n^{\pm}}\right| e^{-\frac{\eta}{2}\frac{L}{|\alpha^*|}}$, the constant η being the one defined in (5.7).

Then, successively integrating (5.13) with respect to x_2 and x_1 and using the estimates above, we conclude that

$$\left\|\varphi_a^{L,2}\right\|_{H^2(\Omega_b)} \le C\,e^{-\frac{\eta}{2}\frac{L}{|\alpha^*|}}\left\|q^{\pm}\right\|_{H^{1/2}\left(\Sigma_{\pm}^L\right)},$$

which ends the proof. ∎

Using Corollary 5.4, we finally deduce the following corollary.

COROLLARY 5.6. *The function $\varphi_a^{L,2}$ converges to zero as $L/|\alpha^*|$ tends to infinity. More precisely, for $L/|\alpha^*|$ large enough, one has the estimate*

$$\left\|\varphi_a^{L,2}\right\|_{H^2(\Omega_b)} \le C\left(e^{-\eta\frac{L}{|\alpha^*|}}\left\|\varphi_h\right\|_{H^2(\Omega_b)} + e^{\left(\left(\frac{k}{M}-\lambda^*\right)\sin(\theta)-\frac{\eta}{2}\right)\frac{L}{|\alpha^*|}}\left\|g_h\right\|_{L^2(\Omega)}\right),$$

where the constant C depends on k and M, η is defined in (5.7)*, and θ denotes the argument of α^*.*

5.4. Conclusion. The gathering of the preceding results yields the inequality

$$\begin{aligned}\|\boldsymbol{u}^L - \boldsymbol{u}\|_{H^1(\Omega_b)^2} \le C\,e^{-\frac{\eta}{2}\frac{L}{|\alpha^*|}}\Bigg(&\|\boldsymbol{\nabla}\varphi_a\|_{H^1(\Omega_b)^2} + \|\mathbf{curl}\,\varphi_h\|_{H^1(\Omega_b)^2} \\ &+ \left(1+\frac{L}{|\alpha^*|}\right)e^{\left(\frac{k}{M}-\lambda^*\right)\sin(\theta)\frac{L}{|\alpha^*|}}\left\|g_h\right\|_{L^2(\Omega)}\Bigg)\end{aligned}$$

and consequently allows us to state a final theorem relative to the convergence of the solution to problem (4.4) when the ratio $L/|\alpha^*|$ tends to infinity.

THEOREM 5.7. *Suppose that assumptions* (4.2) *and* (4.3) *hold. Then, the field $\boldsymbol{u}^L$ tends to $\boldsymbol{u}$ in $H^1(\Omega_b)^2$ as $L/|\alpha^*|$ tends to infinity. Furthermore, for $L/|\alpha^*|$ large enough, one has the estimate*

$$\left\|\boldsymbol{u}^L - \boldsymbol{u}\right\|_{H^1(\Omega_b)^2} \le C\,e^{-\frac{\eta}{2}\frac{L}{|\alpha^*|}},$$

where the constant C depends on k, M, and the solution $\boldsymbol{u}$, the constant η being defined in (5.7).

5.5. Remark on the use of PMLs without regularization. Let us finally tackle the claim made in the introduction of section 4, namely, that PMLs do not work without regularization. Indeed, assume that the approximated displacement field $\boldsymbol{u}^L$ is computed as the solution to the problem

$$\begin{aligned} &\mathrm{D}^2_{\alpha,\lambda}\boldsymbol{u}^L - \boldsymbol{\nabla}_{\alpha,\lambda}\left(\mathrm{div}_{\alpha,\lambda}\,\boldsymbol{u}^L\right) = \boldsymbol{f} \quad \text{in } \Omega^L, \\ &\boldsymbol{u}^L\cdot\boldsymbol{n} = 0 \quad \text{on } \partial\Omega^L, \end{aligned} \tag{5.14}$$

completed by an additional boundary condition at the end of the layers—for instance, $\mathrm{curl}_{\,\alpha,\lambda}\boldsymbol{u}^L = 0$ on $\partial\Omega^L$.

Then, the function $\psi^L = \mathrm{curl}_{\,\alpha,\lambda}\boldsymbol{u}^L$ is a solution to the following problem:

$$\begin{aligned} &\mathrm{D}^2_{\alpha,\lambda}\psi^L = \mathrm{curl}\,\boldsymbol{f} \quad \text{in } \Omega^L, \\ &\psi^L = 0 \quad \text{on } \Sigma^L_{\pm}. \end{aligned} \tag{5.15}$$

For the PML method to work, the field $\boldsymbol{u}^L$ must converge to $\boldsymbol{u}$ in Ω_b as the ratio $L/|\alpha^*|$ tends to infinity, and, consequently, ψ^L must converge to $\psi = \mathrm{curl}\,\boldsymbol{u}$ in Ω_b. We now show that this convergence does not hold. Indeed, the solution ψ^L to problem (5.15) can be sought as the sum $\psi^L = \psi_{\alpha,\lambda} + \widetilde{\psi}^L$, where $\widetilde{\psi}^L$ solves the following problem:

$$\begin{aligned} &\mathrm{D}^2_{\alpha,\lambda}\widetilde{\psi}^L = 0 \quad \text{in } \Omega^L, \\ &\widetilde{\psi}^L = 0 \quad \text{on } \Sigma^L_-, \\ &\widetilde{\psi}^L = -\psi_{\alpha,\lambda} \quad \text{on } \Sigma^L_+. \end{aligned} \tag{5.16}$$

Using the expression of $\psi_{\alpha,\lambda}$ derived previously, we find that

$$\psi_{\alpha,\lambda}(x_+ + L, x_2) = \left(a(x_2) + b(x_2)\left(x_+ + \frac{L}{\alpha^*}\right)\right) e^{\mathrm{i}\left(\frac{k}{M}x_+ + \left(\frac{k}{M}-\lambda^*\right)\frac{L}{\alpha^*}\right)} \quad \forall x_2 \in]0, l[.$$

Then, the expression of $\widetilde{\psi}^L$ can be easily derived by seeking a solution of the form

$$\widetilde{\psi}^L(x_1, x_2) = \begin{cases} \widetilde{a}(x_2)\left(1 + t\,\dfrac{x_1 - x_-}{\alpha^*}\right) e^{\mathrm{i}\left(\frac{k}{M}\,x_- + \left(\frac{k}{M}-\lambda^*\right)\frac{x_1-x_-}{\alpha^*}\right)} & \text{if } x_1 \le x_-, \\ \widetilde{a}(x_2)\left(1 + t\,(x_1 - x_-)\right) e^{\mathrm{i}\frac{k}{M}x_1} & \text{if } x_- \le x_1 \le x_+, \\ \widetilde{a}(x_2)\left(1 + t\left(x_+ - x_- + \dfrac{x_1 - x_+}{\alpha^*}\right)\right) e^{\mathrm{i}\left(\frac{k}{M}\,x_+ + \left(\frac{k}{M}-\lambda^*\right)\frac{x_1-x_+}{\alpha^*}\right)} & \\ \qquad\qquad \text{if } x_1 \ge x_+, & \end{cases}$$

where the function $\widetilde{a}$ and the real number t need to be determined. By construction, the transmission conditions on $\Sigma_\pm$ are automatically satisfied, and we simply use the boundary conditions on $\Sigma^L_\pm$, which give us the two equalities

$$\begin{aligned} &1 - t\frac{L}{\alpha^*} = 0, \\ &\widetilde{a}(x_2)\left(1 + t\left(x_+ - x_- + \frac{L}{\alpha^*}\right)\right) = -\left(a(x_2) + b(x_2)\left(x_+ + \frac{L}{\alpha^*}\right)\right), \end{aligned}$$

so that, finally, $t = \alpha^*/L$ and $\widetilde{a}(x_2) = -\frac{a(x_2)+b(x_2)\left(x_+ + \frac{L}{\alpha^*}\right)}{2 + \frac{\alpha^*}{L}(x_+ - x_-)}$. Clearly, we see that $\widetilde{\psi}^L$ does not converge to zero as $L/|\alpha^*|$ tends to infinity.

6. Numerical applications. Due to its Fredholm type, variational formulation (4.5) is well suited for a finite element approximation, and, for given values of the PML parameters α^* and L, usual rates of convergence (with respect to the mesh stepsize) are ensured. All computations are done with the finite element library MÉLINA [17]. We use P_2 Lagrange finite elements on a nonstructured mesh, and the length of the PML is equal to 10% of the length of the domain $\Omega_b = [0,2] \times [0,1]$. As in the theoretical analysis, the function α is constant in the layer, and the argument of the complex number α^* is fixed and equal[1] to $-\frac{\pi}{4}$, its modulus $|\alpha^*|$ being a parameter in the simulations.

We are interested here in simulating the radiation of a compactly supported source situated in a two-dimensional rigid duct; this is a problem for which no explicit reference solution is available. Nonetheless, we consider as a preliminary study the propagation of acoustic and vortical modes in order to validate the method.

6.1. Mode propagation in a rigid duct.

6.1.1. Acoustic and vortical modes: Some definitions. The so-called modes are solutions with separated variables to the homogeneous, nonregularized Galbrun equation, with the rigid wall boundary condition (2.2). These solutions are of two distinct kinds, called acoustic and vortical modes.

The acoustic modes are of the form

$$\boldsymbol{u}(x_1,x_2) = \begin{cases} C\, e^{\mathrm{i}\beta_n^{\pm} x_1}\, \boldsymbol{e_1} & \text{if } n = 0, \\ C\, e^{\mathrm{i}\beta_n^{\pm} x_1} \left(-\dfrac{\mathrm{i}\beta_n^{\pm} l}{n\pi} \cos\left(\dfrac{n\pi}{l} x_2\right) \boldsymbol{e_1} + \sin\left(\dfrac{n\pi}{l} x_2\right) \boldsymbol{e_2} \right) & \text{if } n \in \mathbb{N}^*, \end{cases}$$

where C is a complex constant and the axial wave numbers $\beta_n^{\pm}$ are given by (3.12). One can see that these fields are irrotational—hence their name. The acoustic modes associated to real valued axial wave numbers are called propagative and evanescent otherwise. Propagative modes with positive (resp., negative) group velocity $\frac{\partial \omega}{\partial \beta}$ are called downstream (resp., upstream) modes, since their energy propagates downstream (resp., upstream) of the mean flow.

The second "family" of solutions to Galbrun's equation consists of a continuum of fields such that

$$\boldsymbol{u}(x_1,x_2) = C\, e^{\mathrm{i}\frac{k}{M} x_1} \left(\frac{\mathrm{i}k}{M}\, \varphi'(x_2)\, \boldsymbol{e_1} + \varphi(x_2)\, \boldsymbol{e_2} \right),$$

where C is a complex constant and φ denotes a scalar function belonging to $H_0^1([0,l])$. These solutions propagate only downstream and are called vortical modes, since they are divergence-free.

6.1.2. Description of the simulations. The following numerical simulations consist of solving problems similar to (4.4), with only one absorbing layer downstream (denoted by Ω_+^L). Each problem was designed in such a way that one of the previously introduced modes is its exact solution. For the propagation of an acoustic mode, we have $\boldsymbol{f} \equiv \boldsymbol{0}$ and $\psi_{\alpha,\lambda} \equiv 0$, the mode being imposed via a nonhomogeneous condition on the boundary Σ_- for the normal displacement $\boldsymbol{u}\cdot\boldsymbol{n}$. In the case of a vortical mode, we still have $\boldsymbol{f} \equiv \boldsymbol{0}$ and a nonhomogeneous boundary condition on Σ_-, but the field $\psi_{\alpha,\lambda}$ has to be computed a priori as the curl of the considered mode.

[1] While apparently arbitrary, this choice simply makes the quantities $-\sin(\arg(\alpha^*))$ and $\cos(\arg(\alpha^*))$, which appear in the definition (5.7) of the coefficient η, to be equal.

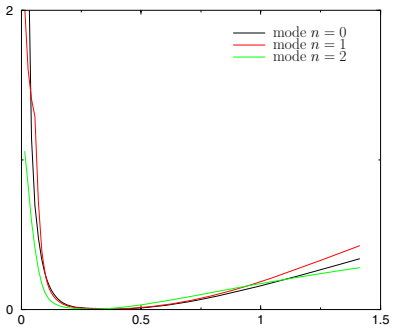

FIG. 1. *Relative error in the* $H^1(\Omega_b)^2$ *norm as a function of* $|\alpha^*|$ *for the computated propagative downstream acoustic modes* ($k = 8$ *and* $M = 0.4$).

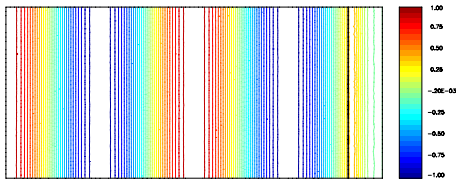

FIG. 2. *Contours of the real part of the component* u_1 *of the computed displacement field for the propagative downstream mode* ($n = 0$, $k = 8$, $M = 0.4$, $\alpha^* = 0.25(1 - \mathrm{i})$).

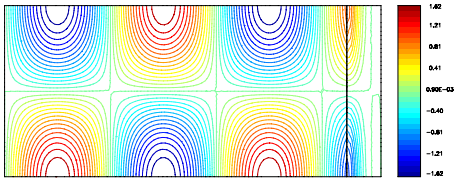

FIG. 3. *Contours of the real part of the component* u_1 *of the computed displacement field for the propagative downstream mode* ($n = 1$, $k = 8$, $M = 0.4$, $\alpha^* = 0.25(1 - \mathrm{i})$).

6.1.3. Numerical results for acoustic modes. In the chosen configuration, characterized by the values $l = 1$, $k = 8$, and $M = 0.4$, six (i.e., three upstream and three downstream) acoustic modes are propagative. The curves plotting the relative error in the $H^1(\Omega_b)$ norm for the computed displacement versus the modulus of α^* for the propagative downstream modes are shown in Figure 1. We observe that each curve contains a minimum plateau where the relative error is below a few percent. For large values of $|\alpha^*|$, the error increases due to the reflection at the end of the layer and behaves as theoretically predicted. For small values of $|\alpha^*|$, the method diverges, the mesh resolution being too coarse to adequately represent the modes in the PML medium, thus producing spurious numerical errors. Similar results were obtained for the propagative upstream modes.

We show in Figures 2 to 4 the contours of the components of the computed displacement for a value of $|\alpha^*|$ such that the error of the method is below one percent.

6.1.4. Numerical results for vortical modes. For the study of the method on vortical perturbations, the transverse dependence of the modes is arbitrarily chosen as $\varphi(x_2) = \sin\left(\frac{m\pi}{l}\, x_2\right)$, where m is a given nonzero integer. In Figure 5 we show

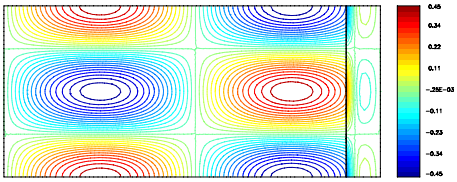

FIG. 4. *Contours of the real part of the component u_1 of the computed displacement field for the propagative downstream mode ($n = 2$, $k = 8$, $M = 0.4$, $\alpha^* = 0.25(1 - \mathrm{i})$).*

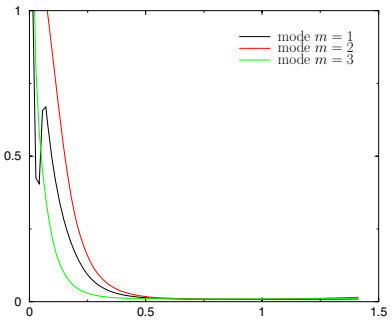

FIG. 5. *Relative error in the $H^1(\Omega_b)^2$ norm as a function of $|\alpha^*|$ for the computed vortical modes ($k = 8$, $M = 0.4$).*

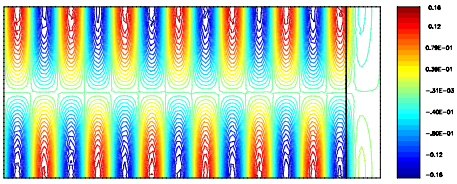

FIG. 6. *Contours of the real part of the component u_1 of the computed displacement field for a vortical mode ($m = 1$, $k = 8$, $M = 0.4$, $\alpha^* = 0.65(1 - \mathrm{i})$).*

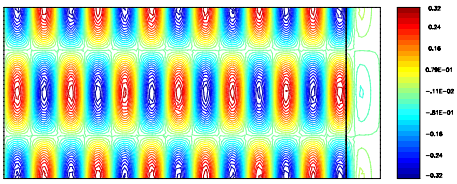

FIG. 7. *Contours of the real part of the component u_1 of the computed displacement field for a vortical mode ($m = 2$, $k = 8$, $M = 0.4$, $\alpha^* = 0.65(1 - \mathrm{i})$).*

the relative error of the method, plotted versus the modulus of the coefficient α^* for values of the integer m equal to 1, 2, and 3. The contours of the components of the corresponding computed solutions when the relative error is below one percent are presented in Figures 6 to 8.

The convergence of the PML method is also obtained in this case for appropriate values of $|\alpha^*|$. However, by comparing Figures 1 and 5, one can already point out a potential difficulty that may be encountered in practice when both irrotational and

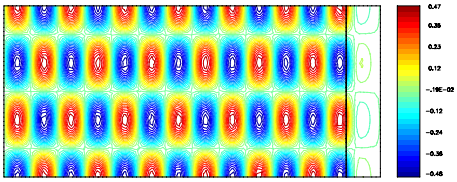

FIG. 8. *Contours of the real part of the component u_1 of the computed displacement field for a vortical mode ($m = 3$, $k = 8$, $M = 0.4$, $\alpha^* = 0.65(1 - \mathrm{i})$).*

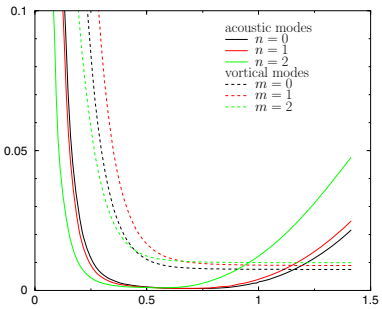

FIG. 9. *Relative error in the $H^1(\Omega_b)^2$ norm as a function of $|\alpha^*|$ for several computed modes ($k = 8$, $M = 0.4$).*

vortical perturbations are present, as the values of $|\alpha^*|$ that allow a good agreement between the exact and the computed solutions in the two cases are quite different. Indeed, the propagation constant of the vortical modes, which is equal to $\frac{k}{M}$, leads to more significant damping in the layer for these modes than for the acoustic ones. On the other hand, the finite element error for vortical modes is higher, since their wavelength is generally much shorter than that of their acoustic counterparts. This fact may cause some discretization issues as $|\alpha^*|$ becomes small.[2]

However, a compromise can be found by using a thicker layer. For instance, we have repeated the previous simulations with a layer of length equal to 25% of the length of the domain Ω_b. The obtained results are presented in Figure 9, and one can now observe a partial match between the respective ranges of values of $|\alpha^*|$ for which the relative errors are below a few percent.

6.2. Radiation of compactly supported sources.

6.2.1. Acoustic source. We next simulate the radiation of an irrotational, compactly supported source which is placed in the duct, defined in polar coordinates by $\boldsymbol{f}(r, \theta) = |r - r_C|\, \boldsymbol{e_r}$ in the ball of center $C = (1, 0.5)$ and with radius equal to 0.15, and vanishing elsewhere. This case happens to be more complex than the previous one because of the absence of any reference solution, which would permit the measuring of the precision of the method and the choosing of an adequate value for the parameter $|\alpha^*|$. The real parts of the components of the computed displacement field are shown in Figure 10. The acoustic mode mainly radiated by the source is the one of index $n = 2$. The convective effect of the uniform flow can clearly be seen, as the wavelength of the computed solution is shorter upstream of the source than downstream.

[2]Note that these issues, related to the mesh stepsize, appear as well without PMLs, when the speed of the flow is slow (that is, when the Mach number M is close to zero) or at high frequencies (that is, when the wave number k is large).

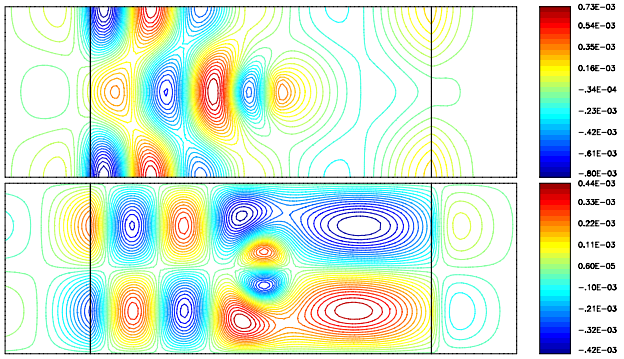

FIG. 10. *Contours of the real part of components u_1 (top) and u_2 (bottom) of the computed displacement field for the radiation of an acoustic source ($k = 8$, $M = 0.4$, $\alpha^* = 0.5(1 - \mathrm{i})$).*

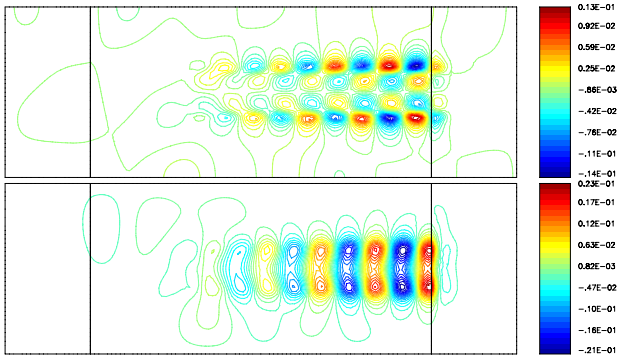

FIG. 11. *Contours of the real part of components u_1 (top) and u_2 (bottom) of the computed displacement field for the radiation of a vortical source ($k = 8$, $M = 0.4$, $\alpha^* = 0.5(1 - \mathrm{i})$).*

6.2.2. Rotational source. The simulation of the radiation of a compactly supported source whose curl is nonzero, which is defined in polar coordinates by $\boldsymbol{f}(r, \theta) = |r - r_C| \arctan(\frac{r \sin\theta - r_C \sin\theta_C}{r \cos\theta - r_C \cos\theta_C})\, \boldsymbol{e_r}$ in the ball of center $C = (0.7, 0.5)$ and with radius equal to 0.15, and vanishing elsewhere, is presented in Figure 11. It is located slightly upstream of the center of the domain Ω_b. One can observe the hydrodynamic wake generated by the source and convected by the flow, whose amplitude increases linearly with respect to the coordinate x_1. The acoustic perturbations, where present, have a negligible amplitude compared to the vortical ones.

Appendix. Study of a second order transport equation. This appendix is devoted to the second order transport equation (3.3), which is written here as

$$\mathrm{D}_\varepsilon^2 \psi^\varepsilon = g, \tag{6.1}$$

with g a compactly supported source belonging to $L^2(\Omega)$. We know from Lemma 3.1 that (6.1) has a unique solution in $L^2(\Omega)$. We also have the following result.

LEMMA 6.1. *The solution in $L^2(\Omega)$ to* (6.1) *vanishes upstream of the support of the source g and satisfies the estimate*

$$\|\psi^\varepsilon\|_{L^2(\Omega)} \leq C_\varepsilon \|g\|_{L^2(\Omega)}, \tag{6.2}$$

where C_ε denotes a positive constant depending on the parameter ε.

Proof. From the proof of Lemma 3.1, we know that

$$\psi^\varepsilon(x_1,x_2) = G_\varepsilon * g(\cdot,x_2)(x_1) = \frac{1}{M^2}\int_{-\infty}^{x_1} (x_1-z)\, e^{\mathrm{i}\frac{k_\varepsilon}{M}(x_1-z)} g(z,x_2)\,\mathrm{d}z,$$

where the kernel G_ε denotes the causal Green's function of the differential operator D^2_ε. Setting the bounds $d_- = \min_{x_2\in[0,h]}\{x_1\in\mathbb{R} \mid (x_1,x_2)\in \operatorname{supp} g\}$ and $d_+ = \max_{x_2\in[0,h]}\{x_1\in\mathbb{R} \mid (x_1,x_2)\in \operatorname{supp} g\}$, we consider the following cases.

If $x_1 < d_-$, one has $]-\infty,x_1]\cap[d_-,d_+] = \varnothing$; thus $\psi^\varepsilon(x_1,x_2)\equiv 0$ for any $x_2\in[0,l]$. The solution then vanishes upstream of the support of the source.

If $d_- \le x_1 \le d_+$, one has $\psi^\varepsilon(x_1,x_2) = \frac{1}{M^2}\int_{d_-}^{x_1}(x_1-z)\, e^{\mathrm{i}\frac{k_\varepsilon}{M}(x_1-z)} g(z,x_2)\,\mathrm{d}z$ for any $x_2\in[0,l]$. The Cauchy–Schwarz inequality then yields

$$|\psi^\varepsilon(x_1,x_2)|^2 \le \frac{1}{M^4}\left(\int_{d_-}^{x_1}(x_1-z)^2\, e^{-\frac{2\varepsilon}{M}(x_1-z)}\,\mathrm{d}z\right)\left(\int_{d_-}^{x_1}|g(z,x_2)|^2\,\mathrm{d}z\right),$$

and one obtains

$$\int_{d_-}^{d_+}\int_0^l |\psi^\varepsilon(x_1,x_2)|^2\,\mathrm{d}x_1\,\mathrm{d}x_2 \le C_{1\varepsilon}\,\|g\|^2_{L^2(\Omega)},$$

with $C_{1\varepsilon} = \frac{(d_+-d_-)^4}{M^4} e^{-\frac{2\varepsilon}{M}(d_+-d_-)}$.

Finally, if $x_1 > d_+$, we have

$$\psi^\varepsilon(x_1,x_2) = \left(-\frac{1}{M^2}\int_{d_-}^{d_+} z\, e^{-\mathrm{i}\frac{k_\varepsilon}{M}z} g(z,x_2)\,\mathrm{d}z + \frac{x_1}{M^2}\int_{d_-}^{d_+} e^{-\mathrm{i}\frac{k_\varepsilon}{M}z} g(z,x_2)\,\mathrm{d}z\right) e^{\mathrm{i}\frac{k_\varepsilon}{M}x_1}.$$

Observing that the variables can be separated in the expression above so that

$$\psi^\varepsilon(x_1,x_2) = (a_\varepsilon(x_2) + x_1\, b_\varepsilon(x_2))\; e^{\mathrm{i}\frac{k_\varepsilon}{M}x_1}, \tag{6.3}$$

one arrives at

$$\int_{d_+}^{+\infty}\int_0^l |\psi^\varepsilon(x_1,x_2)|^2\,\mathrm{d}x_1\,\mathrm{d}x_2 \le \|a_\varepsilon\|_{L^2([0,l])}\int_{d_+}^{+\infty} e^{-\frac{2\varepsilon}{M}x_1}\,\mathrm{d}x_1 + \|b_\varepsilon\|_{L^2([0,l])}\int_{d_+}^{+\infty}|x_1|\, e^{-\frac{2\varepsilon}{M}x_1}\,\mathrm{d}x_1.$$

Additionally, we have that $|a_\varepsilon(x_2)|^2 \le \frac{1}{M^4}\int_{d_-}^{d_+} z^2\, e^{-\frac{2\varepsilon}{M}z}\,\mathrm{d}z\int_{d_-}^{d_+}|g(z,x_2)|^2\,\mathrm{d}z$ and $|b_\varepsilon(x_2)|^2 \le \frac{1}{M^4}\int_{d_-}^{d_+} e^{-\frac{2\varepsilon}{M}z}\,\mathrm{d}z\int_{d_-}^{d_+}|g(z,x_2)|^2\,\mathrm{d}z$; hence

$$\int_{d_+}^{+\infty}\int_0^l |\psi^\varepsilon(x_1,x_2)|^2\,\mathrm{d}x_1\,\mathrm{d}x_2 \le C_{2\varepsilon}\,\|g\|^2_{L^2(\Omega)},$$

with $C_{2\varepsilon} = \frac{1}{M^4}\max\left(\int_{d_-}^{d_+} z^2 e^{-\frac{2\varepsilon}{M}z}\,\mathrm{d}z\int_{d_+}^{+\infty} e^{-\frac{2\varepsilon}{M}x_1}\,\mathrm{d}x_1, \int_{d_-}^{d_+} e^{-\frac{2\varepsilon}{M}z}\,\mathrm{d}z\int_{d_+}^{+\infty}|x_1|\, e^{-\frac{2\varepsilon}{M}x_1}\,\mathrm{d}x_1\right)$.

We finally set $C_\varepsilon = \sqrt{\max(C_{1\varepsilon}, C_{2\varepsilon})}$. ∎

FINITE ELEMENT APPROXIMATION OF SOLUBLE SURFACTANT SPREADING ON A THIN FILM*

JOHN W. BARRETT†, ROBERT NÜRNBERG†, AND MARK R. E. WARNER†

Abstract. We consider a fully practical finite element approximation of the following system of nonlinear degenerate parabolic equations:

$$\frac{\partial u}{\partial t} + \frac{1}{2}\,\nabla\cdot(u^2\,\nabla[\sigma(v)]) - \frac{1}{3}\,\nabla\cdot(u^3\,\nabla w) = 0,$$
$$w = -c\,\Delta u - \delta\,u^{-\nu} + a\,u^{-3},$$
$$\frac{\partial v}{\partial t} + \nabla\cdot(u\,v\,\nabla[\sigma(v)]) - \frac{1}{2}\,\nabla\cdot(u^2\,v\,\nabla w) - \rho_s\,\Delta v - K\,(\psi - v) = 0,$$
$$\frac{\partial \psi}{\partial t} + \frac{1}{2}\,u\,\nabla[\sigma(v)]\cdot\nabla\psi - \frac{1}{3}\,u^2\,\nabla w\cdot\nabla\psi - \rho_b\,u^{-1}\nabla\cdot(u\nabla\psi) + \beta\,K\,u^{-1}(\psi - v) = 0.$$

The above equations model a Marangoni driven thin film laden with a soluble surfactant, in which the bulk surfactant concentration has been vertically averaged. The model accounts for the presence of both attractive, $a \geq 0$, and repulsive, $\delta > 0$ with $\nu > 3$, van der Waals forces. Here u is the height of the film, v is the concentration of the interfacial surfactant species, ψ is the concentration of the surfactant species within the bulk phase, and $\sigma(v) := 1 - v$ is the typical surface tension. Moreover, $\rho_s \geq 0$, $\rho_b > 0$, and $c > 0$ are the inverses of the surface Peclet number, the bulk Peclet number, and the modified capillary number, respectively; finally, $\beta > 0$ and $K > 0$ are parameters that characterize the solubility and the rate of interfacial adsorption. In addition to showing stability bounds for our approximation, we prove convergence and hence existence of a solution to this nonlinear degenerate parabolic system (i) in one space dimension when $\rho_s > 0$ and, moreover, (ii) in two space dimensions if, in addition, $\nu \geq 7$. Furthermore, iterative schemes for solving the resulting nonlinear discrete system are discussed. Finally, some numerical experiments are presented.

Key words. thin film flow, surfactant, fourth order degenerate parabolic system, finite elements, convergence analysis

1. Introduction.

In the recent papers [5, 6], abbreviated to BGN and BN throughout this paper, the authors proposed and analyzed a fully practical finite element approximation of a system of nonlinear degenerate parabolic equations describing an *insoluble* surfactant driven monolayer. Here, we generalize that system to a model in which the chemical may demonstrate varying degrees of solubility allowing for adsorption and desorption between the bulk phase and an interfacial concentration. This extended model is given by

$$\frac{\partial u}{\partial t} + \frac{1}{2}\,\nabla\cdot(u^2\,\nabla[\sigma(v)]) - \frac{1}{3}\,\nabla\cdot(u^3\,\nabla w) = 0, \tag{1.1a}$$

$$w = -c\,\Delta u + \phi(u), \tag{1.1b}$$

$$\frac{\partial v}{\partial t} + \nabla\cdot(u\,v\,\nabla[\sigma(v)]) - \frac{1}{2}\,\nabla\cdot(u^2\,v\,\nabla w) - \rho_s\,\Delta v - K\,(\psi - v) = 0, \tag{1.1c}$$

$$\frac{\partial \psi}{\partial t} + \frac{1}{2}\, u\, \nabla[\sigma(v)] \cdot \nabla \psi - \frac{1}{3}\, u^2\, \nabla w \cdot \nabla \psi - \rho_b\, u^{-1} \nabla \cdot\, (u\, \nabla \psi)$$

$$+ \beta\, K\, u^{-1}\, (\psi - v) = 0 \tag{1.1d}$$

in Ω_T, where $\Omega_T := \Omega \times (0, T]$ and Ω is a bounded domain in $\mathbb{R}^d$, $d = 1$ or 2. The above model, derived using lubrication theory and a cross-sectional averaging technique that removes the vertical dependence of the bulk species [12], models the flow of a surface tension gradient driven surfactant (chemical) laden thin film. Here u denotes the film height, v the concentration of the interfacial surfactant species, ψ the cross-sectionally averaged chemical concentration per unit height within the fluid layer, and w the pressure (reduced if van der Waals forces are present, that is, $\phi \not\equiv 0$). In addition, $\sigma \in C^1(\mathbb{R}_{\geq 0})$ with

$$\sigma(s) \geq 0, \quad \sigma'(s) < 0 \quad \forall\ s \in \mathbb{R}_{\geq 0} \tag{1.2}$$

is the constitutive equation of state relating the surface tension σ to the interfacial concentration v. We note that σ is a strictly monotonically decreasing function of v, which is natural to assume as the surfactant lowers surface tension. An empirical model proposed by Sheludko [15], often used in the engineering literature and that maps $\sigma : [0, 1] \to [0, 1]$, is

$$\sigma(s) := (\alpha + 1)\, [1 + \theta(\alpha)\, s]^{-3} - \alpha, \quad \text{where } \theta(\alpha) := (1 + \alpha^{-1})^{\frac{1}{3}} - 1, \tag{1.3}$$

in which $\alpha \in \mathbb{R}_{>0}$ relates to the activity of the surfactant; cf. [11, p. 262]. Of course the above model assumes that $v(\cdot, \cdot) \in [0, 1]$, which is a physically reasonable assumption. In modeling studies it is often further assumed that the surfactant concentration is dilute, in which case the limit $\alpha \to \infty$ is taken, and the equation of state (1.3) simplifies to $\sigma(s) := 1 - s$. For the van der Waals forces in (1.1b), we take the form suggested in [13]; that is,

$$\phi(u) = \phi^+(u) + \phi^-(u), \quad \phi^+(u) := -\delta\, u^{-\nu}, \quad \nu > 3, \quad \phi^-(u) := a\, u^{-3}, \tag{1.4}$$

where $a \in \mathbb{R}_{\geq 0}$ is the scaled dimensionless Hamaker constant and $\delta \in \mathbb{R}_{\geq 0}$ represents the effect of repulsive van der Waals forces. In (1.1a)–(1.1d), $\rho_s \in \mathbb{R}_{\geq 0}$, $\rho_b \in \mathbb{R}_{>0}$, and $c \in \mathbb{R}_{>0}$ are a nondimensional surface diffusivity (inverse of the surface Peclet number), a bulk diffusivity (inverse of the bulk Peclet number), and the modified capillary number, respectively. In order to permit the cross-sectional averaging process one has assumed that vertical diffusion is sufficiently fast for the bulk concentration to become independent of y, the vertical variable, at leading order. A necessary condition of this process is that the product of ρ_b and the dimensional film aspect ratio squared must be negligible at leading order in the lubrication approximation, and hence in practical applications ρ_b is not "too large." The parameter $\beta \in \mathbb{R}_{>0}$ indicates the degree of solubility of the chemical and emerges from the lubrication scaling as a ratio of the rate of adsorption to the rate of desorption of the chemical at the interface, $y = u$. We note that in the insoluble limit, $\beta \to \infty$, whereby the chemical accumulates preferentially at the interface, (1.1d) collapses to $\psi = v$, and the system (1.1a)–(1.1d) reduces to the insoluble surfactant system, (1.1a)–(1.1c) with $\psi \equiv v$, considered in BGN and BN. Finally, $K \in \mathbb{R}_{>0}$ is a parameter that describes the ratio of the time scale of the flow to the time scale of desorption. Applications of the system (1.1a)–(1.1d) range from the medical treatment of premature infants to industrial coating and drying processes; see BGN for further details and references.

As u and v can take on zero values, (1.1a)–(1.1d) is a degenerate parabolic system, which is fourth order in u. This degeneracy makes the analysis/numerical analysis of the system particularly difficult. As there is no maximum principle for parabolic equations of fourth order, a naive discretization does not guarantee the nonnegativity of the approximation to u. If $\delta = 0$, following [2], BGN imposed the nonnegativity of the discrete approximation to u as a constraint; whereas if $\delta > 0$, the positivity of the approximation to u can be guaranteed for an appropriate discretization through the singularity in ϕ^+. In both cases, BGN proposed a finite element approximation of the insoluble surfactant system, (1.1a)–(1.1c) with $\psi \equiv v$, and were able to derive stability bounds in space dimensions $d = 1$ and 2. However, their main convergence result was restricted to $\rho_s > 0$ and one space dimension. The latter was due to the fact that the a priori bounds they derived guarantee only in one space dimension that the discrete approximation to u is uniformly bounded and equicontinuous, which was necessary to be able to pass to the limit in the discrete problem. For similar reasons, the results on related degenerate parabolic equations of fourth order in [1, 2, 3, 4, 8, 10] were restricted to one space dimension. However, recently in [9], Grün proved convergence in two space dimensions of a finite element approximation to the thin film equation in the absence of surfactant/chemical, (1.1a)–(1.1b) with $v \equiv 0$ and $u(\cdot, 0) > 0$. In BN the techniques in BGN and [9] were adapted to propose a finite element approximation to the insoluble surfactant system, (1.1a)–(1.1c) with $\psi \equiv v$, and prove convergence in one space dimension if $\rho_s, a, \delta, u(\cdot, 0) > 0$ and, moreover, in two space dimensions if in addition $\nu \geq 7$. It is the aim of this paper to adapt the techniques in BN in order to prove convergence of a finite element approximation to (1.1a)–(1.1d). To this end, we will identify and exploit an underlying Lyapunov structure and extend the usage of two entropy-type estimates that were introduced in BGN and BN, respectively.

Throughout this paper, as in BGN and BN, we restrict ourselves to the linearized form of the constitutive equation of state

$$\sigma(v) := 1 - v, \tag{1.5}$$

the $\alpha \to \infty$ limit of (1.3). However, the techniques in this paper do apply to a general σ satisfying (1.2); see Remark 2.2 below. As remarked previously, the physically relevant values of v lie in the interval $[0, 1]$. Noting this, it is convenient for the analysis in this paper, as well as in BGN and BN, to replace the terms $u^i\, v$, $i = 1 \to 2$, in (1.1c) by $u^i\, \lambda(v)$, and similarly replace ψ in the first three terms of (1.1d) by $\lambda(\psi)$, where $\lambda : \mathbb{R} \to (-\infty, 1]$ is defined as

$$\lambda(s) := \min\{s, \lambda_M\}, \quad \text{with } \lambda_M := 1. \tag{1.6}$$

We will return to this point later in this section.

Altogether, in this paper we consider the following initial boundary value problem.

(P) Find functions $u, w, v, \psi : \Omega \times [0, T] \to \mathbb{R}$ such that

$$\frac{\partial u}{\partial t} + \frac{1}{2}\,\nabla \cdot (u^2\, \nabla[\sigma(v)]) - \frac{1}{3}\,\nabla \cdot (u^3\, \nabla\, w) = 0 \qquad \text{in } \Omega_T, \tag{1.7a}$$

$$w = -c\,\Delta u + \phi(u) \qquad \text{in } \Omega_T, \tag{1.7b}$$

$$\frac{\partial v}{\partial t} + \nabla \cdot (u\, \lambda(v)\, \nabla[\sigma(v)]) - \frac{1}{2}\,\nabla \cdot (u^2\, \lambda(v)\, \nabla w) - \rho_s\,\Delta v - K(\psi - v) = 0 \qquad \text{in } \Omega_T, \tag{1.7c}$$

$$\frac{\partial (u\, \lambda(\psi))}{\partial t} + \frac{1}{2}\,\nabla \cdot \left(u^2\, \lambda(\psi)\, \nabla[\sigma(v)]\right)$$

$$-\frac{1}{3}\,\nabla\cdot\left(u^3\,\lambda(\psi)\,\nabla w\right)-\rho_b\,\nabla\cdot(u\,\nabla\psi)+\beta\,K\,(\psi-v)=0\quad\text{in }\Omega_T, \tag{1.7d}$$

$$u(x,0)=u^0(x)>0,\quad v(x,0)=v^0(x)\geq 0,\quad \psi(x,0)=\psi^0(x)\geq 0\quad\forall\, x\in\Omega, \tag{1.7e}$$

$$\begin{aligned}&\frac{1}{2}\,u^2\,\frac{\partial[\sigma(v)]}{\partial\nu_{\partial\Omega}}-\frac{1}{3}\,u^3\,\frac{\partial w}{\partial\nu_{\partial\Omega}}=\frac{\partial u}{\partial\nu_{\partial\Omega}}=u\,\lambda(v)\,\frac{\partial[\sigma(v)]}{\partial\nu_{\partial\Omega}}-\frac{1}{2}\,u^2\,\lambda(v)\,\frac{\partial w}{\partial\nu_{\partial\Omega}}-\rho_s\,\frac{\partial v}{\partial\nu_{\partial\Omega}}\\&=\frac{1}{2}\,u^2\,\lambda(\psi)\,\frac{\partial[\sigma(v)]}{\partial\nu_{\partial\Omega}}-\frac{1}{3}\,u^3\,\lambda(\psi)\,\frac{\partial w}{\partial\nu_{\partial\Omega}}-\rho_b\,u\,\frac{\partial\psi}{\partial\nu_{\partial\Omega}}=0\quad\text{on }\partial\Omega\times(0,T),\end{aligned} \tag{1.7f}$$

where $\nu_{\partial\Omega}$ is normal to $\partial\Omega$, the Lipschitz boundary of Ω, and $T>0$ is a fixed positive time. In the above $c,\rho_b,K,\beta\in\mathbb{R}_{>0}$, and $\rho_s\in\mathbb{R}_{\geq 0}$ are given constants, while $\sigma\in C^1(\mathbb{R}_{\geq 0})$ and $\phi:\mathbb{R}_{>0}\to\mathbb{R}$ are given by (1.2) and (1.4), with $a\geq 0$, $\delta>0$, and u^0, v^0, and ψ^0 are given initial profiles.

Note that (1.7d) is just a combination of (1.1a) and the modified (1.1d), obtained by multiplying (1.1a) with $\lambda(\psi)$ and the modified (1.1d) with u. This is crucial for the analysis in this paper, as it allows us to exploit a Lyapunov structure that was not available before. The other main ingredients of our approach are two energy estimates for the surfactant driven flow combined with a regularization procedure. In particular, for any given $\varepsilon\in(0,\lambda_M)$, we introduce the regularized function

$$\lambda_\varepsilon(s):=\max\{\lambda(s),\varepsilon\}, \tag{1.8}$$

which yields the regularized system (P_ε), i.e., (P) with $\{u,w,v,\psi,\lambda\}$ replaced by $\{u_\varepsilon,w_\varepsilon,v_\varepsilon,\psi_\varepsilon,\lambda_\varepsilon\}$. On defining the horizontal velocity field $\vec{\mathcal{V}}_\varepsilon(y)$, similarly to BGN and BN, as

$$\vec{\mathcal{V}}_\varepsilon(y)=y\,\nabla[\sigma(v_\varepsilon)]+\left(\frac{1}{2}\,y^2-y\,u_\varepsilon\right)\nabla w_\varepsilon, \tag{1.9}$$

where the modified pressure $w_\varepsilon=-c\,\Delta u_\varepsilon+\phi(u_\varepsilon)$, we can recast the system (P_ε) in terms of this velocity field as follows:

$$\frac{\partial u_\varepsilon}{\partial t}+\nabla\cdot\left(\int_0^{u_\varepsilon}\vec{\mathcal{V}}_\varepsilon(y)\;\mathrm{d}y\right)=0, \tag{1.10a}$$

$$\frac{\partial v_\varepsilon}{\partial t}+\nabla\cdot(\lambda_\varepsilon(v_\varepsilon)\,\vec{\mathcal{V}}_\varepsilon(u_\varepsilon))=\rho_s\,\Delta v_\varepsilon+K\,(\psi_\varepsilon-v_\varepsilon)\,, \tag{1.10b}$$

$$\begin{aligned}&\frac{\partial(u_\varepsilon\,\lambda_\varepsilon(\psi_\varepsilon))}{\partial t}+\nabla\cdot\left(\lambda_\varepsilon(\psi_\varepsilon)\int_0^{u_\varepsilon}\vec{\mathcal{V}}_\varepsilon(y)\;\mathrm{d}y\right)=\rho_b\,\nabla\cdot\,(u_\varepsilon\,\nabla\psi_\varepsilon)-\beta\,K(\psi_\varepsilon-v_\varepsilon),\\&\nu_{\partial\Omega}\cdot\int_0^{u_\varepsilon}\vec{\mathcal{V}}_\varepsilon(y)\;\mathrm{d}y=\nu_{\partial\Omega}\cdot(\lambda_\varepsilon(v_\varepsilon)\,\vec{\mathcal{V}}_\varepsilon(u_\varepsilon)-\rho_s\,\nabla v_\varepsilon)\\&=\nu_{\partial\Omega}\cdot\left(\lambda_\varepsilon(\psi_\varepsilon)\int_0^{u_\varepsilon}\vec{\mathcal{V}}_\varepsilon(y)\;\mathrm{d}y-\rho_b\,u_\varepsilon\,\nabla\psi_\varepsilon\right)=0.\end{aligned} \tag{1.10c, 1.10d}$$

We see from (1.9) that (P) is derived on assuming a no-slip condition at $y=0$.

In order to derive the crucial energy estimates, we introduce the regularized function F_ε such that

$$F_\varepsilon''(s) = [\lambda_\varepsilon(s)]^{-1} \quad \text{and} \quad F_\varepsilon(1) = F_\varepsilon'(1) = 0, \tag{1.11}$$

which implies that

$$F_\varepsilon(s) := \begin{cases} \frac{s^2-\varepsilon^2}{2\,\varepsilon} + (\ln\varepsilon - 1)\,s + 1, & s \le \varepsilon, \\ s\,(\ln s - 1) + 1, & \varepsilon \le s \le 1, \\ \frac{1}{2}\,(s-1)^2, & 1 \le s. \end{cases} \tag{1.12}$$

Hence $F_\varepsilon \in C^{2,1}(\mathbb{R})$ and, for later purposes, we note that

$$F_\varepsilon(s) \ge \frac{s^2}{4} - \frac{1}{2} \quad \forall\ s \ge 0 \qquad \text{and} \qquad F_\varepsilon(s) \ge \frac{s^2}{2\,\varepsilon} \quad \forall\ s \le 0\,; \tag{1.13}$$

see (2.4) in BGN. In addition, it is easily deduced that

$$\frac{[F_\varepsilon'(s)]^2}{F_\varepsilon''(s)} \le \begin{cases} 2\,\varepsilon^{-1}\,[s]_-^2 + 8\,\exp(-1), & s \le \varepsilon, \\ 4\,\exp(-2), & \varepsilon \le s \le 1, \end{cases} \quad \text{where } [s]_\pm := \pm\max\{\pm s, 0\}. \tag{1.14}$$

We also introduce

$$\widehat{F}_\varepsilon(s) := F_\varepsilon(\lambda_\varepsilon(s)) \equiv \lambda_\varepsilon(s)\,F_\varepsilon'(s) - s + 1. \tag{1.15}$$

As F_ε is convex, it follows that

$$[\lambda_\varepsilon(s) - \lambda_\varepsilon(r)]F_\varepsilon'(s) \ge \widehat{F}_\varepsilon(s) - \widehat{F}_\varepsilon(r) \quad \forall\ r, s \in \mathbb{R}. \tag{1.16}$$

We will now derive several formal estimates for $\{u_\varepsilon, w_\varepsilon, v_\varepsilon, \psi_\varepsilon\}$. Testing equation (1.10a) with w_ε and combining and noting (1.9) and (1.10d) yields that

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega \Big[\frac{c}{2}\,|\nabla u_\varepsilon|^2 + \Phi(u_\varepsilon)\Big]\,\mathrm{d}x + \int_\Omega \left(\int_0^{u_\varepsilon} |\partial_y \vec{\mathcal{V}}_\varepsilon(y)|^2\,\mathrm{d}y\right)\mathrm{d}x = -\int_\Omega \vec{\mathcal{V}}_\varepsilon(u_\varepsilon)\cdot\nabla v_\varepsilon\ \mathrm{d}x, \tag{1.17}$$

where Φ is an antiderivative of ϕ, i.e., $\Phi' \equiv \phi$. Testing (1.10b) with $F_\varepsilon'(v_\varepsilon)$ and noting (1.10d) and (1.11) yields that

$$\begin{aligned} &\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega F_\varepsilon(v_\varepsilon)\ \mathrm{d}x + \rho_s \int_\Omega F_\varepsilon''(v_\varepsilon)\,|\nabla v_\varepsilon|^2\,\mathrm{d}x \\ &\qquad = \int_\Omega \vec{\mathcal{V}}_\varepsilon(u_\varepsilon)\cdot\nabla v_\varepsilon\ \mathrm{d}x + K\int_\Omega (\psi_\varepsilon - v_\varepsilon)\,F_\varepsilon'(v_\varepsilon)\ \mathrm{d}x. \end{aligned} \tag{1.18}$$

Moreover, it follows from testing (1.10c) with $F_\varepsilon'(\psi_\varepsilon)$ and testing (1.10a) with $\psi_\varepsilon - 1$, on noting (1.15), $F_\varepsilon'(\lambda_\varepsilon(\psi_\varepsilon))\,\frac{\partial[\lambda_\varepsilon(\psi_\varepsilon)]}{\partial t} = F_\varepsilon'(\psi_\varepsilon)\,\frac{\partial[\lambda_\varepsilon(\psi_\varepsilon)]}{\partial t}$, (1.10d), and (1.11), that

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega u_\varepsilon\,\widehat{F}_\varepsilon(\psi_\varepsilon)\ \mathrm{d}x &= \int_\Omega \frac{\partial(u_\varepsilon\,\lambda_\varepsilon(\psi_\varepsilon))}{\partial t}\,F_\varepsilon'(\psi_\varepsilon)\ \mathrm{d}x - \int_\Omega \frac{\partial u_\varepsilon}{\partial t}\,(\psi_\varepsilon - 1)\ \mathrm{d}x \\ &= -\rho_b\int_\Omega u_\varepsilon\,F_\varepsilon''(\psi_\varepsilon)\,|\nabla\psi_\varepsilon|^2\,\mathrm{d}x - \beta\,K\int_\Omega (\psi_\varepsilon - v_\varepsilon)\,F_\varepsilon'(\psi_\varepsilon)\ \mathrm{d}x. \end{aligned} \tag{1.19}$$

Combining (1.17), (1.18), and (1.19) yields that

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega \left[\frac{c}{2}\,|\nabla u_\varepsilon|^2 + \Phi(u_\varepsilon) + F_\varepsilon(v_\varepsilon) + \frac{1}{\beta}\,u_\varepsilon\,\widehat{F}_\varepsilon(\psi_\varepsilon)\right]\mathrm{d}x + \rho_s\int_\Omega F_\varepsilon''(v_\varepsilon)\,|\nabla v_\varepsilon|^2\,\mathrm{d}x\\ + \frac{\rho_b}{\beta}\int_\Omega u_\varepsilon\,F_\varepsilon''(\psi_\varepsilon)\,|\nabla\psi_\varepsilon|^2\,\mathrm{d}x + \int_\Omega\left(\int_0^{u_\varepsilon}|\partial_y\vec{\mathcal{V}}_\varepsilon(y)|^2\,\mathrm{d}y\right)\mathrm{d}x\\ + K\int_\Omega (F_\varepsilon'(\psi_\varepsilon) - F_\varepsilon'(v_\varepsilon))\,(\psi_\varepsilon - v_\varepsilon)\,\mathrm{d}x = 0.\end{aligned} \tag{1.20}$$

Due to the singularity in Φ at the origin, it immediately follows from (1.20) that $u_\varepsilon(\cdot,t) > 0$ for all $t \in (0,T)$ if $u_\varepsilon(\cdot,0) > 0$. In addition, it follows from (1.9), on applying a Young inequality

$$|r\,s| \le \frac{\gamma}{2}\,r^2 + \frac{1}{2\gamma}\,s^2 \quad \forall\ r,\,s \in \mathbb{R},\quad \gamma \in \mathbb{R}_{>0}, \tag{1.21}$$

that

$$\int_0^{u_\varepsilon}|\partial_y\vec{\mathcal{V}}_\varepsilon(y)|^2\,\mathrm{d}y \ge \frac{1}{8}\,u_\varepsilon\,|\nabla[\sigma(v_\varepsilon)]|^2 + \frac{1}{21}\,u_\varepsilon^3\,|\nabla w_\varepsilon|^2\,; \tag{1.22}$$

see (1.7) in BGN for details.

From (1.20), (1.11), (1.8), and (1.6), one can deduce uniform bounds on ∇v_ε and $u_\varepsilon\,\nabla\psi_\varepsilon$ in $L^2(\Omega_T)$. We note the crucial role that the cut-off λ_M in (1.6) plays in these estimates. Of course the cut-off λ_M can be chosen arbitrarily large, and it played no real role in our finite element approximation of (P_ε), as our computed approximations to both v_ε and ψ_ε were always strictly less than λ_M, which we set to be one. However, as it does not appear possible to obtain a priori $L^\infty(\Omega_T)$ bounds on v_ε and ψ_ε, one requires some (arbitrarily large) cut-off in (1.6) and hence in certain coefficients in (1.7a)–(1.7f), as the Lyapunov structure above is based on the relationship (1.11).

In order to obtain the second estimate, we also define a function $G \in C^\infty(\mathbb{R}_{>0})$ such that $u^3\,\nabla[G'(u)] = \nabla u$; that is,

$$G''(s) = s^{-3} \Rightarrow G'(s) = -\frac{1}{2}\,s^{-2} \Rightarrow G(s) = \frac{1}{2}\,s^{-1}, \tag{1.23}$$

where the constants of integration have been chosen to be zero. Testing (1.10a) with $G'(u_\varepsilon)$ and testing (1.1b) with $-\Delta u_\varepsilon$ yields, on noting (1.10d) and applying (1.21) (see (1.10)–(1.12) in BN for details), that

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega G(u_\varepsilon)\,\mathrm{d}x + \frac{c}{3}\int_\Omega |\Delta u_\varepsilon|^2\,\mathrm{d}x + \frac{1}{4}\int_\Omega (\phi^+)'(u_\varepsilon)\,|\nabla u_\varepsilon|^2\,\mathrm{d}x\\ \le C\left[\int_\Omega u_\varepsilon\,|\nabla[\sigma(v_\varepsilon)]|^2\,\mathrm{d}x + \int_\Omega |\nabla u_\varepsilon|^2\,\mathrm{d}x\right].\end{aligned} \tag{1.24}$$

From (1.24), (1.20), and (1.22) one can show that u_ε is uniformly bounded in $L^2(0,T;H^2(\Omega))$ if $u_\varepsilon(\cdot,0) > 0$. Furthermore, the bound (1.13) together with (1.20) yields that $\int_{\Omega_T}[v_\varepsilon]_-^2\,\mathrm{d}x\,\mathrm{d}t \le C\,\varepsilon$. One can use this, together with the last bound in (1.20), to deduce that $\int_{\Omega_T} F_\varepsilon(\psi_\varepsilon)\,\mathrm{d}x\,\mathrm{d}t \le C$ and hence that $\int_{\Omega_T}[\psi_\varepsilon]_-^2\,\mathrm{d}x\,\mathrm{d}t \le C\,\varepsilon$.

It is the goal of this paper to derive a finite element method that is consistent with the formal energy estimates (1.20) and (1.24). We stress that it is only the bound (1.24) that requires the presence of the repulsive van der Waals forces, $\delta > 0$, to control the surfactant term in (1.10a). In the absence of a surfactant/chemical, (1.24) holds with $(a, \delta > 0)$ and without $(a = \delta = 0)$ van der Waals forces.

This paper is organized as follows. In section 2 we formulate a fully practical finite element approximation of the degenerate system (P) and derive discrete analogues of the energy estimates (1.20) and (1.24). In doing so, we adapt a technique introduced in [17] and [10] for deriving a discrete entropy bound for the thin film equation. In section 3 we prove convergence, and hence existence, of a solution to the system (P) in one space dimension if $\rho_s, \delta > 0$ and in two space dimensions if, in addition, $\nu \geq 7$. In section 4 we state an iterative scheme for solving the nonlinear discrete system at each time level and present some numerical computations in both one and two space dimensions.

Finally we note that there is very little work in the PDE literature on surfactant-type problems. To our knowledge, there is no work on the degenerate soluble system (P). A numerical study of (P) can be found in [16]. We stress that this paper is a nontrivial extension of the insoluble surfactant system, (1.7a)–(1.7c) with $\psi = v$, studied in BN. First, one has to identify the Lyapunov structure for (P), which we have outlined in this introduction. Second, proving convergence of our finite element approximation to (P) and hence proving existence of a solution to (P) is far more difficult in this case. As stated earlier, we will establish a finite element approximation, which satisfies discrete analogues of (1.20) and (1.24). For the insoluble surfactant one has control on the discrete analogue of $\int_{\Omega_T} |\nabla v_\varepsilon|^2 \,\mathrm{d}x\,\mathrm{d}t$ if $\rho_s > 0$, whereas for the chemical we have control only on the discrete analogue of $\int_{\Omega_T} u_\varepsilon \,|\nabla \psi_\varepsilon|^2 \,\mathrm{d}x\,\mathrm{d}t$. This degeneracy, as we have no a priori positive lower bound on u_ε, causes a number of new difficulties in the convergence analysis.

Notation and auxiliary results. Let $D \subset \mathbb{R}^d$, $d = 1$ or 2, with a Lipschitz boundary ∂D if $d = 2$. We adopt the standard notation for Sobolev spaces, denoting the norm of $W^{m,q}(D)$ $(m \in \mathbb{N}, q \in [1, \infty])$ by $\|\cdot\|_{m,q,D}$ and the seminorm by $|\cdot|_{m,q,D}$. We extend these norms and seminorms in the natural way to the corresponding spaces of vector and matrix valued functions. For $q = 2$, $W^{m,2}(D)$ will be denoted by $H^m(D)$ with the associated norm and seminorm written as, respectively, $\|\cdot\|_{m,D}$ and $|\cdot|_{m,D}$. For notational convenience, we drop the domain subscript on the above norms and seminorms in the case $D \equiv \Omega$. Throughout $(\cdot,\cdot)$ denotes the standard L^2 inner product over Ω, while q' denotes for any $q \in [1, \infty]$ the "dual exponent" such that $\frac{1}{q} + \frac{1}{q'} = 1$. In addition we define $\fint \eta := (\eta, 1)/\underline{m}(\Omega)$ for all $\eta \in L^1(\Omega)$, where $\underline{m}(D)$ denotes the measure of D.

It is convenient to introduce the operator $\mathcal{G} : (W^{1,q'}(\Omega))' \to W^{1,q}(\Omega)$ such that

$$(\nabla \mathcal{G} z, \nabla \eta) + (\mathcal{G} z, \eta) = \langle z, \eta \rangle_{q'} \quad \forall\ \eta \in W^{1,q'}(\Omega), \tag{1.25}$$

where here and throughout $\langle \cdot, \cdot \rangle_{q'}$ denotes the duality pairing between $(W^{1,q'}(\Omega))'$ and $W^{1,q'}(\Omega)$ for any $q \in (1, 2]$.

Throughout C denotes a generic constant independent of h, τ, and ε, the mesh and temporal discretization parameters and the regularization parameter. In addition, $C(a_1, \ldots, a_I)$ denotes a constant depending on the arguments $\{a_i\}_{i=1}^I$. Furthermore, $.^{(\star)}$ denotes an expression with or without the superscript $\star$.

2. Finite element approximation. We consider the finite element approximation of (P) under the following assumptions on the mesh.

(A) Let Ω be a convex polygonal domain if $d = 2$. Let $\{\mathcal{T}^h\}_{h>0}$ be a quasi-uniform family of partitionings of Ω into disjoint open simplices κ with $h_\kappa := \operatorname{diam}(\kappa)$ and $h := \max_{\kappa\in\mathcal{T}^h} h_\kappa$, so that $\overline{\Omega} = \cup_{\kappa\in\mathcal{T}^h}\overline{\kappa}$. In addition, it is assumed for $d = 2$ that all simplices $\kappa \in \mathcal{T}^h$ are right-angled.

Associated with $\mathcal{T}^h$ is the finite element space $S^h := \{\chi \in C(\overline{\Omega}) : \chi|_\kappa \text{ is linear for all } \kappa \in \mathcal{T}^h\} \subset H^1(\Omega)$. We also introduce $S^h_{\geq 0} := \{\chi \in S^h : \chi \geq 0 \text{ in } \Omega\} \subset H^1_{\geq 0}(\Omega) := \{\eta \in H^1(\Omega) : \eta \geq 0 \text{ a.e. in } \Omega\}$ and similarly $S^h_{>0}$ and $H^1_{>0}(\Omega)$. Let J be the set of nodes of $\mathcal{T}^h$ and $\{p_j\}_{j\in J}$ the coordinates of these nodes. Let $\{\chi_j\}_{j\in J}$ be the standard basis functions for S^h; that is, $\chi_j \in S^h_{\geq 0}$ and $\chi_j(p_i) = \delta_{ij}$ for all $i, j \in J$. We introduce $\pi^h : C(\overline{\Omega}) \to S^h$, the interpolation operator, such that $(\pi^h\eta)(p_j) = \eta(p_j)$ for all $j \in J$. A discrete semi-inner product on $C(\overline{\Omega})$ is then defined by

$$(\eta_1, \eta_2)^h := \int_\Omega \pi^h(\eta_1(x)\,\eta_2(x))\,\mathrm{d}x = \sum_{j\in J} m_j\,\eta_1(p_j)\,\eta_2(p_j), \tag{2.1}$$

where $m_j := (1, \chi_j) > 0$. The induced discrete seminorm is then $|\eta|_h := [\,(\eta,\eta)^h\,]^{\frac{1}{2}}$, where $\eta \in C(\overline{\Omega})$. We introduce also the L^2 projection $Q^h : L^2(\Omega) \to S^h$ defined by $(Q^h\eta, \chi)^h = (\eta, \chi)$ for all $\chi \in S^h$.

Similarly to the approach in [10, 17], we introduce matrices $\Lambda_\varepsilon : S^h \to [L^\infty(\Omega)]^{d\times d}$ and $\Xi : S^h_{>0} \to [L^\infty(\Omega)]^{d\times d}$ such that for all $z^h \in S^h$, $\chi \in S^h_{>0}$ and a.e. in Ω

$$\Lambda_\varepsilon(z^h),\ \Xi(\chi) \text{ are symmetric and positive semidefinite,} \tag{2.2a}$$

$$\Lambda_\varepsilon(z^h)\,\nabla\pi^h[F'_\varepsilon(z^h)] = \nabla z^h, \quad [\Xi(\chi)]^3\,\nabla\pi^h[G'(\chi)] = \nabla\chi. \tag{2.2b}$$

The construction of these matrices can be found in BN. Throughout we make use of the fact that the matrices $\Xi(\chi)$ and $\Lambda_\varepsilon(z^h)$ commute for any $\chi \in S^h_{>0}$ and $z^h \in S^h$.

As in BN, it is convenient to split Φ (recall (1.20)) into its convex and concave parts. We have for given $a \in \mathbb{R}_{\geq 0}$, $\delta \in \mathbb{R}_{>0}$, and $\nu > 3$ that for all $s \in \mathbb{R}_{>0}$

$$\Phi(s) = \Phi^+(s) + \Phi^-(s), \quad \text{where } \Phi^+(s) := \frac{\delta}{\nu-1}\,s^{1-\nu}, \quad \Phi^-(s) := -\frac{a}{2}\,s^{-2}. \tag{2.3}$$

It holds, on recalling (1.4), that $\phi^+ \equiv (\Phi^+)'$ and $\phi^- \equiv (\Phi^-)'$. For future reference, we note that the following hold for all $r, s \in \mathbb{R}_{>0}$:

$$\begin{aligned} \Phi(s) &\geq -\frac{a\,(\nu-3)}{2\,(\nu-1)}\left(\frac{a}{\delta}\right)^{\frac{2}{\nu-3}} \quad \text{and} \\ -\Phi^-(s) &\leq \frac{a\,(\nu-3)}{2\,(\nu-1)}\left(\frac{2\,a}{\delta}\right)^{\frac{2}{\nu-3}} + \frac{1}{2}\,\Phi^+(s). \end{aligned} \tag{2.4}$$

In addition to $\mathcal{T}^h$, let $0 = t_0 < t_1 < \cdots < t_{N-1} < t_N = T$ be a partitioning of $[0, T]$ into possibly variable time steps $\tau_n := t_n - t_{n-1}$, $n = 1 \to N$. We set $\tau := \max_{n=1\to N}\tau_n$. For any given $\varepsilon \in (0, 1)$, we then consider the following fully practical finite element approximation of (P) with $\sigma(v)$ given by (1.5) and $\phi(u)$ given by (1.4):

($\mathrm{P}_\varepsilon^{h,\tau}$) For $n \geq 1$ find $\{U_\varepsilon^n, W_\varepsilon^n, V_\varepsilon^n, \Psi_\varepsilon^n\} \in [S^h]^4$ such that for all $\chi \in S^h$

$$\left(\frac{U_\varepsilon^n - U_\varepsilon^{n-1}}{\tau_n}, \chi\right)^h + \frac{1}{3}\left([\Xi(U_\varepsilon^n)]^3 \nabla W_\varepsilon^n, \nabla\chi\right)$$

$$= -\frac{1}{2}\left([\Xi(U_\varepsilon^n)]^{\frac{3}{2}} [\Xi(U_\varepsilon^{n-1})]^{\frac{1}{2}} \nabla V_\varepsilon^{n-1}, \nabla\chi\right), \tag{2.5a}$$

$$c\,(\nabla U_\varepsilon^n, \nabla\chi) + (\phi^+(U_\varepsilon^n) + \phi^-(U_\varepsilon^{n-1}), \chi)^h = (W_\varepsilon^n, \chi)^h, \tag{2.5b}$$

$$\left(\frac{V_\varepsilon^n - V_\varepsilon^{n-1}}{\tau_n}, \chi\right)^h + \rho_s\,(\nabla V_\varepsilon^n, \nabla\chi) + \left(\Xi(U_\varepsilon^n)\,\Lambda_\varepsilon(V_\varepsilon^n)\,\nabla V_\varepsilon^n, \nabla\chi\right)$$

$$- K\,(\Psi_\varepsilon^n - V_\varepsilon^n, \chi)^h = -\frac{1}{2}\left([\Xi(U_\varepsilon^n)]^2\,\Lambda_\varepsilon(V_\varepsilon^n)\,\nabla W_\varepsilon^n, \nabla\chi\right), \tag{2.5c}$$

$$\left(\frac{U_\varepsilon^n\,\lambda_\varepsilon(\Psi_\varepsilon^n) - U_\varepsilon^{n-1}\,\lambda_\varepsilon(\Psi_\varepsilon^{n-1})}{\tau_n}, \chi\right)^h + \rho_b\,(U_\varepsilon^n\,\nabla\Psi_\varepsilon^n, \nabla\chi)$$

$$+ \frac{1}{3}\left([\Xi(U_\varepsilon^n)]^3\,\Lambda_\varepsilon(\Psi_\varepsilon^n)\,\nabla W_\varepsilon^n, \nabla\chi\right) + \beta\,K\,(\Psi_\varepsilon^n - V_\varepsilon^n, \chi)^h$$

$$= -\frac{1}{2}\left([\Xi(U_\varepsilon^n)]^{\frac{3}{2}} [\Xi(U_\varepsilon^{n-1})]^{\frac{1}{2}}\,\Lambda_\varepsilon(\Psi_\varepsilon^n)\,\nabla V_\varepsilon^{n-1}, \nabla\chi\right), \tag{2.5d}$$

where $U_\varepsilon^0 \in S^h_{>0}$, $V_\varepsilon^0 \in S^h$, and $\Psi_\varepsilon^0 \in S^h$ are approximations of u^0, v^0, and ψ^0, respectively, e.g., $U_\varepsilon^0 \equiv \pi^h u^0$ or $Q^h u^0$ and similarly for V_ε^0 and Ψ_ε^0.

Remark 2.1. ($\mathrm{P}_\varepsilon^{h,\tau}$) is the natural extension of the approximation of the insoluble surfactant system studied in BN. In particular, on setting $\Psi_\varepsilon^n \equiv V_\varepsilon^n$, $n = 1 \to N$, equations (2.5a)–(2.5c) collapse to the approximation in BN. Note that we approximate u^2 by $[\Xi(U_\varepsilon^n)]^{\frac{3}{2}}\,[\Xi(U_\varepsilon^{n-1})]^{\frac{1}{2}}$ in (2.5d) in order for our discrete stability bounds, the analogues of (1.20) and (1.24), to hold. Furthermore, as $U_\varepsilon^0 > 0$, one can ensure that $\Xi(U_\varepsilon^{n-1})$ and $\phi^-(U_\varepsilon^{n-1})$ are well defined for $n \geq 1$; see Theorem 2.3 below.

Remark 2.2. The restriction of σ to the linear case (1.5) is not crucial for the analysis in this paper. However, this choice simplifies our considerations and is also more practical. Different choices of σ, e.g., (1.3), can be incorporated; see Remark 2.2 in BN for details.

Below we recall some well-known results concerning S^h for any $\kappa \in \mathcal{T}^h$, $\chi, z^h \in S^h$, $m \in \{0,1\}$, $p \in [1,\infty]$, $s \in [2,\infty]$ if $d = 1$, and $s \in (2,\infty]$ if $d = 2$:

$$|\chi|_{m,r,\kappa} \leq C\,h_\kappa^{-d\,(\frac{1}{p}-\frac{1}{r})}\,|\chi|_{m,p,\kappa} \quad \text{for any } r \in [p,\infty]\,, \tag{2.6}$$

$$\lim_{h\to 0} \|(I-\pi^h)\eta\|_{1,s} = 0 \quad \forall\ \eta \in W^{1,s}(\Omega)\,, \tag{2.7}$$

$$|(I-\pi^h)\eta|_{m,s,\kappa} \leq C\,h_\kappa^{1-m}\,|\eta|_{1,s,\kappa} \quad \forall\ \eta \in W^{1,s}(\kappa)\,, \tag{2.8}$$

$$\|\pi^h[\chi\,z^h]\|_{1,p} \leq C\,\left[|\chi\,z^h|_{0,p} + |\chi\,\nabla z^h|_{0,p} + |z^h\,\nabla\chi|_{0,p}\right], \tag{2.9}$$

$$\int_\kappa \chi^2\,\mathrm{d}x \leq \int_\kappa \pi^h[\chi^2]\,\mathrm{d}x \leq (d+2)\int_\kappa \chi^2\,\mathrm{d}x\,, \tag{2.10}$$

$$|(\chi, z^h) - (\chi, z^h)^h| \leq |(I-\pi^h)(\chi\,z^h)|_{0,1} \leq C\,h^{1+m}\,|\chi|_{m,p}\,|z^h|_{1,p'}. \tag{2.11}$$

On recalling (2.1), we see that the operator Q^h satisfies

$$(Q^h\eta)(p_j) = m_j^{-1}(\eta,\chi_j) \quad \forall\, j\in J \Rightarrow |Q^h\eta|_{0,\infty} \le |\eta|_{0,\infty}, \quad \forall\, \eta\in L^\infty(\Omega), \tag{2.12}$$

and, in addition, it holds for $m\in\{0,1\}$ that

$$|(I-Q^h)\eta|_{m,r} \le C\,h^{1-m}\,|\eta|_{1,r} \quad \forall\,\eta\in W^{1,r}(\Omega), \quad \text{for any } r\in[2,\infty]. \tag{2.13}$$

We note that assumption (A) and (1.11) yield that

$$\int_\kappa \nabla z^h\cdot\nabla\pi^h[F_\varepsilon'(z^h)]\,\mathrm{d}x \ge |z^h|^2_{1,\kappa} \qquad \forall\, z^h\in S^h, \quad \forall\,\kappa\in\mathcal{T}^h; \tag{2.14}$$

see (2.13) in BN for details. It is also easily established that

$$|z^h|_{0,q} \le C\,h^{-1}\,\|\mathcal{G}z^h\|_{1,q} \quad \forall\, z^h\in S^h, \quad \text{for any } q\in(1,2]. \tag{2.15}$$

We note that the results (2.13) and (2.15) above exploit the fact that we have a quasi-uniform family of partitionings $\{\mathcal{T}^h\}_{h>0}$. Finally, we introduce the "discrete Laplacian" operator $\Delta^h : S^h\to S^h$ such that $(\Delta^h z^h,\chi)^h = -(\nabla z^h,\nabla\chi)$ for all $\chi\in S^h$.

THEOREM 2.3. *Let $\phi(\cdot)$ satisfy* (1.4) *with $\delta>0$. Let the assumptions* (A) *hold and $\{U_\varepsilon^{n-1},V_\varepsilon^{n-1},\Psi_\varepsilon^{n-1}\}\in S^h_{>0}\times[S^h]^2$. Then for all $\varepsilon\in(0,1)$ and for all h, $\tau_n>0$ there exists a solution $\{U_\varepsilon^n,W_\varepsilon^n,V_\varepsilon^n,\Psi_\varepsilon^n\}\in S^h_{>0}\times[S^h]^3$ to the nth step of* ($\mathrm{P}_\varepsilon^{h,\tau}$) *with $\fint U_\varepsilon^n = \fint U_\varepsilon^{n-1}$ and $\fint(V_\varepsilon^n+\frac{1}{\beta}\,\pi^h[U_\varepsilon^n\,\lambda_\varepsilon(\Psi_\varepsilon^n)]) = \fint(V_\varepsilon^{n-1}+\frac{1}{\beta}\,\pi^h[U_\varepsilon^{n-1}\,\lambda_\varepsilon(\Psi_\varepsilon^{n-1})])$.*

Proof. Existence of a solution $\{U_\varepsilon^n,W_\varepsilon^n\}\in S^h_{>0}\times S^h$ to (2.5a)–(2.5b) follows from Lemma 2.1 in BN. To prove the existence of $\{V_\varepsilon^n,\Psi_\varepsilon^n\}$ to (2.5c)–(2.5d) we will make use of the *Brouwer fixed point theorem* (see, e.g., [14, Theorem 9.36, p. 357]). This is a nontrivial extension of the existence proof for V_ε^n in Theorem 2.1 of BGN. Let $\mathcal{J}:=\#J$ and let $g:\mathbb{R}^{2\mathcal{J}}\to\mathbb{R}^{2\mathcal{J}}$ be defined by

$$\begin{aligned}
g_j(\underline{V},\underline{\Psi}) &:= \frac{1}{\tau_n}\,(V,\chi_j)^h + \rho_s\,(\nabla V,\nabla\chi_j) + (\Xi(U_\varepsilon^n)\,\Lambda_\varepsilon(V)\,\nabla V,\nabla\chi_j)\\
&\qquad - K\,(\Psi-V,\chi_j)^h + \frac{1}{2}\,([\Xi(U_\varepsilon^n)]^2\,\Lambda_\varepsilon(V)\,\nabla W_\varepsilon^n,\nabla\chi_j),\\
g_{j+\mathcal{J}}(\underline{V},\underline{\Psi}) &:= \frac{1}{\beta}\left[\frac{1}{\tau_n}\,(U_\varepsilon^n\,\lambda_\varepsilon(\Psi),\chi_j)^h + \rho_b\,(U_\varepsilon^n\,\nabla\Psi,\nabla\chi_j)\right.\\
&\qquad + \frac{1}{3}\,([\Xi(U_\varepsilon^n)]^3\,\Lambda_\varepsilon(\Psi)\,\nabla W_\varepsilon^n,\nabla\chi_j) + \beta\,K\,(\Psi-V,\chi_j)^h\\
&\qquad \left. + \frac{1}{2}\,([\Xi(U_\varepsilon^n)]^{\frac{3}{2}}\,[\Xi(U_\varepsilon^{n-1})]^{\frac{1}{2}}\,\Lambda_\varepsilon(\Psi)\,\nabla V_\varepsilon^{n-1},\nabla\chi_j)\right] \quad \forall\, j\in J,
\end{aligned}$$

where $V\equiv\sum_{j\in J}V_j\,\chi_j$, $\Psi\equiv\sum_{j\in J}\Psi_j\,\chi_j$, and $\{\underline{V},\underline{\Psi}\}:=(V_1,\ldots,V_{\mathcal{J}},\Psi_1,\ldots,\Psi_{\mathcal{J}})^T\in\mathbb{R}^{2\mathcal{J}}$. Hence a solution $\{V_\varepsilon^n,\Psi_\varepsilon^n\}$ of (2.5c)–(2.5d) is such that for $j=1\to\mathcal{J}$

$$g_j(\underline{V}_\varepsilon^n,\underline{\Psi}_\varepsilon^n) = \tfrac{1}{\tau_n}(V_\varepsilon^{n-1},\chi_j)^h, \qquad g_{j+\mathcal{J}}(\underline{V}_\varepsilon^n,\underline{\Psi}_\varepsilon^n) = \tfrac{1}{\beta\,\tau_n}(U_\varepsilon^{n-1}\lambda_\varepsilon(\Psi_\varepsilon^{n-1}),\chi_j)^h.$$

On noting Lemma 2.1 in BGN we have that g is continuous, and hence it is sufficient to show that g is coercive. We have that for all $\{V,\Psi\}\in[S^h]^2$

$$\begin{aligned}\sum_{j\in J}\left(g_j(\underline{V},\underline{\Psi})\,V_j+g_{j+\mathcal{J}}(\underline{V},\underline{\Psi})\,\Psi_j\right)&=\frac{1}{\tau_n}\,|V|_h^2+\rho_s\,|V|_1^2\\&+\left(\Xi(U_\varepsilon^n)\,\Lambda_\varepsilon(V)\,\nabla V,\nabla V\right)+K\,|\Psi-V|_h^2+\frac{1}{2}\left([\Xi(U_\varepsilon^n)]^2\,\Lambda_\varepsilon(V)\,\nabla W_\varepsilon^n,\nabla V\right)\\&+\frac{1}{\beta}\left[\frac{1}{\tau_n}\left(U_\varepsilon^n\,\lambda_\varepsilon(\Psi),\Psi\right)^h+\rho_b\,|(U_\varepsilon^n)^{\frac12}\,\nabla\Psi|_0^2+\frac{1}{3}\left([\Xi(U_\varepsilon^n)]^3\,\Lambda_\varepsilon(\Psi)\,\nabla W_\varepsilon^n,\nabla\Psi\right)\right.\\&\left.+\frac{1}{2}\left([\Xi(U_\varepsilon^n)]^{\frac32}\,[\Xi(U_\varepsilon^{n-1})]^{\frac12}\,\Lambda_\varepsilon(\Psi)\,\nabla V_\varepsilon^{n-1},\nabla\Psi\right)\right].\end{aligned}\tag{2.16}$$

From (1.21) and Lemma 2.1 in BGN we have that

$$\begin{aligned}&\frac{1}{2}\left|\left([\Xi(U_\varepsilon^n)]^2\,\Lambda_\varepsilon(V)\,\nabla W_\varepsilon^n,\nabla V\right)\right|\\&\quad\le\frac{1}{2}\left(\Xi(U_\varepsilon^n)\,\Lambda_\varepsilon(V)\,\nabla V,\nabla V\right)+\frac{1}{8}\left([\Xi(U_\varepsilon^n)]^3\,\Lambda_\varepsilon(V)\,\nabla W_\varepsilon^n,\nabla W_\varepsilon^n\right)\\&\quad\le\frac{1}{2}\left(\Xi(U_\varepsilon^n)\,\Lambda_\varepsilon(V)\,\nabla V,\nabla V\right)+C(U_\varepsilon^n,\,W_\varepsilon^n),\end{aligned}\tag{2.17a}$$

and similarly, on additionally noting Lemma 2.2 in BN and $U_\varepsilon^n\in S^h_{>0}$, that

$$\frac{1}{3\beta}\left|\left([\Xi(U_\varepsilon^n)]^3\,\Lambda_\varepsilon(\Psi)\,\nabla W_\varepsilon^n,\nabla\Psi\right)\right|\le\frac{\rho_b}{4\beta}\left(U_\varepsilon^n\,\nabla\Psi,\nabla\Psi\right)+C(\beta,\rho_b,U_\varepsilon^n,\,W_\varepsilon^n),\tag{2.17b}$$

$$\begin{aligned}&\frac{1}{2}\left([\Xi(U_\varepsilon^n)]^{\frac32}\,[\Xi(U_\varepsilon^{n-1})]^{\frac12}\,\Lambda_\varepsilon(\Psi)\,\nabla V_\varepsilon^{n-1},\nabla\Psi\right)\\&\quad\le\frac{\rho_b}{4\beta}\left(U_\varepsilon^n\,\nabla\Psi,\nabla\Psi\right)+C(\beta,\rho_b,U_\varepsilon^{n-1},U_\varepsilon^n,\,V_\varepsilon^{n-1}).\end{aligned}\tag{2.17c}$$

Moreover, it follows from (1.8) that

$$\frac{1}{\tau_n\beta}\left|\left(U_\varepsilon^n\,\lambda_\varepsilon(\Psi),\Psi\right)^h\right|\le\gamma\,|\Psi|_h^2+C(\gamma,\beta,\tau_n,U_\varepsilon^n)\qquad\text{for any fixed }\gamma>0.\tag{2.17d}$$

Combining (2.16) and (2.17)–(2.17d) yields that

$$\begin{aligned}\sum_{j\in J}\left(g_j(\underline{V},\underline{\Psi})\,V_j+g_{j+\mathcal{J}}(\underline{V},\underline{\Psi})\,\Psi_j\right)&\ge\frac{1}{\tau_n}\,|V|_h^2+K\,|\Psi-V|_h^2-\gamma\,|\Psi|_h^2-C\\&\ge\left(\frac{1}{\tau_n}-K_0\right)|V|_h^2+\left(\frac{K_0}{2}-\gamma\right)|\Psi|_h^2-C\\&\ge\frac{K_0}{4}\left[\,|V|_h^2+|\Psi|_h^2\,\right]-C\qquad\forall\;\{V,\Psi\}\in[S^h]^2,\end{aligned}\tag{2.18}$$

where $K_0\in(0,K]$ and $\gamma\in\mathbb{R}_{>0}$ are chosen sufficiently small. Hence the coerciveness of g follows from (2.18) and (2.1). Therefore, on noting the aforementioned theorem, we have existence of $\{V_\varepsilon^n,\Psi_\varepsilon^n\}$ to (2.5c)–(2.5d) and hence existence of a solution

$\{U_\varepsilon^n, W_\varepsilon^n, V_\varepsilon^n, \Psi_\varepsilon^n\}$ to $(\mathrm{P}_\varepsilon^{h,\tau})$. The integral relations follow immediately from choosing $\chi \equiv 1$ in (2.5a), (2.5c), and (2.5d). ∎

LEMMA 2.4. *Let the assumptions of Theorem* 2.3 *hold. Then for all* $\varepsilon \in (0,1)$ *and for all* h, $\tau_n > 0$ *a solution* $\{U_\varepsilon^n, W_\varepsilon^n, V_\varepsilon^n, \Psi_\varepsilon^n\}$ *to the* n*th step of* $(\mathrm{P}_\varepsilon^{h,\tau})$ *is such that*

$$\begin{aligned}
&\mathcal{E}(U_\varepsilon^n, V_\varepsilon^n, \Psi_\varepsilon^n) + \frac{c}{2}\,|U_\varepsilon^n - U_\varepsilon^{n-1}|_1^2 + \frac{1}{2}\,|V_\varepsilon^n - V_\varepsilon^{n-1}|_h^2 \\
&\qquad + \rho_s\,\tau_n\,(\nabla V_\varepsilon^n, \nabla \pi^h[F_\varepsilon'(V_\varepsilon^n)]) + \frac{1}{\beta}\,\rho_b\,\tau_n\,\big(U_\varepsilon^n\,\nabla\Psi_\varepsilon^n, \nabla\pi^h[F_\varepsilon'(\Psi_\varepsilon^n)]\big) \\
&\qquad + \tau_n\,K\,(\Psi_\varepsilon^n - V_\varepsilon^n, F_\varepsilon'(\Psi_\varepsilon^n) - F_\varepsilon'(V_\varepsilon^n))^h + \frac{\tau_n}{24}\,([\Xi(U_\varepsilon^n)]^3\,\nabla W_\varepsilon^n, \nabla W_\varepsilon^n) \\
&\qquad + \frac{5}{8}\,\tau_n\,(\Xi(U_\varepsilon^n)\,\nabla V_\varepsilon^n, \nabla V_\varepsilon^n) \\
&\quad \le \mathcal{E}(U_\varepsilon^{n-1}, V_\varepsilon^{n-1}, \Psi_\varepsilon^{n-1}) + \frac{\tau_n}{2}\,(\Xi(U_\varepsilon^{n-1})\,\nabla V_\varepsilon^{n-1}, \nabla V_\varepsilon^{n-1}),
\end{aligned} \tag{2.19}$$

where $\mathcal{E}(U_\varepsilon^n, V_\varepsilon^n, \Psi_\varepsilon^n) := \frac{c}{2}\,|U_\varepsilon^n|_1^2 + (\Phi(U_\varepsilon^n) + F_\varepsilon(V_\varepsilon^n), 1)^h + \frac{1}{\beta}\,(U_\varepsilon^n, \widehat{F}_\varepsilon(\Psi_\varepsilon^n))^h$ *and* $\widehat{F}_\varepsilon$ *is as defined in* (1.15). *Furthermore, if* $\phi(\cdot)$ *satisfies* (1.4) *with* $\nu \ge 7$, *then*

$$\begin{aligned}
&(G(U_\varepsilon^n), 1)^h + \frac{\tau_n}{4}\,(\nabla\pi^h[\phi^+(U_\varepsilon^n)], \nabla U_\varepsilon^n) + \frac{c}{3}\,\tau_n\,|\Delta^h U_\varepsilon^n|_h^2 \\
&\qquad \le (G(U_\varepsilon^{n-1}), 1)^h + \frac{\tau_n}{8}(\nabla\pi^h[\phi^+(U_\varepsilon^{n-1})], \nabla U_\varepsilon^{n-1}) \\
&\qquad\quad + C\,\tau_n\,\big[\,|U_\varepsilon^n|_1^2 + |U_\varepsilon^{n-1}|_1^2\,\big] + \frac{\tau_n}{4}\,(\Xi(U_\varepsilon^{n-1})\,\nabla V_\varepsilon^{n-1}, \nabla V_\varepsilon^{n-1}).
\end{aligned} \tag{2.20}$$

Proof. First, upon substitution of the trial function $\chi \equiv W_\varepsilon^n$ into the height equation (2.5a), we obtain

$$\begin{aligned}
&(U_\varepsilon^n - U_\varepsilon^{n-1}, W_\varepsilon^n)^h + \frac{\tau_n}{3}([\Xi(U_\varepsilon^n)]^3\,\nabla W_\varepsilon^n, \nabla W_\varepsilon^n) \\
&\qquad = -\frac{\tau_n}{2}\,([\Xi(U_\varepsilon^n)]^{\frac{3}{2}}\,[\Xi(U_\varepsilon^{n-1})]^{\frac{1}{2}}\,\nabla V_\varepsilon^{n-1}, \nabla W_\varepsilon^n).
\end{aligned} \tag{2.21}$$

Substituting $\chi \equiv U_\varepsilon^n - U_\varepsilon^{n-1}$ into (2.5b) and noting the identity $2\,r\,(r-s) = (r^2 - s^2) + (r-s)^2$, the convexity of Φ^+, and the concavity of Φ^- gives

$$\begin{aligned}
&\frac{c}{2}\,|U_\varepsilon^n|_1^2 - \frac{c}{2}\,|U_\varepsilon^{n-1}|_1^2 + \frac{c}{2}\,|U_\varepsilon^n - U_\varepsilon^{n-1}|_1^2 + (\Phi(U_\varepsilon^n) - \Phi(U_\varepsilon^{n-1}), 1)^h \\
&\qquad \le (W_\varepsilon^n, U_\varepsilon^n - U_\varepsilon^{n-1})^h.
\end{aligned} \tag{2.22}$$

Combining (2.21) and (2.22) yields

$$\begin{aligned}
&\frac{c}{2}\,|U_\varepsilon^n|_1^2 + (\Phi(U_\varepsilon^n), 1)^h + \frac{\tau_n}{3}\,([\Xi(U_\varepsilon^n)]^3\,\nabla W_\varepsilon^n, \nabla W_\varepsilon^n) + \frac{c}{2}\,|U_\varepsilon^n - U_\varepsilon^{n-1}|_1^2 \\
&\quad \le \frac{c}{2}\,|U_\varepsilon^{n-1}|_1^2 + (\Phi(U_\varepsilon^{n-1}), 1)^h - \frac{\tau_n}{2}\,([\Xi(U_\varepsilon^n)]^{\frac{3}{2}}\,[\Xi(U_\varepsilon^{n-1})]^{\frac{1}{2}}\,\nabla V_\varepsilon^{n-1}, \nabla W_\varepsilon^n).
\end{aligned} \tag{2.23}$$

Furthermore, choosing $\chi \equiv \pi^h[F_\varepsilon'(V_\varepsilon^n)]$ in the interfacial equation (2.5c) and noting the properties (2.2a)–(2.2b) of Λ_ε yields that

$$\begin{aligned}&(V_\varepsilon^n - V_\varepsilon^{n-1}, F_\varepsilon'(V_\varepsilon^n))^h + \rho_s\,\tau_n\,(\nabla V_\varepsilon^n, \nabla \pi^h[F_\varepsilon'(V_\varepsilon^n)])\\ &\quad + \tau_n\,(\Xi(U_\varepsilon^n)\,\nabla V_\varepsilon^n, \nabla V_\varepsilon^n) - \tau_n\,K\,(\Psi_\varepsilon^n - V_\varepsilon^n, \pi^h[F_\varepsilon'(V_\varepsilon^n)])^h\\ &\quad = -\frac{\tau_n}{2}\,([\Xi(U_\varepsilon^n)]^2\,\nabla W_\varepsilon^n, \nabla V_\varepsilon^n).\end{aligned} \tag{2.24}$$

Now $F_\varepsilon'' \geq 1$ implies that

$$(V_\varepsilon^n - V_\varepsilon^{n-1}, F_\varepsilon'(V_\varepsilon^n))^h \geq (F_\varepsilon(V_\varepsilon^n) - F_\varepsilon(V_\varepsilon^{n-1}), 1)^h + \frac{1}{2}\,|V_\varepsilon^{n-1} - V_\varepsilon^n|_h^2\,. \tag{2.25}$$

Combining (2.24) and (2.25) gives

$$\begin{aligned}&(F_\varepsilon(V_\varepsilon^n), 1)^h + \frac{1}{2}\,|V_\varepsilon^{n-1} - V_\varepsilon^n|_h^2 + \rho_s\,\tau_n\,(\nabla V_\varepsilon^n, \nabla \pi^h[F_\varepsilon'(V_\varepsilon^n)])\\ &\quad + \tau_n\,(\Xi(U_\varepsilon^n)\,\nabla V_\varepsilon^n, \nabla V_\varepsilon^n) - \tau_n\,K\,(\Psi_\varepsilon^n - V_\varepsilon^n, F_\varepsilon'(V_\varepsilon^n))^h\\ &\quad \leq (F_\varepsilon(V_\varepsilon^{n-1}), 1)^h - \frac{\tau_n}{2}\,([\Xi(U_\varepsilon^n)]^2\,\nabla W_\varepsilon^n, \nabla V_\varepsilon^n).\end{aligned} \tag{2.26}$$

Similarly, choosing $\chi \equiv \pi^h[F_\varepsilon'(\Psi_\varepsilon^n)]$ in the bulk chemical equation (2.5d) and using the properties (2.2a)–(2.2b) gives

$$\begin{aligned}&(U_\varepsilon^n\,\lambda_\varepsilon(\Psi_\varepsilon^n) - U_\varepsilon^{n-1}\,\lambda_\varepsilon(\Psi_\varepsilon^{n-1}), F_\varepsilon'(\Psi_\varepsilon^n))^h + \tau_n\,\rho_b\,(U_\varepsilon^n\,\nabla \Psi_\varepsilon^n, \nabla \pi^h[F_\varepsilon'(\Psi_\varepsilon^n)])\\ &\qquad + \frac{\tau_n}{3}\,([\Xi(U_\varepsilon^n)]^3\,\nabla W_\varepsilon^n, \nabla \Psi_\varepsilon^n) + \tau_n\,\beta\,K\,(\Psi_\varepsilon^n - V_\varepsilon^n, F_\varepsilon'(\Psi_\varepsilon^n))^h\\ &\quad = -\frac{\tau_n}{2}\,([\Xi(U_\varepsilon^n)]^{\frac{3}{2}}\,[\Xi(U_\varepsilon^{n-1})]^{\frac{1}{2}}\,\nabla V_\varepsilon^{n-1}, \nabla \Psi_\varepsilon^n).\end{aligned}$$

Combining this with the height equation (2.5a) for $\chi \equiv \Psi_\varepsilon^n$ gives

$$\begin{aligned}&(U_\varepsilon^n\,\lambda_\varepsilon(\Psi_\varepsilon^n) - U_\varepsilon^{n-1}\,\lambda_\varepsilon(\Psi_\varepsilon^{n-1}), F_\varepsilon'(\Psi_\varepsilon^n))^h - (U_\varepsilon^n - U_\varepsilon^{n-1}, \Psi_\varepsilon^n)^h\\ &\quad = -\tau_n\,\rho_b\,(U_\varepsilon^n\,\nabla \Psi_\varepsilon^n, \nabla \pi^h[F_\varepsilon'(\Psi_\varepsilon^n)]) - \tau_n\,\beta\,K\,(\Psi_\varepsilon^n - V_\varepsilon^n, F_\varepsilon'(\Psi_\varepsilon^n))^h.\end{aligned} \tag{2.27}$$

We recall (1.15) and (1.16) and also note that $(U_\varepsilon^n - U_\varepsilon^{n-1}, 1)^h = 0$, which follows from inserting $\chi \equiv 1$ into (2.5a). Then the left-hand side of (2.27) may be rewritten as

$$\begin{aligned}&(U_\varepsilon^n\,\lambda_\varepsilon(\Psi_\varepsilon^n) - U_\varepsilon^{n-1}\,\lambda_\varepsilon(\Psi_\varepsilon^{n-1}), F_\varepsilon'(\Psi_\varepsilon^n))^h - (U_\varepsilon^n - U_\varepsilon^{n-1}, \Psi_\varepsilon^n)^h\\ &\quad = (U_\varepsilon^n - U_\varepsilon^{n-1}, \lambda_\varepsilon(\Psi_\varepsilon^n)\,F_\varepsilon'(\Psi_\varepsilon^n) - \Psi_\varepsilon^n)^h + (\lambda_\varepsilon(\Psi_\varepsilon^n) - \lambda_\varepsilon(\Psi_\varepsilon^{n-1}), U_\varepsilon^{n-1}\,F_\varepsilon'(\Psi_\varepsilon^n))^h\\ &\quad \geq (U_\varepsilon^n - U_\varepsilon^{n-1}, \widehat{F}_\varepsilon(\Psi_\varepsilon^n) - 1)^h + (\widehat{F}_\varepsilon(\Psi_\varepsilon^n) - \widehat{F}_\varepsilon(\Psi_\varepsilon^{n-1}), U_\varepsilon^{n-1})^h\\ &\quad = (U_\varepsilon^n\,\widehat{F}_\varepsilon(\Psi_\varepsilon^n) - U_\varepsilon^{n-1}\,\widehat{F}_\varepsilon(\Psi_\varepsilon^{n-1}), 1)^h,\end{aligned}$$

and thus

$$\begin{aligned}&(U_\varepsilon^n\,\widehat{F}_\varepsilon(\Psi_\varepsilon^n) - U_\varepsilon^{n-1}\,\widehat{F}_\varepsilon(\Psi_\varepsilon^{n-1}), 1)^h\\ &\quad \leq -\tau_n\,\rho_b\,(U_\varepsilon^n\,\nabla \Psi_\varepsilon^n, \nabla \pi^h[F_\varepsilon'(\Psi_\varepsilon^n)]) - \tau_n\,\beta\,K\,(\Psi_\varepsilon^n - V_\varepsilon^n, F_\varepsilon'(\Psi_\varepsilon^n))^h.\end{aligned} \tag{2.28}$$

Combining (2.23), (2.26), and (2.28) and noting Young's inequality (1.21) yields that

$$\begin{aligned}
&\mathcal{E}(U_\varepsilon^n, V_\varepsilon^n, \Psi_\varepsilon^n) + \frac{c}{2}\,|U_\varepsilon^n - U_\varepsilon^{n-1}|_1^2 + \frac{1}{2}\,|V_\varepsilon^n - V_\varepsilon^{n-1}|_h^2 + \rho_s\,\tau_n\,(\nabla V_\varepsilon^n, \nabla \pi^h[F_\varepsilon'(V_\varepsilon^n)])\\
&\qquad + \frac{1}{\beta}\,\tau_n\,\rho_b\,(U_\varepsilon^n\,\nabla\Psi_\varepsilon^n, \nabla\pi^h[F_\varepsilon'(\Psi_\varepsilon^n)]) + \tau_n\,K\,(\Psi_\varepsilon^n - V_\varepsilon^n, F_\varepsilon'(\Psi_\varepsilon^n) - F_\varepsilon'(V_\varepsilon^n))^h\\
&\qquad + \frac{\tau_n}{3}\,([\Xi(U_\varepsilon^n)]^3\,\nabla W_\varepsilon^n, \nabla W_\varepsilon^n) + \tau_n\,(\Xi(U_\varepsilon^n)\,\nabla V_\varepsilon^n, \nabla V_\varepsilon^n)\\
&\le \mathcal{E}(U_\varepsilon^{n-1}, V_\varepsilon^{n-1}, \Psi_\varepsilon^{n-1}) - \frac{\tau_n}{2}\,([\Xi(U_\varepsilon^n)]^2\,\nabla W_\varepsilon^n, \nabla V_\varepsilon^n)\\
&\qquad - \frac{\tau_n}{2}\,([\Xi(U_\varepsilon^n)]^{\frac{3}{2}}\,[\Xi(U_\varepsilon^{n-1})]^{\frac{1}{2}}\,\nabla W_\varepsilon^n, \nabla V_\varepsilon^{n-1})\\
&\le \mathcal{E}(U_\varepsilon^{n-1}, V_\varepsilon^{n-1}, \Psi_\varepsilon^{n-1}) + \frac{\zeta+\gamma}{4}\,\tau_n\,([\Xi(U_\varepsilon^n)]^3\,\nabla W_\varepsilon^n, \nabla W_\varepsilon^n)\\
&\qquad + \frac{\tau_n}{4\zeta}\,(\Xi(U_\varepsilon^{n-1})\,\nabla V_\varepsilon^{n-1}, \nabla V_\varepsilon^{n-1}) + \frac{\tau_n}{4\gamma}\,(\Xi(U_\varepsilon^n)\,\nabla V_\varepsilon^n, \nabla V_\varepsilon^n)
\end{aligned}$$

for arbitrary choices of ζ, $\gamma > 0$. Choosing $\zeta = \frac{1}{2}$ and $\gamma = \frac{2}{3}$ leads to the desired result for the discrete energy structure (2.19).

The desired result (2.20) was derived in Lemma 2.4 in BN. ∎

Remark 2.5. We note that (2.19) and (2.20) are the discrete analogues of the formal energy estimates (1.20) (on noting (1.22)) and (1.24), respectively.

THEOREM 2.6. *Let $\phi(\cdot)$ satisfy* (1.4) *with $\delta > 0$. Let the assumptions* (A) *hold and $\{U_\varepsilon^0, V_\varepsilon^0, \Psi_\varepsilon^0\} \in S_{>0}^h \times [S^h]^2$. Then for all $\varepsilon \in (0,1)$, $h > 0$ and for all time partitions $\{\tau_n\}_{n=1}^N$ a solution $\{U_\varepsilon^n, W_\varepsilon^n, V_\varepsilon^n, \Psi_\varepsilon^n\}_{n=1}^N$ to $(\mathrm{P}_\varepsilon^{h,\tau})$ is such that $\fint U_\varepsilon^n = \fint U_\varepsilon^0$ and $\fint (V_\varepsilon^n + \frac{1}{\beta}\,\pi^h[U_\varepsilon^n\,\lambda_\varepsilon(\Psi_\varepsilon^n)]) = \fint (V_\varepsilon^0 + \frac{1}{\beta}\,\pi^h[U_\varepsilon^0\,\lambda_\varepsilon(\Psi_\varepsilon^0)])$, $n = 1 \to N$, and if $\tau_n \le \frac{5}{4}\,\omega\,\tau_{n-1}$, $n = 2 \to N$, for an $\omega \in (0,1)$, then*

$$\begin{aligned}
&c\max_{n=1\to N}\|U_\varepsilon^n\|_1^2 + \max_{n=1\to N}(\Phi(U_\varepsilon^n),1)^h + \max_{n=1\to N}(F_\varepsilon(V_\varepsilon^n),1)^h\\
&\qquad + c\sum_{n=1}^N \|U_\varepsilon^n - U_\varepsilon^{n-1}\|_1^2 + \sum_{n=1}^N |V_\varepsilon^n - V_\varepsilon^{n-1}|_0^2\\
&\qquad + \rho_s\sum_{n=1}^N \tau_n\,(\nabla V_\varepsilon^n, \nabla\pi^h[F_\varepsilon'(V_\varepsilon^n)]) + \sum_{n=1}^N \tau_n\,([\Xi(U_\varepsilon^n)]^3\,\nabla W_\varepsilon^n, \nabla W_\varepsilon^n)\\
&\qquad + (1-\omega)\sum_{n=1}^N \tau_n\,(\Xi(U_\varepsilon^n)\,\nabla V_\varepsilon^n, \nabla V_\varepsilon^n) + \rho_b\sum_{n=1}^N \tau_n\,(U_\varepsilon^n\,\nabla\Psi_\varepsilon^n, \nabla\Psi_\varepsilon^n)\\
&\qquad + K\sum_{n=1}^N \tau_n\,(\Psi_\varepsilon^n - V_\varepsilon^n, F_\varepsilon'(\Psi_\varepsilon^n) - F_\varepsilon'(V_\varepsilon^n))^h \le C\,\mathcal{C}^0,
\end{aligned} \tag{2.29a}$$

where

$$\mathcal{C}^0 := 1 + \|U_\varepsilon^0\|_1^2 + (\Phi(U_\varepsilon^0) + F_\varepsilon(V_\varepsilon^0),1)^h + (U_\varepsilon^0, \widehat{F}_\varepsilon(\Psi_\varepsilon^0))^h + (\Xi(U_\varepsilon^0)\,\nabla V_\varepsilon^0, \nabla V_\varepsilon^0). \tag{2.29b}$$

In addition,

$$\max_{n=1\to N}|V_\varepsilon^n|_0^2+\varepsilon^{-1}\max_{n=1\to N}|\pi^h[V_\varepsilon^n]_-|_0^2+\rho_s\sum_{n=1}^N\tau_n\,\|V_\varepsilon^n\|_1^2+K\sum_{n=1}^N\tau_n\,|\Psi_\varepsilon^n-V_\varepsilon^n|_0^2$$

$$+\sum_{n=1}^N\tau_n\,\big[\,(F_\varepsilon(\Psi_\varepsilon^n),1)^h+|\Psi_\varepsilon^n|_0^2+\varepsilon^{-1}\,|\pi^h[\Psi_\varepsilon^n]_-|_0^2\,\big]\le C\,\mathcal{C}^0, \tag{2.30}$$

and, on letting $B_\varepsilon^n:=\pi^h[U_\varepsilon^n\,\lambda_\varepsilon(\Psi_\varepsilon^n)]$, $n=0\to N$, *we have that*

$$\sum_{n=1}^N\tau_n\left[\left\|\mathcal{G}\left[\frac{U_\varepsilon^n-U_\varepsilon^{n-1}}{\tau_n}\right]\right\|_{1,q}^2+\left\|\mathcal{G}\left[\frac{V_\varepsilon^n-V_\varepsilon^{n-1}}{\tau_n}\right]\right\|_{1,q}^2+\left\|\mathcal{G}\left[\frac{B_\varepsilon^n-B_\varepsilon^{n-1}}{\tau_n}\right]\right\|_{1,q}^2\right]$$

$$+\sum_{n=1}^N\tau_n\,\|B_\varepsilon^n\|_{1,q}^2\le C\left(\max_{n=0\to N}\{|[\Xi(U_\varepsilon^n)]^3|_{0,r},|(U_\varepsilon^n)^{\frac12}|_{0,r}\}\right)\mathcal{C}^0, \tag{2.31a}$$

where $q=2$ *and* $r=\infty$ *if* $d=1$, $q\in(1,2)$; *and* $r=\frac{2q}{2-q}$ *if* $d=2$; *and*

$$|[\Xi(U_\varepsilon^n)]^\alpha|_{0,s}\le C\,\|U_\varepsilon^n\|_1^\alpha\qquad\forall\ \alpha\in(0,\infty),\quad\forall\ s\in\begin{cases}[1,\infty] & \text{if } d=1,\\ [1,\infty) & \text{if } d=2.\end{cases} \tag{2.31b}$$

Furthermore, if $\phi(\cdot)$ *satisfies* (1.4) *with* $\nu\ge7$, *then*

$$\max_{n=1\to N}(G(U_\varepsilon^n),1)^h+c\sum_{n=1}^N\tau_n\,|\Delta^hU_\varepsilon^n|_h^2+\sum_{n=1}^N\tau_n\,(\nabla\pi^h[\phi^+(U_\varepsilon^n)],\nabla U_\varepsilon^n)$$

$$\le C\,\big[\,\mathcal{C}^0+(G(U_\varepsilon^0),1)^h+(\nabla\pi^h[\phi^+(U_\varepsilon^0)],\nabla U_\varepsilon^0)\,\big]. \tag{2.32}$$

Proof. Summing the discrete energy estimate (2.19) from $n=1\to k$ and using $\tau_n\le\frac54\,\omega\,\tau_{n-1}$, $n=2\to k$, yields for any $k\le N$ that

$$\begin{aligned}&\mathcal{E}(U_\varepsilon^k,V_\varepsilon^k,\Psi_\varepsilon^k)+\frac12\sum_{n=1}^k\big[c\,|U_\varepsilon^n-U_\varepsilon^{n-1}|_1^2+|V_\varepsilon^n-V_\varepsilon^{n-1}|_h^2\big]\\&\quad+\rho_s\sum_{n=1}^k\tau_n\,(\nabla V_\varepsilon^n,\nabla\pi^h[F_\varepsilon'(V_\varepsilon^n)])+\frac{1}{\beta}\,\rho_b\sum_{n=1}^k\tau_n\,(U_\varepsilon^n\,\nabla\Psi_\varepsilon^n,\nabla\pi^h[F_\varepsilon'(\Psi_\varepsilon^n)])\\&\quad+\sum_{n=1}^k\tau_n\left[K\,(\Psi_\varepsilon^n-V_\varepsilon^n,F_\varepsilon'(\Psi_\varepsilon^n)-F_\varepsilon'(V_\varepsilon^n))^h+\frac{1}{24}\,([\Xi(U_\varepsilon^n)]^3\,\nabla W_\varepsilon^n,\nabla W_\varepsilon^n)\right]\\&\quad+\frac58\,(1-\omega)\sum_{n=1}^k\tau_n\,(\Xi(U_\varepsilon^n)\,\nabla V_\varepsilon^n,\nabla V_\varepsilon^n)\\&\quad\le\mathcal{E}(U_\varepsilon^0,V_\varepsilon^0,\Psi_\varepsilon^0)+\frac{\tau_1}{2}\,(\Xi(U_\varepsilon^0)\,\nabla V_\varepsilon^0,\nabla V_\varepsilon^0).\end{aligned} \tag{2.33}$$

Similarly to (2.14), it holds that

$$(U_\varepsilon^n\,\nabla z^h,\nabla\pi^h[F_\varepsilon'(z^h)])\ge|(U_\varepsilon^n)^{\frac12}\,\nabla z^h|_0^2\qquad\forall\ z^h\in S^h. \tag{2.34}$$

Therefore, on noting (1.13), (2.4), (2.1), (2.10), (2.34), and a Poincaré inequality, the bounds (2.29a) follow directly from (2.33).

Combining the third bound in (2.29a) and (1.13) yields the first two bounds in (2.30). These, together with the sixth bound in (2.29a), yield, on noting (2.14), the third bound in (2.30). Moreover, the fourth bound in (2.30) follows from (1.11) and the last bound in (2.29a). We will now prove the final three bounds in (2.30). First, by the convexity of F_ε, we have for all r, $s \in \mathbb{R}$ that

(2.35)
$$F_\varepsilon(r) \leq F_\varepsilon(s) + (r-s)\,F_\varepsilon'(r) = F_\varepsilon(s) + (r-s)\,(F_\varepsilon'(r) - F_\varepsilon'(s)) + (r-s)\,F_\varepsilon'(s).$$

The last term on the right-hand side of (2.35) is only nonnegative if either $r \leq s \leq 1$ or $r \geq s \geq 1$, in which case we have that

(2.36)
$$2\,(r-s)\,F_\varepsilon'(s) \leq F_\varepsilon''(s)\,(r-s)^2 + \frac{[F_\varepsilon'(s)]^2}{F_\varepsilon''(s)} \leq (r-s)\,(F_\varepsilon'(r) - F_\varepsilon'(s)) + \frac{[F_\varepsilon'(s)]^2}{F_\varepsilon''(s)}.$$

The fifth bound in (2.30) then follows from (2.35), (2.36), (2.29a), (1.14), and the first two bounds in (2.30). This, together with (1.13), then yields the last two bounds in (2.30).

From (1.25), (2.5c), Lemma 2.1 in BGN, and (2.13) we obtain that

$$\begin{aligned}
&\left(\nabla\mathcal{G}\left[\frac{V_\varepsilon^n - V_\varepsilon^{n-1}}{\tau_n}\right], \nabla\eta\right) + \left(\mathcal{G}\left[\frac{V_\varepsilon^n - V_\varepsilon^{n-1}}{\tau_n}\right], \eta\right) = \left(\frac{V_\varepsilon^n - V_\varepsilon^{n-1}}{\tau_n}, Q^h\eta\right)^h \\
&\quad = -\rho_s\,(\nabla V_\varepsilon^n, \nabla Q^h\eta) - \Bigg(\Xi(U_\varepsilon^n)\,\Lambda_\varepsilon(V_\varepsilon^n)\,\nabla V_\varepsilon^n \\
&\qquad + \frac{1}{2}\,[\Xi(U_\varepsilon^n)]^2\Lambda_\varepsilon(V_\varepsilon^n)\,\nabla W_\varepsilon^n, \nabla Q^h\eta\Bigg) + K\,(\Psi_\varepsilon^n - V_\varepsilon^n, Q^h\eta)^h \qquad (2.37)\\
&\quad \leq C[\,\rho_s\,|\nabla V_\varepsilon^n|_0 + |[\Xi(U_\varepsilon^n)]^{\frac12}|_{0,r}(|[\Xi(U_\varepsilon^n)]^{\frac12}\,\nabla V_\varepsilon^n|_0 \\
&\qquad + |[\Xi(U_\varepsilon^n)]^{\frac32}\,\nabla W_\varepsilon^n|_0)\,]|\eta|_{1,q'} + C\,K\,|\Psi_\varepsilon^n - V_\varepsilon^n|_0\,|\eta|_{0,q'}.
\end{aligned}$$

In a similar fashion, it follows from (2.5d) that

(2.38)
$$\begin{aligned}
&\left(\nabla\mathcal{G}\left[\frac{B_\varepsilon^n - B_\varepsilon^{n-1}}{\tau_n}\right], \nabla\eta\right) + \left(\mathcal{G}\left[\frac{B_\varepsilon^n - B_\varepsilon^{n-1}}{\tau_n}\right], \eta\right) \\
&\quad = \left(\frac{U_\varepsilon^n\,\lambda_\varepsilon(\Psi_\varepsilon^n) - U_\varepsilon^{n-1}\,\lambda_\varepsilon(\Psi_\varepsilon^{n-1})}{\tau_n}, Q^h\eta\right)^h \\
&\quad = -\rho_b\left(U_\varepsilon^n\,\nabla\Psi_\varepsilon^n, \nabla Q^h\eta\right) - \frac{1}{3}\left([\Xi(U_\varepsilon^n)]^3\,\Lambda_\varepsilon(\Psi_\varepsilon^n)\,\nabla W_\varepsilon^n, \nabla Q^h\eta\right) \\
&\qquad - \beta\,K\left(\Psi_\varepsilon^n - V_\varepsilon^n, Q^h\eta\right)^h - \frac{1}{2}\left([\Xi(U_\varepsilon^n)]^{\frac32}\,[\Xi(U_\varepsilon^{n-1})]^{\frac12}\,\Lambda_\varepsilon(\Psi_\varepsilon^n)\,\nabla V_\varepsilon^{n-1}, \nabla Q^h\eta\right) \\
&\quad \leq C[\,|[\Xi(U_\varepsilon^n)]^{\frac32}|_{0,r}(|[\Xi(U_\varepsilon^{n-1})]^{\frac12}\,\nabla V_\varepsilon^{n-1}|_0 + |[\Xi(U_\varepsilon^n)]^{\frac32}\,\nabla W_\varepsilon^n|_0) \\
&\qquad + \rho_b\,|(U_\varepsilon^n)^{\frac12}|_{0,r}\,|(U_\varepsilon^n)^{\frac12}\,\nabla\Psi_\varepsilon^n|_0\,]|\eta|_{1,q'} + C\,\beta\,K\,|\Psi_\varepsilon^n - V_\varepsilon^n|_0\,|\eta|_{0,q'}.
\end{aligned}$$

Moreover, it follows from (2.9) and (1.8) that

$$\begin{aligned}\|B_\varepsilon^n\|_{1,q} &\leq C\,\left[|U_\varepsilon^n\,\pi^h[\lambda_\varepsilon(\Psi_\varepsilon^n)]|_{0,q} + |U_\varepsilon^n\,\nabla\pi^h[\lambda_\varepsilon(\Psi_\varepsilon^n)]|_{0,q} + |\pi^h[\lambda_\varepsilon(\Psi_\varepsilon^n)]\,\nabla U_\varepsilon^n|_{0,q}\right]\\ &\leq C\,\left[\|U_\varepsilon^n\|_1 + |(U_\varepsilon^n)^{\frac12}|_{0,r}\,|(U_\varepsilon^n)^{\frac12}\,\nabla\Psi_\varepsilon^n|_0\right].\end{aligned} \tag{2.39}$$

Combining (2.37), a similar bound for the discrete U_ε time derivative (see [6, (2.73)]), (2.38), (2.39), the assumptions on τ_n, and the bounds (2.29a) and (2.30) yields the bounds (2.31a).

The desired result (2.31b) was proved in Theorem 2.2 in BN.

Finally, summing (2.20) from $n = 1 \to k$, observing that $\tau_n \leq \frac{5}{4}\,\omega\,\tau_{n-1}$, $n = 2 \to k$, and noting the first and eighth bounds in (2.29a) yields (2.32). ∎

Remark 2.7. We note that all the results in this section hold also in the absence of attractive van der Waals forces, $a = 0$. The same holds true for the results quoted from BN, even though it was not explicitly stated there.

LEMMA 2.8. *Let u^0, v^0, $\psi^0 \in H^1_{\geq 0}(\Omega)$, with $u^0 \in L^\infty(\Omega)$ and $u^0(x) \geq \zeta > 0$ for a.e. $x \in \Omega$, and let the assumptions* (A) *hold. On choosing either $\{U_\varepsilon^0, V_\varepsilon^0, \Psi_\varepsilon^0\} \equiv \{Q^h u^0, Q^h v^0, Q^h \psi^0\}$ or $\{U_\varepsilon^0, V_\varepsilon^0, \Psi_\varepsilon^0\} \equiv \{\pi^h u^0, \pi^h v^0, \pi^h \psi^0\}$ if either $d = 1$ or $\{u^0, v^0, \psi^0\} \in [W^{1,e}(\Omega)]^3$ with $e > 2$, it follows that $\{U_\varepsilon^0, V_\varepsilon^0, \Psi_\varepsilon^0\} \in [S^h_{\geq 0}]^3$ with $U_\varepsilon^0 \geq \zeta$ are such that for all $h > 0$*

$$\mathcal{C}^0 + (G(U_\varepsilon^0), 1)^h + (\nabla\pi^h[\phi^+(U_\varepsilon^0)], \nabla U_\varepsilon^0) \leq C. \tag{2.40}$$

Proof. The desired result (2.40) follows immediately from (2.29b), (2.12), (2.8), (2.13), (2.3), (1.12), (1.23), (1.4), and Lemma 2.2 in BN. ∎

3. Convergence. Let

$$U_\varepsilon(t) := \frac{t - t_{n-1}}{\tau_n}\,U_\varepsilon^n + \frac{t_n - t}{\tau_n}\,U_\varepsilon^{n-1}, t \in [t_{n-1}, t_n], \quad n \geq 1, \tag{3.1a}$$

and

$$U_\varepsilon^+(t) := U_\varepsilon^n, \qquad U_\varepsilon^-(t) := U_\varepsilon^{n-1}, t \in (t_{n-1}, t_n], \quad n \geq 1. \tag{3.1b}$$

We note for future reference that

$$U_\varepsilon - U_\varepsilon^\pm = (t - t_n^\pm)\,\frac{\partial U_\varepsilon}{\partial t}, \quad t \in (t_{n-1}, t_n), \quad n \geq 1, \tag{3.2}$$

where $t_n^+ := t_n$ and $t_n^- := t_{n-1}$. We introduce also $\bar\tau(t) := \tau_n$ for $t \in (t_{n-1}, t_n]$, $n \geq 1$.

Using the above notation, and introducing analogous notation for $W_\varepsilon, V_\varepsilon, \Psi_\varepsilon$, and B_ε (recall (2.31a)), ($\mathrm{P}_\varepsilon^{h,\tau}$) can be restated as follows.

Find $\{U_\varepsilon, W_\varepsilon^+, V_\varepsilon, \Psi_\varepsilon\} \in C([0,T]; S^h) \times L^\infty(0,T; S^h) \times [C([0,T]; S^h)]^2$ such that

for all $\chi \in L^2(0,T;S^h)$

$$\int_0^T \left[\left(\frac{\partial U_\varepsilon}{\partial t}, \chi \right)^h + \frac{1}{3} \left([\Xi(U_\varepsilon^+)]^3 \, \nabla W_\varepsilon^+, \nabla \chi \right) \right] \mathrm{d}t$$

$$= -\frac{1}{2} \int_0^T \left([\Xi(U_\varepsilon^+)]^{\frac{3}{2}} \, [\Xi(U_\varepsilon^-)]^{\frac{1}{2}} \, \nabla V_\varepsilon^-, \nabla \chi \right) \mathrm{d}t, \tag{3.3a}$$

$$\int_0^T \left[\left(\frac{\partial V_\varepsilon}{\partial t}, \chi \right)^h + \rho_s \left(\nabla V_\varepsilon^+, \nabla \chi \right) + \left(\Xi(U_\varepsilon^+) \, \Lambda_\varepsilon(V_\varepsilon^+) \, \nabla V_\varepsilon^+, \nabla \chi \right) \right.$$

$$\left. - K \left(\Psi_\varepsilon^+ - V_\varepsilon^+, \chi \right)^h \right] \mathrm{d}t = -\frac{1}{2} \int_0^T \left([\Xi(U_\varepsilon^+)]^2 \, \Lambda_\varepsilon(V_\varepsilon^+) \, \nabla W_\varepsilon^+, \nabla \chi \right) \mathrm{d}t, \tag{3.3b}$$

$$\int_0^T \left[\left(\frac{\partial B_\varepsilon}{\partial t}, \chi \right)^h + \rho_b \left(U_\varepsilon^+ \, \nabla \Psi_\varepsilon^+, \nabla \chi \right) + \frac{1}{3} \left([\Xi(U_\varepsilon^+)]^3 \, \Lambda_\varepsilon(\Psi_\varepsilon^+) \, \nabla W_\varepsilon^+, \nabla \chi \right) \right.$$

$$\left. + \beta \, K \left(\Psi_\varepsilon^+ - V_\varepsilon^+, \chi \right)^h \right] \mathrm{d}t$$

$$= -\frac{1}{2} \int_0^T \left([\Xi(U_\varepsilon^+)]^{\frac{3}{2}} [\Xi(U_\varepsilon^-)]^{\frac{1}{2}} \, \Lambda_\varepsilon(\Psi_\varepsilon^+) \, \nabla V_\varepsilon^-, \nabla \chi \right) \mathrm{d}t, \tag{3.3c}$$

where for a.a. $t \in (0,T)$ and for all $z^h \in S^h$

$$\left(W_\varepsilon^+(\cdot,t), z^h \right)^h = c \left(\nabla U_\varepsilon^+(\cdot,t), \nabla z^h \right) + \left(\phi^+(U_\varepsilon^+(\cdot,t)) + \phi^-(U_\varepsilon^-(\cdot,t)), z^h \right)^h ; \tag{3.3d}$$

that is, $W_\varepsilon^+ \equiv -c \, \Delta^h U_\varepsilon^+ + \pi^h[\phi^+(U_\varepsilon^+) + \phi^-(U_\varepsilon^-)]$.

LEMMA 3.1. *Let $\rho_s > 0$, $\phi(\cdot)$ satisfy (1.4) with $\delta > 0$, and $u^0 \in H^1(\Omega) \cap L^\infty(\Omega)$ with $u^0 \geq \zeta > 0$ a.e. and $v^0, \psi^0 \in H^1_{\geq 0}(\Omega)$. Let $\{\mathcal{T}^h, U_\varepsilon^0, V_\varepsilon^0, \Psi_\varepsilon^0, \{\tau_n\}_{n=1}^N, \varepsilon\}_{h>0}$ be such that*

(i) *either $\{U_\varepsilon^0, V_\varepsilon^0, \Psi_\varepsilon^0\} \equiv \{Q^h u^0, Q^h v^0, Q^h \psi^0\}$ or $\{U_\varepsilon^0, V_\varepsilon^0, \Psi_\varepsilon^0\} \equiv \{\pi^h u^0, \pi^h v^0, \pi^h \psi^0\}$ if either $d = 1$ or $\{u^0, v^0, \psi^0\} \in [W^{1,e}(\Omega)]^3$ with $e > 2$;*

(ii) *Ω and $\{\mathcal{T}^h\}_{h>0}$ fulfill assumption (A), $\varepsilon \in (0,1)$, and $\tau_n \leq \frac{5}{4} \, \omega \, \tau_{n-1}$, $n = 2 \to N$, for an $\omega \in (0,1)$;*

(iii) *$\tau \, h^{-d\left(1-\frac{2}{p}\right)} \to 0$ and $\varepsilon \, h^{-d\left(\frac{1}{2}-\frac{1}{p}\right)} \to 0$ as $h \to 0$, where $p = 2$ if $d = 1$ and $p > 2$ if $d = 2$.*

Then there exist a subsequence of $\{U_\varepsilon, W_\varepsilon^+, V_\varepsilon, \Psi_\varepsilon\}_h$, where $\{U_\varepsilon, W_\varepsilon^+, V_\varepsilon, \Psi_\varepsilon\}$ solve ($\mathrm{P}_\varepsilon^{h,\tau}$), and functions

$$u \in L^\infty(0,T;H^1_{\geq 0}(\Omega)) \cap H^1(0,T;(W^{1,q'}(\Omega))'), \tag{3.4a}$$

$$v \in L^\infty(0,T;L^2(\Omega)) \cap L^2(0,T;H^1_{\geq 0}(\Omega)) \cap H^1(0,T;(W^{1,q'}(\Omega))'), \tag{3.4b}$$

$$\psi \in L^2(0,T;L^2_{\geq 0}(\Omega)), \text{ such that} \tag{3.4c}$$

$$\lambda(v), \, \lambda(\psi) \in L^\infty(\Omega_T), \tag{3.4d}$$

with $u(\cdot,0) = u^0(\cdot)$ *in* Y_1, $v(\cdot,0) = v^0(\cdot)$ *in* Y_2, *where* $H^1(\Omega) \overset{c}{\hookrightarrow} Y_1$, $L^2(\Omega) \overset{c}{\hookrightarrow} Y_2$, *and* $\fint u(\cdot,t) = \fint u^0 > 0$, $\fint [v(\cdot,t) + \frac{1}{\beta}\, u(\cdot,t)\, \lambda(\psi(\cdot,t))] = \fint [v^0 + \frac{1}{\beta}\, u^0\, \lambda(\psi^0)]$ *for a.a.* $t \in (0,T)$ *such that as* $h \to 0$

$$\text{(3.5a)}\quad U_\varepsilon,\ U_\varepsilon^\pm \to u \qquad \text{weak-}* \text{ in } L^\infty(0,T;H^1(\Omega)),$$

$$\text{(3.5b)}\quad V_\varepsilon,\ V_\varepsilon^\pm \to v \qquad \text{weak-}* \text{ in } L^\infty(0,T;L^2(\Omega)),\ \text{weakly in } L^2(0,T;H^1(\Omega)),$$

$$\text{(3.5c)}\quad \Psi_\varepsilon^+ \to \psi \qquad \text{weakly in } L^2(\Omega_T),$$

$$\text{(3.5d)}\quad \mathcal{G}\frac{\partial U_\varepsilon}{\partial t} \to \mathcal{G}\frac{\partial u}{\partial t} \quad \text{and} \quad \mathcal{G}\frac{\partial V_\varepsilon}{\partial t} \to \mathcal{G}\frac{\partial v}{\partial t} \qquad \text{weakly in } L^2(0,T;W^{1,q}(\Omega)),$$

$$\text{(3.6a)}\quad (U_\varepsilon)^\alpha, (U_\varepsilon^\pm)^\alpha \to u^\alpha \quad \text{for any } \alpha \in (0,\infty), \qquad \text{strongly in } L^2(0,T;L^s(\Omega)),$$

$$\text{(3.6b)}\quad V_\varepsilon,\ V_\varepsilon^\pm \to v \qquad \text{strongly in } L^2(0,T;L^p(\Omega)),$$

$$\text{(3.7a)}\quad [\Xi(U_\varepsilon^\pm)]^\alpha \to u^\alpha\, \mathcal{I} \quad \text{for any } \alpha \in (0,\infty), \qquad \text{strongly in } L^2(0,T;L^s(\Omega)),$$

where $s \in [2,\infty]$ *and* $q = 2$ *if* $d = 1$, $s \in [2,\infty)$, *and* $q \in (1,2)$ *if* $d = 2$.

Furthermore, if $d = 1$, *or* $d = 2$ *and* $\nu \geq 7$ *in* (1.4), *then* u *in addition to* (3.4a) *satisfies*

$$u \in L^2(0,T;H^2(\Omega)), \tag{3.8}$$

and there exists a subsequence of $\{U_\varepsilon, W_\varepsilon^+, V_\varepsilon, \Psi_\varepsilon\}_h$ *satisfying* (3.5a)–(3.5d), (3.6a)–(3.6b), (3.7a)–(3.7b), *and as* $h \to 0$

$$\text{(3.9a)}\quad \Delta^h U_\varepsilon^+ \to \Delta u \qquad \text{weakly in } L^2(\Omega_T),$$

$$\text{(3.9b)}\quad U_\varepsilon,\ U_\varepsilon^\pm \to u \qquad \text{weakly in } L^2(0,T;W^{1,p}(\Omega)),$$

$$\text{(3.9c)}\quad U_\varepsilon,\ U_\varepsilon^\pm \to u \qquad \text{strongly in } L^2(0,T;C^{0,\gamma}(\overline{\Omega})) \quad \text{for any } \gamma \in \left(0, 1 - \tfrac{d}{p}\right),$$

and for a.a. $t \in (0,T)$

$$\text{(3.9d)}\quad u(\cdot,t) \in C^{0,\gamma}(\overline{\Omega}) \quad \text{with} \quad u(x,t) \geq \zeta(t) > 0 \qquad \forall\ x \in \overline{\Omega}.$$

On extracting a further subsequence, it also holds as $h \to 0$ *that for a.a.* $t \in (0,T)$

$$\text{(3.10a)}\quad \pi^h[\phi^\pm(U_\varepsilon^\pm)](\cdot,t) \to \phi^\pm(u(\cdot,t)) \qquad \text{strongly in } C(\overline{\Omega}),$$

$$\text{(3.10b)}\quad W_\varepsilon^+(\cdot,t) \to w(\cdot,t) \equiv -c\,\Delta u(\cdot,t) + \phi(u(\cdot,t)) \qquad \text{weakly in } H^1(\Omega),$$

$$\text{(3.10c)}\quad [\Xi(U_\varepsilon^+)]^{\frac{3}{2}}\, \nabla W_\varepsilon^+ \to u^{\frac{3}{2}}\, \nabla w \qquad \text{weakly in } L^2(\Omega_T).$$

Moreover, we have that

$$U_\varepsilon,\ U_\varepsilon^\pm \to u \qquad \text{strongly in } L^2(0,T;H^1(\Omega)). \tag{3.11}$$

Proof. Noting the definitions (3.1a)–(3.1b) and [6, (1.19)] , the bounds in (2.29a)–

(2.31b) together with (2.40) and our assumption (i) imply that

(3.12)

$$\begin{aligned}
&\|U_\varepsilon^{(\pm)}\|^2_{L^\infty(0,T;H^1(\Omega))} + \|V_\varepsilon^{(\pm)}\|^2_{L^\infty(0,T;L^2(\Omega))} + \rho_s \,\|V_\varepsilon^{(\pm)}\|^2_{L^2(0,T;H^1(\Omega))}\\
&\quad + \varepsilon^{-1}\|\pi^h[V_\varepsilon^+]_-\|^2_{L^\infty(0,T;L^2(\Omega))} + \|\Psi_\varepsilon^+\|^2_{L^2(\Omega_T)} + \varepsilon^{-1}\|\pi^h[\Psi_\varepsilon^+]_-\|^2_{L^2(\Omega_T)}\\
&\quad + \left\|\bar\tau^{\frac12}\frac{\partial U_\varepsilon}{\partial t}\right\|^2_{L^2(0,T;H^1(\Omega))} + \left\|\bar\tau^{\frac12}\frac{\partial V_\varepsilon}{\partial t}\right\|^2_{L^2(\Omega_T)} + \|\,[\Xi(U_\varepsilon^+)]^{\frac32}\,\nabla W_\varepsilon^+\|^2_{L^2(\Omega_T)}\\
&\quad + \|(U_\varepsilon^+)^{\frac12}\,\nabla\Psi_\varepsilon^+\|^2_{L^2(\Omega_T)} + \left\|\mathcal{G}\frac{\partial U_\varepsilon}{\partial t}\right\|_{L^2(0,T;W^{1,q}(\Omega))} + \left\|\mathcal{G}\frac{\partial V_\varepsilon}{\partial t}\right\|_{L^2(0,T;W^{1,q}(\Omega))}\\
&\quad \le C.
\end{aligned}$$

Furthermore, we deduce from (3.2), (3.12), and (2.6) that

$$\|U_\varepsilon - U_\varepsilon^\pm\|^2_{L^2(0,T;H^1(\Omega))} \le \left\|\bar\tau\,\frac{\partial U_\varepsilon}{\partial t}\right\|^2_{L^2(0,T;H^1(\Omega))} \le C\,\tau, \tag{3.13a}$$

$$\|V_\varepsilon - V_\varepsilon^\pm\|^2_{L^2(0,T;L^p(\Omega))} \le C\,h^{-d\,(1-\frac2p)}\,\|V_\varepsilon - V_\varepsilon^\pm\|^2_{L^2(\Omega_T)} \le C\,h^{-d\,(1-\frac2p)}\,\tau. \tag{3.13b}$$

Hence on noting (3.12), (3.13a)–(3.13b), $U_\varepsilon > 0$, (1.6), assumption (iii), and a standard compact embedding result (see, e.g., [6, (1.20a)]), we can choose a subsequence $\{U_\varepsilon, W_\varepsilon^+, V_\varepsilon, \Psi_\varepsilon\}_h$ such that the convergence results (3.4a)–(3.4c), at first without the nonnegativity constraints on v and ψ, (3.5a)–(3.5d), and (3.6a)–(3.6b) for $\alpha = 1$ hold. Then (3.4a)–(3.4c) and Theorem 2.3 yield, on noting a standard compact embedding result (see, e.g., [6, (1.20b)]), assumption (i), (2.8), and (2.13), that the subsequence satisfies the additional initial and integral conditions.

The proof of the results (3.6a) for $\alpha \in (0,\infty)$, (3.7a)–(3.7b) can be found in the proof of Lemma 3.1 in BN. Furthermore, we note that Lemma 2.1 in BGN and (3.7b) imply that $\lambda(v) \ge 0$ a.e. $\Rightarrow v \ge 0$ a.e., and hence $H^1_{\ge0}(\Omega)$ in (3.4b). Moreover, on noting that $\|[\Psi_\varepsilon^+]_-\|_{L^2(\Omega_T)} \le \|\pi^h[\Psi_\varepsilon^+]_-\|_{L^2(\Omega_T)}$, the sixth bound in (3.12) shows that $[\Psi_\varepsilon^+]_- \to 0$ weakly in $L^2(\Omega_T)$, which implies that $[\Psi_\varepsilon^+]_+ \to \psi$ weakly in $L^2(\Omega_T)$. Hence $L^2_{\ge0}(\Omega)$ in (3.4c), and the results (3.4d) hold on noting (1.6).

The proof, using the key entropy estimate (2.32) in the case $d = 2$, of the results (3.8)–(3.9b), the result (3.9c) if $d = 1$, and the result on U_ε in (3.9c) if $d = 2$ can be found in the proof of Lemma 3.1 in BN. To prove the result on $U_\varepsilon^\pm$ in (3.9c) for the case $d = 2$, we note the following. For any $\gamma \in (0, 1-\frac2p)$ and any $\bar p \in (\frac{2}{1-\gamma}, p)$ it holds on noting the compact embedding $W^{1,\bar p}(\Omega) \overset{c}{\hookrightarrow} C^{0,\gamma}(\overline\Omega)$, (3.13a), and (3.9b) that

$$\begin{aligned}
\|U_\varepsilon - U_\varepsilon^\pm\|_{L^2(0,T;C^{0,\gamma}(\overline\Omega))} &\le \|U_\varepsilon - U_\varepsilon^\pm\|_{L^2(0,T;W^{1,\bar p}(\Omega))}\\
&\le \|U_\varepsilon - U_\varepsilon^\pm\|^{\mu}_{L^2(0,T;H^1(\Omega))}\,\|U_\varepsilon - U_\varepsilon^\pm\|^{1-\mu}_{L^2(0,T;W^{1,p}(\Omega))} \le C\,\tau^{\frac{\mu}{2}},
\end{aligned} \tag{3.14}$$

where $\mu = \frac{2\,(p-\bar p)}{(p-2)\,\bar p} \in (0,1)$. Combining (3.14), assumption (iii), and the established result on U_ε in (3.9c) yields the desired result (3.9c). Then the strong convergence result (3.9c) yields the remaining results (3.9d)–(3.10c); see the proof of Lemma 3.2 in BN for details.

Finally, we have that

$$\|\nabla(U_\varepsilon^+ - u)\|^2_{L^2(\Omega_T)} \le \left|\int_{\Omega_T} \nabla(U_\varepsilon^+ - u)\cdot\nabla u \,\mathrm{d}x\,\mathrm{d}t\right| + \left|\int_{\Omega_T} \nabla(U_\varepsilon^+ - \pi^h u)\cdot\nabla U_\varepsilon^+ \,\mathrm{d}x\,\mathrm{d}t\right| + \left|\int_{\Omega_T} \nabla(\pi^h u - u)\cdot\nabla U_\varepsilon^+ \,\mathrm{d}x\,\mathrm{d}t\right|, \tag{3.15a}$$

where, on noting (2.10),

$$\begin{aligned}\left|\int_{\Omega_T} \nabla(U_\varepsilon^+ - \pi^h u).\nabla U_\varepsilon^+ \,\mathrm{d}x\,\mathrm{d}t\right| &= \left| - \int_0^T (\Delta^h U_\varepsilon^+, U_\varepsilon^+ - \pi^h u)^h \,\mathrm{d}t\right| \\ &\le C\,\|\Delta^h U_\varepsilon^+\|_{L^2(\Omega_T)}\,\|U_\varepsilon^+ - \pi^h u\|_{L^2(\Omega_T)}.\end{aligned} \tag{3.15b}$$

Combining (3.15a)–(3.15b), (3.5a), (2.32), (2.7), (3.4a), (3.6a), and (3.13a) yields (3.11). ∎

Remark 3.2. We remark that in the case $d = 1$ one can prove stronger versions of (3.9c)–(3.10b); see the proof of Lemma 3.1 in BN for details. We note that in BN a further time step assumption was introduced for $d = 2$, in order to prove the results (3.9c)–(3.10c). However, the proof given here shows that this assumption is not necessary; see (3.14).

Remark 3.3. One can adapt the approximation ($\mathrm{P}_\varepsilon^{h,\tau}$) when there are no repulsive van der Waals forces ($\delta = 0$), by replacing Ξ with Ξ_ε (see Remark 3.2 in BN for details) and here in addition by replacing $U_\varepsilon^n\,\nabla\Psi_\varepsilon^n$ with $\pi^h[U_\varepsilon^n]_+\,\nabla\Psi_\varepsilon^n$ in (2.5d). Similarly, to the insoluble surfactant system studied in BN one can now no longer guarantee the nonnegativity of U_ε. However, in contrast to the system studied in BN, it is not clear that one can prove convergence in the case $d = 1$ by adapting the techniques in BGN.

LEMMA 3.4. *Let all the assumptions of Lemma* 3.1 *hold, and in addition assume that if* $d = 2$, *then* $p \in (2,6)$, $q \in [\frac{4p}{3p-2}, 2)$, *and* $\tau\, h^{-3d(\frac12-\frac1p)} \to 0$ *as* $h \to 0$. *Then there exists a subsequence of* $\{U_\varepsilon, W_\varepsilon^+, V_\varepsilon, \Psi_\varepsilon\}_h$ *such that as* $h \to 0$

$$\mathcal{G}\frac{\partial B_\varepsilon}{\partial t} \to \mathcal{G}\frac{\partial(u\,\lambda(\psi))}{\partial t} \quad \text{weakly in } L^2(0,T;W^{1,q}(\Omega)), \tag{3.16a}$$

$$\Xi[U_\varepsilon^+]\,\Lambda_\varepsilon(\Psi_\varepsilon^+) \to u\,\lambda(\psi)\,\mathcal{I} \quad \text{strongly in } L^2(0,T;L^p(\Omega)), \tag{3.16b}$$

$$(U_\varepsilon^+)^{\frac12}\,\nabla\Psi_\varepsilon^+ \to u^{\frac12}\,\nabla\psi \quad \text{weakly in } L^2(\Omega_T). \tag{3.16c}$$

Proof. Noting the definitions (3.1a)–(3.1b) and the bounds in (2.29a)–(2.31b) together with (2.40), (2.39) for $n = 0$, our assumption (i), (2.12), (2.13), and (2.8) imply that

$$\|B_\varepsilon^{(\pm)}\|^2_{L^2(0,T;W^{1,q}(\Omega))} + \left\|\mathcal{G}\frac{\partial B_\varepsilon}{\partial t}\right\|_{L^2(0,T;W^{1,q}(\Omega))} \le C \tag{3.17}$$

and hence, on noting a standard compact embedding result (see, e.g., [6, (1.20a)]), that

$$\begin{aligned} B_\varepsilon &\to b \quad \text{strongly in } L^2(0,T;L^s(\Omega)) \quad \text{as } h \to 0, \\ \mathcal{G}\frac{\partial B_\varepsilon}{\partial t} &\to \mathcal{G}\frac{\partial b}{\partial t} \quad \text{weakly in } L^2(0,T;W^{1,q}(\Omega)) \quad \text{as } h \to 0, \end{aligned} \tag{3.18}$$

where $b \in L^2(0,T;L^s(\Omega))$ still needs to be identified. Moreover, on noting (2.6), (1.25), (3.2), and (3.17), it holds for $q = p = 2$ if $d = 1$ and $q \in [\frac{4p}{3p-2}, 2)$ if $d = 2$ that

$$\begin{aligned}
\|B_\varepsilon - B_\varepsilon^\pm\|^2_{L^2(0,T;L^p(\Omega))} &\leq C\,h^{-2d(\frac12-\frac1p)}\,\|B_\varepsilon - B_\varepsilon^\pm\|^2_{L^2(0,T;L^2(\Omega))}\\
&\leq C\,\tau\,h^{-2d(\frac12-\frac1p)}\left\|\mathcal{G}\frac{\partial B_\varepsilon}{\partial t}\right\|_{L^2(0,T;W^{1,q}(\Omega))}\|B_\varepsilon^\pm\|_{L^2(0,T;W^{1,q'}(\Omega))}\\
&\leq C\,\tau\,h^{-2d(\frac12-\frac1p)}\,h^{-d(\frac1q-\frac17)}\|B_\varepsilon^\pm\|_{L^2(0,T;W^{1,q}(\Omega))}\\
&\leq C\,\tau\,h^{-2d(\frac12-\frac1p)}\,h^{-d(\frac{2-q}{q})} \leq C\,\tau\,h^{-3d(\frac12-\frac1p)} \to 0 \quad \text{as } h\to 0. \qquad (3.19)
\end{aligned}$$

In addition, on noting (2.8), (1.8), and (2.6), it holds for $n = 0 \to N$ that

$$\begin{aligned}
|B_\varepsilon^n - U_\varepsilon^n\,\lambda_\varepsilon(\Psi_\varepsilon^n)|^2_{0,p} &\leq \sum_{\kappa\in\mathcal{T}^h}[\underline{m}(\kappa)]^{\frac2p}\,|(I-\pi^h)[U_\varepsilon^n\,\lambda_\varepsilon(\Psi_\varepsilon^n)]|^2_{0,\infty,\kappa}\\
&\leq C\sum_{\kappa\in\mathcal{T}^h}[\underline{m}(\kappa)]^{\frac2p}h_\kappa^2\,|U_\varepsilon^n\,\Psi_\varepsilon^n|^2_{1,\infty,\kappa} \leq C\sum_{\kappa\in\mathcal{T}^h}h_\kappa^2\,|U_\varepsilon^n\,\Psi_\varepsilon^n|^2_{1,p,\kappa}\\
&\leq C\sum_{\kappa\in\mathcal{T}^h}h_\kappa^2\,h_\kappa^{-2d(\frac1q-\frac1p)}|U_\varepsilon^n\,\Psi_\varepsilon^n|^2_{1,q,\kappa} \leq C\,h^{2-2d(\frac1q-\frac1p)}\,|U_\varepsilon^n\,\Psi_\varepsilon^n|^2_{1,q}\\
&\leq C\,h^{2-2d(\frac1q-\frac1p)}\,\big[|U_\varepsilon^n|_1^2 + |(U_\varepsilon^n)^{\frac12}|^2_{0,r}\,|(U_\varepsilon^n)^{\frac12}\,\nabla\Psi_\varepsilon^n|_0^2\big], \qquad (3.20)
\end{aligned}$$

where $r = \infty$ if $d = 1$ and $r = \frac{2q}{2-q}$ if $d = 2$. Therefore it follows from (3.20), (3.12), and our assumptions on p and q that $\|B_\varepsilon^+ - U_\varepsilon^+\,\lambda_\varepsilon(\Psi_\varepsilon^+)\|_{L^2(0,T;L^p(\Omega))} \to 0$ and hence, on noting (3.18) and (3.19), that

$$U_\varepsilon^+\,\lambda_\varepsilon(\Psi_\varepsilon^+) \to b \qquad \text{strongly in } L^2(0,T;L^p(\Omega)) \quad \text{as } h\to 0. \qquad (3.21)$$

Combining (3.21), (3.6a), (3.9d), (3.12), and (1.8) yields, on possibly extracting a further subsequence, that $\lambda_\varepsilon(\Psi_\varepsilon^+) \to u^{-1}b$ strongly in $L^2(0,T;L^p(\Omega))$ as $h\to 0$ and in particular that $u^{-1}b \in [0,1]$ a.e. in Ω_T. Moreover, it follows from (1.6), (1.8), (3.12), and assumption (iii) that

$$\|\lambda(\Psi_\varepsilon^+) - \lambda_\varepsilon(\Psi_\varepsilon^+)\|_{L^2(0,T;L^2(\Omega))} \leq C\,\varepsilon + \|[\Psi_\varepsilon^+]_-\|_{L^2(0,T;L^2(\Omega))} \leq C\,\varepsilon^{\frac12} \to 0 \quad \text{as } h\to 0.$$

Hence

$$\lambda(\Psi_\varepsilon^+) \to u^{-1}b \qquad \text{strongly in } L^2(0,T;L^2(\Omega)) \quad \text{as } h\to 0. \qquad (3.22)$$

Combining (3.22), (1.6), and (3.5c) yields that $u^{-1}b = \psi = \lambda(\psi)$ a.e. where $u^{-1}b < 1$. It remains to identify b, where $u^{-1}b = 1$. Let $\mathcal{A} := \{(x,t) \in \Omega_T : (u^{-1}b)(x,t) = 1,\ \psi(x,t) < 1\}$. On assuming that $\underline{m}(\mathcal{A}) > 0$, it follows from (3.5c), (1.6), and (3.22) that

$$\begin{aligned}
\underline{m}(\mathcal{A}) &= \int_{\Omega_T}\mathcal{H}_\mathcal{A}\,\mathrm{d}x\,\mathrm{d}t > \int_{\Omega_T}\psi\,\mathcal{H}_\mathcal{A}\,\mathrm{d}x\,\mathrm{d}t \leftarrow \int_{\Omega_T}\Psi_\varepsilon^+\,\mathcal{H}_\mathcal{A}\,\mathrm{d}x\,\mathrm{d}t\\
&\geq \int_{\Omega_T}\lambda(\Psi_\varepsilon^+)\,\mathcal{H}_\mathcal{A}\,\mathrm{d}x\,\mathrm{d}t \to \int_{\Omega_T}1\,\mathcal{H}_\mathcal{A}\,\mathrm{d}x\,\mathrm{d}t = \underline{m}(\mathcal{A}),
\end{aligned}$$

where $\mathcal{H}_\mathcal{A}$ is the characteristic function of $\mathcal{A}$. This is a contradiction and hence $\underline{m}(\mathcal{A}) = 0$. This means that $\psi \geq 1$ a.e. where $u^{-1}b = 1$, i.e., $u^{-1}b = 1 = \lambda(\psi)$ a.e.

where $u^{-1}b = 1$. Combining this with the earlier result on b yields that $b = u\,\lambda(\psi)$ a.e. in Ω_T. This proves, on recalling (3.18), that $B_\varepsilon \to u\,\lambda(\psi)$ strongly in $L^2(0,T;L^s(\Omega))$ as $h \to 0$, and that (3.16a) holds.

Similarly to (3.20), we have on noting Lemma 2.1 in BGN, Lemma 2.3 in BN, and (3.7a) that

$$\begin{aligned}
&\|U_\varepsilon^+\,\lambda_\varepsilon(\Psi_\varepsilon^+)\,\mathcal{I} - \Xi(U_\varepsilon^+)\,\Lambda_\varepsilon(\Psi_\varepsilon^+)\|^2_{L^2(0,T;L^p(\Omega))}\\
&\quad\le \|U_\varepsilon^+\,[\lambda_\varepsilon(\Psi_\varepsilon^+)\,\mathcal{I} - \Lambda_\varepsilon(\Psi_\varepsilon^+)]\|^2_{L^2(0,T;L^p(\Omega))} + \|\,[U_\varepsilon^+\,\mathcal{I} - \Xi(U_\varepsilon^+)]\,\Lambda_\varepsilon(\Psi_\varepsilon^+)\|^2_{L^2(0,T;L^p(\Omega))}\\
&\quad\le \int_0^T \sum_{\kappa\in\mathcal{T}^h} h_\kappa^2\,|U_\varepsilon^+\,\nabla\Psi_\varepsilon^+|^2_{0,p,\kappa}\,\mathrm{d}t + \|U_\varepsilon^+\,\mathcal{I} - \Xi(U_\varepsilon^+)\|^2_{L^2(0,T;L^p(\Omega))} \to 0 \quad \text{as } h\to 0.
\end{aligned}$$

Combining this and (3.21) yields the desired result (3.16b).

Finally, it follows from (3.12) that $(U_\varepsilon^+)^{\frac12}\,\nabla\Psi_\varepsilon^+ \to z$ weakly in $L^2(\Omega_T)$, where $z \in L^2(\Omega_T)$. But for any $\eta \in C_0^\infty(\overline{\Omega}_T)$, which is dense in $L^2(\Omega_T)$, we have, on recalling (3.6a), (3.5c), and (3.11), that

$$\begin{aligned}
\int_0^T (u^{\frac12}\,z,\eta)\,\mathrm{d}t &\leftarrow \int_0^T (U_\varepsilon^+\,\nabla\Psi_\varepsilon^+,\eta)\,\mathrm{d}t = -\int_0^T \left[(\Psi_\varepsilon^+\,\nabla U_\varepsilon^+,\eta) + (\Psi_\varepsilon^+\,U_\varepsilon^+,\nabla\cdot\eta)\right]\,\mathrm{d}t\\
&\to -\int_0^T (\psi\,\nabla u,\eta)\,\mathrm{d}t - \int_0^T (\psi\,u,\nabla\cdot\eta)\,\mathrm{d}t = \int_0^T (u\,\nabla\psi,\eta)\,\mathrm{d}t. \qquad (3.23)
\end{aligned}$$

Hence $z = u^{\frac12}\,\nabla\psi$ in $L^2(\Omega_T)$ and (3.16c) holds. ∎

THEOREM 3.5. *Let all the assumptions of Lemma* 3.4 *hold. Then there exist a subsequence of* $\{U_\varepsilon, W_\varepsilon^+, V_\varepsilon, \Psi_\varepsilon\}_h$, *where* $\{U_\varepsilon, W_\varepsilon^+, V_\varepsilon, \Psi_\varepsilon\}$ *solve* $(\mathrm{P}_\varepsilon^{h,\tau})$, *and functions* $\{u,w,v,\psi\}$ *satisfying* (3.4a)–(3.4d), (3.8), *and* (3.9d). *In addition, as* $h \to 0$ *the following hold:* (3.5a)–(3.5d), (3.6a)–(3.6b), (3.7a)–(3.7b), (3.9a)–(3.9c), (3.10a)–(3.10b) *for a.a.* $t \in (0,T)$, (3.10c), (3.11), *and* (3.16a)–(3.16c). *Moreover, we have that* u *and* v *fulfill* $u(\cdot,0) = u^0(\cdot)$ *in* Y_1, $v(\cdot,0) = v^0(\cdot)$ *in* Y_2, *where* $H^1(\Omega) \overset{c}{\hookrightarrow} Y_1$, $L^2(\Omega) \overset{c}{\hookrightarrow} Y_2$. *Furthermore,* $\{u,w,v,\psi\}$ *satisfy for all* $\eta \in L^2(0,T;W^{1,q'}(\Omega))$, *with* $q' = 2$ *if* $d = 1$ *and* $q' \in (2, \frac{4p}{p+2}]$, *where* $p \in (2,6)$, *if* $d = 2$,

$$\int_0^T \left\langle \frac{\partial u}{\partial t},\eta\right\rangle_{q'}\mathrm{d}t + \int_{\Omega_T}\left[\frac13\,u^3\,\nabla w\cdot\nabla\eta + \frac12\,u^2\,\nabla v\cdot\nabla\eta\right]\mathrm{d}x\,\mathrm{d}t = 0, \qquad (3.24a)$$

$$\begin{aligned}
&\int_0^T \left\langle \frac{\partial v}{\partial t},\eta\right\rangle_{q'}\mathrm{d}t + \int_{\Omega_T}[\,\rho_s\,\nabla v\cdot\nabla\eta + u\,\lambda(v)\,\nabla v\cdot\nabla\eta\,]\,\mathrm{d}x\,\mathrm{d}t\\
&\qquad + \int_{\Omega_T}\left[\frac12\,u^2\,\lambda(v)\,\nabla w\cdot\nabla\eta - K\,(\psi - v)\,\eta\right]\mathrm{d}x\,\mathrm{d}t = 0, \qquad (3.24b)
\end{aligned}$$

$$\begin{aligned}
&\int_0^T \left\langle \frac{\partial(u\,\lambda(\psi))}{\partial t},\eta\right\rangle_{q'}\mathrm{d}t + \int_{\Omega_T}\left[\rho_b\,u\,\nabla\psi\cdot\nabla\eta + \frac13\,u^3\,\lambda(\psi)\,\nabla w\cdot\nabla\eta\right]\mathrm{d}x\,\mathrm{d}t\\
&\qquad + \int_{\Omega_T}\left[\frac12\,u^2\,\lambda(\psi)\,\nabla v\cdot\nabla\eta + \beta\,K\,(\psi - v)\,\eta\right]\mathrm{d}x\,\mathrm{d}t = 0, \qquad (3.24c)
\end{aligned}$$

where for a.a. $t \in (0,T)$

$$\int_\Omega [\,w(\cdot,t)\,\xi - c\,\nabla u(\cdot,t).\,\nabla\xi - \phi(u(\cdot,t))\,\xi\,]\,\mathrm{d}x = 0 \qquad \forall\ \xi \in H^1(\Omega). \qquad (3.24d)$$

Proof. On choosing $z^h \equiv \pi^h \tilde{\xi}$, where $\tilde{\xi} \in W^{1,p}(\Omega)$, in (3.3d); it follows from (2.1), (2.10), (2.7), (3.5a), and (3.10a)–(3.10b) that (3.24d) holds for $\xi \equiv \tilde{\xi}$. The desired result (3.24d) then holds for any $\xi \in H^1(\Omega)$ via a density argument.

For any $\eta \in L^2(0,T;W^{1,q'}(\Omega))$ and $\widetilde{\eta} \in H^1(0,T;W^{1,\infty}(\Omega))$, we choose $\chi \equiv \pi^h \eta$ in (3.3a)–(3.3c) and then analyze the subsequent terms. The results (3.24a) and (3.24b), for the case $K = 0$, are then derived from (3.3a) and (3.3b), with $K = 0$; their proof can be found in the proof of Theorem 3.1 in BN. Hence it is sufficient to prove (3.24c), as the convergence of the term involving K in (3.24b) then follows from the convergence of the corresponding term in (3.24c).

First, (2.11), (2.15), an interpolation estimate in time (see [6, (1.19)]), (3.12), (3.17), and (2.8), on noting that $\|B_\varepsilon\|_{L^\infty(0,T;L^2(\Omega))} \leq \|U_\varepsilon\|_{L^\infty(0,T;L^2(\Omega))}$, yield that

(3.25)
$$
\begin{aligned}
&\left| \int_0^T \left[\left(\frac{\partial B_\varepsilon}{\partial t}, \pi^h \eta \right)^h - \left(\frac{\partial B_\varepsilon}{\partial t}, \pi^h \eta \right) \right] \mathrm{d}t \right| \\
&\leq \left| \int_0^T \left[\left(\frac{\partial B_\varepsilon}{\partial t}, \pi^h [\eta - \widetilde{\eta}] \right)^h - \left(\frac{\partial B_\varepsilon}{\partial t}, \pi^h [\eta - \widetilde{\eta}] \right) \right] \mathrm{d}t \right| \\
&\quad + \left| - \int_0^T \left(B_\varepsilon, \frac{\partial (\pi^h \widetilde{\eta})}{\partial t} \right)^h \mathrm{d}t + (B_\varepsilon(\cdot,T), \pi^h \widetilde{\eta}(\cdot,T))^h - (B_\varepsilon(\cdot,0), \pi^h \widetilde{\eta}(\cdot,0))^h \right. \\
&\qquad \left. + \int_0^T \left(B_\varepsilon, \frac{\partial (\pi^h \widetilde{\eta})}{\partial t} \right) \mathrm{d}t - (B_\varepsilon(\cdot,T), \pi^h \widetilde{\eta}(\cdot,T)) + (B_\varepsilon(\cdot,0), \pi^h \widetilde{\eta}(\cdot,0)) \right| \\
&\leq C \left\| \mathcal{G} \frac{\partial B_\varepsilon}{\partial t} \right\|_{L^2(0,T;W^{1,q}(\Omega))} \|\pi^h [\eta - \widetilde{\eta}]\|_{L^2(0,T;W^{1,q'}(\Omega))} \\
&\qquad + C\, h\, \|B_\varepsilon\|_{L^\infty(0,T;L^2(\Omega))}\, \|\pi^h \widetilde{\eta}\|_{H^1(0,T;H^1(\Omega))} \\
&\leq C\, \|\eta - \widetilde{\eta}\|_{L^2(0,T;W^{1,q'}(\Omega))} + C\, h\, \|\widetilde{\eta}\|_{H^1(0,T;W^{1,q'}(\Omega))}.
\end{aligned}
$$

Furthermore, it follows from (1.25) and (3.17) that

$$
\begin{aligned}
\left| \int_0^T \left(\frac{\partial B_\varepsilon}{\partial t}, (I - \pi^h)\eta \right) \mathrm{d}t \right| &\leq C \left\| \mathcal{G} \frac{\partial B_\varepsilon}{\partial t} \right\|_{L^2(0,T;W^{1,q}(\Omega))} \|(I - \pi^h)\eta\|_{L^2(0,T;W^{1,q'}(\Omega))} \\
&\leq C\, \|(I - \pi^h)\eta\|_{L^2(0,T;W^{1,q'}(\Omega))}. \qquad (3.26)
\end{aligned}
$$

Combining (3.25), the denseness of $H^1(0,T;W^{1,\infty}(\Omega))$ in $L^2(0,T;W^{1,q'}(\Omega))$, (3.26), (2.7), (1.25), and (3.16a) yields for all $\eta \in L^2(0,T;W^{1,q'}(\Omega))$ that

$$
\int_0^T \left(\frac{\partial B_\varepsilon}{\partial t}, \pi^h \eta \right)^h \mathrm{d}t \to \int_0^T \left\langle \frac{\partial (u\, \lambda(\psi))}{\partial t}, \eta \right\rangle_{q'} \mathrm{d}t \quad \text{as } h \to 0. \qquad (3.27)
$$

Similarly to the above, it follows from (2.1), (2.11), (2.8), (3.5b), and (3.5c) that for all $\eta \in L^2(0,T;W^{1,q'}(\Omega))$

$$
\int_0^T \left(\Psi_\varepsilon^+ - V_\varepsilon^+, \pi^h \eta \right)^h \mathrm{d}t \to \int_0^T (\psi - v, \eta)\, \mathrm{d}t \quad \text{as } h \to 0. \qquad (3.28)
$$

In view of (3.12), (3.4a), [6, (1.19)], and (3.16c), we deduce with r as defined in

(2.31a) that for all $\eta \in L^2(0,T;W^{1,q'}(\Omega))$ and for all $\widetilde{\eta} \in H^1(0,T;W^{1,\infty}(\Omega))$

$$\begin{aligned}
&\left|\int_0^T (U_\varepsilon^+ \nabla \Psi_\varepsilon^+, \nabla[\widetilde{\eta} - \pi^h \eta]\,)\,\mathrm{d}t\right| + \left|\int_0^T (u\,\nabla\psi, \nabla[\widetilde{\eta} - \eta]\,)\,\mathrm{d}t\right| \\
&\quad \le \|(U_\varepsilon^+)^{\frac12}\|_{L^\infty(0,T;L^r(\Omega))}\, \|(U_\varepsilon^+)^{\frac12}\,\nabla \Psi_\varepsilon^+\|_{L^2(\Omega_T)}\, \|\widetilde{\eta} - \pi^h\eta\|_{L^2(0,T;W^{1,q'}(\Omega))} \\
&\qquad + \|u^{\frac12}\|_{L^\infty(0,T;L^r(\Omega))}\, \|u^{\frac12}\,\nabla\psi\|_{L^2(\Omega_T)}\, \|\widetilde{\eta} - \eta\|_{L^2(0,T;W^{1,q'}(\Omega))} \\
&\quad \le C\,\big[\|(I-\pi^h)\eta\|_{L^2(0,T;W^{1,q'}(\Omega))} + \|\eta - \widetilde{\eta}\|_{L^2(0,T;W^{1,q'}(\Omega))}\big]. \qquad (3.29)
\end{aligned}$$

Similarly to the above, on noting in addition (2.31b), Lemma 2.1 in BGN, (3.10c), (3.4d), and (3.4b), we deduce for all $\eta \in L^2(0,T;W^{1,q'}(\Omega))$ and for all $\widetilde{\eta} \in H^1(0,T;W^{1,\infty}(\Omega))$

$$\begin{aligned}
&\left|\int_0^T ([\Xi(U_\varepsilon^+)]^3\,\Lambda_\varepsilon(\Psi_\varepsilon^+)\,\nabla W_\varepsilon^+, \nabla[\widetilde{\eta} - \pi^h\eta]\,)\,\mathrm{d}t\right| + \left|\int_0^T (u^3\,\lambda(\psi)\,\nabla w, \nabla[\widetilde{\eta} - \eta]\,)\,\mathrm{d}t\right| \\
&\quad \le \|[\Xi(U_\varepsilon^+)]^{\frac32}\|_{L^\infty(0,T;L^r(\Omega))}\, \|[\Xi(U_\varepsilon^+)]^{\frac32}\,\nabla W_\varepsilon^+\|_{L^2(\Omega_T)}\, \|\widetilde{\eta} - \pi^h\eta\|_{L^2(0,T;W^{1,q'}(\Omega))} \\
&\qquad + \|\lambda(\psi)\|_{L^\infty(\Omega_T)}\, \|u^{\frac32}\|_{L^\infty(0,T;L^r(\Omega))}\, \|u^{\frac32}\,\nabla w\|_{L^2(\Omega_T)}\, \|\widetilde{\eta} - \eta\|_{L^2(0,T;W^{1,q'}(\Omega))} \\
&\quad \le C\,\big[\|(I-\pi^h)\eta\|_{L^2(0,T;W^{1,q'}(\Omega))} + \|\eta - \widetilde{\eta}\|_{L^2(0,T;W^{1,q'}(\Omega))}\big]
\end{aligned}$$

and

$$\begin{aligned}
&\left|\int_0^T ([\Xi(U_\varepsilon^+)]^{\frac32}\,[\Xi(U_\varepsilon^-)]^{\frac12}\,\Lambda_\varepsilon(\Psi_\varepsilon^+)\,\nabla V_\varepsilon^-, \nabla[\widetilde{\eta} - \pi^h\eta]\,)\,\mathrm{d}t\right| \\
&\qquad + \left|\int_0^T (u^2\,\lambda(\psi)\,\nabla v, \nabla[\widetilde{\eta} - \eta]\,)\,\mathrm{d}t\right| \\
&\quad \le \|[\Xi(U_\varepsilon^+)]^{\frac32}\,[\Xi(U_\varepsilon^-)]^{\frac12}\|_{L^\infty(0,T;L^r(\Omega))}\, \|\nabla V_\varepsilon^-\|_{L^2(\Omega_T)}\, \|\widetilde{\eta} - \pi^h\eta\|_{L^2(0,T;W^{1,q'}(\Omega))} \\
&\qquad + \|\lambda(\psi)\|_{L^\infty(\Omega_T))}\, \|u^2\|_{L^\infty(0,T;L^r(\Omega))}\, \|\nabla v\|_{L^2(\Omega_T)}\, \|\widetilde{\eta} - \eta\|_{L^2(0,T;W^{1,q'}(\Omega))} \\
&\quad \le C\,\big[\|(I-\pi^h)\eta\|_{L^2(0,T;W^{1,q'}(\Omega))} + \|\eta - \widetilde{\eta}\|_{L^2(0,T;W^{1,q'}(\Omega))}\big]. \qquad (3.30)
\end{aligned}$$

For all $\widetilde{\eta} \in H^1(0,T;W^{1,\infty}(\Omega))$, it follows from (3.6a), (3.16c), (3.7a), (3.16b), (3.10c), (3.4a), (3.4d), [6, (1.19)], (2.31b), (3.1b), (3.12), and (3.5b) that as $h \to 0$

$$\int_{\Omega_T} (U_\varepsilon^+)^{\frac12}\,[(U_\varepsilon^+)^{\frac12}\,\nabla\Psi_\varepsilon^+]\,\nabla\widetilde{\eta}\,\mathrm{d}x\,\mathrm{d}t \to \int_{\Omega_T} u^{\frac12}\,[u^{\frac12}\,\nabla\psi]\,\nabla\widetilde{\eta}\,\mathrm{d}x\,\mathrm{d}t, \qquad (3.31a)$$

$$\begin{aligned}
&\int_{\Omega_T} [\Xi(U_\varepsilon^+)]^{\frac12}\,[\Xi(U_\varepsilon^+)\,\Lambda_\varepsilon(\Psi_\varepsilon^+)]\,[\,[\Xi(U_\varepsilon^+)]^{\frac32}\,\nabla W_\varepsilon^+]\,\nabla\widetilde{\eta}\,\mathrm{d}x\,\mathrm{d}t \\
&\qquad \to \int_{\Omega_T} u^{\frac12}\,[u\,\lambda(\psi)]\,[u^{\frac32}\,\nabla w]\,\nabla\widetilde{\eta}\,\mathrm{d}x\,\mathrm{d}t, \qquad (3.31b)
\end{aligned}$$

$$\begin{aligned}
&\int_{\Omega} [\Xi(U_\varepsilon^+)]^{\frac12}\,[\Xi(U_\varepsilon^-)]^{\frac12}\,[\,[\Xi(U_\varepsilon^+)]\,\Lambda_\varepsilon(\Psi_\varepsilon^+)]\,\nabla V_\varepsilon^-\,\nabla\widetilde{\eta}\,\mathrm{d}x\,\mathrm{d}t \\
&\qquad \to \int_{\Omega_T} u\,[u\,\lambda(\psi)]\,\nabla v\,\nabla\widetilde{\eta}\,\mathrm{d}x\,\mathrm{d}t. \qquad (3.31c)
\end{aligned}$$

Noting that $H^1(0,T;W^{1,\infty}(\Omega))$ is dense in $L^2(0,T;W^{1,q'}(\Omega))$ and (2.7), we obtain the desired result (3.24c) on combining (3.3c), (3.27)–(3.30), and (3.31a)–(3.31c). Hence $\{u,\, w,\, v,\, \psi\}$ satisfy (3.24a)–(3.24d) as well as the stated results of Lemmas 3.1 and 3.4. ∎

4. Numerical results. Before presenting some numerical results in both one and two space dimensions, we briefly state algorithms for solving the resulting system of algebraic equations for $\{U_\varepsilon^n, W_\varepsilon^n, V_\varepsilon^n, \Psi_\varepsilon^n\}$ arising at each time level from the approximation ($\mathrm{P}_\varepsilon^{h,\tau}$). As (2.5a)–(2.5b) in ($\mathrm{P}_\varepsilon^{h,\tau}$) are independent of $\{V_\varepsilon^n, \Psi_\varepsilon^n\}$, we first solve these to obtain $\{U_\varepsilon^n, W_\varepsilon^n\}$; then we solve (2.5c)–(2.5d) for $\{V_\varepsilon^n, \Psi_\varepsilon^n\}$. We use the following iterative approach to solve (2.5a)–(2.5b) for $\{U_\varepsilon^n, W_\varepsilon^n\}$: Given $U_\varepsilon^{n,0} \in S^h_{>0}$, for $k \geq 1$ find $\{U_\varepsilon^{n,k}, W_\varepsilon^{n,k}\} \in [S^h]^2$ such that for all $\chi \in S^h$

$$\left(\frac{U_\varepsilon^{n,k} - U_\varepsilon^{n-1}}{\tau_n}, \chi\right)^h + \frac{1}{3}\left([\Xi(U_\varepsilon^{n,k-1})]^3\, \nabla W_\varepsilon^{n,k}, \nabla\chi\right)$$

$$= -\frac{1}{2}\left([\Xi(U_\varepsilon^{n,k-1})]^{\frac{3}{2}}\, [\Xi(U_\varepsilon^{n-1})]^{\frac{1}{2}}\, \nabla V_\varepsilon^{n-1}, \nabla\chi\right), \tag{4.1a}$$

$$c\,(\nabla U_\varepsilon^{n,k}, \nabla\chi) + (\phi^+(U_\varepsilon^{n,k}) + \phi^-(U_\varepsilon^{n-1}), \chi)^h = (W_\varepsilon^{n,k}, \chi)^h. \tag{4.1b}$$

Then, having obtained $\{U_\varepsilon^n, W_\varepsilon^n\}$, we solve (2.5c)–(2.5d) for $\{V_\varepsilon^n,\ \Psi_\varepsilon^n\}$ using the following iterative approach: Given $\{V_\varepsilon^{n,0}, \Psi_\varepsilon^{n,0}\} \in [S^h]^2$, for $k \geq 1$ find $\{V_\varepsilon^{n,k}, \Psi_\varepsilon^{n,k}\} \in [S^h]^2$ such that for all $\chi \in S^h$

$$\left(\frac{V_\varepsilon^{n,k} - V_\varepsilon^{n-1}}{\tau_n}, \chi\right)^h + \rho_s\,(\nabla V_\varepsilon^{n,k}, \nabla\chi) + (\Xi(U_\varepsilon^n)\,\Lambda_\varepsilon(V_\varepsilon^{n,k-1})\,\nabla V_\varepsilon^{n,k}, \nabla\chi)$$

$$- K\left(\Psi_\varepsilon^{n,k-1} - V_\varepsilon^{n,k}, \chi\right)^h = -\frac{1}{2}\left([\Xi(U_\varepsilon^n)]^2\,\Lambda_\varepsilon(V_\varepsilon^{n,k-1})\,\nabla W_\varepsilon^n, \nabla\chi\right), \tag{4.2a}$$

$$\left(\frac{U_\varepsilon^n \lambda_\varepsilon(\Psi_\varepsilon^{n,k}) - U_\varepsilon^{n-1}\lambda_\varepsilon(\Psi_\varepsilon^{n-1})}{\tau_n}, \chi\right)^h + \rho_b\left(U_\varepsilon^n\,\nabla\Psi_\varepsilon^{n,k}, \nabla\chi\right)$$

$$+ \frac{1}{3}\left([\Xi(U_\varepsilon^n)]^3\,\Lambda_\varepsilon(\Psi_\varepsilon^{n,k-1})\,\nabla W_\varepsilon^n, \nabla\chi\right) + \beta K\left(\Psi_\varepsilon^{n,k} - V_\varepsilon^{n,k}, \chi\right)^h$$

$$= -\frac{1}{2}\left([\Xi(U_\varepsilon^n)]^{\frac{3}{2}}\,[\Xi(U_\varepsilon^{n-1})]^{\frac{1}{2}}\,\Lambda_\varepsilon(\Psi_\varepsilon^{n,k-1})\,\nabla V_\varepsilon^{n-1}, \nabla\chi\right). \tag{4.2b}$$

Equations (4.1a)–(4.1b) and (4.2a)–(4.2b) are natural extensions of the iterative procedure proposed in [10] for solving a finite element approximation of the thin film equation. Note that we have chosen the iterative method such that (4.2a) and (4.2b) decouple. As $U_\varepsilon^{n,k-1} > 0$, it is easily established on noting Lemma 2.2 in BN that there exists a unique solution $\{U_\varepsilon^{n,k}, W_\varepsilon^{n,k}\} \in S^h_{>0} \times S^h$ to (4.1a)–(4.1b). As (4.2a) is linear, existence of $V_\varepsilon^{n,k}$ follows from uniqueness; this is easily established on noting (2.2a) and $\rho_s \geq 0$. Existence and uniqueness of $\Psi_\varepsilon^{n,k}$ follow from the monotonicity of λ_ε and the positivity of $U_\varepsilon^n > 0$. Hence the iterations (4.1a)–(4.1b) and (4.2a)–(4.2b) are well defined.

For the iterative algorithms (4.1a)–(4.1b) and (4.2a)–(4.2b) we set, for $n \geq 1$, $\{U_\varepsilon^{n,0}, V_\varepsilon^{n,0}, \Psi_\varepsilon^{n,0}\} \equiv \{U_\varepsilon^{n-1}, V_\varepsilon^{n-1}, \Psi_\varepsilon^{n-1}\}$ and adopted the stopping criteria

$$|U_\varepsilon^{n,k} - U_\varepsilon^{n,k-1}|_{0,\infty} < tol,\ |V_\varepsilon^{n,k} - V_\varepsilon^{n,k-1}|_{0,\infty} < tol, \quad \text{and} \quad |\Psi_\varepsilon^{n,k} - \Psi_\varepsilon^{n,k-1}|_{0,\infty} < tol,$$

respectively, with $tol = 10^{-8}$. Furthermore, we then set $\{U_\varepsilon^n, W_\varepsilon^n, V_\varepsilon^n, \Psi_\varepsilon^n\} \equiv \{U_\varepsilon^{n,k}, W_\varepsilon^{n,k}, V_\varepsilon^{n,k}, \Psi_\varepsilon^{n,k}\}$ for (4.1a)–(4.1b) and (4.2a)–(4.2b).

Remark 4.1. The nonlinear system (4.1a)–(4.1b) can be solved using an inexact Newton's method, applying a BiCGSTAB algorithm at each Newton iteration. The linear system (4.2a), on the other hand, can be solved efficiently using a conjugate

gradient algorithm. The nonlinear system (4.2b) can be solved with a nonlinear SOR method, similar to the one employed in [7]. In particular, in each step and at each vertex a scalar nonlinear equation of the form $\alpha_1\,\lambda_\varepsilon(s) + \alpha_2\,s = \alpha_3$, $s \in \mathbb{R}$, where α_1, $\alpha_2 > 0$, has to be solved, which is straightforward as λ_ε is monotone.

Although we are unable to show convergence of the iterations (4.1a)–(4.1b) and (4.2a)–(4.2b) for $\{U_\varepsilon^n, W_\varepsilon^n\}$ and $\{V_\varepsilon^n, \Psi_\varepsilon^n\}$, respectively, we observed good convergence properties in practice.

4.1. Numerical results for $d = 1$. First, we present numerical experiments in one space dimension. Throughout we choose a uniform partitioning of $\Omega = (-L, L)$, where $L \geq 1$, with mesh points $p_j = -L + (j-1)h$, $j = 1 \to 2^{10}+1$, where $h = 2^{-9}\,L$. In addition we choose uniform time steps $\tau_n = \tau = 10^{-3}$ and throughout set the regularization parameter $\varepsilon = 10^{-5}$. For the initial profiles u^0, v^0, and ψ^0, we set

$$u^0(x) = 1 \quad \text{and} \quad v^0(x) = \frac{1}{2}\left[1 - \tanh(10\,|x| - 5)\right], \quad \psi^0(x) = 0, \tag{4.3}$$

which resembles a uniform liquid film of unit height with surfactant on top of it, and the film is uncontaminated by the chemical. In the absence of both surfactant and chemical, a uniform film is a steady state. We choose $U_\varepsilon^0 \equiv \pi^h u^0$, $V_\varepsilon^0 \equiv \pi^h v^0$, and $\Psi_\varepsilon^0 \equiv \pi^h \psi^0$ as the discrete initial data on noting that u^0, v^0, $\psi^0 \in W^{1,\infty}(\Omega)$.

We now report on the evolutions of U_ε, V_ε, and Ψ_ε for similar parameters as in some of the experiments in [16, Fig. 5]. We set $L = 10$, $c = 10^{-3}$, $\rho_s = 10^{-5}$, $\rho_b = 10^{-2}$, $K = 1$, $a = 0$, $\delta = 10^{-5}$, and $\nu = 4$ and used the initial data (4.3). We then varied the solubility parameter, by choosing $\beta = 0.01, 1$, or 100. The different evolution results can be seen in Figure 1, where we plot U_ε and V_ε both at time $t = 5$ and at different final times T. Note that for brevity only V_ε is displayed since in all cases after a short time Ψ_ε is graphically indistinguishable from it. This is to be expected from the Lyapunov structure (2.29a) (see also (1.20)) on noting (1.11) and (1.8).

One can clearly see the effect of the parameter β on the evolution. On the one hand, the larger the value of β the faster Ψ_ε attains the profile of V_ε. On the other hand, since the quantity $\fint(V_\varepsilon^n + \frac{1}{\beta}\,\pi^h[U_\varepsilon^n\,\lambda_\varepsilon(\Psi_\varepsilon^n)]) = \fint(V_\varepsilon^0 + \frac{\varepsilon}{\beta})$ is preserved, the value of β dictates how much surfactant material V_ε remains on the film surface. In particular, after a sufficiently long time it holds that $\fint V_\varepsilon^n \approx \fint \Psi_\varepsilon^n$ and $\fint(V_\varepsilon^n + \frac{1}{\beta}\,\pi^h[U_\varepsilon^n\,V_\varepsilon^n]) \approx \fint V_\varepsilon^0$. Hence if β is such that $\varepsilon \ll \beta \ll 1$, the original drop of surfactant almost completely disappears, leading to a comparatively small change in the liquid film height that quickly smooths out. In the case of a very large β, recall that $\beta \to \infty$ models insoluble surfactant spreading; the initial amount of surfactant is almost completely preserved, leading to a fast propagating wave front.

Finally, note that the presence of repulsive van der Waals forces ($\delta > 0$) has no effect on the evolution in this case, as the film height is always bounded well away from zero.

When attractive van der Waals forces are included, however, this has a marked effect on the film evolution. We repeated the above experiments for a value of $a = 5 \times 10^{-4}$, and the results can be seen in Figure 2. Note that for $\beta = 0.01$ and 1 the film has thinned considerably in some areas due to the presence of attractive van der Waals forces, although it can never actually rupture ($U_\varepsilon = 0$) due to the repulsive van der Waals forces, ϕ^+. In fact, it holds that $\min_{x\in\overline{\Omega}} U_\varepsilon(x,T) = \arg\min_{s\in\mathbb{R}_{>0}} \Phi(s) = (\frac{\delta}{a})^{\frac{1}{\nu-3}} = 0.02$. For $\beta = 100$, on the other hand, the film has not yet completely thinned at the displayed time.

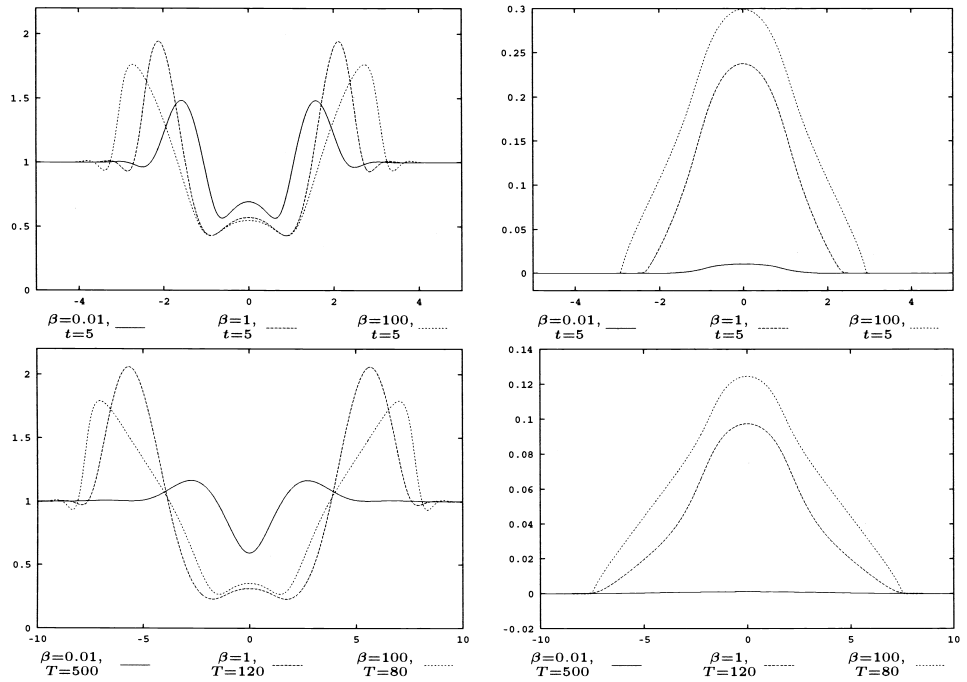

FIG. 1. *$U_\varepsilon(x,t)$ and $V_\varepsilon(x,t)$ for $\beta \in \{0.01, 1, 100\}$ and time $t = 5$ (above), and for different final times $t = T$ (below).*

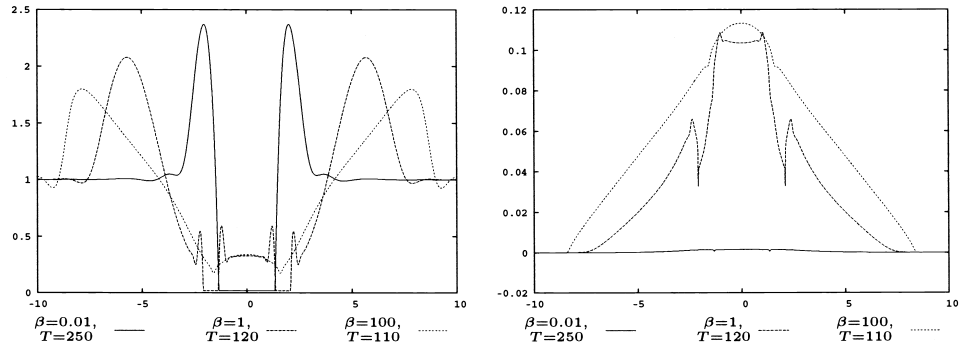

FIG. 2. *$U_\varepsilon(x,T)$ and $V_\varepsilon(x,T)$ for $\beta \in \{0.01, 1, 100\}$ for different final times T.*

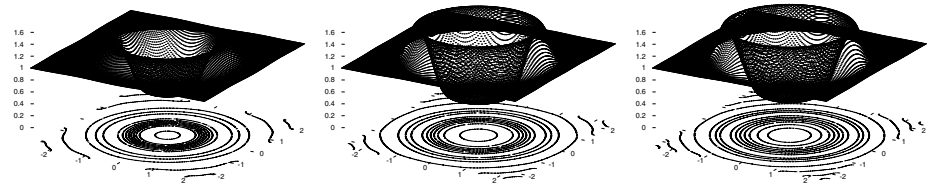

FIG. 3. *$U_\varepsilon(x,T)$ for $\beta = 0.01$, $T = 5$ (left), for $\beta = 1$, $T = 3$ (middle), and for $\beta = 100$, $T = 2$ (right).*

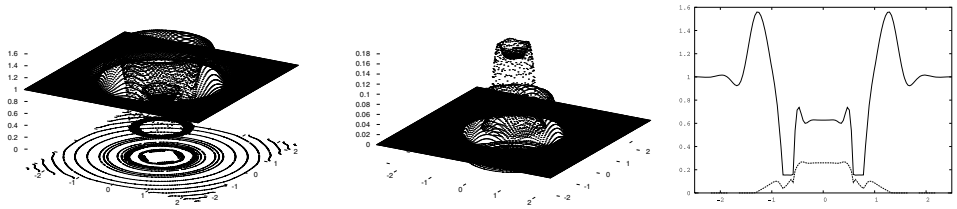

FIG. 4. $U_\varepsilon(x,T)$ *and* $V_\varepsilon(x,T)$ *for* $\beta = 0.01$ *and* $T = 1$. *On the right a plot of* $U_\varepsilon(x,T)\,|_{x_2=0}$ *and* $V_\varepsilon(x,T)\,|_{x_2=0}$.

4.2. Numerical results for $d = 2$. Finally, we present a numerical experiment in two space dimensions with $\Omega = (-L,L) \times (-L,L)$. We took a uniform mesh of squares of length $h = \frac{2L}{128}$, each of which was divided into two triangles by its northeast diagonal. We chose the following parameters for $(\mathrm{P}_\varepsilon^{h,\tau})$: $L = 2.5$, $c = 10^{-3}$, $\rho_s = 10^{-5}$, $\rho_b = 10^{-2}$, $K = 1$, $a = 0$, $\delta = 10^{-5}$, $\nu = 7$, $\tau_n = \tau = 10^{-3}$, and $\varepsilon = 10^{-5}$. For the initial profiles we chose (4.3). We set $U_\varepsilon^0 \equiv \pi^h u^0$, $V_\varepsilon^0 \equiv \pi^h v^0$, and $\Psi_\varepsilon \equiv \pi^h \psi^0$. In Figure 3 we plot $U_\varepsilon(x,T)$ for $\beta = 0.01, 1$, and 100 at different final times T.

Though on a slower time scale, the results are qualitatively similar to the experiments in one space dimension. The same holds true when including attractive van der Waals forces in the simulation. See Figure 4, where we plot U_ε and V_ε for $\beta = 0.01$ and the same parameters as above except $a = 0.02$. Again for brevity only V_ε is displayed since Ψ_ε is graphically indistinguishable from it. Note that here $\min_{x\in\overline{\Omega}} U_\varepsilon(x,T) \approx \arg\min_{s\in\mathbb{R}_{>0}} \Phi(s) = (\frac{\delta}{a})^{\frac{1}{\nu-3}} \approx 0.15$.

CONTINUOUS INTERIOR PENALTY FINITE ELEMENT METHOD FOR OSEEN'S EQUATIONS*

ERIK BURMAN†, MIGUEL A. FERNÁNDEZ‡, AND PETER HANSBO§

Abstract. In this paper we present an extension of the continuous interior penalty method of Douglas and Dupont [*Interior penalty procedures for elliptic and parabolic Galerkin methods*, in Computing Methods in Applied Sciences, Lecture Notes in Phys. 58, Springer-Verlag, Berlin, 1976, pp. 207–216] to Oseen's equations. The method consists of a stabilized Galerkin formulation using equal order interpolation for pressure and velocity. To counter instabilities due to the pressure/velocity coupling, or due to a high local Reynolds number, we add a stabilization term giving L^2-control of the jump of the gradient over element faces (edges in two dimensions) to the standard Galerkin formulation. Boundary conditions are imposed in a weak sense using a consistent penalty formulation due to Nitsche. We prove energy-type a priori error estimates independent of the local Reynolds number and give some numerical examples recovering the theoretical results.

Key words. finite element methods, stabilized methods, continuous interior penalty, Oseen's equations

1. Introduction.

The construction of finite element methods for the incompressible Navier–Stokes equations that are robust and accurate for a wide range of Reynolds numbers remains a challenging problem. The standard Galerkin method requires the fulfillment of the inf-sup or Babuska–Brezzi condition, which leads to the need for formulations using mixed interpolations (see [7, 27]). From the computational point of view it is, however, more practical to use equal order interpolation for the velocity and pressure spaces, which requires that stability is imposed in some other fashion. One possibility is to construct *stabilized* finite element methods where some terms are added to the standard Galerkin formulation in order to enhance the stability properties of the method. To be useful the method must also be stable with respect to the convective terms and give sufficient control of the incompressibility condition.

A favored approach has been to stabilize both the velocities and the pressure using the streamline upwind Petrov–Galerkin (SUPG) method originally proposed by Brooks and Hughes in [9]. This method was first analyzed for the Navier–Stokes equations in a velocity vorticity formulation by Johnson and Saranen in [32], and then in a pressure velocity formulation by Hansbo and Szepessy in [29], by Franca and Frey

in [24], and by Tobiska and Verfürth in [38]. The SUPG method owes its success to the unified treatment of velocities and pressures. It allows for a priori error estimates that are independent of the Reynolds number and has been used extensively in practice with good results. Nevertheless, the SUPG method has some undesirable features:

- artificial boundary conditions on velocities and pressure are introduced;
- artificial nonsymmetric terms are introduced;
- the least squares term introduces nonphysical pressure/velocity couplings;
- the least squares term makes mass lumping impossible and the choice of time-stepping methods limited; most clear-cut from a theoretical point of view is a space-time finite element approach using discontinuous approximation in time;
- it is not yet fully understood how to use mixed finite elements in combination with the SUPG method (for recent advances see [26]).

To overcome these disadvantages, alternative stabilization techniques have been developed such as the projection method proposed by Codina [17] and Codina and Blasco [18], the subgrid viscosity method or local projection method proposed by Guermond [28] and Becker and Braack [1], the polynomial pressure projection method by Dohrmann and Bochev reported in [19], and the pressure-Poisson stabilization of the Stokes equations proposed by Bochev and Gunzburger in [2].

Recently, the continuous interior penalty method of Douglas and Dupont [20] was revived as an alternative. The idea is to add a least squares penalization on the gradient jump between neighboring elements as a unified treatment of all the above-mentioned instabilities. It was shown in [13, 15] that the method stabilizes both instabilities due to dominating convection and instabilities due to the velocity/pressure coupling. Moreover, it was shown in [10] how this method provides a natural link between conforming and nonconforming stabilized finite element methods. It was used in [14] to provide a Reynolds number independent stabilized formulation for the classical nonconforming P_1 Crouzeix–Raviart approximation for the velocities combined with elementwise constant pressures.

In this paper we extend the face oriented stabilization method to Oseen's equations, using equal order interpolation for velocities and pressure. For the case of similar stabilization strategies for element pairs satisfying the inf-sup condition we refer the reader to [11]. We follow the framework proposed in [10] using weakly imposed boundary conditions as introduced by Nitsche (see [36, 25]). Although the constants of our analysis inevitably depend on the parameters of the problem (since the solution depends on the physical parameters), the stabilization terms allow us to trade the need of coercivity in the H^1-norm for coercivity in the weaker L^2-norm plus the stabilization term, which vanishes at optimal rate under refinement. To exploit this in the analysis, we add a zero order term to Oseen's equations. With this additional term we obtain estimates that do not explode as the viscosity goes to zero, provided the exact solution is sufficiently regular.

With the proposed method, all the above-mentioned inconveniences of the SUPG method are alleviated. The formulation allows for general unstructured meshes and variable polynomial degree. The main inconveniences of the present method, however, are as follows:

- Added couplings in the Jacobian matrix: the bandwidth of the system matrix doubles in two space dimensions and triples in three space dimensions. This may increase the computational cost of the linear system solution, for instance, if an incomplete LU factorization is used as preconditioner.

- The method requires stabilization terms to be evaluated on the faces of the elements and hence a table of nearest neighbors for computation of the jumps. Such features are present typically when using adaptivity with a posteriori error estimation or for discontinuous Galerkin (DG) methods.

However, all stabilization terms have the same structure, allowing for one computation of one global stabilization matrix based on the gradient jumps of one component. The parameter values that change from time-step to time-step may then be updated using locally averaged weights. When time-stepping the Navier–Stokes equations this means that the stabilization matrix has to be constructed only once and for one component. This is in stark contrast to the SUPG method, where the stabilization terms have to be reconstructed at every time-step for consistency.

The outline of the paper is as follows: In the next section we introduce our model problem, Oseen's equations, and formulate the interior penalty finite element method. In section 3 we discuss the question of stability, we prove a lemma of fundamental importance for the stability of the method, and we show that the discrete problem has a unique solution. We then proceed and prove (quasi-) optimal a priori error estimates in section 4 with special focus on how to make the estimates independent of the local Reynolds number. Finally, in section 5, we study the performance of the numerical scheme on some linear model cases in three space dimensions. We make some concluding remarks in section 6 and some outlooks to future developments, with special emphasis on the relation between the present method and variational multiscale methods (VMS) in large eddy simulations (LES).

2. A finite element method for Oseen's equations. Let Ω be a Lipschitz-continuous domain in $\mathbb{R}^d$ ($d = 2$ or 3) with a polyhedral boundary $\partial\Omega$ and outward pointing normal $\mathbf{n}$. We will consider the Sobolev spaces $W^{m,q}(\Omega)$, with norm $\|\cdot\|_{m,q,\Omega}$, $m \geq 0$, and $q \geq 1$. In particular, we have $L^q(\Omega) = W^{0,q}(\Omega)$. We use the standard notation $H^m(\Omega) \stackrel{\text{def}}{=} W^{m,2}(\Omega)$. The norm of $H^m(\Omega)$ is denoted by $\|\cdot\|_{m,\Omega}$ and its seminorm by $|\cdot|_{m,\Omega}$. The space of $L^2(\Omega)$ divergence free functions is denoted by $H_0(\mathrm{div};\Omega)$. The scalar product in $L^2(\Omega)$ is denoted by $(\cdot,\cdot)$ and its norm by $\|\cdot\|_{0,\Omega}$. The closed subspaces $H_0^1(\Omega)$, consisting of functions in $H^1(\Omega)$ with zero trace on $\partial\Omega$, and $L_0^2(\Omega)$, consisting of functions in $L^2(\Omega)$ with zero mean in Ω, will also be used. Oseen's equations take the form

$$\left\{\begin{array}{rl} \sigma\mathbf{u} + \boldsymbol{\beta}\cdot\nabla\mathbf{u} - 2\nabla\cdot(\nu\boldsymbol{\epsilon}(\mathbf{u})) + \nabla p = \mathbf{f} & \text{in } \Omega, \\ \nabla\cdot\mathbf{u} = 0 & \text{in } \Omega, \\ \mathbf{u} = 0 & \text{on } \partial\Omega, \end{array}\right. \tag{2.1}$$

where $\mathbf{u} \in [H_0^1(\Omega)]^d \cap H_0(\mathrm{div};\Omega)$, $\boldsymbol{\beta} \in [W^{1,\infty}(\Omega)]^d \cap H_0(\mathrm{div};\Omega)$, $p \in L_0^2(\Omega)$, $\boldsymbol{\epsilon}(\mathbf{u})$ stands for the strain rate tensor

$$\boldsymbol{\epsilon}(\mathbf{u}) \stackrel{\text{def}}{=} \frac{1}{2}\Big(\nabla\mathbf{u} + (\nabla\mathbf{u})^{\mathrm{T}}\Big),$$

$\mathbf{f} \in [L^2(\Omega)]^d$ is a given source term, and σ, ν are positive constants.

The weak formulation of problem (2.1) reads as follows: find $(\mathbf{u}, p) \in [H_0^1(\Omega)]^d \times L_0^2(\Omega)$ such that

$$\left\{\begin{array}{c} a(\mathbf{u},\mathbf{v}) + b(p,\mathbf{v}) = (\mathbf{f},\mathbf{v}), \\ b(q,\mathbf{u}) = 0 \end{array}\right. \quad \forall (\mathbf{v},q) \in [H_0^1(\Omega)]^d \times L_0^2(\Omega), \tag{2.2}$$

where

$$
\begin{aligned}
a(\mathbf{u},\mathbf{v}) &\stackrel{\text{def}}{=} (\sigma\,\mathbf{u},\,\mathbf{v}) + (\boldsymbol{\beta}\cdot\nabla\mathbf{u},\,\mathbf{v}) + 2(\nu\boldsymbol{\epsilon}(\mathbf{u}),\boldsymbol{\epsilon}(\mathbf{v})),\\
b(p,\mathbf{v}) &\stackrel{\text{def}}{=} -(p,\nabla\cdot\mathbf{v}).
\end{aligned}
\tag{2.3}
$$

The well-posedness of this problem follows by the Lax–Milgram lemma applied in the space $[H_0^1(\Omega)]^d \cap H_0(\mathrm{div};\Omega)$ (see, for instance, [27]).

Let $\{\mathcal{T}_h\}_{0<h\le 1}$ denote a family of triangulations of the domain Ω without hanging nodes. For each triangulation $\mathcal{T}_h$, the subscript $h \in (0,1]$ refers to the level of refinement of the triangulation, which is defined by

$$
h \stackrel{\text{def}}{=} \max_{K\in\mathcal{T}_h} h_K,
$$

with h_K the diameter of K. We also define the elementwise constant function $\tilde{h}|_K = h_K$. The interior of a triangle K will be denoted by $\overset{\circ}{K}$, and $\mathcal{N}(K)$ will stand for the set of elements sharing at least one node with the element K. Moreover, we will assume that the family $\{\mathcal{T}_h\}_{0<h\le 1}$ has the following regularity properties:

1. Local shape regularity: for all $K \in \mathcal{T}_h$ with $h \in (0,1]$ there holds

$$
\frac{h_K}{\rho_K} < c_0,
\tag{2.4}
$$

where ρ_K stands for the diameter of the largest ball contained in K, and c_0 is a fixed positive constant.

2. Local quasi-uniformity: for all $K \in \mathcal{T}_h$ with $h \in (0,1]$ there holds

$$
\frac{1}{\rho} h_{K'} \le h_K \le \rho h_{K'} \quad \forall K' \in \mathcal{N}(K),
\tag{2.5}
$$

where $\rho > 1$ is a given parameter depending on the local uniformity of $\{\mathcal{T}_h\}_{0<h\le 1}$.

We will also assume that the data are sufficiently well resolved in the sense that there exists $\rho_{\boldsymbol{\beta}} > 1$ such that

$$
\frac{1}{\rho_{\boldsymbol{\beta}}}\|\boldsymbol{\beta}\|_{0,\infty,K'} \le \|\boldsymbol{\beta}\|_{0,\infty,K} \le \rho_{\boldsymbol{\beta}}\|\boldsymbol{\beta}\|_{0,\infty,K'} \quad \forall K' \in \mathcal{N}(K).
\tag{2.6}
$$

Note that this is a hypothesis on the mesh and not on the data. Under the assumption that $\boldsymbol{\beta} \in W^{1,\infty}(\mathcal{N}(K))$ this can be ensured by

$$
|\boldsymbol{\beta}|_{1,\infty,\mathcal{N}(K)} \le c_{\boldsymbol{\beta}} h_K^{-1} \|\boldsymbol{\beta}\|_{0,\infty,\mathcal{N}(K)}
\tag{2.7}
$$

for some constant $c_{\boldsymbol{\beta}} > 0$ small enough.

For the error analysis, we shall use the trace inequality

$$
\|v\|_{0,\partial K}^2 \le C_{\mathrm{T}}\Big(h_K^{-1}\|v\|_{0,K}^2 + h_K\|v\|_{1,K}^2\Big) \quad \forall v \in H^1(K),
\tag{2.8}
$$

where C_{T} is a generic constant independent of h_K (for a proof, see [37, p. 26]).

For a given piecewise continuous function φ, the jump $[\![\varphi]\!]$ over a face f is defined by

$$
[\![\varphi]\!](\mathbf{x}) \stackrel{\text{def}}{=} \begin{cases} \lim\limits_{t\to 0^+} (\varphi(\mathbf{x}-t\mathbf{n}_f) - \varphi(\mathbf{x}+t\mathbf{n}_f)) & \text{if} \quad f \not\subset \partial\Omega,\\ 0 & \text{if} \quad f \subset \partial\Omega, \end{cases}
$$

where $\mathbf{n}_f$ is a normal unit vector on f and $\mathbf{x} \in f$.

In this paper we let V_h^k denote the standard space of continuous functions of piecewise polynomial order $k \geq 1$,

$$V_h^k \stackrel{\text{def}}{=} \left\{ v \in H^1(\Omega) \,:\, v_{|K} \in P_k(K) \quad \forall K \in \mathcal{T}_h \right\},$$

and $H^2(\mathcal{T}_h)$ the space of piecewise H^2 functions

$$H^2(\mathcal{T}_h) \stackrel{\text{def}}{=} \left\{ v : \Omega \longrightarrow \mathbb{R} \,:\, v_{|K} \in H^2(K) \quad \forall K \in \mathcal{T}_h \right\}.$$

For the velocities we will use the space $[V_h^k]^d$ and for the pressure we will use $Q_h^k = V_h^k \cap L_0^2(\Omega)$. In what follows, we let $\pi_{h,k}$, $i_{h,k}$, and $\mathcal{C}_{h,k}$ denote (respectively) the L^2-projection operator, the nodal interpolation operator, and the Clément interpolant onto the finite element spaces, and we make no notational difference between the projection onto the velocity and pressure spaces. We also introduce a piecewise linear approximated velocity $\boldsymbol{\beta}_h \in [V_h^1]^d$ such that

$$\|\boldsymbol{\beta} - \boldsymbol{\beta}_h\|_{0,\infty,K} \leq C h_K |\boldsymbol{\beta}|_{1,\infty,K} \quad \forall K \in \mathcal{T}_h. \tag{2.9}$$

Here and in the following C denotes a constant independent of the problem parameters and the local mesh size, but not necessarily of the local mesh geometry. Denoting the product space $W_h^k \stackrel{\text{def}}{=} [V_h^k]^d \times Q_h^k$ our finite element method reads as follows: find $(\mathbf{u}_h, p_h) \in W_h^k$ such that

$$a_h(\mathbf{u}_h, \mathbf{v}_h) + b_h(p_h, \mathbf{v}_h) - b_h(q_h, \mathbf{u}_h) + j_{\mathbf{u}}(\mathbf{u}_h, \mathbf{v}_h) + j_p(p_h, q_h) = (\mathbf{f}, \mathbf{v}_h) \tag{2.10}$$

for all $(\mathbf{v}_h, q_h) \in W_h^k$, and with

$$\begin{aligned} a_h(\mathbf{u}_h, \mathbf{v}_h) \stackrel{\text{def}}{=}\ & a(\mathbf{u}_h, \mathbf{v}_h) - \langle 2\nu\boldsymbol{\epsilon}(\mathbf{u}_h)\mathbf{n}, \mathbf{v}_h\rangle_{\partial\Omega} - \langle \mathbf{u}_h, 2\nu\boldsymbol{\epsilon}(\mathbf{v}_h)\mathbf{n}\rangle_{\partial\Omega} \\ & - \langle \boldsymbol{\beta}\cdot\mathbf{n}\mathbf{u}_h, \mathbf{v}_h\rangle_{\partial\Omega_{\text{in}}} + \langle \gamma(\nu/\tilde{h})\mathbf{u}_h, \mathbf{v}_h\rangle_{\partial\Omega} \\ & + \langle \gamma \max\{|\boldsymbol{\beta}|, \nu/\tilde{h}\}\mathbf{u}_h\cdot\mathbf{n}, \mathbf{v}_h\cdot\mathbf{n}\rangle_{\partial\Omega}, \end{aligned} \tag{2.11}$$

$$b_h(p_h, \mathbf{v}_h) \stackrel{\text{def}}{=} b(p_h, \mathbf{v}_h) + \langle p_h, \mathbf{v}_h\cdot\mathbf{n}\rangle_{\partial\Omega}, \tag{2.12}$$

$$\begin{aligned} j_{\mathbf{u}}(\mathbf{u}_h, \mathbf{v}_h) \stackrel{\text{def}}{=}\ & \sum_{K\in\mathcal{T}_h} \gamma\xi(\mathrm{Re_K}) h_K^2 \int_{\partial K} \|\boldsymbol{\beta}\cdot\mathbf{n}\|_{0,\infty,\partial K} [\![\mathbf{n}\cdot\nabla\mathbf{u}_h]\!]\cdot[\![\mathbf{n}\cdot\nabla\mathbf{v}_h]\!]\,\mathrm{d}s \\ & + \sum_{K\in\mathcal{T}_h} \gamma\xi(\mathrm{Re_K})\|\boldsymbol{\beta}\|_{0,\infty,K} h_K^2 \int_{\partial K} [\![\nabla\cdot\mathbf{u}_h]\!][\![\nabla\cdot\mathbf{v}_h]\!]\,\mathrm{d}s, \end{aligned} \tag{2.13}$$

$$j_p(p_h, q_h) \stackrel{\text{def}}{=} \sum_{K\in\mathcal{T}_h} \gamma\xi(\mathrm{Re_K}) \frac{h_K^2}{\|\boldsymbol{\beta}\|_{0,\infty,K}} \int_{\partial K} [\![\nabla p_h]\!]\cdot[\![\nabla q_h]\!]\,\mathrm{d}s, \tag{2.14}$$

$\mathbf{n}$ the outward pointing normal to $\partial\Omega$, and using the notation

$$\mathrm{Re}_K \stackrel{\text{def}}{=} \frac{\|\boldsymbol{\beta}\|_{0,\infty,K} h_K}{\nu}, \quad \xi(\lambda) \stackrel{\text{def}}{=} \min\{1,\lambda\}, \quad \partial\Omega_{\text{in}} \stackrel{\text{def}}{=} \{\mathbf{x}\in\partial\Omega \,:\, (\boldsymbol{\beta}\cdot\mathbf{n})(\mathbf{x}) < 0\},$$

$$\langle x, y\rangle_{\partial\Omega} \stackrel{\text{def}}{=} \sum_{\substack{K\,\in\,\mathcal{T}_h \\ K\,\cap\,\partial\Omega\,\neq\,\emptyset}} \int_{\partial K\cap\partial\Omega} xy\,\mathrm{d}s, \quad \tilde{h}\in H^2(\mathcal{T}_h) \quad \text{with} \quad \tilde{h}_{|K} \stackrel{\text{def}}{=} h_K.$$

To keep down notation we have used a canonical stabilization parameter γ for all terms. In practice this term, however, can be chosen distinctly for different terms. The gradient jump terms serve three purposes:

1. stabilization of the convective terms (the first sum in (2.13));
2. giving additional control of the incompressibility condition (the second sum in (2.13)); and
3. making the discretization inf-sup stable (the sum in (2.14)).

We will see in the analysis that these three objectives are all obtained in the same fashion and that essentially the gradient jump operator can stabilize any instability provoked by a first order term.

Assuming sufficient regularity of the exact solution the above formulation is strongly consistent. More generally we have the following result.

LEMMA 2.1 (modified Galerkin orthogonality). *Assume that* $(\mathbf{u}, p)$*, the solution of* (2.1)*, belongs to the space* $[H^{3/2+\varepsilon}(\Omega)]^d \times L^2_0(\Omega)$*, with* $\varepsilon > 0$*, and let* $(\mathbf{u}_h, p_h) \in W_h^k$ *be the solution of* (2.10)*. Then*

$$a_h(\mathbf{u} - \mathbf{u}_h, \mathbf{v}_h) + b_h(p - p_h, \mathbf{v}_h) - b_h(q_h, \mathbf{u} - \mathbf{u}_h) + j_{\mathbf{u}}(\mathbf{u} - \mathbf{u}_h, \mathbf{v}_h) - j_p(p_h, q_h) = 0$$

for all $(\mathbf{v}_h, q_h) \in W_h^k$*.*

Proof. This is an immediate consequence of the consistency of the standard Galerkin method and the fact that, under the regularity assumptions, $j_{\mathbf{u}}(\mathbf{u}, \mathbf{v}_h) = 0$ since $[\![\nabla \mathbf{u}]\!]_f = 0$ for all interior faces f. ∎

3. Stability of the method. Stability in the face oriented stabilization method is based on the following lemma, which was proved for piecewise linear continuous approximation in [10] (for a similar result with applications to DG methods see [33]). Here we extend this result to arbitrary polynomial degree. Note that we give a lower bound as well. This is not needed for the analysis but shows that in some sense the stabilizing terms are optimal.

LEMMA 3.1. *There exist an interpolation operator* $\pi^*_{h,k} : [H^2(\mathcal{T}_h)]^d \longrightarrow [V_h^k]^d$ *and constants* γ*,* γ_{low} *depending on the local mesh geometry and the polynomial degree, but not on the local mesh size, such that*

$$\gamma_{low} j_{\boldsymbol{\beta}}(\mathbf{v}_h, \mathbf{v}_h) \le \| h^{\frac{1}{2}} \big(\boldsymbol{\beta}_h \cdot \nabla \mathbf{v}_h - \pi^*_{h,k}(\boldsymbol{\beta}_h \cdot \nabla \mathbf{v}_h) \big) \|^2_{0,\Omega} \le j_{\boldsymbol{\beta}}(\mathbf{v}_h, \mathbf{v}_h)$$

for all $\mathbf{v}_h \in [V_h^k]^d$*, where*

$$j_{\boldsymbol{\beta}}(\mathbf{v}_h, \mathbf{v}_h) = \gamma \sum_{K \in \mathcal{T}_h} \int_{\partial K} h_K^2 |\boldsymbol{\beta}_h \cdot \mathbf{n}|^2 |[\![\nabla \mathbf{v}_h \mathbf{n}]\!]|^2 \, \mathrm{d}s.$$

Proof. First note that, as pointed out in [10], $[\![\boldsymbol{\beta}_h \cdot \nabla \mathbf{u}_h]\!] = \boldsymbol{\beta}_h \cdot \mathbf{n} [\![\mathbf{n} \cdot \nabla \mathbf{u}_h]\!]$. For each node x_i, let n_i be the number of elements containing x_i as a node. Then we define a quasi-interpolant $\pi^*_{h,k}$ of degree k by

$$\pi^*_{h,k} \mathbf{v}(x_i) \stackrel{\text{def}}{=} \frac{1}{n_i} \sum_{\{K \,:\, x_i \in K\}} \mathbf{v}_{|K}(x_i) \quad \forall \mathbf{v} \in [H^2(\mathcal{T}_h)]^d.$$

For each element $K \in \mathcal{T}_h$ consider the function

$$\delta_K \stackrel{\text{def}}{=} h_K^{\frac{1}{2}} \big(\boldsymbol{\beta}_h \cdot \nabla \mathbf{v}_{h|K} - \pi^*_{h,k}(\boldsymbol{\beta}_h \cdot \nabla \mathbf{v}_h)_{|K} \big).$$

Clearly, $\delta_K(x_j) = 0$ for each interior node $x_j \in \overset{\circ}{K}$, whereas on the element faces, i.e., for all nodes $x_j \in \partial K$, we have

$$\begin{aligned}\delta_K(x_j) &= h_K^{\frac{1}{2}} \frac{1}{n_j} \sum_{\{K' : x_j \in K'\}} \boldsymbol{\beta}_h \cdot \big(\nabla \mathbf{v}_{h|K}(x_j) - \nabla \mathbf{v}_{h|K'}(x_j)\big) \\ &= h_K^{\frac{1}{2}} \frac{1}{n_j} \sum_{\{K' : x_j \in K'\}} \sum_{f \in P(K,K')} \boldsymbol{\beta}_h(x_j) \cdot [\![\nabla \mathbf{v}_h]\!]_f(x_j), \end{aligned} \tag{3.1}$$

where $P(K, K')$ stands for the set of faces between K and K' (the shortest path). We now introduce the reference element $\hat{K}$ and, for each $K \in \mathcal{T}_h$, the affine mapping

$$F_K(\hat{\mathbf{x}}) = B_K \hat{\mathbf{x}} + \mathbf{b}_K \quad \forall \hat{\mathbf{x}} \in \hat{K},$$

such that $F_K(\hat{K}) = K$. Finally, let φ_j^K for $j = 1, \dots, k$ be the basis functions on K. Since $\delta_K(x_j) = 0$ for each interior node $x_j \in \overset{\circ}{K}$, $\|\delta_K \circ F_K\|_{0,\partial\hat{K}}^2 = 0$ implies that $\delta_K \circ F_K = 0$ in $\hat{K}$. Therefore, by equivalence of norms on discrete spaces, using a standard scaling argument (see [27, p. 96]) and (3.1), it follows that

$$\begin{aligned}\|\delta_K\|_{0,K}^2 &= \det B_K \|\delta_K \circ F_K\|_{0,\hat{K}}^2 \\ &\le C \det B_K \|\delta_K \circ F_K\|_{0,\partial\hat{K}}^2 \\ &= \int_{\partial\hat{K}} \frac{1}{|B_K^{-\mathrm{T}} \hat{\mathbf{n}}|} |\delta_K \circ F_K|^2 \underbrace{\det B_K |B_K^{-\mathrm{T}} \hat{\mathbf{n}}| \, \mathrm{d}\hat{s}}_{\mathrm{d}s} \\ &\le C |B_K^{\mathrm{T}}| \int_{\partial K} |\delta_K|^2 \, \mathrm{d}s \\ &\le C h_K \int_{\partial K} |\delta_K|^2 \, \mathrm{d}s \\ &\le C h_K \int_{\partial K} \sum_{j=1}^{k} |\delta_K(x_j)|^2 (\varphi_j^K)^2 \, \mathrm{d}s \\ &\le C h_K^2 \int_{\partial K} \sum_{j=1}^{k} \frac{1}{n_j} \sum_{\{K' : x_j \in K'\}} \sum_{e \in P(K,K')} |\boldsymbol{\beta}_h(x_j) \cdot [\![\nabla \mathbf{v}_h]\!]_e(x_j)|^2 (\varphi_j^K)^2 \, \mathrm{d}s \\ &\le C h_K^2 \int_{\partial K} \sum_{j=1}^{k} \frac{1}{n_j} \sum_{f \in E(K)} |\boldsymbol{\beta}_h(x_j) \cdot [\![\nabla \mathbf{v}_h]\!]_f(x_j)|^2 (\varphi_j^K)^2 \, \mathrm{d}s \\ &\le C h_K^2 \sum_{f \in E(K)} \int_f |\boldsymbol{\beta}_h \cdot [\![\nabla \mathbf{v}_h]\!]_f|^2 \, \mathrm{d}s, \end{aligned}$$

where, in the two last inequalities, $E(K)$ denotes the set of faces containing some node of K. On the other hand, the local quasi-regularity of $\mathcal{T}_h$ implies that the maximum number of occurrences of a face in all the sets $E(K)$ is bounded by a fixed constant independent of h_K. Then, by summation on K, we get the upper bound

$$\begin{aligned}\|h^{\frac{1}{2}} \big(\boldsymbol{\beta}_h \cdot \nabla \mathbf{v}_h - \pi_{h,k}^*(\boldsymbol{\beta}_h \cdot \nabla \mathbf{v}_h)\big)\|_{0,\Omega}^2 &\le C \sum_{K \in \mathcal{T}_h} h_K^2 \sum_{f \in E(K)} \int_f |\boldsymbol{\beta}_h \cdot [\![\nabla \mathbf{v}_h]\!]_e|^2 \, \mathrm{d}s, \\ &\le C \sum_{K \in \mathcal{T}_h} \int_{\partial K} h_K^2 |\boldsymbol{\beta}_h \cdot [\![\nabla \mathbf{v}_h]\!]|^2 \, \mathrm{d}s. \end{aligned}$$

The lower bound follows by considering the L^2-norm of the discontinuous function δ over the reference patch $\hat{G}$ consisting of the reference element $\hat{K}$ and its nearest neighbors. Clearly if $\|\delta\|_{\hat{G}} = 0$, then $\boldsymbol{\beta}_h \cdot \nabla \mathbf{v}_h = \pi^*_{h,k} \boldsymbol{\beta}_h \cdot \nabla \mathbf{v}_h$ in $\hat{G}$. This means that $\boldsymbol{\beta}_h \cdot \nabla \mathbf{v}_h$ is continuous in $\hat{G}$ and hence $\sum_{f \in E(K)} \int_f h_K [\![\boldsymbol{\beta}_h \cdot \nabla \mathbf{v}_h]\!]^2 \, \mathrm{d}s = 0$. Hence by norm equivalence on discrete spaces we have

$$\sum_{f \in E(K)} \int_f [\![\boldsymbol{\beta}_h \cdot \nabla \mathbf{v}_h]\!]^2 \, \mathrm{d}s \leq \|\delta_G\|^2_{0,G}.$$

The claim then follows in the same fashion as the first part of the proof by scaling and extension to all of $\mathcal{T}_h$. ∎

Using the same technique we immediately have the following corollary where for simplicity the lower bounds are omitted.

COROLLARY 3.2. *Under the same assumptions as Lemma* 3.1 *we have, with* $\alpha > 0$ *and* ϕ *some function that is constant per element,*

$$\begin{aligned} \|\phi^{\frac{1}{2}} \big(\nabla \cdot \mathbf{v}_h - \pi^*_{h,k}(\nabla \cdot \mathbf{v}_h)\big)\|^2_{0,\Omega} &\leq \gamma \sum_{K \in \mathcal{T}_h} \int_{\partial K} \phi h_K [\![\nabla \cdot \mathbf{v}_h]\!]^2 \, \mathrm{d}s, \\ \|\phi^{\frac{1}{2}} \big(\nabla q_h - \pi^*_{h,k}(\nabla q_h)\big)\|^2_{0,\Omega} &\leq \gamma \sum_{K \in \mathcal{T}_h} \int_{\partial K} \phi h_K |[\![\nabla q_h]\!]|^2 \, \mathrm{d}s \end{aligned} \tag{3.2}$$

for all $(\mathbf{v}_h, q_h) \in W^k_h$ *and with* $\gamma > 0$ *constants independent of* h.

We now introduce the following mesh-dependent norm for the velocity:

$$\begin{aligned} |\!|\!| \mathbf{v}_h |\!|\!|^2 \stackrel{\text{def}}{=} \|\sigma^{\frac{1}{2}} \mathbf{v}_h\|^2_{0,\Omega} + \|\nu^{\frac{1}{2}} \nabla \mathbf{v}_h\|^2_{0,\Omega} + j_{\mathbf{u}}(\mathbf{v}_h, \mathbf{v}_h) + \||\boldsymbol{\beta} \cdot \mathbf{n}|^{\frac{1}{2}} \mathbf{v}_h\|^2_{0,\partial\Omega} \\ + \|\gamma^{\frac{1}{2}} (\nu/\tilde{h})^{\frac{1}{2}} \mathbf{v}_h\|^2_{0,\partial\Omega} + \|\gamma^{\frac{1}{2}} \max\{|\boldsymbol{\beta}|, \nu/\tilde{h}\}^{\frac{1}{2}} \mathbf{v}_h \cdot \mathbf{n}\|^2_{0,\partial\Omega} \end{aligned} \tag{3.3}$$

for all $\mathbf{v}_h \in [V^k_h]^d$.

The following lemma gives the coercivity of our discrete operator with respect to this mesh-dependent norm.

LEMMA 3.3 (coercivity). *There exists a constant* $C > 0$, *depending only on* Ω *and* γ, *such that*

$$a_h(\mathbf{v}_h, \mathbf{v}_h) + j_{\mathbf{u}}(\mathbf{v}_h, \mathbf{v}_h) \geq C |\!|\!| \mathbf{v}_h |\!|\!|^2$$

for all $\mathbf{v}_h \in [V^k_h]^d$.

Proof. From (2.10) we get

$$\begin{aligned} a_h(\mathbf{v}_h, \mathbf{v}_h) + j_{\mathbf{u}}(\mathbf{v}_h, \mathbf{v}_h) \geq \|\sigma^{\frac{1}{2}} \mathbf{v}_h\|^2_{0,\Omega} + 2\|\nu^{\frac{1}{2}} \boldsymbol{\epsilon}(\mathbf{v}_h)\|^2_{0,\Omega} + j_{\mathbf{u}}(\mathbf{v}_h, \mathbf{v}_h) \\ + \frac{1}{2} \||\boldsymbol{\beta} \cdot \mathbf{n}|^{\frac{1}{2}} \mathbf{v}_h\|^2_{0,\partial\Omega} + \|\gamma^{\frac{1}{2}} (\nu/\tilde{h})^{\frac{1}{2}} \mathbf{v}_h\|^2_{0,\partial\Omega} \\ + \|\gamma^{\frac{1}{2}} \max\{|\boldsymbol{\beta}|, \nu/\tilde{h}\}^{\frac{1}{2}} \mathbf{v}_h \cdot \mathbf{n}\|^2_{0,\partial\Omega} \\ - \langle 4\nu \boldsymbol{\epsilon}(\mathbf{v}_h) \mathbf{n}, \mathbf{v}_h \rangle_{\partial\Omega}, \end{aligned} \tag{3.4}$$

where we used the fact that, after integration by parts and since $\nabla \cdot \boldsymbol{\beta} = 0$,

$$(\boldsymbol{\beta} \cdot \nabla \mathbf{v}_h, \mathbf{v}_h) = \frac{1}{2} \langle \boldsymbol{\beta} \cdot \mathbf{n} \mathbf{v}_h, \mathbf{v}_h \rangle_{\partial\Omega}.$$

The last term in (3.4) can be bounded using the Cauchy–Schwarz inequality followed by a trace inequality, to obtain

$$|\langle 4\nu\boldsymbol{\epsilon}(\mathbf{v}_h)\mathbf{n},\mathbf{v}_h\rangle_{\partial\Omega}| \leq 8\frac{C_{\mathrm{T}}}{\gamma}\|\nu^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{v}_h)\|^2_{0,\Omega} + \frac{1}{2}\|\gamma^{\frac{1}{2}}(\nu/\tilde{h})^{\frac{1}{2}}\mathbf{v}_h\|^2_{0,\partial\Omega}.$$

In what follows we will assume that

$$\gamma > 4C_{\mathrm{T}} > 0, \tag{3.5}$$

and therefore

$$\lambda(\gamma) \stackrel{\text{def}}{=} 2 - 8\frac{C_{\mathrm{T}}}{\gamma} > 0.$$

From (3.4), we then get

$$\begin{aligned} a_h(\mathbf{v}_h,\mathbf{v}_h) + j_{\mathbf{u}}(\mathbf{v}_h,\mathbf{v}_h) \geq{}& \|\sigma^{\frac{1}{2}}\mathbf{v}_h\|^2_{0,\Omega} + \lambda(\gamma)\|\nu^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{v}_h)\|^2_{0,\Omega} + j_{\mathbf{u}}(\mathbf{v}_h,\mathbf{v}_h) \\ &+ \frac{1}{2}\||\boldsymbol{\beta}\cdot\mathbf{n}|^{\frac{1}{2}}\mathbf{v}_h\|^2_{0,\partial\Omega} + \frac{1}{2}\|\gamma^{\frac{1}{2}}(\nu/\tilde{h})^{\frac{1}{2}}\mathbf{v}_h\|^2_{0,\partial\Omega} \\ &+ \|\gamma^{\frac{1}{2}}\max\{|\boldsymbol{\beta}|,\nu/\tilde{h}\}^{\frac{1}{2}}\mathbf{v}_h\cdot\mathbf{n}\|^2_{0,\partial\Omega}, \end{aligned}$$

and consequently

$$\begin{aligned} a_h(\mathbf{v}_h,\mathbf{v}_h) + j_{\mathbf{u}}(\mathbf{v}_h,\mathbf{v}_h) \geq{}& \|\sigma^{\frac{1}{2}}\mathbf{v}_h\|^2_{0,\Omega} + j_{\mathbf{u}}(\mathbf{v}_h,\mathbf{v}_h) \\ &+ \min_{\substack{K\in\mathcal{T}_h \\ K\cap\partial\Omega\neq\emptyset}} \left\{\lambda(\gamma), \frac{\gamma}{4h_K}\right\}\left(\|\nu^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{v}_h)\|^2_{0,\Omega} + \|\nu^{\frac{1}{2}}\mathbf{v}_h\|^2_{0,\partial\Omega}\right) \\ &+ \frac{1}{2}\||\boldsymbol{\beta}\cdot\mathbf{n}|^{\frac{1}{2}}\mathbf{v}_h\|^2_{0,\partial\Omega} + \frac{1}{4}\|\gamma^{\frac{1}{2}}(\nu/\tilde{h})^{\frac{1}{2}}\mathbf{v}_h\|^2_{0,\partial\Omega} \\ &+ \|\gamma^{\frac{1}{2}}\max\{|\boldsymbol{\beta}|,\nu/\tilde{h}\}^{\frac{1}{2}}\mathbf{v}_h\cdot\mathbf{n}\|^2_{0,\partial\Omega}. \end{aligned}$$

In particular, since $0 < h \leq 1$ and by choosing (accordingly with (3.5))

$$\gamma \stackrel{\text{def}}{=} \varepsilon + 4C_{\mathrm{T}},$$

with $\varepsilon > 0$ sufficiently small, one obtains

$$\lambda(\gamma) < \frac{\gamma}{4h_K} \quad \forall K\in\mathcal{T}_h, \quad K\cap\partial\Omega\neq\emptyset.$$

We then conclude the proof using Korn's inequality (see [6]). ∎

In what follows, we shall make use of the following discrete pressure and velocity subspaces:

$$\begin{aligned} C^1_{h,k} &\stackrel{\text{def}}{=} \left\{q_h\in Q^k_h \,:\, j_p(q_h,q_h) = 0\right\}, \\ V^{\mathrm{div}}_{h,k} &\stackrel{\text{def}}{=} \left\{\mathbf{v}_h\in[V^k_h]^d \,:\, b_h(q_h,\mathbf{v}_h) = 0 \quad \forall q_h\in C^1_{h,k}\right\}. \end{aligned}$$

In addition, $Q^k_h\backslash C^1_{h,k}$ will stand for the supplementary of $C^1_{h,k}$ in Q^k_h, i.e.,

$$Q^k_h = (Q^k_h\backslash C^1_{h,k}) \oplus C^1_{h,k}.$$

The following lemma ensures, in particular, that $V_{h,k}^{\mathrm{div}}$ is not trivial.

LEMMA 3.4. *There exists a constant $\boldsymbol{\beta} > 0$, independent of h, such that*

$$\inf_{q_h \in C_{h,k}^1} \sup_{\mathbf{v}_h \in [V_h^k]^d} \frac{|b_h(q_h, \mathbf{v}_h)|}{\|q_h\|_{0,\Omega} \|\mathbf{v}_h\|_{1,\Omega}} \geq \beta.$$

Proof. Let $q_h \in C_{h,k}^1$. From [27, Corollary 2.4], there exists $\mathbf{v}_q \in [H_0^1(\Omega)]^d$ such that

$$\nabla \cdot \mathbf{v}_q = q_h, \quad \|\mathbf{v}_q\|_{1,\Omega} \leq C \|q_h\|_{0,\Omega}. \tag{3.6}$$

Thus, using integration by parts and (2.12), we have

$$\begin{aligned} \|q_h\|_{0,\Omega}^2 &= (q_h, \nabla \cdot \mathbf{v}_q) \\ &= (q_h, \nabla \cdot \mathbf{v}_q - \nabla \cdot \pi_{h,k} \mathbf{v}_q) + (q_h, \nabla \cdot \pi_{h,k} \mathbf{v}_q) \\ &= (\nabla q_h, \mathbf{v}_q - \pi_{h,k} \mathbf{v}_q) - \langle q_h, (\pi_{h,k} \mathbf{v}_q) \cdot \mathbf{n} \rangle_{\partial\Omega} \\ &\quad + (q_h, \nabla \cdot \pi_{h,k} \mathbf{v}_q) \\ &= (\nabla q_h, \mathbf{v}_q - \pi_{h,k} \mathbf{v}_q) - b_h(q_h, \pi_{h,k} \mathbf{v}_q). \end{aligned} \tag{3.7}$$

Since $q_h \in C_{h,k}^1$, it follows that $\nabla q_h \in [V_h^k]^d$. Thus, using the orthogonality of the L^2-projection, we have

$$(\nabla q_h, \mathbf{v}_q - \pi_{h,k} \mathbf{v}_q) = 0.$$

Thus, from (3.7), it follows that

$$|b_h(q_h, \pi_{h,k} \mathbf{v}_q)| = \|q_h\|_{0,\Omega}^2.$$

In addition, using H^1-stability of the L^2-projection (see [5]) and (3.6), we have

$$\begin{aligned} \|\pi_{h,k} \mathbf{v}_q\|_{1,\Omega} &\leq C \|\mathbf{v}_q\|_{1,\Omega} \\ &\leq C \|q_h\|_{0,\Omega}, \end{aligned}$$

which completes the proof. ∎

We now state the well-posedness of the discrete problem.

THEOREM 3.5. *The discrete problem* (2.10) *has a unique solution.*

Proof. Problem (2.10) can be written, in operator form, as

$$\begin{aligned} A\mathbf{u}_h + B^T p_h &= M\mathbf{f} \quad \text{in} \quad \left([V_h^k]^d\right)', \\ B\mathbf{u}_h &= Jp_h \quad \text{in} \quad [Q_h^k]', \end{aligned} \tag{3.8}$$

with $A \in \mathcal{L}([V_h^k]^d, ([V_h^k]^d)')$, $M \in \mathcal{L}([L^2(\Omega)]^d, ([V_h^k]^d)')$, $B \in \mathcal{L}\left([V_h^k]^d, (Q_h^k)'\right)$, and $J \in \mathcal{L}\left(Q_h^k, (Q_h^k)'\right)$ defined by

$$\begin{aligned} \langle A\mathbf{u}_h, \mathbf{v}_h \rangle &\stackrel{\text{def}}{=} a_h(\mathbf{u}_h, \mathbf{v}_h) + j_{\mathbf{u}}(\mathbf{u}_h, \mathbf{v}_h), \\ \langle M\mathbf{f}, \mathbf{v}_h \rangle &\stackrel{\text{def}}{=} (\mathbf{f}, \mathbf{v}_h), \\ \langle B\mathbf{v}_h, q_h \rangle &\stackrel{\text{def}}{=} b_h(q_h, \mathbf{v}_h), \\ \langle Jp_h, q_h \rangle &\stackrel{\text{def}}{=} j(p_h, q_h). \end{aligned}$$

We also introduce the operator $B^1 \in \mathcal{L}([V_h^k]^d, (C_{h,k}^1)')$ defined by

$$\langle B^1 \mathbf{v}_h, q_h \rangle \stackrel{\text{def}}{=} b_h(q_n, \mathbf{v}_h) \quad \forall (\mathbf{v}_h, q_h) \in [V_h^k]^d \times C_{h,k}^1;$$

in other words,

$$B^1 \mathbf{v}_h \stackrel{\text{def}}{=} (B\mathbf{v}_h)_{|C_{h,k}^1} \quad \forall \mathbf{v}_h \in [V_h^k]^d.$$

From Lemma 3.4, it follows that B^1 is surjective and $(B^1)^{\mathrm{T}}$ is injective (see [27, p. 58]). We then deduce that $V_{h,k}^{\mathrm{div}} \stackrel{\text{def}}{=} \mathrm{Ker}(B^1) \neq \{0\}$.

Let us consider the following reduced formulation (derived from (2.10) with $(\mathbf{v}_h, q_h) \in V_{h,k}^{\mathrm{div}} \times (Q_h^k \backslash C_{h,k}^1)$): find $(\mathbf{u}_h, \tilde{p}_h) \in V_{h,k}^{\mathrm{div}} \times (Q_h^k \backslash C_{h,k}^1)$ such that

$$\begin{aligned} A\mathbf{u}_h + B^T \tilde{p}_h &= M\mathbf{f} \quad \text{in} \quad \left(V_{h,k}^{\mathrm{div}}\right)', \\ B\mathbf{u}_h &= J\tilde{p}_h \quad \text{in} \quad \left(Q_h^k \backslash C_{h,k}^1\right)'. \end{aligned} \tag{3.9}$$

Since, by construction, $C_{h,k}^1 = \mathrm{Ker}(J)$, we conclude that J is invertible in $Q_h^k \backslash C_{h,k}^1$. Hence, from (3.9), we have

$$\tilde{p}_h = J^{-1}_{|Q_h^k \backslash C_{h,k}^1} B\mathbf{u}_h. \tag{3.10}$$

By plugging this expression into the first equation of (3.9), we obtain that $\mathbf{u}_h \in V_{h,k}^{\mathrm{div}}$ solves

$$\left(A + B^T J^{-1}_{|Q_h^k \backslash C_{h,k}^1} B\right) \mathbf{u}_h = M\mathbf{f} \quad \text{in} \quad \left(V_{h,k}^{\mathrm{div}}\right)'.$$

Existence and uniqueness of $\mathbf{u}_h$ follow by the positivity of A (Lemma 3.3) and the nonnegativity of $B^T J^{-1}_{|Q_h^k \backslash C_{h,k}^1} B$. We may then recover $\tilde{p}_h$ uniquely from (3.10). Therefore, the reduced problem (3.9) has a unique solution. On the other hand, from the first equation of (3.9), it follows that

$$A\mathbf{u}_h + B^T \tilde{p}_h - M\mathbf{f} \in \left(\mathrm{Ker}(B^1)\right)^0,$$

with $\left(\mathrm{Ker}(B^1)\right)^0$ standing for the *polar set* of $\mathrm{Ker}(B^1)$. From Lemma 3.4, it follows that B^1 is an isomorphism from $C_{h,k}^1$ onto $\left(\mathrm{Ker}(B^1)\right)^0$ (see [27, p. 58]). Thus, there exists a unique $p^1 \in C_{h,k}^1$ such that

$$A\mathbf{u}_h + B^T \tilde{p}_h - M\mathbf{f} = (B^1)^{\mathrm{T}} p^1 \quad \text{in} \quad \left([V_h^k]^d\right)'. \tag{3.11}$$

Therefore, from (3.11) and (3.9), and by noticing that $(B^1)^{\mathrm{T}} p^1 = B^{\mathrm{T}} p^1$ and $Jp^1 = 0$, it follows that problem (2.10) has a unique solution, given by $(\mathbf{u}_h, p_h \stackrel{\text{def}}{=} \tilde{p}_h - p^1)$. ∎

4. Convergence of the method. The parameter for the pressure stabilization scales as $h_K^2/\|\boldsymbol{\beta}\|_{0,\infty,K}$ when the local Reynolds number Re_K is big, and as h_K^3/ν when Re_K is small. The stabilizing terms acting on the velocity scale as $\|\boldsymbol{\beta}\|_{0,\infty,K} h_K^2$ at a high local Reynolds number and as $\mathrm{Re}_K \|\boldsymbol{\beta}\|_{0,\infty,K} h_K^2$ for a low Reynolds number. The factor $\mathrm{Re}_K \|\boldsymbol{\beta}\|_{0,\infty,K} h_K^2$ in the velocity stabilization may be omitted in the low Reynolds regime without perturbing the convergence. We will now show that this scaling gives optimal a priori error estimates in the high (local) Reynolds number

regime when the solution is smooth, $(\mathbf{u}, p) \in [H^{k+1}(\Omega)]^{d+1}$, and in the low (local) Reynolds number regime under standard regularity assumptions. We then prove, using the Aubin–Nitsche duality technique (see, e.g., [21]), that the velocities have optimal convergence order also in the L^2-norm, when the local Reynolds number is low, without any modification of the stabilization.

First, we summarize some stability properties of the L^2-projection with weighted norms and show an approximability result for the triple norm (3.3).

REMARK 4.1. *In the remainder of this section, $C > 0$ stands for a generic constant independent of h and the physical parameters.*

To prove approximability for the L^2-projection on locally quasi-uniform meshes we need some additional stability for the L^2-projection from [3] that we state here without proof.

LEMMA 4.2. *For $\rho, \eta > 0$ sufficiently small and for all $\phi \in V_h^1$ satisfying*

$$\phi > 0, \quad |\nabla \phi(\mathbf{x})| \leq \eta h_K^{-1} \phi(\mathbf{x}) \quad \forall \mathbf{x} \in K, \quad \forall K \in \mathcal{T}_h,$$

there holds

$$\|\phi \pi_{h,k} u\|_{0,\Omega} \leq C \|\phi u\|_{0,\Omega} \quad \forall u \in L^2(\Omega),$$
$$\|\phi \nabla \pi_{h,k} u\|_{0,\Omega} \leq C \|\phi \nabla u\|_{0,\Omega} \quad \forall u \in H^1(\Omega).$$

A direct consequence of this result is stated in the following corollary.

COROLLARY 4.3. *Under the assumptions of the previous lemma, we have*

$$\left(\sum_{|\boldsymbol{\alpha}| \leq l} \|\phi \partial^{\boldsymbol{\alpha}} (u - \pi_{h,k} u)\|_{0,\Omega}^2 \right)^{\frac{1}{2}} \leq C \left(\sum_{K \in \mathcal{T}_h} \|\phi\|_{0,\infty,K}^2 h^{2(r_u - l)} \|u\|_{r_u,\Omega}^2 \right)^{\frac{1}{2}}$$

for all $u \in H^r(\Omega)$, with $r \geq 1$, $r_u \stackrel{\text{def}}{=} \min\{r, k+1\}$, $0 \leq l \leq r_u$, $\boldsymbol{\alpha} \in \mathbb{N}^d$, and ∂^α the standard multi-index notation for high order derivatives.

In order to obtain localized estimates we now show that the weights appearing in our stabilization allow for L^2-stability.

LEMMA 4.4. *Let $\phi_i \in H^2(\mathcal{T}_h)$, $i = 1, \ldots, 5$, be piecewise constant functions defined by*

$$\phi_{1|K} \stackrel{\text{def}}{=} \nu^{-\frac{1}{2}} \min\left\{ \mathrm{Re}_K^{-\frac{1}{2}}, 1 \right\}, \quad \phi_{2|K} \stackrel{\text{def}}{=} \|\boldsymbol{\beta}\|_{0,\infty,K}^{\frac{1}{2}} h_K^{-\frac{1}{2}},$$
$$\phi_{3|K} \stackrel{\text{def}}{=} h_K^{-\frac{1}{2}} \|\boldsymbol{\beta}\|_{0,\infty,K}^{\frac{1}{2}} \xi(\mathrm{Re}_K)^{-\frac{1}{2}}, \quad \phi_{4|K} \stackrel{\text{def}}{=} \phi_{3|K}^{-1}, \quad \phi_{5|K} \stackrel{\text{def}}{=} h_K^{-r},$$

with $r \geq 1$, for all $K \in \mathcal{T}_h$, and let $\phi_i^* \stackrel{\text{def}}{=} \pi_{h,1}^* \phi_i$. Then, there holds

$$\left.\begin{aligned} \phi_i (\rho_{\boldsymbol{\beta}} \rho)^{-\frac{1}{2}} \leq \phi_i^* \leq (\rho_{\boldsymbol{\beta}} \rho)^{\frac{1}{2}} \phi_i \\ |\nabla \phi_i^*| \leq c_0 (\rho_{\boldsymbol{\beta}} \rho - 1) h_K^{-1} \phi_i^* \end{aligned}\right\} \quad \text{for} \quad i = 1, 2,$$

$$\left.\begin{aligned} \phi_i \rho_{\boldsymbol{\beta}}^{-\frac{1}{2}} \rho^{-1} \leq \phi_i^* \leq \rho_{\boldsymbol{\beta}}^{\frac{1}{2}} \rho \phi_i \\ |\nabla \phi_i^*| \leq c_0 (\rho_{\boldsymbol{\beta}} \rho^2 - 1) h_K^{-1} \phi_i^* \end{aligned}\right\} \quad \text{for} \quad i = 3, 4,$$

$$\left.\begin{aligned} \phi_5 \rho^{-r} \leq \phi_5^* \leq \rho^r \phi_5, \\ |\nabla \phi_5^*| \leq c_0 (\rho^{2r} - 1) h_K^{-1} \phi_5^* \end{aligned}\right.$$

in K, for all $K \in \mathcal{T}_h$, with $c_0 > 0$ the constant in (2.4).

Proof. We give the proof only for ϕ_1; the argument for the rest is similar. First, note that for all $K \in \mathcal{T}_h$,

$$\begin{aligned}\max_{x\in K}\phi_1^* &\le \max_{K'\in\mathcal{N}(K)} \nu^{-\frac{1}{2}} \min\{\mathrm{Re}_{K'}^{-\frac{1}{2}}, 1\} \\ &= \max_{K'\in\mathcal{N}(K)} \min\{\|\boldsymbol{\beta}\|_{0,\infty,K'}^{-\frac{1}{2}} h_{K'}^{-\frac{1}{2}}, \nu^{-\frac{1}{2}}\}.\end{aligned} \tag{4.1}$$

We now distinguish two cases. On one hand, if $\mathrm{Re}_K \le 1$, we have $\phi_{1|K} = \nu^{-\frac{1}{2}}$. Thus, from (4.1) and since $\rho_{\boldsymbol{\beta}}\rho > 1$, it follows that

$$\begin{aligned}\max_{x\in K}\phi_1^* &\le \nu^{-\frac{1}{2}} \\ &\le (\rho\rho_\beta)^{\frac{1}{2}}\phi_{1|K}.\end{aligned}$$

On the other hand, if $\mathrm{Re}_K > 1$, we get $\phi_{1|K} = \|\boldsymbol{\beta}\|_{0,\infty,K}^{-\frac{1}{2}} h_K^{-\frac{1}{2}}$. Therefore, from (4.1) and the assumptions on the mesh (2.5) and (2.6), we have

$$\begin{aligned}\max_{x\in K}\phi_1^* &\le \max_{K'\in\mathcal{N}(K)} \{\|\boldsymbol{\beta}\|_{0,\infty,K'}^{-\frac{1}{2}} h_{K'}^{-\frac{1}{2}}\} \\ &\le (\rho\rho_\beta)^{\frac{1}{2}} \|\boldsymbol{\beta}\|_{0,\infty,K}^{-\frac{1}{2}} h_K^{-\frac{1}{2}} \\ &= (\rho\rho_\beta)^{\frac{1}{2}}\phi_{1|K}.\end{aligned}$$

The lower bound follows in a similar fashion.

Finally, for the derivative, using the bounds on ϕ_1^* and the regularity of the mesh (2.4), and since $\rho_{\boldsymbol{\beta}}\rho > 1$, we obtain

$$\begin{aligned}|\nabla\phi_{1|K}^*| &\le \frac{\max_{x\in K}\phi_1^* - \min_{x\in K}\phi_1^*}{\rho_K} \\ &\le \frac{(\rho_{\boldsymbol{\beta}}\rho)^{\frac{1}{2}} - (\rho_{\boldsymbol{\beta}}\rho)^{-\frac{1}{2}}}{\rho_K}\phi_{1|K} \\ &\le c_0(\rho_{\boldsymbol{\beta}}\rho - 1)h_K^{-1}\phi_1^*,\end{aligned}$$

which completes the proof. ∎

REMARK 4.5. *It follows from Lemma* 4.4 *that for the weight functions* ϕ_i^*, $1 \le i \le 5$, *the stability estimate of Lemma* 4.2 *holds, provided* $\rho_{\boldsymbol{\beta}}$ *and* ρ *are sufficiently close to* 1. *From now on we assume that this is the case.*

The following lemma states the approximation properties of the L^2-projection in the triple norm $|\!|\!| \cdot |\!|\!|$.

LEMMA 4.6 (velocity approximability). *Assume that* $\rho_{\boldsymbol{\beta}}$ *and* ρ *are sufficiently close to* 1. *Then, there holds*

$$|\!|\!|\mathbf{u} - \pi_{h,k}\mathbf{u}|\!|\!|^2 \le C \sum_{K\in\mathcal{T}_h} \left(\sigma h_K^{2r_{\mathbf{u}}} + \max\{\nu, \|\boldsymbol{\beta}\|_{0,\infty,K} h_K\}\, h_K^{2(r_{\mathbf{u}}-1)}\right) \|\mathbf{u}\|_{r_{\mathbf{u}},K}^2$$

for all $\mathbf{u} \in [H^r(\Omega)]^d$, *with* $r \ge 2$ *and* $r_{\mathbf{u}} = \min\{k+1, r\}$.

Proof. First note that

$$|\!|\!|\mathbf{u} - \pi_{h,k}\mathbf{u}|\!|\!|^2 \le |\!|\!|i_{h,k}\mathbf{u} - \pi_{h,k}\mathbf{u}|\!|\!|^2 + |\!|\!|i_{h,k}\mathbf{u} - \mathbf{u}|\!|\!|^2.$$

We give the proof for the first term only. The argument for the second term is similar. By the stability estimate for the L^2-projection Lemma 4.2 we have

$$\begin{aligned}\|\sigma^{\frac{1}{2}}(i_{h,k}\mathbf{u}-\pi_{h,k}\mathbf{u})\|_{0,\Omega}^2 &\le C\|\sigma^{\frac{1}{2}}(\mathbf{u}-i_{h,k}\mathbf{u})\|_{0,\Omega}^2\\ &\le C\sum_{K\in\mathcal{T}_h}\sigma h_K^{2r_{\mathbf{u}}}\|\mathbf{u}\|_{r_{\mathbf{u}},K}^2.\end{aligned}$$

Using now the H^1-stability of the L^2-projection on locally quasi-uniform meshes (see [5]) we get

$$\begin{aligned}\|\nu^{\frac{1}{2}}\nabla(i_{h,k}\mathbf{u}-\pi_{h,k}\mathbf{u})\|_{0,\Omega}^2 &\le C\|\nu^{\frac{1}{2}}\nabla(i_{h,k}\mathbf{u}-\mathbf{u})\|_{0,\Omega}^2\\ &\le C\sum_{K\in\mathcal{T}_h}\nu h^{2(r_{\mathbf{u}}-1)}\|\mathbf{u}\|_{r_{\mathbf{u}},\Omega}.\end{aligned}$$

We treat the boundary terms using the trace inequality (2.8) in combination with Lemma 4.2 and approximation, which yields

$$\begin{aligned}(4.2)\quad &\|\max\{|\boldsymbol{\beta}|,\nu/\tilde{h}\}^{\frac{1}{2}}(i_{h,k}\mathbf{u}-\pi_{h,k}\mathbf{u})\|_{0,\partial\Omega}^2\\ &\le C\sum_{\substack{K\in\mathcal{T}_h\\ K\cap\partial\Omega\neq\emptyset}}\|\max\{\|\boldsymbol{\beta}\|_{0,\infty,K},\nu h_K^{-1}\}^{\frac{1}{2}}(i_{h,k}\mathbf{u}-\pi_{h,k}\mathbf{u})\|_{0,K\cap\partial\Omega}^2\\ &\le C\sum_{K\in\mathcal{T}_h}\|h_K^{-\frac{1}{2}}\max\{\|\boldsymbol{\beta}\|_{0,\infty,K},\nu h_K^{-1}\}^{\frac{1}{2}}(i_{h,k}\mathbf{u}-\pi_{h,k}\mathbf{u})\|_{0,K}^2\\ &\le C\sum_{K\in\mathcal{T}_h}\|\phi_3^*(i_{h,k}\mathbf{u}-\pi_{h,k}\mathbf{u})\|_{0,K}^2\\ &= C\sum_{K\in\mathcal{T}_h}\|\phi_3^*\pi_{h,k}(i_{h,k}\mathbf{u}-\mathbf{u})\|_{0,K}^2\\ &\le C\sum_K\max\{\|\boldsymbol{\beta}\|_{0,\infty,K}h_K,\nu\}h_K^{2(r_{\mathbf{u}}-1)}\|\mathbf{u}\|_{r_{\mathbf{u}},K}^2.\end{aligned}$$

The interior penalty terms are treated in the same fashion as the boundary terms. We have

$$\begin{aligned}(4.3)\quad j_{\mathbf{u}}(\mathbf{u}-\pi_{h,k}\mathbf{u},\mathbf{u}-\pi_{h,k}\mathbf{u}) &\le j_{\mathbf{u}}(i_{h,k}\mathbf{u}-\pi_{h,k}\mathbf{u},i_{h,k}\mathbf{u}-\pi_{h,k}\mathbf{u})\\ &\quad + j_{\mathbf{u}}(\mathbf{u}-i_{h,k}\mathbf{u},\mathbf{u}-i_{h,k}\mathbf{u}).\end{aligned}$$

The first term in this inequality can be estimated using that $\xi(\mathrm{Re}_K)\le 1$, the trace inequality (2.8), an inverse inequality, and the H^1-stability of the L^2-projection (see [5]), which yields

(4.4)

$$\begin{aligned}j_{\mathbf{u}}(i_{h,k}\mathbf{u}-\pi_{h,k}\mathbf{u},i_{h,k}\mathbf{u}-\pi_{h,k}\mathbf{u}) &\le C\sum_{K\in\mathcal{T}_h}\|\boldsymbol{\beta}\|_{0,\infty,K}\xi(\mathrm{Re}_K)h_K^2\|\nabla(i_{h,k}\mathbf{u}-\pi_{h,k}\mathbf{u})\|_{0,\partial K}^2\\ &\le C\sum_{K\in\mathcal{T}_h}\|\boldsymbol{\beta}\|_{0,\infty,K}h_K^{-1}\|i_{h,k}\mathbf{u}-\pi_{h,k}\mathbf{u}\|_{0,K}^2\\ &\le C\|\phi_2^*(i_{h,k}\mathbf{u}-\pi_{h,k}\mathbf{u})\|_{0,\Omega}^2\\ &\le C\sum_K\|\boldsymbol{\beta}\|_{0,\infty,K}h_K^{2r_{\mathbf{u}}-1}\|\mathbf{u}\|_{r_{\mathbf{u}},K}^2,\end{aligned}$$

and so the proof is finished. ∎

For the pressure, we have the following result.

LEMMA 4.7 (pressure approximability). *Under the assumptions of Lemma* 4.6*, there holds*

$$\|\tilde{h}^{\frac{1}{2}}\phi_1^*(p-\pi_{h,k}p)\|_{0,\partial\Omega}^2+\|\phi_1^*(p-\pi_{h,k}p)\|_{0,\Omega}^2+j(\pi_{h,k}p,\pi_{h,k}p)$$
$$\leq C\sum_{K\in\mathcal{T}_h}\min\{\|\boldsymbol{\beta}\|_{0,\infty,K}^{-1},h_K/\nu\}h_K^{2s_p-1}\|p\|_{s_p,K}^2$$

for all $p\in H^s(\Omega)$ *with* $s\geq 1$ *and* $s_p\overset{\text{def}}{=}\min\{k+1,s\}$.

Proof. As p may be only $H^1(\Omega)$, we must replace the nodal interpolant by the Clément interpolant in the analysis. The proof for the first term is similar to (4.2), by replacing $i_{h,k}$ by $\mathcal{C}_{h,k}$. The estimate for the second term follows from Corollary 4.3. Finally, for the interior penalty term, since $[\![\mathcal{C}_{h,k}\nabla p]\!]=0$ and using a trace inequality followed by an inverse inequality, we have

$$\begin{aligned}
j(\pi_{h,k}p,\pi_{h,k}p)&=\sum_{K\in\mathcal{T}_h}\xi(\mathrm{Re_K})\frac{h_K^2}{\|\boldsymbol{\beta}\|_{0,\infty,K}}|[\![\nabla\pi_{h,k}p-\mathcal{C}_{h,k}\nabla p]\!]|^2\\
&\leq C\sum_{K\in\mathcal{T}_h}\xi(\mathrm{Re_K})\frac{h_K}{\|\boldsymbol{\beta}\|_{0,\infty,K}}\|\nabla\pi_{h,k}p-\mathcal{C}_{h,k}\nabla p\|_{0,K}^2\\
&\leq C(\|\phi_4^*\nabla\pi_{h,k}(p-\mathcal{C}_{h,k}p)\|_{0,K}^2+\|\phi_4^*\nabla(p-\mathcal{C}_{h,k}p)\|_{0,K}^2\\
&\quad+\|\phi_4^*(\nabla p-\mathcal{C}_{h,k}\nabla p)\|_{0,K}^2)\\
&\leq C\sum_{K\in\mathcal{T}_h}\min\{\|\boldsymbol{\beta}\|_{0,\infty,K}^{-1}h_K,h_K^2/\nu\}h_K^{2(s_p-1)}\|p\|_{s_p,K}^2,
\end{aligned}$$

where we concluded using the stability lemma, Lemma 4.2, with weight function ϕ_4^*, and the optimal approximation properties of the Clément interpolant (see [16, 21]). ∎

4.1. Energy norm error estimate. In this section we prove convergence in the triple norm. These results are optimal independently of the local Reynolds number when the exact solution is sufficiently smooth.

We start by proving a technical lemma.

LEMMA 4.8. *For all* $\mathbf{v}_h\in[V_h^k]^d$*, there holds*

$$\sum_{K\in\mathcal{T}_h}h_K^2\int_{\partial K}\|\boldsymbol{\beta}_h\cdot\mathbf{n}\|_{0,\infty,\partial K}|[\![\mathbf{n}\cdot\nabla\mathbf{v}_h]\!]|^2\,\mathrm{d}s\leq C\left(j_{\mathbf{u}}(\mathbf{v}_h,\mathbf{v}_h)+\|\nu^{\frac{1}{2}}\nabla\mathbf{v}_h\|_{0,\Omega}^2\right),$$

$$\sum_{K\in\mathcal{T}_h}\phi_{1|K}^{-1}h_K\int_{\partial K}[\![\nabla\cdot\mathbf{v}_h]\!]^2\,\mathrm{d}s\leq C\left(j_{\mathbf{u}}(\mathbf{v}_h,\mathbf{v}_h)+\|\nu^{\frac{1}{2}}\nabla\mathbf{v}_h\|_{0,\Omega}^2\right).$$

Proof. Let A_1 denote the set of elements $K\in\mathcal{T}_h$ such that $\xi(\mathrm{Re}_K)\geq 1$, and A_2 the set of elements such that $\xi(\mathrm{Re}_K)<1$. It then follows that $|\beta|_{\infty,0,K}h_K<\nu$ for $K\in A_2$, and we may write

$$\sum_{K\in\mathcal{T}_h} h_K^2 \int_{\partial K} \|\boldsymbol{\beta}_h\cdot\mathbf{n}\|_{0,\infty,\partial K} |[\![\mathbf{n}\cdot\nabla\mathbf{v}_h]\!]|^2\,\mathrm{d}s$$
$$\le \sum_{K\in A_1} h_K^2 \int_{\partial K} \|\boldsymbol{\beta}_h\cdot\mathbf{n}\|_{0,\infty,\partial K} |[\![\mathbf{n}\cdot\nabla\mathbf{v}_h]\!]|^2\,\mathrm{d}s + \sum_{K\in A_2} h_K\nu \int_{\partial K} |[\![\mathbf{n}\cdot\nabla\mathbf{v}_h]\!]|^2\,\mathrm{d}s$$
$$\le \sum_{K\in\mathcal{T}_h} \int_{\partial K} h_K^2 \xi(\mathrm{Re}_K) \|\boldsymbol{\beta}_h\cdot\mathbf{n}\|_{0,\infty,\partial K} |[\![\mathbf{n}\cdot\nabla\mathbf{v}_h]\!]|^2\,\mathrm{d}s + C\|\nu^{\frac{1}{2}}\nabla\mathbf{v}_h\|_{0,\Omega}^2,$$

where the last inequality follows by a trace inequality, an inverse inequality in the second term, and extending the sums over all $\mathcal{T}_h$.

The second inequality follows in a similar fashion, noting that

$$\sum_{K\in\mathcal{T}_h} \phi_{1|K}^{-1} h_K \int_{\partial K} [\![\nabla\cdot\mathbf{v}_h]\!]^2\,\mathrm{d}s \le C \sum_{K\in\mathcal{T}_h} h_K \max\{\|\boldsymbol{\beta}\|_{0,\infty,K} h_K, \nu\} \int_{\partial K} [\![\nabla\cdot\mathbf{v}_h]\!]^2\,\mathrm{d}s$$
$$\le \sum_{K\in A_1} h_K^2 \|\boldsymbol{\beta}\|_{0,\infty,K} \xi(\mathrm{Re}_K) \int_{\partial K} [\![\nabla\cdot\mathbf{v}_h]\!]^2\,\mathrm{d}s + \|\nu^{\frac{1}{2}}\nabla\mathbf{v}_h\|_{0,A_2}^2,$$

and so the proof is completed. ∎

The main result of this paragraph is stated in the following theorem.

THEOREM 4.9. *Assume* $(\mathbf{u},p)\in[H^r(\Omega)]^d\times H^s(\Omega)$, *with* $r\ge 2$ *and* $s\ge 1$, *is the solution of* (2.1) *and* $(\mathbf{u}_h,p_h)\in W_h^k$ *is the solution of* (2.10). *Then, under the assumptions of Lemma* 4.6, *there holds*

$$|\!|\!|\mathbf{u}-\mathbf{u}_h|\!|\!| \le C\left[\sum_{K\in\mathcal{K}} \left(\sigma h_K^{2r_{\mathbf{u}}} + \max\{\|\boldsymbol{\beta}\|_{0,\infty,K} h_K,\nu\} h_K^{2(r_{\mathbf{u}}-1)}\right) \|\mathbf{u}\|_{r_{\mathbf{u}},K}^2\right]^{\frac{1}{2}}$$
$$+C\max_{K\in\mathcal{T}_h}\left\{\sigma^{-\frac{1}{2}}|\boldsymbol{\beta}|_{1,\infty,K} h_K^{r_{\mathbf{u}}}\right\}\|\mathbf{u}\|_{r_{\mathbf{u}},\Omega} + C\left(\sum_{K\in\mathcal{T}_h} \min\{\|\boldsymbol{\beta}\|_{0,\infty,K}^{-1}, h_K/\nu\} h_K^{2s_p-1} \|p\|_{s_p,K}^2\right)^{\frac{1}{2}},$$

with $r_{\mathbf{u}} = \min\{k+1,r\}$ *and* $s_p = \min\{k+1,s\}$.

Proof. Let us decompose the error $\mathbf{u}-\mathbf{u}_h$ in two parts:

$$\mathbf{u}-\mathbf{u}_h = \underbrace{\mathbf{u}-\pi_{h,k}\mathbf{u}}_{\mathbf{e}^\pi} + \underbrace{\pi_{h,k}\mathbf{u}-\mathbf{u}_h}_{-\mathbf{e}_h} = \mathbf{e}^\pi - \mathbf{e}_h.$$

We also consider the discrete pressure error

$$y_h \overset{\mathrm{def}}{=} p_h - \pi_{h,k}p. \tag{4.5}$$

It follows then that

$$|\!|\!|\mathbf{u}-\mathbf{u}_h|\!|\!| \le |\!|\!|\mathbf{e}^\pi|\!|\!| + |\!|\!|\mathbf{e}_h|\!|\!|.$$

Lemma 4.6 gives an estimate for $|\!|\!|\mathbf{e}^\pi|\!|\!|$. Hence, it suffices to estimate $|\!|\!|\mathbf{e}_h|\!|\!|$.

Using coercivity and orthogonality, namely, Lemmas 3.3 and 2.1, we get

$$\begin{aligned} C|\!|\!|\mathbf{e}_h|\!|\!|^2 + j_p(y_h,y_h) &\le a_h(\mathbf{e}_h,\mathbf{e}_h) + j_{\mathbf{u}}(\mathbf{e}_h,\mathbf{e}_h) + j_p(y_h,y_h) \\ &= a_h(\mathbf{e}^\pi,\mathbf{e}_h) + b_h(y^\pi,\mathbf{e}_h) - b_h(y_h,\mathbf{e}^\pi) \\ &\quad + j_{\mathbf{u}}(\mathbf{e}^\pi,\mathbf{e}_h) - j_p(\pi_{h,k}p,y_h). \end{aligned} \tag{4.6}$$

By an application of the Cauchy–Schwarz inequality in the symmetric part of the discrete elliptic operator and integrating by parts in the convective term, we obtain

$$a_h(\mathbf{e}^\pi,\mathbf{e}_h) \le |\!|\!|\mathbf{e}^\pi|\!|\!|\,|\!|\!|\mathbf{e}_h|\!|\!| + |(\mathbf{e}^\pi,\boldsymbol{\beta}\cdot\nabla\mathbf{e}_h)| \\ - \langle 2\nu\boldsymbol{\epsilon}(\mathbf{e}^\pi)\mathbf{n},\mathbf{e}_h\rangle_{\partial\Omega} - \langle \mathbf{e}^\pi, 2\nu\boldsymbol{\epsilon}(\mathbf{e}_h)\mathbf{n}\rangle_{\partial\Omega},$$

where, for simplicity, the boundary term from the integration by parts has been included in the first term on the right-hand side. We note that in the same way we have, using the Cauchy–Schwarz inequality, a trace inequality and a local inverse inequality,

$$\langle 2\nu\boldsymbol{\epsilon}(\mathbf{e}_h)\mathbf{n},\mathbf{e}^\pi\rangle_{\partial\Omega} \le C|\!|\!|\mathbf{e}_h|\!|\!|\,|\!|\!|\mathbf{e}^\pi|\!|\!|. \tag{4.7}$$

For the second boundary term we use the Cauchy–Schwarz inequality followed by a trace inequality and an approximation argument, similar to (4.3)–(4.4), to obtain

$$\langle 2\nu\boldsymbol{\epsilon}(\mathbf{e}^\pi)\mathbf{n},\mathbf{e}_h\rangle_{\partial\Omega} \le C\left(\sum_{K\in\mathcal{T}_h}\nu h_K^{2(r_\mathbf{u}-1)}\|\mathbf{u}\|^2_{r_\mathbf{u},K}\right)^{\frac12}|\!|\!|\mathbf{e}_h|\!|\!|. \tag{4.8}$$

The convective term is controlled using a local inverse inequality, Lemma 4.4, Corollary 4.3, and the orthogonality of the L^2-projection, after having replaced the continuous velocity field $\boldsymbol{\beta}$ by its piecewise linear interpolant $\boldsymbol{\beta}_h$,

$$\begin{aligned}
|(\mathbf{e}^\pi,\boldsymbol{\beta}\cdot\nabla\mathbf{e}_h)| &\le |(\mathbf{e}^\pi,(\boldsymbol{\beta}-\boldsymbol{\beta}_h)\cdot\nabla\mathbf{e}_h)| + |(\mathbf{e}^\pi,\boldsymbol{\beta}_h\cdot\nabla\mathbf{e}_h)| \\
&\le C\sum_{K\in\mathcal{T}_h}|\boldsymbol{\beta}|_{1,\infty,K}\|\mathbf{e}^\pi\|_{0,K}h_K\|\nabla\mathbf{e}_h\|_{0,K} \\
&\quad + \left|\left(\mathbf{e}^\pi,\boldsymbol{\beta}_h\cdot\nabla\mathbf{e}_h - \pi^*_{h,k}(\boldsymbol{\beta}_h\cdot\nabla\mathbf{e}_h)\right)\right| \\
&\le C\sum_{K\in\mathcal{T}_h}\sigma^{-\frac12}|\boldsymbol{\beta}|_{1,\infty,K}h_K^{r_\mathbf{u}}\|\phi_5^*\mathbf{e}^\pi\|_{0,K}\|\sigma^{\frac12}\mathbf{e}_h\|_{0,K} \\
&\quad + \left|\left(\mathbf{e}^\pi,\boldsymbol{\beta}_h\cdot\nabla\mathbf{e}_h - \pi^*_{h,k}(\boldsymbol{\beta}_h\cdot\nabla\mathbf{e}_h)\right)\right| \\
&\le C\max_{K\in\mathcal{T}_h}\{\sigma^{-\frac12}|\boldsymbol{\beta}|_{1,\infty,K}h_K^{r_\mathbf{u}}\}\|\mathbf{u}\|_{r_\mathbf{u},\Omega}|\!|\!|\mathbf{e}_h|\!|\!| \\
&\quad + \|\phi_2\mathbf{e}^\pi\|_{0,\Omega}\left\|\phi_2^{-1}\left(\boldsymbol{\beta}_h\cdot\nabla\mathbf{e}_h - \pi^*_{h,k}(\boldsymbol{\beta}_h\cdot\nabla\mathbf{e}_h)\right)\right\|_{0,\Omega}.
\end{aligned}$$

Now we apply Lemma 3.1 to obtain

$$\begin{aligned}
&\|\phi_2\mathbf{e}^\pi\|_{0,\Omega}\left\|\phi_2^{-1}\left(\boldsymbol{\beta}_h\cdot\nabla\mathbf{e}_h - \pi^*_{h,k}(\boldsymbol{\beta}_h\cdot\nabla\mathbf{e}_h)\right)\right\|_{0,\Omega} \\
&\qquad \le C\|\phi_2^*\mathbf{e}^\pi\|_{0,\Omega}\left(\sum_{K\in\mathcal{T}_h}\int_{\partial K}h_K^2\|\boldsymbol{\beta}\cdot\mathbf{n}\|_{0,\infty,\partial K}|[\![\mathbf{n}\cdot\nabla\mathbf{u}_h]\!]|^2\,\mathrm{d}s\right)^{\frac12} \\
&\qquad\qquad \le C\left(\sum_{K\in\mathcal{T}_h}\|\boldsymbol{\beta}\|_{0,\infty,K}h_K^{2r_\mathbf{u}-1}\|\mathbf{u}\|^2_{r_\mathbf{u},K}\right)^{\frac12}|\!|\!|\mathbf{e}_h|\!|\!|,
\end{aligned}$$

where we used Corollary 4.3 and Lemma 4.8 in the last inequality.

Collecting terms we have

$$\begin{aligned}
a_h(\mathbf{e}^\pi,\mathbf{e}_h) &\le C|\!|\!|\mathbf{e}^\pi|\!|\!|\,|\!|\!|\mathbf{e}_h|\!|\!| + C\max_{K\in\mathcal{T}_h}\{\sigma^{-\frac12}|\boldsymbol{\beta}|_{1,\infty,K}h_K^{r_\mathbf{u}}\}|\!|\!|\mathbf{e}_h|\!|\!| \\
&\quad + C\left(\sum_{K\in\mathcal{T}_h}\max\{\|\boldsymbol{\beta}\|_{0,\infty,K}h_K,\nu\}h_K^{2(r_\mathbf{u}-1)}\|\mathbf{u}\|^2_{r_\mathbf{u},K}\right)^{\frac12}|\!|\!|\mathbf{e}_h|\!|\!|.
\end{aligned} \tag{4.9}$$

For the second term in (4.6), using the orthogonality of the L^2-projection, Lemmas 4.7 and 4.8, and replacing $\mathbf{u}$ with p in (4.2), we have

$$\begin{aligned} b_h(y^\pi, \mathbf{e}_h) &= -(y^\pi, \nabla\cdot\mathbf{e}_h - \pi^*_{h,k}(\nabla\cdot\mathbf{e}_h)) + \langle y^\pi, \mathbf{e}_h\cdot\mathbf{n}\rangle_{\partial\Omega} \\ &\le \|\phi_1^* y^\pi\|_{0,\Omega}\|\phi_1^{-1}(\nabla\cdot\mathbf{e}_h - \pi^*_{h,k}(\nabla\cdot\mathbf{e}_h))\|_{0,\Omega} + \|\phi_1^*\tilde{h}^{\frac12} y^\pi\|_{0,\partial\Omega}|\!|\!|\mathbf{e}_h|\!|\!| \\ &\le C\left(\sum_{K\in\mathcal{T}_h}\min\{\|\boldsymbol{\beta}\|^{-1}_{0,\infty,K}, h_K/\nu\}h_K^{2s_p-1}\|p\|^2_{s_p,K}\right)^{\frac12}|\!|\!|\mathbf{e}_h|\!|\!|. \end{aligned} \tag{4.10}$$

In a similar fashion, after integration by parts in the third term, one obtains

$$\begin{aligned} b_h(y_h, \mathbf{e}^\pi) &= -(y_h, \nabla\cdot\mathbf{e}^\pi) + \langle y_h, \mathbf{e}^\pi\cdot\mathbf{n}\rangle_{\partial\Omega} \\ &= (\nabla y_h, \mathbf{e}^\pi) \\ &= (\nabla y_h - \pi^*_{h,k}(\nabla y_h), \mathbf{e}^\pi) \\ &\le C\|\phi_3^{-1}\big(\nabla y_h - \pi^*_{h,k}(\nabla y_h)\big)\|_{0,\Omega}\|\phi_3^*\mathbf{e}^\pi\|_{0,\Omega} \\ &\le C j_p(y_h, y_h)^{\frac12}\left(\sum_{K\in\mathcal{T}_h}\max\{\|\boldsymbol{\beta}\|_{0,\infty,K}h_K, \nu\}h_K^{2(r_{\mathbf{u}}-1)}\|\mathbf{u}\|^2_{r_{\mathbf{u}},K}\right)^{\frac12}. \end{aligned} \tag{4.11}$$

Finally, using Lemma 4.7, for the interior penalty terms we have

$$\begin{aligned} j_{\mathbf{u}}(\mathbf{e}^\pi, \mathbf{e}_h) + j_p(\pi_{h,k}p, y_h) &\le C|\!|\!|\mathbf{e}^\pi|\!|\!||\!|\!|\mathbf{e}_h|\!|\!| + j_p(\pi_{h,k}p, \pi_{h,k}p)^{\frac12} j_p(y_h, y_h)^{\frac12} \\ &\le C|\!|\!|\mathbf{e}^\pi|\!|\!||\!|\!|\mathbf{e}_h|\!|\!| + C j_p(y_h, y_h)^{\frac12}\left(\sum_{K\in\mathcal{T}_h}\min\{\|\boldsymbol{\beta}\|^{-1}_{0,\infty,K}, h_K/\nu\}h_K^{2s_p-1}\|p\|^2_{s_p,K}\right)^{\frac12}. \end{aligned} \tag{4.12}$$

We conclude the proof by collecting the results of (4.9)–(4.12) in (4.6) and applying the approximation lemma, Lemma 4.6. ∎

The following corollary follows from (4.6) in combination with (4.5) and Lemma 4.7.

COROLLARY 4.10. *Under the assumptions of Theorem* 4.9*, there holds*

$$\begin{aligned} j_p(p_h, p_h) \le{}& C\max_{K\in\mathcal{T}_h}\left\{\sigma^{-\frac12}|\boldsymbol{\beta}|_{1,\infty,K}h_K^{r_{\mathbf{u}}}\right\}\|\mathbf{u}\|_{r_{\mathbf{u}},\Omega} \\ &+ C\left[\sum_{K\in\mathcal{K}}\left(\sigma h_K^{2r_{\mathbf{u}}} + \max\{\|\boldsymbol{\beta}\|_{0,\infty,K}h_K, \nu\}h^{2(r_{\mathbf{u}}-1)}\right)\|\mathbf{u}\|^2_{r_{\mathbf{u}},K}\right]^{\frac12} \\ &+ C\left(\sum_{K\in\mathcal{T}_h}\min\{\|\boldsymbol{\beta}\|^{-1}_{0,\infty,K}, h_K/\nu\}h_K^{2s_p-1}\|p\|^2_{s_p,K}\right)^{\frac12}. \end{aligned}$$

REMARK 4.11. *In a physical situation the velocity gradient on boundaries with no-slip conditions is known to scale as* $|\boldsymbol{\beta}|_{1,\infty,\partial\Omega} \sim \nu^{-\frac12}$*. If in the boundary layer* $h_K \sim \nu$*, that is, a low local Reynolds number on the boundary, then the estimate is dominated by the* $H^1(\Omega)$ *contribution from the boundary that converges at optimal rate since the layer is resolved. The condition* (2.7) *is satisfied with* $c_{\boldsymbol{\beta}} \sim \nu^{\frac12}$ *showing that the strongest constraint on the mesh is not that of* (2.7)*, but that of the* $\frac{h_K}{\nu}$ *contribution on the boundary. In laminar free-flow we can expect* $|\boldsymbol{\beta}|_{1,\infty,K} \le c\|\boldsymbol{\beta}\|_{0,\infty,K}$ *to hold, and hence the convergence in the* L^2*-norm in this regime is of the quasi-optimal rate* $h^{k+\frac12}$ *for a sufficiently regular solution.*

4.2. Recovering the pressure. In this section, we provide an estimate of the L^2-norm of the pressure error. This is the aim of the following theorem, which ensures that the pressure converges at the rate of the velocity.

THEOREM 4.12. *Assume* $(\mathbf{u},p)\in[H^r(\Omega)]^d\times H^s(\Omega)$, *with* $r\geq 2$ *and* $s\geq 1$, *is the solution of* (2.1) *and* $(\mathbf{u}_h,p_h)\in W_h^k$ *is the solution of* (2.10). *Then, under the assumptions of Lemma* 4.6, *there holds*

$$\|p-p_h\|_{0,\Omega}\leq C\left(C_{\mathrm{L}}\sigma^{\frac{1}{2}}+\max_{K\in\mathcal{T}_h}\{\|\boldsymbol{\beta}\|_{0,\infty,K}h_K,\nu\}^{\frac{1}{2}}+\sigma^{-\frac{1}{2}}\|\boldsymbol{\beta}\|_{0,\infty,\Omega}\right)C_{\mathbf{u}},$$

with $C_{\mathbf{u}}$ *the convergence rate of* $|||\mathbf{u}-\mathbf{u}_h|||$ *given by Theorem* 4.9, *and* C_L *a positive constant depending only on* Ω.

Proof. Following [27, Corollary 2.4], there exists $\mathbf{v}_p\in[H_0^1(\Omega)]^d$ such that

$$\nabla\cdot\mathbf{v}_p=p-p_h,\quad \|\mathbf{v}_p\|_{0,\Omega}\leq C_{\mathrm{L}}\|p-p_h\|_{0,\Omega},\quad |\mathbf{v}_p|_{1,\Omega}\leq C\|p-p_h\|_{0,\Omega},\tag{4.13}$$

with $C_{\mathrm{L}}>0$ a constant, depending on Ω, which scales as a distance. Thus, using the modified Galerkin orthogonality (Lemma 2.1), we readily obtain

$$\begin{aligned}\|p-p_h\|_{0,\Omega}^2&=(p-p_h,\nabla\cdot\mathbf{v}_p)\\&=(p-p_h,\nabla\cdot(\mathbf{v}_p-\pi_{h,k}\mathbf{v}_p))+\langle p-p_h,\pi_{h,k}\mathbf{v}_p\cdot\mathbf{n}\rangle_{\partial\Omega}\\&\quad+a_h(\mathbf{u}-\mathbf{u}_h,\pi_{h,k}\mathbf{v}_p)+j_{\mathbf{u}}(\mathbf{u}-\mathbf{u}_h,\pi_{h,k}\mathbf{v}_p).\end{aligned}$$

Thus, after integrating by parts, we get

$$\|p-p_h\|_{0,\Omega}^2=\underbrace{(\nabla(p-p_h),\mathbf{v}_p-\pi_{h,k}\mathbf{v}_p)}_{T_1}+\underbrace{a_h(\mathbf{u}-\mathbf{u}_h,\pi_{h,k}\mathbf{v}_p)+j_{\mathbf{u}}(\mathbf{u}-\mathbf{u}_h,\pi_{h,k}\mathbf{v}_p)}_{T_2}.\tag{4.14}$$

For the first term, using the orthogonality of the L^2-projection, the Cauchy–Schwarz inequality, Corollary 3.2, (4.13), and Corollary 4.3, we get

$$\begin{aligned}T_1&=(\nabla(p-p_h)-\pi_{h,k}\nabla p+\pi_{h,k}^*\nabla p_h,\mathbf{v}_p-\pi_{h,k}\mathbf{v}_p)\\&\leq\|\tilde{h}(\nabla p-\pi_{h,k}\nabla p)\|_{0,\Omega}\|\tilde{h}^{-1}(\mathbf{v}_p-\pi_{h,k}\mathbf{v}_p)\|_{0,\Omega}\\&\quad+C\|\phi_3^{-1}(\nabla p_h-\pi_{h,k}^*\nabla p_h)\|_{0,\Omega}\|\phi_3^*(\mathbf{v}_p-\pi_{h,k}\mathbf{v}_p)\|_{0,\Omega}\\&\leq C\Bigg[\Bigg(\sum_{K\in\mathcal{T}_h}h_K^{2s_p-1}\|p\|_{s_p,K}^2\Bigg)^{\frac{1}{2}}\\&\quad+\max_{K\in\mathcal{T}_h}\{\nu,\|\boldsymbol{\beta}\|_{0,\infty,K}h_K\}^{\frac{1}{2}}j_p(p_h,p_h)^{\frac{1}{2}}\Bigg]\|p-p_h\|_{0,\Omega}.\end{aligned}\tag{4.15}$$

Using the definition (2.11) of the bilinear form a_h, and after integration by parts in the convective term, we have

$$\begin{aligned}T_2&\leq|||\mathbf{u}-\mathbf{u}_h|||\,|||\pi_{h,k}\mathbf{v}_p|||+(\mathbf{u}-\mathbf{u}_h,\boldsymbol{\beta}\cdot\nabla\pi_{h,k}\mathbf{v}_p)\\&\quad-\langle 2\nu\boldsymbol{\epsilon}(\mathbf{u}-\mathbf{u}_h)\mathbf{n},\pi_{h,k}\mathbf{v}_p\rangle_{\partial\Omega}-\langle\mathbf{u}-\mathbf{u}_h,2\nu\boldsymbol{\epsilon}(\pi_{h,k}\mathbf{v}_p)\mathbf{n}\rangle_{\partial\Omega}.\end{aligned}\tag{4.16}$$

For the convective term we have, using the H^1-stability of the L^2-projection (see [5]) and (4.13),

$$\begin{aligned}(\mathbf{u}-\mathbf{u}_h,\boldsymbol{\beta}\cdot\nabla\pi_{h,k}\mathbf{v}_p)&\leq\sigma^{-\frac{1}{2}}\|\boldsymbol{\beta}\|_{0,\infty,\Omega}\|\sigma^{\frac{1}{2}}(\mathbf{u}-\mathbf{u}_h)\|_{0,\Omega}\|\nabla\pi_{h,k}\mathbf{v}_p\|_{0,\Omega}\\&\leq C\sigma^{-\frac{1}{2}}\|\boldsymbol{\beta}\|_{0,\infty,\Omega}|||\mathbf{u}-\mathbf{u}_h|||\,\|p-p_h\|_{0,\Omega}.\end{aligned}\tag{4.17}$$

The boundary terms are controlled in the following fashion:

$$\begin{aligned}(4.18)\quad &\langle 2\nu\boldsymbol{\epsilon}(\mathbf{u}-\mathbf{u}_h)\mathbf{n}, \pi_{h,k}\mathbf{v}_p\rangle_{\partial\Omega} + \langle \mathbf{u}-\mathbf{u}_h, 2\nu\boldsymbol{\epsilon}(\pi_{h,k}\mathbf{v}_p)\mathbf{n}\rangle_{\partial\Omega}\\ &\quad\le C\|(\nu\tilde{h})^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{u}-\mathbf{u}_h)\|_{0,\partial\Omega}|\!|\!|\pi_{h,k}\mathbf{v}_p|\!|\!| + C\|(\nu\tilde{h})^{\frac{1}{2}}\boldsymbol{\epsilon}(\pi_{h,k}\mathbf{v}_p)\|_{0,\partial\Omega}|\!|\!|\mathbf{u}-\mathbf{u}_h|\!|\!|.\end{aligned}$$

In addition, as in (4.7) and (4.8), we have

$$\begin{aligned}(4.19)\quad \|(\nu\tilde{h})^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{u}-\mathbf{u}_h)\|_{0,\partial\Omega} &\le \|(\nu\tilde{h})^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{e}^{\pi})\|_{0,\partial\Omega} + \|(\nu\tilde{h})^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{e}_h)\|_{0,\partial\Omega},\\ &\le C\left[\left(\sum_{K\in\mathcal{T}_h}\nu h_K^{2(r_{\mathbf{u}}-1)}\|\mathbf{u}\|^2_{r_{\mathbf{u}},K}\right)^{\frac{1}{2}} + |\!|\!|\mathbf{e}_h|\!|\!|\right].\end{aligned}$$

In the same fashion, we obtain

$$(4.20)\qquad \|(2\nu\tilde{h})^{\frac{1}{2}}\boldsymbol{\epsilon}(\pi_{h,k}\mathbf{v}_p)\|_{0,\partial\Omega} \le C|\!|\!|\pi_{h,k}\mathbf{v}_p|\!|\!|.$$

Finally, from (4.13), it follows that

$$(4.21)\qquad |\!|\!|\pi_{h,k}\mathbf{v}_p|\!|\!| \le C\left(C_L\sigma^{\frac{1}{2}} + \max_{K\in\mathcal{T}_h}\{\|\boldsymbol{\beta}\|_{0,\infty,K}h_K,\nu\}^{\frac{1}{2}}\right)\|p-p_h\|_{0,\Omega}.$$

We conclude the proof by collecting the estimations (4.15)–(4.20) in (4.14), using (4.21) and Theorem 4.9. ∎

REMARK 4.13. *Let us notice that the three terms appearing in the error estimate of the previous theorem scale with the right dimensions.*

4.3. Low Reynolds number optimality. The following theorem gives an optimal L^2-error estimate for velocity when the local Reynolds number is low.

THEOREM 4.14. *Assume that the solution* $(\mathbf{u},p)$ *of* (2.1) *belongs to* $[H^2(\Omega)]^d \times H^1(\Omega)$ *and let* $(\mathbf{u}_h,p_h)\in W_h^k$ *be the solution of* (2.10). *Assume also that*

$$(4.22)\qquad \|\boldsymbol{\beta}\|_{0,\infty,K}h_K \le \nu \quad \forall K\in\mathcal{T}_h,$$

and that the solution (φ,ψ) *of the adjoint problem*

$$(4.23)\qquad \begin{cases}\sigma\varphi - \boldsymbol{\beta}\cdot\nabla\varphi - 2\nu\nabla\cdot\boldsymbol{\epsilon}(\varphi) - \nabla\psi = \mathbf{u}-\mathbf{u}_h \quad in \quad \Omega,\\ \nabla\cdot\varphi = 0 \quad in \quad \Omega,\\ \varphi = 0 \quad on \quad \partial\Omega\end{cases}$$

belongs to $[H^2(\Omega)]^d\times[H^1(\Omega)]$ *and satisfies*

$$(4.24)\qquad \|\varphi\|_{2,\Omega} + \|\psi\|_{1,\Omega} \le C\|\mathbf{u}-\mathbf{u}_h\|_{0,\Omega}.$$

Then, there holds

$$\|\mathbf{u}-\mathbf{u}_h\|_{0,\Omega} \le ch^2\big(\|\mathbf{u}\|_{2,\Omega} + \|p\|_{1,\Omega}\big),$$

with constant $c>0$ *independent of* h, *but depending on the physical parameters.*

Proof. Multiplying the first equation of (4.23) by $\mathbf{u}-\mathbf{u}_h$ and the second by $-(p-p_h)$, integrating by parts, and using the modified Galerkin orthogonality (Lemma 2.1), it follows that

$$\begin{aligned}\|\mathbf{u}-\mathbf{u}_h\|_{0,\Omega}^2 &= a_h(\mathbf{u}-\mathbf{u}_h,\varphi)+b_h(p-p_h,\varphi)-b_h(\psi,\mathbf{u}-\mathbf{u}_h)\\ &= \underbrace{a_h(\mathbf{u}-\mathbf{u}_h,\varphi-\pi_{h,k}\varphi)+b_h(p-p_h,\varphi-\pi_{h,k}\varphi)-b_h(\psi-\pi_{h,k}\psi,\mathbf{u}-\mathbf{u}_h)}_{T_1}\\ &\quad+\underbrace{j_{\mathbf{u}}(\mathbf{u}-\mathbf{u}_h,\varphi-\pi_{h,k}\varphi)}_{T_2}+\underbrace{j_p(p_h,\pi_{h,k}\psi)}_{T_3}.\end{aligned}$$

Following the argument of the proofs of Theorems 4.9 and 4.12, and using Lemma 4.6 and (4.22), we get

$$\begin{aligned}T_1 &\le |||\mathbf{u}-\mathbf{u}_h|||\,|||\varphi-\pi_{h,k}\varphi||| + |(\mathbf{u}-\mathbf{u}_h,\boldsymbol{\beta}\cdot\nabla(\varphi-\pi_{h,k}\varphi))|\\ &\quad-\langle 2\nu\boldsymbol{\epsilon}(\mathbf{u}-\mathbf{u}_h)\mathbf{n},\varphi-\pi_{h,k}\varphi\rangle_{\partial\Omega}-\langle\mathbf{u}-\mathbf{u}_h,2\nu\boldsymbol{\epsilon}(\varphi-\pi_{h,k}\varphi)\mathbf{n}\rangle_{\partial\Omega}\\ &\le Ch\left(|||\mathbf{u}-\mathbf{u}_h|||\,\|\varphi\|_{2,\Omega}+\|p-p_h\|_{0,\Omega}\|\varphi\|_{2,\Omega}+|||\mathbf{u}-\mathbf{u}_h|||\,\|\psi\|_{1,\Omega}\right).\end{aligned}$$

Using Cauchy–Schwarz, Lemma 4.6, and (4.22), one obtains

$$\begin{aligned}T_2 &\le j_{\mathbf{u}}(\mathbf{u}-\mathbf{u}_h,\mathbf{u}-\mathbf{u}_h)^{\frac12}\,j_{\mathbf{u}}(\varphi-\pi_{h,k}\varphi,\varphi-\pi_{h,k}\varphi)^{\frac12}\\ &\le Ch^{\frac32}|||\mathbf{u}-\mathbf{u}_h|||\,\|\varphi\|_{2,\Omega}.\end{aligned}$$

Finally, from Lemma 4.7 and (4.22), for the last term we have

$$\begin{aligned}T_3 &\le j_p(p_h,p_h)^{\frac12}\,j_p(\pi_{h,k}\psi,\pi_{h,k}\psi)^{\frac12}\\ &\le Chj_p(p_h,p_h)^{\frac12}\,\|\psi\|_{1,\Omega}.\end{aligned}$$

The proof concludes by combining the above estimations with Theorems 4.9 and 4.12, Corollary 4.10, (4.22), and the assumed regularizing behavior (4.24). ∎

Let us sum up the results provided by Theorems 4.9 and 4.12. When the local Reynolds number is high and the solution is regular, we enjoy an optimal $O(h^{k+\frac12})$ convergence order of the error in the L^2-norm for the velocity and the pressure. For less regular solutions, for instance, when the pressure is in $H^1(\Omega)$ and the velocity is in $[H^2(\Omega)]^d$, we get an optimal $O(h)$ estimate in the energy norm, when the local Reynolds number is low, but a suboptimal estimate of $O(h^{\frac12})$ when the local Reynolds number is high. This is due to the fact that the inconsistencies in the pressure stabilization pollute the energy norm estimate for the velocities.

REMARK 4.15. *Note that by adding the L^2-coercivity, we can use the stabilization term to control the convective term without using the H^1-coercivity; this leads to a quasi-optimal estimate in the weaker L^2-norm, with a ν-weighted H^1 contribution showing that the stabilization handles the numerical instability induced by treating nonsymmetric terms using the standard Galerkin method. In case $\sigma=0$ the H^1 estimate obtained by a standard energy argument will scale as $\nu^{-\frac12}$, reflecting the physical instability of the problem.*

5. Numerical results. In this section we report several numerical experiments that show the good convergence properties of our stabilized finite element method. In particular, we recover the convergence rates obtained in section 4.

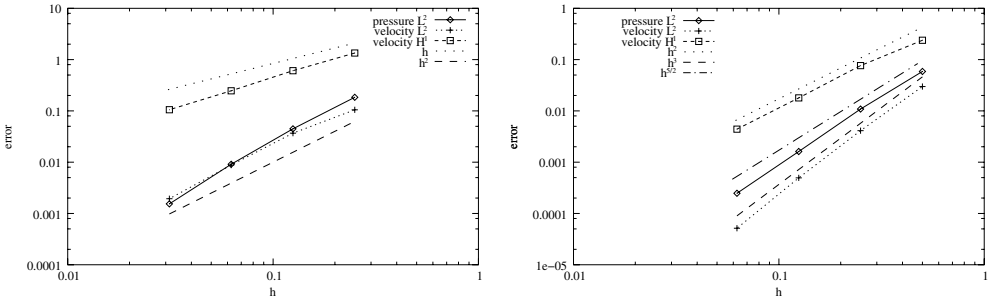

FIG. 5.1. *Convergence history: Linear elements* ($k = 1$) *(left) and quadratic elements* ($k = 2$) *(right).*

We consider problem (2.1) in three dimensions with nonhomogeneous boundary conditions. The right-hand side $\mathbf{f}$ and the boundary data are chosen in order to ensure that the exact solution of (2.1) is given by the following expression [22]:

$$
\begin{aligned}
u_1(x_1,x_2,x_3) &= be^{a(x_1-x_3)+b(x_2-x_3)} - ae^{a(x_3-x_2)+b(x_1-x_2)},\\
u_2(x_1,x_2,x_3) &= be^{a(x_2-x_1)+b(x_3-x_2)} - ae^{a(x_1-x_3)+b(x_2-x_3)},\\
u_3(x_1,x_2,x_3) &= be^{a(x_3-x_2)+b(x_1-x_2)} - ae^{a(x_2-x_1)+b(x_3-x_1)},\\
p(x_1,x_2,x_3) &= (a^2+b^2+ab)\Big[e^{a(x_1-x_2)+b(x_1-x_3)} + e^{a(x_2-x_3)+b(x_2-x_1)}\\
&\qquad + e^{a(x_3-x_1)+b(x_3-x_2)}\Big]
\end{aligned}
\tag{5.1}
$$

with $\boldsymbol{\beta} = \mathbf{u}$, $\sigma = 1$, $\nu = 10^{-4}$, $a = b = 0.75$, and $\Omega = (0,1)^3$ the unit cube.

The resulting continuous problem was solved approximately using the stabilized discrete formulation (2.10); however, the boundary conditions were strongly enforced. All numerical tests have been performed using conforming linear and quadratic finite elements for velocity and pressure, namely, P_1/P_1 and P_2/P_2 (implemented in a three-dimensional research code [23]). The stabilization parameter involved in the jumps terms (2.13) and (2.14) were chosen as

$$
\gamma = \begin{cases} \dfrac{1}{8} & \text{if} \quad k = 1, \\ \dfrac{1}{32} & \text{if} \quad k = 2. \end{cases}
$$

In Figure 5.1 we show, respectively, the velocity and pressure convergence histories for $k = 1$ and $k = 2$. Note that, in both cases, the numerical solution exhibits optimal convergence order and is hence in agreement with Theorems 4.9 and 4.12.

We show in Figure 5.2 the pressure contours in two different meshes (which are depicted in Figure 5.3) using linear elements. No spurious pressure oscillations are observed. We report in Figure 5.4 the contours of the second component of $\mathbf{u}_h$, u_{h2}, in the left plot with full stabilization and in the right plot setting the stabilization parameter for the term associated with the streamline derivative to zero, on the cutting plane $x = 0.5$. Although the exact solution is smooth, the plot of the unstabilized solution (right) exhibits spurious oscillations. Note that the spurious velocity oscillations (right) are completely controlled by the streamline-derivative jumps (left).

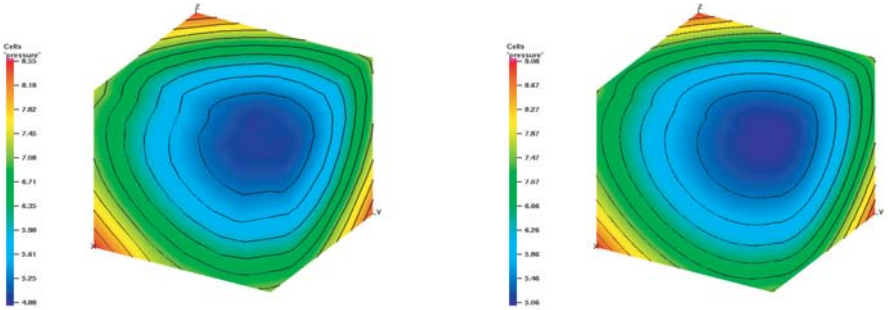

FIG. 5.2. *Pressure contours: Coarse mesh (left) and fine mesh (right).*

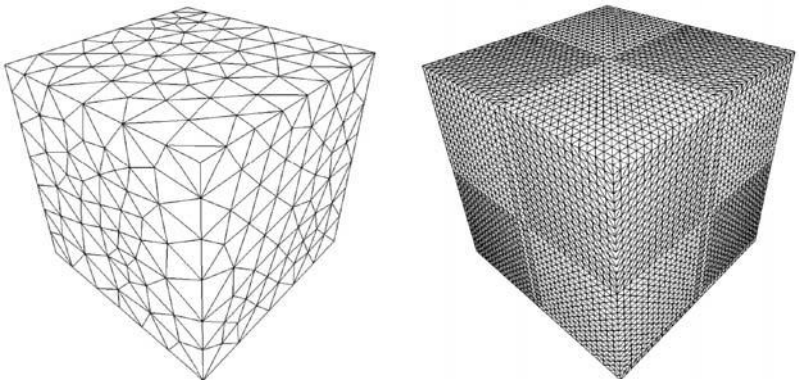

FIG. 5.3. *Coarse mesh (*2929 *tetrahedra) and fine mesh (*196608 *tetrahedra).*

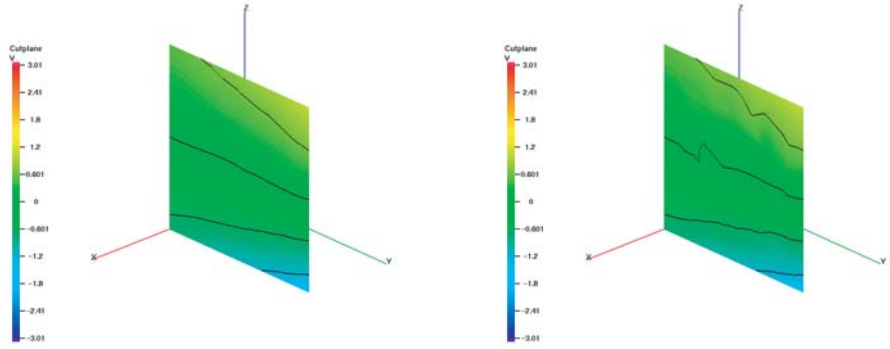

FIG. 5.4. *Velocity (u_{h2}) contours on a cutting plane: Stabilized (left), with $\gamma_\beta = 0$ (right).*

In what follows we will replace, in (5.1), the expression for the pressure by

$$p(x_1, x_2, x_3) = \begin{cases} 2x_2 & \text{if} \quad 0 \le x_2 \le \dfrac{1}{2}, \\ 2(1 - x_2) & \text{if} \quad \dfrac{1}{2} \le x_2 \le 1. \end{cases}$$

Clearly, this function satisfies $p \in H^1(\Omega)$ but does not belong to $H^2(\Omega)$. Figure 5.5

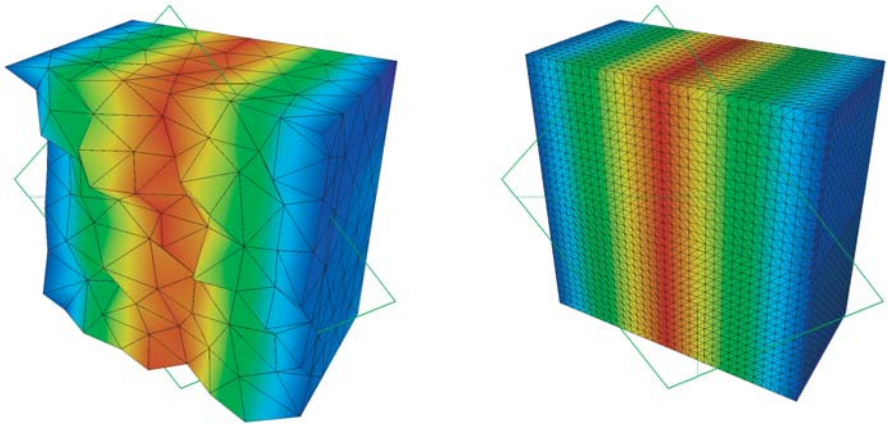

FIG. 5.5. *Cutting plane pressure: Coarse mesh and fine mesh.*

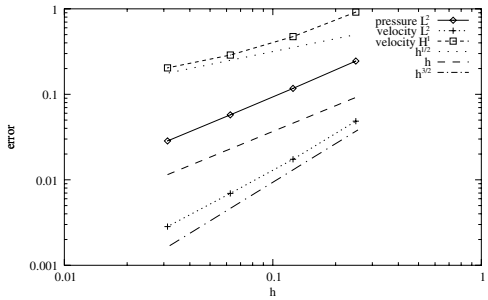

FIG. 5.6. *Convergence history: Linear elements, nonsmooth pressure, stabilization, parameters chosen as in* (2.13) *and* (2.14).

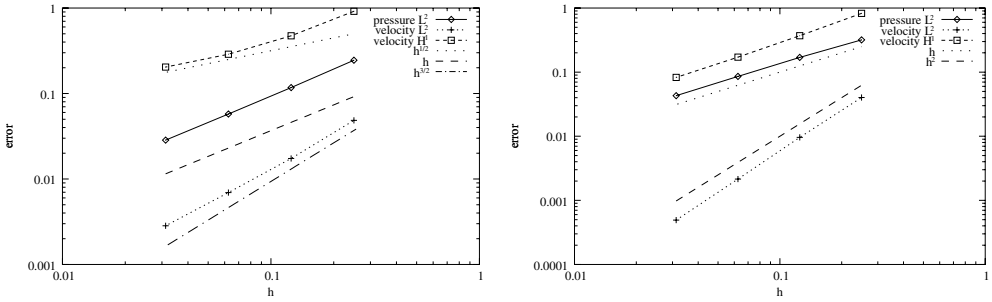

FIG. 5.7. *Convergence history: Linear elements, nonsmooth pressure, parameters chosen as in* (2.13) *and* (2.14). *Left: High Reynolds number. Right: Low Reynolds number.*

shows the pressure contours in a cut of a coarse and a fine mesh. Once more no spurious pressure oscillations are observed. Figure 5.6 shows the velocity and pressure convergence histories using linear elements. We get the suboptimal $O(h^{\frac{1}{2}})$ order for the velocity in the H^1-norm in the case of high local Reynolds numbers, in agreement with Theorem 4.9. The L^2-norm of the velocities, on the other hand, is still not far from the quasi-optimal $O(h^{\frac{3}{2}})$ convergence order. As expected, when the local Reynolds is low (for instance $\nu = 0.1$), we recover the optimal $O(h)$; see Figure 5.7,

left graphic. In addition, as predicted in Theorem 4.14, we notice that the convergence order for the velocity in the L^2-norm is $O(h^2)$.

6. Conclusion and outlook. In this paper, we have extended the results reported in [15, 13] to Oseen's equations using equal order interpolation and finite element spaces of arbitrary polynomial order. The stability properties of the method are based on an interior penalty term giving L^2-control of the jump of the gradient over interior element faces. We have shown that such a stabilization operator may be used to control all the nonsymmetric first order terms of Oseen's equations and that they give control only of the part of the operator that is not in the finite element space. In this sense the proposed method is a minimal stabilized method (see [8]).

The convergence analysis shows that the method has (quasi-) optimal convergence properties both in the L^2-norm and in the energy norm when the solution is sufficiently regular or the local Reynolds number is low. When physically realistic regularities are considered ($p \in H^1(\Omega)$) and the local Reynolds number is high, the convergence may become suboptimal $O(h^{\frac{1}{2}})$ due to the inconsistencies in the pressure stabilization. In some numerical examples we illustrated the theoretical results. The method shows very good performance in all regimes. In particular, we observe that in the high Reynolds number regime the scheme degenerates to the theoretical $O(h^{k+\frac{1}{2}})$ convergence in the L^2-norm predicted by the theory only in the case where the pressure is only H^1 and where the theoretical prediction is $O(h^{\frac{1}{2}})$.

The method presented here has some common features with VMS for LES as introduced in [30]. However, unlike the VMS, where two scales V_h and V_H defined by hierarchic meshes are considered (see, e.g., [35, 31, 4]), in our case the finite element space V_h represents the only resolved scale and the "turbulent" viscosity acts only on the gradient component that is not resolved on V_h. Recently, John and Kaya [31] proposed a VMS using a projection method framework which essentially takes the form of a standard Galerkin formulation for $\mathbf{u}_h$ supplemented with the turbulent viscosity acting only on the fine scales in the form of an additional term

$$(\nu_T(I - P_H)\boldsymbol{\epsilon}(\mathbf{u}_h), (I - P_H)\boldsymbol{\epsilon}(\mathbf{v}_h)), \tag{6.1}$$

where P_H is some map from fine scales to coarse scales. Comparing this now with the face oriented stabilization method, we would choose $H = h$ and thus make the turbulent viscosity act only on the scales that are not resolved on the space V_h. Applying Lemma 3.1 we immediately get an interior penalty interpretation of the term (6.1), with $P_H \overset{\text{def}}{=} \pi^*_{h,k}$,

$$\|\nu_T^{\frac{1}{2}}(I - \pi^*_{h,k})\boldsymbol{\epsilon}(\mathbf{u}_h)\|^2_\Omega \leq \sum_{K\in\mathcal{T}_h} \int_{\partial K} \nu_T h_K [\![\boldsymbol{\epsilon}(\mathbf{u}_h)]\!] : [\![\boldsymbol{\epsilon}(\mathbf{u}_h)]\!] \,\mathrm{d}s,$$

and we conclude that a possible subgrid modeling term would be

$$j_T(\mathbf{u}_h, \mathbf{v}_h) = \sum_{K\in\mathcal{T}_h} \int_{\partial K\setminus\partial\Omega} \nu_T h_K [\![\boldsymbol{\epsilon}(\mathbf{u}_h)]\!] : [\![\boldsymbol{\epsilon}(\mathbf{v}_h)]\!] \,\mathrm{d}s,$$

where the choice of ν_T now is a modeling issue. It should be noted that the choice $\nu_T = \gamma h_K$ gives us a term which is asymptotically equivalent to the face penalty operator using the whole gradient. However, other choices of ν_T based on modeling considerations are possible.

For sufficiently high polynomial degree there exists a C^1 subspace of V_h with approximation properties. It follows that the solution may be decomposed into one C^1 part which is untouched by the stabilizing terms and another C^0 part which is penalized. We conclude that the method enjoys the scale separation property characteristic for VMS as proposed in [30] by polynomial order rather than by hierarchic meshes. Future work will focus on the extension of the present method to the Navier–Stokes equations both from a numerical and a theoretical standpoint.

Finally, we remark that the Nitsche-type weak boundary conditions used in this paper, while nonstandard, have the benefit of acting as slip boundary conditions in the high Reynolds number regime and as no-slip conditions when the boundary layers are resolved; this may be favorable in LES (see Layton [34]).

Acknowledgment. The authors wish to thank the anonymous reviewers for their careful reading of the manuscript and their many constructive comments.

PRECONDITIONERS FOR GENERALIZED SADDLE-POINT PROBLEMS*

CHRIS SIEFERT† AND ERIC DE STURLER‡

Abstract. We propose and examine block-diagonal preconditioners and variants of indefinite preconditioners for block two-by-two generalized saddle-point problems. That is, we consider the nonsymmetric, nonsingular case where the (2,2) block is small in norm, and we are particularly concerned with the case where the (1,2) block is different from the transposed (2,1) block. We provide theoretical and experimental analyses of the convergence and eigenvalue distributions of the preconditioned matrices. We also extend the results of [de Sturler and Liesen, *SIAM J. Sci. Comput.*, 26 (2005), pp. 1598–1619] to matrices with nonzero (2,2) block and to the use of approximate Schur complements. To demonstrate the effectiveness of these preconditioners we show convergence results, spectra, and eigenvalue bounds for two model Navier–Stokes problems.

Key words. saddle-point problems, generalized saddle-point problems, iterative methods, preconditioning, Krylov subspace methods, eigenvalue bounds

1. Introduction.

We examine preconditioners for real systems of the form

$$\mathcal{A}\begin{bmatrix} x \\ y \end{bmatrix} \equiv \begin{bmatrix} A & B^T \\ C & D \end{bmatrix}\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} f \\ g \end{bmatrix}, \tag{1.1}$$

where $A \in \mathbb{R}^{n\times n}$, $D \in \mathbb{R}^{m\times m}$, and $n > m$. For many relevant problems, $D = 0$ and $B \neq C$, and such problems are referred to as generalized saddle-point problems [24]. For other problems we consider $D \neq 0$, but $\|D\|_2$ is small enough that the problem retains the characteristics of a generalized saddle-point problem. In many such problems, the nonzero (2,2) block arises from a stabilization term. However, this is not always the case. In a problem involving metal deformation [35], for example, it derives from very slight compressibility. In addition, we note that certain approaches to stabilization lead to systems where $B \neq C$ [3, 24], [27, sections 7.5 and 9.4] although many other problems have $B = C$. Finally, our preconditioners allow A to be singular. We consider all of these cases, which arise in many applications, ranging from stabilized formulations of the Navier–Stokes equations [4, 11, 27] to metal deformation [35] and interior point methods [13].

Problems of this type have been of recent interest [1, 8, 9, 18, 20, 23], as have their symmetric counterparts [7, 10, 14, 26, 31, 34] and the case where $D = 0$ [2, 5, 6, 8, 15, 19, 21, 23, 32]. However, preconditioners for the case where $B \neq C$ have not received as much attention. Though they are considered in [8, 18, 23], these papers do not provide numerical experiments for such problems. We will do this in the present paper. In [8], a detailed analysis is provided for two classes of preconditioners for

the case where $B \neq C$ and $D = 0$. Here, we extend these preconditioners to the case where $D \neq 0$ and to allow for approximations to the Schur complement matrix that arises in the preconditioner. Our preconditioners for (1.1) derive from a matrix splitting, $A = F - E$. Our purpose is to derive preconditioners that result in tightly clustered eigenvalues. In general, this leads to fast convergence for Krylov subspace methods, although in the nonsymmetric case the eigenvectors may play a role as well.

In this paper we assume that the matrix is nonsingular or that the singularity can be easily removed, such as the constant pressure mode in the Oseen problem [12]. For the splitting, we assume that F and $(D - CF^{-1}B^T)$ are nonsingular. In section 2, we propose a block-diagonal preconditioner that is a generalization of the preconditioners discussed in [18] and [8]. In section 3, we use this preconditioner to derive a second preconditioned system, which is a generalization of the *related system* presented in [8]. For the $D = 0$ case, the related system corresponds to an efficient implementation of a constraint preconditioner; see also [5, 6, 14, 26]. In section 4, we extend both types of preconditioner to the use of approximate Schur complements. Our analysis focuses on the $D \neq 0$ case, but we provide specializations to the $D = 0$ case as well. While the block-diagonally preconditioned system may be very effective or more convenient in certain situations, the related system is generally the better preconditioner, offering much faster convergence for a modest increase in the computational cost per iteration. Therefore, in section 5 on numerical experiments we focus on the related system.

We propose preconditioners with exact (sections 2 and 3) and with approximate (section 4) Schur complements, and we discuss the convergence for the preconditioned systems and the clustering of the eigenvalues. We explore two model problems in section 5. The first, which arises from a finite element discretization of the Navier–Stokes equations, has $D \neq 0$ and $A \neq A^T$. The second, which arises from a spectral collocation approach for an incompressible Stokes problem, has $B \neq C$ and $D = 0$. We use eigenvalue bounds and numerical experiments to illustrate that reasonable choices for splittings and approximate Schur complements yield good convergence. Our analysis also illustrates the issues involved in choosing splittings and approximate Schur complements to achieve effective preconditioning. Although eigenvalue bounds are often wide, they nevertheless indicate good eigenvalue clustering for reasonable choices for splittings and approximate Schur complements.

2. Block-diagonal preconditioners (exact Schur complement). We consider a splitting of the (1,1) block, $A = F - E$, where F is easy to solve with and $(D - CF^{-1}B^T)^{-1}$ exists. Note that $-(D - CF^{-1}B^T)$ is the Schur complement of the matrix

$$\begin{bmatrix} F & B^T \\ C & D \end{bmatrix}, \tag{2.1}$$

and we will use the phrase *exact Schur complement* to refer to $-(D - CF^{-1}B^T)$. Next, we introduce the following block-diagonal preconditioner as a straightforward generalization of preconditioners in [8, 18]:

$$\mathcal{P}(F) = \begin{bmatrix} F^{-1} & 0 \\ 0 & -(D - CF^{-1}B^T)^{-1} \end{bmatrix}. \tag{2.2}$$

Preconditioning from the left or the right with $\mathcal{P}$ yields a system of the form

$$\mathcal{B}(F) \begin{bmatrix} \tilde{x} \\ \tilde{y} \end{bmatrix} = \begin{bmatrix} I - S & N \\ M & Q \end{bmatrix} \begin{bmatrix} \tilde{x} \\ \tilde{y} \end{bmatrix} = \begin{bmatrix} \tilde{f} \\ \tilde{g} \end{bmatrix}, \tag{2.3}$$

where $\mathcal{B}(F)$ is either $\mathcal{PA}$ or $\mathcal{AP}$. For example, the matrix from the left-preconditioned system is

$$\mathcal{P}(F)\mathcal{A} = \begin{bmatrix} I - F^{-1}E & F^{-1}B^T \\ -(D - CF^{-1}B^T)^{-1}C & -(D - CF^{-1}B^T)^{-1}D \end{bmatrix},$$

implicitly defining S, N, M, and Q in (2.3) for the left-preconditioned case. Apart from the preconditioned (2,2) block Q, this resembles the system arising from the zero (2,2) block case. For the rest of this paper, we assume that Q is diagonalizable. While $MN = I$ for the $D = 0$ case [23, 8], for $D \neq 0$ we have

$$\begin{aligned} MN &= -(D - CF^{-1}B^T)^{-1}CF^{-1}B^T = -(D - CF^{-1}B^T)^{-1}(-D + CF^{-1}B^T + D) \\ &= I + Q. \end{aligned} \tag{2.4}$$

This is true for both the left- and right-preconditioned cases. In the $D = 0$ case, NM is a projector [8]. For the $D \neq 0$ case, it is not, as $(NM)^2 = NM + NQM$.

In section 2.1 we derive the eigendecomposition of the matrix

$$\mathcal{B}_0 = \begin{bmatrix} I & N \\ M & Q \end{bmatrix}, \tag{2.5}$$

when $I+Q$ (and thus B^T and C) have full rank. We use this in section 2.2 to develop bounds for the eigenvalues of $\mathcal{B}(F)$ using perturbation theory. Finally, in section 2.3, we discuss the case when $I + Q$ is rank-deficient.

2.1. Eigenvalues and eigenvectors of $\mathcal{B}_0$. Assume that $I + Q$ (and thus B^T and C) have full rank. We wish to find λ, u, and v such that

$$u + Nv = \lambda u, \tag{2.6}$$

$$Mu + Qv = \lambda v. \tag{2.7}$$

First, we assume $\lambda = 1$. Substituting this into (2.6) and using $Q = MN - I$ in (2.7) yields

$$Nv = 0 \quad \text{and} \quad Mu = 2v. \tag{2.8}$$

Since B^T has full column rank by assumption, this implies that $v = 0$ and that $\mathcal{B}_0$ has only eigenpairs of the form

$$\left(1, \begin{bmatrix} u \\ 0 \end{bmatrix}\right), \qquad \text{where } u \in \text{null}\,(M)\,. \tag{2.9}$$

Since C has full row rank, so does M, and $\mathcal{B}_0$ has precisely $n-m$ distinct eigenpairs of this type. Next, we consider the case where $\lambda \neq 1$. Solving (2.6) for u and substituting into (2.7) yields

$$\lambda Q v_j = (\lambda^2 - \lambda - 1)v_j. \tag{2.10}$$

Hence, the v_j must be eigenvectors of Q. We have assumed that Q has a full set of eigenpairs, $Qv_j = \delta_j v_j$, for $j = 1, \ldots, m$. We then solve (2.10) for λ to yield

$$\lambda_j^{\pm} = \frac{(1 + \delta_j) \pm \sqrt{4 + (1 + \delta_j)^2}}{2}; \tag{2.11}$$

cf. [11]. Using (2.6) with the eigenvectors of Q for v yields the vectors u. We finally rescale the eigenvector by $(\lambda_j^{\pm} - 1)$ to yield eigenpairs of the form

$$\left(\lambda_j^{\pm}, \begin{bmatrix} Nv_j \\ (\lambda_j^{\pm} - 1)v_j \end{bmatrix}\right). \tag{2.12}$$

Note that $\lambda_j^- \neq 1$ regardless of the choice of δ_j, and $\lambda_j^+ = 1$ only if $\delta_j = -1$. However, the latter would contradict the assumption that $I + Q$ has full rank. Thus, $\mathcal{B}_0$ has $2m$ eigenpairs corresponding to $\lambda \neq 1$. This completes a full set of eigenpairs for $\mathcal{B}_0$. Let U_1 be a matrix whose columns form an orthonormal basis for null (M) (cf. (2.9)), and let U_2 be the matrix with normalized columns $u_j = Nv_j$, where $Qv_j = \delta_j v_j$; cf. (2.12). Furthermore, let $\Lambda^+ = \operatorname{diag}(\lambda_j^+)$ and $\Lambda^- = \operatorname{diag}(\lambda_j^-)$, where $\operatorname{diag}(\cdot)$ denotes the diagonal matrix with the given arguments. Then, the following matrix, $\mathcal{Y}$, is an eigenvector matrix of $\mathcal{B}_0$:

$$\mathcal{Y} \equiv \left[\begin{array}{c|c} Y_{11} & Y_{12} \\ \hline Y_{21} & Y_{22} \end{array}\right] = \left[\begin{array}{cc|c} U_1 & U_2 & U_2 \\ 0 & V(\Lambda^+ - I) & V(\Lambda^- - I) \end{array}\right]. \tag{2.13}$$

For our perturbation results we also need

$$\mathcal{Z} = \mathcal{Y}^{-1} = \begin{bmatrix} Z_{11} & Z_{12} \\ Z_{21} & Z_{22} \end{bmatrix}. \tag{2.14}$$

Using the block-inversion formula in [17, section 0.7.3] we obtain [29, 30]

$$Z_{11} = \begin{bmatrix} I_{n-m} & 0 \\ 0 & \Upsilon^+ \end{bmatrix} Y_{11}^{-1} = \hat{I}_n Y_{11}^{-1}, \tag{2.15}$$

$$Z_{21} = -\begin{bmatrix} 0 & \Upsilon^- \end{bmatrix} Y_{11}^{-1}, \tag{2.16}$$

$$Z_{12} = -\begin{bmatrix} 0 \\ (\Lambda^- - \Lambda^+)^{-1} V^{-1} \end{bmatrix}, \tag{2.17}$$

$$Z_{22} = \left(V(\Lambda^- - \Lambda^+)\right)^{-1}, \tag{2.18}$$

with $\Upsilon^+ = \operatorname{diag}((\lambda_j^- - 1)/(\lambda_j^- - \lambda_j^+))$ and $\Upsilon^- = \operatorname{diag}((\lambda_j^+ - 1)/(\lambda_j^- - \lambda_j^+))$. For $Q = 0$ (because $D = 0$), the eigendecomposition of $\mathcal{B}_0$ reduces to the case discussed in [8].

2.2. Perturbation bounds on the eigenvalues of $\mathcal{B}(F)$. We are now ready to consider the eigenvalues of $\mathcal{B}(F)$ and derive bounds on the spectrum. Throughout this paper $\|\cdot\|$ indicates the 2-norm.

THEOREM 2.1. *Consider matrices $\mathcal{B}(F)$ of the form* (2.3). *Let $\mathcal{Y}$ be the eigenvector matrix of $\mathcal{B}_0$, as given by* (2.13). *Then for each eigenvalue $\lambda_{\mathcal{B}}$ of $\mathcal{B}(F)$ there exists an eigenvalue λ of $\mathcal{B}_0$ such that*

$$|\lambda_{\mathcal{B}} - \lambda| \leq \left\| \mathcal{Y}^{-1} \begin{bmatrix} S & 0 \\ 0 & 0 \end{bmatrix} \mathcal{Y} \right\| \tag{2.19}$$

$$\leq 2 \max\left(1, \|\Upsilon^+\|, \|\Upsilon^-\|\right) \|Y_{11}^{-1} S Y_{11}\|. \tag{2.20}$$

Proof. Since $\mathcal{B}_0$ is diagonalizable, (2.19) follows from a classic result in perturbation theory [33, Theorem IV.1.12]. We expand the right-hand side of (2.19) using

(2.13)–(2.17) to get (see also [8])

$$
\begin{aligned}
|\lambda_{\mathcal{B}} - \lambda| &\le \left\| \begin{bmatrix} \hat{I}_n Y_{11}^{-1} S Y_{11} & \hat{I}_n Y_{11}^{-1} S Y_{12} \\ -\begin{bmatrix} 0 & \Upsilon^- \end{bmatrix} Y_{11}^{-1} S Y_{11} & -\begin{bmatrix} 0 & \Upsilon^- \end{bmatrix} Y_{11}^{-1} S Y_{12} \end{bmatrix} \right\| \\
&\le \max(1, \|\Upsilon^+\|, \|\Upsilon^-\|) \\
&\quad \cdot \left\| \begin{bmatrix} Y_{11}^{-1} S U_1 & Y_{11}^{-1} S U_2 & Y_{11}^{-1} S U_2 \\ -\begin{bmatrix} 0 & I \end{bmatrix} Y_{11}^{-1} S U_1 & -\begin{bmatrix} 0 & I \end{bmatrix} Y_{11}^{-1} S U_2 & -\begin{bmatrix} 0 & I \end{bmatrix} Y_{11}^{-1} S U_2 \end{bmatrix} \right\|.
\end{aligned}
$$

Using the consistency of the 2-norm, we can simplify this to (see also [8])

$$
\begin{aligned}
|\lambda_{\mathcal{B}} - \lambda| &\le \sqrt{2} \max(1, \|\Upsilon^+\|, \|\Upsilon^-\|) \left\| \begin{bmatrix} Y_{11}^{-1} S Y_{11} \\ -\begin{bmatrix} 0 & I \end{bmatrix} Y_{11}^{-1} S Y_{11} \end{bmatrix} \right\| \\
&\le 2 \max(1, \|\Upsilon^+\|, \|\Upsilon^-\|) \left\| Y_{11}^{-1} S Y_{11} \right\|. \qquad \square
\end{aligned}
$$

The $\Upsilon^{\pm}$ terms can be large only if $\delta_j \approx -1 \pm 2i$. For the problems discussed in section 5, the δ_j's are well separated from this value, because $\|D\|$ is small and the problem and preconditioner are relatively well conditioned. The following lemma provides bounds on the $\|\Upsilon^{\pm}\|$. We explicitly consider the special case where the δ_j's are real (and thus bounded away from $-1 \pm 2i$). This occurs in the important case that D is symmetric and the Schur complement is definite. For the following proof and subsequent discussions, we define the function $p(z) = 4 + (1+z)^2$.

LEMMA 2.2. *Let Υ^+ and Υ^- be defined as above.*

1. *If $\delta_j \in \mathbb{R}$, for all j, then*

$$\max(1, \|\Upsilon^+\|, \|\Upsilon^-\|) \le \frac{1+\sqrt{2}}{2}.$$

Moreover, if $\delta_j \ge -1$, for all j, then $\max(1, \|\Upsilon^+\|, \|\Upsilon^-\|) = 1$.

2. *If $\delta_j \in \mathbb{C}$ and $\exists \alpha : |\delta_j| \le \alpha < \sqrt{5}$ for $j = 1, \ldots, m$, then*

$$\max(1, \|\Upsilon^+\|, \|\Upsilon^-\|) \le \max\left(1, \frac{1}{2} + \frac{1+\alpha}{2\sqrt{2\left(\sqrt{5}-\alpha\right)}}\right).$$

Proof. Substituting $\lambda_j^{\pm}$ from (2.11) into $\Upsilon^+ = \operatorname{diag}(\lambda_j^- - 1)/(\lambda_j^- - \lambda_j^+)$ and $\Upsilon^- = \operatorname{diag}(\lambda_j^+ - 1)/(\lambda_j^- - \lambda_j^+)$ gives

$$\Upsilon^{\pm} = \operatorname{diag}\left(\frac{1-\delta_j}{2\sqrt{4+(1+\delta_j)^2}} \pm \frac{1}{2}\right) = \operatorname{diag}\left(\frac{1-\delta_j}{2\sqrt{p(\delta_j)}} \pm \frac{1}{2}\right). \tag{2.21}$$

The proof for the real case now follows from basic calculus.

For the complex case, note that $p(\delta) = (\delta + 1 + 2i)(\delta + 1 - 2i)$. Any δ must be at least distance 2 from one of the roots of $p(\delta)$. We assume without loss of generality that δ is near $-1+2i$. The value $\delta_* = (-1+2i)\alpha/\sqrt{5}$ minimizes $|\delta + 1 - 2i|$ subject to $|\delta| \le \alpha$, and we have $|\delta_* + 1 - 2i| = \sqrt{5} - \alpha$. So, we have $|p(\delta)| \ge 2\left(\sqrt{5} - \alpha\right)$. Using this inequality for $|p(\delta)|$ after taking norms in (2.21) completes the proof. $\square$

In practice, the bound for the complex case is quite modest. For example, if $|\delta_j| \le 1$ for all j, then our bound on $\max(1, \|\Upsilon^+\|, \|\Upsilon^-\|)$ is about 1.136. Likewise, if $|\delta_j| \le 2$ for all j, the bound is about 1.470.

We derive a bound on $\left\|Y_{11}^{-1}SY_{11}\right\|$ following the approach in [8]. Recall that $Y_{11} = [U_1\ U_2]$, where $U_1^T U_1 = I$, and $U_2 = NV$ with unit columns. Let $U_2 = V_2\Theta$, where $V_2^T V_2 = I$. Furthermore, let $\omega_1 = \|U_1^T V_2\|$, which is the cosine of the smallest principal angle between range $(U_1) =$ null (NM) and range $(U_2) =$ range (NM).

LEMMA 2.3. *Define Y_{11}, S, U_1, U_2, V_2, Θ, and ω_1 as above, and let $\kappa(.)$ denote the 2-norm condition number. Then*

$$\left\|Y_{11}^{-1}SY_{11}\right\| \leq \kappa(\Theta)\left(\frac{1+\omega_1}{1-\omega_1}\right)^{1/2}\|S\|. \tag{2.22}$$

Proof. We have $\|Y_{11}^{-1}SY_{11}\| \leq \kappa(Y_{11})\|S\|$, where

$$Y_{11} = \begin{bmatrix} U_1 & V_2 \end{bmatrix}\begin{bmatrix} I & 0 \\ 0 & \Theta \end{bmatrix},$$

since U_2 has unit columns $\|\Theta\| \geq 1$ and $\|\Theta^{-1}\| \geq 1$. So, our bound simplifies to

$$\|Y_{11}^{-1}SY_{11}\| \leq \kappa(\Theta)\ \kappa\left(\begin{bmatrix} U_1 & V_2 \end{bmatrix}\right)\|S\| \leq \kappa(\Theta)\left(\frac{1+\omega_1}{1-\omega_1}\right)^{1/2}\|S\|, \tag{2.23}$$

where the second inequality follows from the bound on $\kappa([U_1\ V_2])$ from Lemma 3.6 in [8]. ∎

COROLLARY 2.4. *Let Θ and ω_1 be defined as above.*

1. *If $\delta_j \in \mathbb{R}$ for all j, then*

$$|\lambda_{\mathcal{B}} - \lambda| \leq (1+\sqrt{2})\kappa(\Theta)\left(\frac{1+\omega_1}{1-\omega_1}\right)^{1/2}\|S\|. \tag{2.24}$$

2. *If $\delta_j \in \mathbb{C}$ and $\exists\alpha : |\delta_j| \leq \alpha < \sqrt{5}$ for $j = 1, \ldots, m$, then*

$$|\lambda_{\mathcal{B}} - \lambda| \leq 2\max\left(1, \frac{1}{2} + \frac{1+\alpha}{2\sqrt{2\left(\sqrt{5}-\alpha\right)}}\right)\kappa(\Theta)\left(\frac{1+\omega_1}{1-\omega_1}\right)^{1/2}\|S\|. \tag{2.25}$$

Proof. Use Lemmas 2.2 and 2.3 in Theorem 2.1. ∎

We see that the clustering of the eigenvalues depends mainly on $\|S\|$ and the size of the δ_j, unless $\omega_1 \approx 1$ or $\kappa(\Theta)$ large. This implies that the block-diagonally preconditioned system can have as many as $2m+1$ eigenvalue clusters, one for $\lambda = 1$ and one for each $\lambda_j^{\pm}$. Hence, the convergence of Krylov methods may not be very good for the block-diagonally preconditioned system, even if $\|S\|$ is small. Examples in section 5 will illustrate this. However, when the δ_j and $\|S\|$ are small, the block-diagonal preconditioner will give good convergence. This typically happens for small mesh width when D and Q are h-dependent; see Table 5.1. In addition, the block-diagonal preconditioner provides an intermediate step to a better preconditioner described in section 3.

2.3. Rank-deficiency of $I + Q$. In section 2.1, we made the assumption that $I + Q$ has full rank (for $D = 0$, this is always true). We now briefly discuss the rank-deficient case.

There are three sources of potential rank-deficiency in $I + Q$. The first two are rank-deficiency in C and B^T. The third is when there are vectors v such that $Nv \neq 0$

and $Nv \in \text{null}\,(M)$. This implies that $MNv = (I+Q)v = 0$ and v is an eigenvector of Q. This case occurs when F^{-1} (for left preconditioning) or $-(D - CF^{-1}B^T)^{-1}$ (for right preconditioning) maps a nontrivial vector from range $\left(B^T\right)$ into null (C).

Assume that $I+Q$, C, and B^T are rank deficient by k, l_c, and l_b, respectively. Note that $k \geq \max(l_b, l_c)$, since $I+Q = -(D-CF^{-1}B^T)^{-1}CF^{-1}B^T$ and the product of matrices cannot be of higher rank than any of its factors.

Our previous analysis remains valid for the $2(m-k)$ eigenpairs (2.11) that correspond to $\delta_j \neq -1$. It is also valid for the k eigenpairs where $\delta_j = -1$ that correspond to λ_j^-. Since the Schur complement is invertible, M must also be rank deficient by l_c. Thus, the number of eigenpairs of the form (2.9) equals $\dim(\text{null}\,(M)) = n - m + l_c$. This gives a total of $n + m - k + l_c$ eigenpairs, leaving us to find $k - l_c$ eigenpairs.

From (2.8), we have that all eigenvectors corresponding to $\lambda = 1$ must satisfy $Nv = 0$ and $Mu = 2v$. Since $\dim(\text{null}\,(N)) = l_b$, there are l_b independent vectors v that satisfy $Nv = 0$. Unfortunately, there may be as many as l_c independent vectors v where $Mu = 2v$ has no solution. If we do not have $k - l_c$ independent vectors v such that $Mu = 2v$ has a solution, then $\mathcal{B}_0$ is defective. The analysis of section 2.1 does not permit any other eigenvectors.

For the missing eigenpairs we have that $\lambda_j^+ \to 1$ as $\delta_j \to -1$. Therefore, we look for principal vectors of grade two (see [16]) for $\lambda = 1$. These vectors satisfy the equations

$$Nv = \tilde{u} \quad \text{and} \quad Mu = 2v, \tag{2.26}$$

where $\tilde{u} \neq 0$ and $\tilde{u} \in \text{null}\,(M)$. We note that there are k independent vectors v such that $(I+Q)v = 0$. Since there are precisely l_b independent vectors v such that $Nv = 0$, there must be $k - l_b$ such vectors v that satisfy $Nv = \tilde{u}$ with $\tilde{u} \neq 0$ and $M\tilde{u} = 0$. This gives k independent vectors v that satisfy the first equation of either (2.8) or (2.26).

There exists a space of dimension l_c such that $Mu = 2v$ has no solution. However, since we have k independent v's to propose, we are guaranteed to find $k - l_c$ independent vectors v's that satisfy this equation. This gives us either our remaining eigenvectors or principal vectors of grade two. This also guarantees us that we have Jordan blocks of size at most two.

In the special case when $k = l_b = l_c$, we have $k - l_c = 0$, so we have a full set of eigenvectors. We can apply the analysis described in the full rank case with k additional eigenpairs $(1, [\tilde{u}_{n-m+j}^T, 0^T]^T)$ for $j = 1, \ldots, k$, replacing the corresponding eigenpairs $(\lambda_j^+, [(Nv_j)^T, (\lambda_j^+ - 1)v_j^T]^T)$ for which $\delta_j = -1$. Let U_1 be such that $U_1^T U_1 = I_{n-m+l_c}$ and range $(U_1) = \text{null}\,(M)$. Let $\widetilde{V}$ be such that $\widetilde{V}^T\widetilde{V} = I_{l_c}$ and range$(\widetilde{V}) = \text{null}\,(I+Q)$. Further, let the columns of $\widehat{V}$ be the eigenvectors of Q corresponding to the eigenvalues $\delta_j \neq -1$, scaled such that $U_2 = N\widehat{V}$ has unit columns. Finally, let the diagonal matrices $\widehat{\Lambda}^+$ and $\widehat{\Lambda}^-$ contain the eigenvalues λ_j^+ and λ_j^- corresponding to the eigenvalues $\delta_j \neq -1$ ordered consistently with the columns of $\widehat{V}$. Then the eigenvector matrix of $\mathcal{B}_0$ is given by

$$\mathcal{Y} = \left[\begin{array}{cc|cc} U_1^{(n-m+l_c)} & U_2^{(m-l_c)} & N\tilde{V}^{(l_c)} & U_2^{(m-l_c)} \\ \hline 0 & \widehat{V}(\widehat{\Lambda}^+ - I) & -2\widetilde{V} & \widehat{V}(\widehat{\Lambda}^- - I) \end{array}\right], \tag{2.27}$$

where superscripts in the top row indicate the number of columns. The corresponding eigenvalues are those from (2.9) and (2.11). We can then use the eigenvector matrix

of $\mathcal{B}_0$ given in (2.27) to derive bounds on the eigenvalues, as for the full rank case. The reduction in the number of columns of U_2 may in fact reduce the factor $\kappa(\Theta)$ in Corollary 2.4. An important example of this case is the stabilized Navier–Stokes (Oseen) problem [11], where $C = B$ and F is positive definite.

3. Fixed-point method and its related system (exact Schur complement). We now consider an alternative solution method that leads to faster convergence in general; cf. [8]. In the $D = 0$ case this approach leads to an efficient implementation of so-called constraint preconditioners; cf. [6, 5, 14, 26]. We can derive the following splitting from (2.3):

$$\mathcal{B}(F)\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} I-S & N \\ M & Q \end{bmatrix}\begin{bmatrix} x \\ y \end{bmatrix} = \left(\mathcal{B}_0 - \begin{bmatrix} S & 0 \\ 0 & 0 \end{bmatrix}\right)\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} \tilde{f} \\ \tilde{g} \end{bmatrix}. \tag{3.1}$$

Note that

$$\mathcal{B}_0^{-1} = \begin{bmatrix} I-NM & N \\ M & -I \end{bmatrix}. \tag{3.2}$$

We left-multiply (3.1) by $\mathcal{B}_0^{-1}$ to yield the fixed-point iteration,

$$\begin{bmatrix} x_{k+1} \\ y_{k+1} \end{bmatrix} = \begin{bmatrix} (I-NM)S & 0 \\ MS & 0 \end{bmatrix}\begin{bmatrix} x_k \\ y_k \end{bmatrix} + \begin{bmatrix} \hat{f} \\ \hat{g} \end{bmatrix}. \tag{3.3}$$

Note that this iteration is formally the same as for the $D = 0$ case in [5, 8]. Since x_{k+1} and y_{k+1} depend only on x_k, we need to iterate only on the x_k variables; see also [4, pp. 214–215] and [8]. The x-component of the fixed-point of (3.3) satisfies the so-called *related system* for the fixed-point iteration [16],

$$(I-(I-NM)S)x = \hat{f}.\ ^{1} \tag{3.4}$$

The full-size related system (that is, with the y component) and $D \neq 0$ has been examined elsewhere for special cases. In [26], A is symmetric positive definite and spectrally equivalent to the identity, and so the splitting $F = I$ is used. In [14], F is symmetric positive definite. In both of these cases $B = C$.

3.1. Eigenvalue bounds for fixed-point matrix and related system. In this section we assume $n-m \geq m$, but equivalent results are obtained for $m > n-m$. Let U_1 and U_2 be defined as in (2.13), $\Delta = \operatorname{diag}(\delta_j)$, and let $U_2 = V_2\Theta$ with $V_2^T V_2 = I$. Then, we have $NMU_1 = 0$, $NMU_2 = NMNV = NV(I+\Delta)$, and therefore

$$(I-NM) = \begin{bmatrix} U_1 & V_2 \end{bmatrix}\begin{bmatrix} I & 0 \\ 0 & -\Theta\Delta\Theta^{-1} \end{bmatrix}\begin{bmatrix} U_1 & V_2 \end{bmatrix}^{-1}. \tag{3.5}$$

In the rank-deficient case, we can use (2.27). So, for this approach rank-deficiency has a potential advantage in terms of the conditioning of Θ. To analyze $\|I-NM\|$ we need the following singular value decomposition (SVD):

$$U_1^T V_2 = \Phi\Omega\Psi^T, \quad \text{where } 1 > \omega_1 \geq \omega_2 \geq \cdots \geq \omega_m. \tag{3.6}$$

[1] The full-size related system derives from using (2.1) as a left-preconditioner; see also [8].

Following [8], we define W by $W\Sigma = V_2\Psi - U_1\Phi\Omega$, where the diagonal matrix $\Sigma = \mathrm{diag}((1-\omega_j^2)^{1/2})$ contains the sines of the principal angles between range (U_1) and range (V_2). Then, $[U_1\ W]$ is orthogonal, and we can decompose V_2 as follows:

$$V_2 = U_1\Phi\Omega\Psi^T + W\Sigma\Psi^T. \tag{3.7}$$

THEOREM 3.1. *Let U_1,V_2, and ω_1 be defined as above. Let λ_R be an eigenvalue of the related system matrix in* (3.4). *Then,*

$$\left.\begin{matrix}\rho((I-NM)S)\\ |1-\lambda_R|\end{matrix}\right\} \le (1-\omega_1^2)^{-1/2}(1+\|\Theta\Delta\Theta^{-1}\|)\|S\|,$$

where $\rho(\cdot)$ designates the spectral radius.

Proof. The proof of this theorem largely follows [8]. Note that the result for $\rho((I-NM)S)$ immediately implies the result for $|1-\lambda_R|$. We have $\rho((I-NM)S) \le \|I-NM\|\|S\|$. Let $Z = -\Theta\Delta\Theta^{-1}$. Then,

$$\|I-NM\| = \left\|[U_1\ V_2]\begin{bmatrix} I & 0\\ 0 & Z\end{bmatrix}[U_1\ V_2]^{-1}\right\| \tag{3.8}$$

$$\le \left\|[U_1\ V_2]\begin{bmatrix} I & 0\\ 0 & 0\end{bmatrix}[U_1\ V_2]^{-1}\right\| + \left\|[U_1\ V_2]\begin{bmatrix} 0 & 0\\ 0 & Z\end{bmatrix}[U_1\ V_2]^{-1}\right\| \tag{3.9}$$

$$\le (1-\omega_1^2)^{-1/2} + (1-\omega_1^2)^{-1/2}\|Z\| = (1-\omega_1^2)^{-1/2}(1+\|Z\|). \tag{3.10}$$

The first term in (3.9) is the norm of an oblique projection. Given the SVD in (3.6), this norm equals $(1-\omega_1^2)^{-1/2}$ [22, section 5.15]. We establish the bound for the second term as follows:

$$\left\|[U_1\ V_2]\begin{bmatrix} 0 & 0\\ 0 & Z\end{bmatrix}[U_1\ V_2]^{-1}\right\| = \max_{U_1a+V_2b\neq 0}\frac{\|V_2Zb\|}{\|U_1a+V_2b\|}. \tag{3.11}$$

Without loss of generality we may assume $\|b\| = 1$, so that $\|V_2Zb\| \le \|Z\|$. From (3.7) we see that $\|U_1a+V_2b\| = \|U_1a+U_1\Phi\Omega\Psi^Tb+W\Sigma\Psi^Tb\|$, which for any given b is minimized by $a = -\Phi\Omega\Psi^Tb$. This gives $\|U_1a+V_2b\| = \|W\Sigma\Psi^Tb\|$, which in turn is minimized for $b = \psi_1$. Hence, we have

$$\left\|[U_1\ V_2]\begin{bmatrix} 0 & 0\\ 0 & Z\end{bmatrix}[U_1\ V_2]^{-1}\right\| = \max_{U_1a+V_2b\neq 0}\frac{\|V_2Zb\|}{\|U_1a+V_2b\|} \le (1-\omega_1^2)^{-1/2}\|Z\|. \tag{3.12}$$

Therefore, by using (3.8)–(3.12) we have

$$\rho((I-NM)S) \le (1-\omega_1^2)^{-1/2}(1+\|\Theta\Delta\Theta^{-1}\|)\|S\|. \qquad \square$$

If the δ_j are clustered, the influence of $\kappa(\Theta)$ is small.

COROLLARY 3.2. *Let $\hat\delta = \arg\min_{z\in\mathbb{C}}\max_j|z-\delta_j|$ and $\tilde\delta_j = \delta_j - \hat\delta$. Then*

$$\left.\begin{matrix}\rho((I-NM)S)\\ |1-\lambda_R|\end{matrix}\right\} \le (1-\omega_1^2)^{-1/2}(1+\hat\delta+\kappa(\Theta)\max|\tilde\delta_j|)\|S\|.$$

Proof. Note that $\Delta = \hat\delta I + \mathrm{diag}(\tilde\delta_j)$, so $\Theta\Delta\Theta^{-1} = \hat\delta I + \Theta\ \mathrm{diag}(\tilde\delta_j)\,\Theta^{-1}$. $\square$

So, the eigenvalues of the related system cluster around 1, and the tightness of the clustering is controlled through $\|S\|$. Note that the factor containing ω_1 in Corollary 3.2 is no larger than the corresponding factor for the block-diagonally preconditioned system in Corollary 2.4. In addition, the influence of the $\kappa(\Theta)$ term is smaller for the related system if the δ_j are clustered. This generally leads to better clustering and tighter bounds for the related system than for the block-diagonally preconditioned system. Because of these advantages, the related system will generally have faster convergence than the block-diagonally preconditioned system.

3.2. Satisfying "constraints". In the $D = 0$ case, the second block of equations in (1.1) often represents a set of constraints. For the $D \neq 0$ case, this may or may not be the case. So-called constraint preconditioners in the $D = 0$ case have the advantage that each iterate of a Krylov subspace method for the preconditioned system satisfies the constraints if the initial guess is chosen appropriately. Fixed-point methods such as (3.3) often satisfy the constraints after a single step. This is the case for the fixed-point method proposed in [8] for $D = 0$. It turns out that we can prove an analogous property for the $D \neq 0$ case.

LEMMA 3.3. *For any initial guess* $[x_0^T, y_0^T]^T$, *the iterates,* $[x_k^T, y_k^T]^T$, *for* $k = 1, 2, \ldots,$ *of* (3.3) *satisfy* $Mx_k + Qy_k = \tilde{g}$ *in* (2.3) *and* $Cx_k + Dy_k = g$ *in* (1.1).

The proof can be found in [29, 30].

COROLLARY 3.4. *After the first iteration of* (3.3), *all fixed-point updates are in the null space of* $[M\ Q]$.

This follows trivially from Lemma 3.3.

We can also show that the iterates of a Krylov subspace method will satisfy the constraints if the initial guess satisfies the constraints (cf. [8]). We first give a general result and then specialize it to our problem. For the remainder of this section, A and C are arbitrary matrices, not the matrices referred to in (1.1). We return to the nomenclature of (1.1) in the next section.

THEOREM 3.5. *Let* $A \in \mathbb{R}^{n\times n}$, $b \in \mathbb{R}^n$, $C \in \mathbb{R}^{m\times n}$, *and* $d \in \mathbb{R}^m$, *and define the iteration* $x_{k+1} = Ax_k + b$. *Further, let the iterates* x_k *satisfy* $Cx_k = d$ *for* $k \geq 1$ *and any starting vector* x_0. *Then, the iterates* $x^{(m)}$, $m \geq 0$, *of a Krylov method applied to the (related) system,* $(I - A)x = b$, *will satisfy* $Cx^{(m)} = d$ *if* $Cx^{(0)} = d$.

The proof can be found in [29, 30].

COROLLARY 3.6. *The iterates,* $[x^{(m)^T}, y^{(m)^T}]^T$, *of any Krylov method applied to the full* $n+m$ *related system for* (3.3) *satisfy* $Mx^{(m)} + Qy^{(m)} = \tilde{g}$ *and* $Cx^{(m)} + Dy^{(m)} = g$ *if the initial guess is the result of at least one step of fixed-point iteration* (3.3).

Proof. Use Theorem 3.5, with A as fixed-point iteration matrix in (3.3), $b = [\hat{f}^T\ \hat{g}^T]^T$, $C = [M\ Q]$, and $d = \hat{g}$. ∎

4. Approximate Schur complement. It may be expensive to compute the Schur complement matrix $(D - CF^{-1}B^T)$ or to compute and apply its inverse (or factors). So, we would like to use a cheap approximation to the inverse of the Schur complement. We now consider the effect of such an approximation on the eigenvalue clustering of the preconditioned matrices and on the resulting convergence. Let $S_1 = -(D - CF^{-1}B^T)$ denote the actual Schur complement and S_2^{-1} denote our approximation to its inverse. As we only need to apply S_2^{-1}, no explicit representation of S_2 is needed. Finally, let $S_2^{-1}S_1 = I + \mathcal{E}$.

4.1. Eigenvalue analysis of the block-diagonally preconditioned system. Now, the block-diagonal preconditioner is as follows:

$$\mathcal{P}(F, S_2) = \begin{bmatrix} F^{-1} & 0 \\ 0 & S_2^{-1} \end{bmatrix}.$$

We multiply (1.1) from the left by $\mathcal{P}(F, S_2)$. We refer to the resulting preconditioned matrix as $\mathcal{B}(F, S_2)$. The system of equations with $\mathcal{B}(F, S_2)$ is as follows:

$$\begin{bmatrix} I - S & N \\ M_2 & Q_2 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \left(\begin{bmatrix} I & N \\ M & Q \end{bmatrix} - \begin{bmatrix} S & 0 \\ -\mathcal{E}M & -\mathcal{E}Q \end{bmatrix} \right) \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} \tilde{f} \\ \tilde{g} \end{bmatrix}, \tag{4.1}$$

where M, N, and Q are defined as in section 2, $M_2 = S_2^{-1}C$, and $Q_2 = S_2^{-1}D$. Note also that $M_2 = S_2^{-1}S_1S_1^{-1}C = (I+\mathcal{E})M$ and analogously $Q_2 = (I+\mathcal{E})Q$. Using (4.1), we can bound the eigenvalues of $\mathcal{B}(F,S_2)$ by considering the perturbation of the eigenvalues of $\mathcal{B}_0$ analogously to our bounds in section 2.2.

THEOREM 4.1. *Let $\lambda_{\mathcal{B}}$ be an eigenvalue of $\mathcal{B}(F,S_2)$, λ be an eigenvalue of $\mathcal{B}_0$, and $Qv_j = \delta_j v_j$.*

1. *If $\delta_j \in \mathbb{R}$ for $j = 1,\dots,m$, then*

$$|\lambda_{\mathcal{B}} - \lambda| \le (1+\sqrt{2})\kappa(\Theta)\left(\frac{1+\omega_1}{1-\omega_1}\right)^{1/2}\|S\| + \max_j\left\{|1+\delta_j\lambda_j^+|, |1+\delta_j\lambda_j^-|\right\}\kappa(V)\|\mathcal{E}\|.$$

2. *If $\delta_j \in \mathbb{C}$ and $\exists\alpha > 0$ s.t. $|\delta_j| \le \alpha < \sqrt{5}$ for $j = 1,\dots,m$, then*

$$|\lambda_{\mathcal{B}} - \lambda| \le 2\max\left(1, \frac{1}{2} + \frac{1+\alpha}{2\sqrt{2\left(\sqrt{5}-\alpha\right)}}\right)\kappa(\Theta)\left(\frac{1+\omega_1}{1-\omega_1}\right)^{1/2}\|S\| + \frac{2+(1+\sqrt{5})\alpha+2\alpha^2}{\sqrt{2\left(\sqrt{5}-\alpha\right)}}\kappa(V)\|\mathcal{E}\|.$$

3. *If $D = 0$, then*

$$|\lambda_{\mathcal{B}} - \lambda| \le 2\left(\frac{1+\omega_1}{1-\omega_1}\right)^{1/2}\|S\| + \frac{2\sqrt{5}}{5}\|\mathcal{E}\|.$$

Proof. In section 2.1 we have already derived the eigendecomposition of $\mathcal{B}_0$. From this decomposition we get the following perturbation bound (see [33, Theorem IV.1.12]):

$$\begin{aligned} |\lambda_{\mathcal{B}} - \lambda| &\le \left\|\mathcal{Y}^{-1}\begin{bmatrix} S & 0 \\ -\mathcal{E}M & -\mathcal{E}Q \end{bmatrix}\mathcal{Y}\right\| \\ &\le \left\|\mathcal{Y}^{-1}\begin{bmatrix} S & 0 \\ 0 & 0 \end{bmatrix}\mathcal{Y}\right\| + \left\|\mathcal{Y}^{-1}\begin{bmatrix} 0 & 0 \\ \mathcal{E}M & \mathcal{E}Q \end{bmatrix}\mathcal{Y}\right\|. \end{aligned} \tag{4.2}$$

Corollary 2.4 gives bounds for the first term in (4.2). So, we need bounds only for the second term.

Define $\mathcal{X}$ such that

$$\mathcal{X} = \mathcal{Y}^{-1}\begin{bmatrix} 0 & 0 \\ \mathcal{E}M & \mathcal{E}Q \end{bmatrix}\mathcal{Y}.$$

We have

$$\begin{bmatrix} 0 & 0 \\ \mathcal{E}M & \mathcal{E}Q \end{bmatrix}\mathcal{Y} = \begin{bmatrix} 0 & 0 \\ -\mathcal{E}(MY_{11}+QY_{21}) & -\mathcal{E}(MY_{12}+QY_{22}) \end{bmatrix},$$

where $MU_1 = 0$ and $MU_2 = MNV = (I+Q)V = V(I+\Delta)$. This gives $MY_{12} = MU_2 = V(I+\Delta)$, $MY_{11} = [0\ V(I+\Delta)]$, $QY_{22} = V\Delta(\Lambda^- - I)$, and $QY_{21} = [0\ V\Delta(\Lambda^+ - I)]$. So, the previous equation reduces to

$$\begin{bmatrix} 0 & 0 \\ \mathcal{E}M & \mathcal{E}Q \end{bmatrix}\mathcal{Y} = \left[\begin{array}{cc|c} 0 & 0 & 0 \\ 0 & -\mathcal{E}V(I+\Delta\Lambda^+) & -\mathcal{E}V(I+\Delta\Lambda^-) \end{array}\right]. \tag{4.3}$$

We then multiply (4.3) from the left by $\mathcal{Y}^{-1}$ (see (2.14)–(2.17)) and refactor to yield

$$\mathcal{X} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & (\Lambda^- - \Lambda^+)^{-1} & 0 \\ 0 & 0 & -(\Lambda^- - \Lambda^+)^{-1} \end{bmatrix} \begin{bmatrix} 0 & 0 & 0 \\ 0 & V^{-1}\mathcal{E}V & V^{-1}\mathcal{E}V \\ 0 & V^{-1}\mathcal{E}V & V^{-1}\mathcal{E}V \end{bmatrix} \mathcal{W},$$

where

$$\mathcal{W} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & I + \Delta\Lambda^+ & 0 \\ 0 & 0 & I + \Delta\Lambda^- \end{bmatrix}.$$

Using the consistency of the 2-norm, we have the following bound on $\|\mathcal{X}\|$:

$$\|\mathcal{X}\| \leq 2\|(\Lambda^- - \Lambda^+)^{-1}\| \max_j \left\{|1 + \delta_j\lambda_j^+|, |1 + \delta_j\lambda_j^-|\right\} \kappa(V)\|\mathcal{E}\|. \tag{4.4}$$

The remainder of the proof concerns the bounds on the right-hand side of (4.4) for each particular case.

For the first part of the theorem, assume $\delta_j \in \mathbb{R}$ for $j = 1, \ldots, m$. We have

$$\begin{aligned} \lambda_j^- - \lambda_j^+ &= \frac{1 + \delta_j - \sqrt{4 + (1+\delta)^2}}{2} - \frac{1 + \delta_j + \sqrt{4 + (1+\delta)^2}}{2} = -\sqrt{4 + (1+\delta_j)^2} \\ &= -\sqrt{p(\delta)}. \end{aligned}$$

Clearly, $|1/(\lambda_j^- - \lambda_j^+)|$ obtains its maximum at $\delta_j = -1$. This yields $|1/(\lambda_j^- - \lambda_j^+)| \leq 1/2$. We can use this in (4.4) to complete the proof of the first bound.

For the second part of the theorem, we assume $\exists \alpha > 0$ s.t. $|\delta_j| \leq \alpha < \sqrt{5}$ for $j = 1, \ldots, m$. First we derive a bound for $\|(\Lambda^- - \Lambda^+)^{-1}\|$. Recall the lower bound on $p(\delta)$ in the proof of Lemma 2.2 and note that $|1/(\lambda_j^- - \lambda_j^+)| = 2/\sqrt{|p(\delta_j)|}$. So, we have $\|(\Lambda^- - \Lambda^+)^{-1}\| \leq (2(\sqrt{5} - \alpha))^{-1/2}$. Furthermore, we have

$$|1 + \delta_j\lambda_j^\pm| = \left|1 + \delta_j \frac{1 + \delta_j \pm \sqrt{4 + (1+\delta_j)^2}}{2}\right| \leq 1 + \frac{|\delta_j||1 + \delta_j| + |\delta_j|\sqrt{|4 + (1+\delta_j)^2|}}{2}.$$

We can bound $|\delta + 1 - 2i|$ and $|\delta + 1 + 2i|$ from above by $\sqrt{5} + \alpha$; so, $\sqrt{|4 + (1+\delta_j)^2|} \leq \sqrt{5} + \alpha$. Thus, we have
