$$|1 + \delta_j\lambda_j^\pm| \leq 1 + \frac{\alpha(1+\alpha) + \alpha\left(\sqrt{5} + \alpha\right)}{2} = 1 + \frac{1 + \sqrt{5}}{2}\alpha + \alpha^2.$$

Substituting these bounds into (4.4) yields

$$\|\mathcal{X}\| \leq \frac{2 + (1 + \sqrt{5})\alpha + 2\alpha^2}{\sqrt{2\left(\sqrt{5} - \alpha\right)}} \kappa(V)\|\mathcal{E}\|. \tag{4.5}$$

We can then substitute this result into (4.2) to prove the second part of the theorem.

For the third part of the theorem, we assume $D = 0$. We bound the first term in (4.2) using Theorem 2.1, Lemma 2.2 for $\delta \geq -1$, and Lemma 2.3 where $\kappa(\Theta) = 1$. This follows from the fact that U_2 can be chosen to be orthogonal (see [8]).

For the second term in (4.2), since $Q = 0$, $\delta_j = 0$, so $\lambda_j^- - \lambda_j^+ = -\sqrt{5}$, and we can choose $V = I$. We then substitute this into (4.4). ∎

In practice, in the complex case the term involving α will generally be modest. For example, if $\alpha = 1$, it is about 4.6022, and for $\alpha = 2$, it is about 23.9727.

If we compare the bounds from Theorem 4.1 with those from Corollary 2.4 for the block-diagonal preconditioner with the exact Schur complement, $(D - CF^{-1}B^T)$, we see that the deterioration of the bounds is $O(\|\mathcal{E}\|)$. Note that the factors that multiply the $\|\mathcal{E}\|$ are all constants with respect to the choice of the approximate Schur complement, S_2^{-1}. This is about as good as we can hope for. The bounds also demonstrate that there is no point in investing in a really good splitting when a poor approximation to the Schur complement is used or vice versa. Rather, we should be equally attentive to both if we want good eigenvalue clustering.

4.2. Eigenvalue analysis of the related system. If we follow the approach in section 3 to generate the related system for this problem, we would generate precisely the related system derived from (3.3), with S_1^{-1} instead of S_2^{-1} [8]. Therefore, we use an alternative splitting of $\mathcal{B}(F)$,

$$\mathcal{B}(F) = \begin{bmatrix} I & N \\ M_2 & Q_2 + \mathcal{E} \end{bmatrix} - \begin{bmatrix} S & 0 \\ 0 & \mathcal{E} \end{bmatrix},$$

and derive the related system for this splitting. Due to the $\mathcal{E}$ term in the splitting, however, we cannot reduce the size of our system. Instead, we get

$$\begin{bmatrix} I - (I - NM_2)S & -N\mathcal{E} \\ -M_2 S & I + \mathcal{E} \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} \hat{f} \\ \hat{g} \end{bmatrix}. \tag{4.6}$$

For a special problem in magnetostatics, a linear system similar to (4.6) was derived in [26]. If we use the choices for the splitting and approximations from [26], we obtain basically the same system to be solved. In [26], the authors only outline the qualitative behavior of the eigenvalues in the case that $\mathcal{E}$ is sufficiently small.

THEOREM 4.2. *For any eigenvalue, λ_R, of the related system matrix* (4.6),

$$|1 - \lambda_R| \le \sqrt{1 + \|N\|^2}\sqrt{1 + \|M_2\|^2}\max\left(\|S\|, \|\mathcal{E}\|\right).$$

Proof. Note that the matrix in (4.6) can be split as follows:

$$\begin{aligned} \begin{bmatrix} I - (I - NM_2)S & -N\mathcal{E} \\ -M_2 S & I + \mathcal{E} \end{bmatrix} &= I - \begin{bmatrix} I - NM_2 & N \\ M_2 & -I \end{bmatrix} \begin{bmatrix} S & 0 \\ 0 & \mathcal{E} \end{bmatrix} \\ &= I - \begin{bmatrix} I & -N \\ 0 & I \end{bmatrix} \begin{bmatrix} I & 0 \\ M_2 & -I \end{bmatrix} \begin{bmatrix} S & 0 \\ 0 & \mathcal{E} \end{bmatrix}. \end{aligned}$$

Expressing our matrix as a perturbation of the identity and using a classic perturbation bound (see [33]) yields

$$|1 - \lambda_R| \le \left\| \begin{bmatrix} I & -N \\ 0 & I \end{bmatrix} \begin{bmatrix} I & 0 \\ M_2 & -I \end{bmatrix} \begin{bmatrix} S & 0 \\ 0 & \mathcal{E} \end{bmatrix} \right\|.$$

Noting that

$$\left\| \begin{bmatrix} I & -N \\ 0 & I \end{bmatrix} \right\| \le \sqrt{1 + \|N\|^2} \qquad \text{and} \qquad \left\| \begin{bmatrix} I & 0 \\ M_2 & -I \end{bmatrix} \right\| \le \sqrt{1 + \|M_2\|^2},$$

we obtain

$$|1 - \lambda_R| \le \sqrt{1 + \|N\|^2}\sqrt{1 + \|M_2\|^2}\max\left(\|S\|, \|\mathcal{E}\|\right). \qquad \square$$

The terms $\|N\|$ and $\|M_2\|$ in the bound from Theorem 4.2 are fairly benign. They are bounded by the norms of the off-diagonal blocks of the unpreconditioned matrix (1.1) and the norms of the inverses of the splitting and approximate Schur complement. Note that the latter two are chosen by the user. Moreover, if we use a good preconditioner for this problem and therefore both our splitting and approximate Schur complement are reasonably accurate, the norms of their inverses will not be large relative to the norm of (1.1), unless (1.1) is itself poorly conditioned.

Just as for the block-diagonally preconditioned system, the eigenvalue perturbation of the related system depends on both $\|S\|$ and $\|\mathcal{E}\|$. Again, there is no advantage in making one significantly smaller than the other. Thus, we should be equally attentive to both $\|S\|$ and $\|\mathcal{E}\|$ in order to achieve tight clustering and fast convergence.

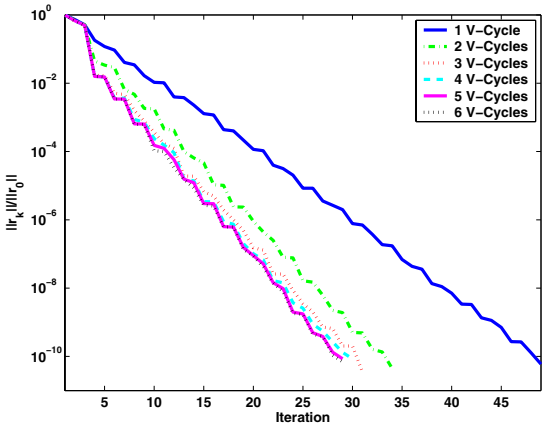
5. Numerical experiments. We present numerical experiments for two model problems, both arising from the Navier–Stokes equations.

The first model problem involves a stabilized finite element discretization of the Navier–Stokes equations. We use the software toolkit for a two-dimensional leaky lid-driven cavity problem developed for the Winter School in Scientific Computing and Iterative Methods hosted by the Chinese University of Hong Kong in December 1995 and made available by David Silvester [11]. Using this toolkit, we can easily apply the preconditioners and analysis from this paper to the stabilized Navier–Stokes problem (Oseen case). This problem is nonsymmetric but has $B = C$. Excellent work has been done by others on preconditioners for this specific problem [11, 31, 34], which we do not intend to supplant. Rather, our goal is to illustrate the effect of the preconditioners proposed in this paper on the convergence behavior and the eigenvalue distributions for a problem which is well understood and easily accessible to the community.

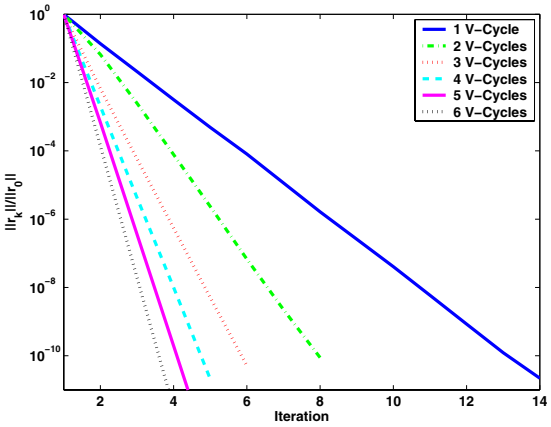
In particular, we show what happens to the convergence of GMRES, the eigenvalues, and our eigenvalue bounds as we improve the splitting ($\|S\| \to 0$) and the approximate Schur complement ($\|\mathcal{E}\| \to 0$). We also succinctly compare the block-diagonally preconditioned systems (2.3) and (4.1) with the related systems (3.4) and (4.6), in terms of both eigenvalues and convergence. We also illustrate the importance of *balancing* the quality of the splitting and the Schur complement to avoid wasted effort. Finally, we study the influence of the mesh width on the convergence of the related system.

The second model problem involves a spectral collocation discretization for the incompressible Stokes equations on a square [3, 27]. This application has $B \neq C$ and $D = 0$, and this particular formulation uses the Chebyshev nodes for the collocation sites to allow the rapid computation of Gauss–Lobatto quadrature. To our knowledge, this is the first presentation of convergence and eigenvalue results in the literature for preconditioners for generalized saddle-point problems with $B \neq C$. For this application, we present GMRES convergence results as well as the locations of the eigenvalues of the preconditioned system.

5.1. Navier–Stokes with finite elements. For our first experiments, we choose a 16×16 grid, viscosity parameter $\nu = 0.1$, and stabilization parameter $\beta = 0.25$. After removing the constant pressure mode, the system has 705 unknowns. Since multigrid cycles are actually matrix splittings, we use a number of multigrid V-cycles to define the splitting of the (1,1) block. For each V-cycle we use three SOR-Jacobi pre- and post-smoothing steps with relaxation parameter $\omega = 0.25$. As a purely algebraic alternative, we also employ an ILUT factorization of the (1,1) block and vary the drop tolerance to change the accuracy of our splitting [28].



(a) Block-Diagonal Preconditioner (2.3).

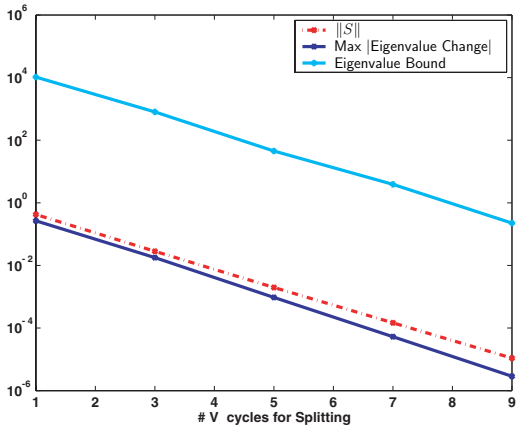


(b) Related System (3.4).

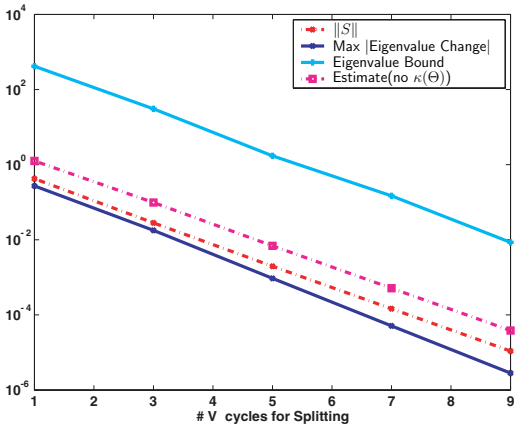
FIG. 5.1. *Convergence of GMRES for both types of preconditioners, using the exact Schur complement and varying the number of V-cycles for the splitting.*

We start with the exact Schur complement, varying the number of V-cycles for the splitting from one to six. Figures 5.1(a) and 5.1(b) show the convergence history for preconditioned GMRES for the block-diagonally preconditioned system and the related system, respectively. Note that the related system converges in significantly fewer iterations, for any choice of the number of V-cycles, demonstrating the performance difference between the two preconditioned systems.

We have also computed the eigenvalue perturbation and the eigenvalue bounds for both preconditioned systems, using up to nine V-cycles for the splitting, with the exact Schur complement. Figure 5.2(a) shows the maximum absolute eigenvalue perturbation from $\lambda \in \{1, \lambda_j^{\pm}\}$ for the block-diagonally preconditioned system (2.3), and Figure 5.2(b) shows the maximum absolute eigenvalue perturbation from 1 for the related system (3.4).



(a) Block-Diagonal Preconditioner (2.3).

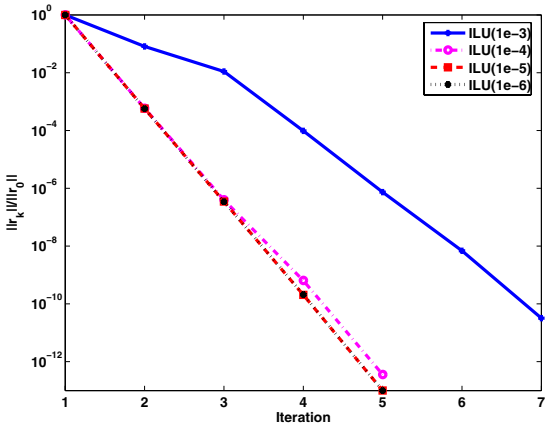


(b) Related System (3.4).

FIG. 5.2. *Maximum absolute eigenvalue perturbation and perturbation bounds, for both types of preconditioners, using the exact Schur complement and varying the number of V-cycles for the splitting.*

As we use a better splitting for A (more V-cycles), we see that the eigenvalue bound decreases with approximately the same rate as the corresponding eigenvalue perturbations, although the bound is pessimistic. This pessimism is mostly due to the $\kappa(\Theta)$ factor. Figure 5.2(b) includes an *estimate* of the perturbation for the related system, which consists of the bound in Corollary 3.2 with $\kappa(\Theta)$ replaced by one. Both the bound and our estimate follow the trend in the actual eigenvalue perturbation well as the number of V-cycles increases. The figure shows that the bounds and the estimate give good qualitative, respectively quantitative, descriptions of the eigenvalue perturbation as the splitting improves.

The eigenvalue perturbation bound for the related system (3.4) is much smaller than for the block-diagonally preconditioned system (2.3). However, the actual max-



(a) Using five V-cycles for the splitting of the (1,1) block and varying the approximate Schur complement.

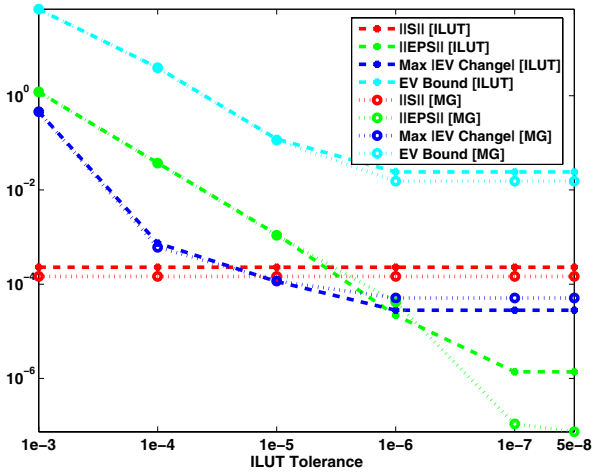
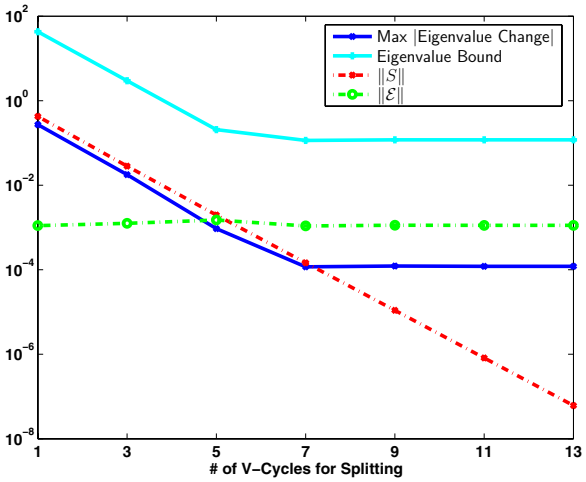
FIG. 5.3. *Convergence results for the related system using an approximate Schur complement.*

imum eigenvalue perturbation for both systems is about equal. For the related system, this represents a single eigenvalue cluster around 1, which means that the bound proves fast convergence for about 6 V-cycles or more, and the actual (max) perturbation indicates good convergence already for 1 V-cycle. On the other hand, for the block-diagonally preconditioned system, this represents $2m+1$ (potentially) distinct clusters around 1 and $\lambda_j^{\pm}$ for $j = 1, \ldots, m$. The existence of multiple clusters in this case, compared with the single cluster for the related system, explains the difference in their convergence behavior. These multiple clusters also explain the diminishing returns of improving the splitting for the block-diagonal preconditioner shown in



(a) Using seven V-cycles or ILUT(1e − 5) for the splitting and varying the approximate Schur complement.



(b) Using the approximate Schur complement with ILUT(1e − 5) and varying the number of V-cycles for the splitting.

FIG. 5.4. *The effects of* $\|S\|$ *and* $\|\mathcal{E}\|$ *on the related system using the approximate Schur complement.*

Figure 5.1(a). As we see similar differences between the preconditioners for the other test cases, we show results only for the related system for the remainder of this section.

We illustrate the convergence behavior for the preconditioner with an approximate Schur complement as a function of the accuracy of the approximation by using an ILUT decomposition [28]. While this may not be a practical choice, it serves our purposes for this paper because it allows us to progressively increase the accuracy of

TABLE 5.1

Effect of the number of grid points per dimension (n) on $\max_j |\delta_j|$ and the number of GMRES iterations for the related system (4.6) using a splitting of 5 V-cycles and various approximate Schur complements.

		Number of GMRES iterations			
n	$\max \lvert\delta_j\rvert$	ILUT(1e-3)	ILUT(1e-4)	ILUT(1e-5)	ILUT(1e-6)
4	1.72e+00	5	5	5	5
8	5.92e-01	5	4	4	4
16	1.60e-01	7	5	5	5
32	4.07e-02	13	6	5	5

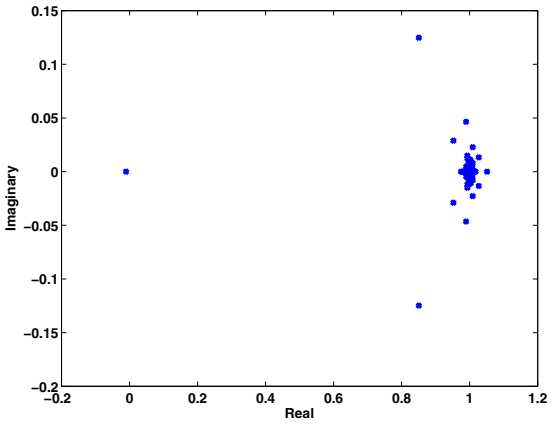
the approximation to the inverse of the Schur complement. We use drop tolerances ranging from $1e-3$ to $5e-8$.

Figures 5.3(a) and 5.3(b) show the effects of improving the splitting (for multigrid and ILUT) and the approximation to the Schur complement on the convergence of GMRES for the related system (4.6). First, in Figure 5.3(a), we vary the drop tolerance for the approximate Schur complement and fix the number of V-cycles for the splitting at five. Then, in Figure 5.3(b), we demonstrate a number of splittings using V-cycles and ILUT, and fix the drop tolerance at $1e-5$ for the approximate Schur complement. The convergence results are quite good, regardless of the choice of splitting.

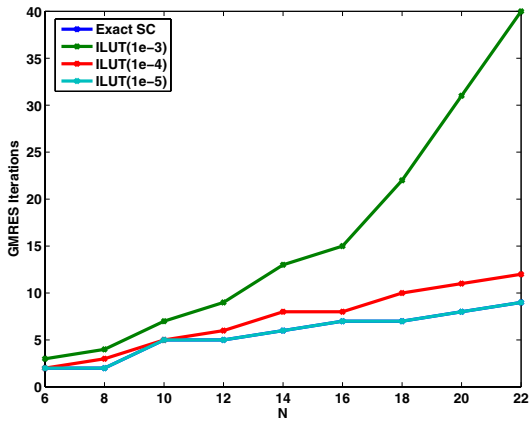
The convergence rates in Figures 5.3(a) and 5.3(b) hit a point of diminishing returns, past which improving either the splitting or the approximate Schur complement while leaving the other unchanged does not improve convergence. To explain this, we show the eigenvalue perturbations from 1 and the perturbation bound for the same example in Figure 5.4. In both plots, the eigenvalue perturbation (and bound) cease to decrease shortly after $\|S\|$ is less than $\|\mathcal{E}\|$ or vice versa. This demonstrates that the eigenvalue bound from Theorem 4.2 is indicative of the actual eigenvalue perturbation and the resulting convergence behavior, and that using a significantly more accurate splitting than approximate Schur complement, or vice versa, yields little additional benefit. Finally, note that for reasonable choices of splitting and approximation to the Schur complement the bounds are less than 1, indicating that the eigenvalues are clustered away from the origin. This should lead to rapid convergence for Krylov methods.

Varying the number of grid points per dimension, $n = 1/h$, gives some insight into how the convergence of the related system (4.6) depends on h. Table 5.1 summarizes these results. First, note that $|\delta_j|$ decreases with h. This leads to significant reductions of the factors involving δ_j in the theorems of sections 2, 3, and 4. In particular, with respect to Corollary 3.2 for the related system and Corollary 2.4 and Theorem 4.1 for the block-diagonal preconditioner, note that for small h the δ_j are nearly real. Moreover, note that the convergence of GMRES for the related system (4.6) depends only mildly on h. A good splitting and a reasonably accurate approximate Schur complement seem to lead to h-independent convergence.

5.2. Incompressible Stokes with spectral collocation. We will build discretizations with polynomials of degree up to 22 for this problem. The largest system will be of size 1241. We use an odd-even ordering for the velocity unknowns to exploit the orthogonality properties of Chebyshev polynomials and put the (1,1) block in block-diagonal form. We use ILUT with a drop tolerance of $1e-4$ for the splitting of the (1,1) block, and for the approximate Schur complement we use ILUT with a drop tolerance between $1e-3$ and $1e-5$. Figure 5.5(a) shows the eigenvalues of the



(a) Eigenvalues of related system for polynomial degree $N = 22$ using an approximate Schur complement with ILUT(1e − 4).



(b) GMRES iteration count versus maximum polynomial degree (N) for various approximate Schur complements. The iteration counts for the exact Schur complement coincide with those for the approximate Schur complement with ILUT(1e-5).

FIG. 5.5. *Eigenvalues and iteration counts for the related system* (4.6) *from spectral discretization of the incompressible Stokes equations with an ILUT*(1e−4) *splitting and an approximate Schur complement.*

related system for the largest problem, $N = 22$. Except for a single eigenvalue of $O(1e-2)$, the eigenvalues are tightly clustered around one. As expected, this leads to rapid convergence, as shown in Figure 5.5(b). Moreover, the GMRES iteration count for the related system with an approximate Schur complement (with the exception of ILUT(1e − 3)) shows only modest dependence on the maximum polynomial degree

N. Hence, even for fully asymmetric problems, our preconditioners are effective and show the potential of scaling well to larger problems.

6. Conclusions and future work. We have proposed and analyzed variants of indefinite preconditioners (the related system) and block-diagonal preconditioners for the $D \neq 0$ case, including the use of approximate Schur complements. We have illustrated their performance in terms of convergence, eigenvalue perturbations, and eigenvalue bounds using well-known model problems. Further analysis should help tighten the eigenvalue bounds, in particular using the consistency property of matrix norms less. We also aim to specialize our methods to particular problems. We are currently exploring applications from metal deformation, porous media flow, optimization, and electromagnetics.

Acknowledgments. We gratefully acknowledge the use of the software toolkit for a two-dimensional leaky lid-driven cavity problem developed by David Silvester in collaboration with Howard Elman, Bernd Fischer, Alison Ramage, and Andy Wathen.

We also gratefully acknowledge the reviewers for many suggestions that helped improve this paper.

STABILITY PROPERTIES OF THE PERONA–MALIK SCHEME*

SELIM ESEDOĞLU†

Abstract. The Perona–Malik scheme is a numerical technique for denoising digital images without blurring object boundaries (edges). In general, solutions generated by this scheme do not satisfy a comparison principle. We identify conditions under which two solutions initially ordered remain ordered, and we state (restricted) comparison principles. These allow us to study stability properties of the scheme. We also explore what these results say in the limit as the discretization size goes to 0.

1. Introduction.

Denoising is a fundamental procedure in digital image processing and an essential tool in many computer vision applications such as edge detection and segmentation. Its goal is to estimate a clean image from a given corrupted one. Mathematically, a two-dimensional grayscale image can be represented as a function $f(x)$ mapping a domain D in the plane (usually a rectangle, representing the computer screen) to the unit interval $[0, 1]$. The value of the function f at a given point $x \in D$ then represents the grayscale intensity (brightness) of the pixel found at that location: for instance, 0 can represent black, and 1 white. Image denoising tries to reduce, usually by some averaging operation, the rapid oscillations in f that are due to the presence of noise.

Partial differential equation (PDE) based image denoising models have enjoyed a great deal of success and have become very popular in the field. In this approach, the given noisy image f is taken to be the initial condition for some parabolic PDE, which is solved for a length of time chosen by the user. The solution at this later time is then taken to be the denoised version of the image. One of the first and most elementary denoising techniques, namely, convolution of the image by a Gaussian kernel, can be interpreted this way: it is the solution of the standard heat equation with the original noisy image taken as the initial condition, where the variance of the Gaussian kernel used is related to the length of time for which the PDE is solved. Although this is an effective denoising technique, it has the important disadvantage of blurring boundaries of objects (edges) in the image, where the function f has large gradients or a discontinuity. From an applications point of view, what is desired is a denoising method that can preserve sharp object boundaries.

In their seminal papers [6, 7], Perona and Malik proposed a numerical scheme for edge preserving image denoising that appears to be the finite difference discretization of a nonlinear diffusion equation which can become backward parabolic. The continuous in time version of their scheme has the following form:

$$\dot{u}_{i,j}(t) = D_1^- \left(R_\kappa \left(D_1^+ u_{i,j} \right) \right) + D_2^- \left(R_\kappa \left(D_2^+ u_{i,j} \right) \right), \tag{1}$$

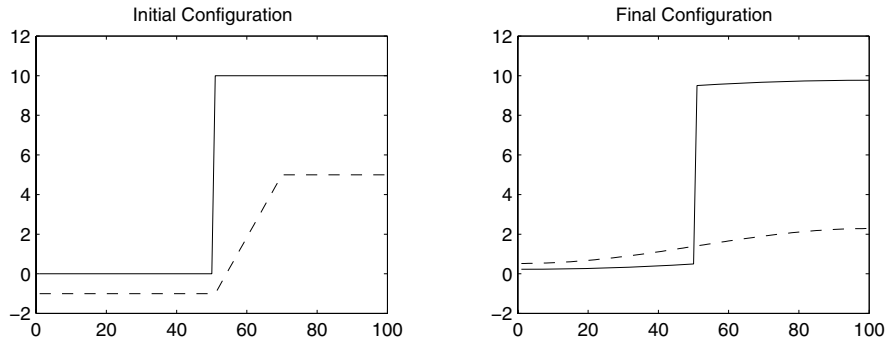

FIG. 1. *Violation of comparison principle. The solution represented by the dashed line remains in the well-posed (parabolic) regime at all times. Nevertheless, order is lost. It is very easy to understand why this happens: The dashed line has a small enough slope to be completely in the parabolic regime of scheme* (1)*, so that it is evolved essentially by the heat equation toward a constant state (its average). On the other hand, the solid line hardly evolves at all because its large gradient in the middle is far into the "edge preserving" regime of the scheme, where such "discontinuities" are maintained for large times by the scheme, which was designed precisely to behave as such.*

where D_m^+ and D_m^- are the standard forward and backward difference operators in the mth coordinate direction, and the function R_κ satisfies important properties which we explain in section 2. The indices i and j run over the pixels arranged in a two-dimensional uniform grid. In image processing literature, it is common to use either periodic or homogeneous Neumann boundary conditions so as to keep constant the total intensity of the image being processed.

The motivation of Perona and Malik in proposing their method (1) was to replace the standard heat equation with a nonlinear parabolic PDE which is designed to suppress diffusion at regions of large gradient, since such regions are likely to contain edges. Indeed, scheme (1) seems to be a natural discretization for the PDE

$$u_t = (R_\kappa(u_x))_x + (R_\kappa(u_y))_y. \tag{2}$$

The essence of Perona and Malik's technique is contained in the choice of the function $R_\kappa(\xi)$; the success of the scheme in preserving sharp edges (until they disappear) is due to this choice. But for the functions R_κ that Perona and Malik advocate in their papers, PDE (2) becomes backward parabolic in regions where the gradient of the solution is larger than some threshold that depends on the parameter κ. As such, there is no well-posedness theory for this PDE. That makes it interesting to investigate continuum limits (limits as $h \to 0$) for scheme (1). And understanding how the behavior of a denoising technique such as (1) depends on the discretization step size is important since it is very common to have the same image at various resolutions.

In this paper we state a *restricted* comparison principle for the semidiscrete Perona–Malik scheme (1). We note that a *restriction* of the kind we consider is necessary because the standard comparison result does not hold for scheme (1). We illustrate this easy-to-see fact by a simple numerical example (Figure 1). Subsequently, we apply the comparison principle to explore stability properties of the scheme at fixed discretization step size $h > 0$ and also in the limit $h \to 0^+$. We also expose some effects the precise shape of the function R_κ has on the behavior of the scheme.

In practice, scheme (1) exhibits much better stability properties than one would expect from backward diffusion equations [11], which are notoriously ill-posed. Moreover, it is extremely effective at its intended purpose. It has therefore become an intriguing issue to explain the better than expected stability properties of Perona and Malik's technique. Some aspects of this surprisingly tame behavior have been explained by previous authors; we believe with this paper we further our understanding of this problem.

Another interesting issue is what effects the precise shape of the nonlinear function R_κ has on the scheme. Perona and Malik, and subsequently many other authors, reported numerical experiments with a variety of choices (each of which conforms to the fundamental properties we listed in section 2), and on occasion mentioned differences in observed behavior [8]. Indeed, based on numerical experiments, even with functions R_κ that have identical parabolicity thresholds, the behavior can still be quite different. The results presented in this paper allow us to reveal and quantify some differences.

2. Perona–Malik scheme. As we remarked above, it is the choice of $R_\kappa(\xi)$ that distinguishes Perona and Malik's technique from previous techniques. In [6], they report numerical experiments using scheme (1) with

$$R_\kappa(\xi) = \frac{\xi}{1+\xi^2/\kappa} \text{ and } R_\kappa(\xi) = \xi \exp\left(\frac{-\xi^2}{\kappa}\right).$$

Other choices used in practice include

$$R_\kappa(\xi) = \xi\left(1+\frac{\xi^2}{\kappa}\right)^{(\beta-1)}, \text{ where } \beta \in \left(0, \frac{1}{2}\right).$$

These choices share the following essential characteristics:

1. $\xi R_\kappa(\xi) \geq 0$ for all ξ.
2. The parameter κ defines a positive critical value $z(\kappa)$ such that

$$R'_\kappa(\xi) \begin{cases} < 0 \text{ for } |\xi| > z(\kappa), \text{ and} \\ \geq 0 \text{ otherwise.} \end{cases} \tag{3}$$

3. $R_\kappa(\xi) \to 0$ as $|\xi| \to \infty$.

Figure 2 illustrates $R_\kappa(\xi)$ for such a choice. The desirable properties of the Perona–Malik scheme seem to hold in practice whenever the function $R_\kappa(\xi)$ in (1) satisfies the properties above. The results presented in this paper apply to (1) under all such choices of $R_\kappa(\xi)$.

In (2), R'_κ appears as the diffusion coefficient. Therefore, as we indicated in the previous section, the parameter κ constitutes a threshold value: when the gradient of grayscale intensity, $D_m^+ u_{i,j}$, is large compared to κ, (2) violates parabolicity.

Encouraged by favorable numerical results, some previous mathematical work on the Perona–Malik technique deals with understanding whether (2) can be given a well-posedness theory, so that the PDE (2) can be properly understood as the continuum limit of scheme (1). The paper [5] by Kichenassamy and the paper [4] by Kawohl and Kutev pursue this direction. The present work is drastically different from them in spirit: we do not try to understand (2) at all; instead, we deal directly with scheme (1) and study its properties. This is also the approach pursued in [2], where a continuum limit for (1) is established that differs from (2).

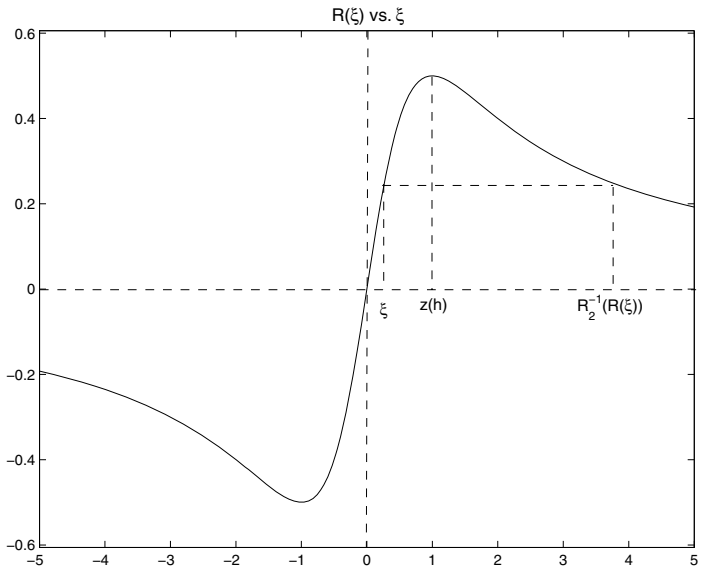

FIG. 2. *A typical choice for the function $R_h(\xi)$ that appears in the scheme. Here $R_h(\xi) = \xi/(1+\xi^2/h)$ with $h = 1$.*

Nevertheless, we make use of ideas from the work of these previous researchers; indeed, the motivation for this paper came from [4]. There, Kawohl and Kutev establish a restricted comparison principle for *continuum* solutions of (2). In this paper, we strive to find conditions under which two *discrete* solutions generated by the scheme (1) can be compared. In the end, however, we did not obtain direct discrete analogues of Kawohl and Kutev's results; the conditions and results in this paper are entirely different.

Let us note that computer vision is not the only context in which Perona–Malik-type equations and their associated issues come up. The recent paper [10] proposes a PDE model for granular flow that has much in common with the Perona–Malik equation and presents analysis directed at questions closely related to the ones raised in the image denoising literature.

Finally, we must mention that there are other very successful variational, edge preserving, image denoising techniques. One example is the total variation based image denoising model of Rudin, Osher, and Fatemi (ROF) [9]. Unlike the Perona–Malik scheme, the nonlinear PDE involved in this model has a well-understood theory, as it never becomes backward parabolic (although it can degenerate). Indeed, it is well known, for instance, that the nonlinear PDE that constitutes the essence of the ROF model (the total variation flow) is monotone (preserves the order of solutions) without the need for any restrictions such as the ones considered in this paper.

3. Comparison principle. We begin by introducing some notation. First, from now on the subscript κ in R_κ will be suppressed, but it will be understood that R comes with a parameter κ. Notice that for $y \notin \{-R(z(\kappa)), 0, R(z(\kappa))\}$, it holds that $R(\xi) = y$ for exactly two distinct values of ξ: one in $[-z(\kappa), z(\kappa)]$, and the other in $[-z(\kappa), z(\kappa)]^c$. We will denote by R_1 and R_2 the restriction of R to the domains

$[-z(\kappa), z(\kappa)]$ and $(-z(\kappa), z(\kappa))^c$, respectively:

$$R_1(\xi) := R(\xi)|_{[-z(\kappa),z(\kappa)]} \text{ and } R_2(\xi) := R(\xi)|_{(-z(\kappa),z(\kappa))^c}.$$

Then, R_1 and R_2 are one-to-one functions on their respective domains (the restriction is on the variable ξ); their inverses will be denoted R_1^{-1} and R_2^{-1}, respectively.

We will speak of the "jump set" $S(\phi)$ of a function $\{\phi_{i,j}\}$ defined on the grid; with that we mean the collection of indices defined by

$$S(\phi) := \left\{(i,j) : \max\left(\left|D_1^+\phi_{i,j}\right|, \left|D_2^+\phi_{i,j}\right|\right) \geq z(\kappa)\right\}.$$

Also, we adopt the terminology in [4] to say that ϕ is *supersonic* on $S(\phi)$ and *subsonic* elsewhere.

PROPOSITION 1. *Let $\{u_{i,j}(t)\}$ and $\{v_{i,j}(t)\}$ be solutions generated by the Perona–Malik scheme* (1)*, subject to Neumann boundary conditions. Assume that*

1. $|D_m^+ v_{i,j}(t)| < z(\kappa)$ *for all* (i,j), $t \in [0,T]$, *and* $m = 1, 2$, *and*
2. $|D_m^+ u_{i,j}(t)| \leq R_2^{-1}\left(R(|D_m^+ v_{i,j}(t)|)\right)$ *for all* (i,j), $t \in [0,T]$, *and* $m = 1, 2$.

Then if $\{u_{i,j}(t)\}$ and $\{v_{i,j}(t)\}$ are strictly ordered at $t = 0$, they remain ordered for all $t \in [0,T]$; i.e.,

1. *if* $u_{i,j}(0) > v_{i,j}(0)$, *then* $u_{i,j}(t) \geq v_{i,j}(t)$ *for all* $t \in [0,T]$, *and*
2. *if* $u_{i,j}(0) < v_{i,j}(0)$, *then* $u_{i,j}(t) \leq v_{i,j}(t)$ *for all* $t \in [0,T]$.

Proof. We treat only the first case $u_{i,j}(0) > v_{i,j}(0)$, the second case being completely analogous. Suppose the conclusion is false. Then there exists $t_0 \in (0,T]$ such that

$$\begin{aligned} &u_{i,j}(t) > v_{i,j}(t) \text{ for all } (i,j) \text{ and } t \in [0,t_0), \text{ and} \\ &u_{k,l}(t_0) = v_{k,l}(t_0) \text{ for some } (k,l). \end{aligned}$$

Consequently, $\dot{v}_{k,l}(t_0) - \dot{u}_{k,l}(t_0) \geq 0$, and hence

$$\begin{aligned} &D_1^- R\left(D_1^+ v_{k,l}(t_0)\right) - D_1^- R\left(D_1^+ u_{k,l}(t_0)\right) \\ &\quad + D_2^- R\left(D_2^+ v_{k,l}(t_0)\right) - D_2^- R\left(D_2^+ u_{k,l}(t_0)\right) \geq 0. \end{aligned}$$

Therefore,

$$\text{either } D_1^- R\left(D_1^+ v_{k,l}(t_0)\right) - D_1^- R\left(D_1^+ u_{k,l}(t_0)\right) \geq 0 \tag{4a}$$

$$\text{or } D_2^- R\left(D_2^+ v_{k,l}(t_0)\right) - D_2^- R\left(D_2^+ u_{k,l}(t_0)\right) \geq 0. \tag{4b}$$

Without loss of generality, assume that (4a) is true. That means that

$$R\left(D_1^+ v_{k,l}(t_0)\right) - R\left(D_1^+ u_{k,l}(t_0)\right) + R\left(D_1^+ u_{k-1,l}(t_0)\right) - R\left(D_1^+ v_{k-1,l}(t_0)\right) \geq 0. \tag{5}$$

But now, by hypotheses 1 and 2 of the proposition,

$$\left(R\left(D_1^+ v_{k,l}(t_0)\right) - R\left(D_1^+ u_{k,l}(t_0)\right)\right)\left(D_1^+ v_{k,l}(t_0) - D_1^+ u_{k,l}(t_0)\right) \geq 0, \tag{6a}$$

and

$$\begin{aligned} &\left(R\left(D_1^+ u_{k-1,l}(t_0)\right) - R\left(D_1^+ v_{k-1,l}(t_0)\right)\right) \\ &\quad \times \left(D_1^+ u_{k-1,l}(t_0) - D_1^+ v_{k-1,l}(t_0)\right) \geq 0. \end{aligned} \tag{6b}$$

Inequality (6a) can be verified by considering the three cases $R(D_1^+ u_{k,l}(t_0)) \in [-R_2^{-1}(R(|D_1^+ v_{k,l}(t_0)|)), -z(\kappa))$, and $R(D_1^+ u_{k,l}(t_0)) \in [-z(\kappa), z(\kappa)]$, and $R(D_1^+ u_{k,l}(t_0))$

$\in (z(\kappa), R_2^{-1}(R(|D_1^+ v_{k,l}(t_0))]$. Inequality (6b) can be verified by considering the analogous cases. By definition of t_0, we also have

$$\begin{aligned} D_1^+ v_{k,l}(t_0) - D_1^+ u_{k,l}(t_0) = D_1^+ \left(v_{k,l} - u_{k,l}\right)(t_0) \le 0, \text{ and} \\ D_1^+ u_{k-1,l}(t_0) - D_1^+ v_{k-1,l}(t_0) = D_1^+ \left(u_{k-1,l} - v_{k-1,l}\right)(t_0) \le 0. \end{aligned} \tag{7}$$

So we get, in particular,

$$\left(R\left(D_1^+ v_{k,l}(t_0)\right) - R\left(D_1^+ u_{k,l}(t_0)\right)\right) \times \left(R\left(D_1^+ u_{k-1,l}(t_0)\right) - R\left(D_1^+ v_{k-1,l}(t_0)\right)\right) \ge 0.$$

By (5),

$$\begin{aligned} R\left(D_1^+ v_{k,l}(t_0)\right) - R\left(D_1^+ u_{k,l}(t_0)\right) \ge 0, \\ R\left(D_1^+ u_{k-1,l}(t_0)\right) - R\left(D_1^+ v_{k-1,l}(t_0)\right) \ge 0. \end{aligned}$$

By (6a) and (6b) that means that

$$\begin{aligned} D_1^+ v_{k,l}(t_0) - D_1^+ u_{k,l}(t_0) \ge 0, \\ D_1^+ u_{k-1,l}(t_0) - D_1^+ v_{k-1,l}(t_0) \ge 0. \end{aligned} \tag{8}$$

Finally, (7) and (8) imply that

$$D_1^+ v_{j,l}(t_0) = D_1^+ u_{j,l}(t_0) \text{ for } j = k-1, k,$$

and thus

$$v_{j,l}(t_0) = u_{j,l}(t_0) \text{ for } j = k-1, k, k+1.$$

As a result, equality holds in (4a). Therefore, (4b) is also true. The same line of reasoning we used for (4a) now gives

$$v_{k,j}(t_0) = u_{k,j}(t_0) \text{ for } j = l-1, l, l+1.$$

Repetition of this argument (with k replaced by $k \pm 1$, l replaced by $l \pm 1$, and so on) gives

$$v_{i,j}(t_0) = u_{i,j}(t_0) \text{ for all } (i,j).$$

But then uniqueness of the solution to system (1) implies that

$$v_{i,j}(t) = u_{i,j}(t) \text{ for all } (i,j) \text{ and } t \ge t_0,$$

which proves the proposition. □

Remark. Proposition 1 has been stated and proved only on a two-dimensional grid for simplicity; the statement is true, and the proof works, with small modifications, for any space dimension.

Remark. It is not hard to check that the analogue of Proposition 1 holds for the discrete-in-time version of scheme (1), when forward Euler time steps are used with time step size satisfying $\delta t \le \frac{\min\{\delta x, \delta y\}^2}{4 \max\{1, \|R'\|_{L^\infty}\}}$, with δx and δy the uniform grid sizes in the two coordinate directions. Other statements in this paper can also be generalized to the fully discrete version of scheme (1).

Proposition 1 allows for comparison when one of the solutions is "smooth" (i.e., subsonic). In the case of one space dimension, we shall say a bit more: the next proposition allows for the comparison of more general one-dimensional signals. Its proof is a slight variation on that of Proposition 1. Its hypotheses will be justified in the next section, especially through Proposition 4. And eventually, it will find an application in section 4.3, where we will consider the behavior of scheme (1) as $h \to 0^+$.

PROPOSITION 2. *Let $\{u_j(t)\}$ and $\{v_j(t)\}$ be one-dimensional solutions generated by the Perona–Malik scheme* (1)*, subject to Neumann boundary conditions. Assume that*

1. $S(v(t)) = S(v(0)) := \{p_1, \dots, p_n\} \subseteq S(u(t))$ *for all* $t \in [0,T]$,
2. $|D^+u_j(t)| \le R_2^{-1}(R(|D^+v_j(t)|)$ *for all* $j \notin S(v(0))$ *and* $t \in [0,T]$, *and*
3. $sign(u_i(0) - v_i(0)) = sign(u_j(0) - v_j(0))(-1)^{k-k'} \neq 0$ *for* $i \in \{p_k + 1, \dots, p_{k+1}\}$ *and* $j \in \{p_{k'} + 1, \dots, p_{k'+1}\}$.

Then, for all $t \in [0,T]$ *we have*

$$\big(u_j(t) - v_j(t)\big)\big(u_j(0) - v_j(0)\big) \ge 0.$$

Proof. The conclusion is satisfied for some positive time by continuity; suppose that it fails for the first time at $t = t_0 < T$ and at index k. Without loss of generality, let us assume that $u_k(0) > v_k(0)$. Define $\alpha : \mathbf{Z} \to \{0,1\}$ as follows:

$$\alpha(j) := \begin{cases} 1 \text{ if } j \in S(v(0)), \\ 0 \text{ otherwise.} \end{cases}$$

By definitions of t_0 and k, and by hypothesis 3, we have

$$\begin{aligned} \big(D^+u_k(t_0) - D^+v_k(t_0)\big)(-1)^{\alpha(k)} &\ge 0, \\ \big(D^+u_{k-1}(t_0) - D^+v_{k-1}(t_0)\big)(-1)^{\alpha(k-1)} &\le 0. \end{aligned} \tag{9}$$

Hypothesis 2 implies, as in the proof of Proposition 1, that

$$\big(R(D^+u_j(t)) - R(D^+v_j(t))\big)\big(D^+u_j(t) - D^+v_j(t)\big) \ge 0 \text{ if } j \notin S(v(0)). \tag{10}$$

On the other hand, if $j \in S(v(0))$, then $|D^+u_j|, |D^+v_j| \ge z(\kappa)$; and since R is decreasing on $(-z(\kappa), z(\kappa))^c$ we get

$$\big(R(D^+u_j(t)) - R(D^+v_j(t))\big)\big(D^+u_j(t) - D^+v_j(t)\big) \le 0 \text{ if } j \in S(v(0)). \tag{11}$$

We can summarize (10) and (11) as

$$\big(R(D^+u_j(t)) - R(D^+v_j(t))\big)\big(D^+u_j(t) - D^+v_j(t)\big)(-1)^{\alpha(j)} \ge 0. \tag{12}$$

Furthermore, the definition of t_0 implies that

$$\begin{aligned} \dot{u}_k(t_0) - \dot{v}_k(t_0) &= R(D^+u_k(t_0)) - R(D^+v_k(t_0)) \\ &\quad - R(D^+u_{k-1}(t_0)) + R(D^+v_{k-1}(t_0)) \\ &\le 0. \end{aligned} \tag{13}$$

But now, (9) and (12) mean that

$$\big(R(D^+u_k(t_0)) - R(D^+v_k(t_0))\big) \times \big(R(D^+v_{k-1}(t_0)) - R(D^+u_{k-1}(t_0))\big) \ge 0. \tag{14}$$

Combined with (13), (14) implies that

$$\begin{aligned} R(D^+u_k(t_0)) - R(D^+v_k(t_0)) &\le 0, \\ R(D^+v_{k-1}(t_0)) - R(D^+u_{k-1}(t_0)) &\le 0. \end{aligned} \tag{15}$$

In light of (12), these inequalities lead to the following conclusion:

$$\begin{aligned} \left(D^+u_k(t_0) - D^+v_k(t_0)\right)(-1)^{\alpha(k)+1} &\ge 0, \\ \left(D^+u_{k-1}(t_0) - D^+v_{k-1}(t_0)\right)(-1)^{\alpha(k-1)} &\ge 0. \end{aligned} \tag{16}$$

But then, (16) and (9) give

$$D^+\left(u_j(t_0) - v_j(t_0)\right) = 0 \text{ for } j = k-1, k$$

so that

$$u_j(t_0) = v_j(t_0) \text{ for } j = k-1, k, k+1.$$

That, much like in the proof of Proposition 1, leads to the conclusion of the proposition. □

4. Applications. The comparison principles stated and proved in the previous section are simply tools; indeed, their hypotheses require knowledge of the solutions involved for all time. Here, in section 4.1, we use them to state some down-to-earth results, such as the stability property that is the content of Theorem 5. Then, in section 4.2, we give concrete examples of how those results can be applied in practice. Section 4.3 is devoted to exploring what these results say in the limit as $h \to 0^+$.

4.1. Stability results. We begin by recording a few simple but important properties of scheme (1) that will help us apply Propositions 1 and 2.

LEMMA 3. *Let $\{u_{i,j}(t)\}$ be the solution generated by scheme* (1) *from subsonic initial data. Then*

$$\sup_{i,j,t} |D_m^+ u_{i,j}(t)| \le \sup_{i,j} |D_m^+ u_{i,j}(0)| \text{ for each } m = 1, 2.$$

Proof. It is easy to see that in the subsonic regime, scheme (1) satisfies a maximum principle for difference quotients. This in turn prevents the solution from entering the supersonic regime if the initial data is subsonic. The conclusion of the lemma follows. □

In what follows, we will often specialize to the one-dimensional version of the Perona–Malik scheme (1), which then reduces to

$$\dot{u}_j(t) = D^-\left(R_\kappa\left(D^+u_j\right)\right). \tag{17}$$

Next, we recall an important property of scheme (17): supersonic regions shrink in time.

PROPOSITION 4. *Let $\{u_j(t)\}$ be a solution generated by scheme* (17). *Then $S(u(t_2)) \subseteq S(u(t_1))$ whenever $0 \le t_1 \le t_2$.*

Proof. See [3], where it first appeared, or [2]. □

Remark. The conclusion of Proposition 4 is false in two dimensions: supersonic regions can grow, as shown by the numerical experiment in Figure 3.

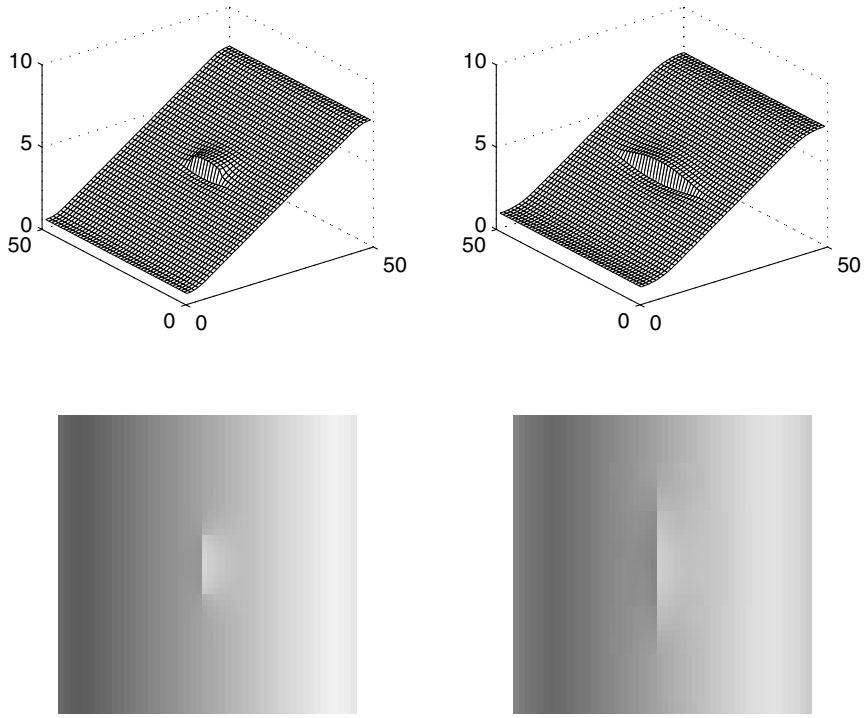

FIG. 3. *Jump set (or the supersonic regime) can grow in two dimensions. Here, a small "crack" in the initial data propagates.*

Our first application deals with subsonic data corrupted by low amplitude noise. We estimate the difference between the evolutions of corrupted and uncorrupted data in terms of the amplitude of the noise. The hypotheses of Proposition 1 involve all $t \geq 0$. We will use in our proof comparison functions that will bound, one from above and the other from below, the solution generated from the corrupted data. As we shall explain, these comparison functions will satisfy the hypotheses of Proposition 1 automatically for all time. Moreover, their definitions will involve only the uncorrupted initial data.

THEOREM 5. *Let $\{\phi_{i,j}\}$ be subsonic initial data, i.e.,*

$$M := \max_{i,j,m} |D_m^+ \phi_{i,j}| < z(\kappa).$$

Let $\{u_{i,j}(t)\}$ be the solution generated by scheme (1) *from $\{\phi_{i,j}\}$, and let $\{u_{i,j}^n(t)\}$ be the one generated from $\{(\phi + n)_{i,j}\}$. If*

$$\max_{i,j} |n_{i,j}| < \frac{h}{2} \left(R_2^{-1} \left(R(M) \right) - M \right),$$

then

$$\max_{i,j} \left| u_{i,j}^n(t) - u_{i,j}(t) \right| \leq \max_{i,j} |n_{i,j}| \ \textit{for all } t \geq 0.$$

Proof. Fix a $\delta > 0$ such that

$$\max_{i,j} |n_{i,j}| < \delta < \frac{h}{2}\left(R_2^{-1}\left(R(M)\right) - M\right).$$

The upper and lower comparison functions, which we shall denote by $v^-_{i,j}(t)$ and $v^+_{i,j}(t)$, respectively, will simply be

$$v^{\pm}_{i,j}(t) := u_{i,j}(t) \pm \delta. \tag{18}$$

Then $v^{\pm}_{i,j}(t)$ are clearly solutions of (1). Furthermore, $u^n_{i,j}(0) \in (v^-_{i,j}(0), v^+_{i,j}(0))$. Since the initial condition $\phi_{i,j}$ is subsonic, by Lemma 3, $u_{i,j}(t)$ and therefore also $v^{\pm}_{i,j}(t)$ are subsonic for all time. Thus, hypothesis 1 in Proposition 1 is satisfied. Moreover, again by virtue of Lemma 3, we have

$$\max_{i,j,m,t} |D^+_m u_{i,j}(t)| = \max_{i,j,m,t} |D^+_m v^{\pm}_{i,j}(t)| = M. \tag{19}$$

Also, the inequality in hypothesis 2 of Proposition 1 is *strictly* satisfied at $t = 0$ since

$$|D^+_m u^n_{i,j}(0)| \le |D^+_m u_{i,j}(0)| + \frac{2}{h}\max_{i,j}|n_{i,j}| < R_2^{-1}(R(M)) \le R_2^{-1}\left(R(|D^+_m u_{i,j}(0)|)\right)$$

by our assumption on the amplitude of the noise $n_{i,j}$. We will now show that in fact hypothesis 2 is strictly satisfied for all time. Suppose not; then there exists $t_0 > 0$ such that

$$\left|D^+_m u^n_{i,j}(t)\right| < R_2^{-1}\left(R\left(|D^+_m u_{i,j}(t)|\right)\right)$$

for all (i,j), $m \in \{1,2\}$, and $t \in [0, t_0)$, and

$$\left|D^+_m u^n_{k,l}(t_0)\right| = R_2^{-1}\left(R\left(|D^+_m u_{k,l}(t_0)|\right)\right)$$

for some (k,l) and some $m \in \{1,2\}$. By (19), that means that

$$\left|D^+_m u^n_{k,l}(t_0)\right| \ge R_2^{-1}\left(R(M)\right). \tag{20}$$

We also have

$$\begin{aligned} \left|D^+_m u^n_{k,l}(t_0)\right| &\le \left|D^+_m (u^n - u)_{k,l}(t_0)\right| + \left|D^+_m u_{k,l}(t_0)\right| \\ &\le \left|D^+_m (u^n - u)_{k,l}(t_0)\right| + M \end{aligned} \tag{21}$$

again by (19). Combining (20) and (21) we get

$$\left|D^+_m (u^n - u)_{k,l}(t_0)\right| \ge R_2^{-1}\left(R(M)\right) - M > \frac{2\delta}{h}.$$

That means we have

$$\left|u^n_{i,j}(t_0) - u_{i,j}(t_0)\right| > \delta \text{ for some } (i,j) \in \{k, k+1\} \times \{l, l+1\}. \tag{22}$$

On the other hand, since both hypotheses of Proposition 1 are satisfied on $t \in [0, t_0)$, we have

$$v^-_{i,j}(t) \le u^n_{i,j}(t) \le v^+_{i,j}(t) \text{ for all } t \in [0, t_0)$$

and, by continuity, also at $t = t_0$. Combined with (18) this means

$$\left|u^n_{i,j}(t_0) - u_{i,j}(t_0)\right| \le \delta \text{ for all } (i,j),$$

which contradicts (22). ∎

An immediate consequence of Theorem 5 is the following elementary corollary, which is, unlike the theorem, one-dimensional. It tells us that a smooth one-dimensional signal corrupted by low amplitude noise is rapidly denoised and provides an upper bound on the denoising time.

COROLLARY 6. *Let ϕ_j, n_j, u_j, u^n_j, and M be as in Theorem 5, and assume that n_j satisfies the hypothesis of that theorem. If we set*

$$T := \inf\{t_0 \ge 0 : S(u^n) \text{ is empty for all } t \ge t_0\},$$

then we have the estimate

$$T \le \frac{2\max_j |\phi_j + n_j|}{R\left(\frac{2}{h}\max_j |n_j| + M\right)}.$$

Proof. The interesting case is when $S(u^n(0))$ is nonempty; under that assumption, for any $\delta > \max_j |n_j|$ we have $2\delta/h + M > z(\kappa)$. Fix an $\varepsilon > 0$ small enough so that

$$R\left(z(\kappa) - \varepsilon\right) > R\left(\frac{2\delta}{h} + M\right).$$

For $k \in S(u^n(0))$, let

$$T^\varepsilon_k := \inf\left\{t \ge 0 : |D^+ u^n_k(t)| = z(\kappa) - \varepsilon\right\}.$$

In view of Proposition 4, we have

$$T < \max_k T^\varepsilon_k.$$

So fix a $k \in S(u^n(0))$; without loss of generality, we may assume that $D^+u^n_k(0) > 0$. By Theorem 5,

$$D^+ u^n_k(t) < \frac{2\delta}{h} + M \text{ for all } t \ge 0.$$

Furthermore, since R is a decreasing function on $[z(\kappa), \infty)$, for $t \in [0, T^\varepsilon_k]$ we have

$$z(\kappa) - \varepsilon \le D^+ u^n_k(t) < \frac{2\delta}{h} + M \Rightarrow R(D^+u^n_k(t)) > R\left(\frac{2\delta}{h} + M\right). \tag{23}$$

That gives

$$\frac{d}{dt}\sum_{j=1}^{k} h\left(\max_j |\phi_j + n_j| - u^n_j\right) = -R(D^+u^n_k) \le -R\left(\frac{2\delta}{h} + M\right),$$

where the inequality follows via (23) for as long as $t \in [0, T^\varepsilon_k]$. Also, since $|u^n_k(t)| \le \max_j |\phi_j + n_j|$ for all $t \ge 0$, we have

$$2\left(\max_j |\phi_j + n_j|\right) - T^\varepsilon_k R\left(\frac{2\delta}{h} + m\right) \ge 0.$$

Letting $\delta \to \max_j |n_j|$ from above leads to the desired inequality. ∎

4.2. Examples. In this section, we apply the results of the previous subsection in some practical situations.

Example 1. Take the function in Figure 4. It has maximum slope $M = 4$. The Perona–Malik scheme (17) is applied using the choice

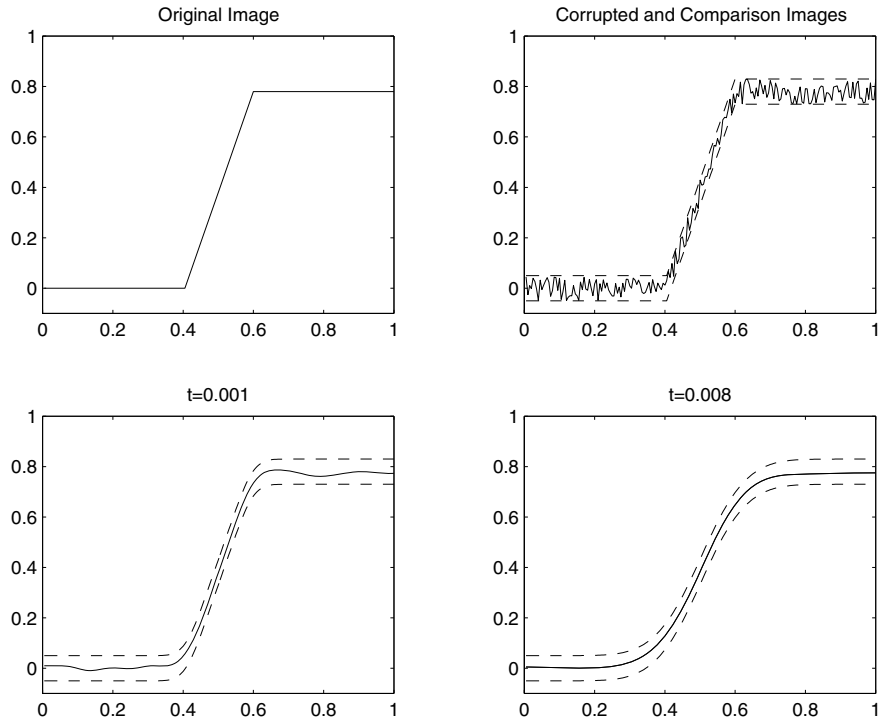

FIG. 4. *An application of the comparison principle. The corrupted initial data (which is not subsonic) quickly becomes subsonic, and no artificial "edges" are introduced. The noise amplitude here is* 0.05*, and the maximum amplitude allowed by Theorem* 5 *is* 0.0525*.*

$$R(\xi) = \frac{\xi}{1 + \frac{\xi^2}{100}} \tag{24}$$

for the nonlinear function appearing in the scheme. According to this choice, the threshold value of slope is $z(\kappa) = 10$. We calculate the maximum noise amplitude allowed by Theorem 5 to be 0.0525. The corrupted signal in the example of Figure 4, which is not subsonic, was obtained by adding noise of amplitude 0.05 to the original signal.

The evolution shown in Figure 5 is obtained by adding a specific perturbation of amplitude 0.06 to the original signal. We see how the comparison principle gets violated.

Example 2. We now compare the effects of the precise shape of the function $R(\xi)$ on the behavior of the scheme, by using the same original image as in our first example, but the different nonlinear function

$$R(\xi) = \xi \exp\left(-\frac{\xi^2}{200}\right), \tag{25}$$

which has the same threshold value of the slope as for (24) of the first example, namely, $z(\kappa) = 10$. The maximum amplitude of noise allowed by Theorem 5 this time (for $R(\xi)$ given by (25)) turns out to be between 0.034 and 0.03425—significantly smaller than that for (24).

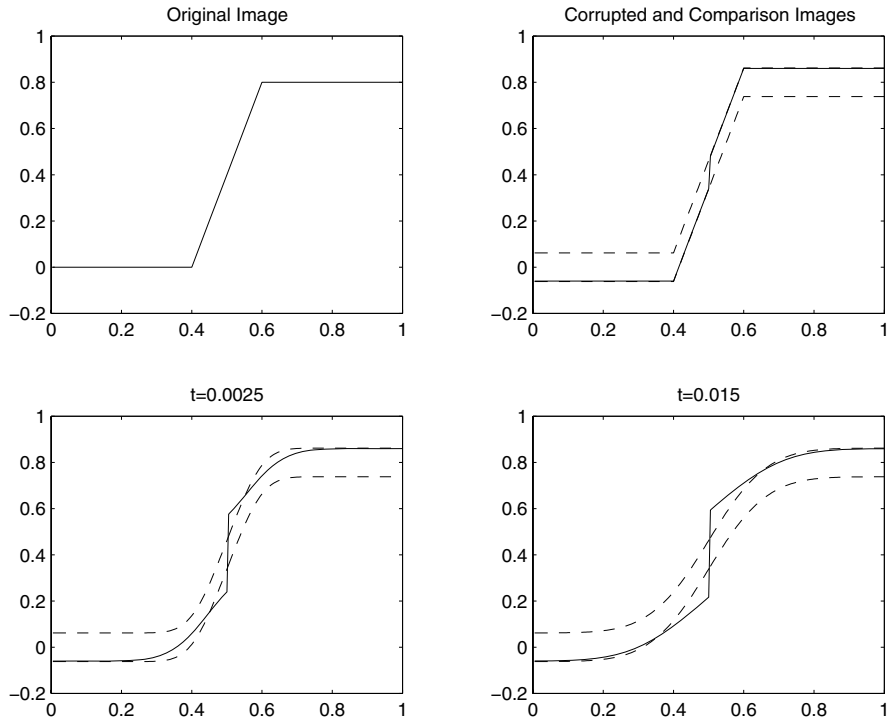

FIG. 5. *Effects of a perturbation with a (deliberately chosen) noise of amplitude that exceeds the maximum amplitude allowed. Here, the noise amplitude is* 0.06*, higher than what Theorem* 5 *allows, which is* 0.0525*. The result is an artificial "edge."*

Theorem 5 thus suggests a way to quantify the difference in stability properties of scheme (1) with respect to the two choices of $R_\kappa(\xi)$. It is easy to see that this difference is important; we illustrate it with a numerical example: Figure 6 shows the evolution of the original image perturbed by a (contrived) noise of amplitude 0.05 under scheme (17) using the two choices for $R(\xi)$ given in (24) and (25). We emphasize again that although the two choices of R are different, the value of κ in each case has been chosen so that the critical points of the two functions (that determine boundary of sub- and supersonic regions) are the same. However, the perturbation amplitude 0.05 is above the allowed limit for (25), and below it for (24). The evolutions can then be seen to be very different. The perturbation used in this and the previous example simply consisted of shifting the graph of the initial condition along $x \geq 0$ by a small amount, so as to introduce a "tear" in the middle of the graph where the gradient of the unperturbed initial condition is largest.

4.3. Limit as $h \to 0^+$. In [2], the continuum limit of scheme (17) is investigated with the function $R_\kappa(\xi)$ given by

$$R_\kappa(\xi) = \xi \left(1 + \frac{\xi^2}{\kappa}\right)^{(\beta-1)}, \text{ where } \beta \in \left[0, \frac{1}{2}\right). \tag{26}$$

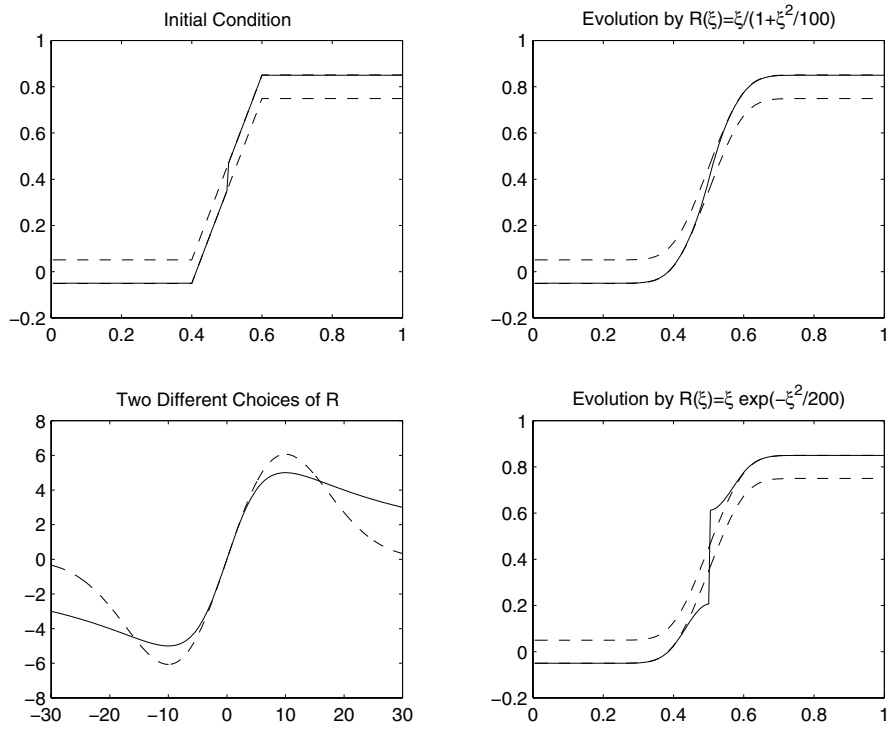

FIG. 6. *Evolution via different choices for the function R_κ. The upper left-hand figure illustrates the initial signal and comparison functions; the initial signal was obtained from that of Example* 1 (*Figure* 4) *after modifying by a deliberately chosen perturbation. The lower left-hand figure shows the two distinct choices for the function $R(\xi)$ used in this example: The dashed line is the graph of $R(\xi) = \xi \exp(-\xi^2/200)$, and the solid line is the graph of $R(\xi) = \xi/(1 + \xi^2/100)$. The second column shows the evolution of the initial image and comparison functions with $R(\xi) = \xi/(1+\xi^2/100)$ and $R(\xi) = \xi \exp(-\xi^2/200)$ (comparison functions are shown with dashed lines). For both of these functions, $z(\kappa) = 10$.*

When $\beta \in (0, \frac{1}{2})$ the evolution that (17) generates is the gradient descent for the discrete energy

$$\mathbf{E}_u^h(t) := \sum_j h\Phi_{\kappa,\beta}\left((D^+u_j(t))^2\right), \tag{27}$$

where

$$\Phi_{\kappa,\beta}(\xi) := \frac{\kappa}{\beta}\left(\left(1 + \frac{\xi}{\kappa}\right)^\beta - 1\right). \tag{28}$$

The continuum limit studied in [2] is obtained by scaling the parameter κ (and hence the threshold point $z(\kappa)$) with respect to the discretization step size h as follows:

$$\kappa(h) = h^{(2\beta-1)/(1-\beta)} \Rightarrow z(h) := \frac{1}{\sqrt{1-2\beta}} h^{(2\beta-1)/(2-2\beta)}. \tag{29}$$

Such scalings were studied previously in the stationary setting by Chambolle in [1] to obtain interesting continuum limits for discrete energies similar to (27); the approach

taken in [2] follows Chambolle's lead in adjusting the threshold z with respect to the grid size h but concerns the time dependent problem. The resulting evolution is defined for piecewise smooth one-dimensional signals; it takes place on a domain that changes at discrete times and is described as follows.

For a given piecewise smooth initial data $\phi : [0,1] \to [0,1]$ with jump discontinuities at $p_1, \dots, p_N \in (0,1)$, we solve the linear heat equation $u_t = u_{xx}$ on the domain $(0,1) - \{p_1, \dots, p_N\}$, subject to homogeneous Neumann boundary conditions at $x = 0$ and $x = 1$, and to the nonlinear boundary conditions

$$u_x(p_j^{\pm}, t) = \big(u(p_j^+, t) - u(p_j^-, t)\big)\,\big|u(p_j^+, t) - u(p_j^-, t)\big|^{2\beta-2} \tag{30}$$

at the discontinuity points. The condition (30) *becomes singular whenever one of the discontinuities, say, the one at p_j, heals (i.e., when $u(p_j^+, t) = u(p_j^-, t)$); at such special times, we merge the two intervals (p_{j-1}, p_j) and (p_j, p_{j+1}) into one longer interval (p_{j-1}, p_{j+1}) and continue the evolution according to the heat equation on the new (and smaller) collection of intervals.*

The claim is that the numerical solutions generated by scheme (17) converge, as $h \to 0$, to the continuum evolution described above, provided that the threshold $z(\kappa)$ is scaled with respect to h according to formula (29), and that the approximate (discrete) initial data ϕ^h converge to the continuum data ϕ in some suitable sense. The proof in [2] for this statement involves a number of technical hypotheses. One of the most restrictive among them requires the "jump sets" of $\phi^h$and ϕ to be *compatible*: it is assumed that $S(\phi^h)$ and $\{p_1, \dots, p_N\}$ are in one-to-one correspondence.

A discussion of the most general conditions under which convergence takes place would be very technical and out of place. But, as an application of Proposition 2, we will show that under suitable hypotheses, the jump sets $S(\phi^h)$ of the approximate initial data become compatible with $\{p_1, \dots, p_N\}$ after an arbitrarily small initial interval of time. To that end, let $\{h_n\}_{n=1}^{\infty}$ be a sequence of positive numbers such that $h_n \to 0$ as $n \to \infty$, and let $x_j^{h_n}$ denote the grid points for the uniform discretization size h_n. Assume that a sequence ϕ^{h_n} of discrete initial data satisfies

$$\lim_{n\to\infty} \max_j \left|\phi_j^{h_n} - \phi(x_j^{h_n})\right| = 0.$$

Then we have the following result.

THEOREM 7. *Let $\{u^{h_n}(t)\}_n$ be the discrete solutions generated from $\{\phi^{h_n}\}_n$ by scheme* (17)*, where R is given by* (26) *and κ is scaled as in* (29)*. Then, given any $\varepsilon > 0$, there exists $K \in \mathbf{N}$ such that for any $n > K$ the following property holds at some $t \in [0, \varepsilon)$:*

$$|D^+ u_j^{h_n}(t)| \geq z(\kappa) \text{ only if } \{p_1, \dots, p_N\} \cap [x_j^{h_n}, x_{j+1}^{h_n}] \text{ is nonempty.}$$

Proof. The jump sets of initial data ϕ^{h_n} can be much larger than that of ϕ; the idea is to construct comparison functions $\psi^{n,\pm}$ whose jump sets precisely match $\{p_1, \dots, p_N\}$, and then compare using Proposition 2. We first define

$$M := \max_i \max_{x \in (p_i, p_{i+1})} |\phi'(x)|, \qquad m := \min_i \left|\phi(p_i^+) - \phi(p_i^-)\right|,$$

$$\tilde{S}_n := \left\{ j \in \mathbf{N} : \left| D^+ \phi_j^{h_n} \right| \geq \frac{m}{2h_n} \right\}, \qquad \alpha(j) := \sharp \left\{ i \in \tilde{S}_n : i < j \right\}.$$

Convergence of the approximate initial data ϕ^{h_n} to ϕ uniformly on the grid implies

that for large enough n we have

$$\begin{aligned} &j \in \tilde{S}_n \Rightarrow p_i \in [x_j, x_{j+1}] \text{ for some } i, \text{ and} \\ &p_i \in [x_j, x_{j+1}] \Rightarrow \{j, j+1\} \cap \tilde{S}_n \neq \emptyset. \end{aligned} \tag{31}$$

For $\delta \in (0, \frac{m}{4})$, we construct the pair of comparison functions $\psi^{n,\pm}(t)$ via scheme (17) from the following initial data:

$$\psi_j^{n,\pm}(0) = \phi(x_j^{h_n}) \pm \delta(-1)^{\alpha(j)}.$$

Then, $\psi^{n,\pm}(0)$ satisfy the following properties:

$$S\left(\psi^{n,\pm}(0)\right) = \tilde{S}\left(\phi^{h_n}\right), \tag{32a}$$

$$\sharp S(\psi^{n,\pm}(0)) = N, \text{ and} \tag{32b}$$

$$\sup_n \mathbf{E}^{h_n}_{\psi^{n,\pm}}(0) < \infty. \tag{32c}$$

Furthermore,

$$\limsup_{n\to\infty} \max_{j \notin S(\psi^{n,\pm})} \left|D^+\psi^{n,\pm}\right| = M < \infty. \tag{32d}$$

We recall a few points from [2]: First, by virtue of property (32c), the evolutions $\{\psi^{n,\pm}(t)\}_n$ are Hölder continuous in time with values in L^∞ of space, *uniformly* in n. Moreover, the difference quotients of $\psi^{n,\pm}(t)$ satisfy the maximum principle on the complements of their jump sets, while the jump sets remain constant. In light of these comments and of Proposition 4, we can determine a $T > 0$ so that for all $t \in [0, T]$ the following hold:

$$S(\psi^{n,\pm}(t)) = S(\psi^{n,\pm}(0)), \tag{33a}$$

$$\max_{j \notin S(\psi^{n,\pm})} \left|D^+\psi^{n,\pm}(t)\right| \leq 2M. \tag{33b}$$

The dependence of κ on h_n, as prescribed in (29), implies that

$$C := \liminf_{n\to\infty} h_n R_2^{-1}\left(R(2M)\right) > 0 \tag{33c}$$

so that, by (33b) for large enough n,

$$R_2^{-1}\left(R(D^+\psi_j^{n,\pm}(t))\right) > \frac{C}{2h_n} \text{ for all } j \notin S\left(\psi_j^{n,\pm}(0)\right) \text{ and } t \in [0, T]. \tag{33d}$$

Choose $\delta < C/4$. For large enough n, we will certainly have

$$(-1)^{\alpha(j)}\psi_j^{n,-}(t) < u_j^{h_n}(t) < (-1)^{\alpha(j)}\psi_j^{n,+}(t) \tag{33e}$$

for some positive time. Then (32a), (33a), and (33e) verify hypotheses 1 and 3 of Proposition 2 for positive time. Meanwhile, (33d), (33e), and the choice of δ verify hypothesis 2 of Proposition 2 at $t = 0$. But as in the proof of Theorem 5, since (33d) holds for all $t \in [0, T]$, these are sufficient to ensure that the three hypotheses of Proposition 2 are satisfied for all $t \in [0, T]$ and lead to the conclusion that we want:

$$(-1)^{\alpha(j)}\psi_j^{n,-}(t) \leq u_j^{h_n}(t) \leq (-1)^{\alpha(j)}\psi_j^{n,+}(t) \text{ for all } t \in [0, T]. \tag{34}$$

At this stage, it is possible to repeat the proof of Corollary 6 to get an estimate of how quickly jumps of height less than 2δ vanish; the upper bound one obtains goes to 0 when we send first $n \to \infty$ and then $\delta \to 0$. □

Remark. In some sense, Theorem 7 says that given an initial piecewise smooth signal corrupted by noise (i.e., a signal with a few large and many small jumps), the Perona–Malik scheme denoises the signal by quickly removing the small jumps and maintaining the large ones. This stability property hinged on inequality (33c) in our proof, and is a result of the choice of the constitutive function (26) and scaling (29). It is in contrast to the different function and scaling considered in [3] that lead to a different continuum limit for which such a stability property is not to be expected.

Remark. As h gets smaller, the hypotheses of the discrete comparison principles discussed in this paper get more restrictive. In fact, if h is sent to 0 while κ is fixed, we arrive at the Perona–Malik PDE (2), to which our arguments do not extend. However, scaling (29) implies that $z(h) \to \infty$ as $h \to 0^+$ (albeit at a slower rate than $1/h$). This allows for some form of the restricted comparison principle to be maintained in the limit; it allowed us to state Theorem 2, which concerns a continuum evolution.

Acknowledgment. The author would like to thank his former advisor Robert V. Kohn for his continuing attention and encouragement.

MATRIX-FREE INTERPOLATION ON THE SPHERE*

M. GANESH† AND H. N. MHASKAR‡

Abstract. We study a subspace of bivariate trigonometric polynomials for interpolating functions on the sphere. We give an explicit construction for a system of interpolation nodes, and the corresponding basis for this space, that allows a (discrete) fast Fourier transform-type formula for the interpolant. We prove that the uniform norm of our interpolation operator is of the order $(\log M)^2$, where M is the number of interpolation points. We also construct a minimal quadrature rule for our space (with a number of points equal to the dimension of the space), and describe an associated interpolation operator.

Key words. sphere, interpolation, discrete orthogonal projection, minimal quadrature

1. Introduction.

Approximation of differentiable functions on the sphere and analysis of the error in the uniform norm are important ingredients for solving partial differential equations on spherical geometries [4, 5, 6]. Advances in approximation theory on the sphere are required, for example, to measure earth's atmospheric flow and gravitational potential, to simulate sound waves scattered by spherical geometries, to identify the shape of the scattering objects, and for image reconstructions in cosmology.

One popular strategy for approximation of functions is interpolation. Construction of an interpolatory approximation to an unknown function f defined on a set Ω consists of (i) designing a set of nodes $x_j \in \Omega$ and a class of functions ϕ_j defined on Ω, $j = 1, \dots, M$, that forms a basis for a space V and (ii) computing an approximant $I_M f = \sum_{j=1}^{M} a_j(f)\phi_j \in V$ such that $I_M f(x_k) = f(x_k), k = 1, \dots, M$. The matrix $\mathbf{A} := [\phi_j(x_k)]_{j,k=1,\dots,M}$ is called the *interpolation matrix*. We say that $\{x_1, \dots, x_M\}$ is a *set of uniqueness* for V if $\mathbf{A}$ is invertible, or equivalently, for $v \in V$, the fact that $v(x_k) = 0$ for $k = 0, \dots, M$ implies that $v \equiv 0$. It is clear that the vector $\mathbf{a}$ of coefficients in $I_M f$ satisfies the matrix equation

$$\mathbf{A}\mathbf{a} = [f(x_1), \dots, f(x_M)]^T. \tag{1.1}$$

Thus, some of the important problems in this theory are an efficient evaluation of the coefficient vector $\mathbf{a}$ and an estimation of the *Lebesgue constant* (uniform norm) of the operator I_M, defined to be the infimum of all Λ_M for which

$$\sup_{x\in\Omega} |I_M f(x)| \le \Lambda_M \sup_{x\in\Omega} |f(x)|.$$

A classical example is the interpolation on the unit circle, $\{e^{ix} : x \in [0, 2\pi)\}$. We

define the nodes x_j and the basis ϕ_j by

$$x_j := \frac{2(j+N)\pi}{2N+1}, \quad \phi_j(x) := \frac{\exp(ijx)}{\sqrt{2N+1}}, \quad -N \le j \le N.$$

In this case (using a well-known identity for complex exponentials (see (4.1))), the inverse of the resulting interpolation matrix A_{trig} is $\overline{A_{trig}^T}$. Hence, for a function f defined on $[0, 2\pi]$, the solution of the interpolation problem can be written explicitly as follows:

$$I_{2N+1}f(x) = \sum_{j=-N}^{N} a_j(f)\phi_j(x) = \sum_{\ell=-N}^{N} f(x_\ell)K_N(x, x_\ell), \tag{1.2}$$

where

$$a_j(f) := \sum_{\ell=-N}^{N} f(x_\ell)\overline{\phi_j(x_\ell)}, \quad -N \le j \le N, \quad K_N(x,y) = \sum_{j=-N}^{N} \phi_j(x)\overline{\phi_j(y)}.$$

We note that each $a_j(f)$ is the discrete Fourier transform (DFT), and hence, for a fixed x, the $\mathcal{O}(N^2)$ summations in $I_{2N+1}f(x)$ can be computed with $\mathcal{O}(N \log N)$ operations, using the fast Fourier transform (FFT). The Lebesgue constant in this case is $\mathcal{O}(\log N)$.

Formulas similar to (1.2) also hold in the case of interpolation at the zeros of an arbitrary orthogonal polynomial system on a real interval [3, section I.4]. This fact is a simple consequence of the Gauss–Jacobi quadrature formula, which, although based on the zeros of a polynomial of degree n, is exact for integrating polynomials of degree $2n-1$. In Proposition 2.1 below, we will use the same arguments as in [3, section I.4] and [10, Lemma 3] to observe that the existence of suitable quadrature formulas implies the existence of interpolation formulas similar to (1.2). One common feature in all these examples is that one does not need to solve a matrix equation to solve the interpolation problem. We say that the interpolation is *matrix-free* when a system of interpolation nodes and basis functions is given explicitly, so that a formula analogous to the FFT-type representation (1.2) defines an interpolation operator.

If Ω is the unit sphere $\mathbb{S}^2 := \{(x,y,z) \in \mathbb{R}^3 : x^2+y^2+z^2 = 1\}$, one may think of a simple strategy for interpolation by considering the coordinate transformation

$$\hat{\mathbf{x}} = \boldsymbol{p}(\theta, \phi) := (\sin\theta\cos\phi, \sin\theta\sin\phi, \cos\theta)^{\mathrm{T}}, \quad \hat{\mathbf{x}} \in \mathbb{S}^2. \tag{1.3}$$

We may then think of a function on $\mathbb{S}^2$ as a periodic function of θ and ϕ, and use bivariate trigonometric interpolation to fit the data. One problem with this straightforward approach is that not all the bivariate trigonometric polynomials are continuous functions of points on $\mathbb{S}^2$. Several authors have considered approximation by special classes of bivariate trigonometric polynomials and special bases for the same. We refer the reader to [2, sections 18.26, 18.27] and references therein for an interesting account.

In [5], a subspace of bivariate trigonometric polynomials was introduced for facilitating interpolation of functions on the sphere. However, a matrix-free interpolant construction was not discussed in [5]. In this paper, we introduce a different subspace spanned by a basis of the form $Q_n^m(\cos\theta)\exp(im\phi)$, where Q_n^m is the associated Chebyshev or Legendre functions of degree n and order at most 2. These two bases

lead to FFT-type matrix-free interpolation, corresponding to two systems of points on the sphere. This fact will be proved using a suitable quadrature formula as a consequence of Proposition 2.1.

We prove that the uniform norm of the interpolation operator, based on one of the systems of points, is $\mathcal{O}(\log^2 N)$. The other system of points allows us to construct quadrature formulas that are exact for integration of elements of a higher order space with respect to the area measure on $\mathbb{S}^2$. We demonstrate numerically that the two interpolation operators provide the same degree of approximation for the ten benchmark functions studied in [11] and references therein.

It might be interesting to compare interpolation from our spaces with that from the classical spherical polynomials. First, we observe that our space $\mathcal{X}_N$ defined after Theorem 2.1 below consists of all bivariate trigonometric polynomials of coordinate-wise degree at most N that are functions on the sphere and that do not contain terms with the frequencies $\sin N\theta$ (cf. (1.3)). Therefore, if $\mathbb{P}_n$ denotes the class of all spherical polynomials of degree at most n (i.e., the class of the restrictions to $\mathbb{S}^2$ of all trivariate algebraic polynomials of total degree at most n), then $\mathbb{P}_{N-1} \subset \mathcal{X}_N$. Moreover, the dimension of $\mathcal{X}_N$ is approximately twice that of $\mathbb{P}_{N-1}$.

The case of spherical polynomial interpolation is very different from our constructions. Sloan [10] has proved that it is not possible to construct a matrix–free interpolation operator onto $\mathbb{P}_N$ for $N \geq 3$ using a quadrature formula that is exact on $\mathbb{P}_{2N}$ (see [10, Lemma 3]). Several authors including Sündermann [13], Golitschek and Light [7], Xu [17, 18], and Laín Fernández [8] have constructed point systems with various symmetry properties for which a spherical polynomial interpolation matrix is guaranteed to be invertible. To the best of our knowledge, the norm of the resulting spherical polynomial interpolation operator as well as the computationally important condition number of the interpolation matrix have not been investigated.

The problem of finding points on the sphere for which a polynomial interpolation matrix is invertible and well conditioned has been studied computationally by Sloan and Womersley [11, 12] by imposing such additional constraints as to minimize the Lebesgue constant of the resulting operator or to maximize the determinant of the interpolatory matrix. It is conjectured that the Lebesgue constant of the best quality interpolation operator constructed in [11, 12] is $\mathcal{O}(N)$. In view of the smoothing properties of the surface integral operators arising in applications in elasticity theory, potential theory, and scattering of sound waves from three dimensional smooth spherical geometries, it is important for the projection operators to have Lebesgue constants that are $\mathcal{O}(N^\alpha)$ for some $\alpha < 1$ [4, 5, 6].

In the next section, we discuss the construction of the space and discuss the degree of approximation, interpolation, and quadrature in this space. Numerical experiments are presented in section 3, and the proofs of the results in section 2 are given in section 4.

2. Main results. In this paper, let C^* denote the class of all continuous functions on $\mathbb{R}^2$ that are 2π-periodic in each of their variables, equipped with the uniform norm $\|\circ\|_\infty^*$. The space of all continuous functions on $\mathbb{S}^2$, equipped with the uniform norm $\|\circ\|_\infty$, will be denoted by $C(\mathbb{S}^2)$. For $f \in C(\mathbb{S}^2)$, let $f^*(\theta,\phi) := f(\boldsymbol{p}(\theta,\phi))$, where $\boldsymbol{p}(\theta,\phi)$ are the polar coordinates defined in (1.3). It is clear that $f \in C(\mathbb{S}^2)$ if and only if $f^* \in C^*$, and f^* satisfies the following symmetry conditions:

$$f^*(-\theta,\phi+\pi) = f^*(\theta,\phi), \quad \theta,\phi \in \mathbb{R}, \tag{2.1}$$

and

$$f^*(0,\phi), \quad f^*(\pi,\phi) \text{ are independent of } \phi. \tag{2.2}$$

We will denote by C° the subspace of C^* comprising of functions satisfying the above two conditions. If $g \in C^\circ$, there exists a unique $f \in C(\mathbb{S}^2)$ such that $g = f^*$. We will write $f = g^\circ$. For integer $N \geq 2$, the space $\mathbb{H}_N$ denotes the class of all bivariate trigonometric polynomials of order at most N; i.e., the span of $\{e^{i\ell\theta}e^{im\phi}\}_{|\ell|,|m|\leq N}$. The space of all univariate algebraic polynomials of degree at most N will be denoted by Π_N.

Our first objective is to obtain a detailed description of $C^\circ \cap \mathbb{H}_N$.

THEOREM 2.1. *Let $N \geq 0$ be an integer. We have $T \in C^\circ \cap \mathbb{H}_N$ if and only if*

$$T(\theta,\phi) = S_0(\cos\theta) + \sin^2\theta \sum_{\substack{|\ell|\leq N,\ \ell\neq 0 \\ \ell \text{ even}}} Q_\ell(\cos\theta)\exp(i\ell\phi) + \sin\theta \sum_{\substack{|\ell|\leq N \\ \ell \text{ odd}}} R_\ell(\cos\theta)\exp(i\ell\phi) \tag{2.3}$$

$$= L(\cos\theta) + \sin^2\theta \sum_{\substack{|\ell|\leq N \\ \ell \text{ even}}} Q_\ell(\cos\theta)\exp(i\ell\phi) + \sin\theta \sum_{\substack{|\ell|\leq N \\ \ell \text{ odd}}} R_\ell(\cos\theta)\exp(i\ell\phi), \tag{2.4}$$

where $S_0 \in \Pi_N$, $L \in \Pi_1$, and for $|\ell| \leq N$, $Q_\ell \in \Pi_{N-2}$, $R_\ell \in \Pi_{N-1}$.

In this paper, we are interested in the spaces

$$\begin{aligned} \mathcal{X}_N^* &= \{T \in C^\circ \cap \mathbb{H}_N : T \text{ satisfies (2.3) with } R_\ell \in \Pi_{N-2}\}, \\ \mathcal{X}_N &= \{T^\circ : T \in \mathcal{X}_N^*\}. \end{aligned} \tag{2.5}$$

Thus, $\mathcal{X}_N$ comprises those T° for which the terms corresponding to $\sin N\theta$ are absent from the expansion of T. It is easy to see from (2.5) and (2.4) that the dimension of $\mathcal{X}_N$ is given by

$$d_N := 2 + (N-1)(2N+1) = 2N^2 - N + 1. \tag{2.6}$$

If $P \in \mathbb{P}_{N-1}$, then $P^* \in \mathbb{H}_{N-1} \cap C^\circ$. Therefore, $\mathbb{P}_{N-1} \subset \mathcal{X}_N$. The dimension of $\mathbb{P}_{N-1}$ is N^2, which is slightly more than half the dimension of $\mathcal{X}_N$. This is partly because $\mathcal{X}_N$ consists of polynomials with coordinatewise degree at most N, rather than total degree at most N, but clearly, $\mathcal{X}_N$ contains many elements which are not spherical polynomials of any degree.

Next, we describe the construction of a matrix-free interpolation scheme for the space $\mathcal{X}_N$. Before launching into the details of these constructions, we formulate in an abstract setting a proposition that shows a close connection between minimal quadrature formulas and interpolation. If Ω is a nonempty set, and V is a vector space of functions on Ω, we recall that a subset $\mathcal{C} \subseteq \Omega$ is a *set of uniqueness* for V if $P \in V$ and $P(x) = 0$ for all $x \in \mathcal{C}$ imply that $P \equiv 0$. The following proposition summarizes standard constructions in the theory of interpolation at the zeros of orthogonal polynomials on a real interval [3, section I.4] and appears in essence also as [10, Lemma 3].

PROPOSITION 2.1. *Let $d \geq 1$ be an integer, Ω be a set containing at least d elements, V be a d-dimensional vector space of functions on Ω, $\mathcal{C} = \{x_1, \ldots, x_d\} \subseteq \Omega$ be a set of uniqueness for V, and $w_1, \ldots, w_d > 0$. Let $\{\Phi_1, \ldots, \Phi_d\}$ be an orthonormal basis for V with respect to the inner product*

$$\langle P, Q\rangle = \sum_{k=1}^{d} w_k P(x_k)\overline{Q(x_k)},$$

and

$$K(x,y) := \sum_{k=1}^{d} \Phi_k(x)\overline{\Phi_k(y)}.$$

Then

$$w_k^{-1} = \sum_{j=1}^{d} |\Phi_j(x_k)|^2, \qquad k = 1, \ldots, d. \tag{2.7}$$

If $\mathcal{Y} := \{y_1, \ldots, y_d\} \subset \mathbb{C}$ *and*

$$g(\mathcal{Y}, x) := \sum_{k=1}^{d} w_k y_k K(x, x_k), \tag{2.8}$$

then $g(\mathcal{Y})$ *is the unique element of* V *satisfying* $g(\mathcal{Y}, x_j) = y_j$, $j = 1, \ldots, d$.

We note that $K(\circ, \circ)$ is the reproducing kernel of $(V, \langle \circ, \circ \rangle)$, and that for any $f \in V$, the interpolant $g(\{f(x_k)\}_{k=1,\ldots,d}, x)$ is just $\langle f, K(\circ, x)\rangle = f(x)$.

We now describe our matrix-free constructions for interpolation from the space $\mathcal{X}_N$. In what follows, we will assume that $N \geq 2$ and write

$$N_0 = N, \quad N_m = N - 2 \quad \text{for } m \neq 0. \tag{2.9}$$

First, we describe an orthonormal basis for $\mathcal{X}_N$. In the remainder of this section, let P_n denote the Legendre polynomial of degree n, normalized so that $P_n(1) = 1$. The associated Legendre function of degree n and order m is defined by

$$P_n^m(x) := (1 - x^2)^{m/2} \frac{d^m}{dx^m} P_n(x). \tag{2.10}$$

We recall that the classical spherical harmonics are defined by

$$Y_n^m(\boldsymbol{p}(\theta, \phi)) := \alpha_n^m P_n^{|m|}(\cos\theta) \exp(im\phi), \quad |m| \leq n, \tag{2.11}$$

where the *Condon–Shortley phase* α_n^m is given by

$$\alpha_n^m := \begin{cases} (-1)^m \sqrt{\frac{2n+1}{4\pi} \frac{(n-m)!}{(n+m)!}} & \text{if } m \geq 0, \\ (-1)^m \alpha_n^{|m|} & \text{if } m < 0. \end{cases} \tag{2.12}$$

The polynomials $\{Y_n^m \ : \ n = 0, \ldots, N, \ |m| \leq n\}$ form an orthonormal basis for the space $\mathbb{P}_N$ of all spherical polynomials of degree N, are eigenfunctions of the Laplace–Beltrami operator, and play a very important role in the theory of functions on the sphere. Following the representation (2.3), we define

$$G_n^m(\boldsymbol{p}(\theta, \phi)) := \begin{cases} Y_n^0(\boldsymbol{p}(\theta, 0)) & \text{if } m = 0, \\ Y_{n+1}^1(\boldsymbol{p}(\theta, 0)) \exp(im\phi) & \text{if } m \text{ is odd}, \\ Y_{n+2}^2(\boldsymbol{p}(\theta, 0)) \exp(im\phi) & \text{if } m \text{ is even}, m \neq 0. \end{cases} \tag{2.13}$$

Using (2.5) and (2.3), it is not difficult to check that $\{G_n^m \ : \ n = 0, \ldots, N_m, |m| \leq N\}$ is an orthonormal basis for $\mathcal{X}_N$:

$$\int_{\mathbb{S}^2} G_n^m(\boldsymbol{p}(\theta, \phi)) G_{n'}^{m'}(\boldsymbol{p}(\theta, \phi)) d(\boldsymbol{p}(\theta, \phi)) = \delta_{(n,m),(n',m')}, \tag{2.14}$$

where $d(\boldsymbol{p}(\theta,\phi))$ is the area element of $\mathbb{S}^2$, given by $\sin\theta d\theta d\phi$. They satisfy the following differential equations on $\mathbb{S}^2$ and in the unit ball in $\mathbb{R}^3$, where Δ_* denotes the Laplace–Beltrami operator, and Δ denotes the Laplacian in three variables.

$$(\Delta_* + n(n+1))\, G_n^m(\boldsymbol{p}(\theta,\phi)) = \begin{cases} 0 & \text{if } m=0, \\ \dfrac{1-m^2}{\sin^2(\theta)} G_n^m(\boldsymbol{p}(\theta,\phi)) & \text{if } m \text{ is odd}, \\ \dfrac{4-m^2}{\sin^2(\theta)} G_n^m(\boldsymbol{p}(\theta,\phi)) & \text{if } m \text{ is even}, m\neq 0, \end{cases} \tag{2.15}$$

$$\Delta\left(r^n G_n^m(\boldsymbol{p}(\theta,\phi))\right) = \begin{cases} 0 & \text{if } m=0, \\ \dfrac{1-m^2}{r^2\sin^2(\theta)} G_n^m(\boldsymbol{p}(\theta,\phi)) & \text{if } m \text{ is odd}, \\ \dfrac{4-m^2}{r^2\sin^2(\theta)} G_n^m(\boldsymbol{p}(\theta,\phi)) & \text{if } m \text{ is even}, m\neq 0. \end{cases} \tag{2.16}$$

In accordance with Proposition 2.1, we obtain a quadrature formula based on d_N points that is exact for integration of elements of $\mathcal{X}_{2N-1}$, and describe an interpolation operator for these nodes. This construction is based on the *Gauss–Lobatto quadrature rule*, given by the zeros of $P_N^1(\cos\theta)$. Thus, let $\widehat{\theta}_0 < \cdots < \widehat{\theta}_{N-2}$ be points on $(0,\pi)$, such that $P_N^{'}(\cos\widehat{\theta}_n) = 0$, $n = 0,\ldots,N-2$, $\widehat{\theta}_{N-1} = 0$, $\widehat{\theta}_N = \pi$, and

$$\widetilde{\phi}_m := \frac{2(m+N)\pi}{2N+1}, \quad -N \le m \le N. \tag{2.17}$$

Let

$$\mathcal{C}_N^q = \{\boldsymbol{p}(\widehat{\theta}_n, \widetilde{\phi}_m) \ : \ n = 0,\ldots,N-2,\ |m| \le N\} \cup \{\hat{\mathbf{n}}, \hat{\mathbf{s}}\}, \tag{2.18}$$

where $\hat{\mathbf{n}}$ and $\hat{\mathbf{s}}$ denote the north and south poles, respectively. We note that $\mathcal{C}_N^q$ contains exactly d_N elements. We define the corresponding discrete inner product by

$$\begin{aligned} \langle f, g\rangle_N^q = {} & \frac{4\pi}{N(N+1)(2N+1)} \sum_{|m|\le N} \sum_{n=0}^{N-2} \frac{f(\boldsymbol{p}(\widehat{\theta}_n,\widetilde{\phi}_m))\overline{g(\boldsymbol{p}(\widehat{\theta}_n,\widetilde{\phi}_m))}}{[P_N(\cos\widehat{\theta}_n)]^2} \\ & + \frac{4\pi}{N(N+1)}\left\{f(\hat{\mathbf{n}})\overline{g(\hat{\mathbf{n}})} + f(\hat{\mathbf{s}})\overline{g(\hat{\mathbf{s}})}\right\}. \end{aligned} \tag{2.19}$$

With

$$(g_n^m)^{-1} := \begin{cases} 2 + 1/N & \text{if } m=0 \text{ and } n=N, \\ 2 - 3/(N+2) & \text{if } 0\neq m \text{ even and } n = N-2, \\ 1 & \text{otherwise}, \end{cases} \tag{2.20}$$

we will show in the proof of Theorem 2.2 below that the functions $\{\sqrt{g_n^m} G_n^m\}$ form an orthonormal basis for $\mathcal{X}_N$, orthonormalized with respect to the inner product $\langle \circ, \circ\rangle_N^q$. In view of Proposition 2.1, a matrix–free interpolation operator can now be defined easily with the kernel

$$\mathcal{K}_N^q(\hat{\mathbf{x}},\hat{\mathbf{y}}) := \sum_{|m|\le N} \sum_{n=0}^{N_m} g_n^m G_n^m(\hat{\mathbf{x}}) G_n^m(\hat{\mathbf{y}}). \tag{2.21}$$

The following theorem summarizes some facts regarding our constructions so far.

THEOREM 2.2. *Let $N \geq 2$ be an integer. For $T \in \mathcal{X}_{2N-1}$, we have*

$$\int_{\mathbb{S}^2} T\left(\boldsymbol{p}(\theta,\phi)\right) d(\boldsymbol{p}(\theta,\phi)) = \frac{4\pi}{N(N+1)(2N+1)} \sum_{|m|\leq N} \sum_{n=0}^{N-2} \frac{T(\boldsymbol{p}(\widehat{\theta}_n, \widetilde{\phi}_m))}{[P_N(\cos\widehat{\theta}_n)]^2} + \frac{4\pi}{N(N+1)} \left\{T(\hat{\mathbf{n}}) + T(\hat{\mathbf{s}})\right\}. \tag{2.22}$$

For $f \in C(\mathbb{S}^2)$, let

$$\begin{aligned} \mathcal{G}_N f(\hat{\mathbf{x}}) := {} & \frac{4\pi}{N(N+1)(2N+1)} \sum_{|m|\leq N} \sum_{n=0}^{N-2} [P_N(\cos\widehat{\theta}_n)]^{-2} \\ & \times f(\boldsymbol{p}(\widehat{\theta}_n, \widetilde{\phi}_m)) \mathcal{K}_N^q(\hat{\mathbf{x}}, \boldsymbol{p}(\widehat{\theta}_n, \widetilde{\phi}_m)) \\ & + \frac{4\pi}{N(N+1)} \left\{f(\hat{\mathbf{n}}) \mathcal{K}_N^q(\hat{\mathbf{x}}, \hat{\mathbf{n}}) + f(\hat{\mathbf{s}}) \mathcal{K}_N^q(\hat{\mathbf{x}}, \hat{\mathbf{s}})\right\}. \end{aligned} \tag{2.23}$$

Then $\mathcal{G}_N f$ is the unique element of $\mathcal{X}_N$ that satisfies $\mathcal{G}_N f(\xi) = f(\xi)$ for $\xi \in \mathcal{C}_N^q$.

We believe that our proof of (2.31) below can be adapted to show that the Lebesgue constant of $\mathcal{G}_N$ is $\mathcal{O}(\sqrt{N})$, and we hope to report on this in the near future, along with similar constructions for spheres embedded in Euclidean spaces of dimensions higher than 3. On the other hand, we remark that a direct application of the representation (2.23) leads only to an estimate $\mathcal{O}(N)$, using standard techniques as in [14].

Next, we describe another construction for the nodes that leads to a matrix-free interpolation operator with uniform norm $\mathcal{O}((\log N)^2)$. Let

$$\widetilde{\theta}_n := \frac{(n+1)\pi}{N}, \quad n = 0, \ldots, N-2, \quad \widetilde{\theta}_{N-1} := 0,\ \widetilde{\theta}_N := \pi, \tag{2.24}$$

and $\widetilde{\phi}_m$ be defined by (2.17). For the points of interpolation, we choose the set

$$\mathcal{C}_N^i :== \{\boldsymbol{p}(\widetilde{\theta}_n, \widetilde{\phi}_m) : n = 0, \ldots, N-2,\ |m| \leq N\} \cup \{\hat{\mathbf{n}}, \hat{\mathbf{s}}\}.$$

To describe a basis for $\mathcal{X}_N$, we recall that the formula $T_n(\cos\theta) = \cos n\theta$ defines a unique polynomial T_n of degree n, called the Chebyshev polynomial (of first kind). Analogous to the associated Legendre functions, we define the associated Chebyshev functions by

$$C_n^m(x) = (1-x^2)^{m/2} \frac{d^m}{dx^m} T_n(x).$$

Our basis functions are defined by

$$Z_n^m(\boldsymbol{p}(\theta,\phi)) := \begin{cases} C_n^0(\cos\theta) & \text{if } m = 0, \\ C_{n+1}^1(\cos\theta) e^{im\phi} & \text{if } m \text{ is odd}, \\ C_{n+2}^2(\cos\theta) e^{im\phi} & \text{if } m \neq 0,\ m \text{ is even}. \end{cases} \tag{2.25}$$

These functions are not orthogonal with respect to the standard L^2 inner product on $\mathbb{S}^2$. However, we observe that an application of Proposition 2.1 requires only the

orthogonality of the functions with respect to a discrete inner product based at the points in question. Accordingly, we define

$$\langle f,g\rangle_N := \frac{2\pi^2}{N(2N+1)}\sum_{|m|\le N}\sum_{n=0}^{N-2} f(\boldsymbol{p}(\widetilde{\theta}_n,\widetilde{\phi}_m))\overline{g(\boldsymbol{p}(\widetilde{\theta}_n,\widetilde{\phi}_m))} + \frac{2\pi^2}{2N}\{f(\hat{\mathbf{n}})\overline{g(\hat{\mathbf{n}})}+f(\hat{\mathbf{s}})\overline{g(\hat{\mathbf{n}})}\}. \tag{2.26}$$

With the normalization factors

$$(z_{n,N}^m)^{-1} := \begin{cases} 2\pi^2 & \text{if } m=0,\ n=0,N,\\ \pi^2 & \text{if } m=0,\ n=1,\dots,N,\\ (n+1)^2\pi^2 & \text{if } m \text{ odd},\ n=0,\dots,N-2,\\ (n+2)^4\pi^2(1-(n+2)^{-2}) & \text{if } m \text{ even},\ m\neq 0,\ n=0,\dots,N-3,\\ 2(n+2)^4\pi^2(1-(n+2)^{-1}) & \text{if } m \text{ even},\ m\neq 0,\ n=N-2, \end{cases} \tag{2.27}$$

we will show in the proof of Theorem 2.3 below that the function $\{\sqrt{z_n^m}Z_n^m\}$ is an orthonormal basis for $\mathcal{X}_N$ with respect to this inner product. The interpolation operator can now be described using the kernel

$$\mathcal{K}_N(\hat{\mathbf{x}},\hat{\mathbf{y}}) := \sum_{|m|\le N}\sum_{n=0}^{N_m} z_{n,N}^m Z_n^m(\hat{\mathbf{x}})Z_n^m(\hat{\mathbf{y}}). \tag{2.28}$$

THEOREM 2.3. *Let $N\ge 2$ be an integer, $f\in C(\mathbb{S}^2)$, and*

$$\mathcal{I}_N f(\hat{\mathbf{x}}) := \frac{2\pi^2}{N(2N+1)}\sum_{|m|\le N}\sum_{n=0}^{N-2} f(\boldsymbol{p}(\widetilde{\theta}_n,\widetilde{\phi}_m))\mathcal{K}_N(\hat{\mathbf{x}},\boldsymbol{p}(\widetilde{\theta}_n,\widetilde{\phi}_m)) + \frac{\pi^2}{N}\left\{f(\hat{\mathbf{n}})\mathcal{K}_N(\hat{\mathbf{x}},\hat{\mathbf{n}})+f(\hat{\mathbf{s}})\mathcal{K}_N(\hat{\mathbf{x}},\hat{\mathbf{s}})\right\}. \tag{2.29}$$

Then $\mathcal{I}_N f$ is the unique element of $\mathcal{X}_N$ that satisfies $\mathcal{I}_N f(\xi)=f(\xi)$ for each $\xi\in\mathcal{C}_N^i$.

In the next theorem, we discuss the approximation properties of the operator $\mathcal{I}_N$. If $V\subset C^*$, we define

$$\text{dist }(f,V) := \inf_{P\in V}\|f-P\|_\infty^*, \quad f\in C^*, \tag{2.30}$$

with a similar definition for dist (f,V) when $f\in C(\mathbb{S}^2)$ and $V\subset C(\mathbb{S}^2)$. Throughout this paper, c denotes a generic constant, independent of N. Its value may be different at different occurrences, even within a single formula.

THEOREM 2.4. *For integer $N\ge 2$ and $f\in C(\mathbb{S}^2)$, we have*

$$\|\mathcal{I}_N f\|_\infty \le c(\log N)^2\|f\|_\infty \tag{2.31}$$

and

$$\|f-\mathcal{I}_N f\|_\infty \le c(\log N)^2 \text{ dist }(f^*,\mathbb{H}_{N-1}) \le c(\log N)^2 \text{ dist }(f,\mathbb{P}_{N-1}). \tag{2.32}$$

The connection between the smoothness of f^* and the superalgebraic convergence of dist $(f^*,\mathbb{H}_{N-1})$ to zero has been investigated in detail in classical approximation theory [16]. We note that since the space $\mathbb{P}_{N-1}^*$ corresponding to spherical polynomials of degree at most $N-1$ is contained in $\mathbb{H}_{N-1}$, dist $(f^*,\mathbb{H}_{N-1})\le$ dist $(f^*,\mathbb{P}_{N-1}^*)=$ dist$(f,\mathbb{P}_{N-1})$.

3. Numerical experiments. We demonstrate the quality of our interpolatory operators by computing estimates of the uniform norm errors $\|\mathcal{I}_N f_i - f_i\|_\infty$ and $\|\mathcal{G}_N f_i - f_i\|_\infty,\ i = 1, \ldots, 10$, where $f_1, \ldots, f_{10}$ are the benchmark functions on the sphere (see [11] and references therein), defined for $\hat{\mathbf{x}} = (x_1, x_2, x_3) \in \mathbb{S}^2$, by

$$f_1(\hat{\mathbf{x}}) = x_1x_2x_3, \qquad f_2(\hat{\mathbf{x}}) = \exp(x_1), \qquad f_3(\hat{\mathbf{x}}) = \exp(x_1 + x_2 + x_3)/10,$$

$$f_4(\hat{\mathbf{x}}) = -5\sin(1 + 10x_3),\ f_5(\hat{\mathbf{x}}) = \sum_{i=1}^{5} \alpha_i \exp(-\beta_i \mathrm{dist}(\hat{\mathbf{x}}, \hat{\mathbf{y}}_i)^{2\gamma_i}),\ f_6(\hat{\mathbf{x}}) = \frac{1}{101 - 100x_3},$$

$$f_7(\hat{\mathbf{x}}) = |x_1| + |x_2| + |x_3|, \qquad f_8(\hat{\mathbf{x}}) = \frac{1}{f_7(\hat{\mathbf{x}})}, \qquad f_9(\hat{\mathbf{x}}) = \frac{\sin^2(1 + f_7(\hat{\mathbf{x}}))}{10},$$

and

$$f_{10}(\hat{\mathbf{x}}) = \begin{cases} \cos^2\left(\frac{3\pi}{2}\mathrm{dist}(\hat{\mathbf{x}}, \boldsymbol{p}(\pi/4, 5\pi/4))\right) & \text{if } \mathrm{dist}(\hat{\mathbf{x}}, \boldsymbol{p}(\pi/4, 5\pi/4)) < 1/3, \\ 0, & \text{if } \mathrm{dist}(\hat{\mathbf{x}}, \boldsymbol{p}(\pi/4, 5\pi/4)) \geq 1/3, \end{cases}$$

where the $\mathrm{dist}(\hat{\mathbf{x}}, \hat{\mathbf{y}}) = \cos^{-1}(\hat{\mathbf{x}} \cdot \hat{\mathbf{y}})$ is the geodesic distance between two points $\hat{\mathbf{x}}, \hat{\mathbf{y}} \in \mathbb{S}^2$, and the parameters $\hat{\mathbf{y}}_i = (y_{i,1}, y_{i,2}, y_{i,3})$ and $\alpha_i, \beta_i, \gamma_i,\ i = 1, \ldots, 5$, in the test function f_5 are in Table 1. The functions $f_i,\ i = 1, \ldots, 6$, are analytic; f_7, f_8, and f_9 are continuous, but not continuously differentiable, and the locally supported cosine cap function f_{10} is once (but not twice) continuously differentiable function on $\mathbb{S}^2$.

We computed approximations of these functions in $\mathcal{X}_N$, using the interpolation operators $\mathcal{I}_N$ and $\mathcal{G}_N$. For each $i = 1, \ldots, 10$, the uniform norm errors $\|f_i - \mathcal{I}_N f_i\|_\infty$ and $\|f_i - \mathcal{G}_N f_i\|_\infty$ were estimated by taking the maximum of errors over $12,000$ points on the sphere.

The results in Tables 2–5 show that both $\mathcal{I}_N f_i$ and $\mathcal{G}_N f_i$ provide a similar quality of approximation of $f_i,\ i = 1, \ldots, 10$. The tables clearly demonstrate also that our operators yield a better reconstruction of these functions with their various smoothness properties than the (matrix-dependent) interpolatory and noninterpolatory polynomial approximations of the same functions discussed in [11, pp. 222–223]. (The functions denoted here by f_5 and f_6 are denoted in [11, pp. 222–223] by f_6 and f_5, respectively.) We note again that the construction of the interpolatory operators $\mathcal{I}_N f_i,\ \mathcal{G}_N f_i,\ i = 1, \ldots, 10$, does not require a numerical solution of any linear system of equations. Moreover, Theorem 2.4 shows that the Lebesgue constant of $\mathcal{I}_N$ is $\mathcal{O}\left((\log N)^2\right)$.

4. Proofs.

Proof of Theorem 2.1. It is clear that any expression of the form on the right-hand side of (2.4) is in $C^\circ \cap \mathbb{H}_N$. Let $T \in C^\circ \cap \mathbb{H}_N$, and

$$T(\theta, \phi) =: \sum_{|\ell|, |k| \leq N} a_{\ell,k} e^{ik\theta} e^{i\ell\phi}.$$

Then, recalling that for integers $k \geq 0$, $\cos k\theta$ and $\sin k\theta / \sin\theta$ are polynomials in $\cos\theta$ of degree k and $k-1$, respectively, we obtain

$$\begin{aligned} T(\theta,\phi) &= (1/2)(T(\theta,\phi) + T(-\theta,\phi+\pi)) \\ &= \sum_{|\ell|,|k|\leq N} a_{\ell,k} \frac{e^{ik\theta} + (-1)^\ell e^{-ik\theta}}{2} e^{i\ell\phi} \\ &= \sum_{\substack{|\ell|\leq N \\ \ell \text{ even}}} \sum_{k=0}^{N} a_{\ell,k} \cos k\theta e^{i\ell\phi} + i \sum_{\substack{|\ell|\leq N \\ \ell \text{ odd}}} \sum_{k=1}^{N} a_{\ell,k} \sin k\theta e^{i\ell\phi} \\ &= \sum_{\substack{|\ell|\leq N \\ \ell \text{ even}}} S_\ell(\cos\theta) e^{i\ell\phi} + \sin\theta \sum_{\substack{|\ell|\leq N \\ \ell \text{ odd}}} R_\ell(\cos\theta) e^{i\ell\phi}, \end{aligned}$$

where $S_\ell \in \Pi_N$ and $R_\ell \in \Pi_{N-1}$, $|\ell| \leq N$. There exist $Q_\ell \in \Pi_{N-2}$, $L_\ell \in \Pi_1$ such that $S_\ell(\cos\theta) = (1-\cos^2\theta)Q_\ell(\cos\theta) + L_\ell(\cos\theta)$. Since $T(0,\phi)$ and $T(\pi,\phi)$ are independent

of ϕ, we have $S_\ell(\pm 1) = 0$ if $\ell \neq 0$. Therefore, $L_\ell = 0$ for $|\ell| \leq N$, ℓ even, and $\ell \neq 0$. □

Proof of Proposition 2.1. Let $\mathbf{A} = [a_{j,k}]$ be the collocation matrix defined by $a_{j,k} = \Phi_k(x_j)$. Since $\mathcal{C}$ is a set of uniqueness, $\mathbf{A}$ is invertible. Also, the orthonormality of $\{\Phi_k \ : \ k = 1, \ldots, d\}$ is equivalent to the statement that $\overline{\mathbf{A}^T} D \mathbf{A} = I$, where $D = \text{diag}\,[w_1, \ldots, w_d]$. This leads to $\overline{\mathbf{A}^T} D = \mathbf{A}^{-1}$, and $D^{-1} = \mathbf{A}\overline{\mathbf{A}^T}$. This is (2.7). With $\mathbf{y} = [y_1, \ldots, y_d]^T$, and $\mathbf{b}(x) = [\Phi_1(x), \ldots, \Phi_d(x)]^T$, we have

$$g(\mathcal{Y}, x) = \mathbf{b}(x)^T \overline{\mathbf{A}^T} D \mathbf{y} = \mathbf{b}(x)^T \mathbf{A}^{-1} \mathbf{y}.$$

This completes the proof. □

The next lemma describes some sets of uniqueness for $\mathcal{X}_N$.

LEMMA 4.1. *Let $N \geq 2$ be an integer, $\theta_0, \ldots, \theta_{N-2}$ be distinct points in $(0, \pi)$, and $\theta_{N-1} = 0$, $\theta_N = \pi$, and ϕ_m, $|m| \leq N$, be distinct points on $[0, 2\pi)$. Then the set*

$$\mathcal{C} = \{\boldsymbol{p}(\theta_n, \phi_m) \ : \ n = 0, \ldots, N-2, \ |m| \leq N\} \cup \{\hat{\mathbf{n}}, \hat{\mathbf{s}}\}$$

consists of d_N distinct elements and is a set of uniqueness for $\mathcal{X}_N$.

Proof. Let $T \in \mathcal{X}_N^*$, and for $|\ell| \leq N$, $Q_\ell, R_\ell \in \Pi_{N-2}$, $Q_0 \in \Pi_N$ be found so that

$$T(\theta, \phi) = Q_0(\cos\theta) + \sin^2\theta \sum_{\substack{|\ell| \leq N, \ \ell \neq 0 \\ \ell \text{ even}}} Q_\ell(\cos\theta) \exp(i\ell\phi) + \sin\theta \sum_{\substack{|\ell| \leq N \\ \ell \text{ odd}}} R_\ell(\cos\theta) \exp(i\ell\phi),$$

and $T^\circ(\boldsymbol{p}(\theta_n, \phi_m)) = 0$, $n = 0, \ldots, N$, $|m| \leq N$. For any n, $T(\theta_n, \circ)$ is a trigonometric polynomial of degree at most N. Since this polynomial has $2N+1$ distinct zeros, $\{\phi_m\}_{|m| \leq N}$, it must be identically zero. This yields $Q_0(\cos\theta_n) = 0$ for $n = 0, \ldots, N$, and $Q_\ell(\cos\theta_n) = R_\ell(\cos\theta_n) = 0$, $n = 0, \ldots, N-2$, $\ell \neq 0$. Since $Q_0 \in \Pi_N$ and $Q_\ell, R_\ell \in \Pi_{N-2}$ for $\ell \neq 0$, this implies that each of these polynomials is identically equal to zero. Thus, $T \equiv 0$, and hence, $T^\circ \equiv 0$. □

We are now in a position to prove Theorems 2.2 and 2.3. We observe that for any integer $M \geq 1$, and integer k,

$$\frac{1}{M} \sum_{m=0}^{M-1} \exp(2\pi i k m/M) = \begin{cases} 1 & \text{if } k = 0 \bmod M, \\ 0 & \text{otherwise.} \end{cases} \tag{4.1}$$

In particular,

$$\int_0^{2\pi} e^{ik\phi} d\phi = \frac{2\pi}{M} \sum_{m=0}^{M-1} \exp(2\pi i k m/M), \quad |k| \leq M-1. \tag{4.2}$$

Proof of Theorem 2.2. It is well known [1, (25.4.32), p. 888] that for $P \in \Pi_{2N-1}$, we have

$$\begin{aligned} &\int_0^\pi P(\cos\theta) \sin\theta d\theta \\ &\quad = \frac{2}{N(N+1)} \sum_{n=0}^{N-2} \frac{P(\cos\widehat{\theta}_n)}{\left[P_N(\cos\widehat{\theta}_n)\right]^2} + \frac{2}{N(N+1)} \left\{P(\cos\widehat{\theta}_0) + P(\cos\widehat{\theta}_N)\right\}. \end{aligned} \tag{4.3}$$

(The notation in [1] is somewhat different.) The equation (2.22) follows from the definition of the space $\mathcal{X}_N$ and the quadrature formulas (4.2) and (4.3).

In this proof only, we adopt the notation P_n^0 for the Legendre polynomial P_n and write

$$F_n^m(x) := \begin{cases} \alpha_n^0\ P_n^0(x) & \text{if } m = 0, \\ \alpha_{n+1}^1\ P_{n+1}^1(x) & \text{if } m \text{ is odd}, \\ \alpha_{n+2}^2\ P_{n+2}^2(x) & \text{if } m \text{ is even}, m \neq 0, \end{cases} \tag{4.4}$$

and we let $-N \le m, j \le N$, and $n = 0, \dots, N_m$, $l = 0, \dots, N_j$. Using (2.19), (2.13), (4.4), and (4.1) we get

$$\begin{aligned} \langle G_n^m, G_l^j \rangle_N^q = \delta_{m,j} \left[\frac{4\pi}{N(N+1)} \sum_{q=0}^{N-2} \frac{F_n^m(\cos\widehat{\theta}_q) F_l^j(\cos\widehat{\theta}_q)}{[P_N^0(\cos\widehat{\theta}_q)]^2} \right] \\ + \frac{4\pi}{N(N+1)} [F_n^m(-1)F_l^j(-1) + F_n^m(1)F_l^j(1)]. \end{aligned} \tag{4.5}$$

Let $j = m$. In view of (2.9) and (4.4), $F_n^m(x)F_l^m(x)$ is a polynomial of degree at most $2N-1$ on $[-1,1]$ for all $l = 0, \dots, N_m$, $0 \le n < N_m$, and also for $n = N_m$, if m is odd. Since the associated Legendre functions are orthonormal, (4.3) and (4.5) show that

$$\langle G_n^m, G_l^m \rangle_N^q = 0 \quad \text{if } n \neq l,$$

$$\langle G_n^m, G_n^m \rangle_N^q = 1 \quad \text{if } n \neq N_m, \quad \langle G_n^m, G_n^m \rangle_N^q = 1 \quad \text{if } n = N_m \quad \text{and} \quad m \text{ odd}.$$

Thus, we have shown that

$$\langle G_n^m, G_l^j \rangle_N^q = (g_n^m)^{-1} \delta_{n,l} \delta_{m,j} \tag{4.6}$$

for all n, m, l, j in question, except for the case when m is even, and $n = l = N_m$.

Next, let $m = 0$, and $n = l = N$. Using (4.5), (2.9), and (4.4), we have

$$\begin{aligned} \langle G_N^0, G_N^0 \rangle_N^q &= \frac{2N+1}{N(N+1)} \left(\sum_{q=0}^{N-2} \frac{[P_N^0(\cos\widehat{\theta}_q)]^2}{[P_N^0(\cos\widehat{\theta}_q)]^2} + [P_N^0(-1)]^2 + [P_N^0(1)]^2 \right) \\ &= \frac{2N+1}{N(N+1)} (N - 1 + 1 + 1) = 2 + 1/N. \end{aligned} \tag{4.7}$$

Finally, let m be even, $m \neq 0$, and $l = n = N_m = N-2$. In view of (4.4) and (2.12), we see that

$$[F_n^m(x)]^2 = \frac{2N+1}{4\pi} \frac{(N-2)!}{(N+2)!} [P_N^2(x)]^2.$$

Since $P_N^2(x) = (1-x^2)\frac{d^2}{dx^2} P_N^0(x)$, and P_N^0 is a solution of the Legendre differential equation [15, (4.2.1) with $\alpha = \beta = 0$], we have $P_N^2(x) = 2x\frac{d}{dx} P_N^0(x) - N(N+1)P_N^0(x)$. Since the Gauss–Lobatto quadrature points $x_q := \cos\widehat{\theta}_q \in (-1,1)$, $q = 0, \dots, N-2$, are zeros of the derivative of P_N^0, we have $P_N^2(x_q) = -N(N+1)P_N^0(x_q)$ for $q = 0, \dots, N-2$. We substitute this expression for $P_N^2(x_q)$ in (4.5), and recall that $P_N^2(\pm 1) = 0$ to obtain for even m

$$\langle G_{N-2}^m, G_{N-2}^m \rangle_N^q = \frac{2N+1}{(N-1)(N+2)} \left(\sum_{q=0}^{N-2} \frac{[P_N^0(x_q)]^2}{[P_N^0(x_q)]^2} \right) = \frac{2N+1}{(N+2)} = 2 - 3/(N+2). \tag{4.8}$$

The equations (4.6), (4.7), (4.8), and (2.20) show that $\{\sqrt{g_n^m}G_n^m\}$ is a basis for $\mathcal{X}_N$, orthonormalized with respect to the inner product $\langle \circ, \circ \rangle_N^q$. Lemma 4.1 shows that $\mathcal{C}_N^q$ is a set of uniqueness for $\mathcal{X}_N$. Therefore, the proof of Theorem 2.2 is complete in view of Proposition 2.1. ∎

The proof of Theorem 2.3 is very similar to that of Theorem 2.2, although the details are somewhat different. First, we obtain an analogue of (4.3).

LEMMA 4.2. *Let $N \geq 1$ be an integer. For $P \in \Pi_{2N-1}$, we have*

$$\int_0^\pi P(\cos\theta)d\theta = \frac{\pi}{N}\sum_{j=0}^{N-2} P(\cos\widetilde{\theta}_j) + \frac{\pi}{2N}\{P(\cos\widetilde{\theta}_{N-1}) + P(\cos\widetilde{\theta}_N)\}. \tag{4.9}$$

Proof. We observe that for $k = 0, \ldots, 2N-1$

$$\begin{aligned}
&\frac{1}{N}\sum_{j=0}^{N-2}\cos k\widetilde{\theta}_j + \frac{1}{2N}\{\cos k\widetilde{\theta}_{N-1} + \cos k\widetilde{\theta}_N\}\\
&\quad = \frac{1}{2N}\left\{\sum_{\ell=1}^{N-1}\exp(\pi ik\ell/N) + \exp(\pi ik(2N-\ell)/N)\right\} + \frac{1}{2N}\{\cos k(0) + \cos k\pi\}\\
&\quad = \frac{1}{2N}\sum_{\ell=0}^{2N-1}\exp(2\pi ik\ell/(2N)) = \delta_{k,0}.
\end{aligned}$$

This implies (4.9) when $P(\cos\theta) = \cos k\theta$, $k = 0, \ldots, 2N-1$. ∎

In the remainder of this section, we will write

$$\langle f, g\rangle_N^i := \frac{\pi}{N}\sum_{j=0}^{N-2} f(\cos\widetilde{\theta}_j)\overline{g(\cos\widetilde{\theta}_j)} + \frac{\pi}{2N}\left\{f(1)\overline{g(1)} + f(-1)\overline{g(-1)}\right\}. \tag{4.10}$$

The following lemma summarizes certain properties of the associated Chebyshev functions that we will need.

LEMMA 4.3. *Let $N \geq 2$ be an integer. Then $\langle C_n^m, C_{n'}^m\rangle_N^i = 0$ if $m = 0, 1, 2$, $n, n' = m, \ldots, N$, $n \neq n'$. Further,*

$$\langle C_n^m, C_n^m\rangle_N^i = \begin{cases} \pi & \text{if } m = 0,\ n = 0, N,\\ \pi/2 & \text{if } m = 0,\ n = 1, \ldots, N-1,\\ n^2\pi/2 & \text{if } m = 1,\ n = 1, \ldots, N-1,\\ (n^4\pi/2)(1-n^{-2}) & \text{if } m = 2,\ n = 2, \ldots, N-1,\\ n^4\pi(1-n^{-1}) & \text{if } m = 2,\ n = N. \end{cases} \tag{4.11}$$

Proof. In this proof only, we introduce the polynomials

$$U_n(\cos\theta) := \frac{\sin(n+1)\theta}{\sin\theta}, \qquad V_n(\cos\theta) := (1/2)U_{n+1}'(\cos\theta). \tag{4.12}$$

We note that

$$C_n^0 = T_n,\ C_n^1(\cos\theta) = n\sin n\theta = n\sin\theta U_{n-1}(\cos\theta),\ C_n^2(\cos\theta) = 2n\sin^2\theta V_{n-2}(\cos\theta).$$

Further, the polynomials U_n and V_n are the ultraspherical polynomials denoted in [15, p. 80] by $P_n^{(1)}$ and $P_n^{(2)}$, respectively. Therefore, using a straightforward computation

in the case of C_n^0 and C_n^1, and the orthogonality of $\{P_n^{(2)}\}$ in the case of C_n^2, we obtain

$$\int_0^\pi C_n^m(\cos\theta)C_{n'}^m(\cos\theta)d\theta = 0, \quad m = 0,1,2,\ n \neq n', \quad n = m, m+1, \ldots. \tag{4.13}$$

Similarly, using [15, (4.7.15), p. 81] in the case of C_n^2, we get

$$\int_0^\pi C_n^m(\cos\theta)^2 d\theta = \begin{cases} \pi & \text{if } n = m = 0, \\ \pi/2 & \text{if } m = 0, n = 1,2,\ldots, \\ n^2\pi/2 & \text{if } m = 1, n = 1,2,\ldots, \\ (n^4\pi/2)(1-n^{-2}) & \text{if } m = 2, n = 2,3,\ldots. \end{cases} \tag{4.14}$$

The quadrature formula (4.9) now shows that $\langle C_n^m, C_{n'}^m\rangle_N^i = 0$ if $m = 0,1,2$, $n, n' = m,\ldots,N$, $n \neq n'$, as well as all the equations in (4.11), except for the cases $m = 0$, $n = N$, and $m = 2$, $n = N$. The case $m = 0$, $n = N$ is clear from the definitions. Let $m = 2$, $n = N$. From the differential equation for Chebyshev polynomials, we see that with $x = \cos\theta$,

$$C_N^2(x) = (1-x^2)T_N''(x) = xT_N'(x) - N^2T_N(x) = N\cot\theta\sin(N\theta) - N^2\cos(N\theta).$$

Thus, $C_N^2(\pm 1) = 0$, and $C_N^2(\cos\widetilde{\theta}_j) = (-1)^j N^2$. The last equation in (4.11) is now easy to obtain from the definitions. ∎

Proof of Theorem 2.3. In this proof only, let

$$F_n^m(x) := \begin{cases} C_n^0(x) & \text{if } m = 0,\ n = 0,\ldots,N, \\ C_{n+1}^1(x) & \text{if } m \text{ is odd, } |m| \le N,\ n = 0,\ldots,N-2, \\ C_{n+2}^2(x) & \text{if } m \text{ is even, } |m| \le N,\ m \neq 0,\ n = 0,\ldots,N-2. \end{cases}$$

Using (4.1) with $M = 2N+1$ and the fact that $C_{n+m}^m(\pm 1) = 0$ if $m = 1,2$, we obtain as in the proof of Theorem 2.2 that for integers $|m|, |m'| \le N$, $n = 0,\ldots,N_m$, $n' = 0,\ldots,N_{m'}$,

$$\langle Z_{n'}^{m'}, Z_n^m\rangle_N = \begin{cases} 0, & m \neq m' \text{ or } n \neq n', \\ 2\pi\langle F_n^m, F_n^m\rangle_N^i & \text{if } n = n',\ m = m'. \end{cases} \tag{4.15}$$

Together with (2.27) and (4.11), this shows that $\{\sqrt{z_n^m}Z_n^m\}$ is an orthonormal basis for $\mathcal{X}_N$. Lemma 4.1 shows that $\mathcal{C}_N^i$ is a set of uniqueness for $\mathcal{X}_N$. Therefore, the proof of Theorem 2.2 is complete in view of Proposition 2.1. ∎

In order to prove Theorem 2.4, we need a representation for $\mathcal{I}_N f$ in (2.29) using the Dirichlet kernels. For integer $m \ge 1$, let

$$D_m^*(\theta) = \frac{1}{2} + \sum_{k=1}^{m-1}\cos k\theta + \frac{1}{2}\cos m\theta = \frac{\sin m\theta}{2\tan(\theta/2)},$$

$$D_m(\phi) = \sum_{|k|\le m}\exp(ik\phi) = \frac{\sin(m+1/2)\phi}{\sin(\phi/2)} = D_{m,e}(\phi) + D_{m,o}(\phi), \tag{4.16}$$

where

$$D_{m,e}(\phi) = \sum_{|2k|\le m}\exp(2ki\phi) = \frac{1}{2}\{D_m(\phi) + D_m(\phi+\pi)\},$$

$$D_{m,o}(\phi) = \sum_{|2k+1|\le m}\exp((2k+1)i\phi) = \frac{1}{2}\{D_m(\phi) - D_m(\phi+\pi)\}.$$

We note that

$$D_N^*(\widetilde{\theta}_j - \widetilde{\theta}_k) = N\delta_{j,k},\ D_N(\widetilde{\phi}_m - \widetilde{\phi}_\ell) = (2N+1)\delta_{\ell,m}. \tag{4.17}$$

LEMMA 4.4. *For $f \in C(\mathbb{S}^2)$, we have*

(4.18)

$$\begin{aligned}
&\mathcal{I}_N f(\boldsymbol{p}(\theta,\phi)) \\
&= \frac{1}{N(2N+1)} \sum_{j=0}^{N-2} \sum_{|m|\le N} f(\boldsymbol{p}(\widetilde{\theta}_j, \widetilde{\phi}_m))\{(D_N^*(\theta - \widetilde{\theta}_j) + D_N^*(\theta + \widetilde{\theta}_j))D_{N,e}(\phi - \widetilde{\phi}_m) \\
&\qquad + (D_N^*(\theta - \widetilde{\theta}_j) - D_N^*(\theta + \widetilde{\theta}_j))D_{N,o}(\phi - \widetilde{\phi}_m)\} \\
&\qquad + \frac{1}{N}\{f(\hat{\mathbf{n}})D_N^*(\theta) + f(\hat{\mathbf{s}})D_N^*(\theta - \pi)\}.
\end{aligned}$$

Proof. In this proof only, we denote the right-hand side of (4.18) by $T(\theta,\phi)$. Clearly, each of the summands on the right-hand side of (4.18), and hence T, is in $\mathbb{H}_N$. We observe that for all θ, ϕ, $j = 0,\dots,N-2$, $|m| \le N$,

$$\begin{aligned}
&(D_N^*(-\theta - \widetilde{\theta}_j) + D_N^*(-\theta + \widetilde{\theta}_j))D_{N,e}((\phi+\pi) - \widetilde{\phi}_m) \\
&= (D_N^*(\theta - \widetilde{\theta}_j) + D_N^*(\theta + \widetilde{\theta}_j))D_{N,e}(\phi - \widetilde{\phi}_m),
\end{aligned}$$

and

$$D_N^*(-\widetilde{\theta}_j) + D_N^*(\widetilde{\theta}_j) = D_N^*(\pi - \widetilde{\theta}_j) + D_N^*(\pi + \widetilde{\theta}_j) = 0.$$

Hence, for $j = 0,\dots,N-2$, $|m| \le N$,

$$(D_N^*(\theta - \widetilde{\theta}_j) + D_N^*(\theta + \widetilde{\theta}_j))D_{N,e}(\phi - \widetilde{\phi}_m) \in \mathcal{X}_N^*.$$

Similarly, for all θ, ϕ, $j = 0,\dots,N-2$, $|m| \le N$,

$$\begin{aligned}
&(D_N^*(-\theta - \widetilde{\theta}_j) - D_N^*(-\theta + \widetilde{\theta}_j))D_{N,o}((\phi+\pi) - \widetilde{\phi}_m) \\
&= (D_N^*(\theta - \widetilde{\theta}_j) - D_N^*(\theta + \widetilde{\theta}_j))D_{N,o}(\phi - \widetilde{\phi}_m),
\end{aligned}$$

and

$$D_N^*(-\widetilde{\theta}_j) - D_N^*(\widetilde{\theta}_j) = D_N^*(\pi - \widetilde{\theta}_j) - D_N^*(\pi + \widetilde{\theta}_j) = 0.$$

Moreover,

$$\cos N(\theta - \widetilde{\theta}_j) - \cos N(\theta + \widetilde{\theta}_j) = \cos(N\theta - j\pi - \pi) - \cos(N\theta + j\pi + \pi) = 0.$$

Therefore, none of the terms $D_N^*(\theta - \widetilde{\theta}_j) - D_N^*(\theta + \widetilde{\theta}_j)$ can contain a term involving $\sin N\theta$. Thus,

$$(D_N^*(\theta - \widetilde{\theta}_j) - D_N^*(\theta + \widetilde{\theta}_j))D_{N,o}(\phi - \widetilde{\phi}_m) \in \mathcal{X}_N^*.$$

It is clear that $D_N^*(\theta)$ and $D_N^*(\theta - \pi)$ are also in $\mathcal{X}_N^*$. Thus, each of the summands on the right-hand side in (4.18) may be viewed as functions on $\mathbb{S}^2$, and as such, are in $\mathcal{X}_N$. Thus, $T^\circ \in \mathcal{X}_N$.

Now, for $\ell = 0, \dots, N-2$, $|\nu| \le N$, we may use (4.17) and (4.1) to conclude that

$$\begin{aligned} &T(\widetilde{\theta}_\ell, \widetilde{\phi}_\nu) \\ &\quad = \frac{1}{2N+1} \sum_{|m|\le N} f(\boldsymbol{p}(\widetilde{\theta}_\ell, \widetilde{\phi}_m))\big\{D_{N,e}(\widetilde{\phi}_\nu - \widetilde{\phi}_m) + D_{N,o}(\widetilde{\phi}_\nu - \widetilde{\phi}_m)\big\} \\ &\quad = \frac{1}{2N+1} \sum_{|m|\le N} f(\boldsymbol{p}(\widetilde{\theta}_\ell, \widetilde{\phi}_m)) D_N(\widetilde{\phi}_\nu - \widetilde{\phi}_m) = f(\boldsymbol{p}(\widetilde{\theta}_\ell, \widetilde{\phi}_\nu)). \end{aligned}$$

The equation (4.17) also leads to $T^\circ(\hat{\mathbf{n}}) = f(\hat{\mathbf{n}})$ and $T^\circ(\hat{\mathbf{s}}) = f(\hat{\mathbf{s}})$. ∎

Our next lemma relates the degrees of approximation of a function $f \in C(\mathbb{S}^2)$ from $\mathcal{X}_N$ with that of $f^* \in C^\circ$ from $\mathbb{H}_N$.

LEMMA 4.5. *Let $N \ge 2$ be an integer, $f \in C(\mathbb{S}^2)$. Then*

$$\text{dist } (f^*, \mathbb{H}_N) \le \text{ dist } (f, \mathcal{X}_N) \le 5 \text{ dist } (f^*, \mathbb{H}_{N-1}). \tag{4.19}$$

Proof. The first inequality in (4.19) is obvious since $\mathcal{X}_N \subset \mathbb{H}_N$. Let $T \in \mathbb{H}_{N-1}$ be chosen so that $\|f^* - T\|_\infty^* = \text{ dist } (f^*, \mathbb{H}_{N-1})$. Then $U(\theta, \phi) := (1/2)[T(\theta, \phi) + T(-\theta, \phi + \pi)]$ satisfies (2.1), and

$$\|f^* - U\|_\infty^* = \text{dist } (f^*, \mathbb{H}_{N-1}). \tag{4.20}$$

Since U satisfies (2.1), there exist $S_\ell \in \Pi_{N-1}$, $R_\ell \in \Pi_{N-2}$, $|\ell| \le N-1$, such that

$$U(\theta, \phi) = \sum_{\substack{|\ell|\le N-1 \\ \ell \text{ even}}} S_\ell(\cos\theta) e^{i\ell\phi} + \sin\theta \sum_{\substack{|\ell|\le N-1 \\ \ell \text{ odd}}} R_\ell(\cos\theta) e^{i\ell\phi}.$$

For any $\phi \in \mathbb{R}$, we have

$$\max\left\{ \left| f(\hat{\mathbf{n}}) - \sum_{\substack{|\ell|\le N-1 \\ \ell \text{ even}}} S_\ell(1) e^{i\ell\phi} \right|, \ \left| f(\hat{\mathbf{s}}) - \sum_{\substack{|\ell|\le N-1 \\ \ell \text{ even}}} S_\ell(-1) e^{i\ell\phi} \right| \right\} \le \text{ dist } (f^*, \mathbb{H}_{N-1}). \tag{4.21}$$

Therefore,

$$|f(\hat{\mathbf{n}}) - S_0(1)| = \left| \frac{1}{2\pi} \int_0^{2\pi} \left\{ f(\hat{\mathbf{n}}) - \sum_{\substack{|\ell|\le N-1 \\ \ell \text{ even}}} S_\ell(1) e^{i\ell\phi} \right\} d\phi \right| \le \text{ dist } (f^*, \mathbb{H}_{N-1}). \tag{4.22}$$

Similarly,

$$|f(\hat{\mathbf{s}}) - S_0(-1)| \le \text{ dist } (f^*, \mathbb{H}_{N-1}). \tag{4.23}$$

The estimates (4.21), (4.22), (4.23) lead to

$$\left| \sum_{\substack{1\le|\ell|\le N-1 \\ \ell \text{ even}}} S_\ell(\pm 1) e^{i\ell\phi} \right| \le 2 \text{ dist } (f^*, \mathbb{H}_{N-1}). \tag{4.24}$$

Now, let

$$\widetilde{S}_\ell(x) = S_\ell(x) - S_\ell(1)(1+x)/2 - S_\ell(-1)(1-x)/2, \qquad 1 \le |\ell| \le N-1,\ \ell \text{ even},$$

and

$$\widetilde{U}(\theta,\phi) = S_0(\cos\theta) + \sum_{\substack{1\le|\ell|\le N-1\\ \ell \text{ even}}} \widetilde{S}_\ell(\cos\theta)e^{i\ell\phi} + \sin\theta \sum_{\substack{|\ell|\le N-1\\ \ell \text{ odd}}} R_\ell(\cos\theta)e^{i\ell\phi}.$$

In view of Theorem 2.1, $\widetilde{U} \in \mathcal{X}_N^*$. It is easy to verify using (4.20), (4.22), (4.23), and (4.24) that $\|f^* - \widetilde{U}\|_\infty^* \le 5 \text{ dist } (f^*, \mathbb{H}_{N-1})$. □

Finally, we are in a position to prove Theorem 2.4.

Proof of Theorem 2.4. In this proof only, let

$$\begin{aligned} L_N := \sup_{\theta,\phi\in\mathbb{R}} \Bigg[& \frac{1}{N(2N+1)} \sum_{j=0}^{N-2} \sum_{|m|\le N} \big\{ \big| D_N^*(\theta-\widetilde{\theta}_j) + D_N^*(\theta+\widetilde{\theta}_j)\big| |D_{N,e}(\phi-\widetilde{\phi}_m)| \\ & + \big| D_N^*(\theta-\widetilde{\theta}_j) - D_N^*(\theta+\widetilde{\theta}_j)\big| |D_{N,o}(\phi-\widetilde{\phi}_m)| \big\} \\ & + \frac{1}{N}\left\{ |D_N^*(\theta)| + |D_N^*(\theta-\pi)| \right\} \Bigg]. \end{aligned} \tag{4.25}$$

Using [9, (3.4), (3.6)], we estimate the discrete sums above by the integral norms of the Dirichlet kernels. Well-known bounds on Dirichlet kernels (see, for example, [5, 19]) now imply that

$$L_N \le c \int_{-\pi}^{\pi} |D_N^*(t)| dt \int_{-\pi}^{\pi} \{ |D_{N,e}(t)| + |D_{N,o}(t)| \}\, dt + c \le c(\log N)^2.$$

The estimate (2.31) is now clear from (4.18).

If $T \in \mathcal{X}_N$, then $\mathcal{I}_N(T) = T$. Therefore, using (2.31), we obtain that for any $T \in \mathcal{X}_N$,

$$\begin{aligned} \|f - \mathcal{I}_N f\|_\infty = \|f - T - \mathcal{I}_N(f-T)\|_\infty &\le \|f-T\|_\infty + c(\log N)^2 \|f-T\|_\infty \\ &\le c(\log N)^2 \|f-T\|_\infty. \end{aligned}$$

This implies (2.32). □

A SPECTRAL ORDER METHOD FOR INVERTING SECTORIAL LAPLACE TRANSFORMS*

MARÍA LÓPEZ-FERNÁNDEZ†, CÉSAR PALENCIA†, AND ACHIM SCHÄDLE‡

Abstract. Laplace transforms which admit a holomorphic extension to some sector strictly containing the right half plane and exhibiting a potential behavior are considered. A spectral order, parallelizable method for their numerical inversion is proposed. The method takes into account the available information about the errors arising in the evaluations. Several numerical illustrations are provided.

Key words. Laplace transform, numerical inversion, parabolic, spectral order, parallelizable

1. Introduction.

In a variety of situations, the problem arises of inverting numerically the Laplace transform $U(z)$ of a given mapping of interest $u(t)$. Roughly speaking, it turns out that the wider the set W where $U(z)$ can be computed, the easier the inversion is. For instance, if W is an interval (a, b) then the numerical inversion becomes an ill-posed problem [1, 5, 6]. On the other hand, if W is the complement of some bounded region, then the efficient Talbot method [16, 22] is at hand.

In the present paper we focus on the particular situation where W is a sector symmetric with respect to the real axis, strictly containing the right half plane, and we assume that $U(z)$ exhibits a potential behavior on W. We say then that $U(z)$ is *sectorial*. Precisely, there is a renewed interest in the numerical inversion of *sectorial* mappings [7, 8, 9, 10, 13, 14, 18] mainly due to its applicability to linear, non-homogeneous evolution equations of parabolic type (both in the context of abstract IVPs and Volterra equations), as well as their discretizations in space [3, 4, 11]. In this context, the inversion approach presents several computational advantages (a drastic reduction of the number of linear systems to be solved and two levels of parallelism), its main disadvantages being that the Laplace transform $F(z)$ of the source term must be *sectorial* (which in turn, as we comment below, demands the source term to be holomorphic on a sector containing the half axis $t > 0$) and that it requires evaluations of $F(z)$ at nodes with $\operatorname{Re} z < 0$. This issue is considered in [9]. Another way to overcome these difficulties is presented in [14], where the source term is locally approximated by holomorphic mappings with simple Laplace transforms. More recently, these restrictions are overcome in [12, 17], where the ideas in the present paper are adapted so as to provide accurate reconstructions of the traditional Runge–Kutta approximations to the solutions of such parabolic problems. These reconstructions require no regularity on the source term of the problem.

In the present paper we consider the issue of the numerical inversion of *sectorial* mappings by itself. By definition, a holomorphic mapping taking values in a complex

Banach space X,

$$U : W \subset \mathbb{C} \to X,$$

is said to be *sectorial* if W is the complement of some acute sector of the form

$$\Sigma_\delta = \{z \in \mathbb{C} : |\arg(-z)| \le \delta\}, \qquad 0 < \delta < \frac{\pi}{2}, \tag{1.1}$$

and if there exist constants $M > 0$ and $\mu \in \mathbb{R}$ such that

$$\|U(z)\| \le \frac{M}{|z|^\mu}, \qquad z \notin \Sigma_\delta. \tag{1.2}$$

It is known that a *sectorial* mapping is a Laplace transform (which for $\mu \le 0$ is understood in the Operational Calculus sense). In fact, let $U : W \to \mathbb{C}$ be a holomorphic mapping satisfying (1.1) and (1.2) for some $0 < \delta < \pi/2$, $M > 0$, and $\mu \in \mathbb{R}$. For $t > 0$, set

$$u(t) = \frac{1}{2\pi i} \int_\Gamma e^{tz} U(z)\, dz, \tag{1.3}$$

where Γ is a simple contour, lying in W, and parametrizable by a regular mapping $S : (-\infty, +\infty) \to \mathbb{C}$ such that

$$\lim_{x \to \pm\infty} \operatorname{Im} S(x) = \pm\infty \quad \text{and} \quad \lim_{x \to \pm\infty} \frac{\operatorname{Re} S(x)}{|x|} < 0.$$

Since the last condition implies

$$\operatorname{Re} z \le -b|z| \qquad \text{as } z \to \infty,\ z \in \Gamma,$$

for some $b > 0$, the integrand in (1.3) is absolutely convergent. Moreover, $u(t)$ is independent of the particular choice of Γ. Then, proceeding as in the proof of Theorem 2.6.1 in [2], it is easy to conclude that:

(i) u admits a holomorphic extension $u(\tau)$ to any sector of the form $|\arg(\tau)| \le \delta'$, with $0 < \delta' < \pi/2 - \delta$, and there $\|u(\tau)\| = \mathcal{O}(|\tau|^{\mu-1})$.

(ii) If $\mu > 0$, then U is the Laplace transform of u in the classical sense; i.e.,

$$U(z) = \int_0^{+\infty} e^{-zt} u(t)\, dt, \qquad \operatorname{Re} z > 0.$$

(iii) If $\mu \le 0$, then $u(t)$ might not be integrable in the neighborhood of the origin. However, after selecting an integer number $m \ge 1$, with $m + \mu \ge 1$, the previous comment shows that u is the derivative of order m of a mapping $v : (0, +\infty) \to X$, whose Laplace transform is $V(z) = U(z)/z^m$.

Thus, our goal is to numerically reconstruct $u(t)$ from the knowledge of a moderate number of evaluations of $U(z)$ at suitable nodes $z \notin \Sigma_\delta$. Let us point out that, from a practical point of view, it is essential to take into account that these evaluations are going to be affected by errors.

Notice that in case $U(z)$ satisfies a similar inequality,

$$\|U(z)\| \le \frac{M}{|z - \omega|^\mu}, \qquad z \notin \omega + \Sigma_\delta,$$

for some $\omega \in \mathbb{R}$, then, by using the shifting theorem, the inversion of $U(z)$ is reduced to that of a Laplace transform $\widetilde{U}(z)$ fulfilling (1.2). Since the respective originals $u(t)$ and $\widetilde{u}(t)$ are related by $u(t) = e^{\omega t}\widetilde{u}(t)$, we can just approximate $\widetilde{u}(t)$. This is why the analysis is restricted to the situation $\omega = 0$, i.e., to (1.2).

Now, as in [8, 9, 10, 13, 14], we choose Γ as the branch of a hyperbola and a parametrization $S : (-\infty, +\infty) \to \mathbb{C}$ of Γ which admits a holomorphic extension to a horizontal strip around the real axis. The numerical method we propose is simply the truncated trapezoidal rule, applied to the definite integral arising after parametrizing (1.3) by S, used with $2n + 1$ nodes $x_k = kh$, $-n \le k \le n$, and a suitable step size $h > 0$. The properties of S allow us to use the ideas and results in [20, 21], where the trapezoidal rule applied to holomorphic mappings on strips is considered. As already noted in [8, 9, 10, 13], the fast decay of our integrand yields an improvement of the more general estimates in [20, 21].

Very often, for instance, in the context of IVPs (see Illustration 3 in section 5), the main computational effort of the method is due to the evaluations of $U(z)$ at the nodes $z_k = S(x_k)$, $-n \le k \le n$. An important feature of the present approach is that the same evaluations can be used to approximate $u(t)$ at different $t > 0$ [7, 8, 9, 13, 16]. Accordingly, our goal is to obtain a uniform error estimate for the approximation of $u(t)$ on intervals of the form $[t_0, \Lambda t_0]$, with given $t_0 > 0$ and $\Lambda \ge 1$, rather than at a fixed $t > 0$. Essentially, this was the aim in [13], whose basic estimates we borrow. Notice also that the algorithm presents two levels of parallelism since, first, the evaluations of $U(z)$ at the involved nodes and, second, the evaluations of $u(t)$ at a selected finite set of values of $t \in [t_0, \Lambda t_0]$, can be carried out on different processors [7, 8, 9, 13, 14].

In the present paper, by considering a different choice of the geometrical and scale parameters from the one in [8, 9, 13], we improve the results there in two different ways:

(i) We get a better error bound, which now turns out to be a genuine spectral estimate of the form $\mathcal{O}(e^{-cn})$, instead of $\mathcal{O}(e^{-cn/\ln n})$.
(ii) We also get a weaker dependence of the exponential factor c on Λ than in [13], since now $c = \mathcal{O}(1/\ln \Lambda)$.

This means, in practice, that with a moderate number of evaluations of $U(z)$ we can accurately approximate $u(t)$ uniformly on intervals $[t_0, t_1]$ with $\Lambda = t_1/t_0 >> 1$, say, $\Lambda = 50$. Moreover, it is interesting to note that, for $\mu > 1$ in (1.2), with a different selection of parameters, we can achieve a uniform error estimate like $\mathcal{O}(e^{-c\sqrt{n}})$, for $0 \le t \le 1$, by using the same quadrature nodes. This can be shown by an argument similar to the one used in the proof of Proposition 2.7 in [9].

On the other hand, for the choice of parameters we propose, the precision ρ used in the evaluations of $U(z)$ at the required nodes plays a more relevant role than in [13]. In fact, ignoring that we always have $\rho > 0$ would result in large actual errors for $n >> 1$, as simple numerical experiments show (see Illustration 1 in section 5). This drawback is overcome by minimizing the estimate we get for the actual error (Theorem 2), which leads to a (ρ, n)-dependent choice of parameters. With this choice, the actual error finally behaves for moderate n like $\mathcal{O}(e^{-cn})$, with $c = \mathcal{O}(1/\ln \Lambda)$, and for large n like $\mathcal{O}(\rho)$. This optimal choice of parameters demands, of course, some information about the size of ρ. In the absence of it, we propose an n-dependent choice of parameters for which the actual error behaves like $\mathcal{O}(\rho + e^{-cn})$, with $c = \mathcal{O}(1/(\ln n + \ln \Lambda))$. All the above estimates are uniform on $t_0 \le t \le \Lambda t_0$, with fixed $t_0 > 0$ and $\Lambda > 1$. Moreover, the error constants are made explicit in the analysis and turn out to be reasonable.

The outline of the paper is as follows. In section 2 we describe the numerical method and show, in Theorem 1, how to achieve (i) and (ii). The propagation of errors is studied in section 3. The choice of parameters is considered in section 4, and four simple numerical illustrations of the theoretical results are provided in section 5.

2. The numerical method. Given δ in (1.1) and following the ideas in [13], we select α, $d > 0$ such that

$$0 < \alpha - d < \alpha + d < \frac{\pi}{2} - \delta. \tag{2.1}$$

Defining

$$T(w) = 1 - \sin(\alpha + iw),$$

this mapping transforms each horizontal straight line $\operatorname{Im} w = y$, $-d \le y \le d$, into the left branch of the hyperbola given by

$$\left(\frac{\operatorname{Re} z - 1}{\sin(\alpha - y)}\right)^2 - \left(\frac{\operatorname{Im} z}{\cos(\alpha - y)}\right)^2 = 1, \tag{2.2}$$

with center at $(1, 0)$ and foci at $(0, 0)$ and $(2, 0)$, whose asymptotes make angles $\pm[\pi/2 - (\alpha - y)]$ with the real axis. Therefore, T transforms the horizontal strip

$$D_d = \{z \in \mathbb{C} : |\operatorname{Im} z| \le d\}$$

into the region in the complex plane limited by the left branches corresponding to $y = \pm d$ in (2.2); cf. Figure 2.1.

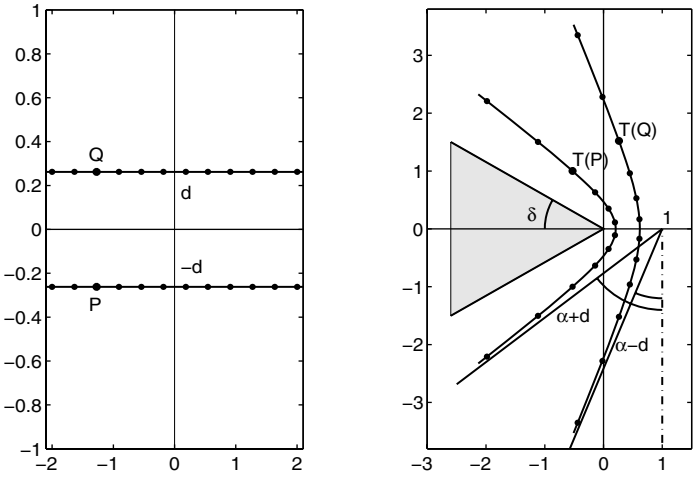

FIG. 2.1. *The horizontal strip (left) is transformed into the area limited by the left branches of two hyperbola (right). Additionally the sector Σ_δ is shown.*

Introducing a parameter $\lambda > 0$, the parametrization of Γ in (1.3) can be defined as

$$\Gamma = \{\lambda T(x) : x \in \mathbb{R}\};$$

i.e., Γ is the branch of a hyperbola corresponding to the image of the real axis under $S = \lambda T$. This results in

$$u(t) = \int_{-\infty}^{+\infty} G_t(x)\, dx\ , \qquad t > 0,$$

where $G_t : D_d \to X,\ t > 0$, is the mapping

$$G_t(w) = -\frac{\lambda}{2\pi i} \exp(\lambda t T(w)) U(\lambda T(w)) T'(w).$$

Once the parameters α, d, and λ have been fixed, we set $x_k = kh,\ k \in \mathbb{Z}$, and consider the approximation to $u(t)$ given by

$$u_n(t) = h \sum_{k=-n}^{n} G_t(x_k), \qquad t > 0. \tag{2.3}$$

The proof of the main result in [13, Theorem 2], shows that for $\mu = 1$ in (1.2)

(2.4)
$$\|u(t) - u_n(t)\| \le M \cdot \varphi(\alpha, d) \cdot L(\lambda t \sin(\alpha - d)) \cdot e^{\lambda t} \Big(\frac{1}{e^{2\pi d/h} - 1} + \frac{1}{e^{\lambda t \sin\alpha \cosh(nh)}} \Big),$$

where

$$\varphi(\alpha, d) = \frac{2}{\pi} \sqrt{\frac{1 + \sin(\alpha + d)}{1 - \sin(\alpha + d)}},$$

and $L(x)$, $x > 0$, is the function

$$L(x) = 1 + |\ln(1 - e^{-x})|.$$

Notice that $L(x)$ is decreasing in x, $L(x) \approx |\ln x|$, as $x \to 0^+$, and $L(x)$ tends to 1, as $x \to +\infty$.

As we commented in the introduction, in many applications the computational effort to obtain $u_n(t)$ is mainly due to the evaluations of $U(z)$ at $z = \lambda T(x_k),\ -n \le k \le n$, but these evaluations could be carried out in parallel. Another attractive feature of (2.3) is that the same evaluations of $U(z)$ can be used to compute $u_n(t)$ for different $t > 0$. In fact, as we see below, with the appropriate choice of parameters, we can use the same evaluations of $U(z)$ so as to have a spectral estimate

$$\|u(t) - u_n(t)\| = \mathcal{O}(e^{-cn})$$

uniform on intervals $t_0 \le t \le t_1$. The exponential factor c turns out to depend weakly on the ratio $\Lambda = t_1/t_0$, given that $c = \mathcal{O}(1/\ln\Lambda)$.

For simplicity the next theorem is restricted to the situation $\mu = 1$ in (1.2). The cases $\mu > 1$ and $\mu < 1$ are treated in subsequent remarks.

THEOREM 1. *Assume that U satisfies* (1.2) *with $\mu = 1$. Fixing α and d according to* (2.1)*, for $t_0 > 0$, $\Lambda \ge 1$, $0 < \theta < 1$, and $n \ge 1$, the choice of parameters*

$$h = \frac{1}{n} a(\theta), \qquad \lambda = \frac{2\pi d n (1 - \theta)}{t_0 \Lambda a(\theta)}, \tag{2.5}$$

with

$$a(\theta) = \operatorname{arccosh}\Big(\frac{\Lambda}{(1-\theta)\sin\alpha}\Big),$$

yields the uniform estimate on $t_0 \le t \le \Lambda t_0$,

$$\|u(t) - u_n(t)\| \le M \cdot \varphi(\alpha, d) \cdot L(\lambda t_0 \sin(\alpha - d)) \cdot \frac{2\epsilon_n(\theta)^\theta}{1 - \epsilon_n(\theta)}, \tag{2.6}$$

where

$$\epsilon_n(\theta) = \exp\Big(-\frac{2\pi d}{a(\theta)} n\Big).$$

The theorem shows, just by selecting any $0 < \theta < 1$, a genuine spectral order of convergence in n of the form $\mathcal{O}(e^{-cn})$, where $c = \mathcal{O}(1/\ln\Lambda)$ (cf. [8, 9, 10, 13]).

Proof. Set $\sigma = \lambda t_0$. For $t_0 \le t \le \Lambda t_0$, (2.4) implies the uniform bound

$$\|u(t) - u_n(t)\| \le M \cdot \varphi(\alpha, d) \cdot L(\sigma \sin(\alpha - d)) \cdot e^{\Lambda\sigma}\Big(\frac{1}{e^{2\pi d/h} - 1} + \frac{1}{e^{\sigma \sin\alpha \cosh(nh)}}\Big).$$

Our choice of h and λ is precisely the one guaranteeing that

$$\exp\Big(\frac{2\pi d}{h}\Big) = \exp(\sigma \sin\alpha \cosh(nh)) = \frac{1}{\epsilon_n(\theta)};$$

hence

$$\frac{1}{e^{2\pi d/h} - 1} + \frac{1}{e^{\sigma \sin\alpha \cosh(nh)}} \le \frac{2e^{-2\pi d/h}}{1 - e^{-2\pi d/h}} = \frac{2\epsilon_n(\theta)}{1 - \epsilon_n(\theta)}.$$

The proof ends after remarking that

$$e^{\Lambda\sigma}\epsilon_n(\theta) = \epsilon_n(\theta)^{\theta-1}\epsilon_n(\theta) = \epsilon_n(\theta)^\theta. \qquad \square$$

To end the section we comment, in the two following remarks, on the situation $\mu \ne 1$ in (1.2). We omit details in the proofs, which are completely analogous to the one of Theorem 1.

Remark 1. Assume that U satisfies (1.2) with $\mu > 1$. By Remark 1 in [13] we have

$$\|u(t) - u_n(t)\| \le M \cdot \varphi(\alpha, d, \mu) \cdot L(\lambda t \sin(\alpha - d)) \cdot \frac{e^{\lambda t}}{\lambda^{\mu-1}}\Big(\frac{1}{e^{2\pi d/h} - 1} + \frac{1}{e^{\lambda t \sin\alpha \cosh(nh)}}\Big),$$

where

$$\varphi(\alpha, d, \mu) = \frac{2}{\pi}\sqrt{\frac{1 + \sin(\alpha + d)}{(1 - \sin(\alpha + d))^{2\mu-1}}}.$$

Thus, for $0 < \theta < 1$, the same choice of values for h and λ as in Theorem 1 gives the bound

$$\|u(t) - u_n(t)\| \le M \cdot \varphi(\alpha, d, \mu) \cdot L(\lambda t_0 \sin(\alpha - d)) \cdot \lambda^{1-\mu} \cdot \frac{2\epsilon_n(\theta)^\theta}{1 - \epsilon_n(\theta)},$$

uniformly for $t_0 \le t \le \Lambda t_0$. This estimate is again spectral in n, since

$$\lambda^{1-\mu} = \mathcal{O}\Big(\Big(\frac{\Lambda t_0}{n}\Big)^{\mu-1}\Big).$$

Remark 2. Assume now that U satisfies (1.2) with $\mu < 1$. By Remark 1 in [13], for a fixed $s \in (0,1)$, there holds

$$\|u(t)-u_n(t)\| \le M\cdot\varphi_s(\alpha,d,\mu)\cdot L(s\lambda t\sin(\alpha-d))\cdot\frac{e^{\lambda t}}{t^{1-\mu}}\Big(\frac{1}{e^{2\pi d/h}-1}+\frac{1}{e^{s\lambda t\sin\alpha\cosh(nh)}}\Big),$$

where now

$$\varphi_s(\alpha,d,\mu) = \frac{2}{\pi}\sqrt{\frac{1+\sin(\alpha+d)}{1-\sin(\alpha+d)}}\Big(\frac{1-\mu}{(1-s)e\sin(\alpha-d)}\Big)^{1-\mu}.$$

In this situation, for $\theta \in (0,1)$ we choose

$$h = \frac{1}{n}a_s(\theta), \qquad \lambda = \frac{2\pi dn(1-\theta)}{t_0\Lambda a_s(\theta)},$$

where

$$a_s(\theta) = \operatorname{arccosh}\Big(\frac{\Lambda}{\mathrm{s}(1-\theta)\sin\alpha}\Big).$$

Setting

$$\epsilon_{s,n}(\theta) = \exp\Big(\frac{-2\pi dn}{a_s(\theta)}\Big),$$

we get the spectral estimate

$$\|u(t)-u_n(t)\| \le M\cdot\varphi_s(\alpha,d,\mu)\cdot L(s\lambda t_0\sin(\alpha-d))\cdot t_0^{\mu-1}\frac{2\epsilon_{s,n}(\theta)^\theta}{1-\epsilon_{s,n}(\theta)}$$

uniformly for $t_0 \le t \le \Lambda t_0$.

3. Error propagation. Numerical experiments (see section 5) show that for large values of n the estimate (2.6) is no longer true in practice. The explanation of this apparently contradictory behavior lies in the influence of the errors when evaluating U and the elementary functions involved. For the sake of simplicity, we consider first the case $\mu = 1$ in (1.2). The situations $\mu > 1$ and $\mu < 1$ are considered in subsequent remarks.

Let $z_k = \lambda T(x_k)$, $-n \le k \le n$, be the nodes used in (2.3). Clearly, in practice, as numerical approximation to $u(t)$ we actually obtain

$$\bar{u}_n(t) = \sum_{k=-n}^{n}\omega_k(t)U_k, \tag{3.1}$$

where, for $-n \le k \le n$, $\omega_k(t) \in \mathbb{C}$ and $U_k \in X$, are approximations to

$$-\frac{\lambda h}{2\pi i}\exp(\lambda t z_k)T'(x_k)$$

and $U(z_k)$, respectively.

To estimate the actual error $\|u(t) - \bar{u}_n(t)\|$ we need to make some assumptions on the approximations used. To this end, we are going to focus on two frequent possibilities, depending on whether we have information on absolute or relative errors due to the evaluations. To be precise, we are going to assume that there exists $\rho > 0$ such that, simultaneously for all $-n \le k \le n$, we have either

$$\|U(z_k) - U_k\| \le \rho \quad \text{and} \quad \omega_k(t) = -\frac{\lambda h}{2\pi i} \exp(\lambda t z_k) T'(x_k) \tag{3.2}$$

or

$$\left\| -\frac{\lambda h}{2\pi i} \exp(\lambda t z_k) T'(x_k) U(z_k) - \omega_k(t) U_k \right\| \le \rho \left\| -\frac{\lambda h}{2\pi i} \exp(\lambda t z_k) T'(x_k) U(z_k) \right\|. \tag{3.3}$$

Situation (3.2) arises, for instance, when $U_k \approx U(z_k)$ are provided by means of some auxiliary routine, say, by solving a linear system, with prescribed absolute accuracy ρ, and moreover the errors due to the evaluations of the elementary functions involved turn out to be negligible compared to ρ. Situation (3.3) is typical when $U(z)$ is an elementary function that can be evaluated with relative accuracy ρ.

The next theorem yields an estimate of the actual error for these situations. We maintain the notation introduced in Theorem 1.

THEOREM 2. *Assume that U satisfies* (1.2) *with $\mu = 1$. Fix α, d according to* (2.1). *For $t_0 > 0$, $\Lambda \ge 1$, $0 < \theta < 1$, and $n \ge 1$, select the parameters*

$$h = \frac{1}{n} a(\theta), \qquad \lambda = \frac{2\pi d n (1-\theta)}{t_0 \Lambda a(\theta)}.$$

Assume also that $\omega_k(t) \in \mathbb{C}$, $t_0 \le t \le t_1$, $U_k \in X$, $-n \le k \le n$, satisfy either (3.2) *or* (3.3). *Then, the actual error is estimated by*

$$\|u(t) - \bar{u}_n(t)\| \le M \cdot \Phi \cdot Q \cdot \left(\varepsilon \epsilon_n(\theta)^{\theta - 1} + \frac{\epsilon_n(\theta)^{\theta}}{1 - \epsilon_n(\theta)} \right), \tag{3.4}$$

uniformly on $t_0 \le t \le \Lambda t_0$, where either

(a) $\varepsilon = \rho/(M t_0)$,

$$\Phi = \max\left\{ \frac{2}{\pi} \sqrt{\frac{1 + \sin(\alpha + d)}{1 - \sin(\alpha + d)}}, \frac{1}{2\pi \sin \alpha} \right\},$$

and

$$Q = \max\{2L(\lambda t_0 \sin(\alpha - d)), 2 + (2 + \lambda t_0)h\}$$

in case (3.2) *holds, or*

(b) $\varepsilon = \rho$,

$$\Phi = \frac{2}{\pi} \sqrt{\frac{1 + \sin(\alpha + d)}{1 - \sin(\alpha + d)}},$$

and

$$Q = \max\{2L(\lambda t_0 \sin(\alpha - d)), 1/2(h + L(\lambda t_0 \sin \alpha))\},$$

in case (3.3) *holds.*

Notice that Q depends logarithmically on α, d, $1-\theta$, and Λ.

The estimate (3.4) given by the theorem, with a fixed $0<\theta<1$, shows again a spectral order of convergence $\mathcal{O}(e^{-cn})$, with $c=\mathcal{O}(1/\ln\Lambda)$, but only for moderate n, to be more precise, as long as $\epsilon_n(\theta)\geq\varepsilon$. On the other hand, for fixed θ, (3.4) goes to $+\infty$ exponentially as $n\to+\infty$. However, this apparent drawback is overcome by selecting θ in a suitable way, as we explain in section 4.

Proof. By writing

$$\|u(t)-\bar{u}_n(t)\|\leq\|u(t)-u_n(t)\|+\|u_n(t)-\bar{u}_n(t)\|,$$

and noticing that, for the corresponding Q, (2.6) implies

$$\|u(t)-u_n(t)\|\leq M\cdot\Phi\cdot Q\frac{\epsilon_n(\theta)^\theta}{1-\epsilon_n(\theta)},$$

the proof is reduced to show that

$$\|u_n(t)-\bar{u}_n(t)\|\leq M\cdot\Phi\cdot Q\varepsilon\epsilon_n(\theta)^{\theta-1}. \tag{3.5}$$

Assume first that (3.2) holds. This situation was already studied in section 5 in [13]. As it is shown there, for $t_0\leq t\leq\Lambda t_0$, we have

$$\|u_n(t)-\bar{u}_n(t)\|\leq\frac{\lambda e^{\lambda\Lambda t_0}\rho}{2\pi}h\sum_{k=-n}^{n}e^{-\gamma\cosh x_k}\cosh x_k,$$

where $\gamma=\lambda t_0\sin\alpha$. By noticing that the function $se^{-\gamma s}$, $s\geq0$, attains its maximum $1/(\gamma e)$ at the point $s_0=1/\gamma$ and is monotonic on the intervals $[0,s_0]$ and $[s_0,+\infty)$, it is easy to see that

$$\begin{aligned}h\sum_{k=-n}^{n}e^{-\gamma\cosh x_k}\cosh x_k&\leq h+2h\sum_{k=1}^{n}e^{-\gamma\cosh x_k}\cosh x_k\\&\leq h+\frac{4h}{\gamma e}+2\int_0^{+\infty}e^{-\gamma\cosh x}\cosh x\,dx\\&\leq\frac{(\gamma+2)h+2}{\gamma},\end{aligned}$$

whence, recalling that $\varepsilon=\rho/(t_0M)$, we get

$$\|u_n(t)-\bar{u}_n(t)\|\leq\frac{M}{2\pi\sin\alpha}[2+(2+\lambda t_0)h]e^{\lambda\Lambda t_0}\varepsilon. \tag{3.6}$$

Using now that

$$e^{\Lambda\lambda t_0}=\epsilon_n(\theta)^{\theta-1}, \tag{3.7}$$

we readily obtain (3.5).

Assume now that (3.3) holds. Proceeding as in the proof of Lemma 1 and Theorem 2 in [13], and denoting

$$\varphi(\alpha,0)=\frac{2}{\pi}\sqrt{\frac{1+\sin\alpha}{1-\sin\alpha}},$$

we get

$$\begin{aligned}\|u_n(t)-\bar{u}_n(t)\| &\le \frac{\rho M e^{\lambda t}}{2\pi} h \sum_{k=-n}^{n} e^{-\lambda t \sin\alpha \cosh x_k}\left|\frac{T'(x_k)}{T(x_k)}\right| \\ &\le \frac{M\varphi(\alpha,0)}{4}\rho e^{\lambda t} h \sum_{k=-n}^{n} e^{-\lambda t \sin\alpha \cosh x_k} \\ &\le \frac{M\varphi(\alpha,0)}{2}\rho e^{\lambda t}\left(h+\int_0^{+\infty} e^{-\lambda t \sin\alpha \cosh x}\,dx\right) \\ &\le \frac{M\varphi(\alpha,0)}{2}\rho e^{\lambda t}(h+L(\lambda t \sin\alpha)).\end{aligned}$$

Hence, using again (3.7) and the inequality $\varphi(\alpha,0)\le\varphi(\alpha,d)$, we deduce (3.5). ∎

The behavior for $\mu \neq 1$ in (1.2) is considered in the following remarks, whose proofs are a combination of Remarks 1 and 2 and the arguments used in [13, Theorem 2]. Notice that (3.6) is independent of μ.

Remark 3. Assume that $\mu > 1$ in (1.2) and fix $0<\theta<1$. Then, for the choice of parameters in Theorem 2 and uniformly on $t_0 \le t \le \Lambda t_0$, we have the following.

(a) In case (3.2) it holds that

$$\|u(t)-\bar{u}_n(t)\| \le M\cdot\Phi\cdot Q\cdot\left(\varepsilon\epsilon_n(\theta)^{\theta-1}+\lambda^{1-\mu}\frac{\epsilon_n(\theta)^{\theta}}{1-\epsilon_n(\theta)}\right),$$

with $\varepsilon=\rho/(Mt_0)$,

$$\Phi=\max\left\{\frac{2}{\pi}\sqrt{\frac{1+\sin(\alpha+d)}{(1-\sin(\alpha+d))^{2\mu-1}}},\frac{1}{2\pi\sin\alpha}\right\},$$

and

$$Q=\max\{2L(\lambda t_0\sin(\alpha-d)),2+(2+\lambda t_0)h\}.$$

(b) In case (3.3) it holds that

$$\|u(t)-\bar{u}_n(t)\| \le M\cdot\Phi\cdot Q\cdot\lambda^{1-\mu}\cdot\left(\varepsilon\epsilon_n(\theta)^{\theta-1}+\frac{\epsilon_n(\theta)^{\theta}}{1-\epsilon_n(\theta)}\right),$$

with $\varepsilon=\rho$,

$$\Phi=\frac{2}{\pi}\sqrt{\frac{1+\sin(\alpha+d)}{(1-\sin(\alpha+d))^{2\mu-1}}},$$

and

$$Q=\max\{2L(\lambda t_0\sin(\alpha-d)),1/2(h+L(\lambda t_0\sin\alpha))\}.$$

Remark 4. Assume that $\mu<1$ in (1.2) and fix $0<s,\theta<1$. Then, for the choice of parameters in Remark 2 and uniformly on $t_0\le t\le\Lambda t_0$, we have the following.

(a) In case (3.2) it holds that

$$\|u(t) - \bar{u}_n(t)\| \leq M \cdot \Phi \cdot Q \cdot \left(\varepsilon \epsilon_{s,n}(\theta)^{\theta-1} + t_0^{\mu-1} \frac{\epsilon_{s,n}(\theta)^{\theta}}{1 - \epsilon_{s,n}(\theta)} \right),$$

with $\varepsilon = \rho/(Mt_0)$,

$$\Phi = \max \left\{ \frac{2}{\pi} \sqrt{\frac{1+\sin(\alpha+d)}{1-\sin(\alpha+d)}} \Big(\frac{1-\mu}{(1-s)e\sin(\alpha-d)} \Big)^{1-\mu}, \frac{1}{2\pi \sin\alpha} \right\},$$

and

$$Q = \max\{2L(s\lambda t_0 \sin(\alpha - d)), 2 + (2 + \lambda t_0)h\}.$$

(b) In case (3.3) it holds that

$$\|u(t) - \bar{u}_n(t)\| \leq M \cdot \Phi \cdot Q \cdot \left(\lambda^{1-\mu} \varepsilon \epsilon_{s,n}(\theta)^{\theta-1} + t_0^{\mu-1} \frac{\epsilon_{s,n}(\theta)^{\theta}}{1 - \epsilon_{s,n}(\theta)} \right),$$

with $\varepsilon = \rho$,

$$\Phi = \frac{2}{\pi} \sqrt{\frac{1+\sin(\alpha+d)}{1-\sin(\alpha+d)}} \Big(\frac{1-\mu}{(1-s)e\sin(\alpha-d)} \Big)^{1-\mu},$$

and

$$Q = \max\{2L(s\lambda t_0 \sin(\alpha - d)), 1/2(h + L(s\lambda t_0 \sin\alpha))\}.$$

4. The choice of parameters. With Theorem 2 in mind, we now try to derive a strategy for the choice of parameters. First, (3.4) shows that it is of interest to select α away from zero and $\alpha + d$ away from $\pi/2$. The dependence of the actual error on $\alpha - d$ is less important, since it is logarithmic.

Suppose α and d have already been chosen; then for a given n we take h and λ as indicated in Theorem 2 and we fix $0 < \theta < 1$. Assume also that we have an estimation of ρ and set $\varepsilon = \rho/(Mt_0)$ or $\varepsilon = \rho$ as in Theorem 2. Then, since in practice we always have $\rho > 0$ and hence $\varepsilon > 0$, it turns out that $\varepsilon \epsilon_n(\theta)^{\theta-1} \to +\infty$ as $n \to +\infty$. Hence, it is clear that increasing the number of nodes might result in a worse estimate (3.4). In fact, increasing n may result in worse approximations, as Illustration 1 in section 5 shows.

To overcome this drawback we let θ be a free parameter for the moment. Given $\varepsilon > 0$ and n, after selecting α and d, neglecting the logarithmic factor Q, and taking into account that typically $\epsilon_n(\theta) << 1$, the best thing we can do is to choose $0 < \theta < 1$ so as to minimize the term

$$\varepsilon \epsilon_n(\theta)^{\theta-1} + \epsilon_n(\theta)^{\theta}; \tag{4.1}$$

i.e., we must tune θ depending on $\varepsilon > 0$ and n. By a direct calculation it can be proven that the first derivative of $\epsilon_n(\theta)^{\theta-1}$ with respect to θ is increasing in θ. The same is true for $\epsilon_n(\theta)^{\theta}$ (in this case the proof, though elementary, is more difficult). We conclude that the expression in (4.1) defines a strictly convex function of θ. Moreover, its derivative is < 0 at 0^+ and tends to $+\infty$ as $\theta \to 1^-$. Therefore, (4.1) attains its minimum exactly for one value $\theta_{\varepsilon,n} \in (0, 1)$, which is the one we propose to be used.

Though it is not easy to express the dependence of $\theta_{\varepsilon,n}$ on n and ε, this can be easily done numerically (see section 5).

Since, up to logarithmic factors, the choice $\theta = \theta_{\varepsilon,n}$ in (3.4) is optimal, it is clear that with this choice we get for the actual error:

(a) A spectral order of convergence $\mathcal{O}(e^{-cn})$, with $c = \mathcal{O}(1/\ln \Lambda)$, for moderate values of n. In fact, already for any fixed $0 < \theta < 1$, (3.4) shows that the error behaves like $\mathcal{O}(e^{-cn})$ as long as $\epsilon_n(\theta) \le \varepsilon$, i.e., for $n = \mathcal{O}(|\ln \varepsilon|)$.

(b) The errors are not propagated. In fact, already with the nonoptimal choice

$$\theta = 1 - \frac{1}{n},$$

(3.4) reads

$$\|u(t) - \bar{u}_n(t)\| = \mathcal{O}(\varepsilon + e^{-cn}) \tag{4.2}$$

uniformly on $t_0 \le t \le \Lambda t_0$, with $c = \mathcal{O}(1/(\ln \Lambda + \ln n))$. This remark tells us that, for large values of n, the actual error saturates at level ε, as observed in the numerical experiments (see section 5).

In the previous discussion it was essential to assume that we had some information about ε. Notice that, even in case we do not have such information, the choice $\theta = 1 - 1/n$, which led to (4.2), is always available. This bound is almost spectral in n, depends weakly on Λ, and prevents error amplification.

5. Numerical illustrations. In this section we give four numerical illustrations. The first two concern elementary Laplace transforms which are assumed to be computed with a relative error of order $\rho \approx$ eps, where eps stands for the machine precision (eps $= 10^{-16}$ in our computations). In the last two illustrations we do not assume any information about the errors due to the computations of the Laplace transforms.

Illustration 1. We first show, by means of a simple example, that for $n >> 1$ (2.6) fails in the presence of errors in the evaluations. To this end, we consider the mapping $u(t) = e^{-t}$, whose Laplace transform is $U(z) = 1/(1+z)$.

This function satisfies (1.2) for all $\delta > 0$ and $M = 1/\sin\delta$. We fix $\theta = 0.5$, $\alpha = 0.7$, and $d = 0.6$, and choose the parameters h, λ as stated in the theorem for all the values of n. In Figure 5.1 we plot in a semilogarithmic scale the absolute actual error, i.e.,

$$\ln \max_{t\in[t_0,\Lambda t_0]} \|u(t) - \bar{u}_n(t)\|$$

versus n (recall that $\bar{u}_n(t)$ stands for the actual computed approximation to $u(t)$; see (3.1)). This is done for $\Lambda = 5, 50$ and $t_0 = 1$. This figure shows that the error decays exponentially for the first values of n, saturates near ε level, and then grows like $\mathcal{O}(e^{cn})$.

Next, to study the behavior of the error and its estimate with respect to θ, we repeat the previous experiment for $\Lambda = 5$, with $\theta = 0.5$ and $\theta = 0.99$. The actual error and the corresponding theoretical estimate are depicted in Figure 5.2. We observe that the value of n where the error starts growing is well predicted by Theorem 2. Also, we see that enlarging θ results in a slower error propagation.

Finally, we tune parameters as explained in section 4. For $\Lambda = 5,\ 50$, in Figure 5.3 (left) we plot the optimal values of θ against n. In Figure 5.3 (right) we plot

$$\ln \max_{t\in[t_0,\Lambda t_0]} \|u(t) - \bar{u}_n(t)\|$$

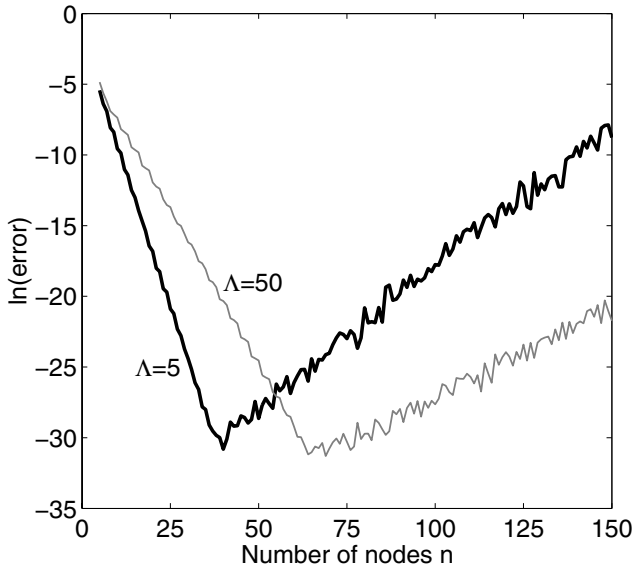

FIG. 5.1. $\ln \max_{t\in[t_0,\Lambda t_0]} \|u(t) - \bar{u}_n(t)\|$ *versus* n *for* u *in Illustration* 1*, with* $\theta = 0.5$ *fixed,* $\alpha = 0.7$*,* $d = 0.6$*, and* $t_0 = 1$*. The gray line corresponds to* $\Lambda = 50$ *and the black to* $\Lambda = 5$*.*

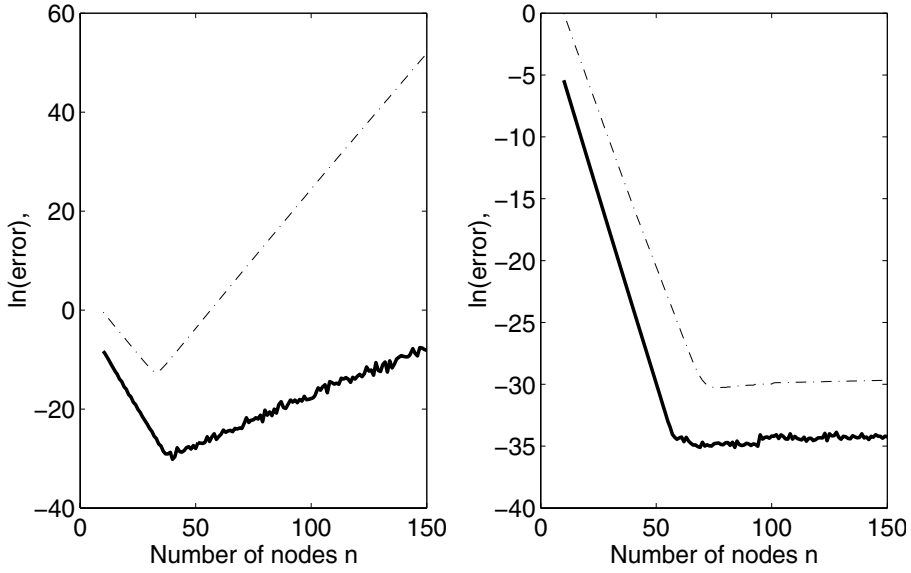

FIG. 5.2. *Observed error (continuous) and theoretical estimate (dashed) for* u *in Illustration* 1 *with fixed* θ *versus* n*, in semilogarithmic scale. Left: For* $\theta = 0.5$*. Right: For* $\theta = 0.99$*. In both cases,* $\Lambda = 5$*.*

(continuous line) and the logarithm of the corresponding values of the theoretical error estimate (dashed line) obtained in Theorem 2, versus n, once θ is optimal. We maintain $\alpha = 0.7$, $d = 0.6$, and $t_0 = 1$.

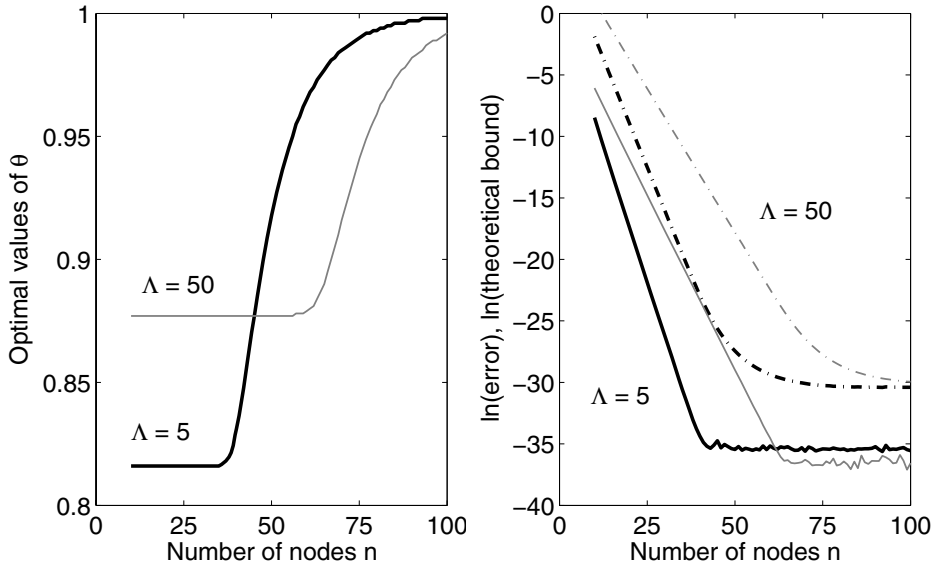

FIG. 5.3. *Left: Optimal θ versus n. Right: Natural logarithms of* $\max_{t\in[t_0,\Lambda t_0]} \|u(t) - \bar{u}_n(t)\|$ *(continuous) and the theoretical estimate (dashed) versus n, for u in Illustration* 1. *The gray lines correspond to $\Lambda = 50$ and the black to $\Lambda = 5$.*

Illustration 2. Take $\beta = 1.5$ and set

$$U(z) = \frac{z^{\beta-1}}{z^\beta + 1};$$

i.e., $U(z)$ is the Laplace transform of

$$u(t) = M_\beta(-t^\beta),$$

where M_β stands for the Mittag–Leffler function of order β (see [15]). Notice that U satisfies (1.2) for any $\delta \in (\pi/3, \pi/2)$, with $\mu = 1$ and $M = 1/\sin(\beta(\pi - \delta))$. We consider here as an exact solution the one computed with 500 nodes and take $\alpha = \pi/12$, $d = 0.25$, and $t_0 = 1$.

This example was already considered in [13]. In order to compare the performance of the strategy proposed in [13] with the one proposed in the present paper, we first compute $\bar{u}_n(t)$ by selecting the parameters as in [13]. In Figure 5.4 (left) we plot in semilogarithmic scale the theoretical estimate and actual error for $\Lambda = 2, 5$, which are acceptable. In Figure 5.4 (right) we do the same for $\Lambda = 50$ and conclude that the approach in [13] is not at all useful for large values of Λ. However, the corresponding computation obtained by using the strategy in section 4 yields the plot in Figure 5.5, which shows a satisfactory spectral order of convergence even for $\Lambda = 50$.

Illustration 3. We consider the inhomogeneous heat equation on the unit square $\Omega = (0,1)^2$ with zero initial value and a convective heat flux at the boundary

$$\left\{ \begin{array}{lcl} u_t(t,x) & = & \Delta u(t,x) + f(x), \text{ for } x \in \Omega,\ t \geq 0, \\ \partial_\nu u(t,x) & = & -u(t,x), \text{ for } x \in \partial\Omega,\ t \geq 0, \\ u(0,x) & = & 0, \text{ for } x \in \Omega, \end{array} \right. \tag{5.1}$$

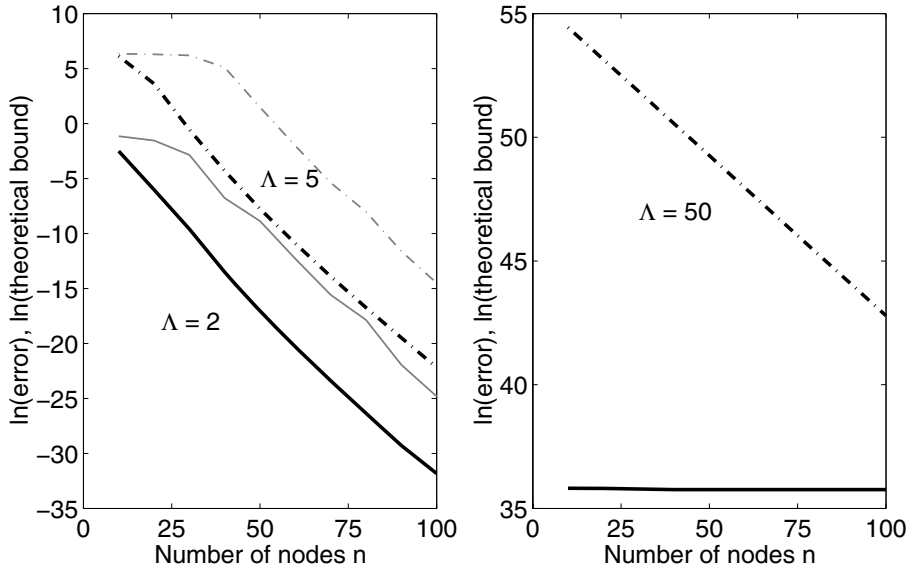

FIG. 5.4. *Natural logarithms of* $\max_{t\in[t_0,\Lambda t_0]} \|u(t) - \bar{u}_n(t)\|$ *(continuous) and the theoretical estimate (dashed) versus* n*, for* u *in Illustration* 2 *proceeding as in* [13] *for* $\delta = \pi/3$*,* $t_0 = 1$*. The gray lines correspond to* $\Lambda = 50$ *and the black to* $\Lambda = 5$*.*

where f is the indicator function of the rectangle $R = [0.6, 0.8] \times [0.2, 0.8]$, i.e., $f = 1$ on R and $f = 0$ elsewhere.

Problem (5.1) is semidiscretized in space by using linear finite elements on a triangular grid. Denoting by $V_h \subset L^2(\Omega)$ the space of elements and by $U_h(z)$ the Laplace transform of the semidiscrete solution $u_h(t)$, we get

$$U_h(z) = \frac{1}{z}(z - \Delta_h)^{-1} P_h f,$$

with $\Delta_h : V_h \to V_h$ the discrete Laplacian and P_h the orthogonal projection of f onto V_h. Now, for fixed $h > 0$, we try to approximate $u_h(t)$ by inverting $U_h(z)$. Notice that, since Δ_h is definite negative, certainly $U_h(z)$ satisfies (1.2) for any $0 < \delta < \pi/2$ and $M = 1/\sin(\delta)$. Notice also that, working in coordinates relative to the standard basis of elements, $U_h(z)$ is represented by a vector valued mapping $\mathbf{U}_h(z)$ satisfying

$$zM_h\mathbf{U}_h(z) + S_h\mathbf{U}_h(z) = \frac{1}{z}\mathbf{f}_h,$$

where M_h and S_h stand for the mass and stiffness matrices and where $\mathbf{f}_h$ is the vector formed by the scalar products of f with the elements of the basis. Thus, one evaluation of $U(z_k)$ at a given node z_k requires the solution of one linear system of the above form.

In the experiment we generate a mesh, shown in the left of Figure 5.6, with 542 triangles by means of the mesh generator Triangle [19]. Linear systems are solved using MATLAB's sparse LU factorization UMFPACK. Since $u_h(t)$ is unknown, the errors are estimated in the $L^2(\Omega)$-norm with respect to a reference solution $\bar{u}_{h,500}(t)$ obtained with 500 nodes. In the absence of precise information about ρ, both for this reference solution and for the rest of the approximations $\bar{u}_{h,n}(t)$ to $u_h(t)$, we take

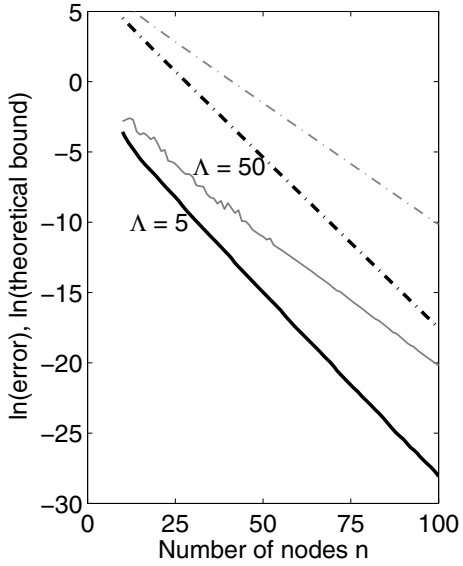

FIG. 5.5. *Natural logarithm of* $\max_{t\in[t_0,\Lambda t_0]} \|u(t) - \bar{u}_n(t)\|$ *(continuous) and the theoretical estimate (dashed) versus* n*, for* u *in Illustration* 2*. The gray lines correspond to* $\Lambda = 50$ *and the black to* $\Lambda = 5$*.*

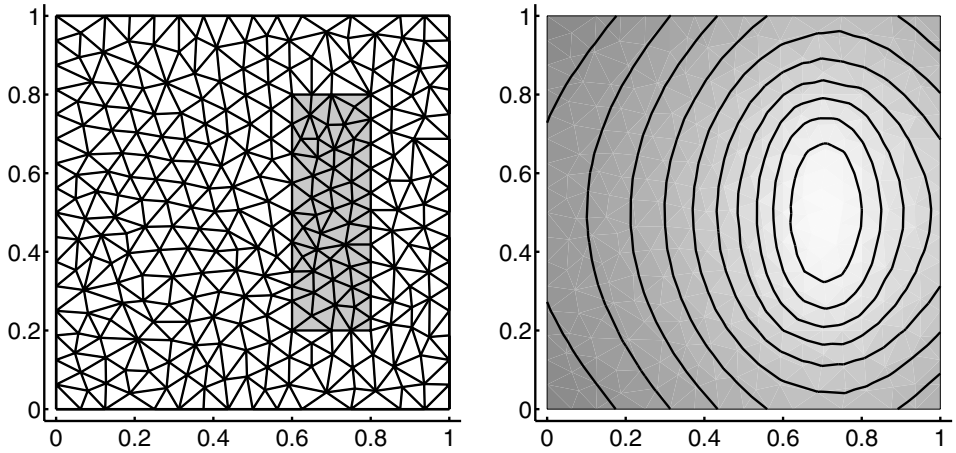

FIG. 5.6. *Left: Mesh of* Ω*, with the set* R *indicated in dark gray. Right: Temperature distribution at* $t = 0.5$ *in false-color representation (white corresponds to temperature* 1 *and black to* 0*).*

$\theta = 1 - 1/n$, as indicated in section 4. In Figure 5.7, for the parameters $\alpha = 0.7$, $d = 0.6$, $t_0 = 0.01$, and $\theta = 1 - 1/n$, we plot $\ln \max_{t\in[t_0,\Lambda t_0]} \|\bar{u}_{h,500}(t) - \bar{u}_{h,n}(t)\|$ against n for $\Lambda = 5$, 50. This plot shows the predicted behavior.

Illustration 4. We consider again the Laplace transform $U(z) = 1/(1+z)$ of the exponential function $u(t) = e^{-t}$ as in Illustration 1. The values of α, d, and t_0 are again 0.7, 0.6, and 1, respectively.

We add, on purpose, perturbations of maximum size 10^{-4} to the evaluations of

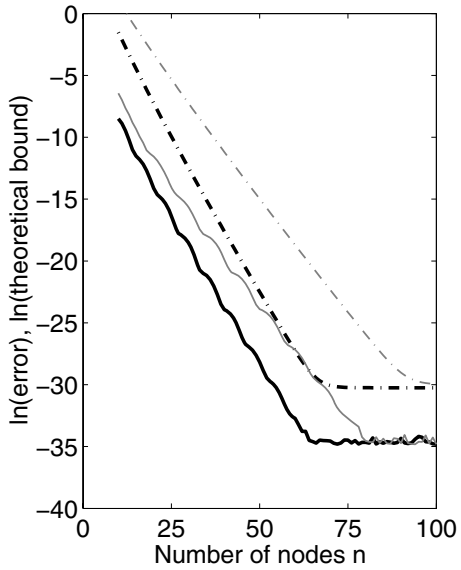

FIG. 5.7. *Left: Natural logarithm of* $\max_{t\in[t_0,\Lambda t_0]} \|u(t)-\bar{u}_n(t)\|$ *(continuous) and the theoretical estimate (dashed) versus* n*, for* u *in Illustration* 3*. The gray lines correspond to* $\Lambda = 50$ *and the black to* $\Lambda = 5$*.*

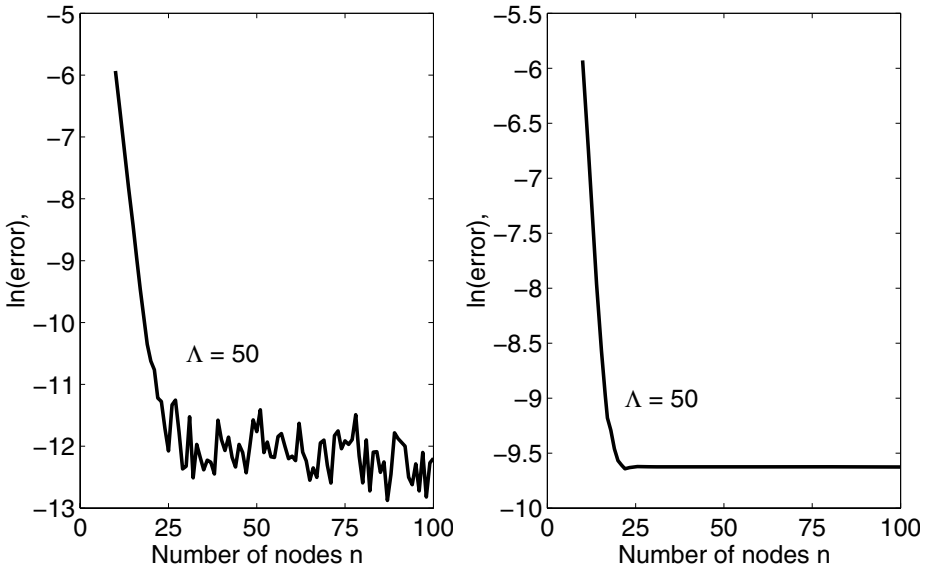

FIG. 5.8. $\ln \max_{t\in[t_0,\Lambda t_0]} \|u(t) - \bar{u}_n(t)\|$ *versus* n*, for* u *in Illustration* 4 *with* $\theta = 1 - 1/n$*,* $\alpha = 0.7$*,* $d = 0.6$*,* $t_0 = 1$*, and* $\Lambda = 50$*. Left: Random perturbation. Right: Worst case perturbation.*

U at the required nodes. Thus, we use (3.1) with

$$U_k = U(z_k) + \eta_k, \qquad -n \le k \le n,$$

with $|\eta_k| \le \rho = 10^{-4}$. Now we try to approximate $u(t)$ without using the available information about ρ. In this situation, as explained in section 4, we take $\theta = 1 - 1/n$.

In fact, we compare two types of perturbations.

We first generate complex, random, independent perturbations η_k in such a way that $|\eta_k|$ and $\arg(\eta_k)$ are uniformly distributed on $[0, 10^{-4}]$ and $[0, 2\pi]$, respectively. In Figure 5.8 (left), we show the resulting actual error, which behaves much better than predicted by (4.2). The explanation is that cancellations are likely compensating the effects of the independent random perturbations. A finer analysis of the observed behavior is beyond the scope of the present paper.

Second, for each $-n \le k \le n$, we consider the perturbation

$$\eta_k = 10^{-4} \exp(-i \arg(\omega_k(t_0))),$$

with $\omega_k(t_0)$ defined in (3.1). These perturbations correspond to the worst possible case in (3.2) for $t = t_0 = 1$. Now, the resulting actual error, plotted in Figure 5.8 (right), fits quite well with (4.2).

Acknowledgments. The authors wish to express their gratitude to Prof. T. Hohage for a suggestion concerning [13] which is used in section 3 of the present paper. The useful comments made by the referees during the revision process also helped to improve the quality of the work.

PROJECTION METHODS AND CONDITION NUMBERS IN UNIFORM NORM FOR FREDHOLM AND CAUCHY SINGULAR INTEGRAL EQUATIONS*

M. C. DE BONIS† AND G. MASTROIANNI†

Dedicated to Professor Francesco Costabile on the occasion of his 60th birthday

Abstract. In this paper the authors propose a numerical method for the approximate solution of some classes of Fredholm and Cauchy integral equations including the "discrete collocation" and "collocation" methods.

Key words. Cauchy singular integral equation, Fredholm integral equations, projection method, Lagrange interpolation, Fourier sum

DOI. 10.1137/050626934

1. Introduction. This paper deals with the numerical treatment of some classes of Fredholm and Cauchy integral equations. In the last few decades, several authors proposed numerical methods in order to obtain polynomial approximations of the solutions. Among them we mention [1, 4, 12, 14, 15, 16, 17, 18, 19, 32, 41, 45, 46, 47, 48], where the so-called *collocation* and *discrete collocation* methods are considered. Such procedures essentially consist of three steps: first, look for an approximate solution as a (weighted) polynomial; second, approximate the (Fredholm) integral by a quadrature formula; and third, project the equation onto a finite dimensional space of (weighted) polynomials by collocation. The stability and the convergence of the method are proved on a finite dimensional equation equivalent to the system. But, as a simple example shows, the uniform boundedness of the condition number of the discrete operator does not imply the well-conditioning of the system that is crucial in order to compute the approximate solution.

If the above-mentioned equations are considered in suitable L^p-spaces with $1 < p < +\infty$, then, using Marcinkievicz bases (see [20, 21]), one can associate a well-conditioned system of linear equations to a discrete and well-conditioned operator. The case $p = +\infty$ is still open and we are going to investigate it in this paper. To be more precise, we shall consider some classes of Fredholm and Cauchy singular integral equations in a subspace of continuous functions which are related to the kernels of the equations. Since in these spaces sequences of uniformly bounded polynomial projections do not exist, we shall use sequences of projections $\{\Gamma_m\}_m$ (essentially of Lagrange or Fourier type) such that $\|\Gamma_m\| \sim \log m$. The simple procedure showed in section 2 (see Remark 1), constructs uniquely solvable polynomial equations whose solutions converge as the best approximation (except for an extra log factor). Using a suitable basis, we derive a well-conditioned linear system equivalent to the finite dimensional equation, whose solution is the array of the coefficients of the polyno-

mial. The error estimates are sharp and cover the ones available in the literature (in the uniform norm). The proposed procedure includes the discrete collocation and collocation methods.

The case of nonsingular kernels is considered in subsection 2.3. In Theorem 2.2 we show that the approximation error does not change, while the linear system is strongly simplified.

Section 3 is devoted to the numerical treatment of the Cauchy singular integral equations with constant coefficients and compact perturbation, having index $\chi \in \{0, 1\}$. By regularization, we derive equivalent Fredholm equations having nonsingular kernels which are transforms of the original kernels by means of singular operators. Very recently it was shown in [9] that the problem is led back to the case of Fredholm equations with nonsingular kernel. In section 4 we give the proofs of the previous results.

2. Projection methods for Fredholm equations.

2.1. Function spaces. We are going to consider the integral equations in the space

$$C_v = \Big\{ f \in C^0((-1,1)) \ : \ \lim_{|x|\to 1} (fv)(x) = 0 \Big\},$$

where $C^0(A)$ is the collection of the continuous functions in $A \subset [-1,1]$ and $v(x) := v^{\gamma,\delta}(x) = (1-x)^\gamma (1+x)^\delta$ is a Jacobi weight. In the case $\gamma = 0$ (respectively, $\delta = 0$) C_v consists of all continuous functions on $(-1,1]$ (respectively, $[-1,1)$) such that

$$\lim_{x\to -1} (fv)(x) = 0 \quad \Big(\lim_{x\to 1} (fv)(x) = 0 \Big).$$

In the case $\gamma = \delta = 0$, we set $C_v = C^0([-1,1])$. The space C_v equipped with the norm

$$\|f\|_{C_v} := \max_{|x|\le 1} |(fv)(x)| =: \|fv\|$$

is complete. For brevity, we shall write $\|f\|_A := \max_{x\in A} |f(x)|, \ A \subseteq [-1,1]$.

In what follows we will also consider functions belonging to the Besov space $B_{r,q}(v)$. In order to define $B_{r,q}(v)$ we introduce the seminorms

$$\|f\|_{\gamma,\delta,r,q} = \begin{cases} \displaystyle\left(\int_0^1 \left[\frac{\Omega^k_\varphi(f,t)_{v^{\gamma,\delta}}}{t^r} \right]^q \frac{dt}{t} \right)^{\frac{1}{q}}, & 1 \le q < +\infty, \\ & k > r > 0, \\ \displaystyle\sup_{t>0} \frac{\Omega^k_\varphi(f,t)_{v^{\gamma,\delta}}}{t^r}, & q = +\infty, \end{cases} \tag{2.1}$$

where [10]

$$\Omega^k_\varphi(f,t)_{v^{\gamma,\delta}} := \sup_{0<h\le t} \|(\Delta^k_{h\varphi} f) v^{\gamma,\delta}\|_{I_{h,k}},$$

$k \in \mathbb{N}, I_{h,k} := [-1 + 4k^2h^2, 1 - 4k^2h^2], 0 < t < 1, \varphi(x) = \sqrt{1-x^2}$, and

$$\Delta^k_{h\varphi} f(x) := \sum_{i=0}^k (-1)^i \binom{k}{i} f\left(x + h\varphi(x) \left(\frac{k}{2} - i \right) \right).$$

We will set $\|f\|_{r,q} := \|f\|_{0,0,r,q}$.

Thus, the Besov spaces are [11]

$$B_{r,q}(v) = \{f \in C_v : \|f\|_{\gamma,\delta,r,q} < +\infty\}, \quad \gamma, \delta \geq 0, \quad r \in \mathbb{R}^+, \quad 1 \leq q \leq +\infty, \tag{2.2}$$

and they are equipped with the norm

$$\|f\|_{B_{r,q}(v)} = \|fv\| + \|f\|_{\gamma,\delta,r,q}. \tag{2.3}$$

As previously done we will set $B_{r,q} := B_{r,q}(v^{0,0})$. In the case $q = +\infty$, $B_{r,\infty}(v), r > 0$, are the well-known Zygmund spaces and we will set $Z_r(v) := B_{r,\infty}(v)$, $Z_r := Z_r(v^{0,0})$.

In the following $\mathcal{C}$ denotes a positive constant which may have different values in different formulas. We will write $\mathcal{C} \neq \mathcal{C}(a, b, \dots)$ to say that $\mathcal{C}$ is independent of the parameters $a, b, \dots$. If $A, B \geq 0$ are quantities depending on some parameters, we write $A \sim B$, if there exists a positive constant $\mathcal{C}$ independent of the parameters of A and B, such that

$$\frac{B}{\mathcal{C}} \leq A \leq \mathcal{C}B.$$

2.2. Projection methods. Now we consider the Fredholm integral equation of the second kind

$$f(y) + \lambda \int_{-1}^{1} h(x, y) f(x) v^{\alpha,\beta}(x) dx = g(y), \tag{2.4}$$

where $v^{\alpha,\beta}$ is a Jacobi weight, $\lambda \in \mathbb{R}$, and h, g are given functions. Letting

$$(Kf)(y) = \lambda \int_{-1}^{1} h(x, y) f(x) v^{\alpha,\beta}(x) dx,$$

we can rewrite (2.4) as

$$(I + K)f = g, \tag{2.5}$$

where I denotes the identity operator.

We will consider (2.5) in C_v with γ and δ according to

$$\begin{aligned} &\max\left\{0, \frac{\alpha}{2} + \frac{1}{4}\right\} \leq \gamma < \min\left\{\frac{\alpha}{2} + \frac{3}{4}, 1 + \alpha\right\}, \\ &\max\left\{0, \frac{\beta}{2} + \frac{1}{4}\right\} \leq \delta < \min\left\{\frac{\beta}{2} + \frac{3}{4}, 1 + \beta\right\}, \end{aligned} \tag{2.6}$$

and we state the following assumptions:

$$g \in Z_r(v), \tag{2.7}$$

$$\sup_{t>0} \frac{\Omega_\varphi^k(Kf, t)_v}{t^r} \leq \mathcal{C}\|fv\|, \quad k > r > 0, \quad f \in C_v. \tag{2.8}$$

Note that (2.8) can be true even if the kernel $h(x, y)$ is weakly singular. For example, if

$$h(x, y) = \frac{1}{|x - y|^\mu}, \quad 0 < \mu < 1,$$

then (2.8) is true with $r \leq 1-\mu$ (see [30, Lemma 4.1]). Obviously, if the kernel $h(x,y)$ belongs to the Zygmund space $Z_r(v)$ w.r.t. y, then (2.8) is automatically satisfied.

Under the assumptions (2.7)–(2.8), the solution f^* of (2.4) (if it exists) can be "well" approximated by polynomials. In order to show this we denote by $L_m^{\alpha,\beta}$ the Lagrange projection based on the zeros of the mth orthonormal Jacobi polynomial $p_m(v^{\alpha,\beta})$, i.e., with $F \in C_v$,

$$L_m^{\alpha,\beta}(F,x) = \sum_{i=1}^{m} l_i^{\alpha,\beta}(x) F(x_i), \quad l_i^{\alpha,\beta}(x) = \frac{p_m(v^{\alpha,\beta},x)}{p_m'(v^{\alpha,\beta},x_i)(x-x_i)},$$

$x_1 < x_2 < \cdots < x_m$, $x_i = x_{m,i}^{\alpha,\beta}$ being the zeros of $p_m(v^{\alpha,\beta})$.

By means of this projection we introduce the polynomial sequence $\{g_m\}_m$, with $g_m = L_m^{\alpha,\beta}(g)$, and the sequence of operators $\{K_m\}_m$, where $(K_m f)(y) = L_m^{\alpha,\beta}(Kf,y)$. Obviously, for every $f \in C_v$, we have $K_m f \in \mathbb{P}_{m-1}$, $\mathbb{P}_{m-1}$ being the set of all algebraic polynomials of degree at most $m-1$. So, we are going to solve the sequence of polynomial equations

$$(I+K_m)f_m = g_m, \quad m = 1,2,\ldots, \tag{2.9}$$

where $f_m \in \mathbb{P}_{m-1}$ is unknown. Denoting by $\lambda_k^{\alpha,\beta} = \lambda_k(v^{\alpha,\beta})$, $k = 1,\ldots,m$, the Christoffel numbers w.r.t. $v^{\alpha,\beta}$, the following theorem holds.

THEOREM 2.1. *Assuming that* $\operatorname{Ker}(I+K) = \{0\}$ *in* C_v, *we denote by* f^* *the unique solution of* (2.5) *for a given* g. *If* (2.6)–(2.8) *are satisfied, then, for* m *sufficiently large (say,* $m > m_0$*), the equation* $(I+K_m)f_m = g_m$ *has the unique solution* $f_m^* \in \mathbb{P}_{m-1}$ *satisfying the estimate*

$$\|(f^* - f_m^*)v\| \leq \mathcal{C}\frac{\log m}{m^r}\|g\|_{Z_r(v)}, \quad r \geq 1, \tag{2.10}$$

where $\mathcal{C} \neq \mathcal{C}(m, f^*)$.

If we expand f_m^* *in the basis* $\{\varphi_i\}_{i=1,\ldots,m}$, *with* $\varphi_i = \frac{l_i^{\alpha,\beta}}{v(x_i)}$, *i.e., we write*

$$f_m^*(y) = \sum_{i=1}^{m} a_i \varphi_i(y),$$

then the array $\mathbf{a} = (a_1,\ldots,a_m)$ *of the coefficients is the unique solution of the system of linear equations*

$$\sum_{k=1}^{m}\left[\delta_{i,k} + \lambda\ \lambda_k^{\alpha,\beta}\frac{v(x_i)}{v(x_k)}S_m^{\alpha,\beta}(h(\cdot,x_i),x_k)\right]a_k = (gv)(x_i), \quad i = 1,\ldots,m, \tag{2.11}$$

where $v(x) = v^{\gamma,\delta}(x)$ *and*

$$S_m^{\alpha,\beta}(F,x) = \sum_{\nu=0}^{m-1} c_\nu(y) p_\nu(v^{\alpha,\beta},x), \quad c_\nu(y) = \int_{-1}^{1} p_\nu(v^{\alpha,\beta},x)F(x)v^{\alpha,\beta}(x)dx,$$

is the Fourier sum of a function F.

Finally, denoting by A_m *the matrix of the system* (2.11) *and by* $\operatorname{cond}(A_m) = \|A_m\|\|A_m^{-1}\|$ *its condition number in uniform norm (the so-called row sum norm), if*

$$\sup_{|y|\leq 1}\int_{-1}^{1} v^{\alpha-\gamma,\beta-\delta}(x)|h(x,y)|\log\left(2 + v^{\alpha-\gamma,\beta-\delta}(x)|h(x,y)|\right)dx < +\infty, \tag{2.12}$$

we have

$$\sup_m \frac{\mathrm{cond}(A_m)}{\log m} < +\infty. \tag{2.13}$$

In conclusion, if the assumptions (2.7)–(2.8) and (2.12) are satisfied, then choose γ and δ according to (2.6), solve the system (2.11), which is well conditioned (except for an extra $\log m$ factor), and construct the approximate solution f_m^*. The degree of f_m^*, or, equivalently, the order of the linear system, is chosen according to the required error and using the estimate (2.10).

The following remark includes a short discussion on the assumptions.

Remark 1. The choice of the space $C_v, v = v^{\gamma,\delta}$, with γ, δ satisfying (2.6), is crucial. Indeed the norms in C_v of the projections $L_m^{\alpha,\beta}$ and $S_m^{\alpha,\beta}$ are the smallest (except for a constant) (see Lemmas 4.1 and 4.2). Moreover, since, by virtue of (2.6), we can always choose $\gamma, \delta > 0$, Theorem 2.1 covers some cases of kernels and known terms unbounded in ± 1.

The assumption (2.8) implies the compactness of the operator $K : C_v \to C_v$ (see, for example, [51, p. 93]). Finally, if the norms in (2.7)–(2.8) are replaced by the Besov norms, then Theorem 2.1 is still true (see its proof). We used the Zygmund norm only to simplify the notation in the proofs.

2.3. The case of nonsingular kernels. In the shown procedure the Fourier sum of $h(x, y)$ generates the main computational effort. On the other hand several procedures concerning the most frequently used kernels are available in the literature (among others we mention [42, 43, 34]). It appears necessary if the kernel is weakly singular. But, if the kernel is smooth (for example, it belongs to the Zygmund space $Z_r(v)$), then with $h_x(y) = h_y(x) = h(x, y)$, both the norms

$$\sup_{|y|\le 1} \|[S_m^{\alpha,\beta} h_y - h_y]v\| \quad \text{and} \quad \sup_{|y|\le 1} \|[L_m^{\alpha,\beta} h_y - h_y]v\|$$

are dominated by $\|h_y\|_{Z_r(v)} m^{-r} \log m$ and we can replace in the system (2.11) $S_m^{\alpha,\beta}(h(x_i, \cdot), x_k)$ by $L_m^{\alpha,\beta}(h(x_i, \cdot), x_k) = h(x_k, x_i)$. Obviously, the new system

$$\sum_{k=1}^{m} \left[\delta_{i,k} + \lambda\ \lambda_k^{\alpha,\beta} \frac{v(x_i)}{v(x_k)} h(x_k, x_i) \right] a_k = (gv)(x_i), \quad i = 1, \dots, m, \tag{2.14}$$

is much easier. Moreover, if A_m is the matrix of the system (2.14) and $\mathrm{cond}(A_m)$ is its condition number in uniform norm, we deduce the next theorem.

THEOREM 2.2. *Assume that in $C_{v^{\gamma,\delta}}$, with γ, δ satisfying* (2.6)*, we have* $\mathrm{Ker}(I + K) = \{0\}$*, and let f^* be the unique solution of* (2.5) *for a given g. If*

$$\|g\|_{Z_r(v)} < +\infty, \tag{2.15}$$

$$\sup_{|x|\le 1} \|h_x\|_{Z_r(v)} < +\infty, \tag{2.16}$$

$$\sup_{|y|\le 1} v(y) \|h_y\|_{Z_r} < +\infty, \tag{2.17}$$

then we get

$$\sup_m \frac{\mathrm{cond}(A_m)}{\log m} < +\infty. \tag{2.18}$$

Moreover, denoting by $(a_1, \dots, a_m)$ *the unique solution of* (2.14)*, the polynomial*

$$f_m^*(y) = \sum_{i=1}^{m} a_i \varphi_i(y), \quad \varphi_i = \frac{l_i^{\alpha,\beta}}{v(x_i)},$$

verifies the estimate

$$\|(f^* - f_m^*)v\| \le C \left(\frac{\log m}{m^r} \right), \quad r \ge 1, \tag{2.19}$$

where the constant C *is independent of* m *and* f^**.*

In the next section we will give an application of Theorem 2.2.

3. Cauchy singular integral equations with constant coefficients. We consider one class of Cauchy singular integral equations with constant coefficients a and b satisfying $a^2 + b^2 = 1$ and which can be defined with the help of only one parameter $\alpha \in (0, 1)$. This class of equations appears in several problems of applied sciences and a wide literature on this topic is available. In particular, we mention the fundamental books and papers [14, 15, 16, 17, 18, 26, 32, 35, 37, 41, 45] and the references therein.

In this section we will consider this class of equations in the space of continuous functions with uniform norm and, using the regularization method [32, 37, 41], we get Fredholm equations. This procedure seems to be more complicated than the direct methods [14, 15, 16, 17, 18, 45]. But the authors have recently proved in [9] precise results on the mapping properties of the singular operators that are the dominant part of the Cauchy singular integral equations. By virtue of such results and under suitable assumptions on the kernels and the known terms, the numerical treatment of such equations goes back to an application of Theorem 2.2.

3.1. Equations with index 0. Consider the equation

$$(\hat{A}f)(y) + \int_{-1}^{1} k(x, y) f(x) v^{\alpha,-\alpha}(x) dx = g(y), \tag{3.1}$$

where

$$(\hat{A}f)(y) = \cos \pi\alpha f(y) v^{\alpha,-\alpha}(y) - \frac{\sin \pi\alpha}{\pi} \int_{-1}^{1} \frac{f(x)}{x - y} v^{\alpha,-\alpha}(x) dx, \quad 0 < \alpha < 1. \tag{3.2}$$

Assume $g \in Z_r(v^{0,\alpha})$ and $k_x \in Z_r(v^{0,\alpha}), r \ge 1$, uniformly w.r.t. x. An equivalent Fredholm equation can be obtained multiplying (3.1) from the left by the operator A defined as

$$(Af)(y) = \cos \pi\alpha f(y) v^{-\alpha,\alpha}(y) + \frac{\sin \pi\alpha}{\pi} \int_{-1}^{1} \frac{f(x)}{x - y} v^{-\alpha,\alpha}(x) dx. \tag{3.3}$$

Since (see, e.g., [9, 30]) $A\hat{A}f = \hat{A}Af = f, f \in Z_r(v^{0,\alpha})$, under the assumptions on g and k_x we get

$$f(y) + \int_{-1}^{1} (Ak_x)(y) f(x) v^{\alpha,-\alpha}(x) dx = (Ag)(y). \tag{3.4}$$

The equations (3.1) and (3.4) are uniquely solvable if the respective homogeneous problems have only the trivial solutions. We consider (3.4) in $C_{v^{\alpha+\gamma,\delta}}$ with $(\alpha+\gamma)$ and δ satisfying (2.6) with $\beta=-\alpha$, i.e., with γ and δ such that

$$\max\left\{0,-\frac{\alpha}{2}+\frac{1}{4}\right\}\le\gamma,\quad \delta<\min\left\{-\frac{\alpha}{2}+\frac{3}{4},1-\alpha\right\}. \tag{3.5}$$

Moreover, setting

$$\Psi(x,y):=(Ak_x)(y),\quad G(y):=(Ag)(y),$$

we rewrite (3.4) as follows:

$$f(y)+\int_{-1}^{1}\Psi(x,y)f(x)v^{\alpha,-\alpha}(x)dx=G(y). \tag{3.6}$$

If we want to apply Theorem 2.2, it is sufficient that G and Ψ verify in $C_{v^{\alpha+\gamma,\delta}}$ the assumptions (2.15)–(2.17). Now, in [9] (see also [30]) the following equivalence has been proved:

$$\|g\|_{Z_r(v^{0,\alpha})}\sim\|Ag\|_{Z_r(v^{\alpha,0})}. \tag{3.7}$$

The last one is crucial to prove the following lemma.

LEMMA 3.1. *If $0<\alpha<1$ and $\gamma,\delta\ge 0$, then we have*

$$\|G\|_{Z_r(v^{\alpha+\gamma,\delta})}\le\mathcal{C}\|g\|_{Z_r(v^{0,\alpha})}, \tag{3.8}$$

$$\sup_{|x|\le1}\|\Psi_x\|_{Z_r(v^{\alpha+\gamma,\delta})}\le\mathcal{C}\sup_{|x|\le1}\|k_x\|_{Z_r(v^{0,\alpha})}, \tag{3.9}$$

$$\sup_{|y|\le1}v^{\alpha+\gamma,\delta}(y)\|\Psi_y\|_{Z_r}\le\mathcal{C}\left[\sup_{|y|\le1}v^{\gamma,\delta+\alpha}(y)\|k_y\|_{Z_r}+\sup_{|y|\le1}v^{\gamma,\delta+\alpha}(y)\left\|\frac{\partial}{\partial y}k_y\right\|_{Z_r}\right], \tag{3.10}$$

with $r>0$, $\Psi_x(y)=\Psi_y(x)=\Psi(x,y)$, and $\mathcal{C}\ne\mathcal{C}(G,\Psi,x,y)$.

As a consequence of Lemma 3.1, if the right-hand sides of (3.8)–(3.10) are finite, then the functions G and Ψ of (3.6) satisfy in $C_{v^{\alpha+\gamma,\delta}}$ the assumptions (2.15)–(2.17) of Theorem 2.2 and we can deduce the following proposition.

PROPOSITION 3.1. *Assume that the original equation* (3.1) *is uniquely solvable in $C_{v^{\alpha+\gamma,\delta}}$. If the kernel k and the known term g of* (3.1) *satisfy*

$$\|g\|_{Z_r(v^{0,\alpha})}<+\infty, \tag{3.11}$$

$$\sup_{|x|\le1}\|k_x\|_{Z_r(v^{0,\alpha})}<+\infty, \tag{3.12}$$

$$\sup_{|y|\le1}v^{\gamma,\delta+\alpha}(y)\|k_y\|_{Z_r}+\sup_{|y|\le1}v^{\gamma,\delta+\alpha}(y)\left\|\frac{\partial}{\partial y}k_y\right\|_{Z_r}<+\infty, \tag{3.13}$$

with γ,δ according to (3.5)*, then, for m sufficiently large (say, $m>m_0$), the polynomial*

$$f_m^*(y)=\sum_{i=1}^{m}a_i\varphi_i(y),\quad \varphi_i=\frac{l_i^{\alpha,-\alpha}}{v^{\alpha+\gamma,\delta}(x_i)},\quad p_m^{\alpha,-\alpha}(x_i)=0,$$

where $(a_1, \dots, a_m)$ *is the solution of the linear system*

(3.14)
$$\sum_{k=1}^{m} \left[\delta_{i,k} + \lambda_k^{\alpha,-\alpha} \frac{v^{\alpha+\gamma,\delta}(x_i)}{v^{\alpha+\gamma,\delta}(x_k)} \Psi(x_k, x_i) \right] a_k = G(x_i) v^{\alpha+\gamma,\delta}(x_i), \quad i = 1, 2, \dots, m,$$

converges to the exact solution f^* *and*

$$\| (f_m^* - f^*) v^{\alpha+\gamma,\delta} \| \leq \mathcal{C} \frac{\log m}{m^r} \| g \|_{Z_r(v^{0,\alpha})}, \tag{3.15}$$

where $\mathcal{C} \neq \mathcal{C}(m, f^*, g)$.

Of course, by virtue of Theorem 2.2, the matrix of the system (3.14) is well conditioned.

Now we want to give some numerical remarks on the computation of the quantities $\Psi(x_k, x_i)$ and $G(x_i), i, k = 1, \dots, m$, in the system (3.14). Looking at their expressions

$$\Psi(x_k, x_i) = \cos \pi\alpha k(x_k, x_i) v^{-\alpha,\alpha}(x_i) + \frac{\sin \pi\alpha}{\pi} \int_{-1}^{1} \frac{k(x_k, t)}{t - x_i} v^{-\alpha,\alpha}(t) dt \tag{3.16}$$

and

$$G(x_i) = \cos \pi\alpha g(x_i) v^{-\alpha,\alpha}(x_i) + \frac{\sin \pi\alpha}{\pi} \int_{-1}^{1} \frac{g(t)}{t - x_i} v^{-\alpha,\alpha}(t) dt, \tag{3.17}$$

we can see that the only difficulty (if the analytical expression is not available) consists in the computation of the Hilbert transforms. The last ones can be computed using one of the several methods available in literature which are based on Gaussian rules, on product rules [5, 6, 7, 8, 33], or on suitable transformation of the integrand [2, 13, 22, 36, 40, 50]. Here, for completeness, we propose substituting $G(x_i)$ and $\Psi(x_k, x_i), k, i = 1, \dots, m$, with

$$\Psi_m(x_k, x_i) = \frac{\sin \alpha\pi}{\pi} \sum_{j=1}^{m} \frac{k(x_k, t_j)}{t_j - x_i} \lambda_{m,j}^{-\alpha,\alpha} \tag{3.18}$$

and

$$G_m(x_i) = \frac{\sin \alpha\pi}{\pi} \sum_{j=1}^{m} \frac{g(t_j)}{t_j - x_i} \lambda_{m,j}^{-\alpha,\alpha}, \tag{3.19}$$

where t_j are the zeros of $p_m^{-\alpha,\alpha}$. Then, we solve the new system

$$\sum_{k=1}^{m} \left[\delta_{i,k} + \lambda_k^{\alpha,-\alpha} \frac{v^{\alpha+\gamma,\delta}(x_i)}{v^{\alpha+\gamma,\delta}(x_k)} \Psi_m(x_k, x_i) \right] \bar{a}_k = G_m(x_i) v^{\alpha+\gamma,\delta}(x_i), \quad i = 1, \dots, m, \tag{3.20}$$

and we construct the approximate solution $f_m^{**}(y) = \sum_{i=1}^{m} \bar{a}_i \varphi_i(y)$. Obviously, we have to compare the norm $\| (f^* - f_m^{**}) v^{\alpha+\gamma,\delta} \|$ with $\| (f^* - f_m^*) v^{\alpha+\gamma,\delta} \|$. To this end the following propositions hold.

PROPOSITION 3.2. *If we assume that $k(x,y)$ and g satisfy* (3.12) *and* (3.11)*, respectively, then we have*

$$\sup_{1\le i,k\le m} v^{\alpha,0}(x_i)|\Psi(x_k,x_i)-\Psi_m(x_k,x_i)| \le \mathcal{C}\frac{\log m}{m^r}\sup_{|x|\le 1}\|k_x\|_{Z_r(v^{0,\alpha})} \tag{3.21}$$

$$\sup_{1\le i\le m} v^{\alpha,0}(x_i)|G(x_i)-G_m(x_i)| \le \mathcal{C}\frac{\log m}{m^r}\|g\|_{Z_r(v^{0,\alpha})}, \tag{3.22}$$

where $\mathcal{C}\neq\mathcal{C}(m,k,g)$.

PROPOSITION 3.3. *If A_m and A_m^* denote the matrices of the systems* (3.14) *and* (3.20)*, respectively, then*

$$\lim_m \frac{\operatorname{cond}(A_m^*)}{\operatorname{cond}(A_m)} = 1 \tag{3.23}$$

and, moreover,

$$\|(f^*-f_m^{**})v^{\alpha+\gamma,\delta}\| \le \mathcal{C}\left(\frac{\log^2 m}{m^r}\right), \tag{3.24}$$

where the constant $\mathcal{C}$ is independent of m and f^*.

Therefore, the condition numbers of the systems (3.14) and (3.20) are comparable, and, if the system (3.20) replaces (3.14), then the estimate (3.15) is perturbed by a $\log m$ factor.

Finally, note that we could consider (3.1) in the space $C_{v^{\alpha,0}}$ as proposed in [30]. But such an approach implies considering two different linear systems in the cases $0<\alpha<\frac{1}{2}$ and $\alpha\ge\frac{1}{2}$. Anyway, the results on the condition numbers of the respective linear systems and the convergence of both methods are equivalent.

3.2. Equation with index 1. Concerning the equation

$$(Df)(y)+\int_{-1}^{1} k(x,y)f(x)v^{-\alpha,\alpha-1}(x)dx = g(y), \tag{3.25}$$

with

$$(Df)(y)=\cos\pi\alpha f(y)v^{-\alpha,\alpha-1}(y)+\frac{\sin\pi\alpha}{\pi}\int_{-1}^{1}\frac{f(x)}{x-y}v^{-\alpha,\alpha-1}(x)dx, \tag{3.26}$$

we assume $g\in Z_r(v^{\alpha,1-\alpha})$ and $k_x\in Z_r(v^{\alpha,1-\alpha})$, uniformly w.r.t. x. We multiply (3.25) from the left by the operator $\hat{D}$ with

$$(\hat{D}f)(y)=\cos\pi\alpha f(y)v^{\alpha,1-\alpha}(y)-\frac{\sin\pi\alpha}{\pi}\int_{-1}^{1}\frac{f(x)}{x-y}v^{\alpha,1-\alpha}(x)dx. \tag{3.27}$$

Since [9] $D\hat{D}f=f$ and

$$\hat{D}Df = f-\frac{\int_{-1}^{1}f(x)v^{-\alpha,\alpha-1}(x)dx}{\int_{-1}^{1}v^{-\alpha,\alpha-1}(x)dx},$$

with

$$\frac{\int_{-1}^{1}f(x)v^{-\alpha,\alpha-1}(x)dx}{\int_{-1}^{1}v^{-\alpha,\alpha-1}(x)dx}=A\in\mathbb{R}, \tag{3.28}$$

(3.25) becomes

$$f(y)+\int_{-1}^{1}(\hat{D}k_x)(y)f(x)v^{-\alpha,\alpha-1}(x)dx=(\hat{D}g)(y)+A. \tag{3.29}$$

Equation (3.25) cannot be uniquely solvable, since the index of the operator in the spaces under consideration is equal to 1. Consequently, one has to consider (3.25) together with the additional condition (3.28) for a given constant A. Then (3.25), (3.28) is equivalent to (3.29). Letting

$$\Gamma(x,y)=(\hat{D}k_x)(y) \quad \text{and} \quad G_1(y)=(\hat{D}g)(y),$$

and assuming $A=0$, (3.29) can be rewritten as

$$f(y)+\int_{-1}^{1}\Gamma(x,y)f(x)v^{-\alpha,\alpha-1}(x)dx=G_1(y). \tag{3.30}$$

We consider (3.30) in $C_{v^{\gamma,\delta}}$ and we choose γ,δ replacing α by $-\alpha$ and β by $\alpha-1$ in (2.6). Thus, we take

$$\begin{aligned}\max\left\{0,-\frac{\alpha}{2}+\frac{1}{4}\right\}\le\gamma<\min\left\{-\frac{\alpha}{2}+\frac{3}{4},1-\alpha\right\},\\ \max\left\{0,\frac{\alpha}{2}-\frac{1}{4}\right\}\le\delta<\min\left\{\frac{\alpha}{2}+\frac{1}{4},\alpha\right\}.\end{aligned} \tag{3.31}$$

Now the equivalence

$$\|g\|_{Z_r(v^{\alpha,1-\alpha})}\sim\|\hat{D}g\|_{Z_r} \tag{3.32}$$

was proved by the authors in [9, (3.19)]. Then, as in subsection 3.1, we can deduce the next proposition.

PROPOSITION 3.4. *Assume that* (3.30) *is uniquely solvable in* $C_{v^{\gamma,\delta}}$ *and* (3.31) *holds true. If*

$$\|g\|_{Z_r(v^{\alpha,1-\alpha})}<+\infty, \tag{3.33}$$

$$\sup_{|x|\le1}\|k_x\|_{Z_r(v^{\alpha,1-\alpha})}<+\infty, \tag{3.34}$$

$$\sup_{|y|\le1}v^{\alpha+\gamma,1-\alpha+\delta}(y)\|k_y\|_{Z_r}+\sup_{|y|\le1}v^{\alpha+\gamma,1-\alpha+\delta}(y)\left\|\frac{\partial}{\partial y}k_y\right\|_{Z_r}<+\infty, \tag{3.35}$$

then the polynomial

$$f_m^*(y)=\sum_{i=1}^{m}a_i\varphi_i(y),\quad \varphi_i=\frac{l_i^{-\alpha,\alpha-1}}{v^{\gamma,\delta}(x_i)},\quad p_m^{-\alpha,\alpha-1}(x_i)=0,$$

where $(a_1,\dots,a_m)$ *is the solution of the linear system*

$$\sum_{k=1}^{m}\left[\delta_{i,k}+\ \lambda_k^{-\alpha,\alpha-1}\frac{v^{\gamma,\delta}(x_i)}{v^{\gamma,\delta}(x_k)}\Gamma(x_k,x_i)\right]a_k=G_1(x_i)v^{\gamma,\delta}(x_i),\quad i=1,2,\dots,m, \tag{3.36}$$

converges to the unique solution f^* *of* (3.25) *with* $A = 0$ *and we have*

$$\|(f_m^* - f^*)v^{\gamma,\delta}\| \le \mathcal{C}\left(\frac{\log m}{m^r}\right), \tag{3.37}$$

where $\mathcal{C} \ne \mathcal{C}(m, f^*)$.

As in the previous case, the system (3.36) can be replaced by

$$\sum_{k=1}^{m}\left[\delta_{i,k} + \lambda_{m,k}^{-\alpha,\alpha-1}\frac{v^{\gamma,\delta}(x_i)}{v^{\gamma,\delta}(x_k)}\Gamma_{m-1}(x_k, x_i)\right]\bar{a}_k = G_{1,m-1}(x_i)v^{\gamma,\delta}(x_i), \quad i = 1, \dots, m, \tag{3.38}$$

where

$$\Gamma_{m-1}(x_k, x_i) = \frac{\sin\alpha\pi}{\pi}\sum_{j=1}^{m-1}\frac{k(x_k, t_j)}{x_i - t_j}\lambda_{m-1,j}^{\alpha,1-\alpha}, \tag{3.39}$$

$$G_{1,m-1}(x_i) = \frac{\sin\alpha\pi}{\pi}\sum_{j=1}^{m-1}\frac{g(t_j)}{x_i - t_j}\lambda_{m-1,j}^{\alpha,1-\alpha}, \tag{3.40}$$

and t_j are the zeros of the Jacobi polynomial $p_{m-1}^{\alpha,1-\alpha}$.

Propositions analogous to Propostions 3.2 and 3.3 hold true also in this case, but, for the sake of brevity, we omit the details.

4. Proofs. We need some notation and preliminary results.

We denote by

$$E_m(f)_{v^{\gamma,\delta}} = \inf_{P\in\mathbb{P}_m}\|(f - P)v^{\gamma,\delta}\|$$

the error of best approximation of a function f in $C_{v^{\gamma,\delta}}$. We set $E_m(f) := E_m(f)_{v^{0,0}}$.

For all functions $f \in C_{v^{\gamma,\delta}}$ we have [10, p. 94]

$$E_m(f)_{v^{\gamma,\delta}} \le \mathcal{C}\int_0^{\frac{1}{m}}\frac{\Omega_\varphi^k(f,t)_{v^{\gamma,\delta}}}{t}dt. \tag{4.1}$$

In particular, from (4.1) we deduce

$$E_m(f)_{v^{\gamma,\delta}} \le \frac{\mathcal{C}}{m^r}\|f\|_{Z_r(v^{\gamma,\delta})} \quad \forall f \in Z_r(v^{\gamma,\delta}), \tag{4.2}$$

$$E_m(f)_{v^{\gamma,\delta}} \le \frac{\mathcal{C}}{m^r}\|f\|_{B_{r,q}(v^{\gamma,\delta})} \quad \forall f \in B_{r,q}(v^{\gamma,\delta}). \tag{4.3}$$

The following lemmas will be useful in what follows.

LEMMA 4.1. *For* α, β, γ, *and* δ *satisfying* (2.6) *and for every* $f \in C_{v^{\gamma,\delta}}$, *we have*

$$\|(L_m^{\alpha,\beta}f)v^{\gamma,\delta}\| \le \mathcal{C}(\log m)\|fv^{\gamma,\delta}\| \tag{4.4}$$

or, equivalently,

$$\|(f - L_m^{\alpha,\beta}f)v^{\gamma,\delta}\| \le \mathcal{C}(\log m)E_{m-1}(f)_{v^{\gamma,\delta}}. \tag{4.5}$$

Moreover, for every function $f \in C^0([-1,1])$, we have

$$\int_{-1}^{1} |L_m^{\alpha,\beta}(f,x)| v^{\alpha-\gamma,\beta-\delta}(x)dx \le \mathcal{C}\|f\|, \tag{4.6}$$

$$\int_{-1}^{1} |f(x) - L_m^{\alpha,\beta}(f,x)| v^{\alpha-\gamma,\beta-\delta}(x)dx \le \mathcal{C}E_{m-1}(f). \tag{4.7}$$

Here the constant $\mathcal{C}$ is independent of m and f.

Proof. The bound (4.4) is Theorem 2.2 in [27], while (4.6) is a special case of Nevai's result in [38]. □

LEMMA 4.2. *For α, β, γ, and δ satisfying* (2.6) *and for every $g \in C_{v^{\gamma,\delta}}$, we have*

$$\|(S_m^{\alpha,\beta} g)v^{\gamma,\delta}\| \le \mathcal{C}(\log m)\|g v^{\gamma,\delta}\| \tag{4.8}$$

or, equivalently,

$$\|(g - S_m^{\alpha,\beta} g)v^{\gamma,\delta}\| \le \mathcal{C}(\log m)E_{m-1}(g)_{v^{\gamma,\delta}}. \tag{4.9}$$

Moreover, for every function g such that

$$A(g) := \int_{-1}^{1} v^{\alpha-\gamma,\beta-\delta}(x)|g(x)| \log\left(2 + v^{\alpha-\gamma,\beta-\delta}(x)|g(x)|\right)dx < +\infty, \tag{4.10}$$

we get

$$\int_{-1}^{1} |S_m^{\alpha,\beta}(g,x)| v^{\alpha-\gamma,\beta-\delta}(x)dx \le \mathcal{C}A(g). \tag{4.11}$$

Here the constant $\mathcal{C}$ is independent of m, f, and g.

Proof of Lemma 4.2. The bound (4.8) can be found in [23]. To prove (4.11), for the sake of simplicity of notation, we assume $\alpha = \beta$ and $\gamma = \delta$, and we set $v^l(x) = (1-x^2)^l$. Using the Pollard transformation (cf. [44]) we can write

$$\begin{aligned} S_m^{\alpha}(g,x) = {} & \alpha_m p_m(v^\alpha, x)c_m + \beta_m [p_m(v^\alpha, x)H(p_{m-1}(v^\alpha\varphi^2)\varphi^2 g v^\alpha, x) \\ & - p_{m-1}(v^\alpha, x)H(p_m(v^\alpha\varphi^2)\varphi^2 g v^\alpha, x)], \end{aligned}$$

where $\alpha_m \sim \beta_m \sim 1$, c_m is the mth Fourier coefficient, and H is the Hilbert transform. Denote by $\|F\|_1$ the L^1-norm of F. Since, by the Remez inequality (see [29] and [31]) we have

$$\|S_m^{\alpha}(g)v^{\alpha-\gamma}\|_1 \le \mathcal{C}\|S_m^{\alpha}(g)v^{\alpha-\gamma}\|_{L^1(I_m)},$$

where $I_m = \left[-1 + \frac{\mathcal{C}}{m^2}, 1 - \frac{\mathcal{C}}{m^2}\right]$, we get

$$\begin{aligned} \|S_m^{\alpha}(g)v^{\alpha-\gamma}\|_1 \le {} & \mathcal{C}\left(\|p_m(v^\alpha)v^{\alpha-\gamma}\|_{L^1(I_m)}|c_m| \right. \\ & + \|p_m(v^\alpha)v^{\alpha-\gamma}H(p_{m-1}(v^\alpha\varphi^2)\varphi^2 g v^\alpha)\|_{L^1(I_m)} \\ & \left. + \|p_{m-1}(v^\alpha\varphi^2)v^{\alpha-\gamma}\varphi^2 H(p_m(v^\alpha)v^\alpha g)\|_{L^1(I_m)}\right) \\ := {} & A_1 + A_2 + A_3. \end{aligned} \tag{4.12}$$

Recalling [49, (8.21.18), p. 198]

$$|p_m(v^\alpha; x)v^{\frac{\alpha}{2}+\frac{1}{4}}(x)| \le \mathcal{C} \ne \mathcal{C}(m), \quad x \in I_m, \tag{4.13}$$

for A_1 we have

$$\begin{aligned} A_1 &\le \mathcal{C}\|v^{\frac{\alpha}{2}-\frac{1}{4}-\gamma}\|_1 \int_{-1}^{1} |g(x)p_m(v^\alpha,x)v^\alpha(x)|dx \\ &\le \mathcal{C}\|v^{\frac{\alpha}{2}-\frac{1}{4}-\gamma}\|_1 \|gv^{\frac{\alpha}{2}-\frac{1}{4}}\|_1. \end{aligned}$$

Taking into account the assumption $\gamma < \frac{\alpha}{2}+\frac{3}{4}$, we have $\frac{\alpha}{2}-\frac{1}{4}-\gamma > -1$ and then $\|v^{\frac{\alpha}{2}-\frac{1}{4}-\gamma}\|_1 \le \mathcal{C}$. Moreover, from the assumption $\gamma > \frac{\alpha}{2}+\frac{1}{4}$ we deduce $\frac{\alpha}{2}-\frac{1}{4} > \alpha-\gamma$ and then $\|gv^{\frac{\alpha}{2}-\frac{1}{4}}\|_1 \le \|gv^{\alpha-\gamma}\|_1$. Therefore, by (4.10), we get

$$A_1 \le \mathcal{C}\|gv^{\alpha-\gamma}\|_1 \le \mathcal{C}A(g). \tag{4.14}$$

Moreover, recalling that [32]

$$\int f(x)H(g;x)dx = -\int g(x)H(f;x)dx, \quad f \in L^p, \quad g \in L^q, \quad \frac{1}{p}+\frac{1}{q}=1, \quad p>1,$$

and applying (4.13), we have

$$A_2 \le \mathcal{C}\int_{-1}^{1} v^{\frac{\alpha}{2}-\frac{1}{4}-\gamma}(t)|H(p_{m-1}(v^\alpha\varphi^2)\varphi^2 v^\alpha g;t)|dt.$$

Letting $G = \operatorname{sgn}(H(p_{m-1}(v^\alpha\varphi^2)\varphi^2 v^\alpha g))$, we get

$$\begin{aligned} A_2 &\le \mathcal{C}\int_{-1}^{1} |p_{m-1}(v^\alpha\varphi^2)\varphi^2(t)v^\alpha(t)g(t)||H(v^{\frac{\alpha}{2}-\frac{1}{4}-\gamma}G;t)|dt \\ &\le \mathcal{C}\int_{-1}^{1} \left(v^{\frac{\alpha}{2}+\frac{1}{4}}(t)|g(t)| \left| \int_{-1}^{1} v^{\frac{\alpha}{2}-\frac{1}{4}-\gamma}(x)\frac{G(x)}{x-t}dx \right| \right) dt \\ &:= \int_{-1}^{1} (v^{\frac{\alpha}{2}+\frac{1}{4}}(t)|g(t)|I_1(t))dt. \end{aligned}$$

It remains to estimate $I_1(t)$. Setting $\sigma := \frac{\alpha}{2}-\frac{1}{4}-\gamma$, in virtue of the assumption $\frac{\alpha}{2}+\frac{1}{4} \le \gamma < \frac{\alpha}{2}+\frac{3}{4}$, we have $-1 < \sigma < 0$ and

$$\begin{aligned} I_1(t) &= \left| v^\sigma(t)H(G;t) + v^\sigma(t)\int_{-1}^{1} \frac{v^\sigma(x)-v^\sigma(t)}{v^\sigma(t)(x-t)}G(x)dx \right| \\ &\le v^\sigma(t)|H(G;t)| + v^\sigma(t)\int_{-1}^{1} \left| \frac{v^{-\sigma}(t)-v^{-\sigma}(x)}{v^{-\sigma}(x)(x-t)} \right| dx \\ &\le v^\sigma(t)|H(G;t)| + v^\sigma(t)\int_{-1}^{1} |x-t|^{-1-\sigma}v^\sigma(x)dx \\ &\le v^\sigma(t)(|H(G;t)|+\mathcal{C}). \end{aligned}$$

Thus, since $G \in L^\infty$ and (4.10) holds, using a result in [39] we get

$$\begin{aligned} A_2 &\le \mathcal{C}\int_{-1}^{1} |g(t)|(1+|H(G;t)|)v^{\alpha-\gamma}(t)dt \\ &\le \mathcal{C}\int_{-1}^{1} v^{\alpha-\gamma}(t)|g(t)|\log(2+v^{\alpha-\gamma}(t)|g(t)|)dt = \mathcal{C}A(g). \end{aligned} \tag{4.15}$$

Analogously we can prove that

$$A_3 \le \mathcal{C} A(g). \tag{4.16}$$

Finally, combining (4.14)–(4.16) with (4.12), (4.11) follows. □

Now we can prove Theorem 2.1.

Proof of Theorem 2.1. Since $g_m = L_m^{\alpha,\beta}(g)$ and $g \in Z_r(v)$, using (4.5) and (4.2) we get

$$\|(g - g_m)v\| \le \mathcal{C}\frac{\log m}{m^r}\|g\|_{Z_r(v)}. \tag{4.17}$$

Moreover, since $K_m f = L_m^{\alpha,\beta}(Kf)$, by (4.5), (4.1), and (2.8) we obtain

$$\|(Kf - K_m f)v\| \le \mathcal{C}(\log m)E_{m-1}(Kf)_v \le \frac{\mathcal{C}}{m^r}(\log m)\|fv\|. \tag{4.18}$$

By a well-known result of linear algebra we have $\sup_m \|(I + K_m)^{-1}\| < +\infty$ and

$$\operatorname{cond}(I + K_m) = \operatorname{cond}(I + K) + \mathcal{O}\left(\frac{\log m}{m^r}\right). \tag{4.19}$$

Moreover, by the identity

$$f^* - f_m^* = (I + K_m)^{-1}[(g - g_m) + (K_m - K)(I + K)^{-1}g] \tag{4.20}$$

we get

$$\begin{aligned}\|(f^* - f_m^*)v\| &\le \mathcal{C}[\|(g - g_m)v\| + \|gv\|\|K - K_m\|_{C_v \to C_v}] \\ &\le \mathcal{C}\frac{\log m}{m^r}\|g\|_{Z_r(v)},\end{aligned} \tag{4.21}$$

i.e., (2.10).

In order to obtain the system (2.11), we consider $f_m + K_m f_m = g_m$ and we expand $K_m f$, g_m, and f_m in the basis $\{\varphi_i\}_{i=1,\dots,m}$, with $\varphi_i = \frac{l_{m,i}(v^{\alpha,\beta})}{v(x_i)}$. Since, for every $q \in \mathbb{P}_{m-1}$, we have

$$q(x) = \sum_{i=1}^m \varphi_i(x)\gamma_i, \quad \gamma_i = q(x_i)v^{\gamma,\delta}(x_i),$$

we can write

$$f_m(y) = \sum_{i=1}^m \varphi_i(y)a_i, \quad g_m(y) = \sum_{i=1}^m \varphi_i(y)b_i, \quad b_i = v^{\gamma,\delta}(x_i)g(x_i),$$

and

$$(K_m f_m)(y) = \sum_{i=1}^m \varphi_i(y)v^{\gamma,\delta}(x_i)(Kf_m)(x_i).$$

Moreover,

$$\begin{aligned}(Kf_m)(x_i) &= \lambda\sum_{k=1}^m \frac{a_k}{v(x_k)}\int_{-1}^1 h(x, x_i)l_k^{\alpha,\beta}(x)v^{\alpha,\beta}(x)dx \\ &= \lambda\sum_{k=1}^m \lambda_k^{\alpha,\beta}\frac{a_k}{v(x_k)}S_m^{\alpha,\beta}(h(\cdot, x_i), x_k)\end{aligned}$$

and then

$$(K_m f_m)(y) = \lambda \sum_{i=1}^{m} \varphi_i(y) v^{\gamma,\delta}(x_i) \sum_{k=1}^{m} \lambda_k^{\alpha,\beta} \frac{a_k}{v(x_k)} S_m^{\alpha,\beta}(h(\cdot, x_i), x_k),$$

$\lambda_k^{\alpha,\beta}, k = 1, \dots, m$, being the Christoffel numbers. Therefore, the finite dimensional equation

$$(I + K_m) f_m = g_m$$

is equivalent to

$$\sum_{i=1}^{m} \varphi_i(y) a_i + \lambda \sum_{i=1}^{m} \varphi_i(y) v^{\gamma,\delta}(x_i) \sum_{k=1}^{m} \frac{\lambda_k^{\alpha,\beta}}{v^{\gamma,\delta}(x_k)} S_m^{\alpha,\beta}(h(\cdot, x_i), x_k) a_k = \sum_{i=1}^{m} \varphi_i(y) b_i,$$

and then (2.11) follows.

Now we prove (2.13). By (2.11), using a Marcinkievicz inequality [28] and $\lambda_k^{\alpha,\beta} \sim v^{\alpha,\beta}(x_k) \frac{\sqrt{1-x_k^2}}{m} \sim v^{\alpha,\beta}(x_k) \Delta x_k$, $\Delta x_k = x_{k+1} - x_k$, we have

$$\begin{aligned}
\|A_m\| &\le 1 + |\lambda| \max_{1 \le i \le m} v(x_i) \sum_{k=1}^{m} \frac{\lambda_k^{\alpha,\beta}}{v(x_k)} |S_m^{\alpha,\beta}(h(\cdot, x_i), x_k)| \\
&\sim 1 + |\lambda| \max_{1 \le i \le m} \sum_{k=1}^{m} v^{\alpha-\gamma,\beta-\delta}(x_k) \Delta x_k |S_m^{\alpha,\beta}(h(\cdot, x_i), x_k)| v(x_i) \\
&\le 1 + \mathcal{C} \max_{1 \le i \le m} \int_{-1}^{1} |S_m^{\alpha,\beta}(v(x_i) h(\cdot, x_i), t)| v^{\alpha-\gamma,\beta-\delta}(t) dt.
\end{aligned}$$

By the assumption (2.12), by virtue of Lemma 4.2, we get

$$\|A_m\| \le \mathcal{C}. \tag{4.22}$$

It remains to estimate $\|A_m^{-1}\|$. By virtue of the equivalence of the system (2.11) with the equation $(I + K_m) f_m = g_m$, for every $\eta = (\eta_1, \dots, \eta_m)$ there exists a unique $\theta = (\theta_1, \dots, \theta_m)$ such that $\theta = A_m^{-1} \eta$ if and only if $\tilde{\theta}(y) = (I + K_m)^{-1} \tilde{\eta}(y)$, where

$$\tilde{\theta}(y) = \sum_{i=1}^{m} \varphi_i(y) \theta_i, \quad \theta_i = (\tilde{\theta} v)(x_i), \quad \text{and} \quad \tilde{\eta}(y) = \sum_{i=1}^{m} \varphi_i(y) \eta_i, \quad \eta_i = (\tilde{\eta} v)(x_i).$$

Then, for all η, by (4.19) it results that

$$\begin{aligned}
\|A_m^{-1} \eta\|_{l^\infty} &= \|\theta\|_{l^\infty} \le \|\tilde{\theta} v\| \\
&= \|(I + K_m)^{-1} \tilde{\eta} v\| \\
&\le \|(I + K_m)^{-1}_{|\mathbb{P}_{m-1}}\| \ \|\eta\|_{l^\infty} \ \|L_m^{\alpha,\beta}\|_{C_v \to C_v} \\
&\le \mathcal{C} \|(I + K)^{-1}\| \ \|\eta\|_{l^\infty} \|L_m^{\alpha,\beta}\|_{C_v \to C_v}.
\end{aligned}$$

Using (4.4) we get

$$\|A_m^{-1}\| \le \mathcal{C} \log m. \tag{4.23}$$

Since $\operatorname{cond}(A_m) = \|A_m\| \|A_m^{-1}\|$, by (4.22) and (4.23), (2.13) follows. ∎

Proof of Theorem 2.2. We first look for a finite dimensional equation equivalent to the system (2.14). To this end, we introduce the sequence of operators $\{K_m\}_m$ defined as

$$(K_m f)(y) = L_m^{\alpha,\beta}(K^* f, y),$$

with

$$(K^* f)(y) = (K_m^* f)(y) = \lambda \int_{-1}^{1} L_m^{\alpha,\beta}(h_y, x) f(x) v^{\alpha,\beta}(x) dx,$$

and the polynomial sequence

$$g_m(y) = L_m^{\alpha,\beta}(g, y).$$

Thus, the equation we are looking for is

$$(I + K_m) f_m = g_m, \quad m = 1, 2, \ldots, \tag{4.24}$$

where f_m is the unknown polynomial of degree at most $m-1$. Expanding $K_m f_m$, g_m, and f_m in the basis $\{\varphi_i\}_{i=1,\ldots,m}, \varphi_i(x) = \frac{l_i^{\alpha,\beta}(x)}{v^{\gamma,\delta}(x_i)}$, we get the system (2.14).

Now we prove (2.18). By (2.14) we have

$$\begin{aligned}
\|A_m\| &\le 1 + |\lambda| \max_{1\le i\le m} v(x_i) \sum_{k=1}^{m} \frac{\lambda_k^{\alpha,\beta}}{v(x_k)} |h(x_k, x_i)| \\
&\sim 1 + |\lambda| \max_{1\le i\le m} \sum_{k=1}^{m} v^{\alpha-\gamma,\beta-\delta}(x_k) \Delta x_k |h(x_k, x_i) v(x_i)| \\
&\le 1 + \mathcal{C} \left(\max_{-1\le x,y\le 1} |h(x,y)| v^{\gamma,\delta}(y) \right) \int_{-1}^{1} v^{\alpha-\gamma,\beta-\delta}(x) dx.
\end{aligned}$$

By the assumptions (2.6) and (2.16), we deduce

$$\|A_m\| \le \mathcal{C}. \tag{4.25}$$

By (4.25) and (4.23) we obtain (2.18).

To prove (2.19) we will use the inequality (4.21). Taking into account (4.17), we need to estimate only $\|K - K_m\|_{C_v \to C_v}$.

Adding and subtracting $K^* f$, we have

$$\begin{aligned}
\|(Kf - K_m f)v\| &= \|(Kf - K^* f)v\| + \|(K^* f - K_m f)v\| \\
&:= A + B.
\end{aligned} \tag{4.26}$$

We first estimate A. Using (4.7), we get

$$\begin{aligned}
&|(Kf)(y) - (K^* f)(y)| v(y) \\
&\quad = v(y) \left| \lambda \int_{-1}^{1} [h_y(x) - L_m^{\alpha,\beta}(h_y, x)] v^{\alpha-\gamma,\beta-\delta}(x) (fv)(x) dx \right| \\
&\quad \le \mathcal{C} \|fv\| v(y) \int_{-1}^{1} \left| h_y(x) - L_m^{\alpha,\beta}(h_y, x) \right| v^{\alpha-\gamma,\beta-\delta}(x) dx \\
&\quad \le \mathcal{C} \|fv\| v(y) E_{m-1}(h_y).
\end{aligned}$$

By the assumption (2.17) and (4.2) we have

$$A \le \frac{\mathcal{C}}{m^r}\|fv\|. \tag{4.27}$$

Concerning B, under the assumptions (2.6), by (4.5), we obtain

$$B \le \mathcal{C}(\log m)E_{m-1}(K^*f)_v. \tag{4.28}$$

In order to estimate $E_{m-1}(K^*f)_v$ by means of the inequality (4.1), we proceed to the evaluation of $\Omega^k_\varphi(K^*f,t)_v$. Using (4.6), we get

$$\begin{aligned}|v(y)\Delta^k_{h\varphi}(K^*f)(y)| &= \left|\lambda\int_{-1}^{1} L_m^{\alpha,\beta}(v(y)\Delta^k_{h\varphi}h_y,x)v^{\alpha-\gamma,\beta-\delta}(x)(fv)(x)dx\right| \\ &\le \mathcal{C}\|fv\|\int_{-1}^{1}|L_m^{\alpha,\beta}(v(y)\Delta^k_{h\varphi}h_y,x)|v^{\alpha-\gamma,\beta-\delta}(x)dx \\ &\le \mathcal{C}\|fv\|v(y)\sup_{|x|\le 1}|\Delta^k_{h\varphi}h_x(y)|.\end{aligned}$$

Taking the supremum on $y\in[-1+4k^2h^2,1-4k^2h^2]$ first and then the supremum on $0<h\le t$, we get

$$\Omega^k_\varphi(K^*f,t)_v \le \mathcal{C}\|fv\|\sup_{|x|\le 1}\Omega^k_\varphi(h_x,t)_v \le \mathcal{C}t^r\|fv\|\sup_{|x|\le 1}\|h_x\|_{Z_r(v)}.$$

Thus, using inequality (4.1) and the assumption (2.16), (4.28) becomes

$$B \le \frac{\mathcal{C}}{m^r}(\log m)\|fv\|. \tag{4.29}$$

Combining (4.27) and (4.29) with (4.26), we get

$$\|K-K_m\|_{C_v\to C_v} \le \frac{\mathcal{C}}{m^r}(\log m). \tag{4.30}$$

Finally, substituting (4.17) and (4.30) into (4.21), we deduce (2.19). □

Proofs of section 3. We first give some notation and preliminary results.

We define in $C_{v^{\gamma,\delta}}$ the rth φ-modulus of continuity as

$$\begin{aligned}\omega^k_\varphi(f,t)_{v^{\gamma,\delta}} = \Omega^k_\varphi(f,t)_{v^{\gamma,\delta}} &+ \inf_{P\in\mathbb{P}_{k-1}}\|(f-P)v^{\gamma,\delta}\|_{C[-1,-1+4k^2t^2]} \\ &+ \inf_{P\in\mathbb{P}_{k-1}}\|(f-P)v^{\gamma,\delta}\|_{C[1-4k^2t^2,1]},\end{aligned}$$

where $0<t\le\frac{1}{2k}$. Also we use the notation $\omega_\varphi=\omega^1_\varphi$. Note that, if $f\in B_{r,q}(v^{\gamma,\delta}), 1\le q\le+\infty, r\in\mathbb{R}^+$, then $\omega^k_\varphi(f,t)_{v^{\gamma,\delta}}\sim\Omega^k_\varphi(f,t)_{v^{\gamma,\delta}}$. The following proposition holds.

PROPOSITION 4.3. *Let* $0<\alpha<1$. *Then, for* $f\in Z_r(v^{\gamma,\delta+\alpha})$ *and* γ,δ *satisfying* (3.5), *we have*

$$|v^{\alpha+\gamma,\delta}(y)(Af)(y)| \le \mathcal{C}\left[\|fv^{\gamma,\delta+\alpha}\| + \int_0^{1/2}\frac{\omega_\varphi(f,t)_{v^{\gamma,\delta+\alpha}}}{t}dt\right], \tag{4.31}$$

where $|y|\le 1$ *and* $\mathcal{C}\ne\mathcal{C}(f,y)$.

Proof. It is not hard to deduce (4.31) by [24, Theorem 3.1] (see also [3, pp. 46–47] and [30, Proof of Theorem 2.2]). ∎

PROPOSITION 4.4. *Let* $0 < \alpha < 1$. *The inequality*

$$\inf_{P\in\mathbb{P}_m} \|v^{\alpha,0}A(f-P_m)\| \leq \mathcal{C}\left[E_m(f)_{v^{0,\alpha}}\log m + \int_0^{\frac{1}{m}} \frac{\omega_\varphi^k(f,t)_{v^{0,\alpha}}}{t}dt\right] \quad \forall f \in C_{v^{0,\alpha}} \tag{4.32}$$

holds, where $1 \leq k < m$ *and* $\mathcal{C} \neq \mathcal{C}(m,f)$.

Proof. The proof of (4.32) can be found in [30, Proof of Theorem 2.2]. ∎

Proof of Lemma 3.1. Recalling (3.7), we obtain

$$\|G\|_{Z_r(v^{\alpha+\gamma,\delta})} = \|Ag\|_{Z_r(v^{\alpha+\gamma,\delta})} \leq \|Ag\|_{Z_r(v^{\alpha,0})} \leq \mathcal{C}\|g\|_{Z_r(v^{0,\alpha})}, \tag{4.33}$$

i.e., (3.8). Analogously it is possible to prove (3.9).

It remains to prove (3.10). We have

$$v^{\alpha+\gamma,\delta}(y)\|\Psi_y\|_{Z_r} = v^{\alpha+\gamma,\delta}(y)\|\Psi_y\| + v^{\alpha+\gamma,\delta}(y)\sup_{t>0}\frac{\Omega_\varphi^k(\Psi_y,t)}{t^r} := B_1 + B_2. \tag{4.34}$$

Concerning B_1, applying (4.31) we get

$$\begin{aligned} v^{\alpha+\gamma,\delta}(y)|\Psi(x,y)| &= v^{\alpha+\gamma,\delta}(y)|(Ak_x)(y)| \\ &\leq v^{\alpha+\gamma,\delta}(y)\left|k(x,y)v^{-\alpha,\alpha}(y) + \int_{-1}^{1}\frac{k(x,z)}{z-y}v^{-\alpha,\alpha}(z)dz\right| \\ &\leq \mathcal{C}\sup_{|y|\leq 1} v^{\gamma,\delta+\alpha}(y)|k(x,y)| + \mathcal{C}\int_0^1 \frac{\omega_\varphi(k_x,t)_{v^{\gamma,\delta+\alpha}}}{t}dt. \end{aligned} \tag{4.35}$$

Recalling that

$$\omega_\varphi(k_x,t)_{v^{\gamma,\delta+\alpha}} \leq \mathcal{C}t\sup_{|y|\leq 1}\left|\varphi(y)v^{\gamma,\delta+\alpha}(y)\frac{\partial}{\partial y}k(x,y)\right|,$$

we obtain

$$B_1 \leq \mathcal{C}\sup_{|y|\leq 1} v^{\gamma,\delta+\alpha}(y)\sup_{|x|\leq 1}|k(x,y)| + \mathcal{C}\sup_{|y|\leq 1} v^{\gamma,\delta+\alpha}(y)\sup_{|x|\leq 1}\left|\frac{\partial}{\partial y}k(x,y)\right|. \tag{4.36}$$

Analogously, replacing k_x by $\Delta^k_{h\varphi(x)}k_x$ in (4.35), we deduce

$$\begin{aligned} v^{\alpha+\gamma,\delta}(y)|\Delta^k_{h\varphi(x)}\Psi(x,y)| &= v^{\alpha+\gamma,\delta}(y)|A(\Delta^k_{h\varphi(x)}k_x)(y)| \\ &\leq \mathcal{C}\sup_{|y|\leq 1} v^{\gamma,\delta+\alpha}(y)|\Delta^k_{h\varphi(x)}k(x,y)| \\ &\quad + \mathcal{C}\sup_{|y|\leq 1} v^{\gamma,\delta+\alpha}(y)\left|\Delta^k_{h\varphi(x)}\frac{\partial}{\partial y}k(x,y)\right| \end{aligned}$$

and then, taking the supremum on $x \in [-1+4k^2h^2, 1-4k^2h^2]$ as first and the supremum on $0 < h \leq t$ as second, we get

$$B_2 \leq \mathcal{C}\sup_{|y|\leq 1} v^{\gamma,\delta+\alpha}(y)\sup_{t>0}\frac{\Omega_\varphi^k(k_y,t)}{t^r} + \mathcal{C}\sup_{|y|\leq 1} v^{\gamma,\delta+\alpha}(y)\sup_{t>0}\frac{\Omega_\varphi^k\left(\frac{\partial}{\partial y}k_y,t\right)}{t^r}. \tag{4.37}$$

Finally, combining (4.36) and (4.37) with (4.34), (3.10) follows. ∎

Proof of Proposition 3.2. We first note that (3.18) and (3.19) can be obtained by replacing g and k_x with their Lagrange polynomials based on the zeros $t_1, \dots, t_m$ of $p_m^{-\alpha,\alpha}$ and taking into account that by [25]

$$A\left[\frac{p_m^{-\alpha,\alpha}}{\cdot - t_j}\right](y) = \frac{p_m^{\alpha,-\alpha}(y) - p_m^{\alpha,-\alpha}(t_j)}{y - t_j}$$

and

$$\frac{p_m^{\alpha,-\alpha}(t_j)}{[p_m^{-\alpha,\alpha}]'(t_j)} = \frac{\sin\alpha\pi}{\pi}\lambda_{m,j}^{-\alpha,\alpha},$$

we have

$$(Al_{m,j})(x_i) = \frac{\sin\alpha\pi}{\pi}\frac{\lambda_{m,j}^{-\alpha,\alpha}}{t_j - x_i}.$$

Moreover, letting $x_i = x_{m,i}^{\alpha,-\alpha} = \cos\theta_{m,i}^{\alpha,-\alpha}$ and $t_j = t_{m,j}^{-\alpha,\alpha} = \cos\theta_{m,j}^{-\alpha,\alpha}$, from a result in [25] we have

$$\min_{i,j} |\theta_{m,i}^{\alpha,-\alpha} - \theta_{m,j}^{-\alpha,\alpha}| \geq \frac{\mathcal{C}}{m}. \tag{4.38}$$

Now we prove (3.22). Recalling that $G = Ag$ and $G_m = AL_m^{-\alpha,\alpha}(g)$ and denoting by P_{m-1} the polynomial of best approximation of g, we get

$$\begin{aligned} |G(y) - G_m(y)| &= |A[g - L_m^{-\alpha,\alpha}(g)](y)| \\ &\leq |A(g - P_{m-1})(y)| + |AL_m^{-\alpha,\alpha}(g - P_{m-1})](y)|. \end{aligned}$$

Therefore

$$\begin{aligned} v^{\alpha,0}(x_i)|G(x_i) - G_m(x_i)| \leq\ & v^{\alpha,0}(x_i)|A(g - P_{m-1})(x_i)| \\ & + \frac{1}{\pi}v^{\alpha,0}(x_i)\left|\sum_{j=1}^{m}\frac{g(t_j) - P_{m-1}(t_j)}{t_j - x_i}\lambda_{m,j}^{-\alpha,\alpha}\right| \\ :=\ & B_1 + B_2. \end{aligned} \tag{4.39}$$

Using (4.32) and (4.2) we get

$$B_1 \leq \mathcal{C}\frac{\log m}{m^r}\|g\|_{Z_r(v^{0,\alpha})}. \tag{4.40}$$

Recalling that [49] $\lambda_{m,j}^{-\alpha,\alpha} \sim \Delta t_j\ v^{-\alpha,\alpha}(t_j), \Delta t_j = t_{j+1} - t_j$, we obtain

$$B_2 \leq \mathcal{C}\|(g - P_{m-1})v^{0,\alpha}\|v^{\alpha,0}(x_i)\sum_{j=1}^{m}\frac{\Delta t_j}{|x_i - t_j|}v^{-\alpha,0}(t_j).$$

Moreover, since by virtue of (4.38) we have (see, for instance, [3, (5.16)])

$$\sum_{j=1}^{m}\frac{\Delta t_j}{|x_i - t_j|}v^{-\alpha,0}(t_j) \leq Cv^{-\alpha,0}(x_i)\log m,$$

we get

$$B_2 \leq \mathcal{C}(\log m) E_{m-1}(g)_{v^{0,\alpha}}$$

and, applying (4.2), we obtain

$$B_2 \leq \mathcal{C}\frac{\log m}{m^s}\|g\|_{Z_s(v^{0,\alpha})}. \tag{4.41}$$

Combining (4.39) with (4.40) and (4.41), (3.22) follows. Analogously we can prove (3.21).

Notice that from the previous discrete error estimate one can deduce an estimate of the (global) operator norm; see, e.g., the proof of Proposition 3.3. □

Proof of Proposition 3.3. Denote by $A_m a = b$ and $A_m^* \bar{a} = b^*$ the systems (3.14) and (3.20), respectively. We first show that $\mathrm{cond}(A_m) \sim \mathrm{cond}(A_m^*)$. Since, for $m > m_0$, A_m^{-1} exists, the identity

$$A_m^* = A_m[I_m + A_m^{-1}(A_m^* - A_m)]$$

holds true. Moreover, $\|A_m^{-1}\| \leq \mathcal{C}\log m$ (see the proof of Theorem 2.1) and by Proposition 3.2 we deduce

$$\|A_m - A_m^*\| \leq \mathcal{C}\frac{\log m}{m^r}. \tag{4.42}$$

Therefore, $\lim_m \|A_m^{-1}(A_m^* - A_m)\| = 0$. Consequently $(A_m^*)^{-1}$ exists and

$$\lim_m \frac{\mathrm{cond}(A_m^*)}{\mathrm{cond}(A_m)} \leq 1.$$

On the other hand, we use the identity

$$A_m = A_m^*[I_m + (A_m^*)^{-1}(A_m - A_m^*)]$$

to prove that

$$\lim_m \frac{\mathrm{cond}(A_m)}{\mathrm{cond}(A_m^*)} \leq 1$$

and, consequently,

$$\lim_m \frac{\mathrm{cond}(A_m^*)}{\mathrm{cond}(A_m)} = 1.$$

In order to estimate $f^* - f_m^{**}$ in $C_{v^{\alpha+\gamma,\delta}}$, we premise some notation. Denoting by B_z the operator B acting w.r.t. the variable z, we set

$$(Kf)(y) := \int_{-1}^{1} (Ak_x)(y) f(x) v^{\alpha,-\alpha} dx,$$

$$(K_m f)(y) := (L_m^{\alpha,-\alpha}\tilde{K}f)(y)$$

with

$$(\tilde{K}f)(y) := \int_{-1}^{1} (L_{m,x}^{\alpha,-\alpha} A_y k)(x,y) f(x) v^{\alpha,-\alpha}(x) dx$$

and

$$(K_m^* f)(y) := (L_m^{\alpha,-\alpha} K^* f)(y)$$

with

$$(K^* f)(y) := \int_{-1}^{1} (L_{m,x}^{\alpha,-\alpha} A_y L_{m,y}^{-\alpha,\alpha} k)(x,y) f(x) v^{\alpha,-\alpha}(x) dx.$$

It is not hard to prove that the finite dimensional equations

$$f_m + K_m f_m = L_m A g$$

and

$$f_m + K_m^* f_m = L_m^{\alpha,-\alpha} A L_m^{-\alpha,\alpha} g$$

are equivalent to the systems (3.14) and (3.20), respectively, in the basis $\{\varphi_i\}_i$, with $\varphi_i = \frac{l_i^{\alpha,-\alpha}}{v^{\alpha+\gamma,\delta}(x_i)} (x_i = x_i^{\alpha,-\alpha})$.

Therefore, to estimate $\|(f^* - f_m^{**}) v^{\alpha+\gamma,\delta}\|$ by means of (4.20) it remains to prove that $K_m^* \to K$ and $L_m^{\alpha,-\alpha} A L_m^{-\alpha,\alpha} g \to Ag$ in $C_{v^{\alpha+\gamma,\delta}}$.

It is sufficient to consider the difference $K_m - K$ in the set of the polynomial of degree at most $m-1$. Thus, for all $f_m \in \mathbb{P}_m$, we have

$$\begin{aligned} v^{\alpha+\gamma,\delta}(y) |(K f_m)(y) - (K_m^* f_m)(y)| &\le v^{\alpha+\gamma,\delta}(y) |(K f_m)(y) - (K_m f_m)(y)| \\ &\quad + v^{\alpha+\gamma,\delta}(y) |(K_m f_m)(y) - (K_m^* f_m)(y)|. \end{aligned}$$

The first addendum at the right-hand side is dominated by $\mathcal{C} \frac{\log m}{m^r} \|f_m v^{\alpha+\gamma,\delta}\|$ in view of (4.18). About the second addendum, using (4.4), we get

$$\begin{aligned} &v^{\alpha+\gamma,\delta}(y) |(K_m f_m)(y) - (K_m^* f_m)(y)| \\ &\quad = |v^{\alpha+\gamma,\delta}(y) L_m^{\alpha,-\alpha} (\tilde{K} f_m - K^* f_m, y)| \\ &\quad \le \mathcal{C} \log m \max_{i=1,\dots,m} v^{\alpha+\gamma,\delta}(x_i) |(\tilde{K} f_m)(x_i) - (K^* f_m)(x_i)| \\ &\quad = \mathcal{C} \log m \max_{i=1,\dots,m} v^{\alpha+\gamma,\delta}(x_i) \left| \int_{-1}^{1} L_m^{\alpha,-\alpha} ((A_y k)(\cdot, x_i) \right. \\ &\qquad \left. - (A_y L_{m,y}^{-\alpha,\alpha} k)(\cdot, x_i), x) f_m(x) v^{\alpha,-\alpha}(x) dx \right|. \end{aligned}$$

Applying the Gaussian quadrature rule to the last integral and using (4.42), we get

$$\begin{aligned} &v^{\alpha+\gamma,\delta}(y) |(K_m f_m)(y) - (K_m^* f_m)(y)| \\ &\quad \le \mathcal{C} \log m \max_{i=1,\dots,m} v^{\alpha+\gamma,\delta}(x_i) \left| \sum_{k=1}^{m} \lambda_k^{\alpha,-\alpha} [\Psi(x_k, x_i) - \Psi_m(x_k, x_i)] f_m(x_k) \right| \\ &\quad \le \mathcal{C} \max_{|x| \le 1} |f_m(x) v^{\alpha+\gamma,\delta}(x)| (\log m) \|A_m - A_m^*\| \\ &\quad \le \mathcal{C} \|f_m v^{\alpha+\gamma,\delta}\| \frac{\log^2 m}{m^r}. \end{aligned}$$

Thus, we have

$$\|v^{\alpha+\gamma,\delta}(K f - K_m^* f)\| \le \mathcal{C} \|f v^{\alpha+\gamma,\delta}\| \frac{\log^2 m}{m^r}. \tag{4.43}$$

In order to estimate $Ag - L_m^{\alpha,-\alpha} A L_m^{-\alpha,\alpha} g$ we have

$$\begin{aligned} & v^{\alpha+\gamma,\delta}(y)|(Ag)(y) - (L_m^{\alpha,-\alpha} A L_m^{-\alpha,\alpha} g)(y)| \\ & \quad \le v^{\alpha+\gamma,\delta}(y)|(Ag)(y) - (L_m^{\alpha,-\alpha} Ag)(y)| \\ & \qquad + v^{\alpha+\gamma,\delta}(y)|(L_m^{\alpha,-\alpha} Ag)(y) - (L_m^{\alpha,-\alpha} A L_m^{-\alpha,\alpha} g)(y)|. \end{aligned}$$

Since, by (4.33), $g \in Z_r(v^{0,\alpha})$ implies $Ag \in Z_r(v^{\alpha+\gamma,\delta})$, using (4.5), (4.2), and (3.7), the first addendum at the right-hand side is dominated by $\mathcal{C}\frac{\log m}{m^r}\|g\|_{Z_r(v^{0,\alpha})}$. Moreover, about the second addendum, using (4.4) and (3.22), we get

$$\begin{aligned} & v^{\alpha+\gamma,\delta}(y)|(L_m^{\alpha,-\alpha} Ag)(y) - (L_m^{\alpha,-\alpha} A L_m^{-\alpha,\alpha} g)(y)| \\ & \quad = |v^{\alpha+\gamma,\delta}(y) L_m^{\alpha,-\alpha}(Ag - A L_m^{-\alpha,\alpha} g)| \\ & \quad \le \mathcal{C} \log m \max_{i=1,\dots,m} v^{\alpha+\gamma,\delta}(x_i)|G(x_i) - G_m(x_i)| \\ & \quad \le \mathcal{C}\frac{\log^2 m}{m^r}\|g\|_{Z_r(v^{0,\alpha})}. \end{aligned}$$

Consequently, we get

$$\|v^{\alpha+\gamma,\delta}(Ag - L_m^{\alpha,-\alpha} A L_m^{-\alpha,\alpha} g)\| \le \mathcal{C}\frac{\log^2 m}{m^r}\|g\|_{Z_r(v^{0,\alpha})}. \tag{4.44}$$

Finally, combining (4.43) and (4.44) with (4.20), (3.24) follows. ∎

Acknowledgments. The authors are grateful to Prof. P. Junghanns for his useful remarks and thank the referees for their contribution in improving the paper.

ANALYSIS OF DISCONTINUOUS FINITE ELEMENT METHODS FOR GROUND WATER/SURFACE WATER COUPLING*

CLINT DAWSON†

Abstract. We derive and analyze new numerical approaches for modeling coupled ground water/surface water flow. In this coupled model, surface water flow is described by the depth-averaged shallow water equations, while ground water is modeled by saturated Darcy flow. The coupling between the two models assumes continuity of pressure and water flux across the ground water/surface water interface. The coupled model is approximated by a local discontinuous Galerkin method for ground water flow and a discontinuous Galerkin method for surface water flow. A priori error estimates are derived for this approach. A closely related approach where the well-known mixed finite element method is applied to the ground water flow equations is also described and analyzed. One advantage of these approaches is that they allow for the ground water and surface water domains to be meshed independently, under some mild restrictions.

Key words. ground water flow equations, shallow water equations, mixed finite element method, discontinuous Galerkin method, coupled method

1. Introduction.

Comprehensive water resource management requires a careful study of the interactions of ground water and surface water. As noted in a recent report of the United States Geological Survey [45], "Traditionally, management of water resources has focused on surface water or ground water as if they were separate entities ... Effective policies and management practices must be built on a foundation that recognizes that surface water and ground water are simply two manifestations of a single integrated resource." This article gives a number of examples of ground water/surface water interactions and the effect these interactions have on the environment and the water cycle.

In this paper, we focus on the numerical approximation of coupled ground water/surface water flow. Surface water flow models are derived from the incompressible Navier–Stokes equations and can take many forms, including two- and three-dimensional shallow water models, overland flow, and kinematic and diffusive wave models; see [42] for an overview of shallow water hydrodynamics. Ground water flow models include single phase Darcy flow and various multiphase models which account for unsaturated flow through the vadose zone, e.g., the Richards equation or a two-phase air-water model [23]. These models are fairly well understood within their respective regimes. How these models should be coupled is still a question open for debate.

The coupling of Stokes and Darcy flows has been studied mathematically and numerically in several recent papers; see, for example [27, 35, 5], where the coupling is imposed through the Beavers–Joseph–Saffman interface conditions [8, 36, 25]. Application of these conditions to the coupling of surface and ground water flow is discussed

in Miglio, Discacciati, and Quarteroni [30], where a three-dimensional nonhydrostatic shallow water model is coupled with Darcy flow; the authors prove well-posedness of the model in the case of linear Stokes flow and formulate an iterative method to solve the coupled system.

In the engineering literature, various numerical models for coupling depth-averaged shallow water flow equations with single and multiphase ground water flow equations have been investigated; see, for example, [37, 39, 47, 46, 38]. Within these models, the coupling between surface and ground water is imposed in various ways. One approach that has been proposed is to compute an "exchange flux." This approach assumes the existence of an interfacial domain connecting the two domains, referred to as the conductance concept [2, 40]. The interfacial domain is characterized by a thickness parameter m and permeability k. The flux is then calculated as the ratio $\lambda = k/m$ multiplied by the difference between the surface water and ground water pressures at the interface. The exchange flux enters into the ground water and surface water flow equations through source terms. The drawback to this approach is that the presence of such a distinct interfacial domain has not been observed in the field [14]; thus determining k and m is problematic. The use of the conductance concept in numerical modeling of ground water/surface water coupling dates back to at least 1969 [24].

Another approach, which is often used in multiphysics problems [29, 32], is to assume continuity of normal flux and of an appropriately defined "pressure" across the interface. This is equivalent to the conductance concept if the thickness parameter m goes to zero and is also part of the Beavers–Joseph–Saffman interface conditions for coupling Darcy flow with the three-dimensional nonhydrostatic shallow water equations as discussed in [30]. This approach is studied for ground water/surface water coupling in a recent paper by Kollet and Maxwell [26] and is the approach we will take here, though the way we implement the interface conditions is different. The flow model we consider is based on the depth-averaged, two-dimensional shallow water equations coupled with a saturated ground water flow model. The depth-averaged shallow water equations are widely used for surface water flow modeling, because vertical effects are often negligible in comparison to the horizontal. Upon depth averaging, the ground water normal velocity at the ground water/surface water interface enters the shallow water continuity equation as a source term. The continuity of pressure is enforced by assuming that the ground water hydraulic head is equal to the surface water height at the interface. Thus, the ground water flow equations have a time-dependent Dirichlet boundary condition at the surface water interface, where the boundary value satisfies the shallow water equations. Unlike the Darcy/Stokes couplings mentioned above, the surface water momentum equation is not directly involved in this coupling.

Based upon this model, we derive a weak formulation and discuss the approximation of the weak solution using discontinuous and mixed finite element methods. Discontinuous Galerkin (DG) and mixed finite element (MFE) methods have been extensively studied for elliptic flow problems such as ground water flow [44, 34, 31, 15, 33, 12, 11, 10, 7, 6, 4, 3, 13, 16, 43, 41, 22, 21]. More recently, DG methods have been applied to the shallow water equations [1, 18, 19]. These methods have certain features, which have been discussed at length in these and other papers, which make them of interest for approximating the flow models under consideration here. One advantage of these methods for modeling ground water/surface water interaction is that boundary conditions are enforced weakly, which allows for flexibility in the coupling. In particular, the ground water and surface water domains can be meshed independently of each other with some minor restrictions. Another advantage of

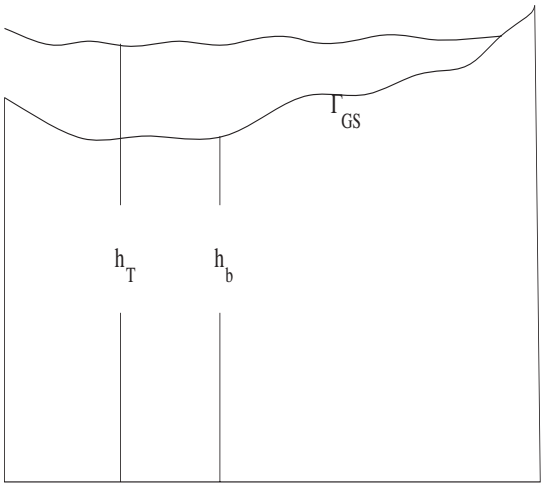

FIG. 1. *Schematic of a ground water/surface water interface.*

these methods, which has been well documented, is that they provide for locally conservative, flux-continuous flow fields. This property is important when coupling the flow equations with a transport model, for example, when considering contaminant transport [20].

In the next section, we derive the coupled flow model under consideration. We express the ground water flow equations in mixed form and consider the approximation of this model using the local discontinuous Galerkin (LDG) method as described in [17, 15]. We approximate the shallow water flow model also using a DG method as described in [19]. The coupling between the formulations is through a source term in the shallow water equations and a boundary term in the ground water flow equation. We refer to this approach as the LDG/DG method. In section 4 we derive a priori error estimates for this coupled method under very mild assumptions on how the ground water and surface water domains are discretized.

The flexibility of the LDG method allows us to easily formulate an approach based on the MFE method [33] for ground water flow, coupled with the DG method for surface water. We refer to this approach as MFE/DG, and error estimates for this approach are derived in section 5.

Finally, in section 6, we give some preliminary numerical results for the LDG/DG method on a model ground water/surface water flow problem.

2. Problem definition. Let h_b denote the bathymetric height of the ground water/surface water interface, measured relative to a reference z plane; see Figure 1. We assume that h_b is a continuous, piecewise differentiable function. Let h_T denote the total surface water height above this reference plane, and let the surface water depth $h_s = h_T - h_b$.

In the ground water domain $\Omega_{\rm g}$, let h_g denote the hydraulic head, also measured relative to the reference z-plane, and let $\mathbf{u}_g = (u_g, v_g, w_g)$ denote the ground water velocity. The ground water flow equations are given by

$$\left.\begin{array}{l} \mathbf{u}_g = -K\nabla_{(x,y,z)} h_g, \\ \nabla_{(x,y,z)} \cdot \mathbf{u}_g = f_g \end{array}\right\}, \quad (x,y,z) \in \Omega_{\rm g}, \tag{1}$$

where K is a symmetric, positive definite, hydraulic conductivity tensor and f_g models ground water source/sink terms. Here

$$\nabla_{(x,y,z)} = \left(\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z} \right).$$

Assuming continuity of pressure across the ground water/surface water interface, we have the boundary conditions

$$h_g = h_T \quad \text{on } \Gamma_{GS}, \tag{2}$$

$$h_g = h_g^D \quad \text{on } \Gamma_D, \tag{3}$$

$$\mathbf{u}_g \cdot \mathbf{n}_g = u_N \quad \text{on } \Gamma_N. \tag{4}$$

Here $\Gamma_{GS} \subset \partial\Omega_{\mathrm{g}}$ represents the ground water/surface water interface, $\Gamma_D \subset \partial\Omega_{\mathrm{g}}$ is the Dirichlet portion of the boundary external to Γ_{GS}, Γ_N is the Neumann portion of the boundary, and $\mathbf{n}_g$ is the outward normal to $\partial\Omega_{\mathrm{g}}$. We will assume that $\Gamma_D \cup \Gamma_{GS} \neq \emptyset$.

The shallow water flow equations are obtained from the three-dimensional Navier–Stokes equations under the hydrostatic pressure assumption [42]. Note that the surface Γ_{GS} is described by the bathymetry $h_b(x, y)$ for points (x, y) contained in some two-dimensional parameter space Ω_{s}; thus the normal $\mathbf{n}_g$ to this surface is proportional to the vector $(-\partial h_b/\partial x, -\partial h_b/\partial y, 1)$. The depth-integrated shallow water equations are then defined over the domain Ω_{s}. First, the shallow water continuity equation is obtained by integrating the incompressibility condition $\nabla_{(x,y,z)} \cdot \mathbf{u} = 0$ over the water depth, where $\mathbf{u} = (u_s, v_s, w_s)$ is the three-dimensional surface water velocity. Applying the kinematic boundary condition at the free surface [42] and the continuity of flux across the ground water/surface water interface results in

$$\partial_t h_s + \nabla_{(x,y)} \cdot (\mathbf{u}_s h_s) = \mathbf{u}_g \cdot (-\nabla_{(x,y)} h_b, 1), \quad (x, y) \in \Omega_{\mathrm{s}}, \quad t > 0, \tag{5}$$

where $\nabla_{(x,y)}$ is the gradient operator in x-y space. Here $\mathbf{u}_s = (\bar{u}_s, \bar{v}_s)$ is the depth-averaged horizontal surface water velocity, defined by

$$\bar{u}_s(x, y) \equiv \frac{1}{h_s} \int_0^{h_s} u_s(x, y, z) dz$$

with a similar definition for $\bar{v}_s$. In (5), we are neglecting other external sources/sinks such as rainfall and evaporation. The depth-averaged shallow water momentum equation is

$$\partial_t \mathbf{u}_s + \mathbf{u}_s \cdot \nabla_{(x,y)} \mathbf{u}_s + \tau_{bf} \mathbf{u}_s + g \nabla_{(x,y)} h_T - \mu \nabla_{(x,y)} \cdot (\nabla_{(x,y)} \mathbf{u}_s) = \mathcal{F}, \tag{6}$$

where $\tau_{bf} \geq 0$ is a bottom friction coefficient, g is gravitational acceleration, $\mu > 0$ is the horizontal eddy viscosity, and $\mathcal{F}$ represents additional forcing terms, such as wind stress, atmospheric pressure gradient, etc. For simplicity, we will assume linear bottom friction so that $\tau_{bf} = \tau_{bf}(x, y)$.

Let the domain boundary $\partial\Omega_s$ be divided into inflow and outflow regions $\partial\Omega_s = \partial\Omega_{s,in} \cup \partial\Omega_{s,out}$ defined as

$$\partial\Omega_{s,in} = \{(x, y) \in \partial\Omega_{\mathrm{s}} : \mathbf{u}_s \cdot \mathbf{n}_s < 0\}, \tag{7}$$

$$\partial\Omega_{s,out} = \{(x, y) \in \partial\Omega_{\mathrm{s}} : \mathbf{u}_s \cdot \mathbf{n}_s \geq 0\}, \tag{8}$$

where $\mathbf{n}_s$ is the outward normal to $\partial\Omega_s$, and consider the following boundary and initial conditions:

$$h_s(\cdot,0) = h_s^0, \quad \Omega_{\rm s}, \tag{9}$$

$$\mathbf{u}_s(\cdot,0) = \mathbf{u}_s^0, \quad \Omega_{\rm s}, \tag{10}$$

$$h_s = h_s^I, \quad \partial\Omega_{s,in} \times (0,T], \tag{11}$$

$$\mathbf{u}_s = \hat{\mathbf{u}}_s, \quad \partial\Omega_s \times (0,T], \tag{12}$$

where h_s^I is a specified inflow water height and $\hat{\mathbf{u}}_s$ is a specified velocity.

Therefore, the coupling between ground water and surface water flow equations in this setting occurs in the boundary conditions for ground water flow and the forcing term for the surface water elevation. Even though we have assumed a simple ground water flow model, the same type of coupling would occur if ground water flow were described by the Richards equation, for example.

We will discretize the ground water flow equation using the LDG method as described in [15]. Later we will see that the general framework of the LDG method allows us to also consider the approximation of these equations by the MFE method [33] by restricting our finite element spaces. We will discretize the primitive continuity equation (5) and momentum equation (6) also using DG methods. In particular we apply a method described in [19], where the advection term in (6) is discretized by the upwinding technique of Lesaint and Raviart [28], and the eddy viscosity terms are discretized using a nonsymmetric, interior penalty Galerkin method (NIPG) [34].

3. The LDG/DG Method. Let $\{\mathcal{T}_{\Delta_g,g}\}_{\Delta_g>0}$ denote a family of regular finite element partitions of $\Omega_{\rm g}$ such that no individual element $\Omega_{e,g}$ crosses $\partial\Omega_g$. Let $\Delta_{e,g}$ denote the element diameter with Δ_g being the maximal element diameter. We also assume that each element $\Omega_{e,g}$ is Lipschitz and affinely equivalent to one of several reference elements [9]. Similarly, let $\{\mathcal{T}_{\Delta_s,s}\}_{\Delta_s>0}$ denote a family of regular finite element partitions of $\Omega_{\rm s}$, where Δ_s is the maximal element diameter. We do not require that the partitions match up at the interface Γ_{GS}. We allow $\mathcal{T}_{\Delta_g,g}$ and $\mathcal{T}_{\Delta_s,s}$ to be nonconforming within their respective domains; i.e., element boundaries do not have to align. We assume, however, that the number of elements sharing a face is bounded independently of Δ_g or Δ_s. We assume further that each triangulation is locally quasi-uniform [9].

On each triangulation $\mathcal{T}_{\Delta_g,g}$ we will approximate $\mathbf{u}_g$ in the space $\mathcal{V}_{\Delta_g,g}$ and h_g in the space $\mathcal{W}_{\Delta_g,g}$, where

$$\mathcal{V}_{\Delta_g,g} = \{\mathbf{v} \in L^2(\Omega_{\rm g})^3 : \mathbf{v}|_{\Omega_{e,g}} \in (\mathcal{S}(\Omega_{e,g}))^3 \quad \forall\, \Omega_{e,g} \in \Omega_{\rm g}\}, \tag{13}$$

$$\mathcal{W}_{\Delta_g,g} = \{w \in L^2(\Omega_{\rm g}) : w|_{\Omega_{e,g}} \in \mathcal{S}(\Omega_{e,g}) \quad \forall\, \Omega_{e,g} \in \Omega_{\rm g}\}. \tag{14}$$

We will assume that $\mathcal{S}$ consists of complete polynomials of degree $k_g \geq 1$.

Similarly, on each triangulation $\mathcal{T}_{\Delta_s,s}$, we approximate h_s in the space $\mathcal{W}_{\Delta_s,s}$ and $\mathbf{u}_s$ in the space $\mathcal{V}_{\Delta_s,s}$, which consist of complete polynomials of degree $k_s \geq 1$ defined on each element.

In our numerical procedure defined below, $\mathbf{u}_g \approx \boldsymbol{U}_g \in \mathcal{V}_{\Delta_g,g}$, $h_g \approx H_g \in \mathcal{W}_{\Delta_g,g}$, $\mathbf{u}_s \approx \boldsymbol{U}_s \in \mathcal{V}_{\Delta_s,s}$, and $h_s \approx H_s \in \mathcal{W}_{\Delta_s,s}$.

Suppose e is an interior face in either finite element mesh; then e has two elements adjacent to it, which we label Ω_e^- and Ω_e^+. Further suppose $(\mathbf{v}, w)$ are smooth functions defined on these elements. Let $(\mathbf{v}^\pm, w^\pm)$ denote the traces of $(\mathbf{v}, w)$ on e from the interiors of the elements Ω_e^+ and Ω_e^-, respectively. Let $\mathbf{n}^-$ denote the normal vector

to e pointing from Ω_e^- to Ω^+ with a similar definition for $\mathbf{n}^+$ (hence $\mathbf{n}^+ = -\mathbf{n}^-$). We define the average $\{\cdot\}$ and the jump $[\![\cdot]\!]$ for $\mathbf{x} \in e$ as follows:

$$\{\mathbf{v}\} = (\mathbf{v}^- + \mathbf{v}^+)/2, \qquad \{w\} = (w^- + w^+)/2, \tag{15}$$

$$[\![\mathbf{v}]\!] = \mathbf{v}^+ \cdot \mathbf{n}^+ + \mathbf{v}^- \cdot \mathbf{n}^-, \qquad [\![w]\!] = w^+\mathbf{n}^+ + w^-\mathbf{n}^-. \tag{16}$$

We will use the $L^2(R)$ inner product notation $(\cdot,\cdot)_R$ for domains $R \in \mathbb{R}^d$ and the notation $\langle\cdot,\cdot\rangle_R$ to denote integration over $(d-1)$-dimensional surfaces. Let $\|\cdot\|_R$ denote the $L^2(R)$ norm on any spatial region R. The notation $\langle\cdot,\cdot,\rangle_{\mathcal{E}_{i,g}}$ denotes integration over all interior element faces in $\Omega_{\rm g}$, and $\langle\cdot,\cdot,\rangle_{\mathcal{E}_{i,s}}$ denotes integration over all interior element faces in $\Omega_{\rm s}$.

The LDG and DG weak forms of (1) and (5)–(6) are obtained as follows. Multiply the first equation in (1) by a function $\mathbf{v}_g$ which is in $(H^1(\Omega_{e,g}))^3$, integrate by parts, and sum over all elements; define

$$\begin{aligned}\mathcal{A}_g(\mathbf{u}_g, h_g, h_s; \mathbf{v}_g) &\equiv (K^{-1}\mathbf{u}_g, \mathbf{v}_g)_{\Omega_{\rm g}} - (h_g, \nabla_{(x,y,z)} \cdot \mathbf{v}_g)_{\Omega_{\rm g}} \\ &\quad + \langle \{h_g\}, [\![\mathbf{v}_g]\!]\rangle_{\mathcal{E}_{i,g}} + \langle h_g, \mathbf{v}_g \cdot \mathbf{n}_g\rangle_{\Gamma_N} + \langle h_s, \mathbf{v}_g \cdot \mathbf{n}_g\rangle_{\Gamma_{GS}}.\end{aligned} \tag{17}$$

Then by (1), (2), and (3),

$$\mathcal{A}_g(\mathbf{u}_g, h_g, h_s; \mathbf{v}_g) = -\langle h_b, \mathbf{v}_g \cdot \mathbf{n}_g\rangle_{\Gamma_{GS}} - \langle h_g^D, \mathbf{v}_g \cdot \mathbf{n}_g\rangle_{\Gamma_D}. \tag{18}$$

By the continuity of h_g, $\{h_g\} = h_g$, but this notation will be useful in defining the LDG method. Next, multiply the second equation in (1) by $w_g \in H^1(\Omega_{e,g})$. Let

$$\begin{aligned}&\mathcal{B}_g(\mathbf{u}_g, h_g, h_s; w_g) \equiv (\nabla_{(x,y,z)} \cdot \mathbf{u}_g, w_g)_{\Omega_{\rm g}} - \langle [\![\mathbf{u}_g]\!], \{w_g\}\rangle_{\mathcal{E}_{i,g}} \\ &- \langle \mathbf{u}_g \cdot \mathbf{n}_g, w_g\rangle_{\Gamma_N} + \langle \sigma_g [\![h_g]\!], [\![w_g]\!]\rangle_{\mathcal{E}_{i,g}} + \langle \sigma_g(h_g - h_s), w_g\rangle_{\Gamma_{GS}} + \langle \sigma_g h_g, w_g\rangle_{\Gamma_D}.\end{aligned} \tag{19}$$

Here we add some jump and penalty terms which are necessary to stabilize the method; the penalty function $\sigma_g > 0$ will be discussed in more detail below. By (1) and the boundary conditions (2)–(4),

$$\begin{aligned}\mathcal{B}_g(\mathbf{u}_g, h_g, h_s; w_g) &= -\langle u_N, w_g\rangle_{\Gamma_N} + \langle \sigma_g h_b, w_g\rangle_{\Gamma_{GS}} \\ &\quad + \langle \sigma_g h_g^D, w_g\rangle_{\Gamma_D} + (f_g, w_g)_{\Omega_{\rm g}}.\end{aligned} \tag{20}$$

Multiply (5) by a test function $w_s \in H^1(\Omega_{e,s})$, integrate by parts, and apply the boundary condition (11); define

$$\begin{aligned}\mathcal{B}_s(\mathbf{u}_g, \mathbf{u}_s, h_g, h_s; w_s) &\equiv (\partial_t h_s, w_s)_{\Omega_{\rm s}} - (\mathbf{u}_s h_s, \nabla_{(x,y)} w_s)_{\Omega_{\rm s}} + \langle \{\mathbf{u}_s\} h_s^{\uparrow}, [\![w_s]\!]\rangle_{\mathcal{E}_{i,s}} \\ &\quad - \langle \sigma_g(h_g - h_s), w_s\rangle_{\Gamma_{GS}} - \langle \mathbf{u}_g \cdot \mathbf{n}_g, w_s\rangle_{\Gamma_{GS}} + \langle \mathbf{u}_s \cdot \mathbf{n}_s h_s, w_s\rangle_{\partial\Omega_{s,out}} \\ &\quad + \langle \mathbf{u}_s \cdot \mathbf{n}_s h_s^I, w_s\rangle_{\partial\Omega_{s,in}}.\end{aligned} \tag{21}$$

Here we have added a penalty term on the interface Γ_{GS} similar to the fifth term in (19). The penalty function σ_g is the same as in the corresponding term in (19). We have also used the fact that by the definition of the domain $\Omega_{\rm s}$ and the surface integral

$$\langle \mathbf{u}_g \cdot \mathbf{n}_g, w_s\rangle_{\Gamma_{GS}} = (\mathbf{u}_g \cdot (-\nabla_{(x,y)} h_b, 1), w_s)_{\Omega_{\rm s}}.$$

In addition we define the "upwind" value of h_s on an interior element face e by

$$h_s^{\uparrow} = \begin{cases} h_s^-, & \{\boldsymbol{U}_s\} \cdot \mathbf{n}^- > 0, \\ h_s^+, & \{\boldsymbol{U}_s\} \cdot \mathbf{n}^+ > 0. \end{cases} \tag{22}$$

For the true solution h_s, $h_s^{\uparrow} = h_s$, but note that in general the upwind value is defined using the approximation $\boldsymbol{U}_s \approx \mathbf{u}_s$. Thus by (5)

$$\mathcal{B}_s(\mathbf{u}_g, \mathbf{u}_s, h_g, h_s; w_s) = -\langle \sigma_g h_b, w_s \rangle_{\Gamma_{GS}}. \tag{23}$$

Finally, as in [19], we discretize the momentum equation (6) using the Lesaint–Raviart upwinding method for the advective terms. For each element $\Omega_{e,s} \in \mathcal{T}_{\Delta_s,s}$, let

$$\partial\Omega_{e,s}^{-} = \{\mathbf{x} \in \partial\Omega_{e,s} : \{\boldsymbol{U}_s\} \cdot \mathbf{n}_e < 0\},$$

where $\mathbf{n}_e$ is the unit outward normal to $\partial\Omega_{e,s}$. This set is defined using the approximation $\boldsymbol{U}_s$. Multiply (6) by a test function $\mathbf{v}_s \in (H^2(\Omega_{e,s}))^2$ and apply the NIPG method for diffusion terms; define

$$\begin{aligned}
\mathcal{A}_s(\mathbf{u}_s, h_s; \mathbf{v}_s) \equiv\ & (\partial_t \mathbf{u}_s, \mathbf{v}_s)_{\Omega_s} + (\mathbf{u}_s \cdot \nabla_{(x,y)} \mathbf{u}_s, \mathbf{v}_s)_{\Omega_s} \\
& + \sum_{\partial\Omega_{e,s}^{-} \in \mathcal{T}_{\Delta_s,s}} \langle |\{\mathbf{u}_s\} \cdot \mathbf{n}_e| (\mathbf{u}_s^{\text{int}} - \mathbf{u}_s^{\text{ext}}), \mathbf{v}_s^{\text{int}} \rangle_{\partial\Omega_{e,s}^{-}} + (\tau_{bf} \mathbf{u}_s, \mathbf{v}_s)_{\Omega_s} \\
& + (g \nabla_{(x,y)} h_s, \mathbf{v}_s)_{\Omega_s} - \langle g [\![h_s]\!], \{\mathbf{v}_s\} \rangle_{\mathcal{E}_{i,s}} - \langle g h_s, \mathbf{v}_s \cdot \mathbf{n} \rangle_{\partial\Omega_{s,in}} \\
& + \mu (\nabla_{(x,y)} \mathbf{u}_s, \nabla_{(x,y)} \mathbf{v}_s)_{\Omega_s} - \mu \langle \{\nabla_{(x,y)} \mathbf{u}_s\}, [\![\mathbf{v}_s]\!] \rangle_{\mathcal{E}_{i,s}} + \mu \langle \{\nabla_{(x,y)} \mathbf{v}_s\}, [\![\mathbf{u}_s]\!] \rangle_{\mathcal{E}_{i,s}} \\
& - \mu \langle \nabla_{(x,y)} \mathbf{u}_s \cdot \mathbf{n}, \mathbf{v}_s \rangle_{\partial\Omega_s} + \mu \langle \nabla_{(x,y)} \mathbf{v}_s \cdot \mathbf{n}, \mathbf{u}_s \rangle_{\partial\Omega_s} \\
& + \langle \sigma_s [\![\mathbf{u}_s]\!], [\![\mathbf{v}_s]\!] \rangle_{\mathcal{E}_{i,s}} + \langle \sigma_s \mathbf{u}_s, \mathbf{v}_s \rangle_{\partial\Omega_s}.
\end{aligned} \tag{24}$$

Here $\mathbf{v}^{\text{int}}$ and $\mathbf{v}^{\text{ext}}$ denote the traces of $\mathbf{v}$ from the interior and exterior of $\Omega_{e,s}$, respectively, and when $\partial\Omega_{e,s}$ belongs to the domain boundary, we take $\mathbf{u}_s^{\text{ext}} = \hat{\mathbf{u}}_s$. Also σ_s is a positive penalty parameter. Thus, by (6), (11), and (12)

$$\begin{aligned}
\mathcal{A}_s(\mathbf{u}_s, h_s; \mathbf{v}_s) = & -(g \nabla_{(x,y)} h_b, \mathbf{v}_s)_{\Omega_s} - \langle g h_s^I, \mathbf{v}_s \cdot \mathbf{n} \rangle_{\partial\Omega_{s,in}} \\
& + \mu \langle \nabla_{(x,y)} \mathbf{v}_s \cdot \mathbf{n}, \hat{\mathbf{u}}_s \rangle_{\partial\Omega_s} + \langle \sigma_s \hat{\mathbf{u}}_s, \mathbf{v}_s \rangle_{\partial\Omega_s} + (\mathcal{F}, \mathbf{v}_s)_{\Omega_s}.
\end{aligned} \tag{25}$$

The LDG/DG method can then be stated as follows. We seek approximations $\boldsymbol{U}_g(\cdot,t) \in \mathcal{V}_{\Delta_g,g}$, $H_g(\cdot,t) \in \mathcal{W}_{\Delta_g,g}$, $\boldsymbol{U}_s(\cdot,t) \in \mathcal{V}_{\Delta_s,s}$, and $H_s(\cdot,t) \in \mathcal{W}_{\Delta_s,s}$ which satisfy for each $t > 0$

$$\mathcal{A}_g(\boldsymbol{U}_g, H_g, H_s; \mathbf{v}_g) = -\langle h_b, \mathbf{v}_g \cdot \mathbf{n}_g \rangle_{\Gamma_{GS}} - \langle h_g^D, \mathbf{v}_g \cdot \mathbf{n}_g \rangle_{\Gamma_D}, \quad \mathbf{v}_g \in \mathcal{V}_{\Delta_g,g}, \tag{26}$$

$$\begin{aligned}
\mathcal{B}_g(\boldsymbol{U}_g, H_g, H_s; w_g) = & -\langle u_N, w_g \rangle_{\Gamma_N} + \langle \sigma_g h_b, w_g \rangle_{\Gamma_{GS}} \\
& + \langle \sigma_g h_g^D, w_g \rangle_{\Gamma_D} + (f_g, w_g)_{\Omega_g}, \quad w_g \in \mathcal{W}_{\Delta_g,g},
\end{aligned} \tag{27}$$

$$\mathcal{B}_s(\boldsymbol{U}_g, \boldsymbol{U}_s, H_g, H_s; w_s) = -\langle \sigma_g h_b, w_s \rangle_{\Gamma_{GS}}, \quad w_s \in \mathcal{W}_{\Delta_s,s}, \tag{28}$$

$$\begin{aligned}
\mathcal{A}_s(\boldsymbol{U}_s, H_s; \mathbf{v}_s) = & -(g \nabla_{(x,y)} h_b, \mathbf{v}_s)_{\Omega_s} - \langle g h_s^I, \mathbf{v}_s \cdot \mathbf{n} \rangle_{\partial\Omega_{s,in}} \\
& + \mu \langle \nabla_{(x,y)} \mathbf{v}_s \cdot \mathbf{n}, \hat{\mathbf{u}}_s \rangle_{\partial\Omega_s} + \langle \sigma_s \hat{\mathbf{u}}_s, \mathbf{v}_s \rangle_{\partial\Omega_s} \\
& + (\mathcal{F}, \mathbf{v}_s)_{\Omega_s}, \quad \mathbf{v}_s \in \mathcal{V}_{\Delta_s,s}.
\end{aligned} \tag{29}$$

Furthermore, $H_s(\cdot,0)$ and $\boldsymbol{U}_s(\cdot,0)$ are defined to be the L^2 projections of h_s^0 and $\mathbf{u}_s^0$, respectively, defined by

$$(H_s(\cdot,0) - h_s^0, w_s)_{\Omega_s} = 0, \quad w_s \in \mathcal{W}_{\Delta_s,s}, \tag{30}$$

$$(\boldsymbol{U}_s(\cdot,0) - \mathbf{u}_s^0, \mathbf{v}_s)_{\Omega_s} = 0, \quad \mathbf{v}_s \in \mathcal{V}_{\Delta_s,s}. \tag{31}$$

Computationally, and in the analysis below, we redefine the sets $\partial\Omega_{s,in}$ and $\partial\Omega_{s,out}$ in (7) and (8) to coincide with where $\boldsymbol{U}_s \cdot \mathbf{n}_s < 0$ and $\boldsymbol{U}_s \cdot \mathbf{n}_s \geq 0$, respectively.

4. An a priori error estimate. In this section, we derive an a priori error estimate for the LDG/DG method (26)–(31).

To begin the estimate, we define $\pi \mathbf{u}_g \in \mathcal{V}_{\Delta_g,g}$, $\pi h_g \in \mathcal{W}_{\Delta_g,g}$, $\pi \mathbf{u}_s \in \mathcal{V}_{\Delta_s,s}$, and $\pi h_s \in \mathcal{W}_{\Delta_s,s}$ to be projections of the true solution into the approximating spaces. These projections will be specified below. Next, we define $\Psi_g = \boldsymbol{U}_g - \pi \mathbf{u}_g$, $\Theta_g = \mathbf{u}_g - \pi \mathbf{u}_g$, $\kappa_g = H_g - \pi h_g$, and $\eta_g = h_g - \pi h_g$ with similar definitions for κ_s, η_s, Ψ_s, and Θ_s. By linearity and Galerkin orthogonality, we have

$$\mathcal{A}_g(\Psi_g, \kappa_g, \kappa_s; \mathbf{v}_g) = \mathcal{A}_g(\Theta_g, \eta_g, \eta_s; \mathbf{v}_g), \tag{32}$$

$$\mathcal{B}_g(\Psi_g, \kappa_g, \kappa_s; w_g) = \mathcal{B}_g(\Theta_g, \eta_g, \eta_s; w_g). \tag{33}$$

Define

$$\mathcal{B}_{s,L}(\mathbf{u}_g, h_g, h_s; w_s) \equiv (\partial_t h_s, w_s)_{\Omega_s} - \langle \sigma_g(h_g - h_s), w_s \rangle_{\Gamma_{GS}} - \langle \mathbf{u}_g \cdot \mathbf{n}_g, w_s \rangle_{\Gamma_{GS}}.$$

Then from (23) and (28),

$$\begin{aligned}
&\mathcal{B}_{s,L}(\Psi_g, \kappa_g, \kappa_s; w_s) - (\boldsymbol{U}_s \kappa_s, \nabla_{(x,y)} w_s)_{\Omega_s} + \langle \{\boldsymbol{U}_s\} \kappa_s^{\uparrow}, [\![w_s]\!] \rangle_{\mathcal{E}_{i,s}} + \langle \boldsymbol{U}_s \cdot \mathbf{n}_s \kappa_s, w_s \rangle_{\partial\Omega_{s,out}} \\
&= \mathcal{B}_{s,L}(\Theta_g, \eta_g, \eta_s; w_s) - (\mathbf{u}_s h_s - \boldsymbol{U}_s \pi h_s, \nabla_{(x,y)} w_s)_{\Omega_s} + \langle \mathbf{u}_s h_s - \{\boldsymbol{U}_s\} \pi h_s^{\uparrow}, [\![w_s]\!] \rangle_{\mathcal{E}_{i,s}} \\
&\quad + \langle (\mathbf{u}_s h_s - \boldsymbol{U}_s \pi h_s) \cdot \mathbf{n}_s, w_s \rangle_{\partial\Omega_{s,out}} + \langle (\mathbf{u}_s - \boldsymbol{U}_s) \cdot \mathbf{n}_s h_s^I, w_s \rangle_{\partial\Omega_{s,in}}.
\end{aligned} \tag{34}$$

Define

$$\begin{aligned}
\mathcal{A}_{s,L}(\mathbf{u}_s, h_s; \mathbf{v}_s) &\equiv (\partial_t \mathbf{u}_s, \mathbf{v}_s)_{\Omega_s} + (\tau_{bf} \mathbf{u}_s, \mathbf{v}_s)_{\Omega_s} \\
&\quad + (g \nabla_{(x,y)} h_s, \mathbf{v}_s)_{\Omega_s} - \langle g [\![h_s]\!], \{\mathbf{v}_s\} \rangle_{\mathcal{E}_{i,s}} - \langle g h_s, \mathbf{v}_s \cdot \mathbf{n} \rangle_{\partial\Omega_{s,in}} \\
&\quad + \mu (\nabla_{(x,y)} \mathbf{u}_s, \nabla_{(x,y)} \mathbf{v}_s)_{\Omega_s} - \mu \langle \{\nabla_{(x,y)} \mathbf{u}_s\}, [\![\mathbf{v}_s]\!] \rangle_{\mathcal{E}_{i,s}} + \mu \langle \{\nabla_{(x,y)} \mathbf{v}_s\}, [\![\mathbf{u}_s]\!] \rangle_{\mathcal{E}_{i,s}} \\
&\quad - \mu \langle \nabla_{(x,y)} \mathbf{u}_s \cdot \mathbf{n}, \mathbf{v}_s \rangle_{\partial\Omega_s} + \mu \langle \nabla_{(x,y)} \mathbf{v}_s \cdot \mathbf{n}, \mathbf{u}_s \rangle_{\partial\Omega_s} \\
&\quad + \langle \sigma_s [\![\mathbf{u}_s]\!], [\![\mathbf{v}_s]\!] \rangle_{\mathcal{E}_{i,s}} + \langle \sigma_s \mathbf{u}_s, \mathbf{v}_s \rangle_{\partial\Omega_s}.
\end{aligned} \tag{35}$$

Then from (25) and (29) (recalling $\mathbf{u}_s^{\text{int}} = \mathbf{u}_s^{\text{ext}}$),

$$\begin{aligned}
&\mathcal{A}_{s,L}(\Psi_s, \kappa_s; \mathbf{v}_s) \\
&= \mathcal{A}_{s,L}(\Theta_s, \eta_s; \mathbf{v}_s) + (\mathbf{u}_s \cdot \nabla_{(x,y)} \mathbf{u}_s - \boldsymbol{U}_s \cdot \nabla_{(x,y)} \boldsymbol{U}_s, \mathbf{v}_s)_{\Omega_s} \\
&\quad - \sum_{\partial\Omega_{e,s}^- \in \mathcal{T}_{\Delta_s,s}} \langle |\{\boldsymbol{U}_s\} \cdot \mathbf{n}_e| (\boldsymbol{U}_s^{\text{int}} - \boldsymbol{U}_s^{\text{ext}}), \mathbf{v}_s^{\text{int}} \rangle_{\partial\Omega_{e,s}^-}.
\end{aligned} \tag{36}$$

We now set $\mathbf{v}_g = \Psi_g$, $w_g = \kappa_g$, $\mathbf{v}_s = \Psi_s$, and $w_s = \kappa_s$ above and manipulate several of the resulting terms.

First, in (36), integrating by parts,

$$\begin{aligned}
&(g \nabla_{(x,y)} \kappa_s, \Psi_s)_{\Omega_s} - \langle g [\![\kappa_s]\!], \{\Psi_s\} \rangle_{\mathcal{E}_{i,s}} - \langle g \kappa_s, \Psi_s \cdot \mathbf{n}_s \rangle_{\partial\Omega_{s,in}} \\
&= -(g \kappa_s, \nabla_{(x,y)} \cdot \Psi_s)_{\Omega_s} + \langle g \{\kappa_s\}, [\![\Psi_s]\!] \rangle_{\mathcal{E}_{i,s}} + \langle g \kappa_s, \Psi_s \cdot \mathbf{n}_s \rangle_{\partial\Omega_{s,out}}.
\end{aligned} \tag{37}$$

Thus (36) becomes

$$\begin{aligned}
&(\partial_t \Psi_s, \Psi_s)_{\Omega_s} + (\tau_{bf} \Psi_s, \Psi_s)_{\Omega_s} + \mu (\nabla_{(x,y)} \Psi_s, \nabla_{(x,y)} \Psi_s)_{\Omega_s} \\
&+ \langle \sigma_s [\![\Psi_s]\!], [\![\Psi_s]\!] \rangle_{\mathcal{E}_{i,s}} + \langle \sigma_s \Psi_s, \Psi_s \rangle_{\partial\Omega_s} \\
&= \mathcal{A}_{s,L}(\Theta_s, \eta_s; \mathbf{v}_s) + (\mathbf{u}_s \cdot \nabla_{(x,y)} \mathbf{u}_s - \boldsymbol{U}_s \cdot \nabla_{(x,y)} \boldsymbol{U}_s, \mathbf{v}_s)_{\Omega_s} \\
&\quad - \sum_{\partial\Omega_{e,s}^- \in \mathcal{T}_{\Delta_s,s}} \langle |\{\boldsymbol{U}_s\} \cdot \mathbf{n}_e| (\boldsymbol{U}_s^{\text{int}} - \boldsymbol{U}_s^{\text{ext}}), \mathbf{v}_s^{\text{int}} \rangle_{\partial\Omega_{e,s}^-} \\
&\quad + (g \kappa_s, \nabla_{(x,y)} \cdot \Psi_s)_{\Omega_s} - \langle g \{\kappa_s\}, [\![\Psi_s]\!] \rangle_{\mathcal{E}_{i,s}} - \langle g \kappa_s, \Psi_s \cdot \mathbf{n}_s \rangle_{\partial\Omega_{s,out}}.
\end{aligned} \tag{38}$$

Next, in (34), integrating by parts and using the definitions of $\partial\Omega_{s,out}$ and $\partial\Omega_{s,in}$ yields

$$\begin{aligned}
&-(\boldsymbol{U}_s\kappa_s, \nabla_{(x,y)}\kappa_s)_{\Omega_s} + \langle\{\boldsymbol{U}_s\}\kappa_s^{\uparrow}, [\![\kappa_s]\!]\rangle_{\mathcal{E}_{i,s}} + \langle \boldsymbol{U}_s\cdot\mathbf{n}_s, \kappa_s^2\rangle_{\partial\Omega_{s,out}}\\
&= \frac{1}{2}(\nabla_{(x,y)}\cdot\boldsymbol{U}_s, \kappa_s^2)_{\Omega_s} - \frac{1}{2}\langle[\![\boldsymbol{U}_s\kappa_s^2]\!], 1\rangle_{\mathcal{E}_{i,s}} + \langle\{\boldsymbol{U}_s\}\kappa_s^{\uparrow}, [\![\kappa_s]\!]\rangle_{\mathcal{E}_{i,s}}\\
&\quad + \frac{1}{2}\langle|\boldsymbol{U}_s\cdot\mathbf{n}_s|, \kappa_s^2\rangle_{\partial\Omega_{s,in}} + \frac{1}{2}\langle|\boldsymbol{U}_s\cdot\mathbf{n}_s|, \kappa_s^2\rangle_{\partial\Omega_{s,out}}. \qquad (39)
\end{aligned}$$

Using $[\![\mathbf{v}w]\!] = \{\mathbf{v}\}\cdot[\![w]\!] + [\![\mathbf{v}]\!]\{w\}$ and $\frac{1}{2}[\![w^2]\!] = [\![w]\!]\{w\}$ and the definition of $\kappa_s^{\uparrow}$, we obtain

$$\begin{aligned}
&-\frac{1}{2}\langle[\![\boldsymbol{U}_s\kappa_s^2]\!], 1\rangle_{\mathcal{E}_{i,s}} + \langle\{\boldsymbol{U}_s\}\kappa_s^{\uparrow}, [\![\kappa_s]\!]\rangle_{\mathcal{E}_{i,s}}\\
&= \langle\kappa_s^{\uparrow}[\![\kappa_s]\!]\{\boldsymbol{U}_s\} - \frac{1}{2}[\![\kappa_s^2]\!]\{\boldsymbol{U}_s\} - \frac{1}{2}\{\kappa_s^2\}[\![\boldsymbol{U}_s]\!], 1\rangle_{\mathcal{E}_{i,s}}\\
&= \langle(\kappa_s^{\uparrow} - \{\kappa_s\})\{\boldsymbol{U}_s\}, [\![\kappa_s]\!]\rangle_{\mathcal{E}_{i,s}} - \frac{1}{2}\langle\{\kappa_s\}^2, [\![\boldsymbol{U}]\!]_s\}\rangle_{\mathcal{E}_{i,s}}\\
&= \frac{1}{2}\left[\langle|\{\boldsymbol{U}_s\}\cdot\mathbf{n}^-|, [\kappa_s^- - \kappa_s^+]^2\rangle_{\mathcal{E}_{i,s}} - \langle\{\kappa_s^2\}, [\![\boldsymbol{U}_s]\!]\rangle_{\mathcal{E}_{i,s}}\right]. \qquad (40)
\end{aligned}$$

Integration by parts gives

$$\begin{aligned}
&-(\mathbf{u}_s h_s - \boldsymbol{U}_s\pi h_s, \nabla_{(x,y)}\kappa_s)_{\Omega_s} + \langle(\mathbf{u}_s h_s - \{\boldsymbol{U}_s\}\pi h_s^{\uparrow}, [\![\kappa_s]\!]\rangle_{\mathcal{E}_{i,s}}\\
&\qquad + \langle(\mathbf{u}_s h_s - \boldsymbol{U}_s\pi h_s)\cdot\mathbf{n}_s, \kappa_s\rangle_{\partial\Omega_{s,out}} + \langle(\mathbf{u}_s - \boldsymbol{U}_s)\cdot\mathbf{n}_s h_s^I, \kappa_s\rangle_{\partial\Omega_{s,in}}\\
&= (\nabla_{(x,y)}\cdot(\mathbf{u}_s h_s - \boldsymbol{U}_s\pi h_s), \kappa_s)_{\Omega_s} - \langle[\![\kappa_s(\mathbf{u}_s h_s - \boldsymbol{U}_s\pi h_s)]\!], 1\rangle_{\mathcal{E}_{i,s}}\\
&\qquad + \langle(\mathbf{u}_s h_s - \{\boldsymbol{U}_s\}\pi h_s^{\uparrow}, [\![\kappa_s]\!]\rangle_{\mathcal{E}_{i,s}} + \langle\boldsymbol{U}_s\cdot\mathbf{n}_s(\pi h_s - h_s^I), \kappa_s\rangle_{\partial\Omega_{s,in}}. \qquad (41)
\end{aligned}$$

Combining (39)–(41) with (34), we find

$$\begin{aligned}
&(\partial_t\kappa_s, \kappa_s)_{\Omega_s} - \langle\sigma_g(\kappa_g - \kappa_s), \kappa_s\rangle_{\Gamma_{GS}} - \langle\Psi_g\cdot\mathbf{n}_g, \kappa_s\rangle_{\Gamma_{GS}}\\
&\quad + \frac{1}{2}\left[\langle|\{\boldsymbol{U}_s\}\cdot\mathbf{n}^-|, [\kappa_s^- - \kappa_s^+]^2\rangle_{\mathcal{E}_{i,s}} + \langle|\boldsymbol{U}_s\cdot\mathbf{n}_s|, \kappa_s^2\rangle_{\partial\Omega_{s,in}} + \langle|\boldsymbol{U}_s\cdot\mathbf{n}_s|, \kappa_s^2\rangle_{\partial\Omega_{s,out}}\right]\\
&= \mathcal{B}_{s,L}(\Theta_g, \eta_g, \eta_s; \kappa_s) - \frac{1}{2}(\nabla_{(x,y)}\cdot\boldsymbol{U}_s, \kappa_s^2)_{\Omega_s} + \frac{1}{2}\langle\{\kappa_s^2\}, [\![\boldsymbol{U}_s]\!]\rangle_{\mathcal{E}_{i,s}}\\
&\quad + (\nabla_{(x,y)}\cdot(\mathbf{u}_s h_s - \boldsymbol{U}_s\pi h_s), \kappa_s)_{\Omega_s} - \langle[\![\kappa_s(\mathbf{u}_s h_s - \boldsymbol{U}_s\pi h_s)]\!], 1\rangle_{\mathcal{E}_{i,s}}\\
&\quad + \langle(\mathbf{u}_s h_s - \{\boldsymbol{U}_s\}\pi h_s^{\uparrow}, [\![\kappa_s]\!]\rangle_{\mathcal{E}_{i,s}} + \langle\boldsymbol{U}_s\cdot\mathbf{n}_s(\pi h_s - h_s^I), \kappa_s\rangle_{\partial\Omega_{s,in}}. \qquad (42)
\end{aligned}$$

Furthermore, by (32) and (33),

$$\begin{aligned}
&\mathcal{A}_g(\Psi_g, \kappa_g, \kappa_s; \Psi_g) + \mathcal{B}_g(\Psi_s, \kappa_g, \kappa_s; \kappa_g)\\
&= (K^{-1}\Psi_g, \Psi_g)_{\Omega_g} + \langle\kappa_s, \Psi_g\cdot\mathbf{n}_g\rangle_{\Gamma_{GS}} + \langle\sigma_g[\![\kappa_g]\!], [\![\kappa_g]\!]\rangle_{\mathcal{E}_{i,s}}\\
&\quad + \langle\sigma_g(\kappa_g - \kappa_s), \kappa_g\rangle_{\Gamma_{GS}} + \langle\sigma_g\kappa_g, \kappa_g\rangle_{\Gamma_D}\\
&= \mathcal{A}_g(\Theta_g, \eta_g, \eta_s; \Psi_g) + \mathcal{B}_g(\Theta_g, \eta_g, \eta_s; \kappa_g). \qquad (43)
\end{aligned}$$

Adding (38), (42), and (43), we find the error equation

$$
\begin{aligned}
&||K^{-1/2}\Psi_g||^2_{\Omega_{\rm g}} + ||\sigma_g^{1/2}[\![\kappa_g]\!]||^2_{\mathcal{E}_{i,g}} + ||\sigma_g^{1/2}\kappa_g||^2_{\Gamma_D} + ||\sigma_g^{1/2}(\kappa_g-\kappa_s)||^2_{\Gamma_{GS}}\\
&+\frac{1}{2}\left[\langle|\{\boldsymbol{U}_s\}\cdot\mathbf{n}^-|,[\kappa_s^- - \kappa_s^+]^2\rangle_{\mathcal{E}_{i,s}} + \langle|\boldsymbol{U}_s\cdot\mathbf{n}_s|,\kappa_s^2\rangle_{\partial\Omega_{s,in}} + \langle|\boldsymbol{U}_s\cdot\mathbf{n}_s|,\kappa_s^2\rangle_{\partial\Omega_{s,out}}\right]\\
&+(\partial_t\kappa_s,\kappa_s)_{\Omega_s} + (\partial_t\Psi_s,\Psi_s)_{\Omega_s} + ||\tau_{bf}^{1/2}\Psi_s||^2_{\Omega_s} + \mu||\nabla_{(x,y)}\Psi_s||^2_{\Omega_s}\\
&+||\sigma_s^{1/2}[\![\Psi_s]\!]||^2_{\mathcal{E}_{i,s}} + ||\sigma_s^{1/2}\Psi_s||^2_{\partial\Omega_s}\\
&=\mathcal{A}_g(\Theta_g,\eta_g,\eta_s;\Psi_g) + \mathcal{B}_g(\Theta_g,\eta_g,\eta_s;\kappa_g) + \mathcal{B}_{s,L}(\Theta_g,\eta_g,\eta_s;\kappa_s) + \mathcal{A}_{s,L}(\Theta_s,\eta_s;\Psi_s)\\
&\quad-\sum_{\partial\Omega^-_{e,s}\in\mathcal{T}_{\Delta_s,s}}\langle|\{\boldsymbol{U}_s\}\cdot\mathbf{n}_e|(\boldsymbol{U}_s^{\rm int}-\boldsymbol{U}_s^{\rm ext}),\Psi_s^{\rm int}\rangle_{\partial\Omega^-_{e,s}}\\
&\quad+(\mathbf{u}_s\cdot\nabla_{(x,y)}\mathbf{u}_s - \boldsymbol{U}_s\cdot\nabla_{(x,y)}\boldsymbol{U}_s,\Psi_s)_{\Omega_{\rm s}}\\
&\quad-\frac{1}{2}(\nabla_{(x,y)}\cdot\boldsymbol{U}_s,\kappa_s^2)_{\Omega_s} + \frac{1}{2}\langle\{\kappa_s^2\},[\![\boldsymbol{U}_s]\!]\rangle_{\mathcal{E}_{i,s}}\\
&\quad+(\nabla_{(x,y)}\cdot(\mathbf{u}_s h_s - \boldsymbol{U}_s\pi h_s),\kappa_s)_{\Omega_{\rm s}} - \langle[\![\kappa_s(\mathbf{u}_s h_s - \boldsymbol{U}_s\pi h_s)]\!],1\rangle_{\mathcal{E}_{i,s}}\\
&\quad+\langle\mathbf{u}_s h_s - \{\boldsymbol{U}_s\}\pi h_s^{\uparrow},[\![\kappa_s]\!]\rangle_{\mathcal{E}_{i,s}} + \langle\boldsymbol{U}_s\cdot\mathbf{n}_s(\pi h_s - h_s^I),\kappa_s\rangle_{\partial\Omega_{s,in}}\\
&\quad+(g\kappa_s,\nabla_{(x,y)}\cdot\Psi_s)_{\Omega_s} - \langle g\{\kappa_s\},[\![\Psi_s]\!]\rangle_{\mathcal{E}_{i,s}} - \langle g\kappa_s,\Psi_s\cdot\mathbf{n}_s\rangle_{\partial\Omega_{s,out}}\\
&\equiv\mathcal{A}_g(\Theta_g,\eta_g,\eta_s;\Psi_g) + \mathcal{B}_g(\Theta_g,\eta_g,\eta_s;\kappa_g) + \mathcal{B}_{s,L}(\Theta_g,\eta_g,\eta_s;\kappa_s) + \mathcal{A}_{s,L}(\Theta_s,\eta_s;\Psi_s)\\
&+\sum_{i=1}^{11}E_i. \qquad (44)
\end{aligned}
$$

Next, we consider the terms on the right-hand side of (44). To begin note that

$$
\begin{aligned}
\mathcal{A}_g(\Theta_g,\eta_g,\eta_s;\Psi_g) &= (K^{-1}\Theta_g,\Psi_g)_{\Omega_{\rm g}} - (\eta_g,\nabla_{(x,y,z)}\cdot\Psi_g)_{\Omega_{\rm g}} + \langle\{\eta_g\},[\![\Psi_g]\!]\rangle_{\mathcal{E}_{i,g}}\\
&\quad+\langle\eta_g,\Psi_g\cdot\mathbf{n}_g\rangle_{\Gamma_N} + \langle\eta_s,\Psi_g\cdot\mathbf{n}_g\rangle_{\Gamma_{GS}}\\
&\equiv A_{g,1}+\cdots+A_{g,5}. \qquad (45)
\end{aligned}
$$

Adding terms and integrating by parts, we find

$$
\begin{aligned}
&\mathcal{B}_g(\Theta_g,\eta_g,\eta_s;\kappa_g) + \mathcal{B}_{s,L}(\Theta_g,\eta_g,\eta_s;\kappa_s)\\
&=(\nabla_{(x,y,z)}\cdot\Theta_g,\kappa_g)_{\Omega_{\rm g}} - \langle[\![\Theta_g]\!],\{\kappa_g\}\rangle_{\mathcal{E}_{i,g}} + \langle\Theta_g\cdot\mathbf{n}_g,\kappa_g\rangle_{\Gamma_N}\\
&\quad+\langle\sigma_g[\![\eta_g]\!],[\![\kappa_g]\!]\rangle_{\mathcal{E}_{i,g}} + \langle\sigma_g(\eta_g-\eta_s),\kappa_g\rangle_{\Gamma_{GS}} + \langle\sigma_g\eta_g,\kappa_g\rangle_{\Gamma_D}\\
&\quad+(\partial_t\eta_s,\kappa_s)_{\Omega_{\rm s}} - \langle\sigma_g(\eta_g-\eta_s),\kappa_s\rangle_{\Gamma_{GS}} - \langle\Theta_g\cdot\mathbf{n}_g,\kappa_s\rangle_{\Gamma_{GS}}\\
&=(\Theta_g,\nabla_{(x,y,z)}\kappa_g)_{\Omega_{\rm g}} + \langle\{\Theta_g\},[\![\kappa_g]\!]\rangle_{\mathcal{E}_{i,g}} + \langle\Theta_g\cdot\mathbf{n}_g,\kappa_g-\kappa_s\rangle_{\Gamma_{GS}} + \langle\Theta_g\cdot\mathbf{n}_g,\kappa_g\rangle_{\Gamma_D}\\
&\quad+\langle\sigma_g[\![\eta_g]\!],[\![\kappa_g]\!]\rangle_{\mathcal{E}_{i,g}} + \langle\sigma_g(\eta_g-\eta_s),\kappa_g-\kappa_s\rangle_{\Gamma_{GS}} + \langle\sigma_g\eta_g,\kappa_g\rangle_{\Gamma_D} + (\partial_t\eta_s,\kappa_s)_{\Omega_{\rm s}}\\
&\equiv B_1+\cdots+B_8. \qquad (46)
\end{aligned}
$$

Furthermore,

$$
\begin{aligned}
&\mathcal{A}_{s,L}(\Theta_s,\eta_s;\Psi_s) = (\partial_t\Theta_s,\Psi_s)_{\Omega_{\rm s}} + (\tau_{bf}\Theta_s,\Psi_s)_{\Omega_{\rm s}}\\
&\quad+(g\nabla_{(x,y)}\eta_s,\Psi_s)_{\Omega_{\rm s}} - \langle g[\![\eta_s]\!],\{\Psi_s\}\rangle_{\mathcal{E}_{i,s}} - \langle g\eta_s,\Psi_s\cdot\mathbf{n}\rangle_{\partial\Omega_{s,in}}\\
&\quad+\mu(\nabla_{(x,y)}\Theta_s,\nabla_{(x,y)}\Psi_s)_{\Omega_{\rm s}} - \mu\langle\{\nabla_{(x,y)}\Theta_s\},[\![\Psi_s]\!]\rangle_{\mathcal{E}_{i,s}} + \mu\langle\{\nabla_{(x,y)}\Psi_s\},[\![\Theta_s]\!]\rangle_{\mathcal{E}_{i,s}}\\
&\quad-\mu\langle\nabla_{(x,y)}\Theta_s\cdot\mathbf{n},\Psi_s\rangle_{\partial\Omega_s} + \mu\langle\nabla_{(x,y)}\Psi_s\cdot\mathbf{n},\Theta_s\rangle_{\partial\Omega_s}\\
&\quad+\langle\sigma_s[\![\Theta_s]\!],[\![\Psi_s]\!]\rangle_{\mathcal{E}_{i,s}} + \langle\sigma_s\Theta_s,\Psi_s\rangle_{\partial\Omega_s}\\
&\equiv A_{s,1}+\cdots+A_{s,12}. \qquad (47)
\end{aligned}
$$

We choose $\pi\mathbf{u}_g$, πh_g, $\pi\mathbf{u}_s$, and πh_s to be the L^2 projections of $\mathbf{u}_g$, h_g, $\mathbf{u}_s$, and h_s into the spaces $\mathcal{V}_{\Delta_g,g}$, $\mathcal{W}_{\Delta_g,g}$, $\mathcal{V}_{\Delta_s,s}$, and $\mathcal{W}_{\Delta_s,s}$, respectively. These are defined by

$$(\pi\mathbf{u}_g - \mathbf{u}_g, \mathbf{v}_g)_{\Omega_g} = 0, \quad \mathbf{v}_g \in \mathcal{V}_{\Delta_g,g}, \tag{48}$$

$$(\pi h_g - h_g, w_g)_{\Omega_g} = 0, \quad w_g \in \mathcal{W}_{\Delta_g,g}, \tag{49}$$

$$(\pi\mathbf{u}_s - \mathbf{u}_s, \mathbf{v}_s)_{\Omega_s} = 0, \quad \mathbf{v}_s \in \mathcal{V}_{\Delta_s,s}, \tag{50}$$

$$(\pi h_s - h_s, w_s)_{\Omega_s} = 0, \quad w_s \in \mathcal{W}_{\Delta_s,s}. \tag{51}$$

We note that by our assumptions on the approximating spaces,

$$\mathbf{v}_g \in \mathcal{V}_{\Delta_g,g} \Rightarrow \nabla_{(x,y,z)} \cdot \mathbf{v}_g \in \mathcal{W}_{\Delta_g,g}$$

and

$$w_g \in \mathcal{W}_{\Delta_g,g} \Rightarrow \nabla_{(x,y,z)} w_g \in \mathcal{V}_{\Delta_g,g}.$$

Thus by (48)–(51) terms $A_{g,2} = B_1 = B_8 = A_{s,1} = 0$.

In the estimates below, we will use the trace theorem [9].

THEOREM 4.1. *Suppose that region R has a Lipschitz boundary. Then there exists a constant K^t such that*

$$||v||^2_{\partial R} \le K^t[\nu^{-1}||v||^2_R + \nu||\nabla v||^2_R] \quad \forall v \in H^1(R), \tag{52}$$

where $\nu = \operatorname{diam}(R)$.

We will also use the standard inverse inequality:

$$||\nabla w||_{\Omega_e} \le K^i \Delta_e^{-1} ||w||_{\Omega_e}, \tag{53}$$

where Ω_e is in Ω_g or Ω_s and w is in one of our finite-dimensional approximating spaces. Based on these results, for $v \in H^1(\Omega_e)$ and w in one of our approximating spaces, an argument we will use repeatedly in various ways is

$$\begin{aligned} \langle v^{\text{int}}, w^{\text{int}} \rangle_{\partial\Omega_e} &\le ||v^{\text{int}}||_{\partial\Omega_e} ||w^{\text{int}}||_{\partial\Omega_e} \\ &\le K^t[\Delta_e^{-1}||v||^2_{\Omega_e} + \Delta_e||\nabla v||^2_{\Omega_e}]^{1/2}[\Delta_e^{-1}||w||^2_{\Omega_e} + \Delta_e||\nabla w||^2_{\Omega_e}]^{1/2} \\ &\le K^t(1 + (K^i)^2)^{1/2}[\Delta_e^{-2}||v||^2_{\Omega_e} + ||\nabla v||^2_{\Omega_e}]^{1/2}||w||_{\Omega_e}. \end{aligned} \tag{54}$$

We will make the following assumptions on our solution and projections:

$$\begin{aligned} &||\mathbf{u}_s||_{L^\infty(0,T;W_1^\infty(\Omega_s))} + ||h_s||_{L^\infty(0,T;W_1^\infty(\Omega_s))} \\ &+||\pi\mathbf{u}_s||_{L^\infty(0,T;L^\infty(\Omega_s))} + ||\pi h_s||_{L^\infty(0,T;L^\infty(\Omega_s))} \le K^m, \end{aligned} \tag{55}$$

where K^m is independent of Δ_s. We will also assume that a constant $K^M \ge 2K^m$ exists, independent of Δ_s, for which

$$||\Psi_s||_{L^\infty(0,T;L^\infty(\Omega_s))} + ||\kappa_s||_{L^\infty(0,T;L^\infty(\Omega_s))} \le K^M. \tag{56}$$

We will show inductively that for $k_s, k_g > 1$ our estimate does not in fact depend on K^M.

On any face γ in the mesh $\mathcal{T}_{\Delta_g,g}(\mathcal{T}_{\Delta_s,s})$, let E_γ denote the set of elements sharing the face, and let Δ_γ be the maximum element diameter over all elements in E_γ. We will assume that

$$\sigma_{g(s)}|_\gamma = \mathcal{O}(\Delta_\gamma^{-1}). \tag{57}$$

Finally, we make the following assumption on the ground water and surface water meshes on Γ_{GS}.

Assumption GS. Let the set E_{GS} be defined as follows:

$$E_{GS} = \{\Omega_{e,g} \subset \Omega_{\rm g} : \partial\Omega_{e,g} \cap \Gamma_{GS} \neq \emptyset\}. \tag{58}$$

For elements $\Omega_{e,g}$ in the set E_{GS}, assume that $\partial\Omega_{e,g} \cap \Gamma_{GS}$, when mapped to $\Omega_{\rm s}$, intersects a finite number of elements $\Omega_{\bar{e},s}$ bounded independently of Δ_g or Δ_s and that

$$\Delta_{\bar{e},s}\Delta_{e,g}^{-1} = \mathcal{O}(1).$$

We repeatedly make use of Young's inequality

$$ab \leq \frac{\epsilon}{2}a^2 + \frac{1}{2\epsilon}b^2, \quad a,b \in \mathbb{R}, \epsilon > 0. \tag{59}$$

Furthermore, let $\mathcal{C}$ denote a generic positive constant which may depend on other constants. We will make explicit this dependence in the arguments below.

First, it is easily seen that

$$A_{g,1} \leq \mathcal{C}(K)||\Theta_g||^2_{\Omega_{\rm g}} + \epsilon_1||K^{-1/2}\Psi_g||^2_{\Omega_{\rm g}}. \tag{60}$$

Applying (54), we find

$$\begin{aligned} A_{g,3} + A_{g,4} &= \langle [\![\Psi_g]\!], \{\eta_g\}\rangle_{\mathcal{E}_{i,g}} + \langle \eta_g, \Psi_g \cdot \mathbf{n}_g\rangle_{\Gamma_N} \\ &\leq \epsilon_1||K^{-1/2}\Psi_g||^2_{\Omega_{\rm g}} + \mathcal{C}(K^t, K^i, K)\sum_{\Omega_{e,g}}[\Delta_{e,g}^{-2}||\eta_g||^2_{\Omega_{e,g}} + ||\eta_g||^2_{H^1(\Omega_{e,g})}]. \end{aligned} \tag{61}$$

Applying Theorem 4.1 to Ψ_g and Assumption GS,

$$\begin{aligned} A_{g,5} &= \langle \Psi_g \cdot \mathbf{n}_g, \eta_s\rangle_{\Gamma_{GS}} \\ &\leq \mathcal{C}\sum_{\Omega_e \in E_{GS}} ||\Psi_g||_{\partial\Omega_{e,g}}||\eta_s||_{\partial\Omega_{e,g}} \\ &\leq \epsilon_1||K^{-1/2}\Psi_g||^2_{\Omega_{\rm g}} + \mathcal{C}(K^t, K^i, K)\sum_{\Omega_{e,g}\in E_{GS}} \Delta_{e,g}^{-1}||\eta_s||^2_{\partial\Omega_{e,g}} \\ &\leq \epsilon_1||K^{-1/2}\Psi_g||^2_{\Omega_{\rm g}} + \mathcal{C}(K^t, K^i, K)\sum_{\Omega_{e,s}} \Delta_{e,s}^{-1}||\eta_s||^2_{\Omega_{e,s}}. \end{aligned} \tag{62}$$

Next, by (57) and Theorem 4.1,

$$\begin{aligned} B_2 + B_3 + B_4 &= \langle \{\Theta_g\}, [\![\kappa_g]\!]\rangle_{\mathcal{E}_{i,g}} + \langle \Theta_g \cdot \mathbf{n}_g, \kappa_g - \kappa_s\rangle_{\Gamma_{GS}} + \langle \Theta_g \cdot \mathbf{n}_g, \kappa_g\rangle_{\Gamma_D} \\ &= \langle \sigma^{-1/2}\{\Theta_g\}, \sigma^{1/2}[\![\kappa_g]\!]\rangle_{\mathcal{E}_{i,g}} + \langle \sigma^{-1/2}\Theta_g \cdot \mathbf{n}_g, \sigma^{1/2}(\kappa_g - \kappa_s)\rangle_{\Gamma_{GS}} \\ &\quad + \langle \sigma^{-1/2}\Theta_g \cdot \mathbf{n}_g, \sigma^{1/2}\kappa_g\rangle_{\Gamma_D} \\ &\leq \mathcal{C}[\,||\sigma^{-1/2}\Theta_g||^2_{\Gamma_D} + ||\sigma^{-1/2}\Theta_g||^2_{\mathcal{E}_{i,g}} + ||\sigma^{-1/2}\Theta_g||^2_{\Gamma_{GS}}] \\ &\quad + \epsilon_2[\,||\sigma^{1/2}[\![\kappa_g]\!]||^2_{\mathcal{E}_{i,g}} + ||\sigma^{1/2}(\kappa_g - \kappa_s)||^2_{\Gamma_{GS}} + ||\sigma^{1/2}\kappa_g||^2_{\Gamma_D}] \\ &\leq \mathcal{C}(K^t)\sum_{\Omega_{e,g}}[\,||\Theta_g||^2_{\Omega_{e,g}} + \Delta^2_{e,g}||\Theta_g||^2_{H^1(\Omega_{e,g})}] \\ &\quad + \epsilon_2[\,||\sigma^{1/2}[\![\kappa_g]\!]||^2_{\mathcal{E}_{i,g}} + ||\sigma^{1/2}(\kappa_g - \kappa_s)||^2_{\Gamma_{GS}} + ||\sigma^{1/2}\kappa_g||^2_{\Gamma_D}]. \end{aligned} \tag{63}$$

Similarly,

$$\begin{aligned} B_5 + B_6 + B_7 \leq \mathcal{C}[\ & ||\sigma^{1/2}[\![\eta_g]\!]||^2_{\mathcal{E}_{i,g}} + ||\sigma^{1/2}\eta_g||^2_{\Gamma_{GS}} \\ & + ||\sigma^{1/2}\eta_s||^2_{\Gamma_{GS}} + ||\sigma^{1/2}\eta_g||^2_{\Gamma_D}] \\ & + \epsilon_2[\ ||\sigma^{1/2}[\![\kappa_g]\!]||^2_{\mathcal{E}_{i,g}} + ||\sigma^{1/2}(\kappa_g - \kappa_s)||^2_{\Gamma_{GS}} \\ & + ||\sigma^{1/2}\kappa_g||^2_{\Gamma_D}] \\ \leq \mathcal{C}(K^t) & \sum_{\Omega_{e,g}} [\Delta^{-2}_{e,g}||\eta_g||^2_{\Omega_{e,g}} + ||\eta_g||^2_{H^1(\Omega_{e,g})}] \\ & + \epsilon_2[\ ||\sigma^{1/2}[\![\kappa_g]\!]||^2_{\mathcal{E}_{i,g}} + ||\sigma^{1/2}(\kappa_g - \kappa_s)||^2_{\Gamma_{GS}} \\ & + ||\sigma^{1/2}\kappa_g||^2_{\Gamma_D}]. \end{aligned} \tag{64}$$

Next, consider

$$\begin{aligned} A_{s,2} + A_{s,3} + A_{s,6} &= (\tau_{bf}\Theta_s, \Psi_s)_{\Omega_s} + (g\nabla_{(x,y)}\eta_s, \Psi_s)_{\Omega_s} + \mu(\nabla_{(x,y)}\Theta_s, \nabla_{(x,y)}\Psi_s)_{\Omega_s} \\ &\leq \mathcal{C}[\ ||\tau^{1/2}_{bf}\Theta_s||^2_{\Omega_s} + ||\nabla_{(x,y)}\eta_s||^2_{\Omega_s} + \mu||\nabla_{(x,y)}\Theta_s||^2_{\Omega_s}] \\ &\quad + \frac{1}{2}||\tau^{1/2}_{bf}\Psi_s||^2_{\Omega_s} + \mathcal{C}||\Psi_s||^2_{\Omega_s} + \frac{\mu}{8}||\nabla_{(x,y)}\Psi_s||^2_{\Omega_s}. \end{aligned} \tag{65}$$

By (54),

$$\begin{aligned} A_{s,4} + A_{s,5} + A_{s,8} + A_{s,10} = & -\langle g[\![\eta_s]\!], \{\Psi_s\}\rangle_{\mathcal{E}_{i,s}} - \langle g\eta_s, \Psi_s \cdot \mathbf{n}\rangle_{\partial\Omega_{s,in}} \\ & + \mu\langle\{\nabla_{(x,y)}\Psi_s\}, [\![\Theta_s]\!]\rangle_{\mathcal{E}_{i,s}} + \mu\langle\nabla_{(x,y)}\Psi_s \cdot \mathbf{n}, \Theta_s\rangle_{\partial\Omega_s} \\ \leq \mathcal{C}||\Psi_s||^2_{\Omega_s} & + \frac{\mu}{8}||\nabla_{(x,y)}\Psi_s||^2_{\Omega_s} \\ & + \mathcal{C}(K^t, K^i)\sum_{\Omega_{e,s}} [\Delta^{-2}_{e,s}||\eta_s||^2_{\Omega_{e,s}} + ||\eta_s||^2_{H^1(\Omega_{e,s})}] \\ & + \mathcal{C}(K^t, K^i, \mu)\sum_{\Omega_{e,s}} [\Delta^{-2}_{e,s}||\Theta_s||^2_{\Omega_{e,s}} + ||\Theta_s||^2_{H^1(\Omega_{e,s})}]. \end{aligned} \tag{66}$$

By (57) and Theorem 4.1,

$$\begin{aligned} A_{s,7} + A_{s,9} &= -\mu\langle\{\nabla_{(x,y)}\Theta_s\}, [\![\Psi_s]\!]\rangle_{\mathcal{E}_{i,s}} - \mu\langle\nabla_{(x,y)}\Theta_s \cdot \mathbf{n}, \Psi_s\rangle_{\partial\Omega_s} \\ &\leq \mathcal{C}(\mu)[\ ||\sigma^{-1/2}\{\nabla_{(x,y)}\Theta_s\}||^2_{\mathcal{E}_{i,s}} + ||\sigma^{-1/2}\nabla_{(x,y)}\Theta_s||^2_{\partial\Omega_s}] \\ &\quad + \epsilon_3[\ ||\sigma^{1/2}_s[\![\Psi_s]\!]||^2_{\mathcal{E}_{i,s}} + ||\sigma^{1/2}_s\Psi_s||^2_{\partial\Omega_s}] \\ &\leq \mathcal{C}(K^t, \mu)\sum_{\Omega_{e,s}}[\ ||\nabla_{(x,y)}\Theta_s||^2_{\Omega_{e,s}} + \Delta^2_{e,s}||\nabla_{(x,y)}\Theta_s||^2_{H^1(\Omega_{e,s})}] \\ &\quad + \epsilon_3[\ ||\sigma^{1/2}_s[\![\Psi_s]\!]||^2_{\mathcal{E}_{i,s}} + ||\sigma^{1/2}_s\Psi_s||^2_{\partial\Omega_s}]. \end{aligned} \tag{67}$$

Furthermore,

$$\begin{aligned} A_{s,11} + A_{s,12} &= \langle\sigma_s[\![\Theta_s]\!], [\![\Psi_s]\!]\rangle_{\mathcal{E}_{i,s}} + \langle\sigma_s\Theta_s, \Psi_s\rangle_{\partial\Omega_s} \\ &\leq \epsilon_3[\ ||\sigma^{1/2}_s[\![\Psi_s]\!]||^2_{\mathcal{E}_{i,s}} + ||\sigma^{1/2}_s\Psi_s||^2_{\partial\Omega_s}] \\ &\quad + \mathcal{C}[\ ||\sigma^{1/2}_s[\![\Theta_s]\!]||^2_{\mathcal{E}_{i,s}} + ||\sigma^{1/2}_s\Theta_s||^2_{\partial\Omega_s}] \\ &\leq \epsilon_3[\ ||\sigma^{1/2}_s[\![\Psi_s]\!]||^2_{\mathcal{E}_{i,s}} + ||\sigma^{1/2}_s\Psi_s||^2_{\partial\Omega_s}] \\ &\quad + \mathcal{C}(K^t)\sum_{\Omega_{e,s}}[\ \Delta^{-2}_{e,s}||\Theta_s||^2_{\Omega_{e,s}} + ||\Theta_s||^2_{H^1(\Omega_{e,s})}]. \end{aligned} \tag{68}$$

Consider next

$$
\begin{aligned}
E_1 &= -\sum_{\partial\Omega^-_{e,s}\in\mathcal{T}_{\Delta_s},s} \langle |\{\boldsymbol{U}_s\}\cdot\mathbf{n}_e|(\boldsymbol{U}_s^{\text{int}}-\boldsymbol{U}_s^{\text{ext}}),\Psi_s^{\text{int}}\rangle_{\partial\Omega^-_{e,s}} \\
&\le \sum_{\partial\Omega^-_{e,s}\in\mathcal{T}_{\Delta_s},s} \langle |\{\Psi_s+\pi\mathbf{u}_s\}\cdot\mathbf{n}_e||[\![\Psi_s]\!]-[\![\Theta_s]\!]|,|\Psi_s^{\text{int}}|\rangle_{\partial\Omega^-_{e,s}} \\
&\le \mathcal{C}(K^M,K^m)\sum_{\partial\Omega^-_{e,s}\in\mathcal{T}_{\Delta_s},s}[\ ||\sigma_s^{1/2}[\![\Theta_s]\!]||_{\partial\Omega^-_{e,s}}+||\sigma_s^{1/2}[\![\Psi_s]\!]||_{\partial\Omega^-_{e,s}}]||\sigma_s^{-1/2}\Psi_s^{\text{int}}||_{\partial\Omega^-_{e,s}} \\
&\le \mathcal{C}(K^t,K^m,K^M)\sum_{\Omega_{e,s}}[\Delta_{e,s}^{-2}||\Theta_s||^2_{\Omega_{e,s}}+||\Theta_s||^2_{H^1(\Omega_{e,s})}]+\mathcal{C}(K^M,K^m,K^t,K^i)||\Psi_s||^2_{\Omega_s} \\
&\quad +\epsilon_3[\ ||\sigma_s^{1/2}[\![\Psi_s]\!]||^2_{\mathcal{E}_{i,s}}+||\sigma_s^{1/2}\Psi_s||^2_{\partial\Omega_s}], \qquad (69)
\end{aligned}
$$

$$
\begin{aligned}
E_2 &= (\mathbf{u}_s\cdot\nabla_{(x,y)}\mathbf{u}_s-\boldsymbol{U}_s\cdot\nabla_{(x,y)}\boldsymbol{U}_s,\Psi_s)_{\Omega_s} \\
&= ((\mathbf{u}_s-\boldsymbol{U}_s)\cdot\nabla_{(x,y)}\mathbf{u}_s,\Psi_s)_{\Omega_s}+((\Psi_s+\pi\mathbf{u}_s)\cdot\nabla_{(x,y)}(\Theta_s-\Psi_s),\Psi_s)_{\Omega_s} \\
&\le \mathcal{C}(K^m,K^M)[\ ||\Theta_s||^2_{\Omega_s}+||\nabla_{(x,y)}\Theta_s||^2_{\Omega_s}]+\mathcal{C}(K^m,K^M,\mu^{-1})||\Psi_s||^2_{\Omega_s} \\
&\quad +\frac{\mu}{8}||\nabla_{(x,y)}\Psi_s||^2, \qquad (70)
\end{aligned}
$$

$$
\begin{aligned}
E_3 &= -\frac{1}{2}(\nabla_{(x,y)}\cdot\boldsymbol{U}_s,\kappa_s^2)_{\Omega_s} \\
&= -\frac{1}{2}(\nabla_{(x,y)}\cdot(\Psi_s-\Theta_s+\mathbf{u}_s),\kappa_s^2)_{\Omega_s} \\
&\le \frac{\mu}{8}||\nabla_{(x,y)}\Psi_s||^2_{\Omega_s}+\mathcal{C}(K^M)||\nabla_{(x,y)}\Theta_s||^2_{\Omega_s}+\mathcal{C}(K^m,K^M,\mu^{-1})||\kappa_s||^2_{\Omega_s}, \qquad (71)
\end{aligned}
$$

$$
\begin{aligned}
E_4 &= \frac{1}{2}\langle\{\kappa_s^2\},[\![\boldsymbol{U}_s]\!]\rangle_{\mathcal{E}_{i,s}} \\
&= \frac{1}{2}\langle\{\kappa_s^2\},[\![\Psi_s-\Theta_s]\!]\rangle_{\mathcal{E}_{i,s}} \\
&\le \mathcal{C}(K^M)[\ ||\sigma_s^{1/2}[\![\Psi_s]\!]||_{\mathcal{E}_{i,s}}+||\sigma_s^{1/2}[\![\Theta_s]\!]||_{\mathcal{E}_{i,s}}]\ ||\sigma_s^{-1/2}\{\kappa_s\}||_{\mathcal{E}_{i,s}} \\
&\le \epsilon_3||\sigma_s^{1/2}[\![\Psi_s]\!]||^2_{\mathcal{E}_{i,s}}+\mathcal{C}(K^t)\sum_{\Omega_{e,s}}[\ \Delta_{e,s}^{-2}||\Theta_s||^2_{\Omega_{e,s}}+||\Theta_s||^2_{H^1(\Omega_{e,s})}] \\
&\quad +\mathcal{C}(K^M,K^t,K^i)||\kappa_s||^2_{\Omega_s}, \qquad (72)
\end{aligned}
$$

$$
\begin{aligned}
E_5 &= (\nabla_{(x,y)}\cdot(\mathbf{u}_sh_s-\boldsymbol{U}_s\pi h_s),\kappa_s)_{\Omega_s} \\
&= (\nabla_{(x,y)}\cdot(\mathbf{u}_s(h_s-\pi h_s)),\kappa_s)_{\Omega_s}+(\nabla_{(x,y)}\cdot((\mathbf{u}_s-\boldsymbol{U}_s)\pi h_s),\kappa_s)_{\Omega_s} \\
&= ((\nabla_{(x,y)}\cdot\mathbf{u}_s)\eta_s,\kappa_s)_{\Omega_s}+(\mathbf{u}_s\cdot\nabla_{(x,y)}\eta_s,\kappa_s)_{\Omega_s} \\
&\quad +(\pi h_s\nabla_{(x,y)}\cdot(\Theta_s-\Psi_s),\kappa_s)_{\Omega_s}+((\Theta_s-\Psi_s)\cdot\nabla_{(x,y)}(h_s-\eta_s),\kappa_s)_{\Omega_s} \\
&\le \mathcal{C}(K^m,K^M)||\Theta_s||^2_{H^1(\Omega_s)}+\mathcal{C}(K^m,K^M)||\eta_s||^2_{H^1(\Omega_s)}+\frac{\mu}{8}||\nabla_{(x,y)}\Psi_s||^2_{\Omega_s} \\
&\quad +\mathcal{C}(K^m,K^M,\mu^{-1})||\kappa_s||^2_{\Omega_s}. \qquad (73)
\end{aligned}
$$

Using $[\![ab]\!]=\{a\}[\![b]\!]+[\![a]\!]\{b\}$ and $\{ab\}=\{a\}\{b\}+\frac{1}{4}[\![a]\!][\![b]\!]$, we find

$$
\begin{aligned}
E_6+E_7 &= -\langle[\![\kappa_s(\mathbf{u}_sh_s-\boldsymbol{U}_s\pi h_s)]\!],1\rangle_{\mathcal{E}_{i,s}}+\langle\mathbf{u}_sh_s-\{\boldsymbol{U}_s\}\pi h_s^{\uparrow},[\![\kappa_s]\!]\rangle_{\mathcal{E}_{i,s}} \\
&= \langle(\eta_s^{\uparrow}-\{\eta_s\})\{\boldsymbol{U}_s\}-\frac{1}{4}[\![\eta_s]\!][\![\boldsymbol{U}_s]\!],[\![\kappa_s]\!]\rangle_{\mathcal{E}_{i,s}} \\
&\quad +\langle\{\pi h_s\}([\![\Psi_s]\!]-[\![\Theta_s]\!])-[\![\eta_s]\!]\{\boldsymbol{U}_s\},\{\kappa_s\}\rangle_{\mathcal{E}_{i,s}}. \qquad (74)
\end{aligned}
$$

By (54)

$$\langle(\eta_s^{\uparrow} - \{\eta_s\})\{\boldsymbol{U}_s\}, [\![\kappa_s]\!]\rangle_{\mathcal{E}_{i,s}} \leq \mathcal{C}(K^m, K^M) \sum_{\Omega_{e,s}} [\ \Delta_{e,s}^{-2} ||\eta_s||^2_{\Omega_{e,s}} + ||\eta_s||^2_{H^1(\Omega_{e,s})}]$$

$$+C(K^i)||\kappa_s||^2_{\Omega_s} \tag{75}$$

with similar estimates for the above terms involving $[\![\eta_s]\!]$. An identical bound to (72) is obtained for the remaining term, $\langle\{\pi h_s\}([\![\Psi_s]\!] - [\![\Theta_s]\!], \{\kappa_s\}\rangle_{\mathcal{E}_{i,s}}$, in (74). Continuing,

$$\begin{aligned} E_8 &= \langle \boldsymbol{U}_s \cdot \mathbf{n}_s(\pi h_s - h_s^I), \kappa_s\rangle_{\partial\Omega_{s,in}} \\ &\leq \mathcal{C}(K^m, K^M)||\eta_s||^2_{\partial\Omega_{s,in}} + \epsilon_4\langle|\boldsymbol{U}_s \cdot \mathbf{n}_s|, |\kappa_s|^2\rangle_{\partial\Omega_{s,in}} \\ &\leq \mathcal{C}(K^m, K^M, K^t) \sum_{\Omega_{e,s}} [\ \Delta_{e,s}^{-1} ||\eta_s||^2_{\Omega_{e,s}} + \Delta_{e,s}||\eta_s||^2_{H^1(\Omega_{e,s})}] \\ &\quad +\epsilon_4\langle|\boldsymbol{U}_s \cdot \mathbf{n}_s|, |\kappa_s|^2\rangle_{\partial\Omega_{s,in}} \end{aligned} \tag{76}$$

and

$$\begin{aligned} E_9 &= (g\kappa_s, \nabla_{(x,y)} \cdot \Psi_s)_{\Omega_s} \\ &\leq \mathcal{C}(\mu^{-1})||\kappa_s||^2_{\Omega_s} + \frac{\mu}{8}||\nabla_{(x,y)}\Psi_s||^2_{\Omega_s}. \end{aligned} \tag{77}$$

Finally,

$$\begin{aligned} E_{10} + E_{11} &= -\langle g\{\kappa_s\}, [\![\Psi_s]\!]\rangle_{\mathcal{E}_{i,s}} - \langle g\kappa_s, \Psi_s \cdot \mathbf{n}_s\rangle_{\partial\Omega_{s,out}} \\ &\leq \mathcal{C}||\sigma_s^{-1/2}\{\kappa_s\}||_{\mathcal{E}_{i,s}}||\sigma_s^{1/2}[\![\Psi_s]\!]||_{\mathcal{E}_{i,s}} \\ &\quad +\mathcal{C}||\sigma_s^{-1/2}\kappa_s||_{\partial\Omega_{s,out}}||\sigma_s^{1/2}\Psi_s||_{\partial\Omega_{s,out}} \\ &\leq \mathcal{C}(K^t, K^i)||\kappa_s||^2_{\Omega_s} \\ &\quad +\epsilon_3[\ ||\sigma_s^{1/2}[\![\Psi_s]\!]||^2_{\mathcal{E}_{i,s}} + ||\sigma_s^{1/2}\Psi_s||^2_{\partial\Omega_{s,out}}]. \end{aligned} \tag{78}$$

By standard approximation theory, for $\mathbf{u}_g$, h_g, $\mathbf{u}_s$, and h_s sufficiently smooth,

$$||\Theta_g||_{\Omega_{e,g}} + \Delta_{e,g}||\Theta_g||_{H^1(\Omega_{e,g})} \leq \mathcal{C}(\mathbf{u}_g)\Delta_{e,g}^{k_g+1}, \tag{79}$$

$$||\eta_g||_{\Omega_{e,g}} + \Delta_{e,g}||\eta_g||_{H^1(\Omega_{e,g})} \leq \mathcal{C}(h_g)\Delta_{e,g}^{k_g+1}, \tag{80}$$

$$||\Theta_s||_{\Omega_{e,s}} + \Delta_{e,s}||\Theta_s||_{H^1(\Omega_{e,s})} + \Delta_{e,s}^2||\Theta_s||_{H^2(\Omega_{e,s})} \leq \mathcal{C}(\mathbf{u}_s)\Delta_{e,s}^{k_s+1}, \tag{81}$$

$$||\eta_s||_{\Omega_{e,s}} + \Delta_{e,s}||\eta_s||_{H^1(\Omega_{e,s})} \leq \mathcal{C}(h_s)\Delta_{e,s}^{k_s+1}. \tag{82}$$

Using (60)–(78) to bound the right-hand side of (44), choosing ϵ_1–ϵ_4 sufficiently small, and applying (79)–(82), we find

$$\begin{aligned} &\frac{1}{2}||K^{-1/2}\Psi_g||^2_{\Omega_g} + \frac{1}{2}\partial_t||\kappa_s||^2_{\Omega_s} + \frac{1}{2}\partial_t||\Psi_s||^2_{\Omega_s} + \frac{\mu}{4}||\nabla_{(x,y)}\Psi_s||^2_{\Omega_s} \\ &+\frac{1}{2}[\ ||\sigma_g^{1/2}[\![\kappa_g]\!]||^2_{\mathcal{E}_{i,g}} + ||\sigma_g^{1/2}\kappa_g||^2_{\Gamma_D} + ||\sigma_g^{1/2}(\kappa_g - \kappa_s)||^2_{\Gamma_{GS}}] \\ &\leq \mathcal{C}(K, K^t, K^i, K^m, K^M, \mu, \mathbf{u}_g, h_g, \mathbf{u}_s, h_s)(\Delta_g^{2k_g} + \Delta_s^{2k_s}) \\ &\quad +\mathcal{C}(K^t, K^i, K^m, K^M, \mu^{-1})[\ ||\kappa_s||^2_{\Omega_s} + ||\Psi_s||^2_{\Omega_s}]. \end{aligned} \tag{83}$$

Integrating in time from 0 to T and applying (30), (31), Gronwall's lemma, and the triangle inequality, we obtain the following error estimate.

THEOREM 4.2. *Assume* $\mathbf{u}_g$, h_g, $\mathbf{u}_s$, *and* h_s *are sufficiently smooth so that approximation bounds* (79)–(82) *hold. Assume that the ground water and surface water meshes satisfy Assumption GS and that the penalty functions* σ_g *and* σ_s *satisfy* (57). *Then the LDG/DG method* (26)–(31) *satisfies*

$$\left(\int_0^T ||K^{1/2}\Psi_g||^2_{\Omega_g} dt\right)^{1/2}$$
$$+\left(\int_0^T [\ ||\sigma_g^{1/2}[\![\kappa_g]\!]||^2_{\mathcal{E}_{i,g}} + ||\sigma_g^{1/2}\kappa_g||^2_{\Gamma_D} + ||\sigma_g^{1/2}(\kappa_g-\kappa_s)||^2_{\Gamma_{GS}}]dt\right)^{1/2}$$
$$+||\kappa_s(\cdot,T)||_{\Omega_s} + ||\Psi_s(\cdot,T)||_{\Omega_s} \le \tilde{\mathcal{C}}(\Delta_g^{k_g} + \Delta_s^{k_s}),$$

where $\tilde{\mathcal{C}}$ *depends on* K, μ, K^t, K^i, K^M, K^m, $\mathbf{u}_g$, h_g, $\mathbf{u}_s$, *and* h_s. *Applying the triangle inequality, we obtain*

$$\left(\int_0^T ||K^{1/2}(\mathbf{u}_g - \boldsymbol{U}_g)||^2_{\Omega_g} dt\right)^{1/2}$$
$$+||(h_s - H_s)(\cdot,T)||_{\Omega_s} + ||(\mathbf{u}_s - \boldsymbol{U}_s)(\cdot,T)||_{\Omega_s} \le \tilde{\mathcal{C}}(\Delta_g^{k_g} + \Delta_s^{k_s}).$$

We recall another inverse inequality, valid in two dimensions,

$$||w(\cdot,t)||_{L^\infty(\Omega_s)} \le \mathcal{C}^\infty \Delta_s^{-1} ||w(\cdot,t)||_{\Omega_s}, \tag{84}$$

where $\mathcal{C}^\infty$ is independent of Δ_s and $w(\cdot,t)$ is in either $\mathcal{W}_{\Delta_s,s}$ or $\mathcal{V}_{\Delta_s,s}$. Assuming that k_g and $k_s \ge 2$ and Δ_s and $\Delta_s^{-1}\Delta_g^2$ are sufficiently small, we have

$$||\kappa_s||_{L^\infty(0,T;L^\infty(\Omega_s))} \le \mathcal{C}^\infty \tilde{\mathcal{C}} \Delta_s^{-1}[\ \Delta_g^2 + \Delta_s^2] \ll K^M \tag{85}$$

and similarly for Ψ_s. Then we can remove the dependence of $\tilde{C}$ on K^M.

4.1. An estimate for H_g. The estimate (4.2) does not say anything about the accuracy of H_g. Estimates for the error $h_g - H_g$ follow from a duality argument.

In this section, let $\nabla = \nabla_{(x,y,z)}$, let $e_g = h_g - H_g$, and assume that ϕ satisfies

$$-\nabla\cdot(K\nabla\phi) = e_g, \quad \Omega_g \tag{86}$$

with the boundary conditions

$$\phi = 0, \quad \Gamma_D \cup \Gamma_{GS}, \tag{87}$$
$$K\nabla\phi\cdot\mathbf{n}_g = 0, \quad \Gamma_N. \tag{88}$$

Define $\mathbf{q} = -K\nabla\phi$. We assume problem (86)–(88) satisfies the standard elliptic regularity bounds, so that

$$||\phi||_{H^2(\Omega_g)} + ||\mathbf{q}\cdot\mathbf{n}_g||_{\Gamma_D\cup\Gamma_{GS}} \le \mathcal{C}_r ||e_g||_{\Omega_g}, \tag{89}$$

where the constant $\mathcal{C}_r$ depends on the domain Ω and the coefficient K.

Multiplying (86) by e_g and integrating by parts,

$$\begin{aligned} ||e_g||^2_{\Omega_g} &= (h_g - H_g, \nabla\cdot\mathbf{q})_{\Omega_g} \\ &= -(\nabla h_g, \mathbf{q})_{\Omega_g} + \langle h_g, \mathbf{q}\cdot\mathbf{n}_g\rangle_{\Gamma_D} + \langle h_T, \mathbf{q}\cdot\mathbf{n}_g\rangle_{\Gamma_{GS}} \\ &\quad +(\nabla H_g, \mathbf{q})_{\Omega_g} - \langle [\![H_g]\!], \mathbf{q}\rangle_{\mathcal{E}_{i,g}} - \langle H_g, \mathbf{q}\cdot\mathbf{n}_g\rangle_{\Gamma_D} - \langle H_g, \mathbf{q}\cdot\mathbf{n}_g\rangle_{\Gamma_{GS}}. \end{aligned} \tag{90}$$

Let π again denote L^2 projection into the appropriate LDG approximating space. Then

$$\begin{aligned} -(\nabla h_g, \mathbf{q}) &= (\nabla h_g, \pi\mathbf{q} - \mathbf{q})_{\Omega_g} - (\nabla h_g, \pi\mathbf{q})_{\Omega_g} \\ &= (\nabla h_g - \pi(\nabla h_g), \pi\mathbf{q} - \mathbf{q})_{\Omega_g} + (K^{-1}\mathbf{u}_g, \pi\mathbf{q})_{\Omega_g}. \end{aligned} \tag{91}$$

An alternate form of (17) is obtained by integration by parts:

$$\begin{aligned} \mathcal{A}_g(\boldsymbol{U}_g, H_g, H_s; \mathbf{v}_g) = (K^{-1}\boldsymbol{U}_g, \mathbf{v}_g)_{\Omega_g} &+ (\nabla H_g, \mathbf{v}_g)_{\Omega_g} \\ &- \langle H_g, \mathbf{v}_g \cdot \mathbf{n}_g\rangle_{\Gamma_D} - \langle [\![H_g]\!], \{\mathbf{v}_g\}\rangle_{\mathcal{E}_{i,g}} \\ &- \langle H_g - H_s, \mathbf{v}_g \cdot \mathbf{n}_g\rangle_{\Gamma_{GS}}. \end{aligned}$$

Therefore, by (26),

$$\begin{aligned} (\nabla H_g, \mathbf{q})_{\Omega_g} &= (\nabla H_g, \pi\mathbf{q})_{\Omega_g} \\ &= -(K^{-1}\boldsymbol{U}_g, \pi\mathbf{q})_{\Omega_g} + \langle [\![H_g]\!], \{\pi\mathbf{q}\}\rangle_{\mathcal{E}_{i,g}} \\ &\quad + \langle H_g - h_g^D, \pi\mathbf{q} \cdot \mathbf{n}_g\rangle_{\Gamma_D} + \langle H_g - H_T, \pi\mathbf{q} \cdot \mathbf{n}_g\rangle_{\Gamma_{GS}}, \end{aligned} \tag{92}$$

where $H_T = H_s + h_b$. Combining (90)–(92) and using $[\![h_g]\!] = 0$ on $\mathcal{E}_{i,g}$, we obtain

$$\begin{aligned} ||e_g||^2_{\Omega_g} = (K^{-1}(\mathbf{u}_g - \boldsymbol{U}_g), \pi\mathbf{q})_{\Omega_g} &+ \langle [\![H_g - h_g]\!], \{\pi\mathbf{q}\} - \mathbf{q}\rangle_{\mathcal{E}_{i,g}} \\ &+ \langle h_g - H_g, (\mathbf{q} - \pi\mathbf{q}) \cdot \mathbf{n}_g\rangle_{\Gamma_D} + \langle h_T - H_T, \mathbf{q} \cdot \mathbf{n}_g\rangle_{\Gamma_{GS}} \\ &+ \langle H_g - H_T, (\pi\mathbf{q} - \mathbf{q}) \cdot \mathbf{n}_g\rangle_{\Gamma_{GS}} + (\nabla h_g - \pi(\nabla h_g), \pi\mathbf{q} - \mathbf{q})_{\Omega_g}. \end{aligned} \tag{93}$$

Next, consider

$$(K^{-1}(\mathbf{u}_g - \boldsymbol{U}_g), \pi\mathbf{q})_{\Omega_g} = (K^{-1}(\mathbf{u}_g - \boldsymbol{U}_g), \mathbf{q})_{\Omega_g} + (K^{-1}(\mathbf{u}_g - \boldsymbol{U}_g), \pi\mathbf{q} - \mathbf{q})_{\Omega_g}. \tag{94}$$

Integrating by parts,

$$\begin{aligned} (K^{-1}(\mathbf{u}_g - \boldsymbol{U}_g), \mathbf{q})_{\Omega_g} &= -(K^{-1}(\mathbf{u}_g - \boldsymbol{U}_g), K\nabla\phi)_{\Omega_g} \\ &= (\nabla \cdot (\mathbf{u}_g - \boldsymbol{U}_g), \phi)_{\Omega_g} + \langle [\![\boldsymbol{U}_g]\!], \phi\rangle_{\mathcal{E}_{i,g}} \\ &\quad + \langle \boldsymbol{U}_g \cdot \mathbf{n}_g \ - u_N, \phi\rangle_{\Gamma_N}. \end{aligned} \tag{95}$$

Furthermore,

$$(\nabla \cdot (\mathbf{u}_g - \boldsymbol{U}_g), \phi)_{\Omega_g} = (\nabla \cdot (\mathbf{u}_g - \boldsymbol{U}_g), \phi - \pi\phi)_{\Omega_g} + (\nabla \cdot (\mathbf{u}_g - \boldsymbol{U}_g), \pi\phi)_{\Omega_g}, \tag{96}$$

and by (20) and (27),

$$\begin{aligned} (\nabla \cdot (\mathbf{u}_g - \boldsymbol{U}_g), \pi\phi)_{\Omega_g} &= \langle [\![\mathbf{u}_g - \boldsymbol{U}_g]\!], \{\pi\phi\}\rangle_{\mathcal{E}_{i,g}} + \langle \mathbf{u}_g \cdot \mathbf{n}_g - \boldsymbol{U}_g \cdot \mathbf{n}_g, \pi\phi\rangle_{\Gamma_N} \\ &\quad + \langle \sigma_g [\![H_g - h_g]\!], [\![\pi\phi]\!]\rangle_{\mathcal{E}_{i,g}} + \langle \sigma_g(H_g - H_T), \pi\phi\rangle_{\Gamma_{GS}} \\ &\quad + \langle \sigma_g(H_g - h_g), \pi\phi\rangle_{\Gamma_D}. \end{aligned} \tag{97}$$

Combining (94)–(97), we find

$$\begin{aligned} (K^{-1}(\mathbf{u}_g - \boldsymbol{U}_g), \pi\mathbf{q})_{\Omega_g} &= (K^{-1}(\mathbf{u}_g - \boldsymbol{U}_g), \pi\mathbf{q} - \mathbf{q})_{\Omega_g} + (\nabla \cdot (\mathbf{u}_g - \boldsymbol{U}_g), \phi - \pi\phi)_{\Omega_g} \\ &\quad + \langle [\![\boldsymbol{U}_g - \mathbf{u}_g]\!], \phi - \{\pi\phi\}\rangle_{\mathcal{E}_{i,g}} + \langle \boldsymbol{U}_g \cdot \mathbf{n}_g - \mathbf{u}_g \cdot \mathbf{n}_g, \phi - \pi\phi\rangle_{\Gamma_N} \\ &\quad + \langle \sigma_g [\![H_g - h_g]\!], [\![\pi\phi]\!]\rangle_{\mathcal{E}_{i,g}} + \langle \sigma_g(H_g - H_T), \pi\phi\rangle_{\Gamma_{GS}} \\ &\quad + \langle \sigma_g(H_g - h_g), \pi\phi\rangle_{\Gamma_D}. \end{aligned} \tag{98}$$

Finally, substituting (98) into (93), we obtain

$$\begin{aligned}||e_g||^2_{\Omega_g} &= (K^{-1}(\mathbf{u}_g - \boldsymbol{U}_g), \pi\mathbf{q} - \mathbf{q})_{\Omega_g} + (\nabla\cdot(\mathbf{u}_g - \boldsymbol{U}_g), \phi - \pi\phi)_{\Omega_g} \\ &\quad + \langle [\![\boldsymbol{U}_g - \mathbf{u}_g]\!], \phi - \{\pi\phi\}\rangle_{\mathcal{E}_{i,g}} + \langle \boldsymbol{U}_g\cdot\mathbf{n}_g - \mathbf{u}_g\cdot\mathbf{n}_g, \phi - \pi\phi\rangle_{\Gamma_N}. \\ &\quad + \langle [\![H_g - h_g]\!], \{\pi\mathbf{q}\} - \mathbf{q}\rangle_{\mathcal{E}_{i,g}} + \langle h_g - H_g, (\mathbf{q} - \pi\mathbf{q})\cdot\mathbf{n}_g\rangle_{\Gamma_D} \\ &\quad + \langle H_g - H_T, (\pi\mathbf{q} - \mathbf{q})\cdot\mathbf{n}_g\rangle_{\Gamma_{GS}} + \langle h_T - H_T, \mathbf{q}\cdot\mathbf{n}_g\rangle_{\Gamma_{GS}} \\ &\quad + \langle \sigma_g [\![H_g - h_g]\!], [\![\pi\phi]\!]\rangle_{\mathcal{E}_{i,g}} + \langle \sigma_g(H_g - H_T), \pi\phi\rangle_{\Gamma_{GS}} \\ &\quad + \langle \sigma_g(H_g - h_g), \pi\phi\rangle_{\Gamma_D} + (\nabla h_g - \pi(\nabla h_g), \pi\mathbf{q} - \mathbf{q})_{\Omega_g} \\ &\equiv F_1 + \cdots + F_{12}. \end{aligned} \tag{99}$$

By approximation theory,

$$||\pi\mathbf{q} - \mathbf{q}||_{\Omega_{e,g}} + \Delta_{e,g}||\pi\mathbf{q} - \mathbf{q}||_{H^1(\Omega_{e,g})} \le \mathcal{C}(\mathcal{C}_r)\Delta_{e,g}||\phi||_{H^2(\Omega_{e,g})}, \tag{100}$$

$$||\pi\phi - \phi||_{\Omega_{e,g}} + \Delta_{e,g}||\pi\phi - \phi||_{H^1(\Omega_{e,g})} \le \mathcal{C}(\mathcal{C}_r)\Delta^2_{e,g}||\phi||_{H^2(\Omega_{e,g})}. \tag{101}$$

In the arguments below, let $\bar{\mathcal{C}}$ be a generic constant which depends on $\mathcal{C}_r$ and $\tilde{\mathcal{C}}$ from Theorem 4.2. Integrating (99) in time and applying Theorem 4.1 and inverse inequality (53), the bounds (100)–(101), (89), and the result of Theorem 4.2, we obtain

$$\begin{aligned}&\int_0^T [F_1 + \cdots + F_4]dt \\ &\le \int_0^T \sum_e ||K^{-1/2}(\mathbf{u}_g - \boldsymbol{U}_g)||_{\Omega_{e,g}}||\pi\mathbf{q} - \mathbf{q}||_{\Omega_{e,g}}dt \\ &\quad + \int_0^T \sum_e ||\mathbf{u}_g - \boldsymbol{U}_g||_{H^1(\Omega_{e,g})}||\phi - \pi\phi||_{\Omega_{e,g}}dt \\ &\quad + \int_0^T \sum_e [\,||\mathbf{u}_g - \boldsymbol{U}_g||^2_{\Omega_{e,g}} + \Delta^2_{e,g}||\nabla(\mathbf{u}_g - \boldsymbol{U}_g)||^2_{\Omega_{e,g}}]^{1/2} \\ &\qquad \times [\,\Delta^{-2}_{e,g}||\phi - \pi\phi||^2_{\Omega_{e,g}} + ||\nabla(\phi - \pi\phi)||^2_{\Omega_{e,g}}]^{1/2}dt \\ &\le \bar{\mathcal{C}}\Delta_g(\Delta_g^{k_g} + \Delta_s^{k_s})\left(\int_0^T ||e_g||^2_{\Omega_g}dt\right)^{1/2}. \end{aligned} \tag{102}$$

Consider

$$\begin{aligned}F_5 &= \langle [\![H_g - h_g]\!], \{\pi\mathbf{q} - \mathbf{q}\}\rangle_{\mathcal{E}_{i,g}} \\ &= \langle \sigma_g^{1/2}[\![\kappa_g - \eta_g]\!], \sigma_g^{-1/2}\{\pi\mathbf{q} - \mathbf{q}\}\rangle_{\mathcal{E}_{i,g}} \\ &\le \left(||\sigma_g^{1/2}[\![\kappa_g]\!]||_{\mathcal{E}_{i,g}} + ||\sigma_g^{1/2}[\![\eta_g]\!]||_{\mathcal{E}_{i,g}}\right)||\sigma_g^{-1/2}\{\pi\mathbf{q} - \mathbf{q}\}||_{\mathcal{E}_{i,g}}. \end{aligned} \tag{103}$$

By (57), Theorem 4.1, and (100),

$$\begin{aligned}||\sigma_g^{-1/2}\{\pi\mathbf{q} - \mathbf{q}\}||_{\mathcal{E}_{i,g}} &\le \mathcal{C}\sum_e [\,||\pi\mathbf{q} - \mathbf{q}||^2_{\Omega_{e,g}} + \Delta^2_{e,g}||\nabla(\pi\mathbf{q} - \mathbf{q})||^2_{\Omega_{e,g}}]^{1/2} \\ &\le \mathcal{C}\Delta_g||e_g||_{\Omega_g}; \end{aligned} \tag{104}$$

hence by Theorem 4.2 and estimates on η_g we find

$$\int_0^T F_5 dt \le \bar{\mathcal{C}}\Delta_g(\Delta_g^{k_g} + \Delta_s^{k_s})\left(\int_0^T ||e_g||^2_{\Omega_g}dt\right)^{1/2}. \tag{105}$$

A similar argument gives the same bound for F_6 and F_7, since $H_g - H_T = \kappa_g - \kappa_s + \eta_s - \eta_g$. For F_8,

$$\begin{aligned}\int_0^T \langle h_T - H_T, \mathbf{q}\cdot\mathbf{n}_g\rangle_{\Gamma_{GS}} dt &= \int_0^T \langle \eta_s - \kappa_s, \mathbf{q}\cdot\mathbf{n}_g\rangle_{\Gamma_{GS}} dt \\ &\le \bar{\mathcal{C}} \int_0^T \left[||\eta_s||_{\Omega_s} + ||\kappa_s||_{\Omega_s}\right] ||e_g||_{\Omega_g} dt \\ &\le \bar{\mathcal{C}}(\Delta_g^{k_g} + \Delta_s^{k_s}) \left(\int_0^T ||e_g||^2_{\Omega_g} dt\right)^{1/2} \end{aligned} \tag{106}$$

by Theorem 4.2. Next, consider

$$\begin{aligned} F_9 &= \langle \sigma_g [\![H_g - h_g]\!], [\![\pi\phi]\!]\rangle_{\mathcal{E}_{i,g}} \\ &= \langle \sigma_g [\![\kappa_g - \eta_g]\!], [\![\pi\phi - \phi]\!]\rangle_{\mathcal{E}_{i,g}} \\ &\le \left(||\sigma_g^{1/2}[\![\kappa_g]\!]||_{\mathcal{E}_{i,g}} + ||\sigma_g^{1/2}[\![\eta_g]\!]||_{\mathcal{E}_{i,g}}\right) ||\sigma_g^{1/2}[\![\pi\phi - \phi]\!]||_{\mathcal{E}_{i,g}}. \end{aligned} \tag{107}$$

Similar to (104),

$$||\sigma_g^{1/2}[\![\pi\phi - \phi]\!]||_{\mathcal{E}_{i,g}} \le \mathcal{C}\Delta_g ||e_g||_{\Omega_g}; \tag{108}$$

therefore

$$\int_0^T F_9 \, dt \le \bar{\mathcal{C}}\Delta_g(\Delta_g^{k_g} + \Delta_s^{k_s+1/2}) \left(\int_0^T ||e_g||^2_{\Omega_g} dt\right)^{1/2}. \tag{109}$$

A similar argument gives the same bound for F_{10} and F_{11}, since $\phi = 0$ on Γ_D and Γ_{GS}. Finally,

$$\begin{aligned} F_{12} &= (\nabla h_g - \pi(\nabla h_g), \pi\mathbf{q} - \mathbf{q})_{\Omega_g} \\ &\le \bar{\mathcal{C}}\Delta_g^{k_g+1} \left(\int_0^T ||e_g||^2_{\Omega_g} dt\right)^{1/2}. \end{aligned} \tag{110}$$

Combining bounds (102)–(110) with (99), we obtain the following estimate for e_g.

THEOREM 4.3. *Under the assumptions of Theorem* 4.2 *and the regularity of the dual solution* ϕ*, we have*

$$\left(\int_0^T ||h_g - H_g)||^2 dt\right)^{1/2} \le \mathcal{C}(C_r, \tilde{C})(\Delta_g^{k_g} + \Delta_s^{k_s}).$$

This estimate unfortunately does not give the additional power of Δ_g which is obtained in the purely elliptic case considered in [15]. The problem is in the term F_8, which involves the coupling between ground water and surface water. Theorem 4.3 essentially tells us that the error in H_g is no better than the error in H_s, which is not terribly surprising.

5. The MFE/DG method. The flexibility of the LDG framework (26)–(29) easily allows for a MFE approximation of the ground water flow equations. This can be accomplished by restricting the finite element spaces $\mathcal{V}_{\Delta_g,g}$ and $\mathcal{W}_{\Delta_g,g}$ to be

standard mixed spaces; see, for example, [33, 12, 10, 11, 16]. In this section, we assume that the mesh $\mathcal{T}_{\Delta_g,g}$ is regular and conforming and denote by $\mathcal{V}^M_{\Delta_g,g}$ and $\mathcal{W}^M_{\Delta_g,g}$ MFE approximating spaces of order $k_g \geq 0$. Thus, functions in $\mathcal{W}^M_{\Delta_g,g}$ are piecewise polynomials of degree k_g, $\mathcal{V}^M_{\Delta_g,g} \subset H(\mathrm{div};\Omega_g)$, and the spaces satisfy the Babuška–Brezzi (BB) *inf-sup* condition. Furthermore,

$$\nabla_{(xyz)} \cdot \mathbf{v} \in \mathcal{W}^M_{\Delta_g,g} \quad \forall\, \mathbf{v} \in \mathcal{V}^M_{\Delta_g,g}. \tag{111}$$

For simplicity, in this section we will assume that $u_N = 0$. When this is not the case, we enforce the Neumann boundary condition by setting $\boldsymbol{U}_g \cdot \mathbf{n}_g = \tilde{u}_N$, where $\tilde{u}_N$ is the projection of u_N into a space of Lagrange multiplier functions defined on Γ_N; see, for example, [4]. The analysis below carries through with this modification at the expense of including some additional terms which have been analyzed in previous papers. Denote

$$\mathcal{V}^{M,0}_{\Delta_g,g} = \mathcal{V}^M_{\Delta_g,g} \cap \{\mathbf{v}_g : \mathbf{v}_g \cdot \mathbf{n}_g|_{\Gamma_N} = 0\}.$$

Define

$$\begin{aligned}
\mathcal{A}^M_g(\mathbf{u}_g, h_g, h_s; \mathbf{v}_g) &\equiv (K^{-1}\mathbf{u}_g, \mathbf{v}_g)_{\Omega_g} - (h_g, \nabla_{(x,y,z)} \cdot \mathbf{v}_g)_{\Omega_g} \\
&\quad + \langle h_s, \mathbf{v}_g \cdot \mathbf{n}_g \rangle_{\Gamma_{GS}}, \qquad (112)\\
\mathcal{B}^M_g(\mathbf{u}_g; w_g) &\equiv (\nabla_{(x,y,z)} \cdot \mathbf{u}_g, w_g)_{\Omega_g}, \qquad (113)\\
\mathcal{B}^M_s(\mathbf{u}_g, \mathbf{u}_s, h_s; w_s) &\equiv (\partial_t h_s, w_s)_{\Omega_s} - (\mathbf{u}_s h_s, \nabla_{(x,y)} w_s)_{\Omega_s} + \langle \{\mathbf{u}_s\} h_s^{\uparrow}, [\![w_s]\!] \rangle_{\mathcal{E}_{i,s}} \\
&\quad - \langle \mathbf{u}_g \cdot \mathbf{n}_g, w_s \rangle_{\Gamma_{GS}} + \langle \mathbf{u}_s \cdot \mathbf{n}_s h_s, w_s \rangle_{\partial\Omega_{s,out}} \\
&\quad + \langle \mathbf{u}_s \cdot \mathbf{n}_s h_s^I, w_s \rangle_{\partial\Omega_{s,in}}. \qquad (114)
\end{aligned}$$

The MFE/DG method then is to find $\boldsymbol{U}_g \in \mathcal{V}^{M,0}_{\Delta_g,g}$, $H_g \in \mathcal{W}^M_{\Delta_g,g}$, $\boldsymbol{U}_s \in \mathcal{V}_{\Delta_s,s}$, and $H_s \in \mathcal{W}_{\Delta_s,s}$ which satisfy

$$\mathcal{A}^M_g(\boldsymbol{U}_g, H_g, H_s; \mathbf{v}_g) = -\langle h_b, \mathbf{v}_g \cdot \mathbf{n}_g \rangle_{\Gamma_{GS}} - \langle h_g^D, \mathbf{v}_g \cdot \mathbf{n}_g \rangle_{\Gamma_D}, \quad \mathbf{v}_g \in \mathcal{V}^{M,0}_{\Delta_g,g}, \tag{115}$$

$$\mathcal{B}^M_g(\boldsymbol{U}_g; w_g) = (f_g, w_g)_{\Omega_g}, \quad w_g \in \mathcal{W}^M_{\Delta_g,g}, \tag{116}$$

$$\begin{aligned}
\mathcal{B}^M_s(\mathbf{u}_g, \mathbf{u}_s, h_s; w_s) &= 0, \quad w_s \in \mathcal{W}_{\Delta_s,s}, \qquad (117)\\
\mathcal{A}_s(\boldsymbol{U}_s, H_s; \mathbf{v}_s) &= -(g\nabla_{(x,y)} h_b, \mathbf{v}_s)_{\Omega_s} - \langle g h_s^I, \mathbf{v}_s \cdot \mathbf{n} \rangle_{\partial\Omega_{s,in}} \\
&\quad + \mu \langle \nabla_{(x,y)} \mathbf{v}_s \cdot \mathbf{n}, \hat{\mathbf{u}}_s \rangle_{\partial\Omega_s} + \langle \sigma_s \hat{\mathbf{u}}_s, \mathbf{v}_s \rangle_{\partial\Omega_s} \\
&\quad + (\mathcal{F}, \mathbf{v}_s)_{\Omega_s}, \quad \mathbf{v}_s \in \mathcal{V}_{\Delta_s,s}, \quad \mathbf{v}_s \in \mathcal{V}_{\Delta_s,s}. \qquad (118)
\end{aligned}$$

Furthermore, $H_s(\cdot, 0)$ and $\boldsymbol{U}_s(\cdot, 0)$ are defined to be the L^2 projections of h_s^0 and $\mathbf{u}_s^0$, respectively.

5.1. An a priori error estimate. Proceeding as above, let $\Pi\mathbf{u}_g$, πh_g, $\pi\mathbf{u}_s$, and πh_s be projections of the true solutions. The projections πh_g, $\pi\mathbf{u}_s$, and πh_s are defined to be L^2 projections as before; $\Pi\mathbf{u}_g$ will denote the well-known "Π-projection" of $\mathbf{u}_g$ into $\mathcal{V}^{M,0}_{\Delta_g,g}$ [33], which satisfies, among other properties,

$$(\nabla_{(x,y,z)} \cdot (\Pi\mathbf{u}_g - \mathbf{u}_g), w_g)_{\Omega_g} = 0, \quad w_g \in \mathcal{W}^M_{\Delta_g,g}. \tag{119}$$

Defining Ψ_g, Θ_g, κ_g, η_g, κ_s, and η_s as above, we obtain

$$\mathcal{A}^M_g(\Psi_g, \kappa_g, \kappa_s; \mathbf{v}_g) = \mathcal{A}^M_g(\Theta_g, \eta_g, \eta_s; \mathbf{v}_g), \tag{120}$$

$$\mathcal{B}^M_g(\Psi_g; w_g) = \mathcal{B}^M_g(\Theta_g; w_g). \tag{121}$$

Define

$$\mathcal{B}^M_{s,L}(\mathbf{u}_g, h_s; w_s) \equiv (\partial_t h_s, w_s)_{\Omega_s} - \langle \mathbf{u}_g \cdot \mathbf{n}_g, w_s \rangle_{\Gamma_{GS}}. \tag{122}$$

Then

$$\begin{aligned}
&\mathcal{B}^M_{s,L}(\Psi_g, \kappa_s; w_s) - (\boldsymbol{U}_s \kappa_s, \nabla_{(x,y)} w_s)_{\Omega_s} + \langle \{\boldsymbol{U}_s\} \kappa_s^{\uparrow}, [\![w_s]\!] \rangle_{\mathcal{E}_{i,s}} + \langle \boldsymbol{U}_s \cdot \mathbf{n}_s \kappa_s, w_s \rangle_{\partial \Omega_{s,out}} \\
&= \mathcal{B}^M_{s,L}(\Theta_g, \eta_s; w_s) - (\mathbf{u}_s h_s - \boldsymbol{U}_s \pi h_s, \nabla_{(x,y)} w_s)_{\Omega_s} + \langle \mathbf{u}_s h_s - \{\boldsymbol{U}_s\} \pi h_s^{\uparrow}, [\![w_s]\!] \rangle_{\mathcal{E}_{i,s}} \\
&+ \langle (\mathbf{u}_s h_s - \boldsymbol{U}_s \pi h_s) \cdot \mathbf{n}_s, w_s \rangle_{\partial \Omega_{s,out}} + \langle (\mathbf{u}_s - \boldsymbol{U}_s) \cdot \mathbf{n}_s h_s^I, w_s \rangle_{\partial \Omega_{s,in}}.
\end{aligned} \tag{123}$$

Furthermore, (36) holds as before. Manipulating (123) as in (39)–(41) and adding the result to (36), (120), and (121), we find

$$\begin{aligned}
&||K^{-1/2} \Psi_g||^2_{\Omega_g} + (\partial_t \kappa_s, \kappa_s)_{\Omega_s} + (\partial_t \Psi_s, \Psi_s)_{\Omega_s} + ||\tau_{bf}^{1/2} \Psi_s||^2_{\Omega_s} + \mu ||\nabla_{(x,y)} \Psi_s||^2_{\Omega_s} \\
&+ \frac{1}{2} \left[\langle |\boldsymbol{U}_s \cdot \mathbf{n}^-|, [\kappa_s^- - \kappa_s^+]^2 \rangle_{\mathcal{E}_{i,s}} + \langle |\boldsymbol{U}_s \cdot \mathbf{n}_s|, \kappa_s^2 \rangle_{\partial \Omega_{s,in}} + \langle |\boldsymbol{U}_s \cdot \mathbf{n}_s|, \kappa_s^2 \rangle_{\partial \Omega_{s,out}} \right] \\
&+ \langle \sigma_s [\![\Psi_s]\!], [\![\Psi_s]\!] \rangle_{\mathcal{E}_{i,s}} + \langle \sigma_s \Psi_s, \Psi_s \rangle_{\partial \Omega_s} \\
&= \mathcal{A}^M_g(\Theta_g, \eta_g, \eta_s; \Psi_g) + \mathcal{B}^M_g(\Theta_g, \eta_g, \eta_s; \kappa_g) + \mathcal{B}^M_{s,L}(\Theta_g, \eta_s; \kappa_s) + \mathcal{A}_{s,L}(\Theta_s, \eta_s; \Psi_s) \\
&\quad - \sum_{\partial \Omega^-_{e,s} \in \mathcal{T}_{\Delta_s,s}} \langle |\{\boldsymbol{U}_s\} \cdot \mathbf{n}_e| (\boldsymbol{U}_s^{\text{int}} - \boldsymbol{U}_s^{\text{ext}}), \Psi_s^{\text{int}} \rangle_{\partial \Omega^-_{e,s}} \\
&\quad + (\mathbf{u}_s \cdot \nabla_{(x,y)} \mathbf{u}_s - \boldsymbol{U}_s \cdot \nabla_{(x,y)} \boldsymbol{U}_s, \Psi_s)_{\Omega_s} \\
&\quad - \frac{1}{2} (\nabla_{(x,y)} \cdot \boldsymbol{U}_s, \kappa_s^2)_{\Omega_s} + \frac{1}{2} \langle \{\kappa_s^2\}, [\![\boldsymbol{U}_s]\!] \rangle_{\mathcal{E}_{i,s}} \\
&\quad + (\nabla_{(x,y)} \cdot (\mathbf{u}_s h_s - \boldsymbol{U}_s \pi h_s), \kappa_s)_{\Omega_s} - \langle [\![\kappa_s (\mathbf{u}_s h_s - \boldsymbol{U}_s \pi h_s)]\!], 1 \rangle_{\mathcal{E}_{i,s}} \\
&\quad + \langle \mathbf{u}_s h_s - \{\boldsymbol{U}_s\} \pi h_s^{\uparrow}, [\![\kappa_s]\!] \rangle_{\mathcal{E}_{i,s}} + \langle \boldsymbol{U}_s \cdot \mathbf{n}_s (\pi h_s - h_s^I), \kappa_s \rangle_{\partial \Omega_{s,in}} \\
&\quad + (g \kappa_s, \nabla_{(x,y)} \cdot \Psi_s)_{\Omega_s} - \langle g \{\kappa_s\}, [\![\Psi_s]\!] \rangle_{\mathcal{E}_{i,s}} - \langle g \kappa_s, \Psi_s \cdot \mathbf{n}_s \rangle_{\partial \Omega_{s,out}} \\
&\equiv \mathcal{A}^M_g(\Theta_g, \eta_g, \eta_s; \Psi_g) + \mathcal{B}^M_g(\Theta_g, \eta_g, \eta_s; \kappa_g) + \mathcal{B}^M_{s,L}(\Theta_g, \eta_s; \kappa_s) + \mathcal{A}_{s,L}(\Theta_s, \eta_s; \Psi_s) \\
&\quad + \sum_{i=1}^{11} E_i,
\end{aligned} \tag{124}$$

where E_1 through E_{11} are the same as in (44).

By the properties of the Π-projection and L^2 projection,

$$\mathcal{A}^M_g(\Theta_g, \eta_g, \eta_s; \Psi_g) = (K^{-1} \Theta_g, \Psi_g)_{\Omega_g} + \langle \eta_s, \Psi_g \cdot \mathbf{n}_g \rangle_{\Gamma_{GS}} \tag{125}$$

and

$$\mathcal{B}^M_g(\Theta_g; \kappa_g) + \mathcal{B}^M_{s,L}(\Theta_g, \eta_s; \kappa_s) = -\langle \Theta_g \cdot \mathbf{n}_g, \kappa_s \rangle_{\Gamma_{GS}}. \tag{126}$$

The two terms on the right-hand side of (125) are handled precisely as in (60) and (62). The term on the right-hand side of (126) is bounded by

$$\mathcal{C} ||\Theta_g \cdot \mathbf{n}_g||^2_{\Gamma_{GS}} + ||\kappa_s||^2_{\Omega_s}. \tag{127}$$

The approximation properties of the Π-projection and L^2 projection give

$$||\eta_g||_{\Omega_g} + ||\Theta_g||_{\Omega_g} + ||\Theta_g \cdot \mathbf{n}_g||_{\Gamma_{GS}} \leq \mathcal{C}(\mathbf{u}_g) \Delta_g^{k_g+1}.$$

The remaining terms on the right-hand side of (124) are handled as in section 4. We obtain the following result.

THEOREM 5.1. *Assume* $\mathbf{u}_g$, h_g, $\mathbf{u}_s$, *and* h_s *are sufficiently smooth and that the ground water and surface water meshes satisfy Assumption GS. Then the MFE/DG method* (115)–(118) *satisfies*

$$\left(\int_0^T ||K^{1/2}(\mathbf{u}_g - \boldsymbol{U}_g)||^2 dt\right)^{1/2}$$
$$+||(h_s - H_s)(\cdot,T)||_{\Omega_s} + ||(\mathbf{u}_s - \boldsymbol{U}_s)(\cdot,T)||_{\Omega_s} \le \tilde{\mathcal{C}}(\Delta_g^{k_g+1} + \Delta_s^{k_s}),$$

where $\tilde{\mathcal{C}}$ *depends on* K, K^t, K^i, K^m, K^M, μ, $\mathbf{u}_g$, h_g, $\mathbf{u}_s$, *and* h_s.

5.2. An estimate for H_g. Let $\nabla = \nabla_{(x,y,z)}$. We consider again a dual problem

$$-\nabla \cdot (K\nabla\phi) = H_g - \pi h_g, \quad \Omega_{\mathrm{g}} \tag{128}$$

with the boundary conditions

$$\phi = 0, \quad \Gamma_D \cup \Gamma_{GS}, \tag{129}$$

$$K\nabla\phi \cdot \mathbf{n}_g = 0, \quad \Gamma_N. \tag{130}$$

Define $\mathbf{q} = -K\nabla\phi$, and let $\Pi\mathbf{q}$ be its Π-projection. Then, using properties of the Π- and L^2 projections,

$$\begin{aligned} ||\kappa_g||^2_{\Omega_{\mathrm{g}}} &= (\kappa_g, \nabla\cdot\mathbf{q})_{\Omega_{\mathrm{g}}} \\ &= (\kappa_g, \nabla\cdot\Pi\mathbf{q})_{\Omega_{\mathrm{g}}} \\ &= (H_g - h_g, \nabla\cdot\Pi\mathbf{q})_{\Omega_{\mathrm{g}}} \\ &= (K^{-1}(\boldsymbol{U}_g - \mathbf{u}_g), \Pi\mathbf{q})_{\Omega_{\mathrm{g}}} + \langle h_s - H_s, \Pi\mathbf{q}\cdot\mathbf{n}_g\rangle_{\Gamma_{GS}}, \end{aligned} \tag{131}$$

where in the last step we have used the orthogonality relation

$$\mathcal{A}_g^M(\mathbf{u}_g - \boldsymbol{U}_g, h_g - H_g, h_s - H_s; \mathbf{v}_g) = 0.$$

By the definition of $\mathbf{q}$ and integration by parts,

$$\begin{aligned} (K^{-1}(\boldsymbol{U}_g - \mathbf{u}_g), \Pi\mathbf{q})_{\Omega_{\mathrm{g}}} &= (K^{-1}(\boldsymbol{U}_g - \mathbf{u}_g), \mathbf{q})_{\Omega_{\mathrm{g}}} + (K^{-1}(\boldsymbol{U}_g - \mathbf{u}_g), \Pi\mathbf{q} - \mathbf{q})_{\Omega_{\mathrm{g}}} \\ &= (K^{-1}(\boldsymbol{U}_g - \mathbf{u}_g), -K\nabla\phi)_{\Omega_{\mathrm{g}}} + (K^{-1}(\boldsymbol{U}_g - \mathbf{u}_g), \Pi\mathbf{q} - \mathbf{q})_{\Omega_{\mathrm{g}}} \\ &= (\nabla\cdot(\boldsymbol{U}_g - \mathbf{u}_g), \phi)_{\Omega_{\mathrm{g}}} + (K^{-1}(\boldsymbol{U}_g - \mathbf{u}_g), \Pi\mathbf{q} - \mathbf{q})_{\Omega_{\mathrm{g}}}. \end{aligned} \tag{132}$$

By the fact that

$$\mathcal{B}_g^M(\mathbf{u}_g - \boldsymbol{U}_g; w_g) = 0,$$

we easily see that

$$\nabla\cdot(\boldsymbol{U}_g - \Pi\mathbf{u}_g) \equiv 0,$$

and therefore

$$(\nabla\cdot(\boldsymbol{U}_g - \mathbf{u}_g), \phi)_{\Omega_{\mathrm{g}}} = (\nabla\cdot(\Pi\mathbf{u}_g - \mathbf{u}_g), \phi - \pi\phi)_{\Omega_{\mathrm{g}}}, \tag{133}$$

where $\pi\phi$ is the L^2 projection of ϕ into $\mathcal{W}^M_{\Delta_g,g}$. Substituting into (131), we obtain

$$||\kappa_g||^2_{\Omega_g} = (\nabla\cdot(\Pi\mathbf{u}_g - \mathbf{u}_g), \phi - \pi\phi)_{\Omega_g} + (K^{-1}(\boldsymbol{U}_g - \mathbf{u}_g), \Pi\mathbf{q} - \mathbf{q})_{\Omega_g} + \langle h_s - H_s, \Pi\mathbf{q}\cdot\mathbf{n}_g\rangle_{\Gamma_{GS}}. \tag{134}$$

Using the well-known estimate for the Π-projection

$$||\nabla\cdot(\mathbf{u}_g - \Pi\mathbf{u}_g)||_{\Omega_g} \le C\Delta_g^{k_g+1} \tag{135}$$

and the approximation properties of $\pi\phi$ and $\Pi\mathbf{q}$,

$$\left(\int_0^T ||\kappa_g||^2_{\Omega_g} dt\right)^{1/2} \le \mathcal{C}\left[\Delta_g^{k_g+2} + \left(\int_0^T \left[\Delta_g^2 ||K^{-1/2}(\boldsymbol{U}_g - \mathbf{u}_g)||^2_{\Omega_g} + ||h_s - H_s||^2_{\Omega_s}\right] dt\right)^{1/2}\right].$$

Therefore by Theorem 5.1 we obtain the following result.

THEOREM 5.2. *Under the assumptions of Theorem* 5.1 *and elliptic regularity of the adjoint problem* (128)–(130)*, the scheme* (115)–(117) *satisfies*

$$\left(\int_0^T ||H_g - \pi h_g||^2_{\Omega_g} dt\right)^{1/2} \le \mathcal{C}(\Delta_g^{k_g+1} + \Delta_s^{k_s}). \tag{136}$$

Using the triangle inequality, an immediate result of this theorem is the following corollary.

COROLLARY 5.3.

$$\left(\int_0^T ||H_g - h_g||^2_{\Omega_g} dt\right)^{1/2} \le \mathcal{C}(\Delta_g^{k_g+1} + \Delta_s^{k_s}). \tag{137}$$

6. Numerical results. In this section, we present some preliminary numerical results for the LDG/DG method described above. We consider a two-dimensional ground water domain Ω_g, pictured in Figure 2 with a coarse triangular discretization. The dimensions of the domain are roughly 100 by 100 cm. The top boundary of Ω_g is the ground water/surface water interface Γ_{GS}; thus Ω_s is the interval $0 < x < 100$ cm.

In Ω_s, we solve the full surface water flow equations (5)–(6) with $g = 9.81$ cm/s and $\mu = \mathcal{F} = 0$. The bottom friction coefficient $\tau_{bf} = 10\ s^{-1}$. The initial water height $h_T = 101$ cm. At the left boundary $x = 0$, we assume a total inflow height of 106 cm, which is ramped up linearly over a 60 s time period. The right boundary $x = 100$ is treated as a land boundary with $\mathbf{u}_s = 0$. Piecewise linear approximations are used for both $\mathbf{u}_s$ and h_s.

In the analysis presented above, we have not considered time discretization. This is an important issue in ground water/surface water coupling, as the temporal scales in the two regimes can be vastly different. We will examine this issue in more detail in future work. For now, the system (5)–(6) is discretized in time using an explicit second-order Runge–Kutta method with a time step of size Δt_s. Typically, Δt_s is fairly small, on the order of a second. The ground water flow equations are then

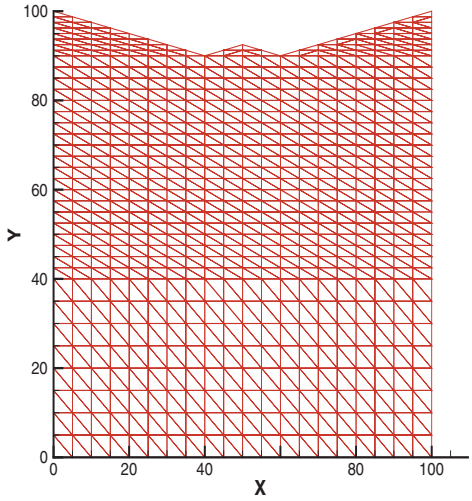

FIG. 2. *Ground water domain Ω_g with a coarse finite element mesh.*

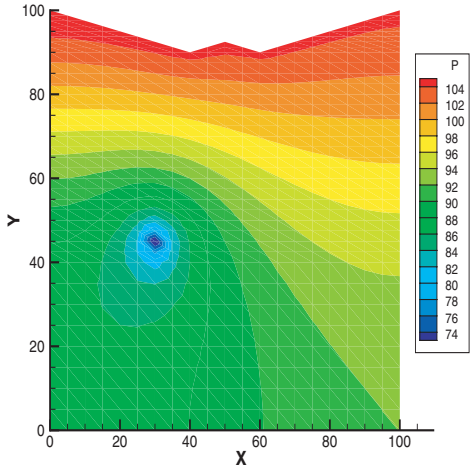

FIG. 3. *Ground water head H_g at $t = 1200$ s, computed on the mesh in Figure 2.*

solved at time steps $\Delta t_g = M\Delta t_s$ with $M \geq 1$. For the problem considered here, $\Delta t_s = .1$ s, and we have varied M to examine its effect.

In the ground water domain, the boundary conditions are no-flow ($u_N = 0$) on all boundaries except Γ_{GS}. We introduce a point sink

$$f_g(x, y) = \bar{f}\delta(x - \bar{x}, y - \bar{y}),$$

where $(\bar{x}, \bar{y}) = (30, 45)$ cm and $\bar{f} = -.3$ s^{-1}. The hydraulic conductivity $K = .00922$ cm/s. The approximations $\boldsymbol{U}_g$ and H_g are both piecewise linear.

In Figure 3, the ground water head H_g is shown at time $t = 1200$ s, computed on the triangular mesh given in Figure 2. This mesh contains 1256 elements. We can see from the head contours that flow is directed from the surface water domain into the ground water and towards the sink. In this case, the ground water flow equations were solved every 60 s or every 600 shallow water time steps. A new flux $\boldsymbol{U}_g \cdot \mathbf{n}_g$

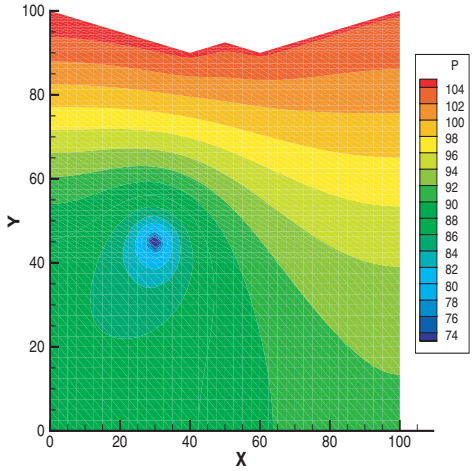

FIG. 4. *Ground water head H_g at $t = 1200$ s, computed on once refined mesh.*

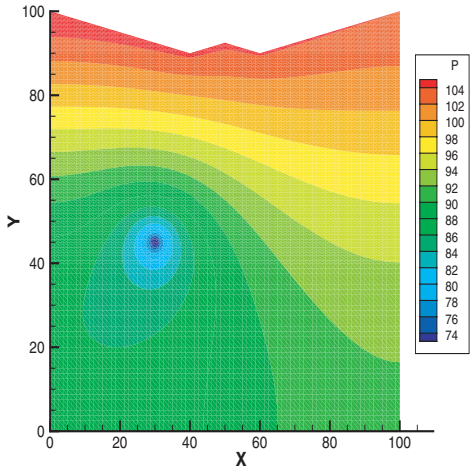

FIG. 5. *Ground water head H_g at $t = 1200$ s, computed on twice refined mesh.*

was computed at the end of each of these steps and fed back into the shallow water continuity equation (5).

The mesh was then refined twice, using edge bisection, giving meshes with 5024 and 20096 elements, respectively. On the second mesh, the ground water flow equations were solved every 30 s and, for the finest mesh, every 15 s. Contours of the solution h_g on these meshes are given in Figures 4 and 5. As observed in these figures, there is little difference between the solutions, except near the point sink. As the mesh is refined, the sink is better approximated. These results were not seen to be sensitive to the choice of M. In all of these simulations, the penalty parameter $\sigma_g = .01(\Delta_\gamma)^{-1}$ with Δ_γ defined as in (57).

The surface water heights at different times for the three different meshes are plotted in Figures 6–8. Figure 6 presents a plot of the total water height $H_T = H_s + h_b$ at time $t = 60$ s. Figures 7 and 8 are at 600 and 1200 s, respectively. In our runs, the surface water mesh aligns with the faces of the ground water mesh on Γ_{GS} mapped onto Ω_s. Thus, for the coarsest discretization, seen in Figure 2, there are 20 elements

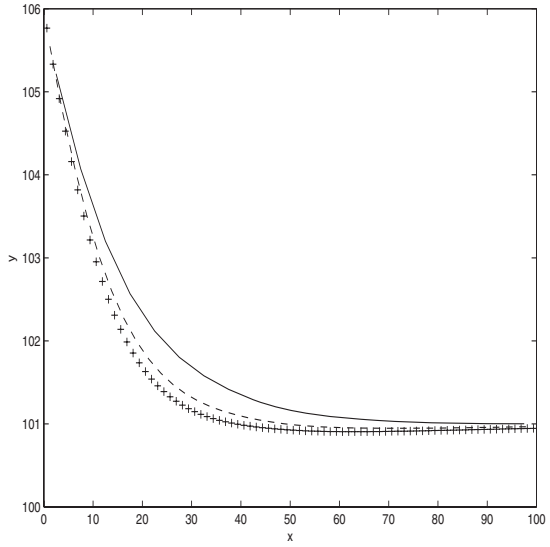

FIG. 6. *Surface water height* H_T *at* $t = 60$ s*, computed with* 20 *elements (solid),* 40 *elements* (−)*, and* 80 *elements* (+)*.*

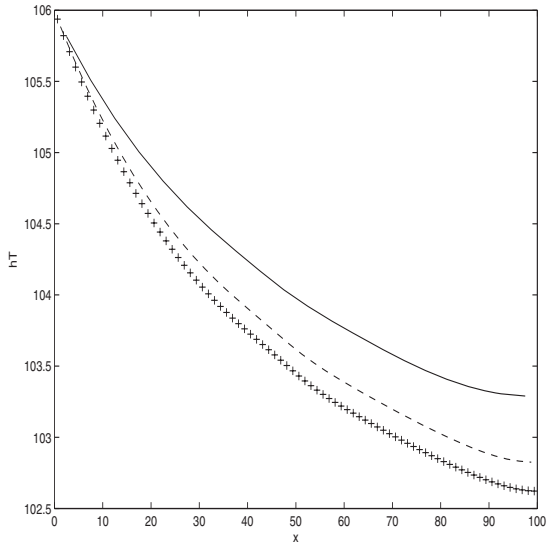

FIG. 7. *Surface water height* H_T *at* $t = 600$ s*, computed with* 20 *elements (solid),* 40 *elements* (−)*, and* 80 *elements* (+)*.*

in the surface water domain $0 < x < 100$ cm. The two finer discretizations of the domain have 40 and 80 elements in the interval, respectively. As seen in the figures, the solutions agree fairly well at the earlier time, but as time increases, the difference between the solutions also increases. The solutions with 40 and 80 elements are more similar, however, indicating that the surface water solution is starting to converge. These results suggest the need to further refine the mesh in the surface water domain, perhaps independently of the mesh used in the ground water domain. This issue will be explored further in future research.

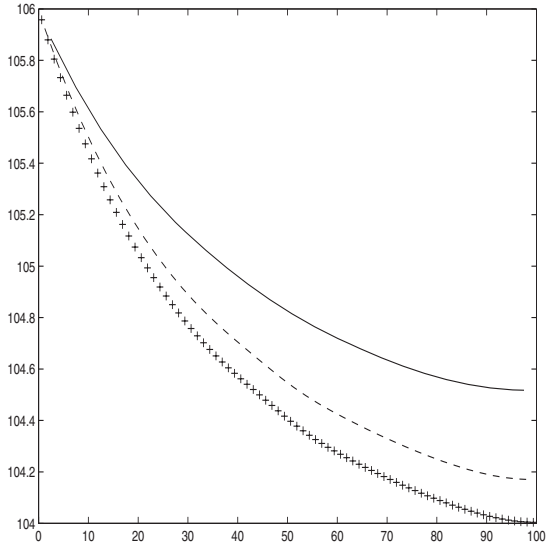

FIG. 8. *Surface water height H_T at $t = 1200$ s, computed with 20 elements (solid), 40 elements (−), and 80 elements (+).*

TABLE 1
Total ground water flux across Γ_{GS} for the three different meshes.

Mesh	Total flux
1	−360.01
2	−359.98
3	−359.99

As another check on the numerical solutions, we examined a "quantity of interest," namely, the total ground water flux across the interface Γ_{GS}. By setting $w_g \equiv 1$ in (20), we see that the true flux satisfies in this case

$$\int_0^T \int_{\Gamma_{GS}} \mathbf{u}_g \cdot \mathbf{n}_g ds dt = \int_0^T \int_{\Omega_g} f_g dx dt = \int_0^T \bar{f} dt = -.3T.$$

Our numerical solution $\boldsymbol{U}_g$ satisfies

$$\int_0^T \int_{\Gamma_{GS}} [\boldsymbol{U}_g \cdot \mathbf{n}_g + \sigma_g (H_g - H_T)] ds dt = \int_0^T \int_{\Omega_g} f_g dx dt.$$

In Table 1, we have computed

$$\int_0^T \int_{\Gamma_{GS}} \boldsymbol{U}_g \cdot \mathbf{n}_g ds dt$$

for the three meshes used to compute the solutions above with $T = 1200$. As observed in this table, the total flux agrees with the exact value of -360 to about five significant digits; the difference shows the effect of the penalty term $\sigma_g(H_g - H_T)$.

7. Conclusions. In this paper, we have analyzed DG and MFE methods for ground water/surface water coupling. The analysis gives the expected order of accuracy for the ground water velocity $\mathbf{u}_g$ and surface water velocity $\mathbf{u}_s$ but is suboptimal

for the ground water head h_g and the surface water height h_s. This appears to be unavoidable due to the coupling but deserves further study.

Our preliminary numerical results indicate that the ground water response to rapid changes in the surface water height is fairly slow, and one does not need to solve the ground water flow equations on the time scale of the surface water time step. Our results also suggest the need to use finer spatial discretization in the surface water domain than in the ground water domain. Numerical issues in temporal and spatial scaling which arise in these couplings will be the subject of future research, as will extensions to higher dimensions and to multiphase ground water flow.

CONVERGENCE OF AN IMPLICIT FINITE ELEMENT METHOD FOR THE LANDAU–LIFSHITZ–GILBERT EQUATION*

SÖREN BARTELS† AND ANDREAS PROHL‡

Abstract. The Landau–Lifshitz–Gilbert equation describes the dynamics of ferromagnetism, where strong nonlinearity and nonconvexity are hard to tackle: so far, existing explicit schemes to approximate weak solutions suffer from severe time-step restrictions. In this paper, we propose an implicit fully discrete scheme and verify unconditional convergence.

Key words. ferromagnetism, Landau–Lifshitz–Gilbert equation, nonconvexity, finite elements, convergence

DOI. 10.1137/050631070

1. Introduction.

The phenomenological Landau–Lifshitz–Gilbert equation (LLG) describes the dynamics of ferromagnetism; let $\alpha \geq 0$ denote the damping parameter, and then the magnetization $\mathbf{m} : (0,T)\times\Omega \to S^2$, for $S^2 = \{\mathbf{x} \in \mathbb{R}^3 | \, |\mathbf{x}| = 1\}$, solves

$$\mathbf{m}_t = -\alpha\, \mathbf{m} \times (\mathbf{m} \times \Delta\mathbf{m}) + \mathbf{m} \times \Delta\mathbf{m}\,, \tag{1.1}$$

supplemented by initial and boundary conditions, $\mathbf{m}(0) = \mathbf{m}_0 \in W^{1,2}(\Omega; S^2)$, and $\partial_{\mathbf{n}}\mathbf{m} = 0$ on $(0,T)\times\partial\Omega$. A proper definition of weak solutions is given below. Limiting equations are the Heisenberg equation ($\alpha \to 0$) and heat flow for harmonic maps ($\alpha \to \infty$) (see [1, Propositions 5.1, 5.2]):

$$\mathbf{m}_t = \mathbf{m} \times \Delta\mathbf{m} \quad (\alpha \to 0)\,, \qquad \mathbf{m}_t = \Delta\mathbf{m} + |\nabla\mathbf{m}|^2\mathbf{m} \quad (\alpha \to \infty)\,. \tag{1.2}$$

The construction of convergent schemes for (1.1) is a nontrivial task, due to the nonconvex side-constraint $|\mathbf{m}| = 1$ a.e. in $(0,T)\times\Omega$, which is difficult to realize in a numerical approximation scheme. Explicit time integrators of high order coupled with occasional updates to ensure the sphere constraint are common strategies in engineering literature but suffer from nonreliable dynamics [5]. Implicit strategies to discretize LLG in time often introduce artificial damping, which prevents computed iterates from remaining on the sphere and excludes a (discrete) energy law to hold to conclude convergence. Remedies have been made, partially addressing the dual requirements of efficiency and reliability: (i) projection methods have been constructed, which independently deal with the nonconvex algebraic constraint; however, no (discrete) energy principle is available, and convergence to LLG is known only in the case of existing classical/strong solutions to LLG (see [4, 10, 9]); (ii) explicit/implicit discretizations of Ginzburg–Landau penalizations that involve an additional parameter

$\varepsilon > 0$ are used [8, 9], which allow for a discrete energy principle, possibly for restricted choices of spatiotemporal discretization parameters; see [5]. We refer the reader to [7] for a recent review of mathematical ferromagnetism.

Recently, a first explicit scheme is proposed in [2], where also (weak sub-) convergence towards weak solutions is verified; this program is continued in [3], where $k = o\big(\alpha^2 h^{1+\frac{n}{2}}\big)$ is identified to be sufficient for stability and convergence; sharpness of these restrictions is evidenced by computational studies in [3]. From this background, we look for an implicit scheme exempt from restricting requirements for numerical parameters, and with higher flexibility with respect to (small) choices of $\alpha > 0$. The construction of our discretization is based on a reformulation of (1.1) by Gilbert (see, e.g., [7]),

$$\mathbf{m}_t + \alpha\, \mathbf{m} \times \mathbf{m}_t = (1+\alpha^2)\, \mathbf{m} \times \Delta \mathbf{m}\,.$$

Given the lowest order finite element space $\mathbf{V}_h \subset W^{1,2}(\Omega;\mathbb{R}^3)$ subordinate to a triangulation $\mathcal{T}_h$ of Ω and a time-step size $k > 0$, our approximation scheme reads as follows.

ALGORITHM 1.1. *Let* $\mathbf{m}_h^0 \in \mathbf{V}_h$. *Given* $j \geq 0$ *and* $\mathbf{m}_h^j \in \mathbf{V}_h$, *determine* $\mathbf{m}_h^{j+1} \in \mathbf{V}_h$ *from*

$$\begin{aligned}(d_t \mathbf{m}_h^{j+1}, \boldsymbol{\phi}_h)_h + \alpha\,(\mathbf{m}_h^j \times d_t \mathbf{m}_h^{j+1}, \boldsymbol{\phi}_h)_h \\ = (1+\alpha^2)(\overline{\mathbf{m}}_h^{j+1/2} \times \tilde{\Delta}_h \overline{\mathbf{m}}_h^{j+1/2}, \boldsymbol{\phi}_h)_h \quad \forall\, \boldsymbol{\phi}_h \in \mathbf{V}_h\,.\end{aligned}$$

Here $(\cdot,\cdot)_h$ denotes a discrete version (reduced integration) of the inner product in $L^2(\Omega;\mathbb{R}^3)$, $\tilde{\Delta}_h : W^{1,2}(\Omega;\mathbb{R}^3) \to \mathbf{V}_h$ is a discrete version of the Laplace operator, and we use $d_t\varphi^j := k^{-1}\big(\varphi^j - \varphi^{j-1}\big)$ for $j \geq 1$ and $\overline{\varphi}^{j+1/2} := \frac{1}{2}\big(\varphi^{j+1} + \varphi^j\big)$ for $j \geq 0$ and a sequence $\{\varphi^j\}_{j\geq 0}$; we refer the reader to section 2 for details.

REMARK 1.1. *The (linear) second term in Algorithm* 1.1 *is motivated by the identity*

$$\mathbf{m}_h^j \times d_t \mathbf{m}_h^{j+1} = \left(\overline{\mathbf{m}}_h^{j+1/2} - \frac{k}{2} d_t \mathbf{m}_h^{j+1}\right) \times d_t \mathbf{m}_h^{j+1} = \overline{\mathbf{m}}_h^{j+1/2} \times d_t \mathbf{m}_h^{j+1}\,.$$

It is well known that weak solutions to (1.1) solve

$$\mathbf{m}_t = \operatorname{div}\big(\mathbf{m} \times \nabla \mathbf{m}\big) + \alpha\big(\Delta \mathbf{m} + |\,\nabla \mathbf{m}\,|^2 \mathbf{m}\big)$$

in the distributional sense; cf. [1, 6]. Corresponding relations need not hold for discretizations, due to the competition of local and nonlocal aspects inherent to fully discrete finite element based methods. Lemma 6.1 below shows that solutions of Algorithm 1.1 satisfy

(1.3)
$$\begin{aligned}(d_t \mathbf{m}_h^{j+1}, \boldsymbol{\phi}_h)_h + \alpha\big(\nabla \overline{\mathbf{m}}_h^{j+1/2}, \nabla \boldsymbol{\phi}_h\big) = \alpha\big(|\,\nabla \overline{\mathbf{m}}_h^{j+1/2}\,|^2 \overline{\mathbf{m}}_h^{j+1/2}, \boldsymbol{\phi}_h\big) \\ - \big(\overline{\mathbf{m}}_h^{j+1/2} \times \nabla \overline{\mathbf{m}}_h^{j+1/2}, \nabla \boldsymbol{\phi}_h\big) + \mathrm{Corr}\end{aligned}$$

for all $\boldsymbol{\phi}_h \in \mathbf{V}_h$ and a correcting term "Corr".

Lemma 3.1 below states conservation of $|\,\mathbf{m}_h^j\,| = 1$ at the nodes of the triangulation $\mathcal{T}_h$ and verifies a discrete energy law for solutions to Algorithm 1.1. This indicates that the forcing correction term Corr serves to balance the damping effect of the implicit Euler method with employed reduced integration and local averaging

tools in Algorithm 1.1. The unconditional stability of Algorithm 1.1 allows us to prove subconvergence to a weak solution of (1.1).

The remainder of this paper is organized as follows. Preliminaries are stated in section 2. Our main result is Theorem 3.1, which verifies unconditional convergence for Algorithm 1.1; a simple fixed-point iteration is proposed in Algorithm 4.1, whose convergence is established for $k = \mathcal{O}(h^2)$, uniformly for values $\alpha \leq C$, in section 4. We discuss numerical experiments which motivate finite-time blow-up in section 5, allowing for direct comparison with results for values $\alpha = \mathcal{O}(1)$ in [3] and study of the limiting case $\alpha \to 0$. Section 6 proves (1.3) and illustrates difficulties in the construction of convergent implicit finite element schemes.

2. Preliminaries. Throughout this paper we assume that $\mathcal{T}_h$ is a quasi-uniform regular triangulation of the polygonal or polyhedral bounded Lipschitz domain $\Omega \subset \mathbb{R}^n$ into triangles or tetrahedra for $n = 2$ or $n = 3$, respectively. We define the lowest order finite element space $\mathbf{V}_h \subset W^{1,2}(\Omega;\mathbb{R}^3)$ by

$$\mathbf{V}_h = \left\{ \boldsymbol{\phi}_h \in C(\overline{\Omega};\mathbb{R}^3) : \boldsymbol{\phi}_h|_K \in \mathcal{P}_1(K;\mathbb{R}^3) \quad \forall\, K \in \mathcal{T}_h \right\},$$

where $\mathcal{P}_1(K;\mathbb{R}^3)$ denotes the set of polynomials of total degree less than or equal to one restricted to the element $K \in \mathcal{T}_h$. Given the set of nodes $\left\{ \mathbf{x}_\ell : \ell \in L \right\}$ of the triangulation $\mathcal{T}_h$, the nodal interpolation operator $\mathcal{I}_h : C(\overline{\Omega};\mathbb{R}^3) \to \mathbf{V}_h$ satisfies $\mathcal{I}_h\boldsymbol{\phi}(\mathbf{x}_\ell) = \boldsymbol{\phi}(\mathbf{x}_\ell)$ for all $\ell \in L$. Given functions $\mathbf{f}, \mathbf{g} \in L^2(\Omega;\mathbb{R}^m)$ and letting $\langle \cdot, \cdot \rangle$ denote the inner product in $\mathbb{R}^m$ we set

$$\big(\mathbf{f}, \mathbf{g}\big) = \int_\Omega \langle \mathbf{f}, \mathbf{g} \rangle \, \mathrm{d}\mathbf{x}\,.$$

For continuous functions $\boldsymbol{\phi}, \boldsymbol{\mathfrak{Z}} \in C(\overline{\Omega};\mathbb{R}^3)$ we define

$$\big(\boldsymbol{\phi},\, \boldsymbol{\mathfrak{Z}}\big)_h = \int_\Omega \mathcal{I}_h\big(\langle \boldsymbol{\phi}, \boldsymbol{\mathfrak{Z}} \rangle\big) \, \mathrm{d}\mathbf{x} = \sum_{\ell \in L} \beta_\ell \langle \boldsymbol{\phi}(\mathbf{x}_\ell), \boldsymbol{\mathfrak{Z}}(\mathbf{x}_\ell) \rangle$$

for certain weights $\beta_\ell > 0$, $\ell \in L$. If for each $\ell \in L$ we denote by $\varphi_\ell \in C(\overline{\Omega})$ the nodal basis function which is $\mathcal{T}_h$-elementwise affine and satisfies $\varphi_\ell(\mathbf{x}_\ell) = 1$ and $\varphi_\ell(\mathbf{x}_m) = 0$ for all $m \in L \setminus \{\ell\}$, then we have $\beta_\ell = \int_\Omega \varphi_\ell \, \mathrm{d}\mathbf{x}$. We define $||\boldsymbol{\phi}||_h^2 = \big(\boldsymbol{\phi},\, \boldsymbol{\phi}\big)_h$ and notice that

$$\| \boldsymbol{\phi}_h \|_{L^2}^2 \leq \| \boldsymbol{\phi}_h \|_h^2 \leq (n+2) \, \| \boldsymbol{\phi}_h \|_{L^2}^2$$

for all $\boldsymbol{\phi}_h \in V_h$. We define a discrete Laplace operator $\tilde{\Delta}_h : W^{1,2}(\Omega;\mathbb{R}^3) \to \mathbf{V}_h$ by

$$-(\tilde{\Delta}_h\boldsymbol{\phi}, \boldsymbol{\chi}_h)_h = (\nabla\boldsymbol{\phi}, \nabla\boldsymbol{\chi}_h) \quad \forall\, \boldsymbol{\chi}_h \in \mathbf{V}_h\,. \tag{2.1}$$

It is well known that there exists a constant $c_1 > 0$ such that for all $\boldsymbol{\phi}_h \in \mathbf{V}_h$ there holds

$$||\nabla\boldsymbol{\phi}_h||_{L^2} \leq c_1 h^{-1} ||\boldsymbol{\phi}_h||_{L^2}, \tag{2.2}$$

where h is the maximal mesh-size in $\mathcal{T}_h$, i.e., $h = \max\{\mathrm{diam}(K) : K \in \mathcal{T}_h\}$. Choosing $\boldsymbol{\chi}_h = \tilde{\Delta}_h\boldsymbol{\phi}_h$ in (2.1) and using (2.2) we observe that for all $\boldsymbol{\phi}_h \in \mathbf{V}_h$ there holds

$$||\tilde{\Delta}_h\boldsymbol{\phi}_h||_h^2 = -\big(\nabla\boldsymbol{\phi}_h, \nabla\tilde{\Delta}_h\boldsymbol{\phi}_h\big) \leq ||\nabla\boldsymbol{\phi}_h||_{L^2} ||\nabla\tilde{\Delta}_h\boldsymbol{\phi}_h||_{L^2} \leq c_1 h^{-1} ||\nabla\boldsymbol{\phi}_h||_{L^2} ||\tilde{\Delta}_h\boldsymbol{\phi}_h||_h. \tag{2.3}$$

Given $\boldsymbol{\phi}_h \in \mathbf{V}_h$ and a node $\mathbf{x}_\ell$ for some $\ell \in L$, we obtain from using $\boldsymbol{\chi}_h = \varphi_\ell \tilde{\Delta}_h \boldsymbol{\phi}_h(\mathbf{x}_\ell)$ in (2.1) that

$$
\begin{aligned}
|\tilde{\Delta}_h \boldsymbol{\phi}_h(\mathbf{x}_\ell)|^2 &= \beta_\ell^{-1} \big(\tilde{\Delta}_h \boldsymbol{\phi}_h, \boldsymbol{\chi}_h\big)_h = -\beta_\ell^{-1} \big(\nabla \boldsymbol{\phi}_h, \nabla \boldsymbol{\chi}_h\big) \\
&= -\beta_\ell^{-1} \sum_{\substack{m \in L : \exists K \in \mathcal{T}, \\ \mathbf{x}_m, \mathbf{x}_\ell \in K}} \langle \boldsymbol{\phi}_h(\mathbf{x}_m), \tilde{\Delta}_h \boldsymbol{\phi}_h(\mathbf{x}_\ell) \rangle (\nabla \varphi_m, \nabla \varphi_\ell) \\
&\le c_2 h^{-2} ||\boldsymbol{\phi}_h||_{L^\infty} |\tilde{\Delta}_h \boldsymbol{\phi}_h(\mathbf{x}_\ell)|,
\end{aligned} \tag{2.4}
$$

where we used (2.2), that given a node $\mathbf{x}_\ell$ the cardinality of the set $\{m \in L : \exists K, \mathbf{x}_m, \mathbf{x}_\ell \in K\}$ is bounded h-independently, and that $||\varphi_m||_{L^2} \le c \beta_\ell^{1/2}$ for all $m \in L$.

3. Unconditional convergence. We first recall the definition of a weak solution to LLG. Throughout this section we abbreviate $\Omega_T = (0,T) \times \Omega$.

DEFINITION 3.1. *Let $\mathbf{m}_0 \in W^{1,2}(\Omega; S^2)$; then $\mathbf{m}$ is called the weak solution to LLG if for all $T > 0$*

(1) *$\mathbf{m} \in W^{1,2}(\Omega_T; \mathbb{R}^3)$ such that $|\,\mathbf{m}\,| = 1$ a.e. in Ω_T;*

(2) *for all $\boldsymbol{\phi} \in C^\infty\big(\Omega_T; \mathbb{R}^3\big)$ there holds*

$$
\begin{aligned}
&\int_{\Omega_T} \langle \mathbf{m}_t, \boldsymbol{\phi} \rangle \, \mathrm{d}\mathbf{x}\mathrm{d}t + \alpha \int_{\Omega_T} \langle \mathbf{m} \times \mathbf{m}_t, \boldsymbol{\phi} \rangle \, \mathrm{d}\mathbf{x}\mathrm{d}t \\
&= \qquad -(1+\alpha^2) \int_{\Omega_T} \langle \mathbf{m} \times \nabla \mathbf{m}, \nabla \boldsymbol{\phi} \rangle \, \mathrm{d}\mathbf{x}\mathrm{d}t \,;
\end{aligned}
$$

(3) *$\mathbf{m}(0) = \mathbf{m}_0$ in the sense of traces;*

(4) *for almost all $T' \in (0,T)$ there holds*

$$
\frac{1}{2} \int_\Omega |\,\nabla \mathbf{m}(T')\,|^2 \, \mathrm{d}\mathbf{x} + \frac{\alpha}{1+\alpha^2} \int_{\Omega_{T'}} |\,\mathbf{m}_t\,|^2 \, \mathrm{d}\mathbf{x}\mathrm{d}t \le \frac{1}{2} \int_\Omega |\,\nabla \mathbf{m}_0\,|^2 \, \mathrm{d}\mathbf{x} \,.
$$

The following lemma provides discrete counterparts of (1) and (4). We remark that the well-posedness of Algorithm 1.1, i.e., the existence of a unique sequence $\{\mathbf{m}_h^j\}_{j \ge 0}$ that solves Algorithm 1.1, can be deduced from a classical argument; see, e.g., [1, sect. 3].

LEMMA 3.1. *Suppose that $|\mathbf{m}_h^0(\mathbf{x}_\ell)| = 1$ for all $\ell \in L$. Then the sequence $\{\mathbf{m}_h^j\}_{j \ge 0}$ produced by Algorithm 1.1 satisfies for all $j \ge 0$*

$$
\begin{aligned}
&\text{(i)} \quad |\,\mathbf{m}_h^{j+1}(\mathbf{x}_\ell)\,| = 1 \quad \forall \ell \in L \,, \\
&\text{(ii)} \quad \frac{1}{2} d_t \| \nabla \mathbf{m}_h^{j+1} \|_{L^2}^2 + \frac{\alpha}{1+\alpha^2} \| \, d_t \mathbf{m}_h^{j+1} \|_h^2 = 0 \,.
\end{aligned}
$$

Proof. Verification of (i) follows from choosing $\boldsymbol{\phi}_h = \varphi_\ell \overline{\mathbf{m}}_h^{j+1/2}(\mathbf{x}_\ell) \in \mathbf{V}_h$ for $\ell \in L$ in Algorithm 1.1. In order to verify (ii), we first choose $\boldsymbol{\phi}_h = -\tilde{\Delta}_h \overline{\mathbf{m}}_h^{j+1/2}$ and find

$$
\frac{1}{2} d_t \| \nabla \mathbf{m}_h^{j+1} \|_{L^2}^2 + \alpha \big(\overline{\mathbf{m}}_h^{j+1/2} \times d_t \mathbf{m}_h^{j+1}, \tilde{\Delta}_h \overline{\mathbf{m}}_h^{j+1/2}\big)_h = 0 \,.
$$

Choosing $\boldsymbol{\phi}_h = d_t \mathbf{m}_h^{j+1}$ yields

$$
\frac{\alpha}{1+\alpha^2} \| \, d_t \mathbf{m}_h^{j+1} \|_h^2 = \alpha \big(\overline{\mathbf{m}}_h^{j+1/2} \times \tilde{\Delta}_h \overline{\mathbf{m}}_h^{j+1/2}, d_t \mathbf{m}_h^{j+1}\big)_h .
$$

A combination of the two identities proves (ii) and completes the proof of the lemma. ∎

DEFINITION 3.2. *For* $\mathbf{x} \in \Omega$ *and* $t \in [t_j, t_{j+1})$ *define*

$$\mathbf{M}(t,\mathbf{x}) := \frac{t-t_j}{k}\mathbf{m}_h^{j+1}(\mathbf{x}) + \frac{t_{j+1}-t}{k}\mathbf{m}_h^{j}(\mathbf{x})\,,$$
$$\mathbf{M}^-(t,\mathbf{x}) := \mathbf{m}_h^{j}(\mathbf{x})\,, \quad \mathbf{M}^+(t,\mathbf{x}) := \mathbf{m}_h^{j+1}(\mathbf{x})\,, \quad \overline{\mathbf{M}}(t,\mathbf{x}) := \overline{\mathbf{m}}_h^{j+1/2}\,.$$

Given any $T' > 0$, (ii) in Lemma 3.1 may be rewritten as

$$\frac{1}{2}||\nabla \mathbf{M}^+(T')||_{L^2}^2 + \frac{\alpha}{1+\alpha^2}\int_0^{T'} ||\mathbf{M}_t||_h^2 \,\mathrm{d}t \le \frac{1}{2}||\nabla \mathbf{M}(0)||_{L^2}^2.$$

This bound yields the existence of some $\mathbf{m} \in W^{1,2}(\Omega_T;\mathbb{R}^3)$ which is the weak limit (as $k,h \to 0$) of a subsequence such that

$$\begin{gathered}\mathbf{M} \rightharpoonup \mathbf{m} \ \text{ in } W^{1,2}(\Omega_T,\mathbb{R}^3)\,,\\ \nabla\mathbf{M}^-,\, \nabla\mathbf{M}^+, \nabla\overline{\mathbf{M}} \rightharpoonup \nabla\mathbf{m} \ \text{ in } L^2(\Omega_T,\mathbb{R}^3)\,,\\ \mathbf{M}^-,\, \mathbf{M}^+,\, \overline{\mathbf{M}} \to \mathbf{m} \ \text{ in } L^2(\Omega_T,\mathbb{R}^3)\,.\end{gathered}$$

Since $|\,\mathbf{M}^-(t,\mathbf{x}_\ell)\,| = 1$ for every $\ell \in L$ and almost all $t \in (0,T)$, there holds for every $K \in \mathcal{T}_h$

$$\begin{aligned}\|\,|\,\mathbf{M}^-\,|^2 - 1\,\|_{L^2(K)} &\le Ch\,\|\,\nabla\big(|\,\mathbf{M}^-\,|^2-1\big)\,\|_{L^2(K)} = Ch\,\|\,2(\nabla\mathbf{M}^-)\mathbf{M}^-\,\|_{L^2(K)}\\ &\le 2Ch\,\|\,\nabla\mathbf{M}^-\,\|_{L^2(K)}\,,\end{aligned}$$

which implies $|\,\mathbf{M}^-\,| \to 1$ in $L^2(\Omega_T;\mathbb{R}^3)$, and hence $|\,\mathbf{m}\,| = 1$ a.e. in Ω_T. Algorithm 1.1 may be written as follows: taking $\boldsymbol{\phi}_h(t) := \mathcal{I}_h\boldsymbol{\phi}(t,\cdot)$, for $\boldsymbol{\phi} \in C^\infty(\Omega_T;\mathbb{R}^3)$, there holds

(3.1)
$$\int_0^T (\mathbf{M}_t,\boldsymbol{\phi}_h)_h\,\mathrm{d}t + \alpha\int_0^T (\mathbf{M}^-\times\mathbf{M}_t,\boldsymbol{\phi}_h)_h\,\mathrm{d}t = (1+\alpha^2)\int_0^T \big(\overline{\mathbf{M}}\times\tilde{\Delta}_h\overline{\mathbf{M}},\boldsymbol{\phi}_h\big)_h\,\mathrm{d}t\,.$$

Effects of reduced integration are controlled using the fact that for all $\boldsymbol{\chi}_h, \boldsymbol{\eta}_h \in \mathbf{V}_h$ there holds

$$|\,(\boldsymbol{\chi}_h,\boldsymbol{\eta}_h)_h - (\boldsymbol{\chi}_h,\boldsymbol{\eta}_h)\,| \le Ch\,\|\,\boldsymbol{\chi}_h\,\|_{L^2}\|\,\nabla\boldsymbol{\eta}_h\,\|_{L^2}.$$

This implies that for almost all $t \in (0,T)$ we have

$$\big|(\mathbf{M}_t,\boldsymbol{\phi}_h)_h - (\mathbf{M}_t,\boldsymbol{\phi}_h)\big| \le Ch\,\|\,\mathbf{M}_t\,\|_{L^2}\|\,\nabla\boldsymbol{\phi}_h\,\|_{L^2}$$

and allows us to prove that

$$\int_0^T (\mathbf{M}_t,\boldsymbol{\phi}_h)_h\,\mathrm{d}t \to \int_0^T (\mathbf{m}_t,\boldsymbol{\phi})\,\mathrm{d}t.$$

Using that for $\boldsymbol{\chi}_h \in \mathbf{V}_h$ and $\boldsymbol{\eta} \in C(\overline{\Omega};\mathbb{R}^3)$ there holds $(\boldsymbol{\chi}_h,\boldsymbol{\eta})_h = (\boldsymbol{\chi}_h,\mathcal{I}_h\boldsymbol{\eta})_h$, and employing a triangle inequality and standard estimates for nodal interpolation results in

$$\big|(\mathbf{M}_t,\mathbf{M}^-\times\boldsymbol{\phi}_h)_h - \big(\mathbf{M}_t,(\mathrm{Id}\pm\mathcal{I}_h)(\mathbf{M}^-\times\boldsymbol{\phi}_h)\big)\big| \le Ch\,\|\,\mathbf{M}_t\,\|_{L^2}\|\,\nabla(\mathbf{M}^-\times\boldsymbol{\phi}_h)\,\|_{L^2}\,.$$

This yields

$$\int_0^T (\overline{\mathbf{M}} \times \mathbf{M}_t, \boldsymbol{\phi}_h)_h \mathrm{d}t \to \int_0^T (\mathbf{m} \times \mathbf{m}_t, \boldsymbol{\phi}) \mathrm{d}t\,.$$

The only troublesome limit is for the last term in (3.1). We write

$$\begin{aligned}\big(\overline{\mathbf{M}} \times \tilde{\Delta}_h \overline{\mathbf{M}}, \boldsymbol{\phi}_h\big)_h &= (\overline{\mathbf{M}} \times \boldsymbol{\phi}_h, \tilde{\Delta}_h \overline{\mathbf{M}})_h = \big((\mathrm{Id} - \mathcal{I}_h)(\overline{\mathbf{M}} \times \boldsymbol{\phi}_h), \tilde{\Delta}_h \overline{\mathbf{M}}\big)_h \\ &\quad + \big(\nabla(\mathcal{I}_h - \mathrm{Id})(\overline{\mathbf{M}} \times \boldsymbol{\phi}_h), \nabla \overline{\mathbf{M}}\big) + \big(\nabla(\overline{\mathbf{M}} \times \boldsymbol{\phi}_h), \nabla \overline{\mathbf{M}}\big) =: I + II + III\,.\end{aligned}$$

Control of I uses the bound $\| \tilde{\Delta}_h \boldsymbol{\chi} \|_{L^2} \le c_1 h^{-1} \| \nabla \boldsymbol{\chi} \|_{L^2}$ and estimates for nodal interpolation

$$\begin{aligned} I &\le C h^2 h^{-1} \sum_{K \in \mathcal{T}_h} \| D^2(\overline{\mathbf{M}} \times \boldsymbol{\phi}_h) \|_{L^2(K)} \| \nabla \overline{\mathbf{M}} \|_{L^2(K)} \\ &\le C h \| \nabla \overline{\mathbf{M}} \|_{L^2} \| \nabla \boldsymbol{\phi}_h \|_{L^\infty} \| \nabla \overline{\mathbf{M}} \|_{L^2}\,.\end{aligned}$$

A similar argumentation proves

$$II \le C h \sum_{K \in \mathcal{T}_h} \| D^2\big(\overline{\mathbf{M}} \times \boldsymbol{\phi}_h\big) \|_{L^2(K)} \| \nabla \overline{\mathbf{M}} \|_{L^2(K)} \le C h \| \nabla \overline{\mathbf{M}} \|_{L^2} \| \nabla \boldsymbol{\phi}_h \|_{L^\infty} \| \nabla \overline{\mathbf{M}} \|_{L^2}.$$

We use that given any $\boldsymbol{\mathfrak{Z}}, \boldsymbol{\chi} \in W^{1,2}(\Omega; \mathbb{R}^3)$ there holds $\langle \nabla \boldsymbol{\mathfrak{Z}}, \nabla(\boldsymbol{\mathfrak{Z}} \times \boldsymbol{\chi}) \rangle = \langle \nabla \boldsymbol{\mathfrak{Z}}, \boldsymbol{\mathfrak{Z}} \times \nabla \boldsymbol{\chi} \rangle$ to verify

$$III = \big(\nabla(\overline{\mathbf{M}} \times \boldsymbol{\phi}_h), \nabla \overline{\mathbf{M}}\big) = \big(\overline{\mathbf{M}} \times \nabla \boldsymbol{\phi}_h, \nabla \overline{\mathbf{M}}\big).$$

A combination of the last four assertions shows

$$\int_0^T \big(\overline{\mathbf{M}} \times \tilde{\Delta}_h \overline{\mathbf{M}}, \boldsymbol{\phi}_h\big)_h \,\mathrm{d}t \to \int_0^T (\mathbf{m} \times \nabla \boldsymbol{\phi}, \nabla \mathbf{m})\,\mathrm{d}t = \int_0^T \big(\nabla(\mathbf{m} \times \boldsymbol{\phi}), \nabla \mathbf{m}\big)\,\mathrm{d}t\,.$$

This proves our main theorem.

THEOREM 3.1. *Suppose* $|\mathbf{m}_h^0(\mathbf{x}_\ell)| = 1$ *for all* $\ell \in L$, *and let* $\{\mathbf{m}_h^j\}_{j \ge 0}$ *solve Algorithm* 1.1. *Assume that* $\mathbf{m}_h^0 \to \mathbf{m}_0$ *in* $W^{1,2}(\Omega, \mathbb{R}^3)$ *for* $h \to 0$. *For* $k, h \to 0$ *there exists* $\mathbf{m} \in W^{1,2}(\Omega_T; \mathbb{R}^3)$ *such that* $\mathbf{M}$ *subconverges to* $\mathbf{m}$ *in* $W^{1,2}(\Omega_T, \mathbb{R}^3)$, *and* $\mathbf{m}$ *is a weak solution of LLG.*

4. Solving the nonlinear system. In the numerical experiments reported below we employ the following fixed-point iteration to solve the nonlinear system in Algorithm 1.1.

ALGORITHM 4.1. *Set* $\mathbf{m}_h^{j+1,0} := \mathbf{m}_h^j$ *and* $\ell := 0$.

(i) *Compute* $\mathbf{m}_h^{j+1,\ell+1} \in \mathbf{V}_h$ *such that for all* $\boldsymbol{\phi}_h \in \mathbf{V}_h$ *there holds*

(4.1)
$$\begin{aligned}\frac{1}{k}(\mathbf{m}_h^{j+1,\ell+1}, \boldsymbol{\phi}_h)_h + \frac{\alpha}{k}(\mathbf{m}_h^j \times \mathbf{m}_h^{j+1,\ell+1}, \boldsymbol{\phi}_h)_h - \frac{1+\alpha^2}{4}(\mathbf{m}_h^{j+1,\ell+1} \times \tilde{\Delta}_h \mathbf{m}_h^{j+1,\ell}, \boldsymbol{\phi}_h)_h \\ - \frac{1+\alpha^2}{4}(\mathbf{m}_h^{j+1,\ell+1} \times \tilde{\Delta}_h \mathbf{m}_h^j, \boldsymbol{\phi}_h)_h - \frac{1+\alpha^2}{4}(\mathbf{m}_h^j \times \tilde{\Delta}_h \mathbf{m}_h^{j+1,\ell+1}, \boldsymbol{\phi}_h)_h \\ = \frac{1}{k}(\mathbf{m}_h^j, \boldsymbol{\phi}_h)_h + \frac{1+\alpha^2}{4}(\mathbf{m}_h^j \times \tilde{\Delta}_h \mathbf{m}_h^j, \boldsymbol{\phi}_h)_h.\end{aligned}$$

(ii) *If* $||\mathbf{m}_h^{j+1,\ell+1} - \mathbf{m}_h^{j+1,\ell}||_h \le \varepsilon$, *then stop and set* $\mathbf{m}_h^{j+1} := \mathbf{m}_h^{j+1,\ell+1}$.
(iii) *Set* $\ell := \ell + 1$ *and go to* (i).

Setting $\varepsilon = 0$, the following lemma shows that the iteration converges, provided that $k \le ch^2/(1+\alpha^2)$ for an (h,k,α)-independent constant factor $c > 0$ that depends only on the geometry of $\mathcal{T}_h$.

LEMMA 4.1. *Suppose that* $|\mathbf{m}_h^j(\mathbf{x}_m)| \le c_3$ *for some* $c_3 > 0$ *and all* $m \in L$ *and that* $\gamma := \sqrt{5}(1+\alpha^2)c_1^2 c_3 h^{-2} k/4 < 1$. *Then for all* $\ell \ge 0$ *there exists a unique solution* $\mathbf{m}_h^{j+1,\ell+1}$ *to* (4.1). *For all* $\ell \ge 1$ *there holds*

$$||\mathbf{m}_h^{j+1,\ell+1} - \mathbf{m}_h^{j+1,\ell}||_h \le \Theta \frac{\gamma}{1-\gamma} ||\mathbf{m}_h^{j+1,\ell} - \mathbf{m}_h^{j+1,\ell-1}||_h, \tag{4.2}$$

provided that $\Theta := \frac{1+c_3\rho}{(1/c_3)-\rho} > 0$ *for* $\rho := (1+\alpha^2)c_2 k h^{-2}/4$. *Moreover, for all* $\ell \ge 0$ *and all* $\boldsymbol{\phi}_h \in \mathbf{V}_h$ *there holds*

$$\begin{aligned} &\big|(d_t \mathbf{m}_h^{j+1,\ell+1}, \boldsymbol{\phi}_h)_h \;+\; \alpha(\mathbf{m}_h^j \;\times\; d_t \mathbf{m}_h^{j+1,\ell+1}, \boldsymbol{\phi}_h)_h \\ &\qquad -(1 \;+\; \alpha^2)(\overline{\mathbf{m}}_h^{j+1/2,\ell+1} \;\times\; \tilde{\Delta}_h \overline{\mathbf{m}}_h^{j+1/2,\ell+1}, \boldsymbol{\phi}_h)_h\big| \\ &\le \Theta\sqrt{5}\frac{1+\alpha^2}{4} c_1^2 h^{-2} ||\mathbf{m}_h^{j+1,\ell+1} - \mathbf{m}_h^{j+1,\ell}||_h ||\boldsymbol{\phi}_h||_h, \end{aligned}$$

where $d_t \mathbf{m}_h^{j+1,\ell+1} = k^{-1}(\mathbf{m}_h^{j+1,\ell+1} - \mathbf{m}_h^j)$ *and* $\overline{\mathbf{m}}_h^{j+1/2,\ell+1} = \frac{1}{2}(\mathbf{m}_h^{j+1,\ell+1} + \mathbf{m}_h^j)$.

By the Banach fixed-point theorem, contraction property (4.2) implies for $|\,\mathbf{m}_h^j(\mathbf{x}_m)\,| = 1$ for all $m \in L$ the existence of a unique $\mathbf{m}_h^{j+1,*} \in \mathbf{V}_h$ which solves Algorithm 1.1 for $j' := j$, and thus again satisfies Lemma 3.1.

Proof. We abbreviate $\mu = (1+\alpha^2)/4$. For $\boldsymbol{\phi}_h = \mathbf{m}_h^{j+1,\ell+1}$ the left-hand side of (4.1) is bounded from below by

$$\begin{aligned} &\frac{1}{k}||\mathbf{m}_h^{j+1,\ell+1}||_h^2 - \mu(\mathbf{m}_h^j \times \tilde{\Delta}_h \mathbf{m}_h^{j+1,\ell+1}, \mathbf{m}_h^{j+1,\ell+1})_h \\ &\quad \ge \frac{1}{k}||\mathbf{m}_h^{j+1,\ell+1}||_h^2 - \mu||\mathbf{m}_h^j||_{L^\infty}||\tilde{\Delta}_h \mathbf{m}_h^{j+1,\ell+1}||_h ||\mathbf{m}_h^{j+1,\ell+1}||_h \\ &\quad \ge \left(\frac{1}{k} - \mu\sqrt{5}c_1^2 c_3 h^{-2}\right) ||\mathbf{m}_h^{j+1,\ell+1}||_h^2, \end{aligned}$$

where we used $||\mathbf{m}_h^j||_{L^\infty} \le c_3$ and $||\tilde{\Delta}_h \mathbf{m}_h^{j+1,\ell+1}||_h \le c_1^2\sqrt{5}h^{-2}||\mathbf{m}_h^{j+1,\ell+1}||_h$. Therefore, the bilinear form defined by the left-hand side of (4.1) is positive definite on $\mathbf{V}_h \times \mathbf{V}_h$ if $\gamma < 1$, and then (4.1) admits a unique solution. Let $m \in L$ be such that $||\mathbf{m}_h^{j+1,\ell}||_{L^\infty} = |\mathbf{m}_h^{j+1,\ell}(\mathbf{x}_m)|$. Choosing $\boldsymbol{\phi}_h = \varphi_m \mathbf{m}_h^{j+1,\ell}(\mathbf{x}_m)$ in the equation for $\mathbf{m}_h^{j+1,\ell}$ proves

$$\begin{aligned} \frac{1}{k}|\mathbf{m}_h^{j+1,\ell}(\mathbf{x}_m)|^2 &\le \mu|\mathbf{m}_h^j(\mathbf{x}_m)|\,|\tilde{\Delta}_h \mathbf{m}_h^{j+1,\ell}(\mathbf{x}_m)|\,|\mathbf{m}_h^{j+1,\ell}(\mathbf{x}_m)| \\ &\quad + \frac{1}{k}|\mathbf{m}_h^j(\mathbf{x}_m)|\,|\mathbf{m}_h^{j+1,\ell}(\mathbf{x}_m)| + \mu|\mathbf{m}_h^j(\mathbf{x}_m)|\,|\tilde{\Delta}_h \mathbf{m}_h^j(\mathbf{x}_m)|\,|\mathbf{m}_h^{j+1,\ell}(\mathbf{x}_m)| \\ &\le c_3\mu|\tilde{\Delta}_h \mathbf{m}_h^{j+1,\ell}(\mathbf{x}_m)|\,|\mathbf{m}_h^{j+1,\ell}(\mathbf{x}_m)| + c_3\frac{1}{k}|\mathbf{m}_h^{j+1,\ell}(\mathbf{x}_m)| \\ &\quad + c_3\mu|\tilde{\Delta}_h \mathbf{m}_h^j(\mathbf{x}_m)|\,|\mathbf{m}_h^{j+1,\ell}(\mathbf{x}_m)|. \end{aligned}$$

There holds $|\tilde{\Delta}_h \boldsymbol{\phi}_h(\mathbf{x}_m)| \le c_2 h^{-2}||\boldsymbol{\phi}_h||_{L^\infty}$ for all $\boldsymbol{\phi}_h \in \mathbf{V}_h$, and hence

$$||\mathbf{m}_h^{j+1,\ell}||_{L^\infty} \le \frac{1 + c_3 k\mu c_2 h^{-2}}{(1/c_3) - k\mu c_2 h^{-2}} = \Theta.$$

Subtraction of two subsequent equations in the fixed-point iteration yields

$$\begin{aligned}
&\frac{1}{k}(\mathbf{m}_h^{j+1,\ell+1}-\mathbf{m}_h^{j+1,\ell},\boldsymbol{\phi}_h)_h+\frac{\alpha}{k}(\mathbf{m}_h^{j}\times[\mathbf{m}_h^{j+1,\ell+1}-\mathbf{m}_h^{j+1,\ell}],\boldsymbol{\phi}_h)_h\\
&-\mu([\mathbf{m}_h^{j+1,\ell+1}-\mathbf{m}_h^{j+1,\ell}]\times\tilde\Delta_h\mathbf{m}_h^{j+1,\ell},\boldsymbol{\phi}_h)_h-\mu(\mathbf{m}_h^{j+1,\ell}\times\tilde\Delta_h[\mathbf{m}_h^{j+1,\ell}-\mathbf{m}_h^{j+1,\ell-1}],\boldsymbol{\phi}_h)_h\\
&-\mu([\mathbf{m}_h^{j+1,\ell+1}-\mathbf{m}_h^{j+1,\ell}]\times\tilde\Delta_h\mathbf{m}_h^{j},\boldsymbol{\phi}_h)_h-\mu(\mathbf{m}_h^{j}\times\tilde\Delta_h[\mathbf{m}_h^{j+1,\ell+1}-\mathbf{m}_h^{j+1,\ell}],\boldsymbol{\phi}_h)_h=0
\end{aligned}$$

for all $\boldsymbol{\phi}_h\in\mathbf{V}_h$. Choosing $\boldsymbol{\phi}_h:=\mathbf{m}_h^{j+1,\ell+1}-\mathbf{m}_h^{j+1,\ell}$ shows

$$\begin{aligned}
||\mathbf{m}_h^{j+1,\ell+1}-\mathbf{m}_h^{j+1,\ell}||_h&\le k\mu\Theta||\tilde\Delta_h[\mathbf{m}_h^{j+1,\ell}-\mathbf{m}_h^{j+1,\ell-1}]||_h\\
&\quad+c_3k\mu||\tilde\Delta_h[\mathbf{m}_h^{j+1,\ell+1}-\mathbf{m}_h^{j+1,\ell}]||_h.
\end{aligned}$$

Using $||\tilde\Delta_h\boldsymbol{\phi}_h||_h\le c_1^2\sqrt{5}h^{-2}||\boldsymbol{\phi}_h||_h$ for all $\boldsymbol{\phi}_h\in\mathbf{V}_h$ we deduce the first estimate of the lemma. In order to verify the second estimate we notice that owing to (4.1), $\mathbf{m}_h^j\times\mathbf{m}_h^j=0$, and the above estimate $||\mathbf{m}_h^{j+1,\ell+1}||_{L^\infty}\le\Theta$ there holds for all $\boldsymbol{\phi}_h\in\mathbf{V}_h$

$$\begin{aligned}
&(d_t\mathbf{m}_h^{j+1,\ell+1},\boldsymbol{\phi}_h)_h+\alpha(\mathbf{m}_h^{j}\times d_t\mathbf{m}_h^{j+1,\ell+1},\boldsymbol{\phi}_h)_h-\mu(\overline{\mathbf{m}}_h^{j+1/2,\ell+1}\times\tilde\Delta_h\overline{\mathbf{m}}_h^{j+1/2,\ell+1},\boldsymbol{\phi}_h)_h\\
&\quad=\frac{1}{k}(\mathbf{m}_h^{j+1,\ell+1},\boldsymbol{\phi}_h)_h-\frac{1}{k}(\mathbf{m}_h^{j},\boldsymbol{\phi}_h)_h\\
&\qquad+\frac{\alpha}{k}(\mathbf{m}_h^{j}\times\mathbf{m}_h^{j+1,\ell+1},\boldsymbol{\phi}_h)_h-\frac{\alpha}{k}(\mathbf{m}_h^{j}\times\mathbf{m}_h^{j},\boldsymbol{\phi}_h)_h\\
&\qquad-\ \mu(\mathbf{m}_h^{j+1,\ell+1}\times\tilde\Delta_h\mathbf{m}_h^{j+1,\ell+1},\boldsymbol{\phi}_h)_h-\mu(\mathbf{m}_h^{j+1,\ell+1}\times\tilde\Delta_h\mathbf{m}_h^{j},\boldsymbol{\phi}_h)_h\\
&\qquad-\mu(\mathbf{m}_h^{j}\times\tilde\Delta_h\mathbf{m}_h^{j+1,\ell+1},\boldsymbol{\phi}_h)_h-\mu(\mathbf{m}_h^{j}\times\tilde\Delta_h\mathbf{m}_h^{j},\boldsymbol{\phi}_h)_h\\
&\quad=\mu(\mathbf{m}_h^{j+1,\ell+1}\times\tilde\Delta_h\mathbf{m}_h^{j+1,\ell},\boldsymbol{\phi}_h)_h-\mu(\mathbf{m}_h^{j+1,\ell+1}\times\tilde\Delta_h\mathbf{m}_h^{j+1,\ell+1},\boldsymbol{\phi}_h)_h\\
&\quad\le\mu||\mathbf{m}_h^{j+1,\ell+1}||_{L^\infty}||\tilde\Delta_h(\mathbf{m}_h^{j+1,\ell}-\mathbf{m}_h^{j+1,\ell+1})||_h||\boldsymbol{\phi}_h||_h\\
&\quad\le\Theta\mu c_1^2\sqrt{5}h^{-2}||\mathbf{m}_h^{j+1,\ell}-\mathbf{m}_h^{j+1,\ell+1}||_h||\boldsymbol{\phi}_h||_h,
\end{aligned}$$

which completes the proof of the lemma. ∎

5. Numerical experiments. The implementation of Algorithms 1.1 and 4.1 was performed in MATLAB with an assemblation of the stiffness matrices in C. We set $\varepsilon=h^4$ for the termination criterion in Algorithm 4.1, and it terminated after at most five iterations in all of our experiments. The experiments are defined through the following example which is taken from [3].

EXAMPLE 5.1. *Let $\Omega=(-1/2,1/2)^2$, and let $\mathbf{m}_0:\Omega\to S^2$ be defined by*

$$\mathbf{m}_0(\mathbf{x})=\begin{cases}(0,0,-1) & \text{for } |\mathbf{x}|\ge 1/2,\\ \big(2\mathbf{x}A,A^2-|\mathbf{x}|^2\big)/\big(A^2+|\mathbf{x}|^2\big) & \text{for } |\mathbf{x}|\le 1/2,\end{cases}$$

where $A:=(1-2|\mathbf{x}|)^4/s$ for some $s>0$. The triangulations $\mathcal{T}_\ell$ used in the numerical simulations are defined through a positive integer ℓ and consist of $2^{2\ell+1}$ halved squares with edge length $h=2^{-\ell}$. Motivated by Lemma 4.1 we use $k=h^2/(10(1+\alpha^2))$. As discrete initial data we employ the nodal interpolant of $\mathbf{m}_0$; i.e., we set $\mathbf{m}^0=\mathcal{I}_{\mathcal{T}_\ell}\mathbf{m}_0$ in all experiments.

Figures 1 and 2 display snapshots of the numerical approximation provided by Algorithm 1.1 with $\alpha=1$, $s=1$, and $\ell=4$. The plots in Figure 1 display the first two components of the vector field $\mathbf{M}$ at the nodes of the triangulation (after an appropriate rescaling) and at various times. Figure 2 shows a zoom towards the

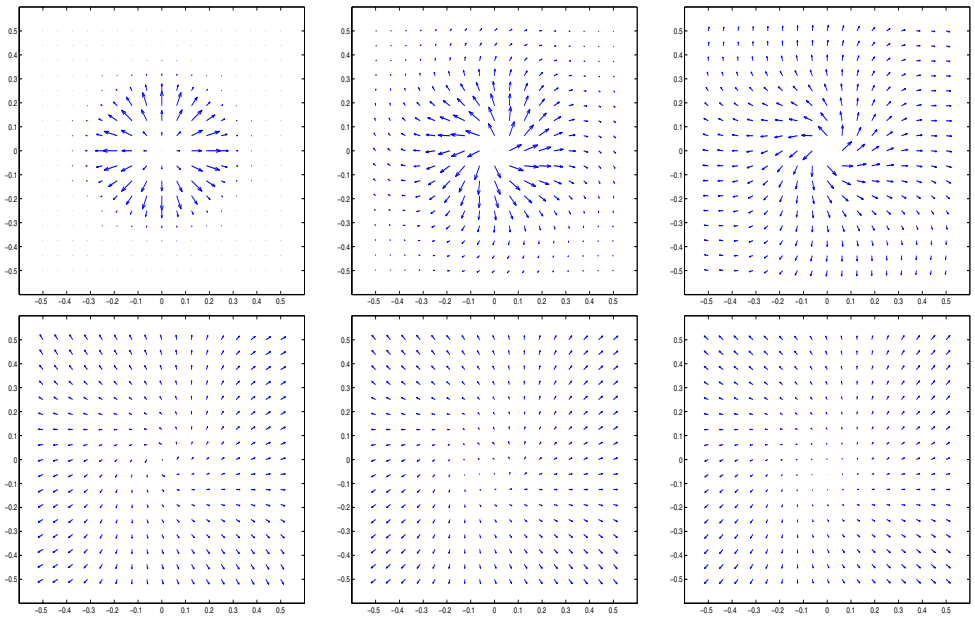

FIG. 1. *Numerical approximation* $\mathbf{M}(t,\cdot)$ *in Example* 5.1 *with* $s = 1$, $\ell = 4$, *and* $\alpha = 1$ *for* $t = 0, 0.0119, 0.0295, 0.0529, 0.0588, 0.0646$.

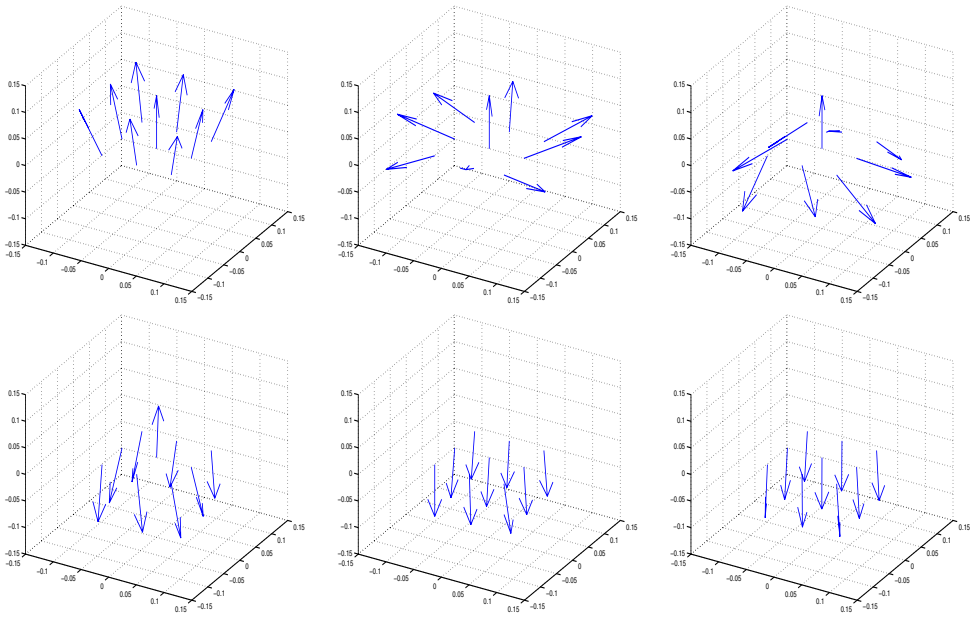

FIG. 2. *Nodal values* $\mathbf{M}(t,\mathbf{x}_m)$ *for nodes* $\mathbf{x}_m$ *close to the origin in Example* 5.1 *with* $s = 1$, $\ell = 4$, *and* $\alpha = 1$ *for* $t = 0, 0.0119, 0.0295, 0.0529, 0.0588, 0.0646$.

origin and reveals that in this experiment regularity of the exact solution cannot be expected. At time $t \approx 0.0529$ the vector at the origin points in another direction than all surrounding vectors, resulting in a large (maximal) $W^{1,\infty}$ norm.

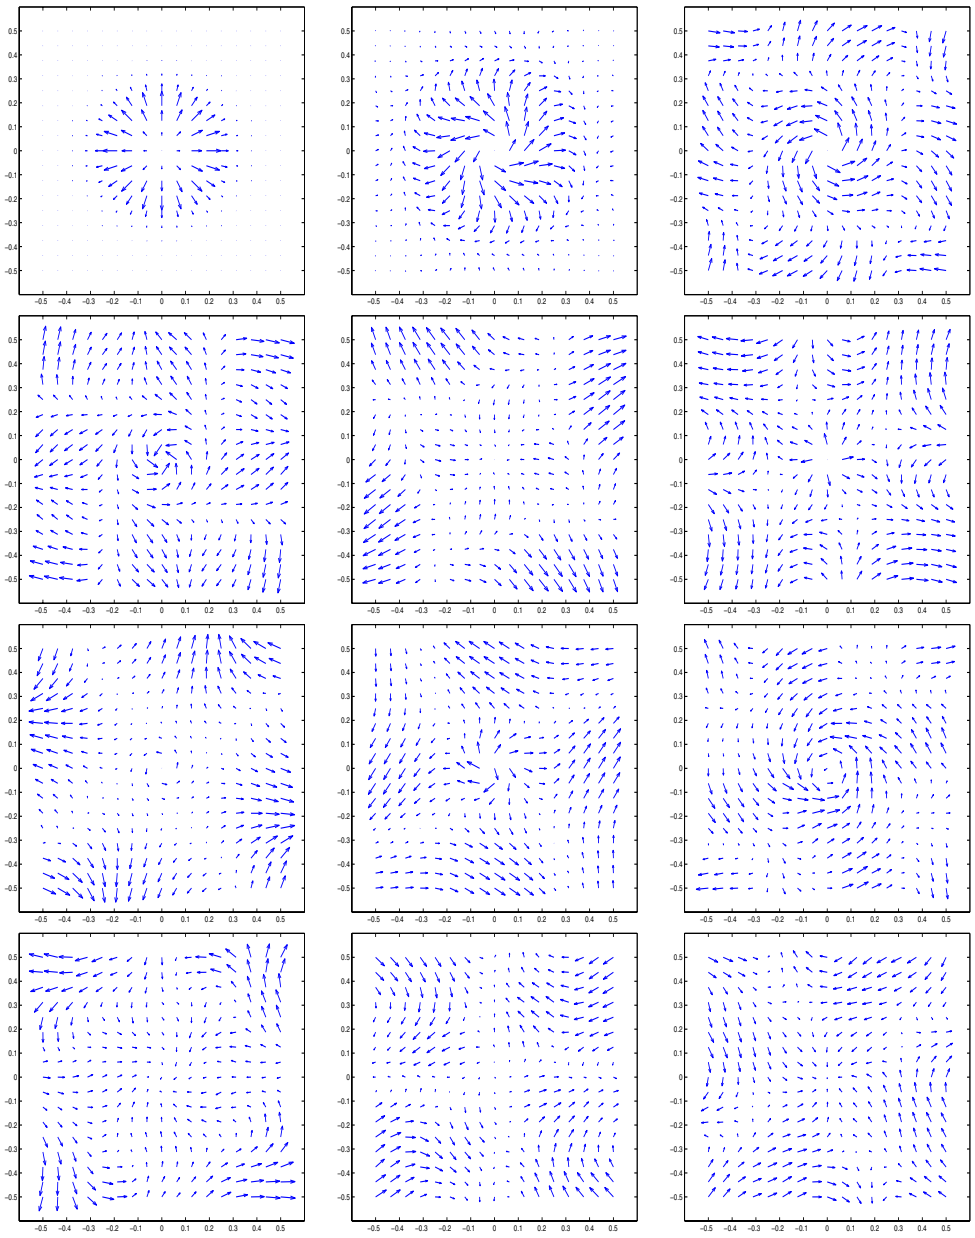

FIG. 3. *Numerical approximation* $\mathbf{M}(t,\cdot)$ *in Example* 5.1 *with* $s=1$, $\ell=4$, *and* $\alpha=1/64$ *for* $t=0,0.0102,0.0297,0.0492,0.0687,0.1078,0.1371,0.1664,0.2054,0.2347,0.2738,0.3031$.

Figures 3 and 4 show similar snapshots for $\alpha=1/64$, $s=1$, and $\ell=4$. Owing to the significantly smaller stabilization corresponding to the small value of α, the numerical solution is even less regular than in the previous experiment and fails to become stationary for times $t\leq 1/2$.

For fixed $\alpha=1$ and $s=4$ we used $\ell=4,5,6$ in Example 5.1. In Figure 5 we

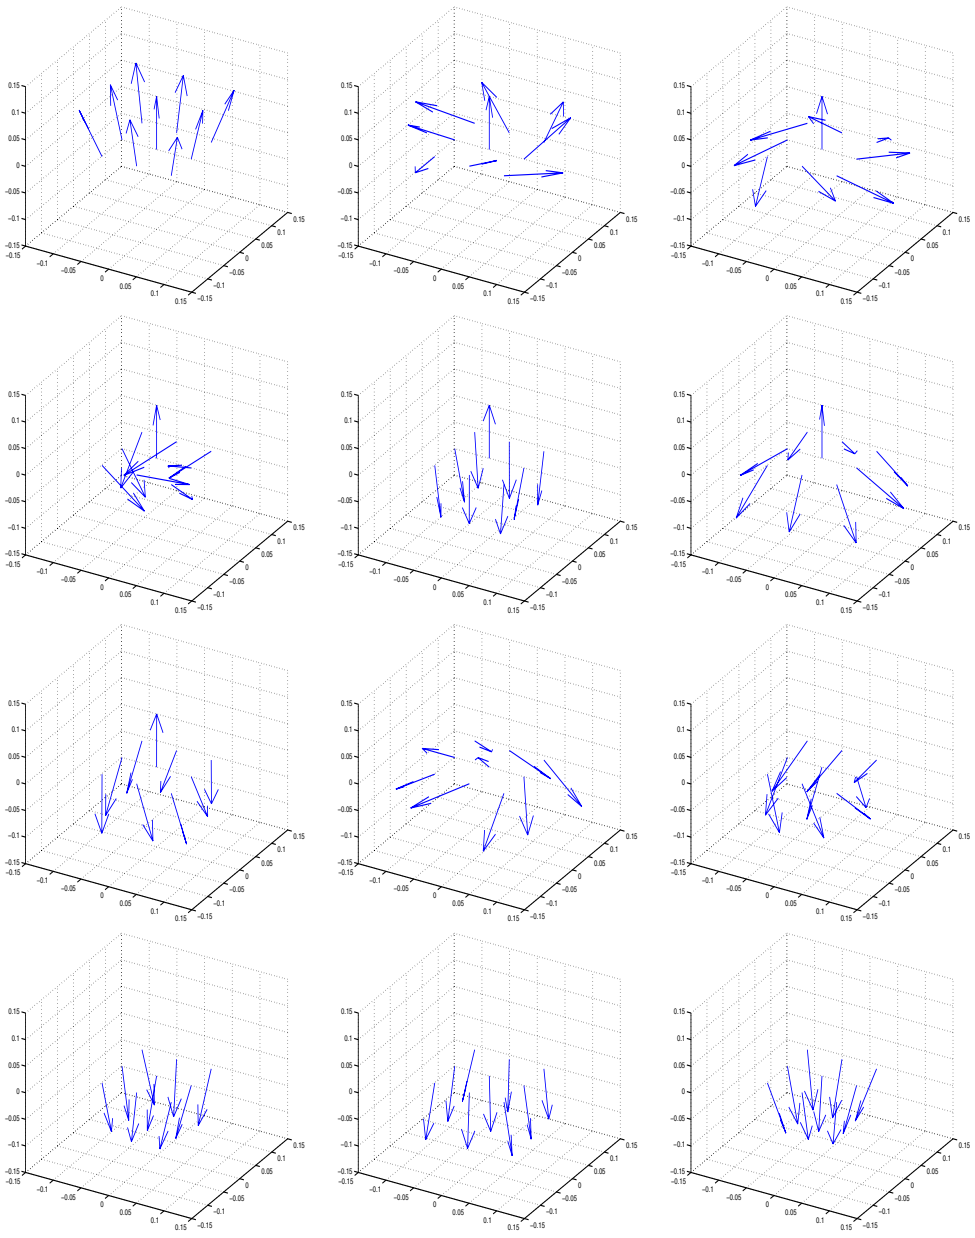

FIG. 4. *Nodal values* $\mathbf{M}(t, \mathbf{x}_m)$ *for nodes* $\mathbf{x}_m$ *close to the origin in Example* 5.1 *with* $s = 1$, $\ell = 4$, *and* $\alpha = 1/64$ *for* $t = 0, 0.0102, 0.0297, 0.0492, 0.0687, 0.1078, 0.1371, 0.1664, 0.2054, 0.2347, 0.2738, 0.3031$.

displayed the energy

$$E(\mathbf{M}(t)) = \frac{1}{2}\int_\Omega |\nabla \mathbf{M}(t,\cdot)|^2 \, \mathrm{d}\mathbf{x}$$

and the $W^{1,\infty}$ seminorm $|\mathbf{M}(t)|_{1,\infty} = ||\nabla \mathbf{M}(t)||_{L^\infty}$ as functions of t for $t \in (0, 6/100)$ for $\ell = 4, 5, 6$. For each $\ell = 4, 5, 6$ the function $t \to ||\nabla \mathbf{M}(t)||_{L^\infty}$ assumes the

maximum value $2\sqrt{2}h^{-1}$ (among functions $\boldsymbol{\phi}_h \in \mathbf{V}_h$ with $|\boldsymbol{\phi}_h(\mathbf{x}_m)| = 1$ for all nodes $\mathbf{x}_m$). We observe that for decreasing mesh-size h the blow-up time (the time at which $||\nabla \mathbf{M}(t)||_{L^\infty}$ assumes its maximum) approaches $t \approx 0.03$. In order to study the dependence of blow-up behavior on the parameter α we ran Algorithm 1.1 in Example 5.1 for fixed $\ell = 5$, $s = 1$ and for $\alpha = 1, 1/4, 1/16, 1/64, 1/256$. The plot in Figure 6 indicates that the blow-up time approaches the time $t \approx 0.06$ for decreasing α. The experimental values for $\alpha = 1/64$ and $\alpha = 1/256$ almost coincide.

We remark that the results of our experiments for $\alpha = 1, 1/4, 1/16$ are similar to the results obtained in [3] with an explicit scheme. The implicit scheme of this article allows us to use smaller values for α which lead to too restrictive conditions on the time step size for the explicit scheme of [3]. For the triangulations employed here and for $\alpha = 1$ the total runtimes of the explicit scheme (using reduced integration) and the implicit scheme are comparable. We stress, however, that for small values of α or three-dimensional problems the explicit scheme from [3] is of limited practical use.

6. Proof of (1.3).

LEMMA 6.1. *Assume that* $|\mathbf{m}_h^0(\mathbf{x}_\ell)| = 1$ *for all* $\ell \in L$, *and let* $\{\mathbf{m}_h^j\}_{j\geq 0}$ *solve Algorithm* 1.1. *There holds for all* $\boldsymbol{\phi}_h \in \mathbf{V}_h$

$$(d_t \mathbf{m}_h^{j+1}, \boldsymbol{\phi}_h)_h + \alpha\big(\nabla \overline{\mathbf{m}}_h^{j+1/2}, \nabla \boldsymbol{\phi}_h\big) = \alpha\big(|\nabla \overline{\mathbf{m}}_h^{j+1/2}|^2 \overline{\mathbf{m}}_h^{j+1/2}, \boldsymbol{\phi}_h\big) - \big(\overline{\mathbf{m}}_h^{j+1/2} \times \nabla \overline{\mathbf{m}}_h^{j+1/2}, \nabla \boldsymbol{\phi}_h\big) + \mathrm{Corr}$$

for a correcting term $\mathrm{Corr} = \mathrm{Corr_A} + \mathrm{Corr_B}$, *with*

$$\mathrm{Corr_A} := \frac{\alpha}{2}\big(\nabla|\overline{\mathbf{m}}_h^{j+1/2}|^2, \nabla\langle \overline{\mathbf{m}}_h^{j+1/2}, \boldsymbol{\phi}_h\rangle\big) + \frac{\alpha^2}{1+\alpha^2}\Big(d_t \mathbf{m}_h^{j+1}, [1 - |\overline{\mathbf{m}}_h^{j+1/2}|^2]\boldsymbol{\phi}_h\Big)_h + \alpha\Big(\nabla \overline{\mathbf{m}}_h^{j+1/2}, \nabla[(1 - |\overline{\mathbf{m}}_h^{j+1/2}|^2)\boldsymbol{\phi}_h]\Big),$$

and $\mathrm{Corr_B} = \sum_{i=1}^3 \mathrm{Corr_{B_i}}$ *given in the proof below.*

Proof. Given any $\boldsymbol{\mathfrak{Z}}_h \in \mathbf{V}_h$ choose $\boldsymbol{\phi}_h = \mathcal{I}_h(\overline{\mathbf{m}}_h^{j+1/2} \times \boldsymbol{\mathfrak{Z}}_h)$ in Algorithm 1.1; then the properties of $(\cdot,\cdot)_h$ imply

$$\big(\overline{\mathbf{m}}_h^{j+1/2} \times d_t \mathbf{m}_h^{j+1}, \boldsymbol{\mathfrak{Z}}_h\big)_h + \alpha\big(\overline{\mathbf{m}}_h^{j+1/2} \times (\overline{\mathbf{m}}_h^{j+1/2} \times d_t \mathbf{m}_h^{j+1}), \boldsymbol{\mathfrak{Z}}_h\big)_h = (1+\alpha^2)\big(\overline{\mathbf{m}}_h^{j+1/2} \times (\overline{\mathbf{m}}_h^{j+1/2} \times \tilde{\Delta}_h \overline{\mathbf{m}}_h^{j+1/2}), \boldsymbol{\mathfrak{Z}}_h\big)_h. \tag{6.1}$$

Owing to $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = \langle \mathbf{a}, \mathbf{c}\rangle \mathbf{b} - \langle \mathbf{a}, \mathbf{b}\rangle \mathbf{c}$ for all $\mathbf{a}, \mathbf{b}, \mathbf{c} \in \mathbb{R}^3$, the second term on the left-hand side in (6.1) may be rewritten as

$$\alpha\big(\langle \overline{\mathbf{m}}_h^{j+1/2}, d_t \mathbf{m}_h^{j+1}\rangle \overline{\mathbf{m}}_h^{j+1/2}, \boldsymbol{\mathfrak{Z}}_h\big)_h - \alpha\big(|\overline{\mathbf{m}}_h^{j+1/2}|^2 d_t \mathbf{m}_h^{j+1}, \boldsymbol{\mathfrak{Z}}_h\big)_h = \frac{\alpha}{2}\big((d_t|\mathbf{m}_h^{j+1}|^2)\overline{\mathbf{m}}_h^{j+1/2}, \boldsymbol{\mathfrak{Z}}_h\big)_h - \alpha\big(|\overline{\mathbf{m}}_h^{j+1/2}|^2 d_t \mathbf{m}_h^{j+1}, \boldsymbol{\mathfrak{Z}}_h\big)_h,$$

and the first term on the left-hand side vanishes owing to Lemma 3.1. We again use the above vector identity to recast the right-hand side of (6.1) as

$$(1+\alpha^2)\big(\langle \overline{\mathbf{m}}_h^{j+1/2}, \tilde{\Delta}_h \overline{\mathbf{m}}_h^{j+1/2}\rangle \overline{\mathbf{m}}_h^{j+1/2}, \boldsymbol{\mathfrak{Z}}_h\big)_h - (1+\alpha^2)\big(|\overline{\mathbf{m}}_h^{j+1/2}|^2 \tilde{\Delta}_h \overline{\mathbf{m}}_h^{j+1/2}, \boldsymbol{\mathfrak{Z}}_h\big)_h. \tag{6.2}$$

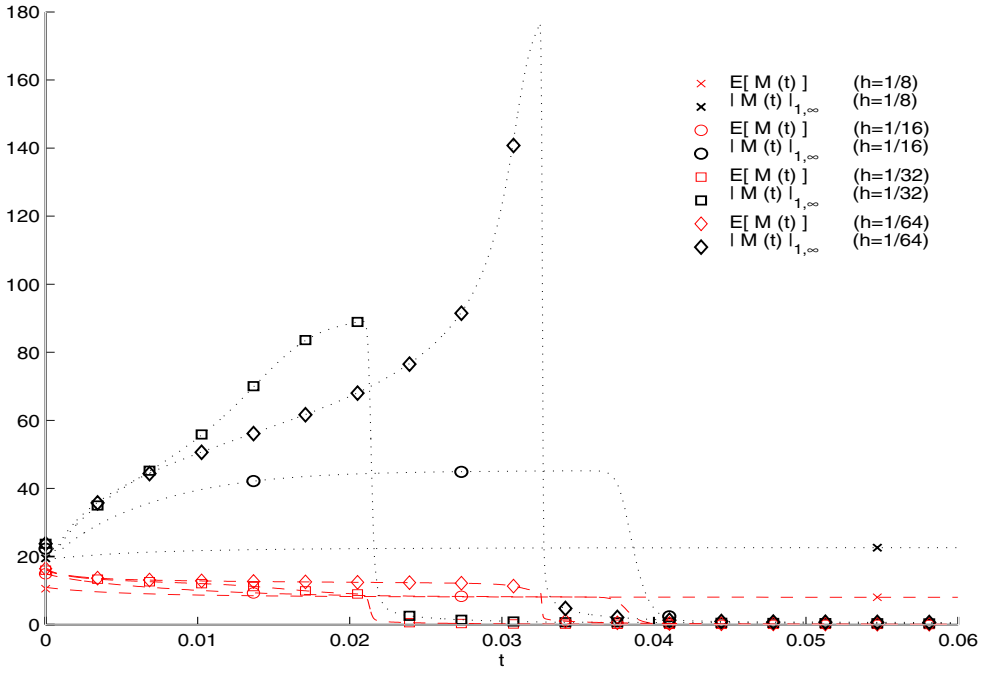

FIG. 5. *Energy and* $W^{1,\infty}$ *seminorm for decreasing mesh-sizes in Example* 5.1 *with* $\alpha = 1$ *and* $s = 4$.

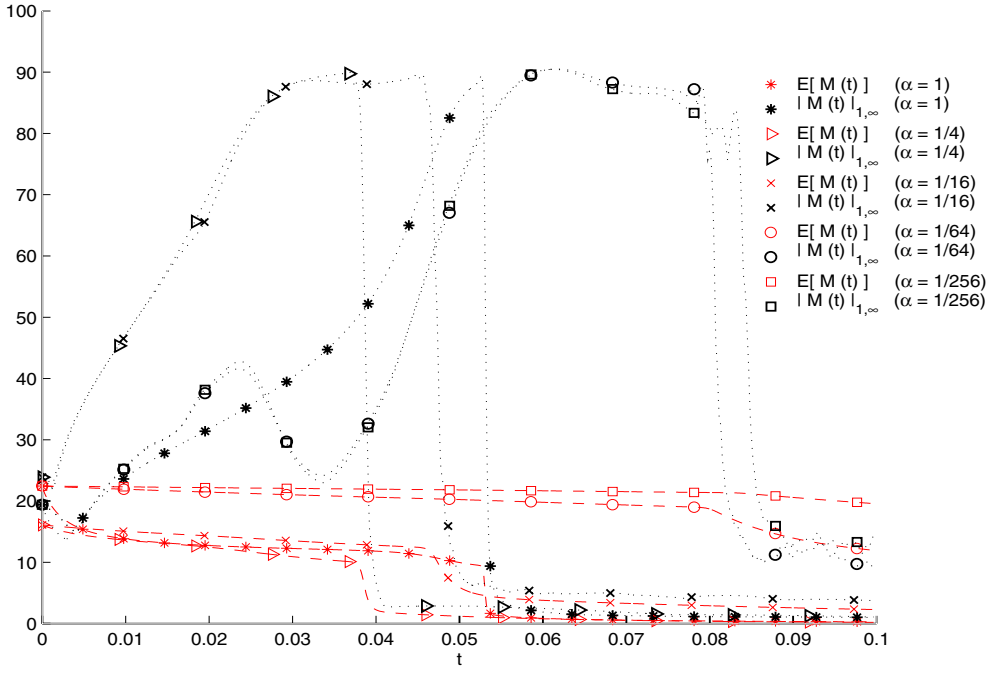

FIG. 6. *Energy and* $W^{1,\infty}$ *seminorm in Example* 5.1 *for* $\ell = 5$, $s = 1$, *and* $\alpha = 1, 1/4, 1/16, 1/64, 1/256$.

We proceed independently with arising two terms: intermitting the Lagrange interpolant for the nonlinear term in the first case to benefit from (2.1) yields

$$\begin{aligned}
&\Big(\big(\mathrm{Id}\pm\mathcal{I}_h\big)\big(\langle\overline{\mathbf{m}}_h^{j+1/2},\mathfrak{Z}_h\rangle\overline{\mathbf{m}}_h^{j+1/2}\big),\tilde{\Delta}_h\overline{\mathbf{m}}_h^{j+1/2}\big)\Big)_h\\
&\qquad=\Big(\big(\mathrm{Id}-\mathcal{I}_h\big)\big(\langle\overline{\mathbf{m}}_h^{j+1/2},\mathfrak{Z}_h\rangle\overline{\mathbf{m}}_h^{j+1/2}\big),\tilde{\Delta}_h\overline{\mathbf{m}}_h^{j+1/2}\big)\Big)_h\\
&+\Big(\nabla\big((\mathrm{Id}-\mathcal{I}_h)(\langle\overline{\mathbf{m}}_h^{j+1/2},\mathfrak{Z}_h\rangle\overline{\mathbf{m}}_h^{j+1/2})\big),\nabla\overline{\mathbf{m}}_h^{j+1/2}\Big)\\
&-\Big(\nabla\big(\langle\overline{\mathbf{m}}_h^{j+1/2},\mathfrak{Z}_h\rangle\overline{\mathbf{m}}_h^{j+1/2}\big),\nabla\overline{\mathbf{m}}_h^{j+1/2}\Big),
\end{aligned}$$

where the first two terms on the right-hand side are referred to as Corr_{B_1}. For the last term, we resume

$$\begin{aligned}
\big(\nabla\overline{\mathbf{m}}_h^{j+1/2},\nabla(\langle\overline{\mathbf{m}}_h^{j+1/2},\mathfrak{Z}_h\rangle\overline{\mathbf{m}}_h^{j+1/2})\big)&=\big(|\,\nabla\overline{\mathbf{m}}_h^{j+1/2}\,|^2\overline{\mathbf{m}}_h^{j+1/2},\mathfrak{Z}_h\big)\\
&\quad+\frac{1}{2}\big(\nabla|\,\overline{\mathbf{m}}_h^{j+1/2}\,|^2,\nabla\langle\overline{\mathbf{m}}_h^{j+1/2},\mathfrak{Z}_h\rangle\big).
\end{aligned}$$

Similarly, we account for effects of reduced integration and local averaging inherent to the scheme for the second term in (6.2),

$$\begin{aligned}
\Big(\big(\mathrm{Id}\pm\mathcal{I}_h\big)\big(|\,\overline{\mathbf{m}}_h^{j+1/2}\,|^2\mathfrak{Z}_h\big),\tilde{\Delta}_h\overline{\mathbf{m}}_h^{j+1/2}\Big)_h&=\Big(\big(\mathrm{Id}-\mathcal{I}_h\big)\big(|\,\overline{\mathbf{m}}_h^{j+1/2}\,|^2\mathfrak{Z}_h\big),\tilde{\Delta}_h\overline{\mathbf{m}}_h^{j+1/2}\Big)_h\\
+\Big(\nabla\big((\mathrm{Id}-\mathcal{I}_h)(|\,\overline{\mathbf{m}}_h^{j+1/2}\,|^2\mathfrak{Z}_h)\big),\nabla\overline{\mathbf{m}}_h^{j+1/2}\Big)&-\big(\nabla(|\,\overline{\mathbf{m}}_h^{j+1/2}\,|^2\mathfrak{Z}_h),\nabla\overline{\mathbf{m}}_h^{j+1/2}\big),
\end{aligned}$$

where the first two terms on the right-hand side are gathered in Corr_{B_2}. Finally, by Algorithm 1.1 and $\langle\mathbf{a}\times\mathbf{b},\mathbf{c}\rangle=-\langle\mathbf{a}\times\mathbf{c},\mathbf{b}\rangle$, the first term in (6.1) is identical to

$$\begin{aligned}
&-\frac{1}{\alpha}\big(d_t\mathbf{m}_h^{j+1},\mathfrak{Z}_h\big)_h+\frac{1+\alpha^2}{\alpha}\big(\overline{\mathbf{m}}_h^{j+1/2}\times\tilde{\Delta}_h\overline{\mathbf{m}}_h^{j+1/2},\mathfrak{Z}_h\big)_h\\
&\qquad=-\frac{1}{\alpha}\big(d_t\mathbf{m}_h^{j+1},\mathfrak{Z}_h\big)_h+\frac{1+\alpha^2}{\alpha}\big(\nabla(\overline{\mathbf{m}}_h^{j+1/2}\times\mathfrak{Z}_h),\nabla\overline{\mathbf{m}}_h^{j+1/2}\big)+\mathrm{Corr}_{B_3}
\end{aligned}$$

for $\mathrm{Corr}_{B_3}=-((\mathrm{Id}-\mathcal{I}_h)(\overline{\mathbf{m}}_h^{j+1/2}\times\mathfrak{Z}_h),\tilde{\Delta}_h\overline{\mathbf{m}}_h^{j+1/2})_h-(\nabla\big((\mathrm{Id}-\mathcal{I}_h)(\overline{\mathbf{m}}_h^{j+1/2}\times\mathfrak{Z}_h)\big),\nabla\overline{\mathbf{m}}_h^{j+1/2})$. Reassembling (6.1) then yields to

$$\begin{aligned}
\big((1+\alpha^2|\,\mathbf{m}_h^{j+1/2}\,|^2)d_t\mathbf{m}_h^{j+1},\mathfrak{Z}_h\big)_h&=(1+\alpha^2)\big(\nabla(\overline{\mathbf{m}}_h^{j+1/2}\times\mathfrak{Z}_h),\nabla\overline{\mathbf{m}}_h^{j+1/2}\big)\\
+\alpha(1+\alpha^2)\Big[\big(|\,\nabla\overline{\mathbf{m}}_h^{j+1/2}\,|^2\overline{\mathbf{m}}_h^{j+1/2},\mathfrak{Z}_h\big)&+\frac{1}{2}\big(\nabla|\,\overline{\mathbf{m}}_h^{j+1/2}\,|^2,\nabla\langle\overline{\mathbf{m}}_h^{j+1/2},\mathfrak{Z}_h\rangle\big)\\
-\big(\nabla\overline{\mathbf{m}}_h^{j+1/2},\nabla(|\,\overline{\mathbf{m}}_h^{j+1/2}\,|^2\mathfrak{Z}_h)\big)\Big]&+\alpha\Big(\mathrm{Corr}_{\mathrm{A}}+\big(1+\alpha^2\big)\,\mathrm{Corr}_{\mathrm{B}}\Big).
\end{aligned}$$

Rearranging terms then yields to the assertion. ∎

ANALYSIS OF A MULTISCALE DISCONTINUOUS GALERKIN METHOD FOR CONVECTION-DIFFUSION PROBLEMS*

A. BUFFA†, T. J. R. HUGHES‡, AND G. SANGALLI§

Abstract. We study a multiscale discontinuous Galerkin method introduced in [T. J. R. Hughes, G. Scovazzi, P. Bochev, and A. Buffa, *Comput. Meth. Appl. Mech. Engrg.*, 195 (2006), pp. 2761–2787] that reduces the computational complexity of the discontinuous Galerkin method, seemingly without adversely affecting the quality of results. For a stabilized variant we are able to obtain the same error estimates for the convection-diffusion equation as for the usual discontinuous Galerkin method. We assess the stability of the unstabilized case numerically and find that the inf-sup constant is positive, bounded uniformly away from zero, and very similar to that for the usual discontinuous Galerkin method.

Key words. multiscale, discontinuous Galerkin, convection-diffusion

1. Introduction.

The discontinuous Galerkin method has undergone rapid development in recent years (see, e.g., [10] and [9]). Although it has been shown to possess advantageous properties in a number of circumstances, its practical utility has been limited by the much larger number of degrees-of-freedom it requires compared with continuous Galerkin methods [13]. This problem has persisted since the inception of the method and has only been recently addressed with the development of a multiscale discontinuous Galerkin method [17] that has the computational structure and cost of a conforming method. The new method utilizes local, element-wise problems to develop a transformation between the parameterization of the discontinuous space and a related, smaller, continuous space. The transformation enables a direct construction of the global matrix problem in terms of the degrees-of-freedom of the continuous space. In the multiscale interpretation, the continuous field is viewed as the coarse scales, and the discontinuous field is viewed as the sum of the coarse and fine scales. The discontinuous part of the solution can be determined by elementwise postprocessing of the continuous solution. In [17] it was shown numerically that the new method at least retains the quality of the discontinuous Galerkin method, and in some instances improves upon it, while at the same time it has the potential to significantly reduce computational cost. A more general framework encompassing the ideas is presented in [3].

In this paper we initiate the mathematical analysis of the method developed in [17]. In section 2 we present the boundary-value problem under consideration,

namely, convection-diffusion, and give general definitions necessary for subsequent developments. In section 3 we introduce a discontinuous Galerkin (DG) method that employs interior penalty stabilization and allows for symmetric, neutral, and skew-symmetric treatment of element interface terms corresponding to the diffusion operator. We also introduce a stabilized variant (SDG) that accounts for control of the streamline derivative on element interiors. The DG method is shown to be coercive with respect to the norm induced by its bilinear form, referred to as the DG-norm, and, likewise, the SDG method is shown to be coercive with respect to the SDG-norm induced by its bilinear form. However, the DG-norm is weak in that, in the convective limit, it controls only jumps on element interfaces. In [11], convergence of the DG method in the DG-norm was proved by utilizing the L^2-interpolant, circumventing the need for a stronger stability condition. Here we prove that the DG method is inf-sup stable with respect to the SDG-norm, and this enables us to prove its convergence in the SDG-norm by standard means.

In section 4 we present the multiscale generalizations of DG and SDG, referred to as MDG and SMDG, respectively. We define the local, elementwise problems, which amount to the DG method on individual elements with weakly enforced boundary conditions specified by the shared degrees-of-freedom of the continuous representation, and we define the "interscale transfer spaces" which emanate from the solutions of the local problems. The MDG and SMDG methods amount to the DG and SDG methods in interscale transfer spaces. We prove the inf-sup stability of the local problems in term of the SDG-norm, without streamline-derivative stabilization in the local problems. We also establish the approximation properties of the interscale transfer spaces. With these, and the fact that SDG is coercive on the discontinuous space, we are able to prove convergence and establish the same error estimates for SMDG as for SDG (and DG). Thus, the behavior of the SMDG method is completely understood. This is not the case for the easier MDG method. Indeed, the convergence proof for MDG poses an additional obstacle, namely, DG is inf-sup stable with respect to the SDG-norm on the entire discontinuous space but not necessarily inf-sup stable on the interscale transfer subspace. This problem remains open. However, a numerical assessment of the situation is made in section 5, where the inf-sup constant is calculated for a class of boundary-value problems over a range of convection and diffusion parameters, and on structured meshes. For the cases considered, we find that the MDG method is inf-sup stable with respect to the SDG-norm, and the values of the inf-sup constant are very similar to those for the DG method. These results are consistent with the numerical evaluations performed in [17]. We also assess the stability behavior of the methods in terms of the interior penalty parameter and confirm that MDG behaves in a similar fashion to DG. Results for SMDG are analogous to those for MDG and thus are omitted for brevity. Conclusions are drawn in section 6.

2. Preliminaries.

2.1. Problem description. Let Ω be a bounded *polygonal* domain in $\mathbb{R}^{n_{\mathrm{d}}}$. The strong form of the boundary value problem we are interested in is the following:

$$\begin{aligned} -\kappa\Delta\phi + \boldsymbol{a}\cdot\nabla\phi &= f \quad \text{in } \Omega, \\ \phi &= g \quad \text{on } \Gamma, \end{aligned} \tag{2.1}$$

where $\kappa \geq 0$ is the diffusion coefficient, $\boldsymbol{a}$ is the solenoidal velocity vector field defined on $\overline{\Omega}$, and $\Gamma = \partial\Omega$ is the boundary on which Dirichlet conditions are imposed. More general boundary conditions may be considered as well; see [15] and [17]. We

assume that the values of the diffusion coefficient κ and the velocity field $\boldsymbol{a}$ ensure wellposedness of (2.1). Additional assumptions on these coefficients will be set later.

2.2. General definitions. We introduce the following partition of the boundary:

$$\Gamma^- = \{x \in \Gamma : \boldsymbol{a}(x) \cdot \boldsymbol{n}(x) \leq 0\}, \tag{2.2}$$

$$\Gamma^+ = \{x \in \Gamma : \boldsymbol{a}(x) \cdot \boldsymbol{n}(x) > 0\}, \tag{2.3}$$

where $\boldsymbol{n}$ is the outward unit normal with respect to Γ. Γ^- will be referred to as the *inflow* boundary and Γ^+ as the *outflow* boundary.

Let $\{\mathcal{T}_h\}_h$ be a family of partitions of Ω into elements T. Each $\mathcal{T}_h$ is assumed to be *admissible* in the sense of Ciarlet [8], and *shape regular* (i.e., the elements verify a minimum angle condition, uniformly with respect to h). The elements $T \in \mathcal{T}_h$ are either triangles/quadrilaterals in two dimensions or tetrahedra/hexahedra in three dimensions. Let h_T denote the diameter of T and $h = \max_{T\in\mathcal{T}_h} h_T$. We denote by $\mathcal{E}_h$ the set of all edges of $\mathcal{T}_h$ (*including* edges on the boundary Γ) and by $\mathcal{E}_h^o$ the set of internal edges (*excluding* edges on the boundary Γ) and, by abuse of notation, we denote by Γ both the boundary $\partial\Omega$ and the collection of edges lying on it.

We also define a partition of the element boundary ∂T:

$$\Gamma_T^- = \{x \in \partial T : \boldsymbol{a}(x) \cdot \boldsymbol{n}(x) \leq 0\}, \tag{2.4}$$

$$\Gamma_T^+ = \{x \in \partial T : \boldsymbol{a}(x) \cdot \boldsymbol{n}(x) > 0\}. \tag{2.5}$$

Here $\Gamma_T^{\mp}$ represent the element inflow/outflow boundary, respectively, so that $\partial T = \Gamma_T = \Gamma_T^+ \cup \Gamma_T^-$.

In order to derive a discontinuous Galerkin formulation, following [1], *jumps* and *averages* for scalar and vector fields have to be defined on the edges in $\mathcal{E}_h$. Therefore, consider an interior edge $e \in \mathcal{E}_h^o$, and denote by T^+ and T^-, respectively, the downwind and upwind elements that share it, and by $\boldsymbol{n}^+$ and $\boldsymbol{n}^-$ their respective outward-pointing unit normals. Given a scalar field ν, possibly discontinuous across e, we set $\nu^{\pm} = \nu|_{T^{\pm}}$ on e and define

$$\langle \nu \rangle = \frac{1}{2}(\nu^+ + \nu^-) \qquad [\![\nu]\!] = \nu^+\boldsymbol{n}^+ + \nu^-\boldsymbol{n}^-. \tag{2.6}$$

Analogously, for a vector field $\boldsymbol{\tau}$ we set $\boldsymbol{\tau}^{\pm} = \boldsymbol{\tau}|_{T^{\pm}}$ on e and define

$$\langle \boldsymbol{\tau} \rangle = \frac{1}{2}(\boldsymbol{\tau}^+ + \boldsymbol{\tau}^-) \qquad [\![\boldsymbol{\tau}]\!] = \boldsymbol{\tau}^+ \cdot \boldsymbol{n}^+ + \boldsymbol{\tau}^- \cdot \boldsymbol{n}^-. \tag{2.7}$$

The previous definitions are specialized on the edges on Γ as

$$\langle \nu \rangle = \nu, \qquad [\![\nu]\!] = \nu\ \boldsymbol{n}, \qquad \langle \boldsymbol{\tau} \rangle = \boldsymbol{\tau}, \qquad \forall e \in \Gamma. \tag{2.8}$$

We will extensively make use of the following *biased* identity (based on [1, Formula (3.3)]):

$$\begin{aligned} \sum_{T\in\mathcal{T}_h} \int_{\Gamma_T} \boldsymbol{\tau}\cdot\boldsymbol{n}\ \nu = \sum_{e\in\mathcal{E}_h^o} \left(\int_e \nu^{\pm} [\![\boldsymbol{\tau}]\!] + \int_e [\![\nu]\!] \cdot \boldsymbol{\tau}^{\mp} \right) \\ + \sum_{e\in\Gamma} \int_e \nu\ \boldsymbol{\tau}\cdot\boldsymbol{n}. \end{aligned} \tag{2.9}$$

In what follows, C is a constant, possibly different at each occurrence, which is independent of h and of the coefficients κ and $\boldsymbol{a}$. Moreover, $\alpha \lesssim \beta$ means $\alpha \leq C\beta$, while $\alpha \sim \beta$ means $\alpha \lesssim \beta$ and $\beta \lesssim \alpha$.

We suppose that κ and $\boldsymbol{a}$ are constant on each element $T \in \mathcal{T}_h$. We make use of the following notation: $\kappa_T = \kappa|_T$, $\boldsymbol{a}_T = \boldsymbol{a}|_T$, and $a_T = |\boldsymbol{a}_T|$. Finally, we assume that for any pair of elements T^+ and T^- sharing an edge,

$$\kappa_{T^+} \sim \kappa_{T^-}. \tag{2.10}$$

3. The discontinuous Galerkin method.

3.1. Method description. Given a positive index k, the following approximation space is introduced:

$$V_h = \{v \in L^2(\Omega) : v|_T \in \mathcal{P}^k(T), \quad \forall T \in \mathcal{T}_h\}, \tag{3.1}$$

where $\mathcal{P}^k(T)$ is the space of polynomials of degree at most k supported on T.

A possible DG formulation for (2.1) is as follows: find $\phi^{DG} \in V_h$ such that

$$B^{DG}(\phi^{DG}, \mu) = L^{DG}(g, f; \mu) \qquad \forall\, \mu \in V_h, \tag{3.2}$$

where

$$\begin{aligned} B^{DG}(\nu, \mu) = &- \sum_{T \in \mathcal{T}_h} \int_T \boldsymbol{\nabla}\mu \cdot (\boldsymbol{a}\nu - \kappa \boldsymbol{\nabla}\nu) \\ &+ \sum_{e \in \mathcal{E}_h^o} \int_e \left([\![\mu]\!] \cdot (\boldsymbol{a}\nu^- - \kappa^- \nabla \nu^-) + s\kappa^- \nabla \mu^- [\![\nu]\!] \right) \\ &+ \sum_{e \in \Gamma} \int_e s\kappa \nabla \mu \cdot \boldsymbol{n} \nu - \kappa \nabla \nu \cdot \boldsymbol{n} \mu \\ &+ \sum_{e \in \Gamma^+} \int_e \mu\nu \boldsymbol{a} \cdot \boldsymbol{n} + \varepsilon \sum_{e \in \mathcal{E}_h} \int_e \frac{\langle \kappa \rangle}{h_\perp} [\![\mu]\!] \cdot [\![\nu]\!], \end{aligned}$$

and

$$\begin{aligned} L^{DG}(g, f; \mu) = &\int_\Omega \mu f + \sum_{e \in \Gamma} \left(\varepsilon \int_e \frac{\langle \kappa \rangle}{h_\perp} \mu g + \int_e s\kappa \nabla \mu \cdot \boldsymbol{n} g \right) \\ &- \sum_{e \in \Gamma^-} \int_e \boldsymbol{a} \cdot \boldsymbol{n} \mu g; \end{aligned}$$

s is either -1, 0, or 1 (corresponding to symmetric, neutral, and skew-symmetric interior penalty methods), and for each $e \in \mathcal{E}_h^o$, we set $h_\perp = \frac{|T^+| + |T^-|}{2\,|e|}$, while for $e \in \Gamma$ we set $h_\perp = \frac{|T|}{|e|}$.

Remark 3.1. Notice that on each internal edge $e \in \mathcal{E}_h^o$ the normal component of the velocity field $\boldsymbol{a}$ is continuous, owing to the assumption $\operatorname{div}(\boldsymbol{a}) = 0$.

It will be useful to write the bilinear form $B^{DG}(\cdot, \cdot)$ as a sum of two contributions: the "diffusive" part and the "convective" part:

$$B^{DG}(\nu, \mu) = B^{DG}_{\mathfrak{D}}(\nu, \mu) + B^{DG}_{\mathfrak{C}}(\nu, \mu), \tag{3.3}$$

where

$$B^{DG}_{\mathfrak{D}}(\nu,\mu) = \sum_{T\in\mathcal{T}_h}\int_T \boldsymbol{\nabla}\mu\cdot\kappa\boldsymbol{\nabla}\nu - \sum_{e\in\mathcal{E}_h^o}\int_e [\![\mu]\!]\cdot\kappa^-\nabla\nu^- + s\kappa^-\nabla\mu^-[\![\nu]\!] + \sum_{e\in\Gamma}\int_e s\kappa\nabla\mu\cdot\boldsymbol{n}\nu - \kappa\nabla\nu\cdot\boldsymbol{n}\mu + \varepsilon\sum_{e\in\mathcal{E}_h}\int_e \frac{\langle\kappa\rangle}{h_\perp}[\![\mu]\!]\cdot[\![\nu]\!], \tag{3.4}$$

$$B^{DG}_{\mathfrak{C}}(\nu,\mu) = \sum_{T\in\mathcal{T}_h} -\int_T \boldsymbol{\nabla}\mu\cdot\boldsymbol{a}\nu + \sum_{e\in\mathcal{E}_h^o}\int_e [\![\mu]\!]\cdot\boldsymbol{a}\nu^- + \sum_{e\in\Gamma^+}\int_e \mu\nu\boldsymbol{a}\cdot\boldsymbol{n}. \tag{3.5}$$

We also define the DG-norm

$$\|\nu\|^2_{DG} = \|\nu\|^2_{\mathfrak{D}} + \|\nu\|^2_{\mathfrak{C}}, \tag{3.6}$$

where

$$\begin{aligned}\|\nu\|^2_{\mathfrak{D}} &= \sum_{T\in\mathcal{T}_h}\left(\kappa_T|\nu|^2_{H^1(T)} + h_T^2\kappa_T|\nu|^2_{H^2(T)}\right) + \varepsilon\sum_{e\in\mathcal{E}_h}\left(h_\perp^{-1}\|\langle\kappa\rangle[\![\nu]\!]\|^2_{L^2(e)}\right),\\ \|\nu\|^2_{\mathfrak{C}} &= \sum_{e\in\mathcal{E}_h}\||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}[\![\nu]\!]\|^2_{L^2(e)}.\end{aligned} \tag{3.7}$$

The DG formulation is consistent: let ϕ be the solution of (2.1); then it is easy to verify that

$$B^{DG}(\phi,\mu) = L^{DG}(g,f;\mu) \qquad \forall\,\mu\in V_h.$$

As far as the stability is concerned, we first recall that the form $B^{DG}(\cdot,\cdot)$ is coercive with respect to the DG-norm, as stated in the next proposition.

PROPOSITION 3.2. *For each value of s, there exists positive $\bar\varepsilon$ such that, for all $\varepsilon > \bar\varepsilon$, there exists $\alpha_{DG} > 0$ such that $B^{DG}(\mu,\mu) \geq \alpha_{DG}\|\mu\|^2_{DG}$ for all $\mu\in V_h$. Moreover, α_{DG} is independent of the mesh-size h and the coefficients κ and $\boldsymbol{a}$.*

Proof. The coercivity of the convection term easily follows by integration by parts:

$$B^{DG}_{\mathfrak{C}}(\mu,\mu) \geq \frac{1}{2}\|\mu\|^2_{\mathfrak{C}}.$$

Moreover, analogously to the stability proof provided in [1], there exists $\bar\varepsilon$ such that, under the assumption $\varepsilon > \bar\varepsilon$, the coercivity of the diffusive term holds; that is,

$$B^{DG}_{\mathfrak{D}}(\mu,\mu) \geq \beta_1\|\mu\|^2_{\mathfrak{D}}. \tag{3.8}$$

Actually, when $s = 1$ (skew-symmetric case) the result holds for any $\varepsilon > 0$. ∎

The coercivity as given in Proposition 3.2 is enough to provide an estimate of the form

$$\|\phi - \phi^{DG}\|^2_{DG} \lesssim \sum_{T\in\mathcal{T}_h}\left[\left(a_T h_T^{2k+1} + \kappa_T h_T^{2k}\right)|\phi|^2_{H^{k+1}(T)}\right], \tag{3.9}$$

which can be obtained by reasoning as in [11], for example. On the other hand, if the convection dominates and the exact solution ϕ is smooth, the quantity $\|\phi - \phi^{DG}\|_{DG}$ is basically a measure of the jumps of the discrete solution. In this case the estimate (3.9) gives very little information on the error $\phi - \phi^{DG}$.

In order to improve the control of the error, we can add an SUPG (streamline-upwind Petrov–Galerkin) stabilization [7] to the DG formulation. Then, we set

$$B^{SDG}(\nu,\mu) = B^{DG}(\nu,\mu) + \sum_{T\in\mathcal{T}_h} \tau_T \int_T (\mathcal{L}_T\nu)(\boldsymbol{a}\cdot\nabla\mu), \tag{3.10}$$

$$L^{SDG}(g,f;\mu) = L^{DG}(g,f;\mu) + \sum_{T\in\mathcal{T}_h} \tau_T \int_T f(\boldsymbol{a}\cdot\nabla\mu), \tag{3.11}$$

where $\mathcal{L}_T\nu = -\kappa\Delta\nu + \boldsymbol{a}\cdot\nabla\nu$ on T and τ_T is a stabilization parameter. The combination of SUPG and DG formulations was first proposed in [18] for linear convection problems, and then in [22] for convection-diffusion problems. In particular, the method proposed in [22] is similar to the present one (the difference being that, in [22], only the convective flux is upwinded).

For the purpose of the error analysis, the required asymptotic behavior of τ_T is $\tau_T \sim \frac{h_T}{a_T}$ in the convection-dominated regime (i.e., when $\frac{\kappa_T}{h_T\,a_T} \lesssim 1$), and $\tau_T \sim \frac{h_T^2}{\kappa_T}$ in the diffusion-dominated regime (i.e., when $\frac{h_T a_T}{\kappa_T} \lesssim 1$). We simply set

$$\tau_T = \tau \min\left\{\frac{h_T}{a_T}, \frac{h_T^2}{\kappa_T}\right\}, \tag{3.12}$$

where τ is a positive real number at our disposal.

The SDG (*stabilized discontinuous Galerkin*) formulation reads as follows: find $\phi^{SDG} \in V_h$ such that

$$B^{SDG}(\phi^{SDG},\mu) = L^{SDG}(g,f;\mu) \qquad \forall\,\mu\in V_h. \tag{3.13}$$

For the theoretical analysis of the SDG scheme (3.13), we will need the SDG-norm

$$\|\nu\|_{SDG}^2 = \|\nu\|_{DG}^2 + \sum_{T\in\mathcal{T}_h} \tau_T \|\boldsymbol{a}\cdot\nabla\nu\|_{L^2(T)}^2 \tag{3.14}$$

and the related

$$|\!|\!|\nu|\!|\!|_{SDG}^2 = \|\nu\|_{SDG}^2 + \sum_{e\in\mathcal{E}_h^0} \||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}\nu^-\|_{L^2(e)}^2 + \sum_{T\in\mathcal{T}_h} \tau_T^{-1}\|\nu\|_{L^2(T)}^2. \tag{3.15}$$

It is immediate that the SDG formulation is consistent. Moreover, the problem (3.13) admits a unique solution under suitable assumptions, as a consequence of the following known result.

PROPOSITION 3.3. *For each value of s, there exist positive $\overline{\tau}$ and $\overline{\varepsilon}$ such that, for all $\tau < \overline{\tau}$ and $\varepsilon > \overline{\varepsilon}$, there exists $\alpha_{SDG} > 0$ such that*

$$B^{SDG}(\mu,\mu) \geq \alpha_{SDG}\|\mu\|_{SDG}^2 \qquad \forall\,\mu\in V_h, \tag{3.16}$$

where α_{SDG} is independent of the mesh-size h and the coefficients κ and $\boldsymbol{a}$. Moreover,

$$B^{SDG}(\nu,\mu) \lesssim |\!|\!|\nu|\!|\!|_{SDG}\|\mu\|_{SDG} \qquad \forall\,\nu\in V_h + H^1(\Omega)\,, \qquad \mu\in V_h. \tag{3.17}$$

Proof. We first note that, due to (3.12),

$$\sum_{T\in Th} \tau_T\|\kappa\Delta\mu\|_{L^2(T)}^2 \lesssim \sum_{T\in Th} \tau\kappa_T h_T^2 |\mu|_{H^2(T)}^2 \lesssim \|\mu\|_{\mathfrak{D}}^2. \tag{3.18}$$

Thanks to Proposition 3.2, when ε is greater than a suitable $\bar{\varepsilon}$ we have

$$B^{SDG}(\mu,\mu) \geq \alpha_{DG}\|\mu\|^2_{SDG} - \sum_{T\in\mathcal{T}_h} \tau_T \int_T (\kappa\Delta\mu)(\boldsymbol{a}\cdot\nabla\mu).$$

By the Cauchy–Schwarz inequality and (3.18), (3.16) is proved by choosing τ sufficiently small.

In order to prove (3.17), we proceed in a standard way as follows:

$$B^{SDG}(\nu,\mu) = B^{DG}_{\mathfrak{D}}(\nu,\mu) + B^{DG}_{\mathfrak{C}}(\nu,\mu) + \sum_{T\in\mathcal{T}_h} \tau_T \int_T (\boldsymbol{a}\cdot\nabla\mu)(\mathcal{L}_T\nu) = I + II + III.$$

We estimate the three terms separately. First, by reasoning similar to that of [1],

$$I = B^{DG}_{\mathfrak{D}}(\nu,\mu) \lesssim \|\nu\|_{\mathfrak{D}}\|\mu\|_{\mathfrak{D}}. \tag{3.19}$$

Second, by the Cauchy–Schwarz inequality,

$$\begin{aligned} II &= \sum_{T\in\mathcal{T}_h} -\int_T \boldsymbol{a}\cdot\nabla\mu\,\nu + \sum_{e\in\mathcal{E}^o_h}\int_e [\![\mu]\!]\cdot\boldsymbol{a}\nu^- + \sum_{e\in\Gamma^+}\int_e \mu\nu\boldsymbol{a}\cdot\boldsymbol{n} \\ &\lesssim \|\mu\|_{SDG}\left(\sum_{e\in\mathcal{E}^0_h\cup\Gamma^+} \||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}\nu^-\|^2_{L^2(e)} + \sum_{T\in\mathcal{T}_h}\tau_T^{-1}\|\nu\|^2_{L^2(T)}\right)^{1/2} \\ &\lesssim \|\mu\|_{SDG}|\!|\!|\nu|\!|\!|_{SDG}. \end{aligned} \tag{3.20}$$

Third, again by the Cauchy–Schwarz inequality, and by (3.18),

$$III = \sum_{T\in\mathcal{T}_h} \tau_T \int_T (\boldsymbol{a}\cdot\nabla\mu)(-\kappa\Delta\nu + \boldsymbol{a}\cdot\nabla\nu) \lesssim \|\mu\|_{SDG}\|\nu\|_{SDG}. \tag{3.21}$$ ∎

3.2. Error estimate. We first provide an error estimate for the SDG method (3.13).

PROPOSITION 3.4. *Let ϕ be the solution of* (2.1)*, and assume $\phi \in H^{k+1}(\Omega)$. Let ϕ^{SDG} be given by* (3.13)*. Under the assumption of Proposition* 3.3*, the following error estimate holds:*

$$\|\phi - \phi^{SDG}\|_{SDG} \lesssim \left(\sum_{T\in\mathcal{T}_h} \left(a_T h_T^{2k+1} + \kappa_T h_T^{2k}\right)|\phi|^2_{H^{k+1}(T)}\right)^{1/2}. \tag{3.22}$$

Proof. Let $\phi^I \in V_h$ be the usual nodal interpolant of ϕ. Using coercivity and continuity, and (3.16) and (3.17), together with consistency, we get

$$\begin{aligned} \alpha_{SDG}\|\phi^{SDG} - \phi^I\|^2_{SDG} &\leq B^{SDG}(\phi^{SDG} - \phi^I, \phi^{SDG} - \phi^I) \\ &= B^{SDG}(\phi - \phi^I, \phi^{SDG} - \phi^I) \\ &\lesssim |\!|\!|\phi - \phi^I|\!|\!|_{SDG}\|\phi^{SDG} - \phi^I\|_{SDG}. \end{aligned} \tag{3.23}$$

For the usual local estimates on the interpolation error $\phi - \phi^I$ we readily obtain

$$|\!|\!|\phi - \phi^I|\!|\!|_{SDG} \lesssim \left(\sum_{T\in\mathcal{T}_h} \left(\kappa_T h_T^{2k} + \tau_T a_T^2 h_T^{2k} + \tau_T^{-1} h_T^{2k+2} + \tau_T \kappa_T^2 h_T^{2k-2}\right)|\phi|^2_{H^{k+1}(T)}\right)^{1/2}.$$

When choosing the stabilization parameter τ_T according to (3.12), by direct comparison, we see that (3.22) follows. ∎

For the pure discontinuous Galerkin method (3.2), a suitable control on the streamline derivative can be obtained, as was first studied in [19] for the pure convection (scalar hyperbolic) equation. In the following result, we prove an inf-sup condition for the bilinear form $B^{DG}(\cdot,\cdot)$ with respect to the SDG-norm. This improves the stability result stated in Proposition 3.2.

THEOREM 3.5. *There exists $\bar{\varepsilon}$ such that for all $\varepsilon \geq \bar{\varepsilon}$,*

$$\inf_{\nu\in V_h} \sup_{\mu\in V_h} \frac{B^{DG}(\nu,\mu)}{\|\nu\|_{SDG}\|\mu\|_{SDG}} \geq \beta_{DG} > 0, \tag{3.24}$$

where β_{DG} is independent of h, κ, $\boldsymbol{a}$, and the domain.

Proof. Given $\nu \in V_h$, we choose $\mu = \nu + \gamma \sum_{T\in\mathcal{T}_h} \tau_T(\boldsymbol{a}\cdot\nabla\nu)_{|T} = \nu + \gamma\mu_2$, where γ is a positive parameter at our disposal. Note that $\mu \in V_h$, as the velocity field is piecewise constant on $\mathcal{T}_h$. We prove the following:

$$\|\mu\|_{SDG} \lesssim \|\nu\|_{SDG}, \tag{3.25}$$

$$B(\nu,\mu) \geq \beta\|\nu\|^2_{SDG}. \tag{3.26}$$

We start by proving (3.25). To this end, we need to estimate the different terms of $\|\mu_2\|_{SDG}$. Recall that, from (3.12),

$$\tau_T \leq \tau\frac{h_T^2}{\kappa_T} \tag{3.27}$$

and

$$\tau_T \leq \tau\frac{h_T}{a_T}. \tag{3.28}$$

Using (3.28) and a local inverse inequality, we have

$$\begin{aligned}\tau_T\|\boldsymbol{a}\cdot\nabla(\tau_T\,\boldsymbol{a}\cdot\nabla\nu)\|^2_{L^2(T)} &\leq \tau_T^3 a_T^2\|\nabla(\boldsymbol{a}\cdot\nabla\nu)\|^2_{L^2(T)}\\ &\leq (\tau C_{inv})^2\tau_T\|\boldsymbol{a}\cdot\nabla\nu\|^2_{L^2(T)},\end{aligned} \tag{3.29}$$

where C_{inv} is the constant of the local inverse inequality. From (3.29) we get

$$\sum_{T\in\mathcal{T}_h} \tau_T\|\boldsymbol{a}\cdot\nabla\mu_2\|^2_{L^2(T)} \lesssim \|\nu\|^2_{SDG}. \tag{3.30}$$

Consider an internal edge $e \in \mathcal{E}_h^o$, and denote by T^- and T^+ the adjacent upwind and downwind elements. We have

$$\begin{aligned}\|[\![\mu_2]\!]\|^2_{L^2(e)} &\lesssim \|\mu_{2|T^-}\|^2_{L^2(e)} + \|\mu_{2|T^+}\|^2_{L^2(e)}\\ &\leq \tau_{T^-}^2\|(\boldsymbol{a}\cdot\nabla\nu)_{|T^-}\|^2_{L^2(e)} + \tau_{T^+}^2\|(\boldsymbol{a}\cdot\nabla\nu)_{|T^+}\|^2_{L^2(e)}.\end{aligned} \tag{3.31}$$

Using the trace inequality,

$$\|\xi\|^2_{L^2(e)} \leq C_{tr}(h_T^{-1}\|\xi\|^2_{L^2(T)} + \|\xi\|_{L^2(T)}\|\nabla\xi\|_{L^2(T)}),$$

which holds for all $\xi \in H^1(T)$, and a local inverse inequality, we also have

$$\|(\boldsymbol{a}\cdot\nabla\nu)_{|T^\pm}\|^2_{L^2(e)} \leq C'_{inv}h_{T^\pm}^{-1}\|\boldsymbol{a}\cdot\nabla\nu\|^2_{L^2(T^\pm)}, \tag{3.32}$$

where $C'_{inv} = C_{tr}(1 + C_{inv})$. From (3.31) and (3.32) together with (3.28), we obtain

$$\||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}[\![\mu_2]\!]\|_{L^2(e)} \lesssim \tau_{T^+}^{1/2}\|\boldsymbol{a}\cdot\nabla\nu\|_{L^2(T^+)} + \tau_{T^-}^{1/2}\|\boldsymbol{a}\cdot\nabla\nu\|_{L^2(T^-)}.$$

Similarly, for a boundary edge $e \in \Gamma$, if $e \subset \Gamma_T$, then

$$\||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}[\![\mu_2]\!]\|_{L^2(e)} \lesssim \tau_T^{1/2}\|\boldsymbol{a}\cdot\nabla\nu\|_{L^2(T)}.$$

Summarizing, we have proved

$$\|\mu_2\|_{\mathfrak{C}}^2 \lesssim \sum_{T\in\mathcal{T}_h} \tau_T\|\boldsymbol{a}\cdot\nabla\nu\|_{L^2(T)}^2. \tag{3.33}$$

By the inverse inequality, as in (3.29), we have

$$\kappa_T\|\nabla\mu_2\|_{L^2(T)}^2 \le \kappa_T a_T^2\tau_T^2|\nu|_{H^2(T)}^2 \lesssim C_{inv}^2\kappa_T\|\nabla\nu\|_{L^2(T)}^2. \tag{3.34}$$

On the other hand, recalling (2.10), (3.31)–(3.32) implies that, for each $e \in \mathcal{E}_h^o$,

$$\frac{\langle\kappa\rangle}{h_\perp}\|[\![\mu_2]\!]\|_{L^2(e)}^2 \lesssim \kappa_{T^+}\|\nabla\nu\|_{L^2(T^+)}^2 + \kappa_{T^-}\|\nabla\nu\|_{L^2(T^-)}^2, \tag{3.35}$$

or, for $e \in \Gamma$,

$$\frac{\langle\kappa\rangle}{h_\perp}\|[\![\mu_2]\!]\|_{L^2(e)}^2 \lesssim \kappa_T\|\nabla\nu\|_{L^2(T)}^2. \tag{3.36}$$

This proves that

$$\|\mu_2\|_{\mathfrak{D}} \le C_{\mathfrak{D}}\|\nu\|_{\mathfrak{D}} \tag{3.37}$$

where $C_{\mathfrak{D}}$ is a constant independent of the mesh-size and the problem parameters. The bounds (3.30), (3.33), and (3.37) give $\|\mu_2\|_{SDG} \lesssim \|\nu\|_{SDG}$ and finally (3.25).

We turn now to the proof of (3.26). First of all, we have

$$B_{\mathfrak{C}}^{DG}(\nu,\nu) = \frac{1}{2}\sum_{e\in\mathcal{E}_h}\||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}[\![\nu]\!]\|_{L^2(e)}^2.$$

On the other hand, by integration by parts and (2.9),

$$B_{\mathfrak{C}}^{DG}(\nu,\mu_2) = \sum_{T\in\mathcal{T}_h}\left(\tau_T\int_T|\boldsymbol{a}\cdot\nabla\nu|^2 - \int_{\Gamma_T^-}\tau_T\,(\boldsymbol{a}\cdot\nabla\nu)^+\,[\![\boldsymbol{a}\nu]\!]\right), \tag{3.38}$$

and, using (3.32),

$$\begin{aligned}
\sum_{T\in\mathcal{T}_h}\int_{\Gamma_T^-}\tau_T\,(\boldsymbol{a}\cdot\nabla\nu)^+\,[\![\boldsymbol{a}\nu]\!] &\le \sum_{T\in\mathcal{T}_h}\tau_T\||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}(\boldsymbol{a}\cdot\nabla\nu)^+\|_{L^2(\Gamma_T^-)} \\
&\qquad\cdot\||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}[\![\nu]\!]\|_{L^2(\Gamma_T^-)} \\
&\le \frac{1}{2\lambda}\sum_{T\in\mathcal{T}_h}\tau_T^2\||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}(\boldsymbol{a}\cdot\nabla\nu)^+\|_{L^2(\Gamma_T^-)}^2 \\
&\quad + \frac{\lambda}{2}\sum_{T\in\mathcal{T}_h}\||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}[\![\nu]\!]\|_{L^2(\Gamma_T^-)}^2 \\
&\le \frac{\tau C'_{inv}}{2\lambda}\sum_{T\in\mathcal{T}_h}\tau_T\|\boldsymbol{a}\cdot\nabla\nu\|_{L^2(T)}^2 \\
&\quad + \frac{\lambda}{2}\sum_{e\in\mathcal{E}_h}\||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}[\![\nu]\!]\|_{L^2(e)}^2
\end{aligned}$$

for any $\lambda > 0$. Using these estimates, we have

$$
\begin{aligned}
B^{DG}_{\mathfrak{C}}(\nu,\mu) \geq & \left(1-\frac{\gamma\,\lambda}{2}\right)\sum_{e\in\mathcal{E}_h} \||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}[\![\nu]\!]\|^2_{L^2(e)} \\
& + \gamma\left(1-\frac{\tau C'_{inv}}{2\lambda}\right)\sum_{T\in\mathcal{T}_h}\tau_T\|\boldsymbol{a}\cdot\nabla\nu\|^2_{L^2(T)}.
\end{aligned}
\tag{3.39}
$$

For the estimation of the diffusion part $B^{DG}_{\mathfrak{D}}(\nu,\mu)$, we use coercivity (3.8), continuity (e.g., see (3.19)) of $B^{DG}_{\mathfrak{D}}(\cdot,\cdot)$, and the estimate (3.37) to obtain

$$
\begin{aligned}
B^{DG}_{\mathfrak{D}}(\nu,\mu) &= B^{DG}_{\mathfrak{D}}(\nu,\nu) + \gamma B^{DG}_{\mathfrak{D}}(\nu,\mu_2) \\
&\geq \beta_1\|\nu\|^2_{\mathfrak{D}} - \gamma\widetilde{\beta}_2\|\mu_2\|_{\mathfrak{D}}\|\nu\|_{\mathfrak{D}} \\
&\geq (\beta_1 - \gamma C_{\mathfrak{D}}\widetilde{\beta}_2)\|\nu\|^2_{\mathfrak{D}}.
\end{aligned}
\tag{3.40}
$$

Summing equations (3.39) and (3.40), and setting $\beta_2 = C_{\mathfrak{D}}\widetilde{\beta}_2$, we obtain

$$
\begin{aligned}
B^{DG}(\nu,\mu) \geq & (\beta_1-\gamma\beta_2)\|\nu\|^2_{\mathfrak{D}} \\
& + \left(1-\frac{\gamma\,\lambda}{2}\right)\sum_{e\in\mathcal{E}_h} \||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}[\![\nu]\!]\|^2_{L^2(e)} \\
& + \gamma\left(1-\frac{\tau C'_{inv}}{2\lambda}\right)\sum_{T\in\mathcal{T}_h}\tau_T\|\boldsymbol{a}\cdot\nabla\nu\|^2_{L^2(T)}.
\end{aligned}
$$

The theorem is then proved by choosing $\lambda = \tau C'_{inv}$ and $\gamma = \min\left\{\lambda^{-1}, \frac{\beta_1}{2\beta_2}\right\}$. ∎

Remark 3.6. Results analogous to those of Theorem 3.5 can be obtained for other DG formulations, such as the interior penalty method.

From Theorem 3.5 we deduce the following error estimate for the DG scheme.

COROLLARY 3.7. *Let ϕ be the solution of* (2.1), *and assume $\phi \in H^{k+1}(\Omega)$; let ϕ^{DG} be the solution of* (3.2). *We have*

$$
\|\phi-\phi^{DG}\|_{SDG} \lesssim \left(\sum_{T\in\mathcal{T}_h}\left(a_T h_T^{2k+1} + \kappa_T h_T^{2k}\right)|\phi|^2_{H^{k+1}(T)}\right)^{1/2}.
\tag{3.41}
$$

Proof. Let $\phi^I \in V_h$ be the nodal interpolant of ϕ and let $\zeta = \phi^{DG} - \phi^I$. Let $\mu \in V_h$ be a test function satisfying (3.25)–(3.26). Using consistency and Proposition 3.3,

$$
\begin{aligned}
\beta\|\zeta\|^2_{SDG} &\leq B^{DG}(\zeta,\mu) = B^{DG}(\phi-\phi^I,\mu) \\
&\lesssim |\!|\!|\phi-\phi^I|\!|\!|_{SDG}\|\mu\|_{SDG} \\
&\lesssim \left(\sum_{T\in\mathcal{T}_h}\left(a_T h_T^{2k+1} + \kappa_T h_T^{2k}\right)|\phi|^2_{H^{k+1}(T)}\right)^{1/2}\|\zeta\|_{SDG}.
\end{aligned}
$$

We deduce (3.41) by the triangle inequality. ∎

4. The multiscale discontinuous Galerkin method. In this section, we present a reduction technique, referred to as the MDG method, which was first introduced in [17]. Furthermore, a stabilized variant of this method, referred to as SMDG, will be introduced subsequently.

The main idea is the following: (i) Solve (3.2) or (3.13) on a suitable subspace of V_h preserving the stability and approximation properties; (ii) Use a multiscale paradigm and local problems to perform the elimination of degrees-of-freedom for both the test and trial spaces.

4.1. Method description. We introduce the spaces $\overline{V}_h = V_h \cap H^1(\Omega)$ and, for all $T \in \mathcal{T}_h$, $V_h(T) = V_h|_T$ (note that this is nothing other than the space of degree k polynomials on T). The *local problems* read as follows: for all $\bar{\nu} \in \overline{V}_h$, find $\nu \in V_h$ such that for all $T \in \mathcal{T}_h$,

$$b_T(\nu, \mu) = \ell_T(\bar{\nu}, f; \mu) \quad \forall\, \mu \in V_h(T), \tag{4.1}$$

where we have set

$$\begin{aligned} b_T(\nu,\mu) &= \int_T \kappa \nabla\nu\cdot\nabla\mu - \int_{\Gamma_T} (\kappa\nabla\nu\cdot\boldsymbol{n}\mu - s\kappa\boldsymbol{\nabla}\mu\cdot\boldsymbol{n}\nu) + \varepsilon\int_{\Gamma_T}\frac{\kappa}{h_\perp}\mu\nu \\ &\quad - \int_T \boldsymbol{\nabla}\mu\cdot\boldsymbol{a}\nu + \int_{\Gamma_T^+}(1+\delta)\,\mu\nu\boldsymbol{a}\cdot\boldsymbol{n}, \\ \ell_T(\bar{\nu}, f;\mu) &= -\int_{\Gamma_T^-}\mu\bar{\nu}\boldsymbol{a}\cdot\boldsymbol{n} + \delta\int_{\Gamma_T^+}\mu\bar{\nu}\boldsymbol{a}\cdot\boldsymbol{n} + \varepsilon\int_{\Gamma_T}\frac{\kappa}{h_\perp}\mu\bar{\nu} \\ &\quad + \int_{\Gamma_T} s\kappa\boldsymbol{\nabla}\mu\cdot\boldsymbol{n}\bar{\nu} + \int_T f\,\mu. \end{aligned} \tag{4.2}$$

Observe that (4.1) is a DG formulation for the local problem $\mathcal{L}_T\nu = f$ on T, with $\nu = \bar{\nu}$ on the boundary Γ_T. Comparing the local DG formulation (4.1) with the global DG formulation (3.2), notice that the former has an extra term, which depends on a new parameter $\delta > 0$. This new term is needed for implementation purposes (see [17]).

We denote by $\mathfrak{T}_h : \overline{V}_h \times L^2(\Omega) \to V_h$ the operator which associates to each $(\bar{\nu}, f) \in \overline{V}_h \times L^2(\Omega)$ the solution ν of the local problems (4.1) on each element $T \in \mathcal{T}_h$. The stability of (4.1), which is stated below (in Lemma 4.4), implies that the problems (4.1) admit unique solutions on each element $T \in \mathcal{T}_h$; that is, the operator $\mathfrak{T}_h$ is well defined. $\mathfrak{T}_h$ represents the "interscale transfer operator," and the associated "interscale transfer spaces" are the (affine) manifold

$$\mathfrak{T}_h(\overline{V}_h, f) = \left\{\mathfrak{T}_h(\bar{\nu}, f) \mid \bar{\nu} \in \overline{V}_h\right\}$$

and the (linear) manifold

$$\mathfrak{T}_h(\overline{V}_h, 0) = \left\{\mathfrak{T}_h(\bar{\nu}, 0) \mid \bar{\nu} \in \overline{V}_h\right\}.$$

With this notation, the MDG method reads as follows: find $\phi^{MDG} \in \mathfrak{T}_h(\overline{V}_h, f)$ such that

$$B^{DG}(\phi^{MDG}, \mu) = L^{DG}(g, f; \mu) \quad \forall \mu \in \mathfrak{T}_h(\overline{V}_h, 0). \tag{4.3}$$

Its stabilized version SMDG reads as follows: find $\phi^{SMDG} \in \mathfrak{T}_h(\overline{V}_h, f)$ such that

$$B^{SDG}(\phi^{SMDG}, \mu) = L^{SDG}(g, f; \mu) \quad \forall \mu \in \mathfrak{T}_h(\overline{V}_h, 0). \tag{4.4}$$

Notice that SMDG is an SUPG stabilization of MDG.

Remark 4.1. The spaces $\mathfrak{T}_h(\overline{V}_h, f)$ and $\mathfrak{T}_h(\overline{V}_h, 0)$ can be parameterized by means of the degrees-of-freedom of $\overline{V}_h$ lying on the "skeleton" $\Sigma = \cup_{e\in\mathcal{E}_h} e$.

Remark 4.2. The *MDG* method can be interpreted as a multiscale technique (see [4, 12, 14, 16]). Both trial and test discontinuous functions $\nu \in V_h$ can be split into a continuous *coarse* scale $\bar{\nu}$ plus a discontinuous *fine* scale $\nu' = \nu - \bar{\nu}$. Performing integration by parts in (4.1), we find that ν' satisfies

$$b_T(\nu', \mu) = \int_T (f - \mathcal{L}_T\bar{\nu})\mu \quad \forall \mu \in V_h(T). \tag{4.5}$$

Equation (4.5) suggests a relationship between the MDG approach and the *RFB* (residual-free bubble) approach (see, e.g., [5, 6, 21]). Consider, for the sake of simplicity, the case of lowest order approximation $k = 1$. Actually ν' in (4.5) can be understood as the DG approximation of the *exact* residual-free bubble ν^{bubble}, which satisfies $\mathcal{L}_T\nu^{bubble} = f - \mathcal{L}_T\bar{\nu}$ on T, with $\nu^{bubble} = 0$ on the boundary ∂T. A DG approximation of the *exact* residual-free bubble has also been used in the *DB* (*discontinuous bubble*) implementation of the RFB formulation (see [20]). The major difference between MDG and DB is that for the latter the space of test functions was $\overline{V}_h$ instead of $\mathfrak{T}_h(\overline{V}_h, 0)$. The relation between these two approaches deserves further investigation.

4.2. Approximation properties of $\mathfrak{T}_h(\overline{V}_h, f)$. The first step in the analysis of problems (4.3) and (4.4) is the study of the approximation properties of the interscale transfer affine space $\mathfrak{T}_h(\overline{V}_h, f)$.

THEOREM 4.3 (approximation). *Let ϕ be the solution of* (2.1); *then there exists $\nu \in \mathfrak{T}_h(\overline{V}_h, f)$ such that*

$$\|\!|\phi - \nu|\!\|_{SDG} \lesssim \left(\sum_{T\in\mathcal{T}_h} \left(a_T h_T^{2k+1} + \kappa_T h_T^{2k} \right) |\phi|^2_{H^{k+1}(T)} \right)^{1/2}. \tag{4.6}$$

Before proving Theorem 4.3, we need some lemmas. On each element $T \in \mathcal{T}_h$, we introduce the following local norm:

$$\begin{aligned} \|\nu\|^2_{SDG(T)} := {} & \kappa_T|\nu|^2_{H^1(T)} + h_T^2\kappa_T|\nu|^2_{H^2(T)} + \tau_T\|\boldsymbol{a}\cdot\nabla\nu\|^2_{L^2(T)} \\ & + \varepsilon h_T^{-1}\kappa_T\|\nu\|^2_{L^2(\Gamma_T)} + \||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}\nu\|^2_{L^2(\Gamma_T)}. \end{aligned} \tag{4.7}$$

The next lemma states that the local problems (4.1) are stable.

LEMMA 4.4 (local stability). *There exist positive $\overline{\varepsilon}$ and $\overline{\delta}$ such that for all $\varepsilon \geq \overline{\varepsilon}$ and $\delta \leq \overline{\delta}$,*

$$\inf_{\nu\in V_h(T)} \sup_{\mu\in V_h(T)} \frac{b_T(\nu,\mu)}{\|\nu\|_{SDG(T)}\|\mu\|_{SDG(T)}} \geq \beta_b > 0 \qquad \forall T \in \mathcal{T}_h, \tag{4.8}$$

and the constant β_b is independent of T, κ, and $\boldsymbol{a}$.

Proof. If $\delta = 0$, then (4.8) is a particular case of (3.24) where the domain is T (endowed with a one-element mesh) instead of Ω. Then, for $\delta = 0$, given $\nu \in V_h(T)$ there exists $\mu \in V_h(T)$ such that

$$\begin{aligned} \|\mu\|_{SDG(T)} &\leq \|\nu\|_{SDG(T)}, \\ b_T(\nu,\mu) &\geq \beta_{DG}\|\nu\|^2_{SDG(T)}. \end{aligned} \tag{4.9}$$

If $\delta \neq 0$, given $\nu \in V_h(T)$ and for the same $\mu \in V_h(T)$ as in (4.9), we have

$$\begin{aligned} &\|\mu\|_{SDG(T)} \leq \|\nu\|_{SDG(T)}, \\ &b_T(\nu,\mu) \geq \beta_{DG}\|\nu\|^2_{SDG(T)} + \int_{\Gamma_T^+} \delta\mu\nu\boldsymbol{a}\cdot\boldsymbol{n}. \end{aligned} \tag{4.10}$$

Moreover,

$$\left|\int_{\Gamma_T^+} \delta\mu\nu\boldsymbol{a}\cdot\boldsymbol{n}\right| \leq \delta\|\mu\|_{SDG(T)}\|\nu\|_{SDG(T)}.$$

Then, for $\delta \leq \overline{\delta} = \beta_{DG}/2$, from (4.10) we get

$$\begin{aligned} &\|\mu\|_{SDG(T)} \leq \|\nu\|_{SDG(T)}, \\ &b_T(\nu,\mu) \geq \frac{\beta_{DG}}{2}\|\nu\|^2_{SDG(T)}, \end{aligned} \tag{4.11}$$

which gives (4.8) for $\beta_b = \beta_{DG}/2$. ∎

The local problems are consistent: let ϕ be the solution of (2.1); then

$$b_T(\phi,\mu) = \ell_T(\phi,f,\mu) \qquad \forall \mu \in V_h, \qquad \forall T \in \mathcal{T}_h. \tag{4.12}$$

In the following lemma we state a Poincaré-like estimate for the norm $\|\cdot\|_{SDG(T)}$.

LEMMA 4.5. *For each element $T \in \mathcal{T}_h$ and each function $\nu \in H^1(T)$, the following estimate holds:*

$$\tau_T^{-1}\|\nu\|^2_{L^2(T)} \lesssim \|\nu\|^2_{SDG(T)}. \tag{4.13}$$

Proof. Fix an element $T \in \mathcal{T}_h$. Because of the definition (3.12) of τ_T, (4.13) is a consequence of the two Poincaré estimates

$$\frac{a_T}{h_T}\|\nu\|^2_{L^2(T)} \lesssim \frac{h_T}{a_T}\|\boldsymbol{a}\cdot\nabla\nu\|^2_{L^2(T)} + \||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}\nu\|^2_{L^2(\Gamma_T)}, \tag{4.14}$$

$$\frac{\kappa_T}{h_T^2}\|\nu\|^2_{L^2(T)} \lesssim \kappa_T|\nu|^2_{H^1(T)} + h_T^{-1}\|\kappa^{1/2}\nu\|^2_{L^2(\Gamma_T)}. \tag{4.15}$$

The inequality (4.15) is a consequence of the standard Poincaré inequality plus a scaling argument. Therefore, we concentrate on the less common (4.14). Let η be the solution of the problem

$$\boldsymbol{a}\cdot\nabla\eta = 1 \quad \text{on } T \quad \text{and} \quad \eta|_{\Gamma_T^-} = 0.$$

It is easy to verify that $\|\eta\|_{L^\infty(T)} \leq \frac{h_T}{a_T}$. Given $v \in H^1(T)$, we estimate $\|\cdot\|_{L^2(T)}$ as follows:

$$\begin{aligned} \|\nu\|^2_{L^2(T)} &= \int_T \nu^2\,\boldsymbol{a}\cdot\nabla\eta = -\int_T \boldsymbol{a}\cdot\nabla(\nu^2)\,\eta + \int_{\Gamma_T^+} \boldsymbol{a}\cdot\boldsymbol{n}\,\eta\,\nu^2 \\ &\leq \|\eta\|_{L^\infty(T)}(2\|\boldsymbol{a}\cdot\nabla\nu\|_{L^2(T)}\|\nu\|_{L^2(T)} + \||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}\nu\|^2_{L^2(\Gamma_T)}) \\ &\leq \frac{h_T}{a_T}(2\|\boldsymbol{a}\cdot\nabla\nu\|_{L^2(T)}\|\nu\|_{L^2(T)} + \||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}\nu\|^2_{L^2(\Gamma_T)}) \\ &\leq \frac{2h_T^2}{a_T^2}\|\boldsymbol{a}\cdot\nabla\nu\|^2_{L^2(T)} + \frac{1}{2}\|\nu\|^2_{L^2(T)} + \frac{h_T}{a_T}\||\boldsymbol{a}\cdot\boldsymbol{n}|^{1/2}\nu\|^2_{L^2(\Gamma_T)}. \end{aligned}$$

The inequality (4.14) follows, dividing both sides by $\frac{h_T}{a_T}$. ∎

Proof of Theorem 4.3. Let $\phi^I \in V_h$ be the nodal interpolant of ϕ and let ν be the solution of the following local problems:

$$b_T(\nu_{|T}, \mu) = \ell_T(\phi^I, f, \mu) \qquad \forall \mu \in V_h, \qquad \forall T \in \mathcal{T}_h.$$

We have $\nu \in \mathfrak{T}_h(\overline{V}_h, f)$ and will show that ν verifies the estimate (4.6). First, we prove that

$$|\!|\!| \phi - \nu |\!|\!|^2_{SDG} \lesssim \sum_{T \in \mathcal{T}_h} \|\phi - \nu\|^2_{SDG(T)}. \tag{4.16}$$

It is immediate that

$$\|\phi - \nu\|^2_{SDG} + \sum_{e \in \mathcal{E}_h^0 \cup \Gamma^+} \||\boldsymbol{a} \cdot \boldsymbol{n}|^{1/2} (\phi - \nu)^-\|^2_{L^2(e)} \lesssim \sum_{T \in \mathcal{T}_h} \|\phi - \nu\|^2_{SDG(T)}, \tag{4.17}$$

and, making use of (4.13), we also have

$$\sum_{T \in \mathcal{T}_h} \tau_T^{-1} \|\nu\|^2_{L^2(T)} \lesssim \sum_{T \in \mathcal{T}_h} \|\phi - \nu\|^2_{SDG(T)}. \tag{4.18}$$

Therefore, from (4.16) and the usual triangle inequality, we get

$$|\!|\!| \phi - \nu |\!|\!|^2_{SDG} \lesssim \sum_{T \in \mathcal{T}_h} \|\phi - \phi^I\|^2_{SDG(T)} + \sum_{T \in \mathcal{T}_h} \|\phi^I - \nu\|^2_{SDG(T)} = I + II.$$

Let us concentrate on II first. Fix a generic $T \in \mathcal{T}_h$; then consistency (4.12) implies

$$b_T(\phi - \nu, \mu) = \ell_T(\phi - \phi^I, 0; \mu) \qquad \forall \mu \in V_h(T). \tag{4.19}$$

By Lemma 4.4, there exists $\widetilde{\mu} \in V_h(T)$ such that $\|\widetilde{\mu}\|_{SDG(T)} \lesssim \|\phi^I - \nu\|_{SDG(T)}$ and

$$\begin{aligned} \|\phi^I - \nu\|^2_{SDG(T)} &\lesssim b_T(\phi^I - \nu, \widetilde{\mu}) \\ &= b_T(\phi^I - \phi, \widetilde{\mu}) + b_T(\phi - \nu, \widetilde{\mu}) \\ &= b_T(\phi^I - \phi, \widetilde{\mu}) + \ell_T(\phi - \phi^I, 0; \widetilde{\mu}). \end{aligned} \tag{4.20}$$

We have

$$\begin{aligned} b_T(\phi^I - \phi, \widetilde{\mu}) &\lesssim (\|\phi^I - \phi\|_{SDG(T)} + \tau_T^{-1} \|\phi^I - \phi\|_{L^2(T)}) \|\widetilde{\mu}\|_{SDG(T)}, \\ \ell_T(\phi - \phi^I, \widetilde{\mu}) &\lesssim \|\phi^I - \phi\|_{SDG(T)} \|\widetilde{\mu}\|_{SDG(T)}. \end{aligned} \tag{4.21}$$

Thanks to (4.20)–(4.21) and the Poincaré estimate (4.13), we obtain

$$\begin{aligned} \|\phi^I - \nu\|_{SDG(T)} &\lesssim \|\phi^I - \phi\|_{SDG(T)} + \tau_T^{-1} \|\phi^I - \phi\|_{L^2(T)} \\ &\lesssim \|\phi^I - \phi\|_{SDG(T)}. \end{aligned}$$

Squaring and summing over all the elements, we end up with

$$II \lesssim I.$$

Finally, observe that, by using the standard estimates for the interpolation error, we easily get

$$I \lesssim \left(\sum_{T \in \mathcal{T}_h} \left(a_T h_T^{2k+1} + \kappa_T h_T^{2k} \right) |\phi|^2_{H^{k+1}(T)} \right)^{1/2}.$$

This gives (4.6). ∎

4.3. Error estimate. An optimal error estimate for the SMDG method readily follows from Theorem 4.3 and Proposition 3.3.

THEOREM 4.6. *Let ϕ and ϕ^{SMDG} be the solutions of* (2.1) *and* (4.4)*, respectively. Under the same assumption as in Proposition* 3.3,

$$\|\phi - \phi^{SMDG}\|_{SDG} \lesssim \left(\sum_{T\in\mathcal{T}_h} \left(a_T h_T^{2k+1} + \kappa_T h_T^{2k}\right) |\phi|^2_{H^{k+1}(T)} \right)^{1/2}. \tag{4.22}$$

Proof. Let $\nu \in \mathfrak{T}_h(\overline{V}_h, f)$ be the approximant of ϕ given by Theorem 4.3, and let $\zeta = \phi^{SMDG} - \nu$. Linearity ensures that $\zeta \in \mathfrak{T}_h(\overline{V}_h, 0)$; that is, it is an admissible test function for (4.4). Repeating the same steps as in Proposition 3.4, we obtain the estimate

$$\|\phi - \phi^{SMDG}\|_{SDG} \lesssim |\!|\!| \phi - \nu |\!|\!|_{SDG}.$$

The statement is then proved by using Theorem 4.3. ∎

Remark 4.7. The problem of providing an optimal error estimate for MDG remains open. The error estimate (3.9) for DG, proved in [11], makes use of an interpolant which is the L^2-projection of ϕ onto V_h, which is not generally available in $\mathfrak{T}_h(\overline{V}_h, f)$. On the other hand, the stronger error estimate (3.41) we have proved in section 3, still for DG, relies on the validity of the inf-sup condition (3.24). A similar error analysis for the MDG method would need the following inf-sup condition:

$$\inf_{\nu\in\mathfrak{T}_h(\overline{V}_h,0)} \sup_{\mu\in\mathfrak{T}_h(\overline{V}_h,0)} \frac{B^{DG}(\nu,\mu)}{\|\nu\|_{SDG}\|\mu\|_{SDG}} \geq \beta_{MDG} > 0, \tag{4.23}$$

where β_{MDG} has to be independent of h. The inf-sup condition (4.23) is *not* a consequence of (3.24). One of the objectives of the next section is the numerical evaluation of the inf-sup constant β_{MDG} in (4.23).

5. Selection of parameters. The stability of the numerical schemes we have considered depends on the parameters ε (which specify the amount of *interior penalty* stabilization in all the formulations) and τ (which specifies the amount of streamline stabilization in SDG and SMDG). In this section, we want to investigate in more detail the relation between the stability of the schemes and the value of the parameters for a specific model problem. Moreover, we investigate numerically the validity of (4.23) and we demonstrate that (4.23) holds, at least for the cases covered by our numerical experiments.

We consider a square domain $\Omega = [0,1]^2$ and a uniform partition $\mathcal{T}_h$ of $N \times N$ square elements. Then, we select bilinear finite element spaces, discontinuous for V_h and globally continuous for $\bar{V}_h$. We restrict ourselves to the simplest case of constant coefficients κ and $\boldsymbol{a}$. Numerical testing of this configuration has been performed in [17]. Here, we want to measure the stability of the schemes by a numerical evaluation of the inf-sup constant

$$\inf_{\nu\in V_h} \sup_{\mu\in V_h} \frac{B(\nu,\mu)}{\|\nu\|_{SDG}\|\mu\|_{SDG}} \tag{5.1}$$

for the DG and SDG formulations (where $B(\cdot,\cdot) \equiv B^{DG}(\cdot,\cdot)$ and $B(\cdot,\cdot) \equiv B^{SDG}(\cdot,\cdot)$, resp.) and

$$\inf_{\nu\in\mathfrak{T}_h(\overline{V}_h,0)} \sup_{\mu\in\mathfrak{T}_h(\overline{V}_h,0)} \frac{B(\nu,\mu)}{\|\nu\|_{SDG}\|\mu\|_{SDG}} \tag{5.2}$$

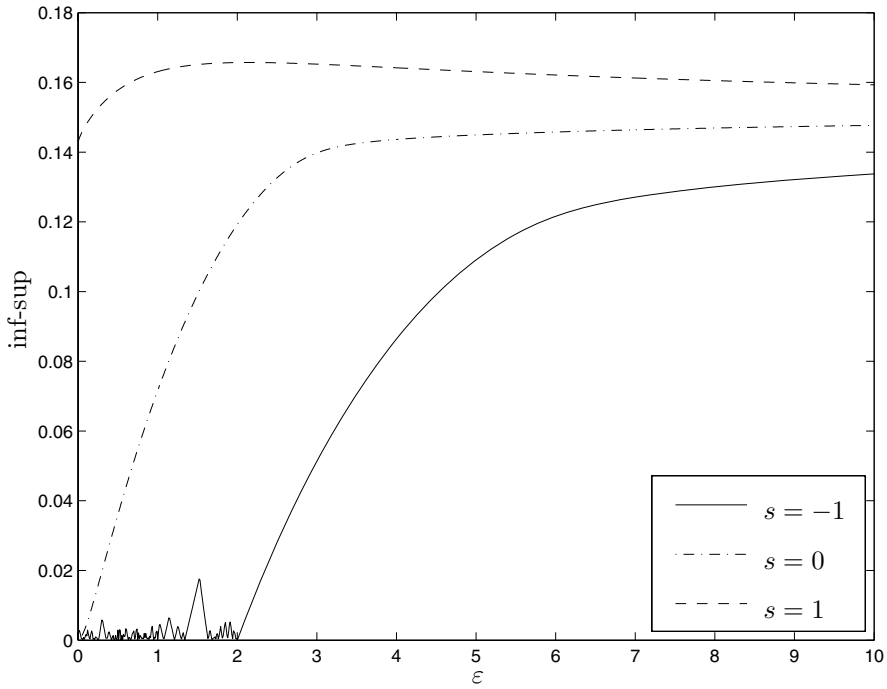

FIG. 5.1. *Inf-sup constant of the DG method versus ε.*

for the MDG and SMDG formulations (where $B(\cdot,\cdot) \equiv B^{DG}(\cdot,\cdot)$ and $B(\cdot,\cdot) \equiv B^{SDG}(\cdot,\cdot)$, resp.). The evaluation of (5.1) and (5.2) can be performed through a generalized eigenvalue computation (see, e.g., [2] for details). In what follows we assume $\delta = 0$. Very similar results are obtained with the choice $\delta = 0.01$, proposed in [17], which has advantages from the implementation standpoint.

5.1. The interior penalty parameter. First, we study the effect of ε, the amount of interior penalty stabilization. We focus on the diffusion-dominated regime, where the interior penalty term plays a role, setting $\kappa = 1$ and $\|\boldsymbol{a}\| = 10^{-10}$. The values of (5.1) and (5.2) are plotted in Figure 5.1 and 5.2, respectively, for the DG and MDG schemes (similar result are obtained for the stabilized SDG and SMDG schemes), and for a partition of 10×10 elements ($N = 10$). The symmetric version ($s = -1$), the skew-symmetric version ($s = 1$), as well as the neutral version ($s = 0$) are considered. We confirm that the skew-symmetric version is stable for all positive ϵ, while the other two formulations are unstable if the interior penalty stabilization is too small. Nevertheless, the symmetric version attains more accurate numerical solutions and is preferred (see [17]). We also observe that the MDG scheme needs less interior penalty stabilization than the DG scheme. This is not surprising: indeed, roughly speaking, in the diffusive regime, $\mathfrak{T}_h(\overline{V}_h, 0)$ is composed of functions that are *almost* continuous, and therefore the interior penalty stabilization is needed only on the boundary of Ω.

5.2. The SUPG parameter and the inf-sup stability of MDG. Second, we analyze the role of the streamline stabilization. We select, from now on, the symmetric version ($s = -1$) and we take $\varepsilon = 6$ (this gives sufficient interior penalty stabilization

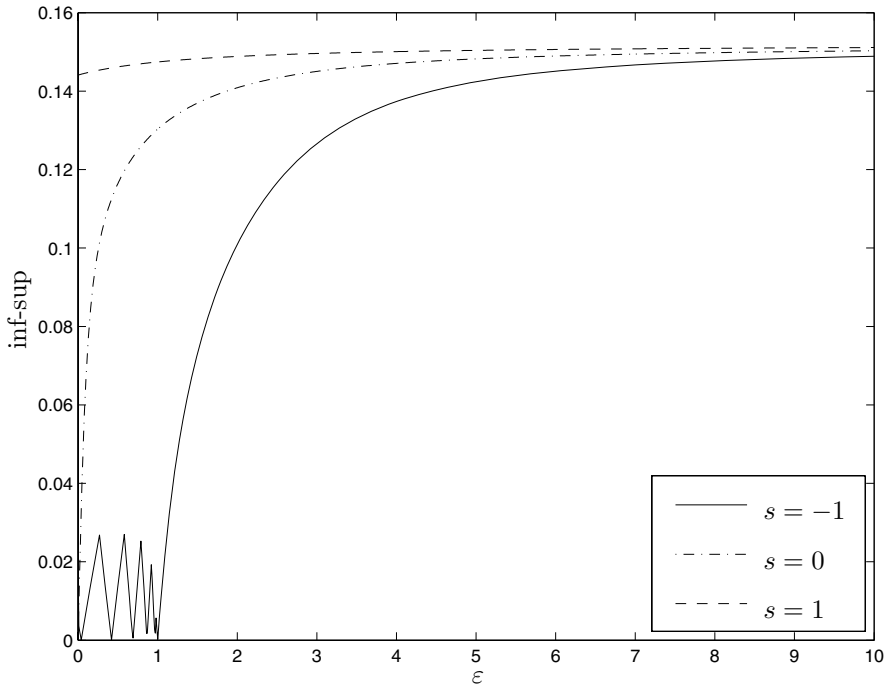

FIG. 5.2. *Inf-sup constant of the MDG method versus* ε.

to both DG and SDG, as seen in section 5.1). We know, from Theorem 3.5, that there is no need of streamline stabilization in the DG method. This is confirmed in Figure 5.3, where (5.1) is plotted for different κ and $\boldsymbol{a} = [\cos\theta, \sin\theta]$, on a grid of 10×10. We have set $\tau = 1/2$ in the definition of $\|\cdot\|_{SDG}$. The values of (5.1) are bounded away from zero, uniformly with respect to the operator coefficients. In Figure 5.4 we focus the attention on the convection-dominated regime, which is now the most interesting case: we set $\kappa = 10^{-6}$ and compute (5.1) for different $\boldsymbol{a} = [\cos\theta, \sin\theta]$ on different uniform meshes of $N \times N$ elements. We confirm that the inf-sup condition holds uniformly with respect to the mesh-size.

The major result of this section is the evaluation of the stability of the MDG scheme. Actually, the MDG scheme turns out to be stable with respect to the $\|\cdot\|_{SDG}$ for the model case considered here: in Figure 5.5 we plot the inf-sup constant (5.2) for different κ and $\boldsymbol{a} = [\cos\theta, \sin\theta]$ on the uniform 10×10 grid, while in Figure 5.6 we plot (5.2) in the convection-dominated regime ($\kappa = 10^{-6}$) for different directions of the convective field $\boldsymbol{a}$ and different uniform meshes. Our conclusion is that, at least for this model case, the MDG scheme is inf-sup stable; that is, condition (4.23) holds with β_{MDG} independent of the problem coefficients and the mesh-size. From this, and reasoning as in Theorem 4.6, we can infer the optimal error estimate for the MDG scheme:

$$\|\phi - \phi^{MDG}\|_{SDG} \lesssim \left(\sum_{T \in \mathcal{T}_h} \left(a_T h_T^{2k+1} + \kappa_T h_T^{2k} \right) |\phi|^2_{H^{k+1}(T)} \right)^{1/2}. \tag{5.3}$$

Similar plots and results are obtained for the stabilized SDG and SMDG methods, in accordance with Proposition 3.3, and are omitted.

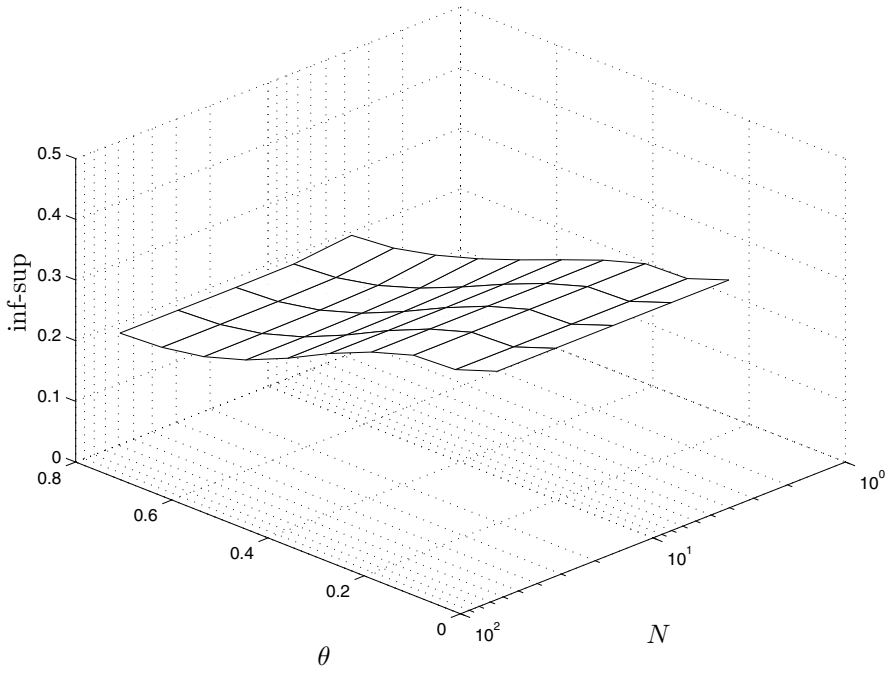

FIG. 5.6. *Inf-sup constant of the MDG method versus* $\boldsymbol{a} = [\cos\theta, \sin\theta]$ *and* N.

6. Conclusions. The mathematical analysis of the multiscale discontinuous Galerkin MDG method introduced in [17] was initiated. This method alleviates a longstanding drawback of discontinuous Galerkin methods, namely, the large size of the solution space. It utilizes local, elementwise problems to generate an interscale transfer operator, enabling the size of the matrix problem to be significantly reduced, apparently without degradation in the quality of results.

We studied MDG and a stabilized version, SMDG. We were able to characterize the approximation properties of the interscale transfer spaces. The corresponding global discontinuous Galerkin methods, DG and SDG, are inf-sup stable and coercive, respectively, with respect to the norm induced by the bilinear form of SDG. Coercivity, but not necessarily inf-sup stability, is inherited by the interscale transfer subspaces. Consequently, we were able to obtain the same error estimates for SMDG as for DG and SDG, but the situation for MDG remains open. Numerical evaluations of the inf-sup constant for MDG indicated that it was positive, bounded uniformly away from zero, and very similar to that for DG. These results are consistent with the numerical calculations performed in [17].

TRUNCATION ERRORS IN EXPONENTIAL FITTING FOR OSCILLATORY PROBLEMS*

J. P. COLEMAN† AND L. GR. IXARU‡

Abstract. A generalization of Peano's kernel theorem due to Ghizzetti and Ossicini [*Quadrature Formulae*, Birkhaüser, Basel, Switzerland, 1970] provides expressions, in the form of integrals, for the truncation errors in a variety of exponential-fitting formulae for oscillatory problems. In some circumstances this leads to an expression analogous to the Lagrange form of remainder; more generally the error can be expressed as a sum of two terms of Lagrange type. Our examples include formulae for quadrature and numerical differentiation, and linear multistep methods for ordinary differential equations. Two families of exponential-fitting quadrature formulae are investigated, one with evenly spaced abscissas and the other based on the philosophy of Gaussian quadrature. In particular, the integral representation can be used to determine the asymptotic rate of decay of the error with increasing frequency for a class of oscillatory integrands.

1. Introduction.

In recent decades a sustained effort has been devoted to the construction of approximate formulae specially adapted for numerical operations on oscillatory functions. Integration of differential equations with oscillatory solutions is an area of current research interest; aspects of the problem were reviewed by Petzold, Jay, and Yen [17]. Quadrature with oscillatory integrands is of interest in its own right, for example, in connection with finite Fourier integrals. Furthermore, the efficient evaluation of such integrals is an essential requirement in the implementation of some methods for differential equations with oscillatory solutions; see Iserles [9].

Many classical approximation formulae are designed to be exact for polynomials of sufficiently low degree. However, a polynomial of low degree can provide a good approximation for a rapidly varying function only on a very short interval. In contrast, approximations based on a few terms of a more appropriate set of basis functions may provide a much better approximation. An exponential-fitting method is designed to be exact when the solution of the differential equation, or the integrand in a quadrature problem, is some suitably chosen combination of exponential functions, perhaps with polynomial terms, or products of polynomials and exponentials. Similar ideas may be applied to interpolation and numerical differentiation, as in [11]. The technique for the construction of the coefficients of such formulae is now well established, and some efficient computer codes are available; see Ixaru and Vanden Berghe [14] and the CD therein. Since we are concerned here with oscillatory problems, the arguments of the exponential functions are purely imaginary.

When the value of a function f at $x_0 + h$ is approximated by a truncated Taylor expansion about x_0, that is, by $f_K(x_0 + h) = \sum_{k=0}^{K} h^k f^{(k)}(x_0)/k!$, the resulting error

may be expressed in the Lagrange form

$$err := f(x_0 + h) - f_K(x_0 + h) = \frac{h^{K+1}}{(K+1)!} f^{(K+1)}(\eta),$$

for some $\eta \in (x_0, x_0 + h)$, if $f^{(K+1)}(x)$ is continuous on $[x_0, x_0 + h]$. That error may also be written, less usefully, as the formal expansion $\sum_{k=K+1}^{\infty} h^k f^{(k)}(x_0)/k!$. Expressions of Lagrange type are also available for the truncation errors in some polynomial-based approximations; examples include the errors in Newton–Cotes and Gaussian quadrature formulae, and the local truncation errors in the explicit and implicit Adams formulae. Although such formulae rarely give useful quantitative bounds, they can give valuable qualitative information. In contrast to the situation for polynomial-based methods, the truncation errors of exponential-fitting methods are not well understood. Comments in the literature are mainly based on the so-called leading term of a formal expansion of the error.

Our objective in this paper is to contribute to the understanding of the truncation errors in exponential fitting methods wherever they are applied. Our starting point is the work of Ghizzetti and Ossicini [8] concerning a class of quadrature formulae which includes exponential-fitting formulae. Their results, which are summarized in section 2, provide both a technique for deriving formulae and, of more relevance to our concern, an expression for the error as an integral. The error formula is a generalization of Peano's kernel theorem. If the kernel function is of constant sign, this leads to an expression analogous to the Lagrange form of remainder. More generally, the error can be expressed as a sum of two terms of Lagrange type.

Several specific formulae obtained by exponential fitting are considered in section 3. It is found that the error is expressible as a single Lagrange term only under severe restrictions on the value of the fitted frequency, and the relationship with the concept of the "leading term" is elucidated. The next section begins with a derivation of an explicit formula for the kernel function for exponential fitting based on the $2N$ functions $x^p \exp(\pm i\omega x)$ for $p = 0, 1, \ldots, N-1$. That provides an expression for the truncation error for a particular class of exponential-fitting quadrature formulae and paves the way for analytical and numerical investigations of the errors in two families of such formulae, one with evenly spaced abscissas and the other based on the philosophy of Gaussian quadrature. Some of the methods investigated here compare favorably with a Filon–Lobatto method advocated by Iserles [9], when applied to an example which he considered.

Section 5 is devoted to a detailed study of the error in a particular two-point exponential-fitting Gaussian formula for a class of oscillatory integrands. It is shown that the integral for the truncation error can provide valuable information on the qualitative behavior of that error at large frequencies.

2. A general scheme. The work of Ghizzetti and Ossicini [8] is concerned with quadrature formulae of the form

$$\int_a^b g(x) f(x)\, dx = \sum_{i=1}^{n} \sum_{k=0}^{m-1} A_{ki} f^{(k)}(x_i) + E[f] \tag{2.1}$$

such that $E[f] = 0$ when f is a solution of a linear differential equation $L[f] = 0$ of order m. It is assumed that

$$a \le x_1 < x_2 < \cdots < x_n \le b.$$

The operator L has the form

$$L = \sum_{k=0}^{m} a_k(x) \frac{d^{m-k}}{dx^{m-k}},$$

with $a_0(x) = 1$. Smoothness conditions on the coefficients are specified in [8]. Here it will be assumed that the functions arising are as smooth as required. The adjoint differential operator L^* is defined by

$$L^*[u] = \sum_{k=0}^{m} (-1)^{m-k} \frac{d^{m-k}}{dx^{m-k}} [a_k(x)u(x)],$$

which may also be written as

$$L^*[u] = \sum_{k=0}^{m} a_k^*(x) \frac{d^{m-k}u(x)}{dx^{m-k}}.$$

The reduced operators corresponding to L are

$$L_r = \sum_{k=0}^{r} a_k(x) \frac{d^{r-k}}{dx^{r-k}} \qquad \text{for} \quad r = 0, \ldots, m-1.$$

Similarly,

$$L_r^* = \sum_{k=0}^{r} a_k^*(x) \frac{d^{r-k}}{dx^{r-k}} \qquad \text{for} \quad r = 0, \ldots, m-1.$$

For example, if

$$L = \frac{d^2}{dx^2} + a_1(x) \frac{d}{dx} + a_2(x),$$

then

$$L_1 = \frac{d}{dx} + a_1(x) \quad \text{and} \quad L_0 = 1.$$

For a sufficiently differentiable function u,

$$L^*[u] = u'' - (a_1 u)' + a_2 u;$$

thus

$$L_1^*[u] = u' - a_1 u \quad \text{and} \quad L_0^*[u] = u.$$

For any two sufficiently differentiable functions u and v, Lagrange's identity takes the form

$$vL[u] - uL^*[v] = \frac{d}{dx} \sum_{k=0}^{m-1} u^{(k)}(x) L_{m-k-1}^*[v].$$

Integration gives

$$\int_\alpha^\beta u(x)L^*[v](x)\,dx = \int_\alpha^\beta v(x)L[u](x)\,dx - \left[\sum_{k=0}^{m-1} u^{(k)}(x) L_{m-k-1}^*[v](x) \right]_{x=\alpha}^{x=\beta}.$$

In particular, this can be applied with $u = f$, $v = \phi_i$ (any solution of the differential equation $L^*[\phi] = g(x)$), $\alpha = x_i$, and $\beta = x_{i+1}$. It is convenient to define $x_0 = a$ and $x_{n+1} = b$, to allow for cases where the end-points of the integration interval are not quadrature abscissas. Let ϕ_0 and ϕ_n be the particular solutions of $L^*[\phi] = g(x)$ which satisfy the conditions

$$L^*_{m-k-1}[\phi_0](a) = 0$$

and

$$L^*_{m-k-1}[\phi_n](b) = 0$$

for $k = 0, 1, \ldots, m-1$. Then, by summing over the index i, as shown by Ghizzetti and Ossicini [8], and also on page 294 of Davis and Rabinowitz [4], we get a quadrature formula of the form (2.1). The quadrature coefficients are

$$A_{ki} = L^*_{m-k-1}\left[\phi_i(x) - \phi_{i-1}(x)\right]\Big|_{x=x_i} \tag{2.2}$$

for $k = 0, \ldots, m-1$ and $i = 1, \ldots, n$; here the functions ϕ_i, for $i = 1, \ldots, n-1$, are any solutions of the differential equation $L^*[\phi](x) = g(x)$. The error term is

$$E[f] = \sum_{i=0}^{n} \int_{x_i}^{x_{i+1}} \phi_i(x) L[f](x)\, dx = \int_a^b \Phi(x) L[f](x)\, dx, \tag{2.3}$$

where

$$\Phi(x) = \phi_i(x) \qquad \text{for} \quad x_i < x < x_{i+1}, \quad i = 0, \ldots, n.$$

It is clear from the form of (2.3) that the truncation error vanishes if $L[f] = 0$.

Milne [16] approached this problem in a different way, expressing the approximating formula and its error in terms of determinants. He also expressed the truncation error in the form (2.3), but without associating the kernel Φ with solutions of the adjoint equation.

If $f^{(m)}$ is bounded, then

$$|E[f]| \le \sup_{a \le x \le b} \Big|L[f](x)\Big| \int_a^b |\Phi(x)|\, dx.$$

If $f \in C^m(a, b)$ and the kernel $\Phi(x)$ is of constant sign, the second mean-value theorem for integrals gives

$$E[f] = L[f](\eta) \int_a^b \Phi(x)\, dx \tag{2.4}$$

for some $\eta \in (a, b)$. However, $\Phi(x)$ may not be of constant sign, and even when it is that fact can be difficult to establish.

We can always write $\Phi(x) = \Phi_+(x) + \Phi_-(x)$, where

$$\Phi_+(x) := \begin{cases} \Phi(x) & \text{for all } x \text{ such that } \ \Phi(x) \ge 0, \\ 0 & \text{otherwise} \end{cases}$$

and

$$\Phi_-(x) := \begin{cases} \Phi(x) & \text{for all } x \text{ such that } \ \Phi(x) \le 0, \\ 0 & \text{otherwise} \end{cases}$$

so that the integral in (2.3) can be expressed as the sum of two integrals,

$$E[f] = \int_a^b \Phi_+(x) L[f](x)\,dx + \int_a^b \Phi_-(x) L[f](x)\,dx. \tag{2.5}$$

Assuming that $f \in C^m(a,b)$, the mean-value theorem can be applied to both integrals to give

$$E[f] = L[f](\eta_+) \int_a^b \Phi_+(x)\,dx + L[f](\eta_-) \int_a^b \Phi_-(x)\,dx \tag{2.6}$$

for some $\eta_+ , \eta_- \in (a\,, b)$.

There is an immense amount of freedom to derive formulae here. Only the functions ϕ_0 and ϕ_n are determined. Every other ϕ_i can be any solution of the inhomogeneous adjoint equation $L^*[\phi](x) = g(x)$. Equation (2.2) would allow us to calculate the quadrature coefficients corresponding to any particular choice of the functions $\phi_i(x)$, but perhaps the more interesting situation is that in which the coefficients have been determined in some other way and we want to have an expression for the truncation error.

2.1. The truncation error of a given formula. Suppose that the coefficients A_{ki} are known. The expression (2.3) for the truncation error may be used if we can find the corresponding functions ϕ_i. Theorem 2.4.1 of Ghizzetti and Ossicini [8] gives

$$\phi_i(x) = -\int_a^x K(t,x) g(t)\,dt + \sum_{k=0}^{m-1} \sum_{j=1}^{i} A_{kj} \left[\frac{\partial^k}{\partial t^k} K(t,x) \right]_{t=x_j} \tag{2.7}$$

for $i = 0, 1, \ldots, n$, with the convention that the sum does not appear when $i = 0$. Here K is the resolvent kernel corresponding to the operator L; i.e., $K(x,z)$ is the solution of $L[u](x) = 0$ such that

$$\left[\frac{\partial^k}{\partial x^k} K(x,z) \right]_{x=z} = \delta_{k,m-1} \tag{2.8}$$

for $k = 0, 1, \ldots, m-1$. It follows that

$$\phi_{i+1}(x) = \phi_i(x) + \sum_{k=0}^{m-1} A_{k,i+1} \left[\frac{\partial^k}{\partial t^k} K(t,x) \right]_{t=x_{i+1}};$$

thus it is easy to build up the ϕ-functions recursively once $K(t,x)$ and $\phi_0(x)$ are known.

3. Some examples. Here we investigate the errors in several exponential-fitting formulae by means of the general scheme presented in the previous section. We are especially interested in checking if the function $\Phi(x)$ is of constant sign. It will be seen that in most cases this is not true and therefore the Lagrange form of remainder (2.4) does not hold, but (2.6) always applies for sufficiently smooth functions.

3.1. Quadrature based on function values only. The integer m in (2.1) is the order of the differential operator L. For quadrature formulae of the form

$$\int_a^b g(x) f(x)\,dx \approx \sum_{i=1}^{n} a_i f(x_i),$$

exact for functions f which are annihilated by L, we have $A_{0i} = a_i$ for $i = 1, \ldots, n$ and, for those values of i, $A_{ki} = 0$ for $k = 1, \ldots, m-1$. Then (2.7) becomes

$$\phi_i(x) = -\int_a^x K(t,x)g(t)\,dt + \sum_{k=1}^{i} a_k K(x_k, x). \tag{3.1}$$

Example 1. The formula

$$\int_0^h f(x)\,dx \approx \frac{1-\cos\omega h}{\omega \sin\omega h}[f(0) + f(h)] \tag{3.2}$$

is exact for $\cos\omega x$ and $\sin\omega x$. This formula and its error were derived by Vanden Berghe, de Meyer, and Vanthournout [19] as an example of Ehrenmark's technique [6].

Here $g(x) = 1$, $n = 2$, and $m = 2$ with $L[f] = f'' + \omega^2 f$. Also, $x_0 = x_1 = 0$ and $x_2 = x_3 = h$. The function $K(x,t)$ may be expressed as

$$K(x,t) = A\cos\omega(x-t) + B\sin\omega(x-t).$$

The constants A and B are determined by the initial conditions (2.8) and we find that

$$K(x,t) = \frac{1}{\omega}\sin\omega(x-t). \tag{3.3}$$

Integration of $-K(t,x)$ with respect to t, from 0 to x, gives $\phi_0(x) = (1-\cos\omega x)/\omega^2$ and, from (3.1),

$$\phi_1(x) = \phi_0(x) + \frac{1-\cos\omega h}{\omega\sin\omega h}K(0,x) = \frac{1}{\omega^2} + \frac{\sin\omega(x-h) - \sin\omega x}{\omega^2\sin\omega h}.$$

To investigate the sign of $\phi_1(x)$ on $(0,h)$ it is convenient to define $y = \omega x$, $\theta = \omega h$, and

$$F(y,\theta) = \frac{\sin(y-\theta) - \sin y}{\sin\theta} + 1 = 1 - \frac{\cos(y-\theta/2)}{\cos(\theta/2)}$$

for $\theta \neq (2m+1)\pi$ for integral m. Then $F(y,\theta) = 0$ if and only if $y = 2k\pi$ or $y = 2k\pi + \theta$ for integral k. It follows that $F(y,\theta)$ does not change sign on $(0,\theta)$ when $\theta < 2\pi$. For $\theta > 2\pi$, however, $F(y,\theta)$ changes sign when $y = \theta - 2\pi$. We can conclude that, for steplengths h such that $0 < \theta < 2\pi$ and $\theta \neq \pi$, the truncation error in (3.2) for a sufficiently smooth integrand is

$$E[f] = \left[f''(\eta) + \omega^2 f(\eta)\right]\int_0^h \phi_1(x)\,dx = \frac{2}{\omega^3}\left(\frac{\theta}{2} - \tan\frac{\theta}{2}\right)\left[f''(\eta) + \omega^2 f(\eta)\right] \tag{3.4}$$

for some $\eta \in (0,h)$, a result obtained earlier by Vanden Berghe, de Meyer, and Vanthournout [19]. This analysis does not allow any such conclusion if $\theta > 2\pi$.

It is instructive to see how this result compares with what is available in the literature on exponential fitting, where the error is presented as a formal infinite series; see Ixaru and Vanden Berghe [14]. If $\mathcal{O}$ is an operator acting on some function $y(x)$ and $\mathcal{A}[h, \mathbf{a}]y(x)$ is its approximation with parameters $\mathbf{a} = [a_1, a_2, \ldots]$, then an operator $\mathcal{L}$ is introduced by

$$\mathcal{L}[h, \mathbf{a}]y(x) = (\mathcal{O} - \mathcal{A}[h, \mathbf{a}])y(x).$$

If the coefficients of the formula are determined by requiring that $\mathcal{L}[h, \mathbf{a}]y(x)$ is identically vanishing in x and h when $y(x)$ satisfies the equation $Ly = 0$, where

$$L = D^m + c_1 D^{m-1} + c_2 D^{m-2} + \cdots + c_m$$

with constant $c_1, c_2, \ldots, c_m$ and $D = d/dx$, then, formally,

$$\mathcal{L}[h, \mathbf{a}]y(x) = h^{l+m} \sum_{k=0}^{\infty} h^k T_k^*(\mathbf{z}, \mathbf{a}(\mathbf{z})) D^k L y(x),$$

where the integer l depends of the operator $\mathcal{O}$, and $\mathbf{z} = [z_1, z_2, \ldots]$ is a set of parameters depending on the coefficients c_m and the steplength h. The coefficients T_k^* can be calculated by some algebraic manipulations. In particular, T_0^* has a simple form, as can be seen in the next paragraph and more generally in section 4.2, where this quantity is denoted by T^*.

For the example under discussion we have

$$\mathcal{O}y(x) = \int_x^{x+h} y(x')dx', \qquad \mathcal{A}[h, \mathbf{a}]y(x) = h[a_1 y(x) + a_2 y(x+h)],$$

$m = 2$, $c_1 = 0$, $c_2 = \omega^2$, the vector $\mathbf{z}$ has only one component $z_1 = \theta$, the coefficients of the quadrature formula are $a_1(\theta) = a_2(\theta) = (1 - \cos\theta)/(\theta \sin\theta)$, and

$$T_0^* = \frac{1 - a_1(\theta) - a_2(\theta)}{\theta^2} = \frac{2}{\theta^3}\left(\frac{\theta}{2} - \tan\frac{\theta}{2}\right).$$

The error of the formula (3.2) is then

$$err = \mathcal{L}[h, \mathbf{a}]y(x)|_{x=0}.$$

The first term of the corresponding formal series has the same form as the right-hand side of (3.4), but with the unknown η replaced by 0. However, the new analysis clearly shows that a single term of Lagrange type is correct only if $\theta < 2\pi$.

Example 2. The formula

$$\int_{-h}^{h} f(x)\,dx \approx a_1 f(-h) + a_2 f(0) + a_3 f(h)$$

is exact for 1, x, $\cos\omega x$, and $\sin\omega x$. With $\theta = \omega h$ the coefficients are

$$a_1 = a_3 = \frac{\theta - \sin\theta}{\omega(1 - \cos\theta)}, \qquad a_2 = 2\frac{\sin\theta - \theta\cos\theta}{\omega(1 - \cos\theta)};$$

see equations (4.16) of Ixaru [11]. In this case $g(x) = 1$, and the relevant linear differential operator is

$$L = \frac{d^4}{dx^4} + \omega^2 \frac{d^2}{dx^2};$$

thus $m = 4$. The truncation error is

$$E[f] = \int_{-h}^{h} \Phi(x) L[f](x)\,dx = \int_{-h}^{0} \phi_1(x) L[f](x)\,dx + \int_0^h \phi_2(x) L[f](x)\,dx.$$

The function $K(x,t)$ may be expressed as

$$K(x,t) = A + B(x-t) + C\cos\omega(x-t) + D\sin\omega(x-t).$$

The constants A, B, C, and D are determined by the initial conditions (2.8), and we find that

$$K(x,t) = \frac{x-t}{\omega^2} - \frac{\sin\omega(x-t)}{\omega^3}.$$

Further calculation gives

$$\phi_1(x) = \frac{1}{\omega^4}\left[\frac{1}{2}\omega^2(x+h)^2 - 1 + \cos\omega(x+h) + \frac{\theta-\sin\theta}{1-\cos\theta}\left\{\sin\omega(x+h) - \omega(x+h)\right\}\right].$$

Then

$$\phi_2(x) = \phi_1(x) + a_2K(0,x),$$

and some further algebra shows that $\phi_2(x) = \phi_1(-x)$.

Numerical computations indicate that $\phi_1(x) \le 0$ on $[-h,0]$, for all values of θ for which it is defined, and if this is taken for granted, then

$$\begin{aligned} E[f] &= 2\left[f^{iv}(\eta) + \omega^2 f''(\eta)\right]\int_{-h}^{0}\phi_1(x)\,dx \\ &= \frac{h^5}{6\theta^2}\left[\frac{6}{\theta}\cot\left(\frac{\theta}{2}\right) - 3\cot^2\left(\frac{\theta}{2}\right) - 1\right]\left[f^{iv}(\eta) + \omega^2 f''(\eta)\right], \end{aligned}$$

in accordance with the "leading term" given by (4.17) of [11]. This result was first obtained by Ehrenmark [6] and rederived using ideas of Ghizzetti and Ossicini [8] in [7], where a five-point formula is also considered.

3.2. Numerical differentiation. Equation (2.1) can provide approximations for derivatives in terms of function values if the integral is removed by choosing $g(x) \equiv 0$. In that case the functions ϕ_i satisfy the homogeneous adjoint equation $L^*[\phi](x) = 0$ and, in particular, $\phi_0(x) \equiv 0$ and $\phi_n(x) \equiv 0$. Previously the inhomogeneous term gave the appropriate normalization; now we simply choose a particular value for one of the coefficients.

Example 3. The formula

$$y''(0) \approx a_1[y(h) + y(-h)] + a_2y(0), \tag{3.5}$$

with

$$a_1 = \frac{\theta}{h^2\sin\theta} \qquad \text{and} \qquad a_2 = \frac{\theta(\sin\theta - 2\cos\theta)}{h^2\sin\theta},$$

is exact for $\cos\omega x$, $\sin\omega x$, $x\cos\omega x$, and $x\sin\omega x$. Here

$$L = \left(\frac{d^2}{dx^2} + \omega^2\right)^2.$$

The formula (3.5) corresponds to (2.1) without the error term if we take $g(x) \equiv 0$, $m = 4$, $n = 3$, $x_1 = -h = -x_3$, $x_2 = 0$, $A_{01} = A_{03} = a_1$, $A_{02} = a_2$, $A_{22} = -1$, $A_{21} = 0 = A_{23}$, and $A_{1k} = 0$ for $k = 1,2,3$.

In this case

$$K(x,t) = \frac{1}{2\omega^3}\big[\sin\omega(x-t) - \omega(x-t)\cos\omega(x-t)\big],$$

and

$$\phi_1(x) = a_1 K(-h,x) = \frac{\omega(x+h)\cos\omega(x+h) - \sin\omega(x+h)}{2\omega\theta\sin\theta}.$$

Further calculation gives $\phi_2(x) = \phi_1(-x)$; thus $\Phi(x)$ is an even function.

To investigate the sign of $\phi_1(x)$ on $(-h,0)$, let $z = \omega(x+h)$ and consider

$$u(z) = z\cos z - \sin z$$

on $[0,\theta]$. This oscillatory function of increasing amplitude is negative on $(0,\theta_1)$, where $\theta_1 \approx 4.4934$ is the smallest positive root of the equation $z = \tan z$. On larger intervals $u(z)$ is not of constant sign. For $0 < \theta \le \theta_1$, when $y \in C^4[-h,h]$, the truncation error in the formula (3.5) is

$$\begin{aligned} -E[y] &= -2\left[y^{iv}(\eta) + 2\omega^2 y''(\eta) + \omega^4(\eta)\right]\int_{-h}^{0}\phi_1(x)\,dx \\ &= \frac{2h^2}{\theta^3\sin\theta}(2 + \theta\sin\theta - 2\cos\theta)\left[y^{iv}(\eta) + 2\omega^2 y''(\eta) + \omega^4 y(\eta)\right]. \end{aligned}$$

This is in agreement with the "leading term" given by (3.19) of Ixaru [11]. Here, as elsewhere, the concept of "leading term" needs to be treated with caution; when the mean-value theorem is applicable, η is unknown, and its replacement by some chosen number could give erroneous results. For example, it may be tempting to replace η by 0. If we take $y = x^6$, the "leading term" then vanishes, but the actual error is easily seen to be $-2h^4\theta\operatorname{cosec}\theta$.

It is evident from the symmetry of the formula (3.5) that it is exact for every odd function. That is also clear when the truncation error is expressed as

$$-E[y] = -\int_{-h}^{h}\Phi(x)L[y](x)\,dx,$$

since Φ is an even function and $L[y]$ involves the function y and derivatives of even order only.

3.3. Multistep methods for ODEs. As in section 3.2, we remove the integral in (2.1) by taking $g(x) \equiv 0$.

Example 4. Theorem 4 of Ixaru [11] is concerned with a two-step formula for differential equations of the form $y'' = f(x,y)$, which may be written as

$$y_{n+1} - a_0 y_n + y_{n-1} = h^2(a_1 f_{n+1} + a_2 f_n + a_3 f_{n-1}).$$

If this formula is exact for $x^p\exp(\pm i\omega x)$ with $p = 0,1,2$, the coefficients are

$$a_0 = \frac{6\cos\theta\sin\theta - 2\theta\cos^2\theta + 4\theta}{3\sin\theta + \theta\cos\theta}, \qquad a_1 = a_3 = \frac{\sin\theta}{3\sin\theta + \theta\cos\theta},$$

and

$$a_2 = \frac{4\theta\sin^2\theta - 2\cos\theta(\theta\cos\theta - \sin\theta)}{\theta(3\sin\theta + \theta\cos\theta)}.$$

The two-step formula corresponds to (2.1) with $g(x) \equiv 0$,

$$L = \left(\frac{d^2}{dx^2} + \omega^2\right)^3,$$

$m = 6$, $n = 3$, and the coefficients $A_{01} = -1 = A_{03}$, $A_{02} = a_0$, $A_{11} = 0 = A_{12} = A_{13}$, $A_{21} = A_{23} = h^2 a_1$, $A_{22} = h^2 a_2$, and $A_{ik} = 0$ for $i = 3, 4, 5$ and $k = 1, 2, 3$. In the usual way we find

$$\phi_1(x) = \frac{4\sin\theta - 2\theta\cos\theta}{4\omega^5(3\sin\theta + \theta\cos\theta)}[\sin\omega(x+h) - 3\omega(x+h)\cos\omega(x+h)] - \frac{\sin\theta}{2\omega^3(3\sin\theta + \theta\cos\theta)}(x+h)^2\sin\omega(x+h).$$

A symmetry argument shows that $\phi_2(x) = \phi_1(-x)$.

The local truncation error is

$$-E[y] = -\int_{-h}^{h} \Phi(x) L[y](x)\, dx.$$

When the sign of $\Phi(x)$ is constant on $[-h, h]$, the coefficient of $L[y](\eta)$ in the resulting expression for the truncation error is

$$-\int_{-h}^{h} \Phi(x)\, dx.$$

Evaluation shows that this is the same as the factor quoted in (5.6) of [11]. However, calculations show that the sign of $\Phi(x)$ is no longer constant on $[-h, h]$ when θ exceeds $\theta_{max} \approx 1.625$.

3.4. Interpolation. Modifying (2.1), by introducing a parameter x and taking $m = 1$, we can write

$$\int_a^b g(x,t) f(t)\, dt = \sum_{i=1}^{n} a_i(x) f(x_i) + E[f](x). \tag{3.6}$$

When g is the delta function $g(x,t) = \delta(x-t)$ this becomes

$$f(x) = \sum_{i=1}^{n} a_i(x) f(x_i) + E[f](x)$$

for $x \in (a, b)$. If the functions a_i satisfy the interpolation conditions

$$a_i(x_j) = \delta_{ij} \qquad \text{for} \quad i, j = 1, \ldots, n,$$

the truncation error in the corresponding interpolation formula is given by (2.2) as

$$E[f](x) = \int_a^b \Phi(x,t) L[f](t)\, dt,$$

with

$$\Phi(x,t) = \phi_i(x,t) \qquad \text{for} \quad x_i < t < x_{i+1}, \quad i = 0, \ldots, n,$$

and, from (2.7),

$$\phi_i(x,t) = -\int_a^t K(z,t)\delta(x-z)\,dz + \sum_{j=1}^{n} a_j(x)K(t,x)$$
$$= -K(x,t)\Theta(t-x) + \sum_{j=1}^{n} a_j(x)K(t,x),$$

where Θ is the unit step function

$$\Theta(\alpha) = \begin{cases} 0, & \alpha < 0, \\ 1, & \alpha > 0. \end{cases}$$

Interpolation involving derivative values may be accommodated in this approach by adapting (3.6) to include additional sums.

Example 5. For interpolation by a linear combination of $\cos\omega x$ and $\sin\omega x$, with two interpolation points a and b, a problem considered in [12], the canonical functions are

$$a_1(x) = \frac{\sin\omega(x-b)}{\sin\omega(a-b)}, \qquad a_2(x) = \frac{\sin\omega(x-a)}{\sin\omega(b-a)}.$$

In that case $L[f] = f''+\omega^2 f$, and the kernel function is given by (3.3). The truncation error is

$$E[f](x) = \int_a^b \phi_1(x,t)L[f](t)\,dt,$$

with

$$\phi_1(x,t) = \begin{cases} -\dfrac{\sin\omega(x-b)\sin\omega(a-t)}{\omega\,\sin\omega(b-a)}, & a < t < x, \\ -\dfrac{\sin\omega(x-a)\sin\omega(b-t)}{\omega\,\sin\omega(b-a)}, & x < t < b. \end{cases}$$

The second expression was obtained by using trigonometric identities to simplify the form of $a_1K(a,t) - K(x,t)$. In the limit as $\omega \to 0$,

$$\phi_1(x,t) \to \begin{cases} \dfrac{(x-b)(t-a)}{b-a}, & a < t < x, \\ \dfrac{(x-a)(t-b)}{b-a}, & x < t < b, \end{cases}$$

the Peano kernel for linear interpolation; see, for example, (3.7.12) of [3].

The function $\phi_1(x,t)$ is of constant sign (negative) for all x and t in (a,b) when $\omega(b-a) < \pi$. Then the truncation error of the two-point trigonometric interpolation, for $f \in C^2[a,b]$, is

$$E[f](x) = \left[f''(\eta) + \omega^2 f(\eta)\right] \int_a^b \phi_1(x,t)\,dt$$
$$= \frac{1}{\omega^2}\left[1 - \frac{\cos\omega\left\{(b+a)/2 - x\right\}}{\cos\omega\left\{(b-a)/2 - x\right\}}\right]\left[f''(\eta) + \omega^2 f(\eta)\right]$$

for some $\eta \in (a,b)$. The external factor is the same as that given in [12] and in (4.171) of [14].

Other expressions for the truncation error in mixed interpolation have been obtained in [5], [1], and [2].

4. Quadrature formulae with $L = (D^2 + \omega^2)^N$. In this section we consider a subset of the formulae (2.1), which we write as

$$\int_a^b f(x)dx = \int_{X-h}^{X+h} f(x)dx = \sum_{k=0}^{J} h^{k+1} \sum_{i=1}^{N} a_i^{(k)} f^{(k)}(X + x_i^* h) + \mathcal{L}[h, \mathbf{a}]f(X)\,, \tag{4.1}$$

where $X = (a + b)/2$ and $h = (b - a)/2$. Two families of N-point exponential-fitting quadrature formulae will be considered here, one involving values of the integrand and its first derivative, corresponding to $J = 1$, and the other involving function values only, in which case $J = 0$. For both families we take

$$L = (D^2 + \omega^2)^N,$$

where $D = d/dx$; in the notation of section 2, $m = 2N$.

4.1. The kernel function. A set of $2N$ linearly independent solutions of the differential equation

$$(D^2 + \omega^2)^N y = 0 \tag{4.2}$$

is

$$\{x^p \exp(\pm i\omega x)\}, \quad p = 0, 1, \ldots, N - 1,$$

but it is preferable to use a different set of solutions based on functions which were introduced in [10] and which appear in a slightly different notation in [14]. Let

$$\eta_{-1}(-\omega^2 x^2) := \cos \omega x,$$

and

$$\eta_0(-\omega^2 x^2) := \begin{cases} \dfrac{\sin \omega x}{\omega x} & \text{for } \omega x \neq 0, \\ 1 & \text{for } \omega x = 0. \end{cases}$$

For integers $s > 0$ the functions η_s are defined by the recurrence relation

$$\eta_s(Z) := \frac{1}{Z}[\eta_{s-2}(Z) - (2s - 1)\eta_{s-1}(Z)], \quad s = 1, 2, \ldots, \tag{4.3}$$

and have the power series expansion

$$\eta_s(Z) = 2^s \sum_{q=0}^{\infty} \frac{(q + 1)(q + 2) \cdots (q + s)\, Z^q}{(2q + 2s + 1)!}\,.$$

When $Z \to 0$ they behave as

$$\eta_s(Z) = \frac{2^s s!}{(2s + 1)!} + O\,(Z)\,. \tag{4.4}$$

These functions are related to the spherical Bessel functions by the equation

$$\eta_s(-x^2) = x^{-s} j_s(x), \quad s = 0, 1, 2, \ldots.$$

Differentiation gives

$$\eta_s'(Z) = \frac{1}{2}\eta_{s+1}(Z), \quad s = -1, 0, 1, \ldots. \tag{4.5}$$

Those properties allow us to derive an explicit expression for the resolvent kernel corresponding to the operator $L = (D^2 + \omega^2)^N$.

Let

$$y_N(x) = x^{2N-1}\eta_{N-1}(-\omega^2 x^2).$$

Then (4.5) and (4.3) give

$$y_N'(x) = x^{2N-2}\eta_{N-2}(-\omega^2 x^2),$$

and a second differentiation gives

$$(D^2 + \omega^2)y_N(x) = 2(N-1)x^{2N-3}\eta_{N-2}(-\omega^2 x^2) = 2(N-1)y_{N-1}(x).$$

In particular, $(D^2 + \omega^2)y_1(x) = 0$, with the result that

$$L[y_N](x) := (D^2 + \omega^2)^N y_N(x) = 0.$$

Furthermore, from (4.4),

$$y_N(x) = \frac{2^{N-1}(N-1)!}{(2N-1)!}x^{2N-1} + O\left(x^{2N+1}\right)$$

as $x \to 0$; thus $y_N^{(k)}(0) = 0$ for $0 \le k \le 2N-2$ and $y_N^{(2N-1)}(0) = 2^{N-1}(N-1)!$. It follows that the resolvent kernel corresponding to the operator L is

$$K(t,x) = \frac{y_N(t-x)}{2^{N-1}(N-1)!} = \frac{1}{2^{N-1}(N-1)!}(t-x)^{2N-1}\eta_{N-1}(-\omega^2(t-x)^2). \tag{4.6}$$

The kernel functions derived specifically for Examples 1, 3, and 4 of section 3 are special cases of this formula, corresponding to $N = 1$, 2, and 3, respectively.

4.2. The quadrature error. It is convenient to introduce the dimensionless variables $x^* = (x - X)/h$ and $t^* = (t - X)/h$, in which case x^*, $t^* \in [-1, 1]$. Then

$$K(t,x) = h^{2N-1}K^*(t^*, x^*),$$

where

$$K^*(t^*, x^*) = \frac{1}{2^{N-1}(N-1)!}(t^* - x^*)^{2N-1}\eta_{N-1}(-\theta^2(t^* - x^*)^2). \tag{4.7}$$

The partial derivatives of K with respect to t are

$$\frac{\partial^k}{\partial t^k}K(t,x) = h^{2N-1-k}\frac{\partial^k}{\partial t^{*k}}K^*(t^*, x^*).$$

Then $\Phi(x) = h^{2N}\Phi^*(x^*)$, with

$$\Phi^*(x) = \phi_i^*(x^*) \quad \text{for} \quad x_i^* < x^* < x_{i+1}^*, \qquad i = 0, 1, \ldots, N,$$

where $x_0^* = -1$, $x_{N+1}^* = 1$, and

$$\phi_0^*(x^*) = -\int_{-1}^{x^*} K^*(t^*, x^*)\, dt^*,$$

$$\phi_{i+1}^*(x^*) = \phi_i^*(x^*) + \sum_{k=0}^{J} a_{i+1}^{(k)} \left[\frac{\partial^k}{\partial t^{*k}} K^*(t^*, x^*)\right]_{t^*=x_{i+1}^*} \quad \text{for} \quad i = 0, 1, 2, \ldots, N-1.$$

The formulae given in the previous section are sufficient to build up all these functions in analytic form.

Let $D^* = d/dx^* = hD$. In terms of the dimensionless variables, the quadrature error is

$$err_{ef} = h \int_{-1}^{1} \Phi^*(x^*)(D^{*2} + \theta^2)^N F(x^*)\, dx^*, \tag{4.8}$$

where $F(x^*) = f(x)$.

When the integrand in (4.1) is the unit function, the quadrature error is

$$\int_{X-h}^{X+h} \Phi(x)\omega^{2N}\, dx = h\theta^{2N} \int_{-1}^{1} \Phi^*(x^*)\, dx^* =: h\theta^{2N} T^*(\theta).$$

From the quadrature formula, that error may also be expressed as

$$\int_{X-h}^{X+h} dx - h\sum_{i=1}^{N} a_i^{(0)} = h\left(2 - \sum_{i=1}^{N} a_i^{(0)}\right).$$

Therefore,

$$T^*(\theta) = \frac{2 - \sum_{i=1}^{N} a_i^{(0)}}{\theta^{2N}}.$$

The quadrature coefficients are functions of θ, as in the examples in section 3.

With $\Phi^*(x^*)$ split into $\Phi_+^*(x^*)$ and $\Phi_-^*(x^*)$ as was done earlier for $\Phi(x)$, and with

$$T_\pm^*(\theta) := \int_{-1}^{1} \Phi_\pm^*(x^*)\, dx^*,$$

the quadrature error may be expressed as

$$err_{ef} = h[T_+^*(\theta)(D^{*2} + \theta^2)^N f(\eta_+) + T_-^*(\theta)(D^{*2} + \theta^2)^N f(\eta_-)] \tag{4.9}$$

for some $\eta_+, \eta_- \in (a, b)$, which depend on θ and on the integrand f. It follows that the error can be expressed as a sum of two terms of Lagrange type for *any* θ at which the method is defined, that is, for all θ with the possible exception of a discrete set $\theta_1, \theta_2, \ldots$ of critical values. In at least some cases the simpler form in (2.4) is valid when θ is sufficiently small.

The asymptotic behaviors of $T^*(\theta)$, on one hand, and those of its components $T_\pm^*(\theta)$, on the other, are not necessarily similar. Suppose that for large values of θ the functions $T_\pm^*(\theta)$ are well described by the approximation

$$T_\pm^*(\theta) \approx \pm c(\theta)\theta^{-(2N-\bar{N})} + c_\pm(\theta)\theta^{-2N}, \tag{4.10}$$

where $0 < \bar{N} < 2N$ and the functions $c(\theta)$ and $c_{\pm}(\theta)$, with $c_{+}(\theta) \neq -c_{-}(\theta)$, are oscillating between constant limits; think, for example, of the case where $c(\theta) = c_{+}(\theta) = 1 + \cos\theta$ and $c_{-}(\theta) = -1 + \cos\theta$. Then $T^{*}_{\pm}(\theta)$ will damp out as $\theta^{-(2N-\bar{N})}$, that is, more slowly than their sum $T^{*}(\theta)$ which decays as θ^{-2N}. The determination of this $\bar{N}$ therefore represents a key issue if we want to characterize the asymptotic behavior of the error by means of (4.9).

4.3. Exponential-fitting extended Newton–Cotes rules with $J = 1$. In the N-point rule the (dimensionless) evenly spaced abscissas are

$$x^{*}_{i} = 2(i-1)/(N-1) - 1 \quad (i = 1, 2, \ldots, N), \tag{4.11}$$

and there are $2N$ coefficients to be determined, namely, $a^{(0)}_{i}$ and $a^{(1)}_{i}$ for $i = 1, \ldots, N$. The condition that $\mathcal{L}[h, \mathbf{a}]y(x)$ is identically vanishing in x and in h when $y(x)$ is a solution of the reference differential equation (4.2) is imposed with this aim. The technique is explained in [14]. For the numerical evaluation of these coefficients we used the subroutine `EFEXTQS`.

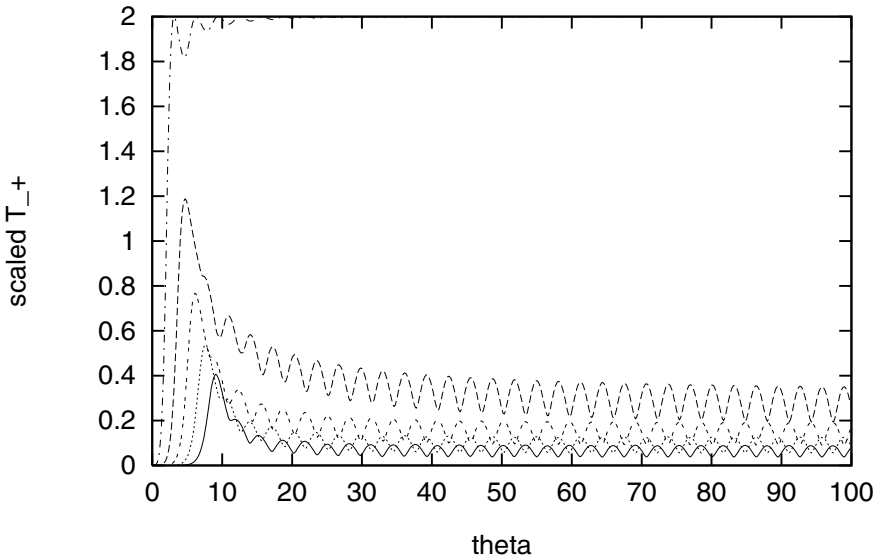

FIG. 1. *Exponential-fitting N-point extended Newton–Cotes rule with $J = 1$: variation with θ of the scaled $T^{*}_{+}(\theta)$ (the first of* (4.12) *with $\bar{N} = N - 2$) for $N = 2$ (dash and dots), $N = 3$ (dashes), $N = 4$ (dash pairs), $N = 5$ (dots), and $N = 6$ (solid).*

To determine $\bar{N}$ for each given N, trial values $0, 1, \ldots$ were considered for $\bar{N}$, and for each of these the behavior of the product $\theta^{2N-\bar{N}}T^{*}_{\pm}(\theta)$ was scanned for large θ. The desired value is that for which this product oscillates between constant limits. This kind of search was undertaken for $2 \leq N \leq 6$, and it led to the conclusion that $\bar{N} = N - 2$. To illustrate this fact, in Figures 1 and 2 we represent the dependence on θ of the functions

$$N^{\bar{N}}\theta^{2N-\bar{N}}T^{*}_{+}(\theta) \text{ and } N^{\bar{N}}\theta^{2N-\bar{N}}T^{*}_{-}(\theta), \tag{4.12}$$

respectively, for $2 \leq N \leq 6$ in Figure 1, and for $3 \leq N \leq 6$ in Figure 2, with $\bar{N} = N - 2$. The factor $N^{\bar{N}}$ was introduced to have the graphs for different N collected in a reduced number of figures.

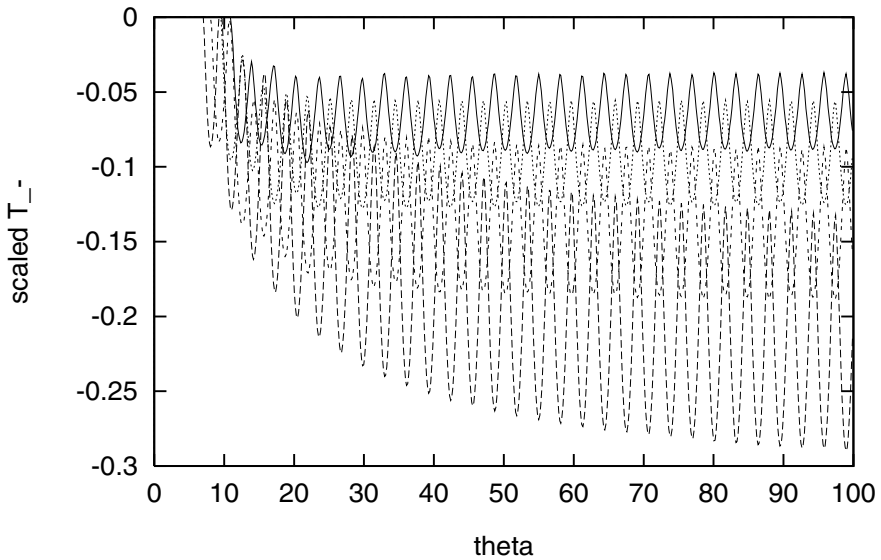

FIG. 2. *Exponential-fitting N-point extended Newton–Cotes rule with $J = 1$: variation with θ of the scaled $T_-^*(\theta)$ (the second of* (4.12) *with $\bar{N} = N - 2$) for $N = 3$ (dashes), $N = 4$ (dash pairs), $N = 5$ (dots), and $N = 6$ (solid).*

It is seen that all these curves exhibit oscillatory variation within limits which become approximately constant as $\theta \to \infty$, thus confirming that $\bar{N} = N - 2$ is the right value of $\bar{N}$. For $N = 2$ we have $\bar{N} = 0$. The reason is that $\Phi^*(x^*)$ is nonnegative everywhere on $x^* \in [-1\,, 1]$ irrespective of θ and then $\Phi_-^*(x^*) = 0$; this is also why the case $N = 2$ is absent from Figure 2.

In order to use our conclusion to predict the asymptotic behavior of the quadrature error as $\theta \to \infty$ it is necessary to specify the class of integrands to be considered. Using the dimensionless variable introduced in section 4.2 we assume that the integrand has the form

$$f(x) = F(x^*) = f_1(x^*)\cos\theta x^* + f_2(x^*)\sin\theta x^*, \tag{4.13}$$

where f_1 and f_2 are sufficiently differentiable functions independent of θ. Then

$$(D^{*2} + \theta^2) f(x) \sim 2\theta\left[f_2'(x^*)\cos\theta x^* - f_1'(x^*)\sin\theta x^*\right],$$

as $\theta \to \infty$. It follows that

$$(D^{*2} + \theta^2)^N f(x) \sim \theta^N g(x^*, \theta), \tag{4.14}$$

where $g(x^*, \theta)$ is bounded as $\theta \to \infty$.

Numerical calculations [15] indicate that $\lim_{\theta\to\infty} a_i^{(0)} = 0$ for $i = 1, 2, \ldots, N$; thus $T^*(\theta) \sim 2\theta^{-2N}$ as $\theta \to \infty$. For integrands of the assumed form the amplitude of the quadrature error given by (4.9) will, in general, damp out asymptotically as $\theta^{\bar{N}-N} = \theta^{-2}$, that is, with one and the same rate for all N. A faster decay is possible only if the unknown points $\eta_\pm^*$ have the property that, in the notation of (4.14), $g(\eta_\pm^*, \theta) = 0$.

To illustrate the quality of this prediction we take the test case

$$I(\omega) = \int_{-1}^{1} \cos[(\omega + 1/2)x]\, dx = \frac{2\sin(\omega + 1/2)}{\omega + 1/2}, \tag{4.15}$$

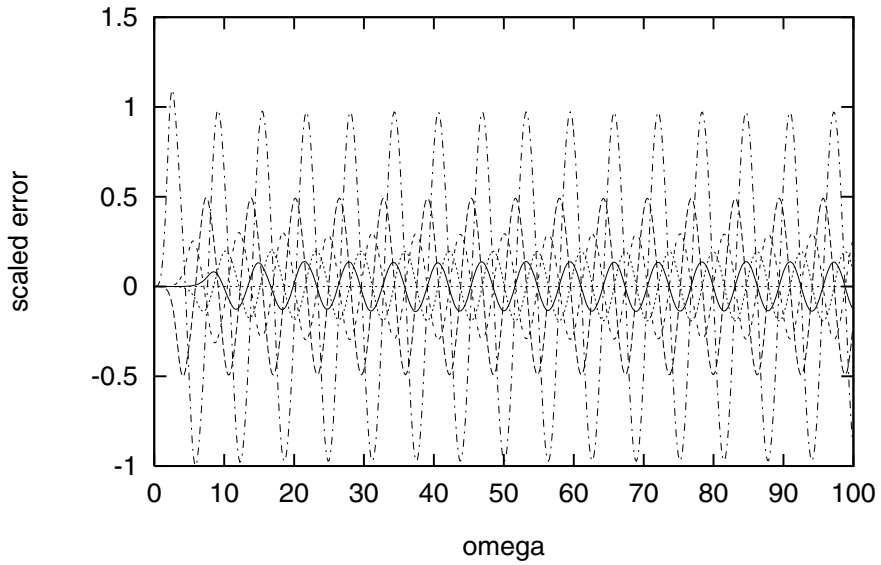

FIG. 3. *Exponential-fitting N-point extended Newton–Cotes rule with $J = 1$ for the integral* (4.15)*: variation with ω of the scaled absolute error* (4.16) *for $N = 2$ (dash and dots), $N = 3$ (dashes), $N = 4$ (dash pairs), $N = 5$ (dots), and $N = 6$ (solid).*

in which $h = 1$ and $\theta = \omega$, and in Figure 3 we present the scaled absolute error

$$N^{\bar{N}}\omega^2[I(\omega) - I_{comput}(\omega)] \tag{4.16}$$

for $2 \le N \le 6$. Each of the five curves oscillates between limits which become approximately constant at large ω, in full agreement with the prediction.

The formal series for the quadrature error, as developed in [14], is

$$\mathcal{L}[h, \mathbf{a}(\theta)]f(X) = h^{2N+1}\sum_{k=0}^{\infty} h^k T_k^*(\theta, \mathbf{a}(\theta))D^k(D^2 + \omega^2)^N f(X)\,. \tag{4.17}$$

The first term of that series is

$$lte_{ef} = hT_0^*(\theta, \mathbf{a}(\theta))(D^{*2} + \theta^2)^N f(X)\,, \tag{4.18}$$

where $T_0^*(\theta, \mathbf{a}(\theta))$ is the function denoted by $T^*(\theta)$ in section 4.2. It is clear from the discussion above that, in general, lte_{ef} damps out as θ^{-N} as $\theta \to \infty$. The authors of [14] recognized that in practice this decay rate is usually too optimistic. In fact, the two-point formula is the only one in this family of methods for which the prediction from the lte_{ef} coincides with that from the integral representation of the error. Our analysis, based on the integral representation of the error, shows why the "leading term" lte_{ef} is not a reliable predictor of the dependence of the quadrature error on θ.

4.4. Exponential-fitting Gaussian rules. These formulae are of the type (4.1) where $J = 0$, but the abscissas are no longer fixed in advance. Again $2N$ parameters are to be determined, but now they are the abscissas x_n^* and the coefficients $a_n^{(0)}$ for $n = 1, 2, \ldots, N$. All these parameters are θ-dependent (see [13]), and they were calculated numerically by the subroutine `EFGAUSS` in [14]. As for the extended Newton–Cotes formulae, numerical computations indicate that $\lim_{\theta\to\infty} a_n^{(0)}(\theta) = 0$ for all relevant values of n.

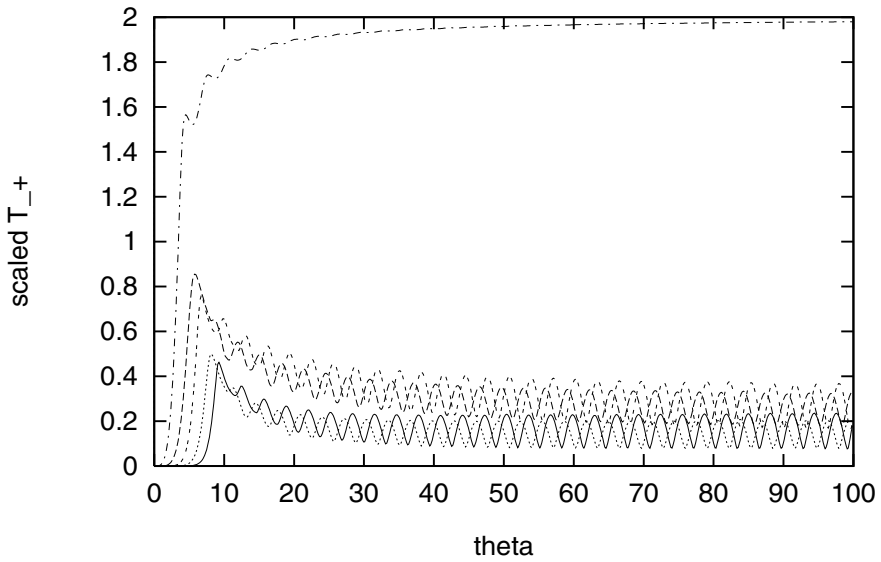

FIG. 4. *Exponential-fitting N-point Gaussian rule: variation with θ of the scaled $T_+^*(\theta)$ (the first of* (4.12) *with $\bar{N} = \lfloor (N-1)/2 \rfloor$) for $N = 2$ (dash and dots), $N = 3$ (dashes), $N = 4$ (dash pairs), $N = 5$ (dots), and $N = 6$ (solid).*

For large θ, the approximation (4.10) applies as in section 4.3, but the values of $\bar{N}$ are different. The same numerical procedure as before was used to determine $\bar{N}$, and in this case we conclude that $\bar{N} = \lfloor (N-1)/2 \rfloor$ where $\lfloor u \rfloor$ is the biggest integer less than or equal to u. For $N \leq 6$ these values are $\bar{N} = 0$ for $N = 1, 2$, $\bar{N} = 1$ for $N = 3, 4$, and $\bar{N} = 2$ for $N = 5, 6$. Thus for $N \geq 4$ they are smaller than the corresponding values for the Newton–Cotes rules. In Figures 4 and 5 we present the two scaled functions displayed in (4.12), the first for $2 \leq N \leq 6$ in Figure 4 and the second for $3 \leq N \leq 6$ in Figure 5; of course, the value $\bar{N} = \lfloor (N-1)/2 \rfloor$ is now used.

For integrands of the form (4.13) this leads to the conclusion that in general the quadrature error decays like $\theta^{\bar{N}-N}$ as $\theta \to \infty$. In particular, for $N = 3$ it decays at least as fast as θ^{-2}, as for the corresponding extended Newton–Cotes rule, but for $N = 4$ or 5 it decays at least as fast as θ^{-3}, and faster decay rates are predicted for larger values of N.

The scaled absolute error

$$N^{\bar{N}} \omega^{N-\bar{N}} [I(\omega) - I_{comput}(\omega)] \tag{4.19}$$

for the test case (4.15) is presented in Figure 6 for $2 \leq N \leq 6$. It confirms the predicted behavior of the quadrature error for this problem. In contrast, the analysis based on the "leading term" of the formal series does not distinguish between the extended Newton–Cotes rule and the corresponding Gaussian rule.

Van Daele, Vanden Berghe, and Vande Vyver [18] recently considered a variety of exponential-fitting Gaussian rules. Truncation error was not their primary concern, and they merely quoted the first nonzero terms in the corresponding formal series for the quadrature error, as developed in [14].

4.5. A numerical comparison with Filon integration. As an illustration of the effectiveness of Filon-type methods for oscillatory integrands, Iserles [9] applied

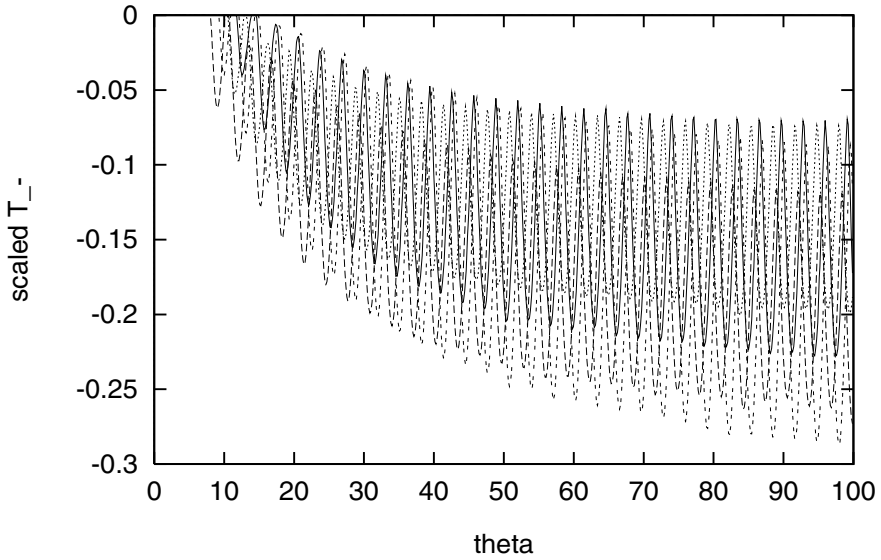

FIG. 5. *Exponential-fitting N-point Gaussian rule: variation with θ of the scaled $T_-^*(\theta)$ (the second of* (4.12) *with $\bar{N} = \lfloor (N-1)/2 \rfloor$) for $N = 3$ (dashes), $N = 4$ (dash pairs), $N = 5$ (dots), and $N = 6$ (solid).*

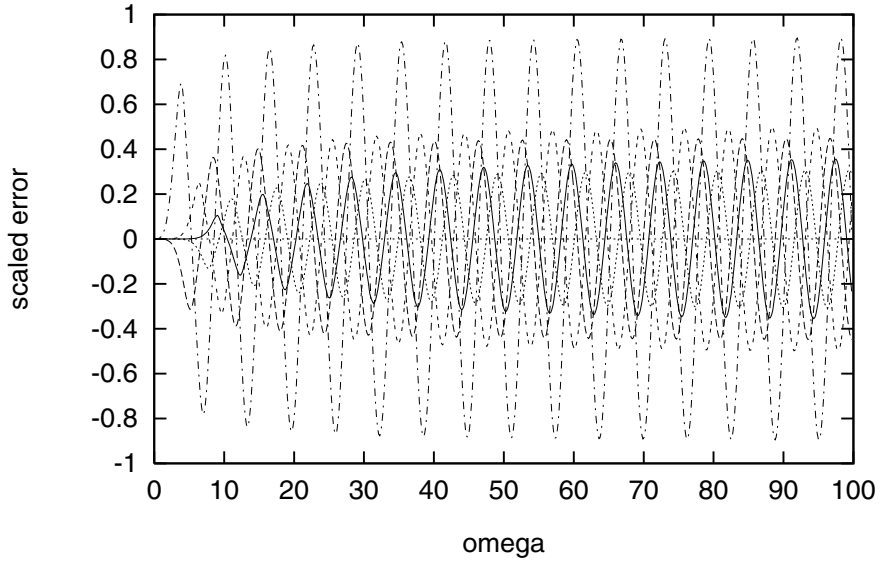

FIG. 6. *Exponential-fitting N-point Gaussian rule for the integral* (4.15): *variation with ω of the scaled absolute error* (4.19) *for $N = 2$ (dash and dots), $N = 3$ (dashes), $N = 4$ (dash pairs), $N = 5$ (dots), and $N = 6$ (solid).*

the three-point Filon–Lobatto formula to the integral

$$I = \int_0^b \exp[(1 + i\omega)x]\, dx = \frac{\exp[(1 + i\omega)b] - 1}{1 + i\omega}$$

for $b = 1/10$, denoted by h in [9]. In our notation, $h = b/2$, so $2\theta = b\omega$.

To provide a comparison with the bottom graph of Figure 3 of [9], our Figure 7 shows the variation with 2θ of the normalized absolute error $(2\theta)^2|I - I_{comput}|$ for

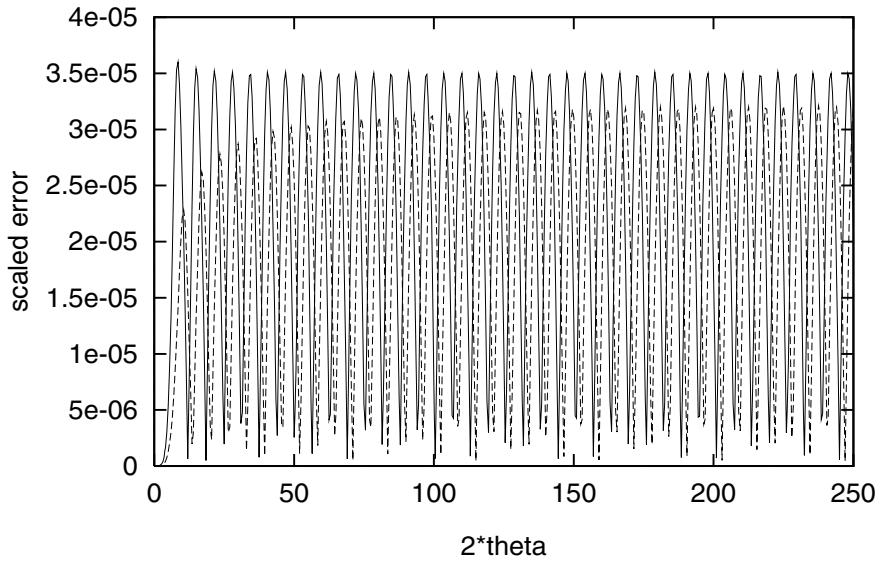

FIG. 7. *Exponential-fitting three-point rules: variation with* 2θ *of the scaled absolute error* $(2\theta)^2|I - I_{comput}|$ *for ENC (solid) and G (broken).*

the two exponential-fitting three-point rules discussed above. The solid line is for the extended Newton–Cotes rule (ENC), and the broken line corresponds to the Gaussian rule (G). To allow the detail to be seen more clearly, the plotting interval here is $[0, 250]$ rather than the larger interval used in [9]. For both methods the error envelope decays as θ^{-2} as predicted. Figure 3 of [9] shows the same rate of decay for Filon–Lobatto integration, but the amplitude of the error is greater by almost an order of magnitude than that of either of the exponential-fitting formulae.

It is also interesting to consider what happens when $N = 4$, since the predicted behaviors of the two exponential-fitting methods are different. The behavior of the extended Newton–Cotes formula is expected to be as for $N = 3$, but for the Gaussian formula the error envelope is expected to decrease at least as fast θ^{-3}. Figure 8 shows $(2\theta)^2|I - I_{comput}|$ for ENC (solid) and $(2\theta)^3|I - I_{comput}|$ for G (broken), confirming those predictions. The analysis of [9] shows that for the Filon–Lobatto method the same rate of decay is expected for $N = 4$ as for $N = 3$.

5. A quadrature formula with $L = D^2(D^2 + \omega^2)$. The way in which the expression for the error was exploited above, to draw conclusions on the behavior of the error at large θ, consisted of combining separate results on the asymptotic behaviors of $T_{\pm}^{*}(\theta)$ and $L[F](x^*)$. It worked successfully in all cases investigated in sections 4.2–4.4, but there are situations when it may fail to reveal correct asymptotic behaviors. Such a case is discussed in this section, where we also present an alternative way based on the use of the integral form of the error without invoking the mean-value theorem.

We consider the two-point exponential-fitting Gaussian rule

$$\int_{X-h}^{X+h} f(x)dx \approx h\left[a_1^{(0)} f(X + x_1^* h) + a_2^{(0)} f(X + x_2^* h)\right], \tag{5.1}$$

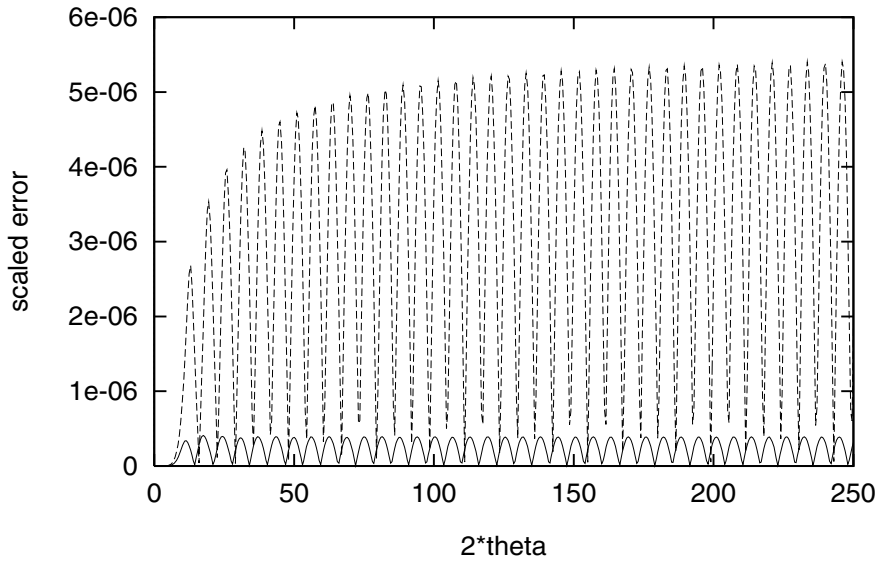

FIG. 8. *Exponential-fitting four-point rules: variation with 2θ of the scaled absolute errors $(2\theta)^2|I - I_{comput}|$ for ENC (solid) and $(2\theta)^3|I - I_{comput}|$ for G (broken).*

which is exact for 1, x, and $\exp(\pm i\omega x)$. The parameters of the required quadrature rule are

$$a_1^{(0)}(\theta) = a_2^{(0)}(\theta) = 1, \quad x_1^*(\theta) = -x_2^*(\theta) = -\arccos[\sin(\theta)/\theta]/\theta = -\arccos[\eta_0(-\theta^2)]/\theta$$

and, by considering the error when $f(x) = x^2$,

$$T_0^*(\theta, \mathbf{a}(\theta)) = T^*(\theta) = \frac{1/3 - [x_1^*(\theta)]^2}{\theta^2} = \frac{1/3 - \{\arccos[\eta_0(-\theta^2)]\}^2/\theta^2}{\theta^2}. \tag{5.2}$$

It is easy to check that, as expected, when $\theta \to 0$ this formula tends to the classical two-point Gauss–Legendre formula, i.e., $x_1^*(\theta)$, $x_2^*(\theta)$, and $T_0^*(\theta)$ tend to $-1/\sqrt{3}$, $1/\sqrt{3}$, and $1/135$, respectively. This quadrature formula was considered, with several others, in [18].

The functions which are to be integrated exactly satisfy the reference differential equation $D^2(D^2 + \omega^2)y = 0$, and the quadrature error is

$$err_{ef} = h \int_{-1}^{1} \Phi^*(x^*) D^{*2}(D^{*2} + \theta^2) F(x^*)\, dx^*, \tag{5.3}$$

where $F(x^*) = f(x)$.

The kernel function corresponding to the operator $D^2(D^2 + \omega^2)$ was derived in connection with Example 2 of section 3. In terms of the dimensionless variables introduced at the beginning of section 4.2,

$$K^*(t^*, x^*) = \frac{t^* - x^*}{\theta^2} - \frac{\sin\theta(t^* - x^*)}{\theta^3}.$$

Let $x_0^* = -1$ and $x_3^* = 1$. Then

$$\Phi^*(x^*) = \begin{cases} \phi_0^*(x^*) & \text{for } -1 < x^* < x_1^*, \\ \phi_1^*(x^*) & \text{for } x_1^* < x^* < x_2^*, \\ \phi_2^*(x^*) & \text{for } x_2^* < x^* < 1, \end{cases}$$

where

$$\begin{aligned}\phi_0^*(x^*) &= -\int_{-1}^{x^*} K^*(t^*, x^*)\, dt^* \\ &= \frac{(1+x^*)^2}{2\theta^2} - \frac{1}{\theta^4} + \frac{\cos\theta(1+x^*)}{\theta^4}, \\ \phi_1^*(x^*) &= \phi_0^*(x^*) + \frac{x_1^* - x^*}{\theta^2} - \frac{\sin\theta(x_1^* - x^*)}{\theta^3}, \\ \phi_2^*(x^*) &= \phi_1^*(x^*) + \frac{x_2^* - x^*}{\theta^2} - \frac{\sin\theta(x_2^* - x^*)}{\theta^3}.\end{aligned}$$

Using the fact that $\cos\theta x_1^* = \sin\theta/\theta$, it can be shown that ϕ_1^* is an even function and that $\phi_2^*(x^*) = \phi_0^*(-x^*)$. It follows that Φ^* is an even function.

It is easily seen that $\phi_0^*(x^*) > 0$ for $-1 < x^* \le x_1^*$; thus $\Phi^*(x^*) > 0$ for $-1 < x^* \le x_1^*$ and $x_2^* \le x^* < 1$. Numerical evidence indicates that $\Phi^*(x^*) > 0$ for all $x^* \in (-1, 1)$. If that is so, then

$$err_{ef} = hT^*(\theta)D^{*^2}(D^{*^2} + \theta^2)F(\eta) \tag{5.4}$$

for some unknown $\eta \in (-1, 1)$.

As in section 4, to investigate the asymptotic behavior of the quadrature error we assume that the integrand has the form (4.13). Then, for fixed x^*, independent of θ,

$$D^{*2}(D^{*2} + \theta^2)F(x^*) \sim 2\theta^3\,[f_1'(x^*)\sin(\theta x^*) - f_2'(x^*)\cos(\theta x^*)] \tag{5.5}$$

as $\theta \to \infty$. Equation (5.2) shows that $T^*(\theta) \sim \theta^{-2}$. Combining the two asymptotic estimates as in earlier sections we can conclude only that err_{ef} could increase like θ as $\theta \to \infty$. This estimate is not confirmed on the test integral (4.15); it is too pessimistic. Indeed, it is clear that $I(\omega) = O(1/\omega)$ as $\omega \to \infty$ and that the approximation given by the two-point formula (5.1), namely,

$$I_{comput} = \cos[(\omega + 1/2)x_1^*(\omega)] + \cos[(\omega + 1/2)x_2^*(\omega)] = 2\cos[(\omega + 1/2)x_1^*(\omega)],$$

has the same asymptotic behavior. Since the leading terms of the two expansions in powers of $1/\omega$ are different, it also follows that

$$I(\omega) - I_{comput} = O(1/\omega) \qquad \text{as} \quad \omega \to \infty.$$

In other words, the actual error decays as $1/\omega$ instead of increasing as ω, as predicted; notice that for this test case we have $h = 1$ and then $\theta = \omega$.

The reason for the discrepancy is not the forms (5.3) or (5.4) of the error but the way in which the latter was exploited. An alternative way consists of using the integral representation (5.3) directly.

In view of (5.5) and the fact that Φ^* is an even function, the asymptotic form of the quadrature error, for fixed h as $\theta \to \infty$, is

$$err_{ef} \sim 4h\theta^3 \int_{-1}^{0} \Phi^*(x^*)G(x^*)\, dx^*, \tag{5.6}$$

where

$$G(x^*) = f_{1o}'(x^*)\sin(\theta x^*) - f_{2e}'(x^*)\cos(\theta x^*),$$

f'_{1o} is the odd part of f'_1, and f'_{2e} is the even part of f'_2. This can be written as

$$4h\theta^3 \left[I_1(\theta) + I_2(\theta) \right],$$

where

$$I_1(\theta) = \int_{-1}^{0} \phi_0^*(x^*) G(x^*)\, dx^*$$

and

$$I_2(\theta) = \int_{x_1^*}^{0} [\phi_1^*(x^*) - \phi_0^*(x^*)] G(x^*)\, dx^*.$$

The integrand in I_1 may be written as a sum of three terms, corresponding to the three terms in ϕ_0^*. Because of the trigonometric factors in the function G, the Riemann–Lebesgue lemma shows that the contributions from the two terms containing θ^{-4} tend to zero faster than θ^{-4}, and we need only consider

$$\frac{1}{2\theta^2} \int_{-1}^{0} (1 + x^*)^2 \left[f'_{1o}(x^*) \sin(\theta x^*) - f'_{2e}(x^*) \cos(\theta x^*) \right] dx^*.$$

Integration by parts, noting that the odd function $f'_{1o}(x^*)$ vanishes when $x^* = 0$, allows us to write this as

$$\frac{1}{2\theta^3} \int_{-1}^{0} [g_1(x^*) \cos(\theta x^*) + g_2(x^*) \sin(\theta x^*)]\, dx^* = O(\theta^{-4});$$

the precise form of the functions g_1 and g_2 arising from the integration by parts is not of any interest.

In the integral

$$I_2(\theta) = \int_{x_1^*}^{0} \left[\frac{x_1^* - x^*}{\theta^2} - \frac{\sin \theta (x_1^* - x^*)}{\theta^3} \right] G(x^*)\, dx^*,$$

the magnitude of the second term is less than $|x_1^*|\, \theta^{-3} \|G\| = O(\theta^{-4})$ as $\theta \to \infty$. The first term in $I_2(\theta)$ is

$$\frac{1}{\theta^2} \int_{x_1^*}^{0} (x_1^* - x^*) \left[f'_{1o}(x^*) \sin(\theta x^*) - f'_{2e}(x^*) \cos(\theta x^*) \right] dx^*.$$

Integration by parts, again using the fact that $f'_{1o}(0) = 0$, reduces this to

$$\frac{1}{\theta^3} \int_{x_1^*}^{0} \left[k_1(x^*) \cos(\theta x^*) + k_2(x^*) \sin(\theta x^*) \right] dx^* = O(\theta^{-4}),$$

and the precise forms of the functions k_1 and k_2 are not important. This leads to the conclusion that for all integrands of the assumed form the error in the approximation provided by the two-point formula (5.1) tends to zero at least as fast as $1/\theta$, as $\theta \to \infty$ for fixed h, in full agreement with our observations for the test integral.

A by-product of this analysis is that the parameter η of (5.4) depends on θ in such a way that $D^{*^2}(D^{*^2} + \theta^2)F(\eta)$ increases no faster than the first power of θ as $\theta \to \infty$.

6. Conclusion. The integral representation of the truncation error, based on the work of Ghizzetti and Ossicini [8], is applicable to a wide variety of exponential-fitting methods for oscillatory problems. The detailed investigations of sections 4 and 5 are concerned with quadrature methods but the truncation errors in exponential-fitting methods for ordinary differential equations and in numerical differentiation formulae could be analyzed in the same way.

Section 4.5 shows that, for the particular example considered there, two three-point exponential-fitting formulae have the same qualitative behavior as a three-point Filon–Lobatto method advocated for such problems [9], but their errors are less by almost an order of magnitude than that of the Filon–Lobatto method. Furthermore, the errors in exponential-fitting Gaussian formulae with larger numbers of abscissas have faster decay rates, whereas the analysis of Iserles [9] shows that the decay rate of the error in Filon–Lobatto methods is not improved by increasing the number of nodes. This suggests that exponential-fitting quadrature methods, and particularly those of Gaussian type, are worthy of further investigation as practical methods for the numerical integration of oscillatory integrands.

Acknowledgment. We are grateful to the referees for their helpful comments, and particularly for an improved argument used just before (3.4).

A PARALLEL METHOD FOR BACKWARD PARABOLIC PROBLEMS BASED ON THE LAPLACE TRANSFORMATION*

JINWOO LEE† AND DONGWOO SHEEN†

Abstract. A parallel method for time discretization of backward parabolic problems is proposed. The problem is reformulated to a set of Helmholtz-type problems with a parameter on a suitably chosen contour in the complex plane. After solving the resulting elliptic equations, which can be solved in parallel, we obtain a regularized solution with high frequency terms cut off by the inverse Laplace transforms without requiring the knowledge of the eigenfunctions of the differential operator. Since the regularized solution is obtained without artificial perturbation and high frequency components of the noise are suppressed, the quality of the solution is improved significantly compared to those obtained by other methods. Two different numerical inversions of Laplace transforms, with an arbitrary high order of accuracy and spectral accuracy, respectively, are used. Error estimates and numerical examples are presented.

Key words. numerical method, backward parabolic, ill-posed problem, Laplace transform, quadrature, parallel method

1. Introduction.

We consider the following backward parabolic problem: given $u_0 \in L^2(\Omega)$, find $u = u(t) = u(\cdot, t) \in H_0^1(\Omega)$ such that

$$u_t + Au = 0 \quad \text{for } t \in (0, T], \quad \text{with } u(\cdot, 0) = u_0(\cdot) \text{ in } \Omega, \tag{1.1}$$

where $-A$ is a uniformly elliptic second-order partial differential operator on a domain Ω with a homogeneous Dirichlet boundary condition. Furthermore, we assume that A is a closed operator in the Hilbert space $L^2(\Omega)$ which generates an analytic semigroup $E(t) = e^{tA}$ and the spectrum $\sigma(-A)$ of $-A$ is contained in a sector $\{z \in \mathbb{C} : |\arg z| < \zeta\}$ for some $\zeta \in (0, \pi/2)$. We also assume that the resolvent $(zI + A)^{-1}$ of $-A$ satisfies

$$\|(zI + A)^{-1}\| \le \frac{C}{1 + |z|} \quad \text{for } z \in \Sigma_\zeta,$$

where the complementary sector Σ_ζ is given by

$$\Sigma_\zeta = \{z \in \mathbb{C} : \zeta < |\arg z| \le \pi\} \cup \{O\}.$$

Problem (1.1) is a well-known ill-posed problem in the sense that the solution does not depend continuously on the data u_0 [15, 19, 29]. However, it can be formulated as a well-posed problem, for instance, by imposing a prescribed bound on the solution at $t = T$ [19]. More precisely, given data $g \in L^2(\Omega)$ with noise, let $u^{(j)}$, $j = 1, 2$, be any two solutions of (1.1) satisfying

$$\|u^{(j)}(T)\| \le M \qquad \text{and} \qquad \|u_0^{(j)} - g\| \le \delta, \tag{1.2}$$

where M and δ are given positive constants and $\|\cdot\|$ denotes the $L^2(\Omega)$-norm. Then it is known [29] that

$$\|u^{(1)}(t) - u^{(2)}(t)\| \le 2M^{t/T}\delta^{1-t/T} \quad \text{for } t \in (0, T], \tag{1.3}$$

which follows directly from the convexity of $F(t) = \log \|u^{(1)}(t) - u^{(2)}(t)\|^2$. We thus have continuous dependence on the data, and any numerical solution of the problem can be regarded as a kind of *regularized* solution depending on the two constraints M and δ in (1.2).

Stable numerical methods for backward parabolic problems can be applied to several practical areas such as image processing, mathematical finance, and physics. However, the ill-posedness nature of the problems requires certain types of regularization techniques. One approach to regularize the ill-posed problems is based on the use of eigenfunction expansion [17, 28, 23, 25, 30], where the eigenpairs of the corresponding elliptic operator are available. Another approach is to use the method of quasi reversibility [4, 7, 8, 12, 13, 14, 21, 27]. Other approaches include the least squares methods with Tikhonov-type regularization [2, 16, 18, 24, 26] and the use of heat kernel [9]. Buzbee and Carasso [4] introduced a method of transforming the problem (1.1) into a second-order in time problem. Later Carasso [5, 6] introduced the concept of a supplementary constraint such as that of slow evolution from the continuation boundary (SECB). The methods of quasi reversibility and Tikhonov regularization introduce artificial contamination, which is not from noises, to the numerical solutions. We thus expect to improve the solution quality if we can avoid any artificial perturbation and effectively suppress the influence of high frequency noises, which is the purpose of this paper. We also indicate that parallel algorithms have not yet been seriously addressed; however, see [24].

In this paper, we develop a parallel numerical method without any perturbation to obtain a regularized solution to problem (1.1). Instead of attacking problem (1.1) in the original space-time domain setting, we take the Laplace transform in time to have a set of complex-valued, Helmholtz-type problems with a parameter on a suitably chosen contour Γ in a control domain. After solving the resulting elliptic problems, the regularized time-domain solution with high frequency terms cut off can be recovered by applying the inverse Laplace transformation numerically. Two different choices of contour Γ will be described in detail in the next section. The first contour introduced in [32] requires no information on eigenpairs of the operator A, while the second one proposed in [22], which is more efficient, requires information on eigenvalues only. Since we obtain solutions without modifying the original problem and high frequency terms of noise are cut-off automatically, solution quality is improved significantly, especially as time goes on to the final time T (see the end of section 2.3).

The outline of the rest of the paper is as follows. In the next section, two numerical schemes are introduced based on the Laplace transformation of (1.1). In section 3, basic stability and error estimates are derived for these numerical schemes. Some numerical results are given in section 4.

2. The numerical schemes. Let us reformulate problem (1.1) by formally performing the Laplace transformation in time. Then

$$z\widehat{u} + A\widehat{u} = u_0 \text{ in } \Omega \quad \text{for } z \in \rho(-A) \tag{2.1}$$

with the homogeneous Dirichlet boundary condition on $\partial\Omega$, where $\rho(-A)$ is the resolvent set of $-A$. First, denote by $\{\phi_k\}_{k=1}^{\infty}$ and $\{\lambda_k\}_{k=1}^{\infty}$ the orthonormal eigenfunctions

of $-A$ and the corresponding eigenvalues which satisfy $0 < \operatorname{Re}\lambda_1 \le \operatorname{Re}\lambda_2 \le \cdots \to +\infty$. The solution $\widehat{u}(z)$ of (2.1) is then given in the following form:

$$\widehat{u}(z) = (zI + A)^{-1}u_0 = \sum_{k=1}^{\infty} \frac{1}{z-\lambda_k}(u_0, \phi_k)\phi_k, \tag{2.2}$$

since the solution of (1.1), if any, admits the representation

$$u(t) = \sum_{k=1}^{\infty} e^{\lambda_k t}(u_0, \phi_k)\phi_k. \tag{2.3}$$

In (2.3) we can observe that small errors on u_0 grow without bound, which is the source of ill-posedness. Among several regularization methods [17, 23] to avoid such an error growth, we shall employ a method of cutting off high frequency terms in the current paper.

From now on, denote by $\widehat{u}^{u_0}$ and $\widehat{u}^{g}$ the solutions to (2.1) with data u_0 and g, respectively. We begin by defining our regularization $u^{\Gamma,u_0}(t)$, using the Laplace inversion formula, by

$$u^{\Gamma,u_0}(t) = \frac{1}{2\pi \mathrm{i}} \int_{\Gamma} e^{zt}\widehat{u}^{u_0}(z)\, dz, \tag{2.4}$$

where, for some positive integer N,

$$\Gamma = \{z \in \mathbb{C} | \operatorname{Re}\lambda_N < \operatorname{Re} z < \operatorname{Re}\lambda_{N+1}\} \subset \rho(-A), \tag{2.5}$$

and the direction of Γ is taken such that $\operatorname{Im}(z)$ is increasing from $-\infty$ to $+\infty$. The contour Γ will be deformed subsequently for the sake of computational efficiency, and we will see that λ_i's need not be known explicitly for $\Gamma = \Gamma_1$ (see section 2.1 for the definition of Γ_1).

Notice that

$\displaystyle\sum_{k=N+1}^{\infty} \frac{1}{z-\lambda_k}(u_0, \phi_k)\phi_k$ is analytic in the half plane left of the straight line contour Γ,

which, incorporated into (2.2) and (2.4), implies that

$$\begin{aligned} u^{\Gamma,u_0}(t) &= \frac{1}{2\pi \mathrm{i}} \sum_{k=1}^{\infty} \int_{\Gamma} \frac{e^{zt}}{z-\lambda_k}(u_0, \phi_k)\phi_k\, dz \\ &= \frac{1}{2\pi \mathrm{i}} \sum_{k=1}^{N} \int_{\Gamma} \frac{e^{zt}}{z-\lambda_k}(u_0, \phi_k)\phi_k\, dz = \sum_{k=1}^{N} e^{\lambda_k t}(u_0, \phi_k)\phi_k, \end{aligned} \tag{2.6}$$

which is a spectral representation of $u^{\Gamma,u_0}(t)$ with high frequency terms cut off. The resulting $u^{\Gamma,g}(t)$ with a given data g satisfying (1.2) instead of u_0 fulfills the following stability condition:

$$\|u(t) - u^{\Gamma,g}(t)\| \le 2M^{t/T}\delta^{1-t/T} \quad \text{for } t \in (0, T] \tag{2.7}$$

if we choose N in (2.5) to be the largest integer such that

$$\operatorname{Re}\lambda_N \le \frac{1}{T}\log\frac{M}{\delta}$$

holds. See section 3 for more details.

2.1. The numerical procedure using a hyperbolic contour. We now deform the straight line contour Γ in (2.4) into the left-hand branch of a hyperbola, as in [32], with the asymptotes having slopes $\pm\kappa$, which crosses the real axis at $\gamma - \nu$, by setting

$$\Gamma_1 = \{z : z = z(\omega) = \sigma(\omega) + \mathrm{i}\kappa\omega,\ -\infty < \omega < \infty\} \subset \rho(-A), \qquad \sigma(\omega) = \gamma - \sqrt{\omega^2 + \nu^2}, \tag{2.8}$$

for suitable parameters $\nu > 0$ (usually $\nu = 0.5$) and $\kappa > 0$, where γ will be chosen such that $\gamma - \nu = (1/T)\log(M/\delta)$, provided $\gamma - \nu$ does not coincide with any $\operatorname{Re}\lambda_i$. Then we have $\operatorname{Re}\lambda_N < \gamma - \nu < \operatorname{Re}\lambda_{N+1}$ for N used in Theorem 3.1. The parameters of Γ_1 are chosen such that the eigenvalues $\lambda_1, \ldots, \lambda_N$ are to the left of the contour Γ_1, while the rest of eigenvalues are to the right of Γ_1. At the end of section 3.1 we will remark on the flexible choice of Γ_1. With the deformed contour Γ_1, the integral (2.4) can be written as

$$u^{\Gamma_1,u_0}(t) = \frac{1}{2\pi\mathrm{i}} \int_{-\infty}^{\infty} e^{z(\omega)t} \widehat{u}^{u_0}(z(\omega)) z'(\omega)\, d\omega. \tag{2.9}$$

We notice that, as $\omega \to \pm\infty$, $e^{z(\omega)t}$ goes to zero rapidly, which accelerates convergence. Next, we transform the infinite interval $(-\infty, \infty)$ for ω in (2.9) into a finite one. For this, let $\psi : (-\infty, \infty) \to (-1, 1)$ be defined by $\psi(\omega) = \tanh(\frac{\tau\omega}{2})$ as in [32]. In particular, by applying the change of variables $y = \psi(\omega)$ or, equivalently, $\omega = \psi^{-1}(y) = \frac{1}{\tau}\log\frac{1+y}{1-y}$ with the parameter $\tau > 0$ to be determined later, the integral (2.9) can be transformed into one on $(-1, 1)$ for y, where the trapezoidal rule can be applied to get

$$U_{L_1,\tau}^{\Gamma_1,u_0}(t) = \frac{1}{2\pi\mathrm{i}} \frac{1}{L_1} \sum_{j=-L_1+1}^{j=L_1-1} e^{z_j t} \widehat{u}^{u_0}(z_j) \frac{dz}{d\omega}(\omega_j) \frac{d\psi^{-1}}{dy}(y_j), \tag{2.10}$$

where

$$z_j = z(\omega_j), \quad \omega_j = \psi^{-1}(y_j) = \frac{1}{\tau}\log\frac{1+y_j}{1-y_j}, \quad \text{and } y_j = \frac{j}{L_1},\ -L_1 < j < L_1. \tag{2.11}$$

The change of variables here spreads the equidistant points y_j's in $(-1, 1)$ over $\mathbb{R}$ to ω_j's such that we have a finer grid near the origin where the integrand is relatively larger and a coarser grid where the integrand becomes relatively smaller. In [32], it is shown that this quadrature scheme has an arbitrary high order of accuracy for forward parabolic problems. In this paper we prove similarly that the same accuracy holds, although the properties of integrands are slightly different. The basic error estimate essentially shows that, for any positive integer r,

$$\|u^{\Gamma,u_0}(t) - U_{L_1,\tau}^{\Gamma_1,u_0}(t)\| \le \frac{C}{L_1^r} \left(\frac{\beta M}{\delta}\right)^{t/T} \|u_0\| \quad \text{for } t > r\tau, \tag{2.12}$$

where C depends on various parameters and $\beta > 1$ is a constant.

2.2. The numerical procedure using a union of small circles. When the eigenvalues of the operator $-A$ are known, we can deform the contour in (2.4) into a union of disjoint small circles around the eigenvalues of $-A$ [22], which enables us

to reduce computational costs significantly when the number of dominant eigenvalues is relatively small. Set $d = \min_{1\le k\le N} \min_{l\neq k} |\lambda_k - \lambda_l|$ and assume that $d > 0$. For a sufficiently small $\varepsilon \in (0, d)$ (such that the circle $|z - \lambda_k| = \varepsilon$ contains no other eigenvalues than λ_k for all k), we define the second contour Γ_2 by

$$\Gamma_2 = \bigcup_{k=1}^{N} C_k \subset \rho(-A), \quad C_k = \{z : z = \lambda_k + \varepsilon e^{\mathrm{i}\theta}, 0 \le \theta \le 2\pi\}, \tag{2.13}$$

where N is again the largest integer such that $\operatorname{Re}\lambda_N \le (1/T)\log(M/\delta)$ holds. With this Γ_2, (2.4) can be written as

$$u^{\Gamma_2,u_0}(t) = \frac{1}{2\pi i}\sum_{k=1}^{N}\int_{C_k} e^{zt}\widehat{u}^{u_0}(z)\,dz. \tag{2.14}$$

After applying the change of variables $z = \lambda_k + \varepsilon e^{\mathrm{i}\theta}$ on each circle C_k and the trapezoidal rule, we have

$$U_{L_2}^{\Gamma_2,u_0}(t) = \frac{1}{2\pi}\sum_{k=1}^{N}\frac{2\pi}{L_2}\sum_{j=0}^{L_2-1} e^{z_{k,j}t}\widehat{u}^{u_0}(z_{k,j})\varepsilon e^{\mathrm{i}\theta_j}, \tag{2.15}$$

where $z_{k,j} = \lambda_k + \varepsilon e^{\mathrm{i}\theta_j}$ and $\theta_j = \frac{2\pi}{L_2}j$ for $0 \le j \le L_2 - 1$. The efficiency of this scheme originates in that the interval of the integral could be arbitrarily small by letting ε be small (it should not be too small because of the machine precision; see section 3.2). The error estimate of this scheme results in spectral accuracy of the form

$$\|U_{L_2}^{\Gamma_2,u_0}(t) - u^{\Gamma,u_0}(t)\| = C\left(\frac{\beta' M}{\delta}\right)^{t/T}\left(\varepsilon'^{L_2} + \frac{eps}{\varepsilon}\right)\|u_0\|, \tag{2.16}$$

where C is independent of ε and L_2, *eps* is the machine precision, and $\varepsilon' = \varepsilon/d$, for $\beta' = e^{\varepsilon T} > 1$. With a double precision calculation, *eps* can be as small as about 10^{-16}.

2.3. The fully discrete schemes. The fully discrete scheme is achieved by combining the time-discretization procedure, either (2.10) or (2.15), with the finite element method for spatial approximation procedure. For this, let $(V_h)_{h>0}$ denote a family of standard piecewise linear finite element subspaces of $H_0^1(\Omega)$. Let $a(\cdot,\cdot)$ be the natural sesquilinear form associated with A. Then the finite element approximation $\widehat{u}_h^{u_0}(z) \in V_h$ to the solution $\widehat{u}^{u_0}(z)$ of (2.1) satisfies

$$z(\widehat{u}_h^{u_0}(z), v) + a(\widehat{u}_h^{u_0}(z), v) = (u_0, v) \quad \forall v \in V_h, \forall z \in \rho(-A). \tag{2.17}$$

Thus the spatially discretized approximation U_h^{Γ,u_0} to u^{Γ,u_0} in (2.4) is given by

$$U_h^{\Gamma,u_0}(t) = \frac{1}{2\pi\mathrm{i}}\int_{\Gamma} e^{zt}\widehat{u}_h^{u_0}(z)\,dz. \tag{2.18}$$

By combining the time-discretization procedure, either (2.10) or (2.15), with the finite element method the fully discretized solution is given by either

$$U_{L_1,h,\tau}^{\Gamma_1,u_0}(t) = \frac{1}{2\pi\mathrm{i}}\frac{1}{L_1}\sum_{j=-L_1+1}^{j=L_1-1} e^{z_j t}\widehat{u}_h^{u_0}(z_j)\frac{dz}{d\omega}(\omega_j)\frac{d\psi^{-1}}{dy}(y_j) \tag{2.19}$$

or

$$U_{L_2,h}^{\Gamma_2,u_0}(t) = \frac{1}{L_2}\sum_{k=1}^{N}\sum_{j=0}^{L_2-1} e^{z_{k,j}t}\widehat{u}_h^{u_0}(z_{k,j})\varepsilon e^{\mathrm{i}\theta_j}, \tag{2.20}$$

respectively. If inexact data g is given, g will be used instead of u_0, which will be analyzed in section 3.

To conclude this section, let us indicate two special features of the proposed methods. First, the methods can be implemented in parallel in the main part, solving a set of elliptic equations (2.1), of the procedures without any essential data communication among processors since they are independent of each other. This idea goes back to [11, 10] for solving wave propagation problems in the space-frequency domain setting, and it was later applied to forward parabolic problems [31, 32] and to a forward integro-differential equation with positive memory [20]. Second, the methods proposed in the current paper do not introduce any perturbation from the original problem, unlike others [2, 4, 7, 8, 12, 13, 14, 16, 18, 24, 26, 30], and therefore the solution quality of our method is much better than that of others. The trick is in *formally* reformulating the problem into problems in the Laplace transformed setting as in (2.1). The reformulated equation (2.1) is well defined and well posed, although one cannot perform the Laplace transform of the solution (2.3) since it does not exist for any $z \in \mathbb{C}$. Thus we choose to start from this equation. When it is inverted by using the Laplace inversion formula (2.4), the contour Γ has to be selected, and it gives a natural way of controlling the frequency terms. Noticing that eigenvalues of $-A$ correspond to the poles of $\widehat{u}(z)$ (see (2.2)) we see that the poles to the left of Γ are taken and those to the right of Γ are discarded (see (2.6)). In this way the regularization is performed naturally without perturbing anything, and the high frequency components of noise whose eigenvalues are bigger than λ_N cause no influence on the numerical solutions. This feature improves the quality of the solutions remarkably, which will be illustrated in section 4.

3. Stability and error estimates. In this section we analyze the stability of and error estimates of the two numerical procedures introduced in the previous section. Before going into the details of both properties, we first state and prove an error estimate between the exact solution u of (1.1) with constraints (1.2) and the regularized solution $u^{\Gamma,g}$ in (2.4) with given data g satisfying (1.2).

THEOREM 3.1. *Let $g \in L^2(\Omega)$ be given. Suppose that u is an exact solution of* (1.1) *with constraints* (1.2). *If N in* (2.5) *is chosen to be the largest integer such that* $\operatorname{Re}\lambda_N \le (1/T)\log(M/\delta) < \operatorname{Re}\lambda_{N+1}$, *then the following error bound holds:*

$$\|u(t) - u^{\Gamma,g}(t)\| \le 2M^{t/T}\delta^{1-t/T} \text{ for } t \in (0,T]. \tag{3.1}$$

Proof. Let us consider the regularized solution with exact data u_0, say $u^{\Gamma,u_0}(t)$, and N be the largest integer such that $\operatorname{Re}\lambda_N \le (1/T)\log(M/\delta) \operatorname{Re}\lambda_{N+1}$. From (1.2) and (2.3), it follows that $\sum_{k=1}^{\infty} c_k^2 e^{2\operatorname{Re}\lambda_k T} \le M^2$ with $c_k = (u_0, \phi_k)$, and therefore

$$\begin{aligned}\|u(t) - u^{\Gamma,u_0}(t)\|^2 &= \sum_{k=N+1}^{\infty} c_k^2 e^{2\operatorname{Re}\lambda_k t} = \sum_{k=N+1}^{\infty} c_k^2 e^{2\operatorname{Re}\lambda_k t} e^{2\operatorname{Re}\lambda_k T} e^{-2\operatorname{Re}\lambda_k T}\\ &\le e^{2(t-T)\operatorname{Re}\lambda_{N+1}} \sum_{k=N+1}^{\infty} c_k^2 e^{2\operatorname{Re}\lambda_k T}\\ &\le (\delta/M)^{2(1-t/T)} M^2 = \delta^{2(1-t/T)} M^{2t/T}. \end{aligned} \tag{3.2}$$

Similarly, the difference between the two regularizations with initial data u_0 and g is estimated as follows: with $g_k = (g, \phi_k)$,

$$\|u^{\Gamma,u_0}(t) - u^{\Gamma,g}(t)\|^2 = \sum_{k=1}^{N}(c_k - g_k)^2 e^{2\,\mathrm{Re}\,\lambda_k t} \le e^{2\,\mathrm{Re}\,\lambda_N t}\sum_{k=1}^{N}(c_k - g_k)^2$$
$$\le (M/\delta)^{2t/T}\delta^2 = M^{2t/T}\delta^{2(1-t/T)} \tag{3.3}$$

since we have $\sum_{k=1}^{\infty}(c_k - g_k)^2 \le \delta^2$ by (1.2). The assertion is then obtained by the triangle inequality. ∎

3.1. Analysis of the numerical procedure using a hyperbolic contour. As we mentioned in section 2.1, we put $\gamma - \nu = (1/T)\log(M/\delta)$, provided it does not coincide with any λ_i. Let

$$\Sigma_{\zeta_1,\gamma-\nu} = \{z \in \mathbb{C} : \zeta_1 < |\arg(z - \gamma + \nu)| < \pi - \zeta_1\} \cup \mathcal{N}_{\gamma-\nu} \subset \rho(-A), \tag{3.4}$$

where $\mathcal{N}_{\gamma-\nu}$ is a neighborhood of $\gamma - \nu$ that does not contain any eigenvalue of $-A$, and $\zeta_1 \in (0, \pi/2)$ is chosen such that $\Gamma_1 \subset \Sigma_{\zeta_1,\gamma-\nu}$. By (2.2), we can find a constant $B_1 > 0$, independent of z, such that

$$\|(zI + A)^{-1}\| \le \frac{B_1}{1 + |z - \gamma + \nu|} \quad \text{for } z \in \Sigma_{\zeta_1,\gamma-\nu}. \tag{3.5}$$

We notice that $B_1 = O(\eta^{-1})$, where η is a distance between the two sets $\Sigma_{\zeta_1,\gamma-\nu}$ and $\sigma(-A)$, the spectrum of $-A$. From now on set $\beta = e^{\nu T}$. We then have the following stability estimate.

THEOREM 3.2. *Let $U_{L_1,\tau}^{\Gamma_1,g}$ be the approximation defined by* (2.10) *of the regularized solution $u^{\Gamma_1,g}$ given by* (2.9)*, with u_0 replaced by g. Then, for $t > \tau$,*

$$\|U_{L_1,\tau}^{\Gamma_1,g}\| \le C(\beta M/\delta)^{t/T}\|g\|,$$

where $C = \sqrt{2}(2 - \frac{1}{L_1})\sqrt{1+\kappa^2}B_1/(\tau\pi)$.

Proof. From (2.8), (2.10), and (2.11) it follows that

$$\|U_{L_1,\tau}^{\Gamma_1,g}(t)\| \le \frac{1}{2\pi}\frac{1}{L_1}\sum_{j=-L_1+1}^{L_1-1}|e^{z_j t}|\|\widehat{u}^g(z_j)\|\left|\frac{dz}{d\omega}(\omega_j)\frac{d\psi^{-1}}{dy}(y_j)\right|$$
$$\le \frac{\sqrt{1+\kappa^2}e^{\gamma t}}{\sqrt{2}\pi L_1}\sum_{j=-L_1+1}^{L_1-1}e^{-|\omega_j|t}\left|\frac{d\psi^{-1}}{dy}(y_j)\right|\|\widehat{u}^g(z_j)\|$$
$$\le \frac{\sqrt{1+\kappa^2}e^{\gamma t}}{\sqrt{2}\pi L_1}\sqrt{\sum_{j=-L_1+1}^{L_1-1}\left(e^{-|\omega_j|t}\frac{d\psi^{-1}}{dy}(y_j)\right)^2}\sqrt{\sum_{j=-L_1+1}^{L_1-1}\|\widehat{u}^g(z_j)\|^2} \tag{3.6}$$

since $\left|\frac{dz}{d\omega}(\omega_j)\right| \le \sqrt{2}$. Now, for $j \ge 0$,

$$e^{-|\omega_j|t}\frac{d\psi^{-1}}{dy}(y_j) = e^{-\frac{t}{\tau}\log\frac{1+y_j}{1-y_j}}\frac{2}{\tau}\frac{1}{1-y_j^2} = \frac{2}{\tau}\frac{(1-y_j)^{t/\tau-1}}{(1+y_j)^{t/\tau+1}} \le \frac{2}{\tau} \quad \text{if } t > \tau. \tag{3.7}$$

The same bound holds for $j < 0$. Since $\gamma = \log(M/\delta)/T + \nu$, we have

$$e^{\gamma t} = (\beta M/\delta)^{t/T}, \tag{3.8}$$

where we recall that $\beta = e^{\nu T}$. Next, by using (2.8) and (3.5), we have, for $z \in \Sigma_{\zeta_1,\gamma-\nu}$,

$$\begin{aligned}\|\widehat{u}^g(z(\omega))\| = \|(z(\omega)I + A)^{-1}g\| &\le \frac{B_1}{1+|z(\omega)-\gamma+\nu|}\|g\| \\ &\le \frac{B_1}{1+\kappa|\omega|}\|g\| \le B_1\|g\|, \end{aligned} \tag{3.9}$$

which, combined with (3.6), completes the proof. □

Our error analysis is based on an Euler–Maclaurin-type proposition [32].

PROPOSITION 3.3 (Sheen, Sloan, and Thomeé [32]). *Let $r \ge 1$ be given and assume that $v \in C^r(\mathbb{R}; L^2(\Omega))$ and*

$$\|v^{(j)}(\omega)\| = O(e^{-r\tau|\omega|}) \quad \text{for } j \le r \text{ as } |\omega| \to \infty.$$

Furthermore, if $\|v(\omega)\| = o(e^{-\tau|\omega|})$ for $r = 1$, then we have the error estimate

$$\|Q_{L_1,\tau}(v) - I(v)\| \le C_r \frac{1}{L_1^r}\left(1 + \frac{1}{\tau^r}\right)\int_{-\infty}^{\infty} e^{r\tau|\omega|}\sum_{j=0}^{r}\|v^{(j)}(\omega)\|\,d\omega,$$

where

$$I(v) := \int_{-\infty}^{\infty} v(\omega)\,d\omega \quad \text{and} \quad Q_{L_1,\tau}(v) := \frac{1}{L_1}\sum_{j=-L_1+1}^{L_1-1} v(\omega_j)\frac{d\psi^{-1}}{dy}(y_j). \tag{3.10}$$

The proof of Proposition 3.3 is given in [32].

Proposition 3.3 implies that the formula (3.10) is of an arbitrary high order of accuracy, provided $v(\omega)$ vanishes appropriately fast at infinity. Based on Proposition 3.3, we derive an error estimate between the regularized solution $u^{\Gamma_1,g}$ given in (2.4) and its time-discretized approximation $U^{\Gamma_1,g}_{L_1,\tau}(t)$ given in (2.10) using g instead of u_0.

LEMMA 3.4. *Let $u^{\Gamma_1,g}(t)$ and $U^{\Gamma_1,g}_{L_1,\tau}(t)$ be the regularized solution defined by* (2.4) *and its approximation defined by* (2.10)*, respectively, with initial data g instead of u_0 and r a positive integer. Then, for $t > r\tau$, we have*

$$\|u^{\Gamma_1,g}(t) - U^{\Gamma_1,g}_{L_1,\tau}(t)\| \le \frac{C_{r,t}}{L_1^r}\left(\frac{\beta M}{\delta}\right)^{t/T}\|g\|, \tag{3.11}$$

where $C_{r,t} = C_r\frac{(1+\kappa^2)^{r/2}}{k}(1+t^r)(1+\frac{1}{\tau^r})(1+\log_+\frac{\kappa}{t-r\tau})$ and $\log_+ x = \max(0,\log x)$.

Proof. Set $v(\omega,t) = \frac{1}{2\pi i}e^{z(\omega)t}\widehat{u}^g(z(\omega))z'(\omega)$. Then, from (2.9) and (2.10), with u_0 replaced by g, it follows that

$$u^{\Gamma_1,g}(t) - U^{\Gamma_1,g}_{L_1,\tau}(t) = I(v(\cdot,t)) - Q_{L_1,\tau}(v(\cdot,t)).$$

Our aim is to apply Proposition 3.3, and for this we need to bound the derivatives of the function $\widehat{u}^g(z)$ on Γ_1. Since $\frac{d^j}{dz^j}(zI+A)^{-1} = (-1)^j j!(zI+A)^{-j-1}$, (3.9) and an induction on j imply that

$$\left\|\frac{d^j}{dz^j}\widehat{u}^g(z)\right\| \le \frac{C_j}{1+\kappa|\omega|}\|g\| \quad \text{for } z \in \Gamma_1. \tag{3.12}$$

The Leibniz rule is then applied to obtain

$$\left\| \frac{\partial^j}{\partial \omega^j} v(t,\omega) \right\| \le C_r \left(1+t^r\right) \frac{(1+\kappa^2)^{r/2} e^{t\sigma(\omega)}}{1+\kappa|\omega|} \|g\| \quad \text{for } j \le r, \quad \omega \in \mathbb{R},$$

where $C_r > 0$ is a constant depending on $\|\frac{d^j}{d\omega^j}\sigma(\omega)\|_{L_\infty(\mathbb{R})}$ for $j \le r$. Since $\sigma(\omega) \approx -|\omega|$ for large $|\omega|$ the assumptions of Proposition 3.3 are thus satisfied if $t > r\tau$, and the proposition implies that

$$\|u^{\Gamma_1,g}(t) - U^{\Gamma_1,g}_{L_1,\tau}(t)\| \le C_r L_1^{-r} \left(1+\tau^{-r}\right)\left(1+t^r\right) e^{\gamma t} \int_{-\infty}^{\infty} \frac{(1+\kappa^2)^{r/2} e^{-|\omega|(t-r\tau)}}{1+\kappa|\omega|}\, d\omega\, \|g\|,$$

since we have $\sigma(\omega) \le \gamma - |\omega|$. To bound the integral that remains, notice that $\int_0^\infty e^{-\omega t}(1+\omega)^{-1}\, d\omega \le C(1+\log_+(1/t))$, which can be verified easily by arithmetic calculations. Then (3.8) is used to complete the proof of the lemma. ∎

Remark 3.5. The parameter r appears only in the theorem, not in the method. Its implication is that the larger the r, the faster the convergence. And the above estimate is valid at least for $t > \tau$. In the numerical examples in section 4, we choose $\tau = 1/2$.

Next we deal with the space-discretization error.

LEMMA 3.6. *Let $U^{\Gamma_1,g}_{L_1,\tau}(t)$ and $U^{\Gamma_1,g}_{L_1,h,\tau}(t)$ be defined as in* (2.10) *and* (2.19)*, respectively, using g instead of u_0. Then, for $t > \tau$, we have*

$$\|U^{\Gamma_1,g}_{L_1,\tau}(t) - U^{\Gamma_1,g}_{L_1,h,\tau}(t)\| \le Ch^2(\beta M/\delta)^{t/T}\|g\|, \tag{3.13}$$

where $C = C\sqrt{1+\kappa^2}\left(\frac{2L_1-1}{L_1\tau}\right)$.

Proof. Combining (2.10), (2.19), and (2.8) we have

$$\begin{aligned}\|U^{\Gamma_1,g}_{L_1,\tau}(t) - U^{\Gamma_1,g}_{L_1,h,\tau}(t)\| &\le \frac{1}{2\pi}\frac{1}{L_1}\sum_{j=-L_1+1}^{L_1-1} |e^{z_j t}| \|\widehat{u}^g(z_j) - \widehat{u}^g_h(z_j)\| \left|\frac{dz}{d\omega}(\omega_j)\frac{d\psi^{-1}}{dy}(y_j)\right| \\ &\le C\sqrt{1+\kappa^2}h^2\|g\|e^{\gamma t}\frac{1}{L_1}\sum_{j=-L_1+1}^{L_1-1} e^{-|\omega_j|t}\left|\frac{d\psi^{-1}}{dy}(y_j)\right| \qquad (3.14)\end{aligned}$$

since, for h small (see [33]),

$$\|\widehat{u}^g(z) - \widehat{u}^g_h(z)\| \le Ch^2\|g\| \qquad \text{for } z \in \Gamma_1.$$

Owing to (3.7),

$$\frac{1}{L_1}\sum_{j=-L_1+1}^{L_1-1} e^{-|\omega_j|t}\left|\frac{d\psi^{-1}}{dy}(y_j)\right| \le \frac{2}{\tau}\left(\frac{2L_1-1}{L_1}\right).$$

Then (3.8) is used to complete the proof. ∎

Finally, combining Theorem 3.1, Lemma 3.4, Lemma 3.6, and the triangle inequality, we obtain the main result of this subsection.

THEOREM 3.7. *Let $u(t)$ be an exact solution of* (1.1)*, $g \in L^2(\Omega)$ be given satisfying* (1.2)*, and $U^{\Gamma_1,g}_{L_1,h,\tau}(t)$ be our fully discretized approximation to $u(t)$ defined by* (2.19)*. Then we have, for any integer $r \ge 1$,*

$$\begin{aligned}\|u(t) - U^{\Gamma_1,g}_{L_1,h,\tau}(t)\| &\le 2M^{t/T}\delta^{1-t/T} \\ &\quad + C\left(\frac{\beta M}{\delta}\right)^{t/T}\left(\frac{(1+\kappa^2)^{r/2}}{\kappa}\frac{1}{L_1^r} + \sqrt{1+\kappa^2}h^2\right)\|g\| \quad \textit{for} \quad r\tau < t < T.\end{aligned}$$

Remark 3.8. The choice of contour Γ_1 is flexible by letting the parameter κ variable with the asymptotes having slopes ± 1 and the real axis cut at $\gamma - \nu$. Indeed, in (2.8), let $\kappa = \kappa(\omega)$ be chosen such that the contour Γ_1 can be nearly parallel to the imaginary axis until it meets the line $y = \pm \tan\zeta$ if the eigenvalue $\operatorname{Re}\lambda_{N-1}$ is close to $\operatorname{Re}\lambda_N$. Inside the sector Σ_ζ the contour can be deformed analytically to have asymptotes with slopes ± 1 in order to have fast convergence. Corresponding to the contour

$$\Gamma_1 = \{z : z = z(\omega) = \sigma(\omega) + \mathrm{i}\kappa(\omega)\omega, -\infty < \omega < \infty\} \subset \rho(-A),$$
$$\sigma(\omega) = \gamma - \sqrt{\omega^2 + \nu^2},$$

suitable modifications in the analysis can be carried out accordingly.

3.2. Analysis of the numerical procedure using a union of small circles. Let us turn to analyzing the case of the second numerical scheme under the assumption that the eigenvalues of $-A$ are known. We shall see that the quadrature scheme (2.15) with Γ_2 is of spectral accuracy. Since Γ_2 is a compact subset of $\rho(-A)$, we may assume that

$$\|(zI + A)^{-1}\| \le B_2 \quad \text{for } z \in \Gamma_2, \tag{3.15}$$

with B_2 independent of z. From (2.2) and (2.13) it follows that $B_2 = O(\varepsilon^{-1})$.

Set $\beta' = e^{\varepsilon T}$. We then have the following stability estimate.

THEOREM 3.9. *Let $U_{L_2}^{\Gamma_2,u_0}(t)$ be the approximation defined by* (2.15) *of the regularized solution* (2.14)*. Then we have*

$$\|U_{L_2}^{\Gamma_2,u_0}(t)\| \le CN(\beta' M/\delta)^{t/T}\|u_0\| \quad \textit{for } t > 0.$$

Proof. By using (2.2), (2.15), and (3.15), a direct estimation leads to

$$\left\|U_{L_2}^{\Gamma_2,u_0}(t)\right\| = \left\|\sum_{k=1}^{N}\frac{1}{L_2}\sum_{j=0}^{L_2-1} e^{z_{k,j}t}\widehat{u}(z_{k,j})\varepsilon e^{\mathrm{i}\theta_j}\right\|$$
$$\le B_2 N\varepsilon e^{(\lambda_N+\varepsilon)t}\|u_0\| \le CNe^{(\operatorname{Re}\lambda_N+\varepsilon)t}\|u_0\|,$$

owing to the fact $B_2 = O(\varepsilon^{-1})$. Finally, since $\operatorname{Re}\lambda_N \le \log(M/\delta)/T$, one has

$$e^{(\operatorname{Re}\lambda_N+\varepsilon)t} \le (\beta' M/\delta)^{t/T}, \tag{3.16}$$

which proves the theorem. ∎

Recalling that $d = \min_{1\le k\le N}\min_{l\ne k}|\lambda_k - \lambda_l|$ and $\varepsilon < d$ (see section 2.2), we have the following lemma.

LEMMA 3.10. *Let $u^{\Gamma_2,g}(t)$ and $U_{L_2}^{\Gamma_2,g}(t)$ be the regularized solution defined by* (2.14) *and its approximation defined by* (2.15)*, respectively, with g instead of u_0 and L_2 a positive integer. Then we have, for some $C > 0$ independent of ε and L_2,*

$$\|u^{\Gamma_2,g}(t) - U_{L_2}^{\Gamma_2,g}(t)\| \le CN\left(\frac{\beta' M}{\delta}\right)^{t/T}\left(\varepsilon'^{L_2} + \frac{eps}{\varepsilon}\right)\|g\| \quad \textit{for } t > 0, \tag{3.17}$$

where eps is the machine precision, and $\varepsilon' = \varepsilon/d$.

Proof. Let $F(z) = e^{zt}\widehat{u}^g(z)$. By (2.2), $F(z)$ has simple poles at $z = \lambda_k$ and thus has a Laurent series expansion of the form

$$F(z) = \sum_{m=-1}^{\infty} c_{k,m}(z-\lambda_k)^m \quad \text{for } |z-\lambda_k| < d, \tag{3.18}$$

where $c_{k,m} = \frac{1}{2\pi \mathrm{i}} \int_{C_k} \frac{F(z)}{(z-\lambda_k)^{m+1}}\, dz$. Due to Cauchy's residue theorem, we get

$$u^{\Gamma_2,g}(t) = \sum_{k=1}^{N} c_{k,-1}. \tag{3.19}$$

Plugging (3.18) into (2.15) with u_0 replaced by g and rearranging the summand, we have

$$\begin{aligned} U_{L_2}^{\Gamma_2,g}(t) &= \sum_{k=1}^{N} \frac{1}{L_2} \sum_{m=-1}^{\infty} c_{k,m}\varepsilon^{m+1} \left(\sum_{j=0}^{L_2-1} (e^{\mathrm{i}\theta_{m+1}})^j \right) \\ &= \sum_{k=1}^{N} \left(c_{k,-1} + c_{k,L_2-1}\varepsilon^{L_2} + c_{k,2L_2-1}\varepsilon^{2L_2} + \cdots \right). \end{aligned} \tag{3.20}$$

The last equality follows from the fact that if $m+1$ is a multiple of L_2, the sum with index j becomes L_2; otherwise, it is $\frac{1-(e^{\mathrm{i}\theta_{m+1}})^{L_2}}{1-e^{\mathrm{i}\theta_{m+1}}}$, which is 0. Under the assumption of no machine round-off error, one then has the following type of bound: $\|u^{\Gamma_2,g}(t) - U_{L_2}^{\Gamma_2,g}(t)\| \le CN\varepsilon^{L_2}$. However, the extra term eps/ε in (3.17) will be included due to the round-off errors which become significant if ε is too small. For the derivation of this and various examples which show the validity of this estimation, we refer the reader to [22].

Now we calculate $c_{k,m}$ explicitly to get the final error form. By inserting (2.2) into $c_{k,m}$, for $m \ge 0$, we get $c_{k,m} = (1/2\pi\mathrm{i}) \int_{C_k} G(z)/(z-\lambda_k)^{m+1} dz$, where $G(z) = \sum_{l\neq k} \frac{e^{zt}}{z-\lambda_l} g_l\phi_l$, and $g_l = (g, \phi_l)$. Notice that $G(z)$ is analytic inside C_k and recall the definition of d. Since $\beta' = e^{\varepsilon T} > 1$, we have, by Cauchy's integral theorem for derivatives, the Leibniz rule, and (3.16), that

$$\begin{aligned} \|c_{k,m}\| &= \frac{1}{m!}\|G^{(m)}(\lambda_k)\| = \left\| \sum_{r=0}^{m} \frac{1}{m!} \binom{m}{r} t^{m-r} e^{\lambda_k t} (-1)^r r! \sum_{l\neq k} \frac{g_l\phi_l}{(\lambda_k-\lambda_l)^{r+1}} \right\| \\ &\le t^m e^{\mathrm{Re}\,\lambda_N t} \left\| \sum_{r=0}^{m} \frac{t^{-r}}{(m-r)!} \sum_{l\neq k} \frac{g_l\phi_l}{|\lambda_k-\lambda_l|^{r+1}} \right\| \\ &\le t^m e^{\mathrm{Re}\,\lambda_N t} \frac{1}{d} \sum_{r=0}^{m} \frac{1}{(m-r)!} \left(\frac{1}{dt}\right)^r \|g\| \\ &= \frac{1}{d} e^{\mathrm{Re}\,\lambda_N t} \sum_{s=0}^{m} \frac{(dt)^s}{s!} \frac{1}{d^m} \|g\| \\ &\le \frac{1}{d^{m+1}} e^{dt} \left(\frac{\beta' M}{\delta}\right)^{t/T} \|g\| \quad \text{for } k \le N. \end{aligned} \tag{3.21}$$

The last estimate combined with (3.19) and (3.20) leads to

$$\begin{aligned}\|u^{\Gamma_2,g}(t) - U_{L_2}^{\Gamma_2,g}(t)\| &= \sum_{k=1}^{N}\sum_{m=1}^{\infty} \|c_{k,mL_2-1}\varepsilon^{mL_2}\| \\ &\le N\sum_{m=1}^{\infty}\left(\frac{\varepsilon}{d}\right)^{mL_2} e^{dt}\left(\frac{\beta' M}{\delta}\right)^{t/T}\|g\| \\ &= N\frac{(\varepsilon')^{L_2}}{1-(\varepsilon')^{L_2}} e^{dt}\left(\frac{\beta' M}{\delta}\right)^{t/T}\|g\| \\ &\le CN\left(\frac{\beta' M}{\delta}\right)^{t/T}\left(\varepsilon'^{L_2} + \frac{eps}{\varepsilon}\right)\|g\|,\end{aligned}$$

with $C = \frac{e^{dT}}{1-(\varepsilon')^{L_2}}$, where the machine precision truncation was considered in the last estimate. This completes the proof. ∎

Remark 3.11. Inequality (3.21) is the worst case estimate. Although there exist concrete examples that show that the above estimate is sharp, most experiments similar to the examples in section 4 exhibit that d acts as 1.

Remark 3.12. For a fixed L_2, we should have $(\frac{\varepsilon}{d})^{L_2} + \frac{eps}{\varepsilon} \ge 2(\frac{eps}{d})^{L_2/(L_2+1)}$ with equality holding for $\varepsilon = d^{L_2/(L_2+1)} eps^{1/(L_2+1)}$, which is an optimal choice of ε for a fixed L_2. With this ε the error bound tends to $C \cdot eps/d$ as L_2 tends to ∞.

Remark 3.13. In our case of computing $F(z)$ numerically, the smaller the ε one chooses, the more computational costs one needs in order to achieve a given tolerance. Thus Remark 3.12 says that any choice of ε and L_2 such that $(\varepsilon/d)^{L_2}$ is less than a given tolerance is economic, provided $\varepsilon > d^{L_2/(L_2+1)} eps^{1/(L_2+1)}$. In the examples in section 4 we regard d as 1.

Next we consider the space-discretization error.

LEMMA 3.14. *Using g instead of u_0, let $U_{L_2}^{\Gamma_2,g}(t)$ and $U_{L_2,h}^{\Gamma_2,g}(t)$ be as in* (2.15) *and* (2.20)*, respectively. Then we have*

$$|U_{L_2}^{\Gamma_2,g}(t) - U_{L_2,h}^{\Gamma_2,g}(t)\| \le CNh^2(\beta' M/\delta)^{t/T}\|g\| \quad for\ t > 0. \tag{3.22}$$

Proof. The lemma is a consequence of the estimate $\|\widehat{u}^g(z) - \widehat{u}_h^g(z)\| \le Ch^2\|g\|$ for $z \in \Gamma_2$ and Theorem 3.9 with u_0 replaced by g. ∎

We are, finally, in a position to state the main result of this subsection.

THEOREM 3.15. *Let $g \in L^2(\Omega)$ be given data satisfying* (1.2)*, $u(t)$ be an exact solution of* (1.1)*, and $U_{L_2,h}^{\Gamma_2,g}$ be the fully discretized approximation to $u(t)$ defined by* (2.20)*. Then we have*

$$\|u(t) - U_{L_2,h}^{\Gamma_2,g}(t)\| \le 2M^{t/T}\delta^{1-t/T} + CN\left(\frac{\beta' M}{\delta}\right)^{t/T}\left(\varepsilon'^{L_2} + \frac{eps}{\varepsilon} + h^2\right)\|g\|, \tag{3.23}$$

for $0 < t < T$, with $\varepsilon' = \varepsilon/d$.

Proof. The proof is just a combination of Theorem 3.1, Lemma 3.10, Lemma 3.14, and the triangle inequality. ∎

4. Numerical examples. Examples 1, 2, and 3 have been chosen to illustrate the convergence theory developed in section 3. The complicated solution profiles produced in Examples 4 and 5 demonstrate the high quality of the regularized numerical

solutions compared with that of other recently proposed numerical methods [2, 24]. Parallel performance is reported in Example 6.

In each example the initial data with noise are generated by adding a perturbation to the exact initial data. Let x_i, $1 \le i \le J$, be a uniform partition of Ω. For each i, let $rd(x_i)$ be a pseudorandom number selected from $(-1, 1)$. Then define $rd : \Omega \to [-1, 1]$ by linear interpolation of $rd(x_i)$ and set $per(x) := \delta \cdot rd(x)/|\Omega|^{d/2}$, where d and δ denote the dimension of Ω and amplitude, respectively.

Example 1. Let $\Omega = (0, \pi)$ and $T = 4$. Then consider the following backward parabolic problem:

$$u_t + u_{xx} = 0 \quad \text{in } \Omega \times (0, T), \tag{4.1a}$$

$$u = 0 \quad \text{on } \partial\Omega \times (0, T), \tag{4.1b}$$

$$u_0(x) = e^{-4} \sin x + e^{-16} \sin 2x \quad \text{for } x \in \Omega, \tag{4.1c}$$

with the exact solution $u(x, t) = e^{t-4} \sin x + e^{4(t-4)} \sin 2x$. Notice that the eigenpairs are $\phi_k = \sqrt{2/\pi} \sin kx$, and $\lambda_k = k^2, k = 1, 2, \ldots$. In this case we have $\|u(\cdot, T)\| = 1.89$. Set $M = 2$ and $\delta = 10^{-2}$ in (1.2). Then $\lambda_N \le (1/T) \log(M/\delta) = 1.32$, by which $\lambda_1 = 1$ is the largest eigenvalue bounded. Thus we have $N = 1$ in Theorem 3.1.

In implementation, (2.19) is applied with the contour Γ_1 given in (2.8) with the parameters chosen in the following fashion without requiring information on eigenpairs:

- we take $\nu = 0.5$ and $\tau = 0.5$;
- γ is chosen such that $\gamma - \nu = (1/T) \log(M/\delta) = 1.32$ at which the contour crosses the real axis; in this case, $\gamma = 1.82$.

In practice where the exact eigenvalues are not known, we recommend that γ is chosen such that $\gamma - \nu = (1/T) \log(M/\delta)$ if it does not coincide with any eigenvalue of $-A$. If $(1/T) \log(M/\delta)$ happens to be an eigenvalue of $-A$ (this occurs with probability 0), replace $(1/T) \log(M/\delta)$ with a slightly larger number so that it is not an eigenvalue and assign the resulting value as $\gamma - \nu$ to choose γ such that (3.4) is satisfied.

Now we would like to verify Theorem 3.1, or equivalently Theorem 3.7, provided the term $2M^{t/T}\delta^{1-t/T}$ is dominant. To use (2.19), $L_1 = 64$ and $h = \pi/600$ are chosen so that the term $2M^{t/T}\delta^{1-t/T}$ is dominant in (3.15).

TABLE 1

L^2 errors for Example 1: *actually computed L^2 errors and the predicted L^2 error bounds for $\delta = 10^{-2}$ and 10^{-4}.*

t	L^2 errors with $\delta = 10^{-2}$		L^2 errors with $\delta = 10^{-4}$	
	Computed	Predicted	Computed	Predicted
1	0.586E-02	0.752E-01	0.592E-04	0.238E-02
2	0.159E-01	0.283E+00	0.450E-03	0.283E-01
3	0.490E-01	0.106E+01	0.230E-01	0.336E+00
4	0.126E+01	0.400E+01	0.125E+01	4.000E+00

Table 1 shows the computational results for the L^2 errors and the error bounds, $2M^{t/T}\delta^{1-t/T}$, predicted by the Theorem 3.1. To illustrate the effects of different noise levels, we also showed errors with $\delta = 10^{-4}$, leaving the other parameters fixed except $\gamma = (1/T) \log(M/\delta) + \nu = 2.98$. Observe that the computational results in Table 1 are better than those predicted bounds by the theorem. However, it is well known [5, 17] that the estimate (3.1) is sharp, and one cannot improve this

without introducing a supplementary constraint such as that of slow evolution from the continuation boundary (SECB) [5, 6].

Example 2. In this example we report the L^2 error estimates for the first method (2.19) of time discretization to solve the same problem as in Example 1 with the data u_0 replaced by $u_0 = e^{-4}\sin x$ without adding noise. This enables the term $2M^{t/T}\delta^{1-t/T}$ in (3.15) to be neglected. In this case, $1/T\log(M/\delta)$ is infinity, which implies that the contour should contain all eigencomponents of the solution. The solution $u(x,t) = e^{t-4}\sin x$ contains 1 eigencomponent, and thus $\gamma - \nu$ should be greater than 1. Therefore we assigned $\gamma = 1.82, \nu = 0.5$, and $\tau = 0.5$ as in Example 1. Keeping the term $C(\beta M/\delta)^{t/T}/L_1^r$ to be dominant in (3.15) by choosing a sufficiently small $h(= \pi/5000)$, we vary L_1 to see the error behavior. Table 2 summarizes the L^2 errors. The values in the parentheses denote the error reduction ratios defined by $\log_2(e_{L_1/2}/e_{L_1})$, where e_{L_1} is the L^2 error with L_1 in (3.15). Notice that the rates of convergence, while erratic, are asymptotically as large as the order $t/\tau = 2t$ predicted by Theorem 3.7. That is, the error reduction ratios at time t become larger than $2t$ as L_1 is chosen sufficiently large.

TABLE 2
L^2 errors (and their reduction ratios) for Example 2.

$t\backslash L_1$	4	8	16	32
1.0	0.144E-02	0.645E-03(1.16)	0.305E-05(7.72)	0.419E-06(2.86)
2.0	0.120E-01	0.154E-02(2.97)	0.613E-05(7.97)	0.109E-07(9.13)
3.0	0.112E+00	0.196E-02(5.84)	0.192E-04(6.67)	0.455E-07(8.73)
4.0	0.842E+00	0.162E-01(5.70)	0.791E-04(7.68)	0.164E-06(8.91)

Example 3. Now we examine the second method (2.20) for the same problem as in Example 2. Thus parameters in (2.13) are chosen such that $N = 1$ and $\lambda_1 = 1$. Since the time-discretization errors for this method become small very rapidly, it is not easy to make the term $\varepsilon^{L_2} + eps/\varepsilon$ be dominant in (3.23). However, in [22] the theoretical and computational results have already been shown for this scheme without space variable to show the rate $\varepsilon^{L_2} + eps/\varepsilon$. In the current example, instead of varying ε and L_2, we thus fix $L_2 = 4$ and $\varepsilon = 10^{-2} > eps^{(1/L_2+1)} \approx 10^{-3}$ (see Remark 3.13) in (3.23) and vary h eight times smaller at each step which will reduce errors 1/64 times. This would verify that the space-discretization errors are dominant compared to their time-discretization counterparts.

TABLE 3
L^2 errors (and their reduction ratios) for Example 3.

$t\backslash h$	1/30	1/240	1/1920	1/15360
1.0	0.665E-04	0.976E-06(6.09)	0.154E-07(5.99)	0.510E-08(1.59)
2.0	0.330E-03	0.496E-05(6.05)	0.790E-07(5.97)	0.124E-07(2.67)
3.0	0.131E-02	0.200E-04(6.04)	0.328E-06(5.93)	0.202E-07(4.02)
4.0	0.471E-02	0.722E-04(6.03)	0.126E-05(5.84)	0.395E-07(5.00)

The numerical results in Table 3 provide confirmation of the behavior predicted by Theorem 3.15, where the predicted space-discretization error-reduction ratio is 6 since we choose h to be 1/8 times smaller at each step and the predicted time-discretization error $\varepsilon^{L_2} + eps/\varepsilon$ is about 10^{-8}. In the columns with $h = 1/240$ and $h = 1/1920$, the

apparent reduction ratios are more or less in agreement with the theory, while the ratios in the last column are less than 6 since the time-discretization errors, which are about 10^{-8}, are actively deteriorating the numerical solutions.

We now proceed to deal with two more complicated examples than the previous ones: the example employed in [24] which has severely oscillatory data and a similar example which appeared in [1, 2] with nonsmooth data. Consider the backward parabolic problem:

$$u_t + cu_{xx} = 0, \quad \Omega \times (0,T), \tag{4.2a}$$

$$u = 0, \quad \partial\Omega, \tag{4.2b}$$

with given noisy data $g \in L^2(\Omega)$. Let $\Omega = (0,l), l = 1$, or π. Here c is a positive constant that controls the diffusion speed. In this case, eigenvalues are $c(k\pi/l)^2, k = 1, 2, \ldots$. Thus when we apply Γ_2, in (2.13) $\lambda_k = c(k\pi/l)^2$, and N is chosen by the maximum integer k such that $c(k\pi/l)^2 \le (1/T)\log(M/\delta)$.

Example 4. Consider the problem (4.2) with $l = 1$, $T = 16$, $c = 1/87960$, and $u(x,T) = \sin(25\pi x^2)$. Since no analytic expression for u_0 is available, we solved a forward problem starting from $u(\cdot,T)$ using the method introduced in [32] to approximate u_0 as well as $u(\cdot,T/4), u(\cdot,T/2)$, $u(\cdot,3T/4), u(\cdot,7T/8)$, and $u(\cdot,15T/16)$, with errors less than 10^{-7}, which are served as reference solutions for (4.2).

The constant c is chosen so that the size of the oscillations in u_0 close to the right endpoint is less than 1 percent of that of $u(T)$ at the right endpoint. In [24], a similar data u_0 is used such that the size of oscillations in u_0 close to the right endpoint is less than 10 percent of their initial size. (Indeed, in [24] the constant $c = 1$ is used with very small time duration, with which the solutions agree with ours. Observe that any c and T in (4.2) give equivalent solutions if cT is constant.) Once u_0 is calculated, multiplicative noise is added (see Figure 1(c)) to make g such that $g = u_0(1 + per(x))$ with $\delta = 10^{-3}$, which should be stressed by comparing this with the choice $\delta = 10^{-6}$ in [24].

We have $\|u(\cdot,T)\| = M \approx 0.69$, and $(1/T)\log(M/\delta) \approx 0.41$. Thus when applying Γ_1, we choose $\nu = 0.5, \tau = 0.5$, and $\gamma = 0.91$. Also we used the discretization parameters $L_1 = 200$ and $h = 1/1000$. When we apply Γ_2, we choose $L_2 = 3, \varepsilon = eps^{1/(L_2+1)} \approx 10^{-4}$, and $h = 1/5000$. Figures 1(a) and 1(b) show the exact and the computed solutions at $t = T$ based on the contours Γ_1 and Γ_2, respectively.

Table 4 shows the predicted L^2 error bounds by Theorem 3.7 and the computed errors at various t values for the two contours Γ_1 and Γ_2. In order to compare with the method proposed in [24], computational results in [24] are also presented. The results from [24] are given in L^∞ errors, and thus we calculate L^∞ errors also in the parenthesis, although they are not much different since solutions are smooth.

We observe that the method [24] gives better results at $t = T/4$, but as we proceed to the final time our methods provide better solutions. Such an observation is expected for the following reasons. First, our methods recover information on eigenpairs without artificial contaminant since they do not perturb the original differential equation. Second, high frequency components of noise (larger than λ_N) do not affect our numerical solutions since they are automatically cut off in implementation.

We remark that the noise amplitude of our data g is 10^3 times as big as that in [24], and the loss of information on given data is worse than that of [24] by 10 times. With such a bad data our methods recover solutions relatively well.

We should also remark that the computed errors are much better than the predicted bounds given in Theorem 3.7. Even at $t = T$ when we lose continuous depen-

T	1.38E+00	1.26E-02 (3.30E-02)	1.20E-02 (3.33E-02)	-

dence on the data theoretically, the computed L^∞ errors are of only 3.30 and 3.33 percent. This is typically the case when the diffusion coefficient is small, and the very high frequency components of the noise do not play a dominant role. This can be explained theoretically if we introduce further constraints, SECB [5, 6], which would be treated in a future work.

Finally, we would like to discuss our choice of $(c, T) = (1/87960, 16)$, which corresponds to $(c, T) = (1, 0.0001819)$. Although our T with $c = 1$ is bigger than that of [24], it is still small. While making "reasonable recovery," how large a T can one choose? It depends on the definition of "reasonable recovery" and which method one uses. Let us fix the L^2-norm of noises; say it is about 10^{-3}. We can say, for example, if the L^2 error of the recoverd image is less than 0.2, it is a "reasonable recovery." With our method, we can make $(c, T) = (1, 0.0002018)$. Recovered and the exact solutions are shown in Figure 2(a), where we observe highly tilted values as x approaches 1, which come from noises. Thus it is still challenging to make T as large as possible with such highly oscillating profiles.

Example 5. Now we consider (4.2) with $l = \pi$, $T = 4$, and $c = 1/32$, and the piecewise linear solution at $t = T$ given by

$$u(\cdot, T) = \begin{cases} 0, & 0 \le x \le \frac{\pi}{2}, \\ \frac{16}{\pi}x - 8, & \frac{\pi}{2} \le x \le \frac{3}{4}\pi, \\ 16 - \frac{16}{\pi}x, & \frac{3}{4}\pi \le x \le \pi. \end{cases} \tag{4.3}$$

As in Example 4, we integrate forward in time starting from $u(T)$ to generate u_0, $u(T/4)$, $u(T/2)$, and $u(3T/4)$, which are served as reference solutions for the problem. Additive noises are introduced by $g = u_0 + per$ with $\delta = 10^{-3}$. In this case $\|u(T)\| = M \approx 2.89$, and we choose $\gamma = (1/T)\log(M/\delta) + \nu \approx 2.49, L_1 = 100$, and $h = \pi/1000$ for Γ_1. For Γ_2 we take $L_2 = 4, \varepsilon = 10^{-2} > eps^{1/(L_2+1)} \approx 10^{-3}$, and $h = \pi/1000$. Table 5 shows L^2 errors, and Figure 2(b) presents the exact and the computed solution profiles at $t = T$ based on the contour Γ_1. Although the authors in [1, 2] stated a pessimistic opinion about approximating $u(T) \notin C^1$, our methods recover this profile in relatively good shape even with noisy data. The noise used for Example 5 is plotted in Figure 2(c).

Example 6. Finally, in order to observe the parallel performance of the proposed method, we solve a spatially three-dimensional (3D) problem version of (4.1)

($\Omega = (0,1)^3$ and $T = 1$) with $u_0(x) = \sin(\pi x)\sin(\pi y)\sin(\pi z)$. In this case, the exact solution is $u(x,t) = e^{3\pi^2 t}\sin(\pi x)\sin(\pi y)\sin(\pi z)$. For a fully discretized numerical solution, (2.19) is applied with $L_1 = 32$. $\gamma = 31.5$, and $\nu = \tau = 0.5$ are used for defining Γ_1 (see Example 2 for these selections). To obtain $\widehat{u}_h^{u_0}(z_j)$ ($j = 1, \ldots, L_1 - 1$) in (2.19), we solved (2.1) using the Q_1-conforming (*e.g., trilinear*) finite element space V_h based on the $64 \times 64 \times 64$ uniform hexahedron triangulation of Ω (see, for instance, [3]). Then in order to calculate $U_{L_1,h,\tau}^{\Gamma_1,u_0}(1)$, p processors ($p = 1, 2, 4, 8, 16, 32$) are employed to compute $L_1(=32)$ independent elliptic problems (2.1) for $z_j, j = 0, \ldots, L_1$, by evenly distributing them to p processors. For example if $p = 32$, each processor solves only one equation. The computing clock time in seconds from solving linear equations derived from (2.17) until obtaining $U_{L_1,h,\tau}^{\Gamma_1,u_0}(1)$ required with p processors are reported in Table 6. The speedup defined by (computing time for 1 processor)/(computing time for p processors) is also presented and a nearly perfect speedup is observed. The result is expected since the most time-consuming part in obtaining $\widehat{u}_h^{u_0}(z_j)$ for $j = 0, \ldots, L_1 - 1$ can be solved independently without data communication. Finally, we remark that obviously such a perfect speedup is expected when $p \leq L_1$. The computation of this example was carried out using a parallel machine whose nodes are based on the IBM PowerPC970 (2.2GHz) 2-way CPUs with 1 Giga Byte Myrinet network link.

5. Conclusion. In this paper, a parallel method has been proposed to solve backward parabolic problems. The algorithm is based on the Laplace transformation in time of the original time-dependent problems on a suitable contour in the complex plane. The time dependence of the resulting Laplace transformed problems is thus suppressed. After solving elliptic problems for each point on the complex contour, a numerical inversion of Laplace transformed solutions will recover the time-dependent solutions.

The proposed scheme to solve parabolic problems backwards in time does not introduce an artificial parameter in order to regularize the numerical solutions. Theories and numerical examples show the proposed method gives optimal stability without perturbing anything, resulting in improved quality of the regularized solutions.

Additionally our scheme is highly scalable for parallel implementaion in the realm of time discretization.

Acknowledgments. The authors wish to express thanks to the anonymous referees for their valuable suggestions to improve the original version. Thanks also go to Dr. Taeyoung Ha for providing a parallel 3D finite element code.

ANISOTROPIC MESH REFINEMENT: THE CONDITIONING OF GALERKIN BOUNDARY ELEMENT MATRICES AND SIMPLE PRECONDITIONERS*

IVAN G. GRAHAM† AND WILLIAM MCLEAN‡

Abstract. In this paper we obtain upper and lower bounds on the spectrum of the stiffness matrix arising from a finite element Galerkin approximation (using nodal basis functions) of a bounded, symmetric bilinear form which is elliptic on a Sobolev space of real index $m \in [-1, 1]$. The key point is that the finite element mesh is required to be neither quasi-uniform nor shape-regular, so that our theory allows anisotropic meshes often used in practice. (However, we assume that the polynomial degree of the elements is fixed.) Our bounds indicate the ill-conditioning which can arise from anisotropic mesh refinement. In addition we obtain spectral bounds for the diagonally scaled stiffness matrix, which indicate the improvement provided by this simple preconditioning. For the special case of boundary integral operators on a two-dimensional screen in $\mathbb{R}^3$, numerical experiments show that our bounds are sharp. We find that diagonal scaling essentially removes the ill-conditioning due to mesh degeneracy, leading to the same asymptotic growth in the condition number as arises for a quasi-uniform mesh refinement. Our results thus generalize earlier work by Bank and Scott [*SIAM J. Numer. Anal.*, 26 (1989), pp. 1383–1394] and Ainsworth, McLean, and Tran [*SIAM J. Numer. Anal.*, 36 (1999), pp. 1901–1932] for the shape-regular case.

Key words. symmetric elliptic problems, boundary integral equations, Galerkin approximation, anisotropic refinement, spectral bounds, diagonal scaling, condition number estimates

1. Introduction.

Edge and corner singularities are characteristic features of solutions to three-dimensional (3D) elliptic boundary value problems and, in both finite element and boundary element methods, are commonly dealt with by some kind of local mesh refinement. Typically, an edge singularity is strongly *anisotropic*: the lack of smoothness occurs only in directions normal to the edge. For this reason, the local mesh refinement should also be anisotropic if we are to minimize the number of degrees of freedom used to achieve a sufficiently small error in, say, the energy norm. Extra refinement is not needed parallel to an edge, except maybe in the vicinity of a corner. The meshes that result from such local refinement are certainly not quasi-uniform and usually even fail to be *shape-regular* because elements near edges but away from any corner may have a very large aspect ratio.

In this paper we investigate the influence of such meshes on the condition number of the stiffness matrix arising in the Galerkin approximation of a class of symmetric elliptic problems. Our general framework includes as special cases the single layer and the hypersingular boundary integral equations for the Laplacian on the surface of a 3D Lipschitz domain or on a Lipschitz screen as well as the Dirichlet problem for second-order symmetric elliptic PDEs. We obtain general bounds for the spectrum of

the resulting Galerkin matrix in terms of quantities which depend on the geometry of the elements and the particular basis functions utilized.

In addition we study in detail two model problems—the weakly singular and hypersingular equations for the Laplacian on a rectangular screen, discretized using classical tensor-product power-graded meshes. For these model problems our general estimates yield explicit bounds in terms of the number of degrees of freedom and the strength of the power grading. We show by numerical experiments that our estimates are sharp and, moreover, exhibit a strong increase in the condition number as the maximum aspect ratio of the elements increases.

These results have practical implications for the performance of iterative techniques such as conjugate gradients, which are often used as solvers for the dense linear systems which arise in these methods (usually combined with a fast matrix-vector multiplication such as fast multipole [12] or panel-clustering [8]). Efficient solvers require effective preconditioners, and as a first step in this direction we also analyze in detail the use of diagonal scaling. We obtain general estimates for the spectrum of the diagonally scaled matrix and again investigate this in fine detail for the special cases of the model problems mentioned above.

Throughout the paper Γ will denote either a bounded, d-dimensional Lipschitz surface in $\mathbb{R}^{d+1}$, for $d = 2$, or a bounded Lipschitz domain in $\mathbb{R}^d$, for $d = 2$ or 3. In the former case, the surface Γ may be open or closed. B will denote a bounded and *symmetric* bilinear form such that, for some Sobolev index m satisfying $|m| \le 1$, $B : \widetilde{H}^m(\Gamma) \times \widetilde{H}^m(\Gamma) \to \mathbb{R}$, and

$$c\|v\|^2_{\widetilde{H}^m(\Gamma)} \le B(v,v) \le C\|v\|^2_{\widetilde{H}^m(\Gamma)} \quad \text{for all } v \in \widetilde{H}^m(\Gamma), \tag{1.1}$$

where c and C are positive constants. Thus the energy space for B is equivalent to the Sobolev space $\widetilde{H}^m(\Gamma)$. (Here we are working with standard Sobolev spaces on Γ; see section 3 for more detail.)

We shall consider approximations of the following variational problem: Find $u \in \widetilde{H}^m(\Gamma)$ such that

$$B(u,v) = \langle f, v\rangle_\Gamma \quad \text{for all } v \in \widetilde{H}^m(\Gamma), \tag{1.2}$$

where, with $d\sigma$ denoting the usual surface element on Γ,

$$\langle f, v\rangle_\Gamma = \int_\Gamma f v \, d\sigma.$$

By the Lax–Milgram lemma, (1.2) has a unique solution $u \in \widetilde{H}^m(\Gamma)$ for each $f \in H^{-m}(\Gamma)$.

Within this abstract framework we can treat not only some boundary element methods, in particular with $m = \pm 1/2$, but also finite element methods for symmetric H^1 elliptic PDEs with homogeneous Dirichlet boundary conditions.

To approximate the solution u of (1.2), we introduce a finite-dimensional subspace $X \subseteq \widetilde{H}^m(\Gamma)$ and then apply Galerkin's method, seeking $u_X \in X$ such that

$$B(u_X, v) = \langle f, v\rangle_\Gamma \quad \text{for all } v \in X. \tag{1.3}$$

In this paper we are concerned only with the h-version of the finite element method in which X is a space of piecewise polynomials of fixed degree with respect to a family of increasingly refined partitions (or meshes) $\{\mathcal{P}\}$ on Γ. The partition $\mathcal{P}$ contains

elements $K \in \mathcal{P}$ which have diameter h_K and diameter of largest inscribed ball ρ_K. We will introduce a basis for X consisting of nodal basis functions $\{\phi_j : j \in \mathcal{N}\}$, where $\mathcal{N}$ is a suitable index set with cardinality N. We will define the allowable partitions, elements, and basis functions more precisely in section 3. Writing $u_X = \sum_{k\in\mathcal{N}} \alpha_k \phi_k$, inserting into (1.3), and choosing $v = \phi_j$ for each $j \in \mathcal{N}$ leads to the $N \times N$ linear system

$$\boldsymbol{B}\boldsymbol{\alpha} = \boldsymbol{f}, \tag{1.4}$$

with a symmetric positive definite matrix $\boldsymbol{B} = [B(\phi_k, \phi_j)]$, a solution vector $\boldsymbol{\alpha} = [\alpha_k]$, and a right-hand side vector $\boldsymbol{f} = [\langle f, \phi_j\rangle]$.

The conditioning of $\boldsymbol{B}$ in the case of shape-regular mesh refinement (i.e., $h_K \lesssim \rho_K$ for all $K \in \mathcal{P}$) was investigated by Ainsworth, McLean, and Tran in [1, 2], where the condition number estimate

$$\operatorname{cond}(\boldsymbol{B}) \lesssim \left(\frac{h_{\max}}{h_{\min}}\right)^{d-2m} N^{2|m|/d} \quad \text{for } 2|m| < d \tag{1.5}$$

was proved. Here, $h_{\max} = \max_{K\in\mathcal{P}} h_K$ and $h_{\min} = \min_{K\in\mathcal{P}} h_K$. (For matrices $\boldsymbol{B}$ with positive spectrum, $\operatorname{cond}(\boldsymbol{B}) := \lambda_{\max}(\boldsymbol{B})/\lambda_{\min}(\boldsymbol{B})$, where $\lambda_{\max}(\boldsymbol{B})$ and $\lambda_{\min}(\boldsymbol{B})$ denote the largest and smallest eigenvalues of $\boldsymbol{B}$, respectively. The symbols $\lesssim$ and $\simeq$ indicate (in)equality up to a hidden constant, independent of the mesh; see section 3.) In the limiting cases $2m = -d$ and $2m = d$ an additional logarithmic factor occurs in the bound (1.5).

For quasi-uniform meshes, $h_{\max} \simeq h_{\min} \simeq h$ so the bound (1.5) gives the well-known result that $\operatorname{cond}(\boldsymbol{B}) = O(N^{2|m|/d}) = O(h^{-2|m|})$. However, this bound deteriorates if the global mesh ratio $h_{\max}/h_{\min}$ becomes large, and the deterioration becomes stronger as the Sobolev index m becomes more negative. Fortunately, such additional growth in the condition number is easily eliminated by *diagonal scaling*. In fact, let $\boldsymbol{D}$ denote the diagonal matrix formed from $\boldsymbol{B}$ by setting all the off-diagonal entries to zero, and put

$$\boldsymbol{B}' = \boldsymbol{D}^{-1/2}\boldsymbol{B}\boldsymbol{D}^{-1/2}. \tag{1.6}$$

Then it is shown in [1] that in the shape-regular case we have

$$\operatorname{cond}(\boldsymbol{D}^{-1}\boldsymbol{B}) = \operatorname{cond}(\boldsymbol{B}') \lesssim N^{2|m|/d} \quad \text{for } 2|m| < d. \tag{1.7}$$

We remark that $\boldsymbol{B}' = [B(\phi'_j, \phi'_k)]$ is just the Galerkin matrix that arises if we scale the nodal basis so that $\phi'_j = \phi_j/\sqrt{B(\phi_j, \phi_j)}$ has unit energy; i.e., $B(\phi'_j, \phi'_j) = 1$.

This paper obtains bounds analogous to (1.5) and (1.7) for the case when the $\{\mathcal{P}\}$ is no longer required to be shape-regular, and each partition $\mathcal{P}$ may contain elements K for which the aspect ratio h_K/ρ_K approaches infinity as the mesh is refined.

In particular we show that in the case of the weakly singular and hypersingular boundary integral operators (and except possibly for some logarithmic factors), diagonal scaling removes the ill-conditioning produced by the high aspect ratios, restoring the rate of growth of the condition number (in terms of the number of degrees of freedom) to essentially what it would be for a quasi-uniform mesh with the same number of degrees of freedom.

We remark that our results not only generalize the results [1, 2] to more general meshes, but they also generalize some of the earlier results of Bank and Scott [3],

who obtained the analogous result for H^1 finite elements and shape-regular mesh sequences.

The layout of this paper is as follows. In section 2 we motivate the theory by describing the results for the weakly singular and hypersingular operators in detail, without proofs. In section 3 we set the theoretical scene by describing the class of finite (boundary) elements which we shall consider (which allow degenerate meshes), and we introduce the corresponding nodal bases. A key step in the theory in [1, 2] is the proving of estimates for Sobolev norms of nodal basis functions. In section 4 we extend these estimates to the case of non–shape-regular meshes. Here we make essential use of recently derived inverse estimates for finite element functions on anisotropic meshes [7]. In section 5 we obtain general bounds on the spectra of $\boldsymbol{B}$ and $\boldsymbol{B}'$ in terms of the geometry of the elements and the Sobolev norms of the nodal basis functions. For the case of power graded meshes and the weakly singular and hypersingular operators these lead to quantitative spectral estimates which are tested in the numerical experiments in section 6. These eperiments show that the results for $\boldsymbol{B}'$ are not completely sharp. Sharper results for special cases, which explain the numerical results, are proved in section 7. Finally, section 8 presents some additional numerical results using a more complicated family of meshes.

2. Examples.

2.1. Two integral equations. The *weakly singular* (or *single-layer*) boundary integral equation,

$$\frac{1}{4\pi}\int_\Gamma \frac{u(y)}{|x-y|}\,d\sigma_y = f(x) \quad \text{for } x\in\Gamma, \tag{2.1}$$

arises, for example, in the solution of the Dirichlet problem for the Laplace equation in the region exterior to Γ. This equation (2.1) may be written in the form (1.2), with

$$B(u,v) = \frac{1}{4\pi}\iint_{\Gamma\times\Gamma} \frac{u(y)v(x)}{|x-y|}\,d\sigma_x\,d\sigma_y. \tag{2.2}$$

Then B satisfies the norm equivalence (1.1) for $m=-1/2$.

The *hypersingular* integral equation,

$$-\frac{1}{4\pi}\int_\Gamma \left(\frac{\partial}{\partial\nu_x}\frac{\partial}{\partial\nu_y}\frac{1}{|x-y|}\right)u(y)\,d\sigma_y = f(x) \quad \text{for } x\in\Gamma, \tag{2.3}$$

arises, for example, in the solution of the Neumann problem for the Laplace equation. (Here $\partial/\partial\nu_x$ denotes the normal derivative at $x\in\Gamma$, and the integral is defined as the finite part integral in the sense of Hadamard.) The integration by parts procedure of Nédélec [10], [9, Theorem 9.15] allows us to write the associated bilinear form as

$$B(u,v) = \frac{1}{4\pi}\iint_{\Gamma\times\Gamma} \frac{\mathbf{curl}_\Gamma u(x)\cdot\mathbf{curl}_\Gamma v(y)}{|x-y|}\,d\sigma_x\,d\sigma_y, \tag{2.4}$$

where $\mathbf{curl}_\Gamma$ denotes the surface curl operator. The norm equivalence (1.1) holds for $m=+1/2$. If the surface Γ is flat, then $\mathbf{curl}_\Gamma$ can be replaced by the two-dimensional (2D) gradient operator ∇.

It is well known that the solutions of (2.1) and (2.3) in general exhibit singular behavior near the edges and corners of Γ. In particular near the interior of an edge, the solution u of (2.1) typically has a singularity of order $O(\rho^{\alpha-1})$ as $\rho\to 0$, where ρ

is the distance of a point from the edge and $\alpha > 1/2$ depends on the angle subtended by the boundary Γ near the edge. The solution of (2.3) typically has a singularity of order $O(\rho^\alpha)$. More complicated behavior appears near corners. The full detail is well known; see, e.g., [4, 5, 11].

2.2. Power-graded meshes. For the h-version of the boundary integral method, it is common to approximate (2.1) and (2.3) using power-graded meshes. To describe these, first consider the special case of a flat, square screen

$$\Gamma = \{\, x \in \mathbb{R}^3 : 0 < x_1 < 1, 0 < x_2 < 1, x_3 = 0 \,\}, \tag{2.5}$$

and think of Γ as a subset of $\mathbb{R}^2$ by writing $x = (x_1, x_2) = (x_1, x_2, 0)$ for $x \in \Gamma$. Choose a *grading exponent* $\beta \geq 1$ and define a mesh on the interval $(0, 1)$ by

$$t_j = \begin{cases} \dfrac{1}{2}\left(\dfrac{2j}{n}\right)^\beta & \text{if } 0 \leq j \leq n/2, \\ 1 - t_{n-j} & \text{if } n/2 < j \leq n. \end{cases} \tag{2.6}$$

For $\beta = 1$ the mesh is uniform, but as β increases from 1, the points are more concentrated at each end of the interval. The length $\Delta t_j = t_j - t_{j-1}$ of the jth interval satisfies

$$\Delta t_j \simeq \frac{1}{n}\left(\frac{j}{n}\right)^{\beta-1} \simeq \Delta t_{n-j} \quad \text{for } 1 \leq j \leq n/2. \tag{2.7}$$

We construct the corresponding product mesh with n^2 elements on Γ with vertices

$$t_{(j_1,j_2)} = (t_{j_1}, t_{j_2}) \quad \text{for } 0 \leq j_1 \leq n \text{ and } 0 \leq j_2 \leq n. \tag{2.8}$$

Elements K near any corner are shape-regular with $h_K \simeq (1/n)^\beta \simeq \rho_K$. Away from the boundary they are also shape-regular with $h_K \simeq 1/n \simeq \rho_K$. However, near the middle of an edge we have $h_K \simeq 1/n$ and $\rho_K \simeq (1/n)^\beta$; hence if $\beta > 1$, then degeneracy occurs with the maximum aspect ratio for the elements growing like $n^{\beta-1}$; see Figure 1. This construction can be generalized to other polyhedral surfaces; see, e.g., [11, 5] and Example 5.5 below.

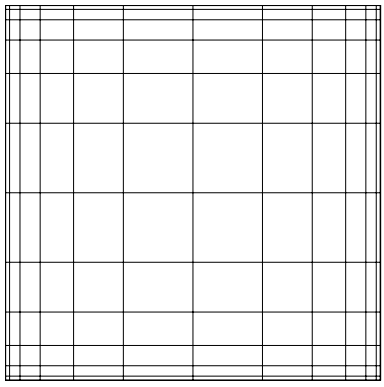

FIG. 1. *Power-graded tensor-product mesh with $\beta = 3$ and $N = 14^2$ elements.*

2.3. Condition number estimates. As an illustration of the results which we shall prove later in this paper, let us suppose we apply the Galerkin method to the weakly singular equation (2.1), with Γ given by (2.5) and with the subspace $X \subset \widetilde{H}^{-1/2}(\Gamma)$ chosen to be the space of piecewise-constant functions on the mesh (2.8). The dimension of X is $N = n^2$. In Theorems 5.7 and 7.4 we will prove that in this case the Galerkin matrix $\boldsymbol{B}$ satisfies the spectral bounds $\lambda_{\max}(\boldsymbol{B}) \lesssim N^{-1}$ and $\lambda_{\min}(\boldsymbol{B}) \gtrsim N^{-3\beta/2}$, whereas the diagonally scaled Galerkin matrix $\boldsymbol{B}'$ satisfies

$$\lambda_{\max}(\boldsymbol{B}') \lesssim N^{1/2} \times \begin{cases} 1 & \text{if } 1 \le \beta < 2, \\ (1+\log N)^{1/2} & \text{if } \beta = 2, \\ (1+\log N)^2 & \text{if } \beta > 2 \end{cases}$$

and

$$\lambda_{\min}(\boldsymbol{B}') \gtrsim \begin{cases} 1 & \text{if } \beta = 1, \\ (1+\log N)^{-1} & \text{if } \beta > 1. \end{cases}$$

Hence, $\operatorname{cond}(\boldsymbol{B})$ grows like $N^{(3\beta/2)-1}$, whereas $\operatorname{cond}(\boldsymbol{B}')$ essentially grows like $N^{1/2}$, which is the rate of growth in the case of shape-regular meshes.

On the other hand, suppose we solve (2.3), with Γ given by (2.5) and with $X \subset \widetilde{H}^{1/2}(\Gamma)$ chosen to be the space of continuous piecewise-bilinear functions on the mesh (2.8) which vanish at the boundary of Γ. The dimension of X is $N = (n-1)^2 = O(n^2)$. In Theorems 5.8 and 7.5, we shall prove that

$$\lambda_{\max}(\boldsymbol{B}) \lesssim N^{-1/2} \quad \text{and} \quad \lambda_{\min}(\boldsymbol{B}) \gtrsim \begin{cases} N^{-1} & \text{for } 1 \le \beta < 2, \\ N^{-1}(1+\log N)^{-1} & \text{for } \beta = 2, \\ N^{-\beta/2} & \text{for } \beta > 2, \end{cases}$$

whereas $\boldsymbol{B}'$ satisfies

$$\lambda_{\max}(\boldsymbol{B}') \lesssim 1 \quad \text{and} \quad \lambda_{\min}(\boldsymbol{B}') \gtrsim N^{-1/2} \times \begin{cases} 1 & \text{for } 1 \le \beta < 2, \\ (1+\log N)^{-1/2} & \text{for } \beta = 2, \\ (1+\log N)^{-2} & \text{for } \beta > 2. \end{cases}$$

Thus, in this case the condition number of $\boldsymbol{B}$ grows like $N^{(\beta-1)/2}$ (for $\beta > 2$), whereas the condition number of $\boldsymbol{B}'$ again essentially grows only like $N^{1/2}$ (for any $\beta \ge 1$), which is again the rate of growth in the shape-regular case.

3. General framework. In this section we set up the theoretical apparatus in which the general spectral estimates of section 5 will be proved. Recall that Γ denotes either a bounded (open or closed) d-dimensional Lipschitz surface in $\mathbb{R}^{d+1}$, for $d = 2$, or a bounded Lipschitz domain in $\mathbb{R}^d$, for $d = 2$ or 3.

We define the Sobolev spaces $H^s(\Gamma)$, $\widetilde{H}^s(\Gamma)$, $|s| \le 1$ in the usual way; see, for example, [9] for details. In particular, when Γ is a Lipschitz domain or an open Lipschitz surface, $u \in \widetilde{H}^1(\Gamma)$ implies that u has vanishing trace on the boundary of Γ. For $0 < s < 1$, $\widetilde{H}^s(\Gamma)$ interpolates between $L_2(\Gamma)$ and $\widetilde{H}^1(\Gamma)$. In any case, $H^{-s}(\Gamma)$ is the dual of $\widetilde{H}^s(\Gamma)$ and $\widetilde{H}^{-s}(\Gamma)$ is the dual of $H^s(\Gamma)$ for all $|s| \le 1$. When Γ is a closed surface, $\widetilde{H}^s(\Gamma) = H^s(\Gamma)$ for all $|s| \le 1$. (Higher order Sobolev spaces can be defined on domains and on smooth enough surfaces, but we do not need these here.)

In what follows we will also be interested in Sobolev norms of various functions defined over subdomains $\hat{\Gamma} \subset \Gamma$. Since different equivalent norms for $H^s(\hat{\Gamma})$ or $\widetilde{H}^s(\hat{\Gamma})$ might scale differently with the size of $\hat{\Gamma}$, we follow the notation used in [1] and write $|||u|||_{H^s(\hat{\Gamma})}$ and $|||u|||_{\widetilde{H}^s(\hat{\Gamma})}$ to indicate the specific norms obtained for $|s| \le 1$ by real interpolation and duality, starting from the usual norm in $L_2(\hat{\Gamma})$ and the Sobolev norms

$$|||u|||^2_{H^1(\hat{\Gamma})} = \|u\|^2_{L_2(\hat{\Gamma})} + |u|^2_{H^1(\hat{\Gamma})} \quad \text{and} \quad |||u|||^2_{\widetilde{H}^1(\hat{\Gamma})} = |u|^2_{H^1(\hat{\Gamma})} = \sum_{|\alpha|=1} \|\partial^\alpha u\|^2_{L_2(\hat{\Gamma})}.$$

Note that $|\cdot|_{H^1(\hat{\Gamma})}$ is only a seminorm on $H^1(\hat{\Gamma})$ but is a norm on $\widetilde{H}^1(\hat{\Gamma})$. (The distinction between $\|\cdot\|_{H^s(\hat{\Gamma})}$ and $|||\cdot|||_{H^s(\hat{\Gamma})}$ is significant only when $\hat{\Gamma}$ is a proper subset of Γ. In what follows we will freely interchange $\|\cdot\|_{H^s(\Gamma)}$ and $|||\cdot|||_{H^s(\Gamma)}$.)

For later use, we recall [11, Lemma 3.2], [1, Theorem 4.1] that *if* $\Gamma_1, \Gamma_2, \ldots, \Gamma_N$ *is a partitioning of a bounded Lipschitz domain* Γ *into nonoverlapping Lipschitz domains, then for* $|s| \le 1$,

$$|||v|||^2_{\widetilde{H}^s(\Gamma)} \le \sum_{j=1}^N |||v|||^2_{\widetilde{H}^s(\Gamma_j)} \quad \textit{and} \quad \sum_{j=1}^N |||u|||^2_{H^s(\Gamma_j)} \le |||u|||^2_{H^s(\Gamma)}. \tag{3.1}$$

We also note that (see [1, eq. (4.1)])

$$\|u\|_{H^s(\Gamma)} \lesssim \|u\|_{\widetilde{H}^s(\Gamma)} \quad \text{if } u \in \widetilde{H}^s(\Gamma) \cap L_2(\Gamma), \text{ for all } |s| \le 1, \tag{3.2}$$

and that [9, p. 320]

$$|||v|||_{\widetilde{H}^s(\hat{\Gamma})} \lesssim |||v|||^{1-s}_{L_2(\hat{\Gamma})} |||v|||^s_{\widetilde{H}^1(\hat{\Gamma})} \quad \text{and} \quad |||v|||_{\widetilde{H}^{-s}(\hat{\Gamma})} \lesssim |||v|||^{1-s}_{L_2(\hat{\Gamma})} |||v|||^s_{\widetilde{H}^{-1}(\hat{\Gamma})} \quad \text{for } 0 < s < 1. \tag{3.3}$$

As mentioned in section 1, we will be considering a family of partitions $\{\mathcal{P}\}$ of Γ. Each partition $\mathcal{P}$ consists of relatively open, pairwise-disjoint finite elements $K \subset \Gamma$ with the property $\overline{\Gamma} = \cup\{\overline{K} : K \in \mathcal{P}\}$. For each $K \in \mathcal{P}$, h_K denotes its diameter and ρ_K the diameter of the largest sphere whose intersection with $\overline{\Gamma}$ lies entirely inside $\overline{K}$. Also, for any measurable subset S of Γ, $|S|$ denotes its d-dimensional measure.

In order to impose a simple geometric character on the mesh $\mathcal{P}$, we assume that each $K \in \mathcal{P}$ is diffeomorphic to a simple reference element. More precisely, let $\hat{\sigma}^d$ denote the unit simplex and $\hat{\kappa}^d = [0,1]^d$ the unit cube in $\mathbb{R}^d$. Thus, $\hat{\sigma}^2$ is the triangle with vertices $(0,0)$, $(1,0)$, $(0,1)$ and $\hat{\sigma}^3$ is the tetrahedron with vertices $(0,0,0)$, $(1,0,0)$, $(0,1,0)$, $(0,0,1)$.

We assume that for each $K \in \mathcal{P}$, there exists a reference element $\hat{K} = \hat{\sigma}^d$ or $\hat{\kappa}^d$ and a bijective map $\chi_K : \hat{K} \to K$, with both χ_K and χ_K^{-1} smooth. (Here, for simplicity, "smooth" means $\mathcal{C}^\infty$.) Each element has vertices and edges, defined to be the images of the vertices and edges of the corresponding unit element under χ_K. In the 3D case, the element also has faces, comprising the images of the faces of the unit element. We assume each partition is *conforming*; i.e., for each K, $K' \in \mathcal{P}$ with $K \ne K'$, the intersection $\overline{K} \cap \overline{K'}$ is allowed to be either empty, a vertex, an edge, or (when $d = 3$) a face of both K and K'. The requirement that χ_K is smooth ensures that edges of Γ ($d = 2$) and edges of $\partial\Gamma$ ($d = 3$) are confined to edges of elements $K \in \mathcal{P}$.

Let J_K denote the $3 \times d$ Jacobian of χ_K. Then

$$\int_K f(\mathbf{x})dx = \int_{\hat{K}} f(\chi_K(\hat{\mathbf{x}}))g_K(\hat{\mathbf{x}})d\hat{x}, \quad \text{where} \quad g_K := \left(\det J_K^T J_K\right)^{1/2}. \tag{3.4}$$

In addition to the assumption that χ_K and χ_K^{-1} are smooth, we also require the following assumption on J_K.

ASSUMPTION 3.1. *There exist positive constants D, E such that*

$$D^{-1}|K|^2 \le \det\big(J_K(\hat{\mathbf{x}})^T J_K(\hat{\mathbf{x}})\big) \le D|K|^2, \tag{3.5a}$$

$$E\rho_K^2 \le \lambda_{\min}\big(J_K(\hat{\mathbf{x}})^T J_K(\hat{\mathbf{x}})\big), \tag{3.5b}$$

uniformly for $\hat{\mathbf{x}} \in \hat{K}$, $K \in \mathcal{P}$, and $\mathcal{P} \in \mathcal{F}$.

Assumption 3.1 holds, for example, when K is a planar triangle ($d = 2$) or a tetrahedron ($d = 3$) and χ_K is affine. It is also satisfied by bilinear maps from the unit square to quadrilaterals ($d = 2$), provided that the quadrilaterals are not too far from parallelograms. These and other examples are explored in [7].

Assumption 3.1 describes the quality of the maps which take the unit element $\hat{K}$ to each K. We also need assumptions on how the size and shape of neighboring elements in our mesh may vary. Here we impose *only very weak local conditions which require the meshes to be neither quasi-uniform nor shape-regular.* In addition, we need a uniform bound on the number of elements that touch the ith node $\mathbf{x}_i$.

ASSUMPTION 3.2. *There exist positive constants F, G, H and an integer M such that for all $\mathcal{P} \in \mathcal{F}$,*

$$h_K \le F\ h_{K'}\,, \quad \rho_K \le G\ \rho_{K'}\,, \quad |K| \le H\ |K'| \quad \text{for all } K, K' \in \mathcal{P} \text{ with } \overline{K} \cap \overline{K'} \ne \emptyset, \tag{3.6a}$$

$$\text{and also} \qquad \max_{i \in \mathcal{N}} \#\{K \in \mathcal{P} : \mathbf{x}_i \in \overline{K}\} \ \le\ M. \tag{3.6b}$$

Note that condition (3.6a) requires that h_K and ρ_K do not vary too rapidly between neighboring elements. This allows elements with a large aspect ratio, provided that their immediate neighbors have a comparable aspect ratio. It is clear that the power meshes (2.8) satisfy Assumption 3.2.

From now on, if $A(\mathcal{P})$ and $B(\mathcal{P})$ are two mesh-dependent quantities, then the inequality $A(\mathcal{P}) \lesssim B(\mathcal{P})$ will mean that there is a constant C independent of $\mathcal{P}$, such that $A(\mathcal{P}) \le CB(\mathcal{P})$. ($C$ may depend on D, E, F, G, or M.) Also the notation $A(\mathcal{P}) \simeq B(\mathcal{P})$ will mean that $A(\mathcal{P}) \lesssim B(\mathcal{P})$ and $B(\mathcal{P}) \lesssim A(\mathcal{P})$.

For an integer $\ell \ge 0$ and a reference element $\hat{K} \in \{\hat{\sigma}^d, \hat{\kappa}^d\}$, we define

$$\mathbb{P}^\ell(\hat{K}) = \begin{cases} \text{polynomials of total degree } \le \ell \text{ on } \hat{K} & \text{if } \hat{K} = \hat{\sigma}^d, \\ \text{polynomials of coordinate degree } \le \ell \text{ on } \hat{K} & \text{if } \hat{K} = \hat{\kappa}^d \end{cases}$$

and the finite element spaces

$$\mathcal{S}_0^\ell(\mathcal{P}) = \{u \in L^\infty(\Gamma) : u \circ \chi_K \in \mathbb{P}^\ell(\hat{K}), K \in \mathcal{P}\} \quad \text{for } \ell \ge 0,$$
$$\mathcal{S}_1^\ell(\mathcal{P}) = \{u \in C^0(\Gamma) : u \circ \chi_K \in \mathbb{P}^\ell(\hat{K}), K \in \mathcal{P}\} \quad \text{for } \ell \ge 1.$$

Finally we introduce suitable bases for these spaces. In this paper we consider standard nodal bases defined as follows. Let $d(\ell)$ denote the dimension of $\mathbb{P}^\ell(\hat{K})$

and choose a set of nodes $\{\hat{\mathbf{x}}_p : p = 1, \ldots, d(\ell)\} \subset \overline{\hat{K}}$ with the property that each $\hat{u} \in \hat{\mathbb{P}}^\ell(\hat{K})$ is uniquely determined by its values at the $\hat{\mathbf{x}}_p$. Then there are basis functions $\{\hat{\phi}_p\ , p = 1, \ldots, d(\ell)\}$ with the property $\hat{\phi}_p(\hat{\mathbf{x}}_q) = \delta_{p,q}$. From these we can define basis functions on the open set K (implicitly) by $\phi_{p,K} \circ \chi_K = \hat{\phi}_p$. We extend $\phi_{p,K}$ to $\overline{K}$ by continuity and then (discontinuously) to the whole of Γ by zero. If we introduce the nodes $\mathbf{x}_{p,K} := \chi_K(\hat{\mathbf{x}}_p) \in \overline{K}$, then clearly

$$\phi_{p,K}(\mathbf{x}_{q,K'}) = \delta_{(p,K),(q,K')} \quad \text{for} \quad p, q = 1, \ldots, d(\ell), \quad K, K' \in \mathcal{P}. \tag{3.7}$$

The functions

$$\{\phi_{p,K} : \ p = 1, \ldots d(\ell), \ K \in \mathcal{P}\} \tag{3.8}$$

then constitute a suitable basis of $\mathcal{S}_0^\ell(\mathcal{P})$. When $\ell = 0$ we have the simple piecewise constant functions, and the nodes $\mathbf{x}_K = \mathbf{x}_{1,K}$ can be chosen as the centroids of each K.

For $\mathcal{S}_1^\ell(\mathcal{P})$, we require further that if two elements K and K' share a common edge e, then this edge is parametrized *equally from both sides*. More precisely, we require that if $\chi_K^{-1}(e) = \hat{e}$ and $\chi_{K'}^{-1}(e) = \hat{e}'$, then there exists an affine mapping $\gamma : \hat{e} \to \hat{e}'$ such that χ_K and $\chi_{K'} \circ \gamma$ coincide pointwise on $\hat{e}$. We assume that the points $\mathbf{x}_{p,K}$ and $\mathbf{x}_{p,K'}$ restricted to e coincide and that the values of u at these points are sufficient to determine uniquely $u|_e$ on e. (This condition is satisfied in the simplest case when χ_K and $\chi_{K'}$ are both affine maps.) In this case any $u \in \mathcal{S}_1^\ell(\mathcal{P})$ is determined uniquely by its values at the set of global nodes $\{\mathbf{x}_{p,K} : \ p = 1, \ldots, d(\ell), \ K \in \mathcal{P}\}$, where coincident nodes on the boundary of more than one element now constitute a single degree of freedom. Denoting this set more abstractly by $\{\mathbf{x}_k : k \in \mathcal{N}\}$ for some suitable index set of nodes (or degrees of freedom) $\mathcal{N}$, our basis for $\mathcal{S}_1^\ell(\mathcal{P})$ is

$$\{\phi_k : k \in \mathcal{N}\}, \tag{3.9}$$

where $\phi_k \in \mathcal{S}_1^\ell(\mathcal{P})$ is the unique function satisfying

$$\phi_k(\mathbf{x}_{k'}) = \delta_{k,k'} \quad \text{for all } k, \, k' \in \mathcal{N}. \tag{3.10}$$

A simple example is the space of the continuous bilinear functions on a mesh of quadilaterals, with nodes chosen to be the vertices of the elements.

Clearly the basis (3.8) may be written in the abstract form (3.9) by allowing the set $\mathcal{N}$ to contain double indices of the form (p, K). With this notation, (3.10) follows from (3.7). Moreover, in any case,

$$\Gamma_k \subseteq \bigcup \left\{\overline{K} : \mathbf{x}_k \in \overline{K}\right\}, \quad \text{where } \ \Gamma_k := \operatorname{supp} \phi_k. \tag{3.11}$$

Throughout the rest of the paper N denotes the cardinality of the nodal set $\mathcal{N}$.

4. Sobolev norm of a nodal basis function. We now establish some technical estimates needed in the next section in our proofs of the spectral bounds for $\boldsymbol{B}$ and $\boldsymbol{B}'$. For these we need the following notation. For $k \in \mathcal{N}$, define

$$\begin{aligned} h_k &= \text{average of those } h_K \text{ for which } x_k \in \overline{K}, \\ \rho_k &= \text{average of those } \rho_K \text{ for which } x_k \in \overline{K}, \end{aligned}$$

and note that the second inequality in (3.6a) implies that

$$\min_{x_k\in\overline{K}}\rho_K \lesssim \rho_k \lesssim \max_{x_k\in\overline{K}}\rho_K \quad \text{for } k\in\mathcal{N}. \tag{4.1}$$

The following theorem is closely related to [7, Theorems 3.2 and 3.6].

THEOREM 4.1. *Let $\{\phi_k\}_{k\in\mathcal{N}}$ be a nodal basis for $\mathcal{S}_i^\ell(\mathcal{P})\subset\widetilde{H}^m(\Gamma)$, where $i=0$ or 1.*

(i) *If $0\le m\le 1$, then $|||\phi_k|||_{\widetilde{H}^m(\Gamma_k)}\lesssim\rho_k^{-m}\|\phi_k\|_{L_2(\Gamma_k)}$.*

(ii) *If $-1\le m\le 0$, then $\rho_k^{-m}\|\phi_k\|_{L_2(\Gamma_k)}\lesssim|||\phi_k|||_{H^m(\Gamma_k)}$.*

Proof. The proof follows the same lines as the proofs of [7, Theorems 3.2 and 3.6], in which the same result is proved on the whole domain Γ. To get the proof of the present result, one has to check only that the arguments in [7] remain true if the global norm $|||\cdot|||_{\widetilde{H}^s(\Gamma)}$ is replaced by the local norm $|||\cdot|||_{\widetilde{H}^s(\Gamma_k)}$. We recall that the latter norm is obtained for $s\in(0,1)$ by interpolation between the norms $\|\cdot\|_{L_2(\Gamma_k)}$ and $|\cdot|_{H^1(\Gamma_k)}$ and then by duality for $s\in[-1,0]$. Now, following the arguments in [7, Theorem 3.2], it is easily seen that

$$|\phi_k|^2_{H^1(\Gamma_k)}=\sum_{\substack{K\in\mathcal{P}\\K\subset\Gamma_k}}\int_K|\nabla\phi_k|^2\lesssim\rho_k^{-2}\sum_{\substack{K\in\mathcal{P}\\K\subset\Gamma_k}}\|\phi_k\|^2_{L_2(K)}=\rho_k^{-2}\|\phi_k\|^2_{L_2(\Gamma_k)}.$$

The proof of (i) for $m=1$ follows directly, and result (i) then follows by interpolation (3.3).

For (ii), note first that when $m\in[-1,0]$, the definition of the dual space implies

$$|||\phi_k|||_{H^m(\Gamma_k)}\ge\frac{|(\phi_k,w)_{\Gamma_k}|}{|||w|||_{\widetilde{H}^{-m}(\Gamma_k)}} \tag{4.2}$$

for any $w\in\widetilde{H}^{-m}(\Gamma_k)$, not identically zero. The proof is completed by constructing a test function $w\in\widetilde{H}^{-m}(\Gamma_k)$ with the properties

$$|(\phi_k,w)_{\Gamma_k}| \;\gtrsim\; \rho_k^2\|\phi_k\|^2_{L_2(\Gamma_k)}, \tag{4.3}$$

$$|||w|||_{\widetilde{H}^{-m}(\Gamma_k)} \;\lesssim\; \rho_k^{2+m}\|\phi_k\|_{L_2(\Gamma_k)}. \tag{4.4}$$

The required construction of w is given in the proof of [7, Theorem 3.6], where the estimates (4.3) and (4.4) with $m=-1$ are established (see [7, eqs. (3.14), (3.15)] and put $\alpha=0$ and $k=1$). The proof of (4.4) for $m\in[-1,0]$ is obtained by establishing it for $m=0$ and then interpolating with $m=-1$. To establish (4.4) for $m=0$ one has to look closely at the argument in [7, Theorem 3.6]. For any $K\in\mathcal{P}$, $K\subset\Gamma_k$, it is shown that there exists a subset $t(K)\subset K$ and a function $P_{t(K)}\in\widetilde{H}^1(K)$ such that $\phi_k|_{t(K)}$ is one-signed and such that $\|P_{t(K)}\|_{L_2(K)}\simeq|t(K)|^{1/2}$. The hidden constants in this estimate are independent of k,K and the mesh. Then the w which satisfies (4.3) and (4.4) with $m=-1$ is defined as $w=\sum_{K\subset\Gamma_k}\rho_K^2\operatorname{sign}(\phi_k|_{t(K)})\inf_{x\in t(K)}|\phi_k(x)|P_{t(K)}$. Then

$$\begin{aligned}\|w\|^2_{L_2(\Gamma_k)}&=\sum_{K\subset\Gamma_k}\rho_K^4\Big(\inf_{x\in t(K)}|\phi_k(x)|\Big)^2\|P_{t(K)}\|^2_{L_2(t(K))}\\&\lesssim\rho_k^4\sum_{K\subset\Gamma_k}\Big(\inf_{x\in t(K)}|\phi_k(x)|\Big)^2|t(K)|\lesssim\rho_k^4\|\phi_k\|^2_{L_2(\Gamma_k)},\end{aligned}$$

as required. ∎

Theorem 4.1 is the key component in the proof of the next result, which in turn is a partial generalization of [1, Lemma 4.7] and [1, Theorem 4.8].

THEOREM 4.2. *Let $k \in \mathcal{N}$.*

(i) *If $1 \le p \le \infty$, then $\|\phi_k\|_{L_p(\Gamma)} = \|\phi_k\|_{L_p(\Gamma_k)} \simeq |\Gamma_k|^{1/p}$.*

(ii) *If $0 \le m \le 1$, then $\|\phi_k\|^2_{\widetilde{H}^m(\Gamma)} \lesssim |||\phi_k|||^2_{\widetilde{H}^m(\Gamma_k)} \lesssim |\Gamma_k|\rho_k^{-2m}$.*

(iii) *If $-1 \le m \le 0$, then $|\Gamma_k|\rho_k^{-2m} \lesssim |||\phi_k|||^2_{H^m(\Gamma_k)} \lesssim \|\phi_k\|^2_{H^m(\Gamma)}$.*

(iv) *If $0 \le 2m < d$, then $\|\phi_k\|^2_{H^m(\Gamma)} \gtrsim |\Gamma_k|^{1-2m/d}$.*

(v) *If $-d < 2m \le 0$, then $\|\phi_k\|^2_{\widetilde{H}^m(\Gamma)} \lesssim |\Gamma_k|^{1-2m/d}$.*

Proof. (i) By the definition of ϕ_k,

$$\|\phi_k\|^p_{L_p(\Gamma_k)} = \sum_{\substack{K\in\mathcal{P}\\ K\subset\Gamma_k}} \int_K |\phi_k|^p.$$

For a typical $K \subset \Gamma_k$, recall (3.4) and write $\int_K |\phi_k|^p = \int_{\hat{K}} |\hat{\phi}_k|^p g_K \simeq |K| \int_{\hat{K}} |\hat{\phi}_k|^p \simeq |K|$ by Assumption 3.1. Now sum over all elements $K \subset \Gamma_k$ to obtain the result.

The left-hand inequality in (ii) follows directly from the left-hand inequality in (3.1), while the right-hand inequality in (ii) follows from part (i) of Theorem 4.1 and part (i) of the present theorem.

Similarly, in part (iii), we use the right-hand inequality in (3.1) and part (ii) of Theorem 4.1, combined with part (i) of the present theorem.

To prove (iv), we put $p = 2d/(d-2m) \in [2,\infty)$ and apply the Sobolev imbedding theorem together with part (i) above to obtain

$$\|\phi_k\|^2_{H^m(\Gamma)} \gtrsim \|\phi_k\|^2_{L_p(\Gamma)} \simeq |\Gamma_k|^{2/p} = |\Gamma_k|^{1-2m/d}.$$

Part (v) follows using a dual imbedding: For $q = 2d/(d-2m) \in (1,2]$,

$$\|\phi_k\|^2_{\widetilde{H}^m(\Gamma)} \lesssim \|\phi_k\|^2_{L_q(\Gamma)} \simeq |\Gamma_k|^{2/q} = |\Gamma_k|^{1-2m/d}. \qquad \square$$

5. Bounds on the extremal eigenvalues. In this section we obtain general bounds on the spectra of the matrices $\boldsymbol{B}$ and $\boldsymbol{B}'$ which were defined in (1.4) and (1.6). Since $\boldsymbol{B}$ is symmetric, these may be obtained by estimating the Rayleigh quotient $\boldsymbol{\alpha}^T\boldsymbol{B}\boldsymbol{\alpha}/\boldsymbol{\alpha}^T\boldsymbol{\alpha}$ from above and from below. For a typical $v \in X$ we write

$$v = \sum_{k\in\mathcal{N}} v_k, \quad \text{where } v_k = \alpha_k\phi_k \text{ and } \alpha_k = v(x_k). \tag{5.1}$$

Then, since

$$\boldsymbol{\alpha}^T\boldsymbol{B}\boldsymbol{\alpha} = B(v,v) \simeq \|v\|^2_{\widetilde{H}^m(\Gamma)} \quad \text{and} \quad \boldsymbol{\alpha}^T\boldsymbol{\alpha} = \sum_{k\in\mathcal{N}} v(x_k)^2,$$

if we show the bounds

$$\lambda_X \sum_{k\in\mathcal{N}} v(x_k)^2 \lesssim \|v\|^2_{\widetilde{H}^m(\Gamma)} \lesssim \Lambda_X \sum_{k\in\mathcal{N}} v(x_k)^2 \quad \text{for all } v \in X, \tag{5.2}$$

then we have the estimates $\lambda_{\max}(\boldsymbol{B}) \lesssim \Lambda_X$ and $\lambda_{\min}(\boldsymbol{B}) \gtrsim \lambda_X$.

Similarly, for the diagonally scaled matrix $\boldsymbol{B}'$, note that

$$\boldsymbol{\alpha}^T\boldsymbol{D}\boldsymbol{\alpha} = \sum_{k\in\mathcal{N}} \alpha_k^2 B(\phi_k,\phi_k) = \sum_{k\in\mathcal{N}} B(v_k,v_k) \simeq \sum_{k\in\mathcal{N}} \|v_k\|^2_{\widetilde{H}^m(\Gamma)}.$$

Thus if we can show that

$$\lambda'_X \sum_{k\in\mathcal{N}} \|v_k\|^2_{\widetilde{H}^m(\Gamma)} \lesssim \|v\|^2_{\widetilde{H}^m(\Gamma)} \lesssim \Lambda'_X \sum_{k\in\mathcal{N}} \|v_k\|^2_{\widetilde{H}^m(\Gamma)} \quad \text{for all } v \in X, \tag{5.3}$$

then it will follow that $\lambda_{\max}(\boldsymbol{B}') \lesssim \Lambda'_X$ and $\lambda_{\min}(\boldsymbol{B}') \gtrsim \lambda'_X$.

For each element $K \in \mathcal{P}$, let $\mathcal{N}(K) = \{\, k \in \mathcal{N} : \Gamma_k \cap K \neq \emptyset \,\}$. Our assumptions on the family of partitions $\{\mathcal{P}\}$ imply that

$$\text{the cardinality of } \mathcal{N}(K) \text{ for } K \in \mathcal{P} \text{ is bounded independently of } \mathcal{P} \tag{5.4}$$

and that for each $\mathcal{P}$ the index set $\mathcal{N}$ may be partitioned into disjoint subsets $\mathcal{N}_1$, $\mathcal{N}_2, \ldots, \mathcal{N}_L$ having the property

$$\text{interior}(\operatorname{supp}\phi_k) \cap \text{interior}(\operatorname{supp}\phi_{k'}) = \emptyset \quad \text{if } k,\, k' \in \mathcal{N}_\ell \text{ and } k \neq k', \tag{5.5}$$

in such a way that L is bounded independently of $\mathcal{P}$.

In Lemmas 5.1 and 5.2 we will obtain bounds on the spectra of $\boldsymbol{B}$ and $\boldsymbol{B}'$, some of which involve the quantities

$$\Phi_{m,k} := \frac{|\Gamma_k|\rho_k^{-2m}}{\|\phi_k\|^2_{\widetilde{H}^m(\Gamma)}}\,, \quad k \in \mathcal{N}. \tag{5.6}$$

Simple bounds on $\Phi_{m,k}$ may be obtained by employing Theorem 4.2 and (3.2) to obtain

$$\Phi_{m,k} \lesssim 1 \text{ for } -1 \le m \le 0 \qquad \text{and} \qquad \Phi_{m,k} \gtrsim \frac{|\Gamma_k|^{2m/d}}{\rho_k^{2m}} \text{ for } -d < 2m \le 0, \tag{5.7}$$

$$\Phi_{m,k} \gtrsim 1 \text{ for } 0 \le m \le 1 \qquad \text{and} \qquad \Phi_{m,k} \lesssim \frac{|\Gamma_k|^{2m/d}}{\rho_k^{2m}} \text{ for } 0 \le 2m < d. \tag{5.8}$$

(Note that in the shape-regular case, (5.8) and (5.7) are sharp estimates, since $|\Gamma_k|^{1/d} \simeq h_k \simeq \rho_k$, and thus $\Phi_{m,k} \simeq 1$ for $2|m| < d$.)

In the next two lemmas we shall decompose an arbitrary $v \in X \subset \widetilde{H}^m(\Gamma)$ as in (5.1).

LEMMA 5.1. *For $-1 \le m \le 0$ and $-d < 2m$, we have*

$$\min_{k\in\mathcal{N}} |\Gamma_k|\rho_k^{-2m} \;\lesssim\; \lambda_{\min}(\boldsymbol{B}) \;\le\; \lambda_{\max}(\boldsymbol{B}) \;\lesssim\; \left(\sum_{k\in\mathcal{N}} |\Gamma_k|^{1-d/2m}\right)^{-2m/d},$$

$$\min_{k\in\mathcal{N}} \Phi_{m,k} \;\lesssim\; \lambda_{\min}(\boldsymbol{B}') \;\le\; \lambda_{\max}(\boldsymbol{B}') \;\lesssim\; \left(\sum_{k\in\mathcal{N}} |\Gamma_k|\rho_k^{-d}\right)^{-2m/d}.$$

The lower bounds continue to hold if the hypothesis is weakened to just $-1 \le m \le 0$.

Proof. With $q = 2d/(d-2m) \in (1,2]$, and using the dual Sobolev embedding, we obtain $\|v\|_{\widetilde{H}^m(\Gamma)} \lesssim \|v\|_{L_q(\Gamma)}$. Now, using Hölder's inequality and property (5.5), we obtain

$$\begin{aligned} \|v\|_{\widetilde{H}^m(\Gamma)} &\lesssim \|v\|_{L_q(\Gamma)} \lesssim \sum_{\ell=1}^{L} \left\| \sum_{k\in\mathcal{N}_\ell} v_k \right\|_{L_q(\Gamma)} \\ &\lesssim \left(\sum_{\ell=1}^{L} \left\| \sum_{k\in\mathcal{N}_\ell} v_k \right\|^q_{L_q(\Gamma)} \right)^{1/q} \lesssim \left(\sum_{k\in\mathcal{N}} \|v_k\|^q_{L_q(\Gamma)} \right)^{1/q}. \end{aligned} \tag{5.9}$$

Moreover from Hölder's inequality with $1/p + q/2 = 1$ and with w_k denoting any positive weight, we have

$$\sum_{k\in\mathcal{N}} \|v_k\|^q_{L_q(\Gamma)} \le \left(\sum_{k\in\mathcal{N}} \left(w_k^{q/2}\right)^p\right)^{1/p} \left(\sum_{k\in\mathcal{N}} \left(w_k^{-q/2}\|v_k\|^q_{L_q(\Gamma)}\right)^{2/q}\right)^{q/2}$$
$$\lesssim \left(\sum_{k\in\mathcal{N}} w_k^{pq/2}\right)^{1/p} \left(\sum_{k\in\mathcal{N}} w_k^{-1}\|v_k\|^2_{L_q(\Gamma)}\right)^{q/2}.$$

Combining this with (5.9), we obtain

$$\|v\|^2_{\widetilde{H}^m(\Gamma)} \lesssim \left(\sum_{k\in\mathcal{N}} w_k^{pq/2}\right)^{2/(pq)} \sum_{k\in\mathcal{N}} w_k^{-1}\|v_k\|^2_{L_q(\Gamma)}. \tag{5.10}$$

Note that $2/q = 1 - 2m/d$, $p = 1 - d/(2m)$, and $pq/2 = -d/(2m)$. By choosing $w_k = |\Gamma_k|^{2/q}$ in (5.10) and applying Theorem 4.2 (i), we obtain

$$\|v\|^2_{\widetilde{H}^m(\Gamma)} \lesssim \left(\sum_{k\in\mathcal{N}} |\Gamma_k|^{1-d/2m}\right)^{-2m/d} \sum_{k\in\mathcal{N}} v(x_k)^2,$$

which, together with (5.2) implies the upper bound for $\lambda_{\max}(\boldsymbol{B})$.

On the other hand, with $w_k = |\Gamma_k|^{2/q-1}\rho_k^{2m}$, it follows from Theorem 4.2(i), (iii) that

$$w_k^{-1}\|v_k\|^2_{L_q(\Gamma)} \simeq v(x_k)^2|\Gamma_k|\rho_k^{-2m} \lesssim v(x_k)^2\|\phi_k\|^2_{H^m(\Gamma)} = \|v_k\|^2_{H^m(\Gamma)}.$$

Since $w_k^{pq/2} = |\Gamma_k|^{p-pq/2}(\rho_k^{2m})^{pq/2} = |\Gamma_k|\rho_k^{-d}$, (5.10) leads to

$$\|v\|^2_{\widetilde{H}^m(\Gamma)} \lesssim \left(\sum_{k\in\mathcal{N}} |\Gamma_k|\rho_k^{-d}\right)^{-2m/d} \sum_{k\in\mathcal{N}} \|v_k\|^2_{H^m(\Gamma)}.$$

The upper bound for $\lambda_{\max}(\boldsymbol{B}')$ follows by (3.2) and (5.3).

Now consider the lower bounds. Given $k \in \mathcal{N}$, choose an element $K \in \mathcal{P}$ such that $x_k \in \overline{K}$. Then, with $\hat{v} = v \circ \chi_K$, and using equivalence of norms on finite-dimensional spaces, we have

$$v(x_k)^2 \le \|v\|^2_{L_\infty(K)} = \|\hat{v}\|^2_{L_\infty(\hat{K})} \simeq \|\hat{v}\|^2_{L_2(\hat{K})} \simeq |K|^{-1}\|v\|^2_{L_2(K)}. \tag{5.11}$$

Moreover, using [7, Theorem 3.6, Remark 3.8] applied on the single element K, we obtain $\|v\|_{L_2(K)} \lesssim \rho_K^m |||v|||_{H^m(K)}$. Combining this with (5.11) and using Assumption 3.2, we get

$$v(x_k)^2 \lesssim |K|^{-1}\rho_K^{2m}|||v|||^2_{H^m(K)} \lesssim |\Gamma_k|^{-1}\rho_k^{2m}|||v|||^2_{H^m(K)}. \tag{5.12}$$

Hence using (5.4) and (3.1),

$$\sum_{k\in\mathcal{N}} v(x_k)^2 \lesssim \left(\max_{k\in\mathcal{N}} |\Gamma_k|^{-1}\rho_k^{2m}\right) \sum_{K\in\mathcal{P}} |||v|||^2_{H^m(K)} \lesssim \left(\max_{k\in\mathcal{N}} |\Gamma_k|^{-1}\rho_k^{2m}\right)\|v\|^2_{H^m(\Gamma)},$$

and the lower bound for $\lambda_{\min}(\boldsymbol{B})$ follows by (3.2). To obtain the lower bound for $\lambda_{\min}(\boldsymbol{B}')$, we use the definition (5.6) of $\Phi_{m,k}$ combined with (5.12) to obtain

$$\|v_k\|^2_{\widetilde{H}^m(\Gamma)} = v(x_k)^2\|\phi_k\|^2_{\widetilde{H}^m(\Gamma)} = \Phi_{m,k}^{-1}\left[v(x_k)^2|\Gamma_k|\rho_k^{-2m}\right] \lesssim \Phi_{m,k}^{-1}|||v|||^2_{H^m(K)}. \tag{5.13}$$

Then the required estimate follows by summing over k and using (3.1). ∎

LEMMA 5.2. *For $0 \le m \le 1$ and $2m < d$, we have*

$$\left(\sum_{k\in\mathcal{N}} |\Gamma_k|^{1-d/2m}\right)^{-2m/d} \lesssim \lambda_{\min}(\boldsymbol{B}) \le \lambda_{\max}(\boldsymbol{B}) \lesssim \max_{k\in\mathcal{N}} |\Gamma_k|\rho_k^{-2m},$$

$$\left(\sum_{k\in\mathcal{N}} |\Gamma_k|\rho_k^{-d}\right)^{-2m/d} \lesssim \lambda_{\min}(\boldsymbol{B}') \le \lambda_{\max}(\boldsymbol{B}') \lesssim \max_{k\in\mathcal{N}} \Phi_{m,k}.$$

The upper bounds continue to hold if the hypothesis is weakened to just $0 \le m \le 1$.

Proof. Using the decomposition (5.1) of v, we have

$$\begin{aligned}\|v\|^2_{\widetilde{H}^m(\Gamma)} &= \Big\|\sum_{\ell=1}^L \sum_{k\in\mathcal{N}_\ell} v_k\Big\|^2_{\widetilde{H}^m(\Gamma)} \le \left(\sum_{\ell=1}^L \Big\|\sum_{k\in\mathcal{N}_\ell} v_k\Big\|_{\widetilde{H}^m(\Gamma)}\right)^2 \\ &\le L\sum_{\ell=1}^L \Big\|\sum_{k\in\mathcal{N}_\ell} v_k\Big\|^2_{\widetilde{H}^m(\Gamma)} \lesssim \sum_{k\in\mathcal{N}} |||v_k|||^2_{\widetilde{H}^m(\Gamma_k)},\end{aligned} \tag{5.14}$$

where we used the left-hand inequality in (3.1) and the property (5.5). By Theorem 4.2(ii),

$$|||v_k|||^2_{\widetilde{H}^m(\Gamma_k)} = v(x_k)^2|||\phi_k|||^2_{\widetilde{H}^m(\Gamma_k)} \lesssim v(x_k)^2|\Gamma_k|\rho_k^{-2m}. \tag{5.15}$$

Substituting this into (5.14) yields

$$\|v\|^2_{\widetilde{H}^m(\Gamma)} \lesssim \left(\max_{j\in\mathcal{N}} |\Gamma_j|\rho_j^{-2m}\right) \sum_{k\in\mathcal{N}} v(x_k)^2,$$

which, recalling (5.2), implies the upper bound for $\lambda_{\max}(\boldsymbol{B})$.

To obtain the upper bound for $\lambda_{\max}(\boldsymbol{B}')$, we use (5.15) to write

$$|||v_k|||^2_{\widetilde{H}^m(\Gamma_k)} \lesssim v(x_k)^2|\Gamma_k|\rho_k^{-2m} = v(x_k)^2\Phi_{m,k}\|\phi_k\|^2_{\widetilde{H}^m(\Gamma)} = \Phi_{m,k}\|v_k\|^2_{\widetilde{H}^m(\Gamma)}.$$

Then we combine this with (5.14) and (5.3) to obtain the result.

Now we consider the lower bounds. Let $p = 2d/(d-2m) \in [2,\infty)$ so that $\|v\|_{L_p(\Gamma)} \lesssim \|v\|_{H^m(\Gamma)}$. Clearly $v(x_k)^2 \le \|v\|^2_{L_\infty(K)}$ for some $K \in \mathcal{P}$, $K \subseteq \Gamma_k$. Also $v\circ\chi_K = \hat{v}$, with $\hat{v} \in \mathbb{P}^\ell(\hat{K})$, and by equivalence of norms on finite-dimensional spaces, combined with Assumptions 3.1 and 3.2, we have

$$v(x_k)^2 \le \|v\|^2_{L_\infty(K)} = \|\hat{v}\|^2_{L_\infty(\hat{K})} \simeq \|\hat{v}\|^2_{L_p(\hat{K})} \simeq |K|^{-2/p}\|v\|^2_{L_p(K)} \lesssim |\Gamma_k|^{-2/p}\|v\|^2_{L_p(\Gamma_k)}. \tag{5.16}$$

Hence, by Hölder's inequality with $2/p + 1/q = 1$,

$$\sum_{k\in\mathcal{N}} v(x_k)^2 \lesssim \left(\sum_{j\in\mathcal{N}} \left(|\Gamma_j|^{-2/p}\right)^q\right)^{1/q} \left(\sum_{k\in\mathcal{N}} \|v\|^p_{L_p(\Gamma_k)}\right)^{2/p} \lesssim \left(\sum_{j\in\mathcal{N}} |\Gamma_j|^{-2q/p}\right)^{1/q} \|v\|^2_{L_p(\Gamma)},$$

where we used the property (5.4). Now, since $2/p = 1 - 2m/d$ we have $1/q = 2m/d$ and

$$\sum_{k\in\mathcal{N}} v(x_k)^2 \lesssim \left(\sum_{j\in\mathcal{N}} |\Gamma_j|^{1-d/2m}\right)^{2m/d} \|v\|^2_{H^m(\Gamma)},$$

which, in view of (3.2) and (5.2), proves the lower bound for $\lambda_{\min}(\boldsymbol{B})$.

To estimate $\lambda_{\min}(\boldsymbol{B}')$, we use Theorem 4.2(ii) and (5.16) to obtain

$$\|v_k\|^2_{\widetilde{H}^m(\Gamma)} = v(x_k)^2\|\phi_k\|^2_{\widetilde{H}^m(\Gamma)} \lesssim v(x_k)^2|\Gamma_k|\rho_k^{-2m} \lesssim |\Gamma_k|^{1-2/p}\rho_k^{-2m}\|v\|^2_{L_p(\Gamma_k)}. \tag{5.17}$$

Thus, recalling $1 - 2/p = 2m/d$ and employing again (5.4),

$$\begin{aligned}&\sum_{k\in\mathcal{N}} \|v_k\|^2_{\widetilde{H}^m(\Gamma)} \lesssim \sum_{k\in\mathcal{N}} |\Gamma_k|^{2m/d}\rho_k^{-2m}\|v\|^2_{L_p(\Gamma_k)}\\ &\lesssim \left(\sum_{j\in\mathcal{N}} \left(|\Gamma_j|^{2m/d}\rho_j^{-2m}\right)^q\right)^{1/q}\left(\sum_{k\in\mathcal{N}} \|v\|^p_{L_p(\Gamma_k)}\right)^{2/p} \lesssim \left(\sum_{j\in\mathcal{N}} |\Gamma_j|\rho_j^{-d}\right)^{2m/d}\|v\|^2_{H^m(\Gamma)},\end{aligned}$$

which, again using (3.2) and (5.3), gives the lower bound for $\lambda_{\min}(\boldsymbol{B}')$. ∎

REMARK 5.3. *The left-hand side of the first inequality in Lemma* 5.2 *and the right-hand side of the first inequality in Lemma* 5.1 *should be interpreted as the appropriate limit when* $m \to 0$. *Observe that these lemmas reproduce several known results as special cases. For example, putting* $m = 0$, *we obtain estimates for the "mass matrix" corresponding to an operator of order* 0*:*

$$\min_{k\in\mathcal{N}} |\Gamma_k| \lesssim \lambda_{\min}(\boldsymbol{B}) \le \lambda_{\max}(\boldsymbol{B}) \lesssim \max_{k\in\mathcal{N}} |\Gamma_k| \quad \textit{and} \quad 1 \lesssim \lambda_{\min}(\boldsymbol{B}') \le \lambda_{\max}(\boldsymbol{B}') \lesssim 1.$$

These are well-known, at least for the shape-regular case (i.e., $|\Gamma_k| \sim \rho_k^d \sim h_k^d$*). Moreover, in the shape-regular case for general* m *and* d, *it is easy to see that Lemmas* 5.2 *and* 5.1 *imply the previously proved estimate* (1.7). *Lemmas* 5.2 *and* 5.1 *can be combined with* (5.8) *and* (5.7) *to obtain general spectral estimates in the non–shape-regular case, in terms of the computable quantities* $|\Gamma_k|$ *and* ρ_k *and generic mesh-independent constants. In what follows we shall illustrate the uses of these estimates for operators of general order* m, *but (since boundary integral equations is our main application), we shall restrict this illustration to the case*

$$d = 2 \quad \textit{and} \quad |\Gamma_k| \sim h_k\rho_k \quad \textit{for each} \quad k \in \mathcal{N}. \tag{5.18}$$

Then we have the following corollary for operators of general order m.

COROLLARY 5.4. (i) *Assume* (5.18). *For* $-1 < m \le 0$,

$$\begin{aligned}\min_{k\in\mathcal{N}}(h_k\rho_k^{1-2m}) \;\lesssim\; \lambda_{\min}(\boldsymbol{B}) \;\le\; \lambda_{\max}(\boldsymbol{B}) \;\lesssim\; \left(\sum_{k\in\mathcal{N}} (h_k\rho_k)^{1-1/m}\right)^{-m},\\ \min_{k\in\mathcal{N}}(h_k\rho_k^{-1})^m \;\lesssim\; \lambda_{\min}(\boldsymbol{B}') \;\le\; \lambda_{\max}(\boldsymbol{B}') \;\lesssim\; \left(\sum_{k\in\mathcal{N}} h_k\rho_k^{-1}\right)^{-m}.\end{aligned}$$

(ii) *For* $0 \le m < 1$,

$$\left(\sum_{k\in\mathcal{N}} (h_k\rho_k)^{1-1/m}\right)^{-m} \lesssim \lambda_{\min}(\boldsymbol{B}) \le \lambda_{\max}(\boldsymbol{B}) \lesssim \max_{k\in\mathcal{N}} \left(h_k\rho_k^{1-2m}\right),$$
$$\left(\sum_{k\in\mathcal{N}} h_k\rho_k^{-1}\right)^{-m} \lesssim \lambda_{\min}(\boldsymbol{B}') \le \lambda_{\max}(\boldsymbol{B}') \lesssim \max_{k\in\mathcal{N}} \left(h_k\rho_k^{-1}\right)^m.$$

The hypersingular and weakly singular examples considered in section 2.1 are then obtained from the special cases $m = 1/2$ and $m = -1/2$. These estimates can be applied to any mesh specified by the user. To illustrate its use on a typical class of meshes, let us consider the following example.

EXAMPLE 5.5. *Suppose* Γ *is a plane convex polygon with perimeter* γ. *For some fixed* $\delta > 0$, *let* $\gamma^{\parallel}$ *be the inscribed polygon, each of whose edges* $e^{\parallel}$ *is parallel to and a perpendicular distance* δ *from a corresponding edge* e *of* γ. *To mesh* Γ, *extend each* $e^{\parallel}$ *in a straight line at each end until it touches* γ. *For* δ *sufficiently small, this subdivides* Γ *into near-vertex rhombi, near-edge trapezia, and an inner polygon. For each* e, *draw* $n-1$ *parallel lines inside* Γ, *a perpendicular distance* $(i/n)^\beta$ *from* e, *for* $i = 1, \ldots, n-1$. *(The last of these lines is an extension of* $e^{\parallel}$.*) This defines a mesh of quadrilaterals on each of the rhombi. For each near-edge trapezium, introduce a quadrilateral mesh by subdividing each of its parallel sides uniformly with* n *subintervals and draw straight lines between corresponding points. Finally subdivide the interior polygon* $\Gamma^{\rm int}$ *with a quasi-uniform mesh with* $O(n^2)$ *(triangular or quadrilateral) elements, whose nodes on* γ *coincide with the nodes already specified. (See Figure* 2.*) This mesh has* $N = O(n^2)$ *elements, and the mesh in Figure* 1 *is a particular case.*

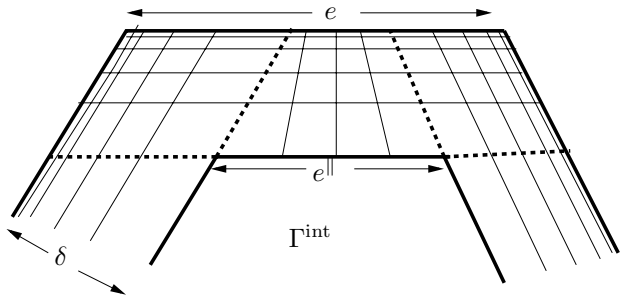

FIG. 2. *Section of mesh on polygon* Γ, *depicting two near-vertex rhombi and a near-edge trapezium.*

LEMMA 5.6. *For the class of meshes specified in Example* 5.5 *we have*

$$\sum_{k\in\mathcal{N}} h_k\rho_k^{-1} \lesssim \begin{cases} N & \text{for } 1 \le \beta < 2, \\ N(1+\log N) & \text{for } \beta = 2, \\ N^{\beta/2} & \text{for } \beta > 2, \end{cases}$$

(5.19)

$$\sum_{k\in\mathcal{N}} (\rho_k h_k)^{-1} \lesssim \begin{cases} N^2, & \text{for } 1 \le \beta < 2, \\ N^2(1+\log N)^2, & \beta = 2, \\ N^\beta, & \text{for } \beta > 2. \end{cases}$$

Proof. For the quasi-uniform mesh on $\Gamma^{\rm int}$ the required estimates follow from the standard inequalities $\rho_k \gtrsim h_k \gtrsim N^{-1/2}$. Therefore we have to consider only the near-vertex rhombi and the near-edge trapezia.

Any typical near-vertex rhombus is the image of the unit square $[0,1]^2$ under an invertible affine map. Moreover, the mesh on any near-vertex rhombus can be obtained by applying this affine map to the tensor product mesh with vertices $\big((i/n)^\beta, (j/n)^\beta\big)$. Without loss of generality, we can estimate the quantities (5.19) for this unit square because mesh-independent constants are not important. In this case, with $t_j = (j/n)^\beta$ we have $\Delta t_j = t_j - t_{j-1} \simeq n^{-1}(j/n)^{\beta-1}$ and so we have

$$\begin{aligned}\sum_{k\in\mathcal{N}} h_k \rho_k^{-1} &\simeq \sum_{i=1}^n \sum_{j=1}^i \frac{\Delta t_i}{\Delta t_j} \simeq \sum_{i=1}^n \sum_{j=1}^i \frac{(i/n)^{\beta-1}}{(j/n)^{\beta-1}} \\ &= n^2 \sum_{i=1}^n \left(\frac{i}{n}\right)^{\beta-1} \frac{1}{n} \sum_{j=1}^i \left(\frac{j}{n}\right)^{1-\beta} \frac{1}{n} \simeq n^2 \int_{1/n}^1 s^{\beta-1} \int_{1/n}^s t^{1-\beta}\, dt\, ds,\end{aligned}$$

from which the left-hand inequality in (5.19) follows (on recalling that $N \sim n^2$). Similarly,

$$\begin{aligned}\sum_{k\in\mathcal{N}} (\rho_k h_k)^{-1} &\simeq \sum_{i=1}^n \sum_{j=1}^n \frac{1}{\Delta t_i\, \Delta t_j} \simeq \sum_{i=1}^n \sum_{j=1}^i n^2 \left(\frac{i}{n}\right)^{1-\beta} \left(\frac{j}{n}\right)^{1-\beta} \\ &\simeq n^4 \sum_{i=1}^n \left(\frac{i}{n}\right)^{1-\beta} \frac{1}{n} \sum_{j=1}^i \left(\frac{j}{n}\right)^{1-\beta} \frac{1}{n} \simeq n^4 \int_{1/n}^1 s^{1-\beta} \int_{1/n}^s t^{1-\beta}\, dt\, ds,\end{aligned}$$

from which the right-hand inequality in (5.19) follows.

The meshes on the near-edge trapezia can be obtained as images of the unit square under a nonsingular bilinear map, meshed with the tensor-product mesh $\big(i/n, (j/n)^\beta\big)$, and the estimates (5.19) are then obtained analogously to those above. ∎

The following theorems now follow by combining Corollary 5.4 with Lemma 5.6.

THEOREM 5.7. *Consider the weakly singular boundary integral equation* (2.1) *on the polygon* Γ *discretized as in Example* 5.5. *Then for conforming boundary elements of any degree in* $\widetilde{H}^{-1/2}(\Gamma)$ *and with the nodal basis introduced in section* 3,

1. *the Galerkin matrix* $\boldsymbol{B}$ *satisfies the spectral bounds* $\lambda_{\max}(\boldsymbol{B}) \lesssim N^{-1}$ *and* $\lambda_{\min}(\boldsymbol{B}) \gtrsim N^{-3\beta/2}$, *and*
2. *the diagonally scaled Galerkin matrix* $\boldsymbol{B}'$ *satisfies*

$$\lambda_{\max}(\boldsymbol{B}') \lesssim \begin{cases} N^{1/2} & \text{for } 1 \le \beta < 2, \\ N^{1/2}(1+\log N)^{1/2} & \text{for } \beta = 2, \\ N^{\beta/4} & \text{for } \beta > 2, \end{cases} \qquad \text{and} \quad \lambda_{\min}(\boldsymbol{B}') \gtrsim N^{-(\beta-1)/4}.$$

Proof. Elementary estimates for the meshes in Example 5.5 yield, for each $k \in \mathcal{N}$,

$$N^{-\beta/2} \lesssim \rho_k \le h_k \lesssim N^{-1/2}. \tag{5.20}$$

We apply Corollary 5.4 with $m = -1/2$. The bounds for $\lambda_{\max}(\boldsymbol{B})$ and $\lambda_{\min}(\boldsymbol{B})$ and the lower bound for $\lambda_{\min}(\boldsymbol{B}')$ follow immediately from (5.20), whereas the upper bound for $\lambda_{\max}(\boldsymbol{B}')$ follows from Lemma 5.6. ∎

THEOREM 5.8. *Consider the hypersingular boundary integral equation* (2.3) *on the polygonal screen* Γ *discretized as in Example* 5.5. *For conforming boundary elements of any degree in* $\widetilde{H}^{1/2}(\Gamma)$ *and with the nodal basis introduced in section* 3,

1. *the Galerkin matrix* $\boldsymbol{B}$ *satisfies the spectral bounds* $\lambda_{\max}(\boldsymbol{B}) \lesssim N^{-1/2}$ *and*

$$\lambda_{\min}(\boldsymbol{B}) \gtrsim \begin{cases} N^{-1} & \text{for } 1 \le \beta < 2, \\ N^{-1}(1+\log N)^{-1} & \text{for } \beta = 2, \\ N^{-\beta/2} & \text{for } \beta > 2, \end{cases}$$

2. *the diagonally scaled Galerkin matrix* $\boldsymbol{B}'$ *satisfies* $\lambda_{\max}(\boldsymbol{B}') \lesssim N^{(\beta-1)/4}$ *and*

$$\lambda_{\min}(\boldsymbol{B}') \gtrsim \begin{cases} N^{-1/2} & \text{for } 1 \le \beta < 2, \\ N^{-1/2}(1+\log N)^{-1/2} & \text{for } \beta = 2, \\ N^{-\beta/4} & \text{for } \beta > 2. \end{cases}$$

Proof. Note that the condition that the finite element space is $\widetilde{H}^{1/2}(\Gamma)$-conforming implies that it must be chosen from the class $\{v \in \mathcal{S}_1^\ell(\mathcal{P}) : v|_{\partial\Gamma} = 0\}$ for some $\ell \ge 1$.

We apply Corollary 5.4 with $m = 1/2$. The upper bounds for $\lambda_{\max}(\boldsymbol{B})$ and $\lambda_{\max}(\boldsymbol{B}')$ follow immediately from (5.20), whereas the lower bounds follow from Lemma 5.6. ∎

6. Numerical experiments. In this section we report some numerical experiments with the integral equations from section 2 on the square screen (2.5), with the power-graded meshes (2.8).

First we consider the weakly singular equation discretized using piecewise-constant basis functions. For $\beta = 2$ and $\beta = 3$, Tables 1 and 2 show the extremal eigenvalues and the condition numbers of $\boldsymbol{B}$ and of $\boldsymbol{B}'$. From one row of the table to the next, the number of subintervals along each axis doubles, so the number of degrees of freedom N increases by a factor of 4. For each of the six quantities under investigation, the left-hand column shows the quantity itself whereas the right-hand column gives the apparent exponent μ such that the quantity is proportional to N^μ. (To compute μ, we simply divide the logarithm of the ratio of successive values by $\log 4$.) The observed exponent values indicate that the estimates of Theorem 5.7 are sharp for $\boldsymbol{B}$ but not for $\boldsymbol{B}'$. However, the improved spectral bounds for $\boldsymbol{B}'$, proved

later in Theorem 7.4, appear to be sharp up to logarithmic factors. We remark that $\beta = 3$ gives the optimal convergence rate $O(N^{-3})$ for the capacitance of Γ, when piecewise constant elements are used (see, e.g., [6]).

Our second experiment is for the hypersingular equation discretized using continuous piecewise-bilinear basis functions. Tables 3 and 4 give our results for $\beta = 2$ and $\beta = 3$, which indicate that the estimates in Theorem 5.8 are (essentially) sharp for $\boldsymbol{B}$ but not for $\boldsymbol{B}'$. However, the improved spectral bounds for $\boldsymbol{B}'$, proved later in Theorem 7.5, appear to be sharp up to logarithmic factors.

The remainder of the paper is devoted to explaining our numerical results for $\boldsymbol{B}'$.

7. Sharper results for special cases.

7.1. Improved spectral bounds for $\boldsymbol{B}'$. For each of the model problems of section 2, the observed rate of growth for $\operatorname{cond}(\boldsymbol{B}')$ is slower than the rate predicted by the results proved in section 5 if the mesh grading is sufficiently strong, more precisely, if $\beta > 2$. However, the next lemma leads to bounds that are sharp to within logarithmic factors for $\lambda_{\max}(\boldsymbol{B}')$ (weakly singular case) and for $\lambda_{\min}(\boldsymbol{B}')$ (hypersingular case). Recall that γ denotes the perimeter of the open surface Γ.

LEMMA 7.1. *Let* $d_k = \sup_{x\in\Gamma_k} \operatorname{dist}(x,\gamma)$ *and assume that* $d_{\min} := \min_{k\in\mathcal{N}} d_k$ *is sufficiently small.*

1. *For the weakly singular boundary integral equation* (2.1) *on an open surface discretized with conforming finite elements of any degree in* $\widetilde{H}^{-1/2}(\Gamma)$,
$$\lambda_{\max}(\boldsymbol{B}') \lesssim \left(\log\frac{1}{d_{\min}}\right)^2 \max_{j\in\mathcal{N}} \frac{d_j}{\rho_j}.$$
2. *For the hypersingular boundary integral equation* (2.3) *on an open surface discretized with conforming finite elements of any degree in* $\widetilde{H}^{1/2}(\Gamma)$,
$$\lambda_{\min}(\boldsymbol{B}') \gtrsim \left(\log\frac{1}{d_{\min}}\right)^{-2} \min_{j\in\mathcal{N}} \frac{\rho_j}{d_j}.$$

Proof. First we prove part 2. Let $v \in X \subset \widetilde{H}^{1/2}(\Gamma)$ and decompose v as in (5.1). Taking $p = 2$ in (5.17) we have

$$\|v_k\|^2_{\widetilde{H}^m(\Gamma)} \le \rho_k^{-2m} \|v\|^2_{L_2(\Gamma_k)} \quad \text{for } 0 \le m \le 1 \text{ and } 0 \le 2m < d. \tag{7.1}$$

Now define $w(x)$ by $w(x) = \operatorname{dist}(x,\gamma)$. It can be shown [9, Lemma 3.32] that

$$\|vw^{-s}\|^2_{L_2(\Gamma)} = \int_\Gamma w(x)^{-2s} v(x)^2\,dx \lesssim \frac{1}{(\frac12 - s)^2} \|v\|^2_{H^s(\Gamma)} \quad \text{for } \tfrac14 \le s < \tfrac12, \tag{7.2}$$

where the hidden constant is independent of $s \in [\frac{1}{4}, \frac{1}{2})$. Since $w(x) \lesssim d_k$ for $x \in \Gamma_k$, using (7.1) with $m = 1/2$, we obtain

$$\|v_k\|^2_{\widetilde{H}^{1/2}(\Gamma)} \lesssim \rho_k^{-1}\|v\|^2_{L_2(\Gamma_k)} \lesssim \rho_k^{-1}\|(d_k/w)^s v\|^2_{L_2(\Gamma_k)} = \frac{d_k^{2s}}{\rho_k}\|vw^{-s}\|^2_{L_2(\Gamma_k)}, \quad s > 0.$$

Hence, using (7.2), we have

$$\begin{aligned}\sum_{k\in\mathcal{N}} \|v_k\|^2_{\widetilde{H}^{1/2}(\Gamma)} &\lesssim \left(\max_{j\in\mathcal{N}} \frac{d_j^{2s}}{\rho_j}\right) \sum_{k\in\mathcal{N}} \|vw^{-s}\|^2_{L_2(\Gamma_k)} \\ &\lesssim \left(\max_{j\in\mathcal{N}} \frac{d_j^{2s}}{\rho_j}\right)\|vw^{-s}\|^2_{L_2(\Gamma)} \lesssim \frac{1}{(\frac{1}{2}-s)^2}\left(\max_{j\in\mathcal{N}} \frac{d_j^{2s}}{\rho_j}\right)\|v\|^2_{H^s(\Gamma)},\end{aligned}$$

where the hidden constants are independent of $s \in [\frac{1}{4}, \frac{1}{2})$. Now with $\epsilon := (\log 1/d_{\min})^{-1}$, it follows that $d_j^{-2\epsilon} \lesssim 1$ for all $j \in \mathcal{N}$. Hence putting $s = \frac{1}{2} - \epsilon$, we obtain

$$\sum_{k\in\mathcal{N}} \|v_k\|^2_{\widetilde{H}^{1/2}(\Gamma)} \lesssim \left(\log \frac{1}{d_{\min}}\right)^2 \left(\max_{j\in\mathcal{N}} \frac{d_j}{\rho_j}\right)\|v\|^2_{H^{1/2}(\Gamma)}.$$

The estimate in part 2 follows at once.

To prove part 1, we apply a duality argument. Suppose $\frac{1}{4} \le s < \frac{1}{2}$. Then applying Cauchy–Schwarz together with (7.2) we obtain

$$\big|\langle v, \psi\rangle_{L_2(\Gamma)}\big| = \big|\langle vw^s, \psi w^{-s}\rangle_{L_2(\Gamma)}\big| \lesssim \|vw^s\|_{L_2(\Gamma)}\|\psi w^{-s}\|_{L_2(\Gamma)} \lesssim \frac{1}{\frac{1}{2}-s}\|vw^s\|_{L_2(\Gamma)}\|\psi\|_{H^s(\Gamma)},$$

and hence $\|v\|_{\widetilde{H}^{-s}(\Gamma)} \lesssim (\frac{1}{2}-s)^{-1}\|vw^s\|_{L_2(\Gamma)}$. Recalling (5.1) and (5.4), this implies that

(7.3)
$$\|v\|^2_{\widetilde{H}^{-1/2}(\Gamma)} \lesssim \|v\|^2_{\widetilde{H}^{-s}(\Gamma)} \lesssim (\tfrac{1}{2}-s)^{-2}\|vw^s\|^2_{L_2(\Gamma)} \lesssim (\tfrac{1}{2}-s)^{-2}\sum_{k\in\mathcal{N}} \|v_k w^s\|^2_{L_2(\Gamma)}.$$

Taking $p = 2$ in Theorem 4.2(i), and then using Theorem 4.2(iii) and (3.2), we see that

$$\begin{aligned}\|v_k w^s\|^2_{L_2(\Gamma)} &\lesssim d_k^{2s}\alpha_k^2\|\phi_k\|^2_{L_2(\Gamma)} \simeq \frac{d_k^{2s}}{\rho_k}\,\alpha_k^2|\Gamma_k|\rho_k \\ &\lesssim \frac{d_k^{2s}}{\rho_k}\,\alpha_k^2\|\phi_k\|^2_{\widetilde{H}^{-1/2}(\Gamma)} = \frac{d_k^{2s}}{\rho_k}\,\|v_k\|^2_{\widetilde{H}^{-1/2}(\Gamma)}, \quad \text{where } \alpha_k = v(x_k).\end{aligned} \tag{7.4}$$

So, combining (7.3) and (7.4) and putting $s = \frac{1}{2} - \epsilon$ with $\epsilon = (\log 1/d_{\min})^{-1}$, as above, we obtain

$$\|v\|^2_{\widetilde{H}^{-1/2}(\Gamma)} \lesssim \left(\log \frac{1}{d_{\min}}\right)^2 \left(\max_{j\in\mathcal{N}} \frac{d_j}{\rho_j}\right) \sum_{k\in\mathcal{N}} \|v_k\|^2_{\widetilde{H}^{-1/2}(\Gamma)},$$

which proves part 1. ∎

7.2. Improved bounds for $\Phi_{m,k}$. For the rest of the paper, we restrict our attention to piecewise-constant and continuous piecewise-bilinear basis functions on power-graded tensor-product meshes as defined in section 2.2.

We saw in (5.7) that $\Phi_{m,k} \lesssim 1$ if $-1 \le m \le 0$. The next lemma gives a sharp two-sided bound for the special case that occurs in our numerical experiments.

LEMMA 7.2. *For the piecewise-constant nodal basis on a rectangular mesh,*

$$1 \gtrsim \Phi_{-1/2,k} \gtrsim \frac{1}{1+\log(h_k/\rho_k)}.$$

Proof. We may assume without loss of generality that $\Gamma_k = [-h_k/2, h_k/2] \times [-\rho_k/2, \rho_k/2]$. For brevity we omit the subscript k for the remainder of the proof. Define the one-dimensional (1D) piecewise-constant basis function

$$\psi(x,h) = \begin{cases} 1 & \text{for } -h/2 < x < h/2, \\ 0 & \text{otherwise,} \end{cases}$$

and write the tensor-product basis function as $\phi(x) = \psi(x_1,h)\psi(x_2,\rho)$. Recalling (5.7), we see that the result will follow from the upper bound

$$\|\phi\|^2_{\widetilde{H}^{-1/2}(\Gamma)} \lesssim h\rho^2\left(1+\log\frac{h}{\rho}\right). \tag{7.5}$$

Denote the 2D Fourier transform of ϕ by

$$\hat\phi(\xi) = \int_{\mathbb{R}^2} e^{-i2\pi\xi\cdot x}\phi(x)\,dx = \hat\psi(\xi_1,h)\hat\psi(\xi_2,\rho),$$

where $\hat\psi$, the 1D Fourier transform of ψ, is given by

$$\hat\psi(\xi_1,h) = \int_{-h/2}^{h/2} e^{-i2\pi\xi_1 x_1}\,dx_1 = h\,\mathrm{sinc}(\xi_1 h), \qquad \mathrm{sinc}(z) = \begin{cases} \dfrac{\sin\pi z}{\pi z}, & z \ne 0, \\ 1, & z = 0. \end{cases}$$

Note that $|\hat\psi(\xi,h)| \le \min(h, |\xi|^{-1})$. We have the norm equivalence

$$\begin{aligned} \|\phi\|^2_{\widetilde{H}^{-1/2}(\Gamma)} = \|\phi\|^2_{\widetilde{H}^{-1/2}(\mathbb{R}^2)} &\simeq \int_{\mathbb{R}^2} (1+|\xi|^2)^{-1/2}|\hat\phi(\xi)|^2\,d\xi \\ &= \int_{-\infty}^{\infty} |\hat\psi(\xi_1,h)|^2 \int_{-\infty}^{\infty} (1+\xi_1^2+\xi_2^2)^{-1/2}|\hat\psi(\xi_2,\rho)|^2\,d\xi_2\,d\xi_1 \\ &=: I_1 + I_2 + I_3 + I_4 + I_5, \end{aligned}$$

with

$$I_1 = \int_{\substack{-\infty<\xi_1<\infty,\\ |\xi_2|>\rho^{-1}}}, \quad I_2 = \int_{\substack{|\xi_1|<h^{-1},\\ |\xi_2|<h^{-1}}}, \quad I_3 = \int_{\substack{|\xi_1|<h^{-1}\\ h^{-1}<|\xi_2|<\rho^{-1}}},$$

$$I_4 = \int_{\substack{|\xi_1|>h^{-1},\\ |\xi_2|<h^{-1}}}, \quad I_5 = \int_{\substack{|\xi_1|>h^{-1}\\ h^{-1}<|\xi_2|<\rho^{-1}}}.$$

By Plancherel's theorem,

$$\begin{aligned} I_1 &\le \int_{-\infty}^{\infty} |\hat\psi(\xi_1,h)|^2\,d\xi_1 \int_{|\xi_2|>\rho^{-1}} |\xi_2|^{-1}|\hat\psi(\xi_2,\rho)|^2\,d\xi_2 \\ &\le 2\int_{-\infty}^{\infty} |\psi(x_1,h)|^2\,dx_1 \int_{\rho^{-1}}^{\infty} \xi_2^{-3}\,d\xi_2 = h\rho^2. \end{aligned}$$

Using polar coordinates we find that

$$I_2 \le \int_{-h^{-1}}^{h^{-1}} h^2 \int_{-h^{-1}}^{h^{-1}} (1+\xi_1^2+\xi_2^2)^{-1/2}\rho^2 \, d\xi_2 \, d\xi_1 \le h^2\rho^2 \int_0^{h^{-1}\sqrt{2}} (1+r^2)^{-1/2} 2\pi r \, dr \le 2\pi\sqrt{2}\, h\rho^2,$$

and simple estimation gives

$$I_3 \le 4\int_0^{h^{-1}} h^2 \, d\xi_1 \int_{h^{-1}}^{\rho^{-1}} \xi_2^{-1}\rho^2 \, d\xi_2 = 4h\rho^2 \int_{h^{-1}}^{\rho^{-1}} \frac{d\xi_2}{\xi_2} = 4h\rho^2 \log\frac{h}{\rho},$$

$$I_4 \le 4\int_{h^{-1}}^{\infty} \xi_1^{-2} \int_0^{h^{-1}} \xi_1^{-1}\rho^2 \, d\xi_2 \, d\xi_1 = 4h^{-1}\rho^2 \int_{h^{-1}}^{\infty} \xi_1^{-3} \, d\xi_1 = 2h\rho^2,$$

$$I_5 \le 4\int_{h^{-1}}^{\infty} \xi_1^{-2} \, d\xi_1 \int_{h^{-1}}^{\rho^{-1}} \xi_2^{-1}\rho^2 \, d\xi_2 = 4h\rho^2 \log\frac{h}{\rho}. \qquad \square$$

LEMMA 7.3. *Let Γ be the square screen (2.5). For the continuous, piecewise-bilinear nodal basis on the power-graded mesh with vertices defined by (2.8), we have*

$$\Phi_{m,k} \simeq 1 \quad \textit{for } 0 \le m \le 1.$$

Proof. Without loss of generality, we may assume that x_k is the origin and that $\Gamma_k = [-h_-, h_+] \times [-\rho_-, \rho_+]$ with $h_\pm \simeq h_k$ and $\rho_\pm \simeq \rho_k$. We define the 1D continuous, piecewise-linear basis function on the interval $(-h_-, h_+)$,

$$\psi(x, h_+, h_-) = \begin{cases} 1 + \dfrac{x}{h_-} & \text{for } -h_- < x < 0, \\ 1 - \dfrac{x}{h_+} & \text{for } 0 < x < h_+, \\ 0 & \text{otherwise,} \end{cases}$$

and write the bilinear basis function on Γ_k by $\phi(x) = \psi(x_1, h_+, h_-)\psi(x_2, \rho_+, \rho_-)$. Recalling (5.8), we see that the result will follow from the lower bound

$$\|\phi\|^2_{\widetilde{H}^m(\Gamma)} \gtrsim h\rho^{1-2m}. \tag{7.6}$$

Since $\|\phi\|^2_{L_2(\Gamma)} \simeq h\rho$ and $|\phi|^2_{H^1(\Gamma)} \simeq h\rho(h^{-2} + \rho^{-2})$, the cases $m = 0$ and $m = 1$ are obvious. If $0 < m < 1$, then we use the norm equivalence

$$\|\phi\|^2_{\widetilde{H}^m(\Gamma)} = \|\phi\|^2_{\widetilde{H}^m(\mathbb{R}^2)} \simeq \int_{\mathbb{R}^2} (1 + |\xi|^2)^m |\hat{\phi}(\xi)|^2 \, d\xi,$$

where

$$\hat{\phi}(\xi) = \hat{\psi}(\xi_1, h_+, h_-)\hat{\psi}(\xi_2, \rho_+, \rho_-)$$

and

$$\hat{\psi}(\xi, h_+, h_-) = \frac{1}{(2\pi\xi)^2} \left\{ \frac{1 - e^{i2\pi\xi h_-}}{h_-} + \frac{1 - e^{-i2\pi\xi h_+}}{h_+} \right\}.$$

Since $(1 + |\xi|^2)^m \ge |\xi_2|^{2m}$ we see that

$$\|\phi\|^2_{\widetilde{H}^m(\mathbb{R}^2)} \gtrsim \int_{\mathbb{R}^2} |\xi_2|^{2m} |\hat{\phi}(\xi)|^2 \, d\xi = \int_{-\infty}^{\infty} \left|\hat{\psi}(\xi_1, h_+, h_-)\right|^2 d\xi_1 \int_{-\infty}^{\infty} |\xi_2|^{2m} \left|\hat{\psi}(\xi_2, \rho_+, \rho_-)\right|^2 d\xi_2, \tag{7.7}$$

and by Plancherel's theorem,

$$\int_{-\infty}^{\infty} \bigl|\hat{\psi}(\xi_1, h_+, h_-)\bigr|^2 \, d\xi_1 = \int_{-\infty}^{\infty} \bigl|\psi(x_1, h_+, h_-)\bigr|^2 \, dx_1 = \frac{h_+ + h_-}{3}. \tag{7.8}$$

Now define $h = (h_+ + h_-)/2$, $\Delta h = (h_+ - h_-)/2$, $\rho = (\rho_+ + \rho_-)/2$, and $\Delta\rho = (\rho_+ - \rho_-)/2$, so that $h_\pm = h \pm \Delta h$ and $\rho_\pm = \rho \pm \Delta\rho$. Using the substitution $\xi_2 = t/\rho$ in (7.7), we see that

$$\|\phi\|^2_{\widetilde{H}^m(\mathbb{R}^2)} \gtrsim h \int_{-\infty}^{\infty} |t/\rho|^{2m} \bigl|\hat{\psi}(t/\rho, \rho_+, \rho_-)\bigr|^2 \, \frac{dt}{\rho} = h\rho^{1-2m} \int_{-\infty}^{\infty} |t|^{2m} \bigl|\rho^{-1}\hat{\psi}(t/\rho, \rho_+, \rho_-)\bigr|^2 \, dt.$$

Putting $\epsilon = \Delta\rho/\rho = (\rho_+ - \rho_-)/(\rho_+ + \rho_-) \in (-1, 1)$, a simple calculation gives

$$\rho^{-1}\hat{\psi}(t/\rho, \rho_+, \rho_-) = (1-\epsilon) f_+[(1-\epsilon)t] + (1+\epsilon) f_-[(1+\epsilon)t], \text{ where } f_\pm(t) = \frac{1 - e^{\pm i 2\pi t}}{(2\pi t)^2}.$$

Since $f_\pm(t) = \mp i/(2\pi t) + O(1)$ as $t \to 0$ and $f_\pm(t) = O(t^{-2})$ as $t \to \infty$, the integral

$$I(\epsilon) = \int_{-\infty}^{\infty} |t|^{2m} \bigl|\rho^{-1}\hat{\psi}(t/\rho, \rho_+, \rho_-)\bigr|^2 \, dt$$

is analytic for $|\epsilon| < 1$, and (since $\rho_- = \rho_+ = \rho$ when $\epsilon = 0$) we have

$$I(0) = \int_{-\infty}^{\infty} |t|^{2m} \left(\frac{\sin \pi t}{\pi t}\right)^4 dt \simeq 1 \quad \text{for } 0 \le m \le 1.$$

The lower bound (7.6) follows for $0 < m < 1$ because $\max_{k\in\mathcal{N}} \epsilon_k \to 0$ as $N \to \infty$. ∎

7.3. Sharper versions of the theorems in section 5.

THEOREM 7.4. *Consider the weakly singular boundary integral equation* (2.1) *on the square screen* (2.5). *Then for piecewise-constant nodal basis functions with the mesh* (2.8),

$$\lambda_{\max}(\boldsymbol{B}') \lesssim N^{1/2} \times \begin{cases} 1 & \text{if } 1 \le \beta < 2, \\ (1 + \log N)^{1/2} & \text{if } \beta = 2, \\ (1 + \log N)^2 & \text{if } \beta > 2, \end{cases}$$

and

$$\lambda_{\min}(\boldsymbol{B}') \gtrsim \begin{cases} 1 & \text{if } \beta = 1, \\ (1 + \log N)^{-1} & \text{if } \beta > 1. \end{cases}$$

Proof. Note that $d_{\min}$ (defined in Lemma 7.1) satisfies $d_{\min} = n^{-\beta} \simeq N^{-\beta/2}$. Note also that

$$\max_{k\in\mathcal{N}} \frac{d_k}{\rho_k} = \max_{1\le j\le n/2} \frac{t_j}{\Delta t_j} \simeq \max_{1\le j\le n/2} \frac{(j/n)^\beta}{n^{-1}(j/n)^{\beta-1}} = \max_{1\le j\le n/2} j \simeq n \simeq N^{1/2}. \tag{7.9}$$

Hence, from part 1 of Lemma 7.1 we obtain

$$\lambda_{\max}(\boldsymbol{B}') \lesssim N^{1/2}(1 + \log N)^2 \quad \text{for all } \beta \ge 1.$$

We can combine this with Theorem 5.7 to obtain the required bounds on $\lambda_{\max}(\boldsymbol{B}')$. The proof is completed by using Lemmas 5.1 and 7.2 to obtain

$$\lambda_{\min}(\boldsymbol{B}') \gtrsim \min_{k\in\mathcal{N}} \Phi_{-1/2,k} \simeq \frac{1}{1+\log(n^{-1}/n^{-\beta})} \simeq \frac{1}{1+(\beta-1)\log n}$$
$$\simeq \begin{cases} 1 & \text{for } \beta = 1, \\ (1+\log N)^{-1} & \text{for } \beta > 1. \end{cases} \qquad \square$$

THEOREM 7.5. *Consider the hypersingular boundary integral equation* (2.3) *on the square screen* (2.5). *Then with conforming piecewise bilinear nodal basis functions on the mesh* (2.8),

$$\lambda_{\max}(\boldsymbol{B}') \lesssim 1 \quad \textit{and} \quad \lambda_{\min}(\boldsymbol{B}') \gtrsim N^{-1/2} \times \begin{cases} 1 & \textit{for } 1 \le \beta < 2, \\ (1+\log N)^{-1/2} & \textit{for } \beta = 2, \\ (1+\log N)^{-2} & \textit{for } \beta > 2. \end{cases}$$

Proof. Lemmas 5.1 and 7.3 imply that $\lambda_{\max}(\boldsymbol{B}') \lesssim \max_{k\in\mathcal{N}} \Phi_{1/2,j} \lesssim 1$. For $\beta > 2$ we sharpen the bound in Theorem 5.8 by using part 2 of Lemma 7.1. In fact, $d_{\min} \simeq n^{-\beta} \simeq N^{-\beta/2}$ and, by (7.9), $\min_{k\in\mathcal{N}} \rho_k/d_k \simeq N^{-1/2}$. Hence $\lambda_{\min}(\boldsymbol{B}') \gtrsim N^{-1/2}/(1+\log N)^2$, completing the proof. $\square$

8. Numerical experiments with a different family of meshes. To conclude, we present some numerical results for the weakly singular equation (2.1) over the nonconvex, polygonal screen

$$\Gamma = (-1,1)^2 \setminus ([0,1]\times[-1,0]). \tag{8.1}$$

The meshes are constructed by a pseudoadaptive procedure that starts with a uniform mesh and then selectively bisects elements so that the relation between h_K, ρ_K and the distance to the nearest edge or corner is equivalent to that for a power-graded mesh with a chosen grading exponent $\beta \ge 1$. For simplicity, we grade only into the edges and vertex of the re-entrant corner; i.e., we ignore the other four edges and five corners. Figure 3 shows a typical mesh. Strictly speaking, our theory does not

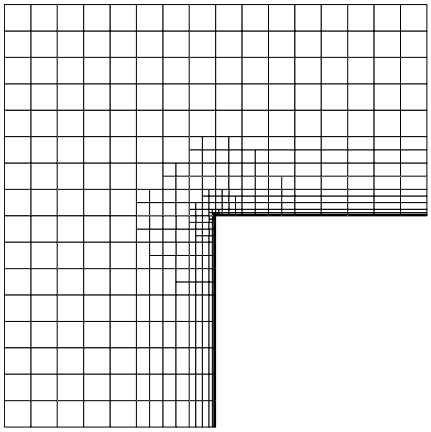

FIG. 3. *Anisotropic mesh on nonconvex screen, produced by a pseudoadaptive procedure,* $N = 488$, $\beta = 3$.

cover this example because we require conforming meshes, although in practical terms there is no need to enforce any interelement continuity condition at the hanging nodes because we use discontinuous (piecewise-constant) nodal basis functions. Tables 5 and 6 give our numerical results using meshes with $\beta = 2$ and $\beta = 3$. The asymptotic behavior of the extremal eigenvalues and the condition numbers is essentially the same as we observed previously, in Tables 1 and 2, for simple tensor-product, power-graded meshes on a square screen with the same choices of β.

Acknowledgment. We thank Dr. E. Georgoulis for very helpful comments.

TWO-LEVEL SCHWARZ ALGORITHMS WITH OVERLAPPING SUBREGIONS FOR MORTAR FINITE ELEMENTS*

HYEA HYUN KIM† AND OLOF B. WIDLUND†

Abstract. Preconditioned conjugate gradient methods based on two-level overlapping Schwarz methods often perform quite well. Such a preconditioner combines a coarse space solver with local components which are defined in terms of subregions that form an overlapping covering of the region on which the elliptic problem is defined. Precise bounds on the rate of convergence of such iterative methods have previously been obtained in the case of conforming lower order and spectral finite elements as well as in a number of other cases. In this paper, this domain decomposition algorithm and analysis are extended to mortar finite elements. It is established that the condition number of the relevant iteration operator is independent of the number of subregions and varies with the relative overlap between neighboring subregions linearly as in the conforming cases previously considered.

Key words. domain decomposition, elliptic finite element problems, preconditioned conjugate gradients, mortar finite elements, overlapping Schwarz algorithms

1. Introduction.

In this paper, the well-known two-level Schwarz method (see, e.g., [15, Chap. 3]) is extended to mortar finite element methods. Mortar finite element methods were first introduced in [7]. They are nonconforming finite element methods based on a partitioning, not necessarily geometrically conforming, of the region Ω into substructures Ω_i. Thus, in three dimensions, vertices and edges of one substructure can fall in the interior of edges and/or faces of its neighbors and in two dimensions vertices can divide edges of neighboring substructures. In each of the substructures, we choose a conforming standard finite element or a spectral element method without much regard for its neighbors. Even if the substructures are geometrically conforming, e.g., when the set of substructures forms a regular finite element triangulation, the local finite element meshes need not. We can also use spectral finite element spaces of different order in different substructures, and we can mix finite elements and spectral elements as well. In this paper, we will work out a theory only for the case of piecewise linear mortar finite elements; we treat both the more conventional mortar finite elements and those introduced by Wohlmuth [16, 17].

We note that Achdou and Maday have considered a related problem in [1]. However, in their paper, the principal issue is to establish the convergence and best possible error bounds for finite element methods based on overlapping subdomains. Typically, the meshes in the regions common to two or more overlapping subdomains do not match, and mortar conditions are used to introduce a weak continuity between the boundary values of one component of the finite element solution and the interior val-

ues of different components along the boundary of the first subdomain. In the final subsection of their paper a convergence result similar to ours, and that for standard conforming elements, is formulated and established. We note that in our paper, we instead consider overlapping Schwarz methods for the standard mortar methods. For references to earlier work by Cai, Dryja, and Sarkis, which is related to Achdou's and Maday's work, see the reference section of [1].

Finally, a word about the history of this project. The second author worked on algorithms of this kind almost ten years ago; the work was then not completed, but some results were presented in a talk at the 1996 ECCOMAS conference in Paris. The basic idea of using three independent decompositions of the region, including one for a conforming finite element space on a regular coarse grid, was inspired by a paper by Chan, Smith, and Zou [9]. Around the same time, Dan Stefanica conducted numerical experiments which demonstrated that there is very little difference in the performance of the two-level overlapping Schwarz method for a mortar case and a regular conforming finite element case if the subdomains and the overlap are chosen similarly. The work then lay dormant until it recently was reexamined by the present authors; many details have now been added and a more complete theory has now been developed.

2. The elliptic problem and mortar finite element methods. To simplify the notation, we consider only Poisson's equation. As usual, we formulate our elliptic problem as follows: find $u \in V$, such that

$$a(u,v) = \int_\Omega \nabla u \cdot \nabla v \, dx = f(v) \quad \forall v \in V. \tag{2.1}$$

The definition of $V \subset H^1(\Omega)$ incorporates the boundary conditions, and the region Ω is assumed to be bounded and polyhedral; a homogeneous Dirichlet condition is imposed on a nonempty subset $\partial\Omega_D$ of the boundary $\partial\Omega$ of Ω and a natural boundary condition is given on $\partial\Omega_N = \partial\Omega \backslash \partial\Omega_D$. (Inhomogeneous Neumann boundary data can be incorporated into the right-hand side of (2.1).) It is well known that the bilinear form $a(\cdot,\cdot)$ is self-adjoint, elliptic, and bounded in $V \times V$. Our analysis is equally valid for two and three dimensions. The bilinear form $a(u,v)$ is directly related to the Sobolev space $H^1(\Omega)$ that is defined by the seminorm and norm

$$|u|^2_{H^1(\Omega)} = a(u,u) \quad \text{and} \quad \|u\|^2_{H^1(\Omega)} = |u|^2_{H^1(\Omega)} + \|u\|^2_{L^2(\Omega)},$$

respectively.

The discretization of an elliptic, second order problem starts by partitioning the computational domain Ω into a union of nonoverlapping substructures, $\{\Omega_i\}_{i=1}^I$, and an interface Γ, defined by $(\cup_{i\neq j}\partial\Omega_i \cap \partial\Omega_j) \setminus \partial\Omega_D$, which is a set of points that belong to the boundaries of at least two substructures. The restriction to an individual substructure Ω_i, of the mortar finite element space considered in detail in this paper, will just be a standard piecewise linear finite element space defined on a quasi-uniform mesh. The meshes of two neighboring substructures do not necessarily match on their common interface, and the elements of the discrete space V^h are typically discontinuous across the interface Γ. Instead of pointwise continuity, the interface jumps are made orthogonal to a carefully chosen space of trial functions. In our work, we primarily consider the second generation mortar element methods for which continuity is not even imposed at the vertices or wire baskets (the union of the edges and vertices) of the substructures. Even if the meshes match across the interface between adjacent

substructures, the mortar finite element functions will not, generally, be pointwise continuous.

This weak continuity is introduced in terms of a set of *mortars* $\{\gamma_m\}_{m=1}^M$ obtained by selecting open edges/faces of the substructures such that

$$\overline{\Gamma} = \cup_{m=1}^M \overline{\gamma}_m, \quad \gamma_m \cap \gamma_n = \emptyset \ \text{ if } m \neq n.$$

Each edge/face and mortar γ_m is viewed as belonging to just one substructure. The remaining edges/faces are the *nonmortars* and are denoted by δ_n. The restrictions of the triangulations of the different substructures to the mortars and nonmortars typically will not match and are denoted by γ_m^h and δ_n^h, respectively; discontinuous mortar finite element functions have two different traces on the interface Γ given by one-sided limits of finite element functions defined on the individual substructures. The continuity across the interface of a conforming finite element method is replaced by weak continuity across the individual nonmortars: for each n, we define a space of test functions $M(\delta_n)$ given by the restriction, to the nonmortar δ_n, of the finite element space defined on the substructure of which δ_n is an edge/face. In two dimensions, the elements of $M(\delta_n)$ are subject to the constraints that they are constant in the first and last mesh intervals of δ_n^h. In three dimensions, the value of a test function of $M(\delta_n)$ at a node on $\partial\delta_n$ is given by a fixed convex combination of nodal values at its next neighbors in δ_n; cf. Belgacem and Maday [5]. We will call this the standard Lagrange multiplier space. In the spectral case, we would use as test functions polynomials of a degree two less.

Lagrange multiplier spaces with dual bases have been developed by Wohlmuth [16, 17]. Each basis function associated with these Lagrange multiplier spaces is supported on a few mesh intervals just as for the standard Lagrange multiplier spaces. They are discontinuous and lead to a diagonal matrix instead of the mass matrix appearing in the standard mortar matching condition. Our algorithm and our proofs can be applied both to the standard and dual Lagrange multiplier spaces, and $M(\delta_n)$ can therefore represent either the standard or the dual Lagrange multiplier space.

In this paper, we consider partitions $\{\Omega_i\}_{i=1}^I$, where the Ω_i are geometrically nonconforming. We assume that $\{\Omega_i\}_{i=1}^I$ form a regular partition of Ω, i.e., the size of Ω_i is comparable to that of its neighboring substructures. We will impose some assumptions on the meshes and the Lagrange multiplier space $M(\delta_n)$. A nonmortar $\delta_n \subset \partial\Omega_i$ can be partitioned into several edges/faces $\{\delta_{n,j}\}_j$ by mortar neighbors $\Omega_{m(n,j)}$ with boundaries which intersect $\partial\Omega_i$ along $\delta_{n,j}$, i.e., $\delta_{n,j} = \partial\Omega_{m(n,j)} \cap \partial\Omega_i$. We will use the following assumptions on the meshes and the Lagrange multiplier space in some of our work.

ASSUMPTION 1. *Each subpartition $\delta_{n,j}$ of a nonmortar is the union of entire elements.*

ASSUMPTION 2. *The Lagrange multiplier space $M(\delta_{n,j})$ are defined on each edge/face of the partition $\delta_{n,j}$ individually. Standard or dual Lagrange multiplier spaces are thus given on each $\delta_{n,j}$ which inherits the triangulation from δ_n^h. The Lagrange multiplier space $M(\delta_n)$ on δ_n is then defined by*

$$M(\delta_n) = \prod_{\delta_{n,j}} M(\delta_{n,j}).$$

With these assumptions, mortar methods provide a best approximation even for geometrically nonconforming partitions. Without them, an additional factor $|\log(h)|$ will appear in the error bound; see [2]. See also [3, 4, 5, 7], where error bounds of

the same type as for standard conforming methods are derived. We will first analyze two-level overlapping Schwarz algorithms for mortar methods under Assumptions 1 and 2 and later derive a slightly weaker result after removing these assumptions.

The *mortar projection* π_n maps all of $L_2(\delta_n)$ onto the finite element space defined on the nonmortar mesh δ_n^h. For two dimensions and for a given $w \in L_2(\delta_n)$ with given values at v_{n_1} and v_{n_2}, the endpoints of δ_n, we define $\pi_n(w, w^{(n)}(v_{n_1}), w^{(n)}(v_{n_2}))$ on δ_n^h by

$$\int_{\delta_n} (w - \pi_n(w, w^{(n)}(v_{n_1}), w^{(n)}(v_{n_2})))\psi ds = 0 \quad \forall \psi \in M(\delta_n). \tag{2.2}$$

We note that only the values at the interior nodes of δ_n are determined by this condition; the values $w^{(n)}(v_{n_1})$ and $w^{(n)}(v_{n_2})$ are genuine degrees of freedom. Similarly, for three dimensions, the values in the interior of δ_n are determined not only by the values on the part of Γ opposite the nonmortar, but also by the nodal values on $\partial\delta_n$.

As when working with other nonconforming methods, the original bilinear form $a(\cdot,\cdot)$ is replaced by $a^\Gamma(\cdot,\cdot)$ defined as the sum of the contributions from the individual substructures to $a(\cdot,\cdot)$:

$$a^\Gamma(u_h, v_h) = \sum_{i=1}^{I} a_{\Omega_i}(u_h, v_h). \tag{2.3}$$

For $u_h = v_h$, we obtain the square of what is often called a *broken norm*. The norm has been broken along Γ and it is finite for any element of the mortar space even if it is discontinuous across Γ. The resulting discrete variational problem gives rise to a linear system with a symmetric, positive definite matrix.

After these preparations, the mortar finite element space V^h, and the problem as a whole, can be fully defined. The discrete problem is then the following: find $u \in V^h$ such that

$$a^\Gamma(u, v) = f^\Gamma(v) \quad \forall v \in V^h, \tag{2.4}$$

where $a^\Gamma(u, v)$ is defined in (2.3) and, similarly, $f^\Gamma(v)$ is the sum of contributions from the different substructures.

3. The Dryja–Widlund algorithm. We now describe the additive Schwarz method introduced in Dryja and Widlund [10]; cf. also Smith, Bjørstad, and Gropp [14, Chap. 5] and, for many details, Toselli and Widlund [15, Chap. 3]. This additive Schwarz method for an overlapping subdomain partition performs quite well even for partitions with small overlap as first established in Dryja and Widlund [11]. The condition number bound given in [11] has also been proven to be optimal by Brenner [8]. We now use two additional decompositions of the region Ω, in addition to the set of substructures $\{\Omega_i\}$, used to define the mortar finite element problem, namely, a set of overlapping subregions $\{\widetilde{\Omega}_j\}$ and an independent coarse mesh $\{\tau_l^H\}$. Let X_i^h be the finite element space on the substructure Ω_i equipped with a quasi-uniform triangulation $\mathcal{T}^h(\Omega_i)$. Throughout this paper, we will impose the following assumptions on these partitions.

ASSUMPTION 3. *The diameter H_i of a substructure Ω_i is comparable to the diameter H of any triangle τ_l^H that intersects it.*

ASSUMPTION 4. *The diameter H_i of a substructure Ω_i satisfies*

$$H_i \leq C\widetilde{H}_j,$$

where $\widetilde{H}_j$ is the diameter of any subregion $\widetilde{\Omega}_j$ that intersects it.

ASSUMPTION 5. *The mesh sizes of the substructures that intersect along a common edge/face are comparable.*

The $\widetilde{\Omega}_j$ can be quite arbitrary; a local subspace V_j will be associated with each of them, essentially by making all genuine degrees of freedom associated with nodes outside $\widetilde{\Omega}_j$ equal to zero. More precisely, the space V_j is given by

$$V_j = \left\{ v \in \prod_{i=1}^{I} X_i^h \ : \ v(x) = 0 \text{ for } x \in \Omega \setminus \widetilde{\Omega}_j, \text{ or } x \in \delta_n \right\}, \quad j = 1, \ldots, N,$$

where δ_n denotes any nonmortar edges/faces. The space V_0 is V^H, the space of continuous, piecewise linear functions on an independent coarse mesh given by its elements τ_l^H. We further impose zero Dirichlet conditions, on the elements of V_j, on $\partial\widetilde{\Omega}_j \cap \partial\Omega_D$ and on the elements of V_0, on $\partial\Omega_D$.

We note that the overlap can be quite small. Thus, if no degrees of freedom are shared between neighboring subregions, the overlap is on the order of h, the diameter of the elements of the fine discretization. Our analysis applies in this case as well, in which case our Schwarz method corresponds to a block Jacobi preconditioner augmented by a coarse solver.

It is now appropriate essentially to follow the description and analysis of Schwarz methods given in Smith, Bjørstad, and Gropp [14] and Toselli and Widlund [15]. Our iterative method is given in terms of $N + l$ finite element spaces $V_j^h, j = 0, \ldots, N$, which are subspaces of V^h and are associated with the space V_j:

$$V_j^h = I^m(V_j).$$

The interpolation operator $I^m : \prod_{i=1}^{I} C(\Omega_i) \rightarrow V^h$ is defined by

$$I^m(u) = \sum_{i=1}^{I} \left(I_i^h(u) + \sum_{\delta_n \subset \partial\Omega_i} \widetilde{\pi}_n \left(I_{m(\delta_n)}^h(u) - I_i^h(u) \right) \right), \tag{3.1}$$

where $I_i^h(u)$ is the nodal value interpolant in the space X_i^h and $\widetilde{\pi}_n(w)$ is the zero extension of $\pi_n(w)$ to $\overline{\Omega}_i$. Here $\pi_n(w)$ denotes $\pi_n(w, 0, 0)$; see (2.2). (In the following, we will use the simple notation $\pi_n(w)$ instead of $\pi_n(w, 0, 0)$.) It has been shown that $\pi_n(w)$ is L^2-stable but not H^1-stable; see [17, Chap. 1]. We recall that δ_n denotes a nonmortar edge/face of $\partial\Omega_i$ and that $\{\delta_{n,j}\}_j$ is the partition of δ_n described in section 2, i.e., $\delta_{n,j} = \partial\Omega_{m(n,j)} \cap \partial\Omega_i$. The interpolant $I_{m(\delta_n)}^h(u)$ is defined by

$$I_{m(\delta_n)}^h(u) = I_{m(n,j)}^h(u) \ \text{ on } \delta_{n,j},$$

and it can thus be discontinuous across the boundaries of $\delta_{n,j}$. The mortar finite element space V^h can then be represented as the sum

$$V^h = V_0^h + V_1^h + \cdots + V_N^h \,. \tag{3.2}$$

Remark 1. The local spaces $\{V_j^h\}_{j=1}^N$, in which our Schwarz algorithm will be considered, consist of functions defined on the whole domain Ω, and not just on the subregion $\widetilde{\Omega}_j$, as in the standard Schwarz algorithms described in [15, Chap. 3]. Therefore the trivial extension operator from V_j^h to V^h will not appear in our algorithm.

We note that the support of each function in V_j^h is contained in the union of the substructures Ω_i that intersect the subregion $\widetilde{\Omega}_j$.

It is often more economical to use approximate rather than exact solvers for the subspace problems. The approximate solvers can be described in terms of inner products $\tilde{a}_j(\cdot,\cdot)$ defined on $V_j^h \times V_j^h$. One assumption that needs to be checked for each of them is the existence of a constant ω such that

$$a^{\Gamma}(u,u) \leq \omega \tilde{a}_j(u,u) \quad \forall u \in V_j^h \ . \tag{3.3}$$

In terms of matrices, this inequality becomes a one-sided bound of a submatrix of the stiffness matrix, given by $a^{\Gamma}(\cdot,\cdot)$ and V_j^h, in terms of the matrix given by $\tilde{a}_j(\cdot,\cdot)$.

A projection-like operator $T_j : V^h \to V_j^h$ is now defined for each j by

$$\tilde{a}_j(T_j u, \phi_h) = a^{\Gamma}(u, \phi_h) \quad \forall \phi_h \in V_j^h \ . \tag{3.4}$$

It is easy to show that the operator T_j is positive semidefinite and symmetric with respect to $a^{\Gamma}(\cdot,\cdot)$ and that the minimal constant ω in (3.3) is $\|T_j\|_a$, i.e.,

$$\|T_j\|_a \leq \omega; \tag{3.5}$$

see [15, Chap. 2]. Additive and multiplicative Schwarz methods can now be defined straightforwardly in terms of polynomials of the operators T_j. We note that if exact solvers, and thus genuine projections P_j, are used, then $\omega = 1$. The operator relevant to an additive Schwarz operator is $T = \sum_{j=0}^{N} T_j$. In the case of no coarse space and the local spaces forming a direct sum, this operator is a block-Jacobi operator, with one block for each subspace.

In order to estimate the rate of convergence of our special, or any other, additive Schwarz methods, we need upper and lower bounds for the spectrum of the operator relevant in the conjugate gradient iteration. A lower bound can be obtained by using the following lemma; see, e.g., Zhang [18], Smith, Bjørstad, and Gropp [14], or Toselli and Widlund [15, Chap. 2].

LEMMA 1. *Let T_j be the operators defined in* (3.4) *and let $T = T_0 + T_1 + \cdots + T_N$. Then*

$$a(T^{-1}u, u) = \min_{u = \sum u_j} \sum \tilde{a}_j(u_j, u_j), \ u_j \in V_j^h.$$

Therefore, if a representation, $u = \sum u_j$, can be found, such that

$$\sum \tilde{a}_j(u_j, u_j) \leq C_0^2 a(u,u) \quad \forall u \in V^h,$$

then

$$\lambda_{min}(T) \geq C_0^{-2}.$$

For the algorithms considered in this paper, and many other domain decomposition algorithms, it is easy to show that there is an upper bound for T which is proportional to ω.

In this paper, our results are formulated only for additive algorithms and with exact solvers for the subdomain problems. The corresponding bounds for the multiplicative variants, etc., can easily be worked out using the general Schwarz theory; see, e.g., Smith, Bjørstad, and Gropp [14] or Toselli and Widlund [15, Chap. 2].

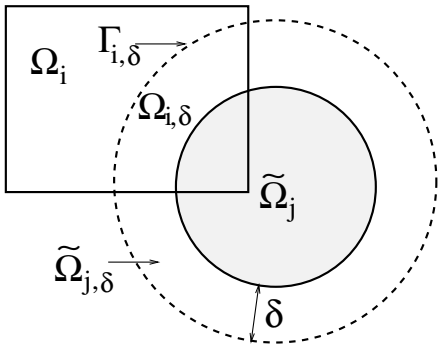

FIG. 1. *The substructure Ω_i intersects the subregion $\widetilde{\Omega}_j$ (interior of the dashed circle); $\widetilde{\Omega}_{j,\delta}$ (the part between the dashed and the solid circles) is the support of $\nabla\theta_j$, $\Omega_{i,\delta}$ is the part of $\widetilde{\Omega}_{j,\delta}$ which belongs to Ω_i, and $\Gamma_{i,\delta}$ is a part of the boundary of $\Omega_{i,\delta}$ that divides Ω_i into two parts.*

4. The lower bound. We will find a lower bound of the two-level Schwarz algorithm. A stable decomposition of $u = \sum_{j=0}^{N} u_j$ will be provided with

$$C_0^2 = C \max_{j=1,\ldots,N} \{(1 + H_j/\delta_j)\}.$$

Here H_j is the diameter of the subregion $\widetilde{\Omega}_j$ and δ_j is the overlapping width of $\widetilde{\Omega}_j$, i.e., the minimal width of the subset of $\widetilde{\Omega}_j$ which is common to some neighbors, and C is a constant independent of the mesh sizes, the subregion diameters, and the number of subregions; see Figure 1. We first assume that the five assumptions hold and later derive a bound for C_0^2 with an additional $\log(H/h)$ factor for the general case for which Assumptions 1 and 2 are removed.

4.1. Technical tools. In this section, we will collect a number of technical tools that are used in proving our main results. Some of the tools can be borrowed directly from Toselli and Widlund [15, Chap. 3], but some work also needs to be done that is directly related to the mortar finite element method.

As before, $\Omega \subset R^d, d = 2$ or 3, is a bounded, polygonal region, $\{\Omega_i\}_{i=1}^I$ is a nonoverlapping decomposition of Ω into substructures, and $\{\widetilde{\Omega}_j\}_{j=1}^N$ that of a set of overlapping subregions. Let $\{\widetilde{\theta}_j\}_{j=1}^N$ be a partition of unity for the overlapping partition $\{\widetilde{\Omega}_j\}_{j=1}^N$ of Ω, with the following properties (see, e.g., [15, sect. 3.2]):

$$\begin{aligned}
&0 \le \tilde{\theta}_j(x) \le 1, \quad x \in \widetilde{\Omega}_j,\\
&\operatorname{supp}(\widetilde{\theta}_j) \subset \widetilde{\Omega}_j,\\
&\sum_{j=1}^{N} \widetilde{\theta}_j = 1,\\
&|\nabla\widetilde{\theta}_j| \le \frac{C}{\delta_j}.
\end{aligned}$$

We will employ a modified partition of unity θ_j obtained by interpolating $\widetilde{\theta}_j$ on the triangulations $\{\mathcal{T}^h(\Omega_i)\}_{i=1}^I$. The θ_j will be discontinuous across substructure interfaces. However, we can easily check that the modified partition of unity $\{\theta_j\}_{j=1}^N$ has the same properties as $\{\widetilde{\theta}_j\}_{j=1}^N$ when restricted to any substructure Ω_i because these properties hold for each elements of $\{\mathcal{T}^h(\Omega_i)\}_{i=1}^I$.

We now consider the case in Figure 1. The substructure Ω_i intersects the subregion $\widetilde{\Omega}_j$. We denote the support of $\nabla\theta_j$ by $\widetilde{\Omega}_{j,\delta}$ and the intersection of Ω_i and $\widetilde{\Omega}_{j,\delta}$ by $\Omega_{i,\delta}$. As in Figure 1, we select $\Gamma_{i,\delta}$ as a part of the boundary of $\Omega_{i,\delta}$ that divides the domain Ω_i into two parts. We will prove the following lemma, which is similar to [15, Lem. 3.10].

LEMMA 2. *Let u be an arbitrary element of $H^1(\Omega_i)$. Then*

$$\|u\|^2_{L^2(\Omega_{i,\delta})} \le C\,\delta^2\big((1+H_i/\delta)|u|^2_{H^1(\Omega_i)} + 1/(H_i\delta)\|u\|^2_{L^2(\Omega_i)}\big),$$

where H_i denotes the diameter of Ω_i and δ is the overlapping width of $\widetilde{\Omega}_j$, a subregion that intersects Ω_i.

Proof. Let us cover $\Omega_{i,\delta}$ by shape-regular patches $\{P_l\}_l$ with $O(\delta)$ diameters. We may assume that the $P_{l,\Gamma}$ $(:= \partial P_l \cap \Gamma_{i,\delta})$ have positive measure. By using a Friedrichs inequality (see Toselli and Widlund [15, Lem. A.17]) for each patch P_l and summing over all patches, we obtain

$$\|u\|^2_{L^2(\Omega_{i,\delta})} \le C\left(\delta^2|u|^2_{H^1(\Omega_{i,\delta})} + \delta\|u\|^2_{L^2(\Gamma_{i,\delta})}\right). \tag{4.1}$$

From the embedding $H^{1/2}(\Gamma_{i,\delta}) \subset L^2(\Gamma_{i,\delta})$, a trace theorem, and a scaling argument, we obtain

$$\begin{aligned}
\|u\|^2_{L^2(\Gamma_{i,\delta})} &= H_i^{d-1}\|\widehat{u}\|^2_{L^2(\widehat{\Gamma}_{i,\delta})}\\
&\le CH_i^{d-1}\|\widehat{u}\|^2_{H^{1/2}(\widehat{\Gamma}_{i,\delta})}\\
&\le CH_i^{d-1}\|\widehat{u}\|^2_{H^1(\widehat{\Omega}_{i,1})}\\
&= CH_i^{d-1}\left(|\widehat{u}|^2_{H^1(\widehat{\Omega}_i)} + \|\widehat{u}\|^2_{L^2(\widehat{\Omega}_i)}\right)\\
&= CH_i^{d-1}\left(H_i^{2-d}|u|^2_{H^1(\Omega_i)} + H_i^{-d}\|u\|^2_{L^2(\Omega_i)}\right).
\end{aligned}$$

Here the hat designates a dilated domain with diameter 1 or a function defined on the scaled domain, and $\Omega_{i,1}$ is a part of Ω_i divided by $\Gamma_{i,\delta}$. By combining the above estimate with (4.1), the desired bound follows. ∎

We also have the following generalized Poincaré–Friedrichs inequality (see Nečas [13]).

LEMMA 3. *Let Φ be a seminorm on $H^1(\Omega)$ with the following properties:*

(1) $\Phi(\phi) \le C_1\|\phi\|_{1,\Omega} \quad \forall\phi \in H^1(\Omega)$.

(2) *For a constant function c, $\Phi(c) = 0$ iff $c = 0$.*

Then we have a generalized Poincaré–Friedrichs inequality for $H^1(\Omega)$,

$$\|\phi\|_{0,\Omega} \le CH^{d/2}\left(H^{(2-d)/2}|\phi|_{1,\Omega} + H^{k(\Phi)}\Phi(\phi)\right) \quad \forall\phi \in H^1(\Omega),$$

where d is the dimension of the domain Ω, H is the diameter of Ω, and the constant C is independent of H; $\Phi(\phi)$ is homogeneous of degree $k(\Phi)$, i.e., $k(\Phi)$ is the real number which makes $H^{k(\Phi)}\Phi(\phi)$ invariant to scaling.

A prime example is provided by

$$\Phi(\phi) = \left|\int_\gamma \phi\,ds\right| \quad \forall\phi \in H^1(\Omega).$$

Then the two assumptions of Lemma 3 hold for $\Phi(\phi)$ and the application of the Poincaré–Friedrichs inequality for ϕ with a zero average on γ, i.e., $\Phi(\phi) = 0$, gives

$$\|\phi\|_{0,\Omega} \leq CH|\phi|_{1,\Omega}. \tag{4.2}$$

We will now consider two cases. In the first, the meshes and Lagrange multipliers satisfy Assumptions 1 and 2 on the nonconformity of the subdomain partition $\{\Omega_i\}_{i=1}^I$. In the second, we will drop these assumptions. In the latter case, the Lagrange multiplier space $M(\delta_n)$ is then a standard or dual Lagrange multiplier space defined on the triangulation δ_n^h, without partitioning it into $\{\delta_{n,j}\}_j$. The following approximation properties hold for both the standard and the dual Lagrange multiplier spaces; see [7, 12, 17].

LEMMA 4. *Let $0 < \alpha \leq 1/2$. For $v \in H^\alpha(\delta_{n,j})$, there exists a $\psi \in M(\delta_{n,j})$ such that*

$$\|v - \psi\|_{0,\delta_{n,j}} \leq Ch^\alpha |v|_{H^\alpha(\delta_{n,j})},$$

where h denotes the diameter of the elements of the nonmortar δ_n.

LEMMA 5. *Let $0 < \alpha \leq 1/2$. For $v \in H^\alpha(\delta_n)$, there exists $\psi \in M(\delta_n)$ such that*

$$\|v - \psi\|_{(H^\alpha(\delta_n))'} \leq Ch^{2\alpha} |v|_{H^\alpha(\delta_n)},$$

where h denotes the diameter of the nonmortar elements and $(H^\alpha(\delta_n))'$ is the dual space of $H^\alpha(\delta_n)$.

LEMMA 6. *Let the meshes and Lagrange multiplier spaces satisfy Assumptions* 1 *and* 2. *Then, for $v = (v_1, \ldots, v_I) \in V^h$, we have*

$$\|v_i - v_j\|_{0,\delta_{n,j}} \leq Ch_i^{1/2} \left(|v_i|_{1,\Omega_i} + |v_j|_{1,\Omega_j} \right),$$

where Ω_i and Ω_j are the nonmortar and mortar substructures of the interface $\delta_{n,j} = \partial\Omega_i \cap \partial\Omega_j$.

Proof. We have

$$\begin{aligned} \|v_i - v_j\|_{0,\delta_{n,j}}^2 &= \int_{\delta_{n,j}} (v_i - v_j)(v_i - v_j - \psi)\, ds \\ &\leq \|v_i - v_j\|_{0,\delta_{n,j}} \|v_i - v_j - \psi\|_{0,\delta_{n,j}}. \end{aligned}$$

This inequality holds for an arbitrary $\psi \in M(\delta_{n,j})$. Applying Lemma 4 with $\alpha = 1/2$ and a trace theorem, we obtain

$$\min_{\psi \in M_{\delta_{n,j}}} \|v_i - v_j - \psi\|_{0,\delta_{n,j}} \leq Ch_i^{1/2} \left(|v_i|_{1,\Omega_i} + |v_j|_{1,\Omega_j} \right). \qquad \square$$

We now consider a general case without the extra Assumptions 1 and 2 on the meshes and Lagrange multiplier spaces. The set of nonmortars $\{\delta_n\}_n$ is selected from the edges/faces of the subdomain partition, and the Lagrange multiplier spaces $M(\delta_n)$ are defined on the finite elements associated with the nonmortar interfaces δ_n. We recall that any nonmortar edge/face $\delta_n \subset \partial\Omega_i$ is partitioned into

$$\overline{\delta}_n = \cup_j \overline{\delta}_{n,j}, \quad \delta_{n,j} = \delta_n \cap \partial\Omega_{n_j}.$$

The mortar matching condition is then

$$\int_{\delta_n} (v_{i(n)} - \phi)\psi\, ds = 0 \quad \forall \psi \in M(\delta_n), \tag{4.3}$$

where ϕ is given by $\phi = v_{n_j}$ on $\delta_{n,j}$. We see that $\phi \in H^{1/2-\epsilon}(\delta_n)$ for any $0 < \epsilon \le 1/2$. Moreover the following estimate holds for ϕ; see [6].

LEMMA 7. *Let each subdomain Ω_{n_j} be scaled by H_i, the diameter of the subdomain Ω_i. Then, for any $0 < \epsilon \le 1/2$, we have*

$$\sqrt{\epsilon}\|\phi\|_{H^{1/2-\epsilon}(\delta_n)} \le C \sum_j \|v_{n_j}\|_{1,\Omega_{n_j}},$$

where ϕ is given by $\phi = v_{n_j}$ on $\delta_n \cap \partial\Omega_{n_j}$.

In the general case, without Assumptions 1 and 2, the space V^h consists of functions $v = (v_1, \ldots, v_I)$ satisfying the mortar matching condition (4.3) on each nonmortar edge/face δ_n. Let us denote by $\{\psi_l\}_l$ a basis for the Lagrange multiplier space $M^h(\delta_n)$. We also select $\{\psi_{j_k}\}_k$ from $\{\psi_l\}_l$ such that supp $(\psi_{j_k}) \subset \delta_{n,j}$ $(= \delta_n \cap \partial\Omega_{n_j})$, and set $\psi_{n,j} = \sum_k \psi_{j_k}$; we assume that at least one such ψ_{j_k} exists for every $\delta_{n,j}$. We will then show that the L^2-norm of the jump across δ_n is bounded by the sum of H^1-seminorms of the functions on the subdomains Ω_k for which $\partial\Omega_k$ intersects δ_n with a positive measure.

LEMMA 8. *Let $\delta_n \subset \partial\Omega_i$ be a nonmortar edge/face. For the general case, without Assumptions 1 and 2, we have*

$$\|v_i - \phi\|_{0,\delta_n} \le C h_i^{1/2} \left(\log \frac{H_i}{h_i}\right)^{1/2} \left(|v_i|_{1,\Omega_i} + \sum_j |v_{n_j}|_{1,\Omega_{n_j}}\right)$$

for $v = (v_1, \ldots, v_I) \in V^h$, where ϕ is given by $\phi = v_{n_j}$ on $\delta_{n,j}$.

Proof. We first dilate Ω_i and Ω_{n_j} so that the diameter of Ω_i is 1. The triangles/tetrahedra of each subdomain are then also scaled by the diameter H_i. We obtain

$$\begin{aligned}
\|v_i - \phi\|^2_{0,\delta_n} &= \int_{\delta_n} (v_i - \phi)(v_i - \phi - \psi)\, ds \\
&\le \|v_i - \phi\|_{H^{1/2-\epsilon}(\delta_n)} \|v_i - \phi - \psi\|_{(H^{1/2-\epsilon}(\delta_n))'} \\
&\le C\|v_i - \phi\|_{H^{1/2-\epsilon}(\delta_n)} h_i^{2(1/2-\epsilon)} |v_i - \phi|_{H^{1/2-\epsilon}(\delta_n)} \\
&\le C h_i^{1-2\epsilon} \|v_i - \phi\|^2_{H^{1/2-\epsilon}(\delta_n)}. \qquad (4.4)
\end{aligned}$$

Here $\psi \in M(\delta_n)$ is the best approximation and h_i is the scaled mesh size. We have also used the mortar matching condition and Lemma 5 for the function $v_i - \phi \in H^{1/2-\epsilon}(\delta_n)$.

We now define

$$\tilde{v}_i = v_i - c_{ij}, \quad \tilde{\phi} = v_{n_j} - c_{ij} \quad \text{on } \delta_{n,j},$$

where

$$c_{ij} = \frac{\int_{\delta_{n,j}} v_i \psi_{n,j}\, ds}{\int_{\delta_{n,j}} \psi_{n,j}\, ds} = \frac{\int_{\delta_{n,j}} v_{n_j} \psi_{n,j}\, ds}{\int_{\delta_{n,j}} \psi_{n,j}\, ds}.$$

The equality above holds because of the mortar matching condition for $v = (v_1, \ldots, v_I) \in V^h$ and the fact that the function $\psi_{n,j} \in M^h(\delta_n)$ is supported in $\delta_{n,j}$. We also have

$$\tilde{v}_i - \tilde{\phi} = v_i - \phi \quad \text{in } L^2(\delta_n), \quad \tilde{v}_i - \tilde{\phi} \in H^{1/2-\epsilon}(\delta_n).$$

From these properties and by applying (4.4) to $\widetilde{v}_i - \widetilde{\phi}_i$, we obtain

$$\|v_i - \phi\|^2_{0,\delta_n} \leq C h_i^{1-2\epsilon} \|\tilde{v}_i - \tilde{\phi}\|^2_{H^{1/2-\epsilon}(\delta_n)}.$$

Applying Lemma 7 to $\tilde{v}_i$ and $\tilde{\phi}$ gives

$$\|v_i - \phi\|_{0,\delta_n} \leq C h_i^{1/2-\epsilon} \epsilon^{-1/2} \sum_j \left(\|v_i - c_{ij}\|_{1,\Omega_i} + \|v_{n_j} - c_{ij}\|_{1,\Omega_{n_j}} \right).$$

Let

$$\Phi_{ij}(w) = \left| \int_{\delta_{n,j}} w \, \psi_{n,j} \, ds \right|.$$

Since $\psi_{n,j}$ is bounded from above by a constant, independent of the mesh parameters, and $\int_{\delta_{n,j}} \psi_{n,j} \, ds > 0$, $\Phi_{ij}(w)$ satisfies the two properties of Lemma 3; positivity of the integral also holds for the dual Lagrange multiplier case. By applying Lemma 3 to $v_i - c_{ij}$ and $v_{n_j} - c_{ij}$, with the seminorm Φ_{ij}, we obtain

$$\|v_i - c_{ij}\|_{1,\Omega_i} \leq C |v_i|_{1,\Omega_i}, \quad \|v_{n_j} - c_{ij}\|_{1,\Omega_{n_j}} \leq C |v_{n_j}|_{1,\Omega_{n_j}}.$$

Therefore,

$$\|v_i - \phi\|_{0,\delta_n} \leq C h_i^{1/2-\epsilon} \epsilon^{-1/2} \left(|v_i|_{1,\Omega_i} + \sum_j |v_{n_j}|_{1,\Omega_{n_j}} \right).$$

Letting $\epsilon = 1/|\log h_i|$ gives $\log(h_i^{-\epsilon}) = 1$ and results in the bound

$$\|v_i - \phi\|_{0,\delta_n} \leq C h_i^{1/2} |\log h_i|^{1/2} \left(|v_i|_{1,\Omega_i} + \sum_j |v_{n_j}|_{1,\Omega_{n_j}} \right). \tag{4.5}$$

By considering the scaling, we find

$$\|v\|_{0,\delta_n} = H_i^{(d-1)/2} \|\hat{v}\|_{0,\hat{\delta}_n}, \quad |v|_{1,\Omega_i} = H_i^{(d-2)/2} |\hat{v}|_{1,\hat{\Omega}_i}. \tag{4.6}$$

Here $\hat{\delta}_n$ and $\hat{\Omega}_i$ denote the scaled domains and $\hat{v}$ denotes the function defined on the scaled set $\hat{\delta}_n$ or $\hat{\Omega}_i$. We then obtain

$$\begin{aligned}
\|v_i - \phi\|_{0,\delta_n} &= H_i^{(d-1)/2} \|\hat{v}_i - \hat{\phi}\|_{0,\hat{\delta}_n} \\
&\leq C H_i^{(d-1)/2} \hat{h}_i^{1/2} |\log \hat{h}_i|^{1/2} \left(|\hat{v}_i|_{1,\hat{\Omega}_i} + \sum_j |\hat{v}_{n_j}|_{1,\hat{\Omega}_{n_j}} \right) \\
&\leq C H_i^{(d-1)/2} H_i^{-(d-2)/2} \hat{h}_i^{1/2} |\log \hat{h}_i|^{1/2} \left(|v_i|_{1,\Omega_i} + \sum_j |v_{n_j}|_{1,\Omega_{n_j}} \right) \\
&\leq C H_i^{1/2} \left(\frac{h_i}{H_i} \right)^{1/2} \left(\log \frac{H_i}{h_i} \right)^{1/2} \left(|v_i|_{1,\Omega_i} + \sum_j |v_{n_j}|_{1,\Omega_{n_j}} \right).
\end{aligned}$$

Here we have used (4.5), (4.6) and that $\hat{h}_i = h_i/H_i$. ∎

4.2. The stability of a certain interpolation operator. Let $I^H : V^h \to V^H$ be a stable quasi interpolant in both the H^1- and L^2-norms in the following sense:

$$\sum_{i=1}^{I} |I^H u|^2_{1,\Omega_i} \le C \sum_{i=1}^{I} |u|^2_{1,\Omega_i},$$
$$\sum_{i=1}^{I} \frac{1}{H_i^2} \|u - I^H u\|^2_{0,\Omega_i} \le C \sum_{i=1}^{I} |u|^2_{1,\Omega_i},$$

where H_i denotes the diameter of Ω_i. We then obtain the same bound for $u_0 = I^m(I^H u)$.

LEMMA 9. *Let $u_0 = I^m(I^H u)$ for $u \in V^h$. Then u_0 satisfies*

$$\sum_{i=1}^{I} |u_0|^2_{1,\Omega_i} \le C \sum_{i=1}^{I} |u|_{1,\Omega_i},$$
$$\sum_{i=1}^{I} \frac{1}{H_i^2} \|u - u_0\|^2_{0,\Omega_i} \le C \sum_{i=1}^{I} |u|^2_{1,\Omega_i}.$$

Proof. We find, using (3.1), that

$$|u_0|^2_{1,\Omega_i} \le C \left\{ |I_i^h(I^H u)|^2_{1,\Omega_i} + \sum_{\delta_n \subset \partial\Omega_i} \left| \widetilde{\pi}_n \left(I^h_{m(\delta_n)}(I^H u) - I_i^h(I^H u) \right) \right|^2_{1,\Omega_i} \right\}.$$

From the H^1-stability of the nodal value interpolant I_i^h for functions in V^H (see [15, Lem. 3.8]), the first term above is bounded by

$$|I_i^h(I^H u)|^2_{1,\Omega_i} \le C |I^H u|^2_{1,\Omega_i}. \tag{4.7}$$

We estimate the second term by

$$\begin{aligned} &\left| \widetilde{\pi}_n \left(I^h_{m(\delta_n)}(I^H u) - I_i^h(I^H u) \right) \right|^2_{1,\Omega_i} \\ &\quad \le C h_i^{-1} \left\| \pi_n \left(I^h_{m(\delta_n)}(I^H u) - I_i^h(I^H u) \right) \right\|^2_{0,\delta_n} \qquad (4.8) \\ &\quad \le C h_i^{-1} \left\{ \|I^h_{m(\delta_n)}(I^H u) - I^H u\|^2_{0,\delta_n} + \|I_i^h(I^H u) - I^H u\|^2_{0,\delta_n} \right\} \\ &\quad \le C h_i^{-1} \left\{ \sum_{\delta_{n,j} \subset \delta_n} h_{m(n,j)} |I^H u|^2_{1,\Omega_{m(n,j)}} + h_i |I^H u|^2_{1,\Omega_i} \right\}, \qquad (4.9) \end{aligned}$$

where $\delta_{n,j} = \partial\Omega_{m(n,j)} \cap \partial\Omega_i$. We have used an inverse inequality, the stability of π_n in $L^2(\delta_n)$, and the approximation property of the nodal value interpolation operator for $I^H u \in V^H$ provided by [15, Lem. 3.8]. Adding (4.7) and (4.9) over all nonmortar sides and subdomains and using Assumption 5 and the H^1-stability of the coarse interpolation operator I^H, we obtain

$$\sum_{i=1}^{I} |u_0|^2_{1,\Omega_i} \le C \sum_{i=1}^{I} |u|^2_{1,\Omega_i}.$$

We now estimate

$$\begin{aligned}&\|u-u_0\|^2_{0,\Omega_i}\\ &\le C\left\{\left\|u-I^h_i(I^Hu)\right\|^2_{0,\Omega_i}+\sum_{\delta_n\subset\partial\Omega_i}\left\|\widetilde{\pi}_n\left(I^h_{m(\delta_n)}(I^Hu)-I^h_i(I^Hu)\right)\right\|^2_{0,\Omega_i}\right\}.\end{aligned}\tag{4.10}$$

The first term is bounded by

$$\begin{aligned}\|u-I^h_i(I^Hu)\|^2_{0,\Omega_i}&\le 2\|u-I^Hu\|^2_{0,\Omega_i}+2\|I^h_i(I^Hu)-I^Hu\|^2_{0,\Omega_i}\\ &\le C\left\{\|u-I^Hu\|^2_{0,\Omega_i}+h_i^2|I^Hu|^2_{1,\Omega_i}\right\}.\end{aligned}$$

By using (4.8) and (4.9), we bound the second term of (4.10) as follows:

$$\begin{aligned}&\left\|\widetilde{\pi}_n\left(I^h_{m(\delta_n)}(I^Hu)-I^h_i(I^Hu)\right)\right\|^2_{0,\Omega_i}\\ &\le Ch_i\left\|\pi_n\left(I^h_{m(\delta_n)}(I^Hu)-I^h_i(I^Hu)\right)\right\|^2_{0,\delta_n}\\ &\le C\left(h_i^2|I^Hu|^2_{1,\Omega_i}+\sum_{\delta_{n,j}\subset\delta_n}h_ih_{m(n,j)}|I^Hu|^2_{1,\Omega_{m(n,j)}}\right)\\ &\le C\left(H_i^2|I^Hu|^2_{1,\Omega_i}+\sum_{\delta_{n,j}\subset\delta_n}H^2_{m(n,j)}|I^Hu|^2_{1,\Omega_{m(n,j)}}\right).\end{aligned}$$

In (4.10), summing the second term over the nonmortar sides gives

$$\|u-u_0\|^2_{0,\Omega_i}\le C\left(\|u-I^Hu\|^2_{0,\Omega_i}+\sum_{\delta_n\subset\partial\Omega_i}\sum_{|\partial\Omega_l\cap\delta_n|>0}H_l^2|I^Hu|^2_{1,\Omega_l}\right).$$

From the assumption that the diameter of Ω_i is comparable to those of its neighbors Ω_l, a coloring argument, and the L^2- and H^1-stability of the interpolation I^Hu, we obtain the second bound of the lemma. ∎

We now introduce our coarse interpolation operator $I^H:V^h\to V^H$. Let K be a triangle/tetrahedron in the coarse triangulation of Ω. Each vertex y_l of the triangle belongs to at least one substructure Ω_k (or to $\partial\Omega_k$) of the nonoverlapping partition. We denote the subdomain containing the vertex y_l by Ω_l. The set w_K is the union of the elements in T^H, the boundary of which intersects the boundary of the given element K. We consider a case as in Figure 2. The interpolation is defined by the values

$$(I^Hu)(y_l)=\frac{1}{|w_{y_l}|}\int_{w_{y_l}}u\,dx,$$

where $w_{y_l}=w_K\cap\Omega_l$ and $|w_{y_l}|$ denotes the volume of w_{y_l}. In the following, we show that this coarse interpolation operator is stable in both the H^1- and L^2-norms.

LEMMA 10. *The coarse interpolant $I^H:V^h\to V^H$ satisfies*

$$\sum_{i=1}^I\frac{1}{H_i^2}\|u-I^Hu\|^2_{0,\Omega_i}\le C\sum_{i=1}^I|u|^2_{1,\Omega_i},$$

$$\sum_{i=1}^I|I^Hu|^2_{1,\Omega_i}\le C\sum_{i=1}^I|u|^2_{1,\Omega_i}.$$

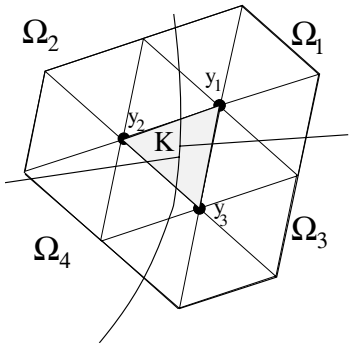

FIG. 2. *The region w_K divided by a geometrically nonconforming subdomain partition.*

Proof. We first estimate

$$\|I^H u\|_{0,K}^2 \le C \sum_{l=1}^{3} |(I^H u)(y_l)|^2 \|\phi_l\|_{0,K}^2 \le C \sum_{l=1}^{3} \|u(x)\|_{0,w_{y_l}}^2 \frac{|K|}{|w_{y_l}|}, \tag{4.11}$$

where ϕ_l is the nodal basis function of the vertex y_l of the coarse triangle K. In general, we can have more than one subdomain Ω_k which intersects K and does not contain any vertices of K. For simplicity, we assume that we have only one such subdomain and denote it by Ω_4 (see Figure 2).

Let us denote by c_l the average of u over the subdomain Ω_l, and by K_l the common part of K and Ω_l, and let

$$c_l = \frac{1}{|\Omega_l|} \int_{\Omega_l} u \, dx, \quad K_l = K \cap \Omega_l \quad \forall\, l = 1, \ldots, 4. \tag{4.12}$$

We then obtain

$$\begin{aligned} \|u - I^H u\|_{0,K}^2 &= \|u - c_1 - I^H(u - c_1)\|_{0,K}^2 \\ &\le 2\|u - c_1\|_{0,K}^2 + 2\|I^H(u - c_1)\|_{0,K}^2 \\ &\le C \left\{ \|u - c_1\|_{0,K}^2 + \sum_{l=1}^{3} \|u - c_1\|_{0,w_{y_l}}^2 \frac{|K|}{|w_{y_l}|} \right\} \qquad (4.13) \\ &\le C \left\{ \sum_{l=1}^{3} \|u - c_1\|_{0,w_{y_l}}^2 + \|u - c_1\|_{0,K_4}^2 \right\}. \qquad (4.14) \end{aligned}$$

Here we have used the identity $I^H(c_1) = c_1$, the estimate (4.11), and the fact that the factor $|K|/|w_{y_l}|$ is bounded from above independently of any mesh parameters.

From the Poincaré inequality and Assumption 3, we have

$$\|u - c_l\|_{0,w_{y_l}}^2 \le C H_K^2 \, |u|_{1,\Omega_l}^2, \quad l = 1, 2, 3.$$

We now consider

$$\|u - c_1\|_{0,w_{y_2}}^2 \le 2\|u - c_2\|_{0,w_{y_2}}^2 + 2\|c_2 - c_1\|_{0,w_{y_2}}^2.$$

Let

$$c_{12} = \frac{1}{|\Gamma_{12}|} \int_{\Gamma_{12}} u|_{\Omega_1} \, ds = \frac{1}{|\Gamma_{12}|} \int_{\Gamma_{12}} u|_{\Omega_2} \, ds,$$

where Γ_{12} is the common edge/face of Ω_1 and Ω_2. The identity follows from the mortar matching condition for the function u. We then have

$$\|c_2 - c_1\|^2_{0,w_{y_2}} \leq C \left\{ |c_2 - c_{12}|^2 + |c_1 - c_{12}|^2 \right\} |w_{y_2}|.$$

The first term in the above equation is written as

$$\begin{aligned} c_2 - c_{12} &= \frac{1}{|\Omega_2|} \int_{\Omega_2} u_2 \, dx - \frac{1}{|\Gamma_{12}|} \int_{\Gamma_{12}} u_2 \, ds \\ &= \frac{1}{|\Omega_2|} \int_{\Omega_2} \left(u_2 - \frac{1}{|\Gamma_{12}|} \int_{\Gamma_{12}} u_2 \, ds \right) dx, \end{aligned}$$

where $u_2 = u|_{\Omega_2}$. Let

$$\widetilde{u}_2 = u_2 - \frac{1}{|\Gamma_{12}|} \int_{\Gamma_{12}} u_2.$$

Applying the Poincaré inequality to $\widetilde{u}_2$ and using the Hölder inequality, we obtain

$$|c_2 - c_{12}|^2 \leq C H_2^{2-d} |u|^2_{1,\Omega_2}.$$

Similarly, we obtain

$$|c_1 - c_{12}|^2 \leq C H_1^{2-d} |u|^2_{1,\Omega_1}.$$

We then have

$$\|c_2 - c_1\|^2_{0,w_{y_2}} \leq C H_K^2 (|u|^2_{1,\Omega_1} + |u|^2_{1,\Omega_2}).$$

Here we have used that $|w_{y_2}| \leq H_K^d$ for $d = 2, 3$ and Assumption 3. The estimate of the remaining terms in (4.14) can be done similarly and gives

$$\|u - I^H u\|^2_{0,K} \leq C H_K^2 \sum_{l=1}^{4} |u|^2_{1,\Omega_l}. \tag{4.15}$$

By summing the above inequality over all K which intersect Ω_i, we obtain

$$\begin{aligned} \frac{1}{H_i^2} \|u - I^H u\|^2_{0,\Omega_i} &\leq \frac{1}{H_i^2} \sum_{K \cap \Omega_i \neq \emptyset} \|u - I^H u\|^2_{0,K} \\ &\leq C \frac{1}{H_i^2} \sum_{K \cap \Omega_i \neq \emptyset} H_K^2 \left(\sum_{\Omega_l \cap K \neq \emptyset} |u|^2_{1,\Omega_l} \right). \end{aligned}$$

The fact that the H_i is comparable to H_K and a coloring argument give the first estimate of the lemma. We note that we also have the following estimate from (4.13) and (4.15):

$$\|u - c_1\|^2_{0,K} \leq C H_K^2 \sum_{l=1}^{4} |u|_{1,\Omega_l}. \tag{4.16}$$

We now estimate

$$\begin{aligned}|I^H u|^2_{1,K} &= |I^H u - c_1|^2_{1,K} \\ &\le C H_K^{-2} \|I^H u - c_1\|^2_{0,K} \\ &\le C H_K^{-2} \left(\|I^H u - u\|^2_{0,K} + \|u - c_1\|^2_{0,K} \right),\end{aligned}$$

where c_1 is the constant defined in (4.12). We have used an inverse inequality. By using (4.15) and (4.16), we obtain

$$|I^H u|^2_{1,K} \le C \sum_{l=1}^{4} |u|^2_{1,\Omega_l}.$$

The second estimate of the lemma follows by summing the above term over all triangles K and a coloring argument. ∎

Remark 2. For the general case, without Assumptions 1 and 2, we choose

$$c_{12} = \frac{\int_{\Gamma_{12}} u|_{\Omega_1} \psi_{12}\, ds}{\int_{\Gamma_{12}} \psi_{12}\, ds} = \frac{\int_{\Gamma_{12}} u|_{\Omega_2} \psi_{12}\, ds}{\int_{\Gamma_{12}} \psi_{12}\, ds},$$

where ψ_{12} is the sum of the basis functions for $M^h(\delta_n)$ that are supported in Γ_{12}. The identity holds for $u \in V^h$. The arguments in the proof of Lemma 10 can also be applied to this general case and give the same bounds.

LEMMA 11. *Under Assumptions* 1 *and* 2, *and for* $u \in V^h$, *there exists a stable decomposition*

$$u = u_0 + u_1 + \cdots + u_N$$

such that

$$\sum_{i=0}^{N} a^{\Gamma}(u_i, u_i) \le C \max_{i=1,\ldots,N} \left\{ \left(1 + \frac{H_i}{\delta_i} \right) \right\} a^{\Gamma}(u, u),$$

where H_i *and* δ_i *denote the diameter of the subregion* $\widetilde{\Omega}_i$ *and the overlapping width of* $\widetilde{\Omega}_i$.

Proof. We take $u_0 = I^m(I^H(u))$ using the interpolants I^m and I^H provided in Lemmas 9 and 10. We then define

$$u_i = I^m(\widetilde{u}_i), \quad \widetilde{u}_i = \theta_i(u - u_0) \quad \text{for } i = 1, \ldots, N.$$

From $u - u_0 \in V^h$ and $\sum_{i=1}^{N} \theta_i = 1$, we see that

$$u - u_0 = I^m(u - u_0) = \sum_{i=1}^{N} u_i.$$

The function u_i is supported as in Figure 3 and can be written as

$$u_i = I^m(\widetilde{u}_i) = \sum_{l=1}^{6} \left(I^h_{k_l}(\widetilde{u}_i) + \sum_{\delta_n \subset \partial\Omega_{k_l}} \widetilde{\pi}_{\delta_n} \left(I^h_{m(\delta_n)}(\widetilde{u}_i) - I^h_{k_l}(\widetilde{u}_i) \right) \right).$$

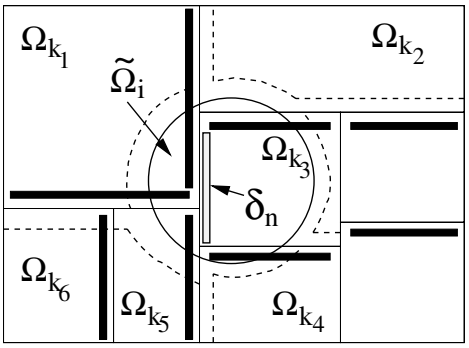

FIG. 3. *Nonconforming subdomain partition: mortar sides of interfaces (black bars), support of the functions $u_i \in V_i^h\,(= I^m(V_i))$ corresponding to the overlapping subdomain $\widetilde{\Omega}_i$ (interior of the dotted line); the subdomain Ω_{k_3} meets Ω_{k_1} and Ω_{k_5} along the nonmortar interface δ_n.*

Here $I^h_{m(\delta_n)}(\widetilde{u}_i)$, on δ_n in Figure 3, is given by

$$I^h_{m(\delta_n)}(\widetilde{u}_i) = \begin{cases} I^h_{k_1}(\widetilde{u}_i) \text{ on } \delta_{n,1} = \partial\Omega_{k_1} \cap \delta_n, \\ I^h_{k_5}(\widetilde{u}_i) \text{ on } \delta_{n,5} = \partial\Omega_{k_5} \cap \delta_n. \end{cases}$$

We will now prove that

$$\sum_{i=1}^{N} a^{\Gamma}(u_i, u_i) \le C \max_{i=1,\ldots,N} \left\{ \left(1 + \frac{H_i}{\delta_i}\right) \right\} a^{\Gamma}(u, u).$$

The required bound then follows by combining with Lemma 9. We consider

$$\begin{aligned} a^{\Gamma}(u_i, u_i) &= \sum_{l=1}^{6} |u_i|^2_{1,\Omega_{k_l}} \\ &= \sum_{l=1}^{6} \left| I^h_{k_l}(\widetilde{u}_i) + \sum_{\delta_n \subset \partial\Omega_{k_l}} \widetilde{\pi}_{\delta_n} \left(I^h_{m(\delta_n)}(\widetilde{u}_i) - I^h_{k_l}(\widetilde{u}_i) \right) \right|^2_{1,\Omega_{k_l}}. \end{aligned} \tag{4.17}$$

We note that $\widetilde{u}_i|_{\Omega_{k_l}}$ is a continuous and piecewise quadratic function defined on $T^h(\Omega_{k_l})$. From [15, Lem. 3.9], we have

$$|I^h_{k_l}(\widetilde{u}_i)|^2_{1,\Omega_{k_l}} \le C|\widetilde{u}_i|^2_{1,\Omega_{k_l}}. \tag{4.18}$$

For the second term of (4.17), we obtain

$$\begin{aligned} \left| \widetilde{\pi}_{\delta_n} \left(I^h_{m(\delta_n)}(\widetilde{u}_i) - I^h_{k_l}(\widetilde{u}_i) \right) \right|^2_{1,\Omega_{k_l}} &\le C h_{k_l}^{-2} h_{k_l} \left\| \pi_{\delta_n} \left(I^h_{m(\delta_n)}(\widetilde{u}_i) - I^h_{k_l}(\widetilde{u}_i) \right) \right\|^2_{0,\delta_n} \\ &\le C h_{k_l}^{-1} \left\| I^h_{m(\delta_n)}(\widetilde{u}_i) - I^h_{k_l}(\widetilde{u}_i) \right\|^2_{0,\delta_n}. \end{aligned} \tag{4.19}$$

Here we have used an inverse inequality, the quasi uniformity of the triangulation in the subdomain Ω_{k_l}, and the L^2-continuity of the mortar projection π_{δ_n}. We now

consider the term $\|I^h_{m(\delta_n)}(\widetilde{u}_i) - I^h_{k_l}(\widetilde{u}_i)\|^2_{0,\delta_n}$ for δ_n and $l = 3$ in Figure 3:

$$\begin{aligned}
&\left\|I^h_{m(\delta_n)}(\widetilde{u}_i) - I^h_{k_3}(\widetilde{u}_i)\right\|^2_{0,\delta_n} \\
&= \left\|I^h_{k_1}(\widetilde{u}_i) - I^h_{k_3}(\widetilde{u}_i)\right\|^2_{0,\delta_{n,1}} + \left\|I^h_{k_5}(\widetilde{u}_i) - I^h_{k_3}(\widetilde{u}_i)\right\|^2_{0,\delta_{n,5}} \\
&\le C\left(\left\|I^h_{k_1}(\widetilde{u}_i) - \widetilde{u}_i|_{\Omega_{k_1}}\right\|^2_{0,\delta_{n,1}} + \left\|I^h_{k_3}(\widetilde{u}_i) - \widetilde{u}_i|_{\Omega_{k_3}}\right\|^2_{0,\delta_{n,1}} + \left\|\widetilde{u}_i|_{\Omega_{k_1}} - \widetilde{u}_i|_{\Omega_{k_3}}\right\|^2_{0,\delta_{n,1}}\right. \\
&\quad \left. + \left\|I^h_{k_5}(\widetilde{u}_i) - \widetilde{u}_i|_{\Omega_{k_5}}\right\|^2_{0,\delta_{n,5}} + \left\|I^h_{k_3}(\widetilde{u}_i) - \widetilde{u}_i|_{\Omega_{k_3}}\right\|^2_{0,\delta_{n,5}} + \left\|\widetilde{u}_i|_{\Omega_{k_5}} - \widetilde{u}_i|_{\Omega_{k_3}}\right\|^2_{0,\delta_{n,5}}\right),
\end{aligned}$$

where $\delta_{n,j} = \partial\Omega_{k_j} \cap \partial\Omega_{k_3}$ for $j = 1, 5$.

Let $w = u - u_0$. We now consider

$$\begin{aligned}
&\|\widetilde{u}_i|_{\Omega_{k_1}} - \widetilde{u}_i|_{\Omega_{k_3}}\|^2_{0,\delta_{n,1}} \\
&= \|I^h_{k_1}(\widetilde{\theta}_i)w|_{\Omega_{k_1}} - I^h_{k_3}(\widetilde{\theta}_i)w|_{\Omega_{k_3}}\|^2_{0,\delta_{n,1}} \\
&\le C\left(\sum_{l=1,3} \|(I^h_{k_l}(\widetilde{\theta}_i) - \widetilde{\theta}_i)w|_{\Omega_{k_l}}\|^2_{0,\delta_{n,1}} + \|\widetilde{\theta}_i(w|_{\Omega_{k_1}} - w|_{\Omega_{k_3}})\|^2_{0,\delta_{n,1}}\right). \qquad (4.20)
\end{aligned}$$

Using the approximation property of the nodal value interpolant, $\|\nabla\widetilde{\theta}_i\|_\infty \le C/\delta_i$, and a trace theorem, the first term above can be estimated:

$$\begin{aligned}
\|(I^h_{k_l}(\widetilde{\theta}_i) - \widetilde{\theta}_i)w|_{\Omega_{k_l}}\|^2_{0,\delta_{n,1}} &\le \|I^h_{k_l}(\widetilde{\theta}_i) - \widetilde{\theta}_i\|^2_{0,\delta_{n,1}}\|w|_{\Omega_{k_l}}\|^2_{0,\delta_{n,1}} \\
&\le Ch_{k_l}|\widetilde{\theta}_i|^2_{1,\Omega_{k_l}}\|w\|^2_{1,\Omega_{k_l}} \\
&\le Ch_{k_l}\frac{1}{\delta_i^2}|\Omega_{k_l,\delta_i}|\|w\|^2_{1,\Omega_{k_l}},
\end{aligned}$$

where $|\Omega_{k_l,\delta_i}|$ denotes the volume of the set Ω_{k_l,δ_i}, which is the support of $\nabla\widetilde{\theta}_i$ contained in Ω_{k_l}. In general, we have $|\Omega_{k_1,\delta_i}| \le C\delta_i^{d-1}H_{k_l}$ with $d = 2$ or 3. Using this, we obtain

$$\|(I^h_{k_l}(\widetilde{\theta}_i) - \widetilde{\theta}_i)w|_{\Omega_{k_l}}\|^2_{0,\delta_{n,1}} \le Ch_{k_l}\left(1 + \frac{H_{k_l}}{\delta_i}\right)\left(|w|^2_{1,\Omega_{k_l}} + \frac{1}{H^2_{k_l}}\|w\|^2_{0,\Omega_{k_l}}\right). \qquad (4.21)$$

Using Lemma 6, the second term in (4.20) is bounded by

$$\begin{aligned}
&\left\|\widetilde{\theta}_i(w|_{\Omega_{k_j}} - w|_{\Omega_{k_3}})\right\|^2_{0,\delta_{n,j}} \\
&\le C\left\|\widetilde{\theta}_i\right\|^2_{\infty,\delta_{n,j}}\left\|w|_{\Omega_{k_j}} - w|_{\Omega_{k_3}}\right\|^2_{0,\delta_{n,j}} \\
&\le Ch_{k_3}\left(|w|^2_{1,\Omega_{k_j}} + |w|^2_{1,\Omega_{k_3}}\right), \quad j = 1, 5. \qquad (4.22)
\end{aligned}$$

Combining (4.20) with (4.21) and (4.22), and the approximation property of the nodal interpolation operators $I^h_{k_j}$, $j = 1, 3, 5$, for the functions $\widetilde{u}_i$, which are continu-

ous and piecewise quadratic on $T^h(\Omega_{k_j})$, lead to the following estimate:

(4.23)
$$\left\|I^h_{m(\delta_n)}(\widetilde{u}_i) - I^h_{k_3}(\widetilde{u}_i)\right\|^2_{0,\delta_n} \leq Ch_{k_3}\left(\sum_{j=1,3,5}|\widetilde{u}_i|^2_{1,\Omega_{k_j}} + \left(1+\frac{H_i}{\delta_i}\right)\sum_{j=1,3,5}\left(|w|^2_{1,\Omega_{k_j}} + \frac{1}{H^2_{k_j}}\|w\|^2_{0,\Omega_{k_j}}\right)\right),$$

where H_i is the diameter of the subregion $\widetilde{\Omega}_i$. Here we have used Assumptions 4 and 5.

Combining the estimates in (4.23), (4.19), and (4.18) with (4.17), we obtain

$$a^\Gamma(u_i,u_i) \leq C\left(\sum_{l\in\mathcal{S}_i}|\widetilde{u}_i|^2_{1,\Omega_{k_l}} + \left(1+\frac{H_i}{\delta_i}\right)\sum_{l\in\mathcal{S}_i}\left(|u-u_0|^2_{1,\Omega_{k_l}} + \frac{1}{H_{k_l}}\|u-u_0\|^2_{0,\Omega_{k_l}}\right)\right),$$

where $\mathcal{S}_i = \{l \,:\, \Omega_{k_l}\cap\widetilde{\Omega}_i \neq \emptyset\}$, the set of indices k_l of the substructures which intersect the subregion $\widetilde{\Omega}_i$. The first term of the above equation is estimated as follows:

$$\begin{aligned}|\widetilde{u}_i|^2_{1,\Omega_{k_l}} &= \left\|\nabla\left(\widetilde{\theta}_i(u-u_0)\right)\right\|^2_{0,\Omega_{k_l}}\\ &\leq C\left\{\int_{\Omega_{k_l}}\left|(u-u_0)\nabla\widetilde{\theta}_i\right|^2 dx + \int_{\Omega_{k_l}}\left|\widetilde{\theta}_i\nabla(u-u_0)\right|^2 dx\right\}\\ &\leq C\left\{\frac{1}{\delta_i^2}\int_{\Omega_{k_l,\delta_i}}(u-u_0)^2\,dx + |u-u_0|^2_{1,\Omega_{k_l}}\right\},\end{aligned}$$

where Ω_{k_l,δ_i} is the support of $\nabla\widetilde{\theta}_i$ contained in Ω_{k_l}. We then obtain by applying Lemma 2 to $\int_{\Omega_{k_l,\delta_i}}(u-u_0)^2\,dx$:

$$\frac{1}{\delta_i^2}\int_{\Omega_{k_l,\delta_i}}(u-u_0)^2\,dx \leq C\left(\left(1+\frac{H_{k_l}}{\delta_i}\right)|u-u_0|^2_{1,\Omega_{k_l}} + \frac{1}{H_{k_l}\delta_i}\|u-u_0\|^2_{0,\Omega_{k_l}}\right).$$

Using Assumption 4, we have

$$a^\Gamma(u_i,u_i) \leq C\left(1+\frac{H_i}{\delta_i}\right)\left(\sum_{l\in\mathcal{S}_i}|u-u_0|^2_{1,\Omega_{k_l}} + \sum_{l\in\mathcal{S}_i}\frac{1}{H^2_{k_l}}\|u-u_0\|^2_{0,\Omega_{k_l}}\right).$$

By summing the above estimate over all the subregions $\widetilde{\Omega}_i$, using a coloring argument and the estimates in Lemma 9, we obtain

$$\begin{aligned}\sum_{i=1}^N a^\Gamma(u_i,u_i) &\leq C\max_{i=1,\ldots,N}\left\{\left(1+\frac{H_i}{\delta_i}\right)\right\}\left(\sum_{l=1}^N|u-u_0|^2_{1,\Omega_l} + \sum_{l=1}^N\frac{1}{H_l^2}\|u-u_0\|^2_{0,\Omega_l}\right)\\ &\leq C\max_{i=1,\ldots,N}\left\{\left(1+\frac{H_i}{\delta_i}\right)\right\}a^\Gamma(u,u). \qquad \square\end{aligned}$$

Remark 3. In the above lemma, we use Assumption 5, which states that the mesh sizes are comparable between neighboring subdomains. On any interface of two

subdomains, denote by h_m and h_{nm} the mesh sizes of the mortar subdomain and the nonmortar subdomain, respectively. If they satisfy

$$h_m \leq C h_{nm}, \tag{4.24}$$

then the result of Lemma 11 holds without the assumption of comparable meshes between neighboring subdomains. However, condition (4.24) is the opposite of the one considered in previous work on the mortar methods; see [17, sect. 1.5.3].

By combining the bound in Lemma 11 with Lemma 1 and the upper bound (3.5), we obtain the following condition number bound.

THEOREM 1. *With Assumptions* 1 *and* 2*, the two-level additive algorithm satisfies*

$$\kappa\left(\sum_{i=0}^{N} T_i\right) \leq C \max_{i=1,\ldots,N}\left\{\left(1+\frac{H_i}{\delta_i}\right)\right\},$$

where C depends on the constant ω in (3.5)*.*

For the general case, we bound the term in (4.22) by using Lemma 8:

$$\sum_{j=1,5} \|\widetilde{\theta}_i(w|_{\Omega_{k_j}} - w|_{\Omega_{k_3}})\|^2_{0,\delta_{n,j}} \leq C h_{k_3} \log\left(\frac{H_{k_3}}{h_{k_3}}\right) \sum_{j=1,3,5} |w|^2_{1,\Omega_{k_j}}.$$

This gives the bound in the general case:

$$\sum_{i=0}^{N} a^{\Gamma}(u_i,u_i) \leq C \max_{i=1,\ldots,N}\left\{\left(1+\frac{H_i}{\delta_i}\right) \max_{\Omega_{k_l}\cap\, \mathrm{supp}(V_i^h)\neq\emptyset}\left\{\log\left(\frac{H_{k_l}}{h_{k_l}}\right)\right\}\right\} a^{\Gamma}(u,u),$$

where $\mathrm{supp}(V_i^h)$ denotes the support of the functions in the space V_i^h. By combining this bound with Lemma 1 and the upper bound (3.5), we obtain the following condition number bound.

THEOREM 2. *Without Assumptions* 1 *and* 2*, the two-level additive algorithm satisfies*

$$\kappa\left(\sum_{i=0}^{N} T_i\right) \leq C \max_{i=1,\ldots,N}\left\{\left(1+\frac{H_i}{\delta_i}\right) \max_{\Omega_{k_l}\cap\, supp(V_i^h)\neq\emptyset}\left\{log\left(\frac{H_{k_l}}{h_{k_l}}\right)\right\}\right\},$$

where C depends on the constant ω in (3.5)*.*

SUBSPACE TRUST-REGION METHODS FOR LARGE BOUND-CONSTRAINED NONLINEAR EQUATIONS*

STEFANIA BELLAVIA† AND BENEDETTA MORINI†

Abstract. Trust-region methods for solving large bound-constrained nonlinear systems are considered. These allow for spherical or elliptical trust regions where the search for an approximate solution is restricted to a low-dimensional space. A general formulation for these methods is introduced and global and superlinear/quadratic convergence is shown under standard assumptions. Viable approaches for implementation in conjunction with Krylov methods are discussed and the practical performance of the resulting algorithms is shown.

Key words. bound-constrained nonlinear systems, subspace trust-region methods, inexact Newton step, Krylov subspace methods

DOI. 10.1137/040611951

1. Introduction.

A number of applications arising in chemical engineering [18, 21], power engineering [37], and PDE-constrained optimization [4] are naturally stated as large constrained nonlinear systems. In particular, systems where the variables are subjected to lower and upper bounds are fairly general because sets of algebraic equations and inequalities and the Karush–Kuhn–Tucker (KKT) systems can be cast in such form.

This paper is concerned with the development of a trust-region method for solving large bound-constrained nonlinear systems

$$F(x) = 0, \qquad x \in \Omega. \tag{1.1}$$

Here $F : X \to \mathbb{R}^n$ is a continuously differentiable mapping, $X \subseteq \mathbb{R}^n$ is an open set containing the feasible region Ω, and Ω is an n-dimensional box, $\Omega = \{x \in \mathbb{R}^n : l \leq x \leq u\}$. These inequalities are meant componentwise and $l \in (\mathbb{R} \cup -\infty)^n$, $u \in (\mathbb{R} \cup \infty)^n$.

The development of globally convergent methods for large unconstrained nonlinear systems has received a great deal of attention; see, e.g., [2, 6, 7, 15, 23, 26, 27]. The methods proposed suggest that the search directions employed in the global strategy might belong to a low-dimensional subspace as such directions may often be computed cheaply. Therefore, they avoid the factorization of the matrices involved and consider the combination of global strategies such as linesearch techniques and model trust-region algorithms with Krylov methods. The resulting procedures belong to the framework of the inexact Newton methods [12].

The main computational effort in trust-region methods is the solution of the so-called trust-region problem, which is to find the minimizer of some model of the objective function within a region where the model adequately reflects the objective function. For small and medium problems, solving the trust-region problem relies on

matrix factorization. When n is large, several authors have suggested restricting the search for an approximate solution to such a problem to a low-dimensional subspace. Thus, the full space trust-region problem is replaced with a subspace trust-region problem and a large overhead of computing is avoided; see [10] and the references therein. Proposed approaches include the truncated conjugate gradient method [32, 33], the truncated Lanczos approach [9, 17], the two-dimensional subspace minimization [5, 8], and a subspace dogleg method [6, 7].

Numerical methods for problem (1.1) differ from the procedures for unconstrained nonlinear systems in several respects. They are augmented with strategies that enforce feasibility of the iterates. In addition, major modifications in the globalization techniques are necessary. We are aware of the trust-region methods [1, 3, 16, 34, 35] tailored for small- and medium-size problems and of the procedures [28, 29] appropriate for large systems. Focusing on the approaches for large problems, Qi, Tong, and Li [28] propose an active set projected trust-region algorithm for bound-constrained nonlinear systems. As a result of the active set strategy, the trust-region problem may be of reduced dimension, which is potentially cheaper when the method is applied to large problems. The method by Qi, Qi, and Sun [29] concerns the solution of the KKT systems. The trust-region problem is built around those components of the current iterates which are far from the boundary of the positive orthant, and it is solved by the truncated conjugate gradient method.

In this paper we introduce a prototype subspace trust-region method for large bound-constrained nonlinear systems. Our proposal is to investigate the idea of solving the trust-region problem in a small subspace while still attaining global and local fast convergence. Both spherical and elliptical trust-regions are allowed. To ensure global convergence properties we use a generalized Cauchy step. Fast local convergence relies on mild conditions on the subspace and is independent of the way of computing an approximate trust-region solution. At each iteration the trial step used to compute the new iterate is a linear combination of the generalized Cauchy step and the approximate trust-region solution.

The general scheme proposed serves as a paradigm for some specific implementations. In particular, the theoretical results obtained suggest ways to implement it by using Krylov solvers [30]. The first proposal is a two-dimensional subspace strategy. The second is a dogleg subspace strategy in conjunction with the iterative linear solver GMRES [31]. Both strategies compute an approximate solution of the related subspace trust-region problem with a low computational cost and require matrix-vector products only. In this regard, we remark that the computation of the generalized Cauchy point calls for the product of the transpose of the Jacobian of F with vectors. Thus, the proposed strategies cannot be implemented in a matrix-free manner, i.e., without computing the whole Jacobian matrix. On the other hand if the Jacobian of F is not available, these products can be effectively computed by using software for automatic differentiation [36].

We mention that [6, 7] propose a matrix-free Newton-GMRES dogleg strategy for unconstrained nonlinear systems where the Cauchy point is replaced by the steepest descent direction in a space generated by GMRES. But, in our opinion, this approach cannot be easily extended to constrained problems.

In section 2 we describe the main features of a trust-region method for problem (1.1), and in section 3 we propose a prototype method for large problems. In section 4 we provide global and local convergence properties. In section 5 we discuss ways in which an implementation of our procedure may be developed. Finally, in

section 6 we provide computational experiments showing the practical performance of our algorithm.

1.1. Notation. Throughout the paper we use the following notation. For any mapping $F : X \to \mathbb{R}^n$, differentiable at a point $x \in X \subset \mathbb{R}^n$, the Jacobian matrix of F at x is denoted by $F'(x)$ and $F(x_k)$ is denoted by F_k. To represent the ith component of x, the symbol $(x)_i$ is used but, when clear from the context, the brackets are omitted. For any vector $y \in \mathbb{R}^n$, the 2-norm is denoted by $\|y\|$ and the open ball with center y and radius ρ is indicated by $B_\rho(y)$, i.e., $B_\rho(y) = \{x : \|x - y\| < \rho\}$. The identity matrix of dimension n is denoted by I.

2. Preliminaries. In this section we provide the essential features of a trust-region method for the solution of (1.1). The sequence $\{x_k\}$ generated is expected to converge to a point which solves the optimization problem

$$\min_{x\in\Omega} f(x) = \min_{x\in\Omega} \frac{1}{2}\|F(x)\|^2. \tag{2.1}$$

In fact, the solutions to (1.1) solve the constrained minimization problem (2.1). A solution x^* of (2.1) satisfies

$$D^{-2}(x^*)\nabla f(x^*) = 0, \tag{2.2}$$

where $\nabla f(x) = F'(x)^T F(x)$, $D(x)$ is the diagonal scaling matrix

$$D(x) = \operatorname{diag}(|v_1(x)|^{-1/2}, |v_2(x)|^{-1/2}, \ldots, |v_n(x)|^{-1/2}), \tag{2.3}$$

and

$$v_i(x) = \begin{cases} x_i - u_i & \text{if} \quad (\nabla f(x))_i < 0 \quad \text{and} \quad u_i < \infty, \\ x_i - l_i & \text{if} \quad (\nabla f(x))_i > 0 \quad \text{and} \quad l_i > -\infty, \\ \min\{x_i - l_i,\, u_i - x_i\} & \text{if} \quad (\nabla f(x))_i = 0 \quad \text{and} \quad l_i > -\infty \text{ or } u_i < \infty, \\ 1 & \text{otherwise} \end{cases}$$

for $i = 1, \ldots, n$; see [11].

Numerical methods for (1.1) need well-angled directions to handle the bounds. In particular, search directions biased toward the interior of Ω are required. This way, sufficiently large steps in these directions are allowed before violating the constraints. If x_k lies in Ω, the following scaled gradient of f is well angled with respect to the bounds:

$$d_k = -D_k^{-2}\nabla f_k.$$

This is due to the fact that D_k^{-2} penalizes the step ∇f_k, preventing a step directly toward a boundary point. Moreover, by (2.2) d_k monitors the progress toward a solution of problem (2.1).

In a framework for (1.1), we consider the trust-region problem

$$\min_{p\in\mathbb{R}^n}\{m_k(p) : \quad \|G_k\, p\| \le \Delta_k\}, \tag{2.4}$$

where Δ_k is the current trust-region radius, m_k is the quadratic model for f at x_k,

$$m_k(p) = \frac{1}{2}\|F_k + F_k' p\|^2,$$

and $G_k = G(x_k) \in \mathbb{R}^{n\times n}$ with $G : \mathbb{R}^n \to \mathbb{R}^{n\times n}$ defined as

$$G(x) = I \qquad \text{or} \qquad G(x) = D(x).$$

The first choice of G is used in [28, 34, 35] and yields the standard spherical trust-region problem. The choice $G(x) = D(x)$, $x \in \mathbb{R}^n$, has been considered in [1, 3] and gives rise to an elliptical trust region. In this case, for decreasing values of Δ_k, the solution to problem (2.4) tends to become parallel to d_k.

For all the proposed methods, the iterates x_k are forced to belong to Ω in order to deal with problems where F is not defined outside Ω. Moreover, since D is not defined on the boundary of Ω, the methods given in [1, 3] generate strictly feasible iterates, $x_k \in \text{int}(\Omega) = \{x \in \mathbb{R}^n : \ l < x < u\}$.

To find the next iterate, a key role is played by a so-called generalized Cauchy step $p_c(\Delta_k)$ depending on the scaled gradient d_k. The vector $p_c(\Delta_k)$ has the form

$$p_c(\Delta_k) = \tau_k \, d_k, \tag{2.5}$$

and it is such that $x_k + p_c(\Delta_k) \in \text{int}(\Omega)$. The value of τ_k is fixed as follows. Consider

$$\hat{\tau}_k = \min\left\{ \frac{\|D_k^{-1}\nabla f_k\|^2}{\|F_k' D_k^{-2}\nabla f_k\|^2}, \frac{\Delta_k}{\|G_k D_k^{-2}\nabla f_k\|} \right\} = \underset{\|\tau G_k d_k\| \le \Delta_k}{\text{argmin}} \ m_k(\tau d_k). \tag{2.6}$$

If $x_k + \hat{\tau}_k d_k \in \text{int}(\Omega)$, we let $\tau_k = \hat{\tau}_k$ in (2.5). Otherwise we let λ_k be the stepsize along d_k to the boundary, i.e.,

$$\lambda_k = \min_{1\le i\le n} \Lambda_i, \quad \text{where} \quad \Lambda_i = \begin{cases} \max\{\frac{l_i - (x_k)_i}{(d_k)_i}, \frac{u_i - (x_k)_i}{(d_k)_i}\} & \text{if } (d_k)_i \neq 0, \\ \infty & \text{if } (d_k)_i = 0, \end{cases}$$

and set τ_k smaller than λ_k. Summarizing, the parameter τ_k is given by

$$\tau_k = \begin{cases} \hat{\tau}_k & \text{if } x_k + \hat{\tau}_k d_k \in \text{int}(\Omega), \\ \theta\lambda_k, & \theta \in (0,\, 1), \text{ otherwise.} \end{cases} \tag{2.7}$$

In [11], it has been shown that global convergence to a first-order stationary point of (2.1) depends on obtaining, at each iteration, at least as much decrease in m_k as a fixed fraction of the decrease attained by the generalized Cauchy step $p_c(\Delta_k)$. In particular, letting $p(\Delta_k)$ be the step taken to update x_k, $p(\Delta_k)$ must satisfy the following condition

$$\rho_c(p(\Delta_k)) = \frac{m_k(0) - m_k(p(\Delta_k))}{m_k(0) - m_k(p_c(\Delta_k))} \ge \beta_1 \tag{2.8}$$

for a given constant $\beta_1 \in (0, 1)$.

Finally, as for the unconstrained problems, the sufficient improvement condition

$$\rho_f(p(\Delta_k)) = \frac{f(x_k) - f(x_k + p(\Delta_k))}{m_k(0) - m_k(p(\Delta_k))} \ge \beta_2 \tag{2.9}$$

is required to hold for a given constant $\beta_2 \in (0, 1)$. Namely, if (2.9) is satisfied, then $p(\Delta_k)$ is accepted, the new iterate $x_{k+1} = x_k + p(\Delta_k)$ is formed, and the trust-region radius may be increased. Otherwise, $p(\Delta_k)$ is rejected and Δ_k is shrunk.

3. A paradigm method for large-scale problems. In this section we present a general trust-region scheme for large bound-constrained nonlinear systems. Since the main source of computational effort of a trust-region algorithm is the work for solving problem (2.4), we replace (2.4) by the following subspace trust-region problem:

$$\min_{p\in S_k}\{m_k(p): \quad \|G_k\, p\| \le \Delta_k\}. \tag{3.1}$$

In fact, for a small subspace S_k of $\mathbb{R}^n$ the solution of (3.1) can be computed cheaply. At each iteration our scheme includes the choice of the subspace S_k, the solution of the subspace trust-region problem (3.1), and the construction of a step which combines the generalized Cauchy step and the subspace trust-region solution.

Our subspace model trust-region approach is based upon finding a small-dimension subspace S_k of $\mathbb{R}^n$ such that the minimum value of m_k on S_k is a fraction of $m_k(0)$. In particular, we fix S_k so that

$$p_k = \operatorname*{argmin}_{p\in S_k} m_k(p), \qquad m_k(p_k) \le \eta_k^2\, m_k(0), \tag{3.2}$$

with $\eta_k \in [0, 1)$. Clearly, by (3.2)

$$F_k'\, p_k = -F_k + r_k, \qquad \|r_k\| \le \eta_k \|F_k\|, \tag{3.3}$$

i.e., p_k is an inexact Newton step for the problem $F(x) = 0$; see [12].

To provide a flexible scheme, here we deliberately do not specify how to determine S_k and the solution $p_{tr}(\Delta_k)$ to (3.1). In section 5 we will show that these tasks can be readily implemented in different ways.

In regard to the problem of finding the actual step from x_k, our aim is to find a step $p(\Delta_k)$ producing a strictly feasible iterate $x_{k+1} = x_k + p(\Delta_k)$ and a sufficient reduction in the values of both the model function m_k and the objective function f.

To maintain strict feasibility we employ the interior modification of the projection onto Ω proposed in [19]. Namely, we form the vector

$$\bar{p}_{tr}(\Delta_k) = \alpha_k(P(x_k + p_{tr}(\Delta_k)) - x_k), \tag{3.4}$$

where $\alpha_k \in (0, 1)$ and $P(x)$ is the classical projection of x onto Ω, i.e., $(P(x))_i = \max\{l_i, \min\{x_i, u_i\}\}$, $i = 1, \ldots, n$. Clearly, $x_k + \bar{p}_{tr}(\Delta_k) \in \operatorname{int}(\Omega)$ and $(p_{tr}(\Delta_k))_i$ and $(\bar{p}_{tr}(\Delta_k))_i$ have the same sign. In fact, the point $x_k + \bar{p}_{tr}(\Delta_k)$ is the classical projection of $x_k + p_{tr}(\Delta_k)$ onto Ω, followed by a small step toward the interior of Ω. We remark that

$$\|\bar{p}_{tr}(\Delta_k)\| < \|p_{tr}(\Delta_k)\|. \tag{3.5}$$

Then we follow along the lines of [3] and seek a vector of the form

$$p(\Delta_k) = t\, p_c(\Delta_k) + (1 - t)\bar{p}_{tr}(\Delta_k), \qquad t \in [0, 1), \tag{3.6}$$

satisfying (2.8). Specifically, if $\rho_c(\bar{p}_{tr}(\Delta_k)) \ge \beta_1$, we take $t = 0$. Otherwise, since $m_k(t\, p_c(\Delta_k) + (1 - t)\, \bar{p}_{tr}(\Delta_k))$ is a quadratic function in t and $\rho_c(p_c(\Delta_k)) = 1$, it is easy to see that there exists $t \in (0, 1)$ such that $p(\Delta_k)$ satisfies $\rho_c(p(\Delta_k)) = \beta_1$. Next, we summarize the process for finding $p(\Delta_k)$.

ALGORITHM I. Finding a step that satisfies the model decrease (2.8).
Input parameters: $x_k \in \mathrm{int}(\Omega)$, $\bar{p}_{tr}(\Delta_k)$, $p_c(\Delta_k)$.

1. Set $t = 0$.
2. If $\rho_c(\bar{p}_{tr}(\Delta_k)) < \beta_1$
   Compute $u_1 = F_k' \, p_c(\Delta_k)$, $u_2 = F_k' \bar{p}_{tr}(\Delta_k)$, $u = u_1 - u_2$, $z = -F_k - u_2$,
   $$w = (z^T u)^2 - 2\,\|u\|^2 \left(F_k^T(u_2 - \beta_1 u_1) + \|u_2\|^2/2 - \|u_1\|^2/2\right).$$
   Set $t = (\, z^T u - w^{\frac{1}{2}})/\|u\|^2$.
3. Compute $p(\Delta_k)$ by (3.6).

We point out that the inclusion of $p_c(\Delta_k)$ in (3.6) ensures the existence of a vector $p(\Delta_k)$ satisfying (2.8). Then it enables the method to converge globally. Furthermore, the use of $\bar{p}_{tr}(\Delta_k)$ in (3.6) and suitable choices of the sequences $\{\eta_k\}$ and $\{\alpha_k\}$ yield rapid local convergence. The convergence analysis provided in the next section will highlight these features.

Below we summarize the overall procedure named the subspace interior affine trust-region (SIATR) method.

SIATR METHOD.
Input parameters: the starting point $x_0 \in \mathrm{int}(\Omega)$, the function G, $\Delta_{min} > 0$, the initial trust-region size $\bar{\Delta}_0 \geq \Delta_{min}$, β_1, β_2, δ, $\theta \in (0, 1)$.

For $k = 0, 1, \ldots$

1. Set $\Delta_k = \bar{\Delta}_k/\delta$.
2. Choose $\alpha_k \in (0, 1)$, $\eta_k \in [0, 1)$.
3. Repeat
   3.1 Set $\Delta_k = \delta\Delta_k$.
   3.2 Find $S_k \subset \mathbb{R}^n$ s.t. (3.2) holds.
   3.3 Compute the solution $p_{tr}(\Delta_k)$ to (3.1).
   3.4 Form $\bar{p}_{tr}(\Delta_k)$ by (3.4).
   3.5 Compute $p_c(\Delta_k)$ by (2.5) and (2.7).
   3.6 Find $p(\Delta_k)$ by Algorithm I.
   Until $\rho_f(p(\Delta_k)) \geq \beta_2$
4. Set $x_{k+1} = x_k + p(\Delta_k)$.
5. Choose $\bar{\Delta}_{k+1} \geq \Delta_{min}$.

In the SIATR method, $\bar{\Delta}_k$ is the initial value of the trust-region radius at the kth iteration. To develop our convergence analysis, we force $\bar{\Delta}_k$ to be greater than or equal to a fixed threshold $\Delta_{min} > 0$ for all $k \geq 0$. In this regard, we remark that the strategy for choosing $\bar{\Delta}_{k+1}$ does not affect our convergence results and that in step 5 it can be chosen following classical strategies based on the agreement between the model function m_k and the function f at iteration k.

4. Convergence analysis. In this section we develop a theoretical foundation for the SIATR method. We assume the following.

Assumption 1. F' is Lipschitz continuous in $L = \cup_{k=0}^{\infty} \{x \in X \ : \ \|x - x_k\| \leq r\}$, $r > 0$, with constant $2\gamma_L$.

Assumption 2. $\|F'\|$ is bounded above on L and $\chi_J = \sup_{x \in L} \|F'(x)\|$.

We begin studying the features of $p(\Delta_k)$. First, if $\|\nabla f_k\| \neq 0$, then condition (2.9) is met after a finite number of repetitions of step 3. This can be proved following along the lines of [3, Lemma 3.2]. Second, by Algorithm I we have $\rho_c(p(\Delta_k)) \geq \rho_c(\bar{p}_{tr}(\Delta_k))$ i.e.,

$$m_k(p(\Delta_k)) \leq m_k(\bar{p}_{tr}(\Delta_k)). \tag{4.1}$$

Third, the decrease attained in the value of m_k by $p(\Delta_k)$ is given in the following result.

LEMMA 4.1. *Assume that* $\|\nabla f_k\| \neq 0$. *If* $p(\Delta_k)$ *satisfies* (2.8), *then*

$$m_k(0) - m_k(p(\Delta_k)) \geq \frac{1}{2}\beta_1 \|D_k^{-1}\nabla f_k\| \min\left\{\frac{\Delta_k}{\|G_k D_k^{-1}\|}, \frac{\|D_k^{-1}\nabla f_k\|}{\|F_k' D_k^{-1}\|^2}, \frac{\theta\|D_k^{-1}\nabla f_k\|}{\|\nabla f_k\|_\infty}\right\}.$$

Proof. To prove the thesis we provide a lower bound for $m_k(0) - m_k(p_c(\Delta_k))$. By (2.5) we know that $p_c(\Delta_k)$ takes the form $p_c(\Delta_k) = \tau_k d_k$. Suppose $\tau_k = \hat{\tau}_k$ with $\hat{\tau}_k = \Delta_k/\|G_k D_k^{-2}\nabla f_k\|$. Since (2.6) implies $\hat{\tau}_k \leq \|D_k^{-1}\nabla f_k\|^2/\|F_k' D_k^{-2}\nabla f_k\|^2$, we get

$$m_k(0) - m_k(p_c(\Delta_k)) = \hat{\tau}_k\left(\|D_k^{-1}\nabla f_k\|^2 - \frac{1}{2}\hat{\tau}_k\|F_k' D_k^{-2}\nabla f_k\|^2\right) \geq \frac{1}{2}\hat{\tau}_k\|D_k^{-1}\nabla f_k\|^2$$

$$\geq \frac{1}{2}\frac{\Delta_k}{\|G_k D_k^{-1}\|}\|D_k^{-1}\nabla f_k\|. \tag{4.2}$$

In the case that either $\tau_k = \hat{\tau}_k = \|D_k^{-1}\nabla f_k\|^2/\|F_k' D_k^{-2}\nabla f_k\|^2$ or $\tau_k = \theta\lambda_k$, we know from [1, Lemma 3.3] that

$$m_k(0) - m_k(p_c(\Delta_k)) \geq \frac{1}{2}\frac{\|D_k^{-1}\nabla f_k\|^2}{\|F_k' D_k^{-1}\|^2}, \tag{4.3}$$

$$m_k(0) - m_k(p_c(\Delta_k)) \geq \frac{1}{2}\,\theta\,\frac{\|D_k^{-1}\nabla f_k\|^2}{\|\nabla f_k\|_\infty}, \tag{4.4}$$

respectively. From (2.8), (4.2), (4.3), and (4.4) the thesis follows. ∎

Now we can formalize the global convergence properties of the SIATR method. They essentially derive from forcing (2.8) and can be easily proved following along the lines of [3, Theorem 3.1] and using Lemma 4.1.

THEOREM 4.1. *If the sequence* $\{x_k\}$ *generated by the SIATR method is bounded, then all the limit points of* $\{x_k\}$ *are stationary points for the problem* (2.1), *i.e.,*

$$\lim_{k\to\infty} \|D_k^{-1}\nabla f_k\| = 0.$$

Further, if there exists a limit point $x^* \in \operatorname{int}(\Omega)$ *of* $\{x_k\}$ *such that* $F'(x^*)$ *is nonsingular, then* $\|F_k\| \to 0$ *and all the accumulation points of* $\{x_k\}$ *solve problem* (1.1).

Moreover, if there exists a limit point $x^* \in \Omega$ such that $F(x^*) = 0$ and $F'(x^*)$ is invertible, then $\{x_k\}$ converges to x^*. To prove this fact, we first recall some technical results.

LEMMA 4.2. *Let* $x^* \in \Omega$ *be a limit point of the sequence* $\{x_k\}$ *generated by the SIATR method such that* $F(x^*) = 0$ *and* $F'(x^*)$ *is nonsingular. Let* $K_1 = 2\,\|F'(x^*)\|$, $K_2 = 2\,\|F'(x^*)^{-1}\|$, *and* $\mu = \max\{K_1, K_2\}/2$ *and let* $\Gamma \in (0, 1/\mu)$ *be given. Then there exists* $\rho > 0$ *so that if* $x \in B_\rho(x^*)$, *then* $x \in L$ *and*

$$\|x - x^*\| \leq K_2\,\|F(x)\|, \tag{4.5}$$

$$\|F(x)\| \leq K_1\,\|x - x^*\|, \tag{4.6}$$

$$\|F'(x)^{-1}\| \leq K_2, \tag{4.7}$$

$$\|F(x) - F(z) - F'(z)(x - z)\| \leq \Gamma\|x - z\|^2 \quad \textit{for all } z \in B_\rho(x^*). \tag{4.8}$$

Proof. The existence of $\rho > 0$ so that if $\|x - x^*\| \leq \rho$, then $x \in L$ is shown in [3, Lemma 3.3]. Conditions (4.5)–(4.7) follows from [22, Lemma 4.3.1]. Finally, (4.8) is given in [25, Lemma 3.2.10]. ∎

The next theorem shows the convergence of the sequence $\{x_k\}$.

THEOREM 4.2. *Assume that x^* is a limit point of the sequence $\{x_k\}$ generated by the SIATR method such that $F(x^*) = 0$ and $F'(x^*)$ is nonsingular. Then $\{x_k\}$ converges to x^*.*

Proof. First, note that, by (4.5), there exists a neighborhood of x^* where $\|F(x)\| > 0$ if $x \neq x^*$. This implies that x^* is an isolated solution of (1.1). Moreover, since the sequence $\{\|F_k\|\}$ is monotone decreasing, it is convergent. Then the assumption $F(x^*) = 0$ implies $\|F_k\| \to 0$ and every limit point of $\{x_k\}$ is a solution of (1.1). Then, as the point x^* is an isolated solution of (1.1), it is an isolated limit point of the sequence $\{x_k\}$.

Let ρ be as in Lemma 4.2, let $\{x_{k_j}\}$ be a subsequence such that $x_{k_j} \to x^*$, and let j_0 be the index such that $x_{k_j} \in B_\rho(x^*) \cap \Omega$ when $k_j \geq k_{j_0}$. Note that $\lim_{k_j \to \infty} \|\nabla f_{k_j}\| = 0$. Assume $k_j \geq k_{j_0}$. To prove the thesis, we examine the asymptotic behavior of $p_c(\Delta_{k_j})$ and $\bar{p}_{tr}(\Delta_{k_j})$. By (2.5) and $\tau_k \leq \frac{\|D_{k_j}^{-1}\nabla f_{k_j}\|^2}{\|F'_{k_j} D_{k_j}^{-2}\nabla f_{k_j}\|^2}$, we obtain the following:

$$\begin{aligned} \|p_c(\Delta_{k_j})\| &\leq \frac{\|D_{k_j}^{-1}\nabla f_{k_j}\|^2}{\|D_{k_j}^{-2}\nabla f_{k_j}\|}\|{F'_{k_j}}^{-1}\|^2 = \frac{\nabla f_{k_j}^T (D_{k_j}^{-2}\nabla f_{k_j})}{\|D_{k_j}^{-2}\nabla f_{k_j}\|}\|{F'_{k_j}}^{-1}\|^2 \\ &\leq \|\nabla f_{k_j}\|\|{F'_{k_j}}^{-1}\|^2. \end{aligned} \tag{4.9}$$

By (4.7) and $\lim_{k_j \to \infty} \|\nabla f_{k_j}\| = 0$, we conclude that $\lim_{k_j \to \infty} \|p_c(\Delta_{k_j})\| = 0$.

Regarding $p_{tr}(\Delta_{k_j})$, by construction $m_k(p_{tr}(\Delta_{k_j})) \leq m_k(0)$ i.e., letting $\hat{r}_{k_j} = F'_{k_j} p_{tr}(\Delta_{k_j}) + F_{k_j}$ we have $\|\hat{r}_{k_j}\| \leq \|F_{k_j}\|$. Then

$$\|p_{tr}(\Delta_{k_j})\| = \|{F'}_{k_j}^{-1}(-F_{k_j} + \hat{r}_{k_j})\| \leq 2\,\|{F'}_{k_j}^{-1}\|\,\|F_{k_j}\| \leq 2\,K_2\,\|F_{k_j}\|.$$

Thus, $\|F_k\| \to 0$ and (3.5) yield $\lim_{k_j \to \infty} \|\bar{p}_{tr}(\Delta_{k_j})\| = 0$.

Hence, we have $\lim_{k_j \to \infty} \|p(\Delta_{k_j})\| = 0$ and using [24, Lemma 4.10] we conclude that $\{x_k\}$ converges to x^*. ∎

We now move on to discuss the convergence rate issues. We make the additional hypothesis $\|G_k p_k\| \to 0$ as $k \to \infty$. In practice, this condition may fail to hold only when $G_k = D_k$ and x^* belongs to the boundary of Ω. On the other hand, it is guaranteed when $G_k = I$ or when $G_k = D_k$ and x^* lies in the interior of Ω. To show this, note that by (3.3) and (4.7) we get

$$\|p_k\| = \|{F'}_k^{-1}(-F_k + r_k)\| \leq (1 + \eta_k)\,\|{F'}_k^{-1}\|\,\|F_k\| \leq 2\,K_2\,\|F_k\|, \tag{4.10}$$

and this implies that $\|p_k\| \to 0$ as $k \to \infty$. Also, it is easy to see that $\|D_k\| \leq \sqrt{2/\bar{\rho}}$ whenever $x_k \in B_{\bar{\rho}/2}(x^*)$ with $x^* \in \mathrm{int}(\Omega)$ and $\bar{\rho}$ sufficiently small that $B_{\bar{\rho}}(x^*) \subset \mathrm{int}(\Omega)$ [1, Corollary 3.1]. Then $\|D_k p_k\| \to 0$ as $k \to \infty$ when $x^* \in \mathrm{int}(\Omega)$.

First, we prove that eventually, for Δ_k equal to the initial trust-region radius $\bar{\Delta}_k$, the trust-region constraint in (3.1) becomes inactive, i.e., $p_{tr}(\bar{\Delta}_k)$ is the minimizer p_k of m_k on S_k. Moreover, we study the features of $p_{tr}(\bar{\Delta}_k)$, $\bar{p}_{tr}(\bar{\Delta}_k)$, and $p(\bar{\Delta}_k)$ when x_k is sufficiently near to x^*. Then we will show how the choice of η_k's and α_k's affects the convergence rate of the SIATR method.

From now on, with γ_L and χ_J as in Assumptions 1 and 2 and K_1, K_2, and Γ as

in Lemma 4.2, we let

$$K^* = \|F'(x^*)\| \, \|F'(x^*)^{-1}\|, \tag{4.11}$$

$$\nu = 8\, K^* \, (K_2 \chi_J + 1), \tag{4.12}$$

$$\delta_k = K_2 \Gamma \nu^2 \|x_k - x^*\| + 4\, K^* \, \eta_k, \tag{4.13}$$

$$\psi_k = \chi_J \delta_k + \gamma_L \nu^2 \|x_k - x^*\| + K_1 (1 - \alpha_k), \tag{4.14}$$

$$\sigma_k = \max\{\psi_k,\, K_2 (\, \Gamma \nu^2 \|x_k - x^*\| + \psi_k)\}. \tag{4.15}$$

LEMMA 4.3. *Assume that there exists a solution x^* of (1.1) such that $F'(x^*)$ is nonsingular and that the sequence $\{x_k\}$ generated by the SIATR method converges to x^*. Suppose that either*

- *$G_k = I$, $k \geq 0$, or*
- *$G_k = D_k$, $k \geq 0$, and $\|D_k p_k\| \to 0$ as $k \to \infty$.*

Then, for ρ as in Lemma 4.2, there exists $\rho_1 \leq \rho$ such that for all $x_k \in B_{\rho_1}(x^*) \cap \text{int}(\Omega)$,

$$p_{tr}(\bar{\Delta}_k) = p_k, \tag{4.16}$$

where p_k is given in (3.2) and $\bar{\Delta}_k$ is the initial trust-region radius at kth iteration. Further, when $x_k \in B_{\rho_1}(x^*) \cap \text{int}(\Omega)$ we have

$$\|F_k + F_k' p_{tr}(\bar{\Delta}_k)\| \leq K_1 \, \eta_k \|x_k - x^*\|, \tag{4.17}$$

$$\|\bar{p}_{tr}(\bar{\Delta}_k)\| < \|p_{tr}(\bar{\Delta}_k)\| \leq \nu \|x_k - x^*\|, \tag{4.18}$$

$$\|p(\bar{\Delta}_k)\| \leq \nu \|x_k - x^*\|. \tag{4.19}$$

Proof. The relationship (4.16) is proved by using the fact that $\bar{\Delta}_k \geq \Delta_{min}$, i.e., $\bar{\Delta}_k$ is bounded below from zero for each $k \geq 0$. Let $G_k = I$ for all $k \geq 0$. By (4.10) $\lim_{k \to \infty} \|p_k\| = 0$. Then, there exists $\rho_1 \leq \rho$ such that $\|p_k\| \leq \bar{\Delta}_k$ when $x_k \in B_{\rho_1}(x^*) \cap \text{int}(\Omega)$. Since p_k is feasible for the trust-region problem (3.1), the thesis (4.16) follows. Now consider the case $G_k = D_k$ for all $k \geq 0$. The assumption $\lim_{k \to \infty} \|D_k p_k\| = 0$ implies that there exists $\rho_1 \leq \rho$ such that p_k solves the trust-region problem (3.1) whenever $x_k \in B_{\rho_1}(x^*) \cap \text{int}(\Omega)$ and (4.16) again follows.

The remaining results are proved independently of the form of G_k. By (4.16) and (3.2) we obtain $\|F_k + F_k' p_{tr}(\bar{\Delta}_k)\| \leq \eta_k \|F_k\|$. Thus, (4.6) implies (4.17).

The result (4.18) is derived noting that by (3.5), (4.16), (4.10), (4.6), and (4.11) we get

$$\|\bar{p}_{tr}(\bar{\Delta}_k)\| < \|p_{tr}(\bar{\Delta}_k)\| \leq 2\, K_2 \, \|F_k\| \leq 8\, K^* \, \|x_k - x^*\|. \tag{4.20}$$

Then, by (4.12) relation (4.18) follows.

Finally, (4.9), (4.7), (4.6), and Assumption 2 yield $\|p_c(\bar{\Delta}_k)\| \leq 4 K^* K_2 \chi_J \|x_k - x^*\|$. Hence, by (3.6) and (4.20)

$$\|p(\bar{\Delta}_k)\| \leq \|p_c(\bar{\Delta}_k)\| + \|\bar{p}_{tr}(\bar{\Delta}_k)\| \leq 8\, K^* \, (K_2 \, \chi_J + 1) \, \|x_k - x^*\|.$$

This, along with (4.12), proves (4.19). ∎

LEMMA 4.4. *Assume that there exists a solution x^* of (1.1) such that $F'(x^*)$ is nonsingular and that the sequence $\{x_k\}$ generated by the SIATR method converges to x^*. Suppose that either*

- *$G_k = I$, $k \geq 0$, or*
- *$G_k = D_k$, $k \geq 0$, and $\|D_k p_k\| \to 0$ as $k \to \infty$.*

Then, for ρ_1 as in Lemma 4.3 and $x_k \in B_{\rho_2}(x^*) \cap \mathrm{int}(\Omega)$, $\rho_2 \le \rho_1/(1+\nu)$, we have

$$\|F_k + F_k' \bar{p}_{tr}(\bar{\Delta}_k)\| \le \sigma_k \|x_k - x^*\|, \tag{4.21}$$

$$\|x_k + \bar{p}_{tr}(\bar{\Delta}_k) - x^*\| \le \sigma_k \|x_k - x^*\|, \tag{4.22}$$

where $\bar{\Delta}_k$ is the initial trust-region radius at the kth iteration.

Proof. Let $0 < \rho_2 \le \rho_1/(1+\nu)$ and let k be sufficiently large to have $x_k \in B_{\rho_2}(x^*) \cap \mathrm{int}(\Omega)$. To begin, note that from (4.5) and (4.8), any vector $x_k + q \in B_{\rho_1}(x^*)$ satisfies

$$\begin{aligned} \|x_k + q - x^*\| &\le K_2(\|F(x_k+q) - F_k - F_k' q\| + \|F_k + F_k' q\|) \\ &\le K_2(\Gamma \|q\|^2 + \|F_k + F_k' q\|). \end{aligned} \tag{4.23}$$

From (4.18) we get $\|x_k + p_{tr}(\bar{\Delta}_k) - x^*\| \le \|x_k - x^*\| + \|p_{tr}(\bar{\Delta}_k)\| \le \rho_2(1+\nu) \le \rho_1$. Analogously, $\|x_k + \bar{p}_{tr}(\bar{\Delta}_k) - x^*\| \le \rho_1$. Hence, $x_k + p_{tr}(\bar{\Delta}_k)$ and $x_k + \bar{p}_{tr}(\bar{\Delta}_k)$ belong to $B_{\rho_1}(x^*)$. Further, from (4.23), (4.17), and (4.18) we get

$$\|x_k + p_{tr}(\bar{\Delta}_k) - x^*\| \le \delta_k \|x_k - x^*\|, \tag{4.24}$$

where δ_k is given in (4.13).

Now, letting $\hat{p} = P(x_k + p_{tr}(\bar{\Delta}_k)) - x_k$, we derive an upper bound for $\|F_k + F_k' \hat{p}\|$. First, we note that $\|\hat{p}\| \le \|p_{tr}(\bar{\Delta}_k)\|$ and recall the nonexpansivity of the projection operator $P(\cdot)$, i.e., $\|x_k + \hat{p} - x^*\| \le \|x_k + p_{tr}(\bar{\Delta}_k) - x^*\|$. Then, by

$$\begin{aligned} F_k + F_k' \hat{p} &= F(x_k + \hat{p}) - F(x^*) + \int_0^1 (F'(x_k) - F'(x_k + t\hat{p}))\hat{p}\, dt \\ &= \int_0^1 F'(x^* + t(x_k + \hat{p} - x^*))(x_k + \hat{p} - x^*) dt \\ &\quad + \int_0^1 (F'(x_k) - F'(x_k + t\hat{p}))\hat{p}\, dt \end{aligned} \tag{4.25}$$

and using Assumptions 1–2, (4.24), and (4.18), we obtain

$$\begin{aligned} \|F_k + F_k' \hat{p}\| &\le \chi_J \|x_k + p_{tr}(\bar{\Delta}_k) - x^*\| + \gamma_L \|p_{tr}(\bar{\Delta}_k)\|^2 \\ &\le (\chi_J \delta_k + \gamma_L \nu^2 \|x_k - x^*\|) \|x_k - x^*\|. \end{aligned} \tag{4.26}$$

Further, from (3.4), (4.26), (4.6), and (4.14) we get

$$\|F_k + F_k' \bar{p}_{tr}(\bar{\Delta}_k)\| \le \alpha_k \|F_k + F_k' \hat{p}\| + (1 - \alpha_k)\|F_k\| \tag{4.27}$$

$$\le \psi_k \|x_k - x^*\|, \tag{4.28}$$

and (4.15) yields the thesis (4.21).

Finally (4.22) is derived by (4.23), (4.18), (4.28), and (4.15), as follows:

$$\|x_k + \bar{p}_{tr}(\bar{\Delta}_k) - x^*\| \le K_2(\Gamma \nu^2 \|x_k - x^*\| + \psi_k)\, \|x_k - x^*\|. \qquad \square$$

4.1. Superlinear convergence. In this section we show that if $\eta_k \to 0$ and $\alpha_k \to 1$ as $k \to \infty$, then eventually the step $\bar{p}_{tr}(\bar{\Delta}_k)$ satisfies both conditions (2.8) and (2.9). Then, for k sufficiently large, $p(\bar{\Delta}_k) = \bar{p}_{tr}(\bar{\Delta}_k)$ and the actual step is not biased toward the generalized Cauchy step. Moreover,

- $x_k \to x^*$ superlinearly;
- $x_k \to x^*$ quadratically if $\eta_k = O(\|F_k\|)$ and $\alpha_k = 1 - O(\|F_k\|)$ as $k \to \infty$.

THEOREM 4.3. *Assume that there exists a solution x^* of (1.1) such that $F'(x^*)$ is nonsingular and that the sequence $\{x_k\}$ generated by the SIATR method converges to x^*. Suppose that $\eta_k \to 0$, $\alpha_k \to 1$, as $k \to \infty$, and either*

- *$G_k = I$, $k \geq 0$, or*
- *$G_k = D_k$, $k \geq 0$, and $\|D_k p_k\| \to 0$ as $k \to \infty$.*

Then, eventually, $\bar{p}_{tr}(\bar{\Delta}_k)$ satisfies (2.8) and (2.9) and the sequence $\{x_k\}$ converges to x^* superlinearly. Moreover, if $\eta_k = O(\|F_k\|)$, $\alpha_k = 1 - O(\|F_k\|)$ as $k \to \infty$, the convergence rate is quadratic.

Proof. Let ζ be such that

$$\zeta < \min\left\{ \rho_2, \frac{1-\beta_2}{2K_2\Gamma\nu^2} \right\}, \tag{4.29}$$

with ρ_2 as in Lemma 4.4, K_2 and Γ as in Lemma 4.2, and ν as in (4.12). Let k be sufficiently large to have $x_k \in B_\zeta(x^*) \cap \text{int}(\Omega)$ and

$$\sigma_k < \frac{1}{K_2} \min\left\{ \sqrt{1-\beta_1}, \frac{1}{2} \right\}, \tag{4.30}$$

where σ_k is given in (4.15). This condition is met for k sufficiently large since

$$\sigma_k = O(\|x_k - x^*\| + \eta_k + (1-\alpha_k)), \qquad k \to \infty. \tag{4.31}$$

First, we prove that $\bar{p}_{tr}(\bar{\Delta}_k)$ satisfies (2.8), i.e., $p(\bar{\Delta}_k) = \bar{p}_{tr}(\bar{\Delta}_k)$. By (2.8), (4.21), (4.5), and (4.30), it follows that

$$\rho_c(\bar{p}_{tr}(\bar{\Delta}_k)) \geq 1 - \frac{\|F_k + F_k'\bar{p}_{tr}(\bar{\Delta}_k)\|^2}{\|F_k\|^2} \geq 1 - \sigma_k^2 K_2^2 > \beta_1. \tag{4.32}$$

Second, we prove that $\rho_f(\bar{p}_{tr}(\bar{\Delta}_k)) \geq \beta_2$. Note that

$$\rho_f(\bar{p}_{tr}(\bar{\Delta}_k)) = 1 - \frac{\|F(x_k + \bar{p}_{tr}(\bar{\Delta}_k))\|^2 - \|F_k + F_k'\bar{p}_{tr}(\bar{\Delta}_k)\|^2}{\|F_k\|^2 - \|F_k + F_k'\bar{p}_{tr}(\bar{\Delta}_k)\|^2} \tag{4.33}$$

and

$$\begin{aligned} \|F(x_k + \bar{p}_{tr}(\bar{\Delta}_k))\|^2 - \|F_k + F_k'\bar{p}_{tr}(\bar{\Delta}_k)\|^2 &= \|F(x_k + \bar{p}_{tr}(\bar{\Delta}_k)) - F_k - F_k'\bar{p}_{tr}(\bar{\Delta}_k)\|^2 \\ &+ 2(F(x_k + \bar{p}_{tr}(\bar{\Delta}_k)) - F_k - F_k'\bar{p}_{tr}(\bar{\Delta}_k))^T \\ &\times (F_k + F_k'\bar{p}_{tr}(\bar{\Delta}_k)). \end{aligned}$$

Note that (4.29) implies $\zeta < 1/(2K_2\Gamma\nu^2)$ and (4.30) implies $2\sigma_k < 1/K_2$. Then by (4.8), (4.21), and (4.18) we get

$$\begin{aligned} \|F(x_k + \bar{p}_{tr}(\bar{\Delta}_k))\|^2 - \|F_k + F_k'\bar{p}_{tr}(\bar{\Delta}_k)\|^2 &\leq \Gamma^2\|\bar{p}_{tr}(\bar{\Delta}_k)\|^4 + 2\sigma_k\Gamma\|\bar{p}_{tr}(\bar{\Delta}_k)\|^2\|x_k - x^*\| \\ &\leq \Gamma\nu^2(\Gamma\nu^2\|x_k - x^*\| + 2\sigma_k)\|x_k - x^*\|^3 \\ &\leq \frac{3\Gamma\nu^2}{2K_2}\|x_k - x^*\|^3. \end{aligned}$$

Further, from (4.5), (4.21), and (4.30) we get

$$\|F_k\|^2 - \|F_k + F_k'\bar{p}_{tr}(\bar{\Delta}_k)\|^2 \geq \left(\frac{1}{K_2^2} - \sigma_k^2\right)\|x_k - x^*\|^2 > \frac{3}{4K_2^2}\|x_k - x^*\|^2.$$

Therefore, by (4.33) and (4.29) we get

$$\rho_f(\bar{p}_{tr}(\bar{\Delta}_k)) \geq 1 - 2K_2\Gamma\nu^2\|x_k - x^*\| > \beta_2.$$

Hence, $x_{k+1} = x_k + \bar{p}_{tr}(\bar{\Delta}_k)$ and from (4.22) we conclude $\|x_{k+1} - x^*\| \leq \sigma_k\|x_k - x^*\|$. The form of σ_k given in (4.31) ensures superlinear convergence rate if $\eta_k \to 0$ and $\alpha_k \to 1$ as $k \to \infty$. Moreover, if $\eta_k = O(\|F_k\|)$ and $1 - \alpha_k = O(\|F_k\|)$, by (4.5)–(4.6), we get $\sigma_k = O(\|x_k - x^*\|)$, and this yields the quadratic convergence rate. ∎

4.2. Linear convergence and norm weighted analysis. In this section we characterize the convergence order of the SIATR method dropping the assumption $\eta_k \to 0$ for $k \to \infty$. In particular, we let $\eta_k \leq \eta_{max} < \bar{\eta} < 1$, $k \geq 0$, and provide convergence results which are in accordance with those of inexact Newton methods for unconstrained nonlinear systems [12].

Following along the lines of the previous analysis, in the next theorem we show that if $\bar{\eta}$ is sufficiently small, then the sequence $\{x_k\}$ converges at a linear rate.

THEOREM 4.4. *Assume that there exists a solution x^* of (1.1) such that $F'(x^*)$ is nonsingular and that the sequence $\{x_k\}$ generated by the SIATR method converges to x^*. Suppose that either*

- *$G_k = I$, $k \geq 0$, or*
- *$G_k = D_k$, $k \geq 0$, and $\|D_k p_k\| \to 0$ as $k \to \infty$.*

Then there exists $\bar{\eta} < 1$ such that if $\eta_k \leq \eta_{max} < \bar{\eta}$ for $k \geq 0$ and $\alpha_k \to 1$, as $k \to \infty$, then eventually $\bar{p}_{tr}(\bar{\Delta}_k)$ satisfies (2.8)–(2.9) and the sequence $\{x_k\}$ converges to x^* linearly.

Proof. Let k be sufficiently large to have $x_k \in B_\zeta(x^*) \cap \mathrm{int}(\Omega)$ with ζ given in (4.29). Since we intend to proceed as in Theorem 4.3, we need to ensure (4.30). Further, to provide linear convergence rate, σ_k given in (4.15) must be such that $\sigma_k < 1$.

Note that from (4.13)–(4.15) it follows that

$$\psi_k \leq \nu^2(\gamma_L + K_2\Gamma\chi_J)\|x_k - x^*\| + K_1(1 - \alpha_k) + 4\chi_J K^*\eta_{max},$$
$$\sigma_k \leq \max\{1,\, K_2\}\,\psi_k + K_2\Gamma\nu^2\|x_k - x^*\|.$$

Since $\lim_{k\to\infty}\alpha_k = 1$, $\lim_{k\to\infty}\|x_k - x^*\| = 0$, letting

$$\bar{\eta} < \min\left\{1,\, \frac{1}{4\,K^*\,\chi_J\max\{1,\,K_2\}},\, \frac{\min\{\sqrt{1-\beta_1},\,\frac{1}{2}\}}{4\,K^*\,K_2\,\chi_J\max\{1,\,K_2\}}\right\}, \tag{4.34}$$

we can take $\zeta > 0$ sufficiently small such that $\sigma_k < \min\{1,\, \frac{1}{K_2}\min\{\sqrt{1-\beta_1},\,\frac{1}{2}\}\}$ for $x_k \in B_\zeta(x^*) \cap \mathrm{int}(\Omega)$ and k sufficiently large. Thus, both $\sigma_k < 1$ and (4.30) hold, and proceeding as in Theorem 4.3, we conclude that $\bar{p}_{tr}(\bar{\Delta}_k)$ satisfies (2.8)–(2.9) and $x_{k+1} = x_k + \bar{p}_{tr}(\bar{\Delta}_k)$. Finally, (4.22) yields linear convergence rate. ∎

Trivially, (4.34) implies that $\bar{p}_{tr}(\bar{\Delta}_k)$ is not guaranteed to satisfy (2.8) for any $\bar{\eta} < 1$. On the other hand, if no other condition is imposed than requiring the sequence $\{\eta_k\}$ to be uniformly bounded away from 1, the linear convergence of the sequence $\{x_k\}$ depends on the norm used. Introducing the weighted norm

$$\|\cdot\|_* = \|F'(x^*)\cdot\|,$$

we prove that $\{x_k\}$ converges to x^* linearly in the sense that $\|x_{k+1} - x^*\|_* \leq \bar{\eta}\,\|x_k - x^*\|_*$ for any $\bar{\eta} < 1$. To prove this result we need to provide some useful bounds employing the weighted norm. With μ and Γ as in Lemma 4.2, we let

$$\omega_1 = 1/(1 - \Gamma\mu), \qquad \omega_2 = 1 + \Gamma\mu. \tag{4.35}$$

LEMMA 4.5. *Assume that there exists a solution x^* of (1.1) such that $F'(x^*)$ is nonsingular and that the sequence $\{x_k\}$ generated by the SIATR method converges to x^*. Suppose that either*

- $G_k = I$, $k \geq 0$, *or*
- $G_k = D_k$, $k \geq 0$, *and* $\|D_k p_k\| \to 0$ *as* $k \to \infty$.

Then there exists $\rho_3 > 0$ so that if $x_k \in B_{\rho_3}(x^*) \cap \text{int}(\Omega)$, then

$$\|x_k - x^*\|_* \leq \omega_1 \|F_k\|, \tag{4.36}$$

$$\|F_k\| \leq \omega_2 \|x_k - x^*\|_*, \tag{4.37}$$

$$\|F_k + F_k' p_{tr}(\bar{\Delta}_k)\| \leq \eta_k \omega_2 \|x_k - x^*\|_*, \tag{4.38}$$

$$\|p_{tr}(\bar{\Delta}_k)\| \leq \nu_* \|x_k - x^*\|_*, \tag{4.39}$$

$$\|p(\bar{\Delta}_k)\| \leq \nu_* \|x_k - x^*\|_*, \tag{4.40}$$

with $\nu_* = 2\, K_2 \omega_2\, (K_2\, \chi_J + 1)$.

Proof. Note that

$$\frac{1}{\mu}\|y\| \leq \|y\|_* \leq \mu \|y\| \quad \text{for all } y \in \mathbb{R}^n. \tag{4.41}$$

Let ρ_1 be as in Lemma 4.3 and Γ as in Lemma 4.2. From the continuity of F' there exists $0 < \rho_3 < \rho_1$, so that

$$\|F'(x) - F'(x^*)\| \leq \Gamma, \qquad \|F'(x)^{-1} - F'(x^*)^{-1}\| \leq \Gamma \tag{4.42}$$

for $x \in B_{\rho_3}(x^*) \cap \text{int}(\Omega)$. In what follows, let $x_k \in B_{\rho_3}(x^*) \cap \text{int}(\Omega)$.

By (4.42), (4.41), and (4.35) we obtain (4.36) as follows:

$$\begin{aligned}
\|F_k\| &= \|F'(x^*)(x^* - x_k) - \int_0^1 (F'(x^* + t(x_k - x^*)) - F'(x^*))(x_k - x^*)\, dt\|, \\
&\geq \left| \|x_k - x^*\|_* - \left\| \int_0^1 (F'(x^* + t(x_k - x^*)) - F'(x^*))(x_k - x^*)\, dt \right\| \right| \\
&\geq (1 - \Gamma\mu)\|x_k - x^*\|_*.
\end{aligned}$$

Further, (4.37) follows from

$$\begin{aligned}
\|F(x)\| &\leq \int_0^1 \|F'(x^* + t(x_k - x^*)) - F'(x^*)\|\, \|x_k - x^*\| + \|F'(x^*)(x_k - x^*)\| dt \\
&\leq (\Gamma\mu + 1)\|x_k - x^*\|_*
\end{aligned}$$

and (4.35).

Since from Lemma 4.3 it follows that $p_{tr}(\bar{\Delta}_k) = p_k$, by (3.2) and (4.37) we trivially obtain (4.38). Moreover, from (4.10) and (4.37) we get $\|p_{tr}(\bar{\Delta}_k)\| \leq 2K_2\omega_2\|x_k - x^*\|_*$, and this yields (4.39). Finally, (4.9), Assumption 2, (4.7), and (4.37) yield $\|p_c(\bar{\Delta}_k)\| \leq K_2^2\, \chi_J\, \omega_2 \|x_k - x^*\|_*$. Then (4.40) is obtained by (3.6) and (3.5) as follows:

$$\|p(\bar{\Delta}_k)\| \leq \|p_c(\bar{\Delta}_k)\| + \|\bar{p}_{tr}(\bar{\Delta}_k)\| \leq 2\omega_2\, K_2\, (K_2\, \chi_J + 1)\, \|x_k - x^*\|_*. \qquad \square$$

Next we establish conditions under which $x_{k+1} = x_k + p(\bar{\Delta}_k)$ for k sufficiently large and for any $\bar{\eta} < 1$. Then the linear convergence rate of $\{x_k\}$ in the weighted norm is shown.

THEOREM 4.5. *Assume that there exists a solution x^* of (1.1) such that $F'(x^*)$ is nonsingular and that the sequence $\{x_k\}$ generated by the SIATR method converges to x^*. Suppose that $\eta_k \le \eta_{max} < \bar{\eta} < 1$, $k \ge 0$, $\alpha_k \to 1$, as $k \to \infty$ and either*

- *$G_k = I$, $k \ge 0$, or*
- *$G_k = D_k$, $k \ge 0$, and $\|D_k p_k\| \to 0$ as $k \to \infty$,*

If, for k sufficiently large,

$$P(x_k + p_{tr}(\bar{\Delta}_k)) - x_k = p_{tr}(\bar{\Delta}_k), \tag{4.43}$$

then $p(\bar{\Delta}_k)$ satisfies (2.9) and the sequence $\{x_k\}$ converges to x^* linearly in the sense that

$$\|x_{k+1} - x^*\|_* \le \bar{\eta}\, \|x_k - x^*\|_*.$$

Proof. Let $0 < \rho_4 \le \rho_3/(1+\nu)$, where ρ_3 is as in the proof of Lemma 4.5 and ν is given in (4.12). Let k be sufficiently large to have $x_k \in B_{\rho_4}(x^*) \cap \mathrm{int}(\Omega)$. From (4.19) it follows that $x_k + p(\bar{\Delta}_k)$ belongs to $B_{\rho_3}(x^*) \cap \mathrm{int}(\Omega)$. Let

$$\bar{\epsilon}_k = \omega_2(\alpha_k\, \eta_k + 1 - \alpha_k), \tag{4.44}$$

$$\epsilon_k = \omega_1(\Gamma \nu_*^2 \|x_k - x^*\|_* + \bar{\epsilon}_k). \tag{4.45}$$

By hypothesis, $\hat{p} = P(x_k + p_{tr}(\bar{\Delta}_k)) - x_k = p_{tr}(\bar{\Delta}_k)$. Then by (4.1), (4.27), (4.38), (4.37), and (4.44) it follows that

$$\begin{aligned} \|F_k + F_k' p(\bar{\Delta}_k)\| &\le \|F_k + F_k' \bar{p}_{tr}(\bar{\Delta}_k)\| \le \omega_2(\alpha_k \eta_k + 1 - \alpha_k)\|x_k - x^*\|_* \\ &= \bar{\epsilon}_k\, \|x_k - x^*\|_*. \end{aligned} \tag{4.46}$$

Using (4.36) and proceeding as in (4.23), we obtain

$$\|x_k + q - x^*\|_* \le \omega_1 \|F(x_k + q)\| \le \omega_1(\Gamma \|q\|^2 + \|F_k + F_k' q\|)$$

for any vector $x_k + q \in B_{\rho_3}(x^*)$. Then (4.40), (4.46), and (4.45) give

$$\|x_k + p(\bar{\Delta}_k) - x^*\|_* \le \epsilon_k\, \|x_k - x^*\|_*. \tag{4.47}$$

Note that $\omega_1 \to 1$, $\omega_2 \to 1$ as $\Gamma \to 0$. Since $\alpha_k \to 1$ as $k \to \infty$, there exist Γ and ζ sufficiently small such that

$$\omega_1 \omega_2 < \frac{\bar{\eta}}{\eta_{max}}, \qquad \bar{\epsilon}_k < \frac{\bar{\eta}}{\omega_1} < \frac{1}{\omega_1}, \qquad \text{and} \qquad \epsilon_k < \bar{\eta} \tag{4.48}$$

whenever $x_k \in B_\zeta(x^*) \cap \mathrm{int}(\Omega)$ for k sufficiently large. As a consequence, eventually $p(\bar{\Delta}_k)$ satisfies (2.9). In fact, following along the lines of Theorem 4.3 and using (4.46), (4.40), and (4.36), we obtain

$$\begin{aligned} \rho_f(p(\bar{\Delta}_k)) &= 1 - \frac{\|F(x_k + p(\bar{\Delta}_k))\|^2 - \|F_k + F_k' p(\bar{\Delta}_k)\|^2}{\|F_k\|^2 - \|F_k + F_k' p(\bar{\Delta}_k)\|^2} \\ &\ge 1 - \frac{\Gamma^2 \|p(\bar{\Delta}_k)\|^4 + 2\Gamma \bar{\epsilon}_k \|p(\bar{\Delta}_k)\|^2 \|x_k - x^*\|_*}{(\frac{1}{\omega_1^2} - \bar{\epsilon}_k^2)\|x_k - x^*\|_*^2} \\ &\ge 1 - \frac{\Gamma \nu_*^2 (\Gamma \nu_*^2 \|x_k - x^*\|_* + 2\bar{\epsilon}_k)\|x_k - x^*\|_*}{\frac{1}{\omega_1^2} - \bar{\epsilon}_k^2}. \end{aligned}$$

Hence for k sufficiently large, $\rho_f(p(\bar{\Delta}_k)) \geq \beta_2$, $x_{k+1} = x_k + p(\bar{\Delta}_k)$, and from (4.47) and (4.48) the proof is completed. □

We conclude this section by noting that the assumption (4.43) is guaranteed whenever x^* belongs to the interior of Ω, as $\|p_{tr}(\bar{\Delta}_k)\|$ tends to zero, while it is an additional condition when x^* lies on the boundary of Ω. This assumption allows us to obtain (4.47) where $\epsilon_k < \bar{\eta}$ as $k \to \infty$. This yields linear convergence in the weighted norm for any $\bar{\eta} < 1$. On the contrary, if $P(x_k + p_{tr}(\bar{\Delta}_k)) - x_k \neq p_{tr}(\bar{\Delta}_k)$, proceeding as in Lemma 4.4, we cannot derive a bound on $\|x_k + p(\bar{\Delta}_k) - x^*\|_*$ with analogous properties. In fact, we only manage to get a bound of the form (4.47) where $\epsilon_k < \bar{\eta}\,\chi_J K_2$ for k sufficiently large.

5. Applications. To develop viable approaches for large-scale problems, this section discusses the two issues left unspecified in the description of the SIATR method: the choice of the subspace S_k and the way of solving the subspace trust-region problem (3.1).

Since there is no finite method of determining the exact solution of (3.1), an approximation to it is used. Remarkably, it is easy to see that the convergence properties of the SIATR method take place using an approximate solution $p_{tr}(\Delta_k)$ to (3.1) which satisfies the following two mild conditions:

(a) $m_k(p_{tr}(\Delta_k)) \leq m_k(0)$;

(b) $p_{tr}(\Delta_k) = p_k$ when p_k is feasible for (3.1).

The key is that global convergence is provided by $p_c(\Delta_k)$ and rapid local convergence is ensured if eventually p_k is the solution of (3.1).

We outline a subspace dogleg strategy for solving (3.1) approximately. Let $S_k = span\{s_1, s_2, \ldots, s_r\}$, $S_k^G = span\{G_k s_1, G_k s_2, \ldots, G_k s_r\}$. Once an orthonormal basis $W \in \mathbb{R}^{n\times r}$ for S_k^G has been constructed, a vector $p \in S_k$ is such that $G_k p = Wq$ for some $q \in \mathbb{R}^r$, and instead of (3.1), one can consider the spherical trust-region problem

$$\min_{q\in\mathbb{R}^r} \{\phi_k(q) : \quad \|q\| \leq \Delta_k\}, \tag{5.1}$$

where ϕ_k is the quadratic model on $\mathbb{R}^r$

$$\phi_k(q) = \frac{1}{2}\|F_k + F_k' G_k^{-1} W q\|^2. \tag{5.2}$$

Let $q_{tr}(\Delta_k)$ be the dogleg solution to (5.1); see [10]. Its evaluation calls for the Cauchy point $q_c(\Delta_k)$ for (5.1) and for the vector

$$q_k = \operatorname*{argmin}_{q\in\mathbb{R}^r} \phi_k(q). \tag{5.3}$$

We remark that $q_k = W^T G_k p_k$ with p_k given in (3.2). Therefore, if one of the two vectors p_k and q_k is known, the other one can be trivially evaluated.

Once $q_{tr}(\Delta_k)$ has been computed, coming back into the original space, the vector

$$p_{tr}(\Delta_k) = G_k^{-1} W q_{tr}(\Delta_k) \tag{5.4}$$

is built. It approximately solves (3.1) and satisfies both (a) and (b). In fact, (a) is straightforward and (b) is due to the fact that $G_k p_k \in S_k^G$, i.e., $WW^T G_k p_k = G_k p_k$. This yields $\|q_k\| = \|W^T G_k p_k\| = \|G_k p_k\|$. Then q_k is feasible for (5.1) if p_k is feasible for (3.1). Consequently, $q_{tr}(\Delta_k) = q_k$ whenever $\|q_k\| \leq \Delta_k$, and this implies $p_{tr}(\Delta_k) = p_k$ whenever $\|G_k p_k\| \leq \Delta_k$.

This discussion leads to the subspace dogleg strategy sketched below.

ALGORITHM II. A subspace dogleg strategy for (3.1).
Input parameters $x_k \in \mathrm{int}(\Omega)$, $\Delta_k > 0$, $\eta_k \in [0,1)$, G_k, ∇f_k.

1. Choose a subspace $S_k = span\{s_1, s_2, \ldots, s_r\}$ such that (3.2) holds.
2. Find an orthonormal basis $W \in \mathbb{R}^{n\times r}$ for $S_k^G = span\{G_k s_1, G_k s_2, \ldots, G_k s_r\}$.
3. Compute the vector $q_k \in \mathbb{R}^r$ satisfying (5.3).
4. Compute the Cauchy step $q_c(\Delta_k) = -\hat{\mu}_k W^T G_k^{-1} \nabla f_k$ with

$$\begin{aligned} \hat{\mu}_k &= \operatorname*{argmin}_{\|\mu W^T G_k^{-1}\nabla f_k\| \le \Delta_k} \phi_k(-\mu W^T G_k^{-1}\nabla f_k) \\ &= \min\left\{ \frac{\|W^T G_k^{-1}\nabla f_k\|^2}{\|F_k' G_k^{-1} W W^T G_k^{-1}\nabla f_k\|^2}, \frac{\Delta_k}{\|W^T G_k^{-1}\nabla f_k\|} \right\}. \end{aligned} \tag{5.5}$$

5. Find the dogleg solution $q_{tr}(\Delta_k)$ to (5.1):

$$q_{tr}(\Delta_k) = \begin{cases} q_k & \text{if } \|q_k\| \le \Delta_k, \\ q_c(\Delta_k) & \text{if } \|q_c(\Delta_k)\| = \Delta_k, \\ sq_k + (1-s)q_c(\Delta_k), s \in (0,1), \text{ s.t. } \|q_{tr}(\Delta_k)\| = \Delta_k & \text{otherwise.} \end{cases}$$

6. Compute $p_{tr}(\Delta_k)$ by (5.4).

We recall that (3.2) holds whenever the subspace S_k contains an inexact Newton step p_k^I for the problem $F(x) = 0$ such that

$$F_k' p_k^I = -F_k + r_k, \qquad \|r_k\| \le \eta_k \|F_k\|. \tag{5.6}$$

Our main purpose now is to show that Krylov subspace methods for solving (5.6) provide the way to perform steps 1–3 of the above algorithm effectively. The resulting methods belong to the class of trust-region Newton–Krylov methods [6, 7, 15]. Moreover, thanks to our convergence results, the linear system (5.6) can be solved with an accuracy that increases as the solution is approached, and oversolving can be avoided by choosing suitable sequences $\{\eta_k\}$; see [27].

Two-dimensional subspace minimization. A possible approach consists in determining p_k^I by a Krylov method and fixing

$$S_k = span\{p_k^I, G_k^{-2}\nabla f_k\}.$$

This way, Algorithm II sketches a two-dimensional subspace trust-region strategy. Step 2 requires one step of the Gram–Schmidt procedure to compute W. The least-squares problem $\min_{q\in\mathbb{R}^2} \|F_k + F_k' G_k^{-1} W q\|^2$ in step 3 can be solved without much effort either by the QR factorization of the $n \times 2$ matrix $F_k' G_k^{-1} W$ or by solving the normal equations.

In the case $G_k = D_k$, $k \ge 0$, the vector $p_{tr}(\Delta_k)$ produces as much decrease in the quadratic model m_k as the generalized Cauchy point $p_c(\Delta_k)$. To show this fact, note that by $d_k \in S_k$ and $G_k d_k = -D_k^{-1}\nabla f_k \in S_k^G$, it trivially follows that $D_k^{-1}\nabla f_k = W W^T D_k^{-1}\nabla f_k$. Consequently, it is easy to see that $G_k^{-1} W q_c(\Delta_k) = \hat{\tau}_k d_k$, where $\hat{\tau}_k$ is given in (2.6) and

$$m_k(p_{tr}(\Delta_k)) = \phi_k(q_{tr}(\Delta_k)) \le \phi_k(q_c(\Delta_k)) = m_k(p_c(\Delta_k)),$$

i.e., $p_{tr}(\Delta_k)$ satisfies (2.8).

GMRES subspace strategy. Another implementation of the subspace dogleg strategy can be proposed in connection with the GMRES method [31]. GMRES shows a certain optimality among all Krylov methods, BICGSTAB, TFQMR etc., commonly used in the solution of general linear systems. In practice, it minimizes the residual norm $(2\,m_k(p))^{\frac{1}{2}} = \|F_k + F_k'\,p\|$ over all corrections in the current Krylov subspace. Due to this property it is possible to define subspace dogleg strategies using information provided by GMRES; see, e.g., [6, 7, 20].

For the sake of clarity, we sketch the application of GMRES to $F_k'p = -F_k$ in order to solve (5.6). For details we refer to [31]. Given $p_k^0 \in \mathbb{R}^n$, GMRES generates a sequence of iterates $\{p_k^m\}$, $p_k^m \in \mathbb{R}^n$, $m \geq 0$, until $\|F_k'\,p_k^m + F_k\| \leq \eta_k \|F_k\|$. Then $p_k^I = p_k^m$ is set. Each vector p_k^m solves the least-squares problem

$$\min_{p \in p_k^0 + K_m} \|F_k + F_k'\,p\|, \tag{5.7}$$

where K_m is the Krylov subspace $K_m = span\{r_k^0, F_k' r_k^0, (F_k')^2 r_k^0, \ldots, (F_k')^{m-1} r_k^0\}$ and $r_k^0 = -F_k'\,p_k^0 - F_k$. To accomplish the solution of (5.7), GMRES computes an orthonormal basis $V_m = [v_1, \ldots, v_m] \in \mathbb{R}^{n \times m}$ of K_m by the Arnoldi process. It is known that $F_k' V_m = V_{m+1} H_m$, where $V_{m+1} = [v_1, \ldots, v_{m+1}] \in \mathbb{R}^{n \times (m+1)}$ is the orthonormal basis for K_{m+1} and $H_m \in \mathbb{R}^{(m+1) \times m}$ is an Hessenberg matrix. The QR factorization of H_m is required and cheaply performed for all $m \geq 0$.

Typically the restarted procedure GMRES(m_M) is applied. Suppose the vector p_k^I is generated using the GMRES(m_M) method. By construction, p_k^I minimizes $m_k(p)$ within the affine subspace $p_k^0 + K_m$. Then if $p_k^0 = 0$, it is convenient to perform steps 1–3 of the subspace dogleg strategy as follows. Setting

$$S_k = K_m,$$

trivially, we get $p_k = p_k^I$. Moreover, $W = V_m$ if $G_k = I$, $k \geq 0$, while for the other choice of G the matrix W has to be computed. Finally, step 3 is completed by setting $q_k = W^T G_k p_k$.

If $p_k^0 \neq 0$, let

$$S_k = span\{v_1, \ldots, v_m, p_k^0\}.$$

If $G_k = I$, $k \geq 0$, an orthonormal basis W for S_k is easily obtained adding one column to the matrix V_m. Such a column can be computed with one step of the Gram–Schmidt procedure. Otherwise, the whole matrix W must be computed. To evaluate q_k we compute the solution p_k to problem (3.2) and let $q_k = W^T G_k p_k$. In particular, letting $T_k = [V_m, p_k^0] \in \mathbb{R}^{n \times r}$, $r = m + 1$, p_k has the form

$$p_k = T_k y_k, \qquad y_k = \operatorname*{argmin}_{y \in \mathbb{R}^r} \|F_k + F_k'\,T_k\,y\|.$$

If the columns of $F_k'\,T_k$ are linearly independent, i.e., the columns of T_k are linearly independent, the solution y_k is unique. Moreover, the Cholesky factorization $R_k^T R_k$ of the matrix $(F_k'\,T_k)^T F_k'\,T_k \in \mathbb{R}^{r \times r}$ can be computed, exploiting the QR factorization of the Hessenberg matrix H_m provided by GMRES and solving one upper triangular system of dimension m; see [6]. A complication to this global strategy arises when $F_k' T_k$ is ill-conditioned. We can monitor this occurrence estimating the condition number of the small matrix R_k. If such a number is greater than a fixed threshold, we may perturb the quadratic model $\|F_k + F_k'\,T_k\,y\|^2$ following the strategy given in [13, p. 151].

Finally, we make some comments on the use of preconditioning techniques. Let P^{-1} be the preconditioner employed. Since our stopping criterion for computing the inexact Newton step p_k^I is based on the unpreconditioned residuals, we focus on the linear system $F_k' P^{-1} s = -F_k$ with $p = P^{-1} s$. Without loss of generality, we concentrate on the case where a null initial guess for GMRES, $s_k^0 = 0$, is chosen, restart is not used, and the choice $G_k = I$, $k \geq 0$, is adopted. Then the Krylov space generated by GMRES has the form

$$K_m^p = \{r_k^0, (F_k' P^{-1}) r_k^0, (F_k' P^{-1})^2 r_k^0, \ldots, (F_k' P^{-1})^{m-1} r_k^0\},$$

where $r_k^0 = -F_k$. Clearly, the vector $s_k^I \in K_m^p$ such that $\|F_k' P^{-1} s_k^I + F_k\| \leq \eta_k \|F_k\|$ gives rise to the vector $p_k^I = P^{-1} s_k^I$ satisfying (5.6).

To design the subspace dogleg strategy, it is convenient to set $S_k = span\{P^{-1} v_1, P^{-1} v_2, \ldots, P^{-1} v_m\}$, where $v_1, \ldots, v_m$ is the orthonormal basis of K_m^p computed by GMRES. This way, $p_k^I \in S_k$ and $p_k = p_k^I$ holds. Moreover, computing an orthonormal basis for S_k requires the application of an orthonormalization procedure.

6. Numerical experiments. In this section, some computational results are discussed to illustrate the viability of our proposals. They have been selected to show the behavior of both of the subspace dogleg strategies on problems with different features and are not meant to be exhaustive.

We implemented the SIATR method with spherical trust regions, $G_k = I$, $k \geq 0$, in a Fortran code. We refer to the SIATR method with the two-dimensional subspace strategy as `SIATR-2D` and to the SIATR method with the GMRES subspace strategy as `SIATR-G`.

The inexact Newton step p_k^I was computed using the iterative linear solver GMRES with null initial guess [31]. Restart was not employed and a maximum of 50 GMRES iterations was allowed. If after 50 GMRES iterations condition (5.6) had not been met, our algorithm continued with p_k^I given by the last computed GMRES iterate.

In all runs, we set $\bar{\Delta}_0 = 1$, $\Delta_{min} = \sqrt{\epsilon_m}$, where ϵ_m denotes the machine precision, $\beta_1 = 0.1$, $\beta_2 = 0.25$, $\theta = 0.99995$. For the computation of the projected step (3.4) we used $\alpha_k = \max\{0.95, 1 - \|F_k\|\}$, $k > 0$. The strategy for updating Δ_k was the same as in [3, p. 17]

Here we report numerical experiments performed with machine precision $\epsilon_m = 2 \times 10^{-16}$ on a 1.7 GHz Intel Pentium M with 512K cache. Convergence is declared when $\|F_k\| \leq 10^{-8}$, while failure is declared when a maximum number of 200 iterations are performed. We conducted experiments with two choices of the forcing terms η_k proposed in [27]: *Choice* 1 and *Choice* 2. In our implementation we use $\eta_0 = 0.9$ and the safeguards suggested in [27, p. 305]. In Choice 2 we set the parameters as $\gamma = 0.9$ and $\alpha = 2$.

For the purpose of this presentation we consider two representative test problems: the seven diagonal problem [23] and the Bratu complementarity problem [14]. The first problem was solved with $n = 5000$. It has more than one solution, and in order to approximate the positive solution, we formulated it as a bound-constrained nonlinear system with $l_i = 0$, $u_i = \infty$, $i = 1, \ldots, n$. The Bratu complementarity problem was reformulated as a system of $n = 5 \times 10^4$ smooth bound-constrained nonlinear equations with $l_i = 0$ and $u_i = \infty$ for $i = 1, \ldots, n$. It depends on a parameter λ and we considered the value $\lambda = 6$.

The two problems display different features: the seven diagonal problem has the solution in the interior of Ω and preconditioning is not required. On the other hand

TABLE 6.1
Performance with Choice 1 *and Choice* 2 *of* η_k*'s.*

		Seven diagonal						Bratu					
		SIATR-2D			SIATR-G			SIATR-2D			SIATR-G		
η_k	l	NIT	NF	NLIT	NIT	NF	NLIT	NIT	NF	NLIT	NIT	NF	NLIT
Choice 1	0	34	35	377	37	38	514	30	31	197	28	29	257
	1	*	*	*	40	41	632	30	31	373	29	30	297
	2	20	21	65	20	21	65	30	31	432	30	31	443
	3	38	41	104	35	37	89	*	*	*	*	*	*
Choice 2	0	22	23	157	24	25	243	18	19	355	15	16	195
	1	62	66	1284	27	28	251	19	20	406	16	17	304
	2	7	8	65	7	8	67	19	20	358	20	21	408
	3	33	38	112	29	35	106	*	*	*	*	*	*

the solution of the Bratu problem lies on the boundary of the feasible set and a preconditioner is needed to speed up the convergence of GMRES. In our runs we employed the ILU(0) preconditioner. For both problems we used four initial guesses: $x_0^{(l)} = 10^{l-2}$ with $l = 0, 1, 2, 3$.

In reporting the numerical results we provide the following: the parameter l used to form the initial guess; the number NIT of nonlinear iterations; the number NF of function evaluations; and the number NLIT of linear iterations performed by GMRES. An asterisk indicates a failure.

Table 6.1 shows the performance of the subspace dogleg strategies achieved with both choices of η_k's. It gives an indication of the computational cost in terms of nonlinear iterations and GMRES iterations. The SIATR-G method seems to perform slightly better in terms of nonlinear iterations and GMRES iterations. This behavior could be predictable since in the SIATR-G method we search for an approximate trust-region solution within a subspace of dimension larger than two. On the other hand, as we pointed out in the previous section, performing the GMRES Subspace strategy may be more expensive than performing the two-dimensional subspace strategy. Hence, for the runs where the two approaches are comparable in terms of linear and nonlinear iterations, the overall cost of the SIATR-2D method may be expected to be lower. However, comparing the two strategies in terms of execution time, it comes out that the extra work for the GMRES subspace strategy has a minor impact on the overall performance of the SIATR-G method.

7. Conclusions. We have introduced a prototype trust-region method for large bound-constrained nonlinear systems. The proposed method involves the solution of the subspace trust-region problems (3.1). The crucial issue in such an approach is the choice of the subspaces S_k. We have investigated this point, showing how to choose such subspaces in order to ensure both strong convergence properties and practical viability in the large scale setting. The convergence results provided are in accordance with those of inexact Newton methods for unconstrained nonlinear systems. To our knowledge, this is the first contribution in interior methods for general large-scale nonlinear systems with simple bounds.

We have implemented algorithms that are based on the proposed paradigm. They are consistent with the convergence theory and involve Krylov methods to construct the subspaces S_k. The numerical results provided indicate that our subspace trust-region approaches are a promising tool for large-scale computation.

Acknowledgment. We would like to thank one of the referees for carefully reading the manuscript and for several suggestions that improved the presentation of this work.

ON THE STABILITY OF EVOLUTION GALERKIN SCHEMES APPLIED TO A TWO-DIMENSIONAL WAVE EQUATION SYSTEM*

M. LUKÁČOVÁ-MEDVIĎOVÁ†, G. WARNECKE‡, AND Y. ZAHAYKAH‡

Abstract. The subject of the paper is the analysis of stability of the evolution Galerkin (EG) methods for the two-dimensional wave equation system. We apply von Neumann analysis and use the Fourier transformation to estimate the stability limits of both the first and the second order EG methods.

Key words. hyperbolic systems, wave equation, evolution Galerkin schemes, discrete Fourier transformation, amplification matrix, CFL condition

1. Introduction.

Evolution Galerkin (EG) methods were proposed to approximate first order hyperbolic problems. These schemes were introduced by Lin, Morton, and Süli; see, e.g., [8] for scalar problems and [9] for one-dimensional systems. The first generalization to two-dimensional systems was made in [23] by Ostkamp for the wave equation system as well as for the Euler equations of gas dynamics. In [13] Lukáčová-Medvid'ová, Morton, and Warnecke studied systematically approximate evolution operators and constructed new EG schemes with better accuracy and stability properties. Further EG schemes as well as the approximate evolution operator of the solution for the wave equation system in three space dimensions were derived in [28]. These methods and their finite volume versions were applied to the linearized Euler equations and Maxwell equations [16]. Higher order finite volume EG (FVEG) methods have been introduced and studied in [12], [14], [15], and [17]. In [11], [15], [6] the FVEG schemes have been generalized to fully nonlinear systems of hyperbolic conservation laws, such as the Euler equations of gas dynamics, shallow water equations, and the shallow water magnetohydrodynamic equations. For hyperbolic conservation laws with source terms, the so-called well-balanced FVEG schemes are proposed in [20]. In general, the FVEG schemes produce very accurate numerical solutions within CPU time comparable to some other well-known finite volume methods. In particular, genuinely multidimensional features, such as oblique shocks, are resolved very well; cf., e.g., [11], [15]. For example, it has been shown in [15] that the global error of the second order FVEG scheme using (7.1)–(7.3) and (8.1)–(8.3) is approximately six times smaller than the error of the Lax–Wendroff (rotated Richtmyer) scheme as well as of the second order wave propagation algorithm of LeVeque [7].

The FVEG methods belong to the class of the so-called genuinely multidimensional schemes. The goal is to have a method which approximates possibly all of the

infinitely many directions of wave propagation. The reader is referred, for example, to [3], [4], [7], [22], [25] for other genuinely multidimensional schemes.

The main objective of this paper is the analysis of the stability of the evolution Galerkin schemes. In [13] we have proven that the EG schemes are conditionally stable. However, the precise stability limits were not computed there. The goal of this paper is to find stability limits by analysis of the spectrum of the corresponding discrete operators for the EG as well as FVEG schemes; cf. [11], [13]. First, we consider the so-called EG3 scheme for the wave equation system in two space dimensions. We apply the discrete Fourier transform to obtain the amplification matrix. It turns out that its structure is too complex in order to derive precise stability limits theoretically. Anyway, we find theoretical stability estimates for a simplified problem. This is then compared with the experimental estimate of the spectrum of the amplification matrix of the EG3 scheme.

Further, we derive amplification matrices for the first- and the second order FVEG schemes based on the approximate evolution operators. The spectral radius of the amplification matrices is estimated experimentally by a built-in MATLAB procedure. Hence the stability limit of the schemes is estimated numerically.

The outline of this paper is as follows: in the next section we survey the general theory that we used to derive the exact integral equations. The exact integral equations as well as the approximate evolution operators for the two-dimensional wave equation system are given in section 3. In section 4 we recall the evolution Galerkin schemes. In section 5 we introduce the discrete Fourier transform as well as the spectral norm that serve as tools in our analysis. In section 6 we present the derivation of a stability condition for a simplified problem and compare the theoretical estimate, which we obtained by means of the Fourier analysis, with the experimental limit of the original problem. In section 7 we consider the first order finite volume schemes based on the approximate evolution operator E_Δ^{const}. We determine the amplification matrices and estimate their stability limits. Finally in section 8 we determine the amplification matrices of the second order finite volume schemes based on the approximate evolution operator E_Δ^{bilin} and estimate the stability limits.

2. General theory. In this section we recall the exact integral equations for a general linear hyperbolic system using the concept of bicharacteristics. Consider a general form of linear hyperbolic system

$$\mathbf{U}_t + \sum_{k=1}^{d} \mathcal{A}_k \mathbf{U}_{x_k} = 0, \;\; \mathbf{x} = (x_1, \ldots, x_d)^T \in \mathbb{R}^d, \tag{2.1}$$

where the coefficient matrices $\mathcal{A}_k$, $k = 1, \ldots, d$, are elements of $\mathbb{R}^{p\times p}$ and the dependent variables are $\mathbf{U} = (u_1, \ldots, u_p)^T = \mathbf{U}(\mathbf{x}, t) \in \mathbb{R}^p$. Let $\mathcal{A}(\mathbf{n}) = \sum_{k=1}^{d} n_k \mathcal{A}_k$ be the *pencil matrix*, where $\mathbf{n} = (n_1, \ldots, n_d)^T$ is a unit vector in $\mathbb{R}^d$. Since the system (2.1) is hyperbolic the matrix $\mathcal{A}(\mathbf{n})$ has p real eigenvalues λ_k, $k = 1, \ldots, p$, and p corresponding linearly independent right eigenvectors $\mathbf{r}_k = \mathbf{r}_k(\mathbf{n})$, $k = 1, \ldots, p$. Let $\mathcal{R} = [\mathbf{r}_1 | \mathbf{r}_2 | \ldots | \mathbf{r}_p]$ be the matrix of right eigenvectors. We define the characteristic variable $\mathbf{W} = \mathbf{W}(\mathbf{n})$ as $\partial \mathbf{W}(\mathbf{n}) = \mathcal{R}^{-1} \partial \mathbf{U}$. Since the system (2.1) has constant coefficient matrices $\mathcal{A}_k$ we have $\mathbf{W} = \mathcal{R}^{-1}\mathbf{U}$ or $\mathbf{U} = \mathcal{R}\,\mathbf{W}$.

Transforming system (2.1) by multiplying it with $\mathcal{R}^{-1}$ from the left we get

$$\mathcal{R}^{-1}\mathbf{U}_t + \sum_{k=1}^{d} \mathcal{R}^{-1}\mathcal{A}_k \mathcal{R}\, \mathcal{R}^{-1}\mathbf{U}_{x_k} = 0. \tag{2.2}$$

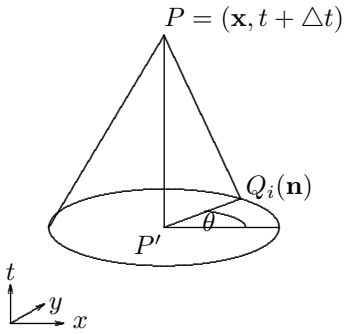

FIG. 1. *Bicharacteristics along the Mach cone through P and $Q_i(\mathbf{n})$, $d = 2$.*

Let $\mathcal{B}_k = \mathcal{R}^{-1}\mathcal{A}_k\mathcal{R} = (b_{ij}^k)_{i,j=1}^p$, where $k = 1, 2, \ldots, d$; then the system (2.2) can be rewritten in the following form using the characteristic variables:

$$\mathbf{W}_t + \sum_{k=1}^{d} \mathcal{B}_k \mathbf{W}_{x_k} = 0.$$

Now we decompose $\mathcal{B}_k$ into the diagonal part $\mathcal{D}_k$ and the remaining part $\mathcal{B}'_k$, i.e., $\mathcal{B}_k = \mathcal{D}_k + \mathcal{B}'_k$. We obtain

$$\mathbf{W}_t + \sum_{k=1}^{d} \mathcal{D}_k \mathbf{W}_{x_k} = -\sum_{k=1}^{d} \mathcal{B}'_k \mathbf{W}_{x_k} =: \mathbf{S}. \tag{2.3}$$

The ith bicharacteristic corresponding to the ith equation of (2.3) is defined by

$$\frac{d\mathbf{x}_i}{d\tilde{t}} = \mathbf{b}_{ii}(\mathbf{n}) = (b_{ii}^1, b_{ii}^2, \ldots, b_{ii}^d)^T,$$

where $i = 1, \ldots, p$. The diagonal entries b_{ii}^k of the matrices $\mathcal{B}_k$, $k = 1, \ldots, d$, $i = 1, \ldots, p$, create the ray velocity vector $\mathbf{b}_{ii}$; cf. [1]. We consider the bicharacteristics backwards in time and set the initial conditions $\mathbf{x}_i(t + \Delta t, \mathbf{n}) = \mathbf{x}$ for all $\mathbf{n} \in \mathbb{R}^d$ and $i = 1, \ldots, p$, i.e., $\mathbf{x}_i(\tilde{t}, \mathbf{n}) = \mathbf{x} - \mathbf{b}_{ii}(\mathbf{n})(t + \Delta t - \tilde{t})$.

We will integrate the ith equation of the system (2.3) from the point $P \equiv (\mathbf{x}, t + \Delta t) \in \mathbb{R}^p \times \mathbb{R}_+$ down to the point $Q_i(\mathbf{n}) = (\mathbf{x}_i(t, \mathbf{n}), t) = (\mathbf{x} - \Delta t \mathbf{b}_{ii}, t)$, where the bicharacteristic hits the plane at time t; see Figure 1. Note that bicharacteristics are straight lines because the system is linear and has constant coefficients. Now the ith equation reads

$$\frac{\partial w_i}{\partial t} + \sum_{k=1}^{d} b_{ii}^k \frac{\partial w_i}{\partial x_k} = -\left(\sum_{j=1, i\neq j}^{d} \left(b_{ij}^1 \frac{\partial w_j}{\partial x_1} + b_{ij}^2 \frac{\partial w_j}{\partial x_2} + \cdots + b_{ij}^d \frac{\partial w_j}{\partial x_d} \right) \right) = S_i. \tag{2.4}$$

Taking a vector $\sigma_i = (b_{ii}^1, b_{ii}^2, \ldots, b_{ii}^d, 1)$, we can define the directional derivative

$$\frac{dw_i}{d\sigma_i} = \left(\frac{\partial w_i}{\partial x_1}, \frac{\partial w_i}{\partial x_2}, \ldots, \frac{\partial w_i}{\partial x_d}, \frac{\partial w_i}{\partial t} \right) \cdot \sigma_i = \frac{\partial w_i}{\partial t} + b_{ii}^1 \frac{\partial w_i}{\partial x_1} + b_{ii}^2 \frac{\partial w_i}{\partial x_2} + \cdots + b_{ii}^d \frac{\partial w_i}{\partial x_d}.$$

Hence the ith equation (2.4) can be rewritten as follows:

$$\frac{dw_i}{d\sigma_i} = S_i = -\sum_{j=1, i\neq j}^{d} \left(b_{ij}^1 \frac{\partial w_j}{\partial x_1} + b_{ij}^2 \frac{\partial w_j}{\partial x_2} + \cdots + b_{ij}^d \frac{\partial w_j}{\partial x_d} \right).$$

Integration from P to $Q_i(\mathbf{n})$ gives

$$w_i(P) - w_i(Q_i(\mathbf{n})) = S_i', \tag{2.5}$$

where

$$S_i' = \int_t^{t+\Delta t} S_i(\mathbf{x}_i(\tilde{t},\mathbf{n}),\tilde{t},\mathbf{n})d\tilde{t} = \int_0^{\Delta t} S_i(\mathbf{x}_i(t+\Delta t-\tau,\mathbf{n}),t+\Delta t-\tau,\mathbf{n})\mathrm{d}\tau.$$

The reverse transformation of (2.5) into a system written in the original physical variables is done by multiplication with $\mathcal{R}$ from the left and $(d-1)$-dimensional integration of the variable $\mathbf{n}$ over the unit sphere O in $\mathbb{R}^d$. This leads to the integral representation of the solution in the point $\mathbf{x}$ at time $t+\Delta t$:

$$\mathbf{U}(P) = \mathbf{U}(\mathbf{x},t+\Delta t) = \frac{1}{|O|}\int_O \mathcal{R}(\mathbf{n}) \begin{pmatrix} w_1(Q_1(\mathbf{n}),\mathbf{n}) \\ w_2(Q_2(\mathbf{n}),\mathbf{n}) \\ w_3(Q_3(\mathbf{n}),\mathbf{n}) \\ \vdots \\ w_p(Q_p(\mathbf{n}),\mathbf{n}) \end{pmatrix} \mathrm{d}O + \tilde{\mathbf{S}}, \tag{2.6}$$

where

$$\tilde{\mathbf{S}} = (\tilde{S}_1,\tilde{S}_2,\ldots,\tilde{S}_p)^T = \frac{1}{|O|}\int_O \mathcal{R}(\mathbf{n})\mathbf{S}'\mathrm{d}O = \frac{1}{|O|}\int_O\int_0^{\Delta t} \mathcal{R}(\mathbf{n})\mathbf{S}(t+\Delta t-\tau,\mathbf{n})\mathrm{d}\tau\mathrm{d}O$$

and $|O|$ corresponds to the measure of the domain of integration.

3. Exact integral equations and approximate evolution operators for the wave equation system. In this section we illustrate the application of the general theory of bicharacteristics for the two-dimensional system of wave equations. We recall the exact integral equations and present their possible approximation, the so-called EG3 approximate evolution operator. Consider the two-dimensional wave equation system

$$\begin{aligned} \phi_t + c(u_x + v_y) &= 0, \\ u_t + c\phi_x &= 0, \\ v_t + c\phi_y &= 0, \end{aligned} \tag{3.1}$$

where c is a given positive constant representing the speed of sound. We will recall here the exact integral equations derived in [13]. Let $P = (x,y,t+\Delta t)$, $P' = (x,y,t)$, $Q = (x + c\Delta t\cos\theta, y + c\Delta t\sin\theta, t) = (\mathbf{x} + c\Delta t\mathbf{n}(\theta), t)$ and let the so-called source term be given as

$$S = c\left[u_x\sin^2\theta - (u_y+v_x)\sin\theta\cos\theta + v_y\cos^2\theta\right]; \tag{3.2}$$

then *exact integral equations* for the wave equation system (3.1) are given as

$$\phi_P = \frac{1}{2\pi}\int_0^{2\pi} (\phi_Q - u_Q\,\cos\theta - v_Q\,\sin\theta)\,\mathrm{d}\theta + \tilde{S}_1, \tag{3.3}$$

$$u_P = \frac{1}{2}u_{P'} + \frac{1}{2\pi}\int_0^{2\pi} (-\phi_Q\,\cos\theta + u_Q\,\cos^2\theta + v_Q\,\sin\theta\,\cos\theta)\,\mathrm{d}\theta + \tilde{S}_2, \tag{3.4}$$

$$v_P = \frac{1}{2}v_{P'} + \frac{1}{2\pi}\int_0^{2\pi} (-\phi_Q\,\sin\theta + u_Q\,\cos\theta\,\sin\theta + v_Q\,\sin^2\theta)\,\mathrm{d}\theta + \tilde{S}_3, \tag{3.5}$$

where

$$\tilde{S}_1 = \frac{-1}{2\pi}\int_0^{2\pi}\int_0^{\triangle t} S(\mathbf{x}+c\tau\mathbf{n}(\theta), t+\Delta t-\tau,\theta)\,\mathrm{d}\tau\,\mathrm{d}\theta,$$

$$\tilde{S}_2 = \frac{1}{2\pi}\int_0^{2\pi}\int_0^{\triangle t} \cos\theta S(\mathbf{x}+c\tau\mathbf{n}(\theta), t+\Delta t-\tau,\theta)\,\mathrm{d}\tau\,\mathrm{d}\theta$$

$$-\frac{1}{2\pi}\int_0^{2\pi}\int_0^{\triangle t} \left[c\phi_x(\mathbf{x}, t+\Delta t-\tau)\sin^2\theta - c\phi_y(\mathbf{x}, t+\Delta t-\tau)\sin\theta\cos\theta\right]\,\mathrm{d}\tau\,\mathrm{d}\theta,$$

$$\tilde{S}_3 = \frac{1}{2\pi}\int_0^{2\pi}\int_0^{\triangle t} \sin\theta S(\mathbf{x}+c\tau\mathbf{n}(\theta), t+\Delta t-\tau,\theta)\,\mathrm{d}\tau\,\mathrm{d}\theta$$

$$-\frac{1}{2\pi}\int_0^{2\pi}\int_0^{\Delta t} \left[c\phi_y(\mathbf{x}, t+\Delta t-\tau)\cos^2\theta - c\phi_x(\mathbf{x}, t+\Delta t-\tau)\sin\theta\cos\theta\right]\,\mathrm{d}\tau\,\mathrm{d}\theta.$$

The above integral equations give us an implicit formulation of the solution at the point $P = (x, y, t^{n+1})$. In order to obtain an explicit numerical scheme it is necessary to use numerical quadrature rules in order to approximate the time integral from 0 to Δt. Using the backward rectangle rule leads to an $\mathcal{O}(\Delta t^2)$ approximation of the time integrals appearing in $\tilde{S}_1$, $\tilde{S}_2$, and $\tilde{S}_3$. Further we use the following result [13, Lemma 2.1]:

$$\Delta t\int_0^{2\pi} S(t,\theta)\mathrm{d}\theta = \int_0^{2\pi}(u\cos\theta + v\sin\theta)\mathrm{d}\theta,$$

$$\Delta t\int_0^{2\pi} S(t,\theta)\cos\theta\mathrm{d}\theta = \int_0^{2\pi}(u\cos 2\theta + v\sin 2\theta)\mathrm{d}\theta,$$

$$\Delta t\int_0^{2\pi} S(t,\theta)\sin\theta\mathrm{d}\theta = \int_0^{2\pi}(u\sin 2\theta + v\cos 2\theta)\mathrm{d}\theta. \tag{3.6}$$

Note that these formulae allow us to replace the derivatives of our dependent variables in S by the variables themselves. Rectangle rule approximation for the time integral and (3.6) yield the so-called EG3 approximate evolution operator.

Approximate evolution operator for EG3.

$$\phi_P = \frac{1}{2\pi}\int_0^{2\pi}(\phi_Q - 2u_Q\cos\theta - 2v_Q\sin\theta)\mathrm{d}\theta + O(\Delta t^2), \tag{3.7}$$

$$u_P = \frac{1}{2}u_{P'} + \frac{1}{2\pi}\int_0^{2\pi}(-2\phi_Q\cos\theta + u_Q(3\cos^2\theta - 1) + 3v_Q\sin\theta\cos\theta)\mathrm{d}\theta + O(\Delta t^2), \tag{3.8}$$

$$v_P = \frac{1}{2}v_{P'} + \frac{1}{2\pi}\int_0^{2\pi}(-2\phi_Q\sin\theta + 3u_Q\sin\theta\cos\theta + v_Q(3\sin^2\theta - 1))\mathrm{d}\theta + O(\Delta t^2). \tag{3.9}$$

We refer the reader to [13, 28] for other approximate evolution operators EG1, EG2, EG4. In what follows we will concentrate on the stability analysis of the EG3 scheme, for which the best numerical results have been obtained; see [13]. The stability analysis for other schemes can be done in an analogous way.

4. Evolution Galerkin schemes. In this section we describe EG schemes in the finite difference framework as well as FVEG schemes. The main idea behind EG schemes is the following. Transported quantities are evolved in time along the bicharacteristics and then projected onto a finite element space. These methods connect finite element methods with the theory of bicharacteristics. In the finite volume framework the approximate operators are used only in order to compute fluxes on cell interfaces. Thus, instead of one-dimensional Riemann solvers, which work only in the normal directions to the cell interfaces, we compute the approximate solution at cell interfaces by a multidimensional evolution operator. This can be considered as a predictor step. In the corrector step the finite volume update is made.

Consider a mesh in $\mathbb{R}^2$, which consists of the square mesh cells

$$\begin{aligned}\Omega_{kl} &= \left[\left(k-\frac{1}{2}\right)h, \left(k+\frac{1}{2}\right)h\right] \times \left[\left(l-\frac{1}{2}\right)h, \left(l+\frac{1}{2}\right)h\right] \\ &= \left[x_k - \frac{h}{2}, x_k + \frac{h}{2}\right] \times \left[y_l - \frac{h}{2}, y_l + \frac{h}{2}\right],\end{aligned}$$

where $h > 0$ is the mesh size parameter, and $k, l \in \mathbb{Z}$. Let us denote by $E(s) : (L^2(\mathbb{R}^2))^p \to (L^2(\mathbb{R}^2))^p$ the exact evolution operator for a general hyperbolic system (2.1), i.e.,

$$\mathbf{U}(., t+s) = E(s)\mathbf{U}(., t). \tag{4.1}$$

We suppose that S_h^m is a finite element space consisting of piecewise polynomials of degree $m \geq 0$ with respect to the square mesh. Assume a constant time step, i.e., $t_n = n\Delta t$. Let $\mathbf{U}^n$ be an approximation in the space S_h^m to the exact solution $\mathbf{U}(., t_n)$ at time $t_n \geq 0$. We consider $E_\tau : (L^2(\mathbb{R}^2))^p \to (L^2(\mathbb{R}^2))^p$ to be a suitable approximate evolution operator for $E(\tau)$. In practice we will use restrictions of E_τ to the subspace S_h^m for $m \geq 0$. Then we can define the general class of EG methods as follows.

DEFINITION 4.1. *Starting from some initial data $\mathbf{U}^0 \in S_h^m$ at time $t = 0$, an* EG method *is recursively defined by means of*

$$\mathbf{U}^{n+1} = P_h E_\tau \mathbf{U}^n, \tag{4.2}$$

where P_h is the L^2-projection given by the integral averages in the following way:

$$P_h \mathbf{U}^n|_{\Omega_{kl}} = \frac{1}{|\Omega_{kl}|} \int_{\Omega_{kl}} \mathbf{U}(x, y, t_n) \mathrm{d}x\mathrm{d}y. \tag{4.3}$$

In this paper we will limit our considerations to the cases where $m = 0$. In this case the integrals that we obtain from the projection are evaluated either exactly using the fact that the approximate values $\mathbf{U}^n$ are piecewise constant or by means of some numerical quadrature rules. Using piecewise constants, the resulting schemes will only be of first order accuracy, even when E_τ is approximated to a higher order. Higher order accuracy can be obtained either by taking $m > 0$ or by inserting a recovery stage R_h before the evolution step in (4.2) to give

$$\mathbf{U}^{n+1} = P_h E_\tau R_h \mathbf{U}^n. \tag{4.4}$$

Here we have denoted by $R_h : S_h^m \to S_h^r$ a recovery operator, $r > m \geq 0$, and consider our approximate evolution operator E_τ on S_h^r. To implement (4.4), rather complex three-dimensional integrals need to be evaluated exactly. This approach seems to be hardly feasible for efficient derivation and implementation of higher order methods. A simplification that we used is to apply the multidimensional evolution only on the cell interfaces. This latter approach leads to the FVEG methods.

DEFINITION 4.2. *Starting from some initial data* $\mathbf{U}^0 \in S_h^m$, *the* finite volume evolution Galerkin (FVEG) method *is recursively defined by means of*

$$\mathbf{U}^{n+1} = \mathbf{U}^n - \frac{1}{h}\int_0^{\Delta t} \sum_{j=1}^{2} \delta_{x_j} \mathbf{f}_j(\tilde{\mathbf{U}}^{n+\frac{\tau}{\Delta t}}) \mathrm{d}\tau, \tag{4.5}$$

where $\delta_{x_j}\mathbf{f}_j(\tilde{\mathbf{U}}^{n+\frac{\tau}{\Delta t}})$ *represents an approximation to the edge flux difference and* δ_x *is defined by* $\delta_x v(x) = v(x+\frac{h}{2}) - v(x-\frac{h}{2})$. *The cell boundary value* $\tilde{\mathbf{U}}^{n+\frac{\tau}{\Delta t}}$ *is evolved using the approximate evolution operator* E_τ *to* $t_n + \tau$ *and averaged along the cell boundary, i.e.,*

$$\tilde{\mathbf{U}}^{n+\frac{\tau}{\Delta t}} = \sum_{k,l\in\mathbb{Z}} \left(\frac{1}{|\partial\Omega_{kl}|} \int_{\partial\Omega_{kl}} E_\tau R_h \mathbf{U}^n dS \right) \chi_{kl}, \tag{4.6}$$

where χ_{kl} *is the characteristic function of* $\partial\Omega_{kl}$.

For more details on higher order FVEG schemes, see [10], [15], [17], where the error analysis as well as numerical experiments are presented. Using the L^2-projection (4.3), the approximate evolution operator E_τ, and (4.5), (4.6), the EG and FVEG schemes can be written in the finite difference form

$$\mathbf{U}_{kl}^{n+1} = \mathbf{U}_{kl}^n + \sum_{r=1-}^{1} \sum_{s=-1}^{1} \mathcal{C}_{rs} \mathbf{U}_{k+r,l+s}^n, \tag{4.7}$$

where

$$\mathcal{C}_{rs} = \begin{pmatrix} \alpha_{rs}^1 & \beta_{rs}^1 & \gamma_{rs}^1 \\ \alpha_{rs}^2 & \beta_{rs}^2 & \gamma_{rs}^2 \\ \alpha_{rs}^3 & \beta_{rs}^3 & \gamma_{rs}^3 \end{pmatrix}. \tag{4.8}$$

Here the entries $\alpha_{rs}^m, \beta_{rs}^m, \gamma_{rs}^m$, $m = 1, 2, 3$, are chosen appropriately according to the approximate evolution operator E_τ used. In the appendix the stencil matrices α^m, β^m, and γ^m, $m = 1, 2, 3$, are displayed for some EG schemes.

5. Basic tools. As we mentioned above our stability considerations are based on Fourier analysis. We first recall some basic concepts; see, e.g., [24]. Let $\{\psi_{kl}^n\}_{k,l=-\infty}^{\infty}$ be a two-dimensional sequence in ℓ_2.

DEFINITION 5.1. *The discrete Fourier transformation of* $\{\psi_{kl}^n\} \in \ell_2$ *is the function* $\hat{\psi^n} \in L_2\big(\big[-\frac{\pi}{h}, \frac{\pi}{h}\big] \times \big[-\frac{\pi}{h}, \frac{\pi}{h}\big]\big)$ *defined by*

$$\hat{\psi}^n(\xi,\eta) = h^2 \sum_{k=-\infty}^{\infty} \sum_{l=-\infty}^{\infty} \psi_{kl}^n \exp^{-ih(k\xi+l\eta)}.$$

Similarly to the continuous Fourier transform, we have both an inverse formula and Parseval's identity.

LEMMA 5.2 (inverse formula). *If* $\{\psi_{kl}^n\} \in \ell_2$ *and* $\hat{\psi}^n$ *is the discrete Fourier transform of* $\{\psi_{kl}^n\}$*, then*

$$\psi_{kl}^n = \frac{1}{4\pi^2} \int_{-\frac{\pi}{h}}^{\frac{\pi}{h}} \int_{-\frac{\pi}{h}}^{\frac{\pi}{h}} \hat{\psi}^n(\xi,\eta)\, \exp^{ih(k\xi+l\eta)}\, \mathrm{d}\xi\, \mathrm{d}\eta.$$

LEMMA 5.3 (Parseval's identity). *If* $\{\psi_{kl}^n\} \in \ell_2$ *and* $\hat{\psi}^n$ *is the discrete Fourier transform of* $\{\psi_{kl}^n\}$*, then*

$$||\hat{\psi}^n|| = ||\psi_{kl}^n||,$$

where the first norm is the L_2*-norm on* $\left[-\frac{\pi}{h}, \frac{\pi}{h}\right] \times \left[-\frac{\pi}{h}, \frac{\pi}{h}\right]$ *and the second norm is the* ℓ_2*-norm.*

Hence we have the following result.

LEMMA 5.4. *The sequence* $\{\psi_{kl}^n\}$ *is bounded in* ℓ_2 *if and only if the sequence* $\{\hat{\psi}^n\}$ *is bounded in* $L_2\left(\left[-\frac{\pi}{h}, \frac{\pi}{h}\right] \times \left[-\frac{\pi}{h}, \frac{\pi}{h}\right]\right)$.

In order to study the stability of linear numerical schemes the Fourier transform is used. This leads to a bound on the spectral radius of the so-called amplification matrix. The spectral radius of a square complex matrix $\mathcal{A}$ with eigenvalues λ_i is defined to be

$$\rho(\mathcal{A}) = \max_i |\lambda_i|. \tag{5.1}$$

The spectral norm of the matrix $\mathcal{A}$ is defined as

$$||\mathcal{A}|| = \sup_{\mathbf{x}\neq 0} \frac{||\mathcal{A}\mathbf{x}||}{||\mathbf{x}||}. \tag{5.2}$$

The norms on the right-hand side of (5.2) are the Euclidean norms of the vectors $\mathcal{A}\mathbf{x}$ and $\mathbf{x}$, respectively. Note that for the spectral norm, as for any matrix norm, we always have $||\mathcal{A}|| \geq \rho(\mathcal{A})$.

6. Estimate of the stability limit. In [13, Lemma 5.1] Lukáčová-Medvid'ová, Morton, and Warnecke proved the following stability result for EG schemes. There exists $\nu_{max} < 1$ such that EG schemes for the two-dimensional wave equation system (3.1) are stable for any ν such that $0 \leq \nu \leq \nu_{max}$, where $\nu = c\frac{\Delta t}{h}$ is the CFL number. The goal of this section is to estimate ν_{max} for the EG3 scheme by means of a von Neumann stability analysis. We refer to [2] for a related approach used to estimate stability limits of other finite volume schemes for the Maxwell equations. Analogous calculations can be done also for other EG schemes of type EG1, EG2, EG4 as well as for the FVEG schemes. First we apply the discrete Fourier transform to both sides of (4.7):

$$\hat{\mathbf{U}}^{n+1} = \hat{\mathbf{U}}^n + h^2 \sum_{k=-\infty}^{\infty} \sum_{l=-\infty}^{\infty} \left(\sum_{r=-1}^{1} \sum_{s=-1}^{1} \mathcal{C}_{rs} \mathbf{U}_{k+rl+s}^n \right) \exp^{-ih(k\xi+l\eta)}. \tag{6.1}$$

By making the change of variables $k' = k + r$ and $l' = l + s$ we get

$$h^2 \sum_{k=-\infty}^{\infty} \sum_{l=-\infty}^{\infty} \left(\sum_{r=-1}^{1} \sum_{s=-1}^{1} \mathcal{C}_{rs} \mathbf{U}_{k+rl+s}^n \right) \exp^{-ih(k\xi+l\eta)}$$

$$= \sum_{r=-1}^{1} \sum_{s=-1}^{1} \mathcal{C}_{rs} \exp^{ih(r\xi+s\eta)} \left(h^2 \sum_{k'=-\infty}^{\infty} \sum_{l'=-\infty}^{\infty} \mathbf{U}_{k'l'}^n \exp^{-ih(k'\xi+l'\eta)} \right)$$

$$= \sum_{r=-1}^{1} \sum_{s=-1}^{1} \mathcal{C}_{rs} \exp^{ih(r\xi+s\eta)} \hat{\mathbf{U}}^n. \tag{6.2}$$

Thus, using this expression in (6.1), we get

$$\hat{\mathbf{U}}^{n+1} = \left(\mathcal{I} + \sum_{r=-1}^{1} \sum_{s=-1}^{1} \mathcal{C}_{rs} \exp^{ih(r\xi+s\eta)} \right) \hat{\mathbf{U}}^n, \tag{6.3}$$

where $\mathcal{I}$ is the identity matrix. The coefficient of $\hat{\mathbf{U}}^n$ in (6.3),

$$\mathcal{T}(\xi,\eta) = \mathcal{I} + \sum_{r=-1}^{1} \sum_{s=-1}^{1} \mathcal{C}_{rs} \exp^{ih(r\xi+s\eta)}, \tag{6.4}$$

is called the amplification matrix of the finite difference scheme (4.7). Applying recursively the result of (6.3) $n+1$ times yields

$$\hat{\mathbf{U}}^{n+1} = \left(\mathcal{I} + \sum_{r=-1}^{1} \sum_{s=-1}^{1} \mathcal{C}_{rs} \exp^{ih(r\xi+s\eta)} \right)^{n+1} \hat{\mathbf{U}}^0 = \mathcal{T}^{n+1}(\xi,\eta)\hat{\mathbf{U}}^0. \tag{6.5}$$

We note that if $||\mathcal{T}(\xi,\eta)|| \le 1$, then $||\hat{\mathbf{U}}^{n+1}|| \le ||\hat{\mathbf{U}}^0||$, which means that the $\{\hat{\mathbf{U}}^n\}$ is L^2-stable. Consider the EG3 scheme, i.e., the numerical scheme based on equations (3.7)–(3.9); see also the stencil matrices in the appendix. After some calculation we obtain the entries of the amplification matrix $\mathcal{T}(\xi,\eta)$:

$$T_{11}(\xi,\eta) = 1 + \frac{\nu^2}{\pi} - \frac{4\nu}{\pi} + \frac{\nu^2}{\pi}\cos(h\xi)\cos(h\eta) + \left(\frac{2\nu}{\pi} - \frac{\nu^2}{\pi}\right)(\cos(h\xi) + \cos(h\eta)),$$

$$T_{12}(\xi,\eta) = -i\left(\frac{4\nu^2}{3\pi}\sin(h\xi)\cos(h\eta) + \left(\nu - \frac{4\nu^2}{3\pi}\right)\sin(h\xi)\right),$$

$$T_{13}(\xi,\eta) = -i\left(\frac{4\nu^2}{3\pi}\cos(h\xi)\sin(h\eta) + \left(\nu - \frac{4\nu^2}{3\pi}\right)\sin(h\eta)\right),$$

$$T_{22}(\xi,\eta) = 1 - \frac{2\nu}{\pi} + \frac{\nu^2}{2\pi} + \frac{\nu^2}{2\pi}\cos(h\xi)\cos(h\eta) + \left(\frac{2\nu}{\pi} - \frac{\nu^2}{2\pi}\right)\cos(h\xi) - \frac{\nu^2}{2\pi}\cos(h\eta),$$

$$T_{23}(\xi,\eta) = \frac{-3\nu^2}{8}\sin(h\xi)\sin(h\eta),$$

$$T_{33}(\xi,\eta) = 1 - \frac{2\nu}{\pi} + \frac{\nu^2}{2\pi} + \frac{\nu^2}{2\pi}\cos(h\xi)\cos(h\eta) + \left(\frac{2\nu}{\pi} - \frac{\nu^2}{2\pi}\right)\cos(h\eta) - \frac{\nu^2}{2\pi}\cos(h\xi),$$

$$T_{21}(\xi,\eta) = T_{12}(\xi,\eta), \qquad T_{31}(\xi,\eta) = T_{13}(\xi,\eta), \qquad T_{32}(\xi,\eta) = T_{23}(\xi,\eta).$$

Using the substitutions $S_\xi = \sin(h\xi)$, $s_\xi = \sin(\frac{h\xi}{2})$, $S_\eta = \sin(h\eta)$, and $s_\eta = \sin(\frac{h\eta}{2})$, we can write the amplification matrix $\mathcal{T} = \mathcal{T}(\xi,\eta)$ as

$$\mathcal{T} = \begin{pmatrix} C_{11} & -i\nu C_\xi & -i\nu C_\eta \\ -i\nu C_\xi & C_{22} & \nu^2 C_{\xi\eta} \\ -i\nu C_\eta & \nu^2 C_{\xi\eta} & C_{33} \end{pmatrix},$$

where

$$
\begin{aligned}
C_{11} &= 1 - \frac{4\nu}{\pi}(s_\xi^2 + s_\eta^2) + \frac{4\nu^2}{\pi} s_\xi^2 s_\eta^2,\\
C_\xi &= S_\xi\left(1 - \frac{8\nu}{3\pi} s_\eta^2\right),\\
C_\eta &= S_\eta\left(1 - \frac{8\nu}{3\pi} s_\xi^2\right),\\
C_{\xi\eta} &= \frac{-3}{8} S_\xi S_\eta,\\
C_{22} &= 1 - \frac{4\nu}{\pi} s_\xi^2 + \frac{2\nu^2}{\pi} s_\xi^2 s_\eta^2,\\
C_{33} &= 1 - \frac{4\nu}{\pi} s_\eta^2 + \frac{2\nu^2}{\pi} s_\xi^2 s_\eta^2.
\end{aligned}
$$

Set

$$
\mathcal{E} = \begin{pmatrix} i & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix};
$$

then

$$
\mathcal{Q} = \begin{pmatrix} C_{11} & -\nu C_\xi & -\nu C_\eta \\ \nu C_\xi & C_{22} & \nu^2 C_{\xi\eta} \\ \nu C_\eta & \nu^2 C_{\xi\eta} & C_{33} \end{pmatrix} = \mathcal{E}^{-1}\mathcal{T}\mathcal{E},
$$

which means that $\mathcal{T}$ and $\mathcal{Q}$ are similar matrices and thus have the same eigenvalues. Moreover, the matrix $\mathcal{Q}$ can be decomposed as

$$
\mathcal{Q} = \mathcal{I} - \nu\,(\mathcal{D} + \mathcal{C}) + \nu^2 \tilde{\mathcal{C}},
$$

where

$$
\mathcal{D} = \begin{pmatrix} d+f & 0 & 0 \\ 0 & d & 0 \\ 0 & 0 & f \end{pmatrix}, \quad \mathcal{C} = \begin{pmatrix} 0 & C_\xi & C_\eta \\ -C_\xi & 0 & 0 \\ -C_\eta & 0 & 0 \end{pmatrix}, \quad \tilde{\mathcal{C}} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & C_{\xi\eta} \\ 0 & C_{\xi\eta} & 0 \end{pmatrix},
$$

$$
d = \frac{4}{\pi} s_\xi^2 - \frac{2\nu}{\pi} s_\xi^2 s_\eta^2 = \frac{2}{\pi} s_\xi^2 (2 - \nu s_\eta^2), \quad f = \frac{4}{\pi} s_\eta^2 - \frac{2\nu}{\pi} s_\xi^2 s_\eta^2 = \frac{2}{\pi} s_\eta^2 (2 - \nu s_\xi^2).
$$

Let

$$
\mathcal{H} = \mathcal{I} - \nu(\mathcal{D} + \mathcal{C}), \tag{6.6}
$$

and let $||.||_\star$ be an operator norm such that $||\mathcal{H}||_\star = ||\mathcal{J}||_\infty$, where $\mathcal{J}$ is a scaled Jordan normal form of $\mathcal{H}$ having $\epsilon \ll 1$ on the first off-diagonal and eigenvalues of $\mathcal{H}$ on the diagonal. According to [5] we know that the following property holds: $\rho(\mathcal{H}) < 1$ if and only if $||\mathcal{H}||_\star < 1$. Since all norms in finite-dimensional spaces are equivalent we have

$$
||\mathcal{Q} - (\mathcal{I} - \nu(\mathcal{D} + \mathcal{C}))||_\star \le c\,||\mathcal{Q} - (\mathcal{I} - \nu(\mathcal{D} + \mathcal{C}))|| = c\,\nu^2 |C_{\xi\eta}| = O(\nu^2). \tag{6.7}
$$

Thus, using (6.7) we obtain

$$
\rho(\mathcal{Q}) \le ||Q||_\star \le ||\mathcal{H}||_\star + c\nu^2, \tag{6.8}
$$

and it suffices to study the spectrum of matrix $\mathcal{H}$, since $\rho(\mathcal{H}) < 1$ if and only if $||\mathcal{H}||_\star < 1$.

Further, since $\mathcal{H} = \mathcal{I} - \nu(\mathcal{D} + \mathcal{C})$ and due to the form of $\mathcal{D}, \mathcal{C}$ it can be shown readily that $||\mathcal{H}||_\infty = |1 + c_1\nu + c_2\nu^2|$ for some constants $c_1, c_2 \in \mathbb{R}$. Since all norms in finite-dimensional spaces are equivalent, there exist $k_1, k_2 > 0$, such that for any matrix $\mathcal{M} \in \mathbb{R}^{(3,3)}$

$$k_1||\mathcal{M}||_\infty \le ||\mathcal{M}||_\star \le k_2||\mathcal{M}||_\infty .$$

In particular, if $\mathcal{M} = \mathcal{H}$, we have for any $\nu > 0$

$$k_1|1 + c_1\nu + c_2\nu^2| \le ||\mathcal{H}||_\star \le k_2|1 + c_1\nu + c_2\nu^2|. \tag{6.9}$$

Thus, it is clear that $||\mathcal{H}||_\star$ depends at most quadratically on ν, i.e., $||\mathcal{H}||_\star = |1 + c_3\nu + c_4\nu^2|$. Now, if we assume that $||\mathcal{H}||_\star < 1$, the linear term has to be negative, i.e., $c_3 < 0$, as otherwise $||\mathcal{H}||_\star$ cannot be strictly less than 1 for $\nu \le 1$. Thus, if $||\mathcal{H}||_\star < 1$, we can find small enough ν such that $||\mathcal{H}||_\star + c\nu^2 \le 1$ and $\rho(Q) \le 1$ due to (6.8).

Unfortunately, we cannot give any quantitative estimate on ν since we do not know how large the constant c in (6.8) is. However, we know from [13] that there exists $\nu_{\max} > 0$ such that for all $\nu \in (0, \nu_{\max}]$ we have $\rho(Q) \le 1$.

In what follows we will study the spectrum of the matrix $\mathcal{H}$ and find ν such that $\rho(\mathcal{H}) < 1$. Note that for all $(\xi, \eta) \in [\frac{-\pi}{h}, \frac{\pi}{h}] \times [\frac{-\pi}{h}, \frac{\pi}{h}]$ the entries of $\mathcal{H}$ are bounded. We need to estimate the spectral radius of $\mathcal{H}$ for all choices of ξ, η, and ν, $0 < \nu \le 1$.

First of all, it is easy to see that in a special case when $\xi = 0 = \eta$ we have $d = f = C_\xi = C_\eta = C_{\xi\eta} = 0$ and $\mathcal{Q} = \mathcal{I} = \mathcal{H}$. Thus, trivially $\rho(\mathcal{H}) = \rho(\mathcal{Q}) = 1$ for any ν. Therefore in what follows it suffices to study the case when $\xi \ne 0$ or $\eta \ne 0$.

Since $0 \le s_\xi^2 \le 1$ and $0 \le s_\eta^2 \le 1$ and $\nu \le 1$, then $d \ge 0$ and $f \ge 0$. Now the matrices $\mathcal{D}, \mathcal{C}$ are real and $\mathcal{C}$ is skewsymmetric. Hence $\mathcal{D} + \mathcal{C}$ has either three real eigenvalues or one real eigenvalue and two complex conjugate eigenvalues.

Consider a *real eigenvalue*, say $\lambda = \lambda_r$. Let $\mathbf{v} = (v_1, v_2, v_3)$ be the corresponding eigenvector; then $\mathbf{v}^T(\mathcal{D} + \mathcal{C})\mathbf{v} = \mathbf{v}^T\lambda_r\mathbf{v}$. Since $\mathcal{C}$ is skewsymmetric, then $\mathbf{v}^T\mathcal{C}\mathbf{v} = 0$. Hence we get

$$(d + f - \lambda_r)v_1^2 + (d - \lambda_r)v_2^2 + (f - \lambda_r)v_3^2 = 0. \tag{6.10}$$

The coefficients in (6.10) cannot all have the same sign for v_1^2, v_2^2, $v_3^2 > 0$. Therefore, we get the estimates

$$0 \le \min(d, f) \le \lambda_r \le d + f. \tag{6.11}$$

Let μ_r be a real eigenvalue of $\mathcal{H}$; then $\mu_r = 1 - \nu\lambda_r$. Hence $|\mu_r| < 1$ is equivalent to $-1 < 1 - \nu\lambda_r < 1$. According to (6.11) we assume now that

$$\lambda_r > 0; \tag{6.12}$$

the case $\lambda_r = 0$ will be treated separately later; cf. (6.22). Further,

$$1 - \frac{4\nu}{\pi}\left(s_\xi^2 + s_\eta^2\right) + \frac{4\nu^2}{\pi}s_\xi^2 s_\eta^2 \le 1 - \nu\lambda_r < 1.$$

To ensure that $|\mu_r| < 1$ we need

$$1 - \frac{4\nu}{\pi}\left(s_\xi^2 + s_\eta^2\right) + \frac{4\nu^2}{\pi}s_\xi^2 s_\eta^2 > -1.$$

The last inequality reads

$$\nu^2\left(\frac{4}{\pi}s_\xi^2 s_\eta^2\right)-\nu\left(\frac{4}{\pi}\left(s_\xi^2+s_\eta^2\right)\right)+2>0. \tag{6.13}$$

It suffices to bound ν so that $2-\nu\frac{4}{\pi}(s_\xi^2+s_\eta^2)>0$. Since $(s_\xi^2+s_\eta^2)\le 2$, this is true if

$$\nu<\frac{\pi}{4}\approx 0.7854. \tag{6.14}$$

Now let us assume that μ_c is a *complex eigenvalue* of $\mathcal{H}$. Then $\mu_c=1-\nu\lambda_c$, where λ_c is a complex eigenvalue of the matrix $\mathcal{D}+\mathcal{C}$. This implies that

$$|\mu_c|^2=1-2\nu\mathrm{Re}(\lambda_c)+\nu^2|\lambda_c|^2.$$

Thus $|\mu_c|^2<1$ is equivalent to $\nu^2|\lambda_c|^2-2\nu\mathrm{Re}(\lambda_c)<0$. Since $\lambda_r>0$ (cf. (6.12)), we have

$$\nu^2\lambda_r|\lambda_c|^2-2\nu\lambda_r\mathrm{Re}(\lambda_c)<0. \tag{6.15}$$

Let $b=C_\xi$ and $c=C_\eta$. It is well known that

$$\begin{aligned}\det(\mathcal{D}+\mathcal{C})&=d^2f+f^2d+b^2f+c^2d=\lambda_r|\lambda_c|^2,\\ \mathrm{Tr}(\mathcal{D}+\mathcal{C})&=2(d+f)=\lambda_r+\lambda_c+\bar{\lambda_c}=\lambda_r+2\mathrm{Re}(\lambda_c).\end{aligned}$$

Hence (6.15) reads

$$p(\lambda_r)=\lambda_r^2-2(d+f)\lambda_r+\nu(d^2f+f^2d+b^2f+c^2d)<0. \tag{6.16}$$

Let us consider the polynomial

$$p=p(\lambda)=\lambda^2-2(d+f)\lambda+\nu(d^2f+f^2d+b^2f+c^2d).$$

The discriminant of p gives

$$\begin{aligned}\Delta&=4(d+f)^2-4\nu(d^2f+f^2d+b^2f+c^2d)\\ &=4(d^2+f^2)+8fd-4\nu(d^2f+f^2d+b^2f+c^2d).\end{aligned}$$

It suffices to show that the following inequality holds:

$$8fd-4\nu(d^2f+f^2d+b^2f+c^2d)>0,$$

which leads to $\Delta>4(d^2+f^2)\ge 0$. Now

$$\begin{aligned}8fd=\frac{32}{\pi^2}s_\xi^2s_\eta^2(2-\nu s_\eta^2)(2-\nu s_\xi^2)&=\frac{32}{\pi^2}s_\xi^2s_\eta^2(4-2\nu(s_\xi^2+s_\eta^2)+\nu^2s_\xi^2s_\eta^2)\\ &\ge\frac{32}{\pi^2}s_\xi^2s_\eta^2(4-2\nu(s_\xi^2+s_\eta^2)).\end{aligned}$$

Note that the last inequality is strict if $\xi\neq 0$ and $\eta\neq 0$. Hence,

$$8fd\ge\frac{32}{\pi^2}s_\xi^2s_\eta^2(4-4\nu)=\frac{128}{\pi^2}s_\xi^2s_\eta^2(1-\nu). \tag{6.17}$$

If $\xi\neq 0$ and $\eta\neq 0$, the inequality in (6.17) is strict.

Further, we have

$$d^2 f = \frac{8}{\pi^3} s_\xi^4 s_\eta^2 (2-\nu s_\eta^2)^2 (2-\nu s_\xi^2) \le \frac{64}{\pi^3} s_\xi^4 s_\eta^2 \le \frac{64}{\pi^3}, \tag{6.18}$$

$$b^2 f = S_\xi^2 (1 - \frac{8\nu^2}{3\pi} s_\eta^2)^2 \frac{2}{\pi} s_\eta^2 (2-\nu s_\xi^2) \le \frac{4}{\pi} S_\xi^2 s_\eta^2 \le \frac{4}{\pi}. \tag{6.19}$$

Again, note that in the case that either $\xi = 0$ or $\eta = 0$, the inequality in (6.18) is strict.

Analogously, we obtain

$$f^2 d \le \frac{64}{\pi^3} \qquad \text{and} \qquad c^2 d \le \frac{4}{\pi}.$$

Therefore,

$$-4\nu(d^2 f + f^2 d + b^2 f + c^2 d) \ge -4 \frac{128 + 8\pi^2}{\pi^3} \nu; \tag{6.20}$$

if $\xi = 0$ or $\eta = 0$, the above inequality is strict.

Combining (6.17) and (6.20) we get

$$\begin{aligned} 8df - 4\nu(d^2 f + f^2 d + b^2 f + c^2 d) &> \frac{128}{\pi^2} s_\xi^2 s_\eta^2 (1-\nu) - 4\left(\frac{128+8\pi^2}{\pi^3}\right)\nu \\ &= \frac{128}{\pi^2} s_\xi^2 s_\eta^2 - \nu\left(\frac{128}{\pi^2} s_\xi^2 s_\eta^2 + 4\left(\frac{128+8\pi^2}{\pi^3}\right)\right) \ge 0. \end{aligned}$$

The last inequality implies

$$\nu \le \frac{\frac{128}{\pi^2} s_\xi^2 s_\eta^2}{4\left(\frac{128+8\pi^2}{\pi^3}\right) + \frac{128}{\pi^2} s_\xi^2 s_\eta^2} \le \frac{\frac{128}{\pi^2}}{4\left(\frac{128+8\pi^2}{\pi^3}\right) + \frac{128}{\pi^2} s_\xi^2 s_\eta^2}.$$

Since

$$4\left(\frac{128+8\pi^2}{\pi^3}\right) + \frac{128}{\pi^2} s_\xi^2 s_\eta^2 \ge 4\left(\frac{128+8\pi^2}{\pi^3}\right)$$

we then have

$$\frac{1}{4\left(\frac{128+8\pi^2}{\pi^3}\right) + \frac{128}{\pi^2} s_\xi^2 s_\eta^2} \le \frac{1}{4\left(\frac{128+8\pi^2}{\pi^3}\right)}.$$

Therefore we get

$$\nu \le \frac{\frac{128}{\pi^2}}{\frac{4(128+8\pi^2)}{\pi^3}} = \frac{32\pi}{128+8\pi^2} \approx 0.4858. \tag{6.21}$$

Thus we have obtained a sufficient condition on ν for $\Delta > 0$. For $\nu \le 0.4858$ we have $\Delta > 4(d^2 + f^2) \ge 0$.

Since $\lambda_r > 0$ (cf. (6.12)), $p(\lambda)$ has two distinct real roots r_1 and r_2, where

$$r_1 = (d+f) - \frac{\sqrt{\Delta}}{2}, \qquad r_2 = (d+f) + \frac{\sqrt{\Delta}}{2}.$$

Inequality (6.11) gives $\lambda_r < r_2$. To show that $\lambda_r > r_1$ note that from $\Delta > 4(d^2+f^2)$ we have $r_1 < (d+f) - \sqrt{d^2+f^2}$. Furthermore $\sqrt{d^2+f^2} \geq \max(d,f)$. Therefore

$$r_1 < (d+f) - \sqrt{d^2+f^2} \leq (d+f) - \max(d,f) = \min(d,f) \leq \lambda_r.$$

Hence $\lambda_r \in (r_1, r_2)$. This implies that $p(\lambda_r) < 0$, as we wished to show; cf. (6.16).

Moreover, since $\lambda_r \geq 0$ (cf. (6.11)), we need to consider the case $\lambda_r = 0$. Then either $d = 0$ or $f = 0$. Suppose $d = \frac{2}{\pi} s_\xi^2 (2 - \nu s_\eta^2) = 0$; the case $f = 0$ is analogous. Then we have that $s_\xi = 0$, $\xi = 0$, and

$$\mathcal{D} + \mathcal{C} = \begin{pmatrix} \frac{4}{\pi} s_\eta^2 & 0 & S_\eta \\ 0 & 0 & 0 \\ -S_\eta & 0 & \frac{4}{\pi} s_\eta^2 \end{pmatrix}. \tag{6.22}$$

Note that in this case $\mathcal{Q} = \mathcal{H}$, $\mu_r = 1$ and we need to find the condition on ν to ensure that $\rho(\mathcal{H}) = \rho(\mathcal{Q}) \leq 1$. The eigenvalues of $\mathcal{D} + \mathcal{C}$ are 0, $\frac{4}{\pi} s_\eta^2 \pm i S_\eta$. Now $|\mu_c|^2 = |1 - \nu\lambda_c|^2 \leq 1$ gives

$$\left(1 - \nu\left(\frac{4}{\pi} s_\eta^2 + i S_\eta\right)\right)\left(1 - \nu\left(\frac{4}{\pi} s_\eta^2 - i S_\eta\right)\right) = \left(\left(1 - \frac{4}{\pi}\nu s_\eta^2\right)^2 + \nu^2 S_\eta^2\right)$$
$$= 1 - \frac{8\nu}{\pi} s_\eta^2 + \frac{16\nu^2}{\pi^2} s_\eta^4 + \nu^2 S_\eta^2 \leq 1.$$

This leads to

$$-\frac{8\nu}{\pi} s_\eta^2 + \nu^2 \left(\frac{16}{\pi^2} s_\eta^4 + S_\eta^2\right) \leq 0.$$

Suppose $s_\eta \neq 0$, as otherwise $\eta = 0$ and $\xi = 0$, which is a special case that has already been considered above. Then we have

$$-\frac{8}{\pi} + \nu\left(\frac{16}{\pi^2} s_\eta^2 + \left(\frac{S_\eta}{s_\eta}\right)^2\right) \leq 0,$$
$$\nu\left(\frac{16}{\pi^2} s_\eta^2 + \left(\frac{S_\eta}{s_\eta}\right)^2\right) \leq \frac{8}{\pi}.$$

The last inequality yields

$$\nu \leq \frac{\frac{8}{\pi}}{\left(\frac{16}{\pi^2} s_\eta^2 + \left(\frac{S_\eta}{s_\eta}\right)^2\right)}. \tag{6.23}$$

Since

$$\frac{16}{\pi^2} s_\eta^2 + \left(\frac{S_\eta}{s_\eta}\right)^2 \leq 4,$$

it suffices to take ν such that

$$\nu \leq \frac{2}{\pi} \approx 0.6366. \tag{6.24}$$

Finally (6.14), (6.21), and (6.24) imply that if

$$\nu \leq \frac{32\pi}{128 + 8\pi^2} \approx 0.4858, \tag{6.25}$$

then either $\rho(\mathcal{Q}) = \rho(\mathcal{H}) = 1$ or $\rho(\mathcal{H}) < 1$. Hence we have proved the following result.

LEMMA 6.1. *Consider the EG3 scheme. Then there exists ν small enough such that $\rho(\mathcal{T}) \leq 1$, where $\mathcal{T}$ is the amplification matrix of the discrete operator representing the EG3 scheme.*

More precisely, we know that $\rho(\mathcal{T}) \leq \|\mathcal{H}\|_* + O(\nu^2)$, where $\mathcal{H}$ is the matrix defined in (6.6). *Moreover, if $\nu \leq \frac{32\pi}{128+8\pi} \approx 0.4858$, then $\rho(\mathcal{H}) < 1$ and $\|\mathcal{H}\|_* < 1$, except for the special case when $\rho(\mathcal{H}) = \rho(\mathcal{T}) = 1$. Otherwise, there is ν small enough such that $\rho(\mathcal{T}) \leq 1$.*

In Table 1 we have estimated the stability limit of the scheme EG3 using the standard MATLAB procedure `eig` for the eigenvalues of the matrix $\mathcal{T}$. Note that our theoretical result $\nu \approx 0.4858$ for a simplified problem gives a stronger estimate on the CFL number than the experimental results for the original problem. They show that the EG3 scheme stays stable up to $\nu = 0.58$. In Figure 2 (left) we plot the eigenvalues of the matrix $\mathcal{H}$ as well as the unit circle. A similar plot with different scale is shown in Figure 2 (right). In Figure 3 we show, using different scales, the eigenvalues of the amplification matrix corresponding to the first order EG3 scheme. We illustrate that it is possible to include all eigenvalues inside the unit circle for the CFL number up to 0.58. Throughout the paper in order to plot the eigenvalues of amplification matrices we have used 100×100 values of $h\xi$, $h\eta \in [-\pi, \pi]$.

7. Approximate evolution operator E_Δ^{const} for piecewise constant data. In [11], Lukáčová-Medvid'ová, Morton and Warnecke proposed new approximate evolution operators E_Δ^{const} and E_Δ^{bilin} for the two-dimensional wave equation system and for the Euler equations of gas dynamics. Extensive numerical experiments presented in [11] indicate that these new operators improve the stability of the FVEG schemes considerably; i.e., in particular, our numerical tests indicated that they have a larger stability range than the EG3 method, which we considered in section 6. We will show that for special choices of discretization techniques stability limits close to the natural limit of 1 can be achieved. Numerical experiments, presented in [11], for these FVEG schemes confirm high accuracy as well as good multidimensional behavior of the new FVEG schemes. The key idea of the development of these new operators was to exploit the fact that the exact explicit solution to the one-dimensional wave equation system is available. Our new approximate operators are constructed in such a way

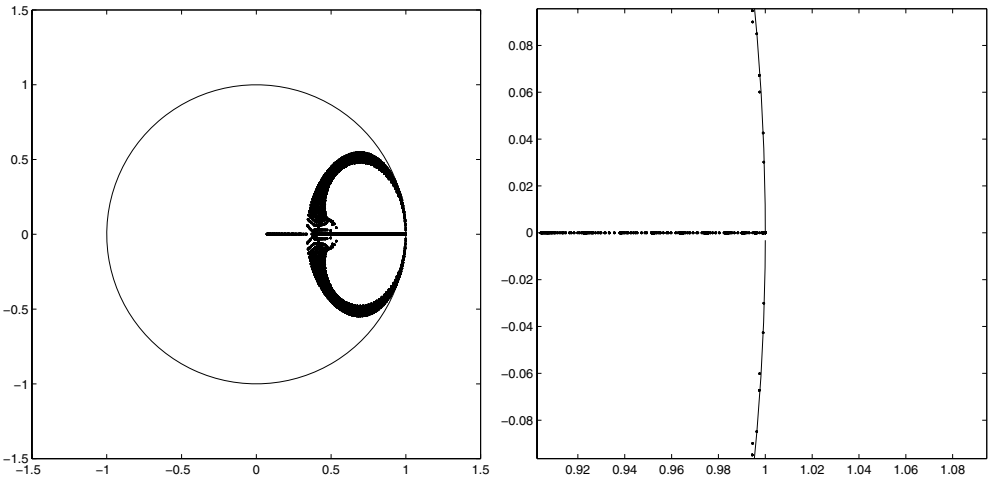

FIG. 2. *Eigenvalues of the matrix* $\mathcal{H}$*,* $CFL = 0.48$*.*

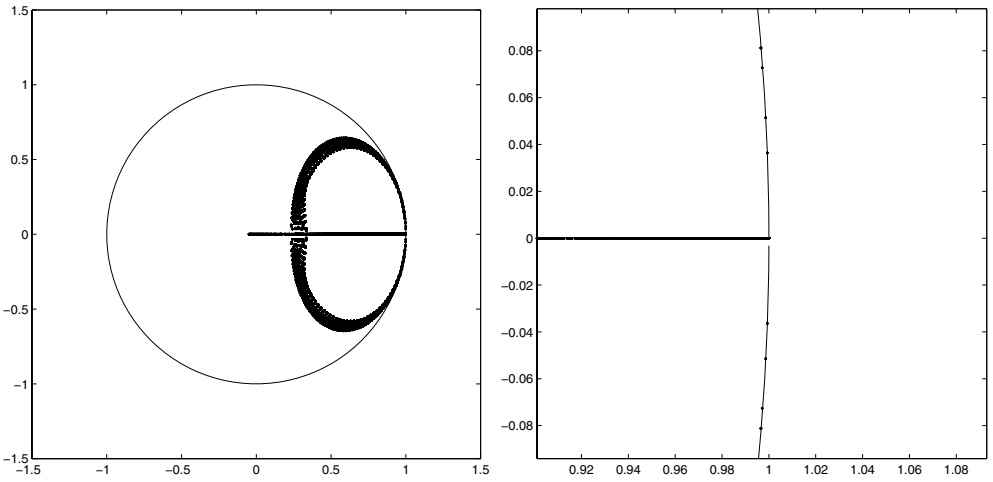

FIG. 3. *Eigenvalues of the amplification matrix of the first order EG*3 *scheme for* $CFL = 0.58$*.*

that this exact solution is reproduced exactly for given one-dimensional data. Thus, the approximate evolution operator E_Δ^{const} calculates exactly any one-dimensional wave which is represented by a piecewise constant data and propagates either in the x- or the y-direction. An analogous situation holds for the operator E_Δ^{bilin} and approximated waves by means of continuous piecewise bilinear data. The approximate evolution operator E_Δ^{const} for piecewise constant data reads (cf. [11])

$$\phi_P = \frac{1}{2\pi}\int_0^{2\pi} (\phi_Q - u_Q \mathrm{sgn}(\cos\theta) - v_Q \mathrm{sgn}(\sin\theta))\mathrm{d}\theta, \tag{7.1}$$

$$u_P = \frac{1}{2\pi}\int_0^{2\pi} \left(-\phi_Q \mathrm{sgn}(\cos\theta) + u_Q\left(\frac{1}{2} + \cos^2\theta\right) + v_Q \sin\theta\cos\theta\right)\mathrm{d}\theta, \tag{7.2}$$

$$v_P = \frac{1}{2\pi}\int_0^{2\pi} \left(-\phi_Q \mathrm{sgn}(\sin\theta) + u_Q \sin\theta\cos\theta + v_Q\left(\frac{1}{2} + \sin^2\theta\right)\right)\mathrm{d}\theta. \tag{7.3}$$

Integrations from 0 to 2π around the sonic circle in (7.1)–(7.3) are evaluated exactly. In this way all of the infinitely many directions of wave propagation are taken into account explicitly. For the cell interface integration along $\partial\Omega$ in (4.6) we have two possibilities. These edge integrals can be computed either exactly or numerically. Exact cell interface integration yields, e.g., for the vertical edge, the intermediate values

$$\begin{aligned}
\tilde{\Phi}_{edge}^{n+\frac{1}{2}} &= \left(1+\frac{\nu}{2\pi}\delta_y^2\right)\mu_x\Phi^n - \left(\frac{1}{2}+\frac{\nu}{4\pi}\delta_y^2\right)\delta_x U^n - \frac{\nu}{\pi}\mu_x\mu_y\delta_y V^n,\\
\tilde{U}_{edge}^{n+\frac{1}{2}} &= -\left(\frac{1}{2}+\frac{\nu}{4\pi}\delta_y^2\right)\delta_x\Phi^n + \left(1+\frac{5\nu}{12\pi}\delta_y^2\right)\mu_x U^n + \frac{\nu}{6\pi}\delta_x\mu_y\delta_y V^n,
\end{aligned} \tag{7.4}$$

where $\mu_x f(x) = \frac{1}{2}\left(f\left(x+\frac{h}{2}\right)+f\left(x-\frac{h}{2}\right)\right)$, $\delta_x^2 f(x) = f(x+h)-2f(x)+f(x-h)$.

The stencil matrices of this FVEG scheme are given in the appendix. Another possibility for evaluating the cell interface integrals is to use some numerical quadrature. In this way, further simplification in the derivation of the scheme can be made. Instead of the two-dimensional integrals along the cell interfaces and around the sonic circle, only the sonic circle integrals need to be evaluated exactly. In our experiments we used the trapezoidal rule and Simpson's rule for the cell interface integration. Thus, we need to determine $\tilde{\mathbf{U}}^{n+\frac{1}{2}}$:

$$\begin{aligned}
\tilde{\Phi}_{vertex}^{n+\frac{1}{2}} &= \mu_x\mu_y\Phi^n - \frac{1}{2}\mu_y\delta_x U^n - \frac{1}{2}\mu_x\delta_y V^n,\\
\tilde{U}_{vertex}^{n+\frac{1}{2}} &= -\frac{1}{2}\mu_y\delta_x\Phi^n + \mu_x\mu_y U^n + \frac{1}{4\pi}\delta_x\delta_y V^n,\\
\tilde{\Phi}_{midpoint}^{n+\frac{1}{2}} &= \mu_x\Phi^n - \frac{1}{2}\delta_x U^n,\\
\tilde{U}_{midpoint}^{n+\frac{1}{2}} &= -\frac{1}{2}\delta_x\Phi^n + \mu_x U^n.
\end{aligned} \tag{7.5}$$

The stencil matrices of the FVEG scheme with trapezoidal and Simpson quadratures for the cell interface integration are given in the appendix.

Analogously to section 6, we can show that the amplification matrix $\mathcal{T}$ of the first order FVEG scheme with exact edge integrals is similar to the matrix

$$\mathcal{Q} = \mathcal{I} - \nu\left(\mathcal{D}+\mathcal{C}\right) + \nu^2\tilde{\mathcal{C}},$$

where the matrix $\mathcal{D}$ is defined, as before, with

$$d = 2s_\xi^2\left(1-\frac{2\nu}{\pi}s_\eta^2\right), \qquad f = 2s_\eta^2\left(1-\frac{2\nu}{\pi}s_\xi^2\right).$$

The matrices $\mathcal{C}$ and $\tilde{\mathcal{C}}$ are given as

$$\mathcal{C} = \begin{pmatrix} 0 & C_\xi - \frac{\nu}{3\pi}S_\xi s_\eta^2 & C_\eta - \frac{\nu}{3\pi}S_\eta s_\xi^2 \\ -C_\xi & 0 & 0 \\ -C_\eta & 0 & 0 \end{pmatrix}, \qquad \tilde{\mathcal{C}} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & C_{\xi\eta} \\ 0 & C_{\xi\eta} & 0 \end{pmatrix},$$

where

$$\begin{aligned}
C_\xi &= S_\xi\left(1-\frac{2\nu}{\pi}s_\eta^2\right), \qquad C_\eta = S_\eta\left(1-\frac{2\nu}{\pi}s_\xi^2\right),\\
C_{\xi\eta} &= \frac{-1}{\pi}S_\xi S_\eta.
\end{aligned}$$

Since the matrix $\mathcal{C}$ is not skewsymmetric, it is now not possible to carry out an analysis similar to the one in section 6 in order to estimate the stability limit. Instead we use the MATLAB procedure `eig` to estimate the stability limit. The results are given in Table 2. In column 2 we present the stability limit of the first order FVEG scheme with exact edge integrals. The stability limit of this scheme is improved considerably: the scheme is stable approximately up to CFL = 0.89. Column 3 demonstrates that the first order scheme based on the trapezoidal rule is stable up to the natural stability limit 1. Column 4 shows that the stability of the first order scheme based on Simpson's rule is also increased: the scheme is stable approximately up to CFL = 0.75.

TABLE 2
Stability limit using $\rho_{\xi,\eta}(\mathcal{T}(\xi,\eta))$.

0.80	1.0000000000	1.0000000000	
0.89	1.0000000000	1.0000000000	
0.90	1.0007993640	1.0000000000	
1.00		1.0000000000	
1.01		1.0200000000	

In Figure 4 we plot, using different scales, the eigenvalues of the amplification matrices corresponding to the first order FVEG schemes based on the operator (7.1)–(7.3). The top two panels are obtained using exact integration along cell interfaces; in the middle panels the trapezoidal rule was used to approximate interface integrals. In the bottom two panels we have plotted eigenvalues of the amplification matrix of the FVEG3 scheme with Simpson's quadrature for the cell interface integrals. Analogously to the previous section, it is possible to include all eigenvalues into the unit disc.

8. Approximate evolution operator E_{Δ}^{bilin} for piecewise bilinear data. In this section we investigate the stability of the second order finite volume schemes proposed by Lukáčová-Medvid'ová, Morton, and Warnecke in [11]. These schemes are based on the approximate evolution operator E_{Δ}^{bilin}, which is given as follows:

$$\phi_P = \left(1-\frac{\pi}{2}\right)\phi'_P + \frac{1}{2\pi}\int_0^{2\pi}\left(\frac{\pi}{2}\phi_Q - 2u_Q\cos\theta - 2v_Q\sin\theta\right)\mathrm{d}\theta + O(\Delta t^2), \tag{8.1}$$

$$u_P = \left(1-\frac{\pi}{4}\right)u'_P + \frac{1}{2\pi}\int_0^{2\pi}\Big(-2\cos\theta\phi_Q + \frac{\pi}{2}u_Q\left(3\cos^2\theta-1\right) + \frac{3\pi}{2}v_Q\sin\theta\cos\theta\Big)\mathrm{d}\theta + O(\Delta t^2), \tag{8.2}$$

$$v_P = \left(1-\frac{\pi}{4}\right)v'_P + \frac{1}{2\pi}\int_0^{2\pi}\Big(-2\sin\theta\phi_Q + \frac{3\pi}{2}u_Q\sin\theta\cos\theta + \frac{\pi}{2}v_Q\left(3\sin^2\theta-1\right)\Big)\mathrm{d}\theta + O(\Delta t^2). \tag{8.3}$$

Analogously to E_{Δ}^{const}, this approximate evolution operator is designed so that it computes any one-dimensional linear plane wave propagating in the x- or y-direction exactly; for more details see [11]. In order to obtain second order finite volume schemes

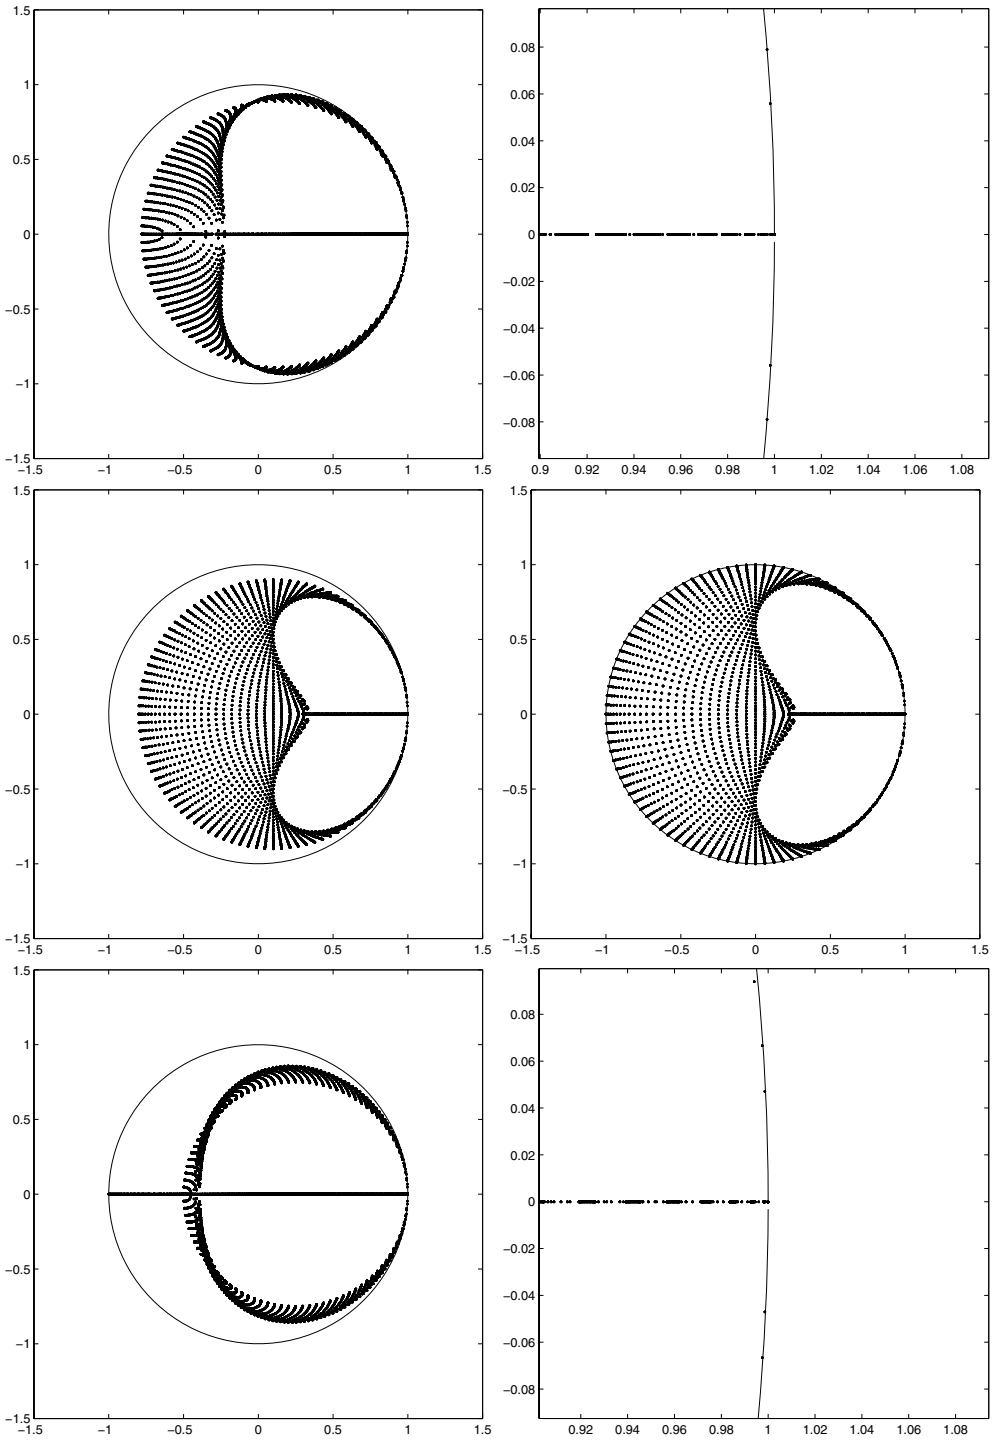

FIG. 4. *Eigenvalues of the amplification matrices; top: exact interface integration for the* $CFL = 0.89$ (*right zoom*)*; middle: interface integrals approximated using the trapezoidal rule for the* $CFL = 0.9, 1.0$.*; bottom: interface integrals approximated by Simpson's rule for the* $CFL = 0.75$ (*right zoom*).

we carry out a recovery stage before applying the approximate evolution operator; see Definition 4.2. The following two types of bilinear recoveries have been considered in [11]:

$$R_h^C\mathbf{U}\big|_{\Omega_{kl}} = \Big(\mu_x^2\mu_y^2 + \frac{x-x_k}{h}\mu_x\mu_y^2\delta_x + \frac{y-y_l}{h}\mu_x^2\mu_y\delta_y + \frac{(x-x_k)(y-y_l)}{h^2}\mu_x\mu_y\delta_x\delta_y\Big)\mathbf{U}_{kl}, \tag{8.4}$$

$$R_h^D\mathbf{U}\big|_{\Omega_{kl}} = \Big(1 + \frac{x-x_k}{h}\mu_x\mu_y^2\delta_x + \frac{y-y_l}{h}\mu_x^2\mu_y\delta_y + \frac{(x-x_k)(y-y_l)}{h^2}\mu_x\mu_y\delta_x\delta_y\Big)\mathbf{U}_{kl}. \tag{8.5}$$

Note that the recovery (8.4) is continuous, while the recovery (8.5) is discontinuous and conservative. We use the midpoint rule to approximate the time integral in (4.5). Denoting the cell interface intermediate value that is computed in the predictor step (4.6) by $\tilde{\mathbf{U}}^{n+\frac{1}{2}}$, we obtain the following schemes:

$$\begin{aligned}
&\text{scheme A} && \tilde{\mathbf{U}}^{n+\frac{1}{2}} = E_\Delta^{bilin}R_h^C\mathbf{U}^n + E_\Delta^{const}(1-\mu_x^2\mu_y^2)\mathbf{U}^n,\\
&\text{scheme B} && \tilde{\mathbf{U}}^{n+\frac{1}{2}} = E_\Delta^{bilin}R_h^C\mathbf{U}^n,\\
&\text{scheme C} && \tilde{\mathbf{U}}^{n+\frac{1}{2}} = E_\Delta^{bilin}R_h^D\mathbf{U}^n.
\end{aligned}$$

Each of these schemes has two further types according to the evaluation of the cell interface integrals. We used the subscripts $1, 2$ to distinguish between them. Thus, 1 corresponds to Simpson's rule and 2 to the trapezoidal rule. For example, for the scheme C_2 the predicted values along the right cell interface are

$$\begin{aligned}
\tilde{\Phi}^{n+\frac{1}{2}} &= \left[1+\left(\frac{-\pi}{32}+\frac{\nu}{16}\right)\delta_x^2\mu_y^2+\left(\frac{-\pi}{32}+\frac{\nu}{16}\right)\delta_y^2\mu_x^2+\left(\frac{\pi}{32}-\frac{\nu}{8}+\frac{\nu^2}{32}\right)\delta_x^2\delta_y^2\right]\mu_x\mu_y\Phi^n\\
&+\left[\frac{-2}{\pi}+\left(\frac{1}{2\pi}-\frac{\nu}{8}\right)\mu_x^2\mu_y^2+\left(\frac{1}{8\pi}-\frac{\nu}{16\pi}\right)\delta_y^2\mu_x^2+\left(\frac{-1}{2\pi}+\frac{\nu}{8}+\frac{\nu}{4\pi}-\frac{\nu^2}{6\pi}\right)\mu_x^2\delta_y^2\right]\delta_x\mu_yU^n\\
&+\left[\frac{-2}{\pi}+\left(\frac{1}{8\pi}-\frac{\nu}{16\pi}\right)\delta_x^2\mu_y^2+\left(\frac{1}{2\pi}-\frac{\nu}{8}\right)\mu_x^2\mu_y^2+\left(\frac{-1}{2\pi}+\frac{\nu}{8}+\frac{\nu}{4\pi}-\frac{\nu^2}{6\pi}\right)\mu_y^2\delta_x^2\right]\delta_y\mu_xV^n,
\end{aligned}$$

$$\begin{aligned}
\tilde{U}^{n+\frac{1}{2}} &= \left[\frac{-2}{\pi}+\left(\frac{1}{2\pi}-\frac{\nu}{8}\right)\mu_x^2\mu_y^2+\left(\frac{1}{8\pi}-\frac{\nu}{16\pi}\right)\delta_y^2\mu_x^2\right.\\
&\qquad\left.+\left(\frac{-1}{2\pi}+\frac{\nu}{8}+\frac{\nu}{4\pi}-\frac{\nu^2}{6\pi}\right)\mu_x^2\delta_y^2\right]\delta_x\mu_y\Phi^n\\
&+\left[1+\left(\frac{-\pi}{64}+\frac{\nu}{16}\right)\delta_x^2\mu_y^2-\frac{\pi}{64}\delta_y^2\mu_x^2+\left(\frac{\pi}{64}-\frac{\nu}{16}+\frac{\nu^2}{64}\right)\delta_x^2\delta_y^2\right]\mu_x\mu_yU^n\\
&+\left[\frac{1}{8}+\left(\frac{1}{16}-\frac{\nu}{8}+\frac{\pi\nu^2}{64}\right)\mu_x^2\mu_y^2\right]3\delta_x\delta_yV^n,
\end{aligned}$$

with the equation for $\tilde{V}^{n+\frac{1}{2}}$ that is analogous to that for $\tilde{U}^{n+\frac{1}{2}}$. Further, we can express analogously the predicted values for the other cell interfaces as well as for other schemes. Substituting the predicted values in the corrector step (4.5) yields, for

all second order finite volume schemes FVEG-A, B, C,

(8.6)
$$\mathbf{U}_{kl}^{n+1} = \mathbf{U}_{kl}^{n} + \sum_{r=-1}^{1}\sum_{s=-1}^{1} \mathcal{C}_{rs}\mathbf{U}_{k+rl+s}^{n} + \mathcal{C}_{rs}^{x}\mathbf{U}_{x_{k+rl+s}}^{n} + \mathcal{C}_{rs}^{y}\mathbf{U}_{y_{k+rl+s}}^{n} + \mathcal{C}_{rs}^{xy}\mathbf{U}_{xy_{k+rl+s}}^{n},$$

where $\mathcal{C}_{rs}^{x}$, $\mathcal{C}_{rs}^{y}$, and $\mathcal{C}_{rs}^{xy}$ are the coefficient matrices corresponding to the approximation of x-, y-, and xy-slopes. Moreover,

$$\mathbf{U}_{x_{k+rl+s}}^{n} = \mu_x\mu_y^2\delta_x\mathbf{U}_{k+rl+s}^{n}, \qquad \mathbf{U}_{y_{k+rl+s}}^{n} = \mu_x^2\mu_y\delta_y\mathbf{U}_{k+rl+s}^{n},$$
$$\mathbf{U}_{xy_{k+rl+s}}^{n} = \mu_x\mu_y\delta_x\delta_y\mathbf{U}_{k+rl+s}^{n}.$$

Applying a von Neumann analysis and the Fourier transforms we obtain the amplification matrices $\mathcal{T}$. It should be pointed out that their structure is too complicated to apply estimates of the spectral radius similar to those in section 6 for the first order EG3 scheme. Anyway, we can use the standard MATLAB procedure to determine the eigenvalues of $\mathcal{T}$. The corresponding stability limits for the FVEG schemes are given in Table 3.

TABLE 3
Stability limits of the second order FVEG schemes.

	Trapezoidal rule	Simpson's rule
Scheme A	0.94	0.75
Scheme B	0.78	-
Scheme C	0.78	0.58

We should note that all CFL limits given in Table 3 have also been confirmed by various numerical experiments. In Figures 5 and 6 we plot, using different scales, the eigenvalues of the amplification matrices corresponding to the second order FVEG schemes: scheme A_i, B_i, and C_i, where $i = 1, 2$. Similarly to the previous cases, these plots indicate that all eigenvalues are included in the unit disc. Note that different quadrature rules have a considerable effect on the form of the spectrum of the resulting amplification matrix. For example, Simpson's quadrature rule for cell interface integrals yields the spectrum which is more compact. Further, it follows from Figure 5 that the second order FVEG scheme based on the operator (8.1)–(8.3) with the continuous nonconservative recovery (8.4) with Simpson's rule, i.e., scheme B_1, is unconditionally unstable. This fact has also been confirmed by other numerical tests for the wave equation system with discontinuous solution. We have found for all CFL numbers, no matter how small they were chosen, instabilities in the solution for fine enough meshes. We would like to remark that the loss of stability of EG schemes under numerical integration has been also observed even for the scalar linear hyperbolic equation by Morton, Priestly, and Süli [21].

Remarks. The derivation of the EG and FVEG schemes might be considered at first sight a rather complex task. In fact, the finite difference formulation (4.7), (4.8) which uses the stencil matrices (cf. appendix) is used only for theoretical analysis. In practice we implement the approximate evolution operators (3.7)–(3.9), (7.1)–(7.3), or (8.1)–(8.3) directly. Thus, for example, in the FVEG scheme the flux integrals along cell interfaces are approximated by the Simpson or the trapezoidal rule and the only complexity lies in the implementation of the exact integrals of the type

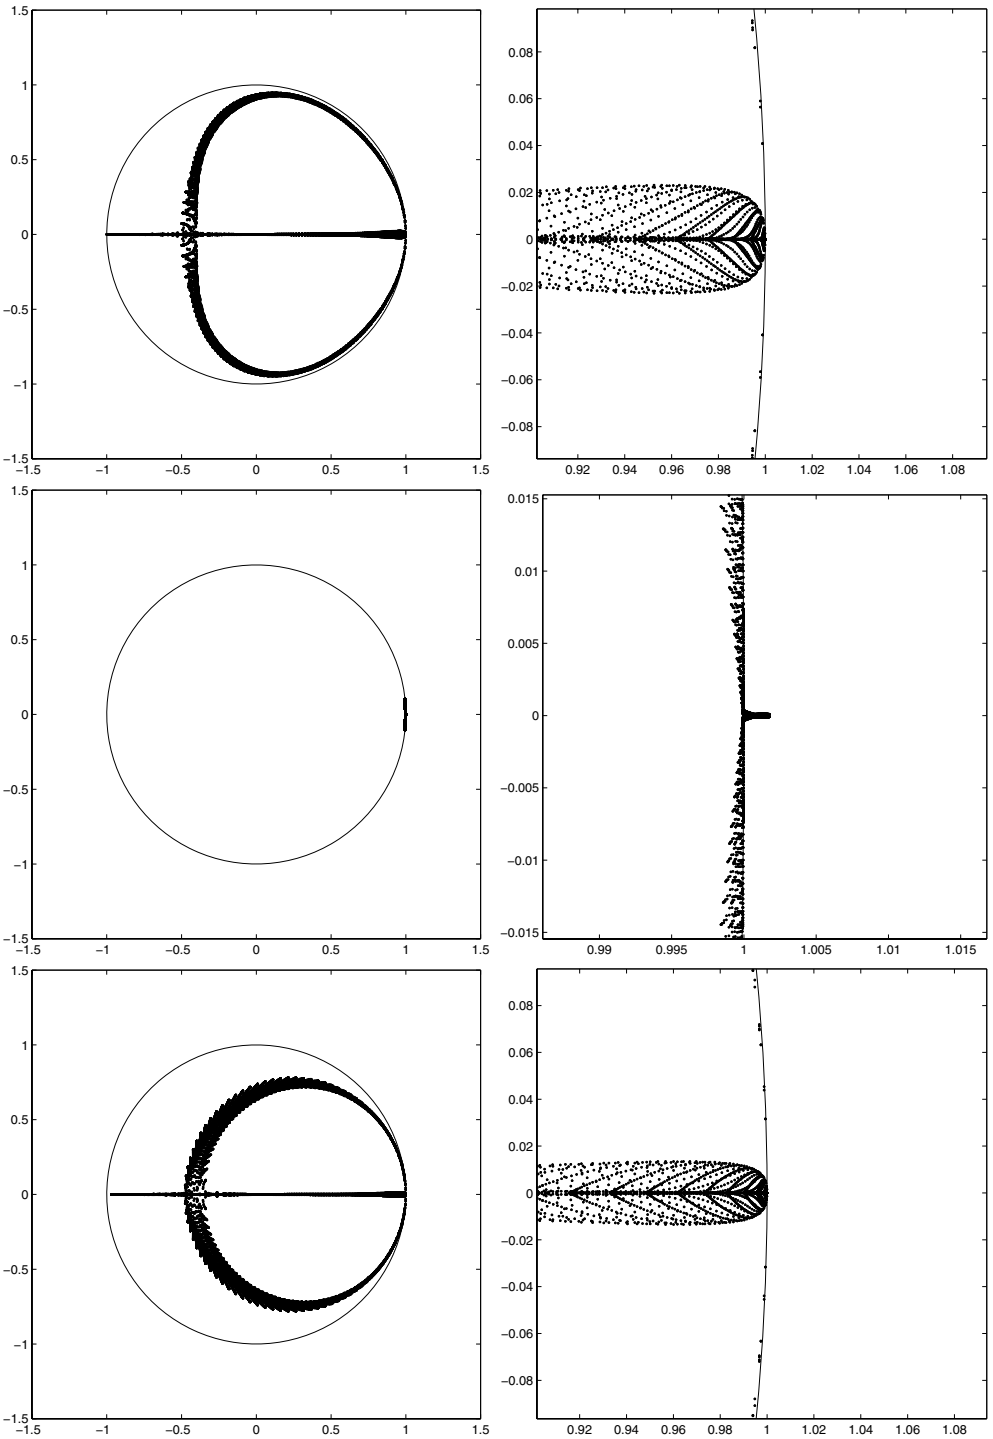

FIG. 5. *Eigenvalues corresponding to the amplification matrices of scheme* A_1 ($CFL = 0.75$), *scheme* B_1 ($CFL = 0.1$), *and scheme* C_1 ($CFL = 0.58$).

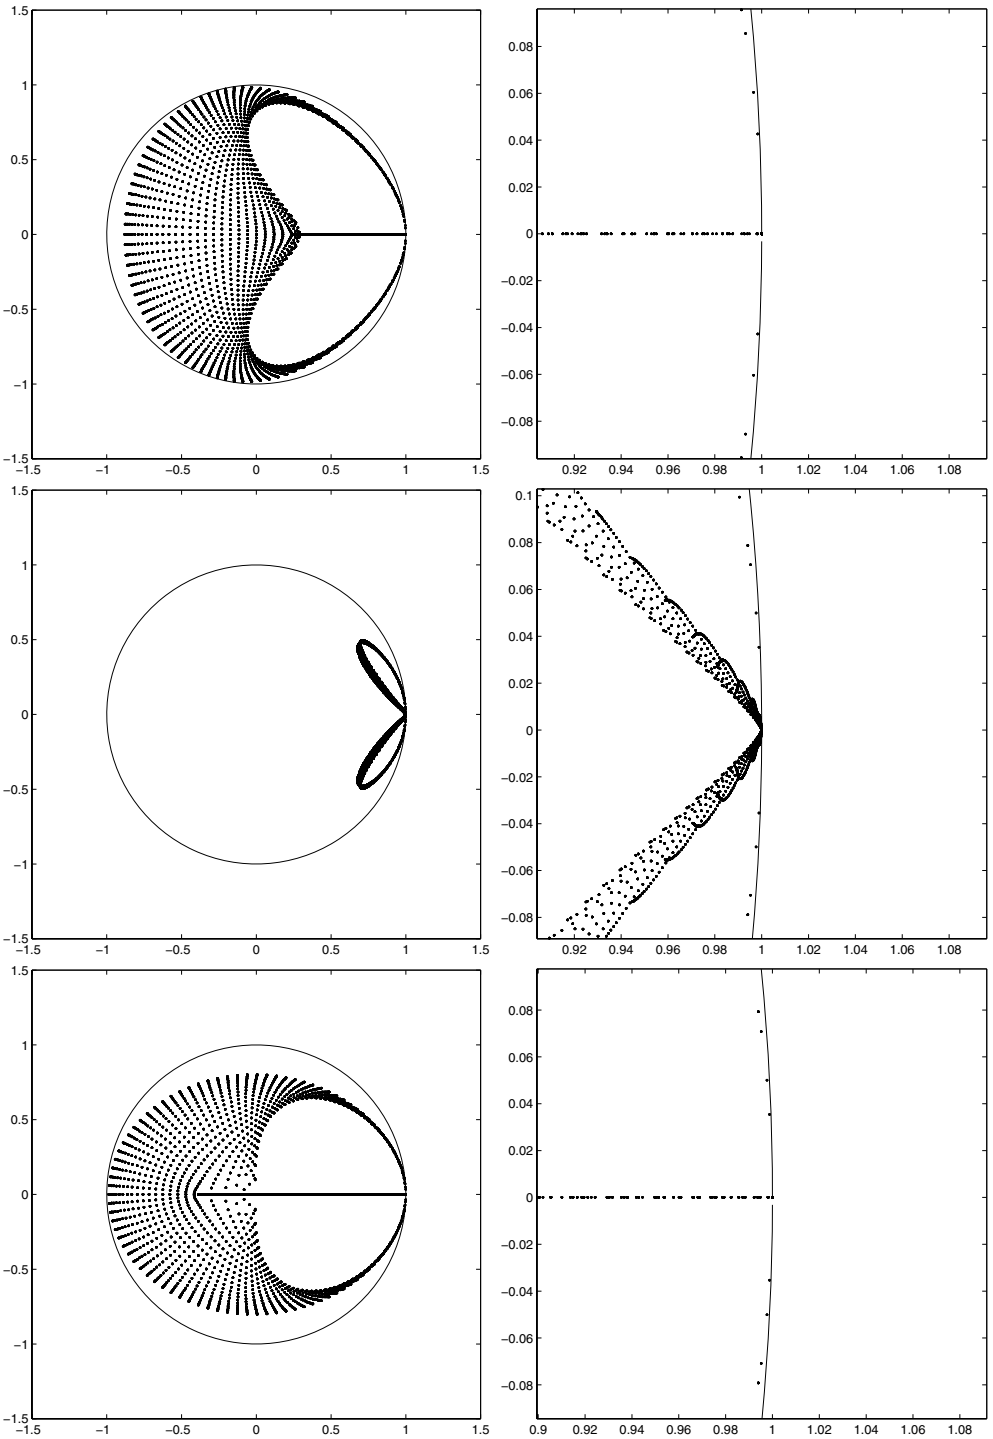

FIG. 6. *Eigenvalues corresponding to the amplification matrices of scheme* A_2 ($CFL = 0.94$), *scheme* B_2 ($CFL = 0.78$), *and scheme* C_2 ($CFL = 0.78$).

$\int_\alpha^\beta \cos^n\theta \sin^m\theta \mathrm{d}\theta$, where $n, m \geq 0$ integers, and $\alpha, \beta \in [0, 2\pi]$ are corresponding angles according to a position of the (slanted) Mach cone. Alternatively, the integrals along the sonic circle, i.e., for θ from 0 to 2π, can be approximated by a suitable numerical quadrature, which further simplifies the implementation of the FVEG schemes.

Based on our knowledge of the EG and FVEG schemes for regular rectangular two-dimensional meshes, some further generalizations have been done. In particular, the FVEG schemes with the approximate evolution operators (3.7)–(3.9), (7.1)–(7.3), and (8.1)–(8.3) have been generalized to three-dimensional problems using regular cubic meshes; see [19]. Further, in [26], [27] the FVEG schemes have been generalized for unstructured triangular meshes. Of course, the stability analysis of the EG schemes on general unstructured meshes is much more involved. One possible way would be to apply the energy analysis in the $L^2(\mathbb{R}^2)$-norm, i.e., to show at least the weak L^2-stability $\|P_h E_{\Delta t}\|_{L^2(\mathbb{R}^2)\to L^2(\mathbb{R}^2)} \leq 1 + C\Delta t$. This is a nontrivial problem, which can be considered in the future.

The absorbing boundary conditions have been studied for the EG schemes extensively in [18]. We have considered simple extrapolation boundary conditions, the characteristic boundary conditions, as well as a perfectly matched layer approach. Numerical experiments reported in [18] indicate that the best results are obtained by combining the EG and FVEG schemes with the perfectly matched layer technique. We have observed no influence of these boundary conditions on stability of the EG schemes. It would be interesting to investigate this question theoretically in the future.

Conclusion. In this paper we have studied the stability of various EG schemes by a von Neumann analysis. The schemes are applied to the linear wave equation system. First, we have discussed theoretical stability estimates of the EG3 schemes, the most favorable one among the finite difference EG schemes considered. Due to the complex structure of the amplification matrix we were able to give theoretical stability estimates only for a simplified problem. Further, we analyzed experimentally the spectral radius of amplification matrix of the EG3 scheme. The experimental analysis indicates that the scheme is stable up to the CFL number 0.58. The stability of the FVEG schemes was studied experimentally, too. It has been shown that new quadratures in time for time integrals in the exact evolution operator, which were proposed in our recent paper [11], improve the stability limits considerably. For example, if the trapezoidal rule is used for the cell interface integrals, the CFL number is 1 and 0.94 for the first and the second order FVEG schemes, respectively. On the other hand, Simpson's quadrature rule reduces the stability range slightly.

Appendix.

EG3 scheme. For the discrete form of the scheme, see (4.4), (4.7), (4.8), and (3.7)–(3.9) for the approximate evolution operator EG3.

$$\alpha^1 := \begin{Bmatrix} \frac{\nu^2}{4\pi} & \frac{\nu}{\pi} - \frac{\nu^2}{2\pi} & \frac{\nu^2}{4\pi} \\ \frac{\nu}{\pi} - \frac{\nu^2}{2\pi} & -\frac{4\nu}{\pi} + \frac{\nu^2}{\pi} & \frac{\nu}{\pi} - \frac{\nu^2}{2\pi} \\ \frac{\nu^2}{4\pi} & \frac{\nu}{\pi} - \frac{\nu^2}{2\pi} & \frac{\nu^2}{4\pi} \end{Bmatrix}, \quad \beta^1 := \begin{Bmatrix} \frac{\nu^2}{3\pi} & 0 & \frac{-\nu^2}{3\pi} \\ \frac{\nu}{2} - \frac{2\nu^2}{3\pi} & 0 & -\frac{\nu}{2} + \frac{2\nu^2}{3\pi} \\ \frac{\nu^2}{3\pi} & 0 & -\frac{\nu^2}{3\pi} \end{Bmatrix},$$

UNCONDITIONAL STABILITY OF CORRECTED EXPLICIT-IMPLICIT DOMAIN DECOMPOSITION ALGORITHMS FOR PARALLEL APPROXIMATION OF HEAT EQUATIONS*

HAN-SHENG SHI† AND HONG-LIN LIAO‡

Abstract. A class of corrected explicit-implicit domain decomposition (CEIDD) methods is investigated for the parallel approximation of linear heat equations. Explicit-implicit domain decomposition (EIDD) methods are computationally and communicationally efficient for each time step but always suffer from small time step size restrictions. By adding an interface correction step to Kuznetsov's EIDD, the one-dimensional CEIDD procedure achieves unconditional stability without discarding the time-stepwise efficiency of the EIDD method. In order to maintain the virtues of the CEIDD method and improve the flexibility in domain partitioning, for solving multidimensional problems, special zigzag-shaped interfaces are suggested in the CEIDD method. Based on noncrossover and crossover types of zigzag interfaces, the resulting CEIDD-ZI algorithms are studied for two strategies of subdomain partition. By the energy method, it shows that the proposed algorithms, including their degenerate cases—the corrected explicit hopscotch schemes—are convergent in the discrete H^1 seminorm and L^2 norm. Numerical experiments confirm the results in our analysis.

Key words. heat equations, nonoverlapping domain decomposition, zigzag-shaped interior boundary, explicit-implicit difference method, stability, convergence

1. Introduction.

We propose a class of corrected explicit-implicit domain decomposition (CEIDD) algorithms for the numerical solution of heat equations

$$u_t = \sum_{m=1}^{d} \frac{\partial}{\partial x_m}\left(a^m(x)\frac{\partial u}{\partial x_m}\right) + f(x,t), \quad (x,t) \in \Omega \times (0,T], \tag{1.1}$$

together with initial and Dirichlet boundary conditions

$$u(x,0) = u^0(x), \quad x \in \Omega, \tag{1.2}$$

$$u(x,t) = u_b(x,t), \quad (x,t) \in \partial\Omega \times (0,T], \tag{1.3}$$

where $\Omega = (0,1)^d$ with $d = 1$ or 2, and the spatial variable $x = (x_m)_{m=1}^d \in \mathbf{R}^d$. The functions $a^m(x)$, $f(x,t)$ are smooth and $a^m(x) \geq a_0$ for a positive constant a_0.

The spatial domain Ω is discretized uniformly with spacing $h = 1/N$ for each spatial variable, where N is an even integer, although different spacing for different spatial variables may be considered in a similar way. And selecting a time step τ and an integer J so that $J\tau = T$, the time interval $(0,T]$ is also discretized uniformly. As usual, the discrete space grid, its boundary, and the discrete time-spatial mesh are denoted by Ω_h, $\partial\Omega_h$, and Ω_h^τ, respectively.

For parallel solutions of time-dependent PDE problems, an interesting approach is to use explicit-implicit alternating algorithms on nonoverlapping domain decomposition; see [4, 5, 6, 8] for related discussions. Kuznetsov [8] proposed a mixed scheme, where the stable implicit scheme is used inside each subdomain while the explicit Euler scheme is applied to obtain the interface solutions on the new time level. Once the interface values are available, the whole problem is completely decoupled and thus can be computed in parallel. Due to the stability constraint, the method is not stable unless time step size $\tau \leq h^2/2$. A similar hybrid scheme was studied by Dawson, Du, and Dupont [4], where instead of using the same spacing h as for the interior points where the fully implicit scheme is applied, a larger spacing h_D is used at interface points where the one-directional implicit predictor scheme is applied. Correspondingly, the stability constraint becomes $\tau \leq h_D^2/2$. These globally noniterative explicit-implicit domain decomposition (EIDD) algorithms are computationally and communicationally efficient for each time step when compared with Schwarz-type domain decomposition elliptic solvers [2, 3] incorporated into implicit temporal discretizations; however, they suffer from stability-related time step restrictions, while Schwarz methods could maintain the good stability of implicit temporal discretization schemes.

Recently, many investigators have turned to improve the stability of EIDD methods because the time-stepwisely efficient EIDD procedures will process great potential for large-scale parallel simulations on distributed memory computers if they are free from time step size restrictions. A penalized EIDD algorithm proposed by Black [1] achieves numerically verified unconditional stability by employing a stable Du Fort–Frankel-type scheme as the explicit predictor; however, it makes the algorithm inconsistent unless $\tau/h \to 0$. Thus consistency comes only after paying a price of restricting time step size $\tau = \mathcal{O}(h^2)$ to achieve a first order temporal accuracy, a restriction quantitatively similar to the restriction on the EIDD methods.

An alternative approach for improving the stability is to apply an implicit correction technique to EIDD algorithms. The idea of implicit correction is to replace the interface predictor value by a new solution on the interface boundaries computed by an implicit corrector scheme. In 1998, Qian and Zhu [9] investigated experimentally the implicit correction technique for Kuznetsov's EIDD method [8] for the one-dimensional (1-D) heat equation and showed the better stability by comparing its results with several other methods. As the generalizations of Qian's algorithm [9], the stabilized EIDD methods proposed by Zhuang and Sun [11] exhibit unconditional stability experimentally for a wide range of multidimensional parabolic problems, from heat equation to convection-diffusion to nondissipative convection-diffusion. However, (P1) both attempts failed to consider the mathematical proofs of the improved stability. Furthermore, for multidimensional problems, the methods in [11] (P2) suffer from a parallel time overload for the interface correction step because some elliptic solver should be used to obtain the interface solutions, and (P3) decrease the flexibility of domain partitioning due to the noncrossover assumption of interior boundaries.

To remedy the disadvantages (P1)–(P3), in this paper, a new class of CEIDD algorithms is reported. First, a generic parallel version of the CEIDD algorithm for computing the solution u_h^k is presented below (also see [11]).

The parallel CEIDD algorithm.

0. Determine the shape of man-made interior interfaces Γ_h and the strategy of domain partitioning. Then divide the entire domain Ω_h into $p = \prod_{m=1}^{d} p_m$ subdomains $\Omega_{h,1}, \ldots, \Omega_{h,p}$ with interface boundary between $\Omega_{h,i}$ and $\Omega_{h,j}$ denoted by Γ_{ij} $(1 \leq i < j < p)$. Assign subdomain $\Omega_{h,i}$ and interface Γ_{ij} to processor P_i. Go to step 1 with $k := 1$.

1. On each processor P_i, compute all of the interface predictors $\tilde{u}_h^k$ on Γ_{ij} in parallel using an explicit scheme and then pass $\tilde{u}_h^k$ from P_i to P_j for the subdomain operation. Go to step 2.
2. Compute solutions u_h^k in parallel inside each subdomain $\Omega_{h,i}$ using any unconditionally stable scheme with the predictors $\tilde{u}_h^k$ computed at step 1 as the interface boundary conditions of Dirichlet type. Then pass part of subdomain data u_h^k from P_j to P_i for the correction computation. Go to step 3.
3. On each processor P_i, throw away the interface predictors obtained at step 1 and bring back u_h^{k-1} on Γ_{ij}. Compute the interface correctors u_h^k on Γ_{ij} in parallel using a fully implicit scheme. If $k = J$, stop the procedure; if not, return to step 1 for the next time level iteration with $k := k + 1$.

In the above algorithm, we consider noncrossover and crossover types of zigzag-shaped interfaces and the corresponding strategies of domain decomposition in step 0. The forward Euler scheme is used at step 1 and the backward Euler scheme is applied at steps 2–3. In other words, the implicit correction technique [9] and special zigzag-shaped interfaces are added to Kuznetsov's EIDD method [8]. The resulting method is denoted by CEIDD-ZI (CEIDD based on zigzag-shaped interfaces). Since the interface between two subdomains is only one point in the 1-D case, the 1-D CEIDD-ZI algorithm is also denoted by CEIDD.

For practical implementations, we always assume that $2 \le p \ll |\Omega_h|$ so that the parallel algorithms are of coarse granularity, where $|\Omega_h|$ is the number of unknown points inside Ω_h. However, for theoretical approaches, it is reasonable to assume that

(1.4) *each subdomain has at least one interior grid point.*

For a negative example, let $p = |\Omega_h|$; then each subdomain has no interior point and step 2 of the algorithm can be omitted. Actually, step 1 is also not needed because the interface predictors $\tilde{u}_h^k$ at Γ_h are thrown away at step 3. Therefore, an elliptic solver has to be employed to find the solutions u_h^k on $\Gamma_h (= \Omega_h)$ at step 3. The solver is carried out on only one processor with other processors standing idle. In such a case, however, CEIDD algorithms are unconditionally stable since it essentially equals a sequential backward Euler scheme. On the other hand, if there exists an empty subdomain, i.e., a subdomain has no interior grid points, the interface nearby can be deleted to make the new subdomain contain at least one interior point.

Under the subdomain-width assumption (1.4), we obtain following results.

1. The CEIDD-ZI methods add negligible computation cost to EIDD algorithms (Propositions 3.1 and 5.1).
2. The CEIDD-ZI methods are unconditionally stable (Theorems 4.3 and 6.3).
3. With an order of $\mathcal{O}\big(\sqrt{1 + \sum_{m=1}^{d}(p_m - 1)h^{-1}(\tau + h^2)}\big)$, the numerical solutions of the CEIDD-ZI methods converge to the exact solution of continuous problem (Theorems 4.4 and 6.4).

For the linear problem considered in the present paper, the unconditional stability of a domain decomposition algorithm is theoretically proved in the sense that the numerical solutions of the algorithm are continuously dependent on the initial value $u^0(x)$ and the outer-forced term $f(x,t)$ without any restrictions of the mesh ratio $r = \tau/h$ and the strategy of domain decomposition.

The context will be organized as follows. The next section presents some notation and auxiliary lemmas. The detailed presentation of the CEIDD method for the 1-D problem is given in section 3. Section 4 has witnessed the rigorous study of the stability and convergence of the CEIDD method based on multisubdomain decompo-

sition. Designing noncrossover and crossover types of zigzag-line interior boundary, we present two-dimensional (2-D) CEIDD-ZI procedures for two strategies of domain decomposition in section 5 together with analysis of computation and communication overhead of the correction. Section 6 provides the theoretical analysis of the two parallel CEIDD-ZI approaches. Numerical experiments are addressed in section 7, and some comments, including the three-dimensional (3-D) extension of CEIDD-ZI algorithms, are presented in the concluding section.

2. Notation and some auxiliary lemmas. For 1-D problems, $\Omega_h^\tau = \{(ih, k\tau) | 1 \le i \le N-1, 0 \le k \le J\}$. With v a mesh function on Ω_h^τ, we denote $\partial_t v^k = (v^k - v^{k-1})/\tau$, $\delta_x v_{i-\frac{1}{2}} = (v_i - v_{i-1})/h$, and

$$\Delta_h v_i = (a_{i+\frac{1}{2}} \delta_x v_{i+\frac{1}{2}} - a_{i-\frac{1}{2}} \delta_x v_{i-\frac{1}{2}})/h = (a_{i+\frac{1}{2}} v_{i+1} - 2\bar{a}_i v_i + a_{i-\frac{1}{2}} v_{i-1})/h^2,$$

where $a_{i-\frac{1}{2}} = a(x_{i-\frac{1}{2}}), \bar{a}_i = (a_{i+\frac{1}{2}} + a_{i-\frac{1}{2}})/2$. Supposing that grid functions $u, v \in \Omega_h$, we define the discrete inner product by $\langle u, v \rangle = h \sum_{i=1}^{N-1} u_i v_i$, the discrete L^2 norm by $\|v\| = \sqrt{\langle v, v \rangle}$, and the H^1 seminorm by

$$|v|_{a,1} = \|\sqrt{a}\delta_x v\| \equiv \sqrt{h \sum_{i=1}^{N} a_{i-\frac{1}{2}} (\delta_x v_{i-\frac{1}{2}})^2}.$$

In the 2-D case, $\Omega_h^\tau = \{(ih, jh, k\tau) | 1 \le i, j \le N-1, 0 \le k \le J\}$. The difference operators are defined similarly, such as $\delta_{x_1} v_{i-\frac{1}{2},j} = (v_{i,j} - v_{i-1,j})/h$,

$$\Delta_{h,1} v_{ij} = (a^1_{i+\frac{1}{2},j} \delta_{x_1} v_{i+\frac{1}{2},j} - a^1_{i-\frac{1}{2},j} \delta_{x_1} v_{i-\frac{1}{2},j})/h,$$

and $\Delta_h v_{ij} = \Delta_{h,1} v_{ij} + \Delta_{h,2} v_{ij}$. We also denote that $\bar{a}^1_{ij} = (a^1_{i+\frac{1}{2},j} + a^1_{i-\frac{1}{2},j})/2$, $\bar{a}^2_{ij} = (a^2_{i,j+\frac{1}{2}} + a^2_{i,j-\frac{1}{2}})/2$, and $\bar{a}^{12}_{ij} = \bar{a}^1_{ij} + \bar{a}^2_{ij}$. The inner product is defined by $\langle u, v \rangle = h^2 \sum_{i,j=1}^{N-1} u_{ij} v_{ij}$, the discrete L^2 norm by $\|v\| = \sqrt{\langle v, v \rangle}$, and the H^1 seminorm by

$$|v|_{a,1} = \sqrt{\|\sqrt{a^1}\delta_{x_1} v\|^2 + \|\sqrt{a^2}\delta_{x_2} v\|^2}.$$

Throughout this paper, the discrete energy method is employed to establish the stability and convergence of parallel CEIDD-ZI algorithms. Some preparatory lemmas are given below.

LEMMA 2.1. *Let $v \in \Omega_h^\tau$. Then it holds that*

(a) $2v^k \partial_t v^k = \partial_t [(v^k)^2] + \tau (\partial_t v^k)^2$;

(b) $2v^{k-1} \partial_t v^k = \partial_t [(v^k)^2] - \tau (\partial_t v^k)^2$.

Proof. Equality (a) can be derived directly from

$$2v^k (v^k - v^{k-1}) = (v^k)^2 - (v^{k-1})^2 + (v^k - v^{k-1})^2,$$

and (b) similarly. ∎

LEMMA 2.2. *Assume that $v \in \Omega_h^\tau$, and $v(x) = 0$ for $x \in \partial\Omega_h$. Then*

(a) $\langle v, \Delta_h v \rangle = -|v|^2_{a,1}$;

(b) $2\langle \partial_t v^k, \Delta_h v^k \rangle = -\partial_t (|v^k|^2_{a,1}) - \tau |\partial_t v^k|^2_{a,1}$.

Proof. The zero boundary condition and Abel integrate formulation of parts lead to (a). Equality (b) can be derived from (a) and Lemma 2.1(a). ∎

LEMMA 2.3 (discrete Gronwall inequality). *Assume that* $\{G^k|k \geq 0\}$ *is a nonnegative sequence,* $\sigma \geq 0$, $\Phi^0 \geq 0$, *and that* F^k *satisfies* $F^0 \leq \Phi^0$,

$$F^k \leq \Phi^0 + \sigma \sum_{l=0}^{k-1} F^l + \sum_{l=0}^{k} G^l, \quad k \geq 1.$$

Then F^k *satisfies*

$$F^k \leq e^{k\sigma}\left(\Phi^0 + \sum_{l=0}^{k} G^l\right), \quad k \geq 0.$$

Proof. An induction argument gives the result; see also [10] for a detail. ∎

3. Parallel CEIDD algorithm for 1-D problems. We decompose the domain $(0,1)$ into p nonoverlapping subdomains. In general, p is related to the problem size and the number of processors in the computer platform, and the subdomains may be of different widths; however, for theoretical considerations, the subdomain-width assumption (1.4) implies that $2 \leq p \leq N/2$, and that there are $(p-1)$ interfaces $\Gamma_h = \bigcup_{\alpha=1}^{p-1} \Gamma_{h,\alpha}$, where

$$\Gamma_{h,\alpha} = \{i_\alpha h|\ 4 \leq i_\alpha + 2 \leq i_{\alpha+1} \leq N-2\}. \tag{3.1}$$

Then Ω_h is decoupled into p nonoverlapping subdomains $\Omega_{h,1} = \{ih|\ 0 < i < i_1\}$, $\Omega_{h,\xi} = \{ih|\ i_{\xi-1} < i < i_\xi\}\,(\xi = 2, \ldots, p-1)$, and $\Omega_{h,p} = \{ih|\ i_{p-1} < i < N\}$, where $\Gamma_{h,\alpha}\,(1 \leq \alpha \leq p-1)$ is the common interface of subdomains $\Omega_{h,\alpha}$ and $\Omega_{h,\alpha+1}$.

Suppose that u_i^k is the numerical approximation of exact solution $u(ih, k\tau)$ on Ω_h^τ; the 1-D CEIDD method on general p subdomains is described below.

THE 1-D PARALLEL CEIDD ALGORITHM ON p SUBDOMAINS.

0. We have p processors denoted as $P_\xi\,(\xi = 1, \ldots, p)$. Assign subdomain $\Omega_{h,\xi}$ to processor P_ξ and interface $\Gamma_{h,\alpha}$ to processor $P_\alpha\,(\alpha = 1, \ldots, p-1)$. To start the procedure, the initial condition (1.2) is discretized as

$$u_i^0 = u^0(ih) \ \text{ on } \ \Omega_h. \tag{3.2}$$

Set $k = 1$ and go to step 1.

1. On each processor P_α, we obtain the predictor value $\tilde{u}_{i_\alpha}^k$ in parallel by applying the explicit Euler scheme to (1.1), that is,

$$\frac{\tilde{u}_{i_\alpha}^k - u_{i_\alpha}^{k-1}}{\tau} = \Delta_h u_{i_\alpha}^{k-1} + f_{i_\alpha}^{k-1} \ \text{ at } \ \Gamma_{h,\alpha}. \tag{3.3}$$

Then pass $\tilde{u}_{i_\alpha}^k$ from P_α to $P_{\alpha+1}$ and go to step 2.

2. The implicit Euler scheme is adopted on each subdomain $\Omega_{h,\xi}$, where the predictor values $\tilde{u}_h^k$ at Γ_h are served the Dirichlet boundary condition, viz.,

$$\begin{cases} \partial_t u_i^k = \Delta_h u_i^k + f_i^k & \text{on } \ \Omega_{h,\xi} \\ u_i^k = \tilde{u}_i^k & \text{at } \ \partial\Omega_{h,\xi} \cap \Gamma_h \\ u_i^k = u_b(ih, k\tau) & \text{at } \ \partial\Omega_{h,\xi} \cap \partial\Omega_h \end{cases} \quad \big(\xi = 1, 2, \ldots, p\big), \tag{3.4}$$

where $\partial\Omega_{h,\xi} \cap \Gamma_h = \{ih|i = i_{\xi-1} \ \text{ and/or } \ i = i_\xi\}$, $\partial\Omega_{h,\xi} \cap \partial\Omega_h$ is always empty except $\partial\Omega_{h,1} \cap \partial\Omega_h = \{0\}$, and $\partial\Omega_{h,p} \cap \partial\Omega_h = \{Nh\}$. Thus, the Thomas algorithm can be applied in parallel on each processor to find the subdomain solutions. Then pass the subdomain data $u_{i_\alpha+1}^k$ from $P_{\alpha+1}$ to P_α for the correction computation. Go to step 3.

3. On each processor P_α, throw away the interface predictors $\tilde{u}^k_{i_\alpha}$ obtained at step 1 and bring back $u^{k-1}_{i_\alpha}$ at $\Gamma_{h,\alpha}$. We obtain the interface solution $u^k_{i_\alpha}$ in parallel by using the implicit Euler scheme,

$$\partial_t u^k_{i_\alpha} = \Delta_h u^k_{i_\alpha} + f^k_{i_\alpha} \quad \text{at} \quad \Gamma_{h,\alpha}. \tag{3.5}$$

If $k = J$, stop the procedure; else, return to step 1 with $k := k + 1$.

For each interface boundary $\Gamma_{h,\alpha}$ ($\alpha = 1, 2, \ldots, p-1$), the interface-related steps (steps 1 and 3) are carried out on the assigned processor P_α, and then data transfer operations between P_α and $P_{\alpha+1}$ are necessary for each time level, as is the case with any EIDD method; however, the implicit correction step of the CEIDD method adds zero communication cost to EIDD algorithms because the data communication at step 2 is also necessary for computing the interface predictors at new time level t^{k+1} in EIDD algorithms.

On the other hand, given the solutions on subdomains, the implicit scheme (3.5) obtains the interface solution explicitly,

$$(1 + 2\bar{a}_{i_\alpha} r)u^k_{i_\alpha} = u^{k-1}_{i_\alpha} + r\left(a_{i_\alpha - \frac{1}{2}} u^k_{i_\alpha - 1} + a_{i_\alpha + \frac{1}{2}} u^k_{i_\alpha + 1}\right) + \tau f^k_{i_\alpha}, \quad 1 \le \alpha \le p-1,$$

where mesh ratio $r = \tau/h^2$. That is to say, the implicit correction (step 3) of the CEIDD algorithm adds negligible computation cost to any EIDD algorithm. Thus the CEIDD method maintains the efficiency in computation and communication of the EIDD methods, as the following proposition states.

PROPOSITION 3.1. *The implicit correction step of the CEIDD algorithm* (3.2)–(3.5) *adds zero communication and negligible computation cost to EIDD algorithms.*

Furthermore, in the next section, we will show that the proposed CEIDD algorithm is unconditionally stable. To end this section, we mention a special CEIDD procedure here for completeness. If there are $\frac{N}{2}$ subdomains, or each subdomain has only one interior point, then Kuznetsov's EIDD method is just the so-called explicit hopscotch scheme [7] and the CEIDD algorithm degenerates to a corrected explicit hopscotch (CEH) scheme, which is a small-block explicit method since the subdomain solution can be computed explicitly by using (3.4). Specifically, for computing solution u^k_h from the data at time level t^{k-1}, the CEH procedure can be described as the following point-related schemes, for $1 \le i \le N-1$:

$$\tilde{u}^k_i = u^{k-1}_i + \tau \Delta_h u^{k-1}_i + \tau f^{k-1}_i, \qquad i \in \text{even}, \tag{3.6}$$

$$(1 + 2\bar{a}_i r)u^k_i = u^{k-1}_i + r(a_{i-\frac{1}{2}} \tilde{u}^k_{i-1} + a_{i+\frac{1}{2}} \tilde{u}^k_{i+1}) + \tau f^k_i, \quad i \in \text{odd}, \tag{3.7}$$

$$(1 + 2\bar{a}_i r)u^k_i = u^{k-1}_i + r(a_{i-\frac{1}{2}} u^k_{i-1} + a_{i+\frac{1}{2}} u^k_{i+1}) + \tau f^k_i, \quad i \in \text{even}, \tag{3.8}$$

where the notation $\tilde{u}^k_0$ and $\tilde{u}^k_N$ is used in (3.7) with complementary definitions: $\tilde{u}^k_0 \equiv u^k_0$ and $\tilde{u}^k_N \equiv u^k_N$. Obviously, the CEH scheme is a fast CEIDD algorithm; however, as revealed later, it suffers from more loss of accuracy compared with the coarsely granular algorithm in the case of $2 < p \ll N$.

4. Theoretical analysis of the 1-D CEIDD algorithm. In this section, the prior estimations of the solution are established by the energy method. And the theoretical results on stability and convergence of the CEIDD algorithm are obtained by using those prior estimations.

LEMMA 4.1 (H^1-estimation). *Let $v^k_h = \{v^k_i | 0 \le i \le N, 0 \le k \le J\}$ satisfy the CEIDD algorithm on p subdomains decoupled by the interfaces Γ_h defined by* (3.1)*:*

$$\frac{\tilde{v}^k_i - v^{k-1}_i}{\tau} = \Delta_h v^{k-1}_i + \tilde{g}^{k-1}_i \quad \text{at} \quad \Gamma_h, \quad 1 \le k \le J, \tag{4.1}$$

$$\begin{cases} \partial_t v_i^k = \Delta_h v_i^k + g_i^k & on \quad \Omega_{h,\xi} \\ v_i^k = \tilde{v}_i^k & at \quad \Gamma_h \end{cases} \quad \big(\xi = 1, 2, \ldots, p\big), \quad 1 \le k \le J, \tag{4.2}$$

$$\partial_t v_i^k = \Delta_h v_i^k + g_i^k \qquad at \quad \Gamma_h, \quad 1 \le k \le J, \tag{4.3}$$

$$v_i^0 = \phi_i, \qquad 0 \le i \le N, \quad 1 \le k \le J, \tag{4.4}$$

$$v_0^k = v_N^k = 0, \qquad 0 \le k \le J. \tag{4.5}$$

Then it holds that

$$E_1^k \le \frac{3}{2} e^{\frac{3}{2}k\tau} \left[E_1^0 + \tau \sum_{l=1}^{k} \big(\|g^l\|^2 + |||g^l|||_{I,1}^2 \big) \right], \quad 1 \le k \le J, \tag{4.6}$$

for $0 < \tau \le 1/3$, *where*

$$E_1^k = |v^k|_{a,1}^2 + 2\tau^2 h^{-1} \sum_{\alpha=1}^{p-1} \bar{a}_{i_\alpha} (\Delta_h v_{i_\alpha}^k)^2,$$

$$|||g^k|||_{I,1}^2 = \sum_{\alpha=1}^{p-1} \left[2\bar{a}_{i_\alpha} \tau h^{-1} (\tilde{g}_{i_\alpha}^{k-1})^2 + \frac{1}{2} \big(h + 4\bar{a}_{i_\alpha} h^{-1} \big) (g_{i_\alpha}^k - \tilde{g}_{i_\alpha}^{k-1})^2 \right].$$

Proof. To make the calculations more transparent and the notation simpler, we are going to write out the proof of this lemma only for two subdomains $\Omega_{h,\xi}$ $(\xi = 1, 2)$ decoupled by the one-point interface $\Gamma_{h,1} = \{i_1 h\}$. The proof in the general p-subdomain case is similar to the 2-subdomain case, but the notation is messier.

For the 2-subdomain case, the interface schemes (4.1) and (4.3) lead to

$$(\tilde{v}_{i_1}^k - v_{i_1}^k) = -\tau^2 (\partial_t \Delta_h v_{i_1}^k) - \tau (g_{i_1}^k - \tilde{g}_{i_1}^{k-1}),$$

and the solution schemes (4.2)–(4.3) read as

$$\partial_t v_i^k = \Delta_h v_i^k + g_i^k, \quad 0 < i < i_1 - 1, \quad 1 \le k \le J, \tag{4.7}$$

$$\partial_t v_{i_1-1}^k = \Delta_h v_{i_1-1}^k + g_{i_1-1}^k + a_{i_1-\frac{1}{2}} (\tilde{v}_{i_1}^k - v_{i_1}^k)/h^2, \quad 1 \le k \le J, \tag{4.8}$$

$$\partial_t v_{i_1}^k = \Delta_h v_{i_1}^k + g_{i_1}^k, \quad 1 \le k \le J, \tag{4.9}$$

$$\partial_t v_{i_1+1}^k = \Delta_h v_{i_1+1}^k + g_{i_1+1}^k + a_{i_1+\frac{1}{2}} (\tilde{v}_{i_1}^k - v_{i_1}^k)/h^2, \quad 1 \le k \le J, \tag{4.10}$$

$$\partial_t v_i^k = \Delta_h v_i^k + g_i^k, \quad i_1 + 1 < i < N, \quad 1 \le k \le J. \tag{4.11}$$

Multiplying (4.7)–(4.11), respectively, by $2h\partial_t v_i^k$, $2h\partial_t v_{i_1-1}^k$, $2h\partial_t v_{i_1}^k$, $2h\partial_t v_{i_1+1}^k$, and $2h\partial_t v_i^k$, summing i, and adding the resulting equalities, we get

$$2\langle \partial_t v^k, \partial_t v^k \rangle = 2\langle \partial_t v^k, \Delta_h v^k \rangle + 2\langle \partial_t v^k, g^k \rangle + Q_{1i_1}^k.$$

By using Lemma 2.2(b) and inequality

$$2\langle \partial_t v^k, g^k \rangle \le \|\partial_t v^k\|^2 + \|g^k\|^2,$$

it follows that

$$\partial_t (|v^k|_{a,1}^2) \le -\|\partial_t v^k\|^2 - \tau |v^k|_{a,1}^2 + \|g^k\|^2 + Q_{1i_1}^k \le \|g^k\|^2 + Q_{1i_1}^k. \tag{4.12}$$

And, for the interface term $Q_{1i_1}^k$, it holds that

$$Q_{1i_1}^k = 2h^{-1} (\tilde{v}_{i_1}^k - v_{i_1}^k) \big(a_{i_1-\frac{1}{2}} \partial_t v_{i_1-1}^k + a_{i_1+\frac{1}{2}} \partial_t v_{i_1+1}^k \big)$$

$$
\begin{aligned}
&= 2h^{-1}(\tilde{v}_{i_1}^k - v_{i_1}^k)\left(h^2\partial_t\Delta_h v_{i_1}^k + 2\bar{a}_{i_1}\partial_t v_{i_1}^k\right)\\
&= -2h^{-1}\Big[\tau^2(\partial_t\Delta_h v_{i_1}^k) + \tau(g_{i_1}^k - \tilde{g}_{i_1}^{k-1})\Big]\Big(h^2\partial_t\Delta_h v_{i_1}^k + 2\bar{a}_{i_1}\Delta_h v_{i_1}^k + 2\bar{a}_{i_1}g_{i_1}^k\Big)\\
&= I_1 + I_2 + I_3 + I_4 + I_5,
\end{aligned}
$$

where, applying Lemma 2.1 and the well-known Young inequality,

$$
\begin{aligned}
I_1 &= -2\tau^2h^{-1}(\partial_t\Delta_h v_{i_1}^k)\left(h^2\partial_t\Delta_h v_{i_1}^k + 2\bar{a}_{i_1}\Delta_h v_{i_1}^k\right)\\
&= -2\tau^2h(\partial_t\Delta_h v_{i_1}^k)^2 - 2\bar{a}_{i_1}\tau^2h^{-1}\partial_t[(\Delta_h v_{i_1}^k)^2] - 2\bar{a}_{i_1}\tau^3h^{-1}(\partial_t\Delta_h v_{i_1}^k)^2,\\
I_2 &= -4\bar{a}_{i_1}\tau^2h^{-1}(\partial_t\Delta_h v_{i_1}^k)g_{i_1}^k \le 2\bar{a}_{i_1}\tau^3h^{-1}(\partial_t\Delta_h v_{i_1}^k)^2 + 2\bar{a}_{i_1}\tau h^{-1}(g_{i_1}^k)^2,\\
I_3 &= -2\tau h(g_{i_1}^k - \tilde{g}_{i_1}^{k-1})(\partial_t\Delta_h v_{i_1}^k) \le 2\tau^2h(\partial_t\Delta_h v_{i_1}^k)^2 + \frac{1}{2}h(g_{i_1}^k - \tilde{g}_{i_1}^{k-1})^2,\\
I_4 &= -4\bar{a}_{i_1}\tau h^{-1}(g_{i_1}^k - \tilde{g}_{i_1}^{k-1})(\Delta_h v_{i_1}^k)\\
&\le 2\bar{a}_{i_1}\tau^2h^{-1}(\Delta_h v_{i_1}^k)^2 + 2\bar{a}_{i_1}h^{-1}(g_{i_1}^k - \tilde{g}_{i_1}^{k-1})^2,\\
I_5 &= -4\bar{a}_{i_1}\tau h^{-1}(g_{i_1}^k - \tilde{g}_{i_1}^{k-1})g_{i_1}^k = -4\bar{a}_{i_1}\tau h^{-1}(g_{i_1}^k)^2 + 4\bar{a}_{i_1}\tau h^{-1}g_{i_1}^k\tilde{g}_{i_1}^{k-1}\\
&\le -2\bar{a}_{i_1}\tau h^{-1}(g_{i_1}^k)^2 + 2\bar{a}_{i_1}\tau h^{-1}(\tilde{g}_{i_1}^{k-1})^2.
\end{aligned}
$$

Thus, adding I_m from $m = 1$ to 5, we obtain

$$
Q_{1i_1}^k \le -2\bar{a}_{i_1}\tau^2h^{-1}\partial_t[(\Delta_h v_{i_1}^k)^2] + 2\bar{a}_{i_1}\tau^2h^{-1}(\Delta v_{i_1}^k)^2 + |||g^k|||_{I,1}^2. \tag{4.13}
$$

From (4.13) and (4.12), it follows that

$$
\partial_t E_1^k \le E_1^k + \|g^k\|^2 + |||g^k|||_{I,1}^2, \qquad 1 \le k \le J,
$$

which leads to

$$
(1-\tau)E_1^k \le E_1^0 + \tau\sum_{l=1}^{k-1}E_1^l + \tau\sum_{l=1}^{k}\left(\|g^l\|^2 + |||g^l|||_{I,1}^2\right), \qquad 1 \le k \le J.
$$

Supposing that $0 < \tau \le 1/3$, we have

$$
E_1^k \le \frac{3}{2}E_1^0 + \frac{3\tau}{2}\sum_{l=1}^{k-1}E_1^l + \frac{3\tau}{2}\sum_{l=1}^{k}\left(\|g^l\|^2 + |||g^l|||_{I,1}^2\right), \qquad 1 \le k \le J.
$$

Then Lemma 2.3 implies prior estimation (4.6), and the proof is complete. ∎

LEMMA 4.2 (L^2-estimation). *Let $v_h^k = \{v_i^k | 0 \le i \le N, 0 \le k \le J\}$ be the solution of the CEIDD algorithm* (4.1)–(4.5). *Then it holds that*

$$
\begin{aligned}
E_2^k \le{}& \frac{3}{2}(J+1)\exp\left(\frac{3}{2}(1+T)k\tau\right)E_2^0\\
&+ \frac{3T}{2}\exp\left(\frac{3}{2}(1+T)k\tau\right)\left[4\tau\sum_{l=0}^{k}E_1^l + \tau\sum_{l=1}^{k}(\|g^l\|^2 + |||g^l|||_{I,2}^2)\right]
\end{aligned} \tag{4.14}
$$

for $0 < \tau \le 1/3, 1 \le k \le J$, where

$$
E_2^k = \tau\sum_{l=0}^{k}\|v^l\|^2 + \tau^3h\sum_{\alpha=1}^{p-1}\sum_{l=0}^{k}(\Delta_h v_{i_\alpha}^l)^2 + 2\tau^2h^{-1}\sum_{\alpha=1}^{p-1}\bar{a}_{i_\alpha}(v_{i_\alpha}^k)^2,
$$

$$|||g^1|||_{I,2}^2 = \sum_{\alpha=1}^{p-1} \left\{ 2\bar{a}_{i_\alpha}\tau^2 h^{-1}\Big[(g_{i_\alpha}^1)^2 + 2(\tilde{g}_{i_\alpha}^0)^2\Big] + h(g_{i_\alpha}^1 - \tilde{g}_{i_\alpha}^0)^2 + 2\bar{a}_{i_\alpha}h^{-1}(\tilde{g}_{i_\alpha}^0)^2 \right\},$$

$$\begin{aligned}|||g^k|||_{I,2}^2 = &\sum_{\alpha=1}^{p-1} 2\bar{a}_{i_\alpha}\tau^2 h^{-1}\Big[(g_{i_\alpha}^k)^2 + 2(g_{i_\alpha}^{k-1})^2 + 2(\tilde{g}_{i_\alpha}^{k-1})^2\Big] \\ &+ \sum_{\alpha=1}^{p-1} \Big[h(g_{i_\alpha}^k - \tilde{g}_{i_\alpha}^{k-1})^2 + 2\bar{a}_{i_\alpha}h^{-1}(g_{i_\alpha}^{k-1} - \tilde{g}_{i_\alpha}^{k-1})^2\Big], \quad k \geq 2.\end{aligned}$$

Proof. As in the proof of Lemma 4.1, we are going to write out this proof only for two subdomains $\Omega_{h,\xi}\,(\xi = 1, 2)$ decoupled by the one-point interface $\Gamma_{h,1} = \{i_1 h\}$ and suppose that v_h^k satisfies (4.7)–(4.11) and (4.4)–(4.5). For the sake of succinctness, we also use the notation

$$G^k \equiv \|v^k\|^2 + \tau^2 h(\Delta_h v_{i_1}^k)^2 + 2\bar{a}_{i_1}\tau^2 h^{-1}\partial_t(v_{i_1}^k)^2;$$

then $G^k = \partial_t E_2^k$ for $1 \leq k \leq J$.

Multiplying (4.7)–(4.11), respectively, by $2hv_i^k$, $2hv_{i_1-1}^k$, $2hv_{i_1}^k$, $2hv_{i_1+1}^k$, and $2hv_i^k$, summing i, and adding the resulting equalities, we get

$$2\left\langle v^k, \partial_t v^k \right\rangle = 2\left\langle v^k, \Delta_h v^k \right\rangle + 2\left\langle v^k, g^k \right\rangle + Q_{2i_1}^k.$$

Owing to

$$2\left\langle v^k, \partial_t v^k \right\rangle = \partial_t(\|v^k\|^2) + \tau\|\partial_t v^k\|^2$$

and

$$2\langle v^k, g^k\rangle \leq \|v^k\|^2 + \|g^k\|^2,$$

the above equality becomes

$$\partial_t(\|v^k\|^2) \leq \|v^k\|^2 + \|g^k\|^2 + Q_{2i_1}^k, \tag{4.15}$$

where the interface term $Q_{2i_1}^k$ reads

$$Q_{2i_1}^k = 2h^{-1}(\tilde{v}_{i_1}^k - v_{i_1}^k)\left(h^2\Delta_h v_{i_1}^k + 2\bar{a}_{i_1}v_{i_1}^k\right).$$

Recalling the expression of $(\tilde{v}_{i_1}^k - v_{i_1}^k)$ and the scheme (4.9), we obtain that

$$\begin{aligned} Q_{2i_1}^k &= 2h^{-1}(\tilde{v}_{i_1}^k - v_{i_1}^k)\left(h^2\Delta_h v_{i_1}^k + 2\bar{a}_{i_1}\tau\partial_t v_{i_1}^k + 2\bar{a}_{i_1}v_{i_1}^{k-1}\right) \\ &= 2h^{-1}(\tilde{v}_{i_1}^k - v_{i_1}^k)\left(h^2\Delta_h v_{i_1}^k + 2\bar{a}_{i_1}\tau\Delta_h v_{i_1}^k + 2\bar{a}_{i_1}v_{i_1}^{k-1} + 2\bar{a}_{i_1}\tau g_{i_1}^k\right) \\ &= -2\tau^2 h^{-1}(2\bar{a}_{i_1}\tau + h^2)(\partial_t\Delta_h v_{i_1}^k)\Delta_h v_{i_1}^k - 4\bar{a}_{i_1}\tau^2 h^{-1}(\partial_t\Delta_h v_{i_1}^k)v_{i_1}^{k-1} \\ &\quad - 4\bar{a}_{i_1}\tau^3 h^{-1}(\partial_t\Delta_h v_{i_1}^k)g_{i_1}^k - 2\tau h^{-1}(2\bar{a}_{i_1}\tau + h^2)(g_{i_1}^k - \tilde{g}_{i_1}^{k-1})\Delta_h v_{i_1}^k \\ &\quad - 4\bar{a}_{i_1}\tau h^{-1}(g_{i_1}^k - \tilde{g}_{i_1}^{k-1})v_{i_1}^{k-1} - 4\bar{a}_{i_1}\tau^2 h^{-1}(g_{i_1}^k - \tilde{g}_{i_1}^{k-1})g_{i_1}^k. \end{aligned} \tag{4.16}$$

For a complete analysis of the term $-4\bar{a}_{i_1}\tau^2 h^{-1}(\partial_t\Delta_h v_{i_1}^k)v_{i_1}^{k-1}$ of (4.16), two cases of k will be discussed: one is $k \geq 2$, the other $k = 1$.

(a) If $k \geq 2$, by using (4.9) and Lemma 2.1, we derive that

$$\begin{aligned}
&-2\tau(\partial_t\Delta_h v_{i_1}^k)v_{i_1}^{k-1} = -2(\Delta_h v_{i_1}^k - \Delta_h v_{i_1}^{k-1})v_{i_1}^{k-1}\\
&= -2(\partial_t v_{i_1}^k - \partial_t v_{i_1}^{k-1})v_{i_1}^{k-1} + 2(g_{i_1}^k - g_{i_1}^{k-1})v_{i_1}^{k-1}\\
&= -\partial_t(v_{i_1}^k)^2 + \tau(\partial_t v_{i_1}^k)^2 + \partial_t(v_{i_1}^{k-1})^2 + \tau(\partial_t v_{i_1}^{k-1})^2 + 2(g_{i_1}^k - g_{i_1}^{k-1})v_{i_1}^{k-1}\\
&= -\tau\partial_t\left[\partial_t(v_{i_1}^k)^2\right] + \tau(\Delta_h v_{i_1}^k + g_{i_1}^k)^2 + \tau(\Delta_h v_{i_1}^{k-1} + g_{i_1}^{k-1})^2 + 2(g_{i_1}^k - g_{i_1}^{k-1})v_{i_1}^{k-1}.
\end{aligned}$$

Then interface term (4.16) follows

$$Q_{2i_1}^k = I_6 + I_7 + I_8 + I_9 + I_{10} + I_{11},$$

in which I_m $(m = 6, 7, \ldots, 11)$ are treated in detail as follows:

$$\begin{aligned}
I_6 &= -2\tau^2 h^{-1}(2\bar{a}_{i_1}\tau + h^2)(\partial_t\Delta_h v_{i_1}^k)\Delta_h v_{i_1}^k - 2\bar{a}_{i_1}\tau^2 h^{-1}\partial_t\left[\partial_t(v_{i_1}^k)^2\right]\\
&\quad + 2\bar{a}_{i_1}\tau^2 h^{-1}(\Delta_h v_{i_1}^k)^2 + 2\bar{a}_{i_1}\tau^2 h^{-1}(\Delta_h v_{i_1}^{k-1})^2\\
&= -\tau^2 h\partial_t(\Delta_h v_{i_1}^k)^2 - 2\bar{a}_{i_1}\tau^2 h^{-1}\partial_t\left[\partial_t(v_{i_1}^k)^2\right] + 4\bar{a}_{i_1}\tau^2 h^{-1}(\Delta_h v_{i_1}^{k-1})^2\\
&\quad - \tau^3 h(\partial_t\Delta_h v_{i_1}^k)^2 - 2\bar{a}_{i_1}\tau^4 h^{-1}(\partial_t\Delta_h v_{i_1}^k)^2,\\
I_7 &= -4\bar{a}_{i_1}\tau^3 h^{-1}(\partial_t\Delta_h v_{i_1}^k)g_{i_1}^k \leq 2\bar{a}_{i_1}\tau^4 h^{-1}(\partial_t\Delta_h v_{i_1}^k)^2 + 2\bar{a}_{i_1}\tau^2 h^{-1}(g_{i_1}^k)^2,\\
I_8 &= -2\tau h(g_{i_1}^k - \tilde{g}_{i_1}^{k-1})\Delta_h v_{i_1}^k \leq \tau^2 h(\Delta_h v_{i_1}^k)^2 + h(g_{i_1}^k - \tilde{g}_{i_1}^{k-1})^2,\\
I_9 &= 4\bar{a}_{i_1}\tau^2 h^{-1}\left[g_{i_1}^k\Delta_h v_{i_1}^k + g_{i_1}^{k-1}\Delta_h v_{i_1}^{k-1} - (g_{i_1}^k - \tilde{g}_{i_1}^{k-1})\Delta_h v_{i_1}^k\right]\\
&= 4\bar{a}_{i_1}\tau^2 h^{-1}\left(\tilde{g}_{i_1}^{k-1}\Delta_h v_{i_1}^k + g_{i_1}^{k-1}\Delta_h v_{i_1}^{k-1}\right)\\
&\leq 2\bar{a}_{i_1}\tau^2 h^{-1}\left[(\Delta_h v_{i_1}^k)^2 + (\Delta_h v_{i_1}^{k-1})^2\right] + 2\bar{a}_{i_1}\tau^2 h^{-1}\left[(g_{i_1}^{k-1})^2 + (\tilde{g}_{i_1}^{k-1})^2\right],\\
I_{10} &= 4\bar{a}_{i_1}\tau h^{-1}(g_{i_1}^k - g_{i_1}^{k-1})v_{i_1}^{k-1} - 4\bar{a}_{i_1}\tau h^{-1}(g_{i_1}^k - \tilde{g}_{i_1}^{k-1})v_{i_1}^{k-1}\\
&\leq 2\bar{a}_{i_1}\tau^2 h^{-1}(v_{i_1}^{k-1})^2 + 2\bar{a}_{i_1}h^{-1}(g_{i_1}^{k-1} - \tilde{g}_{i_1}^{k-1})^2,\\
I_{11} &= 2\bar{a}_{i_1}\tau^2 h^{-1}\left[(g_{i_1}^k)^2 + (g_{i_1}^{k-1})^2\right] - 4\bar{a}_{i_1}\tau^2 h^{-1}(g_{i_1}^k - \tilde{g}_{i_1}^{k-1})g_{i_1}^k\\
&\leq 2\bar{a}_{i_1}\tau^2 h^{-1}\left[(g_{i_1}^{k-1})^2 + (\tilde{g}_{i_1}^{k-1})^2\right].
\end{aligned}$$

Therefore,

$$\begin{aligned}
Q_{2i_1}^k \leq &-\tau^2 h\partial_t(\Delta_h v_{i_1}^k)^2 - 2\bar{a}_{i_1}\tau^2 h^{-1}\partial_t\left[\partial_t(v_{i_1}^k)^2\right]\\
&+ \tau^2 h(\Delta_h v_{i_1}^k)^2 + 2\bar{a}_{i_1}\tau^2 h^{-1}(v_{i_1}^{k-1})^2\\
&+ 2\bar{a}_{i_1}\tau^2 h^{-1}(\Delta_h v_{i_1}^k)^2 + 6\bar{a}_{i_1}\tau^2 h^{-1}(\Delta_h v_{i_1}^{k-1})^2 + |||g^k|||_{I,2}^2, \quad k \geq 2.
\end{aligned} \tag{4.17}$$

Substituting (4.17) into (4.15) and using Lemma 4.1, we obtain

$$\begin{aligned}
\partial_t G^k \leq &\|v^k\|^2 + \tau^2 h(\Delta_h v_{i_1}^k)^2 + 2\bar{a}_{i_1}\tau^2 h^{-1}(v_{i_1}^{k-1})^2\\
&+ E_1^k + 3E_1^{k-1} + \|g^k\|^2 + |||g^k|||_{I,2}^2, \qquad k \geq 2,
\end{aligned}$$

which implies

$$\begin{aligned}
G^n - G^1 \leq &\tau\sum_{l=2}^{n}\|v^l\|^2 + \tau^3 h\sum_{l=2}^{n}(\Delta_h v_{i_1}^l)^2 + 2\bar{a}_{i_1}\tau^3 h^{-1}\sum_{l=1}^{n-1}(v_{i_1}^l)^2\\
&+ \tau\sum_{l=2}^{n}(E_1^l + 3E_1^{l-1}) + \tau\sum_{l=2}^{n}(\|g^l\|^2 + |||g^l|||_{I,2}^2), \qquad k \geq 2.
\end{aligned} \tag{4.18}$$

(b) If $k=1$, by using (4.9) and Lemma 2.1, we have

$$\begin{aligned}&-2\tau(\partial_t\Delta_h v_{i_1}^1)v_{i_1}^0=-2(\Delta_h v_{i_1}^1-\Delta_h v_{i_1}^0)v_{i_1}^0\\&=-2(\partial_t v_{i_1}^1)v_{i_1}^0+2g_{i_1}^1v_{i_1}^0+2(\Delta_h v_{i_1}^0)v_{i_1}^0\\&\le-\partial_t(v_{i_1}^1)^2+\tau(\Delta_h v_{i_1}^1+g_{i_1}^1)^2+2g_{i_1}^1v_{i_1}^0+\tau(\Delta_h v_{i_1}^0)^2+\tau^{-1}(v_{i_1}^0)^2.\end{aligned}$$

Then, by taking $k=1$ in (4.16), we can arrive at

$$Q_{2i_1}^1\le I_{12}+I_{13}+I_{14}+I_{15}+I_{16}+I_{17},$$

where,

$$\begin{aligned}I_{12}&=-2\tau^2h^{-1}(2\bar a_{i_1}\tau+h^2)(\partial_t\Delta_h v_{i_1}^1)\Delta_h v_{i_1}^1-2\bar a_{i_1}\tau h^{-1}\partial_t\left[(v_{i_1}^1)^2\right]\\&\quad+2\bar a_{i_1}\tau^2h^{-1}(\Delta_h v_{i_1}^1)^2+2\bar a_{i_1}\tau^2h^{-1}(\Delta_h v_{i_1}^0)^2\\&=-\tau^2h\partial_t(\Delta_h v_{i_1}^1)^2-2\bar a_{i_1}\tau h^{-1}\partial_t\left[(v_{i_1}^1)^2\right]+4\bar a_{i_1}\tau^2h^{-1}(\Delta_h v_{i_1}^0)^2\\&\quad-\tau^3h(\partial_t\Delta_h v_{i_1}^1)^2-2\bar a_{i_1}\tau^4h^{-1}(\partial_t\Delta_h v_{i_1}^1)^2,\\I_{13}&=-4\bar a_{i_1}\tau^3h^{-1}(\partial_t\Delta_h v_{i_1}^1)g_{i_1}^1\le2\bar a_{i_1}\tau^4h^{-1}(\partial_t\Delta_h v_{i_1}^1)^2+2\bar a_{i_1}\tau^2h^{-1}(g_{i_1}^1)^2,\\I_{14}&=-2\tau h(g_{i_1}^1-\tilde g_{i_1}^0)\Delta_h v_{i_1}^1\le\tau^2h(\Delta_h v_{i_1}^1)^2+h(g_{i_1}^1-\tilde g_{i_1}^0)^2,\\I_{15}&=4\bar a_{i_1}\tau^2h^{-1}\left[g_{i_1}^1\Delta_h v_{i_1}^1-(g_{i_1}^1-\tilde g_{i_1}^0)\Delta_h v_{i_1}^1\right]\\&=4\bar a_{i_1}\tau^2h^{-1}\tilde g_{i_1}^0\Delta_h v_{i_1}^1\le2\bar a_{i_1}\tau^2h^{-1}(\Delta_h v_{i_1}^1)^2+2\bar a_{i_1}\tau^2h^{-1}(\tilde g_{i_1}^0)^2,\\I_{16}&=4\bar a_{i_1}\tau h^{-1}g_{i_1}^1v_{i_1}^0-4\bar a_{i_1}\tau h^{-1}(g_{i_1}^1-\tilde g_{i_1}^0)v_{i_1}^0+2\bar a_{i_1}h^{-1}(v_{i_1}^0)^2\\&\le2\bar a_{i_1}\tau^2h^{-1}(v_{i_1}^0)^2+2\bar a_{i_1}h^{-1}(v_{i_1}^0)^2+2\bar a_{i_1}h^{-1}(\tilde g_{i_1}^0)^2,\\I_{17}&=2\bar a_{i_1}\tau^2h^{-1}(g_{i_1}^1)^2-4\bar a_{i_1}\tau^2h^{-1}(g_{i_1}^1-\tilde g_{i_1}^0)g_{i_1}^1\le2\bar a_{i_1}\tau^2h^{-1}(\tilde g_{i_1}^0)^2.\end{aligned}$$

Therefore,

$$\begin{aligned}Q_{2i_1}^1\le&-\tau^2h\partial_t(\Delta_h v_{i_1}^1)^2-2\bar a_{i_1}\tau h^{-1}\partial_t(v_{i_1}^1)^2\\&+\tau^2h(\Delta_h v_{i_1}^1)^2+2\bar a_{i_1}\tau^2h^{-1}(v_{i_1}^0)^2+2\bar a_{i_1}h^{-1}(v_{i_1}^0)^2\\&+2\bar a_{i_1}\tau^2h^{-1}(\Delta_h v_{i_1}^1)^2+4\bar a_{i_1}\tau^2h^{-1}(\Delta_h v_{i_1}^0)^2+|||g^1|||_{I,2}^2.\end{aligned}\tag{4.19}$$

Inserting (4.19) into (4.15) and multiplying the resulting inequality by τ, we obtain

$$\begin{aligned}G^1\le&\tau\|v^1\|^2+\tau^3h(\Delta_h v_{i_1}^1)^2+2\bar a_{i_1}\tau^3h^{-1}(v_{i_1}^0)^2\\&+\|v^0\|^2+\tau^2h(\Delta_h v_{i_1}^0)^2+2\bar a_{i_1}\tau h^{-1}(v_{i_1}^0)^2\\&+\tau(E_1^1+2E_1^0)+\tau(\|g^1\|^2+|||g^1|||_{I,2}^2).\end{aligned}\tag{4.20}$$

Now we combine the result of (a) with (b) to continue this proof. Adding (4.20) to (4.18), we get

$$\partial_tE_2^n=G^n\le E_2^n+\tau^{-1}E_2^0+\tau\sum_{l=0}^{n-1}E_2^l+4\tau\sum_{l=0}^{n}E_1^l+\tau\sum_{l=1}^{n}(\|g^l\|^2+|||g^l|||_{I,2}^2)$$

for $1\le n\le J$. Furthermore, summing n from 1 to k, we have

$$(1-\tau)E_2^k\le\tau(1+T)\sum_{l=0}^{k-1}E_2^l+(k+1)E_2^0+4\tau T\sum_{l=0}^{k}E_1^l+\tau T\sum_{l=1}^{k}\|g^l\|_*^2,$$

where $\|g^k\|_*^2 = \|g^k\|^2 + |||g^k|||_{I,2}^2$. Supposing that $0 < \tau \le 1/3$; it follows

$$E_2^k \le \frac{3(1+T)\tau}{2}\sum_{l=0}^{k-1} E_2^l + \frac{3(k+1)}{2}E_2^0 + 6\tau T\sum_{l=0}^{k} E_1^l + \frac{3T\tau}{2}\sum_{l=1}^{k}\|g^l\|_*^2.$$

This implies (4.14), due to Lemma 2.3, and this proof is complete. □

Although not explicitly stated, the above proofs are true of the CEH scheme with $p = N/2$. In the analogous proofs, the schemes (4.2)–(4.3) could be rewritten as

$$\begin{aligned} &\partial_t u_i^k = \Delta_h v_i^k + g_i^k && \text{(at interface points)},\\ &\partial_t u_i^k = \Delta_h v_i^k + g_i^k + a_{i-\frac{1}{2}} w_{i-1}^k + a_{i+\frac{1}{2}} w_{i+1}^k && \text{(at interior points)}, \end{aligned}$$

where $w_i^k = (\tilde v_i^k - v_i^k)/h^2$ is defined at interface points and $w_0^k = w_N^k = 0$. Correspondingly, the interface terms $Q_{1i_1}^k$, $Q_{2i_1}^k$ would be replaced with $\sum_{\alpha=1}^{N/2-1} Q_{1i_\alpha}^k$ and $\sum_{\alpha=1}^{N/2-1} Q_{2i_\alpha}^k$, but the other parts of the proofs remain the same.

Obviously, Lemmas 4.1 and 4.2 imply the following stability theorem.

THEOREM 4.3 (stability). *Under the reasonable assumption* (1.4)*, the* 1*-D CEIDD algorithm* (3.2)–(3.5) *is unconditionally stable with respect to the* H^1 *seminorm and the* L^2 *norm.*

Before we end this section, let us briefly discuss the convergence of the CEIDD method. Let $e_i^k = u(ih, k\tau) - u_i^k$ be the error of solution u_i^k computed by the 1-D CEIDD algorithm (3.2)–(3.5), and let $\tilde e_{i_\alpha}^k = u(i_\alpha h, k\tau) - \tilde u_{i_\alpha}^k$ be the error of predictor value $\tilde u_{i_\alpha}^k$ at interface boundaries Γ_h. And the local truncation errors of the backward and forward Euler schemes are denoted by r_i^k, $\tilde r_i^{k-1}$.

It is easy to verify that the error equations of the 1-D CEIDD algorithm (3.2)–(3.5) is the same as (4.1)–(4.5) by assuming $\phi_i \equiv 0$ and replacing the variables $v_i^k, \tilde v_i^k, g_i^k, \tilde g_i^{k-1}$ with $e_i^k, \tilde e_i^k, r_i^k, \tilde r_i^{k-1}$, respectively. Thus, (4.6) of Lemma 4.1 takes the form

$$E_1^k(e) \le \frac{3\tau}{2} e^{\frac{3}{2}k\tau}\sum_{l=1}^{k}\left(\|r^l\|^2 + |||r^l|||_{I,1}^2\right), \quad 1 \le k \le J,$$

and L^2 estimation (4.14) of Lemma 4.2 holds in the form

$$E_2^k(e) \le \frac{3T}{2}\exp\left(\frac{3}{2}(1+T)k\tau\right)\left[4\tau\sum_{l=1}^{k} E_1^l(e) + \tau\sum_{l=1}^{k}(\|r^l\|^2 + |||r^l|||_{I,2}^2)\right].$$

Throughout the paper, any subscripted c, which is fixed in value, will denote a generic positive constant that is dependent on the exact solution $u(x,t)$ and coefficients $a(x)$ but independent of time step τ, spacing h, and the number of subdomains p. By the standard truncation error analysis, we get $|r_i^k| \le c_1(\tau + h^2)$ and $|\tilde r_i^k| \le c_1(\tau + h^2)$. If $a(x)$ is bounded by c_2, it holds that

$$\|r^k\|^2 + |||r^k|||_{I,1}^2 \le 2c_1^2(1+5c_2)\left(1 + (p-1)h^{-1}\right)(\tau + h^2)^2$$

and

$$|e^k|_{a,1} \le \sqrt{E_1^k(e)} \le c_3\sqrt{1 + (p-1)h^{-1}}(\tau + h^2), \quad 1 \le k \le J, \tag{4.21}$$

where $c_3 = \sqrt{3Te^{\frac{3}{2}T}c_1^2(1+5c_2)}$. Similarly,

$$\|r^k\|^2 + |||r^k|||_{I,2}^2 \le 2c_1^2(2+9c_2)\left(1+(p-1)h^{-1}\right)(\tau+h^2)^2$$

and

$$\sqrt{\tau\sum_{l=1}^{k}\|e^l\|^2} \le \sqrt{E_2^k(e)} \le c_4\sqrt{1+(p-1)h^{-1}}(\tau+h^2), \quad 1 \le k \le J, \tag{4.22}$$

where $c_4 = \sqrt{3T^2\exp\left(\frac{3}{2}(1+T)T\right)(2c_1^2+9c_1^2c_2+2c_3^2)}$. Thus, we obtain the following theorem from (4.21) and (4.22).

THEOREM 4.4 (convergence). *If the solution of problem* (1.1)–(1.3) *is sufficiently smooth, the numerical solution of the CEIDD algorithm* (3.2)–(3.5) *converges to the exact solution of* (1.1)–(1.3) *with an order of* $\mathcal{O}(\sqrt{1+(p-1)h^{-1}}(\tau+h^2))$ *with respect to the* H^1 *seminorm and the* L^2 *norm when spacing* h *is sufficiently small and time step size* $\tau = \mathcal{O}(p^{-1/2}h^{1/2+\epsilon})$ *for* $\epsilon > 0$.

We note that, for the coarsely granular algorithm in the case of $2 \le p \ll N$, the accuracy of the CEIDD algorithm is $\mathcal{O}(h^{-1/2}(\tau+h^2))$ as $\tau = \mathcal{O}(h^{1/2+\epsilon})$. Compared with sequential implicit Euler method ($p = 1$), there is a loss of $h^{-1/2}$. However, for the CEH scheme with $p = h^{-1}/2$ (see section 3), the accuracy decreases to $\mathcal{O}(h^{-1}(\tau+h^2))$ with $\tau = \mathcal{O}(h^{1+\epsilon})$, in which a loss of h^{-1} is seen. As for the cause, we return to the upper bounds of $E_1^k(e)$ and $E_2^k(e)$ and observe that the loss of accuracy can be ascribed to the interface-related terms $2\bar{a}_{i_\alpha}h^{-1}(r_{i_\alpha}^k - \tilde{r}_{i_\alpha}^{k-1})^2$ of $|||r^k|||_{I,1}$ and $2\bar{a}_{i_\alpha}h^{-1}(r_{i_\alpha}^{k-1} - \tilde{r}_{i_\alpha}^{k-1})^2$ of $|||r^k|||_{I,2}$. To make this clearer, we refer to the terms I_4 in the proof of Lemma 4.1 and I_{10} in Lemma 4.2. Therefore, it stands to reason that the accumulated truncation errors at interface nodes, introduced by the explicit prediction and implicit correction steps, affect the global accuracy of our CEIDD algorithm.

On the other hand, noticing that $I_{16}(e) = 2\bar{a}_{i_1}h^{-1}(e_{i_1}^0)^2$ (since $e_{i_1}^0 = 0$) in the analogous proof of Lemma 4.2 for L^2 convergence, we can get

$$|||r^1|||_{I,2}^2 = \sum_{\alpha=1}^{p-1}\left[2\bar{a}_{i_\alpha}\tau^2h^{-1}\left((r_{i_\alpha}^1)^2 + (\tilde{r}_{i_\alpha}^0)^2\right) + h(r_{i_\alpha}^1 - \tilde{r}_{i_\alpha}^0)^2\right].$$

Compared with the earlier definition, this formulation removes the main error term. (Actually, the arguments would be true of the 2-D parallel algorithms described in the next two sections but are omitted there.) Thus, an improved accuracy of the CEIDD algorithm would be obtained by using our prior estimations (4.6) and (4.14) if it holds that $|r_{i_\alpha}^k - \tilde{r}_{i_\alpha}^{k-1}| \le c_1\tau h^2$ and $|r_{i_\alpha}^{k-1} - \tilde{r}_{i_\alpha}^{k-1}| \le c_1\tau h^2$; see Example 1 for a 2-D instance. Specifically, we can get

$$|e^k|_{a,1} \le c_5\sqrt{1+(p-1)\tau h^{-1}}(\tau+h^2), \quad 1 \le k \le J,$$

and

$$\sqrt{\tau\sum_{l=1}^{k}\|e^l\|^2} \le c_6\sqrt{1+(p-1)\tau^2h^{-1}}(\tau+h^2), \quad 1 \le k \le J.$$

Thus, the convergence rate reaches $\mathcal{O}(\tau+h^2)$ even for the CEH method.

5. Zigzag interfaces and CEIDD-ZI algorithms for 2-D problems. In the first half of this paper, we proved that the parallel CEIDD procedure is free from stability-related time step restriction and maintains the efficiency in computation and communication of the EIDD methods. For solving 2-D problems (1.1)–(1.3) on $\Omega = (0,1)^2$, we are in a different situation, where the interior interfaces are no longer any nodes but some directional lines such as grid lines. As the implicit correction technique (always, the fully implicit scheme) is applied at points along those straight-line interfaces, an elliptic solver should be employed to compute the solutions [11], and then an extra parallel time would be suffered. Moreover, for large-scale parallel simulations, domain partitioning flexibility is always of the essence, and some crossover interfaces would be necessary. When those straight-line boundaries cross into each other inside the computational domain, however, the situation becomes worse because the globalized transfers of data for computing interface solutions suffer from sustained parallel-time overload.

It seems that the 2-D generalization of the CEIDD algorithm would not inherit the virtues of the 1-D CEIDD method; nevertheless, an alternative approach will do in which the straight-line boundaries are tailored to the special lines of zigzag shape. In this and the following sections, we show that CEIDD-ZI (CEIDD based on zigzag-shaped interfaces) algorithms maintain the virtues of the CEIDD method and improve the flexibility in domain partitioning as well as localize the communication of data.

Under the subdomain-width condition (1.4), we assume that $2 \le p_1 \le N/2$ and $2 \le p_2 \le N/2$. The zigzag-line interfaces, $\Gamma_h = \Gamma_h^1 \cup \Gamma_h^2$, consist of $(p_1 - 1)$ interior boundaries $\Gamma_h^1 = \bigcup_{\alpha=1}^{p_1-1} \Gamma_{h,\alpha}^1$ in the first spatial direction with

$$\Gamma_{h,\alpha}^1 = \{(i_\alpha h, jh) |\ i_\alpha = m_\alpha + \mathrm{mod}(j,2), 3 \le m_\alpha + 2 \le m_{\alpha+1} \le N-3\}, \tag{5.1}$$

and $(p_2 - 1)$ interior boundaries $\Gamma_h^2 = \bigcup_{\beta=1}^{p_2-1} \Gamma_{h,\beta}^2$ in the second with

$$\Gamma_{h,\beta}^2 = \{(ih, j_\beta h) |\ j_\beta = n_\beta + \mathrm{mod}(i,2), 3 \le n_\beta + 2 \le n_{\beta+1} \le N-3\}. \tag{5.2}$$

Then, by those interior interfaces Γ_h, the discrete domain Ω_h is decomposed into $p = p_1 \times p_2$ subdomains $\Omega_{\xi\eta}\,(\xi = 1,2,\ldots,p_1, \eta = 1,2,\ldots,p_2)$. Two examples on the two strategies of domain partitioning are depicted graphically in Figures 5.1–5.2. Denoting that $\gamma_{\xi\eta}^1 = \partial\Omega_{\xi\eta} \cap \partial\Omega_{\xi+1,\eta}$, the common boundary of $\Omega_{\xi\eta}$ and $\Omega_{\xi+1,\eta}$, and $\gamma_{\xi\eta}^2 = \partial\Omega_{\xi\eta} \cap \partial\Omega_{\xi,\eta+1}$, it holds that $\Gamma_{h,\alpha}^1 = \bigcup_{\eta=1}^{p_2} \gamma_{\alpha\eta}^1$ and $\Gamma_{h,\beta}^2 = \bigcup_{\xi=1}^{p_1} \gamma_{\xi\beta}^2$.

We have $p = p_1 \times p_2$ processors denoted as $P_{\xi\eta}$. Similar to the 1-D case, we assign $\Omega_{\xi\eta}$ and $\gamma_{\xi\eta}^1 \cup \gamma_{\xi\eta}^2$ to processor $P_{\xi\eta}$. Suppose that u_{ij}^k is the numerical approximation of the exact solution $u(ih, jh, k\tau)$ on Ω_h^τ; the 2-D CEIDD-ZI method for computing the solution $u_h^k = \{u_{ij}^k | 0 \le i,j \le N\}$ from u_h^{k-1} is described below compactly:

$$\frac{\tilde{u}_{ij}^k - u_{ij}^{k-1}}{\tau} = \Delta_h u_{ij}^{k-1} + f_{ij}^{k-1} \quad \text{on} \quad \Gamma_h, \tag{5.3}$$

$$\begin{cases} \partial_t u_{ij}^k = \Delta_h u_{ij}^k + f_{ij}^k & \text{on} \quad \Omega_{\xi\eta} \\ u_{ij}^k = \tilde{u}_{ij}^k & \text{on} \quad \Gamma_h \end{cases} \begin{pmatrix} \xi = 1,2,\ldots,p_1 \\ \eta = 1,2,\ldots,p_2 \end{pmatrix}, \tag{5.4}$$

$$\partial_t u_{ij}^k = \Delta_h u_{ij}^k + f_{ij}^k \quad \text{on} \quad \Gamma_h, \tag{5.5}$$

$$u_{ij}^0 = u^0(ih, jh) \quad \text{on} \quad \Omega_h, \tag{5.6}$$

$$u_{ij}^k = u_b(ih, jh, k\tau) \quad \text{on} \quad \partial\Omega_h. \tag{5.7}$$

Based on the two strategies of domain decomposition, we distinguish the CEIDD-ZI method on $p_1 \times 1$ subdomains from that on $p_1 \times p_2$ subdomains $(p_2 > 1)$ and denote

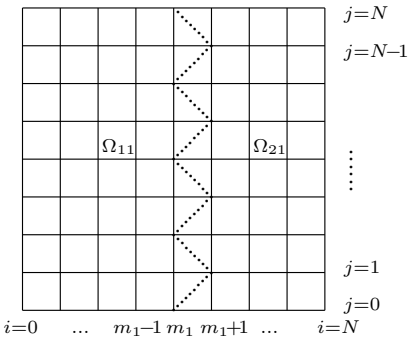

FIG. 5.1. *Strategy* 1: *The zigzag-line interface* Γ_h (*dashed lines*) *divides* Ω_h *into* 2×1 *subdomains for* $p_1 = 2$ *and* $p_2 = 1$.

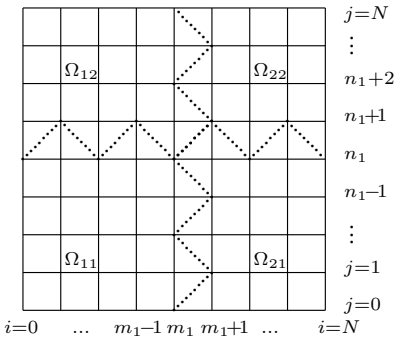

FIG. 5.2. *Strategy* 2: *The zigzag-line interfaces* Γ_h (*dashed lines*) *divide* Ω_h *into* 2×2 *subdomains for* $p_1 = p_2 = 2$.

the former as CEIDD-ZI1 and the later as CEIDD-ZI2; see Figures 5.1–5.2 for the relevant instances.

As for the CEIDD-ZI1 method, $\Gamma_h = \Gamma_h^1$. We compute interface predictor values $\tilde{u}_h^k(\Gamma_h^1)$ by the explicit scheme (5.3); then we get the subdomain solutions $u_h^k(\Omega_{\xi\eta})$ by applying an elliptic solver such as SOR and PCG to implicit scheme (5.4). Once the subdomain solutions are available, the interface solutions $u_h^k(\Gamma_h^1)$ are obtained explicitly by the implicit scheme (5.5) for $1 \le j \le N-1$ and $1 \le \alpha \le p_1 - 1$:

$$\begin{aligned}\left(1 + 2r\bar{a}^{12}_{i_\alpha,j}\right) u^k_{i_\alpha,j} = u^{k-1}_{i_\alpha,j} &+ r\left(a^1_{i_\alpha-\frac{1}{2},j} u^k_{i_\alpha-1,j} + a^1_{i_\alpha+\frac{1}{2},j} u^k_{i_\alpha+1,j}\right) \\ &+ r\left(a^2_{i_\alpha,j-\frac{1}{2}} u^k_{i_\alpha,j-1} + a^2_{i_\alpha,j+\frac{1}{2}} u^k_{i_\alpha,j+1}\right) + \tau f^k_{i_\alpha,j}.\end{aligned}$$

Being similar to the 1-D case, the CEIDD-ZI1 method maintains the efficiency in computation and communication of the 2-D EIDD algorithms.

As for the CEIDD-ZI2 method, we assume that the crossover interfaces $\Gamma^1_{h,\alpha}$, $\Gamma^2_{h,\beta}$ satisfy the intersectant conditions

$$\mathrm{mod}(n_\beta, 2) = \mathrm{mod}(m_\alpha, 2), \quad 1 \le \alpha \le p_1 - 1, 1 \le \beta \le p_2 - 1, \tag{5.8}$$

so any two intersecting zigzag-line interfaces have two common points: $(m_\alpha h, n_\beta h)$ and $(m_\alpha h + h, n_\beta h + h)$ if m_α is even, or $(m_\alpha h, n_\beta h + h)$ and $(m_\alpha h + h, n_\beta h)$ if m_α is odd. Figure 5.2 shows the former case for $\alpha = \beta = 1$. If the intersectant conditions (5.8) are true, the implicit Euler scheme (5.5) applied at the intersecting interfaces Γ_h computes interface solutions explicitly and the data communication is localized. Thus, the CEIDD-ZI2 method also maintains the efficiency in computation and communication of the 2-D EIDD algorithms.

On the contrary, if the intersectant conditions (5.8) do not hold, any two intersecting boundaries have no common grid points; see Figure 5.3 for a simple case. The fully implicit corrector scheme (5.5) introduces some points, such as the "$\circ$" points in Figure 5.3, where the interface solutions should be updated by an elliptic solver on one processor. So, compared with the above case shown in Figure 5.2, more operations of data transferring will be needed for each time level. Then an extra parallel time for data transfers and interface correction is added to the 2-D EIDD algorithms. Thus we arrive at the following conclusion.

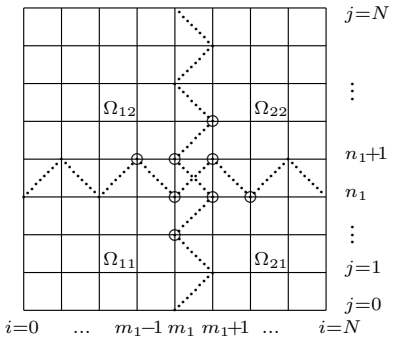

FIG. 5.3. *An elliptic solver is necessary to compute interface solutions on the intersecting zigzag-line interfaces which do not satisfy the intersectant conditions* (5.8).

PROPOSITION 5.1. *Under the intersectant conditions* (5.8)*, the implicit correction step of the CEIDD-ZI algorithm on general $p_1 \times p_2$ subdomains adds zero communication and negligible computation cost to the* 2*-D EIDD algorithms.*

The localization of data communication is important for the two parallel CEIDD-ZI procedures; however, we will prefer CEIDD-ZI2 to CEIDD-ZI1 for large-scale parallel simulations on distributed memory computers because the former has a better efficiency in communication. Given parallel machine number, namely, fixed p, the total data communication cost T_{comm} per time step is an increasing function of the total "length" of the interior boundaries. To carry out a quantitative analysis, we assume that two data transferring operations (one occurs in step 1 to compute subdomain solutions, and the other occurs in step 2 to obtain interface corrector and predictor values) are carried out by $p-1$ processors simultaneously with almost equal load. Suppose that $p = p_1 \times p_2$ and $p_1 \geq p_2 > 1$; the total communication time at each time step satisfies

$$T_{comm,1} = 2\lambda \frac{(p-1)N}{p-1} + \mu$$

for the CEIDD-ZI1 method, and

$$T_{comm,2} = 2\lambda \frac{(p_1-1)N + (p_2-1)N}{p-1} + \mu$$

for the CEIDD-ZI2 method, where λ is some system-dependent data transferring parameter and μ is the communication startup overload. For an efficiency comparison in communication, we define a ratio $\rho = \rho(p_2)$,

$$\rho(p_2) = \frac{T_{comm,1} - T_{comm,2}}{T_{comm,1}} = \frac{2\lambda N}{(2\lambda N + \mu)(p-1)} \left(p - \frac{p}{p_2} - p_2 + 1 \right). \tag{5.9}$$

Obviously, $\rho(1) = 0$ and $\rho(p_2)$ is an increasing function for $1 < p_2 \leq \sqrt{p}$ so that we obtain the following results.

PROPOSITION 5.2. *For given $p = p_1 \times p_2$ processors, the communication cost at each time level of the CEIDD-ZI*2 *algorithm is less than that of the CEIDD-ZI*1 *procedure, and for $1 < p_2 \leq \sqrt{p}$, the larger the value of p_2, the less the cost.*

Similar to the 1-D CEIDD method, if the subdomain solutions are obtained explicitly, the parallel CEIDD-ZI procedures also degenerate to a 2-D CEH scheme. As

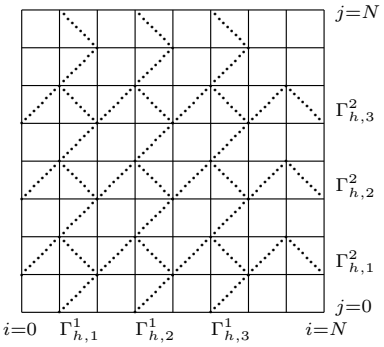

FIG. 5.4. *CEH scheme on* 4×4 *subdomains.*

the special version of the CEIDD-ZI algorithms, the scheme would always be constructed on $\frac{N}{2} \times \frac{N}{2}$ subdomains; see Figure 5.4 for an instance. The unconditional stability of the CEH scheme will be verified in the next section. On the other hand, the CEH method always can be described as the following point-related schemes:

$$\tilde{u}_{ij}^k = u_{ij}^{k-1} + \tau \Delta_h u_{ij}^{k-1} + \tau f_{ij}^{k-1}, \qquad (i+j) \in \text{odd}, \tag{5.10}$$

$$\begin{aligned}(1 + 2\bar{a}_{ij}^{12} r) u_{ij}^k &= u_{ij}^{k-1} + r(a^1_{i-\frac{1}{2},j} \tilde{u}^k_{i-1,j} + a^1_{i+\frac{1}{2},j} \tilde{u}^k_{i+1,j}) \\ &\quad + r(a^2_{i,j-\frac{1}{2}} \tilde{u}^k_{i,j-1} + a^2_{i,j+\frac{1}{2}} \tilde{u}^k_{i,j+1}) + \tau f_{ij}^k, \quad (i+j) \in \text{even},\end{aligned} \tag{5.11}$$

$$\begin{aligned}(1 + 2\bar{a}_{ij}^{12} r) u_{ij}^k &= u_{ij}^{k-1} + r(a^1_{i-\frac{1}{2},j} u^k_{i-1,j} + a^1_{i+\frac{1}{2},j} u^k_{i+1,j}) \\ &\quad + (a^2_{i,j-\frac{1}{2}} u^k_{i,j-1} + a^2_{i,j+\frac{1}{2}} u^k_{i,j+1}) + \tau f_{ij}^k, \quad (i+j) \in \text{odd},\end{aligned} \tag{5.12}$$

where $1 \le i, j \le N-1$.

6. Stability and convergence of CEIDD-ZI algorithms. In this section, H^1 and L^2 prior estimations for difference solutions of the CEIDD-ZI methods are derived by analogy with the 1-D case in section 4.

LEMMA 6.1 (prior estimation). *Let* $v_h^k = \{v_{ij}^k | 0 \le i, j \le N, 0 \le k \le J\}$ *satisfy the CEIDD-ZI*1 *algorithm on* $p_1 \times 1$ *subdomains decoupled by the zigzag-line interfaces* Γ_h^1*:*

$$\frac{\tilde{v}_{ij}^k - v_{ij}^{k-1}}{\tau} = \Delta_h v_{ij}^{k-1} + \tilde{g}_{ij}^{k-1} \quad on \;\; \Gamma_h^1, \quad 1 \le k \le J, \tag{6.1}$$

$$\begin{cases} \partial_t v_{ij}^k = \Delta_h v_{ij}^k + g_{ij}^k & on \;\; \Omega_{\xi,1} \;\; (\xi = 1, 2, \ldots, p_1), \\ v_{ij}^k = \tilde{v}_{ij}^k & on \;\; \Gamma_h^1 \end{cases} \quad 1 \le k \le J, \tag{6.2}$$

$$\partial_t v_{ij}^k = \Delta_h v_{ij}^k + g_{ij}^k \qquad on \;\; \Gamma_h^1, \quad 0 \le k \le J, \tag{6.3}$$

$$v_{ij}^0 = \phi_{ij} \qquad on \;\; \Omega_h, \quad 1 \le k \le J, \tag{6.4}$$

$$v_{ij}^k = 0 \qquad on \;\; \partial\Omega_h, \quad 0 \le k \le J. \tag{6.5}$$

Then the inequalities

$$E_1^k \le \frac{3}{2} e^{\frac{3}{2} k\tau} \left[E_1^0 + \tau \sum_{l=1}^{k} \left(\|g^l\|^2 + |||g^l|||_{I,1}^2 \right) \right], \tag{6.6}$$

$$E_2^k \le \frac{3}{2}(J+1)\exp\left(\frac{3}{2}(1+T)k\tau\right)E_2^0 + \frac{3T}{2}\exp\left(\frac{3}{2}(1+T)k\tau\right)\left[4\tau\sum_{l=0}^{k}E_1^l + \tau\sum_{l=1}^{k}(\|g^l\|^2 + |||g^l|||_{I,2}^2)\right] \tag{6.7}$$

hold for $0<\tau\le 1/3$, $1\le k\le J$, *where* E_1^k, E_2^k, $|||g^k|||_{I,1}$, *and* $|||g^k|||_{I,2}$ *are defined by* (A.1)–(A.4), *respectively, in the case of* $p_2=1$.

Proof. (Estimation on E_1^k.) For the derivation of the H^1 estimation, as was done for Lemma 4.1, this proof is written out only for two subdomains, $\Omega_{\xi,1}$ ($\xi=1,2$), with a zigzag interface $\Gamma_{h,1}^1$ defined by (5.1) for $1\le m_1\le N-3$. For completeness, two cases of m_1 are discussed: one is $2\le m_1\le N-3$, the other is $m_1=1$. Denoting $w_{i_1,j}^k=(\tilde v_{i_1j}^k-v_{i_1j}^k)/h^2$, we derive that

$$h^2 w_{i_1j}^k=(\tilde v_{i_1j}^k-v_{i_1j}^k)=-\tau^2(\partial_t\Delta_h v_{i_1j}^k)-\tau(g_{i_1j}^k-\tilde g_{i_1j}^{k-1}),\qquad 1\le j\le N-1,$$

from the interface schemes (6.1) and (6.3). For convenience, the notation $w_{i_1,0}^k$ and $w_{i_1,N}^k$ is also used with complementary definitions $w_{i_1,0}^k=w_{i_1,N}^k=0$. For $j=1,2,\dots,N-1$, we denote $j\in$ odd to indicate integer j is odd and $j\in$ even to indicate j is even.

(a) If $2\le m_1\le N-3$, the schemes (6.2)–(6.3) would read

$$\partial_t v_{ij}^k=\Delta_h v_{ij}^k+g_{ij}^k,\qquad 0<i<m_1-1,\ 0<j<N, \tag{6.8}$$

$$\partial_t v_{m_1-1,j}^k=\Delta_h v_{m_1-1,j}^k+g_{m_1-1,j}^k,\qquad j\in\text{odd}, \tag{6.9}$$

$$\partial_t v_{m_1-1,j}^k=\Delta_h v_{m_1-1,j}^k+g_{m_1-1,j}^k+a_{m_1-\frac12,j}^1 w_{m_1,j}^k,\qquad j\in\text{even}, \tag{6.10}$$

$$\partial_t v_{m_1j}^k=\Delta_h v_{m_1j}^k+g_{m_1j}^k+a_{(m_1+1)-\frac12,j}^1 w_{m_1+1,j}^k + a_{m_1,j-\frac12}^2 w_{m_1,j-1}^k+a_{m_1,j+\frac12}^2 w_{m_1,j+1}^k,\qquad j\in\text{odd}, \tag{6.11}$$

$$\partial_t v_{m_1j}^k=\Delta_h v_{m_1j}^k+g_{m_1j}^k,\qquad j\in\text{even}, \tag{6.12}$$

$$\partial_t v_{m_1+1,j}^k=\Delta_h v_{m_1+1,j}^k+g_{m_1+1,j}^k,\qquad j\in\text{odd}, \tag{6.13}$$

$$\partial_t v_{m_1+1,j}^k=\Delta_h v_{m_1+1,j}^k+g_{m_1+1,j}^k+a_{m_1+\frac12,j}^1 w_{m_1j}^k + a_{m_1+1,j-\frac12}^2 w_{m_1+1,j-1}^k+a_{m_1+1,j+\frac12}^2 w_{m_1+1,j+1}^k,\qquad j\in\text{even}, \tag{6.14}$$

$$\partial_t v_{m_1+2,j}^k=\Delta_h v_{m_1+2,j}^k+g_{m_1+2,j}^k+a_{(m_1+1)+\frac12,j}^1 w_{m_1+1,j}^k,\qquad j\in\text{odd}, \tag{6.15}$$

$$\partial_t v_{m_1+2,j}^k=\Delta_h v_{m_1+2,j}^k+g_{m_1+2,j}^k,\qquad j\in\text{even}, \tag{6.16}$$

$$\partial_t v_{ij}^k=\Delta_h v_{ij}^k+g_{ij}^k,\qquad m_1+2<i<N,\ 0<j<N. \tag{6.17}$$

From (6.8)–(6.17), it is easy to obtain the following equality with regard to the inner product $\langle\cdot,\cdot\rangle$:

$$2\langle\partial_t v^k,\partial_t v^k\rangle=2\langle\partial_t v^k,\Delta_h v^k\rangle+2\langle\partial_t v^k,g^k\rangle+\sum_{j=1}^{N-1}Q_{1i_1j}^k, \tag{6.18}$$

with $\sum_{j=1}^{N-1}Q_{1i_1j}^k=S_1+S_2$, where

$$S_1=2h^2\sum_{j\in even}w_{m_1,j}^k\big(a_{m_1-\frac12,j}^1\partial_t v_{m_1-1,j}^k+a_{m_1+\frac12,j}^1\partial_t v_{m_1+1,j}^k\big) + 2h^2\sum_{j\in odd}w_{m_1+1,j}^k\big(a_{(m_1+1)-\frac12,j}^1\partial_t v_{m_1,j}^k+a_{(m_1+1)+\frac12,j}^1\partial_t v_{m_1+2,j}^k\big),$$

$$S_2 = 2h^2 \sum_{j\in odd} \big(a^2_{m_1,j-\frac{1}{2}} w^k_{m_1,j-1} + a^2_{m_1,j+\frac{1}{2}} w^k_{m_1,j+1}\big)\partial_t v^k_{m_1 j} + 2h^2 \sum_{j\in even} \big(a^2_{m_1+1,j-\frac{1}{2}} w^k_{m_1+1,j-1} + a^2_{m_1+1,j+\frac{1}{2}} w^k_{m_1+1,j+1}\big)\partial_t v^k_{m_1+1,j}\ .$$

Recalling that $v^k_{i_1,0} = v^k_{i_1,N} = 0$ and $w^k_{i_1,0} = w^k_{i_1,N} = 0$, we transform S_2 into

$$S_2 = 2h^2 \sum_{j\in even} w^k_{m_1,j}\big(a^2_{m_1,j-\frac{1}{2}} \partial_t v^k_{m_1,j-1} + a^2_{m_1,j+\frac{1}{2}} \partial_t v^k_{m_1,j+1}\big) + 2h^2 \sum_{j\in odd} w^k_{m_1+1,j}\big(a^2_{m_1+1,j-\frac{1}{2}} \partial_t v^k_{m_1+1,j-1} + a^2_{m_1+1,j+\frac{1}{2}} \partial_t v^k_{m_1+1,j+1}\big).$$

Due to the definitions of $\Gamma^1_{h,1}$, $\Delta_h v^k_{ij}$, and $\bar a^{12}_{i_1,j}$, it holds that

$$\sum_{j=1}^{N-1} Q^k_{1i_1 j} = 2h^2 \sum_{j=1}^{N-1} w^k_{i_1,j}\big(a^1_{i_1-\frac{1}{2},j} \partial_t v^k_{i_1-1,j} + a^1_{i_1+\frac{1}{2},j} \partial_t v^k_{i_1+1,j}\big) + 2h^2 \sum_{j=1}^{N-1} w^k_{i_1,j}\big(a^2_{i_1,j-\frac{1}{2}} \partial_t v^k_{i_1,j-1} + a^2_{i_1,j+\frac{1}{2}} \partial_t v^k_{i_1,j+1}\big)$$

or, in a simpler form,

$$\sum_{j=1}^{N-1} Q^k_{1i_1 j} = 2\sum_{j=1}^{N-1} (\tilde v^k_{i_1 j} - v^k_{i_1 j})\left[h^2 \partial_t(\Delta_h v^k_{i_1 j}) + 2\bar a^{12}_{i_1 j} \partial_t v^k_{i_1 j}\right].$$

We observe that the interface term $\sum_{j=1}^N Q^k_{1i_1 j}$ is quite similar to $Q^k_{1i_1}$ defined in the proof of Lemma 4.1 by overlooking the summation for j. Therefore, we would deal with the term $\sum_{j=1}^N Q^k_{1i_1 j}$ in the same way and obtain

$$\sum_{j=1}^{N-1} Q^k_{1i_1 j} \le -2\tau^2 \sum_{j=1}^{N-1} \bar a^{12}_{i_1 j} \partial_t[(\Delta_h v^k_{i_1 j})^2] + 2\tau^2 \sum_{j=1}^{N-1} \bar a^{12}_{i_1 j} (\Delta_h v^k_{i_1 j})^2 + |||g^k|||^2_{I,1}. \tag{6.19}$$

Now inserting (6.19) into (6.18), we have

$$\partial_t E^k_1 \le E^k_1 + \|g^k\|^2 + |||g^k|||^2_{I,1}, \qquad 1 \le k \le J,$$

which implies (6.6) for $2 \le m_1 \le N-3$ owing to Lemma 2.3.

(b) If $m_1 = 1$, the schemes (6.8)–(6.10) are not needed and could be cleared away; however, the interface term $\sum_{j=1}^N Q^k_{1i_1 j}$ will have its own form because the term $a^1_{\frac{1}{2},j} \partial_t v^k_{0,j}$ of S_1 is a zero-valued term. Thus we can treat the interface term in the same way, and then (6.6) is also true of $m_1 = 1$.

(Estimation on E^k_2.) Similarly, for the derivation of the L^2 estimation, we could get the following equality:

$$2\langle v^k, \partial_t v^k\rangle = 2\langle v^k, \Delta_h v^k\rangle + 2\langle v^k, g^k\rangle + \sum_{j=1}^{N-1} Q^k_{2i_1 j},$$

where the interface term reads

$$\sum_{j=1}^{N-1} Q_{2i_1j}^k = 2\sum_{j=1}^{N-1}(\tilde{v}_{i_1j}^k - v_{i_1j}^k)\left(h^2\Delta_h v_{i_1,j}^k + 2\bar{a}_{i_1j}^{12} v_{i_1j}^k\right),$$

which is similar to $Q_{2i_1}^k$ defined in Lemma 4.2. Thus, we could obtain that

$$\begin{aligned}\sum_{j=1}^{N-1} Q_{2i_1j}^1 \le & -\tau^2h^2\sum_{j=1}^{N-1}\partial_t(\Delta_h v_{i_1j}^1)^2 - 2\tau\sum_{j=1}^{N-1}\bar{a}_{i_1j}^{12}\partial_t(v_{i_1j}^1)^2\\ &+\tau^2h^2\sum_{j=1}^{N-1}(\Delta_h v_{i_1j}^1)^2 + 2\tau^2\sum_{j=1}^{N-1}\bar{a}_{i_1j}^{12}(v_{i_1}^0)^2 + 2\sum_{j=1}^{N-1}\bar{a}_{i_1j}^{12}(v_{i_1j}^0)^2\\ &+2\tau^2\sum_{j=1}^{N-1}\bar{a}_{i_1j}^{12}(\Delta_h v_{i_1j}^1)^2 + 4\tau^2\sum_{j=1}^{N-1}\bar{a}_{i_1j}^{12}(\Delta_h v_{i_1j}^0)^2 + |||g^1|||_{I,2}^2\end{aligned}$$

and, for $k \ge 2$,

$$\begin{aligned}\sum_{j=1}^{N-1} Q_{2i_1j}^k \le & -\tau^2h^2\sum_{j=1}^{N-1}\partial_t(\Delta_h v_{i_1j}^k)^2 - 2\tau^2\sum_{j=1}^{N-1}\bar{a}_{i_1j}^{12}\partial_t\left[\partial_t(v_{i_1j}^k)^2\right]\\ &+\tau^2h^2\sum_{j=1}^{N-1}(\Delta_h v_{i_1j}^k)^2 + 2\tau^2\sum_{j=1}^{N-1}\bar{a}_{i_1j}^{12}(v_{i_1j}^{k-1})^2\\ &+2\tau^2\sum_{j=1}^{N-1}\bar{a}_{i_1j}^{12}(\Delta_h v_{i_1j}^k)^2 + 6\tau^2\sum_{j=1}^{N-1}\bar{a}_{i_1j}^{12}(\Delta_h v_{i_1j}^{k-1})^2 + |||g^k|||_{I,2}^2.\end{aligned}$$

To complete the proof, one should present the similar arguments for m_1 described above and follow the proof of Lemma 4.2. ∎

LEMMA 6.2 (prior estimation). *Let $v_h^k = \{v_{ij}^k | 0 \le i,j \le N, 0 \le k \le J\}$ satisfy the CEIDD-ZI2 algorithm on $p_1 \times p_2$ subdomains decoupled by the zigzag-line interfaces $\Gamma_h = \Gamma_h^1 \cup \Gamma_h^2$, viz.,*

$$\frac{\tilde{v}_{ij}^k - v_{ij}^{k-1}}{\tau} = \Delta_h v_{ij}^{k-1} + \tilde{g}_{ij}^{k-1} \quad on\ \ \Gamma_h, \quad 1 \le k \le J, \tag{6.20}$$

$$\begin{cases}\partial_t v_{ij}^k = \Delta_h v_{ij}^k + g_{ij}^k & on\ \ \Omega_{\xi,\eta}\ \begin{pmatrix}\xi = 1,2,\ldots,p_1\\ \eta = 1,2,\ldots,p_2\end{pmatrix},\\ v_{ij}^k = \tilde{v}_{ij}^k & on\ \ \Gamma_h\end{cases} \quad 1 \le k \le J, \tag{6.21}$$

$$\partial_t v_{ij}^k = \Delta_h v_{ij}^k + g_{ij}^k \quad on\ \ \Gamma_h, \quad 0 \le k \le J, \tag{6.22}$$

$$v_{ij}^0 = \phi_{ij} \quad on\ \ \Omega_h, \quad 1 \le k \le J, \tag{6.23}$$

$$v_{ij}^k = 0 \quad on\ \ \partial\Omega_h, \quad 0 \le k \le J. \tag{6.24}$$

Then the inequalities

$$E_1^k \le \frac{3}{2}e^{\frac{3}{2}k\tau}\left[E_1^0 + \tau\sum_{l=1}^{k}\left(\|g^l\|^2 + |||g^l|||_{I,1}^2\right)\right], \tag{6.25}$$

$$\begin{aligned}E_2^k \le & \frac{3}{2}(J+1)\exp\left(\frac{3}{2}(1+T)k\tau\right)E_2^0\\ &+\frac{3T}{2}\exp\left(\frac{3}{2}(1+T)k\tau\right)\left[4\tau\sum_{l=0}^{k}E_1^l + \tau\sum_{l=1}^{k}(\|g^l\|^2 + |||g^l|||_{I,2}^2)\right]\end{aligned} \tag{6.26}$$

hold for $0 < \tau \le 1/3$, $1 \le k \le J$, *where* E_1^k, E_2^k, $|||g^k|||_{I,1}$, *and* $|||g^k|||_{I,2}$ *are defined by* (A.1)–(A.4), *respectively.*

Proof. As far as the general case of $p_1 \times p_2$ subdomains, we can discuss the 2×2 subdomains case shown in Figure 5.2. Without any essential difficulty, the schemes (6.21)–(6.22) can read as some similar point-related schemes such as (6.8)–(6.17); however, the lengthy descriptions are messier so they are omitted here. For the H^1 estimation, we get the interface term in the form

$$\sum_{j=1}^{N-1} Q_{1i_1j}^k + \sum_{\substack{i=1\\ i\neq i_1}}^{N-1} Q_{1ij_1}^k = 2\sum_{j=1}^{N-1} (\tilde{v}_{i_1j}^k - v_{i_1j}^k)\left[h^2\partial_t(\Delta_h v_{i_1j}^k) + 2\bar{a}_{i_1j}^{12}\partial_t v_{i_1j}^k\right] + 2\sum_{\substack{i=1\\ i\neq i_1}}^{N-1} (\tilde{v}_{ij_1}^k - v_{ij_1}^k)\left[h^2\partial_t(\Delta_h v_{ij_1}^k) + 2\bar{a}_{ij_1}^{12}\partial_t v_{ij_1}^k\right].$$

Similarly, for the L^2 estimation, the interface term reads

$$\sum_{j=1}^{N-1} Q_{2i_1j}^k + \sum_{\substack{i=1\\ i\neq i_1}}^{N-1} Q_{2ij_1}^k = 2\sum_{j=1}^{N-1} (\tilde{v}_{i_1j}^k - v_{i_1j}^k)\left(h^2\Delta_h v_{i_1j}^k + 2\bar{a}_{i_1j}^{12} v_{i_1j}^k\right) + 2\sum_{\substack{i=1\\ i\neq i_1}}^{N-1} (\tilde{v}_{ij_1}^k - v_{ij_1}^k)\left(h^2\Delta_h v_{ij_1}^k + 2\bar{a}_{ij_1}^{12} v_{ij_1}^k\right).$$

To complete the proof, one could follow the proof of Lemma 6.1. ∎

We note that Lemma 6.2 is true of the CEH scheme with $p_1 = p_2 = N/2$. The tiny difference is that the scheme (6.21), applied at the interior points of each subdomain, always reads as

$$\partial_t v_{ij}^k = \Delta_h v_{ij}^k + g_{ij}^k + a_{i-\frac{1}{2},j}^1 w_{i-1,j}^k + a_{i+\frac{1}{2},j}^1 w_{i+1,j}^k + a_{i,j-\frac{1}{2}}^2 w_{i,j-1}^k + a_{i,j+\frac{1}{2}}^2 w_{i,j+1}^k,$$

in which the four adjoining points of (ih, jh) belong to $\Gamma_h \cup \partial\Omega_h$, and the mesh function $w_{ij}^k = (\tilde{v}_{ij}^k - v_{ij}^k)/h^2$ is defined at interface points together with $w_h^k(\partial\Omega_h) \equiv 0$. Correspondingly, in the proof of Lemma 6.2, the interface terms will be replaced by

$$\sum_{\alpha=1}^{N/2-1}\sum_{j=1}^{N-1} Q_{1i_\alpha j}^k + \sum_{\beta=1}^{N/2-1}\sum_{\substack{i=1\\ i\neq i_\alpha}}^{N-1} Q_{1ij_\beta}^k \quad \text{and} \quad \sum_{\alpha=1}^{N/2-1}\sum_{j=1}^{N-1} Q_{2i_\alpha j}^k + \sum_{\beta=1}^{N/2-1}\sum_{\substack{i=1\\ i\neq i_\alpha}}^{N-1} Q_{2ij_\beta}^k,$$

but Q_{1ij}^k and Q_{2ij}^k have their own forms.

Analogous to the analysis for the 1-D CEIDD algorithm in section 4, it is easy to obtain the results on stability and convergence from Lemmas 6.1 and 6.2.

THEOREM 6.3 (stability). *Under the reasonable assumption* (1.4), *the CEIDD-ZI algorithm* (5.3)–(5.7) *on* $p_1 \times p_2$ *subdomains is unconditionally stable with respect to the* H^1 *seminorm and the* L^2 *norm.*

THEOREM 6.4 (convergence). *If the solution of problem* (1.1)–(1.3) *is sufficiently smooth, spacing* h *is sufficiently small, and time step size* $\tau = \mathcal{O}\left((p_1+p_2)^{-1/2}h^{1/2+\epsilon}\right)$ *for* $\epsilon > 0$, *the numerical solution of the CEIDD-ZI algorithm* (5.3)–(5.7) *converges to the exact solution of* (1.1)–(1.3) *with an order of* $\mathcal{O}(\sqrt{1+(p_1+p_2-2)h^{-1}}(\tau+h^2))$ *in the* H^1 *seminorm and the* L^2 *norm in the sense that*

$$|e^k|_{a,1} \le c_7\sqrt{1+(p_1+p_2-2)h^{-1}}(\tau+h^2), \quad 1 \le k \le J,$$

and

$$\sqrt{\tau\sum_{l=1}^{k}\|e^l\|^2}\le c_8\sqrt{1+(p_1+p_2-2)h^{-1}}(\tau+h^2),\quad 1\le k\le J.$$

Again, for the coarsely granular parallel algorithm in the case of $2<p\ll N^2$, the accuracy of the above CEIDD-ZI algorithms is $\mathcal{O}(h^{-1/2}(\tau+h^2))$ with $\tau=\mathcal{O}(h^{1/2+\epsilon})$, just about the accuracy of the 1-D CEIDD method. However, for the CEH scheme with $p_1=p_2=N/2$, the accuracy decreases to $\mathcal{O}(h^{-1}(\tau+h^2))$ with time step size $\tau=\mathcal{O}(h^{1+\epsilon})$. From the formulations of $|||g^k|||_{I,1}$ and $|||g^k|||_{I,2}$ defined in the appendix, we could conclude that the accumulated truncation errors on the zigzag-line interior boundaries affect the global accuracy of our CEIDD-ZI algorithms.

On the other hand, if the truncation errors on Γ_h satisfy $|r_{ij}^k-\tilde r_{ij}^{k-1}|\le c_1\tau h^2$ and $|r_{ij}^{k-1}-\tilde r_{ij}^{k-1}|\le c_1\tau h^2$, an improved accuracy of CEIDD-ZI algorithms would be obtained by our prior estimations (6.25) and (6.26), and the convergence rate reaches $\mathcal{O}(\tau+h^2)$ even for the CEH scheme (cf. Example 1).

In Theorem 6.4, we notice that, for given $p=p_1\times p_2$ processors, the error bounds arrive at the minimum value with $p_1=p_2$. It means that solutions of different CEIDD-ZI algorithms have some tiny differences in numerical precision although they have the same rate of convergence. Therefore, in point of numerical precision, we may also prefer the CEIDD-ZI2 method to the CEIDD-ZI1 method for large-scale parallel computations, as the following remark states.

Remark 6.5. For given $p=p_1\times p_2$ processors, the numerical solutions of the CEIDD-ZI2 algorithm may be more precise than those of the CEIDD-ZI1 procedure, and for $1<p_2\le\sqrt{p}$, the larger the value of p_2, the better the precision may be.

7. Numerical experiments. In this section, we present some experimental results of the CEIDD-ZI procedures for four 2-D model problems. With the different choices of the initial and boundary conditions (1.2)–(1.3), the first three examples are heat problems,

$$u_t=\Delta u+f(x,y,t),\quad (x,y)\in(0,1)^2,\ t\in(0,T], \tag{7.1}$$

where three different outer-forced terms f are chosen so that we have the following.

Example 1. $u(x,y,t)\equiv u_1(x,y,t)=100tx^3(1-x)^2\cos(2\pi y)$.

Example 2. $u(x,y,t)\equiv u_2(x,y,t)=e^{-2t}\sin(x+y)$.

Example 3. $u(x,y,t)\equiv u_3(x,y,t)=te^{2t}\cos(x+y)$.

The fourth example is a convection-diffusion problem,

$$u_t=\Delta u+30u_x-20u_y+f(x,y,t),\quad (x,y)\in(0,1)^2,\ t\in(0,T], \tag{7.2}$$

where f is chosen so that we have the following.

Example 4. $u(x,y,t)\equiv u_4(x,y,t)=te^{2t}\cos(x+y)$.

For the numerical approximations of each model problem, five different scenarios were considered:

(i) the backward Euler scheme (listed as "BEuler" in the tables) inside the entire nonpartitioned domain; the CEIDD-ZI procedure on

(ii) 2×1 subdomains with 1 zigzag-line interface (5.1) for $m_1=h^{-1}/2$;

(iii) 4×1 subdomains with 3 zigzag-line interfaces (5.1) for $m_\alpha=\alpha h^{-1}/4\,(\alpha=1,2,3)$;

TABLE 7.1
Stability: $u(x,y,t) = u_1(x,y,t)$. The table lists the time-averaged L^2 error of the solution at $T = 1$ with spatial step $h = 1/64$.

CEH	2.47e-02	9.60e-02	3.44e-01	7.92e-01	1.14e+00

(iv) 2×2 subdomains with 2 intersectant zigzag-line interfaces (5.1) and (5.2) for $m_1 = n_1 = h^{-1}/2$; and
(v) the CEH algorithm on $\frac{N}{2} \times \frac{N}{2}$ subdomains.

We consider the backward Euler scheme on the entire nonpartitioned domain as the benchmark for our comparisons since it is the most stable method, and we consider the CEH scheme as a negative example since the scheme has the worst accuracy among our parallel CEIDD-ZI algorithms. In these runs, stability and convergence are carefully examined in the sense of the time-averaged L^2 error, such as the form in Theorem 6.4,

$$\mathcal{E}_h = \sqrt{\tau \sum_{k=1}^{J} \|u(\cdot, k\tau) - u_h^k\|^2} \quad . \tag{7.3}$$

In Tables 7.1–7.4, the discrete solutions are obtained by using the doubling temporal steps with the minimal size $\tau = 1/400$. The errors of the coarsely granular CEIDD-ZI algorithms remain relatively small; even τ is large relative to the spacing h, although they are relatively large to those of the fully implicit Euler scheme. Experimentally, the data in Tables 7.1–7.3 support the stability results (Theorem 6.3) of the CEIDD-ZI algorithms on mesh ratio r and subdomain partition; and the data in Table 7.4 suggest that our parallel procedures may be stable for convection-diffusion problems.

In Tables 7.5–7.8, the solution u is approximated on the halving grids with the coarsest 16×16 grids. Setting time step size $\tau = \mathcal{O}(h^2)$ or $\tau = \mathcal{O}(h)$, the experimental rate (listed as "Rate" in the tables) of convergence, in h, is computed by observing that $\mathcal{E}_h \approx c_9 h^q$ and doing a least squares fit to determine q.

We observe that the solution error of Example 1 presented in Table 7.5 behaves in the manner of the backward Euler scheme as the grid is refined. The improvement accuracy in h is the result of the improved truncation errors on interfaces and subdomains owing to $u_{2,tt}(x,y,t) \equiv 0$, as mentioned in the previous section.

In other cases, the errors of coarsely granular CEIDD-ZI algorithms are large compared to those of the backward Euler scheme for relatively coarse time-spatial meshes; however, as seen in Tables 7.6–7.8, they compare favorably with the error of the backward Euler scheme as the mesh is further refined. For those test problems,

a better rate of convergence than that predicted by Theorem 6.4 is observed; nevertheless, it is mysterious to us.

As far as the numerical precision of solutions, in those experiments, we notice that the 2×1-subdomain approach is always better than the 4-subdomain approaches (4×1 subdomains and 2×2 subdomains), and the 2×2-subdomain is better than the 4×1-subdomain. The former can be explained by Theorem 6.4, and the latter supports Remark 6.5 experimentally.

8. Concluding remarks. The EIDD methods are globally noniterative, nonoverlapping domain decomposition methods, which are computationally and communicationally efficient for each time step; however, they always suffer from either stability- or consistency-related temporal step size restrictions. For 1-D and 2-D heat equations, we developed a class of two-level CEIDD algorithms by adding an implicit correction technique and special zigzag-shaped interfaces to EIDD methods. The proposed parallel CEIDD-ZI algorithms, including their degenerate cases, the CEH schemes, are unconditionally stable (Theorems 4.3 and 6.3) without discarding the advantages of EIDD methods, including good parallelism, the localization of communication, the flexibility of domain partitioning, and the total quantity of computation (Propositions 3.1 and 5.1).

Compared with the SEIDD methods proposed in [11], the CEIDD-ZI methods not only are free from the parallel-time overload of recomputing interface solutions at correction step (Propositions 3.1 and 5.1), but they also increase the flexibility

in domain partitioning by using the noncrossover and crossover interfaces (see, e.g., Figures 5.1 and 5.2). More importantly for parallel simulations on given processors, the flexibility of domain decomposition has another advantage, that is, it reduces the cost of data communication without degrading the order of convergence and the numerical precision of solutions (Proposition 5.2 and Remark 6.5). Compared with the sequential backward Euler method, the coarsely granular CEIDD-ZI methods have an accuracy loss of $h^{-1/2}$ in our analysis; however, they exhibit better accuracy for the model problems in our numerical experiments than that predicted by Theorems 4.4 and 6.4. The point to note is that the algorithms perform well and are promising parallel procedures for solving parabolic problems on coarse-grain parallel machines.

Moreover, the parallel CEIDD-ZI procedures also can be extended to 3-D problems. Given that $2 \le p_m \le N/2\,(m = 1, 2, 3)$, we construct three zigzag-plane interior boundaries,

$$\Gamma^1_{h,\alpha} = \{(i_\alpha h, jh, lh) |\ i_\alpha = m_\alpha + \mathrm{mod}(j + l, 2),\ 3 \le m_\alpha + 2 \le m_{\alpha+1} \le N - 3\},$$

$$\Gamma^2_{h,\beta} = \{(ih, j_\beta h, lh) |\ j_\beta = n_\beta + \mathrm{mod}(i + l, 2),\ 3 \le n_\beta + 2 \le n_{\beta+1} \le N - 3\},$$

$$\Gamma^3_{h,\gamma} = \{(ih, jh, l_\gamma h) |\ l_\gamma = q_\gamma + \mathrm{mod}(i + j, 2),\ 3 \le q_\gamma + 2 \le q_{\gamma+1} \le N - 3\},$$

where $1 \le \alpha \le p_1 - 1$, $1 \le \beta \le p_2 - 1$, and $1 \le \gamma \le p_3 - 1$. Further, we assume that the three zigzag-plane interfaces satisfy the following intersectant conditions:

$$\mathrm{mod}(m_\alpha, 2) = \mathrm{mod}(n_\beta, 2) = \mathrm{mod}(q_\gamma, 2).$$

Denoting that $\Gamma^m_h = \bigcup_{\nu=1}^{p_m - 1} \Gamma^m_{h,\nu}$ and $\Gamma_h = \bigcup_{m=1}^{3} \Gamma^m_h$, the domain Ω_h is decoupled into $p = \prod_{m=1}^{3} p_m$ subdomains by the zigzag-plane interior interfaces Γ_h. Then the 3-D generalizations of our parallel CEIDD-ZI algorithms and their theoretical results are straightforward for 3-D heat equations. In what follows, we can focus on the 2-D problem for further research since the higher-dimensional case can always be considered in a similar way.

Generally, the CEIDD algorithm given in section 1 allows many choices for the shape of interface at step 0, the explicit predictor at step 1, and the subdomain solver at step 2. Different purposes determine different choices at the three steps, and the different choices make different CEIDD algorithms.

To minimize the parallel time cost on interfaces, the zigzag-shaped interfaces are adopted and the corresponding CEIDD-ZI algorithms are developed in this paper. Moreover, to reduce computation cost on each subdomain, some notable operator-splitting techniques based on fractional-step methods [10] could be employed. With this factorization, the resulting factorized CEIDD-ZI procedure becomes completely noniterative, both globally and on each subdomain.

Besides those zigzag-shaped interfaces, a more direct choice is some straight-line interfaces. Provided with possible choices at steps 1 and 2, whether the resulting CEIDD-SI (CEIDD based on straight-line interfaces) procedures are unconditionally stable or not is an interesting problem and still open to us, although some of those algorithms exhibit excellent stability experimentally [11].

It is likely that generalizations can be made to the cases of linear and nonlinear parabolic problems, and with the different space steps on different subdomains for some special purposes. We will consider those generalizations in the future.

Appendix. Some notation for 2-D CEIDD-ZI algorithms. For the 2-D parallel CEIDD-ZI algorithms described in section 5, we introduce the H^1 seminorm energy

$$E_1^k = |v^k|_{a,1}^2 + 2\tau^2 \sum_{\alpha=1}^{p_1-1} \sum_{j=1}^{N-1} \bar{a}_{i_\alpha j}^{12} (\Delta_h v_{i_\alpha j}^k)^2 + 2\tau^2 \sum_{\beta=1}^{p_2-1} \sum_i^* \bar{a}_{ij_\beta}^{12} (\Delta_h v_{ij_\beta}^k)^2 \tag{A.1}$$

and the L^2 norm energy

$$\begin{aligned} E_2^k = \tau \sum_{l=0}^{k} \|v^l\|^2 &+ \sum_{\alpha=1}^{p_1-1} \sum_{j=1}^{N-1} \left[\tau^3 h^2 \sum_{l=0}^{k} (\Delta_h v_{i_\alpha j}^l)^2 + 2\tau^2 \bar{a}_{i_\alpha j}^{12} (v_{i_\alpha j}^k)^2 \right] \\ &+ \sum_{\beta=1}^{p_2-1} \sum_i^* \left[\tau^3 h^2 \sum_{l=0}^{k} (\Delta_h v_{ij_\beta}^l)^2 + 2\tau^2 \bar{a}_{ij_\beta}^{12} (v_{ij_\beta}^k)^2 \right], \end{aligned} \tag{A.2}$$

where the summation $\sum_i^*$ is defined by

$$\sum_i^* = \sum_{\substack{i=1 \\ i \neq i_\alpha}}^{N-1}$$

for $1 \le \alpha \le p_1 - 1$. As for the interior interfaces, we define $|||g^k|||_{I,1}$ as

$$|||g^k|||_{I,1}^2 = \sum_{\alpha=1}^{p_1-1} \sum_{j=1}^{N-1} \mathcal{G}_{1i_\alpha j}^k + \sum_{\beta=1}^{p_2-1} \sum_i^* \mathcal{G}_{1ij_\beta}^k, \tag{A.3}$$

where

$$\mathcal{G}_{1ij}^k = \frac{1}{2}(h^2 + 4\bar{a}_{ij}^{12})(g_{ij}^k - \tilde{g}_{ij}^{k-1})^2 + 2\bar{a}_{ij}^{12}\tau(\tilde{g}_{ij}^{k-1})^2.$$

Similarly, we define $|||g^k|||_{I,2}$ as

$$|||g^k|||_{I,2}^2 = \sum_{\alpha=1}^{p_1-1} \sum_{j=1}^{N-1} \mathcal{G}_{2i_\alpha j}^k + \sum_{\beta=1}^{p_2-1} \sum_i^* \mathcal{G}_{2ij_\beta}^k, \tag{A.4}$$

where

$$\mathcal{G}_{2ij}^1 = 2\bar{a}_{ij}^{12}\tau^2 \left[(g_{ij}^1)^2 + 2(\tilde{g}_{ij}^0)^2 \right] + h^2 (g_{ij}^1 - \tilde{g}_{ij}^0)^2 + 2\bar{a}_{ij}^{12} (\tilde{g}_{ij}^0)^2$$

and, for $k \ge 2$,

$$\begin{aligned} \mathcal{G}_{2ij}^k = {} & 2\bar{a}_{ij}^{12}\tau^2 \left[(g_{ij}^k)^2 + 2(g_{ij}^{k-1})^2 + 2(\tilde{g}_{ij}^{k-1})^2 \right] \\ & + h^2 (g_{ij}^k - \tilde{g}_{ij}^{k-1})^2 + 2\bar{a}_{ij}^{12} (g_{ij}^{k-1} - \tilde{g}_{ij}^{k-1})^2. \end{aligned}$$

Acknowledgment. We would like to express our thanks to two anonymous reviewers whose invaluable critical comments and suggestions helped greatly to improve this article.

A DOMAIN DECOMPOSITION METHOD BASED ON WEIGHTED INTERIOR PENALTIES FOR ADVECTION-DIFFUSION-REACTION PROBLEMS*

ERIK BURMAN† AND PAOLO ZUNINO‡

Abstract. We propose a domain decomposition method for advection-diffusion-reaction equations based on Nitsche's transmission conditions. The advection-dominated case is stabilized using a continuous interior penalty approach based on the jumps in the gradient over element boundaries. We prove the convergence of the finite element solutions of the discrete problem to the exact solution and propose a parallelizable iterative method. The convergence of the resulting domain decomposition method is proved, and this result holds true uniformly with respect to the diffusion parameter. The numerical scheme that we propose here can thus be applied straightforwardly to diffusion-dominated, advection-dominated, and hyperbolic problems. Some numerical examples are presented in different flow regimes showing the influence of the stabilization parameter on the performance of the iterative method, and we compare our method with some other domain decomposition techniques for advection-diffusion equations.

Key words. advection-diffusion problem, interior penalty, finite element approximation, domain decomposition, iterative methods, discontinuous coefficients

1. Introduction.

The solution of large computational problems calls for efficient linear solvers. Domain decomposition has proved to be an attractive way to allow for parallel solving of large problems. A formulation for domain decomposition using a generalization of Nitsche's method for weak boundary conditions has been considered, for instance, by Becker, Hansbo, and Stenberg [2, 24] and by Heinrich and Pietsch [16] for the Poisson problem. This formulation was then generalized to the case of advection-diffusion problems by Toselli [26] using SUPG-type stabilization and more recently by Burman [5]. In this last case, continuous interior penalty stabilization was used to make the method stable in all flow regimes. The interior penalty finite element method for continuous approximation spaces was introduced by Douglas and Dupont [12] and analyzed by Burman and Hansbo in [7] and by Burman in [5].

In this paper we will give a detailed analysis of the domain decomposition method using Nitsche's method. In particular we consider a fully parallel iterative splitting method for advection-diffusion-reaction problems, and we prove its convergence. The present result also automatically carries over to discontinuous Galerkin interior penalty formulations of advection-diffusion problems. Overlapping domain decomposition methods for discontinuous Galerkin methods was considered by Lasser and Toselli [19] and substructuring iterative methods for domain decomposition using SUPG-type stabilized continuous approximation was considered by Rapin and Lube [23]. For an overview of results on domain decomposition for nonsymmetric problems, see Quarteroni and Valli [22] or Toselli and Widlund [27] and the references therein.

The advantages of the method proposed in this paper are to allow for continuous and discontinuous approximation with uniform stability properties with respect to the Péclet number. The discontinuous formulation naturally leads to an iterative method and allows for conservation locally in each subdomain. The continuous approximation, on the other hand, is better suited to handle different diffusive regimes since the interior penalty stabilization parameter is independent of the diffusion parameter. Numerical tests show that the proposed method is robust with respect to varying coefficients. As a model problem we propose the advection-diffusion-reaction equation

$$\begin{cases} \beta \cdot \nabla u + \sigma u - \nabla \cdot \varepsilon \nabla u = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where Ω is a bounded open connected subset of $\mathbb{R}^d$ with a Lipschitz boundary $\partial\Omega$, $d = 2$ or 3 is the space dimension, $\beta \in [W^{1,\infty}(\Omega)]^d$ is a velocity field, $\varepsilon \in L^\infty(\Omega)$, $\varepsilon > 0$, is a diffusion coefficient, and $\sigma > 0$ is the reaction coefficient, $f \in L^2(\Omega)$. The analysis extends to the case $\varepsilon = 0$ in the obvious way if the boundary conditions of the continuous problem are modified and β is such that the problem remains well-posed. We assume that the following coercivity condition holds:

$$\sigma - \frac{1}{2}\nabla \cdot \beta \geq \sigma_0 > 0. \tag{1.2}$$

We define the associated parameter σ_1 by

$$\sigma_1 := \operatorname{ess\,sup}_{x\in\Omega} \frac{|\sigma - \nabla \cdot \beta|^2}{\sigma_0}.$$

Consider a decomposition of the domain Ω into the disjoint subdomains Ω_i, $i = 1, \ldots, N$, with boundaries $\partial\Omega_i$ and with corresponding shape regular disjoint triangulations $\mathcal{T}_{h,i}$, such that $\mathcal{T}_h = \cup_{i=1}^N \mathcal{T}_{h,i} = \cup_{i=1}^N \bar{\Omega}_i = \bar{\Omega}$. Note that we do not suppose that neighboring meshes are conforming over the intersubdomain boundary. The set of interior faces of each triangulation $\mathcal{T}_{h,i}$ will be denoted by $\mathcal{F}_i$. On each triangulation we define a finite element space $V_{h,k,i}$ associated with the subdomain Ω_i,

$$V_{h,k,i} := \{v_h : v_h \in H^1(\Omega_i); v_h|_K \in P_k(K)\ \forall K \in \mathcal{T}_{h,i}\},$$

where $P_k(K)$ denotes the space of polynomials of degree $\leq k$ on K and we let $V_h = \sum_{i=1}^N V_{h,k,i}$. For every function $v_h \in V_h$ we introduce the restriction to subdomain Ω_i, $v_{h,i} = v_h|_{\Omega_i}$. To each subdomain boundary we associate the outward-oriented normal n_i. We will always assume that the solution is sufficiently smooth, i.e., $u \in H^1(\Omega) \cap (\cup_{i=1}^N H^2(\Omega_i))$, and we will assume (weak) continuity of fluxes between subdomains. Typically the diffusion parameter ε may be discontinuous over some subdomain interface, provided the interface is smooth. Let h_K denote the diameter of an element K, and ϱ_K the radius of the largest inscribed ball in K. We henceforth assume that for all meshes $\mathcal{T}_{h,i}$ there holds

$$c_{\mathcal{T}} \leq \max_{K\in\mathcal{T}_{h,i}} \frac{h_K}{\varrho_K} \tag{1.3}$$

with the same positive parameter $c_{\mathcal{T}}$. We introduce a mesh parameter function $\tilde{h}(x)|_K = h_K$ and let $h = \max_{K\in\mathcal{T}_{h,i}} h_K$. Moreover we shall assume that there exists

a constant $\rho > 1$ such that for all elements K in $\mathcal{T}_{h,i}$, $i = 1, \ldots, N$, we have

$$\max_{K' \in \mathcal{N}(K)} h_{K'} \leq \rho \min_{K' \in \mathcal{N}(K)} h_{K'}, \tag{1.4}$$

where $\mathcal{N}(K)$ is the set of elements K' such that $\bar{K} \cap \bar{K}' \neq \emptyset$. Property (1.4) is a local quasi-uniformity property of the mesh. The jump $[x]|_E$ of a quantity x over a face E will be defined by $[x(\xi)]|_E = \lim_{\delta \to 0}(x(\xi - n_E\delta) - x(\xi + n_E\delta))$, where $\xi \in E$ and n_E denotes a normal vector to the face E for interior faces where the normal is fixed but arbitrary, while for faces on a subdomain boundary $E \in \partial\Omega_i$ the normal is outward oriented with respect to the subdomain Ω_i and denoted n_i. Subscripts will be omitted when there is no ambiguity. For faces such that $E \cap \partial\Omega \neq \emptyset$ we set $[x(\xi)]|_E \equiv \lim_{\delta \to 0} x(\xi - n_E\delta)$. By $\{x(\xi)\}|_E$ we denote the average value of x over face E, $\{x(\xi)\}|_E = \lim_{\delta \to 0} \frac{1}{2}(x(\xi - n_E\delta) + x(\xi + n_E\delta))$. We will also use the weighted average $\{x(\xi)\}_w|_E = \lim_{\delta \to 0}(w^- x(\xi - n_E\delta) + w^+ x(\xi + n_E\delta))$, where w^- and w^+ are two positive weights such that $w_- + w_+ = 1$, and for faces on the boundary $\partial\Omega$ we define $\{x(\xi)\}|_E = \{x(\xi)\}_w|_E = \lim_{\delta \to 0} 2x(\xi - n_E\delta)$. Furthermore we will use the notation $(x, y)_X = \int_X x \cdot y \, \mathrm{dx}$, $\langle x, y \rangle_{\partial X} = \int_{\partial X} x \cdot y \, \mathrm{ds}$ with the elementwise counterparts $(x, y)_{X,h} = \sum_{K \in X} \int_K x \cdot y \, \mathrm{dx}$ and $\langle x, y \rangle_{\partial X,h} = \sum_{E \in \partial X} \int_E x \cdot y \, \mathrm{ds}$. Let $\|x\|_X = (x, x)_X^{\frac{1}{2}}$ denote the L^2-norm over X with the elementwise counterpart $\|x\|_{X,h} = (x, x)_{X,h}^{\frac{1}{2}}$. The norm of the space $H^i(X)$ will be denoted $\|x\|_{i,X}$ with $i = 0, 1, 2, \ldots$. The notations $\|x\|_X$ and $\|x\|_{0,X}$ are equivalent. The latter will be used only where it is more appropriate. For other functional spaces the notation will be made completely explicit. We will use c and C to denote generic positive constants independent of h_K but not necessarily of the local mesh geometry.

2. A domain decomposition method based on interior penalties. In this section we will show how domain decomposition using Nitsche's method leads to a continuous/discontinuous Galerkin-type penalty method in a natural way. The approximation is chosen to be continuous on each subdomain. We consider problem (1.1) on Ω and by taking V_h as trial and test space we propose the finite element method: find $u_h \in V_h$ such that

$$A(u_h, v_h) + J(u_h, v_h) + B(u_h, v_h) = (f, v_h) \quad \forall v_h \in V_h, \tag{2.1}$$

where

$$A(u_h, v_h) := \sum_{i=1}^{N} \Big(((\sigma - \nabla \cdot \beta) u_h, v_h)_{\Omega_i} + (\varepsilon \nabla u_h, \nabla v_h)_{\Omega_i} - (u_h, \beta \cdot \nabla v_h)_{\Omega_i} \Big),$$

$$J(u_h, v_h) := \sum_{i=1}^{N} \sum_{E \in \mathcal{F}_i} \left\langle \tilde{\gamma}_{1,i}(h_E) \|\beta \cdot n\|_{L^\infty(E)} [\nabla u_h \cdot n], [\nabla v_h \cdot n] \right\rangle_E,$$

$$B(u_h, v_h) := \sum_{i=1}^{N} \Bigg(\left\langle \beta \cdot n_i^+ u_h, [v_h] \right\rangle_{\partial\Omega_i} - \frac{1}{2} \left\langle \{\varepsilon \nabla u_h \cdot n_i\}_w, [v_h] \right\rangle_{\partial\Omega_i}$$
$$- \frac{1}{2} \left\langle \{\varepsilon \nabla v_h \cdot n_i\}_w, [u_h] \right\rangle_{\partial\Omega_i} + \left\langle \frac{\gamma_{bc} \{\varepsilon\}_w}{\tilde{h}} [u_h], [v_h] \right\rangle_{\partial\Omega_i} \Bigg),$$

and $\beta \cdot n_i^{\pm} := \frac{1}{2}(|\beta \cdot n_i| \pm \beta \cdot n_i)$. The discretization of the advection term corresponds to the standard upwind flux after integration by parts. Note that the bilinear form A corresponds to a standard Galerkin formulation in each subdomain, supplemented with boundary terms on the inner and outer boundaries that appear naturally in the formulation to assure coercivity or consistency. We observe that terms associated with nonhomogeneous boundary data do not appear since we consider $u = 0$ on $\partial\Omega$. The interior penalty stabilization term has been decomposed into one term controlling the jumps in the gradient over *interior* faces of each subdomain Ω_i, that is, $J(u_h, v_h)$, and the terms controlling the jump of the solution over interior boundaries of neighboring subdomains, the upwind flux term and the penalty term $\langle(\gamma_{bc}\{\varepsilon\}_w/\tilde{h})[u_h], [v_h]\rangle_{\partial\Omega_i}$. The stabilization parameter $\tilde{\gamma}_{1,i}(h_E) = \gamma_{ip,i}h_E^2$ depends only on the mesh geometry of the subdomain triangulation $\mathcal{T}_{h,i}$.

Remark 2.1. If the triangulation of each subdomain consists of a single triangle, then the formulation (2.1) is equivalent to a standard interior penalty discontinuous Galerkin method for (1.1). This follows immediately by noting that the interior penalty term on the gradient jumps vanishes since there are no interior faces in the subdomains.

Remark 2.2. Recalling the framework for discontinuous Galerkin methods based on interior penalties by Arnold et al. [1], we observe that the definition of the coupling term $B(u_h, v_h)$ can be made more general by introducing a parameter s that allows us to switch between a symmetric and a nonsymmetric version. Precisely, we consider

$$B(u_h, v_h) := \sum_{i=1}^{N} \Bigg(\left\langle \beta \cdot n_i^{+} u_h, [v_h] \right\rangle_{\partial\Omega_i} - \frac{1}{2} \left\langle \{\varepsilon \nabla u_h \cdot n_i\}_w, [v_h] \right\rangle_{\partial\Omega_i} - \frac{s}{2} \left\langle \{\varepsilon \nabla v_h \cdot n_i\}_w, [u_h] \right\rangle_{\partial\Omega_i} + \left\langle \frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}} [u_h], [v_h] \right\rangle_{\partial\Omega_i} \Bigg),$$

where the symmetric and the nonsymmetric cases are obtained by $s = 1$ and $s = -1$, respectively. In this work we mainly consider $s = 1$, but for comparison the nonsymmetric case will be addressed in section 4.

2.1. A priori error estimate. In this section we will prove that the finite element solution obtained from formulation (2.1) converges to the exact solution of (1.1). The a priori error estimate is proved using the techniques from [2] for the Nitsche matching conditions combined with the technique of [5] for the interior penalty stabilization. The main idea behind the stabilization based on the jump in the gradient between adjacent elements is to introduce a least squares control over the part of the convective derivative that is not in the finite element space. A key result is the following lemma. For a proof of the underlying approximation result between discrete spaces we refer to [18], and for a proof in the context of interior penalty stabilization we refer to [6]. First we define the Oswald quasi-interpolant π_h^* (see [17]).

DEFINITION 2.3. *For each node x_i, let n_i be the number of elements containing x_i as a node. We define a quasi-interpolant π_h^* of degree k by*

$$\pi_h^* v(x_i) := \frac{1}{n_i} \sum_{\{K\,:\,x_i \in K\}} v_{|K}(x_i) \quad \forall v \in \{v : v|_K \in P_k(K)\}.$$

THEOREM 2.4 (stability). *Let $\beta_h \in [V_{h,1,i}]^d$ be the Lagrange interpolant of β and let $u_h \in V_{h,k,i}$. Then there exists a constant $\gamma_{ip,i} \geq c_0 > 0$, depending only on the*

local mesh geometry, such that

$$\|\tilde{h}^{\frac{1}{2}}(\beta_h \cdot \nabla u_h - \pi_h^*(\beta_h \cdot \nabla u_h))\|_{\Omega_i}^2 \leq J_i(u_h, u_h)$$

with

$$J_i(u_h, u_h) = \sum_{E \in \mathcal{F}_i} \int_E \gamma_{ip,i} h_E^2 \|\beta_h \cdot n\|_{L^\infty(E)} [\nabla u_h]^2 \; ds. \tag{2.2}$$

Remark 2.5. Clearly then $\|\tilde{h}^{\frac{1}{2}}(\beta_h \cdot \nabla u_h - \pi_h^*(\beta_h \cdot \nabla u_h))\|_{\Omega_i}^2 \leq J(u_h, u_h)$ since $\|\beta_h \cdot n\|_{L^\infty(E)} \leq \|\beta \cdot n\|_{L^\infty(E)}$.

We define a triple norm on each subdomain as

$$|||w_h|||_i^2 = \|\sigma_0^{\frac{1}{2}} w_h\|_{\Omega_i}^2 + \|\varepsilon^{\frac{1}{2}} \nabla w_h\|_{\Omega_i}^2 + J_i(w_h, w_h) \tag{2.3}$$

and the global triple norm, taking into account also the interface interaction terms, as

$$|||w_h|||^2 = \sum_{i=1}^N \Big(|||w_h|||_i^2 + \|\delta(\varepsilon, \beta)[w_h]\|_{\partial\Omega_i}^2 \Big), \tag{2.4}$$

where $\delta(\varepsilon, \beta) = \frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}} + \frac{1}{2}|\beta \cdot n|$. In what follows, we will also make use of the quantity $\delta^+(\varepsilon, \beta) = \frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}} + \frac{1}{2}\beta \cdot n^+$. The explicit dependence of δ and δ^+ from ε and β will be omitted later on when there is no ambiguity of notation. For the continuity of the bilinear form we will also use the modified norm

$$\begin{aligned}]w_h[^2 = \sum_{i=1}^N \Big(& \|\sigma_1^{\frac{1}{2}} w_h\|_{\Omega_i}^2 + \|\beta\|_{L^\infty(\Omega)} \|\tilde{h}^{-\frac{1}{2}} w_h\|_{\Omega_i}^2 + \|\varepsilon^{\frac{1}{2}} \nabla w_h\|_{\Omega_i}^2 \\ & + \|(\beta \cdot n)^{+\,\frac{1}{2}} w_h\|_{\partial\Omega_i \setminus \partial\Omega}^2 + J_i(w_h, w_h) \Big) + \|(\tilde{h}\varepsilon)^{\frac{1}{2}} \nabla w_h \cdot n\|_{\partial\Omega_i}^2 + \|\delta(\varepsilon, \beta) w_h\|_{\partial\Omega_i}^2. \end{aligned} \tag{2.5}$$

To prove convergence of the discrete solutions of formulation (2.1) to the exact solution of (1.1) we will first prove three preliminary lemmas giving Galerkin orthogonality, coercivity, and approximability. Existence of discrete solutions follows by the coercivity and convergence and is proved in Theorem 2.12.

We first recall a trace inequality and the standard inverse inequality that we will use repeatedly:

$$\|v\|_{0,\partial K}^2 \leq C \Big(h_K^{-1} \|v\|_K^2 + h_K \|v\|_{1,K}^2 \Big) \quad \forall v \in H^1(K), \tag{2.6}$$

$$\|\nabla v\|_K \leq C_{inv} h_K^{-1} \|v\|_K . \tag{2.7}$$

For a proof of (2.6) we refer to [25, p. 26], and for a proof of (2.7) we refer to [9].

LEMMA 2.6 (Galerkin orthogonality). *Let $u \in \cup_{i=1}^N H^2(\Omega_i)$ be the exact solution of* (1.1) *and u_h the solution to* (2.1). *Then there holds*

$$A(u - u_h, v_h) + B(u - u_h, v_h) + J(u - u_h, v_h) = 0 \quad \forall v_h \in V_h.$$

Proof. By assumption we have that $[-\varepsilon \nabla u \cdot n + \beta \cdot n u] = [u] = 0$ in the sense of traces, and since $u \in \cup_{i=1}^N H^2(\Omega_i)$ there holds $J(u, v_h) = 0$. Therefore using the

equality $[ab] = [a]\{b\} + \{a\}[b]$ and the fact that $\{\varepsilon\nabla u\cdot n\}_w - \beta\cdot n^+ u = \{\varepsilon\nabla u\cdot n - \beta\cdot nu\}$ we have

$$
\begin{aligned}
(2.8)\qquad & A(u,v_h) + B(u,v_h) + J(u,v_h) \\
&= A(u,v_h) - \frac{1}{2}\sum_{i=1}^{N} \langle\{\varepsilon\nabla u\cdot n\}_w, [v_h]\rangle_{\partial\Omega_i} + \sum_{i=1}^{N} \left\langle \beta\cdot n^+ u, [v_h]\right\rangle_{\partial\Omega_i} \\
&= A(u,v_h) - \frac{1}{2}\sum_{i=1}^{N} \langle\{\varepsilon\nabla u\cdot n - \beta\cdot nu\}, [v_h]\rangle_{\partial\Omega_i} \\
&= A(u,v_h) - \frac{1}{2}\sum_{i=1}^{N} \int_{\partial\Omega_i\setminus\partial\Omega} [(\varepsilon\nabla u\cdot n - \beta\cdot nu)v_h]\,\mathrm{d}s - \langle\varepsilon\nabla u\cdot n - \beta\cdot nu, v_h\rangle_{\partial\Omega}\,.
\end{aligned}
$$

By an integration by parts in each subdomain we obtain

$$
\begin{aligned}
A(u,v_h) &= \sum_{i=1}^{N} \{(\varepsilon\nabla u, \nabla v_h)_{\Omega_i} - (u, \beta\cdot\nabla v) + ((\sigma - \nabla\cdot\beta)u, v)_{\Omega_i}\} \\
&= \sum_{i=1}^{N} (-\varepsilon\Delta u + \beta\cdot\nabla u + \sigma u, v_h)_{\Omega_i} + \sum_{i=1}^{N} \langle\varepsilon\nabla u\cdot n - \beta\cdot nu, v_h\rangle_{\partial\Omega_i} \\
&= \sum_{i=1}^{N} (f, v_h)_{\Omega_i} + \frac{1}{2}\sum_{i=1}^{N} \int_{\partial\Omega_i\setminus\partial\Omega} [(\varepsilon\nabla u\cdot n - \beta\cdot nu)v_h]\,\mathrm{d}s + \langle\varepsilon\nabla u\cdot n - \beta\cdot nu, v_h\rangle_{\partial\Omega}\,.
\end{aligned}
$$

It then follows from (2.8) that

$$A(u,v_h) + B(u,v_h) + J(u,v_h) = (f, v_h);$$

combining this equality with (2.1) completes the proof. ∎

LEMMA 2.7 (coercivity). *For the formulation* (2.1) *there holds*

$$c|||z_h||| \le A(z_h,z_h) + B(z_h,z_h) + J(z_h,z_h) \quad \forall z_h \in V_h.$$

Proof. We essentially only need to show that the weakly imposed boundary and interface conditions do not destroy coercivity. We have

$$
\begin{aligned}
A(z_h,z_h) + B(z_h,z_h) = \sum_{i=1}^{N} \Bigg(& \int_{\Omega_i} (\sigma - \nabla\cdot\beta)\, z_h^2\,\mathrm{dx} + \|\varepsilon^{\frac{1}{2}}\nabla z_h\|_{\Omega_i}^2 - (z_h, \beta\cdot\nabla z_h)_{\Omega_i} \\
& + \left\langle \beta\cdot n^+ z_h, [z_h]\right\rangle_{\partial\Omega_i} - \langle\{\varepsilon\nabla z_h\cdot n\}_w, [z_h]\rangle_{\partial\Omega_i} + \left\langle \frac{\gamma_{bc}\varepsilon}{\tilde{h}}[z_h], [z_h]\right\rangle_{\partial\Omega_i}\Bigg).
\end{aligned}
\tag{2.9}
$$

Consider the third term on the right-hand side of (2.9). Integration by parts yields

$$
\begin{aligned}
(2.10)\qquad \sum_{i=1}^{N} (\beta\cdot\nabla z_h, z_h)_{\Omega_i} &= -\frac{1}{2}(\nabla\cdot\beta\; z_h, z_h)_{\Omega} + \sum_{i=1}^{N} \frac{1}{2}\left\langle \beta\cdot n\, z_h, z_h\right\rangle_{\partial\Omega_i} \\
&= -\frac{1}{2}(\nabla\cdot\beta\; z_h, z_h)_{\Omega} + \sum_{i=1}^{N} \frac{1}{4}\left\langle \beta\cdot n,\, [z_h^2]\right\rangle_{\partial\Omega_i\setminus\partial\Omega} + \frac{1}{2}\left\langle \beta\cdot n\; z_h,\; z_h\right\rangle_{\partial\Omega}.
\end{aligned}
$$

Applying (2.10) to the third term of (2.9) and using the equality $a(a-b) = \frac{1}{2}(a^2 - b^2 + (a-b)^2)$ we get

$$\begin{aligned}(2.11)\quad &\sum_{i=1}^{N}\Big(-(z_h, \beta\cdot\nabla z_h)_{\Omega_i} + \langle \beta\cdot n^+ z_h, [z_h]\rangle_{\partial\Omega_i}\Big)\\ &= \sum_{i=1}^{N}\left(\frac{1}{2}(\nabla\cdot\beta\ z_h, z_h)_{\Omega_i} - \frac{1}{4}\langle \beta\cdot n, [z_h^2]\rangle_{\partial\Omega_i\setminus\partial\Omega}\right.\\ &\quad\left. + \frac{1}{2}\langle |\beta\cdot n|\ z_h,\ z_h\rangle_{\partial\Omega} + \frac{1}{2}\langle \beta\cdot n^+, [z_h^2]\rangle_{\partial\Omega_i\setminus\partial\Omega} + \frac{1}{2}\langle \beta\cdot n^+[z_h], [z_h]\rangle_{\partial\Omega_i\setminus\partial\Omega}\right).\end{aligned}$$

By observing that $\sum_{i=1}^{N}\frac{1}{2}\langle \beta\cdot n^+, [z_h^2]\rangle_{\partial\Omega_i\setminus\partial\Omega} = \sum_{i=1}^{N}\frac{1}{4}\langle \beta\cdot n, [z_h^2]\rangle_{\partial\Omega_i\setminus\partial\Omega}$ we conclude that

$$\begin{aligned}(2.12)\quad &\sum_{i=1}^{N}\Big(-(z_h, \beta\cdot\nabla z_h)_{\Omega_i} + \langle \beta\cdot n^+ z_h, [z_h]\rangle_{\partial\Omega_i}\Big)\\ &= \sum_{i=1}^{N}\left(\frac{1}{2}(\nabla\cdot\beta\ z_h, z_h)_{\Omega_i} + \frac{1}{2}\langle |\beta\cdot n|\ z_h,\ z_h\rangle_{\partial\Omega} + \frac{1}{2}\langle \beta\cdot n^+[z_h], [z_h]\rangle_{\partial\Omega_i\setminus\partial\Omega}\right).\end{aligned}$$

We now consider the second, fifth, and sixth terms of (2.9). The nonsymmetric boundary integral is split using a Cauchy–Schwarz inequality followed by Young's inequality and controlled by the symmetric terms in the following fashion:

$$\begin{aligned}(2.13)\quad &\sum_{i=1}^{N}\left(\|\varepsilon^{\frac{1}{2}}\nabla z_h\|_{\Omega_i}^2 - \langle\{\varepsilon\nabla z_h\cdot n\}_w, [z_h]\rangle_{\partial\Omega_i} + \left\langle\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}}[z_h], [z_h]\right\rangle_{\partial\Omega_i}\right)\\ &\geq \sum_{i=1}^{N}\left(\|\varepsilon^{\frac{1}{2}}\nabla z_h\|_{\Omega_i}^2 - 2\alpha\|(\tilde{h}\varepsilon)^{\frac{1}{2}}\nabla z_h\cdot n\|_{\partial\Omega_i}^2 + \left\langle\left(\gamma_{bc} - \frac{1}{4\alpha}\right)\frac{\{\varepsilon\}_w}{\tilde{h}}[z_h], [z_h]\right\rangle_{\partial\Omega_i}\right).\end{aligned}$$

As a consequence of the trace inequality (2.6) and inverse estimates we have

$$(2.14)\qquad \|(\tilde{h}\varepsilon)^{\frac{1}{2}}\nabla z_h\cdot n\|_{\partial\Omega_i}^2 \leq C_t\|\varepsilon^{\frac{1}{2}}\nabla z_h\|_{\Omega_i}^2,$$

and by choosing $\alpha = (4C_t)^{-1}$ and $\gamma_{bc} = 2C_t$ we conclude that

$$\begin{aligned}(2.15)\quad &\sum_{i=1}^{N}\left(\|\varepsilon^{\frac{1}{2}}\nabla z_h\|_{\Omega_i}^2 - \langle\{\varepsilon\nabla z_h\cdot n\}_w, [z_h]\rangle_{\partial\Omega_i} + \left\langle\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}}[z_h], [z_h]\right\rangle_{\partial\Omega_i}\right)\\ &\qquad\geq \frac{1}{2}\sum_{i=1}^{N}\left(\|\varepsilon^{\frac{1}{2}}\nabla z_h\|_{\Omega_i}^2 + \left\langle\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}}[z_h], [z_h]\right\rangle_{\partial\Omega_i}\right).\end{aligned}$$

Combining the results of (2.9), (2.12), (2.15) and applying once again (2.14) and recalling the condition (1.2), the lemma follows, with a constant $c = \frac{1}{2}$. ∎

Remark 2.8. The constant C_t depends only on the mesh regularity and can be given an explicit expression in the case of piecewise linear elements (see [2]); for high order elements it can be computed by solving a small local eigenvalue problem (see [15]).

We will now proceed and prove approximability properties of the triple norm. The L^2-projection of u onto V_h will be denoted $\pi_h u$ and the nodal interpolation will be denoted $i_h u$. To avoid globally quasi-uniform meshes we need a stability estimate for the L^2-projection in weighted norms. This problem was considered in [13] and more recently in [3]. In [3] the following weighted stability estimate was proven:

$$\|\phi^* \pi_h u\|_\Omega \leq C \|\phi^* u\|_\Omega, \tag{2.16}$$

where ϕ^* is a piecewise linear weighting function satisfying

$$|\nabla \phi^*|_K| \leq \eta h_K^{-1} \max_{x \in K} \phi^* \tag{2.17}$$

for all K. Stability holds for η sufficiently small. We will use this stability result to prove the following

LEMMA 2.9. *If the polynomial order of the finite element space is k and $u \in H^{k+1}(\Omega)$, then there holds, for ρ sufficiently small,*

$$\sum_{K \in \mathcal{T}_{h,i}} (h_K^{-1} \|(\pi_h u - u)\|_K^2 + h_K \|\nabla(\pi_h u - u)\|_K^2) \leq C \sum_{K \in \mathcal{T}_{h,i}} h_K^{2k+1} \|u\|_{k+1,K}^2. \tag{2.18}$$

Proof. First note that by adding and subtracting the nodal interpolant $i_h u$ in the H^1 contribution of (2.18) and applying a local inverse inequality we have

$$\begin{aligned} &\sum_{K \in \mathcal{T}_{i,h}} h_K \|\nabla(\pi_h u - u)\|_K^2 \\ &\quad \leq C \sum_{K \in \mathcal{T}_{i,h}} (C_{inv}^2 h_K^{-1} \|(\pi_h u - i_h u)\|_K^2 + h_K \|\nabla(i_h u - u)\|_K^2). \end{aligned} \tag{2.19}$$

Hence it is sufficient to consider the L^2-part: $\sum_{K \in \mathcal{T}_{i,h}} h_K^{-\frac{1}{2}} \|(\pi_h u - u)\|_K^2$.

Take $\phi^* = \pi_h^* h_K^{-\frac{1}{2}}$. We must prove that this function satisfies (2.17) and that η can be made as small as needed by diminishing ρ. By the definition of the Oswald interpolant and the local quasi-regularity (1.4) one readily verifies that for all $K \in \mathcal{T}_{h,i}$

$$\max_{x \in K} |\nabla \phi^*| \leq h_K^{-1} \left| \max_{K' \in \mathcal{N}(K)} h_{K'}^{-\frac{1}{2}} - \min_{K' \in \mathcal{N}(K)} h_{K'}^{-\frac{1}{2}} \right| \leq h_K^{-1} (\rho^{\frac{1}{2}} - 1) \min_{K' \in \mathcal{N}(K)} (h_{K'}^{-\frac{1}{2}}).$$

Hence, using the inequality $\min_{K' \in \mathcal{N}(K)} (h_{K'}^{-\frac{1}{2}}) \leq \min_{x \in K} \phi^*$ we have $|\nabla \phi^*|_K| \leq (\rho^{\frac{1}{2}} - 1) h_K^{-1} \min_{x \in K} \phi^*$ on K, and therefore $\eta(\rho) = (\rho^{\frac{1}{2}} - 1)$ can be made arbitrarily small by choosing ρ small. Applying now the weighted stability estimate we have

$$\begin{aligned} \sum_{K \in \mathcal{T}_h} h_K^{-1} \|(\pi_h u - u)\|_K^2 &\leq \rho^{\frac{1}{2}} \|\phi^* (\pi_h u - u)\|_\Omega^2 \\ &\leq 2\rho^{\frac{1}{2}} (\|\phi^* (\pi_h u - i_h u)\|_\Omega^2 + \|\phi^* (i_h u - u)\|_\Omega^2) \\ &\leq C(\rho) \|\phi^* (i_h u - u)\|_\Omega^2 \leq C(\rho) \sum_K h_K^{2k+1} \|u\|_{k+1,\Omega}^2. \end{aligned}$$

∎

LEMMA 2.10 (approximability). *Assume that the family of meshes $\mathcal{T}_{h,i}$ is locally quasi uniform with ρ such that Lemma 2.9 holds. Let $u \in \cup_{i=1}^N H^s(\Omega_i)$ with $s \geq k+1 \geq 2$ and let $\pi_h u$ denote the standard L_2-projection of u onto V_h; then we have that*

$$|||\pi_h u - u||| \leq C(\varepsilon^{\frac{1}{2}} \mathcal{H}(0,u) + \|\beta\|_{L^\infty(\Omega)}^{\frac{1}{2}} \mathcal{H}(1,u) + \sigma_0^{\frac{1}{2}} \mathcal{H}(2,u)),$$

where C is independent of σ, ε, β, and h but depends on the mesh geometry and

$$\mathcal{H}(\alpha,u)=\left(\sum_{i=1}^{N}\sum_{K\in\mathcal{T}_{h,i}}h_K^{2k+\alpha}\|u\|_{k+1,K}^2\right)^{\frac{1}{2}}.$$

Proof. It follows from the stability of the L^2-projection and standard interpolation results that $\|\sigma_0^{\frac{1}{2}}(\pi_h u-u)\|_{\Omega_i}\leq\sigma_0^{\frac{1}{2}}(\sum_{K\in\mathcal{T}_{h,i}}h_K^{2(k+1)}\|u\|_{k+1,K}^2)^{\frac{1}{2}}$. We then write $\xi_h=\pi_h u-i_h u$, where i_h denotes the nodal interpolant, and note that $\xi_h=\pi_h(u-i_h u)$. By the H^1-stability of the L^2-projection on locally quasi-uniform meshes [4, 11] we may write

$$\|\nabla\xi_h\|_{\Omega_i}\leq\|\nabla(u-i_h u)\|_{\Omega_i}\leq C\left(\sum_{K\in\mathcal{T}_{h,i}}h_K^{2k}\|u\|_{k+1,K}^2\right)^{\frac{1}{2}}. \tag{2.20}$$

It immediately follows by means of the triangular inequality that

$$\|\varepsilon^{\frac{1}{2}}\nabla(u-\pi_h u)\|_{\Omega_i}^2\leq C\varepsilon\sum_{K\in\mathcal{T}_{h,i}}h_K^{2k}\|u\|_{k+1,K}^2,$$

and by an application of the inverse inequality and Lemma 2.9 we have

$$\sum_{K\in\mathcal{T}_{h,i}}h_K^3\|\nabla\xi_h\|_{1,\Omega}^2\leq C\sum_{K\in\mathcal{T}_{h,i}}h_K\|\nabla\xi_h\|_{\Omega}^2\leq\sum_{K\in\mathcal{T}_{h,i}}h_K^{2k+1}\|u\|_{k+1,K}^2. \tag{2.21}$$

Using the trace inequality (2.6) together with (2.20) and (2.21), it follows that

$$\begin{aligned}\|(\varepsilon\tilde{h})^{\frac{1}{2}}\nabla(\pi_h u-u)\cdot n\|_{\partial\Omega_i}^2&\leq C\sum_{K\in\mathcal{T}_{h,i}}\left(\varepsilon\|\nabla(\pi_h u-u)\|_K^2+\varepsilon h_K^2\|\nabla(\pi_h u-u)\|_{1,K}^2\right)\\&\leq C\varepsilon\sum_{K\in\mathcal{T}_{h,i}}h_K^{2k}\|u\|_{k+1,\Omega_i}^2.\end{aligned}$$

Using once again (2.6), (2.20), and (2.21) we get in a similar fashion

$$\begin{aligned}&J_1(u-\pi_h u,u-\pi_h u)\\&\leq C\sum_{i=1}^{N}\gamma_{ip,i}\|\beta\|_{L^\infty(\Omega_i)}\sum_{K\in\mathcal{T}_{h,i}}\left(\|\tilde{h}^{\frac{1}{2}}\nabla(u-\pi_h u)\|_K^2+\|\tilde{h}^{\frac{3}{2}}\nabla(u-\pi_h u)\|_{1,K}^2\right)\\&\leq\sum_{i=1}^{N}\|\beta\|_{L^\infty(\Omega_i)}\sum_{K\in\mathcal{T}_{h,i}}h_K^{2k+1}\|u\|_{k+1,\Omega_i}^2.\end{aligned}$$

Finally we note that for the boundary term we have, using (2.6) and (2.20),

$$\begin{aligned}\langle\pi_h u-u,\pi_h u-u\rangle_{\partial\Omega_i}&\leq\sum_{K:\partial K\cap\partial\Omega_i\neq\emptyset}h_K^{-1}\|\pi_h u-u\|_K^2+h_K\|\nabla(\pi_h u-u)\|_K^2\\&\leq\sum_{K\in\mathcal{T}_{h,i}}h_K^{2k+1}\|u\|_{k+1,\Omega_i}^2,\end{aligned}$$

which concludes the proof. ∎

As an immediate consequence of the above result and Lemma 2.9 we have the following.

COROLLARY 2.11. *Under the same assumptions as in Lemma* 2.10 *we have that*

$$|]\pi_h u - u[| \le C(\varepsilon^{\frac{1}{2}}\mathcal{H}(0,u) + \|\beta\|^{\frac{1}{2}}_{L^\infty(\Omega)}\mathcal{H}(1,u) + \sigma_1^{\frac{1}{2}}\mathcal{H}(2,u)),$$

where C is independent of σ, ε, β, and h but depends on the mesh geometry.

THEOREM 2.12 (convergence). *Let $u \in \cup_{i=1}^N H^s(\Omega_i)$ with $s \ge k+1 \ge 2$ be the solution of* (1.1) *and let $u_h \in V_h$ be the solution of* (2.1). *Then the following a priori error estimate holds:*

$$|||u - u_h||| \le C\left(\varepsilon^{\frac{1}{2}}\mathcal{H}(0,u) + \|\beta\|^{\frac{1}{2}}_{L^\infty(\Omega)}\mathcal{H}(1,u) + \left(\sigma_1^{\frac{1}{2}} + \frac{|\beta|_{W^{1,\infty}(\Omega)}}{\sigma_0}\right)\mathcal{H}(2,u)\right).$$

Proof. We decompose the error into two parts: $\eta = u - \pi_h u$ and $\xi_h = \pi_h u - u_h$. It follows that $u - u_h = \eta + \xi_h$. By Lemma 2.10 we know that

$$|||\eta||| \le C(\varepsilon^{\frac{1}{2}}\mathcal{H}(0,u) + \|\beta\|^{\frac{1}{2}}_{L^\infty(\Omega)}\mathcal{H}(1,u) + \sigma_0^{\frac{1}{2}}\mathcal{H}(2,u)),$$

and it is therefore sufficient to study $\xi_h = \pi_h u - u_h$. Using Lemma 2.7 we have

$$c|||\xi_h|||^2 \le A(\xi_h,\xi_h) + B(\xi_h,\xi_h) + J(\xi_h,\xi_h),$$

and by Galerkin orthogonality

$$c|||\xi_h|||^2 \le A(\eta,\xi_h) + B(\eta,\xi_h) + J(\eta,\xi_h).$$

After an integration by parts in the convective term and an application of the Cauchy–Schwarz inequality in all other terms we have

$$c|||\xi_h|||^2 \le |]\eta[|\,|||\xi_h||| + |(\eta, \beta\cdot\nabla\xi_h)|.$$

Using now the orthogonality of the L^2-projection and Lemma 2.4 we may write

$$\begin{aligned} c|||\xi_h|||^2 &\le |]\eta[|\,|||\xi_h||| + |(\eta, \beta_h\cdot\nabla\xi_h - \pi^*\beta_h\cdot\nabla\xi_h)| + |(\eta,(\beta-\beta_h)\cdot\nabla\xi_h) \\ &\le |]\eta[|\,|||\xi_h||| + \|\beta\|_{L^\infty(\Omega)}\|\tilde{h}^{-\frac{1}{2}}\eta\|J(\xi_h,\xi_h)^{\frac{1}{2}} + |\beta|_{W^{1,\infty}(\Omega)}\|\eta\|\ \|\tilde{h}\nabla\xi_h\| \\ &\le |]\eta[|\,|||\xi_h||| + C_i\frac{|\beta|_{W^{1,\infty}(\Omega)}}{\sigma_0}\|\eta\|\ |||\xi_h|||. \end{aligned}$$

The theorem now follows by the approximation Lemma 2.10 and Corollary 2.11. ∎

Remark 2.13. The a priori error analysis carried out in this section holds true for any admissible choice of the weights w^+, w^- (such that $w^+, w^- > 0$ and $w^+ + w^- = 1$) that appear in the definition of $\{\cdot\}_w$ as also proved in [16] and [24]. In the following section we propose a definition of these weights according to the specific characteristics of the problem at hand.

2.2. Optimal choice of the averaging weights. To make the notation simpler, let us assume that only two subdomains Ω_i are considered with corresponding diffusivities ε_i, $i = 1, 2$. In this case, let $\partial\Omega_1 \setminus \partial\Omega$ be the interface between the subdomains and let n_1 be the outer normal with respect to Ω_1. Then we define the weighted average on the interface as $\{x(\xi)\}_w = \lim_{\delta\to 0}(w_1 x(\xi - n_1\delta) + w_2 x(\xi + n_1\delta))$.

The regularity assumptions on the solution u can be expected to hold only as long as $\varepsilon_i \ge \varepsilon_0 > 0$ in all the subdomains and the intersubdomain boundaries are

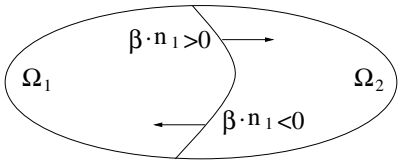

FIG. 2.1. *The model situation.*

smooth enough. In case ε_i vanishes in a subdomain, the weights w_i may be chosen so as to guarantee that the matching conditions automatically recover the physically correct behavior, relaxing the continuity of u but keeping the continuity of the fluxes. It turns out that balancing the diffusive fluxes yields a numerical scheme with the right asymptotic behavior if the diffusion coefficient vanishes in some subdomain. Let us exemplify this on a model case. We consider a domain Ω split into two neighboring subdomains Ω_1 and Ω_2 with a diffusion coefficient ε that is a regular function in each subdomain, but discontinuous across the interface $\partial\Omega_1 \cap \partial\Omega_2$. We choose the weights w_1 and w_2 such that

$$w_i(\xi) := \lim_{\delta \to 0} \frac{\varepsilon(\xi + \delta n_i)}{\varepsilon(\xi + \delta n_i) + \varepsilon(\xi - \delta n_i)} \quad \forall \xi \in \partial\Omega_1 \cap \partial\Omega_2,\ i = 1, 2, \tag{2.22}$$

where n_i is the outward unit normal with respect to Ω_i. We observe that such weights always satisfy $w_1(\xi) + w_2(\xi) = 1$ for all $\xi \in \partial\Omega_1 \cap \partial\Omega_2$. Moreover, in the case of smooth diffusivity across the interface, our choice coincides with the classical one, $w_1 = w_2 = \frac{1}{2}$. Furthermore, let us define $\omega(\xi) := w_1(\xi)\varepsilon_1(\xi) = w_2(\xi)\varepsilon_2(\xi)$. Our choice of the weights implies that $\{\varepsilon_i \nabla u_h \cdot n_i\}_w = 2\omega\{\nabla u_h \cdot n_i\}$, which shows that our method turns out to consider the arithmetic average of the gradients instead of the arithmetic average of the diffusion fluxes in order to construct the consistency term. Using these weights the coupling term between Ω_1 and Ω_2 becomes

$$\begin{aligned} B(u_h, v_h) = \sum_{i=1}^{2} \Bigg(& \langle \beta \cdot n^+ u_h, [v_h] \rangle_{\partial\Omega_i \setminus \partial\Omega} - \langle \omega\{\nabla u_h \cdot n\}, [v_h] \rangle_{\partial\Omega_i \setminus \partial\Omega} \\ & - \langle \omega\{\nabla v_h \cdot n\}, [u_h] \rangle_{\partial\Omega_i \setminus \partial\Omega} + \left\langle \frac{\gamma_{bc} 2\omega}{\tilde{h}} [u_h], [v_h] \right\rangle_{\partial\Omega_i \setminus \partial\Omega} \Bigg). \end{aligned}$$

Consider the case when ε_1 goes to zero; then only the upwind flux term remains. One may readily verify that the coupling term $B(u_h, v_h)$ corresponds to the weak formulation of the conditions

$$\begin{aligned} -\varepsilon_2 \nabla u_{2,h} \cdot n_1 + \beta \cdot n_1 u_{2,h} = \beta \cdot n_1 u_{1,h} \text{ on } \partial\Omega_1 \setminus \partial\Omega, \text{ where } \beta \cdot n_1 > 0, \\ u_{1,h} = u_{2,h} \text{ and } -\varepsilon_2 \nabla u_{2,h} \cdot n_1 = 0 \text{ on } \partial\Omega_1 \setminus \partial\Omega, \text{ where } \beta \cdot n_1 < 0, \end{aligned}$$

which were proposed for the hybrid elliptic-hyperbolic coupling in Gastaldi and Quarteroni [14] (see also [10]). By the symmetry of the weights the same holds in the case $\varepsilon_2 = 0$. The convergence analysis of the iterative method and numerical experience also indicates that this choice of w_1 and w_2 is the only viable one for the iterative algorithm.

3. An iterative splitting method. To introduce and analyze the iterative method we will restrict the discussion to the case of two subdomains Ω_i, $i = 1, 2$,

with interface $\partial\Omega_i \setminus \partial\Omega \neq \emptyset$. Nevertheless, the generalization to the multidomain case is straightforward and will be addressed later on. We denote with $u_{h,i} \in V_{h,k,i}$ the restriction on Ω_i of the global numerical solution. For the sake of simplicity, we also identify with $u_{h,i}$ the function on Ω that is obtained by extending $u_{h,i}$ to zero outside Ω_i. If we consider the formulation (2.1) and decouple the subdomains by using some approximation $u_{h,j}^k$ of $u_{h,j}$ with $j \neq i$ as boundary data from the neighboring subdomain with respect to Ω_i, we obtain the iterative scheme. Given $u_{h,1}^k, u_{h,2}^k$, for $k = 1, 2, \ldots$, find $u_{h,1}^{k+1} \in V_{h,1}$ such that

(3.1)
$$A(u_{h,1}^{k+1}, v_{h,1}) + \tilde{B}(u_{h,1}^{k+1}, u_{h,2}^k, v_{h,1}) + J(u_{h,1}^{k+1}, v_{h,1}) + S(u_{h,1}^{k+1}, u_{h,1}^k, v_{h,1}) = (f, v_{h,1})$$

and $u_{h,2}^{k+1} \in V_{h,2}$ such that

(3.2)
$$A(u_{h,2}^{k+1}, v_{h,2}) + \tilde{B}(u_{h,2}^{k+1}, u_{h,1}^k, v_{h,2}) + J(u_{h,2}^{k+1}, v_{h,2}) + S(u_{h,2}^{k+1}, u_{h,2}^k, v_{h,2}) = (f, v_{h,2}),$$

where

$$S(u_{h,i}^{k+1}, u_{h,i}^k, v_{h,i}) = \sum_{E \in G_h} \left\langle \frac{\gamma_{it}}{\tilde{h}} (u_{h,i}^{k+1} - u_{h,i}^k), v_{h,i} \right\rangle_E$$

are the terms that stabilize the iterations and the trace mesh is defined by

$$G_h = \{E \neq \emptyset : E = \partial K_i \cap \partial K_j;\ \forall K_i \in \mathcal{T}_{h,i};\ \forall K_j \in \mathcal{T}_{h,j};\ i \neq j\},$$

and we recall that $\tilde{h}(x)|_E = h_E$ for all $E \in G_h$.

The stabilization term $S(u_{h,i}^{k+1}, u_{h,i}^k, v_{h,i})$ corresponds to iteration relaxation and is mandatory to get good convergence properties. If S is omitted, we cannot prove convergence of the triple norm. In fact explicit control of the error in the jump over the interface is lost, and numerical experience shows very poor convergence as well for $S = 0$. Moreover, we note that the stabilization term is consistent in the sense that $S(u_{h,i}, u_{h,i}, v_{h,i}) = 0$. Finally, we have denoted with $\tilde{B}(u_{h,i}, u_{h,j}, v_{h,i})$, $i, j = 1, 2$, $j \neq i$, the interface/boundary penalty bilinear form after the iterative splitting, which is defined as follows:

$$\begin{aligned}
&\tilde{B}(u_{h,i}, u_{h,j}, v_{h,i}) = \langle \beta \cdot n_i^+ u_{h,i}, v_{h,i} \rangle_{\partial\Omega_i \setminus \partial\Omega} + \langle \beta \cdot n_i^- u_{h,j}, v_{h,i} \rangle_{\partial\Omega_i \setminus \partial\Omega} \\
&- \langle w_i \varepsilon_i \nabla u_{h,i} \cdot n_i + w_j \varepsilon_j \nabla u_{h,j} \cdot n_i, v_{h,i} \rangle_{\partial\Omega_i \setminus \partial\Omega} - \langle \varepsilon_i w_i \nabla v_{h,i} \cdot n_i, u_{h,i} - u_{h,j} \rangle_{\partial\Omega_i \setminus \partial\Omega} \\
&+ \left\langle 2 \frac{\gamma_{bc} \{\varepsilon\}_w}{\tilde{h}} (u_{h,i} - u_{h,j}), v_{h,i} \right\rangle_{\partial\Omega_i \setminus \partial\Omega} + \left\langle \frac{\gamma_{bc} \varepsilon}{\tilde{h}} u_{h,i}, v_{h,i} \right\rangle_{\partial\Omega_i \cap \partial\Omega} \\
&+ \langle \beta \cdot n^+ u_{h,i}, v_{h,i} \rangle_{\partial\Omega_i \cap \partial\Omega} - \langle \varepsilon_i \nabla u_{h,i} \cdot n, v_{h,i} \rangle_{\partial\Omega_i \cap \partial\Omega} - \langle \varepsilon_i \nabla v_{h,i} \cdot n, u_{h,i} \rangle_{\partial\Omega_i \cap \partial\Omega}.
\end{aligned}$$

Since the data on Ω_j are taken at the earlier iteration for both domains the two problems are decoupled and can be solved in parallel.

The present setting can easily be generalized to the case of several subdomains. Let $\bar{\Omega} = \cup_{i=1}^N \bar{\Omega}_i$ be the partition in N subdomains and let $\Gamma_{ij} = \partial\Omega_i \cap \partial\Omega_j$ be the corresponding interfaces. Then, since the definition of A and J are already general with respect to N, problems (3.1) and (3.2) do not need to be modified in the multidomain case, provided that the definition of $\tilde{B}(u_{h,i}, u_{h,j}, v_{h,i})$ is adapted by replacing $\langle \cdot, \cdot \rangle_{\partial\Omega_i \setminus \partial\Omega}$ with $\sum_{i,j=1}^N \langle \cdot, \cdot \rangle_{\Gamma_{ij}}$. Thanks to the generality of the construction of G_h

the term $S(u_{h,i}, u_{h,i}, v_{h,i})$ remains unchanged. Moreover, in the multidomain case, the system of equations (3.1)–(3.2) should be complemented with one equation for each new subdomain. Although the formal generalization to the multidomain case is straightforward, we do not consider it here in order to reduce the notational complexity in the analysis of the iterative method.

LEMMA 3.1. *The subproblems* (3.1) *and* (3.2) *are well-posed in* $V_{h,i}$ *with respect to the norm* $|||\cdot|||_i$.

Proof. The proof is an immediate consequence of Lemma 2.7 restricted to one subdomain. ∎

We define the splitting error as $e_h^k = u_h - u_h^k$, where u_h is the solution to the finite element formulation of (2.1) and u_h^k is the solution after k iterations of (3.1) and (3.2). We will now state and prove the main result of this section.

THEOREM 3.2. *The iterative method defined by problems* (3.1) *and* (3.2) *converges when the relaxation parameter* γ_{it} *is chosen big enough. More precisely, there exists a positive constant* c (*that is, the coercivity constant of Theorem* 2.7) *such that*

(3.3)
$$c\sum_{k=1}^{\infty}\left|\left|\left|e_h^k\right|\right|\right|^2 \le \sum_{i=1,2}\left(\frac{c}{2}\left\|\varepsilon_i^{\frac{1}{2}}\nabla e_{h,i}^0\right\|_{\Omega_i}^2 + \left\|(\delta^+)^{\frac{1}{2}}e_{h,i}^0\right\|_{\partial\Omega_i\setminus\partial\Omega}^2 + \left\|\left(\frac{\gamma_{it}}{\tilde{h}}\right)^{\frac{1}{2}}e_{h,i}^0\right\|_{\partial\Omega_i\setminus\partial\Omega}^2\right)$$

Proof. By subtracting the decoupled formulation given by (3.1) and (3.2) from the formulation (2.1) we have

$$A(e_{h,1}^{k+1}, v_{h,1}) + \tilde{B}(e_{h,1}^{k+1}, e_{h,2}^k, v_{h,1}) + J(e_{h,1}^{k+1}, v_{h,1}) + S(e_{h,1}^{k+1}, e_{h,1}^k, v_{h,1}) = 0 \tag{3.4}$$

and

$$A(e_{h,2}^{k+1}, v_{h,2}) + \tilde{B}(e_{h,2}^{k+1}, e_{h,1}^k, v_{h,2}) + J(e_h^{k+1}, v_{h,2}) + S(e_{h,2}^{k+1}, e_{h,2}^k, v_{h,2}) = 0. \tag{3.5}$$

We now choose $v_{h,i} = e_{h,i}^{k+1}$ to obtain

$$A(e_h^{k+1}, e_h^{k+1}) + \tilde{B}(e_{h,1}^{k+1}, e_{h,2}^k, e_{h,1}^{k+1}) + \tilde{B}(e_{h,2}^{k+1}, e_{h,1}^k, e_{h,2}^{k+1}) + J(e_h^{k+1}, e_h^{k+1}) + \sum_{i=1,2} S(e_{h,i}^{k+1}, e_{h,i}^k, e_{h,i}^{k+1}) = 0.$$

Proceeding now by adding and subtracting $B(e_h^{k+1}, e_h^{k+1})$ we may write

$$\begin{aligned} A(e_h^{k+1}, e_h^{k+1}) + B(e_h^{k+1}, e_h^{k+1}) + J(e_h^{k+1}, e_h^{k+1}) + \sum_{i=1,2} S(e_{h,i}^{k+1}, e_{h,i}^k, e_{h,i}^{k+1}) \\ = B(e_h^{k+1}, e_h^{k+1}) - \tilde{B}(e_{h,1}^{k+1}, e_{h,2}^k, e_{h,1}^{k+1}) - \tilde{B}(e_{h,2}^{k+1}, e_{h,1}^k, e_{h,2}^{k+1}). \end{aligned} \tag{3.6}$$

The first three terms on the left-hand side will be controlled by the coercivity Lemma 2.7, while the term that stabilizes the iterations can be rewritten as follows:

$$\begin{aligned} \sum_{i=1,2} S(e_{h,i}^{k+1}, e_{h,i}^k, e_{h,i}^{k+1}) &= \sum_{i=1,2}\sum_{E\in G_h}\left\langle\frac{\gamma_{it}}{\tilde{h}}(e_{h,i}^{k+1} - e_{h,i}^k), e_{h,i}^{k+1}\right\rangle_E \\ &= \frac{1}{2}\sum_{i=1,2}\left[\left\|\left(\frac{\gamma_{it}}{\tilde{h}}\right)^{\frac{1}{2}}e_{h,i}^{k+1}\right\|_{\partial\Omega_i\setminus\partial\Omega}^2 - \left\|\left(\frac{\gamma_{it}}{\tilde{h}}\right)^{\frac{1}{2}}e_{h,i}^k\right\|_{\partial\Omega_i\setminus\partial\Omega}^2 \right. \\ &\qquad \left. + \left\|\left(\frac{\gamma_{it}}{\tilde{h}}\right)^{\frac{1}{2}}(e_{h,i}^{k+1} - e_{h,i}^k)\right\|_{\partial\Omega_i\setminus\partial\Omega}^2\right]. \end{aligned} \tag{3.7}$$

It remains to bound the interface residual of the right-hand side:

$$R(e_{h,1}^k, e_{h,1}^{k+1}, e_{h,2}^k, e_{h,2}^{k+1}) = B(e_h^{k+1}, e_h^{k+1}) - \tilde{B}(e_{h,1}^{k+1}, e_{h,2}^k, e_{h,1}^{k+1}) - \tilde{B}(e_{h,2}^{k+1}, e_{h,1}^k, e_{h,2}^{k+1}).$$

The residual R is different from zero only on the interface of the subdomains and consists of three parts:

(A) the advective interface flux term from the advection term;
(B) the symmetric interface flux term from the Laplacian;
(C) the interface penalization term.

We now rearrange the terms for the three above-mentioned cases.

(A) The advective interface fluxes:

$$\sum_{\substack{i,j=1,2\\ i\neq j}} \Big[\langle \beta\cdot n_i^+ e_{h,i}^{k+1}, e_{h,i}^{k+1} - e_{h,j}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega} - \langle \beta\cdot n_i^+ e_{h,i}^{k+1}, e_{h,i}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega} - \langle \beta\cdot n_i^+ e_{h,i}^{k}, -e_{h,j}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega}\Big]$$
$$= \sum_{\substack{i,j=1,2\\ i\neq j}} \Big[\langle \beta\cdot n_i^+ (e_{h,i}^{k} - e_{h,i}^{k+1}), e_{h,j}^{k+1} - e_{h,i}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega} + \langle \beta\cdot n_i^+ (e_{h,i}^{k} - e_{h,i}^{k+1}), e_{h,i}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega}\Big].$$

We observe that

$$\langle \beta\cdot n_i^+ (e_{h,i}^{k} - e_{h,i}^{k+1}), e_{h,j}^{k+1} - e_{h,i}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega} \leq \frac{1}{4\mu_i}\|(\beta\cdot n_i^+)^{\frac12}(e_{h,i}^k - e_{h,i}^{k+1})\|^2_{\partial\Omega_i\setminus\partial\Omega} + \mu_i\|(\beta\cdot n_i^+)^{\frac12}[e_h^{k+1}]\|^2_{\partial\Omega_i\setminus\partial\Omega}$$

and

$$\langle \beta\cdot n_i^+ (e_{h,i}^{k} - e_{h,i}^{k+1}), e_{h,i}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega} = \frac12\|(\beta\cdot n_i^+)^{\frac12} e_{h,i}^k\|^2_{\partial\Omega_i\setminus\partial\Omega} - \frac12\|(\beta\cdot n_i^+)^{\frac12} e_{h,i}^{k+1}\|^2_{\partial\Omega_i\setminus\partial\Omega} - \frac12\|(\beta\cdot n_i^+)^{\frac12}(e_{h,i}^{k+1} - e_{h,i}^k)\|^2_{\partial\Omega_i\setminus\partial\Omega}.$$

By combining these results we obtain

(3.8)
$$\sum_{\substack{i,j=1,2\\ i\neq j}} \Big[\langle \beta\cdot n_i^+ (e_{h,i}^{k} - e_{h,i}^{k+1}), e_{h,j}^{k+1} - e_{h,i}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega} + \langle \beta\cdot n_i^+ (e_{h,i}^{k} - e_{h,i}^{k+1}), e_{h,i}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega}\Big]$$
$$\leq \sum_{i=1,2}\Big[\mu_i\||\beta\cdot n_i|^{\frac12}[e_h^{k+1}]\|^2_{\partial\Omega_i\setminus\partial\Omega} + \frac{1-2\mu_i}{4\mu_i}\||\beta\cdot n_i|^{\frac12}(e_{h,i}^k - e_{h,i}^{k+1})\|^2_{\partial\Omega_i\setminus\partial\Omega} + \frac12\|(\beta\cdot n_i^+)^{\frac12} e_{h,i}^k\|^2_{\partial\Omega_i\setminus\partial\Omega} - \frac12\|(\beta\cdot n_i^+)^{\frac12} e_{h,i}^{k+1}\|^2_{\partial\Omega_i\setminus\partial\Omega}\Big].$$

(B) The boundary part of the Laplacian operator may then be written as

$$-\frac12\sum_{\substack{i,j=1,2\\ i\neq j}}\Big[2\langle\{\varepsilon\nabla e_h^{k+1}\cdot n_i\}_w, e_{h,i}^{k+1} - e_{h,j}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega}$$
$$-\langle \omega\nabla e_{h,i}^{k+1}\cdot n_i + \omega\nabla e_{h,j}^k\cdot n_i, e_{h,i}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega} - \langle \omega\nabla e_{h,i}^{k+1}\cdot n_i, e_{h,i}^{k+1} - e_{h,j}^k\rangle_{\partial\Omega_i\setminus\partial\Omega}$$
$$-\langle \omega\nabla e_{h,i}^{k}\cdot n_i + \omega\nabla e_{h,j}^{k+1}\cdot n_i, -e_{h,j}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega} - \langle \omega\nabla e_{h,j}^{k+1}\cdot n_i, e_{h,i}^{k} - e_{h,j}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega}\Big],$$

which can be rewritten as follows:

$$
\begin{aligned}
-\frac{1}{2}\sum_{\substack{i,j=1,2\\ i\neq j}}\Big[&\langle\omega\nabla e_{h,j}^{k+1}\cdot n_i, e_{h,i}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega}-\langle\omega\nabla e_{h,j}^{k}\cdot n_i, e_{h,i}^{k}\rangle_{\partial\Omega_i\setminus\partial\Omega}\\
&-\langle\omega\nabla e_{h,i}^{k+1}\cdot n_i, e_{h,j}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega}+\langle\omega\nabla e_{h,i}^{k}\cdot n_i, e_{h,j}^{k}\rangle_{\partial\Omega_i\setminus\partial\Omega}\\
&+\langle\omega\nabla(e_{h,i}^{k}-e_{h,i}^{k+1})\cdot n_i, e_{h,j}^{k+1}-e_{h,j}^{k}\rangle_{\partial\Omega_i\setminus\partial\Omega}\\
&+\langle\omega\nabla(e_{h,j}^{k+1}-e_{h,j}^{k})\cdot n_i, e_{h,i}^{k+1}-e_{h,i}^{k}\rangle_{\partial\Omega_i\setminus\partial\Omega}\Big],
\end{aligned}
$$

where we recall that $w_1\varepsilon_1 = w_2\varepsilon_2 = \omega$. For this choice of the averaging weights the first four terms vanish, precisely:

$$
\begin{aligned}
\sum_{\substack{i,j=1,2\\ i\neq j}}\Big[&\langle\omega\nabla e_{h,j}^{k+1}\cdot n_i, e_{h,i}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega}-\langle\omega\nabla e_{h,j}^{k}\cdot n_i, e_{h,i}^{k}\rangle_{\partial\Omega_i\setminus\partial\Omega}\\
&-\langle\omega\nabla e_{h,i}^{k+1}\cdot n_i, e_{h,j}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega}+\langle\omega\nabla e_{h,i}^{k}\cdot n_i, e_{h,j}^{k}\rangle_{\partial\Omega_i\setminus\partial\Omega}\Big]=0.
\end{aligned}
$$

By means of the Cauchy–Schwarz and Young inequalities, we have for the fifth term

$$
\begin{aligned}
\langle\omega\nabla(e_{h,i}^{k}-e_{h,i}^{k+1})\cdot n_i, e_{h,j}^{k+1}-e_{h,j}^{k}\rangle_{\partial\Omega_i\setminus\partial\Omega}&=\sum_{E\in G_h}\langle\omega^{\frac12}\nabla(e_{h,i}^{k}-e_{h,i}^{k+1})\cdot n_i, \omega^{\frac12}(e_{h,j}^{k+1}-e_{h,j}^{k})\rangle_E\\
&\le\sum_{E\in G_h}2\left[h_E^{\frac12}\|\omega^{\frac12}\nabla(e_{h,i}^{k}-e_{h,i}^{k+1})\cdot n_i\|_E\cdot h_E^{-\frac12}\|\omega^{\frac12}(e_{h,j}^{k+1}-e_{h,j}^{k})\|_E\right]\\
&\le\sum_{E\in G_h}\left[\alpha_i h_E\|\omega^{\frac12}\nabla(e_{h,i}^{k}-e_{h,i}^{k+1})\cdot n_i\|_E^2+(\alpha_i h_E)^{-1}\|\omega^{\frac12}(e_{h,j}^{k+1}-e_{h,j}^{k})\|_E^2\right].
\end{aligned}
$$

Then, by virtue of trace and inverse inequalities (see Remark 2.8), there exists a positive constant C_t such that

$$
\begin{aligned}
\sum_{E\in G_h}h_E\|\omega^{\frac12}\nabla(e_{h,i}^{k}-e_{h,i}^{k+1})\cdot n_i\|_E^2&\le C_t\|w_i\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)}\|\varepsilon_i^{\frac12}\nabla(e_{h,i}^{k}-e_{h,i}^{k+1})\|_{\Omega_i}^2\\
&\le C_t\|w_i\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)}\left[\|\varepsilon_i^{\frac12}\nabla e_{h,i}^{k}\|_{\Omega_i}^2+\|\varepsilon_i^{\frac12}\nabla e_{h,i}^{k+1}\|_{\Omega_i}^2\right].
\end{aligned}
$$

We proceed analogously for the term $\langle\omega\nabla(e_{h,j}^{k+1}-e_{h,j}^{k})\cdot n_i, e_{h,i}^{k+1}-e_{h,i}^{k}\rangle_{\partial\Omega_i\setminus\partial\Omega}$.

Summing up all the contributions we obtain that

$$
\begin{aligned}
-\frac{1}{2}\sum_{\substack{i,j=1,2\\ i\neq j}}\Big[&2\langle\omega\nabla(e_{h,i}^{k}-e_{h,i}^{k+1})\cdot n_i, e_{h,j}^{k+1}-e_{h,j}^{k}\rangle_{\partial\Omega_i\setminus\partial\Omega}\\
&+\langle\omega\nabla e_{h,j}^{k+1}\cdot n_i, e_{h,i}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega}-\langle\omega\nabla e_{h,j}^{k}\cdot n_i, e_{h,i}^{k}\rangle_{\partial\Omega_i\setminus\partial\Omega}\\
&-\langle\omega\nabla e_{h,i}^{k+1}\cdot n_i, e_{h,j}^{k+1}\rangle_{\partial\Omega_i\setminus\partial\Omega}+\langle\omega\nabla e_{h,i}^{k}\cdot n_i, e_{h,j}^{k}\rangle_{\partial\Omega_i\setminus\partial\Omega}\Big]\\
\le\sum_{i=1,2}\Big[&\alpha_i C_t\|w_i\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)}\left(\|\varepsilon_i^{\frac12}\nabla e_{h,i}^{k+1}\|_{\Omega_i}^2+\|\varepsilon_i^{\frac12}\nabla e_{h,i}^{k}\|_{\Omega_i}^2\right)\\
&+\frac{\|w_i\varepsilon_i\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)}}{\alpha_i}\|(\tilde h)^{-\frac12}(e_{h,i}^{k+1}-e_{h,i}^{k})\|_{\partial\Omega_i\setminus\partial\Omega}\Big].
\end{aligned}
\tag{3.9}
$$

(C) For the interface penalization term we get

$$\sum_{\substack{i,j=1,2\\ i\neq j}} \left[\left\langle \left(\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}} \right) (e_{h,i}^{k+1} - e_{h,j}^{k+1}), e_{h,i}^{k+1} - e_{h,j}^{k+1} \right\rangle_{\partial\Omega_i\setminus\partial\Omega} \right.$$
$$\left. - \left\langle \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right) (e_{h,i}^{k+1} - e_{h,j}^{k}), e_{h,i}^{k+1} \right\rangle_{\partial\Omega_i\setminus\partial\Omega} - \left\langle \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right) (e_{h,j}^{k+1} - e_{h,i}^{k}), e_{h,j}^{k+1} \right\rangle_{\partial\Omega_i\setminus\partial\Omega} \right].$$

By means of algebraic manipulations we obtain

$$\left\langle \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right) (e_{h,i}^{k+1} - e_{h,j}^{k}), e_{h,i}^{k+1} \right\rangle_{\partial\Omega_i\setminus\partial\Omega} + \left\langle \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right) (e_{h,j}^{k+1} - e_{h,i}^{k}), e_{h,j}^{k+1} \right\rangle_{\partial\Omega_i\setminus\partial\Omega}$$
$$= \left\langle \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right) (e_{h,i}^{k+1} - e_{h,i}^{k}), e_{h,j}^{k+1} - e_{h,i}^{k+1} \right\rangle_{\partial\Omega_i\setminus\partial\Omega} + \left\langle \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right) (e_{h,i}^{k+1} - e_{h,i}^{k}), e_{h,i}^{k+1} \right\rangle_{\partial\Omega_i\setminus\partial\Omega}$$
$$+ \left\langle \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right) (e_{h,j}^{k+1} - e_{h,j}^{k}), e_{h,i}^{k+1} - e_{h,j}^{k+1} \right\rangle_{\partial\Omega_i\setminus\partial\Omega} + \left\langle \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right) (e_{h,j}^{k+1} - e_{h,j}^{k}), e_{h,j}^{k+1} \right\rangle_{\partial\Omega_i\setminus\partial\Omega}$$
$$+ \left\| \left(\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}} \right)^{\frac{1}{2}} [e_h^{k+1}] \right\|^2_{\partial\Omega_i\setminus\partial\Omega}.$$

By virtue of the particular choice of the weights that gives $2\omega = \{\varepsilon\}_w$ and by means of standard inequalities we observe that

$$\left\langle \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right) (e_{h,i}^{k+1} - e_{h,i}^{k}), e_{h,j}^{k+1} - e_{h,i}^{k+1} \right\rangle_{\partial\Omega_i\setminus\partial\Omega} + \left\langle \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right) (e_{h,j}^{k+1} - e_{h,j}^{k}), e_{h,j}^{k+1} - e_{h,j}^{k+1} \right\rangle_{\partial\Omega_i\setminus\partial\Omega}$$
$$\leq \frac{1}{4\mu_i} \left[\left\| \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right)^{\frac{1}{2}} (e_{h,i}^{k+1} - e_{h,i}^{k}) \right\|^2_{\partial\Omega_i\setminus\partial\Omega} + \left\| \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right)^{\frac{1}{2}} (e_{h,j}^{k+1} - e_{h,j}^{k}) \right\|^2_{\partial\Omega_i\setminus\partial\Omega} \right]$$
$$\mu_i \left[\left\| \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right)^{\frac{1}{2}} [e_h^{k+1}] \right\|^2_{\partial\Omega_i\setminus\partial\Omega} + \left\| \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right)^{\frac{1}{2}} [e_h^{k+1}] \right\|^2_{\partial\Omega_i\setminus\partial\Omega} \right]$$
$$= \frac{1}{4\mu_i} \left\| \left(\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}} \right)^{\frac{1}{2}} (e_{h,i}^{k+1} - e_{h,i}^{k}) \right\|^2_{\partial\Omega_i\setminus\partial\Omega} + \mu_i \left\| \left(\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}} \right)^{\frac{1}{2}} [e_h^{k+1}] \right\|^2_{\partial\Omega_i\setminus\partial\Omega}$$

and that

$$\sum_{j=1,2} \left\langle \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right) (e_{h,j}^{k+1} - e_{h,j}^{k}), e_{h,j}^{k+1} \right\rangle_{\partial\Omega_i\setminus\partial\Omega}$$
$$= \frac{1}{2} \sum_{j=1,2} \left[\left\| \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right)^{\frac{1}{2}} e_{h,j}^{k+1} \right\|^2_{\partial\Omega_i\setminus\partial\Omega} - \left\| \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right)^{\frac{1}{2}} e_{h,j}^{k} \right\|^2_{\partial\Omega_i\setminus\partial\Omega} \right.$$
$$\left. + \left\| \left(\frac{\gamma_{bc}\omega}{\tilde{h}} \right)^{\frac{1}{2}} (e_{h,j}^{k+1} - e_{h,i}^{k}) \right\|^2_{\partial\Omega_i\setminus\partial\Omega} \right]$$
$$= \frac{1}{2} \left[\left\| \left(\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}} \right)^{\frac{1}{2}} e_{h,i}^{k+1} \right\|^2_{\partial\Omega_i\setminus\partial\Omega} - \left\| \left(\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}} \right)^{\frac{1}{2}} e_{h,i}^{k} \right\|^2_{\partial\Omega_i\setminus\partial\Omega} \right.$$
$$\left. + \left\| \left(\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}} \right)^{\frac{1}{2}} (e_{h,i}^{k+1} - e_{h,i}^{k}) \right\|^2_{\partial\Omega_i\setminus\partial\Omega} \right].$$

Summing up all the terms of the residual (C) we have

$$
\begin{aligned}
(3.10)\quad & \sum_{i=1,2}\Bigg[\left\langle\left(\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}}\right)(e_{h,i}^{k+1}-e_{h,j}^{k+1}),e_{h,i}^{k+1}-e_{h,j}^{k+1}\right\rangle_{\partial\Omega_i\setminus\partial\Omega}\\
&-\left\langle\left(\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}}\right)(e_{h,i}^{k+1}-e_{h,j}^{k}),e_{h,i}^{k+1}\right\rangle_{\partial\Omega_i\setminus\partial\Omega}-\left\langle\left(\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}}\right)(e_{h,j}^{k+1}-e_{h,i}^{k}),e_{h,j}^{k+1}\right\rangle_{\partial\Omega_i\setminus\partial\Omega}\Bigg]\\
&\le\sum_{i=1,2}\Bigg[\frac{1-2\mu_i}{4\mu_i}\left\|\left(\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}}\right)^{\frac12}(e_{h,i}^{k+1}-e_{h,i}^{k})\right\|^2_{\partial\Omega_i\setminus\partial\Omega}+\mu_i\left\|\left(\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}}\right)^{\frac12}[e_h^{k+1}]\right\|^2_{\partial\Omega_i\setminus\partial\Omega}\\
&\qquad+\frac12\left\|\left(\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}}\right)^{\frac12}e_{h,i}^{k}\right\|^2_{\partial\Omega_i\setminus\partial\Omega}-\frac12\left\|\left(\frac{\gamma_{bc}\{\varepsilon\}_w}{\tilde{h}}\right)^{\frac12}e_{h,i}^{k+1}\right\|^2_{\partial\Omega_i\setminus\partial\Omega}\Bigg].
\end{aligned}
$$

By putting together (3.8), (3.9), (3.10) we obtain the following inequality:

$$
\begin{aligned}
(3.11)\quad & R(e_{h,1}^{k},e_{h,1}^{k+1},e_{h,2}^{k},e_{h,2}^{k+1})\\
&\le\sum_{i=1,2}\Bigg[\alpha_iC_t\|w_i\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)}\left(\|\varepsilon_i^{\frac12}\nabla e_{h,i}^{k+1}\|^2_{\Omega_i}+\|\varepsilon_i^{\frac12}\nabla e_{h,i}^{k}\|^2_{\Omega_i}\right)+\mu_i\|\delta^{\frac12}[e_h^{k+1}]\|^2_{\partial\Omega_i\setminus\partial\Omega}\\
&\quad+\frac{1-2\mu_i}{4\mu_i}\|\delta^{\frac12}(e_{h,i}^{k+1}-e_{h,i}^{k})\|^2_{\partial\Omega_i\setminus\partial\Omega}+\frac{\|w_i\varepsilon_i\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)}}{\alpha_i}\|\tilde{h}^{-\frac12}(e_{h,i}^{k+1}-e_{h,i}^{k})\|^2_{\partial\Omega_i\setminus\partial\Omega}\\
&\qquad+\frac12\|(\delta^+)^{\frac12}e_{h,i}^{k}\|^2_{\partial\Omega_i\setminus\partial\Omega}-\frac12\|(\delta^+)^{\frac12}e_{h,i}^{k+1}\|^2_{\partial\Omega_i\setminus\partial\Omega}\Bigg].
\end{aligned}
$$

It should be noted that the right-hand side of (3.11) consists of terms that are either telescoping or of one of the following forms:

- terms containing $\nabla e_{h,i}^{k+1}$;
- terms containing a part $[e_h^{k+1}]$;
- terms containing a part $e_{h,i}^{k+1}-e_{h,i}^{k}$.

The first and second contributions will be controlled by the triple norm, and the last type of contributions will be controlled by the relaxation terms of (3.7). More precisely, by replacing (3.11) and (3.7) in (3.6) we obtain

$$
\begin{aligned}
(3.12)\quad & \sum_{i=1,2}\Bigg[c\|\sigma_0^{\frac12}e_{h,i}^{k+1}\|^2_{\Omega_i}+cJ(e_{h,i}^{k+1},e_{h,i}^{k+1})\\
&+\left(\frac{\gamma_{it}}{2}-\frac{\|w_i\varepsilon_i\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)}}{\alpha_i}\right)\|\tilde{h}^{-\frac12}(e_{h,i}^{k+1}-e_{h,i}^{k})\|^2_{\partial\Omega_i\setminus\partial\Omega}\\
&\qquad-\frac{1-2\mu_i}{4\mu_i}\|\delta^{\frac12}(e_{h,i}^{k+1}-e_{h,i}^{k})\|^2_{\partial\Omega_i\setminus\partial\Omega}\\
&+(c-\alpha_iC_t\|w_i\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)})\|\varepsilon_i^{\frac12}\nabla e_{h,i}^{k+1}\|^2_{\Omega_i}-\alpha_iC_t\|w_i\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)}\|\varepsilon_i^{\frac12}\nabla e_{h,i}^{k}\|^2_{\Omega_i}\\
&+c\|\delta^{\frac12}[e_h^{k+1}]\|^2_{\partial\Omega_i\cap\partial\Omega}+(c-\mu_i)\|\delta^{\frac12}[e_h^{k+1}]\|^2_{\partial\Omega_i\setminus\partial\Omega}\\
&+\frac12\|(\delta^+)^{\frac12}e_{h,i}^{k+1}\|^2_{\partial\Omega_i\setminus\partial\Omega}-\frac12\|(\delta^+)^{\frac12}e_{h,i}^{k}\|^2_{\partial\Omega_i\setminus\partial\Omega}\\
&+\frac12\left\|\left(\frac{\gamma_{it}}{\tilde{h}}\right)^{\frac12}e_{h,i}^{k+1}\right\|^2_{\partial\Omega_i\setminus\partial\Omega}-\frac12\left\|\left(\frac{\gamma_{it}}{\tilde{h}}\right)^{\frac12}e_{h,i}^{k}\right\|^2_{\partial\Omega_i\setminus\partial\Omega}\Bigg]\le0.
\end{aligned}
$$

Then we choose the coefficients of Young's inequality, α_i and μ_i, as follows:

$$\alpha_i < \frac{c}{2C_t\|w_i\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)}},\ \text{e.g., } \alpha_i = \frac{c}{4C_t\|w_i\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)}};\quad \mu_i < c,\ \text{e.g., } \mu_i = \frac{c}{2};$$

and as a consequence of that, the relaxation parameter γ_{it} becomes

$$\gamma_{it} \geq \frac{8C_t\|w_i\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)}\|w_i\varepsilon_i\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)}}{c} + \frac{\max[1-c,0]}{2c}\left(\gamma_{bc}\|\{\varepsilon\}_w\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)} + \|\beta\cdot n\tilde{h}\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)}\right),\ i=1,2. \tag{3.13}$$

This allows us to rewrite (3.12) as follows:

$$\frac{c}{2}\left|\left|\left|e_h^{k+1}\right|\right|\right|^2 + \sum_{i=1,2}\left[\frac{c}{4}\left\|\varepsilon_i^{\frac{1}{2}}\nabla e_{h,i}^{k+1}\right\|_{\Omega_i}^2 - \frac{c}{4}\left\|\varepsilon_i^{\frac{1}{2}}\nabla e_{h,i}^{k}\right\|_{\Omega_i}^2 + \frac{1}{2}\left\|(\delta^+)^{\frac{1}{2}}e_{h,i}^{k+1}\right\|_{\partial\Omega_i\setminus\partial\Omega}^2 - \frac{1}{2}\left\|(\delta^+)^{\frac{1}{2}}e_{h,i}^{k}\right\|_{\partial\Omega_i\setminus\partial\Omega}^2 + \frac{1}{2}\left\|\left(\frac{\gamma_{it}}{\tilde{h}}\right)^{\frac{1}{2}}e_{h,i}^{k+1}\right\|_{\partial\Omega_i\setminus\partial\Omega}^2 - \frac{1}{2}\left\|\left(\frac{\gamma_{it}}{\tilde{h}}\right)^{\frac{1}{2}}e_{h,i}^{k}\right\|_{\partial\Omega_i\setminus\partial\Omega}^2\right] \leq 0.$$

Finally, summing up from $k=0$ to $k=M-1$, we obtain

$$c\sum_{k=0}^{M-1}\left|\left|\left|e_h^{k+1}\right|\right|\right|^2 + \sum_{i=1,2}\left(\left\|(\delta^+)^{\frac{1}{2}}e_{h,i}^{M}\right\|_{\partial\Omega_i\setminus\partial\Omega}^2 + \left\|\left(\frac{\gamma_{it}}{\tilde{h}}\right)^{\frac{1}{2}}e_{h,i}^{M}\right\|_{\partial\Omega_i\setminus\partial\Omega}^2\right) \leq \sum_{i=1,2}\left(\frac{c}{2}\left\|\varepsilon_i^{\frac{1}{2}}\nabla e_{h,i}^{0}\right\|_{\Omega_i}^2 + \left\|(\delta^+)^{\frac{1}{2}}e_{h,i}^{0}\right\|_{\partial\Omega_i\setminus\partial\Omega}^2 + \left\|\left(\frac{\gamma_{it}}{\tilde{h}}\right)^{\frac{1}{2}}e_{h,i}^{0}\right\|_{\partial\Omega_i\setminus\partial\Omega}^2\right),$$

which implies (3.3). ∎

Remark 3.3. The general statement (3.13) implies the following choices of γ_{it}.

When $\varepsilon_i > 0$ for $i=1,2$ we have $c=\frac{1}{2}$ and $\gamma_{bc} \geq 2C_t$ in order to ensure coercivity. Then we insert $\gamma_{bc} = 2C_t$ into (3.13) and obtain

$$\gamma_{it} \geq 2C_t\left(1+8\|w_i\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)}\right)\|w_i\varepsilon_i\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)} + \|\beta\cdot n\tilde{h}\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)},\ i=1,2.$$

For sufficiently small $\tilde{h}$ this expression can be summarized as $\gamma_{it} \simeq \gamma_{bc}\|\varepsilon\|_{L^\infty(\Omega)}$. When $\varepsilon_1 = 0$ and $\varepsilon_2 > 0$ (or vice versa) we have $w_1 > 0$ and $w_2 = 0$. As a result of that the formula above becomes

$$\gamma_{it} \geq \frac{1}{2}\|\beta\cdot n\tilde{h}\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)},\ \text{i.e., } \frac{\gamma_{it}}{h} \geq \frac{1}{2}\|\beta\cdot n\|_{L^\infty(\partial\Omega_i\setminus\partial\Omega)}.$$

When $\varepsilon_1 = \varepsilon_2 = 0$ the coercivity constant becomes $c=1$. As a result of that (3.13) requires $\gamma_{it} \geq 0$.

4. Numerical results.

All the numerical experiments presented in this section were obtained using the `FreeFem++` library (http://www.freefem.org/ff++/index.htm).

4.1. Approximation and convergence properties of the iterative splitting method.

In this section we analyze the convergence of the iterative splitting method with respect to the mesh size $h = \max_{i=1,2}\max_{K\in\mathcal{T}_{h,i}} h_K$, the number of

subdomains N, and the value of the penalty parameters γ_{it}, γ_{bc}, and $\gamma_{ip,i}$, $i = 1, 2$, for different values of the diffusion parameters ε_i and of the transport field β. To this aim, we consider problem (1.1), where $\sigma = 1$ is fixed and f is chosen so that the exact solution is

$$u(x, y) = \exp(xy)\sin(\pi x)\sin(\pi y), \tag{4.1}$$

on a domain $\Omega =]0, 1[\times]0, 1[$ that has been split into $N = n^2$ subdomains such that $\bar{\Omega} = \cup_{i=1}^{N} \bar{\Omega}_i = \cup_{i_1,i_2=1}^{n} [(i_1 - 1)/n, i_1/n] \times [(i_2 - 1)/n, i_2/n]$, obtaining a checkerboard partition of size $H = 1/n$. The simplest case of two subregions $\bar{\Omega}_1 = [0, \frac{1}{2}] \times [0, 1]$ and $\bar{\Omega}_2 = [\frac{1}{2}, 1] \times [0, 1]$ is also addressed. For each subdomain, we introduce N quasi-uniform meshes $\mathcal{T}_{h,i}$ that can be either conforming or nonconforming on their interfaces, but for the tests presented here we consider conforming discretizations. For the comparison of different cases we choose $u_{h,i}^0 = 0$ for $i = 1, \ldots, N$ and consider a convergence test on the triple norm of the incremental error, namely, the iterations are stopped if $|||u_h^{k+1} - u_h^k|||/|||u_h^{k+1}||| \leq tol$.

First of all, we aim to verify with numerical experiments the infinitesimal order with respect to h provided by Theorem 2.12. Table 4.1 shows that the optimal order of convergence is preserved for both linear and quadratic conforming elements. From now on, we will denote for simplicity $\|\cdot\|_{1,\Omega} \equiv (\sum_{i=1}^{N} \|\cdot\|_{1,\Omega_i})^{\frac{1}{2}}$.

Second, we aim to investigate the influence on the convergence rate of the iterative method of the parameters γ_{bc} and γ_{it} that appear in (3.1), (3.2). We study the number of iterations that the method needs to satisfy a tolerance $tol = 10^{-6}$ on the relative incremental error for several combinations of γ_{bc} and γ_{it}. Table 4.2 suggests

that an effective choice is to consider the small values of γ_{bc}, provided that the discrete problems (3.1), (3.2) remain well-posed according to Lemma 2.7. Recalling Remark 2.2, we analyze separately the symmetric and the nonsymmetric versions of the coupling term $B(u_h, v_h)$. In the symmetric case, Lemma 2.7 requires that $\gamma_{bc} = 2C_t$. In this case, Table 4.2 shows that the theoretical estimate obtained in Remark 3.3 is too restrictive for diffusion-dominated problems. Indeed, much smaller values of the estimated ones ensure better convergence properties. On the contrary, the numerical experiments presented in Table 4.5 suggest that the estimate of Remark 3.3 is effective for advection dominated problems. For the nonsymmetric case the limitations on γ_{bc} necessary for obtaining positivity of the discrete bilinear form change completely, in agreement with the analysis of interior penalty discontinuous Galerkin methods; see [1]. Indeed, only the restriction $\gamma_{bc} > 0$ is necessary. In this setting, the convergence properties of the iterative algorithm are much improved. Conversely, the approximation properties of the scheme are compromised since the discrete problem (2.1) is not adjoint consistent, and thus it does not enjoy optimal approximation properties in the L^2-norm (see [1] for a complete discussion). For the relaxation parameter γ_{it} we observe that in this case the choice $\gamma_{it} \simeq \gamma_{bc} \simeq 2\ 10^{-1}$ is effective.

The key point of this section is the characterization of the dependence of the convergence properties from the maximal mesh element size h and the number of subdomains N for different values of ε and β. More precisely, we analyze the diffusion dominated regimen ($\varepsilon = 1$), the transition regimen ($\varepsilon = 10^{-3}$), and the hyperbolic regimen ($\varepsilon = 0$). Indeed, Figure 4.1 and Table 4.3 show that the behavior of the method differs form one regimen to another. First of all, although Theorem 3.2 does

not characterize the convergence behavior of the iterative method (3.1)–(3.2), Figure 4.1 puts into evidence that the incremental error is reduced according to the law C^k, where k is the iteration index and the constant $0 < C < 1$ is the convergence rate. Following this assumption, the number of iterations needed to satisfy a suitable tolerance on the incremental error is directly proportional to the convergence rate. As a consequence of that, Table 4.3 shows that in the diffusion-dominated regimen the convergence rate is inversely proportional to h and H. Following the heuristic motivations that are presented in [22] and [27], the inverse dependence on H can be explained observing that an iterative method that only exchanges information between neighboring subregions necessarily requires a number of steps to converge that is at least equal to the diameter of the dual graph corresponding to the subdomain partition, which is equivalent to $\mathcal{O}(H^{-1})$ when the diameter of Ω is unitary. The dual graph is constructed by introducing a vertex for each subregion and an edge between two subregions that share an interface. The inverse dependence on h is a consequence of (3.13) (see also Remark 3.3) which states that the relaxation term must be proportional to $\|\varepsilon\|_{L^\infty(\Omega)}/h$. Accordingly, by refining the mesh by a factor two, the number of iterations is doubled. Always in agreement with Remark 3.3 and with the fact that the relaxation term is allowed to vanish together with ε, the convergence rate of the method is less sensitive with respect to h for the transition case and completely insensitive with respect to the mesh size in the hyperbolic case. Indeed, when $\varepsilon = 0$ the number of iterations is only inversely dependent on H, and it is exactly equivalent to the number of steps that are needed to propagate the information along the diagonal of the checkerboard mesh defined by the subdomains, since the transport field is oriented along the diagonal. Furthermore, Table 4.4 suggests that

these results do not deteriorate if the orientation of the transport field β is modified. Indeed, this is an advantage of the method proposed here with respect to the family of nonoverlapping domain decomposition methods arising from transmission conditions of Robin type, whose convergence may turn out to be slow when the transport field is tangential to the interface [21]. This benefit is due to the use of the upwind flux for the advection term. As a consequence of that, the corresponding transmission conditions are not symmetric with respect to β, in contrast to what happens for the family of methods inspired by transmission conditions of Robin type. Finally, we observe that in the hyperbolic case a multiplicative (Gauss–Seidel) iterative scheme is more preforming than the additive (Jacobi) method. For instance, since the subdomains in the checkerboard partition have been numbered by rows, when the transport field β is oriented in the vertical direction the multiplicative algorithm converges in 2 iterations, irrespectively of h and H.

4.2. Comparison of iterative methods. In order to assess the performance of the iterative method based on Nitsche's transmission conditions (denoted with a in Table 4.5 and defined by problems (3.1) and (3.2)) we compare it with the nonoverlapping Schwarz method proposed in [20] (denoted with b) and with the overlapping Schwarz method (denoted with c). For this comparison, we consider the test case proposed in the previous section where the domain Ω has been split into two subdomains, $\Omega_1 = [0, \frac{1}{2}] \times [0, 1]$ and $\Omega_2 = [\frac{1}{2}, 1] \times [0, 1]$. In the case of the overlapping Schwarz method we also introduce two overlapping domains, $\Omega_1^* = [0, \frac{1}{2} + \frac{1}{2}\delta] \times [0, 1]$, $\Omega_2^* = [\frac{1}{2} - \frac{1}{2}\delta, 1] \times [0, 1]$, and corresponding discretizations $\mathcal{T}_{h,i}^*$, $i = 1, 2$. Let $V_{h,i}^*$ be the finite element spaces defined on these meshes. Then, given $u_{h,i}^0$, for $k = 1, 2, \ldots$ we look for $u_{h,i}^k \in V_{h,i}^*$, $i = 1, 2$, such that

$$
\begin{aligned}
A(u_{h,1}^{k+1}, v_{h,1}) + J(u_{h,1}^{k+1}, v_{h,1}) &= (f_1, v_{h,1}) \ \forall v_{h,1} \in V_{h,1}^*, \quad \hat{u}_{h,1}^{k+1} = u_{h,2}^k \text{ on } \partial\Omega_1^* \cap \Omega_2^*, \\
A(u_{h,2}^{k+1}, v_{h,2}) + J(u_{h,2}^{k+1}, v_{h,2}) &= (f_2, v_{h,2}) \ \forall v_{h,2} \in V_{h,2}^*, \quad \hat{u}_{h,2}^{k+1} = u_{h,1}^k \text{ on } \partial\Omega_2^* \cap \Omega_1^*, \\
u_{h,i}^{k+1} &= \frac{1}{2}\hat{u}_{h,i}^{k+1} + \frac{1}{2}u_{h,i}^k \ i = 1, 2.
\end{aligned}
$$

Recalling that the convergence of the overlapping Schwarz method can be accelerated by increasing the thickness of the overlapping region, that is, δ, we consider three cases, $\delta = \bar{h}$, $\delta = 2\bar{h}$, and $\delta = 4\bar{h}$, where $\bar{h}$ is the characteristic size of the quasi-uniform discretizations of Ω_1^* and Ω_2^*. The comparison with these cases will give a measure of the convergence performance of our method.

In Table 4.5, we compare the convergence and the approximation properties of these methods for the diffusion-dominated, the transition, and the hyperbolic regimens. The analysis of this table immediately shows that the method that we propose here is effective for the advection dominated and the hyperbolic regimens. In this case Nitsche's method a provides in general the best performances both for the convergence and the approximation properties for a fixed tolerance on the incremental error $tol = 10^{-6}$ and a given quasi-uniform mesh with $h = 0.05$.

In the diffusion-dominated case, the convergence of method a in the symmetric case is partially slowed down by the relaxation term. We have already observed that the choice $\gamma_{it} = \gamma_{bc}\|\varepsilon\|_{L^\infty(\Omega)}$, motivated by the theoretical estimate derived in Remark 3.3, is not optimal. Indeed, the number of iterations needed to fulfill a tolerance of 10^{-6} on the incremental error is reduced from 354 to 190 if the parameter γ_{it} is divided by a factor of 100. In any case, this correction does not make method a with $s = 1$ (see Remark 2.2) competitive with method b in the diffusion-dominated

TABLE 4.5

The number of iterations necessary to converge with respect to a tolerance tol $= 10^{-6}$ and the approximation error on a given quasi-uniform mesh characterized by $h = 0.05$ and a partition in 2 subdomains. Several instances of the iterative algorithms a, b, and c are considered. The instance of algorithm a with symmetric coupling terms is denoted with $s = 1$, while the nonsymmetric version is denoted with $s = -1$.

case. Conversely, we observe that the convergence properties of the nonsymmetric version of method a is very satisfactory, while the approximation error in the L^2-norm reflects the suboptimality of this method. By comparing the properties of the symmetric and the nonsymmetric versions of method a, we observe that it may be possible to blend the benefits of the two methods by setting up a hybrid strategy (see Table 4.5, method a-hybrid). This consists in applying method a with $s = -1$, $\gamma_{bc} = \gamma_{it} = 2\ 10^{-1}$ until the tolerance equal to 10^{-6} is satisfied on the relative incremental error. As reported in Table 4.5, this procedure requires 43 iterations. Then, starting from the discrete solution computed in this way, we apply method a with $s = 1$, $\gamma_{bc} = 2$, $\gamma_{it} = 2\ 10^{-1}$ in order to improve the approximation error. This method requires 65 additional iterations to converge, and it reduces the L^2 approximation error of the nonsymmetric case from $1.93\ 10^{-3}$ to $1.37\ 10^{-3}$, which is equivalent to the error of the symmetric case. Since it is accurate and converges rapidly, the hybrid method outperforms both the symmetric and the nonsymmetric versions of method a. In the diffusive case, the hybrid method turns out to be almost

equivalent to method b. These considerations promote further studies of the hybrid method and suggest investigating in detail whether the nonsymmetric formulation might be applied as a preconditioner for the symmetric case. Finally, a heuristic comparison with the overlapping Schwarz methods c suggests that method b behaves as an additive overlapping Schwarz algorithm with a relatively generous overlap of magnitude $\delta = 2\bar{h} \equiv 6\%$ of the diameter of Ω. On the other hand, the symmetric Nitsche's method a is almost equivalent to the overlapping method with small overlap $\delta = \bar{h} \equiv 3\%$.

From the point of view of computational cost we observe that the scheme (3.1)–(3.2) requires more effort for the construction of the finite element matrix corresponding to the coupling terms $B(u_h, v_h)$ than the family of Robin–Robin methods. Indeed, for the Robin–Robin methods the coupling matrix is easily constructed since it corresponds to a mass matrix on the degrees of freedom at the interface. Moreover in our case the bandwidth of the coupling matrix is increased because of the presence of first order derivatives in the coupling terms. This drawback is balanced by the fact that basic Robin–Robin iterative splitting methods preserve the optimal approximation properties of Lagrangian finite elements only if a superpenalty technique is applied; see [8]. This technique, however, compromises the convergence properties of the iterative algorithm.

4.3. Approximation of problems with discontinuous coefficients. In this section, we apply the numerical scheme (3.1)–(3.2) for the approximation of advection diffusion problems with discontinuous coefficients. To this purpose, the domain Ω has been split into two subdomains, $\Omega_1 = [0, \frac{1}{2}] \times [0, 1]$ and $\Omega_2 = [\frac{1}{2}, 1] \times [0, 1]$ with $\varepsilon(x) = 1.0$ for $x \in \Omega_1$ and $\varepsilon(x) = 2\ 10^{-2}$ for $x \in \Omega_2$. In the case $\sigma = 0$ and $f = 0$, the exact solution on each subregion Ω_1, Ω_2 can be easily expressed as an exponential function with respect to the x coordinate independently from the y coordinate. The global solution $u(x, y)$ is provided by choosing the value at the interface $x = \frac{1}{2}$ in order to ensure the following matching conditions:

$$\lim_{x \to \frac{1}{2}^-} u(x, y) = \lim_{x \to \frac{1}{2}^+} u(x, y) \quad \text{and} \quad \lim_{x \to \frac{1}{2}^-} -\varepsilon(x)\partial_x u(x, y) = \lim_{x \to \frac{1}{2}^+} -\varepsilon(x)\partial_x u(x, y).$$

More precisely, we set $u(0, y) = 1$, $u(1, y) = 0$, and by consequence of the matching conditions, we obtain

$$u\left(\frac{1}{2}, y\right) = \left[\frac{u(0, y)\exp(\frac{\beta}{2\varepsilon_1})}{1 - \exp(\frac{\beta}{2\varepsilon_1})} + \frac{u(1, y)}{1 - \exp(\frac{\beta}{2\varepsilon_2})}\right]\left[\frac{\exp(\frac{\beta}{2\varepsilon_1})}{1 - \exp(\frac{\beta}{2\varepsilon_1})} + \frac{1}{1 - \exp(\frac{\beta}{2\varepsilon_2})}\right]^{-1}.$$

As a result of that, the exact solution in each subdomain can be expressed as

$$u_1(x, y) = \frac{u(\frac{1}{2}, y) - \exp(\frac{\beta}{2\varepsilon_1})u(0, y) + [u(0, y) - u(\frac{1}{2}, y)]\exp(\frac{\beta x}{\varepsilon_1})}{1 - \exp(\frac{\beta}{2\varepsilon_1})},$$

$$u_2(x, y) = \frac{u(1, y) - \exp(\frac{\beta}{2\varepsilon_2})u(\frac{1}{2}, y) + [u(\frac{1}{2}, y) - u(1, y)]\exp(\frac{\beta(x - \frac{1}{2})}{\varepsilon_2})}{1 - \exp(\frac{\beta}{2\varepsilon_2})}.$$

The resulting function is represented in Figure 4.2. We aim to compare on the test problem defined above the accuracy of the scheme (3.1)–(3.2) with linear elements, precisely $V_h = \sum_{i=1}^{2} V_{h,1,i}$ (denoted by A) with the classical lagrangian linear elements over the whole domain Ω (denoted by B). We point out that in both cases the

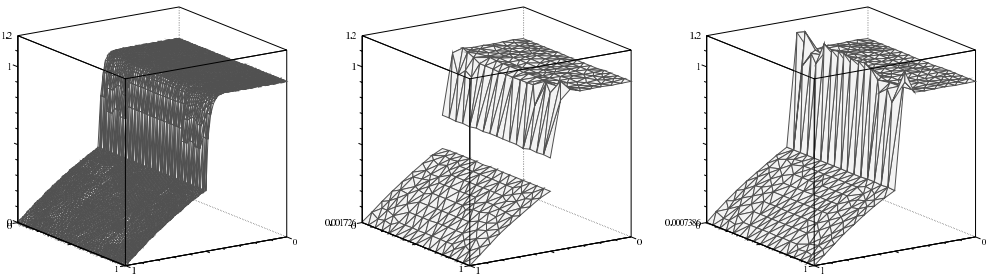

FIG. 4.2. *The nodal interpolant on a very refined mesh of the exact solution u of the test problem at hand (left). The numerical approximation u_h obtained with method A (middle) and method B (right) in the case of the discretization characterized by $h_1 = 0.1$.*

TABLE 4.6

The quantitative comparison of the accuracy of methods A and B. The L^2-norm, $\|u_h - u\|_{0,\Omega}$, the H^1-norm, $\|u_h - u\|_{1,\Omega}$, and the maximum norm, $\|u_h - u\|_{L^\infty(\Omega)}$, are displayed.

	$\|u - u_h\|_{0,\Omega}$		$\|u - u_h\|_{1,\Omega}$		$\|u - u_h\|_{L^\infty(\Omega)}$	
h	Method A	Method B	Method A	Method B	Method A	Method B
0.1	$1.81\ 10^{-2}$	$2.78\ 10^{-2}$	2.07	1.78	$2.13\ 10^{-1}$	$1.71\ 10^{-1}$
0.05	$6.98\ 10^{-3}$	$8.95\ 10^{-3}$	1.31	1.06	$1.07\ 10^{-1}$	$6.32\ 10^{-2}$
0.026	$2.56\ 10^{-3}$	$2.66\ 10^{-3}$	$7.49\ 10^{-1}$	$5.82\ 10^{-1}$	$1.40\ 10^{-1}$	$2.34\ 10^{-2}$

continuous interior penalty stabilization method with $\gamma_{ip,i} = 2\ 10^{-2}$ has been applied to cure the instability of finite elements in the case of advection-dominated problems. We compare the two schemes on a family of quasi-uniform triangulations on Ω_1 and Ω_2 that are conforming at the interface of the subdomains and are characterized by a decreasing maximal element size $h_1 = 0.1$, $h_2 = 0.05$, and $h_3 = 0.026$. The quantitative analysis of the accuracy is based on the following indicators: the L^2-norm of the error, $\|u_h - u\|_{0,\Omega}$; the H^1-norm, $\|u_h - u\|_{1,\Omega}$, which is well defined since $u \in H^1(\Omega)$; and the maximum norm, $\|u_h - u\|_{L^\infty(\Omega)}$. The quantitative data are reported in Table 4.6, while a visual comparison is given in Figure 4.2. The analysis of the results suggests that the scheme (3.1)–(3.2) performs well for the approximation of problems with discontinuous coefficients when the mesh size is not small enough to fully resolve the boundary layers arising in the neighborhood of the region of discontinuity. The benefit of the scheme presented here with respect to the application of classical Lagrangian elements over Ω emerges if we consider the L^2-norm. For the mesh size h_1 method A provides numerical solutions that are smoother than method B (see Figure 4.2), where spurious oscillations appear in the neighborhood of the boundary layer that arise because of the discontinuity of ε. However, we observe that the L^∞ error of method B is smaller than in the case of method A, since for this method L^∞ errors arise when the very steep boundary layer across the discontinuity of ε is approximated with a jump. Finally, the analysis of the H^1-norm of the errors suggests that method B seems to be more prone to approximate the gradients of the solution in the boundary layer, although this benefit is effective when the computational mesh becomes fine enough to reasonably approximate the boundary layer.

5. Concluding remarks. In conclusion, the discretization scheme and the associated iterative method that we have proposed here turn out to be appealing for advection-dominated problems and in the case of discontinuous coefficients. Indeed,

in these cases the method is competitive from the point of view of both computational effort and accuracy. A key role for the good properties when treating such problems is played by the average weights and the upwind treatment of the advection term in the interior penalty strategy applied for the coupling of the subdomains.

Acknowledgment. The authors are grateful for the referee's detailed and constructive criticisms and for the timely management of the manuscript.

SUBGRID STABILIZED DEFECT CORRECTION METHODS FOR THE NAVIER–STOKES EQUATIONS*

SONGUL KAYA†, WILLIAM LAYTON‡, AND BÉATRICE RIVIÈRE‡

Abstract. We consider the synthesis of a recent subgrid stabilization method with defect correction methods. The combination is particularly efficient and combines the best algorithmic features of each. We prove convergence of the method for a fixed number of corrections as the mesh size goes to zero and derive parameter scalings from the analysis. We also present some numerical tests which both verify the theoretical predictions and illustrate the method's promise.

Key words. eddy viscosity, variational multiscale method, high Reynolds numbers, correction steps

DOI. 10.1137/050623942

1. Introduction.

This report studies the synthesis of defect correction methods and subgrid stabilization. Our proposed method adds an eddy viscosity stabilization on only the last few resolved scales on arbitrary, unstructured meshes. Computational considerations for total algorithmic efficiency suggest combining the stabilization method with defect correction when solving *underresolved, equilibrium flow problems*. In this work, we study precisely this combination in that context. We analyze convergence of the combination for the (nonlinear) Navier–Stokes equations. This analysis gives mathematical guidance on the selection of the method's algorithmic parameters. In our accompanying tests, we observe that the subgrid stabilized defect correction method has greater accuracy than the artificial viscosity method without the oscillations reported in the usual (centered) Galerkin finite element method or the unmodified defect correction finite element method.

Let $\Omega \subset \mathbb{R}^d$ ($d = 2$ *or* 3) denote a bounded, regular flow domain. We consider the approximate solution of the Navier–Stokes equations for internal flow on Ω: find $u : \Omega \to \mathbb{R}^d$, $p : \Omega \to \mathbb{R}$ satisfying

$$\begin{aligned} -\nu\Delta u + (u\cdot\nabla)u + \nabla p &= f \quad \text{in } \Omega, \\ \nabla\cdot u &= 0 \quad \text{in } \Omega, \\ u &= 0 \quad \text{on } \partial\Omega, \\ \textstyle\int_\Omega p\, dx &= 0. \end{aligned} \tag{1.1}$$

In (1.1), the coefficient ν is the kinematic viscosity of the fluid, and $f \in L^2(\Omega)^d$ is the body force driving the flow.

Let $(\cdot,\cdot)$, $\|\cdot\|$ denote the usual L^2 inner product and norm, respectively. Define $X := H_0^1(\Omega) := \{v \in L^2(\Omega)^d : \nabla v \in L^2(\Omega)^{d\times d}$ and $v = 0$ on $\partial\Omega\}$, $Q := L_0^2(\Omega) = \{q \in L^2(\Omega) : \int_\Omega q\, dx = 0\}$, and define $b^*(u,v,w) := \frac{1}{2}(u\cdot\nabla v, w) - \frac{1}{2}(u\cdot\nabla w, v)$ for all

$u, v, w \in X$. Integrating by parts gives the following standard variational formulation of (1.1): find $u \in X$, $p \in Q$ satisfying

$$\begin{aligned} \nu(\nabla u, \nabla v) + b^*(u,u,v) - (p, \nabla \cdot v) &= (f,v) \quad \forall v \in X, \\ (\nabla \cdot u, q) &= 0 \qquad \forall q \in Q. \end{aligned} \tag{1.2}$$

For the finite element discretization, we choose the conforming velocity-pressure finite element spaces, $X_h \subset X$ and $Q_h \subset Q$, satisfying the discrete inf-sup condition

$$\inf_{q_h \in Q_h} \sup_{v_h \in X_h} \frac{(q_h, \nabla \cdot v_h)}{\|q_h\| \|\nabla v_h\|} \geq \beta > 0, \tag{1.3}$$

where β is independent of h.

The stabilization we consider requires a coarser finite element velocity space, $X_H \subset X$, corresponding to the large scales of the fluid velocity. Since finite element spaces are constructed based upon triangulations of the domain Ω, typically (although not necessarily for our analysis) $X_H \subset X_h \subset X$. We then define the following space:

$$L_H = \nabla X_H \subset L = L^2(\Omega)^{d \times d}. \tag{1.4}$$

The stabilized finite element method we consider herein is: find $u_h \in X_h$, $p_h \in Q_h$, and $g_H \in L_H$ satisfying

$$\begin{aligned} (\nu + \alpha)(\nabla u_h, \nabla v_h) + b^*(u_h, u_h, v_h) & \\ -\alpha(g_H, \nabla v_h) - (p_h, \nabla \cdot v_h) &= (f, v_h) \quad \forall v_h \in X_h, \\ (\nabla \cdot u_h, q_h) &= 0 \qquad \forall q_h \in Q_h, \\ (g_H - \nabla u_h, l_H) &= 0 \qquad \forall l_H \in L_H, \end{aligned} \tag{1.5}$$

where α is the user-selected stabilization parameter and typically, $\alpha = \mathcal{O}(h)$. It is easy to verify that the last equality in (1.5) implies that g_H is the L^2 projection of ∇u^h, denoted by $\overline{\nabla u_h}$.

In a typical implementation of (1.5), the variables g_H, l_H in L_H are defined on macroelements, i.e., elements of the coarse mesh. Thus, solving (1.5) involves coupling of microvariables (functions in X_h, Q_h) across macroelements. Thus, although these terms are cheap to evaluate in a residual calculation, the bandwidth of the linearized system arising from (1.5) increases substantially, and the solution of the linear system containing these terms is not attractive. This issue is discussed briefly in Layton [31] and at some length in John, Kaya, and Layton [27] and Anitescu, Layton, and Pahlevani [2] for the evolutionary problem.

For this reason, we consider a further defect correction discretization of (1.2) herein. This combination greatly increases efficiency by shifting the macro-micro coupling to a residual calculation. The method consists of an initialization step followed by k-correction steps, where k is the local polynomial degree of X_h.

Initialization step. Solve for $(u_h^1, p_h^1) \in (X_h, Q_h)$ such that

$$\begin{aligned} (\nu + \alpha)(\nabla u_h^1, \nabla v_h) + b^*(u_h^1, u_h^1, v_h) - (p_h^1, \nabla \cdot v_h) &= (f, v_h) \quad \forall v_h \in X_h, \\ (\nabla \cdot u_h^1, q_h) &= 0 \qquad \forall q_h \in Q_h. \end{aligned} \tag{1.6}$$

k-correction steps. Given $(u_h^j, p_h^j) \in (X_h, Q_h)$ for $j = 1, 2 \ldots, k$, solve for $(u_h^{j+1},$

$p_h^{j+1}) \in (X_h, Q_h)$ satisfying

$$
\begin{aligned}
&(\nu+\alpha)(\nabla(u_h^{j+1}-u_h^j),\nabla v_h)+b^*(u_h^{j+1},u_h^{j+1},v_h)-b^*(u_h^j,u_h^j,v_h)-(p_h^{j+1}-p_h^j,\nabla\cdot v_h)\\
&=(f,v_h)-[(\nu+\alpha)(\nabla u_h^j,\nabla v_h)+b^*(u_h^j,u_h^j,v_h)-(p_h^j,\nabla\cdot v_h)-\alpha(g_H^j,\nabla v_h)]\quad\forall v_h\in X_h,\\
&\qquad\qquad(\nabla\cdot u_h^{j+1},q_h)=0\quad\forall q_h\in Q_h,\\
&\qquad\qquad(g_H^j-\nabla u_h^j,l_H)=0\quad\forall l_H\in L_H.
\end{aligned}
\tag{1.7}
$$

Remark 1.1. It is typical that while defect correction methods are algorithmically simple to implement, they are cumbersome to write (as above) and can resist analysis. There are also several equivalent formulations of (1.7) and several algorithmic options within the defect correction idea. We stress that this is not an iteration: only k steps are performed, where k is the local polynomial degree of X_h. Thus, an asymptotic analysis as $j\to\infty$ is irrelevant; we analyze herein the method as $h\to 0$ for fixed j. The algorithmic efficiency of the defect correction method (1.6), (1.7) can be seen by rewriting (1.7) as follows: find $(u_h^{j+1},p_h^{j+1})\in(X_h,Q_h)$ satisfying

$$
\begin{aligned}
&(\nu+\alpha)(\nabla u_h^{j+1},\nabla v_h)+b^*(u_h^{j+1},u_h^{j+1},v_h)\\
&\qquad-(p_h^{j+1},\nabla\cdot v_h)=(f,v_h)+\alpha(g_H^j,\nabla v_h)\quad\forall v_h\in X_h,\\
&\qquad(\nabla\cdot u_h^{j+1},q_h)=0\quad\forall q_h\in Q_h,\\
&\qquad(g_H^j-\nabla u_h^j,l_H)=0\quad\forall l_H\in L_H.
\end{aligned}
\tag{1.8}
$$

Since u_h^j is known in (1.8), g_H^j is explicitly calculable by computing the L^2 projection operator of ∇u_h^j into L_H. Because the natural choice for L_H is $L_H=\nabla X_H$, L_H is typically a space of discontinuous piecewise polynomials of degree $k-1$ on a coarse mesh. Therefore, this projection calculation uncouples into one well-conditioned small linear system per coarse mesh element. Given g_H^j, the solution u_h^{j+1} then only involves solving an artificial viscosity discretization of the Navier–Stokes equations. If $\alpha=\mathcal{O}(h)$, this is known to lead to linearized systems which can be solved efficiently.

An alternative formulation of a defect correction method is to begin with nonlinear, stabilized artificial viscosity approximation (1.6) for (u_h^1,p_h^1) and then correct by solving the linearized problem instead of the nonlinear one. This has the advantage that only one linear solution is needed per correction step. This variation reads: given (u_h^j,p_h^j), find (u_h^{j+1},p_h^{j+1}) satisfying

$$
\begin{aligned}
&(\nu+\alpha)(\nabla(u_h^{j+1}-u_h^j),\nabla v_h)+b^*(u_h^j,u_h^{j+1}-u_h^j,v_h)+b^*(u_h^{j+1}-u_h^j,u_h^j,v_h)\\
&\qquad-(p_h^{j+1}-p_h^j,\nabla\cdot v_h)=(f,v_h)-[(\nu+\alpha)(\nabla u_h^j,\nabla v_h)+b^*(u_h^j,u_h^j,v_h)\\
&\qquad\qquad-(p_h^j,\nabla\cdot v_h)-\alpha(g_H^j,\nabla v_h)]\quad\forall v_h\in X_h,\\
&\qquad\qquad(\nabla\cdot u_h^{j+1},q_h)=0\quad\forall q_h\in Q_h,\\
&\qquad\qquad(g_H^j-\nabla u_h^j,l_H)=0\quad\forall l_H\in L_H.
\end{aligned}
\tag{1.9}
$$

The correction (1.9) is in the familiar residual-update form. It can be simplified to read: find (u_h^{j+1},p_h^{j+1}) satisfying

$$
\begin{aligned}
&(\nu+\alpha)(\nabla u_h^{j+1},\nabla v_h)+b^*(u_h^j,u_h^{j+1},v_h)+b^*(u_h^{j+1},u_h^j,v_h)\\
&-(p_h^{j+1},\nabla\cdot v_h)=(f,v_h)+b^*(u_h^j,u_h^j,v_h)+\alpha(g_H^j,\nabla v_h)\quad\forall v_h\in X_h,\\
&\qquad\qquad(\nabla\cdot u_h^{j+1},q_h)=0\quad\forall q_h\in Q_h,\\
&\qquad\qquad(g_H^j-\nabla u_h^j,l_H)=0\quad\forall l_H\in L_H.
\end{aligned}
\tag{1.10}
$$

1.1. Literature review for the defect correction method. The idea of defect correction is simple and universal. In its initial form, it was considered an algorithmically efficient way to perform Richardson's extrapolation, e.g., Stetter [38]. Since most practical problems do not have enough regularity, the practical importance was not recognized until the work of Hemker [21, 20] and Hemker and Koren [23, 22]. One current view of the defect correction method is that it allows for a solution that is nearly nonsingular for ill-conditioned problems through stabilization and correction; for a sample of recent works, see, e.g., Altase and Burrage [1], Axelsson and Nikolova [4], Juncu [28], Graziadei, Mattheij, and Boonkkamp [16], Heinrichs [19, 18], Desideri and Hemker [6], Nefedov and Mattheij [34], Shaw and Crumpton [37]. For example, when applied to viscoelastic fluid flow (Lee [32]), the defect correction method proved to be the key algorithmic idea for computing with a Weissenberg number beyond which other algorithms failed.

Much analytical insight into defect correction methods was obtained early for periodic constant coefficient problems by local model analysis. The first complete convergence theory for defect correction methods for convection dominated problems in one dimension was performed in Ervin and Layton [8] in which uniform epsilon convergence was proven away from layers. This result was extended to higher dimensions, higher order methods, and unstructured meshes in Axelsson and Layton [3]. Recently, global uniform in epsilon convergence on Shishkin meshes has been proven in one dimension (Frohner, Linss, and Roos [11], Frohner and Roos [12], Hemker, Shishkin, and Shishkina [24]).

It was noticed early by Hemker [21] that the defect correction method overcorrects near layers and should be modified. Various proposals have been advanced, e.g., Hemker [21, 20], Hemker and Koren [22, 23], Ervin and Layton [7]. The one considered herein is to correct the large scales only and leave a small amount of stabilization in the small scales. This is a discretization idea of Layton [31] which is related to ideas of Maday and Tadmor [33], Guermond [17], and Hughes, Mazzei, and Jansen [25]. For current work on this discretization for flow problems, see, e.g., Kaya and Rivière [29], John and Kaya [26], and John, Kaya, and Layton [27].

Because of the attractive form of the defect correction method, it is particularly efficient when used in conjunction with adaptivity. The first theoretical study and computational testing of defect correction plus adaptivity was in Ervin, Layton, and Maubach [9, 10] and Cawood et al. [5]. Interesting recent work in this direction has been done by Nikolova [35] and Axelsson and Nikolova [4]. In particular, [10] considers the problems of stationary turbulence with the Smagorinsky model. It was noted there that the estimators decompose into residuals associated with the base discretization's numerical error, the defect correction method's update error, and the turbulence model's modelling error—an interesting feature of both the defect correction method and adaptive solution of various turbulence models.

2. Mathematical preliminaries. The error analysis we shall perform for the method (1.6), (1.7) will be for nonsingular solutions of the Navier–Stokes equations (1.1), (1.2). We thus collect a few useful facts about nonsingular solutions.

DEFINITION 2.1. *Let V and V_h denote, respectively, the divergence free subspaces of X and X_h:*

$$V := \{v \in X : (q, \nabla \cdot v) = 0 \quad \forall q \in Q\},$$
$$V_h := \{v_h \in X_h : (q_h, \nabla \cdot v_h) = 0 \quad \forall q \in Q_h\}.$$

Although typically $V_h \subsetneq V$, it is known that under the discrete inf-sup condition (1.3), functions in V are well approximated by ones in V_h (Girault and Raviart [14]).

LEMMA 2.2. *Let the discrete inf-sup condition* (1.3) *hold. Then for any* $v \in V$

$$\inf_{v_h \in V_h} \|\nabla(v - v_h)\| \le C \left(1 + \frac{1}{\beta}\right) \inf_{v_h \in X_h} \|\nabla(v - v_h)\|. \tag{2.1}$$

Proof. We refer to [14, p. 60, (1.12)] for the proof of this lemma. ∎

We shall define by M as a finite constant with

$$M = \sup_{u,v,w \in X} \frac{|b^*(u,v,w)|}{\|\nabla u\| \|\nabla v\| \|\nabla w\|}.$$

DEFINITION 2.3. *u is a nonsingular solution of* (1.1) *if there is a $\mu(u,\nu) > 0$ such that*

$$\inf_{v \in V} \sup_{w \in V} \frac{\nu(\nabla v, \nabla w) + b^*(u,v,w) + b^*(v,u,w)}{\|\nabla v\| \|\nabla w\|} \ge \mu(u,\nu) > 0. \tag{2.2}$$

DEFINITION 2.4. *u is an isolated solution of* (1.1) *if there is a $\delta > 0$ such that there exists no other solution u' of* (1.1) *with $\|\nabla(u - u')\| < \delta$.*

The following basic facts are known concerning the equilibrium Navier–Stokes equations (1.1).

PROPOSITION 2.5. (a) *Given $f \in H^{-1}(\Omega)^d$, there exists at least one $(u,p) \in (X,Q)$ satisfying* (1.1).

(b) *For $\|f\|$ small enough, that solution is unique and nonsingular.*

(c) *There is an open dense subset $\mathcal{D} \subset H^{-1}(\Omega)^d$ such that for all $f \in \mathcal{D}$, all solutions of* (1.1) *are nonsingular and the number of solutions for each $f \in \mathcal{D}$ is finite and odd.*

(d) *A nonsingular solution is isolated.*

(e) *Let u be a nonsingular solution of* (1.1) *with data f, and $\tilde{u}$ another solution with data $\tilde{f}$. If $\|\nabla(u - \tilde{u})\| \le \mu(u,\nu)/(2M)$, then*

$$\|\nabla(u - \tilde{u})\| \le \frac{2}{\mu(u,\nu)} \|f - \tilde{f}\|_{-1}.$$

Proof. (a), (b), (c) are well known in the Navier–Stokes equations literature; see, e.g., [14, Theorems 2.4, p. 115, and 2.5, p. 118] for (a), [14, Theorem 1.3, p. 108] for (b), and Temam [39] for (c). Nonsingularity of the (unique) solution under the small data condition is proven in Remark 2.3, p. 119 of [14]. Part (d) is a standard result about nonsingular solutions of nonlinear problems; see, e.g., the remark on page 116 of [14]. Part (e) was proven in [30] and follows from nonsingularity and the mean value theorem. Indeed, subtraction and the usual type arguments imply that

$$\mu(u,\nu)\|\nabla(u - \tilde{u})\| \le \|f - \tilde{f}\|_{-1} + 2M\|\nabla(u - \tilde{u})\|^2,$$

from which (e) follows. ∎

Since the set of invertible operators is open and $b^*(\cdot,\cdot,\cdot)$ is continuous in X, it is known that the point of linearization in various terms of (2.2) can be shifted slightly without changing the essential conclusions.

LEMMA 2.6. *Let u be a nonsingular solution of* (1.1). *Then there is a $\delta > 0$ such that for any $\alpha < \delta$, u' and $u'' \in V$ with $\|\nabla(u - u')\| < \delta$, $\|\nabla(u - u'')\| < \delta$ satisfying*

$$\inf_{v \in V} \sup_{w \in V} \frac{(\nu + \alpha)(\nabla v, \nabla w) + b^*(u',v,w) + b^*(v,u'',w)}{\|\nabla v\| \|\nabla w\|} \ge \frac{1}{2}\mu(u,\nu).$$

Proof. This is a standard result for $\mathcal{C}^1$ operators in nonlinear analysis (Schwartz [36]). It is used in error analysis in [14, Lemma 3.3, p. 130]. ∎

It will be important to note that if (1.3) holds, the infimum and supremum in Lemma 2.6 can also be taken over V_h.

LEMMA 2.7. *Let u be a nonsingular solution of* (1.1). *Then there is a $\delta > 0$ such that for any $\alpha < \delta$, u' and $u'' \in V$ or V_h with $\|\nabla(u - u')\| < \delta$, $\|\nabla(u - u'')\| < \delta$ satisfying*

$$\inf_{v_h \in V_h} \sup_{w_h \in V_h} \frac{(\nu + \alpha)(\nabla v_h, \nabla w_h) + b^*(u', v_h, w_h) + b^*(v_h, u'', w_h)}{\|\nabla v_h\| \|\nabla w_h\|} \geq \frac{1}{2}\mu(u, \nu).$$

Proof. For the proof, see Girault and Raviart [14, Lemma 3.3, p. 130] and especially [14, Remark 3.1, p. 130] that follows. The analysis in Remark 3.1 is a continuity argument and applies with $u'' \neq u'$ (both close enough to u). ∎

3. Error analysis. The basic principle of the defect correction method in this context is that each step attempts to increase the rate of convergence by one power of h up to the order of the basic method. To begin, note that (u_h^1, p_h^1) is just the usual artificial viscosity approximation to (u, p). Since the error analysis for this step is standard (and a special case of the general step in which $(u_h^0, p_h^0) = (0, 0)$), we present the result only. The error analysis uses basic tools from [14, 15] and requires a few basic assumptions on (X_h, Q_h) that assume that (1.3) holds and that (X_h, Q_h) become dense in (X, Q) as $h \to 0$. Specifically, we assume the following proposition.

PROPOSITION 3.1. *Let* (1.3) *hold. For any $\alpha \geq 0$ and $f \in H^{-1}(\Omega)^d$, the algorithm* (1.6), (1.7) *is well defined: there exist approximate solutions (u_h^j, p_h^j) for $j = 1, 2, \ldots$.*

Proof. Existence of (u_h^1, p_h^1) follows from the fact that $(X_h,\ Q_h)$ is finite dimensional, the fixed point theory, and the following a priori bounds:

$$(\alpha + \nu)\|\nabla u_h^1\| \leq \|f\|_{-1}, \tag{3.1}$$

$$\|p_h^1\| \leq \beta^{-1}(2 + M(\alpha + \nu)^{-2})\|f\|_{-1}. \tag{3.2}$$

The first result (3.1) is obtained by setting $v_h = u_h^1$ in (1.1). The second (3.2) follows from (1.3), exactly as for the usual Galerkin approximation.

Given $(u_h^j, p_h^j) \in (X_h, Q_h)$, the same argument can be used only in the formulation (1.8) to prove existence of (u_h^{j+1}, p_h^{j+1}), provided only that $\|g_H^j\|$ is bounded. To see this, note that in the second equation of (1.8), g_H^j is the L^2 projection into L_H of ∇u_h^j. Thus, $\|g_H^j\| \leq \|\nabla u_h^j\| < \infty$, which is the required bound. ∎

A similar result is true for the defect correction using the linearization (1.6), (1.9), provided that h is small enough.

PROPOSITION 3.2. *Let* (1.3) *hold. Consider the algorithm* (1.6), (1.9) *(or equivalently,* (1.6), (1.10)*). Assume that u is a nonsingular solution of* (1.1). *Fix a function $f \in H^{-1}(\Omega)$. Let $\alpha \geq 0$ tend to zero as h tends to zero. Then, there is $h_0 > 0$ such that for $h \leq h_0$, (u_h^2, p_h^2) exists and is unique. More generally, if u_h^j is close enough to u in X, then (u_h^{j+1}, p_h^{j+1}) exists and is unique.*

Proof. This is a linearization argument. First we note that since (u_h^1, p_h^1) is the artificial viscosity approximation to a nonsingular solution, standard error analysis of branches of nonsingular solutions, e.g., [14, 15], shows that $\lim u_h^1 = u$ as h tends to 0 (see Proposition 3.3 for more detail). Now consider the correction step (1.10). It can be rewritten as: find $u_h^2 \in V_h$ satisfying

$$(\nu + \alpha)(\nabla u_h^2, \nabla v_h) + b^*(u_h^1, u_h^2, v_h) + b^*(u_h^2, u_h^1, v_h) = (G, v_h) \quad \forall v_h \in V_h,$$

where $G = G(u_h^1, p_h^1, g_H^1, \dots)$ is known in terms of problem data and the solution of the first step (u_h^1, p_h^1). Since $u_h^1 \to u$ and u is a nonsingular solution, Lemma 2.7 implies that this linear problem has a unique solution. Thus, u_h^2 exists.

The remainder of the proof is an induction argument which follows similarly: once u_h^2 exists uniquely and the linearization (1.10) at u_h^1 is invertible, it will follow that u_h^2 converges to u as h tends to 0 (with appropriate error estimates). This implies that u_h^3 exists uniquely and the argument is repeated. ∎

Remark 3.1. This argument fails if (1.10) is an *iteration* since the constants involved depend on j, but it is correct since it is a *correction* only performed a fixed number of times. Concerning the error in u_h^1, we have the following proposition.

PROPOSITION 3.3. *Assume the spaces* (X_h, Q_h) *satisfy* (1.3). *Suppose* u *is a nonsingular solution of the* (1.1). *Suppose* α *tends to* 0 *as* h *tends to* 0. *Then, there is* $h_0 > 0$ *such that for* $h \le h_0$ *the error in* (u_h^1, p_h^1) *satisfies*

$$\|\nabla(u - u_h^1)\| \le C(\beta)\left[\frac{2}{\mu(u,\nu)}\left(\alpha + \nu + \frac{2M}{\nu}\|f\|_{-1}\right) + 1\right] \inf_{v_h \in X_h} \|\nabla(u - v_h)\| + \frac{2}{\mu(u,\nu)}\left[\inf_{\lambda_h \in Q_h} \|p - \lambda_h\| + \alpha\|\nabla u\|\right],$$

$$\|p - p_h^1\| \le \left(1 + \frac{1}{\beta}\right) \inf_{\lambda_h \in Q_h} \|p - \lambda_h\| + \frac{1}{\beta}\left(\nu + \alpha + \frac{2M}{\nu}\|f\|_{-1}\right)\|\nabla(u - u_h^1)\| + \frac{\alpha}{\beta}\|\nabla u\|.$$

Proof. The proof that $u_h^1 \to u$ is standard, since u_h^1 is just the usual artificial viscosity approximation, following, e.g., [14, 15]. We shall thus give the proof of only the error bound since it gives the ideas of the proof of the general case in a simpler context. The true solution (u, p) satisfies for any $v_h \in V_h$, $\lambda_h \in Q_h$

$$(\nu + \alpha)(\nabla u, \nabla v_h) + b^*(u, u, v_h) - (p - \lambda_h, \nabla \cdot v_h) = (f, v_h) + \alpha(\nabla u, \nabla v_h). \tag{3.3}$$

Let $\tilde{u} \in V_h$ be an approximation to u and write $e^1 = u - u_h^1 = \eta - \phi_h$, where $\phi_h = u_h^1 - \tilde{u}$ and $\eta = u - \tilde{u}$. Subtracting from (3.3), equation (1.6) for (u_h^1, p_h^1) gives

$$(\nu + \alpha)(\nabla e^1, \nabla v_h) + b^*(u, u, v_h) - b^*(u_h^1, u_h^1, v_h) = (p - \lambda_h, \nabla \cdot v_h) + \alpha(\nabla u, \nabla v_h). \tag{3.4}$$

The nonlinear term can be rewritten as

$$\begin{aligned} b^*(u, u, v_h) - b^*(u_h^1, u_h^1, v_h) &= b^*(e^1, u, v_h) + b^*(u_h^1, e^1, v_h) \\ &= b^*(\eta, u, v_h) - b^*(\phi_h, u, v_h) + b^*(u_h^1, \eta, v_h) - b^*(u_h^1, \phi_h, v_h). \end{aligned}$$

Using this decomposition of $b^*(\cdot,\cdot,\cdot)$ and splitting $e^1 = \eta - \phi_h$ gives

$$\begin{aligned} &(\nu + \alpha)(\nabla \phi_h, \nabla v_h) + b^*(\phi_h, u, v_h) + b^*(u_h^1, \phi_h, v_h) \\ &\quad = (\nu + \alpha)(\nabla \eta, \nabla v_h) + b^*(\eta, u, v_h) \\ &\qquad + b^*(u_h^1, \eta, v_h) - (p - \lambda_h, \nabla \cdot v_h) - \alpha(\nabla u, \nabla v_h) \quad \forall (v_h, \lambda_h) \in (V_h, Q_h). \end{aligned} \tag{3.5}$$

Applying standard bounds to the right-hand side of (3.5) gives

$$\begin{aligned} &\frac{1}{\|\nabla v_h\|}[(\nu + \alpha)(\nabla \phi_h, \nabla v_h) + b^*(\phi_h, u, v_h) + b^*(u_h^1, \phi_h, v_h)] \\ &\le (\nu + \alpha)\|\nabla \eta\| + M(\|\nabla u\| + \|\nabla u_h^1\|)\|\nabla \eta\| + \|p - \lambda_h\| + \alpha\|\nabla u\|. \end{aligned}$$

Taking the supremum over $v_h \in V_h$, using Lemma 2.7 and a priori bounds on $\|\nabla u\|$ and $\|\nabla u_h^1\|$ yield

$$\frac{1}{2}\mu(u,\nu)\|\nabla\phi_h\| \le \left[\alpha+\nu+M\|f\|_{-1}\left(\frac{1}{\nu}+\frac{1}{\nu+\alpha}\right)\right]\|\nabla\eta\| + \|p-\lambda_h\| + \alpha\|\nabla u\|.$$

By using the triangle inequality, taking the infimum over $v^h \in V^h$, $\lambda^h \in Q^h$, and using Lemma 2.2, one obtains the required result.

For the pressure estimate (just as for the Stokes problem) we begin with the error equation for $v_h \in X_h$ (rather than V_h):

$$(p-p_h^1, \nabla\cdot v_h) = (\nu+\alpha)(\nabla e^1, \nabla v_h) + b^*(e^1, u, v_h) - b^*(u_h^1, e^1, v_h) - \alpha(\nabla u, \nabla v_h).$$

Write $p - p_h^1 = p - \lambda_h - (p_h^1 - \lambda_h)$, where $\lambda_h \in Q_h$ approximates p well. Then

$$\begin{aligned}(p_h^1-\lambda_h, \nabla\cdot v_h) &= (p-\lambda_h, \nabla\cdot v_h) - (\nu+\alpha)(\nabla e^1, \nabla v_h)\\ &\quad - b^*(e^1, u, v_h) + b^*(u_h^1, e^1, v_h) + \alpha(\nabla u, \nabla v_h)\\ &\le [\|p-\lambda_h\| + (\nu+\alpha)\|\nabla e^1\| + M(\|\nabla u\| + \|\nabla u_h^1\|)\|\nabla e^1\|\\ &\quad + \alpha\|\nabla u\|]\|\nabla v_h\|.\end{aligned}$$

Dividing by $\|\nabla v_h\|$, taking the supremum over $v_h \in X_h$, using the inf-sup condition (1.3), and the triangle inequality, we have

$$\begin{aligned}\|p-p_h^1\| &\le \left(1+\frac{1}{\beta}\right)\|p-\lambda_h\| + \frac{1}{\beta}(\nu+\alpha)\|\nabla e^1\|\\ &\quad + \frac{M}{\beta}(\|\nabla u\| + \|\nabla u_h^1\|)\|\nabla e^1\| + \frac{\alpha}{\beta}\|\nabla u\|.\end{aligned}$$

Finally, using a priori bounds (3.1), $\nu\|\nabla u\| \le \|f\|_{-1}$ gives the required result. ∎

Concerning the error in the method we consider the variant (1.6), (1.9) in which one linearized problem is solved per correction step. Intuitively, one would expect that the defect correction method (1.6), (1.7) would be more robust and more accurate. On the other hand, complete error analysis of the defect correction method with nonlinear correction (1.6), (1.7) is an open problem in the case of large data and nonsingular solutions.

PROPOSITION 3.4. *Consider* (1.6), (1.9). *Let u be a nonsingular solution of the* (1.1) *and suppose* (1.3) *holds. Then, there is a $\delta > 0$ such that if $\|\nabla(u-u_h^j)\| < \delta$, for $j = 1, 2\ldots,$*

$$\begin{aligned}\frac{1}{2}\mu(u,\nu)\|\nabla(u-u_h^{j+1})\| &\le C(\beta)\left(\nu+\alpha+\frac{1}{2}\mu(u,\nu)+2M(\delta+\|\nabla u\|)\right)\inf_{v_h\in X_h}\|\nabla(u-v_h)\|\\ &\quad + \sqrt{2}\inf_{\lambda_h\in Q_h}\|p-\lambda_h\| + \alpha\|\nabla u - \overline{\nabla u}\|\\ &\quad + M\|\nabla(u-u_h^j)\|^2 + \alpha\|\overline{\nabla(u-u_h^j)}\|,\\ \beta\|p-p_h^{j+1}\| &\le C\inf_{\lambda_h\in Q_h}\|p-\lambda_h\| + [\nu+\alpha+2M\|\nabla u\|]\|\nabla(u-u_h^{j+1})\|\\ &\quad + M\|\nabla(u-u_h^j)\|^2 + \alpha\|\overline{\nabla(u-u_h^j)}\| + \alpha\|\nabla u - \overline{\nabla u}\|.\end{aligned}$$

Proof. The variational formulation of (1.1) can be rewritten as follows: for any $v_h \in V_h$ and $\lambda_h \in Q_h$,

$$\begin{aligned}&(\nu+\alpha)(\nabla u,\nabla v_h)+b^*(u_h^j,u,v_h)+b^*(u,u_h^j,v_h)-(p-\lambda_h,\nabla\cdot v_h)\\&=(f,v_h)+[b^*(u_h^j,u,v_h)+b^*(u,u_h^j,v_h)-b^*(u,u,v_h)]\\&\quad+\alpha(\overline{\nabla u},\nabla v_h)+\alpha(\nabla u-\overline{\nabla u},\nabla v_h).\end{aligned}\tag{3.6}$$

The square bracketed term on the right-hand side of (3.6) becomes

$$b^*(u_h^j,u,v_h)+b^*(u,u_h^j,v_h)-b^*(u,u,v_h)=-b^*(u-u_h^j,u-u_h^j,v_h)+b^*(u_h^j,u_h^j,v_h).\tag{3.7}$$

Let $e^{j+1}=u-u_h^{j+1}$, $e^j=u-u_h^j$ and note that $g_H=\overline{\nabla u_h^j}$ (by (1.10)). With this notation subtract (1.10) from (3.6) and use (3.7) for the nonlinear terms on the right-hand side. This gives

$$\begin{aligned}&(\nu+\alpha)(\nabla e^{j+1},\nabla v_h)+b^*(u_h^j,e^{j+1},v_h)+b^*(e^{j+1},u_h^j,v_h)\\&=(p-\lambda_h,\nabla\cdot v_h)-b^*(e^j,e^j,v_h)+\alpha(\overline{\nabla e^j},\nabla v_h)\\&+\alpha(\nabla u-\overline{\nabla u},\nabla v_h)\quad\forall(v_h,\lambda_h)\in(V_h,Q_h).\end{aligned}$$

The remainder of the proof follows that of Proposition 3.3: we first split $e^{j+1}=\eta-\phi_h$, $\eta=u-\tilde{u}$, and $\phi_h=u_h^{j+1}-\tilde{u}$, where $\tilde{u}\in V_h$ approximates u well. By using this decomposition, nonlinear terms can be written as

$$\begin{aligned}&b^*(u_h^j,e^{j+1},v_h)+b^*(e^{j+1},u_h^j,v_h)\\&=b(u_h^j,\eta,v_h)-b(u_h^j,\phi_h,v_h)+b(\eta,u_h^j,v_h)-b(\phi_h,u_h^j,v^h).\end{aligned}$$

Then, the use of splitting error and Lemma 2.7 give that for δ small enough (i.e., for u_h^j close enough to u) the linear problem for e^{j+1} satisfies the inf-sup stability condition. Thus, the following inequality for ϕ_h holds:

$$\begin{aligned}\frac{1}{2}\mu(u,\nu)\|\nabla\phi_h\|&\le(\nu+\alpha+2M\|\nabla u_h^j\|)\|\nabla\eta\|\\&\quad+\sqrt{2}\|p-\lambda_h\|+M\|\nabla e^j\|^2+\alpha\|\overline{\nabla e^j}\|+\alpha\|\nabla u-\overline{\nabla u}\|.\end{aligned}$$

Since u_h^j is close enough to $u\in X$, we have $\|\nabla u_h^j\|\le\delta+2\|\nabla u\|$. The triangle inequality then implies that

$$\begin{aligned}\frac{1}{2}\mu(u,\nu)\|\nabla e^{j+1}\|&\le\left(\nu+\alpha+\frac{1}{2}\mu(u,\nu)+2M(\delta+\|\nabla u\|)\right)\|\nabla\eta\|\\&\quad+\sqrt{2}\|p-\lambda_h\|+M\|\nabla e^j\|^2+\alpha\|\overline{\nabla e^j}\|+\alpha\|\nabla u-\overline{\nabla u}\|.\end{aligned}$$

The pressure bound also follows from the case $j=1$. ∎

The error estimate Proposition 3.4 has four terms. The first term $\|\nabla(u-v_h)\|$ is the error in the best approximation to $(u,p)\in(X_h,Q_h)$. The second term $\|\nabla e^j\|^2$ is the linearization error. Since this is quadratic, it is typically a higher order term. The third, $\alpha\|\overline{\nabla e^j}\|$, shows that each step of the defect correction method improves the error in the previous step by one power of h (recall that typically $\alpha=\mathcal{O}(h)$). The last term $\alpha\|\nabla u-\overline{\nabla u}\|$ arises from the error of the stabilized discretization.

As a result of Proposition 3.4, we can give the following corollaries.

COROLLARY 3.5. *In addition to the assumptions of Proposition* 3.4*, suppose* $h \le H \to 0$ *as* $h \to 0$ *and* $\alpha \to 0$ *as* $h \to 0$*. Suppose also* X_h, Q_h*,* L_H *become dense in* X, Q*, and* L*, respectively, as* $h \to 0$*. Then, there is an* $h_0 > 0$ *such that for* $h \le h_0$ *and* $j = 1, 2, \dots k$*,* $u_h^j \to u$ *as* $h \to 0$*.*

COROLLARY 3.6. *Suppose* X_h*,* Q_h*,* L_H *consist of piecewise polynomials of degree* $k, k-1$*, and* $k-1$*, respectively. Suppose also that* $u \in H^{k+1}(\Omega) \cap X$*,* $p \in H^k(\Omega) \cap Q$*. Then,*

$$\|\nabla(u - u_h^1)\| \le C(u,p)[h^k + \alpha],$$

and in general,

$$\|\nabla(u - u_h^j)\| \le C(u,p,j)[h^k + \alpha H^k + \alpha^j].$$

This follows by inserting the approximation theoretical orders of convergence into the right-hand side of Proposition 3.4 and keeping only dominant terms. For example,

$$\begin{aligned}\|\nabla(u - u_h^2)\| &\le C(u,p)[h^k + (h^k + \alpha)^2 + \alpha(h^k + \alpha) + \alpha H^k] \\ &\le C(u,p)[h^k + \alpha H^k + \alpha^2].\end{aligned}$$

The error estimate in the corollary explains the typical algorithmic choices:

$$\begin{aligned} j &\ge k : \text{correction step}, \\ \alpha &= \alpha_0 h : \text{regularization parameter}, \\ H &\le C h^{1-\frac{1}{k}} : \text{length scale of large structures}. \end{aligned}$$

4. Numerical studies. In this section, we consider some numerical experiments for the implementation of defect correction algorithms proposed with (1.6), (1.10). In particular, we present two numerical examples: one is a known analytical solution; and the other is the driven cavity problem.

All computations are carried out in the domain $\Omega = [0,1] \times [0,1]$. We divide our domain into triangles. We use Taylor–Hood elements, i.e., continuous piecewise quadratic functions for the velocity space X_h and continuous piecewise linear functions for the pressure space Q_h. It is well known that this conforming pair of finite element spaces satisfies the inf-sup condition (1.3). The coarse space L_H is chosen to be ∇X_H, where X_H is the space of continuous piecewise quadratics on the coarse mesh. For every grid, the first artificial viscosity system (1.6) is solved with $\alpha = h$. Then, k (the polynomial degree of the velocity approximation) defect correction steps are performed. Hence, two correction steps are required for the Taylor–Hood element. All the nonlinear systems are solved by using the Newton method with stopping criterion 10^{-6}. Corollary 3.6 suggests that the algorithmic choices for h and H should be $h \sim H^2$ or, equivalently, $H \sim h^{1/2}$ in order to obtain optimal error rates.

As a first numerical illustration, we study a numerical convergence to confirm the error estimate given in Proposition 3.4. The prescribed solution is given by

$$u = -4y^3x^2, \quad v = 2xy^4, \quad p = 2x + 3y - 2.$$

Dirichlet boundary conditions are chosen, and the right-hand side f is such that (u, v, p) is the solution of (1.1). In this example, our numerical results are performed for $\nu = 1$. For the Taylor–Hood finite element spaces, the theory predicts a convergence rate of $\mathcal{O}(h^2)$ in the energy norm, $\mathcal{O}(h^3)$ in the L^2 norm for the velocity, and $\mathcal{O}(h^2)$ for the pressure.

Note that, since we try to verify the theory in this simplest setting, the first numerical test problem does not require either a subgrid eddy viscosity method or defect correction method for an accurate solution. However, the method (1.6), (1.10) is fully comparable to the standard finite approach in this laminar case. In Table 1, the error in the usual Galerkin discretization of the Navier–Stokes equations is presented. In particular, we give L^2 and H_0^1 errors and the corresponding convergence rates. As theory predicts, the optimal convergence rates are obtained. In Table 2, we present convergence rates by using the artificial viscosity (AV) method where we perform only initialization step (1.6) to solve Navier–Stokes equations. Since we choose $\alpha = h$, it is expected and observed that the convergence rates for this method are suboptimal. In Table 3, the experimental rates of convergence for the subgrid stabilized defect correction method are presented. The scalings between coarse and fine mesh are chosen such that $H \leq h^{1/2}$ is satisfied. These numerical results demonstrate that the rates of convergence are optimal, as the theory predicts. Hence, the stabilization used in the method (1.6), (1.10) does not degrade rates of convergence in laminar flows.

Our second example is the benchmark problem of the underresolved driven cavity at high Reynolds numbers. This problem is chosen because there is benchmark data available for comparison. Even though the zero boundary condition assumed in the theory is not valid here, the convergence theory can be extended to nonzero boundary conditions smooth enough to be the trace of an H^1 function. In this benchmark problem, flow is driven by the tangential velocity field applied to the top boundary in the absence of other body forces. On the segment $\{(x, 1) : 0 < x < 1\}$, the velocity is equal to $u = (1, 0)$. On the rest of the boundary, zero Dirichlet conditions are imposed.

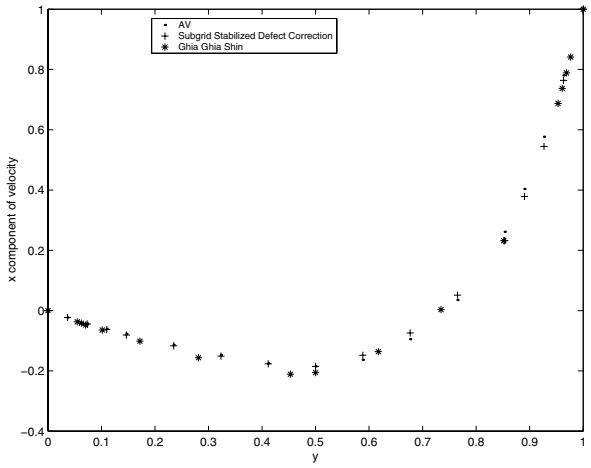

FIG. 1. *Vertical midlines for* $\nu = 10^{-2}$ *for* $H = 1/4, h = 1/8$.

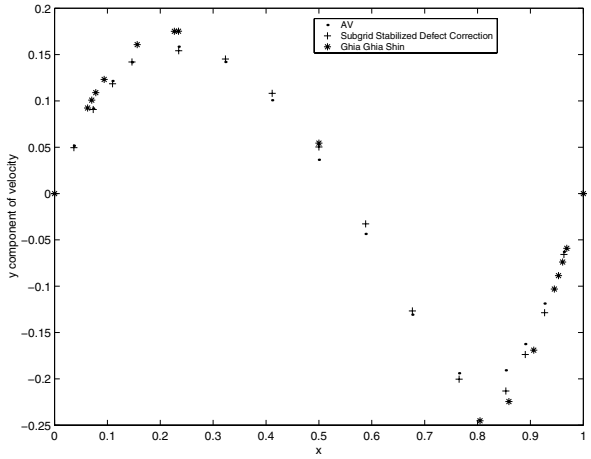

FIG. 2. *Horizontal midlines for* $\nu = 10^{-2}$ *for* $H = 1/4, h = 1/8$.

The drawbacks of usual, centered Galerkin methods for convection dominated problems are well known and well documented. Also, the drawbacks of the unmodified defect correction method, although less well known, are very well documented since the 1982 work of Hemker [21, 20]. Thus, the focus of our experiments on the driven cavity problem is to (i) show that the subgrid stabilized defect correction method gives high quality, coarse mesh solutions (comparable to the benchmark, fine mesh results of Ghia, Ghia, and Shin [13]), (ii) illustrate that stabilization of the finest resolved scales is effective in suppressing the oscillations on the scales typical of the unstabilized defect correction method, and (iii) illustrate the very substantial improvement in the results produced by the relatively inexpensive correction steps.

We compute an approximate solution for $\nu = 10^{-2}$, $\nu = 25 \times 10^{-4}$, and $\nu = 3125 \times 10^{-7}$ for the driven cavity flow with regularization parameter $\alpha_0 = 0.1$. In particular, we draw the x component of velocity along the vertical centerline and

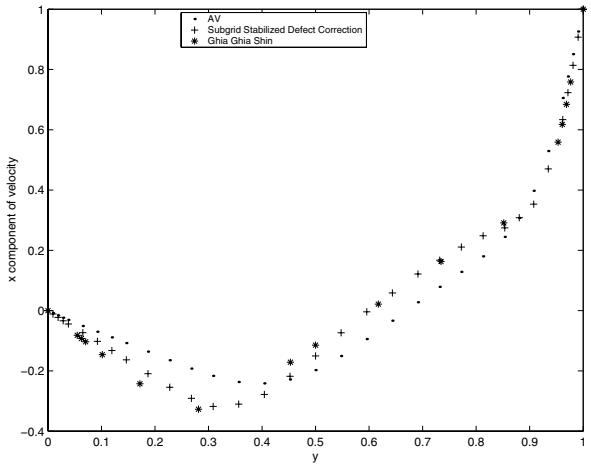

FIG. 3. *Vertical midlines for* $\nu = 25 \times 10^{-4}$ *for* $H = 1/8, h = 1/16$.

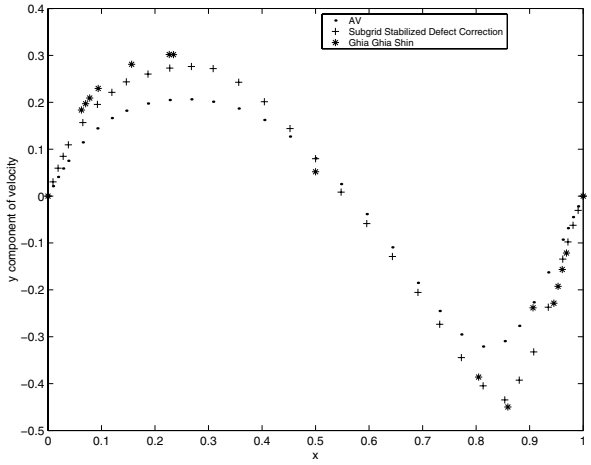

FIG. 4. *Horizontal midlines for* $\nu = 25 \times 10^{-4}$ *for* $H = 1/8, h = 1/16$.

y component of velocity along the horizontal centerlines. We compare our results to those obtained by Ghia, Ghia, and Shin [13]. The present numerical simulations are considered on a very coarse mesh ($h = 1/8, h = 1/16, h = 1/32$) and they are compared to the very fine mesh ($h = 1/129$) of [13]. Ghia's algorithm is based on the time dependent streamfunction using the coupled implicit and multigrid methods. Their results are used as benchmark data as basis for comparison.

In Figures 1–6, we compare the results obtained by the AV method, the subgrid stabilized defect correction method (1.6), (1.10), and the results of [13]. In the case $\nu = 10^{-2}$, there is very little difference between the vertical midlines for all three methods (Figure 1). For the horizontal midlines, the subgrid stabilized defect correction method is closer to Ghia, Ghia, and Shin's results than the artificial viscosity (see Figure 2).

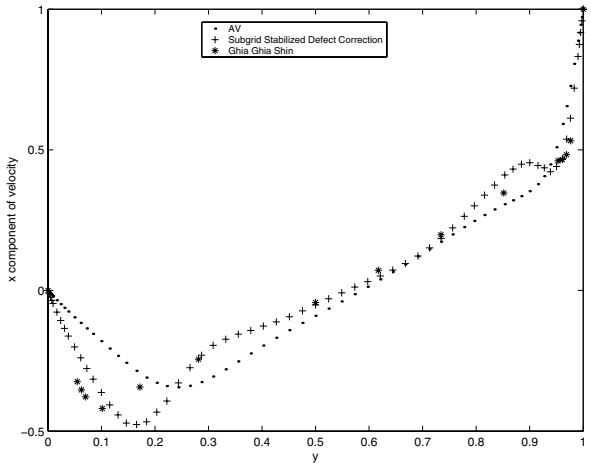

FIG. 5. *Vertical midlines for* $\nu = 3125 \times 10^{-7}$ *for* $H = 1/16, h = 1/32$.

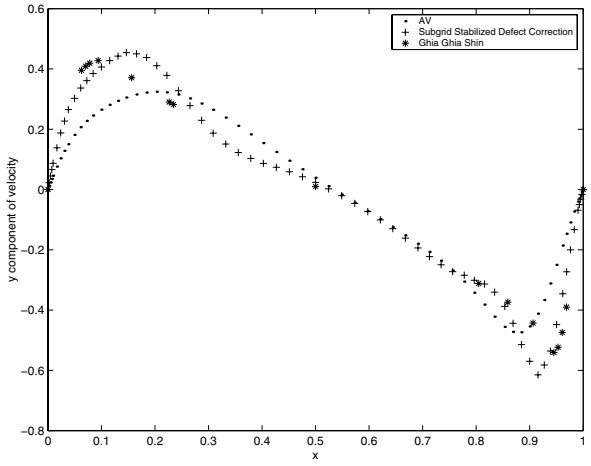

FIG. 6. *Horizontal midlines for* $\nu = 3125 \times 10^{-7}$ *for* $H = 1/16, h = 1/32$.

In the cases of $\nu = 25 \times 10^{-4}$ and $\nu = 3125 \times 10^{-7}$, namely for higher Reynolds number, Figures 3, 4, 5, and 6 clearly show that the subgrid stabilized defect correction method performs much better than the artificial viscosity method, and is comparable to the results obtained by Ghia, Ghia, and Shin on a more refined mesh.

5. Conclusion. The natural combination of defect correction with multiscale stabilization retains the best features of both methods and overcomes many of their deficits. The combination is accurate and efficient, and a convergence theory of the combination is developed. This latter theory shows that the good accuracy and stability properties are no accident—they are general features of the method.

This combination has strong promise, but many open questions remain including the correct extension of the method to time dependent problems, further numerical analysis (other norms, error functionals, ...), and more extensive testing.

CONVERGENCE OF A FINITE DIFFERENCE SCHEME FOR THE CAMASSA–HOLM EQUATION*

HELGE HOLDEN† AND XAVIER RAYNAUD‡

Abstract. We prove that a certain finite difference scheme converges to the weak solution of the Cauchy problem on a finite interval with periodic boundary conditions for the Camassa–Holm equation $u_t - u_{xxt} + 3uu_x - 2u_xu_{xx} - uu_{xxx} = 0$ with initial data $u|_{t=0} = u_0 \in H^1([0,1])$. Here it is assumed that $u_0 - u_0'' \geq 0$, and in this case the solution is unique, globally defined, and energy preserving.

Key words. Camassa–Holm equation, convergence of finite difference schemes

DOI. 10.1137/040611975

1. Introduction.

In the past decade, the Camassa–Holm equation [3]

$$u_t - u_{xxt} + 2\kappa u_x + 3uu_x - 2u_xu_{xx} - uu_{xxx} = 0 \tag{1.1}$$

has received considerable attention. With κ positive it models (see [4, 16, 12]) propagation of unidirectional gravitational waves in a shallow water approximation, with u representing the fluid velocity. The Camassa–Holm equation possesses many intriguing properties: It is, for instance, completely integrable and experiences wave breaking in finite time for a large class of initial data. Most attention has been given to the case with $\kappa = 0$ on the full line, that is,

$$u_t - u_{xxt} + 3uu_x - 2u_xu_{xx} - uu_{xxx} = 0, \tag{1.2}$$

which has so-called peakon solutions, i.e., solutions of the form $u(x,t) = ce^{-|x-ct|}$ for real constants c. Local and global well-posedness results as well as results concerning breakdown are proved in [9, 14, 17, 20].

In this paper we study the Camassa–Holm equation (1.1) on a finite interval with periodic boundary conditions. It is known that certain initial data give global solutions, while other classes of initial data experience wave breaking in the sense that u_x becomes unbounded while the solution itself remains bounded. It suffices to treat the case $\kappa = 0$, since solutions with nonzero κ are obtained from solutions with zero κ by the transformation $v(x,t) = u(x + \kappa t, t) - \kappa$. More precisely, the fundamental existence theorem, due to Constantin and Escher [10], reads as follows: If $u_0 \in H^3([0,1])$ and $m_0 := u_0 - u_0'' \in H^1([0,1])$ is nonnegative, then (1.2) has a unique global solution $u \in C([0,T), H^3([0,1])) \cap C^1([0,T), H^2([0,1]))$ for any T positive. However, if $m_0 \in H^1([0,1])$, with u_0 not identically zero but $\int m_0\,dx = 0$, then the maximal time interval of existence is finite. Furthermore, if $u_0 \in H^1([0,1])$

and $m_0 = u_0 - u_0''$ is a positive Radon measure on $[0,1]$, then (1.2) has a unique global weak solution. Additional results in the periodic case can be found in [7, 10, 8, 11, 18]. Numerical results can be found in [4], where Camassa, Holm, and Hyman study (1.2) using a pseudospectral method. Numerical schemes based on multipeakons are examined in [2, 6, 5, 15].

In this paper, we prove convergence of a particular finite difference scheme for the equation, thereby giving a constructive approach to the actual determination of the solution. We work in the case where one has global solutions, that is, when $m_0 \geq 0$. The scheme is semidiscrete: Time is not discretized, and we have to solve a system of ordinary differential equations. We reformulate (1.1) to give meaning in $C([0,T]; H^1[0,1])$ to solutions such as peakons, and we prove that our scheme converges in $C([0,T]; H^1[0,1])$.

More precisely, we prove the following: Assume that v^n is a sequence of continuous, periodic, and piecewise linear functions on intervals $[(i-1)/n, i/n]$, $i = 1, \dots, n$, that converges to the initial data v in $H^1([0,1])$ as $n \to \infty$. Let $u^n = u^n(x,t)$ be the solution of the following system of equations:

$$\begin{aligned} m_t^n &= -D_-(m^n u^n) - m^n D u^n, \\ m^n &= u^n - D_- D_+ u^n, \end{aligned} \tag{1.3}$$

with initial condition $u^n|_{t=0} = v^n$. Here $D_\pm$ denotes forward and backward difference operators relative to the lattice with spacing $1/n$, and $D = (D_+ + D_-)/2$. Extrapolate u^n from its lattice values at points i/n to obtain a continuous, periodic, and piecewise linear function also denoted u^n. Assume that $v^n - D_- D_+ v^n \geq 0$. Then u^n converges in $C([0,T]; H^1([0,1]))$ as $n \to \infty$ to the solution u of the Camassa–Holm equation with initial condition $u|_{t=0} = v$. The result includes the case when the initial data $v \in H^1$ is such that $v - v_{xx}$ is a positive Radon measure; see Corollary 2.5. For the actual computations we discretize (1.3) using the forward Euler method. We prove convergence of that method; see Theorem 3.1.

The numerical scheme (1.3) is tested on various initial data. In addition, we study experimentally the convergence of other numerical schemes for the Camassa–Holm equation. The numerical results are surprisingly sensitive in the explicit form of the scheme, and, among the various schemes we have implemented, only the scheme (1.3) converges to the unique solution.

2. Convergence of the numerical scheme. We consider periodic boundary conditions and solve the equation on the interval $[0,1]$. We are looking for solutions that belong to $H^1([0,1])$, which is the natural space for the equation. Introduce the partition of $[0,1]$ in points separated by a distance $h = 1/n$ denoted $x_i = hi$ for $i = 0, \dots, n-1$. For any $(u_0, \dots, u_{n-1})$ in $\mathbb{R}^n$, we can define a continuous, periodic, piecewise linear function u by

$$u(x_i) = u_i, \tag{2.1}$$

in other words, the periodic polygon that passes through the points (x_i, u_i) for $i = 0, \dots, n-1$. It defines a bijection between $\mathbb{R}^n$ and the set of continuous, periodic, piecewise linear functions with possible break points at x_i, and we will use this bijection throughout this paper.

Given $u = (u_0, \dots, u_{n-1})$, the quantity $D_\pm u$ given by

$$(D_\pm u)_i = \frac{\pm 1}{h}(u_{i\pm 1} - u_i)$$

gives the right and left derivatives, respectively, of u at x_i. In these expressions, u_{-1} and u_n are derived from the periodicity conditions: $u_{-1} = u_{n-1}$ and $u_n = u_0$. The average Du between the left and right derivatives is given by

$$(Du)_i = \frac{1}{2}\big((D_+u)_i + (D_-u)_i\big) = \frac{1}{2h}(u_{i+1} - u_{i-1}).$$

The Camassa–Holm equation preserves the H^1-norm. In order to see that, we rewrite (1.2) in its Hamiltonian form (see [3]):

$$m_t = -(mu)_x - mu_x, \tag{2.2}$$

with

$$m = u - u_{xx}. \tag{2.3}$$

Assuming that u is smooth enough so that integration by parts can be carried out, we get

$$\begin{aligned}\frac{d}{dt}\|u\|_{H^1}^2 &= 2\int_0^1 (u_t - u_{xxt})u\,dx = 2\int_0^1 um_t\,dx\\ &= -2\int_0^1 u(mu)_x\,dx - 2\int_0^1 umu_x\,dx\\ &= 2\int_0^1 u_xmu\,dx - 2\int_0^1 umu_x\,dx = 0,\end{aligned}$$

and the H^1-norm of u is preserved.

From (2.3) and (2.2), we derive a finite difference approximation scheme for the Camassa–Holm equation and prove that it converges to the right solution. This is our main result.

THEOREM 2.1. *Let v^n be a sequence of continuous, periodic, and piecewise linear functions on $[0,1]$ that converges to v in $H^1([0,1])$ as $n \to \infty$ and such that $v^n - D_-D_+v^n \geq 0$. Then, for any given $T > 0$, the sequence $u^n = u^n(x,t)$ of continuous, periodic, and piecewise linear functions determined by the system of ordinary differential equations*

$$\begin{aligned}m_t^n &= -D_-(m^nu^n) - m^nDu^n,\\ m^n &= u^n - D_-D_+u^n,\end{aligned} \tag{2.4}$$

with initial condition $u^n|_{t=0} = v^n$, converges in $C([0,T];H^1([0,1]))$ as $n \to \infty$ to the solution u of the Camassa–Holm equation (1.2) *with initial condition $u|_{t=0} = v$.*

If we interpret the functions as vectors in (2.4) (cf. (2.1)), the multiplications are term-by-term multiplications of vectors. We also have to rewrite (1.2) in order to make it well defined in the sense of distributions for functions that at least belong to $C([0,T];H^1([0,1]))$; more precisely,

$$u_t - u_{xxt} = -\frac{3}{2}(u^2)_x - \frac{1}{2}(u_x^2)_x + \frac{1}{2}(u^2)_{xxx}. \tag{2.5}$$

A function u in $L^\infty([0,T];H^1)$ is said to be a solution of the periodic Camassa–Holm equation if it is periodic and satisfies (2.5) in the sense of distributions. In [11], a

different definition of weak solutions for the Camassa–Holm equation is presented. After proving our main theorem at the end of this section, we also prove that these two definitions are equivalent.

In order to solve (2.4), we need to compute u^n from m^n. It is simpler first to consider sequences that are defined in $\mathbb{R}^{\mathbb{Z}}$, the set of all sequences, and then discuss the periodic case. Let L denote the linear operator from $\mathbb{R}^{\mathbb{Z}}$ to $\mathbb{R}^{\mathbb{Z}}$ given, for all $u \in \mathbb{R}^{\mathbb{Z}}$, by

$$Lu = u - D_- D_+ u.$$

We want to find an expression for L^{-1}. Introduce the Kronecker delta by $\delta_i = 1$ if $i = 0$, and zero otherwise. It is enough to find a solution g of

$$Lg = \delta$$

which decays sufficiently fast at infinity because $L^{-1}m$ is then given, for any bounded $m \in \mathbb{R}^{\mathbb{Z}}$, by the discrete convolution product of g and m:

$$L^{-1}m_i = \sum_{j \in \mathbb{Z}} g_{i-j} m_j.$$

For i nonzero the function g satisfies

$$g_i - n^2(g_{i+1} - 2g_i + g_{i-1}) = 0. \tag{2.6}$$

The general solution of (2.6) for all $i \in \mathbb{Z}$ is given by

$$g_i = Ae^{\kappa_1 i} + Be^{\kappa_2 i},$$

where A, B are constants, $\kappa_1 = \ln x_1$, $\kappa_2 = \ln x_2$, and x_1 and x_2 are the solutions of

$$-n^2x^2 + (1 + 2n^2)x - n^2 = 0.$$

Here x_1 and x_2 are real and positive, and $x_1x_2 = 1$ implies that $\kappa_2 = -\kappa_1$. We set $\kappa = \kappa_1 = -\kappa_2$. After some calculations, we get

$$\kappa = \ln\left(\frac{1 + 2n^2 + \sqrt{1 + 4n^2}}{2n^2}\right). \tag{2.7}$$

We take g of the form

$$g_i = c\, e^{-\kappa|i|}$$

so that g satisfies (2.6) for all $i \neq 0$ and decays at infinity. The constant c is determined by the condition that $(Lg)_0 = 1$, which yields

$$c = \frac{1}{1 + 2n^2(1 - e^{-\kappa})}.$$

We periodize g in the following manner:

$$g_i^p \equiv \sum_{k \in \mathbb{Z}} g_{i+kn} = c\frac{e^{-\kappa i} + e^{\kappa(i-n)}}{1 - e^{-\kappa n}}$$

for $i \in \{0, \dots, n-1\}$. The inverse of L on the set of periodic sequences is then given by

$$u_i = L^{-1} m_i = \sum_{j=0}^{n-1} g_{i-j}^p m_i = \frac{c}{1 - e^{-\kappa n}} \sum_{j=0}^{n-1} (e^{-\kappa(i-j)} + e^{\kappa(i-j-n)}) m_j. \tag{2.8}$$

Hence,

$$L\left(\sum_{j=0}^{n-1} g_{i-j}^p m_j \right)_i = L\left(\sum_{l \in \mathbb{Z}} g_{i-l} m_l \right)_i = m_i.$$

For sufficiently smooth initial data ($u_0 \in H^3$ and $m_0 \in H^1$) which satisfies $m_0 \geq 0$, Constantin and Escher [9] proved that there exists a unique global solution of the Camassa–Holm equation belonging to $C(\mathbb{R}_+; H^3) \cap C^1(\mathbb{R}_+; H^2)$. The proof of this result relies heavily on the fact that if m is nonnegative at $t = 0$, then m remains nonnegative for all $t > 0$. An important feature of our scheme is that it preserves this property. (For simplicity we have here dropped the superscript n appearing on u and m.)

LEMMA 2.2. *Assume that $m_i(0) \geq 0$ for all $i = 0, \dots, n-1$. For any solution $u(t)$ of the system (2.4), we have that $m_i(t) \geq 0$ for all $t \geq 0$ and for all $i = 0, \dots, n-1$.*

Proof. Let us assume that there exist $t > 0$ and $i \in \{0, \dots, n-1\}$ such that

$$m_i(t) < 0. \tag{2.9}$$

We consider the time interval F in which m remains positive:

$$F = \{t \geq 0 \mid m_i(\tilde{t}) \geq 0 \text{ for all } \tilde{t} \leq t \text{ and } i \in \{0, \dots, n-1\}\}.$$

Because of assumption (2.9), F is bounded and we define

$$T = \sup F.$$

By definition of T, for any integer $j > 0$, there exists a $\tilde{t}_j$ and an i_j such that $T < \tilde{t}_j < T + \frac{1}{j}$ and $m_{i_j}(\tilde{t}_j) < 0$. The function $m_{i_j}(t)$ is a continuously differentiable function of t. Hence, $m_{i_j}(T) \geq 0$ and there exists a t_j such that

$$m_{i_j}(t_j) = 0,$$

with $T \leq t_j < T + \frac{1}{j}$.

Since i_j can only take a finite number of values ($i_j \in \{0, \dots, n-1\}$), there exists a $p \in \{0, \dots, n-1\}$ and a subsequence j_k such that $i_{j_k} = p$. The function $m_p(t)$ belongs to C^1 and, since $t_{j_k} \to T$, we have

$$m_p(T) = 0. \tag{2.10}$$

We denote by G the set of indices for which (2.10) holds:

$$G = \{k \in \{0, \dots, n-1\} \mid m_k(T) = 0\}.$$

G is nonempty because it contains p. If $G = \{0, \dots, n-1\}$, then $m_k(T) = 0$ for all k and m must be the zero solution, because we know from Picard's theorem that the solution of (2.4) is unique.

If $G \neq \{0, \dots, n-1\}$, then there exists an $l \in \{0, \dots, n-1\}$ such that

$$m_{l-1}(T) > 0, \quad m_l(T) = 0, \quad \frac{dm_l}{dt}(T) \leq 0. \tag{2.11}$$

The last condition, $\frac{dm_l}{dt}(T) \leq 0$, comes from the definition of T that would be contradicted if we had $\frac{dm_l}{dt}(T) > 0$. Note that we also use the periodicity of m, which in particular means that if $l = 0$, then $m_{l-1}(T) = m_{-1}(T) = m_{n-1}(T)$.

In (2.4), for $i = l$ and $t = T$, the terms involving $m_l(T)$ cancel and

$$\frac{dm_l}{dt}(T) = \frac{m_{l-1}(T)u_{l-1}(T)}{h}.$$

The fact that all the $m_i(T)$ are positive, with one of them, $m_{l-1}(T)$, strictly positive, implies that u_i is strictly positive for all indices i; see (2.8). Since, in addition, $m_{l-1}(T) > 0$, we get

$$\frac{dm_l}{dt}(T) > 0,$$

which contradicts the last inequality in (2.11), and therefore our primary assumption (2.9) does not hold. The lemma is proved. □

We want to establish a uniform bound on the H^1-norm of the sequence u^n. Recall that u^n is a continuous piecewise linear function (with respect to the space variable), and its L^2-norm can be computed exactly. We find

$$\|u^n\|_{L^2}^2 = \frac{1}{n}\sum_{i=0}^{n-1}\frac{1}{3}((u_{i+1}^n)^2 + u_i^n u_{i+1}^n + (u_i^n)^2). \tag{2.12}$$

The derivative u_x^n of u^n is piecewise constant, and therefore we have

$$\|u_x^n\|_{L^2}^2 = \frac{1}{n}\sum_{i=0}^{n-1}(D_+u^n)_i^2. \tag{2.13}$$

We define a renormalized norm $\|\cdot\|_{l^2}$ and the corresponding scalar product on $\mathbb{R}^n$ by

$$\|u^n\|_{l^2} = \sqrt{\frac{1}{n}\sum_{i=0}^{n-1}(u_i^n)^2}, \quad \langle u^n, v^n\rangle_{l^2} = \frac{1}{n}\sum_{i=0}^{n-1}u_i^n v_i^n.$$

The following inequalities hold:

$$\frac{1}{2}\|u^n\|_{l^2} \leq \|u^n\|_{L^2} \leq \|u^n\|_{l^2}, \tag{2.14}$$

which make the two norms $\|\cdot\|_{l^2}$ and $\|\cdot\|_{L^2}$ uniformly equivalent independently of n. In (2.14), u^n either denotes an element of $\mathbb{R}^n$ or the corresponding continuous piecewise linear function as defined previously. By using the Cauchy–Schwarz inequality and the periodicity of u^n, it is not hard to prove that

$$\|u^n\|_{L^2} \leq \|u^n\|_{l^2}.$$

For the other equality, it suffices to see that (2.12) can be rewritten as

$$\|u^n\|_{L^2}^2 = \frac{1}{3n}\sum_{i=0}^{n-1}\left[\left(u_{i+1}^n + \frac{1}{2}u_i^n\right)^2 + \frac{3}{4}(u_i^n)^2\right],$$

which implies

$$\frac{1}{2}\|u^n\|_{l^2} \le \|u^n\|_{L^2}.$$

We are now in a position to establish a uniform bound on the H^1-norm of u^n. Let $E_n(t)$ denote

$$E_n(t) = \left(\|u^n(t)\|_{l^2}^2 + \|D_+u^n(t)\|_{l^2}^2\right)^{\frac{1}{2}}, \tag{2.15}$$

which provides an approximation of the H^1-norm of $u^n(t)$. We have, from (2.14) and (2.13),

$$\frac{1}{2}\|u^n(t)\|_{H^1} \le E_n(t) \le \|u^n(t)\|_{H^1}. \tag{2.16}$$

The derivative of $E_n(t)^2$ reads

$$\begin{aligned}
\frac{dE_n(t)^2}{dt} &= \frac{2}{n}\sum_{i=0}^{n-1}\left[u_i^n u_{i,t}^n + D_+u_i^n D_+u_{i,t}^n\right] \\
&= \frac{2}{n}\sum_{i=0}^{n-1}(u_i^n - D_-D_+u_i^n)_t u_i^n \quad \text{(summation by parts)} \\
&= -\frac{2}{n}\sum_{i=0}^{n-1}\left[D_-(m^nu^n)_i u_i^n + m_i^n Du_i^n u_i^n\right] \quad \text{by (2.4)} \\
&= \frac{2}{n}\sum_{i=0}^{n-1}\left[m_i^n u_i^n (D_+u_i^n - Du_i^n)\right].
\end{aligned}$$

Since

$$D_+u_i^n - Du_i^n = \frac{1}{2}\left[D_+u_i^n - D_+u_{i-1}^n\right] = \frac{1}{2n}D_-D_+u_i^n,$$

we get

$$\frac{dE_n(t)^2}{dt} = \frac{1}{n}\sum_{i=0}^{n-1}\left[m_i^n u_i^n \frac{1}{n}D_-D_+u_i^n\right] = \frac{1}{n^2}\sum_{i=0}^{n-1}\left[m_i^n u_i^n(-m_i^n + u_i^n)\right], \tag{2.17}$$

and, because u_i^n is positive (see (2.8)),

$$\frac{dE_n^2(t)}{dt} \le \frac{1}{n^2}\sum_{i=0}^{n-1} m_i^n (u_i^n)^2. \tag{2.18}$$

A summation by parts gives us that

$$\frac{1}{n}\sum_{i=0}^{n-1} m_i^n u_i^n = E_n(t)^2.$$

Since L^∞ is continuously embedded in H^1, there exists a constant $\mathcal{O}(1)$, independent of n, such that

$$\max_i u_i^n \le \mathcal{O}(1)\,\|u^n\|_{H^1} \le \mathcal{O}(1)E_n(t).$$

Hence, (2.18) implies

$$E_n'(t) \le \frac{\mathcal{O}(1)}{n} E_n(t)^2$$

and, after integration,

$$\frac{1}{E_n(t)} \ge \frac{1}{E_n(0)} - \frac{\mathcal{O}(1)}{n} t.$$

Since $u^n(0) = v^n$ tends to v in H^1, $\|u^n(0)\|_{H^1}$ and therefore $E_n(0)$ are bounded. It implies that $E_n(0)^{-1}$ is bounded from below by a strictly positive constant and, for any given $T > 0$, there exists $N \ge 0$ and constant $C' > 0$ such that for all $n \ge N$ and all $t \in [0, T]$, we have $E_n(0)^{-1} - \mathcal{O}(1)t/n \ge 1/C'$. Hence,

$$\|u^n\|_{H^1} \le 2E_n(t) \le 2C' \tag{2.19}$$

and, by (2.16), the H^1-norm of $u^n(t)$ is uniformly bounded in $[0, T]$. This result also guarantees the existence of solutions to (2.4) in $[0, T]$ (at least, for n big enough) because, on $[0, T]$, we have that $\max_i |u_i^n(t)| = \|u^n(\cdot\,, t)\|_{L^\infty} \le \mathcal{O}(1)\,\|u^n(t)\|_{H^1}$ remains bounded.

To prove that we can extract a converging subsequence of u^n, we need some estimates on the derivative of u^n.

LEMMA 2.3. *We have the following properties:*

(i) u_x^n *is uniformly bounded in* $L^\infty([0, 1])$.
(ii) u_x^n *has a uniformly bounded total variation.*
(iii) u_t^n *is uniformly bounded in* $L^2([0, 1])$.

Proof. (i) From (2.8), we get

$$D_+ u_i^n = \frac{c}{1 - e^{-\kappa n}} \sum_{j=0}^{n-1} \left[m_j^n e^{-\kappa(i-j)} \left(\frac{e^{-\kappa} - 1}{h} \right) + m_j^n e^{\kappa(i-j-n)} \left(\frac{e^{\kappa} - 1}{h} \right) \right],$$

where κ is given by (2.7).

One easily gets the following expansion for κ as h tends to 0:

$$\kappa = h + o(h^2),$$

which implies that for all $i \in \{0, \dots, n-1\}$,

$$\begin{aligned} |D_+ u_i^n| &\le (1 + \mathcal{O}(h)) \frac{c}{1 - e^{-\kappa n}} \sum_{j=0}^{n-1} \left(\left| m_j^n \right| e^{-\kappa(i-j)} + \left| m_j^n \right| e^{\kappa(i-j-n)} \right) \\ &\le (1 + \mathcal{O}(h)) \frac{c}{1 - e^{-\kappa n}} \sum_{j=0}^{n-1} \left(m_j^n e^{-\kappa(i-j)} + m_j^n e^{\kappa(i-j-n)} \right) \\ &\le (1 + \mathcal{O}(h))\, u_i^n, \end{aligned} \tag{2.20}$$

where we have used the positivity of m^n and relation (2.8). Hence, since $\|u^n\|_{L^\infty}$ is uniformly bounded, we get a uniform bound on $\|u_x^n\|_{L^\infty}$.

(ii) For each t the total variation of $u_x^n(\,\cdot\,,t)$ is given by

$$\mathrm{TV}(u_x^n) = \sup_{\phi\in C^1, \|\phi\|_{L^\infty}\le 1} \int_0^1 u_x^n(x)\phi_x(x)\,dx.$$

On the interval (x_i, x_{i+1}), the function u_x^n is constant and equal to $D_+u_i^n$. Therefore,

$$\begin{aligned}\int_0^1 u_x^n(x)\phi_x(x)\,dx &= \sum_{i=0}^{n-1} D_+u_i^n \int_{x_i}^{x_{i+1}} \phi_x(x)\,dx = \sum_{i=0}^{n-1} D_+u_i^n(\phi(x_{i+1})-\phi(x_i))\\ &= \sum_{i=0}^{n-1} \frac{1}{n} D_+u_i^n D_+\phi(x_i) = -\sum_{i=0}^{n-1} \frac{1}{n}(D_-D_+u_i^n)\phi(x_i)\end{aligned}$$

and

$$\mathrm{TV}(u_x^n) \le \frac{1}{n}\sum_{i=0}^{n-1} |D_-D_+u_i^n|\,.$$

Since m_i^n and u_i^n are positive for all i,

$$|D_-D_+u_i^n| = |m_i^n - u_i^n| \le m_i^n + u_i^n \le 2u_i^n - D_-D_+u_i^n.$$

When summing over i on the right-hand side of the last inequality, we see that the term $D_-D_+u_i^n$ disappears, and we get

$$\mathrm{TV}(u_x^n) \le 2\max_i u_i^n \le \mathcal{O}(1)\,\|u^n\|_{H^1} \le \mathcal{O}(1)$$

for all t.

(iii) In order to make the ideas clearer, we first sketch the proof directly on (2.2). Assuming that m is positive and u is in H^1, we see how, from (2.2), u_t can be defined as an element of $L^2([0,1])$. This will be useful when we afterwards derive a uniform bound for u_t^n in $L^2([0,1])$.

For all smooth v, we have

$$\int_0^1 u_t\, v\,dx = \int_0^1 (\mathcal{L}^{-1}m_t)\, v\,dx,$$

where $\mathcal{L}$ denotes the operator $\mathcal{L}u = u - u_{xx}$, which is a self-adjoint homeomorphism from H^2 to L^2. If we let $w = \mathcal{L}^{-1}v$, the continuity of $\mathcal{L}^{-1}$ implies

$$\|w\|_{H^2} \le \mathcal{O}(1)\,\|v\|_{L^2} \tag{2.21}$$

for some constant $\mathcal{O}(1)$ independent of v.

We find

$$\begin{aligned}\int_0^1 u_t\, v\,dx &= \int_0^1 \left(\mathcal{L}^{-1}m_t\right) v\,dx = \int_0^1 m_t\,\mathcal{L}^{-1}v\,dx \quad (\mathcal{L}^{-1}\text{ is self-adjoint})\\ &= -\int_0^1 ((mu)_x + mu_x)w\,dx = \int_0^1 (muw_x - mu_xw)\,dx.\end{aligned}$$

The integrals here must be understood as distributions. Even so, some terms (like mu_x) are not well defined as distributions. However, we get the same results rigorously by considering the equation written as a distribution (2.5). We have

$$\left|\int_0^1 u_t\, v\, dx\right| \le \int_0^1 (|muw_x| + |mu_x w|)\, dx \\ \le (\|u\|_{L^\infty}\, \|w_x\|_{L^\infty} + \|u_x\|_{L^\infty}\, \|w\|_{L^\infty}) \int_0^1 |m|\ dx.$$

Recall that $\|u\|_{L^\infty}$ and $\|u_x\|_{L^\infty}$ are uniformly bounded. Furthermore, m positive implies $\int_0^1 |m| = \int_0^1 m = \int_0^1 u \le \|u\|_{L^\infty}$, and therefore m is also uniformly bounded. From (2.21) and the fact that H^1 is continuously embedded in L^∞, we get

$$\|w_x\|_{L^\infty} \le \mathcal{O}(1)\, \|w_x\|_{H^1} \le \mathcal{O}(1)\, \|w\|_{H^2} \le \mathcal{O}(1)\, \|v\|_{L^2}\,,$$

and similarly

$$\|w\|_{L^\infty} \le \mathcal{O}(1)\, \|v\|_{L^2}\,.$$

Finally,

$$\left|\int_0^1 u_t\, v\, dx\right| \le \mathcal{O}(1)\, \|v\|_{L^2}\,,$$

which implies, by Riesz's representation theorem, that u_t is in L^2 and

$$\|u_t\|_{L^2} \le \mathcal{O}(1).$$

We now turn to the analogous derivations in the discrete case. Consider the sequence u^n. The aim is to derive a uniform bound for u_t^n in L^2. We take a continuous piecewise linear function v^n,

$$\langle u_t^n, v^n\rangle_{l^2} = \left\langle L^{-1} m_t^n, v^n\right\rangle_{l^2} = \left\langle m_t^n, L^{-1} v^n\right\rangle_{l^2}\,, \tag{2.22}$$

because L and therefore L^{-1} are self-adjoint.

Let w^n denote

$$w^n = L^{-1} v^n.$$

We have

$$\langle v^n, w^n\rangle_{l^2} = \langle Lw^n, w^n\rangle_{l^2} = \frac{1}{n}\sum_{i=0}^{n-1} (w_i^n - D_- D_+ w_i^n)\, w_i^n = \frac{1}{n}\sum_{i=0}^{n-1} \left[(w_i^n)^2 + (D_+ w_i^n)^2\right].$$

Then, after using (2.16) and Cauchy–Schwarz, we get

$$\|w^n\|_{H^1}^2 \le 4\, \|v^n\|_{l^2}\, \|w^n\|_{l^2}\,.$$

By (2.14), (2.16) we find

$$\|w^n\|_{H^1}^2 \le \mathcal{O}(1)\, \|v^n\|_{l^2}\, \|w^n\|_{H^1}$$

and

$$\|w^n\|_{H^1} \leq \mathcal{O}(1)\,\|v^n\|_{l^2}\,, \tag{2.23}$$

where $\mathcal{O}(1)$ is a constant independent of n. Since H^1 is continuously embedded in L^∞, we get

$$\max_i |w_i^n| \leq \mathcal{O}(1)\,\|v^n\|_{l^2}\,. \tag{2.24}$$

Let us define y^n as follows:

$$y_i^n = (D_+ w^n)_{i-1}.$$

We want to find a bound on y^n. From (2.14) and (2.23), we get

$$\|y^n\|_{l^2} \leq \|w^n\|_{H^1} \leq \mathcal{O}(1)\,\|v^n\|_{l^2}\,. \tag{2.25}$$

We also have, using the definition of y^n and w^n,

$$D_+ y^n = D_- D_+ w^n = w^n - v^n,$$

which gives

$$\|D_+ y^n\|_{l^2} \leq \mathcal{O}(1)\,\|v^n\|_{l^2} \tag{2.26}$$

because, by (2.23),

$$\|w^n\|_{l^2} \leq \mathcal{O}(1)\,\|v^n\|_{l^2}\,.$$

Equations (2.25), (2.26), and (2.16) give us a uniform bound on the H^1-norm of y^n:

$$\|y^n\|_{H^1} \leq \mathcal{O}(1)\,\|v^n\|_{l^2}\,.$$

Since H^1 is continuously embedded in L^∞, we get

$$\max_i |D_+ w_i^n| = \max_i |y_i^n| = \|y^n\|_{L^\infty} \leq \mathcal{O}(1)\,\|v^n\|_{l^2}\,. \tag{2.27}$$

Going back to (2.22), we have

$$\begin{aligned}\langle u_t^n, v^n\rangle_{l^2} &= \langle m_t^n, w^n\rangle_{l^2} = \langle -D_-(m^n u^n) - m^n D u^n, w^n\rangle_{l^2} \\ &= \langle m^n u^n, D_+ w^n\rangle_{l^2} - \langle m^n D u^n, w^n\rangle_{l^2}\,.\end{aligned}$$

Hence,

$$|\langle u_t^n, v^n\rangle_{l^2}| \leq \frac{1}{n}\left(\max_i |u_i^n| \max_i |D_+ w_i^n| + \max_i |D_+ u_i^n| \max_i |w_i^n|\right) \sum_{i=0}^{n-1} |m_i^n|\,.$$

The functions u_i^n and $D_+ u_i^n$ are uniformly bounded with respect to n and

$$\begin{aligned}\frac{1}{n}\sum_{i=0}^{n-1} |m_i^n| &= \frac{1}{n}\sum_{i=0}^{n-1} m_i^n \quad (m^n \text{ is positive}) \\ &= \frac{1}{n}\sum_{i=0}^{n-1} u_i^n \quad \left(\text{cancellation of } \textstyle\sum_{i=0}^{n-1} D_- D_+ u_i^n\right) \\ &\leq \mathcal{O}(1) \qquad (u_i^n \text{ is bounded}).\end{aligned}$$

Finally, using the bounds we have derived on w^n (see (2.24)) and D_+w^n (see (2.27)), we get

$$|\langle u_t^n, v^n\rangle_{l^2}| \leq \mathcal{O}(1)\,\|v^n\|_{l^2}\,.$$

Taking $v^n = u_t^n$ yields

$$\|u_t^n\|_{l^2} \leq \mathcal{O}(1),$$

which, since the l^2- and L^2-norms are uniformly equivalent, gives us a uniform bound on $\|u_t^n\|_{L^2}$. □

To prove the existence of a converging subsequence of u^n in $C([0,T],H^1)$ we recall the following compactness theorem given by Simon [21, Corollary 4].

THEOREM 2.4 (Simon [21]). *Let X, B, Y be three continuously embedded Banach spaces*

$$X \subset B \subset Y,$$

with the first inclusion, $X \subset B$, compact. We consider a set $\mathcal{F}$ of functions mapping $[0,T]$ into X. If $\mathcal{F}$ is bounded in $L^\infty([0,T],X)$ and $\frac{\partial \mathcal{F}}{\partial t} = \{\frac{\partial f}{\partial t} \mid f \in \mathcal{F}\}$ is bounded in $L^r([0,T],Y)$, where $r > 1$, then $\mathcal{F}$ is relatively compact in $C([0,T],B)$.

We now turn to the proof of our main theorem.

Proof of Theorem 2.1. (i) First we establish that there exists a subsequence of u^n that converges in $C([0,T],H^1)$ to an element $u \in H^1$. To apply Theorem 2.4, we have to determine the Banach spaces with the required properties. In our case, we take X as the set of functions of H^1 which have derivatives of bounded variation:

$$X = \left\{v \in H^1 \mid v_x \in \mathrm{B}V\right\}.$$

X endowed with the norm

$$\|v\|_X = \|v\|_{H^1} + \|v_x\|_{BV} = \|v\|_{H^1} + \|v_x\|_{L^\infty} + \mathrm{TV}(v_x)$$

is a Banach space. Let us prove that the injection $X \subset H^1$ is compact. We consider a sequence v_n which is bounded in X. Since $\|v_n\|_{L^\infty}$ is bounded ($H^1 \subset L^\infty$ continuously), there exists a point x_0 such that $v_n(x_0)$ is bounded and we can extract a subsequence (that we still denote v_n) such that $v_n(x_0)$ converges to some $l \in \mathbb{R}$. By Helly's theorem, we can also extract a subsequence such that

$$v_{n,x} \to w \quad \text{a.e.} \tag{2.28}$$

for some $w \in L^\infty$. By Lebesgue's dominated convergence theorem, it implies that $v_{n,x} \to w$ in L^2. We set

$$v(x) = l + \int_{x_0}^{x} w(s)\,ds.$$

We have that $v_x = w$ a.e. We also have

$$v_n(x) = v_n(x_0) + \int_{x_0}^{x} v_{n,x}(s)\,ds,$$

which together with (2.28) implies that v_n converges to v in L^∞. Therefore v_n converges to v in H^1 and X is compactly embedded in H^1.

The estimates we have derived previously give us that u^n and u_t^n are uniformly bounded in $L^\infty([0,T],X)$ and $L^\infty([0,T],L^2)$, respectively. Since $X \subset H^1 \subset L^2$ with the first inclusion compact, Simon's theorem gives us the existence of a subsequence of u^n that converges in $C([0,T],H^1)$ to some $u \in H^1$.

(ii) Next we show that the limit we get is a solution of the Camassa–Holm equation (1.2).

Let us now take φ in $C^\infty([0,1]\times[0,T])$ and multiply, for each i, the first equation in (2.4) by $h\varphi(x_i,t)$. We denote by φ^n the continuous piecewise linear function given by $\varphi^n(x_i,t)=\varphi(x_i,t)$. We sum over i and get, after one summation by parts,

$$\begin{aligned}\sum_{i=0}^{n-1} h\left(u_{i,t}^n - (D_-D_+u_i^n)_t\right)\varphi_i^n = &\underbrace{\sum_{i=0}^{n-1} h(u_i^n)^2 D_+\varphi_i}_{\text{A}} - \underbrace{\sum_{i=0}^{n-1} hu_i^n D_-D_+u_i^n D_+\varphi_i^n}_{\text{B}}\\ &\underbrace{-\sum_{i=0}^{n-1} hu_i^n Du_i^n\varphi_i^n}_{\text{C}} + \underbrace{\sum_{i=0}^{n-1} hD_-D_+u_i^n Du_i^n\varphi_i^n}_{\text{D}}.\end{aligned} \tag{2.29}$$

We are now going to prove that each term in this equality converges to the corresponding terms in (2.5).

Term A. We want to prove that

$$\left\langle (u^n)^2 D_+\varphi^n\right\rangle \to \int_0^1 u^2\varphi_x\,dx, \tag{2.30}$$

where we have introduced the notation

$$\langle u\rangle = h\sum_{i=0}^{n-1} u_i$$

to denote the average of a quantity u. We have

$$\begin{aligned}\left|\int_0^1 u^2\varphi_x\,dx - \left\langle (u^n)^2 D_+\varphi^n\right\rangle\right| \le &\left|\int_0^1 (u^2-(u^n)^2)\varphi_x\,dx\right|\\ &+\left|\int_0^1 (u^n)^2(\varphi_x - D_+\varphi^n)\,dx\right|\\ &+\left|\int_0^1 (u^n)^2 D_+\varphi^n\,dx - \left\langle (u^n)^2 D_+\varphi^n\right\rangle\right|.\end{aligned}$$

The first term tends to zero because $u^n \to u$ in L^2 for all $t\in[0,T]$. The second tends to zero by Lebesgue's dominated convergence theorem. It remains to prove that the last term tends to zero.

The integral of a product between two continuous piecewise linear function, v and w, and a piecewise constant function z can be computed explicitly. We skip the details of the calculation and directly give the result:

$$\int_0^1 zvw\,dx = \frac{1}{3}\langle zS_+vS_+w\rangle + \frac{1}{6}\langle zS_+vw\rangle + \frac{1}{6}\langle zvS_+w\rangle + \frac{1}{3}\langle zvw\rangle. \tag{2.31}$$

Here S_+ and S_- denote shift operators

$$(S_\pm u)_i = u_{i\pm 1}.$$

After using (2.31) with $v = w = u^n$ and $z = D_+\varphi^n$, we get

$$\int_0^1 (u^n)^2 D_+\varphi^n - \left\langle (u^n)^2 D_+\varphi^n \right\rangle = \frac{1}{3}\left\langle (S_+u^n - u^n) D_+\varphi^n u^n \right\rangle + \frac{1}{3}\left\langle (u^n)^2 D_+(S_-\varphi^n - \varphi^n)\right\rangle.$$

We use the uniform equivalence of the l^2- and L^2-norms to get the following estimate:

$$\begin{aligned}\left\langle (S_+u^n - u^n) D_+\varphi^n u^n \right\rangle &\le \|S_+u^n - u^n\|_{l^2}\, \|D_+\varphi^n u^n\|_{l^2} \quad \text{(Cauchy–Schwarz)}\\ &\le \mathcal{O}(1)\, \|u^n(\,\cdot + h) - u^n(\,\cdot\,)\|_{L^2}. \end{aligned} \tag{2.32}$$

Since $u_n \in H^1$, we have (see, for example, [1])

$$\|u^n(\,\cdot + h) - u^n(\,\cdot\,)\|_{L^2} \le h\, \|u_x^n\|_{L^2} \le \mathcal{O}(1)h$$

because $\|u_x^n\|_{L^\infty}$ is uniformly bounded. Hence $|\langle (S_+u^n - u^n) D_+\varphi^n u^n\rangle|$ tends to zero. The quantity $\left\langle (u^n)^2 D_+(S_-\varphi^n - \varphi^n)\right\rangle$ tends to zero because φ is C^∞ and u^n uniformly bounded. We have proved (2.30).

Term B. We want to prove

$$\langle u^n D_-D_+u^n D_+\varphi^n\rangle \to \frac{1}{2}\int_0^1 u^2\varphi_{xxx}\,dx - \int_0^1 u_x^2\varphi_x. \tag{2.33}$$

We rewrite $u^nD_-D_+u^n$ in such a way that the discrete double derivative D_-D_+ does not appear in a product (so that we can later sum by parts). We have

$$u^nD_-D_+u^n = \frac{1}{2}(D_-D_+((u^n)^2) - D_+u^nD_+u^n - D_-u^nD_-u^n).$$

We can prove in the same way as we did for term A that

$$\begin{aligned}\left\langle D_-D_+((u^n)^2) D_+\varphi^n\right\rangle &= \left\langle (u^n)^2 D_-D_+D_+\varphi^n\right\rangle \quad \text{(summation by parts)}\\ &\to \int_0^1 u^2\varphi_{xxx}\,dx.\end{aligned}$$

The quantity $(u_x^n)^2\varphi_x^n$ is a piecewise constant function. Therefore,

$$\int_0^1 (u_x^n)^2\varphi_x^n\,dx = \langle D_+u^nD_+u^nD_+\varphi^n\rangle.$$

Since $u_x^n \to$ in L^2 for all $t \in [0,T]$ and

$$\int_0^1 u_x^2\varphi_x\,dx - \langle D_+u^nD_+u^nD_+\varphi^n\rangle = \int_0^1 (u_x^2 - (u_x^n)^2)\varphi_x\,dx + \int_0^1 (u_x^n)^2(\varphi_x - \varphi_x^n)\,dx,$$

we have

$$\langle D_+u^nD_+u^nD_+\varphi^n\rangle \to \int_0^1 u_x^2\varphi_x\,dx.$$

In the same way, we get

$$\langle D_- u_i^n D_- u_i^n D_+ \varphi^n \rangle \to \int_0^1 u_x^2 \varphi_x$$

and (2.33) is proved.

Term C. We want to prove

$$\langle u^n D u^n \varphi^n \rangle \to \int_0^1 u u_x \varphi \, dx. \tag{2.34}$$

We have

$$\begin{aligned}\int_0^1 u u_x \varphi \, dx - \langle u^n D_+ u^n \varphi^n \rangle = &\int_0^1 (u - u^n) u_x \varphi \, dx + \int_0^1 u^n (u_x - u_x^n) \varphi \, dx \\ &+ \int_0^1 u^n u_x^n (\varphi - \varphi^n) \, dx + \int_0^1 u^n u_x^n \varphi^n \, dx \\ &- \langle u^n D_+ u^n \varphi^n \rangle .\end{aligned}$$

The first two terms converge to zero because $u^n \to u$ in H^1 for all $t \in [0, T]$. The third term converges to zero by Lebesgue's dominated convergence theorem. We use (2.31) to evaluate the last integral:

$$\begin{aligned}\int_0^1 u^n u_x^n \varphi^n \, dx = &\frac{1}{3} \langle D_+ u^n S_+ u^n S_+ \varphi^n \rangle + \frac{1}{6} \langle D_+ u^n S_+ u^n \varphi^n \rangle \\ &+ \frac{1}{6} \langle D_+ u^n u^n S_+ \varphi^n \rangle + \frac{1}{3} \langle D_+ u^n u^n \varphi^n \rangle .\end{aligned}$$

Using the same type of arguments as those we have just used for term A, we can show that

$$\int_0^1 u^n u_x^n \varphi^n \, dx \to \langle D_+ u^n u^n \varphi^n \rangle .$$

Thus, in order to prove (2.34), it remains to prove that

$$\langle D_+ u^n u^n \varphi^n \rangle - \langle D u^n u^n \varphi^n \rangle \to 0. \tag{2.35}$$

Since $D = \frac{1}{2}(D_+ + D_-)$, we have

$$\langle D_+ u^n u^n \varphi^n \rangle - \langle D u^n u^n \varphi^n \rangle = \frac{1}{2} \langle (D_+ u^n - D_- u^n) u^n \varphi^n \rangle$$

and

$$\begin{aligned}|\langle (D_+ u^n - D_- u^n) u^n \varphi^n \rangle| &\le C \sum_{i=0}^{n-1} h \left| D_+ u_i^n - D_+ u_{i-1}^n \right| \\ &\le \mathcal{O}(1) \int_0^1 |u_x^n(x) - u_x^n(x-h)| \, dx \\ &\le \mathcal{O}(1) h \ \mathrm{TV}(u_x^n).\end{aligned}$$

Since $\mathrm{TV}(u_x^n)$ is uniformly bounded, (2.35) holds and we have proved (2.34).

Term D. We want to prove that

$$\langle D_- D_+ u^n D u^n \varphi^n \rangle \to -\frac{1}{2} \int_0^1 u_x^2 \varphi_x \, dx. \tag{2.36}$$

We have

$$\frac{1}{2} \int_0^1 u_x^2 \varphi_x \, dx + \langle D_- D_+ u^n D u^n \varphi^n \rangle \tag{2.37}$$

$$= \frac{1}{2} \int_0^1 (u_x^2 - (u_x^n)^2) \varphi_x \, dx + \frac{1}{2} \int_0^1 (u_x^n)^2 (\varphi_x - D_- \varphi^n) \, dx \tag{2.38}$$

$$- \frac{1}{2} \langle D_+ (D_+ u^n D_+ u^n) \varphi^n \rangle + \langle D_- D_+ u^n D u^n \varphi^n \rangle . \tag{2.39}$$

The two first terms on the right-hand side tend to zero. After using the identity

$$D_+ (D_+ u^n D_+ u^n) = D_+ D_+ u^n D_+ u^n + D_+ D_+ u^n D_+ S_+ u^n,$$

we can rewrite the two last terms in (2.37) as

$$\begin{aligned}
&-\frac{1}{2} \langle D_+ (D_+ u^n D_+ u^n) \varphi^n \rangle + \langle D_- D_+ u^n D u^n \varphi^n \rangle \\
&\quad = -\frac{1}{2} \langle D_- D_+ S_+ u^n D_+ u^n \varphi^n \rangle - \frac{1}{2} \langle D_- D_+ S_+ u^n D_+ S_+ u^n \varphi^n \rangle \\
&\qquad + \frac{1}{2} \langle D_- D_+ u^n D_+ S_- u^n \varphi^n \rangle + \frac{1}{2} \langle D_- D_+ u^n D_+ u^n \varphi^n \rangle \\
&\quad = \frac{1}{2} \langle D_- D_+ u^n D_- u^n (\varphi^n - S_- \varphi^n) \rangle + \frac{1}{2} \langle D_- D_+ u^n D_+ u^n (\varphi^n - S_- \varphi^n) \rangle ,
\end{aligned}$$

which tends to zero because, as we have seen before, due to the positivity of m, $\langle |D_- D_+ u_i^n D_+ u_i^n| \rangle$ is uniformly bounded. We have proved (2.36).

Up to now we have not really considered the time variable. We integrate (2.29) with respect to time and integrate by parts the left-hand side:

$$\begin{aligned}
\int_0^T \sum_{i=0}^{n-1} h \left(u_{i,t}^n - D_- D_+ u_{i,t}^n \right) \varphi(x_i, t) \, dt = &- \int_0^T \sum_{i=0}^{n-1} h \left(u_i^n - D_- D_+ u_i^n \right) \varphi_t(x_i, t) \, dt \\
&+ \left[\sum_{i=0}^{n-1} h \left(u_i^n - D_- D_+ u_i^n \right) \varphi(x_i, t) \right]_{t=0}^{t=T};
\end{aligned}$$

after summing by parts, the limit of this expression is (we use Lebesgue's dominated convergence theorem with respect to x and t)

$$- \int_0^T \int_0^1 u(\varphi_t - \varphi_{txx}) \, dx dt + \left[\int_0^1 u(\varphi - \varphi_{xx}) \, dx \right]_{t=0}^{t=T}.$$

It is not hard to see that the right-hand side of (2.29) is uniformly bounded by a constant, and we can integrate over time and use the Lebesgue dominated convergence theorem to conclude that u is indeed a solution of (2.5) in the sense of distribution.

The analysis in [11] shows that the weak solution of the Camassa–Holm equation with initial conditions satisfying $m(x, 0) \geq 0$ is unique. This implies that in our

algorithm not only a subsequence but the whole sequence u^n converges to the solution. However, in [11], a solution of the Camassa–Holm equation is defined as an element u of H^1 satisfying

$$u_t + uu_x + \left[\int_{-\infty}^{\infty} p(x-y)[u^2(y,t) + \frac{1}{2}u_x^2(y,t)]\,dy\right]_x = 0, \tag{2.40}$$

where p is the solution of

$$\mathcal{A}p \equiv (I - \partial_x^2)p = \delta.$$

We want to prove that weak solutions of (2.40) and (2.5) are the same. Periodic distributions belong to the class of tempered distribution $\mathcal{S}'$ (see, for example, [13]). The operator $\mathcal{A}$ defines a homeomorphism on the Schwartz class $\mathcal{S}$ (or class of rapidly decreasing function): The Fourier transform is a homeomorphism on $\mathcal{S}$, and $\mathcal{A}$ restricted to $\mathcal{S}$ can be written as

$$\mathcal{A} = \mathcal{F}^{-1}(1+\xi^2)\mathcal{F}, \tag{2.41}$$

where ξ denotes the frequency variable. It is clear from (2.41) that the inverse of $\mathcal{A}$ in $\mathcal{S}$ is

$$\mathcal{A}^{-1} = \mathcal{F}^{-1}\frac{1}{1+\xi^2}\mathcal{F}.$$

Hence $\mathcal{A}$ is a homeomorphism on $\mathcal{S}$.

We can now define the inverse $\mathcal{A}^{-1}$ of $\mathcal{A}$ in $\mathcal{S}'$. Given T in $\mathcal{S}'$, $\mathcal{A}^{-1}T$ is given by

$$\left\langle \mathcal{A}^{-1}T, \phi \right\rangle = \left\langle T, \mathcal{A}^{-1}\phi \right\rangle, \quad \phi \in \mathcal{S}.$$

It is easy to check that $\mathcal{A}^{-1}$ indeed satisfies

$$\mathcal{A}^{-1}\mathcal{A} = \mathcal{A}\mathcal{A}^{-1} = \mathrm{Id},$$

and that $\mathcal{A}^{-1}$ is continuous on $\mathcal{S}'$. The operator $\mathcal{A}$ is therefore a homeomorphism on $\mathcal{S}'$.

Let u be a solution of (2.40). Then we have

$$u_t + \partial_x\left(\frac{u^2}{2}\right) + \partial_x\mathcal{A}^{-1}\left[u^2 + \frac{1}{2}u_x^2\right] = 0. \tag{2.42}$$

The operators ∂_x and $\mathcal{A}^{-1}$ commute because ∂_x and $\mathcal{A}$ commute. We apply $\mathcal{A}$ on both sides of (2.42) and get

$$u_t - u_{xxt} + \mathcal{A}\partial_x\left(\frac{1}{2}u^2\right) + \partial_x\left[u^2 + \frac{1}{2}u_x^2\right] = 0, \tag{2.43}$$

which is exactly (2.5). Since $\mathcal{A}$ is a bijection, (2.43) also implies (2.42), and we have proved that the weak solutions of (2.5) are the same as the weak solutions given by (2.40). □

In Theorem 2.1, some restrictions on the initial data v are implicitly imposed by the condition $v^n - D_-D_+v^n \geq 0$. We are going to prove that if $v \in H^1([0,1])$ is periodic with $v - v_{xx} \in \mathcal{M}^+$, where $\mathcal{M}^+$ denotes the space of positive Radon measures, then there exists a sequence of piecewise linear, continuous, periodic functions v^n that converges to v in H^1 and satisfies $v^n - D_-D_+v^n \geq 0$ for all n.

We can then apply Theorem 2.1 and get the existence result contained in the following corollary, which coincides with results obtained in [11] by a different method.

COROLLARY 2.5. *If $u_0 \in H^1$ is such that $u_0 - u_{0,xx} \in \mathcal{M}^+$, then the Camassa–Holm equation has a global solution in $C(\mathbb{R}_+, H^1)$. The solution is obtained as a limit of the numerical scheme defined by* (2.4).

To apply Theorem 2.1, we need to prove that, given $u \in H^1([0,1])$ such that $u - u_{xx} \in \mathcal{M}^+$, there exists a sequence u^n of piecewise linear, continuous, and periodic functions such that

$$u^n \to u \text{ in } H^1,$$
$$u^n - D_- D_+ u^n \geq 0.$$

Let $\{\psi_i^n\}$ be a partition of unity associated with the covering $\cup_{i=0}^{n-1}(x_{i-1}, x_{i+1})$. For all $i \in \{0, \dots, n-1\}$, the functions ψ_i^n are nonnegative with supp $\psi_i^n \subset (x_{i-1}, x_{i+1})$, and $\sum_{i=0}^{n-1} \psi_i^n = 1$. Define

$$v_i^n = \frac{1}{h} \langle u - u_{xx}, \psi_i^n \rangle$$

and

$$u_i^n - D_- D_+ u_i^n = v_i^n. \tag{2.44}$$

Recall that the operator $u^n - D_- D_+ u^n$ is invertible (see (2.8)), so that u^n is well defined by (2.44). Since $u - u_{xx}$ belongs to $\mathcal{M}^+$ and $\psi_i^n \geq 0$, we have $v_i^n = u_i^n - D_- D_+ u_i^n \geq 0$, and it only remains to prove that u^n converges to u in H^1. Since the application $\mathcal{L} : H^1 \to H^{-1}$ given by $\mathcal{L}u = u - u_{xx}$ is an homeomorphism, it is equivalent to prove that

$$u^n - u_{xx}^n \to u - u_{xx} \text{ in } H^{-1}.$$

The homeomorphism $\mathcal{L}$ is also an isometry, so that

$$\|\mathcal{L}u\|_{H^{-1}} = \|u\|_{H^1}.$$

We can find a bound on $\|u^n\|_{H^1}$. Let E_n be defined, as before, by

$$E_n = \left(h \sum_{i=0}^{n-1} \left[(u_i^n)^2 + (D_+ u^n)_i^2 \right] \right)^{\frac{1}{2}}.$$

Inequality (2.16) still holds. We have

$$\begin{aligned}
E_n^2 &= h \sum_{i=0}^{n-1} (u_i^n - D_- D_+ u_i^n) u_i^n \\
&= h \sum_{i=0}^{n-1} v_i^n u_i^n \\
&\leq \|u^n\|_{L^\infty} \sum_{i=0}^{n-1} h v_i^n \\
&\leq \|u^n\|_{L^\infty} \left\langle u - u_{xx}, \sum_{i=0}^{n-1} \psi_i^n \right\rangle \\
&\leq \|u^n\|_{L^\infty} \|u - u_{xx}\|_{\mathcal{M}^+} \quad \left(\text{since } \textstyle\sum_{i=0}^{n-1} \psi_i^n = 1\right).
\end{aligned}$$

Hence, since L^∞ is continuously embedded in H^1, there exists a constant C (independent of n) such that

$$E_n^2 \le C \|u^n\|_{H^1} \|u - u_{xx}\|_{\mathcal{M}^+}.$$

We use (2.16) to get the bound on $\|u^n\|_{H^1}$ we were looking for:

$$\|u^n\|_{H^1} \le 4C \|u - u_{xx}\|_{\mathcal{M}^+}.$$

To prove that $u^n - u^n_{xx} \to u - u_{xx}$ in H^{-1}, since $\|u^n - u^n_{xx}\|_{H^{-1}} = \|u^n\|_{H^1}$ is uniformly bounded, we just need to prove that

$$\langle u^n - u^n_{xx}, \varphi \rangle \to \langle u - u_{xx}, \varphi \rangle$$

for all φ belonging to a dense subset of H^1 (for example, C^∞).

The function u^n is continuous and piecewise linear. Its second derivative u^n_{xx} is therefore a sum of Dirac functions,

$$u^n_{xx} = \sum_{i=0}^{n-1} h D_- D_+ u_i^n \delta_{x_i},$$

and, for any φ in C^∞, we have

$$\begin{aligned}
\langle u^n - u^n_{xx}, \varphi \rangle &= \int_0^1 u^n(x)\varphi(x)\,dx - h\sum_{i=0}^{n-1} D_- D_+ u_i^n \varphi(x_i) \\
&= \int_0^1 u^n(x)(\varphi(x) - \varphi^n(x))\,dx + \int_0^1 u^n(x)\varphi^n(x)\,dx \\
&\quad - h\sum_{i=0}^{n-1} u_i^n \varphi_i^n + h\sum_{i=0}^{n-1} v_i \varphi_i^n,
\end{aligned} \tag{2.45}$$

where φ^n denotes the piecewise linear, continuous function that coincides with φ on x_i, $i = 0, \dots, n-1$.

The first integral in (2.45) tends to zero by the Lebesgue dominated convergence theorem. We use (2.31) to compute the second integral:

$$\int_0^1 u^n(x)\varphi^n(x)\,dx = \frac{2}{3}\langle u^n \varphi^n \rangle + \frac{1}{6}\langle S_+ u^n \varphi^n \rangle + \frac{1}{6}\langle u^n S^+ \varphi^n \rangle.$$

One can prove that this term tends to $\langle u^n \varphi^n \rangle$ (see the proof of the convergence of term A in the proof of Theorem 2.1). The last sum equals

$$\sum_{i=0}^{n-1} h v_i^n \varphi(x_i) = \left\langle u - u_{xx}, \sum_{i=0}^{n-1} \varphi_i^n \psi_i^n(x) \right\rangle.$$

For all $x \in [0,1]$, there exists a k such that $x \in [x_k, x_{k+1}]$. Then

$$\begin{aligned}
\left| \varphi(x) - \sum_{i=0}^{n-1} \varphi_i^n \psi_i^n(x) \right| &= \left| \sum_{i=0}^{n-1} (\varphi(x) - \varphi(x_i)) \psi_i^n(x) \right| \\
&\le |\varphi(x) - \varphi(x_k)| + |\varphi(x) - \varphi(x_{k+1})| \\
&\le 2 \sup_{|z-y| \le h} |\varphi(y) - \varphi(z)|
\end{aligned}$$

and therefore, by the uniform continuity of φ,

$$\sum_{i=0}^{n-1} \varphi(x_i)\psi_i^n(x) \to \varphi(x) \text{ in } L^\infty.$$

Thus,

$$\sum_{i=0}^{n-1} hv_i^n \varphi(x_i) = \left\langle u - u_{xx}, \sum_{i=0}^{n-1} \varphi(x_i)\psi_i^n \right\rangle \to \langle u - u_{xx}, \varphi \rangle$$

and, from (2.45), we get

$$\langle u^n - u_{xx}^n, \varphi \rangle \to \langle u - u_{xx}, \varphi \rangle .$$

As already explained, this implies that

$$u^n \to u \text{ in } H^1.$$

3. Numerical results. The numerical scheme (2.4) is semidiscrete: The time derivative has not been discretized, and hence we work with a system of ordinary differential equations. However, for numerical computations we integrate in time by using an explicit Euler method. Given a positive time T and $l \in \mathbb{N}$, we consider the time step $\Delta t = T/l$. We compute $m_j^{n,l}$, the approximate value of m^n at time $t_j = j\Delta t$, by taking

$$m_{j+1}^{n,l} = m_j^{n,l} + \Delta t \left(-D_-(m_j^{n,l} u_j^{n,l}) - m_j^{n,l} D u_j^{n,l} \right), \tag{3.1}$$

where

$$m_j^{n,l} = u_j^{n,l} - D_- D_+ u_j^{n,l}. \tag{3.2}$$

Here $m_j^{n,l} = (m_{0,j}^{n,l}, \dots, m_{n-1,j}^{n,l})$ and $u_j^{n,l} = (u_{0,j}^{n,l}, \dots, u_{n-1,j}^{n,l})$. Given $m_j^{n,l}$, one can still recompute $u_j^{n,l}$ using (2.8), that is,

$$u_{i,j}^{n,l} = L^{-1} m_{i,j}^{n,l} = \frac{c}{1 - e^{-\kappa n}} \sum_{k=0}^{n-1} (e^{-\kappa(i-k)} + e^{\kappa(i-k-n)}) m_{k,j}^{n,l}. \tag{3.3}$$

Lemma 2.2 does not apply in this setting, and the proof of convergence for the fully discrete scheme proceeds differently. Writing (2.4) as

$$m_t^n = f(m^n),$$

where $f\colon \mathbb{R}^n \to \mathbb{R}^n$, we observe (cf. (2.4) and (2.8)) that each component of $f(x)$ is a polynomial in the components $x_0, \dots, x_{n-1}$ of x. Hence, f is continuously differentiable. From (2.19) and (2.4), we obtain that when n is large enough, there exists a constant C which is independent of n such that

$$|m_i^n(t)| \le 5n^2 \max_i |u_i^n(t)| \le Cn^2$$

for all $t \in [0, T]$. Hence, $m^n(t)$ is bounded in $[0, T]$ and therefore the Euler method converges (see, for example, [19]), that is,

$$\lim_{l \to \infty} \max_{j=1,\dots,l} \left\| m_j^{n,l} - m^n(t_j) \right\| = 0. \tag{3.4}$$

All norms are equivalent in finite-dimensional vector spaces, and therefore (3.4) holds for any norm in $\mathbb{R}^n$. We denote by $m^{n,l}(t)$ the piecewise linear function in $C([0,T],\mathbb{R}^n)$ satisfying $m^{n,l}(t_j) = m_j^{n,l}$. It is given by

$$m^{n,l}(t) = \frac{1}{\Delta t}(t_{j+1} - t)m_j^{n,l} + \frac{1}{\Delta t}(t - t_j)m_{j+1}^{n,l}$$

for $t \in [t_j, t_{j+1}]$. Let us prove that

$$\lim_{l\to\infty} \left\|m^{n,l} - m^n\right\|_{C([0,T],\mathbb{R}^n)} = 0. \tag{3.5}$$

We have, for $t \in [t_j, t_{j+1}]$,

(3.6)

$$\begin{aligned} m^{n,l}(t) - m^n(t) = {} & \frac{1}{\Delta t}(t_{j+1} - t)(m_j^{n,l} - m^n(t_j)) + \frac{1}{\Delta t}(t - t_j)(m_{j+1}^{n,l} - m^n(t_{j+1})) \\ & + \frac{1}{\Delta t}(t_{j+1} - t)(m^n(t_j) - m^n(t)) + \frac{1}{\Delta t}(t - t_j)(m^n(t_{j+1}) - m^n(t)). \end{aligned}$$

Let $\varepsilon > 0$. Since $m^n \in C([0,T],\mathbb{R}^n)$, m^n is uniformly continuous, and there exists $\delta > 0$ such that $\|m^n(t_1) - m^n(t_2)\| < \varepsilon/2$ for all $t_1, t_2 \in [0,T]$ with $|t_2 - t_1| < \delta$. We can choose l large enough so that $\Delta t = T/l < \delta$. Then, for $t \in [t_j, t_{j+1}]$, we have $t - t_j < \delta$ and $t_{j+1} - t < \delta$, and

$$\begin{aligned} & \left\| \frac{1}{\Delta t}(t_{j+1} - t)(m^n(t_j) - m^n(t)) + \frac{1}{\Delta t}(t - t_j)(m^n(t_{j+1}) - m^n(t_{j+1})) \right\| \\ & \qquad < \frac{1}{\Delta t}(t_{j+1} - t)\frac{\varepsilon}{2} + \frac{1}{\Delta t}(t - t_j)\frac{\varepsilon}{2} \\ & \qquad < \frac{\varepsilon}{2}. \end{aligned} \tag{3.7}$$

By (3.4), we can choose l large enough so that $\max_{j=1,\dots,l} \|m_j^{n,l} - m^n(t_j)\| < \varepsilon/2$. Hence,

$$\left\| \frac{1}{\Delta t}(t_{j+1} - t)(m_j^{n,l} - m^n(t_j)) + \frac{1}{\Delta t}(t - t_j)(m_{j+1}^{n,l} - m^n(t_{j+1})) \right\| < \frac{\varepsilon}{2}. \tag{3.8}$$

Comparing (3.6), (3.7), and (3.8), we obtain

$$\left\|m^{n,l}(t) - m^n(t)\right\| < \varepsilon$$

for l large enough and any $t \in [0,T]$. Hence, (3.5) is proved. The mapping $L^{-1}\colon \mathbb{R}^n \to \mathbb{R}^n$, $L^{-1}m^n = u^n$, is continuous, and therefore we have $\lim_{l\to\infty} \left\|u^{n,l} - u^n\right\|_{C([0,T],\mathbb{R}^n)} = 0$. Finally, after using the identification of $\mathbb{R}^n$ with the set of continuous, periodic, piecewise linear functions, we get that

$$\lim_{l\to\infty} u^{n,l} = u^n,$$

and, from Theorem 2.1,

$$\lim_{n\to\infty} \lim_{l\to\infty} u^{n,l} = u$$

in $C([0,T],H^1)$. We summarize the result in the following theorem.

THEOREM 3.1. *Let $\Delta t = T/l$, and define the function $u_{i,j}^{n,l}$ by (3.1)–(3.3). Define the corresponding interpolating function $u^{n,l}$ in $C([0,T],H^1)$ by*

$$u^{n,l}(x,t) = \frac{n}{\Delta t}\Big((t_{j+1}-t)\big[(x_{i+1}-x)u_{i,j}^{n,l} + (x-x_i)u_{i+1,j}^{n,l}\big] + (t-t_j)\big[(x_{i+1}-x)u_{i,j+1}^{n,l} + (x-x_i)u_{i+1,j+1}^{n,l}\big]\Big)$$

for $x \in [x_i, x_{i+1}]$ and $t \in [t_j, t_{j+1}]$. Then

$$\lim_{n\to\infty}\lim_{l\to\infty} u^{n,l} = u \tag{3.9}$$

in $C([0,T],H^1)$, where u is the solution of the Camassa–Holm equation (1.2).

To compute the discrete spatial derivative, we need at each step to compute u from m. The function u is given by a discrete convolution product,

$$u_i = h\sum_{j=0}^{n-1} g_{i-j}^p m_j.$$

It is advantageous to apply the fast Fourier transform (FFT); see [13]. In the frequency space, a convolution product becomes a multiplication which is cheap to evaluate. Going back and forth to the frequency space is not very expensive due to the efficiency of the FFT. We use a formula of the form (see [13] for more details):

$$u = \mathcal{F}_N^{-1}(\mathcal{F}_N[g]\cdot\mathcal{F}_N[m]),$$

where $\mathcal{F}_N$ denotes the FFT.

We have tested algorithm (3.1) with single and double peakons. In the single peakon case, the initial condition is given by

$$u(x,0) = c\frac{\cosh(d-\frac{a}{2})}{\sinh\frac{a}{2}}, \tag{3.10}$$

which is the periodized version of $u(x,0) = ce^{-|x|}$. The period is denoted by a, and $d = \min(x, a-x)$ is the distance from x to the boundary of the interval $[0,a]$. The peakons travel at a speed equal to their height, that is,

$$u(x,t) = ce^{-|x-ct|}.$$

If u satisfies the initial condition $u(x,0) = e^{-|x|}$, then $m = 2\delta$ at $t = 0$ and we take

$$m_i(0) = \begin{cases} \frac{2}{h} & \text{if } i = 0, \\ 0 & \text{otherwise} \end{cases} \tag{3.11}$$

as the initial discrete condition. The function m_i gives a discrete approximation of 2δ. Figure 1 shows the result of the computation for different refinements. Figure 2 indicates that the computed solution converges to the exact solution.

The sharp increase of the error $\|u(t) - u^n(t)\|_{H^1}$ at time $t = 0$ can be predicted by looking at (2.17), which gives a first-order approximation of the time derivative of $\|u(t)\|_{H^1}^2$:

$$\frac{dE_n(t)^2}{dt} = -\sum_{i=0}^{n-1} u_i(hm_i)^2 + \mathcal{O}(h).$$

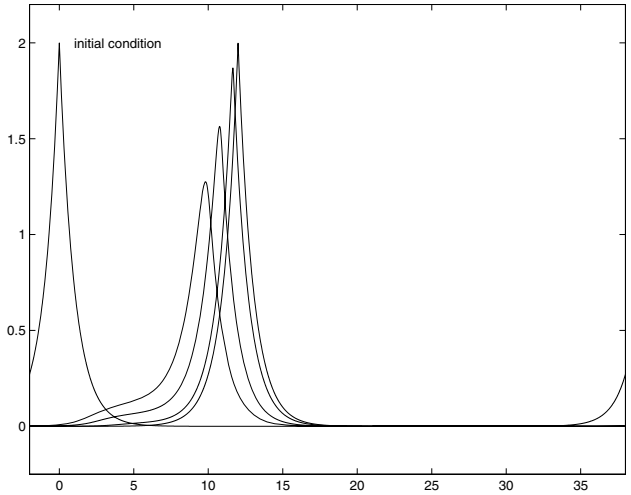

FIG. 1. *Periodic single peakon. The initial condition is given by* $u(x,0) = 2e^{-|x|}$ *and period* $a = 40$. *The computed solutions are shown at time* $t = 6$ *for* (*from left to right*) $n = 2^{10}$, $n = 2^{12}$, $n = 2^{14}$ *together with the exact solution* (*at the far right*).

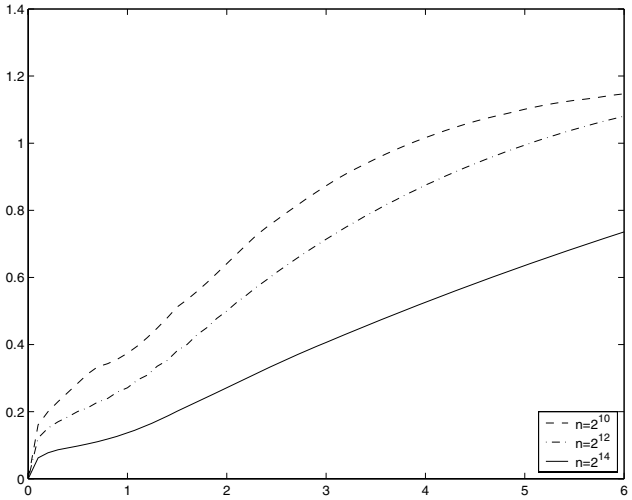

FIG. 2. *Plot of* $\|u(t) - u^n(t)\|_{H^1} / \|u(t)\|_{H^1}$ *in the one peakon case of Figure* 1.

Hence,

$$\frac{d\,\|u\|_{H^1}^2}{dt} \approx \frac{dE_n(t)^2}{dt} \approx -4 \quad \text{at } t = 0.$$

At the beginning of the computation, we can therefore expect a sharp decrease of the H^1-norm. To get convergence in H^1, it is therefore necessary that the solution becomes smooth enough so that $\frac{d\|u\|_{H^1}^2}{dt} \to 0$. In any case, we cannot hope for high accuracy and convergence rate in this case. Figures 3 and 4 show the same plots in the two-peakon case.

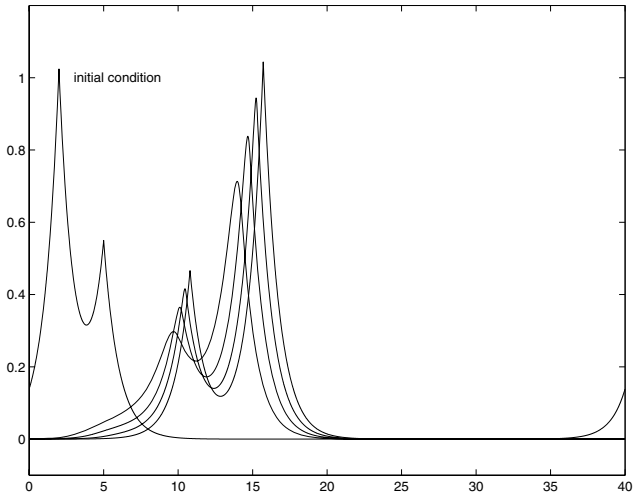

FIG. 3. *Two peakon case. The initial condition is the periodized version of* $2e^{-|x-2|} + e^{-|x-5|}$. *The computed solutions are shown at time* $t = 12$ *for* (*from left to right*) $n = 2^{10},\ n = 2^{12},\ n = 2^{14}$ *together with the exact solution* (*at the far right*).

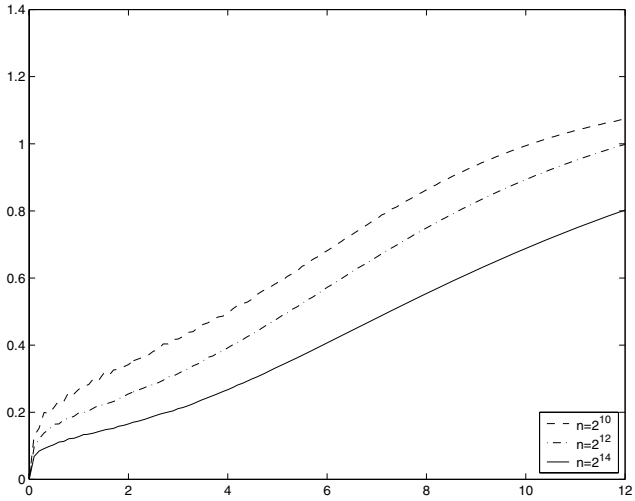

FIG. 4. *Plot of* $\|u(t) - u^n(t)\|_{H^1} / \|u(t)\|_{H^1}$ *in the two peakon case of Figure* 3.

We have tested our algorithm with smooth initial conditions. In this case, the H^1-norm remains constant in a much more accurate manner. The convergence is probably much better than for nonsmooth solutions, but we have no analytical solution with which to compare.

Other time integration methods (second-order Runge–Kutta method, variable-order Adams–Bashforth–Moulton) have also been tried and the results do not differ significantly from those given by (3.1). It follows that the Camassa–Holm equation is not very sensitive to the way time is discretized. But the situation is completely

different when we consider different space discretizations. The schemes

$$m_t = -D_-(mu)_i - m_i D_+ u_i, \tag{3.12}$$

$$m_t = -D(mu)_i - m_i D u_i, \tag{3.13}$$

$$m_t = -D_+(mu)_i - m_i D_- u_i \tag{3.14}$$

are all at first glance good candidates for solving the Camassa–Holm equation. They preserve the H^1-norm, are finite difference approximations of (2.2), and finally look very similar to (2.4). But, tested on a single peakon, (3.12) produces a peakon that grows, (3.13) produces oscillations, and (3.14) behaves in a completely unexpected manner (at the first time step, m becomes a negative Dirac function and starts traveling backward!).

Let us have a closer look at the scheme (3.12). We compute $\frac{dE_n^2}{dt}$:

$$\frac{1}{2}\frac{dE_n^2}{dt} = \sum_{i=0}^{n-1} m_{i,t}^n u_i^n = \sum_{i=0}^{n-1} \big(- D_-(m^n u^n)_i u_i - m_i^n D_+ u_i u_i \big) = 0.$$

Thus, E_n is exactly preserved. Lemma 2.2 still holds since the same proof applies to (3.12). It allows us to derive the bounds of Lemma 2.3 and, after applying Simon's theorem, we get the existence of a converging subsequence. The problem is that, in general, this subsequence *does not* converge to the solution of the Camassa–Holm equation. In order to see that, we compare how our original algorithm (3.12) and algorithm (3.13) handle a peakon solution $u = ce^{-|x-ct|}$. The only terms that differ are $m^n Du^n$ and $m^n D_+ u^n$. We have proved earlier that for any smooth function φ,

$$\sum_{i=0}^{n-1} m_i^n Du_i^n \varphi(x_i) \to \frac{1}{2}\int_0^1 (u^2 - u_x^2)\varphi(x)\,dx$$

as $n \to \infty$. In the peakon case, $u^2 = u_x^2$ and this term tends to zero. Roughly speaking, we can say that m^n converges to a Dirac function (see (3.11)), but at the same time it is multiplied by Du^n, which is the average of the left and right derivatives and which tends to zero at the top of the peak. Eventually the whole product $m^n Du^n$ tends to zero. We follow the same heuristic approach with the term $m^n D_+ u^n$ in (3.13). This time, m^n is multiplied by the right derivative $D_+ u^n$ of u^n, which tends, at the top of the peak, to $-c$. Hence, $-m^n D_+ u^n$ tends to $c\delta$ and not zero, as it would if (3.13) converged to the correct solution. This example shows how sensitive the numerical approximation is, regarding the explicit form of the finite difference scheme, for the Camassa–Holm equation.

Acknowledgments. H. H. acknowledges helpful discussions with Nils Henrik Risebro and Kenneth H. Karlsen on discretizations of the Camassa–Holm equation.

POSTPROCESSING THE FINITE ELEMENT METHOD FOR SEMILINEAR PARABOLIC PROBLEMS*

YUBIN YAN†

Abstract. In this paper we consider postprocessing of the finite element method for semilinear parabolic problems. The postprocessing amounts to solving a linear elliptic problem on a finer grid (or higher-order space) once the time integration on the coarser mesh is completed. The convergence rate is increased at almost no additional computational cost. This procedure was introduced and analyzed in García-Archilla and Titi [*SIAM J. Numer. Anal.*, 37 (2000), pp. 470–499]. We extend the analysis to the fully discrete case and prove error estimates for both space and time discretization. The analysis is based on error estimates for the approximation of time derivatives by difference quotients.

1. Introduction.

In this paper we shall consider postprocessing of the finite element method for the semilinear parabolic problem

$$u_t - \Delta u = F(u) \quad \text{in}\,\Omega \quad \text{for}\ t \in (0,T], \tag{1.1}$$

$$u = 0 \quad \text{on}\ \partial\Omega \quad \text{for}\ t \in (0,T], \quad \text{with}\, u(0) = v,$$

where Ω is a bounded domain in $\mathbf{R}^d$, $d = 1, 2, 3$, with a sufficiently smooth boundary $\partial\Omega$, $u_t = \partial u/\partial t$, Δ is the Laplacian, and $F : \mathbf{R} \to \mathbf{R}$ is a smooth function.

Let $H = L_2(\Omega)$. We define the unbounded operator $A = -\Delta$ on H with domain of definition $\mathcal{D}(A) = H^2 \cap H_0^1$, where, for integer $m \geq 1$, $H^m = H^m(\Omega)$ denotes the standard Sobolev space $W_2^m(\Omega)$, and $H_0^1 = H_0^1(\Omega) = \{v \in H^1 : v|_{\partial\Omega} = 0\}$. Then A is a closed, densely defined, and self-adjoint positive definite operator in H with compact inverse. The initial-boundary value problem (1.1) may then be formulated as the following initial value problem:

$$u_t + Au = F(u) \quad \text{for}\ 0 < t \leq T, \quad \text{with}\, u(0) = v, \tag{1.2}$$

in the Hilbert space H, where $F : H \to H$ is a nonlinear operator, and $v \in H$.

Recently, a postprocessing technique was introduced to increase the efficiency of the Galerkin method of spectral type; see Canuto et al. [5], de Frutos, García-Archilla, and Novo [7], and de Frutos and Novo [8], [10]. Postprocessed methods yield greater accuracy than standard Galerkin schemes at nearly the same computational cost. In García-Archilla and Titi [14], the postprocessing technique was extended to the h-version of the finite element method for dissipative partial differential equations. There, the authors prove that the postprocessed method has a higher rate of convergence than the standard finite element method when higher-order finite elements,

rather than linear finite elements, are used. Error estimates in L_2 and H^1 norms in the spatially semidiscrete case are obtained. More recently, in de Frutos and Novo [9], the authors show that the postprocessing technique can also be applied to linear finite elements and the convergence rate can be improved in the H^1 norm, but not in the L_2 norm. The analysis is restricted to the spatially semidiscrete case.

The purpose of the present paper is to derive the error estimates in the fully discrete case for the postprocessed finite element method applied to (1.2). To do this, we introduce the time-stepping method to compute the discrete solution of (1.2) and define a difference quotient approximation to the time derivative. We then define the postprocessing step in the fully discrete case and show the error estimates for the postprocessing method by using the error estimates for time derivatives. For simplicity we consider error estimates only in the L_2 norm. Our technique of proof is related to, but different from, the one employed by García-Archilla and Titi [14]. Our technique is applicable to both semidiscrete and fully discrete cases. However, we should point out that García-Archilla and Titi [14] also treat a nonlinear convection term. It is not quite clear how it is possible to generalize our method to deal with a nonlinear convection term.

The paper is organized as follows. In section 2, we introduce some basic notation and lemmas. In section 3 we consider error estimates for the postprocessed finite element method in the semidiscrete case. In section 4, we consider error estimates in the fully discrete case. In section 5, we consider the starting approximation of time derivatives. Finally, in section 6, we consider higher-order time-stepping in the context of the linear homogeneous problem.

By C_0 we denote positive constant independent of the functions and parameters concerned, but not necessarily the same at different occurrences.

2. Preliminaries. Let $\mathcal{T}$ denote a partition of Ω into disjoint triangles τ such that no vertex of any triangle lies on the interior of a side of another triangle and such that the union of the triangles determines a polygonal domain $\Omega_h \subset \Omega$ with boundary vertices on $\partial\Omega$. Let h denote the maximal length of the sides of the triangulation $\mathcal{T}_h$. We assume that the triangulations are quasi-uniform in the sense that the triangles of $\mathcal{T}_h$ are of essentially the same size.

Let r be any nonnegative integer. We denote by $\|\cdot\|_r$ the norm in H^r. Let $\{S_h\} = \{S_{h,r}\} \subset H_0^1$ be a family of finite element spaces with accuracy of order $r \geq 2$, i.e., S_h consists of continuous functions on the closure $\bar{\Omega}$ of Ω which are polynomials of degree at most $r-1$ in each triangle of $\mathcal{T}_h$ and which vanish outside Ω_h, such that, for small h,

$$\inf_{\chi \in S_h} \{\|v-\chi\| + h\|\nabla(v-\chi)\|\} \leq Ch^s\|v\|_s \quad \text{for } 1 \leq s \leq r,$$

when $v \in H^s \cap H_0^1$.

The semidiscrete problem of (1.2) is to find the approximate solution $u_h(t) = u_h(\cdot,t) \in S_h$ for each t, such that

$$u_{h,t} + A_h u_h = P_h F(u_h), \quad \text{with } u_h(0) = v_h, \tag{2.1}$$

where $v_h \in S_h$, $P_h : L_2 \to S_h$ is the L_2 projection onto S_h, and $A_h : S_h \to S_h$ is the discrete analogue of A, defined by

$$(A_h\psi, \chi) = A(\psi, \chi) \quad \forall\, \psi, \chi \in S_h. \tag{2.2}$$

Here $A(\cdot,\cdot) = (\nabla\cdot, \nabla\cdot)$ is the bilinear form on H_0^1 obtained from A.

Error estimates for finite element methods for semilinear parabolic problems with various conditions on the nonlinearity have been considered in many papers; see, e.g., Akrivis, Crouzeix, and Makridakis [1], [2], Crouzeix, Thomée, and Wahlbin [6], Elliott and Larsson [11], [12], Helfrich [16], Johnson et al. [17], Thomée [27], Thomée and Wahlbin [28], and Wheeler [29]. The long time behavior of finite element solutions was studied by Elliott and Stuart [13], Larsson [18], [19], and Larsson and Sanz-Serna [20], [21].

Let us now describe the idea of the postprocessed finite element method proposed by García-Archilla and Titi [14]. Suppose that we want to obtain high-order approximation, for instance, $O(h^{r+2})$. Then we can use, in every time step, either a family of high-order finite element spaces $\tilde{S}_h := S_{h,r+2}$ with accuracy of order $r+2$, or a family of finite element space $\tilde{S}_h := S_{\tilde{h},r}$ with accuracy of order r, but with finer partition $\mathcal{T}_{\tilde{h}}$ of the domain Ω, such that $h^{r+2} = \tilde{h}^r$. In [14], another technique, called the *postprocessed finite element method*, is presented, which improves the convergence rate without using a high-order finite element space $\tilde{S}_h$ in every time step. Suppose that we are interested in the solution of (1.2) at a given time T. At time T, rewriting (1.2), we have

$$Au(T) = -u_t(T) + F(u(T)). \tag{2.3}$$

Thus, $u(T)$ can be seen as the solution of an elliptic problem whose right-hand side is not known but can be approximated. García-Archilla and Titi first compute $u_h(T)$ by (2.1) in the finite element space S_h, then replace $u_t(T)$ by $u_{h,t}(T)$ and solve (or, in practice, approximate) the following linear elliptic problem: find $\tilde{u}(T) \in \mathcal{D}(A)$, such that

$$A\tilde{u}(T) = -u_{h,t}(T) + F(u_h(T)), \tag{2.4}$$

which is the postprocessing step.

They obtained the following error estimate, with $\ell_h = 1 + \log(T/h^2)$:

$$\|\tilde{u}(T) - u(T)\| \le C(u)\ell_h h^{r+2} \quad \text{for } r \ge 4, \tag{2.5}$$

where $C(u)$ is some constant depending on u. A similar result holds for $r \ge 3$ with order $O(h^{r+1})$, but without the factor ℓ_h.

The proof is based on superconvergence for elliptic finite element methods in norms of negative order, which is the reason for the restriction $r \ge 3$.

We note that the bound (2.5) is an improvement over the error estimates for the standard Galerkin method, which is $O(h^r)$. In practice $\tilde{u}$ cannot be computed exactly, since in general it does not belong to a finite element space. However, one can approximate the solution $\tilde{u}$ of (2.4) by some $\tilde{u}_h$ belonging to a finite element space $\tilde{S}_h$ of approximation order $r+2$ as described above. More precisely, we pose the following semidiscrete problem corresponding to (2.4): find $\tilde{u}_h \in \tilde{S}_h$, such that

$$\tilde{A}_h\tilde{u}_h(T) = \tilde{P}_h\big(-u_{h,t}(T) + F(u_h(T))\big), \tag{2.6}$$

where $\tilde{P}_h : L_2 \to \tilde{S}_h$ is the L_2 projection onto $\tilde{S}_h$ and $\tilde{A}_h$ is the discrete analogue of A with respect to $\tilde{S}_h$. The standard error estimate reads (see, e.g., Brenner and Scott [4])

$$\|\tilde{u}_h(T) - \tilde{u}(T)\| \le C(u)h^{r+2}. \tag{2.7}$$

Combining (2.5) and (2.7), we have

$$\|\tilde{u}_h(T) - u(T)\| \le \|\tilde{u}_h(T) - \tilde{u}(T)\| + \|\tilde{u}(T) - u(T)\| \le C(u)\ell_h h^{r+2} \quad \text{for } r \ge 4.$$

Let us now introduce norms of negative order. Consider the stationary problem

$$Au = f. \tag{2.8}$$

The variational form of this problem is to find $u \in H_0^1 = H_0^1(\Omega)$, such that

$$A(u, \varphi) = (f, \varphi) \quad \forall\, \varphi \in H_0^1.$$

The standard Galerkin finite element problem is to find $u_h \in S_h$, such that

$$A(u_h, \chi) = (f, \chi) \quad \forall\, \chi \in S_h. \tag{2.9}$$

Let $G : L_2 \to H_0^1$ be the exact solution operator of (2.8) and define the approximate solution operator $G_h : L_2 \to S_h$ by $G_h f = u_h$ so that $u_h = G_h f \in S_h$ is the solution of (2.9). We recall that G_h is the self-adjoint, positive semidefinite on L_2 and positive definite on S_h. We note that $G : L_2 \to H_0^1 \cap H^2$ is the inverse operator of $A : H_0^1 \cap H^2 \to L_2$, i.e., $G = A^{-1}$, and similarly $G_h = A_h^{-1}$ on S_h, where A_h is the discrete Laplacian of A defined by (2.2). Moreover, we will use the following properties (see, Thomée [27, Chapter 2]):

$$G_h P_h = G_h \quad \text{and} \quad G_h = R_h G, \tag{2.10}$$

where $R_h : H_0^1 \to S_h$ is the elliptic projection, or Ritz projection, defined by

$$A(R_h u, \chi) = A(u, \chi) \quad \forall\, \chi \in S_h. \tag{2.11}$$

The negative order norm is defined by

$$|v|_{-s} = \|G^{s/2} v\| = (G^s v, v)^{1/2} \quad \text{for } s \ge 0.$$

We have (see Thomée [27, Chapter 6])

$$\|(G_h - G)f\| \le Ch^r \|f\|_{r-2} \quad \text{for } f \in H^{r-2},\ r \ge 2, \tag{2.12}$$

and

$$|(G_h - G)f|_{-2} \le Ch^{r+2} \|f\|_{r-2} \quad \text{for } f \in H^{r-2}, \quad r \ge 4. \tag{2.13}$$

We will use (2.12) and (2.13) in section 6 for the homogeneous parabolic problem by using a higher-order time-stepping method.

Remark 2.1. The estimate (2.13) and its like require higher elliptic regularity of the A operator. To see this, let us mention some related results here; see Schatz, Sloan, and Wahlbin [22]. We denote by $\|\cdot\|_r$ the standard Sobolev norm in H^r for $r > 0$.

Case 1. A Dirichlet problem in a plane polygonal domain. Consider the problem

$$-\Delta u = f \quad \text{in}\, \Omega, \qquad u = 0 \quad \text{on}\, \partial\Omega,$$

where Ω is a plane polygonal domain. It is well known how the solution behaves near the corners of the domain (see Grisvard [15]), and using suitable mesh refinements if necessary (see Babuška [3]) we shall assume that

$$\min_{\chi \in S_h} \|u - \chi\|_1 \le Ch^{r-1} \|u\|_r, \quad r \ge 2.$$

A standard duality argument gives

$$\|u_h - u\|_{-(r-2)} \le Ch^{2r-2}, \quad r \ge 2.$$

Case 2. A Dirichlet problem in smooth plane domain. Consider the problem

$$Au = f \quad \text{in } \Omega, \qquad u = g \quad \text{on } \partial\Omega,$$

where Ω is a smooth domain and A is an elliptic operator. As in Scott [25], assume that the boundary interpolation nodes satisfy some special conditions; if A is properly elliptic, then we can show

$$\|u_h - u\|_{-s} \le Ch^{r+s}\big(\|u\|_r + \|g\|_{r+s}\big), \quad s \ge 0.$$

Case 3. A homogeneous Dirichlet problem in smooth domain in $\mathbf{R}^d$. Consider the problem

$$Au = f \quad \text{in } \Omega, \qquad u = 0 \quad \text{on } \partial\Omega,$$

where Ω is a smooth domain and A is an elliptic operator. For our finite element spaces we take isoparametric elements which approximate the boundary to order h^r. For u smooth enough it was proved in Schatz and Wahlbin [24], with $\ell_h = \ln 1/h$, that

$$\|u_h - u\|_{W^1_\infty} \le C\ell_h h^{r-1}.$$

By the duality argument, we then get

$$\|u_h - u\|_{-(r-2)} \le C\ell_h^2 h^{2r-2}.$$

Case 4. A homogeneous Neumann problem in smooth domain in $\mathbf{R}^d$. Consider the problem

$$Au = f \quad \text{in } \Omega, \qquad \frac{\partial u}{\partial n} = g \quad \text{on } \partial\Omega,$$

where Ω is a smooth domain and A is an elliptic operator. Let $\partial\Omega$ be smooth and let the finite elements at $\partial\Omega$ be curved, exactly fitting $\partial\Omega$. It was proved in Scott [26] that, with $\ell_h = \ln 1/h$,

$$\|u_h - u\|_{W^1_\infty} \le C\ell_h h^{r-1}.$$

By the duality argument, we then get

$$\|u_h - u\|_{-(r-2)} \le C\ell_h^2 h^{2r-2}.$$

We also introduce a discrete negative order seminorm on L_2 by

$$|v|_{-s,h} = \|G_h^{s/2} v\| = (G_h^s v, v)^{1/2} \quad \text{for } s \ge 0;$$

it corresponds to the discrete semi-inner product $(v, w)_{-s,h} = (G_h^s v, w)\ \forall\ v, w \in L_2$. Since G_h is positive definite on S_h, $|v|_{-s,h}$ and $(v, w)_{-s,h}$ define a norm and an inner product there. We also find that the discrete negative-order seminorm is equivalent

to the corresponding continuous norm, modulo a small error. More precisely, we have the following bounds; see, e.g., Thomée [27, Lemma 6.3].

LEMMA 2.1. *We have, for* $0 \le s \le r$,

$$|v|_{-s,h} \le C_0(|v|_{-s} + h^s\|v\|) \quad \text{and} \quad |v|_{-s} \le C_0(|v|_{-s,h} + h^s\|v\|).$$

We also need Gronwall's lemma.

LEMMA 2.2. *If* a, b *are nonnegative constants and*

$$0 \le u(t) \le a + b\int_0^t u(s)\,ds \quad \text{for } 0 \le t \le T,$$

then we have

$$u(t) \le ae^{bt} \quad \text{for } 0 \le t \le T.$$

For the nonlinear operator F, we have the following bounds; see García-Archilla and Titi [14, Lemma 3].

LEMMA 2.3. *Let* $u \in H^r(\Omega) \cap H_0^1(\Omega)$, $r \ge 4$, *and* $\chi \in H_0^1(\Omega) \cap L^\infty(\Omega)$. *Assume that* F *is a smooth function. Further assume that* $d \le 3$ *and* $\|u-\chi\|_{L_\infty} \le K$ *for some positive number* K. *Then there is a constant* $C = C(\|u\|_r, K)$ *such that*

$$\|F(u) - F(\chi)\| \le C\|u - \chi\| \tag{2.14}$$

and

$$|F(u) - F(\chi)|_{-2} \le C\big(|u - \chi|_{-2} + \|u - \chi\|^2\big). \tag{2.15}$$

Remark 2.2. In our application of Lemma 2.3, we will choose u to be the solution of (1.2) and χ to be the corresponding finite element approximation solution u_h. It is obvious that u_h and u satisfy the assumptions of Lemma 2.3. For instance, $\|u_h - u\|_\infty \le K$ can be achieved by using the inverse inequality, provided we know that the L_2 error estimate for $u_h - u$ is $O(h^r)$; see Thomée [27, Chapter 14].

3. Semidiscrete approximation. In this section we will consider the error estimates for the *postprocessed finite element method* for the semilinear parabolic problem (1.2) in the semidiscrete case. The main theorem in this section is the following.

THEOREM 3.1. *Let* $r \ge 4$ *and let* S_h *and* $\tilde{S}_h$ *be the finite element spaces of orders* r *and* $r + 2$, *respectively, as described in section* 2. *Let* $\tilde{u}_h$ *and* u *be the solutions of* (2.6) *and* (1.2), *respectively. Assume that* F *satisfies* $\|F(u)\|_r \le C_0$ *in addition to the assumptions in Lemma* 2.3. *Let* u_h *be the solution of* (2.1). *Assume that* $v_h = R_h v, v \in H_0^1$, *and*

$$\sup_{s\in[0,T]} \|u_h(s) - u(s)\|_{L_\infty} \le K$$

and

$$\sup_{s\in[0,T]} \big(\|u(s)\|_r + \|u_t(s)\|_r + \|u_{tt}(s)\|_r\big) \le M \tag{3.1}$$

for some positive numbers K, M, T. *Then there is a constant* $C = C(K, M, T)$ *such that, with* $\ell_h = 1 + \log(T/h^2)$,

$$\|\tilde{u}_h(T) - u(T)\| \le C\ell_h h^{r+2}. \tag{3.2}$$

To prove Theorem 3.1, it suffices to show the bounds of $|u_h - u|_{-l}$ and $|u_{h,t} - u_t|_{-l}$ for $l = 0, 2$. We first split

$$u_h - u = (u_h - \hat{u}_h) + (\hat{u}_h - u) = \eta + e, \tag{3.3}$$

where $\hat{u}_h$ satisfies

$$\hat{u}_{h,t} + A_h \hat{u}_h = P_h F(u), \quad \hat{u}_h(0) = v_h. \tag{3.4}$$

Since u satisfies

$$u_t + Au = F(u), \quad u(0) = v, \tag{3.5}$$

the desired bounds of $e = \hat{u}_h - u$ and e_t follow from the error estimates for the linear parabolic problem because the right-hand side of (3.4) is independent of $\hat{u}_h$. In other words we only need to consider the nonlinear term F when we show the bounds of $\eta = u_h - \hat{u}_h$ and η_t. Note that η satisfies

$$\eta_t + A_h \eta = P_h(F(u_h) - F(u)), \quad \eta(0) = 0. \tag{3.6}$$

By Duhamel's principle, we have

$$\eta(t) = \int_0^t E_h(t-s) P_h \big(F(u_h(s)) - F(u(s))\big)\, ds. \tag{3.7}$$

Our main task is to consider the bounds for $|\eta|_{-l}$, $|\eta_t|_{-l}$, $l = 0, 2$.

We remark that since $\eta(0) = 0$, we don't need to consider the term $E_h(T)\eta(0)$ in (3.7). This observation is very useful in the fully discrete case.

Our first lemma in this section is the error estimate for the solution of (1.2).

LEMMA 3.2. *Let u_h and u be the solutions of* (2.1) *and* (1.2), *respectively. Assume that F satisfies the assumptions in Lemma* 2.3. *Further assume that $v_h = R_h v$ and*

$$\sup_{0 \le s \le T} \|u_h(s) - u(s)\|_{L_\infty} \le K \tag{3.8}$$

and

$$\sup_{0 \le s \le T} \big(\|u(s)\|_r + \|u_t(s)\|_r\big) \le M_1 \tag{3.9}$$

for some positive numbers K, M_1, T. Then there is a constant $C = C(K, M_1, T)$ such that

$$\sup_{0 \le t \le T} \|u_h(t) - u(t)\| \le Ch^r \quad \textit{for } r \ge 2 \tag{3.10}$$

and

$$\sup_{0 \le t \le T} |u_h(t) - u(t)|_{-2} \le Ch^{r+2} \quad \textit{for } r \ge 4. \tag{3.11}$$

The proof of Lemma 3.2 is similar to the proof of Lemma 3.3, so we omit it here.

Our next lemma is the error estimates for the time derivative of the solution of (1.2).

LEMMA 3.3. *Let u_h and u be the solutions of (2.1) and (1.2), respectively. Assume that F satisfies the assumptions in Lemma 2.3. Further assume that $v_h = R_h v$, $v \in H_0^1$, and*

$$\sup_{0\le s\le T} \|u_h(s) - u(s)\|_{L_\infty} \le K \tag{3.12}$$

and

$$\sup_{0\le s\le T} \big(\|u(s)\|_r + \|u_t(s)\|_r + \|u_{tt}(s)\|_r\big) \le M_2 \tag{3.13}$$

for some positive numbers K, M_2, T. Then there is a constant $C = C(K, M_2, T)$ such that, with $\ell_h = 1 + \log(T/h^2)$,

$$\sup_{0\le t\le T} \|u_{h,t}(t) - u_t(t)\| \le C\ell_h h^r, \quad r \ge 2, \tag{3.14}$$

and

$$\sup_{0\le t\le T} |u_{h,t}(t) - u_t(t)|_{-2} \le C\ell_h h^{r+2}, \quad r \ge 4. \tag{3.15}$$

Proof. We write

$$u_{h,t} - u_t = (u_{h,t} - \hat{u}_{h,t}) + (\hat{u}_{h,t} - u_t) = \eta_t + e_t.$$

Following the proofs of Theorems 1.3 and 6.2 in Thomée [27] for the error estimate $|e|_{-l}$, $l = 0, 2$, we can show the following error estimates for $|e_t|_{-l}$, $l = 0, 2$:

$$\|e_t(t)\| \le \|\hat{u}_{h,t}(0) - u_t(0)\| + C_0 h^r \Big(\|u_t(0)\|_r + \int_0^t \|u_{tt}\|_r \, ds\Big)$$

and

$$|e_t(t)|_{-2} \le |\hat{u}_{h,t}(0) - u_t(0)|_{-2} + C_0 h^{r+2} \Big(\|u_t(0)\|_r + \int_0^t \|u_{tt}\|_r \, ds\Big).$$

We observe that, by (3.4), and by noting that $\hat{u}_h(0) = R_h u(0)$,

$$\begin{aligned} \hat{u}_{h,t}(0) &= -A_h \hat{u}_h(0) + P_h F(u(0)) = -A_h R_h u(0) + P_h F(u(0)) \\ &= P_h\big(Au(0) + F(u(0))\big) = P_h u_t(0). \end{aligned}$$

We therefore have, by the error bounds for the L_2 projection,

$$\|\hat{u}_{h,t}(0) - u_t(0)\| = \|(P_h - I)u_t(0)\| \le C_0 h^r \|u_t(0)\|_r$$

and

$$|\hat{u}_{h,t}(0) - u_t(0)|_{-2} \le C_0 h^{r+2} \|u_t(0)\|_r.$$

Thus, we get

$$\|e_t(t)\| \le C_0 h^r \Big(\|u_t(0)\|_r + \int_0^t \|u_{tt}\|_r \, ds\Big) \le C(M_2, T) h^r \tag{3.16}$$

and, similarly,

$$|e_t(t)|_{-2} \le C(M_2,T)h^{r+2}. \tag{3.17}$$

We now turn to $|\eta_t|_{-l},\ l=0,2$. Using the fact $\|A_hE_h(t)\| \le C_0(t+h^2)^{-1}$ (see Schatz, Thomée, and Wahlbin [23]), we have

$$\int_0^t \|A_hE_h(t-s)\|\,ds \le C_0(1+\log(T/h^2)) \le C_0\ell_h. \tag{3.18}$$

By (3.7), we have

$$\begin{aligned}\eta_t(t) &= P_h(F(u_h(t))-F(u(t))) \\ &\quad - \int_0^t A_hE_h(t-s)P_h\big(F(u_h(s))-F(u(s))\big)\,ds.\end{aligned} \tag{3.19}$$

Thus, by (3.10), (3.18), and Lemma 2.3,

$$\begin{aligned}\|\eta_t(t)\| &\le \|P_h(F(u_h(t))-F(u(t)))\| \\ &\quad + \int_0^t \big\|A_hE_h(t-s)P_h\big(F(u_h(s))-F(u(s))\big)\big\|\,ds \\ &\le C(K,M_2,T)(1+\ell_h)\sup_{0\le s\le T}\|u_h(s)-u(s)\| \le C(K,M_2,T)\ell_h h^r.\end{aligned} \tag{3.20}$$

For $|\eta_t(t)|_{-2}$, we have, by (3.19),

$$\begin{aligned}|\eta_t(t)|_{-2} &\le |P_h(F(u_h(t))-F(u(t)))|_{-2} \\ &\quad + \int_0^t \big|A_hE_h(t-s)P_h\big(F(u_h(t))-F(u(t))\big)\big|_{-2}\,ds.\end{aligned}$$

Here, by Lemmas 2.1 and 2.3 and by (3.10), (3.11),

$$\begin{aligned}|P_h(F(u_h)-F(u))|_{-2} &\le C_0\big(h^2\|P_h(F(u_h)-F(u))\| + \|G_hP_h(F(u_h)-F(u))\|\big) \\ &\le C(\|u\|_r,K)\big(h^2\|u_h-u\| + \|u_h-u\|^2 + |u_h-u|_{-2}\big) \\ &\le C(K,M_2,T)h^{r+2}.\end{aligned}$$

Thus, by (3.18),

$$|\eta_t(t)|_{-2} \le C(K,M_2,T)\ell_h h^{r+2}.$$

Together these estimates complete the proof. ∎

Proof of Theorem 3.1. Combining (2.3) and (2.4), we have, with $\tilde{G}_h = \tilde{A}_h^{-1}$,

$$\begin{aligned}\tilde{u}_h(T)-u(T) &= \tilde{G}_h\tilde{P}_h(-u_{h,t}+F(u_h)) - G(-u_t+F(u)) \\ &= (\tilde{G}_h\tilde{P}_h - G)\big(-u_{h,t}+F(u_h)+u_t-F(u)\big) \\ &\quad - (\tilde{G}_h\tilde{P}_h - G)(u_t-F(u)) \\ &\quad + G(-u_{h,t}+F(u_h)+u_t-F(u)).\end{aligned}$$

Thus, by Lemmas 2.3, 3.2, and 3.3, we get, noting that $\|(\tilde{G}_h\tilde{P}_h - G)f\| \le Ch^s\|f\|_{s-2}$ for $0 \le s \le r+2$,

$$\begin{aligned}\|\tilde{u}_h(T) - u(T)\| &\le C_0h^2\big(\|u_{h,t} - u_t\| + \|F(u_h) - F(u)\|\big)\\ &\quad + C_0h^{r+2}\big(\|u_t\|_r + \|F(u)\|_r\big)\\ &\quad + |u_{h,t} - u_t|_{-2} + |F(u_h) - F(u)|_{-2}\\ &\le C(K, M, T)\ell_h h^{r+2}.\end{aligned}$$

The proof is complete. ∎

Remark 3.1. We remark that the "closeness assumption" of Theorem 3.1, i.e., $\sup_{s\in[0,T]}\|u_h(s) - u(s)\|_{L_\infty} \le K$, as well as similar assumptions in Lemmas 3.2 and 3.3 (inequalities (3.8), (3.12), respectively), require some restrictions on the semilinearity. For example, as stated in Thomée [27, Chapter 14, pp. 224], $F'(u)$ needs to grow "mildly" in order to obtain the "closeness assumption," without using inverse inequalities. For $d = 3$, the semilinearity assumption reads $|F'(u)| \le C(1+|u|^p)$, $p \le 2$, while for $d = 2$, p can be chosen arbitrarily.

Otherwise, we may need the inverse inequalities. However, as indicated in Thomée [27, Chapter 14, pp. 224] such properties are valid for $r > d/2$ for quasi-uniform partitions in the d-dimensional case. Similar observations are also needed for the fully discrete case.

4. Completely discrete approximation. In this section we will consider the postprocessed finite element method for (1.2) in the fully discrete case.

We use the similar technique developed in section 3 to derive the error estimates in the fully discrete case. Let $t_n = nk$, k being the time step. We will use the notation $u^j = u(t_j)$ and $u_t^j = u_t(t_j)$ below. We define the following backward Euler method, with $\bar{\partial}U^n = (U^n - U^{n-1})/k$:

$$\bar{\partial}U^n + A_hU^n = P_hF(U^n), \quad n \ge 1, \quad \text{with } U^0 = v_h. \tag{4.1}$$

It is natural to approximate $u_{h,t}(T)$, $T = t_n$, in (2.4) by $\bar{\partial}U^n$ for fixed n. The postprocessing step in the fully discrete case is to find $\tilde{u}(T) \in \mathcal{D}(A)$, such that

$$A\tilde{u}(T) = -\bar{\partial}U^n + F(U^n). \tag{4.2}$$

The semidiscrete problem of (4.2) is to find $\tilde{u}_h(T) \in \tilde{S}_h$, such that

$$\tilde{A}_h\tilde{u}_h(T) = \tilde{P}_h(-\bar{\partial}U^n + F(U^n)). \tag{4.3}$$

Let $\hat{U}^n$ be the solution of

$$\bar{\partial}\hat{U}^n + A_h\hat{U}^n = P_hF(u^n), \quad n \ge 1, \quad \text{with } \hat{U}^0 = v_h. \tag{4.4}$$

We have the following theorem.

THEOREM 4.1. *Let $r \ge 4$ and let S_h and $\tilde{S}_h$ be the finite element spaces of orders r and $r+2$, respectively, as described in section 2. Let $\tilde{u}_h$ and u be the solutions of (4.3) and (1.2), respectively. Assume that F satisfies $\|F(u^n)\|_r \le C_0$ in addition to the assumptions in Lemma 2.3. Let $T = t_n$ be a fixed time. Let U^n be the solution of (4.1). Assume that $v_h = R_hv, v \in H_0^1$, and*

$$\sup_{0\le t_n\le T}\|U^n - u(t_n)\|_{L_\infty} \le K$$

and

$$\sup_{0\le s\le T}\big(\|u(s)\|_r+\|u_t(s)\|_r+\|u_{tt}(s)\|+|u_{tt}(s)|_{-2}+\|Au_{tt}(s)\|\big)\le M \tag{4.5}$$

for some positive numbers K, M, T. Then there is a constant $C = C(K, M, T)$ such that, with $\ell_k = 1 + \log(T/k)$, k being the time step,

$$\|\tilde u_h(T)-u(T)\|\le C_0\big(\|\bar\partial\hat U^1-u_t(t_1)\|+|\bar\partial\hat U^1-u_t(t_1)|_{-2}\big)+C\ell_k(h^{r+2}+k).$$

We now state a lemma for the error estimate of the approximation U^n of $u(t_n)$ in the L_2 norm.

LEMMA 4.2. *Let U^n and u be the solutions of* (4.1) *and* (1.2)*, respectively. Assume that F satisfies the assumptions in Lemma* 2.3*. Further assume that $v_h = R_h v$, and*

$$\sup_{0\le t_n\le T}\|U^n-u(t_n)\|_{L_\infty}\le K \tag{4.6}$$

and

$$\sup_{0\le s\le T}\big(\|u(s)\|_r+\|u_t(s)\|_r+\|u_{tt}(s)\|+|u_{tt}(s)|_{-2}\big)\le M_3 \tag{4.7}$$

for some positive numbers K, M_3, T. Then there is a constant $C = C(K, M_3, T)$ such that

$$\sup_{0\le t_n\le T}\|U^n-u(t_n)\|\le C(h^r+k),\quad r\ge 2, \tag{4.8}$$

and

$$\sup_{0\le t_n\le T}|U^n-u(t_n)|_{-2}\le C(h^{r+2}+k),\quad r\ge 4. \tag{4.9}$$

Proof. We split

$$U^n-u(t_n)=(U^n-\hat U^n)-(\hat U^n-u(t_n))=\eta^n+e^n,$$

where $\hat U^n$ is defined by (4.4).

For $e^n=\hat U^n-u(t_n)$, we have, by the standard error estimates for linear parabolic problems (see, e.g., Thomée [27, Theorem 1.5]),

$$\begin{aligned}\|e^n\|&\le C_0\|R_hv-v\|+C_0h^r\Big(\|v\|_r+\int_0^{t_n}\|u_t\|_r\,ds\Big)+C_0k\int_0^{t_n}\|u_{tt}(s)\|\,ds\\&\le C(M_3,T)(h^r+k).\end{aligned} \tag{4.10}$$

For $\eta^n=U^n-\hat U^n$, noting that, by (4.4) and (4.1),

$$\begin{cases}\bar\partial\eta^n+A_h\eta^n=P_h(F(U^n)-F(u^n))\quad\text{for } n\ge 1,\\ \eta^0=0,\end{cases} \tag{4.11}$$

we have, by Lemma 2.3, with $r(\lambda)=1/(1+\lambda)$,

$$\begin{aligned}\|\eta^n\|&\le k\sum_{j=1}^n\|r(kA_h)^{n-j+1}\|\,\|P_h(F(U^j)-F(u^j))\|\\&\le C_0k\sum_{j=1}^n\|F(U^j)-F(u^j)\|\le C(K,M_3)\Big(k\sum_{j=1}^n\|\eta^j\|+k\sum_{j=1}^n\|e^j\|\Big).\end{aligned}$$

Further, by the discrete Gronwall lemma and (4.10), we have

$$\|\eta^n\| \le C(K, M_3, T)(h^r + k),$$

which shows (4.8).

Now we turn to (4.9). Following the proof of (4.10), we can show that

$$\begin{aligned} |e^n|_{-2} &\le C_0|R_h v - v|_{-2} + C_0 h^{r+2}\Big(\|v\|_r + \int_0^t \|u_t\|_r\, ds\Big) \\ &\quad + C_0 k \int_0^{t_n} |u_{tt}(s)|_{-2}\, ds \\ &\le C(M_3, T)(h^{r+2} + k). \end{aligned} \tag{4.12}$$

To estimate $|\eta^n|_{-2}$, we first note that, by Lemma 2.1,

$$|\eta^n|_{-2} \le C_0(h^2\|\eta^n\| + \|G_h\eta^n\|). \tag{4.13}$$

Here, by (4.11), $G_h\eta^n$ satisfies

$$\begin{cases} \bar\partial(G_h\eta^n) + A_h(G_h\eta^n) = G_h P_h(F(U^n) - F(u^n)) \quad \text{for } n \ge 1, \\ \eta^0 = 0, \end{cases} \tag{4.14}$$

which implies

$$G_h\eta^n = k\sum_{j=1}^{n} r(kA_h)^{n-j+1} G_h P_h(F(U^j) - F(u^j)).$$

Note that, by Lemmas 2.1 and 2.3,

$$\begin{aligned} \|G_h P_h(F(U^j) - F(u^j))\| &= |F(U^j) - F(u^j)|_{-2,h} \\ &\le C(\|u\|_r, K)\big(h^2\|U^j - u^j\| + \|U^j - u^j\|^2 + |U^j - u^j|_{-2}\big). \end{aligned}$$

Hence, by the stability of $r(\lambda)$,

$$\begin{aligned} \|G_h\eta^n\| \le C(K, M_3)\Big(& k\sum_{j=1}^{n} |\eta^j|_{-2} + h^2 k\sum_{j=1}^{n} \|U^j - u^j\| \\ & + k\sum_{j=1}^{n}(\|U^j - u^j\|^2 + |e^j|_{-2})\Big). \end{aligned}$$

Combining this with (4.13) and using the discrete Gronwall lemma, we get, by (4.8) and (4.12),

$$|\eta^n|_{-2} \le C(K, M_3, T)(h^{r+2} + k). \tag{4.15}$$

Together these estimates complete the proof. ∎

We also need the following lemma for the error estimate of the approximation $\bar\partial U^n$ of $u_t(t_n)$.

LEMMA 4.3. *Let U^n and u be the solutions of* (4.1) *and* (1.2)*, respectively. Assume that F satisfies the assumptions in Lemma* 2.3*. Further assume that $v_h = R_h v, v \in H_0^1$, and*

$$\sup_{0\le t_n\le T} \|U^n - u(t_n)\|_{L_\infty} \le K \tag{4.16}$$

and

$$\sup_{0\le s\le T}\big(\|u(s)\|_r+\|u_t(s)\|_r+\|u_{tt}(s)\|_r+\|u_{tt}(s)\|+\|Au_{tt}(s)\|\big)\le M_4 \tag{4.17}$$

for some positive numbers K, M_4, T. Then there is a constant $C=C(K,M_4,T)$ such that, with $\ell_k=1+\log(T/k)$, k being the time step,

$$\sup_{k\le t_n\le T}\|\bar\partial U^n-u_t(t_n)\|\le C_0\|\bar\partial\hat U^1-u_t(t_1)\|+C\ell_k(h^r+k) \tag{4.18}$$

and

$$\sup_{k\le t_n\le T}|\bar\partial U^n-u_t(t_n)|_{-2}\le C_0|\bar\partial\hat U^1-u_t(t_1)|_{-2}+C\ell_k(h^{r+2}+k). \tag{4.19}$$

Proof. We use the same notation as in Lemma 4.2 and write

$$\begin{aligned}\bar\partial U^n-u_t(t_n)&=(\bar\partial U^n-\bar\partial\hat U^n)+(\bar\partial\hat U^n-u_t(t_n))\\&=\bar\partial\eta^n+\big(\bar\partial\hat U^n-u_t(t_n)\big).\end{aligned}$$

We first show

$$\begin{aligned}\|\bar\partial\hat U^n-u_t(t_n)\|&\le C_0\|\bar\partial\hat U^1-u_t(t_1)\|+C_0h^r\Big(\|u_t(0)\|_r+\int_0^{t_n}\|u_{tt}\|_r\,ds\Big)\\&\quad+C_0k\int_0^{t_n}\|Au_{tt}(s)\|\,ds\\&\le C_0\|\bar\partial\hat U^1-u_t(t_1)\|+C(M_4,T)(h^r+k).\end{aligned} \tag{4.20}$$

To show (4.20), we write

$$\bar\partial\hat U^n-u_t(t_n)=(\bar\partial\hat U^n-R_hu_t(t_n))+(R_hu_t(t_n)-u_t(t_n))=\theta^n+\rho^n.$$

In the standard way ρ^n is bounded as desired, and it remains to consider $\theta^n\in S_h$. We have

$$\bar\partial\theta^n+A_h\theta^n=P_h\omega^n\quad\text{for } n\ge 2,$$

where

$$\omega^n=(R_h-I)\bar\partial u_t(t_n)+A(\bar\partial u^n-u_t^n)=\sigma^n+\tau^n.$$

By the stability estimate (see, e.g., Thomée [27, Theorem 10.2]),

$$\|\theta^n\|\le C_0\|\theta^1\|+C_0k\sum_{j=2}^n\|\sigma^j\|+C_0k\sum_{j=2}^n\|\tau^j\|\quad\text{for } n\ge 2. \tag{4.21}$$

We have

$$k\|\sigma^n\|\le C_0h^r\int_{t_{n-1}}^{t_n}\|u_{tt}\|_r\,ds$$

and

$$k\|\tau^n\|\le C_0k\|A(\bar\partial u^n-u_t^n)\|\le C_0k\int_{t_{n-1}}^{t_n}\|Au_{tt}(s)\|\,ds.$$

Together with $\|\theta^1\| \le \|\bar\partial U^1 - u_t^1\| + \|\rho^1\|$, with the obvious bounds for $\|\rho^1\|$, this completes the proof of (4.20).

For $\|\bar\partial\eta^n\|$, we have, by (4.11),

$$\bar\partial\eta^n = P_h(F(U^n) - F(u^n)) - k\sum_{j=1}^{n} A_h r(kA_h)^{n-j+1} P_h(F(U^n) - F(u^n)). \tag{4.22}$$

Using the smoothing property

$$k\sum_{j=1}^{n} \|A_h r(kA_h)^{n-j+1}\| \le C_0\ell_k, \tag{4.23}$$

which follows from

$$\begin{aligned} k\sum_{j=1}^{n} \|A_h r(kA_h)^{n-j+1}\| &\le C_0 k\sum_{j=1}^{n} t_{n-j+1}^{-1} = C_0\Big(1 + k\sum_{j=1}^{n-1} t_{n-j+1}^{-1}\Big) \\ &\le C_0\Big(1 + \int_{t_1}^{t_n} \frac{1}{s}\,ds\Big) \le C_0(1 + \log(t_n/k)) \le C_0\ell_k, \end{aligned}$$

we have, by Lemma 2.3 and (4.8),

$$\begin{aligned} \|\bar\partial\eta^n\| &\le C(K, M_4)\big(\|U^n - u^n\| + \ell_k \max_{1\le j\le n} \|U^j - u^j\|\big) \\ &\le C(K, M_4, T)\ell_k(h^r + k). \end{aligned} \tag{4.24}$$

Together these estimates complete the proof of (4.18).

Now we turn to estimate (4.19). Following the proof of (4.20), we can show

$$\begin{aligned} |\bar\partial\hat U^n - u_t(t_n)|_{-2} &\le C_0|\bar\partial\hat U^1 - u_t(t_1)|_{-2} + C_0h^{r+2}\Big(\|u_t(0)\|_r + \int_0^{t_n} \|u_{tt}\|_r\,ds\Big) \\ &\quad + C_0k\int_0^{t_n} \|u_{tt}(s)\|\,ds, \\ &\le C_0|\bar\partial\hat U^1 - u_t(t_1)|_{-2} + C(M_4, T)(h^{r+2} + k). \end{aligned} \tag{4.25}$$

For $|\bar\partial\eta^n|_{-2}$, we have, using (4.22), and by Lemmas 2.1 and 2.3,

$$|\bar\partial\eta^n|_{-2} \le C(K, M_4, T)\ell_k \max_{1\le j\le n} \big(h^2\|U^j - u^j\| + \|U^j - u^j\|^2 + |U^j - u^j|_{-2}\big).$$

Thus, by (4.8) and (4.9),

$$|\bar\partial\eta^n|_{-2} \le C(K, M_4, T)\ell_k(h^{r+2} + k). \tag{4.26}$$

Together these estimates complete the proof. □

Proof of Theorem 4.1. Combining (2.3) and (4.3), we have, with $\tilde G_h = \tilde A_h^{-1}$,

$$\begin{aligned} \tilde u_h(T) - u(T) &= \tilde G_h\tilde P_h(-\bar\partial U^n + F(U^n)) - G(-u_t(t_n) + F(u^n)) \\ &= (\tilde G_h\tilde P_h - G)\big(-\bar\partial U^n + F(U^n) + u_t(t_n) - F(u^n)\big) \\ &\quad - (\tilde G_h\tilde P_h - G)\big(u_t(t_n) - F(u^n)\big) \\ &\quad + G\big(-\bar\partial U^n + F(U^n) + u_t(t_n) - F(u^n)\big). \end{aligned}$$

Thus, noting that $\|(\tilde{G}_h\tilde{P}_h - G)f\| \le Ch^s\|f\|_{s-2}$ for $0 \le s \le r+2$, we get

$$\begin{aligned}\|\tilde{u}_h(T) - u(T)\| \le{}& C_0h^2\big(\|\bar{\partial}U^n - u_t(t_n)\| + \|F(U^n) - F(u^n)\|\big)\\ &+ C_0h^{r+2}\|u_t(t_n) - F(u^n)\|_r\\ &+ |\bar{\partial}U^n - u_t(t_n)|_{-2} + |F(U^n) - F(u^n)|_{-2}.\end{aligned}$$

Combining this with Lemmas 2.3, 4.2, and 4.3, we complete the proof. ∎

Remark 4.1. The algorithm works also for the Crank–Nicolson method. We can easily extend the proof of the backward Euler method to the Crank–Nicolson method.

The algorithm works also for the backward Euler method with variable time step if F is independent of solution u. It is not clear how to get the postprocessing error estimates if F depends on u. We will study this in future work.

5. Error estimate for the starting approximation. In this section we will consider the error estimate for the starting approximation of the time derivative $|\bar{\partial}\hat{U}^1 - u_t(t_1)|_{-s},\ s = 0, 2$, which appears in Theorem 4.1, where u and $\hat{U}^1$ satisfy

$$u_t + Au = F(u), \quad \text{with } u(0) = v, \tag{5.1}$$

and

$$\bar{\partial}\hat{U}^1 + A_h\hat{U}^1 = P_hF(u^1), \quad \text{with } \hat{U}^0 = v_h = R_hv, \tag{5.2}$$

respectively.

The semidiscrete problem of (5.1) is to find $\hat{u}_h \in S_h$ such that

$$\hat{u}_{h,t} + A_h\hat{u}_h = P_hF(u), \quad \text{with } \hat{u}_h(0) = R_hv. \tag{5.3}$$

We observe that we use $F(u^1)$ in (5.2); thus $|\bar{\partial}\hat{U}^1 - u_t(t_1)|_{-s},\ s = 0, 2$, can be bounded by the standard technique for nonhomogeneous linear parabolic problems. We have the following theorem.

THEOREM 5.1. *Let $\hat{U}^1$ and u be the solutions of* (5.2) *and* (5.1)*, respectively. Assume that F is continuously differentiable and*

$$\|Au_t(0)\| + \|u_t(0)\|_r + \max_{0\le\tau\le k}\big(\|F'(u(\tau))u_t(\tau)\| + \|u_{tt}(\tau)\|_r\big) \le M_0$$

for some positive number M_0. Then there is a constant $C = C(M_0)$ such that

$$\|\bar{\partial}\hat{U}^1 - u_t(t_1)\| \le C(h^r + k) \tag{5.4}$$

and

$$|\bar{\partial}\hat{U}^1 - u_t(t_1)|_{-2} \le C(h^{r+2} + k). \tag{5.5}$$

Proof. We first show (5.4). We write

$$\bar{\partial}\hat{U}^1 - u_t(t_1) = \big(\bar{\partial}\hat{U}^1 - \hat{u}_{h,t}(t_1)\big) + \big(\hat{u}_{h,t}(t_1) - u_t(t_1)\big).$$

By (3.16), we have

$$\|\hat{u}_{h,t}(t_1) - u_t(t_1)\| \le C_0h^r\Big(\|u_t(0)\|_r + \int_0^{t_1}\|u_{tt}(s)\|_r\,ds\Big). \tag{5.6}$$

For $\bar{\partial}\hat{U}^1 - \hat{u}_{h,t}(t_1)$, we have, by (5.2) and (5.3),

$$\bar{\partial}\hat{U}^1 - \hat{u}_{h,t}(t_1) = A_h(\hat{U}^1 - \hat{u}_h^1).$$

Here, by Taylor's formula, with $r(\lambda) = 1/(1+\lambda)$, $E_h(t) = e^{-tA_h}$,

$$\begin{aligned}\hat{U}^1 - \hat{u}_h^1 &= \big(r(kA_h) - E_h(t_1)\big)R_h v + kr(kA_h)P_h F(u^1) \\ &\quad - \int_0^{t_1} E_h(t_1 - s)P_h F(u(s))\,ds \\ &= \big(r(kA_h) - E_h(t_1)\big)R_h v + kb_0(kA_h)P_h F(u(0)) + kR(F),\end{aligned}$$

where

$$b_0(\lambda) = r(\lambda) - \int_0^1 e^{-(1-s)\lambda}\,ds$$

and

$$\begin{aligned}R(F) &= r(kA_h)\int_0^k P_h F'(u(\tau))u_t(\tau)\,d\tau \\ &\quad - \int_0^1 e^{-(1-s)kA_h}\int_0^{ks} P_h F'(u(\tau))u_t(\tau)\,d\tau\,ds.\end{aligned}$$

Thus, we have

$$\begin{aligned}\bar{\partial}\hat{U}^1 - \hat{u}_{h,t}(t_1) &= \big(r(kA_h) - E_h(t_1)\big)A_h R_h v \\ &\quad + kA_h b_0(kA_h)P_h F(u(0)) + kA_h R(F).\end{aligned}$$

Noting that $A_h R_h = P_h A$ and $\lambda b_0(\lambda) = -\big(r(\lambda) - e^{-\lambda}\big)$, we get

$$\begin{aligned}\bar{\partial}\hat{U}^1 - \hat{u}_{h,t}(t_1) &= \big(r(kA_h) - E_h(t_1)\big)P_h\big(Av - F(u(0))\big) + kA_h R(F) \\ &= \big(r(kA_h) - E_h(t_1)\big)P_h u_t(0) + kA_h R(F) \\ &= I + II.\end{aligned} \tag{5.7}$$

For I, we have, by the error estimate for homogeneous parabolic problems,

$$\begin{aligned}\|I\| &\le \big\|\big(r(kA_h) - E_h(t_1)\big)(P_h - R_h)u_t(0)\big\| + \big\|\big(r(kA_h) - E_h(t_1)\big)R_h u_t(0)\big\| \\ &\le \|(P_h - R_h)u_t(0)\| + C_0 k\|A_h R_h u_t(0)\| \\ &\le C_0 h^r\|u_t(0)\|_r + C_0 k\|Au_t(0)\|.\end{aligned}$$

For II, we write

$$\begin{aligned}II &= kA_h r(kA_h)\int_0^k P_h F'(u(\tau))u_t(\tau)\,d\tau \\ &\quad - kA_h\int_0^1 e^{-(1-s)kA_h}\int_0^{ks} P_h F'(u(\tau))u_t(\tau)\,d\tau\,ds \\ &= II_1 + II_2.\end{aligned}$$

We have, noting that $|\lambda r(\lambda)| \le 1,\ \|P_h\| \le 1$,

$$\begin{aligned}\|II_1\| &\le \|kA_h r(kA_h)\| \int_0^k \|P_h F'(u(\tau))u_t(\tau)\|\, d\tau \\ &\le k \max_{0\le\tau\le k} \|F'(u(\tau))u_t(\tau)\|,\end{aligned}$$

and, by exchanging the integral order and noting that $\int_\epsilon^1 \lambda e^{-(1-s)\lambda}\, ds \le 1$ for $0 \le \epsilon \le 1$,

$$\begin{aligned}\|II_2\| &= \Big\| kA_h \int_0^k P_h F'(u(\tau))u_t(\tau) \int_{\tau/k}^1 e^{-(1-s)kA_h}\, ds d\tau \Big\| \\ &\le k \max_{0\le\tau\le k} \|F'(u(\tau))u_t(\tau)\| \Big\| kA_h \int_{\tau/k}^1 e^{-(1-s)kA_h}\, ds \Big\| \\ &\le k \max_{0\le\tau\le k} \|F'(u(\tau))u_t(\tau)\|.\end{aligned}$$

Together these estimates show

$$\|\bar\partial \hat U^1 - \hat u_{h,t}(t)\| \le C_0\big(h^r \|u_t(0)\|_r + k\|Au_t(0)\| + k \max_{0\le\tau\le k} \|F'(u(\tau))u_t(\tau)\|\big). \tag{5.8}$$

Combining this with (5.6) shows (5.4).

We now turn to (5.5). We again write

$$\bar\partial \hat U^1 - u_t(t_1) = \big(\bar\partial \hat U^1 - \hat u_{h,t}(t_1)\big) + \big(\hat u_{h,t}(t_1) - u_t(t_1)\big).$$

The desired bound for $|\hat u_{h,t}(t_1) - u_t(t_1)|_{-2}$ follows from (3.17).

For $\bar\partial \hat U^1 - \hat u_{h,t}(t_1)$, we have, by Lemma 2.1,

$$|\bar\partial \hat U^1 - \hat u_{h,t}(t_1)|_{-2} \le C_0\big(h^2 \|\bar\partial \hat U^1 - \hat u_{h,t}(t_1)\| + |\bar\partial \hat U^1 - \hat u_{h,t}(t_1)|_{-2,h}\big).$$

Thus, by (5.7),

$$|\bar\partial \hat U^1 - \hat u_{h,t}(t_1)|_{-2,h} \le |I|_{-2,h} + |II|_{-2,h}.$$

For $|I|_{-2,h}$, we have, by the error estimate for homogeneous parabolic problems [30],

$$|I|_{-2,h} = |(r(kA_h) - E_h(t_1))P_h u_t(0)|_{-2,h} \le C_0\big(h^{r+2}\|u_t(0)\|_r + k\|Au_t(0)\|\big).$$

For $|II|_{-2,h}$, we have, noting that $|r(\lambda)| \le 1,\ \int_\epsilon^1 e^{-(1-s)\lambda}\, ds \le 1$ for $0 \le \epsilon \le 1$,

$$\begin{aligned}|II|_{-2,h} &\le \int_0^k \|kr(kA_h)\|\, \|P_h F'(u(\tau))u_t(\tau)\|\, d\tau \\ &\quad + \Big\| k \int_0^k P_h F'(u(\tau))u_t(\tau) \int_{\tau/k}^1 e^{-(1-s)kA_h}\, ds\, d\tau \Big\| \\ &\le k^2 \max_{0\le\tau\le k} \|F'(u(\tau))u_t(\tau)\|.\end{aligned}$$

Hence we get

$$|\bar\partial \hat U^1 - \hat u_{h,t}(t_1)|_{-2,h} \le C_0\big(h^{r+2}\|u_t(0)\|_r + k\|Au_t(0)\| + k^2 \max_{0\le\tau\le k} \|F'(u(\tau))u_t(\tau)\|\big).$$

Combining this with (5.8) shows (5.5).

Together these estimates complete the proof of the theorem. ∎

6. High-order time-stepping. The postprocessing requires very accurate time-stepping in order to match the high-order spatial approximation. It would be natural then to use a time-stepping method of higher order than the backward Euler method of section 4. However, we have not been able to analyze such methods except in the case of linear homogeneous problems, where we can apply the analysis of time derivative approximation from [30].

In this section we consider the linear homogeneous parabolic problem

$$u_t + Au = 0 \quad \text{for } t > 0, \quad \text{with } u(0) = v. \tag{6.1}$$

We define the time-stepping method

$$U^n = r(kA_h)U^{n-1}, \quad U^0 = v_h, \tag{6.2}$$

where $r(\lambda)$ is a rational function and accurate of order $p \geq 1$, i.e.,

$$r(\lambda) - e^{-\lambda} = O(\lambda^{p+1}), \quad \lambda \to 0.$$

For example, if $r(\lambda) = 1/(1+\lambda)$, then we have $(1+kA_h)U^n = U^{n-1}$, which is the backward Euler method. If $r(\lambda) = (1 - \frac{\lambda}{2})/(1 + \frac{\lambda}{2})$, then we have $(1 + \frac{1}{2}kA_h)U^n = (1 - \frac{1}{2}kA_h)U^{n-1}$, which is the Crank–Nicolson method.

Further we define the quotient Q_kU^n to approximate the time derivative $u_{h,t}(t_n)$, with positive integers m_1, m_2 and real numbers c_ν,

$$Q_kU^n = k^{-1} \sum_{\nu=-m_1}^{m_2} c_\nu U^{n+\nu} \quad \text{for } n \geq m_1. \tag{6.3}$$

We assume that the operator Q_k satisfies, for any smooth function u,

$$Q_ku^n - u_t(t_n) = O(k^p), \quad k \to 0. \tag{6.4}$$

The postprocessing step in the fully discrete case is to find $\tilde{u}(T) \in S_h$, $T = t_n$, such that

$$A\tilde{u}(T) = -Q_kU^n. \tag{6.5}$$

The finite element solution of the elliptic problem (6.5) with respect to $\tilde{S}_h$ is to find $\tilde{u}_h(T) \in \tilde{S}_h$, such that

$$\tilde{A}_h\tilde{u}_h(T) = \tilde{P}_h(-Q_kU^n). \tag{6.6}$$

Our main theorem in this section is the following.

THEOREM 6.1. *Let $r \geq 4$ and let S_h and $\tilde{S}_h$ be the finite element spaces of orders r and $r+2$, respectively, as described in section 2. Let $\tilde{u}_h$ and u be the solutions of (6.6) and (6.1), respectively. Let $T = t_n$ be a fixed time. Then we have, if $v_h = R_hv$,*

$$\|\tilde{u}_h(T) - u(T)\| \leq C_0\big(h^{r+2}|v|_{r+2} + k^p|v|_{2(p+1)} + h^{r+2}\|u_t(T)\|_r\big) \quad \textit{for } r \geq 4.$$

Recalling the proof of Theorem 4.1, we note that Theorem 6.1 follows once we have proved appropriate estimates of $\|Q_kU^n - u_t(t_n)\|$ and $|Q_kU^n - u_t(t_n)|_{-2}$, which are given in the following two lemmas.

LEMMA 6.2. *Let U^n and u be the solutions of* (6.2) *and* (6.1), *respectively. Assume that $|r(\lambda)| < 1$ for $\lambda > 0$. Then we have, if $v_h = R_h v$,*

$$\|Q_k U^n - u_t(t_n)\| \le C_0(h^r |v|_{r+2} + k^p |v|_{2(p+1)}).$$

Lemma 6.2 was proved in [30].

LEMMA 6.3. *Let U^n and u be the solutions of* (6.2) *and* (6.1), *respectively. Assume that $|r(\lambda)| < 1$ for $\lambda > 0$. Then we have, if $v_h = R_h v$,*

$$|Q_k U^n - u_t(t_n)|_{-2} \le C_0\big(h^{r+2} |v|_{r+2} + k^p |v|_{2(p+1)}\big).$$

Proof. By Thomée [27, Theorem 6.4], we have

$$\big|u_{h,t}(t) - u_t(t)\big|_{-2} \le C h^{r+2} |v|_{r+2}.$$

Therefore it suffices to show

$$\big|Q_k U^n - u_{h,t}(t_n)\big|_{-2} \le C\big(h^{r+2} |v|_{r+2} + k^p |v|_{2(p+1)}\big), \tag{6.7}$$

which we will prove now.

We first estimate $\big|Q_k U^n - u_{h,t}(t_n)\big|_{-2,h}$. Noting that, with $v_h = R_h v = G_h A v$,

$$\begin{aligned} Q_k U^n - u_{h,t}(t_n) &= k^{-1}\Big(\sum_{\nu=-m_1}^{m_2} c_\nu U^{n+\nu} - (-A_h) e^{-nkA_h}\Big) G_h A v \\ &= k^{-1} g_n(kA_h) G_h A v, \end{aligned}$$

where $g_n(\lambda) = \sum_{\nu=-m_1}^{m_2} r(\lambda)^{n+\nu} - (-\lambda) e^{-n\lambda}$, we need to show

$$\big\|G_h\big(k^{-1} g_n(kA_h) G_h A v\big)\big\| \le C_0\big(h^{r+2} |v|_{r+2} + k^p |v|_{2(p+1)}\big).$$

To do this we set

$$v_k = \sum_{k\lambda_l \le 1} (v, \varphi_l)\varphi_l,$$

where φ_l and λ_l are the eigenfunctions and eigenvalues of the operator A. Then $v_k \in \dot{H}^s$ for each $s \ge 0$. Further, by the definition of the norm in $\dot{H}^s$, we easily find

$$\|A(v - v_k)\| \le k^p |v|_{2p+2}, \tag{6.8}$$

$$|v_k|_{2(p+1)} \le |v|_{2(p+1)}, \tag{6.9}$$

and

$$|v_k|_{r+2l+2} \le k^{-l} |v|_{r+2} \quad \text{for } 0 \le l \le p-1. \tag{6.10}$$

Applying now the identity

$$v = \sum_{j=0}^{p-1} G_h^j (G - G_h) A^{j+1} v + G_h^p A^p v \quad \text{for } v \in \dot{H}^{2p}, \quad \text{where } G_h^0 = I, \tag{6.11}$$

to $v = Av_k$, we get

$$G_h g_n(kA_h)G_hAv_k = \sum_{l=0}^{p-1} g_n(kA_h)G_h^{l+1}\big(G_h(G-G_h)A^{l+2}v_k\big) + G_h g_n(kA_h)G_h^{p+1}A^{p+1}v_k.$$

It is easy to show that (see, e.g., [30, Lemma 3.9])

$$\|g_n(kA_h)G_h^{l+1}\| \le C_0 k^{l+1} \quad \text{for } 0 \le l \le p,\ n \ge 0. \tag{6.12}$$

Thus, by (6.9) and noting the boundedness of G_h,

$$\begin{aligned}\|G_h g_n(kA_h)G_h^{p+1}A^{p+1}v_k\| &\le \|g_n(kA_h)G_h^{p+1}A^{p+1}v_k\| \\ &\le C_0 k^{p+1}\|A^{p+1}v_k\| \le C_0 k^{p+1}|v_k|_{2(p+1)} \le C_0 k^{p+1}|v|_{2(p+1)}.\end{aligned}$$

Further, by (6.10), (6.12), and using (2.13), we have, with $0 \le l \le p-1$,

$$\begin{aligned}&\big\|g_n(kA_h)G_h^{l+1}\big(G_h(G-G_h)A^{l+2}v_k\big)\big\| \le C_0 k^{l+1}\|G_h(G-G_h)A^{l+2}v_k\| \\ &\le C_0 k^{l+1}h^2\|(G-G_h)(A^{l+2}v_k)\| + C_0 k^{l+1}h^{r+2}|A^{l+2}v_k|_{r-2} \\ &\le C_0 k^{l+1}h^{r+2}\|A^{l+2}v_k\|_{r-2} \le C_0 k^{l+1}h^{r+2}|v_k|_{r+2l+2} \le C_0 k h^{r+2}|v|_{r+2}.\end{aligned}$$

Together these estimates imply

$$\|G_h g_n(kA_h)G_hAv_k\| \le C_0 k(h^{r+2}|v|_{r+2} + k^p|v|_{2(p+1)}).$$

Since obviously, by (6.8), the boundedness of G_h, and stability, we get

$$\begin{aligned}\|G_h g_n(kA_h)G_hA(v-v_k)\| &\le \|g_n(kA_h)G_hA(v-v_k)\| \\ &\le C_0 k\|A(v-v_k)\| \le C_0 k^{p+1}|v|_{2(p+1)},\end{aligned}$$

we conclude that

$$\begin{aligned}\|G_h(Q_kU^n - u_{h,t}(t_n))\| &= k^{-1}\|G_h g_n(kA_h)G_hAv\| \\ &\le C_0(h^{r+2}|v|_{r+2} + k^p|v|_{2(p+1)}).\end{aligned}$$

By [30, Theorem 3.8], we have

$$\|Q_kU^n - u_{h,t}(t_n)\| \le C_0(h^r|v|_{r+2} + k^p|v|_{2p}).$$

Thus

$$\begin{aligned}|Q_kU^n - u_{h,t}(t_n)|_{-2} &\le \|(G-G_h)(Q_kU^n - u_{h,t}(t_n))\| \\ &\quad + \|G_h(Q_kU^n - u_{h,t}(t_n))\| \\ &\le C_0(h^{r+2}|v|_{r+2} + k^p|v|_{2(p+1)}).\end{aligned}$$

Together these estimates complete the proof. □

After the preparations above we now come to the proof of Theorem 6.1.

Proof of Theorem 6.1. Combining (6.6) and (6.1), we get, with $\tilde{G}_h = \tilde{A}_h^{-1}$,

$$\begin{aligned}\tilde{u}_h(T) - u(T) &= \tilde{G}_h\tilde{P}_h(-Q_kU^n) - G(-u_t) \\ &= (\tilde{G}_h\tilde{P}_h - G)(-Q_kU^n + u_t(t_n)) \\ &\quad - (\tilde{G}_h\tilde{P}_h - G)u_t(t_n) + G(Q_kU^n - u_t).\end{aligned}$$

Thus, by Lemmas 6.2 and 6.3, and noting that $\|(\tilde{G}_h\tilde{P}_h - G)f\| \le Ch^s\|f\|_{s-2}$ for $0 \le s \le r+2$, we have

$$\begin{aligned}\|\tilde{u}_h(T) - u(T)\| &\le C_0h^2\|Q_kU^n - u_t(t_n)\| \\ &\quad + C_0h^{r+2}\|u_t(t_n)\|_r + |(Q_kU^n - u_t(t_n))|_{-2} \\ &\le C_0\big(h^{r+2}|v|_{r+2} + k^p|v|_{2(p+1)} + h^{r+2}\|u_t(t_n)\|_r\big).\end{aligned}$$

Together these estimates complete the proof. ∎

Acknowledgments. I wish to express my sincere gratitude to Prof. Stig Larsson, Chalmers University of Technology, for suggesting the topic of this paper, and for his support and valuable criticism. I thank Dr. Tony Shardlow for helpful discussions and also thank the referees for a number of valuable comments.

ERROR ESTIMATES TO SMOOTH SOLUTIONS OF RUNGE–KUTTA DISCONTINUOUS GALERKIN METHOD FOR SYMMETRIZABLE SYSTEMS OF CONSERVATION LAWS*

QIANG ZHANG† AND CHI-WANG SHU‡

Abstract. In this paper we study the error estimates to sufficiently smooth solutions of symmetrizable systems of conservation laws for the Runge–Kutta discontinuous Galerkin (RKDG) method. Time discretization is the second-order explicit TVD (total variation diminishing) Runge–Kutta method, and the $\mathbb{P}^k$ (piecewise polynomial) finite element is used. When $k = 1$ (piecewise linear finite element), the error estimate is obtained under the usual CFL condition $\tau \leq \beta h$ for nonlinear systems in one dimension and for linear systems in multiple space dimensions. Here, h is the maximum element length, τ is the time step, and β is a positive constant independent of h and τ. Error estimates for $\mathbb{P}^k$ finite elements with $k > 1$ are obtained under a more restrictive CFL condition.

Key words. discontinuous Galerkin method, finite element method, TVD Runge–Kutta method, error estimates, symmetrizable system, conservation laws

1. Introduction.

In this paper, we continue our work in [24] and present the error estimates of the Runge–Kutta discontinuous Galerkin (RKDG) method for smooth solutions of symmetrizable systems of conservation laws,

$$\boldsymbol{u}_{,t} + \boldsymbol{f}^{(i)}_{,x_i}(\boldsymbol{u}) = 0, \qquad (x,t) \in \Omega \times (0,T], \tag{1.1a}$$

$$\boldsymbol{u}(x,0) = \boldsymbol{u}_0, \qquad x \in \Omega, \tag{1.1b}$$

in the spatial domain $\Omega \in \mathbb{R}^d$ and the time interval $[0,T]$. Here, $\boldsymbol{u}(x,t)\colon \mathbb{R}^d \times \mathbb{R}^+ \to \mathbb{R}^m$ is the dependent solution variable, $\boldsymbol{f}(\boldsymbol{u}) = (\boldsymbol{f}^{(1)}(\boldsymbol{u}), \ldots, \boldsymbol{f}^{(d)}(\boldsymbol{u}))\colon \mathbb{R}^m \to \mathbb{R}^{m\times d}$ is the vector-valued flux function, and the implied summation on the index i is used in (1.1a), i.e., $\boldsymbol{f}^{(i)}_{,x_i} = \sum_{i=1}^d \partial \boldsymbol{f}^{(i)}/\partial x_i$. We do not pay attention to boundary conditions in this paper; hence the solution is considered to be either periodic or compactly supported. For simplicity of presentation, we will give detailed analysis only for the one-dimensional case where $d = 1$ and $\Omega = I = (0,1)$; herein we drop the index i in (1.1). We will, however, point out similarities and differences when the analysis is generalized to multiple space dimensions. We assume, in addition, that each component of the flux function $\boldsymbol{f}(\boldsymbol{u})$ is smooth enough in $\boldsymbol{u}$; for our purpose $C^3(\mathbb{R}^m)$ will suffice. The analysis in this paper is for *smooth* solutions of (1.1). Discontinuous solutions with shocks are not considered.

The RKDG method was introduced and developed by Cockburn and coworkers [4, 5, 3, 2, 6] for solving nonlinear hyperbolic conservation laws; the method uses discontinuous Galerkin (DG) discretization in space and combines it with an explicit total variation diminishing (TVD) Runge–Kutta time-marching algorithm [21]. This method has a good stability property, is flexible for h-p adaptivity, and has a high parallel efficiency. In recent years there has been a lot of activity in the design, analysis, and application of RKDG methods. For more details, we refer to the review article [8].

Although error estimates for linear equations and for the method of lines (continuous in time) version of the RKDG method have been available for a long time (e.g., [15, 14, 7]), error estimates for the fully discrete RKDG method for nonlinear conservation laws with smooth solutions have become available only recently. In [24] we obtained error estimates for scalar conservation laws with piecewise kth-degree polynomial DG spatial discretization coupled with second-order TVD Runge–Kutta time discretization. The analysis assumed the usual CFL condition $\tau \le \beta h$ for the piecewise linear $k = 1$ case, where h is the maximum element length, τ is the time step, and β is a suitable positive constant independent of h and τ. For the higher-order $k > 1$ case, the proof had to assume a much stronger CFL condition $\tau \le \beta h^{4/3}$ for an arbitrary positive constant β. In this paper, we extend these error estimates to symmetrizable systems (see Theorem 2.1).

In the symmetrization theory [20] for the first-order conservation laws, one seeks a mapping $\boldsymbol{u}(\boldsymbol{v})\colon \mathbb{R}^m \to \mathbb{R}^m$ applied to (1.1a) so that when transformed,

$$\boldsymbol{u}_{,\boldsymbol{v}}\boldsymbol{v}_{,t} + \boldsymbol{f}_{,\boldsymbol{v}}\boldsymbol{v}_{,x} = 0, \tag{1.2}$$

the matrix $\boldsymbol{u}_{,\boldsymbol{v}}$ is symmetric positive definite (SPD) and the matrix $\boldsymbol{f}_{,\boldsymbol{v}} = \boldsymbol{f}_{,\boldsymbol{u}}\boldsymbol{u}_{,\boldsymbol{v}}$ is also symmetric, where $\boldsymbol{f}_{,\boldsymbol{v}} = \{\boldsymbol{f}(\boldsymbol{u}(\boldsymbol{v}))\}_{,\boldsymbol{v}}$. We further assume that each component of $\boldsymbol{u}_{,\boldsymbol{v}}$ is Lipschitz continuous with respect to the variable $\boldsymbol{v}$. As is well known, a conservation law system (1.1a) is symmetrizable if and only if it has a convex entropy function [10]. Well-known systems such as the Euler equations of compressible gas dynamics are symmetrizable. If $\boldsymbol{f}_{,\boldsymbol{u}}$ is already symmetric, the system (1.1a) is symmetric. It is rather straightforward to generalize the error estimates in [24] from the scalar case to symmetric systems. However, there are not that many physical systems that are symmetric. On the other hand, as we will see later in this paper, it is significantly more difficult to generalize the error estimates in [24] from the scalar case to symmetrizable systems.

The line of analysis in this paper follows that of [24]. The main techniques are Taylor expansions and energy analysis. In generalizing the analysis from the scalar case to systems, we need to pay attention to the suitable norm in the analysis, to a careful classification of the necessary properties for the numerical fluxes, to the complication related to the fact that derivatives (Jacobians) and second derivatives of the flux functions are matrices and supermatrices, and to a suitable generalization of the a priori assumption about the numerical solution. We will present a series of lemmas, which mostly correspond to those in [24]. If the proofs have only minor differences, we will comment on such differences and will not repeat the details. We will concentrate our analysis on the piecewise $k = 1$ case for the DG method, since higher-order cases can be analyzed with the stronger CFL condition $\tau \le \beta h^{4/3}$, following the same lines as those in [24], once the $k = 1$ case is proved.

An outline of this paper is as follows. In section 2 we present, for (1.1), the RKDG method and the corresponding convergence theorem with the second-order

TVD Runge–Kutta time discretization, where we introduce a definition of the generalized E-flux property for symmetrizable systems of conservation laws. In section 3 we present a proposition for an important matrix which measures the amount of numerical viscosity on each element interface, and perform some elementary analysis to the error equations. We prove the convergence theorem in section 4. Section 5 is an appendix, in which we give the technical details of the estimates omitted in previous sections.

2. RKDG method and the convergence theorem. In this section we will follow [6] and define the RKDG method for the problem (1.1) in one space dimension, presenting the corresponding convergence theorem without proof. The multidimensional scheme can be similarly defined, and the analysis can be carried out in a similar fashion for linear as well as nonlinear symmetrizable systems with a few modifications; see Remark 4.2.

2.1. RKDG method. For each partition of the interval $I = (0,1)$, $\{x_{j+\frac{1}{2}}\}_{j=0}^{N}$, we set $I_j = (x_{j-\frac{1}{2}}, x_{j+\frac{1}{2}})$ and $h_j = x_{j+\frac{1}{2}} - x_{j-\frac{1}{2}}$ for $j = 1, \ldots, N$; we denote the quantity $\max_{1\le j\le N} h_j$ by h. For a given time step $\tau \equiv \tau^n$ (which could actually change from step to step, but is taken as a constant with respect to the time level n for simplicity), the solution of the scheme is denoted by $\boldsymbol{u}_h^n(x) = \boldsymbol{u}_h(x, t^n) = \boldsymbol{u}_h(x, n\tau)$, which belongs to the finite element space

$$\mathbb{V}_h = \{\, \boldsymbol{v} \in [L^1(0,1)]^m : \boldsymbol{v}|_{I_j} \in [\mathbb{P}^k(I_j)]^m,\ j = 1, \ldots, N \,\}, \tag{2.1}$$

where $\mathbb{P}^k(I_j)$ denotes the space of polynomials in I_j of degree at most k. Note that each component of a vector-valued function in $\mathbb{V}_h$ is allowed to have discontinuities across element interfaces.

In what follows, we will consider the standard L^2-projection of a vector-valued function $\boldsymbol{p} \in [L^2(0,1)]^m$ into the finite element space $\mathbb{V}_h$, denoted by $\mathbb{P}_h \boldsymbol{p}$, which is defined as the unique vector-valued function in $\mathbb{V}_h$ such that

$$\int_0^1 \boldsymbol{z}_h^T(x)(\mathbb{P}_h \boldsymbol{p}(x) - \boldsymbol{p}(x))\, dx = 0 \quad \forall \boldsymbol{z}_h \in \mathbb{V}_h, \tag{2.2}$$

where $\boldsymbol{z}^T$ denotes the transpose of the vector $\boldsymbol{z}$.

As usual, at each element interface we will denote, for a vector-valued function $\boldsymbol{z}$, two limiting values from different directions by $\boldsymbol{z}^{\pm}_{j+1/2} = \boldsymbol{z}(x_{j+1/2} \pm 0)$, and denote the average and jump by $\bar{\boldsymbol{z}} = (\boldsymbol{z}^+ + \boldsymbol{z}^-)/2$ and $[\boldsymbol{z}] = \boldsymbol{z}^+ - \boldsymbol{z}^-$, respectively. We also define, for any vector-valued functions $\boldsymbol{p}$ and $\boldsymbol{z}$, the following functional corresponding to the DG spatial discretization:

$$\mathcal{H}_j(\boldsymbol{p}, \boldsymbol{z}) = \int_{I_j} \boldsymbol{z}_{,x}^T \boldsymbol{f}(\boldsymbol{p})\, dx - (\boldsymbol{z}^-_{j+\frac{1}{2}})^T \hat{\boldsymbol{h}}(\boldsymbol{p})_{j+\frac{1}{2}} + (\boldsymbol{z}^+_{j-\frac{1}{2}})^T \hat{\boldsymbol{h}}(\boldsymbol{p})_{j-\frac{1}{2}}, \tag{2.3}$$

where $\hat{\boldsymbol{h}}(\boldsymbol{p}) \equiv \hat{\boldsymbol{h}}(\boldsymbol{p}^-, \boldsymbol{p}^+)$ is a given (locally) Lipschitz continuous numerical flux function consistent with the flux function $\boldsymbol{f}(\boldsymbol{p})$, that is, $\hat{\boldsymbol{h}}(\boldsymbol{p}, \boldsymbol{p}) = \boldsymbol{f}(\boldsymbol{p})$. In this paper, we will also assume that $\hat{\boldsymbol{h}}(\boldsymbol{p})$ is a generalized E-flux function, to be defined in the next subsection 2.2.

The approximate solution in $\mathbb{V}_h$ from time $n\tau$ to $(n+1)\tau$ given by the RKDG method with second-order TVD time discretization can now be defined as follows:

find successively $\boldsymbol{w}_h^n \equiv \boldsymbol{w}_h^n(x) \in \mathbb{V}_h$ and $\boldsymbol{u}_h^{n+1} \equiv \boldsymbol{u}_h^{n+1}(x) \in \mathbb{V}_h$ such that, for any $\boldsymbol{z}_h \equiv \boldsymbol{z}_h(x) \in [\mathbb{P}^k(I_j)]^m$ and $1 \le j \le N$,

$$\int_{I_j} \boldsymbol{z}_h^T \boldsymbol{w}_h^n \, dx = \int_{I_j} \boldsymbol{z}_h^T \boldsymbol{u}_h^n \, dx + \tau \mathcal{H}_j(\boldsymbol{u}_h^n, \boldsymbol{z}_h), \tag{2.4a}$$

$$\int_{I_j} \boldsymbol{z}_h^T \boldsymbol{u}_h^{n+1} \, dx = \frac{1}{2} \int_{I_j} \boldsymbol{z}_h^T \boldsymbol{u}_h^n \, dx + \frac{1}{2} \int_{I_j} \boldsymbol{z}_h^T \boldsymbol{w}_h^n \, dx + \frac{\tau}{2} \mathcal{H}_j(\boldsymbol{w}_h^n, \boldsymbol{z}_h), \tag{2.4b}$$

with the initial value $\boldsymbol{u}_h^0 = \mathbb{P}_h \boldsymbol{u}_0(x)$. This is an explicit time marching method when a local orthogonal basis is chosen for polynomials on I_j or when a small local mass matrix on I_j is inverted. Numerical results and details of this scheme can be found in [9] and [8].

2.2. Generalized E-flux. In this subsection we will introduce an important assumption on the numerical fluxes used in the scheme (2.4). The symmetrizable theory implies that the Jacobian $\boldsymbol{f}_{,\boldsymbol{u}}$ is similar to a symmetric matrix, since

$$\boldsymbol{u}_{,\boldsymbol{v}}^{-1/2} \boldsymbol{f}_{,\boldsymbol{u}} \boldsymbol{u}_{,\boldsymbol{v}}^{1/2} = \boldsymbol{u}_{,\boldsymbol{v}}^{-1/2} \boldsymbol{f}_{,\boldsymbol{v}} \boldsymbol{u}_{,\boldsymbol{v}}^{-1/2} \tag{2.5}$$

and the matrix on the right-hand side is symmetric. It give us a motivation to preserve more properties of the numerical flux from the scalar and symmetric system cases to the symmetrizable system case.

We assume in this paper that the numerical flux function $\hat{\boldsymbol{h}}(\boldsymbol{p})$ is locally Lipschitz continuous and, for $\boldsymbol{r}_i = \boldsymbol{p}^-$, $\bar{\boldsymbol{p}}$, and $\boldsymbol{p}^+$, satisfies

$$(\boldsymbol{p}^+ - \boldsymbol{p}^-)^T \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{s}_i)\{\boldsymbol{f}(\boldsymbol{r}_i) - \hat{\boldsymbol{h}}(\boldsymbol{p})\} \ge 0, \quad i = 1, 2, 3, \tag{2.6}$$

for some reference vectors $\boldsymbol{s}_i$, $i = 1, 2, 3$, which are inside the m-dimensional cube, with $\boldsymbol{p}^+$ and $\boldsymbol{p}^-$ being the endpoints of the longest diagonal line. These reference vectors may depend on the numerical fluxes $\hat{\boldsymbol{h}}$ and on $\boldsymbol{p}^{\pm}$.

The inequality (2.6), for a symmetric system of conservation laws (in which case $\boldsymbol{v}_{,\boldsymbol{u}} \equiv \mathbf{I}$), has been considered in [13] as an E-flux (see [17] for the definition of E-fluxes for scalar conservation laws). Therefore, we refer to a numerical flux satisfying (2.6) as a generalized E-flux. It is easy to verify that the property (2.6) holds for many numerical flux functions constructed from approximate Riemann solvers: for example, the Roe linearization flux function [19], with or without Harten's entropy fix [11], and the global (local) Lax–Friedrichs flux, where $\boldsymbol{s}_i$ may be chosen as the so-called Roe average [19] of $\boldsymbol{p}^+$ and $\boldsymbol{p}^-$.

2.3. The convergence theorem. We now present the main convergence theorem of the RKDG scheme (2.4). The proof will be given in the next two sections.

THEOREM 2.1. *For the symmetrizable system of conservation laws* (1.1)*, assume that the solution* $\boldsymbol{u}$ *and the flux function* $\boldsymbol{f}(\boldsymbol{u})$ *are sufficiently smooth with bounded derivatives. Let* $\boldsymbol{u}_h$ *be the numerical approximate solution of the RKDG scheme* (2.4) *with the second-order TVD Runge–Kutta time discretization, where the numerical flux* $\hat{\boldsymbol{h}}(\cdot, \cdot)$ *is assumed to be a generalized E-flux; namely,* (2.6) *is satisfied. For regular triangulations of* $I = (0, 1)$*, if the finite element space* $\mathbb{V}_h$ *is of piecewise polynomials of degree* $k \ge 1$*, then for small enough* h *there holds the following estimate:*

$$\max_{n\tau \le T} ||\boldsymbol{u}(t^n) - \boldsymbol{u}_h^n||_{L^2(0,1)} \le C(h^{k+1/2} + \tau^2), \tag{2.7}$$

where the positive constant C is independent of h, τ, and the approximate solution $\boldsymbol{u}_h$. This estimate holds for $k \geq 2$ under the restrictive time step condition $\tau \leq \beta h^{4/3}$ with any given positive constant β; meanwhile, it holds for $k = 1$ under the usual CFL condition $\tau \leq \beta h$ with a suitable positive CFL number β which is independent of τ and h.

We remark that the power $h^{k+1/2}$ is optimal for general triangulations [18] for the scalar case but is suboptimal for the one-dimensional case with scalar equations. The proof of the optimal order h^{k+1} for the scalar case requires special upwind fluxes [24], which can be done for the system case (1.1) as well in some special situations. See Remark 4.3 in section 4.

For the generalization of these results to multiple space dimensions, see Remark 4.2 in section 4.

In what follows, we would like to assume as in [24] that each component of the flux function $\boldsymbol{f}(\cdot)$ itself, and its derivatives up to third order, are bounded in the domain $\mathbb{R}^m$. This assumption is nonessential if we consider only smooth solutions of (1.1) to a finite time T. We could achieve the desired boundedness by redefining the flux function $\boldsymbol{f}(\boldsymbol{u})$ outside the range of the solution $\boldsymbol{u}$; cf. [24].

We denote the inverse mapping of $\boldsymbol{u}(\boldsymbol{v})$ by $\boldsymbol{v}(\boldsymbol{u})$. The symmetrizable theory provides that the Jacobians $\boldsymbol{u}_{,\boldsymbol{v}}(\boldsymbol{v})$ and $\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u})$ are both SPD and Lipschitz continuous. Similarly as above, we assume that these properties hold uniformly in the domain $\mathbb{R}^m$ and that the spectrum of the Jacobians is bounded.

We would also like to denote, by C, $C_\star$, M, or ε, a generic positive constant independent of n, h, and τ. Herein, M and ε are used to denote constants which are independent of the solution of (1.1). $C_\star$ is used to emphasize the nonlinearity of $\boldsymbol{f}(\boldsymbol{u})$; i.e., $C_\star = 0$ for a linear flux function $\boldsymbol{f}(\boldsymbol{u}) = \mathbb{C}\boldsymbol{u}$. These constants may have a different value in each occurrence.

3. Error equations, energy equality, and a few estimates. We follow the idea in [24] to obtain the error estimate to sufficiently smooth solutions for the RKDG scheme (2.4). In this section we will present some elementary development similar to that in [24], and we omit the detailed proof if it is similar to that in [24].

3.1. Error equations and energy equality. We denote the error at each stage of the considered RKDG scheme by $\boldsymbol{e}_{\boldsymbol{u}}^n = \boldsymbol{u}(x, t^n) - \boldsymbol{u}_h^n$ and $\boldsymbol{e}_{\boldsymbol{w}}^n = \boldsymbol{w}(x, t^n) - \boldsymbol{w}_h^n$, respectively, where $\boldsymbol{w}(x, t)$ is a vector-valued function in parallel to an Euler forward time marching, namely

$$\boldsymbol{w}(x, t) = \boldsymbol{u}(x, t) + \tau \boldsymbol{u}_{,t}(x, t). \tag{3.1}$$

As is customary in finite element error analysis, we define $\boldsymbol{\xi}_{\boldsymbol{p}} = \mathbb{P}_h \boldsymbol{p} - \boldsymbol{p}_h$ and $\boldsymbol{\eta}_{\boldsymbol{p}} = \mathbb{P}_h \boldsymbol{p} - \boldsymbol{p}$, where $\mathbb{P}_h$ is the local L^2-projection. Then the error is decomposed by $\boldsymbol{e}_{\boldsymbol{p}}^n = \boldsymbol{\xi}_{\boldsymbol{p}}^n - \boldsymbol{\eta}_{\boldsymbol{p}}^n$, where $\boldsymbol{p} = \boldsymbol{u}$ or $\boldsymbol{w}$. The estimates for $\boldsymbol{\eta}_{\boldsymbol{p}}$ will be discussed easily in subsection 3.2, while the estimates to $\boldsymbol{\xi}_{\boldsymbol{p}}$ contain the main difficulty in the analysis.

To perform this analysis, we need the error equations of the RKDG scheme (2.4). These can be obtained by algebraic manipulations similar to those in [23, 24] (cf. Lemma 4.1 in [24]). The error equations are given by

$$\int_{I_j} \boldsymbol{z}_h^T \boldsymbol{\xi}_{\boldsymbol{w}}^n \, dx = \int_{I_j} \boldsymbol{z}_h^T \boldsymbol{\xi}_{\boldsymbol{u}}^n \, dx + \mathcal{K}_j^n(\boldsymbol{z}_h), \tag{3.2a}$$

$$\int_{I_j} \boldsymbol{z}_h^T \boldsymbol{\xi}_{\boldsymbol{u}}^{n+1} \, dx = \int_{I_j} \boldsymbol{z}_h^T \boldsymbol{\xi}_{\boldsymbol{u}}^n \, dx + \frac{1}{2}\mathcal{K}_j^n(\boldsymbol{z}_h) + \frac{1}{2}\mathcal{L}_j^n(\boldsymbol{z}_h), \tag{3.2b}$$

for any $\boldsymbol{z}_h(x) \in [\mathbb{P}^k(I_j)]^m$ and $1 \le j \le N$, where

(3.2c)
$$\mathcal{K}_j^n(\boldsymbol{z}_h) = \int_{I_j} \boldsymbol{z}_h^T(\boldsymbol{\eta}_{\boldsymbol{w}}^n - \boldsymbol{\eta}_{\boldsymbol{u}}^n)\,dx + \tau\mathcal{H}_j(\boldsymbol{u}(t^n), \boldsymbol{z}_h) - \tau\mathcal{H}_j(\boldsymbol{u}_h^n, \boldsymbol{z}_h),$$

(3.2d)
$$\mathcal{L}_j^n(\boldsymbol{z}_h) = \int_{I_j} \boldsymbol{z}_h^T(2\boldsymbol{\eta}_{\boldsymbol{u}}^{n+1} - \boldsymbol{\eta}_{\boldsymbol{w}}^n - \boldsymbol{\eta}_{\boldsymbol{u}}^n + 2\boldsymbol{\zeta}^n)\,dx + \tau\mathcal{H}_j(\boldsymbol{w}(t^n), \boldsymbol{z}_h) - \tau\mathcal{H}_j(\boldsymbol{w}_h^n, \boldsymbol{z}_h).$$

Here $\boldsymbol{\zeta}^n$ is the truncation error in time, with the size $\mathcal{O}(\tau^3)$. Below we will use the short notation $\mathcal{K}^n(\boldsymbol{z}_h) = \sum_{1\le j\le N} \mathcal{K}_j^n(\boldsymbol{z}_h)$ and $\mathcal{L}^n(\boldsymbol{z}_h) = \sum_{1\le j\le N} \mathcal{L}_j^n(\boldsymbol{z}_h)$.

We will use energy estimates to analyze the error of the RKDG scheme (2.4). To this end, we define a norm which depends on the time level n, given by $||\boldsymbol{p}||_n = ||\boldsymbol{v}_{,\boldsymbol{u}}^{1/2}(\boldsymbol{u}_c^n)\boldsymbol{p}||$, for any vector-valued function $\boldsymbol{p}$, where $\boldsymbol{u}_c^n$ is the piecewise constant vector-valued function that is equal to the vector $\boldsymbol{u}(x_j, t^n)$ in each element I_j. The symmetrizable theory guarantees that the $||\cdot||_n$ norm is equivalent to the usual L^2-norm $||\cdot||$.

We first take the test function $\boldsymbol{z}_h = \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)\boldsymbol{\xi}_{\boldsymbol{u}}^n$ in (3.2a) and $\boldsymbol{z}_h = \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{w}_c^n)\boldsymbol{\xi}_{\boldsymbol{w}}^n$ in (3.2b), respectively, which belongs to the finite element space $\mathbb{V}_h$. By adding the two equalities together, we obtain the energy equation

$$||\boldsymbol{\xi}_{\boldsymbol{u}}^{n+1}||_n^2 - ||\boldsymbol{\xi}_{\boldsymbol{u}}^n||_n^2 = ||\boldsymbol{\xi}_{\boldsymbol{u}}^{n+1} - \boldsymbol{\xi}_{\boldsymbol{w}}^n||_n^2 + \mathcal{K}^n(\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)\boldsymbol{\xi}_{\boldsymbol{u}}^n) + \mathcal{L}^n(\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{w}_c^n)\boldsymbol{\xi}_{\boldsymbol{w}}^n) + \mathcal{E}^n, \tag{3.3a}$$

where

$$\mathcal{E}^n = \int_I (\boldsymbol{\xi}_{\boldsymbol{w}}^n)^T(\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n) - \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{w}_c^n))(2\boldsymbol{\xi}_{\boldsymbol{u}}^{n+1} - \boldsymbol{\xi}_{\boldsymbol{u}}^n - \boldsymbol{\xi}_{\boldsymbol{w}}^n)\,dx \tag{3.3b}$$

and $\boldsymbol{w}_c^n$ is defined in the same way as $\boldsymbol{u}_c^n$; i.e., it is the piecewise constant vector-valued function which is equal to the vector $\boldsymbol{w}(x_j, t^n)$ in each element I_j. In order to obtain the error estimate, we shall analyze carefully each term on the right-hand side of this important energy equation (3.3) in the next section.

3.2. Properties of the finite element spaces. In this subsection we present some interpolation approximation and inverse inequalities of the finite element space $\mathbb{V}_h$, which consists of piecewise polynomials of degree at most k. The usual notation for norms and seminorms in Sobolev spaces will be used below.

The local L^2-projection is enough to prove Theorem 2.1 for general numerical flux functions with the suboptimal error bound $Ch^{k+1/2}$. By the standard scaling theory, it is easy to show (cf. [1]) that if $\boldsymbol{u}$ and $\boldsymbol{u}_{,t} \in L^\infty([0,T]; [H^{k+1}(I)]^m)$, then

$$||\boldsymbol{\eta}_{\boldsymbol{p}}^n|| + h||\boldsymbol{\eta}_{\boldsymbol{p}}^n||_\infty + h^{\frac{1}{2}}||\boldsymbol{\eta}_{\boldsymbol{p}}^n||_{\Gamma_h} \le Ch^{k+1} \quad (\boldsymbol{p} = \boldsymbol{u}, \boldsymbol{w},\ \forall n : n\tau \le T), \tag{3.4a}$$

where Γ_h is the set of boundary interfaces of all elements and $||\cdot||_{\Gamma_h}$ is the usual L^2-norm on Γ_h. Noticing the definition (3.1) of $\boldsymbol{w}$ and the linearity of the L^2-projection $\mathbb{P}_h$, we can conclude that if $\boldsymbol{u}_{,t} \in L^\infty([0,T]; [H^{k+1}(I)]^m)$, then

$$||\boldsymbol{\eta}_{\boldsymbol{u}}^{n+1} - \boldsymbol{\eta}_{\boldsymbol{u}}^n|| + ||\boldsymbol{\eta}_{\boldsymbol{w}}^n - \boldsymbol{\eta}_{\boldsymbol{u}}^n|| \le Ch^{k+1}\tau \quad \forall n : n\tau < T. \tag{3.4b}$$

In these inequalities the positive constant C depends solely on $\boldsymbol{u}, \boldsymbol{w}$, and/or $\boldsymbol{u}_{,t}$ and is independent of n, h, and τ.

In the following analysis we will also use some inverse inequalities of the finite element space $\mathbb{V}_h$. For any vector-valued function $\boldsymbol{z}_h \in \mathbb{V}_h$, there is a positive constant C independent of $\boldsymbol{z}_h$ and h such that

$$\text{(i) } ||(\boldsymbol{z}_h)_{,x}|| \le Ch^{-1}||\boldsymbol{z}_h||, \quad \text{(ii) } ||\boldsymbol{z}_h||_{\Gamma_h} \le Ch^{-\frac{1}{2}}||\boldsymbol{z}_h||, \quad \text{(iii) } ||\boldsymbol{z}_h||_\infty \le Ch^{-\frac{1}{2}}||\boldsymbol{z}_h||.$$

For more details of these inverse inequalities, we refer to [1].

3.3. An important matrix related to the numerical flux. In this subsection we will introduce an important matrix $\mathcal{A}(\hat{\boldsymbol{h}};\boldsymbol{p})$ associated with a generalized E-flux function $\hat{\boldsymbol{h}}(\boldsymbol{p})$ satisfying (2.6), which measures the numerical viscosity of the flux on each element interface. It is a generalization of a similar quantity in [24] for the scalar case, although we make a minor modification because the definition of the generalized E-flux (2.6) is weaker than that of an E-flux, as we require the inequality (2.6) to hold only for the end points $\boldsymbol{p}^\pm$ and the midpoint $\bar{\boldsymbol{p}}$, rather than for all points between $\boldsymbol{p}^\pm$ for an E-flux. See also [11].

In the next proposition we will use the following notation. If there exists an invertible matrix $\mathbb{T}$ such that $\mathbb{A} = \mathbb{T}^{-1}\mathbb{B}\mathbb{T}$, where $\mathbb{B} = \mathrm{diag}(\lambda_1, \ldots, \lambda_m)$ is a diagonal matrix, then we denote its absolute value matrix by $|\mathbb{A}| = \mathbb{T}^{-1}\mathrm{diag}(|\lambda_1|, \ldots, |\lambda_m|)\mathbb{T}$. We also denote $\mathbb{J}(\boldsymbol{p}) = \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{p})\boldsymbol{f}_{,\boldsymbol{u}}(\boldsymbol{p}) = \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{p})\boldsymbol{f}_{,\boldsymbol{v}}(\boldsymbol{v}(\boldsymbol{p}))\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{p})$, which is a symmetric matrix in the symmetrizable theory.

PROPOSITION 3.1. *Assume that the generalized E-flux property* (2.6) *holds for the numerical flux* $\hat{\boldsymbol{h}}(\boldsymbol{p}) \equiv \hat{\boldsymbol{h}}(\boldsymbol{p}^-, \boldsymbol{p}^+)$*, which is consistent with the flux* $\boldsymbol{f}(\boldsymbol{p})$*. Define the matrix on each element interface*

$$\mathcal{A}(\hat{\boldsymbol{h}};\boldsymbol{p}) \equiv \mathcal{A}(\hat{\boldsymbol{h}};\boldsymbol{p}^-,\boldsymbol{p}^+) := \begin{cases} \dfrac{1}{6}\mathcal{A}_1 + \dfrac{2}{3}\mathcal{A}_2 + \dfrac{1}{6}\mathcal{A}_3, & \text{if } [\boldsymbol{p}] \neq \boldsymbol{0}, \\ \big|\mathbb{J}(\bar{\boldsymbol{p}})\big|, & \text{if } [\boldsymbol{p}] = \boldsymbol{0}, \end{cases} \tag{3.5a}$$

where

$$\mathcal{A}_i = \frac{\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{s}_i)\{\boldsymbol{f}(\boldsymbol{r}_i) - \hat{\boldsymbol{h}}(\boldsymbol{p})\}[\boldsymbol{p}]^T}{[\boldsymbol{p}]^T[\boldsymbol{p}]}, \qquad i = 1, 2, 3, \tag{3.5b}$$

and $\boldsymbol{r}_i$ *and* $\boldsymbol{s}_i$*,* $i = 1, 2, 3$*, are the vectors defined in subsection* 2.2*. Then for any vector* $\boldsymbol{p} \in \mathbb{R}^m$*, the spectrum of* $\mathcal{A}(\hat{\boldsymbol{h}};\boldsymbol{p})$ *is bounded and* $[\boldsymbol{p}]^T\mathcal{A}(\hat{\boldsymbol{h}};\boldsymbol{p})[\boldsymbol{p}] \ge 0$*; moreover,*

$$\frac{1}{3}[\boldsymbol{p}]^T\big|\mathbb{J}(\bar{\boldsymbol{p}})\big|[\boldsymbol{p}] \le [\boldsymbol{p}]^T\mathcal{A}(\hat{\boldsymbol{h}};\boldsymbol{p})[\boldsymbol{p}] + C_\star||[\boldsymbol{p}]||^3, \tag{3.6}$$

where the positive constant $C_\star$ *is determined solely by the nonlinearity of the flux* $\boldsymbol{f}(\boldsymbol{p})$*, and* $||[\boldsymbol{p}]||$ *is the length of the vector* $[\boldsymbol{p}]$*.*

Proof. The boundedness of spectrum is implied by the Lipschitz continuity of the numerical flux $\hat{\boldsymbol{h}}(\cdot,\cdot)$. The positive property $[\boldsymbol{p}]^T\mathcal{A}(\hat{\boldsymbol{h}};\boldsymbol{p})[\boldsymbol{p}] \ge 0$ is evident, since $[\boldsymbol{p}]^T\mathcal{A}_i[\boldsymbol{p}] \ge 0$ by the generalized E-flux property (2.6).

If $[\boldsymbol{p}] = \boldsymbol{0}$, the conclusion (3.6) is trivial. Otherwise, we start our proof from the equality

$$\begin{aligned}
[\boldsymbol{p}]^T\mathcal{A}_2[\boldsymbol{p}] &= [\boldsymbol{p}]^T\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{s}_2)\{\boldsymbol{f}(\boldsymbol{r}_2) - \hat{\boldsymbol{h}}(\boldsymbol{p})\} \\
&= [\boldsymbol{p}]^T\boldsymbol{v}_{,\boldsymbol{u}}(\bar{\boldsymbol{p}})\{\boldsymbol{f}(\boldsymbol{r}_2) - \boldsymbol{f}(\boldsymbol{r}_j)\} + [\boldsymbol{p}]^T\{\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{s}_2) - \boldsymbol{v}_{,\boldsymbol{u}}(\bar{\boldsymbol{p}})\}\{\boldsymbol{f}(\boldsymbol{r}_2) - \boldsymbol{f}(\boldsymbol{r}_j)\} \\
&\quad + [\boldsymbol{p}]^T\{\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{s}_2) - \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{s}_j)\}(\boldsymbol{f}(\boldsymbol{r}_j) - \hat{\boldsymbol{h}}(\boldsymbol{p})) + [\boldsymbol{p}]^T\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{s}_j)(\boldsymbol{f}(\boldsymbol{r}_j) - \hat{\boldsymbol{h}}(\boldsymbol{p}))
\end{aligned}$$

and proceed to estimate each term on the right-hand side separately. In this equality $\boldsymbol{r}_2 = \bar{\boldsymbol{p}}$, and $\boldsymbol{r}_j$ will be taken as $j = 1$ and 3, namely $\boldsymbol{p}^+$ and $\boldsymbol{p}^-$.

It is easy to see that the absolute values of the middle two terms are bounded by $\mathcal{O}(|||[\boldsymbol{p}]|||^3)$, since $\boldsymbol{f}$, $\hat{\boldsymbol{h}}$, and $\boldsymbol{v}_{,\boldsymbol{u}}$ are all Lipschitz continuous, and that the last term is nonnegative by the generalized E-flux property (2.6).

We estimate the first term by simple Taylor expansions up to second order. We remark that the expansions are performed along the line with endpoints $\boldsymbol{p}^{\pm}$, i.e., for the single-variable function $\tilde{\boldsymbol{f}}(s) = \boldsymbol{f}(s\boldsymbol{p}^+ + (1-s)\boldsymbol{p}^-)$, where $s \in [0,1]$. It is obvious that $\boldsymbol{f}(\boldsymbol{p}^+) = \tilde{\boldsymbol{f}}(1)$, $\boldsymbol{f}(\bar{\boldsymbol{p}}) = \tilde{\boldsymbol{f}}(\frac{1}{2})$, and $\boldsymbol{f}(\boldsymbol{p}^-) = \tilde{\boldsymbol{f}}(0)$. Together with $[\boldsymbol{p}]^T \mathcal{A}_i [\boldsymbol{p}] \geq 0$ for $i = 1, 3$, the Taylor expansions at the point $\bar{\boldsymbol{p}}$ finally give that

$$[\boldsymbol{p}]^T \mathcal{A}(\hat{\boldsymbol{h}}; \boldsymbol{p})[\boldsymbol{p}] \geq \pm \frac{1}{3} [\boldsymbol{p}]^T \boldsymbol{v}_{,\boldsymbol{u}}(\bar{\boldsymbol{p}}) \boldsymbol{f}_{,\boldsymbol{v}}(\boldsymbol{v}(\bar{\boldsymbol{p}})) \boldsymbol{v}_{,\boldsymbol{u}}(\bar{\boldsymbol{p}})[\boldsymbol{p}] - C_\star |||[\boldsymbol{p}]|||^3.$$

Due to the Lipschitz property of $\boldsymbol{f}$ and $\hat{\boldsymbol{h}}$, each component of $\mathcal{A}(\boldsymbol{h}; \bar{\boldsymbol{p}} - \frac{1}{2}\boldsymbol{r}, \bar{\boldsymbol{p}} + \frac{1}{2}\boldsymbol{r})$ is Lipschitz continuous with respect to the variable $\boldsymbol{p}$, on the m-dimensional sphere with diameter $|||[\boldsymbol{p}]|||$. Therefore we have

$$\frac{1}{3} \left| \boldsymbol{r}^T \mathbb{J}(\bar{\boldsymbol{p}}) \boldsymbol{r} \right| \leq \boldsymbol{r}^T \mathcal{A}(\hat{\boldsymbol{h}}; \boldsymbol{p}) \boldsymbol{r} + C_\star |||[\boldsymbol{p}]|||^3 \quad \forall \boldsymbol{r} : ||\boldsymbol{r}|| = \frac{1}{2} |||[\boldsymbol{p}]|||.$$

Thus it is easy to conclude the inequality (3.6). This completes the proof of this proposition. ∎

Remark 3.1. The inequality (3.6) also holds for other numerical flux functions which may violate the generalized E-flux property (2.6) slightly, e.g., the Harten–Hyman flux function [12] and the local Lax–Friedrichs flux function with an entropy fix (cf. [16]). For these fluxes, the deviation to (2.6) is of the order $\mathcal{O}(|||[\boldsymbol{p}]|||_\infty^4)$, which does not affect the proof of inequality (3.6).

In what follows we will adopt some convenient notations about the matrix $\mathcal{A}(\hat{\boldsymbol{h}}; \boldsymbol{p})$. If there is no confusion, we will, for any vector-valued function $\boldsymbol{p}$, denote

$$A(\boldsymbol{p}) = \sum_{1 \leq j \leq N} [\boldsymbol{p}]^T_{j+\frac{1}{2}} \mathcal{A}(\hat{\boldsymbol{h}}; \boldsymbol{p})_{j+\frac{1}{2}} [\boldsymbol{p}]_{j+\frac{1}{2}}.$$

We will also denote by $\varrho(\boldsymbol{p})$ the maximum of the spectral radius of $\mathcal{A}(\hat{\boldsymbol{h}}; \boldsymbol{p})$ over all element interfaces. As a result of Proposition 3.1, we have that each spectrum of $|\mathbb{J}(\boldsymbol{p})|$ is bounded by $3\varrho(\boldsymbol{p}) + C_\star |||[\boldsymbol{p}]|||$. Also, we have that each spectrum is "almost positive"; i.e., if the spectrum is less than zero, then its absolute value must be bounded by $C_\star |||[\boldsymbol{p}]|||$.

3.4. General estimates for the operators $\mathcal{L}$ and $\mathcal{K}$. In this subsection we present a few general inequalities with regard to the operators $\mathcal{L}$ and $\mathcal{K}$ for any test function. They will be used in the next section to estimate the error resulting from the second-order Runge–Kutta time discretization. We remark that all estimates given in this subsection hold for the finite element space $\mathbb{V}_h$ with any degree k.

By subtracting the error equation (3.2a) from (3.2b), for any $1 \leq j \leq N$ we have that

$$\int_{I_j} \boldsymbol{z}_h^T \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)(\boldsymbol{\xi}_{\boldsymbol{u}}^{n+1} - \boldsymbol{\xi}_{\boldsymbol{w}}^n)\, dx = \frac{1}{2}(\mathcal{L}_j^n - \mathcal{K}_j^n)(\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)\boldsymbol{z}_h) \quad \forall\, \boldsymbol{z}_h \in [\mathbb{P}^k(I_j)]^m, \tag{3.7}$$

and consequently $||\boldsymbol{\xi}_{\boldsymbol{u}}^{n+1} - \boldsymbol{\xi}_{\boldsymbol{w}}^n||_n^2 = \frac{1}{2}(\mathcal{L}^n - \mathcal{K}^n)(\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)(\boldsymbol{\xi}_{\boldsymbol{u}}^{n+1} - \boldsymbol{\xi}_{\boldsymbol{w}}^n))$. It is therefore natural to start the analysis with an estimate of the difference between $\mathcal{L}^n$ and $\mathcal{K}^n$ for

an arbitrary test function. The main ingredient in the analysis is to obtain a sharp bound for the errors occurring on the element interfaces.

For the following two lemmas, there are only minor modifications from the scalar case [24] to the system case in the analysis, so we will present here only the estimates without proof. The main modification is that the Taylor expansions are changed from single variable to multiple variables, where the derivative $f'(u)$ and its maximum magnitude are replaced by the Jacobian $\boldsymbol{f}_{,\boldsymbol{u}}(\boldsymbol{u})$ and its maximum spectral radius, respectively. The definition (3.5) on each element interface also yields a few differences, resulting from a new choice of the reference vector for system case, i.e., $\frac{1}{6}\boldsymbol{f}(\boldsymbol{u}_h^-) + \frac{2}{3}\boldsymbol{f}(\bar{\boldsymbol{u}}_h) + \frac{1}{6}\boldsymbol{f}(\boldsymbol{u}_h^+)$, instead of $f(\bar{u}_h)$ in [24] for the scalar case.

LEMMA 3.1. *Assume that the interpolation property* (3.4) *and Proposition* 3.1 *hold. Given any small positive constant ε, we have for any $\boldsymbol{z}_h \in \mathbb{V}_h$ that*

$$\begin{aligned}(\mathcal{L}^n - \mathcal{K}^n)&(\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)\boldsymbol{z}_h)\\ &\le \varepsilon||\boldsymbol{z}_h||_n^2 + M_\varepsilon\tau^2h^{-1}\varrho(\boldsymbol{u}_h^n)A(\boldsymbol{u}_h^n) + M_\varepsilon\tau^2h^{-1}\varrho(\boldsymbol{w}_h^n)A(\boldsymbol{w}_h^n)\\ &+ (C_\star\tau^2h^{-2}||\boldsymbol{e}_{\boldsymbol{u}}^n||_\infty^2 + C\tau^2)||\boldsymbol{\xi}_{\boldsymbol{u}}^n||_n^2 + (C_\star\tau^2h^{-2}||\boldsymbol{e}_{\boldsymbol{w}}^n||_\infty^2 + C\tau^2)||\boldsymbol{\xi}_{\boldsymbol{w}}^n||_n^2\\ &+ C(\Xi(n)h^{2k+2}\tau + \tau^6) - \tau\textstyle\sum_{1\le j\le N}\int_{I_j}\boldsymbol{z}_h^T\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)\boldsymbol{f}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)(\boldsymbol{\xi}_{\boldsymbol{w}}^n - \boldsymbol{\xi}_{\boldsymbol{u}}^n)_{,x}\,dx,\end{aligned}$$

where $\Xi(n) = 1 + C_\star h^{-1}||\boldsymbol{e}_{\boldsymbol{u}}^n||_\infty^2 + C_\star h^{-1}||\boldsymbol{e}_{\boldsymbol{w}}^n||_\infty^2$, the positive constants C and $C_\star$ are independent of n, h, τ and the approximate solutions, and $M_\varepsilon = O(\varepsilon^{-1})$ depends on ε solely.

Similarly, we can get the following lemma to estimate $\mathcal{K}(\cdot)$ by using Taylor expansions of $\boldsymbol{f}(\boldsymbol{u})$ up to second- and third-order derivatives, respectively.

LEMMA 3.2. *Under the assumption of Lemma* 3.1*, we have, for any $\boldsymbol{z}_h \in \mathbb{V}_h$ and any small positive constant ε, the following estimates:*

$$\begin{aligned}\mathcal{K}^n(\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)\boldsymbol{z}_h) \le{}& \varepsilon||\boldsymbol{z}_h||_n^2 + M_\varepsilon\tau^2h^{-1}\varrho(\boldsymbol{u}_h)A(\boldsymbol{u}_h^n) + (C_\star h^{-2}||\boldsymbol{e}_{\boldsymbol{u}}^n||_\infty^2\tau^2 + C\tau^2)||\boldsymbol{\xi}_{\boldsymbol{u}}^n||_n^2\\ &+ (C + C_\star||\boldsymbol{e}_{\boldsymbol{u}}^n||_\infty^2)h^{2k+1}\tau - \tau\sum_{1\le j\le N}\int_{I_j}\boldsymbol{z}_h^T\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)\boldsymbol{f}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)(\boldsymbol{\xi}_{\boldsymbol{u}}^n)_{,x}\,dx,\\ \mathcal{K}^n(\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)\boldsymbol{z}_h) \le{}& \varepsilon||\boldsymbol{z}_h||_n^2 + C\tau^2h^{-2}||\boldsymbol{\xi}_{\boldsymbol{u}}^n||_n^2 + Ch^{2k}\tau^2,\end{aligned}$$

where the positive constants C and $C_\star$ are independent of n, h, τ and the approximate solutions and where $M_\varepsilon = O(\varepsilon^{-1})$ depends solely on ε.

From the error equation (3.2a) we get the identity $||\boldsymbol{\xi}_{\boldsymbol{w}}^n - \boldsymbol{\xi}_{\boldsymbol{u}}^n||_n^2 = \mathcal{K}^n(\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)(\boldsymbol{\xi}_{\boldsymbol{w}}^n - \boldsymbol{\xi}_{\boldsymbol{u}}^n))$. Thus we can take the test function $\boldsymbol{z}_h = \boldsymbol{\xi}_w^n - \boldsymbol{\xi}_u^n$ in the second inequality of Lemma 3.2 and choose the positive constant ε small enough to obtain the following corollary.

COROLLARY 3.1. *Under the assumption of Lemma* 3.1*, we have that*

$$||\boldsymbol{\xi}_{\boldsymbol{w}}^n|| \le C(||\boldsymbol{\xi}_{\boldsymbol{u}}^n|| + h^k\tau) \quad \forall n : n\tau < T \tag{3.8}$$

if the general time-step condition $\tau = \mathcal{O}(h)$ is satisfied, where the positive constant C is independent of n, h, τ and the approximate solutions.

4. Proof of the convergence theorem. In this section we are going to prove only the error estimate (2.7) of the RKDG method with finite element space of piecewise linear polynomials ($k = 1$). The generalization to high order ($k > 1$) with a more restrictive CFL condition is straightforward, along the same line as [24]. To this end, we will analyze each term on the right-hand side of the energy equation (3.3a) separately.

4.1. Estimates to each term on the right-hand side of the energy equation. We will estimate the first three terms in the next two lemmas. First, we look at the last term $\mathcal{E}^n$. By Young's inequality, it is easy to get that

$$\mathcal{E}^n \le \varepsilon ||\boldsymbol{\xi}_{\boldsymbol{u}}^{n+1}||_n^2 \tau + C(||\boldsymbol{\xi}_{\boldsymbol{u}}^{n}||_n^2 + ||\boldsymbol{\xi}_{\boldsymbol{w}}^{n}||_n^2)\tau, \tag{4.1}$$

where ε is a suitably small positive constant, since each component of $\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n) - \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{w}_c^n)$ is of order $\mathcal{O}(\tau)$ from the definition (3.1) of $\boldsymbol{w}(x,t)$.

LEMMA 4.1. *Let $\mathbb{V}_h$ be the space of piecewise linear polynomials ($k=1$). If the interpolation approximation property* (3.4) *and the time-step condition $\tau = \mathcal{O}(h)$ are satisfied, then we have the following estimate:*

$$\begin{aligned} ||\boldsymbol{\xi}_{\boldsymbol{u}}^{n+1} - \boldsymbol{\xi}_{\boldsymbol{w}}^{n}||_n^2 \le & C(\Xi(n)h^3\tau + \tau^6) + \delta_1(n)A(\boldsymbol{u}_h^n)\tau + \delta_2(n)A(\boldsymbol{w}_h^n)\tau \\ & + \left\{ \frac{C_\star \tau^2}{h^2}(||\boldsymbol{e}_{\boldsymbol{u}}^n||_\infty^2 + ||\boldsymbol{e}_{\boldsymbol{w}}^n||_\infty^2) + \frac{C_\star \tau^4}{h^4}||\boldsymbol{e}_{\boldsymbol{u}}^n||_\infty^2 + C\tau^2 \right\} ||\boldsymbol{\xi}_{\boldsymbol{u}}^n||_n^2, \end{aligned} \tag{4.2}$$

where the positive constants C and $C_\star$ are independent of n, h, τ and the numerical solutions and where $\Xi(n)$ has been defined in Lemma 3.1. *Here*

$$\delta_1(n) = \frac{M_1\tau}{h}\varrho(\boldsymbol{u}_h^n) + \frac{M_2\tau^3}{h^3}\varrho(\boldsymbol{u}_h^n)\lambda^2(\boldsymbol{u}^n) \quad \textit{and} \quad \delta_2(n) = \frac{M_3\tau}{h}\varrho(\boldsymbol{w}_h^n), \tag{4.3}$$

where $\lambda(\boldsymbol{u}^n)$ is the maximum spectral radius of $\boldsymbol{f}_{,\boldsymbol{u}}(\boldsymbol{u}^n)$ on all element interfaces and where M_i, $i = 1, 2, 3$, are positive constants independent of the other parameters in (4.3).

Proof. We follow the analysis framework in [24] and sketch the two main steps in the proof.

First, we successively take two test functions both in (3.7) and in Lemma 3.1: the first one is $\boldsymbol{z}_h = \boldsymbol{\xi}_{\boldsymbol{u}}^{n+1} - \boldsymbol{\xi}_{\boldsymbol{w}}^{n}$, and the second is $\boldsymbol{z}_h = -\tau \boldsymbol{f}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)(\boldsymbol{\xi}_{\boldsymbol{w}}^n - \boldsymbol{\xi}_{\boldsymbol{u}}^n)_{,x}$. This is feasible since $\mathbb{V}_h$ is the discontinuous finite element space. By combining the two resulting inequalities and letting each parameter ε be small enough, we can obtain the following estimate:

$$\begin{aligned} ||\boldsymbol{\xi}_{\boldsymbol{u}}^{n+1} - \boldsymbol{\xi}_{\boldsymbol{w}}^{n}||_n^2 \le & C(\Xi(n)h^{2k+2}\tau + \tau^6) + M\tau^2 h^{-1}\varrho(\boldsymbol{w}_h^n)A(\boldsymbol{w}_h^n) + M\tau^2 h^{-1}\varrho(\boldsymbol{u}_h^n)A(\boldsymbol{u}_h^n) \\ & + (C_\star \tau^2 h^{-2}||\boldsymbol{e}_{\boldsymbol{u}}^n||_\infty^2 + C\tau^2)||\boldsymbol{\xi}_{\boldsymbol{u}}^n||_n^2 + (C_\star \tau^2 h^{-2}||\boldsymbol{e}_{\boldsymbol{w}}^n||_\infty^2 + C\tau^2)||\boldsymbol{\xi}_{\boldsymbol{w}}^n||_n^2 \\ & + M\tau^2 \sum_{1\le j\le N} \int_{I_j} (\boldsymbol{\xi}_{\boldsymbol{w}}^n - \boldsymbol{\xi}_{\boldsymbol{u}}^n)_{,x}^T \boldsymbol{v}_{,\boldsymbol{u}}^{1/2}(\boldsymbol{u}_c^n)\mathbb{S}^2(\boldsymbol{u}_c^n)\boldsymbol{v}_{,\boldsymbol{u}}^{1/2}(\boldsymbol{u}_c^n)(\boldsymbol{\xi}_{\boldsymbol{w}}^n - \boldsymbol{\xi}_{\boldsymbol{u}}^n)_{,x}\, dx, \end{aligned}$$

under the general time-step condition $\tau = \mathcal{O}(h)$, where $\mathbb{S}(\boldsymbol{u}_c^n) = \boldsymbol{v}_{,\boldsymbol{u}}^{1/2}(\boldsymbol{u}_c^n)\boldsymbol{f}_{,\boldsymbol{v}}(\boldsymbol{v}(\boldsymbol{u}_c^n))\boldsymbol{v}_{,\boldsymbol{u}}^{1/2}(\boldsymbol{u}_c^n)$, the positive constants C and $C_\star$ are independent of n, h, τ and the approximate solutions, and $M > 0$ is determined solely by the fixed constant ε. We remark that $\mathbb{S}(\boldsymbol{u}_c^n)$ is symmetric and has the same eigenvalues as $\boldsymbol{f}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)$ due to the equality (2.5); therefore the last term in the estimate above is bounded by $M\tau^2\lambda^2(\boldsymbol{u}^n)||(\boldsymbol{\xi}_{\boldsymbol{w}}^n - \boldsymbol{\xi}_{\boldsymbol{u}}^n)_{,x}||_n^2$.

Next, we need to obtain a sharp estimate to $||(\boldsymbol{\xi}_{\boldsymbol{w}}^n - \boldsymbol{\xi}_{\boldsymbol{u}}^n)_{,x}||_n^2$ to complete the proof. To this end, we will use the discontinuity property of the finite element space, especially for the piecewise linear polynomials. Because $\boldsymbol{\xi}_{\boldsymbol{u}}^n \in \mathbb{V}_h$ under consideration is a piecewise linear vector-valued function, its derivative $(\boldsymbol{\xi}_{\boldsymbol{u}}^n)_{,x}$ is a constant vector on each element I_j. Hence, for any vector-valued function $\boldsymbol{p}_h$ (even a function not belonging to $\mathbb{V}_h$) there holds

$$\int_{I_j} (\boldsymbol{p}_h - \widetilde{\boldsymbol{p}_h})^T \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)\boldsymbol{f}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)(\boldsymbol{\xi}_{\boldsymbol{u}}^n)_{,x}\, dx = 0 \quad (1 \le j \le N, \forall n : n\tau < T), \tag{4.4}$$

where $\widetilde{\boldsymbol{p}_h} = h_j^{-1}\int_{I_j}\boldsymbol{p}_h\,dx$ is the average of $\boldsymbol{p}_h$ on each element I_j; i.e., $\int_{I_j}(\boldsymbol{p}-\boldsymbol{p}_h)\,dx = 0$. This property plays an important role in the proof. Unfortunately it holds only for piecewise linear polynomials and not for higher-order piecewise polynomials. This is why we would need stronger time step restriction for the proof of the higher-order $k > 1$ cases.

It is also worthwhile to note, for any $\boldsymbol{p}_h \in \mathbb{V}_h$, that $\boldsymbol{p}_h - \widetilde{\boldsymbol{p}_h}$ and $(\boldsymbol{p}_h)_{,x} = (\boldsymbol{p}_h - \widetilde{\boldsymbol{p}_h})_{,x}$ both belong to the finite element space $\mathbb{V}_h$. This property holds for the DG method with any degree k, but not for the standard conforming finite element methods.

We take $\boldsymbol{p}_h = \boldsymbol{\xi}_{\boldsymbol{w}}^n - \boldsymbol{\xi}_{\boldsymbol{u}}^n$ and get $||(\boldsymbol{\xi}_{\boldsymbol{w}}^n - \boldsymbol{\xi}_{\boldsymbol{u}}^n)_{,x}||_n \le Ch^{-1}||\boldsymbol{p}_h - \widetilde{\boldsymbol{p}_h}||_n$ by the inverse inequality (i). After a simple manipulation, we can get from the error equation (3.2a) that

$$||\boldsymbol{p}_h - \widetilde{\boldsymbol{p}_h}||_n^2 = (\boldsymbol{\xi}_{\boldsymbol{w}}^n - \boldsymbol{\xi}_{\boldsymbol{u}}^n, \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)(\boldsymbol{p}_h - \widetilde{\boldsymbol{p}_h})) = \mathcal{K}^n(\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)(\boldsymbol{p}_h - \widetilde{\boldsymbol{p}_h})).$$

By taking the test function $\boldsymbol{z}_h = \boldsymbol{p}_h - \widetilde{\boldsymbol{p}_h}$ in the first inequality of Lemma 3.2, we observe that the last integral term becomes 0, owing to the identity (4.4). By choosing ε small enough, we obtain the estimate $||\boldsymbol{p}_h - \widetilde{\boldsymbol{p}_h}||_n^2 \le \mathfrak{M}$, where

$$\mathfrak{M} = M\tau^2 h^{-1}\varrho(\boldsymbol{u}_h^n)A(\boldsymbol{u}_h^n) + (C_\star h^{-2}||\boldsymbol{e}_{\boldsymbol{u}}^n||_\infty^2\tau^2 + C\tau^2)||\boldsymbol{\xi}_{\boldsymbol{u}}^n||_n^2 + (C + C_\star||\boldsymbol{e}_{\boldsymbol{u}}^n||_\infty^2)h^3\tau.$$

As a result of this inequality, we have $||(\boldsymbol{\xi}_{\boldsymbol{w}}^n - \boldsymbol{\xi}_{\boldsymbol{u}}^n)_{,x}||_n^2 \le Ch^{-2}\mathfrak{M}$. This sharp estimate completes the proof of this lemma. ∎

LEMMA 4.2. *Let $\mathbb{V}_h$ be the space of piecewise linear polynomials ($k = 1$). If the interpolation approximation property* (3.4) *is satisfied, then we have the following estimates:*

$$\mathcal{K}^n(\boldsymbol{\xi}_{\boldsymbol{u}}^n) \le \Phi(\boldsymbol{e}_{\boldsymbol{u}}^n)||\boldsymbol{\xi}_{\boldsymbol{u}}^n||_n^2\tau - \frac{1}{2}A(\boldsymbol{u}_h^n)\tau + (C + C_\star||\boldsymbol{e}_{\boldsymbol{u}}^n||_\infty^2)h^3\tau, \tag{4.5a}$$

$$\mathcal{L}^n(\boldsymbol{\xi}_{\boldsymbol{w}}^n) \le \Phi(\boldsymbol{e}_{\boldsymbol{w}}^n)||\boldsymbol{\xi}_{\boldsymbol{w}}^n||_n^2\tau - \frac{1}{2}A(\boldsymbol{w}_h^n)\tau + (C + C_\star||\boldsymbol{e}_{\boldsymbol{w}}^n||_\infty^2)h^3\tau + C\tau^5, \tag{4.5b}$$

where the positive constants C and $C_\star$ are independent of n, h, τ and the numerical solutions and where $\Phi(\boldsymbol{e}_{\boldsymbol{p}}^n) = C + C_\star h^{-1}||\boldsymbol{e}_{\boldsymbol{p}}^n||_\infty^2$ for $\boldsymbol{p} = \boldsymbol{u}$ or $\boldsymbol{w}$.

Proof. We will prove only (4.5a) here, since the proof to (4.5b) is similar.

Noticing the periodic or zero (compactly supported) boundary conditions, after some elementary calculations we have an equivalent form of $\mathcal{K}^n(\boldsymbol{\xi}_{\boldsymbol{u}}^n)$. It reads

$$\begin{aligned}
\mathcal{K}^n(\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)\boldsymbol{\xi}_{\boldsymbol{u}}^n) \equiv \sum_{j=1}^N \mathcal{K}_j^n(\boldsymbol{\xi}_{\boldsymbol{u}}^n) &:= \Pi_1 + \Pi_2 + \Pi_3 + \Pi_4 + \Pi_5 \\
&= \sum_{1\le j\le N}\int_{I_j}(\boldsymbol{\xi}_{\boldsymbol{u}}^n)^T\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)(\boldsymbol{\eta}_{\boldsymbol{w}}^n - \boldsymbol{\eta}_{\boldsymbol{u}}^n)\,dx \\
&+ \tau\sum_{1\le j\le N}\int_{I_j}(\boldsymbol{\xi}_{\boldsymbol{u}}^n)_{,x}^T\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)\big(\boldsymbol{f}(\boldsymbol{u}^n) - \boldsymbol{f}(\boldsymbol{u}_h^n)\big)\,dx \\
&+ \tau\sum_{1\le j\le N}\Big\{\big[\boldsymbol{\xi}_{\boldsymbol{u}}^n\big]^T\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_b^n)\big(\boldsymbol{f}(\boldsymbol{u}^n) - \boldsymbol{f}_{Ref}\big)\Big\}_{j+\frac{1}{2}} \\
&+ \tau\sum_{1\le j\le N}\Big\{\big[\boldsymbol{\xi}_{\boldsymbol{u}}^n\big]^T\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_b^n)\big(\boldsymbol{f}_{Ref} - \hat{\boldsymbol{h}}(\boldsymbol{u}_h^n)\big)\Big\}_{j+\frac{1}{2}} \\
&+ \tau\sum_{1\le j\le N}\Big\{\big((\boldsymbol{\xi}_{\boldsymbol{u}}^{n,+})^T\mathbb{E}_b^{n,+} - (\boldsymbol{\xi}_{\boldsymbol{u}}^{n,-})^T\mathbb{E}_b^{n,-}\big)\big(\boldsymbol{f}(\boldsymbol{u}^n) - \hat{\boldsymbol{h}}(\boldsymbol{u}_h^n)\big)\Big\}_{j+\frac{1}{2}},
\end{aligned}$$

where $\boldsymbol{f}_{Ref} = \frac{1}{6}\boldsymbol{f}(\boldsymbol{u}_h^{-,n}) + \frac{2}{3}\boldsymbol{f}(\bar{\boldsymbol{u}}_h^n) + \frac{1}{6}\boldsymbol{f}(\boldsymbol{u}_h^{+,n})$ is the reference vector defined on each element interface. As we have mentioned before, this is different from the original reference $f(\bar{u}_h^n)$ for the scalar case [24]. We will see in the appendix the usage of this reference vector. Here $\mathbb{E}_b^{n,\pm} = \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_{b\pm1/2}^n) - \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_b^n)$, where the subscript b is used to emphasize the evaluation on the element interface, namely, $\boldsymbol{u}_b^n = \boldsymbol{u}_{j+1/2}^n$. It follows from the smoothness assumption of $\boldsymbol{v}_{,\boldsymbol{u}}$ and $\boldsymbol{u}$ that each component of $\mathbb{E}_b^{n,\pm}$ is of the order $\mathcal{O}(h)$.

Below we will follow [24] and separately analyze each term of the above equality.

By the interpolation approximation property (3.4) of the finite element space $\mathbb{V}_h$ and Young's inequality, it is easy to estimate Π_1 and Π_5 in the form

$$\Pi_1 + \Pi_5 \le Ch^4\tau + C||\boldsymbol{\xi}_{\boldsymbol{u}}^n||_n^2\tau, \tag{4.6a}$$

where the inverse property (iii), the Lipschitz property of $\hat{\boldsymbol{h}}$, and the fact that $\mathbb{E}_b^{n,\pm}$ is of the order $\mathcal{O}(h)$ are also used.

We would like to use Taylor expansions up to third order and estimate Π_2 and Π_3 together. In this step, we have to overcome the difficulties resulting from the symmetrizable assumption of the system (1.1). We present only the result here and postpone the technical analysis to the appendix. The final estimate reads

$$\Pi_2 + \Pi_3 \le \Phi(\boldsymbol{e}_{\boldsymbol{u}}^n)||\boldsymbol{\xi}_{\boldsymbol{u}}^n||_n^2\tau + \{C + C_\star||\boldsymbol{e}_{\boldsymbol{u}}^n||_\infty^2\}h^3\tau. \tag{4.6b}$$

We can estimate the last term Π_4 by virtue of the matrix $\mathcal{A}(\hat{\boldsymbol{h}}; \boldsymbol{u}_h^n)$ (see Proposition 3.1) and the following two properties: one is $[\boldsymbol{e}_{\boldsymbol{u}}^n] = -[\boldsymbol{u}_h^n]$ from the continuity of $\boldsymbol{u}^n$, and consequently $[\boldsymbol{\xi}_{\boldsymbol{u}}^n] = [\boldsymbol{\eta}_{\boldsymbol{u}}^n] - [\boldsymbol{u}_h^n]$; the other is the definition of $\mathcal{A}(\hat{\boldsymbol{h}}; \boldsymbol{u}_h^n)$ and the identities $\boldsymbol{f}(\boldsymbol{r}_i^n) - \hat{\boldsymbol{h}}(\boldsymbol{u}_h^n) = \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{s}_i^n)^{-1}\mathcal{A}_i[\boldsymbol{u}_h^n]$, $i = 1, 2, 3$, where $\boldsymbol{r}_i^n$ is $\boldsymbol{u}_h^{n,-}, \bar{\boldsymbol{u}}_h^n$, and $\boldsymbol{u}_h^{n,+}$, respectively. We would also like to mention that $\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{s}_i^n) - \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_b^n)$ is of the order $\mathcal{O}(||\boldsymbol{e}_{\boldsymbol{u}}^n||_\infty)$ by the smoothness of the mapping $\boldsymbol{v}(\boldsymbol{u})$ and the exact solution $\boldsymbol{u}$. After separating Π_4 into six parts as in [24], finally we obtain

$$\Pi_4 \le -\frac{1}{2}A(\boldsymbol{u}_h^n)\tau + C_\star h^{-1}||\boldsymbol{e}_{\boldsymbol{u}}^n||_\infty^2||\boldsymbol{\xi}_{\boldsymbol{u}}^n||_n^2 + Ch^3\tau, \tag{4.6c}$$

by Young's inequality, the properties of the finite element space $\mathbb{V}_h$, and the boundedness of $\boldsymbol{v}_{,\boldsymbol{u}}, \boldsymbol{u}_{,\boldsymbol{v}}$, and $\mathcal{A}(\hat{\boldsymbol{h}}; \boldsymbol{u}_h^n)$.

Now we can get the estimate (4.5a) by summing up all of the estimates (4.6) and complete the proof of this lemma. ∎

4.2. Proof of the convergence theorem. In this subsection we will prove the convergence Theorem 2.1 for the $k = 1$ case using the estimates obtained in subsection 4.1. In addition, we would need to use the a priori technique below.

To deal with the nonlinearity of the flux function $\boldsymbol{f}(\boldsymbol{u})$, we assume a priori that for h small enough there holds

$$||\boldsymbol{u}^n - \boldsymbol{u}_h^n|| \le h. \tag{4.7}$$

This is obviously satisfied for $n = 0$ by $\boldsymbol{u}_h^0 = \mathbb{P}_h\boldsymbol{u}_0(x)$ and the interpolation approximation property (3.4a). We shall later verify the correctness of (4.7) and prove that it still holds true for $n + 1$ if it holds true for a given n. For a linear flux function $\boldsymbol{f} = \mathbb{C}\boldsymbol{u}$, where $\mathbb{C}$ is a constant matrix, this a priori assumption is unnecessary.

It follows that $||\boldsymbol{w}^n - \boldsymbol{w}_h^n|| \le Ch$ from the a priori assumption (4.7) and Corollary 3.1. Then the inverse inequality (iii), together with the approximation property (3.4a) of $\mathbb{V}_h$, implies that

$$||\boldsymbol{e}_{\boldsymbol{p}}^n||_\infty \le Ch^{1/2}, \quad \boldsymbol{p} = \boldsymbol{u}, \boldsymbol{w}. \tag{4.8}$$

By combining all the results in subsection 4.1, together with Corollary 3.1 and (4.8), we can get from the energy equation (3.3) that for h small enough there holds

$$\begin{aligned} &||\boldsymbol{\xi}_{\boldsymbol{u}}^{n+1}||_n^2 - ||\boldsymbol{\xi}_{\boldsymbol{u}}^n||_n^2 + \frac{1}{2}A(\boldsymbol{u}_h^n)\tau + \frac{1}{2}A(\boldsymbol{w}_h^n)\tau \\ &\le \varepsilon||\boldsymbol{\xi}_{\boldsymbol{u}}^{n+1}||_n^2\tau + C(||\boldsymbol{\xi}_{\boldsymbol{u}}^n||_n^2\tau + h^3\tau + \tau^5) + \delta_1(n)A(\boldsymbol{u}_h^n)\tau + \delta_2(n)A(\boldsymbol{w}_h^n)\tau, \end{aligned} \tag{4.9}$$

under a suitable CFL condition $\tau \le \beta h$, where the CFL number β will be determined later. Here, ε is an arbitrary positive constant, and C is a positive constant independent of n, h, τ and the approximate solutions.

The number β can be determined by, for example, $\delta_1(n) \le 1/4$ and $\delta_2(n) \le 1/4$. We would like to mention again that those positive constants that emerged in (4.3), namely M_1, M_2, and M_3, are independent of h and τ. Hence there exists a maximum positive constant r_0 also independent h and τ such that

$$M_1 r_0 \le \frac{1}{8}, \quad M_2 r_0^3 \le \frac{1}{8}, \quad \text{and} \quad M_3 r_0 \le \frac{1}{4}.$$

In the numerical simulation, we often determine each time step τ^n by $\tau^n \le \beta^n h$, where

$$\beta^n = r_0 \min\{\, \varrho(u_h^n)^{-1}, \varrho(w_h^n)^{-1}, (\varrho(u_h^n)\lambda^2(u^n))^{-1/3} \,\}. \tag{4.10}$$

However, in this paper we assume for convenience that the time step is constant τ; hence we write the CFL condition as $\tau \le \beta h$ instead of $\tau^n \le \beta^n h$, where $\beta = \min_{\forall n: n\tau \le T} \beta^n$.

Under the above CFL condition $\tau \le \beta h$, the summation of the inequality (4.9) over n, when ε is suitably small, yields that

$$||\boldsymbol{\xi}_{\boldsymbol{u}}^{n+1}||^2 + \sum_{0\le m\le n} A(\boldsymbol{u}_h^m)\tau + \sum_{0\le m\le n} A(\boldsymbol{w}_h^m)\tau \le C\left(\sum_{0\le m\le n} ||\boldsymbol{\xi}_{\boldsymbol{u}}^m||^2\tau + h^3 + \tau^4\right),$$

where we use the equivalence of $||\cdot||_n$ and $||\cdot||$ and the fact that $\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^{n+1}) - \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c^n)$ is of order $\mathcal{O}(\tau)$. Thus by Gronwall's inequality we can get the following error estimate:

$$||\boldsymbol{\xi}_{\boldsymbol{u}}^{n+1}|| \le C(h^{3/2} + \tau^2) \quad \forall n:\ n\tau \le T, \tag{4.11}$$

where the positive constant C is independent of n, h, τ and the numerical solutions. Then we can easily get the estimate (2.7) for $k = 1$ by the triangle inequality and the interpolation approximation property (3.4a).

Finally let us verify the a priori assumption (4.7) before we complete the proof of Theorem 2.1 for $k = 1$. If assumption (4.7) is satisfied for a certain n, then it follows from (4.11) and the interpolation approximation property (3.4a) that it is also true for $n + 1$. Thus the given a priori assumption (4.7) is reasonable, and all of the estimates above hold for all $n:\ n\tau \le T$.

Remark 4.1. It is worth noting that the condition (4.10) is the usual CFL condition for systems of conservation laws. By Proposition 3.1 we know that for any numerical flux function $\hat{\boldsymbol{h}}$ the spectral radius of $\mathcal{A}(\hat{\boldsymbol{h}}; \boldsymbol{u}_h^n)$ is bounded by a constant times the maximum of the Lipschitz constant of $\hat{\boldsymbol{h}}$. For example, for the linear flux $f = \mathbb{C}u$ the CFL number β determined by (4.10) depends solely on the spectral radius of $\mathbb{C}$. This also explains why the CFL constant β is lower bounded away from zero during a mesh refinement.

Remark 4.2. We have carried out the error estimate and proof for the linear finite element $k = 1$ only in the one dimensional case with generalized E-flux functions. The estimate (2.7) also holds for the linear flux function $f = \mathbb{C}u$ in multiple dimensions, when the a priori assumption (4.7) is unnecessary.

For a higher-order finite element space $k > 1$ in d-dimensional space, the above analysis framework still works for symmetrizable nonlinear systems if we assume $d < 2k - 1$ to ensure an a priori assumption stronger than (4.7), e.g., $||\boldsymbol{u}^n - \boldsymbol{u}_h^n|| \le h^{1+\frac{d}{2}}$. In this case we use Taylor expansion only up to second order. Though Lemma 4.1 holds only for piecewise linear polynomials, we can similarly prove the estimate (2.7) under a more restrictive time-space condition, for example, $\tau = \mathcal{O}(h^{4/3})$. We remark that this stronger condition is necessary, since the method is linearly unstable under the usual CFL condition $\tau \le \beta h$ for $k \ge 2$. For more details, see [24].

Remark 4.3. For certain special numerical flux functions, we can upgrade the error estimate in Theorem 2.1 to be optimal, i.e., $\mathcal{O}(h^{k+1} + \tau^2)$.

These numerical flux functions include those constructed by the flux-vector splitting method, for example, the upwind numerical flux for a linear flux and the Steger–Warming flux [22] for Euler equations. Their common property is that the vector-valued physical flux function is homogeneous of degree 1; i.e., $\boldsymbol{f}(\boldsymbol{u}) = \boldsymbol{f}_{\boldsymbol{u}}(\boldsymbol{u})\boldsymbol{u}$.

To obtain the optimal error estimate in this case, we would need to use a standard trick in the DG analysis as we have done in [24], which consists of two main ingredients. The first one is the Gauss–Radau projection instead of the local L^2-projection, and the other is the upwind setting of the reference vector on each element interface. All the analysis is carried out in projecting to each eigenvector direction. In this case we can strengthen the a priori assumption and consequently use only Taylor expansion up to second order. We omit the details of the proof, as they are similar to those in [24] for the scalar case.

5. Appendix. In this appendix we complete the convergence proof and give a detailed analysis of the inequality (4.6b), namely,

$$\Pi_2 \equiv \Pi_2(\boldsymbol{\xi_u}) = \tau \sum_{1\le j\le N} \int_{I_j} (\boldsymbol{\xi_u})_{,x}^T \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c)\big(\boldsymbol{f}(\boldsymbol{u}) - \boldsymbol{f}(\boldsymbol{u}_h)\big)\, dx,$$
$$\Pi_3 \equiv \Pi_3(\boldsymbol{\xi_u}) = \tau \sum_{1\le j\le N} \Big\{ \big[\boldsymbol{\xi_u}\big]^T \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_b)\big(\boldsymbol{f}(\boldsymbol{u}) - \boldsymbol{f}_{Ref}\big)\Big\}_{j+\frac{1}{2}},$$

where we suppress the subscripts n for clarity and $\boldsymbol{f}_{Ref} = \frac{1}{6}\boldsymbol{f}(\boldsymbol{u}_h^-) + \frac{2}{3}\boldsymbol{f}(\bar{\boldsymbol{u}}_h) + \frac{1}{6}\boldsymbol{f}(\boldsymbol{u}_h^+)$ is the reference vector (see Proposition 3.1). Since $\boldsymbol{e_u} = \boldsymbol{\xi_u} - \boldsymbol{\eta_u}$, we have $\Pi_i = \Pi_i(\boldsymbol{\eta_u}) + \Pi_i(\boldsymbol{e_u})$ for $i = 2, 3$. It is easy to estimate $\Pi_i(\boldsymbol{\eta_u})$, but more technical to estimate $\Pi_i(\boldsymbol{e_u})$.

We can estimate $\Pi_i(\boldsymbol{\eta_u})$, $i = 2, 3$, by the interpolation approximation property and the property of the local L^2-projection. The detailed analysis is very similar to

those in [24], and thus omitted. Finally, this result reads

$$\Pi_2(\boldsymbol{\eta_u}) + \Pi_3(\boldsymbol{\eta_u}) \le C(||\boldsymbol{\xi}||_n^2\tau + h^3\tau). \tag{5.1}$$

In what follows we will give the detailed analysis of $\Pi_i(\boldsymbol{e_u})$. For clarity we will suppress the subscripts $\boldsymbol{u}$ and use implied summation on the indices ι, κ, and σ. We would like to use the following Taylor expansions up to third order:

$$\begin{aligned}
\boldsymbol{f}(\boldsymbol{u}) - \boldsymbol{f}(\boldsymbol{u}_h) &= \boldsymbol{f}_{,\boldsymbol{u}}(\boldsymbol{u})\boldsymbol{e} - \frac{1}{2}\boldsymbol{e}^T\boldsymbol{f}_{,\boldsymbol{u},\boldsymbol{u}}(\boldsymbol{u})\boldsymbol{e} + \frac{1}{6}\{\boldsymbol{f}(\boldsymbol{u}^\star)\}_{,u_\iota u_\kappa u_\sigma}\boldsymbol{e}_\iota\boldsymbol{e}_\kappa\boldsymbol{e}_\sigma \\
&= \boldsymbol{m}_1 + \boldsymbol{m}_2 + \boldsymbol{m}_3, \\
\boldsymbol{f}(\boldsymbol{u}) - \boldsymbol{f}(\boldsymbol{r}_\natural) &= \boldsymbol{f}_{,\boldsymbol{u}}(\boldsymbol{u}_b)\boldsymbol{e}^\natural - \frac{1}{2}(\boldsymbol{e}^\natural)^T\boldsymbol{f}_{,\boldsymbol{u},\boldsymbol{u}}(\boldsymbol{u}_b)\boldsymbol{e}^\natural + \frac{1}{6}\{\boldsymbol{f}(\boldsymbol{u}_b^\natural)\}_{,u_\iota u_\kappa u_\sigma}\boldsymbol{e}_\iota^\natural\boldsymbol{e}_\kappa^\natural\boldsymbol{e}_\sigma^\natural \\
&= \boldsymbol{n}_1^\natural + \boldsymbol{n}_2^\natural + \boldsymbol{n}_3^\natural
\end{aligned}$$

for x inside each element and x on each element interface, respectively. Here $\boldsymbol{u}^\star$ and $\boldsymbol{u}_b^\natural$ are some mean vectors in expansions; $\boldsymbol{r}_\natural$ points to $\boldsymbol{u}_h^-, \bar{\boldsymbol{u}}_h$, and $\boldsymbol{u}_h^+$; and consequently $\boldsymbol{e}^\natural$ points to $\boldsymbol{e}_h^-, \bar{\boldsymbol{e}}_h$, and $\boldsymbol{e}^+$, for $\natural = 1, 2, 3$, respectively.

Corresponding to the above expansions, we have the equality $\Pi_i(\boldsymbol{e_u}) = \sum_{\alpha=1}^3 \pi_{i\alpha}(\boldsymbol{e})$ for $i = 2$ and 3, where

$$\pi_{3\alpha}(\boldsymbol{e}) = \frac{1}{6}\pi_{3\alpha}^1(\boldsymbol{e}) + \frac{2}{3}\pi_{3\alpha}^2(\boldsymbol{e}) + \frac{1}{6}\pi_{3\alpha}^3(\boldsymbol{e}), \tag{5.2a}$$

and for $\alpha, \natural = 1, 2, 3$,

(5.2b)

$$\pi_{2\alpha}(\boldsymbol{e}) = \tau\sum_{1\le j\le N}\int_{I_j}\boldsymbol{e}_{,x}^T\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c)\boldsymbol{m}_\alpha\,dx, \qquad \pi_{3\alpha}^\natural(\boldsymbol{e}) = \tau\sum_{1\le j\le N}\left\{[\boldsymbol{e}]^T\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_b)\boldsymbol{n}_\alpha^\natural\right\}_{j+\frac{1}{2}}.$$

In what follows we analyze carefully the terms above in three groups, i.e., $\pi_{2\alpha}(\boldsymbol{e}) + \pi_{3\alpha}(\boldsymbol{e})$, where the symmetrizable property of the system (1.1) plays an important role.

As we have mentioned before, $\mathbb{J}(\boldsymbol{u}) = \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u})\boldsymbol{f}_{,\boldsymbol{u}}(\boldsymbol{u})$ is a symmetric matrix by the symmetrizable theory. A simple integration by parts reveals that

$$\pi_{21}(\boldsymbol{e}) + \pi_{31}(\boldsymbol{e}) = \tau\sum_{1\le j\le N}\left\{\int_{I_j}\boldsymbol{e}_{,x}^T\mathbb{E}^c(\boldsymbol{u})\boldsymbol{f}_{,\boldsymbol{u}}(\boldsymbol{u})\boldsymbol{e}\,dx - \frac{1}{2}\int_{I_j}\boldsymbol{e}^T\partial_x\mathbb{J}(\boldsymbol{u})\boldsymbol{e}\,dx\right\},$$

where $\mathbb{E}^c = \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u}_c) - \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u})$ with each component of order $\mathcal{O}(h)$. The inverse inequality (i) together with the approximation property (3.4a) shows that $||\boldsymbol{e}_{,x}|| \le Ch^{-1}(||\boldsymbol{e}|| + h^2)$. Then it is easy to see from the formula above that

$$\pi_{21}(\boldsymbol{e}) + \pi_{31}(\boldsymbol{e}) \le C||\boldsymbol{e}||_n^2\tau + h^4\tau. \tag{5.3}$$

The estimate of the second group, i.e., $\pi_{22}(\boldsymbol{e}) + \pi_{32}(\boldsymbol{e})$, is one of the most difficult steps in generalizing the error analysis from the scalar equation to symmetrizable systems when the finite element space $\mathbb{V}_h$ is made up of piecewise linear polynomials. However, this inconvenience can be obviated for high-order piecewise polynomials, because the Taylor expansion would need to be carried out only to the second order if the a priori assumption is strengthened. See Remark 4.2.

Let $\boldsymbol{g} = (g_1, g_2, \ldots, g_m)^T = \boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u})\boldsymbol{e}$ and denote $\mathbb{G}(\boldsymbol{u}) = \boldsymbol{u}_{,\boldsymbol{v}}(\boldsymbol{v}(\boldsymbol{u}))\boldsymbol{f}_{,\boldsymbol{u},\boldsymbol{u}}(\boldsymbol{u})\boldsymbol{u}_{,\boldsymbol{v}}(\boldsymbol{v}(\boldsymbol{u}))$. Here $\mathbb{G}$ is a supermatrix with the component $\mathbb{G}^{i_3}_{i_1,i_2} = \{\boldsymbol{u}_{,\boldsymbol{v}}(\boldsymbol{v}(\boldsymbol{u}))\boldsymbol{f}^{i_3}_{,\boldsymbol{u},\boldsymbol{u}}(\boldsymbol{u})\boldsymbol{u}_{,\boldsymbol{v}}(\boldsymbol{v}(\boldsymbol{u}))\}_{i_1,i_2}$ at the (i_1, i_2, i_3)th position. Then it is easy to see that $\pi_{22}(\boldsymbol{e}) + \pi_{32}(\boldsymbol{e}) = \mathcal{R} + \mathcal{Q} + \mathcal{S}$, where

$$\mathcal{R} = -\frac{\tau}{2}\sum_{j=1}^{N}\int_{I_j} \boldsymbol{g}^T_{,x}\boldsymbol{g}^T\mathbb{G}(\boldsymbol{u})\boldsymbol{g}\,dx,$$

$$\mathcal{Q} = -\frac{\tau}{2}\sum_{j=1}^{N}[\boldsymbol{g}]^T_{j+\frac{1}{2}}\left(\frac{1}{6}(\boldsymbol{g}^-)^T\mathbb{G}(\boldsymbol{u}_b)\boldsymbol{g}^- + \frac{2}{3}\bar{\boldsymbol{g}}^T\mathbb{G}(\boldsymbol{u}_b)\bar{\boldsymbol{g}} + \frac{1}{6}(\boldsymbol{g}^+)^T\mathbb{G}(\boldsymbol{u}_b)\boldsymbol{g}^+\right)_{j+\frac{1}{2}},$$

$$\mathcal{S} = -\frac{\tau}{2}\sum_{j=1}^{N}\int_{I_j} \boldsymbol{e}^T_{,x}\mathbb{E}^c\boldsymbol{g}^T\mathbb{G}(\boldsymbol{u})\boldsymbol{g}\,dx + \frac{\tau}{2}\sum_{j=1}^{N}\int_{I_j} \boldsymbol{e}^T\partial_x\{\boldsymbol{v}_{,\boldsymbol{u}}(\boldsymbol{u})\}\boldsymbol{g}^T\mathbb{G}(\boldsymbol{u})\boldsymbol{g}\,dx.$$

Below we will separately analyze the above terms and will use the implied summation for the indices i_1, i_2, i_3, and j (or b, since $b = j + 1/2$) for clarity.

To this end, we would first like to point out that the component $\{\mathbb{G}(\boldsymbol{u})\}^{i_3}_{i_1i_2}$ is invariant for all rotations of the indices i_1, i_2, and i_3, which we also refer to as the symmetric property of the supermatrix $\mathbb{G}$. It is obvious that $\mathbb{G}^{i_3}_{i_1,i_2} = \mathbb{G}^{i_3}_{i_2,i_1}$, so we need only prove $\mathbb{G}^{i_3}_{i_1,i_2} = \mathbb{G}^{i_2}_{i_1,i_3}$ to verify this important property. We start with the definition of $\mathbb{G}$ and consequently the identity

$$\{\mathbb{G}(\boldsymbol{u})\}^{i_3}_{i_1i_2} = \frac{\partial^2 f_{i_3}}{\partial v_{i_1}\partial v_{i_2}} + \sum_{\kappa,\gamma,\sigma,\ell}\frac{\partial f_\kappa}{\partial u_\gamma}\frac{\partial u_\gamma}{\partial v_{i_3}}\frac{\partial u_\sigma}{\partial v_{i_1}}\frac{\partial u_\ell}{\partial v_{i_2}}\frac{\partial^2 v_\kappa}{\partial u_\sigma\partial u_\ell}, \tag{5.4}$$

where we have used the symmetric property of $\boldsymbol{u}_{,\boldsymbol{v}}$. We have mentioned before that in the symmetrizable theory $\mathbb{J} = \boldsymbol{v}_{,\boldsymbol{u}}\boldsymbol{f}_{,\boldsymbol{u}} = \boldsymbol{v}_{,\boldsymbol{u}}\boldsymbol{f}_{,\boldsymbol{v}}\boldsymbol{v}_{,\boldsymbol{u}}$ is a symmetric matrix. Clearly, a vector-valued function $\boldsymbol{c}(\boldsymbol{u})\colon \mathbb{R}^m \to \mathbb{R}^m$ can be found so that $\boldsymbol{c}_{,\boldsymbol{u}} = \boldsymbol{v}_{,\boldsymbol{u}}\boldsymbol{f}_{,\boldsymbol{u}}$, namely

$$\boldsymbol{c}_{\gamma,\sigma} = \boldsymbol{c}_{\sigma,\gamma} = \frac{\partial c_\sigma}{\partial u_\gamma} = \sum_\kappa \frac{\partial v_\sigma}{\partial u_\kappa}\frac{\partial f_\kappa}{\partial u_\gamma} = \sum_\kappa \frac{\partial v_\kappa}{\partial u_\sigma}\frac{\partial f_\kappa}{\partial u_\gamma}.$$

Its derivative with respect to u_ℓ is given by

$$\frac{\partial^2 c_\sigma}{\partial u_\gamma\partial u_\ell} = \frac{\partial \boldsymbol{c}_{\sigma,\gamma}}{\partial u_\ell} = \sum_\kappa \frac{\partial^2 v_\kappa}{\partial u_\sigma\partial u_\ell}\frac{\partial f_\kappa}{\partial u_\gamma} + \sum_\kappa \frac{\partial v_\kappa}{\partial u_\sigma}\frac{\partial^2 f_\kappa}{\partial u_\gamma\partial u_\ell},$$

which implies that $\sum_\kappa \frac{\partial^2 v_\kappa}{\partial u_\sigma\partial u_\ell}\frac{\partial f_\kappa}{\partial u_\gamma}$ is invariant under the exchange of indices γ and ℓ. As a result, the second term on the right-hand side of identity (5.4) is invariant under the exchange of indices i_2 and i_3. Since $\boldsymbol{f}_{,\boldsymbol{v},\boldsymbol{v}}$ is symmetric in the symmetrizable theory, we can assert from (5.4) that $\mathbb{G}^{i_3}_{i_1,i_2} = \mathbb{G}^{i_2}_{i_1,i_3}$. This verifies the symmetric property of the supermatrix $\mathbb{G}$.

By the symmetric property of $\mathbb{G}$, an integration by parts yields that

$$\mathcal{R} = \frac{\tau}{6}\{\mathbb{G}(\boldsymbol{u}_b)\}^{i_3}_{i_1i_2}[g_{i_1}g_{i_2}g_{i_3}]_b + \frac{\tau}{6}\int_I \partial_x\{\mathbb{G}(\boldsymbol{u})\}^{i_3}_{i_1i_2}g_{i_1}g_{i_2}g_{i_3}\,dx.$$

In order to estimate $\mathcal{R}$ and $\mathcal{Q}$ together, we would like to use the following equality:

$$\begin{aligned}\{\mathbb{G}(\boldsymbol{u}_b)\}^{i_3}_{i_1i_2}[g_{i_1}g_{i_2}g_{i_3}]_b &= \{\mathbb{G}(\boldsymbol{u}_b)\}^{i_3}_{i_1i_2}\left([g_{i_1}]g^+_{i_2}g^+_{i_3} + g^-_{i_1}[g_{i_2}]g^+_{i_3} + g^-_{i_1}g^-_{i_2}[g_{i_3}]\right)_b\\ &= \{\mathbb{G}(\boldsymbol{u}_b)\}^{i_3}_{i_1i_2}\left(g^+_{i_1}g^+_{i_2} + \frac{1}{2}g^-_{i_1}g^+_{i_2} + \frac{1}{2}g^-_{i_2}g^+_{i_1} + g^-_{i_1}g^-_{i_2}\right)_b[g^n_{i_3}]_b,\end{aligned}$$

thanks to the symmetric property of $\mathbb{G}$. Then a direct manipulation shows

$$\mathcal{R}+\mathcal{Q}=\frac{\tau}{6}\int_I \partial_x\{\mathbb{G}(\boldsymbol{u})\}_{i_1 i_2}^{i_3} g_{i_1} g_{i_2} g_{i_3}\,dx \le C||\boldsymbol{e}||_\infty||\boldsymbol{e}||^2. \tag{5.5}$$

This is the reason that the reference vector $\boldsymbol{f}_{Ref}$ is taken as $\frac{1}{6}\boldsymbol{f}(\boldsymbol{u}_h^-)+\frac{2}{3}\boldsymbol{f}(\bar{\boldsymbol{u}}_h)+\frac{1}{6}\boldsymbol{f}(\boldsymbol{u}_h^+)$ in this paper. It avoids the estimate to the term corresponding to the second-order derivatives.

Since each component of $\mathbb{E}^c$ is of order $\mathcal{O}(h)$, it is easy to estimate the last term $\mathcal{S}$ in the second group. The estimate to the last group $\pi_{23}(\boldsymbol{e})+\pi_{33}(\boldsymbol{e})$ is easy to get in a similar way, where we use the inequality $||\boldsymbol{e}||_{\Gamma_h} \le Ch^{-\frac{1}{2}}(||\boldsymbol{e}||+h^2)$ implied by the inverse inequality (iii) and the approximation property (3.4a). Thus we give the final estimate together in the form

$$\mathcal{S}+\pi_{23}(\boldsymbol{e})+\pi_{33}(\boldsymbol{e}) \le C_\star(h^{-1}+1)||\boldsymbol{e}||_\infty^2(||\boldsymbol{e}||^2+h^4)\tau. \tag{5.6}$$

By collecting the above estimates and preprocessing the result using the simple inequality $||\boldsymbol{e}||_\infty \le \frac{1}{2}(h^{-1}||\boldsymbol{e}||_\infty^2+h)$, we can easily get the inequality (4.6b) since $h<1$. We have therefore completed the proof of the convergence theorem.

THE L^2 NORM ERROR ESTIMATES FOR THE DIV LEAST-SQUARES METHOD*

ZHIQIANG CAI† AND JAEUN KU†

Abstract. This paper studies L^2 norm error estimates for the div least-squares method for which the associated homogeneous least-squares functional is equivalent to the $H(\mathrm{div}) \times H^1$ norm for the respective dual and primal variables. Least-squares of this type for the second-order elliptic equations, elasticity, and the Stokes equations are an active area of research, and error estimates in the $H(\mathrm{div}) \times H^1$ norm were previously established. In this paper, we establish optimal L^2 norm error estimates for the primal variable under the minimum regularity requirement through a refined duality argument.

Key words. least-squares method, error estimate, elliptic equations, elasticity, Stokes, incompressible Newtonian flow

1. Introduction.

There is substantial interest in the use of least-squares principles for the approximate solution of partial differential equations with applications in both solid and fluid mechanics. One advantage of the least-squares approach is that the finite element spaces for the individual unknowns may be chosen independently, and thus based on simplicity, availability, and optimality, or may be chosen from the physics of the underlying problem. Moreover, the linear systems of algebraic equations resulting from well-posed least-squares discretizations are always self-adjoint and positive definite.

Many least-squares methods for scalar elliptic equations, elasticity, and the Stokes equations have been proposed and analyzed. The numerical properties depend on the form of the first-order system and the choice of the least-squares norm. Loosely speaking, there are three types of least-squares methods: the inverse approach, the div approach, and the div-curl approach. The inverse approach employs an inverse norm that is further replaced with either the weighted mesh-dependent norm (see [2]) or the discrete H^{-1} norm (see [4]) for computational feasibility. The div approach uses the L^2 norm, and the corresponding homogeneous least-squares functional is equivalent to the $H(\mathrm{div}) \times H^1$ norm. The homogeneous least-squares functional from the div-curl approach is equivalent to the $H(\mathrm{div}) \cap H(\mathrm{curl})$ norm for some variables.

The purpose of this paper is to study the L^2 norm error estimates for the div least-squares method. For the scalar elliptic equations, the div approach based on the flux-pressure formulation has been studied extensively (see, e.g., [3, 6, 9, 10, 12, 13, 14, 15, 16, 17, 18]). The pressure and the flux are referred to as the primal and dual variables, respectively. For elasticity and the Stokes equations, we recently proposed and analyzed the div least-squares approach in [7, 8] based on the stress-

displacement and the stress-velocity formulations, respectively. The displacement and the velocity are referred to as the primal variables, and the stress as the dual variable. It was proved that the homogeneous least-squares functional is equivalent to the $H(\mathrm{div}) \times H^1$ norm. This immediately leads to the error estimate in such a norm. This estimate also yields an optimal L^2 norm error estimate for the dual variable when using appropriate approximation spaces. In this paper, we establish optimal error estimates for the primal variable in the L^2 norm under the minimum regularity requirement. As usual, this estimate is obtained through a duality argument (or the so-called Aubin–Nitche trick for the standard Galerkin finite element method). The key step of the duality argument presented in this paper is to express the L^2 norm error of the primal variable in terms of the bilinear form (see Lemma 5.1). While this is straightforward for the Galerkin method, it is less obvious for the div least-squares method applied to the elasticity and Stokes equations.

Previously, L^2 norm error estimates for the div least-squares method applied to the scalar elliptic problems were studied by several researchers. The optimal L^2 norm error estimate under the minimum regularity assumption was proved for the Poisson equation in [14] (see also [3]). By using extra regularity and special finite element spaces for the flux, an L^2 estimate was obtained in [20] for a divergence form of scalar elliptic problems.

The paper is organized as follows. Section 2 introduces the second-order scalar elliptic partial differential equations, elasticity, and the Stokes equations. The div least-squares formulation and a finite element approximation are described in sections 3 and 4, respectively. In Section 5, we establish optimal L^2 error estimates through the duality argument.

1.1. Notation. We use the standard notation and definitions for the Sobolev spaces $H^s(\Omega)^d$ and $H^s(\partial\Omega)^d$ for $s \geq 0$. The standard associated inner products are denoted by $(\cdot, \cdot)_{s,\Omega}$ and $(\cdot, \cdot)_{s,\partial\Omega}$, and the respective norms are denoted by $\|\cdot\|_{s,\Omega}$ and $\|\cdot\|_{s,\partial\Omega}$. (We suppress the superscript d when the dimension is clear by context. We also omit the subscript Ω from the inner product and norm designation when there is no confusion.) For $s = 0$, $H^s(\Omega)^d$ coincides with $L^2(\Omega)^d$. In this case, the inner product and norm will be denoted by $\|\cdot\|$ and $(\cdot, \cdot)$, respectively. Set

$$H^1_D(\Omega) := \{q \in H^1(\Omega) \,:\, q = 0 \text{ on } \Gamma_D\}.$$

When $\Gamma = \partial\Omega$, denote $H^1_D(\Omega)$ by $H^1_0(\Omega)$. Finally, set

$$H(\mathrm{div}; \Omega) = \{\mathbf{v} \in L^2(\Omega)^d \,:\, \nabla \cdot \mathbf{v} \in L^2(\Omega)\},$$

which is a Hilbert space under the norm

$$\|\mathbf{v}\|_{H(\mathrm{div};\,\Omega)} = \left(\|\mathbf{v}\|^2 + \|\nabla \cdot \mathbf{v}\|^2\right)^{\frac{1}{2}},$$

and define its subspace

$$H_N(\mathrm{div}; \Omega) = \{\mathbf{v} \in H(\mathrm{div}; \Omega) \,:\, \mathbf{n} \cdot \mathbf{v} = 0 \text{ on } \Gamma_N\}.$$

2. Mathematical equations. Let Ω be a bounded, open, connected subset of $\Re^d$ ($d = 2$ or 3) with a Lipschitz continuous boundary $\partial\Omega$. Denote by $\mathbf{n} = (n_1, \ldots, n_d)$ the outward unit vector normal to the boundary. We partition the boundary of the domain Ω into two open subsets Γ_D and Γ_N such that $\partial\Omega = \bar{\Gamma}_D \cup \bar{\Gamma}_N$ and $\Gamma_D \cap \Gamma_N = \emptyset$. For simplicity, we assume that Γ_D is not empty (i.e., $\mathrm{mes}\,(\Gamma_D) \neq 0$). Otherwise, solutions of partial differential equations considered in this paper are unique up to an additive constant.

2.1. Second-order elliptic problems. Consider the second-order elliptic boundary value problem

$$-\nabla \cdot (A\nabla u) + Xu = f \quad \text{in } \Omega \tag{2.1}$$

with boundary conditions

$$u = 0 \quad \text{on } \Gamma_D \quad \text{and} \quad \mathbf{n} \cdot A\nabla u = 0 \quad \text{on } \Gamma_N, \tag{2.2}$$

where the symbols $\nabla\cdot$ and ∇ stand for the divergence and gradient operators, respectively; A is a given $d \times d$ tensor function; X is an at most first-order linear differential operator; and f is a given scalar function. Assume that A is uniformly symmetric positive definite; then there exist positive constants $0 < \Lambda_0 \le \Lambda_1$ such that

$$\Lambda_0 \boldsymbol{\xi}^T \boldsymbol{\xi} \le \boldsymbol{\xi}^T A \boldsymbol{\xi} \le \Lambda_1 \boldsymbol{\xi}^T \boldsymbol{\xi}$$

for all $\boldsymbol{\xi} \in \Re^d$ and almost all $x \in \overline{\Omega}$. Here and hereafter, we assume homogeneous boundary conditions for simplicity. The corresponding variational form of system (2.1) is to find $u \in H_D^1(\Omega)$ such that

$$a(u, v) = (f, v) \quad \forall\, v \in H_D^1(\Omega), \tag{2.3}$$

where the bilinear form is defined by

$$a(u, v) = (A\nabla u, \nabla v) + (Xu, v).$$

The dual problem of (2.3) is to find $z \in H_D^1(\Omega)$ such that

$$a(v, z) = (f, v) \quad \forall\, v \in H_D^1(\Omega). \tag{2.4}$$

For simplicity, assume that both problems (2.3) and (2.4) satisfy the full H^2 regularity estimates

$$\|u\|_2 \le C\,\|f\| \quad \text{and} \quad \|z\|_2 \le C\,\|f\|. \tag{2.5}$$

(See section 5.3 for problems with low regularity.) Here and hereafter, we use C with or without subscripts to denote a generic positive constant, that is, a constant that is independent of the mesh size h and the parameter λ introduced in subsequent sections but that may depend on the domain Ω.

2.2. Elasticity and Stokes equations. For a vector field $\mathbf{v} = (v_1, \ldots, v_d)$, define its gradient as a $d \times d$ tensor,

$$\nabla \mathbf{v} = \begin{pmatrix} \dfrac{\partial v_1}{\partial x_1} & \cdots & \dfrac{\partial v_1}{\partial x_d} \\ \vdots & \ddots & \vdots \\ \dfrac{\partial v_d}{\partial x_1} & \cdots & \dfrac{\partial v_d}{\partial x_d} \end{pmatrix} = \left(\frac{\partial v_i}{\partial x_j} \right)_{d\times d}.$$

Denote the symmetric part of $\nabla \mathbf{v}$ by

$$\boldsymbol{\epsilon}(\mathbf{v}) = \frac{1}{2}\left(\nabla \mathbf{v} + (\nabla \mathbf{v})^t\right) = \left(\epsilon_{ij}(\mathbf{v})\right)_{d\times d} \quad \text{with} \quad \epsilon_{ij}(\mathbf{v}) = \frac{1}{2}\left(\frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i}\right).$$

For the displacement and the velocity fields $\mathbf{v}$, the symmetric part of the gradients $\boldsymbol{\epsilon}(\mathbf{v})$ is referred to as the strain tensor and the strain rate tensor, respectively. For a tensor function $\boldsymbol{\tau} = (\tau_{ij})_{d\times d}$, let $\boldsymbol{\tau}_i = (\tau_{i1}, \ldots, \tau_{id})$ denote its ith-row for $i = 1, \ldots, d$ and define its divergence, normal, and trace by

$$\nabla \cdot \boldsymbol{\tau} = (\nabla \cdot \boldsymbol{\tau}_1, \ldots, \nabla \cdot \boldsymbol{\tau}_d), \quad \mathbf{n} \cdot \boldsymbol{\tau} = (\mathbf{n} \cdot \boldsymbol{\tau}_1, \ldots, \mathbf{n} \cdot \boldsymbol{\tau}_d), \quad \text{and} \quad \operatorname{tr} \boldsymbol{\tau} = \sum_{i=1}^{d} \tau_{ii},$$

respectively. For tensors $\boldsymbol{\tau} = (\tau_{ij})_{d\times d}$ and $\boldsymbol{\gamma} = (\gamma_{ij})_{d\times d}$, define

$$\boldsymbol{\tau} : \boldsymbol{\gamma} \equiv \sum_{i,j=1}^{d} \tau_{ij}\gamma_{ij}.$$

If $\boldsymbol{\tau}$ is symmetric and $\boldsymbol{\gamma}$ skew-symmetric, it is then easy to check that

$$\boldsymbol{\tau} : \boldsymbol{\gamma} = 0. \tag{2.6}$$

Elasticity and Stokes equations may be cast in the following pressure-perturbed form of the generalized Stokes equations

$$\begin{cases} -\nabla \cdot (2\mu\, \boldsymbol{\epsilon}(\mathbf{u}) - p\, \boldsymbol{\delta}) &= \mathbf{f} \quad \text{in} \quad \Omega, \\ \nabla \cdot \mathbf{u} + \dfrac{1}{\lambda} p &= g \quad \text{in} \quad \Omega \end{cases} \tag{2.7}$$

with boundary conditions

$$\mathbf{u} = \mathbf{0} \quad \text{on } \Gamma_D \quad \text{and} \quad \mathbf{n} \cdot (2\mu\, \boldsymbol{\epsilon}(\mathbf{u}) - p\, \boldsymbol{\delta}) = \mathbf{0} \quad \text{on } \Gamma_N, \tag{2.8}$$

where $\mathbf{u}$ represents the displacement and velocity vector field for solids and fluids, respectively; p represents the pressure; $\boldsymbol{\delta} = (\delta_{ij})_{d\times d}$ denotes the identity tensor; $\mathbf{f}$ is a given vector function; g is a given scalar function; and μ and λ are material constants such that $\mu \in [\mu_1, \mu_2]$ with $0 < \mu_1 < \mu_2$ and $\lambda \in (0, \infty]$. The λ and μ are the so-called Lamé and viscosity constants for solids and fluids, respectively. Materials are said to be incompressible when λ is infinite.

Equation (2.7) with $\lambda = \infty$ gives the Stokes equations

$$\begin{cases} -2\mu\, \nabla \cdot (\boldsymbol{\epsilon}(\mathbf{u})) + \nabla p &= \mathbf{f} \quad \text{in} \quad \Omega, \\ \nabla \cdot \mathbf{u} &= g \quad \text{in} \quad \Omega \end{cases} \tag{2.9}$$

with boundary conditions (2.8). When $\Gamma_N = \emptyset$, p is unique up to an additive constant provided that the compatibility condition $\int_\Omega g\, dx = 0$ holds. For $\lambda < \infty$ and $g = 0$, eliminating p in (2.7) and (2.8) yields the elastic equations

$$-2\mu\, \nabla \cdot (\boldsymbol{\epsilon}(\mathbf{u})) - \lambda\, \nabla \nabla \cdot \mathbf{u} = \mathbf{f} \quad \text{in } \Omega \tag{2.10}$$

with boundary conditions

$$\mathbf{u} = \mathbf{0} \quad \text{on } \Gamma_D \quad \text{and} \quad \mathbf{n} \cdot (2\mu\, \boldsymbol{\epsilon}(\mathbf{u}) + \lambda\, (\nabla \cdot \mathbf{u})\, \boldsymbol{\delta}) = \mathbf{0} \quad \text{on } \Gamma_N.$$

Again, we assume that both (2.9) and (2.10) satisfy the full H^2 regularity estimates:

$$\|\mathbf{u}\|_2 + \|p\|_1 \le C\, (\|\mathbf{f}\| + \|g\|_1) \quad \text{and} \quad \|\mathbf{u}\|_2 + \lambda\, \|\nabla \cdot \mathbf{u}\|_1 \le C\, \|\mathbf{f}\|, \tag{2.11}$$

respectively, where C is a positive constant independent of $\mathbf{u}$, p, and λ.

3. Least-squares formulations. Least-squares formulations for the scalar elliptic problems, elasticity, and Stokes equations have been extensively studied. They differ in such choices as the first-order system and the least-squares norm. In this paper, we study only the div least-squares method, which applies the simple L^2 norm to the natural first-order system arising from physical laws in both solid and fluid mechanics.

or the velocity for the

3.1. First-order systems. Introducing the flux (vector) variable

$$\sigma = -A\,\nabla u,$$

the scalar elliptic problems in (2.1) may be rewritten as the following first-order partial differential system

$$\left\{\begin{array}{rcll} A^{-1}\sigma + \nabla u &=& \mathbf{0} & \text{in} \quad \Omega, \\ \nabla\cdot\sigma + Xu &=& f & \text{in} \quad \Omega \end{array}\right. \tag{3.1}$$

with boundary conditions

$$u = 0 \quad \text{on } \Gamma_D \quad \text{and} \quad \mathbf{n}\cdot\sigma = 0 \quad \text{on } \Gamma_N. \tag{3.2}$$

For the generalized Stokes equations, define the compliance tensor of fourth order, $\mathcal{A}_\lambda$, by

$$\mathcal{A}_\lambda\,\boldsymbol{\tau} = \left\{\begin{array}{ll} \dfrac{1}{2\mu}\left(\boldsymbol{\tau} - \dfrac{\lambda}{d\lambda + 2\mu}(\operatorname{tr}\boldsymbol{\tau})\,\boldsymbol{\delta}\right) & \text{for } \lambda \in (0,\,\infty), \\ \dfrac{1}{2\mu}\left(\boldsymbol{\tau} - \dfrac{1}{d}(\operatorname{tr}\boldsymbol{\tau})\,\boldsymbol{\delta}\right) & \text{for } \lambda = \infty. \end{array}\right.$$

Note that

$$\mathcal{A}_\infty\,\boldsymbol{\tau} = \lim_{\lambda\to\infty}\mathcal{A}_\lambda\,\boldsymbol{\tau}.$$

Without loss of generality, we take $\mu = 1/2$. Denote by $\boldsymbol{\sigma}$ the stress tensor and by $\mathbf{u}$ the displacement for linear elasticity or the velocity for the Stokes equations. Consider the following first-order system of partial differential equations studied in [8, 7]:

$$\left\{\begin{array}{rcll} \mathcal{A}_\lambda\,\boldsymbol{\sigma} - \boldsymbol{\epsilon}(\mathbf{u}) &=& \mathbf{0} & \text{in} \quad \Omega, \\ \nabla\cdot\boldsymbol{\sigma} &=& -\mathbf{f} & \text{in} \quad \Omega \end{array}\right. \tag{3.3}$$

with boundary conditions

$$\mathbf{u} = \mathbf{0} \quad \text{on } \Gamma_D \quad \text{and} \quad \mathbf{n}\cdot\boldsymbol{\sigma} = \mathbf{0} \quad \text{on } \Gamma_N. \tag{3.4}$$

Variables σ and u for the scalar elliptic problems in (3.1) are vector and scalar functions, respectively, while variables $\boldsymbol{\sigma}$ and $\mathbf{u}$ for the generalized Stokes equations in (3.3) are the respective tensor and vector functions. First-order system (3.3) may be considered the vector form of (3.1), even though they differ substantially in terms of analysis.

3.2. Least-squares variational problems. Define least-squares functionals as the sum of the L^2 norm of the residuals of the first-order systems in (3.1) and (3.3). Then least-squares variational problems are to minimize the least-squares functionals in appropriate solution spaces. To this end, let us first introduce solution spaces. Define the spaces

$$\mathbf{X}_\lambda \equiv \begin{cases} H_N(\mathrm{div};\,\Omega)^d & \text{for} \quad \lambda \in (0,\,\infty), \\ \{\boldsymbol{\tau} \in H_N(\mathrm{div};\,\Omega)^d \mid \int_\Omega \mathrm{tr}\,\boldsymbol{\tau}\,dx = 0\} & \text{for} \quad \lambda = \infty, \end{cases}$$

and let

$$\Sigma = \begin{cases} H_N(\mathrm{div};\Omega) & \text{for (3.1)}, \\ \mathbf{X}_\lambda & \text{for (3.3)}, \end{cases} \qquad U = \begin{cases} H_D^1(\Omega) & \text{for (3.1)}, \\ H_D^1(\Omega)^d & \text{for (3.3)}. \end{cases}$$

Now, for $f \in L^2(\Omega)$ and $\mathbf{f} \in L^2(\Omega)^d$, define the least-squares functional

$$G(\boldsymbol{\sigma},\,\mathbf{u};\,\mathbf{f}) = \begin{cases} \|A^{1/2}(A^{-1}\sigma + \nabla u)\|^2 + \|\nabla\cdot\sigma + Xu - f\|^2 & \text{for (3.1)}, \\ \|\mathcal{A}_\lambda\,\boldsymbol{\sigma} - \boldsymbol{\epsilon}(\mathbf{u})\|^2 + \|\nabla\cdot\boldsymbol{\sigma} + \mathbf{f}\|^2 & \text{for (3.3)} \end{cases} \tag{3.5}$$

for all $(\boldsymbol{\sigma},\,\mathbf{u}) \in \Sigma \times U$. Here and hereafter, we use boldface letters $(\boldsymbol{\sigma},\,\mathbf{u})$ to denote variables for both problems when there is no danger of confusion. Let

$$|||(\boldsymbol{\tau},\,\mathbf{v})||| = \left(\|\mathbf{v}\|_1^2 + \|\boldsymbol{\tau}\|_{H(\mathrm{div};\,\Omega)}^2\right)^{\frac{1}{2}}.$$

The following theorem was proved in [6] for the scalar elliptic problems in (3.1) and in [8, 7] for the generalized Stokes equations in (3.3).

THEOREM 3.1. *The homogeneous functional $G(\boldsymbol{\tau},\,\mathbf{v}\,;\,\mathbf{0})$ is equivalent to $|||(\boldsymbol{\tau},\,\mathbf{v})|||^2$; i.e., there exists a positive constant C_1 such that*

$$\frac{1}{C_1}\,|||(\boldsymbol{\tau},\,\mathbf{v})|||^2 \le G(\boldsymbol{\tau},\,\mathbf{v}\,;\,\mathbf{0}) \le C_1\,|||(\boldsymbol{\tau},\,\mathbf{v})|||^2 \tag{3.6}$$

hold for all $(\boldsymbol{\tau},\,\mathbf{v}) \in \Sigma \times U$. Moreover, the constant C_1 is independent of λ for the generalized Stokes problems.

The variational problem corresponding to the L^2 norm least-squares functional is to minimize functional (3.5) over $\Sigma \times U$, that is, to find $(\boldsymbol{\sigma},\,\mathbf{u}) \in \Sigma \times U$ such that

$$G(\boldsymbol{\sigma},\,\mathbf{u}\,;\,\mathbf{f}) = \inf_{(\boldsymbol{\tau},\,\mathbf{v})\in\Sigma\times U} G(\boldsymbol{\tau},\,\mathbf{v}\,;\,\mathbf{f}). \tag{3.7}$$

Let us define a bilinear form $b(\cdot;\,\cdot)$ on $(\Sigma \times U) \times (\Sigma \times U)$ by

$$b(\boldsymbol{\sigma},\mathbf{u};\,\boldsymbol{\tau},\mathbf{v}) = \begin{cases} (\sigma + A\nabla u,\,A^{-1}\tau + \nabla v) + (\nabla\cdot\sigma + Xu,\,\nabla\cdot\tau + Xv) & \text{for (3.1)}, \\ (\mathcal{A}_\lambda\boldsymbol{\sigma} - \boldsymbol{\epsilon}(\mathbf{u}),\,\mathcal{A}_\lambda\boldsymbol{\tau} - \boldsymbol{\epsilon}(\mathbf{v})) + (\nabla\cdot\boldsymbol{\sigma},\,\nabla\cdot\boldsymbol{\tau}) & \text{for (3.3)} \end{cases}$$

for all $(\boldsymbol{\sigma},\,\mathbf{u};\,\boldsymbol{\tau},\,\mathbf{v}) \in (\Sigma \times U) \times (\Sigma \times U)$, and define a linear form $F(\cdot)$ on $\Sigma \times U$ by

$$F(\boldsymbol{\tau},\mathbf{v}) = \begin{cases} (f,\,\nabla\cdot\tau + Xv) & \text{for (3.1)}, \\ (-\mathbf{f},\,\nabla\cdot\boldsymbol{\tau}) & \text{for (3.3)} \end{cases}$$

for all $(\boldsymbol{\tau},\,\mathbf{v}) \in \Sigma \times U$. Then (3.7) can be written in equivalent form as follows: Find $(\boldsymbol{\sigma},\,\mathbf{u}) \in \Sigma \times U$ such that

$$b(\boldsymbol{\sigma},\,\mathbf{u};\,\boldsymbol{\tau},\,\mathbf{v}) = F(\boldsymbol{\tau},\,\mathbf{v}) \quad \forall\ (\boldsymbol{\tau},\,\mathbf{v}) \in \Sigma \times U. \tag{3.8}$$

4. Least-squares finite element approximations. Theorem 3.1 guarantees that conforming finite element spaces of $\Sigma \times U$ for the dual and primal variables may be chosen independently. But it does not imply that any choice leads to an optimal approximation in terms of both the regularity and the approximation property. It is important to note that the basic error estimations of least-squares methods in the energy norm for the dual and primal variables cannot be obtained separately (see (4.6)) and that the smoothness of the dual variable is one order less than the primal variable in our applications. Because of these constraints, the only finite element spaces having optimal approximations in the above sense are the continuous piecewise polynomials for the primal variable and the Raviart–Thomas elements for the dual variable. Moreover, the system of algebraic equations resulting from these elements can be solved efficiently by fast multigrid methods (see, e.g., [1]). For the above reasons, only these elements are analyzed in this paper. However, it is clear that our subsequent analysis does apply to any other conforming finite element spaces [5, 11] with no essential modification.

For simplicity of presentation, we consider only triangular and tetrahedral elements for the respective two and three dimensions. Assuming that the domain Ω is polygonal, let $\mathcal{T}_h$ be a regular triangulation of Ω (see [11]) with triangular/tetrahedral elements of size $\mathcal{O}(h)$. Let $P_k(K)$ be the space of polynomials of degree k on triangle K and denote the local Raviart–Thomas space of order k on K:

$$RT_k(K) = P_k(K)^d + \mathbf{x}\, P_k(K)$$

with $\mathbf{x} = (x_1, \ldots, x_d)$. The standard $H(\mathrm{div};\, \Omega)$ conforming Raviart–Thomas space of index k [19] and the standard (conforming) continuous piecewise polynomials of degree $k+1$ are defined, respectively, by

$$\Sigma_h^k = \{\boldsymbol{\tau} \in \Sigma \,:\, \boldsymbol{\tau}|_K \in RT_k(K)^m \quad \forall\ K \in \mathcal{T}_h\},$$
$$V_h^{k+1} = \{\mathbf{v} \in U \,:\, \mathbf{v}|_K \in P_{k+1}(K)^m \quad \forall\ K \in \mathcal{T}_h\}$$

where $m = 1$ for the scalar elliptic problems and $m = d$ for the generalized Stokes equations. It is well known (see [11]) that V_h^{k+1} has the following approximation property: Let $k \geq 0$ be an integer and let $l \in [0,\, k+1]$,

$$\inf_{\mathbf{v} \in V_h^{k+1}} \|\mathbf{u} - \mathbf{v}\|_1 \leq C\, h^l\, \|\mathbf{u}\|_{l+1} \tag{4.1}$$

for $\mathbf{u} \in H^{l+1}(\Omega)^m \cap U$. It is also well known (see [19]) that Σ_h^k has the following approximation property: Let $k \geq 0$ be an integer and let $l \in [1,\, k+1]$,

$$\inf_{\boldsymbol{\tau} \in \Sigma_h^k} \|\boldsymbol{\sigma} - \boldsymbol{\tau}\|_{H(\mathrm{div};\, \Omega)} \leq C\, h^l\, (\|\boldsymbol{\sigma}\|_l + \|\nabla \cdot \boldsymbol{\sigma}\|_l) \tag{4.2}$$

for $\boldsymbol{\sigma} \in H^l(\Omega)^{m \times m} \cap \Sigma$ with $\nabla \cdot \boldsymbol{\sigma} \in H^l(\Omega)^m$. Since the smoothness of $\boldsymbol{\sigma}$ and $\nabla \cdot \boldsymbol{\sigma}$ is one order less than $\mathbf{u}$, we choose k to be the smallest integer greater than or equal to $l - 1$.

The finite element discretization of our least-squares variational problem is the following: Find $(\boldsymbol{\sigma}_h,\, \mathbf{u}_h) \in \Sigma_h^k \times V_h^{k+1}$ such that

$$G(\boldsymbol{\sigma}_h,\, \mathbf{u}_h;\, \mathbf{f}) = \min_{(\boldsymbol{\tau},\, \mathbf{v}) \in \Sigma_h^k \times V_h^{k+1}} G(\boldsymbol{\tau},\, \mathbf{v};\, \mathbf{f}). \tag{4.3}$$

Equivalently, to find $(\boldsymbol{\sigma}_h, \mathbf{u}_h) \in \Sigma_h^k \times V_h^{k+1}$ such that

$$b(\boldsymbol{\sigma}_h, \mathbf{u}_h; \boldsymbol{\tau}, \mathbf{v}) = F(\boldsymbol{\tau}, \mathbf{v}) \quad \forall\, (\boldsymbol{\tau}, \mathbf{v}) \in \Sigma_h^k \times V_h^{k+1}. \tag{4.4}$$

Note that we have the orthogonal property

$$b(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h, \mathbf{u} - \mathbf{u}_h; \boldsymbol{\tau}, \mathbf{v}) = 0 \quad \forall\, (\boldsymbol{\tau}, \mathbf{v}) \in \Sigma_h^k \times V_h^{k+1}. \tag{4.5}$$

By Theorem 3.1 and the fact that $\Sigma_h^k \times V_h^{k+1}$ is a subspace of $\Sigma \times U$, (4.3) has a unique solution. The following error estimations in the energy norm follow directly from Theorem 3.1, the orthogonal property in (4.5), the Cauchy–Schwarz inequality, and the approximation properties in (4.1) and (4.2) (see also [6, 7, 8]).

THEOREM 4.1. *Assume that the solution* $(\boldsymbol{\sigma}, \mathbf{u})$ *of* (3.7) *is in* $H^l(\Omega)^{m\times m} \times H^{l+1}(\Omega)^m$ *and that the divergence of the stress* $\nabla\cdot\boldsymbol{\sigma}$ *is in* $H^l(\Omega)^m$ $(m = 1$ *or* $d)$*. Let* k *be the smallest integer greater than or equal to* $l-1$*. Then with* $(\boldsymbol{\sigma}_h, \mathbf{u}_h) \in \Sigma_h^k \times V_h^{k+1}$ *denoting the solution to* (4.3)*, the following error estimate holds:*

$$|||(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h, \mathbf{u} - \mathbf{u}_h)||| \le C \left(\inf_{\boldsymbol{\tau}\in\Sigma_h^k} \|\boldsymbol{\sigma} - \boldsymbol{\tau}\|_{H(\mathrm{div};\Omega)} + \inf_{\mathbf{v}\in V_h^{k+1}} \|\mathbf{u} - \mathbf{v}\|_1 \right) \tag{4.6}$$

$$\le C\, h^l \left(\|\boldsymbol{\sigma}\|_l + \|\nabla\cdot\boldsymbol{\sigma}\|_l + \|\mathbf{u}\|_{l+1} \right). \tag{4.7}$$

5. The L^2 norm error estimates. This section presents the main results of this paper on the optimal L^2 norm estimates of $\mathbf{u} - \mathbf{u}_h$. As usual, these estimates are established through the duality argument. The key step of this argument is to express $\|\mathbf{u} - \mathbf{u}_h\|^2$ in terms of the bilinear form (see Lemma 5.1). While this is straightforward for the Galerkin finite element method, it is nontrivial for the div least-squares method.

LEMMA 5.1. *Let* $(\boldsymbol{\sigma}, \mathbf{u})$ *and* $(\boldsymbol{\sigma}_h, \mathbf{u}_h)$ *be the solutions of* (3.7) *and* (4.3)*, respectively. Assume that the regularity estimates in* (2.5) *and* (2.11) *hold. Then there exists* $(\boldsymbol{\gamma}, \mathbf{w})$ *such that*

$$\|\mathbf{u} - \mathbf{u}_h\|^2 = b(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h, \mathbf{u} - \mathbf{u}_h; \boldsymbol{\gamma}, \mathbf{w}) \tag{5.1}$$

and that

$$\|\boldsymbol{\gamma}\|_1 + \|\nabla\cdot\boldsymbol{\gamma}\|_1 + \|\mathbf{w}\|_2 \le C\, \|\mathbf{u} - \mathbf{u}_h\|. \tag{5.2}$$

For the Galerkin method, $(\boldsymbol{\gamma}, \mathbf{w})$ in Lemma 5.1 is simply the solution of the corresponding dual problem. As developed later in this section, for the least-squares method, $(\boldsymbol{\gamma}, \mathbf{w})$ is chosen to be the solution of another auxiliary problem whose right-hand side involves the solution of the corresponding dual problem. This lemma will be proved separately for the scalar elliptic problems and the generalized Stokes equations in the respective sections 5.1 and 5.2. With Lemma 5.1, the optimal L^2 norm error estimates may be proved easily.

THEOREM 5.1. *Under the assumptions of Theorem* 4.1 *and Lemma* 5.1*, the following error estimate holds:*

$$\|\mathbf{u} - \mathbf{u}_h\| \le C\, h\, |||(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h, \mathbf{u} - \mathbf{u}_h)||| \tag{5.3}$$

$$\le C\, h^{l+1} \left(\|\boldsymbol{\sigma}\|_l + \|\nabla\cdot\boldsymbol{\sigma}\|_l + \|\mathbf{u}\|_{l+1} \right). \tag{5.4}$$

Proof. It follows from Lemma 5.1, the orthogonality property in (4.5), the Cauchy–Schwarz inequality, and the approximation properties in (4.1) and (4.2) with $l = 1$ that for any $(\boldsymbol{\gamma}_h, \mathbf{w}_h) \in \Sigma_h^k \times V_h^{k+1}$,

$$\begin{aligned}\|\mathbf{u} - \mathbf{u}_h\|^2 &= b(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h, \mathbf{u} - \mathbf{u}_h; \boldsymbol{\gamma}, \mathbf{w}) = b(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h, \mathbf{u} - \mathbf{u}_h; \boldsymbol{\gamma} - \boldsymbol{\gamma}_h, \mathbf{w} - \mathbf{w}_h)\\ &\le C\,|||(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h, \mathbf{u} - \mathbf{u}_h)||| \inf_{(\boldsymbol{\gamma}_h, \mathbf{w}_h) \in \Sigma_h^k \times V_h^{k+1}} |||(\boldsymbol{\gamma} - \boldsymbol{\gamma}_h, \mathbf{w} - \mathbf{w}_h)|||\\ &\le C\,h\,|||(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h, \mathbf{u} - \mathbf{u}_h)|||\,(\|\boldsymbol{\gamma}\|_1 + \|\nabla \cdot \boldsymbol{\gamma}\|_1 + \|\mathbf{w}\|_2)\\ &\le C\,h\,|||(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h, \mathbf{u} - \mathbf{u}_h)||| \cdot \|\mathbf{u} - \mathbf{u}_h\|.\end{aligned}$$

Dividing $\|\mathbf{u} - \mathbf{u}_h\|$ on both sides of the above inequality gives (5.3) which, combined with Theorem 4.1, implies (5.4). This completes the proof of the theorem. ∎

5.1. The scalar elliptic problems.

Proof of Lemma 5.1. Let $z \in H_D^1(\Omega)$ be the solution of (2.4) with $f = u - u_h$. The regularity estimate in (2.5) for the dual problem implies

$$\|z\|_2 \le C\,\|u - u_h\|. \tag{5.5}$$

By taking $v = u - u_h$ in (2.4), adding and subtracting $(\sigma - \sigma_h, \nabla v)$, and integrating by parts, we have

$$\begin{aligned}\|u - u_h\|^2 &= a(u - u_h, z) = (A\nabla(u - u_h), \nabla z) + (X(u - u_h), z)\\ &= ((\sigma - \sigma_h) + A\nabla(u - u_h), \nabla z) + (\nabla \cdot (\sigma - \sigma_h) + X(u - u_h), z).\end{aligned}$$

Now, to show the validity of Lemma 5.1, it suffices to find $(\gamma, w) \in H_N(\mathrm{div}; \Omega) \times H_D^1(\Omega)$ such that

$$\begin{cases} A^{-1}\gamma + \nabla w &= \nabla z \quad \text{in} \quad \Omega,\\ \nabla \cdot \gamma + Xw &= z \quad \text{in} \quad \Omega \end{cases} \tag{5.6}$$

and that

$$\|w\|_2 + \|\gamma\|_1 + \|\nabla \cdot \gamma\|_1 \le C\,\|u - u_h\|. \tag{5.7}$$

To do so, let $w \in H_D^1(\Omega)$ be the solution of the scalar elliptic problems in (2.1) and (2.2) with the right-hand side $f = z - \nabla \cdot (A\nabla z)$. The regularity estimate in (2.5) for the dual problem and the triangle inequality implies

$$\|w\|_2 \le C\,\|z - \nabla \cdot (A\nabla z)\| \le C\,\|z\|_2 \le C\,\|u - u_h\|. \tag{5.8}$$

Let $\gamma = A\nabla(z - w)$. It is then easy to check that (γ, w) satisfies (5.6). Now, (5.7) follows from (5.5), (5.8), and the facts that

$$\|\gamma\|_1 = \|A\nabla(z - w)\|_1 \le C\,(\|z\|_2 + \|w\|_2)$$

and that

$$\|\nabla \cdot \gamma\|_1 = \|z - Xw\|_1 \le C\,(\|z\|_1 + \|w\|_2)\,.$$

This completes the proof of Lemma 5.1 for the scalar elliptic problems. ∎

5.2. The generalized Stokes equations. The regularity estimate of the generalized Stokes equation in (2.7) is a consequence (2.11).

LEMMA 5.2. *For* $\mathbf{f} \in L^2(\Omega)^d$ *and* $g \in H^1(\Omega)$, *solution* $(\mathbf{u}, p) \in \left(H_D^1(\Omega)^d \cap H^2(\Omega)^d\right) \times H^1(\Omega)$ *of the generalized Stokes equations in* (2.7) *and* (2.8) *satisfies the a priori estimate*

$$\|\mathbf{u}\|_2 + \|p\|_1 \leq C\left(\|\mathbf{f}\| + \|g\|_1\right), \tag{5.9}$$

where the positive constant C *is independent of* λ.

Proof. When $\lambda = \infty$, let $(\hat{\mathbf{u}}, \hat{p})$ be the solution of (2.9) and (2.8); then (5.9) is simply the first inequality in (2.11), that is,

$$\|\hat{\mathbf{u}}\|_2 + \|\hat{p}\|_1 \leq C\left(\|\mathbf{f}\| + \|g\|_1\right). \tag{5.10}$$

When $\lambda \neq \infty$, let $(\mathbf{u}, p)$ be the solution of (2.7) and (2.8), and set $(\mathbf{u}^*, p^*) = (\mathbf{u} - \hat{\mathbf{u}}, p - \hat{p})$. It is easy to check that $(\mathbf{u}^*, p^*)$ satisfies (2.7) with $\mathbf{f} = \mathbf{0}$, $g = -\frac{1}{\lambda}\hat{p}$ and boundary conditions (2.8), that is,

$$\left\{\begin{array}{rcll} -\nabla \cdot (\boldsymbol{\epsilon}(\mathbf{u}^*) - p^* \boldsymbol{\delta}) &=& \mathbf{0} & \text{in } \Omega, \\ \nabla \cdot \mathbf{u}^* + \dfrac{1}{\lambda} p^* &=& -\dfrac{1}{\lambda}\hat{p} & \text{in } \Omega \end{array}\right. \tag{5.11}$$

with $\mathbf{u}^* = \mathbf{0}$ on Γ_D and $\mathbf{n} \cdot (\boldsymbol{\epsilon}(\mathbf{u}^*) - p^* \boldsymbol{\delta}) = \mathbf{0}$ on Γ_N. Substituting $p^* = -\lambda \nabla \cdot \mathbf{u}^* - \hat{p}$ into the first equation of (5.11) gives

$$-\nabla \cdot \boldsymbol{\epsilon}(\mathbf{u}^*) - \lambda \nabla \nabla \cdot \mathbf{u}^* = -\nabla \hat{p}$$

with $\mathbf{u}^* = \mathbf{0}$ on Γ_D and $\mathbf{n} \cdot (\boldsymbol{\epsilon}(\mathbf{u}^*) + \lambda\,(\nabla \cdot \mathbf{u}^*)\,\boldsymbol{\delta}) = \mathbf{0}$ on Γ_N. By the regularity estimate in (2.11) for the elastic equations, (5.10), and the triangle inequality, we have that

$$\|\mathbf{u}^*\|_2 + \lambda \|\nabla \cdot \mathbf{u}^*\|_1 \leq C \|\nabla \hat{p}\| \leq C\left(\|\mathbf{f}\| + \|g\|_1\right)$$

and that

$$\|p^*\|_1 = \|\lambda \nabla \cdot \mathbf{u}^* + \hat{p}\|_1 \leq \|\lambda \nabla \cdot \mathbf{u}^*\|_1 + \|\hat{p}\|_1 \leq C\left(\|\mathbf{f}\| + \|g\|_1\right).$$

Now, (5.9) is an immediate consequence of the fact that $(\mathbf{u}, p) = (\mathbf{u}^* + \hat{\mathbf{u}}, p^* + \hat{p})$, the triangle inequality, and (5.10). This completes the proof of the lemma. ∎

With the H^2 regularity estimate for the generalized Stokes equations, we are now ready to prove Lemma 5.1 for both the elastic and Stokes equations by the duality argument.

Proof of Lemma 5.1. Let $\mathbf{e}_h = \mathbf{u} - \mathbf{u}_h$ and $E_h = \boldsymbol{\sigma} - \boldsymbol{\sigma}_h$. It is easy to see that

$$\mathbf{e}_h = \mathbf{0} \quad \text{on } \Gamma_D \quad \text{and} \quad \mathbf{n} \cdot E_h = \mathbf{0} \quad \text{on } \Gamma_N. \tag{5.12}$$

Consider the following dual problem: Let $(\mathbf{z}, r) \in H_0^1(\Omega) \times L^2(\Omega)$ be the solution of the perturbed Stokes equation in (2.7) and (2.8) with the right-hand sides $\mathbf{f} = \mathbf{u} - \mathbf{u}_h$ and $g = 0$, that is,

$$\left\{\begin{array}{rcll} -\nabla \cdot (\boldsymbol{\epsilon}(\mathbf{z}) - r\,\boldsymbol{\delta}) &=& \mathbf{e}_h & \text{in } \Omega, \\ \nabla \cdot \mathbf{z} + \dfrac{1}{\lambda} r &=& 0 & \text{in } \Omega \end{array}\right. \tag{5.13}$$

with boundary conditions

$$\mathbf{z} = \mathbf{0} \quad \text{on } \Gamma_D \quad \text{and} \quad \mathbf{n} \cdot (\boldsymbol{\epsilon}(\mathbf{z}) - r\,\boldsymbol{\delta}) = \mathbf{0} \quad \text{on } \Gamma_N. \tag{5.14}$$

It follows from Lemma 5.2 that

$$\|\mathbf{z}\|_2 + \|r\|_1 \le C\,\|\mathbf{u} - \mathbf{u}_h\|. \tag{5.15}$$

To establish Lemma 5.1, we first use the above dual problem to derive the following equality:

$$\|\mathbf{e}_h\|^2 = (\mathcal{A}_\lambda E_h - \boldsymbol{\epsilon}(\mathbf{e}_h),\, r\,\boldsymbol{\delta} - \nabla\,\mathbf{z}) + (\nabla \cdot E_h,\, -\mathbf{z}). \tag{5.16}$$

To this end, using the first equation in (5.13), integration by parts, boundary conditions (5.12) and (5.14), and (2.6), we have

$$\begin{aligned}
\|\mathbf{e}_h\|^2 &= (\mathbf{e}_h,\, -\nabla \cdot (\boldsymbol{\epsilon}(\mathbf{z}) - r\,\boldsymbol{\delta})) \\
&= (\nabla\,\mathbf{e}_h,\, \boldsymbol{\epsilon}(\mathbf{z}) - r\,\boldsymbol{\delta}) + \int_{\partial\Omega} \mathbf{e}_h \cdot (\mathbf{n} \cdot (\boldsymbol{\epsilon}(\mathbf{z}) - r\,\boldsymbol{\delta})) \\
&= (\boldsymbol{\epsilon}(\mathbf{e}_h),\, \boldsymbol{\epsilon}(\mathbf{z}) - r\boldsymbol{\delta}) = (\boldsymbol{\epsilon}(\mathbf{e}_h),\, \nabla\,\mathbf{z} - r\boldsymbol{\delta}) \\
&= (\mathcal{A}_\lambda E_h - \boldsymbol{\epsilon}(\mathbf{e}_h),\, r\boldsymbol{\delta} - \nabla\,\mathbf{z}) + (\mathcal{A}_\lambda E_h,\, \nabla\,\mathbf{z}) - (\mathrm{tr}(\mathcal{A}_\lambda E_h),\, r). \qquad (5.17)
\end{aligned}$$

By the definition of $\mathcal{A}_\lambda$, integration by parts, boundary conditions (5.12) and (5.14), and the second equation in (5.13), we have

$$\begin{aligned}
(\mathcal{A}_\lambda E_h,\, \nabla\,\mathbf{z}) &= \left(E_h - \frac{\lambda}{d\,\lambda + 1}(\mathrm{tr}\,E_h)\,\boldsymbol{\delta},\, \nabla\,\mathbf{z}\right) = (E_h,\, \nabla\,\mathbf{z}) - \frac{\lambda}{d\,\lambda + 1}((\mathrm{tr}\,E_h)\,\boldsymbol{\delta},\, \nabla\,\mathbf{z}) \\
&= -(\nabla\cdot\, E_h,\, \mathbf{z}) + \int_{\partial\Omega} (\mathbf{n} \cdot E_h) \cdot \mathbf{z} - \frac{\lambda}{d\,\lambda + 1}(\mathrm{tr}\,E_h,\, \nabla \cdot \mathbf{z}) \\
&= (\nabla\cdot\, E_h,\, -\mathbf{z}) + \frac{1}{d\,\lambda + 1}(\mathrm{tr}\,E_h,\, r),
\end{aligned}$$

which, together with the fact that

$$\mathrm{tr}\,(\mathcal{A}_\lambda\,E_h) = \frac{1}{d\,\lambda + 1}\mathrm{tr}\,E_h,$$

implies

$$(\mathcal{A}_\lambda E_h,\, \nabla\,\mathbf{z}) = (\nabla\cdot\, E_h,\, -\mathbf{z}) + (\mathrm{tr}(\mathcal{A}_\lambda\,E_h),\, r). \tag{5.18}$$

Now, (5.16) follows from (5.17) and (5.18).

Next, we want to find $(\boldsymbol{\gamma},\, \mathbf{w})$ such that

$$\begin{cases} \mathcal{A}_\lambda\,\boldsymbol{\gamma} - \boldsymbol{\epsilon}(\mathbf{w}) &= r\,\boldsymbol{\delta} - \nabla\,\mathbf{z} \quad \text{in} \quad \Omega, \\ \nabla \cdot \boldsymbol{\gamma} &= -\mathbf{z} \quad \text{in} \quad \Omega \end{cases} \tag{5.19}$$

and that

$$\|\mathbf{w}\|_2 + \|\boldsymbol{\gamma}\|_1 + \|\nabla \cdot \boldsymbol{\gamma}\|_1 \le C\,\|\mathbf{e}_h\|. \tag{5.20}$$

To do so, let $(\mathbf{w}, s)$ be the solution of the perturbed Stokes equation in (2.7) and (2.8) with the right-hand sides

$$\mathbf{f} = -\triangle \mathbf{z} + \mathbf{z} \quad \text{and} \quad g = -\frac{d\,\lambda + 2}{\lambda}\, r,$$

that is,

$$\left\{ \begin{array}{rcll} -\nabla \cdot (\boldsymbol{\epsilon}(\mathbf{w}) - s\,\boldsymbol{\delta}) & = & -\triangle \mathbf{z} + \mathbf{z} & \text{in} \quad \Omega, \\ \nabla \cdot \mathbf{w} + \dfrac{1}{\lambda}\, s & = & -\dfrac{d\,\lambda + 2}{\lambda}\, r & \text{in} \quad \Omega \end{array} \right. \tag{5.21}$$

with boundary conditions

$$\mathbf{w} = \mathbf{0} \quad \text{on } \Gamma_D \quad \text{and} \quad \mathbf{n} \cdot (\boldsymbol{\epsilon}(\mathbf{w}) - s\,\boldsymbol{\delta}) = \mathbf{0} \quad \text{on } \Gamma_N.$$

It then follows from Lemma 5.2 and (5.15) that

$$\begin{aligned} \|\mathbf{w}\|_2 + \|s\|_1 &\le C \left(\| - \triangle \mathbf{z} + \mathbf{z}\| + \left\| \frac{d\,\lambda + 2}{\lambda}\, r \right\|_1 \right) \\ &\le C\, (\|\mathbf{z}\|_2 + \|r\|_1) \le C\, \|\mathbf{e}_h\|. \end{aligned} \tag{5.22}$$

Now, let

$$\boldsymbol{\gamma} = -\nabla\, \mathbf{z} + \boldsymbol{\epsilon}(\mathbf{w}) - s\,\boldsymbol{\delta}. \tag{5.23}$$

Then applying the divergence operator to (5.23) and using the first equation in (5.21) yield the second equation in (5.19). Applying the trace operator to (5.23) and using the second equations in both (5.13) and (5.21), we have

$$\operatorname{tr} \boldsymbol{\gamma} = -\frac{d\,\lambda + 1}{\lambda}\, (s + r).$$

Hence,

$$s = -\frac{\lambda}{d\,\lambda + 1} \operatorname{tr} \boldsymbol{\gamma} - r,$$

which, combined with (5.23), implies the first equation in (5.19). Therefore, $(\boldsymbol{\gamma}, \mathbf{w})$ satisfies (5.19). To prove that $(\boldsymbol{\gamma}, \mathbf{w})$ also satisfies (5.20), it follows from (5.23), the triangle inequality, and (5.22) that

$$\|\boldsymbol{\gamma}\|_1 \le \|\nabla\, \mathbf{z}\|_1 + \|\boldsymbol{\epsilon}(\mathbf{w})\|_1 + d\, \|s\|_1 \le C\, (\|\mathbf{z}\|_2 + \|\mathbf{w}\|_2 + \|s\|_1) \le C\, \|\mathbf{e}_h\|$$

and from the second equation of (5.19) and (5.22) that

$$\|\nabla \cdot \boldsymbol{\gamma}\|_1 = \|\mathbf{z}\|_1 \le C\, \|\mathbf{e}_h\|,$$

which, combined with (5.22), implies (5.20).

Finally, combining (5.16) and (5.19) yields (5.1) with $(\boldsymbol{\gamma}, \mathbf{w})$ satisfying (5.2). This completes the proof of Lemma 5.1 for both the elasticity and Stokes equations. ∎

5.3. Extension to problems with low regularity. Extensions of our results in this paper to problems with low regularity can be carried out in a similar fashion. To this end, we assume the following $H^{1+\alpha}$ regularity estimates with $\alpha \in [1/2, 1)$:

$$\|u\|_{1+\alpha} \le C\,\|f\|_{1-\alpha} \quad \text{and} \quad \|z\|_{1+\alpha} \le C\,\|f\|_{1-\alpha} \tag{5.24}$$

for problems (2.3) and (2.4), respectively, and

$$\|\mathbf{u}\|_{1+\alpha} + \|p\|_\alpha \le C\,(\|\mathbf{f}\|_{1-\alpha} + \|g\|_\alpha) \quad \text{and} \quad \|\mathbf{u}\|_{1+\alpha} + \lambda\,\|\nabla\cdot\mathbf{u}\|_\alpha \le C\,\|\mathbf{f}\|_{1-\alpha} \tag{5.25}$$

for problems (2.9) and (2.10), respectively. The assumption on $\alpha \ge 1/2$ is needed in order to define the Raviart–Thomas elements. For any $\boldsymbol{\sigma} \in H^\alpha(\Omega)^{m\times m} \cap \Sigma$ with $\nabla\cdot\boldsymbol{\sigma} \in H^\alpha(\Omega)^m$, we assume the following approximation property for Σ_h^k: There exists $0 < \beta \le \alpha$ such that

$$\inf_{\boldsymbol{\tau}\in\Sigma_h^k} \|\boldsymbol{\sigma} - \boldsymbol{\tau}\|_{H(\mathrm{div};\,\Omega)} \le C\,h^\beta\,(\|\boldsymbol{\sigma}\|_\alpha + \|\nabla\cdot\boldsymbol{\sigma}\|_\alpha)\,. \tag{5.26}$$

THEOREM 5.2. *Assume that the solution* $(\boldsymbol{\sigma}, \mathbf{u})$ *of* (3.7) *is in* $H^\alpha(\Omega)^{m\times m} \times H^{\alpha+1}(\Omega)^m$ *and that the divergence of the stress* $\nabla\cdot\boldsymbol{\sigma}$ *is in* $H^\alpha(\Omega)^m$ ($m = 1$ *or* d) *with* $\alpha \in [1/2, 1)$. *Suppose that approximation property* (5.26) *holds; then with* $(\boldsymbol{\sigma}_h, \mathbf{u}_h) \in \Sigma_h^0 \times V_h^1$ *denoting the solution to* (4.3), *the following error estimate holds:*

$$|||(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h,\, \mathbf{u} - \mathbf{u}_h)||| \le C\,h^\beta\,(\|\boldsymbol{\sigma}\|_\alpha + \|\nabla\cdot\boldsymbol{\sigma}\|_\alpha) + C\,h^\alpha\,\|\mathbf{u}\|_{1+\alpha}. \tag{5.27}$$

Proof. The proof of (5.27) is standard and identical to that of (4.7). ∎

THEOREM 5.3. *Assume that the regularity estimates in* (5.24) *and* (5.25) *hold. Under the assumptions of Theorem* 5.2, *we have the following* L^2 *norm error estimates:*

$$\|\mathbf{u} - \mathbf{u}_h\| \le C\,h^\beta\,|||(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h,\, \mathbf{u} - \mathbf{u}_h)||| \tag{5.28}$$

$$\le C\,h^{2\,\beta}\,(\|\boldsymbol{\sigma}\|_\alpha + \|\nabla\cdot\boldsymbol{\sigma}\|_\alpha + \|\mathbf{u}\|_{1+\alpha})\,. \tag{5.29}$$

Proof. In a similar fashion, one can first establish the $H^{1+\alpha}$ regularity for the generalized Stokes equations in (2.7) and (2.8) and then prove that there exists $(\boldsymbol{\gamma}, \mathbf{w})$ such that

$$\|\mathbf{u} - \mathbf{u}_h\|^2 = b(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h,\, \mathbf{u} - \mathbf{u}_h;\, \boldsymbol{\gamma},\, \mathbf{w})$$

and that

$$\|\boldsymbol{\gamma}\|_\alpha + \|\nabla\cdot\boldsymbol{\gamma}\|_\alpha + \|\mathbf{w}\|_{\alpha+1} \le C\,\|\mathbf{u} - \mathbf{u}_h\|.$$

Now, error bound (5.28) easily follows in a way similar to that of (5.3), and (5.29) is then a direct consequence of (5.28) and (5.27). ∎

STRONG STABILITY FOR ADDITIVE RUNGE–KUTTA METHODS*

INMACULADA HIGUERAS†

Abstract. Space discretization of some time-dependent partial differential equations gives rise to ordinary differential equations containing additive terms with different stiffness properties. In these situations, additive Runge–Kutta (ARK) methods are used. The aim of this paper is to study monotonicity properties (also known as strong stability) for ARK methods. A new definition of absolute monotonicity for ARK methods is given and some of its properties are investigated. With this concept, monotonicity for ARK schemes under certain stepsize restrictions can be ensured. Some ARK methods from the literature are analyzed. As expected, monotonicity for each Runge–Kutte (RK) method does not ensure monotonicity for the ARK scheme. Some numerical examples show the applicability of these results.

Key words. Runge–Kutta, strong stability preserving, absolutely monotonic, radius of absolute monotonicity, CFL coefficient

1. Introduction.

We consider initial value problems for ordinary differential equations (ODEs) of the form

$$\begin{aligned} \frac{d}{dt}u(t) &= f\left(u(t)\right) + \tilde{f}\left(u(t)\right), \qquad t \geq t_0, \\ u(t_0) &= u_0\,. \end{aligned} \tag{1.1}$$

We assume that $t_0 \in \mathbb{R}$, $u_0 \in \mathbb{R}^m$, and f and $\tilde{f}$ are continuous functions from $\mathbb{R}^m$ to $\mathbb{R}^m$ with different stiffness properties such that for each $t_0 \in \mathbb{R}$ and $u_0 \in \mathbb{R}^m$ problem (1.1) has a unique solution $u : [t_0, \infty) \to \mathbb{R}^m$. Such systems often arise from space discretization of time-dependent partial differential equations (PDEs) by the method of lines [2, 3, 4, 7, 17, 19, 20, 22, 27]. We assume too that $\|\cdot\| : \mathbb{R}^m \to \mathbb{R}$ is a convex function (e.g., a norm, an entropy function, etc.), such that for any $t_0 \in \mathbb{R}$ and any solution $u(t)$ to (1.1) we have

$$\|u(t)\| \leq \|u(t_0)\| \qquad \text{for all } \ t \geq t_0\,. \tag{1.2}$$

In order to obtain property (1.2) for the solution of (1.1), some conditions must be imposed on the functions f and $\tilde{f}$. In the rest of the paper we assume that $(f, \tilde{f}\|\cdot\|)$ satisfy

$$\left\| y + \frac{1}{\rho}\ f(y) \right\| \leq \| y \| \qquad \text{for all } y \in \mathbb{R}^m\,, \tag{1.3}$$

$$\left\| y + \frac{1}{\tilde{\rho}}\ \tilde{f}(y) \right\| \leq \| y \| \qquad \text{for all } y \in \mathbb{R}^m \tag{1.4}$$

for some fixed $\rho, \tilde{\rho} > 0$, and we denote this class of problems by $\mathcal{F}(\rho, \tilde{\rho})$. Recall that (1.3)–(1.4) imply that these inequalities also hold for any τ with $0 \le \tau \le 1/\rho$ [18, Theorem 5.1]. Under these assumptions it is straightforward to prove that (1.3)–(1.4) imply that for $u(t)$, the solution of (1.1), we have

$$D_+ \|u(t)\| \le 0\,,$$

where D_+ denotes the right-hand derivative, and hence (1.2) holds. For details see [13].

Given the initial value problem (1.1) a common class of one step methods for solving it numerically is that of the additive Runge–Kutta (ARK) methods. An s-stage ARK method is defined by two $s \times s$ real matrices $\mathcal{A}$ and $\tilde{\mathcal{A}}$, and two real vectors $b, \tilde{b} \in \mathbb{R}^s$. From u_n, the numerical approximation of the solution $u(t)$ at $t = t_n$, we obtain u_{n+1}, the numerical approximation of the solution at $t_{n+1} = t_n + h$, by

$$u_{n+1} = u_n + h \sum_{i=1}^{s} b_i f(U_i) + h \sum_{i=1}^{s} \tilde{b}_i \tilde{f}(U_i)\,, \tag{1.5}$$

where the internal stages U_i are given as

$$U_i = u_n + h \sum_{j=1}^{s} a_{ij} f(U_j) + h \sum_{j=1}^{s} \tilde{a}_{ij} \tilde{f}(U_j)\,. \tag{1.6}$$

The Runge–Kutta (RK) methods $(\mathcal{A}, b)$ and $(\tilde{\mathcal{A}}, \tilde{b})$ are chosen with the aim of integrating system (1.1) with low computational cost. For example, if f represents the nonstiff part of the system and $\tilde{f}$ the stiff part, an explicit method can be used for f and an implicit one for $\tilde{f}$. ARK methods combining implicit and explicit schemes are known in the literature as IMplicit–EXplicit (IMEX) RK methods [2, 19, 17]. We remark that the problems we have in mind have a stiff behavior and therefore, the use of an explicit method for the whole problem is not possible.

Denoting the coefficients of the ARK method by

$$\mathbb{A} = \begin{pmatrix} \mathcal{A} & 0 \\ b^t & 0 \end{pmatrix}, \qquad \tilde{\mathbb{A}} = \begin{pmatrix} \tilde{\mathcal{A}} & 0 \\ \tilde{b}^t & 0 \end{pmatrix},$$

we can write (1.5)–(1.6) in compact form as

$$U = e \otimes u_n + h(\mathbb{A} \otimes I) F(U) + h(\tilde{\mathbb{A}} \otimes I) \tilde{F}(U)\,, \tag{1.7}$$

where $e = (1, \ldots, 1)^t \in \mathbb{R}^{s+1}$, $U = (U_1^t, \ldots, U_s^t, u_{n+1}^t)^t \in \mathbb{R}^{(s+1)m}$, $F(U) = (f(U_1)^t, \ldots, f(U_s)^t, 0)^t \in \mathbb{R}^{(s+1)m}$, and similarly $\tilde{F}(U)$. The symbol $\otimes$ denotes the Kronecker product (see, e.g., [16, section 12.1])

$$A \otimes B = \begin{pmatrix} a_{11}B & \cdots & a_{1m}B \\ \vdots & & \vdots \\ a_{m1}B & \cdots & a_{mm}B \end{pmatrix}.$$

Some properties of the Kronecker product, namely $(A \otimes B)\,(C \otimes D) = (A\,B \otimes C\,D)$, $(A \otimes B)^{-1} = A^{-1} \otimes B^{-1}$, where the matrices involved have the proper dimensions and properties, will be used later on.

The internal stage U_i approximates $u(t_n + c_i h)$, where $c_i = \sum_{j=1}^{s} a_{ij}$. Furthermore, for many methods it holds that $c_i \geq 0$, $i = 1, \ldots, s$, and thus $t_n + c_i h \geq t_n$. Therefore, if we solve numerically an ODE (1.1) with $(f, \tilde{f}, \|\cdot\|) \in \mathcal{F}(\rho, \tilde{\rho})$ with an ARK method, a natural requirement for the internal stages and the numerical solution is

$$\|U_i\| \leq \|u_n\|, \qquad i = 1, \ldots, s, \tag{1.8}$$

$$\|u_{n+1}\| \leq \|u_n\| \tag{1.9}$$

for all $n \geq 0$, probably under a stepsize restriction $h \leq \Delta t_{MAX}$. Following the nomenclature for RK methods, we will say that an ARK scheme that satisfies (1.8)–(1.9) is strongly stable.

Monotonicity properties (1.8)–(1.9) for RK methods have been studied by several authors [5, 23, 24, 25, 10, 9, 21, 26]; see [12] for a review. The aim of this paper is to study these properties for ARK methods. As we will see in this paper, it is not true that two strongly stable RK methods give rise to a strongly stable ARK method. This fact is not surprising because in general the fact that a property holds for methods $(\mathcal{A}, b)$ and $(\tilde{\mathcal{A}}, \tilde{b})$ separately does not imply that it holds for the ARK method. This situation is well known for the order of consistency of an ARK scheme, where, together with the order conditions for each method, some extra coupling conditions are required (see, e.g., [17, 20]). Similarly, where stability issues for ARK methods have been studied by some authors [4, 17], it has been found that extra conditions must be considered.

As far as we know, strong stability has not been studied for ARK schemes. The closest research is found in [20], where, in the context of hyperbolic systems with relaxation, IMEX methods are used to solve problems of the form

$$\frac{d}{dt}\, u(t) = f(u(t)) + \frac{1}{\varepsilon}\, \tilde{f}(u(t)),$$

where ε is the stiffness parameter. For this problem, monotonicity in the stiff limit, i.e., when $\varepsilon \to 0$, is studied. For this purpose, in [20] the concept of the asymptotic preserving (AP) method is used. In this case, under certain conditions for the implicit scheme, monotonicity can be recovered under the only stability restriction introduced by the explicit part of the IMEX scheme. However, the results obtained in [20] do not cover the case of moderate values of ε.

For RK methods the radius of absolute monotonicity gives stepsize restrictions for monotonicity [18, 5]. In this paper we extend this concept for ARK methods and give sufficient conditions for monotonicity.

The rest of the paper is organized as follows. Section 2 is devoted to the extension of the radius of absolute monotonicity for ARK methods and the study of some of its properties. Stepsize restrictions for monotonicity are given in terms of this radius in section 3. This section ends with subsections 3.1 and 3.2, where the previous results are related to the Shu–Osher forms and perturbed RK schemes. With the new concept defined, the monotonicity properties of some methods from the literature are analyzed in section 4. Some numerical experiments are shown in section 5. The paper ends with some conclusions and open questions for future work in section 6.

2. Absolute monotonicity for additive RK methods. In the context of contractive and monotone RK methods, the concept of radius of absolute monotonicity

plays an important role [18, 5]. We review the definitions of absolute monotonicity and radius of absolute monotonicity as follows.

DEFINITION 2.1 (see [18, Definition 2.4]). *An s-stage RK method with coefficients* $\mathbb{A}$ *is said to be absolutely monotonic (a.m.) at a given point* $\xi \leq 0$ *if the matrix* $I - \xi\mathbb{A}$ *is nonsingular and*

$$(I - \xi\mathbb{A})^{-1}\mathbb{A} \geq 0\,, \tag{2.1}$$

$$(I - \xi\mathbb{A})^{-1}e \geq 0\,, \tag{2.2}$$

where $e = (1, 1, \ldots, 1)^t \in \mathbb{R}^{s+1}$*, and the vector inequalities are understood componentwise. Further, the method is said to be a.m. on a given set* $\Omega \subset \mathbb{R}$ *if it is a.m. at each* $\xi \in \Omega$*. The radius of absolute monotonicity* $R(\mathbb{A})$ *is defined by*

$$R(\mathbb{A}) = \sup\{\, r \,|\, r \geq 0 \text{ and } \mathbb{A} \text{ is a.m. on } [-r, 0]\,\}\,. \tag{2.3}$$

If there is no $r > 0$ *such that* $\mathbb{A}$ *is a.m. on* $[-r, 0]$*, we set* $R(\mathbb{A}) = 0$*.*

Our first aim is to extend this concept for ARK methods $(\mathbb{A}, \tilde{\mathbb{A}})$ and analyze some of its properties. For a better understanding of that extension, we briefly show how conditions (2.1)–(2.2) in Definition 2.1 arise in [18].

In [18] the scalar linear problems $u' = \lambda u$ and $u' = \lambda(t)u$, and the vectorial linear problem $u' = L(t)u(t)$, with $L(t)$ an $m \times m$ matrix, are considered. In compact form, with $U = (U_1^t, \ldots, U_s^t, u_{n+1}^t)^t \in \mathbb{R}^{(s+1)m}$ (cf. (1.7)), an RK method $\mathbb{A}$ for these problems gives, respectively, $U = \phi(h\lambda)u_n$, with

$$\phi(z) = (I_{s+1} - z\mathbb{A})^{-1}\, e;$$

$U = K\left(\text{diag}\,(h\lambda_1, \ldots, h\lambda_s, 0)\right) u_n$, with

$$K(Z) = (I_{s+1} - \mathbb{A}Z)^{-1}\, e$$

and Z a diagonal matrix; and $U = \mathbb{K}\left(\text{diag}\,(hL_1, \ldots, hL_s, 0)\right) \otimes u_n$, with $L_i = L(t_n + c_i h)$,

$$\mathbb{K}(\mathbb{Z}) = \left(I_{(s+1)\cdot m} - (\mathbb{A} \otimes I_m)\mathbb{Z}\right)^{-1} (e \otimes I_m)\,,$$

and $\mathbb{Z}$ a block diagonal matrix. The concepts of absolute monotonicity at a given point $\xi \in \mathbb{R}$ for ϕ, K, and $\mathbb{K}$ are given in [18, p. 487]. Roughly speaking they mean the nonnegativity of all coefficients of the Taylor expansion about $z = \xi$, $Z = \xi I_{s+1}$, or $\mathbb{Z} = \xi I_{(s+1)\cdot m}$, respectively. In particular, for $\mathbb{Z} = \xi I_{(s+1)\cdot m} + \mathbb{W}$, with $\mathbb{W}$ sufficiently close to zero, we obtain

$$\mathbb{K}(\mathbb{Z}) = \left[I_{(s+1)\cdot m} - (\mathsf{A}(\xi) \otimes I_m)\mathbb{W}\right]^{-1} (\mathsf{e}(\xi) \otimes I_m)\,,$$

where $\mathsf{A}(\xi) = (I_{s+1} - \xi\mathbb{A})^{-1}\mathbb{A}$ and $\mathsf{e}(\xi) = (I_{s+1} - \xi\mathbb{A})^{-1}e$. Thus with $\mathsf{A}(\xi) \geq 0$ and $\mathsf{e}(\xi) \geq 0$ (see (2.1)–(2.2)), we obtain the absolute monotonicity of $\mathbb{K}$ at $\xi I_{(s+1)\cdot m}$.

Similarly, if we consider now the additive problems $u' = -(\lambda + \tilde{\lambda})u$ and $u' = -(\lambda(t) + \tilde{\lambda}(t))u$, and the vectorial linear problem $u' = -(L(t) + \tilde{L}(t))u(t)$, with $\tilde{L}(t)$ an $m \times m$ matrix, an ARK method $(\mathbb{A}\,, \tilde{\mathbb{A}})$ gives, respectively,

$$U = \phi(h\lambda, h\tilde{\lambda})u_n,$$

with

$$\phi(z, \tilde{z}) = \left(I_{s+1} - z\mathbb{A} - \tilde{z}\tilde{\mathbb{A}}\right)^{-1} e;$$

$U = K\left(\text{diag }(h\lambda_1, \ldots, h\lambda_s, 0), \text{diag }(h\tilde{\lambda}_1, \ldots, h\tilde{\lambda}_s, 0)\right) u_n$, with

$$K(Z, \tilde{Z}) = \left(I_{s+1} - \mathbb{A}Z - \tilde{\mathbb{A}}\tilde{Z}\right)^{-1} e$$

and Z, $\tilde{Z}$ diagonal matrices; and

$$U = \mathbb{K}\left(\text{diag }(hL_1, \ldots, hL_s, 0), \text{diag }(h\tilde{L}_1, \ldots, h\tilde{L}_s, 0)\right) \otimes u_n,$$

with

$$\mathbb{K}(\mathbb{Z}, \tilde{\mathbb{Z}}) = \left(I_{(s+1)\cdot m} - (\mathbb{A} \otimes I_m)\mathbb{Z} - (\tilde{\mathbb{A}} \otimes I_m)\tilde{\mathbb{Z}}\right)^{-1} (e \otimes I_m)$$

and $\mathbb{Z}$, $\tilde{\mathbb{Z}}$ block diagonal matrices. For $\mathbb{Z} = \xi I_{(s+1)\cdot m} + \mathbb{W}$, $\tilde{\mathbb{Z}} = \tilde{\xi} I_{(s+1)\cdot m} + \tilde{\mathbb{W}}$, with $\mathbb{W}$, $\tilde{\mathbb{W}}$ sufficiently close to zero, we obtain

$$\mathbb{K}(\mathbb{Z}, \tilde{\mathbb{Z}}) = \left[I_{(s+1)\cdot m} - (\mathsf{A}(\xi, \tilde{\xi}) \otimes I_m)\mathbb{W} - (\tilde{\mathsf{A}}(\xi, \tilde{\xi}) \otimes I_m)\tilde{\mathbb{W}}\right]^{-1} \left(\mathsf{e}(\xi, \tilde{\xi}) \otimes I_m\right),$$

where now $\mathsf{A}(\xi, \tilde{\xi})$, $\tilde{\mathsf{A}}(\xi, \tilde{\xi})$, and $\mathsf{e}(\xi, \tilde{\xi})$ are defined, respectively, by (2.4), (2.5), and (2.6) below. Thus with $\mathsf{A}(\xi, \tilde{\xi}) \geq 0$, $\tilde{\mathsf{A}}(\xi, \tilde{\xi}) \geq 0$ and $\mathsf{e}(\xi, \tilde{\xi}) \geq 0$, we obtain that all the coefficients in the Taylor expansion of $\mathbb{K}(\mathbb{Z}, \tilde{\mathbb{Z}})$ at $(\xi I_{(s+1)\cdot m}, \tilde{\xi} I_{(s+1)\cdot m})$ are nonnegative. This analysis lead us to the extension of Definition 2.1 as follows.

DEFINITION 2.2. *An s-stage ARK method* $(\mathbb{A}, \tilde{\mathbb{A}})$ *is said to be a.m. at a given point* $(\xi, \tilde{\xi})$ *with* $\xi, \tilde{\xi} \leq 0$ *if the matrix* $I - \xi\mathbb{A} - \tilde{\xi}\tilde{\mathbb{A}}$ *is invertible and*

$$\mathsf{A}(\xi, \tilde{\xi}) = (I - \xi\mathbb{A} - \tilde{\xi}\tilde{\mathbb{A}})^{-1}\mathbb{A} \geq 0\,, \tag{2.4}$$

$$\tilde{\mathsf{A}}(\xi, \tilde{\xi}) = (I - \xi\mathbb{A} - \tilde{\xi}\tilde{\mathbb{A}})^{-1}\tilde{\mathbb{A}} \geq 0\,, \tag{2.5}$$

$$\mathsf{e}(\xi, \tilde{\xi}) = (I - \xi\mathbb{A} - \tilde{\xi}\tilde{\mathbb{A}})^{-1}e \geq 0\,. \tag{2.6}$$

Further, the additive method is said to be a.m. on a given set $\Omega \in \mathbb{R}^2$ *if it is absolutely monotonic at each* $(\xi, \tilde{\xi}) \in \Omega$.

Observe that for RK we worked in $\mathbb{R}$, but for ARK methods we have to work in $\mathbb{R}^2$. For this reason we define the region of absolute monotonicity as follows.

DEFINITION 2.3. *The region of absolute monotonicity, denoted by* $\mathcal{R}(\mathbb{A}, \tilde{\mathbb{A}})$, *is defined by*

$$\mathcal{R}(\mathbb{A}, \tilde{\mathbb{A}}) = \{\, (r, \tilde{r}) \,|\, r \geq 0\,, \tilde{r} \geq 0, \text{ and } (\mathbb{A}, \tilde{\mathbb{A}}) \text{ is a.m. on } [-r, 0] \times [-\tilde{r}, 0] \,\}\,.$$

Finally, for RK methods the radius of absolute monotonicity is given by the supremum (2.3), which is a part of the frontier of the set

$$\{\, r \,|\, r \geq 0 \text{ and } \mathbb{A} \text{ is a.m. on } [-r, 0] \,\}\,.$$

For ARK schemes we consider a part of the frontier of the region of a.m. $\mathcal{R}(\mathbb{A}, \tilde{\mathbb{A}})$.

DEFINITION 2.4. *The curve of absolute monotonicity, denoted by* $\partial\mathcal{R}(\mathbb{A}, \tilde{\mathbb{A}})$, *is the frontier of the set* $\mathcal{R}(\mathbb{A}, \tilde{\mathbb{A}})$ *excluding the coordinate axis (see Figure* 2.1*).*

If there is no $r > 0$, $\tilde{r} > 0$ *such that* $(\mathbb{A}, \tilde{\mathbb{A}})$ *is a.m. on* $[-r, 0] \times [-\tilde{r}, 0]$, *we set* $\partial\mathcal{R}(\mathbb{A}, \tilde{\mathbb{A}}) = (0, 0)$.

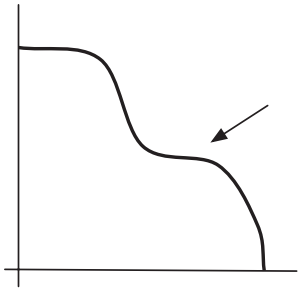

FIG. 2.1. *Curve of absolute monotonicity.*

Later on we will prove the absolute monotonicity of the ARK method at a given point $(r, \tilde{r})$ considering the absolute monotonicity of the ARK method on the semi-open line connecting the origin and the point $(r, \tilde{r})$. We give the following definition.

DEFINITION 2.5. *For $r, \tilde{r} \geq 0$ we will say that $\partial\mathcal{R}(\mathbb{A}, \tilde{\mathbb{A}}) \geq (r, \tilde{r})$ if $(\mathbb{A}, \tilde{\mathbb{A}})$ is a.m. at $\mathcal{L}(r, \tilde{r})$, where*

$$\mathcal{L}(r, \tilde{r}) = \left\{ (\xi, \tilde{\xi}) \,\middle|\, \xi \in (-r, 0] \,,\, \tilde{\xi} = \frac{\tilde{r}}{r} \right\} . \tag{2.7}$$

Once the basic definitions are given, we go deeper into the concept of radius of absolute monotonicity. In [18, Lemma 4.4] it is proved that under certain conditions, for the absolute monotonicity of an RK method $\mathbb{A}$ on a given interval $[-r, 0]$, it is sufficient to consider the absolute monotonicity at the left endpoint $-r$. Our next goal is to prove that a similar result is also true for ARK methods $(\mathbb{A}, \tilde{\mathbb{A}})$. We begin with some technical lemmas.

LEMMA 2.6. *Consider an order m matrix C such that $C \geq 0$. Assume too that the matrix $I + C$ is nonsingular and $C\,(I + C)^{-1} \geq 0$. Then $I - \xi C$ is nonsingular for all $\xi \in [-2, 0]$.*

Proof. As $C\,(I + C)^{-1} \geq 0$ and $C \geq 0$, then $(I + C)^{-1} = I - C\,(I + C)^{-1}$ is an M-matrix, and hence [16, section 15.2] for the spectral radius of $C\,(I + C)^{-1}$ we have spectral radius $\left(C\,(I + C)^{-1}\right) < 1$. Therefore $\left|\lambda I - C\,(I + C)^{-1}\right| \neq 0$ for all λ with $|\lambda| \geq 1$. For $\xi \neq -1$ we have that

$$\left|I - (\xi + 1)\, C\,(I + C)^{-1}\right| = (\xi + r)^m \left| \frac{1}{\xi + 1} I - C\,(I + C)^{-1} \right| ,$$

obtaining that $\left|I - (\xi + 1)\, C\,(I + C)^{-1}\right| \neq 0$ for all ξ with $|\xi + 1| \leq 1$. Finally, from

$$|I - \xi\, C| = |I - (\xi + 1)\, C\,(I + C)^{-1}| \cdot |I + C|$$

we obtain that $I - \xi\, C$ is nonsingular for all $\xi \in [-2, 0]$. ∎

Observe that we have proved that under certain assumptions, the regularity of $I - \xi\, C$ for $\xi = -1$ implies the regularity of this matrix for ξ in the interval $[-1, 0]$ (see (2.7)).

For the next result we need the concept of an a.m. function for functions $f : \mathbb{R}^2 \to \mathbb{R}$, and matrices whose elements are functions.

DEFINITION 2.7. *A function $\psi(z, \tilde{z}) = P(z, \tilde{z})/Q(z, \tilde{z})$, where P and Q are polynomials, is said to be a.m. at a given point $(\xi, \tilde{\xi}) \in \mathbb{R}^2$ if $Q(\xi, \tilde{\xi}) \neq 0$ and*

$(d^{j+k}\psi/d\tilde{z}^j dz^k)(\xi,\tilde{\xi}) \geq 0$, $k = 0, 1, \ldots$, $j = 0, 1, \ldots$. *For matrices whose elements are functions, we will say that they are a.m. at a given point* $(\xi,\tilde{\xi})$ *if each element is a.m. at* $(\xi,\tilde{\xi})$.

Observe that Definition 2.7 is an extension of the concept of an a.m. function given in [18, Definition 2.1].

As the name indicates, the concept of absolute monotonicity given in Definition 2.2 for an ARK method is closely related to the concept of absolute monotonicity for a function given in Definition 2.7.

LEMMA 2.8. *Consider the functions* $\mathsf{A}(\xi,\tilde{\xi})$, $\tilde{\mathsf{A}}(\xi,\tilde{\xi})$, *and* $\mathsf{e}(\xi,\tilde{\xi})$, *defined by* (2.4), (2.5), *and* (2.6), *respectively. Then the ARK method* $(\mathbb{A},\tilde{\mathbb{A}})$ *is a.m. at* $(\xi_0,\tilde{\xi}_0)$ *if and only if the functions* $\mathsf{A}(\xi,\tilde{\xi})$, $\tilde{\mathsf{A}}(\xi,\tilde{\xi})$, *and* $\mathsf{e}(\xi,\tilde{\xi})$ *are a.m. at* $(\xi_0,\tilde{\xi}_0)$.

Proof. Recall that from Definition 2.2, the ARK method $(\mathbb{A},\tilde{\mathbb{A}})$ is absolutely monotonic at $(\xi_0,\tilde{\xi}_0)$ if and only if $\mathsf{A}(\xi_0,\tilde{\xi}_0) \geq 0$, $\tilde{\mathsf{A}}(\xi_0,\tilde{\xi}_0) \geq 0$, and $\mathsf{e}(\xi_0,\tilde{\xi}_0) \geq 0$. The if part is trivial. For the only if part we simply have to observe that

$$\begin{aligned}
\frac{d\mathsf{A}(\xi,\tilde{\xi})}{d\xi} &= \mathsf{A}(\xi,\tilde{\xi})^2\,,\\
\frac{d\mathsf{A}(\xi,\tilde{\xi})}{d\tilde{\xi}} &= \tilde{\mathsf{A}}(\xi,\tilde{\xi})\,\mathsf{A}(\xi,\tilde{\xi})\,,\\
\frac{d\tilde{\mathsf{A}}(\xi,\tilde{\xi})}{d\xi} &= \mathsf{A}(\xi,\tilde{\xi})\,\tilde{\mathsf{A}}(\xi,\tilde{\xi})\,,
\end{aligned}$$

and hence from $\mathsf{A}(\xi_0,\tilde{\xi}_0) \geq 0$ and $\tilde{\mathsf{A}}(\xi_0,\tilde{\xi}_0) \geq 0$, after a recursion process, we obtain the absolute monotonicity of $\mathsf{A}(\xi,\tilde{\xi})$, $\tilde{\mathsf{A}}(\xi,\tilde{\xi})$ at $(\xi_0,\tilde{\xi}_0)$. We proceed in a similar way for $\mathsf{e}(\xi,\tilde{\xi})$. ∎

We go deeper into the concept of absolute monotonicity for a function in a given point. In the following lemma, $\overline{A}$ denotes the closure of the set A. See (2.7) for the definition of $\mathcal{L}(r,\tilde{r})$.

LEMMA 2.9. *Let* $\psi(z,\tilde{z}) = P(z,\tilde{z})/Q(z,\tilde{z})$ *be a rational function, where* P *and* Q *are polynomials. Suppose that* ψ *is a.m. at a given point* $(-r,-\tilde{r})$. *Assume too* $Q(z,\tilde{z}) \neq 0$ *on an open neighborhood* $\mathcal{N}$ *containing* $\overline{\mathcal{L}(r,\tilde{r})}$. *Then* ψ *is a.m. on* $\overline{\mathcal{L}(r,\tilde{r})}$.

Proof. The proof follows along the lines of Lemma 3.1 in [18]. The Taylor expansion of ψ at $(-r,-\tilde{r})$ gives

$$\psi(z,\tilde{z}) = \psi(-r,-\tilde{r}) + \frac{\partial\psi}{\partial z}(-r,-\tilde{r})(z+r) + \frac{\partial\psi}{\partial\tilde{z}}(-r,-\tilde{r})(\tilde{z}+\tilde{r}) + \cdots\,,$$

with $\psi(-r,-\tilde{r}) \geq 0$, $\frac{\partial\psi}{\partial z}(-r,-\tilde{r}) \geq 0$, $\frac{\partial\psi}{\partial\tilde{z}}(-r,-\tilde{r}) \geq 0$, ... which is valid in $\mathcal{N}$. To see this, we simply have to use the ideas in the proof of [18, Lemma 3.1]. In particular the Taylor expansion is valid for $(z,\tilde{z}) \in \overline{\mathcal{L}(r,\tilde{r})}$. Term by term differentiation shows that ψ is absolutely monotonic at $\overline{\mathcal{L}(r,\tilde{r})}$. ∎

LEMMA 2.10. *Let* $\psi(z,\tilde{z}) = P(z,\tilde{z})/Q(z,\tilde{z})$ *be a rational function, where* P *and* Q *are polynomials. Suppose that* ψ *is a.m. on* $\mathcal{L}(r,\tilde{r})$. *Then* ψ *is a.m. on* $\overline{\mathcal{L}(r,\tilde{r})}$.

Proof. The proof follows along the lines of Lemma 3.6 in [18]. We have to prove that ψ is a.m. at $(r,\tilde{r})$. If $(r,\tilde{r})$ is not a pole of ψ, then the absolute monotonicity follows from a limit argument. If $(r,\tilde{r})$ is a pole of ψ, then on a neighborhood of $(r,\tilde{r})$ on $\mathcal{L}(r,\tilde{r})$ we have $\psi(z,\tilde{z}) < 0$ or $D_{(z,\tilde{r}/r\,z)}\psi(z,\tilde{z}) < 0$, where $D_v f$ denotes the derivative of f in the direction v. In both cases we get a contradiction with the absolute monotonicity of ψ. ∎

For ARK methods, we are in a position to prove a result similar to Lemma 4.4 in [18].

PROPOSITION 2.11. *Consider an ARK method* $(\mathbb{A}, \tilde{\mathbb{A}})$ *and real positive numbers* r, $\tilde{r}$. *Then* $\partial R(\mathbb{A}, \tilde{\mathbb{A}}) \geq (r, \tilde{r})$ *if and only if* $(\mathbb{A}, \tilde{\mathbb{A}})$ *is a.m. at* $(\xi, \tilde{\xi}) = (-r, -\tilde{r})$ *and* $\mathbb{A} \geq 0$, $\tilde{\mathbb{A}} \geq 0$.

Proof. 1. We begin by assuming that $\partial R(\mathbb{A}, \tilde{\mathbb{A}}) \geq (r, \tilde{r})$. Then $(\mathbb{A}, \tilde{\mathbb{A}})$ is a.m. at $(\xi, \tilde{\xi}) \in \mathcal{L}(r, \tilde{r})$. By Lemma 2.8 the functions $\mathsf{A}(\xi, \tilde{\xi})$, $\tilde{\mathsf{A}}(\xi, \tilde{\xi})$, and $\mathsf{e}(\xi, \tilde{\xi})$ are a.m. at $(\xi, \tilde{\xi}) \in \mathcal{L}(r, \tilde{r})$. We can now apply componentwise Lemma 2.10 to get that they are also a.m. at $(\xi, \tilde{\xi})$ with $\xi \in [-r, 0]$ and $\tilde{\xi} = \frac{r}{\tilde{r}}\,\xi$ and in particular at $(-r, -\tilde{r})$. Application of Lemma 2.8 once more gives the absolute monotonicity of $(\mathbb{A}, \tilde{\mathbb{A}})$ at $(r, \tilde{r})$. In particular the method is a.m. at $(\xi, \tilde{\xi}) = (0, 0)$, and hence $\mathbb{A} \geq 0$ and $\tilde{\mathbb{A}} \geq 0$.

2. We assume now that $(\mathbb{A}, \tilde{\mathbb{A}})$ is a.m. at $(\xi, \tilde{\xi}) = (-r, -\tilde{r})$ and $\mathbb{A} \geq 0$, $\tilde{\mathbb{A}} \geq 0$. Using Lemma 2.6 for $C = r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}}$, we get that $I - \xi\mathbb{A} - \tilde{\xi}\tilde{\mathbb{A}}$ is nonsingular for all $(\xi, \tilde{\xi})$ with $\xi \in [-r, 0]$ and $\tilde{\xi} = \frac{\tilde{r}}{r}\,\xi$, and therefore the functions $\mathsf{A}(\xi, \tilde{\xi})$, $\tilde{\mathsf{A}}(\xi, \tilde{\xi})$, and $\mathsf{e}(\xi, \tilde{\xi})$ are well defined for $(\xi, \tilde{\xi}) = (\xi, \frac{\tilde{r}}{r}\,\xi)$ with $\xi \in [-r, 0]$. Hence, by Lemma 2.9 we get that the method is a.m. at $(\xi, \tilde{\xi})$ with $\xi \in [-r, 0]$ and $\tilde{\xi} = \frac{\tilde{r}}{r}\,\xi$, i.e., $\partial R(\mathbb{A}, \tilde{\mathbb{A}}) \geq (r, \tilde{r})$. ∎

The relevance of Proposition 2.11 is that to prove the absolute monotonicity of an ARK method in the segment that connects the origin and the point $(-r, -\tilde{r})$, it is enough to check the absolute monotonicity of the method $(\mathbb{A}, \tilde{\mathbb{A}})$ at $(-r, -\tilde{r})$, and the nonnegativity of $\mathbb{A}$ and $\tilde{\mathbb{A}}$. Hence, to prove the absolute monotonicity of an ARK scheme in a region, it is enough to check the absolute monotonicity of the method at the curve of absolute monotonicity and the nonnegativity of the coefficient matrices.

We finish the section with a lemma that will justify the validity of the results for any convex function $\|\cdot\|$.

LEMMA 2.12. *Assume that the ARK method* $(\mathbb{A}, \tilde{\mathbb{A}})$ *is a.m. at* $(-r, -\tilde{r})$ *with* $r, \tilde{r} \geq 0$. *Then*

$$0 \leq \mathsf{e}(-r, -\tilde{r}) \leq e\,, \tag{2.8}$$

$$0 \leq r\,\mathsf{A}(-r, -\tilde{r}) \leq E\,, \tag{2.9}$$

$$0 \leq \tilde{r}\,\tilde{\mathsf{A}}(-r, -\tilde{r}) \leq E\,, \tag{2.10}$$

$$\mathsf{e}(-r, -\tilde{r}) + r\,\mathsf{A}(-r, -\tilde{r})\,e + \tilde{r}\,\tilde{\mathsf{A}}(-r, -\tilde{r})\,e = e\,, \tag{2.11}$$

where E *denotes the matrix whose elements are equal to* 1 *and* $\mathsf{e}(\xi, \tilde{\xi})$, $\mathsf{A}(\xi, \tilde{\xi})$ *and* $\tilde{\mathsf{A}}(\xi, \tilde{\xi})$ *are given by* (2.4)–(2.6). *Hence, for* x, y, $z \in \mathbb{R}^{s+1}$, *componentwise, the expression*

$$\mathsf{e}(-r, -\tilde{r})\,x + r\,\mathsf{A}(-r, -\tilde{r})\,y + \tilde{r}\,\tilde{\mathsf{A}}(-r, -\tilde{r})\,z$$

is a convex combination of x_i, y_i, *and* z_i.

Proof. The lower bounds in (2.8)–(2.10) come from the absolute monotonicity at $(-r, -\tilde{r})$. To prove the upper bounds, we proceed as follows. As the method is a.m. at $(-r, -\tilde{r})$, we have

$$(I + r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})^{-1}(r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})\,e \geq 0 \tag{2.12}$$

and as

$$(I + r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})^{-1}(r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}}) = I - (I + r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})^{-1}\,,$$

we can write (2.12) as

$$\left(I - (I + r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})^{-1}\right) e \geq 0\,,$$

which gives the upper bound in (2.8). Furthermore, from

$$(I + r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})^{-1} e \geq 0\,,$$

as

$$(I + r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})^{-1} = I - (I + r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})^{-1}(r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})\,,$$

we obtain

$$(I + r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})^{-1}(r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})\, e \leq e\,. \tag{2.13}$$

The upper bounds in (2.9)–(2.10) come from inequality (2.13) and the fact that

$$(I + r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})^{-1} r\mathbb{A} \geq 0\,, \qquad (I + r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})^{-1} \tilde{r}\tilde{\mathbb{A}} \geq 0\,.$$

Finally, (2.11) is straightforward. ∎

3. Monotonicity for ARK methods. Once we have defined and studied the concept of absolute monotonicity for an ARK method $(\mathbb{A}, \tilde{\mathbb{A}})$, we are in a position to prove the main result that ensures monotonicity for the ARK method under certain stepsize restrictions.

THEOREM 3.1. *Assume that the ARK method* $(\mathbb{A}, \tilde{\mathbb{A}})$ *is a.m. at* $(-r, -\tilde{r})$. *Then for*

$$h \leq r\,\frac{1}{\rho}, \qquad h \leq \tilde{r}\,\frac{1}{\tilde{\rho}} \tag{3.1}$$

it holds that

$$\|U_i\| \leq \|u_n\|\,, \qquad i = 1, \ldots, s\,, \qquad\qquad \|u_{n+1}\| \leq \|u_n\|\,.$$

Proof. The proof is similar to the one in [13]. The ARK method can be written as

$$U = e \otimes u_n + h(\mathbb{A} \otimes I)F(U) + h(\tilde{\mathbb{A}} \otimes I)\tilde{F}(U)\,. \tag{3.2}$$

Observe that the conditions on the problems imply, for h satisfying (3.1), that

$$\left\| U_i + \frac{h}{r} F(U_i) \right\| \leq \| U_i \|\,, \qquad \left\| U_i + \frac{h}{\tilde{r}} \tilde{F}(U_i) \right\| \leq \| U_i \|\,. \tag{3.3}$$

In formula (3.2) we add to both sides $((r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}}) \otimes I)U$, obtaining

$$(I + ((r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}}) \otimes I))\, U = e \otimes u_n + (\mathbb{A} \otimes I)(rU + hF(U)) + (\tilde{\mathbb{A}} \otimes I)(\tilde{r}U + h\tilde{F}(U))\,,$$

or equivalently

$$U = \mathsf{e}(-r, -\tilde{r}) \otimes u_n + (r\,\mathsf{A}(-r, -\tilde{r}) \otimes I) \left(U + \frac{h}{r} F(U)\right)$$

$$+ \left(\tilde{r}\,\tilde{\mathsf{A}}(-r, -\tilde{r}) \otimes I\right) \left(U + \frac{h}{\tilde{r}} \tilde{F}(U)\right)\,, \tag{3.4}$$

where $\mathsf{e}(\xi,\tilde{\xi})$, $\mathsf{A}(\xi,\tilde{\xi})$, and $\tilde{\mathsf{A}}(\xi,\tilde{\xi})$ are given by (2.4)–(2.6). If we take norms, the conditions on $\mathsf{e}(-r,-\tilde{r})$, $\mathsf{A}(-r,-\tilde{r})$, and $\tilde{\mathsf{A}}(-r,-\tilde{r})$ imply

$$[\|U\|] \le \mathsf{e}(-r,-\tilde{r}) \otimes \|u_n\| + (r\,\mathsf{A}(-r,-\tilde{r}) \otimes I) \left[\left\|U + \frac{h}{r} F(U)\right\|\right]$$

$$+ \left(\tilde{r}\,\tilde{\mathsf{A}}(-r,-\tilde{r}) \otimes I\right) \left[\left\|U + \frac{h}{\tilde{r}} \tilde{F}(U)\right\|\right], \tag{3.5}$$

where $[\|U\|] = (\|U_1\|, \ldots, \|U_s\|, \|u_{n+1}\|)^t \in \mathbb{R}^{s+1}$. Conditions (3.3) imply now

$$[\|U\|] \le \mathsf{e}(-r,-\tilde{r}) \otimes \|u_n\| + \left((r\mathsf{A}(-r,-\tilde{r}) + \tilde{r}\tilde{\mathsf{A}}(-r,-\tilde{r})) \otimes I\right) [\|U\|],$$

and hence

$$((I + r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})^{-1} \otimes I)\,[\|U\|] \le ((I + r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})^{-1} e) \otimes \|u_n\|, \tag{3.6}$$

where we have used that $(I - r\mathsf{A}(-r,-\tilde{r}) - \tilde{r}\tilde{\mathsf{A}}(-r,-\tilde{r})) = (I + r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}})^{-1}$. We simply have to multiply (3.6) by $I + r\mathbb{A} + \tilde{r}\tilde{\mathbb{A}} \ge 0$ to get

$$[\|U\|] \le e \otimes \|u_n\|. \qquad \square$$

Remark 1.

(a) By Lemma 2.12, the derivation of inequality (3.5) from (3.4) is valid not only for norms $\|\cdot\|$ but also for any convex function $\psi : \mathbb{R}^m \to \mathbb{R}$.

(b) We have obtained a conditional monotonicity result. We are not interested in unconditional monotonicity because for RK methods it is known that explicit RK methods cannot be unconditionally monotone, and for implicit RK methods, unconditional monotonicity implies that the order of the method is at most one (see [18] or [12]). Hence IMEX methods cannot be unconditionally monotone. For unconditional monotone implicit ARK methods, the same order restriction holds, i.e., $p \le 1$, because to obtain an order p RK method, each RK method must have order p.

(c) If the method $\mathbb{A}$ is a.m. at $-r$, then the RK scheme is monotone under stepsize restriction $h \le r/\rho$. Similarly, if the method $\tilde{\mathbb{A}}$ is a.m. at $-r$, then the RK scheme is monotone under stepsize restriction $h \le \tilde{r}/\tilde{\rho}$. However, in order to obtain monotonicity for the ARK method $(\mathbb{A}, \tilde{\mathbb{A}})$ we require absolute monotonicity at $(-r,-\tilde{r})$. Depending on the shape of $\mathcal{R}(\mathbb{A}, \tilde{\mathbb{A}})$, sharper stepsize restrictions may occur to maintain monotonicity of the ARK method. In order to have a good monotone ARK scheme, not only must the RK methods $\mathbb{A}$ and $\tilde{\mathbb{A}}$ have a large radius of absolute monotonicity, but the methods also must be properly coupled.

(d) If the exact solution, the internal stages, and the numerical solution are in a subset $\mathcal{B} \subset \mathbb{R}^m$, then in Theorem 3.1 conditions (1.3)–(1.4) can be relaxed to

$$\left\| y + \frac{1}{\rho}\, f(y) \right\| \le \| y \|, \qquad \left\| y + \frac{1}{\tilde{\rho}}\, \tilde{f}(y) \right\| \le \| y \| \qquad \text{for all } y \in \mathcal{B}.$$

Theorem 3.1 gives us monotonicity under the stepsize restriction

$$h \le r\,\frac{1}{\rho}, \qquad h \le \tilde{r}\,\frac{1}{\tilde{\rho}},$$

with $(r, \tilde{r})$ such that the ARK method is a.m. at it. Hence, we should have ARK schemes $(\mathbb{A}, \tilde{\mathbb{A}})$ such that $\partial R(\mathbb{A}, \tilde{\mathbb{A}}) \neq (0, 0)$ because only in this case do we have a positive stepsize restriction for monotonicity. For RK methods, in [18] it is proved that $R(\mathbb{A}) > 0$ if and only if $\mathbb{A} \geq 0$ and

$$\text{Inc}\,(\mathbb{A}^2) \leq \text{Inc}\,\mathbb{A}\,,$$

where Inc F is the incidence matrix of $F = (f_{ij})$, defined as Inc $F = (g_{ij})$, with $g_{ij} = 1$ if $f_{ij} \neq 0$ and $g_{ij} = 0$ if $f_{ij} = 0$.

Our next goal is to give algebraic criteria for $\partial \mathcal{R}(\mathbb{A}, \tilde{\mathbb{A}}) \neq (0, 0)$. We begin by proving the following lemmas.

LEMMA 3.2. *Consider matrices $A = (a_{ij})$, $B = (b_{ij})$, $C = (c_{ij})$, and $D = (d_{ij})$ such that $A \geq 0$, $B \geq 0$, $C \geq 0$, $D \geq 0$. Assume that Inc $B \leq$ Inc C and Inc $(A\,C) \leq$ Inc D. Then*

$$\textit{Inc}\,(A\,B) \leq \textit{Inc}\,D\,.$$

Proof. If $(AB)_{ij} \neq 0$, then $a_{il} b_{lj} \neq 0$ for some l, and hence $a_{il} \neq 0$ and $b_{lj} \neq 0$. From $b_{lj} \neq 0$ and Inc $B \leq$ Inc C, we get that $c_{lj} \neq 0$. Now from $a_{il} \neq 0$ and $c_{lj} \neq 0$ we obtain that $(AC)_{ij} \neq 0$. Finally, from Inc $(A\,C) \leq$ Inc D we obtain that $d_{ij} \neq 0$. ∎

LEMMA 3.3. *If $\mathbb{A} \geq 0$, $\tilde{\mathbb{A}} \geq 0$, and*

$$\textit{Inc}\,(\mathbb{A}^2) \leq \textit{Inc}\,\mathbb{A}\,, \tag{3.7}$$

$$\textit{Inc}\,(\tilde{\mathbb{A}}\,\mathbb{A}) \leq \textit{Inc}\,\mathbb{A}\,, \tag{3.8}$$

then for any k_i, p_i, $i = 1, \ldots, n$, and for any n it holds that

$$\textit{Inc}\,\left((\mathbb{A})^{k_1}(\tilde{\mathbb{A}})^{p_1} \cdots (\mathbb{A})^{k_n}(\tilde{\mathbb{A}})^{p_n}\,\mathbb{A}\right) \leq \textit{Inc}\,\mathbb{A}\,. \tag{3.9}$$

Proof. Lemma 3.2 with $A = \tilde{\mathbb{A}}$ and $D = C = \mathbb{A}$ gives that Inc $B \leq$ Inc $\mathbb{A}$, together with (3.8), implies

$$\text{Inc}\,(\tilde{\mathbb{A}}\,B) \leq \text{Inc}\,\mathbb{A}\,. \tag{3.10}$$

Beginning with (3.8), we can successively use (3.10) for $B = \tilde{\mathbb{A}}\,\mathbb{A}$ to get Inc $(\tilde{\mathbb{A}}^2\mathbb{A}) \leq$ Inc $\mathbb{A}$, for $B = \tilde{\mathbb{A}}^2\,\mathbb{A}$ to get Inc $(\tilde{\mathbb{A}}^3\mathbb{A}) \leq$ Inc $\mathbb{A}$, and in this way obtain

$$\text{Inc}\,(\tilde{\mathbb{A}}^k\,\mathbb{A}) \leq \text{Inc}\,\mathbb{A}\,. \tag{3.11}$$

Similarly, Lemma 3.2 with $A = \mathbb{A}$ and $D = C = \mathbb{A}$ gives that Inc $B \leq$ Inc $\mathbb{A}$ and (3.7) imply

$$\text{Inc}\,(\mathbb{A}\,B) \leq \text{Inc}\,\mathbb{A}\,. \tag{3.12}$$

As (3.11) holds true, we can use (3.12) for $B = \tilde{\mathbb{A}}^k\,\mathbb{A}$ to get Inc $(\mathbb{A}\,\tilde{\mathbb{A}}^k\,\mathbb{A}) \leq$ Inc $\mathbb{A}$, for $B = \mathbb{A}\,\tilde{\mathbb{A}}^k\,\mathbb{A}$ to get Inc $(\mathbb{A}^2\tilde{\mathbb{A}}^k\,\mathbb{A}) \leq$ Inc $\mathbb{A}$, and in this way obtain

$$\text{Inc}\,(\mathbb{A}^p\tilde{\mathbb{A}}^k\,\mathbb{A}) \leq \text{Inc}\,\mathbb{A}\,.$$

Repeating this process, we arrive at (3.9). ∎

The following result gives algebraic criteria for obtaining $\partial\mathcal{R}(\mathbb{A},\tilde{\mathbb{A}}) \neq (0,0)$.

PROPOSITION 3.4. *We have* $\partial\mathcal{R}(\mathbb{A},\tilde{\mathbb{A}}) \neq (0,0)$ *if and only if* $\mathbb{A} \geq 0$, $\tilde{\mathbb{A}} \geq 0$, *and*

$$Inc\,(\mathbb{A}^2) \leq Inc\,\mathbb{A}\,, \tag{3.13}$$

$$Inc\,(\tilde{\mathbb{A}}\,\mathbb{A}) \leq Inc\,\mathbb{A}\,, \tag{3.14}$$

$$Inc\,(\tilde{\mathbb{A}}^2) \leq Inc\,\tilde{\mathbb{A}}\,, \tag{3.15}$$

$$Inc\,(\mathbb{A}\,\tilde{\mathbb{A}}) \leq Inc\,\tilde{\mathbb{A}}\,. \tag{3.16}$$

Proof. The proof is similar to the one in [13]. For real ξ, $\tilde{\xi}$ close to zero, the matrix $(I - \xi\mathbb{A} - \tilde{\xi}\tilde{\mathbb{A}})$ is nonsingular, and hence

$$(I-\xi\mathbb{A}-\tilde{\xi}\tilde{\mathbb{A}})^{-1}\mathbb{A} = \mathbb{A} + (\xi\mathbb{A}+\tilde{\xi}\tilde{\mathbb{A}})\mathbb{A} + \left(\xi^2\mathbb{A}^2 + \xi\tilde{\xi}\left(\mathbb{A}\tilde{\mathbb{A}}+\tilde{\mathbb{A}}\mathbb{A}\right) + \tilde{\xi}^2\tilde{\mathbb{A}}^2\right)\mathbb{A} + \cdots\,, \tag{3.17}$$

$$(I-\xi\mathbb{A}-\tilde{\xi}\tilde{\mathbb{A}})^{-1}\tilde{\mathbb{A}} = \tilde{\mathbb{A}} + (\xi\mathbb{A}+\tilde{\xi}\tilde{\mathbb{A}})\tilde{\mathbb{A}} + \left(\xi^2\mathbb{A}^2 + \xi\tilde{\xi}\left(\mathbb{A}\tilde{\mathbb{A}}+\tilde{\mathbb{A}}\mathbb{A}\right) + \tilde{\xi}^2\tilde{\mathbb{A}}^2\right)\tilde{\mathbb{A}} + \cdots\,. \tag{3.18}$$

From (3.17) and (3.18) we see that $\mathbb{A} \geq 0$, $\tilde{\mathbb{A}} \geq 0$, and (3.13)–(3.16) are necessary conditions for (2.4) and (2.5) to hold on a left neighborhood of $\xi = 0$, $\tilde{\xi} = 0$. To see that they are also sufficient we use them and Lemma 3.3 to state that for any k_i, p_i, $i = 1,\ldots,n$, and for any n, it holds that

$$\begin{aligned}
\text{Inc}\,\left((\mathbb{A})^{k_1}(\tilde{\mathbb{A}})^{p_1}\cdots(\mathbb{A})^{k_n}(\tilde{\mathbb{A}})^{p_n}\,\mathbb{A}\right) &\leq \text{Inc}\,\mathbb{A},\\
\text{Inc}\,\left((\mathbb{A})^{k_1}(\tilde{\mathbb{A}})^{p_1}\cdots(\mathbb{A})^{k_n}(\tilde{\mathbb{A}})^{p_n}\,\tilde{\mathbb{A}}\right) &\leq \text{Inc}\,\tilde{\mathbb{A}}.
\end{aligned}$$

Hence, as $\mathbb{A} \geq 0$ and $\tilde{\mathbb{A}} \geq 0$, in (3.17) and (3.18) we get (2.4) and (2.5), respectively. Observe that inequality (2.6) always holds for r, $\tilde{r}$ close to zero. ∎

This criteria are extremely useful for checking if we have $\partial\mathcal{R}(\mathbb{A},\tilde{\mathbb{A}}) \neq (0,0)$ for a given ARK method. Observe that conditions $\mathbb{A} \geq 0$ and (3.13) imply that $R(\mathbb{A}) > 0$. Similarly, conditions $\tilde{\mathbb{A}} \geq 0$ and (3.16) imply that $R(\tilde{\mathbb{A}}) > 0$. However, some extra coupling conditions, namely (3.14) and (3.15), are needed to get $\partial\mathcal{R}(\mathbb{A},\tilde{\mathbb{A}}) \neq (0,0)$.

Example 1.

(a) The IMEX SSP2(3,3,2) stiffly accurate method [20] is

(3.19)

0	0	0	0
$\frac{1}{2}$	$\frac{1}{2}$	0	0
1	$\frac{1}{2}$	$\frac{1}{2}$	0
$\mathbb{A}$	$\frac{1}{3}$	$\frac{1}{3}$	$\frac{1}{3}$

$\frac{1}{4}$	$\frac{1}{4}$	0	0
$\frac{1}{4}$	0	$\frac{1}{4}$	0
1	$\frac{1}{3}$	$\frac{1}{3}$	$\frac{1}{3}$
$\tilde{\mathbb{A}}$	$\frac{1}{3}$	$\frac{1}{3}$	$\frac{1}{3}$

(SSP stands for strong stability preserving). It can be computed that $R(\mathbb{A}) = 2$ and $R(\tilde{\mathbb{A}}) = \frac{12}{5}$. However, $\partial\mathcal{R}(\mathbb{A},\tilde{\mathbb{A}}) = (0,0)$. In this case condition Inc $(\mathbb{A}\,\tilde{\mathbb{A}}) \leq$ Inc $(\tilde{\mathbb{A}})$ fails for the element $(1,2)$. We can change the implicit

method in (3.19) to

$$\begin{array}{c|ccc} \frac{1}{5} & \frac{1}{5} & 0 & 0 \\ \frac{3}{10} & \frac{1}{10} & \frac{1}{5} & 0 \\ 1 & \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \\ \hline \tilde{\mathbb{A}} & \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \end{array}$$

It can be computed that $R(\tilde{\mathbb{A}}) = \frac{5}{9}(\sqrt{70} - 4)$. Now conditions (3.13)–(3.16) in Proposition 3.4 hold, and hence $\partial\mathcal{R}(\mathbb{A}, \tilde{\mathbb{A}}) \neq (0, 0)$.

(b) The L-stable IMEX SSP3(3,3,2) method [20] is

$$\begin{array}{c|ccc} 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ \frac{1}{2} & \frac{1}{4} & \frac{1}{4} & 0 \\ \hline \mathbb{A} & \frac{1}{6} & \frac{1}{6} & \frac{2}{3} \end{array} \qquad \begin{array}{c|ccc} \gamma & \gamma & 0 & 0 \\ 1-\gamma & 1-2\gamma & \gamma & 0 \\ \frac{1}{2} & \frac{1}{2}-\gamma & 0 & \gamma \\ \hline \tilde{\mathbb{A}} & \frac{1}{6} & \frac{1}{6} & \frac{2}{3} \end{array}$$

with $\gamma = 1 - \frac{1}{\sqrt{2}}$. It can be computed that $R(\mathbb{A}) = 1$ and $R(\tilde{\mathbb{A}}) = \frac{30-24\sqrt{2}}{215\sqrt{2}-304}$. However, $\partial R(\mathbb{A}, \tilde{\mathbb{A}}) = (0, 0)$. Now condition Inc $(\mathbb{A}\,\tilde{\mathbb{A}}) \leq$ Inc $(\tilde{\mathbb{A}})$ fails for the element $(3, 2)$.

3.1. Monotonicity for ARK methods in the Shu–Osher representation. Monotonicity issues for RK schemes written in the Shu–Osher form have been widely studied during the past years (see, e.g., [9, 26, 6, 13] and the references therein). If we have an RK method written in the Shu–Osher representation, the derivation of monotonicity is conceptually much easier. However, as the Shu–Osher form of an RK scheme is not unique, a previous problem, namely, the optimal Shu–Osher representation of an RK method, arises. This and some other related problems were studied in [13, 6]. In this section we briefly extend these topics for ARK methods.

We consider the following extension of the Shu–Osher form:

$$U = \alpha \otimes u_n + ((\Lambda + \tilde{\Lambda}) \otimes I)U + h\,(\Gamma \otimes I)F(U) + h\,(\tilde{\Gamma} \otimes I)\tilde{F}(U)\,, \tag{3.20}$$

where $\alpha \in \mathbb{R}^{s+1}$, and Λ, $\tilde{\Lambda}$, Γ, and $\tilde{\Gamma}$ are $(s+1) \times (s+1)$ matrices such that $(\Lambda + \tilde{\Lambda})\, e + \alpha = e$, the matrix $I - \Lambda - \tilde{\Lambda}$ is invertible, and the last column in Λ, $\tilde{\Lambda}$, Γ, and $\tilde{\Gamma}$ is zero. Scheme (3.20) is an ARK method with $\mathbb{A} = (I - \Lambda - \tilde{\Lambda})^{-1}\Gamma$ and $\tilde{\mathbb{A}} = (I - \Lambda - \tilde{\Lambda})^{-1}\tilde{\Gamma}$, and therefore we will refer to it as a representation of the ARK method.

A monotonicity result for ARK schemes in the form of (3.20) can be given. We state the following proposition, whose proof is omitted because it is similar to that in [13, Proposition 3.9].

PROPOSITION 3.5. *Consider a method in the form of* (3.20) *such that*

$$(I - (\Lambda + \tilde{\Lambda}))\, e \geq 0\,, \quad \Gamma \geq 0\,, \quad \tilde{\Gamma} \geq 0\,, \quad \Lambda - c\,\Gamma \geq 0\,, \quad \tilde{\Lambda} - \tilde{c}\,\tilde{\Gamma} \geq 0\,,$$

for some $c, \tilde{c} \geq 0$. *Then for* $h \leq \min\{c/\rho, \tilde{c}/\tilde{\rho}\}$ *it holds that*

$$\|U_i\| \leq \|u_n\|\,, \qquad i = 1, \ldots, s\,, \qquad\qquad \|u_{n+1}\| \leq \|u_n\|\,.$$

As in Theorem 3.1, Proposition 3.5 ensures monotonicity for ARK schemes. Apparently there is no relationship between the conditions imposed in both of them. However, there is a close link between them.

PROPOSITION 3.6. *Consider an ARK method* $(\mathbb{A}, \tilde{\mathbb{A}})$.

1. *Assume that the ARK method can be written as* $\mathbb{A} = (I - (\Lambda + \tilde{\Lambda}))^{-1}\Gamma$, $\tilde{\mathbb{A}} = (I - (\Lambda + \tilde{\Lambda}))^{-1}\tilde{\Gamma}$, *where*

$$(I - (\Lambda + \tilde{\Lambda}))\, e \geq 0\,, \quad \Gamma \geq 0\,, \quad \tilde{\Gamma} \geq 0\,, \quad \Lambda - c\,\Gamma \geq 0\,, \quad \tilde{\Lambda} - \tilde{c}\,\tilde{\Gamma} \geq 0\,,$$

   and $I - (\Lambda + \tilde{\Lambda} - c\,\Gamma - \tilde{c}\,\tilde{\Gamma})$ *is invertible for some coefficients* $c, \tilde{c} \geq 0$. *Then the method is absolutely monotonic at* $(-c, -\tilde{c})$.
2. *If the method is absolutely monotonic at* $(-c, -\tilde{c})$, *then for*

$$\begin{aligned}
\Lambda &= c\,(I + c\,\mathbb{A} + \tilde{c}\,\tilde{\mathbb{A}})^{-1}\mathbb{A}\,,\\
\tilde{\Lambda} &= c\,(I + c\,\mathbb{A} + \tilde{c}\,\tilde{\mathbb{A}})^{-1}\tilde{\mathbb{A}}\,,\\
\Gamma &= \mathbb{A} - (\Lambda + \tilde{\Lambda})\mathbb{A}\,,\\
\tilde{\Gamma} &= \tilde{\mathbb{A}} - (\Lambda + \tilde{\Lambda})\tilde{\mathbb{A}}\,,
\end{aligned}$$

   we can write $\mathbb{A} = (I - (\Lambda + \tilde{\Lambda}))^{-1}\Gamma$, $\tilde{\mathbb{A}} = (I - (\Lambda + \tilde{\Lambda}))^{-1}\tilde{\Gamma}$, *with*

$$(I - (\Lambda + \tilde{\Lambda}))\, e \geq 0\,, \quad \Gamma \geq 0\,, \quad \tilde{\Gamma} \geq 0\,, \quad \Lambda - c\,\Gamma = 0\,, \quad \tilde{\Lambda} - \tilde{c}\,\tilde{\Gamma} = 0\,.$$

Proof. The proofs of parts 1 and 2 are similar to the ones in [13, Propositions 3.11 and 3.12], respectively. An auxiliary lemma, similar to Lemma 3.10 in [13], is required. ∎

3.2. Monotonicity for perturbed RK methods. Over the past few years [23, 24, 10, 21, 26] (see [9, 25] for a review) a great effort has been made to develop high order methods satisfying (1.8)–(1.9) when the forward Euler discretization of (1.1) satisfies (1.9), i.e.,

$$\|u_n + h f(u_n)\| \leq \|u_n\| \qquad \text{for } h \leq \Delta t_{FE}\,. \tag{3.21}$$

These are SSP methods (or total variation diminishing (TVD) methods). The class of ODEs considered in this context arises from a method of lines approximation of hyperbolic conservation laws. A simple numerical example given in [9] shows that the use of non-SSP methods for the time discretization of these ODEs produces an undesirable overshot. As the forward Euler method has the drawback of a low order of accuracy, higher order SSP methods are of great interest. The idea in [24, 23] is to derive conditions (1.8)–(1.9) from condition (1.9) for the forward Euler method by means of convex combinations.

In [23], the Shu and Osher representations are used to write explicit RK methods $\mathbb{A}$. As pointed out in [13], the Shu and Osher representations with positive coefficients correspond to $R(\mathbb{A}) > 0$, whereas the case with negative coefficients corresponds to RK methods with $R(\mathbb{A}) = 0$. In this case, together with the original problem $y' = f(y)$ with $f(y)$ such that

$$\left\| y - \frac{1}{\rho}\, f(y) \right\| \leq \| y \|\,,$$

an auxiliary problem

$$y' = -\tilde{f}(y)$$

such that

$$\left\| y - \frac{1}{\rho}\, \tilde{f}(y) \right\| \leq \| y \|$$

is also considered. The Shu and Osher representations with negative coefficients are interpreted in [13] as perturbations of an RK method. Given an RK method $\mathbb{A}$, the perturbed RK method $(\mathbb{A}, \tilde{\mathbb{A}})$ is

$$U^{(p)} = e \otimes u_n^{(p)} + h(\mathbb{A} \otimes I) F(U^{(p)}) + h(\tilde{\mathbb{A}} \otimes I) \left(F(U^{(p)}) - \tilde{F}(U^{(p)}) \right)$$

or

$$U^{(p)} = e \otimes u_n^{(p)} + h \left((\mathbb{A} + \tilde{\mathbb{A}}) \otimes I \right) F(U^{(p)}) + h(\tilde{\mathbb{A}} \otimes I) \left(-\tilde{F}(U^{(p)}) \right) .$$

Recall that these equations correspond to the "additive" RK method $(\mathbb{A} + \tilde{\mathbb{A}}, \mathbb{A})$. Observe too that both functions f and $-\tilde{f}$ have the same stiffness properties, i.e., $\rho = \tilde{\rho}$.

Monotonicity issues for perturbed RK methods were studied in [13]. The tool used was the radius of absolute monotonicity for a perturbed RK method $(\mathbb{A}, \tilde{\mathbb{A}})$ [13, Definition 3.1]. It turns out that Definition 3.1 in [13] corresponds to the concept of absolute monotonicity of the additive ARK method $(\mathbb{A} + \tilde{\mathbb{A}}, \mathbb{A})$ at (ξ, ξ) defined in this paper. We consider only values of the form (ξ, ξ) because we are dealing with f and $-\tilde{f}$ such that $\rho = \tilde{\rho}$.

A monotonicity result for a perturbed RK method was proved in [13, Theorem 3.5]. Interpreting the perturbed RK method as an "additive" RK, monotonicity under the stepsize restriction given in Theorem 3.5 in [13] can also be obtained by applying Theorem 3.1 of this paper.

Finally, algebraic criteria for nonnull stepsize restrictions, i.e., for the existence of $r > 0$ such that $(\mathbb{A} + \tilde{\mathbb{A}}, \tilde{\mathbb{A}})$ is a.m. at (r, r), were also given in [13, Proposition 3.6]. More precisely, it was proved that this situation holds if and only if

$$\tilde{\mathbb{A}} \geq 0\,, \ \mathbb{A} + \tilde{\mathbb{A}} \geq 0\,, \tag{3.22}$$

$$\text{Inc}\,((\mathbb{A} + 2\tilde{\mathbb{A}})(\mathbb{A} + \tilde{\mathbb{A}})) \leq \text{Inc}\,(\mathbb{A} + \tilde{\mathbb{A}})\,, \tag{3.23}$$

$$\text{Inc}\,((\mathbb{A} + 2\tilde{\mathbb{A}})\tilde{\mathbb{A}}) \leq \text{Inc}\,(\tilde{\mathbb{A}})\,. \tag{3.24}$$

If we apply the algebraic criteria given in Proposition 3.4 for the "additive" RK method $(\mathbb{A} + \tilde{\mathbb{A}}, \tilde{\mathbb{A}})$, we obtain $\partial\mathcal{R}(\mathbb{A} + \tilde{\mathbb{A}}, \tilde{\mathbb{A}}) \neq (0, 0)$ if and only if (3.22) and

$$\text{Inc}\,((\mathbb{A} + \tilde{\mathbb{A}})^2) \leq \text{Inc}\,(\mathbb{A} + \tilde{\mathbb{A}})\,, \tag{3.25}$$

$$\text{Inc}\,(\tilde{\mathbb{A}}\,(\mathbb{A} + \tilde{\mathbb{A}})) \leq \text{Inc}\,(\mathbb{A} + \tilde{\mathbb{A}})\,, \tag{3.26}$$

$$\text{Inc}\,(\tilde{\mathbb{A}}^2) \leq \text{Inc}\,(\tilde{\mathbb{A}})\,, \tag{3.27}$$

$$\text{Inc}\,((\mathbb{A} + \tilde{\mathbb{A}})\,\tilde{\mathbb{A}}) \leq \text{Inc}\,(\tilde{\mathbb{A}})\,. \tag{3.28}$$

It is straightforward to prove that (3.25)–(3.26) imply (3.23), and (3.27)–(3.28) imply (3.24).

Consequently, the study done in [13] fits completely within the one done in this paper.

4. Examples. The next step is to analyze the regions of a.m. $\mathcal{R}(\mathbb{A},\tilde{\mathbb{A}})$ for some ARK methods $(\mathbb{A},\tilde{\mathbb{A}})$ from the literature with $R(\mathbb{A})>0$, $R(\tilde{\mathbb{A}})>0$. The study is summarized in the following table. The coefficients for the different methods can be seen in the appendix.

Method	$R(\mathbb{A})$	$R(\tilde{\mathbb{A}})$	$\mathcal{R}(\mathbb{A},\tilde{\mathbb{A}})$
ARS(1,1,1)	1	∞	$\{(r,\tilde{r}) \,\vert\, 0\le r\le 1\,,\ 0\le \tilde{r}\}$
SP(1,1,1)	1	∞	$\{(r,\tilde{r}) \,\vert\, 0\le r\le 1\,,\ 0\le \tilde{r}\}$
Störmer–Verlet	2	2	$\{(r,\tilde{r}) \,\vert\, 0\le r\le 2\,,\ 0\le \tilde{r}\le 2\}$
Peaceman–Rachford	2	2	$\{(r,\tilde{r}) \,\vert\, 0\le r\le 2\,,\ 0\le \tilde{r}\le 2\}$
IMEX trapezoidal (7.1)	1	2	$\{(r,\tilde{r}) \,\vert\, 0\le r\le 1\,,\ 0\le \tilde{r}\le 2(1-r)\}$
IMEX trapezoidal (7.2)	1	1	$\{(r,\tilde{r}) \,\vert\, 0\le r\le 1\,,\ 0\le \tilde{r}\le 1-r\}$
IMEX (7.3)	2	$\frac{2}{7}(6+\sqrt{57})$	$\left\{(r,\tilde{r}) \,\vert\, 0\le r\le 2\,,\ 0\le \tilde{r}\le \frac{6+\sqrt{57}}{7}(2-r)\right\}$
CRJ	$\frac{2}{3}$	$\frac{4}{5}$	$\{(r,\tilde{r}) \,\vert\, 0\le r\le \frac{2}{3}\,,\ 0\le \tilde{r}\le \frac{2}{5}(2-3r)\}$
IMEX θ-method ($\theta=1/2$)	1	2	$\{(r,\tilde{r}) \,\vert\, 0\le r\le 1\,,\ 0\le \tilde{r}\le 2(1-r)\}$
ASIRK-2A	1	$\frac{4}{3}$	$\{(r,\tilde{r}) \,\vert\, 0\le r\le 1\,,\ 0\le \tilde{r}\le \frac{4}{3}(1-r)\}$
SSP2(2,2,2)	1	$1+\sqrt{2}$	$\left\{(r,\tilde{r}) \,\vert\, 0\le r\le 1\,,\ 0\le \tilde{r}\le \sqrt{2}(1-r)\right\}$

Observe that for some ARK methods $(\mathbb{A},\tilde{\mathbb{A}})$, namely Ascher–Ruuth–Spiteri scheme ARS(1,1,1), the splitting scheme SP(1,1,1), Störmer–Verlet, and Peaceman–Rachford, the two RK methods are perfectly coupled in the sense that the region of absolute monotonicity is the greatest one, i.e., it is the cartesian product of the regions of absolute monotonicity of both methods.

For some other methods, namely IMEX trapezoidal (7.1) and (7.2), IMEX (7.3), Caflisch–Russo–Jin (CRJ), IMEX θ-method with $\theta=1/2$, and additive semi-implicit Runge–Kutta (ASIRK-2A), the region of absolute monotonicity for the ARK methods is the triangle with vertices the points $(0,0)$, $(0,R(\mathbb{A}))$, and $(R(\tilde{\mathbb{A}}),0)$.

However, for some other methods, the region of absolute monotonicity is smaller than this triangle. For example for the method SSP2(2,2,2) we have found that $R(\mathbb{A})=\sqrt{2}$ and $R(\tilde{\mathbb{A}})=1+\sqrt{2}$, but the region of absolute monotonicity is not the triangle with vertices $(0,0)$, $(0,1)$, and $(1+\sqrt{2},0)$ but the one with vertices $(0,0)$, $(0,1)$, and $(\sqrt{2},0)$.

Besides the cartesian product of both regions, and triangles, some other shapes are possible for the region of absolute monotonicity.

Example 2. We consider the modified IMEX SSP2(3,3,2) method from Example 1 with $R(\mathbb{A})=2$ and $R(\tilde{\mathbb{A}})=\frac{5}{9}(\sqrt{70}-4)$. It can be computed that

$$\mathcal{R}(\mathbb{A},\tilde{\mathbb{A}})=\left\{(r,\tilde{r}) \,\vert\, 0\le r\le 2\,,\ 0\le \tilde{r}\le \phi(r)\right\},$$

where

$$\phi(r)=\begin{cases} \frac{1}{4}(-28+9r)+\frac{1}{4}\sqrt{1264-984r+201r^2} & \text{if} \quad 0\le r\le \frac{1}{64}(119-\sqrt{721})\,, \\ \\ \frac{5}{36}(-16+r)+\frac{5\sqrt{7}}{36}\sqrt{160-128r+31r^2} & \text{if} \quad \frac{1}{64}(119-\sqrt{721})\le r\le 2\,. \end{cases}$$

5. Numerical experiments.

5.1. Experiment 1. We have considered the following PDE of hyperbolic type [18]:

$$\begin{cases} \dfrac{\partial}{\partial t}V(\xi,t) = \dfrac{\partial}{\partial \xi}\left[a(\xi,t)V(\xi,t)\right], \\ V(0,t) = 0\,, \qquad V(\xi,0) = v_0(\xi) \qquad (0 \le \xi \le 1,\, t \ge 0), \end{cases} \tag{5.1}$$

where $a(\xi,t) = -\cos(20\xi + 80t)$, $v_0(\xi) = \xi^2\left(e^{(\xi/200)} - 3\right)$. As $v_0(\xi)$ is continuously differentiable on $[0,1]$ and $v_0(0) = v_0'(0) = 0$, it can be proved that this problem has a unique classical solution V with

$$\int_0^1 |V(\xi,t)|\, d\xi \le \int_0^1 |v_0(\xi)|\, d\xi \qquad \text{for all } t \ge 0\,.$$

We discretize the spatial derivative in (5.1) with backward differences, obtaining the ODE

$$u(t)' = L(t)\, u(t), \tag{5.2}$$

where $L(t)$ satisfies

$$\left\| u + \frac{1}{\rho}\, L(t)\, u \right\| \le \| u \|$$

for $\rho = (\Delta\xi)^{-1}$, with $\| \cdot \|$ defined as

$$\| x \| = \Delta\xi \sum_{i=1}^{n} | x_i |\,.$$

Hence the solution of (5.2) is monotone.

For the numerical solution of (5.2) we have considered the RK methods $\mathbb{A}$ and $\tilde{\mathbb{A}}$ in the IMEX trapezoidal scheme (7.1), for which $R(\mathbb{A}) = 1$ and $R(\tilde{\mathbb{A}}) = 2$. For an RK method $\mathbb{A}$, the stepsize restriction for monotonicity is given by

$$h \le \frac{1}{\rho}\, R(\mathbb{A})\,.$$

Hence, for $\Delta\xi = 1/50$ the explicit method $\mathbb{A}$ is monotone under stepsize restriction $h \le 1 \times 1/50$, whereas the implicit method $\tilde{\mathbb{A}}$ is monotone for $h \le 2 \times 1/50$. However, in our numerical computations we have found that for this initial value problem these bounds are not sharp. For example, for $h = \frac{1}{20}$ both methods are monotone. In Figure 5.1 we show the values of $\| u_n \|$ with the explicit and implicit RK methods for $t \in [0,2]$ with that stepsize.

In order to test monotonicity for the IMEX method, we have considered the artificial problem

$$U(t)' = L(t)U(t) + L(t)U(t) \tag{5.3}$$

with $L(t)$ the same matrix as in (5.2). When the IMEX method is applied to (5.3), the stepsize restrictions for monotonicity for each method do not ensure monotonicity for the IMEX scheme. Figure 5.2 shows the numerical results for $\| u_n \|$ for $t \in [0,2]$ for the IMEX method with $h = \frac{1}{20}$. Observe that, although with this stepsize we obtain monotonicity for each method (see Figure 5.1), monotonicity fails for the IMEX scheme. Monotonicity is obtained under a more severe stepsize restriction.

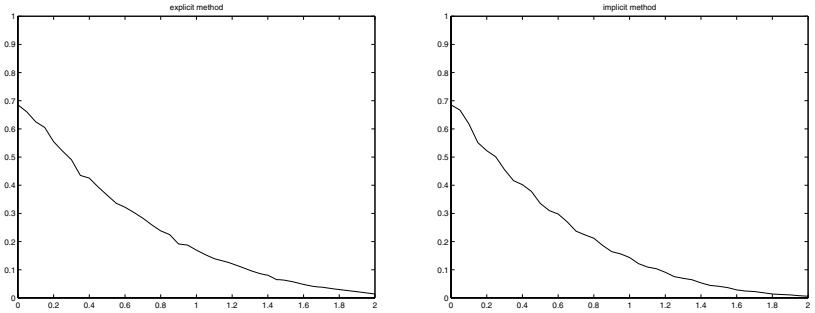

FIG. 5.1. *Left: explicit RK method. Right: implicit RK method.*

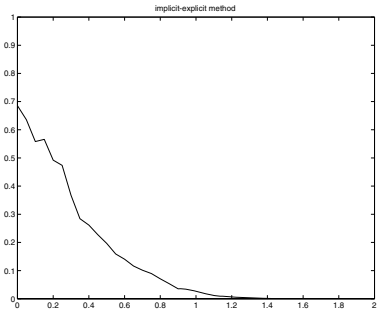

FIG. 5.2. *IMEX method.*

5.2. Experiment 2. We consider the Broadwell model [3], a hyperbolic system with relaxation. We will show how the above results can be used to obtain monotonicity for the entropy function. The problem is

$$\begin{aligned} \partial_t f + \partial_x f &= \frac{1}{\varepsilon}\left(h^2 - fg\right), \\ \partial_t h &= -\frac{1}{\varepsilon}\left(h^2 - fg\right), \\ \partial_t g - \partial_x g &= \frac{1}{\varepsilon}\left(h^2 - fg\right), \end{aligned} \tag{5.4}$$

where ε is a small parameter. We assume periodic boundary conditions. For the continuous problem there exists a function that is monotonically decreasing, namely

$$\mathcal{H}(t) = \int \hat{\mathcal{H}}(x,t)\,dx\,, \tag{5.5}$$

where

$$\hat{\mathcal{H}}(x,t) = f(x,t)\log f(x,t) + 2h(x,t)\log h(x,t) + g(x,t)\log g(x,t)\,.$$

We introduce spatial grid points $x_{j+\frac{1}{2}}$, $j = \ldots, -1, 0, 1, \ldots$ with uniform mesh spacing $\Delta x = x_{j+\frac{1}{2}} - x_{j-\frac{1}{2}}$ for all j. Spatial discretization of (5.4) with the upwind scheme

gives

$$\begin{aligned} \frac{d}{dt} f_j + \frac{f_j - f_{j-1}}{\Delta x} &= \frac{1}{\varepsilon}\left(h_j^2 - f_j g_j\right), \\ \frac{d}{dt} h_j &= -\frac{1}{\varepsilon}\left(h_j^2 - f_j g_j\right), \\ \frac{d}{dt} g_j - \frac{g_{j+1} - g_j}{\Delta x} &= \frac{1}{\varepsilon}\left(h_j^2 - f_j g_j\right). \end{aligned} \tag{5.6}$$

This problem is an additive ODE in the form of (1.1) with the additive terms

$$F_1 = \begin{pmatrix} -\dfrac{f_j - f_{j-1}}{\Delta x} \\ 0 \\ \dfrac{g_{j+1} - g_j}{\Delta x} \end{pmatrix}, \qquad F_2 = \frac{1}{\varepsilon}\left(h_j^2 - f_j g_j\right) \begin{pmatrix} 1 \\ -1 \\ 1 \end{pmatrix}. \tag{5.7}$$

The discrete function for (5.5) is defined by

$$\mathcal{H}_{\Delta x}[f_j(t), h_j(t), g_j(t)] = \Delta x \sum_j \left(f_j(t)\log f_j(t) + 2h_j(t)\log h_j(t) + g_j(t)\log g_j(t)\right),$$

which is also a decreasing function. Hence, if f_j^n, h_j^n, and g_j^n denote the numerical approximations of $f_j(t), h_j(t)$, and $g_j(t)$ at time t_n, respectively, we should have $\mathcal{H}^{n+1} \le \mathcal{H}^n$, where now

$$\mathcal{H}^n = \mathcal{H}_{\Delta x}[f_j^n, h_j^n, g_j^n] = \Delta x \sum_j \left(f_j^n \log f_j^n + 2h_j^n \log h_j^n + g_j^n \log g_j^n\right).$$

In order to apply the results from section 3, we have to compute the parameters ρ and $\tilde{\rho}$ for the functions F_1 and F_2 in (5.7). Whereas the computation of the method parameter is not a difficult task, the sharp computation of problem parameters may be a hard task. In this case, for the function F_1 we have to find the values $\rho > 0$ such that

$$\mathcal{H}_{\Delta x}\left[f_j - \frac{1}{\rho}\frac{f_j - f_{j-1}}{\Delta x}, h_j, g_j + \frac{1}{\rho}\frac{g_{j+1} - g_j}{\Delta x}\right] \le \mathcal{H}_{\Delta x}[f_j, h_j, g_j].$$

It is straightforward to obtain that these inequalities hold for $\rho = 1/\Delta x$. For the function F_2 in (5.7), a value $\tilde{\rho} > 0$ such that

$$\mathcal{H}_{\Delta x}\left[f_j + \frac{1}{\tilde{\rho}\,\varepsilon}(h_j^2 - f_j g_j), h_j - \frac{1}{\tilde{\rho}\,\varepsilon}(h_j^2 - f_j g_j), g_j + \frac{1}{\tilde{\rho}\,\varepsilon}(h_j^2 - f_j g_j)\right] \le \mathcal{H}_{\Delta x}[f_j, h_j, g_j] \tag{5.8}$$

for all f, h, g such that $0 \le \Delta x\,(f + 2h + g) \le K_0$ (see Remark 1(d)) was found in [14], where K_0 is given by

$$K_0 = \Delta x \sum_j \left(f_j^0 + 2h_j^0 + g_j^0\right).$$

This value was $\tilde{\rho} = K_0/(\varepsilon\,\Delta x)$. Observe that in order to compute the discrete entropy function, the numerical solution should be positive. Hence, some extra stepsize restrictions may appear due to numerical positivity preservation.

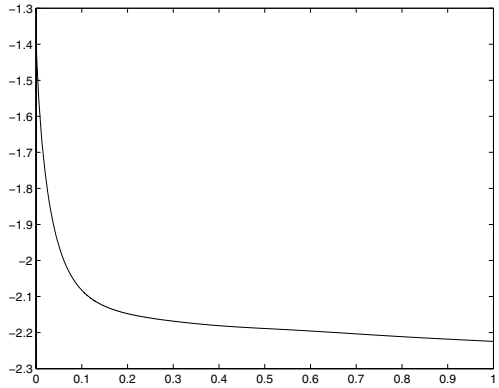

FIG. 5.3. *Entropy function for* (5.6) *($\varepsilon = 0.1$, $\Delta x = 0.01$, and $h = 0.0002$).*

According to Theorem 3.1, for $(r, \tilde{r})$ in the region of absolute monotonicity, we obtain monotonicity for the entropy function under the stepsize restrictions $h \le r\,\Delta x$, $h \le \tilde{r}\,\varepsilon\,\Delta x/K_0$. If we consider the CRJ scheme, we have to compute the intersection of the line connecting $(0, \frac{4}{5}\frac{\varepsilon\,\Delta x}{K_0})$ and $(\frac{2}{3}\Delta x, 0)$ with the bisectrix. In this way we obtain the stepsize restriction

$$h \le \frac{4\Delta x\,\varepsilon}{5K_0 + 6\,\varepsilon}\,. \tag{5.9}$$

We have integrated this problem with the CRJ scheme for $\varepsilon = 0.1$, $\Delta x = 0.01$, and $h = 0.0002$. With these parameters, stepsize restriction (5.9) is satisfied. We have checked that under this stepsize restriction, the numerical solution is positive. In Figure 5.3 we show the discrete entropy function. As expected, it is a decreasing function.

However, from our numerical experiments we have observed that the stepsize restriction (5.9) is not optimal. As pointed out above, the parameter $\tilde{\rho}$ has been obtained, imposing (5.8) for all f, h, and g such that $0 \le \Delta x\,(f + 2h + g) \le K_0$. However, for this problem, $h^2 - f\,g = \vartheta(\varepsilon)$, and this property has not been taken into account. A detailed study, out of the scope of this paper, should be done in order to find better problem parameters. In this context, the concept of the AP method introduced in [19] is an important reference.

6. Conclusions and future work. In this paper we have studied monotonicity issues for ARK methods $(\mathbb{A}, \tilde{\mathbb{A}})$. A new definition of absolute monotonicity for ARK methods has been given and some of its properties have been investigated. It has been proved that for $\partial\mathcal{R}(\mathbb{A}, \tilde{\mathbb{A}}) \neq 0$, it is possible to obtain monotonicity under nontrivial stepsize restrictions. As expected, monotonicity for each RK method does not ensure monotonicity for the ARK method. However, some classical methods in the PDE context, such as the Peaceman–Rachford method, are perfectly coupled and there are no extra stepsize restrictions on the use of the two RK methods as an ARK method.

With regard to the new concept $\mathcal{R}(\mathbb{A}, \tilde{\mathbb{A}})$ at least two questions remain open for future work. The first one is how to construct $(\mathbb{A}, \tilde{\mathbb{A}})$ such that $R(\mathbb{A}, \tilde{\mathbb{A}})$ is as great as possible. The second one is how to extend this concept for additive RK methods constructed with k RK methods.

7. Appendix. In this section we give the coefficients of some methods from the literature.

1. The IMEX ARS(1,1,1) method [2] (or the ASIRK-1A method in [27]) is

$$\begin{array}{c|cc} 0 & 0 & 0 \\ 1 & 1 & 0 \\ \hline \mathbb{A} & 1 & 0 \end{array} \qquad \begin{array}{c|cc} 0 & 0 & 0 \\ 1 & 0 & 1 \\ \hline \tilde{\mathbb{A}} & 0 & 1 \end{array}$$

2. The Störmer–Verlet method (or Lobatto IIIA–IIIB pair) [11] is

$$\begin{array}{c|cc} 0 & 0 & 0 \\ 1 & \frac{1}{2} & \frac{1}{2} \\ \hline \mathbb{A} & \frac{1}{2} & \frac{1}{2} \end{array} \qquad \begin{array}{c|cc} \frac{1}{2} & \frac{1}{2} & 0 \\ \frac{1}{2} & \frac{1}{2} & 0 \\ \hline \tilde{\mathbb{A}} & \frac{1}{2} & \frac{1}{2} \end{array}$$

3. The SP(1,1,1) L-stable method [19] is

$$\begin{array}{c|c} 0 & 0 \\ \hline \mathbb{A} & 1 \end{array} \qquad \begin{array}{c|c} 1 & 1 \\ \hline \tilde{\mathbb{A}} & 1 \end{array}$$

4. The Peaceman–Rachford ARK method [15] is

$$\begin{array}{c|ccc} 0 & 0 & 0 & 0 \\ \frac{1}{2} & \frac{1}{2} & 0 & 0 \\ 1 & \frac{1}{2} & 0 & \frac{1}{2} \\ \hline \mathbb{A} & \frac{1}{2} & 0 & \frac{1}{2} \end{array} \qquad \begin{array}{c|ccc} 0 & 0 & 0 & 0 \\ \frac{1}{2} & 0 & \frac{1}{2} & 0 \\ 1 & 0 & 1 & 0 \\ \hline \tilde{\mathbb{A}} & 0 & 1 & 0 \end{array}$$

5. There are different ways of combining the implicit and explicit trapezoidal rules. One way is by the IMEX method [15, p. 391]

$$\begin{array}{c|cc} 0 & 0 & 0 \\ 1 & 1 & 0 \\ \hline \mathbb{A} & \frac{1}{2} & \frac{1}{2} \end{array} \qquad \begin{array}{c|cc} 0 & 0 & 0 \\ 1 & \frac{1}{2} & \frac{1}{2} \\ \hline \tilde{\mathbb{A}} & \frac{1}{2} & \frac{1}{2} \end{array} \tag{7.1}$$

Another way is by the IMEX method [15, p. 392]

$$\begin{array}{c|ccc} 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & \frac{1}{2} & \frac{1}{2} & 0 \\ \hline \mathbb{A} & \frac{1}{2} & \frac{1}{2} & 0 \end{array} \qquad \begin{array}{c|ccc} 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & \frac{1}{2} & 0 & \frac{1}{2} \\ \hline \tilde{\mathbb{A}} & \frac{1}{2} & 0 & \frac{1}{2} \end{array} \tag{7.2}$$

6. In [20] different SSP$k(s,\sigma,p)$ IMEX methods are constructed. In the notation, SSP$k(s,\sigma,p)$, s, and σ are the numbers of stages of the explicit and implicit method, respectively, and k is the order of the SSP method (the explicit one).

The L-stable IMEX SSP2(2,2,2) method is

$$\begin{array}{c|cc} 0 & 0 & 0 \\ 1 & 1 & 0 \\ \hline \mathbb{A} & \frac{1}{2} & \frac{1}{2} \end{array} \qquad \begin{array}{c|cc} \gamma & \gamma & 0 \\ 1-\gamma & 1-2\gamma & \gamma \\ \hline \tilde{\mathbb{A}} & \frac{1}{2} & \frac{1}{2} \end{array}$$

with $\gamma = 1 - \frac{1}{\sqrt{2}}$.

7. In [1] the following ARK scheme is considered:

$$\begin{array}{c|ccc} 0 & 0 & 0 & 0 \\ \frac{1}{2} & 0 & \frac{1}{2} & 0 \\ 1 & 0 & 1 & 0 \\ \hline \mathbb{A} & 0 & 1 & 0 \end{array} \qquad \begin{array}{c|ccc} \frac{\alpha}{2} & \frac{\alpha}{2} & 0 & 0 \\ \frac{1}{2} & \alpha & \frac{1-2\alpha}{2} & 0 \\ 1+\frac{\alpha}{2} & \alpha & 1-2\alpha & \frac{\alpha}{2} \\ \hline \tilde{\mathbb{A}} & \alpha & 1-2\alpha & \alpha \end{array} \tag{7.3}$$

We have studied it for $\alpha = \frac{1}{6}\left(9 - \sqrt{57}\right)$.

8. The second order IMEX method in [3] is

$$\begin{array}{c|ccc} 0 & 0 & 0 & 0 \\ \hat{\alpha} & \hat{\alpha} & 0 & 0 \\ \eta\,(\hat{\alpha}+\hat{\beta}) & \eta\,\hat{\alpha} & \eta\,\hat{\beta} & 0 \\ \hline \mathbb{A} & \eta\,\hat{\alpha} & \eta\,\hat{\beta} & 0 \end{array} \qquad \begin{array}{c|ccc} 0 & 0 & 0 & 0 \\ \gamma+\beta & \gamma & \beta & 0 \\ \eta\,\mu\,(\gamma+\beta) & \eta\,\gamma & \eta\,\beta & \mu \\ \hline \tilde{\mathbb{A}} & \eta\,\gamma & \eta\,\beta & \mu \end{array}$$

with

$$\beta = \frac{2\mu - 1}{2(\mu - 1)}, \qquad \gamma = -\frac{2\mu^2 - 2\mu + 1}{2\mu(\mu - 1)}, \qquad \eta = -2\mu(\mu - 1),$$
$$\hat{\alpha} = \frac{1}{2\mu}, \qquad \hat{\beta} = \frac{-1}{2(\mu - 1)}.$$

With $\mu = 1/3$, we obtain $\alpha \geq 0$, $\beta > 0$, and $\mu > 0$. We will refer to it as the CRJ IMEX method.

9. The IMEX θ-method [15, p. 383] is

$$\begin{array}{c|cc} 0 & 0 & 0 \\ 1 & 1 & 0 \\ \hline \mathbb{A} & 1 & 0 \end{array} \qquad \begin{array}{c|cc} 0 & 0 & 0 \\ 1 & 1-\theta & \theta \\ \hline \tilde{\mathbb{A}} & 1-\theta & \theta \end{array}$$

Observe that for $\theta = 1$, we obtain the ARS(1,1,1) method above.

10. IMEX methods of the form

$$\begin{array}{c|cccc} 0 & 0 & 0 & 0 & 0 \\ a_1 & a_1 & 0 & 0 & 0 \\ b_{21} & b_{21} & 0 & 0 & 0 \\ c_{21}+a_2 & c_{21} & 0 & a_2 & 0 \\ \hline \mathbb{A} & w_1 & 0 & w_2 & 0 \end{array} \qquad \begin{array}{c|cccc} 0 & 0 & 0 & 0 & 0 \\ a_1 & 0 & a_1 & 0 & 0 \\ b_{21} & 0 & b_{21} & 0 & 0 \\ c_{21}+a_2 & 0 & c_{21} & 0 & a_2 \\ \hline \tilde{\mathbb{A}} & 0 & w_1 & 0 & w_2 \end{array}$$

are considered in [27]. Order 2 is obtained, e.g., for

$$w_1 = \tfrac{1}{2}\,, \quad w_2 = \tfrac{1}{2}\,, \quad b_{21} = 1\,,$$
$$a_1 = \tfrac{1}{4}\,, \quad a_2 = \tfrac{1}{3}\,, \quad c_{21} = \tfrac{5}{12}\,.$$

We will refer to this method as ASIRK-2A.

STABILITY ANALYSIS OF LARGE TIME-STEPPING METHODS FOR EPITAXIAL GROWTH MODELS*

CHUANJU XU† AND TAO TANG‡

Abstract. Numerical methods for solving the continuum model of the dynamics of the molecular beam epitaxy (MBE) require very large time simulation, and therefore large time steps become necessary. The main purpose of this work is to construct and analyze highly stable time discretizations which allow much larger time steps than those of a standard implicit-explicit approach. To this end, an extra term, which is consistent with the order of the time discretization, is added to stabilize the numerical schemes. Then the stability properties of the resulting schemes are established rigorously. Numerical experiments are carried out to support the theoretical claims. The proposed methods are also applied to simulate the MBE models with large solution times. The power laws for the coarsening process are obtained and are compared with previously published results.

Key words. molecular beam epitaxy, epitaxial growth, spectral method, stability, implicit-explicit method, large time-stepping

1. Introduction.

Recently there has been significant research interest in the dynamics of molecular beam epitaxy (MBE) growth. The MBE technique is among the most refined methods for the growth of thin solid films, and it is of great importance for applied studies; see, e.g., [1, 16, 22]. The evolution of the surface morphology during epitaxial growth results in a delicate relation between the molecular flux and the relaxation of the surface profile through surface diffusion of adatoms. It occurs on time and length scales that may span several orders of magnitude. Different kinds of models have been used to describe such phenomena; these typically include *atomistic models, continuum models, and hybrid models.* The atomistic models are usually implemented in the form of molecular dynamics or kinetic Monte Carlo simulations [4, 9, 17]. The continuum models are based on partial differential equations and are appropriate mainly for investigating the temporal evolution of the MBE instability at large time and length scales [11, 24]. The hybrid models can be considered as a compromise between atomistic models and continuum models; see, e.g., [3, 8].

We are interested in the continuum models for the evolution of the MBE growth. Let $h(\mathbf{x}, t)$ be the epitaxy surface height with $\mathbf{x} \in \mathbb{R}^2$ and $t \geq 0$. Under typical conditions for MBE growth, the height evolution equation can be written under mass conservation form (see, e.g., [14]):

$$h_t = -\nabla \cdot J(\nabla h), \tag{1.1}$$

where J is the surface current which can be decomposed into a sum of two currents,

$$J = J_{\mathrm{SD}} + J_{\mathrm{NE}}, \tag{1.2}$$

where J_{SD} is the equilibrium surface current describing the surface diffusion and J_{NE} is the nonequilibrium diffusion current taking into account the Ehrlich–Schwoebel effect [6, 18]. The surface diffusion current has the form

$$J_{\mathrm{SD}} = \delta\nabla(\Delta h), \tag{1.3}$$

where δ is the surface diffusion constant. By using effective free energy formulation, the nonequilibrium diffusion current under consideration can be written in the form

$$J_{\mathrm{NE}}(M) = -\frac{\partial U(M)}{\partial M}, \tag{1.4}$$

where $M = (M_1, M_2) := \nabla h$ is the slope vector and $U(M)$ is the potential depending only on the slope vector. Evidently, the term J_{NE} helps the system (1.1) to evolve toward the states in which the slope M attains the minimum of $U(M)$ because J_{NE} vanishes at the minima of $U(M)$. The minima of this potential is the preferred value of the slope. Consequently, the corresponding system is the so-called epitaxial growth model with slope selection.

The continuum model (1.1) has been extensively applied to modeling interfacial coarsening dynamics in epitaxial growth with slope selection; see, e.g., [12, 14, 24]. In (1.1), the fourth-order term models surface diffusion, and the nonlinear second-order term models the well-known Ehrlich–Schowoebel effect [6, 18], which gives rise to instabilities in the evolution of the surface morphology. The instability then leads to the formation of mounds and pyramids on the growing surface. These pyramid-like structures have been reported in many experiments and numerical simulations; see, e.g., [14, 20, 23]. It is found that the lateral width λ and the height w of these pyramids grow in time as power laws with the same component. Thus, the ratio w/λ, corresponding to the pyramid slope, approaches a constant at large times. Therefore, there is a slope selection in a typical MBE growth. The corresponding coarsening exponents were found from experiments to depend on the symmetry of the surface. Two typical values of the coarsening exponent have been found, namely 1/4 (see, e.g., [14, 20]) and 1/3 (see, e.g., [14, 23]). Some mathematical justification of such predictions was given in [10]. We also point out that the continuum model (1.1)–(1.4) has been derived by Ortiz, Repetto, and Si [15] by using a series expansion of the deposition flux in powers of the surface gradient. They also provided an explicit construction for the pyramid-like coarsening, which allows one to predict characteristic power laws for the pyramid size growth. However, it is difficult to provide growing details, especially for complex thin-film systems.

Numerical simulations with the continuum models are appropriate for investigating the surface growth instability at large times. The direct numerical simulation for (1.1)–(1.4) with different nonequilibrium diffusion currents was performed by Siegert [19], who obtained a power law close to 1/4. Moldovan and Golubovic [14] carried out very comprehensive numerical simulations by using a kinetic scaling theory and obtained a 1/3 power law. It should be pointed out that the simulations reported in [14] were not completely based on a continuum model. Instead, they solved a so-called type-A dynamics equation directly on a hexagonal grid. More recently, the well-posedness of the initial-boundary-value problem of (1.1) is studied by Li and Liu [12]

using the perturbation analysis and Galerkin spectral approximations. In [13], they used variational techniques to obtain some asymptotic results for a no-slope-selection model. Moreover, several scaling laws have been derived in [13].

The main purpose of this study is to provide efficient numerical schemes for solving (1.1), with particular emphasis on the use of large time steps. To obtain meaningful results for power laws, the integration times in simulations have to be very large (say, in the order of 10^4). As a result, it is reasonable to employ larger time steps and a small number of grid points in computations, provided that stability and accuracy can be preserved. It is observed that most of the existing continuum model simulations have used an explicit integration method in time and finite difference type approximation in space. To maintain the stability and to achieve high approximation accuracy, the number of spatial grid points must be large and the time step has to be small. Even with rapidly increasing computational resources, explicit schemes are still limited to simulating early surface evolution and therefore small length scale [12].

The main objectives of this work are threefold: First, we introduce an accurate and efficient semi-implicit Fourier pseudospectral method for solving the time-dependent nonlinear diffusion equations (1.1). To approximate the time derivatives, a backward differentiation is employed. More precisely, the fourth-order term is treated implicitly to reduce the associated stability constraints, while the nonlinear second-order terms are treated explicitly in order to avoid solving the nonlinear equations at each time step. Secondly, a stabilization second-order term is added to the discretized system, which increases the time step dramatically. In real applications, the surface diffusion constant δ may be very small after dimensional scaling. Consequently, direct use of the standard semi-implicit method still suffers from severe stability restriction on the time step. In order to overcome this difficulty, we introduce a stabilization term with constant coefficient A, which allows us to increase the time step significantly. Note that a similar technique has been used by Zhu et al. in the simulation of the Cahn–Hilliard equation [26]. Our main contribution is to show rigorously that the resulting numerical scheme is stable if an appropriate constant A is chosen. Justification of this stabilization technique is provided by considering several numerical tests. Finally, we perform some numerical simulations for the interfacial coarsening dynamics using our proposed schemes. Our numerical results yield a 1/3 power law for the isotropic symmetry surface and 1/4 for the square symmetry surface.

It is worthwhile to mention some recent papers by Feng and Prohl on the numerical analysis for Cahn–Hilliard and Allen–Cahn equations; see, e.g., [7]. They also studied stability issues—the continuous dependence of solutions on the initial data. This is different from our stability concept, which seems more related to the decay of energy. They mainly proved that the stability constant increases to infinity algebraically as a small parameter (similar to our surface diffusion constant δ in (1.3)) goes to 0. This is a big step forward, since usually the blow-up of the constant is exponential if one uses the Gronwall inequality—a standard method.

The organization of the paper is as follows. In section 2, we construct highly stable semi-implicit Fourier spectral methods for solving (1.1), which is of first-order accuracy in time. To improve the numerical stability, an $\mathcal{O}(\Delta t)$ term is added. Detailed stability analysis based on the energy method is provided to show that the proposed methods allow a large time step, and therefore are useful for large time simulations. The second-order semi-implicit methods are investigated in section 3. It will be demonstrated that the stability analysis for higher-order time-stepping methods is much more difficult. Numerical experiments for model problems are presented in

section 4. Section 5 reports some computational results for the coarsening dynamics using the numerical schemes allowing large time steps. Some concluding remarks are given in the final section.

2. Semi-implicit time discretization: First-order methods. To demonstrate the main ideas in scheme designing and stability analysis, we will use two model equations in this work. The first one is of the form

$$h_t = -\delta\Delta^2 h - \nabla\cdot[(1-|\nabla h|^2)\nabla h], \quad (\mathbf{x},t)\in\Omega\times(0,T]. \tag{2.1}$$

The second model equation is of the form

$$h_t = -\delta\Delta^2 h - ((1-|h_x|^2)h_x)_x - ((1-|h_y|^2)h_y)_y, \ \ (\mathbf{x},t)\in\Omega\times(0,T]. \tag{2.2}$$

Hereafter, we use h_t to denote $\frac{\partial h}{\partial t}$, $\nabla h = (h_x, h_y)$. Both model problems are subject to the periodic boundary conditions and suitable initial data, where $\Omega = (0,L)^2$ with $L > 0$. The model (2.1) corresponds to the isotropic surface current, while (2.2) represents the simplest square surface current.

For the MBE simulations, large computational domain is necessary in order to minimize the effect of periodicity assumption and to collect enough statistical information such as mean surface height and width of the pyramid-like structures. Moreover, sufficiently long integration time is necessary in order to detect the epitaxy growth behaviors and to reach the physical scaling regime. On the other hand, to carry out numerical simulations with large time and large computational domain, highly stable and accurate numerical methods are required. To this end, it is natural to use the Fourier spectral approach in space which has been found extremely efficient for periodic problems. As for stability issue, the implicit treatment for the fourth-order terms is employed, and more importantly, a special trick to handle the nonlinear second-order terms is used. The goal is to significantly increase the allowed time steps.

We first consider the MBE model with the isotropic symmetry current, namely, (2.1). A classical first-order semi-implicit scheme is of the form

$$\frac{h^{n+1}-h^n}{\Delta t} + \delta\Delta^2 h^{n+1} = -\nabla\cdot\left[(1-|\nabla h^n|^2)\nabla h^n\right], \ \ n\ge 0. \tag{2.3}$$

It is expected that the implicit treatment for the fourth-order term in (2.3) allows one to relax the time step restriction. However, numerical experiments demonstrate that a larger time step cannot be used for the scheme (2.3) when δ is small; see, e.g., [12]. To improve this, an $\mathcal{O}(\Delta t)$ term is added into the scheme (2.3):

$$\frac{h^{n+1}-h^n}{\Delta t} + \delta\Delta^2 h^{n+1} - A\Delta h^{n+1} = -\nabla\cdot\left[(1-|\nabla h^n|^2 + A)\nabla h^n\right], \ \ n\ge 0, \tag{2.4}$$

where A is a positive constant to be determined later and $h^n \equiv h^n(\mathbf{x})$ is an approximation of $h(\mathbf{x},t)$ at $t = t^n$. The initial data h^0 is given by the initial condition. The purpose for adding the extra terms is to improve the stability condition so that larger time steps can be used. This will be justified theoretically in this section, and will be demonstrated by our numerical results in section 4.

In order to study its stability property, we will use a discrete energy estimate. To this end, we first state the following known result.

LEMMA 2.1 (energy identities [12]). *If $h(\mathbf{x},t)$ is a solution of (2.1), then the following energy identities hold:*

$$\frac{d}{dt}\|h\|^2 + 4E(h) + \|\nabla h\|_{L^4}^4 = |\Omega|, \tag{2.5}$$

$$\frac{d}{dt}E(h) + \|h_t\|^2 = 0, \tag{2.6}$$

where $\|\cdot\|$ is the standard L^2-norm in Ω, L^p is the standard L^p-norm, and

$$E(h) = \int_\Omega \left[\frac{1}{4}(|\nabla h|^2 - 1)^2 + \frac{\delta}{2}|\Delta h|^2\right] d\mathbf{x}. \tag{2.7}$$

We briefly sketch the proof of (2.5) and (2.6), which is useful in deriving its discrete counterparts. It follows from (2.1) that

$$\langle h_t, \varphi\rangle = -\left\langle \nabla\cdot[(1-|\nabla h|^2)\nabla h + \delta\nabla\Delta h], \varphi\right\rangle,$$

where $\langle\cdot,\cdot\rangle$ denotes the standard inner product in the L^2-space. It can be verified directly that setting $\varphi = h$ gives (2.5) and setting $\varphi = h_t$ yields (2.6).

THEOREM 2.1. *If the constant A in (2.4) is sufficiently large, then the following energy inequality holds:*

$$E(h^{n+1}) \le E(h^n), \tag{2.8}$$

where E is defined by (2.7) and h^n is computed by (2.4). Moreover, if the numerical solution is convergent in $L^\infty([0,T];W^{1,\infty}(\Omega))$ as $\Delta t\to 0$, then the constant A can be chosen to satisfy

$$A \ge \frac{3}{2}|\nabla h|^2 - \frac{1}{2} \qquad \text{a.e. in } \Omega\times(0,T], \tag{2.9}$$

where $h(\mathbf{x},t)$ is a solution of (2.1).

Proof. For any L-periodic $H^2(\Omega)$ function φ, it follows from (2.4) that

$$\frac{1}{\Delta t}\left\langle h^{n+1}-h^n, \varphi\right\rangle + \delta\left\langle \Delta h^{n+1}, \Delta\varphi\right\rangle + A\left\langle \nabla(h^{n+1}-h^n), \nabla\varphi\right\rangle + I(\varphi) = 0, \tag{2.10}$$

where

$$I(\varphi) := \left\langle (|\nabla h^n|^2 - 1)\nabla h^n, \nabla\varphi\right\rangle.$$

Letting $\varphi = \delta_t h^n := h^{n+1} - h^n$ gives

$$\frac{1}{\Delta t}\|\delta_t h^n\|^2 + \delta\left\langle \Delta h^{n+1}, \Delta\delta_t h^n\right\rangle + A\left\langle \nabla\delta_t h^n, \nabla\delta_t h^n\right\rangle + I(\delta_t h^n) = 0. \tag{2.11}$$

Observe that

$$\begin{aligned}
I(\delta_t h^n) &= \left\langle |\nabla h^n|^2 - 1, \nabla h^n\cdot\nabla h^{n+1} - |\nabla h^n|^2\right\rangle \\
&= \left\langle |\nabla h^n|^2 - 1, -\frac{1}{2}|\nabla\delta_t h^n|^2 + \frac{1}{2}|\nabla h^{n+1}|^2 - \frac{1}{2}|\nabla h^n|^2\right\rangle \\
&= -\frac{1}{2}\left\langle |\nabla h^n|^2 - 1, |\nabla\delta_t h^n|^2\right\rangle + \frac{1}{2}\left\langle (|\nabla h^n|^2-1)(|\nabla h^{n+1}|^2 - |\nabla h^n|^2), 1\right\rangle \\
&= -\frac{1}{2}\left\langle |\nabla h^n|^2 - 1, |\nabla\delta_t h^n|^2\right\rangle + \frac{1}{2}\left\langle |\nabla h^n|^2\cdot|\nabla h^{n+1}|^2, 1\right\rangle \\
&\quad + \frac{1}{2}\left\langle -|\nabla h^n|^4 - |\nabla h^{n+1}|^2 + |\nabla h^n|^2, 1\right\rangle.
\end{aligned}$$

Using the identity $2a^2b^2 = -(a^2-b^2)^2 + a^4 + b^4$ to the second last term above with $a = |\nabla h^{n+1}|$ and $b = |\nabla h^n|$, we obtain

$$\begin{aligned} I(\delta_t h^n) &= -\frac{1}{2}\left\langle |\nabla h^n|^2 - 1, |\nabla \delta_t h^n|^2 \right\rangle - \frac{1}{4}\left\langle (|\nabla h^{n+1}|^2 - |\nabla h^n|^2)^2, 1 \right\rangle \\ &\quad + \frac{1}{4}\left\langle |\nabla h^{n+1}|^4 + |\nabla h^n|^4, 1 \right\rangle + \frac{1}{2}\left\langle -|\nabla h^n|^4 - |\nabla h^{n+1}|^2 + |\nabla h^n|^2, 1 \right\rangle \\ &= \left\langle -\frac{1}{2}(|\nabla h^n|^2 - 1) - \frac{1}{4}|\nabla h^{n+1} + \nabla h^n|^2, |\nabla \delta_t h^n|^2 \right\rangle \\ &\quad + \frac{1}{4}\left\langle |\nabla h^{n+1}|^4 - |\nabla h^n|^4 - 2|\nabla h^{n+1}|^2 + 2|\nabla h^n|^2, 1 \right\rangle \\ &= \left\langle -\frac{1}{2}(|\nabla h^n|^2 - 1) - \frac{1}{4}|\nabla h^{n+1} + \nabla h^n|^2, |\nabla \delta_t h^n|^2 \right\rangle \\ &\quad + \frac{1}{4}\Big(\| |\nabla h^{n+1}|^2 - 1\|^2 - \| |\nabla h^n|^2 - 1\|^2 \Big). \end{aligned} \tag{2.12}$$

Combining (2.11) and (2.12) yields

$$\begin{aligned} &\frac{1}{\Delta t}\|\delta_t h^n\|^2 + \delta\left\langle \Delta h^{n+1}, \Delta \delta_t h^n \right\rangle + \frac{1}{4}\left(\| |\nabla h^{n+1}|^2 - 1\|^2 - \| |\nabla h^n|^2 - 1\|^2 \right) \\ &\quad + \left\langle A - \frac{1}{2}(|\nabla h^n|^2 - 1) - \frac{1}{4}|\nabla h^{n+1} + \nabla h^n|^2, |\delta_t h^n|^2 \right\rangle = 0. \end{aligned} \tag{2.13}$$

Note that the last term in (2.13) can be made nonnegative provided that

$$A \geq \max_{\mathbf{x}\in\Omega}\left\{ \frac{1}{2}(|\nabla h^n|^2 - 1) + \frac{1}{4}|\nabla h^{n+1} + \nabla h^n|^2 \right\}. \tag{2.14}$$

Observe that

$$\begin{aligned} &\delta\left\langle \Delta h^{n+1}, \Delta \delta_t h^n \right\rangle = \delta\left\langle \Delta h^{n+1}, \Delta h^{n+1} - \Delta h^n \right\rangle \\ &\geq \frac{\delta}{2}\|\Delta h^{n+1}\|^2 - \frac{\delta}{2}\|\Delta h^n\|^2. \end{aligned} \tag{2.15}$$

Consequently, Theorem 2.1 follows from (2.13)–(2.15). ∎

We now consider the MBE model with the square symmetric surface (2.2). An energy equality similar to that for the model (2.1) can be established.

LEMMA 2.2. *If $h(\mathbf{x}, t)$ is a solution of* (2.2), *then the following energy equalities hold:*

$$\frac{d}{dt}E_2(h) + \|h_t\|^2 = 0, \tag{2.16}$$

$$\frac{d}{dt}\|h\|^2 + 4E_2(h) + \|h_x\|_{L^4}^4 + \|h_y\|_{L^4}^4 = 2|\Omega|, \tag{2.17}$$

where

$$E_2(h) = \int_\Omega \left\{ \frac{\delta}{2}|\Delta h|^2 + \frac{1}{4}\left[(h_x^2 - 1)^2 + (h_y^2 - 1)^2 \right] \right\} d\mathbf{x}\,. \tag{2.18}$$

Proof. Equation (2.2) is equivalent to

$$h_t + \delta\Delta^2 h = -\nabla \cdot J, \tag{2.19}$$

where $J = (J_1, J_2)$ is given by

$$J_1 = \left(1 - h_x^2\right) h_x\,, \qquad J_2 = (1 - h_y^2) h_y\,.$$

Multiplying both sides of (2.19) with h_t gives

$$\|h_t\|^2 + \delta \langle \Delta h, (\Delta h)_t \rangle = \langle J, (\nabla h)_t \rangle\,. \tag{2.20}$$

Observe

$$\begin{aligned}\langle J, (\nabla h)_t \rangle &= \left\langle (1 - h_x^2) h_x, h_{xt} \right\rangle + \left\langle (1 - h_y^2) h_y, h_{yt} \right\rangle \\ &= -\frac{1}{4} \frac{d}{dt} \int_\Omega \left[(h_x^2 - 1)^2 + (h_y^2 - 1)^2 \right] d\mathbf{x}.\end{aligned}$$

The above result and (2.20) yield (2.16). Similarly, the energy equality (2.17) can be derived by multiplying (2.19) with h. ∎

Similar to the scheme (2.4), a first-order scheme is constructed for the MBE model (2.2):

$$\begin{aligned}&\frac{h^{n+1} - h^n}{\Delta t} + \delta \Delta^2 h^{n+1} - A \Delta h^{n+1} \\ &= -A \Delta h^n - \left[(1 - (h_x^n)^2) h_x^n \right]_x - \left[(1 - (h_y^n)^2) h_y^n \right]_y\,.\end{aligned} \tag{2.21}$$

THEOREM 2.2. *If A in* (2.21) *is chosen sufficiently large, then the following energy inequality holds:*

$$E_2(h^{n+1}) \le E_2(h^n), \tag{2.22}$$

where E_2 is defined by (2.18) *and h^n is computed by* (2.21). *Moreover, if the numerical solution of* (2.21) *is convergent, then A can be chosen to satisfy*

$$A \ge \max \left\{ \frac{3}{2} h_x^2 - \frac{1}{2},\ \frac{3}{2} h_y^2 - \frac{1}{2} \right\} \qquad \text{a.e. in } \Omega \times (0, T], \tag{2.23}$$

where $h(\mathbf{x}, t)$ is the solution of (2.2).

Proof. The proof follows in the same manner as that of Theorem 2.1. By direct computations, we can obtain

$$\begin{aligned}&\frac{1}{\Delta t} \|\delta_t h^n\|^2 + E_2(h^{n+1}) - E_2(h^n) \\ &\quad + \int \left[A - \frac{1}{2} \left((h_x^n)^2 - 1 \right) - \frac{1}{4} (h_x^{n+1} + h_x^n)^2 \right] (h_x^{n+1} - h_x^n)^2 \, d\mathbf{x} \\ &\quad + \int \left[A - \frac{1}{2} \left((h_y^n)^2 - 1 \right) - \frac{1}{4} (h_y^{n+1} + h_y^n)^2 \right] (h_y^{n+1} - h_y^n)^2 \, d\mathbf{x} = 0.\end{aligned}$$

It follows from the above result that (2.22) holds provided that

$$A \ge \max_{\mathbf{x} \in \Omega} \left\{ \frac{1}{2} \left((h_x^n)^2 - 1 \right) - \frac{1}{4} \left(h_x^{n+1} + h_x^n \right)^2 \right\}$$

and

$$A \ge \max_{\mathbf{x} \in \Omega} \left\{ \frac{1}{2} \left((h_y^n)^2 - 1 \right) - \frac{1}{4} \left(h_y^{n+1} + h_y^n \right)^2 \right\}.$$

If the numerical solution is convergent, then the above conditions become inequality (2.23). ∎

3. Semi-implicit time discretization: Higher-order methods.

3.1. Second-order scheme: BD2/EP2. By combining a second-order backward differentiation (BD2) for the time derivative term and a second-order extrapolation (EP2) for the explicit treatment of the nonlinear term, we arrive at a second-order scheme (BD2/EP2) for (2.1):

(3.1)
$$\begin{aligned}&\frac{3h^{n+1}-4h^n+h^{n-1}}{2\Delta t}+\delta\Delta^2 h^{n+1}-A\Delta h^{n+1}\\ &=-2A\Delta h^n+A\Delta h^{n-1}-\nabla\cdot[(1-|\nabla(2h^n-h^{n-1})|^2)\nabla(2h^n-h^{n-1})]\quad\forall n\geq 1.\end{aligned}$$

As usual, to start the iteration $h^0(\mathbf{x})$ is given by the initial condition, and $h^1(\mathbf{x})$ is computed by the first-order scheme (2.4).

THEOREM 3.1. *If the constant A in* (3.1) *is sufficiently large, then the following energy inequality holds:*

$$\widetilde{E}^{n+1}\leq\widetilde{E}^n+\mathcal{O}(\Delta t^2), \tag{3.2}$$

where $\widetilde{E}^n$ is defined by

$$\widetilde{E}^n=\frac{1}{\Delta t}\|h^n-h^{n-1}\|^2+\frac{1}{4}\left\||\nabla h^n|^2-1\right\|^2+\frac{\delta}{2}\|\Delta h^n\|^2+\frac{A}{2}\|\nabla(h^n-h^{n-1})\|^2. \tag{3.3}$$

In particular, we can obtain

$$E(h^n)\leq E(h^1)+\mathcal{O}(\Delta t), \tag{3.4}$$

where E is defined by (2.7). *Moreover, if the numerical solution of* (3.1) *is convergent in $L^\infty([0,T];W^{1,\infty}(\Omega))$ as $\Delta t\to 0$, then the constant A can be chosen to satisfy*

$$A\geq 3|\nabla h|^2-1\quad a.e.\ in\ \Omega\times(0,T], \tag{3.5}$$

where $h(x,t)$ is a solution of (2.1).

Proof. For ease of notation, let $\delta_t h^n=h^{n+1}-h^n$ and $\delta_{tt}h^n=h^{n+1}-2h^n+h^{n-1}$. Multiplying both sides of (3.1) by $\delta_t h^n$ and integrating the resulting equation in Ω give

$$I_1^n+I_2^n+I_3^n=I_4^n, \tag{3.6}$$

where

$$\begin{aligned}I_1^n&:=\frac{1}{2\Delta t}\langle 3\delta_t h^n-\delta_t h^{n-1}\,,\,\delta_t h^n\rangle,\\ I_2^n&:=\delta\langle\Delta^2 h^{n+1}\,,\,\delta_t h^n\rangle,\\ I_3^n&:=-A\left\langle\Delta\delta_{tt}h^n\,,\,\delta_t h^n\right\rangle,\\ I_4^n&:=-\left\langle\nabla\cdot[(1-|\nabla(2h^n-h^{n-1})|^2)\nabla(2h^n-h^{n-1})]\,,\,\delta_t h^n\right\rangle.\end{aligned}$$

We now estimate them term by term. The estimate for the first three terms is straightforward:

$$I_1^n\geq\frac{5}{4\Delta t}\|\delta_t h^n\|^2-\frac{1}{4\Delta t}\|\delta_t h^{n-1}\|^2\geq\frac{1}{\Delta t}\|\delta_t h^n\|^2-\frac{1}{\Delta t}\|\delta_t h^{n-1}\|^2, \tag{3.7}$$

$$I_2^n=\delta\left\langle\Delta h^{n+1}\,,\,\Delta h^{n+1}-\Delta h^n\right\rangle\geq\frac{\delta}{2}\|\Delta h^{n+1}\|^2-\frac{\delta}{2}\|\Delta h^n\|^2, \tag{3.8}$$

$$\begin{aligned}I_3^n&=A\left\langle\delta_{tt}\nabla h^n\,,\,\delta_t\nabla h^n\right\rangle=A\left\langle\delta_t\nabla h^n-\delta_t\nabla h^{n-1}\,,\,\delta_t\nabla h^n\right\rangle\\ &=\frac{A}{2}\|\delta_t\nabla h^n\|^2-\frac{A}{2}\|\delta_t\nabla h^{n-1}\|^2+\frac{A}{2}\|\delta_{tt}\nabla h^n\|^2.\end{aligned} \tag{3.9}$$

To estimate I_4^n, we need the following two identities. On one hand, we have

(3.10)
$$\begin{aligned}
&\nabla(2h^n - h^{n-1}) \cdot \nabla(h^{n+1} - h^n) \\
&= \nabla(2h^n - h^{n-1}) \cdot \nabla h^{n+1} - \nabla(2h^n - h^{n-1}) \cdot \nabla h^n \\
&= -\frac{1}{2}|\delta_{tt}\nabla h^n|^2 + \frac{1}{2}|\nabla(2h^n - h^{n-1})|^2 + \frac{1}{2}|\nabla h^{n+1}|^2 - \nabla(2h^n - h^{n-1}) \cdot \nabla h^n,
\end{aligned}$$

and on the other hand,

(3.11)
$$\begin{aligned}
&\nabla(2h^n - h^{n-1}) \cdot \nabla(h^{n+1} - h^n) = \nabla h^n \cdot \nabla(h^{n+1} - h^n) + \delta_t \nabla h^n \cdot \delta_t \nabla h^{n-1} \\
&= \frac{1}{2}|\nabla h^{n+1}|^2 - \frac{1}{2}|\nabla h^n|^2 - \frac{1}{2}|\delta_t \nabla h^n|^2 - \frac{1}{2}|\delta_{tt}\nabla h^n|^2 + \frac{1}{2}|\delta_t \nabla h^n|^2 + \frac{1}{2}|\delta_t \nabla h^{n-1}|^2 \\
&= \frac{1}{2}|\nabla h^{n+1}|^2 - \frac{1}{2}|\nabla h^n|^2 - \frac{1}{2}|\delta_{tt}\nabla h^n|^2 + \frac{1}{2}|\delta_t \nabla h^{n-1}|^2.
\end{aligned}$$

Using (3.10) gives

(3.12)
$$\begin{aligned}
&\left\langle -|\nabla(2h^n - h^{n-1})|^2 \nabla(2h^n - h^{n-1}),\, \nabla(h^{n+1} - h^n) \right\rangle \\
&= \frac{1}{2}\left\langle |\nabla(2h^n - h^{n-1})|^2,\, |\delta_{tt}\nabla h^n|^2 \right\rangle + J_4^n,
\end{aligned}$$

where

$$\begin{aligned}
J_4^n &:= \left\langle -|\nabla(2h^n - h^{n-1})|^2,\, \frac{1}{2}|\nabla(2h^n - h^{n-1})|^2 + \frac{1}{2}|\nabla h^{n+1}|^2 - \nabla(2h^n - h^{n-1}) \cdot \nabla h^n \right\rangle \\
&= \frac{1}{2}\left\langle 1,\, -|\nabla(2h^n - h^{n-1})|^4 \right\rangle + \frac{1}{2}\left\langle -|\nabla(2h^n - h^{n-1})|^2,\, |\nabla h^{n+1}|^2 \right\rangle \\
&\quad + \left\langle |\nabla(2h^n - h^{n-1})|^2,\, \nabla(2h^n - h^{n-1}) \cdot \nabla h^n \right\rangle \\
&= -\frac{3}{4}\left\langle 1,\, |\nabla(2h^n - h^{n-1})|^4 \right\rangle + \frac{1}{4}\| |\nabla(2h^n - h^{n-1})|^2 - |\nabla h^{n+1}|^2 \|^2 \\
&\quad - \frac{1}{4}\left\langle 1,\, |\nabla h^{n+1}|^4 \right\rangle + \left\langle |\nabla(2h^n - h^{n-1})|^2,\, \nabla(2h^n - h^{n-1}) \cdot \nabla h^n \right\rangle.
\end{aligned}$$

Using the Schwartz inequality to the last term above gives

$$\begin{aligned}
&\left\langle |\nabla(2h^n - h^{n-1})|^2,\, \nabla(2h^n - h^{n-1}) \cdot \nabla h^n \right\rangle \\
&\le \frac{1}{2}\left\langle |\nabla(2h^n - h^{n-1})|^2,\, |\nabla(2h^n - h^{n-1})|^2 \right\rangle + \frac{1}{2}\left\langle |\nabla(2h^n - h^{n-1})|^2,\, |\nabla h^n|^2 \right\rangle \\
&\le \frac{1}{2}\left\langle 1,\, |\nabla(2h^n - h^{n-1})|^4 \right\rangle + \frac{1}{4}\left\langle 1,\, |\nabla(2h^n - h^{n-1})|^4 \right\rangle + \frac{1}{4}\left\langle 1,\, |\nabla h^n|^4 \right\rangle \\
&= \frac{3}{4}\left\langle 1,\, |\nabla(2h^n - h^{n-1})|^4 \right\rangle + \frac{1}{4}\left\langle 1,\, |\nabla h^n|^4 \right\rangle.
\end{aligned}$$

Combining the above two results gives

(3.13)
$$\begin{aligned}
J_4^n &\le \frac{1}{4}\| |\nabla(2h^n - h^{n-1})|^2 - |\nabla h^{n+1}|^2 \|^2 - \frac{1}{4}\left\langle 1,\, |\nabla h^{n+1}|^4 \right\rangle + \frac{1}{4}\left\langle 1,\, |\nabla h^n|^4 \right\rangle \\
&= \frac{1}{4}\left\langle |\nabla(h^{n+1} + 2h^n - h^{n-1})|^2,\, |\delta_{tt}\nabla h^n|^2 \right\rangle - \frac{1}{4}\left\langle 1,\, |\nabla h^{n+1}|^4 \right\rangle + \frac{1}{4}\left\langle 1,\, |\nabla h^n|^4 \right\rangle.
\end{aligned}$$

Using the definition of I_4^n, together with (3.11), (3.12), and (3.13), we have

$$\begin{aligned}
I_4^n &= \left\langle (1-|\nabla(2h^n-h^{n-1})|^2)\nabla(2h^n-h^{n-1})\,,\,\nabla(h^{n+1}-h^n)\right\rangle \\
&= \frac{1}{2}\|\nabla h^{n+1}\|^2-\frac{1}{2}\|\nabla h^n\|^2-\frac{1}{2}\|\delta_{tt}\nabla h^n\|^2+\frac{1}{2}\|\delta_t\nabla h^{n-1}\|^2 \\
&\quad +\frac{1}{2}\left\langle |\nabla(2h^n-h^{n-1})|^2\,,\,|\delta_{tt}\nabla h^n|^2\right\rangle + J_4^n \\
&\le -\frac{1}{2}\left\langle 1-|\nabla(2h^n-h^{n-1})|^2\,,\,|\delta_{tt}\nabla h^n|^2\right\rangle+\frac{1}{2}\|\nabla h^{n+1}\|^2-\frac{1}{2}\|\nabla h^n\|^2+\frac{1}{2}\|\delta_t\nabla h^{n-1}\|^2 \\
&\quad +\frac{1}{4}\left\langle |\nabla(h^{n+1}+2h^n-h^{n-1})|^2\,,\,|\delta_{tt}\nabla h^n|^2\right\rangle-\frac{1}{4}\left\langle 1,|\nabla h^{n+1}|^4\right\rangle+\frac{1}{4}\left\langle 1,|\nabla h^n|^4\right\rangle \\
&= \left\langle \frac{1}{2}|\nabla(2h^n-h^{n-1})|^2-\frac{1}{2}+\frac{1}{4}|\nabla(h^{n+1}+2h^n-h^{n-1})|^2\,,\,|\delta_{tt}\nabla h^n|^2\right\rangle \\
&\quad -\frac{1}{4}\||\nabla h^{n+1}|^2-1\|^2+\frac{1}{4}\||\nabla h^n|^2-1\|^2+\frac{1}{2}\|\delta_t\nabla h^{n-1}\|^2.
\end{aligned}$$

The above result, together with (3.6) and (3.7)–(3.9), yields

$$\begin{aligned}
\widetilde{E}^{n+1} &\le \widetilde{E}^n+\frac{1}{2}\|\delta_t\nabla h^{n-1}\|^2 \\
&\quad +\left\langle -\frac{A}{2}+\frac{1}{2}|\nabla(2h^n-h^{n-1})|^2-\frac{1}{2}+\frac{1}{4}|\nabla(h^{n+1}+2h^n-h^{n-1})|^2\,,\,|\delta_{tt}\nabla h^n|^2\right\rangle.
\end{aligned}$$

The last term above can be made nonpositive provided that

$$A\ge |\nabla(2h^n-h^{n-1})|^2-1+\frac{1}{2}|\nabla(h^{n+1}+2h^n-h^{n-1})|^2 \qquad \text{a.e. in } \Omega.$$

Using the fact that

$$\|\delta_t\nabla h^{n-1}\|^2=\Delta t^2\|\nabla(h^n-h^{n-1})/\Delta t\|^2=\mathcal{O}(\Delta t^2),$$

we obtain (3.2). Summing (3.2) over n gives $\widetilde{E}^n\le\widetilde{E}^1+\mathcal{O}(\Delta t)$. In particular, by using the definition of $\widetilde{E}$ and the energy E defined by (2.7), we have

$$E(h^n)\le E(h^1)+\mathcal{O}(1)\Delta t,$$

where the $\mathcal{O}(1)$ term is given by

$$\begin{aligned}
\mathcal{O}(1) &= \|(h^1-h^0)/\Delta t\|^2+\frac{A}{2}\Delta t\|\nabla(h^1-h^0)/\Delta t\|^2 \\
&\quad +\sum_{i=1}^{n-1}\Delta t\|\nabla(h^i-h^{i-1})/\Delta t\|^2.
\end{aligned}$$

This completes the proof of this theorem. ∎

Remark 3.1. By comparing (2.9) and (3.5), we notice that the constant A used for the second-order scheme is two times larger than that for the first-order scheme.

Similarly, a second-order scheme of the BD2/EP2-type can be constructed for the square symmetry current model (2.2):

$$\begin{aligned}
&\frac{3h^{n+1}-4h^n+h^{n-1}}{2\Delta t}+\delta\Delta^2h^{n+1}-A\Delta h^{n+1} \\
&\quad =-2A\Delta h^n+A\Delta h^{n-1}-\left[\left(1-(2h_x^n-h_x^{n-1})^2\right)(2h_x^n-h_x^{n-1})\right]_x \\
&\qquad -\left[\left(1-(2h_y^n-h_y^{n-1})^2\right)(2h_y^n-h_y^{n-1})\right]_y.
\end{aligned} \tag{3.14}$$

Then an analysis similar to that of Theorem 3.1 can be carried out to obtain a stability result. The details will be omitted here.

3.2. Third-order scheme: BD3/EP3. A third-order scheme for solving the MBE model of general form (1.1) can be constructed in a similar manner as used in the last subsection. Specifically, we can obtain the BD3/EP3 scheme in the following form:

$$\begin{aligned}(3.15)\quad &\frac{11h^{n+1}-18h^n+9h^{n-1}-2h^{n-2}}{6\Delta t}+\delta\Delta^2 h^{n+1}-A\Delta h^{n+1}\\ &=-A\Delta(3h^n-3h^{n-1}+h^{n-2})-\nabla\cdot J(\nabla(3h^n-3h^{n-1}+h^{n-2}))\quad \forall n\geq 2,\end{aligned}$$

where, in order to start the iteration, h^1, h^2 are calculated via a first- and second-order scheme, respectively.

The stability analysis of the scheme (3.15) requires some very detailed energy estimates and will not be presented here. The numerical results obtained in the next two sections indicate that the third-order time discretization of type (3.15) is also stable as long as the constant A is sufficiently large.

4. Numerical experiments: Stability and accuracy tests. A complete numerical algorithm also requires a discretization strategy in space. Since the Fourier spectral method is one of the most suitable spatial approximation methods for periodic problems [2, 5, 21, 25], it will be employed to handle the spatial discretization. To demonstrate the principal ideas, we consider the full discretization for the MBE model with the isotropic current using the first-order time-stepping method, namely, we will consider only the full discretization for (2.4). It is to find an approximate solution $h_K^n(\mathbf{x})$ in form of a truncated Fourier expansion:

$$h_K^n(\mathbf{x})=\sum_{k_1,k_2=-K}^{K}\hat{h}_{\mathbf{k}}^n\exp(-\mathrm{i}\mathbf{k}\mathbf{x}),$$

where $\mathbf{k}=(k_1,k_2)$ and K is a positive integer. The above expansion is required to satisfy the following weak formulation:

$$\begin{aligned}(4.1)\quad &\frac{1}{\Delta t}\left\langle h_K^{n+1}-h_K^n,\varphi\right\rangle+\delta\left\langle\Delta h_K^{n+1},\Delta\varphi\right\rangle+A\left\langle\nabla h_K^{n+1},\nabla\varphi\right\rangle\\ &=\left\langle(1-|\nabla h_K^n|^2+A)\nabla h_K^n,\nabla\varphi\right\rangle\ \ \forall\varphi\in S_K,\end{aligned}$$

where

$$S_K=\mathrm{span}\{\exp(-\mathrm{i}\mathbf{k}\mathbf{x}),\quad -K\leq k_1,k_2\leq K\}.$$

For the full discretization problem (4.1), an energy inequality similar to that of Theorem 2.1 can be derived (its proof will be omitted here).

THEOREM 4.1. *Consider the numerical scheme* (4.1). *If*

$$(4.2)\qquad A\geq\max_{\mathbf{x}\in\Omega}\left\{\frac{1}{2}(|\nabla h_K^n|^2-1)+\frac{1}{4}|\nabla h_K^{n+1}+\nabla h_K^n|^2\right\},$$

then the solution of (4.1) *satisfies*

$$(4.3)\qquad E(h_K^{n+1})\leq E(h_K^n)\quad\forall n\geq 0,$$

where the energy E is defined by (2.7). *Moreover, if the numerical solution of* (4.1) *is convergent in* $L^\infty([0,T];W^{1,\infty}(\Omega))$ *as* $K\to\infty$ *and* $\Delta t\to 0$, *then the constant* A *can be chosen to satisfy*

$$A \ge \frac{3}{2}|\nabla h|^2 - \frac{1}{2} \qquad a.e.\ in\ \Omega\times(0,T], \tag{4.4}$$

where $h(\mathbf{x},t)$ *is a solution of* (2.1).

By applying the Fourier transformation to (2.4), we obtain a set of ordinary differential equations for each mode $\mathbf{k}$ in the Fourier space,

$$\frac{\hat h_{\mathbf{k}}^{n+1}-\hat h_{\mathbf{k}}^{n}}{\Delta t} + \delta|\mathbf{k}|^4\hat h_{\mathbf{k}}^{n+1} + A|\mathbf{k}|^2\hat h_{\mathbf{k}}^{n+1} = -\mathrm{i}\mathbf{k}\left\{(1-|\nabla h_K^n|^2+A)\nabla h_K^n\right\}_{\mathbf{k}}, \tag{4.5}$$

where $|\mathbf{k}| = \sqrt{k_1^2+k_2^2}$ is the magnitude of $\mathbf{k}$ and $\{f\}_{\mathbf{k}}$ represents the $\mathbf{k}$th-mode Fourier coefficient of the function f. The Fourier coefficients of the nonlinear term $(1-|\nabla h_K^n|^2+A)\nabla h_K^n$ are calculated by performing the discrete fast Fourier transform (FFT). It is readily seen that for a given level n the evaluation of all $\{(1-|\nabla h_K^n|^2+A)\nabla h_K^n\}_{\mathbf{k}}$ requires $8N$ one-dimensional FFT with vector length $N=2K$. This is also the total cost to compute $\hat h_{\mathbf{k}}^{n+1}$ from (4.5). In practical calculation, we work on the spectral space. At the final time level, an additional FFT is needed to recover the physical nodal values $h_K^{n+1}(\mathbf{x})$ from $\hat h_{\mathbf{k}}^{n+1}, -K\le k_1,k_2\le K$.

The purpose of this section is to verify the stability of the proposed numerical schemes in terms of the choice of the constant A. More serious applications will be reported in the next section.

Example 4.1. Consider an isotropic symmetry current model (2.1):

$$\begin{cases} h_t = -\delta\Delta^2 h - \nabla\cdot[(1-|\nabla h|^2)\nabla h], & [0,2\pi]^2\times(0,T],\\ h(\cdot,t)\ \text{is}\ 2\pi-\text{periodic} & \forall t\in(0,T],\\ h(\mathbf{x},0)=h_0(\mathbf{x}) & \forall \mathbf{x}\in[0,2\pi]^2 \end{cases} \tag{4.6}$$

with $\delta = 0.1, 0.01, 0.001$ and

$$h_0(\mathbf{x}) = 0.1(\sin 3x\sin 2y + \sin 5x\sin 5y). \tag{4.7}$$

This problem was used by Li and Liu [12] to study the most unstable modes. It was proved that with the initial condition (4.7) the most unstable modes are those with wave-vectors $\mathbf{k}$ such that $|\mathbf{k}|=\sqrt{5}$. Numerically, they showed that after short interaction of the unstable modes, the solution converges to a *steady state* which consists mainly of one mode only.

Define Δt_c as the largest possible time which allows stable numerical computation. In other words, if the time step is greater than Δt_c, then the numerical solution will blow up. In Table 1, we list the values of Δt_c for the schemes (2.4), (3.1), and (3.15) with different choices of A. All these semidiscrete schemes are approximated by the Fourier spectral methods in space. The Fourier mode number used in the calculations is $K=128$. Several observations are made from Table 1:

- If $A=0$, i.e., if a conventional implicit-explicit approach is used, then the numerical methods suffer from extremely small time steps, in particular when higher-order schemes are used or $\delta\ll 1$.
- The improvement on stability with the use of the constant A is significant. When A is sufficiently large (in this case $A\ge 2$), quite large time steps (in this case $\Delta t\ge 1$) can be used for first- and second-order time discretizations.

TABLE 1
Example 4.1: *stability comparison with different* A *and* δ. *Here* BDr *stands for* r*th-order backward differentiation and* EPr *for* r*th-order extrapolation.*

δ	A	BD1/EP1	BD2/EP2	BD3/EP3
0.1	$A=0$	$\Delta t_c \approx 1$	$\Delta t_c < 0.3$	$\Delta t_c < 0.1$
	$A=1$	$\Delta t_c \approx 1$	$\Delta t_c \approx 1$	$\Delta t_c \approx 0.5$
	$A=2$	$\Delta t_c \approx 1$	$\Delta t_c \approx 1$	$0.2 \le \Delta t_c < 0.5$
0.01	$A=0$	$\Delta t_c < 0.1$	$\Delta t_c < 0.01$	$\Delta t_c < 0.002$
	$A=1$	$\Delta t_c \approx 1$	$\Delta t_c \approx 0.1$	$\Delta t_c \approx 0.002$
	$A=2$	$\Delta t_c \approx 1$	$\Delta t_c \approx 1$	$\Delta t_c \approx 0.05$
0.001	$A=0$	$\Delta t_c < 0.01$	$\Delta t_c < 0.001$	$\Delta t_c < 10^{-4}$
	$A=1$	$\Delta t_c \approx 1$	$\Delta t_c \approx 0.005$	$0.0005 \le \Delta t_c < 10^{-3}$
	$A=2$	$\Delta t_c \approx 1$	$\Delta t_c \approx 1$	$\Delta t_c \approx 0.005$

- The choice of A depends on the order of time discretization. For the third-order methods, a quite small time step has to be used, which is impractical for large time simulations.

We now turn to time accuracy comparison. Since the exact solution for problem (4.6) is unknown, we use numerical results of BD3/EP3 with $\Delta t = 0.0001$ and $K = 128$ as the "exact" solution. The coefficient δ is set to be 0.01 and the numerical errors are computed at $t = 1$. In this case, the "exact" solution obtained by using BD3/EP3 is plotted in Figure 1. Table 2 shows the L^2-errors using several values of A and

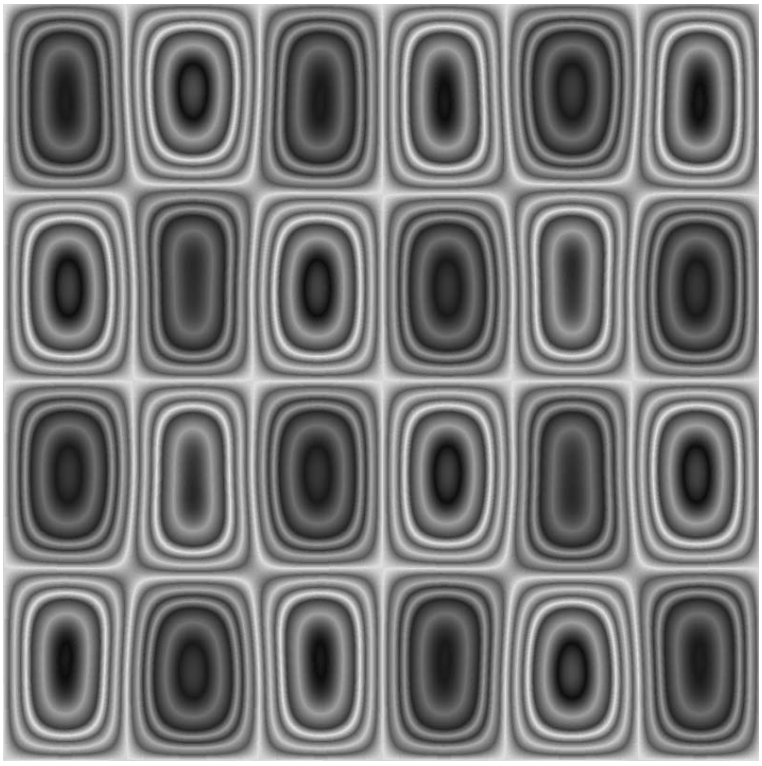

FIG. 1. *Isolines of the solution at* $t = 1$ *for* $\delta = 0.01$.

TABLE 2
Example 4.1: *accuracy with different choices of* A. $\delta = 0.01$.

A	Δt	BD1/EP1	BD2/EP2	BD3/EP3
$A = 0$	$\Delta t = 0.01$	0.72E-03	unstable	unstable
	$\Delta t = 0.005$	0.36E-03	0.24E-04	unstable
	$\Delta t = 0.0025$	0.18E-03	0.61E-05	unstable
	$\Delta t = 0.00125$	0.90E-04	0.16E-05	unstable
$A = 1$	$\Delta t = 0.01$	0.22E-02	0.21E-03	unstable
	$\Delta t = 0.005$	0.11E-02	0.56E-04	unstable
	$\Delta t = 0.0025$	0.51E-03	0.14E-04	unstable
	$\Delta t = 0.00125$	0.25E-03	0.37E-05	0.43E-06
$A = 2$	$\Delta t = 0.01$	0.43E-02	0.32E-03	0.22E-03
	$\Delta t = 0.005$	0.19E-02	0.87E-04	0.21E-04
	$\Delta t = 0.0025$	0.88E-03	0.23E-04	0.30E-05
	$\Delta t = 0.00125$	0.43E-03	0.58E-05	0.53E-06

four time steps. It is seen that once the methods are stable, the expected order of convergence (in time) is obtained.

5. Numerical experiments: Coarsening dynamics. In this section, we present the numerical results by simulating the MBE model (1.1) in cases of both isotropic surface (2.1) and square surface (2.2). The simulations are carried out in the domain $\Omega = (0, 1000)^2$, where double periodic boundary conditions are used in the spatial directions. The initial condition is a random state by assigning a random number varying from -0.001 to 0.001 to each grid point. The second-order schemes, i.e., (3.1) for the isotropic surface model and (3.14) for the square surface model, are used in our simulations. The spatial discretization is based on a Fourier pseudospectral approximation with K denoting the Fourier mode number. In order to investigate the effect of the time and space resolution, different values of Δt and K have been tested.

5.1. Growth on the isotropic symmetry surfaces. First we carry out the simulation of the growth process for the case of isotropic surfaces. In Figures 2 and 3, the isolines of the free energy $F_{free}(\mathbf{x}, t)$ at $t = 40{,}000$ and 80,000 are plotted, respectively, with $(K, \Delta t) = (512, 1)$ and $A = 1$, where $F_{free}(\mathbf{x}, t)$ is defined by

$$F_{free} = \frac{1}{4}(|\nabla h|^2 - 1)^2 + \frac{\delta}{2}|\Delta h|^2.$$

The contourlines of F_{free} are usually used to identify the edges of the pyramidal structures since the free energy is concentrated on the edges. In these two figures the temporal evolution of the morphology of the growing surface is well visualized. It is seen that the edges of the pyramids (white areas) form a random network over the surface and separate the facets of the pyramids. The pyramids grow in time via a coarsening process, as is evident from Figures 2 and 3. Also shown is the randomness of the orientation of the pyramid edges, resulting from the isotropic nature of the surface symmetry. This result is in good agreement with the published results; see, e.g., [14].

Figure 4 presents the power laws of the growth of the interface height $\tilde{h}(t)$ and width $\lambda(t)$ of the pyramidal structures. Here $\tilde{h}(t)$ is defined by

$$\tilde{h}(t) = \left(\frac{1}{|\Omega|}\int_\Omega h^2(\mathbf{x}, t)d\mathbf{x}\right)^{\frac{1}{2}}.$$

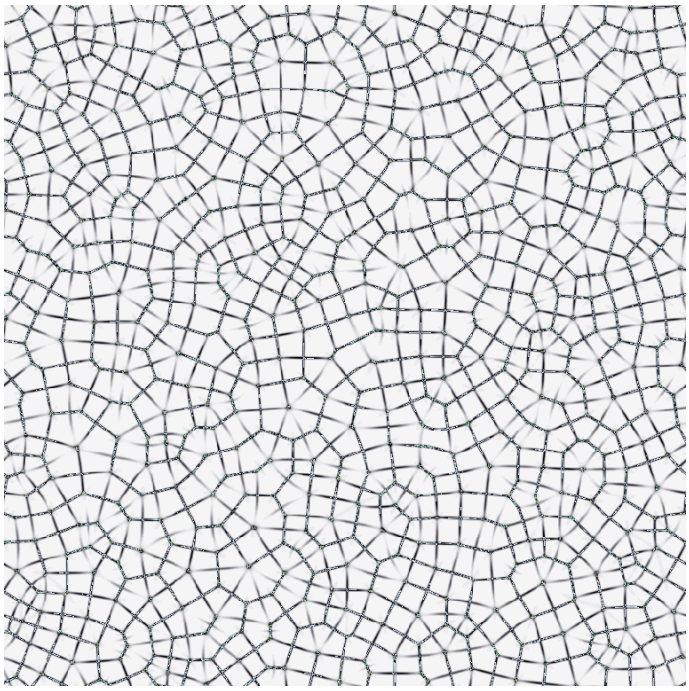

FIG. 2. *The isotropic symmetry surfaces problem: the contour plot at* $t = 40{,}000$, *obtained by using* $K = 512$ *and* $\Delta t = 1$.

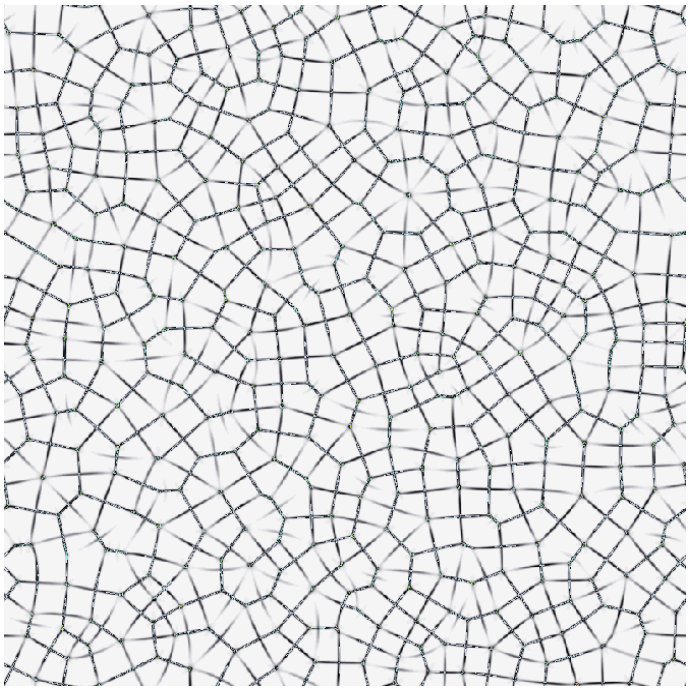

FIG. 3. *Same as Figure* 2, *except at* $t = 80{,}000$.

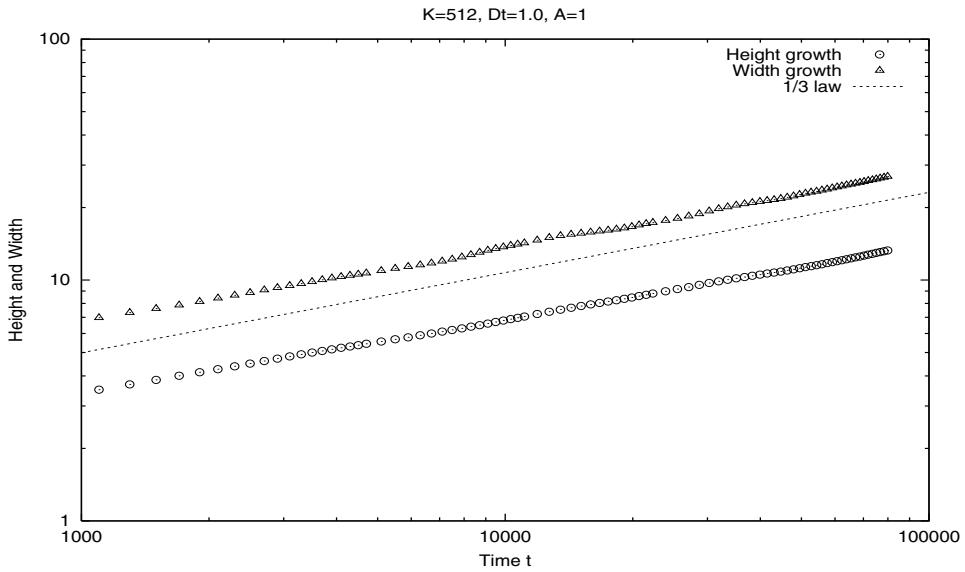

FIG. 4. *The isotropic symmetry surfaces problem: growth power law obtained by using* $K = 512$ *and* $\Delta t = 1$ *(log-to-log scale).*

The width of the pyramid edges $\lambda(t)$ measures the mean size of the network cell, which can be calculated as in [14] from the height-height correlation function

$$K_{hh}(\mathbf{r}, t) = \int_{\Omega} h(\mathbf{x} + \mathbf{r}, t) h(\mathbf{x}, t) d\mathbf{x},$$

where $\mathbf{r}$ is a positive vector. In our calculations, we used a simpler form $\mathbf{r} = (r, r)^T$. With $\mathbf{r} = (r, r)^T$, $K_{hh}(\mathbf{r}, t)$ can be considered as a function of r for fixed t, and shows an oscillatory character reflecting the presence of mound structures. For a given t, the mean pyramid width $\lambda(t)$ is defined as $r_0(t)$, which is the first zero crossing of $K_{hh}(\mathbf{r}, t)$,

$$r_0(t) = \inf\{r > 0, K_{hh}(\mathbf{r}, t) = 0\}.$$

We see from Figure 4 that both vertical height and lateral width of the pyramids grow in time as power law ct^n with exponents n close to $\frac{1}{3}$ (slope of the lines), which is again in good agreement with the existing experimental and numerical results [14, 23].

In order to check the temporal and spatial resolution, we display in Figure 5 the result obtained by using $(K, \Delta t) = (256, 0.5)$, i.e., halving the values of K and Δt. It is observed from Figures 4 and 5 that there is no significant difference between the results obtained by using the two sets of parameters.

To demonstrate the robustness of the proposed method, we plot in Figure 6 the evolution of the mean height

$$\bar{h}(t) = \frac{1}{|\Omega|} \int_{\Omega} h(\mathbf{x}, t) d\mathbf{x}.$$

It is observed that $\bar{h}(t)$ remains practically zero in the entire time intervals. This demonstrates the mass conservation which can be derived from (2.1). The energy defined in (2.7), normalized by the domain size, is plotted in Figure 7. The decay of the energy as observed in Figure 7 agrees with the theoretical result (2.6).

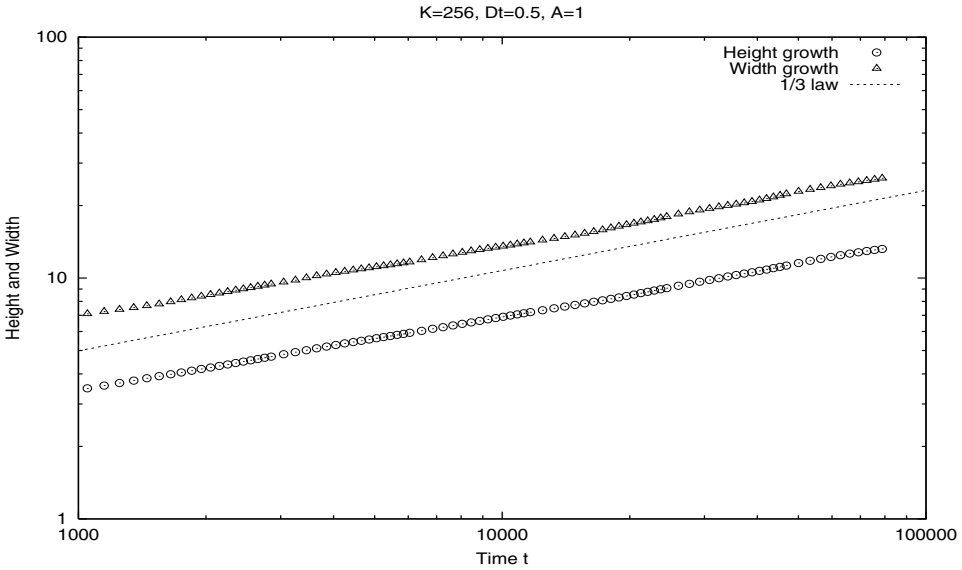

FIG. 5. *Same as Figure* 4, *except with* $K = 256$ *and* $\Delta t = 0.5$.

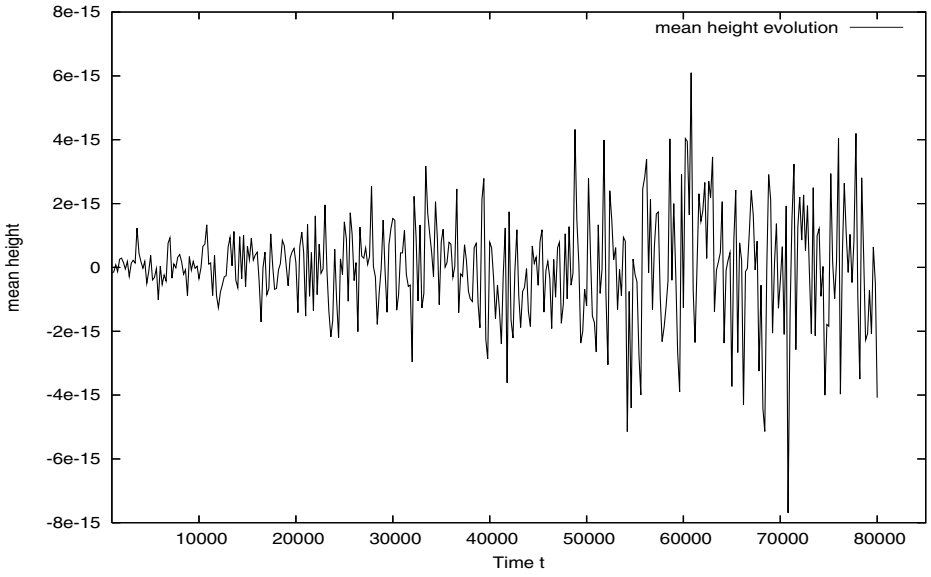

FIG. 6. *Evolution of the mean height as a function of the time.*

5.2. Growth on the square symmetry surfaces. Here we present simulation results obtained by solving the MBE model (2.2). The time discretization used in the simulation is the second-order scheme (3.14), and the space discretization is the same as in the isotropic case but here with Fourier mode number $K = 384$ and time step $\Delta t = 0.2$.

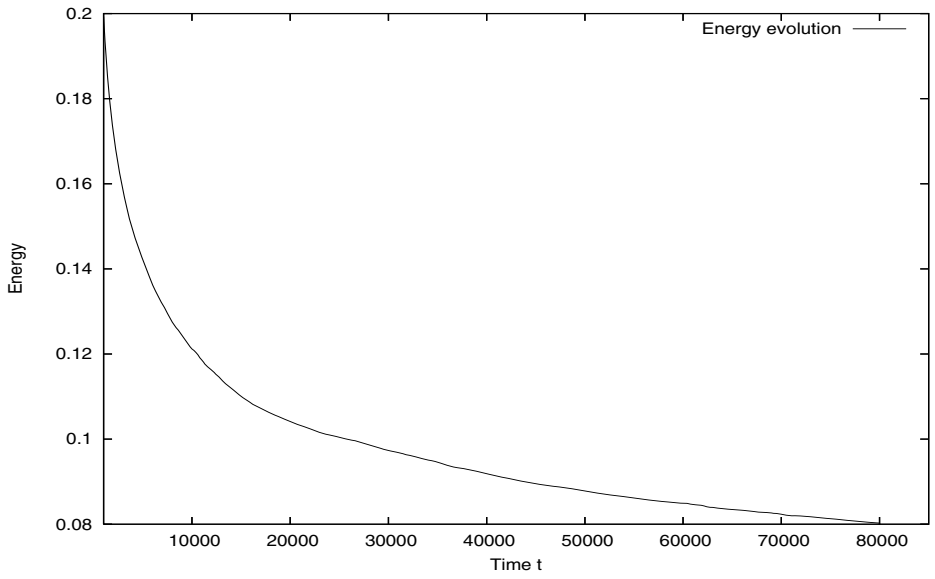

FIG. 7. *Evolution of the energy as a function of the time.*

In Figures 8 and 9, we plot the contourlines of the free energy function F'_{free} corresponding to the square symmetry model,

$$F'_{free} = \frac{\delta}{2}|\Delta h|^2 + \frac{1}{4}\left[(h_x^2-1)^2 + (h_y^2-1)^2\right].$$

As in the case of the isotropic surfaces, pyramid-like structures are growing in the surface with sharp edges carrying most of the energy, identified by the network formed by the white areas. However, in contrast to the isotropic case, the pyramid edges are well oriented toward the four preferred directions reflecting the square symmetry. A careful look at the two figures finds that the well-known dislocation feature is also presented, as reported by many experiments and simulations. Moreover, it is observed from Figure 10 that the power law obtained for the pyramid growth with the square symmetry is close to $\frac{1}{4}$. This is in good agreement with the numerical predictions of Siegert [19] and Moldovan and Golubovic [14].

6. Conclusions. In this work, we have developed and analyzed stable numerical methods for a class of nonlinear diffusion equations modeling epitaxial growth of thin films. Here, stability means that the decay of energy is preserved. In particular, we analyzed the stability properties of a class of semidiscretized (in time) schemes which are designed for large-system and long-time simulations. It is demonstrated that the classical semi-implicit method can be improved by simply adding some linear terms consistent with the truncation errors in time. The linear term consists of mixed derivatives, and the resulting numerical schemes are still semi-implicit with explicit treatment for the nonlinear terms. We also performed numerical simulations using the proposed schemes in time coupled with a Fourier spectral method in space for the molecular beam epitaxy model and determined power laws for the coarsening process. The numerical results are in good agreement with the existing ones, e.g., Moldovan and Golubovic [14] who directly solved a so-called type-A dynamics equation on a hexagonal grid.

One of the future works in this direction is to carry out more rigorous analysis for the large time-stepping techniques, including stability analysis for higher-order schemes (say, third-order time-stepping) and error analysis for the proposed schemes. Obtaining a satisfactory error bound for a numerical scheme for the MBE models seems difficult: A direct error analysis shows that the error bounds are dependent on the surface diffusion constant δ and the solution time interval, which leads to unacceptable estimates for small δ and large T. A desired bound should have weak dependence on δ and T, which seems very difficult. Other future works in this direction include adaptive time integration, i.e., treating the fast dynamics changes and slow changes separately. This is also important in improving the efficiency for the large-time simulations.

Acknowledgments. This work was motivated by several discussions and communications with Bo Li and Jian-Guo Liu during the second author's visit to the Center for Scientific Computation and Mathematical Modeling (CSCAMM) of the University of Maryland. We also thank the referees for helpful suggestions.

FINDING NUMERICAL DERIVATIVES FOR UNSTRUCTURED AND NOISY DATA BY MULTISCALE KERNELS*

LEEVAN LING†

Abstract. The recently developed multiscale kernel of R. Opfer [*Adv. Comput. Math.*, 25 (2006), pp. 357–380] is applied to approximate numerical derivatives. The proposed method is truly mesh-free and can handle unstructured data with noise in any dimension. The method of Tikhonov and the method of L-curve are employed for regularization; no information about the noise level is required. An error analysis is provided in a general setting for all dimensions. Numerical comparisons are given in two dimensions which show competitive results with recently published thin plate spline methods.

Key words. numerical differentiation, multiscale kernel, multivariate interpolation, unstructured data, inverse problems, Tikhonov regularization, L-curve.

1. Introduction. Evaluating derivatives of a function using only information from discrete function values is a typical ill-posed problem. Small measurement errors, including rounding errors, will be greatly amplified during the numerical differentiation process. The problem of *numerical differentiation* arises in many branches of science and engineering. Some practical examples are the identification of discontinuities in image reconstruction [10, 13], resolution enhancement of spectra [17], solving Abel integral equations [7, 12], determination of peaks in chemical spectroscopy [24], determination of discontinuous points of the exact solutions [33], solving integral equations [8], determination of source parameter and diffusion coefficient in parabolic differential equations [6, 14], simulation of constrained mechanical systems of particles [19], singular convolution [25], and many other inverse problems in mathematical physics. The previous literature on numerical differentiation featured plenty of nicely calculated practical solutions, but most research papers on this topic are limited to one dimension or highly structured grids [4, 14, 20, 26, 27, 30, 33]. Numerical methods for higher dimensions are very limited. In particular, many existing methods are based on finite difference schemes [2], wavelet methods [5], and thin plate splines approximation [34]. The goal of this paper is to supply a new, efficient, and practical alternative for scientists and engineers who need to compute numerical differentiation from real-life, large-scale, and noisy multivariate data.

Given some set of real-life data in any dimension, multivariate functions are reconstructed from unstructured data by some specially designed multiscale kernels

$$\Phi(x,\cdot)=\sum_{j=0}^{u}\sum_{k\in\mathbb{Z}^d}\lambda_\sigma^j\varphi(2^jx-k)\varphi(2^j\cdot-k).$$

Since multiscale kernels are proven to be positive definite, for every set of data points we can solve an interpolation problem and write the interpolant in the form

*Received by the editors April 28, 2005; accepted for publication (in revised form) March 27, 2006; published electronically September 26, 2006. This research was partially supported by a Postdoctoral Fellowship from the Japan Society for the Promotion of Science.

of the *kernel representation*:

$$s = \sum_{i=1}^{n} \beta_i \Phi(x_i, \cdot). \tag{1.1}$$

The multiscale property, found in wavelet analysis, is considered a major breakthrough in the development of kernel-based mesh-free methods. We can go one step further and express (1.1) in its *frame representation*:

$$s = \sum_{j=1}^{u} \sum_{k \in \mathbb{Z}^d} \lambda_\sigma^j c_k^j \varphi(2^j \cdot - k), \tag{1.2}$$

where $c_k^j = c_k^j(\{x_i\}, \beta_i)$ are called the frame coefficients. The interpolant obtained will have a frame representation on structured grids instead of the unstructured data. The solution process involves solving a sparse matrix system if the multiscale kernel is compactly supported. Once we determine the multivariate function that interpolates the noisy data, this newly developed method has potential applications in many branches of science and engineering. The well-developed wavelet techniques (e.g., denoising, compression, shape detection, etc.) can be applied thereafter. In this paper, we focus on a classical ill-posed numerical differentiation problem. The derivative of (1.2) can be obtained by replacing φ by $D^\gamma \varphi$. An overview of multiscale kernels will be given in section 2.

In section 3, the instability of numerical differentiation is regularized by the Tikhonov regularization method that seeks a stable approximate interpolant. Error estimates in section 3.1 show that the errors of numerical derivatives blow up when the noise level is high or when the minimum separation distance of the data points is small. This agrees with the ill-posed nature of numerical differentiation. On the other hand, both errors in interpolation and in the derivatives can be minimized with an optimal regularization parameter. In section 4, the L-curve method is employed to numerically locate the optimal regularization parameter. Finally, two bivariate examples are given in section 5 to conclude the paper.

2. Finding numerical derivatives. Consider a symmetric function of the form $\Phi : \Omega \times \Omega \to \mathbb{R}$ for some $\Omega \subset \mathbb{R}^d$ and let $\mathcal{N}_\Phi$ be the *reproducing kernel* of a *native* Hilbert space [29] of Φ. It is proven in the same article that the native space $\mathcal{N}_\Phi$ for a given symmetric positive definite kernel Φ is unique if it exists, and it coincides with the closure of the space of finite linear combination of functions $\Phi(x, \cdot)$, $x \in \Omega$ under the inner product defined via

$$(\Phi(x, \cdot), \Phi(y, \cdot))_{\mathcal{N}_\Phi} = \Phi(x, y) \quad \text{for all} \quad x, y \in \Omega.$$

That is, for every fixed point $x \in \Omega$ and function $\Phi(x, \cdot)$ belongs to $\mathcal{N}_\Phi$, every $f \in \mathcal{N}_\Phi$ can be recovered by an inner product of the form $f(x) = \langle f, \Phi(x, \cdot) \rangle$, $x \in \Omega$. For a detailed treatise of reproducing kernel Hilbert spaces, see Aronszajn [3] or Meschkowski [21].

To begin, we reconstruct multivariate functions from unstructured data by a multiscale technique. The basic concepts of this technique were first investigated by Opfer [23]. The implementation of a *multiscale kernel* (MSK) is out of the scope of this paper and the developments of MSK are only sketched here. We refer the reader to the original dissertation of Opfer for the details.

A function $\varphi : \mathbb{R}^d \to \mathbb{R}$ is called *refinable* if there is a sequence $\{\mathfrak{h}_k\}_{k\in\mathbb{Z}^d}$ of real numbers such that

$$\varphi = \sum_{k\in\mathbb{Z}^d} \mathfrak{h}_k \varphi(2\cdot - k). \tag{2.1}$$

For every level-$j \in \mathbb{Z}$ we define the *shift invariant space*

$$\mathcal{V}_j := \left\{ \sum_{k\in\mathbb{Z}^d} c_k \varphi(2^j \cdot - k) : c_k \in \mathbb{R}, \sum_{k\in\mathbb{Z}^d} (c_k)^2 < \infty \right\}. \tag{2.2}$$

By standard wavelet arguments it follows from (2.1) that the spaces $\{\mathcal{V}_j\}_{j\in\mathbb{Z}}$ form a nested sequence, i.e., $\mathcal{V}_0 \subset \mathcal{V}_1 \subset \cdots \subset \mathcal{V}_u$. The main idea here involves several levels of $\mathcal{V}_j$ in *one* reconstruction scheme.

Let $\varphi : \mathbb{R}^d \to \mathbb{R}$ be a function in $L^2(\mathbb{R}^d)$ with decay $\varphi(x) = \mathcal{O}\big((1+\|x\|)^{-(d+1)/2}\big)$. Let $u \geq 0$ be a fixed integer and $\sigma > d/2$ be a positive real number. Then the kernel $\Phi_\sigma : \mathbb{R}^d \times \mathbb{R}^d \to \mathbb{R}$ given by

$$\Phi_\sigma(x,y) := \sum_{j=0}^{u} \lambda_\sigma^j \underbrace{\left(\sum_{k\in\mathbb{Z}^d} \varphi(2^j x - k)\varphi(2^j y - k) \right)}_{\Phi_{\sigma,j}}, \tag{2.3}$$

where $\lambda_\sigma := 2^{d-2\sigma}$, is a MSK.

THEOREM 2.1 (see [23, Theorem 5.4]). *Every MSK in the form of* (2.3) *is positive semidefinite. Let $B_\rho(c)$ be a ball of radius ρ with center $c \in \mathbb{R}^d$ such that* $\operatorname{supp}(\varphi) \subset B_\rho(c)$. *If the point set $X \subset \mathbb{R}^d$ satisfies*

$$h_{X,\min} := \min_{i\neq j} \|x_i - x_j\|_2 > \rho\, 2^{-u+1}, \tag{2.4}$$

then the matrix $A_X := \big(\Phi_\sigma(x_i,x_k)\big)_{1\leq i,k\leq n}$ is positive definite.

In this paper, we are mainly interested in compactly supported refinable functions φ that clearly satisfy the decay condition required in Theorem 2.1. The resulting MSK are therefore positive definite.

We can find to any given data Y an interpolant of the form (1.1) by solving a sparse symmetric linear collocation system for $\beta \in \mathbb{R}^n$,

$$y_j = \sum_{i=1}^{n} \beta_i \Phi_\sigma(x_i,\, x_j), \quad 1 \leq j \leq n. \tag{2.5}$$

Theorem 2.1 implies that (2.5) has a unique solution if the integer $u = u(h_{X,\min})$ is large enough with respect to the density of the data points X. The MSK scheme is based on the following idea: The kernel representation can be decomposed into a frame representation due to the specially designed structure of Φ_σ. First, $s \in \mathcal{N}_\Phi$ is decomposed into a sequence of functions $s_j \in \mathcal{V}_j$,

$$s = \sum_{i=1}^{n} \beta_i \Phi_\sigma(x_i,\cdot) = \sum_{i=1}^{n} \beta_i \sum_{j=0}^{u} \lambda_\sigma^j \Phi_{\sigma,j}(x_i,\cdot) = \sum_{j=0}^{u} \lambda_\sigma^j \underbrace{\sum_{i=1}^{n} \beta_i \Phi_{\sigma,j}(x_i,\cdot)}_{s_j} = \sum_{j=0}^{u} \lambda_\sigma^j s_j, \tag{2.6}$$

such that each $s_j \in \mathcal{V}_j$ can be further decomposed into

(2.7)
$$s_j = \sum_{i=1}^{n} \beta_i \Phi_{\sigma,j}(x_i, \cdot) = \sum_{k\in\mathbb{Z}^d} \underbrace{\left(\sum_{i=1}^{n} \beta_i \varphi(2^j x_i - k) \right)}_{c_k^j} \varphi(2^j \cdot - k) = \sum_{k\in\mathbb{Z}^d} c_k^j \varphi(2^j \cdot - k).$$

Combining (2.6) and (2.7) gives us the frame representation in the form of (1.2). Functions in lower levels capture the smooth structure of f while the higher levels contain the fine structure of f, including noise. Furthermore, the refinability of the function φ allows the *frame coefficients* c_k^j for $0 \le j \le u-1$ to be computed via

$$c_k^j = \lambda_\sigma^{-j} \sum_{\mu\in\mathbb{Z}^d} \mathfrak{h}_{\mu-2k} c_\mu^{j+1}, \quad k \in \mathbb{Z}^d.$$

Computation of frame coefficients c_k^j requires a nearest neighbor search, e.g., kd-tree [35, Chapter 14], to locate all $x \in X$ inside the support of $\varphi(2^u \cdot - k)$. Note that the number of nonzero c_k^j is finite due to the fact that $|X|$ is finite and φ is compactly supported. The native space $\mathcal{N}_\Phi$ and each $\mathcal{V}_j$ in (2.2) can be equipped with a norm, respectively,

$$\|s\|_{\mathcal{N}_\Phi}^2 = \sum_{j=0}^{u} \lambda_\sigma^{-j} \|s_j\|_{\mathcal{V}_j}^2 \quad \text{and} \quad \|s_j\|_{\mathcal{V}_j}^2 = \sum_{k\in\mathbb{Z}^d} (c_k^j)^2.$$

Let $h_{X,\Omega}$ denote the fill distance of the data points $X \subset \Omega$ given by

$$h_{X,\Omega} := \sup_{y\in\overline{\Omega}} \inf_{x_i\in X_h} \|y - x_i\|_2.$$

If φ satisfies certain smoothness and decay properties, then $\mathcal{N}_\Phi \simeq W^{\sigma,2}$ are norm equivalent and the interpolant obtained by MSK satisfies the standard native space error bound:

THEOREM 2.2 (see [23, Theorem 5.21]). *Let the MSK Φ_σ be constructed with a scaling function φ of an r-regular multiscale analysis of $L^2(\Omega^d)$ with $r > d/2$. Fix an σ with $d/2 < \sigma < r$. Further we assume that $X := \{x_1, \dots, x_n\} \subset \Omega$ is a set of points with fill distance $h_{X,\Omega}$, where $\Omega \subset \mathbb{R}^d$ is a compact set with Lipschitz boundary which satisfies an interior cone condition. Let $f \in H^\sigma(\mathbb{R}^d)$ and s be the interpolant. Let $1 \le q \le \infty$ and $\gamma = (\gamma_1, \dots, \gamma_d)$ be a multi-index such that $|\gamma| < \lfloor\sigma\rfloor - d/2$. Then, there is a constant $C > 0$ independent of f and $h_{X,\Omega}$ such that*

$$\|s - f\|_{W^{|\gamma|,q}(\Omega)} \le C_1 h_{X,\Omega}^{\sigma-|\gamma|-d\left(1/2-1/q\right)_+} \|f\|_{\mathcal{N}_\Phi},$$

where $(x)_+ = x$ if $x \ge 0$ and $(x)_+ = 0$ if $x < 0$.

2.1. Noise data. Let us assume we have points $X := \{x_1, \dots, x_n\} \subset \Omega \subset \mathbb{R}^d$ and noisy data

$$Y_\eta := \{\widetilde{y}_1, \dots, \widetilde{y}_n\} \subset \mathbb{R},$$

where

$$\widetilde{y}_i = y_i + \delta_i = f(x_i) + \eta(x_i),$$

and δ_i are random noise. The noise function η here is not necessarily classically differentiable or even continuous. Assume that we obtain an interpolant in the frame representation

$$s_{\delta,X} = \sum_{j=0}^{u} \lambda_\sigma^j s_{\delta,X,j} = \sum_{j=0}^{u} \sum_{k\in\mathbb{Z}^d} \lambda_\sigma^j c_k^j \varphi(2^j \cdot -k), \tag{2.8}$$

for some noisy data (X, Y_η) by MSK with the following conditions satisfied.

Assumption 2.3. The MSK in (2.3) is constructed by

1. $\sigma \geq 2$ and $\sigma > \frac{d}{2}$,
2. a r-regular φ smooth enough such that $r > \left(2 + \frac{d}{2}\right)$, i.e., $\varphi \in C^r(\Omega)$ with compact support up to order r, and
3. for any given data points X, $u = \lceil 1 + \log_2 \frac{\rho}{h_{X,\min}} \rceil$, where $h_{X,\min}$ is given in (2.4) and ρ as in Theorem 2.1.

The reasons for the above assumptions will soon become clear when we look at the error estimates in section 3.1. Throughout this paper, let γ with $|\gamma| = \gamma_1 + \cdots + \gamma_d = 1$ be a multi-index. Our interest is to approximate or reconstruct the derivatives of f from the noisy data Y_η via

$$(X,\, Y_\eta) \longrightarrow D^\gamma f.$$

From the frame representation (2.8), the numerical derivatives are given by

$$D^\gamma s_{\delta,X} = \sum_{j=0}^{u} \lambda_\sigma^j\, D^\gamma\, s_{\delta,X,j} = \sum_{j=0}^{u} \sum_{k\in\mathbb{Z}^d} \lambda_\sigma^j c_k^j\, D^\gamma \varphi(2^j \cdot -k). \tag{2.9}$$

This numerical procedure is highly unstable. Since the input data Y_η contains noise, the resulting approximated derivatives $D^\gamma s_{\delta,X}$ will contain large errors and therefore are not trustworthy. We select a subset of frame coefficients $\{r_k^j\} \subset \{c_k^j\}$ to *regularize* the numerical derivatives.

Any regularized interpolant g to $s_{\delta,X}$ is in the form of

$$g = \sum_{j=0}^{u} \sum_{k\in\mathbb{Z}^d} \lambda_\sigma^j r_k^j\, \varphi(2^j \cdot -k), \tag{2.10}$$

where $r_k^j \in \{0,\, c_k^j\}$. For some threshold $t_\sigma(j) > 0$ for $0 \leq j \leq u$ and a fixed regularization parameter α, the regularized interpolant is defined to be

$$s_\alpha = \sum_{j=0}^{u} \sum_{k\in\mathbb{Z}^d} \lambda_\sigma^j\, r_k^j\, \varphi(2^j \cdot -k) \;\text{ such that }\; r_k^j = \begin{cases} c_k^j & \text{if } |c_k^j| > t_\sigma(j)\,\alpha, \\ 0 & \text{otherwise.} \end{cases} \tag{2.11}$$

For practical problems, the optimal regularization parameter α^* is not attainable unless η is known *a priori*. In the next section, we specify our choice of threshold $t_\sigma(j)$ using the Tikhonov regularization method. After giving a concrete formula of the threshold $t_\sigma(j)$, we make sure the errors in interpolation and in the gradient of the regularized interpolant in (2.11) is both bounded and well behaved for some suitable α.

3. Regularization. The classical Tikhonov regularization method [31] is a common tool for finding a solution from an unstable system. Using some *a priori* choice strategy for regularization parameters, Hofmann and Yamamoto [18] prove convergence rates for the Tikhonov regularization method. Despite the differences with the classical problem, we seek a *regularized interpolant* s_α to $s_{\delta,X}$ (considered to be fixed here) by the Tikhonov regularization method. For any

$$\tilde{g} = \sum_{j=0}^{u} \sum_{k\in\mathbb{Z}^d} \lambda_\sigma^j \tilde{r}_k^j \, \varphi(2^j \cdot -k) \in \mathcal{V}_u,$$

we define the *error measure* by

$$E(\tilde{g}) = E(\tilde{g}; s_{\delta,X}) := \|s_{\delta,X}\|_{\mathcal{N}_\Phi}^2 - \|g\|_{\mathcal{N}_\Phi}^2 = \sum_{j=0}^{u} \sum_{k\in\mathbb{Z}^d} \lambda_\sigma^{-j} \big((c_k^j)^2 - (\tilde{r}_k^j)^2\big), \tag{3.1}$$

and the *roughness measure* by

$$R(\tilde{g}) := \sum_{j=0}^{u} \sum_{k\in\mathbb{Z}^d} \lambda_\sigma^j |\tilde{r}_k^j| \, |\varphi(2^j \cdot -k)|_{W^{2,2}(\Omega)}, \tag{3.2}$$

such that $|\tilde{g}|_{W^{2,2}(\Omega)}^2 \le R(\tilde{g})$ for any $\tilde{g} \in \mathcal{V}_u$. The error measure depends on the interpolant $s_{\delta,X}$ but both are independent of α.

Given any regularization parameter $\alpha \ge 0$ (consider to be fixed here), the *regularized interpolant* s_α is defined to be the minimizer of $E(\cdot) + \alpha\, R(\cdot)$ over all functions in the form of (2.10), i.e.,

$$E(s_\alpha) + \alpha\, R(s_\alpha) = \inf \big\{ E(g) + \alpha\, R(g) \ \text{ for all } \ g \text{ as in (2.10)} \big\}. \tag{3.3}$$

Although the number of nonzero functions in the form of (2.10) is finite, we have the following theorem to simplify our selection process.

THEOREM 3.1. *For any given $\alpha \ge 0$ the optimizer to* (3.3) *is given by* (2.11) *with*

$$t_\sigma(j) := \big(2^{d-2\sigma+4} \, |\varphi|_{W_{2,2}}^2\big)^j < \infty \ \text{ for all } \ 0 \le j \le u < \infty.$$

Proof. First by changing variables, we obtain

$$|\varphi(2^j \cdot -k)|_{W_{2,2}(\Omega)}^2 = \left\| \sum_{|\gamma|=2} D^\gamma \varphi(2^j \cdot -k) \right\|_{L^2(\Omega)}^2 = 2^{j(4-d)} \, |\varphi|_{W_{2,2}(\Omega)}^2. \tag{3.4}$$

For any g in the form of (2.10), we have

$$\begin{aligned} E(g) + \alpha\, R(g) &= \sum_{j=0}^{u} \sum_{k\in\mathbb{Z}^d} \big(\big(\lambda_\sigma^{-j} (c_k^j)^2 - (r_k^j)^2\big) + \alpha\, \lambda_\sigma^j \, |r_k^j| \, 2^{j(4-d)} \, |\varphi|_{W_{2,2}(\Omega)}^2 \big) \\ &= \underbrace{\left(\sum_{j=0}^{u} \sum_{k\in\mathbb{Z}^d} \lambda_\sigma^{-j} (c_k^j)^2 \right)}_{= \|s_{\delta,X}\|_{\Phi_\sigma}^2} - \left(\sum_{j=0}^{u} \sum_{k\in\mathbb{Z}^d} \lambda_\sigma^{-j} (r_k^j)^2 - \alpha\, \lambda_\sigma^j \, |r_k^j| \, 2^{j(4-d)} \, |\varphi|_{W_{2,2}(\Omega)}^2 \right). \end{aligned}$$

Since $\|s_{\delta,X}\|^2_{\Phi_\sigma}$ is a fixed quantity, the minimizer of (3.3) corresponds to the following condition on r_k^j:

$$\lambda_\sigma^{-j}(r_k^j)^2 - \alpha\,\lambda_\sigma^j\,|r_k^j|\,2^{j(4-d)}\,|\varphi|^2_{W_{2,2}(\Omega)} > 0.$$

After simplification, we obtain $(r_k^j)^2 > t_\sigma(j)|r_k^j|\alpha$. □

Once α is determined, Theorem 3.1 allows us to select $\{r_k^j\}$ from $\{c_k^j\}$ and construct the regularized interpolant and its derivatives.

3.1. Error estimate. In general, interpolation does not make sense on $L^2(\Omega)$ and there are many possibilities of projecting $L^2(\Omega)$ to $\mathcal{N}_\Phi$. Moreover, there are many new results on interpolation in cases where f is not in the native space [22, 28]. For our problem, we will define the necessary projection by interpolation.

Let $\Omega \subset \mathbb{R}^d$ be a domain satisfying the conditions in Theorem 2.2. Suppose that the MSK Φ_σ also satisfies Assumption 2.3 and $f \in \mathcal{N}_\Phi = H^\sigma(\Omega)$. For any fixed center X and noise function $\eta \in L^2(\Omega) \cap C(\Omega)$, the *noise level* is defined as

$$\delta := \sup_{x\in\Omega} |\eta(x)|.$$

It is easy to verify that $\|\eta\|_{L^2(\Omega)} \le V^{1/2}(\Omega)\,\delta$, where $V(\Omega)$ is the volume of $\Omega \subset \mathbb{R}^d$. The noisy input data for interpolation at the points $X \subset \Omega$ is given by $Y_\eta := (f+\eta)\big|_X$ under the assumption that f and η are both well defined at all points $x \in \Omega$.

We define a finite dimensional subspace $V_X \subset \mathcal{N}_\Phi$ to be the span of $\Phi_\sigma(z,\,\cdot)$ and $V_X^{(\gamma)}$ to be the span of $D^\gamma\Phi_\sigma(z,\,\cdot)$, where differentiation acts upon the second variable of Φ_σ for all $z \in X$. Furthermore, we define a *projection map*

$$P_X : L^2(\Omega)\cap C(\Omega) \to \mathbb{R}^{|X|} \;\text{ such that }\; P_X f = \{f(x) :\; x \in X\}$$

that extracts discrete values from a function in $L^2(\Omega)\cap C(\Omega)$ at X so that interpolation is possible and makes sense, and an *interpolation map*

$$I_X : \mathbb{R}^{|X|} \to V_X \;\text{ such that }\; I_X P_X f = I_X f \;\text{ for all }\; f \in \mathcal{N}_\Phi,$$

which maps discrete function values at X to a function in V_X by interpolation using MSK. Last, we define a *truncation map*,

$$T_\alpha : \{1\}^{\mathbb{N}\times\mathbb{Z}^d} \to \{0,\,1\}^{\mathbb{N}\times\mathbb{Z}^d} \;\text{ for all }\; \alpha \ge 0$$

that smoothes out functions by truncating some of their frame coefficients. Furthermore, when no confusion arises, we treat T_α as a map from V_X and $V_X^{(\gamma)}$ onto themselves in the sense that,

$$T_\alpha\left(\sum_{j=0}^{u}\sum_{k\in\mathbb{Z}^d}\lambda_\sigma^j\,c_k^j\,\phi(2^j\cdot - k)\right) := \sum_{j=0}^{u}\sum_{k\in\mathbb{Z}^d}\lambda_\sigma^j\,T_\alpha(c_k^j)\,\phi(2^j\cdot - k),\;\; \phi = \{\varphi,\,D^\gamma\varphi\}.$$

The truncation map T_α, as in (2.11), is a nonlinear map whose actual form depends on the parameter α and the data $(X,\,Y_\eta)$. It can also be interpreted as a countable set $\{\tau_k^j\} \subset \{0,\,1\}^{\mathbb{N}\times\mathbb{Z}^d}$ such that $T_\alpha(c_k^j) = \tau_k^j(\alpha)c_k^j = r_k^j(\alpha)$, where

$$\tau_k^j = \tau_k^j(\alpha) = \begin{cases} 1 & \text{if } r_k^j = c_k^j, \\ 0 & \text{otherwise.} \end{cases} \tag{3.5}$$

Since the number of nonzero $c_k^j \in \{0, 1\}^{\mathbb{N}\times\mathbb{Z}^d}$ is finite, there are infinitely many $c_k^j = 0$ and the corresponding $\tau_k^j = 1$ because $r_k^j = 0 = c_k^j$ for all $\alpha \geq 0$ by (3.5). Thus, there are infinitely many $\tau_k^j = 1$ (frame coefficients being kept) and only a finite number of $\tau_k^j = 0$ (frame coefficients being truncated) for the selected frame coefficients.

With the newly introduced notation, the unknown full interpolant can be expressed by $s := I_X P_X f$. Furthermore, we can write the regularized interpolant in Theorem 3.1 as

$$s_{\delta,X} := I_X P_X (f - \eta) \quad \text{and} \quad s_\alpha = T_\alpha s_{\delta,X}.$$

Moreover, (2.11) can be restated as

$$s_\alpha = T_\alpha s_{\delta,X} = \sum_{j=0}^{u} \sum_{k\in\mathbb{Z}^d} \lambda_\sigma^j \, \tau_k^j c_k^j \, \varphi(2^j \cdot - k).$$

Without any extra assumptions on the noise function η, the threshold $t_\sigma(j)$ and the data points X, the truncation map has the following properties.

PROPOSITION 3.2. *Let $|\gamma| = 1$ and $\mathrm{nz}_j(\cdot)$ be a function with respect to j that returns the number of zero elements in the level-j of a set in $\{0, 1\}^{\mathbb{N}\times\mathbb{Z}^d}$. Denote the $L^2(\Omega)$-induced norm for maps on V_X by $\|\cdot\|_{L^2(\Omega)}$ and define*

$$u_\alpha := \sup\left\{ j \,\middle|\, \tau_k^j \neq 0 \text{ for some } k \in \mathbb{Z}^d, 0 \leq j \leq u \right\}, \tag{3.6}$$

to be the maximum nonzero frame level after truncation. Then the truncation map T_α satisfies:

1. $\|T_\alpha\|_{L^2(\Omega)} = \|T_0 - T_\alpha\|_{L^2(\Omega)} = 1$ *for* $\alpha > 0$.
2. $\|D^\gamma T_\alpha\|_{L^2(\Omega)} = \|T_\alpha D^\gamma\|_{L^2(\Omega)} = 2^{u_\alpha} \, \|D^\gamma \varphi\|_{L^2(\Omega)} \, \|\varphi\|_{L^2(\Omega)}^{-1}$.
3. *For any given data (X, Y_η), the number of frame coefficients being truncated by T_α, denoted by $\mathrm{nz}_j(1 - \tau_k^j(\alpha)) < \infty$, is a bounded nondecreasing simple function in α and $\mathrm{nz}_j(1 - \tau_k^j(0)) = 0$.*

Proof. The perfect candidate to evaluate the above norms is the scaled function in the frame. For each nested space $\mathcal{V}_j$ $(0 \leq j \leq u)$, such function is given by

$$g_{j,k} = \left(2^{jd/2} \, \|\varphi\|_{L^2(\Omega)}^{-1}\right) \varphi(2^j \cdot - k) \in \mathcal{V}_j, \ 0 \leq j \leq u,$$

such that $\|g_{j,k}\|_{L^2(\Omega)} = 1$ and $\|D^\gamma g_{j,k}\|_{L^2(\Omega)} = 2^j \, \|D^\gamma \varphi\|_{L^2(\Omega)} \, \|\varphi\|_{L^2(\Omega)}^{-1}$.

For Proposition 3.2.1 follows directly from the fact that $T_\alpha \neq 0$ for all $\alpha \geq 0$; there exists some (j_1, k_1) and (j_2, k_2) such that $\tau_{k_1}^{j_1} = 1$ and $\tau_{k_2}^{j_2} = 0$ for $0 \leq j_i \leq u$ and $k_i \in \mathbb{Z}^d$ corresponding to a frame coefficient that is kept and truncated by T_α, respectively. Hence, we have

$$\|T_\alpha I_X P_X g_{j_1,k_1}\|_{L^2(\Omega)} = 1, \text{ and } \|(T_0 - T_\alpha) I_X P_X g_{j_2,k_2}\|_{L^2(\Omega)} = 1.$$

To prove Proposition 3.2.2, we first note that the differential operator acts on each φ independently as in (2.9); thus, c_k^j and τ_k^j are independent of the truncation process. *Differentiation after truncation* is the same as *truncation after differentiation*, namely we have $D^\gamma T_\alpha s_j = T_\alpha D^\gamma s_j$ for all $s_j \in \mathcal{V}_j$. For numerical efficiency, the operation $D^\gamma T_\alpha$ is preferred for efficiency.

Since $\|D^\gamma\varphi\|_{L^2(\Omega)}\,\|\varphi\|^{-1}_{L^2(\Omega)}$ is a fixed quantity once φ is fixed, without regularization the noise in the level-j will be greatly amplified as expected,

$$\|D^\gamma I_X P_X g_{j,k}\|_{L^2(\Omega)} = \|D^\gamma g_{j,k}\|_{L^2(\Omega)} \le 2^j\,\|D^\gamma\varphi\|_{L^2(\Omega)}\,\|\varphi\|^{-1}_{L^2(\Omega)}. \tag{3.7}$$

Let u_α be the highest nonzero frame level appearing in the regularized interpolant as in (3.6). Applying the regularization map T_α will "cut off" all levels higher than u_α exclusively and we arrive at the conclusion.

Last, Proposition 3.2.3 follows from the fact that the number of nonzero c_k^j is finite and no regularization is applied when $\alpha = 0$. □

We now turn our focus to the error estimate for $\|f - s_\alpha\|$. First of all,

$$\begin{aligned}\|f - s_\alpha\|_{L^2(\Omega)} &\le \|f - I_X P_X f\|_{L^2(\Omega)} + \|I_X P_X f - s_{\delta,X}\|_{L^2(\Omega)} + \|s_{\delta,X} - T_\alpha s_{\delta,X}\|_{L^2(\Omega)}\\ &= \underbrace{\|f - I_X P_X f\|_{L^2(\Omega)}}_{\text{interp. error}} + \underbrace{\|I_X P_X \eta\|_{L^2(\Omega)}}_{\text{noise}} + \underbrace{\|(T_0 - T_\alpha)s_{\delta,X}\|_{L^2(\Omega)}}_{\text{reg. error}}.\end{aligned}$$

The last inequality uses the fact that

$$\|I_X P_X f - s_{\delta,X}\| = \|I_X P_X f - I_X P_X (f - \eta)\| = \|I_X P_X \eta\|.$$

By Theorem 2.2 with $q = 2$ and $|\gamma| = 0$, the first term (interpolation error) can be bounded by

$$\|I_X P_X f - f\|_{L^2(\Omega)} \le C_1 h^\sigma_{X,\Omega}\,\|f\|_{\mathcal{N}_\Phi},$$

and the second term (noise) is bounded by our assumption on η,

$$\|I_X \eta\|_{L^2(\Omega)} \le V^{1/2}(\Omega)\,\delta.$$

It is straightforward to verify that

$$\|s_j\|^2_{L^2(\Omega)} \le 2^{-jd}\,\|\varphi\|^2_{L^2(\Omega)}\,\|s_j\|^2_{\mathcal{V}_j} \quad \text{for all} \quad s_j \in \mathcal{V}_j. \tag{3.8}$$

For the third term (regularization error), by Theorem 3.1 and (3.8) we have

$$\begin{aligned}\|(T_0 - T_\alpha)s_{\delta,X}\|^2_{L^2(\Omega)} &\le \sum_{j=0}^{u} \|(T_0 - T_\alpha)s_{\delta,X,j}\|^2_{L^2(\Omega)}\\ &\le \|\varphi\|^2_{L^2(\Omega)} \sum_{j=0}^{u}\sum_{k\in\mathbb{Z}^d} 2^{-jd}\big((1-\tau_k^j)c_k^j\big)^2\\ &\le \|\varphi\|^2_{L^2(\Omega)} \sum_{j=0}^{u} 2^{-jd}\mathrm{nz}_j(1-\tau_k^j)\,t_\sigma(j)^2\alpha^2\\ &\le \sum_{j=0}^{u} 2^{-2(\sigma-2)j}\mathrm{nz}_j(1-\tau_k^j)|\varphi|^{2j}_{W_{2,2}}\|\varphi\|^{2(j+1)}_{L^2(\Omega)}\alpha^2\\ &:= \big(C_2(\alpha)\alpha\big)^2.\end{aligned} \tag{3.9}$$

An immediate fact from Proposition 3.2.3 is that $C_2(\alpha)$ is a bounded positive nondecreasing simple function with $C_2(0) = 0$.

For the error in the gradient, we have

$$\begin{aligned}\|\nabla f - \nabla s_\alpha\|_{L^2(\Omega)} &\le \|\nabla f - \nabla I_X P_X f\|_{L^2(\Omega)} + \|\nabla I_X P_X f - \nabla T_\alpha I_X f\|_{L^2(\Omega)} \\ &\quad + \|\nabla T_\alpha I_X P_X f - \nabla s_\alpha\|_{L^2(\Omega)} \\ &\le \underbrace{\|\nabla f - \nabla I_X P_X f\|_{L^2(\Omega)}}_{\text{interp. error}} + \underbrace{\|\nabla (T_0 - T_\alpha) I_X P_X f\|_{L^2(\Omega)}}_{\text{reg. error}} \\ &\quad + \underbrace{\|\nabla T_\alpha I_X P_X P_X \eta\|_{L^2(\Omega)}}_{\text{noise}}.\end{aligned}$$

Using Theorem 2.2 with $q = 2$ and $|\gamma| = 1$, the interpolation error in gradient is again bounded by

$$\|\nabla I_X P_X f - \nabla f\|_{L^2(\Omega)} \le C_1 h_{X,\Omega}^{\sigma-1} \|f\|_{\mathcal{N}_\Phi}.$$

Next, we need a stronger assumption than $\sigma \ge 2$ such that $\mathcal{N}_\Phi \subseteq W^{2,2}(\Omega)$ to make use of an inequality in [1, Theorem 4.14]: For any $0 < \epsilon_0$ there exists a constant $C_3 = C_3(\epsilon_0, \Omega, d) > 0$ such that for $g \in W^{2,2}(\Omega)$ and for all $0 < \epsilon < \epsilon_0$,

$$\|\nabla g\|_{L^2(\Omega)} \le C_3\big(\epsilon\, |g|_{W^{2,2}(\Omega)} + \epsilon^{-1} \|g\|_{L^2(\Omega)}\big). \tag{3.10}$$

By assumption, the unknown function f is "smoother" than the random noise η. Hence, for all $\alpha \ge 0$ the following statement holds

$$\|\nabla (T_0 - T_\alpha) I_X P_X f\|_{L^2(\Omega)} \le \|\nabla (T_0 - T_\alpha) s_{\delta,X}\|_{L^2(\Omega)}.$$

Similar to (3.9), by (3.4) we have

$$\begin{aligned}|(T_0 - T_\alpha) s_{\delta,X}|_{W^{2,2}} &\le \sum_{j=0}^{u} |(T_0 - T_\alpha) s_{\delta,X,j}|_{W^{2,2}} \\ &\le |\varphi|_{W^{2,2}}^2 \sum_{j=0}^{u} \sum_{k \in \mathbb{Z}^d} 2^{j(2-d/2)} \big((1 - \tau_k^j) c_k^j\big)^2 \\ &\le |\varphi|_{W^{2,2}}^2 \sum_{j=0}^{u} 2^{j(2-d/2)} \mathrm{nz}_j (1 - \tau_k^j)\, t_\sigma(j) \alpha \\ &\le \sum_{j=0}^{u} 2^{(6-2\sigma+d/2)j} \mathrm{nz}_j (1 - \tau_k^j) |\varphi|_{W^{2,2}}^{2(j+1)} \alpha \\ &:= C_4(\alpha)\alpha.\end{aligned} \tag{3.11}$$

We choose $\epsilon = 1 < \epsilon_0$ for some fixed ϵ_0. Putting (3.9) and (3.11) into (3.10) yields

$$\|\nabla (T_0 - T_\alpha) I_X f\|_{L^2(\Omega)} \le C_5(\alpha)\alpha.$$

Namely, $C_5(\alpha) = C_3(C_2(\alpha) + C_4(\alpha))$ that is a bounded positive nondecreasing simple function with $C_5(0) = 0$.

All the terms considered so far are stable. Last, and most important, we consider the error in gradient due to the presence of noise. By Proposition 3.2.2, if there exist some (j,k) such that $c_k^j \ne 0$ and $\tau_k^j = 1$, we have

$$\|\nabla T_\alpha I_X P_X \eta\|_{L^2(\Omega)} \le 2^{d/2}\, 2^{u_\alpha}\, \|\nabla \varphi\|_{L^2(\Omega)}\, \|\varphi\|_{L^2(\Omega)}^{-1}\, V^{1/2}(\Omega)\, \delta := C_6(\alpha)\, \delta. \tag{3.12}$$

Otherwise $s_{\delta,X} = 0$, we clearly have $\|\nabla T_\alpha I_X P_X \eta\|_{L^2(\Omega)} = 0$ and $C_6(\alpha) = 0$.

The function $C_6(\alpha)$ in (3.12) is a bounded positive nonincreasing simple function. Since $2^u \geq \frac{2\rho}{h_{X,\min}}$ is the requirement of a positive definite kernel, the gradient error in (3.7) will blow up when one takes finer and finer data points if the noise level $\delta > 0$ is fixed and no regularization is applied.

We summarize all results by the following theorem.

THEOREM 3.3. *For any given data (X, Y_η), let s_α be the regularized interpolant obtained by a MSK satisfying Assumption* 2.3 *and regularized by Theorem* 3.1. *There exist a constant C_1, two bounded positive nondecreasing simple functions $C_2^{\nearrow}(\alpha) \geq C_5^{\nearrow}(\alpha)$ such that $C_2^{\nearrow}(0) = 0 = C_5^{\nearrow}(0)$, and a bounded nonnegative nonincreasing simple function $C_6^{\searrow}(\alpha)$ with $C_6^{\searrow}(0) > 0$ such that the errors in regularized interpolant are bounded by*

$$\|f - s_\alpha\|_{L^2(\Omega)} \leq C_1 h_{X,\Omega}^{\sigma} \|f\|_{\mathcal{N}_\Phi} + V^{1/2}(\Omega)\, \delta + C_2^{\nearrow}(\alpha)\alpha, \tag{3.13}$$

and

$$\|\nabla f - \nabla s_\alpha\|_{L^2(\Omega)} \leq C_1 h_{X,\Omega}^{\sigma-1} \|f\|_{\mathcal{N}_\Phi} + C_5^{\nearrow}(\alpha)\alpha + C_6^{\searrow}(\alpha)\, \delta, \tag{3.14}$$

for all $\alpha \geq 0$. Furthermore, if the noise level $\delta \geq K(f, \sigma)$, there exists a nonzero optimizer α^* *that minimizes the sum of the upper bounds in* (3.13) *and* (3.14).

Proof. For any given data (X, Y_η), the minimizer α^* in the theorem is also a minimizer to the function

$$\big(C_2^{\nearrow}(\alpha) + C_5^{\nearrow}(\alpha)\big)\alpha + C_6^{\searrow}(\alpha)\, \delta. \tag{3.15}$$

By the properties of $C_2^{\nearrow}(\alpha)$ and $C_5^{\nearrow}(\alpha)$, we know that the term $\big(C_2^{\nearrow}(\alpha)+C_5^{\nearrow}(\alpha)\big)\alpha$ is a monotone increasing piecewise linear function. Its jump discontinuities are governed by the term $\mathrm{nz}_j(1 - \tau_k^j(\alpha))$.

The terms $C_6^{\searrow}(\alpha)\delta$ is a nonnegative nonincreasing simple function having jump discontinuities at $0 =: \alpha_{u+1} < \alpha_u \leq \cdots \leq \alpha_0 < \infty$, where α_j is the infimum over α such that jth level is completely truncated, i.e., for all $0 \leq j \leq u$

$$\alpha_j := \inf\{\, \alpha \,\big|\, r_k^j(\alpha) = \tau_k^j c_k^j = 0 \ \text{ for all } \ k \in \mathbb{Z}^d\}.$$

Define $\Delta_k G(\alpha) = G(\alpha_{u-k}) - G(\alpha_{u-k+1})$ for all $0 \leq k < u$. If, for sufficiently large δ, the accumulated drop due to term $C_6^{\searrow}(\alpha)\delta$ is larger than the accumulated growth due to the term $\big(C_2^{\nearrow}(\alpha) + C_5^{\nearrow}(\alpha)\big)\alpha$, i.e.,

$$\delta > K(f, \sigma) := \min_{0 \leq j < u} \left\{ \sum_{k=1}^{j} \Delta_k \frac{(C_2^{\nearrow}(\alpha) + C_5^{\nearrow}(\alpha))\alpha}{C_6^{\searrow}(\alpha)} \right\}, \tag{3.16}$$

then an optimizer $\alpha^* > 0$ exists. ∎

To end this section, note that the constant term $K(f, \sigma)$ in (3.16) decreases as σ increases. If the unknown function f is sufficiently smooth with respect to the noise level δ, our MSK scheme is able to regularize the interpolant. Consider $\delta < K(f, \sigma)$. These cases correspond to small noise levels that are negligible to our regularization technique. As shown in section 5 when $\delta = 0$, while $\alpha^* = 0$ is the theoretical optimizer to (3.15), we would numerically obtain an approximation α_{LC} to α^* such that $0 < \alpha_{LC} < \epsilon_{mach}$ (machine epsilon). In these cases, we set the approximation $\alpha_{LC} = \varepsilon_{mach}$ to filter out extremely small frame coefficients for efficiency.

4. L-curve method. The theoretical existence of α^* does not help us pinpoint its whereabouts. Choosing an optimal α^*, or an approximation α_{LC}, is a separate topic that will be considered in this section.

The L-curve (LC) method was investigated by Hansen and O'Leary [16] to regularize ill-posed systems under different values of the regularization parameter α. The knowledge of the noise level δ is *not necessary*. Vogel [32] shows that the L-curve regularization parameter selection method may fail to converge for a certain class of problems. In our numerical experiments, however, we find that the LC method provides a stable algorithm to find the regularization parameter α.

Our version of the LC method is derived from simplifying both measures in (3.1) and (3.2) for the ease of computation. First, we order the frame coefficients c_k^j by defining an ordered set,

$$\{(\xi_\ell,\, \eta_\ell)\}_{\ell=1}^{\mathrm{nz}(c_k^j)} = \left\{ \left(\left\| c_k^j \varphi(2^j - k) \right\|_{L^2(\Omega)}^2,\, R\big(c_k^j \varphi(2^j - k)\big) \right) \,:\, c_k^j \neq 0 \right\}_{0 \le j \le u,\, k \in \mathbb{Z}^d}$$

such that η_ℓ/ξ_ℓ forms a monotone nondecreasing sequence where $\mathrm{nz}(\cdot)$ returns the number of nonzero elements in the set and $R(\cdot)$ is the roughness measure in (3.2). Then we compute a finite set of points in $\mathbb{R}^2$ by

$$L = \left\{ \left(\|s_{\delta,X}\|_{\Phi_\sigma}^2 - \sum_{\ell=0}^{p} \xi_\ell,\, \sum_{\ell=0}^{p} \eta_\ell \right) \subset \mathbb{R}^2,\ p = 0, 1, \ldots, \mathrm{nz}(c_k^j) \right\},$$

which is known as the *L-curve*.

A suitable regularization parameter α_{LC} is the one near the *corner* on a log-log scale of the L-curve [15]. In numerical computation, finite difference schemes are applied to (the log-values of) these discrete points in order to approximate the curvature of the L-curve. The point with maximum curvature will be labeled as the corner of the L-curve. For numerical efficiency, we impose an extra condition that

$$\alpha_{LC} \ge \epsilon_{mach}.$$

We show some results with the L-curve method in Figure 4.1. The L-curve is shown in Figure 4.1(a) with a corner at $\alpha_{LC} = 5.3761\text{e-}12$. This value is chosen from the curvature of the L-curve, see Figure 4.1(b).

The number of nonzero frame coefficients in the regularized interpolant s_α is 1735 and 520 for $\alpha = \epsilon_{mach}$ and $\alpha = \alpha_{LC}$, respectively. Figure 4.2(a) for ϵ_{mach} and Figure 4.2(b) for α_{LC} show all $|c_k^j|$ and label the selected r_k^j in boldface dots. All c_k^j are ordered by levels, from level-0 on the left to level-u on the right. In both cases, only the c_k^j in the lower few levels with large absolute values are chosen.

TABLE 4.1

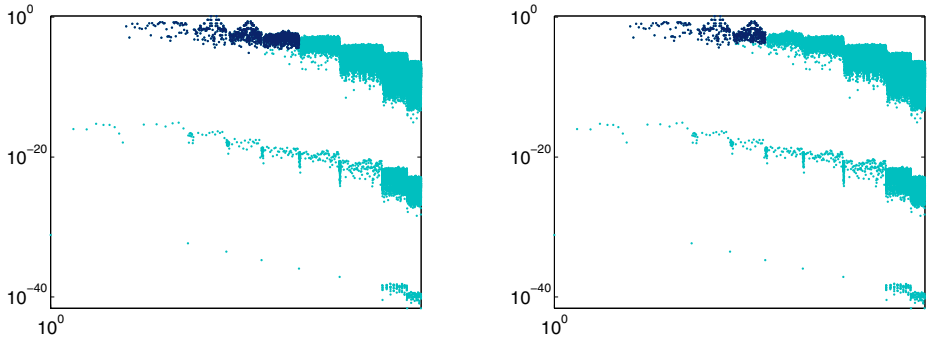
FIG. 4.1. *L-curve method applied to MSK*$(3,3)$ *in section* 5.1 *with* $\delta = 1.018\times10^{-3}$ *on a* 41×41 *uniform grids.*

At first glance, the computation of *all* nonzero c_k^j may look tremendous. In fact, we are showing all 77744 nonzero frame coefficients in Figure 4.2 but some are extremely small, e.g., 2.4e-42. If we are only interested in frame coefficients whose sizes are larger than machine epsilon, we are looking at 71463 coefficients. The distribution of the frame coefficients among all levels are in Table 4.1. After regularization, the maximum evels appears in $\{r_k^j\}$ are l$u_\alpha = 2$ for $\alpha = \alpha_{LC}$ and $u_\alpha = 3$ for $\alpha = \epsilon_{mach}$; readers may already see how this can be computed efficiently.

Our L-curve only makes use of the local property of each function $c_k^j\varphi(2^j\cdot - k)$. Pretruncation does not affect the final outcome. One could pick an intermediate value $0<\upsilon<u$ and compute frame coefficients up to level-υ only. A safeguard of this approach is that the maximum level appearing in the regularized interpolant should be strictly less than υ. If this is not the case, one can compute the frame coefficients for level-$(\upsilon+1)$ and reapply the LC method.



(a) 1735 frame coefficients for $\alpha = \epsilon_{mach}$.

(b) 520 frame coefficients for $\alpha = \alpha_{LC}$.

5. Numerical comparison and demonstration. We demonstrate some bivariate examples in this section. All codes are written in MATLAB. Random noise is generated by the built-in routine RAND with STATE reset to 0. Generated random numbers are scaled to $[-1, 1]$ and multiplied by the noise level δ. For the problem in $\mathbb{R}^2$, tested values for σ are 2 or 3, see Assumption 2.3. The MSK Φ_σ in (2.3) is constructed with the univariate B-spline of order m defined on the knot sequence $[0, 1, \ldots, m]$, denoted by b_m, see [9],

$$\varphi(x, y) = b_m(x)\, b_m(y) \;\text{ such that }\; x, y \in \mathbb{R},\; m = \{3, 4\},$$

that fulfills all assumptions in the previous discussion. Values of σ and m are specified by the notation $MSK(m, \sigma)$ throughout the section.

5.1. Comparison with TPS-based method. The recent work of Wei, Hon, and Wang [34] uses the thin plate spline (TPS) to compute numerical derivatives. The presented TPS-based method requires triangular partitions of data points; the authors claim that the method can become truly mesh-free with additional assumptions. Two regularization parameters are studied in the same paper: $\alpha_1 = \delta^2$ obtained by *a priori* rule and $\alpha_2(\delta)$ obtained by Morozov's discrepancy principle. We denote them by *TPS-AP* and *TPS-DP*, respectively, hereafter. TPS-DP is reported to be the more effective and stable method between the two.

The clear advantages of MSK with L-curve are that it is already in a truly mesh-free setting for any dimension and it does not require any *a priori* knowledge about the noise level δ. Moreover, resultant linear systems of MSK in (2.5) are sparse. To make the comparison as fair as possible, we compare the accuracies of all methods on uniformly distributed grids among many given examples in their papers. Please be reminded that there are still some differences between the problem settings here and in [34].

Let $\Omega = [-2, 2]^2$. The noise levels are chosen to be the reported $\delta = 1.018\text{e-}3$ and $\delta = 1.020\text{e-}2$. The unknown function to be approximated is given by

$$f(x, y) = \sin(\pi x)\sin(\pi y)\exp(-x^2 - y^2), \quad (x, y) \in \mathbb{R}^2,$$

with $\|f\|_{L^2(\Omega)} \approx 0.387$ and $\|\nabla f\|_{L^2(\Omega)} \approx 4.235$. Since the number of evaluation points is not reported in [34], we use the same *root mean square* (RMS) errors on a 100×100 uniformly distributed grids $x_i' \in \Omega$ to measure accuracy for interpolation,

$$\varepsilon(s_\alpha) = \frac{1}{100}\left(\sum_{i=1}^{100^2}(s_\alpha(x_i') - f(x_i'))^2\right)^{1/2},$$

and for gradient approximation,

$$\varepsilon(\nabla s_\alpha) = \frac{1}{100}\left(\sum_{i=1}^{100^2}\|\nabla s_\alpha(x_i') - \nabla f(x_i')\|_{\ell^2}^2\right)^{1/2}.$$

Table 5.1 shows the RMS errors for both tested noise levels on a 21×21 uniform grids. The differences in error should not be overinterpreted as they are influenced by the regularization parameter α_{LC} and the noise function η. It is more important to note that all choices of m and σ result in the same order of accuracy. Under this

point density, MSK shows competitive results and seems to outperform TPS.

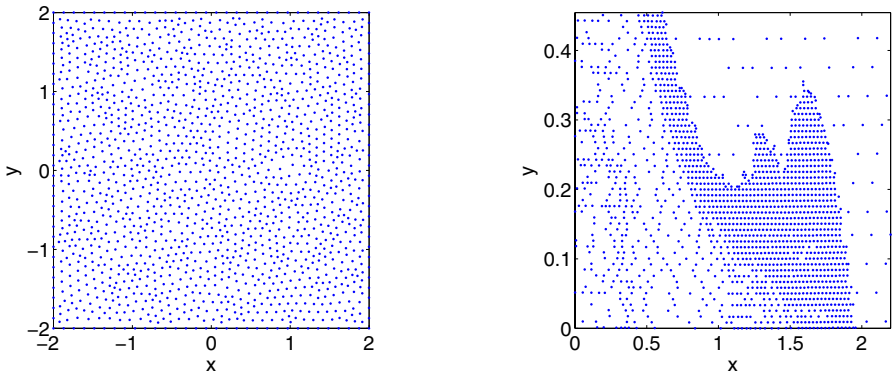
For 1609 unstructured data points, see Figure 5.1(a), with minimum separation distance $h_{X,\min} = 5.092\text{e-}2$ and fill distance $h_{X,\Omega} = 1.317\text{e-}1$. We apply MSK(3,2) to various noise levels. Results are listed in Table 5.2 and graphically demonstrated in Figure 5.2. All regularization parameters are chosen by the LC method except the first row of Table 5.2: $\alpha = 0$ indicates the result of the full interpolant without regularization. Our algorithm runs in the same way as if the data points were structured. The number of selected frame coefficients is listed under the column of $\mathrm{nz}(r_k^j)$ in the table.

Comparing the two noise-free results in Table 5.2, the interpolation error when $\alpha = 0$ is the smallest since the regularization error no longer exists. On the other hand, due to the presence of rounding errors, the regularized interpolant gives better approximation to the gradient than the unregularized full interpolant. In fact, this is true up to $\delta = 1\text{e-}4$. When $\delta \geq 1\text{e-}3$, we have $\alpha_{LC} > \epsilon_{mach}$ and our regularization technique is functioning in these examples; see Theorem 3.3. Overall, the error profile is extremely similar to the TPS-DP, see [34, Figure 5]. The monotonic trend shown in α_{LC} suggests that the proposed LC method is capable of balancing the increasing noise with an increasing regularization parameter.

Our MSK scheme performs equally well when the noise function η is smooth.[1] For completion, MSK(3,2) results in $\varepsilon(s_\alpha) = 0.0025$ and $\varepsilon(\nabla s_\alpha) = 0.0046$ on a 41×41 uniformly distributed grid. Whereas, TPS-DP results in $\varepsilon(s_\alpha) = 0.0035$ and $\varepsilon(\nabla s_\alpha) = 0.0159$.

5.2. Derivative of a landscape data. We demonstrate another example with a set of landscape data [11]; see Figure 5.1(b). The data set, containing 1669 data points, is processed by MSK(3,2) and MSK(3,3) in order to estimate its derivatives.

[1] $\eta(x,y) = 0.005 \sin\left(\frac{1}{2}\pi x\right) \sin\left(\frac{1}{2}\pi y\right)$, see [34, Table 1].



(a) 1609 unstructured points.

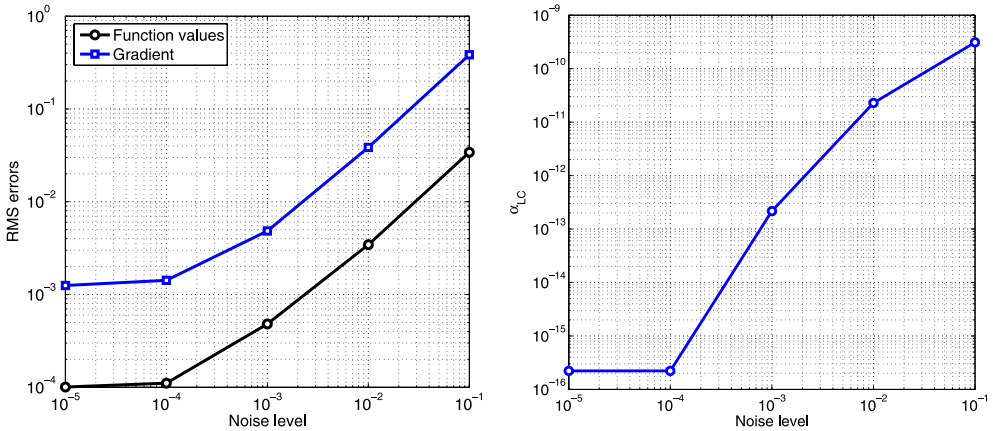
(b) Landscape data points.

FIG. 5.1. *Data points distribution for examples in sections* 5.1 *and* 5.2.

Unlike the previous example, data points are unevenly distributed and there is no exact solution for this example. Hence, the full interpolant $s_{\delta,X}$ will be used for comparison. We only demonstrate the x-derivatives; results for the y-derivatives are similar and are omitted here.

The full interpolant $s_{\delta,X}$ and its x-derivative are shown in Figure 5.3. As we see in section 3.1, the presence of noise does not introduce instability to the interpolation problem. On the other hand, we observe serious oscillations in the derivatives of the full interpolant; see Figure 5.3(b).

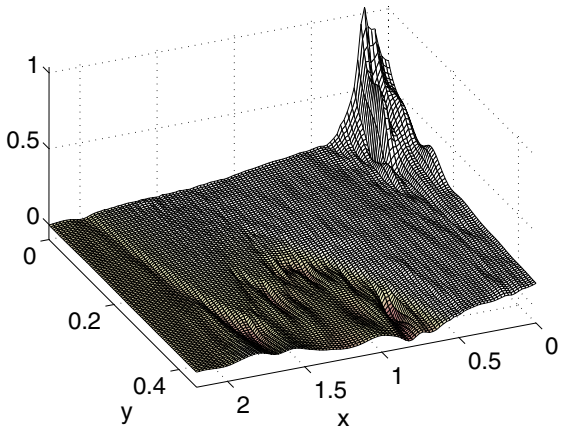
The MSK(3,2) regularized interpolants with $\alpha_{LC} = 5.0626\text{e-}14$ (566 nonzero frame coefficients) are shown in Figure 5.4. The regularized interpolant in Figure 5.4 is very similar to Figure 5.3 but with less local structures. The derivative of the regularized interpolant in Figure 5.4(b) clearly reveal the local features of the landscape.



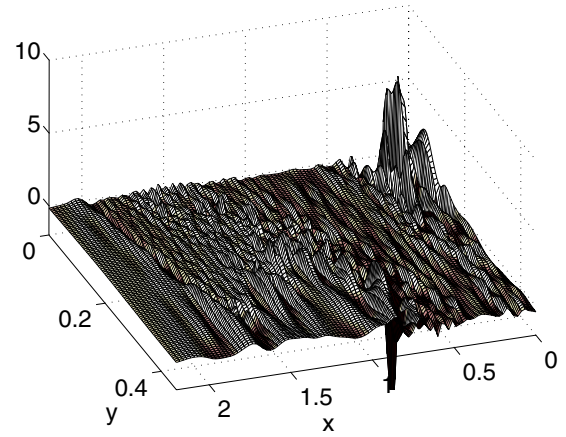
(a) RMS errors.

(b) α_{LC}.

FIG. 5.2. *RMS and* α_{LC} *errors as functions of the noise level* δ.



(a) Full interpolant $s_{\delta,X}$.

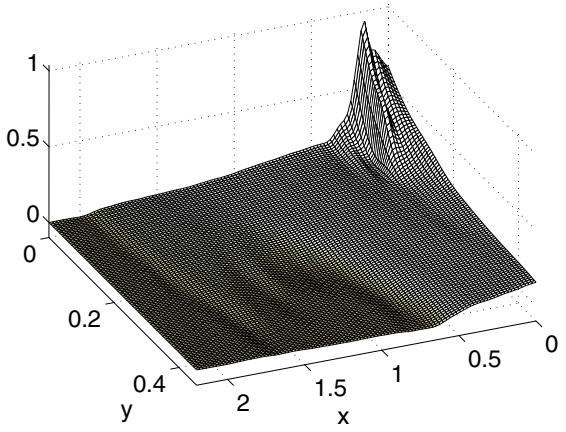


(b) x-derivatives.

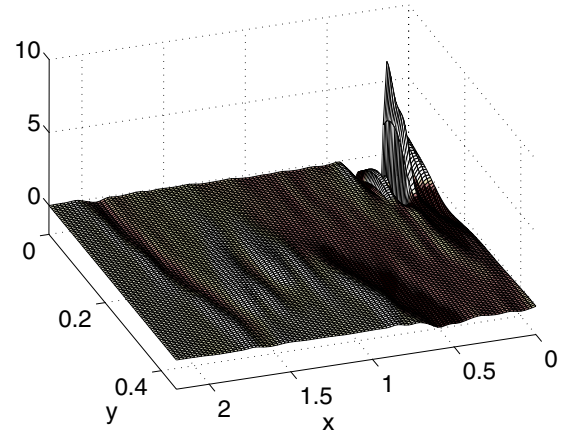
FIG. 5.3. *Full interpolant for the landscape data and its x-derivatives.*

The MSK(m,σ) method assumes the unknown function f lies in $\mathcal{N}_\Phi$ and LC regularizes the interpolant accordingly. If σ is too large, the MSK Φ_σ is very smooth and the MSK scheme will over-regularize the interpolant. Fortunately, nothing will become unbounded. To see this, if we can write the unknown function $f \notin \mathcal{N}_\Phi$ as $f = f_1 + f_2$ where $f_1 \in W^{\sigma,2}$ and $f_2 \in L^2(\Omega) \cap C(\Omega)$, then our results in section 3.1 apply consequently. As an example, Figure 5.5 shows the regularized interpolant of MSK(3,3). The regularization parameter is $\alpha_{LC} = 3.8654\text{e-}12$ resulting in 122 frame coefficients. The resulting regularized interpolant in Figure 5.5 is much smoother than that of MSK(3,2) in Figure 5.4. In fact, it seems too smooth for the landscape data.

For rough data from a function $f \notin \mathcal{N}_\Phi$, we shall treat α_{LC} as an upper estimated



(a) Regularized interpolant s_α with 566 frame coefficients.

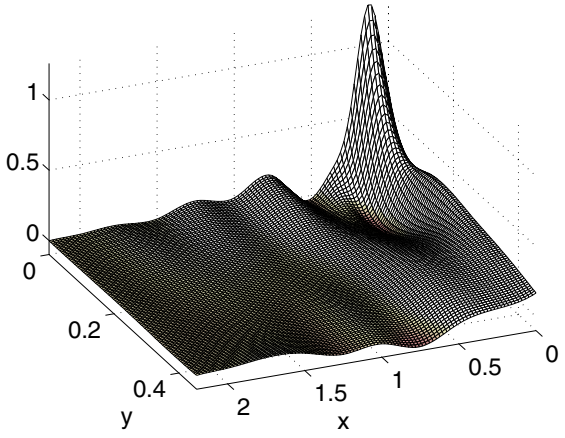


(b) x-derivatives.

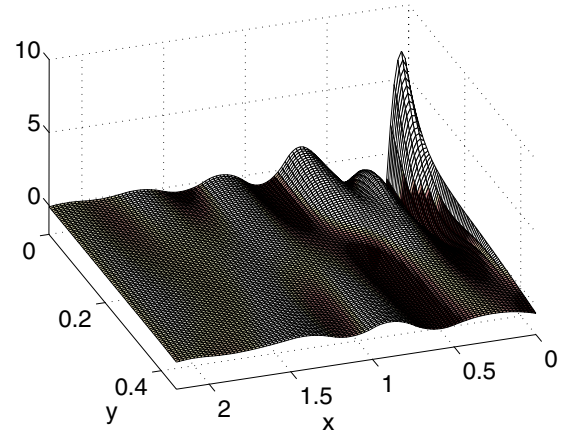
FIG. 5.4. *MSK*(3,2) *regularized interpolant for the landscape data and its x-derivatives.*

parameter. To capture more local features, we could use a regularization parameter $0 < \alpha < \alpha_{LC}$ and obtain results similar to the one from MSK(3,2). The resulting interpolant will contain more local features with any $0 < \alpha < \alpha_{LC}$, while the oscillation in its derivatives are still relatively well behaved. However, we have no robust routine for choosing an optimal regularization parameter in this case.

For unevenly distributed data points, the tolerance to roughness should be proportional to the local density of data points, e.g., a threshold of the form $t_\sigma(j,k)$. Regions with high data point density are expected to have more local features and



(a) Regularized interpolant s_α with 122 frame coefficients.



(b) x-derivatives.

FIG. 5.5. *MSK*(3,3) *regularized interpolant for the landscape data and its x-derivatives.*

higher roughness should therefore be allowed. This allows smooth kernels to capture more local features of the given data set in certain regions. An example of such a density measure is the number of data points in the support of each function $\varphi(2^j \cdot -k)$; the information is already available after computing the frame coefficients. We leave this as an open question for future study.

6. Conclusion. We solve a classical ill-posed numerical differentiation problem by a state-of-the-art matrix-free multiscale kernel based multivariate interpolation method. The theoretical stability for this ill-posed problem is investigated. The

Tikhonov regularization and the LC method are employed to obtain a regularized interpolant. The advantages of the proposed method are (1) the ability to handle problems in higher dimensions; (2) the flexibility to handle real-life, noisy, and multiple-valued data; and (3) the efficiency due to the resultant sparse matrix systems. Numerical examples are given for a bivariate test problem that shows results competitive with the TPS based method and a landscape data set that shows the stability of our scheme even when the unknown function may not be smooth enough for our assumptions.

A HAMILTONIAN-PRESERVING SCHEME FOR THE LIOUVILLE EQUATION OF GEOMETRICAL OPTICS WITH PARTIAL TRANSMISSIONS AND REFLECTIONS*

SHI JIN† AND XIN WEN‡

Abstract. We construct a class of Hamiltonian-preserving numerical schemes for the Liouville equation of geometrical optics, with partial transmissions and reflections. This equation arises in the high frequency limit of the linear wave equation, with a discontinuous index of refraction. In our previous work [*Hamiltonian-preserving schemes for the Liouville equation of geometrical optics with discontinuous local wave speeds*, J. Comput. Phys. 214 (2006), pp. 672–697], we introduced the Hamiltonian-preserving schemes for the same equation when only complete transmissions or reflections occur at the interfaces. These schemes are extended in this paper to the general case of partial transmissions and reflections. The key idea is to build into the numerical flux the behavior of waves at the interface, namely, partial transmissions and reflections that satisfy Snell's law of refraction with the correct transmission and reflection coefficients. This scheme allows a hyperbolic stability condition, under which positivity, and stabilities in both l^1 and l^∞ norms, are established. Numerical experiments are carried out to study the numerical accuracy.

1. Introduction.

In this paper, we construct and study a numerical scheme for the Liouville equation in d-dimension:

$$f_t + H_{\mathbf{v}} \cdot \nabla_{\mathbf{x}} f - H_{\mathbf{x}} \cdot \nabla_{\mathbf{v}} f = 0\,, \quad t > 0, \quad \mathbf{x}, \mathbf{v} \in R^d, \tag{1.1}$$

where the Hamiltonian H possesses the form

$$H(\mathbf{x}, \mathbf{v}) = c(\mathbf{x})|\mathbf{v}| = c(\mathbf{x})\sqrt{v_1^2 + v_2^2 + \cdots + v_d^2} \tag{1.2}$$

with $c(\mathbf{x})$ being the local wave speed of the medium ($1/c(\mathbf{x})$ is the index of refraction); $f(t, \mathbf{x}, \mathbf{v})$ is the density distribution of particles depending on position $\mathbf{x}$, time t, and the slowness vector $\mathbf{v}$. We are concerned with the case when $c(\mathbf{x}) \in W^{1,\infty}$ with isolated *discontinuities* due to different media. The discontinuity in c corresponds to an *interface*, and as a consequence waves crossing this interface will undergo transmissions and reflections.

The bicharacteristics of this Liouville equation (1.1) satisfy the Hamiltonian system

$$\frac{d\mathbf{x}}{dt} = c(\mathbf{x})\frac{\mathbf{v}}{|\mathbf{v}|}, \quad \frac{d\mathbf{v}}{dt} = -c_{\mathbf{x}}|\mathbf{v}|. \tag{1.3}$$

In classical mechanics the Hamiltonian (1.2) of a particle remains a constant along the particle trajectory, even when it is being transmitted or reflected by the interface.

This Liouville equation arises in the phase space description of geometrical optics. It is the high frequency limit of the wave equation

$$u_{tt} - c(\mathbf{x})^2\Delta u = 0, \quad t > 0, \quad \mathbf{x} \in R^d. \tag{1.4}$$

In the past, numerous numerical methods have been proposed for the wave equation (1.4) with discontinuous coefficients c; see [32] and references therein. However, our interest is in the high frequency waves, for which many current numerical methods such as the phase space based level set methods, are based on the Liouville equation (1.1) with smooth c; see [18, 25, 34]. Semiclassical limits of wave equations with transmissions and reflections at the interfaces were studied in [1, 33, 39]. A Liouville equation based level set method for the wave front, but with only reflection, was introduced in [9].

In our previous work [28] two classes of numerical schemes that are suitable for the Liouville equation (1.1) with a discontinuous local wave speed $c(\mathbf{x})$ were constructed. The designing principle there was to build the behavior of waves at the interface—either cross over with a changed velocity according to a constant Hamiltonian, or be reflected with a negative velocity (or momentum)—into the numerical flux; see also earlier works [36, 27]. These schemes were called *Hamiltonian-preserving schemes*. By providing an interface condition, it connects the two domains of Liouville equation with smooth coefficients. This gives a physically relevant selection criterion for a unique solution to the governing equation, which is linearly hyperbolic with singular (discontinuous or measure-valued) coefficients. For a plane wave hitting a flat interface, it selects the solution at the interface governed by *Snell's law of refraction* when the wave length is much shorter than the width of the interface while both lengths go to zero. Nevertheless, this is not the only physically relevant possibility to choose a solution across the interface. When the wave length is much longer than the width of the interface, while both lengths go to zero, the waves can be *partially* transmitted and reflected, and the transmission and reflection coefficients can be analytically computed [33].

The goal of this paper is to construct the numerical scheme which is suitable to deal with partial transmissions and reflections, with computable transmission and reflection coefficients. As in [28], we still use the *Hamiltonian-preserving* principle to determine the transmitted velocity across the interface. The new contribution of this paper is to incorporate the transmission and reflection coefficients into the numerical flux, in order to treat partial transmissions and reflections. This new, explicit scheme, like those in [27, 28], allows a typical hyperbolic stability condition $\Delta t = O(\Delta x, \Delta v)$, under which we also establish the positivity, and l^1 and l^∞ stability theory for the scheme.

In geometrical optics applications, one has to solve the Liouville equation like (1.1) with *measure-valued* initial data

$$f(0, \mathbf{x}, \mathbf{v}) = \rho_0(\mathbf{x})\delta(\mathbf{v} - \mathbf{u}_0(\mathbf{x}));\tag{1.5}$$

see, for example, [38, 14, 25]. The solution at later time remains measure-valued (with finite or even infinite number of concentrations-corresponding to *multivalued* solutions in the physical space). Computation of multivalued solutions in geometrical optics and more generally in nonlinear PDEs has been a very active area of recent research; see [3, 4, 6, 5, 10, 17, 12, 13, 15, 19, 20, 21, 18, 26, 34, 37, 41].

Direct numerical methods (DNM) for the Liouville equation with measure-valued initial data (1.5), which approximate the initial delta function first, then evolve the Liouville equation, could suffer from a poor numerical resolution due to the numerical approximation of the initial data of delta function as well as numerical dissipation [24]. The level set method proposed in [24, 25] decomposes the density distribution f into the bounded level set functions obeying the same Liouville equation, which greatly enhances the numerical resolution. One only involves numerically the delta function at the output time when the moments—which has delta functions in their integrands—need to be evaluated numerically.

However, the extension of this density distribution decomposing approach to the case of partial transmission and reflection is not straightforward. In particular, as the number of transmissions and reflections increase in time, so does the number of needed level set functions satisfying (1.1). This difficulty was already pointed out in [9]. In this paper, when dealing with the measure-valued initial data (1.5) we will just use the DNM. This does not offer the same resolution as those in [28]. It remains an open question on how to extend the decomposition idea of [24, 25] to the case of partial transmissions and reflections.

This paper is organized as follows. In section 2, we present the behavior of waves at an interface, which guides the designing of our scheme. We also give an interface condition (2.5) which allows us to define the analytic solution to the Liouville equation (1.1) with singular coefficients. We present the scheme in 1d in section 3 and study its positivity and stability in both l^∞ and l^1 norms. We extend the scheme to the two space dimension in section 4 in the simple case of an interface aligning with the grids. Numerical examples are given in section 5 to verify the accuracy of the scheme. We make some concluding remarks in section 6.

2. The behavior of waves at an interface.

2.1. Transmissions and reflections at the interface. In geometrical optics, when a wave moves with its density distribution governed by the Liouville equation (1.1), *its Hamiltonian* $H = c|\mathbf{v}|$ *should be preserved across the interface*

$$c^+|\mathbf{v}^+| = c^-|\mathbf{v}^-|, \tag{2.1}$$

where the superscripts $\pm$ indicate the right and left limits of the quantity at the interface. The wave can be partly reflected and partly transmitted. The condition (2.1) can be used to determine the particle velocity on one side of the interface from its value on the other side. When a plane wave hits a flat interface, this condition is equivalent to Snell's law of refraction [28]:

$$\frac{\sin\theta_i}{c^-} = \frac{\sin\theta_t}{c^+} \tag{2.2}$$

and the reflection law

$$\theta_r = \theta_i, \tag{2.3}$$

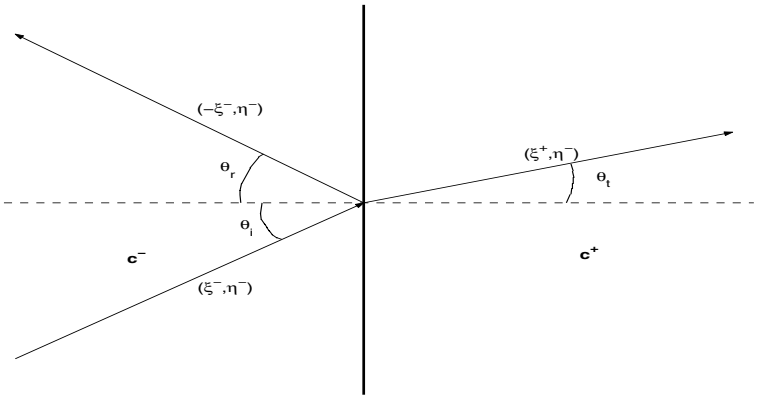

FIG. 2.1. *Wave transmission and reflection at an interface.*

where θ_i, θ_t, and θ_r stand for angles of incident and transmitted and reflected waves; see Figure 2.1. The reflection coefficient is given by

$$\alpha^R = \left(\frac{c^+\cos\theta_i - c^-\cos\theta_t}{c^+\cos\theta_i + c^-\cos\theta_t}\right)^2 \tag{2.4}$$

while the transmission coefficient is $\alpha^T = 1 - \alpha^R$; see, for example, [1, 33, 39].

We will discuss this behavior in more detail in 1D and 2D, respectively.

- The 1D case is simpler. Consider the case when, at an interface, the characteristic on the left of the interface is given by $\xi^- > 0$. Then with probability $\alpha^R = \left(\frac{c^+ - c^-}{c^+ + c^-}\right)^2$, the wave is reflected by the interface with a new velocity $-\xi^-$, and with probability $\alpha^T = 1 - \alpha^R$ it will cross the interface with the new velocity $\xi^+ = \frac{c^-}{c^+}\xi^-$ determined by (2.1).
- The 2D case, when an incident wave hits a vertical interface (see Figure 2.1). Let $\mathbf{x} = (x, y), \mathbf{v} = (\xi, \eta)$. Assume that the incident wave has a velocity (ξ^-, η^-) to the left side of the interface, with $\xi^- > 0$. Since the interface is vertical, (1.3) implies that η is not changed when the wave crosses the interface. There are two possibilities:
  1) $\left(\frac{c^-}{c^+}\right)^2 (\xi^-)^2 + \left[\left(\frac{c^-}{c^+}\right)^2 - 1\right](\eta^-)^2 > 0$. In this case the wave can partially transmit and partially be reflected. With probability $\alpha^R = \left(\frac{c^+\gamma^- - c^-\gamma^+}{c^+\gamma^- + c^-\gamma^+}\right)^2$ the wave is reflected with a new velocity $(-\xi^-, \eta^-)$, where
  $$\gamma^+ = \cos(\theta_t) = \frac{\xi^+}{\sqrt{(\xi^+)^2 + (\eta^-)^2}}, \quad \gamma^- = \cos(\theta_i) = \frac{\xi^-}{\sqrt{(\xi^-)^2 + (\eta^-)^2}}.$$
  With probability $\alpha^T = 1 - \alpha^R$ it will be transmitted with the new velocity (ξ^+, η^-), where
  $$\xi^+ = \sqrt{\left(\frac{c^-}{c^+}\right)^2 (\xi^-)^2 + \left[\left(\frac{c^-}{c^+}\right)^2 - 1\right](\eta^-)^2},$$

is obtained using (2.1).

2) $c^- < c^+$ and $\left(\frac{c^-}{c^+}\right)^2 (\xi^-)^2 + \left[\left(\frac{c^-}{c^+}\right)^2 - 1\right](\eta^-)^2 < 0$. In this case, it is impossible for the wave to transmit, so the wave will be completely reflected with velocity $(-\xi^-, \eta^-)$.

If $\xi^- < 0$, similar behavior can also be analyzed using the constant Hamiltonian condition (2.1).

2.2. The interface condition for density distribution. The solution to the Liouville equation (1.1), which is linearly hyperbolic, can be solved by the method of characteristics. Namely, the density distribution f remains a constant along a bicharacteristic. However, with partial transmissions and reflections, this is no longer true, since f needs to be determined from two bicharacteristics, one accounting for the transmission and the other for reflection. Therefore, we use the following condition at the interface:

$$f(t, \mathbf{x}^+, \mathbf{v}^+) = \alpha^T f(t, \mathbf{x}^-, \mathbf{v}^-) + \alpha^R f(t, \mathbf{x}^+, -\mathbf{v}^+), \tag{2.5}$$

where $\mathbf{v}^-$ is defined from $\mathbf{v}^+$ through the constant Hamiltonian condition (2.1), α^T and α^R are the transmission and reflection coefficients which add up to 1 and vary with $\mathbf{v}^+$ except in the 1D case. *This is the main idea of this paper*, and will be used in constructing the numerical flux across the interface in the next section. As will be seen in the next section, our scheme incorporates the interface condition into the numerical flux.

For hyperbolic systems with discontinuous coefficients, renormalized solution was introduced by DiPerna and Lions [11], and further extended in [7, 8, 22, 23] for uniqueness and stability. The renormalized solution idea cannot be applied here since the coefficients can be measure-valued. Our approach here is to use the interface condition (2.5) to connect two domains in which the Liouville equation has smooth Hamiltonians. Concretely, we define the solution for (1.1) when the local wave speed has discontinuities as follows.

DEFINITION 2.1. *The analytic solution for the Liouville equation* (1.1) *when the local wave speed c has discontinuities is constructed by method of characteristics away from the interface plus the interface condition* (2.5).

Below we justify the well-posedness of the initial value problem, for the simple case of a step function c with a vertical interface. The more general situation remains to be worked out and will be deferred to a future work.

Consider the simple case that the local wave speed $c(\mathbf{x}), \mathbf{x} \in R^d$ is piecewise constant as follows:

$$c(\mathbf{x}) = \begin{cases} c^- & x_1 < 0 \\ c^+ & x_1 > 0, \end{cases} \tag{2.6}$$

where we assume $c^- < c^+$. We will also exclude some singular points, working in the domain defined by

$$\Omega = \left\{(\mathbf{x}, \mathbf{v}) | \mathbf{x} \in R^d, \mathbf{v} \in R^d \backslash \{\mathbf{0}\}\right\} \backslash \{(\mathbf{x}, \mathbf{v}) | x_1 = v_1 = 0\}. \tag{2.7}$$

We have the following theorem.

THEOREM 2.1. *Assume the initial data $f(0, \mathbf{x}, \mathbf{v})$ has a compact support in $\mathbf{v}$. With the solution defined in Definition* 2.1*, the initial value problem to*

$$f_t + H_{\mathbf{v}} \cdot \nabla_{\mathbf{x}} f - H_{\mathbf{x}} \cdot \nabla_{\mathbf{v}} f = 0\,, \quad t > 0, \quad (\mathbf{x}, \mathbf{v}) \in \Omega\,, \tag{2.8}$$

with H given by (1.2)*, c given by* (2.6)*, and Ω given by* (2.7)*, is well-posed in l^∞ and l^1 norms.*

Proof. The proof is based on explicit construction of the analytical solution $f(T,\mathbf{x},\mathbf{v})$. The l^∞ stability follows from the maximum principle, while the key for the l^1 stability is to prove that *the Liouville theorem* (*volume preserving for a Hamiltonian flow*) *holds at the interface for partial tranmissions and reflections.*

To make the following description easier, we define a function extended from the local wave speed (2.6)

$$\widetilde{c}(\mathbf{x},\mathbf{v}) = \begin{cases} c^- & x_1 < 0 \\ c^+ & x_1 > 0 \\ c^- & x_1 = 0,\ v_1 < 0 \\ c^+ & x_1 = 0,\ v_1 > 0, \end{cases} \tag{2.9}$$

which is defined on the whole definition domain Ω. The values of $\widetilde{c}(\mathbf{x},\mathbf{v})$ on $x_1 = 0$, however, are not crucial as long as they are positive.

Split the domain Ω into two parts $\Omega = \Omega_1 \cup \Omega_2$ with

$$\Omega_1 = \left\{ (\mathbf{x},\mathbf{v}) \in \Omega \middle| \, x_1 \left(x_1 - \widetilde{c}(\mathbf{x},\mathbf{v}) \frac{v_1}{|\mathbf{v}|} T \right) > 0 \text{ or } \left(x_1 - \widetilde{c}(\mathbf{x},\mathbf{v}) \frac{v_1}{|\mathbf{v}|} T \right) = 0 \right\},$$

$$\Omega_2 = \left\{ (\mathbf{x},\mathbf{v}) \in \Omega \middle| \, x_1 \left(x_1 - \widetilde{c}(\mathbf{x},\mathbf{v}) \frac{v_1}{|\mathbf{v}|} T \right) < 0 \text{ or } x_1 = 0 \right\},$$

where Ω_1 consists of those points whose positions are not on the interface, and when tracing back along the bicharacteristics, will not hit the interface within time T, except possibly the end point. We further split domain Ω_1, Ω_2 as $\Omega_1 = \Omega_1^- \cup \Omega_1^+$, $\Omega_2 = \Omega_2^- \cup \Omega_2^+$ with

$$\begin{aligned} \Omega_1^- &= \{ (\mathbf{x},\mathbf{v}) \in \Omega_1 | \, x_1 < 0 \}, \\ \Omega_1^+ &= \{ (\mathbf{x},\mathbf{v}) \in \Omega_1 | \, x_1 > 0 \}, \\ \Omega_2^- &= \left\{ (\mathbf{x},\mathbf{v}) \in \Omega_2 \middle| \, \left(x_1 - \widetilde{c}(\mathbf{x},\mathbf{v}) \frac{v_1}{|\mathbf{v}|} T \right) > 0 \right\}, \\ \Omega_2^+ &= \left\{ (\mathbf{x},\mathbf{v}) \in \Omega_2 \middle| \, \left(x_1 - \widetilde{c}(\mathbf{x},\mathbf{v}) \frac{v_1}{|\mathbf{v}|} T \right) < 0 \right\}. \end{aligned}$$

For $(\mathbf{x},\mathbf{v}) \in \Omega_1$, one has

$$f(T,\mathbf{x},\mathbf{v}) = f\left(0, \mathbf{x} - c^- \frac{\mathbf{v}}{|\mathbf{v}|} T, \mathbf{v} \right), \quad (\mathbf{x},\mathbf{v}) \in \Omega_1^-, \tag{2.10}$$

$$f(T,\mathbf{x},\mathbf{v}) = f\left(0, \mathbf{x} - c^+ \frac{\mathbf{v}}{|\mathbf{v}|} T, \mathbf{v} \right), \quad (\mathbf{x},\mathbf{v}) \in \Omega_1^+. \tag{2.11}$$

Define a subset of Ω_2^-

$$\Omega_{2,s} = \left\{ (\mathbf{x},\mathbf{v}) \in \Omega_2^- \middle| \, \left(\frac{c^-}{c^+} \right)^2 |\mathbf{v}|^2 \le v_2^2 + \cdots + v_d^2 \right\}.$$

For $(\mathbf{x},\mathbf{v}) \in \Omega_2$, one has

$$\begin{aligned} &f(T,\mathbf{x},\mathbf{v}) = f(0,\mathbf{x_R},\mathbf{v_R}), && (\mathbf{x},\mathbf{v}) \in \Omega_{2,s}, \\ &f(T,\mathbf{x},\mathbf{v}) = \alpha_T(\mathbf{v_T}) f(0,\mathbf{x_T},\mathbf{v_T}) + \alpha_R(\mathbf{v_R}) f(0,\mathbf{x_R},\mathbf{v_R}), && (\mathbf{x},\mathbf{v}) \in \Omega_2 \backslash \Omega_{2,s}, \end{aligned} \tag{2.12}$$

(2.13)

where $\alpha_T(\mathbf{v}), \alpha_R(\mathbf{v})$ denote the transmission and reflection coefficients determined by the incident wave slowness vector $\mathbf{v}$, with condition $\alpha_T(\mathbf{v})+\alpha_R(\mathbf{v}) = 1$. In geometrical optics, the transmission coefficient also satisfies $\alpha_T(\mathbf{v_T}) = \alpha_T(\mathbf{v_R})$ for the slowness vectors $\mathbf{v_T}, \mathbf{v_R}$ appearing in (2.13), thus it holds that $\alpha_T(\mathbf{v_T}) + \alpha_R(\mathbf{v_R}) = 1$. This contributes to the maximum principle of the solution for (1.1). The positions and slowness vectors $\mathbf{x_T}, \mathbf{v_T}, \mathbf{x_R}, \mathbf{v_R}$ can be explicitly expressed by $\mathbf{x}, \mathbf{v}$ as follows

$$v_{T,1}^2 = \left[\frac{\widehat{c}\,|\mathbf{v}|}{\widehat{c}_T}\right]^2 - v_2^2 - \cdots - v_d^2, \quad v_{T,1}v_1 > 0, \tag{2.14}$$

$$v_{T,i} = v_i, \quad i = 2, \ldots, d, \tag{2.15}$$

$$x_{T,1} = \frac{(\widehat{c}_T)^2 v_{T,1}}{|\mathbf{v}|\widehat{c}}\left(\frac{x_1|\mathbf{v}|}{\widehat{c}\,v_1} - T\right), \tag{2.16}$$

$$x_{T,i} = x_i - v_i\frac{x_1}{v_1} + \frac{(\widehat{c}_T)^2 v_i}{|\mathbf{v}|\widehat{c}}\left(\frac{x_1|\mathbf{v}|}{\widehat{c}\,v_1} - T\right), \quad i = 2, \ldots, d, \tag{2.17}$$

$$v_{R,1} = -v_1, \qquad v_{R,i} = v_i, \quad i = 2, \ldots, d, \tag{2.18}$$

$$x_{R,1} = \frac{\widehat{c}\,v_1}{|\mathbf{v}|}\left(T - \frac{x_1|\mathbf{v}|}{\widehat{c}\,v_1}\right), \tag{2.19}$$

$$x_{R,i} = x_i - v_i\frac{x_1}{v_1} - \frac{\widehat{c}\,v_i}{|\mathbf{v}|}\left(T - \frac{x_1|\mathbf{v}|}{\widehat{c}\,v_1}\right), \quad i = 2, \ldots, d, \tag{2.20}$$

where $\widehat{c}, \widehat{c}_T$ are given by

$$\begin{aligned} &\widehat{c} = c^-, \quad \widehat{c}_T = c^+, \qquad \text{for } (\mathbf{x}, \mathbf{v}) \in \Omega_2^-, \\ &\widehat{c} = c^+, \quad \widehat{c}_T = c^-, \qquad \text{for } (\mathbf{x}, \mathbf{v}) \in \Omega_2^+. \end{aligned}$$

Since the solution $f(T, \mathbf{x}, \mathbf{v})$ can be explicitly expressed as (2.10), (2.11), (2.12), and (2.13), we have proved the existence and uniqueness of the solution for the initial value problem in Theorem 2.1. The l^∞ stability follows easily from the maximum principle and linearity of the Liouville equation.

In the following we prove the l^1-stability of the solution for this initial value problem. Define the l^1-norm of the solution as

$$|f|_1 = \int_\Omega |f(t, \mathbf{x}, \mathbf{v})| d\mathbf{x} d\mathbf{v}.$$

Due to the linearity of the Liouville equation, one only needs to prove that when the initial value is bounded in l^1-norm, then the solution remains bounded in l^1-norm at later time. Assume $|f(0, \mathbf{x}, \mathbf{v})|_1$ exists, we now investigate the relation between $|f(T, \mathbf{x}, \mathbf{v})|_1$ and $|f(0, \mathbf{x}, \mathbf{v})|_1$.

Define the sets

$$\Omega_3^- = \left\{(\mathbf{x}, \mathbf{v}) \in \Omega \,\middle|\, \exists (\mathbf{y}, \mathbf{v}) \in \Omega_1^- \text{ s.t. } \mathbf{x} = \mathbf{y} - c(\mathbf{y})\frac{\mathbf{v}}{|\mathbf{v}|}T\right\},$$

$$\Omega_3^+ = \left\{(\mathbf{x}, \mathbf{v}) \in \Omega \,\middle|\, \exists (\mathbf{y}, \mathbf{v}) \in \Omega_1^+ \text{ s.t. } \mathbf{x} = \mathbf{y} - c(\mathbf{y})\frac{\mathbf{v}}{|\mathbf{v}|}T\right\},$$

$$\Omega_{4,s} = \left\{(\mathbf{x}, \mathbf{v}) \in \Omega \,\middle|\, x_1 < 0,\, x_1 + c^-\frac{v_1}{|\mathbf{v}|}T \geq 0,\, \left(\frac{c^-}{c^+}\right)^2 |\mathbf{v}|^2 \leq v_2^2 + \cdots + v_d^2\right\},$$

$$\Omega_4 = \Omega \backslash \{\Omega_3^- \cup \Omega_3^+ \cup \Omega_{4,s}\}.$$

One has

$$
\begin{aligned}
|f(T,\mathbf{x},\mathbf{v})|_1 &= \int_{\Omega_1^-} |f(T,\mathbf{x},\mathbf{v})| d\mathbf{x}d\mathbf{v} + \int_{\Omega_1^+} |f(T,\mathbf{x},\mathbf{v})| d\mathbf{x}d\mathbf{v} \\
&+ \int_{\Omega_{2,s}} |f(T,\mathbf{x},\mathbf{v})| d\mathbf{x}d\mathbf{v} + \int_{\Omega_2\setminus\Omega_{2,s}} |f(T,\mathbf{x},\mathbf{v})| d\mathbf{x}d\mathbf{v}.
\end{aligned} \tag{2.21}
$$

For the first part in (2.21), since the map $(\mathbf{x},\mathbf{v}) \to (\mathbf{x} + c^- \frac{\mathbf{v}}{|\mathbf{v}|}T, \mathbf{v})$ is volume-preserving, (2.10) gives

$$
\begin{aligned}
\int_{\Omega_1^-} |f(T,\mathbf{x},\mathbf{v})| d\mathbf{x}d\mathbf{v} &= \int_{\Omega_1^-} \left| f\left(0, \mathbf{x} - c^- \frac{\mathbf{v}}{|\mathbf{v}|}T, \mathbf{v}\right)\right| d\mathbf{x}d\mathbf{v} \\
&= \int_{\Omega_3^-} |f(0,\mathbf{x},\mathbf{v})| d\mathbf{x}d\mathbf{v}.
\end{aligned} \tag{2.22}
$$

In the same way, the second part in (2.21) holds

$$
\int_{\Omega_1^+} |f(T,\mathbf{x},\mathbf{v})| d\mathbf{x}d\mathbf{v} = \int_{\Omega_3^+} |f(0,\mathbf{x},\mathbf{v})| d\mathbf{x}d\mathbf{v}. \tag{2.23}
$$

To calculate the last two parts in (2.21), we need to investigate the Jacobians of the maps $(\mathbf{x_T},\mathbf{v_T}) \to (\mathbf{x},\mathbf{v})$ and $(\mathbf{x_R},\mathbf{v_R}) \to (\mathbf{x},\mathbf{v})$. From (2.14)–(2.20), these two maps can be explicitly written out. The nonzero elements in the two Jacobian matrices include

$$
\begin{aligned}
&\frac{\partial x_1}{\partial x_{T,1}}, \frac{\partial x_1}{\partial v_{T,1}}, \frac{\partial x_1}{\partial v_{T,2}}, \dots, \frac{\partial x_1}{\partial v_{T,d}}, \\
&\frac{\partial x_i}{\partial x_{T,1}}, \frac{\partial x_i}{\partial x_{T,i}}, \frac{\partial x_i}{\partial v_{T,1}}, \frac{\partial x_i}{\partial v_{T,2}}, \dots, \frac{\partial x_i}{\partial v_{T,d}}, \quad i = 2,\dots,d, \\
&\frac{\partial v_1}{\partial v_{T,i}}, \quad i = 1,2,\dots,d, \qquad \frac{\partial v_i}{\partial v_{T,i}}, \quad i = 2,\dots,d, \\
&\frac{\partial x_1}{\partial x_{R,1}}, \frac{\partial x_1}{\partial v_{R,1}}, \frac{\partial x_1}{\partial v_{R,2}}, \dots, \frac{\partial x_1}{\partial v_{R,d}}, \\
&\frac{\partial x_i}{\partial x_{R,1}}, \frac{\partial x_i}{\partial x_{R,i}}, \frac{\partial x_i}{\partial v_{R,1}}, \frac{\partial x_i}{\partial v_{R,2}}, \dots, \frac{\partial x_i}{\partial v_{R,d}}, \quad i = 2,\dots,d, \\
&\frac{\partial v_i}{\partial v_{R,i}}, \quad i = 1,2,\dots,d,
\end{aligned}
$$

from which only the diagonal elements influence the Jacobians. They are

$$
\begin{aligned}
&\frac{\partial x_1}{\partial x_{T,1}} = \left(\frac{\widehat{c}}{\widehat{c}_T}\right)^2 \frac{v_1}{v_{T,1}}, \\
&\frac{\partial x_i}{\partial x_{T,i}} = 1, \quad i = 2,\dots,d, \\
&\frac{\partial v_1}{\partial v_{T,1}} = \left(\frac{\widehat{c}_T}{\widehat{c}}\right)^2 \frac{v_{T,1}}{v_1}, \\
&\frac{\partial v_i}{\partial v_{T,i}} = 1, \quad i = 2,\dots,d,
\end{aligned}
$$

$$\frac{\partial x_1}{\partial x_{R,1}} = -1, \qquad \frac{\partial x_i}{\partial x_{R,i}} = 1, \quad i = 2, \dots, d,$$
$$\frac{\partial v_1}{\partial v_{R,1}} = -1, \qquad \frac{\partial v_i}{\partial v_{R,i}} = 1, \quad i = 2, \dots, d.$$

Thus it is verified that the two maps $(\mathbf{x_T}, \mathbf{v_T}) \to (\mathbf{x}, \mathbf{v})$ and $(\mathbf{x_R}, \mathbf{v_R}) \to (\mathbf{x}, \mathbf{v})$ are *volume-preserving*.

For the third part in (2.21), from (2.12) one has

$$\int_{\Omega_{2,s}} |f(T, \mathbf{x}, \mathbf{v})| d\mathbf{x} d\mathbf{v} = \int_{\Omega_{2,s}} |f(0, \mathbf{x_R}, \mathbf{v_R})| d\mathbf{x} d\mathbf{v} = \int_{\Omega_{4,s}} |f(0, \mathbf{x}, \mathbf{v})| d\mathbf{x} d\mathbf{v}. \tag{2.24}$$

For the fourth part in (2.21), from (2.13) one has

$$\begin{aligned}
\int_{\Omega_2 \setminus \Omega_{2,s}} |f(T, \mathbf{x}, \mathbf{v})| d\mathbf{x} d\mathbf{v} &= \int_{\Omega_2 \setminus \Omega_{2,s}} \alpha_T(\mathbf{v_T}) \, |f(0, \mathbf{x_T}, \mathbf{v_T})| d\mathbf{x} d\mathbf{v} \\
&\quad + \int_{\Omega_2 \setminus \Omega_{2,s}} \alpha_R(\mathbf{v_R}) \, |f(0, \mathbf{x_R}, \mathbf{v_R})| d\mathbf{x} d\mathbf{v} \\
&= \int_{\Omega_4} \alpha_T(\mathbf{v}) \, |f(0, \mathbf{x}, \mathbf{v})| d\mathbf{x} d\mathbf{v} + \int_{\Omega_4} \alpha_R(\mathbf{v}) \, |f(0, \mathbf{x}, \mathbf{v})| d\mathbf{x} d\mathbf{v} \\
&= \int_{\Omega_4} |f(0, \mathbf{x}, \mathbf{v})| d\mathbf{x} d\mathbf{v}. \qquad (2.25)
\end{aligned}$$

Together with (2.21), (2.22), (2.23), (2.24), and (2.25), one gets

$$\begin{aligned}
|f(T, \mathbf{x}, \mathbf{v})|_1 &= \int_{\Omega_3^-} |f(0, \mathbf{x}, \mathbf{v})| d\mathbf{x} d\mathbf{v} + \int_{\Omega_3^+} |f(0, \mathbf{x}, \mathbf{v})| d\mathbf{x} d\mathbf{v} \\
&\quad + \int_{\Omega_{4,s}} |f(0, \mathbf{x}, \mathbf{v})| d\mathbf{x} d\mathbf{v} + \int_{\Omega_4} |f(0, \mathbf{x}, \mathbf{v})| d\mathbf{x} d\mathbf{v} \\
&= |f(0, \mathbf{x}, \mathbf{v})|_1.
\end{aligned}$$

This is the l^1-stability—in fact l^1 preservation—of the solution for the initial value problem in Theorem 2.1. ∎

Remark 2.1. In [2], a classical-classical coupling model that connects two domains of classical mechanics with constant potentials with a classical domain $[a, b]$ in between where the potential is variable was introduced, where the interface conditions at a and b were given. When $a = b$, their interface conditions reduce to (2.5).

3. The scheme in 1D.

3.1. The numerical flux. We now describe our finite difference scheme for the 1D Liouville equation

$$f_t + c(x)\text{sign}(\xi) f_x - c_x |\xi| f_\xi = 0\,. \tag{3.1}$$

We employ a uniform mesh with grid points at $x_{i+\frac{1}{2}}, i = 0, \dots, N$, in the x-direction and $\xi_{j+\frac{1}{2}}, j = 0, \dots, M$ in the ξ-direction. The cells are centered at (x_i, ξ_j), $i = 1, \dots, N, j = 1, \dots, M$ with $x_i = \frac{1}{2}(x_{i+\frac{1}{2}} + x_{i-\frac{1}{2}})$ and $\xi_j = \frac{1}{2}(\xi_{j+\frac{1}{2}} + \xi_{j-\frac{1}{2}})$. The uniform mesh size is denoted by $\Delta x = x_{i+\frac{1}{2}} - x_{i-\frac{1}{2}}, \Delta\xi = \xi_{j+\frac{1}{2}} - \xi_{j-\frac{1}{2}}$. We also assume a uniform time step Δt and the discrete time is given by $0 = t_0 < t_1 < \cdots < t_L = T$.

We introduce the mesh ratios $\lambda_x^t = \frac{\Delta t}{\Delta x}, \lambda_\xi^t = \frac{\Delta t}{\Delta \xi}$, assumed to be fixed. The cell average of f is defined by

$$f_{ij} = \frac{1}{\Delta x \Delta \xi} \int_{x_{i-\frac{1}{2}}}^{x_{i+\frac{1}{2}}} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} f(x, \xi, t) d\xi dx.$$

We assume the local wave speed is Lipschitz continuous except at its isolated discontinuous points. Assume that the discontinuous points of the wave speed c are located at the grid points. Let the left and right limits of $c(x)$ at point $x_{i+1/2}$ be $c^+_{i+\frac{1}{2}}$ and $c^-_{i+\frac{1}{2}}$, respectively. Note that if c is continuous at $x_{j+1/2}$, then $c^+_{i+\frac{1}{2}} = c^-_{i+\frac{1}{2}}$. We approximate c by a piecewise linear function

$$c(x) \approx c^+_{j-1/2} + \frac{c^-_{j+1/2} - c^+_{j-1/2}}{\Delta x}(x - x_{j-1/2}).$$

We also define the average wave speed as $c_i = \frac{1}{2}(c^+_{i-\frac{1}{2}} + c^-_{i+\frac{1}{2}})$. We will adopt the flux splitting technique used in [36, 27, 28]. The semidiscrete scheme (with time continuous) reads

$$(f_{ij})_t + \frac{c_i \text{sign}(\xi_j)}{\Delta x}(f^-_{i+\frac{1}{2},j} - f^+_{i-\frac{1}{2},j}) - \frac{c^-_{i+\frac{1}{2}} - c^+_{i-\frac{1}{2}}}{\Delta x \Delta \xi}|\xi_j|(f_{i,j+\frac{1}{2}} - f_{i,j-\frac{1}{2}}) = 0, \tag{3.2}$$

where the numerical fluxes $f_{i,j+\frac{1}{2}}$ are defined using the upwind discretization. Since the characteristics of the Liouville equation may be different on the two sides of the interface, the corresponding numerical fluxes should also be different. The essential part of our algorithm is to define the split numerical fluxes $f^-_{i+\frac{1}{2},j}, f^+_{i-\frac{1}{2},j}$ at each cell interface. We will use (2.5) to define these fluxes.

Assume c is discontinuous at $x_{i+\frac{1}{2}}$. Consider the case $\xi_j > 0$. Using upwind scheme, $f^-_{i+\frac{1}{2},j} = f_{ij}$. However, by (2.5),

$$f^+_{i+\frac{1}{2},j} = \alpha^T f(t, x^-_{i+\frac{1}{2}}, \xi^-) + \alpha^R f(t, x^+_{i+\frac{1}{2}}, -\xi^+)$$

while ξ^- is obtained from $\xi^+ = \xi_j$ from (2.1). Since ξ^- may not be a grid point, we have to define it approximately. One can first locate the two cell centers that bound this velocity, and then use a linear interpolation to evaluate the needed numerical flux at ξ^-. The case of $\xi_j < 0$ is treated similarly. The detailed algorithm to generate the numerical flux is given below.

Algorithm I

- if $\xi_j > 0$

  $f^-_{i+\frac{1}{2},j} = f_{ij}$,

  $\xi' = \dfrac{c^+_{i+\frac{1}{2}}}{c^-_{i+\frac{1}{2}}}\xi_j$

  - if $\xi_k \le \xi' < \xi_{k+1}$ for some k

    $\alpha^R = \left(\dfrac{c^+_{i+\frac{1}{2}} - c^-_{i+\frac{1}{2}}}{c^+_{i+\frac{1}{2}} + c^-_{i+\frac{1}{2}}}\right)^2, \quad \alpha^T = 1 - \alpha^R$

    $f^+_{i+\frac{1}{2},j} = \alpha^T \left(\dfrac{\xi_{k+1} - \xi'}{\Delta \xi} f_{i,k} + \dfrac{\xi' - \xi_k}{\Delta \xi} f_{i,k+1}\right) + \alpha^R f_{i+1,k'}$

where $\xi_{k'} = -\xi_k$

- end
- if $\xi_j < 0$

  $f^+_{i+\frac{1}{2},j} = f_{i+1,j}$,

  $\xi' = \dfrac{c^-_{i+\frac{1}{2}}}{c^+_{i+\frac{1}{2}}}\xi_j$

  - if $\xi_k \le \xi' < \xi_{k+1}$ for some k

    $$\alpha^R = \left(\frac{c^+_{i+\frac{1}{2}} - c^-_{i+\frac{1}{2}}}{c^+_{i+\frac{1}{2}} + c^-_{i+\frac{1}{2}}}\right)^2, \quad \alpha^T = 1 - \alpha^R$$

    $$f^-_{i+\frac{1}{2},j} = \alpha^T\left(\frac{\xi_{k+1} - \xi'}{\Delta\xi} f_{i+1,k} + \frac{\xi' - \xi_k}{\Delta\xi} f_{i+1,k+1}\right) + \alpha^R f_{i,k'}$$

    where $\xi_{k'} = -\xi_k$
  - end

The above algorithm for evaluating numerical fluxes is of first order. One can obtain a second order flux by incorporating the slope limiter, such as the van Leer or minmod slope limiter [31], into the above algorithm. This can be achieved by replacing f_{ik} with $f_{ik} + \frac{\Delta x}{2} s_{ik}$, and replacing $f_{i+1,k}$ with $f_{i+1,k} - \frac{\Delta x}{2} s_{i+1,k}$ in the above algorithm for all possible index k, where s_{ik} is the slope limiter in the x-direction.

After the spatial discretization is specified, one can use any time discretization for the time derivative.

3.2. Positivity and l^∞ contraction. Since the exact solution of the Liouville equation is positive when the initial profile is, it is important that the numerical solution inherits this property.

We only consider the scheme using the first order numerical flux, and the forward Euler method in time. Without loss of generality, we consider the case $\xi_j > 0$ and $c^-_{i+\frac{1}{2}} < c^+_{i-\frac{1}{2}}$ for all i (the other cases can be treated similarly with the same conclusion). The scheme reads

$$\frac{f^{n+1}_{ij} - f^n_{ij}}{\Delta t} + c_i \frac{f_{ij} - (d_1 f_{i-1,k} + d_2 f_{i-1,k+1} + \alpha^R f_{i,k'})}{\Delta x} - \frac{c^-_{i+\frac{1}{2}} - c^+_{i-\frac{1}{2}}}{\Delta x}\xi_j \frac{f_{ij} - f_{i,j-1}}{\Delta\xi} = 0,$$

where d_1, d_2, α^R are nonnegative and $d_1 + d_2 = \alpha^T = 1 - \alpha^R$. We omit the superscript n of f. The above scheme can be rewritten as

$$f^{n+1}_{ij} = \left(1 - c_i\lambda^t_x - \frac{\left|c^-_{i+\frac{1}{2}} - c^+_{i-\frac{1}{2}}\right|}{\Delta x}|\xi_j|\lambda^t_\xi\right) f_{ij} + c_i\lambda^t_x\left(d_1 f_{i-1,k} + d_2 f_{i-1,k+1} + \alpha^R f_{i,k'}\right)$$

$$+ \frac{\left|c^-_{i+\frac{1}{2}} - c^+_{i-\frac{1}{2}}\right|}{\Delta x}|\xi_j|\lambda^t_\xi f_{i,j-1}\,. \tag{3.3}$$

Now we investigate the positivity of scheme (3.3). This is to prove that if $f^n_{ij} \ge 0$ for all (i, j), then this is also true for f^{n+1}. Clearly one just needs to show that all of the coefficients before f^n are nonnegative. A sufficient condition for this is clearly

$$1 - c_i\lambda^t_x - \frac{\left|c^-_{i+\frac{1}{2}} - c^+_{i-\frac{1}{2}}\right|}{\Delta x}|\xi_j|\lambda^t_\xi \ge 0,$$

or

$$\Delta t \max_{i,j} \left[\frac{c_i}{\Delta x} + \frac{\frac{\left|c^-_{i+\frac{1}{2}} - c^+_{i-\frac{1}{2}}\right|}{\Delta x}|\xi_j|}{\Delta \xi} \right] \le 1. \tag{3.4}$$

The quantity $\frac{\left|c^-_{i+\frac{1}{2}} - c^+_{i-\frac{1}{2}}\right|}{\Delta x}$ now represents the wave speed gradient at its *smooth* point, which has a *finite* upper bound since $c \in W^{1,\infty}$. In addition, typically f has a compact support, so in practical computation ξ is confined in a bounded set. Thus our scheme allows a time step $\Delta t = O(\Delta x, \Delta \xi)$.

According to the study in [35], our second order scheme, which incorporates a slope limiter into the first order scheme, is positive under the half CFL condition, namely, the constant on the right-hand side of (3.4) is 1/2.

The above conclusion is drawn on the forward Euler time discretization. One can draw the same conclusion for the second order TVD Runge–Kutta time discretization [40].

The l^∞-contracting property of this scheme:

$$\|f^n\|_\infty \le \|f^0\|_\infty$$

follows easily, because the coefficients in (3.3) are positive and the sum of them is 1.

3.3. The l^1-stability of the scheme. In this section we prove the l^1-stability of the scheme (with the first order numerical flux and the forward Euler method in time). For simplicity, we consider the case when the wave speed has only one discontinuity at grid point $x_{m+\frac{1}{2}}$ with $c^-_{m+\frac{1}{2}} > c^+_{m+\frac{1}{2}}$, and $c'(x) > 0$ at smooth points. The other cases, namely, when $c'(x) \le 0$, or the wave speed having several discontinuity points with increased or decreased jumps, can be discussed similarly. Denote $\lambda_c \equiv c^+_{m+\frac{1}{2}}/c^-_{m+\frac{1}{2}} < 1$.

We consider the general case that $\xi_1 < 0, \xi_M > 0$. For this case, as adopted in [25, 28], the computational domain should exclude a set $O_\xi = \{(x,\xi) \in \mathbb{R}^2 \,|\xi = 0\}$, which causes singularity in the velocity field. For example, we can exclude the following index set:

$$D_o = \left\{ (i,j) \middle| |\xi_j| < \frac{\Delta \xi}{2} \right\},$$

from the computational domain.

Since $c(x)$ has a discontinuity, we also define an index set

$$D_l^4 = \{(i,j) | x_i \le x_m, \xi_j < \lambda_c \xi_1\}.$$

As mentioned in [28], D_l^4 represents the area where waves come from outside of the domain $[x_1, x_N] \times [\xi_1, \xi_M]$. In order to implement our scheme conveniently, this index set is also excluded from the computational domain. Thus the computational domain is chosen as

$$E_d = \{(i,j) | i = 1, \dots, N, j = 1, \dots, M\} \setminus \left\{D_o \cup D_l^4\right\}. \tag{3.5}$$

As a result of excluding the index set D_o from the computational domain, the computational domain is split into two nonoverlapping parts:

$$E_d = \{(i,j) \in E_d | \xi_j > 0\} \cup \{(i,j) \in E_d | \xi_j < 0\} \equiv E_d^+ \cup E_d^-.$$

In [28] we analyzed the l^1-stability of the scheme on E_d^+ and E_d^- separately. Here we will conduct the analysis on the full phase space E_d since transmission and reflection waves coexist at the interface.

We define the l^1-norm of a numerical solution u_{ij} in the set E_d to be

$$|f|_1 = \frac{1}{N_d} \sum_{(i,j)\in E_d} |f_{ij}| \tag{3.6}$$

with N_d being the number of elements in E_d.

Given the initial data $f_{ij}^0, (i,j) \in E_d$. Denote the numerical solution at time T to be $f_{ij}^L, (i,j) \in E_d$. To prove the l^1-stability, we need to show that $|f^L|_1 \le C|f^0|_1$.

Due to the linearity of the scheme, the equation for the error between the analytical and the numerical solutions is the same as (3.3), so in this section, f_{ij} will denote the error. We assume there is no error at the boundary, thus $f_{ij}^n = 0$ at the boundary. If the l^1-norm of the error introduced at each time step in the incoming boundary cells is ensured to be $o(1)$ part of $|f^n|_1$, our following analysis still applies.

Now denote

$$A_i = \frac{1}{\Delta x} \left| c^-_{i+\frac{1}{2}} - c^+_{i-\frac{1}{2}} \right| . \tag{3.7}$$

Since $c(x)$ is Lipschitz continuous at its smooth part, there exists an $A_u > 0$, such that $A_i < A_u, \forall i$. Assume also that there is an $C_m > 0$ such that $c_i > C_m, \forall i$. The finite difference scheme is given as follows:

- When $\xi_j > 0$
  1) if $i \neq m+1$,

$$f_{ij}^{n+1} = \left(1 - A_i|\xi_j|\lambda_\xi^t - c_i\lambda_x^t\right) f_{ij} + A_i|\xi_j|\lambda_\xi^t f_{i,j+1} + c_i\lambda_x^t f_{i-1,j}, \tag{3.8}$$

  2)

$$\begin{aligned} f_{m+1,j}^{n+1} &= \left(1 - A_{m+1}|\xi_j|\lambda_\xi^t - c_{m+1}\lambda_x^t\right) f_{m+1,j} + A_{m+1}|\xi_j|\lambda_\xi^t f_{m+1,j+1} \\ &\quad + c_{m+1}\lambda_x^t(d_{j1}f_{m,k} + d_{j2}f_{m,k+1} + \alpha^R f_{m+1,k'}). \end{aligned} \tag{3.9}$$

- When $\xi_j < 0$
  3) if $i \neq m$,

$$f_{ij}^{n+1} = \left(1 - A_i|\xi_j|\lambda_\xi^t - c_i\lambda_x^t\right) f_{ij} + A_i|\xi_j|\lambda_\xi^t f_{i,j+1} + c_i\lambda_x^t f_{i+1,j}, \tag{3.10}$$

  4)

$$\begin{aligned} f_{mj}^{n+1} &= \left(1 - A_m|\xi_j|\lambda_\xi^t - c_m\lambda_x^t\right) f_{mj} + A_m|\xi_j|\lambda_\xi^t f_{m,j+1} \\ &\quad + c_m\lambda_x^t(d_{j1}f_{m+1,k} + d_{j2}f_{m+1,k+1} + \alpha^R f_{m,k'}), \end{aligned} \tag{3.11}$$

where $0 \le d_{j1}, d_{j2} \le 1$ and $d_{j1} + d_{j2} = \alpha^T = 1 - \alpha^R = 1$. In (3.9) k is determined by $\xi_k \le \lambda_c\xi_j < \xi_{k+1}$ and $\xi_{k'} = -\xi_k$. In (3.11) k is determined by $\xi_k \le \frac{\xi_j}{\lambda_c} < \xi_{k+1}$ and $\xi_{k'} = -\xi_k$.

When summing up all absolute values of f_{ij}^{n+1} in (3.8)–(3.11), one typically gets the following inequality:

$$|f^{n+1}|_1 \le \frac{1}{N_d} \sum_{(i,j)\in E_d} \alpha_{ij}|f_{ij}^n|, \tag{3.12}$$

where the coefficients α_{ij} are positive. One can check that, under the CFL condition (3.4), $\alpha_{ij} \le 1 + 2A_u\Delta t$ except for possibly $(i,j) \in D^-_{m+1} \bigcup D^+_m$, where

$$D^-_{m+1} = \{(i,j) \in E^-_d | i = m+1\}, \quad D^+_m = \{(i,j) \in E^+_d | i = m\}.$$

We next derive the bounds for M^-, M^+ defined as

$$M^- = \max_{(m+1,j)\in D^-_{m+1}} \alpha_{m+1,j}, \quad M^+ = \max_{(m,j)\in D^+_m} \alpha_{m,j}.$$

Define the set

$$S^{m+1}_j = \left\{ j' \middle| \xi_{j'} < 0, \left| \frac{\xi_{j'}}{\lambda_c} - \xi_j \right| < \Delta\xi \right\} \quad \text{for} \quad (m+1,j) \in D^-_{m+1}.$$

Let the number of elements in S^{m+1}_j be N^{m+1}_j. One can check that $N^{m+1}_j \le 2\lambda_c + 1$ because every two elements $j'_1, j'_2 \in S^{m+1}_j$ satisfy $\left| \frac{\xi_{j'_1}}{\lambda_c} - \frac{\xi_{j'_2}}{\lambda_c} \right| \ge \frac{\Delta\xi}{\lambda_c}$.

On the other hand, one can easily check from (3.9) and (3.11), for $(m+1,j) \in D^-_{m+1}$, that

$$\alpha_{m+1,j} < 1 - c_{m+1}\lambda^t_x + c_m\lambda^t_x\,(2\lambda_c+1)\,\alpha^T + \alpha^R c_{m+1}\lambda^t_x = 1 + \alpha^T(c_m + c_{m+1})\lambda^t_x + O(\Delta x),$$

so for sufficiently small Δx, M^- can be bounded by

$$M^- < 1 + 2\alpha^T(c_m + c_{m+1})\lambda^t_x.$$

Similarly, one can prove for sufficiently small Δx, M^+ is also bounded by

$$M^+ < 1 + 2\alpha^T(c_m + c_{m+1})\lambda^t_x.$$

Denote $M' = 2\alpha^T(c_m + c_{m+1})\lambda^t_x$. From (3.12),

$$|f^{n+1}|_1 < (1 + 2A_u\Delta t)\,|f^n|_1 + \frac{M'}{N_d} \sum_{(m+1,j)\in D^-_{m+1}} |f^n_{m+1,j}| + \frac{M'}{N_d} \sum_{(m,j)\in D^+_m} |f^n_{m,j}|. \tag{3.13}$$

Consecutively using (3.13) gives

$$|f^L|_1 < (1 + 2A_u\Delta t)^L \left\{ |f^0|_1 + \frac{M'}{N_d} \sum_{n=0}^{L-1} \left[\sum_{(m+1,j)\in D^-_{m+1}} |f^n_{m+1,j}| \right] + \frac{M'}{N_d} \sum_{n=0}^{L-1} \left[\sum_{(m,j)\in D^+_m} |f^n_{m,j}| \right] \right\}. \tag{3.14}$$

Define

$$S_1 = \sum_{n=0}^{L-1} \left[\sum_{(m+1,j)\in D^-_{m+1}} |f^n_{m+1,j}| \right], \quad S_2 = \sum_{n=0}^{L-1} \left[\sum_{(m,j)\in D^+_m} |f^n_{m,j}| \right]. \tag{3.15}$$

These two terms can be proved in the same way as in [29] to get

$$S_1, S_2 < C_T N_d |f^0|_1, \tag{3.16}$$

where

$$C_T \equiv \exp\left(\frac{2A_u}{C_m}(x_N - x_1)\right)\frac{1}{C_m \lambda_x^t}. \tag{3.17}$$

Combing (3.14) and (3.16),

$$\begin{aligned} |f^L|_1 &< (1 + 2A_u\Delta t)^L \left\{|f^0|_1 + 2C_T M' |f^0|_1\right\} \\ &= \exp(2A_u T)\left[1 + 2C_T M'\right]|f^0|_1 \\ &\equiv C|f^0|_1, \end{aligned}$$

where $C \equiv \exp(2A_u T)[1 + 2C_T M']$.

Thus we prove the following theorem.

THEOREM 3.1. *Let $c(x) \in W^{1,\infty}$ have a discontinuity at one point, and be bounded below from zero, $c(x) > C_m > 0$. Assume f^0 has a finite l^1-norm defined* (3.6) *with a compact support in ξ. Then under the hyperbolic CFL condition* (3.4)*, the solution yielded by the scheme* (3.8)–(3.11) *is stable in l^1-norm:*

$$|f^L|_1 < C|f^0|_1.$$

4. The scheme in two space dimension. Consider the 2D Liouville equation

$$f_t + \frac{c(x,y)\xi}{\sqrt{\xi^2+\eta^2}} f_x + \frac{c(x,y)\eta}{\sqrt{\xi^2+\eta^2}} f_y - c_x\sqrt{\xi^2+\eta^2} f_\xi - c_y\sqrt{\xi^2+\eta^2} f_\eta = 0. \tag{4.1}$$

We employ a uniform mesh with grid points at $x_{i+\frac{1}{2}}, y_{j+\frac{1}{2}}, \xi_{k+\frac{1}{2}}, \eta_{l+\frac{1}{2}}$ in each direction. The cells are centered at $(x_i, y_j, \xi_k, \eta_l)$ with $x_i = \frac{1}{2}(x_{i+\frac{1}{2}} + x_{i-\frac{1}{2}}), y_j = \frac{1}{2}(y_{j+\frac{1}{2}} + y_{j-\frac{1}{2}}), \xi_k = \frac{1}{2}(\xi_{k+\frac{1}{2}} + \xi_{k-\frac{1}{2}}), \eta_l = \frac{1}{2}(\eta_{l+\frac{1}{2}} + \eta_{l-\frac{1}{2}})$. The mesh size is denoted by $\Delta x = x_{i+\frac{1}{2}} - x_{i-\frac{1}{2}}, \Delta y = y_{j+\frac{1}{2}} - y_{j-\frac{1}{2}}, \Delta\xi = \xi_{k+\frac{1}{2}} - \xi_{k-\frac{1}{2}}, \Delta\eta = \eta_{l+\frac{1}{2}} - \eta_{l-\frac{1}{2}}$. We define the cell average of f as

$$f_{ijkl} = \frac{1}{\Delta x\Delta y\Delta\xi\Delta\eta}\int_{x_{i-\frac{1}{2}}}^{x_{i+\frac{1}{2}}}\int_{y_{j-\frac{1}{2}}}^{y_{j+\frac{1}{2}}}\int_{\xi_{k-\frac{1}{2}}}^{\xi_{k+\frac{1}{2}}}\int_{\eta_{l-\frac{1}{2}}}^{\eta_{l+\frac{1}{2}}} f(x,y,\xi,\eta,t)\,d\eta\,d\xi\,dy\,dx.$$

Similar to the 1D case, we approximate $c(x,y)$ by a piecewise bilinear function, and, for convenience, we always provide two interface values of c at each cell interface. When c is smooth at a cell interface, the two potential interface values are identical. We also define the average wave speed in a cell by averaging the four wave speed values at the cell interface:

$$c_{ij} = \frac{1}{4}(c^+_{i-\frac{1}{2},j} + c^-_{i+\frac{1}{2},j} + c^+_{i,j-\frac{1}{2}} + c^-_{i,j+\frac{1}{2}}).$$

The 2D Liouville equation (4.1) can be semidiscretized as

$$(f_{ijkl})_t + \frac{c_{ij}\xi_k}{\Delta x\sqrt{\xi_k^2+\eta_l^2}}\left(f^-_{i+\frac{1}{2},jkl} - f^+_{i-\frac{1}{2},jkl}\right)$$

$$
\begin{aligned}
&+\frac{c_{ij}\eta_l}{\Delta y\sqrt{\xi_k^2+\eta_l^2}}\left(f^-_{i,j+\frac12,kl}-f^+_{i,j-\frac12,kl}\right)\\
&-\frac{c^-_{i+\frac12,j}-c^+_{i-\frac12,j}}{\Delta x\Delta\xi}\sqrt{\xi_k^2+\eta_l^2}\left(f_{ij,k+\frac12,l}-f_{ij,k-\frac12,l}\right)\\
&-\frac{c^-_{i,j+\frac12}-c^+_{i,j-\frac12}}{\Delta y\Delta\eta}\sqrt{\xi_k^2+\eta_l^2}\left(f_{ijk,l+\frac12}-f_{ijk,l-\frac12}\right)\\
=\quad & 0,
\end{aligned}
$$

where the interface values $f_{ij,k+\frac12,l}, f_{ijk,l+\frac12}$ are provided by the upwind approximation, and the split interface values $f^-_{i+\frac12,jkl}, f^+_{i-\frac12,jkl}, f^-_{i,j+\frac12,kl}, f^+_{i,j-\frac12,kl}$ should be obtained using a similar but slightly different algorithm for the 1D case. For example, to evaluate $f^\pm_{i+\frac12,jkl}$ we can extend Algorithm I as

Algorithm I in 2D

- if $\xi_k>0$

  $f^-_{i+\frac12,jkl}=f_{ijkl},\quad \xi_{k_1}=-\xi_k$

  - if $\left(\frac{C^+_{i+\frac12,j}}{C^-_{i+\frac12,j}}\right)^2(\xi_k)^2+\left[\left(\frac{C^+_{i+\frac12,j}}{C^-_{i+\frac12,j}}\right)^2-1\right](\eta_l)^2>0$

    $\xi^-=\sqrt{\left(\frac{C^+_{i+\frac12,j}}{C^-_{i+\frac12,j}}\right)^2(\xi_k)^2+\left[\left(\frac{C^+_{i+\frac12,j}}{C^-_{i+\frac12,j}}\right)^2-1\right](\eta_l)^2}$

    - if $\xi_{k'}\le\xi^-<\xi_{k'+1}$ for some k'

      $\gamma^+=\frac{\xi_k}{\sqrt{(\xi_k)^2+(\eta_l)^2}},\quad \gamma^-=\frac{\xi^-}{\sqrt{(\xi')^2+(\eta_l)^2}}$

      $\alpha^R=\left(\frac{c^+_{i+\frac12}\gamma^- - c^-_{i+\frac12}\gamma^+}{c^+_{i+\frac12}\gamma^- + c^-_{i+\frac12}\gamma^+}\right)^2,\quad \alpha^T=1-\alpha^R$

      $f^+_{i+\frac12,jkl}=\alpha^T\left(\frac{\xi_{k'+1}-\xi^-}{\Delta\xi}f_{ij,k',l}+\frac{\xi^--\xi_{k'}}{\Delta\xi}f_{ij,k'+1,l}\right)+\alpha^R f_{i+1,j,k_1,l}$

    - end
  - else

    $f^+_{i+\frac12,jkl}=f_{i+1,j,k_1,l}$
  - end

- if $\xi_k<0$

  $f^+_{i+\frac12,jkl}=f_{i+1,jkl},\quad \xi_{k_1}=-\xi_k$

  - if $\left(\frac{C^-_{i+\frac12,j}}{C^+_{i+\frac12,j}}\right)^2(\xi_k)^2+\left[\left(\frac{C^-_{i+\frac12,j}}{C^+_{i+\frac12,j}}\right)^2-1\right](\eta_l)^2>0$

    $\xi^+=-\sqrt{\left(\frac{C^-_{i+\frac12,j}}{C^+_{i+\frac12,j}}\right)^2(\xi_k)^2+\left[\left(\frac{C^-_{i+\frac12,j}}{C^+_{i+\frac12,j}}\right)^2-1\right](\eta_l)^2}$

    - if $\xi_{k'}\le\xi^+<\xi_{k'+1}$ for some k'

      $\gamma^+=\frac{|\xi^+|}{\sqrt{(\xi^+)^2+(\eta_l)^2}},\quad \gamma^-=\frac{|\xi_k|}{\sqrt{(\xi_k)^2+(\eta_l)^2}}$

$$\alpha^R = \left(\frac{c^+_{i+\frac{1}{2}}\gamma^- - c^-_{i+\frac{1}{2}}\gamma^+}{c^+_{i+\frac{1}{2}}\gamma^- + c^-_{i+\frac{1}{2}}\gamma^+}\right)^2, \quad \alpha^T = 1 - \alpha^R$$

$$f^-_{i+\frac{1}{2},jkl} = \alpha^T\left(\frac{\xi_{k'+1} - \xi^+}{\Delta\xi} f_{i+1,j,k',l} + \frac{\xi^+ - \xi_{k'}}{\Delta\xi} f_{i+1,j,k'+1,l}\right) + \alpha^R f_{ij,k_1,l}$$

- end
- else

$$f^-_{i+\frac{1}{2},jkl} = f_{i,j,k_1,l} \text{ where } \xi_{k_1} = -\xi_k$$

- end

The flux $f^{\pm}_{i,j+\frac{1}{2},kl}$ can be constructed similarly.

As introduced in section 2, the essential difference between the 1D and 2D flux definitions is that in the 2D case, the phenomenon that a wave is completely reflected at the interface does occur, while in 1D, the transmission and reflection waves always coexist at the interface.

Since the wave speed $c \in W^{1,\infty}$, this scheme, similar to the 1D scheme, is also subject to a hyperbolic CFL condition under which the scheme is positive.

5. Numerical examples. In this section we present numerical examples to demonstrate the validity of the proposed scheme and to study the numerical accuracy. In the numerical computations the second order TVD Runge–Kutta time discretization [40] is used. We use the second order scheme with the van Leer slope limiter in constructing the numerical fluxes except for Example 5.2.

Example 5.1. A 1D problem with exact L^∞-solution. Consider the 1D Liouville equation

$$f_t + c(x)\text{sign}(\xi) f_x - c_x|\xi| f_\xi = 0 \tag{5.1}$$

with a discontinuous wave speed given by

$$c(x) = \begin{cases} 0.6 & x < 0 \\ 0.2 & x > 0. \end{cases}$$

The initial data is given by

$$f(x,\xi,0) = \begin{cases} 1 & x < 0, \xi > 0, \sqrt{x^2 + 4\xi^2} < 1, \\ 1 & x > 0, \xi < 0, \sqrt{x^2 + \xi^2} < 1, \\ 0 & \text{otherwise.} \end{cases} \tag{5.2}$$

In this example the reflection and transmission coefficients α^R, α^T at the interface are $\alpha^R = \dfrac{1}{4}, \alpha^T = \dfrac{3}{4}$. The exact solution for f at $t = 1$ is given by

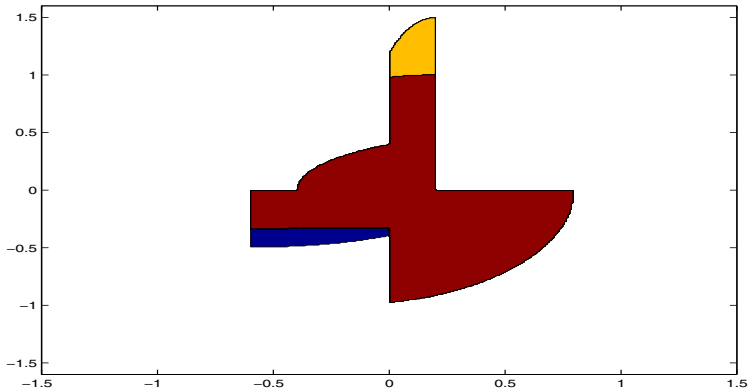

FIG. 5.1. *Example* 5.1*, the nonzero part of the exact solution* $f(x,\xi,1)$ *depicted on the* 400×400 *mesh. The horizontal axis is the position, the vertical axis is the slowness.*

$$f(x,\xi,1)=\begin{cases}\alpha^T & 0<x<0.2,\quad \sqrt{1-(0.2-x)^2}<\xi<1.5\sqrt{1-(3x-0.6)^2};\\ 1 & 0<x<0.2,\quad 0<\xi<\sqrt{1-(0.2-x)^2};\\ 1 & 0<x<0.8,\quad -\sqrt{1-(x+0.2)^2}<\xi<0;\\ 1 & -0.4<x<0,\quad 0<\xi<\dfrac{1}{2}\sqrt{1-(x-0.6)^2};\\ 1 & -0.6<x<0,\quad -\dfrac{1}{3}\sqrt{1-\left(\dfrac{x}{3}+0.2\right)^2}<\xi<0;\\ \alpha^R & -0.6<x<0,\quad -\dfrac{1}{2}\sqrt{1-(x+0.6)^2}<\xi<-\dfrac{1}{3}\sqrt{1-\left(\dfrac{x}{3}+0.2\right)^2};\\ 0 & \text{otherwise,}\end{cases}\tag{5.3}$$

as shown in Figure 5.1.

We are also interested in computing the moments of f, which include the density

$$\rho(x,t)=\int f(x,\xi,t)d\xi$$

and the averaged slowness

$$u(x,t)=\int f(x,\xi,t)\xi d\xi\Big/\rho(x,t).$$

At $t = 1$, the exact density is

$$\rho(x,1) = \begin{cases} \sqrt{1-(x+0.2)^2} & 0.2 < x < 0.8; \\ 1.5\alpha^T\sqrt{1-(3x-0.6)^2} + \alpha^R\sqrt{1-(0.2-x)^2} & \\ +\sqrt{1-(x+0.2)^2} & 0 < x < 0.2; \\ \dfrac{\alpha^T}{3}\sqrt{1-\left(\dfrac{x}{3}+0.2\right)^2} + \dfrac{\alpha^R}{2}\sqrt{1-(x+0.6)^2} & -0.6 < x < -0.4; \\ \dfrac{\alpha^T}{3}\sqrt{1-\left(\dfrac{x}{3}+0.2\right)^2} + \dfrac{\alpha^R}{2}\sqrt{1-(x+0.6)^2} & \\ +\dfrac{1}{2}\sqrt{1-(x-0.6)^2} & -0.4 < x < 0, \\ 0 & \text{otherwise.} \end{cases} \tag{5.4}$$

The averaged slowness only has definition in $[-0.6, 0.8]$ since the density is zero outside this interval. The exact averaged slowness in $[-0.6, 0.8]$ is

$$u(x,1) = \frac{1}{2\rho(x,1)} \begin{cases} -\left[1-(x+0.2)^2\right] & 0.2 < x < 0.8; \\ 2.25\alpha^T\left[1-(3x-0.6)^2\right] + \alpha^R\left[1-(0.2-x)^2\right] & \\ -\left[1-(x+0.2)^2\right] & 0 < x < 0.2; \\ \dfrac{-\alpha^T}{9}\left[1-\left(\dfrac{x}{3}+0.2\right)^2\right] - \dfrac{\alpha^R}{4}\left[1-(x+0.6)^2\right] & -0.6 < x < -0.4; \\ \dfrac{-\alpha^T}{9}\left[1-\left(\dfrac{x}{3}+0.2\right)^2\right] - \dfrac{\alpha^R}{4}\left[1-(x+0.6)^2\right] & \\ +\dfrac{1}{4}\left[1-(x-0.6)^2\right] & -0.4 < x < 0. \end{cases} \tag{5.5}$$

We choose the time step as $\Delta t = \frac{1}{2}\Delta\xi$. The computational domain is chosen as $[x, \xi] \in [-1.5, 1.5] \times [-1.6, 1.6]$. Table 5.1 compares the l^1-error of the numerical solutions for f, ρ on $[-1.5, 1.5]$ and u on $[-0.6, 0.8]$ computed with different meshes, respectively.

The convergence rate of f in the l^1-norm is shown to be about 0.74. This agrees with the well-established theory [30, 42], that the l^1-error by finite difference scheme for a discontinuous solution of a linear hyperbolic equation is at most half order. The convergence rate of ρ and u are shown to be about 0.74 and 0.98, respectively, since the solutions also contain discontinuities away from the interface.

Figure 5.2 shows the numerical density ρ and averaged slowness u computed with a 400× 400 cell along with the exact solutions in the physical space.

Example 5.2. Computing the physical observables of a 1D problem with measure-valued solution. Consider the 1D Liouville equation (5.1), where the wave speed is a

TABLE 5.1
l^1 error of the numerical solutions with different meshes.

meshes	50 × 50	100 × 100	200× 200	400× 400
f	0.179090	0.104788	0.064989	0.038535
ρ	0.124361	0.079007	0.043248	0.025187
u	0.143083	0.063068	0.043079	0.019870

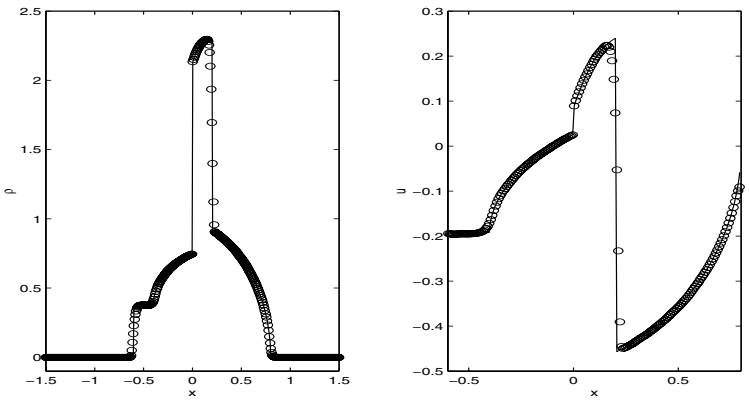

FIG. 5.2. *Example* 5.1, *the density* ρ *and averaged slowness* u *at* $t = 1$. *Solid line: the exact solution; "o": the numerical solutions using the* 400×400 *mesh. Left: the density* ρ*; Right: the averaged slowness* u.

well-shaped function

$$c(x) = \begin{cases} 0.6 & -0.4 < x < 0.4 \\ 1 & \text{else} \end{cases}$$

and the initial data is a delta-function

$$f(x, \xi, 0) = \delta(\xi - w(x)) \tag{5.6}$$

with

$$w(x) = \begin{cases} 0.5, & x \le -1.6; \\ 0.5 - \dfrac{0.4}{(1.6)^2}(x + 1.6)^2, & -1.6 < x \le 0; \\ -0.5 + \dfrac{0.4}{(1.6)^2}(x - 1.6)^2, & 0 < x < 1.6; \\ -0.5, & x \ge 1.6\,. \end{cases} \tag{5.7}$$

Figure 5.2 plots $w(x)$ in dashed lines.

In this example we are interested in the approximation of the density

$$\rho(x, t) = \int f(x, \xi, t) d\xi\,,$$

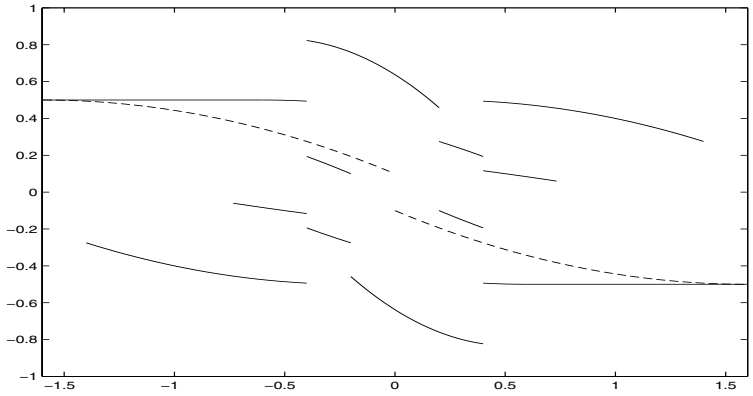

FIG. 5.3. *Example* 5.2, *slowness. Dashed line: the initial slowness* $w(x)$*; Solid line: the slowness at* $t = 1$*. The horizontal axis is the position, the vertical axis is the slowness.*

and the averaged slowness

$$u(x,t) = \frac{\int f(x,\xi,t)\xi d\xi}{\int f(x,\xi,t)d\xi}\,.$$

In the computation, we first approximate the delta function initial data (5.6) by a discrete delta function [16]:

$$\delta_\beta(x) = \begin{cases} \dfrac{1}{\beta}\left(1 - \left|\dfrac{x}{\beta}\right|\right), & |\frac{x}{\beta}| \le 1\,, \\ 0, & |\frac{x}{\beta}| > 1\,. \end{cases} \tag{5.8}$$

If $|\xi_j - w(x_i)| < \beta$, set $f_{ij}^0 = \frac{1}{\beta}\big(1 - |\frac{\xi_j - w(x_i)}{\beta}|\big)$, and $f_{ij}^0 = 0$ otherwise. The choice of the discrete delta function support size β will be made more precise later. We then use the Hamiltonian-preserving scheme to solve the Liouville equation (5.1). Then the moments are recovered by

$$\rho_i^n = \sum_j f_{ij}^n \Delta\xi, \quad u_i^n = \left(\sum_j f_{ij}^n \xi_j \Delta\xi\right) \Big/ \rho_i^n.$$

With partial transmissions and reflections, the exact multivalued slowness at $t = 1$ is depicted as the solid line in Figure 5.3.

In this example the reflection and transmission coefficients α^R, α^T at the wave speed interface are $\alpha^R = \dfrac{1}{16}, \alpha^T = \dfrac{15}{16}$. At $t = 1$, the exact density and averaged

slowness are given by

$$\rho(x,1)=\begin{cases}1, & -1.6<x<-1.4;\\ 1+\alpha^R, & -1.4<x<-0.4-1/3;\\ 1+\alpha^R+0.6\alpha^T, & -0.4-1/3<x<-0.4;\\ 1+\alpha^R+\alpha^T/0.6, & -0.4<x<-0.2;\\ \alpha^T/0.3, & -0.2<x<0.2;\\ 1+\alpha^R+\alpha^T/0.6, & 0.2<x<0.4;\\ 1+\alpha^R+0.6\alpha^T, & 0.4<x<0.4+1/3;\\ 1+\alpha^R, & 0.4+1/3<x<1.4;\\ 1, & 1.4<x<1.6;\end{cases} \tag{5.9}$$

and

$$u(x,1)=\frac{1}{\rho(x,1)}\begin{cases}0.5, & -1.6<x<-1.4;\\ 0.5-\alpha^R\Upsilon(x+0.2), & -1.4<x<-0.4-\frac{1}{3};\\ 0.5-\alpha^R\Upsilon(x+0.2)-0.36\alpha^T\Upsilon(0.6x-1.16), & -0.4-\frac{1}{3}<x<-0.6;\\ \Upsilon(x+0.6)-\alpha^R\Upsilon(x+0.2)-0.36\alpha^T\Upsilon(0.6x-1.16), & -0.6<x<-0.4;\\ \frac{\alpha^T}{0.36}\Upsilon(\frac{x}{0.6}+\frac{13}{15})-\Upsilon(x-1)+\alpha^R\Upsilon(x+1.8), & -0.4<x<-0.2;\\ \frac{\alpha^T}{0.36}\Upsilon(\frac{x}{0.6}+\frac{13}{15})-\frac{\alpha^T}{0.36}\Upsilon(\frac{x}{0.6}-\frac{13}{15}), & -0.2<x<0.2;\\ -\frac{\alpha^T}{0.36}\Upsilon(\frac{x}{0.6}-\frac{13}{15})+\Upsilon(x+1)-\alpha^R\Upsilon(x-1.8), & 0.2<x<0.4;\\ -\Upsilon(x-0.6)+\alpha^R\Upsilon(x-0.2)+0.36\alpha^T\Upsilon(0.6x+1.16), & 0.4<x<0.6;\\ -0.5+\alpha^R\Upsilon(x-0.2)+0.36\alpha^T\Upsilon(0.6x+1.16), & 0.6<x<0.4+\frac{1}{3};\\ -0.5+\alpha^R\Upsilon(x-0.2), & 0.4+\frac{1}{3}<x<1.4;\\ -0.5, & 1.4<x<1.6;\end{cases} \tag{5.10}$$

with $\Upsilon(x)=0.5-\frac{0.4}{(1.6)^2}x^2$.

The time step is chosen as $\Delta t=\frac{1}{2}\Delta\xi$. We will give, respectively, the numerical results computed by the first order Hamiltonian-preserving method and the second order method using the van Leer slope limiter. The choice of β in the first and second order methods are different. In the first order method, we use a linear relation between β and the mesh size $\Delta\xi$: $\beta=\Delta\xi$. In the second order method, this choice does not guarantee the numerical convergence, rather, β must decay to zero slower than $\Delta\xi$. Our numerical experiments indicate that $\beta\sim(\Delta\xi)^{\frac{1}{2}}$ will be appropriate.

Table 5.2 presents the l^1-error of ρ and u computed with several different meshes on the domain $[-1.6,1.6]\times[-1.2,1.2]$ by using the first order method. It can be observed that the l^1-convergence order of the numerical solutions is about 1/2 order. Tables 5.3 and 5.4 present the same errors computed by the second order method with two sets of β's. Clearly, the second order methods give more accurate solutions than the first order method. In comparison between the results by the second order methods with different choices of β, one sees that a smaller β gives more accurate

numerical solutions, but might cause mild oscillations, than a larger one. We do not have a rigorous analysis on the relation between β and $\Delta\xi$ to provide the optimal results by a second order method.

TABLE 5.2
l^1 error of the numerical moments with different meshes $\beta = \Delta\xi$, first order method.

meshes	97 × 80	197 × 160	397× 320	797× 640
ρ	3.3051E-1	2.2438E-1	1.6185E-1	1.1425E-1
u	1.1481E-1	8.4303E-2	6.0016E-2	4.2667E-2

TABLE 5.3
l^1 error of the numerical moments with different meshes $\beta = 5\Delta\xi,\ 7\Delta\xi,\ 10\Delta\xi,\ 14\Delta\xi$ for the four meshes, second order method.

meshes	97 × 80	197 × 160	397× 320	797× 640
ρ	1.8969E-1	9.2800E-2	5.5672E-2	3.3926E-2
u	6.1719E-2	3.1710E-2	1.9006E-2	1.1536E-2

Figure 5.4 shows the numerical solutions of ρ and u using the 797×640 mesh by the first order method along with the exact solutions. The numerical solution captures the correct dynamics and discontinuities, but the resolution is poor even on such a fine mesh. In contrast, Figure 5.5 shows the computed densities ρ using the 797×640 mesh by the second order method with different β's. The results have much higher resolution across the discontinuities than the first order method. However, the numerical density by using $\beta = 14\Delta\xi$ exhibits some small oscillations near the discontinuities between, while the use of a larger $\beta = 42\Delta\xi$ creates no oscillations at the expense of a slight accuracy or resolution loss.

These results show that although the second order method can give more accurate solutions than the first order method, there is a support size parameter β that needs to be properly chosen in order to compromise between convergence and accuracy of the numerical solution. It is not clear how to choose β *a priori*. In the future we will study the feasibility of introducing the decomposition technique proposed in [25] into such a problem with measure-valued data, which could avoid such an inconvenience as well as improve the numerical accuracy and resolution.

Example 5.3. Computing the physical observables of a 2D problem with a L^∞ solution. Consider the 2D Liouville equation (4.1) with a discontinuous wave speed

$$c(x,y) = \begin{cases} 2 & y > 0 \\ 1 & y < 0 \end{cases}$$

and a smooth initial data

$$f(x,y,\xi,\eta,0) = \frac{1}{\pi c_3 c_4} \exp\left(-\left(\frac{x}{c_1}\right)^2 - \left(\frac{y+0.1}{c_2}\right)^2 - \left(\frac{\xi}{c_3}\right)^2 - \left(\frac{\eta-0.1}{c_4}\right)^2 \right),$$

where $c_1 = 0.03, c_3 = 0.05, c_2 = c_4 = 0.025$.

In this example we aim at computing the density which is the zeroth moment of the density distribution

$$\rho(x,y,t) = \int\int f(x,y,\xi,\eta,t) d\xi d\eta. \tag{5.11}$$

TABLE 5.4
l^1 error of the numerical moments with different meshes $\beta = 15\Delta\xi,\ 21\Delta\xi,\ 30\Delta\xi,\ 42\Delta\xi$ for the four meshes, second order method.

meshes	97×80	197×160	397×320	797×640
ρ	4.3791E-1	2.0464E-1	9.0273E-2	3.7545E-2
u	1.3585E-1	6.0953E-2	2.9188E-2	1.2857E-2

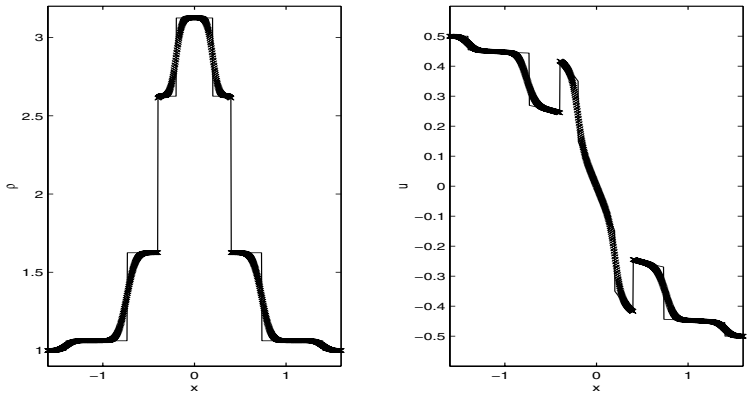

FIG. 5.4. *Example* 5.2*, density ρ and averaged slowness u at $t = 1$. Solid line: the exact solution; "x": numerical solutions by first order method using the* 797×640 *mesh. Left: ρ; Right: u.*

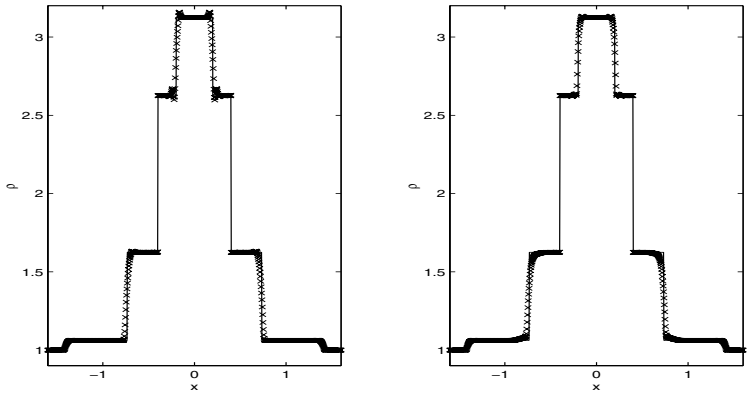

FIG. 5.5. *Example* 5.2*, density ρ at $t = 1$. Solid line: the exact solution; "x": numerical solutions by second order method using the* 797×640 *mesh. Left: $\beta = 14\Delta\xi$; Right: $\beta = 42\Delta\xi$.*

The computational domain is chosen to be $[x, y, \xi, \eta] \in [-0.12, 0.12] \times [-0.2, 0.2] \times [-0.2, 0.2] \times [-0.2, 0.2]$.

The reflection and transmission coefficients α^R, α^T at the interface are given by (2.4). The "exact" solution of ρ is obtained by first solving for $f(x, y, \xi, \eta, t)$ analytically, and then evaluating the integral (5.11) on a very fine mesh in the (ξ, η) space.

The time step is chosen as $\Delta t = \frac{1}{3}\Delta x$. Figures 5.6 and 5.8 show, respectively, the numerical density ρ at $t = 0.12, 0.15$ using different meshes along with the exact solution. Figures 5.7 and 5.9 show, respectively, the numerical density ρ on $x = 0$ at

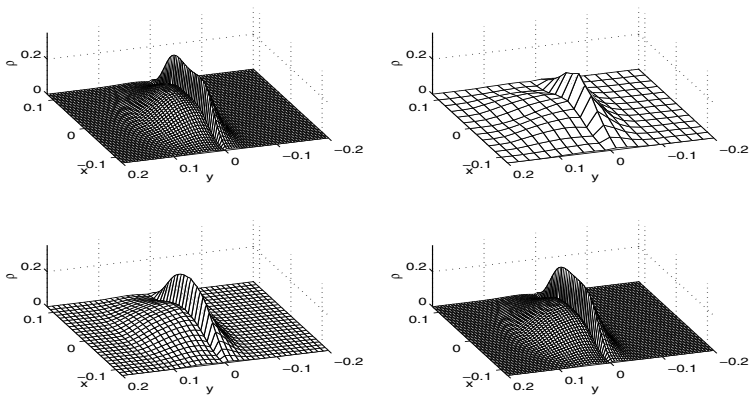

FIG. 5.6. *Example* 5.3, *density* ρ *at* $t = 0.12$. *Upper left: the exact solution; Upper right:* $13 \times 20 \times 14^2$ *mesh; Lower left:* $25 \times 40 \times 26^2$ *mesh; Lower right:* $49 \times 80 \times 50^2$ *mesh.*

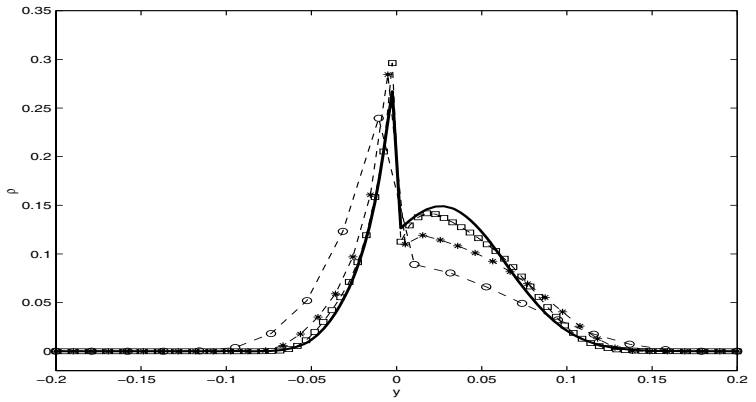

FIG. 5.7. *Example* 5.3, *density* ρ *along* $x = 0$ *at* $t = 0.12$. *Solid line: exact solution; "o":* $13 \times 20 \times 14^2$ *mesh; "*":* $25 \times 40 \times 26^2$ *mesh; "* $\square$ *":* $49 \times 80 \times 50^2$ *mesh.*

$t = 0.12, 0.15$ using different meshes along with the exact solution.

Table 5.5 presents the l^1 errors of ρ computed with different meshes in phase space at $t = 0.12, 0.15$. The convergence rate is slightly higher than first order, which does not suffer from the accuracy degeneration of an usual finite difference method for solving the discontinuous solution of a linear hyperbolic equation—which is at most 1/2 order stated by the well-established theory [30, 42]. This is because the only discontinuity in the solutions is at the interface, which has been taken care of by the Hamiltonian-preserving mechanism, and no linear discontinuity travels to the downstream direction like in the 1D case.

TABLE 5.5

6. Conclusion. In this paper, we extended our previous work [28] to the Liouville equation of geometrical optics with partial transmissions and reflections. Such problems arise in geometrical optics through inhomogeneous media. While still utilizing the constant Hamiltonian structure in constructing the numerical flux, we also account for the transmission and reflection coefficients in the numerical flux. By doing so, the numerical flux automatically absorbs the interface condition. This gives an explicit scheme for the time dependent Liouville equation with discontinuous indices of refraction that can capture correctly the partial transmissions and reflections across the interface. This scheme is subject to a hyperbolic CFL condition, under which the scheme is positive, and stable in both l^1 and l^∞ norms. Numerical experiments are carried out to study the numerical accuracy.

We only extended a finite difference version of the Hamiltonian-preserving scheme developed in [28]. The finite volume version of the method in [28] can also be extended in a similar fashion, but will not be given here.

In the future we will consider analytical issues such as the well-posedness of the problem in a more general context than that discussed in this paper, and the convergence of the numerical scheme. We will also investigate its applications to more

complex interfaces, and develop more effective methods for the measure-valued initial value problem for the same equation.

NUMERICAL ANALYSIS OF CONVECTION-DIFFUSION-REACTION PROBLEMS WITH HIGHER ORDER CHARACTERISTICS/FINITE ELEMENTS. PART I: TIME DISCRETIZATION*

ALFREDO BERMÚDEZ†, MARIA R. NOGUEIRAS†, AND CARLOS VÁZQUEZ‡

Abstract. In this paper a higher order characteristics time discretization scheme is analyzed for a variable coefficient convection-(possibly degenerate)diffusion-reaction equation with mixed Dirichlet–Robin boundary conditions. First, the proposed second order time discretization scheme is rigorously introduced for exact and approximate characteristics. Next, under not very restrictive hypotheses on the data, the $l^\infty(L^2)$ stability is proved and $l^\infty(L^2)$ error estimates of order $O(\Delta t^2)$ are obtained. Lagrange–Galerkin schemes using different finite elements spaces will be analyzed in the second part of this work [to appear in *SIAM J. Numer. Anal.*], where quadrature formulas are proposed for practical implementation.

1. Introduction.

Linear convection-diffusion-reaction equations arise in the mathematical modeling of many important problems from different fields of engineering and applied sciences, such as thermodynamics, fluid mechanics, and finance (see [18], for example). In many cases the diffusive term is smaller than the convective one, giving rise to the so-called convection dominated problems (see [15]). Furthermore, in some convection dominated cases, the diffusive term becomes degenerate, as in some financial models (see, for instance, [26]).

In the framework of numerical solutions of convection dominated problems, a possible strategy is provided by the method of characteristics for time discretization (see the review paper [15]). This approach is based on the discretization of the total (or material) derivative, i.e., the time derivative along the characteristics lines of the convective part of the equation. Many authors have mathematically analyzed and applied the characteristics method to different problems. In [13] and [21], error estimates for the combination of a first order characteristics scheme with both finite differences and classical Lagrange finite elements have been given for time dependent convection-diffusion problems. Its adaptation to steady state convection-diffusion equations has been developed in [8] and its application to Navier–Stokes equations proposed in [21] (see also [7]). The use of standard quadrature formulas to compute the terms appearing in the formulation leads to conditional stability, as opposed to the unconditionally stable exact integrated schemes. This aspect has been studied for

first order schemes in [19] and [25]. More recently, the combination of the classical first order scheme with discontinuous Galerkin methods has been analyzed in [4, 3, 5].

The present paper falls into the frame of higher order Lagrange–Galerkin methods. Increasing the order of time and space approximations can be obtained by using higher order schemes for the discretization of the material derivative and higher order finite element spaces. In [14] multistep Galerkin methods for constant coefficient convection-diffusion problems are studied and the need for analyzing the variable coefficient case is pointed out. Also, in [11, 12] multistep methods for approximating the material time derivative, combined with either mixed finite element or spectral methods, are proposed to solve incompressible Navier–Stokes equations. Stability is proved and optimal error estimates for the fully discretized problem obtained. More recently, in [24], a second order Runge–Kutta method is proposed to approximate the material time derivative when solving a constant coefficient convection-diffusion equation with Dirichlet boundary conditions. Second order in time is maintained by the Crank–Nicolson scheme and an adequate upwinding of the diffusive term.

The present paper extends [24] in four aspects: first, it deals with a (possibly degenerate) variable coefficient diffusive term instead of the simpler Laplacian one. Second, nonzero reaction functions are allowed. Third, a general mixed Dirichlet–Robin boundary condition is considered. Fourth, non-divergence-free velocity fields are handled. While the first two extensions are quite straightforward because we still assume the solutions are smooth, dealing with boundary conditions other than Dirichlet requires nonstandard Green's formulas. Similarly, the fact that the velocity field is not divergence-free makes it necessary to introduce some new terms in the weak formulation. Moreover, although the analysis is given only for velocity fields null on the boundary, the stated Green's formulas allow us to write the weak formulation of problems for which this assumption is not satisfied and, thereby, to write second order schemes for their numerical solution. Actually, these schemes have been successfully applied to some interesting applications in mathematical finance (see [10]).

In this wider setting, the mathematical formalism of continuum mechanics (see, for instance, [16]) is used to express the results and notation related not only to the approximate characteristics proposed in [24] but also to the exact ones. The latter rather than the former can be used in some particularly interesting applications (see [10]), so our analysis also includes, as a novelty, the case where the characteristic lines are exactly computed. Moreover, by using Taylor expansions we rigorously justify some approximations of the characteristics, velocity gradients and their determinants and inverses. A technical proof of an $l^\infty(L^2)$ stability inequality is developed so that it can be appropriately used to obtain $l^\infty(L^2)$ error estimates of order $O(\Delta t^2)$ between the solutions of the time discretized problem and the continuous one. The fully discretized Lagrange–Galerkin scheme with different finite element spaces is analyzed in part two of this work (see [9]). Moreover, in [9] adequate quadrature formulas are proposed for different triangular and quadrangular finite element spaces.

The present paper is organized as follows. In section 2 the strong formulation of the convection-diffusion-reaction problem is posed and notation concerning functional spaces is introduced. In section 3 the characteristics curves associated to the velocity field are rigorously defined and useful results and notation related to them are stated. It is worth mentioning that notation and results are inspired in those handled by classical continuum mechanics textbooks (see, for instance, [16]). In section 4 the variational formulation of the problem is posed. In section 5, first the second order time discretization scheme is introduced for both exact and second order approximate characteristics. Next, under suitable but not very restrictive hypotheses on data

functions, the $l^\infty(L^2)$ stability result is proved for small enough time step. Finally, assuming greater regularity on the data functions, $l^\infty(L^2)$ error estimates of order $O(\Delta t^2)$ for the solution of the time discretized problem are derived.

2. Statement of the problem and functional spaces. Let Ω be a bounded domain in $\mathbb{R}^d$ $(d = 2, 3)$ with Lipschitz boundary, Γ, divided into two parts: $\Gamma = \Gamma_D \cup \Gamma_R$, with $\Gamma_D \cap \Gamma_R = \emptyset$. Let T be a positive constant. We consider the following initial boundary value problem.

(SP) STRONG PROBLEM. *Find a function* $\phi : \Omega \times (0,T) \longrightarrow \mathbb{R}$ *such that*

$$\phi'(\mathbf{x},t) - \operatorname{div}(\mathbf{A}(\mathbf{x})\nabla\phi(\mathbf{x},t)) + \mathbf{v}(\mathbf{x},t)\cdot\nabla\phi(\mathbf{x},t) + r(\mathbf{x})\phi(\mathbf{x},t) = f(\mathbf{x},t) \tag{2.1}$$

for $(\mathbf{x},t) \in \Omega \times (0,T)$*, subject to boundary conditions*

$$\phi(\mathbf{x},t) = 0 \quad \text{on } \Gamma_D \times (0,T), \tag{2.2}$$

$$\alpha\ \phi(\mathbf{x},t) + \mathbf{A}(\mathbf{x})\nabla\phi(\mathbf{x},t)\cdot\mathbf{n}(\mathbf{x}) = g(\mathbf{x},t) \quad \text{on } \Gamma_R \times (0,T) \tag{2.3}$$

and initial condition

$$\phi(\mathbf{x},0) = \phi^0(\mathbf{x}) \quad \text{in } \Omega. \tag{2.4}$$

In the above equations, ϕ' denotes the partial derivative with respect to t, $\mathbf{A} : \overline{\Omega} \longrightarrow \mathcal{S}_d$ denotes the diffusion matrix function, where $\mathcal{S}_d$ is the space of symmetric $d \times d$ matrices, $\mathbf{v} : \overline{\Omega} \times [0,T] \longrightarrow \mathbb{R}^d$ is the convection vector field, $r : \overline{\Omega} \longrightarrow \mathbb{R}$ is the reaction function, $f : \overline{\Omega} \times [0,T] \longrightarrow \mathbb{R}$ and $g : \Gamma_R \times [0,T] \longrightarrow \mathbb{R}$ are given scalar functions, and $\mathbf{n}$ is the outward unit normal vector to Γ.

Let us introduce the Lebesgue spaces $L^p(\Omega)$ and the Sobolev spaces $W^{m,p}(\Omega)$ for $p = 1, 2, \ldots, \infty$ and m an integer. For the particular case $p = 2$, we consider the Hilbert space $L^2(\Omega)$ with the usual inner product $\langle\ ,\ \rangle$, which induces the norm $\|\ \|_0$, and spaces $H^m(\Omega) = W^{m,2}(\Omega)$ equipped with the usual norms $\|\ \|_m$ (see [1] for details). Moreover, we denote by $H^1_{\Gamma_D}(\Omega)$ the closed subspace of $H^1(\Omega)$ defined by

$$H^1_{\Gamma_D}(\Omega) := \{\varphi \in H^1(\Omega),\ \varphi|_{\Gamma_D} = 0\}.$$

For a Banach space X and an integer m, spaces $C^m([0,T],X)$ and $H^m((0,T),X)$ will be abbreviated as $C^m(X)$ and $H^m(X)$, respectively, and endowed with norms

$$\|\varphi\|_{C^m(X)} := \max_{t\in[0,T]}\left\{\max_{j=0,\ldots,m}\|\varphi^{(j)}(t)\|_X\right\},\ \|\varphi\|_{H^m(X)} := \left(\int_0^T \sum_{j=0}^m \left\|\varphi^{(j)}(t)\right\|_X^2 dt\right)^{\frac{1}{2}}.$$

In the above definitions, $\varphi^{(j)}$ denotes the jth derivative of φ with respect to time.

Next, we introduce the Banach space $Z^m = \{\varphi \in C^j(H^{m-j}(\Omega));\ j = 0, \ldots, m\}$ for $m \in Z^+$, equipped with the norm $\|\varphi\|_{Z^m} := \max\{\|\varphi\|_{C^j(H^{m-j})};\ 0 \le j \le m\}$. Similar spaces are considered for the boundary sets Γ_R and Γ_D. For example, for Γ_R we use the notation $\|\cdot\|_{m,\Gamma_R}$, $\|\cdot\|_{Z^m,\Gamma_R}$, etc.

3. Characteristic curves. In this section we define the characteristic lines associated with vector field $\mathbf{v}$ and recall some classical properties satisfied by them.

Thus, for given $(\mathbf{x},t) \in \overline{\Omega} \times [0,T]$, the characteristic line through $(\mathbf{x},t)$ is the vector function $X_e(\mathbf{x},t;\cdot)$ solving the initial value problem

$$\frac{\partial X_e}{\partial\tau}(\mathbf{x},t;\tau) = \mathbf{v}(X_e(\mathbf{x},t;\tau),\tau), \quad X_e(\mathbf{x},t;t) = \mathbf{x}. \tag{3.1}$$

It represents the trajectory described by a material point that is placed at position $\mathbf{x}$ at time t and is driven by the velocity field $\mathbf{v}$. If $\mathbf{v} \in C^0(\overline{\Omega} \times [0,T])$, it is Lipschitz continuous with respect to the first variable and vanishes on Γ; then the characteristic line solving (3.1) is well defined in the whole domain, $[0,T]$, and it is unique for each initial condition $(\mathbf{x},t)$. In this case, as a function on $(\mathbf{x},t;\tau)$, it is Lipschitz continuous in $\Omega \times [0,T] \times [0,T]$. Moreover (see [22]), if $\tau_1,\tau_2,\tau_3 \in [0,T]$ and $\mathbf{x} \in \Omega$, then

$$X_e(\mathbf{x},\tau_1;\tau_3) = X_e(X_e(\mathbf{x},\tau_1;\tau_2),\tau_2;\tau_3). \tag{3.2}$$

Indeed, by replacing $\tau_1 = \tau_3$ we deduce that the mapping $X_e(\cdot,\tau_1;\tau_2) : \overline{\Omega} \longrightarrow \overline{\Omega}$ is one-to-one, with inverse $X_e(\cdot,\tau_2;\tau_1)$.

Next, assuming they exist, we denote by $\mathbf{F}_e$ (respectively, by $\mathbf{L}$) the gradient of X_e (respectively, of $\mathbf{v}$) with respect to the space variable $\mathbf{x}$, i.e.,

$$(F_e)_{rs}(\mathbf{x},t;\tau) := \frac{\partial (X_e)_r}{\partial x_s}(\mathbf{x},t;\tau), \qquad L_{rs}(\mathbf{x},t) := \frac{\partial v_r}{\partial x_s}(\mathbf{x},t).$$

PROPOSITION 3.1. *If $\mathbf{v} \in C^0(C^n(\overline{\Omega}))$ for $n \geq 1$ an integer, then $X_e \in C^0(\overline{\Omega} \times [0,T] \times [0,T])$ and it is C^n with respect to the $\mathbf{x}$ variable.*

Proof. See, for instance, [2]. ∎

It will be useful to compute second order approximations of matrices $\mathbf{F}_e$ and $\mathbf{F}_e^{-1}$. For this, we need the following equations (see [16]):

$$\frac{\partial \mathbf{F}_e}{\partial \tau}(\mathbf{x},t;\tau) = \mathbf{L}(X_e(\mathbf{x},t;\tau),\tau)\mathbf{F}_e(\mathbf{x},t;\tau), \tag{3.3}$$

$$\frac{\partial^2 \mathbf{F}_e}{\partial \tau^2}(\mathbf{x},t;\tau) = \nabla \left(\frac{\partial \mathbf{v}}{\partial t} + \mathbf{L}\mathbf{v} \right)(X_e(\mathbf{x},t;\tau),\tau)\mathbf{F}_e(\mathbf{x},t;\tau). \tag{3.4}$$

By using Gronwall's lemma and (3.3) we can prove the following result.

PROPOSITION 3.2. *If $\mathbf{v} \in C^0(C^1(\overline{\Omega}))$, then*

$$\|\mathbf{F}_e(\mathbf{x},t;\tau)\| \leq e^{\|\mathbf{v}\|_{C^0(C^1(\overline{\Omega}))}|\tau - t|} \quad \forall \mathbf{x} \in \Omega,\ t,\tau \in [0,T]. \tag{3.5}$$

PROPOSITION 3.3. *If $\mathbf{v} \in C^0(C^2(\overline{\Omega})) \cap C^1(C^1(\overline{\Omega}))$, then $\mathbf{F}_e$ satisfies the Taylor expansions*

$$\begin{aligned} \mathbf{F}_e(\mathbf{x},t;s) &= \mathbf{I} + (s-t)\ \mathbf{L}(\mathbf{x},t) \\ &\quad + \int_s^t (\tau - s)\ \nabla \left(\frac{\partial \mathbf{v}}{\partial t} + \mathbf{L}\mathbf{v} \right)(X_e(\mathbf{x},t;\tau),\tau)\mathbf{F}_e(\mathbf{x},t;\tau)\ d\tau, \end{aligned} \tag{3.6}$$

and its inverse, $\mathbf{F}_e^{-1}$, satisfies the Liouville theorem

$$\begin{aligned} \mathbf{F}_e^{-1}(\mathbf{x},t;s) &= \mathbf{I} + (t-s)\ \mathbf{L}(X_e(\mathbf{x},t;s),s) \\ &\quad - \int_s^t (\tau - t)\ \nabla \left(\frac{\partial \mathbf{v}}{\partial t} + \mathbf{L}\mathbf{v} \right)(X_e(\mathbf{x},t;\tau),\tau)\mathbf{F}_e(X_e(\mathbf{x},t;s),s;\tau)\ d\tau. \end{aligned} \tag{3.7}$$

Proof. Expression (3.6) derives from the Taylor expansion, (3.3) and (3.4). To prove (3.7) we differentiate (3.2) for $\tau_1 = \tau_3 = s$ and $\tau_2 = t$ to obtain $\mathbf{F}_e^{-1}(\mathbf{x},t;s) = \mathbf{F}_e(X_e(\mathbf{x},t;s),s;t)$. Then, we use (3.6) and $X_e(X_e(\mathbf{x},t;s),s;\tau) = X_e(\mathbf{x},t;\tau)$. ∎

Now, we develop analogous computations for $\mathsf{det}\ \mathbf{F}_e^{-1}$. To do that, we first use Liouville's theorem (see [2]) and the chain rule, obtaining

$$\frac{\partial}{\partial \tau}\mathsf{det}\ \mathbf{F}_e^{-1}(\mathbf{x},t;\tau) = -\mathsf{det}\ \mathbf{F}_e^{-1}(\mathbf{x},t;\tau)\ \mathrm{div}\ \mathbf{v}(X_e(\mathbf{x},t;\tau),\tau). \tag{3.8}$$

Differentiating (3.8) again we get

$$\frac{\partial^2}{\partial\tau^2}\ \mathsf{det}\ \mathbf{F}_e^{-1}(\mathbf{x},t;\tau) = \mathsf{det}\ \mathbf{F}_e^{-1}(\mathbf{x},t;\tau)\left((\mathrm{div}\ \mathbf{v})^2(X_e(\mathbf{x},t;\tau),\tau)\right.$$
$$\left.\mathrm{div}\left(\frac{\partial\mathbf{v}}{\partial t}+\mathbf{L}\mathbf{v}\right)(X_e(\mathbf{x},t;\tau),\tau)-\left(\mathbf{L}\cdot\mathbf{L}^T\right)(X_e(\mathbf{x},t;\tau),\tau)\right). \tag{3.9}$$

The following propositions can be easily proved.

PROPOSITION 3.4. *If* $\mathbf{v}\in C^0(C^1(\overline{\Omega}))$, *then*

$$\mathsf{det}\ \mathbf{F}_e^{-1}(\mathbf{x},t;\tau)\le e^{\|\mathbf{v}\|_{C^0(C^1(\overline{\Omega}))}|\tau-t|}\quad\forall\mathbf{x}\in\Omega,\ t,\tau\in[0,T]. \tag{3.10}$$

PROPOSITION 3.5. *If* $\mathbf{v}\in C^0(C^2(\Omega))\cap C^1(C^1(\overline{\Omega}))$, *then* $\mathsf{det}\ \mathbf{F}_e^{-1}$ *satisfies*

$$\mathsf{det}\ \mathbf{F}_e^{-1}(\mathbf{x},t;s)=1-(s-t)\ \mathrm{div}\ \mathbf{v}(\mathbf{x},t)+\int_s^t(\tau-s)\ \frac{\partial^2}{\partial\tau^2}\left(\mathsf{det}\ \mathbf{F}_e^{-1}\right)(\mathbf{x},t;\tau)\ d\tau. \tag{3.11}$$

4. Variational formulation. We are going to develop some formal computations in order to give a variational formulation of problem (SP). From the definition of the characteristic curves and by using the chain rule, it follows that

$$\frac{\mathsf{d}\phi}{\mathsf{d}\tau}(X_e(\mathbf{x},t;\tau),\tau)=\phi'(X_e(\mathbf{x},t;\tau),\tau)+\mathbf{v}(X_e(\mathbf{x},t;\tau),\tau)\cdot\nabla\phi(X_e(\mathbf{x},t;\tau),\tau). \tag{4.1}$$

By writing equation (2.1) at point $X_e(\mathbf{x},t;\tau)$ and time τ, and using (4.1), we have

$$\frac{\mathsf{d}\phi}{\mathsf{d}t}(X_e(\mathbf{x},t;\tau),\tau)-\mathrm{div}(\mathbf{A}(X_e(\mathbf{x},t;\tau))\nabla\phi(X_e(\mathbf{x},t;\tau),\tau))$$
$$+r(X_e(\mathbf{x},t;\tau))\phi(X_e(\mathbf{x},t;\tau),\tau)=f(X_e(\mathbf{x},t;\tau),\tau). \tag{4.2}$$

Before giving a weak formulation of (4.2), we state two lemmas. The first one can be considered as a Green's formula.

LEMMA 4.1. *Let* $X:\overline{\Omega}\longrightarrow\overline{X(\Omega)}$, $X\in C^2(\overline{\Omega})$, *be an invertible vector valued function. Let* $\mathbf{F}=\nabla X$ *and assume that* $\mathbf{F}^{-1}\in C^1(\overline{\Omega})$. *Then*

$$\int_\Omega \mathrm{div}\ \mathbf{w}(X(\mathbf{x}))\ \psi(\mathbf{x})\ d\mathbf{x}=\int_\Gamma \mathbf{F}^{-T}(\mathbf{x})\mathbf{n}(\mathbf{x})\cdot\mathbf{w}(X(\mathbf{x}))\ \psi(\mathbf{x})\ dA_{\mathbf{x}}$$
$$-\int_\Omega \mathbf{F}^{-1}(\mathbf{x})\mathbf{w}(X(\mathbf{x}))\cdot\nabla\psi(\mathbf{x})\ d\mathbf{x}-\int_\Omega \mathrm{div}\ \mathbf{F}^{-T}(\mathbf{x})\cdot\mathbf{w}(X(\mathbf{x}))\ \psi(\mathbf{x})\ d\mathbf{x}, \tag{4.3}$$

with $\mathbf{w}\in H^1(X(\Omega))$ *a vector valued function and* $\psi\in H^1(\Omega)$ *a scalar function.*

Proof. First, by the Gauss theorem, we have

$$\int_\Gamma \mathbf{F}^{-T}(\mathbf{x})\mathbf{n}(\mathbf{x})\cdot\mathbf{w}(X(\mathbf{x}))\ \psi(\mathbf{x})\ dA_{\mathbf{x}}=\int_\Omega \mathrm{div}\left(\mathbf{F}^{-1}(\mathbf{w}\circ X)\psi\right)(\mathbf{x})\ d\mathbf{x}. \tag{4.4}$$

Finally, identity (4.3) is obtained by developing the divergence term in (4.4) with

$$\mathrm{div}\left(\mathbf{F}^{-1}(\mathbf{w}\circ X)\psi\right)(\mathbf{x})=\psi(\mathbf{x})\ \mathrm{div}\left(\mathbf{F}^{-1}(\mathbf{w}\circ X)\right)(\mathbf{x})+\nabla\psi(\mathbf{x})\cdot\mathbf{F}^{-1}(\mathbf{x})\mathbf{w}(X(\mathbf{x})),$$
$$\mathrm{div}\left(\mathbf{F}^{-1}(\mathbf{w}\circ X)\right)(\mathbf{x})=\mathbf{F}^{-T}(\mathbf{x})\cdot\nabla\left(\mathbf{w}\circ X\right)(\mathbf{x})+\mathbf{w}(X(\mathbf{x}))\cdot\mathrm{div}\ \mathbf{F}^{-T}(\mathbf{x}),$$
$$\mathbf{F}^{-T}(\mathbf{x})\cdot\nabla\left(\mathbf{w}\circ X\right)(\mathbf{x})=\mathsf{tr}\left(\nabla\left(\mathbf{w}\circ X\right)(\mathbf{x})\mathbf{F}^{-1}(\mathbf{x})\right)$$
$$=\mathsf{tr}\left(\nabla\mathbf{w}(X(\mathbf{x}))\right)=\mathrm{div}\ \mathbf{w}(X(\mathbf{x})).\qquad\square$$

Now, we can multiply (4.2) by a test function $\psi \in H^1_{\Gamma_D}(\Omega)$, integrate in Ω, and apply the usual Green's formula and (4.3) with $X(\mathbf{x}) = X_e(\mathbf{x}, t; \tau)$, obtaining

$$
\begin{aligned}
(4.5)\qquad & \int_\Omega \frac{\mathsf{d}\phi}{\mathsf{d}t}(X_e(\mathbf{x},t;\tau),\tau)\ \psi(\mathbf{x})\ d\mathbf{x} \\
& + \int_\Omega \mathbf{F}_e^{-1}(\mathbf{x},t;\tau)\mathbf{A}(X_e(\mathbf{x},t;\tau))\nabla\phi(X_e(\mathbf{x},t;\tau))\cdot\nabla\psi(\mathbf{x})\ d\mathbf{x} \\
& + \int_\Omega \operatorname{div}\ \mathbf{F}_e^{-T}(\mathbf{x},t;\tau)\cdot\mathbf{A}(X_e(\mathbf{x},t;\tau))\nabla\phi(X_e(\mathbf{x},t;\tau),\tau)\ \psi(\mathbf{x})\ d\mathbf{x} \\
& + \int_\Omega r(X_e(\mathbf{x},t;\tau))\phi(X_e(\mathbf{x},t;\tau),\tau)\ \psi(\mathbf{x})\ d\mathbf{x} \\
& + \int_{\Gamma_R} \mathbf{F}_e^{-T}(\mathbf{x},t;\tau)\mathbf{n}(\mathbf{x})\cdot\mathbf{A}(X_e(\mathbf{x},t;\tau))\nabla\phi(X_e(\mathbf{x},t;\tau))\ \psi(\mathbf{x})dA_{\mathbf{x}} \\
& = \int_\Omega f(X_e(\mathbf{x},t;\tau),\tau)\ \psi(\mathbf{x})\ d\mathbf{x}.
\end{aligned}
$$

Remark 4.1. Notice that as long as the involved functions $\mathbf{v}$, $\mathbf{A}$, r, and f are defined in a wider (time dependent) domain, equations (4.2) and (4.5) are valid without assuming the velocity field vanishes on the boundary. This is the case, for instance, with some interesting problems arising in mathematical finance. Actually, the above formulation has been necessary for the numerical solution of Asian options pricing problems (see [10]). However, the analysis in the present work covers only velocity fields which are null at the boundary, and time independent spatial domains.

LEMMA 4.2. *Let $X : \overline{\Omega} \longrightarrow \overline{\Omega}$, $X \in C^2(\overline{\Omega})$, be an invertible function satisfying $X(\mathbf{x}) = \mathbf{x}\ \forall \mathbf{x} \in \Gamma$. Let $\mathbf{F} = \nabla X$ such that $\mathbf{F}^{-1} \in C^1(\overline{\Omega})$. Then, we have*

$$
(4.6)\qquad \int_\Gamma \mathbf{F}^{-T}(\mathbf{x})\mathbf{n}(\mathbf{x})\cdot\mathbf{w}(\mathbf{x})\ \psi(\mathbf{x})\ dA_{\mathbf{x}} = \int_\Gamma \mathbf{n}(\mathbf{x})\cdot\mathbf{w}(\mathbf{x})\ \psi(\mathbf{x})\ \mathsf{det}\ \mathbf{F}^{-1}(\mathbf{x})\ dA_{\mathbf{x}}
$$

for $\mathbf{w} \in H^1(\Omega)$ and $\psi \in H^1(\Omega)$, where $\mathbf{n}$ is the outward unit normal vector to Γ.

Proof. First we apply the change of variable $\mathbf{x} = X^{-1}(\mathbf{y})$ to get (see [16, p. 53])

$$
\int_\Gamma \mathbf{F}^{-T}(\mathbf{x})\mathbf{n}(\mathbf{x})\cdot\mathbf{w}(\mathbf{x})\ \psi(\mathbf{x})\, dA_{\mathbf{x}} = \int_{\partial X(\Omega)} \mathbf{m}(\mathbf{y})\cdot\mathbf{w}(X^{-1}(\mathbf{y}))\ \psi(X^{-1}(\mathbf{y}))\mathsf{det}\ \mathbf{F}^{-1}(X^{-1}(\mathbf{y}))\, dA_{\mathbf{y}},
$$

where $\partial X(\Omega)$ denotes the boundary of $X(\Omega)$ and $\mathbf{m}$ is the unit normal vector to $\partial X(\Omega)$. Thus, $X(\mathbf{x}) = \mathbf{x}\ \forall \mathbf{x} \in \Gamma$ implies (4.6). ∎

Now, replacing in (4.5) formula (4.6) with $X(\mathbf{x}) = X_e(\mathbf{x}, t; \tau)$, and replacing the Robin condition (2.3), we have

$$
\begin{aligned}
(4.7)\qquad & \int_\Omega \frac{\mathsf{d}\phi}{\mathsf{d}t}(X_e(\mathbf{x},t;\tau),\tau)\ \psi(\mathbf{x})\ d\mathbf{x} \\
& + \int_\Omega \mathbf{F}_e^{-1}(\mathbf{x},t;\tau)\mathbf{A}(X_e(\mathbf{x},t;\tau))\nabla\phi(X_e(\mathbf{x},t;\tau))\cdot\nabla\psi(\mathbf{x})\ d\mathbf{x} \\
& + \int_\Omega \operatorname{div}\ \mathbf{F}_e^{-T}(\mathbf{x},t;\tau)\cdot\mathbf{A}(X_e(\mathbf{x},t;\tau))\nabla\phi(X_e(\mathbf{x},t;\tau),\tau)\ \psi(\mathbf{x})\ d\mathbf{x} \\
& + \int_\Omega r(X_e(\mathbf{x},t;\tau))\phi(X_e(\mathbf{x},t;\tau),\tau)\ \psi(\mathbf{x})\ d\mathbf{x} + \int_{\Gamma_R} \alpha\ \phi(\mathbf{x},\tau)\ \psi(\mathbf{x})\ \mathsf{det}\ \mathbf{F}_e^{-1}(\mathbf{x},t;\tau)\ dA_{\mathbf{x}} \\
& = \int_\Omega f(X_e(\mathbf{x},t;\tau),\tau)\ \psi(\mathbf{x})\ d\mathbf{x} + \int_{\Gamma_R} g(\mathbf{x},\tau)\ \psi(\mathbf{x})\ \mathsf{det}\ \mathbf{F}_e^{-1}(\mathbf{x},t;\tau)\ dA_{\mathbf{x}}.
\end{aligned}
$$

For these previous computations, we have assumed appropriate regularity on the involved data (i.e., $\mathbf{v} \in C^0(C^2(\Omega))$ and $\mathbf{A}\nabla(\cdot)\phi(\cdot,t) \in H^1(\Omega)$ for each $t \in (0,T)$) and that the velocity field, $\mathbf{v}$, vanishes on the boundary, so that the differentiable mapping, $\mathbf{x} \longrightarrow X_e(\mathbf{x},t;\tau)$, satisfies the result stated in Lemmas 4.1 and 4.2.

5. Time discretization. In this section we present a second order characteristics scheme for time semidiscretization of (4.7). Keeping in mind more general applications, it extends the scheme proposed in [24] to the case where the diffusion matrix depends on the space variable and can be degenerate, there are reaction and source terms, and the velocity field is not divergence-free. Moreover, mixed Dirichlet–Robin boundary conditions are allowed instead of merely Dirichlet ones.

In the first part, we develop some computations to motivate the scheme assuming that the characteristic lines are exactly computed. This can be useful in some cases (see, for instance, [10]). Then, after having studied results similar to those in section 3 concerning Euler and Runge–Kutta approximations of the characteristic lines, we propose the scheme. Finally, stability and error estimates are rigorously stated.

5.1. Second order semidiscretized scheme with exact characteristic lines. We propose a time semidiscretization of (4.7) for which we introduce the number of time steps, N, the time step $\Delta t = T/N$, and the mesh points $t_n = n\Delta t$ for $n = 0, 1/2, 1, 3/2, \ldots, N$. Throughout this work, we use the notation $\psi^n(\mathbf{x}) := \psi(\mathbf{x}, t_n)$ for a function $\psi(\mathbf{x},t)$. Moreover, for $n = 0, 1, 2, \ldots$, we define

$$
\begin{aligned}
X_e^n(\mathbf{x}) &:= X_e(\mathbf{x}, t_{n+1}; t_n), & \mathbf{F}_e^n(\mathbf{x}) &:= \mathbf{F}_e(\mathbf{x}, t_{n+1}; t_n),\\
X_e^{n+\frac{1}{2}}(\mathbf{x}) &:= X_e(\mathbf{x}, t_{n+1}; t_{n+\frac{1}{2}}), & \mathbf{F}_e^{n+\frac{1}{2}}(\mathbf{x}) &:= \mathbf{F}_e(\mathbf{x}, t_{n+1}; t_{n+\frac{1}{2}}).
\end{aligned} \tag{5.1}
$$

We recall that $X_e(\mathbf{x}, t_{n+1}; \tau)$ is the unique solution of the Cauchy problem

$$
\frac{\mathsf{d}X_e}{\mathsf{d}\tau}(\mathbf{x}, t_{n+1}; \tau) = \mathbf{v}\left(X_e(\mathbf{x}, t_{n+1}; \tau), \tau\right), \quad X_e(\mathbf{x}, t_{n+1}; t_{n+1}) = \mathbf{x}. \tag{5.2}
$$

The scheme we study arises from fixing $t = t_{n+1}$, $n = 0, 1, \ldots, N-1$, in (4.7) and using a Crank–Nicolson method with respect to τ. Thus, from (5.1), we have

$$
\begin{aligned}
&\int_\Omega \frac{\phi^{n+1}(\mathbf{x}) - \phi^n(X_e^n(\mathbf{x}))}{\Delta t}\ \psi(\mathbf{x})\ d\mathbf{x} + \frac{1}{2}\int_\Omega \mathbf{A}(\mathbf{x})\nabla\phi^{n+1}(\mathbf{x})\cdot\nabla\psi(\mathbf{x})\ d\mathbf{x}\\
&+ \frac{1}{2}\int_\Omega (\mathbf{F}_e^n)^{-1}(\mathbf{x})\mathbf{A}(X_e^n(\mathbf{x}))\nabla\phi^n(X_e^n(\mathbf{x}))\cdot\nabla\psi(\mathbf{x})\ d\mathbf{x}\\
&+ \frac{1}{2}\int_\Omega \operatorname{div}\ (\mathbf{F}_e^n)^{-T}(\mathbf{x})\cdot\mathbf{A}(X_e^n(\mathbf{x}))\nabla\phi^n(X_e^n(\mathbf{x}))\ \psi(\mathbf{x})\ d\mathbf{x}\\
&+ \frac{1}{2}\int_\Omega r(\mathbf{x})\phi^{n+1}(\mathbf{x}) + \frac{1}{2}\int_\Omega r(X_e^n(\mathbf{x}))\phi^n(X_e^n(\mathbf{x}))\ \psi(\mathbf{x})\ d\mathbf{x}\\
&+ \frac{1}{2}\int_{\Gamma_R} \alpha\left(\phi^{n+1}(\mathbf{x}) + \phi^n(\mathbf{x})\ \mathsf{det}\ (\mathbf{F}_e^n)^{-1}(\mathbf{x})\right)\psi(\mathbf{x})\ dA_{\mathbf{x}}\\
&= \frac{1}{2}\int_\Omega \left(f^{n+1}(\mathbf{x}) + f^n(X_e^n(\mathbf{x}))\right)\psi(\mathbf{x}) + \frac{1}{2}\int_{\Gamma_R}\left(g^{n+1}(\mathbf{x}) + g^n(\mathbf{x})\,\mathsf{det}\ (\mathbf{F}_e^n)^{-1}(\mathbf{x})\right)\psi(\mathbf{x})\ dA_{\mathbf{x}}.
\end{aligned} \tag{5.3}
$$

Remark 5.1. In section 5.4 we will prove that approximations involved in scheme (5.3) are of order $O(\Delta t^2)$ at point $(X_e^{n+\frac{1}{2}}(\mathbf{x}), t_{n+\frac{1}{2}})$.

The error of the scheme (5.3) does not change if we replace both $\mathbf{F}_e^{-1}$ and $\mathsf{det}\ \mathbf{F}_e^{-1}$ by their $O(\Delta t^2)$ approximations below, avoiding the matrix inversion computations. That is, by considering $(\mathbf{x}, t; s) = (\mathbf{x}, t_{n+1}; t_n)$ we deduce from (3.7) and (3.11) that

$$(\mathbf{F}_e^n)^{-1}(\mathbf{x}) = \mathbf{I}(\mathbf{x}) + \Delta t\ \mathbf{L}^n(X_e^n(\mathbf{x})) + O(\Delta t^2),$$
$$\mathsf{det}\ (\mathbf{F}_e^n)^{-1}(\mathbf{x}) = 1 + \Delta t\ \mathrm{div}\ \mathbf{v}^{n+1}(\mathbf{x}) + O(\Delta t^2).$$

Moreover, we can also use that $\mathrm{div}(\mathbf{F}_e^n)^{-T}(\mathbf{x}) = \Delta t\ \nabla \mathrm{div}\ \mathbf{v}^n(X_e^n(\mathbf{x})) + O(\Delta t^2)$. Thus, scheme (5.3) is replaced by

$$\begin{aligned}(5.4)\quad &\int_\Omega \frac{\phi^{n+1} - \phi^n(X_e^n)}{\Delta t}\ \psi\ d\mathbf{x} + \int_\Omega \frac{\mathbf{A}\nabla\phi^{n+1} + \mathbf{A}(X_e^n)\nabla\phi^n(X_e^n)}{2} \cdot \nabla\psi\ d\mathbf{x}\\ &+ \frac{\Delta t}{2}\int_\Omega \mathbf{L}^n(X_e^n)\mathbf{A}(X_e^n)\nabla\phi^n(X_e^n)\cdot\nabla\psi\ d\mathbf{x} + \frac{\Delta t}{2}\int_\Omega \nabla \mathrm{div}\ \mathbf{v}^n(X_e^n)\cdot\mathbf{A}(X_e^n)\nabla\phi^n(X_e^n)\ \psi\ d\mathbf{x}\\ &+ \int_\Omega \frac{r\phi^{n+1} + r(X_e^n)\phi^n(X_e^n)}{2}\ \psi\ d\mathbf{x} + \int_{\Gamma_R} \alpha\ \frac{\phi^{n+1} + \phi^n(1 + \Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})}{2}\ \psi\ dA_{\mathbf{x}}\\ &= \int_\Omega \frac{f^{n+1} + f^n(X_e^n)}{2}\ \psi\ d\mathbf{x} + \int_{\Gamma_R} \frac{g^{n+1} + g^n(1 + \Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})}{2}\ \psi\ dA_{\mathbf{x}}.\end{aligned}$$

5.2. Second order semidiscretized scheme with approximate characteristic lines. In most cases the Cauchy problem (5.2) cannot be exactly solved. Instead, following [24], we propose two explicit numerical schemes to approximate $X_e^n(\mathbf{x})$:

$$X_E^n(\mathbf{x}) := \mathbf{x} - \Delta t\ \mathbf{v}^{n+1}(\mathbf{x}) \qquad \text{(first order Euler scheme)},$$
$$X_{RK}^n(\mathbf{x}) := \mathbf{x} - \Delta t\ \mathbf{v}^{n+\frac{1}{2}}\left(\mathbf{x} - \frac{\Delta t}{2}\mathbf{v}^{n+1}(\mathbf{x})\right) \quad \text{(second order Runge–Kutta scheme)}.$$

A similar notation to the one in section 3 is used for the Jacobian of X_E^n, namely,

$$\mathbf{F}_E^n(\mathbf{x}) := \nabla X_E^n(\mathbf{x}) = \mathbf{I}(\mathbf{x}) - \Delta t\ \mathbf{L}^{n+1}(\mathbf{x}). \tag{5.5}$$

Now, we state three lemmas concerning properties of the characteristic line approximations, similar to those satisfied by the exact characteristics. For this, we require the time step to be bounded and the velocity to satisfy the following assumption.

Hypothesis 1. The velocity field $\mathbf{v} \in C^0\left(W^{1,\infty}(\Omega)\right)$ and satisfies $\mathbf{v} = 0$ on Γ.

LEMMA 5.1. *Under Hypothesis* 1, *if* $\|\mathbf{v}\|_{C^0(W^{1,\infty}(\Omega))}\Delta t < 1/2$, *we have* $X_E^n(\overline{\Omega}) = X_{RK}^n(\overline{\Omega}) = \overline{\Omega}$.

Proof. See Proposition 1 in [24]. ∎

LEMMA 5.2. *Under Hypothesis* 1, *if* $\|\mathbf{v}\|_{C^0(W^{1,\infty}(\Omega))}\Delta t < 1/2$, *then*

$$(\mathbf{F}_E^n)^{-1}(\mathbf{x}) = \mathbf{I} + \Delta t\ \mathbf{L}^{n+1}(\mathbf{x}) + \Delta t^2\ \left(\mathbf{L}^{n+1}(\mathbf{x})\right)^2 + O(\Delta t^3). \tag{5.6}$$

Proof. By applying norms to (5.5) we have that $\|\mathbf{I} - \mathbf{F}_E^n(\mathbf{x})\| < 1\ \forall \mathbf{x} \in \Omega$. Thus, $\mathbf{F}_E^n$ is invertible with $(\mathbf{F}_E^n)^{-1}(\mathbf{x}) = \sum_{j=0}^\infty (\mathbf{I}(\mathbf{x}) - \mathbf{F}_E^n(\mathbf{x}))^j$, and (5.6) follows. ∎

COROLLARY 5.3. *Under the assumptions of Lemma* 5.2, $\forall \mathbf{x} \in \Omega$, *we have*

$$\mathsf{det}(\mathbf{F}_E^n)^{-1}(\mathbf{x}) = 1 + \Delta t\ \mathrm{div}\ \mathbf{v}^{n+1}(\mathbf{x}) + O(\Delta t^2), \tag{5.7}$$
$$|\mathsf{det}(\mathbf{F}_E^n)^{-1}(\mathbf{x})| \le 1 + \Delta t\ \|\mathbf{v}\|_{C^0(W^{1,\infty}(\Omega))} + O(\Delta t^2). \tag{5.8}$$

Proof. First, we have $\mathsf{det}(\mathbf{I}+\mathbf{D}) = 1 + \mathsf{tr}\ \mathbf{D} - \frac{1}{2}\left((\mathsf{tr}\ \mathbf{D})^2 - \mathsf{tr}\ \mathbf{D}^2\right) + \mathsf{det}\ \mathbf{D}$ for every tensor $\mathbf{D}$ (see, for instance, [16]). Thus, the result directly follows by replacing, in the previous formula, $\mathbf{D} = (\mathbf{F}_e^n)^{-1}(\mathbf{x}) - \mathbf{I}$ and using (5.6). ∎

LEMMA 5.4. *Under Hypothesis* 1, *if* $\psi \in L^2(\Omega)$ *and* $\|\mathbf{v}\|_{C^0(W^{1,\infty}(\Omega))}\Delta t < 1/2$, *then there exists a positive constant* c *such that*

$$\|\psi \circ X_i^n\|_0^2 \leq (1 + \Delta t\ c)\,\|\psi\|_0^2 \quad \textit{for } n = 0, \ldots, N \textit{ and } i = E, RK. \tag{5.9}$$

Proof. See Lemma 1 in [24]. ∎

Thus, in the case where the characteristic lines and their gradients are not explicitly known, we propose the following approximation of (5.3):

$$\begin{aligned}
&\int_\Omega \frac{\phi^{n+1}(\mathbf{x}) - \phi^n(X_{RK}^n(\mathbf{x}))}{\Delta t}\ \psi(\mathbf{x})\ d\mathbf{x} + \frac{1}{2}\int_\Omega \mathbf{A}(\mathbf{x})\nabla\phi^{n+1}(\mathbf{x})\cdot\nabla\psi(\mathbf{x})\ d\mathbf{x}\\
&\quad + \frac{1}{2}\int_\Omega (\mathbf{F}_E^n)^{-1}(\mathbf{x})\mathbf{A}(X_E^n(\mathbf{x}))\nabla\phi^n(X_E^n(\mathbf{x}))\cdot\nabla\psi(\mathbf{x})\ d\mathbf{x}\\
&\quad + \frac{1}{2}\int_\Omega \mathrm{div}\ (\mathbf{F}_E^n)^{-T}(\mathbf{x})\cdot\mathbf{A}(X_E^n(\mathbf{x}))\nabla\phi^n(X_E^n(\mathbf{x}))\ \psi(\mathbf{x})\ d\mathbf{x}\\
&\quad + \frac{1}{2}\int_\Omega r(\mathbf{x})\phi^{n+1}(\mathbf{x}) + \frac{1}{2}\int_\Omega r(X_E^n(\mathbf{x}))\phi^n(X_E^n(\mathbf{x}))\ \psi(\mathbf{x})\ d\mathbf{x}\\
&\quad + \frac{1}{2}\int_{\Gamma_R} \alpha\left(\phi^{n+1}(\mathbf{x}) + \phi^n(\mathbf{x})\ \mathsf{det}\ (\mathbf{F}_E^n)^{-1}(\mathbf{x})\right)\psi(\mathbf{x})\ dA_{\mathbf{x}}\\
&= \frac{1}{2}\int_\Omega \left(f^{n+1}(\mathbf{x}) + f^n(X_E^n(\mathbf{x}))\right)\psi(\mathbf{x})\ d\mathbf{x}\\
&\quad + \frac{1}{2}\int_{\Gamma_R} \left(g^{n+1}(\mathbf{x}) + g^n(\mathbf{x})\ \mathsf{det}\ (\mathbf{F}_E^n)^{-1}(\mathbf{x})\right)\psi(\mathbf{x})\ dA_{\mathbf{x}}.
\end{aligned} \tag{5.10}$$

Notice that we have used the lowest order characteristics approximation formula preserving second order time accuracy. The error of the semidiscretized scheme (5.10) does not change if we replace both $\mathbf{F}_E^{-1}$ and $\mathsf{det}\ \mathbf{F}_E^{-1}$ by their $O(\Delta t^2)$ approximations given in (5.6) and (5.7), which avoid the inversion of matrix $\mathbf{F}_E^n$.

Finally, we describe the semidiscretized scheme to be analyzed hereafter. Let us introduce $\mathcal{L}_{\Delta t}^{n+\frac{1}{2}}\phi \in (H^1(\Omega))'$ and $\mathcal{F}_{\Delta t}^{n+\frac{1}{2}} \in (H^1(\Omega))'$, defined by

$$\begin{aligned}
\left\langle \mathcal{L}_{\Delta t}^{n+\frac{1}{2}}\phi, \psi\right\rangle &:= \left\langle \frac{\phi^{n+1} - \phi^n \circ X_{RK}^n}{\Delta t}, \psi\right\rangle + \left\langle \frac{\mathbf{A}\nabla\phi^{n+1} + (\mathbf{A}\nabla\phi^n)\circ X_E^n}{2}, \nabla\psi\right\rangle\\
&\quad + \frac{\Delta t}{2}\left\langle (\mathbf{L}^n\mathbf{A}\nabla\phi^n)\circ X_E^n, \nabla\psi\right\rangle + \frac{\Delta t}{2}\left\langle (\nabla\mathrm{div}\ \mathbf{v}^n\cdot\mathbf{A}\nabla\phi^n)\circ X_E^n, \psi\right\rangle\\
&\quad + \left\langle \frac{r\phi^{n+1} + (r\phi^n)\circ X_E^n}{2}, \psi\right\rangle + \alpha\left\langle \frac{\phi^{n+1} + \phi^n(1 + \Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})}{2}, \psi\right\rangle_{\Gamma_R},
\end{aligned} \tag{5.11}$$

$$\left\langle \mathcal{F}_{\Delta t}^{n+\frac{1}{2}}, \psi\right\rangle := \left\langle \frac{f^{n+1} + f^n \circ X_E^n}{2}, \psi\right\rangle + \left\langle \frac{g^{n+1} + g^n(1 + \Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})}{2}, \psi\right\rangle_{\Gamma_R} \tag{5.12}$$

for $\phi \in C^0(H^1(\Omega))$ and $\psi \in H^1(\Omega)$.

Remark 5.2. Regarding the definitions of $\mathcal{L}_{\Delta t}^{n+\frac{1}{2}}$ and $\mathcal{F}_{\Delta t}^{n+\frac{1}{2}}$, only the values of function ϕ at discrete time steps $\{t_n\}_{n=0}^N$ are required. Thus, the above definitions can also be stated for a sequence of functions $\widehat{\phi} = \{\phi^n\}_{n=1}^N \in \left[H^1(\Omega)\right]^N$.

Then, the semidiscretized time scheme can be written as follows:

$$\text{(5.13)}\qquad \begin{cases} \text{Given } \phi^0_{\Delta t}, \text{ find } \widehat{\phi_{\Delta t}} = \{\phi^n_{\Delta t}\}_{n=1}^N \in \left[H^1_{\Gamma_D}(\Omega)\right]^N \text{ such that} \\ \left\langle \mathcal{L}^{n+\frac{1}{2}}_{\Delta t}\widehat{\phi_{\Delta t}}, \psi \right\rangle = \left\langle \mathcal{F}^{n+\frac{1}{2}}_{\Delta t}, \psi \right\rangle \quad \forall \psi \in H^1_{\Gamma_D}(\Omega) \text{ for } n = 0, \ldots, N-1. \end{cases}$$

Remark 5.3. The stability and convergence properties we are going to study in the sections that follow remain valid if we replace the approximations of characteristics appearing in scheme (5.13) by higher order ones or by the exact value. In particular, X^n_E can be replaced by X^n_{RK} or X^n_e, and X^n_{RK} can be replaced by X^n_e in (5.11) and (5.12).

5.3. Stability of the semidiscretized scheme. In order to develop the stability analysis, some assumptions on the different terms of (2.1) are required.

Hypothesis 2. The velocity field $\mathbf{v} \in C^0(W^{2,\infty}(\Omega))$ and satisfies $\mathbf{v} = 0$ on Γ.

Remark 5.4. Throughout this paper c_1 denotes the maximum between the positive constant appearing in Lemma 5.4 and the norm of the velocity in $C^0(W^{2,\infty}(\Omega))$.

Hypothesis 3. The diffusion matrix coefficients, A_{ij}, belong to $W^{1,\infty}(\Omega)$. Moreover, $\mathbf{A}$ is an $m \times m$ symmetric matrix satisfying

$$\text{(5.14)}\qquad \mathbf{A} = \begin{pmatrix} \mathbf{A}_{m_1} & \Theta \\ \Theta & \Theta \end{pmatrix},$$

with $\mathbf{A}_{m_1}$ being a positive definite symmetric $m_1 \times m_1$ matrix ($m_1 \geq 1$), and where Θ denotes an appropriate zero matrix. Moreover, there exists a strictly positive constant δ which is a uniform lower bound for the eigenvalues of $\mathbf{A}_{m_1}$.

As a consequence of Hypothesis 3, there exists a unique positive definite symmetric $m_1 \times m_1$ matrix function, $\mathbf{C}_{m_1}$, such that $\mathbf{A}_{m_1} = (\mathbf{C}_{m_1})^2$. Let us denote by $\mathbf{C}$ the symmetric and positive semidefinite $m \times m$ matrix

$$\text{(5.15)}\qquad \mathbf{C} = \begin{pmatrix} \mathbf{C}_{m_1} & \Theta \\ \Theta & \Theta \end{pmatrix}.$$

Notice that $\mathbf{A} = \mathbf{C}^2$ and $C_{ij} \in W^{1,\infty}(\Omega)$. At this point, let us introduce the constant $c_2 := \max_{i,j} \left\{ \|C_{ij}\|^2_{W^{1,\infty}(\Omega)} \right\}$. Next, let us denote by $\mathbf{B}$ the $m \times m$ matrix

$$\text{(5.16)}\qquad \mathbf{B} = \begin{pmatrix} \mathbf{I}_{m_1} & \Theta \\ \Theta & \Theta \end{pmatrix},$$

where $\mathbf{I}_{m_1}$ is the $m_1 \times m_1$ identity matrix. Clearly, under Hypothesis 3 we have

$$\text{(5.17)}\qquad \delta \|\mathbf{B}\mathbf{w}\|^2_0 \leq \langle \mathbf{A}\mathbf{w}, \mathbf{w} \rangle = \|\mathbf{C}\mathbf{w}\|^2_0 \leq c_2 \|\mathbf{B}\mathbf{w}\|^2_0 \quad \forall \mathbf{w} \in \mathbb{R}^m.$$

Hypothesis 4. The velocity field satisfies $(\mathbf{I} - \mathbf{B})\mathbf{L}(\mathbf{x}, t)\mathbf{B} = \mathbf{0}\ \forall (\mathbf{x}, t) \in \Omega \times [0, T]$.

Remark 5.5. Hypothesis 4 is equivalent to having a velocity field $\mathbf{v}$ whose $m - m_1$ last components depend only on the last $m - m_1$ variables.

Remark 5.6. Under Hypotheses 3 and 4, for every $m \times m$ matrix $\mathbf{E}$ and vectors $\mathbf{w}_1, \mathbf{w}_2 \in \mathbb{R}^m$ it is easy to verify that $\langle \mathbf{E}\mathbf{A}\mathbf{w}_1, \mathbf{w}_2 \rangle = \langle \mathbf{E}\mathbf{A}\mathbf{w}_1, \mathbf{B}\mathbf{w}_2 \rangle$.

Hypothesis 5. The reaction function, $r \in W^{1,\infty}(\Omega)$, satisfies $0 < \gamma \leq r(\mathbf{x})$ in Ω, where γ is a constant.

Under the previous hypothesis, let $c_3 := \|\sqrt{r}\|^2_{W^{1,\infty}(\Omega)}$.

Hypothesis 6. The source function $f \in C^0(L^2(\Omega))$.

Hypothesis 7. In Robin boundary condition (2.3), $g \in C^0(L^2(\Gamma_R))$ and $\alpha > 0$.

It is convenient now to note that Hypothesis 3 also covers the nondegenerate case. This hypothesis is a common assumption in ultraparabolic equations (see, for instance, [23]), which represent a wide class of degenerate diffusion equations arising in many applications (see, for instance, [6]). Furthermore, as stated in [17], ultraparabolic problems either present C^∞ solutions or can be reduced to nondegenerate problems posed in a lower spatial dimension. This is an important point, as the stability and error estimates will be obtained under regularity assumptions on the solution.

Corresponding to the semidiscretized scheme, we have to deal with sequences of functions $\widehat{\psi} = \{\psi^n\}_{n=0}^N$. Thus, we consider spaces $l^\infty((0,T), L^2(\Omega))$, $l^2((0,T), L^2(\Omega))$ (abbreviated to $l^\infty(L^2(\Omega))$ and $l^2(L^2(\Omega))$, respectively) equipped with the norms

$$\left\|\widehat{\psi}\right\|_{l^\infty(L^2(\Omega))} := \max_{n=0}^{N} \|\psi^n\|_0, \qquad \left\|\widehat{\psi}\right\|_{l^2(L^2(\Omega))} := \sqrt{\Delta t \sum_{n=0}^{N} \|\psi^n\|_0^2}.$$

Similar definitions are considered for functional spaces $l^\infty(L^2(\Gamma_R))$ and $l^2(L^2(\Gamma_R))$ associated to the Robin boundary condition. Moreover, let us introduce the notation

$$D_{\Delta t}^n \widehat{\psi} := \frac{\psi^{n+1} - \psi^n}{\Delta t}. \tag{5.18}$$

For the sequence $\|\widehat{\psi}\|_0 := \{\|\psi^n\|_0\}$, let us define

$$D_{\Delta t}^n \left(\|\widehat{\psi}\|_0\right) := \frac{\|\psi^{n+1}\|_0 - \|\psi^n\|_0}{\Delta t}, \tag{5.19}$$

and for $\widehat{D_{\Delta t}\psi} := \left\{D_{\Delta t}^n \widehat{\psi}\right\}_{n=0}^{N-1}$ we define

$$\left\|\widehat{D_{\Delta t}\psi}\right\|_{l^2(L^2(\Gamma_R))} = \sqrt{\Delta t \sum_{n=0}^{N-1} \left\|\frac{\psi^{n+1} - \psi^n}{\Delta t}\right\|_{0,\Gamma_R}^2}. \tag{5.20}$$

Before establishing some technical lemmas, let us recall the Young inequality

$$ab \le \frac{1}{2}\left(ca^2 + \frac{1}{c}b^2\right) \tag{5.21}$$

for $a, b \in R$ and $c > 0$, which will be extensively used in what follows.

LEMMA 5.5. *Let us assume Hypotheses* 2, 3, 4, *and* 5. *Let us suppose* $c_1 \Delta t < 1/2$. *If* $\widehat{\phi_{\Delta t}} = \{\phi_{\Delta t}^n\}_{n=1}^N$ *denotes the solution of* (5.13) *and* $\alpha > 0$, $\delta > 0$ *are the constants appearing, respectively, in Hypothesis* 3 *and* (2.3), *then*

$$\begin{aligned}
&\left\langle \mathcal{L}_{\Delta t}^{n+\frac{1}{2}} \widehat{\phi_{\Delta t}}, \phi_{\Delta t}^{n+1} \right\rangle \\
&\quad \ge D_{\Delta t}^n \left(\frac{1}{2} \left\|\widehat{\phi_{\Delta t}}\right\|_0^2 + \frac{\Delta t}{4} \left\|\mathbf{C}\nabla \widehat{\phi_{\Delta t}}\right\|_0^2 + \frac{\Delta t}{4} \left\|\sqrt{r}\, \widehat{\phi_{\Delta t}}\right\|_0^2 + \frac{\alpha\, \Delta t}{4} \|\widehat{\phi_{\Delta t}}\|_{0,\Gamma_R}^2 \right) \\
&\qquad + \frac{1}{2\Delta t} \left\|\phi_{\Delta t}^{n+1} - \phi_{\Delta t}^n \circ X_{RK}^n\right\|_0^2 + \frac{1}{4} \left\|\mathbf{C}\nabla \phi_{\Delta t}^{n+1} + (\mathbf{C}\nabla \phi_{\Delta t}^n) \circ X_E^n\right\|_0^2 \\
&\qquad + \frac{1}{4} \left\|\sqrt{r}\phi_{\Delta t}^{n+1} + (\sqrt{r}\phi_{\Delta t}^n) \circ X_E^n\right\|_0^2 + \frac{\alpha}{4} \left\|\phi^{n+1} + \phi^n(1 + \Delta t \text{ div } \mathbf{v}^{n+1})\right\|_{0,\Gamma_R}^2 \\
&\qquad - \frac{c}{2} \left(\|\phi_{\Delta t}^n\|_0^2 + \left\|\phi_{\Delta t}^{n+1}\right\|_0^2 \right) - c\Delta t\delta \left(\|\mathbf{B}\nabla \phi_{\Delta t}^n\|_0^2 + \left\|\mathbf{B}\nabla \phi_{\Delta t}^{n+1}\right\|_0^2 \right) \\
&\qquad - c\Delta t \left(\left\|\sqrt{r}\phi_{\Delta t}^n\right\|_0^2 + \left\|\sqrt{r}\phi_{\Delta t}^{n+1}\right\|_0^2 + \alpha \|\phi_{\Delta t}^n\|_{0,\Gamma_R}^2 \right),
\end{aligned} \tag{5.22}$$

where $\mathbf{C}\nabla\widehat{\phi_{\Delta t}} := \{\mathbf{C}\nabla\phi^n_{\Delta t}\}$, $\mathbf{B}\nabla\widehat{\phi_{\Delta t}} := \{\mathbf{B}\nabla\phi^n_{\Delta t}\}$, *and with the constant* c *given by* $c = \max\left\{1, c_1, c_2, (2c_1c_2 + c_1c_2^2)/\delta, c_1c_3/\gamma\right\}$.

Proof. First, we decompose $\left\langle \mathcal{L}_{\Delta t}^{n+\frac{1}{2}}\widehat{\phi_{\Delta t}}, \phi^{n+1}_{\Delta t}\right\rangle = I_1 + I_2 + I_3 + I_4 + I_5 + I_6$, with

$$
\begin{aligned}
I_1 &= \left\langle \frac{\phi^{n+1}_{\Delta t} - \phi^n_{\Delta t}\circ X^n_{RK}}{\Delta t}, \phi^{n+1}_{\Delta t}\right\rangle,\\
I_2 &= \frac{1}{2}\left\langle \mathbf{A}\nabla\phi^{n+1}_{\Delta t} + (\mathbf{A}\nabla\phi^n_{\Delta t})\circ X^n_E, \nabla\phi^{n+1}_{\Delta t}\right\rangle,\\
I_3 &= \frac{\Delta t}{2}\left\langle (\mathbf{L}^n\mathbf{A}\nabla\phi^n_{\Delta t})\circ X^n_E, \nabla\phi^{n+1}_{\Delta t}\right\rangle,\\
I_4 &= \frac{\Delta t}{2}\left\langle (\nabla\ \mathrm{div}\ \mathbf{v}^n\cdot\mathbf{A}\nabla\phi^n_{\Delta t})\circ X^n_E, \phi^{n+1}_{\Delta t}\right\rangle,\\
I_5 &= \frac{1}{2}\left\langle r\phi^{n+1}_{\Delta t} + (r\phi^n_{\Delta t})\circ X^n_E, \phi^{n+1}_{\Delta t}\right\rangle,\\
I_6 &= \alpha\left\langle \frac{\phi^{n+1} + \phi^n(1+\Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})}{2}, \phi^{n+1}_{\Delta t}\right\rangle_{\Gamma_R}.
\end{aligned}
$$

For I_1 we can use Lemma 2 in [24] to obtain

$$
I_1 \geq D^n_{\Delta t}\left(\frac{1}{2}\widehat{\|\phi_{\Delta t}\|_0^2}\right) + \frac{1}{2\Delta t}\left\|\phi^{n+1}_{\Delta t} - \phi^n_{\Delta t}\circ X^n_{RK}\right\|_0^2 - \frac{c_1}{2}\left\|\phi^n_{\Delta t}\right\|_0^2. \tag{5.23}
$$

For I_2 the following lower bound can be stated:

$$
\begin{aligned}
I_2 \geq D^n_{\Delta t}&\left(\frac{\Delta t}{4}\left\|\mathbf{C}\nabla\widehat{\phi_{\Delta t}}\right\|_0^2\right) + \frac{1}{4}\left\|\mathbf{C}\nabla\phi^{n+1}_{\Delta t} + (\mathbf{C}\nabla\phi^n_{\Delta t})\circ X^n_E\right\|_0^2\\
&- \frac{3c_1c_2\Delta t}{4}\left(\|\mathbf{B}\nabla\phi^n_{\Delta t}\|_0^2 + \left\|\mathbf{B}\nabla\phi^{n+1}_{\Delta t}\right\|_0^2\right).
\end{aligned} \tag{5.24}
$$

To prove (5.24) we first use the definition of $D^n_{\Delta t}$, Lemma 5.4, and (5.21) to get

$$
\begin{aligned}
&D^n_{\Delta t}\left(\frac{\Delta t}{4}\left\|\mathbf{C}\nabla\widehat{\phi_{\Delta t}}\right\|_0^2\right) + \frac{1}{4}\left\|\mathbf{C}\nabla\phi^{n+1}_{\Delta t} + (\mathbf{C}\nabla\phi^n_{\Delta t})\circ X^n_E\right\|_0^2 - \frac{c_1c_2\Delta t}{4}\|\mathbf{B}\nabla\phi^n_{\Delta t}\|_0^2\\
&\quad\leq \frac{1}{4}\left(\left\|\mathbf{C}\nabla\phi^{n+1}_{\Delta t}\right\|_0^2 - \|(\mathbf{C}\nabla\phi^n_{\Delta t})\circ X^n_E\|_0^2 + \left\|\mathbf{C}\nabla\phi^{n+1}_{\Delta t} + (\mathbf{C}\ \nabla\ \phi^n_{\Delta t})\circ X^n_E\right\|_0^2\right)\\
&\quad= \frac{1}{2}\left\langle \mathbf{C}\nabla\phi^{n+1}_{\Delta t} + (\mathbf{C}\nabla\phi^n)\circ X^n_E, \mathbf{C}\nabla\phi^{n+1}_{\Delta t}\right\rangle.
\end{aligned}
$$

Next, we introduce the function $Y^n_E(\mathbf{x},\cdot) : [t_n, t_{n+1}] \longrightarrow \overline{\Omega}$, defined by $Y^n_E(\mathbf{x}, s) := \mathbf{x} - (t_{n+1} - s)\mathbf{v}^{n+1}(\mathbf{x})$, which satisfies $Y^n_E(\mathbf{x}, t_n) = X^n_E(\mathbf{x})$ and $Y^n_E(\mathbf{x}, t_{n+1}) = \mathbf{x}$. Moreover, since $\mathbf{A}_{m_1}$ is symmetric and positive definite, $\mathbf{C}_{m_1} = \sqrt{\mathbf{A}_{m_1}}$ is a differentiable function ($\nabla\mathbf{C}$ is the appropriate completion by zeros of $\nabla\mathbf{C}_{m_1}$). Then, by Barrow's rule and the chain rule, the following identity holds:

$$
\mathbf{C}(\mathbf{x}) = \mathbf{C}(X^n_E(\mathbf{x})) + \mathbf{D}^n(\mathbf{x}) \qquad \text{for a.e. } \mathbf{x}\in\Omega, \tag{5.25}
$$

where we have denoted by $\mathbf{D}^n$ the $m\times m$ symmetric matrix defined by

$$
D^n_{ij}(\mathbf{x}) := \int_{t_n}^{t_{n+1}} \nabla C_{ij}(Y^n_E(\mathbf{x}, s))\cdot\mathbf{v}^{n+1}(\mathbf{x})\ ds \qquad \text{for a.e. } \mathbf{x}\in\Omega, \tag{5.26}
$$

which verifies $\left|D_{ij}^n(\mathbf{x})\right| \le c_1\sqrt{c_2}\Delta t$. So, from the previous notation, we have

$$\begin{aligned}\frac{1}{2}\left\langle \mathbf{C}\nabla\phi_{\Delta t}^{n+1} + (\mathbf{C}\nabla\phi_{\Delta t}^{n})\circ X_E^n, \mathbf{C}\nabla\phi_{\Delta t}^{n+1}\right\rangle &= I_2 + \frac{1}{2}\left\langle \mathbf{D}^n(\mathbf{C}\nabla\phi_{\Delta t}^{n})\circ X_E^n, \nabla\phi_{\Delta t}^{n+1}\right\rangle \\ &\le I_2 + \frac{1}{2}\sqrt{1+c_1\Delta t}\sqrt{c_2}\,\|\mathbf{B}\nabla\phi_{\Delta t}^{n}\|_0\ \Delta t c_1\sqrt{c_2}\left\|\mathbf{B}\nabla\phi_{\Delta t}^{n+1}\right\|_0 \\ &\le I_2 + \frac{c_1c_2\Delta t}{2}\left(\|\mathbf{B}\nabla\phi_{\Delta t}^{n}\|_0^2 + \left\|\mathbf{B}\nabla\phi_{\Delta t}^{n+1}\right\|_0^2\right),\end{aligned}$$

where we have used the Cauchy–Schwarz inequality, Hypotheses 2 and 3, Lemma 5.4, inequality (5.21), and the fact that $c_1\Delta t < 1$. Finally, result (5.24) follows.

Next, by first using Remark 5.6 and then the Cauchy–Schwarz inequality, Hypotheses 2 and 3, Lemma 5.4, inequality (5.21), and $c_1\Delta t < 1$, we obtain

$$|I_3| = \frac{\Delta t}{2}\left|\langle(\mathbf{L}^n\mathbf{A}\nabla\phi_{\Delta t}^{n})\circ X_E^n, \mathbf{B}\nabla\phi_{\Delta t}^{n+1}\rangle\right| \le \frac{\Delta t\ c_1c_2}{2}\left(\|\mathbf{B}\nabla\phi_{\Delta t}^{n}\|_0^2 + \left\|\mathbf{B}\nabla\phi_{\Delta t}^{n+1}\right\|_0^2\right).$$

Then when both $I_3 \ge 0$ and $I_3 < 0$, we have

$$I_3 \ge -\frac{c_1c_2\ \Delta t}{2}\left(\|\mathbf{B}\nabla\phi_{\Delta t}^{n}\|_0^2 + \left\|\mathbf{B}\nabla\phi_{\Delta t}^{n+1}\right\|_0^2\right). \tag{5.27}$$

Similarly, for I_4 we obtain the estimate

$$I_4 \ge -\frac{c_1c_2^2\ \Delta t}{2}\|\mathbf{B}\nabla\phi_{\Delta t}^{n}\|_0^2 - \frac{1}{4}\left\|\phi_{\Delta t}^{n+1}\right\|_0^2. \tag{5.28}$$

For the reaction term, we can obtain

$$\begin{aligned}I_5 \ge D_{\Delta t}^n\left(\frac{\Delta t}{4}\left\|\sqrt{r}\,\widehat{\phi_{\Delta t}}\right\|_0^2\right) + \frac{1}{4}\left\|\sqrt{r}\phi_{\Delta t}^{n+1} + (\sqrt{r}\phi_{\Delta t}^{n})\circ X_E^n\right\|_0^2 \\ - \max\{c_1, c_1c_3/\gamma\}\ \frac{\Delta t}{2}\left(\left\|\sqrt{r}\phi_{\Delta t}^{n}\right\|_0^2 + \left\|\sqrt{r}\phi_{\Delta t}^{n+1}\right\|_0^2\right).\end{aligned} \tag{5.29}$$

The proof of (5.29) is analogous to the one of (5.24), but using Hypothesis 5 instead of Hypotheses 2 and 3.

For boundary integral term I_6, we first use some properties of the inner product in the space $L^2(\Gamma_R)$ and the inequality $(1+c_1\Delta t)^2 \le 1 + 3c_1\Delta t$ to get the estimate

$$\|\psi(1+\Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})\|_{0,\Gamma_R}^2 \le (1+c_1\Delta t)^2\|\psi\|_{0,\Gamma_R}^2 \le (1+3c_1\Delta t)\,\|\psi\|_{0,\Gamma_R}^2$$

for $\psi \in L^2(\Gamma_R)$. Thus, we obtain

$$\begin{aligned}I_6 \ge D_{\Delta t}^n\left(\frac{\alpha\Delta t}{4}\left\|\widehat{\phi_{\Delta t}}\right\|_{0,\Gamma_R}^2\right) + \frac{\alpha}{4}\left\|\phi_{\Delta t}^{n+1} + \phi_{\Delta t}^{n}(1+\Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})\right\|_{0,\Gamma_R}^2 \\ - \frac{3}{4}c_1\alpha\Delta t\,\|\phi_{\Delta t}^{n}\|_{0,\Gamma_R}^2.\end{aligned} \tag{5.30}$$

Then, by summing up (5.23), (5.24), (5.27), (5.28), (5.29), and (5.30), inequality (5.22) follows. ∎

Now, we study the stability of a scheme with a more general right-hand side, i.e.,

$$\begin{cases}\text{Given } \phi_{\Delta t}^0, \text{ find } \widehat{\phi_{\Delta t}} = \{\phi_{\Delta t}^n\}_{n=1}^N \in \left[H_{\Gamma_D}^1(\Omega)\right]^N \text{ such that} \\ \left\langle \mathcal{L}_{\Delta t}^{n+\frac{1}{2}}\widehat{\phi_{\Delta t}}, \psi\right\rangle = \left\langle \mathcal{H}_{\Delta t}^{n+\frac{1}{2}}, \psi\right\rangle \quad \forall\psi \in H_D^1(\Omega) \text{ for } n = 0,\dots,N-1,\end{cases} \tag{5.31}$$

with $\left\langle \mathcal{H}_{\Delta t}^{n+\frac{1}{2}}, \psi \right\rangle = \left\langle F^{n+1}, \psi \right\rangle + \left\langle G^{n+1}, \psi \right\rangle_{\Gamma_R}$.

Let us denote $\widehat{F} = \{F^n\}_{n=0}^N \in \left[L^2(\Omega)\right]^{N+1}$ and $\widehat{G} = \{G^n\}_{n=0}^N \in \left[L^2(\Gamma_R)\right]^{N+1}$. Notice that constant $\alpha > 0$ related to Robin boundary condition (2.3) appears explicitly in the following lemmas; however, they remain valid for any positive constant.

LEMMA 5.6. *Let us assume Hypothesis* 2, $F^{n+1} \in L^2(\Omega)$, *and* $G^{n+1} \in L^2(\Gamma_R)$. *If* $c_1 \Delta t < 1$, *then*

$$\begin{aligned} \left\langle F^{n+1}, \psi \right\rangle + \left\langle G^{n+1}, \psi \right\rangle_{\Gamma_R} &\leq \frac{1}{2}\left(\|F^{n+1}\|_0^2 + \|\psi\|_0^2\right) + \left\langle H^{n+1}, \psi - \varphi \right\rangle_{\Gamma_R} \\ &+ \frac{21}{\alpha}\|H^{n+1}\|_{0,\Gamma_R}^2 + \frac{\alpha c_1 \Delta t}{2}\|\varphi\|_{0,\Gamma_R}^2 + \frac{\alpha}{16}\|\psi + \varphi(1 + \Delta t \text{ div } \mathbf{v}^{n+1})\|_{0,\Gamma_R}^2, \end{aligned} \tag{5.32}$$

with $H^{n+1} := G^{n+1}/(2 + \Delta t \text{ div } \mathbf{v}^{n+1})$ $\forall \varphi, \psi \in H^1(\Omega)$ *and* $\alpha > 0$.

Proof. Let us introduce the notation $I_1 = \left\langle F^{n+1}, \psi \right\rangle$ and $I_2 = \left\langle G^{n+1}, \psi \right\rangle_{\Gamma_R}$. For I_1 we only need to apply the Cauchy–Schwarz inequality. For I_2 let us note first that function H^{n+1} is well defined under hypothesis $c_1 \Delta t < 1$. Then I_2 is decomposed into three terms, namely, $I_2 = I_2^1 + I_2^2 + I_2^3$, where

$$\begin{aligned} I_2^1 &= \left\langle H^{n+1}, \psi \right\rangle_{\Gamma_R} - \left\langle H^{n+1}, \varphi \right\rangle_{\Gamma_R}, \\ I_2^2 &= \left\langle H^{n+1}, \varphi \right\rangle_{\Gamma_R} - \left\langle H^{n+1}(1 + \Delta t \text{ div } \mathbf{v}^{n+1}), \varphi(1 + \Delta t \text{ div } \mathbf{v}^{n+1}) \right\rangle_{\Gamma_R}, \\ I_2^3 &= \left\langle H^{n+1}(1 + \Delta t \text{ div } \mathbf{v}^{n+1}), \varphi(1 + \Delta t \text{ div } \mathbf{v}^{n+1}) \right\rangle_{\Gamma_R} + \left\langle H^{n+1}(1 + \Delta t \text{ div } \mathbf{v}^{n+1}), \psi \right\rangle_{\Gamma_R}. \end{aligned}$$

In order to estimate I_2^2 it is easy to show that

$$\begin{aligned} I_2^2 &\leq 3c_1 \Delta t \, \|\varphi\|_{0,\Gamma_R} \|H^{n+1}\|_{0,\Gamma_R} \leq \frac{c_1 \Delta t}{2}\left(\alpha \|\varphi\|_{0,\Gamma_R}^2 + \frac{9}{\alpha}\|H^{n+1}\|_{0,\Gamma_R}^2\right) \\ &\leq \frac{c_1 \alpha \Delta t}{2}\|\varphi\|_{0,\Gamma_R}^2 + \frac{9}{2\alpha}\|H^{n+1}\|_{0,\Gamma_R}^2, \end{aligned}$$

where we have used (5.21) with $a = \|\varphi\|_{0,\Gamma_R}$, $b = 3\|H^{n+1}\|_{0,\Gamma_R}$, and $c = \alpha$.

For I_2^3, (5.21) and estimate $(1 + c_1 \Delta t)^2 \leq 4$ lead to

$$\begin{aligned} I_2^3 &= \left\langle H^{n+1}(1 + \Delta t \text{ div } \mathbf{v}^{n+1}), \psi + \varphi(1 + \Delta t \text{ div } \mathbf{v}^{n+1}) \right\rangle_{\Gamma_R} \\ &\leq \frac{16}{\alpha}\|H^{n+1}\|_{0,\Gamma_R}^2 + \frac{\alpha}{16}\|\psi + \varphi(1 + \Delta t \text{ div } \mathbf{v}^{n+1})\|_{0,\Gamma_R}^2. \end{aligned}$$

Finally, by jointly considering the above inequalities we get (5.32). ∎

The following lemma involves functions defined on Γ_R and velocity field $\mathbf{v}$.

LEMMA 5.7. *Let us assume Hypothesis* 2. *Let* $\{G^n\}_{n=0}^N \in \left[L^2(\Gamma_R)\right]^{N+1}$ *and* $\{H^n\}_{n=0}^N$ *be as in Lemma* 5.6. *If* $c_1 \Delta t < 1$, *then* $\{H^n\}_{n=0}^N \in \left[L^2(\Gamma_R)\right]^{N+1}$ *and*

$$\|H^n\|_{0,\Gamma_R} \leq \|G^n\|_{0,\Gamma_R}. \tag{5.33}$$

Moreover, for any sequence $\{\psi^n\}_{n=0}^N \in \left[L^2(\Gamma_R)\right]^{N+1}$ *and any* $m \in \{0, \ldots, N-1\}$, *the following inequality holds:*

$$\begin{aligned} \left|\sum_{n=0}^{m-1} \left\langle H^{n+1}, \psi^{n+1} - \psi^n \right\rangle_{\Gamma_R}\right| &\leq \frac{\alpha}{16}\|\psi^m\|_{0,\Gamma_R}^2 + \frac{4}{\alpha}\|G^m\|_{0,\Gamma_R}^2 + \frac{\alpha}{16}\left\|\psi^0\right\|_{0,\Gamma_R}^2 \\ + \frac{4}{\alpha}\left\|G^1\right\|_{0,\Gamma_R}^2 + 3\alpha \Delta t \sum_{n=1}^{m-1}\|\psi^n\|_{0,\Gamma_R}^2 &+ \frac{\Delta t}{\alpha}\sum_{n=1}^{m-1}\left\|\frac{G^{n+1} - G^n}{\Delta t}\right\|_{0,\Gamma_R}^2 + \frac{c_1 \Delta t}{\alpha}\sum_{n=1}^{m}\|G^n\|_{0,\Gamma_R}^2 \end{aligned} \tag{5.34}$$

for any $\alpha > 0$ related to condition (2.3).

Proof. First, since $c_1\Delta t < 1$, then $1/3 \le (2 + \Delta t \text{ div } \mathbf{v}^n)^{-1} \le 1$. So, $|H^n(\mathbf{x})| \le |G^n(\mathbf{x})|$ for a.e. $\mathbf{x} \in \Gamma_R$, $H^n \in L^2(\Gamma_R)$, and (5.33) holds. For (5.34), we use the identity

(5.35)
$$\sum_{n=0}^{m-1} \left\langle H^{n+1}, \psi^{n+1} - \psi^n \right\rangle_{\Gamma_R} = \langle H^m, \psi^m \rangle_{\Gamma_R} - \left\langle H^1, \psi^0 \right\rangle_{\Gamma_R} - \Delta t \sum_{n=1}^{m-1} \left\langle \frac{H^{n+1} - H^n}{\Delta t}, \psi^n \right\rangle_{\Gamma_R}.$$

The third term in (5.35) can be bounded as follows:

$$\Delta t \left| \sum_{n=1}^{m-1} \left\langle \frac{H^{n+1} - H^n}{\Delta t}, \psi^n \right\rangle_{\Gamma_R} \right| \le \frac{\Delta t}{\alpha} \sum_{n=1}^{m-1} \left\| \frac{G^{n+1} - G^n}{\Delta t} \right\|_{0,\Gamma_R}^2 + \frac{c_1 \Delta t}{\alpha} \sum_{n=0}^{m-1} \|G^n\|_{0,\Gamma_R}^2 + 3\alpha \Delta t \sum_{n=1}^{m-1} \|\psi^n\|_{0,\Gamma_R}^2, \tag{5.36}$$

where we have used the equality

$$\frac{H^{n+1} - H^n}{\Delta t} = \frac{2(G^{n+1} - G^n)}{\Delta t\ (2 + \Delta t \text{ div } \mathbf{v}^{n+1})(2 + \Delta t \text{ div } \mathbf{v}^n)} + \frac{\text{div } \mathbf{v}^n\ G^{n+1} - \text{div } \mathbf{v}^{n+1}\ G^n}{(2 + \Delta t \text{ div } \mathbf{v}^{n+1})(2 + \Delta t \text{ div } \mathbf{v}^n)},$$

together with (5.21), the stated bound for the term $(2 + \Delta t \text{ div } \mathbf{v}^n)^{-1}$, and Hypothesis 2. The first two terms in (5.35) can be bounded by using (5.21) and (5.33), obtaining

$$\left| \left\langle H^i, \psi^j \right\rangle_{\Gamma_R} \right| \le \frac{4}{\alpha} \|G^i\|_{0,\Gamma_R}^2 + \frac{\alpha}{16} \|\psi^j\|_{0,\Gamma_R}^2 \quad \text{for } (i,j) = (1,0) \text{ and } (m,m). \tag{5.37}$$

Finally, by jointly considering (5.35), (5.36), and (5.37) we get (5.34). ∎

THEOREM 5.8. *Let us assume Hypotheses* 2, 3, 4, *and* 5. *Let* $\widehat{F} \in \left[L^2(\Omega)\right]^{N+1}$, $\widehat{G} \in \left[L^2(\Gamma_R)\right]^{N+1}$, *and* $\widehat{\phi_{\Delta t}} = \{\phi_{\Delta t}^n\}_{n=1}^N$ *be the solution of* (5.31) *subject to initial value* $\phi_{\Delta t}^0 \in H^1(\Omega)$. *Let* $\alpha > 0$ *be the constant appearing in* (2.3). *Then there exist two positive constants* c *and* $d = d(c_1, c_2, \delta, c_3, \gamma)$, *such that if* $\Delta t < d$, *then*

$$\begin{aligned} &\frac{1}{\sqrt{2}} \left\| \widehat{\phi_{\Delta t}} \right\|_{l^\infty(L^2(\Omega))} + \sqrt{\frac{\delta\ \Delta t}{4}} \left\| \mathbf{B}\nabla \widehat{\phi_{\Delta t}} \right\|_{l^\infty(L^2(\Omega))} + \sqrt{\frac{\Delta t}{4}} \left\| \sqrt{r}\, \widehat{\phi_{\Delta t}} \right\|_{l^\infty(L^2(\Omega))} \\ &+ \sqrt{\frac{\alpha \Delta t}{16}} \left\| \widehat{\phi_{\Delta t}} \right\|_{l^\infty(L^2(\Gamma_R))} \le c \left(\frac{1}{2} \left\| \phi_{\Delta t}^0 \right\|_0 + \sqrt{\frac{\delta\ \Delta t}{4}} \left\| \mathbf{B}\nabla \phi_{\Delta t}^0 \right\|_0 + \sqrt{\frac{\Delta t}{4}} \left\| \sqrt{r} \phi_{\Delta t}^0 \right\|_0 \right. \\ &\left. + \sqrt{\frac{\alpha \Delta t}{16}} \left\| \phi_{\Delta t}^0 \right\|_{0,\Gamma_R} + \left\| \widehat{F} \right\|_{l^2(L^2(\Omega))} + \left\| \widehat{G} \right\|_{l^2(L^2(\Gamma_R))} + \Delta t \left\| \widehat{D_{\Delta t} G} \right\|_{l^2(L^2(\Gamma_R))} \right), \end{aligned} \tag{5.38}$$

where $\mathbf{B}\nabla \widehat{\phi_{\Delta t}} := \{\mathbf{B}\nabla \phi_{\Delta t}^n\}$, $\widehat{F} = \{F^n\}_{n=0}^N$, *and* $\widehat{G} = \{G^n\}_{n=0}^N$.

Proof. Sequence $\widehat{\phi_{\Delta t}} = \{\phi_{\Delta t}^n\}_{n=1}^N$ satisfies $\left\langle \mathcal{L}_{\Delta t}^{n+\frac{1}{2}} \widehat{\phi_{\Delta t}}, \phi_{\Delta t}^{n+1} \right\rangle = \left\langle \mathcal{H}_{\Delta t}^{n+\frac{1}{2}}, \phi_{\Delta t}^{n+1} \right\rangle$.

So, we first use Lemma 5.5 to obtain a lower bound left-hand side of this expression:

$$
\begin{aligned}
&\left\langle \mathcal{L}_{\Delta t}^{n+\frac{1}{2}}\widehat{\phi_{\Delta t}},\phi_{\Delta t}^{n+1}\right\rangle \\
&\geq D_{\Delta t}^{n}\left(\frac{1}{2}\left\|\widehat{\phi_{\Delta t}}\right\|_0^2+\frac{\Delta t}{4}\left\|\mathbf{C}\nabla\widehat{\phi_{\Delta t}}\right\|_0^2+\frac{\Delta t}{4}\left\|\sqrt{r}\,\widehat{\phi_{\Delta t}}\right\|_0^2+\frac{\alpha\Delta t}{4}\left\|\widehat{\phi_{\Delta t}}\right\|_{0,\Gamma_R}^2\right)\\
&+\frac{\alpha}{4}\|\phi_{\Delta t}^{n+1}+\phi_{\Delta t}^{n}(1+\Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})\|_{0,\Gamma_R}^2-c\left(\|\phi_{\Delta t}^{n}\|_0^2+\left\|\phi_{\Delta t}^{n+1}\right\|_0^2\right)\\
&-c\Delta t\left(\delta\left(\|\mathbf{B}\nabla\phi_{\Delta t}^{n}\|_0^2+\left\|\mathbf{B}\nabla\phi_{\Delta t}^{n+1}\right\|_0^2\right)+\left\|\sqrt{r}\phi_{\Delta t}^{n}\right\|_0^2+\left\|\sqrt{r}\phi_{\Delta t}^{n+1}\right\|_0^2+\alpha\left\|\phi_{\Delta t}^{n}\right\|_{0,\Gamma_R}^2\right).
\end{aligned}
$$

Second, we use Lemma 5.6 for $\psi=\phi_{\Delta t}^{n+1}$ and $\varphi=\phi_{\Delta t}^{n}$ to obtain the upper bound

$$
\begin{aligned}
\left\langle \mathcal{H}_{\Delta t}^{n+\frac{1}{2}},\phi_{\Delta t}^{n+1}\right\rangle &\leq \frac{1}{2}\left(\left\|F^{n+1}\right\|_0^2+\left\|\phi^{n+1}\right\|_0^2\right)+\left\langle H^{n+1},\phi^{n+1}-\phi^{n}\right\rangle_{\Gamma_R}\\
&+\frac{21}{\alpha}\left\|H^{n+1}\right\|_{0,\Gamma_R}^2+\frac{\alpha c_1\Delta t}{2}\left\|\phi^{n}\right\|_{0,\Gamma_R}^2+\frac{\alpha}{16}\left\|\phi^{n+1}+\phi^{n}(1+\Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})\right\|_{0,\Gamma_R}^2.
\end{aligned}
$$

Next, by jointly considering both estimates, regrouping, and simplifying terms we get

$$
\begin{aligned}
&D_{\Delta t}^{n}\left(\frac{1}{2}\left\|\widehat{\phi_{\Delta t}}\right\|_0^2+\frac{\Delta t}{4}\left\|\mathbf{C}\nabla\widehat{\phi_{\Delta t}}\right\|_0^2+\frac{\Delta t}{4}\left\|\sqrt{r}\,\widehat{\phi_{\Delta t}}\right\|_0^2+\frac{\alpha\Delta t}{4}\left\|\widehat{\phi_{\Delta t}}\right\|_{0,\Gamma_R}^2\right)\\
&\leq\frac{1}{2}\left\|F^{n+1}\right\|_0^2+\frac{21}{\alpha}\left\|H^{n+1}\right\|_{0,\Gamma_R}^2+\left\langle H^{n+1},\phi_{\Delta t}^{n+1}-\phi_{\Delta t}^{n}\right\rangle_{\Gamma_R}+c\left(\|\phi_{\Delta t}^{n}\|_0^2+\left\|\phi_{\Delta t}^{n+1}\right\|_0^2\right)\\
&+c\Delta t\left(\delta\left(\|\mathbf{B}\nabla\phi_{\Delta t}^{n}\|_0^2+\left\|\mathbf{B}\nabla\phi_{\Delta t}^{n+1}\right\|_0^2\right)+\left\|\sqrt{r}\phi_{\Delta t}^{n}\right\|_0^2+\left\|\sqrt{r}\phi_{\Delta t}^{n+1}\right\|_0^2+2\alpha\left\|\phi_{\Delta t}^{n}\right\|_{0,\Gamma_R}^2\right),
\end{aligned}
\tag{5.39}
$$

with $c=\max\left\{1,c_1,c_2,(2c_1c_2+c_1c_2^2)/\delta,c_1c_3/\gamma\right\}$. Now, for fixed integer $m\geq 1$, let us sum (5.39) multiplied by Δt from $n=0$ to $n=m-1$. We obtain

$$
\begin{aligned}
&\frac{1}{2}\|\phi_{\Delta t}^{m}\|_0^2+\frac{\Delta t}{4}\|\mathbf{C}\nabla\phi_{\Delta t}^{m}\|_0^2+\frac{\Delta t}{4}\left\|\sqrt{r}\phi_{\Delta t}^{m}\right\|_0^2+\frac{\alpha\Delta t}{4}\|\phi_{\Delta t}^{m}\|_{0,\Gamma_R}^2\\
&-\frac{1}{2}\|\phi_{\Delta t}^{0}\|_0^2-\frac{\Delta t}{4}\|\mathbf{C}\nabla\phi_{\Delta t}^{0}\|_0^2-\frac{\Delta t}{4}\left\|\sqrt{r}\phi_{\Delta t}^{0}\right\|_0^2-\frac{\alpha\Delta t}{4}\|\phi_{\Delta t}^{0}\|_{0,\Gamma_R}^2\\
&\leq\frac{\Delta t}{2}\sum_{n=1}^{m}\|F^{n}\|_0^2+\frac{21\Delta t}{\alpha}\sum_{n=1}^{m}\|H^{n}\|_{0,\Gamma_R}^2+\Delta t\sum_{n=0}^{m-1}\left\langle H^{n+1},\phi_{\Delta t}^{n+1}-\phi_{\Delta t}^{n}\right\rangle_{\Gamma_R}\\
&+2c\Delta t\sum_{n=0}^{m}\|\phi_{\Delta t}^{n}\|_0^2+2c\Delta t^2\left(\sum_{n=0}^{m}\delta\|\mathbf{B}\nabla\phi_{\Delta t}^{n}\|_0^2+\sum_{n=0}^{m}\left\|\sqrt{r}\phi_{\Delta t}^{n}\right\|_0^2+\sum_{n=0}^{m-1}\alpha\|\phi_{\Delta t}^{n}\|_{0,\Gamma_R}^2\right).
\end{aligned}
$$

Now, by using (5.17) and Lemma 5.7, for $\psi^n=\phi^n$ we get

$$
\begin{aligned}
&\frac{1}{2}\|\phi_{\Delta t}^{m}\|_0^2+\frac{\delta\Delta t}{4}\|\mathbf{B}\nabla\phi_{\Delta t}^{m}\|_0^2+\frac{\Delta t}{4}\left\|\sqrt{r}\phi_{\Delta t}^{m}\right\|_0^2+\frac{3\alpha\Delta t}{16}\|\phi_{\Delta t}^{m}\|_{0,\Gamma_R}^2\\
&\leq\frac{1}{2}\left\|\phi_{\Delta t}^{0}\right\|_0^2+\frac{c_2\Delta t}{4}\left\|\mathbf{B}\nabla\phi_{\Delta t}^{0}\right\|_0^2+\frac{\Delta t}{4}\left\|\sqrt{r}\phi_{\Delta t}^{0}\right\|_0^2+\frac{5\alpha\Delta t}{16}\left\|\phi_{\Delta t}^{0}\right\|_{0,\Gamma_R}^2\\
&+\frac{\Delta t}{2}\sum_{n=1}^{m}\|F^{n}\|_0^2+\frac{25\Delta t}{\alpha}\sum_{n=1}^{m}\|G^{n}\|_{0,\Gamma_R}^2+\frac{c_1\Delta t^2}{\alpha}\sum_{n=1}^{m}\|G^{n}\|_{0,\Gamma_R}^2+\frac{\Delta t^2}{\alpha}\sum_{n=1}^{m-1}\left\|\frac{G^{n+1}-G^{n}}{\Delta t}\right\|_{0,\Gamma_R}^2\\
&+2c\Delta t\sum_{n=0}^{m}\|\phi_{\Delta t}^{n}\|_0^2+2c\Delta t^2\left(\sum_{n=0}^{m}\delta\|\mathbf{B}\nabla\phi_{\Delta t}^{n}\|_0^2+\sum_{n=0}^{m}\left\|\sqrt{r}\phi_{\Delta t}^{n}\right\|_0^2+\frac{5}{2}\sum_{n=1}^{m-1}\alpha\|\phi_{\Delta t}^{n}\|_{0,\Gamma_R}^2\right).
\end{aligned}
$$

Let us introduce, for $n = 0, \dots, N$, the notation

$$\theta_n := \frac{1}{2} \|\phi^n_{\Delta t}\|^2_0 + \frac{\delta \Delta t}{4} \|\mathbf{B}\nabla\phi^n_{\Delta t}\|^2_0 + \frac{\Delta t}{4} \left\|\sqrt{r}\ \phi^n_{\Delta t}\right\|^2_0, \quad \overline{\theta}_n := \frac{\alpha \Delta t}{16} \|\phi^n_{\Delta t}\|^2_{0,\Gamma_R}.$$

With the above notation we have

$$\begin{aligned}(1 - 8c\Delta t)\theta_m + \overline{\theta}_m &\le 8c\Delta t \sum_{n=0}^{m-1} \theta_n + 80c\Delta t \sum_{n=0}^{m-1} \overline{\theta}_n \\ &+ \widetilde{c}\left(\theta_0 + \overline{\theta_0} + \left\|\widehat{F}\right\|^2_{l^2(L^2(\Omega))} + \left\|\widehat{G}\right\|^2_{l^2(L^2(\Gamma_R))} + \Delta t \left\|\widehat{D_{\Delta t} G}\right\|^2_{l^2(L^2(\Gamma_R))}\right),\end{aligned}$$

with $c = \max\left\{1, c_1, c_2, (2c_1c_2 + c_1^2c_2^2)/\delta, c_1c_3/\gamma\right\}$ and $\widetilde{c}$ a positive constant. For Δt small enough, we can apply the discrete Gronwall inequality (see, for instance, [22]) and take the maximum in $q \in \{1, \dots, N\}$. Thus, estimate (5.38) follows. ∎

COROLLARY 5.9 (stability). *Let us assume Hypotheses* 2 *to* 7. *Let* $\widehat{\phi_{\Delta t}} = \{\phi^n_{\Delta t}\}_{n=1}^N$ *be the solution of* (5.13) *subject to initial value* $\phi^0_{\Delta t}$. *Then there exist two positive constants,* c *and* $d = d(c_1, c_2, \delta, c_3, \gamma)$, *such that, for* $\Delta t < d$, *we have*

$$\begin{aligned}&\frac{1}{\sqrt{2}} \left\|\widehat{\phi_{\Delta t}}\right\|_{l^\infty(L^2(\Omega))} + \sqrt{\frac{\delta\ \Delta t}{4}} \left\|\mathbf{B}\nabla\widehat{\phi_{\Delta t}}\right\|_{l^\infty(L^2(\Omega))} + \sqrt{\frac{\Delta t}{4}} \left\|\sqrt{r}\,\widehat{\phi_{\Delta t}}\right\|_{l^\infty(L^2(\Omega))} \\ &+ \sqrt{\frac{\alpha\ \Delta t}{16}} \left\|\widehat{\phi_{\Delta t}}\right\|_{l^\infty(L^2(\Gamma_R))} \le c\left(\frac{1}{2}\left\|\phi^0_{\Delta t}\right\|_0 + \sqrt{\frac{\delta\ \Delta t}{4}}\left\|\mathbf{B}\nabla\phi^0_{\Delta t}\right\|_0 + \sqrt{\frac{\Delta t}{4}}\left\|\sqrt{r}\phi^0_{\Delta t}\right\|_0\right. \\ &\left. + \sqrt{\frac{\alpha\ \Delta t}{16}}\left\|\phi^0_{\Delta t}\right\|_{0,\Gamma_R} + \left\|\widehat{f}\right\|_{l^2(L^2(\Omega))} + \|\widehat{g}\|_{l^2(L^2(\Gamma_R))} + \Delta t \left\|\widehat{D_{\Delta t} g}\right\|_{l^2(L^2(\Gamma_R))}\right),\end{aligned} \tag{5.40}$$

where $\mathbf{B}\nabla\widehat{\phi_{\Delta t}} := \{\mathbf{B}\nabla\phi^n_{\Delta t}\}$.

Proof. The result follows directly by replacing F^{n+1} with $f^{n+1} + f^n \circ X^n_E$ and G^{n+1} with $g^{n+1} + g^n(1 + \Delta t \text{ div } \mathbf{v}^{n+1})$ in (5.38). ∎

5.4. Error estimate for the semidiscretized scheme. The aim of the present section is to estimate the difference between the *discrete solution* of (5.13), $\widehat{\phi_{\Delta t}}$, and $\widehat{\phi} = \{\phi^n\}$, the exact solution of the continuous problem. According to (4.7) for $t = t_{n+1}$ and $\tau = t_{n+\frac{1}{2}}$, the latter solves the problem

$$\left\langle \mathcal{L}^{n+\frac{1}{2}}\widehat{\phi}, \psi\right\rangle = \left\langle \mathcal{F}^{n+\frac{1}{2}}, \psi\right\rangle \quad \forall \psi \in H^1_{\Gamma_D}(\Omega), \tag{5.41}$$

where $\mathcal{L}^{n+\frac{1}{2}}\widehat{\phi} \in (H^1(\Omega))'$ and $\mathcal{F}^{n+\frac{1}{2}} \in (H^1(\Omega))'$ are defined by

$$\begin{aligned}\left\langle \mathcal{L}^{n+\frac{1}{2}}\widehat{\phi}, \psi\right\rangle &:= \left\langle \left(\frac{\mathsf{d}\phi}{\mathsf{d}t}\right)^{n+\frac{1}{2}} \circ X_e^{n+\frac{1}{2}}, \psi\right\rangle + \left\langle \left(\mathbf{F}_e^{n+\frac{1}{2}}\right)^{-1}\left(\mathbf{A}\nabla\phi^{n+\frac{1}{2}}\right) \circ X_e^{n+\frac{1}{2}},\ \nabla\ \psi\right\rangle \\ &+ \left\langle \text{div } \left(\mathbf{F}_e^{n+\frac{1}{2}}\right)^{-\mathrm{T}} \cdot \left(\mathbf{A}\nabla\phi^{n+\frac{1}{2}}\right) \circ X_e^{n+\frac{1}{2}}, \psi\right\rangle \\ &+ \left\langle \left(r\phi^{n+\frac{1}{2}}\right) \circ X_e^{n+\frac{1}{2}}, \psi\right\rangle + \alpha \left\langle \mathsf{det}\ \left(\mathbf{F}_e^{n+\frac{1}{2}}\right)^{-1} \phi^{n+\frac{1}{2}}, \psi\right\rangle_{\Gamma_R}, \\ \left\langle \mathcal{F}^{n+\frac{1}{2}}, \psi\right\rangle &:= \left\langle f^{n+\frac{1}{2}} \circ X_e^{n+\frac{1}{2}}, \psi\right\rangle + \left\langle \mathsf{det}\ \left(\mathbf{F}_e^{n+\frac{1}{2}}\right)^{-1} g^{n+\frac{1}{2}}, \psi\right\rangle_{\Gamma_R} \quad \forall \psi \in H^1(\Omega).\end{aligned}$$

The error estimate to be stated in Theorem 5.21 is proved by means of Theorem 5.8 and the forthcoming Lemmas 5.19 and 5.20. Before doing this, we give some results with sketched proofs (see [20] for further details). Moreover, in what follows, $\widetilde{c_1}$ denotes a generic positive constant related to the norm of the velocity field $\mathbf{v}$ and not necessarily the same at each occurrence.

LEMMA 5.10. *Let us assume that* $\mathbf{v} \in C^2(L^\infty(\Omega)) \cap C^1(W^{1,\infty}(\Omega)) \cap C^0(W^{2,\infty}(\Omega))$ *and vanishes on the boundary,* $\Delta t \|\mathbf{v}\|_{C^0(W^{1,\infty}(\Omega))} < 1/2$, *and* $\varphi \in Z^3$. *Let us define the function* $\xi^{n+\frac{1}{2}}$ *by*

$$\xi^{n+\frac{1}{2}}(\mathbf{x}) := \frac{\mathsf{d}\varphi}{\mathsf{d}t}^{n+\frac{1}{2}} \left(X_e^{n+\frac{1}{2}}(\mathbf{x})\right) - \frac{\varphi^{n+1}(\mathbf{x}) - \varphi^n(X_{RK}^n(\mathbf{x}))}{\Delta t} \quad \forall \mathbf{x} \in \Omega.$$

Then $\xi^{n+\frac{1}{2}} \in L^2(\Omega)$ *and* $\|\xi^{n+\frac{1}{2}}\|_0 \leq \widetilde{c_1} \Delta t^2 \|\varphi\|_{Z^3}$, $n = 0, \ldots, N-1$.

Proof. Let us first write $\xi^{n+\frac{1}{2}}(\mathbf{x}) = \xi_1^{n+\frac{1}{2}}(\mathbf{x}) + \xi_2^{n+\frac{1}{2}}(\mathbf{x})$ with

$$\xi_1^{n+\frac{1}{2}}(\mathbf{x}) := \frac{\mathsf{d}\varphi}{\mathsf{d}t}^{n+\frac{1}{2}} \left(X_e^{n+\frac{1}{2}}(\mathbf{x})\right) - \frac{\varphi^{n+1}(\mathbf{x}) - \varphi^n(X_e^n(\mathbf{x}))}{\Delta t} \quad \forall \mathbf{x} \in \Omega,$$
$$\xi_2^{n+\frac{1}{2}}(\mathbf{x}) := \frac{\varphi^n(X_e^n(\mathbf{x})) - \varphi^n(X_{RK}^n(\mathbf{x}))}{\Delta t} \quad \forall \mathbf{x} \in \Omega.$$

The result follows by applying Taylor expansions to the above functions, noting that $|X_e^n(\mathbf{x}) - X_{RK}^n(\mathbf{x})| \leq \widetilde{c_1} \Delta t^3$. ∎

LEMMA 5.11. *Let us assume that* $\mathbf{v} \in C^1(L^\infty(\Omega)) \cap C^0(W^{1,\infty}(\Omega))$ *and vanishes on the boundary. Let* $\varphi \in Z^2$ *be a given function and* $\xi^{n+\frac{1}{2}} : \Omega \longrightarrow \mathbb{R}^m$ *be defined by*

$$\xi^{n+\frac{1}{2}}(\mathbf{x}) := \varphi(X_e^{n+\frac{1}{2}}(\mathbf{x}), t_{n+\frac{1}{2}}) - \frac{\varphi(\mathbf{x}, t_{n+1}) + \varphi(X_e^n(\mathbf{x}), t_n)}{2}.$$

Then $\xi^{n+\frac{1}{2}} \in L^2(\Omega)$ *and we have*

$$\xi^{n+\frac{1}{2}}(\mathbf{x}) = -\frac{1}{2} \int_{t_{n+\frac{1}{2}}}^{t_{n+1}} (t_{n+1} - s) \, \frac{\mathsf{d}^2\varphi}{\mathsf{d}t^2}(X_e(\mathbf{x}, t_{n+1}; s), s) \, ds$$
$$- \frac{1}{2} \int_{t_{n+\frac{1}{2}}}^{t_n} (t_n - s) \, \frac{\mathsf{d}^2\varphi}{\mathsf{d}t^2}(X_e(\mathbf{x}, t_{n+1}; s), s) \, ds, \quad a.e.\ \mathbf{x} \in \Omega, \quad n = 0, \ldots, N-1.$$

Proof. For the function $G(\tau) := \varphi(X_e(\mathbf{x}, t_{n+1}; \tau), \tau)$, $\tau \in (0, T)$, we have

$$G(\tau) = G(t_{n+\frac{1}{2}}) + (\tau - t_{n+\frac{1}{2}}) G'(t_{n+\frac{1}{2}}) + \int_{t_{n+\frac{1}{2}}}^{\tau} (\tau - s) G''(s) ds.$$

Thus, the result follows by taking successively $\tau = t_n$ and $\tau = t_{n+1}$ and adding both expressions. ∎

LEMMA 5.12. *Let us assume that* $\mathbf{v} \in C^1(W^{1,\infty}(\Omega)) \cap C^0(W^{2,\infty}(\Omega))$ *and vanishes on the boundary. Let* $\mathbf{w} : \Omega \times [0, T] \longrightarrow \mathbb{R}^m$, $\mathbf{w} \in Z^2$, *be a given function, and let* $\vartheta^{n+\frac{1}{2}} : \Omega \longrightarrow \mathbb{R}^m$ *be defined by*

$$\vartheta^{n+\frac{1}{2}}(\mathbf{x}) := \mathbf{F}_e^{-1}(\mathbf{x}, t_{n+1}; t_{n+\frac{1}{2}}) \mathbf{w}(X_e^{n+\frac{1}{2}}(\mathbf{x}), t_{n+\frac{1}{2}})$$
$$- \frac{\mathbf{w}(\mathbf{x}, t_{n+1}) + (\mathbf{F}_e^n)^{-1}(\mathbf{x}) \mathbf{w}(X_e^n(\mathbf{x}), t_n)}{2}.$$

Then $\vartheta^{n+\frac{1}{2}} \in L^2(\Omega)$ *and* $\|\vartheta^{n+\frac{1}{2}}\|_0 \leq \widetilde{c_1}\Delta t^2 \|\mathbf{w}\|_{Z^2}$, $n = 0, \ldots, N-1$. *Moreover, if* $\mathbf{v} \in C^1(W^{2,\infty}(\Omega)) \cap C^0(W^{3,\infty}(\Omega))$ *and* $\mathbf{w} \in C^i(H^{3-i}(\Omega))$, $i = 0, 1, 2$, *then* $\vartheta^{n+\frac{1}{2}} \in H^1(\Omega)$ *and* $\|\text{div } \vartheta^{n+\frac{1}{2}}\|_0 \leq \widetilde{c_1}\ \Delta t^2\ \|\text{div } \mathbf{w}\|_{Z^2}$, $n = 0, \ldots, N-1$.

Proof. The proof follows from applying the Taylor expansion to the auxiliary vector function $G(\tau) := \mathbf{F}_e^{-1}(\mathbf{x}, t_{n+1}; \tau)\mathbf{w}(X_e(\mathbf{x}, t_{n+1}; \tau), \tau)$. ∎

LEMMA 5.13. *Let us assume that* $\mathbf{v} \in C^1(W^{2,\infty}(\Omega)) \cap C^0(W^{3,\infty}(\Omega))$ *and vanishes on the boundary. Let* $\mathbf{w} : \Omega \times [0, T] \longrightarrow \mathbb{R}^m$, $\mathbf{w} \in Z^2$, *be a given function, and let* $\xi^{n+\frac{1}{2}} : \Omega \longrightarrow \mathbb{R}^m$ *be defined by*

$$\xi^{n+\frac{1}{2}}(\mathbf{x}) := \text{div } \mathbf{F}_e^{-\mathrm{T}}(\mathbf{x}, t_{n+1}; t_{n+\frac{1}{2}}) \cdot \mathbf{w}(X_e^{n+\frac{1}{2}}(\mathbf{x}), t_{n+\frac{1}{2}}) - \frac{\text{div } (\mathbf{F}_e^n)^{-\mathrm{T}}(\mathbf{x})\mathbf{w}(X_e^n(\mathbf{x}), t_n)}{2}.$$

Then $\xi^{n+\frac{1}{2}} \in L^2(\Omega)$ *and* $\|\xi^{n+\frac{1}{2}}\|_0 \leq \widetilde{c_1}\Delta t^2 \|\mathbf{w}\|_{Z^2}$, $n = 0, \ldots, N-1$.

Proof. The proof follows from applying the Taylor formula to the auxiliary scalar function $G(\tau) := \text{div } \mathbf{F}_e^{-\mathrm{T}}(\mathbf{x}, t_{n+1}; \tau) \cdot \mathbf{w}(X_e(\mathbf{x}, t_{n+1}; \tau), \tau)$. ∎

LEMMA 5.14. *Assume that* $\mathbf{v} \in C^1(L^\infty(\Omega)) \cap C^0(W^{1,\infty}(\Omega))$ *vanishes on the boundary and* $\Delta t\|\mathbf{v}\|_{C^0(W^{1,\infty}(\Omega))} < 1$. *Let* $\varphi \in H^1(\Omega)$ *and let* ξ^n *be defined by*

$$\xi^n(\mathbf{x}) := \varphi(X_e^n(\mathbf{x})) - \varphi(X_E^n(\mathbf{x})) \quad \textit{for a.e. } \mathbf{x} \in \Omega, \quad n = 0, \ldots, N-1.$$

Then $\xi^n \in L^2(\Omega)$ *and*

$$\xi^n(\mathbf{x}) = \nabla\ \varphi(X_E^n(\mathbf{x}) + \theta\ \mathbf{y}) \cdot \mathbf{y} \quad \textit{for a.e. } \mathbf{x} \in \Omega, \tag{5.42}$$

with $\theta \in (0, 1)$, *and*

$$\mathbf{y} = \int_{t_n}^{t_{n+1}} (s - t_n)\ \frac{\mathsf{d}\mathbf{v}}{\mathsf{d}t}(X_e(\mathbf{x}, t_{n+1}; s), s)\ ds. \tag{5.43}$$

Moreover, if $\mathbf{v} \in C^1(W^{1,\infty}(\Omega)) \cap C^0(W^{2,\infty}(\Omega))$ *and* $\varphi \in H^2(\Omega)$, *then* $\xi^{n+\frac{1}{2}} \in H^1(\Omega)$.

Proof. We use the following first order Taylor expansion of function $\varphi \in H^1(\Omega)$:

$$\varphi(X_e^n(\mathbf{x}), t_n) = \varphi(X_E^n(\mathbf{x}), t_n) + \nabla\ \varphi\,(X_E^n(\mathbf{x}) + \theta(X_e^n(\mathbf{x}) - X_E^n(\mathbf{x}))) \cdot (X_e^n(\mathbf{x}) - X_E^n(\mathbf{x}))$$

for some number $\theta \in (0, 1)$. Next, by applying again a Taylor expansion to function $X_e(\mathbf{x}, t_{n+1}; \tau)$ it follows that

$$X_e^n(\mathbf{x}) - X_E^n(\mathbf{x}) = \int_{t_{n+1}}^{t_n} (t_n - s)\ \frac{\mathsf{d}\mathbf{v}}{\mathsf{d}t}(X_e(\mathbf{x}, t_{n+1}; s), s)\ ds.$$

By jointly considering both Taylor expansions, (5.42) and (5.43) follow, and the regularity of ξ^n is a consequence of the regularity of φ and $\mathbf{v}$. ∎

COROLLARY 5.15. *Let us assume that* $\mathbf{v} \in C^1(L^\infty(\Omega)) \cap C^0(W^{1,\infty}(\Omega))$ *and vanishes on the boundary, and* $\Delta t\|\mathbf{v}\|_{C^0(W^{1,\infty}(\Omega))} < 1$. *Let* $\varphi : \Omega \times [0, T] \longrightarrow \mathbb{R}$, $\varphi \in Z^2$, *be a given function. Let* $\xi^{n+\frac{1}{2}}$ *be the function defined by*

$$\xi^{n+\frac{1}{2}}(\mathbf{x}) := \varphi(X_e^{n+\frac{1}{2}}(\mathbf{x}), t_{n+\frac{1}{2}}) - \frac{\varphi(\mathbf{x}, t_{n+1}) + \varphi(X_E^n(\mathbf{x}), t_n)}{2} \quad \forall \mathbf{x} \in \Omega.$$

Then $\xi^{n+\frac{1}{2}} \in L^2(\Omega)$ *and* $\|\xi^{n+\frac{1}{2}}\|_0 \leq \widetilde{c_1}\ \Delta t^2\ \|\varphi\|_{Z^2}$, $n = 0, \ldots, N-1$, *where* $\widetilde{c_1}$ *is independent of* Δt.

Proof. The proof directly follows from applying Lemmas 5.11 and 5.14. ∎

LEMMA 5.16. *Let us assume that* $\mathbf{v} \in C^1(W^{1,\infty}(\Omega)) \cap C^0(W^{2,\infty}(\Omega))$ *and vanishes on the boundary. Let* Ψ^n *be defined by*

$$\Psi^n(\mathbf{x}) := (\mathbf{F}_e^n)^{-1}(X_e^n(\mathbf{x})) - (\mathbf{I} + \Delta t\ \mathbf{L}^n)(X_e^n(\mathbf{x})) \quad \forall \mathbf{x} \in \Omega.$$

Then $\Psi^n \in L^2(\Omega)$ *for* $n = 0, \ldots, N-1$ *and*

(5.44)
$$\Psi^n(\mathbf{x}) = -\int_{t_n}^{t_{n+1}} (\tau - t_{n+1})\ \nabla\ \frac{\mathsf{d}\mathbf{v}}{\mathsf{d}t}(X_e(\mathbf{x}, t_{n+1}; \tau), \tau)\mathbf{F}_e(X_e^n(\mathbf{x}), t_n; \tau)\ d\tau \text{ for a.e. } \mathbf{x} \in \Omega.$$

Moreover, if $\mathbf{v} \in C^1(W^{2,\infty}(\Omega)) \cap C^0(W^{3,\infty}(\Omega))$, *then* $\Psi^n \in H^1(\Omega)$.

Proof. The result directly follows from replacing $t = t_{n+1}$ and $s = t_n$ in (3.7). ∎

LEMMA 5.17. *Let us assume that* $\mathbf{v} \in C^1(W^{2,\infty}(\Omega)) \cap C^0(W^{3,\infty}(\Omega))$ *and vanishes on the boundary. Let* ϑ^n *be defined by*

$$\vartheta^n(\mathbf{x}) := \text{div}\ (\mathbf{F}_e^n)^{-\mathrm{T}}(X_e^n(\mathbf{x})) - \Delta t \nabla \text{div}\ \mathbf{v}^n(X_e^n(\mathbf{x})) \quad \forall \mathbf{x} \in \Omega.$$

Then $\vartheta^n \in L^2(\Omega)$ *for* $n = 0, \ldots, N-1$ *and*

$$\vartheta^n(\mathbf{x}) = -\int_{t_n}^{t_{n+1}} (\tau - t_{n+1})\ \text{div}\ \left((\mathbf{F}_e)^{\mathrm{T}} \left(\nabla\ \frac{\mathsf{d}\mathbf{v}}{\mathsf{d}t} \right)^{\mathrm{T}} \right) (X_e(\mathbf{x}, t_{n+1}; \tau)\ d\tau \text{ for a.e. } \mathbf{x} \in \Omega.$$

Proof. The assumed regularity for $\mathbf{v}$ allows us to apply Lemma 5.16 and to define $\Psi^n \in H^1(\Omega)$ by (5.44). The result directly follows from applying the div operator to Ψ^n and by taking into account that $\text{div}\left(\mathbf{I} + \Delta t\ (\mathbf{L}^n)^{\mathrm{T}}\right)(\mathbf{y}) = \Delta t \nabla \text{div}\ \mathbf{v}^n(\mathbf{y})$. ∎

Whereas the previous lemmas concern the approximation of functions defined on the whole domain Ω, the one below gives a second order approximation of a function defined on the boundary Γ_R.

LEMMA 5.18. *Let* $\mathbf{v} \in C^0(W^{2,\infty}(\Omega)) \cap C^1(W^{1,\infty}(\Omega))$ *and vanish on the boundary. Let* $\varphi : \Gamma_R \times [0,T] \longrightarrow \mathbb{R}$, $\varphi \in C^2(L^2(\Gamma_R))$, *and let* $\xi^{n+\frac{1}{2}}$ *be a function defined on the boundary* Γ_R *by*

$$\xi^{n+\frac{1}{2}}(\mathbf{x}) := \mathsf{det}\ \left(\mathbf{F}_e^{n+\frac{1}{2}}\right)^{-1}(\mathbf{x})\ \varphi(\mathbf{x}, t_{n+\frac{1}{2}}) - \frac{\varphi(\mathbf{x}, t_{n+1}) + \left(1 + \Delta t\ \text{div}\ \mathbf{v}^{n+1}(\mathbf{x})\right)\varphi(\mathbf{x}, t_n)}{2}$$

for a.e. $\mathbf{x} \in \Gamma_R$. *Then* $\xi^{n+\frac{1}{2}} \in L^2(\Gamma_R)$ *and* $\|\xi^{n+\frac{1}{2}}\|_{0,\Gamma_R} \leq \widetilde{c_1} \Delta t^2 \|\varphi\|_{C^2(L^2(\Gamma_R))}$, $n = 0, \ldots, N-1$, *where* $\widetilde{c_1}$ *is independent of* Δt.

Proof. Let us first write $\xi^{n+\frac{1}{2}}(\mathbf{x}) = \xi_1^{n+\frac{1}{2}}(\mathbf{x}) - \xi_2^n(\mathbf{x})$ with

$$\xi_1^{n+\frac{1}{2}}(\mathbf{x}) := \mathsf{det}\ \left(\mathbf{F}_e^{n+\frac{1}{2}}\right)^{-1}(\mathbf{x})\varphi(\mathbf{x}, t_{n+\frac{1}{2}}) - \frac{\varphi(\mathbf{x}, t_{n+1}) + \mathsf{det}\ (\mathbf{F}_e^n)^{-1}(\mathbf{x})\varphi(\mathbf{x}, t_n)}{2},$$
$$\xi_2^n(\mathbf{x}) := \frac{\mathsf{det}\ (\mathbf{F}_e^n)^{-1}(\mathbf{x})\varphi(\mathbf{x}, t_n) - \left(1 + \Delta t\ \text{div}\ \mathbf{v}^{n+1}(\mathbf{x})\right)\varphi(\mathbf{x}, t_n)}{2}.$$

The proof is achieved by means of Taylor expansions, expressions (3.8) and (3.9) for $t = t_{n+1}$, and Proposition 3.5 for $t = t_{n+1}$ and $s = t_n$. ∎

LEMMA 5.19. *Assume Hypotheses* 3, 4, *and* 5 *hold, and that the coefficients of the problem satisfy* $\mathbf{v} \in C^0(W^{3,\infty}(\Omega)) \cap C^1(W^{2,\infty}(\Omega)) \cap C^2(L^\infty(\Omega))$, $\mathbf{v}|_\Gamma = 0$, $\mathbf{A} \in W^{3,\infty}(\Omega)$, $r \in W^{2,\infty}(\Omega)$, *and that* $\Delta t \|\mathbf{v}\|_{C^0(W^{1,\infty})} < 1/2$. *Let the solution of* (5.41)

satisfy $\phi \in Z^3$, $\nabla\phi \in Z^3$, $\phi|_{\Gamma_R} \in C^2(L^2(\Gamma_R))$. *Then, for each* $n = 0, 1, \ldots, N-1$, *there exist two functions* $\xi_{\mathcal{L}_1}^{n+\frac{1}{2}} : \Omega \longrightarrow \mathbb{R}$ *and* $\xi_{\mathcal{L}_2}^{n+\frac{1}{2}} : \Gamma_R \longrightarrow \mathbb{R}$, *such that*

$$\left\langle \left(\mathcal{L}^{n+\frac{1}{2}} - \mathcal{L}_{\Delta t}^{n+\frac{1}{2}} \right) \widehat{\phi}, \psi \right\rangle = \left\langle \xi_{\mathcal{L}_1}^{n+\frac{1}{2}}, \psi \right\rangle + \left\langle \xi_{\mathcal{L}_2}^{n+\frac{1}{2}}, \psi \right\rangle_{\Gamma_R} \tag{5.45}$$

$\forall \psi \in H^1_{\Gamma_D}(\Omega)$. *Moreover,* $\xi_{\mathcal{L}_1}^{n+\frac{1}{2}} \in L^2(\Omega)$ *and* $\xi_{\mathcal{L}_2}^{n+\frac{1}{2}} \in L^2(\Gamma_R)$ *and the following estimates hold:*

$$\left\| \xi_{\mathcal{L}_1}^{n+\frac{1}{2}} \right\|_0 \leq \widetilde{c_1} \Delta t^2 \left(\|\phi\|_{Z^3} + \|\mathbf{A}\nabla\phi\|_{Z^3} + \|r\phi\|_{Z^2} \right),$$
$$\left\| \xi_{\mathcal{L}_2}^{n+\frac{1}{2}} \right\|_{0,\Gamma_R} \leq \widetilde{c_1} \Delta t^2 \left(\|\mathbf{A}\nabla\phi \cdot \mathbf{n}\|_{Z^2,\Gamma_R} + \alpha \|\phi\|_{C^2(L^2(\Gamma_R))} \right),$$

where $\widetilde{c_1}$ *denotes a constant independent of* Δt *and* $\alpha > 0$ *appears in* (2.3).

Proof. The left-hand side of (5.45) is equal to $I_1 + I_2 + I_3 + I_4 + I_5$, with

$$I_1 = \left\langle \left(\frac{\mathsf{d}\phi}{\mathsf{d}t} \right)^{n+\frac{1}{2}} \circ X_e^{n+\frac{1}{2}}, \psi \right\rangle - \left\langle \frac{\phi^{n+1} - \phi^n \circ X_{RK}^n}{\Delta t}, \psi \right\rangle,$$
$$I_2 = \left\langle \left(\mathbf{F}_e^{n+\frac{1}{2}} \right)^{-1} \left(\mathbf{A} \nabla \phi^{n+\frac{1}{2}} \right) \circ X_e^{n+\frac{1}{2}}, \nabla\psi \right\rangle$$
$$- \left\langle \frac{\mathbf{A}\nabla\phi^{n+1} + ((\mathbf{I} + \Delta t\, \mathbf{L}^n)\mathbf{A}\nabla\phi^n) \circ X_E^n}{2}, \nabla\psi \right\rangle,$$
$$I_3 = \left\langle \mathrm{div} \left(\mathbf{F}_e^{n+\frac{1}{2}} \right)^{-\mathrm{T}} \cdot \left(\mathbf{A}\nabla\phi^{n+\frac{1}{2}} \right) \circ X_e^{n+\frac{1}{2}}, \psi \right\rangle - \left\langle \frac{\Delta t \left(\nabla \mathrm{div}\ \mathbf{v}^n \cdot \mathbf{A}\nabla\phi^n \right) \circ X_E^n}{2}, \psi \right\rangle,$$
$$I_4 = \left\langle (r\phi^{n+\frac{1}{2}}) \circ X_e^{n+\frac{1}{2}}, \psi \right\rangle - \left\langle \frac{r\phi^{n+1} + (r\phi^n) \circ X_E^n}{2}, \psi \right\rangle,$$
$$I_5 = \alpha \left\langle \mathsf{det} \left(\mathbf{F}_e^{n+\frac{1}{2}} \right)^{-1} \phi^{n+\frac{1}{2}}, \psi \right\rangle_{\Gamma_R} - \alpha \left\langle \frac{\phi^{n+1} + \phi^n (1 + \Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})}{2}, \psi \right\rangle_{\Gamma_R}.$$

The bound for I_1 directly follows from Lemma 5.10 for $\varphi = \phi$, so we can define a function $\xi_{I_1}^{n+\frac{1}{2}} \in L^2(\Omega)$ such that

$$I_1 = \left\langle \xi_{I_1}^{n+\frac{1}{2}}, \psi \right\rangle \quad \text{with} \quad \|\xi_{I_1}^{n+\frac{1}{2}}\|_0 \leq \widetilde{c_1} \Delta t^2 \|\phi\|_{Z^3}. \tag{5.46}$$

Term I_2 is written as $I_2 = I_2^1 + I_2^2 + I_2^3$, where

$$I_2^1 = \left\langle \left(\mathbf{F}_e^{n+\frac{1}{2}} \right)^{-1} \left(\mathbf{A} \nabla \phi^{n+\frac{1}{2}} \right) \circ X_e^{n+\frac{1}{2}} - \frac{\mathbf{A}\nabla\phi^{n+1} + (\mathbf{F}_e^n)^{-1} (\mathbf{A}\nabla\phi^n) \circ X_e^n}{2}, \nabla\ \psi \right\rangle,$$
$$I_2^2 = \left\langle \frac{(\mathbf{F}_e^n)^{-1} (\mathbf{A}\nabla\phi^n) \circ X_e^n - ((\mathbf{I} + \Delta t\, \mathbf{L}^n)\mathbf{A}\nabla\phi^n) \circ X_e^n}{2}, \nabla\psi \right\rangle,$$
$$I_2^3 = \left\langle \frac{((\mathbf{I} + \Delta t\, \mathbf{L}^n)\mathbf{A}\nabla\phi^n) \circ X_e^n - ((\mathbf{I} + \Delta t\, \mathbf{L}^n)\mathbf{A}\nabla\phi^n) \circ X_E^n}{2}, \nabla\psi \right\rangle.$$

In order to estimate I_2^1 we apply Lemma 5.12 to $\mathbf{w} = \mathbf{A} \nabla \phi \in C^i(H^{3-i}(\Omega))$ for $i = 0, 1, 2$, so a vector valued function $\vartheta_{I_2^1}^{n+\frac{1}{2}} \in H^1(\Omega)$ can be defined and Green's formula can be applied. Thus, we have

$$I_2^1 = \left\langle \vartheta_{I_2^1}^{n+\frac{1}{2}}, \nabla\ \psi \right\rangle = \left\langle \vartheta_{I_2^1}^{n+\frac{1}{2}} \cdot \mathbf{n}, \psi \right\rangle_{\Gamma_R} - \left\langle \mathrm{div}\ \vartheta_{I_2^1}^{n+\frac{1}{2}}, \psi \right\rangle,$$

where the involved functions are bounded as follows:

(5.47)
$$\left\|\vartheta_{I_2^1}^{n+\frac{1}{2}}\cdot\mathbf{n}\right\|_{0,\Gamma_R}\leq\widetilde{c_1}\Delta t^2\|\mathbf{A}\nabla\phi\cdot\mathbf{n}\|_{Z^2,\Gamma_R},\qquad\left\|\text{div }\vartheta_{I_2^1}^{n+\frac{1}{2}}\right\|_0\leq\widetilde{c_1}\Delta t^2\left\|\text{div }\mathbf{A}\ \nabla\ \phi\right\|_{Z^2}.$$

For I_2^2 we apply Lemma 5.16 for $\mathbf{v}\in C^1(W^{2,\infty}(\Omega))\cap C^0(W^{3,\infty}(\Omega))$, finding a matrix valued function $\Psi_{I_2^2}^n\in H^1(\Omega)$ satisfying

$$\begin{aligned}I_2^2&=\left\langle\Psi_{I_2^2}^n\left(\mathbf{A}\nabla\phi\right)\circ X_e^n,\nabla\ \psi\right\rangle\\&=\left\langle\Psi_{I_2^2}^n\left(\mathbf{A}\nabla\phi\right)\circ X_e^n\cdot\mathbf{n},\ \psi\right\rangle_{\Gamma_R}-\left\langle\text{div}\left(\Psi_{I_2^2}^n\left(\mathbf{A}\nabla\phi\right)\circ X_e^n\right),\ \psi\right\rangle,\end{aligned}$$

where the Green formula has been used for the last equality and with functions on the left-hand side of the inner products bounded as in (5.47). For I_2^3 we apply Lemma 5.14 componentwise to $\varphi^n(\mathbf{x})=[(\mathbf{I}+\Delta t\ \mathbf{L}^n(\mathbf{x}))\mathbf{A}(\mathbf{x})\nabla\phi(\mathbf{x})]_i\in H^2(\Omega)$, and we find a function $\vartheta_{I_2^3}^n\in H^1(\Omega)$, to which we can apply Green's formula obtaining bounds analogous to (5.47). Summing up, we can write I_2 as

$$I_2=\left\langle\xi_{I_2^A}^{n+\frac{1}{2}},\psi\right\rangle+\left\langle\xi_{I_2^B}^{n+\frac{1}{2}},\psi\right\rangle_{\Gamma_R},\tag{5.48}$$

where $\|\xi_{I_2^A}^{n+\frac{1}{2}}\|_0\leq\widetilde{c_1}\Delta t^2\ \|\mathbf{A}\ \nabla\ \phi\|_{Z^3}$ and $\|\xi_{I_2^B}^{n+\frac{1}{2}}\|_{0,\Gamma_R}\leq\widetilde{c_1}\Delta t^2\ \|\mathbf{A}\nabla\phi\cdot\mathbf{n}\|_{Z^2,\Gamma_R}$.

Similar computations with I_3, by using Lemmas 5.13, 5.17, and 5.14, lead to

$$I_3=\left\langle\xi_{I_3}^{n+\frac{1}{2}},\psi\right\rangle,\quad\text{with}\quad\left\|\xi_{I_3}^{n+\frac{1}{2}}\right\|_0\leq\widetilde{c_1}\Delta t^2\ \|\mathbf{A}\nabla\phi\|_{Z^2}.\tag{5.49}$$

For $\xi=r\phi\in Z^2$ we can apply Corollary 5.15 to I_4, obtaining

$$I_4=\left\langle\xi_{I_4}^{n+\frac{1}{2}},\psi\right\rangle,\quad\text{with}\quad\left\|\xi_{I_4}^{n+\frac{1}{2}}\right\|_0\leq\widetilde{c_1}\Delta t^2\ \|r\phi\|_{Z^2}.\tag{5.50}$$

The estimate for I_5 follows from Lemma 5.18 for $\xi=\alpha\phi|_{\Gamma_R}\in C^2(L^2(\Gamma_R))$:

$$I_5=\left\langle\xi_{I_5}^{n+\frac{1}{2}},\psi\right\rangle_{\Gamma_R},\quad\text{with}\quad\left\|\xi_{I_5}^{n+\frac{1}{2}}\right\|_{0,\Gamma_R}\leq\widetilde{c_1}\Delta t^2\|\phi\|_{C^2(L^2(\Gamma_R))}.\tag{5.51}$$

Finally, partial results (5.46), (5.48), (5.49), (5.50), and (5.51) imply (5.45). ∎

LEMMA 5.20. *Assume that* $\mathbf{v}\in C^0(W^{2,\infty}(\Omega))\cap C^1(W^{1,\infty}(\Omega))$ *vanishes on the boundary and* $\Delta t\|\mathbf{v}\|_{C^0(W^{1,\infty})}<1/2$. *Let* $f\in Z^2$ *and* $g\in C^2(L^2(\Gamma_R))$. *Then, for each* $n=0,1,\ldots,N-1$, *there exist* $\xi_f^{n+\frac{1}{2}}:\Omega\longrightarrow\mathbb{R}$ *and* $\xi_g^{n+\frac{1}{2}}:\Gamma_R\longrightarrow\mathbb{R}$, *satisfying*

$$\left\langle\mathcal{F}^{n+\frac{1}{2}}-\mathcal{F}_{\Delta t}^{n+\frac{1}{2}},\psi\right\rangle=\left\langle\xi_f^{n+\frac{1}{2}},\psi\right\rangle+\left\langle\xi_g^{n+\frac{1}{2}},\psi\right\rangle_{\Gamma_R}\quad\forall\psi\in H^1(\Omega).\tag{5.52}$$

Moreover, $\xi_f\in L^2(\Omega)$, $\xi_g\in L^2(\Gamma_R)$, *and the following estimates hold:*

$$\left\|\xi_f^{n+\frac{1}{2}}\right\|_0\leq\widetilde{c_1}\Delta t^2\left\|f\right\|_{Z^2},\qquad\left\|\xi_g^{n+\frac{1}{2}}(\mathbf{x})\right\|_{0,\Gamma_R}\leq\widetilde{c_1}\Delta t^2\left\|g\right\|_{C^2(L^2(\Gamma_R))},$$

with constant $\widetilde{c_1}$ *independent of* Δt.

Proof. The proof follows from Corollary 5.15 and Lemma 5.18. ∎

Lemmas in this section hold under Hypotheses 3, 4, 5 and the following one.

Hypothesis 8. Functions appearing in problem (2.1)–(2.4) satisfy

- $\mathbf{A} \in W^{3,\infty}(\Omega)$, $r \in W^{2,\infty}(\Omega)$;
- $\mathbf{v} \in C^0(W^{3,\infty}(\Omega)) \cap C^1(W^{2,\infty}(\Omega)) \cap C^2(L^\infty(\Omega))$ and $\mathbf{v}|_\Gamma = 0$;
- $f \in Z^2$, $g \in Z^3(\Gamma_R)$, and $\alpha > 0$.

Remark 5.7. Although in Lemma 5.15 only $g \in C^2(L^2(\Gamma_R))$ was required, more smoothness will be necessary in the following theorem.

THEOREM 5.21 (error estimate). *Assume Hypotheses* 3, 4, 5, *and* 8. *Let* $\phi \in Z^3$ *be the solution of* (5.41), $\nabla\phi \in Z^3$, $\phi|_{\Gamma_R} \in Z^3(\Gamma_R)$. *Let* $\phi_{\Delta t} = \{\phi^n_{\Delta t}\}$ *be the solution of* (5.13) *subject to initial value* $\phi^0_{\Delta t} = \phi^0$ *and* $\mathbf{B}\nabla\widehat{\phi_{\Delta t}} = \{\mathbf{B}\nabla\phi^n_{\Delta t}\}$. *Then there exist two positive constants* c *and* $d = d(c_1, c_2, \delta, c_3, \gamma)$ *such that if* $\Delta t < d$, *we have*

$$
\begin{aligned}
(5.53)\qquad & \sqrt{\frac{1}{2}}\left\|\widehat{\phi} - \widehat{\phi_{\Delta t}}\right\|_{l^\infty(L^2(\Omega))} + \sqrt{\frac{\Delta t\ \delta}{4}}\left\|\mathbf{B}\nabla\widehat{\phi} - \mathbf{B}\nabla\widehat{\phi_{\Delta t}}\right\|_{l^\infty(L^2(\Omega))} \\
& + \sqrt{\frac{\Delta t}{4}}\left\|\sqrt{r}\,\widehat{\phi} - \sqrt{r}\,\widehat{\phi_{\Delta t}}\right\|_{l^\infty(L^2(\Omega))} + \sqrt{\frac{\Delta t\ \alpha}{16}}\left\|\widehat{\phi} - \widehat{\phi_{\Delta t}}\right\|_{l^\infty(L^2(\Gamma_R))} \\
& \le c\ \Delta t^2\ \left(\|\phi\|_{Z^3} + \|\mathbf{A}\nabla\phi\|_{Z^3} + \|r\phi\|_{Z^2} + \|\phi\|_{Z^2,\Gamma_R} + \|f\|_{Z^2} + \|g\|_{Z^2,\Gamma_R}\right) \\
& \quad + c\ \Delta t^3\left(\|\phi\|_{Z^3,\Gamma_R} + \|g\|_{Z^3,\Gamma_R}\right).
\end{aligned}
$$

Proof. Let us denote by $e_{\Delta t}$ the difference between the continuous and the discrete solutions, i.e., $e_{\Delta t} = \{e^n_{\Delta t}\}$, with $e^n_{\Delta t} = \phi^n - \phi^n_{\Delta t}$. From (5.41) and (5.13) we have

$$
\left\langle \mathcal{L}^{n+\frac{1}{2}}_{\Delta t}\widehat{e_{\Delta t}}, \psi\right\rangle = \left\langle \left(\mathcal{L}^{n+\frac{1}{2}}_{\Delta t} - \mathcal{L}^{n+\frac{1}{2}}\right)\widehat{\phi}, \psi\right\rangle + \left\langle \mathcal{F}^{n+\frac{1}{2}} - \mathcal{F}^{n+\frac{1}{2}}_{\Delta t}, \psi\right\rangle,
$$

and, as a consequence of Lemmas 5.19 and 5.20, we are led to the following scheme:

$$
(5.54)\quad \left\langle \mathcal{L}^{n+\frac{1}{2}}_{\Delta t}\widehat{e_{\Delta t}}, \psi\right\rangle = \left\langle \xi^{n+\frac{1}{2}}_{\mathcal{L}_1} - \xi^{n+\frac{1}{2}}_{f}, \psi\right\rangle + \left\langle \xi^{n+\frac{1}{2}}_{\mathcal{L}_2} - \xi^{n+\frac{1}{2}}_{g}, \psi\right\rangle_{\Gamma_R} \quad \forall \psi \in H^1_{\Gamma_D}(\Omega).
$$

Next, we apply Theorem 5.8 to (5.54), noting that $e^0_{\Delta t} = 0$. Thus, we obtain

$$
\begin{aligned}
(5.55)\quad & \frac{1}{\sqrt{2}}\|\widehat{e_{\Delta t}}\|_{l^\infty(L^2(\Omega))} + \sqrt{\frac{\delta\ \Delta t}{4}}\|\mathbf{B}\nabla\widehat{e_{\Delta t}}\|_{l^\infty(L^2(\Omega))} + \sqrt{\frac{\Delta t}{4}}\left\|\sqrt{r}\widehat{e_{\Delta t}}\right\|_{l^\infty(L^2(\Omega))} \\
& + \sqrt{\frac{\alpha\ \Delta t}{16}}\|\widehat{e_{\Delta t}}\|_{l^\infty(L^2(\Gamma_R))} \le c\ \Delta t\left(\left\|\widehat{D_{\Delta t}\xi_{\mathcal{L}_2}}\right\|_{l^2(L^2(\Gamma_R))} + \left\|\widehat{D_{\Delta t}\xi_g}\right\|_{l^2(L^2(\Gamma_R))}\right) \\
& \quad + c\left(\left\|\widehat{\xi_{\mathcal{L}_1}}\right\|_{l^2(L^2(\Omega))} + \left\|\widehat{\xi_f}\right\|_{l^2(L^2(\Omega))} + \left\|\widehat{\xi_{\mathcal{L}_2}}\right\|_{l^2(L^2(\Gamma_R))} + \left\|\widehat{\xi_g}\right\|_{l^2(L^2(\Gamma_R))}\right).
\end{aligned}
$$

Thus, error estimate (5.53) follows from the upper bounds for $\xi_{\mathcal{L}_1}$, ξ_f, $\xi_{\mathcal{L}_2}$, and ξ_g given in Lemmas 5.19 and 5.20 and replacing the Robin boundary condition (5.41). ∎

6. Conclusions. We have performed the numerical analysis of second order characteristic semidiscretized schemes for solving linear convection-diffusion-reaction equations, extending the work in [24]. More precisely, we allow for degenerate diffusion coefficients, reaction terms, non-divergence-free velocity fields, and general Dirichlet–Robin boundary conditions. The method has been introduced by using the formalism of continuum mechanics, and weak formulations by means of an appropriate Green's formula are obtained. Although our analysis considers only velocity fields which are null at the boundary and use approximate characteristic lines, we could also deal with more general situations. Second order error estimates have been obtained when smooth enough data and solutions are available.

This paper is completed in [9], where the fully discretized Lagrange–Galerkin scheme is theoretically studied. Moreover, the effect of different proposed quadrature formulas and some numerical examples illustrating the predicted behavior are shown.

NUMERICAL ANALYSIS OF CONVECTION-DIFFUSION-REACTION PROBLEMS WITH HIGHER ORDER CHARACTERISTICS/FINITE ELEMENTS. PART II: FULLY DISCRETIZED SCHEME AND QUADRATURE FORMULAS*

ALFREDO BERMÚDEZ†, MARIA R. NOGUEIRAS†, AND CARLOS VÁZQUEZ‡

Abstract. In this paper a higher order Lagrange–Galerkin discretization method is analyzed when applied to a variable coefficient convection-(possibly degenerated) diffusion-reaction equation with mixed Dirichlet–Robin boundary conditions. In a previous paper [A. Bermúdez, M. R. Nogueiras, and C. Vázquez, *SIAM J. Numer. Anal.*, to appear], the proposed second order time discretization scheme has been rigorously introduced for exact and approximated characteristics. Moreover, the $l^\infty(L^2)$ stability property and $l^\infty(L^2)$ error estimates of order $O(\Delta t^2)$ have been obtained. As a continuation of that work, consistency error estimates of order $O(\Delta t^2 + h^k)$ are obtained for the fully discretized Lagrange–Galerkin scheme. Moreover, adequate quadrature formulas are proposed for the practical implementation of the method with particular finite element spaces. Finally, some numerical tests illustrate the theoretical results and the performance of the combination of second order Lagrange–Galerkin schemes with quadrature formulas.

Key words. convection-diffusion equation, Lagrange–Galerkin methods, stability, error estimates, second order schemes, quadrature formulas

1. Introduction.

In the framework of numerical solution of convection dominated problems (including the degenerate diffusion case arising, for example,in finance [20]) a possible upwinding strategy is provided by the method of characteristics for time discretization (see [11]). This approach is based on the discretization of the total (or material) time derivative. Many authors have mathematically analyzed and applied the characteristics method to different problems [9, 15, 5, 4, 13, 19, 2, 1, 3].

The increase in the order of time and space approximations can be obtained by using higher order schemes for the discretization of the material derivative and higher order finite element spaces. In [10] multistep Galerkin methods for constant coefficients convection-diffusion problems are studied and the need for analyzing the variable coefficient case is pointed out. In [7, 8] multistep methods to approximate the material time derivative, combined with either mixed finite elements or spectral methods for spatial discretization, are analyzed to solve incompressible Navier–Stokes equations. More recently, in [18], a second order Runge–Kutta method is proposed to approximate the material time derivative when solving a constant coefficient

convection-diffusion equation with Dirichlet boundary conditions. Second order in time is achieved by the Crank–Nicholson scheme and an adequate upwinding of the diffusive term.

Our contribution, in both [6] and the present paper, is to extend [18] in several aspects: first, we deal with a (possibly degenerate) variable coefficient diffusive term instead of the more classical Laplacian one. Second, nonzero reaction functions are allowed. Third, a general mixed Dirichlet–Robin boundary condition is considered. Fourth, nondivergence-free velocity fields are handled. Fifth, a complete analysis of the influence of quadrature formulas for different finite element spaces is developed.

In [6] the mathematical formalism of continuum mechanics (see [12]) and Taylor expansions are used to express the results and notations related not only to the approximate characteristics proposed in [18] but also to the exact ones, and an appropriate variational formulation of the problem is obtained. Then, second order characteristics time discretization schemes are introduced. Moreover, the $l^\infty(L^2)$ stability property is stated and $l^\infty(L^2)$ error estimates of order $O(\Delta t^2)$ are obtained.

As a logical continuation of [6], the fully discretized Lagrange–Galerkin scheme with a wide class of finite element spaces is analyzed in the present paper, where the results in [18] are again extended to a more general partial differential equation (PDE) problem. Moreover, adequate quadrature formulas are proposed for the practical implementation with Lagrange finite elements on triangular and quadrangular meshes. Notice that in [18], for piecewise linear Lagrange finite elements, just low order formulas on each element obtained by dividing each mesh triangle were performed. In the present paper, the stability of some of the proposed quadrature formulas is rigorously studied by using Fourier analysis. In this aspect, previous studies about the influence of quadratures in the case of the classical first order Lagrange–Galerkin method applied to transport [13] and convection-diffusion [19] equations are here extended to the second order Lagrange–Galerkin one. Furthermore, some numerical tests illustrate both the theoretical results and the performance of the combination of higher order Lagrange–Galerkin schemes with quadrature formulas.

The present paper is organized as follows. In section 2 the strong formulation of the convection-diffusion-reaction problem is established. In section 3 we introduce the hypotheses on the finite element spaces to be considered for spatial discretization, pose the corresponding fully discretized schemes, and state their stability properties. In section 4, the main result concerning error estimates of the fully discretized schemes is proved. In section 5, stability is analyzed for adequate quadrature formulas combined with particular finite element spaces. Finally, in section 6, several numerical test examples are introduced to illustrate the above theoretical results about the combination of quadrature formulas with second order Lagrange–Galerkin schemes; comparison with first order ones are also included.

2. Statement of the problem, weak formulation, and some hypothesis. Let Ω be a bounded domain in $\mathbb{R}^d$ $(d = 2, 3)$ with Lipschitz boundary, Γ, divided into two parts: $\Gamma = \Gamma_D \cup \Gamma_R$, with $\Gamma_D \cap \Gamma_R = \emptyset$. Let T be a positive constant. We consider the following initial boundary value problem:

(SP) STRONG PROBLEM: *Find a function* $\phi : \Omega \times (0, T) \longrightarrow \mathbb{R}$ *such that*

$$\phi'(\mathbf{x}, t) - \operatorname{div}\left(\mathbf{A}(\mathbf{x})\nabla\phi(\mathbf{x}, t)\right) + \mathbf{v}(\mathbf{x}, t) \cdot \nabla\phi(\mathbf{x}, t) + r(\mathbf{x})\phi(\mathbf{x}, t) = f(\mathbf{x}, t) \tag{2.1}$$

for $(\mathbf{x}, t) \in \Omega \times (0, T)$*, subject to boundary conditions*

$$\phi(\mathbf{x},t) = 0 \text{ on } \Gamma_D \times (0,T), \tag{2.2}$$

$$\alpha\ \phi(\mathbf{x},t) + \mathbf{A}(\mathbf{x})\nabla\phi(\mathbf{x},t)\cdot\mathbf{n}(\mathbf{x}) = g(\mathbf{x},t) \text{ on } \Gamma_R \times (0,T), \tag{2.3}$$

and initial condition

$$\phi(\mathbf{x},0) = \phi^0(\mathbf{x}) \text{ in } \Omega. \tag{2.4}$$

In the above equations, ϕ' denotes the partial derivative with respect to t, $\mathbf{A} : \overline{\Omega} \longrightarrow \mathcal{S}_d$ denotes the diffusion matrix function where $\mathcal{S}_d$ is the space of symmetric $d \times d$ matrices, $\mathbf{v} : \overline{\Omega} \times [0,T] \longrightarrow \mathbb{R}^d$ is the velocity vector field, $r : \overline{\Omega} \longrightarrow \mathbb{R}$ is the reaction function, $f : \overline{\Omega} \times [0,T] \longrightarrow \mathbb{R}$ and $g : \Gamma_R \times [0,T] \longrightarrow \mathbb{R}$ are given scalar functions, and $\mathbf{n}$ is the outward unit normal vector to Γ.

Throughout this paper, we use the notation $\psi^i = \psi(t_i)$ for a time-dependent function and $i = 0, \frac{1}{2}, 1, \ldots$. In [6] the following weak formulation of the above problem has been obtained:

(WP) WEAK PROBLEM: *Find a function* $\phi : \Omega \times (0,T) \longrightarrow \mathbb{R}$ *such that*

$$\left\langle \mathcal{L}^{n+\frac{1}{2}}\widehat{\phi}, \psi \right\rangle = \left\langle \mathcal{F}^{n+\frac{1}{2}}, \psi \right\rangle \forall \psi \in H^1_{\Gamma_D}(\Omega), \tag{2.5}$$

where $\mathcal{L}^{n+\frac{1}{2}}\widehat{\phi} \in (H^1(\Omega))'$ *and* $\mathcal{F}^{n+\frac{1}{2}} \in (H^1(\Omega))'$ *are defined by*

$$\begin{aligned}
\left\langle \mathcal{L}^{n+\frac{1}{2}}\widehat{\phi}, \psi \right\rangle :=& \left\langle \left(\frac{d\phi}{dt}\right)^{n+\frac{1}{2}} \circ X_e^{n+\frac{1}{2}}, \psi \right\rangle + \left\langle \left(\mathbf{F}_e^{n+\frac{1}{2}}\right)^{-1} \left(\mathbf{A}\nabla\phi^{n+\frac{1}{2}}\right) \circ X_e^{n+\frac{1}{2}},\ \nabla\ \psi \right\rangle \\
&+ \left\langle \text{div}\ \left(\mathbf{F}_e^{n+\frac{1}{2}}\right)^{-\mathrm{T}} \cdot \left(\mathbf{A}\nabla\phi^{n+\frac{1}{2}}\right) \circ X_e^{n+\frac{1}{2}}, \psi \right\rangle \\
&+ \left\langle \left(r\phi^{n+\frac{1}{2}}\right) \circ X_e^{n+\frac{1}{2}}, \psi \right\rangle + \alpha \left\langle \det\ \left(\mathbf{F}_e^{n+\frac{1}{2}}\right)^{-1} \phi^{n+\frac{1}{2}}, \psi \right\rangle_{\Gamma_R}, \\
\left\langle \mathcal{F}^{n+\frac{1}{2}}, \psi \right\rangle :=& \left\langle f^{n+\frac{1}{2}} \circ X_e^{n+\frac{1}{2}}, \psi \right\rangle + \left\langle \det\ \left(\mathbf{F}_e^{n+\frac{1}{2}}\right)^{-1} g^{n+\frac{1}{2}}, \psi \right\rangle_{\Gamma_R} \qquad \forall \psi \in H^1(\Omega),
\end{aligned}$$

where $X_e(\mathbf{x},t;\cdot)$ *denotes the characteristic line (associated to* $\mathbf{v}$*) through* $(\mathbf{x},t)$ *and* $\mathbf{F}_e$ *denotes the gradient of* X_e *with respect to* $\mathbf{x}$.

We will adopt the usual notation for the functional spaces involved, which has been recalled in section 1 of [6]. Let us only recall that, for a nonnegative integer m, $Z^m = \left\{\varphi \in C^j(H^{m-j}(\Omega));\ j = 0, \ldots, m\right\}$ is a Banach space when equipped with the norm $\|\varphi\|_{Z^m} := \max\left\{\|\varphi\|_{C^j(H^{m-j})};\ 0 \le j \le m\right\}$.

In [6] a second order characteristics semidiscretized scheme has been proposed and analyzed, obtaining stability and consistency error results under the following hypothesis on the data of the problem:

Hypothesis 1. The velocity field $\mathbf{v} \in C^0\left(W^{2,\infty}(\Omega)\right)$ satisfies $\mathbf{v} = 0$ on Γ.

Remark 2.1. Throughout this paper c_1 denotes the maximum between the positive constant appearing in Lemma 5.4 in [6] and the norm of the velocity in $C^0(W^{2,\infty}(\Omega))$.

Hypothesis 2. The diffusion matrix coefficients, A_{ij}, belong to $W^{1,\infty}(\Omega)$. Moreover, $\mathbf{A}$ is a $m \times m$ symmetric matrix satisfying

$$\mathbf{A} = \begin{pmatrix} \mathbf{A}_{m_1} & \Theta \\ \Theta & \Theta \end{pmatrix}, \tag{2.6}$$

with $\mathbf{A}_{m_1}$ being a positive definite symmetric $m_1 \times m_1$ matrix ($m_1 \geq 1$), and where Θ denotes an appropriate zero matrix. Moreover, there exists a strictly positive constant δ, which is a uniform lower bound for the eigenvalues of $\mathbf{A}_{m_1}$.

As a consequence of Hypothesis 2, there exists a unique positive definite symmetric $m_1 \times m_1$ matrix function, $\mathbf{C}_{m_1}$, such that $\mathbf{A}_{m_1} = (\mathbf{C}_{m_1})^2$. Let us denote by $\mathbf{C}$ the symmetric and positive semidefinite $m \times m$ matrix

$$\mathbf{C} = \begin{pmatrix} \mathbf{C}_{m_1} & \Theta \\ \Theta & \Theta \end{pmatrix}. \tag{2.7}$$

Notice that $\mathbf{A} = \mathbf{C}^2$ and $C_{ij} \in W^{1,\infty}(\Omega)$. Then, let us introduce the constant $c_2 := \max_{i,j} \left\{ \|C_{ij}\|^2_{W^{1,\infty}(\Omega)} \right\}$. Next, let us denote by $\mathbf{B}$ the $m \times m$ matrix

$$\mathbf{B} = \begin{pmatrix} \mathbf{I}_{m_1} & \Theta \\ \Theta & \Theta \end{pmatrix}, \tag{2.8}$$

where $\mathbf{I}_{m_1}$ is the $m_1 \times m_1$ identity matrix. Clearly, under Hypothesis 2 we have

$$\delta \|\mathbf{B}\mathbf{w}\|_0^2 \leq \langle \mathbf{A}\mathbf{w}, \mathbf{w} \rangle = \|\mathbf{C}\mathbf{w}\|_0^2 \leq c_2 \|\mathbf{B}\mathbf{w}\|_0^2 \quad \forall \mathbf{w} \in \mathbb{R}^m. \tag{2.9}$$

Hypothesis 3. The velocity field satisfies $(\mathbf{I} - \mathbf{B})\mathbf{L}(\mathbf{x}, t)\mathbf{B} = \mathbf{0}$ for all $(\mathbf{x}, t) \in \Omega \times [0, T]$, where $\mathbf{L}$ denotes the gradient of $\mathbf{v}$ with respect to $\mathbf{x}$.

Remark 2.2. Under Hypotheses 2 and 3, for every $m \times m$ matrix $\mathbf{E}$ and vectors $\mathbf{w}_1, \mathbf{w}_2 \in \mathbb{R}^m$ it is easy to verify that $\langle \mathbf{E}\mathbf{A}\mathbf{w}_1, \mathbf{w}_2 \rangle = \langle \mathbf{E}\mathbf{A}\mathbf{w}_1, \mathbf{B}\mathbf{w}_2 \rangle$.

Hypothesis 4. The reaction function, $r \in W^{1,\infty}(\Omega)$, satisfies $0 < \gamma \leq r(\mathbf{x})$ in Ω, where γ is a constant.

Under the previous hypothesis, let $c_3 := \|\sqrt{r}\|^2_{W^{1,\infty}(\Omega)}$.

Hypothesis 5. Functions appearing in problem (2.1)–(2.4) satisfy

- $\mathbf{A} \in \mathbf{W}^{3,\infty}(\Omega)$, $r \in W^{2,\infty}(\Omega)$,
- $\mathbf{v} \in C^0(\mathsf{W}^{3,\infty}(\Omega)) \cap C^1(\mathsf{W}^{2,\infty}(\Omega)) \cap C^2(\mathsf{L}^\infty(\Omega))$ and $\mathbf{v}|_\Gamma = 0$,
- $f \in Z^2$, $g \in Z^3(\Gamma_R)$, and $\alpha > 0$.

In the next section we introduce spatial finite elements discretizations of the time semidiscretized scheme proposed in [6]. In other words, we propose and analyze different Lagrange–Galerkin schemes.

3. Space discretization: Finite element method. We propose a spatial discretization by using finite element spaces V_h^k, where h denotes the mesh parameter and the positive integer k is the "approximation degree" in the following sense:

Hypothesis 6. There exists an interpolation operator $\pi_h : C^0(\overline{\Omega}) \longrightarrow V_h^k$ satisfying

$$\|\pi_h \psi - \psi\|_s \leq K\, h^{k+1-s} \|\psi\|_{k+1} \qquad \forall \psi \in C^0(\overline{\Omega}) \cap H^{k+1}(\Omega),\ s = 1, 2, \tag{3.1}$$

for a positive constant K independent of h.

The fully discrete scheme reads

$$\begin{cases} \text{Given } \phi_h^0 \in V_h^k, \text{ find } \widehat{\phi_h} := \{\phi_h^n\}_{n=1}^N \in \left[V_h^k\right]^N \text{ such that} \\ \left\langle \mathcal{L}_{\Delta t}^{n+\frac{1}{2}} \widehat{\phi_h}, \psi_h \right\rangle = \left\langle \mathcal{F}_{\Delta t}^{n+\frac{1}{2}}, \psi_h \right\rangle \quad \forall \psi_h \in V_h^k, \text{ for } n = 0, \ldots, N-1. \end{cases} \tag{3.2}$$

The involved operators are defined as follows:

$$\begin{aligned}\left\langle \mathcal{L}_{\Delta t}^{n+\frac{1}{2}}\phi,\psi\right\rangle :=& \left\langle \frac{\phi^{n+1}-\phi^n\circ X_{RK}^n}{\Delta t},\psi\right\rangle + \left\langle \frac{\mathbf{A}\nabla\phi^{n+1}+(\mathbf{A}\nabla\phi^n)\circ X_E^n}{2},\nabla\psi\right\rangle \\ &+ \frac{\Delta t}{2}\left\langle (\mathbf{L}^n\mathbf{A}\nabla\phi^n)\circ X_E^n,\nabla\psi\right\rangle + \frac{\Delta t}{2}\left\langle (\nabla \text{div } \mathbf{v}^n\cdot\mathbf{A}\nabla\phi^n)\circ X_E^n,\psi\right\rangle \\ &+ \left\langle \frac{r\phi^{n+1}+(r\phi^n)\circ X_E^n}{2},\psi\right\rangle \\ &+ \alpha\left\langle \frac{\phi^{n+1}+\phi^n(1+\Delta t \text{ div } \mathbf{v}^{n+1})}{2},\psi\right\rangle_{\Gamma_R}, \end{aligned} \tag{3.3}$$

$$\left\langle \mathcal{F}_{\Delta t}^{n+\frac{1}{2}},\psi\right\rangle := \left\langle \frac{f^{n+1}+f^n\circ X_E^n}{2},\psi\right\rangle + \left\langle \frac{g^{n+1}+g^n(1+\Delta t \text{ div } \mathbf{v}^{n+1})}{2},\psi\right\rangle_{\Gamma_R}, \tag{3.4}$$

for $\phi\in C^0(H^1(\Omega))$ and $\psi\in H^1(\Omega)$. Functions X_E^n and X_{RK}^n are, respectively, the Euler and Runge–Kutta approximations of the characteristics lines, X_e^n, (see [6]).

The following stability result for the fully discretized scheme can be analogously obtained to the one stated in [6] for the semidiscretized scheme.

THEOREM 3.1 (stability). *Let us assume Hypotheses* 1, 2, 3, *and* 4 *and let* $f\in C^0(L^2(\Omega))$, $g\in C^0(L^2(\Gamma_R))$ *and* $\alpha>0$. *Moreover, let* $\widehat{\phi_h}=\{\phi_h^n\}_{n=1}^N$ *be the solution of* (3.2) *subject to initial value* ϕ_h^0 *and* $\mathbf{B}\nabla\widehat{\phi_h}:=\{\mathbf{B}\nabla\phi_h^n\}_{n=1}^N$. *Then, there exist two positive constants,* c *and* d, $d=d(c_1,c_2,c_3,\delta,\gamma)$, *such that for* $\Delta t<d$ *we have*

$$\begin{aligned}&\frac{1}{\sqrt{2}}\left\|\widehat{\phi_h}\right\|_{l^\infty(L^2(\Omega))}+\sqrt{\frac{\delta\ \Delta t}{4}}\left\|\mathbf{B}\nabla\widehat{\phi_h}\right\|_{l^\infty(L^2(\Omega))}+\sqrt{\frac{\Delta t}{4}}\left\|\sqrt{r}\widehat{\phi_h}\right\|_{l^\infty(L^2(\Omega))} \\ &+\sqrt{\frac{\alpha\ \Delta t}{8}}\left\|\widehat{\phi_h}\right\|_{l^\infty(L^2(\Gamma_R))} \quad\le\quad c\left(\frac{1}{2}\left\|\phi_h^0\right\|_0+\sqrt{\frac{\delta\ \Delta t}{4}}\left\|\mathbf{B}\nabla\phi_h^0\right\|_0+\sqrt{\frac{\Delta t}{4}}\left\|\sqrt{r}\phi_h^0\right\|_0\right. \\ &\left.+\sqrt{\frac{\alpha\ \Delta t}{8}}\left\|\phi_h^0\right\|_{0,\Gamma_R}+\|f\|_{l^2(L^2(\Omega))}+\|g\|_{l^2(L^2(\Gamma_R))}+\Delta t\left\|\widehat{D_{\Delta t}g}\right\|_{l^2(L^2(\Gamma_R))}\right).\end{aligned}$$

4. Error estimates for the fully discretized scheme. In order to study consistency errors of the fully discretized scheme (3.2) let us introduce the notations $\widehat{e_h}:=\widehat{\phi_h}-\widehat{\pi_h\phi}$ and $\widehat{\eta_h}:=\widehat{\phi}-\widehat{\pi_h\phi}$, and state the following lemma.

LEMMA 4.1. *Under Hypotheses* 1, 2, 3, 4, *and* 6, *if* $\phi\in C^0(C^0(\overline{\Omega}))\cap C^0(H^{k+1}(\Omega))\cap H^1(H^k(\Omega))$ *and* $c_1\Delta t<1/2$, *the following inequality holds:*

$$\begin{aligned}&\left\langle \mathcal{L}_{\Delta t}^{n+\frac{1}{2}}\widehat{\eta_h},e_h^{n+1}\right\rangle \\ &\le\frac{1}{8}\left\|\mathbf{C}\ \nabla\ e_h^{n+1}+(\mathbf{C}\ \nabla\ e_h^n)\circ X_E^n\right\|_0^2+D_{\Delta t}^n\left(\frac{\Delta t}{2}\left\langle \mathbf{C}\ \nabla\ \widehat{\eta_h},\mathbf{C}\ \nabla\ \widehat{e_h}\right\rangle\right) \\ &+\frac{1}{8}\left\|\sqrt{r}e_h^{n+1}+(\sqrt{r}e_h^n)\circ X_E^n\right\|_0^2+D_{\Delta t}^n\left(\frac{\Delta t}{2}\left\langle \sqrt{r}\widehat{\eta_h},\sqrt{r}e_h^n\right\rangle\right) \\ &+\frac{\alpha}{8}\left\|e_h^{n+1}+e_h^n(1+\Delta t \text{ div } \mathbf{v}^{n+1})\right\|_{0,\Gamma_R}^2+D_{\Delta t}^n\left(\frac{\alpha\ \Delta t}{2}\left\langle \widehat{\eta_h},\widehat{e_h}\right\rangle_{\Gamma_R}\right)+c\left\|e_h^{n+1}\right\|_0^2 \\ &+c\Delta t\left(\delta\left(\|\mathbf{B}\ \nabla\ e_h^n\|_0^2+\left\|\mathbf{B}\ \nabla\ e_h^{n+1}\right\|_0^2\right)+\left\|\sqrt{r}e_h^n\right\|_0^2+\left\|\sqrt{r}e_h^{n+1}\right\|_0^2+\alpha\left\|e_h^n\right\|_{0,\Gamma_R}^2\right) \\ &+\widetilde{c}K^2h^{2k}\left(\frac{1}{\Delta t}\|\phi'\|_{L^2((t_n,t_{n+1}),H^k(\Omega))}^2+\frac{1}{\Delta t}\|\phi\|_{L^2((t_n,t_{n+1}),H^{k+1}(\Omega))}^2+\Delta t\left\|\phi^n\right\|_{k+1}^2\right)\end{aligned} \tag{4.1}$$

with $c = \max\{1, (c_1c_2+1)/4\delta, c_1c_3/4, c_1\}$, $\widetilde{c}$ *a positive constant, and* $\delta > 0$ *and* $\alpha > 0$ *being the constants appearing, respectively, in Hypothesis* 2 *and* (2.3).

Proof. First, the left-hand side in (4.1) is decomposed as a sum of the terms

$$
\begin{aligned}
I_1 &= \left\langle \frac{\eta_h^{n+1} - \eta_h^n \circ X_{RK}^n}{\Delta t}, e_h^{n+1} \right\rangle, \\
I_2 &= \left\langle \frac{\mathbf{A} \nabla \eta_h^{n+1} + (\mathbf{A} \nabla \eta_h^n) \circ X_E^n}{2}, \nabla e_h^{n+1} \right\rangle, \\
I_3 &= \frac{\Delta t}{2} \left\langle (\mathbf{L}^n \mathbf{A} \nabla \eta_h^n) \circ X_E^n, \nabla e_h^{n+1} \right\rangle, \\
I_4 &= \frac{\Delta t}{2} \left\langle (\nabla \operatorname{div} \mathbf{v}^n \cdot \mathbf{A} \nabla \eta_h^n) \circ X_E^n, e_h^{n+1} \right\rangle, \\
I_5 &= \left\langle \frac{r\eta_h^{n+1} + (r\eta_h^n) \circ X_E^n}{2}, e_h^{n+1} \right\rangle, \\
I_6 &= \alpha \left\langle \frac{\eta_h^{n+1} + \eta_h^n (1 + \Delta t \operatorname{div} \mathbf{v}^{n+1})}{2}, e_h^{n+1} \right\rangle_{\Gamma_R}.
\end{aligned}
\tag{4.2}
$$

In order to work with I_1 we introduce the function $Y_{RK}^n(\mathbf{y}, \cdot) : [t_n, t_{n+1}] \longrightarrow \overline{\Omega}$, defined by $Y_{RK}^n(\mathbf{y}, s) := \mathbf{y} - \mathbf{v}\left(\mathbf{y} - \mathbf{v}^{n+1}(\mathbf{y}) \frac{t_{n+1}-s}{2}, \frac{t_{n+1}+s}{2}\right)(t_{n+1} - s)$. First, applying the chain rule in order to compute its partial derivative with respect to s and its gradient, for $c_1 \Delta t < 1$ it is easy to obtain the following bounds:

$$
\left| \frac{\partial Y_{RK}^n}{\partial s}(\mathbf{y}, s) \right| \leq c_1 + \frac{\Delta t}{2} c_1 + \frac{\Delta t}{2} c_1^2 \leq 1 + 2c_1 \quad \forall (\mathbf{y}, s) \in \Omega \times [t_n, t_{n+1}], \tag{4.3}
$$

$$
\left| \det \left(\nabla Y_{RK}^n \right)^{-1} (\mathbf{y}, s) \right| \leq 1 + c_1 \Delta t \quad \forall (\mathbf{y}, s) \in \Omega \times [t_n, t_{n+1}], \tag{4.4}
$$

where Lemma 5.2 in [6] and Corollary 5.3 in [6] have been used. Moreover, noting that $Y_{RK}^n(\mathbf{y}, t_{n+1}) = \mathbf{y}$ and $Y_{RK}^n(\mathbf{y}, t_n) = X_{RK}^n(\mathbf{y})$, and by using Barrow's rule we have

$$
\begin{aligned}
\frac{\eta_h^{n+1}(\mathbf{y}) - \eta_h^n \left(X_{RK}^n(\mathbf{y}) \right)}{\Delta t} &= \frac{1}{\Delta t} \int_{t_n}^{t_{n+1}} \frac{d\eta_h}{ds} \left((Y_{RK}^n(\mathbf{y}, s), s) \right) \\
= \frac{1}{\Delta t} \int_{t_n}^{t_{n+1}} \eta_h'(Y_{RK}^n(\mathbf{y}, s), s) \, ds &+ \frac{1}{\Delta t} \int_{t_n}^{t_{n+1}} \nabla \eta_h(Y_{RK}^n(\mathbf{y}, s), s) \cdot \frac{\partial Y_{RK}^n}{\partial s}(\mathbf{y}, s) \, ds,
\end{aligned}
\tag{4.5}
$$

where the chain rule has been used for the last equality. Next, by applying Holder's inequality we get

$$
\frac{1}{\Delta t} \int_{t_n}^{t_{n+1}} \eta_h'(Y_{RK}^n(\mathbf{y}, s), s) \, ds \leq \frac{1}{\sqrt{\Delta t}} \left(\int_{t_n}^{t_{n+1}} \left(\eta_h'(Y_{RK}^n(\mathbf{y}, s), s) \right)^2 \, ds \right)^{\frac{1}{2}},
$$

and then

$$
\begin{aligned}
&\int_\Omega \left(\frac{1}{\Delta t} \int_{t_n}^{t_{n+1}} \eta_h'(Y_{RK}^n(\mathbf{y}, s), s) \, ds \right)^2 d\mathbf{y} \leq \frac{1}{\Delta t} \int_{t_n}^{t_{n+1}} \int_\Omega \eta_h'(Y_{RK}^n(\mathbf{y}, s), s)^2 \, d\mathbf{y} \, ds \\
&= \frac{1}{\Delta t} \int_{t_n}^{t_{n+1}} \int_\Omega \eta_h'(\mathbf{z}, s)^2 \det \left(\nabla Y_{RK}^n \right)^{-1} (\mathbf{z}, s) \, d\mathbf{z} \, ds \leq \frac{(1 + c_1 \Delta t)}{\Delta t} \left\| \eta_h' \right\|^2_{L^2((t_n, t_{n+1}), L^2(\Omega))},
\end{aligned}
$$

where the change of variable $\mathbf{z} = Y_{RK}^n(\mathbf{y}, s)$ and estimate (4.4) have been used. Analogously, for the last term of (4.5) we get

$$\int_\Omega \left(\frac{1}{\Delta t} \int_{t_n}^{t_{n+1}} \nabla\, \eta_h(Y_{RK}^n(\mathbf{y}, s), s) \cdot \frac{\partial Y_{RK}^n}{\partial s}(\mathbf{y}, s)\, ds \right)^2 d\mathbf{y}$$
$$\leq \frac{(1 + c_1\Delta t)\,(1 + 2c_1)^2}{\Delta t} \|\nabla\, \eta_h\|^2_{L^2((t_n,t_{n+1}),L^2(\Omega))},$$

where we have also considered estimate (4.3). Finally, by applying Young's inequality to term I_1 and using the above results and Hypothesis 6 for $s = 0$ and $r = k$ we obtain

(4.6)
$$I_1 \leq \frac{(1 + c_1\Delta t)\,(1 + 2c_1)^2\, K^2\, h^{2k}}{2\Delta t} \left(\|\phi'\|^2_{L^2((t_n,t_{n+1}),H^k(\Omega))} + \|\phi\|^2_{L^2((t_n,t_{n+1}),H^{k+1}(\Omega))} \right)$$
$$+ \frac{1}{2}\|e_h^{n+1}\|_0^2.$$

Next, we decompose term I_2 into $I_2 = I_2^1 + I_2^2 + I_2^3$, with

$$I_2^1 = \frac{1}{2}\left\langle \mathbf{C}\,\nabla\,\eta_h^{n+1},\ \mathbf{C}\,\nabla\, e_h^{n+1} \right\rangle - \frac{1}{2}\left\langle \mathbf{C}\,\nabla\,\eta_h^{n},\ \mathbf{C}\,\nabla\, e_h^{n} \right\rangle,$$
$$I_2^2 = \frac{1}{2}\left\langle \mathbf{C}\,\nabla\,\eta_h^{n},\ \mathbf{C}\,\nabla\, e_h^{n} \right\rangle - \frac{1}{2}\left\langle (\mathbf{C}\,\nabla\,\eta_h^{n})\circ X_E^n,\ (\mathbf{C}\,\nabla\, e_h^{n})\circ X_E^n \right\rangle,$$
$$I_2^3 = \frac{1}{2}\left\langle (\mathbf{C}\,\nabla\,\eta_h^{n})\circ X_E^n,\ (\mathbf{C}\circ X_E^n)(\nabla\, e_h^{n+1} + \ \nabla\, e_h^n \circ X_E^n) \right\rangle.$$

Notice that I_2^1 explicitly appears in (4.1). For I_2^2 we apply first the change of variable $\mathbf{y} = X_E^n(\mathbf{x})$ in the integral, Lemma 5.1 in [6], and Hypotheses 2 and 6 obtaining

$$I_2^2 = \frac{1}{2}\int_\Omega (\mathbf{C}\,\nabla\,\eta_h^n)(\mathbf{x}) \cdot (\mathbf{C}\,\nabla\, e_h^n)(\mathbf{x})\, d\mathbf{x} - \frac{1}{2}\int_\Omega (\mathbf{C}\,\nabla\,\eta_h^n \cdot \mathbf{C}\,\nabla\, e_h^n)\circ X_E^n(\mathbf{x})\, d\mathbf{x}$$
$$= \frac{1}{2}\int_\Omega \left(1 - \det((\mathbf{F}_E^n)^{-1}(\mathbf{x}))\right)(\mathbf{C}\,\nabla\,\eta_h^n)(\mathbf{x}) \cdot (\mathbf{C}\,\nabla\, e_h^n)(\mathbf{x})\, d\mathbf{x}$$
$$\leq \frac{c_1 c_2 \Delta t}{4}\left(K^2 h^{2k}\, \|\phi^n\|^2_{k+1} + \|\mathbf{B}\,\nabla\, e_h^n\|_0^2 \right).$$

Now, we replace in I_2^3 equality $\mathbf{C}(X_E^n(\mathbf{x})) = \mathbf{C}(\mathbf{x}) - \mathbf{D}^n(\mathbf{x})$, where

$$D_{ij}^n(\mathbf{x}) := \int_{t_n}^{t_{n+1}} \nabla C_{ij}(Y_E^n(\mathbf{x}, s)) \cdot \mathbf{v}^{n+1}(\mathbf{x})\, ds \ \ a.e.\ \mathbf{x} \in \Omega,$$

with $\left|D_{ij}^n(\mathbf{x})\right| \leq c_1\sqrt{c_2}\Delta t$, and the function $Y_E^n(\mathbf{x}, \cdot) : [t_n, t_{n+1}] \longrightarrow \overline{\Omega}$ is defined by $Y_E^n(\mathbf{x}, s) := \mathbf{x} - (t_{n+1} - s)\mathbf{v}^{n+1}(\mathbf{x})$. Thus, we get

$$I_2^3 = \frac{1}{2}\left\langle (\mathbf{C}\,\nabla\,\eta_h^n)\circ X_E^n\ ,\ \mathbf{C}\,\nabla\, e_h^{n+1} - \mathbf{D}\,\nabla\, e_h^{n+1} + (\mathbf{C}\,\nabla\, e_h^n)\circ X_E^n \right\rangle,$$

and then

$$I_2^3 \leq \|(\mathbf{C}\,\nabla\,\eta_h^n)\circ X_E^n\|_0^2 + \frac{1}{8}\left\|\mathbf{C}\,\nabla\, e_h^{n+1} + (\mathbf{C}\,\nabla\, e_h^n)\circ X_E^n\right\|_0^2 + \frac{1}{8}\left\|\mathbf{D}\,\nabla\, e_h^{n+1}\right\|_0^2.$$

Moreover, we have

$$\|(\mathbf{C}\ \nabla\ \eta_h^n)\circ X_E^n\|_0^2 \le (1+c_1\Delta t)c_2K^2h^{2k}\,\|\phi^n\|_{k+1}^2\,, \tag{4.7}$$

$$\left\|\mathbf{D}\ \nabla\ e_h^{n+1}\right\|_0^2 \le c_1^2c_2\Delta t^2\left\|\mathbf{B}\ \nabla\ e_h^{n+1}\right\|_0^2, \tag{4.8}$$

where, Lemma 5.4 in [6] and Hypotheses 2 and 6 with $r=k+1$ and $s=1$ have been required. Now, by jointly considering estimates for I_2^2 and I_2^3, and the lower bound δ of Hypothesis 2 we can state

$$\begin{aligned} I_2 \le I_2^1 &+ \left(\frac{c_1c_2\Delta t}{4}+(1+c_1\Delta t)c_2\right)K^2h^{2k}\,\|\phi^n\|_{k+1}^2 \\ &+ \frac{(2c_1+c_1^2\Delta t)c_2\Delta t}{8\delta}\,\delta\left(\|\mathbf{B}\ \nabla\ e_h^n\|_0^2+\left\|\mathbf{B}\ \nabla\ e_h^{n+1}\right\|_0^2\right) \\ &+ \frac{1}{8}\left\|\mathbf{C}\ \nabla\ e_h^{n+1}+(\mathbf{C}\ \nabla\ e_h^n)\circ X_E^n\right\|_0^2. \end{aligned} \tag{4.9}$$

Similar reasoning, i.e., Lemma 5.4 in [6] and Hypotheses 1, 2, and 6 lead to

$$\begin{aligned} \|(\mathbf{L}^n\mathbf{A}\ \nabla\eta_h^n)\circ X_E^n\|_0^2 &\le (1+c_1\Delta t)c_1^2c_2^2K^2h^{2k}\ \ \|\phi^n\|_{k+1}^2\,, \\ \|(\nabla\ \mathrm{div}\ \mathbf{v}^n\cdot\mathbf{A}\ \nabla\eta_h^n)\circ X_E^n\|_0^2 &\le (1+c_1\Delta t)c_1^2c_2^2K^2h^{2k}\ \ \|\phi^n\|_{k+1}^2\,. \end{aligned} \tag{4.10}$$

Using these inequalities, I_3 and I_4 can be bounded as follows:

$$I_3 \le \frac{(1+c_1\Delta t)c_1^2c_2^2\Delta t\ K^2\ h^{2k}}{4}\,\|\phi^n\|_{k+1}^2+\frac{\Delta t}{4\delta}\delta\left\|\mathbf{B}\ \nabla\ e_h^{n+1}\right\|_0^2, \tag{4.11}$$

$$I_4 \le \frac{(1+c_1\Delta t)c_1^2c_2^2\Delta t^2\ K^2\ h^{2k}}{4}\,\|\phi^n\|_{k+1}^2+\frac{1}{4}\left\|e_h^{n+1}\right\|_0^2, \tag{4.12}$$

where, in order to estimate I_3, we have used Remark 2.2 and Hypothesis 2.

Next, term I_5 can be decomposed like term I_2, namely, $I_5=I_5^1+I_5^2+I_5^3$, where

$$\begin{aligned} I_5^1 &= \frac{1}{2}\left\langle\sqrt{r}\eta_h^{n+1}\ ,\ \sqrt{r}e_h^{n+1}\right\rangle-\frac{1}{2}\left\langle\sqrt{r}\eta_h^n\ ,\ \sqrt{r}e_h^n\right\rangle \\ I_5^2 &= \frac{1}{2}\left\langle\sqrt{r}\eta_h^n\ ,\ \sqrt{r}e_h^n\right\rangle-\frac{1}{2}\left\langle(\sqrt{r}\eta_h^n)\circ X_E^n\ ,\ (\sqrt{r}e_h^n)\circ X_E^n\right\rangle, \\ I_5^3 &= \frac{1}{2}\left\langle(\sqrt{r}\eta_h^n)\circ X_E^n\ ,\ \sqrt{r}\circ X_E^n\left(e_h^{n+1}+e_h^n\circ X_E^n\right)\right\rangle. \end{aligned} \tag{4.13}$$

Moreover, by using again the definition of Y_E^n, we can rewrite I_5^3 as

$$\begin{aligned} \frac{1}{2}\Bigg\langle(\sqrt{r}\eta_h^n)\circ X_E^n, \sqrt{r}e_h^{n+1}-\left(\int_{t_n}^{t_{n+1}}\nabla\ \sqrt{r}(Y_E^n(\mathbf{x},s))\cdot\mathbf{v}^{n+1}(\mathbf{x})\ ds\right)e_h^{n+1} \\ +\ \left(\sqrt{r}e_h^n\right)\circ X_E^n\Bigg\rangle. \end{aligned}$$

Thus, the same kind of computations used for I_2 lead to the following estimate:

$$\begin{aligned} I_5 \le I_5^1 &+ \left(\frac{c_1c_3\Delta t}{4}+(1+c_1\Delta t)c_3\right)K^2h^{2k}\,\|\phi^n\|_k^2 \\ &+ \frac{(2c_1+c_1^2\Delta t)c_3\Delta t}{8}\left(\left\|\sqrt{r}e_h^n\right\|_0^2+\left\|\sqrt{r}e_h^{n+1}\right\|_0^2\right)+\frac{1}{8}\left\|\sqrt{r}e_h^{n+1}+(\sqrt{r}e_h^n)\circ X_E^n\right\|_0^2. \end{aligned} \tag{4.14}$$

Finally, the boundary integral term I_6 is decomposed as a sum of the three terms

$$I_6^1 = \frac{\alpha}{2}\left\langle \eta_h^{n+1},\ e_h^{n+1}\right\rangle_{\Gamma_R} - \frac{\alpha}{2}\left\langle \eta_h^{n},\ e_h^{n}\right\rangle_{\Gamma_R},$$

$$I_6^2 = \frac{\alpha}{2}\left\langle \eta_h^{n},\ e_h^{n}\right\rangle_{\Gamma_R} - \frac{\alpha}{2}\left\langle \eta_h^{n}(1+\Delta t\ \mathrm{div}\ \mathbf{v}^{n+1}),\ e_h^{n}(1+\Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})\right\rangle_{\Gamma_R},$$

$$I_6^3 = \frac{\alpha}{2}\left\langle \eta_h^{n}(1+\Delta t\ \mathrm{div}\ \mathbf{v}^{n+1}),\ e_h^{n+1}+e_h^{n}(1+\Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})\right\rangle_{\Gamma_R}.$$

Term I_6^1 appears explicitly in (4.1). For I_6^2 and I_6^3 we use Hypothesis 1 and that $c_1\Delta t<1$ to establish the bounds $\left|1-(1+\Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})^2(\mathbf{x})\right| \le c_1\Delta t(2+c_1\Delta t)$ and $(1+\Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})^2(\mathbf{x}) \le 1+2c_1\Delta t+c_1^2\Delta t^2$, for all $\mathbf{x}\in\Omega$. Thus, we have

$$I_6^2 \le \frac{\alpha c_1\Delta t(2+c_1\Delta t)}{4}\left(\|\eta_h^n\|_{0,\Gamma_R}^2+\|e_h^n\|_{0,\Gamma_R}^2\right),$$

$$I_6^3 \le \frac{\alpha(1+2c_1\Delta t+c_1^2\Delta t^2)}{2}\|\eta_h^n\|_{0,\Gamma_R}^2+\frac{\alpha}{8}\left\|e_h^{n+1}+e_h^n(1+\Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})\right\|_{0,\Gamma_R}^2.$$

Next, by using the continuity of the trace mapping, there is $c_\Omega>0$ such that $\|\eta_h^n\|_{0,\Gamma_R}^2 \le c_\Omega\ \|\eta_h^n\|_1^2$. We deduce, by also using Hypothesis 6, that

(4.15)
$$I_6 \le I_6^1+\alpha\left(\frac{c_1\Delta t(2+c_1\Delta t)}{4}+\frac{(1+2c_1\Delta t+c_1^2\Delta t^2)}{2}\right)c_\Omega K^2\ h^{2k}\,\|\phi^n\|_{k+1}^2$$
$$+\frac{\alpha}{8}\left\|e_h^{n+1}+e_h^n(1+\Delta t\ \mathrm{div}\ \mathbf{v}^{n+1})\right\|_{0,\Gamma_R}^2+\frac{\alpha c_1\Delta t(2+c_1\Delta t)}{4}\|e_h^n\|_{0,\Gamma_R}^2.$$

Finally, by jointly considering (4.6), (4.9), (4.11), (4.12), (4.14), and (4.15), and taking into account that $c_1\Delta t<1$, result (4.1) follows. ∎

THEOREM 4.2 (error estimate). *Let us assume Hypotheses* 2, 3, 4, 5, *and* 6. *Let* $\phi\in Z^3\cap C^0(H^{k+1}(\Omega))\cap H^1(H^k(\Omega))$ *be the solution of* (2.5), *with* $\nabla\ \phi\in \mathsf{Z}^3$ *and* $\phi|_{\Gamma_R}\in Z^3(\Gamma_R)$, *and* $\widehat{\phi_h}$ *be the solution of* (3.2) *subject to the initial value* $\phi_h^0=\pi_h\phi^0$. *Let* $\mathbf{B}\ \nabla\ (\widehat{\phi}-\widehat{\phi_h}) := \{\mathbf{B}\ \nabla\ (\phi^n-\phi_h^n)\}_{n=1}^N$. *Then, there exist two positive constants,* c *and* d, *independent of* h *and* Δt, *such that, if* $\Delta t<d$ *we have*

(4.16)
$$\sqrt{\frac{1}{2}}\left\|\widehat{\phi}-\widehat{\phi_h}\right\|_{l^\infty(L^2(\Omega))}+\sqrt{\frac{\Delta t\ \delta}{8}}\left\|\mathbf{B}\ \nabla\ \widehat{\phi}-\mathbf{B}\ \nabla\ \widehat{\phi_h}\right\|_{l^\infty(L^2(\Omega))}$$
$$+\sqrt{\frac{\Delta t}{8}}\left\|\sqrt{r}\widehat{\phi}-\sqrt{r}\widehat{\phi_h}\right\|_{l^\infty(L^2(\Omega))}+\sqrt{\frac{\Delta t\ \alpha}{16}}\left\|\widehat{\phi}-\widehat{\phi_h}\right\|_{l^\infty(L^2(\Gamma_R))}$$
$$\le ch^k\left(\|\phi\|_{H^1(H^k(\Omega))}+\|\phi\|_{C^0(H^{k+1}(\Omega))}\right)$$
$$+c\Delta t^2\left(\|\phi\|_{Z^3}+\|\mathbf{A}\ \nabla\ \phi\|_{\mathsf{Z}^3}+\ \|r\phi\|_{Z^2}+\|\phi\|_{Z^2,\Gamma_R}+\|f\|_{Z^2}+\|g\|_{Z^2,\Gamma_R}\right)$$
$$+c\Delta t^{\frac{5}{2}}\left(\|\phi\|_{Z^3,\Gamma_R}+\|g\|_{Z^3,\Gamma_R}\right).$$

Proof. First, recall that $\widehat{e_h} = \widehat{\eta_h} - \widehat{\phi} + \widehat{\phi_h}$. By also using the definitions of schemes (3.2) and (2.5) the following identity holds:

(4.17)

$$\begin{aligned}
&\left\langle \mathcal{L}_{\Delta t}^{n+\frac{1}{2}} \widehat{e_h}, e_h^{n+1} \right\rangle \\
&\quad = \left\langle \mathcal{L}_{\Delta t}^{n+\frac{1}{2}} \left(\widehat{\eta_h} - \widehat{\phi} + \widehat{\phi_h} \right), e_h^{n+1} \right\rangle \\
&\quad = \left\langle \mathcal{L}_{\Delta t}^{n+\frac{1}{2}} \widehat{\eta_h}, e_h^{n+1} \right\rangle - \left\langle \mathcal{L}_{\Delta t}^{n+\frac{1}{2}} \widehat{\phi}, e_h^{n+1} \right\rangle + \left\langle \mathcal{F}_{\Delta t}^{n+\frac{1}{2}}, e_h^{n+1} \right\rangle \\
&\quad = \left\langle \mathcal{L}_{\Delta t}^{n+\frac{1}{2}} \widehat{\eta_h}, e_h^{n+1} \right\rangle + \left\langle \left(\mathcal{L}^{n+\frac{1}{2}} - \mathcal{L}_{\Delta t}^{n+\frac{1}{2}} \right) \widehat{\phi}, e_h^{n+1} \right\rangle + \left\langle \mathcal{F}_{\Delta t}^{n+\frac{1}{2}} - \mathcal{F}^{n+\frac{1}{2}}, e_h^{n+1} \right\rangle .
\end{aligned}$$

A lower bound for (4.17) is given by Lemma 5.5 in [6], namely,

(4.18)

$$\begin{aligned}
&\left\langle \mathcal{L}_{\Delta t}^{n+\frac{1}{2}} \widehat{e_h}, e_h^{n+1} \right\rangle \\
&\quad \geq D_{\Delta t}^n \left(\frac{1}{2} \left\| \widehat{e_h} \right\|_0^2 + \frac{\Delta t}{4} \left\| \mathbf{C} \nabla \widehat{e_h} \right\|_0^2 + \frac{\Delta t}{4} \left\| \sqrt{r} \widehat{e_h} \right\|_0^2 + \frac{\alpha \Delta t}{4} \left\| \widehat{e_h} \right\|_{0,\Gamma_R}^2 \right) \\
&\qquad + \frac{1}{2\Delta t} \left\| e_h^{n+1} - e_h^n \circ X_{RK}^n \right\|_0^2 + \frac{1}{4} \left\| \mathbf{C} \nabla e_h^{n+1} + (\mathbf{C} \nabla e_h^n) \circ X_E^n \right\|_0^2 \\
&\qquad + \frac{1}{4} \left\| \sqrt{r} e_h^{n+1} + (\sqrt{r} e_h^n) \circ X_E^n \right\|_0^2 + \frac{\alpha}{4} \left\| \phi^{n+1} + \phi^n (1 + \Delta t \ \mathrm{div}\ \mathbf{v}^{n+1}) \right\|_{0,\Gamma_R}^2 \\
&\qquad - \frac{c}{2} \left(\left\| e_h^n \right\|_0^2 + \left\| e_h^{n+1} \right\|_0^2 \right) - c\alpha \Delta t \left\| e_h^n \right\|_{0,\Gamma_R}^2 \\
&\qquad - c\Delta t \left(\left\| \sqrt{r} e_h^n \right\|_0^2 + \left\| \sqrt{r} e_h^{n+1} \right\|_0^2 \right) - c\delta \Delta t \left(\left\| \mathbf{B} \nabla e_h^n \right\|_0^2 + \left\| \mathbf{B} \nabla e_h^{n+1} \right\|_0^2 \right),
\end{aligned}$$

with $c = \max\left\{1, c_1, c_2, (2c_1c_2 + c_1c_2^2)/\delta, c_1c_3/\gamma\right\}$. Now, by using Lemmas 5.19 and 5.20 in [6] we have

(4.19)

$$\begin{aligned}
&\left\langle \left(\mathcal{L}^{n+\frac{1}{2}} - \mathcal{L}_{\Delta t}^{n+\frac{1}{2}} \right) \widehat{\phi}, e_h^{n+1} \right\rangle + \left\langle \mathcal{F}_{\Delta t}^{n+\frac{1}{2}} - \mathcal{F}^{n+\frac{1}{2}}, e_h^{n+1} \right\rangle \\
&\quad = \left\langle \xi_{\mathcal{L}_1}^{n+\frac{1}{2}} - \xi_f^{n+\frac{1}{2}}, e_h^{n+1} \right\rangle + \left\langle \xi_{\mathcal{L}_2}^{n+\frac{1}{2}} - \xi_g^{n+\frac{1}{2}}, e_h^{n+1} \right\rangle_{\Gamma_R} \\
&\quad \leq \left(\left\| \xi_{\mathcal{L}_1}^{n+\frac{1}{2}} \right\|_0^2 + \left\| \xi_f^{n+\frac{1}{2}} \right\|_0^2 \right) + \left\langle H^{n+\frac{1}{2}}, e_h^{n+1} - e_h^n \right\rangle \\
&\qquad + \frac{21}{\alpha} \left(\left\| \xi_{\mathcal{L}_2}^{n+\frac{1}{2}} \right\|_{0,\Gamma_R}^2 + \left\| \xi_g^{n+\frac{1}{2}} \right\|_{0,\Gamma_R}^2 \right) \\
&\qquad + \left\| e_h^{n+1} \right\|_0^2 + \alpha c_1 \ \Delta t \left\| e_h^n \right\|_{0,\Gamma_R}^2 + \frac{\alpha}{8} \left\| e_h^{n+1} + e_h^n (1 + \Delta t \ \mathrm{div}\ \mathbf{v}^{n+1}) \right\|_{0,\Gamma_R}^2 ,
\end{aligned}$$

with $H^{n+\frac{1}{2}}(\mathbf{x}) := (\xi_{\mathcal{L}_2}^{n+\frac{1}{2}}(\mathbf{x}) - \xi_g^{n+\frac{1}{2}}(\mathbf{x}))/\left(2 + \Delta t \ \mathrm{div}\ \mathbf{v}^{n+1}(\mathbf{x})\right)$ a.e. $\mathbf{x} \in \Omega$. Lemma 5.6 in [6] has been applied to the last inequality for the choices $\psi = e_h^{n+1}$ and $\varphi = e_h^n$, first for $F^{n+1} = \xi_{\mathcal{L}_1}^{n+\frac{1}{2}}$, $G^{n+1} = \xi_{\mathcal{L}_2}^{n+\frac{1}{2}}$ and then for $F^{n+1} = -\xi_f^{n+\frac{1}{2}}$, $G^{n+1} = -\xi_g^{n+\frac{1}{2}}$.

By jointly considering the lower bound of (4.17) given in (4.18), the upper bound given in (4.19) and Lemma 4.1 we deduce

(4.20)

$$
\begin{aligned}
&D_{\Delta t}^n\left(\frac{1}{2}\ \|\widehat{e_h}\|_0^2+\frac{\Delta t}{4}\,\|\mathbf{C}\ \nabla\ \widehat{e_h}\|_0^2+\frac{\Delta t}{4}\,\left\|\sqrt{r}\widehat{e_h}\right\|_0^2+\frac{\alpha\Delta t}{4}\,\|\widehat{e_h}\|_{0,\Gamma_R}^2\right)\\
&\quad\le \widetilde{c}K^2h^{2k}\\
&\qquad\times\left(\frac{1}{\Delta t}\,\|\phi'\|^2_{L^2((t_n,t_{n+1}),H^k(\Omega))}+\frac{1}{\Delta t}\,\|\phi\|^2_{L^2((t_n,t_{n+1}),H^{k+1}(\Omega))}+\Delta t\ \|\phi^n\|^2_{k+1}\right)\\
&\qquad+\widetilde{c}\left(\left\|\xi_{\mathcal{L}_1}^{n+\frac12}\right\|_0^2+\left\|\xi_f^{n+\frac12}\right\|_0^2+\left\|\xi_{\mathcal{L}_2}^{n+\frac12}\right\|_{0,\Gamma_R}^2+\left\|\xi_g^{n+\frac12}\right\|_{0,\Gamma_R}^2\right)\\
&\qquad+\left\langle H^{n+\frac12},e_h^{n+1}-e_h^n\right\rangle_{\Gamma_R}\\
&\qquad+\frac{\Delta t}{2}D_{\Delta t}^n\left(\langle\mathbf{C}\ \nabla\ \widehat{\eta_h},\mathbf{C}\ \nabla\ \widehat{e_h}\rangle+\left\langle\sqrt{r}\widehat{\eta_h},\sqrt{r}\widehat{e_h}\right\rangle+\alpha\,\langle\widehat{\eta_h},\widehat{e_h}\rangle_{\Gamma_R}\right)\\
&\qquad+c\left(\|e_h^n\|_0^2+\left\|e_h^{n+1}\right\|_0^2\right)+c\Delta t\left(\left\|\sqrt{r}e_h^n\right\|_0^2+\left\|\sqrt{r}e_h^{n+1}\right\|_0^2\right)\\
&\qquad+c\Delta t\left(\delta\left(\|\mathbf{B}\ \nabla\ e_h^n\|_0^2+\left\|\mathbf{B}\ \nabla\ e_h^{n+1}\right\|_0^2\right)+\alpha\,\|e_h^n\|_{0,\Gamma_R}^2\right),
\end{aligned}
$$

where we omit some positive terms on the left-hand side. In (4.20), $\widetilde{c}$ is a positive constant and $c=\max\left\{2,(3c_1c_2+c_1c_2^2+1)/\delta,c_1c_3(1/\gamma+1/4),c_1,c_2\right\}$. Now, for fixed integer $q\ge 1$, we multiply (4.20) by Δt and sum it from $n=0$ to $n=q-1$. We get

(4.21)

$$
\begin{aligned}
&\frac{1}{2}\,\|e_h^q\|_0^2+\frac{\Delta t}{4}\,\|\mathbf{C}\ \nabla\ e_h^q\|_0^2+\frac{\Delta t}{4}\,\left\|\sqrt{r}e_h^q\right\|_0^2+\frac{\alpha\Delta t}{4}\,\|e_h^q\|_{0,\Gamma_R}^2\\
&\le\frac{1}{2}\,\left\|e_h^0\right\|_0^2+\frac{\Delta t}{4}\,\left\|\mathbf{C}\ \nabla\ e_h^0\right\|_0^2+\frac{\Delta t}{4}\,\left\|\sqrt{r}e_h^0\right\|_0^2+\frac{\alpha\Delta t}{4}\,\left\|e_h^0\right\|_{0,\Gamma_R}^2\\
&\quad+\widetilde{c}K^2h^{2k}\\
&\quad\times\left(\sum_{n=0}^{q-1}\|\phi'\|^2_{L^2((t_n,t_{n+1}),H^k(\Omega))}+\sum_{n=0}^{q-1}\|\phi\|^2_{L^2((t_n,t_{n+1}),H^{k+1}(\Omega))}+\sum_{n=0}^{q-1}\Delta t^2\ \|\phi^n\|^2_{k+1}\right)\\
&\quad+\widetilde{c}\sum_{n=0}^{q-1}\Delta t\left(\left\|\xi_{\mathcal{L}_1}^{n+\frac12}\right\|_0^2+\left\|\xi_f^{n+\frac12}\right\|_0^2+\left\|\xi_{\mathcal{L}_2}^{n+\frac12}\right\|_{0,\Gamma_R}^2+\left\|\xi_g^{n+\frac12}\right\|_{0,\Gamma_R}^2\right)\\
&\quad+\sum_{n=0}^{q-1}\Delta t\left\langle H^{n+\frac12},e_h^{n+1}-e_h^n\right\rangle_{\Gamma_R}+\frac{\Delta t}{2}\left(\langle\mathbf{C}\ \nabla\ \eta_h^q,\mathbf{C}\ \nabla\ e_h^q\rangle-\langle\mathbf{C}\ \nabla\ \eta_h^0,\mathbf{C}\ \nabla\ e_h^0\rangle\right)\\
&\quad+\frac{\Delta t}{2}\left(\left\langle\sqrt{r}\eta_h^q,\sqrt{r}e_h^q\right\rangle-\left\langle\sqrt{r}\eta_h^0,\sqrt{r}e_h^0\right\rangle\right)+\frac{\alpha\Delta t}{2}\left(\langle\eta_h^q,e_h^q\rangle_{\Gamma_R}-\langle\eta_h^0,e_h^0\rangle_{\Gamma_R}\right)\\
&\quad+2c\Delta t\sum_{n=0}^{q}\|e_h^n\|_0^2+2c\Delta t^2\left(\sum_{n=0}^{q}\|\mathbf{B}\ \nabla\ e_h^n\|_0^2+\sum_{n=0}^{q}\left\|\sqrt{r}e_h^n\right\|_0^2+\sum_{n=0}^{q-1}\|e_h^n\|_{0,\Gamma_R}^2\right).
\end{aligned}
$$

Moreover, some terms on the right-hand side of (4.21) can also be bounded. We have

$$
\begin{aligned}
(4.22)\quad & \sum_{n=0}^{q-1} \|\phi'\|^2_{L^2((t_n,t_{n+1}),H^k(\Omega))} + \sum_{n=0}^{q-1} \|\phi\|^2_{L^2((t_n,t_{n+1}),H^{k+1}(\Omega))} + \sum_{n=0}^{q-1} \Delta t^2 \ \|\phi^n\|^2_{k+1} \\
& \leq \|\phi'\|^2_{L^2(H^k(\Omega))} + \|\phi\|^2_{L^2(H^{k+1}(\Omega))} + \Delta t \ T \ \|\phi\|^2_{C^0(H^{k+1}(\Omega))} \\
& \leq \|\phi'\|^2_{L^2(H^k(\Omega))} + (1+\Delta t) T \ \|\phi\|^2_{C^0(H^{k+1}(\Omega))},
\end{aligned}
$$

where T is the measure of the time interval.

Second, by using Lemmas 5.19 and 5.20 in [6] and the fact that $\mathbf{A} \ \nabla \ \phi \cdot \mathbf{n} = g - \alpha\phi$ on the boundary Γ_R we get

$$
\begin{aligned}
& \sum_{n=0}^{q-1} \Delta t \left(\left\| \xi_{\mathcal{L}_1}^{n+\frac{1}{2}} \right\|_0^2 + \left\| \xi_f^{n+\frac{1}{2}} \right\|_0^2 + \left\| \xi_{\mathcal{L}_2}^{n+\frac{1}{2}} \right\|_{0,\Gamma_R}^2 + \left\| \xi_g^{n+\frac{1}{2}} \right\|_{0,\Gamma_R}^2 \right) \\
& \leq \Delta t^4 \ \widetilde{c_1} \ T \ \left(\|\phi\|_{Z^3} + \|\mathbf{A} \ \nabla \ \phi\|_{\mathsf{Z}^3} + \ \|r\phi\|_{Z^2} + \|\alpha\phi\|_{Z^2,\Gamma_R} + \|f\|_{Z^2} + \|g\|_{Z^2,\Gamma_R} \right).
\end{aligned}
$$

Third, by applying Lemma 5.7 in [6], we obtain the estimate

$$
\begin{aligned}
& \left| \sum_{n=0}^{q-1} \Delta t \left\langle H^{n+\frac{1}{2}}, e_h^{n+1} - e_h^n \right\rangle_{\Gamma_R} \right| \leq \frac{\alpha\Delta t}{8} \|e_h^q\|^2_{0,\Gamma_R} + \frac{\alpha\Delta t}{8} \|e_h^0\|^2_{0,\Gamma_R} + 6\alpha\Delta t^2 \sum_{n=0}^{q-1} \|e_h^n\|^2_{0,\Gamma_R} \\
& + \frac{4 + c_1\Delta t}{\alpha} \Delta t \left(\sum_{n=0}^{q} \left\| \xi_{\mathcal{L}_2}^{n+\frac{1}{2}} \right\|_{0,\Gamma_R}^2 + \sum_{n=0}^{q} \left\| \xi_g^{n+\frac{1}{2}} \right\|_{0,\Gamma_R}^2 \right) \\
& + \frac{\Delta t^2}{\alpha} \left(\sum_{n=0}^{q-1} \left\| \frac{\xi_{\mathcal{L}_2}^{n+\frac{1}{2}} - \xi_{\mathcal{L}_2}^{n-\frac{1}{2}}}{\Delta t} \right\|_{0,\Gamma_R}^2 + \sum_{n=0}^{q-1} \left\| \frac{h_g^{n+\frac{1}{2}} - h_g^{n-\frac{1}{2}}}{\Delta t} \right\|_{0,\Gamma_R}^2 \right).
\end{aligned}
$$

Thus, by using again the bounds given in Lemmas 5.19 and 5.20 in [6] we get

$$
\begin{aligned}
& \left| \sum_{n=0}^{q-1} \Delta t \left\langle H^{n+\frac{1}{2}}, e_h^{n+1} - e_h^n \right\rangle_{\Gamma_R} \right| \leq \frac{\alpha\Delta t}{8} \|e_h^q\|^2_{0,\Gamma_R} + \frac{\alpha\Delta t}{8} \|e_h^0\|^2_{0,\Gamma_R} + 6\alpha\Delta t^2 \sum_{n=0}^{q-1} \|e_h^n\|^2_{0,\Gamma_R} \\
& + \frac{5}{\alpha} \Delta t^4 \ T \ \widetilde{c_1} \left(\|\phi\|_{Z^3} + \|\mathbf{A} \ \nabla \ \phi\|_{\mathsf{Z}^3} + \ \|r\phi\|_{Z^2} + \|\alpha \ \phi\|_{Z^2,\Gamma_R} + \|f\|_{Z^2} + \|g\|_{Z^2,\Gamma_R} \right) \\
& + \frac{\Delta t^5 \ T}{\alpha} \left(\|\alpha \ \phi\|_{Z^3,\Gamma_R} + \|g\|_{Z^3,\Gamma_R} \right).
\end{aligned}
$$

Fourth, analogous computations to those developed in Lemma 4.1 give

$$
\begin{aligned}
& \frac{\Delta t}{2} \left\langle \mathbf{C} \ \nabla \ \eta_h^j, \mathbf{C} \ \nabla \ e_h^j \right\rangle \leq \frac{K^2 \ c_2 \ h^{2k} \ \Delta t}{2} \left\| \phi^j \right\|^2_{k+1} + \frac{\Delta t}{8} \left\| \mathbf{C} \ \nabla \ e_h^j \right\|_0^2, \\
& \frac{\Delta t}{2} \left\langle \sqrt{r}\eta_h^j, \sqrt{r} e_h^j \right\rangle \leq \frac{K^2 \ c_3 \ h^{2k} \ \Delta t}{2} \left\| \phi^j \right\|^2_{k+1} + \frac{\Delta t}{8} \left\| \sqrt{r} e_h^j \right\|_0^2, \\
& \frac{\alpha\Delta t}{2} \left\langle \eta_h^j, e_h^j \right\rangle_{\Gamma_R} \leq \alpha K^2 \ c_\Omega \ h^{2k} \ \Delta t \left\| \phi^j \right\|^2_{k+1} + \frac{\alpha \ \Delta t}{16} \left\| e_h^j \right\|^2_{0,\Gamma_R} \quad \text{for } j = 0, q.
\end{aligned}
$$

Next, for $n = 0, \ldots, N$, let us introduce the notation

$$\theta_n := \frac{1}{2} \|e_h^n\|_0^2 + \frac{\delta \Delta t}{8} \|\mathbf{B} \nabla e_h^n\|_0^2 + \frac{\Delta t}{8} \left\|\sqrt{r}\, e_h^n\right\|_0^2, \quad \overline{\theta}_n := \frac{\alpha \Delta t}{16} \|e_h^n\|_{0,\Gamma_R}^2 .$$

With the above notation, the previous estimates lead to

$$(1 - 16c\Delta t)\theta_q + \overline{\theta}_q \leq 16c\Delta t \sum_{n=0}^{q-1} \theta_n + 128c\Delta t \sum_{n=0}^{q-1} \overline{\theta}_n + \widetilde{c}\left(\theta_0 + \overline{\theta_0} + C\right),$$

where C contains the constant terms multiplied by h^{2k}, by Δt^4 and by Δt^5.

Finally, taking into account that $e_h^0 = 0$, the result is concluded by discrete Gronwall's inequality (see, for instance, [17]). ∎

5. Finite element spaces and quadrature formulas. Results concerning stability and consistency of scheme (3.2), when the inner products are exactly integrated, have been proved above for a wide class of finite element spaces (we only require the interpolation property in Hypothesis 6). Nevertheless, numerical integration has to be used in practice to approximate the involved integrals. It is well known that, for the classical first order in time Lagrange–Galerkin method, numerical quadrature can lead to conditional stability [13, 19, 16]. Moreover, new terms may appear in the error estimates (see [15, 13] and the two last paragraphs in section 6).

In the present section we analyze the stability of (3.2) when combined with some finite element spaces and quadrature formulas, extending the studies in the literature regarding the classical scheme. In the next section we present some numerical tests showing the influence of quadrature formulas in both stability and consistency errors. Most of the papers in the literature study the classical Lagrange–Galerkin method for piecewise linear finite elements. Indeed, conditional instability is shown in [13] for Gauss–Legendre, Gauss–Lobatto (with more than three points), Radau and Newton–Cotes formula, when applied to the linear convection equation. This work was extended to the linear convection-diffusion equation in [19] and to a wider class of quadrature formulas in [16]. For both convection and convection-diffusion equations, Gauss–Lobatto quadrature formulas lead to the most stable schemes. However, only the Trapezium rule (or two points Gauss–Lobatto) preserves unconditional stability. We have not found in the bibliography any positive statement concerning the classical Lagrange–Galerkin method when using quadrature formulas for quadratic elements. The above results are established by using Fourier analysis for constant coefficients equations and only in the one dimensional case. In [13] the analysis has been generalized to d dimensions for the linear convection equation under some particular conditions.

In the present paper, for ν and $\mathbf{v}$ constant and $\nu \geq 0$, we consider the linear convection (and convection-diffusion) equation with constant coefficients

$$\frac{\partial \phi}{\partial t} - \nu \Delta \phi + \mathbf{v} \cdot \nabla \phi = 0, \qquad (\mathbf{x}, t) \in \Omega \times [0, T]. \tag{5.1}$$

Only the one dimensional equation with strictly positive velocity is treated. Similar results can be obtained for negative velocity. Moreover, our analysis can be generalized to d dimensions as we will establish in Lemma 5.1. A similar result has been proved in [13] for the classical Lagrange–Galerkin method and constant linear convection equation (i.e., $\nu = 0$ in (5.1)).

Remark 5.1. Although we have stated the previous results for $d = 2, 3$, it is easy to prove similar results for the analogous scheme with $d = 1$. The only difference appears when writing boundary conditions, which are not required in Fourier analysis.

Now, for a family of quadrangular meshes of parameter h, $\mathcal{T}_h$, let us introduce the finite element spaces

$$\mathcal{Q}_h^k := \{f \in C^0(\overline{\Omega}), f|_K \in \mathcal{Q}^k \ \forall K \in \mathcal{T}_h\}, \tag{5.2}$$

with $\mathcal{Q}^k$ being the space of polynomials of degree less than or equal to k in each variable separately. Analogously, for triangular meshes, let us introduce the finite element spaces

$$\mathcal{P}_h^k := \{f \in C^0(\overline{\Omega}), f|_K \in \mathcal{P}^k \ \forall K \in \mathcal{T}_h\}, \tag{5.3}$$

with $\mathcal{P}^k$ the space of polynomials of degree less than or equal to k.

5.1. Study of the one dimensional problem. Let us first introduce the notation $T_x[\psi] := \psi(x - v\Delta t)$, for $x \in \Omega \subset \mathbb{R}$ and $\psi : \Omega \to \mathbb{R}$. Similarly, $T_{(x_1,x_2)}[\psi] := \psi(x_1 - v_1\Delta t, x_2 - v_2\Delta t)$, $T_{x_1}[\psi] := \psi(x_1 - v_1\Delta t, x_2)$ and $T_{x_2}[\psi] := \psi(x_1, x_2 - v_2\Delta t)$, for $\psi : (x_1, x_2) \in \Omega_1 \times \Omega_2 \subset \mathbb{R}^2 \to \mathbb{R}$, and $\mathbf{v} = (v_1, v_2)$. In the previous definitions, Ω, Ω_1, and Ω_2 are intervals of $\mathbb{R}$. Thus, scheme (3.2) applied to the one dimensional version of (5.1) has the form

$$\begin{aligned} &\frac{1}{\Delta t}\int_\Omega \phi_h^{n+1}\psi_j dx + \frac{\nu}{2}\int_\Omega \frac{d\phi_h^{n+1}}{dx}\frac{d\psi_j}{dx}dx \\ &\qquad = \frac{1}{\Delta t}\int_\Omega T_x\left[\phi_h^n\right]\psi_j dx - \frac{\nu}{2}\int_\Omega T_x\left[\frac{d\phi_h^n}{dx}\right]\frac{d\psi_j}{dx}dx, \end{aligned} \tag{5.4}$$

where ψ_j is the jth basis function of the chosen one dimensional finite element space.

Notice that, for $\mathbf{v}$ constant, Euler and Runge–Kutta approximations lead to the same scheme.

LEMMA 5.1. *For a linear convection-diffusion equation in d dimensions with constant coefficients, the second order Lagrange–Galerkin method is just a tensor product of one dimensional second order Lagrange–Galerkin methods assuming that the basis functions themselves are tensor products of the corresponding one dimensional basis functions on a grid which is uniform in each coordinate direction.*

Proof. It is a straightforward adaptation of the one given in [13] for the first order Lagrange–Galerkin method in the case $d = 2$, by adding the new terms (see [14]). The general case can be solved by induction on d. ∎

In order to develop Fourier analysis, we recall the definition of the Courant number, $\mu := v\Delta t/h$, and the Peclet number, $\rho := \nu\Delta t/h^2$. Moreover, in Table 5.1 we write some difference operators with their corresponding Fourier transforms.

Once we have stated Lemma 5.1, we consider the one dimensional Lagrange finite elements of degree k (notice that $\mathcal{Q}_h^k = \mathcal{P}_h^k$ in one dimension). In particular, we study cases $k = 1$ and $k = 2$ combined with the following Gauss–Lobatto quadrature formulas:

$$\int_{x_1}^{x_2} \psi(x)\, dx \approx \frac{x_2 - x_1}{2}\left(\psi(x_1) + \psi(x_2)\right) \qquad \text{(Trapezium)}, \tag{5.5}$$

$$\int_{x_1}^{x_2} \psi(x)\, dx \approx \frac{x_2 - x_1}{6}\left(\psi(x_1) + 4\psi\left(\frac{x_1 + x_2}{2}\right) + \psi(x_2)\right) \qquad \text{(Simpson)}. \tag{5.6}$$

TABLE 5.1
Operators and corresponding Fourier transforms, with $s = \sin(\theta/2)$ *and* $c = \cos(\theta/2)$.

Operator	Fourier transform
$\delta^2[U_j] := U_{j+1} - 2U_j + U_{j-1}$	$-4s^2$
$\Delta_0[U_j] = (U_{j+1} - U_{j-1})/2$	$2isc$
$\Delta_-[U_j] = U_j - U_{j-1}$	$2(isc + s^2)$
$E_r[U_i] = U_{i-r}$	$e^{-ir\theta}$

PROPOSITION 5.2. *If scheme* (3.2) *with* $\mathcal{P}_h^1$ *finite elements on a uniform mesh is applied to the one dimensional equation* (5.1) *combined with the two point Gauss–Lobatto quadrature* (5.5) *in all of the terms, then the method is unconditionally stable.*

Proof. First, let us compute the terms appearing in the jth equation. We use the notation $(\phi_h)_j^n := \phi_h(x_j, t_n)$ for meshpoint (x_j, t_n).

- The mass term is approximated by (5.5) in the form

$$\frac{1}{\Delta t}\int_\Omega \phi_h^{n+1}(x)\ \psi_j(x)\ dx \approx \frac{h}{\Delta t}\ E_0\left[(\phi_h)_j^{n+1}\right].$$

- The stiffness term is exactly integrated by (5.5), giving rise to

$$\frac{\nu}{2}\int_\Omega \frac{d\phi_h^{n+1}}{dx}(x)\ \frac{d\psi_j}{dx}(x)\ dx = -\frac{\nu}{2}\ \frac{1}{h}\delta^2\left[(\phi_h)_j^{n+1}\right].$$

- The integral of the second member term associated to the first order characteristics method, approximated by (5.5), depends on μ in the form

$$\frac{1}{\Delta t}\int_\Omega T_x[\phi_h^n(x)]\ \psi_j(x)\ dx \approx \frac{h}{\Delta t}\ \left(E_0 + (m-\mu)\Delta_- E_{m-1}\right)\left[(\phi_h)_j^n\right],$$

  for a positive integer m such that $m - 1 < |\mu| < m$.
- The integral of the second member term associated to the second order characteristics method is

$$-\frac{\nu}{2}\int_\Omega \frac{dT_x[\phi_h^n]}{dx}(x)\ \frac{d\psi_j}{dx}(x)\ dx \approx \frac{\nu}{2}\ \frac{1}{h}\ \Delta_0\Delta_- E_{m-1}\left[(\phi_h)_j^n\right],$$

  for a positive integer m such that $m - 1 < |\mu| < m$.

In order to apply von Neumann analysis the amplification factor is needed. Considering the approximate integrals computed above and replacing $(\phi_h)_j^n$ with $g^n e^{i\theta j}$, the following expression for the amplification factor is obtained when $|\mu| < 1$:

$$g_{\mu,\rho}(\theta) = \frac{1 - 2\mu(s^2 + isc) + 2\rho(is^3c - s^2c^2)}{1 + 2\rho s^2}, \tag{5.7}$$

with $s = \sin(\theta/2)$ and $c = \cos(\theta/2)$. Now, since

$$|g_{\mu,\rho}(\theta)|^2 = \frac{1 + 4s^2\mu(\mu-1) + 4c^2(\rho^2 s^4 - \rho s^2)}{1 + 4\rho^2 s^4 + 4\rho s^4}, \tag{5.8}$$

easy computations lead to $|g_{\mu,\rho}(\theta)| \le 1$ for all $\theta \in [-\pi/2, \pi/2]$. We can proceed analogously for arbitrary μ. Thus, unconditional stability is stated. ∎

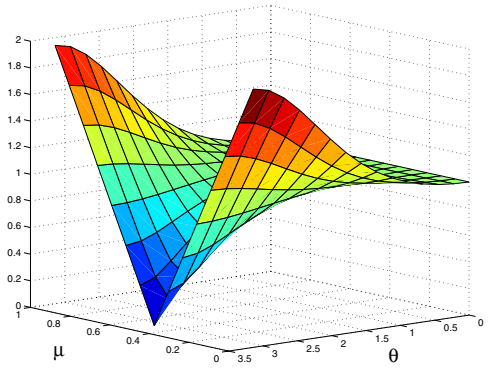

FIG. 5.1. *Modulus of the amplification factor for second order Lagrange–Galerkin method with* $\mathcal{P}_h^1$ *when the exact mass matrix is used.*

Remark 5.2. Note that Proposition 5.2 generalizes results in [13] and [19] for the first order Lagrange–Galerkin method, for which we would have obtained

$$g_{\mu,\rho}(\theta) = \frac{1 - 2\mu(s^2 + isc)}{1 + 4\rho s^2}. \tag{5.9}$$

Remark 5.3. An exact integration of the mass matrix yields

$$I_{m1}^j = \frac{h}{\Delta t}\left(\frac{1}{6}\delta^2\left[(\phi_h)_j^{n+1}\right] - \frac{2}{3}E_0\left[(\phi_h)_j^{n+1}\right]\right),$$

which, combined with the other terms computed in Proposition 5.2, leads to regions of instability. This fact is illustrated in Figure 5.1 by plotting the modulus of the amplification factor as a function of μ and θ for fixed $\rho = 0.19$.

Next, we study quadratic elements for which we have only found the following negative result in the literature (see [13]).

LEMMA 5.3. *The classical Lagrange–Galerkin method applied to the one dimensional version of* (5.1) *with* $\nu = 0$ *and using piecewise quadratic elements has regions of instability if the mass matrix is exactly computed and the right-hand side is evaluated by using a quadrature formula with only interior nodes.*

In the following proposition we prove that the combination of the classical Lagrange–Galerkin method with quadratic elements and Simpson quadrature preserves the unconditional stability of the scheme when applied to the linear convection equation. It is straightforward to prove that a similar result holds for the linear convection-diffusion equation, since the diffusion term is evaluated implicitly.

PROPOSITION 5.4. *If the classical Lagrange–Galerkin scheme with* $\mathcal{P}_h^2$ *finite elements on a uniform mesh is applied to the one dimensional convection equation (*(5.1) *with* $\nu = 0$*) combined with* (5.6) *in all of the terms, then the method is unconditionally stable.*

Proof. First, let us introduce the notation for the basis functions on the reference element: $p_1(x) = 1 - 3x + 2x^2$, $p_2(x) = 4(x - x^2)$, and $p_3(x) = -x + 2x^2$, with the corresponding derivatives denoted by dp_1, dp_2, and dp_3, respectively.

In this case we must take into account that the integrals depend on whether the basis function, ψ_j, corresponds to an interior or to a vertex node. Moreover, for the sake of simplicity, we only consider the case $|\mu| < 1$.

- The mass term provides the approximation $\dfrac{1}{\Delta t}\ \dfrac{2h}{3}E_0\left[(\phi_h)_j^{n+1}\right]$, when j is an interior node, and $\dfrac{1}{\Delta t}\ \dfrac{h}{3}E_0\left[(\phi_h)_j^{n+1}\right]$, otherwise.
- For the second member related to the first order characteristics method we distinguish two cases. First, when j is an interior node and $|\mu| < \frac{1}{2}$ we have

$$\frac{1}{\Delta t}\ \frac{2h}{3}\ \left[(\phi_h)_{j-1}^n\ p_1\left(\frac{1}{2}-\mu\right) + (\phi_h)_j^n\ p_2\left(\frac{1}{2}-\mu\right) + (\phi_h)_{j+1}^n\ p_3\left(\frac{1}{2}-\mu\right)\right];$$

and when $\frac{1}{2} < |\mu| < \frac{3}{2}$, we have

$$\frac{1}{\Delta t}\ \frac{2h}{3}\ \left((\phi_h)_{j-3}^n\, p_1\left(\frac{3}{2}-\mu\right) + (\phi_h)_{j-2}^n\ p_2\left(\frac{3}{2}-\mu\right) + (\phi_h)_{j-1}^n\ p_3\left(\frac{3}{2}-\mu\right)\right).$$

Second, when j is a vertex node and $|\mu| < 1$, we have

$$\frac{1}{\Delta t}\ \frac{h}{3}\ \left((\phi_h)_{j-2}^n\ p_1(1-\mu) + \phi_{j-1}^n\ p_2(1-\mu) + (\phi_h)_j^n\ p_3(1-\mu)\right).$$

The corresponding amplification factors satisfy condition $|g| \leq 1$ (see Figure 5.2), so unconditional stability is reached. □

Remark 5.4. Notice that, when applied to the linear convection equation, the classical scheme and the second order Lagrange–Galerkin scheme (3.2) are exactly the same (assuming the same approximation of the characteristic lines).

In the case of scheme (3.2) combined with quadratic elements and Simpson quadrature formula, only conditional stability has been obtained when $\nu > 0$ (equivalently, when $\rho > 0$). Moreover, the region of instability grows up with the Peclet number and it is very small for low Peclet numbers (see, in Figure 5.3, the norm of the amplification factor as a function of θ and μ for different ρ). Thus, it could be used when convection-dominated features are present. In fact, as Priestley [16] pointed out, "results concerning stability are largely academic in that, for the schemes using the higher order quadratures it can be very hard to generate signs of instability. We know of no examples where, in a physical situation, the quadrature instability has caused any problems." We were also unable to make second order Lagrange–Galerkin method with quadratic elements and Simpson quadrature go unstable. We will present some numerical results in the next section.

5.2. Analysis in d dimensions. Since spaces $\mathcal{Q}_h^k$ satisfy hypotheses of Lemma 5.1, results given in Lemma 5.2 for $k = 1$ and Lemma 5.4 for $k = 2$ can be extended to d dimensions for the corresponding tensor product finite element space and quadrature formulas. In Figure 5.4 nodes of quadrature corresponding to $k = 1$ (left) and $k = 2$ (right) for the two dimensional case are shown.

However, spaces $\mathcal{P}_h^k$ do not satisfy the product property, thus, the theoretical Fourier analysis developed in the present section cannot be applied. Nonetheless, we propose, for the two dimensional case, vertex quadrature for $\mathcal{P}_h^1$ (see Table 5.2) and a seven points quadrature formula for $\mathcal{P}_h^2$ (see Table 5.3). With these formulas we have obtained satisfactory results, as we will illustrate in the next section. Let us notice that, with quadratic elements, also the mid-edges formula has provided good results; however, the mass matrix becomes singular (see [14] for more details).

6. Numerical results. We show numerical results for two numerical examples in two space dimensions. We have tested the above properties of the proposed schemes. We have not found any sign of instability when using scheme (3.2) combined with either $\mathcal{Q}_h^2$ and Simpson rule (only conditionally stable) or $\mathcal{P}_h^2$ and the proposed quadrature formulas (for which, the developed Fourier analysis does not apply).

We notice that, instead of the theoretical $l^\infty(L^2(\Omega))$ norm, we use an approximation denoted by $l^\infty(l^2(\Omega))$, obtained by using quadrature formula in the integrals.

Example 1 (*the rotating Gaussian hill problem*). We choose $\mathbf{A} = \sigma_1 I$, $\mathbf{v} = (-y, x)$, $r = 0$, and $f = 0$ in the domain $\Omega = (-0.5, 0.5) \times (-0.5, 0.5)$, and $T = 2$. Dirichlet boundary conditions and initial condition are chosen so that the solution is

$$\phi(x, y, t) = \frac{\sigma_2}{\sigma_2 + 4\sigma_1 t} \exp\left\{ -\frac{(\bar{x}(t) - x_c)^2 + (\bar{y}(t) - y_c)^2}{\sigma_2 + 4\sigma_1 t} \right\}, \tag{6.1}$$

where $\bar{x} = x \cos t + y \sin t$, $\bar{y} = -x \sin t + y \cos t$, $(x_c, y_c) = (0.25, 0)$, $\sigma_1 = 0.001$, and $\sigma_2 = 0.01$. Moreover, we have artificially imposed $\mathbf{v} = 0$ on Γ (as in [18]) and chosen spatio-temporal meshes in such a way that $X_{RK}^n(\overline{\Omega}) \subset \overline{\Omega}$ $\forall n$. In [18], results for $\mathcal{P}_h^1$ finite elements and a quadrature formula with 10 nodes per triangle are shown.

If Figure 6.1 we represent the computed $l^\infty\left((0,T); l^2(\Omega)\right)$ error obtained versus the number of time steps for two uniform spatial meshes with $N_{dof} = N_{x_1} = N_{x_2}$ degrees of freedom in each direction. We denote by $(\mathcal{LG})_1$ the classical Lagrange–Galerkin scheme and by $(\mathcal{LG})_2$ the second order one given by (3.2). In view of the

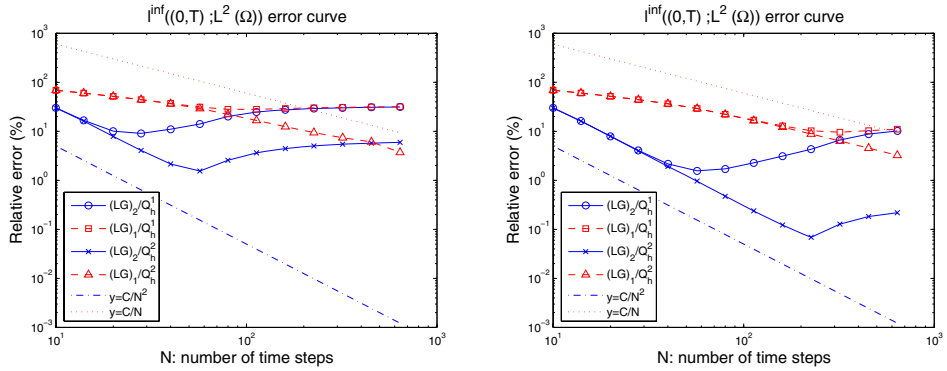

FIG. 6.1. *Computed* $l^\infty((0,T); l^2(\Omega))$ *errors, in log-log scale, for Example* 1 *versus the number of time steps for two fixed spatial meshes: on the left with* $N_{dof} = 67$ *and on the right with* $N_{dof} = 265$.

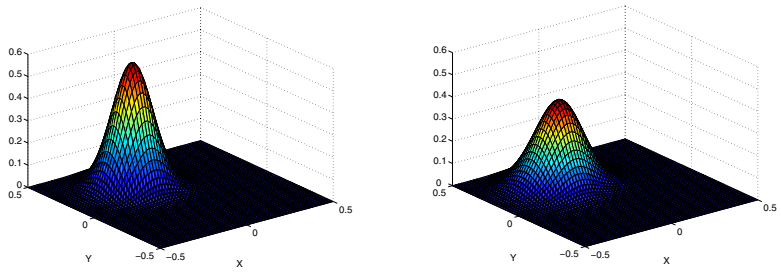


Exact solution. $\mathcal{Q}_h^1$ computed solution.

FIG. 6.2. *Exact and computed solution of Example* 1 *at time* $T = 2$ *with* second order Lagrange–Galerkin method *with* $\mathcal{Q}_h^1$ *and mesh parameters* $h = 0.015625$ *and* $\Delta t = 0.01$.

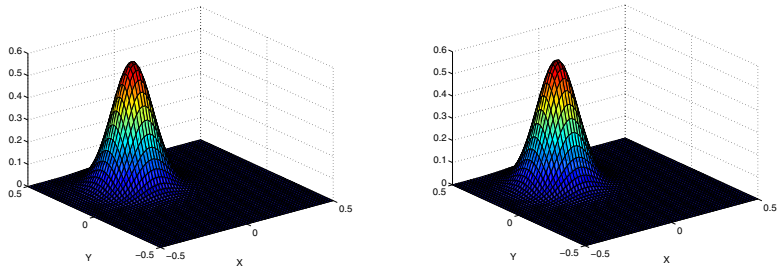
results, we have the following comments:

- The second order Lagrange–Galerkin method proposed ($(\mathcal{LG})_2$) reduces the time error and allows for a lesser number of time steps.
- In both $(\mathcal{LG})_2\mathcal{Q}_h^1$ and $(\mathcal{LG})_2\mathcal{Q}_h^2$, a $O(1/\Delta t)$ term is observed for fixed h.
- Quadratic finite elements lead to a smaller $O(h)$ term than linear ones. Notice that we have used meshes with the same number of degrees of freedom (d.o.f.), or, equivalently, the linear mesh has four times the number of elements of the quadratic mesh. For this reason, and for the same mesh, quadratic elements lead to better algorithms than linear ones.

We can see the exact solution compared to the computed solutions in Figures 6.2 and 6.3, with $\mathcal{Q}_h^1$ and $\mathcal{Q}_h^2$ finite elements, respectively, and mesh parameters $h = 0.015625$ and $\Delta t = 0.01$. Particularly, to be noticed is the reduction of numerical diffusion when using quadratic finite elements.

Example 2 (*a convection-(degenerated) diffusion-reaction problem with variable coefficients*). The spatial domain is $\Omega = (0,1) \times (0,1)$ and $T = 1$. The only nonnull coefficient of the diffusion matrix is $\mathbf{A}_{22}(x_1, x_2) = x_1^2 + 0.5$. Moreover, $\mathbf{v}(x_1, x_2) = (0, x_2)$, $r(x_1, x_2) = x_2$. Neumann boundary conditions are imposed on $\Gamma_{2,-} := \Gamma \cap \{x_2 = 0\}$ (i.e., Robin condition with $\alpha = 0$) and Dirichlet boundary conditions on $\Gamma \setminus \Gamma_{2,-}$. Functions f and g are chosen so that the solution is $\phi(x_1, x_2, t) = e^{x_1+x_2+t}$.

For this problem we want not only to show the performance of scheme (3.2) with different finite element spaces, but also to compare it with the more classical



Exact solution. $\mathcal{Q}_h^2$ computed solution.

FIG. 6.3. *Exact and computed solution of Example* 1 *at time* $T = 2$ *with* second order Lagrange–Galerkin method *with* $\mathcal{Q}_h^2$ *and mesh parameters* $h = 0.015625$ *and* $\Delta t = 0.01$.

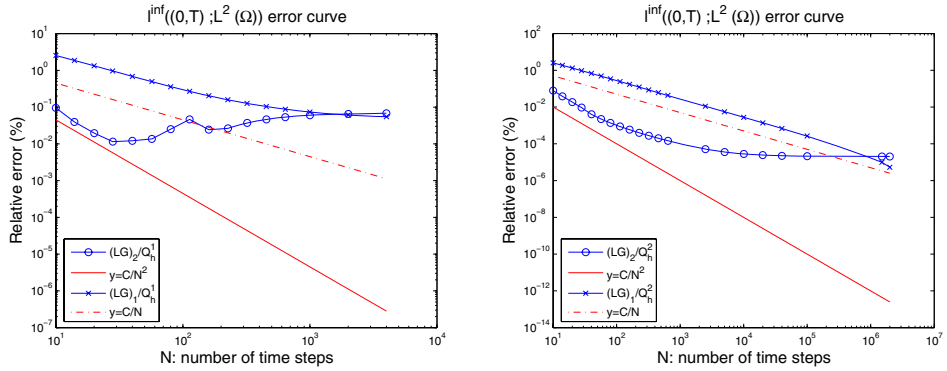


FIG. 6.4. *Computed* $l^\infty((0,T);l^2(\Omega))$ *errors, in log-log scale, for Example* 2 *versus the number of time steps for a fixed spatial mesh. On the left* $\mathcal{Q}_h^1$ *finite elements with* 49 *d.o.f. in each spatial direction. On the right* $\mathcal{Q}_h^2$ *finite elements with* 25 *d.o.f. in each spatial direction.*

characteristics method, when the diffusion, reaction, and source terms are totally implicit in time. In fact, we have observed better errors for $(\mathcal{LG})_2/\mathcal{Q}_h^1$ than for the corresponding first order method. Moreover, for fixed h, a term $1/\Delta t$ is added by the quadrature formula to the error. This behavior is illustrated in Figure 6.4 (left). Notice that an analogous term has already been observed for the $(\mathcal{LG})_1/\mathcal{Q}_h^1$ method in [15, 13].

Similar comments also hold when using $\mathcal{Q}_h^2$ finite elements. However, in this case, it seems that the quadrature formula does not add any error term in the case of the $(\mathcal{LG})_1/\mathcal{Q}_h^2$ method or, at least, a very small time step would be needed to observe it (see Figure 6.4 (right)).

Notice that, at the boundary where the Neumann boundary condition is imposed, the velocity field vanishes, div $\mathbf{v} = 1$, and the term

$$\mathbf{A}(\mathbf{x})\nabla\phi(\mathbf{x},t)\cdot\mathbf{n}|_{\Gamma_{2,-}} = -(x_1^2+0.5)e^{x_1+t}$$

is not null. The necessity of including the $(1+\Delta t \text{ div } \mathbf{v})$ term at the boundary condition is illustrated in Figure 6.5, where for the referred as "Bad $(\mathcal{LG})_2/\mathcal{Q}_h^2$" method we replace this term by 1 (as if div $\mathbf{v} = 0$).

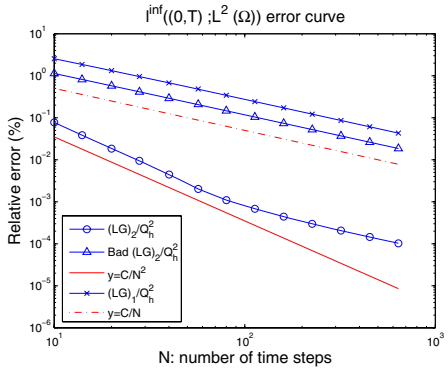

FIG. 6.5. *Computed* $l^\infty((0,T);l^2(\Omega))$ *errors, in log-log scale, for Example* 2 *by using* $\mathcal{Q}_h^2$ *finite elements and different Lagrangian methods.*

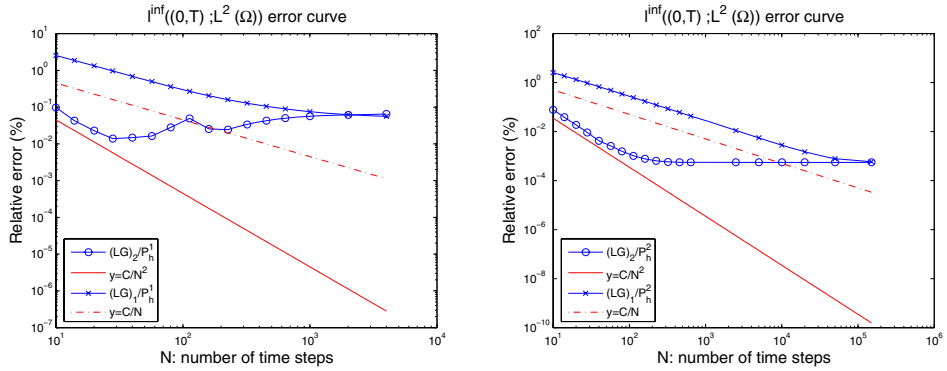

FIG. 6.6. *Computed* $l^\infty((0,T);l^2(\Omega))$ *errors, in log-log scale, for Example* 2 *versus the number of time steps for a fixed spatial mesh. On the left* $\mathcal{P}_h^1$ *FE with* 49 *d.o.f. in each spatial direction. On the right* $\mathcal{P}_h^2$ *with* 25 *d.o.f. in each spatial direction.*

With respect to the computational cost of the algorithms, we remark that first order and second order Lagrange–Galerkin methods take approximately the same time for the same meshes. Moreover, for the same number of degrees of freedom, the $(\mathcal{LG})_2/\mathcal{Q}_h^2$ is quicker than $(\mathcal{LG})_2/\mathcal{Q}_h^1$ due to the different amount of mesh elements (for the same number of nodes, a mesh of linear elements have four times the number of elements of a mesh of quadratic elements).

The conclusion after this second test is that we have obtained better results with $(\mathcal{LG})_2$ than with $(\mathcal{LG})_1$ for similar computing times. Moreover, we have obtained better (accuracy) and quicker (less computing time) results with $(\mathcal{LG})_2/\mathcal{Q}_h^2$ than with $(\mathcal{LG})_2/\mathcal{Q}_h^1$ for the same number of degrees of freedom.

Finally, we have observed an analogous behavior for $\mathcal{P}_h$ finite elements. In Figure 6.6 we show the error versus the number of time steps for fixed spatial meshes.

SPHERICAL INTERFACE DYNAMOS: MATHEMATICAL THEORY, FINITE ELEMENT APPROXIMATION, AND APPLICATION*

KIT HUNG CHAN†, KEKE ZHANG†, AND JUN ZOU‡

Abstract. Stellar magnetic activities such as the 11-year sunspot cycle are the manifestation of magnetohydrodynamic dynamo processes taking place in the deep interiors of stars. This paper is concerned with the mathematical theory and finite element approximation of mean-field spherical dynamos and their astrophysical application. We first investigate the existence, uniqueness, and stability of the dynamo system governed by a set of nonlinear PDEs with discontinuous physical coefficients in spherical geometry, and characterize the system by a saddle-point type variational form. Then we propose a fully discrete finite element approximation to the dynamo system and study its convergence and stability. For the astrophysical application, we perform some fully three-dimensional numerical simulations of a solar interface dynamo using the proposed algorithm, which successfully generates the equatorially propagating dynamo wave with a period of about 11 years similar to that of the Sun.

Key words. spherical interface dynamo, well-posedness, finite element analysis

DOI. 10.1137/050635596

1. Introduction.

Many astrophysical bodies possess intrinsic magnetic fields. The radio signals in connection with Jupiter's magnetic field were first observed more than a half century ago [8] and Jupiter's magnetic field was later measured by the Pioneer spacecraft [1]; the Sun's magnetic field has been observed for a long time [31] and undergone nearly periodic variations with a period of about 11 years. It has been widely accepted that large-scale planetary and stellar magnetic activities represent the manifestation of magnetohydrodynamic dynamo processes taking place in the deep interiors of planets and stars [23, 34, 36, 4]. Though significant progress has been made toward the understanding of quantitative features of stellar magnetic activities, more realistic dynamo simulations in the parameter regime pertaining to stars and planets remain a tough challenge.

Nearly all current stellar and planetary numerical dynamo models employ spectral methods with spherical harmonic functions [35, 19, 22, 7]. The slow Legendre transform and its global nature are computationally inefficient and severely limit the application of spectral methods to general dynamo models, especially to the models with variable physical parameters of space and time. It is becoming increasingly clear that, in order to simulate astrophysical and planetary dynamos using more realistic physical parameters [36], developing other numerically more efficient methods is necessary. The first attempt using finite element methods for numerical dynamo

simulations was made in [11] and proved to be very promising. The current work presents the first mathematical theory and numerical analysis for mean-field spherical dynamos and their application to astrophysical and planetary problems.

Many stars and planets like the Sun and Jupiter are convectively unstable, which drive small-scale turbulent flows as well as large-scale global circulations in their interiors. The small-scale turbulent convective flows are capable of generating large-scale magnetic fields by the complex dynamo processes [24, 9]. A widely accepted theory for the generation of large-scale magnetic fields through the effect of small-scale turbulence in a conducting fluid is called the mean-field dynamo theory [23], in which a key quantity is the turbulent electromotive force defined as

$$\mathcal{E} =< \hat{\mathbf{u}} \times \hat{\mathbf{B}} >\approx \alpha \mathbf{B}, \tag{1.1}$$

where $< . >$ indicates an average in the dynamo domain, $\mathbf{B}$ is the large-scale mean field, $\hat{\mathbf{u}}$ and $\hat{\mathbf{B}}$ denote the fluctuating small-scale velocity and magnetic fields, and α is typically a tensor describing how the small-scale flows generate the large-scale mean field. Furthermore, the small-scale dynamo simulations suggest that the turbulent electromotive force obeys the following relation [9]:

$$\mathcal{E} = \frac{\alpha_0 \, \mathbf{B}}{1 + (\hat{R}_m)^n |\mathbf{B}|^2 / B_{eq}^2}, \tag{1.2}$$

where α_0 is constant, $0 \le n \le 2$ and B_{eq} is the stellar equipartition field and $\hat{R}_m$ is the magnetic Reynolds number measuring the magnitude of the small-scale flow. The factor $(1 + (\hat{R}_m)^n |\mathbf{B}/B_{eq}|^2)$ represents the nonlinear process of alpha quenching (the catastrophic quenching) which saturates the growing magnetic field. It should be noted that the $\hat{R}_m$-dependent quenching expression should be regarded as a simplified steady state expression for the nonlinear dynamo [4]. On the basis of the quenching relation (1.2), one can investigate the dynamo process of large-scale stellar magnetic fields without being complicated by the dynamic effect such as Lorentz forces. In consequence, (1.2) has been frequently used in the numerical study of astrophysical dynamos [26].

In the present study, we consider a general nonlinear kinematic dynamo for stars and planets consisting of three major zones in spherical geometry; see Figure 1. An inner radiative sphere Ω_1 of radius r_1, with magnetic diffusivity $\lambda_1(\mathbf{x})$, rotates uniformly. Magnetic field $\mathbf{B}_1$ cannot be generated in the radiative region by dynamo action. On the top of the radiative core, there exists a turbulent convection zone Ω_2, $r_1 \le r \le r_2$, in which thermal instabilities drive global circulations $\mathbf{u}$ and small-scale turbulent flows $\hat{\mathbf{u}}$. Note that the effect of the small-scale turbulence in the convection zone is described by α. In the current mean-field dynamo model, we shall use a conventional quenching formula by ignoring the $\hat{R}_m$-dependence in the quenching expression. The magnetic diffusivity in the convection zone is denoted by λ_2 while the nonlinear alpha quenching is assumed to be of the form

$$\alpha = \frac{\alpha_0 f(\mathbf{x}, t)}{1 + \sigma |\mathbf{B}/B_{eq}|^2}, \tag{1.3}$$

where $f(\mathbf{x}, t)$ is a model-oriented function, α_0 and σ are constant parameters, and $\mathbf{B}$ is the generated large-scale magnetic field in the convection zone. The outer region Ω_3, $r_2 \le r \le r_3$, exterior to the convection zone is assumed to be nearly electrically

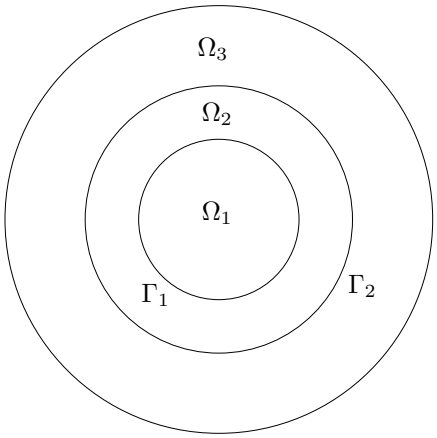

FIG. 1. *Domain Ω, with its inner core Ω_1, convection zone Ω_2, and exterior region Ω_3.*

insulating. We nondimensionalize length by the thickness of the convection zone $d = (r_2 - r_1)$, the magnetic field by the equipartition field B_{eq}, and time by the magnetic diffusion time d^2/λ_2 of the convection zone. This leads to the three sets of dimensionless equations for the three zones in a magnetic star. For the convection fluid shell zone, we have

$$\frac{\partial \mathbf{B}_2}{\partial t} + \nabla \times (\nabla \times \mathbf{B}_2) = R_\alpha \nabla \times \Big(\frac{f(\mathbf{x},t)}{1+\sigma|\mathbf{B}_2|^2} \mathbf{B}_2 \Big) + R_m \nabla \times (\mathbf{u} \times \mathbf{B}_2) \quad \text{in} \quad \Omega_2 \times (0,T) \tag{1.4}$$

$$\nabla \cdot \mathbf{B}_2 = 0 \quad \text{in} \quad \Omega_2 \times (0,T), \tag{1.5}$$

where R_α is a dynamo parameter in connection with the generation process of small-scale turbulence $\hat{\mathbf{u}}$ and R_m is the magnetic Reynolds number associated with the global circulation. For dynamo action to occur, either R_α or R_m must be sufficiently large. The diffusion of the magnetic field $\mathbf{B}_1$ in the inner radiative core with a magnetic diffusivity β_1 can be described by

$$\frac{\partial \mathbf{B}_1}{\partial t} + \nabla \times (\beta_1(\mathbf{x}) \nabla \times \mathbf{B}_1) = 0 \quad \text{in} \quad \Omega_1 \times (0,T), \tag{1.6}$$

$$\nabla \cdot \mathbf{B}_1 = 0 \quad \text{in} \quad \Omega_1 \times (0,T)\,. \tag{1.7}$$

The outer exterior region is usually nearly electrically insulating and governed by

$$\frac{\partial \mathbf{B}_3}{\partial t} + \nabla \times (\beta_3(\mathbf{x}) \nabla \times \mathbf{B}_3) = 0 \quad \text{in} \quad \Omega_3 \times (0,T), \tag{1.8}$$

$$\nabla \cdot \mathbf{B}_3 = 0 \quad \text{in} \quad \Omega_3 \times (0,T)\,, \tag{1.9}$$

where $\beta_3(\mathbf{x})$ is the magnetic diffusivity of the zone.

The above model system will be complemented with the initial conditions

$$\mathbf{B}(\mathbf{x},0) = \mathbf{B}_0(\mathbf{x}) \quad \text{in} \quad \Omega \tag{1.10}$$

and the boundary conditions

$$(\beta_3(\mathbf{x})\nabla \times \mathbf{B}_3) \times \mathbf{n} = 0, \quad \mathbf{B}_3 \cdot \mathbf{n} = 0 \quad \text{on} \quad \partial\Omega \times (0,T), \tag{1.11}$$

here and in what follows, $\mathbf{n}$ stands for the unit outward normal to the boundary $\partial\Omega$ of the entire physical domain Ω, which consists of the inner core Ω_1, the convection zone Ω_2, and the outer exterior region Ω_3. It should be mentioned that the shear near the solar surface, the effect of which is neglected in our interface solar dynamo model in section 6, may play an important role [3].

We shall use Γ_1 and Γ_2 to denote, respectively, the interface between the inner core and outer convection zone and between the convection zone and the outer exterior; see Figure 1. Since the magnetic diffusivity $\beta(\mathbf{x})$ has jumps across the interfaces Γ_1 and Γ_2 the magnetic field must fulfill some physical interface conditions. We shall take the following standard physical jump conditions adopted in the geodynamo modelling across the interfaces:

$$[(\beta(\mathbf{x})\,\nabla \times \mathbf{B}) \times \mathbf{n}] = 0\,, \quad [\mathbf{B}] = 0 \quad \text{on} \quad (\Gamma_1 \cup \Gamma_2) \times (0,T), \tag{1.12}$$

here and in what follows we use $[\mathbf{A}]$ to denote the quantity of jumps of $\mathbf{A}$ across the interfaces, and $\mathbf{n}$ is the outward normal of $\partial\Omega_2$.

Physically speaking, function $f(\mathbf{x},t)$ and the convective flow $\mathbf{u}$ in (1.4) appear only in the fluid shell region. We shall assume that the velocity $\mathbf{u}$ is nonslip on the boundaries of the fluid shell, i.e., both $f(\mathbf{x},t)$ and $\mathbf{u}$ vanish on Γ_1 and Γ_2. Then by viewing $f(\mathbf{x},t)$ and $\mathbf{u}$ to be extended by zero onto the whole physical domain Ω, we can unify (1.4)–(1.5), (1.6)–(1.7), and (1.8)–(1.9) in three regions Ω_1, Ω_2, and Ω_3 as the following mean-field dynamo system:

$$\begin{aligned} \frac{\partial \mathbf{B}}{\partial t} + \nabla \times (\beta(\mathbf{x})\nabla \times \mathbf{B}) &= R_\alpha \nabla \times \Big(\frac{f(\mathbf{x},t)}{1+\sigma|\mathbf{B}|^2}\mathbf{B}\Big) \\ &\quad + R_m \nabla \times (\mathbf{u} \times \mathbf{B}) \quad \text{in} \quad \Omega \times (0,T) \end{aligned} \tag{1.13}$$

$$\nabla \cdot \mathbf{B} = 0 \quad \text{in} \quad \Omega \times (0,T), \tag{1.14}$$

where $\beta(\mathbf{x})$ represents the magnetic diffusivity $\beta_1(\mathbf{x})$, $\beta_2(\mathbf{x})$, and $\beta_3(\mathbf{x})$ in Ω_1, Ω_2, and Ω_3,respectively, with $\beta_2(\mathbf{x})$ normalized to be 1, so $\beta(\mathbf{x})$ is piecewise smooth and may have large jumps across the interfaces.

The rest of this paper is arranged as follows. Section 2 addresses the well-posedness of the mean-field dynamo system, which is then characterized in terms of a saddle-point type formulation in section 3 for the convenient approximation by finite element methods. The existing convergence theory on saddle-point systems is first generalized in section 4, and a fully discrete finite element method is then proposed and the stability and unique existence are studied. The convergence of the fully discrete scheme is established in section 5, for which the key steps are the introduction of a discrete projection operator and a modification of the Scott–Zhang operator as well as the derivations of their approximation error estimates for piecewise smooth functions. The application of the proposed numerical method to a solar interface dynamo is carried out in section 6. Finally some concluding remarks are given in section 7 to summarize the main contributions of the paper.

2. Well-posedness of the mean-field dynamo system. In this section, we shall investigate the existence, uniqueness, and stability of the solutions to the mean-field dynamo system (1.13)–(1.14) with the initial-boundary conditions (1.10)–(1.11)

and the interface conditions (1.12). Due to space limitations, some proof details may be omitted from time to time throughout the paper but can be found in [10].

2.1. Preliminaries. The most frequently used spaces in the subsequent analysis are the following two Sobolev spaces:

$$H(\mathbf{curl};\Omega) = \left\{\mathbf{A} \in L^2(\Omega)^3; \quad \mathbf{curl}\mathbf{A} \in L^2(\Omega)^3\right\},$$
$$H(\mathrm{div};\Omega) = \left\{\mathbf{A} \in L^2(\Omega)^3; \quad \mathrm{div}\mathbf{A} \in L^2(\Omega)\right\},$$

as well as their subspaces

$$H_0(\mathbf{curl};\Omega) = \left\{\mathbf{A} \in L^2(\Omega)^3; \quad \mathbf{curl}\mathbf{A} \in L^2(\Omega)^3,\ \mathbf{A}\times\mathbf{n} = 0 \text{ on } \partial\Omega\right\},$$
$$H_0(\mathrm{div};\Omega) = \left\{\mathbf{A} \in L^2(\Omega)^3, \quad \mathrm{div}\mathbf{A} \in L^2(\Omega),\ \mathbf{A}\cdot\mathbf{n} = 0 \text{ on } \partial\Omega\right\},$$

equipped with the norms

$$\|\mathbf{A}\|_{H(\mathbf{curl};\Omega)} = \left\{\|\mathbf{A}\|^2 + \|\nabla\times\mathbf{A}\|^2\right\}^{\frac{1}{2}}; \quad \|\mathbf{A}\|_{H(\mathrm{div};\Omega)} = \left\{\|\mathbf{A}\|^2 + \|\nabla\cdot\mathbf{A}\|^2\right\}^{\frac{1}{2}}.$$

In the case that the magnetic field is continuous across the interfaces, the intersection of the spaces $H(\mathbf{curl};\Omega)$ and $H(\mathrm{div};\Omega)$ is the natural Sobolev space to be adopted:

$$H(\mathbf{curl},\mathrm{div};\Omega) = \left\{\mathbf{A} \in L^2(\Omega)^3; \quad \mathbf{curl}\mathbf{A} \in L^2(\Omega)^3,\ \mathrm{div}\mathbf{A} \in L^2(\Omega)\right\},$$

$$H_0(\mathbf{curl},\mathrm{div};\Omega) = \left\{\mathbf{A} \in H(\mathbf{curl},\mathrm{div};\Omega); \quad \mathbf{A}\cdot\mathbf{n} = 0 \text{ on } \partial\Omega\right\},$$

both equipped with the norm

$$\|\mathbf{A}\|_{H(\mathbf{curl},\mathrm{div};\Omega)} = \left\{\|\mathbf{A}\|^2 + \|\nabla\times\mathbf{A}\|^2 + \|\nabla\cdot\mathbf{A}\|^2\right\}^{\frac{1}{2}}.$$

As the spaces $H(\mathbf{curl},\mathrm{div};\Omega)$ and $H_0(\mathbf{curl},\mathrm{div};\Omega)$ will be frequently used, we shall write

$$H = H(\mathbf{curl},\mathrm{div};\Omega), \quad H_0 = H_0(\mathbf{curl},\mathrm{div};\Omega).$$

To treat the constraint equation $\nabla\cdot\mathbf{B} = 0$, we shall need the following subspace of $H_0(\mathbf{curl},\mathrm{div};\Omega)$:

$$V = \left\{\mathbf{A} \in H_0(\mathbf{curl},\mathrm{div};\Omega); \quad \nabla\cdot\mathbf{A} = 0 \text{ in } \Omega\right\}.$$

Due to the smoothness of the spherical domain Ω, it is known that the space $H_0(\mathbf{curl},\mathrm{div};\Omega)$ is equivalent to the usual Sobolev space $H^1(\Omega)^3$ (see, e.g., [18]). Therefore the Sobolev space V can also be written equivalently as

$$V = \left\{\mathbf{A} \in H^1(\Omega)^3; \quad \nabla\cdot\mathbf{A} = 0 \text{ in } \Omega,\ \mathbf{A}\cdot\mathbf{n} = 0 \text{ on } \partial\Omega\right\}, \tag{2.1}$$

and the following equivalence holds:

$$\|\mathbf{A}\|_H^2 = \|\mathbf{A}\|^2 + \|\nabla \times \mathbf{A}\|^2 + \|\nabla \cdot \mathbf{A}\| \eqsim \|\mathbf{A}\|_1^2 \quad \forall\, \mathbf{A} \in H_0\,. \tag{2.2}$$

In the previous statement and what follows, $\|\cdot\|_{s,O}$ are always used to stand for the norm in Sobolev space $H^s(O)$ or $H^s(O)^3$ for any real number $s \geq 0$ and open bounded domain O. We will simply write $\|\cdot\|_s$ when $O = \Omega$ and $\|\cdot\|$ when $s = 0$. The notation $(\cdot,\cdot)$ is used for the scalar product in $L^2(\Omega)$ or $L^2(\Omega)^3$, while $\langle\cdot,\cdot\rangle$ is used to denote the dual pairing between any two Hilbert spaces, and it is the extension of the scalar product $(\cdot,\cdot)$. For a nonnegative function $\beta(x)$, we will often use the notation $\|\cdot\|_\beta = (\beta\cdot,\cdot)^{1/2}$. We may also write $Q_T = \Omega\times(0,T)$ sometimes. In various estimates, we shall frequently use C to stand for a generic constant that is independent of the mesh size h, time stepsize τ, and relevant functions involved.

We end this subsection with a collection of some auxiliary results and formulae for later use.

(1) The space V in (2.1) is a closed subspace of $H^1(\Omega)^3$; see [10].

(2) Young's inequality:

$$a\,b \leq \varepsilon a^2 + \frac{1}{4\varepsilon} b^2 \quad \forall\, a, b \in R^1 \ \text{ and } \varepsilon > 0\,.$$

(3) Integration by parts formula which hold for $\mathbf{B} \in H(\mathbf{curl};\Omega)$, $\mathbf{A} \in H^1(\Omega)^3$ and $q \in H^1(\Omega)$:

$$\int_\Omega (\nabla \times \mathbf{B}) \cdot \mathbf{A} d\mathbf{x} = \int_\Omega \mathbf{B} \cdot (\nabla \times \mathbf{A}) d\mathbf{x} - \int_{\partial\Omega} (\mathbf{B} \times \mathbf{n}) \cdot \mathbf{A} ds, \tag{2.3}$$

$$\int_\Omega (\nabla \cdot \mathbf{B}) q d\mathbf{x} = -\int_\Omega \mathbf{B} \cdot \nabla q d\mathbf{x} + \int_{\partial\Omega} (\mathbf{B} \cdot \mathbf{n}) q ds\,. \tag{2.4}$$

(4) Compact embedding lemma [32]. Suppose that X, B, and Y are Banach spaces satisfying $X \subset B \subset Y$ with compact embedding $X \to B$. Then for any $q > 1$, each set bounded both in $L^q(0,T;X)$ and $W^{1,q}(0,T;Y)$ is relatively compact in the space $L^q(0,T;B)$.

(5) Gronwall's inequality. Suppose $h(t)$, $g(t)$ are two nonnegative and square integrable functions on [a, b], $c(t)$ is nondecreasing, and

$$g(t) \leq c(t) + \int_a^t h(s)\, g(s) ds \quad \forall\, t \in [a,b]\,,$$

then the following holds

$$g(t) \leq c(t) \exp\Big(\int_a^t h(s) ds\Big) \quad \forall\, t \in [a,b].$$

2.2. Well-posedness of the mean-field dynamo system. This section is mainly devoted to the well-posedness of the dynamo system (1.4)–(1.12). Due to the jumps in the coefficients, it is not desirable for the system to have classical type solutions. Instead, we shall seek the weak solutions to the mean-field system.

Let us first derive the variational formulation. By multiplying both sides of (1.13) by an $\mathbf{A} \in V$, integrating over Ω and making use of formula (2.3) we obtain

$$\int_\Omega \frac{\partial \mathbf{B}}{\partial t}\cdot \mathbf{A}d\mathbf{x} + \sum_{i=1}^3 \int_{\Omega_i} (\beta\,\nabla\times\mathbf{B})\cdot(\nabla\times\mathbf{A})d\mathbf{x} - \sum_{i=1}^3 \int_{\partial\Omega_i} (\beta\,\nabla\times\mathbf{B})\times\mathbf{n}_i\cdot\mathbf{A}ds$$
$$= R_\alpha \sum_{i=1}^3 \int_{\Omega_i} \Big(\frac{f}{1+\sigma|\mathbf{B}|^2}\mathbf{B}\Big)\cdot(\nabla\times\mathbf{A})d\mathbf{x} - R_\alpha \sum_{i=1}^3 \int_{\partial\Omega_i} \Big(\frac{f}{1+\sigma|\mathbf{B}|^2}\mathbf{B}\times\mathbf{n}_i\Big)\cdot\mathbf{A}ds$$
$$+ R_m \sum_{i=1}^3 \int_{\Omega_i} (\mathbf{u}\times\mathbf{B})\cdot(\nabla\times\mathbf{A})d\mathbf{x} - R_m \sum_{i=1}^3 \int_{\partial\Omega_i} (\mathbf{u}\times\mathbf{B})\times\mathbf{n}_i\cdot\mathbf{A}ds\,.$$

Using the boundary and interface conditions (1.11) and (1.12), we deduce the variational formulation for the dynamo system (1.10)–(1.14).

Find $\mathbf{B}(t)\in V$ such that $\mathbf{B}(0)=\mathbf{B}_0$ and for almost all $t\in(0,T)$,

$$\begin{aligned}&(\mathbf{B}'(t),\mathbf{A}) + (\beta\,\nabla\times\mathbf{B}(t),\nabla\times\mathbf{A})\\ &= R_\alpha\Big(\frac{f(t)}{1+\sigma|\mathbf{B}|^2}\mathbf{B}(t),\nabla\times\mathbf{A}\Big) + R_m(\mathbf{u}(t)\times\mathbf{B}(t),\nabla\times\mathbf{A}) \quad \forall\,\mathbf{A}\in V,\end{aligned} \tag{2.5}$$

here and in what follows, functions of $\mathbf{x}$ and t may be written as functions of t only for simplicity.

The following theorem summarizes the well-posedness of the system (2.5).

THEOREM 2.1. *Assume that $\mathbf{B}_0\in V$, $f\in H^1(0,T;L^\infty(\Omega))$ and $\mathbf{u}\in H^1(0,T;L^\infty(\Omega))$. Then there exists a unique solution $\mathbf{B}$ to the system (2.5) with the regularity*

$$\mathbf{B}\in L^\infty(0,T;V)\cap H^1(0,T;L^2(\Omega)), \tag{2.6}$$

and the solution $\mathbf{B}$ is stable with the following stability estimate:

$$\begin{aligned}&\|\mathbf{B}\|_{L^\infty(0,T;V)} + \|\mathbf{B}\|_{H^1(0,T;L^2(\Omega)^3)}\\ &\le C\,(\|\nabla\times\mathbf{B}(0)\|^2 + \|\mathbf{B}(0)\|^2)\max_{0\le t\le T}(\|f(t)\|^2_{L^\infty(\Omega)} + \|\mathbf{u}(t)\|^2_{L^\infty(\Omega)})\\ &\quad\cdot\exp\Big(C\int_0^T\Big\{\|f(t)\|^2_{L^\infty(\Omega)} + \|f'(t)\|^2_{L^\infty(\Omega)} + \|\mathbf{u}(t)\|^2_{L^\infty(\Omega)} + \|\mathbf{u}'(t)\|^2_{L^\infty(\Omega)}\Big\}dt\Big),\end{aligned} \tag{2.7}$$

where the constant C depends only on the magnetic diffusivity coefficient $\beta(\mathbf{x})$.

Proof. We shall only outline the proof and refer to [10] for the details. As $H^1(\Omega)$ is separable, we know that V is separable. Let $\{\mathbf{w}_k\}_{k=1}^\infty$ be a base of V, and

$$V_m = \{\mathbf{w}_1,\mathbf{w}_2,\dots,\mathbf{w}_m\}\,,\quad m=1,2,3,\dots.$$

Choose $\psi_m\in V_m$ such that $\psi_m\to\mathbf{B}_0$ in V. Then we consider the following approximation of the problem (2.5): Find $\mathbf{B}_m(t)\in V_m$ such that $\mathbf{B}_m(0)=\psi_m$ and for any $\mathbf{A}\in V_m$,

$$\begin{aligned}&(\mathbf{B}_m'(t),\mathbf{A}) + (\beta\nabla\times\mathbf{B}_m(t),\nabla\times\mathbf{A})\\ &= R_\alpha\left(\frac{f}{1+\sigma|\mathbf{B}_m|^2}\mathbf{B}_m(t),\nabla\times\mathbf{A}\right) + R_m(\mathbf{u}\times\mathbf{B}_m(t),\nabla\times\mathbf{A})\,.\end{aligned} \tag{2.8}$$

We claim that the sequence $\{\mathbf{B}_m(t)\}$ is well defined. To see this, we write

$$\mathbf{B}_m(t) = \sum_{j=1}^m \alpha_{j,m}(t)\mathbf{w}_j,\quad \psi_m = \sum_{j=1}^m \gamma_{j,m}\mathbf{w}_j$$

and substitute into (2.8) to get

$$\mathcal{M}\frac{d\alpha_m}{dt} = \mathcal{G}(\alpha_m, t) \quad \text{with} \quad \alpha_m(0) = \gamma_m\,, \tag{2.9}$$

where $\mathcal{M} = (m_{ij})$ with $m_{ij} = (\mathbf{w}_j, \mathbf{w}_i)$, $\mathcal{G}(\alpha_m, t)$ is a vector-valued function of α_m and t, and

$$\gamma_m(t) = (\gamma_{1,m}, \gamma_{2,m}, \ldots, \gamma_{m,m})^t, \quad \alpha_m(t) = (\alpha_{1,m}, \alpha_{2,m}, \ldots, \alpha_{m,m})^t.$$

As $\{\mathbf{w}_m\}$ is linearly independent, the matrix $\mathcal{M}$ is symmetric and positive definite, so it is invertible. Then using the Lipschitz continuity of $\mathcal{G}(\alpha_m, t)$ with respect to α_m, and our subsequent a priori estimates on the solutions to the system (2.8) that ensures the boundedness of $\mathbf{B}_m(t)$ independent of m, one can show (cf. [10]) that the solutions $\{\mathbf{B}_m(t)\}$ of the system (2.8) is well defined in $[0, T]$.

Next, we derive some a priori estimates on the solution to (2.8). By taking $\mathbf{A} = \mathbf{B}_m(t)$ in (2.8), then integrating over $(0, t)$ and using the Cauchy–Schwartz and Gronwall inequality, one can obtain

$$\begin{aligned} &\|\mathbf{B}_m\|^2_{L^\infty(0,T;L^2(\Omega)^3)} + \|\nabla\times\mathbf{B}_m\|^2_{L^2(0,T;L^2(\Omega))} \\ &\le \|\mathbf{B}_m(0)\|_0^2\, \exp\Big(C\int_0^T \Big\{\|f(t)\|^2_{L^\infty(\Omega)} + \|\mathbf{u}(t)|^2_{L^\infty(\Omega)}\Big\}dt\Big)\,. \end{aligned} \tag{2.10}$$

On the other hand, letting $\mathbf{A} = \mathbf{B}'_m(t)$ in (2.8), then integrating over $(0, t)$, applying the integration by parts and the Gronwall's inequality, we have

$$\begin{aligned} &\|\mathbf{B}'_m\|^2_{L^2(Q_T)} + \|\nabla\times\mathbf{B}_m\|^2_{L^\infty(0,T;L^2(\Omega)^3)} \\ &\le \|\mathbf{B}(0)\|^2\, \exp\Big(C\Big\{\|f\|^2_{L^\infty(Q_T)} + \|\mathbf{u}|^2_{L^\infty(Q_T)}\Big\}\Big) \\ &\quad\cdot \exp\Big(C\int_0^T \Big\{\|f(t)\|^2_{L^\infty(\Omega)} + \|f'(t)\|^2_{L^\infty(\Omega)} + \|\mathbf{u}(t)\|^2_{L^\infty(\Omega)} + \|\mathbf{u}'(t)\|^2_{L^\infty(\Omega)}\Big\}dt\Big)\,. \end{aligned} \tag{2.11}$$

Using the estimates (2.10)–(2.11), we can extract a subsequence $\{\mathbf{B}_n\}$ from $\{\mathbf{B}_m\}$ such that

$$\mathbf{B}_n \to \mathbf{B} \text{ weakly star in } L^\infty(0,T;V); \quad \mathbf{B}'_n \to \tilde{\mathbf{B}} \text{ weakly in } L^2(0,T;L^2(\Omega)^3)\,. \tag{2.12}$$

By the compact embedding lemma of subsection 2.1, we know that $H^1(0,T;V') \cap L^2(0,T;V)$ is compactly embedded in $L^2(0,T;L^2(\Omega)^3)$, so we have

$$\mathbf{B}_n \to \mathbf{B} \quad \text{in } L^2(0,T;L^2(\Omega)^3). \tag{2.13}$$

We can show that this $\mathbf{B}(t)$ solves the system (2.5). Therefore (2.5) has at least one solution $\mathbf{B}$, which has the regularity (2.6). ∎

3. Characterization of the dynamo system in terms of a saddle-point type problem. The Sobolev space V in the weak formulation (2.5) involves the solenoidal functions, and it is well known that the solenoidal conditions are difficult to enforce in finite element spaces, especially in three dimensions. Hence the variational formulation (2.5) is inconvenient and ineffective for the use in a fully discrete finite element approximation. Instead, we shall transform the variational problem (2.5) into an equivalent saddle-point type system, which can be more easily adopted for its approximations by finite element methods.

3.1. Characterization of solenoidal functions. Let $\mathcal{D}(\Omega)$ be the set of all infinitely differentiable functions with compact supports in Ω, and $\mathcal{V}$ be the subspace of $\mathcal{D}$ with all solenoidal functions:

$$\mathcal{V} = \Big\{ \mathbf{w} \in \mathcal{D}(\Omega);\ \operatorname{div} \mathbf{w} = 0 \text{ in } \Omega \Big\}.$$

We start with the characterization of the gradient of a distribution. For any distribution function p in Ω, written as $p \in \mathcal{D}'(\Omega)$, it is easy to verify that

$$\langle \nabla p, \mathbf{w} \rangle = \sum_{i=1}^{n} \langle \partial_{x_i} p, w_i \rangle = -\sum_{i=1}^{n} \langle p, \partial_{x_i} w_i \rangle = \langle p, \nabla \cdot \mathbf{w} \rangle = 0 \quad \forall\, \mathbf{w} \in \mathcal{V}.$$

That is, ∇p lies in the polar set of $\mathcal{V}$. The following lemma indicates that the converse of this property is also true (cf. [18]).

LEMMA 3.1. *Let Ω be a bounded Lipschitz domain in R^n and $\mathbf{f} = (f_1, f_2, \ldots, f_n)^t$ with $f_i \in \mathcal{D}'(\Omega)$. Then $\mathbf{f} = \nabla p$ for some $p \in \mathcal{D}'(\Omega)$ if and only if*

$$\langle \mathbf{f}, \mathbf{w} \rangle = 0 \quad \forall\, \mathbf{w} \in \mathcal{V}.$$

If $\partial_{x_i} p \in H^{-1}(\Omega)$, then $p \in L^2(\Omega)$ and

$$\|p\|_{L^2(\Omega)/R} \le C(\Omega) \|\nabla p\|_{H^{-1}(\Omega)}.$$

Moreover, if $\partial_{x_i} p \in L^2(\Omega)$, then $p, \nabla p \in L^2(\Omega)$ and

$$\|p\|_{L^2(\Omega)/R} \le C(\Omega) \|\nabla p\|_{L^2(\Omega)}.$$

3.2. Saddle-point formulation of the mean-field dynamo system. In this subsection, we are going to show that the solution $\mathbf{B}(t)$ of the system (2.5) also solves the following saddle-point type problem for some $p \in L^2(0,T; L^2(\Omega))$:

$$\begin{aligned} &\frac{\partial \mathbf{B}}{\partial t} + \nabla \times (\beta(\mathbf{x})\, \nabla \times \mathbf{B}) + \nabla p \\ &= R_\alpha \nabla \times \Big(\frac{f(\mathbf{x},t)}{1+\sigma|\mathbf{B}|^2} \mathbf{B} \Big) + R_m \nabla \times (\mathbf{u} \times \mathbf{B}) \quad \text{in } \Omega \times (0,T); \end{aligned} \tag{3.1}$$

$$\nabla \cdot \mathbf{B} = 0 \quad \text{in} \quad \Omega \times (0,T), \tag{3.2}$$

where a pressure-like term, namely a Lagrange multiplier p, is introduced in (3.1) to ensure that the divergence condition (3.2) is satisfied. This formulation is done purely for the convenience of the subsequent construction of some stable and convergent finite element approximations; the approach is widely employed in numerical solutions of Maxwell equations (see, e.g., [2]).

To do so, we introduce

$$\tilde{\mathbf{B}}(t) = \int_0^t \mathbf{B}(t) dt, \quad \tilde{\mathbf{F}}(t) = \int_0^t \frac{f}{1+\sigma|\mathbf{B}|^2} \mathbf{B}(t) dt, \quad \tilde{\mathbf{U}}(t) = \int_0^t \mathbf{u}(t) \times \mathbf{B}(t) dt\,.$$

Using the regularity of $\mathbf{B}(t)$ from Theorem 2.1 we have

$$\tilde{\mathbf{B}}(t) \in H^1(0,T;V), \quad \tilde{\mathbf{F}}(t) \in H^1(0,T; L^2(\Omega)^3), \quad \tilde{\mathbf{U}}(t) \in H^1(0,T;V)\,.$$

Clearly, both $\tilde{\mathbf{B}}(t)$ and $\tilde{\mathbf{F}}(t)$ are absolutely continuous with respect to t as $\mathbf{B}(t)$ and $f\,\mathbf{B}(t)/(1+\sigma|\mathbf{B}|^2)$ are integrable in $L^1(0,T)$, and we have

$$\tilde{\mathbf{B}}'(t)=\mathbf{B}(t),\quad \tilde{\mathbf{F}}'(t)=\frac{f}{1+\sigma|\mathbf{B}|^2}\mathbf{B}(t),\quad \tilde{\mathbf{U}}'(t)=\mathbf{u}\times\mathbf{B}(t)\,.$$

Now, integrating both sides of (2.5), we obtain for all $t\in[0,T]$ and $\mathbf{A}\in V$ that

$$(\mathbf{B}(t)-\mathbf{B}_0,\mathbf{A})+(\beta\nabla\times\tilde{\mathbf{B}}(t),\nabla\times\mathbf{A})=R_\alpha(\tilde{\mathbf{F}}(t),\nabla\times\mathbf{A})+R_m(\tilde{\mathbf{U}},\nabla\times\mathbf{A})\,. \tag{3.3}$$

We remark that this equation is defined for every $t\in[0,T]$ as $\mathbf{B}(t)$, $\tilde{\mathbf{B}}(t)$, and $\tilde{\mathbf{F}}(t)$ are all continuous with respect to t. This is why we do not treat the system (2.5) directly but instead its integrated form.

For all $t\in[0,T]$, (3.3) can be written as

$$\langle\mathbf{B}(t)-\mathbf{B}_0+\nabla\times(\beta\nabla\times\tilde{\mathbf{B}}(t))-R_\alpha\nabla\times\tilde{\mathbf{F}}(t)-R_m\nabla\times\tilde{\mathbf{U}}(t),\mathbf{A}\rangle=0\quad\forall\,\mathbf{A}\in V,$$

this with Lemma 3.1 indicates that there exists a $P(t)\in L^2(\Omega)$, for every $t\in[0,T]$, such that

$$\mathbf{B}(t)-\mathbf{B}_0+\nabla\times(\beta\nabla\times\tilde{\mathbf{B}}(t))+\nabla P(t)=R_\alpha\nabla\times\tilde{\mathbf{F}}(t)+R_m\nabla\times\tilde{\mathbf{U}}(t), \tag{3.4}$$

or we can write

$$\nabla P(t)=\mathbf{B}_0-\mathbf{B}(t)-\nabla\times(\beta\nabla\times\tilde{\mathbf{B}}(t))+R_\alpha\nabla\times\tilde{\mathbf{F}}(t)+R_m\nabla\times\tilde{\mathbf{U}}(t). \tag{3.5}$$

Noting the right-hand side of (3.5) lies in $(H_0(\mathbf{curl},\mathrm{div};\Omega))'$, we have

$$\nabla P(t)\in H^1(0,T;H_0(\mathbf{curl},\mathrm{div};\Omega)')\subset H^1(0,T;H^{-1}(\Omega)), \tag{3.6}$$

then by Lemma 3.1 we obtain

$$\|P(t)\|_{L^2(\Omega)/R}\le C\|\nabla P(t)\|_{H^{-1}(\Omega)}\quad\forall\,t\in[0,T],$$

this proves $P(t)\in H^1(0,T;L^2(\Omega))$.

Now (3.1) follows immediately by letting $p(t)=\frac{\partial P(t)}{\partial t}$ and differentiating (3.4) with respect to t, and $p(t)\in L^2(0,T;L^2(\Omega))$.

Adding a term $\gamma(\nabla\cdot\mathbf{B},\nabla\cdot\mathbf{A})$ for some constant $\gamma>0$ in (2.5), an important stabilization term in the subsequent numerical approximation, we are then led to the following theorem.

THEOREM 3.1. *The system* (2.5) *is equivalent to the following variational problem:*

Find $\mathbf{B}(t)\in H_0\equiv H_0(\mathbf{curl},\mathrm{div};\Omega)$ *and* $p(t)\in L^2_0(\Omega)$ *such that* $\mathbf{B}(0)=\mathbf{B}_0$ *and*

$$\begin{cases}(\mathbf{B}'(t),\mathbf{A})+(\beta\nabla\times\mathbf{B}(t),\nabla\times\mathbf{A})+\gamma(\nabla\cdot\mathbf{B}(t),\nabla\cdot\mathbf{A})+(p,\nabla\cdot\mathbf{A})\\ =R_\alpha\Big(\frac{f}{1+\sigma|\mathbf{B}|^2}\mathbf{B}(t),\nabla\times\mathbf{A}\Big)+R_m(\mathbf{u}\times\mathbf{B}(t),\nabla\times\mathbf{A})\quad\forall\,\mathbf{A}\in H_0\\ (\nabla\cdot\mathbf{B},q)=0\quad\forall\,q\in L^2_0(\Omega)\end{cases} \tag{3.7}$$

for a.e. $t\in(0,T)$. *Moreover, we have the following stability estimates for the solution* $(\mathbf{B},p)$*:*

$$\begin{aligned}&\|\mathbf{B}\|_{L^\infty(0,T;V)}+\|\mathbf{B}\|_{H^1(0,T;L^2(\Omega)^3)}+\|p\|_{L^2(0,T;L^2_0(\Omega))}\\ &\le C\,(\|\nabla\times\mathbf{B}(0)\|^2+\|\mathbf{B}(0)\|^2)\max_{0\le t\le T}(\|f(t)\|^2_{L^\infty(\Omega)}+\|\mathbf{u}(t)\|^2_{L^\infty(\Omega)})\\ &\quad\cdot\exp\Big(C\int_0^T\Big\{\|f(t)\|^2_{L^\infty(\Omega)}+\|f'(t)\|^2_{L^\infty(\Omega)}+\|\mathbf{u}(t)\|^2_{L^\infty(\Omega)}+\|\mathbf{u}'(t)\|^2_{L^\infty(\Omega)}\Big\}dt\Big).\end{aligned} \tag{3.8}$$

Proof. From the previous derivations, we know the solution $(\mathbf{B}, p)$ to (2.5) also satisfies (3.1)–(3.2). Then using the interface conditions (1.12), we can directly derive (3.7) from (3.1)–(3.2) by integration by parts. On the other hand, one can readily check by integration by parts that a solution $(\mathbf{B}, p)$ of (3.7) is a solution of (3.1)–(3.2) or (2.5). This proves the equivalence of (2.5) and (3.7).

The uniqueness of the solutions to (3.7) can be done similarly to the proof of Theorem 2.1 (cf. [10]).

The estimates of the first two terms on the left-hand side of (3.8) follow from Theorem 2.1. We next derive the estimate of the last term on the left of (3.8) for p. For this, we introduce a $\phi \in H^1(\Omega) \cap L_0^2(\Omega)$ which satisfies

$$\Delta\phi = p \quad \text{in } \Omega; \quad \frac{\partial \phi}{\partial \mathbf{n}} = 0 \quad \text{on } \partial\Omega.$$

Then it is easy to see by Poincare's inequality that

$$\|\nabla\phi\|^2 \le \|\phi\| \, \|p\| \le C\|p\| \, \|\nabla\phi\|,$$

which gives

$$\|\nabla\phi\| \le C \, \|p\|.$$

Letting $b(\mathbf{A}, q) = \int_\Omega q \nabla \cdot \mathbf{A} d\mathbf{x}$ for any $\mathbf{A} \in H_0$ and $q \in L_0^2(\Omega)$, then we take a special $\mathbf{A} = \nabla\phi$. It is easy to verify that $\mathbf{A} \in H_0$, and

$$\|\mathbf{A}\|_{H_0(\mathbf{curl},\mathrm{div};\Omega)} = \left(\|\nabla\phi\|^2 + \|p\|^2\right)^{\frac{1}{2}} \le C\|p\|\,, \tag{3.9}$$

$$\frac{b(\mathbf{A}, p)}{\|\mathbf{A}\|_{H_0}} = \frac{(p, p)}{\|\mathbf{A}\|_{H_0}} \ge C\|p\|\,. \tag{3.10}$$

But we know from (3.7) that

$$\begin{aligned} b(\mathbf{A}, p) = {} & R_\alpha\Big(\frac{f}{1+\sigma|\mathbf{B}|^2}\mathbf{B}(t), \nabla\times\mathbf{A}\Big) + R_m(\mathbf{u}\times\mathbf{B}(t), \nabla\times\mathbf{A}) \\ & - (\mathbf{B}'(t), \mathbf{A}) - (\beta\nabla\times\mathbf{B}(t), \nabla\times\mathbf{A})\,, \end{aligned}$$

from which and the Cauchy–Schwarz inequality, we obtain

$$\begin{aligned} b(\mathbf{A}, p) &\le R_\alpha\|f(t)\|_{L^\infty(\Omega)}\|\mathbf{B}(t)\| \, \|\nabla\times\mathbf{A}\| + R_m\|\mathbf{u}\times\mathbf{B}(t)\| \, \|\nabla\times\mathbf{A}\| \\ &\quad + \|\mathbf{B}'(t)\| \, \|\mathbf{A}\| + \|\nabla\times\mathbf{B}(t)\|_\beta \, \|\nabla\times\mathbf{A}\|_\beta \\ &\le C\left(\|f(t)\|_{L^\infty(\Omega)}\|\mathbf{B}(t)\| + \|\mathbf{u}(t)\|_{L^\infty(\Omega)}|\mathbf{B}(t)| + \|\mathbf{B}'(t)\| + \|\nabla\times\mathbf{B}(t)\|\right)\|\mathbf{A}\|_{H_0}. \end{aligned}$$

Now the estimate for p follows from this, (3.10), and the estimates of first two terms in (3.8). ∎

4. Finite element approximations. In this section we shall address the finite element approximation of the nonlinear dynamo system (1.4)–(1.12), based on its saddle-point type variational formulation (3.7). As we know, the so-called edge element methods are widely used in numerical solutions of the Maxwell systems [12, 13, 14]. Their main advantages lie in the convenience to incorporate the divergence constraints implicitly and the easy satisfaction of the usual interface conditions which involve tangential components of the fields. But the nonlinear geodynamo system of our current interest requires the continuity of all the components of the magnetic field across the interfaces (see (1.12)), not just the tangential components as in other nondynamo modelling systems. This fact makes the edge element methods inconvenient for the approximation of the geodynamo system (1.4)–(1.12). Instead we shall make use of the standard Lagrange nodal finite element methods.

4.1. Saddle-point system and its approximation. We first recall some existing well-posedness about the general saddle-point system and its approximation. Let X and M be two Hilbert spaces, with scalar products $(\cdot,\cdot)_X$ and $(\cdot,\cdot)_M$, respectively, and $a(v,w)$ and $b(v,q)$ be two continuous bilinear forms on $X\times X$ and $X\times M$, i.e., there exist two positive constants $\|a\|$ and $\|b\|$ such that

$$|a(v,w)|\le \|a\|\,\|v\|_X\|w\|_X \quad \forall\, v,w\in X, \tag{4.1}$$

$$|b(v,q)|\le \|b\|\,\|v\|_X\|q\|_M \quad \forall\, v\in X, q\in M. \tag{4.2}$$

We shall need the kernel space V associated with $b(\cdot,\cdot)$ and the polar set of V:

$$V=\{w\in X;\ b(w,q)=0 \quad \forall\, q\in M\},\quad V^0=\{g\in X';\ \langle g,v\rangle=0 \quad \forall\, v\in X\}\,.$$

Consider the saddle-point system: Find $(u,p)\in X\times M$ such that

$$a(u,v)+b(v,p)=f(v) \quad \forall\, v\in X, \tag{4.3}$$

$$b(u,q)=g(q) \quad \forall\, q\in M, \tag{4.4}$$

where $f\in X'$ and $g\in M'$. The following well-posedness results about this saddle-point system can be found in [6, 18].

LEMMA 4.1. *Assume* (4.1) *and* (4.2)*, and*

$$\sup_{w\in V}\frac{a(v,w)}{\|w\|_X}\ge\alpha\|v\|_X \quad \forall\, v\in V; \tag{4.5}$$

$$\sup_{v\in V}a(v,w)>0 \quad \forall\, w\in V,\ w\neq 0, \tag{4.6}$$

$$\sup_{v\in X}\frac{b(v,q)}{\|v\|_X\|q\|_M}\ge\beta \quad \forall\, q\in M,\ q\neq 0\,. \tag{4.7}$$

Then there exists a unique solution $(u,p)\in X\times M$ *to the saddle-point problem* (4.3)–(4.4).

Now we discuss the approximation of the saddle-point system (4.3)–(4.4). Let $X_h\subset X$ and $M_h\subset M$ be two finite dimensional spaces, and define

$$V_h=\{w_h\in X_h;\ b(w_h,q_h)=0 \quad \forall\, q_h\in M_h\}\,.$$

We then introduce a bilinear form $a_h(\cdot,\cdot)$ defined on $X_h\times M_h$ satisfying

$$a_h(v_h,v_h)\ge\alpha^*\|v_h\|_X^2 \quad \forall v_h\in V_h\,, \tag{4.8}$$

$$|a_h(v_h,w_h)|\le\|a_h\|\,\|v_h\|_X\|w_h\|_X \quad \forall\, v_h,w_h\in X_h \tag{4.9}$$

for two positive constants α^* and $\|a_h\|$. In our later applications, $a_h(\cdot,\cdot)$ comes from some approximation of $a(\cdot,\cdot)$ and is formed from $a(\cdot,\cdot)$ in such a way that numerical integrations on polyhedra with curved faces are replaced by much easier integrations on polyhedra with planar faces.

Then we introduce the approximation of the saddle-point system (4.3)–(4.4).

Find $(u_h,p_h)\in X_h\times M_h$ such that

$$a_h(u_h,v_h)+b(v_h,p_h)=f(v_h) \quad \forall\, v_h\in X_h \tag{4.10}$$

$$b(u_h,q_h)=g(q_h) \quad \forall\, q_h\in M_h\,. \tag{4.11}$$

We have the following convergence theorem (cf. [6]), whose detailed proof can be found in [10].

THEOREM 4.1. *In addition to the assumptions* (4.8)–(4.9)*, we assume that the* inf-sup *condition*

$$\sup_{v_h \in X_h} \frac{b(v_h, q_h)}{\|v_h\|_X \|q_h\|_M} \geq \beta^* \quad \forall\, q_h \in M_h,\ q_h \neq 0\,. \tag{4.12}$$

is also satisfied. Then the system (4.10)–(4.11) *has a unique solution* $(u_h, p_h) \in X_h \times M_h$ *and the following error estimate holds:*

$$\begin{aligned} \|u - u_h\|_X \leq \Big(1 + \frac{\|a_h\|}{\alpha^*}\Big)\Big(1 + \frac{\|b\|}{\beta^*}\Big) \inf_{v_h \in X_h} \|u - v_h\|_X + \|b\| \inf_{\mu_h \in M_h} \|p - \mu_h\|_M \\ + \frac{1}{\alpha^*} \sup_{v_h \in V_h} \frac{a(u, v_h) - a_h(u, v_h)}{\|v_h\|_X}. \end{aligned} \tag{4.13}$$

4.2. A fully discrete finite element method and its stability. In this section, we will propose a fully discrete finite element method for the variational system (3.7). For this purpose, we have to approximate the problem in both time and space. We shall use the backward Euler scheme for time discretization and the popular Hood–Taylor finite elements (cf. [20]) for space discretization.

We start with the partition of the time interval [0, T] and the triangulation of the physical spherical domain Ω. We divide the time interval [0, T] into M equally spaced subintervals using the following nodal points:

$$0 = t_0 < t_1 < t_2 < \cdots < t_M = \mathrm{T},$$

where $t_n = n\,\tau$ for $n = 0, 1, \ldots, M$ and $\tau = T/M$. For any given discrete time sequence $\{u^n\}_{n=0}^M$ with each u^n lying in $L^2(\Omega)$ or $L^2(\Omega)^3$, we define the first order backward finite differences and the averages as follows:

$$\partial_\tau u^n = \frac{u^n - u^{n-1}}{\tau}, \quad \bar{u}^n = \frac{1}{\tau}\int_{t_{n-1}}^{t_n} u(\cdot, s)ds.$$

If $u(\mathbf{x}, t)$ is a function which is continuous with respect to t, we shall often write $u^n(\cdot) = u(\cdot, t_n)$ for $n = 0, 1, \ldots, M$. For the ease of exposition, we may also use the function values for $t \leq 0$, by assuming the convention that $u(\mathbf{x}, t) = u(\mathbf{x}, 0)$ for all $t \leq 0$.

We now introduce the triangulation of the domain Ω, consisting of the inner core Ω_1, the outer core Ω_2, and the exterior zone Ω_3. For the sake of technical treatments, we shall assume that *the outer boundary of the exterior zone* Ω_3 *is a closed convex polygon*; the actual curved boundary case can be treated in the same manner as we handle in this and next section the curved interfaces Γ_1 and Γ_2; see Figure 1.

We first triangulate the inner core Ω_1 using a quasi-uniform triangulation $\mathcal{T}_h^1$ with tetrahedral elements of mesh size h, which form a polyhedral domain $\Omega_h^1 \subset \Omega_1$. The triangulation is done such that the boundary vertices of Ω_h^1 all lie on the boundary of Ω_1.

Then we triangulate the exterior zone Ω_3 using a triangulation $\mathcal{T}_h^3$ with tetrahedral elements, which form a polyhedral domain Ω_h^3. The triangulation is done such that all the vertices on the outer polygonal boundary $\partial\Omega$ are also vertices of Ω_h^3, and the inner boundary vertices of Ω_h^3 all lie on the inner boundary of Ω_3.

Finally we triangulate the outer core Ω_2 using a triangulation $\mathcal{T}_h^2$ with tetrahedral elements, which form a polyhedral domain Ω_h^2. The triangulation is done such that all the vertices on the outer boundary of Ω_h^2 match those vertices on the inner boundary of Ω_h^3, while all the vertices on the inner boundary of Ω_h^2 match the boundary vertices of Ω_h^1.

Now the three individual triangulations $\mathcal{T}_h^1$, $\mathcal{T}_h^2$, and $\mathcal{T}_h^3$ form a global triangulation $\mathcal{T}_h$ of Ω. By $\mathcal{N}_h$ we shall denote the set of all the nodal points of the triangulation $\mathcal{T}_h$, and by $\mathcal{F}_h$ the set of all faces of elements in $\mathcal{T}_h$.

For convenience, any element K of $\mathcal{T}_h$ whose interior has nonempty intersection with the interface Γ_1 and Γ_2 will be called *an interface element*. The set of all interface elements is denoted by $\mathcal{T}_h^*$. Let us introduce some notation needed in the subsequent error estimates. For each interface element $K \in \mathcal{T}_h^*$, we know that K must lie either in Ω_2^h or Ω_3^h according to the construction of the triangulation $\mathcal{T}_h$. And each interface element K is divided by the interface into two parts, written as $\mathcal{K}_1$ and $\mathcal{K}_2$. Since the interfaces Γ_1 and Γ_2 are smooth spheric surfaces, one can show (cf. [17]) that one of the two parts $\mathcal{K}_1$ and $\mathcal{K}_2$, denoted always by $\mathcal{K}$, has a volume of order h_K^4, that is,

$$|\mathcal{K}| \eqsim h_K^4 \,. \tag{4.14}$$

Here and in what follows, we shall often use the symbols $\lesssim$ and $\eqsim$, and $x \lesssim y$ means that $x \le Cy$ for some generic constant C, and $x \eqsim y$ means $x \lesssim y$ and $y \lesssim x$.

Also we may absorb in the generic constant C the upper and lower bounds β_m, β_M, f_M, and u_M of the functions $\beta(\mathbf{x})$, $f(\mathbf{x},t)$, and $\mathbf{u}(\mathbf{x},t)$ over $\Omega \times (0,T)$:

$$\beta_m \le \beta(\mathbf{x}) \le \beta_M \,; \quad |f(\mathbf{x},t)| \,,\ |f_t(\mathbf{x},t)| \le f_M \,; \quad |\mathbf{u}(\mathbf{x},t)| \,,\ |\mathbf{u}_t(\mathbf{x},t)| \le u_M \,.$$

Noting the coefficient $\beta(\mathbf{x})$ in (1.13) has large jumps across the interfaces Γ_1 and Γ_2, hence it may be strongly discontinuous inside each interface element $K \in \mathcal{T}_h^*$, namely when crossing the (curved) common face of two curved polyhedra parts $\mathcal{K}_1$ and $\mathcal{K}_2$ of K. To avoid numerical integrations on polyhedra with curved faces in forming the finite element stiffness matrix, we introduce the following approximations of the coefficients $\beta(\mathbf{x})$, $f(\mathbf{x},t)$, and $\mathbf{u}(\mathbf{x},t)$:

$$\beta_h(\mathbf{x}) = \beta(\mathbf{x}),\ \mathbf{x} \in K \in \mathcal{T}_h \setminus \mathcal{T}_h^* \,; \quad \beta_h(\mathbf{x}) = \beta_i(\mathbf{x}),\ \mathbf{x} \in K \in \mathcal{T}_h^* \cap \Omega_i^h \ (i = 2 \text{ or } 3) \,,$$

$$f_h(\mathbf{x},t) = \begin{cases} 0, & \mathbf{x} \in K \in \mathcal{T}_h^* \cap \Omega_3^h \,; \\ f(\mathbf{x},t), & \text{otherwise} \end{cases} \qquad \mathbf{u}_h(\mathbf{x},t) = \begin{cases} 0, & \mathbf{x} \in K \in \mathcal{T}_h^* \cap \Omega_3^h \\ \mathbf{u}(\mathbf{x},t), & \text{otherwise} \end{cases} .$$

We shall use the Hood–Taylor finite elements (cf. [18, 15, 33]) to approximate the system (3.7), namely the piecewise quadratic polynomials for the magnetic field $\mathbf{B}$ and the piecewise linear polynomials for the Lagrange multiplier p. These spaces can be defined as follows:

$$\begin{aligned} H_h &= \Big\{ \mathbf{w} \in C(\bar{\Omega}) : \ \mathbf{w}|_K \in P_2(K)^3 \ \forall \ K \in \mathcal{T}_h \Big\}, \\ H_{0h} &= \Big\{ \mathbf{w} \in H_h; \ \mathbf{w} \cdot \mathbf{n}_F = 0 \ \forall \, F \in \mathcal{F}_h \cap \partial\Omega \Big\}, \\ Q_h &= \Big\{ q_h \in C(\bar{\Omega}); \ q_h|_K \in P_1(K) \ \forall \ K \in \mathcal{T}_h \Big\} , \end{aligned}$$

where $\mathbf{n}_F$ is the unit normal vector of a face $F \in \mathcal{F}_h$. And the following subspaces of H_{0h} and Q_h will be also needed:

$$\tilde{H}_{0h} = \Big\{ \mathbf{w}_h \in H_{0h}; \ \mathbf{w}_h = 0 \text{ on } \partial\Omega \Big\}, \quad Q_{0h} = \Big\{ q_h \in Q_h; \ \int_\Omega q_h dx = 0 \Big\}.$$

Now, we are ready to propose the fully discrete finite element approximation of the variational problem (3.7) using the approximate functions β_h, f_h, and $\mathbf{u}_h$.

Find $\mathbf{B}_h^n \in H_{0h}$, $p_h^n \in Q_{0h}$ for $n = 1, 2, \ldots, M$ such that $\mathbf{B}_h^0 = S_h\mathbf{B}_0$ and

(4.15)
$$\begin{cases} (\partial_\tau \mathbf{B}_h^n, \mathbf{A}_h) + (\beta_h \nabla\times \mathbf{B}_h^n, \nabla\times \mathbf{A}_h) + \gamma(\nabla\cdot \mathbf{B}_h^n, \nabla\cdot \mathbf{A}_h) + (p_h^n, \nabla\cdot \mathbf{A}_h) \\ \quad = R_\alpha\Big(\frac{f_h^n}{1+\sigma|\mathbf{B}_h^{n-1}|^2}\mathbf{B}_h^n, \nabla\times \mathbf{A}_h\Big) + R_m(\mathbf{u}_h^n\times \mathbf{B}_h^n, \nabla\times \mathbf{A}_h\Big) \quad \forall\, \mathbf{A}_h \in H_{0h}; \\ (\nabla\cdot \mathbf{B}_h^n, q_h) = 0 \quad \forall\, q_h \in Q_{0h}, \end{cases}$$

where S_h is the modified Scott-Zhang interpolation to be defined in section 5. One may replace S_h here by the computationally less expensive standard interpolation operator Π_h induced by the finite element space H_h, but as it will be seen in the subsequent analysis, with Π_h one requires a stronger regularity on the initial data $\mathbf{B}_0$.

We remark that the discrete system (4.15) cannot ensure $\nabla\cdot\mathbf{B}_h^n = 0$, different from the continuous case. The next lemma verifies the well-posedness of the fully discrete scheme (4.15).

LEMMA 4.2. *There exists a unique solution* $(\mathbf{B}_h^n, p_h^n)$ *to the discrete system* (4.15) *for each fixed* n $(1 \le n \le M)$ *and the sequence* $\{\mathbf{B}_h^n\}_{n=0}^M$ *has the following stability estimates:*

$$\max_{1\le n\le M} \|\mathbf{B}_h^n\|^2 + \tau\sum_{n=1}^{M}(\|\nabla\times\mathbf{B}_h^n\|^2 + \|\nabla\cdot\mathbf{B}_h^n\|^2) \lesssim \|\mathbf{B}_h^0\|^2. \tag{4.16}$$

Proof. Inequality (4.16) follows by taking $\mathbf{A}_h = \tau\mathbf{B}_h^n$ in (4.15) and the discrete Gronwall's inequality.

We now verify the existence of solutions to (4.15) for each fixed $n = T/M$ and h by applying the Brouwer fixed point theorem. To this aim, we define a mapping $F_h : (\bar{\mathbf{B}}_h, \bar{p}_h) \to (\mathbf{B}_h, p_h)$ by

$$\begin{cases} \tilde{a}_h(\mathbf{B}_h, \mathbf{A}_h) + \tilde{b}(\mathbf{A}_h, p_h) = \tilde{g}(\bar{\mathbf{B}}_h, \mathbf{A}_h) \quad \forall\, \mathbf{A}_h \in H_{0h}, \\ \tilde{b}(\mathbf{B}_h, q_h) = 0 \quad \forall\, q_h \in Q_{0h}, \end{cases} \tag{4.17}$$

where $\tilde{a}_h$, $\tilde{b}$ and $\tilde{g}$ are given by

$$\tilde{a}_h(\mathbf{B}, \mathbf{A}) = (\mathbf{B}, \mathbf{A}) + \tau(\beta_h\nabla\times\mathbf{B}, \nabla\times\mathbf{A}) + \gamma\tau(\nabla\cdot\mathbf{B}, \nabla\cdot\mathbf{A}),\ \tilde{b}(\mathbf{A}, q) = \tau(q, \nabla\cdot\mathbf{A}),$$
$$\tilde{g}(\mathbf{B}, \mathbf{A}) = (\mathbf{B}_h^{n-1}, \mathbf{A}) + \tau\, R_\alpha\Big(\frac{f_h^n}{1+\sigma|\mathbf{B}_h^{n-1}|^2}\mathbf{B}, \nabla\times\mathbf{A}\Big) + \tau R_m\,(\mathbf{u}_h^n\times\mathbf{B}, \nabla\times\mathbf{A}).$$

By applying Theorem 4.1 one can show that the mapping F_h is well defined; see [10] for details.

We next show that F_h maps a bounded subset of $H_{0h}\times Q_{0h}$ into itself. In fact, taking $\mathbf{A}_h = \mathbf{B}_h$ in the first equation of (4.17), using the second equation and Young's inequality we can obtain

$$\|\mathbf{B}_h\|^2 + \tau\|\nabla\times\mathbf{B}_h\|_{\beta_h}^2 + \gamma\tau\|\nabla\cdot\mathbf{B}_h\|^2 \le \|\mathbf{B}_h^{n-1}\|^2 + \frac{2\tau}{\beta_m}(R_\alpha^2 f_M^2 + 4R_m^2 u_M^2)\|\bar{\mathbf{B}}_h\|^2\,.$$

Thus for any $\bar{\mathbf{B}}_h$ lying in the ball $B(0, r_0) = \{\mathbf{A}_h;\ \|\mathbf{A}_h\|_{H_0} \le r_0\}$ with $r_0 = \sqrt{2}\|\mathbf{B}_h^{n-1}\|$, we have

$$\|\mathbf{B}_h\|^2 + \tau\|\nabla\times\mathbf{B}_h\|_{\beta_h}^2 + \gamma\tau\|\nabla\cdot\mathbf{B}_h\|^2 \le r_0^2$$

when τ is appropriately small such that $4\tau(R_\alpha^2 f_M^2 + 4R_m^2 u_M^2) \le \beta_m$. Next we show that p_h lies in the ball $B(0,\bar{r}_0)$ with

$$\bar{r}_0 = C_0^{-1}\Big(\frac{2}{\tau} + \frac{\sqrt{\gamma}+\sqrt{\beta_M}}{\sqrt{\tau}} + R_\alpha f_M + 2R_m u_M\Big)\, r_0\,.$$

To see this, for any $\mathbf{A}_h \in H_{0h}$, we obtain from (4.17) using the Cauchy–Schwarz inequality that

$$\begin{aligned}\tau(\nabla\cdot\mathbf{A}_h, p_h) \le \Big(&\|\mathbf{B}_h\| + \tau\beta_M^{1/2}\|\nabla\times\mathbf{B}_h\|_\beta + \gamma\tau\|\nabla\cdot\mathbf{B}_h\| \\ &+ \|\mathbf{B}_h^{n-1}\| + \tau R_\alpha f_M\|\bar{\mathbf{B}}_h\| + 2\tau R_m u_M\|\bar{\mathbf{B}}_h\|\Big)\|\mathbf{A}_h\|_{H_0}.\end{aligned}$$

This, combined with the *inf-sup* condition for $\tilde{b}(\cdot,\cdot)$ (cf. [10]), leads to the conclusion that p_h lies in the ball $B(0,\bar{r}_0)$. Thus we have proved that F_h maps the bounded subset $B(0,r_0)\times B(0,\bar{r}_0)$ of $H_{0h}\times Q_{0h}$ into itself. Therefore by the Brouwer fixed point theorem, F_h has a fixed point $(\mathbf{B}_h,p_h)\in B(0,\bar{r}_0)\times B(0,\bar{r}_0)$. This proves the existence of solutions to the system (4.15).

The uniqueness of the solutions can be shown in the same manner as in Theorem 3.1. ∎

5. Convergence analysis of the fully discrete finite element method. This section will be devoted to the convergence analysis on the fully discrete finite element approximation (4.15) to the variational problem (3.7). As we shall see, one of the crucial tools in the analysis relies on the following projection operator P_h which maps functions from the space $H_0\times Q_0 \equiv H_0(\mathbf{curl},\mathrm{div};\Omega)\times L_0^2(\Omega)$ into $H_{0h}\times Q_{0h}$: for any $(\mathbf{B},p)\in H_0\times Q_0$, $(\mathbf{B}_h,p_h) = P_h(\mathbf{B},p)\in H_{0h}\times Q_{0h}$ solves the following saddle-point system:

$$\text{(5.1)}\qquad \begin{cases} (\mathbf{B}_h,\mathbf{A}_h) + a_h(\mathbf{B}_h,\mathbf{A}_h) + (p_h,\nabla\cdot\mathbf{A}_h) \\ \qquad = (\mathbf{B},\mathbf{A}_h) + a(\mathbf{B},\mathbf{A}_h) + (p,\nabla\cdot\mathbf{A}_h) \quad \forall\,\mathbf{A}_h\in H_{0h}, \\ (\nabla\cdot\mathbf{B}_h,q_h) = 0 \quad \forall\, q_h\in Q_{0h}, \end{cases}$$

where for any $\mathbf{B},\mathbf{A}\in H_0$, $a(\mathbf{B},\mathbf{A})$ and $a_h(\mathbf{B},\mathbf{A})$ are given by

$$\begin{aligned} a(\mathbf{B},\mathbf{A}) &= (\beta\,\nabla\times\mathbf{B},\nabla\times\mathbf{A}) + \gamma(\nabla\cdot\mathbf{B},\nabla\cdot\mathbf{A})\,,\\ a_h(\mathbf{B},\mathbf{A}) &= (\beta_h\,\nabla\times\mathbf{B},\nabla\times\mathbf{A}) + \gamma(\nabla\cdot\mathbf{B},\nabla\cdot\mathbf{A})\,.\end{aligned}$$

By taking $\mathbf{A}_h = \mathbf{B}_h$ in (5.1) and using Young's inequality and the bounds of $\beta(\mathbf{x})$ and $\beta_h(\mathbf{x})$, we can directly establish the following stability estimates on the projection P_h (cf. [10]):

LEMMA 5.1. *For any $\mathbf{B}\in H_0$ and $p\in Q_0$, let $(\mathbf{B}_h,p_h)$ be the projection of $(\mathbf{B},p)$ defined by* (5.1)*, then we have*

$$\|\mathbf{B}_h\|_{H_0(\mathbf{curl},\mathrm{div};\Omega)} \lesssim \|\mathbf{B}\|_{H_0(\mathbf{curl},\mathrm{div};\Omega)} + \|p\|\,.$$

Considering the discontinuity of coefficient $\beta(\mathbf{x})$ across the interfaces Γ_1 and Γ_2, the solution $(\mathbf{B},p)$ to the system (3.7) often has higher regularity locally inside each medium subdomain Ω_i $(i=1,2,3)$ than in the entire domain Ω. To make full use of the better local regularities of $(\mathbf{B},p)$ to establish the error estimates of the projection P_h, we can introduce a specially constructed interpolation operator by modifying the

Scott–Zhang operator [29] such that it preserves the boundary condition in H_0: for any $\mathbf{B} \in H_0$, we have $S_h\mathbf{B} \in H_{0h}$ (see [10] for details); and S_h has the following local approximation property (cf. [29, 10]):

$$\|w - S_h w\|_{W^{m,p}(K)} \lesssim h_K^{l-m} \|w\|_{W^{l,p}(S_K)} \quad \forall\, w \in W^{l,p}(S_K), \tag{5.2}$$

where $0 < m \le l$ and S_K is the union of all elements in $\mathcal{T}_h$, whose closure has nonempty intersection with K. We now establish the error estimates of form (5.2) in the entire domain Ω for functions with higher regularities locally in each subdomain Ω_k $(k = 1, 2, 3)$.

LEMMA 5.2. *For any $s \ge 0$, and $u \in X = H^1(\Omega) \cap H^{1+s}(\Omega_k)$ $(k = 1, 2, 3)$,*

$$\|u - S_h u\| \lesssim h^{1+\frac{2s}{3}} \sum_{k=1}^{3} \|u\|_{1+s,\Omega_k}, \quad \|u - S_h u\|_1 \lesssim h^{\frac{2s}{3}} \sum_{k=1}^{3} \|u\|_{1+s,\Omega_k}.$$

Proof. For any $u \in X$, let u_k be the restriction of u on Ω_k $(k = 1, 2, 3)$. Noting the interfaces Γ_1 and Γ_2 are smooth, one can extend (cf. [30]) $u_k \in H^{1+s}(\Omega_k)$ onto the whole domain Ω such that the extended function $\tilde{u}_k \in H^{1+s}(\Omega)$ and

$$\|\tilde{u}_k\|_{1+s,\Omega} \lesssim \|u_k\|_{1+s,\Omega_k} \quad \text{for } k = 1, 2, 3. \tag{5.3}$$

First, we consider the estimate on any noninterface element $K \notin \mathcal{T}_h^*$. Since u has H^{1+s}-regularity in such element K, one can follow the standard error estimate in [29] and make use of our construction of the face τ_i associated with each node a_i to derive

$$\|u - S_h u\|_{\mu,K} \lesssim h^{1+s-\mu} \sum_{i=1}^{3} \|u\|_{1+s,S_K \cap \Omega_i}, \quad \mu = 0, 1. \tag{5.4}$$

The tricky case happens to the interface elements. Without loss of generality, consider an interface element $K \in \mathcal{T}_h^*$ near the interface Γ_1. We analyze the errors in $\mathcal{K}_1$ and $\mathcal{K}_2$ separately. Clearly, $\mathcal{K}_1 \subset \Omega_1$, $\mathcal{K}_2 \subset \Omega_2$, $|\mathcal{K}_1| \eqsim h_K^4$ by (4.14). Then by Hölder's inequality, Sobolev embedding, and (5.2), we derive for any $2 \le p \le 6/(3-2s)$ and $\mu = 0, 1$ that

$$\begin{aligned} \|u - S_h u\|_{\mu,\mathcal{K}_1}^2 &\lesssim h_K^{\frac{4(p-2)}{p}} \|u - S_h u\|_{W^{\mu,p}(\mathcal{K}_1)}^2 \\ &\lesssim h_K^{\frac{4(p-2)}{p}} \|u - S_h u\|_{W^{\mu,p}(K)}^2 \lesssim h_K^{6-2\mu-\frac{8}{p}} \|u\|_{W^{1,p}(S_K)}^2. \end{aligned}$$

But on $\mathcal{K}_2$, by the choice of the face τ_i associated with the node a_i in the definition of S_h we know that

$$\tilde{u}_2 = u_2 \ \text{ on } \ \mathcal{K}_2, \quad S_h\, \tilde{u}_2 = S_h\, u \ \text{ on } \ \mathcal{K}_2.$$

Using this and (5.2), we derive

$$\|u - S_h u\|_{\mu,\mathcal{K}_2}^2 \lesssim \|\tilde{u}_2 - S_h \tilde{u}_2\|_{\mu,\mathcal{K}_2}^2 \lesssim \|\tilde{u}_2 - S_h \tilde{u}_2\|_{\mu,K}^2 \lesssim h_K^{2(1+s-\mu)} \|\tilde{u}_2\|_{1+s,S_K}^2, \tag{5.5}$$

combined with the previous estimate on $\mathcal{K}_1$ and (5.3) yields

$$\sum_{K \in \mathcal{T}_h^*} \|u - S_h u\|_{\mu,K}^2 \lesssim h^{2(1+s-\mu)} \sum_{k=1}^{3} \|\tilde{u}_k\|_{1+s,\Omega_k}^2 + \sum_{K \in \mathcal{T}_h^*} h_K^{6-2\mu-\frac{8}{p}} \|u\|_{W^{1,p}(S_K)}^2. \tag{5.6}$$

Then by Hölder's inequality and the fact that the number of interface elements in $\mathcal{T}_h^* \lesssim h^{-2}$,

$$\sum_{K\in\mathcal{T}_h^*} \|u - S_h u\|_{\mu,K}^2 \lesssim h^{2(1+s-\mu)} \sum_{k=1}^{3} \|u\|_{1+s,\Omega_k}^2 + h^{4-2\mu-\frac{4}{p}} \Big(\sum_{K\in\mathcal{T}_h^*} \|u\|_{W^{1,p}(S_K)}^p \Big)^{2/p}.$$

Now the desired estimate follows by taking $p = 6/(3-2s)$ above and using (5.4). ∎

The following lemma provides a crucial observation needed in the subsequent analysis.

LEMMA 5.3. *Let $\mathcal{K}$ be the interface part of any interface element $K \in \mathcal{T}_h^*$ such that $|\mathcal{K}| \eqsim h_K^4$ (cf. (4.14)), then the following estimates hold:*

$$\|\nabla \times \mathbf{A}_h\|_{0,\mathcal{K}}^2 \lesssim h_K \|\nabla \times \mathbf{A}_h\|_{0,K}^2, \quad \|\mathbf{A}_h\|_{0,\mathcal{K}}^2 \lesssim h_K \|\mathbf{A}_h\|_{0,K}^2 \quad \forall\, \mathbf{A}_h \in H_{0h}. \tag{5.7}$$

Proof. We prove only the first inequality in (5.7), the second is similar. Let K be an interface element with 4 vertices, v_1, v_2, v_3, and v_4, and d_K be the largest distance from the curved side of $\mathcal{K}$ to its opposite face of K. Since the interfaces Γ_1 and Γ_2 are C^∞-smooth, we can easily show that $d_K \le Ch_K^2$. Then we can construct a cube $\mathcal{C}(\mathcal{K})$ such that $\mathcal{K} \subset C(\mathcal{K})$ and $\mathcal{C}(\mathcal{K})$ has a height d_K and a rectangular base of length $\alpha_1 h_K$ and width $\alpha_2 h_K$, where α_1 and α_2 are two positive constants independent of mesh size h. Then we divide $\mathcal{C}(\mathcal{K})$ into 6 small tetrahedra $\mathcal{K}^1, \ldots, \mathcal{K}^6$.

By scaling arguments, one can easily verify the equivalence

$$\|q\|_{0,A}^2 \eqsim |A| \sum_{i=1}^{4} (q(a_i))^2 \quad \forall\, q \in P_1(A) \tag{5.8}$$

for any tetrahedron A with vertices a_1, a_2, a_3, and a_4. Let p be a component of $\nabla \times \mathbf{A}_h$ for some $\mathbf{A}_h \in H_{0h}$, then $p \in P_1(K)$. Clearly we also see $p \in P_1(\mathcal{K})$, and p can be naturally extended to $\tilde{p} \in P_1(\mathcal{C}(\mathcal{K}))$, thus

$$\|p\|_{0,\mathcal{K}}^2 \le \|\tilde{p}\|_{0,\mathcal{C}(\mathcal{K})}^2 \le \sum_{i=1}^{6} \|\tilde{p}\|_{0,\mathcal{K}^i}^2.$$

But using (5.8) and the fact that the value $\tilde{p}$ at any point in $\mathcal{K}^i$ can be expressed as a convex combination of the values of p at the 4 vertices of K, we obtain

$$\|p\|_{0,\mathcal{K}}^2 \lesssim h_K^4 \sum_{j=1}^{4} (p(v_j))^2 \eqsim h_K |K| \sum_{j=1}^{4} (p(v_j))^2 \eqsim h_K \|p\|_{0,K}^2.$$

This proves the first estimate in (5.7). ∎

Using the interpolation error estimates in Lemma 5.2 and the convergence theory in Theorem 4.1, we can now derive the error estimate for the projection operator P_h defined in (5.1).

LEMMA 5.4. *Let $\mathbf{B} \in H_0(\mathbf{curl}, \mathrm{div}; \Omega)$ and $p \in L_0^2(\Omega)$ be given such that $\mathbf{B} \in H^{1+s_1}(\Omega_k)$ in each Ω_k $(k = 1, 2, 3)$ for some $0 \le s_1 < 1$ and $p \in H^{s_2}(\Omega)$ for some $0 \le s_2 < 1$. Then the following error estimates hold for the projection $(\mathbf{B}_h, p_h)$ of $(\mathbf{B}, p)$ defined in (5.1):*

$$\sum_{i=1}^{3} \|\mathbf{B} - \mathbf{B}_h\|_{H(\mathbf{curl},\mathrm{div};\Omega_i)}^2 \lesssim h^{\frac{4s_1}{3}} \sum_{i=1}^{3} \|\mathbf{B}\|_{1+s_1,\Omega_i}^2 + h^{2s_2} \|p\|_{s_2,\Omega}^2.$$

Proof. Let $X = H_0(\mathbf{curl}, \mathrm{div}; \Omega)$ and $M = L^2_0(\Omega)$, $X_h = H_{0h}$, and $M_h = Q_{0h}$, then we can apply Theorem 4.1 to the system (5.1) to obtain

$$\|\mathbf{B} - \mathbf{B}_h\|_{H_0} \lesssim \inf_{\mathbf{A}_h \in H_{0h}} \|\mathbf{B} - \mathbf{A}_h\|_{H_0} + \inf_{q_h \in Q_{0h}} \|p - q_h\| + \sup_{\mathbf{A}_h \in V_h} \frac{a(\mathbf{B}, \mathbf{A}_h) - a_h(\mathbf{B}, \mathbf{A}_h)}{\|\mathbf{A}_h\|_{H_{0h}}} . \tag{5.9}$$

Noting that for $\mathbf{B} \in H_0$, we have $S_h\mathbf{B} \in H_{0h}$. On the other hand, for $p \in L^2_0(\Omega)$, let $\pi_h p$ be its standard L^2 projection in Q_h. Clearly $\pi_h p$ may not be in Q_{0h}. But if we set $\tilde{p}_h = \pi_h p - \overline{\pi_h p}$, where $\overline{q}$ stands for the average of q over Ω for any $q \in L^2(\Omega)$, then we have $\tilde{p}_h \in Q_{0h}$, and the following estimates hold using the standard approximation property of the L^2 projection:

$$\|p - \tilde{p}_h\| = \|(p - \pi_h p) - \overline{(p - \pi_h p)}\| \le \|p - \pi_h p\| \lesssim h^{s_2} \|p\|_{s_2,\Omega} .$$

Using this and Lemma 5.2, we derive by taking $\mathbf{A}_h = S_h\mathbf{B}$ and $q_h = \tilde{p}_h$ in (5.9) that

$$\inf_{\mathbf{A}_h \in H_{0h}} \|\mathbf{B} - \mathbf{A}_h\|_{H_0} + \inf_{q_h \in Q_{0h}} \|p - q_h\| \lesssim h^{\frac{2s_1}{3}} \sum_{i=1}^{3} \|\mathbf{B}\|_{1+s_1,\Omega_i} + h^{s_2} \|p\|^2_{s_2,\Omega} . \tag{5.10}$$

It remains to estimate the last term in (5.9). Let $\mathcal{K}$ be the same as in Lemma 5.3, then by the definition of $a(\cdot,\cdot)$ and $a_h(\cdot,\cdot)$, we can write for any $\mathbf{A}_h \in H_{0h}$ (cf. [10]),

$$a(\mathbf{B}, \mathbf{A}_h) - a_h(\mathbf{B}, \mathbf{A}_h) = \sum_{K \in \mathcal{T}_h^*} \int_{\mathcal{K}} (\beta(x) - \beta_h(x)) \nabla \times \mathbf{B} \cdot \nabla \times \mathbf{A}_h dx .$$

Using the Cauchy–Schwarz inequality, we obtain

$$\begin{aligned} &|a(\mathbf{B}, \mathbf{A}_h) - a_h(\mathbf{B}, \mathbf{A}_h)| \\ &\quad \lesssim \sum_{K \in \mathcal{T}_h^*} \left\{ \|\nabla \times S_h\mathbf{B}\|_{0,\mathcal{K}} \|\nabla \times \mathbf{A}_h\|_{0,\mathcal{K}} + \|\nabla \times (\mathbf{B} - S_h\mathbf{B})\|_{0,\mathcal{K}} \|\nabla \times \mathbf{A}_h\|_{0,\mathcal{K}} \right\} . \end{aligned}$$

By Lemmas 5.3 and 5.2, we deduce

$$\begin{aligned} |a(\mathbf{B}, \mathbf{A}_h) - a_h(\mathbf{B}, \mathbf{A}_h)| &\lesssim \sum_{K \in \mathcal{T}_h^*} h_K \|\nabla \times S_h\mathbf{B}\|_{0,K} \|\nabla \times \mathbf{A}_h\|_{0,K} \\ &\quad + \sum_{K \in \mathcal{T}_h^*} h_K^{1/2} \|\nabla \times (\mathbf{B} - S_h\mathbf{B})\|_{0,K} \|\nabla \times \mathbf{A}_h\|_{0,K} \\ &\lesssim h \|\nabla \times S_h\mathbf{B}\|_{0,\Omega} \|\nabla \times \mathbf{A}_h\|_{0,\Omega} \\ &\quad + h^{1/2} \|\nabla \times (\mathbf{B} - S_h\mathbf{B})\|_{0,\Omega} \|\nabla \times \mathbf{A}_h\|_{0,\Omega} \\ &\lesssim (h + h^{1/2+2s_1/3}) \left(\sum_{k=1}^{3} \|\mathbf{B}\|_{1+s_1,\Omega_k} \right) \|\nabla \times \mathbf{A}_h\|_{0,\Omega} , \end{aligned}$$

and this completes the proof of Lemma 5.4. ∎

Now, the above preparations enable us to make full use of the better local regularity of $\mathbf{B}$ in each subdomain Ω_k to derive the main results of this section, the finite element convergence.

THEOREM 5.1. *Let* $(\mathbf{B}, p) \in H^2(0,T;H_0) \times L^2(0,T;L_0^2(\Omega))$ *be the solution to the variational problem* (3.7) *such that* $\mathbf{B} \in H^1(0,T;H^{1+s_1}(\Omega_k))$ *in each* Ω_k $(k=1,2,3)$ *for some* $0 \le s_1 < 1$ *and* $p \in H^1(0,T;H^{s_2}(\Omega))$ *for some* $0 \le s_2 < 1$. *And let* $(\mathbf{B}_h, p_h)$ *be the finite element solution to the fully discrete finite element approximation* (4.15), *then we have the following error estimates:*

$$\begin{aligned}
&\max_{1\le n\le M} \|\mathbf{B}_h^n - \mathbf{B}^n\|^2 + \tau \sum_{n=1}^{M} \Big\{ \|\nabla\times(\mathbf{B}_h^n - \mathbf{B}^n)\|^2 + \|\nabla\cdot(\mathbf{B}_h^n - \mathbf{B}^n)\|^2 \Big\} \\
&\lesssim h^{\frac{4s_1}{3}} \sum_{k=1}^{3} \|\mathbf{B}\|^2_{H^1(0,T;H^{1+s_1}(\Omega_k))} + h^{2s_2}\|p\|^2_{H^1(0,T;H^{s_2}(\Omega))} \\
&\quad + \tau^2\{\|\mathbf{B}\|^2_{H^2(0,T;H_0)} + \|p\|^2_{L^2(Q_T)}\}.
\end{aligned}$$

Proof. Our aim is to estimate the error $(\mathbf{B}^n - \mathbf{B}_h^n)$. Using the relation

$$\mathbf{B}^n - \mathbf{B}_h^n = (\mathbf{B}^n - \bar{\mathbf{B}}^n) + (\bar{\mathbf{B}}^n - P_h\bar{\mathbf{B}}^n) + (P_h\bar{\mathbf{B}}^n - \mathbf{B}_h^n), \tag{5.11}$$

and the projection results from Lemma 5.4, it suffices to estimate the difference $\xi_h^n = (P_h\bar{\mathbf{B}}^n - \mathbf{B}_h^n)$ in the specified norms. To do so, letting $\mathbf{A} = \tau^{-1}\mathbf{A}_h \in H_{0h}$ and $q = q_h \in Q_{0h}$ in (3.7), then integrating over $[t_{n-1}, t_n]$ we obtain

$$\begin{cases} (\partial_\tau \mathbf{B}^n, \mathbf{A}_h) + (\beta\nabla\times\bar{\mathbf{B}}^n, \nabla\times\mathbf{A}_h) + \gamma(\nabla\cdot\bar{\mathbf{B}}^n, \nabla\cdot\mathbf{A}_h) + (\bar{p}^n, \nabla\cdot\mathbf{A}_h) \\ \qquad = R_\alpha(\bar{f}_B^n, \nabla\times\mathbf{A}_h) + R_m(\overline{\mathbf{u}\times\mathbf{B}}^n, \nabla\times\mathbf{A}_h) \quad \forall\, \mathbf{A}_h \in H_{0h}; \\ (\nabla\cdot\bar{\mathbf{B}}^n, q_h) = 0 \quad \forall\, q_h \in Q_{0h}, \end{cases} \tag{5.12}$$

where

$$\bar{f}_B^n = \frac{1}{\tau}\int_{t_{n-1}}^{t_n} \frac{f}{1+\sigma|\mathbf{B}|^2}\mathbf{B}(t)dt.$$

Subtracting (4.15) from (5.12) yields

$$\begin{aligned}
&(\partial_\tau \xi_h^n, \mathbf{A}_h) + (\beta_h\nabla\times\xi_h^n, \nabla\times\mathbf{A}_h) + \gamma(\nabla\cdot\xi_h^n, \nabla\cdot\mathbf{A}_h) \\
&= (\partial_\tau(P_h\bar{\mathbf{B}}^n - \mathbf{B}^n), \mathbf{A}_h) + R_\alpha\Big(\bar{f}_B^n - \frac{f_h^n}{1+\sigma|\mathbf{B}_h^{n-1}|^2}\mathbf{B}_h^n, \nabla\times\mathbf{A}_h\Big), \\
&\quad + R_m(\overline{\mathbf{u}\times\mathbf{B}}^n - \mathbf{u}_h^n\times\mathbf{B}_h^n, \nabla\times\mathbf{A}_h) \\
&\quad + (\beta_h\nabla\times P_h\bar{\mathbf{B}}^n - \beta\nabla\times\bar{\mathbf{B}}^n, \nabla\times\mathbf{A}_h) + (\nabla\cdot(P_h\bar{\mathbf{B}}^n - \bar{\mathbf{B}}^n), \nabla\cdot\mathbf{A}_h) \\
&\quad + (P_h\bar{p}^n - \bar{p}^n, \nabla\cdot\mathbf{A}_h) + (p_h^n - P_h\bar{p}^n, \nabla\cdot\mathbf{A}_h) \quad \forall\, \mathbf{A}_h \in H_{0h}\,.
\end{aligned}$$

Letting $\mathbf{A}_h = \tau\xi_h^n \in H_{0h}$ above, then using the second equations in both (4.15) and (5.12) and the definition of the projection P_h, we come to (cf. [10])

$$\begin{aligned}
&\tau(\partial_\tau\xi_h^n, \xi_h^n) + \tau(\beta_h\nabla\times\xi_h^n, \nabla\times\xi_h^n) + \gamma\tau(\nabla\cdot\xi_h^n, \nabla\cdot\xi_h^n) \\
&= R_\alpha\tau\Big(\bar{f}_B^n - \frac{f^n}{1+\sigma|\mathbf{B}_h^{n-1}|^2}\mathbf{B}_h^n, \nabla\times\xi_h^n\Big) + R_m\tau(\overline{\mathbf{u}\times\mathbf{B}}^n - \mathbf{u}^n\times\mathbf{B}_h^n, \nabla\times\xi_h^n) \\
&\quad + \tau(\partial_\tau(P_h\bar{\mathbf{B}}^n - \mathbf{B}^n), \xi_h^n) + \tau(\bar{\mathbf{B}}^n - P_h\bar{\mathbf{B}}^n, \xi_h^n) \\
&\quad + \tau\Big(\frac{R_\alpha(f^n - f_h^n)}{1+\sigma|\mathbf{B}_h^{n-1}|^2}\mathbf{B}_h^n + R_m(\mathbf{u}^n - \mathbf{u}_h^n)\times\mathbf{B}_h^n, \nabla\times\xi_h^n\Big) \\
&\equiv: (\mathrm{I})_1 + (\mathrm{I})_2 + (\mathrm{I})_3 + (\mathrm{I})_4 + (\mathrm{I})_5\,.
\end{aligned} \tag{5.13}$$

Obviously, $(\mathrm{I})_4$ can be estimated immediately by the projection property. Below, we shall analyze $(\mathrm{I})_1$, $(\mathrm{I})_2$, $(\mathrm{I})_3$, and $(\mathrm{I})_5$ one by one. For the estimation of $(\mathrm{I})_1$, we first consider

$$(\mathrm{II})_1 \equiv: \bar{f}_B^n - \frac{f^n}{1+\sigma|\mathbf{B}_h^{n-1}|^2}\mathbf{B}_h^n.$$

By direct manipulations, we have (cf. [10])

$$\begin{aligned}(\mathrm{II})_1 = {} & \frac{1}{\tau}\int_{t_{n-1}}^{t_n} \frac{(f-f^n)+\sigma f\,(|\mathbf{B}_h^{n-1}|^2-|\mathbf{B}|^2)+\sigma(f-f^n)|\mathbf{B}|^2}{(1+\sigma|\mathbf{B}|^2)(1+\sigma|\mathbf{B}_h^{n-1}|^2)}\mathbf{B}(t)dt \\ & + \frac{1}{\tau}\int_{t_{n-1}}^{t_n} \frac{f^n}{1+\sigma|\mathbf{B}_h^{n-1}|^2}\Big\{(\mathbf{B}(t)-\bar{\mathbf{B}}^n)+(\bar{\mathbf{B}}^n-P_h\bar{\mathbf{B}}^n)+(P_h\bar{\mathbf{B}}^n-\mathbf{B}_h^n)\Big\}dt,\end{aligned}$$

which can be easily bounded by

(5.14)

$$\begin{aligned}|(\mathrm{II})_1| \le {} & \frac{2}{\tau}\int_{t_{n-1}}^{t_n} |f|\,\{|\mathbf{B}_h^{n-1}-P_h\bar{\mathbf{B}}^{n-1}|+|P_h\bar{\mathbf{B}}^{n-1}-\bar{\mathbf{B}}^{n-1}|+|\bar{\mathbf{B}}^{n-1}-\mathbf{B}|\}dt \\ & + \frac{1}{\tau}\int_{t_{n-1}}^{t_n} |f-f^n|\,|\mathbf{B}(t)|dt + \frac{1}{\tau}\int_{t_{n-1}}^{t_n} |f^n|\,\Big(|\mathbf{B}(t)-\bar{\mathbf{B}}^n|+|\bar{\mathbf{B}}^n-P_h\bar{\mathbf{B}}^n|+|\xi_h^n|\Big)dt.\end{aligned}$$

By the standard error estimates [5, 14, 10], we obtain from (5.14) that

(5.15)

$$|(\mathrm{II})_1| \le 5f_M\Big\{\sqrt{\tau}\|\mathbf{B}\|_{L^2(t_{n-1},t_n)} + \sqrt{\tau}\|\mathbf{B}_t\|_{L^2(t_{n-2},t_n)} + \sum_{k=n-1}^{n}|\xi_h^k| + \sum_{k=n-1}^{n}|P_h\bar{\mathbf{B}}^k-\bar{\mathbf{B}}^k|\Big\}.$$

Similarly, for the estimation of $(\mathrm{I})_2$, we first analyze $(\mathrm{II}_2) := \overline{\mathbf{u}\times\mathbf{B}}^n - \mathbf{u}^n\times\mathbf{B}_h^n$. We write

$$(\mathrm{II})_2 = \frac{1}{\tau}\int_{t_{n-1}}^{t_n}\{(\mathbf{u}(t)-\mathbf{u}^n)\times\mathbf{B}(t)+\mathbf{u}^n\times(\mathbf{B}(t)-\mathbf{B}_h^n)\}dt\,,$$

this leads readily to (with $I_n = (t_{n-1}, t_n]$)

$$|(\mathrm{II})_2| \le u_M\sqrt{\tau}\|\mathbf{B}\|_{L^2(I_n)} + 2u_M(\sqrt{\tau}\|\mathbf{B}_t\|_{L^2(I_n)} + |\bar{\mathbf{B}}^n - P_h\bar{\mathbf{B}}^n| + |\xi_h^n|)\,. \tag{5.16}$$

Next, we estimate the following term needed in (5.13):

$$\begin{aligned}(\mathrm{II})_3 \equiv: {} & \partial_\tau(P_h\bar{\mathbf{B}}^n - \mathbf{B}^n) = \partial_\tau(P_h\mathbf{B}^n-\mathbf{B}^n) + P_h\partial_\tau(\bar{\mathbf{B}}^n-\mathbf{B}^n) \\ = {} & \frac{1}{\tau}\int_{t_{n-1}}^{t_n}(P_h\mathbf{B}_t(s)-\mathbf{B}_t(s))ds + P_h\partial_\tau(\bar{\mathbf{B}}^n-\mathbf{B}^n). \qquad (5.17)\end{aligned}$$

For the second term above, we can write after some manipulations [10] that

$$\partial_\tau(\bar{\mathbf{B}}^n-\mathbf{B}^n) = \frac{1}{\tau^2}\int_{t_{n-1}}^{t_n}\int_{s-\tau}^{s}\int_{s}^{\mu}\mathbf{B}_{tt}(\lambda)d\lambda d\mu ds,$$

this enables us to rewrite $(\mathrm{II})_3$ as

$$(\mathrm{II})_3 = \frac{1}{\tau}\int_{t_{n-1}}^{t_n}(P_h\mathbf{B}_t(s)-\mathbf{B}_t(s))ds + \frac{1}{\tau^2}\int_{t_{n-1}}^{t_n}\int_{s-\tau}^{s}\int_{s}^{\mu}P_h\mathbf{B}_{tt}(\lambda)d\lambda d\mu ds,$$

and so,

$$|(\mathrm{II})_3| \le \frac{1}{\sqrt{\tau}}\|P_h\mathbf{B}_t - \mathbf{B}_t\|_{L^2(I_n)} + \sqrt{\tau}\|P_h\mathbf{B}_{tt}\|_{L^2(I_n)}. \tag{5.18}$$

For the last term $(\mathrm{I})_5$ in (5.13), by Lemma 5.3 and Young's inequality there exists some constant $\tilde{C}$ independent of τ and h such that [10]

$$\begin{aligned} |(\mathrm{I})_5| &\le 2\tau\, h\, \tilde{C}(R_\alpha f_M + 2R_m u_M) \sum_{K\in\mathcal{T}_h^*} \|\mathbf{B}_h^n\|_{0,K}\|\nabla\times\xi_h^n\|_{0,K} \\ &\le \frac{\beta_m}{4}\tau\|\nabla\times\xi_h^n\|^2 + C\tau\, h^2\, \|\mathbf{B}_h^n\|^2\,. \end{aligned} \tag{5.19}$$

Now, we obtain from (5.13) and (5.19) and Young's inequality that

$$\|\xi_h^n\|^2 - \|\xi_h^{n-1}\|^2 + \tau\beta_m\|\nabla\times\xi_h^n\|^2 + \gamma\tau\|\nabla\cdot\xi_h^n\|^2 \lesssim (\mathrm{III})_1, \tag{5.20}$$

where the term $(\mathrm{III})_1$ is given by

$$(\mathrm{III})_1 = \tau\left\{\|(\mathrm{II})_1\|^2 + \|(\mathrm{II})_2\|^2 + \|(\mathrm{II})_3\|^2 + \|\bar{\mathbf{B}}^n - P_h\bar{\mathbf{B}}^n\|^2 + \|\xi_h^n\|^2 + h^2\|\mathbf{B}_h^n\|^2\right\}.$$

Using the estimates for $(\mathrm{II})_1$, $(\mathrm{II})_2$, and $(\mathrm{II})_3$ in (5.15)–(5.18), we can further estimate $(\mathrm{III})_1$ by

$$\begin{aligned} (\mathrm{III})_1 \lesssim{}& \int_{t_{n-1}}^{t_n}\|P_h\mathbf{B}_t(s) - \mathbf{B}_t(s)\|^2 ds + \tau^2\int_{t_{n-1}}^{t_n}\|P_h\mathbf{B}_{tt}(t)\|^2 dt + \tau\{\|\xi_h^{n-1}\|^2 + \|\xi_h^n\|^2\} \\ &+ \tau\left\{\sum_{k=n-1}^{n}\|P_h\bar{\mathbf{B}}^k - \bar{\mathbf{B}}^k\|^2 + \tau\int_{t_{n-2}}^{t_n}(\|\mathbf{B}(t)\|^2 + \|\mathbf{B}_t(t)\|^2)dt\right\} + \tau\, h^2\|\mathbf{B}_h^n\|^2. \end{aligned}$$

Summing both sides of (5.20) over $n = 1, 2, \ldots, k \le M$ yields

$$\begin{aligned} &\|\xi_h^k\|^2 + \beta_m\tau\sum_{n=1}^{k}\|\nabla\times\xi_h^n\|^2 + 2\tau\sum_{n=1}^{k}\|\nabla\cdot\xi_h^n\|^2 \\ &\lesssim \|\xi_h^0\|^2 + \|P_h\mathbf{B}(0) - \mathbf{B}(0)\|^2 + \tau\sum_{n=1}^{k}\|\xi_h^n\|^2 + \tau\, h^2\sum_{n=1}^{k}\|\mathbf{B}_h^n\|^2 \\ &\quad + \int_0^T\|P_h\mathbf{B}_t(t) - \mathbf{B}_t(t)\|^2 dt + \tau^2\int_0^T\|P_h\mathbf{B}_{tt}(t)\|^2 dt \\ &\quad + \tau\sum_{n=1}^{k}\|P_h\bar{\mathbf{B}}^n - \bar{\mathbf{B}}^n\|^2 + \tau\int_0^T(\|\mathbf{B}(t)\|^2 + \|\mathbf{B}_t(t)\|^2)dt\Big\}. \end{aligned} \tag{5.21}$$

Finally using Lemmas 5.1, 5.2, and 5.4, and applying the discrete Gronwall inequality, we are led to the error estimates in Theorem 5.1. ∎

6. Application to a solar interface dynamo. For the astrophysical application of the mathematical theory, we shall concentrate on the numerical modelling of solar interface dynamos. Helioseismology reveals the existence of a highly differentially rotating transition zone at the bottom of the convection zone, which is usually referred to as the solar tachocline [28]. It is thought that the tachocline offers an ideal location for the generation and storage of the Sun's strong toroidal magnetic fields.

In other words, the large-scale solar surface magnetic activities can be interpreted as a result of the rising and emerging of tachocline-seated, strong toroidal magnetic fields driven by magnetic buoyancy [34]. The existence of the tachocline leads to development of the solar interface dynamo first proposed by Parker [25], in which the generation of a weak poloidal magnetic field and a strong toroidal magnetic field takes place in separate fluid regions. Parker's interface dynamo concept depicts an attractive picture of generating a strong toroidal magnetic field within the tachocline while avoiding the dilemma relating to the strong alpha quenching in the convection zone. We shall apply the finite element dynamo theory and algorithm discussed in the previous sections to the problem of solar interface dynamo modelling.

In the solar interface dynamo model, we shall take $\mathbf{u}$ as the solar-like internal differential rotation profile, a result of the helioseismic inversion (e.g., [28]) while the function f is assumed to be given by

$$f(\mathbf{x},t) = \sin^2\theta\cos\theta\sin\left[\pi\frac{(r-r_1)}{(r_2-r_1)}\right],$$

where (r,θ,ϕ) is the spherical polar coordinates. Similar forms have been used in the previous solar dynamo simulations [27, 21, 16]. Furthermore, the weaker pole-equator differential rotation in the convection zone is neglected and the amplification of the toroidal magnetic field only occurs in the tachocline. It follows that the two magnetic induction sources, the generation of a poloidal field in the convection zone, and the amplification of the toroidal field in the tachocline, is spatially separated, as suggested by Parker [25].

We have simulated three nonlinear finite element dynamos at $R_\alpha = 30$ for different magnetic Reynolds numbers, $R_m = 100$, 200, and 500. Figure 2 displays magnetic energies of the three nonlinear dynamo solutions as a function of time. The corresponding butterfly diagram, contours of the azimuthal magnetic field evaluated at the bottom of the convection zone plotted against time, is also shown in Figure 2 for the case with $R_m = 200$. In Figure 3, we illustrate the time-dependent spatial structure of the generated magnetic field in a meridional plane for $R_m = 200$, showing an equatorially propagating dynamo wave similar to that of the solar cycle.

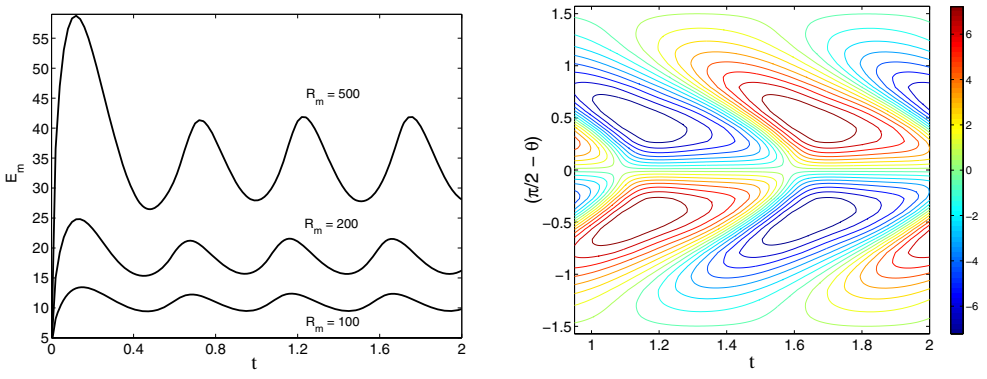

FIG. 2. *The left panel shows magnetic energy E_m of the dynamo as a function of time with a steady tachocline for different values of R_m at $R_\alpha = 30$ with $\beta_1 = 1$, $\beta_2 = 1$, and $\beta_3 = 150$. The right panel displays "a butterfly diagram" for the solution $R_m = 200$ with the azimuthal magnetic field evaluated at the bottom of the convection zone.*

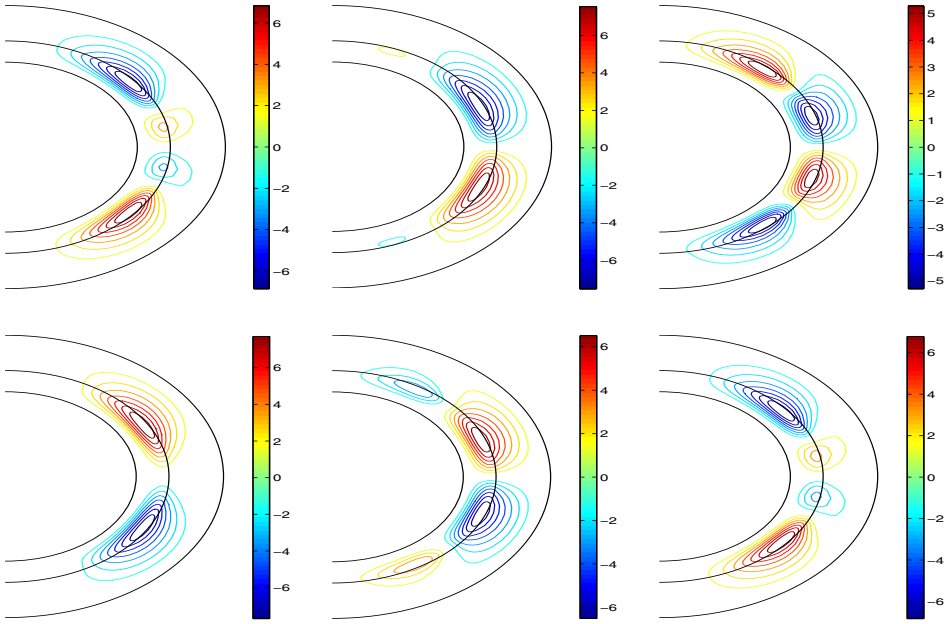

FIG. 3. *Contours of the azimuthal field B_ϕ in a meridional plane plotted at six different instants for $t = 1.0, 1.2, 1.4, 1.6, 1.8, 2.0$ (from top left to right and then from lower left to right) for $R_m = 200$, $\beta_1 = 1$, $\beta_2 = 1$, and $\beta_3 = 150$.*

There are a number of important features shown in our finite element dynamo solutions. First, the effect of the large-scale differential rotation $\mathbf{u}$ in the tachocline always gives rise to an oscillatory dynamo with a period of about one magnetic diffusion unit, which is about 10 years if we adopt $\lambda_2 = 10^8 \mathrm{m}^2\mathrm{s}^{-1}$, approximate to what has been observed in the solar magnetic field. Second, the interface dynamo solutions always select dipolar symmetry and propagate equator ward though the numerical simulation is fully three-dimensional, which is again consistent with the observed feature of the solar magnetic field. Finally, the generated magnetic field mainly concentrates in the vicinity of the interface between the tachocline and the convection zone. A strong toroidal magnetic field in the tachocline is likely to be susceptible to magnetic buoyancy instabilities leading to a quick eruption of the field into the surface of the Sun in the form of sunspots.

7. Concluding remarks. Modelling stellar and planetary dynamos represents an important, highly active research front in astrophysics and planetary physics. Nearly all current stellar dynamo models are based on spectral methods in terms of spherical harmonic expansions, which are computationally inefficient on modern parallel computers and limit the application to general dynamo models, especially to the models with variable physical coefficients of space and time. The finite element method discussed in this paper offers an attractive alternative for simulating dynamos in spherical geometry.

The first attempt at using finite element methods for numerical simulations of spherical dynamos was made in [11]. The current work presents the first mathematical theory and numerical analysis for mean-field spherical dynamos, and it has made contributions in the following aspects: (1) The well-posedness of the mean-field

dynamo system is rigorously demonstrated; the dynamo system is characterized in terms of a saddle-point type formulation which can be conveniently approximated by finite element methods. (2) The existing convergence theory on saddle-point systems is improved and generalized so that the symmetric part of the bilinear form allows the approximations of curved interfaces by straight polygons and numerical integrations on polyhedra with curved faces are replaced by much easier integrations on polyhedra with planar faces; and this is the first work of such type on saddle-point systems. (3) A fully discrete finite element method is proposed for the interface dynamo system with discontinuous coefficients, and error estimates are established under very weak global and local regularity assumptions on the solutions, and this work seems to be the first in achieving error estimates of numerical methods for three-dimensional interface PDEs with curved interfaces, especially for nonlinear PDEs. (4) The application of the proposed numerical method to a solar interface dynamo verifies some important physical observations.

We believe that the mathematical theory and finite element methods for spherical dynamos and their successful application to the solar interface dynamo presented in this paper open up an exciting opportunity for future numerical simulation of stellar dynamos. We also believe that the finite element theory and method developed in the paper would also benefit other research communities in geophysics, planetary physics, and astrophysics where the magnetic field and spherical geometry play an essential role.

OPTIMAL CONTROL OF THE STOKES EQUATIONS: A PRIORI ERROR ANALYSIS FOR FINITE ELEMENT DISCRETIZATION WITH POSTPROCESSING*

ARND RÖSCH† AND BORIS VEXLER†

Abstract. An optimal control problem for 2d and 3d Stokes equations is investigated with pointwise control constraints. This paper is concerned with the discretization of the control by piecewise constant functions. The state and the adjoint state are discretized by finite element schemes. In the paper a postprocessing strategy is suggested, which allows for significant improvement of the accuracy.

Key words. PDE-constrained optimization, finite elements, error estimates, Stokes equations, numerical approximation, control constraints.

AMS subject classifications. 49K20, 49M25, 65N30

DOI. 10.1137/050637364

1. Introduction.

The paper is concerned with the discretization of the optimal control problem

$$\text{minimize} \quad J(v,q) = \frac{1}{2}\|v - v_d\|^2_{L^2(\Omega)^d} + \frac{\nu}{2}\|q\|^2_{L^2(\Omega)^d} \tag{1.1}$$

subject to the Stokes equations (state equation)

$$\begin{aligned} -\Delta v + \nabla p &= f + q && \text{in } \Omega, \\ \nabla \cdot v &= 0 && \text{on } \Omega, \\ v &= 0 && \text{on } \Gamma \end{aligned} \tag{1.2}$$

and subject to the control constraints

$$a \le q(x) \le b \qquad \text{for a.a. } x \in \Omega, \tag{1.3}$$

where Ω is a bounded domain in $\mathbb{R}^d$ with $d = 2, 3$ and Γ is the boundary of Ω. The quantities $a, b \in \mathbb{R}^d$ are constant vectors, the inequality (1.3) is understood componentwise and $\nu > 0$ is a given regularization (or control cost) parameter. We denote by $u = (v, p)$ the solution of (1.2). Moreover, we assume for the desired velocity field v_d and the right-hand side f to be from $L^\infty(\Omega)^d$.

The set of admissible controls Q_{ad} is given by

$$Q_{ad} = \{v \in Q := L^2(\Omega)^d : \ a \le q \le b \ \text{ a.e. in } \Omega\}.$$

We discuss here the discretization of the control and state variables by finite elements. The asymptotic behavior of the discretized problem is studied.

First results in the context of a priori error analysis of optimal control problems go back to papers by Falk [15], Geveci [16], and Malanowski [24]. In the past few

years the theory has been extended to semilinear problems; see Arada, Casas, and Tröltzsch [1] and Casas, Mateos, and Tröltzsch [8]. Error estimates of order h in the L^2-norm and in the L^∞-norm are established in these articles.

Piecewise linear control discretizations for elliptic optimal control problems are studied by Casas and Tröltzsch [9] and Casas [7], containing error estimates of order h and $o(h)$ in the L^2-norm for general cases. For more regular cases an approximation order of $h^{3/2}$ can be proved; see Rösch [27, 28]. An error estimate of order h in the L^∞-norm for an elliptic problem is proved by Meyer and Rösch [26].

However, new discretization concepts have been developed in recent years. The *variational approach* by Hinze [20] and the *superconvergence approach* of Meyer and Rösch [25] can achieve approximation order h^2 in the L^2-norm.

In this paper, we will generalize the superconvergence approach of Meyer and Rösch [25]. The controls are discretized by piecewise constant functions. Clearly, the approximation order of the control cannot be better than h for the optimal control. However, we will show that the point values of the control variable in the barycenter of the elements are approximated with order h^2. Moreover, we will prove that the state and adjoint variable are approximated with order h^2 with respect to the L^2-norm. This allows for a postprocessing step, which leads to h^2 approximation of the control variable in the L^2-norm, too.

Apart from the fact that the Stokes equations have a more complex structure than the equation investigated in [25], this paper contains an essential generalization in the theory. The theory presented in [25] works only for piecewise linear finite elements. The fact that the second derivative of each ansatz function vanishes identically on each triangle is used in a very explicit manner. Consequently, only piecewise linear finite elements defined on triangles can be handled by that technique. We will prove superconvergence results without such restrictions, i.e., only stability and interpolation properties of the elements are requested. Therefore, our results include many different finite element discretization schemes for the 2d and 3d Stokes equations.

To the best of the authors knowledge this is the first paper discussing the discretization error for the optimal control of the Stokes equations with pointwise control constraints. In principle, the classical approach [15, 16] as well as the variational approach [20] can be generalized to the Stokes equations. Of course, several papers are published for the optimal control of the Stokes equations and the Navier–Stokes equations without control constraints; see, e.g., Gunzburger, Hou, and Svobodny [18, 19], Bochev and Gunzburger [4], and Deckelnick and Hinze [14].

Let us remark that the investigated optimal control problems governed by the Stokes equations occur as subproblems in several Newton-type methods for control constrained optimal control problems for the Navier–Stokes equations. The convergence theory of such Newton-type methods requires sufficiently accurate numerical solutions of the subproblems.

The paper is organized as follows: In section 2 a general discretization concept is introduced and the main results are stated. Section 3 contains results from the finite element theory. The proofs of the superconvergence results are placed in section 4. The assumption of the general discretization concept are verified for a specific discretization in section 5. The paper ends with numerical experiments shown in section 6.

2. Discretization and superconvergence results. Throughout this paper, Ω denotes a bounded convex and polygonal domain in $\mathbb{R}^d$, $d = 2, 3$. Moreover, for the case $d = 3$ we assume that edge openings of the domain Ω are smaller than $2\pi/3$.

This will ensure the $W^{1,\infty}$-regularity of the velocity field.

We denote by V and L the Hilbert spaces

$$V := H_0^1(\Omega)^d,$$
$$L := \left\{ p \in L^2(\Omega) : \int_\Omega p(x)\,dx = 0 \right\}.$$

In all that follows, we will omit the subscript L^2 in the norms and inner products if there is no risk of misunderstanding. We look for solutions of the Stokes equations (1.2) in the sense of a weak formulation: the following equation has to be satisfied for arbitrary $\phi = (\psi, \xi) \in V \times L$:

$$a(u,\phi) := (\nabla v, \nabla\psi) - (p, \nabla\cdot\psi) + (\nabla\cdot v, \xi) = (f+q,\psi) =: (F(q),\phi). \tag{2.1}$$

LEMMA 2.1. *Let g be a given function in $L^\infty(\Omega)^d$. Then there exists a unique solution $u = (v,p) \in V \times L$ of*

$$\begin{aligned} -\Delta v + \nabla p &= g \quad && \text{in } \Omega,\\ \nabla\cdot v &= 0 && \text{on } \Omega,\\ v &= 0 && \text{on } \Gamma. \end{aligned} \tag{2.2}$$

Moreover, there exist positive constant c and with $v \in H^2(\Omega)\cap W^{1,\infty}(\Omega)^d$, $p \in H^1(\Omega)$ and

$$\|v\|_{H^2(\Omega)^d} + \|v\|_{W^{1,\infty}(\Omega)^d} + \|p\|_{H^1(\Omega)} \le c\|g\|_{L^\infty(\Omega)^d} \tag{2.3}$$

for $d = 2$ or for $d = 3$ and all edge openings are smaller than $2\pi/3$.

For the proof of this result on polygonal domains especially for $d = 3$, we refer to [13, Theorem 6.3].

We will *assume* that (2.3) is valid for the investigated domain Ω. However, it would be enough for the theory presented here to have this regularity for the optimal adjoint velocity $\bar w$ introduced below.

In order to formulate the optimality system, we introduce the adjoint equation

$$\begin{aligned} -\Delta w - \nabla r &= v - v_d \quad && \text{in } \Omega,\\ \nabla\cdot w &= 0 && \text{on } \Omega,\\ w &= 0 && \text{on } \Gamma. \end{aligned} \tag{2.4}$$

We denote by $z = (w,r) \in V \times L$ the adjoint state. Due to Lemma 2.1 the adjoint velocity w belongs to $H^2(\Omega)^d \cap W^{1,\infty}(\Omega)^d$.

We say that $u = (v,p)$ is the state associated to q if u is the solution of (1.2). Analogously, we call the solution $z = (w,r)$ of (2.4) adjoint state associated to q.

LEMMA 2.2. *There exists a uniquely determined solution $\bar q$ of the optimal control problem* (1.1)–(1.3). *Moreover, a necessary and sufficient condition for the optimality of a control $\bar q$ with associated state $\bar u$ and associated adjoint state $\bar z$, respectively, is that the variational inequality*

$$(\bar w + \nu\bar q, q - \bar q)_Q \ge 0 \quad \text{for all } q \in Q_{ad} \tag{2.5}$$

holds.

The optimal control problem (1.1)–(1.3) is strictly convex and radially unbounded. Hence, there exists a uniquely determined optimal solution and the first order necessary conditions are also sufficient for optimality. Such basic results and an introduction in optimal control theory governed by partial differential equations can be

found for instance in Lions [23]. We remark that the variational inequality (2.5) can be equivalently formulated; see, e.g., Malanowski [24], as

$$\bar{q} = \Pi_{[a,b]}\Big(-\frac{1}{\nu}\bar{w}\Big), \tag{2.6}$$

where the projection Π is defined by

$$\Pi_{[a,b]}(f(x)) = \max(a, \min(b, f(x))).$$

Again, all functions are defined componentwise.

In order to discretize the optimal control problem, we consider a 2- or 3-d mesh $\mathcal{T}_h$ consisting of open cells T, which constitute a nonoverlapping covering of the domain Ω. The cells are either triangles, tetrahedra, quadrilaterals or hexahedra. The mesh parameter h is defined as a cellwise constant function by setting $h_{|T} = h_T$ and h_T is the diameter of K. Usually we use the symbol h also for the maximal cell size, i.e.,

$$h = \max_{T\in\mathcal{T}_h} h_T.$$

The straight parts which make up the boundary ∂T of a cell T are called *faces*. For the mesh $\mathcal{T}_h$ we require to be regular in the following sense; see, e.g., [10], i.e.:

(A1)
- $\bar{\Omega} = \cup_{T\in\mathcal{T}_h} \bar{T}$,
- $T_1 \cap T_2 = \emptyset$ or $T_1 = T_2$, for all $T_1, T_2 \in \mathcal{T}_h$,
- Any face of any cell $T_1 \in \mathcal{T}_h$ is either a subset of the boundary $\partial\Omega$, or a face of another cell $T_2 \in \mathcal{T}_h$.

The control variable q is discretized by piecewise constant elements on the mesh $\mathcal{T}_h$ using the following discrete space:

$$Q_h := \{q_h \in L^2(\Omega)^d : \, q_h|_T \in (\mathcal{P}_0)^d \quad \text{for all} \quad T \in \mathcal{T}_h\}.$$

Here $\mathcal{P}_k$ denotes the polynoms with degree less than or equal to k.

Next, we introduce a general conforming finite element setting for the discretization of the state equation. Let $V_h \subset V$ and $L_h \subset L$ be finite dimensional subspaces with the following properties:

(A2) The space V_h and the mesh $\mathcal{T}_h$ fit in the following sense: Every function $v_h \in V_h$ is piecewise polynomial on $\mathcal{T}_h$

$$v_h|_T \in \mathcal{P}^d \quad \text{for all} \quad T \in \mathcal{T}_h,$$

where $\mathcal{P}$ is a polynomial space.

For a given control $q \in Q$, the state equation (2.1) is discretized using the spaces V_h and L_h as follows: Find $u_h = (v_h, p_h)$ such that

$$a(u_h, \phi_h) + s_h(p_h, \xi_h) = (F(q), \phi_h) \quad \text{for all } \phi_h = (\psi_h, \xi_h) \in V_h \times L_h. \tag{2.7}$$

Here, the term $s_h(\cdot,\cdot)$ denotes a stabilization (continuous, symmetric) bilinear form on $L_h \times L_h$. Such stabilization terms are needed if, e.g., finite elements of equal order for the velocities and pressure are used; see [2] or [6]. For this discretization we require the following conditions: We introduce the space of cellwise H^2 functions

$$V_h^2(\Omega)^d := \{v \in V : \, v|_T \in H^2(T)^d \text{ for all } T \in \mathcal{T}_h\},$$

with a discrete H^2 norm defined by

$$\|\psi_h\|'_{H^2(\Omega)^d} := \left(\|\psi_h\|^2_{H^1(\Omega)^d} + \sum_{T\in\Omega} \|\nabla^2 \psi_h\|^2_{L^2(T)^d} \right)^{1/2}.$$

(A3) There exist interpolation operators $i_h^v : H^2(\Omega)^d \cap V \to V_h$ and $i_h^p : H^1(\Omega) \cap L \to L_h$ with the following approximation properties:

$$\begin{aligned} \|v - i_h^v v\|_{L^2(\Omega)^d} + h\|\nabla(v - i_h^v v)\|_{L^2(\Omega)^d} &\le c_v h^2 \, \|\nabla^2 v\|_{L^2(\Omega)^{d\times d}}, \\ \|v - i_h^v v\|_{L^\infty(\Omega)^d} + h^{2-d/2}\|v - i_h^v v\|'_{H^2(\Omega)^d} &\le c_v h^{2-d/2} \, \|\nabla^2 v\|_{L^2(\Omega)^{d\times d}}, \\ \|p - i_h^p p\|_{L^2(\Omega)} &\le c_p h \, \|\nabla p\|_{L^2(\Omega)}. \end{aligned}$$

For the existence of operators i_h^p we refer to Clément [11].

(A4) There exists a finite dimensional space $\tilde{L}_h \subset L_h$ and a continuous projection operator $\pi\colon L_h \to \tilde{L}_h$ such that

- For the pair $(V_h, \tilde{L}_h)$ the inf-sup condition holds, i.e., there exists a positive constant γ independent of h with

$$\sup_{\phi_h \in V_h} \frac{(p_h, \nabla\cdot\phi_h)}{\|\nabla\phi_h\|_{L^2(\Omega)^d}} \ge \gamma \|p_h\|_{L^2(\Omega)} \quad \text{for all} \quad p_h \in \tilde{L}_h.$$

- There is a positive constant c independent of h such that

$$\|\pi p_h\|_{L^2(\Omega)} \le c\|p_h\|_{L^2(\Omega)} \quad \text{for all} \quad p_h \in L_h.$$

- There is a positive constant c independent of h such that

$$\|p_h - \pi p_h\|^2_{L^2(\Omega)} \le c\, s_h(p_h, p_h) \quad \text{for all} \quad p_h \in L_h.$$

- There is a positive constant c independent of h such that

$$s_h(i_h^p p, i_h^p p) \le ch^2 \|\nabla p\|_{L^2(\Omega)^d} \quad \text{for all} \quad p \in L \cap H^1(\Omega).$$

Remark 2.3. If the inf-sup condition is fulfilled for the pair (V_h, L_h) itself, there is no need for stabilization and we can set $s(p,\xi) \equiv 0$ and $\pi = id_{L_h}$.

Remark 2.4. In the presence of the regularization term $s_h(p_h, \xi_h)$, the discretization (2.7) is not a pure Galerkin scheme for (2.1) any more. Therefore, the question arises, if the approaches "discretize-then-optimize" and "optimize-then-discretize" coincide; see the discussion in Collis and Heinkenschloss [12]. In our setting these two approaches coincide due to the fact, that $s_h(\cdot,\cdot)$ is a symmetric bilinear form.

Moreover, we require the following inverse inequalities:

(A5) There is a positive constant c independent of h such that for all $v_h \in V_h$ holds:

$$\|v_h\|'_{H^2(\Omega)^d} \le ch^{-1}\|v_h\|_{H^1(\Omega)^d} \quad \text{and} \quad \|v_h\|_{L^\infty(\Omega)^d} \le ch^{-d/2}\|v_h\|_{L^2(\Omega)^d}.$$

Let T be an arbitrary element of the mesh $\mathcal{T}_h$. We define an operator $R_h : C(\Omega) \to Q_h$ by

$$(R_h g)(x) = g(S_T),$$

where S_T denotes the barycenter of the element T. The operator R_h is defined componentwise in the case of a vector valued function.

(A6) Let $T \in \mathcal{T}_h$ be an arbitrary element of the discretization and $g \in H^2(T)$ an arbitrary function. We require the following estimates:

$$\left| \int_T g(x) - (R_h g)(x)\, dx \right| \leq ch^2 |T|^{1/2} \|\nabla^2 g\|_{L^2(T)},$$
$$\|g - R_h g\|_{L^\infty(\Omega)} \leq ch\, \|\nabla g\|_{L^\infty(\Omega)}$$

with a positive constant c independent of h.

Remark 2.5. Assumptions (A1)–(A6) are standard properties of finite element discretizations. They are fulfilled for many different conforming element pairs with and without stabilization. We will verify these conditions for one specific discretization in section 5.

For our superconvergence result an additional assumption is needed. It follows from Lemma 2.1, that the optimal adjoint velocity $\bar{w}$ belongs to $H^2(\Omega)^d \cap W^{1,\infty}(\Omega)^d$. However, the regularity of the optimal control is weaker because of the occurrence of kinks caused by the max-function in (2.6). Nevertheless, we can group all elements $T \in \mathcal{T}_h$ into two classes:

$$K_1 := \bigcup_{T \in \mathcal{T}_h,\, \bar{q} \notin H^2(T)^d} T, \qquad K_2 := \bigcup_{T \in \mathcal{T}_h,\, \bar{q} \in H^2(T)^d} T. \tag{2.8}$$

We remark that the properties of the projection operator and Lemma 2.1 imply $\bar{q} \in W^{1,\infty}(\Omega)^d$,

(A7)

$$|K_1| \leq ch.$$

Assumption (A7) is difficult to verify, but is valid in many practical cases.

The discrete optimization problem is given by the minimization of the cost functional (1.1) subject to the discretized state equation (2.7) and subject to $q_h \in Q_h^{ad} = Q_h \cap Q_{ad}$. Similar to the notation for the continuous problem, we denote by $\bar{q}_h \in Q_h^{ad}$, $\bar{u}_h \in V_h \times L_h$, and $\bar{z}_h \in V_h \times L_h$ the optimal control, the associated state, and the adjoint state of the discretized optimal control problem. In the following theorems we formulate our main results.

THEOREM 2.6. *Assume that* (A1)–(A7) *holds. Then the estimate*

$$\|\bar{q}_h - R_h \bar{q}\|_Q \leq ch^2 (\|v_d\|_{L^\infty(\Omega)^d} + \|f\|_{L^\infty(\Omega)^d} + \|\bar{q}\|_{L^\infty(\Omega)^d}) \tag{2.9}$$

is valid with a positive constant c independent of h.

THEOREM 2.7. *The estimates*

$$\|\bar{v} - \bar{v}_h\|_Q \leq ch^2 (\|\bar{q}\|_{L^\infty(\Omega)^d} + \|v_d\|_{L^\infty(\Omega)^d} + \|f\|_{L^\infty(\Omega)^d}) \tag{2.10}$$

$$\|\bar{w} - \bar{w}_h\|_Q \leq ch^2 (\|\bar{q}\|_{L^\infty(\Omega)^d} + \|v_d\|_{L^\infty(\Omega)^d} + \|f\|_{L^\infty(\Omega)^d}) \tag{2.11}$$

are valid provided that (A1)–(A7) *hold.*

THEOREM 2.8. *Assume that* (A1)–(A7) *holds. Then the estimate*

$$\|\tilde{q}_h - \bar{q}\|_Q \leq ch^2 (\|v_d\|_{L^\infty(\Omega)^d} + \|f\|_{L^\infty(\Omega)^d} + \|\bar{q}\|_{L^\infty(\Omega)^d}) \tag{2.12}$$

is valid with

$$\tilde{q}_h = \Pi_{[a,b]} \left(-\frac{1}{\nu} \bar{w}_h \right) \tag{2.13}$$

and a positive constant c independent of h.

The proofs of the Theorems 2.6 and 2.8 are contained in section 4.

Let us briefly explain why these are superconvergence results: The best possible rate for approximation of the optimal solution by a piecewise constant function is h. Therefore we can only expect

$$\|\bar{q} - \bar{q}_h\|_Q = \mathcal{O}(h).$$

However, we will show in Theorem 2.6 that the values in the barycenter are approximated with order h^2. A direct implication of this result will be that the velocity and the adjoint velocity is approximated with order h^2 in the L^2-norm. The projection in (2.13) increases the accuracy of the calculated control to order h^2. Hence, the result of Theorem 2.8 provides a possibility to significantly improve the behavior of the error by a simple postprocessing step (2.13).

Remark 2.9. Theorem 2.7 provides error bounds for the optimal velocity and the adjoint velocity in L^2-norm. As a direct consequence one obtains the corresponding estimates for the velocity with respect to H^1-norm and for the pressure with respect to L^2-norm of order $\mathcal{O}(h)$.

Remark 2.10. Assumption (A7) is essential for quadratic approximation results, i.e., for $\|q - \tilde{q}_h\|_Q = \mathcal{O}(h^2)$. In the absence of this assumption one can obtain by classical techniques:

$$\|\bar{q} - \bar{q}_h\| = \mathcal{O}(h) \quad \text{and} \quad \|\bar{q} - \tilde{q}_h\| = \mathcal{O}(h).$$

3. Results from finite element theory. In this section, we collect results from finite element theory. We define (linear) solution mappings S and S^p of the continuous state equation such that there holds for all $\phi = (\psi, \xi) \in V \times L$, $g \in Q$ and $v^g = S(g)$, $p^g = S^p(g)$:

$$u^g = (v^g, p^g) \in V \times L \,:\, a(u^g, \phi) = (g, \psi). \tag{3.1}$$

In a similar way, we define the solution mappings S_h and S_h^p of the discretized state equation such that there holds for all $\phi_h = (\psi_h, \xi_h) \in V_h \times L_h$, $g \in Q$ and $v_h^g = S_h(g)$, $p_h^g = S_h^p(g)$:

$$u_h^g = (v_h^g, p_h^g) \in V_h \times L_h \,:\, a(u_h^g, \phi_h) + s_h(p_h^g, \xi_h) = (g, \psi_h). \tag{3.2}$$

Although the solution operators S and S_h have better regularity properties, it is more convenient (in particular for section 4) to consider them in the space Q:

$$S\colon Q \to Q, \quad S_h\colon Q \to Q.$$

In the following we provide some properties of these operators based on the assumptions (A1)–(A7). The following lemma ensures the stability of the discretization of the state equation.

LEMMA 3.1. *Under assumptions* (A1)–(A6) *the following modified inf-sup condition holds: There exist positive constants $\tilde{\gamma}$ and c independent of h with*

$$\sup_{\phi_h \in V_h} \frac{(p_h, \nabla \cdot \phi_h) + c\, s(p_h, p_h)}{\|\nabla \phi_h\|_{L^2(\Omega)^d}} \geq \tilde{\gamma} \|p_h\|_{L^2(\Omega)} \quad \textit{for all } p_h \in L_h.$$

Proof. For the proof we refer to [2]. ∎

Next, we define the affine linear operators $P : Q \to Q$ and $P_h : Q \to Q$ by

$$Pq = S^*(S(q+f) - v_d), \quad P_h q = S_h^*(S_h(q+f) - v_d),$$

where S^* and S_h^* denote the adjoint operators of S and S_h, respectively.

LEMMA 3.2. *Assume that the assumption* (A1)–(A6) *hold. Let $q \in Q$ be an arbitrary control. Then, the discretization error of the state equation and the adjoint equation can be estimated by*

(i) $h\|S_h(q+f) - S(q+f)\|_{H^1(\Omega)^d} + \|S_h(q+f) - S(q+f)\|_Q \le ch^2\,(\|q\|_Q + \|f\|_Q)$,
(ii) $\|S_h(q+f) - S(q+f)\|_{L^\infty(\Omega)^d} \le ch^{2-d/2}\,(\|q\|_Q + \|f\|_Q)$,
(iii) $\|S_h(q+f) - S(q+f)\|'_{H^2(\Omega)^d} \le c\,(\|q\|_Q + \|f\|_Q)$,
(iv) $\|P_h q - Pq\|_Q \le ch^2\,(\|q\|_Q + \|f\|_Q + \|v_d\|_Q)$.

Proof. The proof of the error estimate (i) relies on Lemma 3.1 and is given in [2]. The result concerning L^2-estimate can be obtained by standard techniques; see, e.g., [17] for the application of the Aubin–Nitsche trick to the Stokes problem.

For the proof of (ii) we set $g = f + q$ and use the second inverse inequality from (A5) and an interpolation estimate from (A3):

$$\begin{aligned}
\|(S - S_h)(g)\|_{L^\infty(\Omega)^d} &\le \|S(g) - i_h^v S(g)\|_{L^\infty(\Omega)^d} + \|S_h(g) - i_h^v S(g)\|_{L^\infty(\Omega)^d} \\
&\le ch^{2-d/2}\,\|\nabla^2 S(g)\|_{L^2(\Omega)^d} + ch^{-d/2}\|S_h(g) - i_h^v S(g)\|_{L^2(\Omega)^d} \\
&\le ch^{2-d/2}\,\|\nabla^2 S(g)\|_{L^2(\Omega)^d} \\
&\quad + ch^{-d/2}\big\{\|S(g) - i_h^v S(g)\|_{L^2(\Omega)^d} + \|S_h(g) - S(g)\|_{L^2(\Omega)^d}\big\} \\
&\le ch^{2-d/2}\,\|\nabla^2 S(g)\|_{L^2(\Omega)^d} \le ch^{2-d/2}\,\|g\|_{L^2(\Omega)^d}.
\end{aligned}$$

The estimate (iii) follows in the same manner using the first inverse inequality from (A5) and an interpolation estimate from (A3).

The error estimate (iv) is obtained in a similar way as (i). ∎

LEMMA 3.3. *The discretization operators S_h and S_h^* are bounded in the following sense:*

(i) $\|S_h\|_{Q\to V} \le c$, $\|S_h^*\|_{Q\to V} \le c$,
(ii) $\|S_h\|_{Q\to L^\infty(\Omega)^d} \le c$, $\|S_h^*\|_{Q\to L^\infty(\Omega)^d} \le c$,
(iii) $\|S_h\|_{Q\to V_h^2(\Omega)^d} \le c$, $\|S_h^*\|_{Q\to V_h^2(\Omega)^d} \le c$.

Proof. We sketch only the proof for the operator S_h. The results for the adjoint operator S_h^* can be derived by the same techniques. In order to prove the first estimate we set $\phi_h = (S_h(g), S_h^p(g))$ in (3.2) and obtain

$$\|\nabla S_h(g)\|^2_{L^2(\Omega)^d} + s_h(S_h^p(g), S_h^p(g)) = (g, S_h(g)).$$

Due to (A4) we have

$$\|\nabla S_h(g)\|^2_{L^2(\Omega)^d} \le (g, S_h(g)).$$

The assertion follows then by Poincaré inequality.

The second estimate is obtained using (ii) from Lemma 3.2:

$$\|S_h(g)\|_{L^\infty(\Omega)^d} \le \|S(g) - S_h(g)\|_{L^\infty(\Omega)^d} + \|S(g)\|_{L^\infty(\Omega)^d} \le c(1+h)\|g\|_{L^2(\Omega)}.$$

The third estimate is obtained similarly using (iii) from Lemma 3.2. ∎

LEMMA 3.4. *Let the conditions of Lemma* 2.1 *be fulfilled, i.e., in particular,* $w \in H^2(\Omega)^d \cap W^{1,\infty}(\Omega)^d$. *Then the inequality*

$$(\psi_h, \bar{q} - R_h\bar{q}) \le ch^2(\|\psi_h\|_{L^\infty(\Omega)^d} + \|\psi_h\|'_{H^2(\Omega)^d})(\|\bar{q}\|_{L^\infty(\Omega)^d} + \|\bar{w}\|_{W^{2,p'}(\Omega)^d})$$

is satisfied for all $\psi_h \in V_h$ *provided that the assumptions* (A1)–(A7) *are fulfilled.*

Proof. With the sets K_1 and K_2 introduced by (2.8), we obtain

$$(\psi_h, \bar{q} - R_h\bar{q}) = \int_{K_1} \psi_h \cdot (\bar{q} - R_h\bar{q})\,dx + \int_{K_2} \psi_h \cdot (\bar{q} - R_h\bar{q})\,dx. \tag{3.3}$$

Using the $W^{1,\infty}$-regularity of $\bar{q}$, the K_1-part can be estimated as follows:

$$\begin{aligned}\int_{K_1} \psi_h \cdot (\bar{q} - R_h\bar{q})\,dx &= \sum_{T\subset K_1} \int_T \psi_h \cdot (\bar{q} - R_h\bar{q})\,dx \\ &\le \|\psi_h\|_{L^\infty(\Omega)^d} \sum_{T\subset K_1} \|\bar{q} - R_h\bar{q}\|_{L^\infty(T)^d} \int_T dx \\ &\le ch\|\psi_h\|_{L^\infty(\Omega)^d} |\bar{q}|_{W^{1,\infty}(\Omega)^d} |K_1|. \end{aligned} \tag{3.4}$$

Assumption (A7) and the properties of the projection (2.6) yield

$$\begin{aligned}\int_{K_1} \psi_h \cdot (\bar{q} - R_h\bar{q})\,dx &\le ch^2\|\psi_h\|_{L^\infty(\Omega)^d} \|\bar{w}\|_{W^{1,\infty}(\Omega)^d} \\ &\le ch^2\|\psi_h\|_{L^\infty(\Omega)^d} \|\bar{w}\|_{W^{2,p'}(\Omega)^d}. \end{aligned} \tag{3.5}$$

On the K_2-part, we proceed as follows:

$$\begin{aligned}\left|\int_{K_2} \psi_h \cdot (\bar{q} - R_h\bar{q})\,dx\right| &\le \left|\int_{K_2} (\psi_h \cdot R_h\bar{q} - R_h(\psi_h \cdot \bar{q}))\,dx\right| \\ &\quad + \left|\int_{K_2} \psi_h \cdot \bar{q} - R_h(\psi_h \cdot \bar{q})\,dx\right|. \end{aligned} \tag{3.6}$$

Using $R_h(\psi_h \cdot \bar{q}) = R_h\psi_h \cdot R_h\bar{q}$, we find for the first integral

$$\left|\int_{K_2} (\psi_h \cdot R_h\bar{q} - R_h(\psi_h \cdot \bar{q}))\,dx\right| \le \sum_{T\subset K_2} \left|\int_T (\psi_h - R_h\psi_h) \cdot R_h\bar{q}\,dx\right|.$$

Note, that $R_h\bar{q}$ is constant on every element T. Hence, we can continue with

$$\left|\int_{K_2} (\psi_h \cdot R_h\bar{q} - R_h(\psi_h \cdot \bar{q}))\,dx\right| \le \sum_{T\subset K_2} \left|R_h\bar{q} \cdot \int_T (\psi_h - R_h\psi_h)\,dx\right|.$$

Consequently, we find by means of (A6)

$$\begin{aligned}\left|\int_{K_2} (\psi_h \cdot R_h\bar{q} - R_h(\psi_h \cdot \bar{q}))\,dx\right| &\le ch^2 \sum_{T\subset K_2} |T|^{1/2}\|\bar{q}\|_{L^\infty(T)^d} |\psi_h|_{H^2(T)^d} \\ &\le c|\Omega|^{1/2}h^2\|\bar{q}\|_{L^\infty(\Omega)^d} \|\psi_h\|'_{H^2(\Omega)^d} \\ &\le ch^2\|\bar{w}\|_{L^\infty(\Omega)^d} \|\psi_h\|'_{H^2(\Omega)^d}. \end{aligned} \tag{3.7}$$

It remains the second integral in (3.6). Again, we can use (A6):

$$\left|\int_{K_2} \psi_h\cdot\bar q - R_h(\psi_h\cdot\bar q)\,dx\right| \le \sum_{T\subset K_2}\left|\int_T \psi_h\cdot\bar q - R_h(\psi_h\cdot\bar q)\,dx\right| \le ch^2\sum_{T\subset K_2}|T|^{1/2}|\psi_h\cdot\bar q|_{H^2(T)}. \tag{3.8}$$

We will estimate this seminorm by

$$\begin{aligned}|\psi_h\cdot\bar q|_{H^2(T)} &\le \|\psi_h\|_{L^\infty(T)^d}|\bar q|_{H^2(T)^d} + |\psi_h|_{H^2(T)^d}\|\bar q\|_{L^\infty(T)^d}\\ &\quad + 2|\psi_h|_{H^1(T)^d}|\bar q|_{W^{1,\infty}(T)^d}.\end{aligned} \tag{3.9}$$

The projection formula (2.6) and the fact that $\bar q$ smooth is on every $T\subset K_2$ imply

$$\begin{aligned}|\psi_h\cdot\bar q|_{H^2(T)} &\le c(\|\psi_h\|_{L^\infty(T)^d}|\bar w|_{H^2(T)^d}+|\psi_h|_{H^2(T)^d}\|\bar q\|_{L^\infty(T)^d}+|\psi_h|_{H^1(T)^d}|\bar w|_{W^{1,\infty}(T)^d})\\ &\le c(\|\psi_h\|_{L^\infty(\Omega)^d}|\bar w|_{H^2(T)^d}+|\psi_h|_{H^2(T)^d}\|\bar q\|_{L^\infty(\Omega)^d}+|\psi_h|_{H^1(T)^d}|\bar w|_{W^{1,\infty}(\Omega)^d})\end{aligned} \tag{3.10}$$

Combining (3.8) with (3.10) we find

$$\begin{aligned}\left|\int_{K_2} \psi_h\cdot\bar q - R_h(\psi_h\cdot\bar q)\,dx\right| &\le ch^2\sum_{T\subset K_2}|T|^{1/2}(\|\psi_h\|_{L^\infty(\Omega)^d}|\bar w|_{H^2(T)^d}\\ &\quad + |\psi_h|_{H^2(T)^d}\|\bar q\|_{L^\infty(\Omega)^d} + |\psi_h|_{H^1(T)^d}|\bar w|_{W^{1,\infty}(\Omega)^d})\\ &\le ch^2(\|\psi_h\|_{L^\infty(\Omega)^d}\|\bar w\|_{H^2(\Omega)^d}\\ &\quad + \|\psi_h\|'_{H^2(\Omega)^d}\|\bar q\|_{L^\infty(\Omega)^d} + \|\psi_h\|_{H^1(\Omega)^d}\|\bar w\|_{W^{1,\infty}(\Omega)^d}).\end{aligned}$$

By imbedding arguments we end up with

$$\begin{aligned}\left|\int_{K_2} \psi_h\cdot\bar q - R_h(\psi_h\cdot\bar q)\,dx\right| &\le ch^2(\|\psi_h\|_{L^\infty(\Omega)^d}\\ &\quad + \|\psi_h\|'_{H^2(\Omega)^d})(\|\bar q\|_{L^\infty(\Omega)^d} + \|\bar w\|_{W^{2,p'}(\Omega)^d})\end{aligned} \tag{3.11}$$

Inserting (3.7) and (3.11) into (3.6), we obtain

$$\begin{aligned}\left|\int_{K_2} (\psi_h\cdot R_h\bar q - R_h(\psi_h\cdot\bar q))\,dx\right| &\le ch^2(\|\psi_h\|_{L^\infty(\Omega)^d} + \|\psi_h\|'_{H^2(\Omega)^d})\\ &\quad (\|\bar q\|_{L^\infty(\Omega)^d} + \|\bar w\|_{W^{2,p'}(\Omega)^d}).\end{aligned} \tag{3.12}$$

From (3.3), (3.5), and (3.12), the assertion follows immediately. ∎

LEMMA 3.5. *Let $p'>d$ the regularity parameter of Lemma* 2.1 *and* (A1)–(A7) *be fulfilled. Then the estimates*

$$\|S_h(\bar q+f) - S_h(R_h\bar q+f)\|_Q \le ch^2(\|\bar q\|_{L^\infty(\Omega)^d} + \|\bar w\|_{W^{2,p'}(\Omega)^d}) \tag{3.13}$$

$$\|P_h\bar q - P_hR_h\bar q\|_Q \le ch^2(\|\bar q\|_{L^\infty(\Omega)^d} + \|\bar w\|_{W^{2,p'}(\Omega)^d}) \tag{3.14}$$

are valid.

Proof. We start with

$$\begin{aligned}\|S_h(\bar q+f) - S_h(R_h\bar q+f)\|_Q^2 &= (S_h(\bar q+f) - S_h(R_h\bar q+f), S_h(\bar q+f) - S_h(R_h\bar q+f))_Q\\ &= (S_h(\bar q - R_h\bar q), (S_h(\bar q+f) - v_d) - (S_h(R_h\bar q+f) - v_d))_Q\\ &= (\bar q - R_h\bar q, P_h\bar q - P_hR_h\bar q)_Q\\ &\le ch^2(\|P_h\bar q - P_hR_h\bar q\|_{L^\infty(\Omega)^d} + \|P_h\bar q - P_hR_h\bar q\|'_{H^2(\Omega)^d})\\ &\quad \cdot(\|\bar q\|_{L^\infty(\Omega)^d} + \|\bar w\|_{W^{2,p'}(\Omega)^d}),\end{aligned} \tag{3.15}$$

where we have used Lemma 3.4 with $\psi_h = P_h\bar{q} - P_hR_h\bar{q}$. We benefit now from the fact that $P_h\bar{q}$ and $P_hR_h\bar{q}$ are solutions of the discretized adjoint equation, that means $\psi_h = P_h\bar{q} - P_hR_h\bar{q} = S_h^*(S_h(\bar{q}+f) - v_d) - S_h^*(S_h(R_h\bar{q}+f) - v_d) = S_h^*(S_h(\bar{q}+f) - S_h(R_h\bar{q}+f))$. Therefore we obtain by Lemma 3.3

$$\|P_h\bar{q} - P_hR_h\bar{q}\|_{L^\infty(\Omega)^d} \le c\|S_h(\bar{q}+f) - S_h(R_h\bar{q}+f)\|_Q \tag{3.16}$$

and

$$\|P_h\bar{q} - P_hR_h\bar{q}\|'_{H^2(\Omega)^d} \le c\|S_h(\bar{q}+f) - S_h(R_h\bar{q}+f)\|_Q. \tag{3.17}$$

Inserting (3.16) and (3.17) in (3.15) and dividing by $\|S_h(\bar{q}+f) - S_h(R_h\bar{q}+f)\|_Q$, the assertion (3.13) is obtained. Inequality (3.13) and the continuity of S_h in Q yield (3.14). ∎

COROLLARY 3.6. *Let $p' > d$ the regularity parameter of Lemma* 2.1 *and* (A1)–(A7) *be fulfilled. Then the inequality*

$$\|\bar{w} - P_hR_h\bar{q}\|_Q \le ch^2(\|\bar{q}\|_{L^\infty(\Omega)^d} + \|v_d\|_{L^\infty(\Omega)^d} + \|f\|_{L^\infty(\Omega)^d} + \|\bar{w}\|_{W^{2,p'}(\Omega)^d}) \tag{3.18}$$

is valid.

Proof. We apply Lemma 3.2 for $q = \bar{q}$. Using $\bar{w} = P\bar{q}$, we obtain

$$\|\bar{w} - P_h\bar{q}\|_Q \le ch^2(\|\bar{q}\|_{L^\infty(\Omega)^d} + \|v_d\|_{L^\infty(\Omega)^d} + \|f\|_{L^\infty(\Omega)^d})$$

The assertion follows now from (3.14) and the triangle inequality. ∎

4. Superconvergence properties. In this section, we prove the main results stated in section 2. We start with an auxiliary result.

LEMMA 4.1. *The inequality*

$$\nu\|R_h\bar{q} - \bar{q}_h\|_Q^2 \le (R_h\bar{w} - \bar{w}_h, \bar{q}_h - R_h\bar{q})_Q \tag{4.1}$$

is valid provided that the assumptions (A1)–(A7) *hold.*

Proof. First, we recall the optimality condition (2.5):

$$(\bar{w} + \nu\bar{q}, q - \bar{q})_Q \ge 0 \quad \text{for all } q \in Q_{ad}.$$

This formula holds also pointwise a.e. in Ω:

$$(\bar{w}(x) + \nu\bar{q}(x)) \cdot (q(x) - \bar{q}(x)) \ge 0 \quad \text{for all } q \in Q_{ad}.$$

Consider any element T with center of gravity S_T and apply this formula for $x = S_T$ and $q = \bar{q}_h$. This can be done because of the continuity of the functions $\bar{w}$, $\bar{q}$, and $\bar{q}_h$ in this point:

$$(\bar{w}(S_T) + \nu\bar{q}(S_T)) \cdot (\bar{q}_h(S_T) - \bar{q}(S_T)) \ge 0 \quad \text{for all } T \in \mathcal{T}_h.$$

Due to the definition of R_h, this is equivalent to

$$(R_h\bar{w}(S_T) + \nu R_h\bar{q}(S_T)) \cdot (\bar{q}_h(S_T) - R_h\bar{q}(S_T)) \ge 0 \quad \text{for all } T \in \mathcal{T}_h.$$

We integrate this formula over T, add over all T, and get

$$(R_h\bar{w} + \nu R_h\bar{q}, \bar{q}_h - R_h\bar{q})_Q \ge 0. \tag{4.2}$$

Otherwise, the optimal control $\bar{q}_h$ of the discretized problem fulfills the optimality condition

$$(\bar{w}_h + \nu\bar{q}_h, q - \bar{q}_h)_Q \geq 0 \quad \text{for all } q \in Q_h^{ad}. \tag{4.3}$$

We apply this formula for $q = R_h\bar{q}$:

$$(\bar{w}_h + \nu\bar{q}_h, R_h\bar{q} - \bar{q}_h)_Q \geq 0. \tag{4.4}$$

Adding (4.2) and (4.4), we obtain

$$(R_h\bar{w} - \bar{w}_h + \nu(R_h\bar{q} - \bar{q}_h), \bar{q}_h - R_h\bar{q})_Q \geq 0 \tag{4.5}$$

This completes the proof. □

Remark 4.2. Lemma 4.1 is the key to prove our main results. The presented technique benefits from the fact that the controls are discretized by piecewise constant functions. The derivation of the estimate (4.1) motivates our choice for the control discretization.

Now we are able to prove Theorem 2.6.

Proof of Theorem 2.6. We begin by rewriting formula (4.1):

$$\begin{aligned}\nu\|R_h\bar{q} - \bar{q}_h\|_Q^2 &\leq (R_h\bar{w} - \bar{w}_h, \bar{q}_h - R_h\bar{q})_Q \\ &= (R_h\bar{w} - \bar{w}, \bar{q}_h - R_h\bar{q})_Q + (\bar{w} - P_hR_h\bar{q}, \bar{q}_h - R_h\bar{q})_Q \\ &\quad + (P_hR_h\bar{q} - \bar{w}_h, \bar{q}_h - R_h\bar{q})_Q. \end{aligned} \tag{4.6}$$

Let us now estimate these three terms. We start with the first term using (A6) and the fact that $\bar{q}_h - R_h\bar{q}$ is piecewise constant on each element,

$$\begin{aligned}(R_h\bar{w} - \bar{w}, \bar{q}_h - R_h\bar{q})_Q &= \sum_{T\in\mathcal{T}_h}\int_T (R_h\bar{w}(x) - \bar{w}(x)) \cdot (\bar{q}_h(x) - R_h\bar{q}(x))\,dx \\ &= \sum_{T\in\mathcal{T}_h} (\bar{q}_h(S_T) - \bar{q}(S_T)) \cdot \int_T (\bar{w}(S_T) - \bar{w}(x))\,dx \\ &\leq \sum_{T\in\mathcal{T}_h} ch^2|\bar{q}_h(S_T) - \bar{q}(S_T)||T|^{1/2}|\bar{w}|_{H^2(T)^d} \\ &\leq ch^2\|\bar{q}_h - R_h\bar{q}\|_Q\|\bar{w}\|_{W^{2,p'}(\Omega)^d}. \end{aligned} \tag{4.7}$$

The second term in (4.6) is estimated by Corollary 3.6 and the Cauchy–Schwartz inequality:

$$\begin{aligned}(\bar{w} - P_hR_h\bar{q}, \bar{q}_h - R_h\bar{q})_Q \leq ch^2(&\|\bar{q}\|_{L^\infty(\Omega)^d} + \|v_d\|_{L^\infty(\Omega)^d} + \|f\|_{L^\infty(\Omega)^d} \\ &+ \|\bar{w}\|_{W^{2,p'}(\Omega)^d})\|\bar{q}_h - R_h\bar{q}\|_Q. \end{aligned} \tag{4.8}$$

The third term can be omitted because of

$$\begin{aligned}(P_hR_h\bar{q} - \bar{w}_h, \bar{q}_h - R_h\bar{q})_Q &= (P_hR_h\bar{q} - P_h\bar{q}_h, \bar{q}_h - R_h\bar{q})_Q \\ &= (S_h^*(S_h(R_h\bar{q} + f) - v_d) - S_h^*(S_h(\bar{q}_h + f) - v_d), \bar{q}_h - R_h\bar{q})_Q \\ &= (S_h^*S_h(R_h\bar{q} - \bar{q}_h), \bar{q}_h - R_h\bar{q})_Q \\ &= (S_h(R_h\bar{q} - \bar{q}_h), S_h(\bar{q}_h - R_h\bar{q}))_Q \\ &\leq 0. \end{aligned} \tag{4.9}$$

Inserting (4.7)–(4.9) into (4.6), we end up with

$$\nu\|R_h\bar{q}-\bar{q}_h\|_Q^2 \le ch^2(\|\bar{q}\|_{L^\infty(\Omega)^d}+\|v_d\|_{L^\infty(\Omega)^d}+\|f\|_{L^\infty(\Omega)^d} +\|\bar{w}\|_{W^{2,p'}(\Omega)^d})\|\bar{q}_h-R_h\bar{q}\|_Q. \tag{4.10}$$

This inequality is equivalent to the assertion (2.9). ∎

Proof of Theorem 2.7. Using the triangle inequality, we find

$$\begin{aligned}\|\bar{v}-\bar{v}_h\|_Q &= \|S(\bar{q}+f)-S_h(\bar{q}_h+f)\|_Q\\ &\le \|S(\bar{q}+f)-S_h(\bar{q}+f)\|_Q+\|S_h(\bar{q}+f)-S_h(R_h\bar{q}+f)\|_Q+\|S_h(R_h\bar{q}-\bar{q}_h)\|_Q.\end{aligned}$$

The first term is estimated using Lemma 3.2, for the second term we use the assertion from Lemma 3.5, and for the third term we apply Theorem 2.6 and the boundedness of S_h. This yields estimate (2.10).

Inequality (2.11) can be similarly obtained by Corollary 3.6, Theorem 2.6, and the boundedness of S_h and S_h^* in $\mathcal{L}(Q)$. ∎

Next, we prove Theorem 2.8.

Proof of Theorem 2.8. We use the Lipschitz continuity of the projection operator and find

$$\begin{aligned}\|\tilde{q}_h-\bar{q}\|_Q &= \left\|\Pi_{[a,b]}\Big(-\frac{1}{\nu}\bar{w}_h\Big)-\Pi_{[a,b]}\Big(-\frac{1}{\nu}\bar{w}\Big)\right\|_Q\\ &\le \frac{1}{\nu}\|\bar{w}_h-\bar{w}\|_Q.\end{aligned}$$

Inequality (2.11) now implies the assertion. ∎

5. Verification of the assumptions for concrete numerical schemes. In this section we check the assumptions (A1)–(A6) for some discretization schemes. Let $\mathcal{T}_h$ be a shape regular quasi-uniform mesh (see, e.g., Braess [5]) consisting of triangles or quadrilaterals for $d=2$ or tetrahedrons or hexahedrons for $d=3$. Then, the assumption (A1) is automatically fulfilled. If the control is defined on the same mesh, then assumption (A2) is fulfilled, too.

Let P_h^k denote the space of finite elements of order k on a triangle/tetrahedron mesh $\mathcal{T}_h$ and Q_h^k denote the space of finite elements of order k (bi/trilinear, bi/triquadratic etc.) on a quadrilateral/hexahedron mesh $\mathcal{T}_h$.

If $(P_h^k)^d \subset V_h$ and $P_h^l \subset L_h$ (or $(Q_h^k)^d \subset V_h$ and $Q_h^l \subset L_h$) for $k \ge 1$, $l \ge 0$, then the assumptions (A3) and (A5) follow by standard arguments; see, e.g., [5] or [10]. Assumption (A6) is also fulfilled on shape regular quasi-uniform meshes, which can be seen by virtue of the Bramble–Hilbert lemma and a transformation argument.

It still remains to discuss the assumption (A4). As mentioned in Remark 2.3, this assumption is obviously fulfilled, if the pair (V_h, L_h) is stable, i.e., if the inf-sup condition is directly fulfilled for (V_h, L_h). Therefore, our results are justified for all such pairs, as, e.g., "Taylor–Hood element" P_2/P_1, Q_2/Q_1/ or higher order "Taylor–Hood element" P_{k+1}/P_k, Q_{k+1}/Q_k; see [21], different bubble elements (P_1^b/P_0, Q_1^b/Q_0 etc.; see, e.g., [17]) etc.

In what follows we want to recall another discretization scheme, introduced in Becker and Braack [2], which also fulfills the assumption (A4). This scheme will be used in the next section for the numerical example.

For this discretization we assume that the (quadrilateral or hexahedron) mesh $\mathcal{T}_h$ is organized in a patchwise manner. This means, that it results from a coarser regular

mesh $\mathcal{T}_{2h}$ by one uniform refinement. By a "patch" of elements we denote a group of four cells (in 2D) or eight cells (in 3D) in $\mathcal{T}_h$ which results from a common coarser cell in $\mathcal{T}_{2h}$. The finite element spaces are chosen as

$$V_h = (Q_h^1)^d \qquad L_h = Q_h^1.$$

The space $\tilde{L}_h$ is defined as the space of bilinear/trilinear elements on the patch-mesh $\mathcal{T}_{2h}$, i.e., $\tilde{L}_h = Q_{2h}^1$. The stabilization form $s_h(\cdot,\cdot)$ is defined as

$$s_h(p_h, \xi_h) = \delta_0 h^2 \sum_{P \in \mathcal{T}_{2h}} (\nabla p_h - \widetilde{\nabla p_h}, \nabla \xi_h - \widetilde{\nabla \xi_h})_{L^2(P)},$$

where

$$\widetilde{\nabla p_h} = \frac{1}{|P|} \int_P \nabla p_h \, dx.$$

We refer to [2] for the proof that this scheme fulfills the assumption (A4). We note, also that other equal order stabilized schemes are included in our setting; see, e.g., [6].

6. Numerical examples. In this section we present two numerical examples (2D and 3D) illustrating our results. In both examples the Stokes equation are discretized by equal order elements (bilinear in 2D and trilinear in 3D) with a stabilization term as described in the previous section. The resulting finite dimensional optimal control problem is solved by primal-dual active set method; see, e.g., [3] or [22].

6.1. Example in 2D. We consider an optimal control problem as stated in section 1 with

$$\Omega = (0,1)^2, \quad \nu = 1, \quad a = (-0.1, -0.1)^t, \quad b = (0.25, 0.25)^t,$$

and a given solution

$$\begin{aligned} \bar{v}_1 &= \bar{w}_1 = \sin^2(\pi x)\, \sin(\pi y)\, \cos(\pi y), \\ \bar{v}_2 &= \bar{w}_2 = -\sin^2(\pi y)\, \sin(\pi x)\, \cos(\pi x), \\ \bar{p} &= \bar{r} = \sin(2\pi x)\, \sin(2\pi y), \end{aligned}$$

and

$$\bar{q} = \Pi_{[a,b]}\Big(-\frac{1}{\nu} \bar{w} \Big).$$

The data of the problem is then given by

$$\begin{aligned} f &= -\Delta \bar{v} + \nabla \bar{p} - \bar{q}, \\ v_d &= \bar{v} + \Delta \bar{w} + \nabla \bar{r}. \end{aligned}$$

In Figure 6.1 we show the first component of the optimal solution $\bar{q}$. The second component of $\bar{q}$ has a similar structure.

Let us remark that the assumption (A7) is fulfilled for this example. Let

$$\gamma_{ex} := \{x \in \Omega : (\bar{w}_1(x) - a_1)(\bar{w}_1(x) - b_1)(\bar{w}_2(x) - a_2)(\bar{w}_2(x) - b_2) = 0\},$$

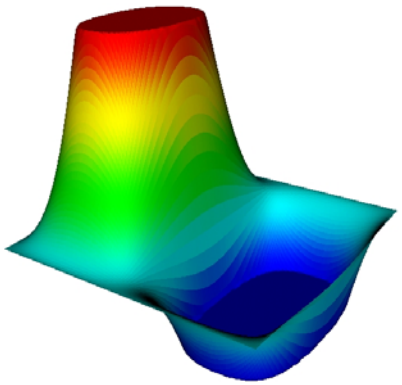

FIG. 6.1. *The first component of the optimal solution* $\bar{q}$.

TABLE 6.1
Convergence of $\|\bar{q} - \bar{q}_h\|_Q$ *and* $\|\bar{q} - \tilde{q}_h\|_Q$ *for* h *tending to zero.*

$h/\sqrt{2}$	$\|\bar{q} - \bar{q}_h\|_Q$	reduction rate	$\|\bar{q} - \tilde{q}_h\|_Q$	reduction rate
2^{-2}	7.65e-2	–	3.84e-2	–
2^{-3}	5.06e-2	1.50	8.59e-3	4.47
2^{-4}	2.73e-2	1.85	1.82e-3	4.72
2^{-5}	1.39e-2	1.97	4.23e-4	4.29
2^{-6}	6.99e-3	1.99	1.02e-4	4.15
2^{-7}	3.51e-3	1.99	2.51e-5	4.06

i.e., the curve (consisting of four connected parts) that separates active and inactive parts of the optimal control. Then we find the estimate

$$|K_1| \leq 2h|\gamma_{ex}|$$

and consequently (A7) holds.

In Table 6.1 we show the behavior of the error $\|\bar{q} - \bar{q}_h\|_Q$ and the error after the postprocessing step, i.e., $\|\bar{q} - \tilde{q}_h\|_Q$ on a sequence of uniformly refined meshes. As expected, we observe first order convergence for $\|\bar{q} - \bar{q}_h\|_Q$ and second order convergence for $\|\bar{q} - \tilde{q}_h\|_Q$.

In Table 6.2 we show the corresponding results concerning the error behavior with respect to $\|\cdot\|_{L^\infty(\Omega)}$. Although we only proved the results concerning the convergence with respect to $\|\cdot\|_{L^2(\Omega)}$, we observe similar behavior also for $\|\cdot\|_{L^\infty(\Omega)}$.

The results concerning the error behavior for the optimal velocity and the optimal pressure are given in Table 6.3. The pressure shows better order of convergence as $\mathcal{O}(h)$. Such effects are known for equal order finite elements on uniform meshes; see, e.g., [2].

6.2. Example in 3D. For the 3D case we construct a similar example as in 2D by setting

$$\Omega = (0,1)^3, \quad \nu = 1, \quad a = (-0.1, -0.1, -0.1)^t, \quad b = (0.25, 0.25, 0.01)^t.$$

TABLE 6.2
Convergence of $\|\bar{q} - \bar{q}_h\|_{L^\infty(\Omega)^d}$ and $\|\bar{q} - \tilde{q}_h\|_{L^\infty(\Omega)^d}$ for h tending to zero.

$h/\sqrt{2}$	$\|\bar{q} - \bar{q}_h\|_{L^\infty(\Omega)^d}$	reduction rate	$\|\bar{q} - \tilde{q}_h\|_{L^\infty(\Omega)^d}$	reduction rate
2^{-2}	2.60e-1	–	1.20e-1	–

2^{-7}	1.63e-2	2.00	1.22e-4	3.88

TABLE 6.3
Convergence of $\|\bar{v} - \bar{v}_h\|_{L^2(\Omega)^d}$ and $\|\bar{p} - \bar{p}_h\|_{L^2(\Omega)}$ for h tending to zero.

$h/\sqrt{2}$	$\|\bar{v} - \bar{v}_h\|_{L^2(\Omega)^d}$	reduction rate	$\|\bar{p} - \bar{p}_h\|_{L^2(\Omega)}$	reduction rate
2^{-2}	6.81e-2	–	4.94e-1	–
2^{-3}	1.68e-2	4.05	1.65e-1	2.99
2^{-4}	4.08e-3	4.12	5.49e-2	3.01
2^{-5}	9.95e-4	4.10	1.91e-2	2.87
2^{-6}	2.47e-4	4.02	6.67e-3	2.86
2^{-7}	6.12e-5	4.04	2.35e-3	2.84

The exact solution is given by

$$\begin{aligned}
\bar{v}_1 &= \bar{w}_1 = 2\,\sin^2(\pi x)\,\sin(2\pi y)\,\sin(2\pi z),\\
\bar{v}_2 &= \bar{w}_2 = -\sin^2(\pi y)\,\sin(2\pi x)\,\sin(2\pi z),\\
\bar{v}_3 &= \bar{w}_3 = -\sin^2(\pi z)\,\sin(2\pi x)\,\sin(2\pi y),\\
\bar{p} &= \bar{r} = \sin(2\pi x)\,\sin(2\pi y)\,\sin(2\pi z),
\end{aligned}$$

and

$$\bar{q} = \Pi_{[a,b]}\Big(-\frac{1}{\nu}\bar{w}\Big).$$

The data of the problem is then determined by

$$\begin{aligned}
f &= -\Delta\bar{v} + \nabla\bar{p} - \bar{q},\\
v_d &= \bar{v} + \Delta\bar{w} + \nabla\bar{r}.
\end{aligned}$$

For this problem, Assumption (A7) is valid for similar reasons as in the previous example. As for the 2D example, we present the behavior of error $\|\bar{q} - \bar{q}_h\|_Q$ and the error after the postprocessing step, i.e., $\|\bar{q} - \tilde{q}_h\|_Q$ in Table 6.4, and for the corresponding L^∞-norm in Table 6.5. In Table 6.6 the error for optimal pressure and velocity are shown.

TABLE 6.4

CONVERGENCE OF AN IMPLICIT SPACETIME GODUNOV FINITE VOLUME METHOD FOR A CLASS OF HYPERBOLIC SYSTEMS*

KATARINA JEGDIC† AND ROBERT L. JERRARD‡

Abstract. We study an implicit spacetime Godunov method for a class of hyperbolic conservation laws known as Temple class systems. We establish the well-posedness of this method, a discrete entropy inequality, a property analogous to the total variation diminishing property of certain numerical schemes for scalar conservation laws, and, as a consequence, the convergence of the numerical method.

Key words. conservation laws, spacetime discontinuous, Temple systems

1. Introduction.

In this paper we prove the convergence of an implicit spacetime Godunov finite volume method for solving certain systems of hyperbolic conservation laws:

$$u_t + f(u)_x = 0, \qquad u : [0,\infty) \times \mathbb{R} \to \mathcal{D} \subset \mathbb{R}^n. \tag{1.1}$$

Here u is the vector of unknown densities of conserved variables, and $f : \mathcal{D} \to \mathbb{R}^n$ is the spatial flux defined on a domain of conservation states $\mathcal{D} \subset \mathbb{R}^n$. The system is supplemented by the initial condition

$$u(0,x) = u_0(x), \qquad x \in \mathbb{R}, \tag{1.2}$$

with the assumption that u_0 is a function of bounded variation.

In the numerical scheme that we consider, we fix a partition $\mathcal{T}_h$ of $[0,\infty)\times\mathbb{R}$ into a union of closed triangles T with diameter $\approx h$ and with pairwise disjoint interiors. We seek an approximate solution u_h in the space $\mathcal{P}_h$ of functions $u : [0,\infty) \times \mathbb{R} \to \mathcal{D}$ that are constant on the interior of each triangle. This approximate solution is required to satisfy an equation of the form

$$\int_{\partial T} F^{num}\, d\mathcal{H}^1 = 0 \tag{1.3}$$

for all triangles T in the triangulation $\mathcal{T}_h$. Here $\mathcal{H}^1$ denotes the one-dimensional Hausdorff measure on ∂T, and F^{num} denotes a numerical flux function, taking values in $\mathbb{R}^n$ and depending on the values of u_h on both sides of ∂T and on the unit normal

to ∂T. The approximate solution u_h is also required to satisfy $u_h(0,\cdot) = u_{0h}$ in a suitable sense, where u_{0h} is a discretization of the initial data.

In this paper we always take the numerical flux in (1.3) to be the Godunov flux, the definition of which is recalled in section 3.2; this is arguably the most natural choice on physical grounds. In general, (1.3) is a massively coupled system of nonlinear equations, since values of u_h on adjacent triangles are coupled through the Godunov flux. Following [18], [20], we define *causal* and *patchwise causal* triangulations (see section 3.4) for which these equations largely decouple and take on a simpler form. Our main results, which are summarized in Theorem 3.3, prove that for these sorts of triangulations, and for a special class of conservation laws known as Temple class systems, approximate solutions generated by (1.3) converge to solutions that verify certain entropy inequalities.

With causal or patchwise causal triangulations and the Godunov flux, (1.3) is suitable for adaptive meshing and parallelization. The computational complexity is $O(N)$, where N is the number of triangles on which the approximate solution is computed. (For compactly supported initial data on a finite time interval, effectively $N \sim h^{-2}$.) In addition, it will be clear that (1.3) with the Godunov flux is consistent with the system (1.1).

Temple class systems were introduced in [27]. We recall their definition in section 2.2. Their chief properties are, first, that they come equipped with a coordinate system of Riemann invariants, in our notation given by a diffeomorphism $b = (b^1, \dots, b^n) : \mathcal{D} \to \mathcal{R} \subset \mathbb{R}^n$; and, second, that the set

$$S_{\alpha,c} := \{u \in \mathcal{D} : b^{\alpha_1}(u) = c_1, \dots, b^{\alpha_k}(u) = c_k\}$$

is an invariant set for solutions of (1.1), for any $\alpha = (\alpha_1, \dots, \alpha_k)$ and $c = (c_1, \dots, c_k)$ with $1 \le \alpha_1 < \cdots < \alpha_k \le n$. (A particular form of this invariance property, adapted to our purposes, is given in Lemma 5.3.) In [27] it was shown that Temple class systems of the sort that we consider are the only genuinely nonlinear, strictly hyperbolic systems with this abundance of invariant submanifolds.

A key point in the proof is an estimate analogous to the well-known total variation diminishing (TVD) property enjoyed by certain numerical schemes for scalar conservation laws. We show that when (1.1) is a Temple class system, for the approximation scheme (1.3) with the Godunov flux and a suitable triangulation $\mathcal{T}_h$, the approximate solution u_h is such that if $w_h^i := b^i(u_h)$, then

$$t \mapsto TV(w_h^i(t,\cdot)) \quad \text{is a nonincreasing function} \tag{1.4}$$

for every $i \in \{1, \dots, n\}$, where TV denotes the total variation. This conclusion is deduced from a related statement that holds on individual triangles, and it easily implies that sequences of approximate solutions are precompact in appropriate norms.

Note that a system that admits a convergent numerical method satisfying (1.4) must itself have the same property, and this implies in particular that $S_{\alpha,c}$, as defined above, is an invariant set for such a system (1.1). Thus (1.4) can hold only if (1.1) is a Temple class system, and hence our analysis relies very heavily on specific properties of Temple class systems.

Related work. The method (1.3) is the $k = 0$ case of various spacetime discontinuous Galerkin (DG) finite element methods, as proposed in [8], [18], [20], for example. Spacetime DG methods were first devised and studied for linear hyperbolic equations; see [14], [11]. They are now well understood for scalar conservation laws, starting with work on the shock-capturing DG method. Convergence of this method (with piecewise

polynomial approximants of arbitrary degree) for scalar conservation laws in d space dimensions was proven by Jaffre, Johnson, and Szepessy [8], and error estimates were established by Cockburn and Gremaud [3]. Related earlier work established convergence of the similar shock-capturing streamline diffusion finite element method (see [24], [25]), which, however, is not a DG method, and error estimates for this method were also given in [3]. The only work that we know of that proves convergence of any DG method for any system of conservation laws is a very recent paper of Arvanitis, Makridakis, and Tzavaras [1] that considers a DG method based on a relaxation approximation. This method, which does not reduce to (1.3) when $k = 0$, is shown in [1] to converge for systems that can be controlled using compensated compactness techniques.

As remarked earlier, our method can also be seen as a Godunov finite volume method, and our analysis is thus related to numerous results in the large literature on Godunov finite volume methods; see [15] for a survey. In particular, LeVeque and Temple [16] and Serre [22] establish the stability of Godunov's method for Temple class systems of two equations, via TVD estimates of the form (1.4). (Serre also proves similar results for the Lax–Friedrichs method and the Glimm scheme.) Our method differs from the basic Godunov scheme and other standard Godunov finite volume methods in that it is a spacetime method, and one which is implicit in the sense that, even in the easiest case, a nonlinear system of n equations in n unknowns must be solved to determine the approximate solution on each spacetime triangle. This causes genuine difficulties. For example, even existence and uniqueness of solutions of the scheme (1.3) is not immediate. Indeed, at the end of section 6 we show by example that the solution of scheme (1.3) need not be unique without suitable restrictions on the mesh, even in the scalar case.[1] It should be noted that, despite these theoretical difficulties, in practice approximate solutions can be computed quite efficiently using Newton's method; see [20] and [18] for related numerical results.

Temple class systems have also been studied by the front tracking method; see, for example, Baiti and Bressan [2], which uses front tracking approximations to establish the existence of a unique Lipschitz semigroup for large data. Heibig [7] proves that entropy solutions of Temple class systems with small total variation are unique.

Contents of this paper. We sketch the organization of this paper. Section 2 presents some notation and summarizes background on hyperbolic conservation laws, including the definition of Temple class systems and related notation that we will use throughout the paper. Section 3 gives a precise formulation of our approximation scheme and states our main results.

In section 4 we present results valid for hyperbolic systems not necessarily of Temple class, including the well-posedness of the numerical method (1.3) for causal triangulations when the flux is globally Lipschitz, and a discrete entropy inequality.

The rest of the paper deals exclusively with Temple class systems. The proof of well-posedness of the approximation scheme on a single causal triangle, with Riemann invariant bounds, is presented in section 5. (Well-posedness does not follow from the general result in section 4, as Temple class systems do not satisfy the global Lipschitz condition assumed there.) In section 6 we prove the corresponding results on a single causal patch. Finally, in section 7 we complete the proof of the main theorem by converting local Riemann invariant bounds (on a single element or patch)

[1] This issue did not arise in [8], [3], as these papers employ the Lax–Friedrichs flux where we use the Godunov flux, and in the scalar case approximate solutions are unique for *strictly* monotone numerical fluxes.

to global estimates that imply compactness sufficient to pass to limits and obtain weak solutions.

2. Definitions, notation, and background.

2.1. Some notation. We write $M^{k\times\ell}$ for the space of $k\times\ell$ matrices. We identify $\mathbb{R}^n$ with $M^{n\times 1}$, except where explicitly noted otherwise. In particular, the state variable u, flux f, and numerical flux F^{num} are understood to be column vectors. If $\zeta:\mathbb{R}^n\to\mathbb{R}^k$ is any function, then $D\zeta$ denotes its gradient, which is understood to be a $k\times n$ matrix. In particular, if ζ is a scalar function on $\mathcal{D}\subset\mathbb{R}^n$, then $D\zeta$ is a row vector.

If M is a matrix, then M^t denotes its transpose.

We write $\|\cdot\|$ to denote the Euclidean norm.

Given $v_1,v_2\in\mathbb{R}^n$, we write (v_1,v_2) to denote the $n\times 2$ matrix whose first and second columns are v_1 and v_2, respectively.

Given $\zeta:\mathbb{R}\to\mathbb{R}^k$, we write $TV(\zeta)$ to denote the total variation of ζ, i.e.,

$$TV(\zeta):=\sup\left\{\sum\|\zeta(x_i)-\zeta(x_{i-1})\|:\cdots<x_{i-1}<x_i<x_{i+1}<\cdots\right\}. \tag{2.1}$$

For $h>0$, $\mathcal{T}_h$ will always denote a triangulation of $[0,\infty)\times\mathbb{R}$, that is, a collection of closed triangles with pairwise disjoint interiors whose union is $[0,\infty)\times\mathbb{R}$. Here h denotes a length scale; we will be more precise about this later. We write T to denote a generic triangle in $\mathcal{T}_h$. We write $\mathcal{P}_h$ to denote the space of functions $u\in L^\infty([0,\infty)\times\mathbb{R};\mathbb{R}^n)$ such that, for every $T\in\mathcal{T}_h$, u is constant on the interior of T.

We write e to denote a generic edge of a triangle $T\in\mathcal{T}_h$. We use the notation

$$\nu_{e,T}:=\text{ outer unit normal to } T \text{ along edge } e.$$

Given $v\in\mathcal{P}_h$, we write v_T to indicate the value of v on the interior of triangle T.

We always make the following assumption about triangulations $\mathcal{T}_h$: for every edge e of a triangle $T\in\mathcal{T}_h$, if e is not contained in $\{t=0\}\times\mathbb{R}$, then there is a unique triangle, denoted T_e, that shares edge e with T, so that $T\cap T_e=e$. Thus v_{T_e} is the value of v "across edge e from triangle T." It will sometimes be convenient to consider a single triangle T, not as part of a triangulation $\mathcal{T}_h$. When we do this, we will write u_{T_e} to denote prescribed data on the exterior of edge e.

2.2. Systems of conservation laws. Consider a system of conservation laws (1.1). We always assume that the system (1.1) is *strictly hyperbolic*, which means that the matrix $Df(u)$ has real and distinct eigenvalues. Let us suppose that $\lambda^1(u)<\cdots<\lambda^n(u)$ for all $u\in\mathcal{D}$. Further, let us denote by $r_i(u)\in\mathbb{R}^n$ and $l_i(u)\in M^{1\times n}$, $i\in\{1,\dots,n\}$, the corresponding right and left eigenvectors, respectively, of the matrix $Df(u)$. We normalize these eigenvectors by requiring that $\|r_i(u)\|=\|l_i(u)\|=1$ for all $i\in\{1,\dots,n\}$ and $u\in\mathcal{D}$.

The ith characteristic field λ^i is called *genuinely nonlinear* if

$$D\lambda^i(u)\,r_i(u)\neq 0 \quad \text{for all } u\in\mathcal{D}. \tag{2.2}$$

If all characteristic fields of the gradient matrix Df are genuinely nonlinear, the system (1.1) is genuinely nonlinear.

We say that system (1.1) has a coordinate system of *Riemann invariants* in $\mathcal{D}$ if there exist a subset $\mathcal{R}\subset\mathbb{R}^n$ and a diffeomorphism $b:\mathcal{D}\to\mathcal{R}$ such that

$$Db(u)\,Df(u)\,Db(u)^{-1}=\Lambda(u) \quad \text{for } u\in\mathcal{D}, \tag{2.3}$$

where $\Lambda(u)$ is the diagonal matrix given by

$$\Lambda(u) := \operatorname{diag}(\lambda^1(u), \dots, \lambda^n(u)).$$

Let us define $a := b^{-1}$. For $w := b(u) \in \mathcal{R}$, we will sometimes use the following notation:

$$\begin{aligned} &\tilde{f}(w) := f(a(w)), \\ &\tilde{\lambda}^i(w) := \lambda^i(a(w)), \quad i \in \{1, \dots, n\}, \\ &\tilde{\Lambda}(w) := \Lambda(a(w)). \end{aligned} \tag{2.4}$$

Notice that (2.3) is equivalent to

$$D\tilde{f}(w) = Da(w)\,\tilde{\Lambda}(w), \quad \text{for } w \in \mathcal{R}. \tag{2.5}$$

Suppose that (1.1) is a strictly hyperbolic system of conservation laws which is genuinely nonlinear and equipped with the coordinate system of Riemann invariants. If in addition, the set

$$a(\{w \in \mathcal{R} : w^i = c\}) \tag{2.6}$$

is contained in a hyperplane in $\mathcal{D}$, for every $i \in \{1, \dots, n\}$ and every constant $c \in \mathbb{R}$, the system (1.1) is said to be a *genuinely nonlinear Temple class* system. As remarked in the introduction, Temple class systems are characterized by the fact that they have numerous invariant submanifolds.

Throughout this paper, when we study genuinely nonlinear Temple class systems, we will assume that the domain of conservation states $\mathcal{D}$ is such that

$$\mathcal{R} = b(\mathcal{D}) \subset \mathbb{R}^n \quad \text{is a rectangle} \tag{2.7}$$

with sides parallel to the coordinate hyperplanes. We will also assume that there exists K_0 (depending on f and $\mathcal{D}$) such that

$$\|Da\|_{L^\infty(\mathcal{R})} + \|Db\|_{L^\infty(\mathcal{D})} \le K_0. \tag{2.8}$$

2.3. Entropy solutions. We next recall the notion of entropy and of an entropy solution. Let (η, ψ) be an *entropy-entropy flux pair* for the system (1.1); this means that $\eta, \psi : \mathcal{D} \to \mathbb{R}$ are smooth functions, η is convex, and

$$D\eta(z)\,Df(z) = D\psi(z) \quad \text{for all } z \in \mathcal{D}. \tag{2.9}$$

Because $D^2\psi$ is symmetric, any entropy η for (1.1) must satisfy

$$D^2\eta(z)\,Df(z) = Df(z)^t\,D^2\eta(z) \quad \text{for all } z \in \mathcal{D}. \tag{2.10}$$

In the case $n = 2$, the PDE system (2.10) reduces to a hyperbolic equation whose solutions form an infinite-dimensional space of entropy functions. When $n > 2$, the system (2.10) is, in general, overdetermined. However, existence of a coordinate system of Riemann invariants is sufficient to nullify this overdeterminancy (see [5, section 7.4]). In particular, Temple class systems are endowed with large numbers of entropy-entropy flux pairs.

Suppose that u is a weak solution of the initial value problem (1.1), (1.2). If the inequality

$$\eta(u)_t + \psi(u)_x \le 0 \tag{2.11}$$

holds in the weak sense on the spacetime domain $[0, \infty) \times \mathbb{R}$ for all entropy-entropy flux pairs (η, ψ) of the system (1.1), then u is called an *entropy solution* of (1.1), (1.2).

3. Main results.

3.1. More notation. We first introduce notation that will enable us to give a precise formulation of our approximation scheme (i.e., (1.3) with the Godunov flux).

We define

$$\mathcal{T}_h^0 := \{T \in \mathcal{T}_h \ : \ \partial T \cap (\{t=0\} \times \mathbb{R}) \text{ is an interval}\}, \tag{3.1}$$

$$\mathcal{T}_h^+ := \mathcal{T}_h \setminus \mathcal{T}_h^0. \tag{3.2}$$

We write $g(u_T, u_{T_e}; \nu)$ to denote the Godunov flux. We define this below, first in full generality, and then in an important and simpler special case. (In fact, we will rarely need the general definition.) With this notation, we seek an approximate solution $u_h \in \mathcal{P}_h$ of (1.1) by requiring that u_h satisfy

$$\int_{\partial T} g(u_{h,T}, u_{h,T_e}; \nu_{e,T}) \, d\mathcal{H}^1 = 0 \quad \text{for every } T \in \mathcal{T}_h^+. \tag{3.3}$$

We also require that the initial condition (1.2) be approximately satisfied in the sense that

$$u_{h,T} = \frac{1}{\mathcal{H}^1(e)} \int_e u_0 \, dx \quad \text{for } \ e := \partial T \cap (\{t=0\} \times \mathbb{R}), \quad \text{for every } T \in \mathcal{T}_h^0. \tag{3.4}$$

3.2. Godunov flux. Formally, the *Godunov flux* associated with $u_1, u_2 \in \mathbb{R}^n$ and a unit (column) vector $\nu = (\nu_t, \nu_x)^t$ is the flux through a line element with spacetime unit normal ν, with values u_1 and u_2 on the two sides of the line element. More precisely, given u_1, u_2, ν as above, if $\nu_x \neq 0$, let $u : (0,\infty) \times \mathbb{R} \to \mathbb{R}^n$ denote the standard entropy solution of the Riemann problem[2] for (1.1) with initial data

$$u(0,x) = \begin{cases} u_1 & \text{if } \operatorname{sign} x = -\operatorname{sign} \nu_x, \\ u_2 & \text{if } \operatorname{sign} x = \operatorname{sign} \nu_x. \end{cases} \tag{3.5}$$

We define

$$\xi_-(u_1, u_2; \nu) := \lim_{(t,x)\cdot\nu \nearrow 0, \ t>0} u(t,x), \qquad \xi_+(u_1, u_2; \nu) := \lim_{(t,x)\cdot\nu \searrow 0, \ t>0} u(t,x).$$

These limits exist, since the solution u of the Riemann problem has bounded variation in x for every t and depends only on $\frac{x}{t}$. We will typically omit the dependence on u_1, u_2, ν and write ξ_-, ξ_+. The fact that u is a weak solution of (1.1) implies that $(\xi_-, f(\xi_-))\,\nu = (\xi_+, f(\xi_+))\,\nu$. Thus the definition of the Godunov flux as

$$g(u_1, u_2; \nu) := (\xi_-, f(\xi_-))\,\nu = (\xi_+, f(\xi_+))\,\nu$$

makes sense. (In fact, in the concrete situations we consider later, it will always be the case that $\xi_+ = \xi_-$, and so we will always write simply ξ and call it the *Godunov value.*) If $\nu = (\nu_t, \nu_x)^t \in \mathbb{R}^2$ is a unit vector with $\nu_x = 0$, then we define

$$g(u_1, u_2; \nu) := (u_1, f(u_1))\,\nu \quad \text{if } \nu_t = 1, \qquad g(u_1, u_2; \nu) := -(u_2, f(u_2))\,\nu \quad \text{if } \nu_t = -1.$$

[2]The Godunov flux $g(u_1, u_2; \nu)$ is generally defined only if the solution of the Riemann problem is defined.

3.3. Causal and semicausal edges. We will study the initial-value problem (1.1), (1.2) in situations for which we know a priori that the solution takes values in some set $\mathcal{D} \subset \mathbb{R}^n$. Let $e \subset \partial T$ be an edge of a triangle. If

$$\big(1,\, \lambda^i(u)\big)\, \nu_{e,T} < 0, \quad i \in \{1, \dots, n\}, \qquad \text{for all } u \in \mathcal{D}, \tag{3.6}$$

then we say that e is an *inflow* edge for element T (see Figure 1(a)). Similarly, if

$$\big(1,\, \lambda^i(u)\big)\, \nu_{e,T} > 0, \quad i \in \{1, \dots, n\}, \qquad \text{for all } u \in \mathcal{D}, \tag{3.7}$$

then we say that e is an *outflow* edge for element T (see Figure 1(b)). We also use the terminology

$$\text{an edge } e \text{ is causal if it is either outflow or inflow,} \tag{3.8}$$

and we further say that e is *semicausal* if it is not causal and

$$(1, \lambda^i(u))\, \nu_{e,T} \neq 0 \quad \text{for all } i \in \{1, \dots, n\} \text{ and } u \in \mathcal{D}. \tag{3.9}$$

We will sometimes write "causal (inflow, outflow, ...) for f, $\mathcal{D}$" to emphasize the dependence on the nonlinearity and the domain of conservation states.

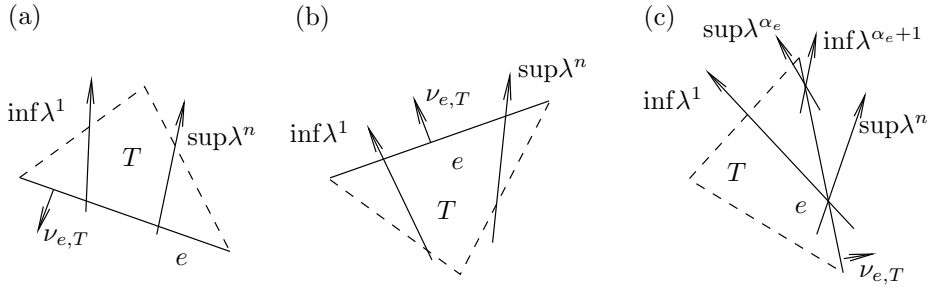

FIG. 1. *Inflow, outflow, and semicausal edges.*

If e is semicausal, then the strict hyperbolicity assumption and the continuity of $u \mapsto \lambda^i(u)$ for all i imply that there exists some $\alpha_e \in \{1, \dots, n-1\}$ such that

$$\lambda^{\alpha_e}(u) < -\frac{\nu_t}{\nu_x} < \lambda^{\alpha_e+1}(u) \tag{3.10}$$

for all $u \in \mathcal{D}$, where $\nu = \nu_{e,T}$ denotes the outer normal to T along edge e (see Figure 1(c)). Thus, there can exist semicausal edges only if $\sup_{u\in\mathcal{D}} \lambda^i(u) \leq \inf_{u\in\mathcal{D}} \lambda^{i+1}(u)$ for some i.

It follows from well-known features of the solution of the Riemann problem that if $u_1, u_2 \in \mathcal{D}$, then

$$\text{if } e \text{ is an inflow edge, then } g(u_1, u_2; \nu_{e,T}) = (u_2, f(u_2))\, \nu_{e,T}, \tag{3.11}$$

$$\text{if } e \text{ is an outflow edge, then } g(u_1, u_2; \nu_{e,T}) = (u_1, f(u_1))\, \nu_{e,T}. \tag{3.12}$$

We will take these last two equations as the *definition* of Godunov flux in situations where the Riemann problem is not necessarily solvable but (3.6) or (3.7) is satisfied.

We will see in Lemma 6.1 that for Temple class systems the Godunov flux also has a relatively simple form across semicausal edges.

3.4. Causal and patchwise causal triangulations. We say that a triangle T is *causal* if all of its edges are causal, and a triangulation $\mathcal{T}_h$ is *causal* if every triangle T in $\mathcal{T}_h$ is causal.

A triangle T is *semicausal* if every edge of T is either causal or semicausal. Our analysis extends to certain semicausal triangulations that we define as follows. Let $\mathcal{T}_h$ be a triangulation of $[0,\infty)\times\mathbb{R}$. A *patch* is defined to be a union of triangles in $\mathcal{T}_h$. A patch $P=\cup_{i=1}^k T_i$ is said to be *causal* if

$$\text{every edge } e\subset\partial P \text{ is causal,} \tag{3.13}$$

$$\text{every triangle } T_i\subset P \text{ has an outflow edge,} \tag{3.14}$$

$$\text{if } e \text{ is an edge of a triangle } T_i\subset P, \text{ and } e\not\subseteq\partial P, \text{ then } e \text{ satisfies (3.9).} \tag{3.15}$$

A triangulation $\mathcal{T}_h$ is said to be *patchwise causal* if it is a union of causal patches. These causal patches can always be assumed to be minimal, which we define to mean that

$$P \text{ does not have any proper subpatch satisfying (3.13)–(3.15).} \tag{3.16}$$

A proper subpatch is defined in the natural way: if $P=\cup_{i=1}^k T_i$ is a patch, then a proper subpatch is a set of the form $P'=\cup_{\ell=1}^j T_{i_\ell}$ for some $j<k$.

For a causal or semicausal triangle T, we write

$$\partial T^- = \text{the inflow portion of } \partial T, \tag{3.17}$$

$$\partial T^+ = \text{the outflow portion of } \partial T, \tag{3.18}$$

$$\partial T^0 = \text{the semicausal portion of } \partial T, \tag{3.19}$$

some of which may be empty.

For causal triangles or patches, the system (3.3) decouples to a certain extent. For example, in view of (3.11), (3.12), on a causal triangle T the scheme (3.3) takes the form

$$(u,f(u))\,n \;+\; \sum_{e\ \text{inflow}} (u_{T_e},f(u_{T_e}))\,n_e = 0, \tag{3.20}$$

where we are writing simply u instead of u_h, and

$$n := \int_{\partial T^+} \nu_{e,T}\; d\mathcal{H}^1, \qquad n_e := \int_e \nu_{e,T}\; d\mathcal{H}^1 = \nu_{e,T}\;\mathcal{H}^1(e). \tag{3.21}$$

We note for future reference that

$$n \;+\; \sum_{e\ \text{inflow}} n_e = \int_{\partial T} \nu\; d\mathcal{H}^1 = 0. \tag{3.22}$$

If the data u_{T_e} is known on all inflow edges, then (3.20) is a system of n equations in unknowns $u=(u^1,\dots,u^n)$, depending on the inflow data and triangle geometry as parameters. Thus, once (3.20) is known to be solvable for suitable inflow data in a single triangle, one can solve the whole system (3.3) one triangle at a time, always considering triangles for which the inflow data have already been found. This strategy is discussed at greater length in numerous references; see, for example, [18], [20]. Note that we require that on every triangle T the approximate solution u_T satisfy $u_T\in\mathcal{D}$,

since this condition is assumed in our definition of causality and indeed is needed to ensure that (3.3) reduces to (3.20).

Similarly, for a patchwise causal triangulation, we write ∂P^- and ∂P^+ to denote the inflow and outflow portions, respectively, of ∂P. We will show that if P is a causal patch, then one can solve (3.3) in P, once inflow data on ∂P^- is known; thus a patch-by-patch solution strategy is possible.

We note the following result.

LEMMA 3.1. *If T is a causal triangle, then it must have either one or two inflow edges.*

Proof. Multiply (3.22) on the left by the vector $(1, \lambda^i(u))$ for some $i \in \{1, \dots, n\}$ and some $u \in \mathcal{D}$. We deduce that $\sum_{j=1}^{3} (1, \lambda^i(u))\ \nu_{e_j,T}\ \mathcal{H}^1(e_j) = 0$, where e_1, e_2, e_3 denote the three edges. This shows that (3.6) cannot hold for all $e_j, j = 1, 2, 3$, and similarly (3.7) cannot hold for all three edges. ∎

LEMMA 3.2. *Let P be a causal patch, and let $T \subset P$ be a triangle with two causal edges. Then T must have an inflow edge.*

Proof. Let e_1, e_2, and e_3 be edges for triangle T. Let us suppose that e_1 is an outflow edge, and let e_3 be an edge which satisfies (3.10) for some $\alpha_{e_3} \in \{1, \dots, n-1\}$. We need to show that e_2 is inflow. Exactly as in the proof of Lemma 3.1, we find that $\sum_{j=1}^{3} (1, \lambda^i(u))\ \nu_{e_j,T}\ \mathcal{H}^1(e_j) = 0$ for all $i \in \{1, \dots, n\}$ and $u \in \mathcal{D}$. Since e_1 is outflow and e_3 satisfies (3.10), there must be some i such that $(1, \lambda^i(u))\ \nu_{e_1,T}$ and $(1, \lambda^i(u))\ \nu_{e_3,T}$ are both positive. Hence $(1, \lambda^i(u))\ \nu_{e_2,T} < 0$ for this i and therefore (since e_2 is causal) for all $i \in \{1, \dots, n\}$. Thus e_2 is an inflow edge, as required. ∎

3.5. Additional mesh-related considerations. We will see that the restriction of the system (3.3) to a causal patch or causal triangle always has a solution that is unique in a certain sense and that is bounded by the inflow data. In order to convert these local statements to global control over an approximate solution u_h, we need to impose some additional restrictions on the triangulations that we will consider.

To derive the TVD-like estimate (1.4) from bounds on the total variation of the Riemann invariants of an approximate solution on individual patches, we will need to assume that for every edge e of every triangle $T \in \mathcal{T}$

$$\text{if } \min_{(t,x)\in e} t > \min_{(t,x)\in T} t, \quad \text{then } e \text{ is an outflow edge for } T. \tag{3.23}$$

The necessity of this assumption is illustrated in Example 7.1. The point is that if an edge e violates (3.23), then information that enters a triangle along this edge can propagate backwards in time within the triangle.

Next, one can easily see from (3.20) and (3.22) that if T is a causal triangle with a single inflow edge e and inflow data u_{T_e}, then $u = u_{T_e}$ is a solution of (3.20). We will later prove that for Temple class systems, this is the only solution in $\mathcal{D}$.

Motivated by this, we say that an edge e is *trivial* if e forms the entire inflow boundary ∂T^- for some causal triangle T, and nontrivial otherwise. Many of our results will assume that there exists a constant $\alpha > 0$ such that

$$\text{if } e \text{ is any nontrivial edge,} \quad \text{then } |\nu_x| \geq \alpha |\nu_t| \quad \text{for } \nu = \nu_{e,T}. \tag{3.24}$$

Assumption (3.24), together with the fact that our solution u_h is constant except along nontrivial edges, is used to obtain bounds on $|u_{h,t}|$ from control over $|u_{h,x}|$. (Here and in what follows, $|u_{h,t}|, |u_{h,x}|$ are understood as nonnegative measures on $(0, \infty) \times \mathbb{R}$).) Bounds on $|u_{h,x}|$ in turn are an immediate consequence of the TVD estimate (1.4).

3.6. Main results. The main result of this paper is the following.

THEOREM 3.3. *Let* (1.1) *be a strictly hyperbolic, genuinely nonlinear Temple class system of conservation laws, and assume that the domain of conservation states* $\mathcal{D} \subset \mathbb{R}^n$ *satisfies* (2.7). *Let* $\mathcal{T}_h$ *be a causal or patchwise causal triangulation. Then there exists a unique solution* $u_h \in \mathcal{P}_h$ *of* (3.3), (3.4) *satisfying*

$$\min_{e \subset (\partial T^- \cup \partial T^0)} w^i_{h,T_e} \le w^i_{h,T} \le \max_{e \subset (\partial T^- \cup \partial T^0)} w^i_{h,T_e} \quad \text{for } w^i_h := b^i(u_h) \tag{3.25}$$

for every $i \in \{1, \dots, n\}$ *and* $T \in \mathcal{T}_h$.

If $\mathcal{T}_h$ *also satisfies* (3.23) *and* (3.24), *then in addition*

$$t \mapsto TV(w^i_h(t, \cdot)) \quad \text{is a nonincreasing function} \tag{3.26}$$

for every $i \in \{1, \dots, n\}$.

Finally, let $\mathcal{T}_h$ *be a sequence of causal or patchwise causal triangulations such that* (3.23) *holds and* (3.24) *is satisfied with a positive constant* α *independent of* h. *Assume also that there exists a constant* C *independent of* h *such that*

$$C^{-1}h \le |e| \le Ch \qquad \text{for every edge } e \text{ of every triangle } T \in \mathcal{T}_h. \tag{3.27}$$

Then the approximate solutions $\{u_h\}$ *are precompact in* $L^1_{loc}([0, \infty) \times \mathbb{R}; \mathbb{R}^n)$, *and any limit of any convergent subsequence* u_{h_k} *with* $h_k \to 0$ *is a distributional solution of* (1.1), (1.2). *Moreover, given any strictly convex entropy* η *with entropy flux* ψ, *there exists a subset* $\mathcal{D}' \subset \mathcal{D}$ *such that if* $u_0(x) \in \mathcal{D}'$ *for almost every* x, *then any limiting solution satisfies the entropy inequality* (2.11) *in the sense of distributions.*

Remark 3.4. One can find $\mathcal{D}' \subset \mathcal{D}$ such that, if $u_0(x) \in \mathcal{D}'$ for almost every x and u_0 has sufficiently small total variation, then there is a unique entropy solution u of (1.1) with initial data u_0, and the whole sequence $\{u_h\}$ of approximate solutions converges to this entropy solution.

The uniqueness assertion has been proven by Heibig [7]. The convergence $u_h \to u$ follows from two considerations. First, the theorem shows that for suitable $\mathcal{D}'$ any limit of a convergent subsequence must satisfy the entropy inequality (2.11) for some fixed strictly convex η. Second, it is well known that if a weak solution of (1.1) has only weak shocks (this can be arranged by a choice of $\mathcal{D}'$) and satisfies the entropy inequality (2.11) for a single strictly convex entropy, it is in fact an entropy solution. A proof of this last fact can be found, for example, in [23, Vol. 1, section 4.3].

Remark 3.5. Numerical simulations in Palaniappan, Haber, and Jerrard (see [20]) in the scalar case employ causal patches in which every patch consists of two triangles separated by a vertical semicausal edge.

Remark 3.6. Implicit in the numerical method (3.3), (3.4) is that the Godunov flux is well defined, and hence that the Riemann problem with initial data (3.5) is solvable for all $(u_1, u_2) \in \mathcal{D} \times \mathcal{D}$. Solutions of the Riemann problem for Temple class systems (see, for example, [22]) as far as we know all assume

$$\max_{u \in \mathcal{D}} \lambda^i(u) \le \min_{u \in \mathcal{D}} \lambda^{i+1}(u)$$

for all i. In fact, our results remain valid when this condition does not hold, provided that we take (3.11), (3.12), and (6.3) as the definitions of $g(u_1, u_2; \nu)$ on inflow, outflow, and semicausal edges, respectively.

We believe that, without (3.23), the numerical method is still convergent, but the proof would be somewhat more complicated. In particular, we give an example in section 7 to show that (3.26) can fail if (3.23) is not assumed.

In section 6 we also give an example showing that approximate solutions can fail to be unique on patches of elements on which we do not assume properties (3.14) and (3.15) from the definition of a causal patch.

4. General hyperbolic systems with causal triangulations. In this section we prove some results that do not use the special structure of Temple class systems, but that do, however, impose causality-type assumptions related to those introduced earlier.

4.1. Well-posedness of the approximation scheme. In this section we prove that, for a hyperbolic conservation law with flux f that is globally Lipschitz on $\mathbb{R}^n$ (but satisfying no other structural conditions), there is a unique solution of the approximation scheme (3.20) on suitable triangles. This is not needed for other results in this paper, but it indicates that one can at least hope to extend our stability and convergence results to more general classes of hyperbolic systems.

Our discussion will focus on triangles with two inflow edges (Figure 2), since the case of triangles with a single inflow edge is much easier. For triangles with two inflow edges, we write e_l and e_r to denote inflow edges on the left and right, respectively, and e to denote the single outflow edge. Defining $n_l = n_{e_l} = \nu_{e_l}\mathcal{H}^1(e_l)$ as in (3.21), and similarly n_r and n, we rewrite (3.20) in the form

$$\mathcal{F}(u_l, u_r, u) := F(u_l)\ n_l + F(u_r)\ n_r + F(u)\ n = 0, \tag{4.1}$$

where u_l, u_r denote prescribed inflow data on edges e_l, e_r. We also use the notation

$$F(z) := (z, f(z)) \in M^{n\times 2}. \tag{4.2}$$

We first prove the following result.

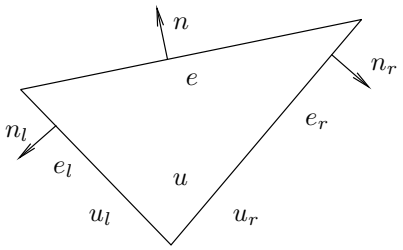

FIG. 2. *An element with two inflow faces.*

THEOREM 4.1. *Consider a system of hyperbolic conservation laws* (1.1) *with a domain of conservation states* $\mathcal{D} \subset \mathbb{R}^n$*, and assume that there exists a constant* $K_1 > 0$ *with the property*

$$\|f(u) - f(v)\| \le K_1 \|u - v\| \quad \text{for every } u, v \in \mathcal{D}. \tag{4.3}$$

Let T *be a triangle such that each edge* e *of* T *satisfies (writing* ν *for* $\nu_{e,T}$*)*

$$|\nu_t| - K_1|\nu_x| > 0. \tag{4.4}$$

Then there exists a constant K_2 *such that if* $u, \tilde{u} \in \mathcal{D}$ *solve* (3.20) *on* T *with inflow data* $\{u_{T_e} \in \mathcal{D} : e \subset \partial T^-\}$ *and* $\{\tilde{u}_{T_e} \in \mathcal{D} : e \subset \partial T^-\}$*, respectively, then*

$$||u - \tilde{u}|| \le K_2 \sum_{e\subset\partial T^-} \|u_{T_e} - \tilde{u}_{T_e}\|. \tag{4.5}$$

In particular, there is at most one solution in $\mathcal{D}$ *for inflow data in* $\mathcal{D}$*.*

Moreover, if $\mathcal{D} = \mathbb{R}^n$, then for any inflow data $\{u_{T_e} \in \mathbb{R}^n : e \subset \partial T^-\}$ there exists a unique solution of (3.20) on triangle T.

Proof. Step 0. First note that (4.3) and (4.4) together imply that T is causal for $f, \mathcal{D}$. This follows from noting that for any $u \in \mathcal{D}$ and all $i \in \{1, \dots, n\}$

$$|\lambda^i(u)| = \|Df(u)\ r_i(u)\| = \left\| \lim_{h \to 0} \frac{1}{h}\ [f(u + hr_i(u)) - f(u)] \right\| \leq K_1,$$

by (4.3). Thus (4.4) implies that if e is an edge with normal $\nu_{e,T} = \nu = (\nu_t, \nu_x)^t$ with $\nu_t > 0$, say, then

$$\nu_t + \lambda^i(u)\, \nu_x \ \geq\ |\nu_t| - K_1 |\nu_x| \ >\ 0,$$

so that e is an outflow edge for T. Similarly if $\nu_t < 0$, then e is an inflow edge for T.

Step 1. We now prove uniqueness and continuous dependence. We start by noting that, for n as defined in (3.21) and any $u, \tilde{u} \in \mathcal{D}$,

$$\begin{aligned} \|(F(u) - F(\tilde{u}))\ n\| &\geq \|u - \tilde{u}\|\ |n_t| - \|f(u) - f(\tilde{u})\|\ |n_x| \\ &\geq \|u - \tilde{u}\|\ (|n_t| - K_1 |n_x|). \end{aligned} \tag{4.6}$$

In view of assumption (4.4) and the definition (3.21) of n (as a multiple of ν), it follows that $u \mapsto F(u)\ n$ is one-to-one, which proves that there can be at most one solution u of (3.20), once the inflow data is specified.

Since the trivial solution $u = u_{T_e}$, where $e = \partial T^-$, always exists on a triangle with only one inflow edge, the uniqueness of solutions proves that (4.5) holds in this case. We next establish (4.5) for triangles with two inflow edges. We use the notation (4.1). Writing out these equations for both u and $\tilde{u}$ and subtracting, we obtain

$$(F(\tilde{u}) - F(u))\ n = (F(u_l) - F(\tilde{u}_l))\ n_l + (F(u_r) - F(\tilde{u}_r))\ n_r.$$

Since f is Lipschitz, the right-hand side is bounded by $C\,(\|u_l - \tilde{u}_l\| + \|u_r - \tilde{u}_r\|)$. Thus (4.6) implies that

$$(|n_t| - K_1 |n_x|)\, \|u - \tilde{u}\| \ \leq C\ (\|u_l - \tilde{u}_l\| + \|u_r - \tilde{u}_r\|).$$

Appealing again to (4.4), this implies (4.5).

Step 2. We now prove the existence of solutions when $\mathcal{D} = \mathbb{R}^n$. We have already done this for triangles with a single inflow edge, so we consider triangles with two inflow edges, and we use the notation (4.1).

Define the set

$$S := \{(u_l, u_r) \in \mathcal{D} \times \mathcal{D} :\ \text{there exists a solution } u(u_l, u_r) \in \mathcal{D} \text{ of (4.1)}\}.$$

Note that S is nonempty, since $\mathcal{F}(u, u, u) = 0$ for every $u \in \mathcal{D}$, due to (3.22).

We next claim that S is open. Let $(u_l, u_r) \in S$, and suppose that $\mathcal{F}(u_l, u_r, u) = 0$. To prove that S contains an open neighborhood of (u_l, u_r), it suffices (via the implicit function theorem) to verify that $D_u \mathcal{F}(u_l, u_r, u)$ is nonsingular, where D_u denotes the gradient with respect to the u variable. Clearly

$$D_u \mathcal{F}(u_l, u_r, u) = DF(u)\ n = n_t\, I + n_x\, Df(u),$$

where I denotes the identity matrix. The eigenvalues of this matrix are $n_t + n_x \lambda^i(u)$. Since e is an outflow edge, the definition (3.7) states that these eigenvalues are all positive, and we conclude that S is open as claimed.

We next show that S is closed. Let $\{(u_{l,k}, u_{r,k})\} \subset S$ be a sequence, and suppose that $(u_{l,k}, u_{r,k}) \to (u_l, u_r)$. For each k, let u_k satisfy $\mathcal{F}(u_{l,k}, u_{r,k}, u_k) = 0$, and let $u = \lim_{k\to\infty} u_k$. This limit exists on account of (4.5), and the continuity of $\mathcal{F}$ implies that $\mathcal{F}(u_l, u_r, u) = 0$. Thus S is closed.

Since S is nonempty, open, and closed, it follows that S is all of $\mathcal{D}$, proving the existence assertion. □

Note that, in Step 2 of the above proof, the verification that S is open uses the fact that $\mathcal{D}$ is open, and similarly our proof that S is closed requires that $\mathcal{D}$ be closed. Thus the argument works only for $\mathcal{D} = \mathbb{R}^n$.

4.2. Discrete entropy condition. The main result of this section is the following discrete entropy condition, which we emphasize holds for general symmetrizable strictly hyperbolic systems.

THEOREM 4.2. *Consider a system of strictly hyperbolic conservation laws* (1.1) *with a domain of conservation states $\mathcal{D} \subset \mathbb{R}^n$, and assume that T is a causal triangle for $f, \mathcal{D}$. Let η be a strictly convex entropy for* (1.1)*, with associated entropy flux ψ. Then there exists a subdomain $\mathcal{D}' \subset \mathcal{D}$, depending on η, such that if $u \in \mathcal{D}'$ solves* (3.20) *with inflow data $\{u_{T_e} \in \mathcal{D}' : e \subset \partial T^-\}$, then*

$$\int_{\partial T^+} (\eta(u_T), \psi(u_T))\, \nu \, d\mathcal{H}^1 \; + \sum_{e \;\; inflow} \int_{\partial T^-} (\eta(u_{T_e}), \psi(u_{T_e}))\; \nu_{e,T} \; d\mathcal{H}^1 \;\leq\; 0. \tag{4.7}$$

The set $\mathcal{D}'$ is characterized in (4.14). In particular, we can take $\mathcal{D}' = \mathcal{D}$ if $\{D\eta(u) \;:\; u \in \mathcal{D}\}$ is convex.

Theorem 4.2 shows that the net entropy flux is given by an integral along the inflow boundary of a quantity that is pointwise positive. To verify this positivity we employ an idea that goes back to Harten and Lax [6] and perhaps earlier, integrating along a suitable path in configuration space; see also Osher [19] for related arguments, and [26], for example, for more recent developments and numerous references.

For the convenience of the reader, we give the complete proof, although parts of it essentially reproduce arguments from [6].

Proof. Fix T and (η, ψ) as in the statement of the theorem. Along an inflow edge $e \subset \partial T^-$ we use the notation $u_- := u_{T_e}$, $f_- := f(u_-)$, and so on. Also, (u, f) denotes $(u_T, f(u_T))$. Then we can rewrite (3.20) in the form

$$\int_{\partial T^-} (u^i, f^i)_-\, \nu \, d\mathcal{H}^1 \; + \int_{\partial T^+} (u^i, f^i)\, \nu \, d\mathcal{H}^1 = 0, \quad i = 1, \ldots, n. \tag{4.8}$$

Define auxiliary functions ξ and ζ by

$$(\xi, \zeta) := \eta_{u^i}(u^i, f^i) - (\eta, \psi), \quad u \in \mathcal{D}, \tag{4.9}$$

where subscripts denote partial differentiation.[3] Using (2.9), we deduce that

$$(\xi, \zeta)_{u^j} = \eta_{u^i u^j}(u^i, f^i) \tag{4.10}$$

for $j \in \{1, \ldots, n\}$. We claim that

$$\int_{\partial T^-} \big(\eta_{u^i}(u^i, f^i)_- - (\xi, \zeta)\big)\; \nu \, d\mathcal{H}^1 + \int_{\partial T^+} \big(\eta_{u^i}(u^i, f^i) - (\xi, \zeta)\big)\; \nu \, d\mathcal{H}^1 = 0. \tag{4.11}$$

[3]Note that in this proof ξ is not the same as the Godunov value defined in section 3.2.

Here (ξ,ζ) denotes $(\xi(u_T),\zeta(u_T))$, which is constant on T, so it is clear that $\int_{\partial T}(\xi,\zeta)\,\nu\,d\mathcal{H}^1 = 0$. The other terms in (4.11) are just the left-hand side of (4.8) multiplied by the constant $\eta_{u_i} = \eta_{u_i}(u_T)$ and implicitly summed over i. Thus (4.11) follows from (4.8). Using the definition (4.9) of (ξ,ζ), we infer from (4.11) that

$$\int_{\partial T^-}(\eta,\psi)_-\ \nu\,d\mathcal{H}^1 + \int_{\partial T^+}(\eta,\psi)\ \nu\,d\mathcal{H}^1 + E = 0, \tag{4.12}$$

where

$$\begin{aligned} E &= \int_{\partial T^-}\left(\eta_{u^i}(u^i,f^i)_- - (\xi,\zeta) - (\eta,\psi)_-\right)\ \nu\,d\mathcal{H}^1 \\ &= \int_{\partial T^-}\left[(\eta_{u^i}-\eta_{u^i,-})(u^i,f^i)_- - (\xi,\zeta) + (\xi,\zeta)_-\right]\ \nu\,d\mathcal{H}^1. \end{aligned}$$

To establish the discrete entropy inequality (4.7), we need to show $E \geq 0$.

Let E_p denote the integrand in E at some fixed point $p \in \partial T^-$. We will prove that $E_p \geq 0$ at every p. To do this, let $u : [0,1] \to \mathcal{D}$ be a path (to be chosen later) such that $u(0) = u_-(p)$ and $u(1) = u(p) = u_T$. Then, using the fundamental theorem of calculus and (4.10),

$$\begin{aligned} E_p &= \int_0^1 \frac{d}{ds}\left\{\eta_{u^i}(u(s))\,(u^i,f^i)_- - (\xi,\zeta)(u(s))\right\}\ \nu\,ds \\ &= \int_0^1 \eta_{u^iu^j}(u(s))\left\{(u^i,f^i)_- - (u^i(s),f^i(u(s)))\right\}\ \nu\,\dot{u}^j(s)\,ds \\ &= \int_0^1 \eta_{u^iu^j}(u(s))\left\{-\int_0^s \frac{d}{dr}(u^i(r),f^i(u(r)))dr\right\}\ \nu\,\dot{u}^j(s)\,ds \\ &= \int_0^1\int_0^s \eta_{u^iu^j}(u(s))\ \left(-\delta_{ik},-f^i_{u_k}(u(r))\right)\ \nu\ \dot{u}^j(s)\,\dot{u}^k(r)\,dr\,ds. \end{aligned}$$

We write $D^2\eta(s) = D^2\eta(u(s))$ and $A(r) = -\nu_t\,I - \nu_x\,Df(u(r))$, where I is the identity matrix. In this notation the integrand above has the form

$$\dot{u}^t(s)\ D^2\eta(s)\ A(r)\ \dot{u}(r). \tag{4.13}$$

A difficulty in analyzing this expression arises from the fact that $D^2\eta$ and $A = -\nu_t\,I - \nu_x\,Df$ are evaluated at distinct points $u(r), u(s)$ and therefore need not be related in any special way. We eliminate this problem by a suitable choice of the path $u(\cdot)$. We define

$$D\eta(u(s)) := s\,D\eta(u_T) + (1-s)\,D\eta(u_-(p)).$$

Since η is strictly convex, $D\eta$ is a bijection onto its image, and so $u(\cdot)$ is well defined as long as the right-hand side above lies in the image of $D\eta$. We therefore select $\mathcal{D}'$ to be any subset of $\mathcal{D}$ such that

$$\mathrm{co}\left(\{D\eta(u) : u \in \mathcal{D}'\}\right) \subset \{D\eta(u) :\ u \in \mathcal{D}\}, \tag{4.14}$$

where $\mathrm{co}(\{\cdots\})$ denotes the convex hull. Then $u(s)$ is well defined, and clearly $u(0) = u_-(p), u(1) = u_T$, as required. By differentiating with respect to s, we find that

$$D^2\eta(s)\ \dot{u}(s) = D\eta(u_T) - D\eta(u_-(p))\ =:\ \gamma.$$

Thus, for this choice of $u(s)$, the expression in (4.13) becomes

$$\dot{u}^t(s)\ D^2\eta(s)\ A(r)\ \dot{u}(r) = \gamma^t\ A(r)\,(D^2\eta(r))^{-1}\ \gamma. \tag{4.15}$$

Note that only the variable r appears on the right-hand side. We conclude the proof by showing that

$$\gamma^t A(r)(D^2\eta(r))^{-1}\gamma \geq 0 \tag{4.16}$$

for every $\gamma \in \mathbb{R}^n$ and every $r \in [0,1]$. We fix r and write simply A and $D^2\eta$. Let r_i denote the ith right eigenvector of $Df(u(r))$, and note that r_i is also an eigenvector for $A(r)$, with eigenvalue $-\nu_t - \nu_x\lambda^i(u(r)) =: \mu^i > 0$, using the inflow assumption (3.6). Let $\gamma_i := D^2\eta\, r_i$, $i = 1,\dots,n$. Then for all i,j,

$$\gamma_j^t\ A\,(D^2\eta)^{-1}\ \gamma_i = r_j^t\ D^2\eta\, A\ r_i = \mu^i(r_j^t\ D^2\eta\ r_i) = \mu^j(r_i^t\ D^2\eta\ r_j)^t.$$

The last identity follows from the fact that $D^2\eta\, A$ is symmetric, which is a consequence of the necessary condition (2.10) for the entropy η. (This is where we use the fact that $(D^2\eta(\cdot))^{-1}$ and $A(\cdot)$ are evaluated at *the same* point r on the right-hand side of (4.15).) Recalling the convexity of η and noting that the eigenvalues of A are distinct (on account of the strict hyperbolicity of (1.1)), we conclude that

$$\gamma_j^t\ A\,(D^2\eta)^{-1}\gamma_i \geq 0 \quad \text{if } i = j, \qquad \gamma_j^t\ A\,(D^2\eta)^{-1}\gamma_i = 0 \quad \text{if } i \neq j.$$

Since $\{\gamma_i\}_{i=1}^n$ form a basis for $\mathbb{R}^n$, this is easily seen to establish (4.16). ∎

5. A single causal triangle. In this section we prove the part of Theorem 3.3 that deals with a single causal triangle, in particular the existence of a unique solution satisfying the Riemann invariant bounds (3.25) in the causal case. In some sense this is the main point of our analysis; we will deduce (3.25) for causal patches from the corresponding estimate for a single causal triangle, and compactness and convergence will then be relatively easy consequences.

The proof uses induction on n, the number of equations in the system. In section 5.1 we consider case $n = 1$ of scalar equations. Some properties of Temple class systems that are used in the induction argument are given in sections 5.2 and 5.3, and the induction argument is carried out in section 5.4.

5.1. Scalar conservation laws. In this section we prove the following.

LEMMA 5.1. *Consider a* scalar *conservation law* (1.1), (1.2), *and assume that the spatial flux function f is Lipschitz continuous in an open interval $\mathcal{D}$. Let T be a causal triangle for $f,\mathcal{D}$. Assume that we are given inflow data satisfying $u_{T_e} \in \mathcal{D}$ for all $e \subset \partial T^-$. Then there exists a unique $u \in \mathcal{D}$ satisfying the approximate equation* (3.20). *Moreover,*

$$\min_{e\subset\partial T^-} u_{T_e} \leq u \leq \max_{e\subset\partial T^-} u_{T_e}, \tag{5.1}$$

with both inequalities in (5.1) *strict unless* $\min_{e\subset\partial T^-} u_{T_e} = \max_{e\subset\partial T^-} u_{T_e}$.

This sort of local maximum principle is well known for Godunov finite volume methods, and more generally for monotone schemes for scalar conservation laws; such results date back to [12], [4]. Similar results are established in [16] for Temple class systems. A lot of recent work has been devoted to constructing higher-order accurate schemes that enjoy a local maximum principle; see, for example, [17], [10]. Since we

do not know of any result exactly of this sort in the implicit spacetime setting that we consider here, we present the straightforward proof for the reader's convenience.

Proof. We first assume that T is a triangle with two inflow edges, e_l on the left and e_r on the right, and we use the notation as in (4.1). In view of (3.22) we can rewrite the approximation scheme (4.1) in the form

$$\mathcal{F}(u_l, u_r, u) = (F(u_l) - F(u))\ n_l + (F(u_r) - F(u))\ n_r = 0. \tag{5.2}$$

Recalling the definition (4.2) of F and fact that e_l is an inflow edge (see (3.6)), we obtain

$$\frac{d}{d\,z}\,(F(z)\ n_l) = n_{l,t} + n_{l,x}\,f'(z) = (1, f'(z))\ n_l < 0, \tag{5.3}$$

and likewise

$$\frac{d}{d\,z}\,(F(z)\ n_r) = (1, f'(z))\ n_r < 0, \tag{5.4}$$

for all $z \in \mathcal{D}$. Hence $u \mapsto \mathcal{F}(u_l, u_r, u)$ is strictly increasing on $\mathcal{D}$. If $u_l = u_r$, it follows that $u = u_l = u_r$ is the unique solution of (5.2). If $u_l \neq u_r$, then let us write $u_* = \min(u_l, u_r), u^* = \max(u_l, u_r)$. It follows from (5.2), (5.3), (5.4) that

$$\mathcal{F}(u_l, u_r, u_*) < 0, \qquad \mathcal{F}(u_l, u_r, u^*) > 0.$$

Thus, again by monotonicity, there exists a unique $u \in (u_*, u^*)$ solving (5.2).

The proof for a triangle with only one inflow edge is similar, but easier. ∎

5.2. Some facts about Temple class systems. The main result of this section is Lemma 5.3, which makes precise the statement that, if in a genuinely nonlinear Temple class system of n equations we fix k coordinates in the coordinate system provided by Riemann invariants, then the system reduces to a genuinely nonlinear Temple class system of $n - k$ equations. This is well known, but we have not seen the exact statement we prove (which is needed in the next section) anywhere in the literature. In order to prove it we need the following.

LEMMA 5.2. *Suppose that* (1.1) *is a genuinely nonlinear Temple class system with domain of conservation states* $\mathcal{D}$. *Then for every* $i \in \{1, \dots, n\}$ *and every constant* $c \in \mathbb{R}$ *there exist nonzero row vectors* $p \in M^{1\times n}$ *and* $q \in M^{1\times 2}$ *such that*

$$p\ F(u) = q \quad \text{for all} \quad u \in b^{-1}\left(\{w \in \mathcal{R} : w^i = c\}\right), \tag{5.5}$$

where $F(u) = (u, f(u))$ *and* b *denotes the diffeomorphism, defined in* (2.3), *from conservation states* u *onto Riemann invariants* w.

Proof. Fix some $i \in \{1, \dots, n\}$ and $c \in \mathbb{R}$, and let

$$\mathcal{C} := b^{-1}\left(\{w \in \mathcal{R} : w^i = c\}\right).$$

The assertion that there exists a nonzero row vector p and a number q_1 such that $pu = q_1$ for all $u \in \mathcal{C}$ is simply the defining attribute (2.6) of genuinely nonlinear Temple class systems.

Since p is orthogonal to $\mathcal{C}$, which is a level set of b^i, it is clear that p is parallel to Db^i on $\mathcal{C}$. However, (2.3) asserts that $Db^i(u)$ is a left eigenvector of $Df(u)$, with eigenvalue $\lambda^i(u)$. Thus p is a left eigenvector of $Df(u)$ for every $u \in \mathcal{C}$. As a result,

$p\ r_j(u) = 0$ for $j \neq i$. It follows that $\{r_j(u) : j \neq i\}$ spans the tangent space to $\mathcal{C}$ at any point $u \in \mathcal{C}$. However, for $j \neq i$ and $u \in \mathcal{C}$,

$$0 = p\ Df(u)\ r_j(u) = D(p\ f(u))\ r_j(u),$$

which asserts that the directional derivative of $p\ f(u)$ in the $r_j(u)$ direction vanishes for $j \neq i$. It follows that all tangential derivatives of $p\ f(u)$ along $\mathcal{C}$ vanish, so that $p\ f(u)$ is constant on $\mathcal{C}$. ∎

We now present our main result of this section.

LEMMA 5.3. *Let* (1.1) *be a genuinely nonlinear Temple class system with domain of conservation states* $\mathcal{D}$ *satisfying* (2.7). *Define*

$$\mathcal{C} := b^{-1}(\{w \in \mathcal{R}\ :\ w^{i_1} = c_1, \ldots, w^{i_k} = c_k\})$$

for some $i_j \in \{1, \ldots, n\}$ *and* $c_j \in \mathbb{R}$. *Then there exist a domain of conservation states* $\overline{\mathcal{D}} \subset \mathbb{R}^{n-k}$, *an affine map* $L : \mathbb{R}^{n-k} \to \mathbb{R}^n$ *that maps* $\overline{\mathcal{D}}$ *onto* $\mathcal{C}$, *and a mapping* $\bar{f} : \overline{\mathcal{D}} \to \mathbb{R}^{n-k}$ *satisfying*

$$f(L\bar{u}) = L\bar{f}(\bar{u}) + K, \quad \bar{u} \in \overline{\mathcal{D}}, \tag{5.6}$$

for some constant vector $K \in \mathbb{R}^n$ *(depending on* i_j, c_j, $j = 1, \ldots, k$*) and such that for the domain of conservation states* $\overline{\mathcal{D}}$

$$\bar{u}_t + \bar{f}(\bar{u})_x = 0 \tag{5.7}$$

is a genuinely nonlinear Temple class system satisfying (2.7). *Furthermore, if* $\bar{\lambda}^j, j = 1, \ldots, n-k$, *denotes the eigenvalues of* $D\bar{f}$, *then*

$$\{\bar{\lambda}^j(\bar{u})\}_{j=1}^{n-k} = \{\lambda^j(L\bar{u})\}_{j \notin \{i_1, \ldots, i_k\}}, \quad \bar{u} \in \overline{\mathcal{D}}. \tag{5.8}$$

Using the lemma, it is easy to show that if $\bar{u} : (0, \infty) \times \mathbb{R} \to \overline{\mathcal{D}}$ is a solution of $\bar{u}_t + \bar{f}(\bar{u})_x = 0$, then $u := L\bar{u}$ solves (1.1) in the same sense. This is clear for classical solutions,

$$u_t + f(u)_x = (L\bar{u})_t + f(L\bar{u})_x = L\bar{u}_t + (L\bar{f}(\bar{u}) + K)_x = L(\bar{u}_t + \bar{f}(\bar{u})_x) = 0,$$

and can similarly be justified for weak solutions. Thus, informally, the lemma states that the system for u reduces in $\mathcal{C}$ to a smaller Temple class system for the new dependent variable $\bar{u}$. Note that this also implies that $\mathcal{C}$ is an invariant submanifold for (1.1), as mentioned in the introduction.

Proof. We give the proof in the case $k = 1$. The general case follows by a straightforward induction argument.

Let $p = (p_1, \ldots, p_n) \in M^{1 \times n}$ and $q = (q_1, q_2) \in M^{1 \times 2}$ be the vectors provided by Lemma 5.2, satisfying (5.5). For concreteness we assume that $p_n \neq 0$; this does not entail any loss of generality. Then for all $u \in \mathcal{C}$ we have

$$u^n = \frac{q_1}{p_n} - \frac{1}{p_n} \sum_{j=1}^{n-1} p_j\, u^j \quad \text{and} \quad f^n(u) = \frac{q_2}{p_n} - \frac{1}{p_n} \sum_{j=1}^{n-1} p_j\, f^j(u). \tag{5.9}$$

For $\bar{u} = (\bar{u}^1, \ldots, \bar{u}^{n-1})^t \in \mathbb{R}^{n-1}$ we define

$$L\bar{u} := \left(\bar{u}^1, \ldots, \bar{u}^{n-1}, \frac{q_1}{p_n} - \frac{1}{p_n} \sum_{j=1}^{n-1} p_j\, \bar{u}^j \right)^t. \tag{5.10}$$

In view of (5.9), the image of L contains $\mathcal{C}$. We next define

$$\overline{\mathcal{D}} := \left\{ \bar{u} \in \mathbb{R}^{n-1} : L\,\bar{u} \in \mathcal{C} \right\}, \tag{5.11}$$

and $\bar{f} := (\bar{f}^1, \dots, \bar{f}^{n-1}) : \overline{\mathcal{D}} \to \mathbb{R}^{n-1}$ is defined by

$$\bar{f}^j(\bar{u}) = f^j(L\bar{u}), \qquad j = 1, \dots, n-1. \tag{5.12}$$

The remainder of the proof simply consists of verifying that $L, \bar{f}, \overline{\mathcal{D}}$ have all the required properties.

First, (5.9) and the definitions of $L, \bar{f}$ imply that

$$f(L\bar{u}) - L\bar{f}(\bar{u}) = \left(0, \dots, 0, \frac{q_2 - q_1}{p_n}\right)^t,$$

so that (5.6) holds. Note that differentiation of (5.6) with respect to $\bar{u}$ gives

$$D_u f(L\bar{u})\; D_{\bar{u}} L = D_{\bar{u}} L\; D_{\bar{u}} \bar{f}(\bar{u}). \tag{5.13}$$

We define $\overline{\mathcal{R}} := \{\bar{w} \in \mathbb{R}^{n-1} \,:\, (\bar{w}^1, \dots, \bar{w}^{i-1}, c, \bar{w}^i, \dots, \bar{w}^{n-1}) \in \mathcal{R}\}$ and

$$\bar{b}(\bar{u}) := (b^1(L\bar{u}), \dots, b^{i-1}(L\bar{u}), b^{i+1}(L\bar{u}), \dots, b^n(L\bar{u})) \qquad \text{for } \bar{u} \in \overline{\mathcal{D}}. \tag{5.14}$$

It is clear that $\bar{b} : \overline{\mathcal{D}} \to \overline{\mathcal{R}}$ is a diffeomorphism and that $\overline{\mathcal{R}}$ is a rectangle in $\mathbb{R}^{n-1}$ such that (2.7) holds for $\overline{\mathcal{D}}$.

We next check that $\bar{b}$ provides a coordinate system of Riemann invariants. Let $j \in \{1, \dots, n-1\}$ and $\bar{u} \in \overline{\mathcal{D}}$ be fixed. By (5.14), there exists $s \in \{1, \dots, n\} \setminus \{i\}$ such that

$$\bar{b}^j(\bar{u}) = b^s(L\bar{u}), \tag{5.15}$$

which further gives

$$D_{\bar{u}} \bar{b}^j(\bar{u}) = D_u b^s(L\bar{u})\; D_{\bar{u}} L. \tag{5.16}$$

Since the original system (1.1) satisfies (2.3), we have that

$$D_u b^s(L\bar{u})\; D_u f(L\bar{u}) = \lambda^s(L\bar{u})\; D_u b^s(L\bar{u}), \tag{5.17}$$

and using (5.16) and (5.13), we obtain

$$D_{\bar{u}} \bar{b}^j(\bar{u})\, D_{\bar{u}} \bar{f}(\bar{u}) = \lambda^s(L\bar{u})\, D_{\bar{u}} \bar{b}^j(\bar{u}), \tag{5.18}$$

implying $\bar{\lambda}^j(\bar{u}) = \lambda^s(L\bar{u})$. Thus (5.7) admits a coordinate system of Riemann invariants, as claimed. Note that the above also implies that (5.8) holds, and moreover it follows from (5.8) that the system (5.7) is strictly hyperbolic.

To verify that (5.7) is a Temple class system, we must also check that (2.6) is satisfied. This is an easy consequence of the definitions; see [9] for more details.

Finally we verify that the system (5.7) is genuinely nonlinear. By arguing as in the verification of (5.18) above, one can check that for j and s as in (5.15), and for $\bar{u} \in \overline{\mathcal{D}}$ with $Lu =: u \in \mathcal{D}$, there exists a nonzero constant c such that $r_s(u) = cD_{\bar{u}} L\; \bar{r}_j(\bar{u})$ and, moreover, $D_u \lambda^s(u) r_s(u) = cD_{\bar{u}} \bar{\lambda}^j(\bar{u}) \bar{r}_j(\bar{u})$; we refer again to [9] for more details. Thus the desired conclusion follows from the fact that (1.1) is genuinely nonlinear. ∎

Remark 5.4. Suppose that (η, ψ) is an entropy-entropy flux pair for system (1.1). Define

$$\bar{\eta}(\bar{u}) := \eta(L\bar{u}) \quad \text{and} \quad \bar{\psi}(\bar{u}) := \psi(L\bar{u}) \tag{5.19}$$

for $\bar{u} \in \overline{\mathcal{D}}$. By the chain rule we have

$$D_{\bar{u}}\bar{\eta}(\bar{u}) = D_u\eta(L\bar{u})\, D_{\bar{u}}L \quad \text{and} \quad D_{\bar{u}}\bar{\psi}(\bar{u}) = D_u\psi(L\bar{u})\, D_{\bar{u}}L. \tag{5.20}$$

With (5.13), this implies $D_{\bar{u}}\bar{\eta}(\bar{u})\ D_{\bar{u}}\bar{f}(\bar{u}) = D_{\bar{u}}\bar{\psi}(\bar{u})$, which means that $(\bar{\eta}, \bar{\psi})$ is an entropy-entropy flux pair for system (5.7).

5.3. Invariant submanifolds for the approximation scheme. As mentioned several times, level sets of the Riemann invariants b^i (defined in (2.3)) form invariant submanifolds for Temple class systems. In this section we prove in effect that these same sets are also invariant submanifolds for the discretized Temple class system (3.20) on a single causal or semicausal triangle.

LEMMA 5.5. *Suppose that* (1.1) *is a genuinely nonlinear Temple class system in domain* $\mathcal{D}$. *Assume that* $n_i = (n_{i,t}, n_{i,x})^t$, $i = 1, 2, 3$, *are such that* $n_1 + n_2 + n_3 = 0$ *and that* $u_1, u_2, u_3 \in \mathcal{D}$ *satisfy the following equation:*

$$F(u_1)\ n_1 + F(u_2)\ n_2 + F(u_3)\ n_3 = 0. \tag{5.21}$$

If for some $i \in \{1, \dots, n\}$ *and some* $c \in \mathbb{R}$, $b^i(u_1) = b^i(u_2) = c$ *and the expression* $(1, \lambda^i(u))\ n^3$ *is of constant nonzero sign for all* $u \in \mathcal{D}$, *then* $b^i(u_3) = c$.

Proof. Let us define set $\mathcal{C} := b^{-1}\left(\{w \in \mathcal{R} : w^i = c\}\right)$, which, by (2.6), is contained in a hyperplane in $\mathcal{D}$. By Lemma 5.2 there exist matrices p and q such that $p\, F(u) = q$ for all $u \in \mathcal{C}$. Multiplying (5.21) on the left by p and using the assumption that $n_1 + n_2 + n_3 = 0$, we obtain

$$(p\ F(u_3) - q)\ n_3 = 0.$$

This implies that for every $v \in \mathcal{C}$ we have

$$p\,((u_3 - v),\ (f(u_3) - f(v)))\ n_3 = 0. \tag{5.22}$$

Define $v_c = b^{-1}(w_c) \in \mathcal{C}$, where $w_c \in \mathcal{R}$ satisfies $w_c^i = c$, $w_c^j = b^j(u_3)$ for all $j \neq i$. Let $v(s) = s\, u_3 + (1 - s)\, v_c$ for $s \in [0, 1]$. We claim that

$$Df(v(s)(u_3 - v_c) = \lambda_i(v(s))(u_3 - v_c) \qquad \text{for all } s \in [0, 1]. \tag{5.23}$$

This is essentially just the well-known fact that, for Temple class systems, integral curves are straight lines. We will first use (5.23) to complete the proof of the lemma, and then for the convenience of the reader we present a proof of (5.23).

Using (5.23), we obtain

$$\begin{aligned} f(u_3) - f(v_c) = \int_0^1 \frac{d}{ds} f(v(s))\, ds &= \int_0^1 Df(v(s))\ (u_3 - v_c)\, ds \\ &= \int_0^1 \lambda^i(v(s))\, ds\, (u_3 - v_c). \end{aligned}$$

Substituting this into (5.22), we find that

$$p\ (u_3 - v_c) \int_0^1 (1, \lambda^i(v(s)))\ n_3\, ds = 0. \tag{5.24}$$

Since $(1, \lambda^i(v(s)))\ n_3$ is of constant nonzero sign for all $s \in [0,1]$, we obtain that $p\ (u_3 - v_c) = 0$ and therefore $p\ u_3 = q_1$. Since $u_3 \in \mathcal{D}$, we conclude that $u_3 \in \mathcal{C}$, which completes the proof.

To prove (5.23), we first recall that the defining property (2.6) of Temple class systems states that for each j the set $b^{-1}(\{w \in \mathcal{R} \ : \ w^j = b^j(u_3)\})$ is a hyperplane. Since this set also contains u_3 and v_c, it must contain the line segment joining them. Thus all Riemann invariants $b^j(v(s))$, $j \neq i$, are constant for $s \in [0,1]$. It follows that

$$\frac{d}{ds} b(v(s)) = Db(v(s))\dot{v}(s) = (0, \dots, 0, \sigma_i(s), 0, \dots 0)^t$$

for some σ_i (in the ith component.) Hence

$$\dot{v}(s) = \sigma_i(s) \quad \big(\text{the } i\text{th column of } Db^{-1}(v(s))\ \big).$$

However, according to (2.3), the ith column of $Db^{-1}(v(s))$ is a multiple of the normalized right eigenvector $r^i(v(s))$. Since $\dot{v}(s) = u_3 - v_c$, this proves (5.23). ∎

5.4. Well-posedness and Riemann invariant bounds. The central part of the proof of Theorem 3.3 is carried out in the following.

LEMMA 5.6. *Let* (1.1) *be a strictly hyperbolic, genuinely nonlinear Temple class system of conservation laws, and assume that the domain of conservation states* $\mathcal{D} \subset \mathbb{R}^n$ *satisfies* (2.7). *Let* T *be a causal triangle for* $f, \mathcal{D}$. *Then for any inflow data* $\{u_{T_e} \in \mathcal{D} \ : \ e \subset \partial T_-\}$ *there exists a unique solution* u *of* (3.20) *satisfying*

$$\min_{e \subset \partial T^-} w^i_{T_e} \ \leq \ w^i_T \ \leq \ \max_{e \subset \partial T^-} w^i_{T_e}, \qquad \text{for } w^i := b^i(u),$$

(5.25) *with both inequalities strict unless equality holds throughout,*

for all $i = 1, \dots, n$.

Similar local maximum principles are proved in [16] and [22] for the Godunov scheme for Temple class systems of two equations.

Proof. The theorem is obvious for triangles with only one inflow edge, so we consider only triangles with two inflow edges, say e_l and e_r on the left and right, respectively, and we write (3.20) in terms of inflow data u_l and u_r as in (4.1).

We will prove the existence of a solution satisfying (5.25) by induction on n, the number of equations in the system. (Uniqueness will be established at the end of the proof). The case $n = 1$ is the case of a scalar equation with strictly convex or concave spatial flux f; this is covered by results of section 5.1.

To do the induction step, let us assume that the conclusion holds for all genuinely nonlinear Temple class systems of $n-1$ equations, and let (1.1) be a genuinely nonlinear Temple class system of n equations. Let us define

$$S := \{(u_l, u_r) \in \mathcal{D} \times \mathcal{D} : \text{ there exists } u \in \mathcal{D} \text{ satisfying (4.1) and (5.25)}\}.$$

We will show $S = \mathcal{D} \times \mathcal{D}$.

Step 1. We prove that for every $i \in \{1, \dots, n\}$ and every constant $c \in \mathbb{R}$,

$$\{(u_l, u_r) \in \mathcal{D} \times \mathcal{D} : b^i(u_l) = b^i(u_r) = c\} \subset S.$$

Fix some $c \in \mathbb{R}$ and $i \in \{1, \dots, n\}$, and let $\mathcal{C} = b^{-1}(\{w \in \mathcal{R} \ : \ w^i = c\})$. According to Lemma 5.3, there exists a set $\overline{\mathcal{D}} \subset \mathbb{R}^{n-1}$ and maps $\bar{f} : \overline{\mathcal{D}} \to \mathbb{R}^{n-1}$ and $L : \mathcal{D} \to \mathcal{C}$ such that (5.6), (5.7), and (5.8) hold. It follows from (5.8) that any triangle that is

causal for $f, \mathcal{D}$ is also causal for $\bar{f}, \overline{\mathcal{D}}$. Thus the induction hypothesis and (5.7) imply that there exists a solution $\bar{u}$ of the equation

$$(\bar{u}_l, \bar{f}(\bar{u}_l))\ n_l + (\bar{u}_r, \bar{f}(\bar{u}_r))\ n_r + (\bar{u}, \bar{f}(\bar{u}))\ n = 0, \tag{5.26}$$

where $\bar{u}_l, \bar{u}_r \in \overline{\mathcal{D}}$ and $L\bar{u}_l = u_l$ and $L\bar{u}_r = u_r$. In addition, $\bar{u}$ satisfies the analogue of (5.25). Let $u := L\bar{u} \in \mathcal{C}$. Then, applying L to (5.26) and recalling from (5.6) that $L\bar{f}(\bar{u}) = f(L\bar{u}) + k$ with k constant, we deduce that

$$\begin{aligned} 0 &= (u_l, f(u_l) + k)\ n_l + (u_r, f(u_r) + k)\ n_r + (u, f(u) + k)\ n \\ &= (u_l, f(u_l))\ n_l + (u_r, f(u_r))\ n_r + (u, f(u))\ n. \end{aligned}$$

We have used (3.22) for the second equality. Also, it is clear from the construction in Lemma 5.3 that L preserves Riemann invariants, and hence that u satisfies (5.25).

Step 2. Let us define

$$\tilde{S} := \{(w_l, w_r) \in \mathcal{R} \times \mathcal{R} : w_l = b(u_l), w_r = b(u_r) \text{ for some } (u_l, u_r) \in S\}.$$

To prove the existence of a solution satisfying (5.25), it suffices to show that $\tilde{S} = \mathcal{R} \times \mathcal{R}$.

Define

$$Q := \{(w_l, w_r) \in \mathcal{R} \times \mathcal{R} : w_r^i > w_l^i \text{ for all } i\}.$$

We will show that

$$Q \subset \tilde{S}. \tag{5.27}$$

Exactly the same arguments can be used to show that

$$\{(w_l, w_r) \in \mathcal{R} \times \mathcal{R} : \pm w_r^i > w_l^i \text{ for all } i\} \subset \tilde{S}$$

for any choice of signs, and so the proof of (5.27) will show that

$$\{(w_l, w_r) \in \mathcal{R} \times \mathcal{R} : w_r^i \neq w_l^i \text{ for all } i\} \subset \tilde{S}.$$

In view of Step 1, the last inclusion implies that $\mathcal{R} \times \mathcal{R} \subset \tilde{S}$. Hence the proof of (5.27) will complete the proof of the existence of a solution satisfying (5.25).

We break the proof of (5.27) into three parts. For all three parts, it is convenient to write (4.1) in Riemann invariant coordinates, in which it takes the form

$$\tilde{F}(w_l)\ n_l + \tilde{F}(w_r)\ n_r + \tilde{F}(w)\ n = 0, \tag{5.28}$$

where $\tilde{F}(w) := F(a(w)) = (a(w), \tilde{f}(w))$ for $w \in \mathcal{R}$. Here we are writing $a = b^{-1}$ and using notation from (2.4).

Step 2a. The set $\tilde{S} \cap Q$ is open in Q.

This follows from exactly the same argument given in Step 2 of the proof of Theorem 4.1. The point is that the outflow condition (3.7) on edge e implies that $D(\tilde{F}(w)\ n)$ is nonsingular for all $w \in \mathcal{R}$, so that if (w_l, w_r, w) solves (5.28), then the implicit function theorem asserts that for w_l', w_r' sufficiently near w_l, w_r, there is a unique solution w' near w, depending smoothly on w_l', w_r'. If $(w_l, w_r) \in Q$, then strict inequality holds in (5.25) for all i, and so strict inequality will also hold in (5.25) for all (w_l', w_r', w') in a neighborhood of (w_l, w_r, w).

Step 2b. The set $\tilde{S} \cap Q$ is nonempty.

Let $w_l \in \mathcal{R}$ be fixed. In view of the considerations in Step 2a, for w_r sufficiently close to w_l there exists a unique w in a neighborhood of w_l such that (5.28) is satisfied. We write $w(w_r)$ to denote this solution w. We must show that there exist w_r such that the solution $w(w_r)$ satisfies (5.25).

We claim that at the point $w = w_r = w_l$, the matrix $\left(\frac{\partial w}{\partial w_r}\right)$ is diagonal, with all entries $\alpha_i, i = 1 \dots, n$, positive and strictly less than 1.

The claim asserts that $w^i(w_r) = w_l^i + \alpha_i(w_r^i - w_l^i) + o(\|w_l - w_r\|)$ as $w_r \to w_l$, which since $0 < \alpha_i < 1$ for all i, implies that $w(w_r)$ satisfies (5.25) for all w_r of the form $w_l + (h, \dots, h)$ when h is positive and sufficiently small. Thus the conclusion of Step 2a follows from the claim about the form of $\partial w/\partial w_r$.

To prove this claim, we differentiate (5.28) with respect to w_r to obtain

$$\Big\{n_{r,x}\, D\tilde{f}(w_r) \,+\, n_{r,t}\, Da(w_r)\Big\} + \Big\{n_x\, D\tilde{f}(w) \,+\, n_t\, Da(w)\Big\}\left(\frac{\partial w}{\partial w_r}\right) = 0.$$

Multiplying on the left by $(Da(w))^{-1}$ and using (2.5), we find that

$$Da(w)^{-1}\; Da(w_r)\; \Big\{n_{r,x}\, \tilde{\Lambda}(w_r) \,+\, n_{r,t}\, I\Big\} + \Big\{n_x\, \tilde{\Lambda}(w) \,+\, n_t\, I\Big\}\left(\frac{\partial w}{\partial w_r}\right) = 0.$$

We now set $w_l = w_r = w$. Then $Da(w)^{-1}\; Da(w_r) = I$. Due to the inflow and outflow conditions (3.6) and (3.7), for every $i \in \{1, \dots, n\}$ we have $(1, \tilde{\lambda}^i(w_r))\; n_r < 0$ and $(1, \tilde{\lambda}^i(w))\; n > 0$. Thus at the point in question,

$$\left(\frac{\partial w}{\partial w_r}\right) = -\begin{bmatrix} \frac{(1,\tilde{\lambda}^1(w_l))\; n_r}{(1,\tilde{\lambda}^1(w_l))\; n} & \cdots & 0 \\ \cdots & \ddots & \cdots \\ 0 & \cdots & \frac{(1,\tilde{\lambda}^n(w_l))\; n_r}{(1,\tilde{\lambda}^n(w_l))\; n} \end{bmatrix},$$

and all the diagonal elements are positive. To show that $\frac{\partial w^i}{\partial w_r^i} < 1$, we need to show $-(1, \tilde{\lambda}^i(w_l))\; n_r < (1, \tilde{\lambda}^i(w_l))\; n$, which, in view of (3.22), is equivalent to showing $(1, \tilde{\lambda}^i(w_l))\; n_l < 0$. This is satisfied, again as a result of the inflow constraint (3.6).

Step 2c. The set $\tilde{S} \cap Q$ is closed in Q.

Let $(w_{l,k}, w_{r,k}) \in \tilde{S} \cap Q$, for $k \in \mathbb{N}$, and suppose $\lim_{k\to\infty}(w_{l,k}, w_{r,k}) = (w_l, w_r) \in Q$. We need to show $(w_l, w_r) \in \tilde{S}$.

For each $k \in \mathbb{N}$, there exists a unique $w_k \in \mathcal{R}$ such that

$$\tilde{F}(w_{l,k})\; n_l + \tilde{F}(w_{r,k})\; n_r + \tilde{F}(w_k)\; n = 0 \tag{5.29}$$

and

$$w_{l,k}^i \;<\; w_k^i \;<\; w_{r,k}^i \quad \text{for } i \in \{1, \dots, n\}. \tag{5.30}$$

From (5.30), we deduce that there exists a convergent subsequence $\{w_{k_m}\}_{k_m}$. Let us denote $w = \lim_{k_m\to\infty} w_{k_m}$. From (5.29) and (5.30) we get that

$$\tilde{F}(w_l)\; n_l + \tilde{F}(w_r)\; n_r + \tilde{F}(w)\; n = 0$$

and

$$w_l^i \;\le\; w^i \le\; w_r^i \quad \text{for } i \in \{1, \dots, n\}. \tag{5.31}$$

Since $(w_l, w_r) \in Q$, we have $w_l^i \neq w_r^i$ for all i. Suppose that at least one of the inequalities in (5.31) is not strict. Then either $w_l^i = w^i$ or $w_r^i = w^i$. By Lemma 5.5, we must have $w_l^i = w^i = w_r^i$, which is contradiction to the assumption. Hence, $(w_l, w_r) \in \tilde{S}$.

Step 3. Finally we prove that there can be only one solution of (3.20) that satisfies (5.25).

Suppose that

$$\tilde{F}(w_l)\ n_l + \tilde{F}(w_r)\ n_r + \tilde{F}(w_k)\ n = 0$$

for $k = 1, 2$, and that both w_1 and w_2 satisfy (5.25). Define $w_r(s) = w_r + s(w_l - w_r)$. The arguments of Step 2 imply that there exist functions $w_k(s), 0 \leq s \leq 1$, such that $s \mapsto w_k(s)$ is C^1,

$$w_k(0) = w_k, \qquad (w_l, w_r(s), w_k(s)) \quad \text{satisfies (5.28) and (5.25)}$$

for $k = 1, 2$. Clearly $w_r(1) = w_l$, and so (5.25) implies that $w_1(1) = w_2(1) = w_l$. Let $S_1 := \{s \in [0,1] : w_1(s) = w_2(s)\}$. We have just shown that S_1 is nonempty. The continuity of w_1, w_2 implies that S_1 is closed, and the same implicit function theorem arguments used above demonstrate that S_1 is relatively open in $[0,1]$. It follows that $S_1 = [0,1]$, and hence that $w_1 = w_1(0) = w_2(0) = w_2$. This completes the proof. ∎

6. A single causal patch. The main result of this section is Lemma 6.2, which establishes those parts of Theorem 3.3 that describe the unique solvability, with bounds on the Riemann invariants, of the approximation scheme (3.3) on a single causal patch. The idea of the proof is to show that on such a patch the individual triangles in fact decouple, in that we can determine a priori the values of the Godunov flux across interior edges, in terms of only the patch geometry and inflow data; then the problem on each triangle can be reduced to the causal case studied earlier.

We first obtain a formula for the Godunov flux that is valid in particular for semicausal edges, such as those that occur in the interior of causal patches.

LEMMA 6.1. *Assume that* (1.1) *is a strictly hyperbolic, genuinely nonlinear Temple class system for which the domain of conservation states* $\mathcal{D} \subset \mathbb{R}^n$ *satisfies* (2.7)*, and suppose also that*

$$\sup_{u \in \mathcal{D}} \lambda^i(u) < \inf_{u \in \mathcal{D}} \lambda^{i+1}(u) \quad \text{for all } i. \tag{6.1}$$

Let $\nu = (\nu_t, \nu_x)^t$ *be a unit vector such that* $\nu_x > 0$ *and satisfying* (3.10) *for some* $\alpha \in \{1, \ldots, n-1\}$*, i.e.,*

$$\lambda^\alpha(u) < -\frac{\nu_t}{\nu_x} < \lambda^{\alpha+1}(u) \quad \text{for all } u \in \mathcal{D}. \tag{6.2}$$

Then for any $u_l, u_r \in \mathcal{D}$*, the Godunov flux is given by* $g(u_l, u_r; \nu) = (\xi, f(\xi))\,\nu$*, where* $\xi = \xi(u_l, u_r; \nu)$ *is expressed in Riemann invariant coordinates by*

$$b(\xi) = (w_r^1, \ldots, w_r^\alpha, w_l^{\alpha+1}, \ldots, w_l^n) \tag{6.3}$$

and $w_l = b(u_l), w_r = b(u_r)$ *denote the Riemann invariants associated with* u_l, u_r*.*

Proof. To determine the Godunov flux $g(u_l, u_r; \nu)$ we need to solve the Riemann problem for (1.1) with initial data

$$u(0, x) = u_l \text{ if } x < 0 \quad \text{and} \quad u(0, x) = u_r \text{ if } x > 0.$$

The solution of the Riemann problem for Temple class systems satisfying (6.1) is described[4] in [22, section 2]. This solution has the form $u(t,x) = v(x/t)$ for some $v : \mathbb{R} \to \mathcal{D}$, which among other properties satisfies

$$v(s) = v_i \quad \text{for all } s \text{ in an interval } (a_i, b_i) \supseteq \left(\sup_{u\in\mathcal{D}} \lambda^i(u), \inf_{u\in\mathcal{D}} \lambda^{i+1}(u) \right),$$

where

$$b(v_i) = (w_r^1, \dots, w_r^i, w_l^{i+1}, \dots, w_l^n).$$

In particular, in view of (6.2) and definitions from section 3.2, this implies that $\xi_-(u_l, u_r; \nu) = \xi_+(u_l, u_r; \nu) = v_\alpha$, which is what we need to show. □

It is not clear how to determine $g(u_l, u_r; \nu)$ from the basic definition in terms of the Riemann problem if condition (6.1) is not satisfied, since as far as we know there is no standard solution of the Riemann problem in this situation. However, our results remain valid if we take (6.3) as the definition of $g(u_l, u_r; \nu)$ in cases when (6.2) holds but (6.1) does not.

We now fix some notation: Let P be a causal patch, minimal in the sense of (3.16), consisting of $k \geq 2$ triangles $T_1, \dots, T_k$. We label the triangles and edges as shown in Figure 3.[5]

Let u_l denote the inflow data on e_0, and u_r the inflow data on e_k, and let u_i denote the solution we seek on triangle T_i. On the patch P the system (3.3) can be rewritten as

$$-F(\xi_{j-1})\, n_{j-1} + F(u_j)\, n_j^o + F(\xi_j)\, n_j = 0, \quad j = 1, \dots, k, \tag{6.4}$$

where

$$\xi_j = \xi(u_j, u_{j+1}; \nu_j), \quad j \in \{1, \dots, k-1\}, \tag{6.5}$$

and where we use the notation

$$\xi_0 = u_l, \qquad \xi_k = u_r. \tag{6.6}$$

Here we use the notation

$$n_j = \nu_j\, \mathcal{H}^1(e_j), \quad n_j^o = \nu_j^o\, \mathcal{H}^1(e_j^o), \quad j = 0, \dots, k. \tag{6.7}$$

We now prove the following result.

[4]Serre discusses only systems of two equations, but the general case is exactly the same.

[5]Note that this is always possible. Indeed, by the definition of a causal patch (see (3.14)) and Lemma 3.2, each triangle T_i must have exactly one outflow edge, which we denote e_i^o. The non-outflow edges will be denoted e_j. The patch inflow boundary must be nonempty, by the argument of Lemma 3.2. We may therefore assume that some triangle, say T_1, has an inflow edge, which we denote e_0. Let us write e_1 to denote the third edge of T_1. This edge cannot be causal, since then $P' = T_1$ would be a proper causal subpatch, in violation of the minimality condition (3.16). Thus the edge must be part of the interior of P, and so there must exist another triangle, say T_2, such that $e_1 = T_1 \cap T_2$. Proceeding in this way, we see that the triangles can be labeled such that T_i and T_{i+1} intersect along an edge e_i for $i = 1, \dots, k-1$. The final triangle T_k can intersect only T_{k-1} (as all other edges of all other triangles are already accounted for), and so its final edge, which we denote e_k, must be inflow.

Let ν_i for $i = 1, \dots, k$ denote the outer unit normal to T_i along e_i or, equivalently, the inner unit normal to T_{i+1}, and let ν_0 denote the inner unit normal to T_1 along e_0. By reversing the ordering of the triangles if necessary, we can assume that

$$-\frac{\nu_{i,t}}{\nu_{i,x}} < -\frac{\nu_{i+1,t}}{\nu_{i+1,x}}, \quad i = 0, \dots, k-1.$$

After fixing notation in this way we arrive at Figure 3.

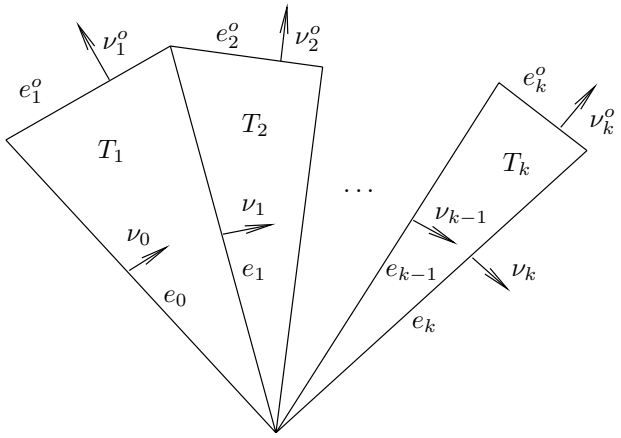

FIG. 3. *A causal patch of $k \geq 2$ triangles.*

LEMMA 6.2. *Let* (1.1) *be a strictly hyperbolic, genuinely nonlinear Temple class system, and assume that* (2.7) *holds for the domain of conservation states $\mathcal{D} \subset \mathbb{R}^n$. Let P be a causal patch of k triangles for $f, \mathcal{D}$ (see Figure* 3*). Then for any inflow data $u_l, u_r \in \mathcal{D}$, there exist unique $u_1, \dots, u_k \in \mathcal{D}$ satisfying* (6.4)–(6.6) *and*

(6.8)
$$\min\{w_{j-1}^i, w_{j+1}^i\} \leq w_j^i \leq \max\{w_{j-1}^i, w_{j+1}^i\} \quad \text{for } i \in \{1, \dots, n\}, j \in \{1, \dots, k\}.$$

Here we use the notation

$$w_0 := b(u_l), \quad w_{k+1} := b(u_r), \quad \text{and } w_j := b(u_j), \qquad j = 1, \dots, k. \tag{6.9}$$

Finally, the solution also satisfies

$$|w_{k+1}^i - w_0^i| = \sum_{j=1}^{k+1} |w_j^i - w_{j-1}^i|, \qquad i = 1, \dots, n. \tag{6.10}$$

Note that (6.8) is exactly conclusion (3.25) of the main Theorem 3.3.

Proof. We have fixed the orientation of the normals on the nonoutflow faces so that $\nu_{j,x} > 0$ for all j. Since e_j is semicausal for $j \in \{1, \dots, k-1\}$, there exist $\alpha_1, \dots, \alpha_{k-1}$ such that $\alpha_0 := 0 < \alpha_1 \leq \cdots \leq \alpha_{k-1} < \alpha_k := n$ such that

$$\lambda^{\alpha_j}(u) < -\frac{\nu_{j,t}}{\nu_{j,x}} < \lambda^{\alpha_j+1}(u) \tag{6.11}$$

for all $u \in \mathcal{D}$ and for all $j \in \{0, \dots, k\}$ (where the left-hand inequality for $j = 0$ and the right-hand inequality for $j = k$ are understood to hold trivially, since λ^0 and λ^{n+1} are not defined.)

Step 1. We first prove that if $u_1, \dots, u_k \in \mathcal{D}$ satisfy (6.4)–(6.6) for inflow data $u_l, u_r \in \mathcal{D}$, then necessarily

$$\xi_j = \xi(u_l, u_r; \nu_j), \quad j \in \{1, \dots, k-1\}, \tag{6.12}$$

where ξ_j is as defined in (6.5). Fix any j. Using the notation (6.9), the formula for the Godunov value $\xi(u_l, u_r; \nu_j)$ from Lemma 6.1, and (6.11), we can write

$$b(\xi_j) = (w^1_{j+1}, \dots, w^{\alpha_j}_{j+1}, w^{\alpha_j+1}_j, \dots, w^n_j). \tag{6.13}$$

In particular, in the coordinate system provided by Riemann invariants, the ith coordinates of ξ_j and u_j are equal for $i = \alpha_j + 1, \dots, n$. Thus, in view of (6.4) and the invariant submanifold property of Lemma 5.5, it must be the case that the same coordinates are shared by ξ_{j-1}. In view of (6.13) (with j replaced by $j-1$), this implies that $w^i_{j-1} = w^i_j$ for $i = \alpha_j + 1, \dots, n$. Since this holds for all j, and since $\alpha_{j-1} \le \alpha_j$, we deduce that

$$b^i(\xi_j) = b^i(\xi_0) = b^i(u_l) = w^i_0 \quad \text{for } i = \alpha_j + 1, \dots, n. \tag{6.14}$$

Similarly, from (6.13) we see that, in the coordinate system given by Riemann invariants, the ith coordinates of ξ_j and u_{j+1} are equal for $i = 1, \dots, \alpha_j$, and so using (6.4) and Lemma 5.5 again, we find that

$$b^i(\xi_j) = b^i(\xi_k) = b^i(u_r) = w^i_{k+1} \quad \text{for } i = 1, \dots, \alpha_j. \tag{6.15}$$

Again appealing to Lemma 6.1 to find an explicit formula for the Godunov value $\xi(u_l, u_r; \nu_j)$, we find that (6.14) and (6.15) together prove (6.12).

Step 2. In view of Step 1, the triangles in the causal patch in effect decouple, and on each triangle T_j, $j = 1, \dots, k$, we must show the existence of a unique solution (with Riemann invariant bounds) for the problem

$$-F(\xi_{j-1})\, n_{j-1} + F(u_j)\, n^o_j + F(\xi_j)\, n_j = 0, \tag{6.16}$$

where now all the values ξ_j are known:

$$\xi_j = \xi(u_l, u_r, \nu_j), \quad j \in \{1, \dots, k-1\}, \tag{6.17}$$

$$\xi_0 = u_l, \quad \xi_k = u_r. \tag{6.18}$$

Fix a triangle T_j. Let us define

$$\mathcal{C}_j := b^{-1}\left(\left\{ w \in \mathcal{R} \ : w^i = \begin{cases} w^i_r, & i = 1, \dots, \alpha_{j-1}, \\ w^i_l, & i = \alpha_j + 1, \dots, n. \end{cases} \right\} \right)$$

From (6.17) and Lemma 6.1 we see that $\xi_{j-1}, \xi_j \in \mathcal{C}_j$. Thus Lemma 5.5 implies that any solution $u_j \in \mathcal{D}$ of (6.16) must also satisfy $u_j \in \mathcal{C}_j$. If $\alpha_{j-1} = \alpha_j$, then we have $\xi_{j-1} = u_j = \xi_j$, and if $\alpha_{j-1} < \alpha_j$, we show that we can find a solution in $\mathcal{C}_j$ by reducing (1.1) to a smaller *causal* Temple class system.

Let $\ell = \alpha_j - \alpha_{j-1}$, so that $n - \ell$ is the number of coordinates in the coordinate system of Riemann invariants that are specified for elements of $\mathcal{C}_j$. By Lemma 5.3, there exist a domain of conservation states $\overline{\mathcal{D}} \subset \mathbb{R}^\ell$, an affine bijection $L : \overline{\mathcal{D}} \to \mathcal{C}_j$, and a mapping $\bar{f} : \overline{\mathcal{D}} \to \mathbb{R}^\ell$ such that

$$\bar{u}_t + \bar{f}(\bar{u})_x = 0 \tag{6.19}$$

is a genuinely nonlinear Temple class system for $\bar{u} \in \overline{\mathcal{D}}$, and

$$f(L\bar{u}) = L\bar{f}(\bar{u}) + K, \qquad \bar{u} \in \overline{\mathcal{D}}, \tag{6.20}$$

where $K \in \mathbb{R}^n$ is some constant. Furthermore, if $\bar{\lambda}^j, j = 1, \dots, \ell$, denotes the eigenvalues of $D\bar{f}$, then

$$\{\bar{\lambda}^j(\bar{u})\}_{j=1}^{\ell} = \{\lambda^j(L\bar{u})\}_{j=\alpha_{j-1}+1}^{\alpha_j}, \quad \bar{u} \in \overline{\mathcal{D}}. \tag{6.21}$$

We assert that edges e_{j-1} and e_j are inflow edges for T_j. Indeed, our choice of notation implies that $\nu_{j,x} > 0$ for all j, so that (6.11) implies that $\nu_{j,t} + \nu_{j,x}\lambda^i(u) < 0$ for all $i \le \alpha_j$ and all $u \in \mathcal{D}$. Also, ν_j is the outer normal to T_j along edge e_j, so e_j satisfies the definition (3.6) of an inflow edge for T_j. Similarly, $\nu_{j-1,t} + \nu_{j-1,x}\lambda^i(u) > 0$ for all $i \ge \alpha_{j-1} + 1$ and all $u \in \mathcal{D}$, and $-\nu_{j-1}$ is the outer normal to T_j along e_{j-1}, from which it follows that e_{j-1} is also an inflow edge for T_j.

Thus T_j is a causal triangle for $\bar{f}, \overline{\mathcal{D}}$, and so Lemma 5.6 implies that there exists a unique solution $\bar{u}_j$ of the equation

$$-(\bar{\xi}_{j-1}, \bar{f}(\bar{\xi}_{j-1}))\, n_{j-1} + (\bar{u}_j, \bar{f}(\bar{u}_j))\, n_j^o + (\bar{\xi}_j, \bar{f}(\bar{\xi}_j))\, n_j = 0, \tag{6.22}$$

where $\bar{\xi}_j \in \overline{\mathcal{D}}$ satisfies $L(\bar{\xi}_j) = \xi_j$, and similarly $\bar{\xi}_{j-1}$. This solution $\bar{u}_j$ also satisfies Riemann invariant bounds (5.25), and is the only solution with this property.

We claim that $u_j := L\bar{u}_j$ satisfies (6.16). Indeed, from (6.20), (6.22), and the fact that $n_j^o + n_{j-1} + n_j = 0$ (see (3.22)) we infer that

$$\begin{aligned}
-F(\xi_{j-1})\, n_{j-1} + F(u_j)\, n_j^o + F(\xi_j)\, n_j & \\
&= -(L\bar{\xi}_{j-1}, f(L\bar{\xi}_{j-1}))\, n_{j-1} + (L\bar{u}_j, f(L\bar{u}_j))\, n_j^o + (L\bar{\xi}_j, f(L\bar{\xi}_j))\, n_j \\
&= -(L\bar{\xi}_{j-1}, L\bar{f}(\bar{\xi}_{j-1}))\, n_{j-1} + (L\bar{u}_j, L\bar{f}(\bar{u}_j))\, n_j^o + (L\bar{\xi}_j, L\bar{f}(\bar{\xi}_j))\, n_j \\
&= -L(\bar{\xi}_{j-1}, \bar{f}(\bar{\xi}_{j-1}))\, n_{j-1} + L(\bar{u}_j, \bar{f}(\bar{u}_j))\, n_j^o + L(\bar{\xi}_j, \bar{f}(\bar{\xi}_j))\, n_j \\
&= 0.
\end{aligned}$$

Step 3. We next claim that u_j satisfies (6.8) and is the only solution of (6.16) with this property. The Riemann invariant bounds satisfied by $\bar{u}_j$ and properties of the map L imply that u_j satisfies

$$\min\{b^i(\xi_{j-1}), b^i(\xi_j)\} \le w_j^i \le \max\{b^i(\xi_{j-1}), b^i(\xi_j)\} \tag{6.23}$$

if $i \in \{\alpha_{j-1} + 1, \dots, \alpha_j\}$. From (6.13) we see that $b^i(\xi_{j-1}) = w_{j-1}^i$ for $i \ge \alpha_{j-1} + 1$, and $b^i(\xi_j) = w_{j+1}^i$ for $i \le \alpha_j$, so that (6.23) becomes (6.8) for $i \in \{\alpha_{j-1} + 1, \dots, \alpha_j\}$. If $i > \alpha_j$, then similarly from (6.14) we see that $b^i(\xi_j) = w_0^i = w_j^i$ (using the fact that $u_j \in \mathcal{C}_j$). Thus in this case (6.8) clearly holds. Similarly, in the case $i \le \alpha_{j-1}$, we deduce (6.8) by noting that $b^i(\xi_{j-1}) = w_{k+1}^i = w_j^i$.

Note in addition that if v_j is any solution of (6.16), then necessarily $v_j \in \mathcal{C}_j$, and by undoing the above arguments one can see that $v_j = L\bar{v}_j$ for some $\bar{v}_j \in \overline{\mathcal{D}}$ solving (6.22) and satisfying suitable Riemann invariant bounds. It follows that $\bar{v}_j = \bar{u}_j$, so that u_j is the only solution of (6.16) for which (6.8) holds.

Step 4. Finally, to prove (6.10), fix some $i \in \{1, \dots, n\}$. There exists some j such that $\alpha_{j-1} < i \le \alpha_j$. It follows from Step 2 (in particular the fact that $u_j \in \mathcal{C}_j$) that

$$w_m^i = w_0^i \quad \text{for } m = 1, \dots, j-1, \qquad w_m^i = w_{k+1}^i \quad \text{for } m = j+1, \dots, k.$$

Together with (6.8), this establishes (6.10). ∎

Remark 6.3. Suppose that all assumptions of the previous lemma hold. Let (η, ψ) be an entropy-entropy flux pair for (1.1), and let a set $\mathcal{D}'$ be characterized by (4.14).

By taking $\mathcal{D}'$ smaller, we can assume that it satisfies (2.7). Consider a triangle T_j, for some $j \in \{1, \dots, k\}$, within the patch, and let $\mathcal{C}_j, \overline{\mathcal{D}}$, and L be as in Step 2 of the previous proof. By Remark 5.4 we have that $(\bar{\eta}, \bar{\psi})$ defined by (5.19) forms an entropy-entropy flux pair for the Temple class system (6.19). Note that, by (5.20) and the fact that the map $L : \overline{\mathcal{D}} \to \mathcal{D}$ is linear, we have $\mathcal{D}' \cap \mathcal{C}_j \subset L(\overline{\mathcal{D}}')$.

By Theorem 4.2 for the system (6.19) and the causal triangle T_j for $\bar{f}, \overline{\mathcal{D}}$, we have that if $\bar{\xi}_{j-1}, \bar{\xi}_j, \bar{u}_j \in \overline{\mathcal{D}}'$, then

$$\int_{e_j^o} \left(\bar{\eta}(\bar{u}_j), \bar{\psi}(\bar{u}_j)\right) \nu_j^o \, d\mathcal{H}^1 + \int_{e_{j-1}} \left(\bar{\eta}(\bar{\xi}_{j-1}), \bar{\psi}(\bar{\xi}_{j-1})\right) (-\nu_{j-1}) \, d\mathcal{H}^1 + \int_{e_j} \left(\bar{\eta}(\bar{\xi}_j), \bar{\psi}(\bar{\xi}_j)\right) \nu_j \, d\mathcal{H}^1 \le 0.$$

Hence, if the inflow data on a causal patch P is such that $\{u_{T_e} \in \mathcal{D}' : e \subset \partial P^-\}$, then for every triangle T within P,

$$\int_{\partial T^+} (\eta(u_T), \psi(u_T)) \, \nu \, d\mathcal{H}^1 + \int_{e \text{ inflow}} (\eta(u_{T_e}), \psi(u_{T_e})) \, \nu_{e,T} \, d\mathcal{H}^1 + \sum_{e \text{ semicausal}} \int_e (\eta(\xi_e), \psi(\xi_e)) \, \nu_{e,T} \, d\mathcal{H}^1 \le 0,$$

where ξ_e denotes the Godunov value along a semicausal edge e of triangle T. Using (3.22) and letting ξ_e denote the inflow value u_{T_e} along an inflow edge, this can be written more concisely in the form

$$\sum_{e \text{ noncausal}} \int_e \left[(\eta(\xi_e), \psi(\xi_e)) - (\eta(u_T), \psi(u_T))\right] \nu_{e,T} \, d\mathcal{H}^1 \le 0. \tag{6.24}$$

Example 6.4. In this example we show that uniqueness of solutions of the approximation scheme can fail if both conditions (3.14) and (3.15) are violated. We do not know whether uniqueness can fail if either condition alone is not satisfied.

Let $P = T_1 \cup T_2 \cup T_3$, as in Figure 4. Consider Burgers' equation (scalar conservation law where $f(u) = \frac{u^2}{2}$) with $\mathcal{D} = [-a, a]$ for any $0 < a < \frac{4}{3}$. It is clear that every edge $e \subset \partial P$ is causal. Let u_i^- denote the inflow data along $T_i \cap \partial P^-$, where ∂P^- denotes the patch inflow boundary, and let u_i denote the approximate solution on T_i. Suppose that

$$u_1^- = 1, \quad u_2^- = 0, \quad \text{and} \quad u_3^- = -1.$$

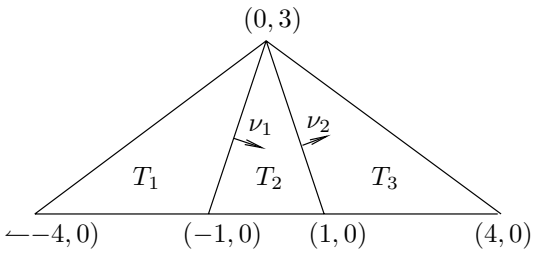

FIG. 4.

We claim that an approximate solution on P is given by

$$u_1 = 1, \quad u_3 = -1, \quad \text{and} \quad u_2 = \sigma, \quad \text{for arbitrary } \sigma \in \left(-\tfrac{1}{3}, \tfrac{1}{3}\right). \tag{6.25}$$
