POINTWISE ERROR ESTIMATES FOR FINITE ELEMENT SOLUTIONS OF THE STOKES PROBLEM*

HONGSEN CHEN†

Abstract. In this paper pointwise error estimates for general finite element approximations of the Stokes problem are established on quasi-uniform grids in R^N. The results obtained in this paper improve and extend the existing error estimates in the maximum norm for the Stokes problem. The new pointwise error estimates exhibit a more local dependence of the errors on the true solution and as a by-product provide logarithm-free bounds for all errors except the error of the velocity approximation of the lowest order.

Key words. finite element method, pointwise error estimate, Stokes problem

1. Introduction.

This paper is devoted to new pointwise error estimates of finite element approximations of the Stokes equations on general quasi-uniform meshes in R^N. The results in this paper represent an improvement on and extension of the existing maximum norm error estimates found in Durán, Nochetto, and Wang [6], which were obtained for two-dimensional problems. Our analysis is based on the technique developed recently by Schatz [15, 16] for the finite element method for second order elliptic problems (see also Schatz and Wahlbin [17]). In contrast to the traditional approach for proving error estimates in the maximum norm with the weighted function method (Scott [19], Natterer [10], Rannacher and Scott [14], etc.), the new method relies on the availability of local error estimate in energy norm for the underlying finite element discretization. The results in [15] indicate a more localized dependence of the errors on the derivatives of the true solution. As a consequence of these estimates error expansion inequalities have been derived and applied to superconvergence and extrapolation and a posteriori estimates (see [16, 8]). The aim of this paper is to extend the new technique from elliptic problems to the Stokes problem, which has a saddle point nature and requires a more careful investigation.

It is well known that the conforming finite element approximation $(\mathbf{u}_h, p_h)$ to the true solution $(\mathbf{u}, p)$ of the Stokes problem admits the following optimal error estimates in energy and L^2 norms (Brezzi and Fortin [4], Girault and Raviart [7]):

$$\|\mathbf{u}-\mathbf{u}_h\|_{H^1(\Omega)} + \|p-p_h\|_{L^2(\Omega)} \le C\Big(\inf_{\mathbf{v}\in\mathbf{V}_h} \|\mathbf{u}-\mathbf{v}\|_{H^1(\Omega)} + \inf_{q\in W_h} \|p-q\|_{L^2(\Omega)}\Big)$$

and

$$\|\mathbf{u}-\mathbf{u}_h\|_{L^2(\Omega)} \le Ch\Big(\inf_{\mathbf{v}\in\mathbf{V}_h} \|\mathbf{u}-\mathbf{v}\|_{H^1(\Omega)} + \inf_{q\in W_h} \|p-q\|_{L^2(\Omega)}\Big),$$

where $\mathbf{V}_h$ is the finite element subspace for velocity unknown and W_h is the finite element subspace for pressure unknown. The spaces $\mathbf{V}_h$ and W_h are assumed to satisfy

a certain condition (e.g., the inf-sup condition) to ensure the solvability and uniqueness of the solution of the resulting finite element system. Under the assumption that there exists a locally constructed projection operator $\Pi^h : \ H_0^1(\Omega)^N \to \mathbf{V}^h$ satisfying

$$(\nabla \cdot (\mathbf{v} - \Pi^h \mathbf{v}), q_h) = 0 \quad \forall \mathbf{v} \in H_0^1(\Omega)^N, \ q_h \in W_h,$$

the following error estimates in the maximum norm have been derived for the two-dimensional Stokes problem (Durán, Nochetto, and Wang [6]):

$$\|\mathbf{u} - \mathbf{u}_h\|_{L^\infty(\Omega)} \le Ch \ln \frac{1}{h} B(\mathbf{u}, p), \tag{1.1}$$

$$\|p - p_h\|_{L^\infty(\Omega)} \le C \left(\ln \frac{1}{h} \right)^{1/2} B(\mathbf{u}, p), \tag{1.2}$$

where

$$B(\mathbf{u}, p) = \inf_{\mathbf{v} \in \mathbf{V}_h} \|\mathbf{u} - \mathbf{v}\|_{W^{1,\infty}(\Omega)} + \inf_{q \in W_h} \|p - q\|_{L^\infty(\Omega)}.$$

Similar error estimates were derived by using weighted inf-sup conditions instead of the local projection operator in Durán and Nochetto [5]. The proofs of these error estimates are based on the estimates in weighted Sobolev norms for some so-called regularized Green's functions and their finite element approximations. This is the standard approach for proving error estimates in the maximum norm for finite element methods. Nevertheless, with this approach it is difficult to generalize these results to the case of higher space dimensions.

Following the approach developed in [15], some new pointwise error estimates for the finite element solutions of the Stokes problem will be derived in this paper. Our new pointwise error estimates for both the velocity and pressure approximations take the following form: for any $z \in \bar{\Omega}$,

$$|\nabla(\mathbf{u} - \mathbf{u}_h)(z)| + |(p - p_h)(z)| \le C \left(\ln \frac{1}{h} \right)^{\bar{s}} B(\mathbf{u}, p, z, s), \quad 0 \le s \le r, \tag{1.3}$$

$$|(\mathbf{u} - \mathbf{u}_h)(z)| \le Ch \left(\ln \frac{1}{h} \right)^{\bar{\bar{s}}} B(\mathbf{u}, p, z, s), \quad 0 \le s \le r - 1, \tag{1.4}$$

where

$$B(\mathbf{u}, p, z, s) = \inf_{\mathbf{v} \in \mathbf{V}_h} \|\mathbf{u} - \mathbf{v}\|_{W^{1,\infty}(\Omega),z,s} + \inf_{q \in W^h} \|p - q\|_{L^\infty(\Omega),z,s},$$

and $\| \cdot \|_{W^{1,\infty}(\Omega),z,s}$ and $\| \cdot \|_{L^\infty(\Omega),z,s}$ are weighted Sobolev norms with the weight function $\sigma_z(x)^s = (h/(|x - z| + h)^s$, and $\bar{s} = 0$ if $0 \le s < r$ and $\bar{s} = 1$ if $s = r$; $\bar{\bar{s}} = 0$ if $0 \le s < r - 1$ and $\bar{\bar{s}} = 1$ if $s = r - 1$. Here, r is the order of approximation of the finite element spaces in the H^1 norm for the velocity and the L^2 norm for the pressure (in most cases, r equals the degree of polynomials used in space $\mathbf{V}^h$).

Notice that estimates (1.4) and (1.1) coincide when $r = 1$, which corresponds to the case of the lowest order finite element spaces because the only possible value of s is zero. Nevertheless, (1.4) indeed improve (1.1) for $r > 1$. Estimates (1.4) and (1.3) are sharper than (1.1) and (1.2) in the sense that (1.4) and (1.3) imply (1.1) and (1.2) but not vice versa. Because of the weighted norms on the bounds of (1.4) and (1.3), they indicate a more local dependence of the errors at z on the true solution

$(\mathbf{u}, p)$ near z than (1.1) and (1.2) do. The larger the r, the higher local properties these estimates provide. Besides the more localized dependence on the true solution, estimates (1.4) and (1.3) also represent sharper bounds for the errors. They provide logarithm-free error bounds for the velocity approximation when $r > 1$ and for the approximations and the derivatives of the velocity and the pressure for any $r \geq 1$. In fact, (1.4) and (1.3) imply the following estimates in the maximum norm:

$$\|\mathbf{u} - \mathbf{u}_h\|_{L^\infty(\Omega)} \leq Ch\left(\ln\frac{1}{h}\right)^{\bar{r}} B(\mathbf{u}, p),$$
$$\|\mathbf{u} - \mathbf{u}_h\|_{W^{1,\infty}(\Omega)} + \|p - p_h\|_{L^\infty(\Omega)} \leq CB(\mathbf{u}, p).$$

Here, $\bar{r} = 0$ if $r > 1$ and $\bar{r} = 1$ if $r = 1$.

The new estimates (1.4) and (1.3) are stated in Theorems 4.2, 5.1, and 6.1 and are proved under abstract assumptions on the finite element spaces. These hypotheses include the quasi-uniformity of the partitions, the approximation properties, the inverse properties, local L^2 error estimates for the Stokes finite element solutions, and the scaling property. Note that the superapproximation property and the inf-sup (stability) condition or the existence of locally orthogonal projection operator are not assumed explicitly. Instead, local error estimates for the velocity in the H^1 norm and the pressure in the L^2 norm are assumed, which can be proved under the assumptions of superapproximation and the presence of local stability or local orthogonal projection operator (see Arnold and Liu [3]).

We end this introduction with a brief outline of the rest of this paper. In section 2, we discuss some preliminaries and introduce notation and assumptions. Section 3 contains estimates of a priori type for the Stokes problem and error estimates for some special auxiliary problems. In section 4, we prove the pointwise error estimate for the pressure approximation. The pointwise error estimates for the velocity and the derivatives of the velocity are proved in sections 5 and 6, respectively.

2. Preliminaries and notation. For the sake of simplicity, we consider the following Stokes problem with a homogeneous Dirichlet boundary condition:

$$\begin{aligned} -\nu\Delta\mathbf{u} + \nabla p &= \mathbf{f} \quad \text{in } \Omega, \\ \nabla\cdot\mathbf{u} &= 0 \quad \text{in } \Omega, \\ \mathbf{u} &= 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{2.1}$$

where $\Omega \subset R^N$ $(N \geq 2)$ is an open subset with a smooth boundary $\partial\Omega$, $\mathbf{u}$ and p are unknown functions called velocity and pressure of the fluid, respectively, $\mathbf{f}$ is a given function, and $\nu > 0$ is a constant representing the viscosity of the fluid. Without loss of generality, we assume that $\nu = 1$.

We shall use the standard notation for Sobolev spaces and their norms (see, e.g., Adams [1]). For nonnegative integer j and real number $1 \leq t \leq \infty$ and subdomain $D \subset \Omega$, denote the Sobolev spaces by $W^{j,t}(D) = \left\{v : \ \|v\|_{W^{j,t}(D)} < \infty\right\}$ with

$$\|v\|_{W^{j,t}(D)} = \left(\sum_{i=0}^{j} |v|^t_{W^{i,t}(D)}\right)^{1/t}, \quad |v|_{W^{i,t}(D)} = \left(\sum_{|\alpha|=i}\int_D |\partial^\alpha v(x)|^t dx\right)^{1/t}.$$

Let $W_0^{j,t}(D)$ denote the completion of $C_0^\infty(D)$ according to the norm $\|\cdot\|_{W^{j,t}(D)}$, where $C_0^\infty(D)$ represents the space of functions with continuous derivatives of arbitrary order and compact supports in D. We also adopt the usual notation

$$H^j(D) = W^{j,2}(D), \quad H_0^j(D) = W_0^{j,2}(D), \quad L^t(D) = W^{0,t}(D).$$

Denote by $(\cdot,\cdot)_D$ the standard inner product in $L^2(D)$ given by $(u,v)_D = \int_D uv\,dx$. When $D=\Omega$, we write $(\cdot,\cdot) = (\cdot,\cdot)_\Omega$. The subspace of $L^2(D)$ consisting of functions of zero mean values is denoted by $L_0^2(D)$, i.e.,

$$L_0^2(D) = \left\{ q \in L^2(D) : \int_D q(x)\,dx = 0 \right\}.$$

For $j \geq 0$ and $1 \leq t < \infty$, the negative Sobolev norm $\|\cdot\|_{W^{-j,t}(D)}$ is defined as follows:

$$\|v\|_{W^{-j,t}(D)} = \sup_{\varphi \in C_0^\infty(D)} \frac{(v,\varphi)}{\|\varphi\|_{W^{j,t'}(D)}},$$

where t' is the conjugate of t, i.e., $1/t + 1/t' = 1$. We will make no distinction in notation between the Sobolev norms for scalar and vector valued functions. For instance, the norm of $\mathbf{u}$ in

$$H^1(D)^N = \overbrace{H^1(D) \times \cdots \times H^1(D)}^{N}$$

is denoted by $\|\mathbf{u}\|_{H^1(D)}$.

The solution $(\mathbf{u}, p)$ of (2.1) satisfies the following weak formulation:

$$\begin{aligned} a(\mathbf{u},\mathbf{v}) - b(\mathbf{v},p) &= (\mathbf{f},\mathbf{v}) \quad \forall\ \mathbf{v} \in H_0^1(\Omega)^N, \\ b(\mathbf{u},q) &= 0 \qquad \forall\ q \in L_0^2(\Omega), \end{aligned} \tag{2.2}$$

where $a(\cdot,\cdot)$ and $b(\cdot,\cdot)$ are bilinear forms defined by

$$a(\mathbf{u},\mathbf{v}) = \int_\Omega \nabla\mathbf{u} : \nabla\mathbf{v}\,dx, \quad b(\mathbf{v},q) = \int_\Omega \nabla\cdot\mathbf{v}\,q\,dx.$$

To define the finite element solution of (2.2), let $\mathbf{V}^h \subset H_0^1(\Omega)^N$ and $W^h \subset L_0^2(\Omega)$ be two families of finite-dimensional subspaces with a parameter $h \in (0,1)$. The finite element approximation $(\mathbf{u}_h, p_h) \in \mathbf{V}^h \times W^h$ is defined to be the solution of

$$\begin{aligned} a(\mathbf{u}_h,\mathbf{v}) - b(\mathbf{v},p_h) &= (\mathbf{f},\mathbf{v}) \quad \forall\ \mathbf{v} \in \mathbf{V}^h, \\ b(\mathbf{u}_h,q) &= 0 \quad \forall\ q \in W^h. \end{aligned} \tag{2.3}$$

By (2.2) and (2.3), the following error equation holds:

$$\begin{aligned} a(\mathbf{u}-\mathbf{u}_h,\mathbf{v}) - b(\mathbf{v},p-p_h) &= 0 \quad \forall\ v \in \mathbf{V}^h, \\ b(\mathbf{u}-\mathbf{u}_h,q) &= 0 \quad \forall\ q \in W^h. \end{aligned} \tag{2.4}$$

We point out that the pointwise error estimates obtained in this paper are all based on the error equation (2.4).

For any subset $D \subset \Omega$, let $\mathbf{V}^h(D)$ denote the set of restrictions of functions in $\mathbf{V}^h$ on D, and $W^h(D)$ the set of restrictions of functions in W^h on D. We also introduce the notation for balls in R^N. Denote by $B_d(x)$ the ball of radius $d>0$ and centered at $x \in R^N$.

Throughout this paper, $\kappa > 0$ denotes a constant. Below, we list the assumptions that will be used by our results.

A.0 (*quasi-uniform partition*). The domain Ω is decomposed into N_h subdomains:

$$\bar{\Omega} = \bigcup_{j=1}^{N_h} \bar{K}_j, \text{ so that } W^h(K_j) \subset C^\infty(K_j),\ j = 1, \ldots, N_h.$$

Furthermore, there are constants $C_0 > 0$ and $\tau_0 > 0$ such that for any $\tau \in (0, \tau_0)$, and $1 \le j \le N_h$ and $x \in \bar{K}_j$, there exists an $\bar{x} \in K_j$ such that

$$B_{\tau h}(\bar{x}) \subset K_j \quad \text{and} \quad |x - \bar{x}| \le C_0 \tau h.$$

A.1 (*approximation properties*). There exist $r \ge 1$ and two linear operators

$$\Pi^h :\ H^1(\Omega)^N \to \mathbf{V}^h \quad \text{and} \quad Q^h :\ L^2(\Omega) \to W^h$$

such that for any $D_1 \subset D_2 \subset \Omega$ with $\operatorname{dist}(D_1, \partial D_2 \backslash \partial\Omega) \ge \kappa h$,

(i) for $0 \le i \le 1 \le j \le r+1$, $2 \le t \le \infty$, and any $\mathbf{v} \in W^{j,t}(D_2)^N$,

$$\|\mathbf{v} - \Pi^h \mathbf{v}\|_{W^{i,t}(D_1)} \le C h^{j-i} |\mathbf{v}|_{W^{j,t}(D_2)};$$

if $N < t \le \infty$,

$$\|\mathbf{v} - \Pi^h \mathbf{v}\|_{W^{1,\infty}(D_1)} \le C h^{r-N/t} \|\mathbf{v}\|_{W^{1+r,t}(D_2)};$$

(ii) for $0 \le i \le j \le r$, $2 \le t \le \infty$, and any $q \in W^{j,t}(D_2)$,

$$\|q - Q^h q\|_{W^{i,t}(D_1)} \le C h^{j-i} |q|_{W^{j,t}(D_2)};$$

if $N < t \le \infty$,

$$\|q - Q^h q\|_{L^\infty(D_1)} \le C h^{r-N/t} \|q\|_{W^{r,t}(D_2)}.$$

A.2 (*inverse properties*). Let $D_1 \subset D_2 \subset \Omega$ with $\operatorname{dist}(D_1, \partial D_2 \backslash \partial\Omega) \ge \kappa h$. Then, for any $1 \le s \le t \le \infty$, $i = 0, 1$, $j \ge 0$ and $\mathbf{v} \in \mathbf{V}^h$, $q \in W^h$,

$$\begin{aligned}
\|\mathbf{v}\|_{W^{i,t}(D_1)} &\le C h^{-N(1/s-1/t)-i-j} \|\mathbf{v}\|_{W^{-j,s}(D_2)}, \\
\|q\|_{L^t(D_1)} &\le C h^{-N(1/s-1/t)-j} \|q\|_{W^{-j,s}(D_2)}, \\
\|q\|_{W^{1,\infty}(K_j)} &\le C h^{-1} \|q\|_{L^\infty(K_j)}, \quad 1 \le j \le N_h.
\end{aligned}$$

A.3 (*local L^2 error estimate*). Let $(\mathbf{v}, q) \in H_0^1(\Omega)^N \times L_0^2(\Omega)$ and $(\mathbf{v}_h, q_h) \in \mathbf{V}^h \times W^h$ satisfy

$$\begin{aligned}
a(\mathbf{v} - \mathbf{v}_h, \varphi) - b(\varphi, q - q_h) &= 0 \quad \forall\ \varphi \in \mathbf{V}^h, \\
b(\mathbf{v} - \mathbf{v}_h, \psi) &= 0 \quad \forall\ \psi \in W^h.
\end{aligned}$$

If $D_1 \subset D_2 \subset \Omega$ with $d = \operatorname{dist}(D_1, \partial D_2 \backslash \partial\Omega) > 0$, then there holds

$$\begin{aligned}
&\|\mathbf{v} - \mathbf{v}_h\|_{H^1(D_1)} + \|q - q_h\|_{L^2(D_1)} \\
&\quad \le C h^r \left(\|\mathbf{v}\|_{H^{r+1}(D_2)} + \|q\|_{H^r(D_2)} \right) \\
&\qquad + C \left(\|\mathbf{v} - \mathbf{v}_h\|_{W^{-t,1}(D_2)} + \|q - q_h\|_{W^{-t-1,1}(D_2)} \right),
\end{aligned}$$

where $t \ge 0$, and the constant $C > 0$ may be dependent on t and d but is independent of h and $\mathbf{v}$ and q.

A.4 (*scaling property*). Let $x_0 \in \bar{\Omega}$ and $d \geq \kappa h$. The linear transformation $y = (x - x_0)/d$ takes the domain $B_d(x_0) \cap \Omega$ into a new domain $\hat{B}_1(x_0)$, $\mathbf{V}^h(B_d(x_0))$ into a new function space $\hat{\mathbf{V}}^{h/d}(\hat{B}_1(x_0))$, and $W^h(B_d(x_0))$ into a new space $\hat{W}^{h/d}(\hat{B}_1(x_0))$. Then, $\hat{\mathbf{V}}^{h/d}(\hat{B}_1(x_0))$ and $\hat{W}^{h/d}(\hat{B}_1(x_0))$ satisfy A.1 and A.2 with h replaced by h/d. The constants occurring in A.1 and A.2 remain unchanged, in particular, independent of d.

Assumptions A.1, A.2, and A.4 are very standard (see [15, 17, 18]). The results in A.3 can be found in Arnold and Liu [3] under additional assumptions such as the availability of the local inf-sup condition or the orthogonal projection operator. Although the results in [3] were obtained for two-dimensional problems, it is easily seen that they can be extended to higher dimensions. Assumption A.0 is used only for the existence of the *regularized* Dirac delta function in the derivation of the pointwise error estimate of the pressure approximation (see section 4 for details).

Throughout this paper we assume that Assumptions A.0, A.1, A.2, A.3, and A.4 are satisfied and use the letter C for generic constants.

Before we end this section, let us introduce some notation about the weighted norms: Following the notation of [15], for a fixed $z \in \bar{\Omega}$, a real number s, and arbitrary $x \in R^N$, define the weight function

$$\sigma_{z,h}^s(x) = \left(\frac{h}{|x - z| + h}\right)^s. \tag{2.5}$$

Clearly, $\sigma_{z,h}^s(x) = \mathcal{O}(1)$ if $s > 0$ and $|x - z| = \mathcal{O}(h)$, $\sigma_{z,h}^s(x) = \mathcal{O}(h^s)$ if $|x - z| = \mathcal{O}(1)$. For $1 \leq t \leq \infty$ and fixed z, we define the following weighted norms:

$$\|\varphi\|_{L^t(\Omega),z,s} = \|\sigma_{z,h}^s \varphi\|_{L^t(\Omega)}, \tag{2.6}$$

$$\|\varphi\|_{W^{1,t}(\Omega),z,s} = \|\varphi\|_{L^t(\Omega),z,s} + \|\nabla\varphi\|_{L^t(\Omega),z,s}. \tag{2.7}$$

It is straightforward to extend this notation to vector valued functions.

3. A priori estimates. In this section, we shall collect and show some results on the regularities of the Stokes problem. These results include the global and local estimates of the higher order derivatives of the true solutions and the global and local error estimates for the finite element approximations of some special auxiliary problems.

The first result is the following global a priori estimates for the Stokes equations.

LEMMA 3.1. *Suppose Ω and $(\mathbf{v}, \mu) \in H_0^1(\Omega)^N \times L_0^2(\Omega)$ are sufficiently smooth. Then, for $k \geq -1$, there holds*

$$\|\mathbf{v}\|_{H^{k+2}(\Omega)} + \|\mu\|_{H^{k+1}(\Omega)} \leq C\left(\|\mathbf{f}\|_{H^k(\Omega)} + \|g\|_{H^{k+1}(\Omega)}\right), \tag{3.1}$$

where $\mathbf{f} = -\Delta\mathbf{v} + \nabla\mu$, $g = \nabla \cdot \mathbf{v}$, and $C > 0$ is a constant independent of $\mathbf{v}$, μ.

Proof. The proof can be found in Ladyzhenskaya [9] and Agmon, Douglis, and Nirenberg [2]. □

Next, we show a special local estimate of the solution of the Stokes problem, which is based on the pointwise bounds for Green's tensors of the Stokes problem.

LEMMA 3.2. *Suppose $D_0 \subset D_1 \subset \Omega$ are sufficiently smooth domains with $d = \operatorname{dist}(D_0, \partial D_1 \backslash \partial\Omega) > 0$, and $\mathbf{f} \in L^\infty(\Omega)$, $g \in C_0^\infty(\Omega)$, $\zeta \in C_0^\infty(\Omega)$ with $(1, \zeta) = 1$. Let $(\mathbf{v}, \mu) \in H_0^1(\Omega)^N \times L_0^2(\Omega)$ be the solution of*

$$-\Delta\mathbf{v} + \nabla\mu = \mathbf{f}, \quad \nabla \cdot \mathbf{v} = g - (1, g)\zeta.$$

If $\mathbf{f}$ *and* g *vanish in* D_1*, then for* $k \geq -1$ *and* $1 \leq t \leq \infty$*, there holds*

$$\begin{aligned}(3.2)\qquad &\|\mathbf{v}\|_{W^{k+2,\infty}(D_0)} + \|\mu\|_{W^{k+1,\infty}(D_0)} \\ &\quad \leq Cd^{-N/t-k}\left(\|\mathbf{f}\|_{L^t(\Omega)} + d^{-1}\|g\|_{L^t(\Omega)}\right) + C\|g\|_{L^1(\Omega)}\|\zeta\|_{W^{k+2,\infty}(\Omega)}.\end{aligned}$$

Proof. For any $x \in D_0$, let $(\mathbf{G}_x^j, Q_x^j)$, $j = 1, \ldots, N$, and $(\mathbf{G}_x^{N+1,\beta}, Q_x^{N+1,\beta})$ be Green's tensor of the Stokes problem (2.1) (see Solonnikov [20], Ladyzhenskaya [9], Stupelis [21], Odqvist [13]) so that $\mathbf{v}$ and μ can be expressed in terms of the components of Green's tensor through the following integrals:

$$(3.3)\qquad \mathbf{v}(x) = \sum_{j=1}^{N}\int_\Omega \mathbf{G}_x^j(y)f_j(y)\,dy + \sum_{|\beta|\leq k+2}\int_\Omega \mathbf{G}_x^{N+1,\beta}(y)\partial_y^\beta \tilde{g}(y)\,dy,$$

$$(3.4)\qquad \mu(x) = \sum_{j=1}^{N}\int_\Omega Q_x^j(y)f_j(y)\,dy + \sum_{|\beta|\leq k+2}\int_\Omega Q_x^{N+1,\beta}(y)\partial_y^\beta \tilde{g}(y)\,dy.$$

Here, $\tilde{g} = g - (1, g)\zeta$, f_j are the components of $\mathbf{f}$, and $\mathbf{G}_x^j$, Q_x^j, $\mathbf{G}_x^{N+1,\beta}$, and $Q_x^{N+1,\beta}$ satisfy the inequalities

$$(3.5)\qquad \begin{aligned}&|\partial_x^{\alpha_x}\partial_y^{\alpha_y}\mathbf{G}_x^j(y)| \leq C\varphi_0(|x-y|; 2-N-|\alpha_x|-|\alpha_y|),\\ &|\partial_x^{\alpha_x}\partial_y^{\alpha_y}Q_x^j(y)| \leq C\varphi_0(|x-y|; 1-N-|\alpha_x|-|\alpha_y|),\\ &|\partial_x^{\alpha_x}\partial_y^{\alpha_y}\mathbf{G}_x^{N+1,\beta}(y)| \leq C\varphi_0(|x-y|; 2-N-|\alpha|+k+1),\\ &|\partial_x^{\alpha}\partial_y^{\beta}Q_x^{N+1,\beta}(y)| \leq C\varphi_0(|x-y|; 1-N-|\alpha|+k+1),\end{aligned}$$

where $j = 1, \ldots, N$, $|\beta| \leq k+2$, and

$$\varphi_0(|x-y|;\tau) = \begin{cases}|x-y|^\tau & \text{if} \quad \tau < 0,\\ 1 + |\ln|x-y|| & \text{if} \quad \tau = 0,\\ 1 & \text{if} \quad \tau > 0.\end{cases}$$

Differentiating (3.4), using the assumption that $\mathbf{f}$ and g vanish in D_1, and integrating by parts, we have

$$\begin{aligned}(3.6)\qquad \partial_x^\alpha\mu(x) = &\sum_{j=1}^{N}\int_{\Omega\setminus D_1}\partial_x^\alpha Q_x^j(y)f_j(y)\,dy + (1,g)\sum_{|\beta|\leq k+2}\int_\Omega \partial_x^\alpha Q_x^{N+1,\beta}(y)\partial^\beta\zeta(y)\,dy\\ &+ \sum_{|\beta|\leq k+2}(-1)^{|\beta|}\int_{\Omega\setminus D_1}\partial_y^\beta\partial_x^\alpha Q_x^{N+1,\beta}(y)g(y)\,dy.\end{aligned}$$

We shall estimate each summation in (3.6) separately. According to (3.5), we have for each j and $|\alpha| \geq 1$,

$$(3.7)\qquad \int_{\Omega\setminus D_1}\partial_x^\alpha Q_x^j(y)f_j(y)\,dy \leq C\int_{\Omega\setminus D_1}|x-y|^{1-N-|\alpha|}|f_j(y)|\,dy.$$

Let t' be the conjugate of t, i.e., $1/t'+1/t=1$. Then, by (3.7) and Hölder's inequality, there holds for $|\alpha|=k+1$

$$\begin{aligned}(3.8)\quad \int_{\Omega\setminus D_1}\partial_x^\alpha Q_x^j(y)f_j(y)\,dy &\le C\left(\int_{\Omega\setminus D_1}|x-y|^{(1-N-|\alpha|)t'}dy\right)^{1/t'}\|f_j\|_{L^t(\Omega)}\\ &\le C\left(\int_d^\infty \rho^{(1-N-|\alpha|)t'}\rho^{N-1}\,d\rho\right)^{1/t'}\|f_j\|_{L^t(\Omega)}\\ &\le Cd^{-N/t-k}\|f_j\|_{L^t(\Omega)}.\end{aligned}$$

Similarly, for the integrals in the second summation of (3.6), we have for $|\alpha|=k+1$

$$\begin{aligned}(3.9)\quad \int_{\Omega\setminus D_1}\partial_y^\beta\partial_x^\alpha Q_x^{N+1,\beta}(y)g(y)\,dy &\le C\left(\int_{\Omega\setminus D_1}|x-y|^{(-N-|\alpha|)t'}dy\right)^{1/t'}\|g\|_{L^t(\Omega)}\\ &\le Cd^{-N/t-k-1}\|g\|_{L^t(\Omega)}.\end{aligned}$$

For the third summation in (3.6), for $|\alpha|=k+1$ there holds

$$\begin{aligned}(3.10)\quad &(1,g)\sum_{|\beta|\le k+2}\int_\Omega \partial_x^\alpha Q_x^{N+1,\beta}(y)\partial^\beta\zeta(y)\,dy\\ &\le C\|g\|_{L^1(\Omega)}\int_\Omega|x-y|^{1-N}\,dy\|\zeta\|_{W^{k+2,\infty}(\Omega)}\le C\|g\|_{L^1(\Omega)}\|\zeta\|_{W^{k+2,\infty}(\Omega)}.\end{aligned}$$

Substituting (3.10), (3.9), and (3.8) into (3.6), we obtain

$$\begin{aligned}(3.11)\quad \|\mu\|_{W^{k+1,\infty}(D_0)} &\le Cd^{-N/t-k}\left(\|\mathbf{f}\|_{L^t(\Omega)}+d^{-1}\|g\|_{L^t(\Omega)}\right)\\ &\quad +C\|g\|_{L^1(\Omega)}\|\zeta\|_{W^{k+2,\infty}(\Omega)}.\end{aligned}$$

Reasoning in the same way, we can also bound $\|\mathbf{v}\|_{W^{k+2,\infty}(D_0)}$ by the right-hand side of (3.11). This completes the proof. ∎

We now turn to the error estimates for the finite element approximation of the Stokes problem in energy and L^2 norms. First of all, we state the following well-known global error estimate.

LEMMA 3.3. *Let* $(\mathbf{u},p)$ *and* $(\mathbf{u}_h,p_h)$ *satisfy* (2.4). *Then,*

$$(3.12)\quad \|\mathbf{u}-\mathbf{u}_h\|_{H^1(\Omega)}+\|p-p_h\|_{L^2(\Omega)}\le C\left(\inf_{\mathbf{v}\in\mathbf{V}^h}\|\mathbf{u}-\mathbf{v}\|_{H^1(\Omega)}+\inf_{q\in W^h}\|p-q\|_{L^2(\Omega)}\right).$$

Proof. The proof is found in Temam [22] or Girault and Raviart [7]. ∎

The results in the next lemma are error estimates of the pressure approximation in some special negative Sobolev norms. They are used for the error estimates of the finite element approximations of the auxiliary Stokes problem constructed during the proofs of our main results in other sections.

LEMMA 3.4. *Suppose* $(\mathbf{u},p)$ *and* $(\mathbf{u}_h,p_h)$ *satisfy* (2.4). *Then,*

$$(3.13)\quad \|p-p_h\|_{H^{-r}(\Omega)}\le Ch^r\left(\inf_{\mathbf{v}\in\mathbf{V}^h}\|\mathbf{u}-\mathbf{v}\|_{H^1(\Omega)}+\inf_{q\in W^h}\|p-q\|_{L^2(\Omega)}\right),$$

$$(3.14)\quad \|p-p_h\|_{H^{-r-1-[N/2]}(\Omega)}\le Ch^r\left(\|\mathbf{u}-\mathbf{u}_h\|_{W^{1,1}(\Omega)}+\|p-p_h\|_{L^1(\Omega)}\right),$$

where $[N/2]$ *denotes the maximum integer less than or equal to* $N/2$.

Proof. For any $\psi \in C_0^\infty(\Omega)$, let $(\mathbf{w}, \lambda) \in H_0^1(\Omega)^N \times L_0^2(\Omega)$ satisfy

$$-\Delta \mathbf{w} + \nabla \lambda = 0, \quad \nabla \cdot \mathbf{w} = \psi - \frac{1}{|\Omega|}(1, \psi) \quad \text{in } \Omega.$$

Then, some simple manipulations give

(3.15)
$$\begin{aligned}(p - p_h, \psi) &= \Big(p - p_h, \psi - \frac{1}{|\Omega|}(1, \psi)\Big) \;=\; b(\mathbf{w}, p - p_h) \\ &= a(\mathbf{u} - \mathbf{u}_h, \Pi^h \mathbf{w} - \mathbf{w}) - b(\Pi^h \mathbf{w} - \mathbf{w}, p - p_h) - b(\mathbf{u} - \mathbf{u}_h, Q^h \lambda - \lambda).\end{aligned}$$

By the Cauchy–Schwarz inequality and the approximation properties in A.1, we have

$$\begin{aligned}(p - p_h, \psi) &\le C \left(\|\mathbf{u} - \mathbf{u}_h\|_{H^1(\Omega)} + \|p - p_h\|_{L^2(\Omega)}\right) \\ &\quad \times \left(\|\mathbf{w} - \Pi^h \mathbf{w}\|_{H^1(\Omega)} + \|\lambda - Q^h \lambda\|_{L^2(\Omega)}\right) \\ &\le C h^r \left(\|\mathbf{u} - \mathbf{u}_h\|_{H^1(\Omega)} + \|p - p_h\|_{L^2(\Omega)}\right) \\ &\quad \times \left(\|\mathbf{w}\|_{H^{1+r}(\Omega)} + \|\lambda\|_{H^r(\Omega)}\right).\end{aligned} \tag{3.16}$$

Using (3.1) of Lemma 3.1,

$$\|\mathbf{w}\|_{H^{1+r}(\Omega)} + \|\lambda\|_{H^r(\Omega)} \le C \left\| \psi - \frac{1}{|\Omega|}(1, \psi) \right\|_{H^r(\Omega)} \le C \|\psi\|_{H^r(\Omega)}$$

and estimate (3.12) of Lemma 3.3 in inequality (3.16), we prove (3.13). To show (3.14), we use (3.15), Hölder's inequality, and the approximation properties in A.1:

$$\begin{aligned}(p - p_h, \psi) &\le C \left(\|\mathbf{u} - \mathbf{u}_h\|_{W^{1,1}(\Omega)} + \|p - p_h\|_{L^1(\Omega)}\right) \\ &\quad \times \left(\|\mathbf{w} - \Pi^h \mathbf{w}\|_{W^{1,\infty}(\Omega)} + \|\lambda - Q^h \lambda\|_{L^\infty(\Omega)}\right) \\ &\le C h^r \left(\|\mathbf{u} - \mathbf{u}_h\|_{W^{1,1}(\Omega)} + \|p - p_h\|_{L^1(\Omega)}\right) \\ &\quad \times \left(\|\mathbf{w}\|_{W^{1+r,\infty}(\Omega)} + \|\lambda\|_{W^{r,\infty}(\Omega)}\right).\end{aligned} \tag{3.17}$$

From the Sobolev embedding theorem (Adam [1]) and (3.1) of Lemma 3.1,

$$\begin{aligned}\|\mathbf{w}\|_{W^{1+r,\infty}(\Omega)} + \|\lambda\|_{W^{r,\infty}(\Omega)} &\le C \left(\|\mathbf{w}\|_{H^{2+r+[N/2]}(\Omega)} + \|\lambda\|_{H^{1+r+[N/2]}(\Omega)}\right) \\ &\le C \|\psi\|_{H^{1+r+[N/2]}(\Omega)}\end{aligned} \tag{3.18}$$

and estimate (3.17), the desired estimate (3.14) follows. This completes the proof of Lemma 3.4. ∎

For the local error estimates, the results will be stated and used for special subdomains of Ω. Without loss of generality we assume *throughout this paper* that $\operatorname{diam}(\Omega) \le 1$. Let

$$d_j = 2^{-j} \quad \text{for } j = 0, 1, 2, \ldots$$

and for any fixed $z \in \Omega$ set

$$\begin{aligned}\Omega_j &= \{x \in \Omega : \; d_{j+1} < |x - z| < d_j\}, \\ \Omega_j^{(1)} &= \{x \in \Omega : \; d_{j+2} < |x - z| < d_{j-1}\}, \\ \Omega_j^{(2)} &= \{x \in \Omega : \; d_{j+3} < |x - z| < d_{j-2}\}, \\ \Omega_j^{(3)} &= \{x \in \Omega : \; d_{j+4} < |x - z| < d_{j-3}\}.\end{aligned} \tag{3.19}$$

Assumption A.3, along with Assumption A.4, takes the following form on the subdomains Ω_j.

LEMMA 3.5. *Let* $(\mathbf{u}, p)$ *and* $(\mathbf{u}_h, p_h)$ *satisfy* (2.4). *If* $d_j \geq \kappa h$, *then*

$$\begin{aligned}(3.20)\quad &\|\mathbf{u}-\mathbf{u}_h\|_{H^1(\Omega_j)} + \|p-p_h\|_{L^2(\Omega_j)}\\ &\leq Ch^r\big(\|\mathbf{u}\|_{H^{r+1}(\Omega_j^{(1)})} + \|p\|_{H^r(\Omega_j^{(1)})}\big)\\ &\quad + Cd_j^{-N/2-1-t}\big(\|\mathbf{u}-\mathbf{u}_h\|_{W^{-t,1}(\Omega_j^{(1)})} + d_j^{1-t_1}\|p-p_h\|_{W^{-t-t_1,1}(\Omega_j^{(1)})}\big),\end{aligned}$$

where $t \geq 0$, $t_1 = 0, 1$.

Proof. Without loss of generality, we assume $z = 0$ and Ω is the unit ball centered at $z = 0$. Then,

$$\Omega_j = \{x \in R^N :\ d_{j+1} < |x| < d_j\}, \quad \Omega_j^{(1)} = \{x \in R^N :\ d_{j+2} < |x| < d_{j-1}\}.$$

Introduce a new variable $\tilde{x} = x/d_{j-1}$. The regions $\Omega_j^{(1)}$ and Ω_j are transferred into regions $\tilde{D}_1$ and $\tilde{D}_0$, respectively,

$$\tilde{D}_0 = \{\tilde{x} \in R^N :\ 1/4 < |\tilde{x}| < 1/2\}, \quad \tilde{D}_1 = \{\tilde{x} \in R^N :\ 1/8 < |\tilde{x}| < 1\}.$$

Then, $\operatorname{dist}(\tilde{D}_0, \partial\tilde{D}_1) = 1/2$. Set

$$\begin{aligned}\tilde{\mathbf{u}}(\tilde{x}) = u(\tilde{x}d_{j-1}), \quad \tilde{\mathbf{u}}_h(\tilde{x}) = \mathbf{u}(\tilde{x}d_{j-1}),\\ \tilde{p}(\tilde{x}) = p(\tilde{x}d_{j-1})d_{j-1}, \quad \tilde{p}_h(\tilde{x}) = p_h(\tilde{x}d_{j-1})d_{j-1}.\end{aligned}$$

Then,

$$\begin{aligned}(3.21)\quad (\tilde{\nabla}(\tilde{\mathbf{u}}-\tilde{\mathbf{u}}_h), \tilde{\nabla}\tilde{\mathbf{v}}) - (\tilde{\nabla}\cdot\tilde{\mathbf{v}}, \tilde{p}-\tilde{p}_h) = 0 \quad \forall\ \tilde{v} \in \tilde{V},\\ (\tilde{\nabla}\cdot(\tilde{\mathbf{u}}-\tilde{\mathbf{u}}_h), \tilde{q}) = 0 \quad \forall\ \tilde{q} \in \tilde{W},\end{aligned}$$

where $\tilde{\mathbf{V}}$ and $\tilde{W}$ are the transferred spaces of $\mathbf{V}^h$ and W^h. We have

$$\begin{aligned}(3.22)\quad &\|\mathbf{u}-\mathbf{u}_h\|_{H^1(\Omega_j)} + \|p-p_h\|_{L^2(\Omega_j)}\\ &\leq d_j^{N/2-1}\big(\|\tilde{\mathbf{u}}-\tilde{\mathbf{u}}_h\|_{H^1(\tilde{D}_0)} + \|\tilde{p}-\tilde{p}_h\|_{L^2(\tilde{D}_0)}\big).\end{aligned}$$

Using Assumption A.3 on problem (3.21), we have for $t \geq 0$ and $t_1 = 0$ or 1,

$$\begin{aligned}(3.23)\quad &\|\tilde{\mathbf{u}}-\tilde{\mathbf{u}}_h\|_{H^1(\tilde{D}_0)} + \|\tilde{p}-\tilde{p}_h\|_{L^2(\tilde{D}_0)}\\ &\leq C(h/d_j)^r\big(|\tilde{\mathbf{u}}|_{H^{r+1}(\tilde{D}_1)} + |\tilde{p}|_{H^r(\tilde{D}_1)}\big)\\ &\quad + C\big(\|\tilde{\mathbf{u}}-\tilde{\mathbf{u}}_h\|_{W^{-t,1}(\tilde{D}_1)} + \|\tilde{p}-\tilde{p}_h\|_{W^{-t-t_1,1}(\tilde{D}_1)}\big).\end{aligned}$$

Noting that

$$|\tilde{\mathbf{u}}|_{H^{1+r}(\tilde{D}_1)} + |\tilde{p}|_{H^r(\tilde{D}_1)} \leq Cd_j^{-N/2+1+r}\big(|\mathbf{u}|_{H^{1+r}(\Omega_j^{(1)})} + |p|_{H^r(\Omega_j^{(1)})}\big)$$

and

$$\begin{aligned}&\|\tilde{\mathbf{u}}-\tilde{\mathbf{u}}_h\|_{W^{-t,1}(\tilde{D}_1)} + \|\tilde{p}-\tilde{p}_h\|_{W^{-t-t_1,1}(\tilde{D}_1)}\\ &\quad \leq Cd_j^{-N-t}\big(\|\mathbf{u}-\mathbf{u}_h\|_{W^{-t,1}(\Omega_j^{(1)})} + d_j^{1-t_1}\|p-p_h\|_{W^{-t-t_1,1}(\Omega_j^{(1)})}\big),\end{aligned}$$

and using (3.22) and (3.23), we complete the proof. ∎

LEMMA 3.6. *For $\rho \in L^\infty(\Omega)$, let $(\Phi, \lambda) \in H_0^1(\Omega)^N \times L_0^2(\Omega)$ be the solution of*

$$-\Delta\Phi + \nabla\lambda = \rho, \quad \nabla \cdot \Phi = 0,$$

and let $(\Phi_h, \lambda_h) \in \mathbf{V}^h \times W^h$ be the finite element approximation of (Φ, λ). If $\mathrm{supp}(\rho) \subset B_{2\kappa h}(z)$ and $\|\rho\|_{L^2(B_{2\kappa h}(z))} \le Ch^{-N/2}$, then

$$\|\Phi - \Phi_h\|_{H^1(B_{Mh}(z))} + \|\lambda - \lambda_h\|_{L^2(B_{Mh}(z))} \le Ch^{1-N/2}, \tag{3.24}$$

and for $j = 0, 1, \ldots, J$, $t_1 = 0$ or 1,

$$\begin{aligned} &\|\Phi - \Phi_h\|_{H^1(\Omega_j)} + \|\lambda - \lambda_h\|_{L^2(\Omega_j)} \\ &\quad \le Cd_j^{-N/2-1}\big(\|\Phi - \Phi_h\|_{L^1(\Omega_j^{(1)})} + d_j^{1-t_1}\|\lambda - \lambda_h\|_{W^{-t_1,1}(\Omega_j^{(1)})}\big) \\ &\qquad + Ch^r d_j^{-N/2+1-r}. \end{aligned} \tag{3.25}$$

Proof. Using Lemmas 3.3 and 3.1, we obtain

$$\begin{aligned} &\|\Phi - \Phi_h\|_{H^1(B_{Mh}(z))} + \|\lambda - \lambda_h\|_{L^2(B_{Mh}(z))} \\ &\quad \le Ch\left(\|\Phi\|_{H^2(\Omega)} + \|\lambda\|_{H^1(\Omega)}\right) \ \le \ Ch\|\rho\|_{L^2(B_{2\kappa h}(z))}, \end{aligned}$$

which implies (3.24) according to the assumption on ρ. To prove (3.25), we use Lemma 3.5 to get

$$\begin{aligned} &\|\Phi - \Phi_h\|_{H^1(\Omega_j)} + \|\lambda - \lambda_h\|_{L^2(\Omega_j)} \\ &\quad \le Ch^r\left(\|\Phi\|_{H^{r+1}(\Omega_j^{(1)})} + \|\lambda\|_{H^r(\Omega_j^{(1)})}\right) \\ &\qquad + Cd_j^{-N/2-1}\left(\|\Phi - \Phi_h\|_{L^1(\Omega_j^{(1)})} + d_j^{1-t_1}\|\lambda - \lambda_h\|_{W^{-t_1,1}(\Omega_j^{(1)})}\right). \end{aligned} \tag{3.26}$$

In view of Lemma 3.2 and the assumption on ρ, it follows that

$$\begin{aligned} &\|\Phi\|_{h^{r+1}(\Omega_j^{(1)})} + \|\lambda\|_{H^r(\Omega_j^{(1)})} \le Cd_j^{N/2}\left(\|\Phi\|_{W^{r+1,\infty}(\Omega_j^{(1)})} + \|\lambda\|_{W^{r,\infty}(\Omega_j^{(1)})}\right) \\ &\quad \le Cd_j^{-N/2+1-r}\|\rho\|_{L^1(B_{2\kappa h}(z))} \le Cd_j^{-N/2+1-r}h^{N/2}\|\rho\|_{L^2(B_{2\kappa h}(z))} \\ &\quad \le Cd_j^{-N/2+1-r}. \end{aligned}$$

Substituting this into (3.26) implies (3.25). Therefore, the proof is complete. ∎

LEMMA 3.7. *Let $(\Phi, \lambda) \in H_0^1(\Omega)^N \times L_0^2(\Omega)$ be the solution of*

$$-\Delta\Phi + \nabla\lambda = 0, \quad \nabla \cdot \Phi = g - (1, g)\zeta,$$

and let $(\Phi_h, \lambda_h) \in \mathbf{V}^h \times W^h$ be the finite element approximation of (Φ, λ), where $\zeta \in C_0^\infty(\Omega)$ is a fixed function satisfying $(1, \zeta) = 1$, and

$$g \in C_0^\infty(B_{2\kappa h}(z)) \quad \text{and} \quad \|g\|_{L^2(B_{2\kappa h}(z))} \le Ch^{-N/2}.$$

Then

$$\|\Phi - \Phi_h\|_{H^1(B_{Mh}(z))} + \|\lambda - \lambda_h\|_{L^2(B_{Mh}(z))} \le Ch^{-N/2}, \tag{3.27}$$

and for $j = 0, 1, \ldots, J$, $t \geq 0$, *and* $t_1 = 0$ *or* 1,

$$\begin{aligned}(3.28)\quad &\|\Phi - \Phi_h\|_{H^1(\Omega_j)} + \|\lambda - \lambda_h\|_{L^2(\Omega_j)} \\ &\leq Cd_j^{-N/2-1-t}\left(\|\Phi - \Phi_h\|_{W^{-t,1}(\Omega_j^{(1)})} + d_j^{1-t_1}\|\lambda - \lambda_h\|_{W^{-t_1-t,1}(\Omega_j^{(1)})}\right) \\ &\quad + Ch^r d_j^{-N/2-r}.\end{aligned}$$

Proof. The proof is analogous to that of Lemma 3.6. In view of Lemmas 3.3 and 3.1, it follows that

$$\begin{aligned}&\|\Phi - \Phi_h\|_{H^1(B_{Mh}(z))} + \|\lambda - \lambda_h\|_{L^2(B_{Mh}(z))} \\ &\quad \leq C\left(\|\Phi\|_{H^1(\Omega)} + \|\lambda\|_{L^2(\Omega)}\right) \leq C\|g - (1,g)\zeta\|_{L^2(B_{2\kappa h}(z))} \\ &\quad \leq C\|g\|_{L^2(B_{2\kappa h}(z))} \leq Ch^{-N/2},\end{aligned}$$

which proves (3.27). To prove (3.28), we use Lemma 3.5,

$$\begin{aligned}(3.29)\quad &\|\Phi - \Phi_h\|_{H^1(\Omega_j)} + \|\lambda - \lambda_h\|_{L^2(\Omega_j)} \\ &\leq Ch^r\left(\|\Phi\|_{H^{r+1}(\Omega_j^{(1)})} + \|\lambda\|_{H^r(\Omega_j^{(1)})}\right) \\ &\quad + Cd_j^{-N/2-1-t}\left(\|\Phi - \Phi_h\|_{W^{-t,1}(\Omega_j^{(1)})} + d_j^{1-t_1}\|\lambda - \lambda_h\|_{W^{-t_1-t,1}(\Omega_j^{(1)})}\right).\end{aligned}$$

By Lemma 3.2 and the assumption on g, it follows that

$$\begin{aligned}&\|\Phi\|_{H^{r+1}(\Omega_j^{(1)})} + \|\lambda\|_{H^r(\Omega_j^{(1)})} \leq Cd_j^{N/2}\left(\|\Phi\|_{W^{r+1,\infty}(\Omega_j^{(1)})} + \|\lambda\|_{W^{r,\infty}(\Omega_j^{(1)})}\right) \\ &\quad \leq Cd_j^{-N/2+1-r}d_j^{-1}\|g - (1,g)\zeta\|_{L^1(B_{2\kappa h}(z))} \leq Cd_j^{-N/2-r}h^{N/2}\|g\|_{L^2(B_{2\kappa h}(z))} \\ &\quad \leq Cd_j^{-N/2-r}.\end{aligned}$$

Substituting this into (3.29), we obtain (3.28) and thus complete the proof. ∎

Now, we have the last lemma of this section.

LEMMA 3.8. *Assume that* $\varphi \in C_0^\infty(\Omega_j^{(1)})^N$, $\psi \in C_0^\infty(\Omega_j^{(1)})$ *satisfying*

$$\|\varphi\|_{L^\infty(\Omega_j^{(1)})} \leq 1, \quad \|\psi\|_{W^{1,\infty}(\Omega_j^{(1)})} \leq 1,$$

and $(\mathbf{v}, \mu) \in H_0^1(\Omega)^N \times L_0^2(\Omega)$ *is the solution of the problem*

$$-\Delta\mathbf{v} + \nabla\mu = \varphi, \quad \nabla\cdot\mathbf{v} = \psi - (1,\psi)\zeta,$$

where $\zeta \in C_0^\infty(\Omega)$ *is a function such that* $(1,\zeta) = 1$. *Then, for any* $\mathbf{e}_1 \in H_0^1(\Omega)$ *and* $e_2 \in L_0^2(\Omega)$, *there holds*

$$\begin{aligned}(3.30)\quad &\left|a(\mathbf{e}_1, \mathbf{v} - \Pi^h\mathbf{v}) - b(\mathbf{v} - \Pi^h\mathbf{v}, e_2) - b(\mathbf{e}_1, \mu - Q^h\mu)\right| \\ &\quad \leq Ch^r d_j^{1-r}\left(\|\mathbf{e}_1\|_{W^{1,1}(\Omega)} + \|e_2\|_{L^1(\Omega)}\right) \\ &\qquad + Chd_j^{N/2}\left(\|\mathbf{e}_1\|_{H^1(\Omega_j^{(2)})} + \|e_2\|_{L^2(\Omega_j^{(2)})}\right).\end{aligned}$$

Proof. Let us start with the following decomposition:

$$(3.31)\qquad a(\mathbf{e}_1, \mathbf{v} - \Pi^h\mathbf{v}) - b(\mathbf{v} - \Pi^h\mathbf{v}, e_2) - b(\mathbf{e}_1, \mu - Q^h\mu) = I_1 + I_2,$$

where

$$I_1 = a_{\Omega\setminus\Omega_j^{(2)}}(\mathbf{e}_1, \mathbf{v}-\Pi^h\mathbf{v}) - b_{\Omega\setminus\Omega_j^{(2)}}(\mathbf{v}-\Pi^h\mathbf{v}, e_2) - b_{\Omega\setminus\Omega_j^{(2)}}(\mathbf{e}_1, \mu - Q^h\mu),$$
$$I_2 = a_{\Omega_j^{(2)}}(\mathbf{e}_1, \mathbf{v}-\Pi^h\mathbf{v}) - b_{\Omega_j^{(2)}}(\mathbf{v}-\Pi^h\mathbf{v}, e_2) - b_{\Omega_j^{(2)}}(\mathbf{e}_1, \mu - Q^h\mu).$$

Here, $a_D(\cdot,\cdot)$ and $b_D(\cdot,\cdot)$ stand for the respective bilinear forms $a(\cdot,\cdot)$ and $b(\cdot,\cdot)$ in which the integrals are computed on the subdomain D. By the Cauchy–Schwarz inequality and the approximation assumption A.1, it follows that

$$\begin{aligned} I_1 &\le C\left(\|\mathbf{e}_1\|_{W^{1,1}(\Omega\setminus\Omega_j^{(2)})} + \|e_2\|_{L^1(\Omega\setminus\Omega_j^{(2)})}\right) \\ &\quad \times C\left(\|\mathbf{v}-\Pi^h\mathbf{v}\|_{W^{1,\infty}(\Omega\setminus\Omega_j^{(2)})} + \|\mu - Q^h\mu\|_{L^\infty(\Omega\setminus\Omega_j^{(2)})}\right) \\ &\le C\left(\|\mathbf{e}_1\|_{W^{1,1}(\Omega\setminus\Omega_j^{(2)})} + \|e_2\|_{L^1(\Omega\setminus\Omega_j^{(2)})}\right) \\ &\quad \times Ch^r\left(\|\mathbf{v}\|_{W^{1+r,\infty}(\Omega\setminus\Omega_j^{(1)})} + \|\mu\|_{W^{r,\infty}(\Omega\setminus\Omega_j^{(1)})}\right). \end{aligned}$$

This, along with Lemma 3.2 and the assumption on φ and ψ, yields

$$\begin{aligned} I_1 &\le Ch^r d_j^{1-r}\left(\|\mathbf{e}_1\|_{W^{1,1}(\Omega\setminus\Omega_j^{(2)})} + \|e_2\|_{L^1(\Omega\setminus\Omega_j^{(2)})}\right) \\ &\quad \times \left(\|\varphi\|_{L^\infty(\Omega_j^{(1)})} + d_j^{-1}\|\psi\|_{L^\infty(\Omega_j^{(1)})}\right) \\ &\le Ch^r d_j^{1-r}\left(\|\mathbf{e}_1\|_{W^{1,1}(\Omega)} + \|e_2\|_{L^1(\Omega)}\right). \end{aligned} \tag{3.32}$$

Here, we have used the fact that ψ vanishes on $\partial\Omega_j^{(1)}$ and, therefore, the following estimate holds:

$$\|\psi\|_{L^\infty(\Omega_j^{(1)})} \le Cd_j\|\psi\|_{W^{1,\infty}(\Omega_j^{(1)})} \le Cd_j. \tag{3.33}$$

According to the Cauchy–Schwarz inequality and A.1, I_2 is estimated as follows:

$$\begin{aligned} I_2 &\le C\left(\|\mathbf{e}_1\|_{H^1(\Omega_j^{(2)})} + \|e_2\|_{L^2(\Omega_j^{(2)})}\right) \\ &\quad \times C\left(\|\mathbf{v}-\Pi^h\mathbf{v}\|_{H^1(\Omega_j^{(2)})} + \|\mu - Q^h\mu\|_{L^2(\Omega_j^{(2)})}\right) \\ &\le C\left(\|\mathbf{e}_1\|_{H^1(\Omega_j^{(2)})} + \|e_2\|_{L^2(\Omega_j^{(2)})}\right) \\ &\quad \times Ch\left(\|\mathbf{v}\|_{H^2(\Omega_j^{(3)})} + \|\mu\|_{H^1(\Omega_j^{(3)})}\right). \end{aligned}$$

Using Lemma 3.1,

$$\begin{aligned} I_2 &\le Ch\left(\|\mathbf{e}_1\|_{H^1(\Omega_j^{(2)})} + \|e_2\|_{L^2(\Omega_j^{(2)})}\right)\left(\|\varphi\|_{L^2(\Omega_j^{(1)})} + \|\psi\|_{H^1(\Omega_j^{(1)})}\right) \\ &\le Chd_j^{N/2}\left(\|\mathbf{e}_1\|_{H^1(\Omega_j^{(2)})} + \|e_2\|_{L^2(\Omega_j^{(2)})}\right). \end{aligned} \tag{3.34}$$

Using (3.32) and (3.34) in (3.31), we conclude (3.30). The proof is complete. ∎

4. Pressure error. In this section we derive the pointwise error estimates for the pressure approximation. The main result of this section is in Theorem 4.2. For our purpose, throughout this section, we denote by δ a fixed nonnegative function which satisfies $\delta \in C_0^\infty(B_1(0)$ and $\int_{R^N} \delta(x)\,dx = 1$. We shall construct a *regularized delta function* $\delta_{z,h}$, following an approach suggested by Durán, Nochetto, and Wang [6].

LEMMA 4.1. *There exists a $\tau \in (0, \tau_0)$ such that for any $q \in W^h$ and $z \in \bar{\Omega}$, there holds the following inequality:*

$$|q(z)| \le 2\,|(\delta_{z,h}, q)|\,,$$

where

$$\delta z,_h = (\tau h)^{-N}\delta\left(\frac{x-\bar{z}}{\tau h}\right) \quad \textit{and} \quad |z-\bar{z}| \le Ch.$$

Proof. For any $q \in W^h$ and $z \in \bar{\Omega}$, we have $z \in \bar{K}_j$ for some $1 \le j \le N_h$ and $y \in \bar{K}_j$ such that $\|q\|_{L^\infty(K_j)} = |q(y)|$. For any $\tau \in (0, \tau_0)$, according to A.0, choose $\bar{z} \in K_j$ so that $B_{\tau h}(\bar{z}) \subset K_j$ and $|y - \bar{z}| < C_0\tau h$. Set $\delta_{z,h} = (\tau h)^{-N}\delta(\frac{x-\bar{z}}{\tau h})$. By the mean value theorem of calculus, there is a $\bar{y} \in B_{\tau h}(\bar{z})$ such that

$$(q, \delta_{z,h}) = \int_{B_{\tau h}(\bar{z})} q\delta_{z,h}\,dx = q(\bar{y}).$$

Using the triangular inequality and the inverse properties in A.2, it follows that

$$\begin{aligned} \|q\|_{L^\infty(K_j)} = |q(y)| \;&\le\; |q(\bar{y})| + |q(y) - q(\bar{y})| \\ &\le |q(\bar{y})| + 2C_0\tau h\|\nabla q\|_{L^\infty(K_j)} \\ &\le |(q, \delta_{z,h})| + C_1\tau\|q\|_{L^\infty(K_j)}. \end{aligned} \tag{4.1}$$

The constant C_1 in (4.1) depends only on C_0 and the inverse properties. Choosing any $\tau \le \tau_1 = \frac{1}{2C_1}$, we obtain

$$\|q\|_{L^\infty(K_j)} \le 2|(q, \delta_{z,h})|.$$

In view of $|q(z)| \le \|q\|_{L^\infty(K_j)}$, we complete the proof. ∎

The main result of this section is the following pointwise error estimate for the pressure approximation.

THEOREM 4.2. *Suppose $(\mathbf{u}, p)$ and $(\mathbf{u}_h, p_h)$ satisfy (2.4). Let $z \in \bar{\Omega}$. Then there exists a constant $C > 0$ independent of $z, \mathbf{u}, p, h$ such that for $0 \le s \le r$ there holds*

$$|(p - p_h)(z)| \le C\left(\ln\frac{1}{h}\right)^{\bar{s}}\left(\inf_{\mathbf{v}\in\mathbf{V}^h}\|\mathbf{u}-\mathbf{v}\|_{W^{1,\infty}(\Omega),z,s} + \inf_{q\in W^h}\|p-q\|_{L^\infty(\Omega),z,s}\right), \tag{4.2}$$

where $\bar{s} = 0$ if $0 \le s < r$ and $\bar{s} = 1$ if $s = r$.

Proof. Let us start with a triangular inequality: for any $q_h \in W^h$,

$$|(p - p_h)(z)| \le |(p - q_h)(z)| + |(q_h - p_h)(z)|. \tag{4.3}$$

Obviously, the first term in (4.3) is bounded by $\|p - q_h\|_{L^\infty(\Omega),z,s}$. For the second term of (4.3), we shall use the result of Lemma 4.1. In fact, according to Lemma 4.1, there exists a $\tau \in (0, \tau_0)$ such that

$$(q_h - p_h)(z) \le 2|(q_h - p_h, \delta_{z,h})|,$$

where

$$\delta_{z,h}(x) = (\tau h)^{-N}\delta((x-\bar{z})/(\tau h)) \quad \text{for some } |z-\bar{z}| \le C_0\tau h. \tag{4.4}$$

Note that $\|\delta_{z,h}\|_{L^1(B_{\tau h}(\bar{z})),z,-s} \le C$ and $(p-q_h,\delta_{z,h}) \le C\|p-q_h\|_{L^\infty(\Omega),z,s}$. From (4.3), it follows that

$$|(p-p_h)(z)| \le C\|p-q_h\|_{L^\infty(\Omega),z,s} + 2|(p-p_h,\delta_{z,h})|. \tag{4.5}$$

Choose a function $\zeta \in C_0^\infty(\Omega)$ satisfying $(1,\zeta)=1$. Then, $\tilde{\delta}_{z,h} \equiv \delta_{z,h} - \zeta \in L_0^2(\Omega) \cap C_0^\infty(\Omega)$ and

$$|(p-p_h,\delta_{z,h})| \le |(p-p_h,\tilde{\delta}_{z,h})| + |(p-p_h,\zeta)|. \tag{4.6}$$

The second term in (4.6) can be estimated by the negative norm of $p-p_h$:

$$\begin{aligned} |(p-p_h,\zeta)| \;&\le\; \|p-p_h\|_{H^{-r}(\Omega)}\|\zeta\|_{H^r(\Omega)} \\ &\le Ch^r\left(\inf_{\mathbf{v}\in\mathbf{V}^h}\|\mathbf{u}-\mathbf{v}\|_{H^1(\Omega)} + \inf_{q\in W^h}\|p-q\|_{L^2(\Omega)}\right) \\ &\le C\left(\inf_{\mathbf{v}\in\mathbf{V}^h}\|\mathbf{u}-\mathbf{v}\|_{W^{1,\infty}(\Omega),z,s} + \inf_{q\in W^h}\|p-q\|_{L^\infty(\Omega),z,s}\right), \end{aligned} \tag{4.7}$$

where $0 \le s \le r$. We shall employ a duality argument in order to estimate the first term in (4.6). Let $(\Phi_z^{(1)},\lambda_z^{(1)}) \in H_0^1(\Omega)^N \times L_0^2(\Omega)$ denote the unique solution of the Stokes problem

$$\begin{aligned} a(\mathbf{v},\Phi_z^{(1)}) - b(\mathbf{v},\lambda_z^{(1)}) &= 0 \quad \forall\, \mathbf{v}\in H_0^1(\Omega)^N, \\ b(\Phi_z^{(1)},q) &= (\tilde{\delta}_{z,h},q) \quad \forall\, q\in L_0^2(\Omega), \end{aligned} \tag{4.8}$$

and let $(\Phi_{z,h}^{(1)},\lambda_{z,h}^{(1)}) \in \mathbf{V}^h \times W^h$ be the corresponding finite element approximation of $(\Phi_z^{(1)},\lambda_z^{(1)})$. Namely, the following error equations are satisfied:

$$\begin{aligned} a(\mathbf{v},\Phi_z^{(1)}-\Phi_{z,h}^{(1)}) - b(\mathbf{v},\lambda_z^{(1)}-\lambda_{z,h}^{(1)}) &= 0 \quad \forall\, \mathbf{v}\in\mathbf{V}^h, \\ b(\Phi_z^{(1)}-\Phi_{z,h}^{(1)},q) &= 0 \quad \forall\, q\in W^h. \end{aligned} \tag{4.9}$$

By using (4.8), (4.9), and (2.4), the first term of (4.6) is represented in terms of the errors $\Phi_{z,h}^{(1)}-\Phi_z^{(1)}$ and $\lambda_z^{(1)}-\lambda_{z,h}^{(1)}$ as follows:

$$\begin{aligned} &(p-p_h,\tilde{\delta}_{z,h}) = b(\Phi_z^{(1)},p-p_h) \\ &= a(\mathbf{u}-\mathbf{v},\Phi_{z,h}^{(1)}-\Phi_z^{(1)}) - b(\mathbf{u}-\mathbf{v},\lambda_{z,h}^{(1)}-\lambda_z^{(1)}) - b(\Phi_{z,h}^{(1)}-\Phi_z^{(1)},p-q), \end{aligned}$$

where $\mathbf{v}\in\mathbf{V}^h$ and $q\in W^h$ are arbitrary functions. Hence, by Hölder's inequality, we have

$$\begin{aligned} |(p-p_h,\tilde{\delta}_{z,h})| \le C\Big(&\|\Phi_z^{(1)}-\Phi_{z,h}^{(1)}\|_{W^{1,1}(\Omega),z,-s} + \|\lambda_z^{(1)}-\lambda_{z,h}^{(1)}\|_{L^1(\Omega),z,-s}\Big) \\ &\times \left(\|\mathbf{u}-\mathbf{v}\|_{W^{1,\infty}(\Omega),z,s} + \|p-q\|_{L^\infty(\Omega),z,s}\right), \end{aligned}$$

which together with (4.7), (4.6), (4.5), and the result of Lemma 4.3 proves (4.2). The proof of Theorem 4.2 is complete. □

Next, we show the estimates for $\Phi_z^{(1)} - \Phi_{z,h}^{(1)}$ and $\lambda_z^{(1)} - \lambda_{z,h}^{(1)}$ in the weighted $W^{1,1}(\Omega)$ and $L^1(\Omega)$ norms, which have been used in the proof of Theorem 4.2.

LEMMA 4.3. *Let* $(\Phi_z^{(1)}, \lambda_z^{(1)})$ *and* $(\Phi_{z,h}^{(1)}, \lambda_{z,h}^{(1)})$ *satisfy* (4.8) *and* (4.9). *Then, there is a constant* $C > 0$ *such that for* $0 \le s \le r$,

$$\|\Phi_z^{(1)} - \Phi_{z,h}^{(1)}\|_{W^{1,1}(\Omega),z,-s} + \|\lambda_z^{(1)} - \lambda_{z,h}^{(1)}\|_{L^1(\Omega),z,-s} \le C\left(\ln\frac{1}{h}\right)^{\bar{s}}, \tag{4.10}$$

where $\bar{s} = 0$ *if* $0 \le s < r$ *and* $\bar{s} = 1$ *if* $s = r$.

Proof. Let $M > 1$ be a real number large enough so that the ball $B_{Mh}(z)$ contains the support of function $\delta_{z,h}$ defined by (4.4). M will be further determined later in this proof. Let J be an integer such that $Mh = 2^{-J}$. Then, $J \le C\ln(1/h)$. Set $\mathbf{e}_1^{(1)} = \Phi_z^{(1)} - \Phi_{z,h}^{(1)}$ and $e_2^{(1)} = \lambda_z^{(1)} - \lambda_{z,h}^{(1)}$. Then, in view of $\Omega = B_{Mh}(z)\bigcup(\bigcup_{j=0}^J \Omega_j)$ and Hölder's inequality, it follows that

$$\begin{aligned}
&\|\mathbf{e}_1^{(1)}\|_{W^{1,1}(\Omega),z,-s} + \|e_2^{(1)}\|_{L^1(\Omega),z,-s} \\
&\quad \le CM^{N/2+s}h^{N/2}(\|\mathbf{e}_1^{(1)}\|_{H^1(B_{Mh}(z))} + \|e_2^{(1)}\|_{L^2(B_{Mh}(z))}) \\
&\qquad + C\sum_{j=0}^J d_j^{s+N/2}h^{-s}(\|\mathbf{e}_1^{(1)}\|_{H^1(\Omega_j)} + \|e_2^{(1)}\|_{L^2(\Omega_j)}).
\end{aligned} \tag{4.11}$$

By applying (3.27) and (3.28) in Lemma 3.7 with $t = 0$, $t_1 = 1$, $g = \delta_{z,h}$, it follows from inequality (4.11) that

$$\begin{aligned}
\|\mathbf{e}_1^{(1)}\|_{W^{1,1}(\Omega),z,-s} + \|e_2^{(1)}\|_{L^1(\Omega),z,-s} &\le CM^{N/2+s} + C\sum_{j=0}^J (h/d_j)^{r-s} \\
&\quad + C\sum_{j=0}^J d_j^{s-1}h^{-s}\left(\|\mathbf{e}_1^{(1)}\|_{L^1(\Omega_j^{(1)})} + \|e_2^{(1)}\|_{W^{-1,1}(\Omega_j^{(1)})}\right) \\
&\le CM^{N/2+s} + C\Theta(r-s) + L_1 + L_2,
\end{aligned} \tag{4.12}$$

where Θ, L_1, and L_2 are defined, respectively, by

$$\Theta(\gamma) = \sum_{j=0}^J (h/d_j)^\gamma,$$

$$L_1 = Ch^{-1}\|\mathbf{e}_1^{(1)}\|_{L^1(\Omega),z,1-s}, \quad L_2 = \sum_{j=0}^J d_j^{s-1}h^{-s}\|e_2^{(1)}\|_{W^{-1,1}(\Omega_j^{(1)})}.$$

We note that since $d_j = 2^{-j}$ and $J \le C\ln\frac{1}{h}$, there holds

$$\Theta(\gamma) = \sum_{j=1}^J \left(\frac{h}{d_j}\right)^\gamma \le \begin{cases} \ln\frac{1}{h} & \text{if } \gamma = 0, \\ \dfrac{1}{M^\gamma(1-2^{-\gamma})} & \text{if } \gamma > 0. \end{cases} \tag{4.13}$$

As one can see, the first two terms in (4.12) are already bounded by $C(\ln 1/h)^{\bar{s}}$. It suffices to estimate $L_1 + L_2$. To this end, we observe that

$$L_1 + L_2 \le CM^{N/2+s} + C\sum_{j=0}^J d_j^{s-1}h^{-s}\left(\|\mathbf{e}_1^{(1)}\|_{L^1(\Omega_j^{(1)})} + \|e_2^{(1)}\|_{W^{-1,1}(\Omega_j^{(1)})}\right), \tag{4.14}$$

which is obtained through the same procedure as is (4.11). We shall estimate the norms $\|\mathbf{e}_1^{(1)}\|_{L^1(\Omega_j^{(1)})}$ and $\|e_2^{(1)}\|_{W^{-1,1}(\Omega_j^{(1)})}$ in the summation of (4.14). Recall the definitions of norms in $L^1(\Omega_j^{(1)})$ and $W^{-1,1}(\Omega_j^{(1)})$,

$$\|\mathbf{e}_1^{(1)}\|_{L^1(\Omega_j^{(1)})} = \sup_{\substack{\varphi\in C_0^\infty(\Omega_j^{(1)})^N \\ \|\varphi\|_{L^\infty(\Omega_j^{(1)})}=1}} (\mathbf{e}_1^{(1)}, \varphi) \tag{4.15}$$

and

$$\|e_2^{(1)}\|_{W^{-1,1}(\Omega_j^{(1)})} = \sup_{\substack{\psi\in C_0^\infty(\Omega_j^{(1)}) \\ \|\psi\|_{W^{1,\infty}(\Omega_j^{(1)})}=1}} (e_2^{(1)}, \psi). \tag{4.16}$$

To estimate $\|\mathbf{e}_1^{(1)}\|_{L^1(\Omega_j^{(1)})}$, for any $\varphi \in C_0^\infty(\Omega_j^{(1)})^N$ satisfying $\|\varphi\|_{L^\infty(\Omega)} = 1$, let $\mathbf{w}_1 \in H_0^1(\Omega)^N$ and $\lambda_1 \in L_0^2(\Omega)$ be the solution of

$$-\Delta \mathbf{w}_1 + \nabla \lambda_1 = \varphi, \quad \nabla \cdot \mathbf{w}_1 = 0 \quad \text{in } \Omega. \tag{4.17}$$

Then, some simple computations yield

$$\begin{aligned}(\mathbf{e}_1^{(1)}, \varphi) &= a(\mathbf{e}_1^{(1)}, \mathbf{w}_1) - b(\mathbf{e}_1^{(1)}, \lambda_1) \\ &= a(\mathbf{e}_1^{(1)}, \mathbf{w}_1 - \Pi^h \mathbf{w}_1) - b(\mathbf{w}_1 - \Pi^h \mathbf{w}_1, e_2^{(1)}) - b(\mathbf{e}_1^{(1)}, \lambda_1 - Q^h \lambda_1).\end{aligned} \tag{4.18}$$

Using Lemma 3.8 for the right-hand side of (4.18), we have

$$\begin{aligned}(\mathbf{e}_1^{(1)}, \varphi) \le Ch^r d_j^{1-r} &\left(\|\mathbf{e}_1^{(1)}\|_{W^{1,1}(\Omega)} + \|e_2^{(1)}\|_{L^1(\Omega)} \right) \\ &+ Chd_j^{N/2} \left(\|\mathbf{e}_1^{(1)}\|_{H^1(\Omega_j^{(2)})} + \|e_2^{(1)}\|_{L^2(\Omega_j^{(2)})} \right).\end{aligned} \tag{4.19}$$

On the other hand, for each $\psi \in C_0^\infty(\Omega_j^{(1)})$ with unit norm $\|\psi\|_{W^{1,\infty}(\Omega)} = 1$, let $(\mathbf{w}_2, \lambda_2) \in H_0^1(\Omega)^N \times L_0^2(\Omega)$ denote the unique solution of the following auxiliary Stokes problem:

$$-\Delta \mathbf{w}_2 + \nabla \lambda_2 = 0, \quad \nabla \cdot \mathbf{w}_2 = \psi - (1, \psi)\zeta \quad \text{in } \Omega.$$

Here, $\zeta \in C_0^\infty(\Omega)$ is a fixed function satisfying $(1, \zeta) = 1$. Then, some straightforward manipulations yield

$$\begin{aligned}(e_2^{(1)}, \psi) &= (e_2^{(1)}, \psi - (1, \psi)\zeta) + (1, \psi)(e_2^{(1)}, \zeta) \\ &= b(\mathbf{w}_2, e_2^{(1)}) + (1, \psi)(e_2^{(1)}, \zeta) \\ &= a(\mathbf{e}_1^{(1)}, \Pi^h \mathbf{w}_2 - \mathbf{w}_2) + b(\mathbf{w}_2 - \Pi^h \mathbf{w}_2, e_2^{(1)}) + b(\mathbf{e}_1^{(1)}, \lambda_2 - Q^h \lambda_2) \\ &\quad + (1, \psi)(e_2^{(1)}, \zeta).\end{aligned}$$

Applying (3.14) of Lemma 3.4,

$$\left\|e_2^{(1)}\right\|_{H^{-1-r-[N/2]}(\Omega)} \le Ch^r \left(\|\mathbf{e}_1^{(1)}\|_{W^{1,1}(\Omega)} + \|e_2^{(1)}\|_{L^1(\Omega)} \right),$$

and Lemma 3.8, we obtain

$$
\begin{aligned}
(e_2^{(1)},\psi) &\le Ch^r d_j^{1-r}\left(\|\mathbf{e}_1^{(1)}\|_{W^{1,1}(\Omega)}+\|e_2^{(1)}\|_{L^1(\Omega)}\right)\\
&\quad + Chd_j^{N/2}\left(\|\mathbf{e}_1^{(1)}\|_{H^1(\Omega_j^{(2)})}+\|e_2^{(1)}\|_{L^2(\Omega_j^{(2)})}\right)\\
&\quad + C\|e_2^{(1)}\|_{H^{-1-r-[N/2]}(\Omega)}\|\zeta\|_{H^{1+r+[N/2]}(\Omega)}\\
&\le Ch^r d_j^{1-r}\left(\|\mathbf{e}_1^{(1)}\|_{W^{1,1}(\Omega)}+\|e_2^{(1)}\|_{L^1(\Omega)}\right)\\
&\quad + Chd_j^{N/2}\left(\|\mathbf{e}_1^{(1)}\|_{H^1(\Omega_j^{(2)})}+\|e_2^{(1)}\|_{L^2(\Omega_j^{(2)})}\right).
\end{aligned}
\tag{4.20}
$$

For the second terms of (4.19) and (4.20), we apply (3.28) of Lemma 3.7 with $t_1=0$, $t=0$ and obtain

$$
\begin{aligned}
&\|\mathbf{e}_1^{(1)}\|_{H^1(\Omega_j^{(2)})}+\|e_2^{(1)}\|_{L^2(\Omega_j^{(2)})}\\
&\quad\le Cd_j^{-N/2-1}\left(\|\mathbf{e}_1^{(1)}\|_{L^1(\Omega_j^{(3)})}+d_j\|e_2^{(1)}\|_{L^1(\Omega_j^{(3)})}\right)+Ch^r d_j^{-N/2-r}.
\end{aligned}
\tag{4.21}
$$

Substituting (4.21) into (4.19) and (4.20) and taking into account the definitions of norms (4.15) and (4.16), we conclude that

$$
\begin{aligned}
&\|\mathbf{e}_1^{(1)}\|_{L^1(\Omega_j^{(1)})}+\|e_2^{(1)}\|_{W^{-1,1}(\Omega_j^{(1)})}\\
&\quad\le Ch^r d_j^{1-r}\left(\|\mathbf{e}_1^{(1)}\|_{W^{1,1}(\Omega)}+\|e_2^{(1)}\|_{L^1(\Omega)}\right)\\
&\qquad + Ch^{1+r}d_j^{-r}+Chd_j^{-1}\|\mathbf{e}_1^{(1)}\|_{L^1(\Omega_j^{(3)})}+Ch\|e_2^{(1)}\|_{L^1(\Omega_j^{(3)})}.
\end{aligned}
\tag{4.22}
$$

Thus, combining (4.22) and (4.14), we have

$$
\begin{aligned}
L_1+L_2 &\le CM^{N/2+s}+C\Theta(r-s)\left(\|\mathbf{e}_1^{(1)}\|_{W^{1,1}(\Omega)}+\|e_2^{(1)}\|_{L^1(\Omega)}\right)\\
&\quad + C\Theta(1+r-s)+C\Theta(1)L_1+C\Theta(1)\|e_2^{(1)}\|_{L^1(\Omega),z,-s}.
\end{aligned}
\tag{4.23}
$$

Notice that $\Theta(\gamma)\to 0$ as $M\to\infty$ for any fixed $\gamma>0$ according to (4.13). Choose M large enough so that $C\Theta(1)\le 1/2$. Then, the term $C\Theta(1)L_1$ on the right-hand side of (4.23) is absorbed into the left-hand side and we arrive at

$$
\begin{aligned}
L_1+L_2 &\le CM^{N/2+s}+C\Theta(1+r-s)+C\Theta(1)\|e_2^{(1)}\|_{L^1(\Omega),z,-s}\\
&\quad + C\Theta(r-s)\left(\|\mathbf{e}_1^{(1)}\|_{W^{1,1}(\Omega)}+\|e_2^{(1)}\|_{L^1(\Omega)}\right).
\end{aligned}
\tag{4.24}
$$

The substitution of (4.24) into (4.12) results in

$$
\begin{aligned}
&\|\mathbf{e}_1^{(1)}\|_{W^{1,1}(\Omega),z,-s}+\|e_2^{(1)}\|_{L^1(\Omega),z,-s}\\
&\quad\le CM^{N/2+s}+C\Theta(r-s)+C\Theta(1+r-s)+C\Theta(1)\|e_2^{(1)}\|_{L^1(\Omega),z,-s}\\
&\qquad + C\Theta(r-s)\left(\|\mathbf{e}_1^{(1)}\|_{W^{1,1}(\Omega)}+\|e_2^{(1)}\|_{L^1(\Omega)}\right).
\end{aligned}
\tag{4.25}
$$

The particular case when $s=0$ in inequality (4.25) implies

$$
\begin{aligned}
\|\mathbf{e}_1^{(1)}\|_{W^{1,1}(\Omega)}+\|e_2^{(1)}\|_{L^1(\Omega)} &\le CM^{N/2}+C\Theta(r)+C\Theta(1+r)+C\Theta(1)\|e_2^{(1)}\|_{L^1(\Omega)}\\
&\quad + C\Theta(r)\left(\|\mathbf{e}_1^{(1)}\|_{W^{1,1}(\Omega)}+\|e_2^{(1)}\|_{L^1(\Omega)}\right),
\end{aligned}
$$

which, choosing M large enough, results in

$$\|\mathbf{e}_1^{(1)}\|_{W^{1,1}(\Omega)} + \|e_2^{(1)}\|_{L^1(\Omega)} \le C. \tag{4.26}$$

Using (4.26) in (4.25), we get (4.10). This completes the proof of Lemma 4.3. ∎

5. Velocity error. This section is devoted to deriving the pointwise error estimate for the velocity error $\mathbf{u} - \mathbf{u}_h$. The result is stated in Theorem 5.1.

THEOREM 5.1. *Suppose* $(\mathbf{u}, p)$ *and* $(\mathbf{u}_h, p_h)$ *satisfy* (2.4). *Let* $z \in \bar{\Omega}$. *Then there exists a constant* $C > 0$ *independent of* $z, \mathbf{u}, p, h$ *such that for* $0 \le s \le r-1$ *there holds*

(5.1)

$$|(\mathbf{u} - \mathbf{u}_h)(z)| \le Ch \left(\ln \frac{1}{h}\right)^{\bar{\bar{s}}} \left(\inf_{\mathbf{v} \in \mathbf{V}^h} \|\mathbf{u} - \mathbf{v}\|_{W^{1,\infty}(\Omega),z,s} + \inf_{q \in W^h} \|p - q\|_{L^\infty(\Omega),z,s} \right),$$

where $\bar{\bar{s}} = 0$ *if* $0 \le s < r-1$ *and* $\bar{\bar{s}} = 1$ *if* $s = r-1$.

Proof. The triangular inequality, the inverse properties in A.2, and the approximation properties in A.1 yield for any $\mathbf{v} \in \mathbf{V}^h$

$$\begin{aligned}
|(\mathbf{u} - \mathbf{u}_h)(z)| &\le |(\mathbf{u} - \mathbf{v})(z)| + Ch^{-N/2} \|\mathbf{v} - \mathbf{u}_h\|_{L^2(B_{2\kappa h}(z))} \\
&\le C\|\mathbf{u} - \mathbf{v}\|_{L^\infty(B_{2\kappa h}(z))} + Ch^{-N/2} \|\mathbf{u} - \mathbf{u}_h\|_{L^2(B_{2\kappa h}(z))} \\
&\le Ch\|\mathbf{u}\|_{W^{1,\infty}(B_{3\kappa h}(z))} + Ch^{-N/2} \|\mathbf{u} - \mathbf{u}_h\|_{L^2(B_{2\kappa h}(z))} \\
&\le Ch\|\mathbf{u}\|_{W^{1,\infty}(\Omega),z,s} + Ch^{-N/2} \|\mathbf{u} - \mathbf{u}_h\|_{L^2(B_{2\kappa h}(z))}.
\end{aligned}$$

Replacing $\mathbf{u}$ by $\mathbf{u} - \mathbf{v}$, we obtain

$$|(\mathbf{u} - \mathbf{u}_h)(z)| \le Ch\|\mathbf{u} - \mathbf{v}\|_{W^{1,\infty}(\Omega),z,s} + Ch^{-N/2} \|\mathbf{u} - \mathbf{u}_h\|_{L^2(B_{2\kappa h}(z))}. \tag{5.2}$$

We shall estimate the second term in (5.2) by employing a duality argument. To this end, define a function

$$\rho(x) = \begin{cases} h^{-N/2}(\mathbf{u} - \mathbf{u}_h)(x) / \|\mathbf{u} - \mathbf{u}_h\|_{L^2(E_{2\kappa h}(x))} & \text{for } x \in B_{2\kappa h}(z), \\ 0 & \text{elsewhere} \end{cases}$$

and let $(\Phi_z^{(2)}, \lambda_z^{(2)}) \in H_0^1(\Omega)^N \times L_0^2(\Omega)$ denote the unique solution of

$$\begin{aligned}
a(\mathbf{v}, \Phi_z^{(2)}) - b(\mathbf{v}, \lambda_z^{(2)}) &= (\rho, \mathbf{v}) \quad \forall\, \mathbf{v} \in H_0^1(\Omega)^N, \\
b(\Phi_z^{(2)}, q) &= 0 \quad \forall\, q \in L_0^2(\Omega),
\end{aligned} \tag{5.3}$$

and let $(\Phi_{z,h}^{(2)}, \lambda_{z,h}^{(2)}) \in \mathbf{V}^h \times W^h$ be the corresponding finite element approximation of $(\Phi_z^{(2)}, \lambda_z^{(2)})$ so that

$$\begin{aligned}
a(\mathbf{v}, \Phi_z^{(2)} - \Phi_{z,h}^{(2)}) - b(\mathbf{v}, \lambda_z^{(2)} - \lambda_{z,h}^{(2)}) &= 0 \quad \forall\, \mathbf{v} \in \mathbf{V}^h, \\
b(\Phi_z^{(2)} - \Phi_{z,h}^{(2)}, q) &= 0 \quad \forall\, q \in W^h.
\end{aligned} \tag{5.4}$$

Then, for any $\mathbf{v} \in \mathbf{V}^h$ and $q \in W^h$, some simple manipulations using (5.3), (2.4), and (5.4) and Hölder's inequality result in

$$\begin{aligned}
&h^{-N/2}\|\mathbf{u} - \mathbf{u}_h\|_{L^2(E_{2\kappa h}(z))} = (\rho, \mathbf{u} - \mathbf{u}_h) = a(\mathbf{u} - \mathbf{u}_h, \Phi_z^{(2)}) - b(\mathbf{u} - \mathbf{u}_h, \lambda_z^{(2)}) \\
&= a(\mathbf{u} - \mathbf{v}, \Phi_z^{(2)} - \Phi_{z,h}^{(2)}) - b(\mathbf{u} - \mathbf{v}, \lambda_z^{(2)} - \lambda_{z,h}^{(2)}) - b(\Phi_z^{(2)} - \Phi_{z,h}^{(2)}, p - q) \\
&\le C \left(\|\Phi_z^{(2)} - \Phi_{z,h}^{(2)}\|_{W^{1,1}(\Omega),z,-s} + \|\lambda_z^{(2)} - \lambda_{z,h}^{(2)}\|_{L^1(\Omega),z,-s} \right) \\
&\quad \times C \left(\|\mathbf{u} - \mathbf{v}\|_{W^{1,\infty}(\Omega),z,s} + \|p - q\|_{L^\infty(\Omega),z,s} \right),
\end{aligned}$$

which, along with (5.2) and Lemma 5.2, yields the desired estimate (5.1). Thus, the proof is complete. ∎

The result of the next lemma is used in the proof of Theorem 5.1. It is a sharp error estimate for the solution of the auxiliary Stokes problem (5.3) and (5.4) in the weighted $W^{1,1}(\Omega)$ and $L^1(\Omega)$ norms.

LEMMA 5.2. *Let $(\Phi_z^{(2)}, \lambda_z^{(2)})$ be the solution of* (5.3) *and let $(\Phi_{z,h}^{(2)}, \lambda_{z,h}^{(2)})$ be the corresponding finite element approximation satisfying* (5.4). *Then, there is a constant $C > 0$ such that for $0 \le s \le r-1$,*

$$\|\Phi_z^{(2)} - \Phi_{z,h}^{(2)}\|_{W^{1,1}(\Omega),z,-s} + \|\lambda_z^{(2)} - \lambda_{z,h}^{(2)}\|_{L^1(\Omega),z,-s} \le Ch \left(\ln \frac{1}{h}\right)^{\bar{\bar{s}}}, \tag{5.5}$$

where $\bar{\bar{s}} = 0$ if $0 \le s < r-1$ and $\bar{\bar{s}} = 1$ if $s = r-1$.

Proof. As before, let $M > 1$ be a real number, whose value will be determined later in the proof, and let J be an integer such that $Mh = 2^{-J}$. Then, $J \le C \ln \frac{1}{h}$. Set $\mathbf{e}_1^{(2)} = \Phi_z^{(2)} - \Phi_{z,h}^{(2)}$ and $e_2^{(2)} = \lambda_z^{(2)} - \lambda_{z,h}^{(2)}$. Then, analogous to inequality (4.11), we have

$$\begin{aligned} &\|\mathbf{e}_1^{(2)}\|_{W^{1,1}(\Omega),z,-s} + \|e_2\|_{L^1(\Omega),z,-s} \\ &\quad \le CM^{N/2+s} h^{N/2} (\|\mathbf{e}_1^{(2)}\|_{H^1(B_{Mh}(z))} + \|e_2^{(2)}\|_{L^2(B_{Mh}(z))}) \\ &\qquad + C \sum_{j=0}^{J} d_j^{s+N/2} h^{-s} (\|\mathbf{e}_1^{(2)}\|_{H^1(\Omega_j)} + \|e_2^{(2)}\|_{L^2(\Omega_j)}). \end{aligned} \tag{5.6}$$

The norms on the right-hand side of (5.6) can be estimated by using (3.24) and (3.25) in Lemma 3.6 with $t_1 = 1$. Consequently,

$$\begin{aligned} \|\mathbf{e}_1^{(2)}\|_{W^{1,1}(\Omega),z,-s} + \|e_2^{(2)}\|_{L^1(\Omega),z,-s} &\le CM^{N/2+s} h + Ch \sum_{j=0}^{J} (h/d_j)^{r-1-s} \\ &\quad + C \sum_{j=0}^{J} d_j^{s-1} h^{-s} \left(\|\mathbf{e}_1^{(2)}\|_{L^1(\Omega_j^{(1)})} + \|e_2^{(2)}\|_{W^{-1,1}(\Omega_j^{(1)})}\right) \\ &\le CM^{N/2+s} h + Ch\Theta(r-1-s) + L_3 + L_4, \end{aligned} \tag{5.7}$$

where

$$L_3 = Ch^{-1} \|\mathbf{e}_1^{(2)}\|_{L^1(\Omega),z,1-s}, \quad L_4 = \sum_{j=0}^{J} d_j^{s-1} h^{-s} \|e_2^{(2)}\|_{W^{-1,1}(\Omega_j^{(1)})}.$$

We are now in a position to estimate $L_3 + L_4$. It follows immediately from the definitions of L_3 and L_4 that

$$L_3 + L_4 \le CM^{N/2+s} h + C \sum_{j=0}^{J} d_j^{s-1} h^{-s} \left(\|\mathbf{e}_1^{(2)}\|_{L^1(\Omega_j^{(1)})} + \|e_2^{(2)}\|_{W^{-1,1}(\Omega_j^{(1)})}\right). \tag{5.8}$$

To estimate $\|\mathbf{e}_1^{(2)}\|_{L^1(\Omega_j^{(1)})}$ and $\|e_2^{(2)}\|_{W^{-1,1}(\Omega_j^{(1)})}$ for each $0 \le j \le J$, recall the definitions of the norms

$$\|\mathbf{e}_1^{(2)}\|_{L^1(\Omega_j^{(1)})} = \sup_{\substack{\varphi \in C_0^\infty(\Omega_j^{(1)})^N \\ \|\varphi\|_{L^\infty(\Omega_j^{(1)})} = 1}} (\mathbf{e}_1^{(2)}, \varphi), \tag{5.9}$$

$$\|e_2^{(2)}\|_{W^{-1,1}(\Omega_j^{(1)})} = \sup_{\substack{\psi\in C_0^\infty(\Omega_j^{(1)})\\ \|\psi\|_{W^{1,\infty}(\Omega_j^{(1)})}=1}} (e_2^{(2)},\psi). \tag{5.10}$$

For each $\varphi \in C_0^\infty(\Omega_j^{(1)})^N$ satisfying $\|\varphi\|_{L^\infty(\Omega)} = 1$, similar to (4.19), we have

$$\begin{aligned}(\mathbf{e}_1^{(2)},\varphi) &\le Ch^r d_j^{1-r}\left(\|\mathbf{e}_1^{(2)}\|_{W^{1,1}(\Omega)} + \|e_2^{(2)}\|_{L^1(\Omega)}\right)\\ &\quad + Chd_j^{N/2}\left(\|\mathbf{e}_1^{(2)}\|_{H^1(\Omega_j^{(2)})} + \|e_2^{(2)}\|_{L^2(\Omega_j^{(2)})}\right),\end{aligned} \tag{5.11}$$

and for each $\psi \in C_0^\infty(\Omega_j^{(1)})$ satisfying $\|\psi\|_{W^{1,\infty}(\Omega)} = 1$, similar to (4.20), we have

$$\begin{aligned}(e_2^{(2)},\psi) &\le Ch^r d_j^{1-r}\left(\|\mathbf{e}_1^{(2)}\|_{W^{1,1}(\Omega)} + \|e_2^{(2)}\|_{L^1(\Omega)}\right)\\ &\quad + Chd_j^{N/2}\left(\|\mathbf{e}_1^{(2)}\|_{H^1(\Omega_j^{(2)})} + \|e_2^{(2)}\|_{L^2(\Omega_j^{(2)})}\right).\end{aligned} \tag{5.12}$$

Using (3.25) of Lemma 3.7 with $t_1 = 0$, the last terms of (5.12) and (5.11) are bounded as follows:

$$\begin{aligned}&\|\mathbf{e}_1^{(2)}\|_{H^1(\Omega_j^{(2)})} + \|e_2^{(2)}\|_{L^2(\Omega_j^{(2)})}\\ &\le Cd_j^{-N/2-1}\left(\|\mathbf{e}_1^{(2)}\|_{L^1(\Omega_j^{(3)})} + d_j\|e_2^{(2)}\|_{L^1(\Omega_j^{(3)})}\right) + Ch^r d_j^{-N/2+1-r}.\end{aligned} \tag{5.13}$$

Substituting (5.11), (5.12), and (5.13) into (5.9) and (5.10), we obtain

$$\begin{aligned}&\|\mathbf{e}_1^{(2)}\|_{L^1(\Omega_j^{(1)})} + \|e_2^{(2)}\|_{W^{-1,1}(\Omega_j^{(1)})}\\ &\le Ch^r d_j^{1-r}\left(\|\mathbf{e}_1^{(2)}\|_{W^{1,1}(\Omega)} + \|e_2^{(2)}\|_{L^1(\Omega)}\right)\\ &\quad + Ch^{1+r}d_j^{1-r} + Chd_j^{-1}\|\mathbf{e}_1^{(2)}\|_{L^1(\Omega_j^{(3)})} + Ch\|e_2^{(2)}\|_{L^1(\Omega_j^{(3)})}.\end{aligned} \tag{5.14}$$

Thus, using (5.14) in (5.8), we obtain

$$\begin{aligned}L_3 + L_4 &\le CM^{N/2+s}h + C\Theta(r-s)\left(\|\mathbf{e}_1^{(2)}\|_{W^{1,1}(\Omega)} + \|e_2^{(2)}\|_{L^1(\Omega)}\right)\\ &\quad + Ch\Theta(r-s) + C\Theta(1)L_3 + C\Theta(1)\|e_2^{(2)}\|_{L^1(\Omega),z,-s}.\end{aligned} \tag{5.15}$$

Because of (4.13), we can choose M large enough so that the term $C\Theta(1)L_3$ becomes so small that it can be absorbed into the left-hand side of (5.15). Therefore,

$$\begin{aligned}L_3 + L_4 &\le CM^{N/2+s}h + Ch\Theta(r-s) + C\Theta(1)\|e_2^{(2)}\|_{L^1(\Omega),z,-s}\\ &\quad + C\Theta(r-s)\left(\|\mathbf{e}_1^{(2)}\|_{W^{1,1}(\Omega)} + \|e_2^{(2)}\|_{L^1(\Omega)}\right).\end{aligned} \tag{5.16}$$

From (5.16) and (5.7), it follows that

$$\begin{aligned}&\|\mathbf{e}_1^{(2)}\|_{W^{1,1}(\Omega),z,-s} + \|e_2^{(2)}\|_{L^1(\Omega),z,-s}\\ &\le CM^{N/2+s}h + Ch\Theta(r-1-s) + Ch\Theta(r-s) + C\Theta(1)\|e_2^{(2)}\|_{L^1(\Omega),z,-s}\\ &\quad + C\Theta(r-s)\left(\|\mathbf{e}_1^{(2)}\|_{W^{1,1}(\Omega)} + \|e_2^{(2)}\|_{L^1(\Omega)}\right).\end{aligned}$$

Choosing M sufficiently large such that $\Theta(1)$ is small enough so that the term $C\Theta(1)\|e_2^{(2)}\|_{L^1(\Omega),z,-s}$ on the right-hand side can be absorbed into the left-hand side, we get

$$\begin{aligned}(5.17)\qquad &\|\mathbf{e}_1^{(2)}\|_{W^{1,1}(\Omega),z,-s}+\|e_2^{(2)}\|_{L^1(\Omega),z,-s}\\ &\quad\le CM^{N/2+s}h+Ch\Theta(r-1-s)+Ch\Theta(r-s)\\ &\qquad+C\Theta(r-s)\left(\|\mathbf{e}_1^{(2)}\|_{W^{1,1}(\Omega)}+\|e_2^{(2)}\|_{L^1(\Omega)}\right).\end{aligned}$$

The special case of (5.17) when $s=0$ is

$$\begin{aligned}\|\mathbf{e}_1^{(2)}\|_{W^{1,1}(\Omega)}+\|e_2^{(2)}\|_{L^1(\Omega)}&\le CM^{N/2+s}h+Ch\Theta(r-1)+Ch\Theta(r)\\ &\quad+C\Theta(r)\left(\|\mathbf{e}_1^{(2)}\|_{W^{1,1}(\Omega)}+\|e_2^{(2)}\|_{L^1(\Omega)}\right),\end{aligned}$$

which, by choosing M large enough, gives

$$\begin{aligned}\|\mathbf{e}_1^{(2)}\|_{W^{1,1}(\Omega)}+\|e_2^{(2)}\|_{L^1(\Omega)}&\le CM^{N/2+s}h+Ch\Theta(r-1)+Ch\Theta(r),\\ &\le Ch+Ch\Theta(r-1).\end{aligned}$$

Combining this with (5.17), we obtain

$$\begin{aligned}&\|\mathbf{e}_1^{(2)}\|_{W^{1,1}(\Omega),z,-s}+\|e_2^{(2)}\|_{L^1(\Omega),z,-s}\\ &\quad\le CM^{N/2+s}h+Ch\Theta(r-1-s)+Ch\Theta(r-s)+Ch\Theta(r-1)\Theta(r-s)\\ &\quad\le Ch\left(\ln\frac{1}{h}\right)^{\bar{s}}.\end{aligned}$$

This completes the proof of Lemma 5.2. ∎

6. Gradient of velocity error. This section is devoted to the pointwise estimate for the derivatives of the velocity error. The main result is stated in Theorem 6.1.

THEOREM 6.1. *Suppose* $(\mathbf{u},p)$ *and* $(\mathbf{u}_h,p_h)$ *satisfy* (2.4). *Let* $z\in\bar{\Omega}$. *Then there exists a constant* $C>0$ *independent of* $z,\mathbf{u},p,h$ *such that for* $0\le s\le r$ *there holds*

$$(6.1)\qquad |\nabla(\mathbf{u}-\mathbf{u}_h)(z)|\le C\left(\ln\frac{1}{h}\right)^{\bar{s}}\left(\inf_{\mathbf{v}\in\mathbf{V}^h}\|\mathbf{u}-\mathbf{v}\|_{W^{1,\infty}(\Omega),z,s}+\inf_{q\in W^h}\|p-q\|_{L^\infty(\Omega),z,s}\right),$$

where $\bar{s}=0$ *if* i $0\le s<r$ *and* $\bar{s}=1$ *if* $s=r$.

Proof. To begin with, using A.1 and A.2 and following a similar procedure as in deriving (5.2), we easily arrive at

$$\begin{aligned}(6.2)\qquad \left|\frac{\partial}{\partial x_i}(\mathbf{u}-\mathbf{u}_h)(z)\right|&\le\left\|\frac{\partial}{\partial x_i}(\mathbf{u}-\mathbf{u}_h)\right\|_{L^\infty(B_{2\kappa h}(z))}\\ &\quad+Ch^{-N/2-1}\left\|\frac{\partial}{\partial x_i}(\mathbf{u}-\mathbf{u}_h)\right\|_{H^{-1}(B_{2\kappa h}(z))}.\end{aligned}$$

By a duality argument and integration by parts,

$$
\begin{aligned}
(6.3)\qquad & h^{-N/2-1}\left\|\frac{\partial}{\partial x_i}(\mathbf{u}-\mathbf{u}_h)\right\|_{H^{-1}(B_{2\kappa h}(z))}\\
&= \sup_{\substack{\varphi\in C_0^\infty(B_{2\kappa h}(z))^N\\ \|\varphi\|_{H^1(B_{2\kappa h}(z))}=1}}\left(h^{-N/2-1}\frac{\partial}{\partial x_i}(\mathbf{u}-\mathbf{u}_h),\varphi\right)\\
&= \sup_{\substack{\varphi\in C_0^\infty(B_{2\kappa h}(z))^N\\ \|\varphi\|_{H^1(B_{2\kappa h}(z))}=1}}\left(\mathbf{u}-\mathbf{u}_h,-h^{-N/2-1}\frac{\partial\varphi}{\partial x_i}\right).
\end{aligned}
$$

Set

$$
(6.4)\qquad \rho_1=-h^{-N/2-1}\frac{\partial\varphi}{\partial x_i},
$$

let $(\Phi_z^{(3)},\lambda_z^{(3)})\in H_0^1(\Omega)^N\times L_0^2(\Omega)$ denote the solution of

$$
(6.5)\qquad \begin{aligned} a(\mathbf{v},\Phi_z^{(3)})-b(\mathbf{v},\lambda_z^{(3)})&=(\rho_1,\mathbf{v})\quad\forall\ \mathbf{v}\in H_0^1(\Omega)^N,\\ b(\Phi_z^{(3)},q)&=0\quad\forall\ q\in L_0^2(\Omega),\end{aligned}
$$

and let $(\Phi_{z,h}^{(3)},\lambda_{z,h}^{(3)})\in\mathbf{V}^h\times W^h$ be the finite element approximation of $(\Phi_z^{(3)},\lambda_z^{(3)})$ so that

$$
(6.6)\qquad \begin{aligned} a(\mathbf{v},\Phi_z^{(3)}-\Phi_{z,h}^{(3)})-b(\mathbf{v},\lambda_z^{(3)}-\lambda_{z,h}^{(3)})&=0\quad\forall\ \mathbf{v}\in\mathbf{V}^h,\\ b(\Phi_z^{(3)}-\Phi_{z,h}^{(3)},q)&=0\quad\forall\ q\in W^h.\end{aligned}
$$

Then, for any $\mathbf{v}\in\mathbf{V}^h$ and $q\in W^h$, arguing in the same way as before, we obtain

$$
\begin{aligned}
&\left(\mathbf{u}-\mathbf{u}_h,h^{-N/2-1}\frac{\partial\varphi}{\partial x_i}\right)=(\rho_1,\mathbf{u}-\mathbf{u}_h)\\
&\quad=a(\mathbf{u}-\mathbf{u}_h,\Phi_z^{(3)})-b(\mathbf{u}-\mathbf{u}_h,\lambda_z^{(3)})\\
&\quad=a(\mathbf{u}-\mathbf{v},\Phi_z^{(3)}-\Phi_{z,h}^{(3)})-b(\mathbf{u}-\mathbf{v},\lambda_z^{(3)}-\lambda_{z,h}^{(3)})-b(\Phi_z^{(3)}-\Phi_{z,h}^{(3)},p-q),
\end{aligned}
$$

which, along with Hölder's inequality and (6.8) of Lemma 6.2, yields

$$
\begin{aligned}
(6.7)\qquad &\left(\mathbf{u}-\mathbf{u}_h,h^{-N/2-1}\frac{\partial\varphi}{\partial x_i}\right)\\
&\le C\left(\|\Phi_z^{(3)}-\Phi_{z,h}^{(3)}\|_{W^{1,1}(\Omega),z,-s}+\|\lambda_z^{(3)}-\lambda_{z,h}^{(3)}\|_{L^1(\Omega),z,-s}\right)\\
&\quad\times C\left(\|\mathbf{u}-\mathbf{v}\|_{W^{1,\infty}(\Omega),z,s}+\|p-q\|_{L^\infty(\Omega),z,s}\right)\\
&\le C\left(\ln\frac{1}{h}\right)^{\bar s}\left(\|\mathbf{u}-\mathbf{v}\|_{W^{1,\infty}(\Omega),z,s}+\|p-q\|_{L^\infty(\Omega),z,s}\right).
\end{aligned}
$$

Estimate (6.7), together with (6.2) and (6.3), shows

$$
\begin{aligned}
&\left|\frac{\partial}{\partial x_i}(\mathbf{u}-\mathbf{u}_h)(z)\right|\\
&\quad\le C\left(\ln\frac{1}{h}\right)^{\bar s}\left(\inf_{\mathbf{v}\in\mathbf{V}^h}\|\mathbf{u}-\mathbf{v}\|_{W^{1,\infty}(\Omega),z,s}+\inf_{q\in W^h}\|p-q\|_{L^\infty(\Omega),z,s}\right),
\end{aligned}
$$

which proves (6.1). ∎

In the rest of this section, we prove the error estimates for the solutions of (6.5) and (6.6) in the weighted $W^{1,1}$ and L^1 norms, which have been used in the proof of Theorem 6.1.

LEMMA 6.2. *Let* $(\Phi_z^{(3)}, \lambda_z^{(3)})$ *and* $(\Phi_{z,h}^{(3)}, \lambda_{z,h}^{(3)})$ *satisfy* (6.5) *and* (6.6). *Then, there is a constant* $C > 0$ *such that for* $0 \le s \le r$,

$$\|\Phi_z^{(3)} - \Phi_{z,h}^{(3)}\|_{W^{1,1}(\Omega),z,-s} + \|\lambda_z^{(3)} - \lambda_{z,h}^{(3)}\|_{L^1(\Omega),z,-s} \le C\left(\ln\frac{1}{h}\right)^{\bar{s}}, \tag{6.8}$$

where $\bar{s} = 0$ *if* $0 \le s < r$ *and* $\bar{s} = 1$ *if* $s = r$.

Proof. The proof of (6.8) follows closely that of (4.10). Let M and J be as before and set $\mathbf{e}_1^{(3)} = \Phi_z^{(3)} - \Phi_{z,h}^{(3)}$ and $e_2^{(3)} = \lambda_z^{(3)} - \lambda_{z,h}^{(3)}$. Then, analogous to (4.11), there holds

$$\begin{aligned}\|\mathbf{e}_1^{(3)}\|_{W^{1,1}(\Omega),z,-s} + \|e_2^{(3)}\|_{L^1(\Omega),z,-s} &\\ \le CM^{N/2+s}h^{N/2}(\|\mathbf{e}_1^{(3)}\|_{H^1(B_{Mh}(z))} + \|e_2^{(3)}\|_{L^2(B_{Mh}(z))}) &\\ + C\sum_{j=0}^{J} d_j^{s+N/2}h^{-s}(\|\mathbf{e}_1^{(3)}\|_{H^1(\Omega_j)} + \|e_2^{(3)}\|_{L^2(\Omega_j)}).&\end{aligned} \tag{6.9}$$

This time, we shall not use (3.24) and (3.25) in Lemma 3.24 for the norms in (6.9) as we did for (5.6). Instead, (3.12) and (3.20) combined with (6.23) of Lemma 6.3 will be used. As a matter of fact, using (3.12) of Lemma 3.3, we obtain

$$\begin{aligned}\|\mathbf{e}_1^{(3)}\|_{H^1(B_{Mh}(z))} + \|e_2^{(3)}\|_{L^2(B_{Mh}(z))} &\\ \le Ch\left(\|\Phi_z^{(3)}\|_{H^2(\Omega)} + \|\lambda_z^{(3)}\|_{H^1(\Omega)}\right) \le Ch\|\rho_1\|_{L^2(\Omega)} \le Ch^{-N/2}.&\end{aligned} \tag{6.10}$$

Applying (3.20) with $t_1 = 1$, $t = 0$ in Lemma 3.5 and (6.23) in Lemma 6.3, we have

$$\begin{aligned}\|\mathbf{e}_1^{(3)}\|_{H^1(\Omega_j)} + \|e_2^{(3)}\|_{L^2(\Omega_j)} &\\ \le Ch^r\left(\|\Phi_z^{(3)}\|_{H^{1+r}(\Omega_j^{(1)})} + \|\lambda_z^{(3)}\|_{H^r(\Omega_j^{(3)})}\right) &\\ + Cd_j^{-N/2-1}\left(\|\mathbf{e}_1^{(3)}\|_{L^1(\Omega_j^{(1)})} + \|e_2^{(3)}\|_{W^{-1,1}(\Omega_j^{(1)})}\right) &\\ \le Ch^r d_j^{-N/2-r} + Cd_j^{-N/2-1}\left(\|\mathbf{e}_1^{(3)}\|_{L^1(\Omega_j^{(1)})} + \|e_2^{(3)}\|_{W^{-1,1}(\Omega_j^{(1)})}\right).&\end{aligned} \tag{6.11}$$

Substituting (6.10) and (6.11) into (6.9), we obtain

$$\|\mathbf{e}_1^{(3)}\|_{W^{1,1}(\Omega),z,-s} + \|e_2^{(3)}\|_{L^1(\Omega),z,-s} \le CM^{N/2+s} + C\Theta(r-s) + L_5 + L_6, \tag{6.12}$$

where L_5 and L_6 are defined by

$$L_5 = Ch^{-1}\|\mathbf{e}_1^{(3)}\|_{L^1(\Omega),z,1-s}, \quad L_6 = \sum_{j=0}^{J} d_j^{s-1}h^{-s}\|e_2^{(3)}\|_{W^{-1,1}(\Omega_j^{(1)})}.$$

Since

$$L_5 + L_6 \le CM^{N/2+s} + C\sum_{j=0}^{J} d_j^{s-1}h^{-s}\left(\|\mathbf{e}_1^{(3)}\|_{L^1(\Omega_j^{(1)})} + \|e_2^{(3)}\|_{W^{-1,1}(\Omega_j^{(1)})}\right), \tag{6.13}$$

we shall estimate the norms $\|\mathbf{e}_1^{(3)}\|_{L^1(\Omega_j^{(1)})}$ and $\|e_2^{(3)}\|_{W^{-1,1}(\Omega_j^{(1)})}$, which are defined through

$$\|\mathbf{e}_1^{(3)}\|_{L^1(\Omega_j^{(1)})} = \sup_{\substack{\varphi\in C_0^\infty(\Omega_j^{(1)})^N \\ \|\varphi\|_{L^\infty(\Omega_j^{(1)})}=1}} (\mathbf{e}_1^{(3)}, \varphi), \tag{6.14}$$

$$\|e_2^{(3)}\|_{W^{-1,1}(\Omega_j^{(1)})} = \sup_{\substack{\psi\in C_0^\infty(\Omega_j^{(1)}) \\ \|\psi\|_{W^{1,\infty}(\Omega_j^{(1)})}=1}} (e_2^{(3)}, \psi). \tag{6.15}$$

For each $\varphi \in C_0^\infty(\Omega_j^{(1)})^N$ with unit norm $\|\varphi\|_{L^\infty(\Omega)} = 1$, and each $\psi \in C_0^\infty(\Omega_j^{(1)})$ with unit norm $\|\psi\|_{W^{1,\infty}(\Omega)} = 1$, following (4.19) and (4.20), we have

$$\begin{aligned}(\mathbf{e}_1^{(3)}, \varphi) \le{}& Ch^r d_j^{1-r} \left(\|\mathbf{e}_1^{(3)}\|_{W^{1,1}(\Omega)} + \|e_2^{(3)}\|_{L^1(\Omega)}\right) \\ &+ Chd_j^{N/2} \left(\|\mathbf{e}_1^{(3)}\|_{H^1(\Omega_j^{(2)})} + \|e_2^{(3)}\|_{L^2(\Omega_j^{(2)})}\right)\end{aligned} \tag{6.16}$$

and

$$\begin{aligned}(e_2^{(3)}, \psi) \le{}& Ch^r d_j^{1-r} \left(\|\mathbf{e}_1^{(3)}\|_{W^{1,1}(\Omega)} + \|e_2^{(3)}\|_{L^1(\Omega)}\right) \\ &+ Chd_j^{N/2} \left(\|\mathbf{e}_1^{(3)}\|_{H^1(\Omega_j^{(3)})} + \|e_2^{(3)}\|_{L^2(\Omega_j^{(2)})}\right).\end{aligned} \tag{6.17}$$

Applying (3.20) with $t_1 = 0$ in Lemma 3.5 and (6.23) in Lemma 6.3,

$$\begin{aligned}&\|\mathbf{e}_1^{(3)}\|_{H^1(\Omega_j)} + \|e_2^{(3)}\|_{L^2(\Omega_j)} \\ &\quad\le Ch^r \left(\|\Phi_z^{(3)}\|_{H^{1+r}(\Omega_j^{(1)})} + \|\lambda_z^{(3)}\|_{H^r(\Omega_j^{(3)})}\right) \\ &\qquad + Cd_j^{-N/2-1} \left(\|\mathbf{e}_1^{(3)}\|_{L^1(\Omega_j^{(1)})} + d_j\|e_2^{(3)}\|_{L^1(\Omega_j^{(1)})}\right) \\ &\quad\le Ch^r d_j^{-N/2-r} + Cd_j^{-N/2-1} \left(\|\mathbf{e}_1^{(3)}\|_{L^1(\Omega_j^{(1)})} + d_j\|e_2^{(3)}\|_{W^{-1,1}(\Omega_j^{(1)})}\right).\end{aligned} \tag{6.18}$$

Substituting (6.18) into (6.16) and (6.17) and then using (6.16) and (6.17) in (6.14) and (6.15), we obtain

$$\begin{aligned}&\|\mathbf{e}_1^{(3)}\|_{L^1(\Omega_j^{(1)})} + \|e_2^{(3)}\|_{W^{-1,1}(\Omega_j^{(1)})} \\ &\le Ch^r d_j^{1-r} \left(\|\mathbf{e}_1^{(3)}\|_{W^{1,1}(\Omega)} + \|e_2^{(3)}\|_{L^1(\Omega)}\right) \\ &\quad + Ch^{1+r} d_j^{-r} + Chd_j^{-1}\|\mathbf{e}_1^{(3)}\|_{L^1(\Omega_j^{(3)})} + Ch\|e_2^{(3)}\|_{L^1(\Omega_j^{(3)})},\end{aligned}$$

which, combined with (6.13), yields

$$\begin{aligned}L_5 + L_6 \le{}& CM^{N/2+s} + \Theta(r-s) \left(\|\mathbf{e}_1^{(3)}\|_{W^{1,1}(\Omega)} + \|e_2^{(3)}\|_{L^1(\Omega)}\right) \\ &+ C\Theta(1+r-s) + C\Theta(1)L_5 + C\Theta(1)\|e_2^{(3)}\|_{L^1(\Omega),z,-s}.\end{aligned} \tag{6.19}$$

Because of (4.13), we can choose M large enough so that

$$\begin{aligned}L_5 + L_6 \le{}& CM^{N/2+s} + C\Theta(1+r-s) + C\Theta(1)\|e_2^{(3)}\|_{L^1(\Omega),z,-s} \\ &+ \Theta(r-s) \left(\|\mathbf{e}_1^{(3)}\|_{W^{1,1}(\Omega)} + \|e_2^{(3)}\|_{L^1(\Omega)}\right).\end{aligned} \tag{6.20}$$

Using (6.20) and (6.12), we arrive at

$$\begin{aligned}(6.21)\quad &\|\mathbf{e}_1^{(3)}\|_{W^{1,1}(\Omega),z,-s}+\|e_2^{(3)}\|_{L^1(\Omega),z,-s}\\ &\le CM^{N/2+s}+C\Theta(r-s)+C\Theta(1+r-s)+C\Theta(1)\|e_2^{(3)}\|_{L^1(\Omega),z,-s}\\ &\quad+\Theta(r-s)\left(\|\mathbf{e}_1^{(3)}\|_{W^{1,1}(\Omega)}+\|e_2^{(3)}\|_{L^1(\Omega)}\right).\end{aligned}$$

Choosing M sufficiently large to cancel the term $C\Theta(1)\|e_2^{(3)}\|_{L^1(\Omega),z,-s}$ on the right-hand side of (6.21), we conclude

$$\begin{aligned}(6.22)\qquad &\|\mathbf{e}_1^{(3)}\|_{W^{1,1}(\Omega),z,-s}+\|e_2^{(3)}\|_{L^1(\Omega),z,-s}\\ &\le CM^{N/2+s}+C\Theta(r-s)+C\Theta(1+r-s)\\ &\quad+\Theta(r-s)\left(\|\mathbf{e}_1^{(3)}\|_{W^{1,1}(\Omega)}+\|e_2^{(3)}\|_{L^1(\Omega)}\right).\end{aligned}$$

Taking $s=0$ in (6.21), we have

$$\begin{aligned}\|\mathbf{e}_1^{(3)}\|_{W^{1,1}(\Omega)}+\|e_2^{(3)}\|_{L^1(\Omega)}&\le CM^{N/2}+C\Theta(r)+C\Theta(1+r)\\ &\quad+\Theta(r)\left(\|\mathbf{e}_1^{(3)}\|_{W^{1,1}(\Omega)}+\|e_2^{(3)}\|_{L^1(\Omega)}\right),\end{aligned}$$

which, when M is chosen sufficiently large, implies

$$\|\mathbf{e}_1^{(3)}\|_{W^{1,1}(\Omega)}+\|e_2^{(3)}\|_{L^1(\Omega)}\le CM^{N/2}+C\Theta(r)+C\Theta(1+r)\le C.$$

Substituting this into (6.21), we get

$$\begin{aligned}&\|\mathbf{e}_1^{(3)}\|_{W^{1,1}(\Omega),z,-s}+\|e_2^{(3)}\|_{L^1(\Omega),z,-s}\\ &\le CM^{N/2+s}+C\Theta(r-s)+C\Theta(1+r-s)+\Theta(r-s)\\ &\le C\left(\ln\frac{1}{h}\right)^{\bar{s}},\end{aligned}$$

which is the desired (6.8). The proof is complete. □

LEMMA 6.3. *Suppose ρ_1 is defined by (6.4) for some $\varphi\in C_0^\infty(B_{2\kappa h}(z))^N$ satisfying $\|\varphi\|_{H^1(B_{2\kappa h}(z))}=1$ and $(\mathbf{v},\lambda)\in H_0^1(\Omega)^N\times L_0^2(\Omega)$ is the solution of*

$$-\Delta\mathbf{v}+\nabla\lambda=\rho_1,\quad \nabla\cdot\mathbf{v}=0\quad \text{in }\ \Omega.$$

Then, there holds

$$(6.23)\qquad \|\mathbf{v}\|_{H^{1+r}(\Omega_j^{(1)})}+\|\lambda\|_{H^r(\Omega_j^{(1)})}\le Cd_j^{-N/2-r}.$$

Proof. We shall start with the integral representation (3.3) and (3.4) for the solution of the Stokes problem. For $x\in\Omega_j^{(1)}$, it follows that

$$(6.24)\qquad \mathbf{v}(x)=\sum_{t=1}^N\int_\Omega \mathbf{G}_x^t(y)\rho_1(y)\,dy,\quad \lambda(x)=\sum_{t=1}^N Q_x^t(y)\rho_1(y)\,dy.$$

In view of (6.4) and integrations by parts,

$$(6.25)\qquad \mathbf{v}(x)=-h^{-N/2-1}\sum_{t=1}^N\int_\Omega \mathbf{G}_x^t(y)\frac{\partial\varphi}{\partial y_i}\,dy=h^{-n/2-1}\sum_{t=1}^N\int_{B_{2\kappa h}(z)}\varphi\frac{\partial\mathbf{G}_x^t(y)}{\partial y_i}\,dy.$$

Differentiating (6.25) and using Hölder's inequality and estimates (3.5), we obtain for multiple index $|\alpha| \le 1 + r$

$$\begin{aligned} \partial_x^\alpha \mathbf{v}(x) &= h^{-N/2-1} \sum_{t=1}^{N} \int_{B_{2\kappa h}(z)} \varphi \partial_{y_i} \partial_x^\alpha \mathbf{G}_x^t(y)\, dy \\ &\le C h^{-N/2-1} d_j^{1-N-|\alpha|} h^{N/2} \|\varphi\|_{L^2(B_{2\kappa h}(z))} \\ &\le C d_j^{-N-r} \|\nabla \varphi\|_{L^2(B_{2\kappa h}(z))} \le C d_j^{-N-r}. \end{aligned} \tag{6.26}$$

Here, we have used the facts that $\|\varphi\|_{H^1(B_{2\kappa h}(z))} = 1$ and $\varphi \in C_0^\infty(B_{2\kappa h}(z))$, which imply

$$\|\varphi\|_{L^2(B_{2\kappa h}(z))} \le Ch \|\nabla \varphi\|_{L^2(B_{2\kappa h}(z))} \le Ch.$$

Thus, integrating (6.26) yields

$$\|\mathbf{v}\|_{H^{1+r}(\Omega_j^{(1)})} \le C d_j^{-N/2-r}. \tag{6.27}$$

With the same procedure, we show

$$\|\lambda\|_{H^r(\Omega_j^{(1)})} \le C d_j^{-N/2-r}. \tag{6.28}$$

Consequently, (6.27) and (6.28) imply (6.23). The proof is complete. ∎

ON THE LONG-TIME STABILITY OF THE IMPLICIT EULER SCHEME FOR THE TWO-DIMENSIONAL NAVIER–STOKES EQUATIONS*

F. TONE† AND D. WIROSOETISNO†‡

Abstract. In this paper we study the stability for all positive time of the fully implicit Euler scheme for the two-dimensional Navier–Stokes equations. More precisely, we consider the time discretization scheme and with the aid of the discrete Gronwall lemma and the discrete uniform Gronwall lemma we prove that the numerical scheme is stable.

Key words. Navier–Stokes equations, discrete Gronwall lemmas, implicit Euler scheme

1. Introduction.

Let $\Omega \subset \mathbb{R}^2$ be an open bounded set with boundary $\partial\Omega$ of class C^2. The Navier–Stokes equations of viscous incompressible fluids are

$$u_t + (u \cdot \nabla)u - \nu\Delta u + \nabla p = f, \tag{1.1}$$

$$\operatorname{div} u = 0, \tag{1.2}$$

where $u = (u_1, u_2)$ is the velocity, p is the pressure, ν is the kinematic viscosity, and f represents body forces applied to the fluid. We complete these equations with the initial condition

$$u(x, 0) = u_0(x), \tag{1.3}$$

with $u_0 : \Omega \to \mathbb{R}^2$ being given, and with the nonslip boundary condition

$$u = 0 \quad \text{on } \partial\Omega. \tag{1.4}$$

In the notation described below, system (1.1)–(1.4) can be written as the functional evolution equation

$$u_t + \nu Au + B(u, u) = f, \quad u(0) = u_0. \tag{1.5}$$

In the two-dimensional case under consideration, the solution to the Navier–Stokes equations is known to be smooth for all time (cf. [13]). The velocity u is bounded uniformly for all time by

$$|u(t)|^2_{L^2(\Omega)^2} \le \mathrm{e}^{-\nu\lambda_1 t}|u_0|^2_{L^2(\Omega)^2} + c\big(1 - \mathrm{e}^{-\nu\lambda_1 t}\big)|f|^2_{L^\infty(\mathbb{R}_+;L^2(\Omega)^2)}, \tag{1.6}$$

where λ_1 is the first eigenvalue of the Stokes operator A, and we have assumed that $f \in L^\infty(\mathbb{R}_+; L^2(\Omega)^2)$. Furthermore, using techniques based on the uniform Gronwall

lemma (cf. [12]), one can bound u uniformly in $H_0^1(\Omega)$ for all $t \geq 0$ by a function which depends on the initial condition

$$|u(t)|^2_{H_0^1(\Omega)^2} \leq K(|u_0|_{H_0^1(\Omega)^2}, |f|_{L^\infty(\mathbb{R}_+;L^2(\Omega)^2)}). \tag{1.7}$$

This dependence on the initial data can be dropped when one considers sufficiently large time, $t \geq T_c(|u_0|_{L^2(\Omega)^2}, |f|_{L^\infty(\mathbb{R}_+;L^2(\Omega)^2)})$, giving

$$|u(t)|^2_{H_0^1(\Omega)^2} \leq K(|f|_{L^\infty(\mathbb{R}_+;L^2(\Omega)^2)}) \quad \forall\, t \geq T_c. \tag{1.8}$$

In this paper we consider a time discretization of (1.5) using the fully implicit Euler scheme

$$\frac{u^n - u^{n-1}}{k} + \nu A u^n + B(u^n, u^n) = f^n, \quad u^0 = u_0, \tag{1.9}$$

where

$$f_n = \frac{1}{\Delta t} \int_{(n-1)\Delta t}^{n\Delta t} f(t)\, dt, \tag{1.10}$$

and seek to obtain similar bounds on $|u^n|_{H_0^1(\Omega)^2}$.

Before we proceed further, we note that a related result for the linearized implicit Euler scheme

$$\frac{u^n - u^{n-1}}{k} + \nu A u^n + B(u^{n-1}, u^n) = f^n, \quad u^0 = u_0, \tag{1.11}$$

is proved in [7]. A different approach for the linearized implicit Euler scheme for the case without forcing term appears in [3].

Important background information on different computational methods can be found in some of the books and articles available in the literature. On finite elements, see, e.g., [4], [6]; on finite differences and finite elements, [9], [13]; on spectral methods, [1], [5].

For the mathematical setting of the problem, we consider the following spaces:

$$V = \{v \in H_0^1(\Omega)^2, \operatorname{div} v = 0\}, \tag{1.12}$$

$$H = \{v \in L^2(\Omega)^2, \operatorname{div} v = 0,\ v \cdot n = 0 \text{ on } \partial\Omega\}, \tag{1.13}$$

where n is the unit outward normal on $\partial\Omega$. The space V is endowed with the scalar product

$$((u, v)) = \sum_{i,j=1}^{2} \int_\Omega \frac{\partial u_i}{\partial x_j}(x) \frac{\partial v_i}{\partial x_j}(x)\, dx \tag{1.14}$$

and with the corresponding norm

$$\|u\| = ((u, u))^{1/2}, \tag{1.15}$$

and H is endowed with the scalar product and the norm of $L^2(\Omega)^2$, denoted by $(\cdot, \cdot)$ and $|\cdot|$.

We denote by A the linear continuous operator from V into V' such that

$$\langle Au, v\rangle_{V',V} = ((u, v)) \quad \forall\, u, v \in V. \tag{1.16}$$

The domain of A in H is denoted by $D(A)$ and, using the regularity theory for the Stokes equation (see, for instance, [13]), one can show that

$$D(A) = H^2(\Omega)^2 \cap V. \tag{1.17}$$

We have the following inclusions:

$$D(A) \subset V \subset H, \tag{1.18}$$

and the so-called Poincaré inequality holds true:

$$|u| \le \frac{1}{\sqrt{\lambda_1}} \|u\| \quad \forall\, u \in V, \tag{1.19}$$

where $\lambda_1 > 0$ is the first eigenvalue of the Stokes operator A.

As is well known, the form (1.5) of the Navier–Stokes equations was derived by Leray [8], using the weak formulation of the Navier–Stokes equations. The latter is obtained by multiplying (1.1) by a test function $v \in V$ and integrating by parts over Ω, using Green's formula, viz.,

$$\frac{d}{dt}(u(t), v) + \nu((u(t), v)) + b(u(t), u(t), v) = (f(t), v) \quad \forall\, v \in V, \tag{1.20}$$

where

$$b(u, v, w) = \sum_{i,j=1,2} \int_\Omega u_i(x) \frac{\partial v_j}{\partial x_i}(x) w_j(x)\, dx. \tag{1.21}$$

The form b is trilinear continuous on $H^1(\Omega)^2$ and enjoys the following properties:

$$|b(u, v, w)| \le c_b |u|^{1/2} |Au|^{1/2} \|v\| |w| \quad \forall\, u \in D(A),\ v \in V,\ w \in H, \tag{1.22}$$

$$|b(u, v, w)| \le c_b |u|^{1/2} \|u\|^{1/2} \|v\| |w|^{1/2} \|w\|^{1/2} \quad \forall\, u, v, w \in V, \tag{1.23}$$

$$b(u, v, v) = 0 \quad \forall\, u, v \in V, \tag{1.24}$$

the last equation implying

$$b(u, v, w) = -b(u, w, v) \quad \forall\, u, v, w \in V. \tag{1.25}$$

Using b, we define the bilinear operator B from $V \times V$ into V' by

$$\langle B(u, v), w \rangle_{V',V} = b(u, v, w) \quad \forall\, u, v, w \in V. \tag{1.26}$$

For more details about the functional spaces $D(A)$, V, and H as well as the operators A, B, and b, the reader is referred to, e.g., [2], [11], and [13].

2. H^1 stability and the main result. Throughout the paper, we assume that $f \in L^\infty(\mathbb{R}_+; H)$ and we set $|f|_\infty := |f|_{L^\infty(\mathbb{R}_+;H)}$. We adopt the following convention: c_i denotes constants that depend only on the parameters such as λ_1, ν, etc.; K_i depend in addition on $u(t_*)$ at some specified time t_* and on the forcing f; κ_i are bounds on the timestep k and may depend on u_0 and f.

In proving the main result, we will need a couple of preliminary lemmas. We begin with an analogue of (1.6), proved in almost the same way (see, e.g., [12, p. 109]).

LEMMA 2.1. *For every $k > 0$, we have*

$$|u^n|^2 \le (1+\nu\lambda_1 k)^{-n}|u_0|^2 + [1-(1+\nu\lambda_1 k)^{-n}]\frac{|f|_\infty^2}{\nu^2\lambda_1^2} \quad \forall\, n \ge 0, \tag{2.1}$$

and there exists $K_1 = K_1(|u_0|, |f|_\infty)$ such that

$$|u^n|^2 \le K_1 \quad \forall\, n \ge 0, \tag{2.2}$$

and

$$\nu \sum_{j=i}^{n} k\|u^j\|^2 \le K_1 + (n-i+1)k\,\frac{|f|_\infty^2}{\nu\lambda_1} \quad \forall\, i = 1, \dots, n. \tag{2.3}$$

Proof. Taking the scalar product of (1.9) with $2ku^n$ in H and using the relation

$$2(\varphi-\psi,\varphi) = |\varphi|^2 - |\psi|^2 + |\varphi-\psi|^2 \quad \forall \varphi,\psi \in H, \tag{2.4}$$

and the skew property (1.24), we obtain

$$|u^n|^2 - |u^{n-1}|^2 + |u^n - u^{n-1}|^2 + 2\nu k\|u^n\|^2 = 2k(f^n, u^n). \tag{2.5}$$

Using the Cauchy–Schwarz inequality and the Poincaré inequality (1.19), we majorize the right-hand side of (2.5) by

$$2k|f^n||u^n| \le \frac{2k}{\sqrt{\lambda_1}}|f^n|\|u^n\| \le \nu k\|u^n\|^2 + \frac{k}{\nu\lambda_1}|f^n|^2. \tag{2.6}$$

Relations (2.5) and (2.6) imply

$$|u^n|^2 - |u^{n-1}|^2 + |u^n - u^{n-1}|^2 + \nu k\|u^n\|^2 \le \frac{k}{\nu\lambda_1}|f^n|^2. \tag{2.7}$$

Using again the Poincaré inequality (1.19), we find from (2.7)

$$|u^n|^2 \le \frac{1}{\alpha}|u^{n-1}|^2 + \frac{k}{\alpha\nu\lambda_1}|f^n|^2, \tag{2.8}$$

where

$$\alpha = 1 + \nu\lambda_1 k. \tag{2.9}$$

Using (2.8) recursively, we find

$$\begin{aligned} |u^n|^2 &\le \frac{1}{\alpha^n}|u^0|^2 + \frac{k}{\nu\lambda_1}\sum_{i=1}^{n}\frac{1}{\alpha^i}|f^{n+1-i}|^2 \\ &\le (1+\nu\lambda_1 k)^{-n}\,|u_0|^2 + \frac{|f|_\infty^2}{\nu^2\lambda_1^2}[1-(1+\nu\lambda_1 k)^{-n}], \end{aligned} \tag{2.10}$$

which proves (2.1); (2.1) easily implies (2.2) with

$$K_1(|u_0|, |f|_\infty) := |u_0|^2 + \frac{1}{\nu^2\lambda_1^2}|f|_\infty^2. \tag{2.11}$$

Now adding up (2.7) with n from i to m and dropping some terms, we find

$$\begin{aligned}\nu k \sum_{j=i}^{m} \|u^j\|^2 &\le |u^{i-1}|^2 + \frac{k}{\nu\lambda_1} \sum_{j=i}^{m} |f^j|^2 \\ &\le K_1 + \frac{|f|_\infty^2}{\nu\lambda_1}(m-i+1)k,\end{aligned} \tag{2.12}$$

which is just (2.3) with n in place of m. ∎

Corollary 2.2. *If*

$$0 < k \le \frac{1}{\nu\lambda_1} =: \kappa_1, \tag{2.13}$$

then

$$|u^n|^2 \le 2\rho_0^2 \quad \forall\, nk \ge T_0(|u_0|, |f|_\infty) := \frac{4}{\nu\lambda_1} \ln\left(\frac{|u_0|}{\rho_0}\right), \tag{2.14}$$

where $\rho_0 := |f|_\infty/(\nu\lambda_1)$.

Proof. From the bound (2.1) on $|u^n|^2$, we infer that

$$|u^n|^2 \le \big(1 + \nu\lambda_1 k\big)^{-n} |u_0|^2 + \rho_0^2,$$

and using assumption (2.13) on k and the fact that $1 + x \ge \exp(x/2)$ if $x \in (0,1)$, we obtain

$$|u^n|^2 \le \exp\Big(-nk\frac{\nu\lambda_1}{2}\Big)|u_0|^2 + \rho_0^2.$$

For $nk \ge T_0$, the above inequality implies conclusion (2.14) of the corollary. ∎

We now seek to obtain uniform bounds on u^n in V similar to those obtained in H (see (2.2)). To this end, we first derive bounds on a finite interval of time (see Proposition 2.5). We then repeatedly use these together with (a discrete uniform Gronwall) Lemma 2.6 on successive intervals to arrive at the desired uniform bounds.

We begin with some preliminary inequalities. Taking the scalar product of (1.9) with $2kAu^n$ in H, we obtain

$$\begin{aligned}&\|u^n\|^2 - \|u^{n-1}\|^2 + \|u^n - u^{n-1}\|^2 + 2\nu k|Au^n|^2 \\ &\quad + 2kb(u^n, u^n, Au^n) = 2k(f^n, Au^n).\end{aligned} \tag{2.15}$$

Using property (1.22) of the trilinear form b and recalling (2.2), we have the following bound of the nonlinear term:

$$\begin{aligned}2kb(u^n, u^n, Au^n) &\le 2\,c_b\,k\,|u^n|^{1/2}\|u^n\||Au^n|^{3/2} \\ &\le \frac{\nu k}{2}|Au^n|^2 + \frac{27c_b^4}{2\nu^3}K_1 k\|u^n\|^4.\end{aligned} \tag{2.16}$$

We bound the right-hand side of (2.15) by Cauchy–Schwarz,

$$\begin{aligned}2k(f^n, Au^n) &\le 2k|f^n||Au^n| \\ &\le \frac{\nu k}{2}|Au^n|^2 + \frac{2}{\nu}k|f^n|^2.\end{aligned} \tag{2.17}$$

Relations (2.15)–(2.17) imply

$$\|u^n\|^2 - \|u^{n-1}\|^2 + \|u^n - u^{n-1}\|^2 + \nu k|Au^n|^2 \leq \frac{27c_b^4}{2\nu^3} K_1 k \|u^n\|^4 + \frac{2}{\nu} k|f^n|^2, \tag{2.18}$$

from which we obtain

$$0 \leq c_2 K_1 k \|u^n\|^4 - \|u^n\|^2 + \|u^{n-1}\|^2 + c_3 k|f|_\infty^2\,, \tag{2.19}$$

where

$$c_2 = \frac{27c_b^4}{2\nu^3} \quad \text{and} \quad c_3 = \frac{2}{\nu}. \tag{2.20}$$

Unlike (2.7), (2.19) does not (directly) provide a useful bound for $\|u^n\|$, so we proceed to show that (2.19) does give a proper bound for $\|u^n\|$ if the timestep k is sufficiently small.

LEMMA 2.3. *Suppose that* $0 < k \leq \kappa_1$ *and assume that, for some* n*, we have*

$$c_2 K_1 k \left(K_2 \|u^{n-1}\|^2 + c_4 |f|_\infty^2\right) \leq \frac{1}{5}, \tag{2.21}$$

where $K_2(|u_0|, |f|_\infty) = 2 + 4c_b^2 K_1/\nu^2$ *and* $c_4 = 4/(\nu^2 \lambda_1)$*. Then* (2.19) *implies*

$$\|u^n\|^2 \leq \|u^{n-1}\|^2 \left[1 + c_5 K_1 k \left(\|u^{n-1}\|^2 + k|f|_\infty^2\right)\right] + c_6 k |f|_\infty^2 \tag{2.22}$$

for some constants c_5 *and* c_6*.*

Proof. Relation (2.19) implies either

$$\|u^n\|^2 \leq \frac{1 - \sqrt{\Delta_{n-1}}}{2c_2 K_1 k} \tag{2.23}$$

or

$$\|u^n\|^2 \geq \frac{1 + \sqrt{\Delta_{n-1}}}{2c_2 K_1 k}, \tag{2.24}$$

where

$$\Delta_{n-1} = 1 - 4c_2 K_1 k (\|u^{n-1}\|^2 + c_3 k |f|_\infty^2) > 0 \quad \text{by (2.13) and (2.21).} \tag{2.25}$$

We now show that (2.21) excludes (2.24). Indeed, taking the scalar product of (1.9) with $2k(u^n - u^{n-1})$ in H, we obtain

$$\begin{aligned} &2|u^n - u^{n-1}|^2 + \nu k \|u^n\|^2 - \nu k \|u^{n-1}\|^2 + \nu k \|u^n - u^{n-1}\|^2 \\ &\quad + 2k\, b(u^n, u^n, u^n - u^{n-1}) = 2k\,(f^n, u^n - u^{n-1}). \end{aligned} \tag{2.26}$$

Using properties (1.23), (1.24), and (1.25) of the trilinear form b and recalling (2.2), we bound the nonlinear term as

$$\begin{aligned} 2kb(u^n, u^n, u^n - u^{n-1}) &= -2kb(u^n, u^n, u^{n-1}) \\ &\leq 2c_b k |u^n| \|u^n\| \|u^{n-1}\| \\ &\leq \frac{\nu}{2} k \|u^n\|^2 + \frac{2c_b^2}{\nu} K_1 k \|u^{n-1}\|^2. \end{aligned} \tag{2.27}$$

We bound the right-hand side of (2.26) using Cauchy–Schwarz,

$$\begin{aligned} 2k(f^n, u^n - u^{n-1}) &\le 2k|f^n||u^n - u^{n-1}| \\ &\le \frac{2}{\sqrt{\lambda_1}} k|f^n|\|u^n - u^{n-1}\| \\ &\le \frac{\nu}{2} k\|u^n - u^{n-1}\|^2 + \frac{2}{\nu\lambda_1} k|f^n|^2. \end{aligned} \tag{2.28}$$

Relations (2.26)–(2.28) imply

$$\begin{aligned} 2|u^n - u^{n-1}|^2 + \frac{\nu}{2} k\|u^n\|^2 - \left(\nu + \frac{2c_b^2}{\nu} K_1\right) k\|u^{n-1}\|^2 \\ + \frac{\nu}{2} k\|u^n - u^{n-1}\|^2 \le \frac{2}{\nu\lambda_1} k|f^n|^2, \end{aligned} \tag{2.29}$$

from which we obtain

$$\|u^n\|^2 \le K_2\|u^{n-1}\|^2 + c_4|f|_\infty^2, \tag{2.30}$$

and using hypothesis (2.21) we find

$$2c_2K_1k\|u^n\|^2 \le 2c_2K_1k\left(K_2\|u^{n-1}\|^2 + c_4|f|_\infty^2\right) < 1, \tag{2.31}$$

which contradicts (2.24). Therefore, (2.19) implies (2.23) and hence

$$\begin{aligned} \|u^n\|^2 &\le \frac{1 - \left[1 - 4c_2K_1k\left(\|u^{n-1}\|^2 + c_3k|f|_\infty^2\right)\right]^{1/2}}{2c_2K_1k} \\ &= 2\frac{\|u^{n-1}\|^2 + c_3k|f|_\infty^2}{1 + \sqrt{1-x}}, \end{aligned} \tag{2.32}$$

where

$$x = 4c_2K_1k(\|u^{n-1}\|^2 + c_3k|f|_\infty^2).$$

Since $x \le 4/5$ by (2.21) and

$$\frac{2}{1+\sqrt{1-x}} \le 1 + \frac{x}{2} \quad \text{if} \quad 0 \le x \le \frac{4}{5},$$

relation (2.32) implies, under assumption (2.21), that

$$\|u^n\|^2 \le \left(\|u^{n-1}\|^2 + c_3k|f|_\infty^2\right)\left[1 + 2c_2K_1k\left(\|u^{n-1}\|^2 + c_3k|f|_\infty^2\right)\right]. \tag{2.33}$$

Using (2.21) once again, (2.33) immediately implies (2.22). ∎

In order to obtain estimates on a finite interval of time, we will inductively use Lemma 2.3, together with the following result, which was proved in [10] and which we repeat here for convenience.

LEMMA 2.4. *Given $k > 0$, an integer $n_* > 0$, and positive sequences ξ_n, η_n, and ζ_n such that*

$$\xi_n \le \xi_{n-1}(1 + k\eta_{n-1}) + k\zeta_n \quad \textit{for } n = 1, \dots, n_*, \tag{2.34}$$

we have, for any $n \in \{2, \dots, n_*\}$,

$$\xi_n \le \xi_0 \exp\left(\sum_{i=0}^{n-1} k\eta_i\right) + \sum_{i=1}^{n-1} k\zeta_i \exp\left(\sum_{j=i}^{n-1} k\eta_j\right) + k\zeta_n\,. \tag{2.35}$$

Proof. Using (2.34) recursively, we derive

$$\xi_n \le \xi_0 \prod_{i=0}^{n-1}(1+k\eta_i) + \sum_{i=1}^{n} k\zeta_i \prod_{j=i}^{n-1}(1+k\eta_j)$$

with the convention that $\prod_{j=\alpha}^{\beta} r_j = 1$ for $\beta < \alpha$. Using the fact that $1 + x \le \mathrm{e}^x$ for all $x \in \mathbb{R}$, the conclusion of the lemma follows. □

PROPOSITION 2.5 (estimates on a finite interval). *Let* $T > 0$ *and let* $K_3(\cdot,\cdot,\cdot)$ *be the function, monotonically increasing in all its arguments, given in* (2.47). *Suppose the timestep* k *is such that*

$$k \le \min\{\kappa_1, \kappa_2(|u_0|, |f|_\infty), \kappa_3(\|u^0\|, |f|_\infty, T)\}, \tag{2.36}$$

where κ_1 *is given by* (2.13), *and*

$$\kappa_2(|u_0|, |f|_\infty) = \frac{1}{10c_2c_4K_1|f|_\infty^2}, \tag{2.37}$$

$$\kappa_3(\|u^0\|, |f|_\infty, T) = \frac{1}{10c_2K_1K_2K_3(\|u^0\|, |f|_\infty, T)}. \tag{2.38}$$

Then (i) *relation* (2.22) *holds for all* $n = 1, \dots, N := \lfloor T/k \rfloor$, *and* (ii)

$$\|u^n\|^2 \le K_3(\|u^0\|, |f|_\infty, nk) \quad \forall\, n = 1, \dots, N := \lfloor T/k \rfloor. \tag{2.39}$$

Proof. Let $T > 0$ and k be such that hypothesis (2.36) is satisfied. We will use induction on n.

Since $\|u^0\|^2 \le K_3(\|u^0\|, |f|_\infty, 0)$, (2.37) and (2.38) imply that condition (2.21) of Lemma 2.3 is satisfied for $n = 1$,

$$c_2K_1k(K_2\|u^0\|^2 + c_4|f|_\infty^2) \le \frac{1}{10} + \frac{1}{10} \le \frac{1}{5}. \tag{2.40}$$

By the same lemma, we have

$$\|u^1\|^2 \le \|u^0\|^2\left[1 + c_5K_1k\left(\|u^0\|^2 + k|f|_\infty^2\right)\right] + c_6k|f|_\infty^2. \tag{2.41}$$

Now assume that (2.21) holds for $n = 1, \dots, m$ for some $m \le N$. Then by Lemma 2.3, (2.22) holds for $n = 1, \dots, m$; furthermore, we can bound $\|u^m\|$ as follows. We write the stepwise bound (2.22) in Lemma 2.3 in the form

$$\xi_n \le \xi_{n-1}(1 + k\eta_{n-1}) + k\zeta, \tag{2.42}$$

where

$$\xi_n = \|u^n\|^2, \quad \eta_n = c_5K_1(\|u^n\|^2 + k|f|_\infty^2), \quad \text{and} \quad \zeta = c_6|f|_\infty^2. \tag{2.43}$$

Our intention is to apply (the discrete Gronwall) Lemma 2.4. So we compute for $i > 0$, using (2.3),

$$\sum_{j=i}^{m-1} k\eta_j = c_5 K_1 \sum_{j=i}^{m-1} k\left(\|u^j\|^2 + k|f|_\infty^2\right) \le c_7 K_1\big[K_1 + (m-i)k|f|_\infty^2\big]; \tag{2.44}$$

similarly, for $i = 0$,

$$\sum_{j=0}^{m-1} k\eta_j = c_5 K_1 \sum_{j=0}^{m-1} k\left(\|u^j\|^2 + k|f|_\infty^2\right) \le c_7 K_1\big(K_1 + mk|f|_\infty^2\big) + c_5 K_1 k\|u^0\|^2. \tag{2.45}$$

We note that, using (2.38) and recalling that $K_2 \ge 2$, the last term can be bounded as

$$c_5 K_1 k\|u^0\|^2 \le \frac{c_5\|u^0\|^2}{10c_2K_2K_3(\|u^0\|,|f|_\infty,T)} \le \frac{c_5}{10c_2K_2}\frac{\|u^0\|^2}{K_3(\|u^0\|,|f|_\infty,0)} \le \frac{c_5}{20c_2}. \tag{2.46}$$

The middle term in (2.35) here is

$$\sum_{i=1}^{m-1} k\zeta\,\exp\left(\sum_{j=i}^{m-1} k\eta_j\right) \le c_6|f|_\infty^2 \sum_{i=1}^{m-1} k\exp(c_7K_1^2 + c_7K_1(m-i)k|f|_\infty^2) \le c_6|f|_\infty^2\exp(c_7K_1^2)mk\;\exp(c_7K_1\,mk\,|f|_\infty^2).$$

The following bound on $\|u^m\|^2$ then follows from (2.35):

$$\begin{aligned}\|u^m\|^2 &\le \|u^0\|^2\exp(c_7K_1\,|f|_\infty^2\,mk)\;\exp(c_7K_1^2 + c_5/(20c_2))\\ &\quad + 2c_6|f|_\infty^2\exp(c_7K_1^2)\,mk\;\exp(c_7K_1\,|f|_\infty^2\,mk)\\ &=: K_3(\|u^0\|,|f|_\infty,mk).\end{aligned} \tag{2.47}$$

We note that the bound K_3 depends on the initial discrete value through its norm $\|u^0\|$ and also on m, but this latter dependence is only through the time mk. We also note the dependence of K_3 on $|u_0|$ through K_1, but K_1 bounds all $|u^n|^2$.

It is now clear that, given the hypothesis of the proposition, the timestep k satisfies condition (2.21) as long as $m \le \lfloor T/k \rfloor$, completing the proof. ∎

Now, since Proposition 2.5 gives a bound on $\|u^n\|^2$ that is valid on a finite time interval only, we are going to extend the result to infinite time by repeatedly applying it and the following (discrete uniform Gronwall) lemma, which is a slightly more general version of the discrete uniform Gronwall lemma of Shen [10].

LEMMA 2.6. *Given $k > 0$, positive integers n_1, n_2, n_* such that $n_1 < n_*$, $n_1 + n_2 + 1 \le n_*$, positive sequences ξ_n, η_n, and ζ_n such that*

$$\xi_n \le \xi_{n-1}(1 + k\eta_{n-1}) + k\zeta_n \quad \textit{for } n = n_1, \dots, n_*, \tag{2.48}$$

and given the bounds

$$\sum_{n=n'}^{n'+n_2} k\eta_n \le a_1(n_1,n_*), \quad \sum_{n=n'}^{n'+n_2} k\zeta_n \le a_2(n_1,n_*), \quad \sum_{n=n'}^{n'+n_2} k\xi_n \le a_3(n_1,n_*) \tag{2.49}$$

for any n' satisfying $n_1 \le n' \le n_* - n_2$, we have

$$\xi_n \le \left(\frac{a_3(n_1,n_*)}{kn_2} + a_2(n_1,n_*) \right) \mathrm{e}^{a_1(n_1,n_*)} \tag{2.50}$$

for any n such that $n_1 + n_2 + 1 \le n \le n_*$.

Proof. Let n_3 and n_4 be such that $n_1 \le n_3 - 1 \le n_4 \le n_2 + n_3 - 1 \le n_* - 1$. Using (2.48) recursively, we derive

$$\xi_{n_2+n_3} \le \xi_{n_4} \prod_{i=n_4}^{n_3+n_2-1} (1+k\eta_i) + \sum_{i=n_4+1}^{n_3+n_2} k\zeta_i \prod_{j=i}^{n_2+n_3-1} (1+k\eta_j) \tag{2.51}$$

with the convention that $\prod_{j=\alpha}^{\beta} r_j = 1$ for $\beta < \alpha$. Using the fact that $1 + x \le \mathrm{e}^x$ for all $x \in \mathbb{R}$, and recalling the first two assumptions in (2.49), we obtain

$$\xi_{n_2+n_3} \le (\xi_{n_4} + a_2) e^{a_1}.$$

Multiplying this inequality by k, summing n_4 from $n_3 - 1$ to $n_2 + n_3 - 2$, and using the third assumption in (2.49) gives the conclusion (2.50) of the lemma. ∎

We are now in a position to give the main result, that is, to derive a uniform bound for $\|u^n\|$ for all $n \ge 1$.

THEOREM 2.7. *Let $u_0 \in V$, $f \in L^\infty(\mathbb{R}_+; H)$, and u^n be the solution of the numerical scheme* (1.9)*. Also, let $r \ge 4\kappa_1$ be arbitrarily fixed and let k be such that*

$$k \le \min\{\kappa_1, \kappa_2(|u_0|, |f|_\infty), \kappa_3(\|u_0\|, |f|_\infty, T_0 + r), \kappa_3(\rho_1, |f|_\infty, r)\}, \tag{2.52}$$

where $\kappa_1 = 1/(\nu\lambda_1)$ was defined in (2.13)*, $\kappa_2(\cdot,\cdot)$ and $\kappa_3(\cdot,\cdot,\cdot)$ are given in Proposition* 2.5*, T_0, the time of entering an absorbing ball for $|u^n|$, is given by* (2.14)*, and $\rho_1(|f|_\infty, r)$ is given in* (2.57)*.*

Then we have

$$\|u^n\|^2 \le K_5(\|u_0\|, |f|_\infty) \quad \forall\, n \ge 1, \tag{2.53}$$

where $K_5(\cdot,\cdot)$ is a continuous function defined on $\mathbb{R}^2_+$, increasing in both arguments. Moreover,

$$\|u^n\|^2 \le K_4(|f|_\infty) \quad \forall\, n \ge N_0 + N_r := \lfloor T_0/k \rfloor + \lfloor r/k \rfloor, \tag{2.54}$$

i.e., $\|u^n\|$ is bounded independently of u_0 beyond $N_0 + N_r$.

Proof. Let $r \ge 4\kappa_1$ be arbitrarily fixed and let k be such that (2.52) holds.

The idea for deriving a uniform bound for $\|u^n\|^2$ for all $n \ge 1$ is as follows:

(i) Applying first Proposition 2.5 on $(0, T_0 + r)$ (that is, for $n = 1, \ldots, N_0 + N_r$), we get an upper bound for $\|u^n\|$ for $n = 1, \ldots, N_0 + N_r$; applying Lemma 2.6, we show that $\|u^{N_0+N_r}\|^2 \le \rho_1^2$, where $\rho_1(|f|_\infty, r)$ is defined in (2.57).

(ii) Iterating Proposition 2.5 and Lemma 2.6, at each step $i \ge 2$, we show that for all $n = N_0 + (i-1)N_r + 1, \ldots, N_0 + iN_r$, $\|u^n\|^2$ is bounded by $K_3(\|u^{N_0+(i-1)N_r}\|,$

$|f|_\infty, r)$; using the estimate on $\|u^{N_0+(i-1)N_r}\|$ from the previous step, we obtain that $\|u^n\|^2$ is bounded independently of the initial value for all $n = N_0 + (i-1)N_r + 1, \dots, N_0 + iN_r$ for every $i \geq 2$ (and thus for all $n \geq N_0 + N_r$).

We now proceed to give a rigorous proof of the theorem.

Noting that, by hypothesis, k satisfies condition (2.36) of Proposition 2.5 with $T = T_0 + r$, we first apply Proposition 2.5 and obtain that (2.22) holds for all $n = 1, \dots, N_0 + N_r$, and

$$\|u^n\|^2 \leq K_3(\|u^0\|, |f|_\infty, nk) \quad \forall\, n = 1, \dots, N_0 + N_r. \tag{2.55}$$

At this point we know that for k satisfying hypothesis (2.52),

$$\|u^n\|^2 \leq \|u^{n-1}\|^2[1 + c_5K_1k(\|u^{n-1}\|^2 + k|f|_\infty^2)] + c_6k|f|_\infty^2 \quad \forall\, n = 1, \dots, N_0 + N_r, \tag{2.56}$$

and we apply (the discrete uniform Gronwall) Lemma 2.6 with $\xi_n = \|u^n\|^2$, $\eta_n = c_5K_1(\|u^n\|^2 + k|f|_\infty^2)$, $\zeta_n = c_6|f|_\infty^2$, $n_1 = N_0 + 1$, $n_2 = N_r - 2$, and $n_* = N_0 + N_r$ to obtain a bound for $\|u^{N_0+N_r}\|$. In computing the sums $a_1(n_1, n_*)$, $a_2(n_1, n_*)$, and $a_3(n_1, n_*)$ that appear there, we note that since all those sums are taken for $n \geq N_0$ and since, by hypothesis, k satisfies condition (2.13) of Corollary 2.2, we can replace K_1, the bound on $|u^n|^2$, by $2\rho_0^2$, whenever the former appears. For every $n' = N_0 + 1, N_0 + 2$, we compute, using (2.3) and (2.14) for the first and last lines,

$$2c_5\rho_0^2 \sum_{n=n'}^{n'+n_2} \big(k\|u^n\|^2 + k^2|f|_\infty^2\big) \leq c_8\rho_0^2(\rho_0^2 + r|f|_\infty^2),$$

$$c_6 \sum_{n=n'}^{n'+n_2} k|f|_\infty^2 \leq c_6\, r|f|_\infty^2,$$

$$\sum_{n=n'}^{n'+n_2} k\|u^n\|^2 \leq c_9(\rho_0^2 + r|f|_\infty^2).$$

Using the conclusion (2.50) of Lemma 2.6 and the fact that $r \geq 4\kappa_1$, we obtain

$$\begin{aligned} \|u^{N_0+N_r}\|^2 &\leq \big[2c_9\big(\rho_0^2/r + |f|_\infty^2\big) + c_6\, r|f|_\infty^2\big] \exp\big(c_8\rho_0^2(\rho_0^2 + r|f|_\infty^2)\big) \\ &=: \rho_1(|f|_\infty; r)^2. \end{aligned} \tag{2.57}$$

Now, since by hypothesis $k \leq \kappa_3(\rho_1, |f|_\infty, r)$ and since $\kappa_3(\cdot,\cdot,\cdot)$ is a decreasing function of its arguments, we can regard $u^{N_0+N_r}$ as our initial data and apply Proposition 2.5 with $T = r$. We obtain that relation (2.22) holds for all $n = N_0 + N_r + 1, \dots, N_0 + 2N_r$, and

$$\|u^n\|^2 \leq K_3(\|u^{N_0+N_r}\|, |f|_\infty, N_rk) \quad \forall\, n = N_0 + N_r + 1, \dots, N_0 + 2N_r. \tag{2.58}$$

Thanks to (2.57) and to the fact that $K_3(\cdot,\cdot,\cdot)$ is an increasing function of all its arguments, we have

$$\|u^n\|^2 \leq K_3(\rho_1, |f|_\infty, N_rk) \quad \forall\, n = N_0 + N_r + 1, \dots, N_0 + 2N_r. \tag{2.59}$$

Applying again Lemma 2.6 with $n_1 = N_0 + N_r + 1$, $n_2 = N_r - 2$, and $n_* = N_0 + 2N_r$, we obtain

$$\|u^{N_0+2N_r}\|^2 \leq \rho_1^2\,. \tag{2.60}$$

Iterating Proposition 2.5 and Lemma 2.6 and reasoning as above, we arrive at

$$\|u^n\|^2 \le K_3(\rho_1, |f|_\infty, r) =: K_4(|f|_\infty) \quad \forall\, n \ge N_0 + N_r, \tag{2.61}$$

and recalling (2.55), we conclude

$$\begin{aligned} \|u^n\|^2 &\le \max\{K_3(\|u_0\|, |f|_\infty, T_0 + r), K_4(|f|_\infty)\} \\ &=: K_5(\|u_0\|, |f|_\infty) \quad \forall\, n \ge 1, \end{aligned} \tag{2.62}$$

thus proving the theorem. □

ON THE PROBLEM OF TESTING THE STRUCTURE OF A MATRIX BY DISPLACEMENT OPERATIONS*

ALBRECHT BÖTTCHER†

Abstract. This paper deals with the problem of testing whether a large matrix X has a prescribed structure by looking at the magnitude of a displacement matrix $D(X)$ associated with the structure. We provide parameters on the basis of which one can judge whether the problem is well-conditioned or ill-conditioned. It turns out that even for very general structures it is the minimal eigenvalues of positive definite and banded Toeplitz matrices that are the most important of these parameters.

Key words. structured matrix, displacement matrix, conditioning, computer verification, Toeplitz matrix, Toeplitz-plus-Hankel, extreme eigenvalues

DOI. 10.1137/040620035

1. Introduction.

Assume our machine has computed and stored an $n \times n$ matrix $X = (x_{ij})_{i,j=1}^n$ and we want to know whether it is a Toeplitz matrix. We could proceed as follows. We let U be the $n \times n$ forward-shift matrix,

$$U = \begin{pmatrix} 0 & 0 & 0 & \cdots & 0 & 0 \\ 1 & 0 & 0 & \cdots & 0 & 0 \\ 0 & 1 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 & 0 \end{pmatrix},$$

and we compute the so-called displacement matrix $XU - UX$, which equals

$$\begin{pmatrix} x_{12} & x_{13} & \cdots & x_{1,n-1} & 0 \\ x_{22} - x_{11} & x_{23} - x_{12} & \cdots & x_{2n} - x_{1,n-1} & -x_{1n} \\ x_{32} - x_{21} & x_{33} - x_{22} & \cdots & x_{3n} - x_{2,n-1} & -x_{2n} \\ \vdots & \vdots & & \vdots & \vdots \\ x_{n2} - x_{n-1,1} & x_{n3} - x_{n-1,2} & \cdots & x_{nn} - x_{n-1,n-1} & -x_{n-1,n} \end{pmatrix}.$$

(This and more general displacement matrices $XU - VX$ were employed in [6, 9] for other purposes.) Let $D(X)$ denote the lower-left $(n-1) \times (n-1)$ submatrix of $XU - UX$. Clearly, X is Toeplitz if and only if $D(X)$ is the zero matrix. As testing whether a numerically computed quantity equals zero is a critical issue, we test whether $D(X)$ is small, say whether $\|D(X)\|_2 < \varepsilon$, where $\|\cdot\|_2$ denotes the Frobenius norm. Does this imply that X is close to a Toeplitz matrix?

We will show that the answer is in the negative theoretically but gives rise to optimism practically.

†Fakultät für Mathematik, Technische Universität Chemnitz, 09107 Chemnitz, Germany (aboettch@mathematik.tu-chemnitz.de).

Let us consider an explicit example. Put $\omega_n = \exp(2\pi i/n)$, $x_j = \omega_n^j$, and $X = \operatorname{diag}(x_1, \dots, x_n)$. Then

$$\begin{aligned}\|D(X)\|_2^2 &= |x_1 - x_2|^2 + |x_2 - x_3|^2 + \cdots + |x_{n-1} - x_n|^2 \\ &= (n-1)|\omega_n - 1|^2 = 4(n-1)\sin^2\frac{\pi}{n}.\end{aligned}$$

Let $\mathcal{T}_n$ be the set of all $n \times n$ Toeplitz matrices. It is easily seen that

$$\operatorname{dist}_2^2(X, \mathcal{T}_n) := \min_{T \in \mathcal{T}_n} \|X - T\|_2^2 = \sum_{j=1}^n \left| x_j - \frac{1}{n}\sum_{k=1}^n x_k \right|^2.$$

Since $\sum x_k = 0$, it follows that $\operatorname{dist}_2^2(X, \mathcal{T}_n) = \sum |x_j|^2 = n$. Consequently, if n is large, then $\|D(X)\|_2$ is small and $\operatorname{dist}_2(X, \mathcal{T}_n)$ is large. This is what we mean by saying that theoretically the answer to the above question is in the negative.

On the other hand, we will prove the following two theorems. Let $\mathbf{K}$ stand for $\mathbf{R}$ or $\mathbf{C}$ and $M_n(\mathbf{K})$ for the $n \times n$ matrices with entries in $\mathbf{K}$. We equip $M_n(\mathbf{K})$ with the Frobenius norm. Further let $\mathcal{T}_n(\mathbf{K})$ denote the set of all Toeplitz matrices in $M_n(\mathbf{K})$. The probability of an event E will be denoted by $P(E)$.

THEOREM 1.1. *We have*

$$\max_{X \notin \mathcal{T}_n(\mathbf{K})} \frac{\operatorname{dist}_2(X, \mathcal{T}_n(\mathbf{K}))}{\|D(X)\|_2} = \frac{1}{2\sin\frac{\pi}{2n}} \sim \frac{n}{\pi}.$$

THEOREM 1.2. *Take X randomly from the unit sphere of $M_n(\mathbf{K})$ with the uniform distribution. Put $\operatorname{dist}_2(X, \mathcal{T}_n(\mathbf{K}))/\|D(X)\|_2 = 0$ if $\|D(X)\|_2 = 0$. Then*

$$P\left(\frac{\operatorname{dist}_2(X, \mathcal{T}_n(\mathbf{K}))}{\|D(X)\|_2} > 10\right) < \frac{13}{n^2} \quad \textit{for} \quad n \geq 10.$$

Theorem 1.1 reveals that if $\|D(X)\|_2 = \varepsilon$, then $\operatorname{dist}_2(X, \mathcal{T}_n(\mathbf{K}))$ is at most about $n\varepsilon/\pi$. This linear growth prevents $n\varepsilon/\pi$ from becoming an astronomic number if ε and n are appropriately adapted. Moreover, Theorem 1.2 tells us that the worst-case situation of Theorem 1.1 is a very rare event for matrices of large sizes. These two conclusions make precise our statement that practically and optimistically the answer to the question raised above is in the affirmative.

The paper is organized as follows. In section 2, we pose and study the problem in the general setting. Section 3 is devoted to what we call string structures. Several concrete string structures are then examined in sections 4–7. In sections 8 and 9, we tackle the Toeplitz-plus-Hankel structure with two different tools. The conclusions are formulated in section 10.

2. The general setting. We assume that the matrix structure we are interested in can be characterized by at most n^2 linear equations for the entries of the matrix. Thus, let $D : M_n(\mathbf{K}) \to M_n(\mathbf{K})$ be a linear operator. We put $\operatorname{Ker} D = \{Y \in M_n(\mathbf{K}) : D(Y) = 0\}$. Given $X \in M_n(\mathbf{K})$, we define $\operatorname{dist}_2(X, \operatorname{Ker} D)$ as $\min_{Y \in \operatorname{Ker} D} \|X - Y\|_2$. We want to determine

$$\max_{X \notin \operatorname{Ker} D} \frac{\operatorname{dist}_2(X, \operatorname{Ker} D)}{\|D(X)\|_2}, \tag{2.1}$$

where $X \notin \operatorname{Ker} D$ is an abbreviation for $X \in M_n(\mathbf{K}) \setminus \operatorname{Ker} D$. Notice that in section 1, $D(X)$ was an $(n-1) \times (n-1)$ matrix. Extending this matrix by a zero row and a zero column we obtain an $n \times n$ matrix, which puts us into the present context.

It will be convenient to change language slightly. Namely, let $i_1 : M_n(\mathbf{K}) \to \mathbf{K}^{n^2}$ and $i_2 : M_n(\mathbf{K}) \to \mathbf{K}^{n^2}$ be two stackings of the entries of matrices in $M_n(\mathbf{K})$ to columns of length n. The concrete choice of i_1 and i_2 may depend on D. Clearly, there is a unique linear operator $\nabla : \mathbf{K}^{n^2} \to \mathbf{K}^{n^2}$ such that $D = i_2^{-1} \circ \nabla \circ i_1$. We freely identify ∇ with an $n^2 \times n^2$ matrix. The Frobenius norm on $M_n(\mathbf{K})$ becomes the ℓ^2 norm $\|\cdot\|$ on $\mathbf{K}^{n^2}$, and for $x \in \mathbf{K}^{n^2}$ and a closed subset F of $\mathbf{K}^{n^2}$ we define $\operatorname{dist}(x, F) = \min_{f \in F} \|x - f\|$. Obviously, (2.1) coincides with

$$\max_{x \notin \operatorname{Ker} \nabla} \frac{\operatorname{dist}(x, \operatorname{Ker} \nabla)}{\|\nabla x\|}. \tag{2.2}$$

For example, to test whether $X = (x_{ij})_{i,j=1}^3$ is of the form

$$\begin{pmatrix} a & b & a \\ b & a & c \\ a & d & a \end{pmatrix} \tag{2.3}$$

with certain numbers $a, b, c, d \in \mathbf{K}$, we may compute $\|D(X)\|_2^2$ with

$$D(X) = \begin{pmatrix} x_{11} - x_{13} & x_{13} - x_{22} & x_{22} - x_{31} \\ x_{31} - x_{33} & 0 & x_{12} - x_{21} \\ 0 & 0 & 0 \end{pmatrix}$$

or $\|\nabla x\|^2$ with

$$\nabla x = \begin{pmatrix} 1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} x_{11} \\ x_{13} \\ x_{22} \\ x_{31} \\ x_{33} \\ x_{12} \\ x_{21} \\ x_{23} \\ x_{32} \end{pmatrix}.$$

The following result is well known. It follows from the equality $I - P_{\operatorname{Ker} D} = D^+ D$, where $P_{\operatorname{Ker} D}$ is the orthogonal projection onto $\operatorname{Ker} D$ and D^+ is the Moore–Penrose inverse of D. For the reader's convenience, we cite it with a self-contained proof.

THEOREM 2.1. *If $s_{\min}^+$ is the smallest nonzero singular value of D, then*

$$\max_{X \notin \operatorname{Ker} D} \frac{\operatorname{dist}_2(X, \operatorname{Ker} D)}{\|D(X)\|_2} = \frac{1}{s_{\min}^+}. \tag{2.4}$$

Proof. We consider ∇ instead of D. Put $N = n^2$. Suppose ∇ has exactly k zero singular values and let $s_{k+1} \le \cdots \le s_N$ be the nonzero singular values. Denote by P_k and Q_k the projections on $\mathbf{K}^N$ that replace, respectively, the last $N - k$ and first k coordinates with zero. Let $\nabla = USV^*$ with $S = \operatorname{diag}(0, \ldots, 0, s_{k+1}, \ldots, s_N)$ be the singular value decomposition. Obviously, $\operatorname{Ker} \nabla = \operatorname{Ran} V P_k$, $\operatorname{Ran} \nabla^* = \operatorname{Ran} V Q_k$.

For $x \in \mathbf{K}$, put $z = V^*x$. Then $x = VP_kz + VQ_kz$ is the decomposition of x corresponding to the orthogonal decomposition $\mathbf{K}^N = \operatorname{Ker}\nabla \oplus \operatorname{Ran}\nabla^*$. It follows that $\operatorname{dist}^2(x, \operatorname{Ker}\nabla) = \|VQ_kz\|^2 = \|Q_kz\|^2$ and $\|\nabla x\|^2 = \|USVV^*Q_z\|^2 = \|SQ_kz\|^2$, which shows that (2.2) is $\|Q_kz\|/\|SQ_kz\| \le 1/s_{k+1}$, with equality for $x = V^*e_{k+1}$, where e_{k+1} is the column whose $(k+1)$st entry is 1 and whose remaining entries are zero. □

THEOREM 2.2. *Consider the random variable $\xi = \|D(X)\|^2/\operatorname{dist}_2^2(X, \operatorname{Ker}D)$, where X is drawn from the uniform distribution on the unit sphere of $M_n(\mathbf{K})$ with the ℓ^2 norm and $\|D(X)\|^2/\operatorname{dist}_2^2(X, \operatorname{Ker}D) := +\infty$ for $X \in \operatorname{Ker}D$. Suppose $\dim\operatorname{Ker}D = k < n^2$. Then the expected value $E\xi$ and the variance $\sigma^2\xi$ satisfy*

$$E\xi = \frac{\|D\|_2^2}{n^2-k}, \quad \sigma^2\xi \le \frac{2\,\|D\|_\infty^4}{n^2-k},$$

respectively, where $\|\cdot\|_\infty$ denotes the spectral norm.

Proof outline. We proceed as in [3], where the result was proved with $\|X\|_2^2$ and n^2 in place of $\operatorname{dist}_2^2(x, \operatorname{Ker}D)$ and n^2-k, respectively. Thus, we turn again to ∇, put $N = n^2$, and use the singular value distribution $\nabla = USV^*$ from the proof of Theorem 2.1. We have to compute $E(\xi^j)$ for $j = 1, 2$. For the sake of simplicity, suppose $\mathbf{K} = \mathbf{R}$. With S_N and B_N denoting the unit sphere and the unit ball of $\mathbf{R}^N$,

$$\begin{aligned}
E(\xi^j) &= \frac{1}{|S_N|}\int_{S_N} \frac{\|\nabla x\|^{2j}}{\operatorname{dist}^{2j}(x, \operatorname{Ker}\nabla)}\,d\sigma(x) = \frac{1}{|B_N|}\int_{B_N} \frac{\|\nabla x\|^{2j}}{\operatorname{dist}^{2j}(x, \operatorname{Ker}\nabla)}\,dx \\
&= \frac{1}{|B_N|}\int_{B_N} \frac{\|SV^*x\|^{2j}}{\operatorname{dist}^{2j}(x, \operatorname{Ran}VP_k)}\,dx = \frac{1}{|B_N|}\int_{B_N} \frac{\|Sy\|^{2j}}{\operatorname{dist}^{2j}(y, \operatorname{Ran}P_k)}\,dy \\
&= \frac{1}{|B_N|}\int_{B_k}\left(\int_{B_{N-k}(r_k)} \frac{(s_{k+1}^2y_{k+1}^2 + \cdots + s_N^2y_N^2)^j}{(y_{k+1}^2 + \cdots + y_N^2)^j}\,dy_{k+1}\ldots dy_N\right)dy_1\ldots dy_k,
\end{aligned}$$

where $r_k = \sqrt{1 - y_1^2 - \cdots - y_k^2}$ and $B_{N-k}(r_k)$ is the ball with the radius r_k. After the substitution $y_i = r_kz_i$ for $i = k+1, \ldots, N$, the inner integral becomes an integral over the ball of radius 1, and this integral was computed in [3]. We are left with

$$\int_{B_k} (1 - y_1^2 - \cdots - y_k^2)^{(N-k)/2} dy_1\ldots dy_k,$$

which can be shown to be $\pi^{k/2}\Gamma((N-k)/2+1)/\Gamma(N/2+1)$ (see [4, No. 676.8(a)] or [13, No. 3.3.2.1]). Putting all pieces together we arrive at the asserted formulas for $E\xi$ and $\sigma^2\xi = E(\xi^2) - (E\xi)^2$. □

COROLLARY 2.3. *Under the hypothesis of Theorem 2.2,*

$$P\left(\frac{\operatorname{dist}_2(X, \operatorname{Ker}D)}{\|D(X)\|_2} > \frac{1}{\varepsilon}\right) \le \frac{2(n^2-k)\|D\|_\infty^4}{(\|D\|_2^2 - (n^2-k)\varepsilon^2)^2}$$

whenever $0 < \varepsilon^2 < \|D\|_2^2/(n^2-k)$.

Proof. The probability in question is $P(\xi < \varepsilon^2) \le P(|\xi - E\xi| > E\xi - \varepsilon^2)$, and Chebyshev's inequality along with Theorem 2.2 shows that the last probability does not exceed

$$\frac{\sigma^2\xi}{(E\xi - \varepsilon^2)^2} \le \frac{2}{n^2-k}\,\frac{\|D\|_\infty^4}{(\|D\|_2^2/(n^2-k) - \varepsilon^2)^2}.$$ □

3. String structures. We start with a partition

$$\{1,\dots,n\}\times\{1,\dots,n\} = L_1\cup\cdots\cup L_M \tag{3.1}$$

of the index set into pairwise disjoint sets $L_1,\dots,L_M$, called strings, and an ordering of the elements of each string. The number of elements in L_m will be denoted by ℓ_m. We further associate a polynomial

$$a_m(x) = a_0^{(m)} + a_1^{(m)}x + \cdots + a_{r_m}^{(m)}x^{r_m} \tag{3.2}$$

with each string and require that $0\le r_m\le \ell_m - 1$. For a matrix $X=(x_{ij})_{i,j=1}^n$, we label the entries with indices in L_m by $x_1^{(m)},\dots,x_{\ell_m}^{(m)}$ (following the ordering of L_m). We say that X has the string structure specified by (3.1) and (3.2) (and the selected orderings in the strings) if the entries of X satisfy the difference equations

$$a_0^{(m)}x_k^{(m)} + a_1^{(m)}x_{k+1}^{(m)} + \cdots + a_{r_m}^{(m)}x_{k+r_m}^{(m)} = 0 \quad (k=1,\dots,\ell_m - r_m) \tag{3.3}$$

for each m. To test whether a given matrix X has this structure, we compute

$$\sum_{m=1}^{M}\sum_{k=1}^{\ell_m - r_m}\left|a_0^{(m)}x_k^{(m)} + a_1^{(m)}x_{k+1}^{(m)} + \cdots + a_{r_m}^{(m)}x_{k+r_m}^{(m)}\right|^2 \tag{3.4}$$

and check whether this is smaller than ε^2. The number of left-hand sides of (3.3) (= the number of terms in sum (3.4)) is $\sum_{m=1}^M(\ell_m - r_m) = n^2 - \sum_{m=1}^M r_m \le n^2$. We denote by $D : M_n(\mathbf{K})\to M_n(\mathbf{K})$ any linear operator that computes the left-hand sides of (3.3) and arranges them in an $n\times n$ matrix, setting the remaining entries of the matrix zero if $\sum r_m\ge 1$. Clearly, (3.4) is just $\|D(X)\|_2^2$.

Example 3.1. Let $L_m = \{(i,j) : i-j = m\}$, $m = -(n-1),\dots,n-1$. The circumstance that the strings are not labeled from 1 to $2n-1$ but from $-(n-1)$ to $n-1$ clearly causes no problems. We order the indices (i,j) in L_m by increasing i. The structure obtained in this way requires that the entries of a matrix satisfy a difference equation along each diagonal of the matrix. For $r_m = 0$ and $a_0^{(m)} = 0$, this is no requirement. If $r_m = 0$ and $a_0^{(m)} = 1$ for all m, then the only matrix with the structure is the zero matrix. In the case where $r_m = 1$ and $a_m(x) = 1-x$ for all m, we arrive at the set of all Toeplitz matrices. In the case where $r_m = 2$ and $a_m(x) = 1-2x+x^2$ for all m, we have the set of all matrices whose entries on each diagonal form an arithmetic progression. The case where $r_m = 1$ and $a_m(x) = \alpha_m - x$ for all m corresponds to the matrices whose entries on the mth diagonal are $c_m, c_m\alpha_m,\dots,c_m\alpha_m^{n-|m|-1}$ with some $c_m\in\mathbf{K}$.

Example 3.2. The choice $L_m = \{(i,j) : i+j = m\}$, $m = 2,\dots,2n$, produces structures of the Hankel type. With $a_m(x) = 1-x$ for all m, we obtain the pure Hankel matrices. Letting $L_1 = \{(i,j) : i+j \text{ is odd}\}$ and $L_2 = \{(i,j) : i+j \text{ is even}\}$ we get chessboard structures. Pure chessboard matrices result from $a_1(x) = a_2(x) = 1-x$. The class of matrices of the form cI is characterized by the partition

$$\{1,\dots,n\}\times\{1,\dots,n\} = \{(1,1),\dots,(n,n)\}\cup\bigcup_{i\ne j}\{(i,j)\}$$

with the polynomial $1-x$ on $\{(1,1),\dots,(n,n)\}$ and the polynomial 1 on the singletons $\{(i,j)\}$. The lower-triangular matrices arise from

$$\{1,\dots,n\}\times\{1,\dots,n\} = \{(i,j) : i\ge j\}\cup\bigcup_{i<j}\{(i,j)\},$$

the zero polynomial on $\{(i,j) : i \ge j\}$, and the polynomial 1 on the singletons $\{(i,j)\}$ with $i < j$. Finally, for matrices of the form (2.3) the partition of $\{1,2,3\} \times \{1,2,3\}$ into strings is $\{(1,1),(1,3),(2,2),(3,1),(3,3)\} \cup \{(1,2),(2,1)\} \cup \{(2,3)\} \cup \{(3,2)\}$, and the polynomials are $1-x$ on the strings of lengths 5 and 2 and are the zero polynomials on the two singletons.

Given polynomial (3.2), we define the function b_m on the complex unit circle $\mathbf{T}$ by $b_m(t) = |a_m(t)|^2$ $(t \in \mathbf{T})$ and expand b_m into its Fourier series,

$$b_m(t) = \sum_{k=-r_m}^{r_m} b_k^{(m)} t^k \quad (t = e^{i\theta} \in \mathbf{T}).$$

We denote by $T(b_m)$ the infinite Toeplitz matrix $(b_{i-j}^{(m)})_{i,j=1}^{\infty}$ and by $T_R(b_m)$ the principal $R \times R$ section $(b_{i-j}^{(m)})_{i,j=1}^{R}$ of $T(b_m)$. The matrices $T_R(b_m)$ are all positive definite. We denote by $\lambda_{\min}(T_R(b_m))$ and $\lambda_{\max}(T_R(b_m))$ the minimal and maximal eigenvalues of $T_R(b_m)$, respectively.

Theorem 2.1 and Corollary 2.3 allow us to compute the maximum of (2.1) and to estimate stochastically the ratio occurring in (2.1) in terms of the quantities $s_{\min}^+$, $\|D\|_2^2$, and $\|D\|_\infty^2$. The following result provides us with these quantities in the case of string structures.

THEOREM 3.3. *For every string structure,*

$$\left(s_{\min}^+\right)^2 = \min_{1 \le m \le M} \lambda_{\min}(T_{\ell_m - r_m}(b_m)),$$

$$\|D\|_2^2 = \sum_{m=1}^{M} (\ell_m - r_m) \sum_{k=1}^{r_m} |a_k^{(m)}|^2, \quad \|D\|_\infty^2 = \max_{1 \le m \le M} \lambda_{\max}(T_{\ell_m - r_m}(b_m)).$$

Proof. After stacking matrices in $M_n(\mathbf{K})$ string by string (and following the ordering within the strings) to columns in $\mathbf{K}^{n^2}$, the operator D becomes an $n^2 \times n^2$ block diagonal matrix $\nabla = \operatorname{diag}(B_1, \ldots, B_M)$ with $\ell_m \times \ell_m$ matrices B_m. The first $\ell_m - r_m$ rows of B_m are the $(\ell_m - r_m) \times \ell_m$ Toeplitz matrix whose first row is $(a_0^{(m)}, a_1^{(m)}, \ldots, a_{r_m}^{(m)}, 0, \ldots, 0)$ and whose first column is $(a_0^{(m)}, 0, \ldots, 0)^\top$. The last r_m rows of B_m are zero. This implies the asserted formula for $\|D\|_2^2$. A straightforward computation gives

$$B_m B_m^* = \begin{pmatrix} T_{\ell_m - r_m}(b_m) & 0 \\ 0 & O_{r_m} \end{pmatrix},$$

where O_{r_m} is the $r_m \times r_m$ zero matrix. This yields the asserted expressions for $s_{\min}^+$ and $\|D\|_\infty^2$. ∎

4. Toeplitz, Hankel, and chessboard structures. Let L_m be as in Example 3.1 and choose $a_m(x) = 1 - x$ for all m. The corresponding structure is the Toeplitz structure. The functions b_m are all $b_m(t) = |t-1|^2$. It is well known (see, e.g., [2, 5, 7]) that the eigenvalues of $T_R(b_m)$ are $\lambda_j = 2 + 2\cos\frac{\pi j}{R+1}$ $(j = 1, \ldots, R)$. Thus, Theorem 3.3 with $\ell_m = n - |m|$ and $r_m = 1$ for $m = -(n-1), \ldots, n-1$ yields

$$\|D\|_2^2 = 2\sum(\ell_m - r_m) = 2n^2 - 2\sum r_m = 2n^2 - 2(2n-1) = 2(n-1)^2,$$

$$\|D\|_\infty^2 = 2 + 2\cos\frac{\pi}{n} = 4\cos^2\frac{\pi}{2n}, \quad \left(s_{\min}^+\right)^2 = 2 - 2\cos\frac{\pi}{n} = 4\sin^2\frac{\pi}{2n}.$$

Theorem 1.1 is now immediate from Theorem 2.1, while Theorem 1.2 follows from Corollary 2.3 and the fact that

$$\frac{2n^2\|D\|_\infty^4}{(\|D\|_2^2 - n^2/100)^2} \le \frac{2n^2 \cdot 4^2}{(2(n-1)^2 - n^2/100)^2} < \frac{13}{n^2} \quad \text{for} \quad n \ge 10.$$

In the Hankel case we take the partition considered in Example 3.2 and arrive at the same results as in the Toeplitz case. In particular, Theorems 1.1 and 1.2 remain literally true with $\mathcal{T}_n(\mathbf{K})$ replaced by the set of all Hankel matrices in $M_n(\mathbf{K})$.

To give another illustration, let us consider chessboard matrices. In this case $L_1, L_2, a_1(x) = a_2(x) = 1 - x$ are as in Example 3.2. The functions b_1, b_2 are again $b_1(t) = b_2(t) = |t-1|^2$, but now $\ell_1 = [n^2/2]$ and $\ell_2 = [(n^2+1)/2]$, where $[q]$ denotes the integral part of q. Thus,

$$\begin{aligned}
\|D\|_2^2 &= \left(\left[\frac{n^2}{2}\right] - 1\right) \cdot 2 + \left(\left[\frac{n^2+1}{2}\right] - 1\right) \cdot 2 = 2(n^2-2), \\
\|D\|_\infty^2 &= 4\cos^2 \frac{\pi}{2[n^2/2 + 1/2]} \sim 4\cos^2 \frac{\pi}{n^2}, \\
\left(s_{\min}^+\right)^2 &= 4\sin^2 \frac{\pi}{2[n^2/2 + 1/2]} \sim 4\sin^2 \frac{\pi}{n^2} \sim \frac{4\pi^2}{n^4},
\end{aligned}$$

which shows that (2.4) increases asymptotically as $n^2/(2\pi)$. From Corollary 2.3 we deduce that nevertheless

$$P\left(\frac{\operatorname{dist}_2(X, \operatorname{Ker} D)}{\|D(X)\|_2} > 10\right) < \frac{33}{n^2} \quad \text{for} \quad n \ge 10.$$

5. Symmetric matrices. These come from the partition

$$\{1, \dots, n\} \times \{1, \dots, n\} = \bigcup_{i<j} \{(i,j), (j,i)\} \cup \bigcup_i \{(i,i)\}$$

with $a_{ij}(x) = 1 - x$ on the doubletons and $a_i(x) = 0$ on the singletons. Theorem 3.3 gives $(s_{\min}^+)^2 = \lambda_{\min}(T_1(|t-1|^2)) = 2$, and hence (2.4) equals $\sqrt{2}/2$ for all n.

6. Vandermonde-like structures. We start with any partition (3.1) and any ordering of the strings. In the classic Vandermonde case, L_m is $\{(i,m) : 1 \le i \le n\}$ and is ordered by increasing i. Let $a_m(x) = \alpha_m - x$. We get

$$b_m(t) = |\alpha_m - t|^2 = 1 + |\alpha_m|^2 - \alpha_m t^{-1} - \overline{\alpha_m} t.$$

The eigenvalues of the tridiagonal Toeplitz matrix $T_R(b_m)$ are

$$1 + |\alpha_m|^2 + 2|\alpha_m| \cos \frac{\pi j}{R+1} \quad (j = 1, \dots, R)$$

(see again [2, 5, 7]). Consequently, by Theorem 3.3,

$$\left(s_{\min}^+\right)^2 = \min_m \left(1 + |\alpha_m|^2 - 2|\alpha_m| \cos \frac{\pi}{\ell_m}\right) = \min_m \left((1 - |\alpha_m|)^2 + 4|\alpha_m| \sin^2 \frac{\pi}{2\ell_m}\right).$$

Thus, if there is a $\delta > 0$ such that $|\alpha_m| \notin (1-\delta, 1+\delta)$, then (2.4) is not greater than $1/\delta$. The ratio (2.4) becomes large only if there is an m such that $|\alpha_m|$ is close to 1 and, at the same time, ℓ_m is large. Note that in the classic case $\ell_m = n$ for all m.

7. Polynomially ill-conditioned structures. We know that (2.4) increases asymptotically as n/π for the Toeplitz and Hankel structures and as $n^2/(2\pi)$ for the chessboard structure. In this section we provide string structures for which (2.4) increases as a polynomial of arbitrarily prescribed degree.

For the sake of definiteness, take partition (3.1) with $L_m = \{(i,m) : 1 \le i \le n\}$ with the ordering induced by increasing i. For each m, let $a_m(x)$ be a polynomial of degree $r_m \le n-1$ and define b_m by $b_m(t) = |a_m(t)|^2$. The asymptotic behavior of the extreme eigenvalues of $T_R(b_m)$ has been studied by many authors, including [5, 8, 10, 11, 12, 15, 21, 22, 23]. These results imply the following (a full proof of which is also given in [2]). If 2γ is the maximal order of the zeros of b_m on $\mathbf{T}$, then there exist constants $0 < C_1 < C_2 < \infty$ depending only on b_m such that

$$C_1 \frac{1}{R^{2\gamma}} \le \lambda_{\min}(T_R(b_m)) \le C_2 \frac{1}{R^{2\gamma}}$$

for all R. Consequently, Theorems 2.1 and 3.3 imply that the ratio (2.4) increases as $n^{\max(r_1,\ldots,r_n)}$.

To be more concrete, let $a_m(x) = (1-x)^r$ for all m. Thus, we require that the entries of each column are the values of a polynomial of degree $r-1$ at $1,\ldots,n$. We have $b_m(t) = |t-1|^{2r}$ for all m. The function $b_m(t) = |t-1|^{2r}$ has exactly one zero $t=1$ on $\mathbf{T}$, and the order of this zero is $2r$. From what was said in the preceding paragraph we deduce that (2.4) increases as n^r. In the special case at hand it is even known from the works cited above that $R^{2r}\lambda_{\min}(T_R(b_m))$ converges to a limit c_r as $R \to \infty$. The limiting constants are rapidly increasing ($c_1 = \pi^2 = 9.8696$, $c_2 \approx 500$, $c_3 \approx 61529$) and c_r can be shown to coincide with the minimal eigenvalue of the differential operator $(-1)^r u^{(2r)}$ on $(0,1)$ with the boundary conditions $u^{(j)}(0) = u^{(j)}(1) = 0$ for $0 \le j \le r-1$ (see [1, 12, 14, 22, 23]). From Theorem 3.3 we also deduce that

$$\|D\|_2^2 = n(n-r)\sum_{k=0}^{r}\binom{r}{k}^2 = \binom{2r}{r} n(n-r),$$
$$\|D\|_\infty^2 = \lambda_{\max}(T_{n-r}(|t-1|^{2r})) \le 2^{2r}$$

(note that $\|T_R(b)\|_\infty \le \max_{t\in\mathbf{T}} |b(t)|$ for every b). Consequently, Corollary 2.3 implies that nonetheless

$$P\left(\frac{\operatorname{dist}_2(X, \operatorname{Ker} D)}{\|D(X)\|_2} > 10\right) \le \frac{2n^2 \cdot 2^{4r}}{\left(\binom{2r}{r} n(n-r) - n^2/100\right)^2} = O\left(\frac{1}{n^2}\right).$$

8. Toeplitz-plus-Hankel matrices I. A Toeplitz-plus-Hankel matrix (T+H matrix, for short) is a matrix of the form $(t_{i-j} + h_{i+j})_{i,j=1}^n$ with $t_k, h_k \in \mathbf{K}$. The T+H structure is not a string structure in the sense of section 3, and hence it is not as easy to detect as a string structure—for example, with unskilled eyes it is not trivial to decide whether

$$\begin{pmatrix} 2.9 & 7.3 & -1.9 \\ 5.4 & 0.3 & 0.7 \\ 5.2 & -1.2 & 1.9 \end{pmatrix}$$

is T+H or not—and, moreover, Theorem 3.3 is not applicable to T+H matrices.

Heinig and Rost [6] observed that in the T+H case one may consider the displacement matrix $XW - WX$, where $W = U + U^\top$ and U is the shift matrix introduced in section 1. One can show that $X \in M_n(\mathbf{K})$ is T+H if and only if the

central $(n-2)\times(n-2)$ submatrix of $XW-WX$ is zero. Consequently, we define $D(X)\in M_n(\mathbf{K})$ as the matrix that results from $XW-WX$ by replacing the first and last rows and the first and last columns with zero. Throughout this section it will be convenient to emphasize the dependence on n. We therefore write W_n and D_n for W and D, respectively. Thus, $X\in M_n(\mathbf{K})$ is T+H if and only if $D_n(X)=0$.

After appropriate stacking, D_n becomes an $n^2\times n^2$ matrix

$$\nabla_n = I\otimes W_n - W_n\otimes I - R_n,$$

where $\otimes$ denotes the Kronecker product. The matrix R_n stems from deleting the first and last rows and columns of XW_n-W_nX. We take advantage of the two lucky circumstances that W_n is Hermitian and that R_n is an $n^2\times n^2$ matrix whose rank is at most $4n-2=o(n^2)$ to prove the following.

THEOREM 8.1. *In the Toeplitz-plus-Hankel case,*

$$\lim_{n\to\infty}\max_{X\notin\operatorname{Ker} D_n}\frac{\operatorname{dist}_2(X,\operatorname{Ker} D_n)}{\|D_n(X)\|_2}=\infty.$$

Proof. We employ the general fact that if $\{A_n\}$ and $\{B_n\}$ are two sequences of $n^2\times n^2$ matrices such that $\operatorname{rank}(A_n-B_n)=o(n^2)$ and if $s_j(A_n)$ and $s_j(B_n)$ are the singular values of A_n and B_n, respectively, then

$$\lim_{n\to\infty}\frac{1}{n^2}\sum_{j=1}^{n^2}(\varphi(s_j(A_n))-\varphi(s_j(B_n)))=0$$

for every compactly supported continuous function φ on $\mathbf{R}$ (see [19, 20]).

We apply this result to $A_n=\nabla_n$ and $B_n=I\otimes W_n-W_n\otimes I$. Given an interval $(a,b)\subset\mathbf{R}$, we denote by $\alpha_n(a,b)$ and $\beta_n(a,b)$ the number of singular values of A_n and B_n in (a,b) (multiplicities taken into account). The eigenvalues of W_n are $\lambda_j=2\cos\frac{\pi j}{n+1}$ $(j=1,\dots,n)$, and hence the eigenvalues of B_n are $\lambda_j-\lambda_k$ $(j,k=1,\dots,n)$. Since W_n and thus B_n is Hermitian, it follows that the singular values of B_n are

$$s_{jk}=|\lambda_j-\lambda_k|=2\left|\cos\frac{\pi j}{n+1}-\cos\frac{\pi k}{n+1}\right|=4\left|\sin\frac{\pi(j-k)}{2n+2}\sin\frac{\pi(j+k)}{2n+2}\right|,$$

where $j,k=1,\dots,n$. Fix $\varepsilon\in(0,1)$. A little thought reveals that

$$\lim_{n\to\infty}\frac{\beta_n(2\varepsilon,3\varepsilon)}{(n+1)^2}=\frac{1}{4\pi^2}\,|G_\varepsilon|,$$

where $|G_\varepsilon|$ is the area of the region

$$G_\varepsilon=\left\{(x,y)\in(0,2\pi)^2 : 2\varepsilon<4\left|\sin\frac{x-y}{2}\sin\frac{x+y}{2}\right|<3\varepsilon\right\}.$$

Clearly, $|G_\varepsilon|>0$ whenever $\varepsilon<2$. Thus, we have

$$\beta_n(2\varepsilon,3\varepsilon)=\frac{|G_\varepsilon|}{4\pi^2}\,n^2+o(n^2)\quad\text{with}\quad|G_\varepsilon|>0.$$

Let $\varphi : \mathbf{R} \to [0,1]$ be a compactly supported continuous function which is identically 1 in $(2\varepsilon, 3\varepsilon)$ and identically 0 outside $(\varepsilon, 4\varepsilon)$. Then

$$\begin{aligned}\alpha_n(\varepsilon, 4\varepsilon) &\geq \sum_{j=1}^{n^2} \varphi(s_j(A_n)) = \sum_{j=1}^{n^2} \varphi(s_j(B_n)) + o(n^2) \\ &\geq \beta_n(2\varepsilon, 3\varepsilon) + o(n^2) = \frac{|G_\varepsilon|}{4\pi^2}\, n^2 + o(n^2),\end{aligned}$$

and since $|G_\varepsilon| > 0$, we conclude that $\alpha_n(\varepsilon, 4\varepsilon) \to \infty$ as $n \to \infty$.

Now pick a large number $C > 0$. By what was just proved, there exists an $n_0 = n_0(C)$ such that $\nabla_n = A_n$ and thus D_n also has a singular value in $(\frac{1}{4C}, \frac{1}{C})$ for all $n \geq n_0$. It follows that the smallest nonzero singular value of D_n does not exceed $1/C$ for $n \geq n_0$. Theorem 2.1 therefore gives

$$\max_{X \notin \operatorname{Ker} D_n} \frac{\operatorname{dist}_2(X, \operatorname{Ker} D_n)}{\|D_n\|_2} > C \quad \text{for} \quad n \geq n_0(C).$$

As $C > 0$ was arbitrary, we arrive at the assertion. □

THEOREM 8.2. *In the Toeplitz-plus-Hankel case,*

$$\|D_n\|_2^2 = 4(n-2)^2, \quad \|D_n\|_\infty \leq 4, \quad \lim_{n\to\infty} \|D_n\|_\infty = 4.$$

Proof. We may write $D_n(X) = P(XW_n - W_nX)$, where $P : M_n(\mathbf{K}) \to M_n(\mathbf{K})$ is the projection on the central $(n-2) \times (n-2)$ matrix. This implies that $\|D_n\|_\infty \leq \|P\|_\infty(\|W_n\|_\infty + \|W_n\|_\infty) = 1 \cdot (1+1) = 4$. To prove that $\|D_n\|_\infty \to 4$, we proceed as in the proof of Theorem 8.1. Namely, $\beta_n(4-3\varepsilon, 4-2\varepsilon) = \frac{1}{4\pi^2}\,|H_\varepsilon| n^2 + o(n^2)$, where $|H_\varepsilon| > 0$ is the area of the region

$$H_\varepsilon = \left\{(x,y) \in (0,2\pi)^2 : 4 - 3\varepsilon < 4\left|\sin\frac{x-y}{2}\sin\frac{x+y}{2}\right| < 4 - 2\varepsilon\right\},$$

which implies that $\alpha_n(4-4\varepsilon, 4-\varepsilon) \to \infty$ as $n \to \infty$. Consequently, D_n has a singular value in $(4-4\varepsilon, 4-\varepsilon)$ if only n is large enough, which shows that $\|D_n\|_\infty \to 4$.

We know that D_n is unitarily similar to the matrix ∇_n introduced in the proof of Theorem 8.1. The matrix ∇_n has $4n-4$ zero rows, and the remaining $(n-2)^2$ rows have $1, 1, -1, -1$, and $n^2 - 4$ zeros as entries. This gives $\|D_n\|_2^2 = 4(n-2)^2$. □

COROLLARY 8.3. *We have*

$$P\left(\frac{\operatorname{dist}_2(X, \operatorname{Ker} D_n)}{\|D_n(X)\|_2} > 10\right) < \frac{79}{n^2} \quad \textit{for} \quad n \geq 10.$$

Proof. From Corollary 2.3 and Theorem 8.2 we deduce that the probability considered is at most $2n^2 \cdot 4^4/(4(n-2)^2 - n^2/100)^2$, which is smaller than $79/n^2$ for $n \geq 10$. □

9. Toeplitz-plus-Hankel matrices II. To estimate the growth rate in Theorem 8.1, we have to exploit heavier machinery. Let $Q = (-\pi, \pi)^2$. For a function $f \in L^\infty(Q)$, the quarter-plane Toeplitz operator $T^{(2)}(f)$ is defined on $\ell^2(\mathbf{N} \times \mathbf{N})$ by

$$\big(T^{(2)}(f)x\big)_{ij} = \sum_{k,\ell=1}^{\infty} f_{i-k,j-\ell}\, x_{k\ell} \quad (i,j \geq 1),$$

where the numbers $f_{k\ell}$ are the Fourier coefficients of f,

$$f_{k\ell} = \frac{1}{4\pi^2} \int_{-\pi}^{\pi} \int_{-\pi}^{\pi} f(x,y) e^{-ikx} e^{-i\ell y}\, dx\, dy.$$

The compression of $T^{(2)}(f)$ to the square $\{1,\dots,n\}\times\{1,\dots,n\}$ is denoted by $T_n^{(2)}(f)$. Writing

$$f(x,y) = \sum_{k,\ell=-\infty}^{\infty} f_{k,\ell} e^{ikx} e^{i\ell y} = \left(\sum_{k=-\infty}^{\infty} f_{k\ell} e^{ikx} \right) e^{i\ell y} =: \sum_{k=-\infty}^{\infty} f_\ell(e^{ix}) e^{i\ell y}, \tag{9.1}$$

one can identify $T_n^{(2)}(f)$ with $(T_n(f_{i-j}))_{i,j=1}^n$, which is a block Toeplitz matrix with Toeplitz blocks. If f is nonnegative and not identically zero, then $T_n^{(2)}(f)$ is positive definite. We denote by $\lambda_{\min}(T_n^{(2)}(f))$ the smallest eigenvalue of $T_n^{(2)}(f)$ and by $s_{\min}^+(n)$ the smallest nonzero singular value of D_n.

THEOREM 9.1. *For $n \ge 3$,*

$$(s_{\min}^+(n))^2 = \lambda_{\min}\big(T_{n-2}^{(2)}(f)\big) \quad \textit{with} \quad f(x,y) = 16 \sin^2 \frac{x+y}{2} \sin^2 \frac{x-y}{2}.$$

Proof. Let ∇_n be as in the preceding section. One can show that

$$\nabla_n \nabla_n^* = J \begin{pmatrix} F_n & 0 \\ 0 & O_{4n-4} \end{pmatrix} J \quad \text{with} \quad F_n = (T_{n-2}(f_{i-j}))_{i,j=1}^{n-2},$$

where J is a permutation matrix and $f_0(t) = 4+t^2+t^{-2}$, $f_1(t) = f_{-1}(t) = -2(t+t^{-1})$, $f_2(t) = f_{-2}(t) = 1$, $f_\ell(t) = 0$ for $|\ell| \ge 3$. By (9.1), we may identify F_n with $T_{n-2}^{(2)}(f)$ for

$$\begin{aligned} f(x,y) &= \sum_{\ell=-2}^{2} f_\ell(e^{ix}) e^{i\ell y} = 4 + 2\cos 2x - 2(2\cos x)(2\cos y) + 2\cos 2y \\ &= 4(\cos x - \cos y)^2 = 16 \sin^2 \frac{x+y}{2} \sin^2 \frac{x-y}{2}. \qquad \square \end{aligned}$$

The following is a significant refinement of Theorem 8.1.

THEOREM 9.2. *There exist constants $0 < C_1 < C_2 < \infty$ such that for all $n \ge 1$,*

$$C_1\, n^2 \le \max_{X \notin \operatorname{Ker} D_n} \frac{\operatorname{dist}_2(X, \operatorname{Ker} D_n)}{\|D_n(X)\|_2} \le C_2\, n^2.$$

Proof outline. By Theorems 2.1 and 9.1, we have to prove that

$$C_3/n^4 \le \lambda_{\min}(T_n^{(2)}(f)) \le C_4/n^4$$

with certain constants $0 < C_3 < C_4 < \infty$. Papers [16, 21, 23] pertain to that question, but they are restricted to the case where $f \ge 0$ has only a single zero and are therefore not applicable to the case at hand. We will instead benefit from the special structure of f.

We identify $\mathbf{K}^n$ with the set $\mathcal{P}_n$ of all trigonometric polynomials of the form $\varphi(x) = \varphi_0 + \varphi_1 e^{ix} + \cdots + \varphi_{n-1} e^{i(n-1)x}$ $(x \in (-\pi,\pi))$. The ℓ^2 norm on $\mathbf{K}^n$ induces

the norm $\|\varphi\|^2 = \int_{-\pi}^{\pi} |\varphi(x)|^2\,dx/(2\pi)$ on $\mathcal{P}_n$. Accordingly, $\ell^2(\{1,\dots,n\}\times\{1,\dots,n\})$ may be identified with $\mathcal{P}_n \otimes \mathcal{P}_n$. For $\varphi \in \mathcal{P}_n \otimes \mathcal{P}_n$,

$$\big(T_n^{(2)}(f)\varphi,\varphi\big) = 16\int_{-\pi}^{\pi}\int_{-\pi}^{\pi} \sin^2\frac{x+y}{2}\,\sin^2\frac{x-y}{2}\,|\varphi(x,y)|^2\,\frac{dx\,dy}{4\pi^2},$$

and using periodicity and substituting $x+y=2\xi$, $x-y=2\eta$, one can show that this is not smaller than

$$C_5\int_{-\pi}^{\pi}\int_{-\pi}^{\pi} \sin^2\xi\,\sin^2\eta\,|\varphi(\xi+\eta,\xi-\eta)|^2\,d\xi\,d\eta = C_5((A_{2n}\otimes A_{2n})\widetilde{\varphi},\widetilde{\varphi}), \tag{9.2}$$

where $C_5>0$ is some constant, $A_{2n}=T_{2n}(\sin^2 x)$, and $\widetilde{\varphi}\in\mathcal{P}_{2n}\otimes\mathcal{P}_{2n}$ is defined by $\widetilde{\varphi}(\xi,\eta)=\varphi(\xi+\eta,\xi-\eta)$. The smallest eigenvalue of A_{2n} is $\sin^2\frac{\pi}{2n+2}$, and hence (9.2) is at least

$$C_5\left(\sin^2\frac{\pi}{2n+2}\right)^2\int_{-\pi}^{\pi}\int_{-\pi}^{\pi}|\varphi(\xi+\eta,\xi-\eta)|^2\,d\xi\,d\eta \ge \frac{C_3}{n^4}\int_{-\pi}^{\pi}\int_{-\pi}^{\pi}|\varphi(x,y)|^2\,\frac{dx\,dy}{4\pi^2}$$

with some constant $C_3>0$. In summary, $(T_n^{(2)}(f)\varphi,\varphi)\ge(C_3/n^4)\|\varphi\|^2$, which implies that $\lambda_{\min}(T_n^{(2)}(f))\ge C_3/n^4$.

The reverse inequality can be proved as in [2, pp. 37–41]. Namely, let $n=6m+k$ with $1\le k\le 6$, define $p_m\in\mathcal{P}_{3m+1}$ by $p_m(x)=(1+e^{ix}+\dots+e^{imx})^3$, and put $\varphi(x,y)=p_m(x+y)p_m(x-y)$. Then $\varphi\in\mathcal{P}_{6m+1}\otimes\mathcal{P}_{6m+1}\subset\mathcal{P}_n\otimes\mathcal{P}_n$ and one can show that

$$\|\varphi\|^2 \ge C_6\left(\int_{-\pi}^{\pi}|p_m(\xi)|^2\,d\xi\right)^2 \ge C_7\,m^{10},$$
$$\|f\varphi\|^2 \le C_8\left(\int_{-\pi}^{\pi}\sin^4\frac{x}{2}\,|p_m(x)|^2\,dx\right)^2 \le C_9\,m^2,$$

where C_6, C_7, C_8, and C_9 are constants in $(0,\infty)$. This implies (again see [2, p. 38]) that

$$1/\lambda_{\min}^2\big(T_n^{(2)}(f)\big) = \|(T_n^{(2)}(f))^{-1}\|_\infty \ge \frac{\|\varphi\|^2}{\|f\varphi\|^2} \ge \frac{C_7}{C_9}\,m^8,$$

whence $\lambda_{\min}(T_n^{(2)}(f)) = O(1/m^4) = O(1/n^4)$.

As pointed out by one of the referees, an alternative proof of the reverse inequality is as follows. From the last line of the proof of Theorem 9.1 we infer that

$$f(x,y)\le 16\left(\frac{x+y}{2}\right)^2\left(\frac{x-y}{2}\right)^2 = (x^2-y^2)^2 \le x^4+y^4 =: g(x,y).$$

Consequently, by a monotonicity argument (for which, see, for example, [16, p. 116]), the minimal eigenvalue of $T_n^{(2)}(f)$ does not exceed the minimal eigenvalue of $T_n^{(2)}(g)$, and the latter is known to be asymptotically equal to a constant times $1/n^4$ (see [16, 21, 22, 23]). □

10. Conclusions. We have provided parameters that allow us to estimate how far a matrix X may be from a given structure $\operatorname{Ker} D$ if the Frobenius norm of the displacement matrix $D(X)$ is small. In this way we can, for each structure, estimate

the conditioning of the problem of testing membership in this structure by checking whether the displacement matrix is small.

In practice, one would perhaps work with the norm $n \max |x_{ij}|$ instead of the Frobenius norm. The treatment of this norm is theoretically more difficult and we have not embarked on this question. However, a consideration of examples shows that the basic qualitative (though not quantitative) results on the conditioning of the problem seem to be independent of the choice of the norm.

We have seen that the more ill-conditioned the string structures, the larger the maximal string length. (The maximal string length is n for $n \times n$ Toeplitz or Hankel matrices and about $n^2/2$ for $n \times n$ chessboard matrices.) In these cases it is advisable to replace consideration of $\|D(X)\|_2$ by the direct computation of $\operatorname{dist}_2(X, \operatorname{Ker} D)$, which is an easy task if an orthonormal basis in $\operatorname{Ker} D$ is available. If, for example, we want to test whether a matrix is constant along prescribed strings, we should replace the entries of each string by their arithmetic mean and test whether the distance of this matrix to the original matrix is small.

The conditioning of checking the Toeplitz-plus-Hankel structure by having recourse to the displacement matrix $XW - WX$ increases as the square of the matrix dimension. The search for alternative tests of the Toeplitz-plus-Hankel structure is therefore desirable.

More generally, as also observed by the referees, the question of testing whether a given matrix has a prescribed structure deserves a further and careful consideration. The message of this paper is that the naive use of displacement operations may at least theoretically be dangerous. We have left open the question of how to do it in the right way. Furthermore, we have restricted ourselves to structures for which the corresponding displacement operations are known or easy to guess. Other important structures, such as locally Toeplitz sequences [18] or generalized locally Toeplitz sequences [17], cannot be tackled by displacement operations in an obvious way. These and related matters await further investigation.

Acknowledgments. I thank Peter Benner and Harold Widom for useful discussions on several aspects of the topic. I am also greatly indebted to the referees for their competent and valuable remarks.

CONVERGENCE OF MULTISTEP TIME DISCRETIZATIONS OF NONLINEAR DISSIPATIVE EVOLUTION EQUATIONS*

ESKIL HANSEN†

Abstract. Global error bounds are derived for multistep time discretizations of fully nonlinear evolution equations on infinite dimensional spaces. In contrast to earlier studies, the analysis presented here is not based on linearization procedures but on the fully nonlinear framework of logarithmic Lipschitz constants and nonlinear semigroups. The error bounds reveal how the contractive or dissipative behavior of the vector field, governing the evolution, and the properties of the multistep method influence the convergence. A multistep method which is consistent of order p is proven to be convergent of the same order when the vector field is contractive or strictly dissipative, i.e., of the same order as in the ODE-setting. In the contractive context it is sufficient to require strong zero-stability of the method, whereas strong A-stability is sufficient in the dissipative case.

1. Introduction.

The evolution equation

$$\dot{u} = f(u), \quad u(0) = \eta,$$

where $u : [0, \infty) \to X$ and the vector field f is a dissipative map on the Banach space X, has received much attention as this type of equation is found in a wide range of applications, e.g., advection-diffusion-reaction processes. In the early 1970s the theory of nonlinear semigroups made it possible to characterize the solutions of evolution equations with fully nonlinear vector fields; see [1, 2, 21]. Shortly thereafter, multistep time discretizations of such evolution equations were analyzed in the literature; see [11, 12, 16], where some stability and convergence results are derived in a Hilbert space context. Studies of multistep discretizations on infinite dimensional spaces have predominantly considered linear vector fields, e.g., [6, 14], where the analysis is based on analytic semigroups (by definition linear). The same analysis is also used when combining multistep and Galerkin methods; this is reviewed in [19]. It is not until just recently that the fully nonlinear setting has been addressed; see, e.g., [5, 13]. Here, bounds of the global error are derived by expressing the vector field as a sum of its linearization and a nonlinear residual, which enables the usage of the linear theory. The aim of this paper is therefore to derive global error bounds in the setting of fully nonlinear problems on infinite dimensional spaces, which are not necessarily linearizable, and to obtain a qualitative understanding of how the mathematical setting and the numerical methods influence such bounds.

2. Preliminaries.

This paper is based on the theory of logarithmic Lipschitz constants, which was developed in [9, 17, 18]. Below follows a short summary of the theory. Assume that X is a real valued Banach space, with norm $\|\cdot\|_X$, and f is a

nonlinear map on X with domain $D(f)$ and range $R(f)$. The Lipschitz constants of f on X are defined as follows.

DEFINITION 2.1. *For u, $v \in D(f)$ define the* lub *and* glb *Lipschitz constants of f on X by*

$$L_X[f] := \sup_{u \neq v} \frac{\|f(u) - f(v)\|_X}{\|u - v\|_X}, \quad l_X[f] := \inf_{u \neq v} \frac{\|f(u) - f(v)\|_X}{\|u - v\|_X}.$$

The basic properties of the Lipschitz constants are given in Proposition 2.2.

PROPOSITION 2.2. *Assume that $R(g) \subseteq D(f)$ in property* 4 *and $D(f) \bigcap D(g) \neq \emptyset$ in properties* 3 *and* 5. *Then,*

1. $L_X[f] \geq 0$,
2. $L_X[\alpha f] = |\alpha| L_X[f]$,
3. $L_X[f + g] \leq L_X[f] + L_X[g]$,
4. $L_X[fg] \leq L_X[f] L_X[g]$,
5. $l_X[f] - L_X[g] \leq l_X[f + g]$.

In order to mimic an inner product space, introduce semi-inner products on X induced by the norm $\|\cdot\|_X$.

DEFINITION 2.3. *Let $u, v \in X$ and define the left $(\cdot,\cdot)_X^-$ and right $(\cdot,\cdot)_X^+$ semi-inner products on X as*

$$(u, v)_X^{\pm} := \|u\|_X \lim_{\varepsilon \to 0\pm} \frac{\|u + \varepsilon v\|_X - \|u\|_X}{\varepsilon}.$$

The semi-inner products exist as they are Gateaux differentials of the norm $\|\cdot\|_X$; see [4]. If the norm is induced by an inner product $\langle\cdot,\cdot\rangle_X$, then $(\cdot,\cdot)_X^{\pm} = \langle\cdot,\cdot\rangle_X$. Like the true inner product, the semi-inner products satisfy the relation $(u, u)_X^{\pm} = \|u\|_X^2$ and the Cauchy–Schwarz inequalities

$$-\|u\|_X \|v\|_X \leq (u, v)_X^{\pm} \leq \|u\|_X \|v\|_X.$$

Next, the logarithmic Lipschitz constants are introduced.

DEFINITION 2.4. *For u, $v \in D(f)$, define the* lub *and* glb *logarithmic Lipschitz constants of f on X as*

$$M_X^{\pm}[f] := \sup_{u \neq v} \frac{(u - v, f(u) - f(v))_X^{\pm}}{\|u - v\|_X^2}, \quad m_X^{\pm}[f] := \inf_{u \neq v} \frac{(u - v, f(u) - f(v))_X^{\pm}}{\|u - v\|_X^2}.$$

Some of the basic properties of the logarithmic Lipschitz constants are given in Proposition 2.5.

PROPOSITION 2.5. *Assume that $D(f) \bigcap D(g) \neq \emptyset$ in property* 4. *Then,*

1. $m_X^{\pm}[-f] = -M_X^{\mp}[f]$,
2. $-L_X[f] \leq m_X^-[f] \leq m_X^+[f] \leq l_X[f]$,
3. $m_X^{\pm}[\alpha f] = \alpha m_X^{\pm}[f]$, $\alpha \geq 0$,
4. $m_X^-[f] + m_X^{\pm}[g] \leq m_X^{\pm}[f + g]$.

The first and second properties in Proposition 2.5 imply that it is preferable to use $m_X^+[f]$ and $M_X^-[f]$, since they correspond to the weakest requirements.

LEMMA 2.6. *If $l_X[f] > 0$, then f is injective and $L_X[f^{-1}] = l_X[f]^{-1}$.*

Proof. Definition 2.1 trivially yields that f is injective when $l_X[f] > 0$ and $f^{-1} : R(f) \to D(f)$ is bijective. Let $u_1, u_2 \in D(f)$, and $v_1 := f(u_1)$, $v_2 := f(u_2)$; then

$$l_X[f]^{-1} = \sup_{u_1 \neq u_2} \frac{\|u_1 - u_2\|_X}{\|f(u_1) - f(u_2)\|_X} = \sup_{v_1 \neq v_2} \frac{\|f^{-1}(v_1) - f^{-1}(v_2)\|_X}{\|v_1 - v_2\|_X} = L_X[f^{-1}]. \qquad \square$$

Lemma 2.6 together with the inequality $m_X^+[f] \le l_X[f]$ yields the following corollary.

COROLLARY 2.7. *If $m_X^+[f] > 0$, then f is injective and $L_X[f^{-1}] \le m_X^+[f]^{-1}$.*

3. Direct product spaces. Introduce the Banach space X^N, i.e., the direct product of N real valued Banach spaces, equipped with the norm $\|\cdot\|_{X,p}$. Elements $U \in X^N$ are denoted as $U = (U_1, \ldots, U_N)^T$, and the norm $\|\cdot\|_{X,p}$ on X^N is defined as

$$\|U\|_{X,p} := \left(\sum_{i=1}^{N} \|U_i\|_X^p \right)^{1/p},$$

when $p < \infty$ and $\|U\|_{X,\infty} := \max_{1 \le i \le N} \|U_i\|_X$. In the error analysis only two types of maps on X^N are needed. To every map f on X we relate the map $\mathcal{F} : D(f)^N \to X^N$ defined as

$$(\mathcal{F}(U))_i := f(U_i) \quad \text{for} \quad i = 1, \ldots, N.$$

The lemma below now follows trivially from the definition of $\|\cdot\|_{X,p}$.

LEMMA 3.1. *$L_{X,p}[\mathcal{F}] = L_X[f]$ and $l_{X,p}[\mathcal{F}] = l_X[f]$.*

Furthermore, to every real matrix $A = \{a_{ij}\}_{i,j=1}^N$ we relate the linear map $\mathcal{A} : X^N \to X^N$ defined as

$$(\mathcal{A}U)_i := \sum_{j=1}^{N} a_{ij} U_j \quad \text{for} \quad i = 1, \ldots, N.$$

LEMMA 3.2. *If $X = l_p(\mathbb{N})$, where $1 \le p < \infty$, equipped with the usual p-norm $\|\cdot\|_p$, then $L_{p,p}[\mathcal{A}] = L_p[A]$ and $l_{p,p}[\mathcal{A}] = l_p[A]$.*

Proof. Every element $u \in l_p(\mathbb{N})$ is the limit of a sequence $\{u^j\}_{j \ge 1}$ where $u^j \in X_j := \{v \in l_p(\mathbb{N}) : v_i = 0,\ \forall i > j\}$, as $\lim_{j \to \infty} \sum_{i>j} |u_i|^p = 0$ when $p < \infty$. Hence,

$$L_{p,p}[\mathcal{A}] = \sup_{j \ge 1} \sup_{\{U \in X_j^N :\, \|U\|_{p,p} = 1\}} \|A \otimes I_{j \times j} U\|_{p,p} \le L_p[A] \sup_{j \ge 1} L_p[I_{j \times j}] = L_p[A].$$

The equality is now obtained as $L_{p,p}[\mathcal{A}] \ge \sup_{\{u \in X_1^N :\, \|u\|_p = 1\}} \|Au\|_p = L_p[A]$. The other equality is obtained by the same procedure. ∎

COROLLARY 3.3. *If there exists a linear isometric imbedding of X into $l_p(\mathbb{N})$, where $1 \le p < \infty$, then $L_{X,p}[\mathcal{A}] \le L_p[A]$ and $l_{X,p}[\mathcal{A}] \ge l_p[A]$.*

Proof. Let the linear map ϕ be the isometric imbedding of X into $l_p(\mathbb{N})$, i.e., $\|\phi u\|_p = \|u\|_X$, and define $\Phi : X^N \to l_p^N(\mathbb{N})$ by $(\Phi U)_i := \phi U_i$ for $i = 1, \ldots, N$. It is easily seen that Φ is an isometric imbedding of X^N into $l_p^N(\mathbb{N})$ and the linearity of ϕ yields that $\Phi\mathcal{A} = \mathcal{A}\Phi$. Hence, by Lemma 3.2,

$$\|\mathcal{A}U\|_{X,p} = \|\Phi\mathcal{A}U\|_{p,p} = \|\mathcal{A}\Phi U\|_{p,p} \le L_{p,p}[\mathcal{A}] \|\Phi U\|_{p,p} = L_p[A] \|U\|_{X,p},$$

which implies that $L_{X,p}[\mathcal{A}] \le L_p[A]$. The other inequality in this corollary follows in the same fashion. ∎

Note that the inequalities related to the Lipschitz constants in Corollary 3.3 can be replaced by equalities if the imbedding is surjective, and in the case of X being a separable Hilbert space the corollary is valid with $p = 2$, as these spaces are linearly and isometrically imbedded into $l_2(\mathbb{N})$. Next, consider the semi-inner products $(\cdot,\cdot)_{X,p}^{\pm}$

on X^N generated by the norm $\|\cdot\|_{X,p}$ for which we introduce the concept of *proper* semi-inner products.

DEFINITION 3.4. *The semi-inner products* $(\cdot,\cdot)^{\pm}_{X,p}$ *are called* proper *if* $M^{\pm}_{X,p}[\mathcal{F}] = M^{\pm}_X[f]$ *and* $m^{\pm}_{X,p}[\mathcal{F}] = m^{\pm}_X[f]$.

LEMMA 3.5. *The semi-inner products* $(\cdot,\cdot)^{\pm}_{X,1}$ *and* $(\cdot,\cdot)^{\pm}_{X,2}$ *are proper.*

Proof. By Definition 2.3 and the construction of the norm $\|\cdot\|_{X,p}$ it follows that

$$(U,V)^{\pm}_{X,1} = \|U\|_{X,1}\sum_{i=1}^{N}\frac{(U_i,V_i)^{\pm}_X}{\|U_i\|_X} \quad \text{and} \quad (U,V)^{\pm}_{X,2} = \sum_{i=1}^{N}(U_i,V_i)^{\pm}_X.$$

The desired equalities are now obtained via these representations together with Definition 2.4. ∎

4. Problem setting. Let X be a real valued Banach space and consider the nonlinear evolution equation

$$\dot{u} = f(u), \quad u(0) = \eta \in D(f), \tag{4.1}$$

where $u : [0,\infty) \to X$ and the vector field f is a nonlinear map on X such that $M^{-}_X[f] < \infty$; i.e., f is dissipative [1], and

$$R(I - hf) = X \quad \forall h > 0 \text{ such that } hM^{-}_X[f] < 1. \tag{4.2}$$

Example 4.1. Define the evolution triple (V, X, V^*) by $V \subset X = X^* \subset V^*$ where $X := L_2[0,1]$ and $V := W^{1,r}_0[0,1]$, with $2 \le r < \infty$. Next, consider the perturbed r-Laplacian $\Delta_r : C^{\infty}_0[0,1] \to X$ defined as

$$\Delta_r : u \mapsto \partial_x(|\partial_x u|^{r-2}\partial_x u) + su,$$

with $s < 0$, and its energetic extension $\Delta_{E,r} : V \to V^*$, i.e.,

$$\Delta_{E,r} : u \mapsto \int_0^1 -(|\partial_x u|^{r-2}\partial_x u)\partial_x(\cdot) + su(\cdot)\mathrm{d}x.$$

Then, the map $f : D \to X$, with $D := \Delta^{-1}_{E,r}(X^*)$ and $\langle f(u), \cdot\rangle_X = \Delta_{E,r}(u)$ for all $u \in D$, fulfills (4.2), $L_X[f] = \infty$, and $M^{\pm}_X[f] \le s$; see sections 26.5 and 31.5 in [21] for details and generalizations.

Before the main propositions are stated, one needs the following definitions [2, 3].

DEFINITION 4.2. *A function* $u : [0,\infty) \to X$ *is said to be a strong solution of* (4.1) *on* $[0,\infty)$ *if* $u \in W^{1,1}([0,\infty), X)$, $u(0) = \eta$, *and* (4.1) *is satisfied a.e. on* $(0,\infty)$.

DEFINITION 4.3. *Let* Ω *be a closed subset of* X. *Then the set* $Q(\omega,\Omega)$ *of* ω*-type semigroups is defined as the collection of maps* $S : [0,\infty)\times\Omega \to \Omega$ *such that*

1. $S^{t+\tau}(u) = S^t S^\tau(u)$ *for all* $u \in \Omega$, $t,\tau \ge 0$,
2. $S^0(u) = u$ *for all* $u \in \Omega$,
3. $S^{(\cdot)}(u) \in C([0,\infty),\Omega)$ *for all* $u \in \Omega$,
4. $L_X[S^t(\cdot)] \le e^{t\omega}$ *for all* $t \ge 0$.

Now, in the setting of (4.1), one may apply the standard nonlinear semigroup theory for dissipative maps; see [1, 3, 21] for proofs and further results.

PROPOSITION 4.4. *For all* $u \in \overline{D(f)}$ *and* $t \ge 0$, *the evolution map*

$$e^{tf}(u) := \lim_{n\to\infty}\left(I - \frac{t}{n}f\right)^{-n}(u)$$

exists, and $e^{(\cdot)f} \in Q(M^{-}_X[f], \overline{D(f)})$.

PROPOSITION 4.5. *If X is a reflexive Banach space, then $e^{(\cdot)f}(\eta)$ is the unique strong solution of* (4.1) *on* $[0,\infty)$.

By comparing the hypothesis of Propositions 4.4 and 4.5, we note that the evolution map can be well defined even if (4.1) does not have a strong solution. This may occur if $\eta \in \overline{D(f)}\backslash D(f)$ or if X is not a reflexive Banach space. Thus, the most general numerical setting is obtained if one considers approximations of the evolution map, i.e., finding a sequence $\{u_i\}$ in X for every fixed $t \in [0,\infty)$ and $\eta \in \overline{D(f)}$ such that $e^{tf}(\eta) = \lim_{i\to\infty} u_i$, rather then approximating the strong solution of (4.1), which is not even necessarily well defined for all $t \in (0,\infty)$.

The multistep approximation $u_n \in X$ of $e^{t_n f}(\eta)$ is defined by the difference equation

$$\text{(4.3)} \qquad \begin{cases} h^{-1}\displaystyle\sum_{i=0}^{k} \alpha_{k-i} u_{n-i} = \sum_{i=0}^{k} \beta_{k-i} f(u_{n-i}), & n \geq 1, \\ \\ u_n = e^{t_n f}(\eta), & n = 1-k, \dots, 0, \end{cases}$$

where $t_n := (n+k-1)h$, $\alpha_k \neq 0$, and α_0 or $\beta_0 \neq 0$. To every multistep method relate the real polynomials ρ and σ, where

$$\rho(\xi) := \sum_{i=0}^{k} \alpha_i \xi^i \quad \text{and} \quad \sigma(\xi) := \sum_{i=0}^{k} \beta_i \xi^i.$$

Denote the sets of roots to ρ and σ by $\{\xi_i^\rho\}_{i=1}^k$ and $\{\xi_i^\sigma\}_{i=1}^k$, respectively. In order for the approximation u_n to be well defined one needs the following assumption:

(A1) $e^{t_n f}(\eta) \in D(f)$ for $n = 1-k, \dots, 0$.

This holds, e.g., for all $t \geq 0$ when $\eta \in D(f)$ and X is a Hilbert space; see [21].

THEOREM 4.6. *If* (A1) *holds and the multistep method (ρ,σ) is implicit, i.e., $\beta_k/\alpha_k > 0$, and $h\beta_k/\alpha_k M_X^-[f] < 1$, then there exists a unique solution to* (4.3).

Proof. Assume that u_{n-k} to u_{n-1} are known elements in $D(f)$. As

$$m_X^+\left[I - h\frac{\beta_k}{\alpha_k} f\right] \geq 1 - h\frac{\beta_k}{\alpha_k} M_X^-[f] > 0,$$

one has, by (4.2) and Corollary 2.7, that $(I - h\beta_k/\alpha_k f)^{-1} : X \to D(f)$ is a bijection and

$$u_n = \left(I - h\frac{\beta_k}{\alpha_k} f\right)^{-1} \left(\frac{1}{\alpha_k} \sum_{i=1}^{k} (-\alpha_{k-i} I + h\beta_{k-i} f)(u_{n-i})\right).$$

By (A1), $u_n \in D(f)$ for $n = 1-k, \dots, 0$, and the proof of the theorem now follows by induction. ∎

Note that the implicitness of the method is a necessity for the existence of a solution to (4.3), as an explicit method with $u_n \in D(f)$ may yield $u_{n+1} \in X\backslash D(f)$ and u_{n+2} is therefore not generally well defined.

DEFINITION 4.7. *A multistep method (ρ,σ) is said to fulfill the stability property*

(S1) *if $|\xi_i^\rho| < 1$ for $i = 1, \dots, k-1$, and $\xi_k^\rho = 1$;*

(S2) *if $|\xi_i^\sigma| < 1$ for $i = 1, \dots, k$;*

(S3) *if $\mathrm{Re}\{\rho(\xi)/\sigma(\xi)\} > 0$ for $|\xi| > 1$.*

The terminology of stability properties varies somewhat in the literature, but most commonly properties (S1), (S2), and (S3) are referred to as strong zero-stability, A_∞-stability, and A-stability, respectively. Methods fulfilling both (S2) and (S3) are usually referred to as strongly A-stable.

DEFINITION 4.8. *A multistep method (ρ, σ) is said to be consistent of order p if*

$$\rho(1) = 0 \quad \textit{and} \quad \sum_{i=0}^{k} \alpha_i i^q = q \sum_{i=0}^{k} \beta_i i^{q-1} \quad \textit{for} \quad q = 1, \ldots, p.$$

The classical ODE-analysis of the global error

$$e_n := e^{t_n f}(\eta) - u_n, \quad n \geq 1,$$

is often based on the order, with respect to h, of the local residual

$$w_n := \sum_{i=0}^{k} (h^{-1}\alpha_{k-i} I - \beta_{k-i} f) \left(e^{t_{n-i} f}(\eta) \right), \quad n \geq 1.$$

The order is usually obtained by a Taylor expansion. If the same approach is to be used here, the following additional assumptions on the evolution map are sufficient:

(A2) $\frac{\mathrm{d}}{\mathrm{d}t}(e^{tf}(\eta)) = f(e^{tf}(\eta))$ for all $t \geq 0$,

(A3) $e^{(\cdot)f}(\eta) \in C^{p+1}([0, \infty), X)$.

These assumptions imply the standard result related to the order of the local residual stated below.

THEOREM 4.9. *If* (A1)–(A3) *hold and the multistep method (ρ, σ) is consistent of order p, then*

$$\|w_n\|_X = O(h^p) \quad \forall n \geq 1.$$

Proof. Assumptions (A1)–(A3) imply that $e^{(\cdot)f}(\eta)$ can be written as a p-order Taylor expansion, since integration by parts is possible in the context of Bochner integrals. Thus, the proof follows as in the ODE-setting; see [7]. ∎

Note that (A1)–(A3) hold if f is a linear map and $\eta \in D(f^{p+1})$; see [15].

5. Global error analysis. The aim is now to derive bounds of the global error by formulating (4.3) and the definition of the local residual as equations in X^N. To this end, introduce the nonlinear map $\mathcal{F} : D(f)^N \to X^N$ related to the vector field f on X and the linear maps $\mathcal{P}$, $\mathcal{S} : X^N \to X^N$ related to the $N \times N$-Toeplitz matrices

$$P := \begin{pmatrix} \alpha_k & \ldots & \alpha_0 & & \\ & \ddots & & & \\ & & \alpha_k & \ldots & \alpha_0 \\ & & & \ddots & \\ & & & & \alpha_k \end{pmatrix} \quad \text{and} \quad S := \begin{pmatrix} \beta_k & \ldots & \beta_0 & & \\ & \ddots & & & \\ & & \beta_k & \ldots & \beta_0 \\ & & & \ddots & \\ & & & & \beta_k \end{pmatrix}.$$

Next, define the nonlinear map $\mathcal{H} : D(f)^N \to X^N$ as

$$\mathcal{H}(U) := h^{-1}\mathcal{P}U - \mathcal{S}\mathcal{F}(U) + V_0,$$

where V_0 is a constant vector in X^N with k nonzero elements given by the initial data. Thus, the numerical approximations $U := (u_N, \ldots, u_1)^T$, the analytic solutions

$V := (e^{t_N f}(\eta), \ldots, e^{t_1 f}(\eta))^T$, and the local residuals $W := (w_N, \ldots, w_1)^T$ fulfill the equations $\mathcal{H}(V) = W$ and $\mathcal{H}(U) = 0$. Hence, $\mathcal{H}(V) - \mathcal{H}(U) = W$; i.e.,

$$h^{-1}\mathcal{P}(V - U) - \mathcal{S}(\mathcal{F}(V) - \mathcal{F}(U)) = W. \tag{5.1}$$

It is possible to derive bounds for the global errors $E := V - U$ from (5.1) if the topology imposed on X^N is correctly chosen. Before the bounds are derived, one needs to relate the stability properties presented in Definition 4.7 to the linear maps $\mathcal{P}$ and $\mathcal{S}$.

LEMMA 5.1. *There exist positive constants C_ρ and C_σ such that if the multistep method (ρ, σ) fulfills*

1. (S1)*, then $L_{X,p}[\mathcal{P}^{-1}] \le C_\rho N$;*
2. (S2) *and is implicit, then $L_{X,p}[\mathcal{S}^{-1}] \le C_\sigma$ for all $N \ge 1$.*

Proof. As P is an upper triangular Toeplitz matrix of size $N \times N$ with one $(\alpha_k \neq 0)$ to $k+1$ nonzero diagonals, the map $\mathcal{P}$ can be represented as

$$\mathcal{P} = \alpha_k \prod_{i=1}^{k} (I - \xi_i^\rho \mathcal{E}), \tag{5.2}$$

where $\mathcal{E}$ is the linear map related to the left shift matrix

$$\begin{pmatrix} 0 & 1 & & \\ & \ddots & \ddots & \\ & & \ddots & 1 \\ & & & 0 \end{pmatrix}.$$

Since $\mathcal{E}$ is nilpotent of order N, one has that

$$(I - \xi_i^\rho \mathcal{E})^{-1} = \sum_{n=0}^{N-1} (\xi_i^\rho)^n \mathcal{E}^n.$$

Hence, $\mathcal{P}^{-1} : X^N \to X^N$ is well defined and

$$L_{X,p}[\mathcal{P}^{-1}] \le \frac{1}{|\alpha_k|} \prod_{i=1}^{k} \sum_{n=0}^{N-1} |\xi_i^\rho|^n L_{X,p}[\mathcal{E}]^n.$$

The first assertion is now obtained as $L_{X,p}[\mathcal{E}] = 1$, and the method (ρ, σ) fulfills stability property (S1); i.e., $|\xi_i^\rho| < 1$ for $i = 1, \ldots, k-1$ and $\xi_k^\rho = 1$. The second assertion follows by making the same factorization of $\mathcal{S}$ as made for $\mathcal{P}$ in the previous part, which is possible as the method is implicit $(\beta_k \neq 0)$, and by using the fact that the method (ρ, σ) fulfills stability property (S2), i.e., $|\xi_i^\sigma| < 1$ for $i = 1, \ldots, k$. ∎

LEMMA 5.2. *If X is a separable Hilbert space and the implicit multistep method (ρ, σ) fulfills* (S2) *and* (S3)*, then $m^{\pm}_{X,2}[\mathcal{S}^{-1}\mathcal{P}] \ge 0$.*

Proof. Corollary 3.3, Lemma 5.1, and the factorization of $\mathcal{P}$ in (5.2) yields that $L_{X,2}[\mathcal{S}^{-1}\mathcal{P}] \le L_2[S^{-1}P] \le C_\sigma |\alpha_k| 2^k$ for all $N \ge 1$. Hence,

$$\begin{aligned} M^+_{X,2}[\mathcal{S}^{-1}\mathcal{P}] &= \sup_{\{U \in X^N : \|U\|_{X,2} = 1\}} \lim_{\varepsilon \to 0+} \frac{\|(\mathcal{I} + \varepsilon \mathcal{S}^{-1}\mathcal{P})U\|_{X,2} - \|U\|_{X,2}}{\varepsilon} \\ &\le \lim_{\varepsilon \to 0+} \frac{L_{X,2}[\mathcal{I} + \varepsilon \mathcal{S}^{-1}\mathcal{P}] - 1}{\varepsilon} \le \lim_{\varepsilon \to 0+} \frac{L_2[I + \varepsilon S^{-1}P] - 1}{\varepsilon} \\ &= \max\{\lambda : \lambda \in \operatorname{spec}((S^{-1}P + P^T S^{-T})/2)\}. \end{aligned}$$

The last equality follows by the well-known theory of logarithmic norms; see [7]. Thus, by Proposition 2.5,

$$m^{\pm}_{X,2}[\mathcal{S}^{-1}\mathcal{P}] \geq -M^{+}_{X,2}[-\mathcal{S}^{-1}\mathcal{P}] \geq \min\{\lambda : \lambda \in \operatorname{spec}((S^{-1}P + P^T S^{-T})/2)\}.$$

Using the analysis of Toeplitz matrices on $l_2(\mathbb{N})$ one has the bound

$$\min\{\lambda : \lambda \in \operatorname{spec}((S^{-1}P + P^T S^{-T})/2)\} \geq \min_{|\xi|=1} \operatorname{Re}\{\rho(\xi)/\sigma(\xi)\}.$$

See [20] for general theory and [10] for the applications in connection to multistep methods. As the method (ρ, σ) fulfills stability properties (S2) and (S3), the function $r : \xi \mapsto \operatorname{Re}\{\rho(\xi)/\sigma(\xi)\}$ is continuous for $|\xi| \geq 1$ and $r(\xi) > 0$ for all $|\xi| > 1$. Hence, $r(\xi) \geq 0$ for $|\xi| = 1$. Combining these results gives the bound

$$m^{\pm}_{X,2}[\mathcal{S}^{-1}\mathcal{P}] \geq \min_{|\xi|=1} \operatorname{Re}\{\rho(\xi)/\sigma(\xi)\} \geq 0,$$

which concludes the proof. ∎

It is now possible to derive a discrete L_2-bound of the global error for an implicit multistep approximation on Hilbert spaces, when the vector field f is (strictly) dissipative but otherwise unbounded.

THEOREM 5.3. *Consider the approximation of $e^{t_N f}(\eta)$, using the implicit multistep method (ρ, σ) on the separable Hilbert space X. If* (A1)–(A3) *hold, $M^{-}_{X}[f] < 0$, and the method (ρ, σ) is consistent of order p and fulfills* (S2) *and* (S3)*, then*

$$\left(h \sum_{i=1}^{N} \|e_i\|^2_X \right)^{1/2} \leq C \frac{\sqrt{t_N}}{-M^{-}_{X}[f]} h^p,$$

where the positive constant C is independent of N, $M^{-}_{X}[f]$, and t_N.

Proof. Equip X^N with the norm $\|\cdot\|_{X,2}$. Note that this norm induces the proper semi-inner products $(\cdot,\cdot)^{\pm}_{X,2}$; see Lemma 3.5. The hypotheses imposed on X and the method (ρ, σ) together with Lemmas 5.1 and 5.2 imply that $\mathcal{S}^{-1}$ is well defined, $L_{X,2}[\mathcal{S}^{-1}] \leq C_\sigma$, and $m^{\pm}_{X,2}[\mathcal{S}^{-1}\mathcal{P}] \geq 0$. It is therefore possible to apply the functional $(E, \mathcal{S}^{-1}(\cdot))^{+}_{X,2}$ to (5.1), which yields the bound

$$\begin{aligned}
(E, \mathcal{S}^{-1}W)^{+}_{X,2} &= (E, h^{-1}\mathcal{S}^{-1}\mathcal{P}(V - U) - [\mathcal{F}(V) - \mathcal{F}(U)])^{+}_{X,2} \\
&\geq m^{+}_{X,2}[h^{-1}\mathcal{S}^{-1}\mathcal{P} - \mathcal{F}]\|E\|^2_{X,2} \\
&\geq (h^{-1} m^{-}_{X,2}[\mathcal{S}^{-1}\mathcal{P}] - M^{-}_{X}[f])\|E\|^2_{X,2}.
\end{aligned}$$

Assume that $M^{-}_{X}[f] < 0$ and use the right Cauchy–Schwarz inequality on the term $(E, \mathcal{S}^{-1}W)^{+}_{X,2}$; then

$$\|E\|_{X,2} \leq \frac{L_{X,2}[\mathcal{S}^{-1}]}{h^{-1} m^{-}_{X,2}[\mathcal{S}^{-1}\mathcal{P}] - M^{-}_{X}[f]} \|W\|_{X,2} \leq \frac{C_\sigma}{-M^{-}_{X}[f]} \|W\|_{X,2}.$$

The desired bound is now obtained by Theorem 4.9 together with the inequality

$$\|W\|_{X,2} \leq \sqrt{N} \max_{1 \leq i \leq N} \|w_i\|_X \leq \sqrt{\frac{t_N}{h}} \max_{1 \leq i \leq N} \|w_i\|_X. \qquad \blacksquare$$

TABLE 5.1
Numerically observed convergence orders.

Δx	IE	BDF2
2^{-7}	$p = 1.0426$	$p = 1.9868$
2^{-8}	$p = 1.0426$	$p = 1.9867$
2^{-9}	$p = 1.0426$	$p = 1.9867$

It is easy to see how the mathematical problem influences the global error bound: the more dissipative the vector field is, i.e., the smaller $M_X^-[f]$, the smaller is the error. One important application of Theorem 5.3 is in the context of nonlinear parabolic PDEs where $X = L_2(\Omega)$. We illustrate this by the numerical example below.

Example 5.4. Consider the evolution governed by the dissipative extension $f : D \to L_2[0,1]$ of the perturbed r-Laplacian

$$\Delta_r : u \mapsto \partial_x(|\partial_x u|^{r-2}\partial_x u) + su$$

presented in Example 4.1. The evolution equation is discretized in space by finite differences on the equidistant grid $\{0, \Delta x, 2\Delta x, \ldots, K\Delta x, 1\}$, i.e., we consider the evolution governed by the vector field $f_{\Delta x} : X_{\Delta x} \to X_{\Delta x}$ defined as

$$(f_{\Delta x}(u))^i := \frac{1}{\Delta x}\left(g\left(\frac{u^{i+1}-u^i}{\Delta x}\right) - g\left(\frac{u^i - u^{i-1}}{\Delta x}\right)\right) + su^i \quad \text{for} \quad i = 1, \ldots, K,$$

where $g = |\cdot|^{r-2}(\cdot)$ and $u^0 = u^{K+1} = 0$. Furthermore, $X_{\Delta x} = (\mathbb{R}^K, \|\cdot\|_{\Delta x})$ with

$$\|u\|_{\Delta x} := \left(\Delta x \sum_{i=1}^{K} |u^i|^2\right)^{1/2}.$$

As Theorem 5.3 requires the multistep method (ρ, σ) to fulfill stability property (S3), we are restricted to methods which are consistent of order one or two, e.g., the implicit Euler $(\xi - 1, \xi)$ and the BDF2 $(3\xi^2/2 - 2\xi + 1/2, \xi^2)$ methods; see [8]. In Table 5.1 the numerically observed convergence orders are given for these multistep discretizations applied to the evolution equation

$$\dot{u} = f_{\Delta x}(u), \quad u(0) = \eta_{\Delta x},$$

with $\eta^i_{\Delta x} = 5e^{-1/i\Delta x(1-i\Delta x)}$, $\{r, s\} = \{3, -1\}$, and $t_N = 0.3$. In the implementation of both methods, the solution of (4.3) was approximated by using Newton's method with an exact Jacobian which is well defined as g is differentiable. The second starting value for the BDF2 method was obtained by an implicit Euler step. The errors were estimated by computing the numerical solutions for $h/t_N \in [h_1, h_2]$ and comparing with the one obtained with $h/t_N = h_0$. The parameters $\{h_0, h_1, h_2\}$ were chosen as $\{2^{-13}, 2^{-10}, 2^{-7}\}$ and $\{2^{-15}, 2^{-13}, 2^{-10}\}$ for the implicit Euler and the BDF2 implementations, respectively. As seen in Table 5.1, the observed convergence orders are independent of Δx and in agreement with Theorem 5.3.

In Theorem 5.3 we obtained the same convergence orders in the discrete L_2-norm as presented in [10] for ODEs, but it is also possible to derive error bounds in the infinity-norm on arbitrary Banach space if one considers approximations of an evolution governed by a Lipschitz continuous vector field on a restricted time interval.

THEOREM 5.5. *Approximate $e^{t_N f}(\eta)$, where $t_N \in (0, 1/(C_1 L_X[f]))$, by using the implicit multistep method (ρ, σ). If* (A1)–(A3) *hold, $h\beta_k/\alpha_k M_X^-[f] < 1$, and the method (ρ, σ) is consistent of order p and fulfills* (S1)*, then*

$$\max_{1 \le i \le N} \|e_i\|_X \le \frac{C_2 t_N}{1 - C_1 t_N L_X[f]} h^p,$$

where the positive constants C_1 and C_2 are independent of N, $L_X[f]$, and t_N.

Proof. Equip X^N with the norm $\|\cdot\|_{X,\infty}$. The hypotheses on the method (ρ, σ) and Lemma 5.1 give that the map $\mathcal{P}^{-1}$ is well defined and that $L_{X,\infty}[\mathcal{P}^{-1}] \le C_\rho N$. Furthermore, factorizing $\mathcal{S}$ as in (5.2) yields that $L_{X,\infty}[\mathcal{S}] \le |\beta_k| 2^k$. Thus, one can apply the functional $\|\mathcal{P}^{-1}(\cdot)\|_{X,\infty}$ to (5.1) and the following bound is obtained:

$$\begin{aligned} \|\mathcal{P}^{-1} W\|_{X,\infty} &= \|h^{-1}(V - U) - \mathcal{P}^{-1}\mathcal{S}(\mathcal{F}(V) - \mathcal{F}(U))\|_{X,\infty} \\ &\ge l_{X,\infty}[h^{-1}\mathcal{I} - \mathcal{P}^{-1}\mathcal{S}\mathcal{F}]\|E\|_{X,\infty} \\ &\ge (h^{-1} - L_{X,\infty}[\mathcal{P}^{-1}] L_{X,\infty}[\mathcal{S}] L_X[f])\|E\|_{X,\infty}. \end{aligned}$$

Assume that $C_1 t_N L_X[f] < 1$, with $C_1 := C_\rho |\beta_k| 2^k$; then

$$\|E\|_{X,\infty} \le \frac{L_{X,\infty}[\mathcal{P}^{-1}]}{h^{-1} - C_1 N L_X[f]} \|W\|_{X,\infty} \le \frac{C_\rho t_N}{1 - C_1 t_N L_X[f]} \|W\|_{X,\infty},$$

and the desired bound follows by Theorem 4.9. ∎

Note how the global error decreases and the time interval $(0, 1/(C_1 L_X[f]))$ increases as the contractive behavior of the vector field increases, i.e., as $L_X[f]$ tends to zero.

6. Conclusions. Using the theory of logarithmic Lipschitz constants, global error bounds have been derived in the setting of multistep time discretizations of fully nonlinear evolution equations on infinite dimensional spaces. The bounds clearly reveal how the contractive or dissipative behavior of the vector field, governing the evolution, and the properties of the multistep method influence the convergence. Furthermore, the obtained convergence results are closely related to the ones found in the ODE-context.

SEMI-ITERATIVE REGULARIZATION IN HILBERT SCALES*

HERBERT EGGER†

Abstract. In this paper we investigate the regularizing properties of semi-iterative regularization methods in Hilbert scales for linear ill-posed problems and perturbed data.

It is well known that standard Landweber iteration can be remarkably accelerated by polynomial acceleration methods leading to *optimal speed of convergence*, which can be obtained by several efficient two-step methods, e.g., the ν-methods by Brakhage. It was observed earlier that a similar speed of convergence, i.e., similar iteration numbers yielding optimal convergence rates, can be obtained if Landweber iteration is performed in Hilbert scales.

We show that a combination of both ideas allows for a further acceleration, yielding optimal convergence rates with only the square root of iterations as compared to the ν-methods or Landweber iteration in Hilbert scales. The theoretical results are illustrated by several examples and numerical tests, including a comparison to the method of conjugate gradients.

Key words. inverse problems, regularization, Hilbert scales, semi-iterative methods

1. Introduction.

In this paper, we study inverse problems of the form

$$Tx = y, \tag{1.1}$$

where $T : \mathcal{X} \to \mathcal{Y}$ is a linear bounded operator between infinite-dimensional Hilbert spaces $\mathcal{X}$ and $\mathcal{Y}$ with range $\mathcal{R}(T) \subset \mathcal{Y}$. It is well known (see, e.g., [6]) that the Moore–Penrose inverse $T^\dagger$, which is defined on $\mathcal{D}(T^\dagger) = \mathcal{R}(T) + \mathcal{R}(T)^\perp$ and maps data $y \in \mathcal{D}(T^\dagger)$ onto the best approximate solution $x^\dagger$, is unbounded if $\mathcal{R}(T)$ is not closed, and hence the solution of (1.1) is ill-posed; in particular, even for $y \in \mathcal{D}(T^\dagger)$ a solution of (1.1) does not depend continuously on the right-hand side and thus has to be regularized.

Especially for large-scale problems, iterative regularization algorithms have turned out to be an attractive alternative to Tikhonov regularization, which is probably the most well-known regularization method (see, e.g., [4, 7]). Application of Landweber iteration (cf. [12]),

$$x_k = x_{k-1} + \omega T^*(y - Tx_{k-1}), \qquad k \geq 1, \tag{1.2}$$

with $0 < \omega < 2/\|T^*T\|$ to the solution of inverse problems has been investigated intensively in the literature (see, e.g., [1, 4, 9] and the references cited there). Formally, (1.2) corresponds to Richardson iteration (successive approximation) applied to the normal equation

$$T^*Tx = T^*y.$$

If $y \in \mathcal{D}(T^\dagger)$, then the iterates x_k converge to $T^\dagger y$; if, however, only perturbed data y^δ with a known upper bound on the noise level

$$\|y - y^\delta\| \le \delta \tag{1.3}$$

are known and $y^\delta \notin \mathcal{D}(T^\dagger)$, which is most probable if (1.1) is ill-posed and $\mathcal{R}(T)$ is not closed, then $\|x_k\|$ tends to infinity.

Iterative methods are turned into regularization algorithms by stopping the iteration after an adequate number k_* of steps. Besides a priori stopping rules, which require knowledge of the smoothness of $x^\dagger - x_0$ in terms of spaces $\mathcal{R}((T^*T)^\mu)$, the discrepancy principle (cf. [4, 14])

$$\|y^\delta - Tx_{k_*}\| \le \tau\delta < \|y^\delta - Tx_k\|, \qquad 0 \le k < k_*, \tag{1.4}$$

with $\tau > 1$ has turned out to be an appropriate a posteriori stopping rule yielding optimal convergence rates for Landweber iteration; i.e., if

$$x^\dagger - x_0 \in \mathcal{R}((T^*T)^\mu), \qquad \mu > 0, \tag{1.5}$$

then stopping by the discrepancy principle (1.4) yields (see, e.g., [4])

$$\|x_{k_*}^\delta - x^\dagger\| = o(\delta^{\frac{2\mu}{2\mu+1}}) \quad \text{and} \quad k_* = O(\delta^{-\frac{2}{2\mu+1}}). \tag{1.6}$$

The main drawback of Landweber iteration is its slow performance, i.e., a large number of iterations needed to obtain the optimal convergence rates (1.6). In order to accelerate the solution process, several *semi-iterative methods* (polynomial acceleration methods) have been proposed and analyzed in the framework of regularization (see, e.g., [8] for an overview). In our numerical experiments, we will use Brakhage's ν-methods [2], for which the number of iteration can be bounded by

$$k_* \sim \delta^{-\frac{1}{2\mu+1}} \quad \text{for} \quad 0 < \mu \le \nu - \tfrac{1}{2} \tag{1.7}$$

in case of stopping according to the discrepancy principle (1.4) (see Theorem 2.1). Thus optimal convergence rates can be obtained with approximately the square root of iterations than needed for ordinary Landweber iteration. Note that in contrast to Landweber iteration, the ν-methods show a saturation phenomenon; i.e., the optimal rates and (1.7) hold only for $\mu \le \nu$, respectively, $\mu \le \nu - 1/2$, if the iteration is stopped according to (1.4).

Regularization in Hilbert scales was introduced by Nătterer [15] in the framework of Tikhonov regularization for linear problems. More recently, the Hilbert scale approach has been investigated also for more general regularization methods for linear problems (see [4, 19]) by means of spectral theory. Originally, Hilbert scales were used to increase the range of optimal convergence for Tikhonov regularization [15, 17] and Landweber iteration for nonlinear inverse problems [18]. In [3], the case $s < 0$ (undersmoothing) was investigated in more detail for Landweber iteration, and it was shown that the application of Hilbert scales can be understood as preconditioning in this case, i.e., the number of iterations needed to get optimal convergence can be reduced, essentially, to (1.7). Additionally, the results in [3] were derived under more general than the usual assumptions for regularization in Hilbert scales (cf. section 3).

The aim of this paper is to show that the combination of polynomial acceleration methods with the Hilbert scale approach leads to a further acceleration of iterative

regularization methods, yielding optimal rates of convergence with stopping indices bounded by $k_* = O(\delta^{-\frac{1}{2(2\mu+1)}})$. In case of mildly ill-posed problems, i.e., if the singular values σ_n of the operator T decay like $O(n^{-\alpha})$ for some $0 < \alpha < 1$, the performance may even be better than that of the conjugate gradient method in the standard spaces, where we have $k_* \leq \delta^{-\frac{1}{(2\mu+1)(1+\alpha)}}$ (cf. [4, Theorem 7.14]). The faster convergence of a Hilbert scale ν-method is also illustrated numerically in Examples 5.1 and 5.3. At least formally, preconditioning in Hilbert scales can also be applied to the conjugate gradient method; a rigorous analysis of such a method will be the subject of a subsequent article.

The paper is organized as follows: in sections 2 and 3, we briefly repeat the main results on convergence of semi-iterative regularization methods and regularization in Hilbert scales. The convergence analysis for semi-iterative methods in Hilbert scales is presented in section 4. We conclude with numerical examples comparing the proposed method to the standard Landweber iteration and ν-methods, Landweber iteration in Hilbert scales, and the conjugate gradient method.

2. Accelerated Landweber methods. While for Landweber iteration (1.2) only information about the last iterate x_{k-1}^δ is used to construct the new approximation x_k^δ, semi-iterative methods make use of all the approximations for $T^\dagger y$ obtained so far: a basic step of a semi-iterative method has the form (cf. [4, 8])

$$\begin{aligned} x_k^\delta &= \mu_{1,k} x_{k-1}^\delta + \cdots + \mu_{k,k} x_0^\delta + \omega_k T^*(y^\delta - T x_{k-1}^\delta), \quad k \geq 1, \\ &\textstyle\sum_{i=1}^k \mu_{i,k} = 1, \qquad \omega_k \neq 0, \end{aligned} \tag{2.1}$$

where we set $x_0^\delta = x_0$. The iterates defined by (2.1) with y^δ replaced by the true data y will be denoted by x_k. Obviously $x_k^\delta - x_0 \in \mathcal{K}_k(T^*T, T^*(y^\delta - Tx_0))$, where

$$\mathcal{K}_k(T^*T, p) := \operatorname{span}\{p, T^*Tp, \dots, (T^*T)^{k-1}p\}$$

denotes the kth Krylov subspace of T^*T with respect to p. Consequently, there exist polynomials $g_k(\lambda)$ and $r_k(\lambda) := 1 - \lambda g_k(\lambda)$ of degree $(k-1)$, respectively, k, such that

$$x_k - x^\dagger = r_k(T^*T)(x_0 - x^\dagger) \qquad \text{and} \qquad x_k^\delta - x_k = g_k(T^*T)T^*(y^\delta - y).$$

In other words, the approximation error $x_k - x^\dagger$ is determined by the *residual polynomials* r_k, while the propagated data error $x_k^\delta - x_k$ is determined by the *iteration polynomials* g_k. Of particular importance are methods whose residual polynomials r_k form an orthogonal sequence with respect to some positive weight function. In this case, the residual polynomials satisfy a three-term recurrence, which also carries over to the iterates; i.e., there exist sequences μ_k and ω_k such that

$$x_k^\delta = x_{k-1}^\delta + \mu_k(x_{k-1}^\delta - x_{k-2}^\delta) + \omega_k T^*(y^\delta - T x_{k-1}^\delta), \quad k \geq 1,$$

with $x_0^\delta = x_{-1}^\delta = x_0$. A specific instance of such methods are the ν-methods by Brakhage [2], which are defined by $\mu_1 = 0$, $\omega_1 = (4\nu+2)/(4\nu+1)$, and

$$\begin{aligned} \mu_k &= \frac{(k-1)(2k-3)(2k+2\nu-1)}{(k+2\nu-1)(2k+4\nu-1)(2k+2\nu-3)}, \\ \omega_k &= 4\frac{(2k+2\nu-1)(k+\nu-1)}{(k+2\nu-1)(2k+2\nu-1)}, \qquad k > 1. \end{aligned}$$

Each ν-method has *optimal speed of convergence* for $x^\dagger - x_0 \in \mathcal{R}((T^*T)^\mu)$ with $0 \le \mu \le \nu$; i.e., its residual polynomials satisfy

$$\|\lambda^\mu r_k(\lambda)\|_{\mathcal{C}[0,1]} = O(k^{-2\mu}) \tag{2.2}$$

for $\mu \le \nu$. In fact, it seems that the estimate (2.2) is the best possible in terms of powers of k for semi-iterative methods with real orthogonal polynomials, cf. [8].

The following theorem (cf. [4, Theorem 6.11]) guarantees convergence rates of optimal order for semi-iterative regularization methods satisfying (2.2) if they are equipped with appropriate stopping rules.

THEOREM 2.1. *Let $y \in \mathcal{R}(T)$, and let the residual polynomials r_k satisfy* (2.2) *for some $\mu_0 > 0$. Then the semi-iterative method* (2.1) *is a regularization method of optimal order for $T^\dagger y \in \mathcal{R}((T^*T)^\mu)$ with $0 < \mu \le \mu_0 - 1/2$, provided the iteration is stopped with $k_* = k_*(\delta, y^\delta)$ according to the discrepancy principle* (1.4) *with fixed $\tau > \sup_{k\in\mathcal{N}} \|r_k\|_{\mathcal{C}[0,1]}$. In this case we have $k_* = O(\delta^{-\frac{1}{2\mu+1}})$ and $\|x_k^\delta - x^\dagger\| = O(\delta^{\frac{2\mu}{2\mu+1}})$.*

Note that even $o(\cdot)$ can be derived for the error $\|x_k^\delta - x^\dagger\|$ (see [4]).

3. Regularization in Hilbert scales. Before we recall some results on regularization in Hilbert scales, we briefly repeat the definition of a Hilbert scale (see [11]): let L be a densely defined, unbounded, self-adjoint and strictly positive operator in $\mathcal{X}$. Then $(\mathcal{X}_s)_{s\in\mathbb{R}}$ denotes the Hilbert scale induced by L if $\mathcal{X}_s$ is the completion of $\bigcap_{k=0}^\infty D(L^k)$ with respect to the Hilbert space norm $\|x\|_s := \|L^s x\|_{\mathcal{X}}$; obviously $\|x\|_0 = \|x\|_{\mathcal{X}}$ (see [11] or [4, section 8.4] for details).

Regularization in Hilbert scales was introduced by Natterer [15] in order to improve convergence rates for Tikhonov regularization. In [18], Landweber iteration for nonlinear problems, which exhibits saturation phenomena similar to that of Tikhonov regularization (i.e., optimal convergence only for $x^\dagger - x_0 \in \mathcal{R}((T^*T)^\mu)$, $\mu \le 1/2$), has been shifted to Hilbert scales (with $s > 0$) in order to overcome the restriction $\mu \le 1/2$.

In [3], the application of the Hilbert scale approach to iterative regularization methods has been investigated from a different point of view: there, the emphasis is on the case $s < 0$, in which the Hilbert scale operator L^{-2s} appearing in the modified Landweber iteration

$$x_{k+1}^\delta = x_k^\delta + L^{-2s}T^*(y^\delta - Tx_k^\delta), \qquad k \ge 0, \tag{3.1}$$

acts as a preconditioner for the adjoint operator T^*. As a consequence, the operator $L^{-2s}T^*T$ in the preconditioned normal equation

$$L^{-2s}T^*Tx = L^{-2s}T^*y^\delta \tag{3.2}$$

has a smaller degree of ill-posedness than T^*T, while being self-adjoint in $\mathcal{X}_s$. For a finite-dimensional approximation, this implies smaller condition numbers of the iteration operators $(L^{-2s}T^*T)$, which in turn yields a faster decrease of the residual and allow to stop the residual earlier.

For a convergence rates analysis of iterative regularization methods in Hilbert scales we will need the following assumption (cf. [3]).

ASSUMPTION 3.1. *For T and L as above assume that*

(A1) *$Tx = y$ has a solution $x^\dagger$.*

(A2) *$\|Tx\| \le \overline{m}\|x\|_{-a}$ for all $x \in \mathcal{X}$ and some $a > 0, \overline{m} > 0$. Moreover, the extension of T to $\mathcal{X}_{-a}$ (again denoted by T) is injective.*

(A3) *For some $s \ge -a$ let $B := TL^{-s}$ be such that $\|B\|_{\mathcal{X},\mathcal{Y}} \le 1$.*

The following result, taken from [3], draws some conclusions from Assumption 3.1, which will be needed for the subsequent convergence analysis.

PROPOSITION 3.2. *Let Assumption* 3.1 *hold. Then condition* (A2) *is equivalent to*

$$\mathcal{R}(T^*) \subset \mathcal{X}_a \qquad \text{and} \qquad \|T^* w\|_a \le \overline{m}\|w\| \quad \text{for all} \quad w \in \mathcal{Y}.$$

Moreover, for all $\nu \in [0,1]$ *it holds that* $\mathcal{D}((B^*B)^{-\frac{\nu}{2}}) = \mathcal{R}((B^*B)^{\frac{\nu}{2}}) \subset \mathcal{X}_{\nu(a+s)}$ *and*

$$\begin{aligned} \|(B^*B)^{\frac{\nu}{2}} x\| &\le \overline{m}^{\nu} \|x\|_{-\nu(a+s)} \qquad \text{for all} \quad x \in \mathcal{X}, \\ \|(B^*B)^{-\frac{\nu}{2}} x\| &\ge \overline{m}^{-\nu} \|x\|_{\nu(a+s)} \qquad \text{for all} \quad x \in \mathcal{D}((B^*B)^{-\frac{\nu}{2}}). \end{aligned} \tag{3.3}$$

Furthermore, (3.5) *is equivalent to*

$$\mathcal{X}_{\tilde a} \subset \mathcal{R}(T^*) \quad \text{and} \quad \|T^* w\|_{\tilde a} \ge \underline{m}\|w\| \quad \text{for all} \quad w \in \mathcal{N}(T^*)^\perp \text{ with } T^* w \in \mathcal{X}_{\tilde a},$$

and if (3.5) *holds, then it follows for all* $\nu \in [0,1]$ *that* $\mathcal{X}_{\nu(\tilde a+s)} \subset \mathcal{R}((B^*B)^{\frac{\nu}{2}}) = \mathcal{D}((B^*B)^{-\frac{\nu}{2}})$ *holds and*

$$\begin{aligned} \|(B^*B)^{\frac{\nu}{2}} x\| &\ge \underline{m}^{\nu} \|x\|_{-\nu(\tilde a+s)} \qquad \text{for all} \quad x \in \mathcal{X}, \\ \|(B^*B)^{-\frac{\nu}{2}} x\| &\le \underline{m}^{-\nu} \|x\|_{\nu(\tilde a+s)} \qquad \text{for all} \quad x \in \mathcal{X}_{\nu(\tilde a+s)}. \end{aligned}$$

Usually, for the analysis of regularization methods in Hilbert scales, a stronger condition than (A2) is used, namely (cf., e.g., [15, 17])

$$\|Tx\| \sim \|x\|_{-a} \qquad \text{for all} \quad x \in \mathcal{X}, \tag{3.4}$$

where the number a can be interpreted as the *degree of ill-posedness*. However, if $s \le 0$, an estimate from below (possibly in a weaker norm), e.g.,

$$\|Tx\| \ge \underline{m}\|x\|_{-\tilde a} \quad \text{for all} \quad x \in \mathcal{X} \quad \text{and some} \quad \tilde a \ge a,\ \underline{m} > 0, \tag{3.5}$$

is only needed to interpret the smoothness condition on $x^\dagger - x_0$ required for the convergence analysis in terms of the Hilbert scale $\{\mathcal{X}_s\}_{s\in\mathbb{R}}$: if (3.4) holds, then it follows from Proposition 3.2 that $\mathcal{X}_{\nu a} = \mathcal{R}((T^*T)^{\nu/2})$ for $|\nu| \le 1$ (see also Remark 3.7 below).

Before we come to our convergence analysis, we briefly discuss the connection of regularization in Hilbert scales to regularization in standard spaces and we point out the appropriate smoothness conditions for $x^\dagger - x_0$.

Remark 3.3. Regularization in Hilbert scales, e.g., (3.1), amounts to standard regularization when considering (the extension of) T as an operator on $\mathcal{X}_s$. The adjoint with respect to the spaces $\mathcal{X}_s$ and $\mathcal{Y}$ is denoted by $T^\sharp = L^{-2s}T^*$, where T^* denotes the adjoint with respect to $\mathcal{X}$ and $\mathcal{Y}$. Hence (3.2) are the normal equations for $Tx = y$ with $T : \mathcal{X}_s \to \mathcal{Y}$. Using the notation $z = L^s x$ and $B = TL^{-s}$, one sees that (1.1) is equivalent to

$$Bz = y, \qquad L^s x = z, \tag{3.6}$$

where in the second problem L^s maps from $\mathcal{X}_s$ to $\mathcal{X}$ and thus is an isomorphism. Applying standard regularization theory to (3.6) yields

$$z_k^\delta = g_k(B^*B)B^* y^\delta, \quad \text{respectively,} \quad x_k^\delta = L^{-s} g_k(B^*B)B^* y^\delta. \tag{3.7}$$

Moreover, the usual source condition for (3.6) reads

$$z^\dagger - z_0 = (B^*B)^\mu w, \quad \text{or equivalently,} \quad x^\dagger - x_0 = L^{-s}(B^*B)^\mu w \tag{3.8}$$

for some $w \in \mathcal{X}$. Due to (3.8), we call $x^\dagger - x_0 = L^{-s}(B^*B)^\mu w$ also a *source condition* below.

As can be seen from the previous remark, the following shifted Hilbert scale will play an important role in the convergence analysis of iterative regularization methods in Hilbert scales, in particular for the formulation of appropriate source, respectively, smoothness conditions.

DEFINITION 3.4. *Let a, $s > -a$, and B be as in Assumption* 3.1. *We define the shifted Hilbert scale $\{\mathcal{X}_r^s\}_{r\in\mathbb{R}}$ by*

$$\begin{aligned} &\mathcal{X}_r^s := \mathcal{D}((B^*B)^{\frac{s-r}{2(a+s)}} L^s) \quad \textit{equipped with the norm} \\ &\|\!|x|\!\|_r := \|(B^*B)^{\frac{s-r}{2(a+s)}} L^s x\|_{\mathcal{X}}. \end{aligned} \tag{3.9}$$

Remark 3.5. Note, that for $s \neq 0$ the spaces $\mathcal{X}_r^s$ form no Hilbert scale over $\mathcal{X}$ in general. In particular, $\mathcal{X}_{-r}^s$ is usually not the dual space of $\mathcal{X}_r^s$. Nevertheless, the spaces $\mathcal{X}_r^s$ have some properties (interpolation, embedding) that justify the notion of *shifted Hilbert scale* (see Proposition 3.6 below). To see that the spaces $\mathcal{X}_u^s$ are natural source sets for (1.1) considered over $\mathcal{X}_s$, observe that

$$\mathcal{X}_u^s = \{L^{-s}(B^*B)^{\frac{u-s}{2(a+s)}} w,\ w \in \mathcal{X}\} = \{(T^\sharp T)^{\frac{u-s}{2(a+s)}} w_s,\ w_s \in \mathcal{X}_s\},$$

where the second equality follows directly for $\frac{u-s}{2(a+s)}$ being integer. For arbitrary indices it follows by interpolation and Proposition 3.2.

The next proposition (cf. [3, Proposition 3]) summarizes the main properties of the shifted Hilbert scale (3.9), which are needed for the convergence analysis below, and clarifies the relation between the spaces $\mathcal{X}_s$ and $\mathcal{X}_r^s$.

PROPOSITION 3.6. *Let Assumption* 3.1 *hold and let $(\mathcal{X}_r^s)_{r\in\mathbb{R}}$ be defined as in Definition* 3.4. *Then the following hold:*

(i) *For $p < q$, the spaces $\mathcal{X}_q^s$ are continuously embedded in $\mathcal{X}_p^s$, i.e., for $x \in \mathcal{X}_q^s$,*

$$\|\!|x|\!\|_p \leq \gamma^{p-q} \|\!|x|\!\|_q,$$

where γ is such that

$$\langle (B^*B)^{-\frac{1}{2(a+s)}} x, x\rangle \geq \gamma \|x\|^2 \quad \textit{for all} \quad x \in \mathcal{D}((B^*B)^{-\frac{1}{2(a+s)}}).$$

(ii) *The interpolation inequality*

$$\|\!|x|\!\|_q \leq \|\!|x|\!\|_p^{\frac{r-q}{r-p}} \|\!|x|\!\|_r^{\frac{q-p}{r-p}}, \qquad p < q < r,$$

holds for all $x \in \mathcal{X}_r^s$.

(iii) *For $s \leq r \leq a + 2s$,*

$$\|x\|_r \leq \overline{m}^{\frac{r-s}{a+s}} \|\!|x|\!\|_r \qquad \textit{for all} \quad x \in \mathcal{X}_r^s \subset \mathcal{X}_r. \tag{3.10}$$

In particular, if $-a/2 \leq s \leq 0$, we obtain

$$\|x\|_0 \leq \overline{m}^{\frac{-s}{a+s}} \|\!|x|\!\|_0 \qquad \textit{for all} \quad x \in \mathcal{X}_0^s \subset \mathcal{X}_0.$$

Moreover,

$$\|\!|x|\!\|_{-a} = \|Tx\| \qquad \textit{for all} \quad x \in \mathcal{X}.$$

(iv) *If, in addition,* (3.5) *is satisfied, then the following estimates hold for* $s \le r \le a + 2s$ *with* $p = s + \frac{r-s}{a+s}(\tilde{a} + s)$*:*

$$\|x\|_p \ge \underline{m}^{\frac{r-s}{a+s}} \|\!|x|\!\|_r \qquad \text{for all} \quad x \in \mathcal{X}_p \subset \mathcal{X}_r^s.$$

Proof. We prove only (3.10) in detail: by definition of the Hilbert scale norm $\|\cdot\|_s$ in (3.9), and with (3.3), we obtain for $x \in \mathcal{X}_r^s \cap \mathcal{X}_r$

$$\|x\|_r = \|L^{r-s} L^s x\| \le \overline{m}^{\frac{r-s}{a+s}} \|(B^*B)^{\frac{s-r}{2(a+s)}} L^s x\| = \|\!|x|\!\|_r.$$

This implies the space inclusion $\mathcal{X}_r^s \subset \mathcal{X}_r$. The other assertions follow similarly from [4, Proposition 8.19] and Proposition 3.2. ∎

Before we begin our convergence analysis, we discuss the assertions of the previous proposition in more detail.

Remark 3.7. Under Assumption 3.1, and for the range $-a \le r \le s$, we have $\mathcal{X}_r \subset \mathcal{X}_r^s$, while for $s \le r \le a + 2s$ the opposite inclusion $\mathcal{X}_r^s \subset \mathcal{X}_r$ holds. If the stronger condition (3.4) holds instead of (A2), then the reverse statements are valid; i.e., both inclusions together yield $\mathcal{X}_r^s = \mathcal{X}_r$ for $-a \le r \le a + 2s$. The restriction $r \le a + 2s$ amounts to $\nu \le 1$ in Proposition 3.2 and can be relaxed if, e.g., the stronger condition $\|(T^*T)^\eta x\| \le \|x\|_{-2\eta a}$ holds for some $\eta > 1/2$, or if L and T commute (cf. [19]), in which case the previous estimate holds for all $\eta > 0$.

If (3.4) holds, we also obtain by Proposition 3.2 and Definition 3.4 that

$$\|(T^*T)^{-\frac{u}{2a}} x\| \sim \|x\|_u = \|L^{u-s} L^s x\| \sim \|\!|x|\!\|_u$$

for $-a \le u \le \min\{a, a+2s\}$. Here, the first estimate holds for $|u| \le a$ and the second for $|\frac{u-s}{a+s}| \le 1$, which is $-a \le u \le a + 2s$.

4. Convergence rates for iterative regularization methods in Hilbert scales. We start by citing a convergence rate result for Landweber iteration in Hilbert scales derived in [3].

THEOREM 4.1. *Let Assumption* 3.1 *hold and* $-a/2 \le s \le 0$*. Additionally, assume* $x^\dagger - x_0 \in \mathcal{X}_u^s$*, i.e.,*

$$x^\dagger - x_0 = L^{-s}(B^*B)^{\frac{u-s}{2(a+s)}} w \tag{4.1}$$

for some $w \in \mathcal{X}$ *and* $u > 0$*. Then*

$$\|x_k^\delta - x^\dagger\| \le c(\delta k^{\frac{a}{2(a+s)}} + k^{-\frac{u}{2(a+s)}} \|\!|x^\dagger - x_0|\!\|_u).$$

If the iteration (3.1) *is stopped according to the a priori rule* $k^* \sim (\|w\|\delta^{-1})^{\frac{2(a+s)}{a+u}}$*, then*

$$\|x_k^\delta - x^\dagger\| = O(\|w\|^{\frac{a}{a+u}} \delta^{\frac{u}{a+u}}).$$

If, alternatively, the iteration is stopped according to the discrepancy principle (1.4)*, then*

$$k_* \sim \delta^{-\frac{2(a+s)}{a+u}} \quad \text{and} \quad \|x_k^\delta - x^\dagger\| = O(\delta^{\frac{u}{a+u}}). \tag{4.2}$$

Remark 4.2. It was mentioned in [3] that, if the usual condition (3.4) holds instead of (A2), then for $0 < u \le a + 2s$ these rates are optimal, i.e., the best possible worst-case error bounds under the given source condition (cf. Remarks 3.3 and 3.5).

Observe that for $s < 0$, the stopping index of the Hilbert scale method is smaller than the one for Landweber iteration; e.g., for $x^\dagger - x_0 \in \mathcal{R}((T^*T)^{\frac{u}{2a}}) \cap \mathcal{X}_u^s$ and $s = -\frac{a}{2}$ the preconditioned iteration yields approximately the square root of iterations compared to standard Landweber. As can be seen from (3.1), the preconditioned iterations are in general not well defined as iterations on $\mathcal{X}$ for $s < -\frac{a}{2}$ and arbitrary $y^\delta \in \mathcal{Y}$.

The rest of this section is devoted to the derivation of a corresponding convergence rate result for general semi-iterative regularization methods in Hilbert scales. Recall the connection of Hilbert scale regularization with standard regularization over $\mathcal{X}_s$; cf. Remark 3.3. The formulae in (3.7) then allow the following closed-form representations of the approximation error and the propagated data error:

$$z_k - z^\dagger = r_k(B^*B)(z_0 - z^\dagger) \qquad \text{and} \qquad z_k^\delta - z_k = g_k(B^*B)B^*(y^\delta - y). \tag{4.3}$$

Noting that $z = L^s x$, this yields

$$\begin{aligned} x_k - x^\dagger &= L^{-s} r_k(B^*B) L^s (x_0 - x^\dagger), \\ x_k^\delta - x_k &= L^{-s} g_k(B^*B) B^*(y^\delta - y). \end{aligned} \tag{4.4}$$

If the residual polynomials are generated by (2.1), the preconditioned iterates x_k^δ can be assembled by the iteration

$$\begin{gathered} x_k^\delta = \mu_{1,k} x_{k-1}^\delta + \cdots + \mu_{k,k} x_0 + \omega_k L^{-2s} T^*(y^\delta - T x_k^\delta), \quad k \geq 1, \\ \textstyle\sum_{i=1}^k \mu_{i,k} = 1, \qquad \omega_k \neq 0. \end{gathered} \tag{4.5}$$

Note that in practice (4.5) is typically a two- or three-term recurrence. The only difference between the preconditioned iteration (4.5) and the standard method (2.1) is that the residuals $T^*(y^\delta - Tx_k)$ are preconditioned by L^{-2s}.

We are now in the position to state and prove the main results.

PROPOSITION 4.3. *Let Assumption* 3.1 *hold with* $-a/2 \leq s \leq 0$, *and let* x_k^δ *be defined by the semi-iterative method* (4.5) *satisfying* (2.2) *for some* $\mu_0 > 0$. *Additionally, assume that* $x^\dagger - x_0 \in \mathcal{X}_u^s$; *i.e.,* (4.1) *holds for some* $w \in \mathcal{X}$ *and* $0 < u \leq 2(a+s)\mu_0$. *Then*

$$\|x_k^\delta - x^\dagger\| \leq C_u(\delta k^{\frac{a}{(a+s)}} + k^{-\frac{u}{(a+s)}} \|w\|). \tag{4.6}$$

Proof. Using the source condition (4.1) and the representation (4.4), we obtain with (3.3) that

$$\begin{aligned} \|x_k - x^\dagger\| &= \|L^{-s} r_k(B^*B)(B^*B)^{\frac{u-s}{2(a+s)}} w\| \\ &\leq c\, \|(B^*B)^{\frac{u}{2(a+s)}} r_k(B^*B)\|\, \|w\|. \end{aligned}$$

By spectral theory and (2.2) this yields for $0 < u \leq 2(a+s)\mu_0$ the estimate

$$\|x_k - x^\dagger\| \leq c_u k^{-\frac{u}{(a+s)}} \|w\|$$

for the approximation error. Similarly, the propagated data error can be estimated by

$$\begin{aligned} \|x_k^\delta - x_k\| = \|L^{-s} g_k(B^*B) B^*(y^\delta - y)\| &\leq c\,\delta\, \|(B^*B)^{\frac{a+2s}{2(a+s)}} g_k(B^*B)\| \\ &\leq c\delta \|\lambda^{\frac{a+2s}{2(a+s)}} g_k(\lambda)\|_{\mathcal{C}[0,1]}. \end{aligned}$$

Next, we derive an estimate for $\|\lambda^\mu g_k(\lambda)\|_{\mathcal{C}[0,1]}$: since $r_k(\lambda) = 1 - \lambda g_k(\lambda)$, we obtain for $0 \le \mu \le 1$ that

$$\begin{aligned}\lambda^\mu g_k(\lambda) &= \lambda^{\mu-1}(1 - r_k(\lambda)) \\ &= [\lambda^{-1}(1 - r_k(\lambda))]^{1-\mu}[1 - r_k(\lambda)]^\mu.\end{aligned}$$

Now, by the mean value theorem, one can find a $\tilde\lambda \in [0,1]$ such that

$$\lambda^{-1}(1 - r_k(\lambda)) = -r_k'(\tilde\lambda),$$

which, together with Markov's inequality ($|r_k'(\lambda)| \le 2k^2$) and $|r_k(\lambda)| \le 2$ for $\lambda \in [0,1]$, yields

$$\lambda^\mu g_k(\lambda) \le 2k^{2(1-\mu)} \quad \text{for} \quad \lambda \in [0,1].$$

Since $-a/2 \le s \le 0$ by assumption, we obtain $0 \le \frac{a+2s}{2(a+s)} \le 1$ and thus by the previous estimates $\|x_k^\delta - x_k\| \le 2\,c\,\delta\,k^{\frac{a}{a+s}}$. ∎

Proposition 4.3 guarantees convergence if k_* is chosen such that $\delta k_*^{\frac{a}{a+s}} \to 0$ and $k_* \to \infty$ with $\delta \to 0$. In order to get convergence rates in terms of δ one has to bound the number of iterations k_* in terms of δ appropriately.

THEOREM 4.4. *Let the assumptions of Proposition* 4.3 *be satisfied and x_k^δ be generated by the method* (4.5) *with residual polynomials r_k satisfying* (2.2) *for some $\mu_0 > 0$. If the iteration is stopped according to the a priori stopping rule $k_* = O(\delta^{\frac{a+s}{a+u}})$, then*

$$\|x_k^\delta - x^\dagger\| = O(\delta^{\frac{u}{a+u}})$$

for $x^\dagger - x_0 \in \mathcal{X}_u^s$ with $0 < u \le 2(a+s)\mu_0$.

If, alternatively, the iteration is stopped according to the discrepancy principle (1.4)*, then*

$$k_* = O(\delta^{\frac{a+s}{a+u}}) \quad \textit{and} \quad \|x_k^\delta - x^\dagger\| = O(\delta^{\frac{u}{a+u}}) \tag{4.7}$$

for $x^\dagger - x_0 \in \mathcal{X}_u^s$ with $0 < u \le 2(a+s)\mu_0 - a$.

Proof. The first result follows immediately from Proposition 4.3. For the second, observe that by (1.4) it follows that for $k < k_*$

$$(\tau - 1)\,\delta \le \|T(x_k^\delta - x_k)\| + \|T(x_k - x^\dagger)\|.$$

Similarly as in the proof of Proposition 4.3, one obtains

$$\|T(x_k^\delta - x_k)\| = \|Bg_k(B^*B)B^*(y^\delta - y)\| \le c\,\delta.$$

Hence, for τ sufficiently large and some $C > 0$,

$$C\delta \le \|T(x_k - x^\dagger)\| \le k^{-\frac{a+u}{a+s}} \|\!|x^\dagger - x_0|\!\|_u,$$

where the last inequality holds for $u \le 2(a+s)\mu_0 - a$. This already yields the bound on k_*. Next, observe that by (1.4) it follows that $\|T(x_{k_*} - x^\dagger)\| \le c\delta$. Application of the interpolation inequality yields

$$\begin{aligned}\|x_k - x^\dagger\| &\le c\,\|T(x_k - x^\dagger)\|^{\frac{u}{a+u}}\,\|w\|^{\frac{a}{a+u}} \\ &\le C\delta^{\frac{u}{a+u}}\,\|w\|^{\frac{a}{a+u}},\end{aligned}$$

which, together with $\|x_{k_*}^\delta - x_{k_*}\| \le c\, k_*^{\frac{a}{a+s}}\delta$ (cf. the proof of Proposition 4.3) and the bound on k_*, yields the a posteriori rate. ∎

Remark 4.5. For $s = 0$, Theorem 4.4 coincides with Theorem 2.1. As in [3], the rate (4.7) can also be proven in the stronger norm $\|\!|x_{k_*}^\delta - x^\dagger|\!\|_0$. Furthermore, it is possible to show that $\|\!|x_k^\delta - x^\dagger|\!\|_u$ stays bounded for $k \le k_*$. Together with $\|\!|x_{k_*}^\delta - x^\dagger|\!\|_{-a} = \|T(x_{k_*}^\delta - x^\dagger)\| = O(\delta)$ and interpolation arguments, one then obtains the rates

$$\|\!|x_k^\delta - x^\dagger|\!\|_r = O(\delta^{\frac{u-r}{a+u}}) \qquad \text{for} \quad -a \le r \le u \tag{4.8}$$

in intermediate norms. If additionally the stronger condition (3.4) holds, then by Proposition 3.6 and Remark 3.7, the spaces $\mathcal{X}_u^s$ and $\mathcal{X}_u$ coincide with equivalent norms for $-a \le u \le a + 2s$, and the rates in (4.8) hold for $\|x_k^\delta - x^\dagger\|_r$ with $-a \le r \le u$ (cf. [10]) and under the usual source condition for regularization in Hilbert scales, namely $x^\dagger - x_0 \in \mathcal{X}_u$. Using the improved a posteriori stopping rule given in [4, section 6], the rates (4.7) even hold for $0 < u \le 2(a+s)\mu_0$, as in the case of a priori stopping with $k_* = c\,\delta^{\frac{a+s}{a+u}}$.

To see the effect of preconditioning, consider $s = -a/2$, and $x^\dagger - x_0 \in \mathcal{R}((T^*T)^\mu) \cap \mathcal{X}_u^s$, where $u = 2a\mu$. Then the following bounds on the stopping index hold: $k_* = O(\delta^{\frac{2}{2\mu+1}})$ for Landweber iteration, $k_* = O(\delta^{\frac{1}{2\mu+1}})$ for ν-methods (with $\nu \ge \mu + 1/2$) or Landweber iteration in Hilbert scales, and $k_* = O(\delta^{\frac{1}{2(2\mu+1)}})$ for the Hilbert scale ν-methods (with $\nu \ge \mu + 1$). For $\mu = 1/2$ and $\delta = 0.01$, this amounts to a reduction of the iteration numbers from 10,000 to 100 to 10, when switching from Landweber iteration to the ν-methods and then to their Hilbert scale versions. This remarkable acceleration will be demonstrated in several numerical examples below.

5. Examples and numerical tests. In this section we present several examples, where the conditions of Assumption 3.1 are satisfied and thus the results of section 4 are applicable. We compare the performance of the proposed Hilbert scale ν-methods with standard Landweber iteration and ν-methods, Landweber iteration in Hilbert scales, and the method of conjugate gradients. For our numerical tests, we use very fine discretizations (by standard piecewise linear finite elements) in order to ensure that discretization errors can be neglected.

As a first example we consider the identification of a source term from distributed measurements.

Example 5.1. Let Ω be a bounded domain in $\mathbb{R}^n$, $n = 2, 3$, with sufficiently smooth boundary (e.g., $\partial\Omega \in \mathcal{C}^{1,1}$ or $\partial\Omega \in \mathcal{C}^{0,1}$ and Ω convex) or let Ω be a parallelepiped. Consider the operator $T : L_2(\Omega) \to L_2(\Omega)$ defined by $Tf = u$, with

$$Au := -\nabla \cdot (q\nabla u) + p \cdot \nabla u + cu = f, \qquad u|_{\partial\Omega} = 0, \tag{5.1}$$

and given sufficiently smooth parameters q, p, and c. Assume that A is uniformly elliptic; then a solution to (5.1) has improved regularity, i.e., $u \in H^2(\Omega) \cap H_0^1(\Omega)$ and $\|u\|_{H^2} \sim \|f\|_{L_2}$. Let $\mathcal{X}_2 = H^2(\Omega) \cap H_0^1(\Omega)$, with $L^2 u = -\Delta u$, define the Hilbert scale $\{\mathcal{X}_s\}_{s\in\mathbb{R}}$ over $\mathcal{X} = L_2(\Omega)$. Then we have $T \sim \mathcal{X}_2$, and thus Assumption 3.1 holds with $a = 2$. Moreover, the stronger condition (3.4) holds.

For our numerical tests, we set $\Omega = [0,1]^2$, $q = c = 1$, and $p = 0$. We choose $s = -a/2 = -1$ for preconditioning and $\nu = 2$ for the ν-methods; note that $\nu \ge 3/2$ is necessary to apply Theorem 4.4 for $u = 2a\mu = 1/2$ in our case. In our experiment, we try to identify the function

$$f^\dagger = (\pi^2 + 1)\sin(\pi x) + (4\pi^2 + 1)\sin(2\pi y)$$

TABLE 5.1

0.001	0.175605	0.17691	0.18289	0.17889	0.17137

corresponding to $u = \sin(\pi x) + \sin(2\pi y)$. As a starting value we choose $f_0 = 0$. With this setting, we have $f^\dagger \in \mathcal{R}((T^*T)^\mu)$ for all $0 \le \mu < 1/8$, and thus one would expect the iteration numbers $k_* \sim \delta^{-8/5}$ for Landweber iteration, $k_* \sim \delta^{-4/5}$ for Landweber iteration in Hilbert scales and the ν-methods, and $k_* \sim \delta^{-2/5}$ for the Hilbert scale ν-method. For $\Omega = [0,1]^2$, the singular values of T behave like $\sigma_n = O(n^{-1})$. Thus, the stopping index for the conjugate gradient method can be bounded by (apply Theorem 7.14 in [4] with $\alpha = 1$)

$$k_*(cg) \le c\delta^{-\frac{1}{(2\mu+1)(1+\alpha)}} = c\delta^{-\frac{1}{2(2\mu+1)}}, \tag{5.2}$$

which is the same bound as that for the proposed Hilbert scale ν-method. Finally, the error should behave like $\|f^\delta_{k_*} - f^\dagger\| \sim \delta^{1/5}$ for all methods.

The numerically observed iteration numbers listed in Table 5.1 yield the rates $k_* = \delta^{-1.54}$ for Landweber iteration, $k_* = \delta^{-0.80}$ for the 2-method, $k_* = \delta^{-0.75}$ for Landweber iteration in Hilbert scales, and $k_* = \delta^{-0.40}$ for the proposed Hilbert scale 2-method. As expected, the iteration numbers for conjugate gradients and the Hilbert scale ν-method are of the same order. Table 5.2 lists the iteration error $e_{k_*} = \|f^\delta_{k_*} - f^\dagger\|$ for our numerical test. The corresponding convergence rates are $e_{k_*} \sim \delta^{0.22}$ for Landweber iteration and $e_{k_*} \sim \delta^{0.23}$ for the other methods. Note that for $\Omega \subset \mathbb{R}^3$, the Hilbert scale method should theoretically outperform the conjugate gradient algorithm, since there we have only $\alpha = 2/3$ in (5.2) yielding $k_*(cg) \sim \delta^{-\frac{3}{5(2\mu+1)}}$, while the estimate for the semi-iterative method in Hilbert scales is still $k_* \sim \delta^{-\frac{1}{2(2\mu+1)}}$.

Regularization in Hilbert scales was originally investigated under the stronger condition (3.4), which is satisfied in Example 5.1. However, in the case $s \le 0$, condition (A2) suffices to obtain the appropriate convergence rates. In the following example, only a weaker estimate from below (3.5) holds. Note that due to Proposition 3.6, the source condition $x^\dagger - x_0 \in \mathcal{X}_u^s$ can still be interpreted in terms of the Hilbert scale $\{\mathcal{X}_s\}_{s\in\mathbb{R}}$.

TABLE 5.3
Iteration numbers k_* and error $e_{k_*} = \|x^\delta_{k_*} - x^\dagger\|$ for the 2-method (nu), the proposed Hilbert scale 2-method (hsnu), and the conjugate gradient algorithm (cg); see Example 5.2.

Example 5.2. As a model problem for linear inverse problems, we consider the following Fredholm integral equation of the first kind: let $T : L_2[0,1] \to L_2[0,1]$ be defined by

$$(Tx)(s) = \int_0^1 s^{1/2} k(s,t) x(t) dt, \tag{5.3}$$

with the standard Green's kernel

$$k(s,t) = \begin{cases} s(1-t), & s < t, \\ t(1-s), & t \le s. \end{cases}$$

Noting that

$$(T^* y)(t) = (1-t) \int_0^t s^{3/2} y(s) ds + t \int_t^1 s^{1/2} (1-s) y(s) ds,$$

we obtain

$$\mathcal{R}(T^*) = \{w \in H^2[0,1] \cap H_0^1[0,1] : t^{-1/2} w''(t) \in L_2[0,1]\}.$$

As a Hilbert scale operator, we choose $L^2 x = -x''$, i.e.,

$$L^s x := \sum_{n=1}^{\infty} (n\pi)^s \langle x, x_n \rangle x_n, \qquad x_n := \sqrt{2} \sin(n\pi \cdot). \tag{5.4}$$

This choice yields $\mathcal{R}(T^*) \subsetneq \mathcal{X}_2 := H^2[0,1] \cap H_0^1[0,1]$; additionally, $\mathcal{R}(T^*) \supset \mathcal{X}_{2.5} := \{w \in H^{2.5}[0,1] \cap H_0^1[0,1] : \rho^{-1/2} w'' \in L_2[0,1]\}$, with $\rho(t) = t(1-t)$. By Theorem 11.7 in [13], we have $\|w\|^2_{2.5} \sim \|w''\|^2_{H^{1/2}} + \|\rho^{-1/2} w''\|^2_{L_2}$, and thus

$$\underline{m} \, \|x\|_{-2.5} \le \|Tx\| \le \overline{m} \, \|x\|_{-2};$$

see [3] for details. As a numerical test, we consider the reconstruction of the function

$$x^\dagger(s) = 2t - \operatorname{sign}(2t-1) - 1$$

and choose $s = -1$ and $x_0 = 0$. In Table 5.3, we report the iteration numbers obtained for the classical ν-method, the one in Hilbert scales, and for the conjugate gradient algorithm. The corresponding stopping indices behave like $k_* \sim \delta^{-0.8}$ for the ν-method, $k_* \sim \delta^{-0.43}$ for the Hilbert scale ν-method, and $k_* \sim \delta^{-0.38}$ for the conjugate gradient algorithm; the convergence rates are $e_{k_*} \sim \delta^{0.2}$ for all examples. Again, the values are almost exactly the ones predicted by the theory ($\mu = 1/8$).

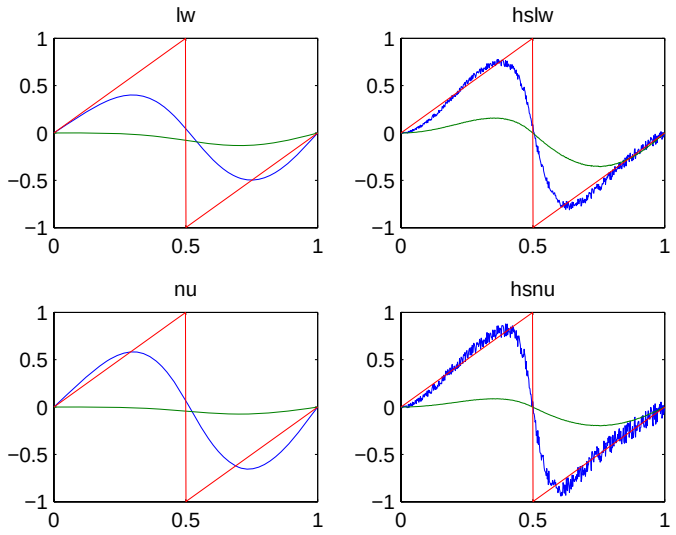

FIG. 5.1. *Iterates x_k^δ and true solution $x^\dagger$ after 1 and 14 iterations ($k_* = 14$ is the stopping index of the Hilbert scale ν-method) for a noise level $\delta = 1\%$; see Example 5.2.*

As a consequence of the preconditioning in Hilbert scales, the updates and iterates of the Hilbert scale iterations are less smooth than those of the standard iterations. Therefore, one may conjecture that especially nonsmooth parts of a solution can be reconstructed faster than without preconditioning. This behavior is illustrated in Figure 5.1. Note that the oscillations that can be seen for the Hilbert scale iterates are small in the norm of $\mathcal{X} = L_2$.

In the next example, we study the problem of *transmission computerized tomography* (see [16]).

Example 5.3. Let $\Omega \subset \mathbb{R}^n$, $n = 2, 3$, be a compact domain with spatially varying density f. In a simple physical model the relative intensity loss along a distance Δx is assumed to satisfy

$$\frac{\Delta I}{I} = f(x)\Delta x.$$

Denoting by $I_1(\theta, s)$ and $I_0(\theta, s)$ the intensities of the X-ray beams measured at the detector and emitter connected by the line parameterized by the distance to the origin s and the direction θ and located outside of the domain Ω, one gets

$$(Rf)(\theta, s) := \int_{x\cdot\theta=s} f(x)dx = -\log \frac{I_1(\theta, s)}{I_0(\theta, s)} = g(\theta, s) \tag{5.5}$$

for $w \in \mathbb{R}^2$, $\|w\| = 1$, and $t > 0$. Determining the unknown density f from measurements of the intensity drop $g(\theta, s)$ corresponds to inversion of the *Radon transform*. By [16, Theorem 5.1], we know that for each α there exist positive constants $c(\alpha, n)$ and $C(\alpha, n)$ such that for $f \in C_0^\infty(\Omega^n)$,

$$c(\alpha, n)\|f\|_{H_0^\alpha(\Omega^n)} \le \|Rf\|_{H^{\alpha+(n-1)/2}(Z)} \le C(\alpha, n)\|f\|_{H_0^\alpha(\Omega^n)},$$

with $\Omega^n \subset \mathbb{R}^n$ denoting the unit ball, and Z the cylinder $S^{n-1} \times \mathbb{R}$. This implies (3.4) for an appropriate choice of spaces; e.g., for $\mathcal{X} = L_2(\Omega^n)$ and $\mathcal{Y} = L_2(Z)$, we see that the Radon transform behaves like differentiation of order one $\frac{1}{2}$ in dimension $n = 2$, and like 1 times differentiation in dimension $n = 3$.

If Ω is a circle with radius r and $f(\theta, s) = f(s)$, and consequently $g(\theta, s) = g(s)$, are radially symmetric, then (5.5) can be reduced to the solution of an *Abel integral equation* of the first kind (see [16]), whose solution we investigate numerically below.

Let $T : L_2[0,1] \to L_2[0,1]$ be defined by

$$(Tx)(s) := \frac{1}{\sqrt{\pi}} \int_0^s \frac{x(t)}{\sqrt{s-t}} dt, \tag{5.6}$$

with data y and "true" solution $x^\dagger = T^\dagger y$. One can show that $(T^2 x)(s) = \int_0^s x(t)dt$, and thus inverting T amounts to differentiation of half order; more precisely (cf. [5]),

$$\mathcal{R}(T) \subset H^r[0,1] \qquad \text{for all} \quad 0 \le r < 1/2.$$

Let the Hilbert scale operator L be defined by

$$L^{2s} x = \sum_{n=0}^{\infty} \lambda_n^s \langle x, x_n \rangle x_n \quad \text{with} \quad x_n(t) = \sqrt{2}\sin(\lambda_n t), \quad \lambda_n = (n + 1/2)\pi, \tag{5.7}$$

with $\mathcal{X} = L_2[0,1]$ and $\mathcal{X}_2 = \{x \in H^1[0,1] : x(0) = 0\}$. Then $\mathcal{R}(T) \subset \mathcal{X}_r$ holds for all $0 < r < 1$ and $0 < a < 1$, and the choice $-1/2 < s = -a/2$ is possible. Thus, the iteration can be preconditioned with L^{-a}, which corresponds to differentiation of fractional order and can be realized efficiently via (5.7) and the fast Fourier transform.

In the numerical test we set $s = -1/2$ (which is the limiting case of allowed choices) and try to identify the unknown density

$$x^\dagger(s) = 2t - \operatorname{sign}(2t - 1) - 1.$$

The iterations are started with $x_0 = 0$. In this setting we have $x^\dagger \in \mathcal{R}((T^*T)^\mu)$ for all $0 \le \mu < 1/2$, and thus we can expect the iteration numbers $k_* \sim \delta^{-1}$ for Landweber iteration, $k_* \sim \delta^{-1/2}$ for the ν-method and Landweber iteration in Hilbert scales, and $k_* \sim \delta^{-1/4}$ for the proposed Hilbert scale ν-method. The stopping index for the conjugate gradient algorithm is bounded by $k_* \sim \delta^{-1/3}$. As mentioned in the introduction, the bound for the Hilbert scale ν-method is stronger than that for the conjugate gradient algorithm if the singular values σ_n of T decay no faster than $n^{-\alpha}$ with some $0 < \alpha < 1$, which is the case here.

The numerically realized rates for the stopping index are $k_* \sim \delta^{-1.0}$ for the Landweber iteration, $k_* \sim \delta^{-0.53}$ for the 2-method, $k_* \sim \delta^{-0.44}$ for the Landweber iteration in Hilbert scales, and $k_* \sim \delta^{-0.4}$ for the conjugate gradient method, and these rates are in good accordance with the theoretically predicted ones. The two Hilbert scales ν-methods yield $k_* \sim \delta^{-0.48}$ for $\nu = 1$ and $k_* \sim \delta^{-0.3}$ for $\nu = 2$. Note that due to the restriction on the qualification μ_0 of the method used in Theorem 4.4, one has to choose

$$\nu \ge \frac{u - s}{2(a + s)} + \frac{1}{2} = 2$$

in order to get an optimal number of iteration and convergence rates for the Hilbert scale ν-method stopped with the discrepancy principle (1.4). This explains the higher

TABLE 5.4

0.001	1116	88	80	21	5

number of iterations needed for the Hilbert scale 1-method; cf. Table 5.4. Finally, for all examples, the iteration error $e_{k_*} = \|x_{k_*}^\delta - x^\dagger\|$ decreases approximately like $\delta^{0.4}$ in accordance to the predicted rate $\delta^{\frac{2\mu}{2\mu+1}}$.

In the final example, we investigate the performance of iterative regularization methods for an exponentially ill-posed problem, namely the *backwards heat equation* and compare the numerical results obtained in [3] to those for ν-methods in Hilbert scales and the conjugate gradient algorithm.

Example 5.4. Consider $Tx = y$ with operator $T : L_2[0,1] \to L_2[0,1]$ defined by $(Tg)(x) = y(x) = u(x,\bar t)$ for some $\bar t > 0$ and

$$-u_t + qu_{xx} = 0, \qquad u(0,t) = u(1,t) = 0, \qquad u(x,0) = g.$$

Let L^s be defined by (5.4). Then we have

$$\|T^* y\|_r \le c(r)\|y\|_0 \qquad \text{for all} \quad r < 2.5,$$

but no estimate from below (3.5) exists.

We consider the numerical reconstruction and compare the numerically observed convergence rates and iteration numbers for the example

$$g^\dagger(x) = 2x - \operatorname{sign}(2x-1) - 1$$

and set $g_0 = 0$. For preconditioning we set $s = -1$, and thus L^{-2s} amounts to twice differentiation. Note, that for exponentially ill-posed problems only a logarithmic convergence rate can be expected under the weak source-condition of our example.

The stopping indices for Example 5.4 listed in Table 5.5 are bounded by $k_* \sim \delta^{-1.54}$ for Landweber iteration, $k_* \sim \delta^{-0.75}$ for the ν-method, $k_* \sim \delta^{-1.02}$ for Landweber iteration in Hilbert scales, and $k_* \sim \delta^{-0.63}$ for the Hilbert scale ν-method. According to Theorem 7.14 in [4], the stopping index for the conjugate gradient method can be bounded by $k(\delta, y^\delta) \le c\,(1 + \log \frac{1}{\delta})$ for exponentially ill-posed problems, i.e., if the singular values σ_n of T decay like $O(q^n)$ with some $q < 1$, which explains the almost

constant iteration numbers for the conjugate gradient method in our numerical test. The numerically observed convergence rates are approximately $\|x_{k_*}^\delta - x^\dagger\| \sim \delta^{0.05}$ for all methods.

STABILIZATION OF LOW-ORDER MIXED FINITE ELEMENTS FOR THE STOKES EQUATIONS*

PAVEL B. BOCHEV†, CLARK R. DOHRMANN‡, AND MAX D. GUNZBURGER§

Abstract. We present a new family of stabilized methods for the Stokes problem. The focus of the paper is on the lowest order velocity-pressure pairs. While not LBB compliant, their simplicity and attractive computational properties make these pairs a popular choice in engineering practice. Our stabilization approach is motivated by terms that characterize the LBB "deficiency" of the unstable spaces. The stabilized methods are defined by using these terms to modify the saddle-point Lagrangian associated with the Stokes equations. The new stabilized methods offer a number of attractive computational properties. In contrast to other stabilization procedures, they are parameter free, do not require calculation of higher order derivatives or edge-based data structures, and always lead to symmetric linear systems. Furthermore, the new methods are unconditionally stable, achieve optimal accuracy with respect to solution regularity, and have simple and straightforward implementations. We present numerical results in two and three dimensions that showcase the excellent stability and accuracy of the new methods.

Key words. Stokes equations, stabilized mixed methods, equal-order interpolation, inf-sup condition

AMS subject classifications. 76D05, 76D07, 65F10, 65F30

DOI. 10.1137/S0036142905444482

1. Introduction.

Despite the fact that they violate the LBB [10] stability condition, low-order velocity-pressure pairs remain a popular practical choice in mixed finite element approximation of incompressible materials; see, e.g., [29] and the references cited therein. This popularity results from factors such as local mass conservation for the lowest order conforming pair (piecewise linear, bilinear or trilinear C^0 velocities, and piecewise constant pressures), simple and uniform data structures for the lowest equal order pair (piecewise linear, bilinear or trilinear C^0 velocities *and* pressures), and algebraic problems with manageable sizes and small bandwidths in three dimensions for both pairs. The latter are of paramount importance in engineering applications, where geometry resolution requires very fine meshes and higher order elements can quickly lead to intractable algebraic problems in three space dimensions; see [27] for an example setting.

To counteract the lack of LBB stability, low-order pairs are usually supplemented by stabilization or postprocessing procedures that remove spurious pressure modes. Unlike penalty methods (see [16, 22, 24, 25]) for which the goal is to uncouple the

pressure and velocity, stabilized methods aim to relax the continuity equation so as to allow application of LBB incompatible spaces. *Consistently stabilized* methods (see, e.g., [1, 2, 3, 5, 15, 20, 21]) accomplish this by using the residual of the momentum equation in the added stabilization terms. However, for low-order pairs, pressure and velocity derivatives in this residual term either vanish or are poorly approximated, causing difficulties in the application of consistent stabilization. One possible remedy is to reformulate the Stokes problem as a first-order system so that the momentum residual contains only first-order terms [5]. This, of course, leads to more unknowns and larger problems to solve. A second approach is to reconstruct the higher order derivatives [23] or to replace the Laplace operator by a discrete operator [8]. In either case, computation of a global L^2 projection may be required.

It is possible to stabilize unstable velocity pressure pairs without using residuals. One example, motivated by fractional step algorithms for time-dependent problems, is the pressure gradient projection (PGP) method (see [6, 7, 13]) and the related local pressure gradient stabilization (LPS) method [4]. In both methods the compressibility constraint is relaxed by subtracting the discontinuous pressure gradient from its projection onto a piecewise polynomial space. The difference is that PGP projects the pressure gradient onto the continuous velocity space and gives rise to a globally coupled problem, while LPS assumes nested spaces and projects the gradient onto an element patch space, which leads to local problems. However, it is clear that both methods are not appropriate for pairs with constant pressure elements.

Other examples of nonresidual stabilization are the local and global pressure jump formulations for the bilinear-constant pair [28, 29]. In these methods, the constraint is relaxed by using the jumps of the discontinuous pressure across element interfaces. Application of pressure jump stabilization requires edge-based data structures, and in the case of the local formulation, subdivision of the mesh into patches. Stabilization of the bilinear-constant pair is also considered in [26] where, instead of pressure jumps, local projections onto 2×2 macroelements are employed to relax the continuity equation.

In this paper, we analyze a new, nonresidual-based approach to the stabilization of low-order mixed finite element discretizations of the Stokes equations, further developing the idea of polynomial-pressure-projection–based stabilization that was presented and studied computationally in [14]. The starting point for the analysis of the method is a lower bound for a discrete negative seminorm of the pressure gradient which quantifies the LBB "deficiency" of an unstable pair. We show that the LBB "deficiency" admits a representation in terms of operators with suitable range spaces. This very general characterization opens up a possibility for stabilizing the mixed Stokes equations in a manner that is independent of the space dimension and the shape of the finite elements and also does not require choosing any mesh-dependent parameters.

Our approach differs from existing residual and nonresidual stabilization techniques in several important aspects. Most notably, the new methods do not require approximation of derivatives, specification of mesh-dependent parameters, or nonstandard data structures. Furthermore, our methods are unconditionally stable, optimally accurate, and always lead to symmetric problems. Their implementation relies on operators whose actions can be evaluated locally at the element level using standard finite element techniques. As a result, an existing code can be easily modified to handle the new stabilization procedures.

The paper is organized as follows. The remainder of this section introduces the notation used throughout the paper. Section 2 reviews the mixed variational formulation of the Stokes problem and a weaker form of the LBB stability condition that holds for the spaces of interest to us. The new method is formulated in section 3. Sections 4 and

5 deal with the stability and the error analysis, respectively, of the new methods while section 6 is a succinct summary of some implementation details. The paper concludes with section 7 in which the results of a series of numerical experiments are collected.

1.1. Nomenclature. In what follows, Ω denotes a simply connected bounded domain in $\mathbb{R}^d$, $d = 2, 3$, with a Lipschitz continuous boundary Γ. Throughout the paper, we employ the standard notation $H^l(\Omega)$, $\|\cdot\|_l$, $(\cdot,\cdot)_l$, $l \geq 0$, for the Sobolev spaces of all functions having square integrable derivatives up to order l on Ω, and the standard Sobolev norm and inner product, respectively. When $l = 0$ we will write $L^2(\Omega)$ instead of $H^0(\Omega)$ and drop the index from the inner product designation. $H_0^l(\Omega)$ will denote the closure of $C_0^\infty(\Omega)$ with respect to the norm $\|\cdot\|_l$ and $L_0^2(\Omega)$ will denote the space of all square integrable functions with vanishing mean. Spaces consisting of vector-valued functions will be denoted in boldface. Throughout the paper we use C to denote a generic positive constant whose value may change from place to place but that remains independent of the mesh parameter h.

In this paper, we formulate methods for the Stokes equations that use pressure and velocity finite element spaces defined with respect to the same partition $\mathcal{T}_h$ of Ω into finite elements Ω_e. For instance, Ω_e can be a hexahedron or a tetrahedron in three dimensions, or a triangle or a quadrilateral in two dimensions. The boundary $\partial\Omega_e$ of an element consists of faces γ_f. In two dimensions, each γ_f is an edge; in three dimensions, γ_f can be triangles or quadrilaterals. We assume that each face is oriented by selecting a normal direction $\mathbf{n}_f$. The set of all interior faces will be denoted by Γ_h. The norm

$$\|u\|_{\Gamma_h} = \left(\sum_{\gamma_f \in \Gamma_h} \int_{\gamma_f} u^2 \, dS \right)^{1/2} \tag{1.1}$$

will prove useful in what follows.

Our main focus is on low-order velocity and pressure pairs. For simplicial elements, we consider the affine finite element families

$$P_1 = \left\{ u^h \in C^0(\Omega) \mid u^h|_{\Omega_e} \in \mathcal{P}_1(\Omega_e) \; \forall \, \Omega_e \in \mathcal{T}_h \right\}, \tag{1.2}$$

where $\mathcal{P}_1(\Omega_e)$ is the space of linear polynomials on Ω_e. For quadrilateral and hexahedral elements we consider the space

$$Q_1 = \left\{ u^h \in C^0(\Omega) \mid u^h|_{\Omega_e} = \widehat{u}^h \circ F^{-1}; \; \widehat{u}^h \in \mathcal{Q}_1(\widehat{\Omega}_e) \right\}, \tag{1.3}$$

where $\widehat{\Omega}_e$ is a reference element, $F : \widehat{\Omega}_e \mapsto \Omega_e$ is a bilinear or a trilinear mapping, and $\mathcal{Q}_1(\Omega_e)$ is the space of all polynomials on $\widehat{\Omega}_e$ whose degree does not exceed 1 in each coordinate direction. Note that unless Ω_e is a parallelogram or a parallelepiped, u^h is not a piecewise polynomial function. For convenience, in what follows we will use the symbol R_1 to represent both kinds of finite element spaces. In accordance with our earlier convention, vector-valued finite element spaces will be denoted in boldface, e.g., $\mathbf{R}_1$. A well-known approximation result (see [18, p. 217]) is that for every $u \in H^2(\Omega)$, there exists a function $u^h \in R_1$ such that

$$\|u - u^h\|_0 + h^{1/2}\|u - u^h\|_{\Gamma_h} + h\|u - u^h\|_1 \leq Ch^2\|u\|_2 \, . \tag{1.4}$$

In addition to the C^0 spaces R_1, we will also need the piecewise constant space

$$R_0 = \left\{ q^h \in L^2(\Omega) \mid q^h|_{\Omega_e} \in \mathcal{P}_0(\Omega_e) \; \forall \, \Omega_e \in \mathcal{T}_h \right\}, \tag{1.5}$$

where $\mathcal{P}_0(\Omega_e)$ is a constant polynomial space on Ω_e. In (1.5), $\mathcal{T}_h$ can be a simplicial or a nonsimplicial partition of Ω into finite elements. The space R_0 has the following approximation property (see [18, p. 102]): for every $q \in H^1(\Omega)$, there exists $q^h \in R_0$ such that

$$\|q - q^h\|_0 \le Ch\|q\|_1 \,. \tag{1.6}$$

Finite element functions satisfy a number of useful inverse inequalities [12]. In particular, we will use the standard inverse inequality

$$\|\nabla q^h\|_0 \le C_I h^{-1}\|q^h\|_0 \tag{1.7}$$

that holds under some mild assumptions on $\mathcal{T}_h$ for all functions in R_1, and the inverse inequality for R_0 functions

$$\|[q^h]\|_{\Gamma_h} \le C_I h^{-1/2}\|q^h\|_0 \quad \forall\, q^h \in R_0 \,, \tag{1.8}$$

where $[q^h]$ denotes the jump of $q^h \in R_0$.

2. Mixed finite element methods for the Stokes problem. We consider the incompressible Stokes problem[1]

$$-\lambda\Delta\mathbf{u} + \nabla p = \mathbf{f} \quad \text{in} \quad \Omega, \tag{2.1}$$

$$\nabla \cdot \mathbf{u} = 0 \quad \text{in} \quad \Omega \tag{2.2}$$

along with the homogeneous velocity boundary condition

$$\mathbf{u} = 0 \quad \text{on } \Gamma \,. \tag{2.3}$$

The mixed variational form of (2.1)–(2.3) is to seek $(\mathbf{u}, p) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ such that

$$Q(\mathbf{u}, p; \mathbf{v}, q) = F(\mathbf{v}, q) \quad \forall\, (\mathbf{v}, q) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega) \,, \tag{2.4}$$

where

$$F(\mathbf{v}) = \int_\Omega \mathbf{f} \cdot \mathbf{v}\, d\Omega \,,$$

$$Q(\mathbf{u}, p; \mathbf{v}, q) = A(\mathbf{u}, \mathbf{v}) + B(\mathbf{v}, p) + B(\mathbf{u}, q) \,, \tag{2.5}$$

$$A(\mathbf{u}, \mathbf{v}) = \lambda \int_\Omega \nabla\mathbf{u} : \nabla\mathbf{v} d\Omega \,, \qquad \text{and} \qquad B(\mathbf{v}, p) = -\int_\Omega p\nabla \cdot \mathbf{v} d\Omega \,. \tag{2.6}$$

[1] We work with a nondimensional form of the Stokes problem. The dimensional form of the Stokes equation has the form

$$-\mu\Delta\mathbf{u} + \nabla p = \rho\mathbf{f} \,,$$

where μ is the given (dynamic) viscosity, ρ is the given fluid density, and $\mathbf{f}$ is a given body force per unit mass. We choose a reference speed u_{ref}, length ℓ_{ref}, and density ρ_{ref} which we use to, respectively, nondimensionalize the velocity $\mathbf{u}$, the position vector $\mathbf{x}$, and the density ρ. We then arrive at (2.1) by nondimensionalizing the pressure p using $\rho_{ref}u_{ref}^2$ and $\rho\mathbf{f}$ using $\rho_{ref}u_{ref}^2/\ell_{ref}$. Then, in (2.1), the nondimensional parameter $\lambda = \mu/(\rho_{ref}\ell_{ref}u_{ref})$ is the inverse of the "Reynolds number."

Solely for the sake of keeping the presentation simple, we make the assumption that μ is constant. For nonconstant μ, the viscous term in the Stokes equations (2.1) is given by $\nabla \cdot (\lambda(\nabla\mathbf{u} + (\nabla\mathbf{u})^T)$, where λ is no longer constant, and, in (2.6), the first bilinear form is given by $A(\mathbf{u}, \mathbf{v}) = 2\int_\Omega \lambda D(\mathbf{u}) : D(\mathbf{v}) d\Omega$, where $D(\mathbf{v}) = \frac{1}{2}(\nabla\mathbf{v} + (\nabla\mathbf{v})^T)$. Only minor modifications in the analyses are needed.

The mixed variational equation (2.4) is the first-order optimality condition for the saddle-point $(\mathbf{u}, p)$ of the Lagrangian functional

$$L(\mathbf{v}, q) = \frac{\lambda}{2}\int_\Omega |\nabla \mathbf{v}|^2\, dx - \int_\Omega q\nabla\cdot\mathbf{v}\, dx - \int_\Omega \mathbf{f}\cdot\mathbf{v}\, dx\,. \tag{2.7}$$

To define a mixed finite element method for the Stokes problem (2.1)–(2.2), we restrict (2.4) to a pair of finite elements subspaces $\mathbf{V}^h \subset \mathbf{H}_0^1(\Omega)$ and $S^h \subset L_0^2(\Omega)$. A stable and accurate solution of (2.4), or equivalently, a stable and accurate approximation of the saddle-point of (2.7), requires that $\mathbf{V}^h$ and S^h satisfy the discrete inf-sup condition

$$\sup_{\mathbf{v}^h\in\mathbf{V}^h,\,\mathbf{v}^h\neq\mathbf{0}} \frac{B(p^h,\mathbf{v}^h)}{\|\mathbf{v}^h\|_1} \geq \gamma\|p^h\|_0 \quad \forall\, p^h \in S^h \tag{2.8}$$

with $\gamma > 0$ independent of h; see [18, 19].

In this paper, we will formulate stabilized mixed methods for the lowest equal order C^0 pair

$$\mathbf{V}^h = \mathbf{R}_1 \cap \mathbf{H}_0^1(\Omega) \quad \text{and} \quad S^h = R_1 \cap L_0^2(\Omega)\,, \tag{2.9}$$

and for the lowest order conforming pair

$$\mathbf{V}^h = \mathbf{R}_1 \cap \mathbf{H}_0^1(\Omega) \quad \text{and} \quad S^h = R_0 \cap L_0^2(\Omega)\,. \tag{2.10}$$

For simplicial elements, (2.10) is the unstable linear-constant pair that provides a textbook example for an overconstrained velocity space; see [19, p. 23]. For quadrilateral elements, it is the bilinear-constant pair that exhibits the notorious checkerboard pressure mode. A common misconception is that once this mode is taken care of, the bilinear-constant pair can be safely used. However, in [9] it is shown that this is not the case and that, in fact, for this pair the constant γ in (2.8) is of order h. The pair (2.9) is an additional classical example of unstable velocity-pressure pairs; see, [19, pp. 21–25].

2.1. Weak inf-sup bounds. In this section, we show that the unstable velocity-pressure pairs (2.9) and (2.10) satisfy a weaker form of the inf-sup condition (2.8). This condition identifies terms that can be used to stabilize the mixed method. To state the relevant form of the weaker inf-sup condition, we first review some results of [17, 30, 31] specialized to (2.9) and (2.10).

LEMMA 2.1. *Let $\mathbf{V}^h$ and S^h be the spaces defined in* (2.9). *Then, there exist positive constants C_1 and C_2 such that*

$$\sup_{\mathbf{v}^h\in\mathbf{V}^h} \frac{\displaystyle\int_\Omega p^h\nabla\cdot\mathbf{v}^h\, d\Omega}{\|\mathbf{v}^h\|_1} \geq C_1\|p^h\|_0 - C_2 h\|\nabla p^h\|_0 \qquad \forall\; p^h \in S^h\,. \tag{2.11}$$

Proof. By the definition of S^h, every $p^h \in S^h$ also belongs to $L_0^2(\Omega)$. As a result, there exists $\mathbf{w} \in \mathbf{H}_0^1(\Omega)$ such that

$$\int_\Omega p^h\nabla\cdot\mathbf{w}\, d\Omega \geq \widetilde{C}_1\|p^h\|_0\|\mathbf{w}\|_1\,. \tag{2.12}$$

Let $\mathbf{w}^h$ denote the interpolant of $\mathbf{w}$ out of $\mathbf{V}^h$. Then, from (1.4)

$$\|\mathbf{w}-\mathbf{w}^h\|_0 + h^{1/2}\|\mathbf{w}-\mathbf{w}^h\|_{\Gamma_h} \le Ch\|\mathbf{w}\|_1 \quad \text{and} \quad \|\mathbf{w}^h\|_1 \le C\|\mathbf{w}\|_1\,. \tag{2.13}$$

Using (2.12), (2.13), and the fact that all elements of S^h are C^0 functions,

$$\begin{aligned}
\frac{\left|\int_\Omega p^h \nabla\cdot\mathbf{w}^h\,d\Omega\right|}{\|\mathbf{w}^h\|_1} &\ge \frac{\left|\int_\Omega p^h\nabla\cdot\mathbf{w}^h\,d\Omega\right|}{C\|\mathbf{w}\|_1}\\
&= \frac{\left|\int_\Omega p^h\nabla\cdot\left(\mathbf{w}^h-\mathbf{w}\right)\,d\Omega + \int_\Omega p^h\nabla\cdot\mathbf{w}\,d\Omega\right|}{C\|\mathbf{w}\|_1}\\
&\ge \frac{\int_\Omega p^h\nabla\cdot\mathbf{w}\,d\Omega}{C\|\mathbf{w}\|_1} - \frac{\left|\int_\Omega \nabla p^h\cdot\left(\mathbf{w}^h-\mathbf{w}\right)\,d\Omega\right|}{C\|\mathbf{w}\|_1}\\
&\ge \frac{\widetilde{C}_1}{C}\|p^h\|_0 - \frac{\|\nabla p^h\|_0\|\mathbf{w}-\mathbf{w}^h\|_0}{C\|\mathbf{w}\|_0} \ge C_1\|p^h\|_0 - C_2h\|\nabla p^h\|_0\,.
\end{aligned} \tag{2.14}$$

Then, since

$$\sup_{\mathbf{v}^h\in\mathbf{V}^h,\,\mathbf{v}^h\neq\mathbf{0}} \frac{\int_\Omega p^h\nabla\cdot\mathbf{v}^h\,d\Omega}{\|\mathbf{v}^h\|_1} \ge \frac{\left|\int_\Omega p^h\nabla\cdot\mathbf{w}^h\,d\Omega\right|}{\|\mathbf{w}^h\|_1}\,, \tag{2.15}$$

the lemma is proved. □

For the velocity-pressure pair (2.10), the discontinuity of the pressure space necessitates some minor modifications in the statement and proof of the weak inf-sup condition.

LEMMA 2.2. *Let $\mathbf{V}^h$ and S^h be the spaces defined in* (2.10). *Then, there exist positive constants C_1 and C_2 such that*

$$\sup_{\mathbf{v}^h\in\mathbf{V}^h} \frac{\displaystyle\int_\Omega p^h\nabla\cdot\mathbf{v}^h\,d\Omega}{\|\mathbf{v}^h\|_1} \ge C_1\|p^h\|_0 - C_2h^{1/2}\|[p^h]\|_{\Gamma_h} \qquad \forall\ p^h\in S^h\,. \tag{2.16}$$

Proof. The pressure space S^h defined in (2.10) is also a subspace of $L^2_0(\Omega)$. Thus, there exists a $\mathbf{w}\in\mathbf{H}^1_0(\Omega)$ and a $\mathbf{w}^h\in\mathbf{V}^h$ that satisfy (2.12) and (2.13). Proceeding as in Lemma 2.1, we find that

$$\begin{aligned}
\frac{\left|\int_\Omega p^h\nabla\cdot\mathbf{w}^h\,d\Omega\right|}{\|\mathbf{w}^h\|_1} &\ge \frac{\left|\int_\Omega p^h\nabla\cdot\mathbf{w}^h\,d\Omega\right|}{C\|\mathbf{w}\|_1}\\
&\ge \frac{\int_\Omega p^h\nabla\cdot\mathbf{w}\,d\Omega}{C\|\mathbf{w}\|_1} - \frac{\left|\int_\Omega p^h\nabla\cdot\left(\mathbf{w}^h-\mathbf{w}\right)\,d\Omega\right|}{C\|\mathbf{w}\|_1}\\
&\ge \frac{\widetilde{C}_1}{C}\|p^h\|_0 - \frac{\left|\int_\Omega p^h\nabla\cdot\left(\mathbf{w}^h-\mathbf{w}\right)\,d\Omega\right|}{C\|\mathbf{w}\|_1}\,.
\end{aligned}$$

Using the fact that p^h is constant on each element Ω_e and integrating by parts gives

$$\int_\Omega p^h\nabla\cdot\left(\mathbf{w}^h-\mathbf{w}\right)\,d\Omega = \sum_{\Omega_e}\int_{\Omega_e} p^h\nabla\cdot\left(\mathbf{w}^h-\mathbf{w}\right)\,d\Omega = \sum_{\Omega_e}\int_{\partial\Omega_e} p^h\mathbf{n}\cdot\left(\mathbf{w}^h-\mathbf{w}\right)\,dS\,.$$

Each interior face γ_f participates twice in this sum. Collecting the two integrals over the same face and using (2.13) we obtain

$$\sum_{\Omega_e} \int_{\partial\Omega_e} p^h \mathbf{n} \cdot \left(\mathbf{w}^h - \mathbf{w}\right)\, dS = \sum_{\gamma_f} \int_{\gamma_f} [p^h] \mathbf{n}_f \cdot \left(\mathbf{w}^h - \mathbf{w}\right)\, dS$$
$$\leq \left(\sum_{\gamma_f} \int_{\gamma_f} [p^h]^2\, dS \right)^{1/2} \left(\sum_{\gamma_f} \int_{\gamma_f} \left|\mathbf{w}^h - \mathbf{w}\right|^2\, dS \right)^{1/2} \leq C h^{1/2} \|[p^h]\|_{\Gamma_h} \|\mathbf{w}\|_1$$

which proves that

$$\frac{\left| \int_\Omega p^h \nabla \cdot \mathbf{w}^h\, d\Omega \right|}{\|\mathbf{w}^h\|_1} \geq C_1 \|p^h\|_0 - C_2 h^{1/2} \|[p^h]\|_{\Gamma_h} \qquad \forall\, p^h \in S^h\,. \tag{2.17}$$

Then, using (2.15), the lemma is proved. □

The terms

$$-h\|\nabla p^h\|_0 \quad \text{and} \quad -h^{1/2}\|[p^h]\|_0 \tag{2.18}$$

appearing in (2.11) and (2.16) quantify the inf-sup "deficiency" of the unstable pairs (2.9) and (2.10), respectively. This observation has been used implicitly in the design of stabilized methods; additional terms are introduced to counterbalance (2.18). For instance, consistently stabilized methods are based on the observation that adding a properly weighted residual of (2.1) to the continuity equation (2.2) will contribute a term that can offset $-h\|\nabla p^h\|_0$. The rest of the added terms are introduced to fulfill the consistency requirement and may actually be destabilizing. As a result, residual-based stabilization must rely on carefully selected values of parameters to keep such terms under control. Nonresidual stabilization follows the same idea but introduces balancing terms that do not involve residuals. For example, in [28], pressure jumps are added directly to the continuity equation to help offset the destabilizing effect of the $-h^{1/2}\|[p^h]\|_0$ term, while in [11] Brezzi and Pitkaranta use the first term in (2.18) to obtain a stabilized formulation for piecewise linear velocity-pressure pairs.

As a template for the design of stabilizing terms, (2.18) is insufficiently general. One is always led to consider either the gradient or the jumps of the pressure. The latter case also has the drawback of requiring face-based assembly and data structures. Below, we will derive an alternative characterization of the inf-sup "deficiency" for low-order spaces that is formulated in terms of abstract operators. This characterization does not involve gradients or jumps, does not depend on the space dimension or the type of the element shapes, and has no explicit dependence on mesh parameters. As a result, it leads to new classes of stabilized mixed methods with attractive computational properties. At this point it will suffice to specify only the ranges of the abstract operators needed to characterize the inf-sup deficiency. As we proceed to establish stability and prove convergence results, more assumptions will be added as needed. The first operator

$$\Pi_0 : L^2(\Omega) \mapsto R_0 \tag{2.19}$$

has a piecewise constant range; it will be used to stabilize (2.9). The second operator

$$\Pi_1 : L^2(\Omega) \mapsto R_1 \tag{2.20}$$

has a continuous range; it will be used to stabilize (2.10).

LEMMA 2.3. *There exists a positive constant C such that*

$$Ch\|\nabla p^h\|_0 \le \|p^h - \Pi_0 p^h\|_0 \qquad \forall\, p^h \in R_1\,. \tag{2.21}$$

There exists another positive constant C such that

$$Ch^{1/2}\|[p^h]\|_0 \le \|p^h - \Pi_1 p^h\|_0 \qquad \forall\, p^h \in R_0\,. \tag{2.22}$$

Proof. To prove (2.21), note that $\Pi_0 p^h$ is constant on each element Ω_e, and so $\nabla(\Pi_0 p^h)|_{\Omega_e} = 0$. As a result, using the inverse inequality (1.7),

$$\begin{aligned} h^2\|\nabla p^h\|_0^2 &= \sum_{\Omega_e} h^2\|\nabla p^h\|_{0,\Omega_e}^2 = \sum_{\Omega_e} h^2\|\nabla(p^h - \Pi_0 p^h)\|_{0,\Omega_e}^2 \\ &\le \sum_{\Omega_e} C_I\|p^h - \Pi_0 p^h\|_{0,\Omega_e}^2 = C_I\|p^h - \Pi_0 p^h\|_0^2\,. \end{aligned}$$

To prove (2.22), note that $\Pi_1 p^h \in R_1 \subset C^0(\Omega)$. Thus, $[(\Pi_1 p^h)|_{\gamma_f}] = 0$ on every interior element face γ_f. Using the inverse inequality (1.8),

$$\begin{aligned} h\|[p^h]\|_{\Gamma_h}^2 &= \sum_{\gamma_f} h\|[p^h]\|_{0,\gamma_f}^2 = \sum_{\gamma_f} h\|[p^h - \Pi_1 p^h]\|_{0,\gamma_f}^2 \\ &= h\|[p^h - \Pi_1 p^h]\|_{\Gamma_h}^2 \le C_I\|p^h - \Pi_1 p^h\|_0\,. \end{aligned}$$

∎

Using (2.21) and (2.22), results of Lemmas 2.1 and 2.2 can be combined into one statement. Let

$$\Pi = \begin{cases} \Pi_0 & \text{if } S^h \text{ is defined by (2.9)},\\ \Pi_1 & \text{if } S^h \text{ is defined by (2.10)}\,. \end{cases} \tag{2.23}$$

COROLLARY 2.4. *Let $\mathbf{V}^h$ and S^h be the spaces defined in* (2.9) *or* (2.10). *Then, there exist positive constants C_1 and C_2 whose values are independent of h and such that*

$$\sup_{\mathbf{v}^h \in \mathbf{V}^h} \frac{\displaystyle\int_\Omega p^h \nabla\cdot \mathbf{v}^h\, d\Omega}{\|\mathbf{v}^h\|_1} \ge C_1\|p^h\|_0 - C_2\|(I-\Pi)p^h\|_0 \qquad \forall\, p^h \in S^h\,. \tag{2.24}$$

We note that Π_0 and Π_1 are complementary in the sense that Π_0 acts on C^0 pressures and has a discontinuous range and Π_1 acts on discontinuous pressures and has a C^0 range. Note that besides the range assumption, Corollary 2.4 does not require any additional hypotheses about Π.

3. The new stabilized mixed methods. We will stabilize (2.4) by using

$$\frac{1}{2}\|(I-\Pi)p\|_0^2 \tag{3.1}$$

to compensate for the inf-sup deficiency of the low-order finite element pairs in (2.9) and (2.10). We add this term to (2.7) to obtain the following modified Lagrangian

functional:[2]

$$\widetilde{L}_m(\mathbf{v},q)=\frac{\lambda}{2}\int_\Omega |\nabla\mathbf{v}|^2\,d\Omega-\int_\Omega q\nabla\cdot\mathbf{v}\,d\Omega-\int_\Omega \mathbf{f}\cdot\mathbf{v}\,d\Omega-\frac{1}{2}\|(I-\Pi)q\|_0^2\,. \tag{3.2}$$

The saddle-point $(\widetilde{\mathbf{u}},\widetilde{p})$ of (3.2) satisfies the variational problem

$$A(\widetilde{\mathbf{u}},\mathbf{v})+B(\widetilde{p},\mathbf{v})=F(\mathbf{v}) \qquad \forall\,\mathbf{v}\in\mathbf{H}_0^1(\Omega), \tag{3.3}$$

$$B(q,\widetilde{\mathbf{u}})-G(\widetilde{p},q)=0 \qquad \forall\,q\in L_0^2(\Omega), \tag{3.4}$$

where

$$G(\widetilde{p},q)=\int_\Omega(\widetilde{p}-\Pi\widetilde{p})(q-\Pi q)\,d\Omega\,. \tag{3.5}$$

Equivalently, we can write (3.3)–(3.4) in the following form: seek $(\widetilde{\mathbf{u}},\widetilde{p})\in\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)$ such that

$$\widetilde{Q}(\widetilde{\mathbf{u}},\widetilde{p};\mathbf{v},q)=F(\mathbf{v},q)\quad\forall\,(\mathbf{v},q)\in\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)\,, \tag{3.6}$$

where

$$\widetilde{Q}(\mathbf{u},p;\mathbf{v},q)=A(\mathbf{u},\mathbf{v})+B(p,\mathbf{v})+B(q,\mathbf{u})-G(p,q)\,. \tag{3.7}$$

The stabilized method is obtained by a restriction of (3.6) or, equivalently, of (3.3)–(3.4) to the finite element spaces (2.9) or (2.10). Thus, we seek $(\mathbf{u}^h,p^h)$ in $\mathbf{V}^h\times S^h$, such that

$$\widetilde{Q}(\mathbf{u}^h,p^h;\mathbf{v}^h,q^h)=F(\mathbf{v}^h,q^h)\quad\forall\,(\mathbf{v}^h,q^h)\in\mathbf{V}^h\times S^h\,. \tag{3.8}$$

The stabilization term (3.1) is not a residual of the Stokes equations. As a result, (3.8) is not a consistent finite element formulation of the Stokes equations. However, as noted earlier, for low-order elements, formally consistent stabilized methods [15, 20, 21] also lose their consistency, and so lack of consistency in our method should not be viewed as a serious flaw.

3.1. Comparison with the penalty method. The last term in (3.2) resembles the term that appears in the *penalized* Lagrangian

$$L_\epsilon(\mathbf{v},q)=\frac{\lambda}{2}\int_\Omega |\nabla\mathbf{v}|^2\,d\Omega-\int_\Omega q\nabla\cdot\mathbf{v}\,d\Omega-\int_\Omega \mathbf{f}\cdot\mathbf{v}\,d\Omega-\frac{\epsilon}{2}\|q\|_0^2\,. \tag{3.9}$$

However, the method (3.8) resulting from (3.2) is fundamentally different from a classical penalty approach based on (3.9). Taking first variations of (3.9) with respect to $\mathbf{v}$ and q gives the variational equation: seek $(\mathbf{u}_\epsilon,p_\epsilon)$ in $\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)$ such that

$$A(\mathbf{u}_\epsilon,\mathbf{v})+B(p_\epsilon,\mathbf{v})=F(\mathbf{v}) \qquad \forall\,\mathbf{v}\in\mathbf{H}_0^1(\Omega), \tag{3.10}$$

$$B(q,\mathbf{u}_\epsilon)-\epsilon D(p_\epsilon,q)=0 \qquad \forall\,q\in L_0^2(\Omega), \tag{3.11}$$

[2]The modified Lagrangian (3.2) is in nondimensional form; its dimensional counterpart has the form

$$\widetilde{L}_m(\mathbf{v},q)=\frac{\mu}{2}\int_\Omega |\nabla\mathbf{v}|^2\,d\Omega-\int_\Omega q\nabla\cdot\mathbf{v}\,d\Omega-\int_\Omega \rho\mathbf{f}\cdot\mathbf{v}\,d\Omega-\frac{\alpha}{2}\|(I-\Pi)q\|_0^2\,,$$

where $\alpha=(\rho_{ref}u_{ref}\ell_{ref})^{-1}=\lambda/\mu$. It is important to note that α *is not a stabilization parameter*, but is merely a parameter introduced to make the dimensional form of the modified Lagrangian dimensionally correct; this observation is made obvious by examining the nondimensional form (3.2) in which the stabilization term $-\frac{1}{2}\|(I-\Pi)p\|_0^2$ is parameter free.

where $D(\cdot,\cdot)$ is the L^2 inner product. The second equation can be used to eliminate the pressure and to obtain an equation in terms of $\mathbf{u}_\epsilon$ only:

$$A(\mathbf{u}_\epsilon,\mathbf{v}) + \frac{1}{\epsilon}\int_\Omega (\nabla\cdot\mathbf{u}_\epsilon)(\nabla\cdot\mathbf{v})\,d\Omega = F(\mathbf{v}) \quad \forall\,\mathbf{v}\in\mathbf{H}^1_0(\Omega)\,. \tag{3.12}$$

Restriction of (3.12) to a discrete velocity space $\mathbf{V}^h$ leads to the classical penalty method. Alternatively, one can discretize (3.10)–(3.11), eliminate the discrete pressure from the linear system, and obtain another problem in terms of the discrete velocity only. Regardless of which version of the penalty method is used, i.e., *eliminate* and then *discretize*, or *discretize* and then *eliminate*, the ensuing penalty problem continues to require a discrete inf-sup compatibility condition. For instance, well-posedness of the *eliminate* and *discretize* method is subject to an inf-sup condition between $\mathbf{V}^h$ and an implicit pressure space defined by $\epsilon p_\epsilon = -\nabla\cdot\mathbf{u}_\epsilon$; see [24, 25]. A classical example of a failure in this method is the locking phenomena that occurs for linear velocities. In this case the implicit pair $(\mathbf{V}^h, S^h)$ is equivalent to the unstable P_1-P_0 element.

Because the penalty method still requires compatible finite element spaces, it is not a stabilization procedure. Rather, it is a solution method that allows one to solve the mixed problem more easily by uncoupling the velocity and pressure. In contrast to (3.10)–(3.11), in (3.8) we seek $(\mathbf{u}^h, p^h)\in\mathbf{V}^h\times S^h$ such that

$$A(\mathbf{u}^h,\mathbf{v}^h) + B(p^h,\mathbf{v}^h) = F(\mathbf{v}^h) \quad \forall\,\mathbf{v}^h\in\mathbf{V}^h \tag{3.13}$$

$$B(q^h,\mathbf{u}^h) - G(p^h,q^h) = 0 \qquad \forall\, q\in S^h\,. \tag{3.14}$$

In addition to the absence of a penalty parameter, another difference between (3.13)–(3.14) and the penalized problem (3.10)–(3.11) is that $G(\cdot,\cdot)$ vanishes for all pressures in the range of Π. As a result, this variable cannot be eliminated from (3.14). Of course, the main difference is that, as we shall see in the next section, (3.13)–(3.14) is stable for the low-order pairs in (2.9) and (2.10), while (3.10)–(3.11) may fail as $\epsilon\to 0$.

The penalty method can be extended to a stabilization procedure by using the stronger H^1-seminorm penalty $\epsilon/2\|\nabla q\|_0^2$ instead of the classical L^2 penalty $\epsilon/2\|q\|_0^2$. This leads to a stabilized finite element method proposed by Brezzi and Pitkaranta [11]. The bound (2.21) in Lemma 2.3 implies that for R^1 pressures their method and (3.8) have similar stability properties. However, (3.8) can be extended to constant pressures, while the method of [11] cannot.

4. Stability. To show that (3.8) is a stable variational problem, we have to additionally assume that Π is continuous as an operator $L^2(\Omega)\mapsto L^2(\Omega)$:

$$\|\Pi p\|_0 \le C\|p\|_0 \quad \forall\, p\in L^2(\Omega)\,. \tag{4.1}$$

Using (4.1), it is easy to show that $\widetilde{Q}$ is continuous, i.e.,

$$\widetilde{Q}(\mathbf{u}^h,p^h;\mathbf{v}^h,q^h) \le C\left(\|\mathbf{u}^h\|_1 + \|p^h\|_0\right)\left(\|\mathbf{v}^h\|_1 + \|q^h\|_0\right) \tag{4.2}$$

for all $(\mathbf{u}^h,p^h)$ and $(\mathbf{v}^h,q^h)$ in $\mathbf{V}^h\times S^h$. We now prove the stability of the variational problem (3.8).

THEOREM 4.1. *Let $(\mathbf{V}^h,S^h)$ be one of the pairs* (2.9) *or* (2.10). *Then, there exists a positive constant C whose value is independent of h such that*

$$\sup_{(\mathbf{v}^h,q^h)\in\mathbf{V}^h\times S^h} \frac{\widetilde{Q}(\mathbf{u}^h,p^h;\mathbf{v}^h,q^h)}{\|\mathbf{v}^h\|_1 + \|q^h\|_0} \ge C\left(\|\mathbf{u}^h\|_1 + \|p^h\|_0\right) \ \forall\,(\mathbf{u}^h,p^h)\in\mathbf{V}^h\times S^h\,. \tag{4.3}$$

Proof. We will construct a pair $(\widehat{\mathbf{v}}^h, \widehat{q}^h)$, such that

$$\widetilde{Q}(\mathbf{u}^h, p^h; \widehat{\mathbf{v}}^h, \widehat{q}^h) \geq C \left(\|\mathbf{u}^h\|_1 + \|p^h\|_0 \right) \left(\|\widehat{\mathbf{v}}^h\|_1 + \|\widehat{q}^h\|_0 \right) .$$

Setting $(\mathbf{v}^h, q^h) = (\mathbf{u}^h, -p^h)$ yields

$$\widetilde{Q}(\mathbf{u}^h, p^h; \mathbf{u}^h, -p^h) = \lambda \|\nabla \mathbf{u}^h\|_0^2 + \| \left(I - \Pi \right) p^h \|_0^2 .$$

For a given arbitrary but fixed pressure $p^h \in S^h$, let $\mathbf{w}$ and $\mathbf{w}^h$ be the functions that satisfy (2.12) and (2.13). Assume that $\mathbf{w}^h$ is normalized so that

$$\|\nabla \mathbf{w}^h\|_0 = \sqrt{\lambda} \, \|p^h\|_0 . \tag{4.4}$$

From (2.14) and (2.21) if $\Pi = \Pi_0$ and (2.17) and (2.22) if $\Pi = \Pi_1$, we have that

$$\int_\Omega p^h \nabla \cdot \mathbf{w}^h \, d\Omega \geq C_1 \|p^h\|_0^2 - C_2 \| \left(I - \Pi \right) p^h \|_0 \|p^h\|_0 .$$

Setting $(\mathbf{v}^h, q^h) = (-\alpha \mathbf{w}^h, 0)$, where α is a real, positive parameter, together with the last inequality and (4.4), yields

$$\begin{aligned}
\widetilde{Q}(\mathbf{u}^h, p^h; -\alpha \mathbf{w}^h, 0) &= -\alpha \int_\Omega \nabla \mathbf{u}^h \cdot \nabla \mathbf{w}^h \, d\Omega + \alpha \int_\Omega p^h \nabla \cdot \mathbf{w}^h \, d\Omega \\
&\geq -\alpha \|\nabla \mathbf{u}^h\|_0 \|\nabla \mathbf{w}^h\|_0 + \alpha \big(C_1 \|p^h\|_0^2 - C_2 \|(I - \Pi) p^h\|_0 \|p^h\|_0 \big) \\
&\geq -\alpha \sqrt{\lambda} \|\nabla \mathbf{u}^h\|_0 \|p^h\|_0 + \alpha \big(C_1 \|p^h\|_0^2 - C_2 \|(I - \Pi) p^h\|_0 \|p^h\|_0 \big) .
\end{aligned}$$

As a result, for $(\mathbf{v}^h, q^h) = (\mathbf{u}^h - \alpha \mathbf{w}^h, -p^h)$, we have the bound

$$\begin{aligned}
\widetilde{Q}(\mathbf{u}^h, p^h; \mathbf{u}^h - \alpha \mathbf{w}^h, -p^h) \geq \|\nabla \mathbf{u}^h\|_0^2 + \| \left(I - \Pi \right) p^h \|_0^2 + \alpha C_1 \|p^h\|_0^2 \\
- \alpha \sqrt{\lambda} \|\nabla \mathbf{u}^h\|_0 \|p^h\|_0 - \alpha C_2 \| \left(I - \Pi \right) p^h \|_0 \|p^h\|_0 .
\end{aligned}$$

Using the ε-inequality with $\varepsilon = C_1/2$, we have that

$$\sqrt{\lambda} \|\nabla \mathbf{u}^h\|_0 \|p^h\|_0 \leq \frac{\lambda}{C_1} \|\nabla \mathbf{u}^h\|_0^2 + \frac{C_1}{4} \|p^h\|_0^2$$

and

$$C_2 \| \left(I - \Pi \right) p^h \|_0 \|p^h\|_0 \leq \frac{C_2^2}{C_1} \| \left(I - \Pi \right) p^h \|_0^2 + \frac{C_1}{4} \|p^h\|_0^2 .$$

In combination with the earlier lower bounds, these inequalities lead to

$$\begin{aligned}
&\widetilde{Q}(\mathbf{u}^h, p^h; \mathbf{u}^h - \alpha \mathbf{w}^h, -p^h) \\
&\qquad \geq \lambda \left(1 - \frac{\alpha}{C_1} \right) \|\nabla \mathbf{u}^h\|_0^2 + \frac{\alpha C_1}{2} \|p^h\|_0^2 + \left(1 - \frac{\alpha C_2^2}{C_1} \right) \| \left(I - \Pi \right) p^h \|_0^2 .
\end{aligned}$$

Choosing

$$\widehat{\alpha} = \min \left\{ \frac{C_1}{2}, \frac{C_1}{2C_2^2} \right\}$$

guarantees that

$$\left(1-\frac{\widehat{\alpha}}{C_1}\right)\geq\frac{1}{2}\quad\text{and}\quad\left(1-\frac{\widehat{\alpha}C_2^2}{C_1}\right)\geq\frac{1}{2}\,.$$

We now set

$$\widehat{\mathbf{v}}^h=\mathbf{u}^h-\widehat{\alpha}\mathbf{w}^h\qquad\text{and}\qquad\widehat{q}^h=-p^h\,.$$

It is then easy to see that

$$\begin{aligned}\widetilde{Q}(\mathbf{u}^h,p^h;\widehat{\mathbf{v}}^h,\widehat{q}^h)&\geq\frac{1}{2}\left(\lambda\|\nabla\mathbf{u}^h\|_0^2+\widehat{\alpha}C_1\|p^h\|_0^2+\|\left(I-\Pi\right)p^h\|_0^2\right)\\&\geq\frac{1}{6}\left(\sqrt{\lambda}\|\nabla\mathbf{u}^h\|_0+\sqrt{\widehat{\alpha}C_1}\|p^h\|_0+\|\left(I-\Pi\right)p^h\|_0\right)^2\\&\geq C\left(\|\nabla\mathbf{u}^h\|_0+\|p^h\|_0\right)^2,\end{aligned}$$

where the last bound follows from $(a+b+c)^2\leq 3(a^2+b^2+c^2)$. Finally, (4.4) implies that

$$\begin{aligned}\|\nabla\widehat{\mathbf{v}}^h\|_0+\|\widehat{q}^h\|_0&=\|\nabla(\mathbf{u}^h-\widehat{\alpha}\mathbf{w}^h)\|_0+\|p^h\|_0\leq\|\nabla\mathbf{u}^h\|_0+\widehat{\alpha}\|\nabla\mathbf{w}^h\|_0+\|p^h\|_0\\&\leq\|\nabla\mathbf{u}^h\|_0+\widehat{\alpha}\sqrt{\lambda}\|p^h\|_0+\|p^h\|_0\leq C\left(\|\nabla\mathbf{u}^h\|_0+\|p^h\|_0\right),\end{aligned}$$

i.e., $(\widehat{\mathbf{v}}^h,\widehat{q}^h)$ is bounded by $(\mathbf{u}^h,p^h)$ in the norm of $\mathbf{H}_0^1(\Omega)\times L^2(\Omega)$. This proves the theorem. □

Together, (4.2) and (4.3) imply that (3.8) is a stable variational problem.

Remark 1. Because $\widetilde{Q}$ is symmetric, (4.3) is sufficient to establish weak coercivity of this form.

Remark 2. The stabilized problem (3.8) is well-posed if (4.2) and (4.3) hold, i.e., if the bilinear form $\widetilde{Q}$ is continuous and weakly coercive. From the proof of Theorem 4.1, it is clear that weak coercivity depends only on Π having the appropriate range. The continuity of $\widetilde{Q}$, on the other hand, is impossible without assuming that Π itself is continuous.

5. Error estimates. To prove convergence of stabilized solutions, the properties of Π must be augmented by an approximation hypothesis. We will assume that

$$\|(I-\Pi)p\|_0\leq Ch\|p\|_1 \tag{5.1}$$

for every $p\in H^1(\Omega)$.

THEOREM 5.1. *Let* $(\mathbf{V}^h,S^h)$ *denote one of the spaces* (2.9) *or* (2.10), *let* $(\mathbf{u},p)$ *be the solution of the Stokes problem* (2.4), *and let* $(\mathbf{u}^h,p^h)\in\mathbf{V}^h\times S^h$ *solve the stabilized mixed problem* (3.8), *where the operator* Π *defined in* (2.23) *satisfies* (4.1). *Then,*

$$\begin{aligned}&\|\mathbf{u}-\mathbf{u}^h\|_1+\|p-p^h\|_0\\&\qquad\leq C\left(\inf_{q^h\in S^h}\|p-q^h\|_0+\inf_{\mathbf{v}^h\in\mathbf{V}^h}\|\mathbf{u}-\mathbf{v}^h\|_1+\|(I-\Pi)p\|_0\right).\end{aligned}\tag{5.2}$$

Proof. Since $(\mathbf{V}^h, S^h)$ is a subspace of $\mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$, we have from (2.4) that

$$A(\mathbf{u}, \mathbf{v}^h) + B(p, \mathbf{v}^h) = F(\mathbf{v}^h) \qquad \forall\, \mathbf{v}^h \in \mathbf{V}^h,$$
$$B(q^h, \mathbf{u}) = 0 \qquad \forall\, q^h \in S^h.$$

Subtracting these equations from (3.13)–(3.14) yields

$$A(\mathbf{u}^h - \mathbf{u}, \mathbf{v}^h) + B(p^h - p, \mathbf{v}^h) = 0 \qquad \forall\, \mathbf{v}^h \in \mathbf{V}^h,$$
$$B(q^h, \mathbf{u}^h - \mathbf{u}) = G(p^h, q) \quad \forall\, q^h \in S^h,$$

or, equivalently,

$$\widetilde{Q}(\mathbf{u}^h - \mathbf{u}, p^h - p; \mathbf{v}^h, q^h) = G(p, q^h) \quad \forall\, (\mathbf{v}^h, q^h) \in \mathbf{V}^h \times S^h\,. \tag{5.3}$$

Let $(\mathbf{w}^h, r^h)$ be an arbitrary pair in $\mathbf{V}^h \times S^h$. We estimate the discrete error

$$\|\mathbf{u}^h - \mathbf{w}^h\|_1 + \|p^h - r^h\|_0$$

using the weak coercivity bound (4.3) and the error "orthogonality" (5.3):

$$\begin{aligned}
&C\left(\|\mathbf{u}^h - \mathbf{w}^h\|_1 + \|p^h - r^h\|_0\right) \\
&\quad\le \sup_{(\mathbf{v}^h, q^h) \in \mathbf{V}^h \times S^h} \frac{\widetilde{Q}(\mathbf{u}^h - \mathbf{w}^h, p^h - r^h; \mathbf{v}^h, q^h)}{\|\mathbf{v}^h\|_1 + \|q^h\|_0} \\
&\quad= \sup_{(\mathbf{v}^h, q^h) \in \mathbf{V}^h \times S^h} \frac{\widetilde{Q}(\mathbf{u}^h - \mathbf{u}, p^h - p; \mathbf{v}^h, q^h) + \widetilde{Q}(\mathbf{u} - \mathbf{w}^h, p - r^h; \mathbf{v}^h, q^h)}{\|\mathbf{v}^h\|_1 + \|q^h\|_0} \\
&\quad= \sup_{(\mathbf{v}^h, q^h) \in \mathbf{V}^h \times S^h} \frac{G(p, q^h) + \widetilde{Q}(\mathbf{u} - \mathbf{w}^h, p - r^h; \mathbf{v}^h, q^h)}{\|\mathbf{v}^h\|_1 + \|q^h\|_0}\,.
\end{aligned}$$

From (4.2) we have that

$$\widetilde{Q}(\mathbf{u} - \mathbf{w}^h, p - r^h; \mathbf{v}^h, q^h) \le C\left(\|\mathbf{u} - \mathbf{w}^h\|_1 + \|p - r^h\|_0\right)\left(\|\mathbf{v}^h\|_1 + \|q^h\|_0\right)$$

and from (4.1) we have that

$$G(p, q^h) \le C G(p, p)^{1/2} \|q^h\|_0\,.$$

As a result, there exists a positive constant C such that

$$\begin{aligned}
&C\left(\|\mathbf{u}^h - \mathbf{w}^h\|_1 + \|p^h - r^h\|_0\right) \\
&\le \sup_{(\mathbf{v}^h, q^h) \in \mathbf{V}^h \times S^h} \frac{G(p, p)^{1/2}\|q^h\|_0 + \left(\|\mathbf{u} - \mathbf{w}^h\|_1 + \|p - r^h\|_0\right)\left(\|\mathbf{v}^h\|_1 + \|q^h\|_0\right)}{\|\mathbf{v}^h\|_1 + \|q^h\|_0} \\
&\le G(p, p)^{1/2} + \left(\|\mathbf{u} - \mathbf{w}^h\|_1 + \|p - r^h\|_0\right) = \left(\|\mathbf{u} - \mathbf{w}^h\|_1 + \|p - r^h\|_0\right) + \|(I - \Pi)p\|_0\,.
\end{aligned}$$

To complete the proof, we use the triangle inequality to obtain

$$\begin{aligned}
&\|\mathbf{u} - \mathbf{u}^h\|_1 + \|p - p^h\|_0 \\
&\qquad\le \left(\|\mathbf{u} - \mathbf{w}^h\|_1 + \|p - r^h\|_0\right) + \left(\|\mathbf{u}^h - \mathbf{w}^h\|_1 + \|p^h - r^h\|_0\right) \\
&\qquad\le C\Big(\|\mathbf{u} - \mathbf{w}^h\|_1 + \|p - r^h\|_0 + \|(I - \Pi)p\|_0\Big)\,,
\end{aligned}$$

and then take the infimum over $\mathbf{w}^h \in \mathbf{V}^h$ and $r^h \in S^h$. ∎

Together with the assumption (5.1) this theorem can be used to show that solutions of (3.8) converge optimally with respect to the solution regularity.

COROLLARY 5.2. *Assume that* $(\mathbf{u}, p) \in \mathbf{H}_0^1(\Omega) \cap \mathbf{H}^2(\Omega) \times L_0^2(\Omega) \cap H^1(\Omega)$ *solves the Stokes problem* (2.1)–(2.2) *and that* $(\mathbf{u}^h, p^h)$ *is the solution of the stabilized mixed problem* (3.8), *where the operator* Π *defined in* (2.23) *satisfies* (4.1) *and* (5.1). *Then,*

$$\|\mathbf{u} - \mathbf{u}^h\|_1 + \|p - p^h\|_0 \leq Ch\left(\|u\|_2 + \|p\|_1\right) . \tag{5.4}$$

Proof. The assertion follows immediately from (5.2) using (1.4), (1.6), and (5.1). ∎

6. Implementation. Among the attractive features of our stabilization approach is the great flexibility in the definition of the stabilization term (3.1). The main prerequisite to achieve stabilization of the mixed method with the low-order finite element pairs (2.9) and (2.10) is to choose a Π with the appropriate range. The simplest way to accomplish this is to use standard finite element projection or interpolation operators. Then, the remaining assumptions about Π are easily verified.

From a practical viewpoint the main factors in the choice of Π are simplicity and locality, i.e., computation of its action must be done at the element level using only standard nodal data structures. With this in mind, a suitable choice of Π_0 to stabilize the lowest equal order pair (2.9) is a local L^2 projection operator. Given a function $q \in L^2(\Omega)$ we define $\Pi_0 : L^2(\Omega) \mapsto R_0$ by $\Pi_0 q = q^h \in R_0$ if and only if

$$\int_{\Omega_e} (\Pi_0 q - q)\, d\Omega_e = 0 \qquad \forall\, \Omega_e \in \mathcal{T}_h\,. \tag{6.1}$$

It is easy to see that

$$\Pi_0 q|_{\Omega_e} = \frac{1}{V(\Omega_e)} \int_{\Omega_e} q\, d\Omega_e$$

is the element average of q and that Π_0 satisfies both assumptions (4.1) and (5.1); see [18, p. 102].

A suitable choice of Π_1 to stabilize the lowest order conforming pair (2.10) is a Clement-like interpolant; see [18, p. 110]. Instead of using a projection onto a patch of elements that share the same node we choose to define our interpolant by using a projection onto the dual (or complementary) volume associated with each node. For piecewise constant pressures this choice leads to a particularly simple formula for the action of Π_1 that does not require explicit construction of a dual cell. Specifically, we define $\Pi_1 : L^2(\Omega) \mapsto R_1$ as follows. For a given node $\mathcal{N}_i$ in $\mathcal{T}_h$, let $\widehat{\Omega}_i$ denote its dual volume. Given a function $q \in L^2(\Omega)$, let q_i be the constant function on $\widehat{\Omega}_i$ that minimizes the functional

$$J_i(q) = \frac{1}{2} \int_{\widehat{\Omega}_i} (q_i - q)^2 \, d\Omega\,; \tag{6.2}$$

then set

$$\Pi_1 q = \sum_{i=1}^{N_{nodes}} q_i N_i(\mathbf{x}) \in R_1\,, \tag{6.3}$$

where N_i denotes the nodal basis of R_1 and N_{nodes} is the number of nodes in $\mathcal{T}_h$. The action of the operator defined in (6.3) can be computed locally at the element level and has the same properties as the usual Clement interpolant, i.e., (4.1) and (5.1) are satisfied. For $q = q^h \in R_0$, the functional in (6.2) further simplifies to

$$J_i(q^h) = \sum_{\Omega_e \cap \Omega_i \neq 0} V_i(\Omega_e)(q_i - q_e^h)^2,$$

where q_e^h is the constant value of q^h on Ω_e and $V_i(\Omega_e)$ is the volume fraction of the element Ω_e that belongs to the dual cell $\widehat{\Omega}_i$ associated with node $\mathcal{N}_i$. For constant pressures, we can choose

$$V_i(\Omega_e) = V(\Omega_e)/n_e\,,$$

where n_e is the number of nodes in Ω_e. Minimization of J_i then yields the formula

$$q_i = \frac{\sum_{\Omega_e \in \Omega_i} V_i(\Omega_e) q_e^h}{\sum_{\Omega_e \in \Omega_i} V_i(\Omega_e)} = \sum_{\Omega_e \in \Omega_i} d_{ie} q_e^h\,,$$

i.e., the nodal values of $\Pi_1 q^h$ are area weighted averages of the surrounding constant pressure values of q^h.

The stabilized mixed problem gives rise to a linear system of algebraic equations with a matrix that has the form

$$\begin{bmatrix} \mathbb{A} & \mathbb{B}^T \\ \mathbb{B} & -\mathbb{G} \end{bmatrix}. \tag{6.4}$$

The matrices $\mathbb{A}$ and $\mathbb{B}$ are assembled in the usual manner from the bilinear forms $A(\cdot,\cdot)$ and $B(\cdot,\cdot)$, respectively, and $\mathbb{G}$ is a symmetric, semidefinite matrix generated at the element level from $G(\cdot,\cdot)$. The form of this matrix depends on the particular operator Π employed in the stabilization. However, computation of $\mathbb{G}$ is completely local and can be accomplished by augmenting the standard nodal assembly process by a few simple calculations. For example, the only information needed to compute $\mathbb{G}$ in the case of Π_1 is the area of each element. This information should be readily available during the standard assembly process; moreover, calculation of $\mathbb{G}$ is simple in comparison to the calculations required to determine $\mathbb{A}$ and $\mathbb{B}$.

It is also easy to see that $\mathbb{G}$ is a sparse matrix. In the case of $\Pi = \Pi_0$, its sparsity pattern is the same as for the standard nodal R_1 pressure mass matrix. In the case of $\Pi = \Pi_1$, the original mass matrix associated with piecewise constant pressures is diagonal while $\mathbb{G}$ is not. Nevertheless, the important point is that the action of $(I - \Pi)$ in both cases is obtained by multiplication of pressure degrees of freedom by a sparse matrix rather than by an inversion of a mass matrix as occurs in determining L^2 projections. As a result, in the context of iterative solution methods, our stabilization method is very efficient as it requires only one sparse matrix-vector multiply per iteration.

7. Numerical examples. In this section, we report on some numerical results obtained using the stabilized method (3.8). The main goal of these experiments is to verify the convergence rates of (5.2) for the low-order pairs (2.9) and (2.10) in two and three space dimensions. For each pair of spaces, we consider both simplicial and nonsimplicial partitions $\mathcal{T}_h$ of the computational domain into finite elements. Figure

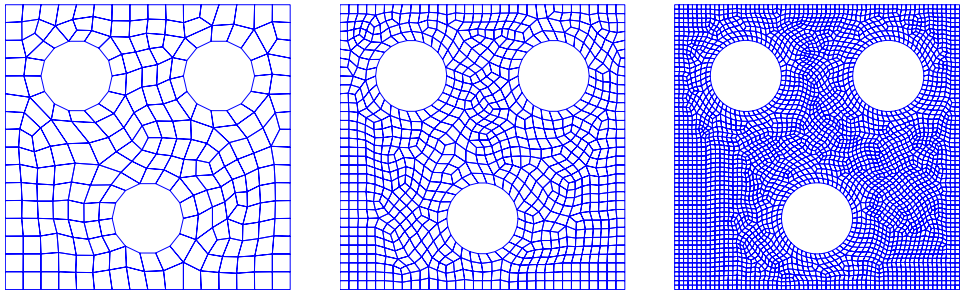

FIG. 7.1. *A sequence of refined nonuniform quadrilateral grids.*

7.1 shows an example of a nonsimplicial sequence of grids used for a convergence study in two dimensions. The following error norms are used for the investigation of convergence rates:

$$e^h_{uL_2} = \|\mathbf{u}^h - \mathbf{u}\|_0 = \sqrt{\sum_{i=1}^{d} \int_\Omega (u_i^h - u_i)^2 d\Omega}, \tag{7.1}$$

$$e^h_{uH_1} = \|\mathbf{u}^h - \mathbf{u}\|_1 = \sqrt{\sum_{i=1}^{d} \int_\Omega \nabla(u_i^h - u_i) \cdot \nabla(u_i^h - u_i) d\Omega}, \tag{7.2}$$

$$e^h_{pL_2} = \|p^h - p\|_0 = \sqrt{\int_\Omega (p^h - p)^2 d\Omega}\,, \tag{7.3}$$

where d denotes the spatial dimension, u_i, $i = 1, \ldots, d$, denote the components of the vector $\mathbf{u}$, and $(\mathbf{u}^h, p^h)$ denotes the stabilized finite element approximation of the exact solution $(\mathbf{u}, p)$. To estimate convergence rates, we select a pair of smooth functions $(\mathbf{u}, p)$, with $\mathbf{u}$ solenoidal and p having zero mean, and evaluate the Stokes equations to generate the source term $\mathbf{f}$ and the boundary data. This synthetic data is then used by (3.8) to approximate the smooth exact solution on a sequence of grids.

The first example is for a unit square with[3] $\lambda = 1$ and the smooth exact solution

$$u_1 = x + x^2 - 2xy + x^3 - 3xy^2 + x^2 y, \tag{7.4}$$

$$u_2 = -y - 2xy + y^2 - 3x^2 y + y^3 - xy^2, \tag{7.5}$$

$$p = xy + x + y + x^3 y^2 - 4/3\,. \tag{7.6}$$

The values of $\mathbf{u}$ on the boundary of the square are constrained to those given by (7.4) and (7.5). To remove the constant pressure mode from the numerical solution, the constraint

$$\int_\Omega p(\mathbf{x}) d\Omega = 0 \tag{7.7}$$

is also imposed. Results for stabilized triangular elements P_1-P_1 and P_1-P_0 and stabilized quadrilateral elements Q_1-Q_1 and Q_1-P_0 are shown in Figure 7.2. The $e^h_{uH_1}$ errors for the continuous pressure elements (P_1-P_1 and Q_1-Q_1) and the discontinuous

[3]The implementation of the new stabilized method for nonconstant viscosity is straightforward by using, e.g., viscosity values at quadrature points.

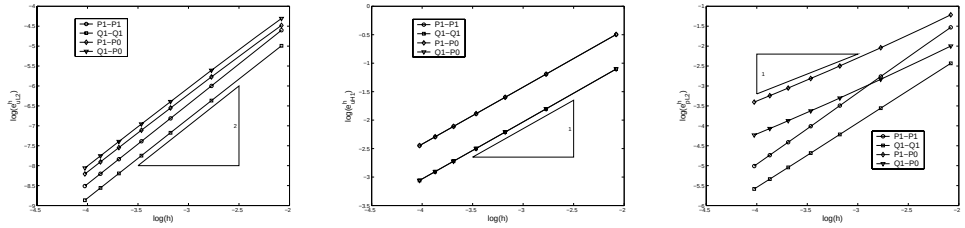

FIG. 7.2. *Errors for the first two-dimensional example (structured meshes).*

TABLE 7.1
Solution errors for triangular stabilized elements normalized with respect to results for the stable MINI element.

	P_1-P_1				P_1-P_0			
$1/h$	$e^h_{uL_2}$	$e^h_{uH_1}$	$e^h_{pL_2}$	e_{div}	$e^h_{uL_2}$	$e^h_{uH_1}$	$e^h_{pL_2}$	e_{div}
8	0.892	0.985	0.588	0.976	1.009	0.986	0.807	0.823
16	0.890	0.996	0.583	0.976	1.114	0.997	1.201	0.826
24	0.890	0.999	0.574	0.976	1.155	1.000	1.552	0.827
32	0.889	1.000	0.565	0.976	1.176	1.001	1.872	0.827
40	0.889	1.001	0.556	0.976	1.189	1.001	2.167	0.828
48	0.889	1.001	0.549	0.976	1.198	1.002	2.442	0.828
56	0.889	1.001	0.542	0.976	1.204	1.002	2.698	0.828

pressure elements (P_1-P_0 and Q_1-P_0) are nearly identical. Although not predicted by theory, the $e^h_{pL_2}$ line segment slopes for the continuous pressure elements exceed those of the discontinuous pressure elements. In all cases, the theoretical convergence rates are confirmed.

For purposes of comparison, we show in Table 7.1 the P_1-P_1 and P_1-P_0 results of Figures 7.2 normalized with respect to those of the stable MINI element. Also shown in the table are the normalized values of the maximum error in the divergence within an element as defined by

$$e_{div} = \max_e \left| \int_{\Gamma_e} \mathbf{u} \cdot \mathbf{n} \, d\Gamma_e \right| , \tag{7.8}$$

where Γ_e is the boundary of element e and $\mathbf{n}$ is the unit outward normal of Γ_e. The normalized maximum errors in the divergence are close to the stable MINI element for both the P_1-P_1 and P_1-P_0 elements. The higher normalized values of $e^h_{pL_2}$ for the P_1-P_0 elements are consistent with previous comments regarding continuous and discontinuous pressure elements.

The second example uses the same exact solution, but now the square domain has three circular cutouts as shown in Figure 7.1. Note that it is necessary to adjust the constant value of 4/3 in (7.6) to satisfy (7.7). Meshes of triangles were obtained from the quadrilateral meshes by splitting each quadrilateral into two triangles. Plots of the error norms for the different element types are shown in Figure 7.3. In this figure, $h_e = 1/\sqrt{N_e}$ where N_e is the number of quadrilateral elements in the mesh. As expected, the error norms become smaller as the meshes are refined.

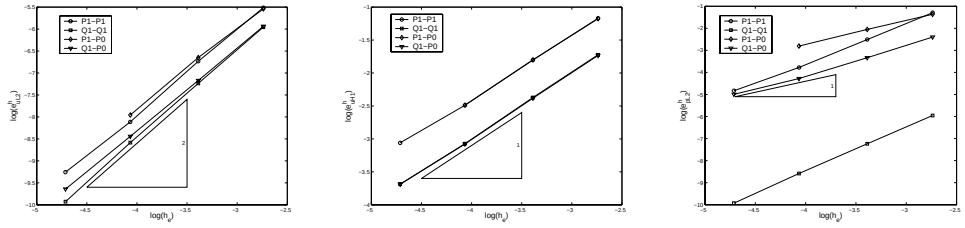

FIG. 7.3. *Errors for the second two-dimensional example (unstructured meshes).*

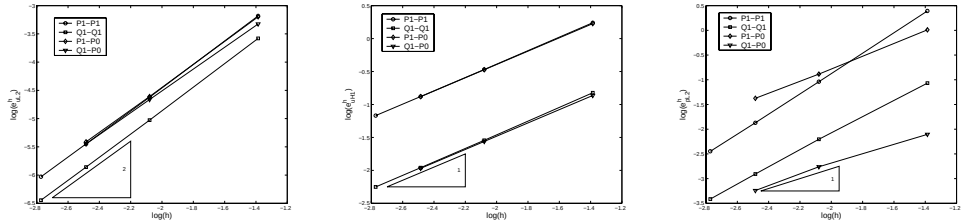

FIG. 7.4. *Errors for the three-dimensional example.*

The final example is for a unit cube with $\lambda = 1$ and the smooth exact solution

$$u_1 = x + x^2 + xy + x^3 y, \tag{7.9}$$

$$u_2 = y + xy + y^2 + x^2 y^2, \tag{7.10}$$

$$u_3 = -2z - 3xz - 3yz - 5x^2 yz, \tag{7.11}$$

$$p = xyz + x^3 y^3 z - 5/32\,. \tag{7.12}$$

The hexahedral meshes have $(1/h)^3$ elements whereas the tetrahedral meshes have $6(1/h)^3$ elements. Plots of the error norms versus element length are shown in Figure 7.4. As was the case for the two-dimensional examples, the theoretical convergence rates are confirmed. Again, the $e^h_{pL_2}$ line segment slopes for the continuous pressure elements are larger than those for the discontinuous pressure elements.

For further examples and numerical studies, we refer to [14].

8. Conclusions. We have formulated a new approach to stabilization of low-order velocity-pressure pairs for the incompressible Stokes equations. Central to our approach is the characterization of the LBB deficiency of the unstable pairs in terms of suitable operators, and their subsequent application in the formulation of a stabilized mixed variational equation. This characterization remains valid for a broad range of operators which makes our stabilization technique extremely flexible and leads to stabilized mixed methods with attractive computational properties. Most notably, our methods do not require selection of mesh-dependent stabilization parameters, retain the symmetry of the original equations, and can be implemented at the element level with minimal additional cost. Numerical examples presented in this paper demonstrate the excellent stability and accuracy properties of the new methods.

Acknowledgments. We thank the anonymous referees for their careful reading of the manuscript and suggestions that helped to improve the paper.

CONVERGENCE OF THE LLOYD ALGORITHM FOR COMPUTING CENTROIDAL VORONOI TESSELLATIONS*

QIANG DU†, MARIA EMELIANENKO‡, AND LILI JU§

Abstract. Centroidal Voronoi tessellations (CVTs) are Voronoi tessellations of a bounded geometric domain such that the generating points of the tessellations are also the centroids (mass centers) of the corresponding Voronoi regions with respect to a given density function. Centroidal Voronoi tessellations may also be defined in more abstract and more general settings. Due to the natural optimization properties enjoyed by CVTs, they have many applications in diverse fields. The Lloyd algorithm is one of the most popular iterative schemes for computing the CVTs but its theoretical analysis is far from complete. In this paper, some new analytical results on the local and global convergence of the Lloyd algorithm are presented. These results are derived through careful utilization of the optimization properties shared by CVTs. Numerical experiments are also provided to substantiate the theoretical analysis.

Key words. centroidal Voronoi tessellations, k-means, optimal vector quantizer, Lloyd algorithm, global convergence, convergence rate

1. Introduction.

A centroidal Voronoi tessellation (CVT) is a special Voronoi tessellation of a given set such that the associated generating points are the centroids (centers of mass) of the corresponding Voronoi regions with respect to a predefined density function [7]. CVTs are indeed special as they enjoy very natural optimization properties which make them very popular in diverse scientific and engineering applications that include art design, astronomy, clustering, geometric modeling, image and data analysis, resource optimization, quadrature design, sensor networks, and numerical solution of partial differential equations [1, 2, 3, 4, 7, 8, 9, 10, 11, 13, 14, 17, 15, 26, 29, 30, 31, 39, 44, 45]. In particular, CVTs have been widely used in the design of optimal vector quantizers in electrical engineering [25, 28, 40, 43]. They are also related to the so-called method of k-means [27] in clustering analysis. CVTs can also be defined in more general cases such as those constrained to a manifold [12, 11] or those corresponding to anisotropic metrics [16, 18], and other abstract settings [7, 9].

For modern applications of the CVT concept in large-scale scientific and engineering problems, it is important to develop robust and efficient algorithms for constructing CVTs in various settings. Historically, a number of algorithms have been studied and widely used [7, 19, 25, 27, 38]. A seminal work is the algorithm first developed in the 1960s at Bell Laboratories by S. Lloyd which remains to this day one of the most popular methods due to its effectiveness and simplicity. The algorithm was later officially published in [35]. It is now commonly referred to as the Lloyd algorithm and is the main focus of this paper.

The Lloyd algorithm has many elegant and simple interpretations [7], but to present it more rigorously, we begin with a more detailed description of the CVT. First of all, we recall the concept of the Voronoi tessellation (or Voronoi diagram). A Voronoi tessellation refers to a tessellation of a given domain $\Omega \in \mathbb{R}^N$ by the Voronoi regions $\{V_i\}_{i=1}^k$ associated with a set of given *generating points* or *generators* $\{\mathbf{z}_i\}_{i=1}^k \subset \Omega$ [22, 33, 41]. For each i, $\{V_i\}_{i=1}^k$ consists of all points in the domain Ω that are closer to $\mathbf{z}_i$ than to all the other generating points. For a given density function ρ defined on Ω, we may define the centroids, or mass centers, of regions $\{V_i\}_{i=1}^k$ by

$$\mathbf{z}_i^* = \frac{\displaystyle\int_{V_i} \mathbf{y}\rho(\mathbf{y})\, d\mathbf{y}}{\displaystyle\int_{V_i} \rho(\mathbf{y})\, d\mathbf{y}}\,. \tag{1.1}$$

Then, a CVT refers to a Voronoi tessellation for which the generators themselves are the centroids of their respective Voronoi regions, that is, $\mathbf{z}_i = \mathbf{z}_i^*$ for all i. We refer to [7] for a more comprehensive review of the mathematical theory and diverse applications of CVTs.

In the seminal work of Lloyd on the least square quantization [35], one of the algorithms proposed for computing the CVTs (referred to as the optimal quantizers in the particular setting) is an iterative algorithm consisting of the following simple steps: starting from an initial Voronoi tessellation corresponding to an old set of generators, a new set of generators is defined by the mass centers of the Voronoi regions. This process is continued until a certain stopping criterion is met. With the notation given above, the Lloyd algorithm for constructing CVTs can be described more precisely by the following procedure.

ALGORITHM 1.1 (Lloyd algorithm for computing CVTs).

Input:

Ω, *the domain of interest;* ρ, *a density function defined on* Ω;
k, *number of generators;* $\{\mathbf{z}_i\}_{i=1}^k$, *the initial set of generators.*

Output:

$\{V_i\}_{i=1}^k$, *a CVT with* k *generators* $\{\mathbf{z}_i\}_{i=1}^k$ *in* Ω.

Iteration:

1. *Construct the Voronoi tessellation* $\{V_i\}_{i=1}^k$ *of* Ω *with generators* $\{\mathbf{z}_i\}_{i=1}^k$.
2. *Take the mass centroids of* $\{V_i\}_{i=1}^k$ *as the new set of generators* $\{\mathbf{z}_i\}_{i=1}^k$.
3. *Repeat procedures* 1 *and* 2 *until some stopping criterion is met.*

Given a set of points $\{\mathbf{z}_i\}_{i=1}^k$ and a tessellation $\{V_i\}_{i=1}^k$ of the domain, we may define the *energy functional* or the *distortion value* for the pair $(\{\mathbf{z}_i\}_{i=1}^k, \{V_i\}_{i=1}^k)$ by

$$\mathcal{H}\Big(\{\mathbf{z}_i\}_{i=1}^k, \{V_i\}_{i=1}^k\Big) = \sum_{i=1}^k \int_{V_i} \rho(\mathbf{y})|\mathbf{y} - \mathbf{z}_i|^2\, d\mathbf{y}\,.$$

The minimizer of $\mathcal{H}$ necessarily forms a CVT which illustrates the optimization property of the CVT [7]. Meanwhile, it is easy to see that the Lloyd algorithm is an energy descent iteration, which gives strong indications of its practical convergence.

The Lloyd algorithm sparked enormous research efforts in later years and its variants have been proposed and studied in many contexts for different applications [25, 28, 40, 43, 35, 24, 23, 32, 34, 36]. A particular extension was made in [30] to combine the deterministic features of the Lloyd algorithm with some random sampling techniques. Despite its great success in applications and a large number of studies over

the last few decades, only limited theoretical results on the Lloyd algorithm have been obtained [7] and many fundamental issues remain open concerning its convergence.

In this paper, we present a systematic study on both the local and the global convergence properties of the Lloyd algorithm. A number of new global convergence theorems are rigorously proved, including the global convergence of subsequences for any density functions, the global convergence of the whole sequence in one-dimensional space, and the global convergence under some nondegeneracy conditions. We also present some theoretical studies on the local convergence properties of the Lloyd algorithm including estimates on the convergence rates. Some numerical results are also presented to substantiate our theoretical investigation. Many of the techniques employed in this paper, in fact, work for more general settings. As an illustration, we analyze the application of the Lloyd algorithm to the construction of the constrained CVTs on a manifold and present some similar convergence theorems.

The rest of the paper is organized as follows. We present our main convergence theorems and some detailed discussions in section 2, followed by the extensions to more general settings that are considered in section 3 and numerical results that are given in section 4. Conclusions are drawn in section 5.

2. Convergence. Since Lloyd's pioneering work, many studies have been made on the convergence of the iteration [21, 24, 32, 36]. For example, the local convergence has been proved for strictly *logarithmically concave* density functions in the one-dimensional space [32]. An extension to CVTs defined on a circle is given in [12]. The convergence analysis in multidimensional space for general density functions is far from complete. There are very few known conditions that guarantee the global convergence. We now present some new results that have not been previously explored in the literature.

For clarity, since a Voronoi tessellation is defined using a point set with k points $\mathbf{Y} = \{\mathbf{y}_i\}_{i=1}^k$ as the respective generators, let us redefine the *energy functional*, or the *distortion value*, as a functional for a pair $(\mathbf{Y}, \mathbf{Z})$ with $\mathbf{Z} = (\mathbf{z}_1, \mathbf{z}_2, \ldots, \mathbf{z}_k) \in \mathbb{R}^{kN}$:

$$\mathcal{H}\Big(\mathbf{Y}, \mathbf{Z}\Big) = \sum_{i=1}^{k} \int_{V_i(\mathbf{Y})} \rho(\mathbf{y}) |\mathbf{y} - \mathbf{z}_i|^2 \, d\mathbf{y} \,,$$

where $\{V_i(\mathbf{Y})\}_{i=1}^k$ are the Voronoi regions with respect to $\{\mathbf{y}_i\}_{i=1}^k$. The Lloyd algorithm may be viewed as a fixed point iteration of the so-called Lloyd map [7], a mapping from a set of distinct generators $\{\mathbf{z}_i\}_{i=1}^k \subset \Omega \subset \mathbb{R}^N$ to the corresponding mass centers, defined by $\mathbf{T} = (\mathbf{T}_1, \mathbf{T}_2, \ldots, \mathbf{T}_k)^T \colon \mathbb{R}^{kN} \to \mathbb{R}^{kN}$ with

$$\mathbf{T}_i(\mathbf{Z}) = \frac{\displaystyle\int_{V_i(\mathbf{Z})} \mathbf{y} \rho(\mathbf{y}) \, d\mathbf{y}}{\displaystyle\int_{V_i(\mathbf{Z})} \rho(\mathbf{y}) \, d\mathbf{y}} \,.$$

A set of generators of a centroidal Voronoi tessellation is obviously a fixed point of $\mathbf{T}$. Moreover, the Lloyd algorithm is equivalent to a fixed point iteration of $\mathbf{T}$:

$$\mathbf{Z}_n = \mathbf{T}(\mathbf{Z}_{n-1}) \qquad \text{for } n \geq 1 \,.$$

Notice that in general, the map $\mathbf{T}$ can be defined only on an open subset of $\Omega^k \subset \mathbb{R}^{kN}$ as we need to ensure that the denominators are nonzero, that is, the corresponding Voronoi regions are nonempty. This, in particular, implies that the

generating points must be distinct. With this being noted, one needs to be cautious in applying general optimization theory concerning the convergence of energy descent algorithms [37] as such abstract theory often requires the compactness of the domain and the closedness of the associated map.

We now first quote some elementary facts for which one may find more detailed discussions in [7] and [41].

LEMMA 2.1. *Let ρ be a positive and smooth density function defined on a smooth bounded domain Ω. Then*

(1) *$\mathcal{H}$ is continuous and differentiable in $\bar{\Omega}^k \times \bar{\Omega}^k$;*

(2) $\mathcal{H}(\mathbf{Z}, \mathbf{T}(\mathbf{Z})) = \min_{\mathbf{Y} \in \bar{\Omega}^k} \mathcal{H}\Big(\mathbf{Z}, \mathbf{Y}\Big)$;

(3) $\mathcal{H}(\mathbf{Z}, \mathbf{Z}) = \min_{\mathbf{Y} \in \bar{\Omega}^k} \mathcal{H}(\mathbf{Y}, \mathbf{Z})$.

Next, we restate the strong connections between the map $\mathbf{T}$, the CVTs, and the Lloyd algorithm that we alluded to earlier.

LEMMA 2.2. *Let $\{\mathbf{Z}_n\}_1^\infty$ be the sequence of generating sets produced by the Lloyd algorithm. Then*

(1) $\mathbf{Z}_n = \mathbf{T}(\mathbf{Z}_{n-1})$;

(2) $\mathcal{H}(\mathbf{Z}_n, \mathbf{Z}_n) \leq \mathcal{H}(\mathbf{Z}_{n-1}, \mathbf{Z}_{n-1})$.

The first conclusion of the above lemma is obvious while the second one follows from properties (2) and (3) of Lemma 2.1 (for more details, see [7]). The results of Lemma 2.2 imply that the distortion (energy) values decrease when they are evaluated at consecutive iterations of the Lloyd algorithm; thus, the energy functional may be viewed as a descent function of the map $\mathbf{T}$, a fact that has been explored in [42], though the notion of a closed algorithm does not readily apply here due to the possible degeneracy of the Lloyd map $\mathbf{T}$ when some of the generating points either coincide or become arbitrarily close.

It is perhaps also interesting to note that the Lloyd algorithm may be viewed as an alternating variable algorithm for minimizing the energy functional, that is, in which one alternates between minimizing $\mathcal{H}(\mathbf{Y}, \mathbf{Z})$ with respect to $\mathbf{Y}$ and $\mathbf{Z}$. It is well known that there are examples of simple optimization problems with special objective functions for which such an alternating variable algorithm does not always converge. It is thus interesting to see whether the special features of the functional $\mathcal{H}$ can help us to establish the convergence of the Lloyd algorithm.

2.1. Existence of convergent subsequence. We now present some new convergence theorems concerning the Lloyd algorithm. It has been shown in [7] that if the density function is positive, except on a measure zero set, stationary points of the energy $\mathcal{H}$ are given by fixed points of the Lloyd map $\mathbf{T}$. The result below justifies that fixed points are attainable as a limit of Lloyd iterations.

THEOREM 2.3. *Any limit point $\mathbf{Z}$ of the Lloyd algorithm is a fixed point of the Lloyd map, and thus, $(\mathbf{Z}, \mathbf{Z})$ is a critical point of $\mathcal{H}$. Moreover, for an iteration started with a given initial guess, all elements in the set of its limit points share the same distortion value.*

Proof. The Lloyd algorithm produces a sequence $\{\mathbf{Z}_n\}$, which is bounded in $\bar{\Omega}^k$, and thus it has a convergent subsequence. Let $\mathbf{Z}$ be a limit point; then there exists a subsequence $\{\mathbf{Z}_{n_j}\}$ such that $\mathbf{Z}_{n_j} \to \mathbf{Z}$ as $n_j \to \infty$. Since the distortion values are monotonically decreasing, it follows that all limiting points must share the same distortion value.

Now, by properties of the iteration, $\mathcal{H}(\mathbf{Z}_n, \mathbf{Z}_n)$ is monotonically decreasing, so

$$\mathcal{H}\Big(\mathbf{Z}, \mathbf{Z}\Big) = \lim \mathcal{H}\Big(\mathbf{Z}_{n_j}, \mathbf{Z}_{n_j}\Big) = \inf \mathcal{H}\Big(\mathbf{Z}_n, \mathbf{Z}_n\Big) \, .$$

On the other hand, we know from Lemma 2.1 that

$$\mathcal{H}_1\Big(\mathbf{U}, \mathbf{Z}_n\Big) \mid_{\mathbf{U}=\mathbf{Z}_n} = 0 \, .$$

Here we use the notation $\mathcal{H}_1$ to denote the partial derivatives with respect to all the components of the first argument (gradient with respect to the first argument $\mathbf{U}$) and $\mathcal{H}_2$ (the gradient) with respect to the second argument.

By continuity, we get

$$\mathcal{H}_1\Big(\mathbf{Z}, \mathbf{Z}\Big) = 0 \, .$$

Now, if $\mathcal{H}_2(\mathbf{Z}, \mathbf{U}) \mid_{\mathbf{U}=\mathbf{Z}} = 0$, $(\mathbf{Z}, \mathbf{Z})$ is a critical point of $\mathcal{H}$ and we are done. Otherwise, there exists some $\mathbf{Y}$ such that

$$\mathcal{H}\Big(\mathbf{Z}, \mathbf{Y}\Big) < \mathcal{H}\Big(\mathbf{Z}, \mathbf{Z}\Big) \, .$$

Thus, for small enough δ, we have for large enough n_j that

$$\begin{aligned}
\mathcal{H}\Big(\mathbf{Z}_{n_j}, \mathbf{Y}\Big) &< \mathcal{H}\Big(\mathbf{Z}, \mathbf{Y}\Big) + \delta \\
&< \mathcal{H}\Big(\mathbf{Z}, \mathbf{Z}\Big) \\
&\leq \mathcal{H}\Big(\mathbf{Z}_{n_j+1}, \mathbf{Z}_{n_j+1}\Big) \\
&\leq \mathcal{H}\Big(\mathbf{Z}_{n_j}, \mathbf{Z}_{n_j+1}\Big) \, .
\end{aligned}$$

This contradicts the fact that

$$\mathcal{H}\Big(\mathbf{Z}_{n_j}, \mathbf{Z}_{n_j+1}\Big) = \min_{\mathbf{Y}} \mathcal{H}\Big(\mathbf{Z}_{n_j}, \mathbf{Y}\Big) \, .$$

Thus, the theorem is proved. □

The above theorem may be simply classified as a theorem for the global convergence of subsequences of the Lloyd algorithm. It leads to a more precise characterization of the algorithm and a hint on why it rarely fails, while also motivating the global convergence theorems for the whole sequence with some additional assumptions that we are going to present next.

2.2. Global convergence. As an immediate consequence of Theorem 2.3, we easily get the following result.

COROLLARY 2.4. *If the fixed point is unique, the Lloyd algorithm converges globally.*

The uniqueness of the fixed point has been established in some special cases in the literature. We will come back to this point later in the section. The uniqueness is obviously not a necessary condition, but we may in fact derive the following convergence theorem.

THEOREM 2.5. *If the set of fixed points with any particular distortion value is finite, the Lloyd algorithm converges globally.*

Proof. Convergence may fail only if the generated sequence possesses infinitely many jumps from a neighborhood of one fixed point to another. Suppose $\mathbf{U}$ and $\mathbf{V}$ are two fixed points with $||\mathbf{U} - \mathbf{V}|| = \delta > 0$. Denote the generated sequence of the Lloyd algorithm as $\mathbf{Z}_n$, i.e., $\mathbf{Z}_{n+1} = \mathbf{T}(\mathbf{Z}_n)$.

Suppose $\mathbf{Z}_{n_r} \to \mathbf{U}$ and $\mathbf{Z}_{n_l} \to \mathbf{V}$. Then for any $\delta > 0$, there exists $M > 0$ such that for all $n_r, n_l > M$ we have $||\mathbf{Z}_{n_r} - \mathbf{U}|| < \delta/3$ and $||\mathbf{Z}_{n_l} - \mathbf{V}|| < \delta/3$. The Lloyd map is continuous near the fixed points (see Proposition 3.5 in [7]), so M can be chosen to be suitably large to assure

$$||\mathbf{T}(\mathbf{Z}_{n_r}) - \mathbf{Z}_{n_r}|| < \delta/3.$$

Now suppose the sequence makes infinitely many jumps from subsequence $\{n_r\}$ to $\{n_l\}$; i.e., there are infinitely many μ, ν s.t. $n_{l_\mu} = n_{r_\nu} + 1$. Then $||\mathbf{T}(\mathbf{Z}_{n_{r_\nu}}) - \mathbf{V}|| = ||\mathbf{Z}_{n_{r_\nu}+1} - \mathbf{V}|| = ||\mathbf{Z}_{n_{l_\mu}} - \mathbf{V}||$. Hence

$$\delta = ||\mathbf{U} - \mathbf{V}|| \le ||\mathbf{U} - \mathbf{Z}_{n_{r_\nu}}|| + ||\mathbf{Z}_{n_{r_\nu}} - \mathbf{T}(\mathbf{Z}_{n_{r_\nu}})|| + ||\mathbf{T}(\mathbf{Z}_{n_{r_\nu}}) - \mathbf{V}|| < \delta.$$

We get a contradiction. □

To this end, we have proved the global convergence of the Lloyd method in case the set of fixed points, Γ, does not have an accumulation point. Note that there are situations where Γ contains accumulation points and all points in Γ share the same distortion value. For example, consider the CVTs formed with two generators in a unit disc centered at the origin for the constant density function. Simple calculation shows that the critical points fill a circle of radius $4/(3\pi)$. That is, due to the rotation symmetry, any pair of points in the opposite ends of such a circle determines a CVT, and all the critical points share the same energy values. Of course, cases like this are very rare, so this fact does not present any difficulties for the convergence of the Lloyd algorithm in most practical applications.

We now present another result which further substantiates the global convergence of Lloyd algorithm in general.

THEOREM 2.6. *If the iterations in the Lloyd algorithm stay in a compact set, where the Lloyd map* $\mathbf{T}$ *is continuous, then the algorithm is globally convergent to a critical point of* $\mathcal{H}$.

Proof. The proposition follows from the global convergence theorem (GCT), [37] and similar arguments have been presented in [42]. Indeed, the Lloyd algorithm can be regarded as a descent method with the descent function given by $\mathcal{H}(\cdot, \mathbf{T}(\cdot))$. Let $\{\mathbf{Z}_n\}_{n=1}^{\infty}$ be a sequence generated by $\mathbf{Z}_{n+1} = \mathbf{T}(\mathbf{Z}_n)$. All $\mathbf{Z}_n$'s are contained in a compact set. If Γ is the set of solutions, $\mathcal{H}(\mathbf{Y}, \mathbf{T}(\mathbf{Y})) < \mathcal{H}(\mathbf{Z}, \mathbf{T}(\mathbf{Z}))$ for all $\mathbf{Z} \notin \Gamma$, $\mathbf{Y} \in \mathbf{T}(\mathbf{Z})$ and $\mathcal{H}(\mathbf{Y}, \mathbf{T}(\mathbf{Y})) = \mathcal{H}(\mathbf{Z}, \mathbf{T}(\mathbf{Z}))$ for all $\mathbf{Z} \in \Gamma$, $\mathbf{Y} \in \mathbf{T}(\mathbf{Z})$. The continuity implies the closedness of $\mathbf{T}$ in a compact set. Applying the GCT, we get the convergence of the sequence $\mathbf{Z}_n$, and the limit $\mathbf{Z}$ is a fixed point of $\mathbf{T}$; thus, the algorithm converges to a critical point of $\mathcal{H}$. □

We note that the compactness of the iteration seems to be intuitively true but it has not been rigorously justified in the literature. The difficulty is related to showing that during the iteration, the generators of the Voronoi regions do not get arbitrarily close as the Lloyd map is not well defined at degenerating points, where some of the generators may coincide.

2.3. The compactness in the one-dimensional case. Here, we take $\Omega = [a, b]$, a compact interval, let ρ be smooth and positive, and assume that $0 < M_1 \le ||\rho||_{\infty,\Omega} \le M_2 < \infty$. Let $M_c = M_2/M_1$; obviously, $M_c \ge 1$. We verify that throughout the Lloyd algorithm, the Voronoi regions remain nondegenerate (i.e., the generating points remain distinct); thus, it will lead to the global convergence.

First, we have the following simple fact.

LEMMA 2.7. *Given an interval $V = [z_l, z_r] \in \Omega$, let z^* be the mass centroid of V with respect to the density function ρ. Then we have*

$$L(V) \le 2M_c \min(z^* - z_l,\ z_r - z^*), \tag{2.1}$$

where $L(V)$ denotes the length of V.

Proof. Without loss of generality, we suppose that $z^* - z_l \le z_r - z^*$. By the definition of mass centroid, we have

$$z^* - z_l = \frac{\displaystyle\int_{z_l}^{z_r} (x - z_l)\rho(x)\, dx}{\displaystyle\int_{z_l}^{z_r} \rho(x)\, dx} \ge \frac{M_1}{2M_2}(z_r - z_l),$$

so we get

$$z_r - z_l \le 2M_c(z^* - z_l).$$

With $z^* - z_l \le z_r - z^*$, we get the inequality (2.1). ∎

Denote by $\{z_i^{(n)}\}_{i=1}^k$ ($z_1^{(0)} < z_2^{(0)} < \cdots < z_k^{(0)}$, $n \ge 0$) the positions of the generators after n iterations in the Lloyd method and by $\{V_i^{(n)} = (y_{i-1}^{(n)}, y_i^{(n)})\}_{i=1}^k$ the corresponding Voronoi regions. Clearly, $y_0^{(n)} = a$ and $y_k^{(n)} = b$. We now present a nondegeneracy result.

LEMMA 2.8. *For any $1 < i < k$, we have*

$$L(V_i^{(n+1)}) < \min\left(\frac{L(V_i^{(n)}) + L(V_{i+1}^{(n)})}{2} + L(V_{i-1}^{(n+1)}),\ \frac{L(V_i^{(n)}) + L(V_{i-1}^{(n)})}{2} + L(V_{i+1}^{(n+1)})\right).$$

Proof. First we have

$$L(V_i^{(n+1)}) = \frac{z_{i+1}^{(n+1)} - z_i^{(n+1)}}{2} + \frac{z_i^{(n+1)} - z_{i-1}^{(n+1)}}{2}.$$

Since $z_i^{(n+1)} \in V_i^{(n)}$, $z_{i+1}^{(n+1)} \in V_{i+1}^{(n)}$, we know

$$\frac{z_{i+1}^{(n+1)} - z_i^{(n+1)}}{2} < \frac{L(V_i^{(n)}) + L(V_{i+1}^{(n)})}{2}.$$

With $L(V_{i-1}^{(n+1)}) > (z_i^{(n+1)} - z_{i-1}^{(n+1)})/2$, we get

$$L(V_i^{(n+1)}) < \frac{L(V_i^{(n)}) + L(V_{i+1}^{(n)})}{2} + L(V_{i-1}^{(n+1)}). \tag{2.2}$$

Similarly, we can prove that

$$L(V_i^{(n+1)}) < \frac{L(V_i^{(n)}) + L(V_{i-1}^{(n)})}{2} + L(V_{i+1}^{(n+1)}). \tag{2.3}$$

Combining (2.2) and (2.3), we complete the proof. ∎

This leads to the following uniform lower bound between the adjacent generators throughout the Lloyd algorithm.

PROPOSITION 2.9. *Let* $d_i^{(n)} = z_{i+1}^{(n)} - z_i^{(n)}$ *for* $i = 1, 2, \ldots, k-1$. *Then we have*

$$d_i^{(n)} > \frac{b-a}{k4^{2k-1}M_c^k}, \qquad n > k\,, \tag{2.4}$$

and consequently,

$$L(V_i^{(n)}) > \frac{b-a}{k4^{2k-1}M_c^k}, \quad 1 < i < k, \quad n > k\,, \tag{2.5}$$

and

$$L(V_i^{(n)}) > \frac{b-a}{2k4^{2k-1}M_c^k}, \quad i = 1 \text{ or } k, \quad n > k\,. \tag{2.6}$$

Proof. Let us consider any $d_i^{(n)}$ for $1 \le i \le k-1$ and $n > k$. Since $d_i^{(n)} = z_{i+1}^{(n)} - z_i^{(n)}$ and $y_i^{(n-1)} < z_{i+1}^{(n)}$, we have

$$y_i^{(n-1)} - z_i^{(n)} < d_i^{(n)}\,.$$

Then from Lemma 2.7, we have

$$L(V_i^{(n-1)}) < 2M_c d_i^{(n)}\,. \tag{2.7}$$

On the other hand, we know that $L(V_i^{(n-1)}) > (z_{i+1}^{(n-1)} - z_i^{(n-1)})/2$, which means

$$d_i^{(n-1)} < 2L(V_i^{(n-1)}) < 4M_c d_i^{(n)}\,.$$

Again by Lemma 2.7, we know that

$$L(V_{i-1}^{(n-2)}) < 8M_c^2 d_i^{(n)}\,.$$

Repeating this process, we have for $j = 1, \ldots, i$,

$$L(V_{i-j+1}^{(n-j)}) < 2^{2j-1}M_c^j d_i^{(n)}\,.$$

Now let us consider $j = i$. Clearly, $V_1^{(n-i)} = (a, y_1^{(n-i)})$, and we have

$$\begin{aligned} L(V_1^{(n-i+1)}) &< L(V_1^{(n-i)}) + L(V_2^{(n-i+1)}) \\ &< 2^{2i-1}M_c^i d_i^{(n)} + 2^{2i-3}M_c^{i-1} d_i^{(n)} \\ &< 4^i M_c^i d_i^{(n)}\,. \end{aligned}$$

Furthermore, by Lemma 2.8, we get

$$\begin{aligned} L(V_2^{(n-i+2)}) &< \frac{L(V_2^{(n-i+1)}) + L(V_1^{(n-i+1)})}{2} + L(V_3^{(n-i+2)}) \\ &< \frac{2^{2i-3}M_c^{i-1}d_i^{(n)} + 4^i M_c^i d_i^{(n)}}{2} + 2^{2i-5}M_c^{i-2}d_i^{(n)} \\ &< 4^i M_c^i d_i^{(n)}\,. \end{aligned}$$

Repeating this process, we have for $j = 1, \ldots, i-1$,

$$L(V_j^{(n-i+j)}) < 4^i M_c^i d_i^{(n)},$$

which means

$$L(V_{i-1}^{(n-1)}) < 4^i M_c^i d_i^{(n)} .$$

Using the same trick again and again, we finally arrive at

$$L(V_{i-j}^{(n-1)}) < 4^{i+j-1} M_c^i d_i^{(n)}, \qquad j = 1, \ldots, i-1.$$

Combining (2.7) and the above equation with $i, j \le k$, we get

$$L(V_j^{(n-1)}) < 4^{2k-1} M_c^k d_i^{(n)}, \qquad j = 1, \ldots, i\,. \tag{2.8}$$

By symmetry, we also have

$$L(V_j^{(n-1)}) < 4^{2k-1} M_c^k d_i^{(n)}, \qquad j = i+1, \ldots, k\,.$$

Then, we get

$$b - a = L(\Omega) = \sum_{j=1}^{k} L(V_j^{(n-1)}) < k 4^{2k-1} M_c^k d_i^{(n)},$$

which implies (2.4), (2.5), and (2.6). ∎

We then have the following theorem.

THEOREM 2.10. *For any positive and smooth density function in one dimension and a given set of k distinct generators as a starting point, the Lloyd map is continuous at any of the iteration points.*

Proof. In order to show the continuity it is enough to justify the fact that Voronoi cells do not collapse. Indeed, after a sufficient number of steps, the latter is the direct consequence of Proposition 2.9. For the initial finite number of iterations, the continuity is obvious. ∎

Finally, using Theorems 2.6 and 2.10, we get Theorem 2.11.

THEOREM 2.11. *The Lloyd algorithm is globally convergent in one dimension for any positive and smooth density function.*

Proof. Using the result of Theorem 2.10, we see that we can define a compact set (away from the degenerating points) such that for any initial condition, the Lloyd iteration (the images of the Lloyd maps) will stay in such a compact set after sufficiently many steps. Thus, we may apply Theorem 2.6 to deduce the convergence of the algorithm. ∎

The above theorem provides an affirmative answer to the question of global convergence of the Lloyd algorithm for the one-dimensional interval case without any restrictive assumptions on the density functions. It remains an open problem to verify the same conclusion in the multidimensional case.

2.4. The logarithmic concave density for the one-dimensional case. Beyond the study on the global convergence, the characterization of the convergence rate is often also important in practice. For instance, one may inquire if a geometric convergence rate can be established. This is indeed verified in [7] for the constant

density function corresponding to the unit interval $[0, 1]$, where, via the spectral analysis of $\mathbf{dT}$ at the minimizer, the established geometric convergence rate r is shown to satisfy

$$\sin^2\left(\frac{\pi}{2(k+1)}\right) \le r \le \sin^2\left(\frac{\pi}{2(k-1)}\right), \tag{2.9}$$

so that asymptotically for large k (the total number of generators) the convergence rate is on the order of $1 - \pi^2/(4k^2)$, as verified by the numerical experiments in the next section.

In general, finding the convergence rate exactly is not possible, but estimates may be obtained from the analytical bounds of the $\|\mathbf{dT}\|$.

First, it follows from Theorem 2.10 that $\mathbf{T} : \Omega^k \to \Omega^k$ is a continuously differentiable mapping away from the degenerate points, where the generating points collapse. If this mapping $\mathbf{T}$ is a contraction, i.e., $||\mathbf{dT}|| < 1$ at all nondegenerate points, the contraction mapping theorem can be used to get a good estimate of the local convergence rate for the corresponding fixed point iteration, which in our case is the Lloyd algorithm. Moreover, the contraction mapping properties also imply that $\mathbf{T}$ has a unique fixed point $\mathbf{z}^*$ in the set of nondegenerate points upon a consistent ordering. Indeed, if there existed two fixed points $\mathbf{x} = \{x_i\}_{i=1}^k$ and $\mathbf{y} = \{y_i\}_{i=1}^k$, with components corresponding to generating points whose coordinates are ordered from small to large, that is, $x_i < x_{i+1}$ and $y_i < y_{i+1}$ for all indices i, then any point along the line segment $(1-t)\mathbf{x} + t\mathbf{y}$ would remain nondegenerate and thus, by uniform continuity, we may assume that

$$\sup_{0\le t\le 1} ||\mathbf{dT}(\mathbf{x} + t(\mathbf{y} - \mathbf{x}))|| \le \alpha(\mathbf{x}, \mathbf{y}) < 1$$

for some constant $\alpha(\mathbf{x}, \mathbf{y})$ independent of t. From the multidimensional form of the mean value theorem, we then get

$$||\mathbf{x} - \mathbf{y}|| = ||\mathbf{Tx} - \mathbf{Ty}|| \le \sup_{0\le t\le 1} ||\mathbf{dT}(\mathbf{x} + t(\mathbf{y} - \mathbf{x}))||\, ||\mathbf{x} - \mathbf{y}|| \le \alpha ||\mathbf{x} - \mathbf{y}||,$$

which is possible only if $\mathbf{x} = \mathbf{y}$; thus, we have the uniqueness. We refer to [32] for similar discussions.

The concept of logarithmic concavity has played an important role in the classification of one-dimensional density functions since it is a class of density functions for which the Lloyd maps can be shown to be contractions [7].

Let us take a closer look at the structure of the Jacobian $\mathbf{dT}$. By the notation of the previous section, for the one-dimensional case (i.e., $\Omega = [a, b]$), we have

$$\frac{\partial T_i}{\partial z_i} = \frac{\partial T_i}{\partial z_{i-1}} + \frac{\partial T_i}{\partial z_{i+1}},$$

$$\frac{\partial T_i}{\partial z_{i-1}} = \frac{\rho(z_i^-)(T_i - z_i^-)}{2R_i}, \qquad \text{and} \qquad \frac{\partial T_i}{\partial z_{i+1}} = \frac{\rho(z_i^+)(z_i^+ - T_i)}{2R_i}, \tag{2.10}$$

where $R_i = \int_{V_i} \rho(y)dy$ and $V_i = [z_i^-, z_i^+]$.

The following useful relation may be found in [7, 24]:

$$R_i^2\left(1 - \sum_j \frac{\partial T_i}{\partial z_j}\right) = \frac{1}{2}\int_{V_i}\int_{V_i} \rho(t)\rho(s)\left(\frac{\rho'(s)}{\rho(s)} - \frac{\rho'(t)}{\rho(t)}\right)(t-s)dt\, ds \tag{2.11}$$

at a fixed point $\mathbf{z} = \mathbf{T}(\mathbf{z})$.

Based on this, it can be shown that for the class of logarithmically concave functions (i.e., $(\log\rho)'' < 0$), the spectral radius of the Jacobi map is less than 1 in the neighborhood of a fixed point. In fact, it is easy to show that the same estimate holds for all points as the identity (2.11) remains universally true. Hence the fixed point of the Lloyd map is unique when the generators are ordered in an increasing manner. The following convergence of the Lloyd algorithm for the logarithmically concave case is easily one of the most popular results studied in the literature.

PROPOSITION 2.12. *In one dimension, in case of logarithmically concave density, the Lloyd algorithm converges globally to the unique fixed point.*

The class of logarithmically concave functions covers many densities used in practice, for instance, linear densities and normal distributions. Notice that the result quoted in Proposition 2.12 does not provide the estimate of the actual distance of the spectral radius from 1. We now focus on getting estimates on $\theta = 1 - ||\mathbf{dT}||$ more accurately. For this, we use a more precise measure of the logarithmic concavity for the density, that is, we assume that

$$\rho(t)\rho(s)\left(\frac{\rho'(s)}{\rho(s)} - \frac{\rho'(t)}{\rho(t)}\right)(t-s) \geq c_0^2(t-s)^2 \tag{2.12}$$

for some constant $c_0 > 0$ and any (t, s) except for a set of measure zero. Upon availability of an estimate of this type, the following conclusion can be reached:

$$1 - ||\mathbf{dT}|| \geq c_0^2 \min_i \left\{ R_i^{-2} \int_{V_i}\int_{V_i} (t-s)^2 dtds \right\} \sim \frac{c_0^2}{12} \min\left\{ \frac{h_i^2}{\rho(\zeta_i)^2} \right\}$$

for some $\zeta_i \in V_i$ and $h_i = z_i^+ - z_i^-$. Let $h = \min_i h_i$, the smallest Voronoi cell size, and $M = \sup_{x\in[0,1]} \rho(x)$; then we can rewrite the above result as follows.

LEMMA 2.13. *For any smooth density ρ satisfying (2.12) on the unit interval, the Lloyd algorithm is globally convergent with a geometric convergence rate no larger than*

$$||\mathbf{dT}|| \leq 1 - \frac{c_0^2}{12}\frac{h^2}{M^2}\ . \tag{2.13}$$

The convergence estimate obtained here essentially depends on characteristics c_0 and the relative size of a Voronoi cell in comparison with the density distribution. Since the minimizer of the energy gives a nondegenerate Voronoi diagram (Proposition 3.5 in [7]), there is a positive lower bound for the distance h in the neighborhood of the solution in terms of the density and the number of generators. Moreover, for large k, due to the asymptotic equipartition of energy property in one dimension [7], after sufficiently many iterations, one can roughly estimate each cell size as

$$h_i \sim k^{-1}\rho(\zeta_i)^{-1/3}\int_0^1 \rho^{1/3}(x)dx\ .$$

Thus, we have effectively $\theta = 1 - ||\mathbf{dT}|| \geq \left(\frac{c_1}{k}\right)^2$, where for large k,

$$c_1 \sim \frac{c_0}{\sqrt{12}M^{4/3}}\int_0^1 \rho^{1/3}(x)dx\ . \tag{2.14}$$

The estimate (2.14) in general tends to be rather pessimistic; for instance, for a linear perturbation of the constant density $\rho(x) = 1 - \epsilon x$ for a small ϵ, we have $c_1 \sim \frac{3}{4\sqrt{12}}(1-(1-\epsilon)^{4/3})$, which is significantly different from $\pi/2$ in the limit as $\epsilon \to 0$ (for the constant density case, c_1 can be estimated more accurately from the estimate (2.9) as $\pi/2$). This is due to the fact that the class of constant densities shares zero value of the parameter c_0. Nevertheless, it allows us to reach the conclusion that the geometric convergence rate for all densities satisfying (2.12) is comparable with that of the constant density in the sense that θ remains of the order k^{-2} for large values of k.

We expect that such a conclusion holds for even more general density functions, but the rigorous analysis is still not available.

3. Extensions to constrained CVTs. We now briefly illustrate how much of our earlier analysis can be extended to more general settings, where the concept of CVTs can be defined. The example to be used is of constrained CVTs on general surfaces as defined in [12].

Consider a compact and smooth surface $\mathbf{S} \subset \mathbb{R}^N$. Similar to the definition of conventional CVTs, for a given set of points $\{\mathbf{z}_i\}_{i=1}^k \in \mathbf{S}$, one may define their corresponding Voronoi regions on $\mathbf{S}$ by

$$V_i = \{\, \mathbf{x} \in \mathbf{S} \;:\; |\mathbf{x}-\mathbf{z}_i| < |\mathbf{x}-\mathbf{z}_j| \quad \text{for } j = 1,\dots,k,\ j \neq i \,\}. \tag{3.1}$$

For a density function ρ defined on the surface $\mathbf{S}$ and positive almost everywhere, one may encounter a problem with the original definition when one defines centroidal Voronoi tessellations $\{(\mathbf{z}_i, V_i)\}_{i=1}^k$ of $\mathbf{S}$: the mass centroids $\{\mathbf{z}_i^*\}_{i=1}^k$ of $\{V_i\}_{i=1}^k$ as defined by (1.1) do not in general belong to $\mathbf{S}$. For example, the mass centroid of any region on the surface of a sphere is always located in the interior of the sphere. Therefore, a generalized definition of a mass centroid on surfaces is needed. For each Voronoi region $V_i \subset \mathbf{S}$, we call $\mathbf{z}_i^c$ the *constrained mass centroid* of V_i on $\mathbf{S}$ if $\mathbf{z}_i^c$ is a solution of the following problem:

$$\min_{\mathbf{z}\in\mathbf{S}} F_i(\mathbf{z})\,, \qquad \text{where} \qquad F_i(\mathbf{z}) = \int_{V_i} \rho(\mathbf{x})|\mathbf{x}-\mathbf{z}|^2\,d\mathbf{x}\,. \tag{3.2}$$

The integral over $\{V_i\}$ is understood as a standard surface integration on $\mathbf{S}$. Note that the constrained mass centroid coincides with the conventional mass center if $\mathbf{S}$ is replaced by $\mathbb{R}^N$ and V_i is a convex subset of $\mathbb{R}^N$. Clearly, for each $i = 1,\dots,k$, $F_i(\cdot)$ is convex. Since $\mathbf{S}$ is compact and $\rho(\cdot)$ is continuous almost everywhere, there exists a constant C such that for any $\mathbf{z}_1, \mathbf{z}_2 \in \mathbf{S}$, we have

$$|F_i(\mathbf{z}_1) - F_i(\mathbf{z}_2)| = \left| \int_{V_i} \rho(\mathbf{x})(|\mathbf{x}-\mathbf{z}_1|^2 - |\mathbf{x}-\mathbf{z}_2|^2)\,d\mathbf{x} \right| \le C|\mathbf{z}_1 - \mathbf{z}_2|\,.$$

Thus, F_i is continuous and compact, and consequently we have the existence of solutions of (3.2), although the solution may not be unique.

We call the tessellation defined by (3.1) a *constrained centroidal Voronoi tessellation* (CCVT) if and only if the points $\{\mathbf{z}_i\}_{i=1}^k$ which serve as the generators associated with the Voronoi regions $\{V_i\}_{i=1}^k$ are the constrained mass centroids of those regions [12]. This definition of CCVT conforms with that of CVT for general spaces and clearly the energy $\mathcal{H}$ defined in (3.2) for CVTs is still valid for CCVTs. In Figure 1, we give two examples of CCVTs, one with six generators constrained to a circle

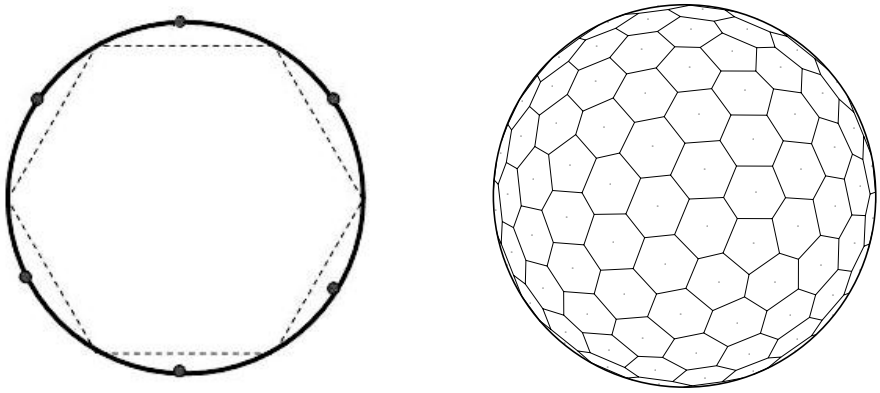

FIG. 1. *Examples of CCVTs for a circle (dots are for generators and dashes show the partition of the constrained Voronoi regions) and for a sphere (dots are generators and lines are planar projections of Voronoi edges). Only portion in one hemisphere is shown.*

(one-dimensional curve) and the other with 162 generators constrained to a sphere (two-dimensional surface). Both correspond to the constant density.

The following generalized Lloyd algorithm for computing CCVTs was proposed in [12].

ALGORITHM 3.1 (Lloyd algorithm for computing CCVTs).

Input:

$\mathbf{S}$, *the surface of interest;* ρ, *a density function defined on* $\mathbf{S}$*;*
k, *number of generators;* $\{\mathbf{z}_i\}_{i=1}^k$, *the initial set of generators.*

Output:

$\{V_i\}_{i=1}^k$, *a CCVT with* k *generators* $\{\mathbf{z}_i\}_{i=1}^k$ *in* $\mathbf{S}$.

Iteration:

1. *Construct the Voronoi tessellation* $\{V_i\}_{i=1}^k$ *of* $\mathbf{S}$ *with generators* $\{\mathbf{z}_i\}_{i=1}^k$.
2. *Take the constrained mass centroids of* $\{V_i\}_{i=1}^k$ *as the new set of generators* $\{\mathbf{z}_i\}_{i=1}^k$.
3. *Repeat the procedures* 1 *and* 2 *until some stopping criterion is met.*

It is clear that Algorithm 3.1 is almost identical to Algorithm 1.1 except the constrained mass centroids are used instead of standard mass centroids in step 2 of each iteration. So Algorithm 3.1 again can be regarded as a fixed point iteration of $\mathbf{T}$, the Lloyd map for CCVTs which now is defined to map the current generators to the constrained mass centroids of the corresponding Voronoi regions. It is transparent that the analysis done in sections 2.1 and 2.2 can be applied here, so we obtain the following general results similar to Theorems 2.3 and 2.5.

THEOREM 3.1. *Any limit point* $\mathbf{Z}$ *of the Lloyd algorithm for computing CCVTs is a fixed point of the Lloyd map for CCVTs, and thus,* $(\mathbf{Z}, \mathbf{Z})$ *is a stationary point of* $\mathcal{H}$*. Moreover, for an iteration started with a given initial guess, all elements in the set of its limit points share the same distortion value. Furthermore, if the set of fixed points with the same distortion value is finite, the Lloyd iteration for CCVTs converges globally.*

Now suppose that $\mathbf{S}$ is a smooth curve without self-intersection such as $\mathbf{S} = f(\Omega)$, where $\Omega = [a, b]$ for some smooth function f; then using the analysis similar to that provided in section 2.3, we obtain the following result.

THEOREM 3.2. *The Lloyd algorithm for computing CCVTs of* $\mathbf{S}$ *is globally convergent for any positive and smooth density function when* $\mathbf{S}$ *is a bounded smooth curve.*

Note that, unlike the one-dimensional conventional CVT in $\mathbb{R}^1$, we have not given any general estimate here on the convergence rate of the Lloyd algorithm for CCVTs. Even for the case where $\mathbf{S}$ is a bounded smooth curve, the geometric convergence rate has not been carefully derived, though the notion of contraction for the Lloyd map has been studied for density functions which share similar logarithmic concave properties with respect to the angular variable in the case of a perfect disc [12]. There are also natural generalizations of the Lloyd algorithm to the anisotropic CVTs as defined in [16] and also [18]. The details are omitted here.

4. Numerical examples. To further substantiate some of our earlier analysis, we now present a few numerical examples. All examples given below correspond to the Lloyd iteration on the interval $[0, 1]$.

4.1. Constant density. In Figure 2, we show a log-log plot of both the numerical estimates and the analytical estimate $1 - ||\mathbf{dT}|| \sim \pi^2/(4k^2)$ with respect to the constant density for various values of k, the number of generating points. The two estimates match very well and the results verify that the analytical estimates are very sharp.

4.2. Nonconstant density. Consider the case of $\rho(x) = e^{-x^2}$. Figure 3 compares the analytical estimate with the computed norms of the Jacobian for different system sizes. Here, the analytical estimate is based on $c_1^2 k^{-2}$ with the constant c_1 estimated by (2.14) with $c_0 = \sqrt{2/e}$, $M = 1$, and $\int_0^1 \rho^{1/3}(x)dx = \sqrt{3\pi} \cdot \mathrm{Erf}(1/\sqrt{3})/2$, which leads to $c_1 = \sqrt{\pi} \cdot \mathrm{Erf}(1/\sqrt{3})/2e \sim 0.19$. The plot is again given in log-log scale, and we see that although we underestimated the exact value of c_1, the slope was equal to -2 for both estimates, which indicates good agreement of the asymptotic rates on the order of $1 - O(1/k^2)$.

Figure 4 gives a similar comparison for $\rho(x) = 1 + x^4 \cos(\pi x)$. The numerical data in this case were compared to the asymptotic rate of $1 - \pi^2/4k^2$.

Figures 5–7 provide some insight into the dependence of the actual convergence factor on the number of generators and on the density function. The convergence factor in the plot is defined as the ratio of the 2-norm defects between two consecutive iterations after sufficiently many steps. A density function of the form $\rho(x) = 1 + \epsilon \cos^2(\pi x)$ is chosen. In Figure 5, we fix the number of generators to be $k = 16$, while letting ϵ vary in the range $[10^{-10}, 10^{10}]$. It is seen that the actual convergence factor and the theoretical estimate given by $||\mathbf{dT}||$ agree well in general.

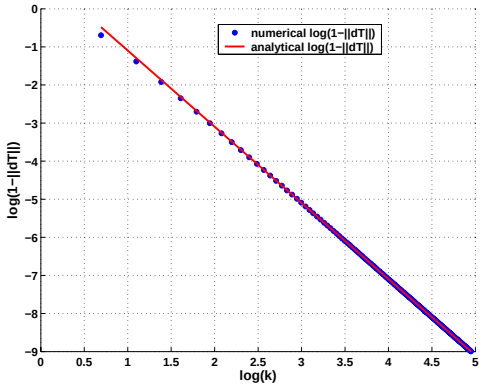

FIG. 2. *Convergence of Lloyd method for constant density.*

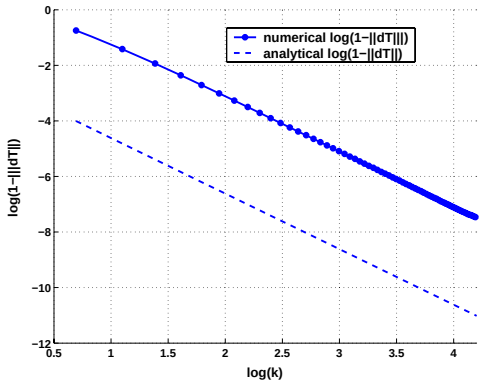

FIG. 3. *Convergence factor of Lloyd method for* $\rho(x) = e^{-x^2}$.

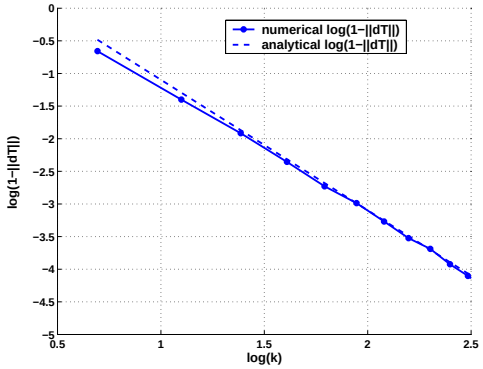

FIG. 4. *Convergence factor of Lloyd method for* $\rho(x) = 1 + x^4 \cos(\pi x)$.

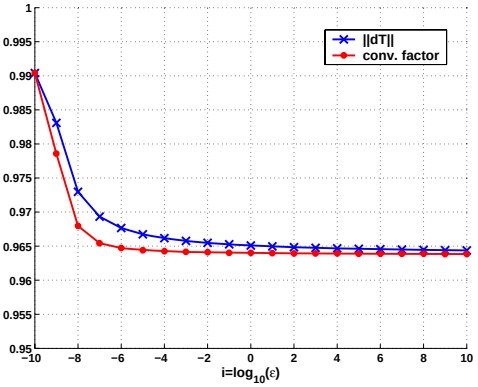

FIG. 5. *Convergence factor for* $k = 16$ *and* $\rho(x) = 1 + \epsilon \cos^2(\pi x)$ *with* $\epsilon = 10^{-10} : 10^{10}$.

To see the effect of the increasing k, in Figure 6 we fix ϵ and let the number of generators vary. The two estimates again compare well with each other.

To see more clearly the dependence of convergence rates on k, we again plot the data in a log-log scale for the density $\rho(x) = 1 + 10^3 \cos^2(\pi x)$ against the number of generators. The slope value of -2 is very evident from Figure 7, which is consistent with our earlier analysis.

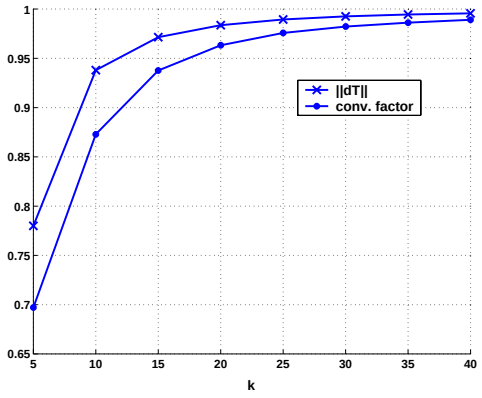

FIG. 6. *Convergence factor for* $\rho(x) = 1 + 10^3 \cos^2(\pi x)$ *and* $k = 2 : 40$.

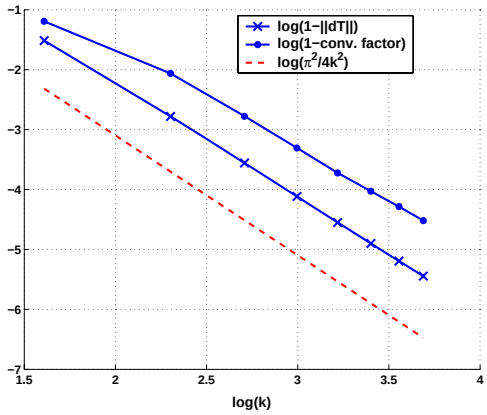

FIG. 7. *Asymptotic behavior of the convergence factor for* $\rho(x) = 1 + 10^3 \cos^2(\pi x)$.

5. Conclusions. In many practical applications of the centroidal Voronoi tessellations, it is very important to find their reliable and efficient constructions. Lloyd algorithm has been one of the most widely used techniques for such purposes. In this paper, a systematic study of both the local and the global convergence properties of the Lloyd algorithm is presented. We established several new convergence theorems, made further characterizations on the properties of the iteration, and performed relevant numerical experiments. We also extended our discussion to more general settings such as the construction of the CCVTs on a manifold. Still, one important open problem remains, that is, the global convergence of the Lloyd algorithm in any dimensions for any smooth density. The nondegeneracy of the Lloyd map should be true in this general case, but its proof has not been produced rigorously except for the one-dimensional case discussed here. We hope that our present study generates some interest along this direction, as there are certainly many issues to be considered further—in particular, the improvement of the Lloyd method for large number of generators. Even in the one-dimensional case, both our theoretical estimates and the experiments indicate the possible slow convergence rates. Recently, we have worked on making improvements in two directions: one is to explore the coupling with Newton-like methods, and another is to introduce the ideas of multilevel schemes [5, 6, 20]. As previously studied in [30], one may also consider parallel implementation issues for

these approaches. In conclusion, there are still many interesting problems associated with the construction of CVTs that can be investigated in the future.

PROJECTION MULTILEVEL METHODS FOR QUASILINEAR ELLIPTIC PARTIAL DIFFERENTIAL EQUATIONS: NUMERICAL RESULTS*

THOMAS A. MANTEUFFEL†, STEPHEN F. MCCORMICK†, OLIVER RÖHRLE‡, AND JOHN RUGE†

Abstract. The goal of this paper is to introduce a new multilevel solver for two-dimensional elliptic systems of nonlinear partial differential equations (PDEs), where the nonlinearity is of the type $u\partial v$. The incompressible Navier–Stokes equations are an important representative of this class and are the target of this study. Using a first-order system least-squares (FOSLS) approach and introducing a new variable for ∂v, for this class of PDEs we obtain a formulation in which the nonlinearity appears as a product of two different dependent variables. The result is a system that is linear within each variable but nonlinear in the cross terms. In this paper, we introduce a new multilevel method that treats the nonlinearities directly. This approach is based on a projection multilevel (PML) method [S. F. McCormick, *Multilevel Projection Methods for Partial Differential Equations*, SIAM, Philadelphia, 1992] applied to the FOSLS functional. The implementation of the discretization process, relaxation, coarse-grid correction, and cycling strategies is discussed, and optimal performance is established numerically. A companion paper [T. A. Manteuffel, S. F. McCormick, and O. Röhrle, *SIAM J. Numer. Anal.*, 44 (2006), pp. 139–152] establishes a two-level convergence proof for this new multilevel method.

1. Introduction.

The goal of nonlinear solution techniques is to solve the discretized nonlinear PDEs efficiently and accurately. Many popular, efficient methods for this purpose are based on multilevel strategies and all require a linearization process somewhere in the algorithm. These methods can be grouped into two broad categories, depending on when and how they apply the linearization step: global linearization such as Newton-type methods (cf. [14, 26]) and local linearization such as Brandt's FAS (full approximation scheme; cf. [6]) or Hackbusch's similar NMGM scheme (nonlinear multigrid method; cf. [17]).

Global linearization methods usually involve the solution of large linear systems of equations. Since substantial multigrid research is directed on developing robust, fast, and efficient linear solvers, there is an extensive repertoire of algorithms and knowledge to draw upon in this category of techniques. On the other hand, it is well known that the basin of attraction for efficient global linearization methods can be relatively small. Some of these problems might be handled by a full multigrid or nested iteration process that uses coarse-level processing to provide fine-level initial guesses. But problems with very small basins of attraction might need more expensive global

search methods. Local linearization methods tend to have a bigger basin of attraction, but often rely on rediscretizing each of the coarser levels separately. This might result in some loss of robustness since, for some problems with strong nonlinearities, the discretization on coarse levels might not accurately reflect the fine-level properties.

Although most research for nonlinear multilevel methods certainly focuses on these two main categories, there also exist other nonlinear solution techniques. For example, Dardyk and Yavneh [13] propose a nonlinear multigrid method that combines global and local linearization. Apparently, it is "at least as good as the more suitable of these two approaches, and often better than both" [13].

This paper introduces a new multilevel method that does not fit into either of these two categories, since we do not appeal to a linearization process anywhere in the algorithm. To achieve this direct approach, we focus on PDEs with nonlinear terms of type $u\partial v$, especially the incompressible Navier–Stokes equations, that we reformulate as a least-squares problem. Least-squares methods are based on a minimization principle for a functional constructed by taking the residual of the governing equations in some Hilbert norm. The intent is to ensure that the minimizer is the solution of the original set of equations and that the formulation is well posed. We should emphasize that our ability to avoid linearization is due to the nature of the functional that we construct. In particular, linearization is not needed in relaxation because the system to which the least-squares principle is applied is linear in its individual unknowns. Application of our solver methodology to other nonquadratic functionals is likely to require linearization in relaxation and coarse-level correction.

Least-squares methods for the Navier–Stokes equations have been addressed, for example, by Bochev and Gunzburger [4], Jiang [19], and Bochev et al. [1, 2]. In this paper, we consider a first-order system least-squares (FOSLS) method, where the functional is constructed by taking the L^2-norm of each interior first-order equation.

Instead of using FAS, Newton, or Newton-like methods to solve the resulting algebraic equations, we want to develop a new multigrid algorithm that can treat the nonlinearity directly and, thus, potentially more effectively. To this end, we consider a *projection multilevel* (*PML*) *method* cf. [24]) that solves an optimization problem by correcting a current approximation using projections onto various subspaces. In the context of FOSLS, the solution to a PDE is the minimizer of the FOSLS functional. So, naturally, we choose the minimization of the FOSLS functional as the optimization problem for our projection method. The minimization is done by corrections from certain finite element subspaces by way of the natural embedding of these spaces into the fine-grid space. The projection of the error that this defines is orthogonal with respect to the inner product associated with the functional, because it is defined as the approximation to the error from the given subspace that is best in the sense of minimizing the functional.

The algorithm developed here is new in that it is constructed with a special discretization approach that achieves optimal complexity. However, the underlying multilevel projection methodology has its origin in the so-called unigrid method introduced in [25], the indefinite-system framework presented in [16], and the Rayleigh–Ritz PML method formalized in [24]. The basic idea is to minimize the objective functional on subspaces that include the relaxation directions from all levels used in the multigrid process. As such, this methodology has been used by Mandel and McCormick for eigenvalue problems (cf. [22]); by Gelman and Mandel for constraint optimization problems (cf. [15]); by McCormick for parameter estimation, transport equations, general eigenvalue problems, Riccati equations, finite volume element methods, and image reconstruction (cf. [24]); by Tai and Xu for general convex optimization prob-

lems (cf. [30]); and by Tai for variational inequalities (cf. [29]). In fact, under certain circumstances, these methods relate to specific forms of classical multilevel methods. Consider, for example, the standard fully variational multigrid method applied to the Poisson problem in two dimensions, as given in [28], with Gauss–Seidel as the smoother, full coarsening, bilinear interpolation, and a nine-point stencil. This classical algorithm could also be classified as a PML method. It can be interpreted, at each stage, as a Rayleigh–Ritz method applied to minimizing the energy functional, where the optimization is taken as a correction over the continuous space projected onto certain subspaces of the fine-grid finite element space. This exemplifies that there exist, under certain circumstances, similarities and relations between a standard multigrid method and a PML method. In fact, PML exhibits the same basic principles as any other multilevel algorithm. Such principles include appropriate discretizations for the fine-grid problem, relaxation, coarsening, coarse-grid solves, interpolation, and cycling strategies.

The challenge in developing such a scheme is to ensure that the cost of processing coarse levels is less expensive in total than that of the fine grid. The major task in addressing this challenge is to cast the coarse subspace projection in terms of coarse-level computation. This ability we call coarse-grid realizability. We show below how this is done for our scheme applied to the Navier–Stokes equations.

To illustrate the basic ideas and principles of this new PML method, we introduce in section 2 a projection-based discretization process. Based on this process, we derive in section 3 an abstract framework for PML. In section 4, we discuss how coarse-grid realizability can be done efficiently for quasi-linear PDEs, for which the highest-order terms are linear. Additionally, we show that this is also feasible for different relaxation types and higher-order discretizations. We conclude this paper by giving numerical results (section 5) for model problems in two dimensions and making a few general remarks. While the numerical results in section 5 show optimal convergence properties, we provide in the companion paper [23] a two-level convergence proof.

2. Embedding operators and discretization by projection. As for any numerical scheme that discretely approximates continuous problems, the discretization process plays an important role. This process is even more important for multilevel schemes since they use a sequence of coarse-grid discretizations that must in some sense be compatible with the fine-grid discretization. For our particular PML method, we want to exploit a natural discretization process by using the same approach on all levels. Even though this seems to be the most natural and straightforward way to obtain discretizations for all levels, there exist other methodologies for which it is more advantageous to use a variational type of discretization process instead. Algebraic multigrid (AMG) is just one example. On coarser levels, AMG applied to a discretized PDE obtains matrices that often differ from what one would obtain using a discretization process analogous to that used on the finest level. For further details on AMG, see [7, 9, 27].

One way to relate a continuous PDE to a discrete problem is to think of the discretization process as a projection from an infinite-dimensional space onto a discrete one, with some nodal or finite element representation. (Here we restrict ourselves to a finite element representation.) To illustrate this process, consider a partial differential operator, $\mathcal{L}$, which maps between two infinite-dimensional spaces, $\boldsymbol{\mathcal{V}}$ and $\boldsymbol{\mathcal{V}}_{\mathcal{L}}$ ($\mathcal{L} : \boldsymbol{\mathcal{V}} \rightarrow \boldsymbol{\mathcal{V}}_{\mathcal{L}}$). For a specific $\mathbf{g} \in \boldsymbol{\mathcal{V}}_{\mathcal{L}}$ and domain Ω, we formally obtain a PDE, which we denote by

$$\mathcal{L}(\mathbf{x}) = \mathbf{g} \qquad \text{in } \Omega. \tag{2.1}$$

For equation (2.1) to be properly defined, it may need to be taken in the weak sense, but this would complicate the discussion. We use the strong form here for simplicity. Note the use of boldface type for unknown $\mathbf{x}$ and source term $\mathbf{g}$. We do this to allow for different types of principal variables, such as pressure, temperature, and velocity. When we want to emphasize this possibility, we write these variables in component form, such as $\mathbf{x} = (\mathrm{x}_1, \ldots, \mathrm{x}_v)^t$.

Now let $\mathcal{S}^h$ be a finite-dimensional subset of $\boldsymbol{\mathcal{V}}$ (e.g., a standard finite element space associated with an approximate mesh size, h). Then denote the natural embedding operator by $\mathcal{P}^h : \mathcal{S}^h \hookrightarrow \boldsymbol{\mathcal{V}}$. This operator leads to a natural discretization of our functional minimization problem as follows. Consider the least-squares functional associated with (2.1):

$$\mathcal{F}(\mathbf{x};\mathbf{g}) = \|\mathcal{L}(\mathbf{x}) - \mathbf{g}\|_{0,\Omega}^2 \qquad \forall \mathbf{x} \in \boldsymbol{\mathcal{V}}. \tag{2.2}$$

Note that $\mathcal{F}(\,\cdot\,;\mathbf{g})$ is a mapping from $\boldsymbol{\mathcal{V}}$ to $\mathbb{R}$. A discrete functional is obtained by defining $\mathcal{F}^h(\mathbf{x}^h;\mathbf{g}) := \mathcal{F}(\mathcal{P}^h\mathbf{x}^h;\mathbf{g})$, with $\mathbf{x}^h \in \mathcal{S}^h$ and $\mathcal{P}^h\mathbf{x}^h \in \boldsymbol{\mathcal{V}}$. Discretization is thus simply a matter of restricting the functional to the discrete space. This is the essence of Rayleigh–Ritz. Note that since $\mathcal{F}^h(\,\cdot\,;\mathbf{g})$ is a mapping from $\mathcal{S}^h$ to $\mathbb{R}$, notations $\mathcal{F}(\mathbf{x}^h;\mathbf{g})$ and $\mathcal{F}^h(\mathbf{x}^h;\mathbf{g})$ are equivalent. From now on, we refer to $\mathcal{F}(\mathbf{x}^h;\mathbf{g})$ as the discrete functional.

The abstract discretization process depends only on the choice of the embedding operator, $\mathcal{P}^h$, and the associated finite element space, $\mathcal{S}^h$. Hence, for coarser levels, we can define the discrete functional in the same way. Let $\mathcal{S}^{2h}$ be a finite-dimensional space (associated with an approximate mesh size, $2h$) and let $\mathcal{P}^{2h} : \mathcal{S}^{2h} \hookrightarrow \boldsymbol{\mathcal{V}}$ be the natural embedding from $\mathcal{S}^{2h}$ into $\boldsymbol{\mathcal{V}}$. Then the coarse-grid discretization of functional (2.2) is given by $\mathcal{F}(\mathbf{x}^{2h};\mathbf{g}) := \mathcal{F}(\mathcal{P}^{2h}\mathbf{x}^{2h};\mathbf{g})$, with $\mathbf{x}^{2h} \in \mathcal{S}^{2h}$. In our framework, for consecutive coarser levels, we typically choose nested spaces, so that $\mathcal{S}^{2^L h} \subset \ldots \mathcal{S}^{2h} \subset \mathcal{S}^h \subset \boldsymbol{\mathcal{V}}$. In this way, the interlevel transfer operators are induced in a natural, straightforward, and advantageous way and are easy to implement within PML. Furthermore, the coarse-grid problems are ensured to be compatible with the procedures used to define the fine-level problem, with the difference being that the coarse-level unknown is an approximation to the fine-level error and not to its solution; that is, the coarse-level correction is of the form $\mathbf{x}^h + \mathbf{c}^{2h}$. (Since $\mathbf{x}^h = \mathcal{P}^h\mathbf{x}^h$ for $\mathbf{x}^h \in \mathcal{S}^h$ and $\mathbf{c}^{2h} = \mathcal{P}^{2h}\mathbf{c}^{2h}$ for $\mathbf{c}^{2h} \in \mathcal{S}^{2h}$, we omit the embedding operators $\mathcal{P}^h$ and $\mathcal{P}^{2h}$ here and henceforth.)

Note that relaxation also depends on the choice of subspaces (and, hence, on the embeddings). We thus have to be particularly careful in picking the underlying subspaces for relaxation and coarsening.

3. Abstract framework of PML. To describe the general framework of PML applied to a functional minimization principle, let $\mathcal{F}(\mathbf{x};\mathbf{g}) : \boldsymbol{\mathcal{V}} \to \mathbb{R}$ and assume that we have a conforming finite element structure in the sense that $\mathcal{S}^{2h} \subset \mathcal{S}^h \subset \boldsymbol{\mathcal{V}}$. The aim of this section is to develop a multilevel framework that applies directly to

$$\mathcal{F}(\mathbf{x}_*^h;\mathbf{g}) = \min_{\mathbf{x}^h \in \mathcal{S}^h} \mathcal{F}(\mathbf{x}^h;\mathbf{g}), \qquad \mathbf{x}_*^h \in \mathcal{S}^h. \tag{3.1}$$

To do this, we focus on two important ingredients of multilevel methods: relaxation and coarsening. Relaxation is a generic term for an iterative process that is typically very inexpensive to use but is effective only at reducing certain "oscillatory" error components. Coarsening refers to the process of determining a coarse-level correction that, we hope, eliminates the "smooth" errors that relaxation leaves behind.

We first provide a general framework for a point or nodal relaxation scheme on the finest level. To maintain a certain form of generality in this section, let $\{\phi_n^h\}_{n=1}^{m_0}$ be a basis for $\mathcal{S}^h$, where m_0 is the dimension of $\mathcal{S}^h$. Then write $\mathcal{S}^h$ as a direct sum of the one-dimensional subspaces, $\mathcal{S}_n^h = \text{span}\{\phi_n^h\}$, $1 \le n \le m_0$: $\mathcal{S}^h = \mathcal{S}_1^h \oplus \cdots \oplus \mathcal{S}_{m_0}^h$. (Higher-dimensional subspaces can be considered for relaxation processes that update several variables at once, e.g., line or box relaxation. However, we consider only the one-dimensional case here for simplicity.)

These definitions set the stage for an abstract definition of a relaxation scheme to approximately solve for $\mathbf{x}_*^h \in \mathcal{S}^h$ in (3.1) by PML. To do so, we want to improve an initial guess, $\mathbf{x}^h$, by corrections, $\mathbf{c}^h \in \mathcal{S}_n^h$, $1 \le n \le m_0$. Thus, one sweep of relaxation consists of performing the following correction steps for each $n = 1, 2, \ldots, m_0$ in turn:

$$\text{(3.2)} \qquad \begin{cases} \mathcal{F}(\mathbf{x}^h + \mathbf{c}_{n^*}^h; \mathrm{g}) = \min\limits_{\mathbf{c}_n^h \in \mathcal{S}_n^h} \mathcal{F}(\mathbf{x}^h + \mathbf{c}_n^h; \mathrm{g}), \\ \mathbf{x}^h \leftarrow \mathbf{x}^h + \mathbf{c}_{n^*}^h. \end{cases}$$

Next, consider the coarse-grid correction process, first in terms of an exact solve, then as an iterative process. Let $\mathbf{x}^h \in \mathcal{S}^h$ be a random initial guess or a current iterate for our PML scheme. Then, the exact coarse-grid solve is described by

$$\text{(3.3)} \qquad \mathcal{F}(\mathbf{x}^h + \mathbf{c}_*^{2h}; \mathrm{g}) = \min_{\mathbf{c}^{2h} \in \mathcal{S}^{2h}} \mathcal{F}(\mathbf{x}^h + \mathbf{c}^{2h}; \mathrm{g}), \qquad \mathbf{c}_*^{2h} \in \mathcal{S}^{2h}.$$

To develop an iterative version of (3.3), we proceed in analogy to fine-grid relaxation. Let $\{\phi_n^{2h}\}_{n=1}^{m_1}$ be a basis for $\mathcal{S}^{2h}$. Then, write $\mathcal{S}^{2h}$ as a direct sum of the one-dimensional subspaces, $\mathcal{S}_n^{2h} = \text{span}\{\phi_n^{2h}\}$, $1 \le n \le m_1$: $\mathcal{S}^{2h} = \mathcal{S}_1^{2h} \oplus \cdots \oplus \mathcal{S}_{m_1}^{2h}$. Then one coarse-grid relaxation sweep consists of performing the following correction steps for each $n = 1, 2, \ldots, m_1$ in turn:

$$\text{(3.4)} \qquad \begin{cases} \mathcal{F}(\mathbf{x}^h + \mathbf{c}_{n^*}^{2h}; \mathrm{g}) = \min\limits_{\mathbf{c}_n^{2h} \in \mathcal{S}_n^{2h}} \mathcal{F}(\mathbf{x}^h + \mathbf{c}_n^{2h}; \mathrm{g}), \\ \mathbf{x}^h \leftarrow \mathbf{x}^h + \mathbf{c}_{n^*}^{2h}. \end{cases}$$

Our notation is at the crux of our ability to make PML practical. Iterative methods are commonly formulated as processes that directly update the original approximation, $\mathbf{x}^h$. Our choice of the more complicated correction form in (3.2) was made for consistency with (3.4). We complicate this notation further below by writing the respective fine- and coarse-level iterative processes as corrections to the approximate solutions, $\mathbf{c}^h$ and $\mathbf{c}^{2h}$, of (3.2) and (3.4). (To avoid further complication, we use $\mathbf{c}^h$ and $\mathbf{c}^{2h}$ to denote either the exact solutions or their approximations, a distinction that is clear by context.) Furthermore, we use these formulations to allow the multiple corrections that come from yet coarser levels. Hopefully, the three-term correction forms that we use in what follows are enough to expose the mechanisms needed to make the process efficient. The key is to write relaxation on the level $4h$ correction as a process that involves only changes to level $4h$ vectors.

To compute the corrections in (3.2) and (3.4), we use fine- and coarse-level relaxation processes. For $\mathbf{x}^h \in \mathcal{S}^h$ fixed and $\mathbf{c}^h \in \mathcal{S}^h$, the current approximation to the exact correction defined in (3.2), the nth step of a fine-grid relaxation sweep is defined by solving

$$\text{(3.5)} \qquad s = \operatorname*{argmin}_{t \in \mathbb{R}} \mathcal{F}(\mathbf{x}^h + \mathbf{c}^h + t\mathbf{d}^h; \mathrm{g}), \qquad s \in \mathbb{R},$$

and forming the update,

$$\mathbf{c}^h \leftarrow \mathbf{c}^h + s\mathbf{d}^h, \tag{3.6}$$

where $\mathbf{d}^h = \phi_n^h$, $1 \le n \le m_0$. Note that (3.5) and (3.6) describe a basic line search method, in direction $\mathbf{d}^h$, with optimal step length s. For simplicity, we combine (3.5) and (3.6) and refer to it as a *directional iteration step*. For given $\mathbf{x}^h$, $\mathbf{c}^h$, and $\mathbf{d}^h$, we denote the operator describing (3.5) and (3.6) by

$$\mathbf{c}^h \leftarrow \mathcal{D}_{\mathbf{x}^h}(\mathbf{c}^h, \mathbf{d}^h). \tag{3.7}$$

In an analogous way, coarse-grid relaxation is defined for $\mathbf{x}^h \in \mathcal{S}^h$ and $\mathbf{c}^{2h} \in \mathcal{S}^{2h}$ by $\mathbf{c}^{2h} \leftarrow \mathcal{D}_{\mathbf{x}^h}(\mathbf{c}^{2h}, \mathbf{d}^{2h})$, where $\mathbf{d}^{2h} = \phi_n^{2h}$, $1 \le n \le m_1$. Successive application of this process yields an abstract formulation of a general PML method. Assume that there are $L+1$ distinct grid levels corresponding to mesh sizes $2^l h$, $l = 0, \ldots, L$. (We label the finest level by superscript h and the coarsest one by superscript $2^L h$.) Assume that each level is defined by a finite-dimensional subspace, $\mathcal{S}^{2^l h}$, that is nested in the sense that $\mathcal{S}^{2^{l+1}h} \subset \mathcal{S}^{2^l h}$, $l = 0, \ldots, L-1$. Suppose that these spaces are written as a direct sum of one-dimensional subspaces: $\mathcal{S}^{2^l h} = \mathcal{S}_1^{2^l h} \oplus \cdots \oplus \mathcal{S}_{m_l}^{2^l h}$, $l = 0, \ldots, L$. Then one $V(0,1)$-PML cycle is defined as follows:

$$\begin{aligned}
&\mathbf{c}^{2^l h} \leftarrow \mathbf{0}, \qquad l = 0, \ldots, L \\
&\text{For } \ l = L, \ldots, 1: \qquad \text{(coarse-grid process)} \\
&\qquad \left[\begin{array}{l} \text{For } n = 0, \ldots, m_l \\ \qquad \mathbf{c}^{2^l h} \leftarrow \mathcal{D}_{\mathbf{x}^h}(\mathbf{c}^{2^l h}, \mathbf{d}_n^{2^l h}), \qquad \mathbf{d}_n^{2^l h} \in \mathcal{S}_n^{2^l h}, \\ \mathbf{c}^{2^{l-1} h} = \mathbf{c}^{2^l h} \end{array} \right. \\
&\text{For } \ l = 0: \qquad \text{(fine-grid process)} \\
&\qquad \left[\begin{array}{l} \text{For } n = 0, \ldots, m_0 \\ \qquad \mathbf{c}^h \leftarrow \mathcal{D}_{\mathbf{x}^h}(\mathbf{c}^h, \mathbf{d}_n^h), \qquad \mathbf{d}_n^h \in \mathcal{S}_n^h, \end{array} \right. \\
&\mathbf{x}^h \leftarrow \mathbf{x}^h + \mathbf{c}^h.
\end{aligned} \tag{3.8}$$

4. Coarse-grid realizability, different relaxation types, and higher-order discretizations. The key to obtaining an efficient multigrid-optimal PML implementation from (3.8) is the capability to perform the directional iteration step efficiently on coarse levels. Since the directional iteration step is based on functional evaluations, we focus now on how to do this efficiently on coarse levels.

4.1. Coarse-grid realizability. To obtain optimality, our multigrid algorithm must achieve two key objectives. First, we must be able to compute the FOSLS functional efficiently. Thus, update $\mathbf{c}^{2h}$ and the resulting new functional value must be computed quickly. Essentially, all level $2h$ calculations should in effect be performed on grid $2h$, not on grid h. Second, it must be possible to go from level $2h$ to level $4h$ without first updating the approximations on grid h.

To show how the first objective can be achieved, we need some additional notation and definitions. For simplicity, we choose the discretization to be the space, $\mathcal{S}^h$, of continuous piecewise-linear functions and the domain, $\Omega \subset \mathbb{R}^2$, to be two-dimensional, simply connected, and polygonal so that it can be partitioned into triangles. We consider here only triangulations by standard linear Lagrange triangles (cf. [5]). We need

to maintain a certain block-structured grid in order to obtain an efficient multigrid-optimal implementation of PML in two dimensions. Each level is defined by a finite-dimensional subspace, $\mathcal{S}^{2^l h}$, nested in the sense that $\mathcal{S}^{2^{l+1}h} \subset \mathcal{S}^{2^l h}$, $l = 0, \ldots, L-1$. For this section, we consider $\mathbf{x}^h = (\mathrm{x}_1^h, \ldots, \mathrm{x}_v^h)^t \in \mathcal{S}^h$ to be an arbitrary but fixed fine-grid approximation to the solution of the PDE. The $\mathbf{x}^h$ components, $\mathrm{x}_i^h : \Omega \to \mathbb{R}$ $(i = 1, \ldots, v)$, represent the different principal PDE variables (e.g., pressure, temperature, energy, and velocity). Further, we denote with $\mathbf{c}^{2^l h}$ a correction to fine-grid approximation $\mathbf{x}^h$ on level l (with approximate mesh size $2^l h$). Each component of correction $\mathbf{c}^{2^l h} = (\mathrm{c}_1^{2^l h}, \ldots, \mathrm{c}_v^{2^l h})^t \in \mathcal{S}^{2^l h}$ is a continuous piecewise-linear function and can be written, restricted to an element $\Omega_j^{2^l h}$, as a linear function as follows:

$$\mathrm{c}_i^{2^l h}(x, y)\Big|_{\Omega_j^{2^l h}} = s_1^{(i,j,l)} + s_2^{(i,j,l)} x + s_3^{(i,j,l)} y. \tag{4.1}$$

This representation holds for all $i = 1, \ldots, v$ and $j = 1, 2, \ldots, N^{(l)}$, where $N^{(l)}$ is the total number of elements on level l. The coefficients, $s_p^{(i,j,l)}$ with $p = 1, 2, 3$, are determined uniquely on level l by solving on each element, $\Omega_j^{2^l h}$ $(j = 1, 2, \ldots, N^{(l)})$, and for each $i = 1, \ldots, v$ the corresponding linear interpolation problem. In contrast to standard finite element practice, (4.1) can be seen as an alternative way to obtain a representation of $\mathbf{c}^h$ in $\mathcal{S}^h$. Standard nodal finite element bases could be used instead to represent (4.1), but this leads to substantially increased complexities for which we could not find an efficient way to avoid.

We next show how $\mathcal{F}(\mathbf{x}^h + \mathbf{c}^h; \mathbf{g})$ is computed for a modifiable fine-grid correction, $\mathbf{c}^h$, and an arbitrary but fixed approximation, $\mathbf{x}^h$. This is an essential step towards a multigrid-optimal algorithm and provides the basis for computing the FOSLS functional efficiently on coarser levels. For simplicity, we focus on one fine-grid element, Ω_j^h. This can be done without any loss of generality, since the sum of all fine-grid element contributions, $\mathcal{F}_{\Omega_j^h}(\mathbf{x}^h + \mathbf{c}^h; \mathbf{g})$, is the functional value, $\mathcal{F}(\mathbf{x}^h + \mathbf{c}^h; \mathbf{g})$. Further, we represent the fine-grid correction, $\mathbf{c}^h$ (level $l = 0$), as in (4.1) and consider its coefficients, $s_p^{(i,j,0)}$, as unknowns. In the next step, we use this representations to express the functional contribution, $\mathcal{F}_{\Omega_j^h}(\mathbf{x}^h + \mathbf{c}^h; \mathbf{g})$, in terms of the coefficients, $s_p^{(i,j,0)}$. Due to the nature of our quasi-linear first-order system and its L^2 least-squares functional, it is possible that the expansion of $\mathcal{F}_{\Omega_j^h}(\mathbf{x}^h + \mathbf{c}^h; \mathbf{g})$, with respect to the coefficients of $\mathbf{c}^h$, includes product terms of the coefficients, $s_p^{(i,j,0)}$, of up to order four. In the context of our new PML method, we regard all these terms as separate unknowns and store them as a matrix, $\mathbf{C}_j^h$. In this way, we are able to write the expansion of $\mathcal{F}_{\Omega_j^h}(\mathbf{x} + \mathbf{c}^h; \mathbf{g})$ as a matrix inner product of the form $\mathbf{A}_j^h : \mathbf{C}_j^h$. In the following, we refer to $\mathbf{A}_j^h$ as the local functional matrix and to $\mathbf{C}_j^h$ as the local coefficient matrix for element Ω_j^h on grid h. Now, whenever $\mathbf{c}^h$ changes on Ω_j^h, we obtain the new functional value, $\mathcal{F}_{\Omega_j^h}(\mathbf{x}^h + \mathbf{c}^h; \mathbf{g})$, by recomputing the local coefficient matrix and by evaluating the matrix inner product.

To show that we can compute the functional on coarser levels by coarse-grid calculations (the first objective), we assume a regular-structured grid. We further assume that four fine-grid elements always form one coarse-grid element. Denote by $\mathbf{C}_k^{2h}$ the coefficient matrix for $\mathbf{c}^{2h}$ on coarse-grid element Ω_k^{2h}. Further, let $\mathbf{C}_j^h$, with $j \in \{i | \Omega_i^h \subset \Omega_k^{2h}\}$, be the coefficient matrices for $\mathbf{c}^{2h}$ restricted to the fine-grid elements, Ω_j^h. The key observation now is to recognize that $\mathbf{C}_k^{2h} = \mathbf{C}_j^h$ for all

$j \in \{i|\Omega_i^h \subset \Omega_k^{2h}\}$. Then, we obtain the functional contribution for coarse-grid element Ω_k^{2h} as follows:

$$\mathcal{F}_{\Omega_k^{2h}}(\mathbf{x}^h + \mathbf{c}^{2h}; \mathbf{g}) = \sum_j \mathbf{A}_j^h : \mathbf{C}_j^h = \left(\sum_j \mathbf{A}_j^h\right) : \mathbf{C}_k^{2h} = \mathbf{A}_k^{2h} : \mathbf{C}_k^{2h}, \tag{4.2}$$

where $j \in \{i|\Omega_i^h \subset \Omega_k^{2h}\}$. Having all local fine-grid functional matrices available, we obtain the local coarse-grid functional matrices by a simple element-by-element addition of the respective fine-grid functional matrices. In this way, we can compute the functional, $\mathcal{F}(\mathbf{x}^h + \mathbf{c}^{2h}; \mathbf{g})$, for fixed fine-grid approximation $\mathbf{x}^h \in \mathcal{S}^h$ and any $\mathbf{c}^{2h} \in \mathcal{S}^{2h}$, entirely by grid $2h$ computations. We remark that, because of the nonlinear nature of our problems, these coarse-grid functional evaluations are possible only for approximations of the form $\mathbf{x}^h + \mathbf{c}^{2^l h}$, $l = 0, \ldots, L$, and not, for example, for approximations of the form $\mathbf{x}^h + \mathbf{c}^{2h} + \mathbf{c}^{4h}$. But, to fulfill the second objective, we would have to be able to compute approximations of the second type. To circumvent this drawback, we simply restrict ourselves to $V(0, \nu)$-cycles. Such a cycle is characterized for our new PML method by the following steps: fix the current approximation/initial guess; compute all local fine-grid functional matrices, $\mathbf{A}_j^h$; calculate the corresponding local coarse-grid functional matrices for all coarse levels; start the relaxation process on the coarsest level by applying ν sweeps there to compute the correction, $\mathbf{c}^{2^L h}$; interpolate this correction to the next finer level; use the interpolated correction as an initial value for relaxation on this next finer level; repeat the steps for $l = L, \ldots, 0$; and update the current approximation, $\mathbf{x}^h$, by $\mathbf{c}^h$.

By introducing local functional matrices and restricting ourselves to structured grids and $V(0, \nu)$-cycles, we can fulfill all the objectives for an efficient and multigrid optimal algorithm. Note that the same efficiency and optimality is retained if, instead of regular-structured grids, we use block-structured grids. Such grids allow the coarsest level to be unstructured, while the subsequent finer levels exhibit a regular structure.

4.2. Relaxation. The description of a $V(0, 1)$-PML cycle defines relaxation in general as $\mathbf{c}^{2^l h} \leftarrow \mathcal{D}_{\mathbf{x}^h}(\mathbf{c}^{2^l h}, \mathbf{d}_n^{2^l h})$, with $n = 0, \ldots, m_l$, where $\mathbf{x}^h$ is the current fine-grid approximation, $\mathbf{c}^{2^l h}$ is a coarse-grid correction on level $2^l h$, $\mathbf{d}_n^{2^l h} \in \mathcal{S}_n^{2^l h}$ is a search direction, and $\mathcal{S}_n^{2^l h}$, $n = 0, \ldots, m_l$, are spaces that decompose $\mathcal{S}^{2^l h}$. We clearly see that picking $\mathcal{S}_n^{2^l h}$ characterizes the type of relaxation. Before illustrating relationships between $\mathcal{S}_n^{2^l h}$ and different relaxation types, we first comment on issues concerning the realization and implementation of directional iteration or relaxation steps in general.

The classical approach for relaxation schemes, such as Gauss–Seidel or damped Jacobi, are based on a finite number of either explicitly given linear equations, typically written in matrix form, or nonlinear equations. Since relaxation for our PML method is based on a nonlinear functional minimization principle, we cannot use them in the same way that most standard approaches present them. To implement relaxation so that we keep the overall promise of avoiding linearization while obtaining an efficient algorithm, we restrict ourselves to a FOSLS functional for quasi-linear PDEs. For this class of PDE formulations, the nonlinearity appears in the functional as a cross product of two different variables, which implies linearity of the weak form with respect to each variable.

To illustrate this linearity, consider a least-squares functional consisting of the product of two variables: $\mathcal{F}([u, v]^t; 0) = \|uv\|_{0,\Omega}^2$. (For clarity, we use u and v instead

of x_1 and x_2.) Let $\mathcal{S}^h$ be a standard finite element space with approximate mesh size h. Then choose a relaxation direction for each variable: $\mathbf{d}_1^h = [d_{u^h}^h, 0]^t \in \mathcal{S}^h$ and $\mathbf{d}_2^h = [0, d_{v^h}^h]^t \in \mathcal{S}^h$. Relaxing on each variable of $\mathcal{F}([u^h, v^h]^t; 0)$ separately, we obtain for $\mathbf{x}^h = [u^h, v^h]^t \in \mathcal{S}^h$ the following relaxation process:

(4.3)
$$\begin{cases} s_1 = \underset{t\in\mathbb{R}}{\operatorname{argmin}}\ \mathcal{F}(\mathbf{x}^h + t\mathbf{d}_1^h; 0) = \underset{t\in\mathbb{R}}{\operatorname{argmin}}\ \mathcal{F}([u^h + td_{u^h}^h, v^h]^t; 0) =: \underset{t\in\mathbb{R}}{\operatorname{argmin}}\ \bar{\mathcal{F}}_1(t), \\ u^h \leftarrow u^h + s_1 d_{u^h}^h \end{cases}$$

and

(4.4)
$$\begin{cases} s_2 = \underset{t\in\mathbb{R}}{\operatorname{argmin}}\ \mathcal{F}(\mathbf{x}^h + t\mathbf{d}_2^h; 0) = \underset{t\in\mathbb{R}}{\operatorname{argmin}}\ \mathcal{F}([u^h, v^h + td_{v^h}^h]^t; 0) =: \underset{t\in\mathbb{R}}{\operatorname{argmin}}\ \bar{\mathcal{F}}_2(t), \\ v^h \leftarrow v^h + s_2 d_{v^h}^h. \end{cases}$$

For our class of PDEs, functions $\bar{\mathcal{F}}_1(t)$ and $\bar{\mathcal{F}}_2(t)$ defined in (4.3) and (4.4) are quadratic polynomials in the scalar, t. To obtain the quadratic formulation for $\bar{\mathcal{F}}_1(t)$ (or $\bar{\mathcal{F}}_2(t)$), we evaluate $\bar{\mathcal{F}}_1(t)$ (or $\bar{\mathcal{F}}_2(t)$) at three different locations and fit the functional values quadratically. In this way, the quadratic polynomial fits $\bar{\mathcal{F}}_1(t)$ (or $\bar{\mathcal{F}}_2(t)$) exactly. Actually, we need only evaluate $\bar{\mathcal{F}}_1(t)$ (or $\bar{\mathcal{F}}_2(t)$) at two locations because the current functional value ($t = 0$) is known. Also, after computing the optimal step length, which is the minimum of the quadratic polynomial, we obtain the new current functional value by plugging s_1 (or s_2) into our quadratically fitted curve.

For nonlinear PDEs with the type of nonlinearity that is the focus of this research, an alternating-variable relaxation process leads to scalar minimization problems in which the objective function is quadratic. This property is due to the nature of our constructed FOSLS functional, but it is no longer true for a relaxation scheme that simultaneously relaxes on both (resp., all) variables. Instead of (4.3) and (4.4), block relaxation on both variables leads to the following relaxation process:

(4.5)
$$\begin{cases} (s_1, s_2) = \underset{(t_1,t_2)\in\mathbb{R}^2}{\operatorname{argmin}}\ \mathcal{F}(\mathbf{x}^h + t_1\mathbf{d}_1^h + t_2\mathbf{d}_2^h; 0) \\ \qquad\quad = \underset{(t_1,t_2)\in\mathbb{R}^2}{\operatorname{argmin}}\ \mathcal{F}(\big[u^h + t_1 d_{u^h}^h, v^h + t_2 d_{v^h}^h\big]; 0) =: \underset{(t_1,t_2)\in\mathbb{R}^2}{\operatorname{argmin}}\ \bar{\mathcal{F}}_3(t_1, t_2), \\ u^h \leftarrow u^h + s_1 d_{u^h}^h, \quad v^h \leftarrow v^h + s_2 d_{v^h}^h. \end{cases}$$

Now, the possibility of performing a relaxation step without appealing to linearization depends on the capability of computing the minimizer of $\bar{\mathcal{F}}_3(t_1, t_2)$. Similar conclusions can be made for PDEs in which derivatives appear to some integer power.

Even though we illustrated only one fine-grid relaxation step for two scalar unknowns, we can apply the same techniques for more than two variables, for unknowns that are vector functions, and on coarser levels. Moreover, at this point, we see why it is extremely important to be able to compute functional values on all levels efficiently. Relaxation is the main contributor to the overall computational cost and is almost solely based on functional evaluations.

We can relax on the unknowns in an alternating fashion, as described by (4.3) and (4.4), for almost any choice of relaxation subspaces, $\mathcal{S}_n^{2^l h}$, and discretization. These choices only affect the type of relaxation. In what follows, we give two examples for

different relaxation types, a Richardson-like scheme and a Gauss–Seidel-like scheme. Although we describe the different relaxation types as if the functional had only one unknown, we still relax on the unknowns in an alternating way.

To obtain a Richardson-like relaxation scheme, we choose $m_l = 1$ on all levels. This means that there is only one relaxation step per sweep. As the single direction, $\mathbf{d}_1^{2^l h} \in \mathcal{S}_1^{2^l h} = \mathcal{S}^{2^l h}$, we make the natural choice of "steepest" descent given by the gradient of the functional with respect to the unknown. We compute the gradient of our nonlinear functional numerically: its value at node n is determined by the forward-difference formula, $\big(\mathcal{F}(\mathbf{x}^{2^l h} + s\,\mathbf{e}_n^{2^l h}; \mathrm{g}) - \mathcal{F}(\mathbf{x}^{2^l h}; \mathrm{g})\big)/s$, where $\mathbf{e}_n^{2^l h}$ is the nth nodal finite element basis function (with value one at grid point n and zero elsewhere) and s is sufficiently small; the discrete representation of the gradient, $\mathbf{d}_1^{2^l h}$, is then just the continuous piecewise polynomial in $\mathcal{S}^{2^l h}$ that has these nodal values.

If we now choose our relaxation subspaces as the span of individual basis or nodal finite element basis functions (with a value of one at a single node and zero at all other nodes), we obtain a coordinate minimization or nonlinear Gauss–Seidel relaxation process. Hence, we choose m_l to be equal to the number of nodes on level l, $\mathbf{d}_n^{2^l h}$ as the nodal finite element basis function, and $\mathcal{S}_n^{2^l h}$ as the space spanned by the nodal basis function of node n. This means that we minimize consecutively over all nodes, n, by computing the step length, $s = \min_{t\in\mathbb{R}} \mathcal{F}(\mathbf{x}^h + \mathbf{c}^{2^l h} + t\mathbf{d}_n^{2^l h}; \mathrm{g})$, and the resultant update, $\mathbf{c}^{2^l h} \leftarrow \mathbf{c}^{2^l h} + s\mathbf{d}_n^{2^l h}$. Note that this is a local process in that the approximation, $\mathbf{x}^h$, changes only at one node per step of the sweep.

Gauß-Seidel is typically a more efficient smoother than a gradient or Richardson-type process.

4.3. Higher-order discretizations. Many engineering problems require more than just a linear finite element discretization. For example, the numerical solution to the Navier–Stokes equations obtained by using linear finite elements and a triangular discretization in a FOSLS formulation usually does not conserve mass very well. This section shows the potential of using higher-order finite elements in our framework of PML. For simplicity, however, we limit ourselves in this section to standard quadratic Lagrange triangles, which generate the space, $\mathcal{S}_Q^h$, of continuous piecewise-quadratic finite elements. It should be noted that any other higher-order discretization or other element type can be implemented in a similar way. Mimicking the representation of linear functions over elements, we describe approximations or corrections in $\mathcal{S}_Q^h$ restricted to an element (in this case, we use a less cumbersome notation as we restrict our correction to a reference element, Ω_{ref}^h) by

$$c^h(x,y)\Big|_{\Omega_{ref}^h} = s_0^h + s_1^h x + s_2^h y + s_3^h xy + s_4^h x^2 + s_5^h y^2. \tag{4.6}$$

Similar to fine-grid level h, we introduce quadratic finite element spaces on coarser levels: $\mathcal{S}_Q^{2^l h}$, $l = 1, \ldots, L$. The subscript Q indicates the use of quadratic ansatz functions to generate the space. We stress that the lack of such a subscript signifies linear ansatz functions. For the multilevel implementation with quadratic finite elements, we use an unstructured triangulation for the coarsest level. All finer levels are obtained by subdividing each coarser-grid-level triangle into four equal triangles. To this end, we consider as follows two different coarse-grid correction processes that differ by the choice of the coarse-grid correction subspaces:

1. On all levels, corrections are obtained from the quadratic finite element subspaces, $\mathcal{S}_Q^{2^l h}$ $(l = 0, \ldots, L)$.

2. Only $\mathcal{S}_Q^h$ is used for the fine-grid corrections, while the coarse-grid process uses corrections from the linear finite element subspaces, $\mathcal{S}^{2^l h}$ $(l = 1, \ldots, L)$.

To achieve for both approaches an efficient or even multigrid-optimal algorithm for quadratic finite elements, we mimic ideas and techniques from previous discussions on linear finite elements. There, we introduced local functional matrices, which led to an efficient way of handling modifications to coarse-grid corrections. These local functional matrices can be computed for quadratic finite elements in a similar way. The key observation, which led to multigrid-optimality, is to recognize the need to use $V(0,\nu)$-cycles instead of $V(\mu,\nu)$-cycles for our PML method.

For the first approach, coarse-grid functional matrices are obtained as in the case for linear finite elements by adding up the respective fine-grid functional matrices. At the end of each cycle, we update the current approximation of the solution, $\mathbf{x}_Q^h$, by $\mathbf{c}_Q^h$, compute the new local functional matrices, and repeat the cycle. For the second approach, we first alter the triangulation from quadratic Lagrange triangles to linear Lagrange triangles. Then we apply a standard $V(0,\nu)$-cycle that involves relaxation on corrections represented by continuous piecewise-linear functions. At the end of this $V(0,\nu)$-cycle, we project the current (piecewise-linear) correction onto the original triangulation with quadratic Lagrange triangles. We continue the cycle by performing ν further relaxation sweeps on the correction, now represented by continuous piecewise-quadratic functions, by updating the current approximation of the solution, $\mathbf{x}_Q^h$, by $\mathbf{c}_Q^h$, and by computing the new local functional matrices to repeat the cycle.

Compared to the first approach, the second has two advantages. First, it allows reuse of most of the code for linear finite elements. Second, the coarsening process is independent of the order of the fine-grid discretization. This property becomes increasingly important as we choose increasingly higher-order discretizations on the finest level. To illustrate this, recall that our PML method treats the nonlinearity directly without any kind of linearization process. Thus, our local functional matrices are growing rapidly in complexity for higher-order discretizations. (The complexity grows for quasi-linear problems even more than for linear ones.) With the second approach, we use a multilevel strategy to compute a piecewise-linear approximation to the fine-grid correction. Having this approximation on the finest level available, we have the advantage of no longer being constrained to use local functional matrices or the same relaxation process as on coarser levels. In principle, we could consider the fine-level correction as a separate minimization process, with the advantage of having a good coarse-grid corrected initial guess. This is very appealing in particular for high-order finite elements.

However, low-order spaces do not always provide an effective coarse-level correction for high-order spaces in the same elements. An alternative is to partition the elements defining the high-order discretization into several smaller elements that could then be used to define the linear correction space (cf. [18, 21]). In our context of standard quadratic finite elements, we could split each quadratic Lagrange triangle into four linear Lagrange triangles. Although, this would violate our assumption of nested finite-dimensional subspaces, we would still obtain a good low-order approximation to the (high-order) correction on the finest level. This is very appealing for high-order element types, in particular, since this allows us, again, to consider the (high-order) fine-level problem as a separate minimization process.

5. Numerical results. Here we report on numerical results for some test problems. First, we study performance of our PML method on a set of nonlinear test

problems by adding a simple nonlinear term to the Laplace operator, using a coefficient, α, that allows us to adjust the strength of nonlinearity. We finish this section by presenting numerical results for our target application, the incompressible Navier–Stokes equations, with particular focus on the so-called Kovasznay flow.

5.1. Measuring convergence factors. Before we provide numerical results on some test problems, we first address the issue of how to measure convergence factors for our method since they play an especially important role in analyzing and evaluating a multigrid iteration.

Let $\mathcal{F}(\mathbf{x}^{2^l h};\mathsf{g})$ be the discrete nonlinear functional for a nonlinear PDE written in FOSLS form, and let $\mathbf{x}_*^{2^l h}$ be the minimizer of $\mathcal{F}(\mathbf{x}^{2^l h};\mathsf{g})$ on level l. Superscript $2^l h$ does not play an essential role here, but we use it anyway to emphasize that the operator stems from a discretization on a certain level, l. Taking our cue from the linear case, we write the functional norm defect of our current approximation as

$$\hat{\delta}_k^{2^l h} = \sqrt{\mathcal{F}(\mathbf{x}_k^{2^l h};\mathsf{g}) - \mathcal{F}(\mathbf{x}_*^{2^l h};\mathsf{g})}, \tag{5.1}$$

where $\mathbf{x}_k^{2^l h}$ is the approximation to the exact solution, $\mathbf{x}_*^{2^l h}$, after the kth iteration step. Note that $\hat{\delta}_k^{2^l h}$ is a positive real number because $\mathbf{x}_*^{2^l h}$ is the minimizer of $\mathcal{F}(\mathbf{x}^{2^l h};\mathsf{g})$. In analogy to computing convergence factors for linear systems (cf. [9, 31]), we define the convergence factor for the kth iteration step on level l by

$$\widehat{CF}_k^{(l)} := \frac{\hat{\delta}_k^{2^l h}}{\hat{\delta}_{k-1}^{2^l h}} = \sqrt{\frac{\mathcal{F}(\mathbf{x}_k^{2^l h};\mathsf{g}) - \mathcal{F}(\mathbf{x}_*^{2^l h};\mathsf{g})}{\mathcal{F}(\mathbf{x}_{k-1}^{2^l h};\mathsf{g}) - \mathcal{F}(\mathbf{x}_*^{2^l h};\mathsf{g})}}. \tag{5.2}$$

Since $\mathcal{F}(\mathbf{x}_*^{2^l h};\mathsf{g})$ is unknown, (5.2) cannot be used directly to compute the convergence factor. Thus, instead of considering the defect, $\hat{\delta}_k^{2^l h}$, as in (5.1), we take the approach of defining the defect of two consecutive approximations:

$$\delta_k^{2^l h} = \sqrt{\mathcal{F}(\mathbf{x}_{k-1}^{2^l h};\mathsf{g}) - \mathcal{F}(\mathbf{x}_k^{2^l h};\mathsf{g})}. \tag{5.3}$$

The attendant convergence factor estimate is then given by

$$CF_k^{(l)} := \frac{\delta_k^{2^l h}}{\delta_{k-1}^{2^l h}} = \sqrt{\frac{\mathcal{F}(\mathbf{x}_{k-1}^{2^l h};\mathsf{g}) - \mathcal{F}(\mathbf{x}_k^{2^l h};\mathsf{g})}{\mathcal{F}(\mathbf{x}_{k-2}^{2^l h};\mathsf{g}) - \mathcal{F}(\mathbf{x}_{k-1}^{2^l h};\mathsf{g})}}. \tag{5.4}$$

Note that this measures requires care with respect to machine precision and numerical cancellation. For example, if $\mathcal{F}(\mathbf{x}_{k-1}^{2^l h};\mathsf{g})$ and $\mathcal{F}(\mathbf{x}_k^{2^l h};\mathsf{g})$ in (5.4) are the same up to near machine precision, then convergence factors can give the impression of degenerating performance.

5.2. A nonlinear model problem. As a first test for our algorithm, we choose a Poisson problem with pure Dirichlet boundary conditions on $\Omega = [0,1] \times [0,1]$ that has been modified by the addition of a nonlinear term, $\alpha p p_x$. Parameter α allows us to vary the strength of the nonlinearity. This model represents a simple nonlinear PDE with the type of nonlinearity that is the focus of this research. Its FOSLS formulation

is given as follows:

$$
\begin{aligned}
\nabla p - \mathbf{u} &= \mathbf{0} && \text{in } \Omega,\\
-\frac{1}{\alpha}\nabla\cdot\,\mathbf{u} + pu_1 &= f_\Omega && \text{in } \Omega,\\
\frac{1}{\alpha}\nabla\times\,\mathbf{u} &= 0 && \text{in } \Omega,\\
p &= f_\Gamma && \text{on } \Gamma_\Omega,\\
\mathbf{n}\times\mathbf{u} &= \mathbf{n}\times f_\Gamma && \text{on } \Gamma_\Omega.
\end{aligned}
\tag{5.5}
$$

where $\nabla p = (u_1, u_2)^t$, $\mathbf{n}$ is the unit outward normal on boundary Γ_Ω, and Ω is the unit square. For further details on FOSLS formulations of the Poisson problem, see [10] and [11]. We choose $p(x, y) = x^2 + y^2$ as the exact solution and thus obtain $f_\Omega = -4/\alpha + (2x^3 + 2xy^2)$ as the right side. For all of our experiments, we use Dirichlet boundary conditions derived from the exact solution. We enforce the boundary conditions strongly by imposing them on the finite element space. Note that (5.5) arises from a more favorable scaling of the first-order system derived from the PDE, $\Delta p + \alpha\, pp_x = \tilde{f}_\Omega$. Hence, parameter α allows us to vary the strength of nonlinear term pp_x, and $\alpha = 0$ reduces it to the linear Poisson problem. Its FOSLS functional is constructed by taking the L^2-norm of each interior equation,

$$
\mathcal{F}(p, \mathbf{u}; \mathbf{g}) = \|\nabla p - \mathbf{u}\|^2_{0,\Omega} + \| -\frac{1}{\alpha}\nabla\cdot\,\mathbf{u} + pu_1 + \frac{4}{\alpha} - (2x^3 + 2xy^2)\|^2_{0,\Omega} + \|\frac{1}{\alpha}\nabla\times\,\mathbf{u}\|^2_{0,\Omega},
\tag{5.6}
$$

where $\mathbf{g} = (\mathbf{0}, f_\Omega, 0)$. The grids are based on a regular triangulation of Ω by 16 elements and 13 grid points. This coarsest level is denoted by $l = 7$, with an approximate mesh size $2^l h$, where h is the approximate mesh size with respect to the finest level. Level 6 is formed by taking every element of level 7 and subdividing it into 4 equal triangles. The midpoints of the coarse-grid element sides are the new fine-grid points. Successively finer levels are constructed in the same way. This refinement leads to 131,585 nodes (with 3 degrees of freedom per node) and 262,144 elements on level 0. A nested iteration algorithm with 10 $V(0, 4)$-Gauss–Seidel relaxation sweeps on each level is used to minimize $\mathcal{F}(p, \mathbf{u}; \mathbf{g})$ in (5.6) over the space consisting of continuous piecewise-linear functions. Extensive experiments with several problems of this type lead us to believe that $V(0, 4)$-cycles achieve nearly the best accuracy-complexity tradeoffs over other such cycling strategies. Since our exact solution cannot be represented exactly by our finite element space, the functional cannot converge to zero, but rather stagnates as the iteration reaches the level of discretization error on each grid. Table 5.1 depicts the functional norms, $\mathcal{F}(p^{2^l h}_{10}, \mathbf{u}^{2^l h}_{10}; \mathbf{g})^{\frac{1}{2}}$, obtained on each level for the linear Poisson problem and α varying between 1 and 10,000. Table 5.2 reports on the corresponding final convergence factors, $CF^{(l)}_{10}$, computed according to (5.4). Here, we choose to report the convergence factor of the last iteration, since it tends to be the worst in our numerical tests.

Note that, on each level, we obtain accuracy close to discretization level within 10 $V(0, 4)$-cycles. We have not used any special technique (e.g., streamline relaxation) to address the changing character of the operator as α increases. Thus, as expected, the final convergence factors degrade as the nonlinearity increases in dominance, but they remain grid-independent. Though one might argue that the convergence factors in the last column of Table 5.2 (α = 10,000) do not exhibit grid-independent convergence

factors, it is believed that grid-independent convergence factors are obtained once a sufficiently small mesh size is reached.

The fact that we reached the level of discretization error is also supported by the functional reduction factors. For continuous piecewise-linear finite elements for our problem, standard theory (cf. [12]) establishes asymptotic $O(h)$ H^1-error bounds, so H^1 ellipticity of our functional yields an $O(h)$ functional-norm bound. We might, thus, expect about a factor of 2 in functional-norm reduction from one level to the next finer one. Let the functional reduction factors as the resolution doubles be defined by

$$\beta_n^{(l)} = \sqrt{\frac{\mathcal{F}(p_n^{2^{l+1}h}, \mathbf{u}_n^{2^{l+1}h}; \mathrm{g})}{\mathcal{F}(p_n^{2^l h}, \mathbf{u}_n^{2^l h}; \mathrm{g})}}, \qquad l = 0, \ldots, L-1. \tag{5.7}$$

Table 5.3 depicts these factors for different levels and strengths of nonlinearity. For all levels and strengths of nonlinearity, we observe a functional reduction factor of about 2, which is consistent with the use of continuous piecewise-linear finite elements.

Next, we analyze error reduction factors as we step through the different levels. Consider again the same FOSLS formulation, levels, and number of V-cycles per level used for the results in Table 5.1. We now compare the numerically obtained solution, $p^{2^l h}$, with the exact solution, $p = x^2 + y^2$, for each level and for each α ($\alpha = 1$, 10, 100, 1,000, and 10,000), measured by the H^1- and L^2-norms. In Figure 5.1, we depict the H^1-error norm versus the number of elements. The L^2-error norm versus the number of elements is shown in Figure 5.2. Since we use a regular refinement strategy to step

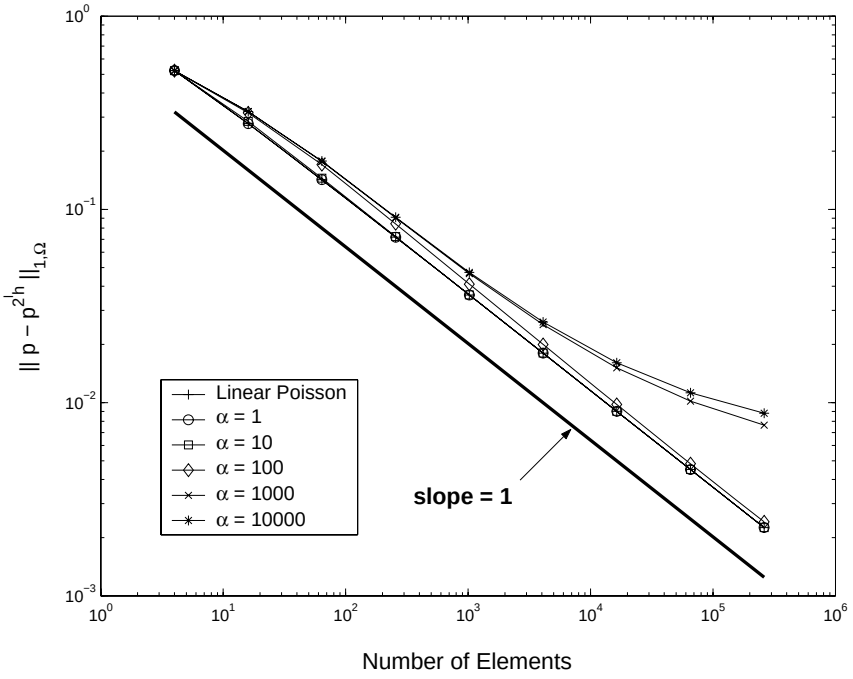

FIG. 5.1. *H^1-error, $\|p - p^{2^l h}\|_{1,\Omega}$, versus the number of elements for the linear Poisson problem and* (5.5) *with* $\alpha = 1$, 10, 100, 1,000, *and* 1,0000.

through the levels (with each refinement, we increase the number of elements by a factor of 4 and, therefore, halve our mesh size), reporting on the number of elements is the same as reporting on the mesh size. For both figures, we use a logarithmic scale for the number of elements (abscissa) and the error-norm (ordinate). For each α, the H^1-error norm (or L^2-error norm) is measured for each level and indicated with data points, which are connected in such a way that each line displays one nested iteration process for some α. Additionally, we include in Figure 5.1 a supporting line with slope 1 and in Figure 5.2 two supporting lines with slopes 1 and 2. These supporting lines should help retrieve an estimate of the error-reduction factors directly from the

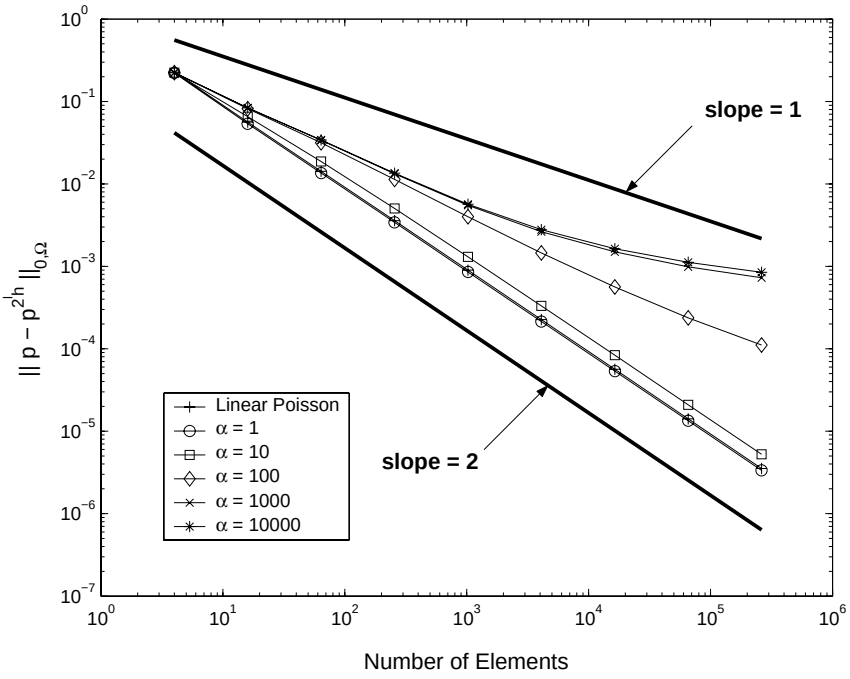

FIG. 5.2. *L^2-error, $\|p-p^{2^l h}\|_{0,\Omega}$, versus the number of elements for the linear Poisson problem and* (5.5) *with* $\alpha = 1$, 10, 100, 1,000, *and* 10,000.

graph. Note that a slope of $\mathbf{s}$ in Figures 5.1 and 5.2 means that

$$\frac{\|p - p^{2^l h}\|}{\|p - p^{2^{l+1} h}\|} \approx \Big(\frac{2^{l+1} h}{2^l h}\Big)^{\mathbf{s}} = 2^{\mathbf{s}}.$$

Hence, slope $\mathbf{s}$ translates to an error-reduction factor of $2^{\mathbf{s}}$. Analyzing Figure 5.1, the error-reduction factor from one level to the next is about 2 for every α. This coincides well with the reported functional reduction factors, $\beta_{10}^{(l)}$, in Table 5.3, and are considered to be optimal for linear finite elements. From the excellent agreement of the FOSLS functional norm and the H^1-error reduction factors, we conclude that the functional in (5.6) appears to be H^1-elliptic. This numerical observation coincides with the theoretical results of the companion paper [23], where we establish H^1 ellipticity of the FOSLS functional based on the Navier–Stokes equations and anticipate it for other quasi-linear PDEs of that class.

In Figure 5.2, we display the L^2-error norms in the same way as the H^1-error in Figure 5.1. We now observe strongly deteriorating L^2-error reduction factors with increasing strength of nonlinearity. One possible explanation for this might involve the Nitsche Trick (cf. [8]), which relates two different error norms to each other (in this case, the H^1-error norm and the L^2-error norm). Its proof is based on the assumption that the exact solution, $\mathbf{x}_*^{2^l h}$, is found on each level. With a nested iteration scheme, we compute on each level only an approximation to $\mathbf{x}_*^{2^l h}$; here, for example, we approximate $\mathbf{x}_*^{2^l h}$ by $\mathbf{x}_{10}^{2^l h}$. In separate experiments, we have been able to recover near-optimal L^2-error reduction factors by using 100 V-cycles instead of 10 on each level. This shows that better algebraic accuracy is needed on each level to control the L^2-error. This should be expected since greater L^2 accuracy is obtained

from the discretization on each level, so nested iteration should have to work harder than for H^1 accuracy to achieve it. Development of effective criteria for a nested iteration strategy that efficiently produces small H^1 and L^2 errors is still an open problem.

5.3. Kovaszany flow. While system (5.5) provides an important problem to test the behavior of the algorithm, our ultimate goal is to solve the Navier–Stokes equations. For concreteness, we focus on the steady-state incompressible Navier–Stokes equations in velocity-pressure formulation given as follows:

$$\begin{aligned} -\frac{1}{Re}\Delta\mathbf{u} + \mathbf{u}\cdot\nabla\mathbf{u} + \nabla p &= \mathbf{0} \qquad \text{in } \Omega, \\ \nabla\cdot\mathbf{u} &= 0 \qquad \text{in } \Omega. \end{aligned} \tag{5.8}$$

Velocity vector variable $\mathbf{u} = (u_1, u_2)^t$ and pressure scalar variable p are nondimensionalized. Re denotes the Reynolds number defined as $Re = (U_{ref}L)/\nu$, where L is a reference length, U_{ref} a reference velocity, and ν the kinematic viscosity (see [19]). Note that the source terms in this system are all zero. We could easily incorporate nonzero terms, but choose this simplification instead because our primary focus is on the algebraic solver and because inhomogeneities are incorporated in the boundary conditions in any case.

To obtain a first-order system from (5.8), we introduce a new velocity-flux tensor variable, $\mathbf{U} = (U_{i,j})_{2\times 2} = (\partial u_j/\partial x_i)_{2\times 2} = \nabla\mathbf{u}^t$. (See [1] for details on the FOSL-Sization of (5.8).) We thus obtain the following first-order velocity-flux form of the Navier–Stokes equations:

$$\begin{aligned} \nabla\mathbf{u}^t - \mathbf{U} &= \mathbf{0} \qquad \text{in } \Omega, \\ -\frac{1}{Re}(\nabla\cdot\mathbf{U})^t + \mathbf{U}^t\mathbf{u} + \nabla p &= \mathbf{0} \qquad \text{in } \Omega, \\ \nabla\cdot\mathbf{u} &= 0 \qquad \text{in } \Omega, \\ \frac{2}{Re}\nabla\times\mathbf{U} &= 0 \qquad \text{in } \Omega. \end{aligned} \tag{5.9}$$

The difference between this system and that proposed in [1] is the factor of 2 in the last equation and the missing trace term, $\nabla tr(\mathbf{U})$. The additional factor is a simple weighting of this equation that, by our empirical observations, results in slightly better numerical results. Concerning the trace term, because of the incompressibility condition expressed by $\partial_x u_1 + \partial_y u_2 = U_{11} + U_{22} = 0$, we are able to eliminate one of the variables by setting $U_{11} = -U_{22}$, which in turn enforces $\nabla tr(\mathbf{U}) = 0$ and therefore makes this trace equation unnecessary. Of course, system (5.9) offers but one approach to reducing the second-order problem to first order. Other choices are given, for example, in [3] and [19]. In any case, the solution of our first-order system is the minimizer of the least-squares functional given by

$$\begin{aligned} \mathcal{F}(\mathbf{u},\mathbf{U},p\,;\mathbf{g}) = \|\nabla\mathbf{u}^t - \mathbf{U}\|_{0,\Omega}^2 + \| - \frac{1}{Re}(\nabla\cdot\mathbf{U})^t + \mathbf{U}^t\mathbf{u} + \nabla p\|_{0,\Omega}^2 \\ + \|\nabla\cdot\mathbf{u}\|_{0,\Omega}^2 + \left\|\frac{2}{Re}\nabla\times\mathbf{U}\right\|_{0,\Omega}^2, \end{aligned} \tag{5.10}$$

where $\mathbf{g} = (\mathbf{0}, \mathbf{0}, 0)$ is the combined right side of the equations in (5.9).

TABLE 5.4

1	8 321/4 096	3.760596e−02	3.67	0.892
0	33 025/16 384	9.993762e−03	3.78	0.897

As a model problem for our algorithm applied to the Navier–Stokes equations, we turn to Kovasznay flow. This particular system is named after L. I. G. Kovasznay, who derived in [20] an analytic solution for the steady-state incompressible Navier–Stokes equations for a special laminar flow problem. We choose this problem as a test case, since it is posed on a rectangular domain, $\Omega = [-.5, 2.0] \times [-.5, 1.5]$, has a smooth solution, and exhibits no singularities. Knowledge of the analytical solution allows us to strongly impose the exact boundary conditions. Actually, for accurate error estimates, we need not appeal to an exact analytic solution, since the FOSLS functional itself naturally provides a sharp error measurement. But use of an exact solution gives a somewhat tighter estimate of any error measure we choose to use.

In Table 5.4, we give the convergence history using continuous piecewise-quadratic functions for the Kovasznay flow problem with a Reynolds number of 40. For the cycling strategy, we choose to use quadratic finite elements for the fine-grid corrections and linear finite element subspaces for the coarse-grid process (see the second approach of section 4.3). The grids are based on a regular triangulation of Ω by 16 elements and 41 nodes. Again, we use a nested iteration approach to step through the levels. On each level, we apply 10 $V(0,4)$-PML cycles, with Gauss–Seidel as smoother. For each level, we report on final functional norm values, $\mathcal{F}(\mathbf{x}_{10}^{2^l h};\mathbf{g})^{\frac{1}{2}}$, the functional reduction factor, $\beta_{10}^{(l)}$, defined as in (5.7), and the final convergence factor, $CF_{10}^{(l)}$, defined as in (5.4).

The results in Table 5.4 show that we also obtain approximate grid-independent convergence factors for the FOSLS formulation of the Navier–Stokes problem and nearly optimal finite element approximation properties. The fact that the functional reduction factor, $\beta_{10}^{(l)}$, is hovering around 3.7 instead of an optimal factor of 4 for quadratic Lagrange finite elements is probably due mostly to the approximations not yet being in the asymptotic range. Note the increase in these factors with decreasing h. (Our tests that increased the number of V-cycles showed only marginal increase in the functional reduction factors.)

Though we report here only on results for $Re = 40$ (the classical setting for the Kovasznay flow), we have done experiments for much higher Reynolds numbers. We obtained similar results, although the convergence factors naturally degraded since the PML scheme was not designed for convection-dominated problems.

PROJECTION MULTILEVEL METHODS FOR QUASILINEAR ELLIPTIC PARTIAL DIFFERENTIAL EQUATIONS: THEORETICAL RESULTS*

THOMAS A. MANTEUFFEL†, STEPHEN F. MCCORMICK†, AND OLIVER RÖHRLE‡

Abstract. In a companion paper [T. A. Manteuffel et al., *SIAM J. Numer. Anal.*, 44 (2006), pp. 120–138], we propose a new multilevel solver for two-dimensional elliptic systems of partial differential equations with nonlinearity of type $u\partial v$. The approach is based on a multilevel projection method (PML) [S. F. McCormick, *Multilevel Projection Methods for Partial Differential Equations*, SIAM, Philadelphia, 1992] applied to a first-order system least-squares functional that allows us to treat the nonlinearity directly. While the companion paper focuses on computation, here we concentrate on developing a theoretical framework that confirms optimal two-level convergence. To do so, we choose a first-order formulation of the Navier–Stokes equations as a basis of our theory. We establish continuity and coercivity bounds for the linearized Navier–Stokes equations and the full nonquadratic least-squares functional, as well as existence and uniqueness of a functional minimizer. This leads to the immediate result that one cycle of the two-level PML method reduces the functional norm by a factor that is uniformly less than 1.

DOI. 10.1137/040617704

1. Introduction. Our companion paper [8] introduces a new multilevel solver for two-dimensional elliptic systems of partial differential equations (PDEs) with nonlinearity of type $u\partial v$. The approach is based on a multilevel projection method (PML) [9] applied to a first-order system least-squares (FOSLS) functional, where the nonlinearity is treated directly, with no need for linearization anywhere in the algorithm. While [8] focuses on computation, the key objective of the present paper is to establish local well-posedness of our functional minimization problem. This result leads to the immediate conclusion that our two-level solver converges linearly with grid independent factors, as observed numerically in [8]. This two-grid result can be extended to W-cycles in the usual way. However, an important alternative would be to establish a V-cycle result based on the general theory developed in [11] and [12]. This alternative would naturally yield grid-dependent convergence bounds because of the weak smoothness assumptions on the problem formulation (i.e., only Lipschitz continuity on the domain boundary).

We base our theory for a two-level PML method on the first-order formulation of the Navier–Stokes formulation given in (2.1). Although we choose this formulation as a foundation for our theoretical framework, it is not limited to it: similar results can be established for other PDEs of this class.

This paper is organized in the following way. Section 2 provides the first-order system formulation, with definitions, notation, and description of one two-level PML cycle step. Section 3 establishes several continuity and coercivity bounds for the Oseen equations as well as for the full nonquadratic least-squares functional. Section 4 shows existence and uniqueness of a functional minimizer, some characteristics of coarse-grid correction and relaxation, and two-grid convergence.

2. First-order system formulation, definitions, notation, and other preliminaries. We use c and C throughout as generic constants that may change value with every occurrence but are independent of mesh size. To keep track of a specific value for a constant, subindices may be used.

FOSLS formulations for the Navier–Stokes equations are discussed in [1, 2, 3, 6]. In the framework of this paper, we consider the first-order velocity-flux formulation of the Navier–Stokes equations given in [1] and [2]:

$$\mathcal{L}(\mathbf{x}) = \mathsf{g} := \begin{cases} \nabla \mathbf{u}^t - \mathbf{U} = \mathbf{0} & \text{in } \Omega, \\ -(\nabla \cdot \mathbf{U})^t + \nabla p + Re\ \mathbf{U}^t \mathbf{u} = \mathbf{f} & \text{in } \Omega, \\ \nabla \cdot \mathbf{u} = 0 & \text{in } \Omega, \\ \nabla \times \mathbf{U} = \mathbf{0} & \text{in } \Omega, \\ \nabla \big(tr \mathbf{U}\big) = \mathbf{0} & \text{in } \Omega, \end{cases} \tag{2.1}$$

where Ω is a subset of $\mathbb{R}^n$ $(n = 2, 3)$ with Lipschitz continuous boundary $\partial\Omega$ and $\mathbf{f} \in L^2(\Omega)^n$. As boundary conditions, without loss of generality, we take $\mathbf{u} = \mathbf{0}$ and $\mathbf{n} \times \mathbf{U} = \mathbf{0}$ on $\partial\Omega$, where $\mathbf{n}$ is the outward unit normal on $\partial\Omega$. Writing the unknowns as $\mathbf{x} = (\mathbf{u}, \mathbf{U}, p)$, then the nonquadratic functional is constructed by taking the L^2-norm of each interior equation:

$$\mathcal{F}(\mathbf{x}; \mathsf{g}) = \|\mathcal{L}(\mathbf{x}) - \mathsf{g}\|^2_{0,\Omega}, \qquad \mathbf{x} \in \boldsymbol{\mathcal{V}}, \tag{2.2}$$

where $\mathsf{g} = (\mathbf{0}, \mathbf{f}, 0, \mathbf{0}, \mathbf{0})^T$ and the space is defined by

$$\boldsymbol{\mathcal{V}} = H^1_0(\Omega)^n \times \mathcal{V}_0 \times (H^1(\Omega)/\mathbb{R})$$

with

$$\mathcal{V}_0 = \{\mathbf{U} \in H^1(\Omega)^{n^2} : \mathbf{n} \times \mathbf{U} = \mathbf{0} \ \text{ on } \ \partial\Omega\}.$$

It is shown in [5] that the Navier–Stokes equations generally have more than one solution, unless the viscosity and the external forces satisfy very stringent requirements. However, it can also be shown that in many practical examples, these solutions are mostly isolated, i.e., there exist a neighborhood in which each solution is unique. Bifurcation phenomena are rare. We thus assume we are in a closed neighborhood, $\overline{\mathcal{B}}(\mathbf{x}_*, r)$, of an isolated solution, $\mathbf{x}_* \in \boldsymbol{\mathcal{V}}$, to (2.1), that is, a global minimum of (2.2), for which $\mathcal{F}(\mathbf{x}_*; \mathsf{g}) = 0$. The neighborhood is taken to be an H^1-ball around $\mathbf{x}_*$ with radius $r > 0$ defined as

$$\mathcal{B}(\mathbf{x}_*, r) := \big\{\mathbf{x} \in \boldsymbol{\mathcal{V}} : \|\mathbf{x} - \mathbf{x}_*\|_{1,\Omega} < r\big\},$$

where

$$\|\mathbf{x}\|^2_{1,\Omega} \equiv \|\mathbf{u}\|^2_{1,\Omega} + \|\mathbf{U}\|^2_{1,\Omega} + \|p\|^2_{1,\Omega}.$$

Its closure is $\overline{\mathcal{B}}(\mathbf{x}_*, r) = \{\mathbf{x} \in \boldsymbol{\mathcal{V}} : \|\mathbf{x} - \mathbf{x}_*\|_{1,\Omega} \leq r\}$. Several places along the way, we assume that r is so small that certain expansions we develop give us the desired bounds.

Denote by $\mathcal{L}'(\mathbf{x})[\mathbf{y}]$ the first Fréchet derivative of operator $\mathcal{L}$ at $\mathbf{x} \in \boldsymbol{\mathcal{V}}$ in direction $\mathbf{y} = (\mathbf{v}, \mathbf{V}, q) \in \boldsymbol{\mathcal{V}}$. Note that the nonlinear term, Re $\mathbf{U}^t\mathbf{u}$, in (2.1) becomes $\mathrm{Re}(\mathbf{V}^t\mathbf{u} + \mathbf{U}^t\mathbf{v})$ in $\mathcal{L}'(\mathbf{x})[\mathbf{y}]$ and that $\mathcal{L}'(\mathbf{x})[\mathbf{y}]$ is linear in $\mathbf{y}$. Also, $\mathcal{L}'(\mathbf{x})$ is the same operator as that for the Oseen equations (cf. [7]). $\mathcal{L}''(\mathbf{x})[\mathbf{y}, \mathbf{z}]$ denotes the second Fréchet derivative at $\mathbf{x}$ in directions $\mathbf{y}$ and $\mathbf{z} = (\mathbf{w}, \mathbf{W}, t) \in \boldsymbol{\mathcal{V}}$. For the linear terms of (2.1), the second Fréchet derivative is the zero operator. For the nonlinear term, we obtain $\mathrm{Re}(\mathbf{V}^t\mathbf{w} + \mathbf{W}^t\mathbf{v})$, so $\mathcal{L}''(\mathbf{x})$ is independent of $\mathbf{x}$.

Another set definition we use later is the closed line segment connecting points $\mathbf{x}, \mathbf{y} \in \boldsymbol{\mathcal{V}}$: $[\mathbf{x}, \mathbf{y}] := \{\theta\mathbf{x} + (1-\theta)\mathbf{y} : 0 \leq \theta \leq 1\}$. This notation should not be confused with the square brackets used for directional derivatives because the operator always immediately precedes the direction.

Having defined the first and second Fréchet derivatives for operator $\mathcal{L}$, we are able to express the first and second Fréchet derivatives of the nonquadratic functional in (2.2) in terms of $\mathcal{L}$ and its derivatives. For $\mathbf{x}, \mathbf{y} \in \boldsymbol{\mathcal{V}}$, the first Fréchet derivative of (2.2) in direction $\mathbf{y}$ is

$$\mathcal{F}'(\mathbf{x}; \mathbf{g})[\mathbf{y}] = 2\langle \mathcal{L}(\mathbf{x}) - \mathbf{g}, \mathcal{L}'(\mathbf{x})[\mathbf{y}] \rangle. \tag{2.3}$$

Its second Fréchet derivative in direction $[\mathbf{y}, \mathbf{y}]$ (needed later for Taylor expansions) is

$$\mathcal{F}''(\mathbf{x}; \mathbf{g})[\mathbf{y}, \mathbf{y}] = 2\,\|\mathcal{L}'(\mathbf{x})[\mathbf{y}]\|_{0,\Omega}^2 + 2\langle \mathcal{L}(\mathbf{x}) - \mathbf{g}, \mathcal{L}''(\mathbf{x})[\mathbf{y}, \mathbf{y}] \rangle. \tag{2.4}$$

Remark 1. As with all multigrid schemes, relaxation is the basis for our PML approach. One choice is steepest descent, which involves a gradient direction, $\mathbf{d}$, in $\boldsymbol{\mathcal{V}}$ and a step size, s, determined as the smallest nonnegative critical point of $\mathcal{F}(\mathbf{x} - s\mathbf{d}; \mathbf{g})$. To understand this step, it is useful to examine the polynomial

$$\mathcal{F}(\mathbf{x} - s\mathbf{d}; \mathbf{g}) = \mathcal{F}(\mathbf{x}; \mathbf{g}) - s\mathcal{F}'(\mathbf{x}; \mathbf{g})[\mathbf{d}] + \frac{s^2}{2}\mathcal{F}''(\mathbf{x}; \mathbf{g})[\mathbf{d}, \mathbf{d}] - \frac{s^3}{6}\mathcal{F}'''(\mathbf{x}; \mathbf{g})[\mathbf{d}, \mathbf{d}, \mathbf{d}] + \frac{s^4}{24}\mathcal{F}^{(4)}(\mathbf{x}; \mathbf{g})[\mathbf{d}, \mathbf{d}, \mathbf{d}, \mathbf{d}].$$

From (2.4), we see that $\mathcal{F}'''(\mathbf{x}; \mathbf{g})[\mathbf{d}, \mathbf{d}, \mathbf{d}] = 6\langle \mathcal{L}'(\mathbf{x})[\mathbf{d}], \mathcal{L}''(\mathbf{x})[\mathbf{d}, \mathbf{d}] \rangle$ and $\mathcal{F}^{(4)}(\mathbf{x}; \mathbf{g})[\mathbf{d}, \mathbf{d}, \mathbf{d}, \mathbf{d}] = 6\langle \mathcal{L}''(\mathbf{x})[\mathbf{d}, \mathbf{d}], \mathcal{L}''(\mathbf{x})[\mathbf{d}, \mathbf{d}] \rangle$. Thus, when $\mathcal{F}''(\mathbf{x}; \mathbf{g}) > 0$, an inspection of this polynomial for $s > 0$ implies that there exists a smallest nonnegative critical point, s, of $\mathcal{F}(\mathbf{x} - s\mathbf{d}; \mathbf{g})$ and that it must be a local minimum of $\mathcal{F}(\mathbf{x}, \mathbf{g})$ such that $\mathcal{F}(\mathbf{x} - s\mathbf{d}; \mathbf{g}) \leq \mathcal{F}(\mathbf{x}; \mathbf{g})$. (Note that either $\mathbf{d} = \mathbf{0}$ and $\mathcal{F}(\mathbf{x} - s\mathbf{d}; \mathbf{g}) = \mathcal{F}(\mathbf{x}; \mathbf{g})$, so $s = 0$, or $\mathcal{F}(\mathbf{x} - s\mathbf{d}; \mathbf{g})$ initially decreases but then tends to $+\infty$ as s goes from 0 to ∞.)

Similar definitions can be made for subspaces of $\boldsymbol{\mathcal{V}}$. Consider a quasi-uniform finite element partition of Ω with approximate mesh size h and let $H^h(\Omega)$ be the corresponding finite element subspace of $H^1(\Omega)$ consisting of piecewise polynomials: a function in $H^h(\Omega)$ is continuous on Ω and polynomial within each element. Let $H_0^h(\Omega)$ denote the subspace of $H^h(\Omega)$ of functions that are zero on $\partial\Omega$. Then define

$$\mathcal{S}^h = H_0^h(\Omega)^n \times \mathcal{V}_0^h \times (H^h(\Omega)/\mathbb{R}) \subset \boldsymbol{\mathcal{V}}$$

with

$$\mathcal{V}_0^h = \{\mathbf{U}^h \in H^h(\Omega)^{n^2} : \mathbf{n} \times \mathbf{U}^h = \mathbf{0} \ \text{ on } \ \partial\Omega\}.$$

Suppose also that we have a corresponding coarser $2h$ level so that the corresponding discrete space, $\mathcal{S}^{2h}$, forms a subspace of $\mathcal{S}^h$. For this paper, we assume standard nested finite element spaces, $S^{2h} \subset S^h \subset \boldsymbol{\mathcal{V}}$, that satisfy the approximation property

$$\inf_{\mathbf{x}^{2h} \in \mathcal{S}^{2h}} \|\mathbf{x}^h - \mathbf{x}^{2h}\|_{0,\Omega}^2 \leq C_1 \, h^2 \, \|\mathbf{x}^h\|_{1,\Omega}^2 \tag{2.5}$$

and the inverse estimate

$$\|\mathbf{x}^h\|_{1,\Omega}^2 \leq \frac{C_2}{h^2} \|\mathbf{x}^h\|_{0,\Omega}^2 \tag{2.6}$$

for all $\mathbf{x}^h$ in $\mathcal{S}^h$, where C_1 and C_2 are positive constants that do not depend on h (see [4]). Further, define a discrete H^1-ball by $\mathcal{B}^h(\mathbf{x}_*, r) = \{\mathbf{x}^h \in \mathcal{S}^h : \|\mathbf{x}^h - \mathbf{x}_*\|_{1,\Omega} < r\}$ and its closure by $\overline{\mathcal{B}}^h(\mathbf{x}_*, r) = \{\mathbf{x}^h \in \mathcal{S}^h : \|\mathbf{x}^h - \mathbf{x}_*\|_{1,\Omega} \leq r\}$. As we said, we choose r progressively smaller in several places in what follows. Nowhere does this requirement depend on h. However, we implicitly assume that no matter how small r becomes, h is so small that $\mathcal{B}^h(\mathbf{x}_*, r) \neq \emptyset$.

Before being able to define the relaxation scheme and two-level PML method, we introduce the discrete functional and its gradient as well as the operator norm associated with the second Fréchet derivative of functional $\mathcal{F}(\mathbf{x}; \mathsf{g})$.

DEFINITION 2.1 (discrete functional and its L^2-gradient). *Let $\mathbf{x}^h \in \overline{\mathcal{B}}^h(\mathbf{x}_*, r)$ and define $\mathcal{F}^h(\mathbf{x}^h; \mathsf{g})$ as the restriction of $\mathcal{F}(\mathbf{x}^h; \mathsf{g})$ to space $\mathcal{S}^h$. Now let $\mathbf{y}^h \in \mathcal{S}^h$. By the definition of the first Fréchet derivative, we have*

$$\mathcal{F}^{h'}(\mathbf{x}^h; \mathsf{g})[\mathbf{y}^h] = \langle \mathcal{L}(\mathbf{x}^h) - \mathsf{g}, \mathcal{L}'(\mathbf{x}^h)[\mathbf{y}^h] \rangle,$$

and, since $\mathcal{S}^h$ is finite dimensional, the Riesz representation theorem guarantees the existence of the discrete L^2-gradient, $\nabla^h \mathcal{F}(\mathbf{x}^h; \mathsf{g}) \in \mathcal{S}^h$, which satisfies

$$\mathcal{F}^{h'}(\mathbf{x}^h; \mathsf{g})[\mathbf{y}^h] = \langle \mathcal{L}'^*(\mathbf{x}^h)\big(\mathcal{L}(\mathbf{x}^h) - \mathsf{g}\big), \mathbf{y}^h \rangle =: \langle \nabla^h \mathcal{F}(\mathbf{x}^h; \mathsf{g}), \mathbf{y}^h \rangle.$$

Note that $\nabla^h \mathcal{F}(\mathbf{x}^h; \mathsf{g}) \in \mathcal{S}^h$ can be defined weakly by $\langle \nabla^h \mathcal{F}(\mathbf{x}^h; \mathsf{g}), \mathbf{y}^h \rangle = \langle \mathcal{L}(\mathbf{x}^h) - \mathsf{g}, \mathcal{L}'(\mathbf{x}^h)[\mathbf{y}^h] \rangle$ for all $\mathbf{y}^h \in \mathcal{S}^h$. Note also that $\nabla^h \mathcal{F}^h(\mathbf{x}^h; \mathsf{g}) = \nabla^h \mathcal{F}^h(\mathbf{x}^h; \mathsf{g}^h)$, where g^h is the L^2-orthogonal projection of g onto space $\mathcal{L}'(\mathbf{x}^h)\mathcal{S}^h$.

Remark 2. Denote by $\mathbf{x}_*^h$ the element in $\mathcal{S}^h$ that minimizes (2.2) over $\overline{\mathcal{B}}^h(\mathbf{x}_*, r)$. Such an element exists because this set is compact and $\mathcal{F}(\mathbf{x}; \mathsf{g})$ is continuous, as we show in Theorem 3.2. Note that if $\mathbf{x}^h \in \mathcal{B}^h(\mathbf{x}_*, r)$ (i.e., the interior of the ball), then $\mathbf{x}_*^h$ is a grid h critical point in the sense that

$$\langle \nabla^h \mathcal{F}(\mathbf{x}_*^h; \mathsf{g}), \mathbf{y}^h \rangle = \langle \mathcal{L}(\mathbf{x}_*^h) - \mathsf{g}, \mathcal{L}'(\mathbf{x}_*^h)[\mathbf{y}^h] \rangle = 0 \tag{2.7}$$

for all $\mathbf{y}^h \in \mathcal{S}^h$, provided $\mathcal{F}''(\mathbf{x}; \mathsf{g})$ is bounded on $\mathcal{B}(\mathbf{x}_*, r)$, as we show in Theorem 3.1. This follows from a standard argument based on Taylor series and outlined as follows: if

$$\begin{aligned} 0 &\leq \mathcal{F}\big(\mathbf{x}_*^h - s \nabla^h \mathcal{F}(\mathbf{x}_*^h; \mathsf{g})\big) - \mathcal{F}(\mathbf{x}_*^h; \mathsf{g}) \\ &= -s \|\nabla^h \mathcal{F}(\mathbf{x}_*^h; \mathsf{g})\|_{0,\Omega}^2 + s^2 \mathcal{F}''(\tilde{\mathbf{x}}^h; \mathsf{g})[\nabla^h \mathcal{F}(\mathbf{x}_*^h; \mathsf{g}), \nabla^h \mathcal{F}(\mathbf{x}_*^h; \mathsf{g})]; \end{aligned}$$

and, for small enough but positive s, we could make the last expression negative (a contradiction) unless $\nabla^h \mathcal{F}(\mathbf{x}_*^h; \mathsf{g}) = 0$. This standard argument is referred to later in the proof of Lemma 4.3 to show that the coarse-grid correction step of PML (described next) is determined by a grid $2h$ critical point. That $\mathbf{x}_*$ is a critical point of $\mathcal{F}(\mathbf{x}; \mathsf{g})$ in $\mathcal{B}(\mathbf{x}_*, r)$ follows simply from (2.3).

DEFINITION 2.2 (discrete operator norm of the second derivative). *Let* $\mathbf{x}^h \in \overline{\mathcal{B}}^h(\mathbf{x}_*, r)$ *and* $\mathbf{y}^h \in \mathcal{S}^h$. *Then the discrete operator norm associated with the second Fréchet derivative of functional* $\mathcal{F}(\mathbf{x}^h; \mathsf{g})$ *is defined by*

$$\left\| |\mathcal{F}''(\mathbf{x}^h; \mathsf{g})| \right\|_{0,h} = \sup_{0 \neq \mathbf{y}^h \in S^h} \frac{\left| \mathcal{F}''(\mathbf{x}^h; \mathsf{g})[\mathbf{y}^h, \mathbf{y}^h] \right|}{\langle \mathbf{y}^h, \mathbf{y}^h \rangle}.$$

Next, we define one step of relaxation. We consider two types of schemes, both of which use the discrete gradient as a descent direction. The first scheme reduces to Richardson for the linear case and the second is optimal steepest descent. The theory focuses on the Richardson-type scheme because it is simpler to analyze and it sets the stage for a simple conclusion for steepest descent.

DEFINITION 2.3 (relaxation). *One step of Richardson-type relaxation is defined by*

$$\mathbf{x}^h \leftarrow \mathbf{x}^h - \frac{\omega}{\left\| |\mathcal{F}''(\mathbf{x}^h; \mathsf{g})| \right\|_{0,h}} \nabla^h \mathcal{F}(\mathbf{x}^h; \mathsf{g}), \tag{2.8}$$

where $\nabla^h \mathcal{F}(\mathbf{x}^h; \mathsf{g})$ *is the search direction,* $1/\left\| |\mathcal{F}''(\mathbf{x}^h; \mathsf{g})| \right\|_{0,h}$ *the basic step length, and* ω *a damping parameter. One step of steepest descent is defined by*

$$\mathbf{x}^h \leftarrow \mathbf{x}^h - s \nabla^h \mathcal{F}(\mathbf{x}^h; \mathsf{g}), \tag{2.9}$$

where s *is chosen as the smallest nonnegative root of*

$$\frac{\partial \mathcal{F}}{\partial s}\Big(\left(\mathbf{x}^h - s \nabla^h \mathcal{F}(\mathbf{x}^h; \mathsf{g}) \right); \mathsf{g} \Big) = 0. \tag{2.10}$$

We now have all the ingredients needed to describe the two-level PML method. Its first step computes the nearest locally optimal coarse-grid correction, which Lemma 4.3 shows must exist uniquely provided we are close enough to $\mathbf{x}_*$. Its second step is one relaxation sweep given by either (2.8) or (2.9). The method in (2.8) is well defined because $\mathcal{F}''(\mathbf{x}^h; \mathsf{g})$ is nonzero, as Theorem 3.1 shows. The method in (2.9) is also well defined, as Remark 1 shows.

Step 1. For a given initial guess, $\mathbf{x}_0^h \in \mathcal{S}^h$, perform the coarse-grid correction step given by $\mathbf{x}_{\frac{1}{2}}^h \leftarrow \mathbf{x}_0^h + \mathbf{x}_*^{2h}$, where $\mathbf{x}_*^{2h}$ is the local minimizer of $\mathcal{F}(\mathbf{x}_0^h + \mathbf{x}^{2h}; \mathsf{g})$ (e.g., it is a grid $2h$ critical point) with minimal H^1-norm:

$$\mathbf{x}_*^{2h} = \operatorname*{argmin}_{\mathbf{x}^{2h} \in S^{2h}} \Big\{ \|\mathbf{x}^{2h}\|_{1,\Omega} : \nabla^{2h} \mathcal{F}(\mathbf{x}_0^h + \mathbf{x}^{2h}; \mathsf{g}) = 0,\ \mathcal{F}(\mathbf{x}_0^h + \mathbf{x}^{2h}; \mathsf{g}) \leq \mathcal{F}(\mathbf{x}_0^h; \mathsf{g}) \Big\}.$$

Step 2. Let $\mathbf{x}_1^h$ be the result of one relaxation step given by (2.8) or (2.9) applied to $\mathbf{x}_{\frac{1}{2}}^h$.

Further iterations of PML are defined in the obvious way, with $\mathbf{x}_k^h$ taking on the role of $\mathbf{x}_0^h$ and $\mathbf{x}_{k+1}^h$ being the result corresponding to $\mathbf{x}_1^h$ for $k = 1, 2, \ldots$.

3. Continuity and coercivity bounds. In this section, we first establish continuity and coercivity for the Oseen equations (Lemma 3.3). We then use Lemmas 3.1 and 3.3 to prove continuity and coercivity of $\mathcal{F}''(\mathbf{x};\mathbf{g})[\mathbf{y},\mathbf{y}]$ as a function of $\mathbf{y} \in \boldsymbol{\mathcal{V}}$, for all $\mathbf{x} \in \overline{\mathcal{B}}(\mathbf{x}_*, r)$ (Theorem 3.1). The results in this section help us later to establish the key objective of our two-level method: one cycle of two-level PML reduces the functional norm by a factor that is bounded uniformly below 1 (Theorem 4.1).

LEMMA 3.1. *There exist a* γ_0*, depending only on* Re *and* Ω*, such that*

$$\|\mathcal{L}''(\mathbf{x})[\mathbf{y},\mathbf{z}]\|_{0,\Omega} \;\leq\; \gamma_0 \|\mathbf{y}\|_{1,\Omega} \|\mathbf{z}\|_{1,\Omega}$$

for all $\mathbf{x}, \mathbf{y}$*, and* $\mathbf{z}$ *in* $\boldsymbol{\mathcal{V}}$*.*

Proof. Recall for $\mathbf{x} = (\mathbf{u}, \mathbf{U}, p)$, $\mathbf{y} = (\mathbf{v}, \mathbf{W}, q)$, and $\mathbf{z} = (\mathbf{w}, \mathbf{W}, t)$ in $\boldsymbol{\mathcal{V}}$ that the second Fréchet derivative for the linear terms of (2.1) is the zero operator. For the nonlinear term, we obtain $\mathrm{Re}(\mathbf{V}^t\mathbf{w} + \mathbf{W}^t\mathbf{v})$. Then, the result follows directly from the Sobolev imbedding theorem about multiplication in Sobolev spaces (Corollary I.1.1 in [5]). ∎

LEMMA 3.2. *For all* $\mathbf{x} = (\mathbf{u}, \mathbf{U}, p) \in \boldsymbol{\mathcal{V}}$*, there exist two positive constants,* $\tilde{c}_3$ *and* $\tilde{C}_3$*, depending only on* Re*,* $\mathbf{x}$*, and* Ω*, such that*

$$\tilde{c}_3(\mathbf{x}) \; \|\mathbf{y}\|_{1,\Omega}^2 \;\leq\; \|\mathcal{L}'(\mathbf{x})[\mathbf{y}]\|_{0,\Omega}^2 \;\leq\; \tilde{C}_3(\mathbf{x}) \; \|\mathbf{y}\|_{1,\Omega}^2$$

for all $\mathbf{y} = (\mathbf{v}, \mathbf{V}, q) \in \boldsymbol{\mathcal{V}}$*.*

Proof. We use the derivation of the regularity estimate, as well as Theorems 3.2, 4.1, and 4.2 in [7], as guidelines for the proof of this lemma. Analogous to the continuity and coercivity proof for $\mathcal{L}'\big((\mathbf{u},p)\big)\big[(\mathbf{v},\mathbf{V},q)\big]$ in [7], we start from the Oseen equations in the following form:

$$\begin{aligned} -\Delta\mathbf{v} + Re\big[(\nabla\mathbf{v}^t)^t\mathbf{u} + \mathbf{U}^t\mathbf{v}\big] + \nabla q &= \mathbf{f}, \\ \nabla\cdot\mathbf{v} &= g, \end{aligned} \tag{3.1}$$

where $g \in L^2(\Omega)$. The first equation differs from that in [7] because $\mathbf{U}$ is used instead of $\nabla\mathbf{u}^t$. We also relax the smoothness assumption by only requiring $\mathbf{u}$ and $\mathbf{U}$ to be in $H_0^1(\Omega)^n$ and $\mathcal{V}_0$, respectively. ([7] requires $\mathbf{u}$ to be in $H_0^2(\Omega)^n$.)

First, we establish an a priori H^1-regularity estimate for the equations in (3.1): if Ω has Lipschitz boundary, then, for $\mathbf{f} \in H_0^{-1}(\Omega)^n$ and $g \in L_0^2(\Omega)$, the weak solution of (3.1), $(\mathbf{v}, q) \in H_0^1(\Omega)^n \times L_0^2(\Omega)$, satisfies the a priori estimate

$$\|\nabla\mathbf{v}^t\|_{0,\Omega} + \|q\|_{0,\Omega} \leq \mathrm{const}\,\big(\|\mathbf{f}\|_{-1,\Omega} + \|g\|_{0,\Omega} + \|\mathbf{v}\|_{\delta_\circ+\delta,\Omega}\big) \tag{3.2}$$

for $\delta \in (0, \frac{1}{2})$, where $\delta_\circ = 0$ for $\Omega \subset \mathbb{R}^2$ and $\delta_\circ = \frac{1}{2}$ for $\Omega \subset \mathbb{R}^3$.

To prove this estimate, we first take the pointwise dot product of the first equation of (3.1) with any $\boldsymbol{\psi} \in H_0^1(\Omega)^n$ and the dot product of the second equation of (3.1) with any $\phi \in L^2(\Omega)$, integrate it over Ω, and use integration by parts. This yields

$$\begin{aligned} \langle\nabla\mathbf{v}^t, \nabla\boldsymbol{\psi}^t\rangle + Re\langle(\nabla\mathbf{v}^t)^t\mathbf{u} + \mathbf{U}^t\mathbf{v}, \boldsymbol{\psi}\rangle - \langle q, \nabla\cdot\boldsymbol{\psi}\rangle &= \langle\mathbf{f}, \boldsymbol{\psi}\rangle, \\ \langle\nabla\cdot\mathbf{v}, \phi\rangle &= \langle g, \phi\rangle. \end{aligned} \tag{3.3}$$

Since $g \in L^2(\Omega)$, we can choose an $\mathbf{s} \in H_0^1(\Omega)^n$, according to Lemma 4.1 in [7], such that

$$\nabla\cdot\mathbf{s} = g \quad \text{and} \quad |\mathbf{s}|_{1,\Omega} \leq C\|g\|_{0,\Omega}. \tag{3.4}$$

Then, setting $\boldsymbol{v} = \mathbf{v} - \mathbf{s} \in H_0^1(\Omega)^n$ in (3.3), we have

(3.5)
$$\begin{cases} \langle \nabla \boldsymbol{v}^t, \nabla \boldsymbol{\psi}^t \rangle + \mathrm{Re}\langle (\nabla \boldsymbol{v}^t)^t \mathbf{u} + \mathbf{U}^t \boldsymbol{v}, \boldsymbol{\psi} \rangle - \langle q, \nabla \cdot \boldsymbol{\psi} \rangle &= \langle \mathbf{f}, \boldsymbol{\psi} \rangle - \langle \nabla \mathbf{s}^t, \nabla \boldsymbol{\psi}^t \rangle \\ & \quad - \mathrm{Re}\langle (\nabla \mathbf{s}^t)^t \mathbf{u} + \mathbf{U}^t \mathbf{s}, \boldsymbol{\psi} \rangle, \\ \langle \nabla \cdot \boldsymbol{v}, \phi \rangle &= \langle 0, \phi \rangle \end{cases}$$

for any $\boldsymbol{\psi} \in H_0^1(\Omega)^n$ and $\phi \in L^2(\Omega)$. For the first equation in (3.5), by taking $\boldsymbol{\psi} = \boldsymbol{v}$, we obtain

(3.6)
$$\begin{aligned} \|\nabla \boldsymbol{v}^t\|_{0,\Omega}^2 &= \langle \mathbf{f}, \boldsymbol{v} \rangle - \langle \nabla \mathbf{s}^t, \nabla \boldsymbol{v}^t \rangle - \mathrm{Re}\big(\langle (\nabla \boldsymbol{v}^t)^t \mathbf{u} + \mathbf{U}^t \boldsymbol{v}, \boldsymbol{v} \rangle + \langle (\nabla \mathbf{s}^t)^t \mathbf{u} + \mathbf{U}^t \mathbf{s}, \boldsymbol{v} \rangle\big) \\ &\le |\langle \mathbf{f}, \boldsymbol{v} \rangle| + |\langle \nabla \mathbf{s}^t, \nabla \boldsymbol{v}^t \rangle| \\ &\quad + \mathrm{Re}\ |\langle \mathbf{U}^t \boldsymbol{v}, \boldsymbol{v} \rangle + \langle (\nabla \boldsymbol{v}^t)^t \mathbf{u}, \boldsymbol{v} \rangle + \langle \mathbf{U}^t \mathbf{s}, \boldsymbol{v} \rangle + \langle (\nabla \mathbf{s}^t)^t \mathbf{u}, \boldsymbol{v} \rangle|. \end{aligned}$$

For the first term of the upper bound in (3.6), recall the definition of the $H^{-1}(\Omega)$ norm:

$$\|\mathbf{f}\|_{-1,\Omega} := \sup_{0 \neq \boldsymbol{v} \in H_0^1(\Omega)} \frac{\langle \mathbf{f}, \boldsymbol{v} \rangle}{|\boldsymbol{v}|_{1,\Omega}} \ \Rightarrow \frac{\langle \mathbf{f}, \boldsymbol{v} \rangle}{|\boldsymbol{v}|_{1,\Omega}} \le \|\mathbf{f}\|_{-1,\Omega} \forall \boldsymbol{v} \neq 0 \in H_0^1(\Omega)^n.$$

Hence for all $\boldsymbol{v} \neq 0 \in H_0^1(\Omega)^n$, we have $\langle \mathbf{f}, \boldsymbol{v} \rangle \le \|\mathbf{f}\|_{-1,\Omega} \|\nabla \boldsymbol{v}\|_{0,\Omega}$. To bound the second term, we use the Cauchy–Schwarz inequality:

$$\langle \nabla \mathbf{s}^t, \nabla \boldsymbol{v}^t \rangle \ \le \ \|\nabla \mathbf{s}^t\|_{0,\Omega} \|\nabla \boldsymbol{v}^t\|_{0,\Omega} \ = \ |\mathbf{s}|_{1,\Omega} \|\nabla \boldsymbol{v}^t\|_{0,\Omega} \overset{(3.4)}{\le} C \|g\|_{0,\Omega} \|\nabla \boldsymbol{v}^t\|_{0,\Omega}.$$

It remains to derive bounds for the last four terms, which are classified in [5] as trilinear. In the following, C denotes a generic constant that might depend on Re, $\Omega, \|\mathbf{u}\|_1$, and $\|\mathbf{U}\|_1$.

According to the Sobolev imbedding theorem I.1.3 in [5], the space $H^1(\Omega)$ is continuously embedded in $L^4(\Omega)$ for $n \le 4$. Then,

$$\begin{aligned} |\langle \mathbf{U}\boldsymbol{v}, \boldsymbol{v} \rangle| = \left| \sum_{i,j=1}^{n} \int_\Omega v_j U_{ij} v_i \, dx \right| &\le \sum_{i,j=1}^{n} \|v_j\|_{0,\Omega} \|U_{ij}\|_{0,4,\Omega} \|v_i\|_{0,4,\Omega} \\ &\le C \|\boldsymbol{v}\|_{0,\Omega} \|\mathbf{U}\|_{1,\Omega} \|\boldsymbol{v}\|_{1,\Omega} \le \ C \|\boldsymbol{v}\|_{\delta_\diamond + \delta, \Omega} \|\mathbf{U}\|_{1,\Omega} |\boldsymbol{v}|_{1,\Omega}. \end{aligned} \tag{3.7}$$

The last inequality is a result of the Poincaré–Friedrichs inequality ($\|\boldsymbol{v}\|_{1,\Omega} \le C|\boldsymbol{v}|_{1,\Omega}$). Applying the Sobolev imbedding theorem to the second trilinear term leads to

$$\langle (\nabla \boldsymbol{v}^t)^t \mathbf{u}, \boldsymbol{v} \rangle \le \|\nabla \boldsymbol{v}^t\|_{0,\Omega} \|\mathbf{u}^t \boldsymbol{v}\|_{0,\Omega} \le \|\nabla \boldsymbol{v}^t\|_{0,\Omega} \|\mathbf{u}\|_{1,\Omega} \|\boldsymbol{v}\|_{\delta_\diamond + \delta, \Omega}. \tag{3.8}$$

Similar arguments hold for the remaining two trilinear terms. Hence,

$$\langle \mathbf{U}^t \mathbf{s}, \boldsymbol{v} \rangle \ \le C \ \|\mathbf{U}\|_{1,\Omega} |\mathbf{s}|_{1,\Omega} \|\boldsymbol{v}\|_{1,\Omega} \le C \ \|\mathbf{U}\|_{1,\Omega} \|\nabla \boldsymbol{v}^t\|_{0,\Omega} \|g\|_{0,\Omega} \tag{3.9}$$

and

$$\langle (\nabla \mathbf{s}^t)^t \mathbf{u}, \boldsymbol{v} \rangle \ \le C \ |\mathbf{s}|_{1,\Omega} \|\mathbf{u}\|_{1,\Omega} \|\boldsymbol{v}\|_{1,\Omega} \le C \ \|\mathbf{u}\|_{1,\Omega} \|\nabla \boldsymbol{v}^t\|_{0,\Omega} \|g\|_{0,\Omega}. \tag{3.10}$$

Combining the results yields

$$\|\nabla \boldsymbol{v}^t\|_{0,\Omega}^2 \le \|\mathbf{f}\|_{-1,\Omega}\|\nabla \boldsymbol{v}\|_{0,\Omega} + C\|g\|_{0,\Omega}\|\nabla \boldsymbol{v}\|_{0,\Omega} + C\|\mathbf{U}\|_{1,\Omega}\|\boldsymbol{v}\|_{\delta_\circ+\delta,\Omega}\|\nabla \boldsymbol{v}\|_{0,\Omega} + C\big(\|\mathbf{U}\|_{1,\Omega} + \|\mathbf{u}\|_{1,\Omega}\big)\|g\|_{0,\Omega}\|\nabla \boldsymbol{v}\|_{0,\Omega}.$$

Canceling $\|\nabla \boldsymbol{v}\|_{0,\Omega}$ gives

$$\|\nabla \boldsymbol{v}^t\|_{0,\Omega} \le C(\mathrm{Re}, \|\mathbf{u}\|_{1,\Omega}, \|\mathbf{U}\|_{1,\Omega}, \Omega)\Big[\|\mathbf{f}\|_{-1,\Omega} + \|g\|_{0,\Omega} + \|\boldsymbol{v}\|_{\delta_\circ+\delta,\Omega}\Big]. \tag{3.11}$$

To bound q, choose $\boldsymbol{\psi} \in H_0^1(\Omega)^n$ according to Lemma 4.1 in [7] such that

$$\nabla\cdot \boldsymbol{\psi} = q \quad \text{and} \quad |\boldsymbol{\psi}|_{1,\Omega} \le C\|q\|_{0,\Omega}. \tag{3.12}$$

Using again the first equation of (3.5), we obtain

$$\begin{aligned}\|q\|_{0,\Omega}^2 &= \langle \nabla \boldsymbol{v}^t, \nabla \boldsymbol{\psi}^t\rangle + Re\langle (\nabla \boldsymbol{v}^t)^t\mathbf{u} + \mathbf{U}^t\boldsymbol{v}, \boldsymbol{\psi}\rangle \\ &\quad - \langle \mathbf{f}, \boldsymbol{\psi}\rangle + \langle \nabla \mathbf{s}^t, \nabla \boldsymbol{\psi}^t\rangle + Re\langle (\nabla \mathbf{s}^t)^t\mathbf{u} + \mathbf{U}^t\mathbf{s}, \boldsymbol{\psi}\rangle \\ &\le \langle \nabla \boldsymbol{v}^t, \nabla \boldsymbol{\psi}^t\rangle + Re\langle (\nabla \boldsymbol{v}^t)^t\mathbf{u} + \mathbf{U}^t\boldsymbol{v}, \boldsymbol{\psi}\rangle \\ &\quad + |\langle \mathbf{f}, \boldsymbol{\psi}\rangle| + \langle \nabla \mathbf{s}^t, \nabla \boldsymbol{\psi}^t\rangle + Re\langle (\nabla \mathbf{s}^t)^t\mathbf{u} + \mathbf{U}^t\mathbf{s}, \boldsymbol{\psi}\rangle.\end{aligned}$$

We proceed similarly as with the bound $\|\nabla \boldsymbol{v}^t\|_{0,\Omega}$. For all $\boldsymbol{\psi} \ne 0 \in H_0^1(\Omega)^n$,

$$\langle \mathbf{f}, \boldsymbol{\psi}\rangle \le \|\mathbf{f}\|_{-1,\Omega}|\boldsymbol{\psi}|_{1,\Omega} \overset{(3.12)}{\le} C\|\mathbf{f}\|_{-1,\Omega}\|q\|_{0,\Omega}, \tag{3.13}$$

$$\langle \nabla \boldsymbol{v}^t, \nabla \boldsymbol{\psi}^t\rangle \le \|\nabla \boldsymbol{v}^t\|_{0,\Omega}\|\nabla \boldsymbol{\psi}^t\|_{0,\Omega} = |\boldsymbol{v}|_{1,\Omega}|\boldsymbol{\psi}|_{1,\Omega} \overset{(3.12)}{\le} C|\boldsymbol{v}|_{1,\Omega}\|q\|_{0,\Omega}, \tag{3.14}$$

and

$$\langle \nabla \mathbf{s}^t, \nabla \boldsymbol{\psi}^t\rangle \le \|\nabla \mathbf{s}^t\|_{0,\Omega}\|\nabla \boldsymbol{\psi}^t\|_{0,\Omega} = |\mathbf{s}|_{1,\Omega}|\boldsymbol{\psi}|_{1,\Omega} \overset{(3.12)}{\le} C|\mathbf{s}|_{1,\Omega}\|q\|_{0,\Omega}. \tag{3.15}$$

The bounds for trilinear terms $\langle (\nabla \boldsymbol{v}^t)^t\mathbf{u}, \boldsymbol{\psi}\rangle$ and $\langle (\nabla \mathbf{s}^t)^t\mathbf{u}, \boldsymbol{\psi}\rangle$ follow directly by applying Lemma IV.2.1 in [5] and the Poincaré–Friedrichs inequality:

$$\langle (\nabla \boldsymbol{v}^t)^t\mathbf{u}, \boldsymbol{\psi}\rangle \le C\,|\boldsymbol{v}|_{1,\Omega}\|\mathbf{u}\|_{1,\Omega}\|\boldsymbol{\psi}\|_{1,\Omega} \le C\,\|\mathbf{u}\|_{1,\Omega}\|\nabla \boldsymbol{v}^t\|_{0,\Omega}|\boldsymbol{\psi}|_{1,\Omega} \tag{3.16}$$

and

$$\langle (\nabla \mathbf{s}^t)^t\mathbf{u}, \boldsymbol{\psi}\rangle \le C\,|\mathbf{s}|_{1,\Omega}\|\mathbf{u}\|_{1,\Omega}\|\boldsymbol{\psi}\|_{1,\Omega} \le C\,\|\mathbf{u}\|_{1,\Omega}|\mathbf{s}|_{1,\Omega}|\boldsymbol{\psi}|_{1,\Omega}. \tag{3.17}$$

For the remaining trilinear terms, we follow the argument in (3.7):

$$\langle \mathbf{U}^t\boldsymbol{v}, \boldsymbol{\psi}\rangle \le C\,\|\mathbf{U}\|_{1,\Omega}\|\boldsymbol{v}\|_{1,\Omega}|\boldsymbol{\psi}|_{1,\Omega} \le C\,\|\mathbf{U}\|_{1,\Omega}\|\nabla \boldsymbol{v}^t\|_{0,\Omega}|\boldsymbol{\psi}|_{1,\Omega} \tag{3.18}$$

and

$$\langle \mathbf{U}^t\mathbf{s}, \boldsymbol{\psi}\rangle \le C\,\|\mathbf{U}\|_{1,\Omega}\|\mathbf{s}\|_{1,\Omega}|\boldsymbol{\psi}|_{1,\Omega} \le C\,\|\mathbf{U}\|_{1,\Omega}|\mathbf{s}|_{1,\Omega}|\boldsymbol{\psi}|_{1,\Omega}. \tag{3.19}$$

With (3.13)–(3.19), we have

$$\begin{aligned}\|q\|_{0,\Omega}^2 &\le C\|\mathbf{f}\|_{-1,\Omega}\|q\|_{0,\Omega} + C|\boldsymbol{v}|_{1,\Omega}\|q\|_{0,\Omega} + C|\mathbf{s}|_{1,\Omega}\|q\|_{0,\Omega} \\ &\quad + C\Big(\|\nabla \boldsymbol{v}^t\|_{0,\Omega} + |\mathbf{s}|_{1,\Omega}\Big)|\boldsymbol{\psi}|_{1,\Omega} \\ &\overset{(3.12)}{\le} C(\mathrm{Re}, \|\mathbf{u}\|_{1,\Omega}, \|\mathbf{U}\|_{1,\Omega}, \Omega)\Big(\|\mathbf{f}\|_{-1,\Omega} + \|\nabla \boldsymbol{v}^t\|_{0,\Omega} + |\mathbf{s}|_{1,\Omega}\Big)\|q\|_{0,\Omega} \\ &\overset{(3.4),(3.11)}{\le} C(\mathrm{Re}, \|\mathbf{u}\|_{1,\Omega}, \|\mathbf{U}\|_{1,\Omega}, \Omega)\Big(\|\mathbf{f}\|_{-1,\Omega} + \|g\|_{0,\Omega} + \|\boldsymbol{v}\|_{\delta_\circ+\delta,\Omega}\Big)\|q\|_{0,\Omega}.\end{aligned}$$

Canceling $\|q\|_{0,\Omega}$ results in

$$\|q\|_{0,\Omega} \;\le\; C(\mathrm{Re}, \|\mathbf{u}\|_{1,\Omega}, \|\mathbf{U}\|_{1,\Omega}, \Omega)\Big(\|\mathbf{f}\|_{-1,\Omega} + \|g\|_{0,\Omega} + \|\boldsymbol{v}\|_{\delta_\circ+\delta,\Omega}\Big). \tag{3.20}$$

Recall that we seek an estimate for $\|\nabla \mathbf{v}^t\|_{0,\Omega} + \|q\|_{0,\Omega}$ in terms of $\mathbf{v}$ and q and not for $\|\nabla \boldsymbol{v}^t\|_{0,\Omega} + \|q\|_{0,\Omega}$ in terms of $\boldsymbol{v}$ and q. Earlier, we defined $\boldsymbol{v}$ to be the difference between $\mathbf{v}$ and $\mathbf{s}$. Now, adding $\mathbf{s}$ to $\boldsymbol{v}$ leads to estimates for $\|\nabla \mathbf{v}^t\|_{0,\Omega} + \|q\|_{0,\Omega}$ in terms of $\mathbf{v}$ and q:

$$\begin{aligned}
\|\nabla \mathbf{v}^t\|_{0,\Omega} \;&\le\; \|\nabla \boldsymbol{v}^t + \nabla \mathbf{s}^t\|_{0,\Omega} \le\; \|\nabla \boldsymbol{v}^t\|_{0,\Omega} + \|\nabla \mathbf{s}^t\|_{0,\Omega} \\
&\overset{(3.11)}{\le}\; C(\mathrm{Re}, \|\mathbf{u}\|_{1,\Omega}, \|\mathbf{U}\|_{1,\Omega}, \Omega)\Big[\|\mathbf{f}\|_{-1,\Omega} + \|g\|_{0,\Omega} + \|\boldsymbol{v}\|_{\delta_\circ+\delta,\Omega} + \|\nabla \mathbf{s}^t\|_{0,\Omega}\Big] \\
&\le\; C(\mathrm{Re}, \|\mathbf{u}\|_{1,\Omega}, \|\mathbf{U}\|_{1,\Omega}, \Omega)\Big[\|\mathbf{f}\|_{-1,\Omega} + \|g\|_{0,\Omega} + \|\mathbf{v}\|_{\delta_\circ+\delta,\Omega} + C|\mathbf{s}|_{1,\Omega}\Big] \\
&\overset{(3.4)}{\le}\; C(\mathrm{Re}, \|\mathbf{u}\|_{1,\Omega}, \|\mathbf{U}\|_{1,\Omega}, \Omega)\Big[\|\mathbf{f}\|_{-1,\Omega} + \|g\|_{0,\Omega} + \|\mathbf{v}\|_{\delta_\circ+\delta,\Omega} + C\|g\|_{0,\Omega}\Big] \\
&\le\; C(\mathrm{Re}, \|\mathbf{u}\|_{1,\Omega}, \|\mathbf{U}\|_{1,\Omega}, \Omega)\Big[\|\mathbf{f}\|_{-1,\Omega} + \|g\|_{0,\Omega} + \|\mathbf{v}\|_{\delta_\circ+\delta,\Omega}\Big].
\end{aligned}$$

Similarly,

$$\begin{aligned}
\|q\|_{0,\Omega} &\le C(\mathrm{Re}, \|\mathbf{u}\|_{1,\Omega}, \|\mathbf{U}\|_{1,\Omega}, \Omega)\Big[\|\mathbf{f}\|_{-1,\Omega} + \|g\|_{0,\Omega} + \|\boldsymbol{v}\|_{\delta_\circ+\delta,\Omega}\Big] \\
&\le C(\mathrm{Re}, \|\mathbf{u}\|_{1,\Omega}, \|\mathbf{U}\|_{1,\Omega}, \Omega)\Big[\|\mathbf{f}\|_{-1,\Omega} + \|g\|_{0,\Omega} + \|\mathbf{v}\|_{\delta_\circ+\delta,\Omega}\Big].
\end{aligned}$$

Combining the bounds for $\|\nabla \mathbf{v}^t\|_{0,\Omega}$ and $\|q\|_{0,\Omega}$ results in the a priori estimate

$$\|\nabla \mathbf{v}^t\|_{0,\Omega} + \|q\|_{0,\Omega} \;\le\; C(\mathrm{Re}, \|\mathbf{u}\|_{1,\Omega}, \|\mathbf{U}\|_{1,\Omega}, \Omega)\Big[\|\mathbf{f}\|_{-1,\Omega} + \|g\|_{0,\Omega} + \|\mathbf{v}\|_{\delta_\circ+\delta,\Omega}\Big]. \tag{3.21}$$

Theorem 4.1 in [7] removes the $\|\mathbf{v}\|_{\delta_\circ+\delta,\Omega}$ term by assuming uniqueness of the solution, $(\mathbf{v}, \mathbf{V}, q) \in \boldsymbol{\mathcal{V}}$. This is a direct consequence of the standard compactness argument. Since $H_0^1(\Omega)$ is compact in $H^{\delta_\circ+\delta}(\Omega)$, where $\delta \in (0, \frac{1}{2})$ and $\delta_\circ = 0$ or $\frac{1}{2}$ depending on the spatial dimension of the domain, we can apply the standard compactness argument to (3.21) in a way similar to the estimate $\|\nabla \mathbf{v}^t\|_{0,\Omega} + \|q\|_{0,\Omega} \;\le\; C(\mathrm{Re}, \mathbf{u}, \Omega)\big[\|\mathbf{f}\|_{-1,\Omega} + \|g\|_{0,\Omega} + \|\mathbf{v}\|_{0,\Omega}\big]$ in the proof of Theorem 4.1 of [7]. We also note that the slightly different constant in (3.21) (compared to the regularity estimate in [7]) has no further implications in [7] on Theorems 3.2, 4.1, and 4.2 or their proofs. Thus, we obtain continuity and coercivity for $\mathcal{L}'(\mathbf{x})[\mathbf{y}]$ under the somewhat weaker assumptions of $\mathbf{x}$ and $\mathbf{y}$ being in $\boldsymbol{\mathcal{V}}$.

We conclude that there exist two positive constants, $\tilde{c_3}$ and $\tilde{C}_3$, which depend on Re, the H^1-norm of $\mathbf{u}$ and $\mathbf{U}$, and Ω, such that

$$\tilde{c_3}(\mathbf{x})\; \|\mathbf{y}\|_{1,\Omega}^2 \;\le\; \|\mathcal{L}'(\mathbf{x})[\mathbf{y}]\|_{0,\Omega}^2 \;\le\; \tilde{C}_3(\mathbf{x})\; \|\mathbf{y}\|_{1,\Omega}^2$$

for all $\mathbf{y} \in \boldsymbol{\mathcal{V}}$. ∎

The next lemma establishes for all $\mathbf{x} \in \overline{\mathcal{B}}(\mathbf{x}_*, r)$ and r sufficiently small a uniform coercivity and continuity bound on $\|\mathcal{L}'(\mathbf{x})[\mathbf{y}]\|_{0,\Omega}^2$.

LEMMA 3.3. *Let $\mathbf{x}_*$ be an isolated solution of (2.2) and let $\tilde{c}_3(\mathbf{x}_*)$ and $\tilde{C}_3(\mathbf{x}_*)$ be the respective coercivity and continuity constants as defined in Lemma 3.2. Then,*

$$c_3\|\mathbf{y}\|_{1,\Omega}^2 \;\le\; \|\mathcal{L}'(\mathbf{x})[\mathbf{y}]\|_{0,\Omega}^2 \;\le\; C_3\|\mathbf{y}\|_{1,\Omega}^2$$

for all $\mathbf{x} = (\mathbf{u}, \mathbf{U}, p) \in \overline{\mathcal{B}}(\mathbf{x}_*, r)$, $\mathbf{y} = (\mathbf{v}, \mathbf{V}, q)$, *and* $\mathbf{z} = (\mathbf{w}, \mathbf{W}, t) \in \boldsymbol{\mathcal{V}}$, *where* $c_3 := \tilde{c}_3(\mathbf{x}_*) - \gamma_0 r^2 > 0$ *provided* $r < \sqrt{\tilde{c}_3(\mathbf{x}_*)/\gamma_0}$ *and* $C_3 := \tilde{C}_3(\mathbf{x}_*) + \gamma_0 r^2 > 0$.

Proof. For all $\mathbf{x}, \mathbf{y} \in \overline{\mathcal{B}}(\mathbf{x}_*, r)$ and r determined later, Lemma 3.2 implies that

$$\begin{aligned}
\|\mathcal{L}'(\mathbf{x})[\mathbf{y}]\|_{0,\Omega}^2 &= \|\mathcal{L}'(\mathbf{x})[\mathbf{y}] - \mathcal{L}'(\mathbf{x}_*)[\mathbf{y}] + \mathcal{L}'(\mathbf{x}_*)[\mathbf{y}]\|_{0,\Omega}^2 \\
&\le \|\mathcal{L}''(\tilde{\mathbf{x}})[\mathbf{x} - \mathbf{x}_*, \mathbf{y}]\|_{0,\Omega}^2 + \|\mathcal{L}'(\mathbf{x}_*)[\mathbf{y}]\|_{0,\Omega}^2 \\
&\le \big(\gamma_0 \|\mathbf{x} - \mathbf{x}_*\|_{1,\Omega}^2 + \tilde{C}_3(\mathbf{x}_*)\big) \|\mathbf{y}\|_{1,\Omega}^2 \\
&\le \big(\gamma_0 r^2 + \tilde{C}_3(\mathbf{x}_*)\big) \|\mathbf{y}\|_{1,\Omega}^2 =: \; C_3 \|\mathbf{y}\|_{1,\Omega}^2
\end{aligned}$$

and

$$\begin{aligned}
\|\mathcal{L}'(\mathbf{x})[\mathbf{y}]\|_{0,\Omega}^2 &= \|\mathcal{L}'(\mathbf{x})[\mathbf{y}] - \mathcal{L}'(\mathbf{x}_*)[\mathbf{y}] + \mathcal{L}'(\mathbf{x}_*)[\mathbf{y}]\|_{0,\Omega}^2 \\
&\ge \; - \|\mathcal{L}''(\tilde{\mathbf{x}})[\mathbf{x} - \mathbf{x}_*, \mathbf{y}]\|_{0,\Omega}^2 + \|\mathcal{L}'(\mathbf{x}_*)[\mathbf{y}]\|_{0,\Omega}^2 \\
&\ge \big(- \gamma_0 \|\mathbf{x} - \mathbf{x}_*\|_{1,\Omega}^2 + \tilde{c}_3(\mathbf{x}_*)\big) \|\mathbf{y}\|_{1,\Omega}^2 \\
&\ge \big(- \gamma_0 r^2 + \tilde{c}_3(\mathbf{x}_*)\big) \|\mathbf{y}\|_{1,\Omega}^2 =: \; c_3 \|\mathbf{y}\|_{1,\Omega}^2.
\end{aligned}$$

Constant C_3 is obviously positive and $r < \sqrt{\frac{\tilde{c}_3(\mathbf{x}_*)}{\gamma_0}}$ ensures that c_3 is positive. ∎

Note that c_3 and C_3 in Lemma 3.3 depend only on Re, r, and Ω.

Next, we derive continuity and coercivity results for the full nonquadratic functional, $\mathcal{F}(\mathbf{x}; \mathbf{g})$. First, we establish these results for its second Fréchet derivative. Then, almost as a direct implication of this, we achieve continuity and coercivity for the functional norm itself. We restrict ourselves to an r that is small enough to ensure that all of these results hold uniformly for $\mathbf{x} \in \overline{\mathcal{B}}(\mathbf{x}_*, r)$.

THEOREM 3.1. *There exists an* $r > 0$ *such that for any* $\mathbf{x} \in \overline{\mathcal{B}}(\mathbf{x}_*, r)$, *the second Fréchet derivative of* $\mathcal{F}(\mathbf{x}; \mathbf{g})$ *in direction* $[\mathbf{y}, \mathbf{y}]$, $\mathbf{y} \in \boldsymbol{\mathcal{V}}$, *is* positive. *Furthermore, there exist two positive constants,* c_4 *and* C_4, *which depend only on* Re, r, *and* Ω, *such that*

$$\mathcal{F}''(\mathbf{x}; \mathbf{g})[\mathbf{y}, \mathbf{z}] \;\le\; C_4 \|\mathbf{y}\|_{1,\Omega} \|\mathbf{z}\|_{1,\Omega} \tag{3.22}$$

and

$$c_4 \|\mathbf{y}\|_{1,\Omega}^2 \;\le\; \mathcal{F}''(\mathbf{x}; \mathbf{g})[\mathbf{y}, \mathbf{y}] \tag{3.23}$$

for any $\mathbf{x} \in \overline{\mathcal{B}}(\mathbf{x}_*, r)$ *and all* $\mathbf{y} \in \boldsymbol{\mathcal{V}}$.

Proof. First, we show that $\mathcal{F}''(\mathbf{x}; \mathbf{g})[\mathbf{y}, \mathbf{y}]$ is positive. Let $\mathbf{x} \in \overline{\mathcal{B}}(\mathbf{x}_*, r)$, with $r < \sqrt{\frac{\tilde{c}_3(\mathbf{x}_*)}{\gamma_0}}$, as in the proof of Lemma 3.3. Then the Cauchy–Schwarz inequality and Lemmas 3.1 and 3.3 show that

$$\begin{aligned}
\langle \mathcal{L}(\mathbf{x}) - g, \mathcal{L}''(\mathbf{x})[\mathbf{y}, \mathbf{y}] \rangle &= \; \langle \mathcal{L}'(\tilde{\mathbf{x}})[\mathbf{x} - \mathbf{x}_*], \mathcal{L}''(\mathbf{x})[\mathbf{y}, \mathbf{y}] \rangle \\
&\le \; \|\mathcal{L}'(\tilde{\mathbf{x}})[\mathbf{x} - \mathbf{x}_*]\|_{0,\Omega} \cdot \|\mathcal{L}''(\mathbf{x})[\mathbf{y}, \mathbf{y}]\|_{0,\Omega} \\
&\le \; \sqrt{C_3 \gamma_0} \; \|\mathbf{x} - \mathbf{x}_*\|_{1,\Omega} \|\mathbf{y}\|_{1,\Omega}^2,
\end{aligned} \tag{3.24}$$

where $\tilde{\mathbf{x}} \in [\mathbf{x}_*, \mathbf{x}] \subset \overline{\mathcal{B}}(\mathbf{x}_*, r)$. Then, by (2.4), (3.24), and Lemma 3.3, we have

$$\begin{aligned}
\mathcal{F}''(\mathbf{x};\mathsf{g})[\mathbf{y},\mathbf{y}] &= 2\ \|\mathcal{L}'(\mathbf{x})[\mathbf{y}]\|_{0,\Omega}^2 + 2\langle \mathcal{L}(\mathbf{x}) - \mathsf{g}, \mathcal{L}''(\mathbf{x})[\mathbf{y},\mathbf{y}]\rangle \\
&\geq 2c_3\|\mathbf{y}\|_{1,\Omega}^2 - 2\sqrt{C_3}\gamma_0\ \|\mathbf{x}-\mathbf{x}_*\|_{1,\Omega}\|\mathbf{y}\|_{1,\Omega}^2 \\
&= \left(2c_3 - 2\sqrt{C_3}\gamma_0\ \|\mathbf{x}-\mathbf{x}_*\|_{1,\Omega}\right)\|\mathbf{y}\|_{1,\Omega}^2 \\
&= \left(2\tilde{c}_3(\mathbf{x}_*) - 2\gamma_0 r^2 - 2\gamma_0 r\sqrt{\tilde{C}_3(\mathbf{x}_*) + \gamma_0 r^2}\right)\ \|\mathbf{y}\|_{1,\Omega}^2 \\
&=:\ c_4(r)\ \|\mathbf{y}\|_{1,\Omega}^2.
\end{aligned}$$

Since $c_4(r)$ is continuous with respect to r and $c_4(0) = 2\tilde{c}_3(\mathbf{x}_*) > 0$, then $c_4(r)$ is positive for small enough $r > 0$. This r ensures that the second Fréchet derivative of $\mathcal{F}(\mathbf{x};\mathsf{g})$ in direction $[\mathbf{y},\mathbf{y}]$ is positive for all $\mathbf{x} \in \overline{\mathcal{B}}(\mathbf{x}_*, r)$.

The upper bound for $\mathcal{F}''(\mathbf{x};\mathsf{g})[\mathbf{y},\mathbf{z}]$ follows by Lemma 3.3, (3.24), and Lemma 3.1:

$$\begin{aligned}
\mathcal{F}''(\mathbf{x};\mathsf{g})[\mathbf{y},\mathbf{z}] &= 2\|\mathcal{L}'(\mathbf{x})[\mathbf{y}]\|_{0,\Omega}\|\mathcal{L}'(\mathbf{x})[\mathbf{z}]\|_{0,\Omega} + 2\langle \mathcal{L}(\mathbf{x}) - \mathsf{g}, \mathcal{L}''(\mathbf{x})[\mathbf{y},\mathbf{z}]\rangle \\
&\leq 2C_3\|\mathbf{y}\|_{1,\Omega}\|\mathbf{z}\|_{1,\Omega} + 2\sqrt{C_3}\gamma_0\|\mathbf{x}-\mathbf{x}_*\|_{1,\Omega}\|\mathbf{y}\|_{1,\Omega}\|\mathbf{z}\|_{1,\Omega} \\
&\leq \left(2C_3 + 2\sqrt{C_3}\gamma_0\, r\right)\|\mathbf{y}\|_{1,\Omega}\|\mathbf{z}\|_{1,\Omega} \\
&=: C_4(r)\ \|\mathbf{y}\|_{1,\Omega}\|\mathbf{z}\|_{1,\Omega}. \qquad \square
\end{aligned}$$

Remark 3. We henceforth assume that the r of Theorem 3.1 is so small that it is less than $0.4\frac{c_3}{\sqrt{C_3}\gamma_0}$. This can always be arranged by choosing r small enough.

Remark 4. The results of Lemma 3.1, Lemma 3.3, and Theorem 3.1 still hold if we restrict ourselves to a subspace of $\boldsymbol{\mathcal{V}}$ by assuming that $\mathbf{x} = \mathbf{x}^h \in \overline{\mathcal{B}}^h(\mathbf{x}_*, r)$, $\mathbf{y} = \mathbf{y}^h \in \mathcal{S}^h$, and $\mathbf{z} = \mathbf{z}^h \in \mathcal{S}^h$.

THEOREM 3.2. *The nonquadratic functional, $\mathcal{F}(\mathbf{x};\mathsf{g})$, is coercive and continuous for all $\mathbf{x} \in \overline{\mathcal{B}}(\mathbf{x}_*, r)$, where r, c_3, and C_3 are defined as in Theorem* 3.1:

$$\frac{1}{2}c_3\|\mathbf{x}-\mathbf{x}_*\|_{1,\Omega}^2 \leq \mathcal{F}(\mathbf{x};\mathsf{g}) \leq \frac{1}{2}C_3\|\mathbf{x}-\mathbf{x}_*\|_{1,\Omega}^2. \tag{3.25}$$

Proof. For any $\mathbf{x} \in \overline{\mathcal{B}}(\mathbf{x}_*, r)$ and some $\tilde{\mathbf{x}} \in [\mathbf{x}_*, \mathbf{x}] \subset \overline{\mathcal{B}}(\mathbf{x}_*, r)$, we have

$$\mathcal{F}(\mathbf{x};\mathsf{g}) = \mathcal{F}(\mathbf{x}_*;\mathsf{g}) + \mathcal{F}'(\mathbf{x}_*;\mathsf{g})[\mathbf{x}-\mathbf{x}_*] + \frac{1}{2}\mathcal{F}''(\tilde{\mathbf{x}};\mathsf{g})[\mathbf{x}-\mathbf{x}_*, \mathbf{x}-\mathbf{x}_*].$$

The result now follows from the fact that $\mathcal{F}(\mathbf{x}_*;\mathsf{g}) = \mathcal{F}'(\mathbf{x}_*;\mathsf{g})[\mathbf{x}-\mathbf{x}_*] = 0$ (see (2.3) for the second equality) and Theorem 3.1. $\square$

A similar result can be easily established for discrete space $\mathcal{S}^h$.

THEOREM 3.3. *The functional norm, $\sqrt{\mathcal{F}(\mathbf{x}^h;\mathsf{g}) - \mathcal{F}(\mathbf{x}_*^h;\mathsf{g})}$, is coercive and continuous for all $\mathbf{x}^h \in \overline{\mathcal{B}}^h(\mathbf{x}_*, r)$, where r, c_3, and C_3 are defined as in Theorem* 3.1:

$$\frac{1}{2}c_3\|\mathbf{x}^h-\mathbf{x}_*^h\|_{1,\Omega}^2 \leq \mathcal{F}(\mathbf{x}^h;\mathsf{g}) - \mathcal{F}(\mathbf{x}_*^h;\mathsf{g}) \leq \frac{1}{2}C_3\|\mathbf{x}^h-\mathbf{x}_*^h\|_{1,\Omega}^2. \tag{3.26}$$

Proof. For any $\mathbf{x}^h \in \overline{\mathcal{B}}^h(\mathbf{x}_*, r)$ and some $\tilde{\mathbf{x}} \in [\mathbf{x}_*, \mathbf{x}^h] \subset \overline{\mathcal{B}}^h(\mathbf{x}_*, r)$, we have

$$\mathcal{F}(\mathbf{x}^h;\mathsf{g}) - \mathcal{F}(\mathbf{x}_*^h;\mathsf{g}) = \mathcal{F}'(\mathbf{x}_*^h;\mathsf{g})[\mathbf{x}^h-\mathbf{x}_*^h] + \frac{1}{2}\mathcal{F}''(\tilde{\mathbf{x}};\mathsf{g})[\mathbf{x}^h-\mathbf{x}_*^h, \mathbf{x}^h-\mathbf{x}_*^h].$$

From Definition 2.1, we know that $\mathcal{F}'(\mathbf{x}_*^h;\mathsf{g})[\mathbf{x}^h-\mathbf{x}_*^h] = \langle \mathcal{L}(\mathbf{x}_*^h)-\mathsf{g}, \mathcal{L}'(\mathbf{x}_*^h)[\mathbf{x}^h-\mathbf{x}_*^h]\rangle = 0$ for all $\mathbf{x}^h - \mathbf{x}_*^h \in \mathcal{S}^h$ (see Remark 2). Hence, continuity and coercivity again follow directly from Theorem 3.1. $\square$

4. Convergence. This section establishes unique minimizers of the functionals we use in $\overline{\mathcal{B}}(\mathbf{x}_*, r)$, $\overline{\mathcal{B}}^h(\mathbf{x}_*, r)$, and $\overline{\mathcal{B}}^{2h}(\mathbf{x}_*, r)$ under the assumption that r and h are sufficiently small. This is done in Lemmas 4.1, 4.2, and 4.3, respectively. Theorem 4.1 then shows that our coarse-grid correction and relaxation steps remain in a closed H^1-ball about $\mathbf{x}_*$ and it establishes uniform convergence of our two-level PML scheme.

LEMMA 4.1. *Let $\mathbf{x}_*$ be an isolated solution of (2.2) and r be defined as in Theorem 3.1. Then $\mathbf{x}_*$ is the unique minimizer in $\overline{\mathcal{B}}(\mathbf{x}_*, r)$ of $\mathcal{F}(\mathbf{x}; \mathsf{g})$. It is characterized by $\mathcal{F}'(\mathbf{x}_*; \mathsf{g})[\mathbf{y}] = \mathbf{0}$ for all $\mathbf{y} \in \boldsymbol{\mathcal{V}}$, that is, it is the unique critical point in $\overline{\mathcal{B}}(\mathbf{x}_*, r)$.*

Proof. The first assertion follows from (3.25). That $\mathbf{x}_*$ is a critical point follows from (2.3). We thus only need to show that it is the only critical point in $\overline{\mathcal{B}}(\mathbf{x}_*, r)$, that is, that $\mathcal{F}'(\mathbf{x}; \mathsf{g})[\mathbf{y}] = \mathbf{0}$ for all $\mathbf{y} \in \boldsymbol{\mathcal{V}}$ and $\mathbf{x} \in \overline{\mathcal{B}}(\mathbf{x}_*, r)$ imply $\mathbf{x} = \mathbf{x}_*$. Under these assumptions, for all $\mathbf{y} \in \boldsymbol{\mathcal{V}}$, we have

$$0 = \mathcal{F}'(\mathbf{x}; \mathsf{g})[\mathbf{y}] - \mathcal{F}'(\mathbf{x}_*; \mathsf{g})[\mathbf{y}] = \mathcal{F}''(\tilde{\mathbf{x}}; \mathsf{g})[\mathbf{y}, \mathbf{x}-\mathbf{x}_*],$$

for some $\tilde{\mathbf{x}} \in [\mathbf{x}_*, \mathbf{x}] \subset \overline{\mathcal{B}}(\mathbf{x}_*, r)$. With $\mathbf{y} = \mathbf{x}-\mathbf{x}_* \in \boldsymbol{\mathcal{V}}$ and Theorem 3.1, we thus obtain

$$0 \ = \mathcal{F}''(\tilde{\mathbf{x}}; \mathsf{g})[\mathbf{x}-\mathbf{x}_*, \mathbf{x}-\mathbf{x}_*] \geq \ c_4 \|\mathbf{x}-\mathbf{x}_*\|_{1,\Omega}^2.$$

Therefore, $\mathbf{x} = \mathbf{x}_*$ and the proof is complete. ∎

Next, we prove the discrete analogue to Lemma 4.1.

LEMMA 4.2. *Let $\mathbf{x}_*$ be an isolated solution of (2.2). Let r, c_4, and C_4 be defined as in Theorem 3.1 and assume that h is sufficiently small. Then there exists a unique minimizer, $\mathbf{x}_*^h$, in $\overline{\mathcal{B}}^h(\mathbf{x}_*, r)$ of $\mathcal{F}(\mathbf{x}; \mathsf{g})$. It is characterized by $\nabla^h \mathcal{F}(\mathbf{x}_*^h; \mathsf{g}) = \mathbf{0}$, that is, it is the unique grid h critical point in $\overline{\mathcal{B}}^h(\mathbf{x}_*, r)$.*

Proof. For $\mathbf{x} = \mathbf{x}^h \in \overline{\mathcal{B}}^h(\mathbf{x}_*, r) \subset \overline{\mathcal{B}}(\mathbf{x}_*, r)$, Theorem 3.2 yields

$$\frac{1}{2} c_4 \|\mathbf{x}^h - \mathbf{x}_*\|_{1,\Omega}^2 \leq \mathcal{F}(\mathbf{x}^h; \mathsf{g}) \leq \frac{1}{2} C_4 \|\mathbf{x}^h - \mathbf{x}_*\|_{1,\Omega}^2. \tag{4.1}$$

We first prove that the minimizer over $\overline{\mathcal{B}}^h(\mathbf{x}_*, r)$, which exists by compactness, is actually in $\mathcal{B}^h(\mathbf{x}_*, r)$. To this end, it suffices to show that there exists an $\mathbf{x}^h \in \mathcal{B}^h(\mathbf{x}_*, r)$ that has a smaller functional value than the minimum of $\mathcal{F}(\mathbf{x}; \mathsf{g})$ on $\partial\mathcal{B}^h(\mathbf{x}_*, r)$. To prove uniqueness of the minimizer, we then use an argument similar to that in Lemma 4.1.

Any $\mathbf{x}_\partial^h \in \partial\mathcal{B}^h(\mathbf{x}_*, r)$ must satisfy $\|\mathbf{x}_\partial^h - \mathbf{x}_*\|_{1,\Omega}^2 = r^2$. Hence, by (4.1), we have

$$\mathcal{F}(\mathbf{x}_\partial^h; \mathsf{g}) \geq \frac{1}{2} c_4 \|\mathbf{x}_\partial^h - \mathbf{x}_*\|_{1,\Omega}^2 = \frac{1}{2} c_4 r^2$$

for all $\mathbf{x}_\partial^h \in \partial\mathcal{B}^h(\mathbf{x}_*, r)$. Now let $r_1 = \sqrt{c_4/C_4}\, r$ and assume that h is so small that $\overline{\mathcal{B}}^h(\mathbf{x}_*, r_1)$ is not empty. Again by (4.1), any $\mathbf{x}^h \in \mathcal{B}^h(\mathbf{x}_*, r_1) \subset \mathcal{B}^h(\mathbf{x}_*, r)$ must satisfy

$$\mathcal{F}(\mathbf{x}^h; \mathsf{g}) \leq \frac{1}{2} C_4 \|\mathbf{x}^h - \mathbf{x}_*\|_{1,\Omega}^2 < \frac{1}{2} C_4 r_1^2 = \frac{1}{2} c_4 r^2 \leq \mathcal{F}(\mathbf{x}_\partial^h; \mathsf{g}).$$

Therefore, the minimizer, $\mathbf{x}_*^h$, of $\mathcal{F}(\mathbf{x}^h; \mathsf{g})$ over $\overline{\mathcal{B}}^h(\mathbf{x}_*, r)$ must actually be in $\mathcal{B}^h(\mathbf{x}_*, r)$. Remark 2 confirms that it is a grid h critical point: $\nabla^h \mathcal{F}(\mathbf{x}_*^h; \mathsf{g}) = \mathbf{0}$.

To prove uniqueness, note that any other minimizer, $\mathbf{x}^h$, in $\mathcal{B}^h(\mathbf{x}_*, r)$ must be a grid h critical point: $\nabla^h \mathcal{F}(\mathbf{x}^h; \mathsf{g}) = \mathbf{0}$. It now suffices to show that $\mathbf{x}_*^h$ is the only grid

h critical point (which also proves the characterization assertion). To this end, note for all $\mathbf{y}^h \in \mathcal{S}^h$ that

$$\begin{aligned} 0 =& \langle \nabla^h \mathcal{F}(\mathbf{x}^h; \mathsf{g}), \mathbf{y}^h \rangle - \langle \nabla^h \mathcal{F}(\mathbf{x}_*^h; \mathsf{g}), \mathbf{y}^h \rangle \\ =& \mathcal{F}'(\mathbf{x}^h; \mathsf{g})[\mathbf{y}^h] - \mathcal{F}'(\mathbf{x}_*^h; \mathsf{g})[\mathbf{y}^h] = \mathcal{F}''(\tilde{\mathbf{x}}^h; \mathsf{g})[\mathbf{y}^h, \mathbf{x}^h - \mathbf{x}_*^h] \end{aligned}$$

for some $\tilde{\mathbf{x}}^h \in \mathcal{B}^h(\mathbf{x}_*, r)$. Again choosing $\mathbf{y}^h = \mathbf{x}^h - \mathbf{x}_*^h \in \mathcal{S}^h \subset \boldsymbol{\mathcal{V}}$ and using Theorem 3.1 yield

$$0 = \mathcal{F}''(\tilde{\mathbf{x}}^h; \mathsf{g})[\mathbf{x}^h - \mathbf{x}_*^h, \mathbf{x}^h - \mathbf{x}_*^h] \geq c_4 \|\mathbf{x}^h - \mathbf{x}_*^h\|_{1,\Omega}^2,$$

which establishes the result. ∎

LEMMA 4.3. *Let r, c_4, and C_4 be defined as in Theorem 3.1 and choose any $r_1 < \sqrt{c_4/C_4}\, r$. Then for $\mathbf{x} \in \overline{\mathcal{B}}(\mathbf{x}_*, r_1)$, there exists a unique minimizer, $\mathbf{x}_*^{2h} = \operatorname{argmin}_{\mathbf{x}^{2h} \in \mathcal{S}^{2h}, \mathbf{x}+\mathbf{x}^{2h} \in \overline{\mathcal{B}}(\mathbf{x}_*, r)} \mathcal{F}(\mathbf{x} + \mathbf{x}^{2h}; \mathsf{g})$. If r is small enough, then this minimizer is characterized by $\nabla^{2h} \mathcal{F}(\mathbf{x} + \mathbf{x}^{2h}; \mathsf{g}) = \mathbf{0}$ with $\mathbf{x} + \mathbf{x}^{2h} \in \overline{\mathcal{B}}(\mathbf{x}_*, r)$, that is, it is the unique grid $2h$ critical point for which $\mathbf{x} + \mathbf{x}^{2h}$ stays in $\overline{\mathcal{B}}(\mathbf{x}_*, r)$. Thus, the result, $\mathbf{x}_{\frac{1}{2}}^h$, of Step 1 of PML stays in $\overline{\mathcal{B}}^h(\mathbf{x}_*, r)$ for any initial guess, $\mathbf{x}_0^h$, in $\overline{\mathcal{B}}^h(\mathbf{x}_*, r_1)$.*

Proof. The minimizer, $\mathbf{x}_*^{2h}$, clearly exists by compactness. (Note that $\{\mathbf{x} + \mathcal{S}^{2h}\} \cap \overline{\mathcal{B}}(\mathbf{x}_*, r)$ is a nonempty set because it contains $\mathbf{x} = \mathbf{x} + 0$.) To prove uniqueness and the fact that $\mathbf{x}_*^{2h}$ is a grid $2h$ critical point, first note that any $\mathbf{x}_\partial \in \partial\mathcal{B}(\mathbf{x}_*, r)$ must, by Theorem 3.2, satisfy $\mathcal{F}(\mathbf{x}_\partial; \mathsf{g}) \geq \frac{1}{2} c_4 \|\mathbf{x}_\partial - \mathbf{x}_*\|_{1,\Omega}^2 = \frac{1}{2} c_4 r^2$. Then, with $\mathbf{x} \in \overline{\mathcal{B}}(\mathbf{x}_*, r_1)$, again Theorem 3.2 implies that

$$\mathcal{F}(\mathbf{x}; \mathsf{g}) \leq \frac{1}{2} C_4 \|\mathbf{x} - \mathbf{x}_*\|_{1,\Omega}^2 \leq \frac{1}{2} C_4 r_1^2 < \mathcal{F}(\mathbf{x}_\partial; \mathsf{g}).$$

Thus, $\mathcal{F}(\mathbf{x} + \mathbf{x}_*^{2h}; \mathsf{g}) \leq \mathcal{F}(\mathbf{x}; \mathsf{g}) < \mathcal{F}(\mathbf{x}_\partial; \mathsf{g})$, which implies that $\mathbf{x} + \mathbf{x}_*^{2h} \in \mathcal{B}(\mathbf{x}_*, r)$. Then $\mathbf{x}_*^{2h}$ must satisfy the gradient condition, which follows by a similar standard argument similar to that of Remark 2.

Uniqueness and the characterization assertion can be now established as in the proofs of Lemmas 4.1 and 4.2. To this end, assume that there exists another minimizer, $\mathbf{x} + \mathbf{x}^{2h} \in \mathcal{B}^h(\mathbf{x}_*, r)$, so that $\nabla^{2h} \mathcal{F}(\mathbf{x} + \mathbf{x}^{2h}; \mathsf{g}) = \mathbf{0}$. It now suffices to show that this grid $2h$ critical point condition implies that $\mathbf{x}^{2h} = \mathbf{x}_*^{2h}$ (which also proves the characterization assertion). To this end, note for all $\mathbf{y}^{2h} \in \mathcal{S}^{2h}$, that

$$\begin{aligned} 0 =& \langle \nabla^{2h} \mathcal{F}(\mathbf{x} + \mathbf{x}^{2h}; \mathsf{g}), \mathbf{y}^{2h} \rangle - \langle \nabla^{2h} \mathcal{F}(\mathbf{x} + \mathbf{x}_*^{2h}; \mathsf{g}), \mathbf{y}^{2h} \rangle \\ =& \mathcal{F}'(\mathbf{x} + \mathbf{x}^{2h}; \mathsf{g})[\mathbf{y}^{2h}] - \mathcal{F}'(\mathbf{x} + \mathbf{x}_*^{2h}; \mathsf{g})[\mathbf{y}^{2h}] = \mathcal{F}''(\mathbf{x} + \tilde{\mathbf{x}}^{2h}; \mathsf{g})[\mathbf{y}^{2h}, \mathbf{x}^{2h} - \mathbf{x}_*^{2h}] \end{aligned}$$

for some $\mathbf{x} + \tilde{\mathbf{x}}^{2h} \in \mathcal{B}^h(\mathbf{x}_*, r)$. As before, this leads to

$$0 = \mathcal{F}''(\mathbf{x} + \tilde{\mathbf{x}}^{2h}; \mathsf{g})[\mathbf{x}^{2h} - \mathbf{x}_*^{2h}, \mathbf{x}^{2h} - \mathbf{x}_*^{2h}] \geq c_4 \|\mathbf{x}^{2h} - \mathbf{x}_*^{2h}\|_{1,\Omega}^2,$$

which proves uniqueness and the characterization assertion.

The final claim follows simply by choosing $\mathbf{x} = \mathbf{x}^h$ and noting that we can choose $r > 0$ so small that the nearest optimally corrected $\mathbf{x}^h$ must be the one in $\overline{\mathcal{B}}(\mathbf{x}_*, r)$. ∎

THEOREM 4.1. *Let r and r_1 as in Lemma 4.3, define $r_0 = \sqrt{c_4/C_4}\, r_1$, and choose h and ω sufficiently small. Then for any $\mathbf{x}_0^h \in \overline{\mathcal{B}}(\mathbf{x}_*, r_0)$, the PML iterates based on*

either (2.8) *or* (2.9) *remain in* $\overline{\mathcal{B}}^h(\mathbf{x}_*, r)$ *and converge linearly with uniformly bounded factor according to*

$$\mathcal{F}(\mathbf{x}^h_{k+1}; \mathrm{g}) - \mathcal{F}(\mathbf{x}^h_*; \mathrm{g}) \leq \kappa \left(\mathcal{F}(\mathbf{x}^h_k; \mathrm{g}) - \mathcal{F}(\mathbf{x}^h_*; \mathrm{g}) \right), \qquad k = 0, 1, 2, \ldots,$$

where $\kappa \in [0, 1)$ *depends only on* Re, r, *and* Ω.

Proof. We omit this fairly straightforward but somewhat lengthy proof and instead refer the reader to [10] for details. ∎

REGULARIZING NEWTON–KACZMARZ METHODS FOR NONLINEAR ILL-POSED PROBLEMS*

MARTIN BURGER† AND BARBARA KALTENBACHER‡

Abstract. We introduce a class of stabilizing Newton–Kaczmarz methods for nonlinear ill-posed problems and analyze their convergence and regularization behavior. As usual for iterative methods for solving nonlinear ill-posed problems, conditions on the nonlinearity (or the derivatives) have to be imposed in order to obtain convergence. As we shall discuss in general and in some specific examples, the nonlinearity conditions obtained for the Newton–Kaczmarz methods are less restrictive than those for previously existing iteration methods and can be verified for several practical applications.

We also discuss the discretization and efficient numerical solution of the linear problems arising in each step of a Newton–Kaczmarz method, and we carry out numerical experiments for two model problems.

Key words. Newton–Kaczmarz methods, ill-posed problems, tomography

1. Introduction.

The aim of this paper is to develop and analyze *Newton–Kaczmarz methods* for nonlinear inverse problems, focusing in particular on the important class of identification problems with multiple boundary data. The main idea of the Kaczmarz method is to split the inverse problem into a finite number of subproblems and to approximate its solution by performing a cyclic iteration over the subproblems.

As a *regularized Newton–Kaczmarz method* we understand the cyclic iteration where at each step one iteration of a regularized Newton method is applied to a subproblem. As we shall discuss in detail in this paper, the benefit from this approach is twofold:

1. Instead of solving one large problem in each iteration step, we can solve several smaller subproblems, which might lead to a reduction of the overall computational effort.
2. Due to the ill-posedness of the problem, conditions on the nonlinearity of the problem have to be imposed in order to ensure convergence of iterative methods (cf. [6] for an overview). These conditions are rather restrictive and cannot be verified for many practical problems, in particular for parameter identification problems using boundary data related to the solutions of partial differential equations. As we shall show below for several applications, the nonlinearity conditions for the Newton–Kaczmarz method are less restrictive and can be verified in more realistic cases.

The price which one has to pay is that at least theoretically it turns out that more a priori information has to be contained in the initial values.

Another motivation for the analysis in this paper is that Kaczmarz-type methods (also called *algebraic reconstruction technique*) have been used in several applications with multiple boundary data (cf. [3, 8, 9, 24, 30]) and performed better than standard iterative methods. This paper, together with the results of Kowar and Scherzer [24] on the Landweber–Kaczmarz method, might serve to provide a theoretical basis.

Many inverse problems can be formulated as nonlinear operator equations,

$$F(x) = y, \tag{1.1}$$

or as collections of p coupled operator equations,

$$F_i(x) = y_i, \qquad i = 0, \dots p-1, \tag{1.2}$$

with nonlinear operators F_i mapping between Hilbert spaces X and Y_i. We will here assume that a solution $x^\dagger$ of (1.2) exists but need not necessarily be unique.

Note that (1.1) can be seen as a special case of (1.2) with $p = 1$; on the other hand, defining

$$F := (F_0, \dots, F_{p-1}), \qquad y := (y_0, \dots, y_{p-1}), \tag{1.3}$$

one can reduce (1.2) to (1.1). However, one potential advantage of (1.2) over (1.1) can be that it might better reflect the structure of the underlying information $(y_0, \dots, y_{p-1})$ leading to the coupled system than could a plain concatenation into one single data element y. The most important feature that we have in mind, however, is that it enables the definition of Newton-type solution methods and to prove their convergence for certain relevant problems, for which Newton-type methods applied to the single equation formulation (1.1) cannot be shown to converge.

In general we assume that we only have noisy data y_i^δ with some noise level δ bounding the noise of every measurement by

$$\|y_i^\delta - y_i\| \le \delta, \tag{1.4}$$

Note that for $p > 1$, this assumption on the noise is more restrictive than the frequently used noise bound

$$\|y^\delta - y\| \le \delta,$$

but it reflects the case of multiple measurements, where an individual noise bound is available for each. If the noise level for each measurement is different, we can make it equal by using a relative scaling between the operators F_i.

Since we are interested in the situation that (1.2) is ill-posed in the sense that small perturbations in the data can lead to large deviations in the solution, and since in practice only noisy data are available, we have to apply suitable regularization techniques (see, e.g., [11, 13, 23, 25, 28, 29, 33]). Typically, the instability in nonlinear inverse problems (1.1) corresponds to a smoothing property of the forward operator F and its linearization $F'(x)$. In particular, for an ill-posed problem, we cannot expect that $F'(x)$ is continuously invertible, and consequently a standard Newton or Gauss–Newton cannot be used. Modified Newton-type methods for solving (1.1) have been studied and analyzed in several recent publications, see; e.g., [1, 6, 14, 15, 22, 31]. Regularization is here achieved by replacing the generally unbounded inverse of $F'(x)$

in the definition of the Newton step by a bounded approximation, defined via a regularizing operator

$$G_\alpha(F'(x)) \approx F'(x)^\dagger.$$

Here, $K^\dagger$ denotes the pseudoinverse of a linear operator K, $\alpha > 0$ is a small regularization parameter, and G_α satisfies

$$G_\alpha(K)y \to K^\dagger y \quad \text{as } \alpha \to 0 \quad \forall y \in \mathcal{R}(K) \tag{1.5}$$

and

$$\|G_\alpha(K)\| \le \Phi(\alpha) \tag{1.6}$$

for any linear operator K within some uniformly bounded set. Note that, especially in view of operators K with unbounded inverses, the constant $\Phi(\alpha)$ has to tend to infinity as α goes to zero; we assume without loss of generality (w.l.o.g.) that $\Phi(\alpha)$ is strictly monotonically decreasing.

Choosing a sequence (α_n) of regularization parameters and applying the bounded operators $G_{\alpha_n}(F'(x_n))$ in place of $F'(x_n)^{-1}$ in Newton's method results in the iteration

$$x_{n+1} = x_n - G_{\alpha_n}(F'(x_n))(F(x_n) - y^\delta). \tag{1.7}$$

If G_α is defined by Tikhonov regularization

$$G_\alpha(K) = (K^*K + \alpha I)^{-1}K^*, \tag{1.8}$$

one arrives at the Levenberg–Marquardt method. (See [15]; for G_α given by a conjugate gradient iteration, see [14], and further work on this class of methods can be found in [32].)

A different class of regularized Newton methods emerged from the iteratively regularized Gauss–Newton method (IRGNM),

$$x_{n+1} = x_0 - G_{\alpha_n}(F'(x_n))(F(x_n) - y^\delta - F'(x_n)(x_n - x_0)),$$

with (1.8), which was first proposed and analyzed by Bakushinskii in [1] and later extended to regularization with general regularization operators G_{α_n} [2]; see also [19, 22]. Here, $\alpha_n \overset{n\to\infty}{\to} 0$ is an a priori chosen monotonically decreasing sequence of regularization parameters. One observes that in the limiting case $\alpha_n \to 0$ (i.e., $G_{\alpha_n}(F'(x_n)) \to F'(x)^\dagger$) also this formulation is equivalent to the usual Newton method.

In order to make these Newton-type methods applicable to multiple equations (1.2), we combine them with a Kaczmarz approach (similar to [24]). Starting from an initial guess $x_{0,i}$, we perform a Newton step for the equation $F_i(x) = y_i$, for i from 0 to $p-1$, and repeat this procedure in a cyclic manner. Incorporating the possibility of different regularization methods G^i for each equation in (1.2), and using the "overloading" notation

$$x_{0,n} := x_{0,mod(n,p)}, \quad F_n := F_{mod(n,p)}, \quad y_n := y_{mod(n,p)}, \quad G_\alpha^n := G_\alpha^{mod(n,p)}, \tag{1.9}$$

this can be written as

$$x_{n+1} = x_{0,n} - G^n_{\alpha_n}(F_n'(x_n))(F_n(x_n) - y_n^\delta - F_n'(x_n)(x_n - x_{0,n})). \tag{1.10}$$

A combination of the Levenberg–Marquardt method with a Kaczmarz approach will be discussed in section 3.

Our convergence analysis will be a local one, i.e., we will work in a neighborhood $\mathcal{B}_\rho(x^\dagger)$ of the solution, which we assume to be a subset of the domains of the operators F_i

$$\mathcal{B}_\rho(x^\dagger) \subseteq \mathcal{D}(F_i), \qquad i = 0, \dots p-1.$$

The remainder of the paper is organized as follows. In section 2 we discuss conditions on the nonlinearity of the problem and so-called source conditions, which are abstract smoothness assumptions on the solution. Section 3 contains a convergence analysis of (1.10) including the case of noisy data and convergence rates under additional regularity assumptions. In section 4, we derive some approaches for the efficient implementation of the proposed methods, and section 5 provides numerical results.

2. Nonlinearity and source conditions. In the following we shall discuss the basic conditions needed for the subsequent analysis in this paper. In particular we shall introduce conditions on the nonlinearity of the involved operators F_i and investigate their applicability to tomography-type problems.

2.1. Nonlinearity conditions. To make these methods well defined, we assume the forward operators F_i to be Fréchet differentiable with derivatives being uniformly bounded in a neighborhood of the solution. This uniform bound has to be such that applicability of the respective regularization method can be guaranteed,

$$\|F_i'(x)\| \le C_S^i \qquad \forall x \in \mathcal{B}_\rho(x^\dagger), \tag{2.1}$$

which can always be achieved by a proper scaling. In order to prove convergence of regularization methods for nonlinear ill-posed problems, one usually needs assumptions not only on the smoothness of the forward operator F but also on the type of nonlinearity it contains. Here we shall mainly consider the condition

$$F_i'(\bar{x}) = F_i'(x) R_i(\bar{x}, x) \qquad \forall \bar{x}, x \in \mathcal{B}_\rho(x^\dagger), \tag{2.2}$$

which means that the range of the Fréchet derivative of each forward operator F_i is locally invariant around the solution. The linear operators $R_i(\bar{x}, x)$ (which need not be known explicitly) should satisfy a Lipschitz type estimate

$$\|R_i(\bar{x}, x) - I\| = \|R_i(\bar{x}, x) - R_i(x, x)\| \le C_R \|\bar{x} - x\|. \tag{2.3}$$

This corresponds to an analogous assumption in the context of $p = 1$, i.e., (1.1),

$$F'(\bar{x}) = F'(x) R(\bar{x}, x) \qquad \forall \bar{x}, x \in \mathcal{B}_\rho(x^\dagger), \tag{2.4}$$

as it was used, e.g., in the convergence analysis of [22] and is closely related to the so-called affine covariant Lipschitz condition in [7]. Condition (2.2) seems to be natural especially in the context of parameter identification in PDEs from boundary measurements where the forward operator consists of a (typically invertible) solution operator for the PDE, composed with a linear operator mapping the PDE solution to the measured boundary values. In fact, by the additional freedom arising from the possibility of having different operators R_i for each i, it can be verified for important applications of parameter identification, like ultrasound tomography (see below)

and impedance tomography, for which other nonlinearity conditions used in literature cannot be proven to hold.

An alternative nonlinearity condition that can be found in the literature on regularization methods for nonlinear inverse problems (1.1) is

$$F'(\bar{x}) = R(\bar{x}, x)F'(x) \qquad \forall \bar{x}, x \in \mathcal{B}_\rho(x^\dagger) \tag{2.5}$$

with regular operators $R(\bar{x}, x)$, i.e., range invariance of the adjoints of $F'(x)$, which is closely related to the tangential cone condition used, e.g., in [14, 15, 17, 21, 22] and to the Newton–Mysovskii conditions discussed in [6].

We want to mention that the nonlinearity condition (2.2) is less restrictive than the corresponding nonlinearity condition (2.4) for the operator F defined by (1.3). If (2.4) holds, we can easily deduce (2.2) by choosing $R_i = R$ for all i. For the alternative condition

$$F_i'(\bar{x}) = R_i(\bar{x}, x)F_i'(x) \qquad \forall \bar{x}, x \in \mathcal{B}_\rho(x^\dagger) \tag{2.6}$$

and the corresponding condition (2.5) for F defined by (1.3), we obtain sufficiency in the other direction, since we can choose R to be the diagonal operator consisting of all R_i to obtain the range invariance of F'^* from (2.6).

Finally, we examine a special case of a decomposition of F_i in a linear singular and a nonlinear regular operator. As we shall see below in several examples, the operators F_i can often be written as the composition of linear trace-type operators with nonlinear parameter-to-solution maps for partial differential equations. Thus we start with a simple observation that allows us to verify the nonlinearity condition for the parameter-to-solution map only. In this context see section 5 in [18], where a class of operators satisfying the nonlinearity condition (2.5) is derived.

LEMMA 2.1. *Let X, Y, Z be Hilbert spaces, and let $L_i \in \mathcal{L}(Z, Y)$. Moreover, let $H_i : X \to Z$, $i = 0, \dots, p-1$, be continuously Fréchet differentiable operators. Then,*

$$F_i = L_i \circ H_i \tag{2.7}$$

satisfies (2.2), (2.3) *if H_i satisfies* (2.2), (2.3).

Moreover, if $H_i'(x)$ is regular for all $x \in \mathcal{B}_\rho(x^\dagger)$ with uniformly bounded inverse, and the map $x \mapsto H_i'(x)$ is Lipschitz continuous, then the condition (2.2), (2.3) *is satisfied by H_i.*

Proof. The first assertion follows from

$$F_i'(\bar{x}) = L_i \circ H_i'(\bar{x}) = L_i \circ H_i'(x) \circ R_i(\bar{x}, x) = F_i'(x) \circ R_i(\bar{x}, x).$$

Moreover, if H_i' is regular, we may define

$$R_i(\bar{x}, x) := H_i'(x)^{-1} H_i'(\bar{x}),$$

which implies (2.2). Due to the regularity of $H_i'(x)^{-1}$ and the Lipschitz-continuity of $x \mapsto H_i'(x)$, we obtain

$$\|R_i(\bar{x}, x) - I\| = \|H_i'(x)^{-1}(H_i'(\bar{x}) - H_i'(x))\| \le C_0 \|H_i'(\bar{x}) - H_i'(x)\| \le C_R \|\bar{x} - x\|,$$

i.e., (2.3) holds. ∎

2.2. Examples. In the following we discuss several examples of inverse problems satisfying the nonlinearity condition including tomography-type problems for partial differential equations in the above framework, and we show that they satisfy the nonlinearity condition (2.2).

Example 1 (reconstruction from the Dirichlet–Neumann map). We start with a rather simple model problem, namely, the estimation of the coefficient $q \geq 0$ in the partial differential equation

$$-\Delta u + qu = 0 \qquad \text{in } \Omega \subset \mathbb{R}^d$$

from measurements of the Neumann value $g = \frac{\partial u}{\partial \nu}$ on $\partial\Omega$ for several different Dirichlet values $u = f$ on $\partial\Omega$.

If we denote the different Dirichlet values by f_i, $i = 0, \ldots, p-1$, and the corresponding measurements by g_i, we may rewrite the problem as

$$F_i(q) = g_i, \qquad i = 0, \ldots, p-1,$$

where $F_i : \mathcal{D}(F_i) \subseteq L^2(\Omega) \to H^{-\frac{1}{2}}(\partial\Omega)$ is the nonlinear operator mapping q to $\frac{\partial u_i}{\partial \nu}$, where $u_i \in H^1(\Omega)$ is the weak solution of

$$\begin{aligned} -\Delta u_i + qu_i &= 0 \qquad \text{in } \Omega, \\ u_i &= f_i \qquad \text{on } \partial\Omega, \end{aligned}$$

and $\mathcal{D}(F_i)$ is to be specified below.

The decomposition (2.7) is obtained with $L : H^1(\Omega) \mapsto H^{-\frac{1}{2}}(\partial\Omega)$ being the trace operator that maps a function to its normal derivative on the boundary, and $H_i : q \mapsto u_i$ is the parameter-to-solution map.

The derivative $v_i = H_i'(q)s$ is given as the unique weak solution of

$$\begin{aligned} -\Delta v_i + qv_i + su_i &= 0 \qquad \text{in } \Omega, \\ v_i &= 0 \qquad \text{on } \partial\Omega. \end{aligned}$$

Formally, we can write $H_i'(q) = -(-\Delta + q)^{-1}(u_i .)$. It can be shown easily that this operator is regular between $L^2(\Omega)$ and $H^1(\Omega)$ if $u_i > 0$. Due to a standard maximum principle for second-order elliptic differential equations, this is the case if $q \geq 0$ and $f_i > 0$. Moreover, since embedding operators are continuous and regular, the operator $H_i'(q)$ is also regular between a Sobolev space $H^\beta(\Omega)$, $\beta \geq 0$, and $H^1(\Omega)$. Thus, if $\beta > \frac{d}{2}$ (i.e., $H^\beta(\Omega) \hookrightarrow C(\bar{\Omega})$) and there exists a minimum norm solution $q^\dagger \in H^\beta(\Omega)$, which is positive in $\bar{\Omega}$, then $q \in \mathcal{B}_\rho(q^\dagger)$ is nonnegative for ρ sufficiently small and due to the above reasoning Lemma 2.1 implies that the nonlinearity condition (2.2), (2.3) is satisfied for $f_i > 0$, if we consider F_i as an operator from $\mathcal{D}(F_i) := \mathcal{B}_\rho(q^\dagger) \subseteq H^\beta(\Omega) =: X$ to $H^{-\frac{1}{2}}(\partial\Omega) =: Y_i$.

Example 2 (reconstruction from multiple sources). In some examples, one rather tries to estimate coefficients in partial differential equations from boundary measurements for different interior sources rather than from different boundary values. We consider the estimation of the coefficient $q \geq 0$ in

$$-\Delta u + qu = h \qquad \text{in } \Omega \subset \mathbb{R}^d$$

subject to a homogeneous Neumann boundary condition $\frac{\partial u}{\partial \nu} = 0$ on $\partial\Omega$, and measurements of the Dirichlet values $u = f$ on $\partial\Omega$ for different sources $h \in H^{-1}(\Omega)$. Problems

of this kind have been discussed by Lowe and Rundell [26, 27] and in an application to semiconductor devices by Fang and Ito [12].

Again, we can decompose the corresponding operators F_i into the trace operator $L : H^1(\Omega) \to L^2(\partial\Omega)$ concatenated with the parameter-to-solution maps $H_i : q \mapsto u_i$ defined by the solution of

$$\begin{aligned} -\Delta u_i + q u_i &= h_i \qquad \text{in } \Omega, \\ \frac{\partial u_i}{\partial \nu} &= 0 \qquad \text{on } \partial\Omega. \end{aligned}$$

The derivative $H_i'(q)$ is almost the same as in the previous example, except for a change from Dirichlet to Neumann boundary conditions. One can verify the regularity of u_i in the same way as above for $h_i > 0$ (which allows one to apply a maximum principle for u_i) and consequently show that the nonlinearity condition (2.2), (2.3) holds.

Example 3 (SPECT). In the application of single photon emission computed tomography (SPECT), one wants to compute the source f and the coefficient $a \geq 0$ from

$$\theta_i \cdot \nabla u_i + a u_i = f \qquad \text{in } \Omega \subset \mathbb{R}^d,$$

for different values θ_i on the unit sphere, and the boundary values

$$\begin{aligned} u_i &= 0 \qquad \text{on } \partial\Omega_i^- := \{\, x \in \partial\Omega \mid \nu(x) \cdot \theta_i \leq 0 \,\}, \\ u_i &= g_i \qquad \text{on } \partial\Omega_i^+ := \{\, x \in \partial\Omega \mid \nu(x) \cdot \theta_i \geq 0 \,\}. \end{aligned}$$

Here, the condition on $\partial\Omega_i^-$ has to be understood as the boundary condition, while the values g_i on $\partial\Omega_i^+$ are the measurements. Thus, the operators F_i map (a, f) to g_i. They can be decomposed into the trace operators $L_i : L^2(\Omega) \to H^{-\frac{1}{2}}(\partial\Omega_i^+)$ and the parameter-to-solution maps $H_i : \mathcal{D}(F_i) \subseteq L^2(\Omega)^2 \to L^2(\Omega), (a, f) \mapsto u_i$.

It can be shown (cf. [30]) that the derivative $v_i = H_i'(a, f)(\hat{a}, \hat{f})$ can be determined as the unique solution of

$$\theta_i \cdot \nabla v_i + a v_i = \hat{f} - \hat{a} u_i \qquad \text{in } \Omega \subset \mathbb{R}^d,$$

subject to $v_i = 0$ on $\partial\Omega_i^-$. If $a > 0$, $f > 0$, a maximum principle applies also to the first-order equation and one may conclude $u_i > 0$, which subsequently can be used to verify the nonlinearity condition (2.2), (2.3) in the same way as for the above examples.

Example 4 (ultrasound tomography). The inverse problem in ultrasound tomography consists in finding $f \in L^2(\Omega)$ from boundary measurements $g_i = u_i$ on $\partial\Omega$ for complex-valued waves $u_i = e^{\mathbf{i}kx\cdot\theta_i} + v_i$, where v_i solves the Helmholtz equations

$$\begin{aligned} \Delta v_i + k^2(1 - f) v_i &= k^2 f e^{\mathbf{i}kx\cdot\theta_i} \qquad \text{in } \Omega, \\ \frac{\partial v_i}{\partial \nu} &= B v_i \qquad \text{on } \partial\Omega, \end{aligned}$$

with B being an appropriate operator representing the radiation condition and k a real parameter controlling the spatial resolution. Again we can decompose the operator $F_i : f \mapsto g_i$ into the trace operator $L : H^1(\Omega) \to L^2(\partial\Omega)$ and the parameter-to-solution map $H_i : \mathcal{D}(F_i) \subseteq L^2(\Omega) \to H^1(\Omega), f \mapsto u_i$.

One can show (cf. [30]) that the derivative $w_i = H_i'(f)$ is defined by the solution of

$$\begin{aligned} \Delta u_i + k^2(1-f)w_i &= k^2 f u_i \qquad \text{in } \Omega, \\ \frac{\partial w_i}{\partial \nu} &= B w_i \qquad \text{on } \partial\Omega. \end{aligned}$$

If f, k are such that the operator $\Delta + k^2(1-f)$ is regular, and if $|u_i| \neq 0$, then one can easily verify the nonlinearity condition in the same way as for the examples above.

Example 5 (nonlinear moment estimation). We finally consider a nonlinear moment estimation problem, which consists in finding $u \in L^2(\Omega)$, $\Omega \subset \mathbb{R}^d$ a bounded domain, given

$$g_i := \int_\Omega k_i(x, u(x))\, dx \in \mathbb{R}^m$$

for given smooth kernel functions $k_i : \Omega \times \mathbb{R} \to \mathbb{R}^m$ (which could, e.g., arise from the discretization of an integral kernel, i.e., $k_i(x, u(x)) = K(x, u(x), y_i)$). Here the operator $F_i : L^2(\Omega) \to \mathbb{R}^m$ is the concatenation of the linear integration operator $L : L^2(\Omega)^m \to \mathbb{R}^m$, $w \mapsto \int_\Omega w\, dx$, and the Nemitskij-type operator $H_i : L^2(\Omega) \to L^2(\Omega), u \mapsto k_i(., u)$. The derivative of the nonlinear operator H_i is given by

$$H_i'(u)v = \frac{\partial k_i}{\partial u}(., u)v.$$

If $k_i \in C(\Omega, C_b^{1,1}(\mathbb{R}))$ and $\frac{\partial k_i}{\partial u} \neq 0$, then $H_i'(u)$ is regular and the map $u \mapsto H_i'(u)$ is Lipschitz continuous, which implies the nonlinearity condition (2.2), (2.3).

2.3. Source conditions. Convergence of regularization methods for ill-posed problems is, as a direct consequence of the instability, in general arbitrarily slow. In order to obtain convergence rates, additional regularity assumptions on the difference between an exact solution $x^\dagger$ and some initial guess x_0 used in the regularization method must be made. These have the form of so-called source wise representation conditions and in our context read as

$$x^\dagger - x_{0,i} = f(F_i'(x^\dagger)^* F_i'(x^\dagger))w_i, \quad i = 0, \dots, p-1, \tag{2.8}$$

for some w_i, where f is some real function and for the positive semidefinite operator $F_i'(x^\dagger)^* F_i'(x^\dagger)$, $f(F_i'(x^\dagger)^* F_i'(x^\dagger))$ is defined via functional calculus (cf., e.g., [11]). Condition (2.8) expresses the assumed regularity of $x^\dagger - x_{0,i}$ in terms of the smoothing property of $F'(x^\dagger)$ mentioned above. Typical functions f used here are

$$f(\lambda) := f_\nu^H(\lambda) := \lambda^\nu \tag{2.9}$$

for some Hölder exponent ν, or the weaker, but for exponentially ill-posed problems more appropriate logarithmic functions

$$f(\lambda) := f_\mu^L(\lambda) = (-\ln(\lambda))^{-\mu}. \tag{2.10}$$

Remark 1. Note that under sufficiently strong source conditions, namely, (2.8) with $f(\lambda) = O(\sqrt{\lambda})$, which corresponds to $\nu \geq \frac{1}{2}$ in (2.9), the nonlinearity assumptions on F (see the previous subsection) can be considerably relaxed in case $p = 1$. In place of (2.4) or (2.5) one only needs Lipschitz continuity of F'. This was observed by

Bakushinskii in [1] for the case $\nu \geq 1$ and IRGNM (see [21] for the case $\nu \geq \frac{1}{2}$) and later extended to several instances of a general G_α (see the monograph by Bakushinskii and Kokurin [2], as well as [22]) including those methods G_α that are considered in this paper (see section 3.3). Actually, it can be shown that the same holds true for the Newton–Kaczmarz method (1.10) for multiple equations.

3. Convergence analysis. In this section we will state a quite general convergence theorem. Its proof is closely related to convergence proofs in [6, 19, 20, 21, 22]. Therefore we shall provide the proof in a somewhat compressed form but highlight the important ideas for the convenience of the reader. We aim at giving the statements in a general and comprehensive way so that they might be of interest even for the special case $p = 1$, i.e., for (1.1). Especially, according to the authors' knowledge, the convergence result with logarithmic source conditions under nonlinearity assumptions of the type considered here is new also for $p = 1$.

3.1. Preliminaries and assumptions. To be able to carry out the estimates in the proof of Theorem 3.1, we have to make some assumptions on the regularization methods G^i, additional to (1.5), (1.6) in the introduction, i.e.,

$$G^i_\alpha(K)y \to K^\dagger y \quad \text{as } \alpha \to 0 \quad \forall y \in \mathcal{R}(K) \tag{3.1}$$

and

$$\|G^i_\alpha(K)\| \leq \Phi(\alpha) \tag{3.2}$$

for all $K \in \mathcal{L}(X, Y_i)$ with $\|K\| \leq C^i_S$. In view of the nonlinearity condition (2.2), we assume that

$$\|G^i_\alpha(KR)KR - G^i_\alpha(K)K\| \leq \bar{C}_G \|R - I\| \tag{3.3}$$

for all $K \in \mathcal{L}(X, Y_i)$, $R \in \mathcal{L}(X, X)$ with $\|K\|, \|KR\| \leq C^i_S$, $\|R - I\| \leq c < 1$, as well as

$$\|G^i_\alpha(K)K\| \leq C_G \qquad \forall K \in \mathcal{L}(X, Y_i) : \ \|K\| \leq C^i_S \tag{3.4}$$

with positive real constants $\bar{C}_G$, c, and C^i_S as in (2.1). To yield convergence rates under additional regularity conditions (2.8), the regularizing operators G^i_α have to converge to the inverse of K at some rate on the set of solutions satisfying (2.8), i.e., a condition of the form

$$\|(I - G^i_\alpha(K)K) f(K^*K)\| \leq \psi(\alpha) \qquad \forall K \in \mathcal{L}(X, Y_i) : \quad \|K\| \leq C^i_S \tag{3.5}$$

is needed, with a strictly monotone function ψ that decreases to zero as $\alpha \to 0$. Moreover, the sequence $\psi(\alpha_n)$ must not tend to zero too fast, in the sense that

$$\frac{\psi(\alpha_n)}{\psi(\alpha_{n+1})} \leq C_\psi \qquad \forall n \in \mathbb{N} \tag{3.6}$$

for some constant $C_\psi \in \mathbb{R}^+$.

In the situation of noisy data, convergence of the reconstructions as the noise level δ tends to zero is only obtained for appropriate choices of the stopping index $N = N(\delta)$ in dependence of the noise level δ. In the general case, convergence can be achieved if $N(\delta)$ is chosen such that

$$N(\delta) \to \infty \quad \text{and} \quad \Phi(\alpha_{N(\delta)}) \cdot \delta \to 0 \qquad \text{as } \delta \to 0 \tag{3.7}$$

and

$$\Phi(\alpha_n)\cdot\delta\le\tau\qquad\forall n\le N(\delta) \tag{3.8}$$

for some $\tau>0$ sufficiently small. If additional source conditions (2.8) hold, an appropriate choice is such that

$$\phi(\alpha_{N(\delta)})\le\delta<\phi(\alpha_n)\qquad\forall n\le N(\delta), \tag{3.9}$$

where

$$\phi(\alpha)=\frac{\tau\psi(\alpha)}{\Phi(\alpha)}$$

for τ defined in (3.8).

3.2. Main result. Now we shall state and prove the main convergence result of this paper, a comprehensive convergence theorem for Newton–Kaczmarz methods.

THEOREM 3.1. *Let x_n be defined by the sequence* (1.10) *with Fréchet differentiable operators F_i satisfying* (2.1), (2.2) *with* (2.3), *data y^δ satisfying* (1.4), *the regularization methods G_α^i fulfilling* (3.1), (3.2), (3.3), (3.4), *for all $K\in\mathcal{L}(X,Y_i)$, $R\in\mathcal{L}(X,X)$ with $\|K\|,\|KR\|\le C_S^i$, $\|R-I\|\le c<1$, and* (3.5), *as well as a sequence α_n tending to zero and satisfying* (3.6). *Moreover, let τ and $\|x_{0,i}-x^\dagger\|$ be sufficiently small and $x_{0,i}-x^\dagger\in\mathcal{N}(F_i'(x^\dagger)^\perp$, $i=0,\dots,p-1$.*

Then, in the noise-free case ($\delta=0$), the sequence x_n converges to $x^\dagger$ as $n\to\infty$. In case of noisy data and with the choice (3.7), (3.8), *$x_{N(\delta)}$ converges to $x^\dagger$ as $\delta\to0$.*

If the source conditions (2.8) *and* (3.5), (3.6) *hold, with $\|w^i\|$ sufficiently small, then the convergence rates*

$$\|x_n-x^\dagger\|=O(\psi(\alpha_n))$$

in the noise-free situation and, with (3.9),

$$\|x_{N(\delta)}-x^\dagger\|=O(\psi(\phi^{-1}(\delta)))$$

in the noisy situation, respectively, hold.

Proof. We will make use of the following lemma, whose proof can be found in [21].

LEMMA 3.2. *Let $\{a_n\}$ be a sequence satisfying*

$$0\le a_n\le a\quad\text{and}\quad\lim_{n\to\infty}a_n=\tilde a\le a.$$

Moreover, we assume that $\{\gamma_n\}$ is a sequence for which the estimate

$$0\le\gamma_{n+1}\le a_n+b\gamma_n+c\gamma_n^2\ ,\qquad n\in\mathbb{N}_0,\ \gamma_0\ge0,$$

holds for some $b,c\ge0$. Let $\underline{\gamma}$ and $\overline{\gamma}$ be defined as

$$\underline{\gamma}:=\frac{2a}{1-b+\sqrt{(1-b)^2-4ac}},\quad\overline{\gamma}:=\frac{1-b+\sqrt{(1-b)^2-4ac}}{2c}.$$

If $b+2\sqrt{ac}<1$ and if $\gamma_0\le\overline{\gamma}$, then

$$\gamma_n\le\max\left(\gamma_0,\underline{\gamma}\right)\ ,\quad n\in\mathbb{N}_0,$$

and if $\tilde{a} < a$, *then*

$$\limsup_{n\to\infty} \gamma_n \le \frac{2\tilde{a}}{1-b+\sqrt{(1-b)^2-4\tilde{a}c}}.$$

To derive a recursive error estimate, we assume that the current iterate x_n is in $\mathcal{B}_\rho(x^\dagger)$ and that $n < N(\delta)$ ($= \infty$ if $\delta = 0$). Then

$$\begin{aligned} x_{n+1} - x^\dagger \;=\; & \Big(I - G^n_{\alpha_n}(F_n'(x^\dagger))F_n'(x^\dagger)\Big)(x_{0,i} - x^\dagger) \\ & + \Big(G^n_{\alpha_n}(F_n'(x^\dagger))F_n'(x^\dagger) - G^n_{\alpha_n}(F_n'(x_n))F_n'(x_n)\Big)(x_{0,i} - x^\dagger) \\ & - G^n_{\alpha_n}(F_n'(x_n))(F_n(x_n) - F_n(x^\dagger) - F_n'(x_n)(x_n - x^\dagger)) \\ & - G^n_{\alpha_n}(F_n'(x_n))(y_n - y_n^\delta). \end{aligned} \tag{3.10}$$

The third term on the right-hand side can be rewritten as

$$G^n_{\alpha_n}(F_n'(x_n))F_n'(x_n)\int_0^1 \Big(R^i(x^\dagger + \theta(x_n - x^\dagger), x_n) - I\Big)d\theta(x_n - x^\dagger)$$

with $i = \mathrm{mod}(n, p)$, so

$$\begin{aligned} \|x_{n+1} - x^\dagger\| \;\le\; & \xi_n \\ & + \bar{C}_G C_R \|x_{0,i} - x^\dagger\| \;\|x_n - x^\dagger\| \\ & + \tfrac{1}{2} C_G C_R \|x_n - x^\dagger\|^2 \\ & + \Phi(\alpha_n)\delta, \end{aligned} \tag{3.11}$$

where

$$\xi_n := \|\Big(I - G^n_{\alpha_n}(F_n'(x^\dagger))F_n'(x^\dagger)\Big)(x_{0,i} - x^\dagger)\| \le \psi(\alpha_n)\|w^i\|,$$

if (2.8) holds and

$$\xi_n \to 0 \quad \text{as } n \to \infty \tag{3.12}$$

also without (2.8). The latter can be seen by (3.1) together with the following subsequence-subsequence argument.

Let $(\xi_{n_m})_{m\in\mathbb{N}}$ be an arbitrary subsequence of $(\xi_n)_{n\in\mathbb{N}}$. Then there exists an $i \in \{0, \dots, p-1\}$ such that the set $\{m \in \mathbb{N} \mid mod(n_m, p) = i\}$ has infinite cardinality. Define by $(m_l)_{l\in\mathbb{N}}$ a numbering of this set in ascending order; then for $(\xi_{n_{m_l}})_{l\in\mathbb{N}}$ we get

$$\xi_{n_{m_l}} = \|\Big(I - G^i_{\alpha_{n_{m_l}}}(F_i'(x^\dagger))F_i'(x^\dagger)\Big)(x_{0,i} - x^\dagger)\| \;\to 0 \text{ for } l \to \infty,$$

since $\alpha_{n_{m_l}} \to 0$ for $l \to \infty$.

Now we can apply induction together with Lemma 3.2 to the sequence

$$\gamma_n := \|x_n - x^\dagger\|.$$

The boundedness (3.8) in the stopping rule and our assumption on closeness of $x_{0,i}$ to $x^\dagger$ and on smallness of τ permit us to make the constants a and b sufficiently small so that the assumptions of the lemma are satisfied, and the bound $\max\{\gamma_0, \underline{\gamma}\}$ is smaller

than ρ, so that we can guarantee that the iterates remain in $\mathcal{B}_\rho(x^\dagger)$ for all $n \le N(\delta)$. Moreover, by (3.12) as well as the asymptotics (3.7) in the stopping rule, we can set $\tilde{a} = 0$ and conclude that x_n converges to $x^\dagger$ as $n \to \infty$ in the noise-free case and as $\delta \to 0$ in the noisy case, respectively.

To prove convergence rates under source conditions, we consider the sequence

$$\gamma_n := \frac{\|x_n - x^\dagger\|}{\psi(\alpha_n)},$$

which satisfies

$$\gamma_{n+1} \le C_\psi \left(\|w^i\| + \bar{C}_G C_R \|x_{0,i} - x^\dagger\| \gamma_n + \frac{1}{2} C_G C_R \psi(\alpha_n) \gamma_n^2 + \frac{\Phi(\alpha_n)}{\psi(\alpha_n)} \delta \right).$$

Hence, Lemma 3.2 together with the stopping rule (3.9) imply that x_n remains in $\mathcal{B}_\rho(x^\dagger)$ for all $n \le N(\delta)$ and that γ_n is uniformly bounded, i.e.,

$$\|x_n - x^\dagger\| \le C\psi(\alpha_n), \tag{3.13}$$

for some constant C. This immediately yields the convergence rate result in the noiseless case. To obtain the error estimate in terms of δ in the noisy case, we make use of the fact that by (3.9)

$$\delta \ge \phi(\alpha_{N(\delta)}),$$

which, since ψ and ϕ are strictly monotonically increasing, by (3.13) implies

$$\psi(\phi^{-1}(\delta)) \ge \psi(\alpha_{N(\delta)}) \ge \frac{1}{C} \|x_{N(\delta)} - x^\dagger\|. \qquad \square$$

The assumption

$$x_{0,i} - x^\dagger \in \mathcal{N}(F_i'(x^\dagger))^\perp, \quad i = 0, \dots, p-1, \tag{3.14}$$

is rather limiting, since the dimensionality of $x_0 - x^\dagger$ is related to the "smaller" space $\mathcal{N}(F_i'(x^\dagger)^\perp$. In the special case $p = 1$, the difference between x_0 and an x_0-minimum-norm-solution $x^\dagger$ will automatically lie within $\mathcal{N}(F'(x^\dagger))^\perp$ under certain nonlinearity conditions (see Proposition 2.1 in [21]). However, for general $p > 1$ one gets only $x_0 - x^\dagger \in (\bigcap_{i=0}^{p-1} \mathcal{N}(F_i'(x^\dagger)))^\perp$ and not (3.14) with $x_{0,i} := x_0$. Thus, condition (3.14) requires the choice of appropriate initial guesses $x_{0,i}$. To see the necessity of condition (3.14) for convergence, consider the linear case

$$F_i x = y_i \ , \qquad i = 0, \dots p-1, \tag{3.15}$$

with $F_i \in \mathcal{L}(X, Y_i)$, $y_i \in Y_i$, $i = 0, \dots p-1$, where the sequence x_n is defined by

$$x_{n+1} = x_{0,n} - G^n_{\alpha_n}(F_n)(F_n x_{0,n} - y_n^\delta). \tag{3.16}$$

In the case of exact data, the error can be written as

$$x_{kp+i+1} - x^\dagger = (I - G^i_{\alpha_{kp+i}}(F_i)F_i)(x_{0,i} - x^\dagger) \tag{3.17}$$

for $n = kp + i$, $k \in \mathbb{N}$, so by (3.1) and $\alpha_n \to \infty$ as $n \to \infty$,

$$x_{kp+i+1} - x^\dagger \to \mathcal{P}_{\mathcal{N}(F_i)^\perp}(x_{0,i} - x^\dagger) \text{ as } k \to \infty,$$

whence convergence of x_n to $x^\dagger$ as $n \to \infty$ implies (3.14).

In this sense, Theorem 3.1 means that the regularized Newton–Kaczmarz method is as least as good as application of Newton's method separately to each of the p equations, which might a priori not be evident due to the mixing up of the equations during the iteration (1.10). Since it takes into account more information, it should intuitively be even better, which is also reflected in our numerical tests, that showed convergence without any specific choice of the initial guesses.

Note that in the linear case, subsequent iterates completely decouple, i.e., subsequences $(x_{kp+i_1})_{k\in\mathbb{N}}$, $(x_{kp+i_2})_{k\in\mathbb{N}}$ are independent of each other for $i_1 \neq i_2$. Thus it suffices to have

$$x_{0,i} - x^\dagger \in \mathcal{N}(F_i)^\perp \tag{3.18}$$

for one $i = \bar{i} \in \{0, \dots, p-1\}$, to obtain convergence of the respective subsequence $x_{kp+\bar{i}+1}$ from standard results for linear regularization methods. The same holds true for convergence rates. Consequently, in order to get convergence (and convergence rates) with noisy data, it suffices to have (3.18) (and $x_{0,i} - x^\dagger \in \mathcal{R}(f(F_i^*F_i))$) for one $i = \bar{i} \in \{0, \dots, p-1\}$ only, and to stop the iteration at an index from the respective subsequence $kp + \bar{i} + 1$ with $k_* = k_*(\delta)$ being determined a priori from (3.7), (3.8), (3.9) or, alternatively, a posteriori from a discrepancy principle

$$\|F_i x_{k_* p+\bar{i}+1} - y_i\| \leq \tau\delta < \|F_i x_{kp+\bar{i}+1} - y_i\|, \qquad 0 \leq k < k_*.$$

Unfortunately this complete decoupling gets lost as soon as the operators F_i are nonlinear. Moreover, we have to remark that already (3.18) for one $i = \bar{i}$ is a very strong condition in case $p > 1$, since it means the other equations for $i \neq \bar{i}$ are not really required for determining $x^\dagger$.

3.3. Standard regularizing operators. Now we shall apply Theorem 3.1 to some regularization methods G^i of particular interest. Moreover, in the abstract source condition (2.8), we insert the most relevant special cases of a Hölder function f in (2.9) or a logarithmic function f in (2.10).

As important examples from a larger class of regularization methods defined by real functions $g_\alpha : \mathbb{R}^+ \mapsto \mathbb{R}^+$ approximating $\lambda \mapsto \frac{1}{\lambda}$ and

$$G_\alpha(K) := g_\alpha(K^*K)K^* \tag{3.19}$$

via functional calculus (cf., e.g., [11, 25]), we consider the following.

- Tikhonov–Philips regularization:

$$G_\alpha(K) = (K^*K + \alpha I)^{-1}K^*, \quad I - G_\alpha(K)K = \alpha(K^*K + \alpha I)^{-1}. \tag{3.20}$$

  In this case, we shall call the arising iterative method the *iteratively regularized Gauss–Newton–Kaczmarz (IRGNK) method*.

- Iterated Tikhonov regularization:

$$\begin{aligned} G_\alpha(K) &= \textstyle\sum_{l=0}^k \prod_{j=l}^k \alpha_j (K^*K + \alpha_j I)^{-1} \frac{1}{\alpha_l} K^*, \\ I - G_\alpha(K)K &= \textstyle\prod_{l=0}^k \alpha_l (K^*K + \alpha_l I)^{-1}, \end{aligned} \tag{3.21}$$

  with the effective regularization parameter

$$\alpha := \frac{1}{\sum_{l=0}^k \frac{1}{\alpha_l}}.$$

We shall call the arising iterative method the *k-iteratively regularized Gauss–Newton–Kaczmarz (IRGNK$_k$) method*. Here we distinguish between the special stationary case

$$\alpha_l :\equiv 1, \tag{3.22}$$

i.e., Lardy's method, and the (due to its faster convergence more attractive, cf. [16]) nonstationary case of, e.g., geometrically decaying α_l

$$\alpha_l := Cq^l \tag{3.23}$$

with $q \in (0,1)$.

- Landweber iteration:

$$G_\alpha(K) = \sum_{l=0}^{k} (I - K^*K)^l K^*, \quad I - G_\alpha(K)K = (I - K^*K)^{k+1}, \tag{3.24}$$
$$\alpha := \frac{1}{k+1},$$

where the scaling is assumed to be done such that $\|I - K^*K\| \leq 1$, i.e., $C_S^i = \sqrt{2}$ in (2.1). For obvious reasons, this method shall be called *Newton–Landweber–Kaczmarz (NLK) method* here and below.

These methods are well known to satisfy (3.1), (3.2) with

$$\Phi(\alpha) = C\frac{1}{\sqrt{\alpha}},$$

as well as (3.4) (cf., e.g., [11, 25, 16]). Moreover, for the Hölder-type source representation functions (2.9), they satisfy (3.5) with

$$\psi(\alpha) = C\alpha^\nu \tag{3.25}$$

(where ν is restricted to the interval $[0,1]$ in Tikhonov regularization, and to the interval $[0,k]$ in iterated Tikhonov regularization), from which one can conclude by Lemma 4 in [20] that they also satisfy (3.5) for the logarithmic functions (2.10) with

$$\psi(\alpha) = C(-\ln(\alpha))^{-\mu},$$

where w.l.o.g. both $\|K\|^2$ and α are restricted to the interval $(0, \exp(-1)]$ (i.e., $C_S^i = \exp(-1/2)$ in (2.1)) in order to avoid the singularity of f_μ^L at zero. Therewith, a decay restriction

$$\frac{\alpha_n}{\alpha_{n+1}} \leq C_\alpha \qquad \forall n \in \mathbb{N} \tag{3.26}$$

is sufficient for (3.6).

COROLLARY 3.3. *Let x_n be defined by the sequence* (1.10) *with Fréchet differentiable operators F_i satisfying* (2.1), (2.2) *with* (2.3), *data y^δ satisfying* (1.4) *and the regularization methods G_α^i defined by Tikhonov–Philips regularization, nonstationary iterated Tikhonov regularization, or Landweber iteration, as well as a sequence α_n tending to zero and satisfying* (3.26). *Moreover, let τ and $\|x_{0,i} - x^\dagger\|$ be sufficiently small and $x_{0,i} - x^\dagger \in \mathcal{N}(F_i'(x^\dagger)^\perp$, $i = 0, \ldots, p-1$.*

Then, the assertions of Theorem (3.1) *hold. In particular, under a Hölder-type source condition* (2.8) *with* (2.9)*, we obtain*

$$\|x_{N(\delta)} - x^\dagger\| = O(\delta^{\frac{2\nu}{2\nu+1}})$$

(where ν is restricted to $[0,1]$ in case of Tikhonov regularization), and under a logarithmic type source condition (2.8) *with* (2.10)

$$\|x_{N(\delta)} - x^\dagger\| = O((-\ln(\delta^2))^{-\mu}).$$

Note that the saturation of iterated Tikhonov regularization at $\nu = k$ does not take effect here, since we do not consider k but $(\sum_{l=0}^{k} \alpha_l^{-1})^{-1}$ as the regularization parameter.

Proof. It remains to show that the differences between applications of the regularization methods to two different operators can be estimated according to (3.3). Tikhonov regularization can make use of estimates presented in [21], as well as in Hohage's thesis [19], namely, for arbitrary $K \in \mathcal{L}(X, Y_i)$, $R \in \mathcal{L}(X, X)$ with $\|R - I\| \le c < 1$,

$$\begin{aligned}
&\|G_\alpha^i(KR)KR - G_\alpha^i(K)K\| \\
&= \alpha \|(K^*K + \alpha I)^{-1} - ((KR)^*KR + \alpha I)^{-1}\| \\
&= \alpha \|((KR)^*KR + \alpha I)^{-1} \Big((KR)^*KR(I - R^{-1}) + (R - I)^*K^*K \Big) (K^*K + \alpha I)^{-1}\| \\
&\le (1 + \tfrac{1}{1-c}) \|R - I\|
\end{aligned}$$

for f according to (2.9) with $\nu \le \frac{1}{2}$ or f according to (2.10).

For the iterative methods—iterated Tikhonov regularization and Landweber iteration—we make use of the identity

$$\prod_{l=0}^{k} A_l - \prod_{l=0}^{k} B_l = \sum_{l=0}^{k} \prod_{j=0}^{l-1} A_j (A_l - B_l) \prod_{j=l+1}^{k} B_j \tag{3.27}$$

for linear operators A_l, B_l, with the notation $\prod_{l=0}^{-1} A_l = I = \prod_{l=k+1}^{k} B_j$, and first consider case (a): to obtain (3.3) for Landweber iteration, we set

$$A_l := (I - (KR)^*KR), \qquad B_l := (I - K^*K), \tag{3.28}$$

and use the fact that

$$A_l - B_l = (KR)^*KR(R^{-1} - I) + (I - R^*)K^*K \tag{3.29}$$

to derive

$$\begin{aligned}
G_\alpha^i(K)K - G_\alpha^i(KR)KR = &\sum_{l=0}^{k} \prod_{j=0}^{l-1} A_j (KR)^*KR(R^{-1} - I) \prod_{j=l+1}^{k} B_j \\
&+ \sum_{l=0}^{k} \prod_{j=0}^{l-1} A_j (I - R^*)K^*K \prod_{j=l+1}^{k} B_j.
\end{aligned} \tag{3.30}$$

To estimate the sums from 0 to k we decompose them into sums from 0 to $[\frac{k}{2}]$ and from $[\frac{k}{2}] + 1$ to k and use the fact that

$$\left\| \prod_{j=0}^{l-1} A_j (KR)^*KR \right\| \le \frac{1}{l+1}, \qquad \left\| \prod_{j=l+1}^{k} K^*KB_l \right\| \le \frac{1}{k-l+1} \tag{3.31}$$

as well as

$$(KR)^*KR = I - A_l, \qquad K^*K = I - B_l \tag{3.32}$$

and a telescope sum trick to obtain, for the first sum on the right-hand side of (3.30),

$$\left\| \sum_{l=[\frac{k}{2}]+1}^{k} \prod_{j=0}^{l-1} A_j (KR)^*KR(R^{-1}-I) \prod_{j=l+1}^{k} B_j \right\| \le \sum_{l=[\frac{k}{2}]+1}^{k} \frac{1}{l+1} \|R^{-1}-I\| \le \|R^{-1}-I\|$$

and

$$\begin{aligned}
&\left\| \sum_{l=0}^{[\frac{k}{2}]} \prod_{j=0}^{l-1} A_j (KR)^*KR(R^{-1}-I) \prod_{j=l+1}^{k} B_j \right\| \\
&= \left\| \sum_{l=0}^{[\frac{k}{2}]} \prod_{j=0}^{l-1} A_j (I-A_l)(R^{-1}-I) \prod_{j=l+1}^{k} B_j \right\| \\
&= \left\| \sum_{l=1}^{[\frac{k}{2}]} \prod_{j=0}^{l-1} A_j (R^{-1}-I)(I-B_l) \prod_{j=l+1}^{k} B_j \right. \\
&\qquad \left. + (R^{-1}-I) \prod_{j=1}^{k} B_j + \prod_{j=0}^{[\frac{k}{2}]} A_j (R^{-1}-I) \prod_{j=[\frac{k}{2}]+1}^{k} B_j \right\| \\
&\le \left(\sum_{l=1}^{[\frac{k}{2}]} \frac{1}{k-l+1} + 2 \right) \|R^{-1}-I\| \le 3\|R^{-1}-I\|
\end{aligned}$$

and analogously for the second sum on the right-hand side of (3.30).

For iterated Tikhonov regularization, the estimates can be obtained analogously, this time with

$$\begin{aligned}
&A_l := \alpha_l((KR)^*KR + \alpha_l I)^{-1}, \qquad B_l := \alpha_l(K^*K + \alpha_l I)^{-1}, \\
&A_l - B_l = A_l \frac{1}{\alpha_l} \Big((KR)^*KR(R^{-1}-I) + (I-R^*)K^*K \Big) B_l, \\
&G_\alpha^i(K)K - G_\alpha^i(KR)KR = \sum_{l=0}^{k} \prod_{j=0}^{l} A_j (KR)^*KR(R^{-1}-I) \prod_{j=l}^{k} B_j \\
&\qquad\qquad + \sum_{l=0}^{k} \prod_{j=0}^{l} A_j (I-R^*)K^*K \prod_{j=l}^{k} B_j,
\end{aligned} \tag{3.33}$$

$$\left\| \prod_{j=0}^{l} A_j (KR)^*KR \right\| \le \left(\sum_{j=0}^{l} \frac{1}{\alpha_j} \right)^{-1}, \qquad \left\| \prod_{j=l}^{k} K^*KB_l \right\| \le \left(\sum_{j=l}^{k} \frac{1}{\alpha_j} \right)^{-1},$$

and

$$\frac{1}{\alpha_l}(KR)^*KR\, A_l \;=\; I - A_l, \qquad \frac{1}{\alpha_l} B_l\, K^*K \;=\; I - B_l$$

in place of (3.28), (3.29), (3.30), (3.31), (3.32), respectively. In the stationary case (3.22), again cutting of the sum at $[\frac{k}{2}]$ and the telescope trick must be used, and in the nonstationary case (3.23), we apply the telescope sum trick to the whole first sum in (3.33) and leave the second sum unchanged. ∎

We finally want to mention that these results can be extended to the situation where discretization is applied to any of the standard regularization methods.

3.4. Levenberg–Marquardt–Kaczmarz. An alternative to considering the regularized Newton–Kaczmarz approach (1.10) is the generalization of a Levenberg–Marquardt method (cf. [15], (1.7)) to the situation of multiple equations in the following form:

$$x_{n+1} = x_n - (F_n'(x_n)^* F_n'(x_n) + \alpha_n I)^{-1} F_n'(x_n)^* (F_n(x_n) - y_n^\delta).$$

Note that this formally corresponds to the (intuitively optimal) formal choice of $x_{0,n} = x_n$ in (1.10), which, however, is not admissible in view of the convergence analysis given here, that requires a cyclic repetition of the starting guesses according to $x_{0,n} = x_{0,mod(n,p)}$.

Under a nonlinearity condition of the type (2.6) and with an appropriate a posteriori choice of the sequence α_n, along the lines of the proofs in [15], and similarly to [24], one can show that the error $\|x_n - x^\dagger\|$ is monotonically decreasing up to an index $n = N(\delta)$ determined by the discrepancy principle, without having to make assumptions of the type (3.14). Moreover, the norms of the residuals are squared summable in case of exact data and therewith

$$F_n(x_n) - y_n \to 0 \text{ as } n \to \infty. \tag{3.34}$$

This implies that there exists a weakly convergent subsequence of x_n. However, the limit of a weakly convergent subsequence $(x_{n_l})_{l\in\mathbb{N}}$ of $(x_n)_{n\in\mathbb{N}}$ need not necessarily be a solution to (1.2), even if the F_i are (weakly) sequentially closed, i.e., for any sequence $(x_k)_{k\in\mathbb{N}} \subseteq \mathcal{D}(F_i)$ and $f_i \in Y_i$,

$$\Big(x_k \rightharpoonup x \wedge F_i(x_k) \to f_i\Big) \quad \Rightarrow \quad \Big(x \in \mathcal{D}(F_i) \wedge F_i(x) = f_i\Big). \tag{3.35}$$

Namely, if, e.g., $(x_{n_l})_{l\in\mathbb{N}} \subseteq (x_{mp+\bar{i}})_{m\in\mathbb{N}}$ for some $\bar{i} \in \{0, \dots, p-1\}$, then (3.34) and (3.35) imply that the weak limit of $(x_{n_l})_{l\in\mathbb{N}}$ is a solution of $F_{\bar{i}}(x) = y_{\bar{i}}$ only but not necessarily of $F_i(x) = y_i$ with $i \neq \bar{i}$. Also, strong convergence to $x^\dagger$ of x_n as $n \to \infty$ in the case of exact data or of $x_{N(\delta)}$ in the noisy situation cannot be proved by methods like those used in [15], [24], even in the linear case. Still, necessary convergence conditions on the initial guess can be expected to be less restrictive for (1.7) than for (1.10) as the linear case with bounded generalized inverses indicates: setting all regularization parameters α_n to zero we arrive at the error recursion

$$x_{n+1} - x^\dagger = \mathcal{P}_{N(F_n)}(x_n - x^\dagger) = \mathcal{P}_{N(F_n)}\mathcal{P}_{N(F_{n-1})} \cdots \mathcal{P}_{N(F_0)}(x_0 - x^\dagger),$$

so that one even obtains termination of the iteration with $x_{n+1} = x^\dagger$ as soon as $\mathcal{P}_{N(F_{n-1})} \cdots \mathcal{P}_{N(F_0)}(x_0 - x^\dagger) \in \mathcal{N}(F_n)^\perp$ for some n.

4. Numerical solution methods. In the following we discuss some possible discretization strategies and methods for the solution of the arising finite-dimensional problems.

4.1. Primal method. For all the optimization approaches discussed above, one can use a standard Galerkin discretization strategy by choosing a finite-dimensional subspace $X^h \subset X$ and solving a weak form of the discretized Newton equation for x_{n+1}^h. For the IRGNK method, we have $G_{\alpha_n}^n = M_n^{-1} F_n'(x_n^h)^*$ with the positive definite operator $M_n := F_n'(x_n^h)^* F_n'(x_n^h) + \alpha_n I$. Using this special form, we can discretize a step of the IRGNK method via

$$\langle M_n(x_{n+1}^h - x_{0,n}^h), \varphi\rangle = -\langle (F_n(x_n^h) - y_n^\delta - F_n'(x_n^h)(x_n^h - x_{0,n}^h)), F_n'(x_n^h)\varphi\rangle \qquad \forall\, \varphi \in X^h.$$

By iterating this discretization procedure k times, one obtains a discrete form of the IRGNK$_k$ method. Due to the positive definiteness of M_n, one can solve this problem iteratively by a preconditioned conjugate gradient method, where all standard preconditioners for the Tikhonov regularization can be used (cf. [34] for an overview).

In the case of the Newton–Landweber iteration, we obtain the same equation for each Landweber step finally leading to x_{n+1}^h but now with $M_n = I$, which gives a quasi-explicit form for the next iteration (one only has to invert a mass matrix corresponding to the identity operator, which does not even change during the iteration).

4.2. Dual method. In the following we shall consider a dual method for the IRGNK, i.e., the Newton–Kaczmarz method with the choice $G_\alpha(K) = (K^*K + \alpha I)^{-1}K^*$. We shall now derive a dual method, which is particularly suitable for the important case that the output spaces Y_i are of lower dimensionality than the parameter space X (which is the case for the examples considered above).

A first observation is that each iteration step of the IRGNK method is equivalent to the minimization problem

$$\frac{1}{2}\|F_n(x_n) + F_n'(x_n)(x - x_n) - y_n\|^2 + \frac{\alpha_n}{2}\|x - x_{0,n}\|^2 \to \min_{x\in X}. \tag{4.1}$$

By defining the right-hand side $z := y_n - F_n(x_n) - F_n'(x_n)x_n$ and the linear operator $K := F_n'(x_n)$, this optimization problem is of the form

$$J_1(Kx) + J_2(x) \to \min_{x\in X} \tag{4.2}$$

with (omitting the index n in the regularization parameter α_n)

$$J_1(y) = \frac{1}{2}\|y - z\|^2, \qquad J_2(x) = \frac{\alpha}{2}\|x - x_{0,n}\|^2.$$

Both the functionals J_1 and J_2 are convex, and therefore standard Fenchel duality (cf. [10]) implies that the primal problem (4.2) is equivalent to the dual problem

$$J_1^*(-v) + J_2^*(K^*v) \to \min_{v\in Y_n}, \tag{4.3}$$

where J_1^* and J_2^* are the conjugate functionals, which are obtained as

$$J_1^*(v) = \sup_{y\in Y_n} \langle v, y\rangle - J_1(y) = \frac{1}{2}\|v + z\|^2 - \frac{1}{2}\|z\|^2,$$

$$J_2^*(w) = \sup_{x\in X} \langle w, x\rangle - J_2(x) = \frac{1}{2\alpha}\|w + \alpha x_{0,n}\|^2 - \frac{\alpha}{2}\|x_{0,n}\|^2.$$

Moreover, the solution v of the dual problem (4.3) and the solution x of the primal problem are connected by the optimality condition

$$K^*v = J_2'(x) = \alpha(x - x_{0,n}).$$

Thus, we may compute $x = x_{0,n} + \frac{1}{\alpha}K^*v$ once we have solved the dual problem.

By ignoring the constant terms in the conjugate functionals, we may equivalently state the dual problem as

$$\frac{1}{2}\|-v+z\|^2+\frac{1}{2\alpha}\|K^*v+\alpha x_{0,n}\|^2\to\min_{v\in Y_n}, \tag{4.4}$$

which can be discretized, e.g., by the Ritz method on a subspace of Y_n, i.e., by minimizing the functional in (4.4) on a finite-dimensional subspace $Y_n^h\subset Y_n$. This automatically yields a discretization of the update in the primal space via $x_n^h-x_{0,n}=\frac{1}{\alpha}K^*v^h$, where v^h is the discrete solution of the dual problem.

The main advantage of a dual strategy is the (possible) lower dimensionality of the spaces Y_n, which yields smaller discrete problems and consequently a faster solution. In many important cases such as the examples presented above, the spaces Y_n do not depend on the iteration index but are the same for each step, such that one does not have to change the basis over the Kaczmarz sweep.

4.3. Primal-dual methods for PDE-constrained problems. As we have seen in the examples above, the operator F_i is defined implicitly via the solution of PDEs in many applications. We formally write the partial differential equation as a nonlinear operator equation of the form

$$E_i(u_i,q)=0,$$

where $E_i:\mathcal{U}\times X\to\mathcal{V}$ is a continuously differentiable nonlinear operator such that $\frac{\partial E_i}{\partial u}$ is regular for each $u\in\mathcal{U}$. The operator F_i is typically obtained as $F_i:=L_i\circ H_i$, where $H_i(q)=u_i$. We shall derive a primal-dual solution method in this case.

One step of the IRGNK method can be rewritten as the constrained problem

$$\frac{1}{2}\|L_nv+L_nu_n-y_n\|^2+\frac{\alpha_n}{2}\|s+q_n-q_{0,n}\|^2\to\min_{(v,s)}$$

subject to the constraint that $v=H_n'(q_n)s$, which can be expressed using the implicit function theorem as

$$\frac{\partial E_{n+1}}{\partial u}(u_n,q_n)v+\frac{\partial E_{n+1}}{\partial q}(u_n,q_n)s=0,$$

where $u_n=H_n(q_n)$. Deriving the KKT conditions for this constrained problem, we obtain an indefinite system for the primal variables v, s, and a dual variable w, given by

$$\begin{pmatrix} L_n^*L_n & 0 & A_n^* \\ 0 & \alpha_nI & B_n^* \\ A_n & B_n & 0 \end{pmatrix}\begin{pmatrix} v \\ s \\ w \end{pmatrix}=\begin{pmatrix} L_n^*y_n-L_n^*L_nu_n \\ \alpha_n(q_{0,n}-q_n) \\ 0 \end{pmatrix}$$

with the linear operators $A_n:=\frac{\partial E_{n+1}}{\partial u}(u_n,q_n)$ and $B_n:=\frac{\partial E_{n+1}}{\partial q}(u_n,q_n)$.

This indefinite system can be discretized using a mixed approach, i.e., we look for a solution (v^h,s^h,w^h) in the finite-dimensional subspaces $\mathcal{U}^h\times X^h\times\mathcal{V}^h$ satisfying

$$\begin{aligned}\langle L_nv,L_n\varphi\rangle+\langle A_n\varphi,w\rangle&=\langle y_n-L_nu_n,L_n\varphi\rangle,\\ \alpha_n\langle s,\sigma\rangle+\langle B_n\sigma,w\rangle&=\alpha_n\langle q_{0,n}-q_n,\sigma\rangle,\\ \langle A_nv,\psi\rangle+\langle B_ns,\psi\rangle&=0\end{aligned}$$

for all $(\varphi,\sigma,\psi)\in\mathcal{V}^h\times X^h\times\mathcal{U}^h$.

The resulting indefinite system can be solved by a preconditioned conjugate gradient method for the Schur complement, or directly by a preconditioned Krylov subspace method for indefinite systems like GMRES, QMR, or MINRES. We refer to [4, 5] for the discussion of solution methods for indefinite systems arising from primal-dual formulations in parameter identification.

5. Numerical examples. In the following we shall present numerical results for two of the examples introduced above.

5.1. Reconstruction with multiple sources. We start with numerical results for Example 2 in the one-dimensional domain $\Omega = (0, 1)$, using $p = 20$ localized sources of the form

$$h_i(x) = 10e^{-10(x-\frac{i+1}{p+1})^2}.$$

The data correspond to the "exact solution" $q^*(x) = 5 + 5x(1 - x)$ and the initial value is $q_0 \equiv 5$. Note that in general we cannot expect the least-squares minimum norm solution $q^\dagger$ to be equal to q^*, since we use only a finite number of measurements. However, we shall see below that the resulting limit $q^\dagger$ is close to q^*, with a difference probably caused due to the limited numerical resolution only.

For the numerical solution we use the iteratively regularized Gauss–Newton–Kaczmarz method, i.e., Tikhonov regularization in $H^1(\Omega)$ as the linear regularization method. The iteration is discretized using a primal-dual method as described above, with piecewise linear finite elements on a uniform grid of size $h = 0.01$.

We first test the convergence behavior in the noise-free case. To this end, we generate the data on the same grid as we later solve the inverse problem and choose the regularization parameters as

$$\alpha_n = \alpha_0 \zeta^{-n} \tag{5.1}$$

with $\zeta = 1.1$ and $\alpha_0 = 10^{-5}$. The convergence behavior is illustrated in Figures 5.1 and 5.2 by the iterates at several different steps. The behavior during the first Kaczmarz sweep is illustrated in Figure 5.1. In iterations 1 and 4, for which we use sources localized close to the left boundary $x = 0$, the convergence is more pronounced close to the left boundary. Vice versa, for later iterations (20), with sources localized close to the right boundary $x = 1$, the reconstruction is better close to the right boundary. In the medium stage of a Kaczmarz sweep, at iterate 8 with sources localized in the middle of the interval $(0, 1)$, the iterate appears almost symmetric. In the later stage of the iteration we plot the iterates q_n at $n = 50, 60$ (i.e., those in the middle and at the end of a Kaczmarz sweep) in Figure 5.2. One observes convergence of the algorithm, which turns out to be slightly faster for the iterates in the middle of the Kaczmarz sweep. The reason for this behavior is mainly the ordering of the sources; one will of course obtain a different behavior for different ordering. We finally provide a quantitative basis for the above observations on the behavior of the iterates in Figure 5.3, where we plot the development of the error $\|q^* - q_n\|$ (dashed, on the left) and of the residual $\|F_n(q_n) - y_n\|$ (on the right). In the left plot we also plot the error at the end of each Kaczmarz sweep $\|q^* - q_{np}\|$ (solid) and in the middle of the Kaczmarz sweep $\|q^* - q_{np+n/2}\|$ (dotted). In this example it turned out that the total error is not always decreasing, but the error at the same stage of the Kaczmarz sweep $\|q^* - q_{np+j}\|$ (for $0 \le j \le p-1$) is decreasing with n. In particular, it seems that the error at the beginning and end of the sweep is always the maximum one in the sweep, while the one in the middle of the sweep is always the minimum one. Since all of them decrease toward zero, we obtain the expected worst-case convergence, but of course

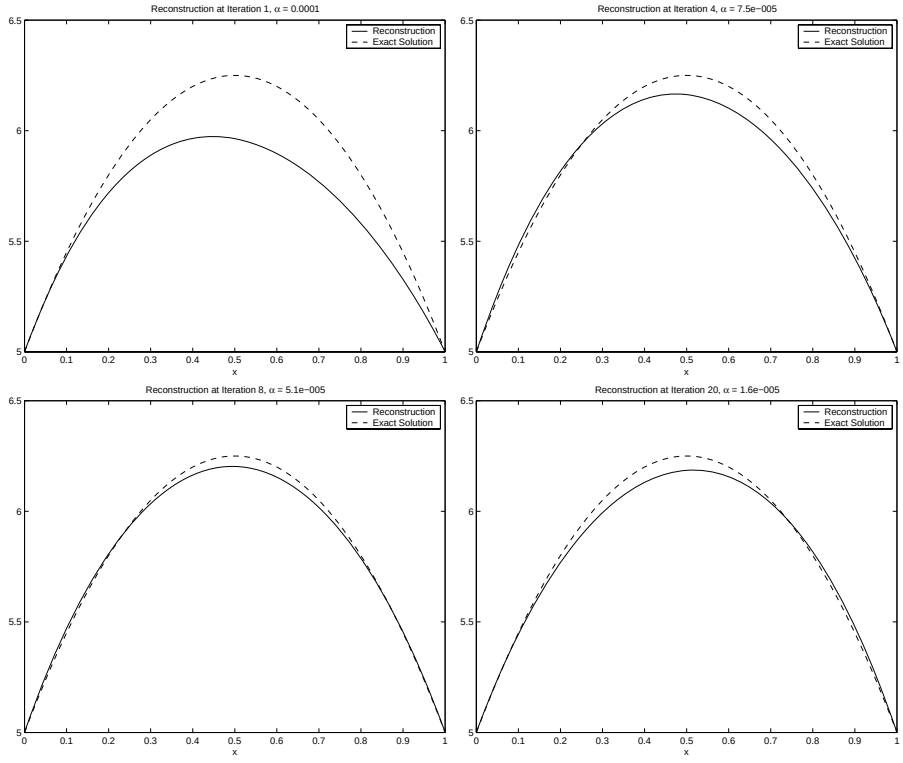

FIG. 5.1. *Reconstructions in the first example, $\delta = 0$, at iterates* 1, 4, 8, *and* 20.

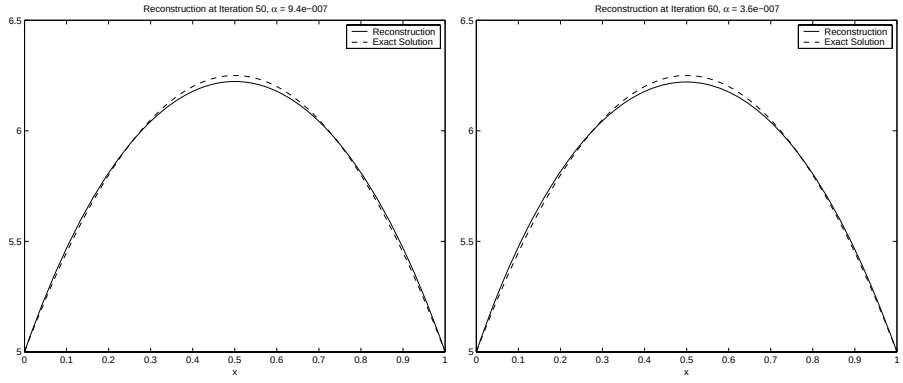

FIG. 5.2. *Reconstructions in the first example, $\delta = 0$, at iterates* 50 *and* 60.

in practice one should consider suitable orderings of the data y_i. The comparison of the residual at different iterates is even more difficult, since the operators and data are different in each step. However, we also obtain that $\|F_{np+j}(q_{np+j}) - y_{np+j}\|$ (for $0 \le j \le p-1$) is decreasing to zero with n.

For the noisy case we generated data on a finer grid of size $h = \frac{1}{347}$ in order to avoid inverse crimes. The resulting data are then perturbed using uniform random noise in the interval $[-\delta, \delta]$. The regularization parameters are chosen again via (5.1) with $\zeta = 1.1$ and $\alpha_0 = 10^{-2}$.

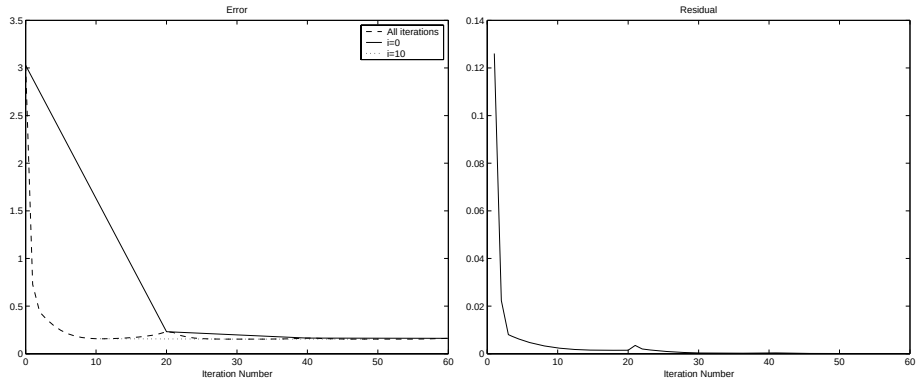

FIG. 5.3. *Plot of error (left) and residual (right) vs. iteration number in the first example,* $\delta = 0$.

We illustrate the reconstructions obtained for different noise levels (close to the minimum of the error during the iteration) in Figure 5.4. In clockwise order the plots show the reconstruction for noise level $\delta = 0.5\%$ (at iteration 90), $\delta = 1\%$ (at iteration 50), $\delta = 3\%$ (at iteration 30), and $\delta = 5\%$ (at iteration 30). One observes that the quality of the reconstruction improves with decreasing δ, i.e., the error of the iterate at the stopping index decreases with δ, thus confirming the convergence result for the noisy case. A quantitative monitoring of error and residual versus the iteration number is presented in Figure 5.5 for $\delta = 1\%$ (top), $\delta = 3\%$ (middle), and $\delta = 5\%$ (bottom). One also sees that the minimal error and residual obtained during the iteration decreases with δ as expected. As usual for ill-posed problems the error decreases only until some iteration step and then increases again although the residual is still decreasing. Note that this statement has to interpreted in a different sense, namely, for the subsequences $np + i$, $0 \le i \le p - 1$. Moreover, the variation in the error and residual during a sweep over the different sources increases with the noise level, which obviously makes the choice of the stopping index more difficult.

We finally investigate the effect of a different choice of regularization operators in each iteration step. With the localized sources we use it seems natural to localize the regularization. For this sake we compute the update from the regularized Newton equation

$$(F_n'(x_n)^* F_n'(x_n) + \alpha_n A + \beta_n B_n)(x_{n+1} - x_n) = -F_n'(x_n)^*(F(x_n) - y_n^\delta) + \alpha_n A(x_{0,n} - x_n),$$

where

$$Av := -\Delta v + v \qquad \text{and} \qquad B_n v := -\mathrm{div}(\omega_n \nabla v) + \omega_n,$$

with the weight functions $\omega_i := |x - \frac{i+1}{p+1}|$. The rationale behind the approach is that the additional part involving the operator B_n damps the update away from the point $\frac{i+1}{p+1}$, which can be considered as the location of the ith source. In this way too-large changes away from the measurement location are avoided, which usually decrease the quality of the reconstruction. The effect of the localized regularization is an improved convergence behavior, and the decay of error and residuals becomes less oscillatory, which is clearly an advantage with respect to the choice of the stopping index. Moreover, the shape of the reconstruction at different iterates depends less significantly on the localization of the last measurements used. We illustrate the

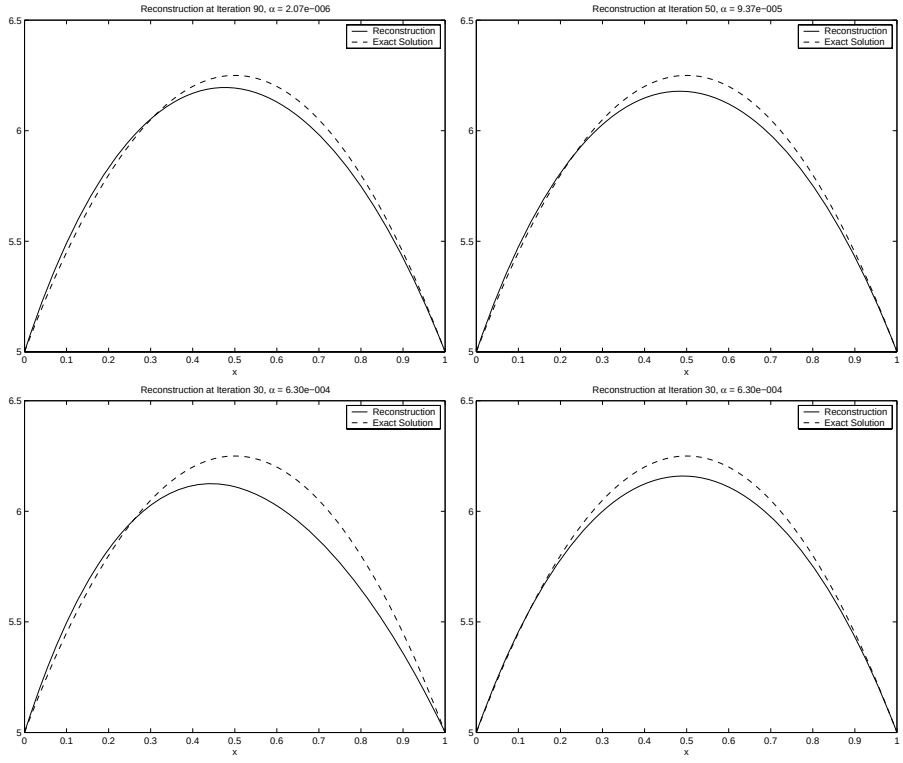

FIG. 5.4. *Reconstructions in the first example, for noise levels $\delta = 0.5\%$ (top left), $\delta = 1\%$ (top right), $\delta = 3\%$ (bottom right), $\delta = 5\%$ (bottom left).*

behavior in Figure 5.6 for 3% noise, in the same setup as above. The additional parameter β_n is chosen as $\beta_n = 0.5(1.01)^{-n}$. Compared to the same case in Figure 5.5 one observes a much smoother decay of the error and no significant differences in the behaviour at different steps of the sweep.

5.2. Reconstruction from Dirichlet–Neumann data. Our second numerical experiment is the solution of Example 1, i.e., the reconstruction of the coefficient q in

$$-\Delta u + qu = 0 \qquad \text{in } \Omega \subset \mathbb{R}^d$$

from $p = 20$ values of the Dirichlet-to-Neumann map. In our numerical example, the two-dimensional domain is $\Omega = (0,1)^2$, on which the differential equation is discretized by finite differences on a uniform grid of size $h = 0.025$.

The applied Dirichlet sources f_j are identically zero on three of the boundary segments and of the form

$$f_j(x_1,x_2) = \begin{cases} 10^3 e^{-50((x_1-j/6)^2} & \text{for } j = 1,\dots,5, x_2 = 0, \\ 10^3 e^{-50((x_1-(j-5)/6)^2} & \text{for } j = 6,\dots,10, x_2 = 1, \\ 10^3 e^{-50((x_2-(j-10)/6)^2} & \text{for } j = 11,\dots,15, x_1 = 0, \\ 10^3 e^{-50((x_2-(j-15)/6)^2} & \text{for } j = 16,\dots,20, x_1 = 1 \end{cases}$$

on the fourth segment, i.e., they approximate Dirac-delta impulses equally distributed over the boundary.

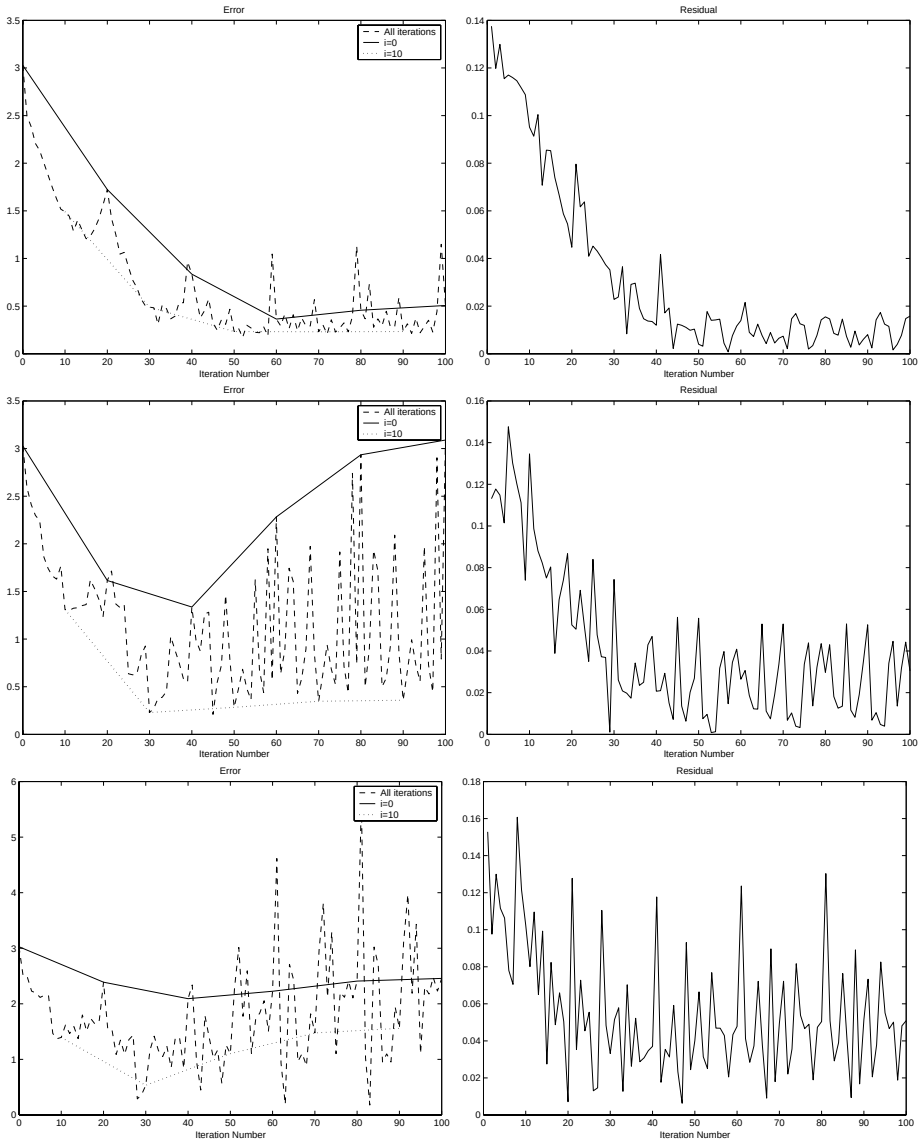

FIG. 5.5. *Plot of error (left) and residual (right) versus iteration number in the first example, for noise levels $\delta = 1\%$ (top), $\delta = 3\%$ (middle), $\delta = 5\%$ (bottom).*

In this case we use the Levenberg–Marquardt–Kaczmarz method, i.e., a Tikhonov-type stabilization in the H^1-norm in each step with prior q_n. This means that in each step of the method, the update $s = q_{n+1} - q_n$ is obtained by solving the minimization problem

$$\frac{1}{2}\left\|\frac{\partial v_n}{\partial \nu} - g_n\right\|^2_{H^{-1/2}(\partial\Omega)} + \frac{\alpha_n}{2}\|s\|^2_{H^1(\Omega)}$$

subject to the linear equation

$$-\Delta v_n + q_n v_n + s u_n = 0 \qquad \text{in } \Omega$$

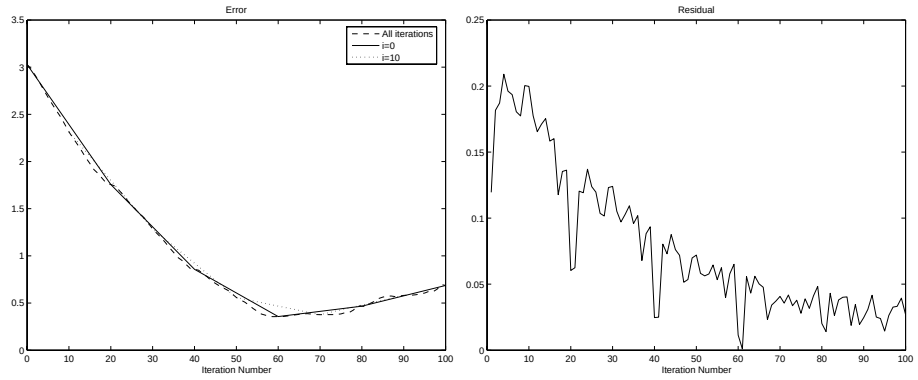

FIG. 5.6. *Plot of error (left) and residual (right) versus iteration number in the first example with localized regularization, for noise level* $\delta = 3\%$.

for v_n with homogeneous Dirichlet boundary values on $\partial\Omega$. The norm in $H^{-1/2}(\partial\Omega)$ of an element g is realized by

$$\|g\|_{H^{-1/2}(\partial\Omega)} := \|\phi_g\|_{H^1(\Omega)},$$

where $\phi_g \in H^1(\Omega)$ is the unique weak solution of

$$\int_\Omega (\nabla\phi_g \cdot \nabla\psi + \phi_g\psi)\ dx = \int_{\partial\Omega} g\psi\ d\sigma \qquad \forall\ \psi \in H^1(\Omega).$$

This means we have to solve an additional Neumann problem to evaluate the norm.

We use a primal-dual approach to discretize this problem, which means that we have to find two Lagrange multipliers corresponding to the partial differential equations for v_n and the function ϕ_g used to evaluate the norm. A careful investigation of the optimality system shows that ϕ_g can be eliminated in favor of one of the Lagrange multipliers, and the optimality system in each step becomes after straightforward transformations

$$\begin{aligned} -\Delta v_n + q v_n + s u_n &= 0, \\ -\Delta\lambda + q\lambda &= 0, \\ -\Delta\mu + \mu + (1-q)v_n - s u_n &= 0, \\ -\Delta s + s + \frac{1}{\alpha} u_n \lambda &= -\Delta(q_0 - q_n) + q_0 - q_n \end{aligned}$$

in Ω, supplemented by the boundary conditions

$$\begin{aligned} v_n &= 0, \\ \lambda - \mu &= \phi_n - \phi_{g_n}, \\ \frac{\partial\mu}{\partial\nu} &= 0, \\ s &= 0 \end{aligned}$$

on $\partial\Omega$. The functions ϕ_n and ϕ_{g_n} are the functions used to evaluate the $H^{-1/2}$-norm of $\frac{\partial u_n}{\partial\nu}$ and g_n, respectively, defined in the same way as ϕ_g above.

We start with some examples using data generated from the parameter

$$\hat{q} = 3 + 5\sin(\pi x)\sin(\pi y)$$

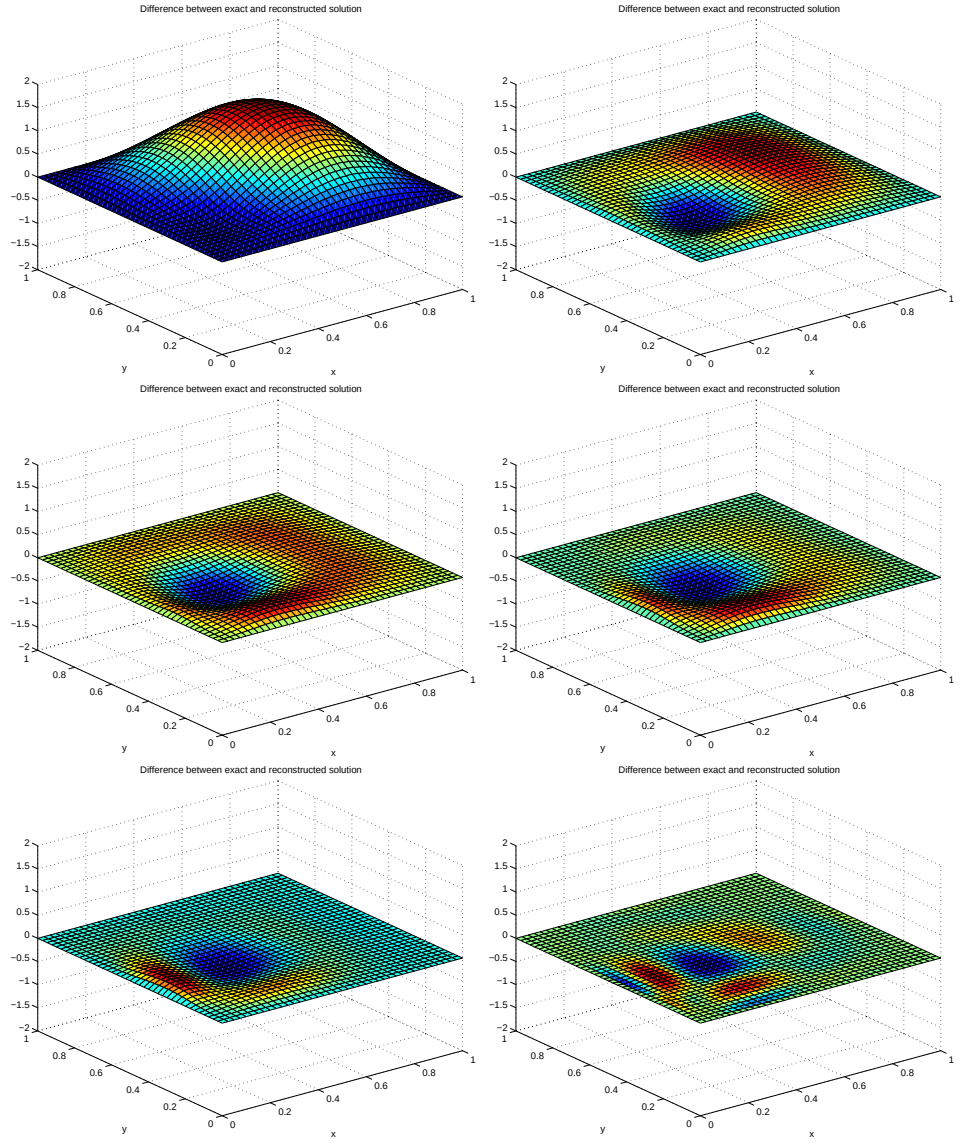

FIG. 5.7. *Difference* $\hat{q} - q_n$ *in the second example at iterates* 1, 2, 3, 5, 10, *and* 100.

and the starting value $q_0 \equiv 3$. Note that again $\hat{q}$ is not necessarily the minimum norm solution of the inverse problem with the above measurements, but since we expect that a successful reconstruction algorithm should at least approximate $\hat{q}$ and since we do not know the minimum norm solution, we measure the error as the difference between $\hat{q}$ and q_n. In order to test the convergence of exact data, we generate data on the same grid as the one used for solving the inverse problem and then perform the IRGNK algorithm with α_n chosen according to (5.1) with $\zeta = 1.05$ and $\alpha_0 = 10^{-8}$.

The difference between $\hat{q}$ and q_n is shown in Figure 5.7, at the iterates $n = 1, 2$ (top), $n = 3, 5$ (middle), and $n = 10, 100$ (bottom). One observes that the error is reduced very fast globally, but one also observes a certain local influence of the sources,

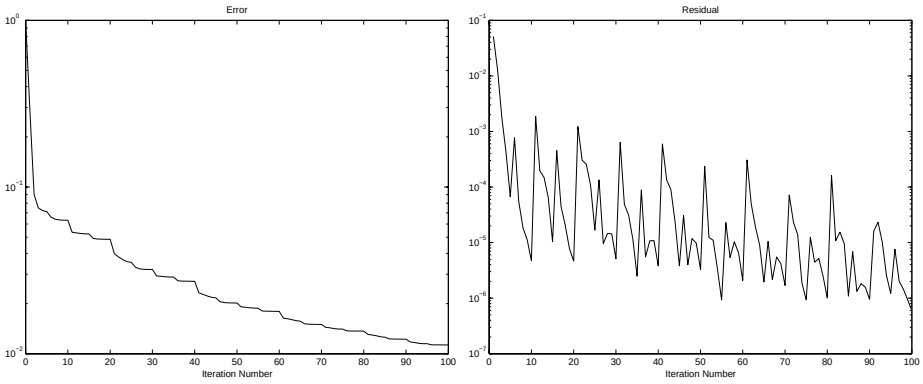

FIG. 5.8. *Semilogarithmic plot of error (left) and residual (right) versus iteration number in the second example,* $\delta = 0$.

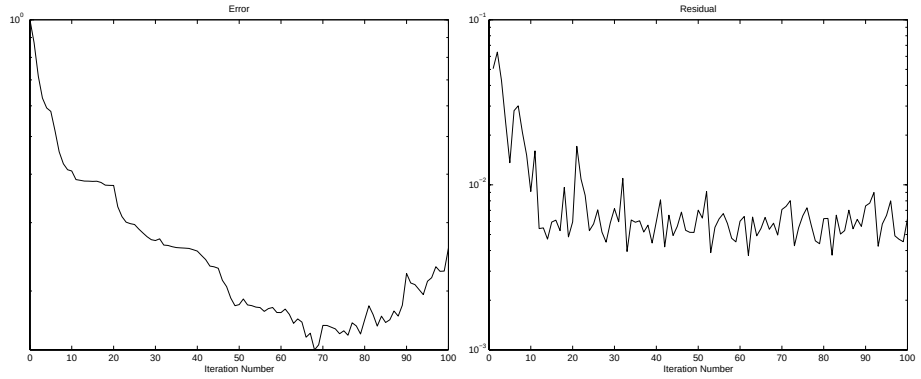

FIG. 5.9. *Semilogarithmic plot of error (left) and residual (right) versus iteration number in the second example,* $\delta = 1\%$.

i.e., the convergence seems faster closer to the support of the boundary sources. The quantitative development of the error $\|\hat{q} - q_n\|$ (left) and the residual $\|F(q_n) - g_n\|$ (right) are shown in a semilogarithmic scale in Figure 5.8.

Moreover, we test the behavior of the algorithm with respect to noise by using Gaussian random noise of variance $\delta = 1\%$ and $\delta = 0.5\%$. We plot the development of the error (left) and the residual (right) in a semilogarithmic scale in Figure 5.9 for $\delta = 1\%$ and in Figure 5.10 for $\delta = 0.5\%$. One observes the expected semiconvergence in both cases, i.e., the error reaches a minimum around which one should stop the iteration, and then starts to increase again. As expected, the minimal error appearing during the iteration decreases with the noise level, one obtains a minimal relative error 0.14 for $\delta = 1\%$ and 0.11 for $\delta = 0.5\%$.

We finally test the behavior for a more complicated exact parameter value

$$\hat{q} = 3 + 2\sin(3\pi x_1)\sin(2\pi x_2).$$

In this case we change the initial value α_0 to 10^{-12} due to the lower sensitivity of the data with respect to this parameter. The development of error and residual are

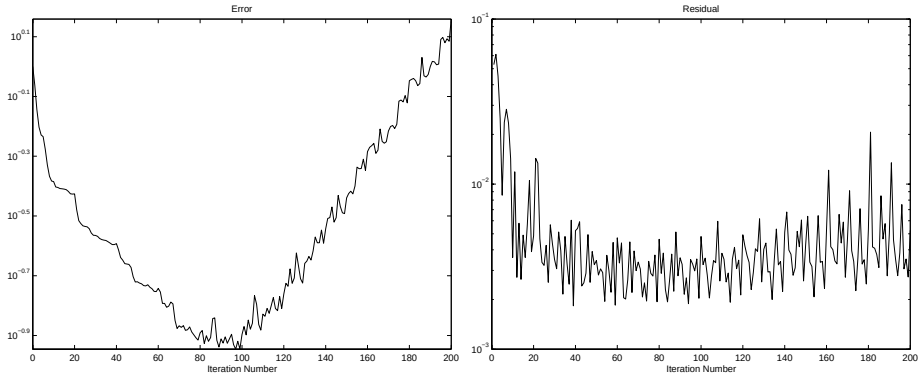

FIG. 5.10. *Semilogarithmic plot of error (left) and residual (right) versus iteration number in the second example,* $\delta = 0.5\%$.

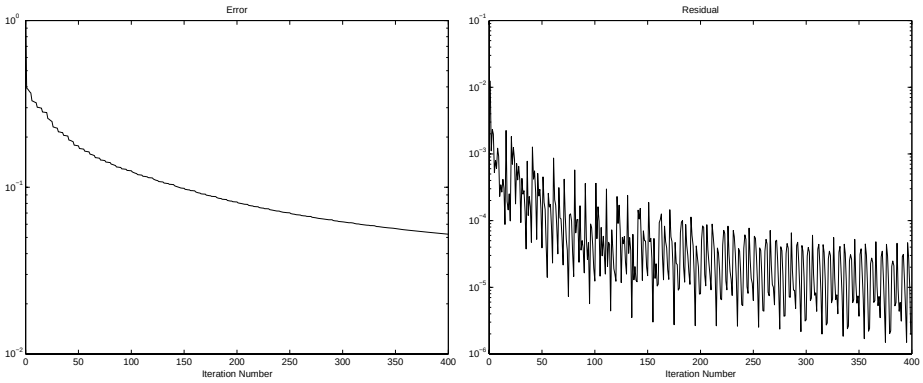

FIG. 5.11. *Semilogarithmic plot of error (left) and residual (right) versus iteration number in the second example for different exact solution,* $\delta = 0$.

shown in semilogarithmic scale in Figure 5.11. One observes that the method seems to converge in this case, too, although more slowly than in the above example, which is also caused by the lower sensitivity.

6. Conclusions and open problems. We have derived a detailed convergence analysis of regularized Newton–Kaczmarz methods for nonlinear ill-posed problems, which—as usual for ill-posed problems—can be carried out under certain conditions on the nonlinearity of the operators involved. As we have demonstrated in several examples from practice, these conditions seem not to be too restrictive in the case of Newton–Kaczmarz methods. Moreover, we have discussed the numerical solution of the linear problems arising in each step of the iteration method by three different approaches. The numerical experiments we carried out confirm the theoretical predictions.

So far, we have discussed a priori stopping rules (in the sense of [11]) only, whereas in practice it seems to be more important to have a posteriori stopping rules, which depend not only on the noise level δ but also on the actual data y^δ. In [24], a stopping rule is proposed for the Landweber–Kaczmarz method that is based on Morozov's discrepancy principle, i.e., a comparison of the residual norm with the noise level. Such

an approach would probably be appropriate also in our Newton–Kaczmarz context. However, we expect that a rigorous convergence analysis with such a residual type stopping criterion would have to be based on a nonlinearity assumption similar to (2.6) (as done in [24]) rather than the condition (2.2) that we have verified for our application examples here.

As mentioned in section 3.2, the condition (3.14) on the initial values poses a severe theoretical restriction that seems to be inevitable for Newton–Kaczmarz methods of the type (1.10) as the linear case shows. A possible way out might be to define the iteration by (1.7). Here the methods of proof considered so far for $p = 1$ (cf. [15]) rely on nonlinearity conditions of the type (2.5) but not on (2.4), in whose extension to $p > 1$, (2.2) we are interested here, however. Thus, new ideas would be necessary for proving convergence, perhaps based on a sweepwise instead of a stepwise analysis.

A DISCONTINUOUS FINITE VOLUME METHOD FOR THE STOKES PROBLEMS*

XIU YE†

Abstract. We develop a new discontinuous finite volume method for solving the Stokes equations on both triangular and rectangular meshes. An optimal error estimate for the approximation of velocity is obtained in a mesh-dependent norm. First order L^2-error estimates are derived for the approximations of both velocity and pressure.

Key words. discontinuous Galerkin method, finite volume methods, Stokes problems

1. Introduction.

Like finite element methods and finite difference methods, finite volume methods are discretization techniques for solving partial differential equations (PDEs). The integral formulation of finite volume schemes for a PDE is obtained by integrating the PDE over a control volume. In general, it represents the conservation of a quantity of interest, such as mass, momentum, or energy in fluid mechanics. Due to this natural association and its simplicity, finite volume methods are widely used in computational fluid mechanics and other applications [5, 6, 17]. Recently, Chou, Kwak, and Vassilevski [7, 8, 9, 10] applied finite volume methods involving nonconforming trial functions for diffusion, diffusion-reaction, and Stokes problems.

The discontinuous Galerkin method is a very active research field, and much literature can be found related to it [1, 2, 3, 4, 11, 12, 14, 16, 20, 19]. Discontinuous Galerkin methods use discontinuous functions as finite element approximation and enforce the connections of the approximation solutions between elements by adding some penalty terms. The flexibility of discontinuous functions gives discontinuous Galerkin methods many advantages, such as high order of accuracy, high parallelizability, localizability, and easy handling of complicated geometries.

Based on the advantages of using discontinuous functions as approximation in discontinuous Galerkin methods, it is natural to consider using discontinuous function as trial functions in the finite volume method, which we called the discontinuous finite volume method. Such method has the flexibility of the discontinuous Galerkin method and the simplicity and conservative properties of the finite volume method. In [21], a new discontinuous finite volume method was developed and analyzed for the second order elliptic problem. The local properties of the discontinuous finite volume method also reflect on the size of its control volume, which is less than half the control volume used in existing finite volume methods.

In this paper, we will extend the ideas developed in [21] to solve the Stokes equations on both triangular and rectangular meshes. In our methods, velocity is approximated by discontinuous piecewise linear functions on triangular mesh and by discontinuous piecewise rotated bilinear functions on rectangular mesh. Piecewise constant functions are used as the test functions for velocity in the discontinuous

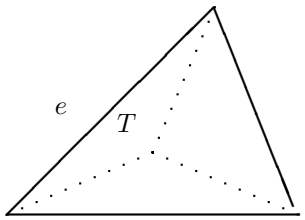

FIG. 1. *Element $T \in \mathcal{T}_h$ for triangular mesh.*

finite volume method. Therefore, after multiplying the differential equations by a test function and integrating by parts, the area integrals in the formulations will disappear, which gives the simplicity of finite volume method.

One of the advantages of using discontinuous approximation functions is it is easy to build high order elements. It is natural to consider using high order elements in the discontinuous finite volume formulations. However, use of higher order trial functions in finite volume methods may result in raising the order of the test functions. This implies that the test functions are no longer the piecewise constant that will cost the simplicity of finite volume methods. Nevertheless, it is worth a future research effort to investigate the high order discontinuous finite volume method.

Since discontinuous functions are used in the approximation, the number of unknowns is greater. However, the small support of the control volume for this method makes the method suitable for domain decomposition since the information can be updated triangle by triangle in the primary partition.

We consider the Stokes equations

$$-\nu\Delta\mathbf{u} + \nabla p = \mathbf{f} \quad \text{in } \Omega, \tag{1}$$

$$\nabla \cdot \mathbf{u} = 0 \quad \text{in } \Omega, \tag{2}$$

$$\mathbf{u} = 0 \quad \text{on } \partial\Omega, \tag{3}$$

where the symbols Δ, ∇, and $\nabla\cdot$ denote the Laplacian, gradient, and divergence operators, respectively, and $\mathbf{f}(x)$ is the external volumetric force acting on the fluid at $x \in \Omega \subset R^2$. We assume $\nu = 1$.

2. Preliminaries and notations. We will use the standard definitions for the Sobolev spaces $H^s(K)$ and their associated inner products $(\cdot,\cdot)_{s,K}$, norms $\|\cdot\|_{s,K}$, and seminorms $|\cdot|_{s,K}$, $s \geq 0$. The space $H^0(K)$ coincides with $L^2(K)$, in which case the norm and inner product are denoted by $\|\cdot\|_K$ and $(\cdot,\cdot)_K$, respectively. If $K = \Omega$, we drop K. Let $L_0^2(\Omega)$ to denote the subspace of $L^2(\Omega)$ consisting of functions with mean value zero.

Let $\mathcal{R}_h$ be a triangular or rectangular partition of Ω with $\text{diam}(\Omega) \leq h$. The triangles or rectangles in $\mathcal{R}_h$ are divided into three or four subtriangles by connecting the barycenter of the triangle or the center of the rectangles to their corner nodes, respectively, as shown in Figures 1 and 2. Then we define the dual partition $\mathcal{T}_h$ of the primal partition $\mathcal{R}_h$ to be the union of the triangles shown in Figures 1 and 2 for both rectangular and triangular mesh.

Let $P_k(T)$ consist of all the polynomials with degree less than or equal to k defined on T. We define the finite dimensional trial function space for velocity on triangular partition by

$$V_h = \{\mathbf{v} \in L^2(\Omega)^2 : \ \mathbf{v}|_K \in P_1(K)^2 \ \ \forall K \in \mathcal{R}_h\}$$

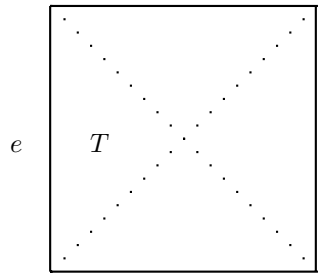

FIG. 2. *Element $T \in \mathcal{T}_h$ for rectangular mesh.*

and on rectangular partition by

$$V_h = \{\mathbf{v} \in L^2(\Omega)^2 : \ \mathbf{v}|_K \in \hat{Q}_1(K)^2 \ \ \forall K \in \mathcal{R}_h\},$$

where $\hat{Q}_1(K)$ denotes the space of functions of the form $a + bx_1 + cx_2 + d(x_1^2 - x_2^2)$ on K. Define the finite dimensional test function space W_h for velocity associated with the dual partition $\mathcal{T}_h$ as

$$W_h = \{\xi \in L^2(\Omega)^2 : \ \xi|_T \in P_0(T)^2 \ \ \forall T \in \mathcal{T}_h\}.$$

Let Q_h be the finite dimensional space for pressure

$$Q_h = \{q \in L_0^2(\Omega) : \ q|_K \in P_0(K) \ \ \forall K \in \mathcal{R}_h\}.$$

Multiplying (1) and (2) by $\xi \in W_h$ and $q \in Q_h$, respectively, we have

$$-\sum_{T\in\mathcal{T}_h} \int_{\partial T} \frac{\partial \mathbf{u}}{\partial \mathbf{n}} \cdot \xi ds + \sum_{T\in\mathcal{T}_h} \int_{\partial T} p\xi \cdot \mathbf{n} ds = (\mathbf{f},\ \xi) \tag{4}$$

and

$$\sum_{K\in\mathcal{R}_h} \int_K \nabla \cdot \mathbf{u} q dx = 0, \tag{5}$$

where $\mathbf{n}$ is the unit outward normal vector on ∂T.

Let $T_j \in \mathcal{T}_h$ $(j = 1, \ldots, t)$ be the triangles in $K \in \mathcal{R}_h$, where $t = 3$ for triangular mesh and $t = 4$ for rectangular mesh, as shown as Figures 3 and 4. Then we have

$$\begin{aligned} \sum_{T\in\mathcal{T}_h} \int_{\partial T} \frac{\partial \mathbf{u}}{\partial \mathbf{n}} \cdot \xi ds &= \sum_{K\in\mathcal{R}_h} \sum_{j=1}^{t} \int_{\partial T_j} \frac{\partial \mathbf{u}}{\partial \mathbf{n}} \cdot \xi ds \\ &= \sum_{K\in\mathcal{R}_h} \sum_{j=1}^{t} \int_{A_{j+1}CA_j} \frac{\partial \mathbf{u}}{\partial \mathbf{n}} \cdot \xi ds + \sum_{K\in\mathcal{R}_h} \int_{\partial K} \frac{\partial \mathbf{u}}{\partial \mathbf{n}} \cdot \xi ds, \end{aligned} \tag{6}$$

where $A_{t+1} = A_1$.

For vectors $\mathbf{v}$ and $\mathbf{n}$, let $\mathbf{v} \otimes \mathbf{n}$ denote the matrix whose ijth component is $v_i n_j$ as in [13]. For two matrix valued variables σ and τ, we define $\sigma : \tau = \sum_{i,j=1}^{2} \sigma_{ij}\tau_{ij}$. Let e be an interior edge shared by two elements K_1 and K_2 in $\mathcal{T}_h$, and let $\mathbf{n}_1$ and $\mathbf{n}_2$

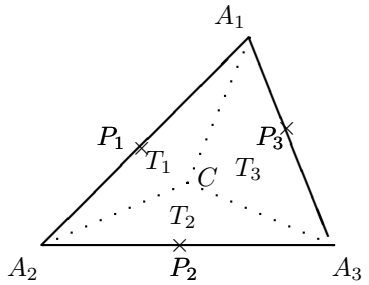

FIG. 3. *Triangular partition and its dual.*

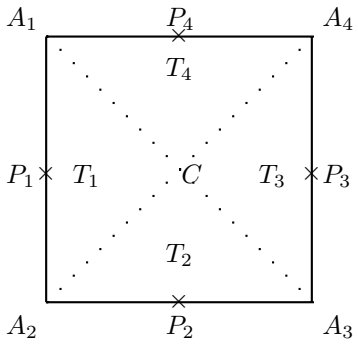

FIG. 4. *Rectangular partition and its dual.*

be unit normal vectors on e pointing exterior to K_1 and K_2, respectively. We define the average $\{\cdot\}$ and jump $[\cdot]$ on e for scalar q, vector $\mathbf{w}$ and τ, respectively.

$$\{q\} = \frac{1}{2}(q|_{\partial K_1} + q|_{\partial K_2}), \quad [q] = q|_{\partial K_1}\mathbf{n}_1 + q|_{\partial K_2}\mathbf{n}_2,$$

$$\{\mathbf{w}\} = \frac{1}{2}(\mathbf{w}|_{\partial K_1} + \mathbf{w}|_{\partial K_2}), \quad [\mathbf{w}] = \mathbf{w}|_{\partial T_K} \cdot \mathbf{n}_1 + \mathbf{w}|_{\partial K_2} \cdot \mathbf{n}_2,$$

and

$$\{\tau\} = \frac{1}{2}(\tau|_{\partial K_1} + \tau|_{\partial K_2}), \quad [\tau] = \tau|_{\partial K_1} \cdot \mathbf{n}_1 + \tau|_{\partial K_2} \cdot \mathbf{n}_2.$$

We also define a matrix valued jump $[\![\cdot]\!]$ for a vector $\mathbf{w}$ as $[\![\mathbf{w}]\!] = \mathbf{w}|_{\partial K_1} \otimes \mathbf{n}_1 + \mathbf{w}|_{\partial K_2} \otimes \mathbf{n}_2$ on e. If e is a edge on the boundary of Ω, define

$$\{q\} = q, \quad [\mathbf{w}] = \mathbf{w} \cdot \mathbf{n}, \quad \{\tau\} = \tau, \quad [\![\mathbf{w}]\!] = \mathbf{w} \otimes \mathbf{n}.$$

Let Γ denote the union of the boundaries of the rectangles K of $\mathcal{R}_h$ and $\Gamma_0 := \Gamma \backslash \partial\Omega$. A straightforward computation gives

$$\sum_{K\in\mathcal{R}_h} \int_{\partial K} q\mathbf{v} \cdot \mathbf{n} ds = \sum_{e\in\Gamma_0} \int_e [q] \cdot \{\mathbf{v}\} ds + \sum_{e\in\Gamma} \int_e \{q\}[\mathbf{v}] ds, \tag{7}$$

$$\sum_{K\in\mathcal{R}_h} \int_{\partial K} \mathbf{v} \cdot \tau\mathbf{n} ds = \sum_{e\in\Gamma_0} \int_e [\tau] \cdot \{\mathbf{v}\} ds + \sum_{e\in\Gamma} \int_e \{\tau\} : [\![\mathbf{v}]\!] ds. \tag{8}$$

Let $\int_\Gamma q ds = \sum_{e\in\Gamma}\int_e q ds$. Using (6), (8), and the fact that $[\nabla \mathbf{u}] = 0$ for $\mathbf{u} \in (H_0^1(\Omega)\cap H^2(\Omega))^2$ on Γ_0, (6) becomes

$$\sum_{T\in\mathcal{T}_h}\int_{\partial T}\frac{\partial \mathbf{u}}{\partial \mathbf{n}}\cdot\xi ds = \sum_{K\in\mathcal{R}_h}\sum_{j=1}^{t}\int_{A_{j+1}CA_j}\frac{\partial \mathbf{u}}{\partial \mathbf{n}}\cdot\xi ds + \int_\Gamma [\![\xi]\!] : \{\nabla \mathbf{u}\} ds.$$

Since $[p] = 0$ for $p \in H^1(\Omega)$ on Γ_0, we also have

$$\sum_{T\in\mathcal{T}_h}\int_{\partial T} p\xi\cdot\mathbf{n} ds = \sum_{K\in\mathcal{R}_h}\sum_{j=1}^{t}\int_{A_{j+1}CA_j} p\xi\cdot\mathbf{n} ds + \int_\Gamma \{p\}[\xi] ds.$$

Let

$$a_0(\mathbf{v},\xi) = -\sum_{K\in\mathcal{R}_h}\sum_{j=1}^{t}\int_{A_{j+1}CA_j}\frac{\partial \mathbf{v}}{\partial \mathbf{n}}\cdot\xi ds - \int_\Gamma [\![\xi]\!] : \{\nabla \mathbf{v}\} ds,$$

$$c(\xi, q) = \sum_{K\in\mathcal{R}_h}\sum_{j=1}^{t}\int_{A_{j+1}CA_j} q\xi\cdot\mathbf{n} ds + \int_\Gamma \{q\}[\xi] ds,$$

and

$$b_0(\mathbf{v}, q) = \sum_{K\in\mathcal{R}_h}\int_K \nabla\cdot\mathbf{v} q dx.$$

It is clear that the solutions $(\mathbf{u}, p)$ of the Stokes equations (1)–(3) satisfy the following:

$$a_0(\mathbf{u},\xi) + c(\xi, p) = (\mathbf{f},\ \xi) \qquad \forall \xi \in W_h, \tag{9}$$

$$b_0(\mathbf{u}, q) = 0 \qquad \forall q \in Q_h. \tag{10}$$

Let $V(h) = V_h + (H^2(\Omega)\cap H_0^1(\Omega))^2$. Define a mapping $\gamma:\ V(h) \to W_h$ as shown in Figure 1 and 2.

$$\gamma\mathbf{v}|_T = \frac{1}{h_e}\int_e \mathbf{v}|_T ds, \quad T \in \mathcal{T}_h,$$

where h_e is the length of the edge e. For $\mathbf{v} = (v_1, v_2)$, γv_i (i=1, 2) is defined as

$$\gamma v_i|_T = \frac{1}{h_e}\int_e v_i|_T ds, \quad T \in \mathcal{T}_h.$$

Define the following bilinear forms:

$$\begin{aligned} A_0(\mathbf{v},\ \mathbf{w}) &= a_0(\mathbf{v},\ \gamma\mathbf{w}) \qquad \forall \mathbf{v}, \mathbf{w} \in V(h),\\ B_0(\mathbf{v}, q) &= b_0(\mathbf{v}, q) \qquad \forall \mathbf{v} \in V(h),\ \forall q \in L_0^2(\Omega),\\ C(\mathbf{v},\ q) &= c(\gamma\mathbf{v},\ q) \qquad \forall \mathbf{v} \in V(h),\ \forall q \in L_0^2(\Omega). \end{aligned}$$

Then systems (9)–(10) are equivalent to

$$A_0(\mathbf{u}, \mathbf{v}) + C(\mathbf{v}, p) = (\mathbf{f},\ \gamma\mathbf{v}) \qquad \forall \mathbf{v} \in V_h, \tag{11}$$

$$B_0(\mathbf{u}, q) = 0 \qquad \forall q \in Q_h. \tag{12}$$

3. Discontinuous finite volume formulation. In this section we propose two discontinuous finite volume formulations based on modification of the weak formulation (11)–(12) for the Stokes problem (1)–(3).

Let us introduce the bilinear forms as follows:

$$A_1(\mathbf{v},\mathbf{w}) = A_0(\mathbf{v},\mathbf{w}) + \alpha \sum_{e\in\Gamma} [\![\gamma\mathbf{v}]\!]_e : [\![\gamma\mathbf{w}]\!]_e$$

and

$$B(\mathbf{v},q) = B_0(\mathbf{v},q) - \int_\Gamma \{q\}[\gamma\mathbf{v}]ds,$$

where $\alpha > 0$ is a parameter to be determined later. For the exact solution $(\mathbf{u}, p)$ of the Stokes problem, we have

$$\begin{aligned} A_0(\mathbf{u},\mathbf{v}) &= A_1(\mathbf{u},\mathbf{v}) \qquad \forall \mathbf{v}\in V_h, \\ B_0(\mathbf{u},q) &= B(\mathbf{u},q) \qquad \forall q\in Q_h. \end{aligned}$$

Therefore, it follows from (11)–(12) that

$$A_1(\mathbf{u},\mathbf{v}) + C(\mathbf{v},p) = (\mathbf{f},\ \gamma\mathbf{v}) \qquad \forall \mathbf{v}\in V_h, \tag{13}$$

$$B(\mathbf{u},q) = 0 \qquad \forall q\in Q_h. \tag{14}$$

The corresponding discontinuous finite volume scheme for (1)–(3) seeks $(\mathbf{u}_h, p_h) \in V_h \times Q_h$ such that

$$A_1(\mathbf{u}_h,\mathbf{v}) + C(\mathbf{v},p_h) = (\mathbf{f},\ \gamma\mathbf{v}) \qquad \forall \mathbf{v}\in V_h, \tag{15}$$

$$B(\mathbf{u}_h,q) = 0 \qquad \forall q\in Q_h. \tag{16}$$

Since the test functions are piecewise constant for velocity, the bilinear forms $A_1(\cdot,\cdot)$ and $C(\cdot,\cdot)$ in (15) do not include the area integral terms like $\sum_K \int_K \nabla\mathbf{u}_h : \nabla\mathbf{v}dx$ that normally present in the finite element formulations for the Stokes problem.

Let

$$A_*(\mathbf{v},\mathbf{w}) = -\sum_{K\in\mathcal{R}_h}\sum_{j=1}^{t}\int_{A_{j+1}CA_j} \frac{\partial\mathbf{v}}{\partial\mathbf{n}}\cdot\gamma\mathbf{w}ds$$

and

$$C_*(\mathbf{v},q) = \sum_{K\in\mathcal{R}_h}\sum_{j=1}^{t}\int_{A_{j+1}CA_j} q\gamma\mathbf{v}\cdot\mathbf{n}ds.$$

Thus

$$A_1(\mathbf{v},\mathbf{w}) = A_*(\mathbf{v},\mathbf{w}) - \int_\Gamma [\![\gamma\mathbf{w}]\!] : \{\nabla\mathbf{v}\}ds + \alpha\sum_{e\in\Gamma}[\![\gamma\mathbf{v}]\!]_e : [\![\gamma\mathbf{w}]\!]_e$$

and

$$C(\mathbf{v},q) = C_*(\mathbf{v},q) + \int_\Gamma \{q\}[\gamma\mathbf{v}]ds.$$

Let $\nabla_h \mathbf{v}$ and $\nabla_h \cdot \mathbf{v}$ be the functions whose restriction to each element $K \in \mathcal{R}_h$ are equal to $\nabla \mathbf{v}$ and $\nabla \cdot \mathbf{v}$, respectively.

LEMMA 3.1. *For any* $\mathbf{v}, \mathbf{w} \in V(h)$, *we have*

$$A_*(\mathbf{v}, \mathbf{w}) = (\nabla_h \mathbf{v}, \nabla_h \mathbf{w}) + \sum_{K \in \mathcal{R}_h} \int_{\partial K} (\gamma \mathbf{w} - \mathbf{w}) \frac{\partial \mathbf{v}}{\partial \mathbf{n}} ds + \sum_{K \in \mathcal{R}_h} (\Delta \mathbf{v}, \mathbf{w} - \gamma \mathbf{w})_K.$$

Furthermore, if $\mathbf{v}, \mathbf{w} \in V_h$, *then*

$$A_*(\mathbf{v}, \mathbf{w}) = (\nabla_h \mathbf{v}, \nabla_h \mathbf{w}).$$

Proof. Using the divergence theorem on each triangle T_j for $\mathbf{v} \in V(h)$ and the fact that $\gamma \mathbf{w}$ is a constant on each T_j, we have

$$\begin{aligned}
A_*(\mathbf{v}, \mathbf{w}) &= -\sum_{K \in \mathcal{R}_h} \sum_{j=1}^{t} \int_{A_{j+1} C A_j} \frac{\partial \mathbf{v}}{\partial \mathbf{n}} \cdot \gamma \mathbf{w} ds \\
&= \sum_{K \in \mathcal{R}_h} \sum_{j=1}^{t} \gamma \mathbf{w} \cdot \int_{A_j A_{j+1}} \frac{\partial \mathbf{v}}{\partial \mathbf{n}} ds - \sum_{K \in \mathcal{R}_h} \sum_{T_j \in K} (\Delta \mathbf{v}, \gamma \mathbf{w})_{T_j} \\
&= \sum_{K \in \mathcal{R}_h} \int_{\partial K} (\gamma \mathbf{w} - \mathbf{w}) \cdot \frac{\partial \mathbf{v}}{\partial \mathbf{n}} ds + \sum_{K \in \mathcal{R}_h} \int_{\partial K} \mathbf{w} \cdot \frac{\partial \mathbf{v}}{\partial \mathbf{n}} ds - \sum_{K \in \mathcal{R}_h} (\Delta \mathbf{v}, \gamma \mathbf{w})_K \\
&= \sum_{K \in \mathcal{R}_h} \int_{\partial K} (\gamma \mathbf{w} - \mathbf{w}) \cdot \frac{\partial \mathbf{v}}{\partial \mathbf{n}} ds + \sum_{K \in \mathcal{R}_h} (\nabla \mathbf{v}, \nabla \mathbf{w})_K + \sum_{K \in \mathcal{R}_h} (\Delta \mathbf{v}, \mathbf{w})_K - \sum_{K \in \mathcal{R}_h} (\Delta \mathbf{v}, \gamma \mathbf{w})_K \\
&= (\nabla_h \mathbf{v}, \nabla_h \mathbf{w}) + \sum_{K \in \mathcal{R}_h} \int_{\partial K} (\gamma \mathbf{w} - \mathbf{w}) \cdot \frac{\partial \mathbf{v}}{\partial \mathbf{n}} ds + \sum_{K \in \mathcal{R}_h} (\Delta \mathbf{v}, \mathbf{w} - \gamma \mathbf{w})_K.
\end{aligned}$$

If $\mathbf{v} \in V_h$, we have $\Delta \mathbf{v} = 0$ on each $K \in \mathcal{R}_h$. Then the third term in the above equation drops out. Since $\frac{\partial \mathbf{v}}{\partial \mathbf{n}}$ is constant for both triangular and rectangular mesh, by the definition of γ, the second term is zero. This completes the proof. ∎

LEMMA 3.2. *For any* $(\mathbf{v}, q) \in V(h) \times L_0^2(\Omega)$, *we have*

$$C_*(\mathbf{v}, q) = -(\nabla_h \cdot \mathbf{v}, q) + \sum_{K \in \mathcal{R}_h} \int_{\partial K} (\mathbf{v} - \gamma \mathbf{v}) \cdot \mathbf{n} q ds + \sum_{K \in \mathcal{R}_h} (\nabla q, \gamma \mathbf{v} - \mathbf{v})_K. \tag{17}$$

Furthermore, if $q \in Q_h$, *then*

$$C_*(\mathbf{v}, q) = -(\nabla_h \cdot \mathbf{v}, q) \tag{18}$$

and

$$C(\mathbf{v},q) = -B(\mathbf{v},q). \tag{19}$$

Proof. Using the divergence theorem on each triangle T_j for $\mathbf{v} \in V_h$, we have

$$\begin{aligned}
C_*(\mathbf{v},q) &= \sum_{K\in\mathcal{R}_h}\sum_{j=1}^{t}\int_{A_{j+1}CA_j}\gamma\mathbf{v}\cdot\mathbf{n}q ds \\
&= -\sum_{K\in\mathcal{R}_h}\sum_{j=1}^{t}\int_{A_jA_{j+1}}\gamma\mathbf{v}\cdot\mathbf{n}q ds + \sum_{K\in\mathcal{R}_h}\sum_{T_j\in K}(\nabla q,\ \gamma\mathbf{v})_{T_j} \\
&= \sum_{K\in\mathcal{R}_h}\int_{\partial K}(\mathbf{v}-\gamma\mathbf{v})\cdot\mathbf{n}q ds - \sum_{K\in\mathcal{R}_h}\int_{\partial K}\mathbf{v}\cdot\mathbf{n}q ds + \sum_{K\in\mathcal{R}_h}(\nabla q,\gamma\mathbf{v})_K \\
&= \sum_{K\in\mathcal{R}_h}\int_{\partial K}(\mathbf{v}-\gamma\mathbf{v})\cdot\mathbf{n}q ds + \sum_{K\in\mathcal{R}_h}(\nabla q,\gamma\mathbf{v})_K - \sum_{K\in\mathcal{R}_h}(\nabla q,\mathbf{v})_K - \sum_{K\in\mathcal{R}_h}(\nabla\cdot\mathbf{v},q)_K \\
&= -(\nabla_h\cdot\mathbf{v},q) + \sum_{K\in\mathcal{R}_h}\int_{\partial K}(\mathbf{v}-\gamma\mathbf{v})\cdot\mathbf{n}q ds + \sum_{K\in\mathcal{R}_h}(\nabla q,\gamma\mathbf{v}-\mathbf{v})_K.
\end{aligned}$$

If $q \in Q_h$, the second and third terms in the above equation drop out. This completes the proof. ∎

We define two norms for $V(h)$ as follows:

$$\begin{aligned}
|\!|\!|\mathbf{v}|\!|\!|_1^2 &= |\mathbf{v}|_{1,h}^2 + \sum_{e\in\Gamma}[\![\gamma\mathbf{v}]\!]_e^2, \\
|\!|\!|\mathbf{v}|\!|\!|^2 &= |\!|\!|\mathbf{v}|\!|\!|_1^2 + \sum_{K\in\mathcal{R}_h} h_K^2|\mathbf{v}|_{2,K}^2,
\end{aligned}$$

where $|\mathbf{v}|_{1,h}^2 = \sum_K |\mathbf{v}|_{1,K}^2$.

The standard inverse inequality implies that there is a constant C such that

$$|\!|\!|\mathbf{v}|\!|\!| \le C|\!|\!|\mathbf{v}|\!|\!|_1 \qquad \forall \mathbf{v}\in V_h. \tag{20}$$

Let K be an element with e as an edge. It is well known (see [1]) that there exists a constant C such that for any function $g \in H^2(K)$,

$$\|g\|_e^2 \le C\left(h_K^{-1}\|g\|_K^2 + h_K|g|_{1,K}^2\right), \tag{21}$$

$$\left\|\frac{\partial g}{\partial \mathbf{n}}\right\|_e^2 \le C(h_K^{-1}|g|_{1,K}^2 + h_K|g|_{2,K}^2), \tag{22}$$

where C depends only on the minimum angle of K.

LEMMA 3.3. *For $\mathbf{v},\mathbf{w}\in V(h)$, we have*

$$A_1(\mathbf{v},\mathbf{w}) \le C|\!|\!|\mathbf{v}|\!|\!||\!|\!|\mathbf{w}|\!|\!|. \tag{23}$$

Proof. By Lemma 3.1, the inequalities (21) and (22), and the Cauchy–Schwarz inequality, we have

$$|A_*(\mathbf{v},\mathbf{w})| \le |(\nabla_h\mathbf{v},\nabla_h\mathbf{w})| + \left|\sum_{K\in\mathcal{R}_h}\int_{\partial K}(\mathbf{w}-\gamma\mathbf{w})\cdot\frac{\partial\mathbf{v}}{\partial\mathbf{n}}ds\right| + \left|\sum_{K\in\mathcal{R}_h}(\Delta\mathbf{v},\mathbf{w}-\gamma\mathbf{w})_K\right|$$
$$\le C(|\mathbf{v}|_{1,h}|\mathbf{w}|_{1,h} + \sum_{K\in\mathcal{R}_h}(h_K^{-1}\|\mathbf{w}-\gamma\mathbf{w}\|_K^2 + h_K|\mathbf{w}-\gamma\mathbf{w}|_{1,K}^2)^{\frac{1}{2}}(h_K^{-1}|\mathbf{v}|_{1,K}^2 + h_K|\mathbf{v}|_{2,K}^2)^{\frac{1}{2}}$$
$$+ \sum_{K\in\mathcal{R}_h} h|\mathbf{v}|_{2,K}|\mathbf{w}|_{1,K})$$
$$\le C\left(|\mathbf{v}|_{1,h}|\mathbf{w}|_{1,h} + \left(\sum_{K\in\mathcal{R}_h}|\mathbf{w}|_{1,K}^2\right)^{\frac{1}{2}}\left(|\mathbf{v}|_{1,h} + \left(\sum_{K\in\mathcal{R}_h}h_K^2|\mathbf{v}|_{2,K}^2\right)^{\frac{1}{2}}\right)\right.$$
$$\left. + \left(\sum_{K\in\mathcal{R}_h}h_K^2|\mathbf{v}|_{2,K}\right)^{\frac{1}{2}}|\mathbf{w}|_{1,h}\right)$$
$$\le C|||\mathbf{v}|||\,|||\mathbf{w}|||.$$

The definition of $A_1(\mathbf{v},\mathbf{w})$ and the inequality above imply that

$$A_1(\mathbf{v},\mathbf{w}) = A_*(\mathbf{v},\mathbf{w}) - \int_\Gamma [\![\gamma\mathbf{w}]\!] : \{\nabla\mathbf{v}\}ds + \alpha\sum_{e\in\Gamma}[\![\gamma\mathbf{v}]\!]_e : [\![\gamma\mathbf{w}]\!]_e$$
$$\le C\left(|||\mathbf{v}|||\,|||\mathbf{w}||| + \left(\sum_{K\in\mathcal{R}_h}(|\mathbf{v}|_{1,K}^2 + h^2|\mathbf{v}|_{2,K}^2)\right)^{\frac{1}{2}}\left(\sum_{e\in\Gamma}[\![\gamma\mathbf{w}]\!]_e^2\right)^{\frac{1}{2}}\right.$$
$$\left. + \alpha\left(\sum_{e\in\Gamma}[\![\gamma\mathbf{v}]\!]_e^2\right)^{\frac{1}{2}}\left(\sum_{e\in\Gamma}[\![\gamma\mathbf{w}]\!]_e^2\right)^{\frac{1}{2}}\right)$$
$$\le C|||\mathbf{v}|||\,|||\mathbf{w}|||. \qquad \square$$

Similarly we can prove the following lemma.

LEMMA 3.4. *For $(\mathbf{v},q)\in V(h)\times L_0^2(\Omega)$, we have*

$$C(\mathbf{v},q) \le C|||\mathbf{v}|||\left(\|q\| + \left(\sum_{K\in\mathcal{R}_h}h_K^2|q|_{1,K}^2\right)^{\frac{1}{2}}\right). \tag{24}$$

If $(\mathbf{v},q)\in V_h\times Q_h$, then

$$C(\mathbf{v},q) \le C|||\mathbf{v}|||\,\|q\|. \tag{25}$$

We will prove the coercivity of the bilinear form $A_1(\cdot,\cdot)$ in V_h in the following lemma.

LEMMA 3.5. *For any $\mathbf{v}\in V_h$, there is a constant C independent of h such that for α large enough*

$$A_1(\mathbf{v},\mathbf{v}) \ge C|||\mathbf{v}|||^2. \tag{26}$$

Proof. The trace inequality (22) and the inverse inequality give that for $\mathbf{v} \in V_h$

$$\begin{aligned}\int_\Gamma [\![\gamma \mathbf{v}]\!] : \{\nabla \mathbf{v}\} ds &\le C \left(\sum_{e\in\Gamma} \int_e h_e \{\nabla \mathbf{v}\}^2 ds \right)^{\frac{1}{2}} \left(\sum_{e\in\Gamma} \int_e h_e^{-1} [\![\mathbf{v}]\!]^2 ds \right)^{\frac{1}{2}} \\ &\le C \left(\sum_{K\in\mathcal{R}_h} (|\mathbf{v}|_{1,K}^2 + h_K^2 |\mathbf{v}|_{2,K}^2) \right)^{\frac{1}{2}} \left(\sum_{e\in\Gamma} [\![\gamma \mathbf{v}]\!]_e^2 \right)^{\frac{1}{2}} \\ &\le C |\!|\!| \mathbf{v} |\!|\!|_1 \left(\sum_{e\in\Gamma} [\![\gamma \mathbf{v}]\!]_e^2 \right)^{\frac{1}{2}}.\end{aligned}$$

Using the inequality above, (20), and Lemma 3.1, we have

$$\begin{aligned}A_1(\mathbf{v},\mathbf{v}) &= (\nabla_h \mathbf{v}, \nabla_h \mathbf{v}) + \alpha \sum_{e\in\Gamma} [\![\gamma \mathbf{v}]\!]_e^2 - \int_\Gamma [\![\gamma \mathbf{v}]\!] : \{\nabla \mathbf{v}\} ds \\ &\ge |\mathbf{v}|_{1,h}^2 + \alpha \sum_{e\in\Gamma} [\![\gamma \mathbf{v}]\!]_e^2 - C |\!|\!| \mathbf{v} |\!|\!|_1 \left(\sum_{e\in\Gamma} [\![\gamma \mathbf{v}]\!]_e^2 \right)^{\frac{1}{2}} \\ &\ge C |\!|\!| \mathbf{v} |\!|\!|_1^2 \ge C |\!|\!| \mathbf{v} |\!|\!|^2.\end{aligned}$$

The last inequality is obtained by using the arithmetic-geometric mean inequality and choosing α large enough. ∎

The proof of Lemma 3.5 indicates that the value of α depends upon the constant in the inverse inequality. Therefore, the value of α for which $A_1(\cdot,\cdot)$ is coercive is mesh dependent. Existing results for saddle-point problems indicate that it is theoretically and computationally important to have coercivity (26). Therefore, the mesh-dependence of the parameter α makes the discontinuous finite volume scheme (15)–(16) less interesting in practical computation.

To overcome the difficulty in the selection of parameter, we introduce a second discontinuous finite volume scheme which is parameter insensitive. To this end, we define a bilinear form as follows:

$$A_2(\mathbf{v},\mathbf{w}) = A_1(\mathbf{v},\mathbf{w}) + \int_\Gamma [\![\gamma \mathbf{v}]\!] : \{\nabla \mathbf{w}\} ds.$$

Similar to the bilinear form $A_1(\cdot,\cdot)$, for the exact solution $(\mathbf{u}, p)$ of the Stokes problem we have

$$A_2(\mathbf{u},\mathbf{v}) = A_0(\mathbf{u},\mathbf{v}) \qquad \forall \mathbf{v} \in V_h.$$

Consequently, the solution of the Stokes problem satisfies the following variational equations:

$$A_2(\mathbf{u},\mathbf{v}) + C(\mathbf{v},p) = (\mathbf{f}, \gamma \mathbf{v}) \qquad \forall \mathbf{v} \in V_h, \tag{27}$$

$$B(\mathbf{u},q) = 0 \qquad \forall q \in W_h. \tag{28}$$

Our second discontinuous finite volume scheme for (1)–(3) seeks $(\mathbf{u}_h, p_h) \in V_h \times W_h$ such that

$$A_2(\mathbf{u}_h,\mathbf{v}) + C(\mathbf{v},p_h) = (\mathbf{f}, \gamma \mathbf{v}) \qquad \forall \mathbf{v} \in V_h, \tag{29}$$

$$B(\mathbf{u}_h,q) = 0 \qquad \forall q \in W_h. \tag{30}$$

To see the coercivity of the bilinear form $A_2(\cdot,\cdot)$, we use its definition to obtain

$$A_2(\mathbf{v},\mathbf{v}) = (\nabla_h\mathbf{v},\nabla_h\mathbf{v}) + \alpha\sum_{e\in\Gamma}[\![\mathbf{v}]\!]_e^2 ds \tag{31}$$
$$= |\!|\!|\mathbf{v}|\!|\!|_1^2 \geq C|\!|\!|\mathbf{v}|\!|\!|^2 \qquad \forall \mathbf{v}\in V_h.$$

Thus, the coercivity (31) holds true for the bilinear form $A_2(\cdot,\cdot)$ with any value of $\alpha > 0$. Similarly, we can prove that

$$A_2(\mathbf{w},\mathbf{v}) \leq C|\!|\!|\mathbf{w}|\!|\!||\!|\!|\mathbf{v}|\!|\!| \qquad \forall \mathbf{w},\mathbf{v}\in V(h). \tag{32}$$

Let $A(\mathbf{v},\mathbf{w}) = A_1(\mathbf{v},\mathbf{w})$ or $A(\mathbf{v},\mathbf{w}) = A_2(\mathbf{v},\mathbf{w})$. In the rest of the paper, we assume that the following is true.

$$A(\mathbf{v},\mathbf{v}) \geq C|\!|\!|\mathbf{v}|\!|\!|^2. \tag{33}$$

If $A(\mathbf{v},\mathbf{w}) = A_2(\mathbf{v},\mathbf{w})$, (33) holds for any $\alpha > 0$. If $A(\mathbf{v},\mathbf{w}) = A_1(\mathbf{v},\mathbf{w})$, (33) holds for only α larger enough.

4. Error estimates. We will derive an optimal error estimates for velocity in the norm $|\!|\!|\cdot|\!|\!|$ and for pressure in the L^2-norm. A first order error estimate for velocity in L^2-norm will be obtained.

Let e be an interior edge shared by two elements K_1 and K_2 in $\mathcal{R}_h$. If $\int_e \mathbf{v}|_{K_1} ds = \int_e \mathbf{v}|_{K_2} ds$, we say that $\mathbf{v}$ is continuous on e. We say that $\mathbf{v}$ is zero at $e \in \partial\Omega$ if $\int_e \mathbf{v} ds = 0$. Define a subspace $\hat{V}_h$ of V_h by

$$\hat{V}_h = \{\mathbf{v}\in L^2(\Omega)^2 :\ \mathbf{v}|_K \in \hat{Q}_1(K)^2\ \forall K\in\mathcal{R}_h \text{ is continuous at } e\in\Gamma_0$$
$$\text{and is zero at } e\in\partial\Omega\}$$

for rectangular mesh and by

$$\hat{V}_h = \{\mathbf{v}\in L^2(\Omega)^2 :\ \mathbf{v}|_K \in P_1(K)^2\ \forall K\in\mathcal{R}_h \text{ is continuous at } e\in\Gamma_0$$
$$\text{and is zero at } e\in\partial\Omega\}$$

for triangular mesh.

It has been proved in [18] and [15] that the following discrete inf-sup condition is satisfied; i.e., there exists a positive constant β_0 such that

$$\sup_{\mathbf{v}\in\hat{V}_h} \frac{(\nabla_h\cdot\mathbf{v},\ q)}{|\mathbf{v}|_{1,h}} \geq \beta_0\|q\| \quad \forall\ q\in Q_h. \tag{34}$$

LEMMA 4.1. *The bilinear form $B(\cdot,\cdot)$ satisfies the discrete inf-sup condition*

$$\sup_{\mathbf{v}\in V_h} \frac{B(\mathbf{v},q)}{|\!|\!|\mathbf{v}|\!|\!|} \geq \beta\|q\| \quad \forall\ q\in Q_h, \tag{35}$$

where β is a positive constant independent of the mesh size h.

Proof. For $\mathbf{v}\in\hat{V}_h\subset V_h$ and $q\in Q_h$, we have $B(\mathbf{v},q) = (\nabla_h\cdot\mathbf{v},q)$ and $|\!|\!|\mathbf{v}|\!|\!|_1 = |\mathbf{v}|_{1,h}$. (34) and (20) imply that for any $q\in Q_h$

$$\beta_0\|q\| \leq \sup_{\mathbf{v}\in\hat{V}_h} \frac{(\nabla_h\cdot\mathbf{v},\ q)}{|\mathbf{v}|_{1,h}} = \sup_{\mathbf{v}\in\hat{V}_h} \frac{B(\mathbf{v},\ q)}{|\!|\!|\mathbf{v}|\!|\!|_1} \leq C \sup_{\mathbf{v}\in V_h} \frac{B(\mathbf{v},\ q)}{|\!|\!|\mathbf{v}|\!|\!|}. \tag{36}$$

With $\beta = \beta_0/C$, we have proved (35). ∎

Define an operator π_K from $H^1(K)$ to $\hat{Q}_1(K)$ or $P_1(K)$ by requiring that for any $v \in H^1(K)$,

$$\int_{e_i} \pi_K v \, ds = \int_{e_i} v \, ds \quad \text{for} \quad i = 1, \ldots, t, \tag{37}$$

where e_i, $i = 1, \ldots, t$, are the t sides of the element $K \in \mathcal{R}_h$. $t = 3$ if K is a triangle and $t = 4$ if K is a rectangle. It was proved in [18] that

$$|\pi_K v - v|_{s,K} \le Ch^{2-s}|v|_{2,K} \quad \forall\, v \in H^2(K), \quad s = 0, 1, 2. \tag{38}$$

For any $\mathbf{v} \in H_0^1(\Omega)^2$, define $\Pi_1 \mathbf{v} \in V_h$ by

$$(\Pi_1 \mathbf{v})_i|_K = \pi_K v_i \quad \forall\, K \in \mathcal{R}_h, \quad i = 1, 2. \tag{39}$$

Using the definition of Π_1 and integration by parts, we can show that

$$B(\mathbf{v} - \Pi_1 \mathbf{v}, q) = 0 \qquad \forall q \in Q_h. \tag{40}$$

The Cauchy–Schwarz inequality implies

$$\begin{aligned} [\![\gamma \mathbf{v}]\!]_e^2 &= \left(\frac{1}{h_e}\int_e [\![\mathbf{v}]\!] ds\right)^2 \le \left(\frac{1}{h_e}\right)^2 \int_e [\![\mathbf{v}]\!]^2 ds \int_e ds \\ &= \int_e \frac{1}{h_e} [\![\mathbf{v}]\!]^2 ds. \end{aligned} \tag{41}$$

(41) and (21) imply that

$$\begin{aligned} \sum_{e\in\Gamma} [\![\gamma(\mathbf{u} - \Pi_1 \mathbf{u})]\!]_e^2 &\le \int_\Gamma \frac{1}{h_e} [\![\mathbf{u} - \Pi_1 \mathbf{u}]\!]^2 ds \\ &\le C\left(|\mathbf{u} - \Pi_1 \mathbf{u}|_{1,h}^2 + \sum_{K\in\mathcal{R}_h} h^{-2}\|\mathbf{u} - \Pi_1 \mathbf{u}\|_K^2\right) \\ &\le Ch^2 \|\mathbf{u}\|_2^2. \end{aligned} \tag{42}$$

The definitions of the norm $|||\cdot|||$, (42), and (38) give

$$\begin{aligned} |||\mathbf{u} - \Pi_1 \mathbf{u}|||^2 &= |\mathbf{u} - \Pi_1 \mathbf{u}|_{1,h}^2 + \sum_{e\in\Gamma} [\![\gamma(\mathbf{u} - \Pi_1 \mathbf{u})]\!]_e^2 + \sum_{K\in\mathcal{R}_h} h^2 |\mathbf{u} - \Pi_1 \mathbf{u}|_{2,K}^2 \\ &\le Ch^2 \|\mathbf{u}\|_2^2. \end{aligned} \tag{43}$$

Let Π_2 be the L^2 projection from $L_0^2(\Omega)$ to the finite element space Q_h.

THEOREM 4.2. *Let $(\mathbf{u}_h, p_h) \in V_h \times Q_h$ be the solution of* (15)–(16) *or* (29)–(30) *and $(\mathbf{u}, p) \in (H^2(\Omega) \cap H_0^1(\Omega))^2 \times L_0^2(\Omega) \cap H^1(\Omega)$ be the solution of* (1)–(3). *Then there exists a constant C independent of h such that*

$$|||\mathbf{u} - \mathbf{u}_h||| + \|p - p_h\| \le Ch(\|\mathbf{u}\|_2 + \|p\|_1). \tag{44}$$

Proof. Let

$$\epsilon_h = \mathbf{u}_h - \Pi_1 \mathbf{u}, \qquad \eta_h = p_h - \Pi_2 p \tag{45}$$

be the error between the finite volume solution $(\mathbf{u}_h, p_h)$ and the projection $(\Pi_1\mathbf{u}, \Pi_2 p)$ of the exact solution. Denote by

$$\epsilon = \mathbf{u} - \Pi_1\mathbf{u}, \qquad \eta = p - \Pi_2 p \tag{46}$$

the error between the exact solution $(\mathbf{u}, p)$ and its projection. Subtracting (15) and (16) from (13) and (14), respectively, or subtracting (29) and (30) from (27) and (28), respectively, and using Lemma 3.2 give that with $A(\cdot,\cdot) = A_1(\cdot,\cdot)$ or $A(\cdot,\cdot) = A_2(\cdot,\cdot)$

$$A(\epsilon_h, \mathbf{v}) - B(\mathbf{v}, \eta_h) = A(\epsilon, \mathbf{v}) - B(\mathbf{v}, \eta), \tag{47}$$

$$B(\epsilon_h, q) = B(\epsilon, q) = 0 \tag{48}$$

for any $\mathbf{v} \in V_h$ and $q \in Q_h$.

By letting $\mathbf{v} = \epsilon_h$ in (47) and $q = \eta_h$ in (48), the sum of (47) and (48) gives

$$A(\epsilon_h, \epsilon_h) = A(\epsilon, \epsilon_h) - B(\epsilon_h, \eta). \tag{49}$$

Thus, it follows from the coercivity (33), the boundedness (23), (32), and (24) that

$$|||\epsilon_h|||^2 \le C \left(|||\epsilon||| |||\epsilon_h||| + \left(\|\eta\| + \left(\sum_{K\in\mathcal{R}_h} h_K^2 |\eta|_{1,K}^2 \right)^{\frac{1}{2}} \right) |||\epsilon_h||| \right),$$

which implies the following:

$$|||\epsilon_h||| \le C \left(|||\epsilon||| + \|\eta\| + \left(\sum_{K\in\mathcal{R}_h} h_K^2 |\eta|_{1,K}^2 \right)^{\frac{1}{2}} \right).$$

The above estimate can be rewritten as

$$|||\mathbf{u}_h - \Pi_1\mathbf{u}||| \le C \left(|||\mathbf{u} - \Pi_1\mathbf{u}||| + \|p - \Pi_2 p\| + \left(\sum_{K\in\mathcal{R}_h} h^2 |p - \Pi_2 p|_{1,K}^2 \right)^{\frac{1}{2}} \right).$$

Now using the triangle inequality, (38), the definition of Π_2, and the inequality above, we get

$$|||\mathbf{u} - \mathbf{u}_h||| \le C \left(|||\mathbf{u} - \Pi_1\mathbf{u}||| + \|\mathbf{u}_h - \Pi_1\mathbf{u}\| \right) \le Ch(\|\mathbf{u}\|_2 + \|p\|_1), \tag{50}$$

which completes the estimate for the velocity approximation.

Discrete inf-sup condition (35), (50), Lemma 3.2, Lemma 3.4, and inverse inequality give

$$\begin{aligned}
\|p_h - \Pi_2 p\| &\le \frac{1}{\beta} \sup_{\mathbf{v}\in V_h} \frac{B(\mathbf{v}, p_h - \Pi_2 p)}{|||\mathbf{v}|||} \le \frac{1}{\beta} \sup_{\mathbf{v}\in V_h} \frac{C(\mathbf{v}, \Pi_2 p - p_h)}{|||\mathbf{v}|||} \\
&= \frac{1}{\beta} \sup_{\mathbf{v}\in V_h} \frac{C(\mathbf{v}, p - p_h) + C(\mathbf{v}, \Pi_2 p - p)}{|||\mathbf{v}|||} \\
&= \frac{1}{\beta} \sup_{\mathbf{v}\in V_h} \frac{A(\mathbf{u} - \mathbf{u}_h, \mathbf{v}) + C(\mathbf{v}, \Pi_2 p - p)}{|||\mathbf{v}|||} \\
&\le C \left(|||\mathbf{u} - \mathbf{u}_h||| + \|p - \Pi_2 p\| + \left(\sum_{K\in\mathcal{R}_h} h_K^2 |p - \Pi_2 p|_{1,K}^2 \right)^{\frac{1}{2}} \right) \\
&\le Ch(\|\mathbf{u}\|_2 + \|p\|_1).
\end{aligned}$$

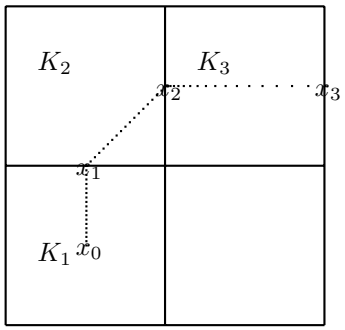

FIG. 5. *A path.*

Using the above inequality and the triangle inequality, we have completed the proof of (44). ∎

We need the following lemma for the L^2 error estimate of velocity.

LEMMA 4.3. *There exists a constant C independent of h such that the following is true:*

$$\|\mathbf{w}\| \le C|||\mathbf{w}||| \qquad \forall \mathbf{w} \in V_h.$$

Proof. The proof is similar to the proof of Lemma 3.1 in [8]. We prove this lemma only for the rectangular element. The same argument can be used to prove the lemma for the triangular element. Let $|e|$ denote the length of edge e.

Let e be an edge shared by two elements K_1 and K_2 in $\mathcal{R}_h$. Let $\mathbf{w} = (w_1, w_2)$. Define $[w_1]_* = w_1|_{\partial K_1} - w_1|_{\partial K_2}$. Interchanging K_1 and K_2 will have no effect on the procedure. Since $[w_1]_*$ is continuous on $e_i \in \Gamma$, there exists $\mathbf{x}_i \in e_i$ such that

$$[\gamma w_1]_* = \frac{1}{|e_i|}\int_{e_i} [w_1]_* ds = [w_1]_*(\mathbf{x}_i) \tag{51}$$

and

$$[\gamma w_1]_*^2 = [\gamma w_1]^2.$$

If e_i is an edge on the boundary, then $\mathbf{x}_i \in e_i$ is a point such that $\int_{e_i} w_1 ds = w_1(\mathbf{x}_i)|e_i|$. For any $\mathbf{x} = \mathbf{x}_0 \in K \in \mathcal{R}_h$, we can find a path from $\mathbf{x}_0$ to $\mathbf{x}_l$, a point on the boundary, by joining a sequence of $\mathbf{x}_i$ as shown in Figure 5, where $\mathbf{x}_i$ $(i = 1, \ldots, l)$ satisfy (51). Let C_0 be a constant such that $lh \le C_0$. Let $\{K_i\}_{i=1}^l$ be the sequence of rectangles in $\mathcal{R}_h$ containing $\mathbf{x}_i$ $(i = 0, \ldots, l)$ as shown in Figure 5.

Define $w_1(\mathbf{x}_0^1) = w_1(\mathbf{x}_0)$, $w_1(\mathbf{x}_1^2) = w_1|_{K_1}(\mathbf{x}_1)$, and $w_1(\mathbf{x}_1^1) = w_1|_{K_2}(\mathbf{x}_1)$. In general, $w_1(\mathbf{x}_i^2) = w_1|_{K_i}(\mathbf{x}_i)$ and $w_1(\mathbf{x}_i^1) = w_1|_{K_{i+1}}(\mathbf{x}_i)$.

The mean value theorem, the Cauchy–Schwarz inequality, and (51) give

$$|w_1(\mathbf{x})|^2 = |w_1(\mathbf{x}_0)|^2 = \left|\sum_{i=1}^{l}(w_1(\mathbf{x}_{i-1}^1) - w_1(\mathbf{x}_i^2)) + \sum_{i=1}^{l}[w_1]_*(\mathbf{x}_i)\right|^2 \tag{52}$$

$$\le Cl\left(\sum_{i=1}^{l}\nabla w_1(\bar{\mathbf{x}}_i)^2(\mathbf{x}_{i-1} - \mathbf{x}_i)^2 + \sum_{i=1}^{l}[\gamma w_1]_{e_i}^2\right), \tag{53}$$

where $\bar{\mathbf{x}}_i \in K_i$ is a point between $\mathbf{x}_{i-1}$ and $\mathbf{x}_i$. As in [8], we have

$$|\nabla w_1(\bar{\mathbf{x}}_i)|^2 h^2 \le C|\nabla w_1|_{K_i}^2. \tag{54}$$

(54) implies

$$|w_1(\mathbf{x})|^2 \le Cl\left(\sum_{i=1}^{l}|\nabla w_1|_{K_i}^2+\sum_{i=1}^{l}[\gamma w_1]_{e_i}^2\right). \tag{55}$$

Integrating (55) over K gives

$$\int_K |w_1(\mathbf{x})|^2 \le Clh^2\left(\sum_{i=1}^{l}|\nabla w_1|_{K_i}^2+\sum_{i=1}^{l}[\gamma w_1]_{e_i}^2\right). \tag{56}$$

Adding over K in such way that the same K_i appears at most l times and using the fact that $lh \le C_0$, we have

$$\|w_1\|^2=\int_\Omega |w_1(\mathbf{x})|^2 \le C\left(|w_1|_{1,h}^2+\sum_{e\in\Gamma}[\gamma w_1]_e^2\right). \tag{57}$$

Similarly, we have (57) hold for w_2. Since $[\![\gamma\mathbf{w}]\!]^2=[\gamma w_1]^2+[\gamma w_2]^2$, we have completed the proof. □

THEOREM 4.4. *Let* $(\mathbf{u}_h,p_h)\in V_h\times Q_h$ *be the solution of* (15)–(16) *or* (29)–(30) *and* $(\mathbf{u},p)\in (H^2(\Omega)\cap H_0^1(\Omega))^2\times L_0^2(\Omega)\cap H^1(\Omega)$ *be the solution of* (1)–(3). *Then there exists a constant* C *independent of* h *such that*

$$\|\mathbf{u}-\mathbf{u}_h\| \le Ch(\|\mathbf{u}\|_2+\|p\|_1). \tag{58}$$

Proof. Using Lemma 4.3, (43), and (44), we have

$$\begin{aligned}\|\mathbf{u}_h-\Pi_1\mathbf{u}\| &\le C[\![\mathbf{u}_h-\Pi_1\mathbf{u}]\!] \le C([\![\mathbf{u}-\mathbf{u}_h]\!]+[\![\mathbf{u}-\Pi_1\mathbf{u}]\!])\\ &\le Ch(\|\mathbf{u}\|_2+\|p\|_1).\end{aligned} \tag{59}$$

(59), (38), and the triangle inequality imply (58). We have completed the proof. □

MULTIGRID ALGORITHMS FOR C^0 INTERIOR PENALTY METHODS*

SUSANNE C. BRENNER† AND LI-YENG SUNG†

Abstract. Multigrid algorithms for C^0 interior penalty methods for fourth order elliptic boundary value problems on polygonal domains are studied in this paper. It is shown that V-cycle, F-cycle and W-cycle algorithms are contractions if the number of smoothing steps is sufficiently large. The contraction numbers of these algorithms are bounded by $Cm^{-\alpha}$, where m is the number of presmoothing (and postsmoothing) steps, α is the index of elliptic regularity, and the positive constant C is mesh-independent. These estimates are established for a smoothing scheme that uses a Poisson solve as a preconditioner, which can be easily implemented because the C^0 finite element spaces are standard spaces for second order problems. Furthermore the variable V-cycle algorithm is also shown to be an optimal preconditioner.

Key words. multigrid methods, discontinuous Galerkin methods, fourth order problems

1. Introduction.

C^0 interior penalty methods [29, 24] are nonconforming finite element methods for fourth order problems. Consider the following variational problem on a bounded polygonal domain in $\mathbb{R}^2$: Find $u \in H_0^2(\Omega)$ such that

$$a(u,v) = \int_\Omega f v \, dx \qquad \forall\, v \in H_0^2(\Omega), \tag{1.1}$$

where

$$a(w,v) = \sum_{i,j=1}^{2} \int_\Omega \frac{\partial^2 w}{\partial x_i \partial x_j} \frac{\partial^2 v}{\partial x_i \partial x_j} \, dx + \int_\Omega b(x) \nabla w \cdot \nabla v \, dx \tag{1.2}$$

and $f \in L_2(\Omega)$. The function $b(x)$ in (1.2) belongs to $C^1(\bar{\Omega})$ and is nonnegative on Ω. Since $\partial\Omega$ is not smooth, the solution u of (1.1) does not belong to $H^4(\Omega)$ even if $f \in C^\infty(\bar{\Omega})$ [31, 37]. In general the shift theorem [28, 4] only holds for f belonging to the Sobolev space $H^{-2+\alpha}(\Omega)$ for some $\alpha \in (\frac{1}{2}, 1]$, i.e., $u \in H^{2+\alpha}(\Omega)$ whenever $f \in H^{-2+\alpha}(\Omega)$ and

$$\|u\|_{H^{2+\alpha}(\Omega)} \le C_\Omega \|f\|_{H^{-2+\alpha}(\Omega)}. \tag{1.3}$$

(We follow the standard notation of Sobolev spaces [1, 27, 23] in this paper.)

When $b = 0$, the variational problem defined by (1.1) corresponds to the biharmonic problem. When $b > 0$, it is a scalar analog of the elliptic system that appears in strain-gradient elasticity theory [30, 41, 44]. Within the framework of finite element methods, it can be solved numerically by conforming C^1 finite elements [9, 2], nonconforming finite elements [36, 3, 40, 39] and mixed finite elements [26].

Let $\mathcal{T}_h$ be either a simplicial triangulation or a convex quadrilateral triangulation of Ω. In the C^0 interior penalty method approach, the discrete space V_h is either a P_ℓ ($\ell \geq 2$) triangular Lagrange finite element space [27, 23] or a Q_ℓ ($\ell \geq 2$) quadrilateral Lagrange tensor product finite element space [27, 23] associated with $\mathcal{T}_h$. The discrete problem for (1.1) is then given by: Find $u_h \in V_h$ such that

$$\mathcal{A}_h(u_h, v) = \int_\Omega f v \, dx \qquad \forall\, v \in V_h, \tag{1.4}$$

where

$$\begin{aligned}\mathcal{A}_h(w,v) = &\sum_{D\in\mathcal{T}_h} \int_D \left(\sum_{i,j=1}^{2} \frac{\partial^2 w}{\partial x_i \partial x_j} \frac{\partial^2 v}{\partial x_i \partial x_j} + b(x) \nabla w \cdot \nabla v \right) dx \\ &+ \sum_{e\in\mathcal{E}_h} \int_e \left(\left\{\!\!\left\{ \frac{\partial^2 w}{\partial n^2} \right\}\!\!\right\} \left[\!\!\left[\frac{\partial v}{\partial n} \right]\!\!\right] + \left\{\!\!\left\{ \frac{\partial^2 v}{\partial n^2} \right\}\!\!\right\} \left[\!\!\left[\frac{\partial w}{\partial n} \right]\!\!\right] \right) ds \\ &+ \sum_{e\in\mathcal{E}_h} \frac{\eta}{|e|} \int_e \left[\!\!\left[\frac{\partial w}{\partial n} \right]\!\!\right] \left[\!\!\left[\frac{\partial v}{\partial n} \right]\!\!\right] ds,\end{aligned} \tag{1.5}$$

$\mathcal{E}_h$ is the set of all the edges of $\mathcal{T}_h$, $|e|$ is the length of the edge e, and $\eta > 0$ is a penalty parameter. The averages $\{\!\{\cdot\}\!\}$ and jumps $[\![\cdot]\!]$ in (1.5) are defined as follows.

Let e be an interior edge of $\mathcal{T}_h$ and n_e be a unit vector normal to e. Then e is shared by two elements $D_\pm \in \mathcal{T}_h$, where n_e is pointing from D_- to D_+, and we define on e

$$\left[\!\!\left[\frac{\partial v}{\partial n} \right]\!\!\right] = \frac{\partial v_+}{\partial n_e} - \frac{\partial v_-}{\partial n_e} \quad \text{and} \quad \left\{\!\!\left\{ \frac{\partial^2 v}{\partial n^2} \right\}\!\!\right\} = \frac{1}{2} \left(\frac{\partial^2 v_+}{\partial n_e^2} + \frac{\partial^2 v_-}{\partial n_e^2} \right), \tag{1.6}$$

where $v_\pm = v\big|_{D_\pm}$. For an edge e on $\partial\Omega$, we take n_e to be the outer unit normal vector and define

$$\left[\!\!\left[\frac{\partial v}{\partial n} \right]\!\!\right] = -\frac{\partial v}{\partial n_e} \quad \text{and} \quad \left\{\!\!\left\{ \frac{\partial^2 v}{\partial n^2} \right\}\!\!\right\} = \frac{\partial^2 v}{\partial n_e^2}.$$

Note that the averages and jumps are independent of the choice of n_e in (1.6).

The C^0 interior penalty method is consistent, and for η sufficiently large (which is assumed to be the case) it is also stable. Therefore the error $u - u_h$ is quasi-optimal with respect to appropriate norms [29, 24]. The C^0 interior penalty approach has certain advantages over other finite element methods:

(i) The finite element spaces are much simpler than the C^1 finite element spaces;
(ii) The lowest order C^0 interior penalty methods (i.e., those based on the P_2 or Q_2 elements) are as simple as the classical nonconforming finite element methods, but unlike such methods, the C^0 interior penalty methods come in a natural hierarchy of arbitrary orders;
(iii) Unlike mixed finite element methods, it is straightforward to construct C^0 interior penalty methods for more complicated elliptic systems;
(iv) The fact that the finite element spaces in the C^0 interior penalty approach are just standard finite element spaces for second order problems can be exploited in the design of effective smoothers for multigrid algorithms.

Remark 1.1. In the absence of hanging nodes, which is the case here, the C^0 interior penalty methods involve fewer degrees of freedom than the completely discontinuous interior penalty methods introduced in [5] because nodal values are shared on interelement boundaries.

In this paper we extend the multigrid theory for classical nonconforming finite elements (cf. [19, 22] and the references therein) to the C^0 interior penalty methods. We will prove the convergence of V-cycle, F-cycle and W-cycle algorithms when the number of smoothing steps is sufficiently large and also the optimality of the variable V-cycle algorithm as a preconditioner. In all these multigrid algorithms we use a preconditioned relaxation scheme that is much more effective than classical smoothers (such as the Richardson and the Gauss-Seidel iterations) and at the same time can be easily implemented because the finite element spaces of the C^0 interior penalty methods are the standard spaces for second order problems.

The rest of the paper is organized as follows. We set the notation and state the multigrid algorithms in section 2, and then we introduce the mesh-dependent norms and establish some basic estimates in section 3. The analysis of W-cycle and variable V-cycle algorithms is carried out in section 4. The analysis of V-cycle and F-cycle algorithms relies on the additive theory developed in [20, 22], which is recalled in section 5. The convergence results for V-cycle and F-cycle algorithms are then established in section 6. In section 7 we present the results of numerical experiments. Appendix A contains some properties of multigrid Poisson solves relevant for the convergence analysis.

For future reference we state here two elementary inequalities:

$$2ab \le \theta^2 a^2 + \theta^{-2} b^2 \qquad \text{for} \quad a, b \in \mathbb{R} \quad \text{and} \quad \theta \in (0,1), \tag{1.7}$$

$$(a+b)^2 \le (1+\theta^2) a^2 + (1+\theta^{-2}) b^2 \qquad \text{for} \quad a, b \in \mathbb{R} \quad \text{and} \quad \theta \in (0,1). \tag{1.8}$$

2. Multigrid algorithms. In this section we describe the multigrid algorithms. In view of their potential for three-dimensional (3D) problems, we will focus on C^0 interior penalty methods that are based on quadrilateral elements. Similar results can of course be obtained for triangular elements.

Let $\mathcal{T}_0$ be a triangulation of Ω by convex quadrilaterals and the triangulations of $\mathcal{T}_1, \mathcal{T}_2, \ldots$ be obtained from $\mathcal{T}_0$ through uniform subdivisions. The mesh sizes $h_k = \max_{D \in \mathcal{T}_k} \operatorname{diam} D$ thus satisfy the relation

$$h_k \approx 2^{-k} h_0. \tag{2.1}$$

Remark 2.1. In order to avoid the proliferation of constants, we will use the notation $A \lesssim B$ ($B \gtrsim A$) to represent the relation $A \le (\text{constant}) \times B$, where the positive constant is mesh-independent, i.e., it is independent of the mesh size h_k and the grid level k. The notation $A \approx B$ is equivalent to $A \lesssim B$ and $B \lesssim A$.

Let $V_k \subset H_0^1(\Omega)$ be the Q_ℓ ($\ell \ge 2$) finite element space associated with $\mathcal{T}_k$ and denote by $\mathcal{A}_k$ the symmetric bilinear form on V_k corresponding to the variational form (1.5) of the C^0 interior penalty method. The kth level discrete problem for the C^0 interior penalty method is: Find $u_k \in V_k$ such that

$$\mathcal{A}_k(u_k, v) = \int_\Omega f v \, dx \qquad \forall\, v \in V_k. \tag{2.2}$$

For η sufficiently large, the bilinear form $\mathcal{A}_k(\cdot,\cdot)$ is positive definite on V_k and we can define the discrete energy norm $\|\cdot\|_{\mathcal{A}_k}$ by

$$\|v\|_{\mathcal{A}_k} = \sqrt{\mathcal{A}_k(v,v)} \qquad \forall\, v \in V_k. \tag{2.3}$$

Note that $\mathcal{A}_k(\zeta_1,\zeta_2)$ is well-defined for $\zeta_1,\zeta_2 \in H^{2+\alpha}(\Omega)\cap H_0^2(\Omega)$, where $\alpha \in (1/2,1]$ is the index of elliptic regularity in (1.3). In fact, $\mathcal{A}_k(\zeta_1,\zeta_2) = a(\zeta_1,\zeta_2)$ because $[\![\partial\zeta_j/\partial n]\!] = 0$. In particular, in view of (1.2) and the Poincaré-Friedrichs inequality [38],

$$\mathcal{A}_k(\zeta,\zeta) = a(\zeta,\zeta) \approx |\zeta|^2_{H^2(\Omega)} \qquad \forall\, \zeta \in H^{2+\alpha}(\Omega)\cap H_0^2(\Omega). \tag{2.4}$$

However, $\mathcal{A}_k(\cdot,\cdot)$ is not positive definite on the space $V_k + [H^{2+\alpha}(\Omega)\cap H_0^2(\Omega)]$. Therefore it is necessary to introduce the following norm $\|\cdot\|_k$ for functions in $V_k + [H^{2+\alpha}(\Omega)\cap H_0^2(\Omega)]$:

$$\begin{aligned}\|w\|_k^2 = &\sum_{D\in\mathcal{T}_k}\Big(|w|^2_{H^2(D)} + |w|^2_{H^1(D)}\Big)\\ &+\sum_{e\in\mathcal{E}_k}\Big(|e|\,\|\{\!\{\partial^2 w/\partial n^2\}\!\}\|^2_{L_2(e)} + |e|^{-1}\|[\![\partial w/\partial n]\!]\|^2_{L_2(e)}\Big).\end{aligned} \tag{2.5}$$

From (2.5) it is easy to see that

$$|\mathcal{A}_k(w_1,w_2)| \lesssim \|w_1\|_k\|w_2\|_k \qquad \forall\, w_1,w_2 \in V_k + [H^{2+\alpha}(\Omega)\cap H_0^2(\Omega)]. \tag{2.6}$$

Furthermore, on V_k itself, we have (cf. (4.18), (4.20) and (4.25) of [24])

$$|v|_{H^2(\Omega,\mathcal{T}_k)} \le \|v\|_k \approx \|v\|_{\mathcal{A}_k} \lesssim |v|_{H^2(\Omega,\mathcal{T}_k)} \qquad \forall\, v \in V_k, \tag{2.7}$$

where

$$|v|^2_{H^2(\Omega,\mathcal{T}_k)} = \sum_{D\in\mathcal{T}_k}|v|^2_{H^2(D)} + \sum_{e\in\mathcal{E}_k}|e|^{-1}\|[\![\partial v/\partial n]\!]\|^2_{L_2(e)}. \tag{2.8}$$

Let the operator $A_k : V_k \longrightarrow V_k'$ be defined by

$$\langle A_k v_1, v_2\rangle = \mathcal{A}_k(v_1,v_2) \qquad \forall\, v_1,v_2 \in V_k, \tag{2.9}$$

where $\langle\cdot,\cdot\rangle$ is the canonical bilinear form between a vector space and its dual. We can then rewrite the discrete problem (2.2) as $A_k u_k = \phi_k$, where $\phi_k \in V_k'$ is defined by $\langle\phi_k, v\rangle = \int_\Omega f v\,dx\ \forall\, v \in V_k$.

Multigrid algorithms [32, 35, 11, 17, 43] are iterative methods for the solution of equations of the form

$$A_k z = \psi, \tag{2.10}$$

where $\psi \in V_k'$ and $z \in V_k$. In the descriptions of the multigrid algorithms below we will denote the natural injection from V_{k-1} to V_k by I_{k-1}^k and its transpose from V_k' to V_{k-1}' by I_k^{k-1}, i.e.,

$$\langle\phi, I_{k-1}^k v\rangle = \langle I_k^{k-1}\phi, v\rangle \qquad \forall\, \phi \in V_k' \quad\text{and}\quad v \in V_{k-1}. \tag{2.11}$$

We also need an operator $B_k : V_k \longrightarrow V_k'$ in the preconditioned relaxation scheme used in the smoothing steps of the multigrid algorithms (cf. (2.17) and (2.19) below). Let $L_k : V_k \longrightarrow V_k'$ be the discrete Laplace operator, i.e.,

$$\langle L_k v_1, v_2\rangle = \int_\Omega \nabla v_1\cdot\nabla v_2\,dx \qquad \forall\, v_1,v_2 \in V_k. \tag{2.12}$$

Since V_k is a standard finite element space for second order problems, it is natural to consider L_k^{-1} as a preconditioner for the fourth order discrete differential operator A_k. In order to maintain the optimal complexity of multigrid algorithms, we use instead an approximation B_k of L_k with the following properties:

(i) B_k is symmetric positive definite, i.e.,

$$\langle B_k v_1, v_2\rangle = \langle B_k v_2, v_1\rangle \qquad \forall\, v_1, v_2 \in V_k, \tag{2.13}$$

$$\langle B_k v, v\rangle > 0 \qquad \forall\, v \in V_k \setminus \{0\}. \tag{2.14}$$

(ii) B_k is spectrally equivalent to the discrete Laplace operator in the sense that

$$\langle L_k v, v\rangle \le \langle B_k v, v\rangle \lesssim \langle L_k v, v\rangle = \|\nabla v\|^2_{L_2(\Omega)} \qquad \forall\, v \in V_k. \tag{2.15}$$

(iii) B_k approximates L_k in the sense that, for some $\beta \in (0, 1/2)$,

$$|v - B_k^{-1} L_k v|_{H^1(\Omega)} \lesssim h_k^{\beta} \|v\|_{H^{1+\beta}(\Omega)} \qquad \forall\, v \in V_k. \tag{2.16}$$

(iv) The cost for computing $B_k^{-1} v$ is of order $O(n_k)$, where n_k is the dimension of V_k.

Remark 2.2. Let $B_k^{-1} : V_k' \longrightarrow V_k$ be the Poisson solve obtained by a symmetric V-cycle algorithm, a symmetric W-cycle algorithm or a symmetric variable V-cycle algorithm. Then B_k satisfies the properties (i), (ii) and (iv). If B_k^{-1} is the Poisson solve obtained by a symmetric W-cycle algorithm with a sufficiently large number of smoothing steps or a symmetric variable V-cycle algorithm, then the operator B_k also satisfies the property (iii). Details can be found in Appendix A.

ALGORITHM 2.3 (V-cycle Algorithm). $MG_V(k, \psi, z_0, m)$ is the approximate solution of (2.10) with initial guess z_0 obtained as follows. If $k = 0$, we use a direct solve to obtain $A_0^{-1}\psi$ as the output of the V-cycle algorithm. If $k \ge 1$, we compute $MG_V(k, \psi, z_0, m)$ recursively in three steps.

Presmoothing. For $1 \le j \le m$, compute z_j recursively by

$$z_j = z_{j-1} + \gamma_k B_k^{-1}(\psi - A_k z_{j-1}), \tag{2.17}$$

where γ_k^{-1} dominates the spectral radius of the operator $B_k^{-1} A_k : V_k \longrightarrow V_k$.

Coarse Grid Correction. Compute

$$z_{m+1} = z_m + I_{k-1}^k MG_V(k-1, \varrho_{k-1}, 0, m), \tag{2.18}$$

where $\varrho_{k-1} = I_k^{k-1}(\psi - A_k z_m)$ is the transferred residual of z_m.

Postsmoothing. For $m + 2 \le j \le 2m + 1$, compute z_j recursively by

$$z_j = z_{j-1} + \gamma_k B_k^{-1}(\psi - A_k z_{j-1}). \tag{2.19}$$

The final output of the V-cycle algorithm is

$$MG_V(k, \psi, z_0, m) = z_{2m+1}. \tag{2.20}$$

ALGORITHM 2.4 (W-cycle Algorithm). If we replace the coarse grid correction step of Algorithm 2.3 by the following procedure, we have the W-cycle algorithm whose output will be denoted by $MG_W(k, \psi, z_0, m)$.

Coarse Grid Correction for the W-cycle. Compute $e_1, e_2 \in V_{k-1}$ by

$$e_j = MG_W(k-1, \varrho_{k-1}, e_{j-1}, m) \qquad \text{for} \quad 1 \le j \le 2, \tag{2.21}$$

where $e_0 = 0$, and set

$$z_{m+1} = z_m + I_{k-1}^k e_2. \tag{2.22}$$

ALGORITHM 2.5 (F-cycle Algorithm). If we replace the coarse grid correction step of Algorithm 2.3 by the following procedure, we have the F-cycle algorithm whose output will be denoted by $MG_F(k, \psi, z_0, m)$.

Coarse Grid Correction for the F-cycle. Let $e_0 = 0 \in V_{k-1}$. Compute $e_1, e_2 \in V_{k-1}$ by $e_1 = MG_F(k-1, \varrho_{k-1}, e_0, m)$, $e_2 = MG_V(k-1, \varrho_{k-1}, e_1, m)$, and set z_{m+1} by (2.22).

ALGORITHM 2.6 (Variable V-cycle Algorithm). If the numbers of smoothing steps in Algorithm 2.3 on different levels are allowed to be different, we have a variable V-cycle algorithm.

3. Mesh-dependent norms and preliminary estimates. In this section we introduce mesh-dependent norms and derive some preliminary estimates. First of all, because of (2.13) and (2.14), we can introduce a discrete inner product [6] related to the preconditioner in the smoothing steps:

$$(v_1, v_2)_k = \langle B_k v_1, v_2 \rangle \qquad \forall\, v_1, v_2 \in V_k. \tag{3.1}$$

It follows from (2.9) and (3.1) that the operator $\mathbb{A}_k = B_k^{-1} A_k : V_k \longrightarrow V_k$ satisfies

$$(\mathbb{A}_k v_1, v_2)_k = \mathcal{A}_k(v_1, v_2) \qquad \forall\, v_1, v_2 \in V_k. \tag{3.2}$$

It is clear from (1.5) and (3.2) that $\mathbb{A}_k$ is symmetric positive definite with respect to the inner product $(\cdot,\cdot)_k$. Furthermore, it follows from (2.3), (2.7), (2.8), (2.15) and standard inverse estimates [27, 23] that the spectral radius $\rho(\mathbb{A}_k)$ of $\mathbb{A}_k$ satisfies

$$\rho(\mathbb{A}_k) \lesssim h_k^{-2}. \tag{3.3}$$

Therefore we can take the parameter γ_k in (2.17) and (2.19) to be Ch_k^2 ($\leq 1/\rho(\mathbb{A}_k)$), where the positive constant C is mesh-independent.

Remark 3.1. In terms of the inner product $(\cdot,\cdot)_k$ the smoothing steps in (2.17) and (2.19) are just Richardson relaxation steps.

Remark 3.2. Using (3.3) it is not difficult to show that, with respect to the natural nodal basis of the Q_ℓ finite element space, the condition number of $\mathbb{A}_k$ (in the energy norm) is of order $O(h_k^{-2})$. On the other hand the condition number of the fourth order discrete differential operator A_k (with respect to the natural nodal basis) is of order $O(h_k^{-4})$. The reduction in the order of the condition number of $\mathbb{A}_k$ greatly improves the performance of the multigrid algorithms (cf. Remark 4.2, Tables 7.1 and 7.4 below).

For $s \in \mathbb{R}$, we define the mesh-dependent norm $|\!|\!| \cdot |\!|\!|_{s,k}$ by

$$|\!|\!| v |\!|\!|_{s,k} = (\mathbb{A}_k^s v, v)_k^{1/2} \qquad \forall\, v \in V_k. \tag{3.4}$$

It is clear from (2.3), (2.15), (3.1), (3.2) and (3.4) that

$$|\!|\!| v |\!|\!|_{0,k} = \sqrt{(v,v)_k} = \sqrt{\langle B_k v, v \rangle} \approx |v|_{H^1(\Omega)} \qquad \forall\, v \in V_k, \tag{3.5}$$

$$|\!|\!| v |\!|\!|_{1,k} = \|v\|_{\mathcal{A}_k} \qquad \forall\, v \in V_k. \tag{3.6}$$

The following well-known properties [7] of mesh-dependent norms follow immediately from (3.2)–(3.4) and the Cauchy-Schwarz inequality:

$$|\!|\!| v |\!|\!|_{s,k} \lesssim h_k^{t-s} |\!|\!| v |\!|\!|_{t,k} \qquad \forall\, v \in V_k \quad \text{and} \quad 0 \le t \le s \le 2, \tag{3.7}$$

$$|\!|\!| v |\!|\!|_{1+s,k} = \sup_{w \in V_k \setminus 0} \frac{\mathcal{A}_k(v,w)}{|\!|\!| w |\!|\!|_{1-s,k}} \qquad \forall\, v \in V_k \quad \text{and} \quad s \in \mathbb{R}. \tag{3.8}$$

Our convergence analysis in subsequent sections relies on the elliptic regularity estimate (1.3). Therefore a relation between the Sobolev norms and the mesh-dependent norms is crucial. For conforming methods such a relation is easy to derive. However, since the C^0 interior penalty methods are nonconforming (i.e., $V_k \not\subset H_0^2(\Omega)$), additional work is required here.

The key ingredient for building a link between Sobolev norms and mesh-dependent norms is the existence [24] of a C^1 finite element which is a *relative* [18, 19] of the Q_ℓ Lagrange element in the sense that (i) the shape functions of the Q_ℓ element are also shape functions of the C^1 element, and (ii) the nodal variables (degrees of freedom) of the Q_ℓ element are also nodal variables of the C^1 element. For example, we can take the C^1 elements from the generalized Bogner-Fox-Schmit family (cf. section 6 of [24]) to be the relatives of the tensor product Lagrange elements, and take the C^1 Argyris elements [2, 24] to be the relatives of the triangular Lagrange elements.

Let $\tilde{V}_k \subset H_0^2(\Omega)$ be the finite element space defined by the C^1 element. We can construct a linear map $E_k : V_k \longrightarrow \tilde{V}_k$ by averaging [24] so that the following properties hold:

$$\Pi_k E_k v = v \qquad \forall\, v \in V_k, \tag{3.9}$$

$$\|E_k v\|_{H^2(\Omega)} \lesssim \|v\|_{\mathcal{A}_k} \qquad \forall\, v \in V_k, \tag{3.10}$$

$$\|E_k v\|_{H^{1+s}(\Omega)} \approx \|v\|_{H^{1+s}(\Omega)} \qquad \forall\, v \in V_k,\ 0 \le s < \frac{1}{2}, \tag{3.11}$$

where $\Pi_k : C^0(\bar{\Omega}) \longrightarrow V_k$ is the nodal interpolation operator.

Remark 3.3. The relation (3.9) and the estimate (3.10) can be found in [24, equation (3.30) and Lemma 3]. The estimate (3.11) can be proved by the arguments in Lemma 9 of [24], where the special case $s = 1 - \alpha$ is established.

Note also that the following estimates (cf. (3.16), (3.18) and (5.3) of [24]) hold for Π_k:

$$\|\Pi_k \zeta\|_{\mathcal{A}_k} \lesssim \|\zeta\|_{H^2(\Omega)} \qquad \forall\, \zeta \in H_0^2(\Omega), \tag{3.12}$$

$$|\zeta - \Pi_k \zeta|_{H^1(\Omega)} \lesssim h_k \|\zeta\|_{H^2(\Omega)} \qquad \forall\, \zeta \in H_0^2(\Omega), \tag{3.13}$$

$$\|\zeta - \Pi_k \zeta\|_k \lesssim h_k^\alpha \|\zeta\|_{H^{2+\alpha}(\Omega)} \qquad \forall \zeta \in H^{2+\alpha}(\Omega), \tag{3.14}$$

where $\|\cdot\|_k$ is the norm defined in (2.5). Furthermore, because the finite elements are relatives, the following discrete estimate is a consequence of the equivalence of norms on finite dimensional vector spaces:

$$|\Pi_k \tilde{v}|_{H^1(\Omega)} \lesssim |\tilde{v}|_{H^1(\Omega)} \qquad \forall\, v \in \tilde{V}_k. \tag{3.15}$$

The following lemma gives useful two-level estimates for the nodal interpolation operator.

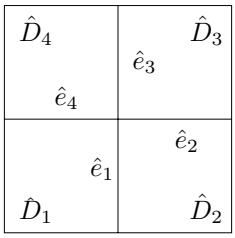

FIG. 3.1. *A subdivided referenced square* $\hat{D}$.

LEMMA 3.4. *The following estimates hold for the nodal interpolation operator*:

$$|v-\Pi_{k-1}v|_{H^1(\Omega)} \lesssim h_k\|v\|_{\mathcal{A}_k} \qquad \forall\, v\in V_k, \tag{3.16}$$

$$\|v-\Pi_{k-1}v\|_{H^{2-\alpha}(\Omega)} \lesssim h_k^{\alpha}\|v\|_{\mathcal{A}_k} \qquad \forall\, v\in V_k, \tag{3.17}$$

$$\|\Pi_{k-1}v\|_{\mathcal{A}_{k-1}} \lesssim \|v\|_{\mathcal{A}_k} \qquad \forall\, v\in V_k. \tag{3.18}$$

Proof. In view of (2.7) and (2.8), the estimate (3.16) is a consequence of

$$|v-\Pi_{k-1}v|^2_{H^1(D)} \lesssim (\operatorname{diam} D)^2\left(\sum_{\substack{D'\in\mathcal{T}_k\\ D'\subset D}}|v|^2_{H^2(D')}+\sum_{\substack{e\subset\mathcal{E}_k\\ e\subset D}}|e|^{-1}\|[\![\partial v/\partial n]\!]\|^2_{L_2(e)}\right) \tag{3.19}$$

for all $v\in V_k$ and $D\in\mathcal{T}_{k-1}$. Since the quadrilaterals in $\mathcal{T}_k$ for $k\geq 0$ are shape regular, we can establish (3.19) by proving the following estimate on the reference square $\hat{D}$:

$$|\hat{v}-\hat{v}^I|^2_{H^1(\hat{D})} \lesssim \sum_{j=1}^4|\hat{v}|^2_{H^2(\hat{D}_j)}+\sum_{j=1}^4\|[\![\partial\hat{v}/\partial n]\!]\|^2_{L_2(\hat{e}_j)} \qquad \forall\, v\in\hat{V}, \tag{3.20}$$

where $\hat{V}\subset H^1(\hat{D})$ is the (finite dimensional) space of continuous functions whose members belong to the polynomial space $Q_\ell(\hat{D}_j)$ for each of the four subsquares $\hat{D}_j$ (cf. Figure 3.1), $\hat{v}^I\in Q_\ell(\hat{D})$ agrees with $\hat{v}$ at the nodes of the Q_ℓ element on $\hat{D}$, and $\hat{e}_j$ for $1\leq j\leq 4$ are interfaces of the subsquares. Now the estimate (3.20) follows from the observation that the square root of the right-hand side of (3.20) defines a norm on the quotient space $\hat{V}/P_1(\hat{D})$ while the square root of the left-hand side defines a seminorm on $\hat{V}/P_1(\hat{D})$.

The estimate (3.17) follows from (3.16) and the inverse estimate [8]

$$|v|_{H^{1+s}(\Omega)} \lesssim h_k^{-s}|v|_{H^1(\Omega)} \qquad \forall\, v\in V_k, \tag{3.21}$$

where $0<s<1/2$.

Finally we derive (3.18) using (2.7), (2.8), (3.18), (3.19), a trace theorem (with scaling) and a standard inverse estimate [27, 23]:

$$\begin{aligned}\|\Pi_{k-1}v\|^2_{\mathcal{A}_{k-1}} &\lesssim \sum_{D\in\mathcal{T}_{k-1}}|\Pi_{k-1}v|^2_{H^2(D)}+\sum_{e\in\mathcal{E}_k}|e|^{-1}\|[\![\partial(\Pi_{k-1}v)/\partial n]\!]\|^2_{L_2(e)}\\ &\lesssim \|\Pi_{k-1}v\|_{\mathcal{A}_{k-1}}+\sum_{e\in\mathcal{E}_k}|e|^{-1}\|[\![\partial v/\partial n]\!]\|^2_{L_2(e)}+\sum_{e\in\mathcal{E}_k}|e|^{-1}\|[\![\partial(v-\Pi_{k-1}v)/\partial n]\!]\|^2_{L_2(e)}\end{aligned}$$

$$\lesssim \|v\|^2_{\mathcal{A}_k} + \sum_{D\in\mathcal{T}_k} (\operatorname{diam} D)^{-2}|v-\Pi_{k-1}v|^2_{H^1(D)} \lesssim \|v\|^2_{\mathcal{A}_k} \qquad \forall\, v\in V_k. \qquad \square$$

In the other direction we can also construct a map from the Sobolev spaces into V_k.

LEMMA 3.5. *There exists a linear map $J_k : L_2(\Omega) \longrightarrow V_k$ with the following properties*:

$$J_k E_k v = v \qquad \forall\, v\in V_k, \tag{3.22}$$

$$\|J_k v\|_{\mathcal{A}_k} \lesssim |v|_{H^2(\Omega)} \qquad \forall\, v\in H^2_0(\Omega), \tag{3.23}$$

$$|J_k v|_{H^1(\Omega)} \lesssim |v|_{H^1(\Omega)} \qquad \forall\, v\in H^1_0(\Omega). \tag{3.24}$$

Proof. We define J_k by

$$J_k v = \Pi_k Q_k v \qquad \forall\, v\in L_2(\Omega), \tag{3.25}$$

where $Q_k : L_2(\Omega) \longrightarrow \tilde{V}_k$ is the L_2 orthogonal projection operator. The relation (3.22) is an obvious consequence of (3.9).

Regarding Q_k we have the estimates [16]

$$\|Q_k v\|_{H^2(\Omega)} \lesssim \|v\|_{H^2(\Omega)} \qquad \forall\, v\in H^2_0(\Omega), \tag{3.26}$$

$$\|Q_k v\|_{H^1(\Omega)} \lesssim \|v\|_{H^1(\Omega)} \qquad \forall\, v\in H^1_0(\Omega). \tag{3.27}$$

The estimates (3.23) and (3.24) follow immediately from (3.12), (3.15) and (3.25)–(3.27). $\square$

LEMMA 3.6. *It holds that*

$$|\!|\!| v |\!|\!|_{s,k} \approx \|E_k v\|_{H^{1+s}(\Omega)} \qquad \forall\, v\in V_k \tag{3.28}$$

provided $0\le s\le 1$ *and* $s\ne 1/2$.

Proof. From (3.5), (3.6), (3.10) and (3.11) we have

$$\|E_k v\|_{H^2(\Omega)} \lesssim |\!|\!| v |\!|\!|_{1,k} \qquad \forall\, v\in V_k,$$
$$\|E_k v\|_{H^1(\Omega)} \lesssim |\!|\!| v |\!|\!|_{0,k} \qquad \forall\, v\in V_k,$$

which implies, by operator interpolation theory for Hilbert scales [42, 33, 11],

$$\|E_k v\|_{H^{1+s}(\Omega)} \lesssim |\!|\!| v |\!|\!|_{s,k} \qquad \forall\, v\in V_k. \tag{3.29}$$

On the other hand, from (3.5), (3.6), (3.23), (3.24) and interpolation, we have

$$|\!|\!| J_k v |\!|\!|_{s,k} \lesssim \|v\|_{H^{1+s}(\Omega)} \qquad \forall\, v\in H^{1+s}_0(\Omega), \tag{3.30}$$

which together with (3.22) implies

$$|\!|\!| v |\!|\!|_{s,k} = |\!|\!| J_k E_k v |\!|\!|_{1+s,k} \lesssim \|E_k v\|_{H^{1+s}(\Omega)} \qquad \forall\, v\in V_k. \qquad \square \tag{3.31}$$

Remark 3.7. The norm equivalence (3.28) is also valid for $s=1/2$ provided the norm on the right-hand side is replaced by the norm $\|\cdot\|_{H^{1+s}_{00}(\Omega)}$ (cf. [34, 42]).

From (3.11) and (3.28) we immediately obtain the following corollary which provides the link between mesh-dependent norms and Sobolev norms.

COROLLARY 3.8. *It holds that*

$$|\!|\!| v |\!|\!|_{s,k} \approx \|v\|_{H^{1+s}(\Omega)} \qquad \forall\, v\in V_k, \tag{3.32}$$

provided $0\le s<1/2$.

Let J_k^* be the adjoint of J_k (restricted to $H_0^2(\Omega)$) with respect to the bilinear form $a(\cdot,\cdot)$ for the continuous problem and the bilinear form $\mathcal{A}_k(\cdot,\cdot)$ for the discrete problem, i.e., $J_k^* : V_k \longrightarrow H_0^2(\Omega)$ satisfies

$$a(J_k^* v, w) = \mathcal{A}_k(v, J_k w) \qquad \forall\, v \in V_k,\ w \in H_0^2(\Omega). \tag{3.33}$$

The following lemma on J_k^* will be useful in the convergence analysis of V-cycle and F-cycle algorithms.

LEMMA 3.9. *Let $\zeta_k \in V_k$ and*

$$\phi(v) = \mathcal{A}_k(\zeta_k, J_k v) \qquad \forall\, v \in H_0^2(\Omega). \tag{3.34}$$

Then $\phi \in H^{-2+\alpha}(\Omega)$,

$$\|\phi\|_{H^{-2+\alpha}(\Omega)} \lesssim |\!|\!| \zeta_k |\!|\!|_{1+\alpha,k}, \tag{3.35}$$

and

$$\mathcal{A}_k(\zeta_k, v) = \phi(E_k v) \qquad \forall\, v \in V_k. \tag{3.36}$$

Furthermore, $\zeta = J_k^* \zeta_k \in H^{2+\alpha}(\Omega) \cap H_0^2(\Omega)$,

$$a(\zeta, w) = \phi(w) \qquad \forall\, w \in H_0^2(\Omega), \tag{3.37}$$

$$\|\zeta\|_{H^{2+\alpha}(\Omega)} \lesssim |\!|\!| \zeta_k |\!|\!|_{1+\alpha,k}, \tag{3.38}$$

and the following estimates hold:

$$\|\zeta - \zeta_k\|_k \lesssim h_k^{\alpha} |\!|\!| \zeta_k |\!|\!|_{1+\alpha,k}, \tag{3.39}$$

$$\|\zeta - \zeta_k\|_{H^{2-\alpha}(\Omega)} \lesssim h_k^{2\alpha} |\!|\!| \zeta |\!|\!|_{1+\alpha,k}. \tag{3.40}$$

Proof. From (3.8), (3.30) and (3.34) we have

$$\phi(v) \le |\!|\!| \zeta_k |\!|\!|_{1+\alpha,k} |\!|\!| J_k v |\!|\!|_{1-\alpha,k} \lesssim |\!|\!| \zeta_k |\!|\!|_{1+\alpha,k} \|v\|_{H^{2-\alpha}(\Omega)}, \tag{3.41}$$

which means that $\phi \in H^{-2+\alpha}(\Omega)$ and (3.35) is valid.

Equation (3.37) follows immediately from (3.33) and (3.34). Then $\zeta = J_k^* \zeta_k \in H^{2+\alpha}(\Omega)$ by elliptic regularity and (3.38) follows from (1.3) and (3.35).

Finally (3.22) and (3.34) imply (3.36). Therefore ζ_k is the solution of a modified C^0 interior penalty method for (3.37) studied in [24] and the error estimates (3.39) and (3.40) follow from (3.35) and Theorems 4 and 6 of [24]. ∎

4. Results for W-cycle and variable V-cycle algorithms. In this section we establish the results for W-cycle and variable V-cycle algorithms. There are two ingredients in the analysis: the *smoothing property* and the *approximation property*.

The effect of one smoothing step in (2.17) and (2.19) is measured by the operator

$$R_k = Id_k - \gamma_k \mathbb{A}_k, \tag{4.1}$$

where Id_k is the identity operator on V_k. The proof of the following result which describes the effect of the smoothing steps can be found, for example, in [32, 23].

LEMMA 4.1. *It holds that*

$$|\!|\!| R_k^m v |\!|\!|_{s,k} \lesssim h_k^{t-s} m^{(t-s)/2} |\!|\!| v |\!|\!|_{t,k} \qquad \forall\, v \in V_k \quad \textit{and} \quad 0 \le t \le s \le 2.$$

Remark 4.2. Without the preconditioner B_k^{-1}, the smoothing property becomes (for appropriately defined mesh-dependent norms)

$$\|\!| R_k^m v |\!\|_{s,k} \lesssim h_k^{t-s} m^{(t-s)/4} \|\!| v |\!\|_{t,k}.$$

In other words, the effect of m smoothing steps without preconditioning is (roughly) equivalent to the smoothing effect of $\sqrt{m}$ many smoothing steps with preconditioning. Therefore the preconditioner greatly enhances the performance of the multigrid algorithms (cf. Tables 7.1 and 7.4 below).

To measure the effect of coarse grid correction, we first recall the following well-known relation $\hat{e}_{k-1} = P_k^{k-1}(z - z_m)$ between the exact solution of the coarse grid residual equation $A_{k-1}\hat{e}_{k-1} = \varrho_{k-1}$ and the error $z - z_m$, where the operator $P_k^{k-1} : V_k \longrightarrow V_{k-1}$ is defined by

$$\mathcal{A}_{k-1}(P_k^{k-1}v, w) = \mathcal{A}_k(v, I_{k-1}^k w) \qquad \forall\, v \in V_k,\ w \in V_{k-1}. \tag{4.2}$$

The approximation property in the following result describes the effect of coarse grid correction.

LEMMA 4.3. *It holds that*

$$\|\!| (Id_k - I_{k-1}^k P_k^{k-1})v |\!\|_{1-\alpha,k} \lesssim h_k^{2\alpha} \|\!| v |\!\|_{1+\alpha,k} \qquad \forall\, v \in V_k, \tag{4.3}$$

where α is the index of elliptic regularity in (1.3).

Proof. Let $v \in V_k$ be arbitrary. We will establish (4.3) by a duality argument. Using the norm equivalence in Corollary 3.8 (with $s = 1 - \alpha$) and duality, we find

$$\begin{aligned} \|\!| (Id_k - I_{k-1}^k P_k^{k-1})v |\!\|_{1-\alpha,k} &\approx \|(Id_k - I_{k-1}^k P_k^{k-1})v\|_{H^{2-\alpha}(\Omega)} \\ &= \sup_{\phi \in H^{-2+\alpha}(\Omega)\setminus\{0\}} \frac{\phi((Id_k - I_{k-1}^k P_k^{k-1})v)}{\|\phi\|_{H^{-2+\alpha}(\Omega)}}. \end{aligned} \tag{4.4}$$

Let $\phi \in H^{-2+\alpha}(\Omega)$ be arbitrary and define $\zeta \in H_0^2(\Omega)$, $\zeta_k \in V_k$ and $\zeta_{k-1} \in V_{k-1}$ by

$$a(\zeta, v) = \phi(v) \qquad \forall\, v \in H_0^2(\Omega), \tag{4.5}$$

$$\mathcal{A}_k(\zeta_k, v) = \phi(v) \qquad \forall\, v \in V_k, \tag{4.6}$$

$$\mathcal{A}_{k-1}(\zeta_{k-1}, v) = \phi(v) \qquad \forall\, v \in V_{k-1}. \tag{4.7}$$

In other words, ζ_k and ζ_{k-1} are the approximations of ζ obtained by the C^0 interior penalty method, and the following error estimates (cf. Theorem 5 of [24]) are valid:

$$\|\zeta - \zeta_k\|_{H^{2-\alpha}(\Omega)} \lesssim h_k^{2\alpha} \|\phi\|_{H^{-2+\alpha}(\Omega)}, \tag{4.8}$$

$$\|\zeta - \zeta_{k-1}\|_{H^{2-\alpha}(\Omega)} \lesssim h_{k-1}^{2\alpha} \|\phi\|_{H^{-2+\alpha}(\Omega)}. \tag{4.9}$$

From (4.6) and (4.7) we have $\mathcal{A}_{k-1}(\zeta_{k-1}, v) = \mathcal{A}_k(\zeta_k, I_{k-1}^k v)$ for all $v \in V_{k-1}$, which implies (cf. (4.2))

$$\zeta_{k-1} = P_k^{k-1}\zeta_k. \tag{4.10}$$

We can now estimate the numerator in (4.4) by (2.1), (3.8), Corollary 3.8, (4.2), (4.6) and (4.8)–(4.10) as follows:

$$
\begin{aligned}
\phi((Id_k - I_{k-1}^k P_k^{k-1})v) &= \mathcal{A}_k(\zeta_k, v) - \mathcal{A}_k(\zeta_k, I_{k-1}^k P_k^{k-1} v) \\
&= \mathcal{A}_k(\zeta_k, v) - \mathcal{A}_{k-1}(P_k^{k-1}\zeta_k, P_k^{k-1} v) \\
&= \mathcal{A}_k(\zeta_k, v) - \mathcal{A}_{k-1}(\zeta_{k-1}, P_k^{k-1} v) \\
&= \mathcal{A}_k(\zeta_k - I_{k-1}^k \zeta_{k-1}, v) \qquad (4.11) \\
&\le |\!|\!| \zeta_k - \zeta_{k-1} |\!|\!|_{1-\alpha,k} |\!|\!| v |\!|\!|_{1+\alpha,k} \\
&\lesssim \|\zeta_k - \zeta_{k-1}\|_{H^{2-\alpha}(\Omega)} |\!|\!| v |\!|\!|_{1+\alpha,k} \\
&\le \big(\|\zeta_k - \zeta\|_{H^{2-\alpha}(\Omega)} + \|\zeta - \zeta_{k-1}\|_{H^{2-\alpha}(\Omega)}\big) |\!|\!| v |\!|\!|_{1+\alpha,k} \\
&\lesssim h_k^{2\alpha} \|\phi\|_{H^{-2+\alpha}(\Omega)} |\!|\!| v |\!|\!|_{1+\alpha,k}.
\end{aligned}
$$

The estimate (4.3) follows from (4.4) and (4.11). □

We can now apply the theory developed in [19, Theorem 4.3, Theorem 4.4, Lemma 4.7 and Theorem 4.8, where the results in [15] for the variable V-cycle is used] to derive the following results for W-cycle and variable V-cycle algorithms.

THEOREM 4.4. *The output $MG_W(k, \psi, z_0, m)$ of the W-cycle algorithm (Algorithm 2.4) applied to* (2.10) *satisfies the following estimate*:

$$
\|z - MG_W(k, \psi, z_0, m)\|_{\mathcal{A}_k} \le \frac{C}{m^\alpha} \|z - z_0\|_{\mathcal{A}_k},
$$

where the positive constant C is mesh-independent, provided that the number of smoothing steps m is greater than a positive integer m_* that is also mesh-independent.

THEOREM 4.5. *The variable V-cycle algorithm (Algorithm 2.6) is an optimal preconditioner provided the following relation is satisfied by m_k (the number of smoothing steps on level k)* :

$$
\beta_0 m_k \le m_{k-1} \le \beta_1 m_k, \qquad (4.12)
$$

where $1 < \beta_0 \le \beta_1$.

Remark 4.6. Theorems 4.4 and 4.5 have been obtained for preconditioners that satisfy (2.13)–(2.15). Therefore they are valid for B_k^{-1} obtained by a symmetric V-cycle algorithm, a symmetric W-cycle algorithm or a variable V-cycle algorithm (cf. Remark 2.2 and Appendix A).

Finally we note that (3.7) and (4.3) imply

$$
\begin{aligned}
|\!|\!| P_k^{k-1} v |\!|\!|_{1-\alpha,k} &\le |\!|\!| v |\!|\!|_{1-\alpha,k} + |\!|\!| v - I_{k-1}^k P_k^{k-1} v |\!|\!|_{1-\alpha,k} \qquad (4.13) \\
&\lesssim |\!|\!| v |\!|\!|_{1-\alpha,k} + h_k^{2\alpha} |\!|\!| v |\!|\!|_{1+\alpha,k} \lesssim |\!|\!| v |\!|\!|_{1-\alpha,k} \qquad \forall\, v \in V_k.
\end{aligned}
$$

The estimate (4.13) will be used in the convergence analysis of V-cycle and F-cycle algorithms.

5. Additive multigrid theory. In this section we briefly review the additive multigrid theory [20, 22] which will be used in the convergence analysis of V-cycle and F-cycle algorithms in section 6.

Let $\mathbb{E}_{k,m} : V_k \longrightarrow V_k$ be the error propagation operator for the kth level V-cycle algorithm, i.e., $z - MG_V(k, \psi, z_0, m) = \mathbb{E}_{k,m}(z - z_0)$, where $MG_V(k, \psi, z_0, m)$ is the

approximate solution of (2.10) obtained by the V-cycle algorithm with initial guess z_0. The operators $\mathbb{E}_k$ satisfy the well-known recurrence relation [32, 35]

$$\mathbb{E}_{k,m} = R_k^m(Id_k - I_{k-1}^k P_k^{k-1} + I_{k-1}^k \mathbb{E}_{k-1,m} P_k^{k-1}) R_k^m \tag{5.1}$$

and the initial condition $\mathbb{E}_k = 0$. Iterating (5.1) leads to the following additive expression [20, 22] for $\mathbb{E}_k$:

$$\mathbb{E}_{k,m} = \sum_{j=2}^{k} T_{k,j,m} R_j^m (Id_j - I_{j-1}^j P_j^{j-1}) R_j^m T_{j,k,m}, \tag{5.2}$$

where (for $j < k$) $T_{k,j,m}$ is the multilevel operator $R_k^m I_{k-1}^k \cdots R_{j+1}^m I_j^{j+1}$ from V_j into V_k, $T_{j,k,m} = P_{j+1}^j R_j^m \cdots P_k^{k-1} R_k^m$ is the adjoint operator of $T_{k,j,m}$ with respect to $\mathcal{A}_k(\cdot,\cdot)$, and $T_{k,k,m} = Id_k$.

A convergence theory for the V-cycle algorithm based on the additive expression (5.2) was developed in [20, 21] for second order problems. It yields the asymptotic behavior of the contraction numbers, which when combined with the results from the multiplicative theory [14, 45, 12, 13] provides a complete generalization of the classical result of Braess and Hackbusch [10] to the case of less than full elliptic regularity. This additive theory has been extended to V-cycle and F-cycle algorithms for classical nonconforming finite elements [22, 46, 47] and to interior penalty methods for second order problems [25].

Note the operator $R_j^m(Id_j - I_{j-1}^j P_j^{j-1}) R_j^m$ that appears in (5.2) is already controlled by the smoothing property (Lemma 4.1) and the approximation property (Lemma 4.3). Therefore the key in the additive approach is to control the multilevel operators $T_{k,j,m}$ and $T_{j,k,m}$. This in turn requires a careful comparison of the mesh-dependent norms on consecutive levels. In this regard the following assumptions of the additive theory [20, 22] need to be verified:

$$\|I_{k-1}^k v\|_{1,k}^2 \le (1+\theta^2)\|v\|_{1,k-1}^2 + C_1\theta^{-2}h_k^{2\mu}\|v\|_{1+\mu,k-1}^2 \qquad \forall\, v \in V_{k-1}, \tag{5.3}$$

$$\|I_{k-1}^k v\|_{1-\tau,k}^2 \le (1+\theta^2)\|v\|_{1-\tau,k-1}^2 + C_2\theta^{-2}h_k^{2\tau}\|v\|_{1,k-1}^2 \qquad \forall\, v \in V_{k-1}, \tag{5.4}$$

$$\|P_k^{k-1} v\|_{1-\tau,k}^2 \le (1+\theta^2)\|v\|_{1-\tau,k}^2 + C_3\theta^{-2}h_k^{2\tau}\|v\|_{1,k}^2 \qquad \forall\, v \in V_k, \tag{5.5}$$

where $\theta \in (0,1)$ is arbitrary, μ and τ are two parameters strictly between 0 and 1, and the positive constants C_1, C_2 and C_3 are independent of the meshes and θ.

Furthermore, we also need the following approximation property which is peculiar to nonconforming methods where the energy norm is not preserved by the coarse-to-fine intergrid transfer operator I_{k-1}^k:

$$\|(Id_{k-1} - P_k^{k-1} I_{k-1}^k) v\|_{1-\mu,k-1} \lesssim h_k^\mu \|v\|_{1,k-1} \qquad \forall\, v \in V_{k-1}. \tag{5.6}$$

Remark 5.1. The estimates (5.3) and (5.6) together imply that (cf. Lemma 4.2 of [22]), for $j \le k$,

$$\|T_{k,j,m} v\|_{1,k} \lesssim \|v\|_{1,j} \qquad \forall\, v \in V_j, \tag{5.7}$$

provided that m is sufficiently large. We can then use (5.4), (5.5) and (5.7) to derive (cf. Lemmas 4.4–4.6 of [22]), for $j \le k$, the following crucial estimate in the additive theory:

$$\|T_{j,k,m} T_{k,j,m} v\|_{1-\tau,j} \lesssim \|v\|_{1-\tau,j} \qquad \forall\, v \in V_j, \tag{5.8}$$

provided m is sufficiently large. The convergence of V-cycle algorithm for sufficiently large m follows from (5.8) and an argument based on a strengthened Cauchy-Schwarz inequality. The convergence of the F-cycle algorithm can then be established by a perturbation argument.

Therefore the heart of our convergence analysis of V-cycle and F-cycle algorithms is the derivation of the estimates (5.3)–(5.6), where there is a lot of freedom in choosing the parameters μ and τ.

We will prove the estimate (5.6) for $\mu = \alpha$ (the index of elliptic regularity in (1.3)) in this section and take up the estimates (5.3)–(5.5) in section 6. The following lemma is a stronger version of (5.6).

LEMMA 5.2. *It holds that*

$$|\!|\!|(Id_{k-1} - P_k^{k-1} I_{k-1}^k)v|\!|\!|_{1-\alpha,k-1} \lesssim h_k^{2\alpha} |\!|\!|v|\!|\!|_{1+\alpha,k-1} \qquad \forall\, v \in V_{k-1}. \tag{5.9}$$

Proof. Let $v \in V_{k-1}$ be arbitrary and define $\phi \in H_0^2(\Omega)$ by

$$\phi(w) = \mathcal{A}_{k-1}(v, J_{k-1} w) \qquad \forall\, w \in H_0^2(\Omega), \tag{5.10}$$

where $J_{k-1} : L_2(\Omega) \longrightarrow V_{k-1}$ is the map in Lemma 3.5. From Lemma 3.9 we have $\phi \in H^{-2+\alpha}(\Omega)$ and

$$\|\phi\|_{H^{-2+\alpha}(\Omega)} \lesssim |\!|\!|v|\!|\!|_{1+\alpha,k-1}. \tag{5.11}$$

Let $\zeta = J_{k-1}^* v$. Again, from Lemma 3.9 we have $\zeta \in H^{2+\alpha}(\Omega) \cap H_0^2(\Omega)$, and

$$\|\zeta - v\|_{H^{2-\alpha}(\Omega)} \lesssim h_{k-1}^{2\alpha} |\!|\!|v|\!|\!|_{1+\alpha,k-1}. \tag{5.12}$$

Finally we define $\zeta_k \in V_k$ to be the solution of the following variational problem:

$$\mathcal{A}_k(\zeta_k, w) = \phi(w) \qquad \forall\, w \in V_k, \tag{5.13}$$

i.e., ζ_k is the solution of the C^0 interior penalty method for (4.5). Therefore we have the following error estimate (cf. Theorem 5 of [24]):

$$\|\zeta - \zeta_k\|_{H^{2-\alpha}(\Omega)} \lesssim h_k^{2\alpha} \|\phi\|_{H^{-2+\alpha}(\Omega)}. \tag{5.14}$$

Moreover, from Corollary 3.8, (5.11) and (5.13) we have

$$\mathcal{A}_k(\zeta_k, w) \le \|\phi\|_{H^{-2+\alpha}(\Omega)} \|w\|_{H^{2-\alpha}(\Omega)} \lesssim |\!|\!|v|\!|\!|_{1+\alpha,k-1} |\!|\!|w|\!|\!|_{1-\alpha,k} \qquad \forall\, w \in V_k,$$

which together with (3.8) implies that

$$|\!|\!|\zeta_k|\!|\!|_{1+\alpha,k} \lesssim |\!|\!|v|\!|\!|_{1+\alpha,k-1}. \tag{5.15}$$

We can now use (2.1), Corollary 3.8, (4.3), (4.13), (5.11), (5.12), (5.14) and (5.15) to complete the proof of the lemma as follows:

$$\begin{aligned}
|\!|\!|(Id_{k-1} - P_k^{k-1} I_{k-1}^k)v|\!|\!|_{1-\alpha,k-1} &\le |\!|\!|v - P_k^{k-1}\zeta_k|\!|\!|_{1-\alpha,k-1} + |\!|\!|P_k^{k-1}(\zeta_k - v)|\!|\!|_{1-\alpha,k-1} \\
&\lesssim \|v - P_k^{k-1}\zeta_k\|_{H^{2-\alpha}(\Omega)} + |\!|\!|\zeta_k - v|\!|\!|_{1-\alpha,k} \\
&\lesssim \|v - \zeta_k\|_{H^{2-\alpha}(\Omega)} + \|\zeta_k - P_k^{k-1}\zeta_k\|_{H^{2-\alpha}(\Omega)} \\
&\lesssim \|v - \zeta\|_{H^{2-\alpha}(\Omega)} + \|\zeta - \zeta_k\|_{H^{2-\alpha}(\Omega)} + |\!|\!|(Id_k - I_{k-1}^k P_k^{k-1})\zeta_k|\!|\!|_{1-\alpha,k} \\
&\lesssim h_k^{2\alpha} |\!|\!|v|\!|\!|_{1+\alpha,k-1} + h_k^{2\alpha} |\!|\!|\zeta_k|\!|\!|_{1+\alpha,k} \lesssim h_k^{2\alpha} |\!|\!|v|\!|\!|_{1+\alpha,k-1}. \qquad \square
\end{aligned}$$

The following corollary is an immediate consequence of (3.7) and (5.9).

COROLLARY 5.3. *The estimate* (5.6) *holds for* $\mu = \alpha$.

Finally we prove a useful relation between the mesh-dependent norm $|\!|\!| \cdot |\!|\!|_{0,k}$ and Sobolev norms that will be used in the derivation of (5.3)–(5.5). We will use C in the proof of the following lemma (and others in section 6) to denote a generic mesh-independent positive constant that can take different values at different occurrences.

LEMMA 5.4. *It holds that*

$$|\!|\!| v |\!|\!|_{0,k}^2 \le (1+\theta^2)|v|_{H^1(\Omega)}^2 + C_4\theta^{-2}h_k^{2\beta}\|v\|_{H^{1+\beta}(\Omega)}^2 \qquad \forall\, v \in V_k,\ 0<\theta<1, \tag{5.16}$$

where β *is the number in* (2.16) *and the positive constant* C_4 *is mesh-independent.*

Proof. Let $\theta \in (0,1)$ and $v \in V_k$ be arbitrary. From (1.7), (2.12), (2.16), (3.5) and Corollary 3.8, we have

$$\begin{aligned}
|\!|\!| v |\!|\!|_{0,k}^2 &= \langle B_k v, v\rangle \\
&= \langle L_k v, v\rangle + \langle B_k(Id_k - B_k^{-1}L_k)v, v\rangle \\
&\le |v|_{H^1(\Omega)}^2 + |\!|\!|(Id_k - B_k^{-1}L_k)v|\!|\!|_{0,k}|\!|\!| v |\!|\!|_{0,k} \\
&\le |v|_{H^1(\Omega)}^2 + \theta^2 |\!|\!| v |\!|\!|_{0,k}^2 + C\theta^{-2}h_k^{2\beta}\|v\|_{H^{1+\beta}(\Omega)}^2 \\
&\le (1+C\theta^2)|v|_{H^1(\Omega)}^2 + C\theta^{-2}h_k^{2\beta}\|v\|_{H^{1+\beta}(\Omega)}^2,
\end{aligned}$$

which is equivalent to (5.16) because θ is arbitrary. ∎

6. Results for *V*-cycle and *F*-cycle algorithms. In this section we will complete the convergence analysis of V-cycle and F-cycle algorithms by deriving the estimates (5.3)–(5.5). We shall take the parameter μ in (5.3) to be α and the parameter τ in (5.4)–(5.5) to be the number β that appears in (2.16).

First we prove a stronger version of (5.3).

LEMMA 6.1. *There exists a positive constant* C_1 *independent of the meshes such that*

$$|\!|\!| I_{k-1}^k v |\!|\!|_{1,k}^2 \le |\!|\!| v |\!|\!|_{k-1}^2 + C_1 h_k^{2\alpha} |\!|\!| v |\!|\!|_{1+\alpha,k-1}^2 \qquad \forall\, v \in V_k,\ k \ge 1. \tag{6.1}$$

Proof. Let $v \in V_{k-1}$ and $\theta \in (0,1)$ be arbitrary, and $\zeta = J_{k-1}^* v$. From (1.5) and (3.6) we have

$$\begin{aligned}
|\!|\!| I_{k-1}^k v |\!|\!|_{1,k}^2 = \mathcal{A}_k(v,v) &= \mathcal{A}_{k-1}(v,v) + \eta \sum_{e\in\mathcal{E}_{k-1}} |e|^{-1}\|[\![\partial v/\partial n]\!]\|_{L_2(e)}^2 \\
&= |\!|\!| v |\!|\!|_{1,k-1}^2 + \eta \sum_{e\in\mathcal{E}_{k-1}} |e|^{-1}\|[\![(\partial v/\partial n) - (\partial\zeta/\partial n)]\!]\|_{L_2(e)}^2.
\end{aligned} \tag{6.2}$$

Moreover, we have, from (2.5),

$$\eta \sum_{e\in\mathcal{E}_{k-1}} |e|^{-1}\|[\![(\partial v/\partial n) - (\partial\zeta/\partial n)]\!]\|_{L_2(e)}^2 \lesssim \|\zeta - v\|_{k-1}^2. \tag{6.3}$$

The estimate (6.1) follows from (6.2), (6.3) and Lemma 3.9. ∎

Since $0 < \beta < 1/2 < \alpha$, the estimates (3.7) and (6.1) imply the following corollary.

COROLLARY 6.2. *It holds that*

$$|\!|\!| I_{k-1}^k v |\!|\!|_{1,k}^2 \le |\!|\!| v |\!|\!|_{1,k-1}^2 + C_1'\theta^{-2}h_k^{2\beta} |\!|\!| v |\!|\!|_{1+\beta,k-1}^2 \qquad \forall\, v \in V_{k-1}, \tag{6.4}$$

where the positive constant C_1' *is mesh-independent.*

LEMMA 6.3. *The estimate* (5.4) *holds for* $\tau = \beta$.

Proof. Let $\theta \in (0,1)$ be arbitrary. From (2.15), (3.5), Corollary 3.8 and (5.16) we have

$$|||I_{k-1}^k v|||_{0,k}^2 \leq (1+\theta^2)|||v|||_{0,k-1}^2 + C_4'\theta^{-2}h_k^{2\beta}|||v|||_{\beta,k-1}^2 \qquad \forall\, v \in V_{k-1}, \tag{6.5}$$

where the positive constant C_4' is mesh-independent.

Let the inner product $(\!(\cdot,\cdot)\!)_{k-1,\theta}$ on V_{k-1} be defined by

$$(\!(v_1,v_2)\!)_{k-1,\theta} = (1+\theta^2)(v_1,v_2)_{k-1} + C_2\theta^{-2}h_k^{2\beta}(\mathbb{A}_{k-1}^{\beta}v_1,v_2)_{k-1} \tag{6.6}$$

for all $v_1, v_2 \in V_{k-1}$, where $C_2 = \max(C_1', C_4')$ is the maximum of the mesh-independent constants in (6.4) and (6.5). Note that $\mathbb{A}_{k-1}$ is symmetric positive definite with respect to the inner product $(\!(\cdot,\cdot)\!)_{k-1,\theta}$.

In view of (3.4) and (6.6), the estimates (6.4) and (6.5) imply

$$|||I_{k-1}^k v|||_{0,k}^2 \leq (\!(\mathbb{A}_k^0 v, v)\!)_{k-1,\theta} \qquad \forall\, v \in V_{k-1}, \tag{6.7}$$

$$|||I_{k-1}^k v|||_{1,k}^2 \leq (\!(\mathbb{A}_k^1 v, v)\!)_{k-1,\theta} \qquad \forall\, v \in V_{k-1}. \tag{6.8}$$

It follows from (3.4), (6.6)–(6.8) and interpolation between Hilbert scales that

$$\begin{aligned}|||I_{k-1}^k v|||_{1-\beta,k}^2 \leq (\!(\mathbb{A}_k^{1-\beta}v,v)\!)_{k-1,\theta}^2 &= (1+\theta^2)|||v|||_{1-\beta,k}^2 \\ &\quad + C_2\theta^{-2}h_k^{2\beta}|||v|||_{1,k-1}^2 \quad \forall\, v \in V_{k-1}. \qquad \square\end{aligned}$$

We now turn to the estimate (5.5). First we have to establish certain two-level estimates for the nodal interpolation operator with respect to the mesh-dependent norms.

LEMMA 6.4. *The following estimate holds*:

$$|||\Pi_{k-1}v|||_{1,k-1}^2 \leq (1+\theta^2)|||v|||_{1,k}^2 + C_\sharp h_k^{2\alpha}|||v|||_{1+\alpha,k}^2 \qquad \forall\, v \in V_k,\ \theta \in (0,1), \tag{6.9}$$

where the constant $C_\sharp$ *is mesh-independent.*

Proof. Let $v \in V_k$ and $\theta \in (0,1)$ be arbitrary. It follows from (1.8), (3.6), (3.18), and (4.3) that

$$\begin{aligned}|||\Pi_{k-1}v|||_{1,k-1}^2 &\leq (1+\theta^2)|||P_k^{k-1}v|||_{1,k-1}^2 + C\theta^{-2}|||\Pi_{k-1}(v-P_k^{k-1}v)|||_{1,k-1}^2 \\ &\leq (1+\theta^2)|||P_k^{k-1}v|||_{1,k-1}^2 + C\theta^{-2}|||v-P_k^{k-1}v|||_{1,k}^2 \\ &\leq (1+\theta^2)^2|||v|||_{1,k-1}^2 + C\theta^{-2}|||v-P_k^{k-1}v|||_{1,k}^2 \\ &\leq (1+\theta^2)^2|||v|||_{1,k-1}^2 + C\theta^{-2}h_k^{2\alpha}|||v|||_{1+\alpha,k}^2,\end{aligned}$$

which implies (6.9) because $\theta \in (0,1)$ is arbitrary. $\square$

Again, since $0 < \beta < 1/2 < \alpha$, the estimates (3.7) and (6.9) imply the following corollary.

COROLLARY 6.5. *It holds that*

$$|||\Pi_{k-1}v|||_{1,k-1}^2 \leq (1+\theta^2)|||v|||_{1,k}^2 + C_\sharp' h_k^{2\beta}|||v|||_{1+\beta,k}^2 \qquad \forall\, v \in V_k,\ \theta \in (0,1), \tag{6.10}$$

where the positive constant $C_\sharp'$ *is mesh-independent.*

LEMMA 6.6. *The following estimate holds*:

$$|||\Pi_{k-1}v|||_{0,k-1}^2 \leq (1+\theta^2)|||v|||_{0,k}^2 + C_\flat h_k^{2\beta}|||v|||_{\beta,k}^2 \qquad \forall\, v \in V_k,\ \theta \in (0,1), \tag{6.11}$$

where the positive constant $C_\flat$ *is mesh-independent.*

Proof. Let $\theta \in (0,1)$ and $v \in V_k$ be arbitrary. First we observe that, by (2.1), (3.6), (3.7), (3.16), (3.21) and Corollary 3.8,

$$\begin{aligned}
|\!|\!|\Pi_{k-1}v|\!|\!|_{\beta,k-1} &\lesssim \|v\|_{H^{1+\beta}(\Omega)} + \|v-\Pi_{k-1}v\|_{H^{1+\beta}(\Omega)} \\
&\lesssim |\!|\!|v|\!|\!|_{\beta,k} + h_k^{-\beta}|v-\Pi_{k-1}v|_{H^1(\Omega)} \\
&\lesssim |\!|\!|v|\!|\!|_{\beta,k} + h_k^{1-\beta}|\!|\!|v|\!|\!|_{1,k} \lesssim |\!|\!|v|\!|\!|_{\beta,k}.
\end{aligned} \tag{6.12}$$

The estimate (6.11) follows from (1.8), (2.1), (2.12), (2.15), (3.5), (3.7), (3.16), (5.16) and (6.12):

$$\begin{aligned}
|\!|\!|\Pi_{k-1}v|\!|\!|_{0,k-1}^2 &\le (1+\theta^2)|\Pi_{k-1}v|_{H^1(\Omega)}^2 + C\theta^{-2}h_{k-1}^{2\beta}|\!|\!|\Pi_{k-1}v|\!|\!|_{\beta,k-1}^2 \\
&\le (1+\theta^2)\big(|v|_{H^1(\Omega)} + |\Pi_{k-1}v - v|_{H^1(\Omega)}\big)^2 + C\theta^{-2}h_k^{2\beta}|\!|\!|v|\!|\!|_{\beta,k}^2 \\
&\le (1+\theta^2)^2|v|_{H^1(\Omega)}^2 + C\theta^{-2}h_k^2\|v\|_{\mathcal{A}_k}^2 + C\theta^{-2}h_k^{2\beta}|\!|\!|v|\!|\!|_{\beta,k}^2 \\
&\le (1+\theta^2)^2|\!|\!|v|\!|\!|_{0,k}^2 + C\theta^{-2}h_k^2|\!|\!|v|\!|\!|_{1,k}^2 + C\theta^{-2}h_k^{2\beta}|\!|\!|v|\!|\!|_{\beta,k}^2 \\
&\le (1+\theta^2)^2|\!|\!|v|\!|\!|_{0,k}^2 + C\theta^{-2}h_k^{2\beta}|\!|\!|v|\!|\!|_{\beta,k}^2,
\end{aligned}$$

which is equivalent to (6.11) because $\theta \in (0,1)$ is arbitrary. ∎

COROLLARY 6.7. *The following estimate holds*:

$$|\!|\!|\Pi_{k-1}v|\!|\!|_{1-\beta,k-1}^2 \le (1+\theta^2)|\!|\!|v|\!|\!|_{1-\beta,k}^2 + C_\natural h_k^{2\beta}|\!|\!|v|\!|\!|_{1,k}^2 \qquad \forall\, v \in V_k,\ \theta \in (0,1), \tag{6.13}$$

where the constant $C_\natural$ is mesh-independent.

Proof. We use the technique in the proof of Lemma 6.3. For any $\theta \in (0,1)$, we define the inner product $(\!(\cdot,\cdot)\!)_{k,\theta}$ on V_k by

$$(\!(v_1,v_2)\!)_{k,\theta}^2 = (1+\theta^2)(v_1,v_2)_k^2 + C_\natural\theta^{-2}h_k^{2\beta}(\mathbb{A}_k^\beta v_1, v_2)_k \tag{6.14}$$

for all $v_1, v_2 \in V_k$, where $C_\natural = \max(C_\sharp', C_\flat)$. Then $\mathbb{A}_k$ is symmetric positive definite with respect to $(\!(\cdot,\cdot)\!)_{k,\theta}$.

In view of (3.4), (6.10), (6.11) and (6.14), we have

$$|\!|\!|\Pi_{k-1}v|\!|\!|_{0,k-1}^2 \le (\!(\mathbb{A}_k^0 v, v)\!)_{k,\theta} \qquad \forall\, v \in V_k, \tag{6.15}$$

$$|\!|\!|\Pi_{k-1}v|\!|\!|_{1,k-1}^2 \le (\!(\mathbb{A}_k^1 v, v)\!)_{k,\theta} \qquad \forall\, v \in V_k. \tag{6.16}$$

The estimate (6.13) follows from (6.15), (6.16) and interpolation between Hilbert scales. ∎

We are now ready to verify (5.5).

LEMMA 6.8. *The estimate* (5.5) *holds for $\tau = \beta$.*

Proof. Let $v \in V_k$ and $\theta \in (0,1)$ be arbitrary. From (1.8), (3.6), (3.7), (3.17), Corollary 3.8, (4.3) and (6.13), we have

$$\begin{aligned}
|\!|\!|P_k^{k-1}v|\!|\!|_{1-\beta,k-1}^2 &\le \big(|\!|\!|\Pi_{k-1}v|\!|\!|_{1-\beta,k-1} + |\!|\!|P_k^{k-1}v - \Pi_{k-1}v|\!|\!|_{1-\beta,k-1}\big)^2 \\
&\le (1+\theta^2)|\!|\!|\Pi_{k-1}v|\!|\!|_{1-\beta,k-1}^2 + C\theta^{-2}h_k^{2(\beta-\alpha)}|\!|\!|P_k^{k-1}v - \Pi_{k-1}v|\!|\!|_{1-\alpha,k-1}^2 \\
&\le (1+\theta^2)|\!|\!|\Pi_{k-1}v|\!|\!|_{1-\beta,k-1}^2 + C\theta^{-2}h_k^{2(\beta-\alpha)}\|P_k^{k-1}v - \Pi_{k-1}v\|_{H^{2-\alpha}(\Omega)}^2 \\
&\le (1+\theta^2)^2|\!|\!|v|\!|\!|_{1-\beta,k}^2 + C\theta^{-2}|\!|\!|v - \Pi_{k-1}v|\!|\!|_{1-\beta,k-1}^2 \\
&\quad + C\theta^{-2}h_k^{2(\beta-\alpha)}\big(\|P_k^{k-1}v - v\|_{H^{2-\alpha}(\Omega)} + \|v-\Pi_{k-1}v\|_{H^{2-\alpha}(\Omega)}\big)^2 \\
&\le (1+\theta^2)^2|\!|\!|v|\!|\!|_{1-\beta,k}^2 + C\theta^{-2}h_k^{2\beta}|\!|\!|v|\!|\!|_{1,k}^2,
\end{aligned}$$

which is equivalent to (5.5) because $\theta \in (0,1)$ is arbitrary. ∎

We have verified the assumptions (5.3)–(5.6) for the additive theory. Therefore we can apply the results in [22] to obtain the following convergence theorems for the V-cycle and F-cycle algorithms.

THEOREM 6.9. *The output $MG_V(k,\psi,z_0,m)$ of the V-cycle algorithm (Algorithm 2.3) applied to (2.10) satisfies the following estimate*:

$$\|z - MG_V(k,\psi,z_0,m)\|_{\mathcal{A}_k} \leq \frac{C}{m^\alpha}\|z - z_0\|_{\mathcal{A}_k},$$

where the positive constant C is mesh-independent, provided that the number of smoothing steps m is greater than a positive integer m_* that is also mesh-independent.

THEOREM 6.10. *The output $MG_F(k,\psi,z_0,m)$ of the F-cycle algorithm (Algorithm 2.5) applied to (2.10) satisfies the following estimate*:

$$\|z - MG_F(k,\psi,z_0,m)\|_{\mathcal{A}_k} \leq \frac{C}{m^\alpha}\|z - z_0\|_{\mathcal{A}_k},$$

where the positive constant C is mesh-independent, provided that the number of smoothing steps m is greater than a positive integer m_* that is also mesh-independent.

Remark 6.11. Theorems 6.9 and 6.10 have been obtained for preconditioners that satisfy (2.13)–(2.16). Therefore they are valid for a Poisson solve B_k^{-1} obtained by a symmetric W-cycle algorithm with a sufficiently large number of smoothing steps or a variable V-cycle algorithm (cf. Remark 2.2 and Appendix A). However, in practice these algorithms behave equally well when the preconditioner is a symmetric V-cycle algorithm with a few smoothing steps (cf. section 7).

7. Numerical experiments. In this section we report the results of some numerical experiments for the biharmonic problem. The finite element we use is the Q_2 rectangular element and the penalty parameter η is taken to be 5.

The first set of experiments involve the biharmonic problem on the unit square, where we can take the index of elliptic regularity α to be 1. The initial triangulation $\mathcal{T}_0$ consists of one element and we compute the contraction numbers of the V-cycle, F-cycle and W-cycle algorithms on the kth level ($1 \leq k \leq 7$) with m presmoothing and m postsmoothing steps. We use the symmetric V-cycle algorithm for the Poisson problem with three presmoothing and three postsmoothing Richardson relaxation steps as the preconditioner in (2.17) and (2.19). The results are recorded in Tables 7.1–7.3. Convergence for the V-cycle, F-cycle and W-cycle algorithms is observed for $m = 5$, $m = 2$ and $m = 1$, respectively. We also observe that the performance of the F-cycle algorithm and the W-cycle algorithm are almost identical for $m \geq 6$.

Numerical experiments show that for moderate grid levels ($k \leq 7$) there is practically no difference in the performance of the multigrid algorithms whether we use a symmetric V-cycle or a symmetric W-cycle Poisson solve as the preconditioner in (2.17) and (2.19).

We also plot the contraction numbers versus the number m of smoothing steps for the 7th level V-cycle and W-cycle algorithms, where m ranges from 20 to 40. Figure 7.1 contains the resulting log-log plot. The asymptotic rate of decrease is observed to be m^{-1}, which agrees with Theorems 4.4 and 6.9.

For comparison we report in Table 7.4 the contraction numbers of the V-cycle algorithm using the Richardson relaxation scheme without a preconditioner as the smoother. Convergence is observed only for $m \geq 75$.

In the second set of experiments we study the biharmonic problem on the L-shaped domain with vertices $(-1,-1)$, $(1,-1)$, $(1,0)$, $(0,0)$, $(0,1)$ and $(-1,1)$. In this case we can take the index of elliptic regularity α to be any number $< \alpha_* = 0.5444837368\ldots$. The initial triangulation $\mathcal{T}_0$ consists of three elements. Again we use the symmetric V-cycle algorithm for the Poisson problem with three presmoothing and three postsmoothing steps as the preconditioner. The behavior of the contraction numbers of the V-cycle, F-cycle and W-cycle algorithms are similar to those observed for the unit square.

Here we only report the results for the V-cycle algorithm in Table 7.5. From the results in Tables 7.1 and 7.5 we see that the performance on the L-shaped domain is

TABLE 7.5
Contraction numbers for the V-cycle algorithm on the L-shaped domain.

k \ m	5	6	7	8	9	10
1	0.16	0.12	0.082	0.059	0.043	0.031
2	0.27	0.21	0.19	0.16	0.14	0.13

4	0.42	0.37	0.34	0.31	0.28	0.26
5	0.45	0.38	0.35	0.32	0.30	0.27
6	0.46	0.40	0.36	0.34	0.31	0.28
7	0.46	0.40	0.37	0.34	0.31	0.29

slightly worse than the performance on the unit square. But it is much better than the rate $m^{-\alpha}$ predicted by Theorem 6.9. This is likely the effect of superconvergence due to the uniform grids used in our computations.

Appendix A. Some properties of multigrid Poisson solves. In this appendix we consider multigrid Poisson solves as the preconditioner in (2.17) and (2.19). We will show that properties (i)–(iv) in section 2 are satisfied by such preconditioners.

Consider the discrete Poisson problem: Find $z \in V_k$ such that

$$L_k z = \psi \qquad \forall\, v \in V_k, \tag{A.1}$$

where L_k is defined in (2.12) and $\psi \in V_k'$.

Let $S_k : V_k' \longrightarrow V_k$ be the solution operator for (A.1) generated by either a symmetric V-cycle algorithm, a symmetric W-cycle algorithm or a symmetric variable V-cycle algorithm (that satisfies (4.12)), with 0 as the initial guess and Richardson relaxation as the smoother. In terms of S_k the output $MG(k, \psi, z_0)$ of the multigrid method can be written as

$$MG(k, \psi, z_0) = z_0 + S_k(\psi - L_k z_0), \tag{A.2}$$

and $Id_k - S_k L_k$ is the error propagation operator.

The operator S_k is symmetric, or equivalently the operator $Id_k - S_k L_k$ is symmetric with respect to the bilinear form $\langle L_k \cdot, \cdot \rangle$ (cf. Lemma 7.1 of [17], where S_k is denoted by B_k). Furthermore (cf. Theorems 5.1, 7.1 and 7.2 of [17]) there exists a number $\delta \in (0, 1)$ independent of k such that

$$0 \le \langle L_k(Id_k - S_k L_k)v, v\rangle \le \delta \langle L_k v, v\rangle \qquad \forall\, v \in V_k. \tag{A.3}$$

We see from (A.3) that S_k is positive definite. Therefore we can define $B_k = S_k^{-1}$ and the operator $B_k : V_k \longrightarrow V_k'$ is symmetric positive definite. Moreover (A.3) implies that the eigenvalues of the operator $Id_k - B_k^{-1} L_k : V_k \longrightarrow V_k$ lie between 0 and δ. Since $Id_k - B_k^{-1} L_k$ is also symmetric with respect to $\langle B_k \cdot, \cdot \rangle$, we deduce that

$$0 \le \langle B_k(Id_k - B_k^{-1} L_k)v, v\rangle \le \delta \langle B_k v, v\rangle \qquad \forall\, v \in V_k. \tag{A.4}$$

The estimate (2.15) follows from (A.4) immediately.

Hence the operator B_k satisfies properties (i) and (ii) in section 2. Property (iv), which states that multigrid algorithms have optimal complexity, is also standard [32]. In particular, Theorem 4.4 and Theorem 4.5 are valid for all three types of multigrid preconditioners.

On the other hand, the proofs of Theorem 6.9 and Theorem 6.10 require property (iii). Below we will demonstrate that (2.16) is satisfied by the B_k generated by W-cycle or variable V-cycle Poisson solves.

Let $B_k^{-1} : V_k' \longrightarrow V_k$ be the preconditioner obtained by a symmetric W-cycle algorithm with m presmoothing and m postsmoothing steps. We have a well-known recurrence relation [32]:

$$\begin{aligned} Id_k - B_k^{-1}L_k =& R_k^m(Id_k - I_{k-1}^k P_k^{k-1})R_k^m \\ &+ R_k^m I_{k-1}^k (Id_{k-1} - B_{k-1}^{-1}L_{k-1})^2 P_k^{k-1} R_k^m, \end{aligned} \tag{A.5}$$

where $I_{k-1}^k : V_{k-1} \longrightarrow V_k$ is the natural injection, $P_k^{k-1} : V_k \longrightarrow V_{k-1}$ is the adjoint of I_k^{k-1} with respect to the bilinear form $\langle L_k \cdot, \cdot \rangle$ and $\langle L_{k-1} \cdot, \cdot \rangle$, and R_k is the error reduction operator of one Richardson relaxation step. Of course at the coarsest level we have $B_0^{-1} = S_0 = L_0^{-1}$ and hence

$$Id_0 - B_0^{-1}L_0 = 0. \tag{A.6}$$

Let β be any number in $(0, 1/2)$. The following estimates are valid [20] for $k \geq 1$:

$$|R_k^m(Id_k - I_{k-1}^k P_k^{k-1})R_k^m v|_{H^1(\Omega)} \lesssim h_k^\beta m^{-\beta/2} \|v\|_{H^{1+\beta}(\Omega)} \qquad \forall v \in V_k, \tag{A.7}$$

$$\|P_k^{k-1} v\|_{H^{1+\beta}(\Omega)} \lesssim \|v\|_{H^{1+\beta}(\Omega)} \qquad \forall\, v \in V_k, \tag{A.8}$$

$$|(Id_k - B_k^{-1}L_k)v|_{H^1(\Omega)} \lesssim m^{-\alpha_*} |v|_{H^1(\Omega)} \qquad \forall\, v \in V_k, \tag{A.9}$$

where $\alpha_* \in (1/2, 1]$ is the index of elliptic regularity for the Poisson problem. Furthermore, we have

$$|R_k^m v|_{H^1(\Omega)} \leq |v|_{H^1(\Omega)} \qquad \forall\, v \in V_k, \text{ and } m \geq 1, \tag{A.10}$$

$$\|R_k^m v\|_{H^{1+\beta}(\Omega)} \leq C \|v\|_{H^{1+\beta}(\Omega)} \qquad \forall\, v \in V_k, \text{ and } m \geq 1, \tag{A.11}$$

where the positive constant C is independent of the meshes.

It follows from (2.1), (A.5), and (A.7)–(A.11) that

$$|v - B_k^{-1}L_k v|_{H^1(\Omega)} \leq C_* h_k^\beta \big[m^{-\beta/2} + \sigma m^{-\alpha_*}\big] \|v\|_{H^{1+\beta}(\Omega)} \qquad \forall\, v \in V_k, \tag{A.12}$$

where C_* is a mesh-independent positive constant, provided that

$$|v - B_{k-1}^{-1}L_{k-1} v|_{H^1(\Omega)} \leq \sigma h_{k-1}^\beta \|v\|_{H^{1+\beta}(\Omega)} \qquad \forall\, v \in V_{k-1}.$$

Hence, if m is sufficiently large, we obtain from (A.6), (A.12) and mathematical induction that

$$|v - B_k^{-1}L_k v|_{H^1(\Omega)} \leq \sigma h_k^\beta \|v\|_{H^{1+\beta}(\Omega)} \qquad \forall\, v \in V_k,\ k \geq 0, \tag{A.13}$$

if σ is the number defined by $\sigma = C_* m^{-\beta/2}/(1 - C_* m^{-\alpha_*})$. Therefore (2.16) is satisfied by the W-cycle preconditioner provided that m is sufficiently large.

Now we consider the preconditioner B_k^{-1} obtained from a variable V-cycle algorithm. Given a positive integer k, we assume that the number m_j of smoothing steps on level j satisfies

$$(1+\epsilon)m_{j+1} \le m_j \qquad \text{for} \quad 0 \le j \le k-1, \tag{A.14}$$

where ϵ is a positive number. We have an additive expression for the error propagation operator:

$$\begin{aligned} Id_k - B_k^{-1}L_k = {} & R_k^{m_k}(Id_k - I_{k-1}^k P_k^{k-1})R_k^{m_k} \\ & + R_k^{m_k} I_{k-1}^k R_{k-1}^{m_{k-1}}(Id_{k-1} - I_{k-2}^{k-1}P_{k-1}^{k-2})R_{k-1}^{m_{k-1}} P_k^{k-1} R_k^{m_k} \\ & + R_k^{m_k} I_{k-1}^k R_{k-1}^{m_{k-1}} I_{k-2}^{k-1} \\ & \times R_{k-2}^{m_{k-2}}(Id_{k-2} - I_{k-3}^{k-2}P_{k-2}^{k-3})R_{k-2}^{m_{k-2}} P_{k-1}^{k-2} R_{k-1}^{m_{k-1}} P_k^{k-1} R_k^{m_k} \\ & + \cdots . \end{aligned} \tag{A.15}$$

The following estimates are valid [20] for $k \ge 1$, $j \le k$ and $v \in V_k$:

$$\|R_k^{m_k}(Id_k - I_{k-1}^k P_k^{k-1})R_k^{m_k} v\|_{H^{1-\beta}(\Omega)} \lesssim h_k^\beta m_k^{-\alpha_* + (\beta/2)} |v|_{H^1(\Omega)}, \tag{A.16}$$

$$\|R_k^{m_k} I_{k-1}^k \cdots R_{j+1}^{m_{j+1}} I_j^{j+1} v\|_{H^{1-\beta}(\Omega)} \lesssim \|v\|_{H^{1-\beta}(\Omega)}, \tag{A.17}$$

$$|P_{j+1}^j R_{j+1}^{m_{j+1}} \cdots P_k^{k-1} R_k^{m_k} v|_{H^1(\Omega)} \lesssim |v|_{H^1(\Omega)}. \tag{A.18}$$

Combining (2.1), (A.6) and (A.15)–(A.18), we find, for any $\beta \in (0, 1/2)$,

$$\begin{aligned} |v - B_k^{-1}L_k v|_{H^{1-\beta}(\Omega)} &\le C_\beta |v|_{H^1(\Omega)} \sum_{j=2}^k h_j^\beta m_j^{-\alpha_* + (\beta/2)} \\ &\le C_\beta |v|_{H^1(\Omega)} \sum_{j=2}^k (2^{(j-k)} h_k)^\beta ((1+\epsilon)^{(j-k)} m_k)^{-\alpha_* + (\beta/2)} \\ &\le C_\beta m_k^{-\alpha_* + (\beta/2)} h_k^\beta |v|_{H^1(\Omega)} \sum_{j=2}^k [2^\beta (1+\epsilon)^{(-\alpha_* + \beta/2)}]^{j-k}, \end{aligned} \tag{A.19}$$

where C_β depends on β but not the meshes. It follows from (A.19) that there exists a positive mesh-independent constant C such that

$$|v - B_k^{-1}L_k v|_{H^{1-\beta}(\Omega)} \le C h_k^\beta |v|_{H^1(\Omega)} \qquad \forall\, v \in V_k \tag{A.20}$$

if we choose $\beta > 0$ so that

$$\beta < \max\left(\frac{1}{2}, \frac{\alpha_* \ln(1+\epsilon)}{\ln(2\sqrt{1+\epsilon})}\right).$$

The estimate (2.16) follows from (A.20) and duality. In other words, property (iii) is satisfied by the variable V-cycle preconditioner under condition (A.14).

hp-DISCONTINUOUS GALERKIN TIME-STEPPING FOR VOLTERRA INTEGRODIFFERENTIAL EQUATIONS*

HERMANN BRUNNER† AND DOMINIK SCHÖTZAU‡

Abstract. We present an *hp*-error analysis of the discontinuous Galerkin time-stepping method for Volterra integrodifferential equations with weakly singular kernels. We derive new error bounds that are explicit in the time-steps, the degrees of the approximating polynomials, and the regularity properties of the exact solution. It is then shown that start-up singularities can be resolved at exponential rates of convergence by using geometrically graded time-steps. Our theoretical results are confirmed in a series of numerical tests.

Key words. Volterra integrodifferential equation, discontinuous Galerkin time-stepping, geometrically refined time-steps, exponential convergence

1. Introduction.

We introduce and analyze the *hp*-version of the discontinuous Galerkin (DG) time-stepping method for the Volterra integrodifferential equation (VIDE):

$$u'(t) + a(t)u(t) + \int_0^t k_\alpha(t-s)b(s)u(s)\,ds = f(t), \qquad t \in [0,T], \tag{1.1}$$
$$u(0) = u_0 \in \mathbb{R}.$$

Here, a, b, and f are real functions that are continuous on $[0,T]$. Moreover, we assume that there are constants $\mu^\star \geq \mu_\star > 0$ such that

$$\mu_\star \leq a(t) \leq \mu^\star, \qquad |b(t)| \leq \mu^\star, \qquad t \in [0,T]. \tag{1.2}$$

The convolution kernel k_α is the weakly singular function given by

$$k_\alpha(s) := s^{-\alpha} \qquad \text{for } \alpha \in (0,1). \tag{1.3}$$

For any initial datum $u_0 \in \mathbb{R}$, the VIDE (1.1) has a unique solution $u : [0,T] \to \mathbb{R}$ which is continuously differentiable; see, e.g., [5, 2] and the references cited therein. More precisely, smooth (analytic) data a, b, and f in (1.1) lead to solutions u that are smooth (analytic) away from $t = 0$, but their second derivatives are unbounded at $t = 0$ and behave like

$$|u''(t)| \leq Ct^{-\alpha}, \qquad t > 0;$$

see [5, 3, 4] and [2, section 7.1]; compare also Theorem 4.1 below. This loss of regularity in u at $t = 0$ has the consequence that on uniform time-steps with length k,

approximations U generated by standard DG or collocation methods only possess low convergence order, that is,

$$\|u - U\|_{L^\infty(0,T)} \leq Ck^{1-\alpha};$$

see [4, 2]. This problem can be overcome by using meshes that are suitably refined near $t = 0$. We will show that the *hp*-version of the DG time-stepping method with geometrically graded time-steps leads to exponential rates of convergence.

The discontinuous Galerkin method was first proposed in [11] as a nonstandard finite element method for the numerical solution of neutron transport problems. Applied to initial-value ODEs, it can be viewed as an implicit single-step scheme that allows for arbitrary variation in the time-steps and the degrees of the approximating polynomials. It has been shown in [11] that despite the underlying Galerkin structure, the discontinuous Galerkin time-stepping method corresponds to certain implicit schemes of Runge–Kutta type. Subsequently, several important issues concerning the a priori and a posteriori error analyses of these schemes have been addressed; see, e.g., [7, 9, 8, 1] and the references therein. DG time-stepping has also been applied successfully to partial differential equations, and, in the context of parabolic problems, a large body of literature exists; we refer here only to the recent monograph [18] and the references cited therein. An error analysis of the DG time-stepping method applied to a parabolic integrodifferential equation was recently presented in [10].

All the works mentioned above are concerned with the *h*-version of the DG time-stepping method where convergence is achieved on successively refined time-steps using a fixed, typically low approximation order. This is in contrast to the so-called *p*- and *hp*-versions, where approximating polynomials of high degree are employed. The *hp*-approach is particularly beneficial for piecewise analytic solutions as its judicious combination of *h*- and *p*-refinement results in exponential rates of convergence. The time discretization of linear parabolic problems by the *hp*-DG time-stepping method was recently analyzed in [15, 19]. (See also [16] for extensions to problems whose spatial operators are not self-adjoint.) In particular, it has been shown that temporal start-up singularities induced by incompatible initial data can be resolved at exponential rates of convergence. Furthermore, in [14], a complete *hp*-error analysis of the DG time-stepping method has been carried out for nonlinear initial value problems in $\mathbb{R}^d$.

In the present work, we derive new *hp*-error bounds in $L^2(0,T)$ and $L^\infty(0,T)$ for the DG time-stepping method applied to the VIDE (1.1). The L^2-framework will be particularly important in the extension of the present results to partial VIDEs. Our estimates are completely explicit in the time-steps, the polynomial degrees, and the regularity properties of the exact solution. While these estimates give optimal convergence rates in the time-steps, they also show that the DG method converges if the polynomial degrees are increased at fixed time-steps. In particular, we prove that the *p*-version DG approach gives spectral accuracy for solutions with smooth time dependence, i.e., the convergence rates are of arbitrarily high algebraic order. In order to resolve start-up singularities induced by the weakly singular kernel k_α in (1.3), we employ time-steps that are geometrically refined toward $t = 0$, combined with polynomial degrees that are linearly increasing. We show that this *hp*-version approach leads to exponential rates of convergence for analytic data a, b, and f, despite the unboundedness of the second derivative of u near $t = 0$. We present a series of numerical experiments that confirm our theoretical results.

Finally, we observe that since the main purpose of this paper is to obtain insight into the basic *hp*-error analysis of DG methods on geometrically graded time-steps

for partial VIDEs, there will be no loss of generality by using the model problem given by (1.1)–(1.3). In a sequel to this paper we shall use this insight as the key to obtain an analogous estimate for partial VIDEs; we will then also describe typical applications of such VIDEs.

The outline of the paper is as follows. In section 2, we introduce the DG time-stepping method for the VIDE (1.1) and prove existence and uniqueness of approximate solutions. In section 3 we carry out a complete *hp*-error analysis of the DG method. In section 4 we show that on the basis of precise regularity results, the solutions of (1.1) can be approximated exponentially fast on time-steps that are geometrically graded toward $t = 0$. Our theoretical results are verified in the numerical tests in section 5. Finally, we end our presentation in section 6 with concluding remarks pointing to future work and open problems.

Throughout, standard notations and conventions are used. For an interval I, we write $L^p(I)$, $1 \le p \le \infty$, for the Lebesgue space of p-integrable functions, endowed with the norm $\|\cdot\|_{L^p(I)}$. We write $W^{k,p}(I)$ for the Sobolev space of order $k \in \mathbb{N}_0$ equipped with the usual norm $\|\cdot\|_{W^{k,p}(I)}$. For a noninteger exponent $s \ge 0$, the space $W^{s,p}(I)$ is defined by the K-method of interpolation. We set $H^s(I) = W^{s,2}(I)$. We write $\mathcal{P}^r(I)$ for the space of all polynomials of degree $\le r$. We denote by C generic constants not necessarily identical at different places but always independent of the discretization parameters of interest (such as time-steps and polynomial degrees).

2. Discontinuous Galerkin time-stepping. In this section, we introduce the discontinuous Galerkin time-stepping method for the numerical approximation of the VIDE (1.1). We then show the existence and uniqueness of the approximate solutions.

2.1. Discontinuous Galerkin discretization. Let $\mathcal{M}$ be a partition of $(0,T)$ into intervals $\{I_m\}_{m=1}^M$ given by $I_m := (t_{m-1}, t_m)$ with nodes

$$0 =: t_0 < t_1 < \cdots < t_{M-1} < t_M := T.$$

The length of I_m is $k_m := t_m - t_{m-1}$. As usual, we set $k := \max_{m=1}^M k_m$. The partition $\mathcal{M}$ is called quasi-uniform if there is a constant $C > 0$ such that $k \le Ck_m$ for all $1 \le m \le M$.

We assign to each interval I_m a polynomial degree $r_m \ge 0$ and introduce the degree vector $\underline{r} = \{r_m\}_{m=1}^M$. We define $|\underline{r}| := \max_{m=1}^M r_m$. The tuple $(\mathcal{M}, \underline{r})$ is called an *hp*-discretization of $(0,T)$. If $r_m = r$ for all $1 \le m \le M$, we simply write $(\mathcal{M}, r)$.

Let $\varphi : (0,T) \to \mathbb{R}$ be a function that is piecewise continuous with respect to the partition $\mathcal{M}$. At the nodes the left- and right-sided limits of φ are defined by

$$\varphi_m^+ = \lim_{s \to 0,\ s>0} \varphi(t_m + s), \qquad 0 \le m \le M-1,$$
$$\varphi_m^- = \lim_{s \to 0,\ s>0} \varphi(t_m - s), \qquad 1 \le m \le M.$$

The jumps across interior nodes are given by $[\![\varphi]\!]_m = \varphi_m^+ - \varphi_m^-$, $1 \le m \le M-1$.

For a given *hp*-discretization $(\mathcal{M}, \underline{r})$ of $(0,T)$, we introduce the discrete space

$$\mathcal{V}(\mathcal{M}, \underline{r}) := \big\{ \varphi \in L^2(0,T) :\ \varphi|_{I_m} \in \mathcal{P}^{r_m}(I_m),\ 1 \le m \le M \big\}. \tag{2.1}$$

Note that functions in $\mathcal{V}(\mathcal{M}, \underline{r})$ can be discontinuous across the nodes $\{t_m\}$.

We consider the following discontinuous Galerkin approximation of the VIDE in (1.1): find $U \in \mathcal{V}(\mathcal{M}, \underline{r})$ such that

$$B_{DG}(U, V) = F_{DG}(V) \tag{2.2}$$

for all $V \in \mathcal{V}(\mathcal{M}, \underline{r})$.

The forms B_{DG} and F_{DG} are given by

$$\begin{aligned} B_{DG}(U,V) := & \sum_{m=1}^{M} \int_{I_m} \Big(U'(t) + a(t)U(t)\Big)V(t)\,dt \\ & + \sum_{m=1}^{M} \int_{I_m} \left(\int_0^t k_\alpha(t-s)b(s)U(s)\,ds\right) V(t)\,dt \\ & + \sum_{m=1}^{M-1} [\![U]\!]_m V_m^+ + U_0^+ V_0^+, \\ F_{DG}(V) := & \, u_0 V_0^+ + \sum_{m=1}^{M} \int_{I_m} f(t)V(t)\,dt. \end{aligned}$$

Note that the exact solution u of problem (1.1) satisfies $B_{DG}(u,V) = F_{DG}(V)$ for all $V \in \mathcal{V}(\mathcal{M}, \underline{r})$. Hence, we have the Galerkin orthogonality property

$$B_{DG}(u-U,V) = 0 \tag{2.3}$$

for all $V \in \mathcal{V}(\mathcal{M}, \underline{r})$.

Remark 2.1. The discontinuous Galerkin discretization in (2.2) is a time-stepping scheme: if U is given on I_n, $1 \le n \le m-1$, we find $U|_{I_m} \in \mathcal{P}^{r_m}(I_m)$ by solving

$$\begin{aligned} & \int_{I_m} \Big(U'(t) + a(t)U(t)\Big)V(t)\,dt + \int_{I_m} \left(\int_{t_{m-1}}^t k_\alpha(t-s)b(s)U(s)\,ds\right) V(t)\,dt + U_{m-1}^+ V_{m-1}^+ \\ & \quad = U_{m-1}^- V_{m-1}^+ + \int_{I_m} f(t)V(t)\,dt - \int_{I_m} \left(\int_0^{t_{m-1}} k_\alpha(t-s)b(s)U(s)\,ds\right) V(t)\,dt \end{aligned}$$

for all $V \in \mathcal{P}^{r_m}(I_m)$. Here, we set $U_0^- = u_0$.

2.2. Existence and uniqueness of discrete solutions. To show that the DG time-stepping method (2.2) defines a unique approximate solution $U \in \mathcal{V}(\mathcal{M}, \underline{r})$, we make use of the discrete Gronwall inequality from [10, Lemma 6.4].

LEMMA 2.2. *Let $\mathcal{M} = \{I_m\}_{m=1}^M$ be a partition of $(0,T)$ with $k = \max_{m=1}^M \{k_m\}$. Let $\{a_m\}_{m=1}^M$ and $\{b_m\}_{m=1}^M$ be sequences of numbers with $0 \le b_1 \le b_2 \le \cdots \le b_M$. Assume that there is a constant $K \ge 0$ such that*

$$a_1 \le b_1, \qquad a_m \le b_m + K \sum_{n=1}^{m} w_{m,n}(\alpha) a_n, \quad m = 2, \ldots, M,$$

where $w_{m,n}(\alpha) = \int_{I_n} (t_m - t)^{-\alpha}\,dt$. Assume further that $\delta = \frac{K k^{1-\alpha}}{1-\alpha} < 1$. Then we have

$$a_m \le C b_m, \qquad m = 1, \ldots, M,$$

with a constant $C > 0$ that solely depends on δ, K, α, and T.

Furthermore, we recall the following technical result from [10, Lemma 6.3].

LEMMA 2.3. *For $f \in L^2(0,\tau)$ and $\alpha \in (0,1)$ there holds*

$$\int_0^\tau \left(\int_0^t (t-s)^{-\alpha} f(s)\,ds\right)^2 dt \le \frac{\tau^{1-\alpha}}{(1-\alpha)} \int_0^\tau (\tau - t)^{-\alpha} \left(\int_0^t f(s)^2\,ds\right) dt.$$

We now address the existence and uniqueness of discrete solutions.

PROPOSITION 2.4. *Let* $(\mathcal{M}, \underline{r})$ *be an hp-discretization of* $(0,T)$ *with*

$$(\mu^\star/\mu_\star)^2 \frac{(Tk)^{(1-\alpha)}}{(1-\alpha)^2} < 1. \tag{2.4}$$

Then the discrete problem (2.2) *has a unique solution* $U \in \mathcal{V}(\mathcal{M}, \underline{r})$.

Remark 2.5. Note that condition (2.4) is independent of the degree vector $\underline{r}$.

Proof. We first show the uniqueness of DG solutions. To this end, let U and $\widetilde{U}$ be two solutions of (2.2). The difference $E = U - \widetilde{U}$ then satisfies

$$\int_{I_m} \Big(E' + aE\Big) V \, dt + E_{m-1}^+ V_{m-1}^+ = E_{m-1}^- V_{m-1}^+ - \int_{I_m} \left(\int_0^t k_\alpha(t-s) b(s) E(s) \, ds \right) V(t) \, dt$$

for any $V \in \mathcal{P}^{r_m}(I_m)$, $m = 1, \ldots, M$. Selecting $V = E$ yields

$$\frac{1}{2} \left(E_m^-\right)^2 + \frac{1}{2} \left(E_{m-1}^+\right)^2 + \int_{I_m} aE^2 \, dt = E_{m-1}^- E_{m-1}^+ - \int_{I_m} \left(\int_0^t k_\alpha(t-s) b(s) E(s) \, ds \right) E(t) \, dt.$$

Since

$$E_{m-1}^- E_{m-1}^+ \le \frac{1}{2} \left(E_{m-1}^-\right)^2 + \frac{1}{2} \left(E_{m-1}^+\right)^2,$$

we have

$$\frac{1}{2} \left(E_m^-\right)^2 + \int_{I_m} aE^2 \, dt \le \frac{1}{2} \left(E_{m-1}^-\right)^2 + \int_{I_m} \left(\int_0^t k_\alpha(t-s) |b(s)E(s)| \, ds \right) |E(t)| \, dt.$$

In view of $E_0^- = 0$, iterating the above estimate yields

$$\frac{1}{2} \left(E_m^-\right)^2 + \int_0^{t_m} aE^2 \, dt \le \int_0^{t_m} \left(\int_0^t k_\alpha(t-s) |b(s)E(s)| \, ds \right) |E(t)| \, dt =: S_m \tag{2.5}$$

for $1 \le m \le M$. By invoking the bounds for a and b in (1.2), the Cauchy–Schwarz inequality, and Lemma 2.3, the integral S_m in (2.5) can be bounded by

$$\begin{aligned} S_m &\le \mu^\star \mu_\star^{-1/2} \left(\int_0^{t_m} \left(\int_0^t k_\alpha(t-s) |E(s)| \, ds \right)^2 dt \right)^{\frac{1}{2}} \left(\int_0^{t_m} aE^2 \, dt \right)^{\frac{1}{2}} \\ &\le \frac{1}{2} (\mu^\star)^2 \mu_\star^{-1} \frac{t_m^{(1-\alpha)}}{(1-\alpha)} \int_0^{t_m} (t_m - t)^{-\alpha} \left(\int_0^t E(s)^2 \, ds \right) dt + \frac{1}{2} \int_0^{t_m} aE^2 \, dt \\ &\le \frac{1}{2} (\mu^\star/\mu_\star)^2 \frac{t_m^{(1-\alpha)}}{(1-\alpha)} \int_0^{t_m} (t_m - t)^{-\alpha} \left(\int_0^t a(s) E(s)^2 \, ds \right) dt + \frac{1}{2} \int_0^{t_m} aE^2 \, dt. \end{aligned}$$

Hence, we obtain

$$\frac{1}{2} \int_0^{t_m} aE^2 \, dt \le \frac{1}{2} (\mu^\star/\mu_\star)^2 \frac{T^{(1-\alpha)}}{(1-\alpha)} \sum_{n=1}^m \left(\int_{I_n} (t_m - t)^{-\alpha} \, dt \right) \left(\int_0^{t_n} aE^2 \, ds \right).$$

Setting $a_m = \int_0^{t_m} aE^2\,dt$ and $b_m = 0$, the Gronwall inequality in Lemma 2.2 gives

$$\int_0^{t_m} aE^2\,dt = 0, \qquad m = 1, \dots, M,$$

provided that (2.4) is satisfied. The boundedness of a thus shows that $E \equiv 0$ and $U \equiv \widetilde{U}$.

As problem (2.2) is linear and finite dimensional, the existence of solutions follows from their uniqueness. This completes the proof. ∎

3. Error analysis. In this section, we derive *hp*-version error bounds for the DG time-stepping method in (2.2).

3.1. Abstract error bounds. We start be showing abstract error bounds. To this end, for a continuous function $u : [0,T] \to \mathbb{R}$, we define the interpolant $\mathcal{I}u \in \mathcal{V}(\mathcal{M}, \underline{r})$ by

$$(\mathcal{I}u)_m^- = u_m^-, \qquad 1 \le m \le M, \tag{3.1}$$

$$\int_{I_m} \mathcal{I}u(t)V'(t)\,dt = \int_{I_m} u(t)V'(t)\,dt, \qquad V \in \mathcal{P}^{r_m}(I_m),\ 1 \le m \le M. \tag{3.2}$$

Remark 3.1. The same interpolant has been used in the h-version analysis in [10]; we also refer to [18] and the references cited therein in the context of parabolic problems. The *hp*-approximation properties of $\mathcal{I}$ have been thoroughly investigated in [14, 15] and will be used in section 3.2.

Let now u be the exact solution of (1.1) and $U \in \mathcal{V}(\mathcal{M}, \underline{r})$ the DG approximation in (2.2). We split the error $e = u - U$ into $e = \eta + \theta$ with $\eta := u - \mathcal{I}u$ and $\theta := \mathcal{I}u - U$. Using Galerkin orthogonality in (2.3) and the construction of $\mathcal{I}u$, the function θ satisfies

(3.3)
$$\int_{I_m} \Big(\theta' + a\theta\Big)V\,dt + \theta_{m-1}^+ V_{m-1}^+ = \theta_{m-1}^- V_{m-1}^+ - \int_{I_m} a\eta V\,dt$$
$$- \int_{I_m} \left(\int_0^t k_\alpha(t-s)b(s)\eta(s)\,ds\right) V(t)\,dt - \int_{I_m} \left(\int_0^t k_\alpha(t-s)b(s)\theta(s)\,ds\right) V(t)\,dt$$

for any $V \in \mathcal{P}^{r_m}(I_m)$ and $m = 1, \dots, M$.

Our first result establishes an L^2-control of θ in terms of η.

LEMMA 3.2. *Let $(\mathcal{M}, \underline{r})$ be an hp-discretization of $(0,T)$ with*

$$\delta = 3(\mu^\star/\mu_\star)^2 \frac{(Tk)^{(1-\alpha)}}{(1-\alpha)^2} < 1. \tag{3.4}$$

Then we have

$$\frac{1}{2}\int_0^{t_m} a\theta^2\,dt + \frac{1}{2}\left(\theta_m^-\right)^2 \le C\int_0^{t_m} a\eta^2\,dt, \qquad m = 1, \dots M,$$

with a constant $C > 0$ that solely depends on $\mu_\star$, $\mu^\star$, α, T, and δ in (3.4).

Remark 3.3. Note that assumption (3.4) is slightly stronger than that in (2.4) and thus implies the existence and uniqueness of discrete solutions.

Proof. We select $V = \theta$ in (3.3). This yields

$$\frac{1}{2}\left(\theta_m^-\right)^2 + \frac{1}{2}\left(\theta_{m-1}^+\right)^2 + \int_{I_m} a\theta^2\,dt = \theta_{m-1}^-\theta_{m-1}^+ - \int_{I_m} a\eta\theta\,dt$$
$$- \int_{I_m}\left(\int_0^t k_\alpha(t-s)b(s)\eta(s)\,ds\right)\theta(t)\,dt - \int_{I_m}\left(\int_0^t k_\alpha(t-s)b(s)\theta(s)\,ds\right)\theta(t)\,dt.$$

Since

$$\theta_{m-1}^-\theta_{m-1}^+ \le \frac{1}{2}\left(\theta_{m-1}^-\right)^2 + \frac{1}{2}\left(\theta_{m-1}^+\right)^2,$$

we obtain

$$\begin{aligned}\frac{1}{2}\left(\theta_m^-\right)^2 + \int_{I_m} a\theta^2\,dt \le \frac{1}{2}\left(\theta_{m-1}^-\right)^2 &+ \int_{I_m} a|\eta\theta|\,dt\\ &+ \int_{I_m}\left(\int_0^t k_\alpha(t-s)|b(s)\eta(s)|\,ds\right)|\theta(t)|\,dt\\ &+ \int_{I_m}\left(\int_0^t k_\alpha(t-s)|b(s)\theta(s)|\,ds\right)|\theta(t)|\,dt.\end{aligned}$$

Iterating this estimate gives

$$\frac{1}{2}\left(\theta_m^-\right)^2 + \int_0^{t_m} a\theta^2\,dt \le T_1 + T_2 + T_3,$$

where

$$\begin{aligned}T_1 &= \int_0^{t_m} a|\eta\theta|\,dt,\\ T_2 &= \int_0^{t_m}\left(\int_0^t k_\alpha(t-s)|b(s)\eta(s)|\,ds\right)|\theta(t)|\,dt,\\ T_3 &= \int_0^{t_m}\left(\int_0^t k_\alpha(t-s)|b(s)\theta(s)|\,ds\right)|\theta(t)|\,dt.\end{aligned}$$

We estimate each of the above terms separately.

First, we note that

$$T_1 \le \frac{3}{2}\int_0^{t_m} a\eta^2\,dt + \frac{1}{6}\int_0^{t_m} a\theta^2\,dt.$$

Next, using the bounds for a and b in (1.2), the Cauchy–Schwarz inequality, and Lemma 2.3, we have

$$\begin{aligned}T_2 &\le \mu^\star\mu_\star^{-1/2}\left(\int_0^{t_m}\left(\int_0^t k_\alpha(t-s)|\eta(s)|\,ds\right)^2 dt\right)^{\frac12}\left(\int_0^{t_m} a\theta^2\,dt\right)^{\frac12}\\ &\le \frac{3}{2}(\mu^\star/\mu_\star)^2\frac{T^{1-\alpha}}{(1-\alpha)}\int_0^{t_m}(t_m-t)^{-\alpha}\left(\int_0^t a(s)\eta(s)^2\,ds\right)dt + \frac{1}{6}\int_0^{t_m} a\theta^2\,dt\\ &\le \frac{3}{2}(\mu^\star/\mu_\star)^2\frac{T^{2(1-\alpha)}}{(1-\alpha)^2}\int_0^{t_m} a\eta^2\,ds + \frac{1}{6}\int_0^{t_m} a\theta^2\,dt.\end{aligned}$$

Analogously, we obtain

$$T_3 \le \frac{3}{2}(\mu^\star/\mu_\star)^2 \frac{T^{1-\alpha}}{(1-\alpha)} \int_0^{t_m} (t_m - t)^{-\alpha} \left(\int_0^t a(s)\theta^2(s) \right) ds\, dt + \frac{1}{6} \int_0^{t_m} a\theta^2\, dt$$
$$\le \frac{3}{2}(\mu^\star/\mu_\star)^2 \frac{T^{1-\alpha}}{(1-\alpha)} \sum_{n=1}^{m} \left(\int_{I_n} (t_m - t)^{-\alpha}\, dt \right) \left(\int_0^{t_n} a\theta^2\, ds \right) + \frac{1}{6} \int_0^{t_m} a\theta^2\, dt.$$

Combining the above estimates results in

$$\frac{1}{2} \left(\theta_m^-\right)^2 + \frac{1}{2} \int_0^{t_m} a\theta^2\, dt \le \max\left\{ \frac{3}{2}, \frac{3}{2}(\mu^\star/\mu_\star)^2 \frac{T^{2(1-\alpha)}}{(1-\alpha)^2} \right\} \int_0^{t_m} a\eta^2\, dt$$
$$+ \frac{3}{2}(\mu^\star/\mu_\star)^2 \frac{T^{1-\alpha}}{(1-\alpha)} \sum_{n=1}^{m} \left(\int_{I_n} (t_m - t)^{-\alpha}\, dt \right) \left(\int_0^{t_n} a\theta^2\, ds \right).$$

Setting

$$a_m = \int_0^{t_m} a\theta^2\, dt,$$
$$b_m = \max\left\{ 3, 3(\mu^\star/\mu_\star)^2 \frac{T^{2(1-\alpha)}}{(1-\alpha)^2} \right\} \int_0^{t_m} a\eta^2\, dt,$$

the assertion follows from Lemma 2.2. ∎

Next, we bound the derivative of θ as follows.

LEMMA 3.4. *We have*

$$\int_{I_m} |\theta'|^2 (t - t_{m-1})\, dt \le C k_m \int_0^{t_m} a(\theta^2 + \eta^2)\, dt, \qquad m = 1, \dots M,$$

with a constant $C > 0$ that solely depends on $\mu_\star$, $\mu^\star$, α, and T.

Proof. We choose $V(t) = \theta'(t)(t - t_{m-1})$ in (3.3) and obtain

$$\int_{I_m} |\theta'|^2 (t - t_{m-1})\, dt \le T_1 + T_2 + T_3 + T_4,$$

where

$$T_1 = \int_{I_m} a|\theta\theta'(t - t_{m-1})|\, dt,$$
$$T_2 = \int_{I_m} a|\eta\theta'(t - t_{m-1})|\, dt,$$
$$T_3 = \int_{I_m} \left(\int_0^t k_\alpha(t-s)|b(s)\eta(s)|\, ds \right) |\theta'(t - t_{m-1})|\, dt,$$
$$T_4 = \int_{I_m} \left(\int_0^t k_\alpha(t-s)|b(s)\theta(s)|\, ds \right) |\theta'(t - t_{m-1})|\, dt.$$

Clearly, using the bounds for a in (1.2),

$$T_1 \le (\mu^\star)^{1/2} \left(\int_{I_m} a\theta^2\, dt \right)^{\frac{1}{2}} k_m^{\frac{1}{2}} \left(\int_{I_m} |\theta'|^2 (t - t_{m-1})\, ds \right)^{\frac{1}{2}},$$
$$T_2 \le (\mu^\star)^{1/2} \left(\int_{I_m} a\eta^2\, dt \right)^{\frac{1}{2}} k_m^{\frac{1}{2}} \left(\int_{I_m} |\theta'|^2 (t - t_{m-1})\, ds \right)^{\frac{1}{2}}.$$

Furthermore, by Lemma 2.3,

$$T_3 \le \mu^\star \left(\int_{I_m} \left(\int_0^t (t-s)^\alpha |\eta(s)|\, ds \right)^2 dt \right)^{\frac{1}{2}} k_m^{\frac{1}{2}} \left(\int_{I_m} |\theta'|^2 (t-t_{m-1})\, ds \right)^{\frac{1}{2}}$$
$$\le \mu^\star \mu_\star^{-1/2} \frac{T^{1-\alpha}}{1-\alpha} \left(\int_0^{t_m} a\eta^2\, dt \right)^{\frac{1}{2}} k_m^{\frac{1}{2}} \left(\int_{I_m} |\theta'|^2 (t-t_{m-1})\, ds \right)^{\frac{1}{2}}.$$

Analogously, we obtain

$$T_4 \le \mu^\star \mu_\star^{-1/2} \frac{T^{1-\alpha}}{1-\alpha} \left(\int_0^{t_m} a\theta^2\, dt \right)^{\frac{1}{2}} k_m^{\frac{1}{2}} \left(\int_{I_m} |\theta'|^2 (t-t_{m-1})\, ds \right)^{\frac{1}{2}}.$$

Combining these estimates results in

$$\int_{I_m} |\theta'|^2 (t-t_{m-1})\, dt \le C k_m \int_0^{t_m} a(\theta^2+\eta^2)\, dt.$$

This completes the proof. ∎

To control the L^∞-norm of θ in terms of the interpolation error η, we make use of the following inverse inequality from [14, Lemma 3.1].

LEMMA 3.5. *On each interval I_m there holds*

$$\|\varphi\|^2_{L^\infty(I_m)} \le C \left(\log(\max\{r_m, 2\}) \int_{I_m} |\varphi'(t)|^2 (t-t_{m-1})\, dt + \left(\varphi_m^-\right)^2 \right),$$

for any $\varphi \in \mathcal{P}^{r_m}(I_m)$, $r_m \ge 0$. The constant $C > 0$ is independent of k_m and r_m. Furthermore, the estimate cannot be improved asymptotically as $r_m \to \infty$.

The following result states an abstract error bound.

THEOREM 3.6. *Let $(\mathcal{M}, \underline{r})$ be an hp-discretization of $(0,T)$ satisfying (3.4). Then the error $u - U$ between the exact solution u and the DG approximation U satisfies*

$$\|u-U\|_{L^2(0,T)} \le C \|u - \mathcal{I}u\|_{L^2(0,T)}$$

and

$$\|u-U\|_{L^\infty(0,T)} \le C \log^{\frac{1}{2}}(\max\{|\underline{r}|, 2\}) \|u - \mathcal{I}u\|_{L^\infty(0,T)}$$

with a constant $C > 0$ that solely depends on $\mu_\star$, $\mu^\star$, α, T, and δ in (3.4).

Proof. As before, we split the error into $u - U = \eta + \theta$. Lemmas 3.2 and 3.4 yield

$$\left(\theta_m^-\right)^2 + \int_0^{t_m} a\theta^2\, dt + \int_0^{t_m} |\theta'|^2 (t-t_{m-1})\, dt \le C \int_0^{t_m} a\eta^2\, dt.$$

In view of the boundedness of a in (1.2), we obtain $\|\theta\|_{L^2(0,T)} \le C\|\eta\|_{L^2(0,T)}$. Furthermore, by Lemma 3.5,

$$\|\theta\|^2_{L^\infty(I_m)} \le C \log(\max\{|\underline{r}|, 2\}) \|\eta\|^2_{L^2(0,T)} \le C \log(\max\{|\underline{r}|, 2\}) \|\eta\|^2_{L^\infty(0,T)}$$

for $1 \le m \le M$. The error bounds follow from the triangle inequality. ∎

3.2. Error bounds. In this section, we employ the *hp*-version approximation properties of the interpolant $\mathcal{I}$ to make explicit the error bounds in Theorem 3.6.

We first recall the following results from [15, Theorem 3.10] and [14, Corollary 3.10]. We denote by Γ the Gamma function.

THEOREM 3.7. *Let $u|_{I_m} \in H^{s_m+1}(I_m)$ for $s_m \geq 0$. Then*

$$\|u - \mathcal{I}u\|^2_{L^2(I_m)} \leq C \left(\frac{k_m}{2}\right)^{2t_m+2} \frac{1}{\max\{1, r_m^2\}} \frac{\Gamma(r_m+1-t_m)}{\Gamma(r_m+1+t_m)} \|u\|^2_{H^{t_m+1}(I_m)}$$

for any real $0 \leq t_m \leq \min\{r_m, s_m\}$. The constant $C > 0$ is independent of k_m, r_m, t_m, and s_m. Moreover, if $u|_{I_m} \in W^{s_m+1,\infty}(I_m)$ for $s_m \geq 0$, then

$$\|u - \mathcal{I}u\|^2_{L^\infty(I_m)} \leq C \left(\frac{k_m}{2}\right)^{2t_m+2} \frac{\Gamma(r_m+1-t_m)}{\Gamma(r_m+1+t_m)} \|u\|^2_{W^{t_m+1,\infty}(I_m)}$$

for any real $0 \leq t_m \leq \min\{r_m, s_m\}$.

From Theorems 3.6 and 3.7 we obtain the following *hp*-error estimates.

THEOREM 3.8. *Let $(\mathcal{M}, \underline{r})$ be an hp-discretization of $(0,T)$ satisfying (3.4), and let $U \in \mathcal{V}(\mathcal{M}, \underline{r})$ be the DG approximation (2.2). Let the exact solution u of (1.1) satisfy*

$$u|_{I_m} \in H^{s_m+1}(I_m), \qquad s_m \geq 0, \qquad m = 1, \ldots, M.$$

Then we have the L^2-error bound

$$\|u - U\|^2_{L^2(0,T)} \leq C \sum_{m=1}^{M} \left(\left(\frac{k_m}{2}\right)^{2t_m+2} \frac{1}{\max\{1, r_m^2\}} \frac{\Gamma(r_m+1-t_m)}{\Gamma(r_m+1+t_m)} \|u\|^2_{H^{t_m+1}(I_m)} \right)$$

for any real $0 \leq t_m \leq \min\{s_m, r_m\}$, $1 \leq m \leq M$. Moreover, if

$$u|_{I_m} \in W^{s_m+1,\infty}(I_m), \qquad s_m \geq 0, \qquad m = 1, \ldots, M,$$

then we have the L^∞-error bound

$$\|u - U\|^2_{L^\infty(0,T)} \leq C \log\left(\max\{|\underline{r}|, 2\}\right) \cdot \max_{m=1}^{M} \left\{ \left(\frac{k_m}{2}\right)^{2t_m+2} \frac{\Gamma(r_m+1-t_m)}{\Gamma(r_m+1+t_m)} \|u\|^2_{W^{t_m+1,\infty}(I_m)} \right\}$$

for any real $0 \leq t_m \leq \min\{s_m, r_m\}$, $1 \leq m \leq M$.

The constants $C > 0$ solely depend on $\mu_\star$, $\mu^\star$, T, α, and δ in (3.4).

We remark that the estimates in Theorem 3.8 are explicit in the time-steps k_m, the polynomial degrees r_m, and the regularity exponents s_m of the exact solution. From the bounds in Theorem 3.8, the following convergence rates can be deduced for the *h*- and *p*-version of the DG time-stepping method.

COROLLARY 3.9. *Let $(\mathcal{M}, r)$ be an hp-discretization of $(0,T)$ satisfying (3.4) with uniform polynomial degree $r \geq 0$. Let u be the exact solution of (1.1) and U the discontinuous Galerkin approximation (2.2). If $u \in H^{s+1}(0,T)$ for $s \geq 0$, we have the L^2-error bound*

$$\|u - U\|_{L^2(0,T)} \leq C \frac{k^{\min(s,r)+1}}{r^{s+1}} \|u\|_{H^{s+1}(0,T)}.$$

Additionally, if $u \in W^{s+1,\infty}(0,T)$ *for* $s \geq 0$*, we have the* L^∞*-error bound*

$$\|u-U\|_{L^\infty(0,T)} \leq C \log\left(\max\{r,2\}\right) \frac{k^{\min(s,r)+1}}{r^s} \|u\|_{W^{s+1,\infty}(0,T)}.$$

The constants $C > 0$ *solely depend on* $\mu_\star$*,* $\mu^\star$*,* T*,* α*,* δ*, in* (3.4) *and the regularity exponent* s*.*

Proof. The proof follows from Theorem 3.8 and Stirling's formula; cf. [17]. ∎

The estimates in Corollary 3.9 show that the DG time-stepping method converges either as the time-steps are decreased ($k \to 0$) or as r is increased ($r \to \infty$). Both estimates are optimal in k. However, while the L^2-estimate is also optimal in the polynomial degree r, the L^∞-estimate is one power of r short from being optimal; this is due to the slightly suboptimal L^∞-approximation properties of the interpolant $\mathcal{I}$ in Theorem 3.7; see also [14].

It can be seen from Corollary 3.9 that for solutions u for which s is large it is more advantageous to increase r rather than to reduce k at fixed, low r. Indeed, if u is smooth on $[0,T]$, arbitrarily high algebraic convergence rates are possible if the polynomial degree r is raised. This is referred to as spectral convergence. Moreover, the p-version of the DG time-stepping method converges exponentially if the solution u is analytic on $[0,T]$. To see this, we first recall the following result.

LEMMA 3.10. *On each interval* I_m *there holds*

$$\|u-\mathcal{I}u\|_{L^2(I_m)} \leq C \inf_{q\in\mathcal{P}^{r_m}(I_m)} \|u-q\|_{H^1(I_m)},$$
$$\|u-\mathcal{I}u\|_{L^\infty(I_m)} \leq C r_m \inf_{q\in\mathcal{P}^{r_m}(I_m)} \|u-q\|_{W^{1,\infty}(I_m)}$$

with a constant $C > 0$ *independent of* I_m*,* r_m*, and* u*.*

Proof. The first estimate follows from [16, Lemma 3.6] and a scaling argument. The second estimate follows similarly from [14, Lemma 3.8]. ∎

THEOREM 3.11. *Let* $(\mathcal{M},r)$ *be an hp-discretization of* $(0,T)$ *satisfying* (3.4)*, with polynomial degree* $r \geq 0$*. Let the exact solution* u *of* (1.1) *be analytic on* $[0,T]$*. For the DG approximation* (2.2)*, we then have the error bound*

$$\|u-U\|_{L^p(0,T)} \leq C\exp(-br), \qquad p=2 \text{ or } p=\infty,$$

with constants $C, b > 0$ *that are independent of* r*.*

Proof. The assertion follows from Theorem 3.6, the results in Lemma 3.10, and standard approximation theory for analytic functions. ∎

4. Exponential convergence for analytic data. The exponential convergence result in Theorem 3.11 is valid for solutions that are analytic in $[0,T]$. However, this regularity assumption is unrealistic since, as discussed previously, solutions of (1.1) with analytic data have strong start-up singularities, due to the presence of the weakly singular kernel k_α, and are analytic only away from $t = 0$. In this section we show that despite this singular behavior, the *hp*-version of the DG method with geometrically graded time-steps near $t = 0$ yields exponential rates of convergence.

4.1. Analyticity of solutions. Let $\mathcal{A}(0,T)$ denote the space of the functions which are analytic on $[0,T]$. A function g in $\mathcal{A}(0,T)$ can be characterized by analyticity constants $C_g, d_g > 0$ and the growth conditions

$$|g^{(s)}(t)| \leq C_g d_g^s \Gamma(s+1), \qquad t\in[0,T],\ s \geq 0.$$

(See [17, pp. 78–79] for details.)

We assume the data a, b, and f to satisfy

$$a,\ b \in \mathcal{A}(0,T), \tag{4.1}$$

$$f(t) = f_1(t) + t^\beta f_2(t), \qquad f_i \in \mathcal{A}(0,T),\ i = 1,2,\ \beta > 0,\ \beta \notin \mathbb{N}. \tag{4.2}$$

The following result describes the analyticity properties of the exact solution u.

THEOREM 4.1. *Assume* (4.1)–(4.2) *and let* $\theta = \min\{2-\alpha, 1+\beta\}$. *Then there exist constants* $C, d > 0$ *depending only on the analyticity constants of* a, b, f_1, *and* f_2, *such that the solution* u *of* (1.1) *satisfies*

$$|u^{(s)}(t)| \le C d^s \Gamma(s+1) t^{\theta - s}, \qquad t \in (0,T],\ s \in \mathbb{N}.$$

Proof. This regularity result slightly generalizes earlier results in [4]; see also [12, 3] and [2]. We give a brief sketch of the proof; additional details can be found in [2, section 7.1].

The initial-value problem for the given VIDE (1.1) is equivalent to the second-kind Volterra integral equation

$$u(t) = g(t) + \int_0^t h_\alpha(t,s) b(s) u(s)\, ds, \quad t \in [0,T], \tag{4.3}$$

with

$$g(t) := u_0 + \int_0^t (f_1(s) + s^\beta f_2(s))\, ds,$$

$$h_\alpha(t,s) \ = \ -a(s) - \int_s^t k_\alpha(v-s) dv.$$

In particular, if $a(t) = a > 0,\ b(t) = \lambda > 0,\ f_i(t) = f_i = \text{const}$ for $t \in [0,T]$, then we have

$$g(t) = u_0 + f_1 t + \frac{f_2}{1+\beta} t^{1+\beta},$$

$$h_\alpha(t,s) = -a - \frac{\lambda}{1-\alpha}(t-s)^{1-\alpha}.$$

The resolvent kernel $R_\alpha(t,s)$ associated with the kernel

$$K_\alpha(t,s) := h_\alpha(t-s) b(s) \quad (t,s) \in D := \{(t,s) :\ 0 \le s \le t \le T\}$$

has the form

$$R_\alpha(t,s) = (t-s)^{1-\alpha} Q_\alpha(t,s), \quad (t,s) \in D.$$

Here,

$$Q_\alpha(t,s) := \sum_{n=1}^{\infty} (t-s)^{(n-1)(2-\alpha)} \Phi_n(t,s;\alpha),$$

where the series is uniformly convergent on D for all $\alpha \in (0,1)$. If the given data a and b are in $\mathcal{A}(0,T)$, then we have $\Phi_n(\cdot,\cdot;\alpha) \in \mathcal{A}(D)$ $(n \ge 1)$ for all $\alpha \in (0,1)$. Here, $\mathcal{A}(D)$ denotes the space of the functions that are analytic on D.

Since the (unique) solution of the VIDE (4.3) is given by

$$u(t) = g(t) + \int_0^t R_\alpha(t,s) g(s)\, ds, \quad t \in [0,T], \tag{4.4}$$

the regularity properties of the nonhomogeneous term g imply the asserted bounds for $u^{(s)}(t)$ on $(0,T]$. ∎

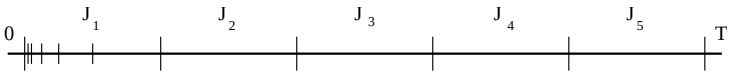

FIG. 4.1. *Example of a geometric partition $\mathcal{M}_{n,\sigma}$ of $(0,T)$. The intervals $\{J_k\}_{k=1}^5$ form the coarse partition while J_1 is geometrically refined toward $t=0$. Here, $n=5$ and $\sigma=0.5$.*

4.2. Exponential convergence for analytic data. In this section, we show that under the analyticity assumption in (4.1)–(4.2), the *hp*-version of the DG time-stepping method leads to exponential rates of convergence.

We start with the following definition.

DEFINITION 4.2. *The basic geometric partition $\widehat{\mathcal{M}}_{n,\sigma}=\{I_m\}_{m=1}^{n+1}$ of $\widehat{J}=(0,1)$ with grading factor $\sigma\in(0,1)$ and n levels of refinement is given by*

$$t_0=0, \qquad t_m=\sigma^{n-m+1}, \qquad 1\le m\le n+1.$$

Away from $t=0$, i.e., for $2\le m\le n+1$, the intervals $I_m\in\widehat{\mathcal{M}}_{n,\sigma}$ satisfy

$$k_m=t_m-t_{m-1}=\lambda t_{m-1}, \qquad \lambda:=\sigma^{-1}(1-\sigma). \tag{4.5}$$

DEFINITION 4.3. *A geometric partition $\mathcal{M}_{n,\sigma}$ of $(0,T)$ with grading factor $\sigma\in(0,1)$ and n levels of refinement is obtained by first quasi-uniformly partitioning $(0,T)$ into intervals $\{J_k\}_{k=1}^K$. The first interval $J_1=(0,t_1)$ near $t=0$ is then further subdivided into $n+1$ subintervals $\{I_m\}_{m=1}^{n+1}$ by linearly mapping to basic geometric mesh $\widehat{\mathcal{M}}_{n,\sigma}$ in Definition 4.2 onto J_1.*

An illustration of a geometric partition $\mathcal{M}_{n,\sigma}$ is given in Figure 4.1. We point out that the coarse intervals $\{J_k\}_{k=2}^K$ will be kept fixed; convergence will be achieved there by increasing the polynomial degrees.

LEMMA 4.4. *Assume (4.1)–(4.2) and set $\theta=\min\{2-\alpha,1+\beta\}$. Let $\mathcal{M}_{n,\sigma}$ be a geometric mesh of $(0,T)$ with $\{J_k\}_{k=1}^K$ denoting the underlying quasi-uniform partition of $(0,T)$ and $\{I_m\}_{m=1}^{n+1}$ the geometric refinement of J_1. Then the solution u of (1.1) satisfies*

$$\|u\|^2_{W^{1,\infty}(I_1)}\le C$$

and

$$\begin{aligned}
\|u\|^2_{W^{s+1,\infty}(I_m)} &\le Cd^{2s}\Gamma(2s+1)\sigma^{2(n-m+2)(\theta-s-1)}, && 2\le m\le n+1,\\
\|u\|^2_{W^{s+1,\infty}(I_k)} &\le Cd^{2s}\Gamma(2s+1), && 2\le k\le K,
\end{aligned}$$

for $s\ge 0$. The constants $C,d>0$ are independent of m, n, and s.

Remark 4.5. We point out that the constants C and d in Lemma 4.4 depend on the underlying quasi-uniform partition $\{J_k\}_{k=1}^K$ of $\mathcal{M}_{n,\sigma}$.

Proof. This is a simple consequence of Theorem 4.1, Definition 4.2, Definition 4.3, and properties of the Gamma function. ∎

DEFINITION 4.6. *Let $\mathcal{M}_{n,\sigma}$ be a geometric mesh of $(0,T)$ with $\{J_k\}_{k=1}^K$ denoting the underlying quasi-uniform partition of $(0,T)$ and $\{I_m\}_{m=1}^{n+1}$ the geometric refinement of J_1. A degree vector $\underline{r}$ on $\mathcal{M}_{n,\sigma}$ is called linear with slope $\mu>0$ if $r_m=\lfloor\mu m\rfloor$ on the geometrically refined elements $\{I_m\}_{m=1}^{n+1}$ and if $r_k=\lfloor\mu(n+1)\rfloor$ on the coarse elements J_k, $2\le k\le K$, away from $t=0$.*

Our next result establishes exponential rates of convergence under the analyticity assumptions in (4.1) and (4.2).

THEOREM 4.7. *Assume* (4.1)–(4.2). *Let* $\mathcal{M}_{n,\sigma}$ *be a geometric partition of* $(0,T)$ *satisfying* (3.4). *Then there exists a slope* $\mu_0 > 0$ *solely depending on* σ, α, β, *and the constants* C *and* d *in Lemma* 4.4 *such that for all linear polynomial degree vectors* $\underline{r}$ *with slope* $\mu \geq \mu_0$ *the DG approximation* $U \in \mathcal{V}(\mathcal{M}_{n,\sigma}, \underline{r})$ *satisfies the error estimate*

$$\|u - U\|_{L^p(0,T)} \leq C \exp(-bN^{\frac{1}{2}}), \qquad p = 2 \text{ or } p = \infty,$$

with constants $C, b > 0$ *that are independent of* $N = \dim(\mathcal{V}(\mathcal{M}_{n,\sigma}, \underline{r}))$.

Proof. We first note that

$$\|u - U\|_{L^2(0,T)} \leq \sqrt{T}\|u - U\|_{L^\infty(0,T)}.$$

In view of this inequality, we only need to prove the bound for the L^∞-error. To do so, we denote by $\{J_k\}_{k=1}^K$ underlying quasi-uniform partition of $\mathcal{M}_{n,\sigma}$ and by $\{I_m\}_{m=1}^{n+1}$ the geometric refinement of the first time-step J_1 near $t = 0$. From Theorem 3.8 and Lemma 3.10, we find

$$\|u - U\|^2_{L^\infty(0,T)} \leq C \log\Big(\max\{\lfloor \mu(n+1)\rfloor, 2\}\Big) \max\left\{\max_{m=1}^{n+1} e_m, \max_{k=2}^{K} e_k\right\}$$

with

$$\begin{aligned} e_m &= \left(\frac{k_m}{2}\right)^{2t_m+2} \frac{\Gamma(r_m+1-t_m)}{\Gamma(r_m+1+t_m)} \|u\|^2_{W^{t_m+1,\infty}(I_m)}, && 1 \leq m \leq n+1, \\ e_k &= \inf_{q \in \mathcal{P}^{r_k}(I_k)} \|u - q\|^2_{W^{1,\infty}(I_k)}, && 2 \leq k \leq K, \end{aligned}$$

and $0 \leq t_m \leq \min(s_m, r_m)$. Due to Theorem 4.1, u is analytic away from $t = 0$ and, hence, the regularity exponents s_m can be chosen arbitrarily large for $m = 2, \ldots, n+1$.

We first bound the errors $\{e_m\}$ on the geometrically refined intervals $\{I_m\}_{m=1}^{n+1}$. On the first element I_1 near $t = 0$, we select $s_1 = t_1 = 0$ and have from Lemma 4.4

$$e_1 \leq Ck_1^2 = C\sigma^{2n}.$$

Next, fix an element I_m, $2 \leq m \leq n+1$, away from $t = 0$. From Lemma 4.4 and the definition of λ in (4.5), we obtain

$$\begin{aligned} e_m &\leq C \left(\frac{\lambda\sigma^{n-m+2}}{2}\right)^{2t_m+2} \\ &\quad \cdot \frac{\Gamma(r_m+1-t_m)}{\Gamma(r_m+1+t_m)} \left(\sigma^{n-m+2}\right)^{2(\theta-t_m-1)} d^{2t_m}\Gamma(2t_m+1) \\ &= C\,\sigma^{(n-m+2)2\theta} \left((\lambda d)^{2t_m} \frac{\Gamma(r_m+1-t_m)}{\Gamma(r_m+1+t_m)}\Gamma(2t_m+1)\right). \end{aligned}$$

Taking $t_m = \gamma_m r_m$ with $\gamma_m \in (0,1)$, Stirling's formula leads to

$$e_m \leq C\sigma^{(n-m+2)2\theta} r_m^{1/2} \left((\lambda d)^{2\gamma_m} \left(\frac{(1-\gamma_m)^{1-\gamma_m}}{(1+\gamma_m)^{1+\gamma_m}}\right)\right)^{r_m}.$$

The function $f_{\lambda,d}(\gamma) = (\lambda d)^{2\gamma} \frac{(1-\gamma)^{1-\gamma}}{(1+\gamma)^{1+\gamma}}$ satisfies

$$0 < \inf_{0<\gamma<1} f_{\lambda,d}(\gamma) =: f_{\lambda,d}(\gamma_{\min}) < 1 \qquad \text{with } \gamma_{\min} = \frac{1}{\sqrt{1+\lambda^2 d^2}}.$$

Set $f_{\min} = f_{\min}(\lambda, d) =: f_{\lambda,d}(\gamma_{\min})$ and select $\gamma_m = \gamma_{\min}$ for $2 \le m \le n+1$. Hence, for $r_m = \lfloor \mu m \rfloor$, we have

$$\begin{aligned} e_m &\le C\sigma^{(n-m+2)2\theta} r_m^{\frac{1}{2}} f_{\min}^{r_m} \le C\sigma^{(n-m+2)2\theta} (\mu m)^{\frac{1}{2}} f_{\min}^{\mu m} \\ &\le C\sigma^{2\theta n} \Big(\mu(n+1)\Big)^{\frac{1}{2}} \Big(\sigma^{(-m+2)2\theta} f_{\min}^{\mu m}\Big). \end{aligned}$$

Let

$$\mu \ge \max\left\{ \frac{2\theta \log(\sigma)}{\log(f_{\min})}, 1 \right\}. \tag{4.6}$$

Then, $f_{\min}^{\mu m} \le \sigma^{2\theta m}$ and, consequently,

$$e_m \le C\sigma^{2\theta n} \Big(\mu(n+1)\Big)^{\frac{1}{2}} (\sigma^{4\theta}) \le C\sigma^{2\theta n} \Big(\mu(n+1)\Big)^{\frac{1}{2}}, \qquad m \ge 2.$$

Thus, we obtain for $1 \le m \le n+1$ the bound

$$e_m \le C \max\left\{ \sigma^{2n}, \sigma^{2\theta n} \Big(\mu(n+1)\Big)^{\frac{1}{2}} \right\}. \tag{4.7}$$

Further, from standard approximation properties for analytic functions, we can bound the errors $\{e_k\}$ on the elements $\{J_k\}_{k=2}^K$ away from $t = 0$ as

$$e_k \le Ce^{-br_k} = Ce^{-b\lfloor \mu(n+1) \rfloor}, \qquad 2 \le k \le K, \tag{4.8}$$

with constants C and b that solely depend on the constants C and d in Lemma 4.4. Combining the estimates in (4.7) and (4.8) yields

$$\|u - U\|^2_{L^\infty(0,T)} \le C \log\big(\max\{\mu(n+1), 2\}\big) \max\left\{ \sigma^{2n}, \sigma^{2n\theta} \big(\mu(n+1)\big)^{\frac{1}{2}}, e^{-b\lfloor \mu(n+1) \rfloor} \right\}.$$

Since we have

$$\log\big(\max\{\mu(n+1), 2\}\big) \max\left\{ \sigma^{2n}, \sigma^{2n\theta} \big(\mu(n+1)\big)^{\frac{1}{2}}, (e)^{-b\lfloor \mu(n+1) \rfloor} \right\} \le C \exp(-bn),$$

as $n \to \infty$, and $N = \dim(\mathcal{V}(\mathcal{M}_{n,\sigma}, \underline{r}) \le Cn^2$, the L^∞-error bound follows. ∎

Remark 4.8. From a practical point of view, it may be more convenient to use a fixed polynomial degree r on a geometric partition $\mathcal{M}_{n,\sigma}$. In this case, exponential convergence results for all $\sigma \in (0,1)$ provided that r is proportional to the number of refinements, i.e., $r = \lfloor \mu(n+1) \rfloor$ with the slope parameter μ. Indeed, we see from the proof of Theorem 4.7 that

$$\|u - U\|_{L^\infty(0,T)} \le C \max(\sigma^{2n}, r^{\frac{1}{2}} f_{\min}^r) \le C \exp(-br) \le C \exp(-bN^{1/2}).$$

Note that condition (4.6) on the slope is not necessary in this case.

5. Numerical experiments. In this section, we present a set of numerical experiments that confirm our theoretical error bounds. Throughout, we consider problem (1.1)–(1.3) with $T = 1$ and

$$a(t) = 1, \qquad b(t) = \exp(t), \qquad u_0 = 0.$$

We choose the right-hand side f such that the solution u of (1.1) is given by

$$u(t) = t^{2-\alpha} \exp(-t). \tag{5.1}$$

Notice that this solution is analytic away from $t = 0$ and that for $\alpha \in (0,1)$, the second derivative u'' is unbounded near $t = 0$. Thus, the solution (5.1) is ideally suited to test the performance of the *hp*-version DG method.

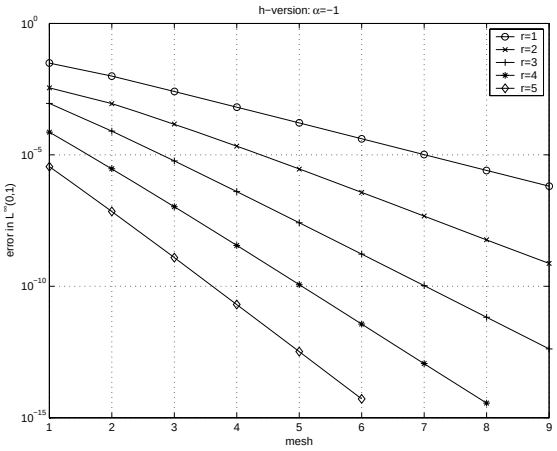

FIG. 5.1. *h-version: solution with* $\alpha = -1$.

5.1. Smooth solution. We start by considering the case $\alpha = -1$ so that u in (5.1) is analytic on $[0, 1]$.

In Figure 5.1, we show the errors in $L^\infty(0, 1)$ that have been obtained for the h-version DG method on a sequence $\{\mathcal{M}_i\}_{i=1}^9$ of equidistant time partitions with fixed polynomial degree $r = 1, \ldots, 5$. The partition $\mathcal{M}_i$ consists of 2^i intervals of length 2^{-i}. Hence, the straight error curves correspond to algebraic convergence in the time-step k, for each polynomial degree. To illustrate this, we compute in Table 5.1 the numerical rates of convergence $\{\kappa_i\}$ given by

$$\kappa_i = \log\left(\frac{e(\mathcal{M}_i)}{e(\mathcal{M}_{i-1})}\right) / \log(0.5)$$

with $e(\mathcal{M}_i)$ denoting the error on the partition $\mathcal{M}_i$ measured in the L^∞-norm. The convergence rates of order $r+1$ are clearly visible, which confirms the h-version result in Corollary 3.9 for a smooth solution.

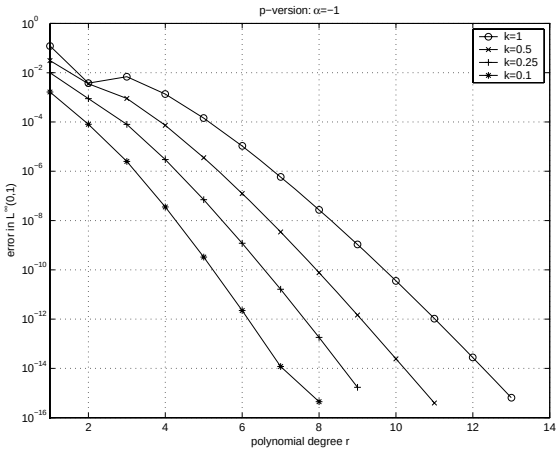

FIG. 5.2. *p-version: solution with* $\alpha = -1$.

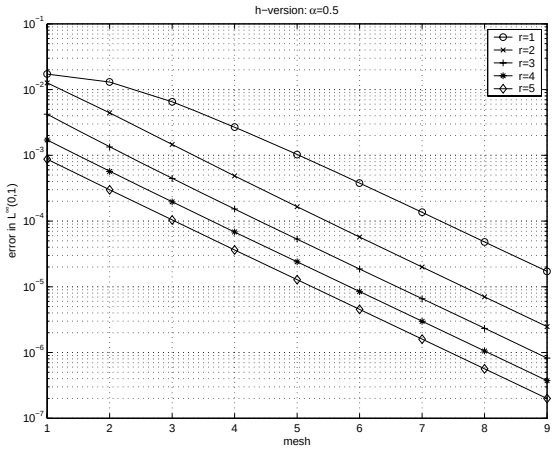

FIG. 5.3. *h-version: solution with* $\alpha = 0.5$.

Next, let us consider the p-version of the DG time-stepping method. To that end, we increase the polynomial degree from $r = 1$ to $r = 50$ for fixed partitions with time-step length $k = 1$, $k = 0.5$, $k = 0.25$, and $k = 0.1$, respectively. The performance of the p-version method is displayed in Figure 5.2. For each of the fixed time partitions the results show that exponential rates of convergence are achieved, in agreement with the theoretical findings in Theorem 3.11. (Remember that for $\alpha = -1$ the solution u is analytic in $[0, 1]$.) As expected, the smaller the underlying fixed time-step the smaller the errors that are actually obtained.

5.2. Nonsmooth solution. Next, we consider the case where $\alpha = 0.5$ so that the solution u in (5.1) has a singularity at $t = 0$. In fact, we have that $u \in W^{1.5,\infty}(0, 1)$ while the second derivative of u is unbounded near $t = 0$. In Figure 5.3, we show the performance of the h-version DG method on the uniform partitions $\mathcal{M}_i$ from section 5.1. The optimal order $r + 1$ is not obtained anymore, due to the loss of smoothness of u near the origin. Instead, the same asymptotic rate of convergence is

TABLE 5.2
h-version: solution with $\alpha = 0.5$.

degree r	i	error	order κ_i

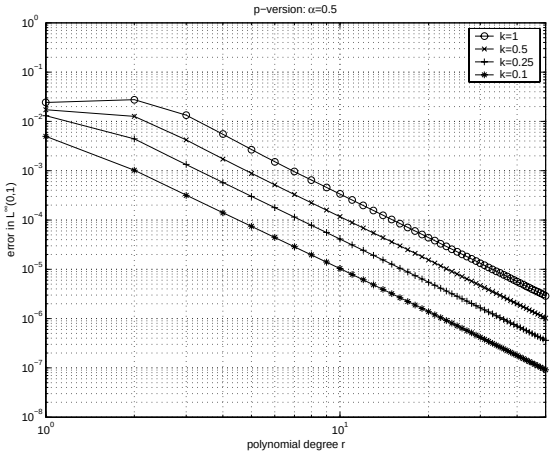

FIG. 5.4. *p-version: solution with* $\alpha = 0.5$.

observed for all polynomial degrees $r \geq 1$. This rate is computed in Table 5.2. It is of the order of 1.5 for all $r \geq 1$, thereby confirming the sharpness of the h-version result in Corollary 3.9.

Since for $\alpha = 0.5$ the solution u in (5.1) has a singularity at $t = 0$, the p-version of the DG method can only be expected to yield algebraic rates of convergence, in contrast to the test in section 5.1. Algebraic convergence behavior is indeed observed in Figure 5.4, where we increase the polynomial degree r on the same time partitions as above. The numerical convergence rates are shown in Table 5.3. In the context of the p-version DG methods, these rates are defined as

$$\kappa_r = -\log\left(\frac{e(r)}{e(r-1)}\right) / \log\left(\frac{r}{r-1}\right),$$

where $e(r)$ denotes the L^∞-error that is obtained for order r (on a fixed partition of

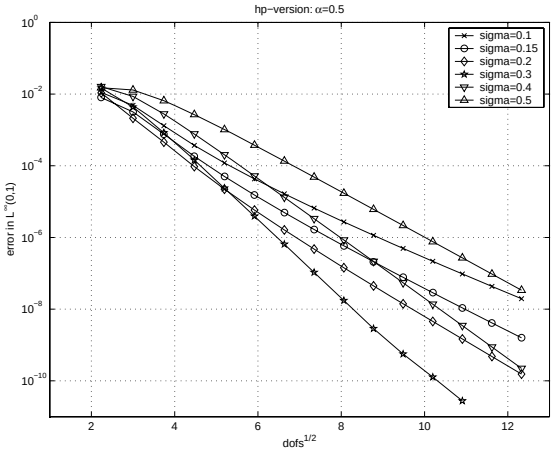

FIG. 5.5. *hp-version: solution with* $\alpha = 0.5$.

$(0, 1)$). We note that Corollary 3.9 ensures at least the order 0.5. However, rates of order 3 are observed in Table 5.3. This indicates that the estimate in Corollary 3.9 is slightly suboptimal in the polynomial degree, as remarked in the discussion after Corollary 3.9. In fact, we observe twice the rate that would correspond to the regularity exponent 1.5 of the exact solution. This doubling phenomena is well-known in p-version finite element methods for second-order boundary-value problems; see [17] and the references therein. In our context, a theoretical explanation of this observation remains an open problem.

Next, we consider the performance of the hp-version time-stepping method on the basic geometric partitions $\widehat{\mathcal{M}}_{n,\sigma} = \{I_m\}_{m=1}^{n+1}$ of $(0, 1)$ introduced in Definition 4.2. In addition, we use linearly increasing polynomial degrees as described in Definition 4.6: on time-step I_m we set $r_m = \lfloor \mu m \rfloor$ with a slope $\mu > 0$. In Figure 5.5, we display the errors against the square root of the number of degrees of freedom in the underlying discretization space, for $\mu = 1$ and various values of the grading factor σ. The straight curves indicate exponential convergence for each grading factor σ, as predicted by Theorem 4.7. It can further be seen that the grading $\sigma = 0.3$ gives the best results; for example, they are several orders of magnitude better than those for $\sigma = 0.5$. This is in contrast to the case of elliptic boundary-value problems, where the optimal

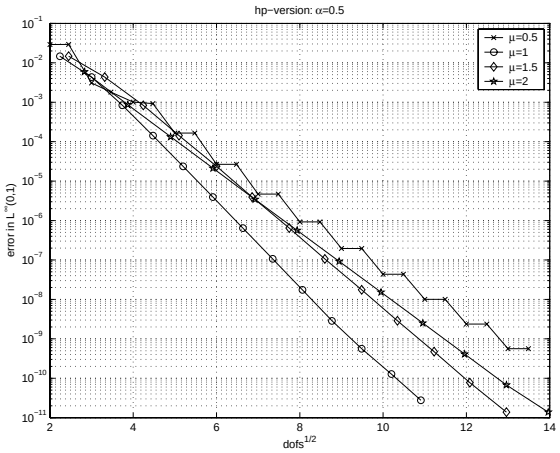

FIG. 5.6. *hp-version: solution with* $\alpha = 0.5$.

TABLE 5.4
h-version: solution with $\alpha = 0.99$.

dofs	error in $L^\infty(0,1)$

44	9.8316e-07

choice of the grading is known to be given by $\sigma \approx 0.15$, independently of the strength of the singularity; see [17] and the references therein. In Figure 5.6, we show the convergence curves for $\sigma = 0.3$ and several values of the slope parameter μ. The exponential convergence rates are less sensitive to variations in this parameter and good results are obtained for $\mu = 1$.

Finally, we test the performance of the *hp*-version DG method for the problem (5.1) with $\alpha = 0.99$. In view of the above discussions, we set $\sigma = 0.3$ and $\mu = 1$. In Table 5.4 it can be seen that with this particular choice, the *hp*-version gives an L^∞-error smaller than $1e-6$ with less than 44 degrees of freedom. To obtain the same error with the *h*-version approach on the meshes $\mathcal{M}_i$ from above and with $r = 2$, more than $10,000$ degrees of freedom are needed. This clearly underlines the suitability of *hp*-version approaches for the numerical approximation of the VIDE (1.1).

6. Concluding remarks. We conclude the paper by pointing out some extensions and future work.

In applications it often happens that at least one of the functions f_1 and f_2 in (4.2) is only *piecewise analytic* on $[0,T]$. According to the proof of Theorem 4.1 (cf. (4.4)) the corresponding solution u of (1.1) inherits this property: it is piecewise analytic on $[0,T]$, with its second derivative unbounded at $t = 0$. If the points in $[0,T]$ at which analyticity is lost are denoted by $\tau_1, \ldots, \tau_l$, it will be necessary to geometrically grade the time-steps individually near each point τ_i, $1 \le i \le l$, in order to obtain exponential convergence.

We mention in passing a related VIDE for which the above observation is relevant. Let (1.1) be replaced by

$$u'(t) + a(t)u(t) + \int_{t-\tau}^{t} k_\alpha(t-s)b(s)u(s)\,ds = f(t), \qquad t \in [0,T], \tag{6.1}$$
$$u(t) = \phi(t), \qquad t \le 0,$$

with delay $\tau > 0$. It is well known (see, e.g., [2, section 7.1]) that, regardless of the smoothness of the given functions, the solution u of (6.1) exhibits lower regularity at the so-called primary discontinuity points $\{\kappa\tau\}_{\kappa\in\mathbb{N}_0}$ induced by the delay τ. If ϕ, a, b, f_1, f_2 are analytic on $[0,T]$, then u will be analytic on each interval $(\kappa\tau,(\kappa+1)\tau]$ but only piecewise analytic on $[0,T]$.

As we mentioned in section 1, we shall study the exponential convergence of the *hp*-version of the DG method for time-stepping in a (spatially semidiscretized) parabolic *partial* VIDE (see [6]) in a forthcoming paper. Assume that such a partial VIDE has the form

$$u_t + Lu + \int_0^t k_\alpha(t-s)Bu(s)\,ds = f, \qquad t \in [0,T],\ x \in \Omega \subset \mathbb{R}^d, \tag{6.2}$$

where $-L$ denotes a strongly elliptic (spatial) partial differential operator and where B is given, for example, by $B = \Delta$ or by the scalar factor $b(s,x)$. If L_h $(= L_h(t))$ and B_h $(= B_h(s))$ denote discrete representations of L and B corresponding to a spatial discretization of (6.2) with respect to a mesh Ω_h of Ω, then (6.2) is approximated by a *system* of ordinary VIDEs analogous to (1.1) in which the roles of $a(t)$ and $b(s)$ are now assumed by the matrices $L_h(t)$ and $B_h(s)$. This suggests that our "scalar" convergence analysis can in principle be extended to these systems of VIDEs. The analysis hinges of course on appropriate regularity results for the solution of (6.2).

The situation becomes rather more difficult if we have $L = 0$ in (6.2) (see, e.g., [13]): we note that the convergence properties of the *hp*-DG method for (1.1) with $a(t) \equiv 0$ are not covered by our analysis and remain open.

Acknowledgments. The authors gratefully acknowledge the suggestion by one of the referees that led to a more general version of Theorem 4.7.

APPROXIMATION THEORY FOR THE p-VERSION OF THE FINITE ELEMENT METHOD IN THREE DIMENSIONS. PART 1: APPROXIMABILITIES OF SINGULAR FUNCTIONS IN THE FRAMEWORK OF THE JACOBI-WEIGHTED BESOV AND SOBOLEV SPACES*

BENQI GUO†

Dedicated to Professor Ivo Babuška on the occasion of his 80th birthday

Abstract. This paper is the first in a series devoted to the approximation theory of the p-version of the finite element method in three dimensions. In this paper, we introduce the Jacobi-weighted Besov and Sobolev spaces in a three-dimensional setting and analyze the approximability of functions in the framework of these spaces. In particular, the Jacobi-weighted Besov and Sobolev spaces with three different weights are defined to precisely characterize the natures of the vertex singularity, the edge singularity, and the vertex-edge singularity, and to explore their best approximabilities in terms of these spaces. In the forthcoming part 2, we will apply the approximabilities of these singular functions to prove the optimal convergence of the p-version of the finite element method for elliptic problems in polyhedral domains, where the singularities of three different types occur and substantially govern the convergence of the finite element solutions.

Key words. p-version, finite element method, Jacobi-weighted Besov and Sobolev spaces, Jacobi projection, vertex singularity, edge singularity, vertex-edge singularity

1. Introduction.

Since the late 1970s, the p-version of the finite element method (FEM), which increases the degree of polynomials on a fixed mesh to obtain higher accuracy, has been widely used in engineering computations. There are several commercial and research codes based on the p- and hp-versions of the finite element method, for example, MSC/PROBE (MacNeal Schwendler), Poly FEM (IBM), MECHANICA (Rasna Corp.), PHLEX (Computational Mechanics), STRESSCHECK (Engineering Software Research & Development), and STRIPE (Aeronautical Research Institute of Sweden).

In 1980 it was shown that the p-version of FEM in two dimensions converges at least as fast as the traditional h-version with quasi-uniform meshes, and that it converges twice as fast as the h-version of FEM if the solution has a singularity of r^γ-type. Since then significant progress for the p-version in one and two dimensions has been made in the past two decades. The estimation of the upper bound of the approximation error in finite element solutions of the p-version in two dimensions was analyzed in [5, 6], and a detailed analysis of the p-version in one dimension is

available in [10]. Very recently, the author and his collaborators further developed the approximation theory of the p-version of the FEM and the boundary element method (BEM) in the framework of the Jacobi-weighted Besov and Sobolev spaces [1, 2, 3, 4, 11, 12]. In this mathematical framework, the lower and upper bounds of approximation error in FEM solutions of the p-version and in BEM solutions of p- and hp-versions for problems in polygonal domains were proved, and the optimal rate of convergence was mathematically established. The spectral method in the framework of the Jacobi-weighted Sobolev spaces has been studied and was successfully applied to singular differential equations [8, 13, 14].

In contrast to the p-version in one and two dimensions, the p-version of FEM in three dimensions is much less developed due to the complexity of three-dimensional problems. Because of a lack of effective mathematical tools and theory to deal with the complexities of three-dimensional singularities in the 1980s and 1990s, only a few results and a little analysis are available in the literature. The upper bounds in approximation error of the p-version in three dimensions were discussed for problems with singularities as a conjecture in [9] without proof and were analyzed in [15] for problems with smooth solutions belonging to $H^k(\Omega), k > 2$.

In this series of papers, we shall precisely characterize singularities and analyze the approximation to singular functions as well as smooth functions in $H^k(\Omega), k > 1$, in the framework of the Jacobi-weighted Besov and Sobolev spaces, and we prove the optimal convergence of the p-version of FEM for problems on polyhedral domains. In the first paper of the series, we shall introduce the Jacobi-weighted Besov and Sobolev spaces in three dimensions and derive the approximation results for functions in these spaces; then we verify that singular functions of different types, which arise from problems in polyhedral domains, belong to the corresponding Jacobi-weighted Besov spaces and prove their approximability by high-order polynomials. Since the approximation to functions in the Jacobi-weighted Besov and Sobolev spaces in one and two dimensions can be generalized to three dimensions without substantial difficulty and the approximability of singular functions follows from the general approximation properties for functions in the Jacobi-weighted Besov spaces and verification of the singularities in appropriate Jacobi-weighted Besov spaces, the crucial part of the paper is to prove that these singular functions belong to different Jacobi-weighted Besov spaces which are precisely designed according to the nature of these singular functions. It is well known that there are singularities of three different types in solutions of problems with piecewise analytic data and on polyhedral domains which severely govern the convergence of the FEM solution, namely, vertex singularity, edge singularity, and vertex-edge singularity. Since the vertex-edge singularity occurs in two directions and is anisotropic, the characterization of the vertex-edge singularity in the Jacobi-weighted Besov spaces is very different from those for the two-dimensional setting [1, 2, 3, 4] and for the vertex singularity and the edge singularity, which reflects the major difficulty as well as significance of the paper. The main theorems of the paper are Theorems 5.2 and 5.3, i.e., $u(x) = \rho^\gamma \sin^\sigma \theta\, \chi(\rho)\, \Psi(\theta)\, \Phi(\phi) \in B^{s,\beta}_\kappa(Q)$ with $s = 2 + 2\min\{\sigma, \gamma + (1+\beta_3)/2\} + \beta_1 + \beta_2$, the Jacobi weight $\beta = (\beta_1, \beta_2, \beta_3)$ with $\beta_i > -1$ arbitrary, and

$$\kappa = \begin{cases} 0 & \text{if } \sigma \neq \gamma + (1+\beta_3)/2, \\ 1/2 & \text{if } \sigma = \gamma + (1+\beta_3)/2, \end{cases}$$

where $Q = (-1,1)^3$ and (ρ, θ, ϕ) are the spherical coordinates with respect to the vertex $(-1,-1,-1)$ and the vertical line $L = \{x = (x_1, x_2, x_3) \mid x_1 = x_2 = -1, x_3 \in$

$(-\infty,\infty)\}$, $\chi(\rho)$, $\Psi(\theta)$, and $\Phi(\phi)$ are the usual C^∞ cutoff functions. It follows immediately from the approximability of functions in the space $B^{s,\beta}_\kappa(Q)$ that

$$\|u-\psi\|_{L^2(Q)} \le Cp^{-(2+2\min\{\sigma,\gamma+1/2\})}(1+\log p)^\kappa$$

and

$$\|u-\varphi\|_{H^1(R_0)} \le Cp^{-2\min\{\sigma,\gamma+1/2\}}\ (1+\log p)^\kappa$$

with

$$\kappa = \begin{cases} 0 & \text{if } \sigma \ne \gamma+1/2, \\ 1/2 & \text{if } \sigma = \gamma+1/2, \end{cases}$$

where R_0 denotes a conic subregion of Q which is the support of u, and ψ and φ are the Jacobi projections of u on the space $\mathcal{P}_p(Q)$ of polynomials of degree $\le p$ associated with the Legendre weight $\beta=(0,0,0)$ and the Chebyshev–Legendre weight $\beta=(-1/2,-1/2,0)$, respectively. It is worth indicating that a logarithmic term appears in the error estimation if $\sigma=\gamma+1/2$, although the function has no logarithmic singularity. This unique feature in three dimensions is precisely explored by the Jacobi-weighted space $B^{s,\beta}_\kappa(Q)$, which is an interpolation space introduced by the modified K-method. The results of this paper and forthcoming ones will significantly improve the approximation theory of the p-version of FEM in three dimensions.

The scope of the paper is as follows. In section 2 we introduce the Jacobi-weighted Besov spaces $B^{s,\beta}_\nu(Q)$ and Sobolev spaces $H^{s,\beta}_\nu(Q)$ with $Q=(-1,1)^3$, $s>0$, and integer $\nu\ge 0$, and derive error estimation of the Jacobi projections in the Jacobi-weighted Sobolev norms. In section 3 we characterize the singularity and analyze the approximability for singular functions of $\rho^\gamma\log^\nu\rho$-type with $\gamma>0,\nu\ge 0$ in terms of the space $B^{s,\beta}_{\nu^*}(Q)$. The singularity and approximability of singular functions of $r^\sigma\log^\mu r$-type with $\sigma>0$ and $\mu\ge 0$ in terms of the space $B^{s,\beta}_{\mu^*}(Q)$ are analyzed in section 4. Section 5 focuses on the characterization of singularities and the best approximation in L^2- and H^1-norms for singular functions of the $\rho^\gamma\sin^\sigma\theta$-type and $\rho^\gamma\sin^\sigma\theta\,\log^\nu\rho\,\log^\mu\sin\theta$-type with $\gamma,\sigma>0$ and integers $\nu,\mu\ge 0$ in terms of the space $B^{s,\beta}_\kappa(Q)$. Some concluding remarks are given in the last section on the effectiveness of the Jacobi-weighted Sobolev and Besov spaces by comparing the error estimations of the h- and p-versions of FEM in terms of Besov and Sobolev spaces with and without the Jacobi weights.

2. Jacobi-weighted Besov and Sobolev spaces. Let $Q=I^3=(-1,1)^3$, and let $\alpha=(\alpha_1,\alpha_2,\alpha_3)$ and $\beta=(\beta_1,\beta_2,\beta_3)$ with integer $\alpha_i\ge 0$ and real number $\beta_i>-1, 1\le i\le 3$. We introduce a weight function

$$w_{\alpha,\beta}(x)=\prod_{i=1}^3 \left(1-x_i^2\right)^{\alpha_i+\beta_i}, \tag{2.1}$$

which is referred to as the Jacobi weight. Obviously, the Jacobi polynomials and their derivatives are orthogonal with the weight $w_{\alpha,\beta}(x)$.

The Jacobi-weighted Sobolev space $H^{k,\beta}(Q)$ with integer k is defined as a closure of C^∞ functions in the norm with the Jacobi weight

$$\|u\|^2_{H^{k,\beta}(Q)}=\sum_{|\alpha|=0}^k \int_Q |D^\alpha u|^2\ w_{\alpha,\beta}(x)\,dx, \tag{2.2}$$

where $D^\alpha u = u_{x_1^{\alpha_1} x_2^{\alpha_2}, x_3^{\alpha_3}}$ and $|\alpha| = \alpha_1 + \alpha_2 + \alpha_3$. By $|u|_{H^{k,\beta}(Q)}$ we denote the seminorm

$$|u|^2_{H^{k,\beta}(Q)} = \sum_{|\alpha|=k} \int_Q |D^\alpha u|^2 \, w_{\alpha,\beta}(x)\, dx.$$

Let $\mathcal{B}^{s,\beta}_{2,q}(Q)$ be the interpolation spaces defined by the K-method

$$(H^{\ell,\beta}(Q), H^{k,\beta}(Q))_{\theta,q},$$

where $0 < \theta < 1, 1 \le q \le \infty, s = (1-\theta)\ell + \theta k$, ℓ and k are integers, $\ell < k$, and

$$\|u\|_{\mathcal{B}^{s,\beta}_{2,q}(Q)} = \left(\int_0^\infty t^{-q\theta} \, |K(t,u)|^q \frac{dt}{t} \right)^{1/q}, \ 1 \le q < \infty, \tag{2.3a}$$

$$\|u\|_{\mathcal{B}^{s,\beta}_{2,\infty}(Q)} = \sup_{t>0} t^{-\theta} \, K(t,u), \tag{2.3b}$$

where

$$K(t,u) = \inf_{u=v+w} \left(\|v\|_{H^{\ell,\beta}(Q)} + t\|w\|_{H^{k,\beta}(Q)} \right). \tag{2.4}$$

In particular, we are interested in the cases $q = 2$ and $q = \infty$. We shall write for $s \ge 0$ and $q = 2$

$$H^{s,\beta}(Q) = \mathcal{B}^{s,\beta}_{2,2}(Q) = (H^{\ell,\beta}(Q), H^{k,\beta}(Q))_{\theta,2}$$

with $0 < \theta < 1$ and $s = (1-\theta)\ell + \theta k$. This space is called the Jacobi-weighted Sobolev space with fractional order if s is not an integer. It has been proved that $\mathcal{B}^{s,\beta}_{2,2}(Q) = H^{m,\beta}(Q)$ if s is an integer m in two dimensions [1]; it can be proved analogously in three dimensions.

For $q = \infty$, we shall write

$$B^{s,\beta}(Q) = \mathcal{B}^{s,\beta}_{2,\infty}(Q) = (H^{\ell,\beta}(Q), H^{k,\beta}(Q))_{\theta,\infty},$$

which is referred to as the Jacobi-weighted Besov space. It is an exact interpolation space of θ-exponent according to [7].

For the best approximation of the singular functions such as $\rho^\gamma \log^\nu \rho, \ \nu > 0$, we need to introduce an interpolation space

$$B^{s,\beta}_\nu(Q) = (H^{\ell,\beta}(Q), H^{k,\beta}(Q))_{\theta,\infty,\nu}$$

with integer $\nu > 0$ by a modified K-method,

$$\|u\|_{B^{s,\beta}_\nu(Q)} = \sup_{t>0} \frac{t^{-\theta} K(t,u)}{(1 + |\log t|)^\nu}. \tag{2.5}$$

Remark 2.1. The space $B^{s,\beta}_0(Q) = B^{s,\beta}(Q)$ is a standard exact interpolation space of θ-exponent; all important properties of exact interpolation spaces such as the reiteration theorem stand for $B^{s,\beta}(Q)$. It has been shown [1] that the space $B^{s,\beta}_\nu(Q)$ with $\nu > 0$ is a uniform interpolation space, but not an exact one. Hence many important properties of exact interpolation spaces do not hold for the space

$B_\nu^{s,\beta}(Q)$ with $\nu > 0$, for instance, the reiteration theorem. Fortunately a partial reiteration theorem was proved which guarantees

$$(H^{\ell,\beta}(Q), H^{k,\beta}(Q))_{\theta,\infty,\nu} = (H^{\ell',\beta}(Q), H^{k',\beta}(Q))_{\theta',\infty,\nu}$$

as long as $(1-\theta)\ell + \theta k = (1-\theta')\ell' + \theta' k' = s$. Hence the space $B_\nu^{s,\beta}(Q)$ is well defined and does not depend on the individual values of ℓ and k but only on their combination $(1-\theta)\ell + \theta k$.

For the definition and properties of exact interpolation spaces of exponent θ, we refer to [7]. For the partial reiteration theorem and various properties of uniform interpolation space $B_\nu^{s,\beta}(Q)$ with integer $\nu > 0$, we refer to [3].

Remark 2.2. For $\beta_1 = \beta_2 = \beta_3 = 0$, the spaces $B_\nu^{s,\beta}(Q)$ are referred to as the Legendre-weighted Besov spaces. They are referred to as the Chebyshev–Legendre-weighted Besov spaces for $\beta_1 = \beta_2 = -1/2, \beta_3 = 0$ and the Chebyshev-weighted Besov spaces for $\beta_1 = \beta_2 = -1/2, \beta_3 > -1$.

We next study the approximation properties for functions in the Jacobi-weighted Sobolev spaces. Let $\mathcal{P}_p(Q)$ be a set of all polynomials of (separate) degree $\le p$. For $u \in H^{k,\beta}(Q), k \ge 0$, we have the Jacobi–Fourier expansion in $H^{0,\beta}(Q)$:

$$u(x) = \sum_{i,j,k=0}^{\infty} C_{ijk}\, P_i(x_1,\beta_1)\, P_j(x_2,\beta_2)\, P_k(x_3,\beta_3),$$

where

$$P_n(x_i,\beta_i) = \frac{(1-x_i^2)^{-\beta}}{2^n\, n!}\, \frac{d^n\,(1-x_i^2)^{\beta+n}}{dx^n}$$

is the Jacobi polynomial of degree n in variable $x_i, 1 \le i \le 3$. Then

$$u_p(x) = \sum_{i,j,k=0}^{p} C_{ijk}\, P_i(x_1,\beta_1)\, P_j(x_2,\beta_2) P_k(x_3,\beta_3)$$

is the projection of $u(x)$ on $\mathcal{P}_p(Q)$.

PROPOSITION 2.1. *Let $u \in H^{k,\beta}(Q)$, and let $u_p(x)$ be the projection of $u(x)$ on $P_p(Q)$ in $H^{0,\beta}(Q)$. Then, $u_p(x)$ is the projection on $P_p(Q)$ in $H^{\ell,\beta}(Q)$ for all $0 \le \ell \le k$, and*

$$|u_p|^2_{H^{\ell,\beta}(Q)} + |u-u_p|^2_{H^{\ell,\beta}(Q)} = |u|^2_{H^{\ell,\beta}(Q)}.$$

Proof. The proposition was proved in [3] for two dimensions. The proof can be carried over easily for one and three dimensions. □

Due to Proposition 2.1, u_p is referred to as the Jacobi projection, for which we have the following approximation property.

THEOREM 2.2. *Let $u \in H^{k,\beta}(Q)$ with integer $k \ge 1$, $\beta_i > -1, 1 \le i \le 3$, and let u_p be its $H^{0,\beta}(Q)$-projection onto $\mathcal{P}_p(Q)$. Then we have for integer $\ell \le k \le p+1$*

$$|u-u_p|_{H^{\ell,\beta}(Q)} \le C\, p^{-(k-\ell)}\, |u|_{H^{k,\beta}(Q)}. \tag{2.6}$$

Proof. The proof for one and two dimensions can be carried here for three dimensions; we will not give the details of the proof, but instead refer to [1]. □

By a standard argument of interpolation spaces, we are able to generalize Theorem 2.2 to an approximation theorem for functions in the Jacobi-weighted Besov spaces $B^{s,\beta}(Q)$.

THEOREM 2.3. *Let $u \in B^{s,\beta}(Q)$, $s > 0$, with $\beta_i > -1, 1 \le i \le 3$, and let u_p be the Jacobi projection of u on $\mathcal{P}_p(Q)$ with $p > s-1$. Then for any real $\kappa \in [0, s)$ there holds*

$$\|u - u_p\|_{H^{\kappa,\beta}(Q)} \le C\, p^{-(s-\kappa)}\, \|u\|_{B^{s,\beta}(Q)} \tag{2.7}$$

with a constant C independent of p.

THEOREM 2.4. *Let $u \in B^{s,\beta}_{\nu}(Q)$, $s > 0, \nu > 0$, with $\beta_i > -1, 1 \le i \le 3$, and let u_p be the Jacobi projection of u on $\mathcal{P}_p(Q)$ with $p > s-1$. Then for any real $\kappa \in [0, s)$, there holds*

$$\|u - u_p\|_{H^{\kappa,\beta}(Q)} \le C\, p^{-(s-\kappa)}\, (1 + \log p)^{\nu} \|u\|_{B^{s,\beta}_{\nu}(Q)} \tag{2.8}$$

with a constant C independent of p.

The proof of Theorems 2.3 and 2.4 for integer κ can be found in [3], and the usual argument of interpolation spaces leads to the estimations for noninteger κ.

3. Approximability of vertex-singular functions. Let $Q = (-1, 1)^3$, and let (ρ, θ, ϕ) be the spherical coordinates with respect to the vertex $(-1, -1, -1)$ and the vertical line $L = \{x = (x_1, x_2, x_3) \mid x_1 = x_2 = -1, x_3 \in (-\infty, \infty)\}$ with $\rho = \{\sum_{i=1}^{3}(x_i + 1)^2\}^{1/2}$, $\theta = \arctan \frac{r}{x_3+1} = \arctan \frac{\{(x_1+1)^2+(x_2+1)^2\}^{1/2}}{x_3+1} \in (0, \pi/2)$, and $\phi = \arctan \frac{x_2+1}{x_1+1} \in (0, \pi/2)$. We now consider the singular functions with $\gamma > 0$,

$$u(x) = \rho^{\gamma}\, \chi(\rho)\, \Phi(\theta, \phi) \tag{3.1}$$

and

$$v(x) = \rho^{\gamma}\, \log^{\nu} \rho\, \chi(\rho)\, \Phi(\theta, \phi) \tag{3.2}$$

with integer $\nu \ge 0$, where $\chi(\rho)$ and $\Phi(\theta, \phi)$ are C^{∞} functions such that for $0 < \rho_0 < 1$

$$\chi(\rho) = 1 \quad \text{for } 0 < \rho < \rho_0/2, \quad \chi(\rho) = 0 \quad \text{for } \rho > \rho_0,$$

and

$$\Phi(\theta, \phi) = 0 \quad \text{for } (\theta, \phi) \notin S_{\kappa_0}.$$

Hereafter, S_{κ_0} denotes a subset of the intersection of the unit sphere and Q such that the angles between the radial $A_1 - x$ and the x_i-axis are larger than κ_0. For $0 < \kappa_0 < \pi/4$, let

$$R_0 = R_{\rho_0,\kappa_0}\{x \in Q \mid 0 < \rho < \rho_0, (\theta, \phi) \in S_{\kappa_0}\}$$

as shown in Figure 3.1. Then there hold for $x \in R_0$

$$\begin{gathered} (2 - \rho_0)(1 + x_i) \le \left(1 - x_i^2\right) \le 2(1 + x_i), \quad 1 \le i \le 3, \\ \kappa_1 \le \frac{1 + x_i}{1 + x_j} \le \kappa_2, \quad 1 \le i, j \le 3, \end{gathered} \tag{3.3}$$

where $\kappa_2 = \cot \kappa_0$ and $\kappa_1 = \tan \kappa_0$. The functions defined in (3.1) and (3.2) reflect a typical singularity, referred to as the vertex singularity, which occurs in the solutions

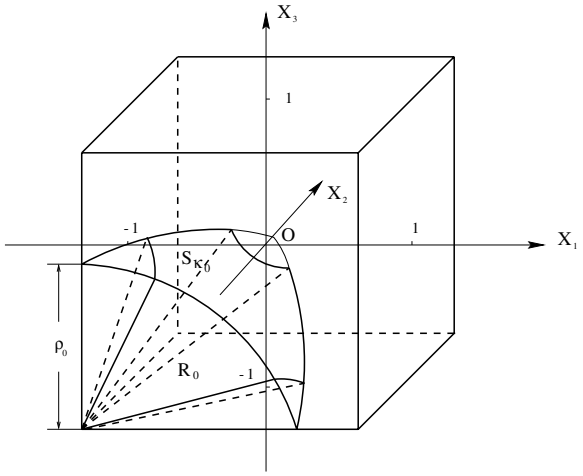

FIG. 3.1. *Cubic domain Q and subregion R_{ρ_0,κ_0}.*

of problems on polyhedral domains and severely affects the convergence of the finite element solution. Therefore, finding the best approximation to these singular functions is essential for the error estimates of the finite element solutions for problems with such singularities. It is worth indicating that the vertex singularity is isotropic, and hence the most appropriate Jacobi-weighted Besov and Sobolev spaces for their best approximation shall be isotropic as well.

3.1. Singular functions of ρ^γ-type.

THEOREM 3.1. *Let $u = \rho^\gamma \chi(\rho)\,\Phi(\theta,\phi)$ as given in* (3.1)*, and let $\beta = (\beta_1,\beta_2,\beta_3)$ with $\beta_i > -1, 1 \le i \le 3$, arbitrary. Then $u \in B^{s,\beta}(Q)$ and $u \in H^{s-\epsilon,\beta}(Q)$ with $s = 2\gamma + 3 + \sum_{i=1}^3 \beta_i$ and $\epsilon > 0$ arbitrary.*

Proof. Let $u_1 = \chi_\delta(\rho)\,u$ and $u_2 = (1-\chi_\delta(\rho))u$ with $\chi_\delta(\rho) = \chi(\frac{\rho}{\delta})$ for $\delta \in (0,\rho_0)$. Then $u = u_1 + u_2$, $u_1 \in H^{0,\beta}(Q)$ and $u_2 \in H^{k,\beta}(Q)$ for any $k > 2\gamma + 3 + \sum_{i=1}^3 \beta_i$. It is easy to see that

$$\|u_1\|^2_{H^{0,\beta}(Q)} \le C\delta^{2\gamma+3+\sum_{i=1}^3 \beta_i} \tag{3.4}$$

and

$$\|u_2\|^2_{H^{k,\beta}(Q)} \le C\delta^{2\gamma+3-k+\sum_{i=1}^3 \beta_i}. \tag{3.5}$$

Selecting $\delta = t^{\frac{2}{k}}$, we have for $t \in (0,1)$

$$\begin{aligned} K(t,u) &\le C\delta^{\gamma+(3+\sum_{i=1}^3 \beta_i)/2}(1 + t\delta^{-k/2}) \\ &\le C\delta^{\gamma+(3+\sum_{i=1}^3 \beta_i)/2} \le Ct^{\frac{2\gamma+3+\sum_{i=1}^3 \beta_i}{k}}, \end{aligned}$$

and for $t \ge 1$, it always holds that

$$K(t,u) \le C\|u\|_{H^{0,\beta}(Q)}.$$

Letting $\theta = \frac{2\gamma+3+\sum_{i=1}^3 \beta_i}{k}$, we have

$$\sup_{t>0} t^{-\theta}\,K(t,u) \le C,$$

which implies that $u \in (H^{0,\beta}(Q), H^{k,\beta}(Q))_{\theta,\infty} = B^{s,\beta}(Q)$ with $s = \theta k = 2\gamma + 3 + \sum_{i=1}^{3} \beta_i$.

If $\theta = \frac{2\gamma + 3 + \sum_{i=1}^{3} \beta_i - \epsilon}{k} = \frac{s-\epsilon}{k}$ with $\epsilon > 0$ arbitrary, then

$$\int_0^1 t^{-2\theta} |K(t,u)|^2 \frac{dt}{t} \le C \int_0^1 t^{-1+2\epsilon/k} dt \le C,$$

which implies that $u \in (H^{0,\beta}(Q), H^{k,\beta}(Q))_{\theta,2} = H^{s-\epsilon,\beta}(Q)$. ∎

The approximability of the singular function of ρ^γ-type is a consequence of Theorems 2.3 and 3.1.

THEOREM 3.2. *For $u = \rho^\gamma \chi(\rho) \Phi(\theta, \phi)$ given in (3.1), there exists $\psi \in \mathcal{P}_p(Q)$ with $p > 2 + 2\gamma$ such that*

$$\|u - \psi\|_{L^2(Q)} \le C p^{-(2\gamma+3)} \|u\|_{B^{2\gamma+3,\beta}(Q)} \tag{3.6}$$

with $\beta = (0,0,0)$. Also, there exists $\varphi \in \mathcal{P}_p(Q), p > 1 + 2\gamma$, such that

$$\|u - \varphi\|_{H^1(R_0)} \le C \|u - \varphi\|_{H^{1,\beta}(Q)} \le C p^{-(2\gamma+1)} \|u\|_{B^{2\gamma+2,\beta}(Q)} \tag{3.7}$$

with $\beta = (-1/3, -1/3, -1/3)$.

Proof. By Theorem 3.1 $u \in B^{s,\beta}(Q)$ with $s = 2\gamma + 3$ and $\beta = (0,0,0)$. Due to Theorem 2.2, the Jacobi projection ψ of u associated with the weight $\beta = (0,0,0)$ on $\mathcal{P}_p(Q)$ with $p > 2 + 2\gamma$ satisfies

$$\|u - \psi\|_{L^2(Q)} = \|u - \psi\|_{H^{0,\beta}(Q)} \le C\, p^{-(2\gamma+3)} \|u\|_{B^{2\gamma+3,\beta}(Q)}.$$

For $\beta = (-1/3, -1/3, -1/3)$, by Theorem 3.1, $u \in B^{s,\beta}(Q)$ with $s = 2\gamma + 2$. Owing to Theorem 2.3, it holds for the Jacobi projection φ of u associated with the weight $\beta = (-1/3, -1/3, -1/3)$ on $\mathcal{P}_p(Q)$ with $p > 1 + 2\gamma$ that

$$|u - \varphi|_{H^{\ell,\beta}(Q)} \le C\, p^{-(2\gamma+2-\ell)} \|u\|_{B^{2\gamma+2,\beta}(Q)}$$

for $\ell = 0, 1$. Note that

$$\|u - \varphi\|_{L^2(Q)} \le \|u - \varphi\|_{H^{0,\beta}(Q)} \le C p^{-(2\gamma+2)} \|u\|_{B^{2\gamma+2,\beta}(Q)}. \tag{3.8}$$

Due to (3.3), for α with $|\alpha| = 1$ and for $x \in R_0$, there exist two constants C_1 and C_2 such that

$$C_1 \le \prod_{1 \le i \le 3} \left(1 - x_i^2\right)^{\alpha_i - 1/3} \le C_2. \tag{3.9}$$

Then, we have

$$\begin{aligned} \int_{R_0} |D^\alpha (u - \varphi)|^2 \, dx &\le C \int_{R_0} |D^\alpha (u - \varphi)|^2 \prod_{1 \le i \le 3} (1 - x_i^2)^{\alpha_i - 1/3} \, dx \\ &\le C \int_Q |D^\alpha (u - \varphi)|^2 \prod_{1 \le i \le 3} (1 - x_i^2)^{\alpha_i - 1/3} \, dx \\ &\le C p^{-2(2\gamma+1)} \|u\|^2_{B^{2\gamma+2,\beta}(Q)}, \end{aligned}$$

which together with (3.8) leads to (3.7). ∎

3.2. Singular functions of $\rho^\gamma \log^\nu \rho$-type. It can be proved that the singular function $v(x) = \rho^\gamma \log^\nu \rho\, \chi(\rho)\, \Phi(\theta, \phi)$, given in (3.2), belongs to the space $B^{s-\epsilon,\beta}(Q)$ with $s = 2\gamma + 3 + \sum_{i=1}^3 \beta_i$ and $\epsilon > 0$ arbitrary. Consequently, the approximation error will lose a rate of $O(p^\epsilon)$. To avoid such a loss, the modified Jacobi-weighted Besov spaces will be the most appropriate spaces for the vertex-singular functions with logarithmic terms to describe the nature of singularity and to explore the best approximation.

THEOREM 3.3. *Let $v(x) = \rho^\gamma \log^\nu \rho\, \chi(\rho)\, \Phi(\theta, \phi)$ as given in (3.2), and let $\beta = (\beta_1, \beta_2, \beta_3)$ with $\beta_i > -1$, $1 \le i \le 3$, arbitrary. Then $v \in H^{s-\epsilon,\beta}(Q)$, and $v \in B^{s,\beta}_{\nu^*}(Q)$, with $s = 2\gamma + 3 + \sum_{i=1}^3 \beta_i$ and $\epsilon > 0$ arbitrary, and*

$$\nu^* = \begin{cases} \max\{\nu - 1, 0\} & \text{if } \gamma \text{ is an integer,} \\ \nu & \text{if } \gamma \text{ is not an integer.} \end{cases} \tag{3.10}$$

Proof. Let $v_1 = \chi_\delta(\rho)\, v$ and $v_2 = (1 - \chi_\delta(\rho))v$ with $\chi_\delta(\rho) = \chi(\frac{\rho}{\delta})$ for $\delta \in (0, \rho_0)$. Then $v = v_1 + v_2$, $v_1 \in H^{0,\beta}(Q)$ and $v_2 \in H^{k,\beta}(Q)$ for any $k > 2\gamma + 3 + \sum_{i=1}^3 \beta_i$. It is easy to see that

$$\|v_1\|^2_{H^{0,\beta}(Q)} \le C\delta^{2\gamma+3+\sum_{i=1}^3 \beta_i} |\log \delta|^{2\nu}$$

and

$$\|v_2\|^2_{H^{k,\beta}(Q)} \le C\delta^{2\gamma+3-k+\sum_{i=1}^3 \beta_i} |\log \delta|^{2\nu}.$$

Selecting $\delta = t^{\frac{2}{k}}$, we have for $t \in (0, 1)$

$$\begin{aligned} K(t, v) &\le C(\|v_1\|_{H^{0,\beta}(Q)} + t\|v_2\|_{H^{k,\beta}(Q)}) \\ &\le C\delta^{\gamma+(3+\sum_{i=1}^3 \beta_i)/2}(1 + t\delta^{-k/2})|\log \delta|^\nu \\ &\le C\delta^{\gamma+(3+\sum_{i=1}^3 \beta_i)/2}(1 + |\log t|)^\nu. \end{aligned}$$

For $t \ge 1$, there hold

$$K(t, v) \le C\|v\|_{H^{0,\beta}(Q)}$$

and

$$\sup_{t>1} \frac{t^{-\theta} K(t, v)}{(1 + |\log t|)^\nu} \le C\|v\|_{H^{0,\beta}(Q)}.$$

Letting $\theta = \frac{2\gamma + 3 + \sum_{i=1}^3 \beta_i}{k}$, we have

$$\sup_{0<t<1} \frac{t^{-\theta} K(t, v)}{(1 + |\log t|)^\nu} \le C,$$

which implies that $v \in (H^{0,\beta}(Q), H^{k,\beta}(Q))_{\theta,\infty,\nu} = B^{s,\beta}_\nu(Q)$ with $s = \theta k = 2\gamma + 3 + \sum_{i=1}^3 \beta_i$. Arguing similarly as in the proof of Theorem 3.1, and selecting $\theta = \frac{2\gamma + 3 + \sum_{i=1}^3 \beta_i - \epsilon}{k} = \frac{s-\epsilon}{k}$ with $\epsilon > 0$ arbitrary, we have

$$\int_0^1 t^{-2\theta} |K(t, u)|^2 \frac{dt}{t} \le C \int_0^1 t^{-1+2\epsilon/k} (1 + |\log t|)^\nu dt \le C,$$

which implies $u \in (H^{0,\beta}(Q), H^{k,\beta}(Q))_{\theta,2} = H^{s-\epsilon,\beta}(Q)$.

If γ is an integer and the integer $\nu \geq 1$, we adopt a different decomposition of $v = v_1 + v_2$ for $\delta \in (0,1)$, namely,

$$v_1 = \rho^\gamma \left(\log^\nu \rho - \log^\nu(\rho+\delta)\right) \chi(\rho)\, \Phi(\theta,\phi)$$

and

$$v_2 = \rho^\gamma \log^\nu(\rho+\delta)\chi(\rho)\, \Phi(\theta,\phi).$$

Then $v_1 \in H^{0,\beta}(Q)$ and $v_2 \in H^{k,\beta}(Q)$ for any $k > 2\gamma + 3 + \sum_{i=1}^3 \beta_i$. Using the arguments in [1, Theorem 3.9], we have

$$\|v_1\|^2_{H^{0,\beta}(Q)} \leq C\delta^{2\gamma+3+\sum_{i=1}^3 \beta_i}\, |\log\delta|^{2(\nu-1)} \tag{3.11}$$

and

$$\|v_2\|^2_{H^{k,\beta}(Q)} \leq C\delta^{2\gamma-k+3+\sum_{i=1}^3 \beta_i}\, |\log\delta|^{2(\nu-1)}. \tag{3.12}$$

Inequalities (3.11) and (3.12) lead to

$$\begin{aligned} K(t,v) &\leq C\delta^{\gamma+(3+\sum_{i=1}^3 \beta_i)/2}(1+t\delta^{-k/2})|\log\delta|^{\nu-1} \\ &\leq C\delta^{\gamma+(3+\sum_{i=1}^3 \beta_i)/2}|\log\delta|^{\nu-1} \end{aligned}$$

and

$$\sup_{0<t<1} \frac{t^{-\theta}K(t,v)}{(1+|\log t|)^{\nu-1}} \leq C$$

with $\delta = t^{\frac{2}{k}}$ and $\theta = \frac{2\gamma+3+\sum_{i=1}^3 \beta_i}{k}$. This implies that $v \in B^{s,\beta}_{\nu-1}(Q)$ with $s = 2\gamma+3+\sum_{i=1}^3 \beta_i$. □

The precise characterization of singularity for the singular function of $\rho^\gamma \log^\nu \rho$-type given by Theorem 3.3 leads to the best approximation to the singular function of this type. The following theorem is a consequence of Theorems 2.4 and 3.3.

THEOREM 3.4. *For $v = \rho^\gamma \log^\nu \rho\, \chi(\rho)\, \Phi(\theta,\phi)$ as given in* (3.2)*, there exists $\psi(x) \in \mathcal{P}_p(Q)$ with $p > 2 + 2\gamma$ such that*

$$\|v-\psi\|_{L^2(Q)} \leq Cp^{-(2\gamma+3)}\, (1+\log p)^{\nu^*}\, \|u\|_{B^{2\gamma+3,\beta}_{\nu^*}(Q)} \tag{3.13}$$

with $\beta = (0,0,0)$. Also, there exists $\varphi(x) \in \mathcal{P}_p(Q)$ with $p > 1 + 2\gamma$ such that

$$\|u-\varphi\|_{H^1(R_0)} \leq Cp^{-(2\gamma+2)}\, (1+\log p)^{\nu^*}\, \|u\|_{B^{2\gamma+2,\beta}_{\nu^*}(Q)} \tag{3.14}$$

with $\beta = (-1/3,-1/3,-1/3)$. In both (3.13) *and* (3.14) *ν^* is given in* (3.10)*.*

Proof. By Theorem 3.3 $v \in B^{s,\beta}_{\nu^*}(Q)$ with $s = 2\gamma+3$ and $\beta = (0,0,0)$. Due to Theorem 2.2, the Jacobi projection ψ of u on $\mathcal{P}_p(Q)$ with $p > 2+2\gamma$ associated with the weight $\beta = (0,0,0)$ satisfies

$$\|u-\psi\|_{L^2(Q)} = \|u-\psi\|_{H^{0,\beta}(Q)} \leq C\, p^{-(2\gamma+3)}\, (1+\log p)^{\nu^*}\, \|u\|_{B^{2\gamma+3,\beta}_{\nu^*}(Q)}.$$

For $\beta = (-1/3, -1/3, -1/3)$, by Theorem 3.1, $v \in B^{s,\beta}_{\nu^*}(Q)$ with $s = 2 + 2\gamma$. Owing to Theorem 2.4, there holds for the Jacobi projection φ of u on $\mathcal{P}_p(Q)$ with $p > 1 + 2\gamma$ associated with the weight $\beta = (-1/3, -1/3, -1/3)$

$$|u - \varphi|_{H^{\ell,\beta}(Q)} \le C\, p^{-(2\gamma+2-\ell)}\, (1 + \log p)^{\nu^*}\, \|u\|_{B^{2\gamma+2,\beta}_{\nu^*}(Q)} \tag{3.15}$$

for $\ell = 0, 1$. Due to (3.9) and Theorem 2.4, we have for $|\alpha| = 1$

$$\begin{aligned}\int_{R_0} |D^\alpha(u-\varphi)|^2\, dx &\le C \int_Q |D^\alpha(u-\varphi)|^2 \prod_{1\le i\le 3} (1 - x_i^2)^{\alpha_i - 1/3} dx \\ &\le C p^{-2(2\gamma+2)}\, (1 + \log p)^{2\nu^*}\, \|u\|^2_{B^{2\gamma+2,\beta}_{\nu^*}(Q)},\end{aligned}$$

which together with (3.15) leads to (3.14). ∎

4. Approximability of edge-singular functions. Let $Q = (-1, 1)^3$, and let (r, ϕ, x_3) be the cylindrical coordinates with respect to the vertex (−1,−1,−1) and the vertical line $L = \{x = (x_1, x_2, x_3) \mid x_1 = x_2 = -1, x_3 \in (-\infty, \infty)\}$. Let $r = \{\sum_{i=1}^2 (x_i + 1)^2\}^{1/2}$, and let $\phi = \arctan \frac{x_2+1}{x_1+1} \in (0, \pi/2)$.

We consider the singular function with $\sigma > 0$:

$$u(x) = r^\sigma\, \chi(r)\, \Phi(\phi)\, \Psi(x_3) \tag{4.1}$$

and

$$v(x) = r^\sigma\, \log^\mu r \chi(r)\, \Phi(\phi)\, \Psi(x_3). \tag{4.2}$$

Here $\chi(r), \Psi(x_3)$, and $\Phi(\phi)$ are C^∞ functions such that for $0 < r_0 < 1$

$$\chi(r) = 1 \quad \text{for } 0 < r < r_0/2, \quad \chi(r) = 0 \quad \text{for } r > r_0,$$

and for $0 < \phi_0 < \pi/4$

$$\Phi(\phi) = 0 \quad \text{for } \phi \notin (\phi_0, \pi/2 - \phi_0),$$

and for $0 < z_0 < 1/2$

$$\Psi(x_3) = 1 \quad \text{for } x_3 \in (-1 + 2z_0, 1 - 2z_0), \quad \Psi(x_3) = 0 \quad \text{for } |x_3| \ge 1 - z_0.$$

Obviously, $u(x)$ and $v(x)$ have a support $R_{r_0,z_0} = \{x \in Q \mid 0 < r < r_0, |x_3| \le 1 - z_0\} \subset Q$. For $0 < \phi_0 < \pi/4$, let

$$R_0 = R_{r_0,\phi_0,z_0} = \{x \in Q \mid 0 < r < r_0, \phi_0 \le \phi \le \pi/2 - \phi_0, |x_3| \le 1 - z_0\},$$

as shown in Figure 4.1. Then there hold for $x \in R_0$

$$\begin{aligned} z_0(2 - z_0) &\le \left(1 - x_3^2\right) \le 1, \\ (2 - \rho_0)(1 + x_i) &\le \left(1 - x_i^2\right) \le 2(1 + x_i), \quad 1 \le i \le 2, \\ \tan\phi_0 &\le \frac{1 + x_2}{1 + x_1} \le \cot\phi_0. \end{aligned} \tag{4.3}$$

The singular functions given in (4.1) and (4.2) reflect another typical singularity in the solutions of problems in polyhedral domains and are referred to as the edge singularity. The characterization of edge singularity in appropriate functional spaces is critical to its approximability and the convergence of the finite element solutions. Although the characterization and approximability of singular functions of $r^\sigma\ \log^\mu r$-type in $Q = (-1, 1)^3$ are similar to those of vertex singular functions of $r^\gamma\ \log^\mu r$-type in two dimensions, it is worth pointing out that the edge singularity in three dimensions is anisotropic and the vertex singularity in two dimensions is isotropic.

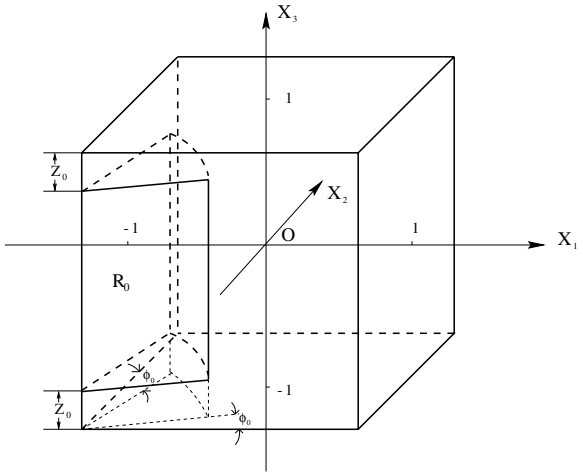

FIG. 4.1. *Cubic domain Q and subregion R_{r_0,ϕ_0,z_0}.*

4.1. Singular functions of r^σ-type.

THEOREM 4.1. *Let $u(x) = r^\sigma\,\chi(r)\,\Phi(\phi)\,\Psi(x_3)$ as given in* (4.1)*, and let $\beta = (\beta_1,\beta_2,\beta_3)$ with $\beta_i > -1$, $1 \le i \le 3$. Then $u \in B^{s,\beta}(Q)$ and $u \in H^{s-\epsilon,\beta}(Q)$ with $s = 2\sigma + 2 + \beta_1 + \beta_2$ and $\epsilon > 0$ arbitrary.*

Proof. Since u is smooth in the variable x_3 and has a support R_{r_0,z_0} in which (4.3) holds and the factor $(1-x_3^2)^{\alpha_3+\beta_3}$ is bounded from above and below, the arguments for the vertex singular functions in two dimensions can be carried over here with a minor modification. We will not repeat these here; see [1, Theorem 2.5] for details of the proof. □

Theorems 4.1 and 2.3 lead to the best approximation of the singular function u.

THEOREM 4.2. *For $u(x) = r^\sigma\,\chi(r)\,\Phi(\phi)\,\Psi(x_3)$ as given in* (4.1)*, there exists $\psi(x) \in \mathcal{P}_p(Q)$ with $p > 1 + 2\sigma$ such that*

$$\|u-\psi\|_{L^2(Q)} \le Cp^{-2(\sigma+1)}\,\|u\|_{B^{2\sigma+2,\beta}(Q)} \tag{4.4}$$

with $\beta_1 = \beta_2 = 0$ and $\beta_3 > -1$ arbitrary. Also, there exists $\varphi(x) \in \mathcal{P}_p(Q)$ with $p > 2\sigma$ such that

$$\|u-\varphi\|_{H^1(R_0)} \le C\|u-\varphi\|_{H^{1,\beta}(Q)} \le Cp^{-2\sigma}\,\|u\|_{B^{1+2\sigma,\beta}(Q)} \tag{4.5}$$

with $\beta_1 = \beta_2 = -1/2$ and $\beta_3 > -1$ arbitrary.

Proof. Due to Theorem 4.1, $u \in B^{2+2\sigma,\beta}(Q)$ with $\beta_1 = \beta_2 = 0$ and $\beta_3 > -1$ arbitrary. By Theorem 2.3, the Jacobi projection ψ of u associated with the weight $\beta = (-1/2,-1/2,\beta_3)$ on $\mathcal{P}_p(Q)$ with $p > 1 + 2\sigma$ satisfies (4.4).

For $\beta_1 = \beta_2 = -1/2$ and $\beta_3 > -1$ arbitrary, $u \in B^{1+2\sigma,\beta}(Q)$. By Theorem 2.4 the Jacobi projection φ of u associated with the weight $\beta = (-1/2,-1/2,\beta_3)$ on $\mathcal{P}_p(Q)$ with $p > 2\sigma$ satisfies

$$\|u-\varphi\|_{H^{\ell,\beta}(Q)} \le Cp^{-2\sigma-1+\ell}\,\|u\|_{B^{1+2\sigma,\beta}(Q)}$$

with $\ell = 0, 1$, which gives

$$p\|u-\varphi\|_{L^2(Q)} + \left\|\frac{\partial(u-\varphi)}{\partial x_3}\right\|_{L^2(Q)} \le Cp^{-2\sigma}\,\|u\|_{B^{1+2\sigma,\beta}(Q)}. \tag{4.6}$$

Due to (4.3), there holds for α with $\sum_{i=1}^{2}\alpha_i = 1$ and for $x \in R_0$, and there exist two constants C_1 and C_2 such that

$$C_1 \le (1-x_3^2)^{\alpha_i+\beta_3} \prod_{1\le i\le 2} (1-x_i^2)^{\alpha_i-1/2} \le C_2,$$

which implies for $|\alpha| = 1$ with $\alpha_3 = 0$

$$\|D^\alpha(u-\varphi)\|_{L^2(R_0)} \le C\|u-\varphi\|_{H^{1,\beta}(Q)} \le Cp^{-2\sigma}\ \|u\|_{B^{1+2\sigma,\beta}(Q)}.$$

This together with (4.6) leads to (4.5). ∎

4.2. Singular functions of $r^\sigma \log^\mu r$-type. For singularity with logarithmic terms we need to use the modified Jacobi-weighted Besov spaces for the best approximation.

THEOREM 4.3. *Let $v(x) = r^\sigma \log^\mu r\ \chi(r)\ \Phi(\phi)\ \Psi(x_3)$ as given in (4.2), and let $\beta = (\beta_1,\beta_2,\beta_3)$ with $\beta_i > -1$, $1 \le i \le 3$. Then $v \in B^{s,\beta}_{\mu^*}(Q)$, and $v \in H^{s-\epsilon,\beta}(Q)$ with $s = 2\sigma + 2 + \beta_1 + \beta_2$ and $\epsilon > 0$ arbitrary and*

$$\mu^* = \begin{cases} \max\{\mu-1, 0\} & \text{if } \gamma \text{ is an integer,} \\ \mu & \text{if } \gamma \text{ is not an integer.} \end{cases} \tag{4.7}$$

Proof. For the same reason mentioned in the proof of Theorem 4.1, the arguments for the vertex singular functions with the logarithmic term in two dimensions can be carried over here; we refer to [1, Theorem 3.8] for noninteger σ and [1, Theorem 3.9] for integer σ. ∎

Theorem 4.3 gives a precise characterization of the singular function of $r^\gamma \log^\mu r$-type, which avoids a loss of $O(p^\epsilon)$ in the approximation error.

THEOREM 4.4. *For $v(x) = r^\sigma \log^\mu r\ \chi(r)\,\Phi(\phi)\,\Psi(x_3)$ as given in (4.2), there exists $\psi(x) \in \mathcal{P}_p(Q), p > 1 + 2\sigma$, such that*

$$\|v-\psi\|_{L^2(Q)} \le Cp^{-(2\sigma+2)}(1+\log p)^{\mu*}\ \|v\|_{B^{2\sigma+2,\beta}_{\mu^*}(Q)} \tag{4.8}$$

with $\beta_1 = \beta_2 = 0$ and $\beta_3 > -1$ arbitrary. Also, there exists $\varphi(x) \in \mathcal{P}_p(Q), p > 2\sigma$, such that

$$\|v-\varphi\|_{H^1(R_0)} \le C\|v-\varphi\|_{H^{1,\beta}(Q)} \le Cp^{-2\sigma}(1+\log p)^{\mu^*}\ \|v\|_{B^{1+2\sigma,\beta}_{\mu^*}(Q)} \tag{4.9}$$

with $\beta_1 = \beta_2 = -1/2$ and $\beta_3 > -1$ arbitrary. In both (4.8) and (4.9) μ^* is given in (4.7).

Proof. The approximability of the singular function v is the consequence of Theorems 2.4 and 4.3. We will not elaborate details of the proof, which are similar to those of Theorems 3.4 and 4.2. ∎

5. Approximability of vertex-edge singular functions. Let $Q = (-1,1)^3$, and let (ρ,θ,ϕ) be the spherical coordinates with respect to the vertex $(-1,-1,-1)$ and the vertical line $L = \{x = (x_1,x_2,x_3) \mid x_1 = x_2 = -1, x_3 \in (-\infty,\infty)\}$ as in section 3.

We now consider the singular functions with real $\gamma,\sigma > 0$ and integers $\nu,\mu \ge 0$,

$$u(x) = \rho^\gamma\ \sin^\sigma\theta\,\chi(\rho)\,\Psi(\theta)\,\Phi(\phi) \tag{5.1}$$

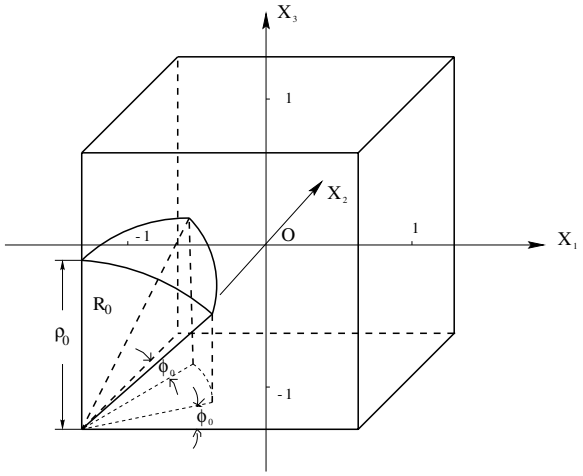

FIG. 5.1. *Cubic domain Q and subregion $R_{\rho_0,\phi_0,\theta_0}$.*

and

$$v(x) = \rho^{\gamma}\, \log^{\nu} \rho\, \sin^{\sigma} \theta\, \log^{\mu} \sin\theta\, \chi(\rho)\, \Psi(\theta)\, \Phi(\phi), \tag{5.2}$$

where $\rho = \{(x_1+1)^2+(x_2+1)^2+(x_3+1)^2\}^{1/2}$, $\chi(\rho)$ and $\Phi(\phi)$ are C^∞ cutoff functions defined in sections 3 and 4 with $0 < \rho_0 < 1$, respectively, and $\Psi(\theta)$ is a C^∞ function such that for $\theta_0 \in (0, \pi/2)$

$$\Psi(\theta) = 1 \quad \text{for } 0 \le \theta \le \theta_0/2, \quad \Psi(\theta) = 0 \quad \text{for } \theta \ge \theta_0.$$

For $0 < \phi_0 < \pi/4$, let

$$R_0 = R_{\rho_0,\theta_0,\phi_0} = \{x \in Q \mid 0 < \rho < \rho_0, \theta \in (0, \theta_0), \phi \in (\phi_0, \pi/2 - \phi_0)\}$$

as shown in Figure 5.1. Then there hold for $x \in R_0$

$$\begin{aligned} (2-\rho_0)(1+x_i) \le (1-x_i^2) &\le 2(1+x_i), \quad 1 \le i \le 3, \\ \frac{1+x_3}{1+x_i} &\ge \cot\theta_0, \quad 1 \le i \le 2, \\ \tan\phi_0 \le \frac{1+x_2}{1+x_1} &\le \cot\phi_0. \end{aligned} \tag{5.3}$$

Obviously, u has a support $R_{\rho_0,\theta_0,\phi_0} = \{x \in Q \mid 0 < \rho < \rho_0, \theta \in (0, \theta_0)\} \subset Q$.

The singularity of the functions given in (5.1) and (5.2) is the well-known vertex-edge singularity for problems on polyhedral domains, which reflect the major difficulties in characterization of the singularity and analysis of the approximability. They combine the vertex and edge singularities and are anisotropic. The combination of two types of singularities makes the analysis totally different from those in a two-dimensional setting and from those in the previous two sections for the vertex-singularity and the edge-singularity in three dimensions. Designing the Jacobi-weighted Besov spaces and proving the regularities in these spaces for the best approximation are extremely difficult and elegant.

5.1. Singular functions of $\rho^\gamma \sin^\sigma \phi$-type.

LEMMA 5.1. *Let $u(x) = \rho^\gamma \sin^\sigma \theta\, \chi(\rho)\, \Psi(\theta)\, \Phi(\phi)$ as given in (5.1). Then $u \in H^{s,\beta}(Q)$ with $\beta_i > -1$, $1 \le i \le 3$, for $s < 2 + 2\min\{\gamma + (1+\beta_3)/2, \sigma\} + \beta_1 + \beta_2$.*

Proof. Note that

$$|D^\alpha u| \le C\rho^{\gamma - |\alpha|} |\sin\theta|^{\sigma - \alpha_1 - \alpha_2}, \tag{5.4}$$

which implies that for $|\alpha| < 2 + 2\min\{\gamma + (1+\beta_3)/2, \sigma\} + \beta_1 + \beta_2$

$$\int_Q |D^\alpha u|^2 \prod_{i=1}^3 \left(1 - x_i^2\right)^{\alpha_i + \beta_i} dx \le C \int_{R_0} \rho^{2\gamma - |\alpha| + 2 + \sum_{i=1}^3 \beta_1} |\sin\theta|^{2\sigma - \alpha_1 - \alpha_2 + 1 + \sum_{i=1}^2 \beta_i} d\rho\, d\theta\, d\phi < \infty.$$

This proves the lemma for integer $s = k$. By a typical argument of interpolation spaces we are able to prove the lemma for noninteger s in general. ∎

THEOREM 5.2. *Let $u(x) = \rho^\gamma \sin^\sigma \theta\, \chi(\rho)\, \Psi(\theta)\, \Phi(\phi)$ as given in (5.1), and let $\beta = (\beta_1, \beta_2, \beta_3)$ with $\beta_i > -1, 1 \le i \le 3$. Then $u \in H^{s-\epsilon,\beta}(Q)$ and $u \in B_\kappa^{s,\beta}(Q)$ with $s = 2 + 2\min\{\sigma, \gamma + (1+\beta_3)/2\} + \beta_1 + \beta_2$, $\epsilon > 0$ arbitrary, and*

$$\kappa = \begin{cases} 0 & \text{if } \sigma \ne \gamma + (1+\beta_3)/2, \\ 1/2 & \text{if } \sigma = \gamma + (1+\beta_3)/2. \end{cases} \tag{5.5}$$

Proof. Since $r = \rho \sin\theta = \{(1+x_1)^2 + (1+x_2)^2\}^{1/2}$, we write

$$u(x) = \rho^{\gamma - \sigma}\, r^\sigma\, \chi(\rho)\, \Phi(\phi)\, \Psi(\theta),$$

and estimate (5.4) can be written as

$$|D^\alpha u(x)| \le C\rho^{\gamma - |\alpha|} |\sin\theta|^{\sigma - \alpha_1 - \alpha_2} \le C(1 + x_3)^{\gamma - \sigma - \alpha_3}\, r^{\sigma - \alpha_1 - \alpha_2}. \tag{5.6}$$

By $\varphi_\delta(r)$ we denote a C^∞ function such that $\varphi_\delta(r) = 1$ for $r < \delta$ and $\varphi_\delta(r) = 0$ for $r > 2\delta$ with $0 < \delta < \rho_0/2$. Let $u_1 = \varphi_\delta(r)u$ and $u_2 = (1 - \varphi_\delta(r))u$. Then $u_1 \in H^{0,\beta}(Q)$ due to Lemma 5.1, and $u_2 \in H^{k,\beta}(Q)$ for any $k > 2 + 2\max\{\gamma + (1+\beta_3)/2, \sigma\} + \beta_1 + \beta_2$.

Let R_{ρ_0,θ_0} be the projection of $R_{\rho_0,\theta_0,\phi_0}$ on the r-x_3 plane,

$$R_{\rho_0,\theta_0} = \{(r, x_3) \mid r\cot\theta_0 \le (1 + x_3) \le (\rho_0^2 - r^2)^{1/2}, 0 \le r \le \rho_0 \sin\theta_0\},$$

and by T_1 and T_2 we denote the triangular and rectangular regions in the r-x_3 plane, respectively,

$$T_1 = \{(r, x_3) \mid\ r\cot\theta_0 \le 1 + x_3 \le 2\delta\cot\theta_0, 0 \le r \le 2\delta\}$$

and

$$T_2 = \{(r, x_3) \mid\ 2\delta\cot\theta_0 \le 1 + x_3 \le \rho_0, 0 \le r \le 2\delta\}$$

as shown in Figure 5.2. Obviously, Supp.$u_1 \subset T_1 \cup T_2$.

Due to (5.6) there holds

$$\begin{aligned} \|u_1\|^2_{H^{0,\beta}(Q)} &= \int_{R_{\rho_0,\theta_0,\phi_0,}} |\varphi_\delta u|^2 \rho^{\sum_{i=1}^3 \beta_i} |\sin\theta|^{\beta_1 + \beta_2}\, dx \\ &\le C \int_{T_1 \cup T_2} (1 + x_3)^{2(\gamma - \sigma) + \beta_3}\, r^{2\sigma + 1 + \beta_1 + \beta_2}\, dr\, dx_3. \end{aligned} \tag{5.7}$$

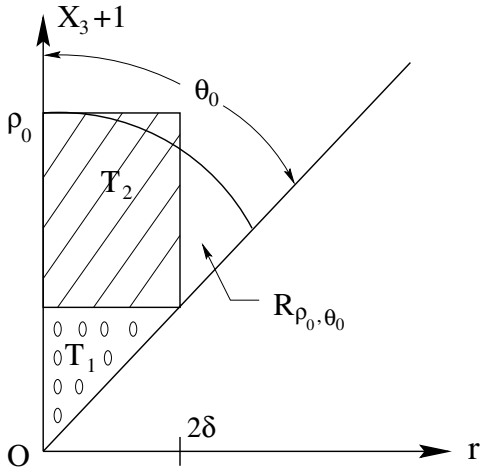

FIG. 5.2. *Regions T_1, T_2, and R_{ρ_0,θ_0}.*

Letting $\tilde{x}_3 = x_3 + 1$, we have by a simple calculation

$$\begin{aligned}
&\int_{T_1} (1+x_3)^{2(\gamma-\sigma)+\beta_3}\, r^{2\sigma+1+\beta_1+\beta_2} dr dx_3 \\
&\le C \int_0^{2\delta\cot\theta_0} \tilde{x}_3^{2(\gamma-\sigma)+\beta_3}\, d\tilde{x}_3 \int_0^{\tilde{x}_3 tan\theta_0} r^{2\sigma+1+\sum_{i=1}^2 \beta_i} dr \\
&\le C\delta^{2\gamma+\sum_{i=1}^3 \beta_i+3}.
\end{aligned} \tag{5.8}$$

We also have for $\sigma \neq \gamma + (1+\beta_3)/2$

$$\begin{aligned}
&\int_{T_2} (1+x_3)^{2(\gamma-\sigma)+\beta_3}\, r^{2\sigma+1+\beta_1+\beta_2}\, dr\, dx_3 \\
&\le C \int_0^{2\delta} r^{2\sigma+1+\beta_1+\beta_2}\, dr \int_{2\delta\cot\theta_0}^{\rho_0} \tilde{x}_3^{2(\gamma-\sigma)+\beta_3}\, d\tilde{x}_3 \\
&\le C(\delta^{2\gamma+3+\sum_{i=1}^3 \beta_i} + \delta^{2\sigma+2+\beta_1+\beta_2}),
\end{aligned} \tag{5.9}$$

and for $\sigma = \gamma + (1+\beta_3)/2$

$$\begin{aligned}
&\int_{T_2} (1+x_3)^{2(\gamma-\sigma)+\beta_3}\, r^{2\sigma+1+\beta_1+\beta_2}\, dr\, dx_3 \\
&\le C \int_0^{2\delta} r^{2\sigma+1+\beta_1+\beta_2} dr \int_{2\delta\cot\theta_0-1}^{\rho_0-1} (1+x_3)^{2(\gamma-\sigma)+\beta_3}\, dx_3 \\
&\le C(1+|\log\delta|)\delta^{2\sigma+2+\beta_1+\beta_2},
\end{aligned} \tag{5.10}$$

which together with (5.7)–(5.10) yields

$$\|u_1\|^2_{H^{0,\beta}(Q)} \le C(1+|\log\delta|)^{2\kappa}\delta^{2+2\min\{\gamma+(1+\beta_3)/2,\sigma\}+\beta_1+\beta_2} \tag{5.11}$$

with κ given in (5.5).

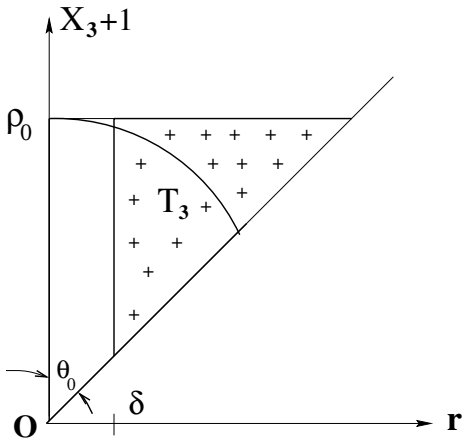

FIG. 5.3. *Region T_3.*

We next estimate $\|u_2\|_{H^{k,\beta}(Q)}$. Note that

$$\frac{\partial^k u_2}{\partial x_1^k} = (1-\varphi_\delta)\frac{\partial^k u}{\partial x_1^k} - \sum_{l=0}^{k-1}\binom{k}{l}\frac{\partial^l u}{\partial x_1^l}\frac{\partial^{k-l}\varphi_\delta}{\partial x_1^{k-l}},$$

and for $0 \le l \le k$

$$\left|\frac{\partial^{k-l}\varphi_\delta}{\partial x_1^{k-l}}\right| \le C\delta^{-(k-l)}.$$

Let

$$T_3 = \{(r, x_3) \mid\ r\cot\theta_0 \le 1 + x_3 \le \rho_0, \delta \le r \le \rho_0 \tan\theta_0\}$$

as shown in Figure 5.3. Obviously, Supp.$(1-\varphi_\delta)\frac{\partial^k u}{\partial x_1^k}$ and Supp.$\frac{\partial^{k-l}\varphi_\delta}{\partial x_1^{k-l}}$ are contained in T_3 for $0 \le l < k$. It is seen that

$$\begin{aligned}
&\int_Q \left|\frac{\partial^k u_2}{\partial x_1^k}\right|^2 (1-x_1^2)^{k+\beta_1}\prod_{i=2}^{3}(1-x_i^2)^{\beta_i}dx \\
&\le C\int_{R_0}\left(\left|\frac{\partial^k u}{\partial x_1^k}\right|^2|1-\varphi_\delta|^2 + \sum_{l=0}^{k-1}\left|\frac{\partial^l u}{\partial x_1^l}\right|^2\left|\frac{\partial^{k-l}\varphi_\delta}{\partial x_1^{k-l}}\right|^2\rho^{k+\sum_{i=1}^3\beta_i}|\sin\theta|^{k+\beta_1+\beta_2}\right)dx.
\end{aligned}$$

Due to (5.6) there hold

$$\begin{aligned}
&\int_{R_0}\left|\frac{\partial^k u}{\partial x_1^k}\right|^2|\varphi_\delta|^2\rho^{k+\sum_{i=1}^3\beta_i}|\sin\theta|^{k+\beta_1+\beta_2}dx \\
&\le C\int_{T_3}(1+x_3)^{2(\gamma-\sigma)-k+\beta_3}\, r^{2\sigma+1-k+\beta_1+\beta_2}\,dr\,dx_3 \\
&\le C\int_{\delta\cot\theta_0}^{\rho_0}\tilde{x}_3^{2(\gamma-\sigma)+\beta_3}\,d\tilde{x}_3\int_{\delta}^{\tilde{x}_3\tan\theta_0} r^{2\sigma+1-k+\beta_1+\beta_2}\,dr \\
&\le C(1+|\log\delta|)^{2\kappa}\delta^{2\gamma+3-k+\sum_{i=1}^3\beta_i}
\end{aligned} \tag{5.12}$$

and, for $l < k$,

$$\begin{aligned}
&\int_{R_0} \left|\frac{\partial^l u}{\partial x_1^l}\right|^2 \left|\frac{\partial^{k-l}\varphi_\delta}{\partial x_1^{k-l}}\right|^2 \rho^{k+\sum_{i=1}^3 \beta_i} |\sin\theta|^{k+\beta_1+\beta_2} dx \\
&\quad \le C\delta^{-2(k-l)} \int_{\delta\cot\theta_0}^{2\delta\cot\theta_0} \tilde{x}_3^{2(\gamma-\sigma)+\beta_3}\, d\tilde{x}_3 \int_{\delta}^{\tilde{x}_3\tan\theta_0} r^{2(\sigma-l)+1+k+\beta_1+\beta_2} dr \\
&\quad \le C\delta^{2(\sigma+1)+\beta_1+\beta_2-k} \int_{\delta\cot\theta_0}^{2\delta\cot\theta_0} \tilde{x}_3^{2(\gamma-\sigma)+\beta_3} d\tilde{x}_3 \\
&\quad \le C(1+|\log\delta|)^{2\kappa}\delta^{2\gamma+\sum_{i=1}^3\beta_i+3-k}.
\end{aligned} \tag{5.13}$$

A combination of (5.12) and (5.13) leads to

$$\int_Q \left|\frac{\partial^k u_2}{\partial x_1^k}\right|^2 \left(1-x_1^2\right)^{k+\beta_1} \prod_{i=1}^2 \left(1-x_i^2\right)^{\beta_i} dx \le C|\log\delta|^{2\kappa}\delta^{2\gamma+\sum_{i=1}^3\beta_i+3-k}.$$

The estimate on $\frac{\partial^k u_2}{\partial x_3^k}$ can be carried out similarly. Due to (5.6) there hold

$$\left|\frac{\partial^k u_2}{\partial x_3^k}\right| = \left|\varphi_\delta \frac{\partial^k u}{\partial x_3^k}\right| \le C(1+x_3)^{\gamma-\sigma-k}\, r^\sigma$$

and

$$\begin{aligned}
&\int_Q \left|\frac{\partial^k u_2}{\partial x_3^k}\right|^2 \prod_{i=1}^2 \left(1-x_i^2\right)^{\beta_i} \left(1-x_3^2\right)^{k+\beta_3} dx \\
&\le C\int_{T_3} \left|\frac{\partial^k u}{\partial x_3^k}\right|^2 \rho^{k+\sum_{i=1}^3\beta_i} |\sin\theta|^{\beta_1+\beta_2} dx \\
&\le C\int_\delta^{\rho_0\tan\theta_0} r^{2\sigma+1+\beta_1+\beta_2} dr \int_{r\cot\theta_0}^{\rho_0} \tilde{x}_3^{2(\gamma-\sigma)-k+\beta_3}\, d\tilde{x}_3 \\
&\le C\delta^{2\gamma+3-k+\sum_{i=1}^3\beta_i}.
\end{aligned}$$

We can treat all terms of $D^\alpha u_2$ with $|\alpha| \le k$ in a similar way, which gives for $k > 2\max\{\sigma, \gamma+1/2+\beta_3\}+2+\beta_1+\beta_2$

$$\|u_2\|^2_{H^{k,\beta}(Q)} \le C(1+|\log\delta|)^{2\kappa}\delta^{2\gamma+\sum_{i=1}^3\beta_i+3-k}. \tag{5.14}$$

Therefore, we have by (5.11) and (5.14)

$$\begin{aligned}
K(t,u) &= \inf_{u=v+w}\{\|v\|_{H^{0,\beta}(Q)} + t\,\|w\|_{H^{k,\beta}(Q)}\} \\
&\le C(\|u_1\|_{H^{0,\beta}(Q)} + t\,\|u_2\|_{H^{k,\beta}(Q)}) \\
&\le C(1+|\log\delta|)^\kappa \delta^{1+\min\{\gamma+(1+\beta_3)/2,\sigma\}+\beta_1/2+\beta_2/2}(1+t\,\delta^{-k/2}).
\end{aligned}$$

Selecting $\delta = t^{2/k}$, we have for $0 < t < 1$

$$K(t,u) \le C(1+|\log t|)^\kappa t^{\frac{2+2\min\{\gamma+(1+\beta_3)/2,\sigma\}+\beta_1+\beta_2}{k}}.$$

For $t \geq 1$, it always holds that

$$K(t,u) \leq C\|u\|_{H^{0,\beta}(Q)}.$$

Choosing $\theta = \frac{2+2\min\{\gamma+(1+\beta_3)/2,\sigma\}+\beta_1+\beta_2}{k}$, we have

$$\sup_{t>0} \frac{t^{-\theta}\, K(t,u)}{(1+|\log t|)^{\kappa}} \leq C,$$

which implies that $u \in \big(H^{0,\beta}(Q), H^{k,\beta}(Q)\big)_{\theta,\infty,\kappa} = B^{s,\beta}_{\kappa}(Q)$ with $s = \theta k = 2\min\{\gamma + (1+\beta_3)/2, \sigma\} + \beta_1 + \beta_2$ and κ given in (5.10).

Selecting $\theta = \frac{2+2\min\{\gamma+(1+\beta_3)/2,\sigma\}+\beta_1+\beta_2-\epsilon}{k} = \frac{s-\epsilon}{k}$ with $\epsilon > 0$ arbitrary gives for either $\sigma = \gamma + (1+\beta_3)/2$ or $\sigma \neq \gamma + (1+\beta_3)/2$

$$\int_0^{\infty} t^{-2\theta} |K(t,u)|^2 \frac{dt}{t} \leq C,$$

which implies that $u \in \big(H^{0,\beta}(Q), H^{k,\beta}(Q)\big)_{\theta,2} = H^{s-\epsilon,\beta}(Q)$. ∎

A combination of Theorems 5.2 and 2.3–2.4 leads to the approximability of the singular function of $\rho^{\gamma}\sin^{\sigma}\phi$-type.

THEOREM 5.3. *There exists $\psi(x) \in \mathcal{P}_p(Q)$ with $p > 1 + 2\min\{\sigma, \gamma + 1/2\}$ such that for $\beta = (0,0,0)$ and $s = 2 + 2\min\{\sigma, \gamma + 1/2\}$*

$$\|u - \psi\|_{L^2(Q)} \leq Cp^{-(2+2\min\{\sigma,\gamma+1/2\})}\, \|u\|_{B^{s,\beta}(Q)} \tag{5.15}$$

if $\sigma \neq \gamma + 1/2$, and

$$\|u - \psi\|_{L^2(Q)} \leq Cp^{-(2+2\min\{\sigma,\gamma+1/2\})}(1+\log p)^{1/2}\, \|u\|_{B^{s,\beta}_{1/2}(Q)}. \tag{5.16}$$

Also, there exists $\varphi(x) \in \mathcal{P}_p(Q)$ with $p > 2\min\{\sigma, \gamma + 1/2\}$ such that for $\beta = (-1/2, -1/2, 0)$ and $s = 1 + 2\min\{\sigma, \gamma + 1/2\}$

$$\|u - \varphi\|_{H^1(R_0)} \leq Cp^{-2\min\{\sigma,\gamma+1/2\}}\, \|u\|_{B^{s,\beta}(Q)} \tag{5.17}$$

if $\sigma \neq \gamma + 1/2$, and

$$\|u - \varphi\|_{H^1(R_0)} \leq Cp^{-2\sigma}(1+\log p)^{1/2}\, \|u\|_{B^{s,\beta}_{1/2}(Q)} \tag{5.18}$$

if $\sigma = \gamma + 1/2$.

Proof. For $\beta = (0,0,0)$, Theorem 5.2 indicates that $u \in B^{s,\beta}(Q)$ if $\sigma \neq \gamma + 1/2$ and $u \in B^{s,\beta}_{1/2}(Q)$ if $\sigma = \gamma + 1/2$ with $s = 2 + 2\min\{\sigma, \gamma + 1/2\}$. Due to Theorems 2.3–2.4, the Jacobi projection ψ of u associated with the weight $\beta = (0,0,0)$ on $\mathcal{P}_p(Q)$ with $p > 1 + 2\min\{\sigma, \gamma + 1/2\}$ satisfies (5.14) and (5.15).

Also for $\beta = (-1/2, -1/2, 0)$, Theorem 5.2 tells us that $u \in B^{s,\beta}(Q)$ if $\sigma \neq \gamma + 1/2$ and $u \in B^{s,\beta}_{1/2}(Q)$ if $\sigma = \gamma + 1/2$ with $s = 1 + 2\min\{\sigma, \gamma + 1/2\}$. Due to Theorems 2.3–2.4, the Jacobi projection φ of u associated with the weight $\beta = (-1/2, -1/2, 0)$ on $\mathcal{P}_p(Q)$ with $p > 2\min\{\sigma, \gamma + 1/2\}$ satisfies for $\ell = 0, 1$

$$|u - \varphi|_{H^{\ell,\beta}(Q)} \leq Cp^{-(2\min\{\sigma,\gamma+1/2\}+1-\ell)}\, \|u\|_{B^{s,\beta}(Q)} \tag{5.19}$$

if $\sigma \neq \gamma + 1/2$, and

$$|u - \varphi|_{H^{\ell,\beta}(Q)} \leq Cp^{-(2\min\{\sigma,\gamma+1/2\}+1-\ell)}(1+\log p)^{1/2}\, \|u\|_{B^{s,\beta}_{1/2}(Q)} \tag{5.20}$$

if $\sigma = \gamma + 1/2$. Note that

$$|u-\varphi|_{L^2(Q)} \le C|u-\varphi|_{H^{0,\beta}(Q)}. \tag{5.21}$$

Due to (5.3), there holds for $x \in R_0 = R_{\rho_0,\theta_0,\phi_0}$ and $|\alpha| = 1$

$$\prod_{i=1}^{2}(1-x_i^2)^{\alpha_i-1/2}\big(1-x_3^2\big)^{\alpha_3} \ge C_1, \tag{5.22}$$

where the positive constants C_1 is independent of x. This implies that for $|\alpha| = 1$

$$\begin{aligned}&\int_{R_0} |D^\alpha(u-\varphi)|^2\,dx\\ &\quad\le C\int_{R_0} |D^\alpha(u-\varphi)|^2 \prod_{i=1}^{2}\big(1-x_i^2\big)^{\alpha_i-1/2}\big(1-x_3^2\big)^{\alpha_3}\,dx\\ &\quad\le C|u-\varphi|^2_{H^{1,\beta}(Q)},\end{aligned}$$

which together with (5.19)–(5.21) leads to (5.17) and (5.18), completing the proof. □

5.2. Singular functions of $\rho^\gamma\ \log^\nu \rho\sin^\sigma\theta\log^\mu\sin\theta$-type. Since the function given in (5.2) can be written as

$$\begin{aligned}v(x) &= \rho^{\gamma-\sigma}\,r^\sigma\ \log^\nu\rho\,(\log\rho-\log r)^\mu\,\chi(\rho)\,\Psi(\theta)\,\Phi(\phi)\\ &= \rho^{\gamma-\sigma}\,r^\sigma\ \log^\nu\rho\,\chi(\rho)\,\Psi(\theta)\,\Phi(\phi)\sum_{l=0}^{\mu}\binom{\mu}{l}(-1)^{\mu-l}\log^l\rho\log^{\mu-l}r,\end{aligned}$$

we need to analyze the functions of this type

$$\begin{aligned}w(x) &= \rho^{\gamma-\sigma}\,r^\sigma\ \log^{\nu+l}\rho\,\log^{\mu-l}r\,\chi(\rho)\,\Psi(\theta)\,\Phi(\phi)\\ &= \rho^{\gamma-\sigma}\,r^\sigma\ \log^{\nu'}\rho\,\log^{\mu'}r\,\chi(\rho)\,\Psi(\theta)\,\Phi(\phi)\end{aligned}$$

with $\nu', \mu' \ge 0$.

THEOREM 5.4. *Let $\beta = (\beta_1,\beta_2,\beta_3)$ with $\beta_i > -1$, $1 \le i \le 3$. Then $w \in H^{s-\epsilon,\beta}(Q)$ and $w(x) \in B^{s,\beta}_{\kappa'}(Q)$ with $s = 2+2\min\{\gamma+(1+\beta_3)/2,\sigma\}+\beta_1+\beta_2$, $\epsilon > 0$ arbitrary, and*

$$\kappa' = \begin{cases}\mu' & \text{if } \sigma < \gamma+(1+\beta_3)/2,\\ \mu'+\nu'+1/2 & \text{if } \sigma = \gamma+(1+\beta_3)/2,\\ \mu'+\nu' & \text{if } \sigma > \gamma+(1+\beta_3)/2.\end{cases} \tag{5.23}$$

Proof. We decompose the function into $w = w_1 + w_2$ with $w_1 = \varphi_\delta(r)u$ and $w_2 = (1-\varphi_\delta(r))w$, where $\varphi_\delta(r)$ is a C^∞ function defined as in the proof of Theorem 5.2. It is easy to verify that $w_1 \in H^{0,\beta}(Q)$ and $w_2 \in H^{k,\beta}(Q)$ for any $k > 2 + 2\max\{\gamma+(1+\beta_3)/2,\sigma\}+\beta_1+\beta_2$.

Let R_{ρ_0,θ_0}, T_i, $1 \le i \le 3$, be the regions defined as in the previous section and shown in Figure 5.2–5.3. There holds

(5.24)

$$\begin{aligned}\|w_1\|^2_{H^{0,\beta}(Q)} &= \int_{R_{\rho_0,\theta_0,\phi_0,}} |\varphi_\delta w|^2\rho^{\sum_{i=1}^3\beta_i}|\sin\theta|^{\beta_1+\beta_2}dx\\ &\le C\int_{T_1\cup T_2}(1+x_3)^{2(\gamma-\sigma)+\beta_3}\log^{2\nu'}(1+x_3)\,r^{2\sigma+1+\beta_1+\beta_2}\log^{2\mu'}r\,dr\,dx_3.\end{aligned}$$

Letting $\tilde{x}_3 = x_3 + 1$, as an analogue to estimates (5.7), we have

(5.25)
$$\begin{aligned}
&\int_{T_1} (1+x_3)^{2(\gamma-\sigma)+\beta_3} \log^{2\nu'}(1+x_3)\, r^{2\sigma+1+\beta_1+\beta_2} \log^{2\mu'} r\, dr\, dx_3 \\
&\quad \le C \int_0^{2\delta\cot\theta_0} \tilde{x}_3^{2(\gamma-\sigma)+\beta_3} \log^{2\nu'} \tilde{x}_3\, d\tilde{x}_3 \int_0^{\tilde{x}_3\tan\theta_0} r^{2\sigma+1+\beta_1+\beta_2} \log^{2\mu'} r\, dr \\
&\quad \le C \int_0^{2\delta\cot\theta_0} \tilde{x}_3^{2\gamma+2+\sum_{i=1}^3 \beta_i} \log^{2(\nu'+\mu')} \tilde{x}_3\, d\tilde{x}_3 \\
&\quad \le C\delta^{2\gamma+\sum_{i=1}^3 \beta_i+3} (1+|\log\delta|)^{2(\nu'+\mu')}.
\end{aligned}$$

Analogously to (5.8)–(5.10) we have, for $\sigma \neq \gamma + (1+\beta_3)/2$,

(5.26)
$$\begin{aligned}
&\int_{T_2} (1+x_3)^{2(\gamma-\sigma)+\beta_3} \log^{2\nu'}(1+x_3)\, r^{2\sigma+1+\beta_1+\beta_2} \log^{2\mu'} r\, dr\, dx_3 \\
&\quad \le C \int_0^{2\delta} r^{2\sigma+1+\beta_1+\beta_2} \log^{2\mu'} r\, dr \int_{2\delta\cot\theta_0}^{\rho_0} \tilde{x}_3^{2(\gamma-\sigma)+\beta_3} \log^{2\nu'} \tilde{x}_3\, d\tilde{x}_3 \\
&\quad \le C(1+\delta^{2(\gamma-\sigma)+1+\beta_3} |\log\delta|^{2\nu'}) \delta^{2\sigma+2+\beta_1+\beta_2} |\log\delta|^{2\mu'} \\
&\quad \le C(\delta^{2\gamma+3+\sum_{i=1}^3 \beta_i} |\log\delta|^{2(\nu'+\mu')} + \delta^{2\sigma+2+\beta_1+\beta_2} |\log\delta|^{2\mu'}),
\end{aligned}$$

and, for $\sigma = \gamma + (1+\beta_3)/2$,

(5.27)
$$\begin{aligned}
&\int_{T_2} (1+x_3)^{2(\gamma-\sigma)+\beta_3} \log^{2\nu'}(1+x_3)\, r^{2\sigma+1+\beta_1+\beta_2} \log^{2\mu'} r\, dr\, dx_3 \\
&\quad \le C \int_0^{2\delta} r^{2\sigma+1+\beta_1+\beta_2} \log^{2\mu'} r\, dr \int_{2\delta\cot\theta_0}^{\rho_0} \tilde{x}_3^{-1} \log^{2\nu'} \tilde{x}_3\, d\tilde{x}_3 \\
&\quad \le C(1+|\log\delta|)^{2\nu'+1} \delta^{2\sigma+2+\beta_1+\beta_2} |\log\delta|^{2\mu'} \\
&\quad \le C|\log\delta|^{2(\nu'+\mu')+1}\, \delta^{2\sigma+2+\beta_1+\beta_2}.
\end{aligned}$$

Combining (5.25)–(5.27) yields

$$\|w_1\|^2_{H^{0,\beta}(Q)} \le C|\log\delta|^{2\kappa'} \delta^{2+2\min\{\sigma,\gamma+(1+\beta_3)/2\}+\beta_1+\beta_2}. \tag{5.28}$$

Similarly we have the following estimate on $\|w_2\|^2_{H^{k,\beta}(Q)}$:

$$\|w_2\|^2_{H^{k,\beta}(Q)} \le C|\log\delta|^{2\kappa'} \delta^{2+2\min\{\sigma,\gamma+(1+\beta_3)/2\}+\beta_1+\beta_2-k}. \tag{5.29}$$

It follows from (5.28) and (5.29) that

$$K(t,w) \le C|\log\delta|^{\kappa'} \delta^{1+\min\{\sigma,\gamma+(1+\beta_3)/2\}+\beta_1/2+\beta_2/2} (1+t\delta^{-k/2}).$$

Selecting $\delta = t^{2/k}$ and $\theta = \frac{2+2\min\{\gamma+(1+\beta_3)/2,\sigma\}+\beta_1+\beta_2}{k}$, we have for $0<t<1$

$$\frac{t^{-\theta} K(t,u)}{(1+|\log t|)^{\kappa'}} \le C,$$

which implies the desired characterization of the singularity of the function $w(x)$ in the spaces $B^{s,\beta}_{\kappa'}(Q)$ with $s = 2 + 2\min\{\gamma + (1+\beta_3)/2, \sigma\} + \beta_1 + \beta_2$ and κ' given in (5.22).

Selecting $\theta = \frac{2+2\min\{\gamma+(1+\beta_3)/2,\sigma\}+\beta_1+\beta_2-\epsilon}{k} = \frac{s-\epsilon}{k}$ with $\epsilon > 0$ arbitrary, we have

$$\int_0^\infty t^{-2\theta}|K(t,u)|^2\frac{dt}{t} \le C,$$

which implies $u \in \big(H^{0,\beta}(Q), H^{k,\beta}(Q)\big)_{\theta,2} = H^{s-\epsilon,\beta}(Q)$. □

The following theorem on the characterization of singularity of the function $v(x)$ is a corollary of Theorem 5.4.

THEOREM 5.5. *Let $v(x)$ be given as in* (5.2)*, and let $\beta_i > -1, 1 \le i \le 3$. Then $w \in H^{s-\epsilon,\beta}(Q)$ and $v(x) \in B^{s,\beta}_\kappa(Q)$ with $s = 2 + 2\min\{\gamma + (1+\beta_3)/2, \sigma\} + \beta_1 + \beta_2$, $\epsilon > 0$ arbitrary, and*

$$\kappa = \begin{cases} \mu & \text{if } \sigma < \gamma + (1+\beta_3)/2, \\ \mu + \nu + 1/2 & \text{if } \sigma = \gamma + (1+\beta_3)/2, \\ \mu + \nu & \text{if } \sigma > \gamma + (1+\beta_3)/2. \end{cases} \tag{5.30}$$

Characterization of singularity of the function $v(x)$ by Theorem 5.5 *and the approximation property described in Theorem* 2.4 *give the approximability of $v(x)$.*

THEOREM 5.6. *Let $v(x)$ be given in* (5.2)*. Then there exists $\psi(x) \in \mathcal{P}_p(Q)$ with $p > 1 + 2\min\{\sigma, \gamma + 1/2\}$ such that for $\beta = (0,0,0)$ and $s = 2 + 2\min\{\sigma, \gamma + 1/2\}$*

$$\|v - \psi\|_{L^2(Q)} \le Cp^{-(2+2\min\{\sigma,\gamma+1/2\})}(1+\log p)^\kappa \, \|u\|_{B^{s,\beta}_\kappa(Q)}. \tag{5.31}$$

Also, there exists $\varphi(x) \in \mathcal{P}_p(Q)$ with $p > 2\min\{\sigma, \gamma + 1/2\}$ such that for $\beta = (-1/2, -1/2, 0)$ and $s = 1 + 2\min\{\sigma, \gamma + 1/2\}$

$$\|v - \varphi\|_{H^1(R_0)} \le Cp^{-2\min\{\sigma,\gamma+1/2\}}(1+\log p)^\kappa \, \|u\|_{B^{s,\beta}_\kappa(Q)}. \tag{5.32}$$

κ in (5.31) *and* (5.32) *is given in* (5.30).

Proof. By Theorem 5.5 $v(x) \in B^{2\min\{\gamma+1/2,\sigma\}+2,\beta}_\kappa(Q)$ with κ specified by (5.30), in particular, for $\beta = (0,0,0)$ and $\beta = (-1/2, -1/2, 0)$.

Applying Theorem 2.4 with $\beta = (0,0,0)$ leads immediately to (5.31). Applying Theorem 2.4 with $\beta = (-1/2, -1/2, 0)$ and arguing as in the proof of Theorem 5.3 we can easily obtain (5.32). Actually, ψ and φ are the Jacobi projection of v associated with the weight $\beta = (0,0,0)$ on $\mathcal{P}_p(Q)$ with $p > 1 + 2\min\{\sigma, \gamma + 1/2\}$ and with the weight $\beta = (-1/2, -1/2, 0)$ on $\mathcal{P}_p(Q)$ with $p > 2\min\{\sigma, \gamma + 1/2\}$, respectively. □

Remark 5.1. κ given in (5.30) reduces to (5.6) if $\nu = \mu = 0$. κ depends on ν and μ, but also on the relation between γ and σ. When $\sigma = \gamma + (1+\beta_3)/2$, $v(x) \in B^{s,\beta}_\kappa(Q)$ with κ increased by an extra value of $1/2$. Consequently, an extra loss of a factor $(1+\log p)^{1/2}$ occurs in the error estimate (5.31) and (5.32), which was mentioned in [16] for the p-version of BEM. Whether the extra value of $1/2$ can be removed or not is an open question for further investigation. Fortunately, the extra value of $1/2$ appears in κ, not in s.

6. Concluding remarks. The singularities of singular functions in three dimensions and their approximabilities have been analyzed in the framework of the Jacobi-weighted Besov and Sobolev spaces. To precisely characterize the singularities and investigate the approximabilities for singular functions of three different

types, Jacobi-weighted Besov and Sobolev spaces associated with three different Jacobi weights are elegantly designed. The most difficult as well as most significant work is the characterization of the functions with the singularity of $\rho^\gamma \log^\nu \rho \sin^\sigma \theta \log^\mu \sin\theta$-type in the Besov space $B^{s,\beta}_\kappa(Q)$ with κ given in (5.30). The singularity of this type is anisotropic and totally different from the singularity in two dimensions. The key for success is the decomposition of the singular function with a cutoff function $\varphi_\delta(r)$, instead of $\varphi_\delta(\rho)$ and $\varphi_\delta(\theta)$, although the singularity appears in ρ and θ. After having tried various decompositions we are convinced that only this decomposition can lead to our desired results. For the best approximation of these singular functions we select different weights, namely, $\beta = (-1/3, -1/3, -1/3)$, $\beta = (-1/2, -1/2, \beta_3)$, $\beta = (-1/2, -1/2, 0)$, respectively. We are also convinced that only this selection can give us the best error estimation in L^2- and H^1-norms. Once the weights are properly selected the approximation results follow in a natural way. Our approach for error estimation for singular functions is different from the usual approach, namely, we do not directly analyze approximation of singular functions, but verify that they belong to certain Jacobi-weighted Besov spaces.

TABLE 6.1

The value of k and s in Sobolev, Besov, and Jacobi-weighted Besov spaces for functions of $\rho^\gamma, r^\sigma, \rho^\gamma \sin^\sigma \theta$-type.

Space	$H^k(Q)$	$H^s(Q)$	$B^s(Q)$	$H^{k,\beta}(Q)$	$B^{s,\beta}(Q)$
ρ^γ	$3/2 + [\gamma]$	$3/2 + \gamma - \epsilon$	$3/2 + \gamma$	$2 + 2\gamma - \epsilon$	$2 + 2\gamma$
r^σ	$1 + [\sigma]$	$1 + \sigma - \epsilon$	$1 + \sigma$	$1 + 2\sigma - \epsilon$	$1 + 2\sigma$
$\rho^\gamma \sin^\sigma \theta$	$1 + [\lambda]$	$1 + \lambda - \epsilon$	$1 + \lambda$	$1 + 2\lambda - \epsilon$	$1 + 2\lambda$

TABLE 6.2

Accuracy of approximation in H^1-norm to singular functions of $\rho^\gamma, r^\sigma, \rho^\gamma \sin^\sigma \theta$-type by the h- and p-versions based on Sobolev, Besov, and Jacobi-weighted Besov spaces.

	h-version		p-version		
Space	$H^s(Q)$	$B^s(Q)$	$H^s(Q)$	$B^s(Q)$	$B^{s,\beta}(Q)$
ρ^γ	$h^{1/2+\gamma-\epsilon}$	$h^{1/2+\gamma+1/2}$	$p^{-(1/2+\gamma-\epsilon)}$	$p^{-(\gamma+1/2)}$	$p^{-(2\gamma+1)}$
r^σ	$h^{\sigma-\epsilon}$	h^σ	$p^{-(\sigma-\epsilon)}$	$p^{-\sigma}$	$p^{-2\sigma}$
$\rho^\gamma \sin^\sigma \theta$	$h^{\lambda-\epsilon}$	h^λ	$p^{-(\lambda-\epsilon)}$	$p^{-\lambda}$	$p^{-2\lambda}$

In Tables 6.1 and 6.2 $\lambda = \min\{\gamma + 1/2, \sigma\}$, $\sigma \neq \gamma + 1/2$, $\beta = (-1/3, -1/3, -1/3)$, $\beta = (-1/2, -1/2, \beta_3)$, $\beta = (-1/2, -1/2, 0)$ for ρ^γ, r^σ, and $\rho^\gamma \sin^\sigma \theta$, respectively.

Although the treatments for singular functions in three dimensions are quite different from and much more difficult than those in one and two dimensions, it is worth indicating that the structures of Jacobi-weighted spaces are basically the same. The difference lies only in the selection of Jacobi weights and in the way of proving that a singular function belongs to the Jacobi-weighted spaces. Hence the mathematical framework of the Jacobi-weighted Besov and Sobolev spaces is robust and uniform for problems in one, two, and three dimensions.

The singular functions with singularities of three different types are typical and appear in the solution of problems with piecewise analytical data on polyhedral domains, which govern the convergence of the finite element solutions of the h-, p-, and hp-versions (associated with quasi-uniform meshes). The function spaces used for

characterizing the singularities depend on the nature of singularities as well as the type of FEMs. Thus, the selection of function spaces is crucial to the best approximation for the finite element solutions. Tables 6.1 and 6.2 tell us how the functional spaces used for characterization of singularities and error analysis affect the estimation of approximation error measured in the H^1-norm. Hence we can conclude that the Jacobi-weighted Besov is the best theoretical tool for analyzing approximation of functions by the p- and hp-versions (associated with quasi-uniform meshes) of the FEM. Meanwhile, it can be shown that it has no substantial impact on the error estimation for the classical h-version of the FEM.

Finally, the framework we set up in three dimensions can be used for the spectral and the boundary element methods, and the analysis and results parallel to those for the finite element can be established for the spectral and the boundary element methods without substantial difficulties.

A PRIMAL-BASED PENALTY PRECONDITIONER FOR ELLIPTIC SADDLE POINT SYSTEMS*

C. R. DOHRMANN† AND R. B. LEHOUCQ‡

Abstract. A primal-based penalty preconditioner is presented for a linear set of equations arising from elliptic saddle point problems. We show that the eigenvalues of the preconditioned matrix are positive real and demonstrate that a variant of the preconditioner can be combined with the conjugate gradient algorithm. Our approach is motivated by two basic observations. First, the solution of a problem with constraints is often similar to the solution of a problem where the constraints are penalized. Second, certain methods of solution not available for a constrained problem are possible for its penalized counterpart so motivating a primal-based Schur complement approach. Numerical examples for elliptic two- and three-dimensional problems are presented that confirm theoretical results and demonstrate the effectiveness of the preconditioner.

Key words. constrained minimization, saddle point systems, mixed finite elements, Stokes problems, block preconditioners

1. Introduction.

We consider linear systems

$$\begin{bmatrix} A & B^T \\ B & -C \end{bmatrix} \begin{bmatrix} u \\ p \end{bmatrix} = \begin{bmatrix} b \\ 0 \end{bmatrix} \tag{1.1}$$

arising from finite element discretizations of saddle point problems. The matrix A is assumed to be symmetric and positive definite on the kernel of B, and C to be symmetric and positive semidefinite. We denote $u \in \mathbb{R}^n$ and $p \in \mathbb{R}^m$ the primal and dual vectors. For instance, in the case of Stokes flow and incompressible elasticity, the primal and dual variables are associated with velocity–pressure and displacement–pressure, respectively.

Several preconditioners have been investigated for specific instances of (1.1). For example, when the saddle point system represents a discrete Stokes or elasticity system, many approaches precondition the dual Schur complement $C + BA^{-1}B^T$ with a matrix spectrally equivalent to the dual mass matrix. Examples include block diagonal preconditioners [12, 25, 17], block triangular preconditioners [11, 16], and inexact Uzawa approaches [6, 9, 4]. A symmetric preconditioner for saddle point systems similar in form to ours that involves preconditioning of the dual Schur complement was recently studied in [14]. Reformulation of the saddle point problem in (1.1) as a symmetric positive definite system was considered in [5] that permits an iterative solution using the conjugate gradient algorithm. See [3, 10] for further information and

references on saddle point systems and their origin. Overlapping Schwarz preconditioners involving solutions of both local and coarse saddle point problems were investigated in [15, 22]. More recently, substructuring preconditioners based on balancing Neumann–Neumann methods [21, 13] and FETI-DP [18] were studied. In contrast to much previous work, we consider a preconditioner for a generic saddle point system that satisfies the minimal conditions stated after (1.1) that preconditions the primal Schur complement.

Our approach builds on the idea of preconditioning indefinite problems using a regularization approach [1] introduced by Axelsson. Preconditioning based on regularization is motivated by the idea that the solution of a penalized problem is close to that of the original constrained problem. We present theory and numerical results that extends [1] to cases where the penalized primal Schur complement $A+B^T\tilde{C}^{-1}B$ is preconditioned rather than factored directly. Here, $\tilde{C}$ is a symmetric positive definite penalty counterpart of C in (1.1).

The primal-based penalty (PBP) preconditioner and accompanying theory are presented in sections 2 and 3, respectively. The preconditioner presented is indefinite, but all the eigenvalues of the preconditioned system are real and positive provided that several mild assumptions are satisfied. A form of the preconditioner suited for conjugate gradients is presented in section 4. Numerical examples presented in section 5 confirm the theory and demonstrate the excellent performance of the preconditioner. Comparisons are also made with other preconditioners for saddle point systems. Some concluding remarks are made in the final section.

2. Preconditioner. The penalized primal Schur complement S_A is defined as

$$S_A = A + B^T\tilde{C}^{-1}B, \tag{2.1}$$

where $\tilde{C}$ is symmetric and positive definite. Since A is assumed to be positive definite on the kernel of B, it follows that S_A is positive definite. We consider a preconditioner $\mathcal{M}$ of the form

$$\mathcal{M} = \begin{bmatrix} I & B^T\tilde{C}^{-1} \\ 0 & -I \end{bmatrix} \begin{bmatrix} \hat{S}_A & 0 \\ 0 & -\tilde{C} \end{bmatrix} \begin{bmatrix} I & 0 \\ \tilde{C}^{-1}B & -I \end{bmatrix}, \tag{2.2}$$

where $\hat{S}_A$ is an approximation of S_A. The action of the preconditioner on a vector r (with primal and dual subvectors r_u and r_p) is

$$\begin{bmatrix} z_u \\ z_p \end{bmatrix} = \begin{bmatrix} I & 0 \\ \tilde{C}^{-1}B & -I \end{bmatrix} \begin{bmatrix} \hat{S}_A^{-1} & 0 \\ 0 & -\tilde{C}^{-1} \end{bmatrix} \begin{bmatrix} I & B^T\tilde{C}^{-1} \\ 0 & -I \end{bmatrix} \begin{bmatrix} r_u \\ r_p \end{bmatrix}, \tag{2.3}$$

leading to the two step application of $\mathcal{M}^{-1}r$ as

1. solve $\hat{S}_A z_u = r_u + B^T\tilde{C}^{-1}r_p$ for z_u,
2. solve $\tilde{C}z_p = Bz_u - r_p$ for z_p.

Each application of the preconditioner requires two solves with $\tilde{C}$ and one solve with $\hat{S}_A$.

3. Analysis of the preconditioner. We now investigate the eigenvalues ν of the generalized eigenproblem

$$\mathcal{A}z = \nu\mathcal{M}z, \tag{3.1}$$

where $\mathcal{A}$ is the coefficient matrix in (1.1). Using a coordinate transformation, these eigenvalues are identical to those of the generalized eigenproblem

$$\mathcal{A}\mathcal{M}^{-1}\mathcal{H}w = \nu\mathcal{H}w, \tag{3.2}$$

where $\mathcal{H}$ is defined as

$$\mathcal{H} = \begin{bmatrix} S_A - \hat{S}_A & 0 \\ 0 & \tilde{C} - C \end{bmatrix}. \tag{3.3}$$

The following lemma and corollary are needed for the main theorem of our paper.

LEMMA 3.1. *Suppose that D and E are symmetric positive definite matrices of order n. If*

$$1 < \rho_1 \leq \frac{w^T D w}{w^T E w} \leq \rho_2$$

for all $w \in \mathbb{R}^n$, then

$$\rho_1 \leq \frac{w^T(DE^{-1}D - D)w}{w^T(D-E)w} \leq \rho_2, \tag{3.4}$$

$$\rho_1 - 1 \leq \frac{w^T(D-E)E^{-1}(D-E)w}{w^T(D-E)w} \leq \rho_2 - 1, \tag{3.5}$$

$$1 - 1/\rho_1 \leq \frac{w^T(D-E)E^{-1}(D-E)w}{w^T(DE^{-1}D - D)w} \leq 1 - 1/\rho_2\,, \tag{3.6}$$

$$1 - 1/\rho_1 \leq \frac{w^T(E^{-1} - D^{-1})w}{w^T E^{-1} w} \leq 1 - 1/\rho_2. \tag{3.7}$$

Proof. If (x, λ) is the largest eigenpair of the matrix pencil (D, E), then

$$\max_w \frac{w^T D w}{w^T E w} = \frac{x^T D x}{x^T E x} \leq \rho_2.$$

Therefore, if we can show that the upper bounds of (3.4) are maximized with x, then the upper bounds are true for all $w \in \mathbb{R}^n$. Because $Dx = Ex\lambda$, then $(DE^{-1}D - D)x = Dx(\lambda - 1)$ and $(D - E)x = Ex(\lambda - 1)$ easily follow. If we premultiply these last two identities by x^T, then

$$x^T(DE^{-1}D - D)x = \frac{x^T D x}{x^T E x} x^T(D-E)x \leq \rho_2 x^T(D-E)x$$

and the upper bound of (3.4) is established. A similar argument with the minimal eigenpair (y, σ) of (D, E) establishes the lower bound.

The identity $(D - E)x = Ex(\lambda - 1)$ implies $x^T(D-E)E^{-1}(D-E)x = x^T(D - E)x(\lambda - 1)$ and so (3.5) is established using a similar argument as used for (3.4). Likewise, (3.6) follows from the identity $x^T(D-E)E^{-1}(D-E)x = x^T(DE^{-1}D - D)x(1 - 1/\lambda)$.

The identity $x^T DE^{-1}Dx = x^T DD^{-1}Dx\lambda$ follows from $Dx = Ex\lambda$ and implies

$$z^T(E^{-1} - D^{-1})z = z^T D^{-1} z(\lambda - 1) = z^T E^{-1} z \left(\frac{\lambda - 1}{\lambda}\right) \leq z^T E^{-1} z \left(\frac{\rho_2 - 1}{\rho_2}\right),$$

where $z = Dx$. The last set of inequalities (3.7) now easily follows. ∎

Using arguments similar to those for the proof of (3.4) in Lemma (3.1) we also have the following result.

COROLLARY 3.2. *Suppose that D is symmetric positive semidefinite and E is symmetric positive definite of order m. If*

$$0 \le \rho_1 \le \frac{w^T D w}{w^T E w} \le \rho_2 < 1$$

for all $w \in \mathbb{R}^m$, then

$$\rho_2 w^T(D-E)w \le w^T(DE^{-1}D - D)w \le \rho_1 w^T(D-E)w. \tag{3.8}$$

THEOREM 3.3. *If $\alpha_1 > 1,\ 0 \le \beta_1 < \beta_2 < 1,\ \gamma_1 > 0$, and*

$$\alpha_1 x^T \hat{S}_A x \le x^T S_A x \le \alpha_2 x^T \hat{S}_A x \quad \forall x \in \mathbb{R}^n, \tag{3.9}$$

$$\beta_1 y^T \tilde{C} y \ \le y^T C y \le \ \beta_2 y^T \tilde{C} y \quad \forall y \in \mathbb{R}^m, \tag{3.10}$$

$$\gamma_1 y^T B \hat{S}_A^{-1} B^T y \ \le y^T \tilde{C} y \le \ \gamma_2 y^T B \hat{S}_A^{-1} B^T y \quad \forall y \in \mathbb{R}^m, \tag{3.11}$$

and

$$0 < y^T \tilde{C} y \quad \forall y (\neq 0) \in \mathbb{R}^m, \tag{3.12}$$

then the eigenvalues of (3.2) *satisfy*

$$\delta_1 \le \nu \le \delta_2,$$

where

$$\delta_1 = \min\{\sigma_2(\alpha_1/\alpha_2), \beta_1 + \sigma_1(1-\beta_2)(\alpha_2\gamma_2)^{-1}\},$$

$$\delta_2 = \max\{2\alpha_2 - \sigma_2, \beta_2 + (1-\beta_1)(2 - \sigma_1/\alpha_2)\gamma_1^{-1}\}$$

and σ_1, σ_2 are arbitrary positive constants that satisfy $\sigma_1 + \sigma_2 = 1$.

Proof. A direct calculation gives

$$\mathcal{A}\mathcal{M}^{-1}\mathcal{H} = \begin{bmatrix} S_A \hat{S}_A^{-1} S_A - S_A & (S_A \hat{S}_A^{-1} - I) B^T P^T \\ PB(\hat{S}_A^{-1} S_A - I) & \mathcal{F} \end{bmatrix}, \tag{3.13}$$

where I is the identity matrix and

$$P = I - C\tilde{C}^{-1}, \quad \mathcal{F} = PB\hat{S}_A^{-1}B^T P^T + C - C\tilde{C}^{-1}C. \tag{3.14}$$

If $z^T = \begin{bmatrix} x^T & y^T \end{bmatrix}$, then the quadratic form $z^T \mathcal{A}\mathcal{M}^{-1}\mathcal{H} z$ contains the terms $x^T(S_A\hat{S}_A^{-1}S_A - S_A)x$, $y^T\mathcal{F}y$ and $y^T PB(\hat{S}_A^{-1}S_A - I)x$. We first estimate the absolute value of this last term.

If σ_1 and σ_2 are positive constants so that $\sigma_1 + \sigma_2 = 1$, then

$$\begin{aligned}
|y^T PB(\hat{S}_A^{-1} S_A - I)x| &= |\sigma_1 y^T PBS_A^{-1}(S_A \hat{S}_A^{-1} S_A - S_A)x + \sigma_2 y^T PB\hat{S}_A^{-1}(S_A - \hat{S}_A)x| \\
&\leq \sigma_1 |y^T PBS_A^{-1}(S_A \hat{S}_A^{-1} S_A - S_A)^{1/2}(S_A \hat{S}_A^{-1} S_A - S_A)^{1/2} x| \\
&\quad + \sigma_2 |y^T PB\hat{S}_A^{-1/2} \hat{S}_A^{-1/2}(S_A - \hat{S}_A)x| \\
&\leq \sigma_1 (y^T PB(\hat{S}_A^{-1} - S_A^{-1})B^T P^T y)^{1/2}(x^T(S_A \hat{S}_A^{-1} S_A - S_A)x)^{1/2} \\
&\quad + \sigma_2 (y^T PB\hat{S}_A^{-1} B^T P^T y)^{1/2}(x^T(S_A - \hat{S}_A)\hat{S}_A^{-1}(S_A - \hat{S}_A)x)^{1/2} \\
&\leq \frac{\sigma_1}{2} y^T PB(\hat{S}_A^{-1} - S_A^{-1})B^T P^T y + \frac{\sigma_1}{2} x^T(S_A \hat{S}_A^{-1} S_A - S_A)x \\
&\quad + \frac{\sigma_2}{2} y^T PB\hat{S}_A^{-1} B^T P^T y + \frac{\sigma_2}{2} x^T(S_A - \hat{S}_A)\hat{S}_A^{-1}(S_A - \hat{S}_A)x,
\end{aligned}$$

where we used the Cauchy–Schwarz inequality and the arithmetic mean inequality. Applications of Lemma 3.1, Corollary 3.2, and our hypothesis give

$$\begin{aligned}
2|y^T PB(\hat{S}_A^{-1} S_A - I)x| \quad &\leq \quad (1-\beta_1)(\gamma_1\alpha_2)^{-1}(\alpha_2 - \sigma_1) y^T(\tilde{C} - C)y \\
&\quad\quad + (\alpha_2 - \sigma_2) x^T(S_A - \hat{S}_A)x,
\end{aligned} \tag{3.15}$$

where we used $y^T P\tilde{C}P^T y \leq (1-\beta_1) y^T(\tilde{C} - C)y$, and

$$\begin{aligned}
(\beta_1 + (1-\beta_2)\gamma_2^{-1}) y^T(\tilde{C} - C)y \quad &\leq y^T \mathcal{F} y \leq \quad (\beta_2 + (1-\beta_1)\gamma_1^{-1}) y^T(\tilde{C} - C)y.
\end{aligned} \tag{3.16}$$

Similarly, we have

$$\begin{aligned}
-2|y^T PB(\hat{S}_A^{-1} S_A - I)x| \quad &\geq \quad -(1-\beta_2)\gamma_2^{-1}(\sigma_2 + \sigma_1(1 - 1/\alpha_2)) y^T(\tilde{C} - C)y \\
&\quad\quad - \alpha_1(\sigma_1 + \sigma_2(1 - 1/\alpha_2)) x^T(S_A - \hat{S}_A)x.
\end{aligned} \tag{3.17}$$

From (3.15)–(3.17) and Lemma 3.1 we obtain

$$\begin{aligned}
z^T \mathcal{A}\mathcal{M}^{-1}\mathcal{H} z &\leq x^T(S_A \hat{S}_A^{-1} S_A - S_A)x + 2|y^T PB(\hat{S}_A^{-1} S_A - I)x| + y^T \mathcal{F} y \\
&\leq (2\alpha_2 - \sigma_2) x^T(S_A - \hat{S}_A)x \\
&\quad + (\beta_2 + (1-\beta_1)(2 - \sigma_1/\alpha_2)\gamma_1^{-1}) y^T(\tilde{C} - C)y
\end{aligned}$$

and

$$\begin{aligned}
z^T \mathcal{A}\mathcal{M}^{-1}\mathcal{H} z &\geq x^T(S_A \hat{S}_A^{-1} S_A - S_A)x - 2|y^T PB(\hat{S}_A^{-1} S_A - I)x| + y^T \mathcal{F} y \\
&\geq \sigma_2(\alpha_1/\alpha_2) x^T(S_A - \hat{S}_A)x \\
&\quad + (\beta_1 + \sigma_1(1-\beta_2)(\alpha_2\gamma_2)^{-1}) y^T(\tilde{C} - C)y,
\end{aligned}$$

where we also used Corollary (3.2). Because $z \in \mathbb{R}^{n+m}$ is arbitrary, our theorem is established. ∎

We now briefly discuss the theorem. If the bounds (3.9)–(3.11) are independent of the discretization parameters, then bounds on the eigenvalues of the preconditioned

system are uniform with respect to the discretization. The difference of positive definite matrices that appears in the leading block of $\mathcal{H}$ can be used to define an inner product and has appeared in [5, 4, 16]. The theory developed here applies to both continuous and discontinuous interpolation of the dual variable in each element, but in practice the preconditioner is limited to the discontinuous case. The use of discontinuous interpolation in the dual variable results in a block diagonal $\tilde{C}$ so that S_A has the same sparsity structure as A.

We conclude this section with a brief discussion of how assumption (3.11) follows from more familiar bounds, e.g., for Stokes problems, if A is positive definite. Assume

$$\zeta_1 y^T B A^{-1} B^T y \leq y^T \tilde{C} y \leq \zeta_2 y^T B A^{-1} B^T y \quad \forall y \in \mathbb{R}^m,$$

where ζ_1 and ζ_2 are mesh independent positive constants. From (2.1) we obtain

$$B S_A^{-1} B^T = B A^{-1} B^T - B A^{-1} B^T (\tilde{C} + B A^{-1} B^T)^{-1} B A^{-1} B^T$$

from which follows the bounds

$$1/(1+\zeta_2) y^T \tilde{C} y \leq y^T B S_A^{-1} B^T y \leq 1/(1+\zeta_1) y^T \tilde{C} y \quad \forall y \in \mathbb{R}^m.$$

Thus, $\tilde{C}$ and $BS_A^{-1}B^T$ are spectrally equivalent. Assumption (3.11) then follows from the transitivity of spectral equivalence and (3.9). The constants γ_1 and γ_2 are independent of mesh parameters and material properties provided the same is true for α_1 and α_2.

4. Preconditioned conjugate gradient algorithm. We now consider a form of the preconditioner suitable for the conjugate gradient algorithm. The original linear system (1.1) can be expressed compactly as

$$\mathcal{A} w = d,$$

where

$$w = \begin{bmatrix} u \\ p \end{bmatrix} \quad \text{and} \quad d = \begin{bmatrix} b \\ 0 \end{bmatrix}.$$

The associated residual r is defined as

$$r = d - \mathcal{A} w.$$

We have shown in Theorem 3.3 that $\mathcal{H}\mathcal{M}^{-1}\mathcal{A}$ is symmetric and positive definite. Furthermore, if the constants in (3.9)–(3.11) are mesh independent, then $\mathcal{H}\mathcal{M}^{-1}\mathcal{A}$ is spectrally equivalent to $\mathcal{H}$. These facts motivate using the conjugate gradient algorithm to solve the equivalent linear system

$$\tilde{\mathcal{A}} w = \tilde{d},$$

where

$$\tilde{\mathcal{A}} = \mathcal{H}\mathcal{M}^{-1}\mathcal{A} \quad \text{and} \quad \tilde{d} = \mathcal{H}\mathcal{M}^{-1} d$$

using $\mathcal{H}$ as a preconditioner. The preconditioned conjugate gradient algorithm for the equivalent linear system is summarized as follows:

1. $w_0 = 0$, $r_0 = d$, $z_0 = \mathcal{M}^{-1} r_0$, $\tilde{r}_0 = \mathcal{H}\mathcal{M}^{-1} r_0$, and $k = 1$.

2. If the norm of r_{k-1} is less than a specified value, then exit. Otherwise,
3. $\beta_k = (z_{k-1}^T \tilde{r}_{k-1})/(z_{k-2}^T \tilde{r}_{k-2}) \qquad (\beta_1 = 0)$.
4. $p_k = z_{k-1} + \beta_k p_{k-1} \qquad (p_1 = z_0)$.
5. $\alpha_k = (z_{k-1} \tilde{r}_{k-1})/(p_k^T \mathcal{H}\mathcal{M}^{-1}\mathcal{A} p_k)$.
6. $w_k = w_{k-1} + \alpha_k p_k$.
7. $r_k = r_{k-1} - \alpha_k \mathcal{A} p_k$.
8. $z_k = z_{k-1} - \alpha_k \mathcal{M}^{-1}\mathcal{A} p_k$.
9. $\tilde{r}_k = \tilde{r}_{k-1} - \alpha_k \mathcal{H}\mathcal{M}^{-1}\mathcal{A} p_k$.
10. Return to Step 2.

The conjugate gradient algorithm described above is somewhat nonstandard in that two additional recurrences appear in steps 7 and 8. Application of the algorithm requires calculations of the form $\mathcal{M}^{-1}a$ and $\mathcal{H}\mathcal{M}^{-1}a$. For $a^T = \begin{bmatrix} a_u^T & a_p^T \end{bmatrix}$ we see that

$$\mathcal{M}^{-1}a = \begin{bmatrix} b_u \\ b_p \end{bmatrix} = \begin{bmatrix} \hat{S}_A^{-1}(a_u + B^T \tilde{C}^{-1} a_p) \\ \tilde{C}^{-1}(B b_u - a_p) \end{bmatrix}$$

and

$$\mathcal{H}\mathcal{M}^{-1}a = \begin{bmatrix} S_A b_u - (a_u + B^T \tilde{C}^{-1} a_p) \\ B b_u - a_p - C b_p \end{bmatrix}.$$

Notice that no calculations involving $\hat{S}_A$ are required. In addition, r_k is the residual of the original linear system at iteration k and can be used to assess convergence.

We remark that Bramble and Pasciak [5] also preconditioned an elliptic saddle point problem into a symmetric and positive definite system that could then be solved using the conjugate gradient algorithm. Klawonn [16] also generated a positive definite preconditioned system using a nonstandard inner product but did not consider a practical implementation.

5. Numerical examples. In this section, (1.1) is solved to a relative residual tolerance of 10^{-6} using both right preconditioned GMRES [24] and preconditioned conjugate gradients (PCG) for some example incompressible elasticity problems. The shear modulus G and Lamé parameter λ for an isotropic material are related to the elastic modulus E and Poisson ratio ν by

$$G = \frac{E}{2(1+\nu)}, \qquad \lambda = \frac{\nu E}{(1+\nu)(1-2\nu)}.$$

For incompressible problems $\nu = 1/2$ and λ is infinite. All the examples in this section use $G = 1$ and $\nu = 1/2$. The preconditioner $\hat{S}_A$ used for S_A is a version of the balancing domain decomposition by constraints (BDDC) preconditioner described in [7] and analyzed in [20] that is well suited to nearly incompressible problems [8]. We note that if the original BDDC preconditioner is used rather than the modified one in [8], then the performance of the PBP preconditioner is sensitive to small changes in ν near 1/2 (see Table 5.1). The penalty matrix $\tilde{C}$ is chosen as the negative (2,2) block of the coefficient matrix in (1.1) for an identical problem with the same shear modulus but a value of ν less than 1/2.

Regarding assumption (3.9), we note that the substructuring preconditioner used for S_A has the attractive property that $\alpha_1 \geq 1$ and α_2 is mesh independent under certain additional assumptions [19]. For the conjugate gradient algorithm we scale

the preconditioned residual associated with the primal Schur complement by 1.01 as a safeguard to ensure that $\mathcal{H}$ is positive definite. Since $\tilde{C}$ is positive definite and $C = 0$, (3.10) holds with $\beta_2 < 1$. Finally, since we use stable finite elements and $\tilde{C}$ is spectrally equivalent to the pressure mass matrix, it follows from the discussion at the end of section 3 that (3.11) holds as well.

For purposes of comparison, we also present results for block diagonal and block triangular preconditioners for (1.1). Given the primal and dual residuals r_u and r_p, the preconditioned residuals z_u and z_p for the block diagonal preconditioner are given by

$$z_u = M_A^{-1} r_u \quad \text{and} \quad z_p = M_p^{-1} r_p,$$

where M_A is the BDDC preconditioner for A and M_p is the dual mass matrix. Note that the shear modulus G was chosen as 1 to obtain proper scaling of z_p. Similarly, the preconditioned residuals for the block triangular preconditioner are given by

$$z_p = -M_p^{-1} r_p \quad \text{and} \quad z_u = M_A^{-1}(r_u - B^T z_p).$$

We note that the majority of computations for the block preconditioners occur in forming and applying the BDDC preconditioner for A. Thus, the setup time and time for each iteration are nearly the same for the PBP preconditioner and the two block preconditioners.

We also make comparisons with the preconditioning technique of Bramble and Pasciak [5]. In Remark 2 of [5], Bramble and Pasciak assume that in the case of the Stokes equation the matrix

$$\begin{bmatrix} I & 0 \\ 0 & BA^{-1}B^T \end{bmatrix}$$

is well conditioned. This is not true in our examples because the dual mass matrix M_p, which is spectrally equivalent to $BA^{-1}B^T$, is not well conditioned. The poor conditioning of M_p is a result of using discontinuous linear interpolation of the dual variable. Let the Cholesky decomposition of M_p be given by $R^T R$. By introducing the change of variables $p = R^{-1}\tilde{p}$, the matrix above becomes

$$\begin{bmatrix} I & 0 \\ 0 & R^{-T}BA^{-1}B^T R^{-1} \end{bmatrix},$$

which is well conditioned. Thus, we make use of the noted change of variables in our implementation of [5]. As is done for the PBP preconditioner, we scale the preconditioned residual associated with M_A by 1.01 to ensure that assumption (2.2) of [5] is satisfied.

The first set of examples is for a two-dimensional plane strain problem on a unit square with all displacement degrees of freedom (dofs) on the boundary constrained to zero. The entries of the right-hand side vector b were chosen as uniformly distributed random numbers in the range from 0 to 1. This choice of b ensures that the nodal forces in the problem have a significant average component without not being overly smooth. For any given mesh, the same values in b are used irrespective of the preconditioner used. For this simple geometry the finite element mesh consists of stable $Q_2 - P_1$ elements. This element uses biquadratic interpolation of displacement and discontinuous linear interpolation of pressure. In two dimensions the element has nine nodes for displacement and three element pressure dofs, while in three dimensions it

TABLE 5.1

Results are shown for both the modified and original BDDC preconditioners for S_A. Results in parentheses are condition number estimates from PCG.

ν	Modified BDDC		Original BDDC	
	GMRES	PCG	GMRES	PCG
0.3	19	22 (16)	19	22 (16)
0.4	15	17 (7.3)	15	17 (7.3)
0.49	11	12 (3.2)	13	13 (3.7)
0.499	10	10 (3.0)	17	19 (8.6)
0.4999	9	10 (2.9)	24	31 (71)
0.49999	9	10 (2.9)	25	44 (697)

has 27 nodes for displacement and four element pressure dofs. In the final example, the stable $P_2^+ - P_1$ element is used for an unstructured mesh in two dimensions. This triangular element uses quadratic interpolation of displacement with an added bubble function and discontinuous linear interpolation of pressure. Descriptions of the $Q_2 - P_1$ and $P_2^+ - P_1$ discontinuous pressure elements can be found in [2].

Results are shown in Table 5.1 for the PBP preconditioner applied to a problem discretized by a 32×32 arrangement of square elements. Condition number estimates of the preconditioned equations are shown in parentheses for the PCG results. These eigenvalue estimates were obtained using the connection between conjugate gradients and the Lanczos method. The BDDC preconditioner is based on a regular decomposition of the mesh into 16 square substructures. Notice that the results are insensitive to changes in ν near the incompressible limit of 1/2 for the modified BDDC preconditioner used in this study.

Table 5.2 shows results for a growing number of substructures with $H/h = 4$, where H and h are the substructure and element lengths, respectively. A small growth in the number of iterations with problem size is evident in the table for all the preconditioners. Notice that the iterations required by PCG are only slightly larger than those for GMRES. The primary advantage of PCG over GMRES is the three-term recurrence that requires less storage. In contrast, GMRES uses a long recurrence and so has increased storage requirements. The PBP preconditioner is competitive with the other preconditioners. Similar results for related three-dimensional problems are shown in Tables 5.3 and 5.4.

The next example is for the unstructured mesh shown in Figure 5.1. The mesh was generated using the Matlab code described in [23]. The original triangular elements were then converted to $P_2^+ - P_1$ elements by adding midedge and center nodes. All displacements are constrained to zero on the mesh boundary for this example. The mesh has 2937 elements and 9046 nodes. Results in Table 5.5 show that the PBP preconditioner is competitive with the other approaches.

In Table 5.6 we present selected results from Tables 5.2, 5.4, and 5.5, where the linear systems involving S_A or A are solved exactly rather than approximately using the BDDC preconditioner. In addition, the results are for a relative residual tolerance reduced to 10^{-9}. Column ν reports the value of Poisson ratio used to define $\tilde{C}$ in the PBP preconditioner. Notice for values of ν away from 1/2 that the PBP preconditioner has no clear advantage over the block triangular preconditioner. This is not the case for $\nu = 0.49999$, where the PBP preconditioner with GMRES iterations

exhibits a tenfold reduction in iterations.

One possible objection to the PBP preconditioner is the need for a user-specified parameter. For the examples considered here, this parameter is simply the Poisson ratio used to define $\tilde{C}$. No parameters were needed for the other three preconditioners because we considered only simple homogeneous problems with a shear modulus equal

to 1. We note that the mass matrix approximation of the dual Schur complement used by the other three preconditioners would need to be scaled appropriately to avoid degraded performance for problems with nonunit or multiple material properties. In contrast, no such scaling is needed by the present approach.

6. Conclusions. A PBP preconditioner was presented for elliptic saddle point systems. We demonstrated that the eigenvalues of the preconditioned linear system are positive and real provided certain assumptions are satisfied. A form of the precon-

ditioner suited for conjugate gradients was also presented. Numerical results in two and three dimensions were consistent with the theoretical results and demonstrated the effectiveness of the preconditioner. Excellent performance of the preconditioner was also evident when compared with other approaches.

We note that the PBP preconditioner employs a preconditioner for the penalized primal Schur complement. In contrast, the other three preconditioners considered in the previous section employ a preconditioner for the dual Schur complement. A basic difference is that the penalized primal Schur complement is known exactly, whereas the dual Schur complement is not. Consequently, it is possible to obtain much better performance from the PBP preconditioner, as shown in Table 5.6. A similar result would also likely hold for nonsymmetric saddle point systems. For example, the penalized primal Schur complement would still be known exactly for Navier–Stokes problems, but a simple mass matrix approximation of the dual Schur complement is known to degrade for increasing values of Reynolds number. Thus, one level of approximation would be removed by using the PBP preconditioner.

Acknowledgments. Theorem 3.3 was motivated in large part by related work in [16] due to Klawonn. The authors also wish to express their thanks to Michele Benzi for bringing to their attention [1] and [14].

A FETI-DP PRECONDITIONER WITH A SPECIAL SCALING FOR MORTAR DISCRETIZATION OF ELLIPTIC PROBLEMS WITH DISCONTINUOUS COEFFICIENTS*

N. DOKEVA†, M. DRYJA‡, AND W. PROSKUROWSKI†

Abstract. We consider two-dimensional elliptic problems with discontinuous coefficients discretized by the finite element method on geometrically conforming nonmatching triangulations across the interface using the mortar technique. The resulting discrete problem is solved by a dual-primal FETI method.

In this paper we introduce and analyze a preconditioner with a special scaling of coefficients and step parameters and establish convergence bounds. We show that the preconditioner is almost optimal with constants independent of the jumps of coefficients and step parameters. Extensive computational evidence is presented that illustrates an almost optimal convergence for a variety of situations (distribution of subregions, grid assignment, grid ratios, number of subregions) for both continuous and discontinuous problems.

Key words. domain decomposition, mortar finite element method, dual-primal FETI preconditioner, nonmatching grids, saddle-point problem, elliptic problems with discontinuous coefficients

1. Introduction.

In this paper we discuss a second order elliptic problem with discontinuous coefficients defined on a polygonal region $\Omega \subset \mathbb{R}^2$ which is a union of many polygons Ω_i. The problem is discretized by the finite element method (FEM) on geometrically conforming nonmatching triangulations across $\overline{\Gamma} = \cup_i \partial\Omega_i \backslash \partial\Omega$ using the mortar technique; see [1]. The resulting discrete problem is solved by a dual-primal FETI (FETI-DP) method; see [5], [6], [7] for the matching triangulation and [3], [4] for the nonmatching one. The method is discussed under the assumption of continuity of the solution at vertices of Ω_i. We prove that the method is convergent and its rate of convergence is almost optimal and independent of the jumps of coefficients, provided that a mortar side is associated with the higher coefficient. Consequently, the method is well suited for parallel processors.

The presented results are a generalization of results obtained in [4] and [3] for problems with continuous and discontinuous coefficients, respectively. In [4] a modified mortar condition at the vertices of substructures is employed using the assumption that the solution at the vertices is continuous, while in [3] a standard approximation to the mortar condition is employed. The preconditioner in [3] which does not use the scaling of the coefficients was tested for the simplest case of four subregions. In general, however, the experiments show that for discontinuous coefficients the preconditioner without proper scaling of coefficients exhibits poor convergence.

In this paper we introduce a preconditioner with special scaling of coefficients and step parameters. The theoretical analysis and experimental results show that the proposed preconditioner exhibits excellent properties for general cases considered here: its convergence is almost optimal with respect to the parameters of triangulations (it depends on a logarithmical factor only) and independent of the jumps of coefficients. Extensive numerical experiments on many subregions are reported.

The paper is organized as follows. In section 2, the differential and discrete problems are formulated. In section 3, a matrix form of the discrete problem is given. The preconditioner is described and analyzed in section 4. The implementation of the method and numerical experiments are presented in section 5.

2. Differential and discrete problem. We consider the following differential problems.

Find $u^* \in H_0^1(\Omega)$ such that

$$a(u^*, v) = f(v), \quad v \in H_0^1(\Omega), \tag{1}$$

where

$$a(u, v) = (\rho(x)\nabla u, \nabla u)_{L^2(\Omega)}, \quad f(v) = (f, v)_{L^2(\Omega)}.$$

We assume that Ω is a polygonal region and $\overline{\Omega} = \cup_{i=1}^N \overline{\Omega}_i$, Ω_i are disjoint polygonal subregions of diameter H_i, $\rho(x) = \rho_i$ is a positive constant on Ω_i, and $f \in L^2(\Omega)$. We solve (1) by the FEM on nonmatching triangulation across $\partial\Omega_i$. To describe a discrete problem the mortar technique is used; see [1] and [8] and the literature therein.

We impose on Ω_i a triangulation with triangular elements and parameter h_i. The resulting triangulation of Ω is nonmatching across $\partial\Omega_i$. We assume that the triangulation on each Ω_i is quasi-uniform. Let $X_i(\Omega_i)$ be a finite element space of piecewise linear continuous functions defined on the introduced triangulation. We assume that functions of $X_i(\Omega_i)$ vanish on $\partial\Omega_i \cap \partial\Omega$. Let

$$X^h(\Omega) = X_1(\Omega_1) \times \cdots \times X_N(\Omega_N).$$

Note that $X^h(\Omega) \subset L^2(\Omega)$ but $X^h(\Omega) \not\subset H_0^1(\Omega)$. To formulate a discrete problem for (1) we use the mortar technique for the geometrically conforming case. For that the following notation is used. Let Γ_{ij} be a common edge of two substructures Ω_i and Ω_j, $\Gamma_{ij} = \partial\Omega_i \cap \partial\Omega_j$. Let $\Gamma = (\cup_i \partial\Omega_i)\backslash\partial\Omega$. We now select open edges $\gamma_m \subset \Gamma$, called *mortar*, such that $\overline{\Gamma} = \cup\overline{\gamma}_m$ and $\gamma_m \cap \gamma_n = 0$ for $m \neq n$. Let Γ_{ij} as an edge of Ω_i be denoted by $\gamma_{m(i)}$ and called *mortar* (master), and let Γ_{ij} as an edge of Ω_j be denoted by $\delta_{m(j)}$ and called *nonmortar* (slave). The criterion for choosing $\gamma_{m(i)}$ as the mortar side is that $\rho_i \geq \rho_j$, the coefficients on Ω_i and Ω_j, respectively.

Let $M(\delta_{m(j)})$ be a subspace of $W_j(\delta_{m(j)})$, the restriction of $X_j(\Omega_j)$ to $\delta_{m(j)}$, $\delta_{m(j)} \subset \partial\Omega_j$. Functions of $M(\delta_{m(j)})$ are constants on elements of the triangulation on $\delta_{m(j)}$ which touch $\partial\delta_{m(j)}$. We say that $u_i \in X_i(\Omega_i)$ and $u_j \in X_j(\Omega_j)$ on $\delta_m \equiv \delta_{m(j)} = \gamma_{m(i)} = \Gamma_{ij}$, an edge common to Ω_i and Ω_j, satisfy the mortar condition if

$$\int_{\delta_m} (u_i - u_j)\psi \, ds = 0, \quad \psi \in M(\delta_m). \tag{2}$$

Note that for the given u_i on $\gamma_{m(i)}$ and u_j on $\partial\delta_{m(j)}$, denoted by $\operatorname{Tr} u_j$, we can compute u_j at the interior nodal points of $\delta_{m(j)}$. Denoting the u_j computed in this

way by $\pi_m(u_i; \mathrm{Tr}\ u_j)$ we have

$$\int_{\delta_m} \pi_m(u_i; \mathrm{Tr}\ u_j)\psi\, ds = \int_{\delta_m} u_i\psi\, ds, \quad \psi \in M(\delta_m),$$

$$\pi_m(u_i; \mathrm{Tr}\ u_j) = \mathrm{Tr}\ u_j \ on\ \partial\delta_m.$$

Note that $\pi_m(u_i; \mathrm{Tr}\ u_j)$ is an element of X_j restricted to $\delta_{m(j)}$.

We are now in a position to introduce V^h, the space for discretization of (1). Let $V^h(\Omega)$ be a subspace of $X^h(\Omega)$ of functions which satisfy the mortar condition (2) for each $\delta_m \subset \Gamma$ and which are continuous at common vertices of the substructures. The discrete problem for (1) in V^h is defined as follows.

Find $u_h^* \in V^h$ such that

$$a_H(u_h^*, v_h) = f(v_h), \quad v_h \in V^h, \tag{3}$$

where $a_H(u,v) = \sum_{i=1}^N a_i(u,v), a_i(u,v) = \rho_i(\nabla u, \nabla v)_{L^2(\Omega_i)}$.

The problem has a unique solution and the error bound is known; see [1]. Using the basis functions of V^h, $V^h =$ span $\{\Phi_k\}$, the problem (3) is rewritten as

$$A\underline{u}_h^* = \underline{f}.$$

The form of Φ_k can be found, for example, in [4]. The matrix A is symmetric positive definite and $\mathrm{cond}(A) \le \frac{C}{\min h_i^2}$, where C here depends on the ρ_i.

3. FETI-DP equation. To derive a FETI-DP method we first rewrite the problem (3) as a saddle-point problem using Lagrange multipliers; see, for example, [8] and the literature therein. For $u = \{u_i\}_{i=1}^N \in X^h(\Omega)$ and $\psi = \{\psi_p\}_{p=1}^P \in M(\Gamma) = \prod_m M(\delta_m)$, the mortar condition (2) can be rewritten as

$$b(u,\psi) \equiv \sum_{i=1}^N \sum_{\delta_{m(i)} \subset \partial\Omega_i} \int_{\delta_{m(i)}} (u_i - u_j)\psi_k\, ds = 0,$$

where $\delta_{m(i)} = \gamma_{m(j)} = \Gamma_{ij}, \psi_k \in M(\delta_{m(i)})$. Let $\widetilde{X}^h(\Omega)$ denote a subspace of $X^h(\Omega)$ of functions which are common to the vertices of substructures.

The problem now consists of finding $(u_h^*, \lambda_h^*) \in \widetilde{X}^h(\Omega) \times M(\Gamma)$ such that

$$a(u_h^*, v_h) + b(v_h, \lambda_h^*) = f(v_h), \quad v_h \in \widetilde{X}^h(\Omega), \tag{4}$$

$$b(u_h^*, \psi_h) = 0, \quad \psi_h \in M(\Gamma). \tag{5}$$

It can be proved that u_h^*, the solution of (4)–(5), is the solution of (3) and vice versa. Therefore the problem (4)–(5) has a unique solution. This can be proved straightforwardly using the inf-sup condition, including the error bound; see [8] and the literature therein.

To derive a matrix form of (4)–(5) we first need a matrix formulation of (5). Using the nodal basis functions $\varphi_{\delta_{m(i)}}^{(l)} \in W_i(\delta_{m(i)})$, $\varphi_{\gamma_{m(j)}}^{(k)} \in W_j(\gamma_{m(j)})$, and $\psi_{\delta_{m(i)}}^{(p)} \in M_m(\delta_{m(i)})$ $(\delta_{m(i)} = \gamma_{m(j)} = \Gamma_{ij})$, (5) can be rewritten on $\bar{\delta}_{m(i)}$ as

$$B_{\delta_{m(i)}} u_{i\delta_{m(i)}} - B_{\gamma_{m(j)}} u_{j\gamma_{m(j)}} = 0, \tag{6}$$

where $u_{i\delta_{m(i)}}$ and $u_{j\gamma_{m(j)}}$ are vectors which represent $u_i|_{\delta_{m(i)}} \in W_i(\delta_{m(i)})$ and $u_j|_{\gamma_m(j)} \in W_j\ (\gamma_{m(j)})$, and ($n_{\delta_{(i)}} \equiv n_{\delta_{m(i)}}$ and $n_{\gamma_{(j)}} \equiv n_{\gamma_{m(j)}}$):

$$B_{\delta_{m(i)}} = \{(\psi^{(p)}_{\delta_{m(i)}}, \varphi^{(k)}_{\delta_{m(i)}})_{L^2(\delta_{m(i)})}\}, \quad p = 1, \dots, n_{\delta(i)}, \quad k = 0, \dots, n_{\delta(i)} + 1,$$

$$B_{\gamma_{m(j)}} = \{(\psi^{(p)}_{\delta_{m(i)}}, \varphi^{(l)}_{\gamma_{m(j)}})_{L^2(\gamma_{m(j)})}\}, \quad p = 1, \dots, n_{\delta(i)}, \quad l = 0, \dots, n_{\gamma_{(j)}} + 1.$$

Here $n_{\delta(i)}, n_{\delta(i)} + 2$, and $n_{\gamma(j)} + 2$ are the dimensions of $M_m(\delta_{m(i)})$, $W_i(\delta_{m(i)})$, and $W_j(\gamma_{m(j)})$, respectively. Note that $B_{\delta_{m(i)}}$ and $B_{\gamma_{m(j)}}$ are rectangular matrices. We split the vectors $u_{i\delta_{m(i)}}$ and $u_{j\gamma_{m(j)}}$ into vectors $u^{(r)}_{i\delta_{m(i)}}$, $u^{(c)}_{i\delta_{m(i)}}$ and $u^{(r)}_{j\gamma_{m(j)}}$, $u^{(c)}_{j\gamma_{m(j)}}$, respectively, where $u^{(c)}_{i\delta_{m(i)}}$ and $u^{(c)}_{j\gamma_{m(j)}}$ represent values of functions u_i and u_j at the end points of $\delta_{m(i)}$ and $\gamma_{m(j)}$, and $u^{(r)}_{i\delta_{m(i)}}$ and $u^{(r)}_{j\gamma_{m(j)}}$ represent values of u_i and u_j at the interior nodal points of $\delta_{m(i)}$ and $\gamma_{m(j)}$. Using this notation one can rewrite (6) as

$$(B^{(r)}_{\delta_{m(i)}} u^{(r)}_{i\delta_{m(i)}} + B^{(c)}_{\delta_{m(i)}} u^{(c)}_{i\delta_{m(i)}}) - (B^{(r)}_{\gamma_{m(j)}} u^{(r)}_{j\gamma_{m(j)}} + B^{(c)}_{\gamma_{m(j)}} u^{(c)}_{j\gamma_{m(j)}}) = 0. \tag{7}$$

Note that

$$B^{(r)}_{\delta_{m(i)}} = \{(\psi^{(p)}_{\delta_{m(i)}}, \varphi^{(k)}_{\delta_{m(i)}})_{L^2(\delta_{m(i)})}\}, \quad p,\ k = 1, \dots, n_{\delta(i)}$$

is a square tridiagonal matrix $n_{\delta(i)} \times n_{\delta(i)}$, symmetric and positive definite and $\mathrm{cond}(B^{(r)}_{\delta_{m(i)}}) \sim 1$, while the remaining matrices $B^{(c)}_{\delta_{m(i)}}$, $B^{(c)}_{\gamma_{m(j)}}$, $B^{(r)}_{\gamma_{m(j)}}$ are rectangular with dimensions $n_{\delta(i)} \times 2$, $n_{\delta(i)} \times 2$, $n_{\delta(i)} \times n_{\gamma(j)}$, respectively.

Let $K^{(l)}$ be the stiffness matrix of $a_l(\cdot\,,\cdot)$. It is represented as

$$K^{(l)} = \begin{pmatrix} K^{(l)}_{ii} & K^{(l)}_{ic} & K^{(l)}_{ir} \\ K^{(l)}_{ci} & K^{(l)}_{cc} & K^{(l)}_{cr} \\ K^{(l)}_{ri} & K^{(l)}_{rc} & K^{(l)}_{rr} \end{pmatrix}, \tag{8}$$

where the rows correspond to the interior unknowns $u^{(i)}_l$ of Ω_l, $u^{(l)}_c$ to its vertices and $u^{(r)}_l$ to its edges.

Using the above notation and the assumption of continuity of u^*_h at the vertices of $\partial\Omega_l$, (4)–(5) can be rewritten as

$$\begin{pmatrix} K_{ii} & K_{ic} & K_{ir} & 0 \\ K_{ci} & \widetilde{K}_{cc} & K_{cr} & B^T_c \\ K_{ri} & K_{rc} & K_{rr} & B^T_r \\ 0 & B_c & B_r & 0 \end{pmatrix} \begin{pmatrix} u^{(i)} \\ u^{(c)} \\ u^{(r)} \\ \widetilde{\lambda}^* \end{pmatrix} = \begin{pmatrix} f^{(i)} \\ f^{(c)} \\ f^{(r)} \\ 0 \end{pmatrix}. \tag{9}$$

Here $\widetilde{\lambda}^* = \{B^{(r)}_{\delta_{m(i)}} \lambda^*_{\delta_{m(i)}}\}, \delta_{m(i)} \subset \Gamma$, u^*_h is the solution of (4)–(5) and is represented by the vectors $u^{(i)}, u^{(c)}$, and $u^{(r)}$, which are the values of u^*_h at the interior nodal points of Ω_l, the vertices of Ω_l, and the remaining nodal points of $\partial\Omega_l \backslash \partial\Omega$, respectively; matrices K_{ii} and K_{rr} are diagonal block-matrices of $K^{(l)}_{ii}$ and $K^{(l)}_{rr}$, respectively, while matrix $\widetilde{K}_{cc}$ is built from diagonal block matrices $K^{(l)}_{cc}$ taking into account that $u^{(c)}$ are the same at the common vertices of substructures. The remaining K-matrices represent coupling between the corresponding unknowns. The mortar condition is

represented by $B = (B_c, B_r)$, where these global matrices are represented by the local ones $((B^{(r)}_{\delta_{m(i)}})^{-1}B^{(c)}_{\delta_{m(i)}},\ -(B^{(r)}_{\delta_{m(i)}})^{-1}B^{(c)}_{\gamma_{m(j)}})$, and $(I^{(r)}_{\delta_{m(i)}}, -(B^{(r)}_{\delta_{m(i)}})^{-1}B^{(r)}_{\gamma_{m(j)}})$, respectively, and $I^{(r)}_{\delta_{m(i)}}$ is an identity matrix of $n_{\delta(i)} \times n_{\delta(i)}$. The form of these matrices follows from (7) after multiplying it by $(B^{(r)}_{\delta_{m(i)}})^{-1}$.

In the system (9) we eliminate the unknowns $u^{(i)}$ and $u^{(c)}$ to obtain

$$\begin{pmatrix} \widetilde{S} & \widetilde{B}^T \\ \widetilde{B} & \widetilde{S}_{cc} \end{pmatrix} \begin{pmatrix} u^{(r)} \\ \widetilde{\lambda}^* \end{pmatrix} = \begin{pmatrix} \widetilde{f}_r \\ \widetilde{f}_c \end{pmatrix}, \tag{10}$$

where

$$\begin{cases} \widetilde{S} = K_{rr} - (K_{ri},\ K_{rc}) \begin{pmatrix} K_{ii} & K_{ic} \\ K_{ci} & \widetilde{K}_{cc} \end{pmatrix}^{-1} \begin{pmatrix} K_{ir} \\ K_{cr} \end{pmatrix}, \\ \widetilde{f}_r = f^{(r)} - (K_{ri},\ K_{rc}) \begin{pmatrix} K_{ii} & K_{ic} \\ K_{ci} & \widetilde{K}_{cc} \end{pmatrix}^{-1} \begin{pmatrix} f^{(i)} \\ f^{(c)} \end{pmatrix}, \\ \widetilde{B} = B_r - (0,\ B_c) \begin{pmatrix} K_{ii} & K_{ic} \\ K_{ci} & \widetilde{K}_{cc} \end{pmatrix}^{-1} \begin{pmatrix} 0 \\ B_c^T \end{pmatrix}, \\ \widetilde{S}_{cc} = -(0,\ B_c) \begin{pmatrix} K_{ii} & K_{ic} \\ K_{ci} & \widetilde{K}_{cc} \end{pmatrix}^{-1} \begin{pmatrix} 0 \\ B_c^T \end{pmatrix}, \\ \widetilde{f}_c = -(0,\ B_c) \begin{pmatrix} K_{ii} & K_{ic} \\ K_{ci} & \widetilde{K}_{cc} \end{pmatrix}^{-1} \begin{pmatrix} f^{(i)} \\ f^{(c)} \end{pmatrix}. \end{cases} \tag{11}$$

Note that $\widetilde{S}$ is invertible since u^*_h is continuous at the vertices of Ω_l and vanishes on $\partial\Omega$.

We next eliminate the unknown $u^{(r)}$ to get for $\widetilde{\lambda}^* \in M(\Gamma)$

$$F\widetilde{\lambda}^* = d, \tag{12}$$

where

$$F = \widetilde{B}\widetilde{S}^{-1}\widetilde{B}^T - \widetilde{S}_{cc} \quad \text{and} \quad d = \widetilde{B}\widetilde{S}^{-1}\widetilde{f}_r - \widetilde{f}_c. \tag{13}$$

This is the FETI-DP equation for the Lagrange multipliers. Since F is positive definite the problem has a unique solution. This problem can be solved by conjugate gradient iterations with a preconditioner discussed in the next section.

4. FETI-DP preconditioner. In this section we define a preconditioner for the problem (12). For that let $S^{(l)}$ denote the Schur complement of $K^{(l)}$, see (8), with respect to unknowns at the nodal points of $\partial\Omega_l$. This matrix is represented as

$$S^{(l)} = \begin{pmatrix} S^{(l)}_{rr} & S^{(l)}_{rc} \\ S^{(l)}_{cr} & S^{(l)}_{cc} \end{pmatrix}, \tag{14}$$

where the second row corresponds to unknowns at the vertices of $\partial\Omega_l$ while the first one corresponds to the remaining unknowns of $\partial\Omega_l$. Note that B_r is a matrix obtained from B defined on functions with zero values at the vertices of Ω_l and let

$$\begin{aligned} S &= \text{ diag } \{S^{(l)}\}_{l=1}^N, \qquad S_{rr} = \text{ diag } \{S^{(l)}_{rr}\}_{l=1}^N, \\ S_{cc} &= \text{ diag } \{S^{(l)}_{cc}\}_{l=1}^N, \qquad S_{cr} = (S^{(1)}_{cr}, \ldots, S^{(N)}_{cr}). \end{aligned} \tag{15}$$

The standard preconditioner developed for continuous problems in [4] is defined as

$$\bar{M}^{-1} = B_r \widehat{S}_{rr} B_r{}^T, \tag{16}$$

where $\widehat{S}_{rr} = \text{ diag } \{\widehat{S}_{rr}^{(i)}\}_{i=1}^N$, $\quad \widehat{S}_{rr}^{(i)} = S_{rr}^{(i)}$ for $\rho_i = 1$.

We employ a special scaling to generalize $\bar{M}$ to problems with discontinuous coefficients. The preconditioner M for (12) is defined as

$$M^{-1} = \widehat{B}_r \widehat{S}_{rr} \widehat{B}_r^T, \tag{17}$$

where
$\widehat{B}_r|_{\delta_{m(i)}} = (\rho_i^{1/2} I_{\delta_{m(i)}}, -\frac{h_{\delta_{m(i)}}}{h_{\gamma_{m(j)}}} \frac{\rho_i}{\rho_j} \rho_i^{1/2} B_{\delta_{m(i)}}^{-1} B_{\gamma_{m(j)}})$ for $\delta_{m(i)} \subset \partial\Omega_i$, $i = 1, \ldots, N$; $h_{\delta_{m(i)}}$ and $h_{\gamma_{m(j)}}$ are the step parameters on $\delta_{m(i)}$ and $\gamma_{m(j)}$, $\delta_{m(i)} = \gamma_{m(j)}$, respectively.

An ordering of substructures Ω_l is called mortar-nonmortar (M-N) ordering if all sides of a fixed Ω_l are mortar while all sides of the neighboring substructures of Ω_l are nonmortar.

THEOREM 4.1. *Let the mortar side be chosen where the coefficient ρ_i is larger. Then for $\lambda \in M(\Gamma)$ the following holds:*

$$c_0 \left(1 + \log \frac{H}{h}\right)^{\alpha} \langle M\lambda, \lambda\rangle \le \langle F\lambda, \lambda\rangle \le c_1 \left(1 + \log \frac{H}{h}\right)^{2} \langle M\lambda, \lambda\rangle, \tag{18}$$

where $\alpha = 0$ for M-N ordering of substructures and $\alpha = -2$ in the general case; c_0 and c_1 are positive constants independent of h_i, H_i, and the jumps of ρ_i; and $h = \min_i h_i, H = \max_i H_i$.

Proof. To prove Theorem 4.1 we need some additional facts. We first reformulate the process of reaching (12) from (9). For that we eliminate $u^{(i)}$ from the system (9). Using the notation (14) and (15) we get

$$S_{rr} u^{(r)} + S_{rc} u^{(c)} + B_r^T \widetilde{\lambda}^* = g_r, \tag{19}$$

$$S_{cr} u^{(r)} + \bar{S}_{cc} u^{(c)} + B_c^T \widetilde{\lambda}^* = g_c, \tag{20}$$

$$B_r u^{(r)} + B_c u^{(c)} = 0. \tag{21}$$

Here S_{rr} and S_{cr} ($S_{cr} = S_{cr}^T$) are defined in (15) while $\bar{S}_{cc}$ is defined by $S_{cc}^{(l)}$ (see (14)), taking into account that $u_l^{(c)}$ are the same at the common vertices of substructures.

We now eliminate $u^{(r)}$ and $u^{(c)}$ in (19)–(21). This leads to (12) with F and d of the form

$$F = F_{rr} + F_{rc} F_{cc}^{-1} F_{cr}, \quad d = d_r + F_{rc} F_{cc}^{-1} d_c. \tag{22}$$

Here

$$F_{rr} = B_r S_{rr}^{-1} B_r^T \tag{23}$$

and

$$F_{rc} = B_c - B_r S_{rr}^{-1} S_{rc}, \quad F_{cc} = \bar{S}_{cc} - S_{cr} S_{rr}^{-1} S_{rc},$$

$$d_c = g_c - S_{cr} S_{rr}^{-1} g_r, \quad d_r = B_r S_{rr}^{-1} g_r.$$

In the proof of Theorem 4.1 we will also need two lemmas.

LEMMA 4.2. *For $w \in X_1(\partial\Omega_1) \times \cdots \times X_N(\partial\Omega_N)$ with the same values at the vertices of Ω_i, the following holds:*

$$|\widehat{B}_r^T B_r z|^2_{\widehat{S}_{rr}} \leq C \left(1 + \log \frac{H}{h}\right)^2 |w|^2_S, \tag{24}$$

provided that ρ_i on the mortar side is larger than on the nonmortar side, where $z = w - I_H w$ and $I_H w$ is a linear interpolant of w on edges of $\partial\Omega_i$ with values w at the end points of the edges.

Proof. A proof of this estimate is a modification of the proof of Lemma 1 from [4]. We have

$$|\widehat{B}_r^T B_r z|^2_{\widehat{S}_{rr}} = \langle \widehat{S}_{rr} \widehat{B}_r^T B_r z, \widehat{B}_r^T B_r z \rangle.$$

Hence

$$|\widehat{B}_r^T B_r z|^2_{\widehat{S}_{rr}} = \sum_{i=1}^{N} |\widehat{B}_r^T B_r z|^2_{\widehat{S}^{(i)}}. \tag{25}$$

Note that $\widehat{B}_r^T B_r z = 0$ at the vertices. Using that, we get

$$|\widehat{B}_r^T B_r z|^2_{\widehat{S}^{(i)}} \leq C \left(\sum_{\delta_{m(i)} \subset \partial\Omega_i} |\widehat{B}_r^T B_r z|^2_{\widehat{S}_{\delta_{m(i)}}} + \sum_{\gamma_{m(i)} \subset \partial\Omega_i} |\widehat{B}_r^T B_r z|^2_{\widehat{S}_{\gamma_{m(i)}}} \right), \tag{26}$$

where $\widehat{S}_{\delta_{m(i)}}$ and $\widehat{S}_{\gamma_{m(i)}}$ are matrix representations of the $H^{1/2}_{00}$-norm on $\delta_{m(i)}$ and $\gamma_{m(i)}$, respectively. From the structure of $\widehat{B}_r$ follows

$$|\widehat{B}_r^T B_r z|^2_{\widehat{S}_{\delta_{m(i)}}} \leq 2 \left(\rho_i |z_i|^2_{\widehat{S}_{\delta_{m(i)}}} + \rho_i |B_{ij} z_j|^2_{\widehat{S}_{\delta_{m(i)}}} \right), \tag{27}$$

where here and below $z = \{z_i\}_{i=1}^N \in X^h(\Gamma)$, the restriction of $X^h(\Omega)$ to Γ, $B_{ij} \equiv (B^{(r)}_{\delta_{m(i)}})^{-1} B^{(r)}_{\gamma_{m(j)}}$, and $\delta_{m(i)} = \gamma_{m(j)}, \gamma_{m(j)} \subset \partial\Omega_j$;

$$|\widehat{B}_r^T B_r z|^2_{\widehat{S}_{\gamma_{m(i)}}} \leq 2 \left(\rho_k \left(\frac{\rho_k}{\rho_i}\right)^2 |\widehat{B}_{ki}^T z_k|^2_{\widehat{S}_{\gamma_{m(i)}}} + \rho_k \left(\frac{\rho_k}{\rho_i}\right)^2 |B_{ki}^T \widehat{B}_{ki} z_i|^2_{\widehat{S}_{\gamma_{m(i)}}} \right), \tag{28}$$

where $B_{ki} \equiv (B^{(r)}_{\delta_{m(k)}})^{-1} B^{(r)}_{\gamma_{m(i)}}$, $\widehat{B}_{ki} = \alpha_{ki} B_{ki}$, $\alpha_{ki} = \frac{h_{\delta_{m(k)}}}{h_{\gamma_{m(i)}}}$, $\gamma_{m(i)} = \delta_{m(k)}$, and $\delta_{m(k)} \subset \partial\Omega_k$. We now estimate each term of (27) and (28).

We estimate the first term of (27) as in [4]:

$$\begin{aligned} &\rho_i |z_i|^2_{\widehat{S}_{\delta_{m(i)}}} \leq C \rho_i (1 + \log \tfrac{H}{h})^2 |w_i|^2_{H^{1/2}(\partial\Omega_i)} \\ &\leq C \rho_i (1 + \log \tfrac{H}{h})^2 |w_i|^2_{\widehat{S}^{(i)}} \leq C (1 + \log \tfrac{H}{h})^2 |w_i|^2_{S^{(i)}}. \end{aligned} \tag{29}$$

To estimate the second term of (27) we use the stability of the mortar projection. Let $\pi_{\delta_{m(i)}}(z_j, 0)$ correspond to $B_{ij}(z_{j|\gamma_{m(j)}})$ for z_j restricted to $\gamma_{m(j)}$. Using that, we have

$$\begin{aligned} &\rho_i |B_{ij} z_j|^2_{\widehat{S}_{\delta_{m(i)}}} \leq C \rho_i ||\pi_{\delta_{m(i)}}(z_j, 0)||^2_{H^{1/2}_{00}(\delta_{m(i)})} \\ &\leq C \rho_i ||z_j||^2_{H^{1/2}_{00}(\gamma_{m(j)})} \leq C \rho_i (1 + \log \tfrac{H}{h})^2 |w_j|^2_{\widehat{S}^{(j)}} \leq C (1 + \log \tfrac{H}{h})^2 |w_j|^2_{S^{(j)}}. \end{aligned} \tag{30}$$

We now estimate the terms of (28). It has been shown in [4, proof of Lemma 1 and (28)] that the following holds:

$$|B_{ki}^T z_k|^2_{\widehat{S}_{\gamma_{m(i)}}} \le C|z_k|^2_{\widehat{S}_{\delta_{m(k)}}} \le C(1+\log\tfrac{H}{h})^2|w_k|^2_{\widehat{S}^{(k)}},$$

under the assumption that $h_{\delta_{m(k)}} \sim h_{\gamma_{m(i)}}$. This assumption can be removed by introducing the scaling $\alpha_{ki} = \frac{h_{\delta_{m(k)}}}{h_{\gamma_{m(i)}}}$ in B_{ki}. Thus, this estimate is valid for $\alpha_{ki}B_{ki}$ without assuming that $h_{\delta_{m(k)}} \sim h_{\gamma_{m(i)}}$; for details see the proof of Lemma 1 in [4].

Thus, the first term of (28) can be estimated as

$$\begin{aligned}&\alpha_{ki}^2\rho_k(\tfrac{\rho_k}{\rho_i})^2|B_{ki}^T z_k|^2_{\widehat{S}_{\gamma_{m(i)}}} \le \alpha_{ki}^2\rho_k|B_{ki}^T z_k|^2_{\widehat{S}_{\gamma_{m(i)}}}\\ &\le \rho_k|z_k|^2_{\widehat{S}_{\delta_{m(k)}}} \le C(1+\log\tfrac{H}{h})^2|w_k|^2_{S^{(k)}}.\end{aligned} \tag{31}$$

It remains to estimate the second term of (28). It has been shown in [4, proof of Lemma 1] that the following holds under the assumption that $h_{\delta_{m(k)}} \sim h_{\gamma_{m(i)}}$:

$$|B_{ki}^T B_{ki} z_i|^2_{\widehat{S}_{\gamma_{m(i)}}} \le C\left(1+\log\frac{H}{h}\right)^2 |w_i|^2_{\widehat{S}^{(i)}}.$$

Thus, using the scaling α_{ki} in $\widehat{B}_{ki}$ we get

$$\begin{aligned}&\alpha_{ki}^2\rho_k(\tfrac{\rho_k}{\rho_i})^2|B_{ki}^T B_{ki} z_i|^2_{\widehat{S}_{\gamma_{m(i)}}} \le \alpha_{ki}^2\rho_k|B_{ki}^T B_{ki} z_i|^2_{\widehat{S}_{\gamma_{m(i)}}}\\ &\le C\rho_k(1+\log\tfrac{H}{h})^2|w_i|^2_{\widehat{S}^{(i)}} \le C(1+\log\tfrac{H}{h})^2|w_i|^2_{S^{(i)}},\end{aligned} \tag{32}$$

without the assumption that $h_{\delta_{m(k)}} \sim h_{\gamma_{m(i)}}$.

Substituting these four estimates (29)–(32) into (27)–(28) and the resulting estimates into (26) gives

$$|\widehat{B}_r^T B_r z|^2_{\widehat{S}^{(i)}} \le C\left(1+\log\frac{H}{h}\right)^2 \left(|w_i|^2_{S^{(i)}} + \sum_j |w_j|^2_{S^{(j)}}\right),$$

where the sum is taken over $\partial\Omega_j$, which intersects $\partial\Omega_i$ by an edge. Using this in (25) provides (24). This completes the proof of Lemma 4.2. ∎

LEMMA 4.3. *For F_{rr} defined in* (23) *and $\lambda \in M(\Gamma)$,*

$$C\left(1+\log\frac{H}{h}\right)^{\alpha} \langle M\lambda,\lambda\rangle \le \langle F_{rr}\lambda,\lambda\rangle, \tag{33}$$

where $\alpha = 0$ for a M-N ordering of substructures Ω_l and $\alpha = -2$ in the general case, and C is independent of h, H, and the jumps of ρ_i.

Proof. A proof of this estimate is a modification of the proof of Theorems 2 and 3 from [4]. We first prove it for the M-N ordering of substructures. In this case $\widehat{B}_r$ can be represented as (see (17))

$$\widehat{B}_r = (\widehat{I}_N, -\widehat{B}_M), \tag{34}$$

where $\widehat{I}_N$ and $\widehat{B}_M$ are block diagonal matrices with blocks $\rho_i^{1/2} I_{\delta_{m(i)}}$ and $\alpha_{ij}\frac{\rho_i}{\rho_j}\rho_i^{1/2}(B^{(r)}_{\delta_{m(i)}})^{-1}B^{(r)}_{\gamma_{m(j)}}$, $\alpha_{ij} = \frac{h_{\delta_{m(i)}}}{h_{\gamma_{m(j)}}}$, corresponding to the N (nonmortar) and

M (mortar) substructures Ω_i, respectively. Matrix B_r is decomposed in the same way. For this ordering we can reorder matrices (15) as

$$S_{rr} = \begin{pmatrix} S_{rr}^N & 0 \\ 0 & S_{rr}^M \end{pmatrix}, \quad \widehat{S}_{rr} = \begin{pmatrix} \widehat{S}_{rr}^N & 0 \\ 0 & \widehat{S}_{rr}^M \end{pmatrix}, \tag{35}$$

where the first row corresponds to the nonmortar subregions and $S_{rr}^N = \mathrm{diag}_{i\in N}\{S_{rr}^{(i)}\}$, while the second one corresponds to mortar subregions and $S_{rr}^M = \mathrm{diag}_{i\in M}\{S_{rr}^{(i)}\}$. Then using (34) we can write preconditioner M (see (17)) in the form

$$M^{-1} = \widehat{B}_r \widehat{S}_{rr} \widehat{B}_r^T = S_{rr}^N + \widehat{B}_M \widehat{S}_{rr}^M \widehat{B}_M^T. \tag{36}$$

Note, since both terms are positive definite, that

$$\langle S_{rr}^N \lambda, \lambda\rangle \le \langle M^{-1}\lambda, \lambda\rangle,$$

and as a consequence

$$\langle M\lambda, \lambda\rangle \le \langle (S_{rr}^N)^{-1}\lambda, \lambda\rangle.$$

Using this and

$$\langle S_{rr}^{-1} B_r^T \lambda, B_r^T \lambda\rangle = \langle (S_{rr}^N)^{-1}\lambda, \lambda\rangle + \langle (S_{rr}^M)^{-1} B_M^T \lambda, B_M^T \lambda\rangle,$$

we obtain (see (23))

$$\lambda_{\min}(M^{-1/2} F_{rr} M^{-1/2}) = \min_{\lambda} \frac{\langle S_{rr}^{-1} B_r^T \lambda, B_r^T \lambda\rangle}{\langle M\lambda, \lambda\rangle} \ge 1,$$

which completes the proof for the M-N ordering.

In the case of a general ordering (non–M-N) of substructures, we have

$$\widehat{B}_r = (\widehat{I}_r^{(n)}, -\widehat{B}_r^{(m)}),$$

where $\widehat{I}_r^{(n)}$ and $\widehat{B}_r^{(m)}$ are block diagonal matrices with blocks $\rho_i^{1/2} I_{\delta_{m(i)}}$ and $\alpha_{ij}\frac{\rho_i}{\rho_j}\rho_i^{1/2}(B_{\delta_{m(i)}}^{(r)})^{-1} B_{\gamma_{m(j)}}^{(r)}$ corresponding to the nonmortar and mortar sides, respectively. In this general case matrix (15) is not block diagonal and is of the form

$$S_{rr} = \begin{pmatrix} S_{rr}^{nn} & S_{rr}^{nm} \\ S_{rr}^{mn} & S_{rr}^{mm} \end{pmatrix}, \tag{37}$$

where the first row corresponds to the nonmortar sides and the second to the mortar sides. We introduce an auxiliary matrix

$$\mathrm{diag}\{S_{rr}\} = \begin{pmatrix} S_{rr}^{nn} & 0 \\ 0 & S_{rr}^{mm} \end{pmatrix}. \tag{38}$$

Using the fact that $S_{rr} = S_{rr}^T > 0$ we get

$$\pm \begin{pmatrix} 0 & S_{rr}^{nm} \\ S_{rr}^{mn} & 0 \end{pmatrix} \le \begin{pmatrix} S_{rr}^{nn} & 0 \\ 0 & S_{rr}^{mm} \end{pmatrix},$$

from which follows that for w with zero values at the vertices of Ω_i we have

$$\langle S_{rr} w, w\rangle \le 2\langle \mathrm{diag}\{S_{rr}\} w, w\rangle. \tag{39}$$

Additionally, the following holds (see Lemma 2 in [4]):

$$\langle \mathrm{diag}\{S_{rr}\}w, w\rangle \le C\left(1+\log\frac{H}{h}\right)^2 \langle S_{rr}w, w\rangle. \tag{40}$$

The proof of Lemma 4.3 reduces to showing that

$$\lambda_{\min}(M^{-1/2}F_{rr}M^{-1/2}) = \min_{\lambda}\frac{\langle S_{rr}^{-1}B_r^T\lambda, B_r^T\lambda\rangle}{\langle(\widehat{B}_r\widehat{S}_{rr}\widehat{B}_r^T)^{-1}\lambda,\lambda\rangle} \ge \frac{C}{(1+\log\frac{H}{h})^2}.$$

(This fact has been proved in Lemma 1 of [4] for $\rho_i = 1$; the generalization for $\rho_i \neq 1$ is straightforward.) We have

$$\lambda_{\min}(M^{-1/2}F_{rr}M^{-1/2}) = \min_{\lambda}\frac{\langle F_{rr}\lambda,\lambda\rangle}{\langle M\lambda,\lambda\rangle} = \min_{\lambda}\frac{\langle (S_{rr})^{-1}B_r^T\lambda, B_r^T\lambda\rangle}{\langle(\widehat{B}_r\widehat{S}_{rr}\widehat{B}_r^T)^{-1}\lambda,\lambda\rangle}. \tag{41}$$

Using (40) we obtain the following estimate:

$$\langle S_{rr}^{nn}\lambda,\lambda\rangle = \langle \widehat{S}_{rr}^{nn}\widehat{I}_r^{(n)}\lambda, \widehat{I}_r^{(n)}\lambda\rangle \le \langle \widehat{S}_{rr}^{nn}\widehat{I}_r^{(n)}\lambda, \widehat{I}_r^{(n)}\lambda\rangle + \langle \widehat{S}_{rr}^{mm}(\widehat{B}_r^{(m)})^T\lambda, (\widehat{B}_r^{(m)})^T\lambda\rangle$$

$$= \langle \mathrm{diag}\{\widehat{S}_{rr}\}\widehat{B}_r^T\lambda, \widehat{B}_r^T\lambda\rangle \le C\left(1+\log\frac{H}{h}\right)^2 \langle \widehat{S}_{rr}\widehat{B}_r^T\lambda, \widehat{B}_r^T\lambda\rangle,$$

where $\widehat{I}_r^{(n)} = \rho_i^{1/2} I_{\delta_{m(i)}}$ on $\delta_{m(i)} \subset \partial\Omega_i$. Hence,

$$\langle(\widehat{B}_r\widehat{S}_{rr}\widehat{B}_r^T)^{-1}\lambda,\lambda\rangle \le C\left(1+\log\frac{H}{h}\right)^2 \langle (S_{rr}^{nn})^{-1}\lambda,\lambda\rangle. \tag{42}$$

On the other hand, by (39)

$$\begin{aligned}\langle (S_{rr}^{nn})^{-1}\lambda,\lambda\rangle &\le \langle (S_{rr}^{nn})^{-1}\lambda,\lambda\rangle + \langle (S_{rr}^{mm})^{-1}\lambda,\lambda\rangle \\ &= \langle \mathrm{diag}\{S_{rr}^{-1}\}\lambda,\lambda\rangle \le 2\langle S_{rr}^{-1}\lambda,\lambda\rangle.\end{aligned} \tag{43}$$

Using (42) and (43) in (41) we get

$$\begin{aligned}\lambda_{\min}(M^{-1/2}F_{rr}M^{-1/2}) &\ge \min_{\lambda}\frac{\langle (S_{rr})^{-1}B_r^T\lambda, B_r^T\lambda\rangle}{C(1+\log\frac{H}{h})^2\langle (S_{rr}^{nn})^{-1}\lambda,\lambda\rangle} \\ &\ge \min_{\lambda}\frac{\langle (S_{rr}^{nn})^{-1}\lambda,\lambda\rangle}{C(1+\log\frac{H}{h})^2\langle (S_{rr}^{nn})^{-1}\lambda,\lambda\rangle} = \frac{1}{C(1+\log\frac{H}{h})^2}.\end{aligned}$$

This completes the proof of Lemma 4.3. □

Proof of Theorem 4.1. To prove the right-hand side (RHS) of Theorem 4.1 we proceed as follows. For $-\lambda \in M(\Gamma)$ we compute $w = (w^{(r)}, w^{(c)})$ by solving (19) and (20) with $g_r = 0$ and $g_c = 0$. Note that this problem has a unique solution under the assumption that $u^{(c)}$ is continuous at the cross points. Using this we get

$$\langle F\lambda,\lambda\rangle = \langle (F_{rr} + F_{rc}F_{cc}^{-1}F_{cr})\lambda,\lambda\rangle \tag{44}$$

$$= \langle (B_rS_{rr}^{-1}B_r^T + (B_c - B_rS_{rr}^{-1}S_{rc})F_{cc}^{-1}F_{cr})\lambda,\lambda\rangle = \langle B_rw^{(r)} + B_cw^{(c)},\lambda\rangle = \langle Bw,\lambda\rangle.$$

Let $I_H w$ be a linear interpolant of w on edges with values w at the end points of each edge. Note that

$$Bw = B(w - I_H w) \equiv B_r z_r$$

since $z_r \equiv w - I_H w = 0$ at the end points of the edges. Using that in (44), we get

$$\langle F\lambda, \lambda\rangle = \langle Bw, \lambda\rangle = \langle B_r z_r, \lambda\rangle. \tag{45}$$

On the other hand, using that $Sw = B^T\lambda$ (see (19) and (20)), we have

$$\begin{aligned}\langle Bw, \lambda\rangle &= \frac{\langle Bw, \lambda\rangle^2}{\langle Bw, \lambda\rangle} = \frac{\langle B_r z_r, \lambda\rangle^2}{\langle Sw, w\rangle} \\ &= \frac{\langle M^{1/2}\lambda, M^{-1/2}B_r z_r\rangle^2}{|S^{1/2}w|^2} \le \frac{|M^{1/2}\lambda|^2 |M^{-1/2}B_r z_r|^2}{|w|_S^2}.\end{aligned} \tag{46}$$

Note that by Lemma 4.2 we get

$$|M^{-1/2}B_r z_r|^2 = \langle \widehat{B}_r \widehat{S}_{rr} \widehat{B}_r^T B_r z_r, B_r z_r\rangle = |\widehat{B}_r^T B_r z_r|^2_{\widehat{S}_{rr}} \le C\left(1 + \log\frac{H}{h}\right)^2 |w|_S^2.$$

Substituting this into (46) we have

$$\langle Bw, \lambda\rangle \le C\left(1 + \log\frac{H}{h}\right)^2 |M^{1/2}\lambda|^2.$$

Using this in (45) we get the RHS estimate of (18).

To prove the left-hand side (LHS) of Theorem 4.1 we first note that

$$\langle F\lambda, \lambda\rangle \ge \langle F_{rr}\lambda, \lambda\rangle,\ \lambda \in M(\Gamma) \tag{47}$$

since $F_{cc}^{-1} > 0$. By Lemma 4.3

$$\langle F_{rr}\lambda, \lambda\rangle \ge c_0\left(1 + \log\frac{H}{h}\right)^{\alpha} \langle M\lambda, \lambda\rangle,$$

where $\alpha = 0$ for M-N ordering of substructures and $\alpha = -2$ in the general case. Using this in (47) we get the LHS of (18). ∎

5. Implementation and numerical results. The test example for all our experiments is the weak formulation, see (1), of

$$-\mathrm{div}(\rho(x)\nabla u) = f(x) \text{ in } \Omega, \tag{48}$$

with the homogenous Dirichlet boundary conditions on $\partial\Omega$, where $\Omega = (0,1)\times(0,1)$ is a union of disjoint square subregions Ω_i, $i = 1, \ldots, N$, and $\rho(x) = \rho_i$ is a positive constant in each Ω_i. The diffusion function $\rho(x)$ is chosen larger on the mortar sides of the interfaces; see Theorem 4.1.

The region Ω is cut into N regular subregions. Below we indicate the distribution of 4 coefficients ρ_i and 4 grids h_i in Ω_i, $i = 1, \ldots, 4$ with a maximum mesh ratio 8 : 1 used in our tests (for larger number of subregions, this pattern of coefficients is repeated).

For the M-N subregion ordering test case we have

$$\begin{pmatrix} 1e6 & 1 \\ 1e2 & 1e4 \end{pmatrix}, \quad \begin{pmatrix} h/8 & h \\ h/2 & h/4 \end{pmatrix}. \tag{49}$$

For the arbitrary (other than M-N) ordering of subregions test case we have

$$\begin{pmatrix} 1e6 & 1e4 \\ 1e2 & 1 \end{pmatrix}, \quad \begin{pmatrix} h/8 & h/4 \\ h/2 & h \end{pmatrix}. \tag{50}$$

Additionally, we test a 4×4 subregions case (denoted by * in the tables) that employs coefficients of the following form without a repetitive pattern:

$$\begin{pmatrix} 1e6 & 1 & 1 & 1e3 \\ 1e4 & 1e2 & 1e6 & 1 \\ 1e2 & 1e5 & 1e4 & 1e2 \\ 10 & 1e3 & 10 & 1e6 \end{pmatrix}, \quad \begin{pmatrix} h/8 & h & h & h/4 \\ h/4 & h/2 & h/8 & h \\ h/2 & h/8 & h/4 & h/2 \\ h & h/4 & h/2 & h/8 \end{pmatrix}. \tag{51}$$

5.1. Implementation. The discrete solution u_h^* of (48) is obtained as follows. Random solution at the nodal points is expressed as $(u^{(i)}, u^{(c)}, u^{(r)})$. Mortar condition on each side of the interface $\delta_{m(i)} = \gamma_{m(j)}$ is represented by (7). This gives on $\delta_{m(i)}$

$$u^{(r)}_{i\delta_{m(i)}} = (B^{(r)}_{\delta_{m(i)}})^{-1}(B^{(r)}_{\gamma_{m(j)}} u^{(r)}_{j\gamma_{m(j)}} + B^{(c)}_{\gamma_{m(j)}} u^{(c)}_{j\gamma_{m(j)}} - B^{(c)}_{\delta_{m(i)}} u^{(c)}_{i\delta_{m(i)}}). \tag{52}$$

The solution u_h^* is obtained from $(u^{(i)}, u^{(c)}, u^{(r)})$ by replacing $u^{(r)}$ on each nonmortar side by values computed by (52) and taking into account the continuity at the cross points: $u^{(c)}_{i\delta_{m(i)}} = u^{(c)}_{j\gamma_{m(j)}}$. For the given u_h^* the discrete RHS $(f^{(i)}, f^{(c)}, f^{(r)})$ is then computed.

Since $K_{ic} = 0 = K_{ci}$ in the case of triangular elements and a piecewise linear continuous finite element space, in the numerical experiments we implement somewhat simplified formulas (11):

$$\widetilde{S} = K_{rr} - K_{ri}K_{ii}^{-1}K_{ir} - K_{rc}\widetilde{K}_{cc}^{-1}K_{cr}, \quad \widetilde{f}_r = f^{(r)} - K_{ri}K_{ii}^{-1}f^{(i)} - K_{rc}\widetilde{K}_{cc}^{-1}f^{(c)},$$

$$\widetilde{B} = B_r - B_c\widetilde{K}_{cc}^{-1}K_{cr}, \quad \widetilde{S}_{cc} = -B_c\widetilde{K}_{cc}^{-1}B_c^T, \quad \text{and} \quad \widetilde{f}_c = -B_c\widetilde{K}_{cc}^{-1}f_c.$$

Computing the RHS of the Schur complement system $d = \widetilde{B}\widetilde{S}^{-1}\widetilde{f}_r - \widetilde{f}_c$ (see (13)) is equivalent to solving N coupled Neumann problems (those with Neumann boundary conditions at the interfaces and, if a subregion is adjacent to the boundary of Ω, with zero Dirichlet conditions at $\partial\Omega$) connected through the cross points and with the only nonzero values at the interfaces:

$$\begin{pmatrix} K_{ii} & 0 & K_{ir} \\ 0 & \widetilde{K}_{cc} & K_{cr} \\ K_{ri} & K_{rc} & K_{rr} \end{pmatrix} \begin{pmatrix} v_i \\ v_c \\ v_r \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ \widetilde{f}_r \end{pmatrix}. \tag{53}$$

Note that this step is implemented using the capacitance matrix approach employing solvers on the subregions only. Note also that computing $\widetilde{f}_r$ requires solving N uncoupled Dirichlet problems $K_{ii}w_i = f^{(i)}$. The final result is then multiplied by $\widetilde{B}$ and corrected by $-\widetilde{f}_c$.

The preconditioned conjugate gradient (PCG) iterations to solve (12) are terminated when the norm of the residual has decreased 10^6 times in the norm generated

by the inverse of the preconditioner M^{-1}. In each PCG iteration, there are two main operations:

1. multiplication by $F = \widetilde{B}\widetilde{S}^{-1}\widetilde{B}^T - \widetilde{S}_{cc}$ (see (13)) and
2. multiplication by $M^{-1} = \widehat{B}_r\widehat{S}_{rr}\widehat{B}_r^T$ (see (17)).

Their implementation is as follows.

1. Given the search directions $p_\delta^k \in R^{n_\delta}$ at all nonmortar sides of the interfaces, we compute $r_\delta^k = Fp_\delta^k = (\widetilde{B}\widetilde{S}^{-1}\widetilde{B}^T - \widetilde{S}_{cc})p_\delta^k$ as follows: we first compute $p^k = \widetilde{B}^T p_\delta^k$; then solve for $(v_i, v_c, v_r)^T$ the N coupled Neumann problems connected through the cross points as in (53) but with the RHS $(0, 0, p^k)^T$; and finally compute $r_\delta^k = \widetilde{B}v_r - \widetilde{S}_{cc}p_\delta^k$.

2. Given the residual $r_\delta^k \in R^{n_\delta}$ at all nonmortar sides of the interfaces we compute $z_\delta^k = M^{-1}r_\delta^k = \widehat{B}_r\widehat{S}_{rr}\widehat{B}_r^T r_\delta^k$, where $\widehat{S}_{rr} = \text{ diag } \{\widehat{S}_{rr}^{(j)}\}$, $\widehat{S}_{rr}^{(j)} = S_{rr}^{(j)}$ for $\rho_i = 1$, $S_{rr}^{(j)} = K_{rr}^{(j)} - K_{ri}^{(j)}(K_{ii}^{(j)})^{-1}K_{ir}^{(j)}$ as follows: we compute $z = \widehat{B}_r^T r_\delta^k$; $v_j = (K_{ii}^{(j)})^{-1}K_{ir}^{(j)}z_j$, $z_j = z|_{\partial\Omega_j}$, which is equivalent to solving N uncoupled Dirichlet problems $K_{ii}^{(j)}v_j = K_{ir}^{(j)}z_j$ for v_j; and finally $z_\delta^k = \widehat{B}_r\widetilde{v}$, where $\widetilde{v} = \{\widetilde{v}_j\}$, $\widetilde{v}_j = K_{rr}^{(j)}z - K_{ri}^{(j)}v_j$.

After solving (12) for $\widetilde{\lambda}^*$ the final solution is obtained by solving the N coupled Neumann problems connected through the cross points (see (9))

$$\begin{pmatrix} K_{ii} & 0 & K_{ir} \\ 0 & \widetilde{K}_{cc} & K_{cr} \\ K_{ri} & K_{rc} & K_{rr} \end{pmatrix} \begin{pmatrix} u^{(i)} \\ u^{(c)} \\ u^{(r)} \end{pmatrix} = \begin{pmatrix} f^{(i)} \\ f^{(c)} - B_c^T\widetilde{\lambda}^* \\ f^{(r)} - B_r^T\widetilde{\lambda}^* \end{pmatrix}.$$

All the experiments were performed with the complete scaling of the preconditioner as in (17), including the scaling involving step parameters. In the tables, $\max \frac{H}{h_i}$ is the largest number of mesh steps on each subregion interface, "dim" is the dimension of the reduced (Schur) matrix, "# it" is the number of the PCG iterations, "$\kappa(Q)$" is the condition number estimate of the iteration matrix, and "error" is the normalized L_2 error. In all the examples the max grid ratio is $8:1$. The criterion for choosing $\gamma_{m(i)}$ as the mortar side is that $\rho_i \geq \rho_j$, the coefficients on Ω_i and Ω_j, and, if equal, where the grid is finer, $h_{\gamma_{m(i)}} \leq h_{\delta_{m(j)}}$, unless indicated otherwise.

5.2. Continuous problems. These examples serve as a comparison with the discontinuous problems investigated in further detail.

Table 1 shows that the preconditioner M of (17) employed for the continuous problem and grids (49) (with the M-N ordering of substructures) is well scalable and gives convergence logarithmically dependent on the step sizes. The exhibited dependence $\kappa(Q) = (1+\log(H/h_{\min}))^p$ with about $p = 1$ is better than the theoretical value of $p = 2$.

Table 2 shows the results for the arbitrary ordering on grids (50). Performance results for M-N ordering (Table 1) and for arbitrary ordering (Table 2) are very similar. In the latter case the computed value in the logarithmic dependence also is about $p = 1$, which is superior to the theoretical estimate of $p = 4$.

If one violates the above-mentioned recommendation and chooses $h_{\delta_{m(i)}} < h_{\gamma_{m(j)}}$, then the rate of convergence deteriorates somewhat; compare Table 3 with the upper part of Table 2.

It should be noted that results presented in Tables 1 to 3 are significantly better than those when the standard preconditioner (16) without the scaling involving step parameters is employed.

5.3. Discontinuous problems. For discontinuous problems the standard preconditioner (16) which does not employ scaling of coefficients exhibits poor convergence, often worse than the conjugate gradient iterations without preconditioning. Fortunately, this preconditioner allows for a multitude of scalings to be employed.

It should be pointed out that in the simplest case of M-N ordering of 2×2 subregions with only two grids and two coefficients $\rho_i : 1 = \rho_N < \rho_M$ investigated in [3], the standard preconditioner (16) displayed convergence almost independent of the ratio H/h_i (although the condition number and the number of iterations were quite high).

Several other scalings have been tried and tested. For example, for the M-N ordering as in (49) the preconditioner $M^{-1} = S_{rr}^N + B_M \widehat{S}_{rr}^M {B_M}^T$ gives convergence

almost independent of the ratio H/h_i and the iteration count is a fraction of that obtained with preconditioner (16). However, none of these simple preconditioner scalings is satisfactory in the case of arbitrary (other than M-N) ordering, in which case a scaling that acts only on the nonmortar sides of the interfaces is required.

The preconditioner M of (17) is one of possible choices of such a scaling, and one that is exhibiting good convergence properties both in the continuous case and the discontinuous one, as we shall demonstrate.

Table 4 shows that in the case of M-N ordering of the subregions the preconditioner M gives convergence independent of the step sizes (the ratio H/h_i), the jump of coefficients, and the number of subregions.

Table 5 shows that for arbitrary ordering of subregions convergence is only logarithmically dependent of the step size, independent of the jump of coefficients, and well scalable (independent on the number of subregions). The exhibited logarithmic dependence $\kappa(Q) = (1 + \log(H/h_{\min}))^p$ with $p = 1.8$ is better than the theoretical estimate $p = 4$.

Viewing Tables 1–2 and 4–5 we can compare performances of our preconditioner for continuous and discontinuous problems. For M-N ordering we observe a much faster rate of convergence in the discontinuous case over the continuous one, while for the arbitrary ordering the rates of convergence do not differ significantly.

TABLE 6

Discontinuous coefficients. Performance comparison for arbitrary ordering with a repetitive pattern of grids as in (50) *versus that of nonrepetitive grids as in* (51) *(denoted by *).*

$\max \frac{H}{h_i}$	4×4 subregions			$4 \times 4^*$ subregions

TABLE 7

Discontinuous coefficients. Performance comparison for the random solution versus that of (54) *on arbitrary ordering of subregions* $4 \times 4^*$ *and grids as in* (51).

$\max \frac{H}{h_i}$	Random solution		Solution as in (54)		
	# it	$\kappa(Q)$	# it	$\kappa(Q)$	Error
32	11	4.13	10	4.16	8.57e-5
64	12	4.41	12	4.42	1.74e-5
128	13	4.91	13	5.33	4.04e-6
256	14	5.71	14	6.33	9.73e-7

Table 6 presents the comparison in performance for arbitrary ordering of 4×4 subregions between the case when the pattern of coefficients and grids is repetitive as in (50) and when it is nonrepetitive as in (51). The differences are not pronounced, which allows us to conclude that the results of experiments elsewhere in this paper with larger numbers of subregions give a reasonable representation.

We have also tested problems with extreme variations of coefficients where coefficients, ρ_i in (49) were replaced by

$$\begin{pmatrix} 1e{+}6 & 1e{+}2 \\ 1e{-}2 & 1e{-}6 \end{pmatrix}.$$

The differences in performance were only slight.

For discontinuous problems with large jump of coefficients the question of choosing sides, i.e., $h_{\gamma_{m(j)}} < h_{\delta_{m(i)}}$ versus $h_{\delta_{m(i)}} < h_{\gamma_{m(j)}}$, has virtually no effect on the convergence rate, in contrast with the continuous problems.

The variational formulation of the problem with discontinuities at the interfaces automatically imposes the continuity of the flux condition in the weak sense. The following solution (that is nonzero at the interfaces) was designed to satisfy this condition in the classical sense:

$$u(x,y) = v(x)(1-v(x))v(y)(1-v(y)), \tag{54}$$

$$v(z) = z - \frac{\sin(2m\pi z)}{2m\pi},$$

where $m = 2^k$, $k = 1$ to 4.

Choosing (54) as the exact solution allows us to test the accuracy of our solver. The results in Table 7 show that the accuracy is clearly $O(h^2)$. One needs to stress, however, that the rate of convergence remains virtually the same as with the random solution; see Table 7.

It should be mentioned that a violation of the theoretical requirement that mortar sides should be chosen where the coefficients are larger leads to a very slow convergence when preconditioner M of (17) is used.

The largest tests reported here (16×16 subregions case in Table 5) were run with the dimension of the reduced (Schur) matrix of 30,240 and about 5,500,000 grid points (degrees of freedom) in the whole domain.

6. Conclusions. In this paper we introduced and analyzed a preconditioner with special scaling involving discontinuous coefficients and step parameters, and established convergence bounds.

Extensive computational evidence presented illustrates an excellent performance of the preconditioner: its convergence is almost optimal for a variety of situations (distribution of subregions, grid assignment, grid ratios, number of subregions) and independent of the jumps of coefficients and the parameter of triangulation. This holds for both continuous and discontinuous problems (in the latter case under the theoretical assumption that a mortar side is associated with the higher coefficient).

The experiments using the proposed preconditioner also show that for discontinuous problems the choice of mortar versus nonmortar sides has little influence on convergence rate. The scaling involving step parameters removes the assumption that $h_{\delta_{m(k)}} \sim h_{\gamma_{m(i)}}$ and, for continuous problems, significantly improves the rate of convergence.

Recent experiments show that the method exhibits almost linear parallel scalability properties; see [2].

NUMERICAL METHODS FOR NONCONSERVATIVE HYPERBOLIC SYSTEMS: A THEORETICAL FRAMEWORK.*

CARLOS PARÉS†

Abstract. The goal of this paper is to provide a theoretical framework allowing one to extend some general concepts related to the numerical approximation of 1-d conservation laws to the more general case of first order quasi-linear hyperbolic systems. In particular this framework is intended to be useful for the design and analysis of well-balanced numerical schemes for solving balance laws or coupled systems of conservation laws. First, the concept of path-conservative numerical schemes is introduced, which is a generalization of the concept of conservative schemes for systems of conservation laws. Then, we introduce the general definition of approximate Riemann solvers and give the general expression of some well-known families of schemes based on these solvers: Godunov, Roe, and relaxation methods. Finally, the general form of a high order scheme based on a first order path-conservative scheme and a reconstruction operator is presented.

Key words. nonconservative products, finite volume method, well-balanced schemes, approximate Riemann solvers, Godunov methods, Roe methods, relaxation methods, high order methods

1. Introduction.

The motivating question of this paper was the design of numerical schemes for P.D.E. systems that can be written under the form

$$\partial_t w + \partial_x F(w) = \mathcal{B}(w) \cdot \partial_x w + S(w)\partial_x \sigma, \tag{1}$$

where the unknown $w(x,t)$ takes values on an open convex set D of $\mathbb{R}^N$; F is a regular function from D to $\mathbb{R}^N$; $\mathcal{B}$ is a regular matrix function from D to $\mathcal{M}_{N\times N}(\mathbb{R})$; S, a function from D to $\mathbb{R}^N$; and $\sigma(x)$, a known function from $\mathbb{R}$ to $\mathbb{R}$.

System (1) includes as particular cases: systems of conservation laws ($\mathcal{B} = 0$, $S = 0$), systems of conservation laws with source term or balance laws ($\mathcal{B} = 0$), and coupled system of balance laws as defined in [7].

More precisely, the discretization of the shallow water systems that govern the flow of one shallow layer or two superposed shallow layers of immiscible homogeneous fluids was focused (see http://www.damflow.org). The corresponding systems can be written, respectively, as a balance law or a coupled system of two balance laws. Systems with similar characteristics also appear in other flow models such as two-phase flows.

It is well known that standard methods that solve correctly systems of conservation laws can fail in solving systems of balance laws, specially when approaching equilibria or near to equilibria solutions. Moreover, they can produce unstable methods when they are applied to coupled systems of conservation or balance laws. In the context of the numerical analysis of systems and coupled systems of balance laws, many authors have studied the design of well-balanced schemes, that is, schemes that

†Departamento de Análisis Matemático, Facultad de Ciencias, Universidad de Málaga, 29071-Málaga, Spain (pares@anamat.cie.uma.es).

preserve some equilibria: see [2], [3], [5], [7], [10], [11], [12], [17], [18], [23], [24], [27], [29], [31], [32], [36], [37], [38], [39], ...

Among the main techniques used in the derivation of well-balanced numerical schemes, one of them consists of choosing first a standard conservative scheme for the discretization of the flux terms and then discretizing the source and the coupling terms in order to obtain a consistent scheme which solves correctly a predetermined family of equilibria. If this first procedure is followed, the calculation of the correct discretization of the source and the coupling terms depends both on the specific problem and the conservative numerical scheme chosen, and it may become rather cumbersome. In [11] it was shown that the technique of modified equations can be helpful in this procedure.

Another technique consists of considering (1) as a particular case of one-dimensional quasi-linear hyperbolic system

$$\frac{\partial W}{\partial t} + \mathcal{A}(W)\frac{\partial W}{\partial x} = 0, \quad x \in \mathbb{R}, t > 0, \tag{2}$$

by adding to the system the trivial equation

$$\frac{\partial \sigma}{\partial t} = 0.$$

Once the system is rewritten under this form, piecewise constant approximations of the solutions are considered, then are updated by means of approximate Riemann solvers at the intercells.

If this second procedure is followed, the main difficulty both from the mathematical and the numerical points of view comes from the presence of nonconservative products, which makes difficult even the definition of weak solutions. Many papers have been devoted to the definition and stability of nonconservative products, and its application to the definition of weak solutions of nonconservative hyperbolic systems; see [1], [4], [6], [9], [13], [14], [26], [34], [41].

In this article we assume the definition of nonconservative products as Borel measures given by Dal Maso, LeFloch, and Murat in [14]. This definition, which depends on the choice of a family of paths in the phases space, allows one to give a rigorous definition of weak solutions of (2). Together with the definition of weak solutions, a notion of *entropy* has to be chosen as the usual Lax's concept or one related to an entropy pair. The classical theory of simple waves of hyperbolic systems of conservation laws and the results concerning the solutions of Riemann problems can then be extended to systems (2).

The choice of the family of paths may be, in general, a difficult task. The goal of this article is, once the choice is done, to provide a theoretical framework for the numerical approximation of the corresponding weak solutions of a strictly hyperbolic system (2) whose characteristic fields are either genuinely nonlinear or linearly degenerate.

The organization of the article is as follows: in section 2, a brief resume of the theory developed in [14] is presented, together with some remarks concerning the choice of paths and some properties of weak solutions.

In section 3 we introduce the concept of path-conservative numerical schemes, which is a generalization of that of conservative schemes for systems of conservation laws: a scheme will be said to be path-conservative if it conserves to some extent the Borel measure related to the nonconservative products.

Section 4 is devoted to the well-balance property: we recall the general definition of a well-balanced numerical scheme proposed in [29] and show that the well-balance property of a scheme is strongly related to its ability to approach stationary contact discontinuities.

In section 5, a general definition of approximate Reimann solvers for (2) is presented. We verify that the generalizations of the classical methods of Roe [35] and Godunov [16] presented respectively in [40] and [30] are particular cases of path-conservative methods based on approximate Riemann solvers fitting this general definition. We give also some guidelines about how to construct relaxation schemes.

Section 6 is devoted to high order methods based on reconstruction techniques. The general form of a scheme based on a first order path-conservative scheme and a reconstruction operator is presented. The schemes constructed in [8] are particular cases in which the first order method is of the Roe type. Some general results concerning the order and well-balance properties of these methods are finally presented.

2. Weak solutions. Consider the problem

$$\frac{\partial W}{\partial t} + \mathcal{A}(W)\frac{\partial W}{\partial x} = 0, \quad x \in \mathbb{R},\ t > 0, \tag{3}$$

where $W(x,t)$ belongs to Ω, an open convex subset of $\mathbb{R}^N$, and $W \in \Omega \mapsto \mathcal{A}(W) \in \mathcal{M}_{N\times N}(\mathbb{R})$ is a smooth locally bounded map. We suppose that system (3) is strictly hyperbolic, that is, for each $W \in \Omega$, $\mathcal{A}(W)$ has N real distinct eigenvalues $\lambda_1(W) < \cdots < \lambda_N(W)$, with associated eigenvectors $R_1(W),\ldots,R_N(W)$. We also suppose that for each $i = 1,\ldots,N$, the characteristic field $R_i(W)$ is either genuinely nonlinear,

$$\nabla\lambda_i(W)\cdot R_i(W) \neq 0, \quad \forall\ W \in \Omega,$$

or linearly degenerate,

$$\nabla\lambda_i(W)\cdot R_i(W) = 0, \quad \forall\ W \in \Omega.$$

The theory developed by Dal Maso, LeFloch, and Murat (see [14]) allows one to give a rigorous definition of nonconservative products associated with the choice of a family of paths in Ω.

Definition 2.1. *A* family of paths *in* $\Omega \subset \mathbb{R}^N$ *is a locally Lipschitz map*

$$\Phi\colon [0,1]\times\Omega\times\Omega \mapsto \Omega,$$

such that:

- $\Phi(0;W_L,W_R) = W_L$ *and* $\Phi(1;W_L,W_R) = W_R$*, for any* $W_L, W_R \in \Omega$*;*
- *for every arbitrary bounded set* $\mathcal{O} \subset \Omega$*, there exists a constant* k *such that*

$$\left|\frac{\partial\Phi}{\partial s}(s;W_L,W_R)\right| \leq k|W_R - W_L|,$$

for any $W_L, W_R \in \mathcal{O}$ *and almost every* $s \in [0,1]$*;*

- *for every bounded set* $\mathcal{O} \subset \Omega$*, there exists a constant* K *such that*

$$\left|\frac{\partial\Phi}{\partial s}(s;W_L^1,W_R^1) - \frac{\partial\Phi}{\partial s}(s;W_L^2,W_R^2)\right| \leq K(|W_L^1 - W_L^2| + |W_R^1 - W_R^2|),$$

for any $W_L^1, W_R^1, W_L^2, W_R^2 \in \mathcal{O}$ *and almost every* $s \in [0,1]$.

Suppose that a family of paths Φ in Ω has been chosen. Then, for $W \in (L^\infty(\mathbb{R} \times \mathbb{R}^+) \cap BV(\mathbb{R} \times \mathbb{R}^+))^N$, the nonconservative product can be interpreted as a Borel measure denoted by $[\mathcal{A}(W)W_x]_\Phi$. If the family of segments is chosen, this interpretation is equivalent to the definition of nonconservative product proposed by Volpert in [41].

Across a discontinuity with speed ξ a weak solution must satisfy the generalized Rankine–Hugoniot condition

$$\int_0^1 \big(\xi\mathcal{I} - \mathcal{A}(\Phi(s; W^-, W^+))\big)\frac{\partial \Phi}{\partial s}(s; W^-, W^+)\, ds = 0, \tag{4}$$

where $\mathcal{I}$ is the identity matrix and W^-, W^+ are the left and right limits of the solution at the discontinuity. In the particular case of a system of conservation laws (that is, if $\mathcal{A}(W)$ is the Jacobian matrix of some flux function $F(W)$), (4) is independent of the family of paths and it reduces to the usual Rankine–Hugoniot condition.

As it occurs in the conservative case, not every discontinuity is admissible. Therefore, a concept of entropic solution has to be assumed, as one of the following definitions.

DEFINITION 2.2. *A weak solution is said to be an entropic solution in the Lax sense if, at each discontinuity, there exists $i \in \{1, \dots, N\}$ such that*

$$\lambda_i(W^+) < \xi < \lambda_{i+1}(W^+) \quad \textit{and} \quad \lambda_{i-1}(W^-) < \xi < \lambda_i(W^-)$$

if the ith characteristic field is genuinely nonlinear or

$$\lambda_i(W^-) = \xi = \lambda_i(W^+)$$

if the ith characteristic field is linearly degenerate.

DEFINITION 2.3. *Given an entropy pair (η, G) for (3), i.e., a pair of regular functions from Ω to $\mathbb{R}$ such that*

$$\nabla G(W) = \nabla \eta(W) \cdot \mathcal{A}(W), \quad \forall\ W \in \Omega,$$

a weak solution is said to be entropic if it satisfies the inequality

$$\partial_t \eta(W) + \partial_x G(W) \le 0,$$

in the distributions sense.

The choice of the family of paths is important as it determines the speed of propagation of discontinuities. For scalar balance laws, rigorous justifications of the choice of the family of paths can be given using different techniques based on weak limits; see [19], [20]. In general, this choice has to be based on the physical background (see [25], [33] for instance). In any case, it is natural from the mathematical point of view to require this family to satisfy some hypotheses concerning the relation of the paths with the integral curves of the characteristic fields. Following [30], here we will assume that the family of paths satisfies the following hypotheses:

(H1) Given two states, W_L and W_R, belonging to the same integral curve γ of a linearly degenerate field, the path $\Phi(s; W_L, W_R)$ is a parameterization of the arc of γ linking W_L and W_R.

(H2) Given two states, W_L and W_R, belonging to the same integral curve γ of a genuinely nonlinear field, R_i, such that $\lambda_i(W_L) < \lambda_i(W_R)$, the path $\Phi(s; W_L, W_R)$ is a parameterization of the arc of γ linking W_L and W_R.

(H3) Let us denote by $\mathcal{RP} \subset \Omega \times \Omega$ the set of pairs (W_L, W_R) such that the Riemann problem

$$\left\{ \begin{array}{l} \dfrac{\partial W}{\partial t} + \mathcal{A}(W)\dfrac{\partial W}{\partial x} = 0, \\ \\ W(x,0) = \left\{ \begin{array}{ll} W_L & \text{if } x < 0, \\ \\ W_R & \text{if } x > 0, \end{array} \right. \end{array} \right. \tag{5}$$

has a unique self-similar solution $W(x,t) = V(x/t; W_L, W_R)$ (where the function V is piecewise regular) composed by at most N simple waves: rarefaction waves, contact discontinuities, or shocks (i.e., discontinuities satisfying the jump condition (4) and the entropy condition given by Definition 2.2 or 2.3). These simple waves connect $J+1$ intermediate states

$$W_0 = W_L; W_1, \ldots, W_{J-1}; W_J = W_R;$$

with $J \leq N$. We assume that, given two states $(W_L, W_R) \in \mathcal{RP}$, the curve described by the path $\Phi(s; W_L, W_R)$ in Ω is equal to the union of those corresponding to the paths $\Phi(s; W_j, W_{j+1})$, $j = 0, \ldots, J-1$.

If the definition of weak solutions of (3) is based on a family of paths satisfying these hypotheses, the following natural properties hold (see [30]).

PROPOSITION 2.4. *Let us suppose that the concept of weak solutions of* (3) *is defined on the basis of a family of paths satisfying hypotheses* (H1)–(H3). *Then*

(i) *Given two states W_L and W_R belonging to the same integral curve of a linearly degenerate field, the contact discontinuity given by*

$$W(x,t) = \left\{ \begin{array}{ll} W_L & \text{if } x < \sigma t, \\ W_R & \text{if } x > \sigma t, \end{array} \right.$$

where σ is the (constant) value of the corresponding eigenvalue through the integral curve, is a weak solution of (3).

(ii) *Let (W_L, W_R) be a pair belonging to $\mathcal{RP}$ and let W be the solution of the corresponding Riemann problem* (5). *The following equality holds:*

$$\left\langle \left[\mathcal{A}(W(\cdot,t))W_x(\cdot,t)\right]_\Phi, 1 \right\rangle = \int_0^1 \mathcal{A}\left(\Phi(s; W_L, W_R)\right) \frac{\partial \Phi}{\partial s}(s; W_L, W_R)\, ds.$$

Consequently, the total mass of the Borel measure $\left[\mathcal{A}(W(\cdot,t))W_x(\cdot,t)\right]_\Phi$ does not depend on t.

(iii) *Let (W_L, W_R) be a pair belonging to $\mathcal{RP}$ and let W_j be any of the intermediate states appearing in the solution of the Riemann problem* (5). *Then*

$$\begin{aligned} &\int_0^1 \mathcal{A}\left(\Phi(s; W_L, W_R)\right) \frac{\partial \Phi}{\partial s}(s; W_L, W_R)\, ds \\ &\quad = \int_0^1 \mathcal{A}\left(\Phi(s; W_L, W_j)\right) \frac{\partial \Phi}{\partial s}(s; W_L, W_j)\, ds \\ &\quad + \int_0^1 \mathcal{A}\left(\Phi(s; W_j, W_R)\right) \frac{\partial \Phi}{\partial s}(s; W_j, W_R)\, ds. \end{aligned}$$

Some general guidelines to construct a family of paths satisfying these hypotheses (at least for pairs $(W_L, W_R) \in \mathcal{RP}$) have been presented in [30].

In the following proposition we establish a property of the solution of a Riemann problem that will be of importance in the definition of generalized approximate Riemann solvers for (3).

PROPOSITION 2.5. *Given $(W_L, W_R) \in \mathcal{RP}$, the solution $W(x,t) = V(x/t; W_L, W_R)$ of the Riemann problem* (5) *satisfies the following equality:*

$$\int_0^1 \mathcal{A}\left(\Phi(s; W_L, W_R)\right) \frac{\partial \Phi}{\partial s}(s; W_L, W_R)\, ds + \int_0^\infty \left(V(v; W_L, W_R) - W_R\right)\, dv + \int_{-\infty}^0 \left(V(v; W_L, W_R) - W_L\right)\, dv = 0. \tag{6}$$

Proof. Let A, T be two positive numbers such that

$$V(x/T; W_L, W_R) = W_L, \quad \text{if } x < -A,$$
$$V(x/T; W_L, W_R) = W_R, \quad \text{if } x > A.$$

Integrating (3) in $[-A, A] \times [0, T]$, we obtain

$$\int_{-A}^{A} V(x/T; W_L, W_R)\, dx - AW_L - AW_R + \int_0^T \left\langle \left[\mathcal{A}(W(\cdot,t))W_x(\cdot,t)\right]_\Phi, 1 \right\rangle\, dt = 0.$$

Then (6) is easily obtained by taking into account (ii) of Proposition 2.4 and making the change of variables $v = x/T$ in the integral at the right-hand side. ∎

Remark 1. If the concept of entropic solution is related to an entropy pair (η, G) with convex η, the following inequality can also be proved for the solution of a Riemann problem:

$$G(W_R) + \int_0^\infty \left(\eta\big(V(v; W_L, W_R)\big) - \eta(W_R)\right)\, dv \le G(W_L) - \int_{-\infty}^0 \left(\eta\big(V(v; W_L, W_R)\big) - \eta(W_L)\right)\, dv. \tag{7}$$

The proof is identical to that corresponding to systems of conservation laws.

3. Path-conservative numerical schemes. The central concept of the theory developed in this article is that of *path-conservative* numerical scheme, which is a generalization of conservative schemes for systems of conservation laws. We recall that, given a system of conservation laws

$$\partial_t W + \partial_x F(W) = 0, \quad x \in \mathbb{R},\ t > 0, \tag{8}$$

the expression of a conservative numerical scheme is as follows:

$$W_i^{n+1} = W_i^n + \frac{\Delta t}{\Delta x}\left(G_{i-1/2} - G_{i+1/2}\right), \tag{9}$$

where Δt and Δx are the time step and the space step, which are supposed to be constant for simplicity; W_i^n represents the approximation of the average of the exact solution at the ith cell $I_i = [x_{i-1/2}, x_{i+1/2}]$ at time $t^n = n\Delta t$,

$$W_i^n \cong \frac{1}{\Delta x} \int_{x_{i-1/2}}^{x_{i+1/2}} W(x, t^n)\, dx,$$

and $G_{i+1/2} = G(W^n_{i-q}, \dots, W^n_{i+p})$ is the numerical flux at the intercell $x_{i+1/2}$,

$$G_{i+1/2} \cong \frac{1}{\Delta t} \int_{t^n}^{t^{n+1}} F(W(x_{i+1/2}, t))\, dt. \tag{10}$$

This expression is usually motivated as follows: a weak solution of (8) satisfies the equality

$$\int_a^b W(x, t_1)\, dx = \int_a^b W(x, t_0)\, dx + \int_{t_0}^{t_1} F(W(a, t))\, dt - \int_{t_0}^{t_1} F(W(b, t))\, dt, \tag{11}$$

for every rectangle $[a, b] \times [t_0, t_1]$ in $\mathbb{R} \times [0, \infty)$, and (9) is the discrete analogue of the equality (11) corresponding to the rectangle $I_i \times [t^n, t^{n+1}]$.

Let us give a reinterpretation of (9) in terms of measures in order to motivate its generalization to nonconservative problems. A weak solution can be understood as a function that satisfies the equality (8) in the sense of distributions. In the particular case of a piecewise regular weak solution, given $t > 0$ the distribution $[F(W(\cdot, t))_x]$ is defined by

$$\begin{aligned} \langle [F(W(\cdot, t))_x], \phi \rangle &= \int_{\mathbb{R}} F(W(x, t))_x \phi(x)\, dx \\ &\quad + \sum_l \left(F(W_l^+) - F(W_l^-) \right) \phi(x_l(t)), \quad \forall\ \phi \in \mathcal{D}(\mathbb{R})^N, \end{aligned} \tag{12}$$

where the derivative appearing in the integral term has to be understood in the pointwise sense; the index l of the sum runs in the number of discontinuities appearing in the solution; $x_l(t)$ is the location at time t of the lth discontinuity; W_l^- and W_l^+ the limits of the solution to the left and right of the lth discontinuity at time t; finally, $\mathcal{D}(\mathbb{R})$ represents the set of functions of class $\mathcal{C}^\infty(\mathbb{R})$ with compact support. The distribution $[F(W(\cdot, t))_x]$ can be interpreted as a Borel measure having the Lebesgue decompostion $\mu_a + \mu_s$, where μ_a is given by

$$\mu_a(E) = \int_E F(W(x, t))_x\, dx,$$

for every Borel set E, and

$$\mu_s = \sum_l \left(F(W_l^+) - F(W_l^-) \right) \delta_{x = x_l(t)}, \tag{13}$$

being $\delta_{x=a}$ the Dirac measure placed at $x = a$. Given a Borel set E, we will denote its measure by

$$\langle [F(W(\cdot, t))_x], 1_E \rangle.$$

Using this notation, (11) can be rewritten as follows:

$$\int_a^b W(x, t_1)\, dx = \int_a^b W(x, t_0)\, dx - \int_{t_0}^{t_1} \left\langle [F(W(\cdot, t))_x], 1_{[a,b]} \right\rangle\, dt. \tag{14}$$

If we now define the piecewise constant function W^n whose value at the cell I_i is the approximation W_i^n, the discrete analogue of (14) would be

$$W_i^{n+1} = W_i^n - \frac{\Delta t}{\Delta x} \langle [F(W^n)_x], 1_{I_i} \rangle, \tag{15}$$

but this equality is not equivalent to (9): notice that the measure $[F(W^n)_x]$ consists only of its singular part

$$\sum_i \left(F(W_{i+1}^n) - F(W_i^n)\right) \delta_{x=x_{i+1/2}},$$

and that the cells I_i have been defined as closed intervals. Therefore, in (15) the punctual mass placed at $x_{i+1/2}$ contribute both to cells I_i and I_{i+1}. In this sense, the conservative numerical scheme (9) can be interpreted as follows: $G_{i+1/2}$ can be considered as an *intermediate flux* that is used to split the Dirac measures placed at the intercells

$$\begin{aligned}\left(F(W_{i+1}^n) - F(W_i^n)\right) \delta_{x=x_{i+1/2}} &= \left(F(W_{i+1}^n) - G_{i+1/2}\right) \delta_{x=x_{i+1/2}} \\ &+ \left(G_{i+1/2} - F(W_i^n)\right) \delta_{x=x_{i+1/2}},\end{aligned}$$

and then, the first summand contributes to cell I_{i+1} and the second one to I_i, i.e.,

$$W_i^{n+1} = W_i^n - \frac{\Delta t}{\Delta x}\left((F(W_i^n) - G_{i-1/2})) + (G_{i+1/2} - F(W_i^n))\right), \tag{16}$$

which is obviously equivalent to (9).

Let us now come back to nonconservative systems (3) and suppose that a family of paths Φ has been chosen to define the weak solutions. If W is again a piecewise regular weak solution, for a given time t the Borel measure related to the nonconservative product is defined as follows:

$$\begin{aligned}\langle [\mathcal{A}(W(\cdot,t))W_x(\cdot,t)]_\Phi, \phi\rangle &= \int_{\mathbb{R}} \mathcal{A}(W(x,t))W_x(x,t)\phi(x)\,dx \\ &+ \sum_l \left(\int_0^1 \mathcal{A}(\Phi(s;W_l^-,W_l^+))\frac{\partial\Phi}{\partial s}(s;W_l^-,W_l^+)\,ds\right)\phi(x_l(t)), \\ &\forall\,\phi\in\mathcal{C}_0(\mathbb{R}),\end{aligned} \tag{17}$$

which is obviously a generalization of (12). In the above equality, the expression W_x appearing in the first integral represents again the pointwise derivative of $W(\cdot,t)$; $x_l(t)$, W_l^-, W_l^+ are like in (12); and $\mathcal{C}_0(\mathbb{R})$ is the set of continuous maps with compact support.

Notice that again this measure can be decomposed as a sum $\mu_a^\Phi + \mu_s^\Phi$ where

$$\mu_a^\Phi(E) = \int_E \mathcal{A}(W(x,t))W_x(x,t)\,dx$$

for every Borel set E, and:

$$\mu_s^\Phi = \sum_l \left(\int_0^1 \mathcal{A}(\Phi(s;W_l^-,W_l^+))\frac{\partial\Phi}{\partial s}(s;W_l^-,W_l^+)\,ds\right)\delta_{x=x_l(t)}. \tag{18}$$

Given a rectangle $[a,b]\times[t_0,t_1]$ in $\mathbb{R}\times[0,\infty)$, a weak solution of (3) satisfies the equality

$$\int_a^b W(x,t_1)\,dx = \int_a^b W(x,t_0)\,dx - \int_{t_0}^{t_1} \langle [\mathcal{A}(W(\cdot,t))W_x(\cdot,t)]_\Phi, 1_{[a,b]}\rangle\,dt \tag{19}$$

that generalizes (11).

The discrete analogue of (19) is now

$$W_i^{n+1} = W_i^n - \frac{\Delta t}{\Delta x}\langle [\mathcal{A}(W^n)W_x^n]_\Phi \, , 1_{I_i}\rangle, \tag{20}$$

where, again, W^n is the piecewise constant function taking the value W_i^n at cell I_i. Newly, the measure $[\mathcal{A}(W^n)W_x^n]_\Phi$ consists only of its singular part,

$$\sum_i \left(\int_0^1 \mathcal{A}(\Phi(s; W_i^n, W_{i+1}^n)) \frac{\partial \Phi}{\partial s}(s; W_i^n, W_{i+1}^n)\, ds \right) \delta_{x=x_{i+1/2}}.$$

Therefore, the punctual masses placed at the intercells have to be decomposed into two terms $D_{i+1/2}^{\pm}$, one contributing to the cell I_i and the other to the cell I_{i+1}. This idea leads to the following definition.

DEFINITION 3.1. *Given a family of paths Ψ, a numerical scheme is said to be Ψ-conservative if it can be written under the form*

$$W_i^{n+1} = W_i^n - \frac{\Delta t}{\Delta x}\big(D_{i-1/2}^+ + D_{i+1/2}^-\big), \tag{21}$$

where

$$D_{i+1/2}^{\pm} = D^{\pm}(W_{i-q}^n, \dots, W_{i+p}^n),$$

D^- and D^+ being two continuous functions from Ω^{p+q+1} to Ω satisfying:

$$D^{\pm}(W, \dots, W) = 0, \quad \forall\ W \in \Omega, \tag{22}$$

and

$$\begin{aligned} &D^-(W_{-q}, \dots, W_p) + D^+(W_{-q}, \dots, W_p) \\ &\qquad = \int_0^1 \mathcal{A}(\Psi(s; W_0, W_1)) \frac{\partial \Psi}{\partial s}(s; W_0, W_1)\, ds, \end{aligned} \tag{23}$$

for every $W_i \in \Omega$, $i = -q, \dots, p$.

This definition generalizes the usual concept of a conservative numerical scheme for a system of conservation laws:

PROPOSITION 3.2. *Let us suppose that (3) is a system of conservation laws, i.e., $\mathcal{A}$ is the Jacobian of a flux function F. Then, every numerical scheme which is Ψ-conservative for some family of paths Ψ is consistent and conservative in the usual sense. Conversely, a consistent conservative numerical scheme is Ψ-conservative for every family of paths Ψ.*

Proof. Observe first that, in the case of a conservative system, (23) reduces to

$$D^-(W_{-q}, \dots, W_p) + D^+(W_{-q}, \dots, W_p) = F(W_1) - F(W_0).$$

Therefore, given a Ψ-conservative numerical scheme (21) we can define a numerical flux function G as follows:

$$\begin{aligned} G(W_{-q}, \dots, W_p) &= D^-(W_{-q}, \dots, W_p) + F(W_0) \\ &= -D^+(W_{-q}, \dots, W_p) + F(W_1). \end{aligned} \tag{24}$$

Then, (21) is equivalent to the conservative scheme (9) corresponding to the numerical flux G. Moreover, from (22) we easily deduce

$$G(W,\dots,W) = F(W).$$

Conversely, given a consistent conservative numerical scheme with numerical flux function G, it can be written under the form (21) by defining

$$\begin{aligned} D^-(W_{-q},\dots,W_p) &= G(W_{-q},\dots,W_p) - F(W_0),\\ D^+(W_{-q},\dots,W_p) &= -G(W_{-q},\dots,W_p) + F(W_1). \end{aligned}$$

It can be easily verified that (22) and (23) are satisfied for every family of paths Ψ. □

Remark 2. According to Proposition 3.2, a path-conservative numerical scheme applied to a conservative problem is just a conservative scheme formulated in the so-called *wave propagation form* (see [28]). It is important to notice that, in despite of its form, a path-conservative numerical scheme (21) is not a *nonconservative numerical scheme* in the usual sense: a numerical scheme for solving a *conservative problem* is said to be nonconservative if it cannot be written under the form (9).

Notice that condition (23) plays a double role. On the one hand, it is used to approximate the punctual masses associated to discontinuities. On the other hand, together with (22), it is a consistency requirement for regular solutions and smooth data. In effect, if W is a regular enough solution and $\mathcal{A}(W)$, $D^{\pm}(W_{-q},\dots,W_p)$ are also regular, from (22) and (23) it can be deduced that

$$\begin{aligned} &\frac{1}{\Delta x}\big(D^+(W(x_{i-q-1},t),\dots,W(x_{i+p-1},t)) + D^-(W(x_{i-q},t),\dots,W(x_{i+p},t))\big)\\ &\qquad = \mathcal{A}(W(x_i,t))W_x(x_i,t) + O(\Delta x). \end{aligned}$$

Path-conservative numerical schemes satisfy a certain *conservation* property. In effect, let W be a weak solution of (3) corresponding to an initial condition W_0 such that

$$W_0(x) = W_L, \quad \forall\ x < -A; \quad W_0(x) = W_R, \quad \forall\ x > A; \tag{25}$$

for some $A > 0$. Given $0 \le t_0 < t_1 < \infty$, W satisfies

$$\int_{\mathbb{R}} \big(W(x,t_1) - W(x,t_0)\big)\,dx = -\int_{t_0}^{t_1} \langle [\mathcal{A}(W(\cdot,t))W_x(\cdot,t)]_\Phi, 1\rangle\,dt. \tag{26}$$

Let us suppose now that a Ψ-conservative scheme is applied to approach this solution and let W^n be the piecewise constant function whose value at the cell I_i is W_i^n. Summing up in (21) and taking into account (17) and (23), we deduce the equality

$$\int_{\mathbb{R}} \big(W^{n+1}(x) - W^n(x)\big)\,dx = -\Delta t\,\langle [\mathcal{A}(W^n)W_x^n]_\Psi, 1\rangle, \tag{27}$$

which is clearly an approximation of (26).

As it was remarked in [29] in the context of Roe schemes, the best choice of the family of paths Ψ appearing in Definition 3.1 is the family Φ selected for the definition of weak solutions: in this case, (26) and (27) makes reference to the same

Borel measure and the jump conditions of weak solutions and numerical solutions are consistent.

In fact, a Lax–Wendroff theorem can be conjectured: if the numerical solutions obtained with a Ψ-conservative converge in an adequate sense, its limit has to be a weak solution whose definition is also related to the family of paths Ψ.

We stress that such a theorem would not be in contradiction with the negative results shown in [22] or [15]; in these works the failure of the convergence of nonconservative schemes to weak solutions of *conservative* problems was studied. But in our case, if the system is conservative, a path-conservative numerical scheme is not a nonconservative scheme (see Remark 2). Nevertheless, this kind of negative results are also expectable if a path-conservative numerical scheme based on a family Ψ is used to approach weak solutions based on a different family of paths Φ: in that case, the consistency for smooth solutions is still provided by (22) and (23) but discontinuities can be incorrectly treated. In fact, a negative result of this type was observed in [29] in the context of the approximation of shallow water systems with source term.

Unfortunately, the construction of Φ-conservative schemes can be difficult or very costly in practice. In this case, a simpler family of paths Ψ has to be chosen, as the family of segments:

$$\Psi(s; W_L, W_R) = W_L + s(W_R - W_L). \tag{28}$$

4. Well-balancing. Well-balancing is related to the numerical approximation of equilibria, i.e., steady state solutions. Notice that system (3) can only have nontrivial steady state solutions if it has some linearly degenerate fields; let $W(x)$ be a regular steady state solution

$$\mathcal{A}(W(x)) \cdot W'(x) = 0 \quad \forall\, x \in \mathbb{R}.$$

If $W'(x) \neq 0$, then 0 is an eigenvalue of $\mathcal{A}(W(x))$ and $W'(x)$ is an associated eigenvector. Therefore, $x \mapsto W(x)$ can be interpreted as a parameterization of an integral curve of a linearly degenerate characteristic field whose corresponding eigenvalue takes the value 0 through the curve. In order to define the concept of well-balancing, let us introduce the set Γ of all the integral curves γ of a linearly degenerate field of $\mathcal{A}(W)$ such that the corresponding eigenvalue vanishes on Γ. According to [29] we introduce the following definitions.

Definition 4.1. *Given a curve $\gamma \in \Gamma$, a numerical scheme for solving* (3)

$$W_j^{n+1} = W_j^n + \frac{\Delta t}{\Delta x} H(W_{j-q}^n, \dots, W_{j+p}^n) \tag{29}$$

is said to be exactly well-balanced for γ if, given any $\mathcal{C}^1$ function $x \in (\alpha, \beta) \subset \mathbb{R} \mapsto W(x) \in \Omega$ such that

$$W(x) \in \gamma, \quad \forall\, x \in (\alpha, \beta), \tag{30}$$

and $p + q + 1$ points in (α, β) $x_{-q}, \dots, x_p$ such that

$$x_{-q} < \cdots < x_p; \quad x_{i+1} - x_i = \Delta x,\ i = -q, \dots, p-1, \tag{31}$$

then

$$H(W(x_{-q}), \dots, W(x_p)) = 0. \tag{32}$$

The scheme is said to be well-balanced with order k for γ if, given any $\mathcal{C}^{k+1}$ function W and any set of points $\{x_{-q}, \dots, x_p\}$ satisfying (30), (31), *then*

$$|H(W(x_{-q}), \dots, W(x_p))| = O\left(\Delta x^{k+1}\right). \tag{33}$$

Finally, the scheme is said to be exactly well-balanced or well-balanced with order k if these properties are satisfied for any curve of Γ.

We have only considered 1-level schemes and uniform meshes in order to avoid an excess of notation, but the definition can be easily extended to more general schemes.

The well-balance property of a scheme is strongly related to its ability to approximate stationary contact discontinuities. We can state for instance the following proposition.

PROPOSITION 4.2. *Given a numerical scheme of the form* (21) *with $q = 0$ and $p = 1$ and a curve γ of Γ, the numerical scheme is exactly well-balanced for γ if and only if it solves exactly every stationary contact discontinuity linking two states belonging to γ.*

Proof. Both properties are satisfied if and only if

$$D^{\pm}(W_0, W_1) = 0, \quad \forall\, W_0, W_1 \in \gamma. \qquad \square$$

Remark 3. For numerical schemes with arbitrary values of p and q the direct implication of the proposition is also valid. To see this, observe first that a numerical scheme is exactly well-balanced for γ if and only if

$$H(W_{-q}, \dots, W_p) = 0,$$

for any given *ordered* set of states $\{W_{-q}, \dots, W_p\}$ of γ, where some of the states can be repeated. Then it can be easily shown that this property implies that the numerical scheme solves exactly stationary contact discontinuities linking two states belonging to γ.

5. Approximate Riemann solvers. This section is devoted to generalize the notion of approximate Riemann solvers introduced in [21] for conservative systems (8) and extended in [5] for balance laws. The organization of this section closely follows Bouchut's book.

DEFINITION 5.1. *Given a family of paths Ψ, a Ψ-approximate Riemann solver for* (3) *is a function $\widetilde{V} : \mathbb{R} \times \Omega \times \Omega \mapsto \Omega$ satisfying the following:*

(i) *for every $W \in \Omega$,*

$$\widetilde{V}(v; W, W) = W \quad \forall\, v \in \mathbb{R}; \tag{34}$$

(ii) *for every W_L, $W_R \in \Omega$ there exist $\lambda_{min}(W_L, W_R)$, $\lambda_{max}(W_L, W_R)$ in $\mathbb{R}$ such that,*

$$\widetilde{V}(v; W_L, W_R) = W_L, \quad \text{if } v < \lambda_{min}(W_L, W_R),$$
$$\widetilde{V}(v; W_L, W_R) = W_R, \quad \text{if } v > \lambda_{max}(W_L, W_R);$$

(iii) *for every $W_L, W_R \in \Omega$,*

$$\begin{aligned} &\int_0^1 \mathcal{A}\left(\Psi(s; W_L, W_R)\right) \frac{\partial \Psi}{\partial s}(s; W_L, W_R)\, ds \\ &\quad + \int_0^{\infty} \left(\widetilde{V}(v; W_L, W_R) - W_R\right) dv \\ &\quad + \int_{-\infty}^0 \left(\widetilde{V}(v; W_L, W_R) - W_L\right) dv = 0. \end{aligned} \tag{35}$$

Notice that (35) is a generalization of the property (6) satisfied by the exact solution of a Riemann problem (5).

Given a Ψ-approximate Riemann solver for (3) a numerical scheme can be constructed as follows:

$$W_i^{n+1} = \frac{1}{\Delta x}\left(\int_{x_{i-1/2}}^{x_i} \widetilde{V}\left(\frac{x - x_{i-1/2}}{\Delta t}; W_{i-1}^n, W_i^n\right) dx + \int_{x_i}^{x_{i+1/2}} \widetilde{V}\left(\frac{x - x_{i+1/2}}{\Delta t}; W_i^n, W_{i+1}^n\right) dx\right). \tag{36}$$

Under a CFL condition 1/2, the numerical scheme can also be written under the form (21) with

$$D_{i+1/2}^- = -\int_{-\infty}^{0} \left(\widetilde{V}(v; W_i^n, W_{i+1}^n) - W_i^n\right) dv, \tag{37}$$

$$D_{i+1/2}^+ = -\int_{0}^{\infty} \left(\widetilde{V}(v; W_i^n, W_{i+1}^n) - W_{i+1}^n\right) dv. \tag{38}$$

PROPOSITION 5.2. *A numerical scheme* (21) *based on a* Ψ*-approximate Riemann solver is* Ψ*-conservative.*

Proof. The proof is straightforward from (37), (38), and Definition 5.1. ∎

Remark 4. If the numerical scheme is intended to solve only weak solutions with *small* discontinuities, i.e., discontinuities linking pairs of states (W_L, W_R) belonging to $\mathcal{RP}$, then it is enough for the approximate Riemann solver $\widetilde{V}$ to be defined in $\mathbb{R} \times \mathcal{RP}$.

A numerical scheme (21) based on a Ψ-approximate Riemann solver is well-balanced for a curve γ of the set Γ, if and only if, given two states W_L and W_R in γ the following equalities hold:

$$\int_{-\infty}^{0} \left(\widetilde{V}(v; W_L, W_R) - W_L\right) dv = 0,$$
$$\int_{0}^{\infty} \left(\widetilde{V}(v; W_L, W_R) - W_R\right) dv = 0.$$

These equalities are trivially satisfied if

$$\widetilde{V}(v; W_L, W_R) = \begin{cases} W_L & \text{if } v < 0, \\ W_R & \text{if } v > 0, \end{cases}$$

i.e., if the approximate Riemann solver is exact for pairs of states (W_L, W_R) belonging to γ.

We recall hereafter some classical choices of approximate Riemann solvers.

5.1. Godunov methods. Godunov methods correspond to the choice of the exact Riemann solver, i.e.,

$$\widetilde{V}(v; W_L, W_R) = V(v; W_L, W_R),$$

being $V(x/t; W_L, W_R)$ the exact solution of the Riemann problem (5). This is clearly a Φ-approximate Riemann solver. Moreover, if the concept of entropic solution is

related to an entropy pair (η, G) with convex η, according to Remark 1 it is *dissipative* for this pair (see [5]).

In [30] it has been shown that if the family of paths satisfies the hypotheses (H1)–(H3) stated in section 2, Godunov methods can be written under the form (21) with

$$D^-_{i+1/2} = \int_0^1 \mathcal{A}\left(\Phi(s; W^n_i, W^n_{i+1/2})\right) \frac{\partial \Phi}{\partial s}(s; W^n_i, W^n_{i+1/2})\, ds,$$
$$D^+_{i+1/2} = \int_0^1 \mathcal{A}\left(\Phi(s, W^n_{i+1/2}, W^n_{i+1})\right) \frac{\partial \Phi}{\partial s}(s; W^n_{i+1/2}, W^n_{i+1})\, ds,$$

where $W^n_{i+1/2}$ is the (constant) value at $x = x_{i+1/2}$ of the solution of the Riemann problem related to the states W^n_i and W^n_{i+1}. If the solution is discontinuous at $x = x_{i+1/2}$ the limit to the left or the right can be chosen indifferently.

Godunov methods are exactly well-balanced (see [30]).

5.2. Roe methods. Approximate Riemann solvers are often constructed as follows: $\widetilde{V}(x/t; W_L, W_R)$ is the solution of a linear Riemann problem

$$\left\{ \begin{array}{l} \dfrac{\partial U}{\partial t} + \mathcal{A}(W_L, W_R)\dfrac{\partial U}{\partial x} = 0, \\ \\ U(x,0) = \left\{ \begin{array}{ll} W_L & \text{if } x < 0, \\ W_R & \text{if } x > 0, \end{array} \right. \end{array} \right. \tag{39}$$

where $\mathcal{A}(W_L, W_R)$ is a linearization of $\mathcal{A}(W)$. It can be easily shown that this is a Ψ-approximate Riemann solver, if and only if, $\mathcal{A}(W_L, W_R)$ is a Roe linearization in the sense defined by Toumi in [40].

DEFINITION 5.3. *Given a family of paths Ψ, a function $\mathcal{A}_\Psi : \Omega \times \Omega \mapsto \mathcal{M}_{N\times N}(\mathbb{R})$ is called a* Roe linearization *if it verifies the following properties:*

1. *for each $W_L, W_R \in \Omega$, $\mathcal{A}_\Psi(W_L, W_R)$ has N distinct real eigenvalues,*
2. *$\mathcal{A}_\Psi(W, W) = \mathcal{A}(W)$, for every $W \in \Omega$,*
3. *for any $W_L, W_R \in \Omega$,*

$$\mathcal{A}_\Psi(W_L, W_R)(W_R - W_L) = \int_0^1 \mathcal{A}(\Psi(s; W_L, W_R)) \frac{\partial \Psi}{\partial s}(s; W_L, W_R)\, ds. \tag{40}$$

Once a Roe linearization $\mathcal{A}_\Psi$ has been chosen, some straightforward calculations allow one to show that, under a CFL condition 1/2, the numerical scheme can be written under the form (21) with

$$D^-_{i+1/2} = \mathcal{A}^-_{i+1/2}(W^n_{i+1} - W^n_i),$$
$$D^+_{i+1/2} = \mathcal{A}^+_{i+1/2}(W^n_{i+1} - W^n_i),$$

where

$$\mathcal{A}_{i+1/2} = \mathcal{A}_\Psi(W^n_i, W^n_{i+1}),$$

and, as usual,

$$\mathcal{L}^\pm_{i+1/2} = \begin{bmatrix} (\lambda_1^{i+1/2})^\pm & & 0 \\ & \ddots & \\ 0 & & (\lambda_N^{i+1/2})^\pm \end{bmatrix}, \ \mathcal{A}^\pm_{i+1/2} = \mathcal{K}_{i+1/2}\mathcal{L}^\pm_{i+1/2}\mathcal{K}^{-1}_{i+1/2} \tag{41}$$

being $\mathcal{L}_{i+1/2}$ the diagonal matrix whose coefficients are the eigenvalues of $\mathcal{A}_{i+1/2}$

$$\lambda_1^{i+1/2} < \lambda_2^{i+1/2} < \cdots < \lambda_N^{i+1/2},$$

and $\mathcal{K}_{i+1/2}$ is a $N \times N$ matrix whose columns are associated eigenvectors.

As in the case of systems of conservation laws, a CFL condition 1 is used in practice, as this condition ensures the linear stability of the method. An entropy-fix technique also has to be added to the numerical scheme.

In [29] it has been shown that a Roe scheme based on a family of paths Ψ is exactly well-balanced for a curve $\gamma \in \Gamma$ if, given two states W_L and W_R in γ, the path $\Psi(s; W_L, W_R)$ is a parameterization of the arc of γ linking these states. In particular, if the family of path Ψ coincides with the family Φ used in the definition of weak solutions, the numerical scheme is exactly well-balanced. The numerical scheme is well-balanced with order k if $\Psi(s; W_L, W_R)$ approximates with order $k+1$ a regular parameterization of the arc of γ linking the states. In particular, a Roe scheme based on the family of segments (28) is always well-balanced with order 2. Moreover, it is exactly well-balanced for curves of Γ that are straight lines (see [29] for details).

The construction of Roe methods for systems of the form (1) has been studied in [29].

5.3. Relaxation methods. The goal of this paragraph is to give some guidelines about the construction of approximate Riemann solvers for nonconservative systems based on the relaxation technique. This has been done for balance laws in [5].

The idea is as follows. First of all, a new nonconservative hyperbolic system is considered,

$$\frac{\partial \widetilde{W}}{\partial t} + \mathcal{B}(\widetilde{W}) \frac{\partial \widetilde{W}}{\partial x} = 0, \quad x \in \mathbb{R},\ t > 0, \tag{42}$$

where $\widetilde{W}$ now takes values in an open convex $\widetilde{\Omega}$ of $\mathbb{R}^{\widetilde{N}}$, with $\widetilde{N} > N$. Again, $\mathcal{B}$ is a smooth locally bounded map from $\widetilde{\Omega}$ to $\mathcal{M}_{\widetilde{N}\times\widetilde{N}}(\mathbb{R})$.

Let us suppose that there exist two linear operators $\mathcal{L} : \widetilde{\Omega} \mapsto \Omega$ and $\mathcal{M} : \Omega \mapsto \widetilde{\Omega}$ such that

$$\mathcal{L}\mathcal{M}(W) = W \quad \forall\ W \in \Omega.$$

In practice, system (42) has to be chosen in such a way that it is possible to easily construct an approximate Riemann solver with good properties (this is the case, for instance, if Riemann problems related to (42) are easy to solve). Then, an approximate Riemann solver for (3) is deduced.

The main difference with the conservative case comes from the fact that, in this case, together with system (42) a family of paths in $\widetilde{\Omega}$ also has to be chosen in order to define the approximate Riemann solver for this system.

The following lemma, whose demonstration is straightforward, gives a sufficient condition to obtain a Ψ-approximate Reimann solver for (3) from a $\widetilde{\Psi}$-approximate Reimann solver for (42).

LEMMA 5.4. *Let Ψ and $\widetilde{\Psi}$ be two families of paths in Ω and $\widetilde{\Omega}$, respectively, such that*

$$\begin{aligned} &\int_0^1 \mathcal{L}\mathcal{B}\big(\widetilde{\Psi}(s; \mathcal{M}(W_L), \mathcal{M}(W_R))\big) \frac{\partial \widetilde{\Psi}}{\partial s}(s; \mathcal{M}(W_L), \mathcal{M}(W_R))\, ds \\ &\qquad = \int_0^1 \mathcal{A}\big(\Psi(s; W_L, W_R)\big) \frac{\partial \Psi}{\partial s}(s; W_L, W_R)\, ds. \end{aligned} \tag{43}$$

Then, if $\mathcal{R}(v;\widetilde{W}_L,\widetilde{W}_R)$ *is a* $\widetilde{\Psi}$*-approximate Reimann solver for* (42)*, the function*

$$\widetilde{V}(v;W_L,W_R)=\mathcal{L}\mathcal{R}(v;\mathcal{M}(W_L),\mathcal{M}(W_R)),$$

gives a Ψ*-approximate Reimann solver for* (3).

Remark 5. It can also be easily shown that, if (η,G) is an entropy pair for (3) and $(\widetilde{\eta},\widetilde{G})$ is an entropy extension to (42) (see [5]), and both η and $\widetilde{\eta}$ are convex functions, then, if $\mathcal{R}$ is dissipative for $(\widetilde{\eta},\widetilde{G})$, $\widetilde{V}$ is dissipative for (η,G).

6. High order schemes based on reconstruction of states. The goal of this section is to obtain a high order scheme for (3) based on a first order path-conservative numerical scheme (21) with $q=0$ and $p=1$, that is,

$$D^{\pm}_{i+1/2}=D^{\pm}(W^n_i,W^n_{i+1}),$$

and a reconstruction operator of order s, i.e., an operator that associates to a given sequence $\{W_i\}$ two new sequences $\{W^-_{i+1/2}\}$, $\{W^+_{i+1/2}\}$ in such a way that, whenever

$$W_i=\frac{1}{\Delta x}\int_{I_i}W(x)\,dx,\quad\forall\ i\in\mathbb{Z},$$

for some smooth function W, then

$$W^{\pm}_{i+1/2}=W(x_{i+1/2})+O\left(\Delta x^s\right),\quad\forall\ i\in\mathbb{Z}.$$

In the case of a system of conservation laws (8), high order methods based on the reconstruction of states can be built using the following procedure: a first order conservative scheme with numerical flux function $G(U,V)$ and a reconstruction operator of order s are first chosen. Next, the method of lines is used: the system is discretized only in space, leaving the problem continuous in time. Let us denote by $\overline{W}_i(t)$ the cell average of solution W of (3) over the cell I_i at time t,

$$\overline{W}_i(t)=\frac{1}{\Delta x}\int_{x_{i-1/2}}^{x_{i+1/2}}W(x,t)\,dx.$$

The following equation can be easily obtained from (8):

$$\overline{W}'_i(t)=\frac{1}{\Delta x}\left(F(W(x_{i-1/2},t))-F(W(x_{i+1/2},t))\right). \tag{44}$$

Now, (44) is approached as follows:

$$W'_i(t)=\frac{1}{\Delta x}\big(\widetilde{G}_{i-1/2}-\widetilde{G}_{i+1/2}\big), \tag{45}$$

with

$$\widetilde{G}_{i+1/2}=G(W^-_{i+1/2}(t),W^+_{i+1/2}(t)), \tag{46}$$

$W_i(t)$ being the approximation to $\overline{W}_i(t)$, and $\{W^{\pm}_{i+1/2}(t)\}$ the reconstructions associated to the sequence $\{W_i(t)\}$. It can be shown that (45)–(46) give a semidiscrete method of order s for (8).

Notice that (45) is a system of ordinary differential equations which is solved using a standard numerical method.

Let us introduce an interpretation of (45) in terms of measures, as it was done in section 2, in order to generalize it to nonconservative systems. First, notice that (44) can also be written under the form

$$\overline{W}_i'(t) = -\frac{1}{\Delta x}\left\langle [F(W(\cdot,t))_x], 1_{I_i}\right\rangle. \tag{47}$$

Next, let us choose at every cell I_i and at every time $t>0$ a regular function P_i^t such that

$$\lim_{x\to x_{i-1/2}^+} P_i^t(x) = W_{i-1/2}^+(t), \qquad \lim_{x\to x_{i+1/2}^-} P_i^t(x) = W_{i+1/2}^-(t). \tag{48}$$

If we consider now the approximation of $W(\cdot,t)$ given by the piecewise regular function $\mathcal{W}^t$ whose restriction to I_i is P_i^t, the discrete analogue of (47) would be

$$W_i' = -\frac{1}{\Delta x}\left\langle [F(\mathcal{W}^t)_x], 1_{I_i}\right\rangle, \tag{49}$$

but, again, (49) is not equivalent to (45). In this case, $[F(\mathcal{W}^t)_x]$ is the sum of a regular measure, whose Radon–Nykodim derivative at the cell I_i is $F(P_i^t)_x$, and the singular measure

$$\sum_i \left(F(W_{i+1/2}^+(t)) - F(W_{i+1/2}^-(t))\right)\delta_{x=x_{i+1/2}}.$$

If, again, the numerical flux of the first order scheme is used to split the Dirac measures placed at the intercells

$$\begin{aligned}&\left(F(W_{i+1/2}^+(t)) - F(W_{i+1/2}^-(t))\right)\delta_{x=x_{i+1/2}}\\ &\quad = \left(F(W_{i+1/2}^+(t)) - \widetilde{G}_{i+1/2}\right)\delta_{x=x_{i+1/2}} + \left(\widetilde{G}_{i+1/2} - F(W_{i+1/2}^-(t))\right)\delta_{x=x_{i+1/2}},\end{aligned}$$

and the first and second summands are assigned, respectively, to the cells I_{i+1} and I_i, we obtain from (49),

$$\begin{aligned}W_i' = -\frac{1}{\Delta x}\Bigg(&F(W_{i-1/2}^+(t)) - \widetilde{G}_{i-1/2} + \widetilde{G}_{i+1/2} - F(W_{i+1/2}^-(t))\\ &+ \int_{x_{i-1/2}}^{x_{i+1/2}} F(P_i^t(x))_x\,dx\Bigg),\end{aligned} \tag{50}$$

which is obviously equivalent to (45).

We go now to the general case (3). In this case, the equation for the cell averages is the following:

$$\overline{W}_i' = -\frac{1}{\Delta x}\langle [\mathcal{A}(W(\cdot,t))W(\cdot,t)_x]_\Phi, 1_{I_i}\rangle. \tag{51}$$

The natural extension of (50) is then

$$W_i' = -\frac{1}{\Delta x}\left(\widetilde{D}_{i-1/2}^+ + \widetilde{D}_{i+1/2}^- + \int_{x_{i-1/2}}^{x_{i+1/2}} \mathcal{A}[P_i^t(x)]\frac{dP_i^t}{dx}(x)\,dx\right), \tag{52}$$

with

$$\widetilde{D}^{\pm}_{i+1/2} = D^{\pm}(W^{-}_{i+1/2}(t), W^{+}_{i+1/2}(t)). \tag{53}$$

In (52) the integral terms are approximations of the regular measure of the Lebesgue decomposition of $[\mathcal{A}(W(\cdot,t))W_x(\cdot,t)]_\Phi$ while the terms $\widetilde{D}^{\pm}_{i-1/2}$ are related to its singular part.

Notice that there is an important difference between the conservative and nonconservative case: while in the conservative case the numerical scheme is independent of the functions P^t_i chosen at the cells (only the property (48) is important), this is not the case for nonconservative systems. As a consequence, while the numerical scheme (45) has order s, in the case of the scheme (52) the order will depend on the choice of the functions P^t_i.

In practice, the definition of the reconstruction operator gives the natural choice of the functions P^t_i, as the usual procedure is the following: given a sequence $\{W_i\}$ of values at the cells, an approximation function is calculated at every cell I_i using the values W_j at a *stencil*,

$$P_i(x; W_{i-l}, \dots, W_{i+r}),$$

with l, r being two natural numbers. The reconstructions $W^{\pm}_{i+1/2}$ are then calculated by taking the limits of these functions at the intercells. These approximations functions are usually calculated by means of interpolation or approximation techniques. The natural choice of P^t_i is thus

$$P^t_i(x) = P_i(x; W_{i-l}(t), \dots, W_{i+r}(t)).$$

Let us now investigate the order of the numerical scheme (52). Notice first that, for regular solutions W, the differential equation (51) can be written as follows:

$$\overline{W}'_i(t) = -\frac{1}{\Delta x}\int_{x_{i-1/2}}^{x_{i+1/2}} \mathcal{A}(W(x,t))W_x(x,t)\,dx. \tag{54}$$

THEOREM 6.1. *Let us suppose that $\mathcal{A}$, $D^{\pm}$ are regular and with bounded derivatives. Let us suppose also that the reconstruction operator is of order s and that, given the sequence defined by*

$$W_i = \frac{1}{\Delta x}\int_{I_i} W(x)\,dx,$$

for any smooth function W, the following approximation properties are satisfied:

$$P_i(x; W_{i-l}, \dots, W_{i+r}) = W(x) + O\left(\Delta x^{s_1}\right) \quad \forall\, x \in I_i,$$
$$\frac{d}{dx}P_i(x; W_{i-l}, \dots, W_{i+r}) = W'(x) + O\left(\Delta x^{s_2}\right) \quad \forall\, x \in I_i.$$

Then (52) *is an approximation of order at least $\bar{s} = \min(s, s_1+1, s_2+1)$ to the system* (54) *in the following sense:*

$$\begin{aligned}\widetilde{D}^{+}_{i-1/2} - \widetilde{D}^{-}_{i+1/2} + \int_{x_{i-1/2}}^{x_{i+1/2}} \mathcal{A}(P^t_i(x))\frac{dP^t_i}{dx}(x)\,dx \\ = \int_{x_{i-1/2}}^{x_{i+1/2}} \mathcal{A}(W(x,t))W_x(x,t)\,dx + O\left(\Delta x^{\bar{s}}\right),\end{aligned} \tag{55}$$

for every smooth enough solution W, being $\{W^{\pm}_{i+1/2}(t)\}$ the reconstructions corresponding to the sequence $\{\overline{W}_i(t)\}$ and P^t_i the functions defined by

$$P^t_i(x) = P_i(x; \overline{W}_{i-l}(t), \dots, \overline{W}_{i+r}(t)).$$

The proof is identical to that of the particular case studied in [8], where general high order numerical schemes based on first order Roe methods were introduced.

Remark 6. For the usual reconstruction techniques one has $s_2 \leq s_1 < s$ and the order of (52) is thus $s_2 + 1$ for nonconservative systems and s for systems of conservation laws. Therefore a loss of accuracy can be observed when a technique of reconstruction is applied to a nonconservative problem. This effect has been detected and verified numerically for WENO-Roe methods in [8].

Notice that (52) can also be written under a form similar to (21),

$$W_i' = -\frac{1}{\Delta x}\left(E^+_{i-1/2} + E^-_{i+1/2}\right), \tag{56}$$

with

$$\begin{aligned} E^+_{i+1/2} &= \widetilde{D}^+_{i+1/2} + \int_{x_{i+1/2}}^{x_{i+1}} \mathcal{A}(P^t_{i+1}(x))\frac{dP^t_{i+1}}{dx}(x)\,dx, \\ E^-_{i+1/2} &= \widetilde{D}^-_{i+1/2} + \int_{x_i}^{x_{i+1/2}} \mathcal{A}(P^t_i(x))\frac{dP^t_i}{dx}(x)\,dx. \end{aligned} \tag{57}$$

Using this notation, the following equality holds:

$$\begin{aligned} E^+_{i+1/2} + E^-_{i+1/2} = &\int_{x_i}^{x_{i+1/2}} \mathcal{A}(P^t_i(x))\frac{dP^t_i}{dx}(x)\,dx \\ &+ \int_0^1 \mathcal{A}(\Psi(s; W^-_{i+1/2}, W^+_{i+1/2}))\frac{\partial \Psi}{\partial s}(s; W^-_{i+1/2}, W^+_{i+1/2})\,ds \\ &+ \int_{x_{i+1/2}}^{x_{i+1}} \mathcal{A}(P^t_{i+1}(x))\frac{dP^t_{i+1}}{dx}(x)\,dx, \end{aligned} \tag{58}$$

with Ψ being the family of paths for which the first order numerical scheme is path-conservative.

This latter equality can be understood as a path-conservation property similar to (23), where now the path linking $W_i(t)$ and $W_{i+1}(t)$ is the composition of three paths:

$$x \in [x_i, x_{i+1/2}] \mapsto P^t_i(x), \tag{59}$$

linking $W_i(t)$ and $W^-_{i+1/2}(t)$;

$$s \in [0,1] \mapsto \Psi(s; W^-_{i+1/2}(t), W^+_{i+1/2}(t)), \tag{60}$$

linking $W^-_{i+1/2}(t)$ and $W^+_{i+1/2}(t)$; and finally,

$$x \in [x_{i+1/2}, x_{i+1}] \mapsto P^t_{i+1}(x), \tag{61}$$

linking $W^+_{i+1/2}(t)$ and $W_{i+1}(t)$. Nevertheless, this family of paths does not depend only on the states $W_i(t)$ and $W_{i+1}(t)$ (as was the case in Definition 3.1) but on the values at the stencil

$$W_{i-l}(t), \dots, W_{i+r}(t).$$

The definition of a well-balanced scheme can be easily extended for semidiscrete methods (see [8]).

DEFINITION 6.2. *Let us consider a semidiscrete method for solving* (3)*:*

$$\begin{cases} W_i' = \frac{1}{\Delta x}\mathcal{H}(\mathbf{W}(t); i), \quad i \in \mathbb{Z}, \\ \mathbf{W}(0) = \mathbf{W}_0, \end{cases} \tag{62}$$

where $\mathbf{W}(t) = \{W_i(t)\}$ *represents the vector of approximations to the cell averages of the exact solution, and* $\mathbf{W}_0 = \{W_i^0\}$ *is the vector of initial data. Let* γ *be a curve of* Γ*. The numerical method* (62) *is said to be exactly well-balanced for* γ *if, given a regular stationary solution* W*, such that*

$$W(x) \in \gamma \quad \forall\ x \in \mathbb{R},$$

the vector $\mathbf{W} = \{W(x_i)\}$*, where* x_i *denotes the center of the cell* I_i*, is a critical point for the system of differential equations* (62)*, i.e.,*

$$\mathcal{H}(\mathbf{W}; i) = 0 \quad \forall\ i,$$

and it is said to be well-balanced with order k *if:*

$$\mathcal{H}(\mathbf{W}; i) = O\left(\Delta x^k\right) \quad \forall\ i.$$

Finally, the semidiscrete method (62) *is said to be exactly well-balanced or well-balanced with order* k *if these properties are satisfied for every curve* γ *of the set* Γ*.*

We give hereafter two results concerning the well-balanced property of this scheme generalizing those presented in [8] for the particular case of Roe-based reconstruction methods, but before then we introduce a new definition.

DEFINITION 6.3. *The reconstruction operator is said to be* exactly well-balanced *for a curve* $\gamma \in \Gamma$ *if, given a sequence* $\{W_i\}$ *in* γ*, the approximation functions satisfy*

$$P_i(x; W_{i-l}, \dots, W_{i+r}) \in \gamma \quad \forall\, x \in [x_{i-1/2}, x_{i+1/2}], \tag{63}$$

for every i*.*

THEOREM 6.4. *Let* γ *belong to* Γ*. Let us suppose that both the first order scheme and the reconstruction operator are exactly well-balanced for* γ*. Then, the numerical scheme* (52) *is also exactly well-balanced for* γ*.*

THEOREM 6.5. *Under the hypothesis of Theorem* 6.1*, the scheme* (52) *is well-balanced with an order of at least* $\bar{s} = \min(s, s_1 + 1, s_2 + 1)$*.*

The proofs of these results are identical to the corresponding theorems stated in [8].

Aknowledgments. The author wishes to thank M. J. Castro, J. M. Gallardo, and M. L. Muñoz for their helpful comments; and to F. Bouchut for stimulating discussions.

STABILIZED FINITE ELEMENT METHODS BASED ON MULTISCALE ENRICHMENT FOR THE STOKES PROBLEM*

RODOLFO ARAYA†, GABRIEL R. BARRENECHEA†, AND FRÉDÉRIC VALENTIN‡

Abstract. This work concerns the development of stabilized finite element methods for the Stokes problem considering nonstable different (or equal) order of velocity and pressure interpolations. The approach is based on the enrichment of the standard polynomial space for the velocity component with multiscale functions which no longer vanish on the element boundary. On the other hand, since the test function space is enriched with bubble-like functions, a Petrov–Galerkin approach is employed. We use such a strategy to propose stable variational formulations for continuous piecewise linear in velocity and pressure and for piecewise linear/piecewise constant interpolation pairs. Optimal order convergence results are derived and numerical tests validate the proposed methods.

Key words. Stokes equation, multiscale functions, SIMPLEST element, bubble function

1. Introduction.

Finite element solution of the Stokes problem poses the basic problem of satisfying the discrete Babuska–Brezzi (or inf-sup) condition (see [24] and the references therein). This is indeed a restriction from the point of view of implementation since equal order velocity and pressure spaces do not satisfy this condition. On the other hand, the minimal space to imagine, namely continuous piecewise linear polynomials for the velocity and piecewise constant polynomials for the pressure, does not satisfy this condition either.

Several solutions have been proposed to overcome this restriction, starting with that in [11] and the first consistent method in [28]. Moreover, in [23, 27, 29, 34] the possibility of considering discontinuous spaces for the pressure was considered and justified. On the other hand, in [14, 13], the idea from [16] has been used to propose a new kind of stabilized finite element methods, with stabilizing terms now containing only jump terms across the interelement boundaries. For an overview of stabilized finite element methods for the Stokes problem, see [19] and [5].

On the other hand, the theoretical justification of stabilized methods has become a subject of interest in the last decade. In [2, 3, 4, 31], the connection between stabilized finite element methods and Galerkin methods enriched with bubble functions has been used to propose new stabilized finite element methods for Stokes-like and linearized Navier–Stokes problems. Also, in [22] *macro* bubbles were used to derive a method analogous to the locally stabilized method from [29] containing jump terms across the interelement boundaries of the macroelements. In the resulting method, the stabilizing

terms are defined over the macroelements, and there is no error analysis or numerical validation of the method. All these works used the so-called bubble condensation procedure, i.e., eliminating the bubble function at the element level and writing the method as the Galerkin part, plus a term derived from the influence of the bubble functions on the formulation. A particular kind of bubble enrichment of the velocity space is the so-called residual-free bubble (RFB) method (cf. [7, 8, 12]), in which the bubble function is now the solution of a problem containing the residual of the continuous equation at the element level (see [9, 10, 32] for the a priori error analysis). This bubble part may be analytically condensed or numerically computed. In the latter case this procedure leads to the two-level finite element method.

The imposition of a zero boundary condition on the element boundary for the RFB has led to some numerical problems. Solutions for these problems have been proposed by relaxing the zero boundary condition, such as the discontinuous enrichment method [18] (for the Helmholtz equation), and, more recently, the multiscale finite element method; see [21], where the main idea may be found, and [20], where the a priori error analysis is performed (for the reaction-diffusion equation, an a posteriori error estimator based on this idea has been proposed and analyzed in [1]). A particularity of such methods is that a Petrov–Galerkin strategy is proposed, in which the test function space is enriched with bubble functions in order to have a local problem containing the residual of the momentum equation on the right-hand side. A special boundary condition (related to the one used in [25, 26, 15]) is imposed in order to solve these local problems analytically. The resulting method is of Petrov–Galerkin type, in which the trial function space is generated by a basis formed by the addition of usual polynomial basis functions and enrichment functions from the solution of the differential problem in each element (which are now, unlike the RFB, known analytically, and hence the method is not of a two-level finite element method type), and in which the test function space is the standard polynomial space.

The purpose of this work is to use the multiscale approach from [21, 20], combined with the static condensation procedure, in order to propose new stabilized finite element methods for the Stokes problem. We proceed as in [21], defining an enrichment function for the trial space for the velocity that no longer vanishes on the element boundary (and hence it is not a bubble function), and then we split it into a bubble part and a function being a harmonic extension of the boundary condition. This boundary condition comes from the solution of an elliptic ODE containing a part of the differential operator at the boundary, and a jump term as the right-hand side. Depending on the jump term chosen, this procedure will lead to different methods. Both functions are condensed, and hence we obtain a method which includes the usual Galerkin-Least-Squares (GLS) stabilizing terms at the element level, plus a positive jump term on the interelement boundaries, each one with a proper stabilization parameter. One special feature of these new methods is that the previously mentioned ODE at the element boundary may be solved analytically, and hence the stabilization parameter associated with the jump terms is known exactly.

The plan of the paper is as follows. In section 2 we present the general framework and derive a general form of the method. In sections 3 and 4 this framework is applied to derive concrete stabilized finite element methods for two families of interpolation spaces, namely $\mathbb{P}^1/\mathbb{P}^0$ and continuous $\mathbb{P}^1/\mathbb{P}^1$ elements. For both cases optimal order a priori error estimates are derived for the natural norms of the unknowns, plus some extra control on the norm of the jumps appearing in the formulation. As we already mentioned, if we change the right-hand side on the boundary condition, we can derive a new method. This is done in section 5, where we give an alternative enrichment

strategy leading to another family of methods, whose analysis is analogous to that of sections 3 and 4, and which contains a boundary term containing the residual of the Cauchy stress tensor on the internal edges of the triangulation. Numerical experiments confirming the theoretical results and comparing the performance of all the methods are presented in section 6, and some final remarks and conclusions are given in section 7.

2. The model problem and the general framework. Let Ω be an open bounded domain in $\mathbb{R}^2$ with polygonal boundary, $\boldsymbol{f} \in L^2(\Omega)^2$ and consider the following Stokes problem:

$$-\nu\,\Delta \boldsymbol{u} + \nabla p = \boldsymbol{f}, \quad \nabla\cdot \boldsymbol{u} = 0 \quad \text{in } \Omega\,, \qquad \boldsymbol{u} = \boldsymbol{0} \quad \text{on } \partial\Omega\,, \tag{1}$$

where $\nu \in \mathbb{R}^+$ is the fluid viscosity.

Now let $\{\mathcal{T}_h\}_{h>0}$ be a family of regular triangulations of Ω, built up using triangles K with boundary ∂K. Let also $\mathcal{E}_h$ be the set of internal edges of the triangulation, $h_K := diam(K)$ and $h := \max\{h_K : K \in \mathcal{T}_h\}$. Let V_h be the usual finite element space of continuous piecewise polynomials of degree k, $1 \le k \le 2$ with zero trace on $\partial\Omega$. Let also Q_h be a space of piecewise polynomials of degree l, $0 \le l \le 1$, which may be continuous or discontinuous in Ω and which belong to $L^2_0(\Omega)$. Let $H^m(\mathcal{T}_h)$ and $H^m_0(\mathcal{T}_h)$ $(m \ge 1)$ be the spaces of functions whose restriction to $K \in \mathcal{T}_h$ belongs to $H^m(K)$ and $H^m_0(K)$, respectively. Furthermore, $(\cdot\,,\cdot)_D$ stands for the inner product in $L^2(D)$ (or in $L^2(D)^2$ or $L^2(D)^{2\times 2}$, when necessary), and we denote by $\|\cdot\|_{s,D}$ $(|\cdot|_{s,D})$ the norm (seminorm) in $H^s(D)$ (or $H^s(D)^2$, if necessary). As usual, $H^0(D) = L^2(D)$, and $|\cdot|_{0,D} = \|\cdot\|_{0,D}$.

In order to propose a Petrov–Galerkin method for the Stokes problem (1), let $E_h \subset H^1_0(\Omega)$ be a finite-dimensional space, called a multiscale space, such that $V_h \cap E_h = \{0\}$. Then, we propose the following Petrov–Galerkin scheme for (1): Find $\boldsymbol{u}_1 + \boldsymbol{u}_e \in [V_h \oplus E_h]^2$ and $p \in Q_h$ such that

$$\nu(\nabla(\boldsymbol{u}_1 + \boldsymbol{u}_e), \nabla \boldsymbol{v}_h)_\Omega - (p, \nabla\cdot \boldsymbol{v}_h)_\Omega + (q, \nabla\cdot(\boldsymbol{u}_1 + \boldsymbol{u}_e))_\Omega = (\boldsymbol{f}, \boldsymbol{v}_h)_\Omega$$

for all $\boldsymbol{v}_h \in [V_h \oplus H^1_0(\mathcal{T}_h)]^2$ and all $q \in Q_h$. Now, this Petrov–Galerkin scheme is equivalent to the following system:

$$\nu(\nabla(\boldsymbol{u}_1 + \boldsymbol{u}_e), \nabla \boldsymbol{v}_1)_\Omega - (p, \nabla\cdot \boldsymbol{v}_1)_\Omega + (q, \nabla\cdot(\boldsymbol{u}_1 + \boldsymbol{u}_e))_\Omega = (\boldsymbol{f}, \boldsymbol{v}_1)_\Omega \ \ \forall (\boldsymbol{v}_1, q) \in V_h^2 \times Q_h, \tag{2}$$

$$\nu(\nabla(\boldsymbol{u}_1 + \boldsymbol{u}_e), \nabla \boldsymbol{v}_b)_K - (p, \nabla\cdot \boldsymbol{v}_b)_K = (\boldsymbol{f}, \boldsymbol{v}_b)_K \quad \forall \boldsymbol{v}_b \in H^1_0(K)^2 \,\forall\, K \in \mathcal{T}_h\,. \tag{3}$$

Equation (3) above is equivalent to

$$(-\nu\Delta \boldsymbol{u}_e, \boldsymbol{v}_b)_K = (\boldsymbol{f} + \nu\Delta \boldsymbol{u}_1 - \nabla p, \boldsymbol{v}_b)_K \quad \forall \boldsymbol{v}_b \in H^1_0(K)^2,$$

which, in strong form, may be written as

$$-\nu\Delta \boldsymbol{u}_e = \boldsymbol{f} + \nu\Delta \boldsymbol{u}_1 - \nabla p \quad \text{in } K. \tag{4}$$

Now, this differential problem must be completed with boundary conditions. For reasons that will become clear in what follows, we will impose the following boundary

condition on $\boldsymbol{u}_e$:

$$\boldsymbol{u}_e = \boldsymbol{g}_e \quad \text{on each } Z \subset \partial K\,, \tag{5}$$

where $\boldsymbol{g}_e = \mathbf{0}$ if $Z \subset \partial\Omega$, and $\boldsymbol{g}_e$ is the solution of

$$\begin{aligned} -\nu\,\partial_{\boldsymbol{ss}}\boldsymbol{g}_e &= \frac{1}{h_Z}\,[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1 + p\mathbf{I}\cdot\boldsymbol{n}]\!] \quad \text{in } Z\,,\\ \boldsymbol{g}_e &= \mathbf{0} \quad \text{at the nodes}\,, \end{aligned} \tag{6}$$

on the internal edges, where $h_Z = |Z|$, $\boldsymbol{n}$ is the normal outward vector on ∂K, $\partial_{\boldsymbol{s}}$, and $\partial_{\boldsymbol{n}}$ are the tangential and normal derivative operators, respectively, $[\![v]\!]$ stands for the jump of v across Z, and $\mathbf{I}$ is the $\mathbb{R}^{2\times 2}$ identity matrix.

REMARK 2.1. *Both the shape of the jump term and the h_Z^{-1} coefficient on the boundary condition have been suggested by the error analysis. On the other hand, if we impose as the right-hand side in* (6) *the residual of the Cauchy stress tensor on ∂K, we have another class of methods. This alternative will be analyzed in section* 5.

Now, on each $K \in \mathcal{T}_h$, we can write $\boldsymbol{u}_e|_K = \boldsymbol{u}_e^K + \boldsymbol{u}_e^{\partial K}$, where

$$\begin{aligned} -\nu\Delta\boldsymbol{u}_e^K &= \boldsymbol{f} + \nu\Delta\boldsymbol{u}_1 - \nabla p \quad \text{in } K\,,\\ \boldsymbol{u}_e^K &= \mathbf{0} \quad \text{on } \partial K\,, \end{aligned} \tag{7}$$

and

$$\begin{aligned} -\nu\Delta\boldsymbol{u}_e^{\partial K} &= \mathbf{0} \quad \text{in } K\,,\\ \boldsymbol{u}_e^{\partial K} &= \boldsymbol{g}_e \quad \text{on } \partial K\,, \end{aligned} \tag{8}$$

where $\boldsymbol{g}_e$ is the solution of (6). Such differential problems are well posed, and (3) is immediately satisfied.

In this way, we can define two operators $\mathcal{M}_K : L^2(K)^2 \to H_0^1(K)^2$ and $\mathcal{B}_K : L^2(\partial K)^2 \to H^1(K)^2$ such that

$$\boldsymbol{u}_e^K = \frac{1}{\nu}\,\mathcal{M}_K(\boldsymbol{f} + \nu\Delta\boldsymbol{u}_1 - \nabla p) \quad \forall K \in \mathcal{T}_h \tag{9}$$

and

$$\boldsymbol{u}_e^{\partial K} = \frac{1}{\nu}\,\mathcal{B}_K\left([\![\nu\,\partial_{\boldsymbol{n}}\boldsymbol{u}_1 + p\mathbf{I}\cdot\boldsymbol{n}]\!]\right) \quad \forall K \in \mathcal{T}_h\,. \tag{10}$$

Next, since the enriched part $\boldsymbol{u}_e$ is fully identified through (9)–(10) (or, equivalently, by (7)–(8)), we can perform statical condensation to derive a stabilized finite element method for our problem (1). First, integrating by parts, we have, on each $K \in \mathcal{T}_h$,

$$\begin{aligned} \nu(\nabla\boldsymbol{u}_e, \nabla\boldsymbol{v}_1)_K &= -\nu(\boldsymbol{u}_e, \Delta\boldsymbol{v}_1)_K + (\boldsymbol{u}_e, \nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1)_{\partial K},\\ (q, \nabla\cdot\boldsymbol{u}_e)_K &= -(\boldsymbol{u}_e, \nabla q)_K + (\boldsymbol{u}_e, q\mathbf{I}\cdot\boldsymbol{n})_{\partial K}. \end{aligned}$$

Using these identities we can rewrite (2) in the following way:

$$\begin{aligned} &\nu(\nabla\boldsymbol{u}_1, \nabla\boldsymbol{v}_1)_\Omega + \sum_{K\in\mathcal{T}_h}\Big[-(\boldsymbol{u}_e, \nu\Delta\boldsymbol{v}_1)_K + (\boldsymbol{u}_e, \nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1)_{\partial K}\Big] - (p, \nabla\cdot\boldsymbol{v}_1)_\Omega\\ &+(q, \nabla\cdot\boldsymbol{u}_1)_\Omega + \sum_{K\in\mathcal{T}_h}\Big[-(\boldsymbol{u}_e, \nabla q)_K + (\boldsymbol{u}_e, q\mathbf{I}\cdot\boldsymbol{n})_{\partial K}\Big] = (\boldsymbol{f}, \boldsymbol{v}_1)_\Omega, \end{aligned} \tag{11}$$

which implies

$$\nu(\nabla \boldsymbol{u}_1, \nabla \boldsymbol{v}_1)_\Omega - (p, \nabla\cdot \boldsymbol{v}_1)_\Omega + (q, \nabla\cdot \boldsymbol{u}_1)_\Omega$$

$$+ \sum_{K\in\mathcal{T}_h} \Big[- (\boldsymbol{u}_e, \nu\Delta \boldsymbol{v}_1 + \nabla q)_K + (\boldsymbol{u}_e^{\partial K}, \nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1 + q\mathbf{I}\cdot\boldsymbol{n})_{\partial K}\Big] = (\boldsymbol{f}, \boldsymbol{v}_1)_\Omega, \tag{12}$$

which, applying characterizations (9)–(10), becomes

$$\nu(\nabla \boldsymbol{u}_1, \nabla \boldsymbol{v}_1)_\Omega - (p, \nabla\cdot \boldsymbol{v}_1)_\Omega + (q, \nabla\cdot \boldsymbol{u}_1)_\Omega$$

$$+ \sum_{K\in\mathcal{T}_h} \Big[\frac{1}{\nu}\left(\mathcal{M}_K(-\nu\Delta \boldsymbol{u}_1 + \nabla p) - \mathcal{B}_K([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1 + p\mathbf{I}\cdot\boldsymbol{n}]\!]\right), \nu\Delta \boldsymbol{v}_1 + \nabla q)_K \tag{13}$$

$$+\frac{1}{\nu}\left(\mathcal{B}_K\left([\![\nu\,\partial_{\boldsymbol{n}}\boldsymbol{u}_1 + p\mathbf{I}\cdot\boldsymbol{n}]\!]\right), \nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1 + q\mathbf{I}\cdot\boldsymbol{n}\right)_{\partial K}\Big]$$

$$= (\boldsymbol{f}, \boldsymbol{v}_1)_\Omega + \sum_{K\in\mathcal{T}_h} \frac{1}{\nu}\left(\mathcal{M}_K(\boldsymbol{f}), \nu\Delta \boldsymbol{v}_1 + \nabla q\right)_K.$$

Using this form, in the next sections we will present concrete stabilized finite element methods for both the simplest possible pair ($\mathbb{P}^1/\mathbb{P}^0$ elements) and equal order $\mathbb{P}^1/\mathbb{P}^1$ continuous finite elements.

3. The simplest element $\mathbb{P}^1/\mathbb{P}^0$.

3.1. The method. For this case, the finite element spaces are given by

$$\mathbf{V}_h := \{\boldsymbol{v} \in C^0(\overline{\Omega})^2 : \boldsymbol{v}|_K \in \mathbb{P}^1(K)^2 \,\forall\, K \in \mathcal{T}_h\} \cap H_0^1(\Omega)^2$$

for the velocity, and

$$Q_h^0 := \{q \in L_0^2(\Omega) : q|_K \in \mathbb{P}^0(K) \,\forall\, K \in \mathcal{T}_h\}$$

for the pressure. Using these spaces, we propose the following stabilized method: Find $(\boldsymbol{u}_1, p_0) \in \mathbf{V}_h \times Q_h^0$ such that

$$\mathbf{B}_0\big((\boldsymbol{u}_1, p_0), (\boldsymbol{v}_1, q_0)\big) = \mathbf{F}_0\big(\boldsymbol{v}_1, q_0\big) \quad \forall\, (\boldsymbol{v}_1, q_0) \in \mathbf{V}_h \times Q_h^0, \tag{14}$$

where

$$\mathbf{B}_0\big((\boldsymbol{u}_1, p_0), (\boldsymbol{v}_1, q_0)\big) := \nu(\nabla \boldsymbol{u}_1, \nabla \boldsymbol{v}_1)_\Omega - (p_0, \nabla\cdot \boldsymbol{v}_1)_\Omega + (q_0, \nabla\cdot \boldsymbol{u}_1)_\Omega$$

$$+ \sum_{Z\in\mathcal{E}_h} \tau_Z\left([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1 + p_0\mathbf{I}\cdot\boldsymbol{n}]\!], [\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1 + q_0\mathbf{I}\cdot\boldsymbol{n}]\!]\right)_Z, \tag{15}$$

$$\mathbf{F}_0\big(\boldsymbol{v}_1, q_0\big) := (\boldsymbol{f}, \boldsymbol{v}_1)_\Omega, \tag{16}$$

and τ_Z is given by

$$\tau_Z := \frac{h_Z}{12\nu}\,. \tag{17}$$

REMARK 3.1. *This method differs somewhat from other existing stabilized finite element methods with discontinuous pressure spaces (see, for example,* [23, 29, 34, 14]).

First, since τ_Z is known exactly, we have no free constants to set. To the authors' knowledge, this is the first time that the stabilization parameter corresponding to jump terms is known exactly. Furthermore, and in contrast to [22]*, the jump terms are derived without the use of a macroelement technique. Finally, another difference is the nature of the jump terms, not only containing pressure jumps, but also the jump on the normal derivative of $\boldsymbol{u}$.*

REMARK 3.2. *One of the drawbacks of the RFB method for the Stokes problem is that, due to the zero boundary condition on the element boundary, there is not a bubble-based enrichment that makes stable the $\mathbb{P}^1/\mathbb{P}^0$ element (see* [6] *for a discussion), and hence, the use of a different boundary condition makes it possible to stabilize the $\mathbb{P}^1/\mathbb{P}^0$ element.*

3.1.1. Derivation of the method. First we note that, using spaces $\mathbf{V}_h$ and Q_h^0, (13) reduces to the following: Find $(\boldsymbol{u}_1, p_0) \in \mathbf{V}_h \times Q_h^0$ such that

$$\begin{aligned} &\nu(\nabla \boldsymbol{u}_1, \nabla \boldsymbol{v}_1)_\Omega - (p_0, \nabla\cdot \boldsymbol{v}_1)_\Omega + (q_0, \nabla\cdot \boldsymbol{u}_1)_\Omega \\ &+ \sum_{Z\in\mathcal{E}_h} \frac{1}{\nu} \left(\mathcal{B}_K\left([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1 + p_0\mathbf{I}\cdot\boldsymbol{n}]\!]\right), [\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1 + q_0\mathbf{I}\cdot\boldsymbol{n}]\!]\right)_Z = (\boldsymbol{f}, \boldsymbol{v}_1)_\Omega \end{aligned} \tag{18}$$

for all $(\boldsymbol{v}_1, q_0) \in \mathbf{V}_h \times Q_h^0$.

REMARK 3.3. *Since $\mathcal{B}_K$ is the inverse of an elliptic operator, by denoting $\boldsymbol{v} = \mathcal{B}_K(\boldsymbol{g})$, we have, for all $\boldsymbol{g} \in L^2(\partial K)^2$,*

$$(\mathcal{B}_K(\boldsymbol{g}), \boldsymbol{g})_{\partial K} = -(\boldsymbol{v}, \partial_{\boldsymbol{ss}}\boldsymbol{v})_{\partial K} = (\partial_{\boldsymbol{s}}\boldsymbol{v}, \partial_{\boldsymbol{s}}\boldsymbol{v})_{\partial K} \geq 0\,,$$

and hence we are adding a positive term to the formulation.

Next we exploit the fact that $[\![\partial_{\boldsymbol{n}}\boldsymbol{u}_1 + p_0\mathbf{I}\cdot\boldsymbol{n}]\!]|_Z$ is a constant function. To do so, we define the (matrix) function $\boldsymbol{b}_K^u := (\mathcal{B}_K(\boldsymbol{e}_1)|\mathcal{B}_K(\boldsymbol{e}_2))$, where $\boldsymbol{e}_1, \boldsymbol{e}_2$ are the canonical vectors in $\mathbb{R}^2$, and we remark that, from its definition, $\boldsymbol{b}_K^u = b_K^u\mathbf{I}$, where b_K^u is the solution of

$$-\Delta b_K^u = 0 \quad \text{in } K, \qquad b_K^u = g(\boldsymbol{s}) \quad \text{on each } Z \subset \partial K, \tag{19}$$

where $g = 0$ if $Z \subset \partial\Omega$, and g satisfies

$$-\partial_{\boldsymbol{ss}} g(\boldsymbol{s}) = \frac{1}{h_Z} \quad \text{in } Z\,, \qquad g = 0 \quad \text{at the nodes}\,, \tag{20}$$

in the internal edges.

REMARK 3.4. *The solution of* (20) *may be calculated explicitly and it is not difficult to realize that*

$$\frac{(b_K^u, 1)_Z}{|Z|} = \frac{h_Z}{12}\,. \tag{21}$$

Finally, since $[\![\partial_{\boldsymbol{n}}\boldsymbol{u}_1 + p_0\mathbf{I}\cdot\boldsymbol{n}]\!]|_Z$ is a constant function we obtain

$$\begin{aligned} &(\mathcal{B}_K([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1 + p_0\mathbf{I}\cdot\boldsymbol{n}]\!]), [\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1 + q_0\mathbf{I}\cdot\boldsymbol{n}]\!])_Z \\ &= \left[\int_Z \boldsymbol{b}_K^u\right] [\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1 + p_0\mathbf{I}\cdot\boldsymbol{n}]\!]\Big|_Z \cdot [\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1 + q_0\mathbf{I}\cdot\boldsymbol{n}]\!]\Big|_Z \\ &= \frac{(b_K^u, 1)_Z}{|Z|} ([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1 + p_0\mathbf{I}\cdot\boldsymbol{n}]\!], [\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1 + q_0\mathbf{I}\cdot\boldsymbol{n}]\!])_Z\,, \end{aligned}$$

and hence replacing this in (18) and using the previous remark, we obtain method (14).

3.2. Error analysis. From now on, C will denote a positive constant independent of h and ν, and that may change its value whenever it is written in two different places.

The next result states the consistency of the proposed method.

LEMMA 3.5. *Let* $(\boldsymbol{u}, p) \in [H^2(\Omega) \cap H_0^1(\Omega)]^2 \times [H^1(\Omega) \cap L_0^2(\Omega)]$ *be the weak solution of* (1) *and* $(\boldsymbol{u}_1, p_0)$ *the solution of* (14). *Then,*

$$\mathbf{B}_0\big((\boldsymbol{u} - \boldsymbol{u}_1, p - p_0), (\boldsymbol{v}_1, q_0)\big) = 0 \quad \forall\, (\boldsymbol{v}_1, q_0) \in \mathbf{V}_h \times Q_h^0. \tag{22}$$

Proof. The results follows by noting that $[\![\nu \partial_{\boldsymbol{n}} \boldsymbol{u} + p\mathbf{I}\cdot \boldsymbol{n}]\!] = \mathbf{0}$ a.e. across all the internal edges. ∎

Moreover, defining the mesh-dependent norm

$$\|(\boldsymbol{v}, q)\|_h := \left[\nu\, |\boldsymbol{v}|_{1,\Omega}^2 + \sum_{Z \in \mathcal{E}_h} \tau_Z \|[\![\nu \partial_{\boldsymbol{n}} \boldsymbol{v} + q\mathbf{I}\cdot \boldsymbol{n}]\!]\|_{0,Z}^2 \right]^{\frac{1}{2}}, \tag{23}$$

we have the following continuity and coercivity results.

LEMMA 3.6. *Let be* $(\boldsymbol{v}, q), (\boldsymbol{w}, r) \in [H^2(\mathcal{T}_h) \cap H_0^1(\Omega)]^2 \times [H^1(\mathcal{T}_h) \cap L_0^2(\Omega)]$. *Then, bilinear form* $\mathbf{B}_0$ *satisfies*

$$\mathbf{B}_0\big((\boldsymbol{v}, q), (\boldsymbol{w}, r)\big) \le \|(\boldsymbol{v}, q)\|_h \|(\boldsymbol{w}, r)\|_h + (\nabla\cdot \boldsymbol{v}, r)_\Omega - (q, \nabla\cdot \boldsymbol{w})_\Omega\,, \tag{24}$$

$$\mathbf{B}_0\big((\boldsymbol{v}, q), (\boldsymbol{v}, q)\big) = \|(\boldsymbol{v}, q)\|_h^2\,. \tag{25}$$

Proof. The result follows immediately from the definition of $\mathbf{B}_0$. ∎

In order to perform the numerical analysis of this method, we will consider the Lagrange interpolation operator $I_h : C^0(\overline{\Omega}) \to V_h$ (if $\boldsymbol{v} = (v_1, v_2) \in C^0(\overline{\Omega})^2$, we denote $I_h(\boldsymbol{v}) = (I_h(v_1), I_h(v_2))$) to approximate the velocity. Then, it is well known (cf. [17]) that

$$|v - I_h(v)|_{m,K} \le C\, h_K^{2-m}\, |v|_{2,K} \qquad \forall v \in H^2(K), \tag{26}$$

$$|v - I_h(v)|_{t,Z} \le C\, h_Z^{2-t-1/2}\, |v|_{2,\omega_Z} \qquad \forall v \in H^2(\omega_Z) \tag{27}$$

for all $K \in \mathcal{T}_h, Z \in \mathcal{E}_h$, where $\omega_Z := \cup\{K \in \mathcal{T}_h : Z \subset \partial K\}$, and $m = 0, 1, 2$, $t = 0, 1$. Let us remark that to obtain the second estimate above, we used the following local trace theorem (for a proof, see [33]): *There exists* $C > 0$, *independent of* h, *such that*

$$\|v\|_{0,\partial K}^2 \le C \left(\frac{1}{h_K} \|v\|_{0,K}^2 + h_K\, |v|_{1,K}^2 \right) \tag{28}$$

for all $v \in H^1(K)$.

In order to approximate the pressure we will consider $\Pi_h : L^2(\Omega) \to Q_h^0$ as the $L^2(\Omega)$-projection onto Q_h^0. This projection satisfies (cf. [17])

$$\|q - \Pi_h(q)\|_{0,\Omega} \le C\, h\, |q|_{1,\Omega} \tag{29}$$

if $q \in H^1(\Omega)$, and hence, using the local trace theorem (28), we obtain

$$\left[\sum_{Z\in\mathcal{E}_h} h_Z \,\|[\![q-\Pi_h(q)]\!]\|_{0,Z}^2\right]^{\frac{1}{2}} \le C\,h\,|q|_{1,\Omega} \tag{30}$$

for all $q \in H^1(\Omega)$.

LEMMA 3.7. *Suppose* $(\boldsymbol{v}, q) \in H^2(\Omega)^2 \times H^1(\Omega)$. *Then,*

$$\|(\boldsymbol{v}-I_h(\boldsymbol{v}), q-\Pi_h(q))\|_h \le Ch\left(\sqrt{\nu}\,|\boldsymbol{v}|_{2,\Omega} + \frac{1}{\sqrt{\nu}}\,|q|_{1,\Omega}\right). \tag{31}$$

Proof. The result follows immediately from the norm definition and (26), (27), (30). ∎

Using previous results we can establish the following convergence result.

THEOREM 3.8. *Let* $(\boldsymbol{u}, p) \in [H^2(\Omega)\cap H_0^1(\Omega)]^2 \times [H^1(\Omega)\cap L_0^2(\Omega)]$ *be the solution of* (1) *and* $(\boldsymbol{u}_1, p_0)$ *the solution of* (14). *Then, the following error estimate holds:*

$$\|(\boldsymbol{u}-\boldsymbol{u}_1, p-p_0)\|_h \le Ch\left(\sqrt{\nu}\,|\boldsymbol{u}|_{2,\Omega} + \frac{1}{\sqrt{\nu}}\,|p|_{1,\Omega}\right). \tag{32}$$

Proof. Let $(\tilde{\boldsymbol{u}}_h, \tilde{p}_h) := (I_h(\boldsymbol{u}), \Pi_h(p)) \in \mathbf{V}_h \times Q_h^0$. From Lemmas 3.5 and 3.6 we know that

$$\begin{aligned}
\|(\boldsymbol{u}-\boldsymbol{u}_1, p-p_0)\|_h^2 &= \mathbf{B}_0\big((\boldsymbol{u}-\boldsymbol{u}_1, p-p_0), (\boldsymbol{u}-\boldsymbol{u}_1, p-p_0)\big)\\
&= \mathbf{B}_0\big((\boldsymbol{u}-\boldsymbol{u}_1, p-p_0), (\boldsymbol{u}-\tilde{\boldsymbol{u}}_h, p-\tilde{p}_h)\big)\\
&\le C\,\|(\boldsymbol{u}-\boldsymbol{u}_1, p-p_0)\|_h\,\|(\boldsymbol{u}-\tilde{\boldsymbol{u}}_h, p-\tilde{p}_h)\|_h\\
&\quad + (\nabla\cdot(\boldsymbol{u}-\boldsymbol{u}_1), p-\tilde{p}_h)_\Omega - (\nabla\cdot(\boldsymbol{u}-\tilde{\boldsymbol{u}}_h), p-p_0)_\Omega\,.
\end{aligned}$$

Now,

$$(\nabla\cdot(\boldsymbol{u}-\boldsymbol{u}_1), p-\tilde{p}_h)_\Omega = -(\nabla\cdot\boldsymbol{u}_1, p-\tilde{p}_h)_\Omega = 0 \tag{33}$$

since $\boldsymbol{u}$ is a solenoidal field and $\nabla\cdot\boldsymbol{u}_1 \in Q_h^0$. On the other hand,

$$\begin{aligned}
(\nabla\cdot(\boldsymbol{u}-\tilde{\boldsymbol{u}}_h), p-p_0)_\Omega &= \sum_{K\in\mathcal{T}_h}\Big[-(\nabla p, \boldsymbol{u}-\tilde{\boldsymbol{u}}_h)_K + (p-p_0, (\boldsymbol{u}-\tilde{\boldsymbol{u}}_h)\cdot\boldsymbol{n})_{\partial K}\Big]\\
&= -(\nabla p, \boldsymbol{u}-\tilde{\boldsymbol{u}}_h)_\Omega + \sum_{K\in\mathcal{T}_h}((p-p_0)\mathbf{I}\cdot\boldsymbol{n}, \boldsymbol{u}-\tilde{\boldsymbol{u}}_h)_{\partial K}\\
&\le |p|_{1,\Omega}\|\boldsymbol{u}-\tilde{\boldsymbol{u}}_h\|_{0,\Omega} + \sum_{Z\in\mathcal{E}_h}([\![(p-p_0)\mathbf{I}\cdot\boldsymbol{n}]\!], \boldsymbol{u}-\tilde{\boldsymbol{u}}_h)_Z\\
&\le Ch^2\,|p|_{1,\Omega}|\boldsymbol{u}|_{2,\Omega} + C\sum_{Z\in\mathcal{E}_h}\frac{h_Z^{\frac{3}{2}}}{\sqrt{\nu}}\,\|[\![(p-p_0)\mathbf{I}\cdot\boldsymbol{n}]\!]\|_{0,Z}\sqrt{\nu}\,|\boldsymbol{u}|_{2,\omega_Z}\\
&\le Ch^2\,|p|_{1,\Omega}|\boldsymbol{u}|_{2,\Omega} + \frac{1}{\gamma}\sum_{Z\in\mathcal{E}_h}\frac{h_Z}{\nu}\,\|[\![(p-p_0)\mathbf{I}\cdot\boldsymbol{n}]\!]\|_{0,Z}^2 + C\gamma\sum_{Z\in\mathcal{E}_h}h^2\nu\,|\boldsymbol{u}|_{2,\omega_Z}^2\\
&\le Ch^2\left((1+\gamma)\,\nu\,|\boldsymbol{u}|_{2,\Omega}^2 + \frac{1}{\nu}|p|_{1,\Omega}^2\right) + \frac{1}{\gamma}\sum_{Z\in\mathcal{E}_h}\frac{h_Z}{\nu}\,\|[\![(p-p_0)\mathbf{I}\cdot\boldsymbol{n}]\!]\|_{0,Z}^2\,,
\end{aligned}$$

where $\gamma > 0$. Now, using the local trace theorem (28) and the fact that $\mathbf{V}_h$ is constituted by linear polynomials we arrive at

$$\begin{aligned}
&\sum_{Z\in\mathcal{E}_h} \frac{h_Z}{\nu} \|[\![(p-p_0)\mathbf{I}\cdot\boldsymbol{n}]\!]\|_{0,Z}^2 \\
&\leq 2\sum_{Z\in\mathcal{E}_h} \frac{h_Z}{\nu} \left(\|[\![\nu\,\partial_{\boldsymbol{n}}(\boldsymbol{u}-\boldsymbol{u}_1)+(p-p_0)\mathbf{I}\cdot\boldsymbol{n}]\!]\|_{0,Z}^2 + \|[\![\nu\,\partial_{\boldsymbol{n}}(\boldsymbol{u}-\boldsymbol{u}_1)]\!]\|_{0,Z}^2 \right) \\
&\leq C\left(\sum_{Z\in\mathcal{E}_h} \left[\frac{h_Z}{\nu} \|[\![\partial_{\boldsymbol{n}}(\boldsymbol{u}-\boldsymbol{u}_1)+(p-p_0)\mathbf{I}\cdot\boldsymbol{n}]\!]\|_{0,Z}^2 \right] + \nu\,|\boldsymbol{u}-\boldsymbol{u}_1|_{1,\Omega}^2 + \nu\,h^2\,|\boldsymbol{u}|_{2,\Omega}^2 \right) \\
&\leq \tilde{C}\,\|(\boldsymbol{u}-\boldsymbol{u}_1,p-p_0)\|_h^2 + C\,\nu\,h^2\,|\boldsymbol{u}|_{2,\Omega}^2\,.
\end{aligned}$$

Hence, choosing $\gamma = 2\tilde{C}$ we obtain

$$\frac{1}{2}\,\|(\boldsymbol{u}-\boldsymbol{u}_1,p-p_0)\|_h^2 \leq Ch^2\left(\nu\,|\boldsymbol{u}|_{2,\Omega}^2+\frac{1}{\nu}|p|_{1,\Omega}^2\right), \tag{34}$$

and the result follows by extracting the square root. ∎

REMARK 3.9. *The last result gives a convergence result for the velocity, plus a convergence result for the jump terms. More precisely, this result implies* $|\boldsymbol{u}-\boldsymbol{u}_1|_{1,\Omega} \leq C\,h$ *and* $\left[\sum_{Z\in\mathcal{E}_h} h_Z\|[\![\partial_{\boldsymbol{n}}(\boldsymbol{u}-\boldsymbol{u}_1)+(p-p_0)\mathbf{I}\cdot\boldsymbol{n}]\!]\|_{0,Z}^2\right]^{\frac{1}{2}} \leq C\,h$, *which are both optimal in order and regularity.*

3.2.1. A convergence result for the pressure. The last result of the previous section does not give convergence on the natural norm of the pressure. That is why a convergence result for the pressure in the $L^2(\Omega)$ norm is now given.

In the proof of the next result we will use the Clément interpolation operator (cf. [17, 24]), $\mathcal{C}_h : H^1(\Omega) \to V_h$. This operator satisfies

$$|v-\mathcal{C}_h(v)|_{m,\Omega} \leq C\,h^{1-m}|v|_{1,\Omega} \qquad \forall v\in H^1(\Omega) \tag{35}$$

for $m = 0, 1$, with the obvious extension to vector-valued functions.

THEOREM 3.10. *Let* $(\boldsymbol{u},p) \in [H^2(\Omega)\cap H_0^1(\Omega)]^2 \times [H^1(\Omega)\cap L_0^2(\Omega)]$ *be the solution of* (1) *and* $(\boldsymbol{u}_1,p_0)$ *the solution of* (14). *Then, the following error estimate holds:*

$$\|p-p_0\|_{0,\Omega} \leq C\,h\left[\nu\,|\boldsymbol{u}|_{2,\Omega}+\,|p|_{1,\Omega}\right]. \tag{36}$$

Proof. From the continuous inf-sup condition (see [24]), there exists $\boldsymbol{w}\in H_0^1(\Omega)^2$ such that $\nabla\cdot\boldsymbol{w} = p-p_0$ in Ω and $|\boldsymbol{w}|_{1,\Omega} \leq C\,\|p-p_0\|_{0,\Omega}$. Let $\boldsymbol{w}_h = \mathcal{C}_h(\boldsymbol{w})$. Then,

applying the consistency of the method we obtain

$$
\begin{aligned}
\|p-p_0\|_{0,\Omega}^2 \;&=\; (\nabla\cdot\boldsymbol{w}, p-p_0)_\Omega \\
&=\; (\nabla\cdot(\boldsymbol{w}-\boldsymbol{w}_h), p-p_0)_\Omega \;+\; (\nabla\cdot\boldsymbol{w}_h, p-p_0)_\Omega \\
&=\; \sum_{K\in\mathcal{T}_h} [-(\boldsymbol{w}-\boldsymbol{w}_h, \nabla p)_K \;+\; (\boldsymbol{w}-\boldsymbol{w}_h, (p-p_0)\mathbf{I}\cdot\boldsymbol{n})_{\partial K}] \\
&\quad +\; \nu\,(\nabla(\boldsymbol{u}-\boldsymbol{u}_1), \nabla\boldsymbol{w}_h)_\Omega \;+\; \sum_{Z\in\mathcal{E}_h} \tau_Z\,([\![\nu\partial_{\boldsymbol{n}}(\boldsymbol{u}-\boldsymbol{u}_1)+(p-p_0)\mathbf{I}\cdot\boldsymbol{n}]\!], [\![\nu\partial_{\boldsymbol{n}}\boldsymbol{w}_h]\!])_Z \\
&\leq \left[\sum_{K\in\mathcal{T}_h} \frac{h_K^2}{\nu}\,|p|_{1,K}^2 \;+\; \sum_{Z\in\mathcal{E}_h} \tau_Z \|[\![(p-p_0)\mathbf{I}\cdot\boldsymbol{n}]\!]\|_{0,Z}^2 \;+\; \nu|\boldsymbol{u}-\boldsymbol{u}_1|_{1,\Omega}^2 \right. \\
&\qquad\qquad \left. +\; \sum_{Z\in\mathcal{E}_h} \tau_Z\,\|[\![\nu\partial_{\boldsymbol{n}}(\boldsymbol{u}-\boldsymbol{u}_1)+(p-p_0)\mathbf{I}\cdot\boldsymbol{n}]\!]\|_{0,Z}^2\right]^{\frac{1}{2}} \\
&\quad \cdot \left[\sum_{K\in\mathcal{T}_h} \frac{\nu}{h_K^2}\,\|\boldsymbol{w}-\boldsymbol{w}_h\|_{0,K}^2 \;+\; \sum_{Z\in\mathcal{E}_h} \tau_Z^{-1}\,\|\boldsymbol{w}-\boldsymbol{w}_h\|_{0,Z}^2 \right. \\
&\qquad\qquad \left. +\,\nu\,|\boldsymbol{w}_h|_{1,\Omega}^2 \;+\; \sum_{Z\in\mathcal{E}_h} \tau_Z\,\|[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{w}_h]\!]\|_{0,Z}^2\right]^{\frac{1}{2}}.
\end{aligned}
$$

Now, using the local trace theorem (28) and (35) we easily obtain

$$
\begin{aligned}
&\left[\sum_{K\in\mathcal{T}_h} \frac{\nu}{h_K^2}\|\boldsymbol{w}-\boldsymbol{w}_h\|_{0,K}^2 + \sum_{Z\in\mathcal{E}_h} \tau_Z^{-1}\|\boldsymbol{w}-\boldsymbol{w}_h\|_{0,Z}^2 + \nu|\boldsymbol{w}_h|_{1,\Omega}^2 + \sum_{Z\in\mathcal{E}_h} \tau_Z\|[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{w}_h]\!]\|_{0,Z}^2\right]^{\frac{1}{2}} \\
&\qquad\qquad \leq C\,\sqrt{\nu}\,|\boldsymbol{w}|_{1,\Omega} \;\leq\; C\,\sqrt{\nu}\,\|p-p_0\|_{0,\Omega}\,.
\end{aligned}
$$

Hence, dividing by $\|p-p_0\|_{0,\Omega}$ and using (28) again we have

$$
\begin{aligned}
&\|p-p_0\|_{0,\Omega} \\
&\leq\; C\,\sqrt{\nu}\left[\sum_{K\in\mathcal{T}_h} \frac{h_K^2}{\nu}\,|p|_{1,K}^2 \;+\; \nu\,|\boldsymbol{u}-\boldsymbol{u}_1|_{1,\Omega}^2 \right. \\
&\qquad \left. +\; \sum_{Z\in\mathcal{E}_h} \tau_Z\,\|[\![\nu\partial_{\boldsymbol{n}}(\boldsymbol{u}-\boldsymbol{u}_1)+(p-p_0)\mathbf{I}\cdot\boldsymbol{n}]\!]\|_{0,Z}^2 \;+\; \tau_Z\,\|[\![\nu\partial_{\boldsymbol{n}}(\boldsymbol{u}-\boldsymbol{u}_1)]\!]\|_{0,Z}^2\right]^{\frac{1}{2}} \\
&\leq\; C\,\sqrt{\nu}\left[\frac{h^2}{\nu}\,|p|_{1,\Omega}^2 \;+\; \|(\boldsymbol{u}-\boldsymbol{u}_1, p-p_0)\|_h^2 \;+\; \nu h^2|\boldsymbol{u}|_{2,\Omega}^2\right]^{\frac{1}{2}} \\
&\leq\; C\,\sqrt{\nu}\left[\frac{h^2}{\nu}\,|p|_{1,\Omega}^2 \;+\; \nu h^2|\boldsymbol{u}|_{2,\Omega}^2\right]^{\frac{1}{2}},
\end{aligned}
$$

and the result follows. □

3.2.2. An error estimate for $\|\boldsymbol{u}-\boldsymbol{u}_1\|_{0,\Omega}$. Throughout this section we will assume that the solution of the following problem, where $(\boldsymbol{u}_1, p_0)$ is the solution of

(14), belongs to $[H^2(\Omega)\cap H_0^1(\Omega)]^2\times[H^1(\Omega)\cap L_0^2(\Omega)]$: Find $(\boldsymbol{\varphi},\pi)$ such that

$$-\nu\,\Delta\,\boldsymbol{\varphi}\,-\,\nabla\pi\,=\,\boldsymbol{u}-\boldsymbol{u}_1,\qquad \nabla\cdot\,\boldsymbol{\varphi}\,=\,0\qquad \text{in }\Omega\,,\tag{37}$$
$$\boldsymbol{\varphi}=\mathbf{0}\qquad \text{on }\partial\Omega.$$

We also assume that the following estimate holds:

$$\nu\,\|\boldsymbol{\varphi}\|_{2,\Omega}\,+\,\|\pi\|_{1,\Omega}\,\leq\,C\,\|\boldsymbol{u}-\boldsymbol{u}_1\|_{0,\Omega}\,.\tag{38}$$

THEOREM 3.11. *Let $(\boldsymbol{u},p)\in[H^2(\Omega)\cap H_0^1(\Omega)]^2\times[H^1(\Omega)\cap L_0^2(\Omega)]$ be the solution of* (1) *and $(\boldsymbol{u}_1,p_0)$ the solution of* (14)*. Then, the following error estimate holds:*

$$\|\boldsymbol{u}-\boldsymbol{u}_1\|_{0,\Omega}\,\leq\,C\,h^2\,\left(\,|\boldsymbol{u}|_{2,\Omega}\,+\,\frac{1}{\nu}\,|p|_{1,\Omega}\right).$$

Proof. Let $(\boldsymbol{\varphi}_h,\pi_h):=(I_h(\boldsymbol{\varphi}),\Pi_h(\pi))\in\mathbf{V}_h\times Q_h^0$. Then, multiplying the first equation in (37) by $\boldsymbol{u}-\boldsymbol{u}_1$ and the second by $-(p-p_0)$, from the definition of bilinear form $\mathbf{B}_0$, the regularity of $(\boldsymbol{\varphi},\pi)$ and the consistency of the method and Lemma 3.6, we obtain

$$\begin{aligned}
\|\boldsymbol{u}-\boldsymbol{u}_1\|_{0,\Omega}^2 &= \nu\,(\nabla\boldsymbol{\varphi},\nabla(\boldsymbol{u}-\boldsymbol{u}_1))_\Omega\,+\,(\pi,\nabla\cdot\,(\boldsymbol{u}-\boldsymbol{u}_1))_\Omega\,-\,(p-p_0,\nabla\cdot\,\boldsymbol{\varphi})_\Omega\\
&= \mathbf{B}_0((\boldsymbol{u}-\boldsymbol{u}_1,p-p_0),(\boldsymbol{\varphi},\pi))\\
&= \mathbf{B}_0((\boldsymbol{u}-\boldsymbol{u}_1,p-p_0),(\boldsymbol{\varphi}-\boldsymbol{\varphi}_h,\pi-\pi_h))\\
&\leq \|(\boldsymbol{u}-\boldsymbol{u}_1,p-p_0)\|_h\|(\boldsymbol{\varphi}-\boldsymbol{\varphi}_h,\pi-\pi_h)\|_h\\
&\quad-\,(p-p_0,\nabla\cdot\,(\boldsymbol{\varphi}-\boldsymbol{\varphi}_h))_\Omega\,+\,(\pi-\pi_h,\nabla\cdot\,(\boldsymbol{u}-\boldsymbol{u}_1))_\Omega\,.
\end{aligned}$$

Now, using (33) we see that $(\pi-\pi_h,\nabla\cdot\,(\boldsymbol{u}-\boldsymbol{u}_1))_\Omega=0$, and hence, using interpolation inequalities (26), Lemma 3.7 and Theorems 3.8 and 3.10, we arrive at

$$\begin{aligned}
&\|\boldsymbol{u}-\boldsymbol{u}_1\|_{0,\Omega}^2\\
&\leq \|(\boldsymbol{u}-\boldsymbol{u}_1,p-p_0)\|_h\|(\boldsymbol{\varphi}-\boldsymbol{\varphi}_h,\pi-\pi_h)\|_h\,+\,\|p-p_0\|_{0,\Omega}\|\nabla\cdot\,(\boldsymbol{\varphi}-\boldsymbol{\varphi}_h)\|_{0,\Omega}\\
&\leq\left[\|(\boldsymbol{u}-\boldsymbol{u}_1,p-p_0)\|_h^2+\frac{1}{\nu}\|p-p_0\|_{0,\Omega}^2\right]^{\frac12}\left[\|(\boldsymbol{\varphi}-\boldsymbol{\varphi}_h,\pi-\pi_h)\|_h^2+\nu\|\nabla\cdot\,(\boldsymbol{\varphi}-\boldsymbol{\varphi}_h)\|_{0,\Omega}^2\right]^{\frac12}\\
&\leq Ch^2\,\left[\nu\,|\boldsymbol{u}|_{2,\Omega}^2+\frac{1}{\nu}\,|p|_{1,\Omega}^2\right]^{\frac12}\,\left[\nu\,|\boldsymbol{\varphi}|_{2,\Omega}^2+\frac{1}{\nu}\,|\pi|_{1,\Omega}^2\right]^{\frac12}\\
&\leq C\frac{1}{\sqrt{\nu}}h^2\,\left(\sqrt{\nu}\,|\boldsymbol{u}|_{2,\Omega}+\frac{1}{\sqrt{\nu}}\,|p|_{1,\Omega}\right)\,\|\boldsymbol{u}-\boldsymbol{u}_1\|_{0,\Omega}\,,
\end{aligned}$$

and the result follows. ∎

4. The method using $\mathbb{P}^1/\mathbb{P}^1$ continuous elements.

4.1. The method. For this case, the finite element space for the velocity is the same as in previous section, but the pressure space is now given by

$$Q_h^1\,:=\,\{q\in C^0(\overline{\Omega})\,:\,q|_K\in\mathbb{P}^1(K)\,\forall\,K\in\mathcal{T}_h\,\}\cap L_0^2(\Omega)\,.$$

As we will see in next section, the method coming directly from (13) is given by the following: Find $(\tilde{\boldsymbol{u}}_1,\tilde{p}_1)\in\mathbf{V}_h\times Q_h^1$ such that

$$\mathbf{B}_1((\tilde{\boldsymbol{u}}_1,\tilde{p}_1),(\boldsymbol{v}_1,q_1))\,=\,\mathbf{F}(\boldsymbol{v}_1,q_1)\qquad\forall\,(\boldsymbol{v}_1,q_1)\in\mathbf{V}_h\times Q_h^1\,,\tag{39}$$

where

$$\mathbf{B}_1((\boldsymbol{u}_1,p_1),(\boldsymbol{v}_1,q_1)) := \mathbf{B}((\boldsymbol{u}_1,p_1),(\boldsymbol{v}_1,q_1)) - \sum_{K\in\mathcal{T}_h}\frac{1}{\nu}\left(\mathcal{B}_K([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1]\!]),\nabla q_1\right)_K, \tag{40}$$

with

$$\begin{aligned}\mathbf{B}\big((\boldsymbol{u}_1,p_1),(\boldsymbol{v}_1,q_1)\big) &:= \nu(\nabla\boldsymbol{u}_1,\nabla\boldsymbol{v}_1)_\Omega - (p_1,\nabla\cdot\boldsymbol{v}_1)_\Omega + (q_1,\nabla\cdot\boldsymbol{u}_1)_\Omega\\ &+ \sum_{K\in\mathcal{T}_h}\tau_K\left(-\nu\Delta\boldsymbol{u}_1+\nabla p_1,\nu\Delta\boldsymbol{v}_1+\nabla q_1\right)_K + \sum_{Z\in\mathcal{E}_h}\tau_Z\left([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1]\!],[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!]\right)_Z,\end{aligned} \tag{41}$$

$$\mathbf{F}\big(\boldsymbol{v}_1,q_1\big) := (\boldsymbol{f},\boldsymbol{v}_1)_\Omega + \sum_{K\in\mathcal{T}_h}\tau_K\left(\boldsymbol{f},\nu\Delta\boldsymbol{v}_1+\nabla q_1\right)_K, \tag{42}$$

$$\tau_K := C_1\frac{h_K^2}{\nu}, \tag{43}$$

where τ_Z is given by (17) and $C_1=\frac{1}{8}$. The value $C_1=\frac{1}{8}$ has been suggested by the error analysis of original method (39) (see Appendix A).

Now, for reasons that we will justify later (see Theorem 4.3 below), we will drop the term

$$-\sum_{K\in\mathcal{T}_h}\left(\frac{1}{\nu}\mathcal{B}_K([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1]\!]),\nabla q_1\right)_K$$

and analyze (and implement) the following simplified version of (39): Find $(\boldsymbol{u}_1,p_1)\in\mathbf{V}_h\times Q_h^1$ such that

$$\mathbf{B}((\boldsymbol{u}_1,p_1),(\boldsymbol{v}_1,q_1)) = \mathbf{F}(\boldsymbol{v}_1,q_1) \qquad \forall\,(\boldsymbol{v}_1,q_1)\in\mathbf{V}_h\times Q_h^1\,. \tag{44}$$

REMARK 4.1. *We see that method* (44) *has the form of a stabilized method of the GLS class, plus a nonstandard jump term formed by the residual of the Cauchy stress tensor on the edges of the triangulation. This will give us control of this residual, which is exclusive to continuous pressure spaces, since in that case pressure jumps vanish.*

REMARK 4.2. *The method is written as the restriction of a consistent method to* $\mathbb{P}^1/\mathbb{P}^1$ *elements simply to avoid some technical difficulties. A nonconsistent presentation may be given and in that case we can prove that the consistency error does not imply a loss of precision.*

As we said before, we will perform the error analysis of method (44). This is due to the fact that the error of method (39) is bounded by that of (44), as stated in the following result, whose proof may be found in Appendix A.

THEOREM 4.3. *Let* $(\boldsymbol{u},p)\in H^2(\Omega)^2\times H^1(\Omega)$ *be the solution of* (1). *Then, method* (39) *is consistent. Moreover,* (39) *has a unique solution* $(\tilde{\boldsymbol{u}}_1,\tilde{p}_1)\in\mathbf{V}_h\times Q_h^1$, *and the following error estimate holds:*

$$|\!|\!|\boldsymbol{u}-\tilde{\boldsymbol{u}}_1|\!|\!|_h^2 + \|p-\tilde{p}_1\|_h^2 \le C\left(|\!|\!|\boldsymbol{u}-\boldsymbol{u}_1|\!|\!|_h^2 + \|p-p_1\|_h^2\right),$$

where $(\boldsymbol{u}_1,p_1)\in\mathbf{V}_h\times Q_h^1$ *is the solution of* (44), *and the norms are defined as in* (49)–(50) *below.*

4.1.1. Derivation of the method. Using spaces $\mathbf{V}_h$ and Q_h^1, (13) reduces to the following: Find $(\boldsymbol{u}_1, p_1) \in \mathbf{V}_h \times Q_h^1$ such that

$$\begin{aligned}
&\nu(\nabla \boldsymbol{u}_1, \nabla \boldsymbol{v}_1)_\Omega - (p_1, \nabla\cdot \boldsymbol{v}_1)_\Omega + (q_1, \nabla\cdot \boldsymbol{u}_1)_\Omega \\
&+ \sum_{K\in\mathcal{T}_h} \frac{1}{\nu} \left(\mathcal{M}_K(\nabla p_1) - \mathcal{B}_K([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1]\!]), \nabla q_1\right)_K \\
&+ \sum_{Z\in\mathcal{E}_h} \frac{1}{\nu} \left(\mathcal{B}_K\left([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1]\!]\right), [\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!]\right)_Z = (\boldsymbol{f}, \boldsymbol{v}_1)_\Omega + \sum_{K\in\mathcal{T}_h} \frac{1}{\nu} \left(\mathcal{M}_K(\boldsymbol{f}), \nabla q_1\right)_K
\end{aligned} \tag{45}$$

for all $(\boldsymbol{v}_1, q_1) \in \mathbf{V}_h \times Q_h^1$. Since $\nabla p_1|_K \in \mathbb{R}^2$, we have

$$\mathcal{M}_K(\nabla p_1) = \left(\mathcal{M}_K(\boldsymbol{e}_1), \mathcal{M}_K(\boldsymbol{e}_2)\right)\nabla p_1 =: \boldsymbol{b}_K^p\, \nabla p_1.$$

As in the previous section, we see that $\boldsymbol{b}_K^p = b_K^p \mathbf{I}$, where b_K^p is the solution of

$$-\Delta b_K^p = 1 \quad \text{in } K, \qquad b_K^p = 0 \quad \text{on } \partial K\,. \tag{46}$$

Hence

$$(\mathcal{M}_K(\nabla p_1), \nabla q_1)_K = \left[\int_K b_K^p\right] \nabla p_1\Big|_K \cdot \nabla q_1\Big|_K = \frac{(b_K^p, 1)_K}{|K|} (\nabla p_1, \nabla q_1)_K\,.$$

On the other hand, from the previous section we know that

$$(\mathcal{B}_K([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1]\!]), [\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!])_Z = \tau_Z\left([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1]\!], [\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!]\right)_Z,$$

where τ_Z has been defined in (17). Moreover, if we suppose that $\boldsymbol{f}$ is piecewise constant, we have $\mathcal{M}_K(\boldsymbol{f}) = b_K^p\, \boldsymbol{f}$, and hence, in the same way as before,

$$(\mathcal{M}_K(\boldsymbol{f}), \nabla q_1)_K = \frac{(b_K^p, 1)_K}{|K|} (\boldsymbol{f}, \nabla q_1)_K.$$

Summing all this up, we arrive at the following expression for (45): Find $(\boldsymbol{u}_1, p_1) \in \mathbf{V}_h \times Q_h^1$ such that

$$\begin{aligned}
&\nu(\nabla \boldsymbol{u}_1, \nabla \boldsymbol{v}_1)_\Omega - (p_1, \nabla\cdot \boldsymbol{v}_1)_\Omega + (q_1, \nabla\cdot \boldsymbol{u}_1)_\Omega + \sum_{K\in\mathcal{T}_h} \frac{(b_K^p, 1)_K}{|K|\nu} (\nabla p_1, \nabla q_1)_K \\
&- \sum_{K\in\mathcal{T}_h} \frac{1}{\nu} (\mathcal{B}_K([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1]\!]), \nabla q_1)_K + \sum_{Z\in\mathcal{E}_h} \frac{(b_K^u, 1)_Z}{|Z|\nu} ([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1]\!], [\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!])_Z \\
&= (\boldsymbol{f}, \boldsymbol{v}_1)_\Omega + \sum_{K\in\mathcal{T}_h} \frac{(b_K^p, 1)_K}{|K|\nu} (\boldsymbol{f}, \nabla q_1)_K
\end{aligned} \tag{47}$$

for all $(\boldsymbol{v}_1, q_1) \in \mathbf{V}_h \times Q_h^1$. Finally, since the mesh is regular by a scaling argument (cf. [31]) we have that

$$\frac{1}{|K|}(b_K^p, 1)_K \sim C_1\, h_K^2\,, \tag{48}$$

where C_1 is a positive constant independent of h and ν. Hence, replacing (48) in (47) and defining τ_K appropriately, we obtain method (39).

REMARK 4.4. *The assumption of the piecewise constant $\boldsymbol{f}$ on the right-hand side is made simply to derive the method, but it does not affect the precision of it. Indeed, if we consider a general $\boldsymbol{f} \in H^1(\Omega)^2$ and take its projection onto the space of piecewise constant functions, we keep the same order of convergence of the method* (*see Appendix* B).

4.2. Error analysis. Let us consider the mesh-dependent norms

$$|||\boldsymbol{v}|||_h^2 := \nu\,|\boldsymbol{v}|_{1,\Omega}^2 + \sum_{Z\in\mathcal{E}_h} \tau_Z \|[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}]\!]\|_{0,Z}^2\,, \tag{49}$$

$$\|q\|_h^2 := \sum_{K\in\mathcal{T}_h} \tau_K |q|_{1,K}^2\,. \tag{50}$$

The first results concern the consistency and well-posedness of stabilized method (44).

LEMMA 4.5. *Let* $(\boldsymbol{u},p)\in[H^2(\Omega)\cap H_0^1(\Omega)]^2\times[H^1(\Omega)\cap L_0^2(\Omega)]$ *be the solution of* (1) *and* $(\boldsymbol{u}_1,p_1)$ *the solution of* (44). *Then,*

$$\mathbf{B}\big((\boldsymbol{u}-\boldsymbol{u}_1,p-p_1),(\boldsymbol{v}_1,q_1)\big)=0\quad\forall\,(\boldsymbol{v}_1,q_1)\in\mathbf{V}_h\times Q_h^1.$$

Proof. The result follows from the definition of $\mathbf{B}$ and the fact that $[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}]\!]=\mathbf{0}$ a.e. on the internal edges. ∎

LEMMA 4.6. *Let be* $(\boldsymbol{v}_1,q_1)\in\mathbf{V}_h\times Q_h^1$. *Then*

$$\mathbf{B}\big((\boldsymbol{v}_1,q_1),(\boldsymbol{v}_1,q_1)\big)=|||\boldsymbol{v}_1|||_h^2+\|q_1\|_h^2.$$

Proof. The result follows from the definition of $\mathbf{B}$ and the fact that $\Delta\boldsymbol{v}_1=\mathbf{0}$ in each $K\in\mathcal{T}_h$. ∎

Now, in order to approximate the velocity we will consider the Lagrange interpolation operator as in the previous section and for the pressure interpolation we will use the Clément interpolation operator $\mathcal{C}_h$ satisfying (35).

The following approximation result will be useful in what follows.

LEMMA 4.7. *Let* $(\boldsymbol{v},q)\in[H^2(\Omega)\cap H_0^1(\Omega)]^2\times[H^1(\Omega)\cap L_0^2(\Omega)]$ *and* $\tilde{q}_h:=\mathcal{C}_h(q)-\frac{(\mathcal{C}_h(q),1)_\Omega}{|\Omega|}$. *Then,*

$$|||\boldsymbol{v}-I_h(\boldsymbol{v})|||_h^2+\sum_{K\in\mathcal{T}_h}\Big[\tau_K^{-1}\|\boldsymbol{v}-I_h(\boldsymbol{v})\|_{0,K}^2+\nu h_K^2\|\Delta(\boldsymbol{v}-I_h(\boldsymbol{v}))\|_{0,K}^2\Big]\le Ch^2\,\nu\,|\boldsymbol{v}|_{2,\Omega}^2, \tag{51}$$

$$\|q-\tilde{q}_h\|_h+\frac{1}{\sqrt{\nu}}\|q-\tilde{q}_h\|_{0,\Omega}\le C\,\frac{h}{\sqrt{\nu}}\,|q|_{1,\Omega}. \tag{52}$$

Proof. The result follows from the norm definition and using $\|q-\tilde{q}_h\|_{0,\Omega}\le\|q-\mathcal{C}_h(q)\|_{0,\Omega}$ combined with (26), (27), and (35). ∎

Using Lemmas 4.5–4.7 we can establish the following convergence result.

THEOREM 4.8. *Let* $(\boldsymbol{u},p)\in[H^2(\Omega)\cap H_0^1(\Omega)]^2\times[H^1(\Omega)\cap L_0^2(\Omega)]$ *be the solution of* (1) *and* $(\boldsymbol{u}_1,p_1)$ *the solution of* (44). *Then, the following error estimate holds:*

$$|||\boldsymbol{u}-\boldsymbol{u}_1|||_h+\|p-p_1\|_h\le C\,h\,\left[\sqrt{\nu}\,|\boldsymbol{u}|_{2,\Omega}+\frac{1}{\sqrt{\nu}}\,|p|_{1,\Omega}\right]. \tag{53}$$

Proof. Let $\tilde{\boldsymbol{u}}_h:=I_h(\boldsymbol{u}),\tilde{p}_h:=\mathcal{C}_h(p)-\frac{(\mathcal{C}_h(p),1)_\Omega}{|\Omega|}$ and $(\eta^{\boldsymbol{u}},\eta^p):=(\boldsymbol{u}-\tilde{\boldsymbol{u}}_h,p-\tilde{p}_h)$. Applying Lemma 4.6 and the consistency of the method, and integrating by parts we

have

$$
\begin{aligned}
&|||\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_h|||_h^2+\|p_1-\tilde{p}_h\|_h^2 = \mathbf{B}((\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_h,p_1-\tilde{p}_h),(\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_h,p_1-\tilde{p}_h))\\
&= \mathbf{B}((\eta^{\boldsymbol{u}},\eta^p),(\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_h,p_1-\tilde{p}_h))\\
&= \nu\,(\nabla\eta^{\boldsymbol{u}},\nabla(\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_h))_\Omega - (\eta^p,\nabla\cdot(\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_h))_\Omega - (\eta^{\boldsymbol{u}},\nabla(p_1-\tilde{p}_h))_\Omega\\
&\quad+\sum_{K\in\mathcal{T}_h}\tau_K\,(-\nu\Delta\eta^{\boldsymbol{u}},\nabla(p_1-\tilde{p}_h))_K+\sum_{K\in\mathcal{T}_h}\tau_K\,(\nabla\eta^p,\nabla(p_1-\tilde{p}_h))_K\\
&\quad+\sum_{Z\in\mathcal{E}_h}\tau_Z\,([\![\nu\partial_{\boldsymbol{n}}\eta^{\boldsymbol{u}}]\!],[\![\nu\partial_{\boldsymbol{n}}(\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_h)]\!])_Z\\
&\le\left[\nu\,|\eta^{\boldsymbol{u}}|_{1,\Omega}^2+\frac{1}{\nu}\,\|\eta^p\|_{0,\Omega}^2+\sum_{K\in\mathcal{T}_h}(\,\tau_K^{-1}\,\|\eta^{\boldsymbol{u}}\|_{0,K}^2+\nu^2\tau_K\,\|\Delta\eta^{\boldsymbol{u}}\|_{0,K}^2\,)\right.\\
&\quad\left.+\|\eta^p\|_h^2+\sum_{Z\in\mathcal{E}_h}\tau_Z\,\|[\![\nu\partial_{\boldsymbol{n}}\eta^{\boldsymbol{u}}]\!]\|_{0,Z}^2\right]^{\frac12}\\
&\quad\cdot\left[3\nu\,|\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_h|_{1,\Omega}^2+3\sum_{K\in\mathcal{T}_h}\tau_K\,\|\nabla(p_1-\tilde{p}_h)\|_{0,K}^2+\sum_{Z\in\mathcal{E}_h}\tau_Z\,\|[\![\nu\partial_{\boldsymbol{n}}(\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_h)]\!]\|_{0,Z}^2\right]^{\frac12}\\
&\quad\le\sqrt{3}\left[|||\eta^{\boldsymbol{u}}|||_h^2+\sum_{K\in\mathcal{T}_h}[\tau_K^{-1}\,\|\eta^{\boldsymbol{u}}\|_{0,K}^2+\nu h_K^2\|\Delta\eta^{\boldsymbol{u}}\|_{0,K}^2]+\|\eta^p\|_h^2+\frac{1}{\nu}\,\|\eta^p\|_{0,\Omega}^2\right]^{\frac12}\\
&\qquad\cdot\left[|||\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_h|||_h^2+\|p_1-\tilde{p}_h\|_h^2\right]^{\frac12}.
\end{aligned}
$$

Hence, dividing by the last term and applying Lemma 4.7 we arrive at

$$
|||\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_h|||_h+\|p_1-\tilde{p}_h\|_h\le C\left[\nu h^2\,|\boldsymbol{u}|_{2,\Omega}^2+\frac{h^2}{\nu}\,|p|_{1,\Omega}^2\right]^{\frac12}. \tag{54}
$$

The result follows using triangular inequality and Lemma 4.7 once more. ∎

REMARK 4.9. *In particular, from the previous theorem we have an $O(h)$ convergence for $|\boldsymbol{u}-\boldsymbol{u}_1|_{1,\Omega}$ and $\left[\sum_{Z\in\mathcal{E}_h}h_Z\,\|[\![\partial_{\boldsymbol{n}}(\boldsymbol{u}-\boldsymbol{u}_1)]\!]\|_{0,Z}^2\right]^{\frac12}$, which are both optimal in order and regularity.*

4.2.1. A convergence result for the pressure. In the last result of the previous section we had an error estimate in the velocity, but, due to the norm definition, we did not guarantee the convergence of the pressure. The next result shows that we have an optimal error estimate in the natural norm of the pressure, which is independent of ν.

THEOREM 4.10. *Let $(\boldsymbol{u},p)\in[H^2(\Omega)\cap H_0^1(\Omega)]^2\times[H^1(\Omega)\cap L_0^2(\Omega)]$ be the solution of (1) and $(\boldsymbol{u}_1,p_1)$ the solution of (44). Then, the following error estimate holds:*

$$
\|p-p_1\|_{0,\Omega}\le C\,h\left[\nu\,|\boldsymbol{u}|_{2,\Omega}+|p|_{1,\Omega}\right]. \tag{55}
$$

Proof. From the continuous inf-sup condition (see [24]), there exists $\boldsymbol{w}\in H_0^1(\Omega)^2$ such that $\nabla\cdot\boldsymbol{w}=p-p_1$ in Ω and $|\boldsymbol{w}|_{1,\Omega}\le C\,\|p-p_1\|_{0,\Omega}$. Let $\boldsymbol{w}_h=\mathcal{C}_h(\boldsymbol{w})\in\mathbf{V}_h$.

Then, applying the consistency of the method, (35), and previous theorem, we obtain

$$\begin{aligned}
\|p-p_1\|_{0,\Omega}^2 &= (\nabla\cdot\boldsymbol{w}, p-p_1)_\Omega \,=\, (\nabla\cdot(\boldsymbol{w}-\boldsymbol{w}_h), p-p_1)_\Omega \,+\, (\nabla\cdot\boldsymbol{w}_h, p-p_1)_\Omega \\
&= -\sum_{K\in\mathcal{T}_h} (\boldsymbol{w}-\boldsymbol{w}_h, \nabla(p-p_1))_K \,+\, \nu\,(\nabla(\boldsymbol{u}-\boldsymbol{u}_1), \nabla\boldsymbol{w}_h)_\Omega \\
&\quad + \sum_{Z\in\mathcal{E}_h} \tau_Z\,([\![\nu\partial_{\boldsymbol{n}}(\boldsymbol{u}-\boldsymbol{u}_1)]\!], [\![\nu\partial_{\boldsymbol{n}}\boldsymbol{w}_h]\!])_Z \\
&\le \sum_{K\in\mathcal{T}_h} \|\boldsymbol{w}-\boldsymbol{w}_h\|_{0,K}|p-p_1|_{1,K} \,+\, \nu\,|\boldsymbol{u}-\boldsymbol{u}_1|_{1,\Omega}|\boldsymbol{w}_h|_{1,\Omega} \\
&\quad + \sum_{Z\in\mathcal{E}_h} \tau_Z\,\|[\![\nu\partial_{\boldsymbol{n}}(\boldsymbol{u}-\boldsymbol{u}_1)]\!]\|_{0,Z}\|[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{w}_h]\!]\|_{0,Z} \\
&\le \left[\sum_{K\in\mathcal{T}_h} \tau_K\,|p-p_1|_{1,K}^2 + \nu\,|\boldsymbol{u}-\boldsymbol{u}_1|_{1,\Omega}^2 \,+\, \sum_{Z\in\mathcal{E}_h} \tau_Z\,\|[\![\nu\partial_{\boldsymbol{n}}(\boldsymbol{u}-\boldsymbol{u}_1)]\!]\|_{0,Z}^2\right]^{\frac12} \\
&\quad \cdot\left[\sum_{K\in\mathcal{T}_h} \tau_K^{-1}\|\boldsymbol{w}-\boldsymbol{w}_h\|_{0,K}^2 \,+\, \nu\,|\boldsymbol{w}_h|_{1,\Omega}^2 \,+\, \sum_{Z\in\mathcal{E}_h} \tau_Z\|[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{w}_h]\!]\|_{0,Z}^2\right]^{\frac12} \\
&\le C\,\sqrt{\nu}\left[|\!|\!|\boldsymbol{u}-\boldsymbol{u}_1|\!|\!|_h + \|p-p_1\|_h\right]\left[|\boldsymbol{w}|_{1,\Omega}^2 \,+\, |\boldsymbol{w}_h|_{1,\Omega}^2\right]^{\frac12} \\
&\le C\,\sqrt{\nu}h\left(\sqrt{\nu}\,|\boldsymbol{u}|_{2,\Omega} \,+\, \frac{1}{\sqrt{\nu}}\,|p|_{1,\Omega}\right)\|p-p_1\|_{0,\Omega}\,,
\end{aligned}$$

where, in order to bound the term $\sum_{Z\in\mathcal{E}_h}\tau_Z\|[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{w}_h]\!]\|_{0,Z}^2$ we have used the local trace result (28) and $\boldsymbol{w}_h|_K\in\mathbb{P}^1(K)^2$. The result follows then by dividing by the last term. ∎

4.2.2. An error estimate for $\|\boldsymbol{u}-\boldsymbol{u_1}\|_{\boldsymbol{0,\Omega}}$. Throughout this section we will assume that the solution of the following problem, where $(\boldsymbol{u}_1, p_1)$ is the solution of (44), belongs to $[H^2(\Omega)\cap H_0^1(\Omega)]^2\times[H^1(\Omega)\cap L_0^2(\Omega)]$: Find $(\boldsymbol{\varphi},\pi)$ such that

$$\begin{aligned}
-\nu\,\Delta\boldsymbol{\varphi} \,-\, \nabla\pi \,=\, \boldsymbol{u}-\boldsymbol{u}_1, \qquad \nabla\cdot\boldsymbol{\varphi} \,=\, 0 \qquad &\text{in } \Omega\,, \\
\boldsymbol{\varphi} = \mathbf{0} \qquad &\text{on } \partial\Omega\,.
\end{aligned} \tag{56}$$

We also assume that the following estimate holds:

$$\nu\,\|\boldsymbol{\varphi}\|_{2,\Omega} \,+\, \|\pi\|_{1,\Omega} \,\le\, C\,\|\boldsymbol{u}-\boldsymbol{u}_1\|_{0,\Omega}\,. \tag{57}$$

THEOREM 4.11. *Under the hypothesis of Theorem* 4.10 *the following error estimate holds:*

$$\|\boldsymbol{u}-\boldsymbol{u}_1\|_{0,\Omega} \,\le\, C\,h^2\left(|\boldsymbol{u}|_{2,\Omega} \,+\, \frac{1}{\nu}\,|p|_{1,\Omega}\right).$$

Proof. Let $(\boldsymbol{\varphi}_h,\pi_h) := (I_h(\boldsymbol{\varphi}), \mathcal{C}_h(\pi) - \frac{(\mathcal{C}_h(\pi),1)_\Omega}{|\Omega|}) \in \mathbf{V}_h\times Q_h^1$. Then, multiplying the first equation in (56) by $\boldsymbol{u}-\boldsymbol{u}_1$ and the second by $-(p-p_1)$, from the definition of bilinear form $\mathbf{B}$, the consistency of the method, the fact that $[\![\partial_{\boldsymbol{n}}\boldsymbol{\varphi}]\!] = \mathbf{0}$ a.e. on the internal edges, interpolation inequalities (26), (27), and (35), and Theorems 4.8

and 4.10, we obtain

$$
\begin{aligned}
&\|\boldsymbol{u}-\boldsymbol{u}_1\|_{0,\Omega}^2 \\
&= \nu\,(\nabla\boldsymbol{\varphi},\nabla(\boldsymbol{u}-\boldsymbol{u}_1))_\Omega \,+\, (\pi,\nabla\cdot(\boldsymbol{u}-\boldsymbol{u}_1))_\Omega \,-\, (p-p_1,\nabla\cdot\boldsymbol{\varphi})_\Omega \\
&= \mathbf{B}((\boldsymbol{u}-\boldsymbol{u}_1,p-p_1),(\boldsymbol{\varphi},\pi)) \,-\, \sum_{K\in\mathcal{T}_h}\tau_K\,(-\nu\Delta(\boldsymbol{u}-\boldsymbol{u}_1)+\nabla(p-p_1),\nu\Delta\boldsymbol{\varphi}+\nabla\pi)_K \\
&= \mathbf{B}((\boldsymbol{u}-\boldsymbol{u}_1,p-p_1),(\boldsymbol{\varphi}-\boldsymbol{\varphi}_h,\pi-\pi_h)) \\
&\quad - \sum_{K\in\mathcal{T}_h}\tau_K\,(-\nu\Delta(\boldsymbol{u}-\boldsymbol{u}_1)+\nabla(p-p_1),\nu\Delta\boldsymbol{\varphi}+\nabla\pi)_K \\
&\le \left[\nu\,|\boldsymbol{u}-\boldsymbol{u}_1|_{1,\Omega}^2+\nu\,\|\nabla\cdot(\boldsymbol{u}-\boldsymbol{u}_1)\|_{0,\Omega}^2+\frac{1}{\nu}\,\|p-p_1\|_{0,\Omega}^2\right. \\
&\quad \left.+\sum_{Z\in\mathcal{E}_h}\tau_Z\,\|[\![\nu\partial_{\boldsymbol{n}}(\boldsymbol{u}-\boldsymbol{u}_1)]\!]\|_{0,Z}^2 \,+\, 2\sum_{K\in\mathcal{T}_h}\tau_K\|-\nu\Delta\boldsymbol{u}+\nabla(p-p_1)\|_{0,K}^2\right]^{\frac12}\cdot \\
&\quad \left[\nu\,|\boldsymbol{\varphi}-\boldsymbol{\varphi}_h|_{1,\Omega}^2+\frac{1}{\nu}\,\|\pi-\pi_h\|_{0,\Omega}^2 \,+\, \nu\,\|\nabla\cdot(\boldsymbol{\varphi}-\boldsymbol{\varphi}_h)\|_{0,\Omega}^2 \,+\, \sum_{K\in\mathcal{T}_h}\tau_K\|\nabla(\pi-\pi_h)\|_{0,K}^2\right. \\
&\quad \left.+\sum_{Z\in\mathcal{E}_h}\tau_Z\,\|[\![\nu\partial_{\boldsymbol{n}}(\boldsymbol{\varphi}-\boldsymbol{\varphi}_h)]\!]\|_{0,Z}^2 \,+\, \sum_{K\in\mathcal{T}_h}\tau_K\|\nu\Delta\boldsymbol{\varphi}+\nabla\pi\|_{0,K}^2\right]^{\frac12} \\
&\le C\left[|\!|\!|\boldsymbol{u}-\boldsymbol{u}_1|\!|\!|_h^2+\nu h^2|\boldsymbol{u}|_{2,\Omega}^2+\|p-p_1\|_h^2+\frac{1}{\nu}\|p-p_1\|_{0,\Omega}^2\right]^{\frac12}\left[\nu h^2|\boldsymbol{\varphi}|_{2,\Omega}^2+\frac{h^2}{\nu}|\pi|_{1,\Omega}^2\right]^{\frac12} \\
&\le C\,\frac{1}{\sqrt{\nu}}\,h^2\,\left(\sqrt{\nu}\,|\boldsymbol{u}|_{2,\Omega}+\frac{1}{\sqrt{\nu}}\,|p|_{1,\Omega}\right)\,\|\boldsymbol{u}-\boldsymbol{u}_1\|_{0,\Omega}\,,
\end{aligned}
$$

and the result follows. ∎

REMARK 4.12. *As we claimed before, the error analysis is independent of the nature of the* $\boldsymbol{f}$ *on the right-hand side, and hence, we have actually justified method* (44) *for a general* $\boldsymbol{f}\in L^2(\Omega)^2$. *In Appendix* B *we will show that if* $\boldsymbol{f}\in H^1(\Omega)^2$, *then the difference between implementing method* (44) *and* $(\boldsymbol{f},\boldsymbol{v}_1)_\Omega+\sum_{K\in\mathcal{T}_h}\nu^{-1}(\mathcal{M}_K(\boldsymbol{f}),\nu\Delta\boldsymbol{v}_1+\nabla q)_K$ *on the right-hand side is smaller than the order of the method. On the other hand, method* (44) *has been justified for any constant* $C_1>0$, *even if it has been presented with* $C_1=\frac18$.

5. An alternative formulation including the residual on the boundary. In this section we propose another class of methods arising from a different choice of enrichment functions. We will denote by R_h the pressure space according to the choice of elements, i.e., $R_h=Q_h^1$ for $\mathbb{P}^1/\mathbb{P}^1$ elements and $R_h=Q_h^0$ for $\mathbb{P}^1/\mathbb{P}^0$ elements. The proposed method reads as follows: Find $(\boldsymbol{u}^r,p^r)\in\mathbf{V}_h\times R_h$ such that

$$
\mathbf{B}_r((\boldsymbol{u}^r,p^r),(\boldsymbol{v}_1,q))=\mathbf{F}(\boldsymbol{v}_1,q)\qquad\forall\,(\boldsymbol{v}_1,q)\in\mathbf{V}_h\times R_h\,, \tag{58}
$$

where

$$
\begin{aligned}
\mathbf{B}_r((\boldsymbol{u}_1,p),(\boldsymbol{v}_1,q)) &= \nu(\nabla\boldsymbol{u}_1,\nabla\boldsymbol{v}_1)_\Omega-(p,\nabla\cdot\boldsymbol{v}_1)_\Omega+(q,\nabla\cdot\boldsymbol{u}_1)_\Omega \\
&\quad+\sum_{K\in\mathcal{T}_h}\tau_K(-\nu\Delta\boldsymbol{u}_1+\nabla p,\nu\Delta\boldsymbol{v}_1+\nabla q)_K \\
&\quad+\sum_{Z\in\mathcal{E}_h}\tilde{\tau}_Z\,([\![-\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1+p\mathbf{I}\cdot\boldsymbol{n}]\!],[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1+q\mathbf{I}\cdot\boldsymbol{n}]\!])_Z\,,
\end{aligned} \tag{59}
$$

$\mathbf{F}$ is given by (42), τ_K by (43), and

$$\tilde{\tau}_Z := \frac{h_Z}{12\alpha\nu}\,, \tag{60}$$

where $\alpha > 0$ will be fixed in order to have a well-posed problem.

This method may be obtained in the same way as method (14) and (44) by taking the enrichment function $\boldsymbol{u}_e$ to be the solution of (4), together with the boundary conditions

$$-\nu\partial_{\boldsymbol{ss}}\boldsymbol{u}_e = \frac{1}{\alpha h_Z}[\![-\nu\partial_{\boldsymbol{n}}\boldsymbol{u}_1^r + p^r\mathbf{I}\cdot\boldsymbol{n}]\!] \text{ on each } Z\subset\partial K, \qquad \boldsymbol{u}_e = \mathbf{0} \text{ at the nodes}\,, \tag{61}$$

on the internal edges, and $\boldsymbol{u}_e = \mathbf{0}$ on $\partial K\cap\partial\Omega$. In fact, using this choice of enrichment we can perform the same derivation from sections 3 and 4, neglecting once more a cross term appearing in $\mathbb{P}^1/\mathbb{P}^1$ discretization.

REMARK 5.1. *This method is different from* (14) *and* (44) *from two viewpoints. First, the boundary term contains the residual of the Cauchy stress tensor on the trial function. This fact comes from the choice of the enriched part as being a corrector for the residual inside the element and on the boundary. The other difference is the stabilization parameter on the edges. Now, this parameter contains a constant to set.*

Now, let $|\!|\!|.|\!|\!|_h$ be the mesh-dependent norm defined by:

$$|\!|\!|(\boldsymbol{v}_1,q)|\!|\!|_h := \left[\nu\,|\boldsymbol{v}_1|^2_{1,\Omega} + \sum_{K\in\mathcal{T}_h}\tau_K\,|q|^2_{1,K} + \sum_{Z\in\mathcal{E}_h}\tilde{\tau}_Z\,\|[\![q]\!]\|^2_{0,Z}\right]^{\frac{1}{2}}. \tag{62}$$

Then, we have the following coercivity result.

LEMMA 5.2. *Let us suppose that $\alpha > C_t/3$, where $C_t > 0$ is the constant from local trace result* (28)*. Then, for all $(\boldsymbol{v}_1,q)\in\mathbf{V}_h\times R_h$ there holds*

$$\mathbf{B}_r((\boldsymbol{v}_1,q),(\boldsymbol{v}_1,q)) \geq \frac{1}{2}\,|\!|\!|(\boldsymbol{v}_1,q)|\!|\!|^2_h\,.$$

Proof. Let $(\boldsymbol{v}_1,q)\in\mathbf{V}_h\times R_h$. Then, since $\Delta\boldsymbol{v}_1 = \mathbf{0}$ on each $K\in\mathcal{T}_h$, applying local trace result (28) and the definition of $\tilde{\tau}_Z$ we obtain

$$\begin{aligned}
\mathbf{B}_r((\boldsymbol{v}_1,q),(\boldsymbol{v}_1,q)) &= \nu|\boldsymbol{v}_1|^2_{1,\Omega} \\
&\quad + \sum_{K\in\mathcal{T}_h}\tau_K\|\nabla q\|^2_{0,K} + \sum_{Z\in\mathcal{E}_h}\tilde{\tau}_Z(-\nu^2\|[\![\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!]\|^2_{0,Z} + \|[\![q]\!]\|^2_{0,Z}) \\
&\geq \nu\,|\boldsymbol{v}_1|^2_{1,\Omega} - \frac{C_t}{6\alpha}\nu\sum_{K\in\mathcal{T}_h}|\boldsymbol{v}_1|^2_{1,K} + \sum_{K\in\mathcal{T}_h}\tau_K\,|q|^2_{1,K} + \sum_{Z\in\mathcal{E}_h}\tilde{\tau}_Z\|[\![q]\!]\|^2_{0,Z} \\
&\geq \frac{1}{2}\,|\!|\!|(\boldsymbol{v}_1,q)|\!|\!|^2_h\,,
\end{aligned}$$

an the result follows. ∎

Once this method has been proved to be stable, following a procedure absolutely analogous to those from sections 3 and 4 we can prove the consistency of (58) and perform a complete error analysis of (58), obtaining the same results as in previous sections.

6. Numerical validations.

6.1. An analytical solution: Convergence validation. For this test case, the domain is taken as the square $\Omega = (0,1) \times (0,1)$, $\nu = 1$, and $\boldsymbol{f}$ is set such that the exact solution of our Stokes problem is given by

$$\begin{aligned} u_1(x,y) &= -256x^2(x-1)^2y(y-1)(2y-1)\,, \\ u_2(x,y) &= -u_1(y,x)\,, \\ p(x,y) &= 150(x-0.5)(y-0.5)\,. \end{aligned}$$

We perform convergence analysis for methods (14), (44), and (58) using continuous $\mathbb{P}^1/\mathbb{P}^1$ and $\mathbb{P}^1/\mathbb{P}^0$ elements.

6.1.1. The $\mathbb{P}^1/\mathbb{P}^1$ case. For this case we first depict in Figures 1–2 the convergence history for method (44). The results reproduce our theoretical results showing an $O(h)$ order of convergence for $|\boldsymbol{u} - \boldsymbol{u}_1|_{1,\Omega}$,

$$|[\![\partial_{\boldsymbol{n}}(\boldsymbol{u} - \boldsymbol{u}_1)]\!]|_h := \left[\sum_{Z \in \mathcal{E}_h} h_Z \|[\![\partial_{\boldsymbol{n}}(\boldsymbol{u} - \boldsymbol{u}_1)]\!]\|^2_{0,Z}\right]^{\frac{1}{2}}$$

and $\|p - p_1\|_{0,\Omega}$, and an $O(h^2)$ convergence for $\|\boldsymbol{u} - \boldsymbol{u}_1\|_{0,\Omega}$.

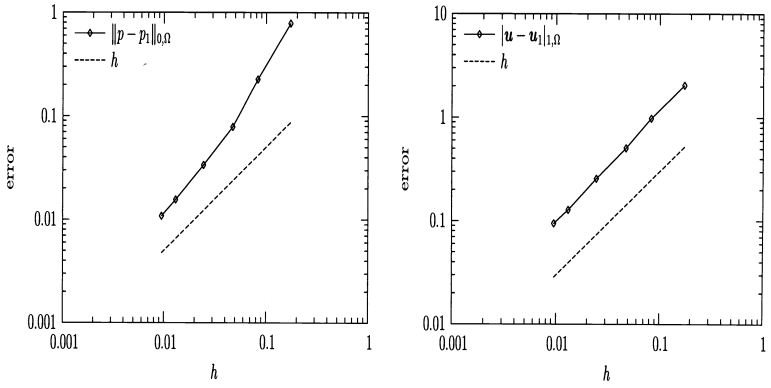

FIG. 1. *Method* (44)*: convergence history for* $\|p - p_1\|_{0,\Omega}$ *and* $|\boldsymbol{u} - \boldsymbol{u}_1|_{1,\Omega}$.

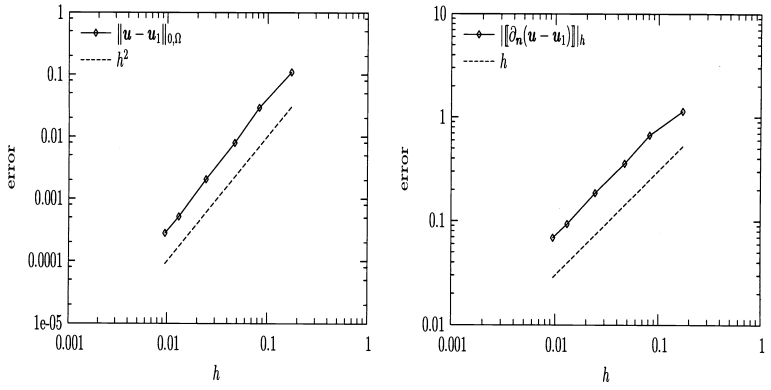

FIG. 2. *Method* (44)*: convergence history for* $\|\boldsymbol{u} - \boldsymbol{u}_1\|_{0,\Omega}$ *and* $|[\![\partial_{\boldsymbol{n}}(\boldsymbol{u} - \boldsymbol{u}_1)]\!]|_h$.

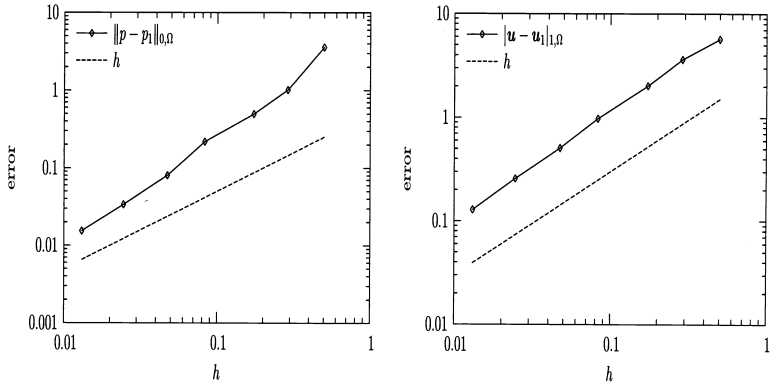

FIG. 3. *Method* (58)*: convergence history for* $\|p - p_1\|_{0,\Omega}$ *and* $|\boldsymbol{u} - \boldsymbol{u}_1|_{1,\Omega}$.

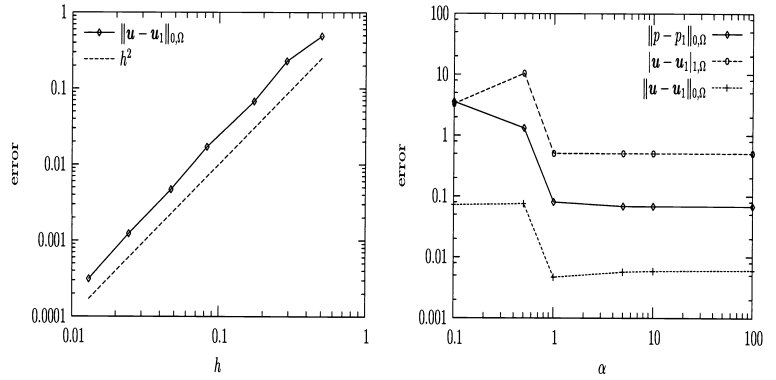

FIG. 4. *Method* (58)*: convergence history for* $\|\boldsymbol{u} - \boldsymbol{u}_1\|_{0,\Omega}$*, and sensitivity of* (58) *with respect to* α.

Method (58) is tested next. The results are depicted in Figures 3–4 using $\alpha = 1$, where the results are in perfect accordance with the theoretical results. The justification of this choice for α may be found in Figure 4 (on the right) where we have depicted the behavior of the error in terms of α (using a mesh of around 2500 elements) and we see that for $\alpha \geq 1$ the error is almost independent of α, showing that the restriction of Lemma 5.2 is not only theoretical, but at the same time showing that, once we are inside the region predicted by the theory, the performance of the method is independent of α.

6.1.2. The $\mathbb{P}^1/\mathbb{P}^0$ case. For this case we first depict in Figures 5–6 the convergence history for method (14). The results reproduce our theoretical results showing an $O(h)$ order of convergence for $|\boldsymbol{u}-\boldsymbol{u}_1|_{1,\Omega}$, $|[\![\partial_{\boldsymbol{n}}(\boldsymbol{u}-\boldsymbol{u}_1)+(p-p_0)\boldsymbol{n}]\!]|_h$ and $\|p-p_0\|_{0,\Omega}$, and an $O(h^2)$ convergence for $\|\boldsymbol{u} - \boldsymbol{u}_1\|_{0,\Omega}$.

Method (58) is tested next. The results are depicted in Figures 7–8 using $\alpha = 1$, where the results are in perfect accordance with the theoretical results, giving an $O(h)$ for $|\boldsymbol{u} - \boldsymbol{u}_1|_{1,\Omega}$, $|[\![p - p_0]\!]|_h$, and $\|p - p_0\|_{0,\Omega}$, and an $O(h^2)$ convergence for $\|\boldsymbol{u} - \boldsymbol{u}_1\|_{0,\Omega}$. Concerning the choice of α, the situation now is quite different from that in the previous section. As a matter of fact, since we only control the pressure

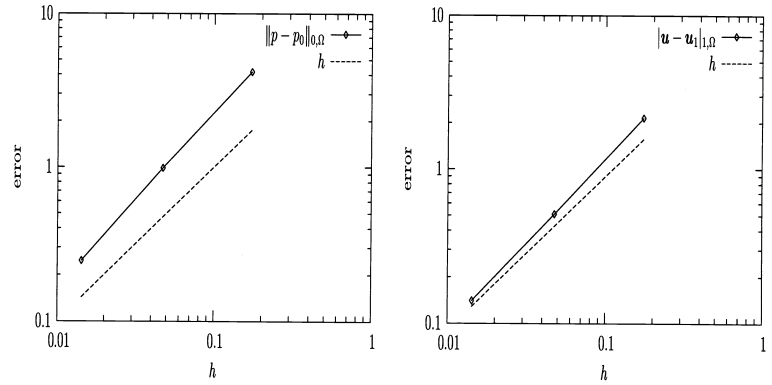

FIG. 5. *Method* (14)*: convergence history for* $\|p - p_0\|_{0,\Omega}$ *and* $|\boldsymbol{u} - \boldsymbol{u}_1|_{1,\Omega}$.

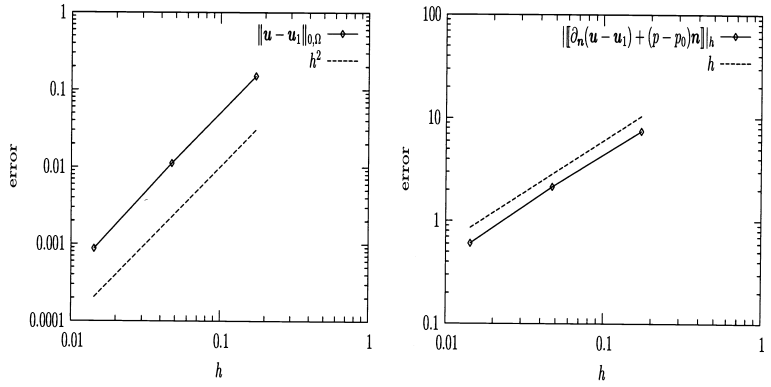

FIG. 6. *Method* (14)*: convergence history for* $\|\boldsymbol{u} - \boldsymbol{u}_1\|_{0,\Omega}$ *and* $|[\![\partial_{\boldsymbol{n}}(\boldsymbol{u} - \boldsymbol{u}_1) + (p - p_0)\boldsymbol{n}]\!]|_h$.

via the jump terms governed by α, we can expect the error to grow as α grows, as it is shown in Figure 9 (for a mesh of 2500 elements) where we see that all the errors attain a minimum at $\alpha = 1$ (i.e., using $\tilde{\tau}_Z = \tau_Z$), and then they present a growing behavior. Values larger than 10 have been tested and the behavior is growing in all the errors. Related experiments have been performed using the GLS method (cf. [27]), obtaining similar results.

6.2. The lid-driven cavity problem. For this case we use the same domain as in the previous section, we set $\boldsymbol{f} = \boldsymbol{0}$, and the boundary conditions $\boldsymbol{u} = \boldsymbol{0}$ on $[\{0\} \times (0,1)] \cup [(0,1) \times \{0\}] \cup [\{1\} \times (0,1)]$ and $\boldsymbol{u} = (1,0)^t$ on $(0,1) \times \{1\}$. In Figure 10 we depict the pressure isovalues for both $\mathbb{P}^1/\mathbb{P}^0$ and $\mathbb{P}^1/\mathbb{P}^1$ approximations (using a mesh of around 1000 elements) showing, in both cases, the absence of oscillations.

7. Concluding remarks. In this paper we have analyzed and tested new stabilized finite element methods for the Stokes problem. These new methods arise from multiscale enrichment of the trial space for the velocity coupled with a Petrov–Galerkin strategy. This Petrov–Galerkin strategy makes it possible to perform statical condensation both at the element level and at the interelement boundary level, making the method take the form of a classical stabilized finite element method, containing jump terms on the interior edges of the triangulation, and with the corresponding

stabilization parameter known exactly. Optimal order error estimates were derived using the natural norms, results that were confirmed by the numerical experiments.

Our belief is that our general methodology may be applied to other mixed problems, namely the Darcy and Brinkman flow problems, and to the advection-diffusion equation. This will be the subject of future works.

Appendix A. Proof of Theorem 4.3.

The consistency of the method is immediate from the fact that $[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{u}]\!] = \mathbf{0}$ a.e. on ∂K. To prove the well-posedness of (39), we prove that $\mathbf{B}_1$ is an elliptic bilinear form. Let $(\boldsymbol{v}_1, q_1) \in \mathbf{V}_h \times Q_h^1$; then from Lemma 4.6 we have that

$$\mathbf{B}_1((\boldsymbol{v}_1, q_1), (\boldsymbol{v}_1, q_1)) \;=\; |\!|\!|\boldsymbol{v}_1|\!|\!|_h^2 + \|q_1\|_h^2 \;-\; \sum_{K\in\mathcal{T}_h} \frac{1}{\nu}(\mathcal{B}_K([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!]), \nabla q_1)_K\,.$$

Now, in order to treat the last term above, let us denote by Z_1, Z_2, Z_3 the sides of K, and let, for $i = 1, 2, 3$, $b_K^{Z_i}$ be the solution of

$$-\Delta b_K^{Z_i} \;=\; 0 \quad \text{in } K, \qquad b_K^{Z_i} \;=\; g_i \quad \text{on each } Z \subset \partial K\,,$$

where $g_i = 0$ if $Z_i \subseteq \partial\Omega$, and g_i is the solution of

$$-\partial_{\boldsymbol{ss}}\, g_i = \frac{1}{h_{Z_i}} \quad \text{in } Z_i, \qquad g_i \;=\; 0 \quad \text{on } \partial K - Z_i\,,$$

otherwise. First, we remark that from the maximum principle, we have that $0 \le b_K^{Z_i} \le \frac{h_{Z_i}}{8}$ in K. On the other hand, it is easy to see that $\mathcal{B}_K([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!]) \;=\; \sum_{i=1}^3 b_K^{Z_i}\,[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!]|_{Z_i}$, and then, using that $|K| \le \frac{h_K^2}{2}$ and the inequality $ab \le \gamma^{-1}\frac{a^2}{4} + \gamma b^2$ $(\gamma > 0)$ (denoting

$\|\cdot\|_{\mathbb{R}^2}$ the Euclidean norm on $\mathbb{R}^2$) we arrive at

$$\begin{aligned}
\sum_{K\in\mathcal{T}_h}\frac{1}{\nu}(\mathcal{B}_K([\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!]),\nabla q_1)_K &= \sum_{K\in\mathcal{T}_h}\sum_{i=1}^{3}\frac{1}{\nu}\,(b_K^{Z_i}\,[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!]|_{Z_i},\nabla q_1)_K\\
&= \sum_{Z\in\mathcal{E}_h}\sum_{K\subset\omega_Z}\frac{(b_K^Z,1)_K}{\nu}\,[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!]|_Z\cdot\nabla q_1|_K\\
&\le \sum_{Z\in\mathcal{E}_h}\sum_{K\subset\omega_Z}\frac{h_Z|K|}{8\nu}\,\|[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!]|_Z\|_{\mathbb{R}^2}\|\nabla q_1|_K\|_{\mathbb{R}^2}\\
&\le \gamma^{-1}\sum_{Z\in\mathcal{E}_h}\sum_{K\subset\omega_Z}\frac{|Z|\,\|[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!]\|_{0,Z}^2}{32\nu}+\gamma\sum_{Z\in\mathcal{E}_h}\sum_{K\subset\omega_Z}\frac{|K|\|\nabla q_1\|_{0,K}^2}{8\nu}\\
&\le \gamma^{-1}\sum_{Z\in\mathcal{E}_h}\frac{h_Z\,\|[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!]\|_{0,Z}^2}{16\nu}+\gamma\sum_{K\in\mathcal{T}_h}\frac{h_K^2\|\nabla q_1\|_{0,K}^2}{8\nu}\,. \qquad (63)
\end{aligned}$$

Hence, choosing $\gamma=\frac{14}{16}<1$ we arrive at

$$\begin{aligned}
\mathbf{B}_1((\boldsymbol{v}_1,q_1),(\boldsymbol{v}_1,q_1)) &\ge |\!|\!|\boldsymbol{v}_1|\!|\!|_h^2+\|q_1\|_h^2-\sum_{Z\in\mathcal{E}_h}\frac{h_Z}{14\nu}\|[\![\nu\partial_{\boldsymbol{n}}\boldsymbol{v}_1]\!]\|_{0,Z}^2-\gamma\sum_{K\in\mathcal{T}_h}\frac{h_K^2}{8\nu}|q_1|_{1,K}^2\\
&\ge C_*(|\!|\!|\boldsymbol{v}_1|\!|\!|_h^2+\|q_1\|_h^2)\,,
\end{aligned}$$

where C_* is a positive constant not depending on h or ν. Now, for the error estimate, applying the coercivity result and the consistency of the method we arrive at

$$\begin{aligned}
C_*\,(|\!|\!|\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_1|\!|\!|_h^2+\|p_1-\tilde{p}_1\|_h^2) &\le \mathbf{B}_1((\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_1,p_1-\tilde{p}_1),(\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_1,p_1-\tilde{p}_1))\\
&= \mathbf{B}_1((\boldsymbol{u}_1-\boldsymbol{u},p_1-p),(\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_1,p_1-\tilde{p}_1))\\
&= -\sum_{K\in\mathcal{T}_h}(\mathcal{B}_K([\![\nu\partial_{\boldsymbol{n}}(\boldsymbol{u}_1-\boldsymbol{u})]\!]),\nabla(p_1-\tilde{p}_1))_K\,. \qquad (64)
\end{aligned}$$

Finally, proceeding as in (63) it is not difficult to see that

$$\begin{aligned}
&\sum_{K\in\mathcal{T}_h}(\mathcal{B}_K([\![\nu\partial_{\boldsymbol{n}}(\boldsymbol{u}_1-\boldsymbol{u})]\!]),\nabla(p_1-\tilde{p}_1))_K\\
&\quad\le C\sum_{Z\in\mathcal{E}_h}\tau_Z\,\|[\![\nu\partial_{\boldsymbol{n}}(\boldsymbol{u}_1-\boldsymbol{u})]\!]\|_{0,Z}^2+\frac{C_*}{2}\sum_{K\in\mathcal{T}_h}\tau_K\,|p_1-\tilde{p}_1|_{1,K}^2\\
&\quad\le C\,(|\!|\!|\boldsymbol{u}-\boldsymbol{u}_1|\!|\!|_h^2+\|p-p_1\|_h^2)+\frac{C_*}{2}\,(|\!|\!|\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_1|\!|\!|_h^2+\|p_1-\tilde{p}_1\|_h^2)\,,
\end{aligned}$$

and hence, there exists $C>0$, independent of h and ν, such that

$$|\!|\!|\boldsymbol{u}_1-\tilde{\boldsymbol{u}}_1|\!|\!|_h^2+\|p_1-\tilde{p}_1\|_h^2\le C\,(|\!|\!|\boldsymbol{u}-\boldsymbol{u}_1|\!|\!|_h^2+\|p-p_1\|_h^2)\,,$$

and the result follows by triangular inequality.

REMARK A.1. *We have proved that the error of method* (39) *is bounded by the error of method* (44). *The same analysis of Theorems* 4.10 *and* 4.11 *may be carried out to prove error estimates on* $\|p-\tilde{p}_1\|_{0,\Omega}$ *and* $\|\boldsymbol{u}-\tilde{\boldsymbol{u}}_1\|_{0,\Omega}$.

Appendix B. The error if $\boldsymbol{f}$ is not piecewise constant. As we claimed before, we have assumed that $\boldsymbol{f}$ is piecewise constant in order to derive (44), but this

assumption does not affect the convergence of the method, and hence (44) may be implemented as it is presented for a general function $\boldsymbol{f} \in L^2(\Omega)^2$. Now, if we do not suppose that $\boldsymbol{f}$ is piecewise constant in the derivation, then method (44) becomes the following: Find $(\boldsymbol{u}_h, p_h) \in \mathbf{V}_h \times Q_h^1$ such that

$$\mathbf{B}((\boldsymbol{u}_h, p_h), (\boldsymbol{v}_1, q_1)) = \mathbf{F}_h(\boldsymbol{v}_1, q_1) \tag{65}$$

for all $(\boldsymbol{v}_1, q_1) \in \mathbf{V}_h \times Q_h^1$, where $\mathbf{B}$ is defined in (41) and $\mathbf{F}_h$ is given by

$$\mathbf{F}_h(\boldsymbol{v}_1, q_1) := (\boldsymbol{f}, \boldsymbol{v}_1)_\Omega + \sum_{K \in \mathcal{T}_h} \frac{1}{\nu} (\mathcal{M}_K(\boldsymbol{f}), \nabla q_1)_K . \tag{66}$$

Clearly, (65) has a unique solution $(\boldsymbol{u}_h, p_h) \in \mathbf{V}_h \times Q_h^1$. Moreover, the following result holds.

THEOREM B.1. *Let us suppose that $\boldsymbol{f} \in H^1(\Omega)^2$. Then, under the hypothesis of Theorems* 4.8, 4.10, *and* 4.11, *the following error estimate holds:*

$$|||\boldsymbol{u} - \boldsymbol{u}_h|||_h + \|p - p_h\|_h \leq Ch \left(\sqrt{\nu}\, |\boldsymbol{u}|_{2,\Omega} + \frac{1}{\sqrt{\nu}} |p|_{1,\Omega} + \frac{1}{\sqrt{\nu}} \|\boldsymbol{f}\|_{1,\Omega} \right) , \tag{67}$$

$$\|p - p_h\|_{0,\Omega} \leq Ch \left(\nu\, |\boldsymbol{u}|_{2,\Omega} + |p|_{1,\Omega} + \|\boldsymbol{f}\|_{1,\Omega} \right) , \tag{68}$$

$$\|\boldsymbol{u} - \boldsymbol{u}_h\|_{0,\Omega} \leq Ch^2 \left(|\boldsymbol{u}|_{2,\Omega} + \frac{1}{\nu} |p|_{1,\Omega} + \frac{1}{\nu} \|\boldsymbol{f}\|_{1,\Omega} \right) . \tag{69}$$

Proof. Let $(\boldsymbol{u}_1, p_1)$ be the solution of (44). First, applying [30, Lem. 5.3.1], we see that

$$\begin{aligned} |||\boldsymbol{u}_1 - \boldsymbol{u}_h|||_h + \|p_1 - p_h\|_h &\leq \sup_{(\boldsymbol{v}_1, q_1) \in \mathbf{V}_h \times Q_h^1 - \{\theta\}} \frac{\mathbf{F}(\boldsymbol{v}_1, q_1) - \mathbf{F}_h(\boldsymbol{v}_1, q_1)}{\|\boldsymbol{v}_1\|_h + \|q_1\|_h} \\ &= \sup_{(\boldsymbol{v}_1, q_1) \in \mathbf{V}_h \times Q_h^1 - \{\theta\}} \frac{\sum_{K \in \mathcal{T}_h} (\tau_K \boldsymbol{f} - \frac{1}{\nu} \mathcal{M}_K(\boldsymbol{f}), \nabla q_1)_K}{\|\boldsymbol{v}_1\|_h + \|q_1\|_h} \\ &\leq \sup_{(\boldsymbol{v}_1, q_1) \in \mathbf{V}_h \times Q_h^1 - \{\theta\}} \frac{\sum_{K \in \mathcal{T}_h} \|\tau_K \boldsymbol{f} - \frac{1}{\nu} \mathcal{M}_K(\boldsymbol{f})\|_{0,K} |q_1|_{1,K}}{\|\boldsymbol{v}_1\|_h + \|q_1\|_h} . \end{aligned} \tag{70}$$

Now, let $\boldsymbol{f}_h$ be the piecewise constant function given by

$$\boldsymbol{f}_h\Big|_K = \frac{1}{|K|} \int_K \boldsymbol{f} .$$

This function, which is the (local) projection on the space of piecewise constant functions, satisfies (cf. [17]) $\|\boldsymbol{f} - \boldsymbol{f}_h\|_{0,K} \leq C\, h_K\, |\boldsymbol{f}|_{1,K}$. Then, applying triangular inequality we arrive at

$$\begin{aligned} \|\tau_K \boldsymbol{f} - \mathcal{M}_K(\boldsymbol{f})\|_{0,K} \leq\ & \|\tau_K (\boldsymbol{f} - \boldsymbol{f}_h)\|_{0,K} + \|\tau_K \boldsymbol{f}_h - \frac{1}{\nu} \mathcal{M}_K(\boldsymbol{f}_h)\|_{0,K} \\ & + \frac{1}{\nu} \|\mathcal{M}_K(\boldsymbol{f}_h - \boldsymbol{f})\|_{0,K} . \end{aligned} \tag{71}$$

The first term is easily bounded using the approximation properties of $\boldsymbol{f}_h$ and the definition of τ_K. Next, since $\mathcal{M}_K(\boldsymbol{f}_h) = b_K^p \boldsymbol{f}_h$ in each $K \in \mathcal{T}_h$, the second term is

bounded in the following way:

$$\begin{aligned}\|\tau_K \boldsymbol{f}_h - \frac{1}{\nu}\mathcal{M}_K(\boldsymbol{f}_h)\|_{0,K} \le\ & |\tau_K| \|\boldsymbol{f}_h\|_{0,K} + \frac{\|b_K^p\|_{0,K}}{\nu}\,\|\boldsymbol{f}_h\|_{\mathbb{R}^2} \\ \le\ & |\tau_K| \|\boldsymbol{f}_h\|_{0,K} + \frac{C_K\,|b_K^p|_{1,K}}{\nu\,|K|^{\frac{1}{2}}}\,\|\boldsymbol{f}_h\|_{0,K}\,,\end{aligned}$$

where $C_K > 0$ is the constant such that $\|v\|_{0,K} \le C_K\,|v|_{1,K}$ for all $v \in H_0^1(K)$. Furthermore, looking carefully at the behavior of the Poincaré constant C_K we can see (cf. [30, Thm. 1.2.5]) that $C_K \le h_K$. On the other hand, from the definition of b_K^p we have $|b_K^p|_{1,K}^2 = (b_K^p, 1)_K$, and then, applying (48) we arrive at

$$\frac{C_K\,|b_K^p|_{1,K}}{\nu\,|K|^{\frac{1}{2}}}\,\|\boldsymbol{f}_h\|_{0,K} \le \frac{h_K\,\sqrt{(b_K^p,1)_K}}{\nu\,|K|^{\frac{1}{2}}}\,\|\boldsymbol{f}_h\|_{0,K} \le C\,\frac{h_K^2}{\nu}\,\|\boldsymbol{f}_h\|_{0,K}\,. \tag{72}$$

To bound the third term in (71) we remark that function $\boldsymbol{e} := \mathcal{M}_K(\boldsymbol{f} - \boldsymbol{f}_h)$ satisfies $-\Delta \boldsymbol{e} = \boldsymbol{f} - \boldsymbol{f}_h$ in K, $\boldsymbol{e} = \boldsymbol{0}$ on ∂K, and hence

$$\|\boldsymbol{e}\|_{0,K} \le C_K^2\,\|\boldsymbol{f} - \boldsymbol{f}_h\|_{0,K} \le h_K^2\,\|\boldsymbol{f} - \boldsymbol{f}_h\|_{0,K} \le C\,h_K^3\,|\boldsymbol{f}|_{1,K}\,. \tag{73}$$

Hence, applying (70)–(73) (and assuming $h \le 1$), we arrive at

$$\begin{aligned}|\!|\!|\boldsymbol{u}_1 - \boldsymbol{u}_h|\!|\!|_h + \|p_1 - p_h\|_h \le\ & C \sup_{(\boldsymbol{v}_1,q_1)\in \mathbf{V}_h\times Q_h^1 - \{\theta\}} \frac{\sum_{K\in\mathcal{T}_h} \frac{h_K^2}{\nu}\|\boldsymbol{f}\|_{1,K}|q_1|_{1,K}}{|\!|\!|\boldsymbol{v}_1|\!|\!|_h + \|q_1\|_h} \\ \le\ & C\,\frac{h}{\sqrt{\nu}}\,\|\boldsymbol{f}\|_{1,\Omega}\,,\end{aligned}$$

and hence (67) follows by triangular inequality and Theorem 4.8. Estimates (68) and (69) are proved as in Theorems 4.10 and 4.11 and by using (67). ∎

ERROR ESTIMATES FOR THE DISCONTINUOUS GALERKIN METHODS FOR PARABOLIC EQUATIONS*

K. CHRYSAFINOS‡ AND NOEL J. WALKINGTON†

Abstract. The classical discontinuous Galerkin method for a general parabolic equation is analyzed. Symmetric error estimates for schemes of arbitrary order are presented. The ideas developed below relax many assumptions required in previous work. For example, different discrete spaces may be used at each time step, and the spatial operator need not be self-adjoint or independent of time. Our error estimates are posed in terms of projections of the exact solution onto the discrete spaces and are valid under the minimal regularity guaranteed by the natural energy estimate. These projections are local and enjoy optimal approximation properties when the solution is sufficiently regular.

Key words. discontinuous Galerkin, parabolic equations, error estimates

AMS subject classification. 65M60

1. Introduction.

We consider the parabolic PDE of the form

$$u_t + A(t)u = F(t), \qquad u(0) = u_0. \tag{1.1}$$

The operators act on Hilbert spaces related through the standard pivot construction, $U \hookrightarrow H \simeq H' \hookrightarrow U'$, where each embedding is continuous and dense. Then, $A(.) : U \to U'$ is a linear map and $F(.) \in U'$. Our goal is to analyze the classical discontinuous Galerkin (DG) scheme and derive fully discrete error estimates under minimal regularity assumptions. The class of DG schemes considered are classical in the sense that the discrete solutions may be discontinuous in time but are conforming in space; i.e., solutions are in (a subspace of) U at each time.

Our techniques also apply to the more general implicit evolution equation [21, 22]

$$(M(t)u)_t + A(t)u = F(t), \qquad u(0) = u_0, \tag{1.2}$$

where $M(.) : H \to H$ is a self-adjoint positive definite operator. The extension of our analysis to this equation will be taken up separately. The analysis below addresses the following issues, which have not yet been adequately considered in the literature:

- The operator $A(.)$ may depend upon time and is not required to be self-adjoint. To date the sharpest estimates for DG approximations exploit classical spectral theory for self-adjoint positive definite operators, and so require A to be such an operator and to be independent of time. When $A(.)$ is not self-adjoint, multiplying (1.1) by u_t does not give an estimate for the time derivative.

- The subspaces of U used for the DG approximations may be different on each time interval $(t^{n-1}, t^n]$. This adds a significant complication to the analysis, which is present even when $A = 0$. Indeed, the first step in our analysis is to consider the DG scheme for an auxiliary parabolic equation which reduces to an ODE in the Hilbert space H when the coercivity constant vanishes. Different subspaces are essential ingredients of adaptive strategies, used in conjunction with a posteriori error estimates to give guaranteed error bounds. Retriangulation is also necessary for many algorithms based upon a Lagrangian coordinate system; an example is presented below.
- DG approximations of equations of the form (1.2) have not been considered in the past. The example below shows that equations of this form arise when Lagrangian schemes are constructed for the convection diffusion equation [5, 6, 7].
- The operator $A(.)$ is not required to be strictly coercive; only semicoercivity of the form $\langle A(.)u, u\rangle \geq c|u|_U^2 - C\|u\|_H^2$ is required. Here $|.|_U$ is a seminorm such that $\|.\|_U^2 = |.|_U^2 + \|.\|_H^2$. This causes significant problems in the analysis of DG schemes since the classical Gronwall argument, used for the continuous problem, fails in the discrete setting. This failure is due to the elementary observation that functions of the form $\chi_{[0,\hat{t})}u$ are not polynomial in time unless $\hat{t}$ is a partition point, and thus they are not available as test functions in the discrete setting.[1] In the past this problem has been circumvented by bounding temporal derivatives of the solution [4, 23] so that the solution between the partition points can be controlled by the values at these points. This line of argument fails for solutions having minimal regularity. These issues are circumvented here by constructing polynomial approximations to the characteristic functions $\chi_{[0,\hat{t})}$.

As stated above, our analysis does not require any regularity beyond the natural bounds that follow from the usual energy estimate. This is essential for control problems, where solutions of the dual problem typically will not enjoy any additional regularity. Our estimates show that the error can be bounded by local projection errors of the solution projected onto the discrete subspaces. This error can also be viewed as a "local truncation error" of the ODE obtained by setting $A = 0$. Care is taken to keep track of how the various constants depend upon the coercivity constant of $A(.)$. This is important for the analysis of problems like the convection diffusion equation, where the coercivity constant is small.

The following equation can be analyzed within the general framework developed here but falls outside of the theory developed, for example, in Thomée's text [23].

Convection diffusion equation. The classical convection diffusion equation is

$$\bar{u}_t + \mathbf{V}.\nabla\bar{u} - \epsilon\Delta\bar{u} = 0,$$

and the problems that arise when ϵ is small are notorious. To address these problems this equation is sometimes considered in a Lagrangian variable. Specifically, let $\tilde{\mathbf{V}}$ be a (numerical) approximation of $\mathbf{V}$, and let $x = \chi(t, X)$ be the change of variables defined by the flow map associated with $\tilde{\mathbf{V}}$; i.e.,

$$\dot{x}(t, X) = \tilde{\mathbf{V}}(t, x(t, X)), \qquad x(0, X) = X.$$

[1] Here $\chi_{[0,\hat{t})}$ is the characteristic function equal to 1 on $[0, \hat{t})$ and zero otherwise.

If $u(t,X) = \bar{u}(t,x(t,X))$, then

$$u_t + (\mathbf{V} - \tilde{\mathbf{V}}) \cdot (F^{-T}\nabla_X u) - \epsilon \left(\frac{1}{J}\right) \operatorname{div}_X \left(JF^{-1}F^{-T}\nabla_X u\right) = 0,$$

where $F_{ij} = \partial x_i/\partial X_j$ is the Jacobian of the mapping and $J = \det(F)$. The natural weak problem for this equation is

$$\int_\Omega \Big(\big(u_t + (\mathbf{V} - \tilde{\mathbf{V}}) \cdot (F^{-T}\nabla_X u)\big)v + \epsilon (F^{-T}\nabla_X u).(F^{-T}\nabla_X v) \Big) J = 0.$$

Using the properties of determinants, we find

$$u_t J = (Ju)_t - \dot{J}u = (Ju)_t - J \operatorname{div}(\tilde{\mathbf{V}})u.$$

If $\operatorname{div}(\tilde{\mathbf{V}}) = 0$, then J is constant and the transformed problem takes the form of (1.1); otherwise, it takes the form of (1.2) with $M(.)u = Ju$, and

$$A(.)u = -\operatorname{div}(\tilde{\mathbf{V}})uJ + (\mathbf{V} - \tilde{\mathbf{V}}).(F^{-T}\nabla_X u)J - \epsilon \operatorname{div}_X \left(JF^{-1}F^{-T}\nabla_X u\right).$$

This statement of the problem generalizes the idea behind the "characteristic Galerkin" scheme introduced by Douglas and Russell in [5] and Dupont in [6].

This change of variables reduces the effective Peclet number from $|\mathbf{V}|/\epsilon$ to $|\mathbf{V} - \tilde{\mathbf{V}}|/\epsilon$, which will be $\mathcal{O}(1)$ if $\tilde{\mathbf{V}}$ is a sufficiently accurate approximation of $\mathbf{V}$. This eliminates many of the numerical difficulties encountered by algorithms based upon the classical statement; however, other problems arise. While the Jacobian of the transformation satisfies $F(0,X) = I$, its condition number grows exponentially if $\tilde{\mathbf{V}}$ is anything other than a rigid motion. In the context of a numerical scheme this problem is circumvented by reinitializing the transformation at each (or every few) time step(s). This reinitialization corresponds to changing the subspace for the numerical solution every (few) time step(s). In essence, a triangular mesh in the X coordinate system will be a distorted mesh in the x coordinate system, and reinitializing the transform corresponds to projecting the solution onto a (straight sided) triangular mesh in the x coordinates. This gives rise to different subspaces at each time step.

1.1. Related results. The discontinuous Galerkin method was first introduced to model and simulate neutron transport by Lasaint and Raviart in [13]. There is an abundant literature concerning applications of the DG scheme for hyperbolic problems; see, e.g., [3, 12, 24] and references within. The DG method for ODEs was considered by Delfour, Hager, and Trochu in [4]. They showed that the DG scheme was superconvergent at the partition points (order $2k+2$ for polynomials of degree k). The superconvergence results (and better rates in the H norm) use a duality argument, and space considerations do not permit us to develop the corresponding estimates in the current setting.

In the context of parabolic equations, DG schemes were first analyzed for linear parabolic problems by Jamet in [11], where $\mathcal{O}(\tau^k)$ results were proved, and by Eriksson, Johnson, and Thomée in [10], where $\mathcal{O}(\tau^{2k-1})$ results were proved for "smooth" initial data among others (τ being the time step size). An excellent exposition of their results and, more generally, the DG method for parabolic equations can be found in Thomée's book [23]. In [23] nodal and interior estimates are presented in various norms. One may also consult [16] for the analysis of a related formulation based on the backward Euler scheme. The relation between the DG scheme and adaptive

techniques was studied in [8] and [9]. Finally, some results concerning the analysis of parabolic integro-differential equations by the DG method are presented in [14] (see also references therein).

In [7] Dupont and Liu introduced the concept of "symmetric error estimates" for parabolic problems. They define such an error estimate to be one of the form

$$|||u - u_h||| \leq C \inf_{w_h \in \mathcal{U}_h} |||u - w_h|||,$$

where u and u_h are the exact and approximate solutions, respectively; $|||.|||$ is an appropriate norm; and $\mathcal{U}_h$ is the discrete subspace in which approximation solutions are sought. While estimates of this form are standard for elliptic problems, this is not the case for evolution problems. For example, error estimates for evolution problems approximated by the implicit Euler scheme frequently involve terms of the form $\|u_{tt}\|_{L^2(\Omega)}$. Symmetric error estimates are useful for problems where the solution u may not be very regular, such as control problems, and are used to develop a posteriori error estimates for adaptive schemes. Symmetric error estimates for moving mesh finite element methods were studied in [7, 15] (see also the references therein). Mesh modification techniques for finite elements were introduced in [17] and [18]. For some earlier work on convection-dominated problems based on the methods of characteristics and mesh modification one may consult [5] and [6], respectively.

An alternative to the symmetric error estimates are estimates of the form

$$|||u - u_h||| \leq C|||u - \mathbb{P}_h u|||, \tag{1.3}$$

where $\mathbb{P}_h : \mathcal{U} \to \mathcal{U}_h$ is a projection which exhibits optimal interpolation properties if u is sufficiently smooth. Estimates of this form enjoy the same advantages found for those proposed by Dupont and Liu. Below, estimates of the form (1.3) are developed for parabolic equations of the form (1.1), where the projection $\mathbb{P}_h u$ is nonlocal. However,

$$|||u - \mathbb{P}_h u||| \leq |||u - \mathbb{P}_h^{loc} u||| + |||\mathbb{P}_h u - \mathbb{P}_h^{loc} u|||,$$

where $\mathbb{P}_h^{loc}$ is a local projection, so the first term can be estimated using classical interpolation theory. The second term $|||\mathbb{P}_h u - \mathbb{P}_h^{loc} u|||$ vanishes if the same subspace of U is used in each partition (t^{n-1}, t^n); otherwise, it depends solely upon the jump in the interpolant of the exact solution at the partition points $\{t^n\}_{n=0}^N$. The size of the constant C in (1.3), and its dependence on various constants, plays an important role; we are careful throughout to state the dependence of the constant upon the various coercivity constants and bounds assumed for the operator A.

Error estimates for Lagrange–Galerkin approximations of convection-dominated problems for divergence-free velocity fields vanishing on the boundary are presented in [2]. Issues related to the stability of Lagrange–Galerkin approximations are also discussed in [19]. Recently there has been a lot of work on the development and analysis of DG methods for elliptic problems. A comprehensive survey and comparison of this work can be found in [1], which contains many references related to this approach.

1.2. Outline. In section 2, the DG scheme is formulated and analyzed for an auxiliary parabolic equation. This section focuses upon the difficulties that arise when different subspaces of U may be used at every time step and when the coercivity constant may be small. Error estimates are first derived at times corresponding to the partition points. Additional arguments using "discrete characteristic functions"

are developed to estimate the error at times in between the partition points. The latter arguments appear to be new.

A priori estimates for the DG approximations of (1.1) are developed in section 3. Estimates are derived in the natural norms associated with the parabolic problem; by "natural" we mean norms that arise in the natural energy estimates obtained by multiplying (1.1) by u. The results of section 2 are used in an essential fashion. Indeed, the difficulties associated with different subspaces of U at each time step are circumvented by comparing the discrete solution of the parabolic equation with an appropriate solution of the auxiliary equation. By using the "discrete characteristic functions" developed in section 2, the self-adjoint assumptions typically imposed upon $A(.)$ may be avoided.

Remark 1. When the same discrete subspace of U is used for each time step, our techniques generalize, and to some extent simplify, the classical analysis. The reader interested in this case needs to read only sections 2.3 on the construction of discrete characteristic functions, and Definition 2.1 for $\mathbb{P}_h^{loc}$, before proceeding to section 3. Remark 4 in section 3 amplifies upon this.

1.3. Notation. It is assumed throughout that the evolution of the solution to (1.1) takes place in a Hilbert space H and that the operators $A(.)$ are defined on another Hilbert space U with $U \hookrightarrow H \simeq H' \hookrightarrow U'$, where each of the embeddings are dense and continuous. The inner product on H is denoted by $(.,.)$, and the induced duality pairing between U and U' is denoted by $\langle .,. \rangle$. The norm on H is often denoted by $|.| \equiv \|.\|_H$, and it is assumed that the norm on U can be written as $\|.\|_U^2 = |.|_U^2 + \|.\|_H^2$, where $|.|_U$ is a seminorm on U (the "principle" part) and is often denoted by $\|.\|$; $\|.\|_U^2 = \|.\|^2 + |.|^2$. Standard notation of the form $L^2[0,T;U]$, $H^1[0,T;U']$, etc. is used to indicate the temporal regularity of functions with values in U, U', etc.

Approximations of (1.1) will be constructed on a partition $0 = t^0 < t^1 < \cdots < t^N = T$ of $[0,T]$; the step sizes are denoted as $\tau^n = t^n - t^{n-1}$, and $\tau = \max_n \tau^n$. On each interval of the form $(t^{n-1}, t^n]$ a subspace U_h^n of U is specified, and the approximate solutions will lie in the space

$$\mathcal{U}_h = \{u_h \in L^2[0,T;U] \mid u_h|_{(t^{n-1},t^n]} \in \mathcal{P}_k(t^{n-1}, t^n; U_h^n)\}.$$

Here $\mathcal{P}_k(t^{n-1}, t^n; U_h^n)$ is the space of polynomials of degree k or less having values in U_h^n. Notice that, by convention, functions in $\mathcal{U}_h$ are left continuous with right limits. We will write u^n for $u_h(t^n) = u_h(t_-^n)$ and let u_+^n denote $u_h(t_+^n)$. This notation is also used with functions like the error $e = u - u_h$. It is assumed that the exact solution, u, is in $C[0,T;H]$, so that the jump in the error at t^n, denoted by $[e^n]$, is $[e^n] = [u^n] = u_+^n - u^n$.

2. DG scheme for an auxiliary equation.

2.1. Background. This section addresses issues that arise when different discrete subspaces are used for each time step of the DG scheme. Schemes for the simplest (heat-type) parabolic equation are considered, which allows issues associated with different spaces at each step and the role of the coercivity constant to be isolated. In the next section the error estimates for the more general equation (1.1) will be obtained by comparing the solutions of the two equations.

Let $(.,.)_U$ be the inner product on U, and let $B : U \to U'$ be the associated Riesz map: $(u,v)_U = \langle Bu, v \rangle$. We consider the problem of recovering a function $u \in L^2[0,T;U] \cap H^1[0,T;U']$, given the initial value $u(0)$ and $f = u_t + \eta Bu$, where

$\eta \geq 0$. Specifically, consider DG finite element approximations of the initial value problem

$$u_t + \eta B u = f, \qquad u(0) = u_0. \tag{2.1}$$

In this situation there exists a unique $u \in L^2[0,T;U] \cap H^1[0,T;U'] \hookrightarrow C[0,T;H]$, which is the solution of the weak problem

$$\begin{aligned}(u(T), v(T)) - \int_0^T \langle u, v_t\rangle + \eta(u,v)_U &= (u_0, v(0)) + \int_0^T \langle f, v\rangle \\ &\forall\, v \in L^2[0,T;U] \cap H^1[0,T;U'].\end{aligned} \tag{2.2}$$

To approximate the solution of (2.2) we introduce a partition $0 = t^0 < t^1 < \cdots < t^N = T$ of $[0,T]$ and a collection $\{U_h^n\}_{n=0}^N$ of subspaces of U. The DG method constructs an approximate solution

$$u_h \in \mathcal{U}_h \equiv \{u \in L^2[0,T;U] \mid u|_{(t^{n-1},t^n]} \in \mathcal{P}_k(t^{n-1},t^n;U_h^n)\}$$

such that

$$(u^n, v^n) - \int_{t^{n-1}}^{t^n} (u_h, v_{ht}) + \eta(u_h, v_h)_U - (u^{n-1}, v_+^{n-1}) = \int_{t^{n-1}}^{t^n} \langle f, v_h\rangle \tag{2.3}$$

for all $v_h \in \mathcal{U}_h$ and each $n = 1, 2, \ldots, N$. Recall that $u^n \equiv u_h(t^n) = u_h(t_-^n)$, and use standard notation, u_+^n, u_-^n, for the traces from above and below, respectively. Integration by parts gives the following alternative form of (2.3):

$$\int_{t^{n-1}}^{t^n} (u_{ht}, v_h) + \eta(u,v)_U + (u_+^{n-1} - u^{n-1}, v_+^{n-1}) = \int_{t^{n-1}}^{t^n} \langle f, v_h\rangle. \tag{2.4}$$

2.2. Error estimate at partition points. In this elementary context it is possible to estimate the error at each partition point t^n using the ideas from [9]. We will need the following projection operators $\mathbb{P}_n^{loc}$ introduced in [10].

DEFINITION 2.1. (1) *The projection* $\mathbb{P}_n^{loc} : C[t^{n-1},t^n;H] \to \mathcal{P}_k(t^{n-1},t^n;U_h^n)$ *satisfies* $(\mathbb{P}_n^{loc}u)^n = P_n u(t^n)$, *and*

$$\int_{t^{n-1}}^{t^n} (u - \mathbb{P}_n^{loc}u, v_h) = 0 \qquad \forall\, v_h \in \mathcal{P}_{k-1}(t^{n-1},t^n;U_h^n).$$

Here we have used the convention $(\mathbb{P}_n^{loc}u)^n \equiv (\mathbb{P}_n^{loc}u)(t^n)$ *and* $P_n : H \to U_h^n$ *is the orthogonal projection operator onto* $U_h^n \subset H$.

(2) *The projection* $\mathbb{P}_h^{loc} : C[0,T;H] \to \mathcal{U}_h$ *satisfies*

$$\mathbb{P}_h^{loc}u \in \mathcal{U}_h \quad \text{and} \quad (\mathbb{P}_h^{loc}u)|_{(t^{n-1},t^n]} = \mathbb{P}_n^{loc}(u|_{[t^{n-1},t^n]}).$$

This projection satisfies the standard approximation properties [23, Theorem 12.1] and can be viewed as the one step DG approximation of $u_t = f$ on the interval $(t^{n-1},t^n]$, with exact initial data $u(t^{n-1})$ and $f = u_t$ specified. For the parabolic problem we will use the analogous *global* projection ($\mathbb{P}_h$ below), which is the DG solution of the auxiliary equation with initial data $u(0)$ and $f = u_t + Bu$ specified.

The following theorem provides a decomposition of the error into the errors due to the changing of the spaces and the projection errors. The former depend upon the size of the coercivity constant η.

THEOREM 2.2. *Let $u_h \in \mathcal{U}_h$ be the approximate solution of* (2.1) *computed using the discontinuous Galerkin scheme* (2.3)*, and write $\hat{e} = \mathbb{P}_h^{loc} u - u_h$. Then there exists a constant $C_k > 0$ depending only upon k such that*

$$|\hat{e}^n|^2 + \frac{\eta}{2}\int_0^{t^n} \|\hat{e}\|_U^2 + \frac{1}{2}\sum_{i=0}^{n-1} |\hat{e}^i - \hat{e}_+^i|^2 \le |\hat{e}^0|^2 + \int_0^{t^n} \eta \|(I - \mathbb{P}_h^{loc})u\|_U^2 + \sum_{i=0}^{n-1} 2\min\left(|(I-P_i)u(t^i)|^2, \frac{C_k^2}{\tau^{i+1}\eta}\|P_{i+1}(I-P_i)u(t^i)\|_{U'}^2 \right). \tag{2.5}$$

Remark 2. Since $P_i(I - P_{i-1}) = 0$ when $U_h^i \subset U_h^{i-1}$, the error estimate reduces to the usual projection errors when the same discrete subspace is used at each time.

Proof. Let $e = u - u_h$ be the total error, and note that the Galerkin orthogonality gives

$$(e^n, v^n) - \int_{t^{n-1}}^{t^n} (e, v_{ht}) + \eta(e, v_h)_U - (e^{n-1}, v_+^{n-1}) = 0. \tag{2.6}$$

Letting $\hat{e} = \mathbb{P}_n^{loc} u - u_h = e - (I - \mathbb{P}_n^{loc})u$ and using the properties of $\mathbb{P}_n^{loc}$ gives

$$\begin{aligned} &(\hat{e}^n, v^n) - \int_{t^{n-1}}^{t^n} (\hat{e}, v_{ht}) + \eta(\hat{e}, v_h)_U - (\hat{e}^{n-1}, v_+^{n-1}) \\ &= ((I - P_{n-1})u(t^{n-1}), v_+^{n-1}) - \int_{t^{n-1}}^{t^n} \eta((I - \mathbb{P}_n^{loc})u, v_h)_U. \end{aligned} \tag{2.7}$$

Setting $v_h = \hat{e}$ shows

$$\begin{aligned} &\frac{1}{2}|\hat{e}^n|^2 + \int_{t^{n-1}}^{t^n} \eta\|\hat{e}\|_U^2 + \frac{1}{2}|\hat{e}^{n-1} - \hat{e}_+^{n-1}|^2 - \frac{1}{2}|\hat{e}^{n-1}|^2 \\ &= ((I - P_{n-1})u(t^{n-1}), \hat{e}_+^{n-1}) - \int_{t^{n-1}}^{t^n} \eta((I - \mathbb{P}_n^{loc})u, \hat{e})_U. \end{aligned}$$

The second term on the right-hand side is bounded using the Cauchy–Schwarz inequality, and the first term is bounded two different ways. Since $\hat{e}^{n-1} \in U_h^{n-1}$, an estimate independent of η is computed as

$$\begin{aligned} ((I - P_{n-1})u(t^{n-1}), \hat{e}_+^{n-1}) &= ((I - P_{n-1})u(t^{n-1}), \hat{e}_+^{n-1} - \hat{e}^{n-1}) \\ &\le |(I - P_{n-1})u(t^{n-1})|^2 + \frac{1}{4}|\hat{e}_+^{n-1} - \hat{e}^{n-1}|^2. \end{aligned}$$

An alternative estimate is obtained upon writing

$$\begin{aligned} ((I - P_{n-1})u(t^{n-1}), \hat{e}_+^{n-1}) &= (P_n(I - P_{n-1})u(t^{n-1}), \hat{e}_+^{n-1}) \\ &\le \|P_n(I - P_{n-1})u(t^{n-1})\|_{U'}\|\hat{e}_+^{n-1}\|_U. \end{aligned}$$

We next appeal to the following "inverse" estimate for functions in $\mathcal{P}(t^{n-1}, t^n, U^n)$:

$$\|\hat{e}_+^{n-1}\|_U^2 \le \frac{C_k^2}{\tau^n}\int_{t^{n-1}}^{t^n} \|\hat{e}\|_U^2.$$

The finite dimensionality of $\mathcal{P}_k(t^{n-1}, t^n)$ shows that such an estimate holds, and a scaling argument shows that the constant takes the form C_k^2/τ^n, where C_k depends only upon k when $\tau^n = t^n - t^{n-1}$. It follows that

$$((I - P_{n-1})u(t^{n-1}), \hat{e}_+^{n-1}) \leq \frac{C_k^2}{\tau^n \eta} \|P_n(I - P_{n-1})u(t^{n-1})\|_{U'}^2 + \frac{\eta}{4} \int_{t^{n-1}}^{t^n} \|\hat{e}\|_U^2.$$

Substituting these estimates into (2.8) and summing completes the proof. ∎

2.3. Discrete characteristic functions. To compute the error at arbitrary times $t \in [t^{n-1}, t^n)$ we would like to substitute $v_h = \chi_{[t^{n-1},t)} u_h$ into (2.4), where $\chi_{[t^{n-1},t)}$ is the characteristic function on $[t^{n-1}, t)$. Clearly this function is not in $\mathcal{U}_h$, so in this section discrete approximations of such characteristic functions are constructed to circumvent this problem.

The construction of the discrete characteristic functions is invariant under translation, so it is convenient to work on the interval $[0, \tau)$ with $\tau = t^n - t^{n-1}$. Consider first polynomials $p \in \mathcal{P}_k(0, \tau)$. A discrete approximation of $\chi_{[0,t)}p$ is the polynomial $\tilde{p} \in \{\tilde{p} \in \mathcal{P}_k(0, \tau) | \tilde{p}(0) = p(0)\}$ satisfying

$$\int_0^\tau \tilde{p}q = \int_0^t pq \qquad \forall\, q \in \mathcal{P}_{k-1}(0, \tau).$$

The above construction is motivated by the fact that setting $q = p'$ gives $\int_0^\tau p'\tilde{p} = \int_0^t pp' = (1/2)(p^2(t) - p^2(0))$.

This elementary construction can be extended to approximations of $\chi_{[0,t)}v$ for $v \in \mathcal{P}_k(0, \tau; V)$, where V is a linear space. If $v \in \mathcal{P}_k(0, \tau; V)$, write $v = \sum_{i=0}^k p_i(t)v_i$, where $\{p_i\} \subset \mathcal{P}_k(0, \tau)$ and $\{v_i\} \subset V$. Then the discrete approximation of $\chi_{[0,t)}v$ in $\mathcal{P}_k(0, \tau; V)$ is defined to be $\tilde{v} = \sum_{i=0}^k \tilde{p}_i(t)v_i$. If V is a semi-inner product space, it is clear that

$$\tilde{v}(0) = v(0) \quad \text{and} \quad \int_0^\tau (\tilde{v}, w)_V = \int_0^t (v, w)_V \qquad \forall\, w \in \mathcal{P}_{k-1}(0, \tau; V). \tag{2.8}$$

The function $\tilde{v}$ could have been characterized directly by this equation instead of using the two stage construction given here. However, it is useful to observe that v is independent of the choice of the specific space V or the inner product $(.,.)_V$.

2.3.1. Estimates for discrete characteristic functions. The construction of the discrete characteristic functions was purely algebraic. The next two lemmas bound the map $v \mapsto \tilde{v}$.

LEMMA 2.3. *The mapping $p \mapsto \tilde{p}$ on $\mathcal{P}_k(0, \tau)$ is linear and continuous, and there exists a constant $\hat{C}_k$ depending only upon k such that $\|\tilde{p} - p\|_{L^2(0,\tau)} \leq \hat{C}_k \|p\|_{L^2(t,\tau)}$. Moreover,*

$$\|\tilde{p} - \chi_{[0,t)}p\|_{L^2(0,\tau)} \leq \|\tilde{p} - p\|_{L^2(0,\tau)} + \|p - \chi_{[0,t)}p\|_{L^2(0,\tau)} \leq (1 + \hat{C}_k)\|p\|_{L^2(t,\tau)}$$

and $\|\tilde{p}\|_{L^2(0,\tau)} \leq (1 + \hat{C}_k)\|p\|_{L^2(0,\tau)}$.

Proof. Since $\tilde{p}(0) = p(0)$, the difference may be factored as $\tilde{p} - p = t\bar{p}$ with $\bar{p} \in \mathcal{P}_{k-1}(0, \tau)$. The definition of $\tilde{p}$ shows that

$$\int_0^\tau t\bar{p}q = \int_0^\tau (\tilde{p} - p)q = -\int_t^\tau pq \qquad \forall\, q \in \mathcal{P}_{k-1}(0, \tau).$$

Setting $q = \bar{p}$ gives

$$c_k \tau \int_0^\tau \bar{p}^2 \le \int_0^\tau t\bar{p}^2 = -\int_t^\tau p\bar{p},$$

where the equivalence of norms on $\mathcal{P}_k$ was used and the scaling was chosen to make c_k independent of τ. The Cauchy–Schwarz inequality then gives

$$(c_k\tau)^2 \int_0^\tau \bar{p}^2 \le \int_t^\tau p^2,$$

which implies

$$c_k^2 \int_0^\tau (\tilde{p} - p)^2 = c_k^2 \int_0^\tau t^2\bar{p}^2 \le c_k^2\tau^2 \int_0^\tau \bar{p}^2 \le \int_t^\tau p^2. \qquad \square$$

The next lemma bounds the map $v \mapsto \tilde{v}$ on $\mathcal{P}_k(0,\tau;V)$, where V is any (semi-) inner product space.

LEMMA 2.4. *Let V be a semi-inner product space; then the mapping $\sum_{i=0}^k p_i(t)v_i \mapsto \sum_{i=0}^k \tilde{p}_i(t)v_i$ on $\mathcal{P}_k(0,\tau;V)$ is continuous in $\|\cdot\|_{L^2[0,\tau;V]}$. In particular,*

$$\|\tilde{v}\|_{L^2[0,\tau;V]} \le C_k \|v\|_{L^2[0,\tau;V]}$$

and

$$\|\tilde{v} - \chi_{[0,t)}v\|_{L^2[0,\tau;V]} \le C_k \|v\|_{L^2[0,\tau;V]},$$

where $C_k = (k+1)^{1/2}(1 + \hat{C}_k)$.

Proof. Without loss of generality write $v = \sum_{i=0}^k p_i(t)v_i$, where $\{p_i\}$ form an orthonormal basis of $\mathcal{P}_k(0,\tau)$ in $L^2(0,\tau)$, so that $\|v\|^2_{L^2[0,\tau;V]} = \sum_{i=0}^k \|v_i\|_V^2$. The lemma then follows by direct computation:

$$\begin{aligned}
\int_0^\tau \|\tilde{v}\|_V^2 &= \int_0^\tau \sum_{i,j=0}^k \tilde{p}_i(t)\tilde{p}_j(t)(v_i, v_j)_V \\
&\le \sum_{i,j=0}^k \|\tilde{p}_i\|_{L^2(0,\tau)} \|\tilde{p}_j\|_{L^2(0,\tau)} \|v_i\|_V \|v_j\|_V \\
&\le (1 + \hat{C}_k)^2 \sum_{i,j=0}^k \|v_i\|_V \|v_j\|_V \\
&\le (1 + \hat{C}_k)^2 (k+1) \left(\sum_{i=0}^k \|v_i\|_V^2 \right) \\
&\le (1 + \hat{C}_k)^2 (k+1) \int_0^\tau \|v\|_V^2.
\end{aligned}$$

The second estimate follows similarly. $\square$

2.4. Error estimates at arbitrary times. We are now ready to prove the main result of this section which shows that the error estimate of Theorem 2.2, which held at discrete times, holds for every time.

THEOREM 2.5. *Let $u_h \in \mathcal{U}_h$ be the approximate solution of* (2.1) *computed using the DG scheme* (2.3). *Let $\hat{e} = \mathbb{P}_h^{loc} u - u_h$, where $\mathbb{P}_h^{loc}$ is the projection defined in Definition* 2.1. *Then there exists a constant $\tilde{C}_k$ depending only upon k such that*

$$\sup_{t^{n-1}\le t\le t^n} |\hat{e}(t)|^2 + \eta \int_0^{t^n} \|\hat{e}\|_U^2 + \sum_{i=0}^{n-1} |\hat{e}^i - \hat{e}_+^i|^2 \le \tilde{C}_k \left(|\hat{e}^0|^2 + \eta \int_0^{t^n} \|(I - \mathbb{P}_h^{loc})u\|_U^2 + \sum_{i=0}^{n-1} \min\left(|(I-P_i)u(t^i)|^2, \frac{C_k^2}{\tau^{i+1}\eta} \|P_{i+1}(I-P_i)u(t^i)\|_{U'}^2 \right) \right),$$

where C_k is the constant appearing in Theorem 2.2.

Proof. Given Theorem 2.2, it suffices to estimate $\sup_{t^{n-1}\le t\le t^n} |\hat{e}(t)|^2$. To bound this term, fix $t \in [t^{n-1}, t^n)$ and substitute $v_h = \tilde{e}$ into (2.7), where $\tilde{e}$ is the discrete approximation of $\chi_{[t^{n-1},t)}\hat{e}$ constructed above, to get

$$\begin{aligned}
&\frac{1}{2}|\hat{e}(t)|^2 + \frac{1}{2}|\hat{e}^{n-1} - \hat{e}_+^{n-1}|^2 - \frac{1}{2}|\hat{e}^{n-1}|^2 \\
&= ((I-P_{n-1})u(t^{n-1}), e_+^{n-1}) - \eta \int_{t^{n-1}}^{t^n} ((I-\mathbb{P}_n^{loc})u, \tilde{e})_U + (\hat{e}, \tilde{e})_U \\
&= ((I-P_{n-1})u(t^{n-1}), e_+^{n-1}) + \eta \int_{t^{n-1}}^{t^n} \frac{1}{2}\|(I-\mathbb{P}_n^{loc})u\|_U^2 + \frac{1}{2}\|\tilde{e}\|^2 + \|\hat{e}\|_U \|\tilde{e}\|_U \\
&= ((I-P_{n-1})u(t^{n-1}), e_+^{n-1}) + \eta \int_{t^{n-1}}^{t^n} \frac{1}{2}\|(I-\mathbb{P}_n^{loc})u\|_U^2 + \left(\frac{C_k}{2} + 1\right) C_k \|\hat{e}\|_U^2.
\end{aligned}$$

Here C_k is the constant in the statement of Lemma 2.4. As in the proof of Theorem 2.2, the first term on the right-hand side may be bounded by

$$|(I-P_{n-1})u(t^{n-1})|^2 + \frac{1}{4}|\hat{e}_+^{n-1} - \hat{e}^{n-1}|^2 \quad \text{or}$$
$$\frac{C_k^2}{\tau^n \eta}\|P_n(I-P_{n-1})u(t^{n-1})\|_{U'}^2 + \frac{\eta}{4}\int_{t^{n-1}}^{t^n} \|\hat{e}\|_U^2.$$

It follows that

$$|\hat{e}(t)|^2 \le |\hat{e}^{n-1}|^2 + \eta \int_{t^{n-1}}^{t^n} C(k)\|\hat{e}\|_U^2 + \|(I-\mathbb{P}_n^{loc})u\|_U^2 + 2\min\left(|(I-P_{n-1})u(t^{n-1})|^2, \frac{C_k^2}{\tau^n\eta}\|P_n(I-P_{n-1})u(t^{n-1})\|_{U'}^2 \right),$$

where $C(k)$ is a constant depending upon k. The proof follows upon using Theorem 2.2 to bound the first two terms on the right-hand side. ∎

The following definition facilitates an interpretation of the above result, which is useful for the analysis of the parabolic problem in the next section.

DEFINITION 2.6. *The projection $\mathbb{P}_h : L^2[0,T;U] \cap H^1[0,T;U'] \to \mathcal{U}_h$ is the DG approximation of the function reconstructed from $f = u' + \eta B u$ and the initial data $u(0)$. That is, $u_h = \mathbb{P}_h u$ is the solution of* (2.3), *where $f = u' + \eta B u$.*

The previous theorem can then be interpreted as an estimate of the difference $\mathbb{P}_h u - \mathbb{P}_h^{loc} u$ between the global and local projections. Bounds on $\mathbb{P}_h^{loc} u - u$ follow directly from interpolation estimates [23].

We finish this section with some comments on the optimality of these estimates in the typical situation where $H = L^2(\Omega)$, $U \subset H^1(\Omega)$, and classical finite element piecewise polynomials of degree ℓ are used to construct the subspaces $\{U_h^n\}_{n=0}^N$. Assuming $u^0 = P_0(u(0))$, $\eta = O(1)$, and $\tau \sim h$, where h is the usual mesh parameter, the error term may be estimated as

$$\eta \int_0^{t^N} \|(I - \mathbb{P}_h^{loc})u\|^2 + \sum_{i=0}^{N-1} \min\left(|(I-P_i)u(t^i)|^2, \frac{C_k^2}{\tau\eta}\|P_{i+1}(I-P_i)u(t^i)\|_{U'}^2\right)$$
$$\sim h^{2\ell} \int_0^T \|D^{\ell+1}u\|_{L^2(\Omega)}^2 + h^{2\ell} \sup_{0\le t\le T} \|D^\ell u\|_{L^2(\Omega)}^2.$$

Here the second term in the $\min(.,.)$ is used, and the regularity assumed matches the expected regularity parabolic equations:

$$\sup_{0\le t\le T} \|D^\ell u\|_{L^2(\Omega)}^2 + \int_0^T \|D^{\ell+1}u\|_{L^2(\Omega)}^2 \le C\left(\|D^\ell u(0)\|_{L^2(\Omega)}^2 + \int_0^T \|D^{\ell-1}f\|_{L^2(\Omega)}^2\right).$$

If the solution u is smooth, the error estimate is still useful when η is small, since if $\tau \sim h$, then

$$\eta \int_0^{t^N} \|(I - \mathbb{P}_h^{loc})u\|^2 + \sum_{i=0}^{N-1} \min\left(|(I-P_i)u(t^i)|^2, \frac{C_k^2}{\tau\eta}\|P_{i+1}(I-P_i)u(t^i)\|_{U'}^2\right)$$
$$\sim \eta h^{2\ell} \int_0^T \|D^{\ell+1}u\|_{L^2(\Omega)}^2 + \min\left(h^{2\ell+1}, \frac{h^{2(\ell+1)}}{\eta}\right) \sup_{0\le t\le T} \|D^{\ell+1}u\|_{L^2(\Omega)}^2.$$

For $\eta \ll h$ a rate of $O(h^{\ell+1/2})$ will be observed. This is typical of the rate attained by the discontinuous method for hyperbolic equations [20], and when $\eta = 0$ is sub-optimal by a factor of $h^{1/2}$.

The above rates are guaranteed to hold independently of how the mesh is chosen at each time step. If the same mesh is used at each step, then $P_{i+1}(I - P_i) = P_i(I - P_i) = 0$, so the second term in the above estimates vanishes. Adaptive mesh refinement and coarsening strategies can be employed to control this term.

3. DG scheme for parabolic PDEs.

3.1. Formulation of the DG scheme.. We now consider approximations of (1.1) using the DG scheme. Optimal error estimates are derived by extending the ideas introduced in section 2. Let $a(\cdot,\cdot)$ denote the natural bilinear form associated with $A(\cdot)$. The following continuity and coercivity conditions will be assumed for $a(.,.)$.

ASSUMPTION 1. *There exist nonnegative constants C_a, C_α, c_a, c_α with $c_a \le C_a$ such that we have*

1. *continuity of the bilinear form and data:*

$$|a(t;u,v)| \le \left(c_a\|u\|^2 + C_a|u|^2\right)^{\frac{1}{2}}\left(c_a\|v\|^2 + C_a|v|^2\right)^{\frac{1}{2}}$$

and

$$|\langle F, v\rangle| \le \|F\|_*\left(c_a\|v\|^2 + C_a|v|^2\right)^{\frac{1}{2}},$$

2. *coercivity of the bilinear form:*

$$a(t;u,u) \geq c_\alpha \|u\|^2 - C_\alpha |u|^2.$$

Remark 3.

(1) The condition $c_a \leq C_a$ is not essential and is made to simplify some of the formula below.

(2) The coercivity constant will enter the estimates through the ratio c_a/c_α. The change to Lagrangian variables in the convection diffusion example presented in the introduction enables this ratio to be bounded independently of the diffusion parameter $\epsilon > 0$.

(3) The norm $\|.\|_*$ is a dual norm equivalent to $\|.\|_{U'}$; however, the constants relating them depend upon $1/c_a$, which may be large.

In this context the natural weak formulation of (1.1) is to find $u \in \mathcal{U} \equiv L^2[0,T;U] \cap H^1[0,T;U']$ such that

$$(u(T),v(T)) + \int_0^T (\langle -u, v_t\rangle + a(t,u,v)) = (u_0, v(0)) + \int_0^T \langle F, v\rangle \tag{3.1}$$

for all $v \in \mathcal{U}$. To approximate the solution of this weak formulation let $0 = t^0 < t^1 < \cdots < t^N = T$ be a partition of $[0,T]$, and let $\{U_h^n\}_{n=0}^N \subset U$ be closed subspaces. The DG method constructs an approximate solution satisfying $u_h|_{(t^{n-1},t^n]} \in \mathcal{P}_k(t^{n-1},t^n;U_h^n)$ and

$$\begin{aligned}(u^n,v^n) + \int_{t^{n-1}}^{t^n} \Big(-\langle u_h, v_{ht}\rangle + a(\cdot;u_h,v_h)\Big) \\ = (u^{n-1},v_+^{n-1}) + \int_{t^{n-1}}^{t^n} \langle F, v_h\rangle \qquad \forall\, v_h \in \mathcal{P}_k(t^{n-1},t^n;U_h^n).\end{aligned} \tag{3.2}$$

Integration of the temporal term by parts yields the alternative representation

$$\begin{aligned}\int_{t^{n-1}}^{t^n} \Big(\langle u_{ht}, v_h\rangle + a(\cdot;u_h,v_h)\Big) + (u_+^{n-1} - u^{n-1}, v_+^{n-1}) \\ = \int_{t^{n-1}}^{t^n} \langle F, v_h\rangle \qquad \forall\, v_h \in \mathcal{P}_k(t^{n-1},t^n;U_h^n).\end{aligned} \tag{3.3}$$

3.2. Preliminary estimates. Classical bounds for the parabolic equation (3.2) are obtained upon selecting $u = v$ in (3.1); the discrete analogue would be to set $v_h = u_h$ in (3.3). Upon observing that

$$\int_{t^{n-1}}^{t^n} \langle u_{ht}, u_h\rangle + (u_+^{n-1} - u^{n-1}, u_+^{n-1}) = \frac{1}{2}|u^n|^2 - \frac{1}{2}|u^{n-1}|^2 + \frac{1}{2}|u_+^{n-1} - u^{n-1}|^2,$$

standard energy arguments and the continuity and coercivity hypotheses in Assumption 1 lead to the inequality

$$\begin{aligned}|u^n|^2 + c_\alpha \int_{t^{n-1}}^{t^n} \|u_h\|^2 + |u^{n-1} - u_+^{n-1}|^2 \\ \leq |u^{n-1}|^2 + \int_{t^{n-1}}^{t^n} \left(\left(1 + \frac{c_a}{c_\alpha}\right) \|F\|_*^2 + (2C_\alpha + C_a)|u_h|^2 \right).\end{aligned} \tag{3.4}$$

When $u_h \in \mathcal{P}_k(t^{n-1}, t^n; U_h^n)$ with $k \geq 2$, this inequality does not control $|u_h(s)|$ for $s \in (t^{n-1}, t^n)$. When u_h is piecewise constant or linear in time ($k = 0$ or 1), the terms on the left-hand side will dominate the last term on the right-hand side for sufficiently small time steps [23, Theorem 12.4]. The case $k > 2$ has not been completely addressed previously; typically strict coercivity is assumed so that $C_\alpha \leq 0$. In this situation it is possible to write

$$\int_{t^{n-1}}^{t^n} \langle F, u_h \rangle \leq \int_{t^{n-1}}^{t^n} \frac{1}{2\epsilon} \|F\|_*^2 + \frac{\epsilon}{2}(|u_h|^2 + \|u_h\|^2)$$

and use a Poincaré inequality to control the last term. However, this requires $\epsilon \sim c_\alpha$ and thus the term $1/2\epsilon$ is large when c_α is small.

Similar difficulties are encountered with error estimates when $k \geq 2$. Letting $e = u - u_h$, the orthogonality condition becomes

$$(e^n, v^n) + \int_{t^{n-1}}^{t^n} (-\langle e, v_{ht} \rangle + a(\cdot; e, v_h)) = (e^{n-1}, v_+^{n-1})$$

for all $v_h \in \mathcal{P}_k(t^{n-1}, t^n; U_h^n)$. Writing

$$e = u - u_h = (u - \mathbb{P}_h u) + (\mathbb{P}_h u - u_h) \equiv e_p + e_h,$$

where $\mathbb{P}_h$ is the projection defined in Definition 2.6, a computation shows that

$$\begin{aligned}(e_h^n, v^n) + \int_{t^{n-1}}^{t^n} (-\langle e_h, v_{ht} \rangle + a(\cdot; e_h, v_h)) - (e_h^{n-1}, v_+^{n-1}) \\ = -(e_p^n, v^n) + \int_{t^{n-1}}^{t^n} \langle e_p, v_{ht} \rangle + (e_p^{n-1}, v_+^{n-1}) - \int_{t^{n-1}}^{t^n} a(\cdot; e_p, v_h).\end{aligned}$$

Since $\mathbb{P}_h u$ is the DG approximation of (2.1), it follows that $e_p = u - \mathbb{P}_h u$ satisfies the orthogonality condition (2.6). The first three terms on the right-hand side then simplify to $-\eta \int_{t^{n-1}}^{t^n} (e_p, v_h)_U$. When $\eta = c_a$ this gives

$$\begin{aligned}(e_h^n, v^n) + \int_{t^{n-1}}^{t^n} (\langle -e_h, v_{ht} \rangle + a(\cdot; e_h, v_h)) - (e_h^{n-1}, v_+^{n-1}) \\ = -\int_{t^{n-1}}^{t^n} a(\cdot; e_p, v_h) + c_a (e_p, v_h)_U.\end{aligned} \tag{3.5}$$

This expression is identical in form to the original scheme (3.2) for u_h with $F(.) = -a(e_p, .) - \eta(e_p, .)_U$. Setting $v_h = e_h$ gives the analogue of (3.4),

$$\begin{aligned}|e_h^n|^2 + c_\alpha \int_{t^{n-1}}^{t^n} \|e_h\|^2 + |e_h^{n-1} - e_{h+}^{n-1}|^2 - |e_h^{n-1}|^2 \\ \leq \int_{t^{n-1}}^{t^n} \left(\left(1 + \frac{4c_a}{c_\alpha} \right) \left(c_a \|e_p\|^2 + C_a |e_p|^2 \right) + (2C_\alpha + c_a)|e_h|^2 \right).\end{aligned} \tag{3.6}$$

Again the natural energy arguments for the DG scheme fail to control $e_h(t)$ for $t \in (t^{n-1}, t^n)$ when c_α is small.

Remark 4. The projection $\mathbb{P}_h$ constructed using the discrete solution of an auxiliary equation is necessary when different subspaces are used for each time step, i.e.,

$U_h^n \neq U_h^{n-1}$. Using the "standard" projection, $\mathbb{P}_h^{loc}u$ in place of $\mathbb{P}_h$ (as in [23]) gives

$$\begin{aligned}(e_h^n, v^n) + \int_{t^{n-1}}^{t^n} \Big(\langle -e_h, v_{ht}\rangle + a(\cdot; e_h, v_h)\Big) \\ = (e_h^{n-1}, v_+^{n-1}) - \int_{t^{n-1}}^{t^n} a(\cdot; e_p^{n-1}, v_h) + (e_p^{n-1}, v_+^{n-1})\end{aligned}$$

with $e_p = u - \mathbb{P}_h^{loc}u$. Note that the last term is equal to $(e_p^{n-1}, v_+^{n-1} - w_-)$ for every $w_- \in U^{n-1}$, and when $U_h^n = U_h^{n-1}$ we may select $w_- = v_+^{n-1}$ to get (3.5) (without the last term on the right, which is not present if η is taken to be 0 instead of c_a).

3.3. Stability and error estimates. In this section we show how the estimates in (3.4) and (3.6) can be augmented to provide bounds on the solution and the error for all times, particularly, for the intermediate times $t \in (t^{n-1}, t^n)$. To do this the discrete characteristic functions developed in section 2.3 will be used. Since (3.2) for u_h and (3.5) for e_h are identical in form, the same line of argument can be applied to obtain bounds or an error estimate, respectively.

THEOREM 3.1. *Let $U \hookrightarrow H \hookrightarrow U'$ be a dense embedding of Hilbert spaces and $\mathcal{U}_h$ be the subspace of $L^2[0,T;U]$ defined in section 2.1, and, let the bilinear form $a : U \times U \to \mathbb{R}$ and linear form $F : U \to \mathbb{R}$ satisfy Assumption 1. Let $u \in L^2[0,T;U] \cap H^1[0,T;U']$ be the solution of (3.1) and $u_h \in \mathcal{U}_h$ be the approximate solution computed using the DG scheme (3.2) on the partition $0 = t^0 < t^1 < \cdots < t^N = T$, and set $\tau \equiv \max_n t^n - t^{n-1}$.*

Then there exists a constant $C > 0$ depending only on k (through the constant C_k of Lemma 2.4), the constants C_a, C_α, and the ratio c_a/c_α such that

$$\begin{aligned}(1-\lambda)|u^n|^2 + \lambda \sup_{t^{n-1}\le s\le t^n} |u_h(s)|^2 + \sum_{i=0}^{n-1} e^{C(t^{n-1}-t^i)}|u^i - u_+^i|^2 \\ + (1-\lambda)\frac{c_\alpha}{2}\int_0^{t^n} \mathrm{e}^{C(t^n-s)}\|u_h(s)\|^2 ds \\ \le \big(1 + T\mathcal{O}(\tau)\big)\left(\mathrm{e}^{Ct^n}|u_h^0|^2 + C\lambda\int_0^{t^n} \mathrm{e}^{C(t^n-s)}\|F(s)\|_*^2\, ds\right)\end{aligned}$$

and

$$\begin{aligned}(1-\lambda)|e_h^n|^2 + \lambda \sup_{t^{n-1}\le s\le t^n} |e_h(s)|^2 + \sum_{i=0}^{n-1} e^{C(t^{n-1}-t^i)}|e_h^i - e_{h+}^i|^2 \\ + (1-\lambda)\frac{c_\alpha}{2}\int_0^{t^n} \mathrm{e}^{C(t^n-s)}\|e_h(s)\|^2 ds \\ \le \big(1 + T\mathcal{O}(\tau)\big)\left(\mathrm{e}^{Ct^n}|e_h^0|^2 + C\lambda\int_0^{t^n} \mathrm{e}^{C(t^n-s)}\big(c_a\|e_p(s)\|^2 + C_a|e_p(s)|^2\big)\, ds\right),\end{aligned}$$

provided $C\tau < 1$. Here $\lambda = 1/(2C_k + 4C_k c_a/c_\alpha + 1) \in (0,1)$, and $e_p = u - \mathbb{P}_h u$ and $e_h = \mathbb{P}_h u - u_h$, where $\mathbb{P}_h : L^2[0,T;U] \cap H^1[0,T;U'] \to \mathcal{U}_h$ is the projection defined in Definition 2.6 (with parameter $\eta = c_a$).

Proof. Since the line of argument to prove each inequality is identical, we prove only the second.

Fix $t \in (t^{n-1}, t^n)$, and let $\tilde{e}_h \in \mathcal{P}_k(t^{n-1}, t^n; U_h^n)$ be the discrete approximation of $\chi_{[t^n,t)} e_h$ constructed in Lemma 2.4. Setting $v_h = \tilde{e}_h$ in (3.5) and moving the term $a(.; e_h, \tilde{e}_h)$ to the right-hand side gives

$$\frac{1}{2}|e_h(t)|^2 + \frac{1}{2}|e_h^{n-1} - e_{h+}^{n-1}|^2 = \frac{1}{2}|e_h^{n-1}|^2 - \int_{t^{n-1}}^{t^n} \left(a(.; e_p, \tilde{e}_h) + c_a(e_p, \tilde{e}_h)_U + a(\cdot; e_h, \tilde{e}_h)\right).$$

The last three terms are estimated separately:

$$\begin{aligned}
\int_{t^{n-1}}^{t^n} a(.; e_h, \tilde{e}_h) &\le \int_{t^{n-1}}^{t^n} (c_a\|e_h\|^2 + C_a|e_h|^2)^{1/2} (c_a\|\tilde{e}_h\|^2 + C_a|\tilde{e}_h|^2)^{1/2} \\
&\le \left(\int_{t^{n-1}}^{t^n} c_a\|e_h\|^2 + C_a|e_h|^2\right)^{1/2} \left(\int_{t^{n-1}}^{t^n} c_a\|\tilde{e}_h\|^2 + C_a|\tilde{e}_h|^2\right)^{1/2} \\
&\le C_k \int_{t^{n-1}}^{t^n} \Big(c_a\|e_h\|^2 + C_a|e_h|^2\Big).
\end{aligned}$$

Lemma 2.4 was used to bound $\tilde{e}_h$ in terms of e_h in the last line. A similar computation shows

$$\begin{aligned}
&\int_{t^{n-1}}^{t^n} a(.; e_p, \tilde{e}_h) + c_a(e_p, \tilde{e}_h)_U \\
&\qquad \le \frac{C_k}{2} \int_{t^{n-1}}^{t^n} \left(\left(\frac{c_a}{c_\alpha} + 1\right)(c_a\|e_p\|^2 + C_a|e_p|^2) + c_\alpha\|e_h\|^2 + C_a|e_h|^2\right).
\end{aligned}$$

Combining the above gives

$$\begin{aligned}
&|e_h(t)|^2 + |e_h^{n-1} - e_{h+}^{n-1}|^2 \le |e_h^{n-1}|^2 \\
&+ C_k \int_{t^{n-1}}^{t^n} \left(\left(1 + \frac{c_a}{c_\alpha}\right)(c_a\|e_p\|^2 + C_a|e_p|^2) + c_\alpha\left(1 + \frac{2c_a}{c_\alpha}\right)\|e_h\|^2 + 3C_a|e_h|^2\right). \qquad (3.7)
\end{aligned}$$

Now form the convex combination of $(1-\lambda)$ for (3.6) and λ for (3.7). The coefficient λ is chosen so that the term involving $\|e_h\|^2$ on the right-hand side of (3.7) is dominated by the corresponding term on the left-hand side of (3.6). Specifically, let

$$\lambda C_k\left(1 + \frac{2c_a}{c_\alpha}\right) = \frac{1}{2}(1-\lambda) \qquad \text{or} \qquad \lambda = \frac{1}{(2C_k + 4C_k c_a/c_\alpha + 1)}.$$

This gives an estimate of the form

$$\begin{aligned}
(1-\lambda)|e_h^n|^2 + \lambda|e_h(t)|^2 + (1-\lambda)\frac{c_\alpha}{2}\int_{t^{n-1}}^{t^n} \|e_h\|^2 + |e_h^{n-1} - e_{h+}^{n-1}|^2 \qquad (3.8) \\
\le |e_h^{n-1}|^2 + C\lambda \int_{t^{n-1}}^{t^n} \Big(c_a\|e_p\|^2 + C_a|e_p|^2 + |e_h|^2\Big),
\end{aligned}$$

where the dependence of C upon the coercivity constants c_α and c_a is only through the ratio c_a/c_α. Bound the first and last terms on the right-hand side by

$$|e_h^{n-1}|^2 \le (1-\lambda)|e_h^{n-1}|^2 + \lambda \sup_{t^{n-2} < s \le t^{n-1}} |e_h(s)|^2$$

and

$$\int_{t^{n-1}}^{t^n} |e_h|^2 \le \tau^n \sup_{t^{n-1}<s\le t^n} |e_h(s)|^2, \qquad \tau^n \equiv t^n - t^{n-1},$$

respectively, and select the time t on the left-hand side so that $|e_h(t)| = \sup_{t^{n-1}<s\le t^n} |e_h(s)|$, to get

$$(1-\lambda)|e_h^n|^2 + \lambda(1-C\tau^n) \sup_{t^{n-1}<s\le t^n} |e_h(s)|^2 + (1-\lambda)\frac{c_\alpha}{2}\int_{t^{n-1}}^{t^n} \|e_h\|^2 + |e_h^{n-1} - e_{h+}^{n-1}|^2$$
$$\le (1-\lambda)|e_h^{n-1}|^2 + \lambda \sup_{t^{n-2}<s\le t^{n-1}} |e_h(s)|^2 + C\lambda \int_{t^{n-1}}^{t^n} (c_a\|e_p\|^2 + C_a|e_p|^2).$$

Upon introducing a factor $(1 - C\tau^n)$ in front of the first term, this inequality takes the form

$$(1-C\tau^n)\alpha^n + \beta^n \le \alpha^{n-1} + f^n,$$

and the theorem follows from the discrete Gronwall inequality. ∎

If the norms $|||.|||_\infty$, $|||.|||_2$ and jump term $J_N(e)$ are defined by

$$|||v|||_\infty^2 = \sup_{0\le s\le T} |v(s)|^2 + c_\alpha \int_0^T \mathrm{e}^{C(T-s)} \|v(s)\|^2\, ds,$$

$$|||v|||_2^2 = \int_0^T \mathrm{e}^{C(T-s)} |v(s)|^2\, ds + c_a \int_0^T e^{C(T-s)} \|v(s)\|^2\, ds,$$

and

$$J_N^2(v) = \sum_{i=0}^{N-1} \mathrm{e}^{C(T-t^i)} |v^i - v_+^i|^2,$$

then Theorem 3.1 states

$$|||\mathbb{P}_h u - u_h|||_\infty^2 + J_N^2(\mathbb{P}_h u - u_h) \le C(T)\left(|P_0 u(0) - u^0|^2 + |||u - \mathbb{P}_h u|||_2^2\right).$$

Since $\int_0^T \mathrm{e}^{C(T-s)}|e_p(s)|^2 \le \mathrm{e}^{CT} \sup_{0\le s\le T} |e_p(s)|^2$, various symmetric error estimates follow. For example, setting $u^0 = P_0 u(0)$ and using the triangle inequality gives

$$|||u - u_h|||_2 \le C(T)|||u - \mathbb{P}_h u|||_2 \quad \text{and} \quad |||u - u_h|||_\infty \le C(T)|||u - \mathbb{P}_h u|||_\infty.$$

Since $\mathbb{P}_h u$ is not a local projection, classical interpolation theory does not immediately yield rates of convergence for a specific problem. However, the results of section 2.4 may be used to estimate the right-hand sides of the above in terms of the local projection $\mathbb{P}_h^{loc} u$.

THEOREM 3.2. *Under the assumptions in Theorem* 3.1 *there exists a positive constant $C(T)$ depending only on k (through the constant C_k of Lemma* 2.4*), the constants C, λ, C_a, C_α, and the ratio c_a/c_α, and the final time T such that the following*

estimate holds:

$$\begin{aligned}|||u-u_h|||_\infty^2 &\le C(T)\big(|e_h^0|^2+|||u-\mathbb{P}_h^{loc}u|||_2^2+|||\mathbb{P}_hu-\mathbb{P}_h^{loc}u|||_\infty^2\big)\\ &\le C(T)\left(|e_h^0|^2+|||u-\mathbb{P}_h^{loc}u|||_\infty^2+c_a\int_0^{t^n}\|(I-\mathbb{P}_h^{loc})u\|_U^2\right.\\ &\qquad\left.+\sum_{i=0}^{n-1}\min\left(|(I-P_i)u(t^i)|^2,\frac{C_k^2}{\tau^{i+1}c_a}\|P_{i+1}(I-P_i)u(t^i)\|_{U'}^2\right)\right),\end{aligned}$$

where $e_h^0=P_0u(0)-u^0$, $\mathbb{P}_h^{loc}u$ *is the local projection defined in Definition* 2.1, *and* $P_n:H\to U_h^n$ *is the orthogonal projection.*

Remark 5. Estimates for the jump terms $J_N(u-u_h)$ can also be obtained. An application of the triangle inequality gives

$$J_N(u-u_h)\le J_N(u-\mathbb{P}_h^{loc}u)+J_N(\mathbb{P}_h^{loc}u-\mathbb{P}_hu)+J_N(\mathbb{P}_hu-u_h).$$

Bounding the last term using Theorem 3.1 shows

$$\begin{aligned}J_N^2(u-u_h)&\le C(T)\Big(J_N(u-\mathbb{P}_h^{loc}u)^2+J_N^2(\mathbb{P}_h^{loc}u-\mathbb{P}_hu)+|e_n^0|^2+|||u-\mathbb{P}_hu|||_2^2\Big)\\ &\le C(T)\Big(|e_n^0|^2+J_N(u-\mathbb{P}_h^{loc}u)^2+|||u-\mathbb{P}_h^{loc}u|||_2^2\\ &\qquad+J_N^2(\mathbb{P}_h^{loc}u-\mathbb{P}_hu)+|||\mathbb{P}_hu-\mathbb{P}_n^{loc}u|||_2^2\Big).\end{aligned}$$

The last two terms may be estimated using Theorem 2.5 to give

$$\begin{aligned}J_N^2(u-u_h)\le C(T)\left(|e_n^0|^2+J_N(u-\mathbb{P}_h^{loc}u)^2+|||u-\mathbb{P}_h^{loc}u|||_2^2+c_a\int_0^{t^n}\|(I-\mathbb{P}_h^{loc})u\|_U^2\right.\\ \left.+\sum_{i=0}^{n-1}\min\left(|(I-P_i)u(t^i)|^2,\frac{C_k^2}{\tau^{i+1}c_a}\|P_{i+1}(I-P_i)u(t^i)\|_{U'}^2\right)\right).\end{aligned}$$

When the solution is smooth, the second term, $J_N(u-\mathbb{P}_h^{loc}u)$, will typically dominate the other terms.

Appendix A. Discrete Gronwall inequality. If $(1-C\tau^n)a^n+b^n\le a^{n-1}+f^n$, the discrete Gronwall inequality states that if $\max_n C\tau^n<1$, then

$$a^N+\sum_{n=1}^N\frac{b^n}{\prod_{i=n}^N(1-C\tau^i)}\le\frac{a^0}{\prod_{i=1}^N(1-C\tau^i)}+\sum_{n=1}^N\frac{f^n}{\prod_{i=n}^N(1-C\tau^i)}.$$

Since

$$\exp\left(\sum_{i=n}^NC\tau^i\right)\le\frac{1}{\prod_{i=n}^N(1-C\tau^i)}\le\left(1-\sum_{i=n}^N(C\tau^i)^2\right)^{-1}\exp\left(\sum_{i=n}^NC\tau^i\right)$$

and $(1-\sum_{i=n}^N(C\tau^i)^2)\ge1-C^2T\tau$, where $\tau=\max_n\tau^n$, we may write

$$a^N+\sum_{n=1}^Ne^{C(t^N-t^n)}b^n\le\big(1+T\mathcal{O}(\tau)\big)\left(\mathrm{e}^{Ct^N}a^0+\sum_{n=1}^N\mathrm{e}^{C(t^N-t^n)}f^n\right),$$

where $t^n=\sum_{i=1}^n\tau^n$.

SHAPE DESIGN IN AORTO-CORONARIC BYPASS ANASTOMOSES USING PERTURBATION THEORY*

VALERY AGOSHKOV†, ALFIO QUARTERONI‡§, AND GIANLUIGI ROZZA§

Abstract. In this paper we present a new approach in the study of aorto-coronaric bypass anastomoses configurations based on small perturbation theory. The theory of optimal control based on adjoint formulation is applied in order to optimize the shape of the zone of the incoming branch of the bypass (the toe) into the coronary (see Figure 2.1). The aim is to provide design indications in the perspective of future development for prosthetic bypasses.

Key words. optimal control, shape optimization, small perturbation theory, finite elements, haemodynamics, aorto-coronaric bypass anastomoses, design of improved medical devices

DOI. 10.1137/040613287

1. Introduction.

We consider the application of optimal control approaches to shape optimization of aorto-coronaric bypass anastomoses [22]. We analyze the "first correction" method which is derived by applying a perturbation method to the initial problem in a domain $\Omega \subset \mathbb{R}^2$ whose boundary $\partial\Omega$ is parameterized by a suitable function f. Then we propose numerical methods for its solution.

The surgical realization of a bypass to overcome a critically stenosed artery is a very common practice in an everyday cardiovascular clinic.

Improvement in the understanding of the genesis of coronary diseases is very important as it allows the reduction of surgical and postsurgical failures. It may also suggest new means in bypass surgical procedures with less invasive methods and the creation of a new shape in bypass configuration [19].

Generally speaking, mathematical modelling and numerical simulation can allow better understanding of phenomena involved in vascular diseases [6, 23, 24].

When a coronary artery is affected by a stenosis, the heart muscle can't be properly oxygenated through blood. Aorto-coronaric anastomosis restores the oxygen amount through a bypass surgery downstream of an occlusion.

At present, different kinds and shapes for aorto-coronaric bypass anastomoses are available and consequently different surgery procedures are used to set up a bypass.

A bypass can be made up either by organic material (e.g., the saphena vein taken from patient's legs or the mammary artery) or by prosthetic material. The current saphenous bypass solution requires the extraction of the saphena vein with possible complications. In this respect, prosthetic bypasses are less invasive. They may feature very different shapes for bypass anastomoses, such as, e.g., cuffed arteriovenous access grafts. Different cuffed models are used such as Taylor Patch [2] and Miller Cuff Bypass [4] but also standard end-to-side anastomoses at different graft angles [3] or other shaped carbon-fiber prostheses. In the cardiovascular system, altered flow conditions such as separation, flow reversal, low and oscillatory shear stress areas, and abnormal pulse patterns are all recognized as potentially important factors in the development of arterial diseases (see [15, 18]). For all these different aspects the design of artificial arterial bypass is a very complex problem. Carbon fiber and collagen cuffed grafts instead of natural saphenous vein can be used for studying new shape design without needing "in loco" reconstruction. In this framework, optimal control (see Lions [12]) by perturbation theory (see Van Dyke [31]) provides a new approach to the problem, with the goal of improving arterial bypass graft on the basis of a better understanding of fluid dynamics aspects involved in the bypass studying.

2. Notation and problem statement. Let Ω be a bounded domain of $\mathbb{R}^2$, $\Gamma \equiv \partial\Omega$ is the boundary of Ω, $\overline{\Omega} = \Omega \cup \partial\Omega$, $\underline{x} := (x, y)$ is a point of $\overline{\Omega}$. For every scalar function ϕ and a vector function $\underline{v}$ whose components are u, v, we recall the definition of the following operators:

$$\nabla\phi = \left(\frac{\partial\phi}{\partial x}, \frac{\partial\phi}{\partial y}\right), \ \nabla \cdot \underline{v} := \mathrm{div}(\underline{v}) := \mathcal{D}(\underline{v}) = \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y},$$
$$\nabla \times \underline{v} := rot(\underline{v}) = \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}, \ \underline{rot}(\phi) = \left(\frac{\partial\phi}{\partial y}, -\frac{\partial\phi}{\partial x}\right).$$

We then recall

$$\underline{rot}(\nabla \times \underline{v}) = -\Delta\underline{v} + \nabla(\nabla \cdot \underline{v}), \ \Delta\phi = \nabla \cdot (\nabla\phi).$$

In what follows, vectors are marked with an underlined notation $\underline{v}$, aggregation of vector quantities $\underline{v}$ with scalar quantities p are indicated with $\underline{Q}$ ($\underline{Q} = (\underline{v}, p)$), $\underline{\Phi}$ or $\hat{\underline{\Phi}}$.

Consider an idealized, two-dimensional bypass bridge configuration of Figure 2.1 and the domain on Figure 2.2, where the dotted line represents the geometry of the complete anastomosis; Γ_{w_2} is the section of the original artery, Γ_{in} is the new anastomosis inflow after bypass surgery, and Γ_{out} is the anastomosis outflow. We consider the following boundary value problem for the Stokes equations [33], used to model low Reynolds blood flow in this study. For mathematical aspects related with fluid mechanics, see, for example, [14]. The problem reads: find $\underline{v}, p$ s.t.

$$\begin{cases} -\nu\Delta\underline{v} + \nabla p = \underline{F} \quad \text{in } \Omega, \\ \nabla \cdot \underline{v} = 0 \quad \text{in } \Omega, \\ \underline{v} = \underline{v}_{in} \quad \text{on } \Gamma_{in}, \ \underline{v} = 0 \quad \text{on } \Gamma_{w_1} \cup \Gamma_{w_3}, \\ -p \cdot \underline{n} + \nu\frac{\partial\underline{v}}{\partial n} = \underline{g}_{out} \quad \text{on } \Gamma_{out} \cup \Gamma_{w_2}, \end{cases} \tag{2.1}$$

where $\underline{n} = (n_1, n_2)$ is the outward unit normal vector on Γ, $\underline{F} = \underline{F}(x, y)$, $\underline{v}_{in} = \underline{v}_{in}(x, y)$, $\underline{g}_{out} = \underline{g}_{out}(x, y)$ are given vector functions, $\nu = \text{const} > 0$ and $v_f = \{\underline{v}_{in}$ on $\Gamma_{in}; \underline{0}$ on $\Gamma_{w_1} \cup \Gamma_{w_3}\}$. In the following we may need to impose some additional restriction on p (for example, $\int_\Omega p d\Omega = 0$ if $\Gamma_{in} = \Gamma$).

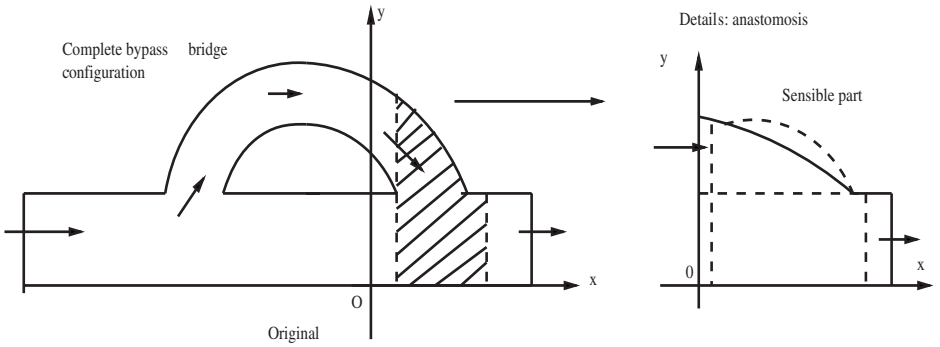

FIG. 2.1. *Idealized, 2-D bypass bridge configuration (left) and details of the sensible part for the optimization process (right). The dotted curve represents a possible shape variation.*

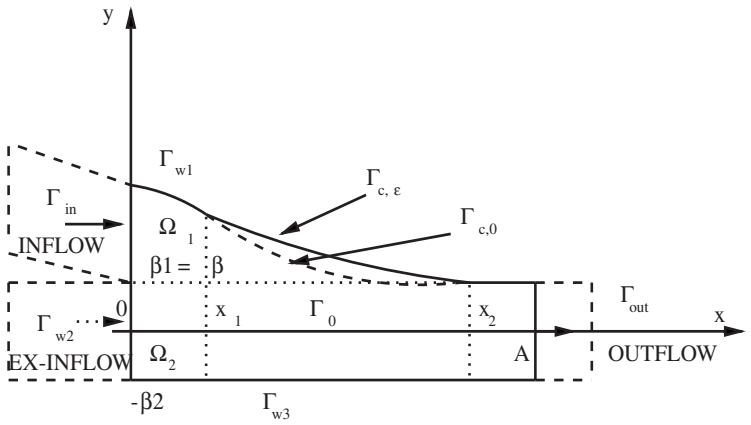

FIG. 2.2. $\overline{\Omega} = \overline{\Omega}_1 \cup \overline{\Omega}_2, \Gamma_w = \Gamma_{w_1} \cup \Gamma_{w_2} \cup \Gamma_{w_3}, \Gamma_0 = \partial\Omega_1 \cap \partial\Omega_2$.

The subset $\Gamma_{c,\varepsilon}$ of Γ_{w_1} is parametrized by a function $f(x,\varepsilon)$ of $\underline{x} \in [x_1, x_2]$ and of small parameter $\varepsilon \in [-\varepsilon_0, \varepsilon_0]$, $\varepsilon_0 = \text{const}$. More precisely, we assume that $f(x,\varepsilon)$ can be developed as follows:

$$f(x,\varepsilon) = f_0(x) + \varepsilon f_1(x) + \varepsilon^2 f_2(x) + \dots, \tag{2.2}$$

where $f_k \in \mathbb{W}^{1,\infty}(x_1,x_2)$, for $k = 0$ (we recall that $\mathbb{W}^{1,\infty}(x_1,x_2)$ is the space of functions $f_k \in \mathbb{L}^\infty(x_1,x_2)$ such that all the distribution derivatives of the first order of f_k are functions of $\mathbb{L}^\infty(x_1,x_2)$), and $f_k \in \mathbb{W}_0^{1,\infty}(x_1,x_2)$, for $k \geq 1$, so that $f_k(x_1) = f_k(x_2) = 0, k \geq 1$. Here the function $f_0(x) > 0$ describes the original subset $\Gamma_{c,0}$ of the boundary of "unperturbed domain...," $\Gamma_{w0} \equiv \partial\Omega_0$ of the domain Ω_0 (see Figure 2.3 (left)), while $f_k(x), k \geq 1$ could be unknown when dealing with a control problem (see section 4).

The weak statement of (2.1) reads: find $\underline{v} \in (\mathbb{H}^1(\Omega))^2$, $p \in \mathbb{L}^2(\Omega)$ s.t.

$$\begin{cases} a(\underline{v},\underline{\hat{v}}) = b(p,\underline{\hat{v}}) + G(\underline{\hat{v}}) \quad \forall\ \underline{\hat{v}} \in \mathbb{X}, \\ b(\hat{p},\underline{v}) = 0 \quad \forall\ \hat{p} \in \mathbb{L}^2(\Omega), \\ \underline{v} = \underline{v}_f \text{ on } \Gamma_{in} \cup \Gamma_{w_1} \cup \Gamma_{w_3}, \end{cases} \tag{2.3}$$

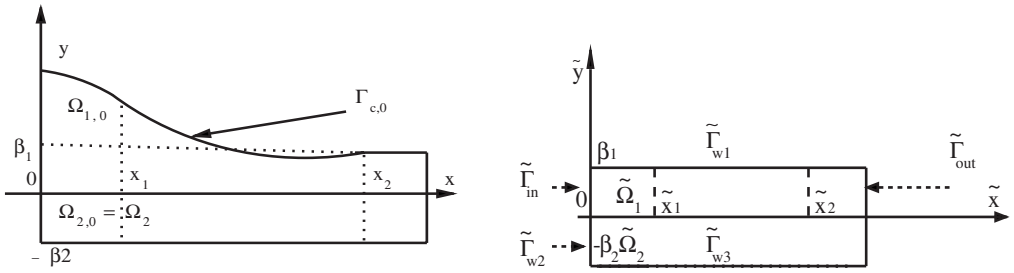

FIG. 2.3. *"Unperturbed domain"* Ω_0, $\overline{\Omega}_0 = \overline{\Omega}_{1,0} \cup \overline{\Omega}_{2,0}$ *(left). The "simple" domain* $\tilde{\Omega}$ *(right).*

where with $\underline{\hat{v}}$ we indicate test functions and

$$a(\underline{v}, \underline{\hat{v}}) = \int_\Omega \nu \nabla \underline{v} \cdot \nabla \underline{\hat{v}} d\Omega$$
$$b(p, \underline{\hat{v}}) = \int_\Omega p \nabla \cdot \underline{\hat{v}} d\Omega,\ G(\underline{\hat{v}}) = \int_\Omega \underline{F} \cdot \underline{\hat{v}} d\Omega + \int_{\Gamma_{out} \cup \Gamma_{w_2}} \underline{g}_{out} \cdot \underline{\hat{v}} d\Gamma,$$
$$\mathbb{X} := \{\underline{\hat{v}} : \underline{\hat{v}} \in (\mathbb{H}^1(\Omega))^2, \underline{\hat{v}} = 0 \text{ on } \Gamma_{in} \cup \Gamma_{w_1} \cup \Gamma_{w_3}\}.$$

Although $a(.,.), b(.,.)$, and $G(.)$, depend on the parametrization f of the part $\Gamma_{c,\varepsilon}$, this dependence will be understood for simplicity of notations.

3. The problem for the perturbation functions. Let us introduce the reference (simple-shaded) domains $\tilde{\Omega}_1 = \{0 < \tilde{x} < A, 0 < \tilde{y} < \beta_1 \equiv \beta\}$, $\tilde{\Omega}_2 = \{0 < \tilde{x} < A, -\beta_2 < \tilde{y} < 0\}$, and $\overline{\tilde{\Omega}} = \overline{\tilde{\Omega}}_1 \cup \overline{\tilde{\Omega}}_2$ (see Figure 2.3 (right)). Then we assume that $f(x, \varepsilon) > 0$ and consider the following variables transformation:

$$\mathrm{T}_f : \overline{\Omega}_1 \cup \overline{\Omega}_2 \to \overline{\tilde{\Omega}},\ \underline{\tilde{x}} = \mathrm{T}_f(\underline{x}),$$

such as T_f is the identity in Ω_2, while $\mathrm{T}_f(x, y) = (x, \frac{\beta}{f(x,y)} y)$ in Ω_1. We set $\underline{\tilde{x}} = (\tilde{x}, \tilde{y})$ and define

$$\underline{\tilde{v}}(\underline{\tilde{x}}) := \underline{v} \circ \mathrm{T}_f^{-1}(\underline{\tilde{x}}) = \underline{v}(\tilde{x}, \tilde{y} f(\tilde{x}, \varepsilon)/\beta),$$

where $\underline{\tilde{v}} = (\tilde{u}, \tilde{v})$. Then,

$$dxdy = \frac{f(\tilde{x}, \epsilon)}{\beta} d\tilde{x} d\tilde{y}$$

and the following relations hold:

$$\text{(3.1)} \qquad \begin{cases} \frac{\partial \phi}{\partial y}(\underline{\tilde{x}}) = \frac{\beta}{f(\tilde{x}, \varepsilon)} \frac{\partial \tilde{\phi}(\underline{\tilde{x}})}{\partial \tilde{y}}, \\ \frac{\partial \phi}{\partial x}(\underline{\tilde{x}}) = \frac{\partial \tilde{\phi}(\underline{\tilde{x}})}{\partial \tilde{x}} - \tilde{y} \frac{f_x(\tilde{x}, \varepsilon)}{f(\tilde{x}, \varepsilon)} \frac{\partial \tilde{\phi}(\underline{\tilde{x}})}{\partial \tilde{y}} \quad \left(\text{with } f_x := \frac{df}{dx}\right), \end{cases}$$

$$\text{(3.2)} \qquad \begin{cases} \tilde{\mathcal{D}}(f)\underline{\tilde{v}}(\underline{\tilde{x}}) := ((\nabla \cdot \underline{v}) \circ \mathrm{T}_f^{-1})(\underline{\tilde{x}}) = \frac{\partial \tilde{u}}{\partial \tilde{x}} - \tilde{y} \frac{f_x(\tilde{x}, \epsilon)}{f(\tilde{x}, \varepsilon)} \frac{\partial \tilde{u}}{\partial \tilde{y}} + \frac{\beta}{f(\tilde{x}, \varepsilon)} \frac{\partial \tilde{v}}{\partial \tilde{y}}, \\ \tilde{\mathcal{R}}(f)\underline{\tilde{v}}(\underline{\tilde{x}}) := ((\nabla \times \underline{v}) \circ \mathrm{T}_f^{-1})(\underline{\tilde{x}}) = \frac{\partial \tilde{v}}{\partial \tilde{x}} - \tilde{y} \frac{f_x(\tilde{x}, \epsilon)}{f(\tilde{x}, \varepsilon)} \frac{\partial \tilde{v}}{\partial \tilde{y}} - \frac{\beta}{f(\tilde{x}, \varepsilon)} \frac{\partial \tilde{u}}{\partial \tilde{y}}. \end{cases}$$

Then in $\tilde{\Omega}$ we have

$$\tilde{\mathcal{D}}(f)\underline{\tilde{v}} = m_2 \tilde{\nabla} \cdot \underline{\tilde{v}} + m_1 \tilde{\mathcal{D}}(f)\underline{\tilde{v}},\ \tilde{\mathcal{R}}(f)\underline{\tilde{v}} = m_2 \tilde{\nabla} \times \underline{\tilde{v}} + m_1 \tilde{\mathcal{R}}(f)\underline{\tilde{v}},$$

where $\tilde{\nabla}\phi := \left(\frac{\partial\phi}{\partial\tilde{x}}, \frac{\partial\phi}{\partial\tilde{y}}\right)$, while m_s is the characteristic function of Ω_s $(s = 1, 2)$. To simplify the notations, from now on we will set (unless otherwise specified)

$$\tilde{\underline{x}} = \underline{x},\ \tilde{\underline{v}}(\tilde{x}, \tilde{y}) := \underline{v}(x, y),\ \tilde{u} = u,\ \tilde{v} = v, \ldots, \tilde{\mathcal{D}} = \mathcal{D}, \tilde{\mathcal{R}} = \mathcal{R},\ \tilde{\Omega} \equiv \Omega,\ \tilde{\Gamma}_{w_k} \equiv \Gamma_{w_k}.$$

Then problem (2.3) in the new variables reads as follows:

$$\left\{\begin{array}{l} a(f; \underline{v}, \hat{\underline{v}}) = b(f; p, \hat{\underline{v}}) + G(f; \hat{\underline{v}}) \quad \forall\ \hat{\underline{v}} \in \mathbb{X}, \\ b(f; \hat{\underline{p}}, \underline{v}) = 0 \quad \forall\ \hat{p} \in \mathbb{L}^2(\Omega), \\ \underline{v} = \underline{v}_f \text{ on } \Gamma_{in} \cup \Gamma_{w_1} \cup \Gamma_{w_3}. \end{array}\right. \tag{3.3}$$

We have emphasized the dependence of $a(f; ., .), b(f; ., .)$, and $G(f; .)$ on f. Therefore, (with $\Omega_1 \equiv \tilde{\Omega}_1, \Omega_2 \equiv \tilde{\Omega}_2$):

$$\begin{aligned} a(f; \underline{v}, \hat{\underline{v}}) &= a_1(f; \underline{v}, \hat{\underline{v}}) + a_2(\underline{v}, \hat{\underline{v}}), \\ a_1(f; \underline{v}, \hat{\underline{v}}) &= \int_{\Omega_1} \frac{f\nu}{\beta} \left(\left(\frac{\partial \underline{v}}{\partial x} - \frac{y f_x}{f}\frac{\partial \underline{v}}{\partial y}\right) \cdot \left(\frac{\partial \hat{\underline{v}}}{\partial x} - \frac{y f_x}{f}\frac{\partial \hat{\underline{v}}}{\partial y}\right) + \frac{\beta^2}{f^2}\frac{\partial \underline{v}}{partialy} \cdot \frac{\partial \hat{\underline{v}}}{\partial y}\right) dxdy \\ a_2(\underline{v}, \hat{\underline{v}}) &= \int_{\Omega_2} \nu \left(\frac{\partial \underline{v}}{\partial x} \cdot \frac{\partial \hat{\underline{v}}}{\partial x} + \frac{\partial \underline{v}}{\partial y} \cdot \frac{\partial \hat{\underline{v}}}{\partial y}\right) dxdy, \\ b(f; p, \hat{\underline{v}}) &= b_1(f; p, \hat{\underline{v}}) + b_2(p, \hat{\underline{v}}), \\ b_1(f; p, \hat{\underline{v}}) &= \int_{\Omega_1} \frac{f}{\beta} p\mathcal{D}(f)\hat{\underline{v}} dxdy, \quad b_2(p, \hat{\underline{v}}) = \int_{\Omega_2} p\nabla \cdot \hat{\underline{v}} dxdy, \\ G(f; \hat{\underline{v}}) &= G_1(f; \hat{\underline{v}}) + G_2(\hat{\underline{v}}), \\ G_1(f; \hat{\underline{v}}) &= \int_{\Omega_1} \frac{f}{\beta} \underline{F} \cdot \hat{\underline{v}} dxdy + \int_{(\Gamma_{out} \cup \Gamma_{w2}) \cap \partial\Omega_1} \underline{g}_{out} \cdot \hat{\underline{v}} d\Gamma, \\ G_2(\hat{\underline{v}}) &= \int_{\Omega_2} \underline{F} \cdot \hat{\underline{v}} dxdy + \int_{(\Gamma_{out} \cup \Gamma_{w2}) \cap \partial\Omega_2} \underline{g}_{out} \cdot \hat{\underline{v}} d\Gamma. \end{aligned}$$

Note that the functions $\hat{\underline{v}},\ \hat{p}$ on (3.3) can be assumed to be independent of ε in what follows.

Assume that the problem (3.3) has a solution $\underline{v}, p$ that is infinitely differentiable with respect to ε:

$$\left\{\begin{array}{l} \underline{v} = \underline{v}_0 + \varepsilon\underline{v}_1 + \varepsilon^2\underline{v}_2 + \ldots \\ p = p_0 + \varepsilon p_1 + \varepsilon^2 p_2 + \ldots, \end{array}\right. \tag{3.4}$$

where $p_k \in \mathbb{L}^2, \underline{v}_k \in \mathbb{X},\ k \geq 1$. Using (2.2), (3.4), and small perturbation techniques we can derive the equations for $\underline{v}_k, p_k,\ k \geq 0$. In particular, $k = 0$ $\underline{v}_0$ and p_0 satisfy

$$\left\{\begin{array}{l} a(f_0; \underline{v}_0, \hat{\underline{v}}) = b(f_0; p_0, \hat{\underline{v}}) + G(f_0; \hat{\underline{v}}) \quad \forall\ \hat{\underline{v}} \in \mathbb{X}, \\ b(f_0; \hat{\underline{p}}, \underline{v}_0) = 0 \quad \forall\ \hat{p} \in \mathbb{L}^2(\Omega), \\ \underline{v}_0 = \underline{v}_f \text{ on } \Gamma_{in} \cup \Gamma_{w_1} \cup \Gamma_{w_3}. \end{array}\right. \tag{3.5}$$

Correspondingly, we define

$$\mathcal{R}_{obs,0} := \mathcal{R}(f_0)\underline{v}_0. \tag{3.6}$$

For $k = 1$ the functions $\underline{v}_1$ and p_1 are the solution of the equations

$$
\left\{
\begin{array}{l}
a(f_0;\underline{v}_1,\hat{\underline{v}}) = b(f_0;p_1,\hat{\underline{v}}) + \frac{\partial}{\partial\varepsilon} b(f;p_0,\hat{\underline{v}})|_{\varepsilon=0} + \\
+ \frac{\partial}{\partial\varepsilon} G(f;\hat{\underline{v}})|_{\varepsilon=0} - \frac{\partial}{\partial\varepsilon} a(f;\underline{v}_0,\hat{\underline{v}})|_{\varepsilon=0} \quad \forall\ \hat{\underline{v}} \in \mathbb{X}, \\
b(f_0;\hat{\underline{p}},\underline{v}_1) + \frac{\partial}{\partial\varepsilon} b(f;\hat{p},\underline{v}_0)|_{\varepsilon=0} = 0 \quad \forall\ \hat{p} \in \mathbb{L}^2(\Omega), \\
\underline{v}_1 = 0 \text{ on } \Gamma_{in} \cup \Gamma_{w_1} \cup \Gamma_{w_3},
\end{array}
\right. \tag{3.7}
$$

where

$$
\frac{\partial}{\partial\varepsilon} b(f;p_0,\hat{\underline{v}})|_{\varepsilon=0} := y b_f(f_1,p_0,\hat{\underline{v}}) = \int_{\Omega_1} \frac{f_1}{\beta} p_0 \mathcal{D}(f_0)\hat{\underline{v}}\,dxdy + \int_{\Omega_1} \frac{f_0}{\beta} p_0 \mathcal{D}_f(f_1,\hat{\underline{v}})dxdy,
$$

$$
\mathcal{D}_f(f_1,\hat{\underline{v}}) := \frac{\partial}{\partial\varepsilon}\mathcal{D}(f)\hat{\underline{v}}|_{\varepsilon=0} = -\left[y\left(\frac{f_{1,x}f_0 - f_{0,x}f_1}{f_0^2}\right)\frac{\partial\hat{u}}{\partial y} + \frac{\beta f_1}{f_0^2}\frac{\partial\hat{v}}{\partial y}\right],
$$

$$
\mathcal{D}_f(f_1,\underline{v}_0) := \frac{\partial}{\partial\varepsilon}\mathcal{D}(f)\underline{v}_0|_{\varepsilon=0} (:= \mathcal{D}_f f_1 \text{ in what follows}),
$$

$$
\frac{\partial}{\partial\varepsilon} G(f;\hat{\underline{v}})|_{\varepsilon=0} := G_1(f_1;\hat{\underline{v}}) = \int_{\Omega_1} \frac{f_1}{\beta} F\cdot\hat{\underline{v}}\,dxdy,
$$

$$
\begin{aligned}
\frac{\partial}{\partial\varepsilon} a(f;\underline{v}_0,\hat{\underline{v}})|_{\varepsilon=0} &:= a_f(f_1;\underline{v}_0,\hat{\underline{v}}) \\
&= \int_{\Omega_1} \frac{f_1\nu}{\beta}\left(\left(\frac{\partial\underline{v}_0}{\partial x} - \frac{y f_{0,x}}{f_0}\frac{\partial\underline{v}_0}{\partial y}\right)\cdot\left(\frac{\partial\hat{\underline{v}}}{\partial x} - \frac{y f_{0,x}}{f_0}\frac{\partial\hat{\underline{v}}}{\partial y}\right)\right. \\
&\qquad \left. + \frac{\beta^2}{f_0^2}\frac{\partial\underline{v}_0}{\partial y}\cdot\frac{\partial\hat{\underline{v}}}{\partial y}\right)dxdy + \\
&\quad - \int_{\Omega_1} \frac{f_0\nu}{\beta} y\frac{(f_{1,x}f_0 - f_{0,x}f_1)}{f_0^2}\left(\frac{\partial\underline{v}_0}{\partial y}\cdot\left(\frac{\partial\hat{\underline{v}}}{\partial x} - \frac{y f_{0,x}}{f_0}\frac{\partial\hat{\underline{v}}}{\partial y}\right)\right. \\
&\qquad \left. + \left(\frac{\partial\underline{v}_0}{\partial x} - \frac{y f_{0,x}}{f_0}\frac{\partial\underline{v}_0}{\partial y}\right)\cdot\frac{\partial\hat{\underline{v}}}{\partial y}\right)dxdy + \\
&\quad - \int_{\Omega_1} \frac{f_0\nu}{\beta}\left(\frac{2\beta^2 f_1}{f_0^3}\right)\frac{\partial\underline{v}_0}{\partial y}\cdot\frac{\partial\hat{\underline{v}}}{\partial y}dxdy.
\end{aligned}
$$

So the problem for $\underline{v}_1,\ p_1$ reads as follows: find $\underline{v}_1 \in \mathbb{X},\ p_1 \in \mathbb{L}^2(\Omega)$ s.t.

$$
\left\{
\begin{array}{l}
a(f_0;\underline{v}_1,\hat{\underline{v}}) - b(f_0;p_1,\hat{\underline{v}}) = b_f(f_1;p_0,\hat{\underline{v}}) + G_1(f_1;\hat{\underline{v}}) - a_f(f_1;\underline{v}_0,\hat{\underline{v}}) \quad \forall\ \hat{\underline{v}} \in \mathbb{X}, \\
b(f_0;\hat{\underline{p}},\underline{v}_1) + b_f(f_1;\hat{p},\underline{v}_0) = 0 \quad \forall\ \hat{p} \in \mathbb{L}^2(\Omega),
\end{array}
\right. \tag{3.8}
$$

This is a generalized Stokes problem [7]. By a similar technique we can derive the equations for $\underline{v}_k,\ p_k$ with $k \geq 2$. However, we will not carry on this development further in this work.

4. The shape optimization problem. Suppose now that the function $f_1(x)$ in (3.7) is unknown as well as $\underline{v}_1,\ p_1$. To complete problem (3.7) we will have to formulate some "additional equations"; otherwise, we should require that f_1 be determined by minimizing a suitable "cost functional. . . ."

Problem (2.3) can be supplemented by the "additional equations":

$$
\mathcal{C}(f,\underline{v},p) = 0, \tag{4.1}
$$

where $\mathcal{C}$ is an operator (linear or nonlinear) defined on $\mathbb{H}_0^1(x_1,x_2)\times\mathbb{X}\times\mathbb{L}^2(\Omega)$. (We now consider $f\in\mathbb{H}_0^1$ for convenience.) We assume $\mathcal{C}$ to be smooth with respect to its variables $f,\underline{v},p$. Using the representations (2.2) and (3.4), we derive from (4.1) the following equation:

$$\mathcal{C}(f,\underline{v},p)=\mathcal{C}(f_0,\underline{v}_0,p_0)+\varepsilon\mathcal{C}_1(f_1,\underline{v}_1,p_1)+\mathcal{O}(\varepsilon^2)=0\quad\forall\,\varepsilon\in[-\varepsilon_0,\varepsilon_0], \tag{4.2}$$

where

$$\mathcal{C}_1(f_1,\underline{v}_1,p_1):=\frac{\partial\mathcal{C}}{\partial\varepsilon}(f,\underline{v},p)|_{\varepsilon=0}. \tag{4.3}$$

If we assume that the data of our problems are such that $\mathcal{C}(f_0,\underline{v}_0,p_0)=0$, then we can use

$$\mathcal{C}_1(f_1,\underline{v}_1,p_1)=0 \tag{4.4}$$

as an additional equation to complete (3.7). An alternative approach would consist of replacing the exact controllability equation (4.4) by the following minimization problem:

$$\inf_{f_1}\int_\Omega\frac{f_0}{\beta}|\mathcal{C}_1(f_1,\underline{v}_1,p_1)|^2dxdy, \tag{4.5}$$

where we assume that $\mathcal{C}_1$ has image in $\mathbb{L}^2(\Omega)$. Note that (4.5) is a weak statement of (4.4).

In the next sections we apply the approach described above for the completion of (3.7) and will use the following special choice of (4.1):

$$\mathcal{C}(f,\underline{v}):=((\nabla\times\underline{v})\circ\mathrm{T}_f^{-1})(x,y)-\mathcal{R}_{obs,\varepsilon}(x,y)\text{ in }\Omega_{wd}\subseteq\Omega, \tag{4.6}$$

where Ω_{wd} is a suitable subset of Ω in which we want our additional equation (or our "control") to take place. Moreover,

$$\mathcal{R}_{obs,\varepsilon}=\mathcal{R}_{obs,0}+\varepsilon\mathcal{R}_{obs,1}+\varepsilon^2\mathcal{R}_{obs,2}+\dots,\ \mathcal{R}_{obs,0}:=((\nabla\times\underline{v}_0)\circ\mathrm{T}_{f_0}^{-1}). \tag{4.7}$$

Then we have: $\mathcal{C}(f_0,\underline{v}_0)=0$, while (4.4) reads

$$\mathcal{C}(f_1,\underline{v}_1)=\mathcal{R}(f_0)\underline{v}_1+m_1\mathcal{R}_f f_1-\mathcal{R}_{obs,1}=0\text{ in }\Omega_{wd}, \tag{4.8}$$

where

$$\mathcal{R}(f_0)\underline{v}_1=(\nabla\times\underline{v}_1)\circ\mathrm{T}_{f_0}^{-1}(x,y)=\frac{\partial v_1}{\partial x}-\frac{yf_{0,x}}{f_0}\frac{\partial v_1}{\partial y}-\frac{\beta}{f_0}\frac{\partial u_1}{\partial y},$$

$$\mathcal{R}_f f_1:=\mathcal{R}_f(f_1,\underline{v}_0)=-y\frac{(f_{1,x}f_0-f_{0,x}f_1)}{f_0^2}\frac{\partial v_0}{\partial y}+\frac{\beta f_1}{f_0^2}\frac{\partial u_0}{\partial y}.$$

Therefore we have the problem: find $\underline{v}_1\in\mathbb{X},\ p_1\in\mathbb{L}^2(\Omega),\ f_1\in\mathbb{H}_0^1(x_1,x_2)$ s.t.

$$\begin{cases} a(f_0;\underline{v}_1,\hat{\underline{v}})=b(f_0;p_1,\hat{\underline{v}})+b_f(f_1;p_0,\hat{\underline{v}})+G_1(f_1;\hat{\underline{v}})-a_f(f_1;\underline{v}_0,\hat{\underline{v}})\quad\forall\,\hat{\underline{v}}\in\mathbb{X},\\ b(f_0;\underline{\hat{p}},\underline{v}_1)+b_f(f_1;\hat{p},\underline{v}_0)=0\quad\forall\,\hat{p}\in\mathbb{L}^2(\Omega),\\ \mathcal{R}(f_0)\underline{v}_1+m_1\mathcal{R}_f f_1-\mathcal{R}_{obs,1}=0\ in\ \Omega_{wd}, \end{cases} \tag{4.9}$$

where $\mathcal{R}_{obs,1}$ is a given function. Problem (4.9) is an "exact controllability problem." These problems have solutions in some particular cases only. For this reason we replace (4.9) by the following optimal control problem: find $\underline{v}_1 \in \mathbb{X},\ p_1 \in \mathbb{L}^2(\Omega)$, $f_1 \in \mathbb{H}^1_0(x_1, x_2)$ s.t.

(4.10)
$$\begin{cases} a(f_0;\underline{v}_1,\underline{\hat{v}}) - b(f_0;p_1,\underline{\hat{v}}) = b_f(f_1;p_0,\underline{\hat{v}}) + G_1(f_1;\underline{\hat{v}}) - a_f(f_1;\underline{v}_0,\underline{\hat{v}}) \quad \forall\ \underline{\hat{v}} \in \mathbb{X}, \\ b(f_0;\hat{p},\underline{v}_1) + b_f(f_1;\hat{p},\underline{v}_0) = 0 \quad \forall\ \hat{p} \in \mathbb{L}^2(\Omega), \\ \inf_{f_1} = \frac{\alpha}{2}||f_1||^2_{\mathbb{H}^1_0(x_1,x_2)} + \gamma_1 J_1(f_1,\underline{v}_1), \end{cases}$$

where

$$J_1(f_1,\underline{v}_1) = \frac{1}{2}\int_\Omega m_{wd}\frac{f_0}{\beta}(\mathcal{R}(f_0)\underline{v}_1 + m_1\mathcal{R}_f f_1 - \mathcal{R}_{obs,1})^2 dxdy,$$

$\alpha = \text{const} \geq 0$ is a small regularization parameter, $\gamma_1 > 0$ is a weight coefficient, and m_{wd} is the characteristic function of Ω_{wd}.

Note that the third equation from (4.9) is considered in (4.10) in the least square sense; then (4.10) for $\alpha = 0$ provides the weak statement of problem (4.9). Otherwise the solution $v_1 = v_1(\alpha),\ p_1 = p_1(\alpha),\ f_1 = f_1(\alpha)$ of (4.10) represents an approximate (regularized) solution of (4.9).

We will also consider a generalized optimal control problem still given by (4.10); however, instead of J_1 we now use

$$J(f_1,\underline{v}_1,p_1) = \gamma_1 J_1(f_1,\underline{v}_1) + \gamma_2 J_2(f_1,\underline{v}_1,p_1).$$

Here $\gamma_2 = \text{const} \geq 0$ is a weight coefficient, while $J_2(f_1,\underline{v}_1,p_1)$ is an additional functional assumed to be quadratic. An example of $J_2(f_1,\underline{v}_1,p_1)$ follows.

Example 1.

(4.11)
$$J_2(f_1,\underline{v}_1,p_1) := J_2(\underline{v}_1,p_1) = \frac{1}{2}\left(||p_1 - p_{out,1}||^2_{\mathbb{L}^2(\Gamma_{out})} + \int_{\Gamma_{out}} |\underline{v}_1 - \underline{v}_{out,1}|^2 d\Gamma\right),$$

where $p_{out}, \underline{v}_{out}$ *are given.*

5. The variational equations of the optimal control problem. While considering (4.10) we can still consider the simple domain Ω of Figure 2.3(right). Another possibility consists of using the new variable transformation

$$T^{-1}_{f_0}(\underline{\tilde{x}}) = \underline{x},\ \underline{\tilde{x}} \in \Omega,\ \underline{x} \in \Omega_0, \tag{5.1}$$

which is the identity in $\tilde{\Omega}_2$, while $T^{-1}_{f_0}(\tilde{x},\tilde{y}) = (\tilde{x}, \frac{f_0(\tilde{x})}{\beta}\tilde{y})$ in $\tilde{\Omega}_1$. After applying (5.1) we will work in the "unperturbed" domain Ω_0 (see Figure 5.1) where the expressions for the bilinear forms in (4.10) become simpler. Let us use the variable transformation (5.1). Indeed problem (4.10) reads upon its reformulation in Ω_0: find $\underline{v} := \underline{v}_1,\ p := p_1, f := f_1$[1] s.t.

(5.2)
$$\begin{cases} a_0(\underline{v},\underline{\hat{v}}) - b_0(p,\underline{\hat{v}}) = b_f(f;p_0,\underline{\hat{v}}) + G_1(f;\underline{\hat{v}}) - a_f(f;\underline{v}_0,\underline{\hat{v}}) \quad \forall\ \hat{v} \in \mathbb{X} \\ b_0(\hat{p},\underline{v}) + b_f(f;\hat{p},\underline{v}_0) = 0 \quad \forall\ \hat{p} \in \mathbb{L}^2(\Omega), \\ \inf_f = \frac{\alpha}{2}||f||^2_{\mathbb{H}^1_0(x_1,x_2)} + J(f,\underline{v},p), \end{cases}$$

[1]From now on we denote $\underline{v}_1 = \underline{v},\ p_1 = p,\ f_1 = f$; however, we should keep in mind that now $\underline{v}, p, f$ represents the "first corrections" of $\underline{v}_0,\ p_0,\ f_0$ on the unperturbed domain.

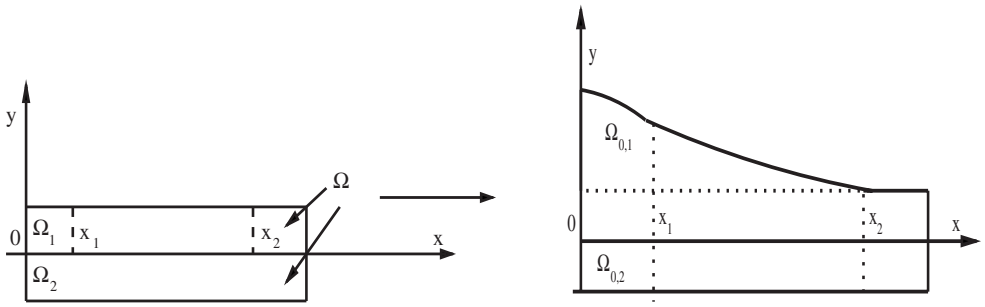

FIG. 5.1. *"Simple" domain* $\Omega \to \Omega_0$.

where

$$
\begin{aligned}
a_0(\underline{v},\underline{\hat{v}}) &= \int_{\Omega_0} \nu \left(\frac{\partial \underline{v}}{\partial x} \cdot \frac{\partial \underline{\hat{v}}}{\partial x} + \frac{\partial \underline{v}}{\partial y} \cdot \frac{\partial \underline{\hat{v}}}{\partial y} \right) dxdy, \\
b_0(p,\underline{\hat{v}}) &= \int_{\Omega_0} p \nabla \cdot \underline{\hat{v}} dxdy, \\
b_f(f,p_0,\underline{\hat{v}}) &= \int_{\Omega_{0,1}} p_0 \mathcal{D}_f(f,\underline{\hat{v}}) dxdy + \int_{\Omega_{0,1}} \frac{f}{f_0} p_0 \nabla \cdot \underline{\hat{v}} dxdy, \\
\mathcal{D}_f(f,\underline{\hat{v}}) &= -\left[y \left(\frac{f_x f_0 - f_{0,x} f}{f_0^2} \right) \frac{\partial \hat{u}}{\partial y} + \frac{f}{f_0} \frac{\partial \hat{v}}{\partial y} \right], \\
\mathcal{D}_f(f,v_0) &:= \mathcal{D}_f f, \\
G_1(f;\underline{\hat{v}}) &= \int_{\Omega_{0,1}} \frac{f}{f_0} \underline{F} \cdot \underline{\hat{v}} dxdy, \\
a_f(f;\underline{v}_0,\underline{\hat{v}}) &= \int_{\Omega_{0,1}} \frac{f\nu}{f_0} \nabla \underline{v}_0 \cdot \nabla \underline{\hat{v}} dxdy + \\
&\quad - \int_{\Omega_{0,1}} \nu y \frac{(f_x f_0 - f_{0,x} f)}{f_0^2} \left(\frac{\partial \underline{v}_0}{\partial y} \cdot \frac{\partial \underline{\hat{v}}}{\partial x} + \frac{\partial \underline{v}_0}{\partial x} \cdot \frac{\partial \underline{\hat{v}}}{\partial y} \right) dxdy + \\
&\quad - \int_{\Omega_{0,1}} \frac{2f\nu}{f_0} \frac{\partial \underline{v}_0}{\partial y} \cdot \frac{\partial \underline{\hat{v}}}{\partial y} dxdy, \\
J(f,\underline{v},p) &= \gamma_1 J_1(f,\underline{v}) + \gamma_2 J_2(f,\underline{v},p), \\
J_1(f,\underline{v}) &= \frac{1}{2} \int_{\Omega_0} m_{wd} |\nabla \times \underline{v} + m_1 \mathcal{R}_f f - \mathcal{R}_{obs,1}|^2 dxdy, \\
\mathcal{R}_f f &:= \mathcal{R}_f(f,\underline{v}_0) = -y \frac{(f_x f_0 - f_{0,x} f)}{f_0^2} \frac{\partial v_0}{\partial y} + \frac{f}{f_0} \frac{\partial u_0}{\partial y}, \\
\nabla \times \underline{v} &= \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}, \ \nabla \cdot \underline{v} = \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y}
\end{aligned}
$$

and $J_2(f,\underline{v},p)$ are given by corresponding expressions. In order to derive the operator form of problem (5.2) we introduce the following real spaces:

$$
\begin{gathered}
\mathbb{X} \subseteq (\mathbb{L}^2(\Omega))^2 \subseteq \mathbb{X}^*, \mathbb{H}^p \subseteq \mathbb{L}^2(\Omega) \subseteq \mathbb{H}^{p*}, \\
\mathbb{H}_f \subseteq \mathbb{L}^2(x_1,x_2) \subseteq \mathbb{H}_f^*, \\
\mathbb{W} := \mathbb{X} \times \mathbb{H}^p \subseteq \mathbb{H}_0 := (\mathbb{L}^2(\Omega))^2 \times \mathbb{L}^2(\Omega) \subseteq \mathbb{W}^*.
\end{gathered}
$$

Let us reformulate (5.2) in the following form: find $\underline{\Phi} := (\underline{v}, p) \in \mathbb{W} = (\mathbb{X} \times \mathbb{H}^p)$, $f \in \mathbb{H}^f$, s.t

$$\begin{cases} \mathcal{L}(\underline{\Phi}, \hat{\underline{\Phi}}) = B(f, \hat{\underline{\Phi}}) \quad \forall\, \hat{\underline{\Phi}} = (\hat{\underline{v}}, \hat{p}) \in \mathbb{W}, \\ \inf_{f \in \mathbb{H}_f} = \frac{\alpha}{2} ||f||^2_{\mathbb{H}^1} + J(f, \underline{\Phi}), \end{cases} \tag{5.3}$$

where

$$\mathcal{L}(\underline{\Phi}, \hat{\underline{\Phi}}) := a_0(\underline{v}, \hat{\underline{v}}) - b_0(p, \hat{\underline{v}}) + b_0(\hat{p}, \underline{v}),$$

$$B(f, \hat{\underline{\Phi}}) := b_f(f, p_0, \hat{\underline{v}}) + G_1(f, \hat{\underline{v}}) - a_f(f, \underline{v}_0, \hat{\underline{v}}) - b_f(f, \hat{p}, \underline{v}_0).$$

Should $\underline{\Phi}$ be a solution of (5.3), then

$$\alpha(f, \hat{f})_{\mathbb{H}_f} + \langle J'_\Phi(f, \underline{\Phi}), \underline{\Phi}_{\hat{f}} \rangle + \langle J'_f(f, \underline{\Phi}), \hat{f} \rangle = 0, \tag{5.4}$$

for any $\hat{f} \in \mathbb{H}_f$ ($\hat{f}$ is the independent variation), where $\underline{\Phi}_{\hat{f}} \in \mathbb{W}$ satisfies the following equation:

$$\mathcal{L}(\underline{\Phi}_{\hat{f}}, \hat{\underline{\Phi}}) = B(\hat{f}, \hat{\underline{\Phi}}) \quad \forall\, \hat{\underline{\Phi}} \in \mathbb{W}. \tag{5.5}$$

In (5.4), $J'_\Phi = \frac{\partial J}{\partial \underline{\Phi}}$ and $J'_f = \frac{\partial J}{\partial f}$ are partial derivatives of J, while $\langle Q, \underline{\Phi} \rangle$ is the duality between $\mathbb{W}$ and $\mathbb{W}^*$ and $\langle g, f \rangle$ the duality between $\mathbb{H}_f$ and $\mathbb{H}^*_f$. Then we can rewrite (5.3) as a system of "optimality conditions":

$$\begin{cases} \mathcal{L}(\underline{\Phi}, \hat{\underline{\Phi}}) = B(f, \hat{\underline{\Phi}}) \quad \forall\, \hat{\underline{\Phi}} \in \mathbb{W}, \\ \alpha(f, \hat{f})_{\mathbb{H}^f} + \langle J'_\Phi(f, \underline{\Phi}), \underline{\Phi}_{\hat{f}} \rangle + \langle J'_f(f, \underline{\Phi}), \hat{f} \rangle = 0 \quad \forall\, \hat{f} \in \mathbb{H}_f. \end{cases} \tag{5.6}$$

The element $\underline{\Phi}_{\hat{f}}$ can be eliminated from (5.6) by introducing the adjoint problem: find $\underline{Q} := (\underline{q}, \sigma) \in \mathbb{W}$ s.t.

$$\mathcal{L}^*(\underline{Q}, \underline{\hat{W}}) := \mathcal{L}(\underline{\hat{W}}, \underline{Q}) = \langle J'_\Phi(f, \underline{\Phi}), \underline{\hat{W}} \rangle \quad \forall\, \underline{\hat{W}} \in \mathbb{W}. \tag{5.7}$$

Since $\underline{\Phi}_{\hat{f}} \in \mathbb{W}$ we can choose $\underline{\hat{W}} = \underline{\Phi}_{\hat{f}}$ in (5.7), yielding

$$\langle J'_\Phi(f, \underline{\Phi}), \underline{\Phi}_{\hat{f}} \rangle = \mathcal{L}(\underline{\Phi}_{\hat{f}}, \underline{Q}) = B(\hat{f}, \underline{Q}) \tag{5.8}$$

and the system of variational equations (5.6) now reads as follows:

$$\begin{cases} \mathcal{L}(\underline{\Phi}, \hat{\underline{\Phi}}) = B(f, \hat{\underline{\Phi}}) \quad \forall\, \hat{\underline{\Phi}} \in \mathbb{W}, \\ \mathcal{L}^*(\underline{Q}, \underline{\hat{W}}) = \langle J'_\Phi(f, \underline{\Phi}), \underline{\hat{W}} \rangle \quad \forall\, \underline{\hat{W}} \in \mathbb{W}, \\ \alpha(f, \hat{f})_{\mathbb{H}_f} + B(\hat{f}, \underline{Q}) + \langle J'_f(f, \underline{\Phi}), \hat{f} \rangle = 0 \quad \forall\, \hat{f} \in \mathbb{H}_f. \end{cases} \tag{5.9}$$

The first equation is the state equation. Let us define the following operators (see [1, 12, 13]):

$$L : \mathbb{W} \to \mathbb{W}^*,\ (L\underline{\Phi}, \hat{\underline{\Phi}})_{\mathbb{H}_0} := \mathcal{L}(\underline{\Phi}, \hat{\underline{\Phi}}) \quad \forall\, \underline{\Phi},\ \hat{\underline{\Phi}} \in \mathbb{W},$$

$$L^* : \mathbb{W} \to \mathbb{W}^*,\ (\underline{\hat{W}}, L^*\underline{Q})_{\mathbb{H}_0} = (L\underline{\hat{W}}, \underline{Q})_{\mathbb{H}_0} \quad \forall\, \underline{Q}, \underline{\hat{W}} \in \mathbb{W},$$

$$B : \mathbb{H}_f \to \mathbb{W}^*,\ (Bf, \underline{\Phi})_{\mathbb{H}_0} = B(f, \underline{\Phi}) \quad \forall\, f, \underline{\Phi},$$

$$\Lambda_w : \mathbb{W}^* \to \mathbb{W}^*,\ (\Lambda_w J_\Phi(f, \underline{\Phi}), \underline{\hat{W}})_{\mathbb{H}_0} := \langle J'_\Phi(f, \underline{\Phi}), \underline{\hat{W}} \rangle,$$

$$\Lambda_f : \mathbb{H}^*_f \to \mathbb{H}^*_f,\ (\Lambda_f J_f(f, \underline{\Phi}), \hat{f})_{\mathbb{L}^2(x_1, x_2)} = \langle J'_f(f, \underline{\Phi}), \hat{f} \rangle.$$

Now the system (5.9) can be written in operator form as follows:

$$\text{(5.10)}\qquad \begin{cases} L\underline{\Phi} = Bf \ \ (in\ \mathbb{W}^*), \\ L^*\underline{Q} = \Lambda_w J_\Phi(f,\underline{\Phi}) \ \ (in\ \mathbb{W}^*), \\ \alpha\Lambda_c f + B^*\underline{Q} + \Lambda_f J_f(f,\underline{\Phi}) = 0 \ \ (in\ (\mathbb{H}_f)^*), \end{cases}$$

where Λ_c is the extension to $\mathbb{H}_f$ of the following operator $\Lambda_{c,0}$:

$$\Lambda_{c,0} f := -f_{xx} + f, \quad \mathcal{D}(\Lambda_{c,0}) = \mathbb{H}^2 \cap \mathbb{H}_f.$$

Remark 1. The system (5.10) with a cost functional $J = \|C\underline{\Phi} - \underline{\Psi}\|^2_{\mathbb{H}_{ob}}$, where $C : \mathbb{W} \to \mathbb{H}_{ob}$ is a given operator and $\underline{\Psi} \in \mathbb{H}_{ob}$ a given observation function has been analyzed in [1]. In this case $J'_f = 0$ and $\Lambda_w J'_\Phi(f,\underline{\Phi}) = C^*(C\underline{\Phi} - \underline{\Psi})$.

6. Uniqueness and existence results. We analyze the particular case where the cost functional J is chosen as outlined by Example 1 of section 4.

Let J be the functional J_2 in Example 1. Then

$$\text{(6.1)}\qquad J(f,\underline{\Phi}) = J(f,\underline{v},p) = \frac{\gamma_1}{2}\int_{\Omega_0} m_{wd}|\nabla\times\underline{v} + m_1\mathcal{R}_f f - \mathcal{R}_{obs,1}|^2 d\Omega + \\ + \frac{\gamma_2}{2}\int_{\Gamma_{out}} \Big(|p - p_{out}|^2 + |\underline{v} - \underline{v}_{out}|^2\Big) d\Gamma.$$

To study the problem in this case we assume that $\Omega_{wd} = \Omega_0$ and we put here:

$$\mathbb{X} := \{\underline{v} : \underline{v} \in (\mathbb{H}^2(\Omega))^2, \underline{v} = 0 \text{ on } \Gamma_{in} \cup \Gamma_{w_1} \cup \Gamma_{w_3}\},$$

$$\mathbb{H}^p := \mathbb{H}^1(\Omega_0), \ \mathbb{H}_f := \mathbb{H}^2(x_1,x_2) \cap \mathbb{H}^1_0(x_1,x_2).$$

Here we consider $\mathbb{H}^2(\Omega_0)$ for velocity in order to use the uniqueness continuation theorem. The derivatives $J'_\Phi(f,\underline{\Phi})$ and $J'_f(f,\underline{\Phi})$ become

$$\langle J'_\Phi(f,\underline{\Phi}), \hat{\underline{\Phi}}\rangle = \gamma_1\int_{\Omega_0} m_{wd}(\nabla\times\underline{v} + m_1\mathcal{R}_f f - \mathcal{R}_{obs,1})\cdot(\nabla\times\hat{\underline{v}})d\Omega + \\ + \gamma_2\int_{\Gamma_{out}}(p - p_{out})\hat{p}d\Gamma + \gamma_2\int_{\Gamma_{out}}(\underline{v} - \underline{v}_{out})\cdot\hat{\underline{v}}d\Gamma,$$

$$\langle J'_f(f,\underline{\Phi}), \hat{f}\rangle = \gamma_1\int_{\Omega_0} m_{wd}(\nabla\times\underline{v} + m_1\mathcal{R}_f f - \mathcal{R}_{obs,1})\mathcal{R}_f\hat{f}d\Omega, \\ \forall\ \hat{\underline{\Phi}} = (\hat{\underline{v}},\hat{p})\ and\ \forall\ \hat{f}.$$

The system of variational equations (5.6) reads: find $\underline{v}_f \in \mathbb{X}, p_f \in \mathbb{H}^p$

$$\text{(6.2)}\qquad \begin{cases} a_0(\underline{v}_f,\hat{\underline{v}}) = b_0(p_f,\hat{\underline{v}}) + F(f,\hat{\underline{v}}) \quad \forall\ \hat{\underline{v}} \in \mathbb{X}, \\ b_0(\hat{\underline{p}},\underline{v}_f) + b_f(f;\hat{p},\underline{v}_0) = 0 \quad \forall\ \hat{p} \in \mathbb{H}^p(\Omega), \\ \alpha(f,\hat{f})_{\mathbb{H}_f} + \gamma_1\int_{\Omega_0} m_{wd}(\nabla\times\underline{v}_f + m_1\mathcal{R}_f f - \mathcal{R}_{obs,1})\cdot(\nabla\times\underline{v}_{\hat{f}} + m_1\mathcal{R}_f\hat{f})d\Omega + \\ +\gamma_2\int_{\Gamma_{out}}((p_f - p_{out})p_{\hat{f}} + (\underline{v}_f - \underline{v}_{out})\cdot\underline{v}_{\hat{f}})d\Gamma = 0 \quad \forall\ \hat{f} \in \mathbb{H}_f, \end{cases}$$

where

$$F(f,\hat{\underline{v}}) := b_f(f,p_0,\hat{\underline{v}}) + G_1(f,\hat{\underline{v}}) - a_f(f,\underline{v}_0,\hat{\underline{v}}),$$

and for every $\hat{f}$, $\underline{v}_{\hat{f}} = \underline{v}_f(\hat{f})$, $p_{\hat{f}} = p_f(\hat{f})$ denote the solution of the system given by the first and second equations in (6.2) corresponding to a right-hand side $f = \hat{f}$. The system (5.9) is: find $\underline{v}_f \in \mathbb{X}, p_f \in \mathbb{H}^p$

(6.3)
$$\begin{cases} a_0(\underline{v}_f, \underline{\hat{v}}) = b_0(p_f, \underline{\hat{v}}) + F(f, \underline{\hat{v}}) \quad \forall\ \underline{\hat{v}} \in \mathbb{X}, \\ b_0(\underline{\hat{p}}, \underline{v}_f) + b_f(f; \hat{p}, \underline{v}_0) = 0 \quad \forall\ \hat{p} \in \mathbb{H}^p(\Omega), \\ a_0(\underline{\hat{q}}, \underline{q}) = -b_0(\sigma, \underline{\hat{q}}) + \gamma_1 \int_{\Omega_0} m_{wd}(\nabla \times \underline{v}_f + m_1 \mathcal{R}_f f - \mathcal{R}_{obs,1}) \cdot (\nabla \times \underline{\hat{q}}) d\Omega + \\ + \gamma_2 \int_{\Gamma_{out}} (\underline{v}_f - \underline{v}_{out}) \cdot \underline{\hat{q}} d\Gamma \quad \forall\ \underline{\hat{q}} \in \mathbb{X}, \\ -b_0(\hat{\sigma}, \underline{q}) = \gamma_2 \int_{\Gamma_{out}} (p_f - p_{out}) \hat{\sigma} d\Gamma \quad \forall\ \hat{\sigma} \in \mathbb{H}^p, \\ \alpha(f, \hat{f})_{\mathbb{H}_f} + F(\hat{f}, \underline{q}) - b_f(\hat{f}; \sigma, \underline{v}_0) + \\ + \gamma_1 \int_{\Omega_0} m_{wd}(\nabla \times \underline{v}_f + m_1 \mathcal{R}_f f - \mathcal{R}_{obs,1}) m_1 \mathcal{R}_f \hat{f} d\Omega = 0 \quad \forall\ \hat{f} \in \mathbb{H}_f. \end{cases}$$

In what follows we assume that the generalized Stokes problem (3.7) (see [7]) has a unique solution for any given $\underline{v}_0$, p_0 (the solution in the unperturbed domain Ω_0) and for each $f \in \mathbb{H}_f$ (see [8]).

Now consider the problem (6.3) for $\alpha > 0$.

PROPOSITION 6.1. *For any $\alpha > 0$, problem* (6.3) *has a unique solution for each given $\underline{\mathcal{R}}_{obs,1}$.*

Proof. Following [1], we formally invert L and L^* in the first and second equations of (5.10), then we substitute $\underline{\Phi}$, $\underline{Q}$ into the third equation and obtain the following weak problem: $f \in \mathbb{H}_f$ satisfies

$$\alpha(f, \hat{f})_{\mathbb{H}_f} + (Af, A\hat{f})_{\mathbb{L}^2(x_1,x_2)} = (G, A\hat{f})_{\mathbb{L}^2(x_1,x_2)} \quad \forall\ \hat{f} \in \mathbb{H}_f, \tag{6.4}$$

where A is a linear operator, which depends on previous operators from variational equations, while G will depend on the data more precisely from (6.2) we obtain:

$$\begin{aligned} (f, \hat{f})_{\mathbb{H}_f} &= (\Lambda_f f, \hat{f})_{\mathbb{L}^2(x_1,x_2)}, \\ (Af, A\hat{f})_{\mathbb{L}^2(x_1,x_2)} &= \gamma_1 \int_\Omega m_{wd}(\nabla \times \underline{v} + m_1 \mathcal{R}_f f) \cdot (\nabla \times \underline{v}_{\hat{f}} + m_1 \mathcal{R}_f \hat{f}) d\Omega + \\ &\quad + \gamma_2 \int_{\Gamma_{out}} (p p_{\hat{f}} + \underline{v} \cdot \underline{v}_{\hat{f}}) d\Gamma, \\ (G, A\hat{f})_{\mathbb{L}^2(x_1,x_2)} &= \gamma_1 \int_\Omega m_{wd} \mathcal{R}_{obs,1} \cdot (\nabla \times \underline{v}_{\hat{f}} + m_1 \mathcal{R}_f \hat{f}) d\Omega + \\ &\quad + \gamma_2 \int_{\Gamma_{out}} (p_{out} p_{\hat{f}} + \underline{v}_{out} \cdot \underline{v}_{\hat{f}}) d\Gamma, \end{aligned}$$

where $\underline{\Phi} = (\underline{v}, p) = L^{-1} B f$, $\underline{\Phi}_{\hat{f}} = (\underline{v}_{\hat{f}}, p_{\hat{f}}) = L^{-1} B \hat{f} \quad \forall\ \hat{f} \in \mathbb{H}_f$.

We see that if $\alpha > 0$, then the problem (6.4) has a unique solution which satisfies and: $\|f\|^2_{\mathbb{H}_f} \le \|G\|^2/(2\alpha) < \infty$. Correspondingly, we can construct $\underline{v}$, p, $\underline{q}$, σ, which jointly with f provides the unique solution of (6.3). □

Now consider the problem (6.3) with $\alpha = 0$.

PROPOSITION 6.2. *Assume that:* (i) *The solution of the generalized Stokes problem satisfies* $\left(\frac{\partial v_0}{\partial y}\right)^2 + \left(\frac{\partial u_0}{\partial y}\right)^2 > 0$ *at* $y = 0$, $x \in (x_1, x_2)$ (ii) *problem* (6.3) *has a solution. Then this solution is unique in the class* $(\mathbb{H}^2(\Omega))^2 \times \mathbb{H}^1(\Omega) \times \mathbb{W}^{1,\infty}(x_1, x_2)$.

Proof. Let $(\underline{v}_1, \dots, f_1)$ and $(\underline{v}_2, \dots, f_2)$ be two solutions of (6.3). Then for $\underline{v} = \underline{v}_1 - \underline{v}_2, \dots, f = f_1 - f_2$ from (6.2) we obtain:

$$\left\{\begin{array}{l} a_0(\underline{v}, \hat{\underline{v}}) = b_0(p, \hat{\underline{v}}) + F(f, \hat{\underline{v}}) \quad \forall\ \hat{\underline{v}} \in \mathbb{X}, \\ b_0(\hat{\underline{p}}, \underline{v}) + b_f(f; \hat{p}, \underline{v}_0) = 0 \quad \forall\ \hat{p} \in \mathbb{H}^p(\Omega), \\ \nabla \times \underline{v} + m_1 \mathcal{R}_f f = 0 \text{ in } \Omega, \\ p = 0,\ \underline{v} = 0 \text{ on } \Gamma_{out}. \end{array}\right. \tag{6.5}$$

Consider the second and third equation from (6.5) in $\Omega_{2,0}$,

$$\nabla \cdot \underline{v} = 0,\ \nabla \times \underline{v} = 0 \text{ in } \Omega_{2,0}.$$

Then $\Delta \underline{v} = 0$ in $\Omega_{2,0}$. Considering $\hat{\underline{v}}$ with $\operatorname{supp}(\hat{\underline{v}}) \subseteq \Omega_{2,0}$ from the first equation of (6.5) we find $\nabla p = 0$, then $p = \text{const}$ in $\Omega_{2,0}$ and $-p \cdot \underline{n} + \nu \frac{\partial \underline{v}}{\partial \underline{n}} = 0$ on Γ_{out}. Since $p = 0$ on Γ_{out}, then $p = 0$ in $\Omega_{2,0}$ and $\nu \frac{\partial \underline{v}}{\partial \underline{n}} = 0$ on Γ_{out}, too. Consequently, $\underline{v}$ satisfies

$$\Delta \underline{v} = 0 \text{ in } \Omega_{2,0},\ \underline{v} = \nu \frac{\partial \underline{v}}{\partial \underline{n}} = 0 \text{ on } \Gamma_{out}.$$

This problem has only the trivial solution $\underline{v} = 0$ in $\Omega_{2,0}$. Since $\underline{v} \in (\mathbb{H}^2(\Omega))^2$, then

$$\underline{v} = \frac{\partial \underline{v}}{\partial \underline{n}} = 0 \text{ on } \Gamma_0 := \{(x, y) : y = 0, x_1 < x < x_2\}.$$

Now consider the second and third equations from (6.5) in $\Omega_{1,0}$:

$$\left\{\begin{array}{l} \nabla \cdot \underline{v} - \left[y\left(\frac{f_x f_0 - f_{0,x} f}{f_0^2}\right) \frac{\partial u_0}{\partial y} + \frac{f}{f_0} \frac{\partial v_0}{\partial y}\right] = 0 \text{ in } \Omega_{1,0}, \\ \nabla \times \underline{v} - \left[y\left(\frac{f_x f_0 - f_{0,x} f}{f_0^2}\right) \frac{\partial v_0}{\partial y} - \frac{f}{f_0} \frac{\partial u_0}{\partial y}\right] = 0 \text{ in } \Omega_{1,0}. \end{array}\right. \tag{6.6}$$

On Γ_0 we have

$$\nabla \cdot \underline{v} - \frac{f}{f_0} \frac{\partial v_0}{\partial y} = 0,\ \nabla \times \underline{v} + \frac{f}{f_0} \frac{\partial u_0}{\partial y} = 0,$$

$$|f(x)| = f_0 \frac{\left[(\nabla \cdot \underline{v})^2 + (\nabla \times \underline{v})^2\right]^{1/2}}{\left[\left(\frac{\partial v_0}{\partial y}\right)^2 + \left(\frac{\partial u_0}{\partial y}\right)^2\right]^{1/2}} \text{ on } \Gamma_0$$

(the dependence of the right-hand side on x and y is understood). Since $\underline{v} = \frac{\partial \underline{v}}{\partial \underline{n}} = \frac{\partial \underline{v}}{\partial y} = 0$ on Γ_0, then

$$\nabla \cdot \underline{v}|_{y=0} = \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y}|_{y=0} = 0,\ \nabla \times \underline{v}|_{y=0} = \frac{\partial v}{\partial y} - \frac{\partial u}{\partial x}|_{y=0} = 0,\ x \in (x_1, x_2),$$

i.e., $f(x) = 0$. Therefore, $\underline{v} = 0,\ p = 0$, too. □

Let us once more note that if $\gamma_2 > 0$ and we introduce into considerations the cost functional J_2, then we overdeterminate the problem (4.4) for $\alpha = 0$ and the initial problem. Therefore in this case we usually have uniqueness results; however, not existence results generally. But in some physical problems the above overdeterminations (and the term $\alpha \|f\|^2_{\mathbb{H}_f}$ also) are reasonable and have a physical sense, therefore in these cases we can consider the optimal control problems like (4.5) as the problems to be independent of the initial problem (where we have only J_1). Here, we also have existence results and can name these optimal control problems as the "optimal shape design problems. . . ." Nevertheless, it is interesting to study solvability results of above variational problems as $\alpha = \gamma_2 = 0$.

7. Iterative processes. In this section we propose some iterative processes which are well suited for solving the variational equations obtained in the previous sections.

Consider the problem (5.10); if for $k = 0, 1, \ldots, f^{(k)}$ is known, then $f^{(k+1)}$ can be determinate by solving the following equations [1]:

$$\left\{\begin{array}{l} L\Phi^{(k)} = Bf^{(k)}, \\ L^*\underline{Q}^{(k)} = \Lambda_w J_\Phi(f^{(k)}, \underline{\Phi}^{(k)}), \\ \Lambda_c w^{(k)} = B^*\underline{Q}^{(k)} + \Lambda_f J_f(f^{(k)}, \underline{\Phi}^{(k)}), \\ f^{(k+1)} = f^{(k)} - \tau_k(\alpha f^{(k)} + w^{(k)}), \end{array}\right. \tag{7.1}$$

where $\{\tau_k\}$ is a family of parameters whose determination follows from the theory of extremal problems [32], the general theory of iterative processes [16, 25, 27], and the ill-posed problems theory [28, 30]. The step (7.1) would read as follows for the variational form (5.9) of problem (5.10):

$$\left\{\begin{array}{l} \mathcal{L}(\underline{\Phi}^{(k)}, \underline{\hat{\Phi}}) = B(f^{(k)}, \underline{\hat{\Phi}}) \quad \forall\ \underline{\hat{\Phi}} \in \mathbb{W}, \\ \mathcal{L}(\underline{\hat{W}}, \underline{Q}^{(k)}) = \langle J'_\Phi(f^{(k)}, \underline{\Phi}^{(k)}), \underline{\hat{W}}\rangle \quad \forall\ \underline{\hat{W}} \in \mathbb{W}, \\ (w^{(k)}, \hat{f})_{\mathbb{H}_f} = B(\hat{f}, \underline{Q}^{(k)}) + \langle J'_f(f^{(k)}, \underline{\Phi}^{(k)}), \hat{f}\rangle \quad \forall\ \hat{f} \in \mathbb{H}_f, \\ f^{(k+1)} = f^{(k)} - \tau_k(\alpha f^{(k)} + w^{(k)}). \end{array}\right. \tag{7.2}$$

Consider now problem (6.2) (with $\Omega_{wd} \subseteq \Omega$). The iterative process (7.2) for this problem reads as follows:

$$\left\{\begin{array}{l} a_0(\underline{v}^{(k)}, \underline{\hat{v}}) = b_0(p^{(k)}, \underline{\hat{v}}) + F(f^{(k)}, \underline{\hat{v}}) \quad \forall\ \underline{\hat{v}} \in \mathbb{X}, \\ b_0(\underline{\hat{p}}, \underline{v}^{(k)}) + b_f(f^{(k)}; \hat{p}, \underline{v}_0) = 0 \quad \forall\ \hat{p} \in \mathbb{H}^p(\Omega), \\ a_0(\underline{\hat{q}}, \underline{q}^{(k)}) = -b_0(\sigma^{(k)}, \underline{\hat{q}}) + \gamma_1 \int_{\Omega_0} m_{wd}(\nabla \times \underline{v}^{(k)} + m_1\mathcal{R}_f f^{(k)} - \mathcal{R}_{obs,1})\cdot \\ \cdot(\nabla \times \underline{\hat{q}})d\Omega + \gamma_2 \int_{\Gamma_{out}} (\underline{v}^{(k)} - \underline{v}_{out}) \cdot \underline{\hat{q}} d\Gamma \quad \forall\ \underline{\hat{q}} \in \mathbb{X}, \\ -b_0(\hat{\sigma}, \underline{q}^{(k)}) = \gamma_2 \int_{\Gamma_{out}} (p^{(k)} - p_{out})\hat{\sigma} d\Gamma \quad \forall\ \hat{\sigma} \in \mathbb{H}^p, \\ (w^{(k)}, \hat{f})_{\mathbb{H}_f} = F(\hat{f}, \underline{\hat{q}}) - b_f(\hat{f}; \hat{\sigma}^{(k)}, \underline{v}_0) + \\ + \gamma_1 \int_{\Omega_0} m_{wd}(\nabla \times \underline{v}^{(k)} + m_1\mathcal{R}_f f^{(k)} - \mathcal{R}_{obs,1}) m_1 \mathcal{R}_f \hat{f} d\Omega \quad \forall\ \hat{f} \in \mathbb{H}_f, \\ f^{(k+1)} = f^{(k)} - \tau_k(\alpha f^{(k)} + w^{(k)}), \quad k = 0, 1, \ldots . \end{array}\right. \tag{7.3}$$

Consider now the *finite dimensional case* in which the function $f, \{f^{(k)}\}, \hat{f}$ are all sought after in a finite-dimensional subspace $\mathbb{H}_{f,N} \subset \mathbb{H}_f$ of dimension $N < \infty$, whose basis $\varphi_i \in \mathbb{W}^{1,\infty}(x_1, x_2), i = 1, 2, \ldots, N$. Then the following theorem holds true.

THEOREM 7.1. *Assume that* $\Omega_{wd} = \Omega, (\frac{\partial v_0}{\partial y})^2 + (\frac{\partial u_0}{\partial y})^2 > 0$ *at* $y = 0, x \in (x_1, x_2)$. *Then:*

1. *the problem* (6.2) *is correctly solvable for* $\alpha \geq 0$ *and all* $N < \infty$*;*
2. *the iterative process* (7.3) *is convergent for any* $\alpha > 0$, $N < \infty$ *and provided the parameters* $\tau_k > 0$, $k = 0, 1, 2, \ldots$ *are small enough;*
3. *if* α *is sufficiently small while* k *is sufficiently large, then* $\{\underline{v}^{(k)}, p^{(k)}, f^{(k)}\}$ *can be taken as an approximate solution of problem* (6.2).

Proof.

1. The existence of the solution for $\alpha > 0$ has been proved early. Let us consider the case $\alpha = 0$. Since $f = \Sigma_{i=1}^{N} a_i \varphi_i \in \mathbb{H}_{f,N}$, then in the form (6.4) with $\alpha = 0$ we conclude that this equation is correctly solvable (because the problem (6.2) can only have a unique solution in $\mathbb{X} \times \mathbb{H}^p \times \mathbb{H}_f$; see Proposition 6.2). We assume the generalized Stokes problem to be correctly solvable for given $f \in \mathbb{H}_f$. Hence the problem (6.2) is correctly solvable too.
2. If $\alpha > 0$, then the bilinear form on the left-hand side of (6.4) is coercive and continuous with respect to the norm $\|f\|_{A,\alpha} = \sqrt{\alpha \|f\|^2_{\mathbb{H}_f} + \|Af\|^2_{\mathbb{L}^2(x_1,x_2)}}$. Then according to the general theory of iterative algorithm the process given by

$$(f^{(k+1)}, \hat{f})_{\mathbb{H}_f} = (f^{(k)}, \hat{f})_{\mathbb{H}_f} - \tau(\alpha(f^{(k)}, \hat{f})_{\mathbb{H}_f} + (Af^{(k)}, A\hat{f})_{\mathbb{L}^2(x_1,x_2)}) -$$

$$-(G, A\hat{f})_{\mathbb{L}^2(x_1,x_2)}, \ k = 0, 1, \ldots$$

is convergent for small $\tau > 0$. Hence the process (7.3) is convergent also and

$$\|\underline{v}^{(k)} - \underline{v}\|_{\mathbb{X}} + \|p^{(k)} - p\|_{\mathbb{H}^p} + \|f - f^{(k)}\|_{\mathbb{H}_f} \to 0, \ k \to \infty. \tag{7.4}$$

If $\Lambda_C^{-1} A^* A \in [C_1, C_2], C_1, C_2 = \text{const}$, and $\tau_k = 2/(2\alpha + C_1 + C_2)$, then (7.4) becomes (see [1]):

(7.5)

$$\|\underline{v}^{(k)} - \underline{v}\|_{\mathbb{X}} + \|p^{(k)} - p\|_{\mathbb{H}^p} + \|f - f^{(k)}\|_{\mathbb{H}_f} \le C\Big(\frac{C_2 - C_1}{2\alpha + C_1 + C_2}\Big)^k \to 0, \ k \to \infty.$$

3. Let $\underline{v}_0, \ p_0, \ f_0$ be a solution of (6.2) when $\alpha = 0$. According to the theory of ill-posed problem ([28] and [30]) we have: $\|f_0 - f_\alpha\|_{\mathbb{H}^p} \to 0$ as $\alpha \to +0$, where $(f_\alpha, \underline{v}_\alpha, p_\alpha)$ is the solution of (6.2) for $\alpha > 0$. Hence

$$\|\underline{v}_0 - \underline{v}_\alpha\|_{\mathbb{X}} + \|p_0 - p_\alpha\|_{\mathbb{H}^p} \to 0, \ as \ \alpha \to +0.$$

Then owing to (7.4) we conclude that the statement of Theorem 7.1 holds true also. □

The simple schemes in Figure 7.1 can be considered as examples of the above problems when $f \in \mathbb{H}_{f,N}$ for small N (the dimension of $\mathbb{H}_{f,N}$).

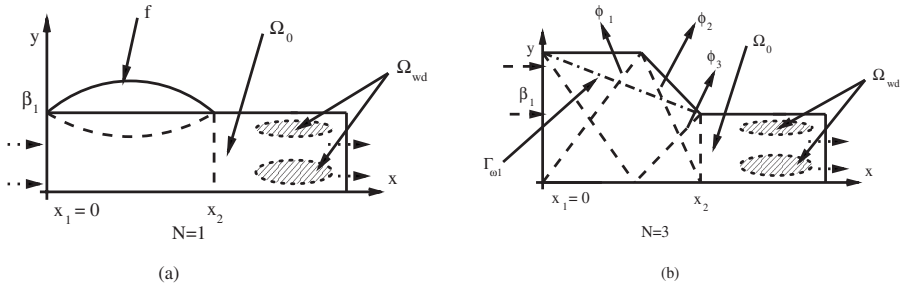

FIG. 7.1. *Domain Ω with N shape functions:* (a) $N = 1$, $f = \beta_1 + a\varphi_0(x)$, $\varphi_0 = x(x_2 - x)$; (b) $N = 3$, $f = \beta_1 + \Sigma_{i=1}^{3} a_i \varphi_i$.

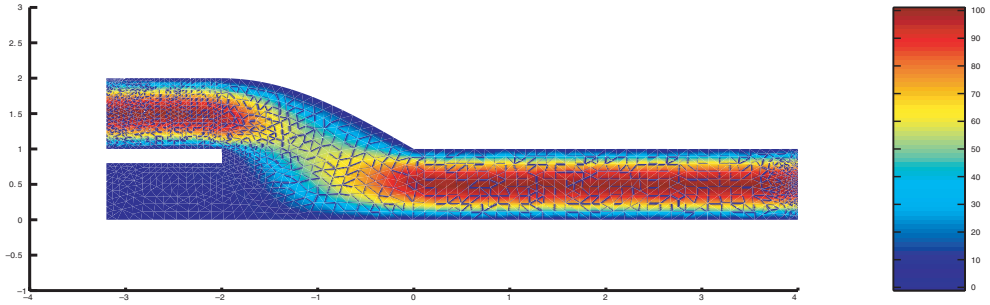

FIG. 8.1. *Idealized two-dimensional bypass configuration before optimal shape design process: Iso-velocity* $[cms^{-1}]$.

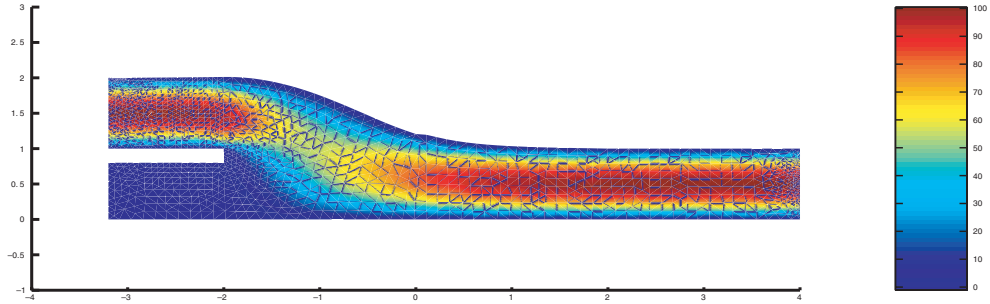

FIG. 8.2. *Bypass configuration at the end of shape optimization using first corrections: Iso-velocity* $[cms^{-1}]$.

8. Test problem and numerical results. To test our method we consider some test problems on simplified configurations. Numerical simulations have been carried out using *Bamg* [11], a Bi-dimensional Anisotropic Mesh Generator and *FreeFem*, a finite element Library developed at INRIA [10], the French National Institute for Research in Computer Science and Control, with the development of algorithms based on control theory and adjoint formulation for generalized Stokes problem. For application of finite element method to incompressible flow, see [9]. In this section we present numerical results using as cost functional the $\mathbb{L}^2$ norm of the vorticity in the downfield zone of the new incoming branch of the bypass.

Wall curvature was considered only in the zone of the incoming branch of the bypass where we set $f_0 = sin(x)$; in other parts we used piecewise constant function. The graft angle of the bypass incoming branch (which influences vorticity) is equal to zero (between the artery and the new incoming branch there isn't a relative angle).

Velocity values $\underline{v}_{in}$ at the inflow are chosen in such a way that the Reynolds number $Re = \frac{\bar{v} \cdot D}{\nu}$ has order 10^3. Blood kinematic viscosity $\nu = \frac{\mu}{\rho}$ is equal to $4 \cdot 10^{-6}\ m^2\ s^{-1}$, blood density $\rho = 1\ g\ cm^{-3}$ and dynamic viscosity $\mu = 4 \cdot 10^{-2}\ g\ cm^{-1} s^{-1}$; $\bar{v}$ is a mean inflow velocity related with $\underline{v}_{in}$, while D is the arterial diameter (3.5 mm) [23].

Figures 8.1–8.3 provide a preliminary account of numerical results and show how the shape of the bypass using generalized steady Stokes equations in an optimal control problem is smoothed out at the corner. Figure 8.1 refers to the original configuration; whereas Figure 8.2 refers to the configuration obtained after 25 iterations of the optimization algorithm (the vorticity has been reduced by about 30%).

9. Future developments. The development of tools for geometry reconstruction from medical data (medical imaging and other noninvasive means) and their integration with numerical simulation could provide improvements in disease diagnosis procedures.

In this study we have focused on the problem of determining the first corrections for the shape design of simplified two-dimensional bypass configurations.

Using the numerical method developed in this paper it is possible to realize the iterative process for solving initial nonlinear problems. For that it is sufficient to consider $f = f_0 + \varepsilon f_1$, where f_0 is the initial configuration and f_1 the computed first correction as the new f_0, then to calculate a new first correction and so on.

Optimal control and shape optimization applied to fully unsteady incompressible Stokes and Navier–Stokes equations and possibly the coupled fluid-structure problem and the setting of the problem in a three-dimensional geometry will provide more realistic design indications concerning surgical prosthesis realizations.

A further development will be devoted to build domain decomposition methods [26] based on optimal control approaches and efficient schemes for reduced-basis methodology approximations (see, for example, [20] and [21]) which could be more efficient for use in a repetitive design environment as optimal shape design methodology requires; see [29] for the state of the art of the problem.

CYCLIC DIGITAL NETS, HYPERPLANE NETS, AND MULTIVARIATE INTEGRATION IN SOBOLEV SPACES*

GOTTLIEB PIRSIC†, JOSEF DICK‡, AND FRIEDRICH PILLICHSHAMMER§

Abstract. Cyclic nets are a special case of digital nets and were recently introduced by Niederreiter. Here we present a construction algorithm for such nets, where we use the root mean square worst-case error of a randomly digitally shifted point set in a weighted Sobolev space as a selection criterion. This yields a feasible construction algorithm since for a cyclic net with q^m points (with fixed bijections and fixed ground field) there are q^m possible choices.

Our results here match the convergence rate and strong tractability results for polynomial lattice rules, hence providing us with an alternative construction algorithm. Further, we improve upon previous results by including constructions over arbitrary finite fields and an arbitrary choice of bijections.

Key words. cyclic digital net, weighted $\mathcal{L}_2$-discrepancy, quasi Monte Carlo algorithm, component-by-component algorithm

1. Introduction.

In quasi Monte Carlo (QMC) one considers the approximation of an integral $\int_{[0,1]^s} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x}$ by the average of $f(\boldsymbol{x}_h)$ for sample points $\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{N-1}$. This approach might appear simple at first, but for high dimensions the question of how to choose a good point set $\{\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{N-1}\}$ becomes a truly challenging problem, with many questions yet to be answered (see, for example, [5, 13]). Generally speaking one wants the points $\{\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{N-1}\}$ to be evenly spread over the unit cube. To assess the quality of a point set $\{\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{N-1}\}$, in other words, to measure the distribution properties of $P = \{\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{N-1}\}$, one often uses a norm of the discrepancy function. The discrepancy function is given by

$$\Delta(P, \boldsymbol{z}) = \frac{A_N(P, [0, \boldsymbol{z}))}{N} - |\boldsymbol{z}|,$$

where $\boldsymbol{z} = (z_1, \ldots, z_s) \in [0,1]^s$, $A_N(P, [0, \boldsymbol{z}))$ is the number of points of P in $[0, \boldsymbol{z}) := \prod_{j=1}^{s} [0, z_j)$ and $|\boldsymbol{z}| = z_1 \cdots z_s$. By taking a norm of this function we obtain a quality measure of the point set P. In this paper we consider the so-called $\mathcal{L}_2$-discrepancy. In the classical case this corresponds to the 2-norm of the discrepancy function. Ever since the paper [20] by Sloan and Woźniakowski it has become popular to consider weighted discrepancies; specifically in our case this means we consider the *weighted*

$\mathcal{L}_{2,\boldsymbol{\gamma}}$-*discrepancy*, which is given by

$$\mathcal{L}^2_{2,\boldsymbol{\gamma}}(P) = \sum_{\substack{u\subseteq\{1,\dots,s\}\\ u\neq\emptyset}} \prod_{j\in u} \gamma_j \int_{[0,1]^{|u|}} |\Delta(P,(\boldsymbol{z}_u,1))|^2 \,\mathrm{d}\boldsymbol{z}_u, \tag{1.1}$$

where $\boldsymbol{z}_u$ denotes the vector from $[0,1]^{|u|}$ containing the components of $\boldsymbol{z}$ whose indices are in u and $(\boldsymbol{z}_u,1)$ is the vector $\boldsymbol{z}$ from $[0,1]^s$ with all components whose indices are not in u replaced by 1. Here $\boldsymbol{\gamma} = (\gamma_1,\gamma_2,\dots)$ is a sequence of nonnegative real numbers γ_j, $j \geq 1$, the so-called weights. As is apparent from (1.1) the weights can be used to modify the importance of lower dimensional projections. We remark that in this paper we consider only product weights and not general weights.

In [20] it was also shown that the $\mathcal{L}_2$-discrepancy coincides with the worst-case error in certain weighted Sobolev spaces. Later on in the paper we prefer to state our results in terms of this worst-case error, as is usually done (for details see section 3). On the other hand it also seems enlightening to understand the geometrical meaning of this worst-case error, hence we also described the measure in terms of the $\mathcal{L}_2$-discrepancy rather than the worst-case error.

With this measure at hand we are able to compare the distribution properties of point sets in the unit cube. The point sets which we consider here are so-called (t,m,s)-nets and were introduced by Niederreiter [10]. A special construction scheme of such nets goes by the name of digital nets. In order to construct a digital net over some finite field, one needs to find $m \times m$ matrices $C_1,\dots,C_s$ with elements in the finite field $\mathbb{F}_q$. This provides us with a point set of q^m points. But the number of possible choices of generating matrices is q^{sm^2}, where s denotes the dimension. Hence using computer search to choose the best one is not feasible for a practically useful number of points. Niederreiter [12] also introduced a special subclass of digital nets, namely, polynomial lattices. Thereby the number of choices is reduced to q^{ms}. Moreover, it was shown in [4] that it is sufficient to search with a special algorithm (component-by-component), which further reduces the number of polynomial lattices considered to sq^m.

An alternative to polynomial lattices are cyclic nets, which were introduced by Niederreiter in 2004 [14]. In this paper we show how we can also construct cyclic nets using algorithms similar to [4]. Indeed, the construction algorithm used for cyclic nets matches the Korobov-type construction of polynomial lattice rules. Both of these have a search space of size at most q^m. Subsequently we also generalize the notion of cyclic nets whereby we succeed in introducing an analogue to the component-by-component algorithm of polynomial lattice rules. In the following we will call this construction scheme hyperplane nets.

The upper bounds presented here are comparable, although they are more general in the sense that we now also allow arbitrary finite fields. (Formerly we considered only finite fields of prime order.) In this situation one also needs bijections between the finite field and the digits $\{0,1,\dots,q-1\}$. The results presented here show that cyclic nets perform just as well as polynomial lattices, also achieving the best possible convergence rate and strong tractability results under appropriate conditions on the weights. Similar results have also been obtained for lattice rules; see [6, 18].

The paper is organized as follows. In the subsequent section we state the definition of (t,m,s)-nets, cyclic nets, hyperplane nets, and Walsh functions. Walsh functions are characters over the group of digital nets and are hence very useful for analyzing digital nets (see [3] for more information). Section 3 is concerned with construction

algorithms for cyclic nets and hyperplane nets. In that section we also prove upper bounds on the $\mathcal{L}_2$-discrepancy (or worst-case error), whereby the good performance of our construction algorithm is ensured. Finally, in an appendix we generalize the results in the appendix of [3], allowing now more general bijections which in turn allows us to obtain results for constructions of cyclic and hyperplane nets over arbitrary finite fields.

2. (t, m, s)-nets in base b. In this section we recall the definition of (digital) (t, m, s)-nets in base b and a special construction of such nets due to Niederreiter.

A detailed theory of (t, m, s)-nets was developed in [10]. (See also [11, Chapter 4] for a survey of this theory.) Those (t, m, s)-nets in a base b provide sets of b^m points in the s-dimensional unit cube $[0, 1)^s$, which are extremely well distributed if the quality parameter t is small.

DEFINITION 2.1 ((t, m, s)-nets). *Let $b \geq 2$, $s \geq 1$, and $0 \leq t \leq m$ be integers. Then a point set P consisting of b^m points in $[0, 1)^s$ forms a (t, m, s)-net in base b if every subinterval $J = \prod_{j=1}^{s} [a_j\, b^{-d_j}, (a_j + 1)\, b^{-d_j})$ of $[0, 1)^s$, with integers $d_j \geq 0$ and integers $0 \leq a_j < b^{d_j}$ for $1 \leq j \leq s$ and of volume b^{t-m}, contains exactly b^t points of P.*

In practice, all concrete constructions of (t, m, s)-nets in base b are based on the general construction scheme of digital nets. To avoid too many technical notions—and since we only deal with this case—in the following we restrict ourselves to digital nets defined over the finite field $\mathbb{F}_q$ of prime-power order q. For a more general definition (over arbitrary finite, commutative rings) see, for example, Niederreiter [11], Larcher [7], or Larcher, Niederreiter, and Schmid [8].

DEFINITION 2.2 (digital (t, m, s)-nets). *Let q be a prime-power and let $s \geq 1$ and $m \geq 1$ be integers. Let $C_1, \ldots, C_s$ be $m \times m$ matrices over $\mathbb{F}_q$. Now we construct q^m points in $[0, 1)^s$: for $0 \leq h \leq q^m - 1$ let $h = h_0 + h_1 q + \cdots + h_{m-1} q^{m-1}$ be the q-adic expansion of h. Consider an arbitrary but fixed bijection $\varphi : \{0, 1, \ldots, q - 1\} \longrightarrow \mathbb{F}_q$. Identify h with the vector $\vec{h} = (\varphi(h_0), \ldots, \varphi(h_{m-1}))^\top \in \mathbb{F}_q^m$, where $\top$ means the transpose of the vector. For $1 \leq j \leq s$ multiply the matrix C_j by $\vec{h}$, i.e.,*

$$C_j \vec{h} =: (y_{j,1}(h), \ldots, y_{j,m}(h))^\top \in \mathbb{F}_q^m,$$

and set

$$x_{h,j} := \frac{\varphi^{-1}(y_{j,1}(h))}{q} + \cdots + \frac{\varphi^{-1}(y_{j,m}(h))}{q^m}.$$

If for some integer t with $0 \leq t \leq m$ the point set consisting of the points

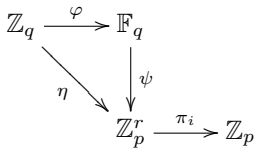
$$\boldsymbol{x}_h = (x_{h,1}, \ldots, x_{h,s})$$

for $0 \leq h < q^m$ is a (t, m, s)-net in base q, then it is called a digital (t, m, s)-net over $\mathbb{F}_q$ or, in brief, a digital net (over $\mathbb{F}_q$). The C_j are called its generating matrices.

Concerning the determination of the quality parameter t of digital nets we refer to Niederreiter [11, Theorem 4.28]; see also [17].

An essential tool for the investigation of digital nets is Walsh functions. A very general definition, corresponding to the most general construction of digital nets over finite rings, was given in [8]. There, Walsh functions over a finite abelian group G, using some bijection φ, were defined. Here we restrict ourselves to the case of $G = \mathbb{F}_{p^r}, p$ prime. We restate the definitions for this special case here for the sake of convenience.

DEFINITION 2.3 (Walsh functions). *Let $q = p^r$, p prime, $r \in \mathbb{N}_0$, and let $\mathbb{F}_q$ be the finite field with q elements. Let $\mathbb{Z}_q = \{0, 1, \dots, q-1\} \subset \mathbb{Z}$ with ring operations modulo q and let $\varphi : \mathbb{Z}_q \longrightarrow \mathbb{F}_q$ be a bijection such that $\varphi(0) = 0$, the neutral element of addition in $\mathbb{F}_q$. Moreover denote by ψ the isomorphism of additive groups $\psi : \mathbb{F}_q \longrightarrow \mathbb{Z}_p^r$ and define $\eta := \psi \circ \varphi$. For $1 \le i \le r$ denote by π_i the projection $\pi_i : \mathbb{Z}_p^r \longrightarrow \mathbb{Z}_p$, $\pi_i(x_1, \dots, x_r) = x_i$.*



Let now $k \in \mathbb{N}_0$ with base q representation $k = \kappa_0 + \kappa_1 q + \cdots + \kappa_{m-1} q^{m-1}$ where $\kappa_l \in \mathbb{Z}_q$ and let $x \in [0,1)$ with base q representation $x = x_1/q + x_2/q^2 + \cdots$. Then the kth Walsh function over the finite field $\mathbb{F}_q$ with respect to the bijection φ is defined by

$$ {}_{\mathbb{F}_q,\varphi}\mathrm{wal}_k(x) := \prod_{l=0}^{m-1} \prod_{i=1}^{r} \exp\left(2\pi \mathtt{i} \frac{(\pi_i \circ \eta)(\kappa_l)(\pi_i \circ \eta)(x_l)}{p}\right). $$

For convenience, in the rest of the paper we will omit the subscript and simply write wal_k if there is no ambiguity.

Multivariate Walsh functions are defined by multiplication of the univariate components, i.e., for $\boldsymbol{x} = (x_1, \dots, x_s) \in [0,1)^s, \boldsymbol{k} = (k_1, \dots, k_s) \in \mathbb{N}_0^s, s > 1$, we set

$$ \mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}) = \prod_{j=1}^{s} \mathrm{wal}_{k_j}(x_j). $$

We summarize some important properties of Walsh functions over finite fields which will be used throughout the paper. The proofs of the subsequent results can be found, e.g., in [9, 15].

PROPOSITION 2.4. *Let p, q, $\mathbb{F}_q$, and φ be as in Definition 2.3. For x, y with q-adic representations $x = \sum_{i=w}^{\infty} x_i q^{-i}$ and $y = \sum_{i=w}^{\infty} y_i q^{-i}$, $w \in \mathbb{Z}$ (hence the following operations are also defined for integers), define $x \oplus_\varphi y := \sum_{i=w}^{\infty} z_i q^{-i}$ where $z_i := \varphi^{-1}(\varphi(x_i) + \varphi(y_i))$ and $\ominus_\varphi x := \sum_{i=w}^{\infty} v_i q^{-i}$ where $v_i := \varphi^{-1}(-\varphi(x_i))$. Further we set $x \ominus_\varphi y := x \oplus_\varphi (\ominus_\varphi y)$. For vectors $\boldsymbol{x}, \boldsymbol{y}$ we define the operations componentwise. Then we have the following:*

1. *For all $k, l \in \mathbb{N}_0$ and all $x, y \in [0,1)$ we have*

$$ \mathrm{wal}_k(x) \cdot \mathrm{wal}_l(x) = \mathrm{wal}_{k \oplus_\varphi l}(x), \quad \mathrm{wal}_k(x) \cdot \mathrm{wal}_k(y) = \mathrm{wal}_k(x \oplus_\varphi y) $$

and

$$ \mathrm{wal}_k(x) \cdot \overline{\mathrm{wal}_l(x)} = \mathrm{wal}_{k \ominus_\varphi l}(x), \quad \mathrm{wal}_k(x) \cdot \overline{\mathrm{wal}_k(y)} = \mathrm{wal}_k(x \ominus_\varphi y). $$

2. *We have*

$$ \sum_{k=0}^{q-1} \mathrm{wal}_l(k/q) = \begin{cases} 0 & \text{if } l \neq 0, \\ q & \text{if } l = 0. \end{cases} $$

3. *We have*

$$ \int_0^1 \mathrm{wal}_0(x)\,\mathrm{d}x = 1 \quad \text{and} \quad \int_0^1 \mathrm{wal}_k(x)\,\mathrm{d}x = 0 \text{ if } k > 0. $$

4. *For all* $\boldsymbol{k}, \boldsymbol{l} \in \mathbb{N}_0^s$ *we have the following orthogonality properties:*

$$\int_{[0,1)^s} \mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})\overline{\mathrm{wal}_{\boldsymbol{l}}(\boldsymbol{x})}\,\mathrm{d}\boldsymbol{x} = \begin{cases} 1 & \text{if } \boldsymbol{k} = \boldsymbol{l}, \\ 0 & \text{otherwise.} \end{cases}$$

5. *For any* $f \in \mathcal{L}_2([0,1)^s)$ *and any* $\boldsymbol{\sigma} \in [0,1)^s$ *we have*

$$\int_{[0,1)^s} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x} = \int_{[0,1)^s} f(\boldsymbol{x} \oplus_\varphi \boldsymbol{\sigma})\,\mathrm{d}\boldsymbol{x}.$$

6. *For any integer* $s \geq 1$ *the system* $\{\mathrm{wal}_{\boldsymbol{k}} : \boldsymbol{k} \in \mathbb{N}_0^s\}$ *is a complete orthonormal system in* $\mathcal{L}_2([0,1)^s)$.

Let $\mathbb{F}_q = \mathbb{Z}_p[\theta]$ such that $\{1, \theta, \ldots, \theta^{r-1}\}$ is a basis of $\mathbb{F}_q$ over $\mathbb{Z}_p$ as a vector space. Then the isomorphism ψ between $\mathbb{F}_q$ and $\mathbb{Z}_p^r$ shall be given by

$$\psi(x) = (x_1, \ldots, x_r)^\top \text{ for } x = \sum_{i=1}^{r} x_i \theta^{i-1}, x_i \in \mathbb{Z}_p.$$

Let ψ be extended to vectors over $\mathbb{F}_q$, i.e., such that for arbitrary m, vectors in $\mathbb{F}_q^m$ get mapped to vectors in $\mathbb{Z}_p^{rm}$.

Also let φ be extended to nonnegative integers by setting

$$\varphi(k) := (\varphi(\kappa_0), \ldots, \varphi(\kappa_{m-1}))^\top \text{ for } k = \sum_{i=0}^{m-1} \kappa_i q^i, k_i \in \{0, \ldots, q-1\}.$$

We will also use the concatenation $\eta(k) := \psi(\varphi(k))$. We have the following commutative diagram:

$$\begin{array}{ccc} \mathbb{Z}_{q^m} & \xrightarrow{\varphi} & \mathbb{F}_q^m \\ & \searrow^{\eta} & \downarrow{\scriptstyle \psi,\Psi} \\ & & \mathbb{Z}_p^{rm} \end{array}$$

We now define a map Ψ of the linear transformations over $\mathbb{F}_q$ into the linear transformations over $\mathbb{Z}_p$. Let the representation of the element θ^r in $\mathbb{F}_q$ be given by $\theta^r = \theta_0 + \theta_1\theta + \cdots + \theta_{r-1}\theta^{r-1}$, $\theta_i \in \mathbb{Z}_p, i = 0, \ldots, r-1$. By Θ we denote the matrix

$$\Theta := \begin{pmatrix} 0 & 0 & 0 & \cdots & \theta_0 \\ 1 & 0 & 0 & \cdots & \theta_1 \\ 0 & 1 & 0 & \cdots & \theta_2 \\ & \vdots & & \ddots & \vdots \\ 0 & \cdots & 0 & 1 & \theta_{r-1} \end{pmatrix}.$$

It is easy to see that Θ acts on a vector $(x_1, \ldots, x_r) \in \mathbb{Z}_p^r$ in the same way as the linear transformation $x \mapsto \theta x, x \in \mathbb{F}_q$ does on $x_1 + x_2\theta + \cdots + x_r\theta^{r-1}$, i.e., $\Theta\psi(x) = \psi(\theta x)$. If $\alpha = \sum_{i=0}^{r-1} a_i\theta^i$ is the representation of an arbitrary element, denote by $\Psi(\alpha)$ the matrix

$$\Psi(\alpha) := \sum_{i=0}^{r-1} a_i \Theta^i.$$

Clearly then $\Psi(\alpha)\psi(x) = \psi(\alpha x)$. By linearity the mapping Ψ can be extended to matrices by applying it to the matrix entries and letting the matrices run together, i.e., with some abuse of notation,

$$\Psi(A) := (\Psi(a_{i,j}))_{i,j} \in \mathbb{Z}_p^{rm_1 \times rm_2} \qquad \text{for } A = (a_{i,j})_{i,j} \in \mathbb{F}_q^{m_1 \times m_2}, a_{i,j} \in \mathbb{F}_q,$$

for arbitrary m_1, m_2. Again by linearity $\Psi(A)\psi(\boldsymbol{x}) = \psi(A\boldsymbol{x})$ holds as well (for $A \in \mathbb{F}_q^{m_1 \times m_2}, \boldsymbol{x} \in \mathbb{F}_q^{m_2}$, $m_1, m_2 \in \mathbb{N}$).

LEMMA 2.5. *Let $\{\boldsymbol{x}_0, \dots, \boldsymbol{x}_{q^m-1}\}$ be a digital net over $\mathbb{F}_q$ with bijection φ, where $\varphi(0) = 0$, generated by the $m \times m$ matrices $C_1, \dots, C_s$ over $\mathbb{F}_q$, $m > 0$. Then for any vector $\boldsymbol{k} = (k_1, \dots, k_s)$ of nonnegative integers $0 \le k_1, \dots, k_s < q^m$ we have*

$$\sum_{h=0}^{q^m-1} {}_{\mathbb{F}_q,\varphi}\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}_h) = \begin{cases} q^m & \text{if } C_1^\top \varphi(k_1) + \cdots + C_s^\top \varphi(k_s) = \boldsymbol{0}, \\ 0 & \text{else}, \end{cases}$$

where $\boldsymbol{0}$ is the zero vector in $\mathbb{F}_q^m$.

Proof. Denote by ω_p the pth root of unity, i.e., $\omega_p = \exp(2\pi\mathtt{i}/p)$. For each k_j, $1 \le j \le s$ let $\kappa_{j,l}$ denote the lth q-adic digit of k_j, i.e., $k_j = \kappa_{j,0} + \cdots + \kappa_{j,m-1}q^{m-1}$. For $0 \le h \le q^m - 1$ let $\boldsymbol{x}_h = (x_{h,1}, \dots, x_{h,s})$. Then we have

$$\begin{aligned}\Sigma &:= \sum_{h=0}^{q^m-1} {}_{\mathbb{F}_q,\varphi}\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}_h) = \sum_{h=0}^{q^m-1} \prod_{j=1}^{s} \prod_{l=0}^{m-1} \prod_{i=1}^{r} \omega_p^{(\pi_i \circ \eta)(\kappa_{j,l})(\pi_i \circ \eta)(x_{h,j,l})} \\ &= \sum_{h=0}^{q^m-1} \prod_{j=1}^{s} \prod_{l=0}^{m-1} \omega_p^{\sum_{i=1}^{r}(\pi_i \circ \eta)(\kappa_{j,l})(\pi_i \circ \eta)(x_{h,j,l})} = \sum_{h=0}^{q^m-1} \prod_{j=1}^{s} \prod_{l=0}^{m-1} \omega_p^{\langle \eta(\kappa_{j,l}), \eta(x_{h,j,l})\rangle},\end{aligned}$$

where $\langle \cdot, \cdot \rangle$ denotes the usual inner product. By the definition of digital nets we have

$$x_{h,j,l} = \varphi^{-1}(\langle \boldsymbol{c}_{j,l}^\top, \vec{h} \rangle),$$

where $\boldsymbol{c}_{j,l}$ denotes the lth row vector of the matrix C_j and where $\vec{h} = (\varphi(h_0), \dots, \varphi(h_{m-1}))^\top$ if $h = h_0 + \cdots + h_{m-1}q^{m-1}$. Therefore we obtain

$$\eta(x_{h,j,l}) = \psi \circ \varphi(\varphi^{-1}(\langle \boldsymbol{c}_{j,l}^\top, \vec{h} \rangle)) = \psi(\langle \boldsymbol{c}_{j,l}^\top, \vec{h} \rangle).$$

Since φ is a bijection we get

$$\begin{aligned}\Sigma &= \sum_{h=0}^{q^m-1} \prod_{j=1}^{s} \prod_{l=0}^{m-1} \omega_p^{\langle \eta(\kappa_{j,l}), \psi(\langle \boldsymbol{c}_{j,l}^\top, \vec{h} \rangle)\rangle} = \sum_{\boldsymbol{h} \in \mathbb{F}_q^m} \prod_{j=1}^{s} \prod_{l=0}^{m-1} \omega_p^{\langle \eta(\kappa_{j,l}), \psi(\langle \boldsymbol{c}_{j,l}^\top, \boldsymbol{h} \rangle)\rangle} \\ &= \sum_{\boldsymbol{h}' \in \mathbb{Z}_p^{rm}} \prod_{j=1}^{s} \prod_{l=0}^{m-1} \omega_p^{\langle \eta(\kappa_{j,l}), \Psi(\boldsymbol{c}_{j,l})\boldsymbol{h}' \rangle} = \sum_{\boldsymbol{h}' \in \mathbb{Z}_p^{rm}} \omega_p^{\langle \boldsymbol{h}', \sum_{j=1}^{s} \sum_{l=0}^{m-1} \Psi(\boldsymbol{c}_{j,l})^\top \eta(\kappa_{j,l}) \rangle}.\end{aligned}$$

We have

$$\sum_{l=0}^{m-1} \Psi(\boldsymbol{c}_{j,l})^\top \eta(\kappa_{j,l}) = \Psi(C_j^\top)\eta(k_j),$$

since, denoting by $c_{j,l,i}$ the components of $\boldsymbol{c}_{j,l}$,

$$\begin{pmatrix} \Psi(\boldsymbol{c}_{j,1})^\top \cdots \Psi(\boldsymbol{c}_{j,m})^\top \end{pmatrix} = \begin{pmatrix} \Psi(c_{j,1,1})^\top & \cdots & \Psi(c_{j,m,1})^\top \\ \vdots & \ddots & \vdots \\ \Psi(c_{j,1,m})^\top & \cdots & \Psi(c_{j,m,m})^\top \end{pmatrix} = \Psi(C_j^\top).$$

So we obtain

$$\Sigma = \sum_{\boldsymbol{h}' \in \mathbb{Z}_p^{rm}} \omega_p^{\langle \boldsymbol{h}', \sum_{j=1}^{s} \Psi(C_j^\top)\eta(k_j)\rangle}.$$

Bringing this into a form where we can evaluate the exponential sums, we get

$$\begin{aligned}\Sigma &= \prod_{l=0}^{m-1} \prod_{i=0}^{r-1} \sum_{h=0}^{p-1} \left(\omega_p^{(i\ m\ +\ l)th\ component\ of\ \left(\sum_{j=1}^{s} \Psi(C_j^\top)\eta(k_j)\right)}\right)^h \\ &= \begin{cases} q^m & \text{if } \Psi(C_1^\top)\eta(k_1) + \cdots + \Psi(C_s^\top)\eta(k_s) = \mathbf{0} \in \mathbb{Z}_p^{rm}, \\ 0 & \text{else,} \end{cases}\end{aligned}$$

and the lemma is proved by noting that

$$\Psi(C_1^\top)\eta(k_1) + \cdots + \Psi(C_s^\top)\eta(k_s) = \psi(C_1^\top\varphi(k_1) + \cdots + C_s^\top\varphi(k_s)) = \mathbf{0}$$

iff

$$C_1^\top\varphi(k_1) + \cdots + C_s^\top\varphi(k_s) = \mathbf{0},$$

since $\psi(0) = 0$. □

We next define cyclic digital nets following Niederreiter's article in [14]. (See this article of Niederreiter for more about the background of this notion and exact definitions of some terms not explained further in this paper.)

DEFINITION 2.6. *Let integers $m \geq 1, s \geq 2$ and a finite field $\mathbb{F}_q$ be given. Fix an element $\alpha \in \mathbb{F}_{q^m}$ and consider the set of polynomials*

$$\mathcal{P}_\alpha := \{f \in \mathcal{P}, f(\alpha) = 0\} \quad \subseteq \quad \mathcal{P} := \{f \in \mathbb{F}_{q^m}[x], \deg(f) < s\}.$$

For each $j = 1, \ldots, s$ choose an ordered basis $\mathcal{B}_j$ of $\mathbb{F}_{q^m}$ over $\mathbb{F}_q$ and define ϕ as the mapping

$$\phi : f(x) = \sum_{j=1}^{s} \gamma_j x^{j-1} \in \mathcal{P} \mapsto (\gamma_{1,1}, \ldots, \gamma_{1,m}, \ldots, \gamma_{s,1}, \ldots, \gamma_{s,m}) \in \mathbb{F}_q^{ms},$$

where $(\gamma_{j,1}, \ldots, \gamma_{j,m})$ is the coordinate vector of γ_j with respect to the chosen basis $\mathcal{B}_j$.

We denote by $\mathcal{C}_\alpha$ the orthogonal subspace in $\mathbb{F}_q^{ms}$ of the image $\mathcal{N}_\alpha := \phi(\mathcal{P}_\alpha)$. Let

$$C_\alpha = (C_1^\top \cdots C_s^\top) \in \mathbb{F}_q^{m \times sm}$$

be a matrix whose row space is $\mathcal{C}_\alpha$. Then the C_j are the generating matrices of a cyclic digital net with respect to $\mathcal{B}_1, \ldots, \mathcal{B}_s$ *and C_α is its overall generating matrix. We shall from now on assume a fixed choice of bases $\mathcal{B}_j$ and will therefore not explicitly mention them again.*

In the following we will again use the idea of employing linear representations (i.e., the mapping ψ), but with $\mathbb{F}_q$ in the role of $\mathbb{Z}_p$ and $\mathbb{F}_{q^m}$ in the role of $\mathbb{F}_q$. To be more precise, let $\mathbb{F}_{q^m} = \mathbb{F}_q[\omega]$, such that the powers of ω form a basis of $\mathbb{F}_{q^m}/\mathbb{F}_q$. Let $\omega^m = \beta_0 + \cdots + \beta_{m-1}\omega^{m-1}, \beta_l \in \mathbb{F}_q$, and P the matrix

$$P := \begin{pmatrix} 0 & 0 & \cdots & \beta_0 \\ 1 & 0 & \cdots & \beta_1 \\ \vdots & \ddots & 0 & \vdots \\ 0 & \cdots & 1 & \beta_{m-1} \end{pmatrix}.$$

Now, if we have the representation of α in $\mathbb{F}_{q^m}$ as $\alpha = \sum_{l=0}^{m-1} a_l \omega^l, a_l \in \mathbb{F}_q$, define

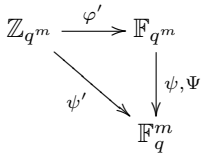
$$\psi(\alpha) := (a_0, \ldots, a_{m-1}) \in \mathbb{F}_q^m, \qquad \Psi(\alpha) := \sum_{l=0}^{m-1} a_l P^l \in \mathbb{F}_q^{m \times m}.$$

Note that for any $\alpha, x \in \mathbb{F}_{q^m} \setminus \{0\}$ we have $\Psi(\alpha)\psi(x) = \psi(\alpha x) \neq \mathbf{0} \in \mathbb{F}_q^m$ as $\alpha x \neq 0 \in \mathbb{F}_{q^m}$. Hence it follows that for any $\alpha \in \mathbb{F}_{q^m} \setminus \{0\}$ we have that the matrix $\Psi(\alpha)$ is regular.

Furthermore, for $k = \sum_{l=0}^{m-1} \kappa_l q^l$, let

$$\varphi'(k) := \sum_{l=0}^{m-1} \varphi(\kappa_l)\omega^l, \qquad \psi'(k) := \psi(\varphi'(k))$$

and define all extensions to vectors and matrices as above. We have the following commutative diagram:



Note that we have $\psi' = \varphi$.

Using similar methods as in Lemma 2.5 we can give the generating matrices for $\mathcal{C}_\alpha$ in the following form.

THEOREM 2.7. *Let $m, s, \mathbb{F}_q$ and $\alpha \in \mathbb{F}_{q^m} = \mathbb{F}_q[\omega]$ be given and define s matrices $B_j = (\psi(b_{j,1}), \ldots, \psi(b_{j,m}))^{-1}$, where the $b_{j,l}$ constitute the chosen basis $\mathcal{B}_j$. Then the generating matrices of the net are given by $C_j = (\Psi(\alpha^{j-1})B_j)^\top = (\Psi(\alpha)^{j-1}B_j)^\top$, $j = 1, \ldots, s$. Furthermore, it follows that C_j is regular for $j = 1, \ldots, s$.*

Proof. Let ϕ_1 be the (additive) isomorphism between $\mathcal{P} \subset \mathbb{F}_{q^m}[x]$ and $\mathbb{F}_{q^m}^s$. To arrive at the ϕ of Definition 2.6 we have to account for the choice of arbitrary bases $\mathcal{B}_j$. We do this by multiplying with the transformation matrix B^{-1}, where B is a square, block diagonal matrix with the matrices B_j of the statement of the theorem in its diagonal. Then $\phi(f) = B^{-1}\psi(\phi_1(f)), f \in \mathcal{P}$. We summarize these relations in the following diagrams:

Our first goal is to describe $\mathcal{N}_\alpha^\circ := \psi(\phi_1(\mathcal{P}_\alpha))$. Clearly, $\phi_1(\mathcal{P}_\alpha)$ is the space of all vectors orthogonal to $(1, \alpha, \ldots, \alpha^{s-1})^\top$. So $\boldsymbol{x} \in \phi_1(\mathcal{P}_\alpha)$ iff

$$\begin{aligned} 0 = (1, \alpha, \ldots, \alpha^{s-1})\boldsymbol{x} \iff \mathbf{0} &= \psi((1, \alpha, \ldots, \alpha^{s-1})\boldsymbol{x}) \\ &= \Psi((1, \alpha, \ldots, \alpha^{s-1}))\psi(\boldsymbol{x}), \end{aligned}$$

hence $\mathcal{N}_\alpha^\circ$ is the orthogonal space to the row space of

$$C_\alpha^\circ := \Psi((1, \alpha, \ldots, \alpha^{s-1})) = (\Psi(1), \Psi(\alpha), \ldots, \Psi(\alpha^{s-1})).$$

If the $\mathcal{B}_j$ are again taken into account, we have that $\mathcal{N}_\alpha$ is the image of $\mathcal{N}_\alpha^\circ$ under the automorphism $\boldsymbol{x} \mapsto B^{-1}\boldsymbol{x}$; accordingly its orthogonal space is the image under $\boldsymbol{x} \mapsto \boldsymbol{x}B$. Thus $C_\alpha := C_\alpha^\circ B$ is the overall generating matrix of the cyclic digital net (i.e., its row space is said to be orthogonal space) and $C_j := (\Psi(\alpha^{j-1})B_j)^\top$ are its generating matrices by the duality theory of digital nets. By the considerations before Lemma 2.5, Ψ is a ring homomorphism, so $\Psi(\alpha^j) = \Psi(\alpha)^j$.

In order to show that the matrices C_j are regular, recall that for any $\alpha \in \mathbb{F}_{q^m} \setminus \{0\}$ the matrix $\Psi(\alpha)$ is regular and as B_j is regular as well, it follows that C_j has to be regular. □

Remark 2.8. Note that every digital net with regular generating matrices C_j is cyclic with respect to some choice of bases $\mathcal{B}_j$. However, the focus in this paper lies on the class of all cyclic nets, i.e., where α runs through all elements in $\mathbb{F}_{q^m} \setminus \{0\}$, for fixed bases $\mathcal{B}_j$ and we show that there is at least one good cyclic net (i.e., good choice of $\alpha \in \mathbb{F}_{q^m} \setminus \{0\}$) for each fixed choice of $\mathcal{B}_j$. Those classes of cyclic nets which we use in our search algorithms do depend on the choice of bases, but once chosen the bases remain fixed throughout the search algorithm. In particular the search space of our algorithm will still be of size q^m for any given choice of bases.

Remark 2.9. It can be shown with a little calculation that Korobov polynomial lattice rules can be constructed (up to reordering of points) as cyclic nets. There, we have all B_j equal to the identity matrix. Note that with a suitably modified definition of cyclic nets (namely, if we consider arbitrary polynomial residue class rings) this also works for composite moduli f.

With similar little difficulty, Schmid's constacyclic shift-nets can be realized as cyclic nets, using the construction for $\mathbb{F}_{q^m} = \mathbb{F}_q[\theta]$, where $\theta^m = k$, if $f(x) = x^m - k$ is irreducible, and k is the factor for the shifted elements. (Again, we could also extend the definition of cyclic nets to include arbitrary polynomial residue class rings instead of only $\mathbb{F}_{q^m}/\mathbb{F}_q$.) Here, all B_j are constant and equal to the first, unshifted matrix C_1, and α is always chosen equal to θ.

These two relations are considered in detail in [16].

In view of Theorem 2.7 we propose the following generalization of the cyclic net construction.

DEFINITION 2.10. *Given a finite field $\mathbb{F}_q$, $\mathbb{F}_{q^m} = \mathbb{F}_q[\omega]$ as above, choose s elements $\alpha_1, \ldots, \alpha_s \in \mathbb{F}_{q^m}$ and regular matrices $B_j \in \mathbb{F}_q^{m\times m}$ and let the generating matrices of a digital net be defined by the matrices $C_j = (\Psi(\alpha_j)B_j)^\top$. A digital net constructed in this manner shall be called a* hyperplane net with respect to $\mathcal{B}_1, \ldots, \mathcal{B}_s$, *where by $\mathcal{B}_j$ we denote the ordered bases corresponding to the matrices B_j as in Theorem* 2.7. *Again, we shall from now on assume a fixed choice of bases $\mathcal{B}_j$ and will therefore no longer explicitly mention them.*

Remark 2.11. Note that the generating matrices C_j of the hyperplane net are regular provided that $\alpha_j \neq 0 \in \mathbb{F}_{q^m}$. For $\alpha_j = 0$ we obtain that $C_j = \mathbf{0} \in \mathbb{F}_q^{m\times m}$, the matrix consisting only of the neutral element with respect to addition in $\mathbb{F}_q$.

As a consequence, by Remark 2.8 a hyperplane net with regular generating matrices can also be considered as a cyclic net for some choice of bases $\mathcal{B}_j$. But the class of all hyperplane nets with fixed bases $\mathcal{B}_j$ is a proper superclass of the class of all cyclic nets with the same fixed bases $\mathcal{B}_j$. Hence the search space over all hyperplane nets is larger than the search space over all cyclic nets, as for the search we fix the bases in advance.

The name of the generalized construction is motivated by the following corollary of Lemma 2.5.

COROLLARY 2.12. *Let $\{\boldsymbol{x}_0, \dots, \boldsymbol{x}_{q^m-1}\}$ be a digital net over $\mathbb{F}_q$ generated by the $m \times m$ matrices $C_1, \dots, C_s$ over $\mathbb{F}_q$, $m > 0$, as given in Definition 2.10. Then for any vector $0 \le k_1, \dots, k_s < q^m$ of nonnegative integers we have*

$$\sum_{h=0}^{q^m-1} {}_{\mathbb{F}_q,\varphi}\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}_h) = \begin{cases} q^m & \text{if } \alpha_1\varphi'(\tau_1(k_1)) + \cdots + \alpha_s\varphi'(\tau_s(k_s)) = 0, \\ 0 & \text{else,} \end{cases}$$

with permutations $\tau_j(k) = \psi'^{-1}(B_j\psi'(k))$, and B_j as in Theorem 2.7.

Proof. By Definition 2.10 and Theorem 2.7, the generating matrices of the net are $C_j = (\Psi(\alpha_j)B_j)^\top$, so by Lemma 2.5 the sum equals q^m, iff (note that $\psi' = \varphi$)

$$\begin{aligned} \sum_{j=1}^{s} C_j^\top \psi'(k_j) &= \sum_{j=1}^{s} \Psi(\alpha_j)B_j\psi'(k_j) \\ = \sum_{j=1}^{s} \Psi(\alpha_j)\psi'(\tau_j(k_j)) = \mathbf{0} &\iff \sum_{j=1}^{s} \psi(\alpha_j\varphi'(\tau_j(k_j))) = \mathbf{0} \\ \iff \psi\left(\sum_{j=1}^{s} \alpha_j\varphi'(\tau_j(k_j))\right) = \mathbf{0} &\iff \sum_{j=1}^{s} \alpha_j\varphi'(\tau_j(k_j)) = 0, \end{aligned}$$

and vanishes otherwise, so the corollary follows. ∎

Remark 2.13. With this corollary it is not difficult to show that an equivalent definition in the spirit of Definition 2.6 exists: replace the $\mathcal{P}$ of Definition 2.6 by the space of linear forms

$$\mathcal{P} = \{f(x_1, \dots, x_s) = x_1\gamma_1 + \cdots + x_s\gamma_s, x_j \in \mathbb{F}_{q^m}\} \subset \mathbb{F}_{q^m}[x_1, \dots, x_s]$$

and $\mathcal{P}_\alpha$ by $\mathcal{P}_{\boldsymbol{\alpha}} = \{f \in \mathcal{P}, f(\alpha_1, \dots, \alpha_s) = 0\}$.

Remark 2.14. Similar to cyclic nets, polynomial lattice rules can be regarded as a special case ($B_j = I$) of hyperplane nets. Note that we shall again need to modify the definition of hyperplane nets to account for composite moduli f. Together with Korobov polynomial lattice rules and cyclic digital nets etc. we get a hierarchy of nets that is dealt with specifically and in more detail in [16].

3. Multivariate integration in weighted Sobolev spaces. In this section we consider multivariate integration in the weighted Sobolev space $H_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}$ induced by the reproducing kernel given by (see [2, 6, 18, 19])

$$K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}(\boldsymbol{x}, \boldsymbol{y}) = \prod_{j=1}^{s}(1 + \gamma_j\varrho_{w_j}(x_j, y_j)),$$

where $\boldsymbol{w} = (w_1, \dots, w_s) \in [0,1]^s$ and

$$\begin{aligned} \varrho_w(x,y) &= \frac{|x-w| + |y-w| - |x-y|}{2} \\ &= \begin{cases} \min(|x-w|, |y-w|) & \text{if } (x-w)(y-w) \ge 0, \\ 0 & \text{otherwise.} \end{cases} \end{aligned}$$

The inner product in $H_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}$ is given by

$$\langle f, g\rangle_{H_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}} := f(\boldsymbol{w})g(\boldsymbol{w}) + \sum_{\substack{u\subseteq\{1,\ldots,s\}\\ u\neq\emptyset}} \prod_{j\in u} \gamma_j^{-1} \int_{[0,1)^{|u|}} \frac{\partial^{|u|} f}{\partial \boldsymbol{x}_u}(\boldsymbol{x}_u, \boldsymbol{w}) \frac{\partial^{|u|} g}{\partial \boldsymbol{x}_u}(\boldsymbol{x}_u, \boldsymbol{w})\,\mathrm{d}\boldsymbol{x}_u,$$

where for $\boldsymbol{x} = (x_1, \ldots, x_s)$ and $u \subseteq \{1, \ldots, s\}$, $u \neq \emptyset$, we use the notation $\boldsymbol{x}_u = (x_j)_{j\in u}$ and $(\boldsymbol{x}_u, \boldsymbol{w})$ denotes the s-dimensional vector whose jth component is x_j if $j \in u$ and w_j if $j \notin u$. The Sobolev space $H_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}$ can also be defined as the set of all square integrable functions where the norm induced by the above inner product is finite.

Choose a prime-power base $q = p^r$ and let $x = \frac{x_1}{q} + \frac{x_2}{q^2} + \cdots$ and $\sigma = \frac{\sigma_1}{q} + \frac{\sigma_2}{q^2} + \cdots$ be the base q representation of x and σ. Further choose a bijection $\varphi : \{0, 1, \ldots, q-1\} \longrightarrow \mathbb{F}_q$ with $\varphi(0) = 0$. Then the digitally shifted point (with respect to the bijection φ) $y = x \oplus_\varphi \sigma$ is given by $y = \frac{y_1}{q} + \frac{y_2}{q^2} + \cdots$, where $y_i = \varphi^{-1}(\varphi(x_i) + \varphi(\sigma_i))$. For vectors $\boldsymbol{x}$ and $\boldsymbol{\sigma}$ we define the digitally shifted point $\boldsymbol{x} \oplus_\varphi \boldsymbol{\sigma}$ componentwise. Obviously, the shift depends on the base q as well as on the bijection φ.

For a point set $P_N = \{\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{N-1}\}$ and a $\boldsymbol{\sigma} \in [0,1)^s$ let $P_{N,\varphi,\boldsymbol{\sigma}} = \{\boldsymbol{x}_0 \oplus_\varphi \boldsymbol{\sigma}, \ldots, \boldsymbol{x}_{N-1} \oplus_\varphi \boldsymbol{\sigma}\}$ be the digitally shifted point set.

We recall that the *worst-case error* $e(P_N, K)$ for the integration of functions f from a reproducing kernel Hilbert space H with reproducing kernel K by means of a QMC-algorithm

$$Q_{N,s}(P_N, f) = \frac{1}{N} \sum_{n=0}^{N-1} f(\boldsymbol{x}_n)$$

using a point set $P_N = \{\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{N-1}\}$ is defined as

$$e(P_N, K) := \sup_{f\in H, \|f\|\leq 1} \left| \int_{[0,1]^s} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x} - Q_{N,s}(P_N, f) \right|.$$

(In [20, Theorem 1] it is shown that for $\boldsymbol{w} = (1, \ldots, 1)$ we have $e(P_N, K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}) = \mathcal{L}_{2,\boldsymbol{\gamma}}(P_N)$, the weighted $\mathcal{L}_{2,\boldsymbol{\gamma}}$-discrepancy of the point set P_N; see (1.1).)

Let the mean square worst-case error $\widehat{e}^2(P_N, K)$ be given by

$$\mathbb{E}[e^2(P_{N,\varphi,\boldsymbol{\sigma}}, K)] = \int_{[0,1)^s} e^2(P_{N,\varphi,\boldsymbol{\sigma}}, K)\,\mathrm{d}\boldsymbol{\sigma}.$$

Then we have $\widehat{e}^2(P_N, K) = e^2(P_N, K_{\mathrm{ds}})$, where

$$K_{\mathrm{ds}}(\boldsymbol{x}, \boldsymbol{y}) := \int_{[0,1)^s} K(\boldsymbol{x} \oplus_\varphi \boldsymbol{\sigma}, \boldsymbol{y} \oplus_\varphi \boldsymbol{\sigma})\,\mathrm{d}\boldsymbol{\sigma}$$

is the so-called shift invariant kernel of the kernel K. The proof of this result is similar to that of [3, Theorem 7].

In Appendix A of this paper it is shown that the shift invariant kernel $K_{\mathrm{ds},q,\boldsymbol{\gamma},\boldsymbol{w},\varphi}$ for the reproducing kernel $K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}$ is given by

$$K_{\mathrm{ds},q,\boldsymbol{\gamma},\boldsymbol{w},\varphi}(\boldsymbol{x}, \boldsymbol{y}) = \sum_{\boldsymbol{k}\in\mathbb{N}_0^s} \widehat{r}_q(\boldsymbol{w}, \boldsymbol{\gamma}, \boldsymbol{k}) \mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}) \overline{\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{y})},$$

where $\boldsymbol{w} = (w_1, \ldots, w_s) \in [0,1]^s$ and $\widehat{r}_q(\boldsymbol{w}, \boldsymbol{\gamma}, \boldsymbol{k}) = \prod_{j=1}^s \widehat{r}_q(w_j, \gamma_j, k_j)$, where

$$\widehat{r}_q(w,\gamma,k) := \begin{cases} 1 + \gamma(w^2 - w + \frac{1}{3}) & \text{if } k = 0, \\ -\frac{\gamma}{2}\left(\frac{1}{3q^{2a}} + \frac{2}{q^{2a}}\Re\left(\sum_{\substack{u,v=0 \\ v \ge u}}^{q-1} \frac{(v-u)\mathrm{wal}_{\kappa_{a-1}}\left(\frac{u \ominus_\varphi v}{q}\right)}{q}\right)\right) & \text{if } k > 0. \end{cases}$$

Here for $k > 0$, κ_{a-1} denotes the most significant bit in the base q representation of k and $\Re$ is the real part function. Note that this result generalizes the result in [3, Appendix A], as we now also allow Walsh functions over arbitrary finite fields and arbitrary bijections ϕ between $\mathbb{Z}_q$ and $\mathbb{F}_q$ which satisfy $\phi(0) = 0$.

Remark 3.1. Since $K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}$ is a reproducing kernel, it is easy to see that the corresponding shift invariant kernel $K_{\mathrm{ds},q,\boldsymbol{\gamma},\boldsymbol{w},\varphi}$ is a reproducing kernel as well and from this one can see (by the properties of reproducing kernels; see [1]) that $\widehat{r}_q(w,\gamma,k)$ is nonnegative for any $k \in \mathbb{N}_0$.

Further, for $x = \frac{x_1}{q} + \frac{x_2}{q^2} + \cdots$ and $y = \frac{y_1}{q} + \frac{y_2}{q^2} + \cdots$ we define $\rho_{\mathrm{ds},q,w}(x,x) := w^2 - w + \frac{1}{2}$ and if $x \neq y$,

$$\rho_{\mathrm{ds},q,w}(x,y) := w^2 - w + \frac{1}{2} - \frac{1}{2q^{i_0+1}} \times \left(\sum_{\substack{u=0 \\ u < u \oplus_\varphi x_{i_0} \ominus_\varphi y_{i_0}}}^{q-1} (u \oplus_\varphi x_{i_0} \ominus_\varphi y_{i_0} - u) + \sum_{\substack{u=0 \\ u < u \oplus_\varphi y_{i_0} \ominus_\varphi x_{i_0}}}^{q-1} (u \oplus_\varphi y_{i_0} \ominus_\varphi x_{i_0} - u) \right), \tag{3.1}$$

where i_0 is the smallest index such that the digits of x and y differ. Note that we have $\rho_{\mathrm{ds},q,w}(x,y) = \rho_{\mathrm{ds},q,w}(x \ominus_\varphi y, 0)$. Using Lemma B.2 it can easily be checked that

$$K_{\mathrm{ds},q,\boldsymbol{\gamma},\boldsymbol{w},\varphi}(\boldsymbol{x},\boldsymbol{y}) = \prod_{j=1}^s (1 + \gamma_j \rho_{\mathrm{ds},q,w_j}(x_j, y_j)).$$

Now we obtain, as in [3], that the mean square worst-case error for integration in the weighted Sobolev space $H_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}$ by using a random digital shift in base q with respect to a bijection φ on the point set $P_N = \{\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{N-1}\}$, with $\boldsymbol{x}_h = (x_{h,1}, \ldots, x_{h,s})$, is given by

$$\begin{aligned} &\widehat{e}^2(P_n, K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}) \\ &= \int_{[0,1)^{2s}} K_{\mathrm{ds},q,\boldsymbol{\gamma},\boldsymbol{w},\varphi}(\boldsymbol{x},\boldsymbol{y})\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}\boldsymbol{y} - \frac{2}{N}\sum_{h=0}^{N-1}\int_{[0,1)^s} K_{\mathrm{ds},q,\boldsymbol{\gamma},\boldsymbol{w},\varphi}(\boldsymbol{x}_h,\boldsymbol{y})\,\mathrm{d}\boldsymbol{y} \\ &\quad + \frac{1}{N^2}\sum_{h,n=0}^{N-1} K_{\mathrm{ds},q,\boldsymbol{\gamma},\boldsymbol{w},\varphi}(\boldsymbol{x}_h,\boldsymbol{x}_n) \\ &= -\prod_{j=1}^s \left(1 + \gamma_j\left(w_j^2 - w_j + \tfrac{1}{3}\right)\right) + \frac{1}{N^2}\sum_{h,n=0}^{N-1}\sum_{\boldsymbol{k}\in\mathbb{N}_0^s} \widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{k})\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}_h)\overline{\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}_n)} \\ &= -\prod_{j=1}^s \left(1 + \gamma_j\left(w_j^2 - w_j + \tfrac{1}{3}\right)\right) + \frac{1}{N^2}\sum_{h,n=0}^{N-1}\prod_{j=1}^s (1 + \gamma_j \rho_{\mathrm{ds},q,w_j}(x_{h,j}, x_{n,j})). \end{aligned}$$

For the special case where the point set $P_{q^m,\varphi}$ is a digital (t,m,s)-net over $\mathbb{F}_q$ with generating matrices $C_1,\dots,C_s$ and bijection φ (the same bijection as for the digital shift) we obtain

$$\begin{aligned}\widehat{e}^2(P_{q^m,\varphi},K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}) &= -\prod_{j=1}^{s}\Big(1+\gamma_j\Big(w_j^2-w_j+\tfrac{1}{3}\Big)\Big)\\ &\quad+\frac{1}{q^{2m}}\sum_{n=0}^{q^m-1}\left(\sum_{h=0}^{q^m-1}\sum_{\boldsymbol{k}\in\mathbb{N}_0^s}\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{k})\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}_h\ominus_\varphi\boldsymbol{x}_n)\right)\\ &= -\prod_{j=1}^{s}\Big(1+\gamma_j\Big(w_j^2-w_j+\tfrac{1}{3}\Big)\Big)\\ &\quad+\frac{1}{q^{2m}}\sum_{n=0}^{q^m-1}\left(\sum_{h=0}^{q^m-1}\prod_{j=1}^{s}(1+\gamma_j\rho_{\mathrm{ds},q,w_j}(x_{h,j}\ominus_\varphi x_{n,j},0))\right).\end{aligned}$$

It is easy to show that a digital net $P_{q^m,\varphi}$ over $\mathbb{F}_q$ generated by matrices $C_1,\dots,C_s$ with bijection φ together with the addition $\oplus_\varphi$ becomes a group. Hence each term in the sum over n has the same value and therefore we obtain

$$\begin{aligned}&\widehat{e}^2(P_{q^m,\varphi},K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}})\\ &= -\prod_{j=1}^{s}\Big(1+\gamma_j\Big(w_j^2-w_j+\tfrac{1}{3}\Big)\Big)+\sum_{\boldsymbol{k}\in\mathbb{N}_0^s}\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{k})\frac{1}{q^m}\sum_{h=0}^{q^m-1}\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}_h)\\ &= -\prod_{j=1}^{s}\Big(1+\gamma_j\Big(w_j^2-w_j+\tfrac{1}{3}\Big)\Big)+\frac{1}{q^m}\sum_{h=0}^{q^m-1}\prod_{j=1}^{s}(1+\gamma_j\rho_{\mathrm{ds},q,w_j}(x_{h,j},0)).\end{aligned}$$

For $k\in\mathbb{N}_0$, $k=\kappa_0+\kappa_1 q+\cdots$ denote an m-bit truncation by

$$\mathrm{tc}_{m,\varphi}(k)=(\varphi(\kappa_0),\dots,\varphi(\kappa_{m-1}))^\top\in\mathbb{F}_q^m.$$

For vectors $\boldsymbol{k}\in\mathbb{N}_0^s$ the mapping $\mathrm{tc}_{m,\varphi}$ is defined componentwise. Further define

$$\mathcal{N}=\{\boldsymbol{k}=(k_1,\dots,k_s)\in(\mathbb{F}_q^m)^s : C_1^\top k_1+\cdots+C_s^\top k_s=\boldsymbol{0}\},$$

where $\boldsymbol{0}$ is the zero vector in $\mathbb{F}_q^m$.

Using these definitions and Lemma 2.5 we obtain the next theorem.

THEOREM 3.2. *Let $P_{q^m,\varphi}=\{\boldsymbol{x}_0,\dots,\boldsymbol{x}_{q^m-1}\}$ be a digital (t,m,s)-net over $\mathbb{F}_q$ generated by $C_1,\dots,C_s$ and with respect to the bijection φ, where $\varphi(0)=0$.*

1. *The mean square worst-case error for integration in the weighted Sobolev space $H_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}$ by using the digital net $P_{q^m,\varphi}$ is given by*

$$\widehat{e}^2(P_{q^m,\varphi},K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}})=\sum_{\substack{\boldsymbol{k}\in\mathbb{N}_0^s\setminus\{\boldsymbol{0}\}\\ \mathrm{tc}_{m,\varphi}(\boldsymbol{k})\in\mathcal{N}}}\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{k}).$$

2. *Let $\boldsymbol{x}_h=(x_{h,1},\dots,x_{h,s})$ for $0\le h\le q^m-1$. Then we have*

$$\begin{aligned}&\widehat{e}^2(P_{q^m,\varphi},K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}})\\ &= -\prod_{j=1}^{s}\Big(1+\gamma_j\Big(w_j^2-w_j+\tfrac{1}{3}\Big)\Big)+\frac{1}{q^m}\sum_{h=0}^{q^m-1}\prod_{j=1}^{s}(1+\gamma_j\rho_{\mathrm{ds},q,w_j}(x_{h,j},0)),\end{aligned}\tag{3.2}$$

where $\rho_{\mathrm{ds},q,w}$ is given by (3.1).

Note that formula (3.2) allows us to compute the mean square worst-case error for integration in the weighted Sobolev space $H_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}$ for any digital net over $\mathbb{F}_q$ in $O(q^m s)$ operations.

3.1. Integration in $H_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}$ with cyclic nets. In this subsection we consider the special case where the digital net used for the QMC rule is a cyclic net.

Let $\alpha \in \mathbb{F}_{q^m}$, $\mathcal{B}_1, \ldots, \mathcal{B}_s$ be s ordered bases of $\mathbb{F}_{q^m}$ over $\mathbb{F}_q$ and let $C_1, \ldots, C_s$ be given as in Theorem 2.7. Then we have

$$\mathcal{N} = \mathcal{N}_\alpha = \phi(\mathcal{P}_\alpha);$$

see Definition 2.6. Let φ be a bijection from $\mathbb{Z}_q$ to $\mathbb{F}_q$ with $\varphi(0) = 0$. The cyclic net generated by $C_1, \ldots, C_s$ with respect to φ will be denoted by $P_{\alpha,\varphi}$.

ALGORITHM 3.3. *Given a dimension $s \geq 2$, an integer $m \geq 1$, and weights $\boldsymbol{\gamma} = (\gamma_j)_{j\geq 1}$,*

1. *Choose a prime power q, a finite field $\mathbb{F}_q$ with q elements, a bijection $\varphi : \{0, 1, \ldots, q-1\} \longrightarrow \mathbb{F}_q$ with $\varphi(0) = 0$, and s ordered bases $\mathcal{B}_1, \ldots, \mathcal{B}_s$ of $\mathbb{F}_{q^m}$ over $\mathbb{F}_q$.*
2. *Find $\alpha \in \mathbb{F}_{q^m} \setminus \{0\}$ that minimizes $\widehat{e}^2(P_{\alpha,\varphi}, K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}})$.*

In the following theorem we show that this construction yields the same upper bound as the Korobov construction of polynomial lattice rules, which is of course not surprising as Korobov polynomial lattice rules are just a special case.

THEOREM 3.4. *Let $s \geq 2$, let q be a prime power, let $\mathbb{F}_q$ be a finite field with q elements, let $\varphi : \{0, 1, \ldots, q-1\} \longrightarrow \mathbb{F}_q$ be a bijection with $\varphi(0) = 0$, and let $\mathcal{B}_1, \ldots, \mathcal{B}_s$ be s ordered bases of $\mathbb{F}_{q^m}$ over $\mathbb{F}_q$. Further let $m \geq 1$. Assume that $\alpha^* \in \mathbb{F}_{q^m} \setminus \{0\}$ is constructed by Algorithm 3.3. Then we have*

$$\widehat{e}^2(P_{\alpha^*,\varphi}, K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}) \leq \Big(\frac{s}{q^m - 1}\Big)^{\frac{1}{\lambda}} \prod_{j=1}^{s} \Big(\Big(1 + \gamma_j \left[w_j^2 - w_j + \tfrac{1}{3}\right]\Big)^{\lambda} + \gamma_j^{\lambda} \zeta_q(\lambda)\Big)^{\frac{1}{\lambda}}$$

for all $\frac{1}{2} < \lambda \leq 1$. Here for $\lambda = 1$, $\zeta_q(1) = \frac{1}{6}$ and for $\frac{1}{2} < \lambda < 1$ we have

$$\zeta_2(\lambda) = \frac{1}{3^{\lambda}(2^{2\lambda} - 2)} \quad \text{and} \quad \zeta_q(\lambda) = \frac{(q-1)q^{2\lambda}}{6^{\lambda}(q^{2\lambda} - q)} \quad \text{for} \quad q \neq 2.$$

Proof. Since

$$\min_{\alpha \in \mathbb{F}_{q^m} \setminus \{0\}} \widehat{e}^2(P_{\alpha,\varphi}, K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}) \leq \left(\frac{1}{q^m - 1} \sum_{\alpha \in \mathbb{F}_{q^m} \setminus \{0\}} \widehat{e}^2(P_{\alpha,\varphi}, K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}})^{\lambda}\right)^{\frac{1}{\lambda}},$$

it is enough to show that the inequality

$$\frac{1}{q^m - 1} \sum_{\alpha \in \mathbb{F}_{q^m} \setminus \{0\}} \widehat{e}^2(P_{\alpha,\varphi}, K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}})^{\lambda} \leq \frac{s}{q^m - 1} \prod_{j=1}^{s} \Big(\Big(1 + \gamma_j \left[w_j^2 - w_j + \tfrac{1}{3}\right]\Big)^{\lambda} + \gamma_j^{\lambda} \zeta_q(\lambda)\Big)$$

holds. With Jensen's inequality, which states that for a sequence (a_k) of nonnegative reals we have

$$\Big(\sum a_k\Big)^{\lambda} \leq \sum a_k^{\lambda}$$

for any $0 < \lambda \le 1$, we obtain

$$\begin{aligned} M_{s,q} &:= \frac{1}{q^m - 1} \sum_{\alpha \in \mathbb{F}_{q^m} \setminus \{0\}} \widehat{e}^2(P_\alpha, K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}})^\lambda \\ &\le \frac{1}{q^m - 1} \sum_{\boldsymbol{l} \in \mathbb{N}_0^s \setminus \{\boldsymbol{0}\}} \widehat{r}_q(\boldsymbol{w}, \boldsymbol{\gamma}, \boldsymbol{l})^\lambda A(\mathrm{tc}_{m,\varphi}(\boldsymbol{l})), \end{aligned}$$

where for $\boldsymbol{k} \in \mathbb{F}_q^{sm}$ we define

$$A(\boldsymbol{k}) := \#\{\alpha \in \mathbb{F}_{q^m} \setminus \{0\} : \boldsymbol{k} \in \mathcal{N}_\alpha\}.$$

Now $\boldsymbol{k} \in \mathbb{F}_q^{sm} \setminus \{\boldsymbol{0}\}$ is contained in $\mathcal{N}_\alpha$ iff α is a zero of the corresponding polynomial $\phi^{-1}(\boldsymbol{k})$. This polynomial has degree of at most $s-1$ and hence it has at most $s-1$ zeros. Thus $A(\boldsymbol{k}) \le s-1$. Further, we have $A(\boldsymbol{0}) = q^m - 1$.

For $\boldsymbol{l} \in \mathbb{N}_0^s$ we have $\mathrm{tc}_{m,\varphi}(q^m \boldsymbol{l}) = \boldsymbol{0}$ and hence

$$\begin{aligned} M_{s,q} &\le \frac{1}{q^m - 1} \Bigg(\sum_{\boldsymbol{l} \in \mathbb{N}_0^s \setminus \{\boldsymbol{0}\}} \widehat{r}_q(\boldsymbol{w}, \boldsymbol{\gamma}, q^m \boldsymbol{l})^\lambda A(\boldsymbol{0}) \\ &\qquad + \sum_{\boldsymbol{l} \in \mathbb{N}_0^s} \sum_{\substack{\boldsymbol{l}^* \in \mathbb{N}_0^s \\ 0 < \|\boldsymbol{l}^*\|_\infty < q^m}} \widehat{r}_q(\boldsymbol{w}, \boldsymbol{\gamma}, \boldsymbol{l}^* + q^m \boldsymbol{l})^\lambda A(\mathrm{tc}_{m,\varphi}(\boldsymbol{l}^*)) \Bigg) \\ &\le \sum_{\boldsymbol{l} \in \mathbb{N}_0^s \setminus \{\boldsymbol{0}\}} \widehat{r}_q(\boldsymbol{w}, \boldsymbol{\gamma}, q^m \boldsymbol{l})^\lambda + \frac{s-1}{q^m - 1} \sum_{\boldsymbol{l} \in \mathbb{N}_0^s} \widehat{r}_q(\boldsymbol{w}, \boldsymbol{\gamma}, \boldsymbol{l})^\lambda. \end{aligned}$$

The first sum in the last line in the inequality above can be estimated by

$$\begin{aligned} &\sum_{\boldsymbol{l} \in \mathbb{N}_0^s \setminus \{\boldsymbol{0}\}} \widehat{r}_q(\boldsymbol{w}, \boldsymbol{\gamma}, q^m \boldsymbol{l})^\lambda \\ &\quad = -\prod_{j=1}^s \widehat{r}_q(w_j, \gamma_j, 0)^\lambda + \prod_{j=1}^s \sum_{k=0}^\infty \widehat{r}_q(w_j, \gamma_j, q^m k)^\lambda \\ &\quad = -\prod_{j=1}^s \left(1 + \gamma_j \left(w_j^2 - w_j + \tfrac{1}{3}\right)\right)^\lambda \\ &\qquad + \prod_{j=1}^s \left(\left(1 + \gamma_j \left(w_j^2 - w_j + \tfrac{1}{3}\right)\right)^\lambda + \sum_{k=1}^\infty \widehat{r}_q(w_j, \gamma_j, q^m k)^\lambda \right) \\ &\quad \le \frac{1}{q^{2\lambda m}} \prod_{j=1}^s \left(\left(1 + \gamma_j \left[w_j^2 - w_j + \tfrac{1}{3}\right]\right)^\lambda + \sum_{k=1}^\infty \widehat{r}_q(w_j, \gamma_j, k)^\lambda \right) \end{aligned}$$

and the second sum is

$$\begin{aligned} \sum_{\boldsymbol{l} \in \mathbb{N}_0^s} \widehat{r}_q(\boldsymbol{w}, \boldsymbol{\gamma}, \boldsymbol{l})^\lambda &= \prod_{j=1}^s \sum_{k=0}^\infty \widehat{r}_q(w_j, \gamma_j, k)^\lambda \\ &= \prod_{j=1}^s \left(\left(1 + \gamma_j \left[w_j^2 - w_j + \tfrac{1}{3}\right]\right)^\lambda + \sum_{k=1}^\infty \widehat{r}_q(w_j, \gamma_j, k)^\lambda \right). \end{aligned}$$

We have

$$\sum_{k=1}^{\infty} \widehat{r}_q(w_j,\gamma_j,k)^\lambda =: \gamma_j^\lambda \mu_q(\lambda).$$

First note that

$$\left|\frac{1}{6}+\Re\left(\sum_{\substack{u,v=0\\ v\geq u}}^{q-1}\frac{(v-u)\mathrm{wal}_{\kappa_{a-1}}\left(\frac{u\ominus_\varphi v}{q}\right)}{q}\right)\right| \leq \frac{1}{6}+\frac{1}{q}\sum_{\substack{u,v=0\\ v\geq u}}^{q-1}(v-u)$$
$$= \frac{1}{6}+\frac{1}{q}\frac{q(q+1)(q-1)}{6} = \frac{q^2}{6}.$$

For $\frac{1}{2}<\lambda<1$ we have

$$\mu_q(\lambda) = \sum_{k=1}^{\infty}\left(-\frac{1}{2}\left(\frac{1}{3q^{2a}}+\frac{2}{q^{2a}}\Re\left(\sum_{\substack{u,v=0\\ v\geq u}}^{q-1}\frac{(v-u)\mathrm{wal}_{\kappa_{a-1}}\left(\frac{u\ominus_\varphi v}{q}\right)}{q}\right)\right)\right)^\lambda$$
$$\leq \sum_{a=1}^{\infty}\sum_{k=q^{a-1}}^{q^a-1}\frac{1}{q^{2\lambda a}}\left(\frac{q^2}{6}\right)^\lambda = \frac{(q-1)q^{2\lambda}}{6^\lambda(q^{2\lambda}-q)} =: \zeta_q(\lambda)$$

and for $\lambda=1$ we have

$$\mu_q(1)$$
$$= -\frac{1}{2}\sum_{a=1}^{\infty}\sum_{k=q^{a-1}}^{q^a-1}\left(\frac{1}{3q^{2a}}+\frac{2}{q^{2a}}\Re\left(\sum_{\substack{u,v=0\\ v\geq u}}^{q-1}\frac{(v-u)\mathrm{wal}_{\kappa_{a-1}}\left(\frac{u\ominus_\varphi v}{q}\right)}{q}\right)\right)$$
$$= -\frac{1}{6}\sum_{a=1}^{\infty}\frac{1}{q^{2a}}(q^a-q^{a-1}) - \Re\left(\sum_{a=1}^{\infty}\frac{1}{q^{2a}}\sum_{k=q^{a-1}}^{q^a-1}\sum_{\substack{u,v=0\\ v\geq u}}^{q-1}\frac{(v-u)\mathrm{wal}_{\kappa_{a-1}}\left(\frac{u\ominus_\varphi v}{q}\right)}{q}\right).$$

Now with Lemma B.1 we obtain

$$\sum_{a=1}^{\infty}\frac{1}{q^{2a}}\sum_{k=q^{a-1}}^{q^a-1}\sum_{\substack{u,v=0\\ v\geq u}}^{q-1}\frac{(v-u)\mathrm{wal}_{\kappa_{a-1}}\left(\frac{u\ominus_\varphi v}{q}\right)}{q}$$
$$= \sum_{a=1}^{\infty}\frac{1}{q^{a+2}}\sum_{\kappa_{a-1}=1}^{q-1}\sum_{\substack{u,v=0\\ v\geq u}}^{q-1}(v-u)\mathrm{wal}_{\kappa_{a-1}}(\tfrac{u\ominus_\varphi v}{q}) = \sum_{a=1}^{\infty}\frac{1}{q^{a+2}}q\frac{1-q^2}{6} = -\frac{q+1}{6q}.$$

Therefore we have

$$\mu_q(1) = -\frac{1}{6q}+\frac{q+1}{6q} = \frac{1}{6} =: \zeta_q(1).$$

Let now $q=2$ and $\frac{1}{2}<\lambda<1$. Then

$$\mu_2(\lambda) = \sum_{a=1}^{\infty}\sum_{k=2^{a-1}}^{2^a-1}\left(-\frac{1}{2}\left(\frac{1}{3\cdot 2^{2a}}+\frac{2}{2^{2a}}\sum_{\substack{u,v=0\\ v\geq u}}^{1}\frac{(v-u)\mathrm{wal}_1\left(\frac{u\ominus_\varphi v}{2}\right)}{2}\right)\right)^\lambda$$

and by using

$$\sum_{\substack{u,v=0\\ v\ge u}}^{1} \frac{(v-u)\mathrm{wal}_1\left(\frac{u\ominus_\varphi v}{2}\right)}{2} = \frac{\mathrm{wal}_1\left(\frac{0\ominus_\varphi 1}{2}\right)}{2} = -\frac{1}{2},$$

we obtain

$$\mu_2(\lambda) = \frac{1}{3^\lambda(2^{2\lambda}-2)} =: \zeta_2(\lambda).$$

The theorem follows. □

The following corollary shows that under certain conditions on the weights we can obtain an upper bound which depends only polynomially on the dimension and thus proving tractability. (See [20] for more information on tractability.) An analogous result was shown for the Korobov construction of polynomial lattice rules; see [4].

COROLLARY 3.5. *Let $s \ge 2$, let q be a prime power, $\mathbb{F}_q$ be a finite field with q elements, $\varphi : \{0,1,\dots,q-1\} \longrightarrow \mathbb{F}_q$ be a bijection with $\varphi(0) = 0$, and $\mathcal{B}_1,\dots,\mathcal{B}_s$ be s ordered bases of $\mathbb{F}_{q^m}$ over $\mathbb{F}_q$. Let $m \ge 1$ and suppose $\alpha^* \in \mathbb{F}_{q^m} \setminus \{0\}$ is constructed by Algorithm 3.3. Let $N = q^m$.*

1. *We have*

$$\widehat{e}(P_{\alpha^*,\varphi}, K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}) \le c_{s,\boldsymbol{w},\boldsymbol{\gamma},\delta} s^{1-\delta} N^{-1+\delta} \qquad \text{for all } 0 < \delta \le \tfrac{1}{2},$$

where

$$c_{s,\boldsymbol{w},\boldsymbol{\gamma},\delta} := 2^{1-\delta} \prod_{j=1}^{s} \left(1 + \gamma_j^{\frac{1}{2(1-\delta)}} \left[\left(w_j^2 - w_j + \tfrac{1}{3}\right)^{\frac{1}{2(1-\delta)}} + \zeta_q\left(\tfrac{1}{2(1-\delta)}\right)\right]\right)^{1-\delta}.$$

2. *Under the assumption*

$$A := \limsup_{s\to\infty} \frac{\sum_{j=1}^{s} \gamma_j}{\log s} < \infty$$

we obtain $c_{s,\boldsymbol{w},\boldsymbol{\gamma},1/2} \le \bar{c}_\eta s^{(A+\eta)/2}$ and therefore

$$\widehat{e}(P_{\alpha^*,\varphi}, K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}) \le \bar{c}_\eta s^{(1+(A+\eta))/2} N^{-\frac{1}{2}} \qquad \text{for all } \eta > 0,$$

where the constant $\bar{c}_\eta$ depends only on the arbitrarily chosen parameter η. Thus the root mean square worst-case error of the cyclic net generated by α^* (with respect to the bijection φ) satisfies a bound which depends only polynomially on the dimension.

The result can be shown using the methods employed in the proof of [4, Corollary 4.8].

3.2. Integration in $H_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}$ with hyperplane nets. In this subsection we consider the special case where the digital net used for the QMC rule is a hyperplane net.

Let $\boldsymbol{\alpha} = (\alpha_1,\dots,\alpha_s) \in \mathbb{F}_{q^m}^s$, $\mathcal{B}_1,\dots,\mathcal{B}_s$ be s ordered bases of $\mathbb{F}_{q^m}$ over $\mathbb{F}_q$ and let $C_1,\dots,C_s$ be given as in Definition 2.10. Let

$$\mathcal{N}_{\boldsymbol{\alpha}} = \{\boldsymbol{k} = (k_1,\dots,k_s) \in (\mathbb{F}_q^m)^s : C_1^\top k_1 + \cdots + C_s^\top k_s = \boldsymbol{0}\},$$

where $\mathbf{0}$ is the zero vector in $\mathbb{F}_q^m$. Let φ be a bijection from $\mathbb{Z}_q$ to $\mathbb{F}_q$ with $\varphi(0) = 0$. The hyperplane net generated by $C_1, \dots, C_s$ with respect to φ will be denoted by $P_{\boldsymbol{\alpha},\varphi}$.

From now on we write $\widehat{e}^2(P_{\boldsymbol{\alpha},\varphi}, K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}) = \widehat{e}^2(\alpha_1, \dots, \alpha_s)$ to stress the dependence of the mean square worst-case error on $\boldsymbol{\alpha} = (\alpha_1, \dots, \alpha_s)$.

ALGORITHM 3.6. *Given a dimension $s \geq 2$, an integer $m \geq 1$, and weights $\boldsymbol{\gamma} = (\gamma_j)_{j \geq 1}$,*

1. *Choose a prime power q, a finite field $\mathbb{F}_q$ with q elements, a bijection $\varphi : \{0, 1, \dots, q-1\} \longrightarrow \mathbb{F}_q$ with $\varphi(0) = 0$, and ordered bases $\mathcal{B}_1, \dots, \mathcal{B}_s$ of $\mathbb{F}_{q^m}$ over $\mathbb{F}_q$.*
2. *Choose $\alpha_1 \in \mathbb{F}_{q^m} \setminus \{0\}$.*
3. *For $d = 2, 3, \dots, s$ find $\alpha_d \in \mathbb{F}_{q^m} \setminus \{0\}$ by minimizing the mean square worst-case error $\widehat{e}^2(\alpha_1, \dots, \alpha_d)$.*

In the following theorem we show that this construction yields the same upper bound as the component-by-component construction of polynomial lattice rules.

THEOREM 3.7. *Let $s \geq 2$, let q be a prime power, let $\mathbb{F}_q$ be a finite field with q elements, let $\varphi : \{0, 1, \dots, q-1\} \longrightarrow \mathbb{F}_q$ be a bijection with $\varphi(0) = 0$, and let $\mathcal{B}_1, \dots, \mathcal{B}_s$ be ordered bases of $\mathbb{F}_{q^m}$ over $\mathbb{F}_q$. Further let $m \geq 1$. Assume that $(\alpha_1^*, \dots, \alpha_s^*) \in (\mathbb{F}_{q^m} \setminus \{0\})^s$ is constructed by Algorithm 3.6. Then for all $d = 1, 2, \dots, s$ we have*

$$\widehat{e}^2(\alpha_1^*, \dots, \alpha_d^*) \leq (q^m - 1)^{-\frac{1}{\lambda}} \prod_{j=1}^{d} \left(\left(1 + \gamma_j \left[w_j^2 - w_j + \tfrac{1}{3} \right] \right)^{\lambda} + \zeta_q(\lambda) \gamma_j^{\lambda} \right)^{\frac{1}{\lambda}}$$

for all $\frac{1}{2} < \lambda \leq 1$. Here $\zeta_q(\lambda)$ is defined as in Theorem 3.4.

Proof. First we show that the inequality

$$\widehat{e}^2(\alpha_1^*, \dots, \alpha_d^*) \leq \left(\frac{1}{q^m - 1} \sum_{\boldsymbol{l} \in \mathbb{N}_0^d} \widehat{r}_q(\boldsymbol{w}, \boldsymbol{\gamma}, \boldsymbol{l})^{\lambda} \right)^{\frac{1}{\lambda}} \tag{3.3}$$

holds for all $d = 1, 2, \dots, s$.

We start with $d = 1$. The generating matrix C_1 is regular for all $\alpha_1 \in \mathbb{F}_{q^m} \setminus \{0\}$ and hence $\mathcal{N}_{\alpha_1} = \{\mathbf{0}\}$. Hence we have

$$\widehat{e}^2(\alpha_1^*) = \sum_{\substack{k \in \mathbb{N}_0 \setminus \{0\} \\ q^m \mid k}} \widehat{r}_q(\omega_1, \gamma_1, k) = \sum_{k=1}^{\infty} \widehat{r}_q(\omega_1, \gamma_1, q^m k) = \frac{1}{q^{2m}} \sum_{k=1}^{\infty} \widehat{r}_q(\omega_1, \gamma_1, k).$$

The result for $d = 1$ now follows by applying Jensen's inequality to the infinite sum above.

Suppose for some $1 \leq d < s$ we have $\boldsymbol{\alpha}^* = (\alpha_1^*, \dots, \alpha_d^*) \in (\mathbb{F}_{q^m} \setminus \{0\})^d$ and

$$\widehat{e}^2(\boldsymbol{\alpha}^*) \leq \left(\frac{1}{q^m - 1} \sum_{\boldsymbol{l} \in \mathbb{N}_0^d} \widehat{r}_q(\boldsymbol{w}, \boldsymbol{\gamma}, \boldsymbol{l})^{\lambda} \right)^{\frac{1}{\lambda}}.$$

Now we have

$$\begin{aligned}\widehat{e}^2(\boldsymbol{\alpha},\alpha_{d+1}) &= \sum_{\substack{(\boldsymbol{l},l_{d+1})\in\mathbb{N}_0^{d+1}\setminus\{\mathbf{0}\}\\(\mathrm{tc}_{m,\varphi}(\boldsymbol{l}),\mathrm{tc}_{m,\varphi}(l_{d+1}))\in\mathcal{N}_{(\boldsymbol{\alpha},\alpha_{d+1})}}} \widehat{r}_q(w_{d+1},\gamma_{d+1},l_{d+1})\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})\\ &= \widehat{r}_q(w_{d+1},\gamma_{d+1},0)\widehat{e}^2(\boldsymbol{\alpha})+\theta(\alpha_{d+1}),\end{aligned}$$

where

$$\theta(\alpha_{d+1}) = \sum_{l_{d+1}=1}^{\infty} \widehat{r}_q(w_{d+1},\gamma_{d+1},l_{d+1}) \sum_{\substack{\boldsymbol{l}\in\mathbb{N}_0^d\\(\mathrm{tc}_{m,\varphi}(\boldsymbol{l}),\mathrm{tc}_{m,\varphi}(l_{d+1}))\in\mathcal{N}_{(\boldsymbol{\alpha},\alpha_{d+1})}}} \widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l}).$$

In Algorithm 3.6, α_{d+1}^* is chosen such that the mean square worst-case error $\widehat{e}^2(\boldsymbol{\alpha}^*,\alpha_{d+1})$ is minimized. Since the only dependence on α_{d+1} is in $\theta(\alpha_{d+1})$, we have $\theta(\alpha_{d+1}^*) \le \theta(\alpha_{d+1})$ for all $\alpha_{d+1}\in\mathbb{F}_{q^m}\setminus\{0\}$. Hence for any $\lambda\le 1$ we obtain

$$\theta(\alpha_{d+1}^*) \le \left(\frac{1}{q^m-1}\sum_{\alpha_{d+1}\in\mathbb{F}_{q^m}\setminus\{0\}}\theta(\alpha_{d+1})^\lambda\right)^{\frac{1}{\lambda}}.$$

From Jensen's inequality it follows that

$$\theta(\alpha_{d+1})^\lambda \le \sum_{l_{d+1}=1}^{\infty} \widehat{r}_q(w_{d+1},\gamma_{d+1},l_{d+1})^\lambda \sum_{\substack{\boldsymbol{l}\in\mathbb{N}_0^d\\(\mathrm{tc}_{m,\varphi}(\boldsymbol{l}),\mathrm{tc}_{m,\varphi}(l_{d+1}))\in\mathcal{N}_{(\boldsymbol{\alpha},\alpha_{d+1})}}} \widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda.$$

If l_{d+1} is a multiple of q^m, then $\mathrm{tc}_{m,\varphi}(l_{d+1})=0$ and the sum is independent of α_{d+1}. Otherwise $\mathrm{tc}_{m,\varphi}(l_{d+1})\ne 0$. We obtain

$$\begin{aligned}\frac{1}{q^m-1}\sum_{\alpha_{d+1}\in\mathbb{F}_{q^m}\setminus\{0\}}\theta(\alpha_{d+1})^\lambda &\le \sum_{\substack{l_{d+1}=1\\q^m\mid l_{d+1}}}^{\infty} \widehat{r}_q(w_{d+1},\gamma_{d+1},l_{d+1})^\lambda \sum_{\substack{\boldsymbol{l}\in\mathbb{N}_0^d\\\mathrm{tc}_{m,\varphi}(\boldsymbol{l})\in\mathcal{N}_{\boldsymbol{\alpha}}}} \widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda\\ &+ \frac{1}{q^m-1}\sum_{\substack{l_{d+1}=1\\q^m\nmid l_{d+1}}}^{\infty} \widehat{r}_q(w_{d+1},\gamma_{d+1},l_{d+1})^\lambda \sum_{\boldsymbol{l}\in\mathbb{N}_0^d} \widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda \sum_{\substack{\alpha_{d+1}\in\mathbb{F}_{q^m}\setminus\{0\}\\(\mathrm{tc}_{m,\varphi}(\boldsymbol{l}),\mathrm{tc}_{m,\varphi}(l_{d+1}))\in\mathcal{N}_{(\boldsymbol{\alpha},\alpha_{d+1})}}} 1.\end{aligned}$$

From $\mathrm{tc}_{m,\varphi}(l_{d+1})\ne 0$ we obtain

$$\begin{aligned}&\sum_{\boldsymbol{l}\in\mathbb{N}_0^d} \widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda \sum_{\substack{\alpha_{d+1}\in\mathbb{F}_{q^m}\setminus\{0\}\\(\mathrm{tc}_{m,\varphi}(\boldsymbol{l}),\mathrm{tc}_{m,\varphi}(l_{d+1}))\in\mathcal{N}_{(\boldsymbol{\alpha},\alpha_{d+1})}}} 1\\ &= \sum_{\substack{\boldsymbol{l}\in\mathbb{N}_0^d\\\mathrm{tc}_{m,\varphi}(\boldsymbol{l})\notin\mathcal{N}_{\boldsymbol{\alpha}}}} \widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda = \sum_{\boldsymbol{l}\in\mathbb{N}_0^d} \widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda - \sum_{\substack{\boldsymbol{l}\in\mathbb{N}_0^d\\\mathrm{tc}_{m,\varphi}(\boldsymbol{l})\in\mathcal{N}_{\boldsymbol{\alpha}}}} \widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda.\end{aligned}$$

Therefore we can estimate

$$\begin{aligned}
&\frac{1}{q^m-1}\sum_{\alpha_{d+1}\in\mathbb{F}_{q^m}\setminus\{0\}}\theta(\alpha_{d+1})^\lambda \le \sum_{\substack{l_{d+1}=1\\ q^m\mid l_{d+1}}}^{\infty}\widehat{r}_q(w_{d+1},\gamma_{d+1},l_{d+1})^\lambda \sum_{\substack{\boldsymbol{l}\in\mathbb{N}_0^d\\ \mathrm{tc}_{m,\varphi}(\boldsymbol{l})\in\mathcal{N}_{\boldsymbol{\alpha}}}}\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda\\
&\quad+\frac{1}{q^m-1}\sum_{\substack{l_{d+1}=1\\ q^m\nmid l_{d+1}}}^{\infty}\widehat{r}_q(w_{d+1},\gamma_{d+1},l_{d+1})^\lambda\left(\sum_{\boldsymbol{l}\in\mathbb{N}_0^d}\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda-\sum_{\substack{\boldsymbol{l}\in\mathbb{N}_0^d\\ \mathrm{tc}_{m,\varphi}(\boldsymbol{l})\in\mathcal{N}_{\boldsymbol{\alpha}}}}\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda\right)\\
&\le\sum_{l=1}^{\infty}\widehat{r}_q(w_{d+1},\gamma_{d+1},q^m l)^\lambda\sum_{\substack{\boldsymbol{l}\in\mathbb{N}_0^d\\ \mathrm{tc}_{m,\varphi}(\boldsymbol{l})\in\mathcal{N}_{\boldsymbol{\alpha}}}}\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda\\
&\quad+\frac{1}{q^m-1}\sum_{l=1}^{\infty}\widehat{r}_q(w_{d+1},\gamma_{d+1},l)^\lambda\left(\sum_{\boldsymbol{l}\in\mathbb{N}_0^d}\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda-\sum_{\substack{\boldsymbol{l}\in\mathbb{N}_0^d\\ \mathrm{tc}_{m,\varphi}(\boldsymbol{l})\in\mathcal{N}_{\boldsymbol{\alpha}}}}\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda\right)\\
&\le\frac{1}{q^m-1}\sum_{l=1}^{\infty}\widehat{r}_q(w_{d+1},\gamma_{d+1},l)^\lambda\sum_{\boldsymbol{l}\in\mathbb{N}_0^d}\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda.
\end{aligned}$$

Here the last inequality follows from the fact that

$$\sum_{l=1}^{\infty}\widehat{r}_q(w_{d+1},\gamma_{d+1},q^m l)^\lambda-\frac{1}{q^m-1}\sum_{l=1}^{\infty}\widehat{r}_q(w_{d+1},\gamma_{d+1},l)^\lambda\le 0,$$

which follows from the definition of $\widehat{r}_q$ and since $\lambda>\frac{1}{2}$. Now we have

$$\theta(\alpha_{d+1}^*)\le\left(\frac{1}{q^m-1}\sum_{l=1}^{\infty}\widehat{r}_q(w_{d+1},\gamma_{d+1},l)^\lambda\sum_{\boldsymbol{l}\in\mathbb{N}_0^d}\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda\right)^{\frac{1}{\lambda}}.$$

From this it follows that

$$\begin{aligned}
\widehat{e}^2(\boldsymbol{\alpha}^*,\alpha_{d+1}^*)&\le\widehat{r}_q(w_{d+1},\gamma_{d+1},0)\widehat{e}^2(\boldsymbol{\alpha}^*)\\
&\quad+\left(\frac{1}{q^m-1}\sum_{l=1}^{\infty}\widehat{r}_q(w_{d+1},\gamma_{d+1},l)^\lambda\sum_{\boldsymbol{l}\in\mathbb{N}_0^d}\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda\right)^{\frac{1}{\lambda}}\\
&\le\left(\frac{1}{q^m-1}\sum_{\boldsymbol{l}\in\mathbb{N}_0^d}\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda\right)^{\frac{1}{\lambda}}\left(\widehat{r}_q(w_{d+1},\gamma_{d+1},0)+\left(\sum_{l=1}^{\infty}\widehat{r}_q(w_{d+1},\gamma_{d+1},l)^\lambda\right)^{\frac{1}{\lambda}}\right).
\end{aligned}$$

Again from Jensen's inequality we obtain

$$\widehat{r}_q(w_{d+1},\gamma_{d+1},0)+\left(\sum_{l=1}^{\infty}\widehat{r}_q(w_{d+1},\gamma_{d+1},l)^\lambda\right)^{\frac{1}{\lambda}}\le\left(\sum_{l=0}^{\infty}\widehat{r}_q(w_{d+1},\gamma_{d+1},l)^\lambda\right)^{\frac{1}{\lambda}}$$

and hence

$$\widehat{e}^2(\boldsymbol{\alpha}^*,\alpha_{d+1}^*)\le\left(\frac{1}{q^m-1}\sum_{\boldsymbol{l}\in\mathbb{N}_0^{d+1}}\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda\right)^{\frac{1}{\lambda}}.$$

This finishes our induction proof of inequality (3.3).

Finally we have

$$\sum_{\boldsymbol{l}\in\mathbb{N}_0^d} \widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{l})^\lambda = \prod_{j=1}^d \sum_{l=0}^\infty \widehat{r}_q(w_j,\gamma_j,l)^\lambda$$
$$= \prod_{j=1}^d \left((1+\gamma_j[w_j^2 - w_j + \tfrac{1}{3}])^\lambda + \sum_{l=1}^\infty \widehat{r}_q(w_j,\gamma_j,l)^\lambda \right).$$

As in the proof of Theorem 3.4 we obtain

$$\sum_{l=1}^\infty \widehat{r}_q(w_j,\gamma_j,l)^\lambda \le \gamma_j^\lambda \zeta_q(\lambda)$$

and the result follows. □

The following corollary shows that under certain conditions on the weights we can obtain an upper bound which depends only polynomially on the dimension, and, with stronger conditions on the weights, we can also obtain an upper bound which is independent of the dimension, thus proving strong tractability. (See [20] for more information on (strong) tractability.) An analogous result was shown for the component-by-component construction of polynomial lattice rules; see [4].

COROLLARY 3.8. *Let $s \ge 2$, let q be prime power, $\mathbb{F}_q$ be a finite field with q elements, $\varphi : \{0,1,\dots,q-1\} \longrightarrow \mathbb{F}_q$ be a bijection with $\varphi(0) = 0$, and $\mathcal{B}_1, \dots \mathcal{B}_s$ be s ordered bases of $\mathbb{F}_{q^m}$ over $\mathbb{F}_q$. Further let $m \ge 1$. Suppose $\boldsymbol{\alpha}^* \in (\mathbb{F}_{q^m} \setminus \{0\})^s$ is constructed by Algorithm 3.6. Let $N = q^m$.*

1. *We have*

$$\widehat{e}(\boldsymbol{\alpha}^*) \le c_{s,\boldsymbol{w},\boldsymbol{\gamma},\delta} N^{-1+\delta} \qquad \text{for all } 0 < \delta \le \tfrac{1}{2},$$

where

$$c_{s,\boldsymbol{w},\boldsymbol{\gamma},\delta} := 2^{1-\delta} \prod_{j=1}^s \left(1 + \gamma_j^{\frac{1}{2(1-\delta)}} \left[\left(w_j^2 - w_j + \tfrac{1}{3}\right)^{\frac{1}{2(1-\delta)}} + \zeta_q\left(\tfrac{1}{2(1-\delta)}\right)\right]\right)^{1-\delta}.$$

2. *Suppose*

$$\sum_{j=1}^\infty \gamma_j^{\frac{1}{2(1-\delta)}} < \infty.$$

Then $c_{s,\boldsymbol{w},\boldsymbol{\gamma},\delta} \le c_{\infty,\boldsymbol{w},\boldsymbol{\gamma},\delta} < \infty$ and we have

$$\widehat{e}(\boldsymbol{\alpha}^*) \le c_{\infty,\boldsymbol{w},\boldsymbol{\gamma},\delta} N^{-1+\delta} \qquad \text{for all } 0 < \delta \le \tfrac{1}{2}.$$

Thus the root mean square worst-case error of the hyperplane net generated by $\boldsymbol{\alpha}^*$ (with respect to the bijection φ) is bounded independently of the dimension.

3. *Under the assumption*

$$A := \limsup_{s\to\infty} \frac{\sum_{j=1}^s \gamma_j}{\log s} < \infty$$

we obtain $c_{s,\boldsymbol{w},\boldsymbol{\gamma},1/2} \le \widetilde{c}_\eta s^{(A+\eta)/2}$ and therefore

$$\widehat{e}(\boldsymbol{\alpha}^*) \le \widetilde{c}_\eta s^{(A+\eta)/2} N^{-\frac{1}{2}} \qquad \text{for all } \eta > 0,$$

where the constant $\widetilde{c}_\eta$ depends only on the arbitrarily chosen parameter η. Thus the root mean square worst-case error of the hyperplane net generated by $\boldsymbol{\alpha}^*$ (with respect to the bijection φ) satisfies a bound which depends only polynomially on the dimension.

The result can be shown using the methods employed in the proof of [4, Corollary 4.5].

Appendix A. Computation of the digital shift invariant kernel. Here we compute the digital shift invariant kernel for the reproducing kernel

$$K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}(\boldsymbol{x},\boldsymbol{y}) = \prod_{j=1}^{s}(1+\gamma_j \varrho_{w_j}(x_j,y_j)),$$

where $\boldsymbol{w} = (w_1,\dots,w_s) \in [0,1]^s$ and

$$\begin{aligned}\varrho_w(x,y) &= \frac{|x-w|+|y-w|-|x-y|}{2}\\ &= \begin{cases}\min(|x-w|,|y-w|) & \text{if } (x-w)(y-w)\ge 0,\\ 0 & \text{otherwise.}\end{cases}\end{aligned}$$

We have

$$\begin{aligned}K_{\mathrm{ds},q,\boldsymbol{\gamma},\boldsymbol{w},\varphi}(\boldsymbol{x},\boldsymbol{y}) &:= \int_{[0,1)^s} K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}(\boldsymbol{x}\oplus_\varphi \boldsymbol{\sigma}, \boldsymbol{y}\oplus_\varphi \boldsymbol{\sigma})\,\mathrm{d}\boldsymbol{\sigma}\\ &= \prod_{j=1}^{s}\int_0^1 K_{\mathrm{sob},1,w_j,\gamma_j}(x_j\oplus_\varphi \sigma, y_j\oplus_\varphi \sigma)\,\mathrm{d}\sigma,\end{aligned}$$

where $K_{\mathrm{sob},1,w,\gamma}(x,y) := 1+\gamma\rho_w(x,y)$. So it suffices to compute

$$K_{\mathrm{ds},q,\gamma,w,\varphi}(x,y) := \int_0^1 K_{\mathrm{sob},1,w,\gamma}(x\oplus_\varphi \sigma, y\oplus_\varphi \sigma)\,\mathrm{d}\sigma.$$

It can easily be seen that the function $K_{\mathrm{sob},1,w,\gamma}(x,y)$ is in $\mathcal{L}_2([0,1)^2)$ and therefore we can apply [3, Lemma 5], from which we find that

$$K_{\mathrm{ds},q,\gamma,w,\varphi}(x,y) = \sum_{k=0}^{\infty}\widehat{K}(k)\mathrm{wal}_k(x)\overline{\mathrm{wal}_k(y)},$$

where

$$\widehat{K}(k) = \int_0^1\int_0^1 K_{\mathrm{sob},1,w,\gamma}(x,y)\overline{\mathrm{wal}_k(x)}\mathrm{wal}_k(y)\,\mathrm{d}x\,\mathrm{d}y.$$

By Proposition 2.4(3) it follows easily that

$$\widehat{K}(k) = \begin{cases}1+\gamma(w^2-w+\frac{1}{3}) & \text{if } k=0,\\ -\frac{\gamma}{2}\int_0^1\int_0^1 |x-y|\mathrm{wal}_k(y\ominus_\varphi x)\,\mathrm{d}x\,\mathrm{d}y & \text{if } k>0.\end{cases}$$

Now we evaluate the last integral.

LEMMA A.1. *Let $q^{a-1} \le k < q^a, \kappa_{a-1} = \lfloor k/q^{a-1} \rfloor > 0$. Then*

$$\tau(k) := \int_{[0,1)^2} |x-y| \mathrm{wal}_k(y \ominus_\varphi x)\,\mathrm{d}x\,\mathrm{d}y$$
$$= \frac{1}{3q^{2a}} + \frac{2}{q^{2a}} \Re \left(\sum_{\substack{u,v=0 \\ v \ge u}}^{q-1} \frac{(v-u)\mathrm{wal}_{\kappa_{a-1}}\left(\frac{u \ominus_\varphi v}{q}\right)}{q} \right),$$

where $\Re$ is the real part function.

Proof. First we remark that

$$\int_{u/q^a}^{(u+1)/q^a} \int_{v/q^a}^{(v+1)/q^a} |x-y|\,\mathrm{d}x\,\mathrm{d}y = \begin{cases} 1/(3q^{3a}) & \text{if } u = v, \\ |v-u|/(q^{3a}) & \text{otherwise.} \end{cases}$$

In the same way as in [3, Appendix A], we partition the unit square into subsquares where the Walsh function is constant and get

$$\tau(k) = \sum_{u,v=0}^{q^a-1} \mathrm{wal}_k\left(\frac{u \ominus_\varphi v}{q^a}\right) \int_{u/q^a}^{(u+1)/q^a} \int_{v/q^a}^{(v+1)/q^a} |x-y|\,\mathrm{d}x\,\mathrm{d}y$$
$$= \frac{1}{3q^{2a}} + \frac{1}{q^{3a}} \sum_{\substack{u,v=0 \\ v>u}}^{q^a-1} (v-u) \left(\mathrm{wal}_k\left(\frac{u \ominus_\varphi v}{q^a}\right) + \overline{\mathrm{wal}_k\left(\frac{u \ominus_\varphi v}{q^a}\right)} \right)$$
$$= \frac{1}{3q^{2a}} + \frac{2}{q^{3a}} \Re \left(\sum_{\substack{u,v=0 \\ v>u}}^{q^a-1} (v-u)\mathrm{wal}_k\left(\frac{u \ominus_\varphi v}{q^a}\right) \right). \tag{A.1}$$

Let

$$0 \le u = qu' + u_0 < v = qv' + v_0 < q^a, \qquad v' > u', \qquad 0 \le u_0, v_0 < q.$$

Since $|\mathrm{wal}_k((u' \ominus_\varphi v')/q^{a-1})| = 1$ and $\sum_{u_0,v_0}(v'-u')\mathrm{wal}_{\kappa_{a-1}}((u_0 \ominus_\varphi v_0)/q) = 0$, we have

$$\left| \sum_{u_0,v_0=0}^{q-1} ((qv'+v_0) - (qu'+u_0))\mathrm{wal}_k\left(\frac{(qu'+u_0) \ominus_\varphi (qv'+v_0)}{q^a}\right) \right| = \left| \sum_{u_0,v_0=0}^{q-1} T_{\kappa_{a-1}}(u_0,v_0) \right|,$$

where $T_\kappa(u,v) := (v-u)\mathrm{wal}_\kappa((u \ominus_\varphi v)/q)$. By the character properties of the Walsh function system

$$\sum_{u_0,v_0=0}^{q-1} T_{\kappa_{a-1}}(u_0,v_0) = \sum_{u_0,v_0=0}^{q-1} (v_0-u_0)\mathrm{wal}_{\kappa_{a-1}}\left(\frac{u_0 \ominus_\varphi v_0}{q}\right) \tag{A.2}$$
$$= \sum_{v_0=0}^{q-1} v_0 \overline{\mathrm{wal}}_{\kappa_{a-1}}\left(\frac{v_0}{q}\right) \sum_{u_0=0}^{q-1} \mathrm{wal}_{\kappa_{a-1}}\left(\frac{u_0}{q}\right) - \sum_{u_0=0}^{q-1} u_0 \mathrm{wal}_{\kappa_{a-1}}\left(\frac{u_0}{q}\right) \sum_{v_0=0}^{q-1} \overline{\mathrm{wal}}_{\kappa_{a-1}}\left(\frac{v_0}{q}\right) = 0.$$

So the only (u,v) left in the sum (A.1) are $(qu'+u_0, qu'+v_0)$ for $0 \le u' < q^{a-1}$. In

this case the summands in the sum of (A.1) equal $T_{\kappa_{a-1}}(u_0, v_0)$ for fixed u', we get

$$\begin{aligned}\tau(k) &= \frac{1}{3q^{2a}} + \frac{2}{q^{3a}}\Re\left(\sum_{u'=0}^{q^{a-1}-1}\sum_{\substack{u_0,v_0=0\\ v_0>u_0}}^{q-1} T_{\kappa_{a-1}}(u_0,v_0)\right)\\ &= \frac{1}{3q^{2a}} + \frac{2}{q^{2a+1}}\Re\left(\sum_{\substack{u_0,v_0=0\\ v_0\geq u_0}}^{q-1}(v_0-u_0)\mathrm{wal}_{\kappa_{a-1}}\left(\frac{u_0\ominus_\varphi v_0}{q}\right)\right),\end{aligned}$$

as claimed. (Note the difference from (A.2) in the summation range of v_0.) ∎

Now define

$$\widehat{r}_q(w,\gamma,k) := \begin{cases} 1+\gamma(w^2-w+\frac{1}{3}) & \text{if } k=0,\\ -\frac{\gamma}{2}\left(\frac{1}{3q^{2a}} + \frac{2}{q^{2a}}\Re\left(\sum\limits_{\substack{u,v=0\\ v\geq u}}^{q-1}\frac{(v-u)\mathrm{wal}_{\kappa_{a-1}}\left(\frac{u\ominus_\varphi v}{q}\right)}{q}\right)\right) & \text{if } k>0,\end{cases}$$

and for $\boldsymbol{w}=(w_1,\dots,w_s)$, $\boldsymbol{k}=(k_1,\dots,k_s)$ and $\boldsymbol{\gamma}=(\gamma_1,\gamma_2,\dots)$ define

$$\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{k}) := \prod_{j=1}^{s}\widehat{r}_q(w_j,\gamma_j,k_j).$$

Then we obtain the following theorem.

THEOREM A.2. *The digital shift invariant kernel for the reproducing kernel $K_{\mathrm{sob},s,\boldsymbol{w},\boldsymbol{\gamma}}(\boldsymbol{x},\boldsymbol{y})$, where the digital shift is taken in prime-power base q and with respect to the bijection φ, is given by*

$$K_{\mathrm{ds},q,\boldsymbol{\gamma},\boldsymbol{w},\varphi}(\boldsymbol{x},\boldsymbol{y}) = \sum_{\boldsymbol{k}\in\mathbb{N}_0^s}\widehat{r}_q(\boldsymbol{w},\boldsymbol{\gamma},\boldsymbol{k})\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})\overline{\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{y})}.$$

Appendix B. Some other useful results. Here we prove two results which are used in section 3.

LEMMA B.1. *With $T_\kappa(u,v) := (v-u)\mathrm{wal}_\kappa((u\ominus_\varphi v)/q)$, for $l\in\{0,\dots,q-1\}$ we have*

$$\sum_{\kappa=1}^{q-1}\sum_{\substack{u,v=0\\ v\geq u}}^{q-1}\mathrm{wal}_\kappa\left(\frac{l}{q}\right)T_\kappa(u,v) = q\left(\frac{1-q^2}{6} + \sum_{\substack{u=0,\\ u<u\oplus_\varphi l}}^{q-1}(u\oplus_\varphi l) - u\right)$$

and

$$\sum_{\kappa=1}^{q-1}\sum_{\substack{u,v=0\\ v\geq u}}^{q-1}\mathrm{wal}_\kappa\left(\frac{l}{q}\right)\overline{T_\kappa(u,v)} = q\left(\frac{1-q^2}{6} + \sum_{\substack{u=0,\\ u<u\ominus_\varphi l}}^{q-1}(u\ominus_\varphi l) - u\right).$$

Proof. For the first sum we have

$$\sum_{\kappa=1}^{q-1}\sum_{\substack{u,v=0\\ v\geq u}}^{q-1}(v-u)\mathrm{wal}_\kappa\left(\frac{l\oplus_\varphi u\ominus_\varphi v}{q}\right) = \sum_{\substack{u,v=0\\ v\geq u}}^{q-1}(v-u)\sum_{\kappa=1}^{q-1}\mathrm{wal}_\kappa\left(\frac{l\oplus_\varphi u\ominus_\varphi v}{q}\right),$$

where the right sum can be simplified such that the last line is equal to

$$\begin{aligned}
&\sum_{\substack{u,v=0\\ v\ge u}}^{q-1}(v-u)\times\begin{cases}q-1 & \text{if } v=u\oplus_\varphi l,\\ -1 & \text{else,}\end{cases}\\
=&\sum_{u=0}^{q-1}\sum_{v=u}^{q-1}-(v-u)+q\sum_{\substack{u,v=0\\ v\ge u, v=u\oplus_\varphi l}}^{q-1}(v-u)=\sum_{d=0}^{q-1}-(q-d)d+q\sum_{\substack{u=0\\ u<u\oplus_\varphi l}}^{q-1}((u\oplus_\varphi l)-u)\\
=&q\left(\frac{-(q^2-1)}{6}+\sum_{\substack{u=0\\ u<u\oplus_\varphi l}}^{q-1}((u\oplus_\varphi l)-u)\right).
\end{aligned}$$

The second part follows from the first by

$$\begin{aligned}
&\sum_{\kappa=1}^{q-1}\sum_{\substack{u,v=0\\ v\ge u}}^{q-1}\mathrm{wal}_\kappa\left(\frac{l}{q}\right)\overline{T_\kappa\Big(u,v\Big)}\\
=&\overline{\sum_{\kappa=1}^{q-1}\sum_{\substack{u,v=0\\ v\ge u}}^{q-1}\overline{\mathrm{wal}_\kappa\left(\frac{l}{q}\right)}T_\kappa\Big(u,v\Big)}=\overline{\sum_{\kappa=1}^{q-1}\sum_{\substack{u,v=0\\ v\ge u}}^{q-1}\mathrm{wal}_\kappa\left(\frac{\ominus_\varphi l}{q}\right)T_\kappa\Big(u,v\Big)},
\end{aligned}$$

which finishes the proof. □

The next lemma was used in section 3 to give an explicit computable representation of the shift invariant kernel $K_{\mathrm{ds},q,\boldsymbol{\gamma},\boldsymbol{w},\varphi}$.

LEMMA B.2. *If $x\neq y$,*

$$\begin{aligned}
&\sum_{k=1}^{\infty}\frac{-\tau(k)}{2}\mathrm{wal}_k(x)\overline{\mathrm{wal}_k(y)}=\frac{1}{6}-\frac{1}{2q^{i_0+1}}\\
&\times\left(\sum_{\substack{u=0,\\ u<u\oplus_\varphi x_{i_0}\ominus_\varphi y_{i_0}}}^{q-1}(u\oplus_\varphi x_{i_0}\ominus_\varphi y_{i_0}-u)+\sum_{\substack{u=0,\\ u<u\oplus_\varphi y_{i_0}\ominus_\varphi x_{i_0}}}^{q-1}(u\oplus_\varphi y_{i_0}\ominus_\varphi x_{i_0}-u)\right)
\end{aligned}$$

with x_{i_0}, y_{i_0} denoting the i_0th fractional q-adic digits of x and y, where i_0 is the smallest index such that the digits differ. For $x=y$ the sum is equal to $1/6$. (Note that for $k>0$ we have $\widehat{r}_q(w,\gamma,k)=-\frac{\gamma}{2}\tau(k)$.)

Proof. Let $D_{a,\kappa}$ denote $D_{a,\kappa}=\sum_{k=\kappa q^{a-1}+\dots}\mathrm{wal}_k$, where the sum ranges over all k with the leading term κq^{a-1} in the q-adic expansion. By the character properties of the Walsh function set we have

$$D_{a,\kappa}=\mathrm{wal}_{\kappa q^{a-1}}\sum_{0\le k<q^{a-1}}\mathrm{wal}_k=\mathrm{wal}_{\kappa q^{a-1}}\cdot q^{a-1}\cdot 1_{[0,q^{-(a-1)})}.$$

First, let $x\neq y$, $i_0=\max(\{i: x_j=y_j \text{ for all } j=0,\dots,i\ge 0\})+1$, where x_i,y_i are the q-adic digits of x and y. Then, with $T_\kappa(u,v)=(v-u)\mathrm{wal}_\kappa((u\ominus_\varphi v)/q)$ as above,

and since $\tau(k)$ depends only on the q-adic length a and most significant digit κ,

$$\begin{aligned}
&\sum_{k=1}^{\infty} \frac{-\tau(k)}{2} \mathrm{wal}_k(x)\overline{\mathrm{wal}_k(y)} = \sum_{a=1}^{\infty}\sum_{\kappa=1}^{q-1} \frac{-\tau(\kappa q^{a-1})}{2} D_{a,\kappa}(x \ominus_\varphi y)\\
&= \sum_{a=1}^{\infty}\sum_{\kappa=1}^{q-1} \frac{1}{q^{2a}} \Re\left(\frac{-1}{q}\sum_{\substack{u,v=0,\\ v\geq u}}^{q-1} T_\kappa(u,v) - \frac{1}{6}\right) D_{a,\kappa}(x \ominus_\varphi y)\\
&= \sum_{a=1}^{i_0-1}\sum_{\kappa=1}^{q-1} \frac{1}{q^{2a}} \Re\left(\frac{-1}{q}\sum_{\substack{u,v=0,\\ v\geq u}}^{q-1} T_\kappa(u,v) - \frac{1}{6}\right) D_{a,\kappa}(x \ominus_\varphi y)\\
&\quad + \sum_{\kappa=1}^{q-1} \frac{1}{q^{2i_0}} \Re\left(\frac{-1}{q}\sum_{\substack{u,v=0,\\ v\geq u}}^{q-1} T_\kappa(u,v) - \frac{1}{6}\right) D_{i_0,\kappa}(x \ominus_\varphi y)\\
&= \sum_{a=1}^{i_0-1}\sum_{\kappa=1}^{q-1} \frac{1}{q^{a+1}} \Re\left(\frac{-1}{q}\sum_{\substack{u,v=0,\\ v\geq u}}^{q-1} T_\kappa(u,v) - \frac{1}{6}\right)\\
&\quad + \sum_{\kappa=1}^{q-1} \frac{1}{2q^{i_0+1}} \left(\frac{-1}{q}\sum_{\substack{u,v=0,\\ v\geq u}}^{q-1} \mathrm{wal}_{\kappa q^{i_0-1}}(x \ominus_\varphi y) T_\kappa(u,v) - \frac{\mathrm{wal}_{\kappa q^{i_0-1}}(x \ominus_\varphi y)}{6}\right)\\
&\quad + \sum_{\kappa=1}^{q-1} \frac{1}{2q^{i_0+1}} \left(\frac{-1}{q}\sum_{\substack{u,v=0,\\ v\geq u}}^{q-1} \mathrm{wal}_{\kappa q^{i_0-1}}(x \ominus_\varphi y) \overline{T_\kappa(u,v)} - \frac{\mathrm{wal}_{\kappa q^{i_0-1}}(x \ominus_\varphi y)}{6}\right)\\
&= \sum_{a=1}^{i_0-1} \frac{1}{q^{a+1}} \left(\frac{q^2-1}{6} - \frac{q-1}{6}\right) + \frac{1}{2q^{i_0+1}} \left(2 \cdot \frac{q^2-1}{6}\right.\\
&\quad \left. - \left(\sum_{\substack{u=0,\\ u<u\oplus_\varphi x_{i_0}\ominus_\varphi y_{i_0}}}^{q-1} (u \oplus_\varphi x_{i_0} \ominus_\varphi y_{i_0} - u) + \sum_{\substack{u=0,\\ u<u\oplus_\varphi y_{i_0}\ominus_\varphi x_{i_0}}}^{q-1} (u \oplus_\varphi y_{i_0} \ominus_\varphi x_{i_0} - u)\right) - 2 \cdot \frac{-1}{6}\right)\\
&= \frac{1}{6} - \frac{1}{2q^{i_0+1}} \left(\sum_{\substack{u=0,\\ u<u\oplus_\varphi x_{i_0}\ominus_\varphi y_{i_0}}}^{q-1} (u \oplus_\varphi x_{i_0} \ominus_\varphi y_{i_0} - u) + \sum_{\substack{u=0,\\ u<u\oplus_\varphi y_{i_0}\ominus_\varphi x_{i_0}}}^{q-1} (u \oplus_\varphi y_{i_0} \ominus_\varphi x_{i_0} - u)\right)
\end{aligned}$$

by Lemma B.1.

If $x = y$, it is easy to see (e.g., by letting $i_0 \to \infty$ in the above term) that the second term vanishes. □

DISCRETE INGHAM INEQUALITIES AND APPLICATIONS*

MIHAELA NEGREANU† AND ENRIQUE ZUAZUA‡

Abstract. In this paper we prove a discrete version of the classical Ingham inequality for nonharmonic Fourier series whose exponents satisfy a gap condition. Time integrals are replaced by discrete sums on a discrete mesh. We prove that, as the mesh becomes finer and finer, the limit of the discrete Ingham inequality is the classical continuous one. This analysis is partially motivated by control-theoretical issues. As an application we analyze the control/observation properties of numerical approximation schemes of the 1-d wave equation. The discrete Ingham inequality provides observability and controllability results which are uniform with respect to the mesh-size in suitable classes of numerical solutions in which the high frequency components have been filtered. We also discuss the optimality of these results in connection with the dispersion diagrams of the numerical schemes.

Key words. wave equation, numerical approximation schemes, nonharmonic analysis, discrete Fourier transform, Ingham inequalities, observability, controllability, dispersion, group velocity

1. Introduction.

Families of "nonharmonic" exponentials $\left\{e^{i\lambda_k t}\right\}$ appear in various fields of mathematics and signal processing. One of the central problems arising in all of these applications is the question of the Riesz basis property.

The following inequality for nonharmonic Fourier series due to Ingham is well known (see [9] and [26, p. 162]): *Assume that the strictly increasing sequence* $\{\lambda_k\}_{k\in\mathbb{Z}}$ *of real numbers satisfies the "gap" condition*

$$\lambda_{k+1} - \lambda_k \geq \gamma \quad \text{for all } k \in \mathbb{Z}, \tag{1.1}$$

for some $\gamma > 0$. *Then, for all* $T > 2\pi/\gamma$ *there exist two positive constants* C_1, C_2 *depending only on* γ *and* T *such that*

$$C_1(T,\gamma) \sum_{k=-\infty}^{\infty} |a_k|^2 \leq \int_0^T \left| \sum_{k=-\infty}^{\infty} a_k e^{it\lambda_k} \right|^2 dt \leq C_2(T,\gamma) \sum_{k=-\infty}^{\infty} |a_k|^2, \tag{1.2}$$

for every complex sequence $(a_k)_{k\in\mathbb{Z}} \in \ell^2$, *where*

$$C_1(T,\gamma) = \frac{2T}{\pi}\left(1 - \frac{4\pi^2}{T^2\gamma^2}\right) > 0, \tag{1.3}$$

$$C_2(T,\gamma) = \frac{8T}{\pi}\left(1 + \frac{4\pi^2}{T^2\gamma^2}\right) > 0, \tag{1.4}$$

and ℓ^2 is the Hilbert space of square summable sequences,

$$\ell^2 = \left\{ \{a_k\} \ : \ \|a_k\|_{\ell^2}^2 = \sum_{k\in\mathbb{N}} |a_k|^2 < \infty \right\}. \tag{1.5}$$

This result shows that the sequence of exponentials $\left\{e^{i\lambda_k t}\right\}$ forms a Riesz basis of its span for $T > 2\pi/\gamma$ (see [26, Chapter 3, p. 112]).

As we have mentioned above, one of the main applications of Ingham's inequality and its variants is the control of wave-like equations and other closely related problems like observability or inverse problems. The problem of observability for wave equations consists of analyzing whether the energy of the waves propagating in a domain with suitable boundary conditions can be estimated in terms of the energy concentrated on a given subregion of the domain (or its boundary) where propagation occurs in a given time interval. On the other hand, the goal in controllability problems is to drive the solutions of a given dynamical system (continuous or discrete) to a given state at a given final time by means of a control acting on the system on that subregion (or its boundary). It is well known that the two problems are equivalent provided one chooses an appropriate functional setting, which depends on the equation (see, for instance, [17]).

In the context of partial differential equations, using the Fourier representation of the solutions, the problem of observability can be reduced to an application of Ingham's inequality in which the sequence $\{\lambda_k\}$ is constituted by the spectrum of the generator of the underlying semigroup. However, the gap condition (1.1) that is required to apply Ingham's inequality often limits the range of applicability of this technique to 1-d problems like strings and beams. This has led to a significant number of controllability results (see [15]) and also to far reaching generalizations of the Ingham theorem under weakened gap conditions (see [2], [4], [5], [8], [12], [13]). The most complete result in this direction has been obtained independently by Baiocchi, Komornik, and Loreti in [2], [3], [4], and Avdonin and Moran in [1].

In the numerical analysis of those observability inequalities and for studying the controllability properties of numerical schemes the need of a discrete version of this inequality arises naturally (see [7], [19], [20], [21]). This paper is devoted to proving a discrete version of that Ingham inequality.

The inequality we prove is uniform with respect to the mesh-size Δt in the time-discretization and, in the limit as $\Delta t \to 0$, yields the classical Ingham inequality above.

The discrete Ingham inequality we prove is the natural tool to prove observability/controllability properties for fully discrete schemes for the approximation of the 1-d wave equation and other closely related models (vibrating beams, Schrödinger equation, etc.) and to show that the controls of the limiting continuous model are the limit of the controls of the full discrete schemes. However, it is important to recall that, as it is by now well known [28], numerical approximation schemes often introduce spurious high frequency solutions that may be an obstacle for uniform (with respect to the mesh-size) observability/controllability results. Thus, one often needs to filter or cut-off those spurious numerical solutions. Our generalization of Ingham's inequality to the discrete context explains how this filtering has to be done in order to guarantee uniform results.

As an example of application of our discrete Ingham inequality we perform the analysis of the observability/controllability properties of the most standard centered fully discrete schemes for the wave equation.

The main reason for the lack of uniform observability/controllability of the numerical high frequency spurious solutions, is that they generate high frequency wave packets for which the group velocity is of the order of the mesh-size ([28]). Thus, as the mesh-size tends to zero, since the velocity becomes smaller and smaller, the time for observability/controllability increasing in a divergent way. This fact is related to the dispersion diagram associated to the numerical approximation scheme, since, roughly, the slope of the dispersion diagram is the group velocity of propagation of wave packets and also coincides with the spectral gap. Part of this article is devoted to explaining the connections of these notions and to show how combining the qualitative information that the dispersion diagram provides with the discrete Ingham inequality, one can get precise information on how the filtering should be implemented, if needed.

As proved in the original article by Ingham (see [9, p. 368]), an L^1-version of inequality (1.2) also holds. More precisely, for every increasing sequence $\{\lambda_k\}_{k\in\mathbb{Z}}$ of real numbers satisfying the "gap" condition (1.1) we also have

$$C_1(T,\gamma)\,|a_k| \le \int_0^T \left| \sum_{k=-\infty}^{\infty} a_k e^{it\lambda_k} \right| dt \le C_2(T,\gamma)\,|a_k| \quad \text{for all } k \in \mathbb{Z} \tag{1.6}$$

for all $T > 2\pi/\gamma$.

In this paper we also prove a discrete version of this inequality.

Our proofs are strongly inspired in that by Ingham (see also [26]), which is based on the use of a suitable cut-off, nonnegative function, with compact support on the time interval $(0,T)$ and whose Fourier transform is "concentrated" around $\tau = 0$. We use the same function in the physical space, but its Fourier transform has to be replaced by the discrete one. One of the key points in the proof is a careful comparison between the continuous and discrete transforms of this weight function. This is done by using a key result by N. Trefethen [23].

This paper is organized as follows: in section 2 we state our discrete Ingham inequality (see Theorem 2.1), we analyze the necessity of its hypotheses and compare both the continuous and discrete inequalities. We also formulate a discrete version of the L^1 analogue (1.6) (see Theorem 2.2). In section 3 we discuss the application of this result to the study of the properties of the solutions of fully discrete approximations of the wave equation. In section 4 the controllability problem for the discrete system is addressed and the main results of existence, characterization, and convergence of the discrete controls are presented and proved. In section 5 we discuss these results in connection with the dispersion diagrams of the discrete equations under consideration. Finally, section 6 is devoted to proving the discrete Ingham inequality and its discrete L^1 version.

The discrete Ingham inequality we present in this paper has been announced in [21].

2. Main results. The main result of this paper is as follows.

THEOREM 2.1 (discrete Ingham inequality). *Let $\{\lambda_k\}_{k\in\mathbb{Z}}$ be an increasing sequence of real numbers satisfying for some $\gamma > 0$ the "gap" condition*

$$\lambda_{k+1} - \lambda_k \ge \gamma > 0 \quad \text{for all } k \in \mathbb{Z}. \tag{2.1}$$

Let $T > 0$ and $0 < \Delta t \le 1$. Assume that $\{\lambda_k\}_{|k|\le N}$ satisfies the additional condition

$$|\lambda_k - \lambda_l| \le \frac{2\pi - (\Delta t)^p}{\Delta t} \quad \text{for all } |k| \le N,\ |l| \le N, \text{ for some } 0 \le p < 1/2, \tag{2.2}$$

where $2N \leq M$ *and* $M = [T/\Delta t - 1]$. *Then, there exists a positive number* $\epsilon(\Delta t)$ *such that, for all* $T > T_0(\Delta t) := 2\pi/\gamma + \epsilon(\Delta t)$, *there exist two positive constants* $C_j(\Delta t, T, \gamma) > 0$, $j = 1, 2$, *such that*

(2.3)
$$C_1(\Delta t, T, \gamma) \sum_{k=-N}^{N} |a_k|^2 \leq \Delta t \sum_{n=0}^{M} \left| \sum_{k=-N}^{N} a_k e^{in\Delta t\lambda_k} \right|^2 \leq C_2(\Delta t, T, \gamma) \sum_{k=-N}^{N} |a_k|^2,$$

for every complex sequence $(a_k)_{k\in\mathbb{Z}} \in \ell^2$.

Moreover, if γ *and* p *in* (2.1) *and* (2.2) *are kept fixed, then* $\epsilon(\Delta t) = o(\Delta t)^{1-2p}$ *and the constants in* (2.3) *satisfy*

(2.4)
$$C_j(\Delta t, T, \gamma) = C_j(T, \gamma) + \delta_j(\Delta t), \quad j = 1, 2, \quad \text{with } \delta_1(\Delta t) \leq 0 \text{ and } \delta_2(\Delta t) \geq 0,$$

where $C_j(T, \gamma)$, $j = 1, 2$, *are the Ingham constants in* (1.3) *and* (1.4) *and* $\lim_{\Delta t\to 0} \delta_j(\Delta t) = 0$, $j = 1, 2$.

Concerning the L^1-version of Ingham inequality in (1.6), the following theorem holds.

THEOREM 2.2. *Under the hypotheses of Theorem* 2.1 *we also have the following discrete version of* (1.6):

(2.5)
$$C_1(\Delta t, T, \gamma)\,|a_k| \leq \Delta t \sum_{n=0}^{M} \left| \sum_{k=-N}^{N} a_k e^{in\Delta t\lambda_k} \right| \leq C_2(\Delta t, T, \gamma)\,|a_k| \quad \text{for all } |k| \leq N.$$

As in Theorem 2.1, *the time* T *and the constants in this inequality remain uniform as* $\Delta t \to 0$ *and converge to those of the continuous Ingham inequality* (1.6).

Remark 2.3. Condition $T > 2\pi/\gamma$ is optimal for the classical Ingham inequality (see [26, p. 163]). In this sense, the condition $T > 2\pi/\gamma + \epsilon(\Delta t)$ in Theorem 2.1 is asymptotically optimal since $\epsilon(\Delta t) \to 0$ as $\Delta t \to 0$.

It is important to emphasize that the time T and the constants C_j, $j = 1, 2$ in (2.3) are uniform in Δt. This is essential for the applications in numerical analysis in which $\Delta t \to 0$. The uniformity may be guaranteed because of the assumptions (2.1)–(2.2) on the sequence $\{\lambda_k\}_k$.

More precisely, when comparing the continuous and discrete inequalities, the following can be said:

- In both continuous and discrete cases, the sequence $\{\lambda_k\}_k$ is required to satisfy the so-called *gap condition* (2.1).
- The restriction (2.2) imposed on $\{\lambda_k\}_k$ in Theorem 2.1 is not needed in the classical continuous Ingham inequality (1.2).
- It is easy to see that, for every $N \in \mathbb{N}$ fixed, if we pass to the limit $\Delta t \to 0$ in (2.3), we get the classical Ingham inequality (1.2). Indeed, for (1.2) to be true for all sequences $(a_k)_{k\in\mathbb{Z}} \in \ell^2$ it is sufficient, by density, to prove it for sequences with only a finite number of nonzero components.
  In that case (1.2) is the limit of (2.3) because of the convergence of the minimal time T and the constants C_j, $j = 1, 2$, in (2.3) to those of (1.2).
  We also have a discrete Ingham inequality (2.3) for every sequence $(\lambda_k)_k$ verifying conditions (2.1) and (2.2), with $0 \leq p \leq 1$. But, if $p \geq 1/2$,

$\varepsilon(\Delta t) = o(\Delta t)^{1-2p} \to \infty$, so $T_0(\Delta t) \to \infty$, and this makes it of little use in practice because we are looking for a uniform (with respect to Δt) time T.

On the other hand, the restriction $2N \leq M$, with $M = [T/\Delta t - 1]$, is sharp. Indeed, when $2N > M$ one can find nontrivial values of the coefficients $\{a_k\}_k$ such that

$$\sum_{k=-N}^{N} a_k e^{in\Delta t\lambda_k} = 0, \quad 0 \leq n \leq M \tag{2.6}$$

and

$$\sum_{k=-N}^{N} |a_k|^2 \neq 0. \tag{2.7}$$

Observe that (2.6) is a system of $M+1$ homogeneous linear equations with $2N+1$ unknown quantities a_k. If $2N > M$, this system necessarily has nontrivial solutions. This is in agreement with common sense. Indeed, in view of the fact that we only make $M+1$ measurements for $n = 0, \ldots, M$ one cannot expect to recover more than $M+1$ coefficients of the solution.

When $2N \leq M$, (2.6)–(2.7) do not hold. However if $\lambda_k - \lambda_l \in 2\pi\mathbb{Z}/\Delta t$ for certain values of k and l with $k \neq l$ the sequence $a_k = -a_l = 1$, $a_n = 0$, $n \neq k$, and l satisfies (2.6). Then, an inequality of type (2.3) is impossible. So, it is natural to impose on the sequence $\{\lambda_k\}_k$ the condition $\lambda_k - \lambda_l \notin 2\pi\mathbb{Z}/\Delta t$ for a discrete Ingham inequality (2.3) to hold.

In fact, to avoid *aliasing* one has to restrict the increasing sequence of real numbers $\{\lambda_k\}_k$ to be such that $\lambda_k - \lambda_l \in [2\pi m/\Delta t, 2\pi(m+1)/\Delta t]$, for some $m \in \mathbb{Z}$. Therefore, it is natural to impose the condition

$$|\lambda_k - \lambda_l| < \frac{2\pi}{\Delta t}.$$

In our theorem this latter condition is implied by the stronger one, (2.2), which is needed for the uniform estimates in (2.3) to hold. More precisely, the restriction $0 \leq p < 1/2$ in (2.2) is needed to guarantee the asymptotically optimal time $T > 2\pi/\gamma + \epsilon(\Delta t)$, with $\epsilon(\Delta t) \to 0$ as $\Delta t \to 0$ since $\epsilon(\Delta t) = o(\Delta t)^{1-2p}$.

Remark 2.4. The condition $T > T_0(\Delta t)$ is necessary for the proof of the first inequality in (2.3) and in (1.6) (to have $C_1(\Delta t, T, \gamma) > 0$). The second inequality in (2.3) and (1.6), respectively, holds for all $T > 0$. In this respect the situation is the same as for the continuous inequalities (1.2).

3. Application to the uniform observability of the full discretizations of the 1-d wave equation.

3.1. The wave equation. This section is motivated by the classical problem of control of waves. More precisely, it is related with the controllability of the 1-d wave equation: given $T > 0$ and $(u^0, u^1) \in L^2(0,1) \times H^{-1}(0,1)$, the problem is to find a control function $v \in L^2(0,T)$ such that the solution of the system

$$\begin{cases} u_{tt} - u_{xx} = 0, & 0 < x < 1, \quad 0 < t < T, \\ u(0,t) = 0, \quad u(1,t) = v(t), & 0 < t < T, \\ u(x,0) = u^0(x), \qquad u_t(x,0) = u^1(x), & 0 < x < 1, \end{cases} \tag{3.1}$$

satisfies

$$u(T) = u_t(T) = 0, \qquad 0 < x < 1. \tag{3.2}$$

This property is well known to be true for $T \geq 2$. This problem has been studied and solved in a much more general setting and, in particular, for multidimensional wave equations [17]. Several approaches to the problem have been developed. In particular, the Hilbert uniqueness method (HUM) introduced by Lions in [17] offers a general way of reducing the problem to the so-called *observability problem* for the adjoint (up to an inversion in time) wave equation in the absence of control:

$$\begin{cases} \phi_{tt} - \phi_{xx} = 0, & 0 < x < 1, \quad 0 < t < T, \\ \phi(0,t) = \phi(1,t) = 0, & 0 < t < T, \\ \phi(x,0) = \phi^0(x), \qquad \phi_t(x,0) = \phi^1(x), & 0 < x < 1. \end{cases} \tag{3.3}$$

It is well known that the energy

$$E(t) = \frac{1}{2} \int_0^1 \left(\mid \phi_x(x,t) \mid^2 + \mid \phi_t(x,t) \mid^2 \right) dx \tag{3.4}$$

of the solutions of (3.3) satisfies

$$\frac{dE(t)}{dt} = E'(t) = 0 \quad \text{for all } t \in [0,T]$$

and therefore is conserved in time.

The observability problem is as follows: *To find $T > 0$ such that there exists a constant $C(T) > 0$ for which*

$$E(0) \leq C(T) \int_0^T \mid \phi_x(1,t) \mid^2 dt \tag{3.5}$$

holds for every solution of (3.3).

HUM allows showing that, once the observability inequality (3.5) is satisfied for the adjoint system (3.3), system (3.1) is controllable in time T. Moreover, HUM provides a systematic method to build the control $v = \phi_x(1,t)$ of minimal $L^2(0,T)$-norm.

In the context of the 1-d wave equation (3.3), inequality (3.5) can be easily proved by several methods including *Fourier series, D'Alembert Formula*, *multiplier techniques*, and *Ingham's theorem* (1.2), provided $T \geq 2$.

In order to solve the problem (3.5) applying the classical Ingham inequality, one uses Fourier series techniques. Indeed, the solution of (3.3) admits the Fourier development

$$\phi(x,t) = \sum_{k \in \mathbb{Z} \setminus \{0\}} a_k e^{i\lambda_k t} \varphi_k(x), \tag{3.6}$$

with $\{\lambda_k\}_k$, $\lambda_k = k\pi = -\lambda_{-k}$, $k > 0$, being the sequence of eigenvalues of the system, $\varphi_k(x) = \sin(k\pi x)$, the corresponding eigenfunctions and $a_k \in \mathbb{C}$ the Fourier coefficients, which can be computed explicitly in terms of the initial data in (3.3).

By definition (3.4) of the conserved energy of the solution ϕ of (3.3) given by (3.6), we have

$$E_\phi = \frac{1}{2} \sum_{k \in \mathbb{Z} \setminus \{0\}} k^2 \pi^2 \left| a_k \right|^2. \tag{3.7}$$

On the other hand, in view of the explicit form of $\phi_x(1,t)$, inequality (3.5) may be written as:

$$\sum_{k\in\mathbb{Z}\setminus\{0\}} k^2\pi^2 \left|a_k\right|^2 \leq C(T)\int_0^T \left|\sum_{k\in\mathbb{Z}\setminus\{0\}} (-1)^k k\pi a_k e^{i\lambda_k t}\right|^2 dt. \tag{3.8}$$

According to Ingham's inequality (1.2), (3.8) holds for $T > 2$, since the gap of the sequence $\{\lambda_k\}_k$ is constant, $\gamma = \pi$, and, consequently, the minimal observability time is $2\pi/\gamma = 2$. In this particular case the inequality holds also for the minimal time $T = 2$. This is due to the orthogonality properties of the trigonometric polynomials. But, in general, i.e., for a general sequence $(\lambda_k)_{k\in\mathbb{Z}}$ satisfying the gap condition (1.1), it is well known that the Ingham inequality (1.2) may fail for the minimal time $T = 2\pi/\gamma$ (see [26, p. 163]).

In order to obtain numerical approximations of the controls, it is natural to analyze the controllability and observability properties of numerical approximation schemes. We first recall some well-known facts about the space semi-discretization schemes to later address space-time discretizations.

3.2. Space semi-discretizations. First, we consider the semi-discrete version of the observability problem (3.5): Take $N \in \mathbb{N}$, set $h = 1/(N+1)$ and consider the finite-difference space semi-discretization of (3.3):

$$\begin{cases} \phi_j'' = \dfrac{\phi_{j+1} - 2\phi_j + \phi_{j-1}}{h^2}, & t > 0, \quad j = 1,\dots,N, \\ \phi_0 = \phi_{N+1} = 0, & t > 0, \\ \phi(0) = \phi_{0,j}, \quad \phi_j'(0) = \phi_{1,j}, & j = 1,\dots,N. \end{cases} \tag{3.9}$$

The energy of system (3.9) is given by

$$E_h(t) = \frac{h}{2}\sum_{j=1}^{N} |\ \phi_j(t)\ |^2 + \frac{h}{2}\sum_{j=0}^{N} \frac{|\ \phi_{j+1}(t) - \phi_j(t)\ |^2}{h^2} \tag{3.10}$$

and it is also conserved in time.

The semi-discrete version of (3.5) is

$$E_h(0) \leq C\int_0^T \left|\frac{\phi_N(t)}{h}\right|^2 dt. \tag{3.11}$$

More precisely, one seeks for a positive constant $C > 0$ such that (3.11) holds.
The corresponding eigenvalue problem is of the form

$$\begin{cases} -[\varphi_{k+1} + \varphi_{k-1} - 2\varphi_k]/h^2 = \lambda^2\varphi_k, \quad k = 1,\dots,N, \\ \varphi_0 = \varphi_{N+1} = 0. \end{cases} \tag{3.12}$$

The eigenvalues and eigenvectors of (3.12) may be computed explicitly (see [10, p. 456]); one then has

$$\begin{cases} \lambda_k^2(h) = \dfrac{4}{h^2}\sin^2\left(\dfrac{\pi k h}{2}\right), & k = 1,\dots,N, \\ \bar\varphi_k \equiv (\varphi_{k,1},\dots,\varphi_{k,N});\ \varphi_{k,j} = \sin(k\pi j h), & j,k = 1,\dots,N. \end{cases} \tag{3.13}$$

The solutions of (3.9) in Fourier series are

$$\bar{\phi} = \sum_{k=-N, k\neq 0}^{N} a_k e^{i\lambda_k(h)t}\bar{\varphi}_k, \tag{3.14}$$

where $\bar{\phi} = (\phi_1, \dots, \phi_N)$.

As pointed out in [11], (3.11) holds for all $T > 0$ and $h > 0$, but, the observability constant in (3.11) may not remain uniformly bounded as $h \to 0$, for any $T > 0$. More precisely,

$$\sup_{\bar{\phi}\in\mathcal{S}_h}\left[\frac{E_h(0)}{\int_0^T \mid \phi_N(t)/h \mid^2 dt}\right] \to \infty, \ as \ h \to 0, \tag{3.15}$$

where $\mathcal{S}_h$ is the set of all solutions of (3.9). This is due to the pathological behavior of the high frequency numerical solutions.

In the light of Ingham's inequality (1.2), the lack of uniform observability as h tends to zero may be explained because of the lack of gap between consecutive eigenvalues (see [11], [28]). In particular, the gap between the largest eigenvalues entering in the Fourier development of the solution of (3.9) may be bounded above as follows:

$$\lambda_N(h) - \lambda_{N-1}(h) \leq \frac{3\pi^2 h}{2} \to 0, \quad \text{as} \quad h \to 0. \tag{3.16}$$

As it was proved in [11], a suitable cut-off or filtering of the spurious numerical high frequencies may be a good cure for these pathologies. Given $0 < \alpha < 1$, we introduce the following classes of filtered solution of (3.9):

$$\mathcal{C}_\alpha(h) = \left\{\bar{\phi} \text{ sol. of (3.9)} \ : \bar{\phi} = \sum_{|k|\leq \alpha N, \ k\neq 0} a_k e^{i\lambda_k t}\bar{\varphi}_k\right\}. \tag{3.17}$$

In the class $\mathcal{C}_\alpha(h)$ the high frequencies corresponding to the indexes $j > \alpha N$ have been cut-off. This guarantees a uniform gap condition

$$\lambda_{k+1}(h) - \lambda_k(h) \geq \pi \cos\left(\frac{\pi\alpha}{2}\right), \quad \text{for} \quad k \leq \alpha/h. \tag{3.18}$$

Consequently, applying Ingham's inequality, we may deduce the uniform observability in the class $\mathcal{C}_\alpha(h)$ for

$$T > T(\alpha) = 2/\cos(\pi\alpha/2). \tag{3.19}$$

Let us explain this in more detail.

By definition (3.10) of the conserved energy and taking into account the orthogonality properties of the eigenvectors (see [11], [20]), we have

$$E_h = \frac{1}{4}\sum_{k=-\alpha N, k\neq 0}^{\alpha N} |a_k|^2 \left(1 + \lambda_k^2(h)\right). \tag{3.20}$$

Then, inequality (3.11) in the class $\mathcal{C}_\alpha(h)$ may be rewritten as

$$\sum_{k=-\alpha N, k\neq 0}^{\alpha N} |a_k|^2 \left(1 + \lambda_k^2(h)\right) \leq C(T)\int_0^T \left|\sum_{k=-\alpha N, k\neq 0}^{\alpha N} \frac{\sin(Nk\pi h)}{h} a_k e^{i\lambda_k t}\right|^2 dt. \tag{3.21}$$

Applying now Ingham's theorem (1.2) for the real sequence $(\lambda_k(h))_{|k|\leq \alpha N}$, in view of (3.18), it follows that if $T > T(\alpha)$ with $T(\alpha)$ as in (3.19), there exists a constant $C > 0$ such that

$$\sum_{k=-\alpha N, k\neq 0}^{\alpha N} \left| a_k \frac{\sin(Nk\pi h)}{h} \right|^2 \leq C(T) \int_0^T \left| \sum_{k=-\alpha N, k\neq 0}^{\alpha N} \frac{\sin(Nk\pi h)}{h} a_k e^{i\lambda_k t} \right|^2 dt, \tag{3.22}$$

holds for every solution of (3.9) in the class $\mathcal{C}_\alpha(h)$. Finally, it is sufficient to observe that

$$\sum_{k=-\alpha N, k\neq 0}^{\alpha N} \left| a_k \frac{\sin(Nk\pi h)}{h} \right|^2 \sim E_h,$$

to obtain a uniform observability inequality (3.11) in each class $\mathcal{C}_\alpha(h)$ for all $0 < \alpha < 1$. Note, however, that the minimal time $T(\alpha)$ depends on the filtering parameter α and, in particular, $T(\alpha) \to 2$ as $\alpha \to 0$ and $T(\alpha) \to \infty$ as $\alpha \to 1$ (see [28] for a rigorous proof).

As a further step towards a complete theory of numerical approximations of controls it is natural to address the same issue for full space-time discretizations. This issue is addressed in the following section.

3.3. Fully discrete approximations. The main ingredient to derive the fully discrete analogue of (3.5) for a finite-difference full discretization of a homogeneous 1-d wave equation (3.3) is the Fourier representation of solutions combined, this time, with our discrete Ingham inequality in Theorem 2.1.

Given $M, N \in \mathbb{N}$ we set $\Delta x = 1/(N+1)$ and $\Delta t = T/(M+1)$ and introduce the nets

$$0 = x_0 < x_1 = \Delta x < \cdots < x_N = N\Delta x < x_{N+1} = 1,$$

$$0 = t_0 < t_1 = \Delta t < \cdots < t_M = M\Delta t < t_{M+1} = T$$

with $x_j = j\Delta x$ and $t_n = n\Delta t$, $j = 0, 1, \ldots, N+1$, $n = 0, 1, \ldots, M+1$.

We consider the following finite-difference discretization of (3.1):

$$\begin{cases} \dfrac{u_j^{n+1} - 2u_j^n + u_j^{n-1}}{(\Delta t)^2} = \dfrac{u_{j+1}^n - 2u_j^n + u_{j-1}^n}{(\Delta x)^2}, & j = 1, 2, \ldots, N;\ n = 1, 2, \ldots, M, \\ u_0^n = 0, \qquad u_{N+1}^n = v_{\Delta x}^n, & n = 1, 2, \ldots, M, \\ u_j^0 = u_{0j}, \quad u_j^1 = \Delta t u_{1j} + u_{0j}, & j = 1, 2, \ldots, N. \end{cases} \tag{3.23}$$

We shall denote by $\bar{u}^n = (u_1^n, \ldots, u_N^n)$ the solution at the time step n. As in the context of the continuous wave equation above, we consider the uncontrolled system

$$\begin{cases} \dfrac{\phi_j^{n+1} - 2\phi_j^n + \phi_j^{n-1}}{(\Delta t)^2} = \dfrac{\phi_{j+1}^n - 2\phi_j^n + \phi_{j-1}^n}{(\Delta x)^2}, & j = 1, 2, \ldots, N; \quad n = 1, 2, \ldots, M, \\ \phi_0^n = \phi_{N+1}^n = 0, & n = 1, 2, \ldots, M, \\ \phi_j^0 = \phi_{0j}, \quad \phi_j^1 = \phi_{0j} + \Delta t \phi_{1j}, & j = 1, 2, \ldots, N, \end{cases} \tag{3.24}$$

a central finite difference discretization of (3.3).

Under the stability condition $\mu = \Delta t/\Delta x \leq 1$ (μ is the Courant number), the scheme (3.24) is convergent of order 2.

However, as observed in [14], the resulting discrete sequence of controls $v^n_{\Delta x} = -\phi^n_N/\Delta x$ obtained with a discrete HUM method may have an unstable behavior as $(\Delta t, \Delta x) \to (0,0)$. More precisely, it is possible to exhibit initial conditions such that the discrete controls $v^n_{\Delta x}$ do not converge towards the control v for (3.1) (see [28]). Once more, filtering of high frequencies is an efficient cure for these instabilities and our discrete Ingham inequality is the tool to analyze how it behaves.

The energy of (3.24) is

$$E_n = \frac{\Delta x}{2}\sum_{j=0}^{N}\left[\left(\frac{\phi_j^{n+1}-\phi_j^n}{\Delta t}\right)^2 + \left(\frac{\phi_{j+1}^{n+1}-\phi_j^{n+1}}{\Delta x}\right)\left(\frac{\phi_{j+1}^n-\phi_j^n}{\Delta x}\right)\right] \geq 0, \tag{3.25}$$

which is a discretization of the continuous energy E in (3.4), and it is conserved in all the time steps $E_n = E_0$, $n = 1, \ldots, M$, for the solutions of (3.24) (see [20]).

Solutions of (3.24) admit the Fourier development (see [20])

$$\bar{\phi}^n = \sum_{k=-N, k\neq 0}^{N} a_k e^{i\lambda_k n\Delta t}\bar{\varphi}_{|k|}, \tag{3.26}$$

with $a_k \in \mathbb{C}$, $\bar{\varphi}_k = (\varphi_{k,1}, \ldots, \varphi_{k,N}) = (\sin(k\pi\Delta x), \ldots, \sin(Nk\pi\Delta x))$ and

$$\lambda_k = \operatorname{sgn}(k)\frac{2}{\Delta t}\arcsin\left(\frac{\Delta t}{\Delta x}\sin\frac{k\pi\Delta x}{2}\right). \tag{3.27}$$

Our goal is to analyze the discrete version of the observability inequality (3.5)

$$E_0 \leq C\left[\Delta t\sum_{n=0}^{M}\left|\frac{\phi_N^n}{\Delta x}\right|^2\right], \tag{3.28}$$

where E_0 is the conserved energy of the solutions of the discrete system (3.24). This inequality implies by HUM a controllability property of the discrete analogue (3.23) of the control system (3.1). Of course, we seek for a positive constant $C > 0$ in (3.28), independent on Δt and Δx. This will yield a family of controls that will be bounded as $\Delta t \to 0$, which constitutes a natural candidate to converge to the control of (3.1).

Inequality (3.28) is the discrete analogue of (3.5). In particular, note that, according to Taylor's formula $\phi_x(1,t) \sim (\phi(1,t) - \phi(1-\Delta x, t))/\Delta x$. Thus, at the discrete level and taking into account that, according to the boundary conditions, $\phi^n_{N+1} = 0$, we obtain $\phi_x(1,t) \sim -\phi^n_N/\Delta x$. Thus, the right-hand side of (3.28) represents a discrete version of the right-hand side term in the continuous observability inequality (3.5).

Inequality (3.28) may also be seen as a time-discretization of the semi-discrete observability inequality (3.11). Note that, in fact, the semi-discrete case corresponds to taking $\mu = 0$ in the fully discrete scheme.

According to Theorem 2.1, the spectral gap between two consecutive eigenvalues plays a very important role in the analysis of the uniform observability inequality (3.28).

It is important to distinguish two cases:

• In the particular case where $\Delta t = \Delta x := h$ ($\mu = 1$) we have

$$\lambda_k = \mathrm{sgn}(k)\frac{2}{h}\arcsin\left(\sin\frac{k\pi h}{2}\right) = \mathrm{sgn}(k)k\pi.$$

Thus,

$$\lambda_{k+1} - \lambda_k = \gamma = \pi.$$

But the condition (2.2) does not hold, because

$$\max_{k,l}|\lambda_k - \lambda_l| = \frac{2\pi - 2\pi\Delta t}{\Delta t}.$$

Note, however, that, in this particular case, due to the orthogonality properties of the family of complex discrete exponentials involved in the Fourier representation of solutions,

$$\sum_{n=0}^{M} e^{in\Delta t\pi(k-l)} = (M+1)\delta_{k,l},$$

where $\delta_{k,l}$ is Kronecker's delta, an inequality of type (2.3) holds immediately and the discrete Ingham inequality is not needed.

Indeed, denoting by $m_k = (-1)^k a_k \sin(k\pi\Delta x)/\Delta x$, the energy of the solutions (3.24) concentrated on the extreme $x = 1$ can be written as

$$\Delta t\sum_{n=0}^{M}\left|\frac{\phi_N}{\Delta x}\right|^2 = \Delta t\sum_{n=0}^{M}\left|\sum_{k=-N}^{N} m_k e^{in\Delta t\pi k}\right|^2 \tag{3.29}$$

and the total energy of the solutions is

$$E_0 = \frac{1}{2}\sum_{k=-N}^{N}|m_k|^2 \tag{3.30}$$

(see [20] for more details). Then, for $T = 2$ we have

$$\begin{aligned} h\sum_{n=0}^{M}\left|\frac{\phi_N}{h}\right|^2 &= h\sum_{n=0}^{M}\left|\sum_{k=-N}^{N} m_k e^{inh\pi k}\right|^2 \\ &= h\sum_{n=0}^{M}\sum_{k=-N}^{N}|m_k|^2 + h\sum_{n=0}^{M}\sum_{k=-N,k\neq l}^{N} m_k\bar{m}_l e^{inh\pi(k-l)} = 2\sum_{k=-N}^{N}|m_k|^2, \end{aligned}$$

and therefore

$$E_0 = \frac{1}{4}\left[h\sum_{n=0}^{M}\left|\frac{\phi_N^n}{h}\right|^2\right].$$

A similar identity holds for the continuous wave equation (3.3) in the minimal observability time $T = 2$. Namely

$$E = \frac{1}{4}\int_0^2 |\phi_x(1,t)|^2$$

for every solution ϕ of (3.3), where E is the energy of the solutions $\phi = \phi(x,t)$.

• In the case when $\mu < 1$ the gap between two consecutive eigenfrequencies decreases at high frequencies and it is of the order of Δx when $\Delta x \to 0$. Indeed, we have

$$
\begin{aligned}
|\lambda_{k+1} - \lambda_k| &= \left| \frac{2}{\Delta t} \left[\arcsin\left(\frac{\Delta t}{\Delta x} \sin \frac{(k+1)\pi\Delta x}{2} \right) - \arcsin\left(\frac{\Delta t}{\Delta x} \sin \frac{k\pi\Delta x}{2} \right) \right] \right| \\
&\le \left| \frac{\pi}{2} \frac{2}{\Delta t} \frac{\Delta t}{\Delta x} \left(\sin \frac{(k+1)\pi\Delta x}{2} - \sin \frac{k\pi\Delta x}{2} \right) \right| \\
&= \left| \frac{\pi}{2} \frac{2}{\Delta x} \left[\sin \frac{k\pi\Delta x}{2} \left(\cos \frac{\pi\Delta x}{2} - 1 \right) + \sin \frac{\pi\Delta x}{2} \cos \frac{k\pi\Delta x}{2} \right] \right| \\
&\le \left| \frac{\pi}{2} \frac{2}{\Delta x} \left| 1 - \cos \frac{\pi\Delta x}{2} \right| + \frac{\pi^2}{2} \cos \frac{k\pi\Delta x}{2} \right| \\
&= \left| \frac{\pi}{2} \frac{2}{\Delta x} 2 \sin^2 \frac{\pi\Delta x}{4} + \frac{\pi^2}{2} \cos \frac{k\pi\Delta x}{2} \right| \le \left| \frac{\pi^2}{2} \left[\frac{\pi\Delta x}{4} + \sin\left(\frac{((N+1)-k)\Delta x\pi}{2} \right) \right] \right|.
\end{aligned}
$$

In particular, the gap for the highest frequencies satisfies

$$
|\lambda_N - \lambda_{N-1}| \le \frac{\pi^2}{2} \left(\frac{\pi\Delta x}{4} + \frac{\pi\Delta x}{2} \right) = \frac{3\pi^3 \Delta x}{8} \to 0, \text{ when } \Delta x \to 0.
$$

So the uniform gap condition (2.1) is not satisfied and we cannot directly apply Theorem 2.1 to prove inequality (3.28). Therefore, as soon as $\mu < 1$, we are in the same situation as for the semi-discrete equation (3.9) in which $\mu = 0$: the lack of spectral gap may produce the degeneracy of the observability constant.

To remedy this lack of uniform estimates, we need to introduce a subclass of solutions of system (3.24) where the high frequency components have been filtered. To do that, given $\alpha \in (0,1)$, the so-called *filtering parameter*, we consider the class $\mathcal{C}_\alpha(\Delta x)$,

$$
\mathcal{C}_\alpha(\Delta x) = \left\{ \bar\phi^n \text{ sol. of (3.24)} \ : \bar\phi^n = \sum_{k=-\alpha N, k\neq 0}^{\alpha N} a_k e^{i\lambda_k n\Delta t} \bar\varphi_{|k|} \right\}, \tag{3.31}
$$

of solutions involving the eigenvalues $\{\lambda_k\}_{k\in[-\alpha N,\alpha N]}$, $k \neq 0$:

$$
\bar\phi^n = \sum_{k=-\alpha N, k\neq 0}^{\alpha N} a_k e^{i\lambda_k n\Delta t} \bar\varphi_{|k|}. \tag{3.32}
$$

Let us first check the gap condition. We have

$$
\begin{aligned}
\lambda_{k+1} - \lambda_k &= \frac{2}{\Delta t} \left[\arcsin\left(\frac{\Delta t}{\Delta x} \sin \frac{(k+1)\pi\Delta x}{2} \right) - \arcsin\left(\frac{\Delta t}{\Delta x} \sin \frac{k\pi\Delta x}{2} \right) \right] \\
&= \frac{\pi \cos \frac{\xi\Delta x}{2}}{\sqrt{1 - \left(\frac{\Delta t}{\Delta x} \sin \frac{\xi\Delta x}{2} \right)^2}} := \gamma_k,
\end{aligned} \tag{3.33}
$$

for every $k \in [-\alpha N, \alpha N]$ and for some $\xi \in [k\pi, (k+1)\pi]$. Therefore, in particular,

$$\lambda_{k+1} - \lambda_k \geq \frac{\pi \cos \frac{N\alpha\pi\Delta x}{2}}{\sqrt{1 - \left(\frac{\Delta t}{\Delta x} \sin \frac{\xi \Delta x}{2}\right)^2}} \geq \pi \cos \frac{N\alpha\pi\Delta x}{2} \geq \pi(1-\alpha).$$

Consequently, for any filtering parameter $\alpha \in (0,1)$, the gap condition (2.1) holds with

$$\gamma_\alpha := \min_{|k| \leq \alpha N} (\gamma_k) \geq \gamma(\alpha) = \pi \cos\left(\frac{N\alpha\pi\Delta x}{2}\right) \geq \pi(1-\alpha). \tag{3.34}$$

On the other hand, by the mean value theorem,

$$\begin{aligned} |\lambda_k - \lambda_l| &= \left| \frac{2}{\Delta t}\left(\arcsin\left(\frac{\Delta t}{\Delta x}\sin\left(\frac{k\pi\Delta x}{2}\right)\right) - \arcsin\left(\frac{\Delta t}{\Delta x}\sin\left(\frac{l\pi\Delta x}{2}\right)\right)\right)\right| \\ &= \left| \frac{2}{\Delta t} \frac{\frac{\Delta t}{\Delta x}\frac{\pi\Delta x}{2}\cos\left(\frac{\xi\pi\Delta x}{2}\right)(k-l)}{\sqrt{1 - \left(\frac{\Delta t}{\Delta x}\right)^2 \sin^2 \frac{\xi\pi\Delta x}{2}}} \right| \leq \left| \frac{2N\alpha\pi\cos\left(\frac{\xi\pi\Delta x}{2}\right)}{\sqrt{1 - \left(\frac{\Delta t}{\Delta x}\right)^2 \sin^2 \frac{\xi\pi\Delta x}{2}}} \right| \\ &\leq \left| \frac{2N\alpha\pi\cos\left(\frac{\xi\pi\Delta x}{2}\right)}{\sqrt{\left(\frac{\Delta t}{\Delta x}\right)^2 - \left(\frac{\Delta t}{\Delta x}\right)^2 \sin^2 \frac{\xi\pi\Delta x}{2}}} \right| = \frac{2N\alpha\pi\Delta x}{\Delta t} = \frac{2\alpha\pi - 2\alpha\pi\Delta x}{\Delta t} \\ &\leq \frac{2\pi\alpha(1-\Delta t)}{\Delta t}. \end{aligned} \tag{3.35}$$

In view of (3.35), by choosing conveniently the filtering parameter α such that

$$\alpha \leq \alpha^*(\Delta t) := \frac{2\pi - (\Delta t)^p}{2\pi(1-\Delta t)}, \tag{3.36}$$

with $0 \leq p < 1/2$, hypothesis (2.2) of Theorem 2.1 is verified.

In practice it is convenient to fix the filtering parameter $0 < \alpha < 1$, independent of Δt. In this way (3.36) is automatically satisfied for Δt small enough, which is the relevant case in numerical approximation problems. On the other hand the gap condition (3.34) is also automatically and uniformly satisfied for the truncated sequence $\{\lambda_k\}_{|k| \leq N\alpha}$.

Note that the gap γ_α (respectively, the minimal observability/ control time $2\pi/\gamma_\alpha$) tends to π (respectively, to 2) when $\alpha \searrow 0^+$ while it converges to zero (respectively, to infinity) when $\alpha \nearrow 1^-$.

Note also that the minimal observability/control time can be taken to be any $T > 2\pi/\gamma_\alpha$ since the minimal time $T(\alpha) = 2\pi/\gamma_\alpha + \epsilon(\Delta t)$ tends to $2\pi/\gamma_\alpha$ as Δt tends to zero.

More precisely, the following theorem holds.

THEOREM 3.1. *For all Courant numbers $0 < \mu < 1$ and all values of the filtering parameter $0 < \alpha < 1$, the observability inequality below holds that*

$$E_0 \leq \frac{1}{2\cos^2 \frac{\alpha\pi}{2} C_1(T, \gamma_\alpha)} \left[\Delta t \sum_{n=0}^{M} \left| \frac{\phi_N}{\Delta x} \right|^2 \right] \tag{3.37}$$

for every solution of (3.24) *in the class $\mathcal{C}_\alpha(\Delta x)$, uniformly as $(\Delta t, \Delta x) \to (0,0)$ for any $T > T(\alpha) = 2\pi/\gamma_\alpha$, with $C_1(T, \gamma_\alpha)$ given by* (1.3). *Moreover,*

1. $T(\alpha) \nearrow \infty$ *as* $\alpha \nearrow 1^-$ *and* $T(\alpha) \searrow 2$ *as* $\alpha \searrow 0^+$.
2. $C_\alpha(T) := \dfrac{1}{2\cos^2 \frac{\alpha\pi}{2} C_1(T,\gamma_\alpha)} \searrow C(T) = \dfrac{1}{2C_1(T,\gamma)}$ *as* $\alpha \searrow 0^+$ *with* $C_1(T,\gamma)$ *given by* (1.3), *where* $C(T)$ *is the constant of the continuous observability inequality* (3.5).

Remark 3.2. This theorem allows the recovery of the uniform observability of the original system (3.3) as the limit when $(\Delta t, \Delta x) \to (0,0)$ of the observability of the solutions of discrete one (3.24) in the classes (3.31) by means of Fourier filtering; the statements in this theorem coincide with the predictions one may deduce from the analysis of the dispersion diagram of the numerical scheme [28], as we shall see in the next section.

Proof (Sketch of the proof). The energy of the solutions (3.26) of the discrete system (3.24), concentrated on $x = 1$ is given by (3.29) and the total energy (3.25) of the solutions is

$$E_0 = \frac{2}{(\Delta x)^2} \sum_k a_k^2 \sin^2 \frac{k\pi\Delta x}{2} = \frac{2}{(\Delta x)^2} \sum_k a_k^2 \frac{\sin^2(k\pi\Delta x)}{4\cos^2 \frac{k\pi\Delta x}{2}} = \frac{1}{2} \sum_k \mid m_k \mid^2 \frac{1}{\cos^2 \frac{k\pi\Delta x}{2}},$$

where $m_k = \sin(Nk\pi\Delta x)/\Delta x$.

For all $k \in [-\alpha N, \alpha N]$ we have $\cos(\alpha\pi/2) \le \cos(\alpha N\pi\Delta x/2) \le \cos(k\pi\Delta x/2) \le 1$ and, in this case,

$$\frac{1}{2} \sum_k \mid m_k \mid^2 \le E_0 \le \frac{1}{2\cos^2 \frac{N\alpha\pi\Delta x}{2}} \sum_k \mid m_k \mid^2 \le \frac{1}{2\cos^2 \frac{\alpha\pi}{2}} \sum_k \mid m_k \mid^2. \tag{3.38}$$

Applying Theorem 2.1 and the Fourier representation (3.32) of the solutions we obtain that, for all $T > 2\pi/\gamma_\alpha + \epsilon(\Delta t)$, there exist positive constants $C_j(\Delta t, T, \gamma_\alpha)$, $j = 1, 2$, such that

$$C_1(\Delta t, T, \gamma_\alpha) \sum_{k=-\alpha N}^{\alpha N} |m_k|^2 \le \Delta t \sum_{n=0}^{M} \left| \sum_{k=-\alpha N}^{\alpha N} m_k e^{in\Delta t\lambda_k} \right|^2 \le C_2(\Delta t, T, \gamma_\alpha) \sum_{k=-N}^{N} |m_k|^2.$$

Therefore, for every α as in (3.36), by (3.38), the following inequalities hold:

$$2\cos^2 \frac{\alpha\pi}{2} C_1(\Delta t, T, \gamma_\alpha) E_0 \le \Delta t \sum_{n=0}^{M} \left| \frac{\phi_N}{\Delta x} \right|^2 \le 2C_2(\Delta t, T, \gamma_\alpha) E_0, \tag{3.39}$$

with $C_j(\Delta t, T, \gamma_\alpha)$, $j = 1, 2$, defined by relations (2.4), for every truncated solution (3.32) of system (3.24) belonging to the class $\mathcal{C}_\alpha(\Delta x)$. □

The uniform observability inequality (3.39) implies uniform controllability results, as we shall prove in the next section, for the projection (over the subspace of unfiltered Fourier components) of solutions of the dual controlled system (3.23). In the limit as $\Delta t, \Delta x \to 0$ one recovers the sharp controllability results of the wave equation (3.1). For the details of the proof of convergence of controls we refer to [20] where the case $\Delta t = \Delta x$ was studied in detail. But, as mentioned above, for this particular one, because of the orthogonality of complex harmonic polynomials, the discrete Ingham inequality is not needed. We also refer to [16] where the convergence of controls for the semi-discretizations of the beam equation was analyzed in detail.

The usual centered finite-difference approximation of the wave equation we have considered here is only a simple example in which the discrete Ingham's theorem can be applied, together with some filtering mechanism, to get uniform observability inequalities. The discrete Ingham inequality can also be applied, for instance, to the implicit fully finite difference approximation of the wave equation, introduced in [18].

4. Uniform controllability of the filtered solutions. In this section, we apply the uniform observability results obtained above to analyze the controllability properties of the fully discrete system (3.23).

Let us define the Hilbert spaces of square summable sequences $\hbar^1$ and $\hbar^{-1}$ as follows:

$$\hbar^1 = \left\{ \{a_k\} \in \ell^2 \ : \quad \|a_k\|^2_{\hbar^1} = \sum_{k\in\mathbb{N}} |\ k\pi a_k\ |^2 < \infty \right\}, \tag{4.1}$$

$$\hbar^{-1} = \left\{ \{a_k\} \in \ell^2 \ : \quad \|a_k\|^2_{\hbar^{-1}} = \sum_{k\in\mathbb{N}} \left| \frac{a_k}{k\pi} \right|^2 < \infty \right\}, \tag{4.2}$$

where the discrete space ℓ^2 is given by (1.5).

For every $\alpha \in (0,1)$, we introduce the space $\mathcal{S}_\alpha$ generated by the eigenvectors $(\bar\varphi_k)$ involved in $\mathcal{C}_\alpha(\Delta x)$ of the filtered solutions of the homogeneous system (3.24) with filtering parameter α:

$$\mathcal{S}_\alpha = span\left\{ \bar\varphi_k : |k| \le \alpha N \right\}. \tag{4.3}$$

For every $s \in \mathbb{R}$, we denote by $\hbar^s_{\Delta x,\alpha}$ the space S_α endowed with the norm

$$\|v\|^2_{s,\Delta x} = \sum_{|k|\le N\alpha} \lambda_k^s \left|a_k\right|^2, \quad \text{for} \quad v \in S_\alpha : v = \sum_{|k|\le N\alpha} a_k \bar\varphi_k,$$

where λ_k are as in (3.27).

For every $\alpha \in (0,1)$ and $T > 0$, we consider the partial controllability problem for system (3.23) in the space $\ell^2 \times \hbar^{-1}$, which consists of finding a control $\bar v^n \in \mathbb{R}^M$ such that, for all initial data $(\bar u^0, \bar u^1) \in \ell^2 \times \hbar^{-1}$, the solution $\bar u^n$ of (3.23) satisfies

$$(\Pi_\alpha \bar u^M, \Pi_\alpha \bar u^{M+1}) = (0,0), \tag{4.4}$$

where Π_α is the orthogonal projection over S_α; i.e.,

$$\left(\Pi_\alpha \bar u^M, \Pi_\alpha \bar u^{M+1}\right) = \left(\sum_{|k|\le N\alpha} c_k \bar\varphi_k, \sum_{|k|\le N\alpha} d_k \bar\varphi_k \right),$$

where (c_k) and (d_k) are the Fourier coefficients of $(\bar u^M, \bar u^{M+1})$ in the basis of the eigenvectors $(\bar\varphi_k)_k$. Observe that we only require to control uniformly the projection Π_α of the solutions of the discrete system (3.23) over subspaces in which the high frequencies have been filtered.

As we shall see this result is a consequence of the partial observability results of the previous section in the class of filtered solutions $\mathcal{C}_\alpha(\Delta x)$.

Multiplying the first equation in (3.23) by an arbitrary solution $\bar\phi^n$ of (3.24) and adding in j and n, we get

$$\Delta t \sum_{n=1}^{M} v^n_{\Delta x} \frac{\phi^n_N}{\Delta x} + \frac{1}{\mu} \sum_{j=0}^{N} \left[u^1_j \phi^0_j - u^0_j \phi^1_j \right] = \frac{1}{\mu} \sum_{j=0}^{N} \left[u^{M+1}_j \phi^M_j - u^M_j \phi^{M+1}_j \right]. \tag{4.5}$$

The solution of system (3.23) may be characterized through a transposition argument based on the identity above. Indeed, given $M,\ N \in \mathbb{N}$, $\bar{v}_{\Delta t} \in \mathbb{R}^M$, and $(\bar{u}^0, \bar{u}^1) \in \mathbb{R}^N \times \mathbb{R}^N$, $\{\bar{u}^n\}$ solves (3.23) if for every $s \in [1, M]$ it holds that

$$L_s(\bar{\phi}^0, \bar{\phi}^1) = \frac{1}{\mu} \sum_{j=1}^{N} \left[u_j^s \phi_j^{s+1} - u_j^{s+1} \phi_j^s \right],$$

or equivalently

$$L_s(\bar{\phi}^0, \bar{\phi}^1) = \frac{1}{\mu} \left(\bar{u}^s, \bar{\phi}^{s+1} \right)_{\mathbb{R}^N} + \frac{1}{\mu} \left(\bar{u}^{s+1}, -\bar{\phi}^s \right)_{\mathbb{R}^N}, \tag{4.6}$$

for every solution $\{\bar{\phi}^n\}$ of the discrete problem (3.24), where the functional L_s: $\mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}$ is such that

$$L_s(\bar{\phi}^0, \bar{\phi}^1) = \frac{1}{\mu} \sum_{j=1}^{N} \left[u_j^0 \phi_j^1 - u_j^1 \phi_j^0 \right] - \Delta t \sum_{n=1}^{s} v_{\Delta x}^n \left[\frac{\phi_N^n}{\Delta x} \right].$$

The projection $\Pi_\alpha \bar{u}^n$ may be characterized by the same variational formulation (4.6), with the only difference being that the test functions in (4.6) are solutions of (3.24) in the class $\mathcal{C}_\alpha(\Delta x)$ (3.31).

Remark 4.1. Identity (4.4) is equivalent, by (4.5), to

$$\Delta t \sum_{n=1}^{M} v_{\Delta x}^n \left[\frac{\phi_N^n}{\Delta x} \right] = \frac{1}{\mu} \sum_{j=0}^{N} \left[u_j^0 \phi_j^1 - u_j^1 \phi_j^0 \right], \tag{4.7}$$

where $(\bar{\phi}^0, \bar{\phi}^1)$ are the initial data corresponding to the solution $\bar{\phi}^n \in \mathcal{C}_\alpha(\Delta x)$ of the discrete system (3.24).

Now let $\Delta x = 1/q$, $\Delta t = \mu/q$, $N = q - 1$, for some $q \in \mathbb{N}$ and $\mu < 1$. We have the following uniform (with respect to $(\Delta t, \Delta x) \to (0, 0)$) partial controllability property.

THEOREM 4.2. *Let $0 < \mu < 1$ and let us fix an arbitrary value of the filtering parameter $0 < \alpha < 1$. For every $T > T(\alpha) = 2\pi/\gamma_\alpha$, the system* (3.24) *is partially controllable on $\ell^2 \times \hbar^{-1}$ with controls $\bar{v}_{\Delta t}^n \in \mathbb{R}^M$ when $M = [Tq/\mu - 1]$. Moreover, the controls of minimal norm are uniformly bounded with respect to Δt. More precisely*

$$\left[\Delta t \sum_{n=0}^{M} |v_{\Delta x}^n|^2 \right]^{1/2} \leq C \|(\bar{u}^1, -\bar{u}^0)\|_{\hbar^{-1} \times \ell^2}, \tag{4.8}$$

where $C = C(T, \gamma_\alpha) > 0$ is a constant independent of $\Delta t \in (0, 1)$.

Proof. Let $(\bar{\phi}^n) \in \mathcal{C}_\alpha(\Delta x)$ be the solution of (3.24) with initial data $(\bar{\phi}^0, \bar{\phi}^1) \in S_\alpha \times S_\alpha$ and define the convex quadratic functional $J_{\Delta x} : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}$, by

$$J_{\Delta x}(\bar{\phi}^0, \bar{\phi}^1) = \frac{\Delta t}{2} \sum_{n=0}^{M} \left| \frac{\phi_N^n}{\Delta x} \right|^2 - \frac{1}{\mu^2} \Delta x \sum_{j=0}^{N} \left(u_j^0 \frac{\phi_j^1 - \phi_j^0}{\Delta t} - \frac{u_j^1 - u_j^0}{\Delta t} \phi_j^0 \right). \tag{4.9}$$

For every $\bar{\phi}^n \in \mathcal{C}_\alpha(\Delta x)$ we have

$$\begin{aligned} \left| \sum_{j=0}^{N} \left(u_j^0 \phi_j^1 - u_j^1 \phi_j^0 \right) \right| &= \left| \left(\Pi_\alpha \bar{u}^1, \bar{\phi}^0 \right)_{\mathbb{R}^N} \right| + \left| \left(\Pi_\alpha \bar{u}^0, -\bar{\phi}^1 \right)_{\mathbb{R}^N} \right| \\ &\leq \|\Pi_\alpha \bar{u}^1\|_{\hbar^{-1}} \|\bar{\phi}^0\|_{\hbar^1} + \|\Pi_\alpha \bar{u}^0\|_{\ell^2} \|\bar{\phi}^1\|_{\ell^2} \\ &\leq \|\Pi_\alpha (\bar{u}^1, -\bar{u}^0)\|_{\hbar^{-1} \times \ell^2} \|(\bar{\phi}^0, \bar{\phi}^1)\|_{\hbar^1 \times \ell^2}. \end{aligned} \tag{4.10}$$

According to (4.10) and the direct observability inequality (the right-hand side term in (3.39)) we deduce that $J_{\Delta x}$ is continuous.

On the other hand, according to the observability inequality (3.37), $J_{\Delta x}$ is uniformly coercive in $\mathcal{C}_\alpha(\Delta x)$,

(4.11)
$$\left|J_{\Delta x}(\bar\phi^0,\bar\phi^1)\right| \geq \left\|(\bar\phi^0,\bar\phi^1)\right\|_{\hbar^1\times\ell^2}\left[C_1(T,\gamma_\alpha)\left\|(\bar\phi^0,\bar\phi^1)\right\|_{\hbar^1\times\ell^2} - \|\Pi_\alpha(\bar u^1,-\bar u^0)\|_{\hbar^{-1}\times\ell^2}\right].$$

Thus, there exists a unique minimizer $(\hat\phi^0,\hat\phi^1)$ of $J_{\Delta x}$,

$$J_{\Delta x}(\hat\phi^0,\hat\phi^1) = \min_{(\bar\phi^0,\bar\phi^1)\in S_\alpha\times S_\alpha} J_{\Delta x}(\bar\phi^0,\bar\phi^1).$$

Let $\hat\phi^n\in\mathcal{C}_\alpha(\Delta x)$ be the solution of the adjoint problem (3.24) with this minimizer as initial datum.

The pair $(\hat\phi^0,\hat\phi^1)$ satisfies the Euler–Lagrange equation

$$\Delta t\sum_{n=0}^{M}\frac{\hat\phi_N^n}{\Delta x}\frac{\phi_N^n}{\Delta x} = \frac{1}{\mu}\sum_{j=0}^{N}\left[u_j^0\phi_j^1 - u_j^1\phi_j^0\right], \tag{4.12}$$

for every initial data $(\bar\phi^0,\bar\phi^1)\in S_\alpha\times S_\alpha$ associated to the solution $\bar\phi^n\in\mathcal{C}_\alpha(\Delta x)$ of (3.24). Therefore, according to (4.7), the control we were looking for is $v_{\Delta x}^n = \hat\phi_N^n/\Delta x$.

To conclude the proof we check the uniform boundedness of the controls $v_{\Delta x}^n$. We have

$$J_{\Delta x}((\hat\phi^0,\hat\phi^1)) \leq J_{\Delta x}(0,0) = 0,$$

and, by (4.10), this implies

$$\frac{\Delta t}{2}\sum_{n=0}^{M}\left|\frac{\hat\phi_N^n}{\Delta x}\right|^2 \leq \|\Pi_\alpha(\bar u^1,-\bar u^0)\|_{\hbar^{-1}\times\ell^2}\|(\bar\phi^0,\bar\phi^1)\|_{\hbar^1\times\ell^2}. \tag{4.13}$$

The discrete energy E_0 of a solution $\bar\phi^n$ of (3.24) with initial data $(\bar\phi^0,\bar\phi^1)$ satisfies

$$E_0 = \frac{1}{2}\|(\bar\phi^0,\bar\phi^1)\|_{\hbar^1\times\ell^2}^2.$$

Now, using the Fourier development (3.32) of the solution $\bar\phi^n$ and applying the observability inequality (3.37) we get

$$\begin{aligned}\|(\bar\phi^0,\bar\phi^1)\|_{\hbar^1\times\ell^2}^2 = 2E_0 &\leq \frac{1}{\cos^2\frac{N\alpha\pi\Delta x}{2}C_1(T,\gamma_\alpha,\Delta t)}\Delta t\sum_{n=0}^{M}\left|\frac{\hat\phi_N^n}{\Delta x}\right|^2\\ &\leq \frac{1}{\cos^2\frac{\alpha\pi}{2}C_1(T,\gamma_\alpha)}\Delta t\sum_{n=0}^{M}\left|\frac{\hat\phi_N^n}{\Delta x}\right|^2.\end{aligned} \tag{4.14}$$

Therefore, in (4.13) we obtain

$$\left[\Delta t\sum_{n=0}^{M}\left|\frac{\hat\phi_N^n}{\Delta x}\right|^2\right]^{1/2} \leq \frac{1}{\sqrt{\cos^2\frac{\alpha\pi}{2}C_1(T,\gamma_\alpha)}}\|\Pi_\alpha(\bar u^1,-\bar u^0)\|_{\hbar^{-1}\times\ell^2}, \tag{4.15}$$

and then, the discrete controls $v^n_{\Delta x} = \hat{\phi}^n_N/\Delta x$ satisfy

$$\left[\Delta t \sum_{n=0}^{M} |v^n_{\Delta x}|^2\right]^{1/2} \leq C(T,\gamma_\alpha)\|\Pi_\alpha(\bar{u}^1, -\bar{u}^0)\|_{\hbar^{-1}\times\ell^2}, \tag{4.16}$$

as stated above. □

Remark 4.3. Note that, with the notations (3.32), the controls $(v^n_{\Delta x})$ are of the form

$$v^n_{\Delta x} = -\frac{\mu}{\Delta t}\sum_{k=-N\alpha}^{N\alpha} \cos(k\pi)\sin(k\pi\Delta t/\mu)\hat{a}_k e^{i\lambda_k n\Delta t}, \tag{4.17}$$

where $(\hat{a}_k)_k$ are the Fourier coefficients of the solution $\hat{\phi}^n \in \mathcal{C}_\alpha(\Delta x)$ of the adjoint problem (3.24), with initial data $(\hat{\phi}^0, \hat{\phi}^1)$ being the minimizer of the functional $J_{\Delta x}$.

Now we show the convergence of the controls $v^n_{\Delta x}$ of the discrete system (3.23) to the HUM control of the continuous one (3.1), as $\Delta t, \Delta x \to 0$.

Given an initial state $(u^0, u^1) \in L^2(0,1)\times H^{-1}(0,1)$ of the continuous system (3.1), we develop it in Fourier series

$$(u^0, u^1) = \sum_{k=1}^{\infty}(c_k, d_k)\varphi_k(x), \tag{4.18}$$

with

$$\sum_{k\in\mathbb{N}}\left[|c_k|^2 + \left|\frac{d_k}{k\pi}\right|^2\right] < \infty. \tag{4.19}$$

We now construct the initial states for the discrete system (3.23) by setting

$$(\bar{u}^0, \bar{u}^1) = \sum_{k=1}^{N}(c_k, c_k\cos(\lambda_k n\Delta t) + \frac{d_k}{\lambda_k}\sin(\lambda_k n\Delta t))\bar{\varphi}_k, \tag{4.20}$$

with λ_k given by (3.27). They may be rewritten as

$$(\bar{u}^0, \bar{u}^1) = \sum_{k=1}^{\infty}(c^N_k, c^N_k\cos(\lambda_k n\Delta t) + \frac{d^N_k}{\lambda_k}\sin(\lambda_k n\Delta t))\bar{\varphi}_k, \tag{4.21}$$

where

$$c^N_k = c_k\chi_N(k), \qquad d^N_k = d_k\chi_N(k),$$

χ_N being the characteristic function of the set $\{1,\dots,N\}$.

In view of Theorem 4.2, there exists a HUM control $(v^n_{\Delta x})$ for the discrete system (3.23), satisfying (4.4), with initial data (4.20).

Let us now prove that the sequence $(v^n_{\Delta x})$ converges (in a sense to be more precise below) to $v \in L^2(0,T)$, which is the HUM control for system (3.1) with initial data (4.18).

To better analyze the convergence of controls, we define the continuous extension of the discrete controls by setting

$$v_{\Delta x}(t) = -\frac{\mu}{\Delta t}\sum_{k\in\mathbb{Z}}\cos(k\pi)\sin(k\pi\Delta t/\mu)\hat{a}_k e^{i\lambda_k t},$$

where $\hat{a}_k$ are taken to be zero for $|k| > \alpha N$. This function, when restricted to the mesh, coincides with $(v^n_{\Delta x})$ (recall that $v^n_{\Delta x}$ is given by (4.17)).

The following convergence result holds.

THEOREM 4.4. *Let $\mu = \Delta t/\Delta x \leq 1$. Consider M, N as in Theorem* 4.2. *Fix $(u_0, u_1) \in L^2(0,1) \times H^{-1}(0,1)$ and consider the continuous and discrete controls v and $v_{\Delta x}$ as above, with the filtering parameter $\alpha \in (0,1)$ and $T > T_\alpha$. Then,*

$$v_{\Delta x}(\cdot) \to v(\cdot) \ \textit{strongly in} \ L^2(0,T) \ \text{as} \ \Delta t \to 0. \tag{4.22}$$

Proof (*Sketch of the proof*). In view of (4.8) it is easy to see that

$$\Delta t \sum_{n=0}^{M} |v^n_{\Delta x}|^2 \leq C, \tag{4.23}$$

and therefore

$$\int_0^T |v_{\Delta x}|^2 \, dt \leq C. \tag{4.24}$$

Then, up to the extraction of a subsequence that we still denote by $\{v_{\Delta x}\}_{\Delta t}$, we have

$$v_{\Delta x}(t) \rightharpoonup v(t) \ \text{ in } \ L^2(0,T) \ \text{ as } \ \Delta t \to 0. \tag{4.25}$$

By a Γ-convergence argument it can also be seen that the limit v is given by

$$v(t) = -\partial_x \hat{\phi}(1,t), \tag{4.26}$$

where $\hat{\phi}$ is the solution of the adjoint problem (3.3) with initial data $(\hat{\phi}^0, \hat{\phi}^1) \in H_0^1(0,1) \times L^2(0,1)$, the unique minimizer of the functional

$$J(\phi^0, \phi^1) = \frac{1}{2} \int_0^T \mid \partial_x \phi(1,t) \mid^2 dt - \int_0^1 u^0 \phi^1 - < u^1, \phi^0 >_{-1,1} \tag{4.27}$$

in the energy space $H_0^1(0,1) \times L^2(0,1)$. By taking limits in (4.7) and thanks to the construction of the initial data to be controlled for the discrete system we obtain

$$0 = \int_0^1 \left[u^1(x)\phi^0(x) - u^0(x)\phi^1(x) dx \right] + \int_0^T v(t) \partial_x \phi(1,t) dt \tag{4.28}$$

and this latter condition is equivalent to the fact that v, the limit in (4.25), is a control for system (3.1), driving the initial data (u^0, u^1) to rest; i.e., $v \in L^2(0,T)$ is the control of minimal L^2-norm.

The limit v being identified in a unique way, we deduce that the whole sequence $v_{\Delta x}$ converges.

Moreover, by the hypotheses of Theorem 4.4, the linear term of the discrete functional $J_{\Delta x}$ in (4.9) converges to the linear term of the functional defined in (4.27). Therefore, proving (4.22) is equivalent to proving that

$$J_{\Delta x}(\hat{\phi}^0_{\Delta x}, \hat{\phi}^1_{\Delta x}) \to J(\hat{\phi}^0, \hat{\phi}^1), \ \text{ as } \ \Delta x \to 0,$$

where $(\hat{\phi}^0_{\Delta x}, \hat{\phi}^1_{\Delta x}) \in S_\alpha \times S_\alpha$ minimizes (4.9) and $(\hat{\phi}^0, \hat{\phi}^1) \in H_0^1(0,1) \times L^2(0,1)$ minimizes (4.27). Indeed, taking into account the convergence of the linear terms in

this functional, and the structure of the functionals (4.9) and (4.27), we deduce the convergence of the norms of the controls that, together with the weak convergence, ensure strong convergence.

Thus, the controls $v_{\Delta x}$ and the controlled discrete solutions $u_{\Delta x}$ converge to the control and the controlled solution of the wave equation (3.1). It is important to note that the projections of the solutions of the controlled system end up covering the whole range of frequencies so that, in the limit, we recover the exact controllability property (3.2) of the continuous wave equation.

The details of the several steps of the proof are given in [19] and we omit them for brevity. □

5. Discrete Ingham inequalities and dispersion diagrams. In this section we discuss the observability results obtained in section 3 applying discrete Ingham inequalities in connection with the dispersion diagrams of the equations and numerical schemes under consideration. We also discuss the optimality of these results. First of all, we introduce and recall some classical concepts and notations.

Any time-dependent scalar, linear partial differential equation with constant coefficients admits plane wave solutions

$$\phi(x,t) = e^{i(\omega t - \xi x)}, \quad \xi \in \mathbb{R},\ \omega \in \mathbb{C}, \tag{5.1}$$

where ξ is the *wave number* and ω is the *frequency*. The relationship

$$\omega = \omega(\xi) \tag{5.2}$$

is known as the *dispersion relation* for the equation.

Any individual *"monochromatic wave"* (involving only one Fourier component) of (5.1) moves at the *phase velocity*

$$c(\xi,\omega) = \frac{\omega(\xi)}{\xi}. \tag{5.3}$$

When one superimposes two waves with nearby propagation velocities, there appear wave packets which can propagate with different velocities. The energy of wave packets propagates at the so-called *group velocity*

$$C(\xi,\omega) = \frac{d\omega(\xi)}{d\xi}. \tag{5.4}$$

In general, the dispersion relation for a partial differential equation is a polynomial relation between ξ and ω, while a discrete model amounts to a trigonometric approximation.

• *Continuous problem.* For the continuous wave equation (3.3) we have $\omega(\xi) = \xi$ and therefore $c(\xi) = C(\xi) = 1$.

• *Semi-discrete problem.* For the semi-discrete scheme (3.9) the dispersion relation is

$$\omega(\xi) = \frac{2}{\Delta x}\sin\frac{\xi\Delta x}{2}, \quad \xi \in \left[-\frac{\pi}{\Delta x}, \frac{\pi}{\Delta x}\right]. \tag{5.5}$$

Note that, at the semi-discrete level, each dispersion relation is $2\pi/\Delta x$–periodic in ξ, and it is natural to take $\xi \in [-\pi/\Delta x, \pi/\Delta x]$ as a fundamental domain.

The phase velocity is in this case

$$c(\xi,\omega)=\frac{2}{\xi\Delta x}\sin\frac{\xi\Delta x}{2}. \tag{5.6}$$

The corresponding group velocity is

$$C(\xi,\omega)=\frac{d\omega(\xi)}{d\xi}=\cos\frac{\xi\Delta x}{2}. \tag{5.7}$$

• *Discrete problem.* The same analysis can be developed for fully discrete schemes. Considering numerical plane waves $\phi_j^n=e^{i(\omega n\Delta t-\xi j\Delta x)}$, for system (3.24), one obtains the dispersion relation

$$\omega(\xi)=\frac{2}{\Delta t}\arcsin\left(\frac{\Delta t}{\Delta x}\sin\frac{\xi\Delta x}{2}\right). \tag{5.8}$$

It is $2\pi/\Delta x$-periodic in ξ and $2\pi/\Delta t$-periodic in ω.

• When $\Delta t=\Delta x$ we obtain

$$\omega(\xi)=\xi. \tag{5.9}$$

This case is particularly interesting since (5.9) coincides with the dispersion relation for the continuous weave equation. In this case, $c(\xi,\omega)=C(\xi,\omega)=1$ and the discrete waves propagate at a constant velocity identically equal to one, like in the continuous case. But, as we shall see, this is a completely exceptional situation.

• When $\mu<1$, the phase velocity is given by

$$c(\xi,\omega)=\frac{2}{\xi\Delta t}\arcsin\left(\frac{\Delta t}{\Delta x}\sin\frac{\xi\Delta x}{2}\right) \tag{5.10}$$

and the group velocity is

$$C(\xi,\omega)=\frac{d\omega(\xi)}{d\xi}=\frac{\cos\frac{\xi\Delta x}{2}}{\sqrt{1-\left(\frac{\Delta t}{\Delta x}\sin\frac{\xi\Delta x}{2}\right)^2}}. \tag{5.11}$$

For $\Delta t=0$ the phase and group velocities in (5.10) and (5.11), which depend on ξ, coincide with those of the semi-discrete case (5.6) and (5.7), respectively, as expected.

Note that, as $\Delta x\to 0$, for all ξ we have

$$C(\xi,\omega)\le\frac{\cos\frac{\xi\Delta x}{2}}{\sqrt{1-\left(\frac{\Delta t}{\Delta x}\right)^2}}\to 0$$

when $\xi=\pi/\Delta x$.

In Figures 1–4 we describe the evolution of the group velocity diagrams starting with the semi-discrete case ($\mu=0$) up to $\mu=1$, for fixed $\Delta x=0.001$.

In general, any discrete dynamics generates spurious high-frequency oscillations that do no exist at the continuous level [23, 25]. Moreover, the interaction of waves with the grid produces a dispersion phenomenon and the velocity of propagation of these high frequency numerical waves may converge to zero when the mesh-size tends to zero. These spurious oscillations weakly converge to zero. Consequently, their

existence is compatible with the convergence of the numerical scheme for solving the initial-value problem. However, when we are dealing with the exact controllability or observability problems, a uniform time for the control of all numerical waves is needed. Since the velocity of propagation of some high frequency numerical waves may tend to zero as the mesh becomes finer and finer, uniform observability and therefore controllability properties of the discrete model may fail for all $T > 0$.

According to Theorem 2.1, the uniform gap between two consecutive eigenvalues is a sufficient (and actually also necessary) property for uniform (with respect to Δx and Δt) observability. On the other hand, the group velocity is the derivative of the eigenfrequencies λ_k and the spectral gap is, as we have seen, $\lambda_{k+1} - \lambda_k$. Both magnitudes are similar, and they become closer as $\Delta x \to 0$.

Thus, to efficiently observe at the point $x = 1$ a wave packet concentrated to the left of $x = 1$ that moves to the left (in the space variable) as t increases, and bounces back at $x = 0$ to eventually reach the observation point $x = 1$, the time needed is

$$T \geq 2/\min_{\xi}\{C(\xi, \omega)\}. \tag{5.12}$$

In the continuous case, (5.12) reduces to the well-known condition for observability $T \geq 2$ and it is uniform for all the frequencies. The minimal time $T = 2$ is the one one obtains in view of Ingham's theorem (1.2) because the gap is $\gamma = \pi$ in this case.

For the semi-discrete case, the observation time is

$$T \geq 2/\min_{\xi}(\cos(\xi \Delta x/2)). \tag{5.13}$$

But $\min_\xi(\cos(\xi\Delta x/2))$ is of the order of Δx, the same order as we have obtained in (3.18) for the spectral gap for the highest frequencies. Consequently, the observation time (5.13) diverges, $T \to \infty$, as $\Delta x \to 0$.

These facts confirm the necessity of filtering the high frequencies. Relation (5.13) shows that the time grows with the high frequencies, in the points where $\cos \xi\Delta x/2 \sim 0$ ($\xi \sim \pi/\Delta x$) and the same result is obtained applying the Ingham inequality.

For the fully discrete problem (3.24) the time needed for observation is

$$T \geq \max_{\xi} \frac{2\sqrt{1 - \left(\frac{\Delta t}{\Delta x} \sin \frac{\xi \Delta x}{2}\right)^2}}{\cos \frac{\xi \Delta x}{2}}. \tag{5.14}$$

Passing to the limit in (5.14) as $\Delta t \to 0$ for fixed Δx, one obtains the same time as in the semi-discrete case (5.13). The observation time grows with the high frequencies, except for the very particular case $\Delta t = \Delta x$, where the time obtained in the previous section, using the orthogonality of the time exponentials, is $T = 2$, which coincides with the observation time given by the group velocity (5.14).

Summarizing, when $0 < \mu < 1$, the sequence of eigenvalues has no uniform gap and the observability time (5.14) tends to infinity. Therefore, as in the semi-discrete case, a suitable filtering of the spurious numerical high frequencies is necessary. Theorem 2.1 provides a sharp result in this direction and its main result coincides with the predictions one may do in view of the structure of the dispersion diagram.

6. Proof of the discrete Ingham inequality. The proof of Theorem 2.1 uses in an essential way some classical properties of the discrete Fourier transform. We recall these properties in subsection 6.1 following [23].

FIG. 1. *Group velocity for the semi-discrete (–) and discrete (- -) cases with* $\mu = \Delta t/\Delta x = 0.1$ *(left),* $\mu = \Delta t/\Delta x = 0.3$ *(middle),* $\mu = \Delta t/\Delta x = 0.5$ *(right),* $\Delta x = 0.001$.

FIG. 2. *Group velocity for the semi-discrete (–) and discrete (- -) cases with* $\mu = \Delta t/\Delta x = 0.9$ *(left),* $\mu = \Delta t/\Delta x = 0.999$ *(middle),* $\mu = \Delta t/\Delta x = 1$ *(right),* $\Delta x = 0.001$.

6.1. The discrete Fourier transform. Let $h > 0$ be a real number and let $\dots, x_{-1}, x_0, x_1, \dots$ be defined by $x_j = jh$. Thus $\{x_j\} = h\mathbb{Z}$, where $\mathbb{Z}$ is the set of integers. The ℓ_h^2-norm of a discrete function $\{v_j\}$ is defined as

$$\|v\|_h = \left[h \sum_{j=-\infty}^{\infty} |v_j|^2 \right]^{1/2}.$$

We denote by l_h^2 the Hilbert space $l_h^2 = \{v : \|v\|_h < \infty\}$, the space of discrete functions of finite $\|\cdot\|_h$ norm.

For any $v \in \ell_h^2$, the discrete Fourier transform of v is the function $\hat{v}$ defined by

$$\hat{v}(\xi) = h \sum_{j=-\infty}^{\infty} e^{-i\xi x_j} v_j, \qquad \xi \in \left[-\frac{\pi}{h}, \frac{\pi}{h} \right]. \tag{6.1}$$

This can be viewed as a discrete approximation of the continuous Fourier transform

$$\hat{u}(\xi) = \int_{-\infty}^{\infty} e^{-i\xi x} u(x) dx, \qquad \xi \in \mathbb{R},$$

if $u = u(x)$ is a sufficiently smooth function such that $u(x_j) = v_j$.

A priori, the sum in (6.1) defines a function $\hat{v}(\xi)$ for all $\xi \in \mathbb{R}$. The function $\hat{v}(\xi)$ is $2\pi/h$ periodic on $\mathbb{R}$ and therefore we analyze it only for $\xi \in [-\pi/h, \pi/h]$ to avoid aliasing.

Let us recall a standard definition. A function u defined on $\mathbb{R}$ is said to have *bounded variation* if there is a constant M such that for any finite m and any points

FIG. 3. *Dispersion relation for the continuous (-.-), semi-discrete (- -) and discrete (–) cases with* $\mu = \Delta t/\Delta x = 0.1$ *(left)* $\mu = \Delta t/\Delta x = 0.3$ *(middle),* $\mu = \Delta t/\Delta x = 0.5$ *(right),* $\Delta x = 0.001$.

FIG. 4. *Dispersion relation for the continuous (-.-), semi-discrete (- -) and discrete (–) cases with* $\mu = \Delta t/\Delta x = 0.9$ *(left),* $\mu = \Delta t/\Delta x = 0.999$ *(middle),* $\mu = \Delta t/\Delta x = 1$ *(right),* $\Delta x = 0.001$.

$x_0 < x_1 < \cdots < x_m$,

$$\sum_{j=1}^{m} \mid u(x_j) - u(x_{j-1}) \mid \leq M.$$

Now we give a fundamental result (see [23, p. 96]) which describes the effect of discretization in the Fourier transform.

THEOREM 6.1. *Suppose that* $u \in L^2(\mathbb{R})$ *is a sufficiently smooth function defined on* $\mathbb{R}$ *and let* $v \in \ell_h^2$ *be the discretization obtained by sampling* u *at the grid points* x_j, *i.e.,* $u(x_j) = v_j$.

Then, if u *has* $p-1$ *continuous derivatives in* $L^2(\mathbb{R})$ *for some* $p \geq 1$ *and a* p*th derivative in* L^2 *that has bounded variation, it follows that*

$$|\hat{v}(\xi) - \hat{u}(\xi)| = o(h^{p+1}), \quad \text{when } h \to 0, \tag{6.2}$$

uniformly on $\xi \in [-\pi/h, \pi/h]$.

Proof. Since u is continuous, apply *Poisson formula*

$$\hat{v}(\xi) = \sum_{j=-\infty}^{\infty} \hat{u}(\xi + 2\pi j/h), \qquad \xi \in [-\pi/h, \pi/h].$$

Thus, for every $u \in L^2(\mathbb{R})$ and $v \in \ell^2$, we obtain

$$\hat{v}(\xi) - \hat{u}(\xi) = \sum_{j=-\infty}^{\infty} \hat{u}(\xi + 2\pi j/h) - \hat{u}(\xi) = \sum_{j=1}^{\infty} [\hat{u}(\xi + 2\pi j/h) + \hat{u}(\xi - 2\pi j/h)],$$

with $\hat{u}$ and $\hat{v}$ the Fourier transforms of u and v, respectively.

If u verifies the hypothesis of Theorem 6.1, then

$$|\hat{u}(\xi)| \leq C_1 |\xi|^{-p-1}, \quad \text{when } \xi \to \infty$$

for some constant C_1. Therefore

$$|\hat{v}(\xi) - \hat{u}(\xi)| \leq C_1 \sum_{j=1}^{\infty} (j\pi/h)^{-p-1} = C_2 h^{p+1} \sum_{j=1}^{\infty} j^{-p-1}.$$

For every $p \geq 1$ this sum converges, which implies (6.2), as required. ∎

6.2. The discrete Fourier transform of Ingham's cut-off function. We study some general properties of a discrete Fourier transform that we shall use in the proof of the discrete Ingham inequality.

Given $M \in \mathbb{N}$ and $T > 0$ we consider the function $g : \mathbb{R} \to \mathbb{R}$

$$g(t) = \sin\left(\frac{t\pi}{T}\right) \chi_{(0,T)}, \tag{6.3}$$

where $\chi_{(0,T)}$ is the characteristic function of the interval $(0, T)$. Function (6.3) is precisely the same that Ingham [9] used in the proof of the continuous inequality (1.2). Its Fourier transform $G : \mathbb{R} \to \mathbb{R}$ is

$$G(\tau) = \int_{-\infty}^{\infty} g(t) e^{it\tau} dt = -2 \cos\frac{T\tau}{2} e^{\frac{iT\tau}{2}} \frac{\pi T}{(T^2\tau^2 - \pi^2)}. \tag{6.4}$$

We define the restriction of g to the grid

$$\ldots < t_{-1} < t_0 = 0 < t_1 < \cdots < t_{M+1} = T < \ldots,$$

with $t_n = n\Delta t$, i.e.,

$$h(n\Delta t) = g(t_n) = \sin(n\Delta t\pi/T)\chi_{M+1}(n),$$

χ_{M+1} being the characteristic function of the set $\{0, \ldots, M+1\}$.

For any $\tau \in \mathbb{R}$ we define the discrete Fourier transform of the discrete function h

$$H(\tau) := \Delta t \sum_{n=-\infty}^{\infty} h(n\Delta t) e^{in\Delta t\tau} \tag{6.5}$$

for all $\tau \in [-\pi/\Delta t, \pi/\Delta t]$.

LEMMA 6.2. *For all Δt, $T > 0$ and $k \in \mathbb{Z}$ we have*

$$H(\tau) = -\frac{\Delta t \cos\frac{T\tau}{2} e^{\frac{iT\tau}{2}} \sin\frac{\Delta t\pi}{T}}{2\sin(\frac{\Delta t}{2T}(T\tau + \pi))\sin(\frac{\Delta t}{2T}(T\tau - \pi))} \tag{6.6}$$

for any $\tau \neq (2k\pi)/\Delta t \pm \pi/T$ with $k \in \mathbb{Z}$ and

$$H\left(\frac{2k\pi}{\Delta t} \pm \frac{\pi}{T}\right) = \mp\frac{T}{2i}, \ k \in \mathbb{Z}. \tag{6.7}$$

The function H defined in (6.5) *is continuous and*

$$\lim_{\tau \to \frac{2k\pi}{\Delta t} \pm \frac{\pi}{T}} H(\tau) = \mp \frac{T}{2i}. \tag{6.8}$$

Proof (*Proof of Lemma* 6.2). We divide the proof into two steps: first, we prove that the explicit expression (6.5) of H is (6.6) and then we study the continuity of H.
• *Step* 1. *From the definition of the function H for all $\tau \neq 2k\pi/\Delta t \pm \pi/T$, $k \in \mathbb{Z}$, we have*

$$H(\tau) \quad = \Delta t \sum_{n=0}^{M} \sin \frac{n\pi\Delta t}{T} e^{in\Delta t\tau} = \Delta t \sum_{n=0}^{M} \frac{e^{\frac{in\pi\Delta t}{T}} - e^{-\frac{in\pi\Delta t}{T}}}{2i} e^{in\Delta t\tau}.$$

Hence

$$H(\tau) = \frac{\Delta t}{2i} \sum_{n=0}^{M} e^{\frac{in\Delta t}{T}(T\tau+\pi)} - \frac{\Delta t}{2i} \sum_{n=0}^{M} e^{\frac{in\Delta t}{T}(T\tau-\pi)}. \tag{6.9}$$

In order to obtain identity (6.5), it is useful to prove it only for any $|\tau| < 2k\pi/\Delta t - \pi/T$ with $k = 1$. Then, taking the periodicity properties of the complex exponentials into account, it is easy to obtain the same result for all $k \in \mathbb{Z}$, $\tau \neq 2k\pi/\Delta t \pm \pi/T$.

The first term on the right-hand side of (6.9) is

(6.10)
$$\begin{aligned}
&\sum_{n=0}^{M} e^{\frac{in\Delta t}{T}(T\tau+\pi)} = \frac{e^{\frac{i(M+1)\Delta t}{T}(T\tau+\pi)} - 1}{e^{\frac{i\Delta t}{T}(T\tau+\pi)} - 1} = \frac{e^{\frac{i(M+1)\Delta t}{T}(T\tau+\pi)} - 1}{\cos(\frac{\Delta t}{T}(T\tau+\pi)) + i\sin(\frac{\Delta t}{T}(T\tau+\pi)) - 1} \\
&= \frac{e^{i(T\tau+\pi)} - 1}{1 - 2\sin^2(\frac{\Delta t}{2T}(T\tau+\pi)) + 2i\sin(\frac{\Delta t}{2T}(T\tau+\pi))\cos(\frac{\Delta t}{2T}(T\tau+\pi)) - 1} \\
&= \frac{-e^{iT\tau} - 1}{2i\sin(\frac{\Delta t}{2T}(T\tau+\pi))(\cos(\frac{\Delta t}{2T}(T\tau+\pi)) + i\sin(\frac{\Delta t}{2T}(T\tau+1\pi)))} \\
&= \frac{-(e^{iT\tau}+1)e^{-\frac{i\Delta t}{2T}(T\tau+\pi)}}{2i\sin(\frac{\Delta t}{2T}(T\tau+\pi))}.
\end{aligned}$$

For the second one we have

(6.11)
$$\begin{aligned}
&\sum_{n=0}^{M} e^{\frac{in\Delta t}{T}(T\tau-\pi)} = \frac{e^{\frac{i(M+1)\Delta t}{T}(T\tau-\pi)} - 1}{e^{\frac{i\Delta t}{T}(T\tau-\pi)} - 1} = \frac{e^{\frac{i(M+1)\Delta t}{T}(T\tau-\pi)} - 1}{\cos\frac{\Delta t}{T}(T\tau-\pi) + i\sin\frac{\Delta t}{T}(T\tau-\pi) - 1} \\
&= \frac{e^{i(T\tau-\pi)} - 1}{-2\sin^2\frac{\Delta t}{2T}(T\tau-\pi) + 2i\sin\frac{\Delta t}{2T}(T\tau-\pi)\cos\frac{\pi\Delta t}{2T}(T\tau-\pi)} \\
&= \frac{-e^{iT\tau} - 1}{2i\sin\frac{\Delta t}{2T}(T\tau-\pi)e^{\frac{i\Delta t}{2T}(T\tau-\pi)}} = \frac{-(e^{iT\tau}+1)e^{-\frac{i\Delta t}{2T}(T\tau-\pi)}}{2i\sin\frac{\Delta t}{2T}(T\tau-\pi)}.
\end{aligned}$$

Substituting (6.10) and (6.11) into (6.9) we obtain

(6.12)

$$
\begin{aligned}
&H(\tau)\\
&= \frac{-\Delta t}{4}\left[\frac{(e^{iT\tau}+1)e^{-\frac{i\Delta t}{2T}(T\tau-\pi)}}{\sin\frac{\Delta t}{2T}(T\tau-\pi)} - \frac{(e^{iT\tau}+1)e^{-\frac{i\Delta t}{2T}(T\tau+\pi)}}{\sin(\frac{\Delta t}{2T}(T\tau+\pi))}\right]\\
&= \frac{-\Delta t(e^{iT\tau}+1)}{4}\left(\frac{\cos\frac{\Delta t}{2T}(T\tau-\pi) - i\sin\frac{\Delta t}{2T}(T\tau-\pi)}{\sin\frac{\Delta t}{2T}(T\tau-\pi)}\right.\\
&\left.-\frac{\cos\frac{\Delta t}{2T}(T\tau+\pi) - i\sin(\frac{\Delta t}{2T}(T\tau+\pi))}{\sin(\frac{\Delta t}{2T}(T\tau+\pi))}\right)\\
&= \frac{-\Delta t(e^{iT\tau}+1)}{4}\left(\frac{\cos\frac{\Delta t}{2T}(T\tau-\pi)}{\sin\frac{\Delta t}{2T}(T\tau-\pi)} - \frac{\cos\frac{\Delta t}{2T}(T\tau+\pi)}{\sin(\frac{\Delta t}{2T}(T\tau+\pi))}\right)\\
&= \frac{-\Delta t(e^{iT\tau}+1)}{4}\left(\frac{\cos\frac{\Delta t}{2T}(T\tau-\pi)\sin\frac{\Delta t}{2T}(T\tau+\pi) - \cos\frac{\Delta t}{2T}(T\tau+\pi)\sin\frac{\Delta t}{2T}(T\tau-\pi)}{\sin\frac{\Delta t}{2T}(T\tau-\pi)\sin(\frac{\Delta t}{2T}(T\tau+\pi)}\right)\\
&= \frac{-\Delta t(e^{iT\tau}+1)}{4\sin\frac{\Delta t}{2T}(T\tau-\pi)\sin\frac{\pi\Delta t}{2T}(T\tau+\pi)}\sin\frac{\pi\Delta t}{T}.
\end{aligned}
$$

Therefore, applying Euler's formula in (6.12) we obtain the following expression for H:

(6.13)

$$
\begin{aligned}
H(\tau) &= \frac{-\Delta t\left(\cos(T\tau)+i\sin(T\tau)+1\right)\sin\frac{\pi\Delta t}{T}}{4\sin\frac{\Delta t}{2T}(T\tau-\pi)\sin(\frac{\Delta t}{2T}(T\tau+\pi))}\\
&= \frac{-\Delta t\left(2\cos^2\frac{T\tau}{2}-1+2i\sin\frac{T\tau}{2}\cos\frac{T\tau}{2}+1\right)\sin\frac{\pi\Delta t}{T}}{4\sin\frac{\Delta t}{2T}(T\tau-\pi)\sin(\frac{\Delta t}{2T}(T\tau+\pi))}\\
&= \frac{-2\Delta t\cos\frac{T\tau}{2}\left(\cos\frac{T\tau}{2}+i\sin\frac{T\tau}{2}\right)\sin\frac{\pi\Delta t}{T}}{4\sin\frac{\Delta t}{2T}(T\tau-\pi)\sin(\frac{\Delta t}{2T}(T\tau+\pi)}\\
&= \frac{-\Delta t\cos\frac{T\tau}{2}e^{\frac{iT\tau}{2}}\sin\frac{\pi\Delta t}{T}}{2\sin\frac{\Delta t}{2T}(T\tau-\pi)\sin(\frac{\pi\Delta t}{2T}(T\tau+\pi))}.
\end{aligned}
$$

Moreover, if $\tau = 2k\pi/\Delta t + \pi/T$, with $k \in \mathbb{Z}$, using the definition (6.5) of H, we deduce that

$$
\begin{aligned}
H(\tau) &= \Delta t\sum_{n=0}^{M}\sin\frac{n\pi\Delta t}{T}e^{in\Delta t\left(\frac{2k\pi}{\Delta t}+\frac{\pi}{T}\right)}\\
&= \Delta t\sum_{n=0}^{M}\frac{e^{\frac{in\Delta t\pi}{T}}-e^{-\frac{in\Delta t\pi}{T}}}{2i}e^{2k\pi in}e^{\frac{in\Delta t\pi}{T}} = \frac{\Delta t}{2i}\sum_{n=0}^{M}e^{\frac{2in\Delta t\pi}{T}} - \frac{\Delta t}{2i}\sum_{n=0}^{M}1\\
&= \frac{\Delta t}{2i}\frac{e^{\frac{2i(M+1)\Delta t\pi}{T}}-1}{e^{\frac{2i\Delta t\pi}{T}}-1} - \frac{\Delta t}{2i}(M+1) = \frac{\Delta t}{2i}\frac{e^{2\pi i}-1}{e^{\frac{2i\Delta t\pi}{T}}-1} - \frac{T}{2i} = -\frac{T}{2i}.
\end{aligned}
$$

For every $\tau = 2k\pi/\Delta t - \pi/T$, with $k \in \mathbb{Z}$,

$$\begin{aligned} H(\tau) &= \Delta t \sum_{n=0}^{M} \sin \frac{n\pi\Delta t}{T} e^{in\Delta t\left(\frac{2k\pi}{\Delta t} - \frac{\pi}{T}\right)} \\ &= \Delta t \sum_{n=0}^{M} \frac{e^{\frac{in\Delta t\pi}{T}} - e^{-\frac{in\Delta t\pi}{T}}}{2i} e^{2k\pi in} e^{\frac{-in\Delta t\pi}{T}} \\ &= \frac{\Delta t}{2i} \sum_{n=0}^{M} 1 - \frac{\Delta t}{2i} e^{\frac{-2i(M+1)\Delta t\pi}{T}} \sum_{n=0}^{M} e^{\frac{2in\Delta t\pi}{T}} \\ &= \frac{\Delta t}{2i}(M+1) - \frac{\Delta t}{2i} \frac{e^{\frac{2i(M+1)\Delta t\pi}{T}} - 1}{e^{\frac{2i\Delta t\pi}{T}} - 1} = \frac{T}{2i} - \frac{\Delta t}{2i} \frac{e^{2\pi i} - 1}{e^{\frac{2i\Delta t\pi}{T}} - 1} = \frac{T}{2i}. \end{aligned}$$

• *Step 2. It is easy to see that H is continuous on $\mathbb{R}\backslash\{\tau : \tau = 2k\pi/\Delta t \pm \pi/T\}$, $k \in \mathbb{Z}$. We now study the continuity of H at the singularities $\tau = 2k\pi/\Delta t \pm \pi/T$. For every $\tau \to 2k\pi/\Delta t \pm \pi/T$, we have $\tau = 2k\pi/\Delta t \pm \pi/T + \varepsilon\pi$, with $\varepsilon \to 0$.*

1. *The case $\tau = 2k\pi/\Delta t + \pi/T + \varepsilon\pi$ with $\varepsilon \to 0$.*
   Using the definition of H we have

$$\begin{aligned} H\left(\frac{2k\pi}{\Delta t} + \frac{\pi}{T} + \varepsilon\pi\right) &= \Delta t \sum_{n=0}^{M} \sin \frac{n\pi\Delta t}{T} e^{in\Delta t\pi\left(\frac{2k}{\Delta t} + \frac{1}{T} + \varepsilon\right)} \\ &= \Delta t \sum_{n=0}^{M} \frac{e^{\frac{in\Delta t\pi}{T}} - e^{-\frac{in\Delta t\pi}{T}}}{2i} e^{in\pi 2k} e^{in\Delta t\pi\left(\frac{1}{T} + \varepsilon\right)}. \end{aligned}$$

   Hence,

$$H\left(\frac{2k\pi}{\Delta t} + \frac{\pi}{T} + \varepsilon\pi\right) = \frac{\Delta t}{2i} \sum_{n=0}^{M} e^{\frac{in\Delta t\pi}{T}(2+T\varepsilon)} - \frac{\Delta t}{2i} \sum_{n=0}^{M} e^{in\Delta t\pi\varepsilon}. \tag{6.14}$$

   For every $|x| < 2T/\Delta t$, according to the classical formula for the sum of a geometric series, the following identity holds:

$$\sum_{n=0}^{M} e^{\frac{in\Delta t\pi}{T}x} = \frac{e^{\frac{i(M+1)\Delta t\pi}{T}x} - 1}{e^{\frac{i\Delta t\pi}{T}x} - 1} = \frac{e^{i\pi x} - 1}{e^{\frac{i\Delta t\pi}{T}x} - 1}. \tag{6.15}$$

   For the first sum entering on the right-hand term of (6.14) we have

$$\sum_{n=0}^{M} e^{\frac{in\Delta t\pi}{T}(2+T\varepsilon)} = \frac{e^{2\pi i} e^{iT\pi\varepsilon} - 1}{e^{\frac{i\Delta t\pi}{T}(2+T\varepsilon)} - 1} = \frac{e^{iT\pi\varepsilon} - 1}{e^{\frac{i\Delta t\pi}{T}(2+T\varepsilon)} - 1}. \tag{6.16}$$

   For the second sum on the right-hand term (6.14), using (6.15) and the fact that $\Delta t\pi/T(2 + T\varepsilon) < 2\pi$, we have

$$\sum_{n=0}^{M} e^{in\Delta t\pi\varepsilon} = \frac{e^{iT\pi\varepsilon} - 1}{e^{i\Delta t\pi\varepsilon} - 1}. \tag{6.17}$$

Finally, replacing (6.16) and (6.17) in (6.14) and taking the limit $\varepsilon \to 0$ we obtain

$$\lim_{\varepsilon\to 0} H\left(\frac{2k\pi}{\Delta t}+\frac{\pi}{T}+\varepsilon\pi\right)= \frac{\Delta t}{2i}\lim_{\varepsilon\to 0}\frac{e^{iT\pi\varepsilon}-1}{e^{\frac{i\Delta t\pi}{T}(2+T\varepsilon)}-1}-\frac{\Delta t}{2i}\lim_{\varepsilon\to 0}\frac{e^{iT\pi\varepsilon}-1}{e^{i\Delta t\pi\varepsilon}-1}$$

$$= 0-\frac{\Delta t}{2i}\lim_{\varepsilon\to 0}\frac{e^{iT\pi\varepsilon}-1}{e^{i\Delta t\pi\varepsilon}-1}=-\frac{\Delta t}{2i}\lim_{\varepsilon\to 0}\frac{i\pi Te^{iT\pi\varepsilon}}{i\Delta t\pi e^{i\Delta t\pi\varepsilon}}=-\frac{T}{2i}.$$

2. *The case $\tau = 2k\pi/\Delta t - \pi/T + \varepsilon\pi$ with $\varepsilon \to 0$.*
We have

$$H\left(\frac{2k\pi}{\Delta t}-\frac{\pi}{T}+\varepsilon\pi\right)=\Delta t\sum_{n=0}^{M}\sin\frac{n\pi\Delta t}{T}e^{in\Delta t\pi\left(\frac{2k}{\Delta t}-\frac{1}{T}+\varepsilon\right)}$$

$$=\Delta t\sum_{n=0}^{M}\frac{e^{\frac{in\Delta t\pi}{T}}-e^{-\frac{in\Delta t\pi}{T}}}{2i}e^{in\pi 2k}e^{in\Delta t\pi\varepsilon}e^{-\frac{in\Delta t\pi}{T}}.$$

Hence

$$H\left(\frac{2k\pi}{\Delta t}-\frac{\pi}{T}+\varepsilon\pi\right)=\frac{\Delta t}{2i}\sum_{n=0}^{M}e^{in\Delta t\pi\varepsilon}-\frac{\Delta t}{2i}\sum_{n=0}^{M}e^{\frac{in\Delta t\pi}{T}(T\varepsilon-2)}. \tag{6.18}$$

By (6.17), for the first sum entering on the right-hand term of (6.18) we have

$$\sum_{n=0}^{M}e^{in\Delta t\pi\varepsilon}=\frac{e^{iT\pi\varepsilon}-1}{e^{i\Delta t\pi\varepsilon}-1}. \tag{6.19}$$

Moreover, in (6.17), applying the identity (6.15) for the second sum on the right-hand term of (6.18), we obtain

$$\sum_{n=0}^{M}e^{-\frac{in\Delta t\pi}{T}(2-T\varepsilon)}=e^{-\frac{i(M+1)\Delta t\pi}{T}(2-T\varepsilon)}\sum_{n=0}^{M}e^{\frac{in\Delta t\pi}{T}(2-T\varepsilon)}$$

$$=\!= e^{-2\pi i}e^{iT\pi\varepsilon}\frac{e^{\frac{i(M+1)\Delta t\pi}{T}(2-T\varepsilon)}-1}{e^{\frac{i\Delta t\pi}{T}(2-T\varepsilon)}-1}=e^{iT\pi\varepsilon}\frac{e^{2\pi i}e^{-iT\pi\varepsilon}-1}{e^{\frac{i\Delta t\pi}{T}(2-T\varepsilon)}-1}$$

$$=\frac{1-e^{iT\pi\varepsilon}}{e^{\frac{i\Delta t\pi}{T}(2-T\varepsilon)}-1}\to 0,\quad \varepsilon\to 0. \tag{6.20}$$

Hence,

$$\lim_{\varepsilon\to 0}H\left(\frac{2k\pi}{\Delta t}-\frac{\pi}{T}+\varepsilon\pi\right)=\frac{T}{\Delta t}\frac{\Delta t}{2i}=\frac{T}{2i}.$$

This concludes the proof of Lemma 6.2. □

Remark 6.3. For $\tau = 0$ in (6.6) we have

$$H(0) \quad =-\frac{\Delta t\sin\frac{\Delta t\pi}{T}}{2\sin\frac{\pi\Delta t}{2T}\sin\left(-\frac{\pi\Delta t}{2T}\right)}=-\frac{\Delta t\sin\frac{\Delta t\pi}{T}}{-2\sin^2\frac{\pi\Delta t}{2T}}$$

$$=\frac{\Delta t2\sin\frac{\Delta t\pi}{2T}\cos\frac{\Delta t\pi}{2T}}{2\sin^2\frac{\pi\Delta t}{2T}}=\frac{\Delta t\cos\frac{\Delta t\pi}{2T}}{\sin\frac{\pi\Delta t}{2T}}=\Delta t\cot\frac{\Delta t\pi}{2T}. \tag{6.21}$$

Taking the limit $\Delta t \to 0$ in (6.6), for every τ fixed, we obtain

$$\lim_{\Delta t \to 0} H(\tau) = -2\cos\frac{T\tau}{2} e^{\frac{iT\tau}{2}} \frac{\pi T}{T^2\tau^2 - \pi^2} = G(\tau) \tag{6.22}$$

and this is the classical Fourier transform of g given by (6.4).

6.3. Proof of Theorem 2.1. *This section is devoted to the proof of the main result of this paper. The proof of the discrete inequality (2.3) follows the strategy used in [26, (pp. 162–163)] to prove the classical Ingham inequality (1.2).*

Proof (Proof of the first (so-called inverse) inequality in (2.3)). We prove the first inequality in (2.3), namely,

$$C_1(\Delta t, T, \gamma) \sum_{k=-N}^{N} |a_k|^2 \le \Delta t \sum_{n=0}^{M} \left| \sum_{k=-N}^{N} a_k e^{in\Delta t\lambda_k} \right|^2 .$$

Taking into account that $\sin(n\Delta t\pi/T) \le 1$, *we have*

$$\begin{aligned} \Delta t \sum_{n=0}^{M} \left| \sum_k a_k e^{in\Delta t\lambda_k} \right|^2 &\ge \Delta t \sum_{n=0}^{M} \sin\frac{n\Delta t\pi}{T} \left| \sum_k a_k e^{in\Delta t\lambda_k} \right|^2 \\ &= \Delta t \sum_{n=0}^{M} \sin\frac{n\Delta t\pi}{T} \sum_k \sum_l a_k \bar{a}_l e^{in\Delta t(\lambda_k - \lambda_l)}. \end{aligned}$$

The function H defined by (6.6) is continuous, hence

$$\begin{aligned} &\Delta t \sum_{n=0}^{M} \sin\frac{n\Delta t\pi}{T} \sum_k \sum_l a_k \bar{a}_l e^{in\Delta t(\lambda_k - \lambda_l)} \\ &= \sum_k \sum_l a_k \bar{a}_l H(\lambda_k - \lambda_l) = H(0) \sum_k |a_k|^2 + \sum_k \sum_{l, l\neq k} a_k \bar{a}_l H(\lambda_k - \lambda_l) \\ &\ge H(0) \sum_k |a_k|^2 - \frac{1}{2} \sum_k \sum_{l, l\neq k} \left(|a_k|^2 + |a_l|^2 \right) |H(\lambda_k - \lambda_l)| \\ &= H(0) \sum_k |a_k|^2 - \sum_k |a_k|^2 \sum_{l, l\neq k} |H(\lambda_k - \lambda_l)| . \end{aligned} \tag{6.23}$$

In the last term in (6.23) we have

$$\sum_{l, k\neq l} |H(\lambda_k - \lambda_l)| = \sum_{\substack{l, k\neq l \\ |\lambda_k - \lambda_l| \le \frac{\pi}{\Delta t}}} |H(\lambda_k - \lambda_l)| + \sum_{\substack{l, k\neq l \\ |\lambda_k - \lambda_l| > \frac{\pi}{\Delta t}}} |H(\lambda_k - \lambda_l)| . \tag{6.24}$$

Moreover, the function H is periodic with period $2\pi/\Delta t$. Consequently, for every $k, l \in \mathbb{Z}$ with $\pi/\Delta t < |\lambda_k - \lambda_l| < 2\pi/\Delta t$, there exist $m_{k,l} \in [-\pi/\Delta t, \pi/\Delta t]$ such that $|m_{k,l}| = 2\pi/\Delta t - |\lambda_k - \lambda_l|$ with the property $H(\lambda_k - \lambda_l) = H(m_{k,l})$. Therefore, using this periodicity property and applying (6.2) from Theorem 6.1 and (6.24) in (6.23),

we obtain

(6.25)
$$\Delta t\sum_{n=0}^{M}\left|\sum_k a_k e^{in\Delta t\lambda_k}\right|^2$$
$$\geq H(0)\sum_k |a_k|^2-\sum_k |a_k|^2\left(\sum_{\substack{l,k\neq l\\ |\lambda_k-\lambda_l|\leq \pi/\Delta t}}|H(\lambda_k-\lambda_l)|+\sum_{\substack{l,k\neq l\\ |m_{k,l}|\leq \pi/\Delta t}}|H(m_{k,l})|\right)$$
$$\geq H(0)\sum_k |a_k|^2-\sum_k |a_k|^2\left(\sum_{\substack{l,k\neq l\\ |\lambda_k-\lambda_l|\leq \pi/\Delta t}}|G(\lambda_k-\lambda_l)|+\sum_{\substack{l,k\neq l\\ |m_{k,l}|\leq \pi/\Delta t}}|G(m_{k,l})|\right)$$
$$+CN(\Delta t)^2\Big).$$

On the other hand, as pointed out in [26, p. 162], for every sequence $\{\lambda_k\}$ satisfying the gap condition (2.1), the function G satisfies

(6.26)
$$\sum_{l\neq k,l=-N}^{N}|G(\lambda_k-\lambda_l)|\leq 2\pi T\sum_{l=-\infty,l\neq k}^{\infty}\frac{1}{T^2\left(\lambda_k-\lambda_l\right)^2-\pi^2}$$
$$\leq 2\pi T\sum_{l=-\infty,l\neq k}^{\infty}\frac{1}{T^2\gamma^2\left(k-l\right)^2-\pi^2}=4\pi T\sum_{r\geq 1}\frac{1}{\frac{T^2\gamma^2}{4\pi^2}4\pi^2r^2-\pi^2}\leq\frac{16\pi}{T\gamma^2}\sum_{r\geq 1}\frac{1}{4r^2-1}$$
$$=\frac{8\pi}{T\gamma^2}\sum_{r\geq 1}\left(\frac{1}{2r-1}-\frac{1}{2r+1}\right)=\frac{8\pi}{T\gamma^2}.$$

Further, for the terms of the sequence $\{\lambda_k\}$ satisfying $\pi/\Delta t <\mid \lambda_k-\lambda_l \mid< (2\pi-(\Delta t)^p)/\Delta t$, (and then, $(\Delta t)^{p-1}\leq |m_{k,l}|\leq \pi/\Delta t$), $k\neq l$, we have

$$|G(m_{k,l})|\leq 2\pi T\frac{1}{T^2\left(m_{k,l}\right)^2-\pi^2}=2\pi T\frac{1}{T^2\left(\frac{2\pi}{\Delta t}-(\lambda_l-\lambda_l)\right)^2-\pi^2}$$
$$\leq 2\pi T\frac{1}{T^2\left(\frac{2\pi}{\Delta t}-\frac{2\pi-(\Delta t)^p}{\Delta t}\right)^2-\pi^2}=2\pi T\frac{\Delta t^2}{T^2(\Delta t)^{2p}-\pi^2\Delta t^2}$$

and it follows that

$$\sum_{l\neq k,l=-N}^{N}|G(m_{k,l})|\leq (N\Delta t)2\pi T\frac{(\Delta t)^{1-2p}}{T^2-\pi^2(\Delta t)^{2-2p}}. \tag{6.27}$$

Using the relations (6.26) and (6.27) in (6.25) we obtain

$$\Delta t\sum_{n=0}^{M}\sin\frac{n\Delta t\pi}{T}\sum_k\sum_l a_k\bar{a}_l e^{in\Delta t(\lambda_k-\lambda_l)}$$
$$\geq H(0)\sum_k |a_k|^2-\sum_k |a_k|^2\left[\frac{8\pi}{T\gamma^2}+NC\Delta t^2+CN\Delta t(\Delta t)^{1-2p}\right] \tag{6.28}$$

when $\Delta t \to 0$. *For the function* $H(0)$ *given by (6.21) we have* $\lim_{\Delta t \to 0} H(0) = 2T/\pi$, *which is equivalent to* $2T/\pi - \theta \le H(0) \le 2T/\pi + \theta$, *with* $\theta \to 0$ *when* $\Delta t \to 0$. *In order to ensure the positivity of all the coefficients* $|a_k|^2$ *in (6.28) it is necessary and sufficient to have*

$$C_1(\Delta t, T, \gamma) := H(0) - \frac{8\pi}{T\gamma^2} - (NC\Delta t^2 + CN\Delta t(\Delta t)^{1-2p}) > 0, \tag{6.29}$$

which is equivalent to

$$T^2 - \frac{T\pi}{2}(\theta + \varepsilon_1) - \frac{4\pi^2}{\gamma^2} > 0,$$

where $\varepsilon_1 = NC\Delta t^2 + CN\Delta t(\Delta t)^{1-2p}$, $C > 0$. *This condition holds for every*

$$T(\Delta t) > T_0(\Delta t) = \frac{\frac{\pi}{2}(\varepsilon_1 + \theta) + \sqrt{\frac{\pi^2}{4}(\theta + \varepsilon_1)^2 + \frac{16\pi^2}{\gamma^2}}}{2} := \frac{2\pi}{\gamma} + \epsilon(\Delta t)$$

with $\epsilon(\Delta t) = C(\Delta t + N\Delta t(\Delta t)^{1-2p})$. *Hence, the inequality (2.3) holds with the constant* $C_1(\Delta t, T, \gamma)$ *defined by the relation (6.29) where* $\delta_1(\Delta t) = -(\varepsilon_1 + \theta)$.

Proof of the second (so-called direct) inequality. We now prove the inequality

$$\Delta t \sum_{n=0}^{M} \left| \sum_{k=-N}^{N} a_k e^{in\Delta t\lambda_k} \right|^2 \le C_2(\Delta t, T, \gamma) \sum_{k=-N}^{N} |a_k|^2 .$$

We have

$$\Delta t \sum_{n=0}^{M} \left| \sum_{k} a_k e^{in\Delta t\lambda_k} \right|^2 = \Delta t \sum_{n=0}^{\left[\frac{M}{2}\right]} \left| \sum_{k} a_k e^{in\Delta t\lambda_k} \right|^2 + \Delta t \sum_{n=\left[\frac{M}{2}\right]+1}^{M} \left| \sum_{k} a_k e^{in\Delta t\lambda_k} \right|^2 . \tag{6.30}$$

Consider the first term on the right-hand side of (6.30),

$$\begin{aligned} \Delta t \sum_{n=0}^{\left[\frac{M}{2}\right]} \left| \sum_{k} a_k e^{in\Delta t\lambda_k} \right|^2 &= \Delta t \sum_{n=\left[\frac{M+1}{4}\right]+1}^{\left[\frac{M}{2}\right]+\left[\frac{M+1}{4}\right]+1} \left| \sum_{k} a_k e^{i\left(n-\left[\frac{M+1}{4}\right]-1\right)\Delta t\lambda_k} \right|^2 \\ &= \Delta t \sum_{n=\left[\frac{M+1}{4}\right]+1}^{\left[\frac{M}{2}\right]+\left[\frac{M+1}{4}\right]} \left| \sum_{k} a_k e^{i\left(n-\left[\frac{M+1}{4}\right]-1\right)\Delta t\lambda_k} \right|^2 + \Delta t \left| \sum_{k} a_k e^{i\left[\frac{M}{2}\right]\Delta t\lambda_k} \right|^2 . \end{aligned} \tag{6.31}$$

Using the properties of the entire part of a real number we have

$$\begin{aligned} &\left[\frac{M+1}{4}\right] \le \frac{M+1}{4} \le \left[\frac{M+1}{4}\right] + 1, \\ &\left[\frac{M}{2}\right] + \left[\frac{M+1}{4}\right] \le \left[\frac{3M+1}{4}\right], \\ &\left[\frac{3M+1}{4}\right] \le \frac{3M+1}{4} \le \left[\frac{3M+1}{4}\right] + 1. \end{aligned}$$

For every $n \in \mathbb{N}$ *with* $\left[\frac{M+1}{4}\right]+1 \leq n \leq \left[\frac{3M+1}{4}\right]$, *we have*

$$\frac{M+1}{4} \leq n \leq \frac{3M+1}{4} \tag{6.32}$$

and

$$\frac{\pi}{4} \leq \frac{n\pi\Delta t}{T} \leq \frac{3\pi}{4},$$

due to the fact that $(M+1)\Delta t = T$.

Therefore, for every $n \in \mathbb{N}$ *as in (6.32) we have* $\sin(n\pi\Delta t/T) \geq \sqrt{2}/2$ *and*

$$\begin{aligned}
&\Delta t \sum_{n=\left[\frac{M+1}{4}\right]+1}^{\left[\frac{M}{2}\right]+\left[\frac{M+1}{4}\right]} \left|\sum_k a_k e^{i\left(n-\left[\frac{M+1}{4}\right]-1\right)\Delta t\lambda_k}\right|^2 + \Delta t\left|\sum_k a_k e^{i\left[\frac{M}{2}\right]\Delta t\lambda_k}\right|^2 \\
&\leq 2\Delta t \sum_{n=\left[\frac{M+1}{4}\right]+1}^{\left[\frac{M}{2}\right]+\left[\frac{M+1}{4}\right]} \sin\frac{n\pi\Delta t}{T}\left|\sum_k a_k e^{i\left(n-\left[\frac{M+1}{4}\right]-1\right)\Delta t\lambda_k}\right|^2 + \Delta t\left|\sum_k a_k e^{i\left[\frac{M}{2}\right]\Delta t\lambda_k}\right|^2 \\
&\leq 2\Delta t \sum_{n=0}^{M} \sin\frac{n\pi\Delta t}{T}\left|\sum_k a_k e^{in\Delta t\lambda_k} e^{-i\left(\left[\frac{M+1}{4}\right]+1\right)\Delta t\lambda_k}\right|^2 + \Delta t\left|\sum_k a_k e^{i\left[\frac{M}{2}\right]\Delta t\lambda_k}\right|^2 \\
&= 2\Delta t \sum_{n=0}^{M} \sin\frac{n\pi\Delta t}{T} \sum_k\sum_l a_k\bar{a}_l e^{in\Delta t(\lambda_k-\lambda_l)} e^{-i\left(\left[\frac{M+1}{4}\right]+1\right)\Delta t(\lambda_k-\lambda_l)} \\
&+\Delta t \sum_k\sum_l a_k\bar{a}_l e^{2i\left[\frac{M}{2}\right]\Delta t(\lambda_k-\lambda_l)} \\
&= 2\sum_k\sum_l a_k\bar{a}_l H(\lambda_k-\lambda_l) e^{-i\left(\left[\frac{M+1}{4}\right]+1\right)\Delta t(\lambda_k-\lambda_l)} + \Delta t\sum_k\sum_l a_k\bar{a}_l e^{i\left[\frac{M}{2}\right]\Delta t(\lambda_k-\lambda_l)} \\
&= 2H(0)\sum_k |a_k|^2 + 2\sum_k\sum_{l,l\neq k} a_k\bar{a}_l H(\lambda_k-\lambda_l) e^{-i\left(\left[\frac{M+1}{4}\right]+1\right)\Delta t(\lambda_k-\lambda_k)} \\
&+\Delta t\sum_k |a_k|^2 + \Delta t\sum_k\sum_{l,l\neq k} a_k\bar{a}_l e^{i\left[\frac{M}{2}\right]\Delta t(\lambda_k-\lambda_k)} \\
&\leq 2H(0)\sum_k |a_k|^2 + \sum_k\sum_{l,l\neq k}\left(|a_k|^2+|a_l|^2\right)|H(\lambda_k-\lambda_l)| + \Delta t\sum_k |a_k|^2
\end{aligned}$$

$$\begin{aligned}
&+\frac{N\Delta t}{2}\sum_k\sum_{l,l\neq k}\left(|a_k|^2+|a_l|^2\right) \\
&\leq 2H(0)\sum_k |a_k|^2 + 2\sum_k |a_k|^2 \sum_{l,l\neq k}|H(\lambda_k-\lambda_l)| + \Delta t\sum_k |a_k|^2 + 2N\Delta t\sum_k |a_k|^2.
\end{aligned} \tag{6.33}$$

Using the same argument (6.2) as in the proof of the inverse inequality, for every $C > 0$, *we have*

$$\sum_{l,k\neq l} |H(\lambda_k - \lambda_l)| \leq \sum_{l\neq k, l=-N}^{N} |G(\lambda_k - \lambda_l)| + CN(\Delta t)^2, \tag{6.34}$$

when Δt *is small enough, with* G *the Fourier transform (6.4) satisfying (6.26) and (6.27).*

Therefore, for every k,

$$\begin{aligned}
&2H(0)\sum_k |a_k|^2 + \sum_k \sum_{l,l\neq k} \left(|a_k|^2 + |a_l|^2\right) |H(\lambda_k - \lambda_l)| + \Delta t \sum_k |a_k|^2 \\
&+\frac{N\Delta t}{2} \sum_k \sum_{l,l\neq k} \left(|a_k|^2 + |a_l|^2\right) \leq 2\Delta t \cot\frac{\Delta t\pi}{2T} \sum_k |a_k|^2 \\
&+2\sum_k |a_k|^2 \left(\frac{8\pi}{T\gamma^2} + NC\Delta t^2 + CN\Delta t(\Delta t)^{1-2p} + 2\Delta t\right) + 2N\Delta t \sum_k |a_k|^2 .
\end{aligned}$$

Hence

$$\Delta t \sum_{n=0}^{\left[\frac{M}{2}\right]} \left|\sum_k a_k e^{in\Delta t\lambda_k}\right|^2 \leq \sum_k |a_k|^2 \left(2\Delta t \cot\frac{\Delta t\pi}{2T} + \frac{16\pi}{T\gamma^2} + \varepsilon(\Delta t)\right), \tag{6.35}$$

with $\varepsilon(\Delta t) = 2NC\Delta t^2 + 2CN\Delta t(\Delta t)^{1-2p} + 2\Delta t + 2N\Delta t$.

For the second right-hand term of (6.30) we have

$$\begin{aligned}
&\Delta t \sum_{n=\left[\frac{M}{2}\right]+1}^{M} \left|\sum_k a_k e^{in\Delta t\lambda_k}\right|^2 = \Delta t \sum_{n=\left[\frac{M}{2}\right]-\left[\frac{M+1}{4}\right]}^{M-\left[\frac{M+1}{4}\right]-1} \left|\sum_k a_k e^{i(n+\left[\frac{M+1}{4}\right]+1)\Delta t\lambda_k}\right|^2 \\
&= \Delta t \sum_{n=\left[\frac{M}{2}\right]+1-\left[\frac{M+1}{4}\right]}^{M-\left[\frac{M+1}{4}\right]-1} \left|\sum_k a_k e^{i(n+\left[\frac{M+1}{4}\right]+1)\Delta t\lambda_k}\right|^2 + \Delta t \sum_k \left|a_k e^{i(\left[\frac{M}{2}\right]+1)\Delta t\lambda_k}\right|^2 .
\end{aligned}$$

Taking into account that

$$M - \left[\frac{M+1}{4}\right] - 1 \leq \frac{3M+1}{4} \text{ and } \left[\frac{M}{2}\right] - \left[\frac{M+1}{4}\right] + 1 \geq \frac{M+1}{4},$$

for every $n \in \mathbb{N}$, *with* $(M+1)/4 \leq n \leq (3M+1)/4$ *we have* $\sin(n\pi\Delta t/T) \geq \sqrt{2}/2$.

Thus,

$$\begin{aligned}
&\Delta t \sum_{n=\left[\frac{M}{2}\right]+1}^{M} \left| \sum_k a_k e^{in\Delta t\lambda_k} \right|^2 \\
&\leq 2\Delta t \sum_{n=\left[\frac{M}{2}\right]+1-\left[\frac{M+1}{4}\right]}^{M-\left[\frac{M+1}{4}\right]-1} \sin\frac{n\pi\Delta t}{T} \left| \sum_k a_k e^{i(n+\left[\frac{M+1}{4}\right]+1)\Delta t\lambda_k} \right|^2 \\
&+\Delta t \sum_k \left| a_k e^{i(\left[\frac{M}{2}\right]+1)\Delta t\lambda_k} \right|^2 \\
&\leq 2\Delta t \sum_{n=0}^{M} \sin\frac{n\pi\Delta t}{T} \left| \sum_k a_k e^{in\Delta t\lambda_k} e^{i(\left[\frac{M+1}{4}\right]+1)\Delta t\lambda_k} \right|^2 + \Delta t \sum_k \left| a_k e^{i(\left[\frac{M}{2}\right]+1)\Delta t\lambda_k} \right|^2 \\
&= 2\Delta t \sum_{n=0}^{M} \sin\frac{n\pi\Delta t}{T} \sum_k \sum_l a_k \bar{a}_l e^{in\Delta t(\lambda_k-\lambda_l)} e^{i\left(\left[\frac{M+1}{4}\right]+1\right)\Delta t(\lambda_k-\lambda_k)} \\
&+\Delta t \sum_k \left| a_k e^{i(\left[\frac{M}{2}\right]+1)\Delta t\lambda_k} \right|^2
\end{aligned}$$

and we obtain the estimate

(6.36)
$$\begin{aligned}
&\Delta t \sum_{n=\left[\frac{M}{2}\right]+1}^{M} \left| \sum_k a_k e^{in\Delta t\lambda_k} \right|^2 \\
&\leq 2H(0) \sum_k |a_k|^2 + 2 \sum_k \sum_{l,l\neq k} |a_k|^2 |H(\lambda_k-\lambda_l)| + 2N\Delta t \sum_k |a_k|^2 \\
&\leq \left(2\Delta t \cot\frac{\Delta t\pi}{2T} + \frac{16\pi}{T\gamma^2} + NC\Delta t^2 + CN\Delta t(\Delta t)^{1-2p} + 2N\Delta t \right) \sum_k |a_k|^2 .
\end{aligned}$$

For the function $H(0)$ defined by the relation (6.21) we have $\lim_{\Delta t\to 0} H(0) = 2T/\pi$.

From (6.30) and (6.35) we get

$$\Delta t \sum_{n=0}^{M} \left| \sum_k a_k e^{in\Delta t\lambda_k} \right|^2 \leq \left(\frac{8T}{\pi} + \frac{32\pi}{T\gamma^2} + \delta_2(\Delta t) \right) \sum_k |a_k|^2 , \tag{6.37}$$

with

$$\delta_2(\Delta t) = 4\varepsilon(\Delta t) + \theta,$$

($2T/\pi - \theta \leq H(0) \leq 2T/\pi + \theta$, with $\theta \to 0$ when $\Delta t \to 0$).

This concludes the proof of Theorem 2.1. □

Proof (Proof of Theorem 2.2). Following the same steps of the above proof we obtain the discrete version (2.5) of the L^1 Ingham's inequality (1.6) given by Theorem 2.2.

More precisely, we have

$$\Delta t \sum_{n=0}^{M} \sin \frac{n\Delta t\pi}{T} \left(\sum_k a_k e^{in\Delta t\lambda_k} \right) e^{-in\Delta t\lambda_k} = \sum_l a_l H(\lambda_k - \lambda_l), \tag{6.38}$$

where function H is defined by (6.6).

Taking $l = \nu$ in (6.38), where $|a_\nu|$ is the greatest $|a_n|$, we deduce

$$\left| \Delta t \sum_{n=0}^{M} \sin \frac{n\Delta t\pi}{T} \left(\sum_k a_k e^{in\Delta t\lambda_k} \right) e^{-in\Delta t\lambda_\nu} \right| \geq |a_\nu H(0)| - |a_\nu| \sum_{k,k\neq\nu} |H(\lambda_k - \lambda_\nu)| . \tag{6.39}$$

Function H is exactly the discrete Fourier transform (6.5) used in the proof of discrete Ingham's inequality (2.3). By (6.24) and the estimates for $|H(\lambda_k - \lambda_\nu)|$ used in the proof of Theorem 2.1, i.e.,

$$\sum_{k,k\neq\nu} |H(\lambda_k - \lambda_\nu)| \leq \left[\frac{8\pi}{T\gamma^2} + NC\Delta t^2 + CN\Delta t(\Delta t)^{1-2p} \right],$$

as in (6.28), we deduce that

$$\Delta t \sum_{n=0}^{M} \left| \sum_{k=-N}^{N} a_k e^{in\Delta t\lambda_k} \right| \geq C_1(\Delta t, T, \gamma) \max |a_n| . \tag{6.40}$$

The direct inequality in (2.5) may be obtained using the same arguments and estimates and we omit the details. □

CONVERGENCE RATE OF A SCHWARZ MULTILEVEL METHOD FOR THE CONSTRAINED MINIMIZATION OF NONQUADRATIC FUNCTIONALS*

L. BADEA†

Abstract. In [L. Badea, *Convergence Rate of a Multiplicative Schwarz Method for Strongly Nonlinear Inequalities*, V. Barbu, I. Lasiecka, D. Tiba, and C. Varsan, eds., Kluwer Academic Publishers, Boston, 2003], the convergence of a subspace correction method applied to the constrained minimization of a functional in a general reflexive Banach space has been proved, provided that the convex set verifies a certain assumption. This assumption is weaker than that in which the convex set is decomposed according to the space decomposition as a sum of subsets. In the Sobolev spaces, the proposed method becomes a multiplicative Schwarz method for the solution of the variational inequalities coming from the minimization of nonquadratic functionals. We prove in this paper that this assumption holds for the one-, two- and multilevel multiplicative Schwarz methods in the finite element space, and we explicitly write the constants in the error estimations depending on the overlapping and mesh parameters. Our error estimates are similar with those obtained for the minimization of quadratic functionals in [L. Badea, X.-C. Tai, and J. Wang, *SIAM J. Numer. Anal.*, (2003), pp. 1052–1073], or with those obtained for the one-obstacle problem in [X.-C. Tai, *Numer. Math.*, 93 (2003), pp. 755–786].

1. Introduction.

Domain decomposition methods provide efficient numerical algorithms to solve very large-scale problems. The great interest in these methods comes from the fact that they are parallelizable on multiprocessor machines. Schwarz overlapping methods represent a typical example of such parallelizable methods, and they are traditionally being classified as multiplicative and additive. The main focus of this paper is the convergence of the multiplicative Schwarz method applied to the constrained minimization of nonquadratic convex functionals.

Naturally, most papers dealing with these methods are dedicated to linear problems. The multiplicative and additive Schwarz methods for elliptic linear problems have been studied by Lions [26, 27, 28]; Chan, Hou, and Lions [10]; P. Le Tallec [25]; A. Quarteroni and A. Valli [33]; Bramble, Pasciak, Wang, and Xu [8]; and Badea [1] for the multiplicative methods, and Dryja [12]; Dryja and Widlund [13], [14]; and Nepomnyaschikh [32] for the additive version.

For the application of the Schwarz method to the solution of the variational inequalities, we can cite the papers written by Hoffman and Zou [19]; Kuznetsov and Neittaanmäki [22]; Kuznetsov, Neittaanmäki, and Tarvainen [23], [24]; Lü, Liem, and Shih [29]; Zeng and Zhou [42]; Tai [35, 36, 37]; Tai and Tseng [39]; Badea and Wang [3]; Badea, Tai, and Wang [4]; and Badea [2], [6], [7].

Also, the multilevel and multigrid methods can be viewed as domain decomposition methods and we can cite the results obtained by Kornhuber [21]; Mandel [31]; and Smith, Bjørstad, and Gropp [34].

However, very few papers deal with the application of these methods to nonlinear problems. We can cite in this direction the papers written by Tai and Espedal [38], Tai and Xu [40] for nonlinear equations, Hoffmann and Zhou [20], Lui [30], Zeng and Zhou in [43] for inequalities having nonlinear source terms, and Badea [5] for a general result concerning the convergence of the method for the constrained minimization of nonquadratic functionals. Evidently, the above lists of citations are not exhaustive and can be completed by many other papers.

Almost exclusively, the convergence of the domain decomposition methods for variational inequalities coming from the minimization of a functional is studied in the case when this functional is quadratic. Also, most papers consider the convex set decomposed according to the space decomposition as a sum of convex subsets. The main goal of this paper is to give error estimates for the one-, two- and multilevel Schwarz domain decomposition methods applied to the constrained minimization of the nonquadratic convex functionals over enough general convex sets.

The convergence of a domain decomposition algorithm solving variational inequalities coming from the minimization of quadratic functionals over convex sets is proved in [2]. In that paper, the convex set, defined by constraints on the function values at the points of the domain, is not supposed to be decomposed as a sum of convex subsets. In [40], a subspace correction method applied to the minimization without constraints of a differentiable and convex functional defined in a reflexive Banach space is introduced. Also, in [5], the convergence of an algorithm in a reflexive Banach space for the constrained minimization of convex functionals is proved. There, in order to prove the convergence, a weaker property than that given in [2] is imposed on the convex set. To the author's knowledge, there are no other papers dealing with the Schwarz method applied to the constrained minimization of nonquadratic functionals. Even if sometimes the conditions on the convex functional are general enough, the authors always consider the space H^1 and implicitly quadratic functionals. For instance, in [4], using the subspace correction techniques in [8] and [41], and more general conditions in [38] on the convex functional, the convergence rate for the one- and two-level algorithms of the method in [2] is given only for the minimization of quadratic functionals. Starting from the general convergence result given in cite [5], we generalize in this paper the results in [4] and [40] to the constrained minimization of nonquadratic functionals. Our error estimates are similar with those obtained for the minimization of quadratic functionals in [4] or [37].

The paper is organized as follows. In section 2, we state the multiplicative Schwarz method as a subspace correction method in a general reflexive Banach space for the constrained minimization of convex functionals. We also give the convergence theorem of this algorithm which has been proven in [5] provided that a certain assumption holds. In sections 3, 4, and 5 we prove that the introduced assumption holds and we estimate the error for the one-, two- and multilevel Schwarz methods, respectively, in the finite element spaces. In these cases, we are able to explicitly write the convergence rate depending on the mesh and domain decomposition parameters. The proof for the two- and multilevel methods is based on a lemma which can be viewed as a Friedrichs–Poincaré inequality for the finite element spaces. In subsection 5.1, we find the convergence rate of the multigrid method from the results obtained for the multilevel method.

Finally, for writing simplicity, we have considered the next sections problems in $W^{1,s}$, but all the obtained results hold reading $[W^{1,s}]^d$ in the place of $W^{1,s}$.

2. General convergence result. We enunciate in this section a general algorithm and give an error estimate theorem for it. This general theory, the proof of the theorem included, are given in detail in [5]. We consider that V is a reflexive Banach space and $V_1, \ldots, V_m$, are some closed subspaces of V. Also, let $K \subset V$ be a nonempty closed convex set, and we make the following

ASSUMPTION 2.1. *There exists a constant C_0 such that for any $w, v \in K$ and $w_i \in V_i$ with $w + \sum_{j=1}^{i} w_j \in K$, $i = 1, \ldots, m$, there exist $v_i \in V_i$, $i = 1, \ldots, m$, satisfying*

$$w + \sum_{j=1}^{i-1} w_j + v_i \in K \text{ for } i = 1, \ldots, m, \tag{2.1}$$

$$v - w = \sum_{i=1}^{m} v_i, \tag{2.2}$$

and

$$\sum_{i=1}^{m} ||v_i||^p \leq C_0^p \left(||v - w||^p + \sum_{i=1}^{m} ||w_i||^p \right). \tag{2.3}$$

This assumption looks complicated enough, but as we shall see in what follows, it is satisfied for a large kind of convex sets in Sobolev spaces. In our proofs, v is the exact solution, w is the solution of the iterative algorithm at a certain iteration, and w_i are its corrections on the subspaces $V_i, i = 1, \ldots, m$. In the case of the convex sets written as a sum of convex subsets, (2.1) and (2.2) are always satisfied. We point out that in the case of the problems without constraints or that of the one-obstacle problems, the above assumption can be taken with $w_i = 0$ (see [37], for instance), and for this reason (2.3) usually is known without the extra terms given by w_i.

We consider a Gâteaux differentiable functional $F : K \to R$, which is supposed to be coercive if K is not bounded, and we assume that for any real number $M > 0$ there exist two functions,

$$\alpha_M(\tau) = A_M \tau^p, \quad \beta_M(\tau) = B_M \tau^{q-1}, \tag{2.4}$$

such that

$$< F'(v) - F'(u), v - u > \geq \alpha_M(||v - u||), \text{ for any } u, v \in K, \ ||u||, ||v|| \leq M, \tag{2.5}$$

and

$$\beta_M(||v - u||) \geq ||F'(v) - F'(u)||_{V'}, \text{ for any } u, v \in K, \ ||u||, ||v|| \leq M, \tag{2.6}$$

where F' is the Gâteaux derivative of F, and $A_M > 0$, $B_M > 0$, $p > 1$, and $q > 1$ are some real constants. We have marked here that the constants A_M and B_M depend on M. It is evident that if (2.5) and (2.6) hold, then

$$\begin{aligned} &\alpha_M(||v - u||) \leq < F'(v) - F'(u), v - u > \leq \beta_M(||v - u||)||v - u||, \\ &\text{for any } u, v \in K, \ ||u||, ||v|| \leq M. \end{aligned} \tag{2.7}$$

It follows from (2.7) that we must take $p \geq q$. Following the way in [17, Lemmas 1.1 and 1.2] we can prove that

$$\begin{aligned} &< F'(u), v-u > +\lambda_M(||v-u||) \leq F(v) - F(u) \\ &\leq < F'(u), v-u > +\mu_M(||v-u||), \text{ for any } u, v \in K,\ ||u||, ||v|| \leq M, \end{aligned} \tag{2.8}$$

where

$$\lambda(\tau) = \tfrac{A_M}{p}\tau^p, \quad \mu(\tau) = \tfrac{B_M}{q}\tau^q. \tag{2.9}$$

It is well known (see [16]) that if V and F satisfy the above assumption, then the minimization problem

$$u \in K : F(u) \leq F(v), \text{ for any } v \in K \tag{2.10}$$

has a unique solution, and it is also the unique solution of the problem

$$u \in K : \ < F'(u), v-u > \geq 0, \text{ for any } v \in K. \tag{2.11}$$

From (2.8), for a given $M > 0$ such that the solution u of (2.11) satisfies $||u|| \leq M$, we have

$$\lambda_M(||v-u||) \leq F(v) - F(u), \text{ for any } v \in K,\ ||v|| \leq M. \tag{2.12}$$

The proposed algorithm corresponding to the subspaces $V_1, \ldots, V_m$ and the convex set K is written as follows.

ALGORITHM 2.1. *We start the algorithm with an arbitrary $u^0 \in K$. At iteration $n+1$, having $u^n \in K$, $n \geq 0$, we compute sequentially for $i = 1, \ldots, m$, $w_i^{n+1} \in V_i$ satisfying*

$$w_i^{n+1} = \arg \min_{\substack{u^{n+\frac{i-1}{m}} + v_i \in K \\ v_i \in V_i}} G(v_i), \ \textit{with } G(v_i) = F(u^{n+\frac{i-1}{m}} + v_i), \tag{2.13}$$

and then we update

$$u^{n+\frac{i}{m}} = u^{n+\frac{i-1}{m}} + w_i^{n+1}.$$

This algorithm does not assume a decomposition of the convex set K depending on the subspaces V_i, and it has been proposed in [2] in an equivalent form. The above form of this algorithm has been proposed in [4] for the constrained minimization of the quadratic functions. As for problem (2.10), since the subspaces V_i are reflexive Banach spaces, problem (2.13) has a unique solution and also satisfies the variational inequality

$$\begin{aligned} &w_i^{n+1} \in V_i,\ u^{n+\frac{i-1}{m}} + w_i^{n+1} \in K : \\ &< F'(u^{n+\frac{i-1}{m}} + w_i^{n+1}), v_i - w_i^{n+1} > \geq 0, \\ &\text{for any } v_i \in V_i,\ u^{n+\frac{i-1}{m}} + v_i \in K. \end{aligned} \tag{2.14}$$

The introduction of some parameters $\varepsilon_{ij} \geq 0$, $i, j = 1, \ldots, m$, is useful to obtain some sharper error estimations, especially in the case of minimization of the quadratic

functionals. Following this way, we assume that for a given $M > 0$, if $v \in K$, $||v|| \leq M$, and $v_i \in V_i$, satisfying $v + v_i \in K$, $||v + v_i|| \leq M$, $i = 1, \ldots, m$, then we have

$$< F'(v + v_i) - F'(v), w_j > \leq \varepsilon_{ij} B_M ||v_i||^{q-1} ||w_j|| \tag{2.15}$$

for any $w_i \in V_i$, $i = 1, \ldots, m$. Evidently, using (2.6), we may always take $\varepsilon_{ij} = 1$, $i, j = 1, \ldots, m$, in (2.15).

In [40], it is proved the convergence of the method for nonlinear equations. The following theorem extends this result to inequalities.

THEOREM 2.1. *We consider that V is a reflexive Banach, $V_1, \ldots, V_m$ are some closed subspaces of V, K is a nonempty closed convex subset of V, and F is a Gâteaux differentiable functional on K which is supposed to be coercive if K is not bounded. We assume that the functional F satisfies* (2.5) *and* (2.6)*, and we make Assumption* 2.1*. On these conditions, if u is the solution of problem* (2.10) *and u^n, $n \geq 0$ are its approximations obtained from Algorithm* 2.1*, then we have the following error estimations:*

(i) *if $p = q$ we have*

$$\begin{aligned} &F(u^n) - F(u) \leq \left(\frac{\hat{C}}{\hat{C}+1}\right)^n \left[F(u^0) - F(u)\right], \\ &||u^n - u||^p \leq \frac{\hat{C}+1}{\bar{C}} \left(\frac{\hat{C}}{\hat{C}+1}\right)^n \left[F(u^0) - F(u)\right]. \end{aligned} \tag{2.16}$$

(ii) *if $p > q$ we have*

$$\begin{aligned} &F(u^n) - F(u) \leq \frac{F(u^0) - F(u)}{\left[1 + n\,\tilde{C}(F(u^0) - F(u))^{\frac{p-q}{q-1}}\right]^{\frac{q-1}{p-q}}}, \\ &||u - u^n||^p \leq \frac{\hat{C}}{\bar{C}} \frac{\left(F(u^0) - F(u)\right)^{\frac{q-1}{p-1}}}{\left[1 + (n-1)\tilde{C}(F(u^0) - F(u))^{\frac{p-q}{q-1}}\right]^{\frac{(q-1)^2}{(p-1)(p-q)}}}. \end{aligned} \tag{2.17}$$

The constants $\hat{C}$, $\bar{C}$, and $\tilde{C}$ are written as

$$\begin{aligned} \hat{C} = \hat{C}(m, C_0, u^0) = B_M \left(\tfrac{p}{A_M}\right)^{\frac{q}{p}} |\varepsilon_{ij}| \Big[&(1 + 2C_0)\left(F(u^0) - F(u)\right)^{\frac{p-q}{p(p-1)}} \\ &+ \left(B_M \left(\tfrac{p}{A_M}\right)^{\frac{q}{p}} |\varepsilon_{ij}|\right)^{\frac{1}{p-1}} C_0^{\frac{p}{p-1}} / \eta^{\frac{1}{p-1}} \Big] / (1 - \eta), \end{aligned} \tag{2.18}$$

$$\bar{C} = \frac{(2 - \eta) A_M}{(1 - \eta) p}, \tag{2.19}$$

$$\tilde{C} = \frac{p - q}{(p - 1)\left(F(u^0) - F(u)\right)^{\frac{p-q}{q-1}} + (q - 1)\hat{C}^{\frac{p-1}{q-1}}}. \tag{2.20}$$

The value of η in the expressions of $\hat{C}$ and $\bar{C}$ can be arbitrary in $(0, 1)$. On the other hand, we see that the constants in the error estimations of $F(u^n) - -F(u)$ in (2.16) and (2.17) are some increasing functions of $\hat{C}$, and there is an $\eta_0 \in (0, 1)$ such that $\hat{C}(\eta_0) \leq \hat{C}(\eta)$ for any $\eta \in (0, 1)$. However, this value η_0 can be found by solving a nonlinear algebraic equation.

We point out that a convergence result can be found (see [5]) under weaker conditions on the functions α_M and β_M than those given in (2.4), and a weaker assumption than Assumption 2.1.

The above algorithm can be viewed as a multiplicative Schwarz method in a subspace correction variant if we use the Sobolev spaces. In this way, we consider for a domain Ω in $\mathbf{R}^d$, $d \geq 1$, with Lipschitz continuous boundary $\partial\Omega$, an overlapping decomposition

$$\Omega = \bigcup_{i=1}^{m} \Omega_i \tag{2.21}$$

in which the subdomains Ω_i have a Lipschitz continuous boundary, too. We associate with the domain Ω the space $V = W_0^{1,s}(\Omega)$, $1 < s < \infty$, and with the subdomains Ω_i the subspaces $V_i = W_0^{1,s}(\Omega_i)$, $i = 1, \ldots, m$. We assume that the convex set $K \subset V$ satisfies

PROPERTY 2.1. *If $v, w \in K$, and if $\theta \in C^1(\Omega)$ with $0 \leq \theta \leq 1$, then $\theta v + (1-\theta)w \in K$.*

For such a convex set, the following proposition has been proved in [5].

PROPOSITION 2.1. *If for the domain decomposition* (2.21) *there exist some continuously differentiable unity partitions $\{\theta_j^i\}_{j=i,\ldots,m}$ associated with $\cup_{j=i}^m \Omega_j$, $i = 1, \ldots, m$, (i.e., for any $i = 1, \ldots, m$,* supp $\theta_j^i \subset \Omega_j$, $\theta_j^i \in C^1(\Omega_j)$, *and $0 \leq \theta_j^i \leq 1$, for $j = i, \ldots, m$, and $\sum_{j=i}^m \theta_j^i = 1$ on $\cup_{j=i}^m \Omega_j$), then Assumption* 2.1 *holds for any convex set K having Property* 2.1.

Consequently, provided that functional F satisfies (2.5) and (2.6), Algorithm 2.1 converges and we can apply Theorem 2.1 to get the convergence rate. The above Sobolev spaces $W_0^{1,s}$ correspond to Dirichlet boundary conditions. Similar results can be obtained if we consider appropriate subspaces of $W^{1,s}$ for the mixed boundary conditions.

The constant C_0 in Assumption 2.1 depends on the domain decomposition parameters. Consequently, since the constants $\hat{C}$ and $\bar{C}$ in the error estimations in Theorem 2.1 depend on C_0, then these estimations will depend on domain decomposition parameters, too. The goal of the next sections is to prove, for the one-, two-level and multilevel multiplicative Schwarz methods, that Assumption 2.1 also holds for any closed convex K satisfying a similar property to that given in 2.1. In these cases we are able to explicitly write the dependence of C_0 on the domain decomposition and mesh parameters.

3. One-level multiplicative Schwarz method. First, let us consider that the domain $\Omega \subset \mathbf{R}^d$ has an overlapping domain decomposition $\{O_i\}_{1 \leq i \leq M}$ and a simplicial mesh partition $\mathcal{T}_h$ of mesh size h. We assume that $\mathcal{T}_h$ is regular (i.e., there exists a constant $C > 0$, independent of h, such that each τ in $\mathcal{T}_h$ contains a ball with the diameter of Ch, and, evidently, it is contained in a ball with the diameter of h; see [11], p. 124, for instance) and it supplies a mesh partition for each subdomain O_i, $i = 1, \ldots, M$, too. In addition, we suppose that there exists a positive constant δ, the overlapping parameter, such that for any $i = 1, \ldots, M$, we have

$$O_i \cap \partial\left(\bigcup_{j \neq i} O_j\right) \neq \emptyset \text{ and } \operatorname{dist}\left(\partial O_i \backslash \partial\Omega, O_i \cap \partial\left(\bigcup_{j \neq i} O_j\right)\right) \geq \delta. \tag{3.1}$$

Now, we assume that there exist m colors such that each subdomain O_i can be marked with one color, and the subdomains with the same color do not intersect with each

other. For suitable overlaps, one can always choose $m = 2$ if $d = 1$, $m \leq 4$ if $d = 2$, and $m \leq 8$ if $d = 3$. Let Ω_i be the union of the subdomains O_j having the color i. In this way, we have obtained an overlapping decomposition (2.21) with overlaps of size δ. Taking into account (3.1), we can assume that the unity partitions $\{\theta_j^i\}_{j=i,\ldots,m}$ associated with $\cup_{j=i}^m \Omega_j$ in Proposition 2.1 satisfy

$$|\partial_{x_k}\theta_j^i| \leq C/\delta, \text{ for any } i = 1,\ldots,m.j = i,\ldots,m, \text{ and } k = 1,\ldots,d, \tag{3.2}$$

As in (3.2), we denote in the following by C a generic constant which does not depend on either the mesh or the domain decomposition parameters.

In this section we prove for the finite element spaces a similar result to that given in Proposition 2.1 for general Sobolev spaces. The proof is also similar to that given in [4] for the minimization of the quadratic functionals. We consider the piecewise linear finite element space

$$V_h = \{v \in C^0(\bar{\Omega}) : v|_\tau \in P_1(\tau),\ \tau \in \mathcal{T}_h,\ v = 0 \text{ on } \partial\Omega\}, \tag{3.3}$$

and also, for $i = 1,\ldots,m$, we take

$$V_h^i = \{v \in V_h : v = 0 \text{ in } \Omega\backslash\Omega_i\} \tag{3.4}$$

as some subspaces of V_h corresponding to the domain decomposition $\Omega_1,\ldots,\Omega_m$. The spaces V_h and V_h^i, $i = 1,\ldots,m$, are considered subspaces of $W^{1,s}$, for some fixed $1 \leq s \leq \infty$. We denote by $||\cdot||_{0,s}$ the norm in L^s, and by $||\cdot||_{1,s}$ and $|\cdot|_{1,s}$ the norm and seminorm in $W^{1,s}$, respectively.

In the following, L_h will be the P_1-Lagrangian interpolation operator which uses the function values at the nodes of the mesh $\mathcal{T}_h$. The convex set K_h is defined as a subset of V_h satisfying the following property.

PROPERTY 3.1. *If $v, w \in K_h$, and if $\theta \in C^1(\Omega)$ with $0 \leq \theta \leq 1$, then $L_h(\theta v + (1-\theta)w) \in K_h$.*

In order to prove that Assumption 2.1 holds, we follow the same way as in [4] or [5]. Taking into account the additivity of the Lagrangian interpolation L_h, (2.1) and (2.2) in Assumption 2.1 can be recurrently proved. Indeed, first we write

$$v_1 = L_h\left(\theta_1^1(v-w) + (1-\theta_1^1)w_1\right), \tag{3.5}$$

and prove that

$$\begin{aligned}
&v_1 \in V_h^1 \text{ and } w + v_1 \in K_h,\\
&v - v_1 + w_1 \in K_h,\\
&v - w - v_1 \in W_0^{1,s}\left(\bigcup_{j=2}^m \Omega_j\right) \text{ and}\\
&v - w - v_1 = 0 \text{ in } \Omega - \overline{\cup_{j=2}^m \Omega_j}.
\end{aligned}$$

Next, for $i = 2,\ldots,m-1$, we write

$$v_i = L_h\left(\theta_i^i(v - w - \sum_{j=1}^{i-1} v_j) + (1-\theta_i^i)w_i\right), \tag{3.6}$$

and prove

$$v_i \in V_h^i \text{ and } w + \sum_{j=1}^{i-1} w_j + v_i \in K_h,$$
$$v - \sum_{j=1}^{i} v_j + \sum_{j=1}^{i} w_j \in K_h,$$
$$v - w - \sum_{j=1}^{i} v_j \in W_0^{1,s}\left(\bigcup_{j=i+1}^{m} \Omega_j\right) \text{ and}$$
$$v - w - \sum_{j=1}^{i} v_j = 0 \text{ in } \Omega - \overline{\cup_{j=i+1}^{m}\Omega_j},$$

assuming that these equations hold for $i-1$. Finally, we take

$$v_m = v - w - \sum_{j=1}^{m-1} v_j. \tag{3.7}$$

To prove inequality (2.3) in Assumption 2.1, we first note that, starting from v_1 given in (3.5) by the recurrent application of (3.6), and then taking v_m given in (3.7), we get that v_i, $i = 1, \ldots, m$, are of the form

$$v_i = L_h\left(\tau_0^i(v-w) + \sum_{j=1}^{i} \tau_j^i w_j\right),\ i = 1, \ldots, m. \tag{3.8}$$

By a simple calculus we get that

$\tau_0^1 = \theta_1^1,\ \tau_1^1 = 1 - \theta_1^1,$
$\tau_0^i = \theta_i^i(1-\theta_{i-1}^{i-1})\cdots(1-\theta_1^1),\ \tau_i^i = 1-\theta_i^i,\ \tau_j^i = -\theta_i^i(1-\theta_{i-1}^{i-1})\cdots(1-\theta_j^j),$
for $i = 2, \ldots, m-1,\ j = 1, \ldots, i-1,$
$\tau_0^m = (1-\theta_{m-1}^{m-1})\cdots(1-\theta_1^1),\ \tau_m^m = 0, \tau_{m-1}^m = -(1-\theta_{m-1}^{m-1}),$
$\tau_j^m = \theta_{m-1}^{m-1}(1-\theta_{m-2}^{m-2})\cdots(1-\theta_j^j),$ for $j = 1, \ldots, m-2.$

Consequently, from (3.2), we have

$$|\tau_j^i| \le 1 \text{ and } |\partial_{x_k}\tau_j^i| \le C(m-1)/\delta,\ i = 1, \ldots, m,\ j = 0, \ldots, i,\ k = 1, \ldots, d. \tag{3.9}$$

For a $v \in V_h$, we get (see, for instance [11, Theorem 3.1.6]) that

$$||\tau_j^i v - L_h(\tau_j^i v)||_{0,s} \le Ch|\tau_j^i v|_{1,s},\ ||\tau_j^i v - L_h(\tau_j^i v)||_{1,s} \le C|\tau_j^i v|_{1,s},$$

and therefore

$$||L_h(\tau_j^i v)||_{1,s} \le C||\tau_j^i v||_{1,s}, \text{ with } v \in V_h, \tag{3.10}$$

for any $i = 1, \ldots, m$, $j = 0, \ldots, i$. On the other hand, from (3.9) we get

$$||\tau_j^i v||_{0,s} \le ||v||_{0,s}, \quad |\tau_j^i v|_{1,s} \le C\left(|v|_{1,s} + \frac{m-1}{\delta}||v||_{0,s}\right), \text{ for any } v \in V_h, \tag{3.11}$$

and therefore, using (3.10), we get

$$||L_h(\tau_j^i v)||_{1,s} \leq C\left(||v||_{1,s} + \frac{m-1}{\delta}||v||_{0,s}\right), \text{ for any } v \in V_h. \tag{3.12}$$

Now, by a application of (3.12) to (3.8) we get

$$||v_i||_{1,s} \leq C\left(1 + \frac{m-1}{\delta}\right)\left(||v-w||_{1,s} + \sum_{j=1}^{i}||w_j||_{1,s}\right), \quad \text{for any } i = 1,\ldots,m. \tag{3.13}$$

Using the above equation we get (2.3) in Assumption 2.1, and have the following proposition.

PROPOSITION 3.1. *Let $\Omega_1,\ldots,\Omega_m$ be the overlapping decomposition of the domain Ω defined in this section. Then, Assumption* 2.1 *holds for the piecewise linear finite element spaces, $V = V_h$ and $V_i = V_h^i$, $i = 1,\ldots,m$, and for any convex set $K = K_h \subset V_h$ having Property* 3.1. *The constant in* (2.3) *of Assumption* 2.1 *can be written as*

$$C_0 = C(m+1)\left(1 + \frac{m-1}{\delta}\right), \tag{3.14}$$

where C is independent of the mesh parameter and the domain decomposition.

Remark 3.1. We notice that the number m of the subdomains Ω_i in the decomposition of Ω is in fact the number of colors of the overlapping domain decomposition $\{O_i\}_{1\leq i\leq M}$, and it depends only on the dimension d of the space $\mathbf{R}^d$. Consequently, error estimations (2.16) and (2.17) in Theorem 2.1 depend only on the size δ of the overlaps through the intermediary of the constant C_0 given in (3.14).

4. Two-level multiplicative Schwarz method. We consider a simplicial mesh partition $\mathcal{T}_h$ of the domain $\Omega \subset \mathbf{R}^d$ of a mesh size h, and a simplicial coarser mesh $\mathcal{T}_H$ with a mesh size H, $\mathcal{T}_h$ being a refinement of $\mathcal{T}_H$. The mesh size h is supposed to approach zero and we shall consider a family of mesh pairs (h, H). We assume that both the families, of fine and coarse meshes, are regular.

As in the previous section, we consider an overlapping decomposition $\Omega = \cup_{i=1}^{M} O_i$, the mesh partition $\mathcal{T}_h$ of Ω supplying a mesh partition for each O_i, $1 \leq i \leq M$. Also, we assume that the overlapping size is δ, i.e., (3.1) is satisfied. In addition, we suppose that there exists a constant C such that

$$\operatorname{diam}(O_i) \leq CH, \ i = 1,\ldots,M. \tag{4.1}$$

Now, we color the subdomains O_i, $i = 1,\ldots,M$, and obtain the subdomains Ω_i, $i = 1,\ldots,m$ as in the previous section. We point out that the domain Ω may be different from

$$\Omega_0 = \bigcup_{\tau\in\mathcal{T}_H} \tau, \tag{4.2}$$

but we assume that if a node of $\mathcal{T}_H$ lies on $\partial\Omega_0$, then it lies on $\partial\Omega$, too, and

$$\Omega\backslash\Omega_0 \subset \bigcup_{x^i \text{ node of } \mathcal{T}_H,\, x^i\in\partial\Omega} S_{x^i}, \tag{4.3}$$

where the sets S_{x^i} are defined as follows. We first denote by ω_i the union of all $\tau \in \mathcal{T}_H$ having x^i as a vertex. Then, S_{x^i} is the union of ω_i with all $\tau \in \mathcal{T}_h$, $\tau \not\subset \Omega_0$, which are contained in the smallest sphere centered at x^i and containing ω_i.

Now, we introduce the continuous, piecewise linear finite element space corresponding to the H-level,

$$V_H^0 = \left\{ v \in C^0(\bar{\Omega}_0) : v|_\tau \in P_1(\tau),\ \tau \in \mathcal{T}_H,\ v = 0 \text{ on } \partial\Omega_0 \right\}, \tag{4.4}$$

and extending the functions of V_H^0 with zero in $\Omega \backslash \Omega_0$, it becomes a subspace of V_h. The convex set $K_h \subset V_h$ is defined as a subset of V_h having Property 3.1.

The two-level Schwarz method is also obtained from Algorithm 2.1 in which we take $V = V_h$, $K = K_h$, and the subspaces $V_0 = V_H^0$, $V_1 = V_h^1$, $V_2 = V_h^2, \ldots, V_m = V_h^m$. As in the previous section, the spaces V_h, V_H^0, V_h^1, $V_h^2, \ldots, V_h^m$, are considered as subspaces of $W^{1,s}$ for $1 \le s \le \infty$. We note that this time the decomposition of the domain Ω contains m overlapping subdomains, but we use $m+1$ subspaces of V, V_0, $V_1, \ldots, V_m$, in Algorithm 2.1. Naturally, this algorithm will converge if Assumption 2.1, written for $m+1$ subspaces, will be satisfied for the previous choice of the convex set K and the subspaces $V_0, V_1, \ldots, V_m$, of V. As in the previous section, we prove that Assumption 2.1 holds and find the constant C_0 depending on the mesh and domain decomposition parameters. First, we have the following lemma in which inequality (4.5) can be viewed as a Friedrichs–Poincaré type for the finite element spaces.

LEMMA 4.1. *Let $\omega \subset \mathbf{R}^d$ be a domain of diameter H, and ω_i, $i = 0, 1, \ldots, N$, be an overlapping decomposition of it, $\omega = \cup_{i=0}^N \omega_i$. We consider a simplicial regular mesh partition $\mathcal{T}_h$ of ω and assume that it supplies a mesh partition for each ω_i, $i = 0, 1, \ldots, N$, too. Let $x^0 \in \bar{\omega}_0$ be a node of $\mathcal{T}_h$. We assume that the overlapping partition of ω satisfies:*

(i) *for any $x \in \bar{\omega}_0$, the line segment $[x^0, x]$ lies in $\bar{\omega}_0$,*

(ii) *for $N > 0$, if $\omega_i \cap \omega_j \neq \emptyset$, $0 \le i \ne j \le N$, then for any $x \in \bar{\omega}_i$, $y \in \bar{\omega}_j$ and $z \in \bar{\omega}_i \cap \bar{\omega}_j$, the line segments $[x, z]$ and $[y, z]$ lie in $\bar{\omega}_i$ and $\bar{\omega}_j$, respectively.*

On these conditions, if v is a continuous function which is linear on each $\tau \in \mathcal{T}_h$, and $v(x^0) = 0$, then

$$||v||_{0,s,\omega} \le C(N,s)C(d,s)HC_{d,s}(H,h)|v|_{1,s,\omega}, \tag{4.5}$$

where

$$C_{d,s}(H,h) = \begin{cases} 1 & \text{if } d = s = 1 \text{ or } 1 \le d < s \le \infty \\ \left(\ln \frac{H}{h} + 1\right)^{\frac{d-1}{d}} & \text{if } 1 < d = s < \infty \\ \left(\frac{H}{h}\right)^{\frac{d-s}{s}} & \text{if } 1 \le s < d < \infty, \end{cases} \tag{4.6}$$

$$C(d,s) = \begin{cases} C & \text{if } d = s = 1 \text{ or } 1 = s < d < \infty \\ C\left(d\frac{s-1}{s-d}\right)^{\frac{s-1}{s}} & \text{if } 1 \le d < s \le \infty \\ Cd^{\frac{d-1}{d}} & \text{if } 1 < d = s < \infty \\ C(d\frac{s-1}{d-s})^{\frac{s-1}{s}} & \text{if } 1 < s < d < \infty. \end{cases} \tag{4.7}$$

and

$$C(N,s) = \begin{cases} 1 & \text{if } N = 0 \\ \text{if } (N+1)\frac{C_\omega^{(N+1)/s}-1}{C_\omega^{1/s}-1} & \text{if } N \neq 0 \end{cases} \tag{4.8}$$

with

$$C_\omega = \max_{\omega_i \cap \omega_j \neq \emptyset} \frac{|\omega_i|}{|\omega_i \cap \omega_j|}. \tag{4.9}$$

In (4.9) *we have denoted by* $|\ \ |$ *the measure of a set, and have marked in* (4.5) *that the norm in* L^s *and the seminorm in* $W^{1,s}$, $1 \leq s \leq \infty$, *refer to the domain* ω. *The constant* C *in* (4.7) *is independent of* H, h, d, s, *and the decomposition of* ω.

Proof. Here we use the polar coordinates. The Jacobian determinant of the transformation from the rectangular coordinates to the polar coordinates can be written as

$$J(r, \varphi) = r^{d-1} E(\varphi),$$

where $E(\varphi)$ is an algebraic expression of cosines and sines of the component angles of φ.

We first consider that $N = 0$, i.e., the decomposition of ω in the statement of the lemma has only one element, $\omega_0 = \omega$. Consequently, for any $x \in \bar{\omega}$, the line segment $[x^0, x]$ lies in $\bar{\omega}$. We take the origin of the system of coordinates at the point x^0, and, using the polar coordinates, a point $x = (x_1, \ldots, x_d)$, will be written as $x = (r, \varphi)$, φ being the system of $d-1$ angles giving the direction of the vector x. We denote by r_φ the maximum size of the radius in the direction φ of the points in $\bar{\omega}$, and consequently, the points on $\partial\omega$ will be written as (r_φ, φ). We denote by o the union of the $\tau \in \mathcal{T}_h$ having a vertex at x^0; let r_0 be the distance from x^0 to $\partial o \backslash \partial\omega$. We consider the open ball with the center at x^0 of radius r_0, $B_{r_0}(x^0)$. For two points $x' = (r', \varphi) \in \omega \cap B_{r_0}(x^0)$ and $x = (r, \varphi) \in \omega \backslash \bar{B}_{r_0}(x^0)$, we have

$$\begin{aligned}
&|v(x)| = |v(r,\varphi)| \leq |v(r',\varphi)| + \left|\textstyle\int_{r'}^{r} \frac{\partial v}{\partial r}(\rho,\varphi) d\rho\right| \\
&= \left|\tfrac{\partial v}{\partial r}(r',\varphi)\right| r' + \left|\textstyle\int_{r'}^{r} \frac{\partial v}{\partial r}(\rho,\varphi) d\rho\right| \leq \left|\nu_1 \tfrac{\partial v}{\partial x_1}(r',\varphi) + \cdots + \nu_d \tfrac{\partial v}{\partial x_d}(r',\varphi)\right| r' \\
&+ \left|\textstyle\int_{r'}^{r_\varphi} \left(\nu_1 \frac{\partial v}{\partial x_1}(\rho,\varphi) + \cdots + \nu_d \frac{\partial v}{\partial x_d}(\rho,\varphi)\right) d\rho\right| \\
&\leq \left(\left|\tfrac{\partial v}{\partial x_1}(r',\varphi)\right| + \cdots + \left|\tfrac{\partial v}{\partial x_d}(r',\varphi)\right|\right) r' \\
&+ \textstyle\int_{r'}^{r_\varphi} \left(\left|\frac{\partial v}{\partial x_1}(\rho,\varphi)\right| + \cdots + \left|\frac{\partial v}{\partial x_d}(\rho,\varphi)\right|\right) d\rho,
\end{aligned} \tag{4.10}$$

where $(\nu_1, \ldots, \nu_d)$ is the unity vector giving the direction of $x = (r, \varphi)$ in the rectangular system of coordinates $(x_1, \ldots, x_d)$. In the following, we find (4.5) for the various values of d and s starting from (4.10).

For $d = s = 1$ or $1 \leq d < s \leq \infty$, we take $r' = 0$ in (4.10). If $d = s = 1$ we get

$$|v(x)| = |v(r,\varphi)| \leq \int_0^{r_\varphi} \left|\frac{\partial v}{\partial x_1}(\rho,\varphi)\right| d\rho.$$

Here, we may have $\varphi = 0$ and $\varphi = \pi$ if x^0 is a inner point in ω, and only $\varphi = 0$ or only $\varphi = \pi$ if $x^0 \in \partial\omega$. Integrating again from 0 to $r_\varphi \leq H$, we get (4.5) for $N = 0$ and $d = s = 1$. If $1 \leq d < s = \infty$, we have

$$|v(x)| \leq r_\varphi d \max_{1 \leq j \leq d} \sup_{0 \leq \rho \leq r_\varphi} \left|\frac{\partial v}{\partial x_j}(\rho,\varphi)\right| \leq CdH|v|_{1,\infty,\omega}.$$

If $1 \leq d < s < \infty$ we have

$$|v(x)|^s \leq d^{s-1} \left[\int_0^{r_\varphi} \rho^{\frac{1-d}{s-1}} d\rho\right]^{s-1} \int_0^{r_\varphi} \left(\left|\frac{\partial v}{\partial x_1}(\rho,\varphi)\right|^s + \cdots + \left|\frac{\partial v}{\partial x_d}(\rho,\varphi)\right|^s\right) \rho^{d-1} d\rho.$$

Multiplying the above inequality by r^{d-1} and integrating from 0 to $r_\varphi \le H$ we get

$$\begin{aligned}&\textstyle\int_0^{r_\varphi} |v(r,\varphi)|^s r^{d-1} dr\\ &\le \left(d\frac{s-1}{s-d}\right)^{s-1} (CH)^s \int_0^{r_\varphi} \left(\left|\frac{\partial v}{\partial x_1}(\rho,\varphi)\right|^s + \cdots + \left|\frac{\partial v}{\partial x_d}(\rho,\varphi)\right|^s\right) \rho^{d-1} d\rho.\end{aligned}$$

By multiplication of this equation with the Jacobian part depending on φ, $E(\varphi)$, and integrating over the $d-1$ dimensional domain of the angles φ, we get (4.5) for $N=0$ and $1 \le d < s < \infty$.

Now, from (4.10) for an arbitrary $0 < r' < r_0$, we get

$$\begin{aligned}|v(x)| = |v(r,\varphi)| &\le \left(\left|\frac{\partial v}{\partial x_1}(r',\varphi)\right| + \cdots + \left|\frac{\partial v}{\partial x_d}(r',\varphi)\right|\right) r_0\\ &+ \int_{r_0}^{r_\varphi} \left(\left|\frac{\partial v}{\partial x_1}(\rho,\varphi)\right| + \cdots + \left|\frac{\partial v}{\partial x_d}(\rho,\varphi)\right|\right) d\rho.\end{aligned} \tag{4.11}$$

Also, since for a fixed φ, $\frac{\partial v}{\partial r}(r',\varphi)$ is constant for $r' \in (0, r_0)$, we have

$$\begin{aligned}&|v(x')|^s = |v(r',\varphi)|^s \le \tfrac{(r')^{s-d}}{d} \textstyle\int_0^{r_0} \left|\frac{\partial v}{\partial \rho}(\rho,\varphi)\right|^s \rho^{d-1} d\rho\\ &\le d^{s-2}(r')^{s-d} \textstyle\int_0^{r_0} \left(\left|\frac{\partial v}{\partial x_1}(\rho,\varphi)\right|^s + \cdots + \left|\frac{\partial v}{\partial x_d}(\rho,\varphi)\right|^s\right) \rho^{d-1} d\rho.\end{aligned}$$

Multiplying the above inequality by $(r')^{d-1}$, and integrating from 0 to r_0, we get

$$\begin{aligned}&\textstyle\int_0^{r_0} |v(\rho,\varphi)|^s \rho^{d-1} d\rho\\ &\le \frac{d^{s-2}}{s} r_0^s \textstyle\int_0^{r_0} \left(\left|\frac{\partial v}{\partial x_1}(\rho,\varphi)\right|^s + \cdots + \left|\frac{\partial v}{\partial x_d}(\rho,\varphi)\right|^s\right) \rho^{d-1} d\rho.\end{aligned} \tag{4.12}$$

Now, if $1 = s < d < \infty$ we get from (4.11),

$$\begin{aligned}&|v(x)| \le \tfrac{1}{d} r_0^{1-d} \textstyle\int_0^{r_0} \left(\left|\frac{\partial v}{\partial x_1}(\rho,\varphi)\right| + \cdots + \left|\frac{\partial v}{\partial x_d}(\rho,\varphi)\right|\right) \rho^{d-1} d\rho\\ &+ r_0^{1-d} \textstyle\int_{r_0}^{r_\varphi} \left(\left|\frac{\partial v}{\partial x_1}(\rho,\varphi)\right| + \cdots + \left|\frac{\partial v}{\partial x_d}(\rho,\varphi)\right|\right) \rho^{d-1} d\rho\\ &\le r_0^{1-d} \textstyle\int_0^{r_\varphi} \left(\left|\frac{\partial v}{\partial x_1}(\rho,\varphi)\right| + \cdots + \left|\frac{\partial v}{\partial x_d}(\rho,\varphi)\right|\right) \rho^{d-1} d\rho.\end{aligned}$$

Using the regularity of the mesh $\mathcal{T}_h$, we have $\frac{r_\varphi}{r} \le C\frac{H}{h}$, and therefore,

$$\textstyle\int_{r_0}^{r_\varphi} |v(\rho,\varphi)| \rho^{d-1} d\rho \le CH \left(\frac{H}{h}\right)^{d-1} \int_0^{r_\varphi} \left(\left|\frac{\partial v}{\partial x_1}(\rho,\varphi)\right| + \cdots + \left|\left|\frac{\partial v}{\partial x_d}(\rho,\varphi\right|\right) \rho^{d-1} d\rho.$$

From this last inequality and (4.12) we get (4.5) for $N=0$ and $1 = s < d < \infty$ by a multiplication with $E(\varphi)$ and integrating over the domain of the angles φ.

Starting again from (4.11), for $1 < d = s < \infty$ or $1 < s < d < \infty$, we get

$$\begin{aligned}&|v(x)|^s \le (2d)^{s-1} \left(\left|\frac{\partial v}{\partial x_1}(r',\varphi)\right|^s + \cdots + \left|\frac{\partial v}{\partial x_d}(r',\varphi)\right|^s\right) r_0^s\\ &+ (2d)^{s-1} \left[\textstyle\int_{r_0}^{r_\varphi} \rho^{\frac{1-d}{s-1}} d\rho\right]^{s-1} \int_{r_0}^{r_\varphi} \left(\left|\frac{\partial v}{\partial x_1}(\rho,\varphi)\right|^s + \cdots + \left|\frac{\partial v}{\partial x_d}(\rho,\varphi)\right|^s\right) \rho^{d-1} d\rho\\ &= 2^{s-1} d^s r_0^{s-d} \textstyle\int_0^{r_0} \left(\left|\frac{\partial v}{\partial x_1}(\rho,\varphi)\right|^s + \cdots + \left|\frac{\partial v}{\partial x_d}(\rho,\varphi)\right|^s\right) \rho^{d-1} d\rho\\ &+ (2d)^{s-1} \left[\textstyle\int_{r_0}^{r_\varphi} \rho^{\frac{1-d}{s-1}} d\rho\right]^{s-1} \int_{r_0}^{r_\varphi} \left(\left|\frac{\partial v}{\partial x_1}(\rho,\varphi)\right|^s + \cdots + \left|\frac{\partial v}{\partial x_d}(\rho,\varphi)\right|^s\right) \rho^{d-1} d\rho.\end{aligned}$$

Consequently,

$$
\begin{aligned}
&\textstyle\int_{r_0}^{r_\varphi} |v(\rho,\varphi)|^s \rho^{d-1} d\rho \\
&\leq (2d)^{s-1} r_\varphi^d r_0^{s-d} \textstyle\int_0^{r_0} \left(\left| \frac{\partial v}{\partial x_1}(\rho,\varphi) \right|^s + \cdots + \left| \frac{\partial v}{\partial x_d}(\rho,\varphi) \right|^s \right) \rho^{d-1} d\rho \\
&+ 2^{s-1} d^{s-2} r_\varphi^d \left[\textstyle\int_{r_0}^{r_\varphi} \rho^{\frac{1-d}{s-1}} d\rho \right]^{s-1} \\
&\cdot \textstyle\int_{r_0}^{r_\varphi} \left(\left| \frac{\partial v}{\partial x_1}(\rho,\varphi) \right|^s + \cdots + \left| \frac{\partial v}{\partial x_d}(\rho,\varphi) \right|^s \right) \rho^{d-1} d\rho.
\end{aligned} \tag{4.13}
$$

Now, from (4.13), if $1 < d = s < \infty$ we get

$$
\begin{aligned}
&\textstyle\int_{r_0}^{r_\varphi} |v(\rho,\varphi)|^d \rho^{d-1} d\rho \\
&\leq 2^{d-1} r_\varphi^d \max \left\{ d^{d-1}, d^{d-2} \left(\ln \tfrac{r_\varphi}{r_0} \right)^{d-1} \right\} \\
&\textstyle\int_0^{r_\varphi} \left(\left| \frac{\partial v}{\partial x_1}(\rho,\varphi \right|^d + \cdots + \left| \frac{\partial v}{\partial x_d}(\rho,\varphi) \right|^d \right) \rho^{d-1} d\rho.
\end{aligned}
$$

Using regularity of the mesh $\mathcal{T}_h$, we get

$$
\begin{aligned}
&\textstyle\int_{r_0}^{r_\varphi} |v(\rho,\varphi)|^d \rho^{d-1} d\rho \\
&\leq d^{d-1} (CH)^d \left(\ln \tfrac{H}{h} + 1 \right)^{d-1} \textstyle\int_0^{r_\varphi} \left(\left| \frac{\partial v}{\partial x_1}(\rho,\varphi) \right|^d + \cdots + \left| \frac{\partial v}{\partial x_d}(\rho,\varphi) \right|^s \right) \rho^{d-1} d\rho.
\end{aligned}
$$

This inequality together with (4.12) prove (4.5) for $N = 0$ and $1 < d = s < \infty$.

Finally, if $1 < s < d < \infty$, we get from (4.13),

$$
\begin{aligned}
&\textstyle\int_{r_0}^{r_\varphi} |v(\rho,\varphi)|^s \rho^{d-1} d\rho \leq 2^{s-1} \max \left\{ d^{s-1} r_\varphi^d r_0^{s-d}, d^{s-2} r_\varphi^s (\frac{s-1}{d-s})^{s-1} \left[\left(\tfrac{r_\varphi}{r_0} \right)^{\frac{d-s}{s-1}} - 1 \right]^{s-1} \right\} \\
&\textstyle\int_0^{r_\varphi} \left(\left| \frac{\partial v}{\partial x_1}(\rho,\varphi) \right|^s + \cdots + \left| \frac{\partial v}{\partial x_d}(\rho,\varphi) \right|^s \right) \rho^{d-1} d\rho,
\end{aligned}
$$

and, consequently,

$$
\begin{aligned}
&\textstyle\int_{r_0}^{r_\varphi} |v(\rho,\varphi)|^s \rho^{d-1} d\rho \\
&\leq (d\tfrac{s-1}{d-s})^{s-1} (CH)^s \left(\tfrac{H}{h} \right)^{d-s} \textstyle\int_0^{r_\varphi} \left(\left| \frac{\partial v}{\partial x_1}(\rho,\varphi) \right|^s + \cdots + \left| \frac{\partial v}{\partial x_d}(\rho,\varphi) \right|^s \right) \rho^{d-1} d\rho.
\end{aligned}
$$

Using again (4.12) and the last inequality, we get (4.5) for $N = 0$ and $1 < s < d < \infty$.

Assume now that $N > 0$, i.e., we have more than one subdomain ω_i, $i = 0, 1, \ldots, N$ in the overlapping decomposition of ω. Such a decomposition is considered when there exist points $x \in \bar{\omega}$ for which the line segment $[x^0, x]$ does not wholly lie in $\bar{\omega}$. Let ω_i and ω_j, $i \neq j$ be two fixed subdomains such that $\omega_i \cap \omega_j \neq \emptyset$. We consider a fixed point $z \in \omega_i \cap \omega_j$, and denoting by z^k and ϕ_k the nodes of $\mathcal{T}_h$ in $\bar{\omega}_i \cap \bar{\omega}_j$ and the corresponding functions in the nodal basis, respectively, for a given $1 \leq s < \infty$, we have

$$
\begin{aligned}
&||v||_{0,s,\omega_j} - \left| \sum_k v(z^k) \phi_k(z) \right| |\omega_j|^{1/s} \leq ||v - \sum_k v(z^k) \phi_k(z)||_{0,s,\omega_j} \\
&= \left\| \sum_k \left(v - v(z^k) \right) \phi_k(z) \right\|_{0,s,\omega_j} \leq \sum_k ||v - v(z^k)||_{0,s,\omega_j} \phi_k(z).
\end{aligned}
$$

Since $v - v(z^k)$ vanishes at z^k, we get from the first part of the proof and the last equation that

$$||v||_{0,s,\omega_j} - \left|\sum_k v(z^k)\phi_k(z)\right| |\omega_j|^{1/s} \le \sum_k C(d,s)HC_{d,s}(H,h)|v|_{1,s,\omega_j}\phi_k(z)$$
$$= C(d,s)HC_{d,s}(H,h)|v|_{1,s,\omega_j},$$

and integrating over $\omega_i \cap \omega_j$, we get

$$|\omega_i \cap \omega_j|||v||_{0,s,\omega_j} \le |\omega_j|^{1/s} \int_{\omega_i\cap\omega_j} |v| + |\omega_i \cap \omega_j|C(d,s)HC_{d,s}(H,h)|v|_{1,s,\omega_j}$$
$$\le |\omega_j|^{1/s}|\omega_i \cap \omega_j|^{(s-1)/s}||v||_{0,s,\omega_i\cap\omega_j} + |\omega_i \cap \omega_j|C(d,s)HC_{d,s}(H,h)|v|_{1,s,\omega_j}.$$

Consequently, we have

$$||v||_{0,s,\omega_j} \le \left(\frac{|\omega_j|}{|\omega_i \cap \omega_j|}\right)^{1/s} ||v||_{0,s,\omega_i} + C(d,s)HC_{d,s}(H,h)|v|_{1,s,\omega_j}. \tag{4.14}$$

It is easy to see that (4.14) holds for $s = \infty$, too. Taking into account that

$$||v||_{0,s,\omega_0} \le C(d,s)HC_{d,s}(H,h)|v|_{1,s,\omega_0}, \tag{4.15}$$

from (4.14) and (4.15), we get (4.5) for $N > 0$. □

Remark 4.1. As stated at the beginning of this section, we are interested in the error estimation for a family of pairs (H,h). In general, since the mesh $\mathcal{T}_h$ is regular, the overlapping decomposition of ω in Lemma 4.1 can be taken such that the number N and the constant C_ω in (4.9) are bounded and independent of (H,h). In this point of view, the constants $C(d,s)$, $C(N,s)$ and C_ω, written in (4.7)–(4.9), can be considered as independent of H and h, and assimilated to the generic constant C. In the following we write (4.5) as

$$||v||_{0,s,\omega} \le CHC_{d,s}(H,h)|v|_{1,s,\omega}, \tag{4.16}$$

where $C = C(N,s)C(d,s)$ and $C_{d,s}(H,h)$ is given in (4.6).

The above lemma can be very useful in various error estimations. The following result, for instance, extends to $W^{1,s}$ that in [9, Lemma 2.3].

COROLLARY 4.1. *Let ω be a domain of diameter H and have a simplicial regular mesh partition $\mathcal{T}_h$. If v is a continuous function which is linear on each $\tau \in \mathcal{T}_h$, and $v = 0$ on $\partial\omega$, then for any $1 \le s \le \infty$ we have*

$$||v||_{0,\infty,\omega} \le CH^{\frac{s-d}{s}}C_{d,s}(H,h)|v|_{1,s,\omega}, \tag{4.17}$$

where $C_{d,s}(H,h)$ is given in (4.6)*, and C is independent of H and h.*

Proof. Let $x^0 \in \bar{\omega}$ be the point where $|v(x^0)| = ||v||_{0,\infty,\omega}$, and $x \in \omega$ a current point. We note that x^0 is a node of $\mathcal{T}_h$. For $1 \le s < \infty$, we have

$$|v(x^0)|^s \le 2^{s-1}|v(x^0) - v(x)|^s + 2^{s-1}|v(x)|^s,$$

and integrating it over ω, using (4.16), we get

$$|\omega|||v||^s_{0,\infty,\omega} \le 2^{s-1}||v(x^0) - v(x)||^s_{0,s,\omega} + 2^{s-1}||v(x)||^s_{0,s,\omega}$$
$$\le 2^{s-1}\left(CHC_{d,s}(H,h)\right)^s |v(x)|^s_{1,s,\omega} + 2^{s-1}||v(x)||^s_{0,s,\omega}.$$

Now, since $v = 0$ on $\partial\omega$, we can apply the classical Friedrichs–Poincaré inequality and obtain (4.17). If $s = \infty$, the proof is similar. ∎

Coming back to the two-level method, let us denote by x^i a node of $\mathcal{T}_H$, by ϕ_i the linear nodal basis function associated with x^i and $\mathcal{T}_H$, and by ω_i the support of ϕ_i. We point out that we consider all the nodal basis functions, including those corresponding to the nodes on $\partial\Omega_0$. Given a $v \in V_h$, let us write

$$I_i^- v = \min_{x\in\omega_i} v(x)^- \quad \text{and} \quad I_i^+ v = \min_{x\in\omega_i} v(x)^+, \tag{4.18}$$

where $v(x)^- = \max(0, -v(x))$ and $v(x)^+ = \max(0, v(x))$. Since v is piecewise linear, $I_i^- v$ or $I_i^+ v$ are attained at a node of $\mathcal{T}_h$ if they are not zero. For a $v \in V_h$, we define

$$I_H^- v := \sum_{x^i \text{ node of } \mathcal{T}_H} (I_i^- v)\phi_i(x) \quad \text{and} \quad I_H^+ v := \sum_{x^i \text{ node of } \mathcal{T}_H} (I_i^+ v)\phi_i(x), \tag{4.19}$$

and we write

$$I_H v = I_H^+ v - I_H^- v. \tag{4.20}$$

The following result extends to that given in [37], where similar operators to I_i^+ have been introduced.

LEMMA 4.2. *For any $v \in V_h$ we have*

$$||I_H v - v||_{0,s,\Omega_0} \le CHC_{d,s}(H,h)|v|_{1,s,\Omega_0} \tag{4.21}$$

and

$$||I_H v||_{0,s,\Omega_0} \le C||v||_{0,s,\Omega_0} \text{ and } |I_H v|_{1,s,\Omega_0} \le CC_{d,s}(H,h)|v|_{1,s,\Omega_0}, \tag{4.22}$$

where Ω_0 is the union of the simplexes in $\mathcal{T}_H$ written in (4.2)*, $C_{d,s}(H,h)$ is defined in* (4.6)*, and C is independent of H, h, and δ. Equations* (4.21) *and* (4.22) *also hold if Ω_0 is replaced by Ω. Moreover, if $\mathcal{K}$ is a convex and closed set in V_h having Property* 3.1*, with $0 \in \mathcal{K}$, then for any $v \in \mathcal{K}$ we have $I_H v \in \mathcal{K} \cap V_H^0$.*

Proof. Let us take an ω_i, the support of the linear basis function ϕ_i corresponding to the node x^i of $\mathcal{T}_H$, and a $v \in V_h$. If v vanishes at a point in ω_i, then $I_i^+ v = I_i^- v = 0$ and v^+ and v^- vanish at some nodes of $\mathcal{T}_h$ in ω_i. Applying Lemma 4.1, we get

$$\begin{aligned} &||v||_{0,s,\omega_i}^s = ||v^+ - v^-||_{0,s,\omega_i}^s = ||v^+||_{0,s,\omega_i}^s + ||v^-||_{0,s,\omega_i}^s \\ &\le [CHC_{d,s}(H,h)]^s \left[|v^+|_{1,s,\omega_i}^s + |v^-|_{1,s,\omega_i}^s\right] = [CHC_{d,s}(H,h)]^s |v|_{1,s,\omega_i}^s. \end{aligned} \tag{4.23}$$

Consequently,

$$||v - I_i^+ v + I_i^- v||_{0,s,\omega_i} \le CHC_{d,s}(H,h)|v|_{1,s,\omega_i}. \tag{4.24}$$

If $v \neq 0$ at any point of ω_i, then either $v^+ = I_i^+ v = 0$ or $v^- = I_i^- v = 0$. Consequently, there exits at least a node of $\mathcal{T}_h$ in ω_i at which $v - I_i^+ v + I_i^- v = v^+ - v^- - I_i^+ v + I_i^- v$ vanishes. From Lemma 4.1, since $I_i^+ v - I_i^- v$ is a constant, we again get (4.24). We notice that, since for any $x \in \omega_i$ the line segment $[x^i, x]$ lies in ω_i, we can take a decomposition of ω_i as in Lemma 4.1 having $N \le 1$. Assuming that $N = 1$, let ω_{i0} and $\omega_{i1} = \omega$ be this decomposition. Since ω_{i0} contains at least one $\tau \in \mathcal{T}_H$ and the mesh $\mathcal{T}_H$ is regular, then, according to (4.9), C_{ω_i} can be taken independent of H and

h. Consequently, $C(N,s)$ in (4.8) is independent of H and h. Now, using (4.24), we get

$$||I_H v - v||^s_{0,s,\omega_i} = \left\| \sum_{x^j \in \omega_i} \left[I_j^+ v - I_j^- v - v \right] \phi_j \right\|^s_{0,s,\omega_i}$$
$$\leq C \sum_{x^j \in \omega_i} ||I_j^+ v - I_j^- v - v||^s_{0,s,\omega_i \cap \omega_j} \leq [CHC_{d,s}(H,h)]^s \sum_{x^j \in \omega_i} |v|^s_{1,s,\omega_j}.$$

Above, x^j are nodes of $\mathcal{T}_H$, and we used the fact that, since the mesh is regular, the maximum number of ω_j which nonemptily intersects a given ω_i is bounded and independent of H. Now, we again use this property to obtain

$$||I_H v - v||^s_{0,s,\Omega_0} \leq \sum_{x^i \in \Omega_0} ||I_H v - v||^s_{0,s,\omega_i}$$
$$\leq [CHC_{d,s}(H,h)]^s \sum_{x^i \in \Omega_0} \sum_{x^j \in \omega_i} |v|^s_{1,s,\omega_j} \leq [CHC_{d,s}(H,h)]^s \sum_{x^i \in \Omega_0} |v|^s_{1,s,\omega_i}.$$

Also, from the regularity of the mesh, it follows that each ω_i contains a bounded number of simplexes of $\mathcal{T}_H$ which is independent of H. Consequently, we have

$$||I_H v - v||^s_{0,s,\Omega_0} \leq [CHC_{d,s}(H,h)]^s \sum_{\tau \in \mathcal{T}_H} |v|^s_{1,s,\tau},$$

and in this way, we get (4.21).

In order to prove (4.22), we notice first that, from the definition of $I_i^+ v$ and $I_i^- v$, we have for any $x \in \omega_i$,

$$\begin{aligned} &0 \leq I_i^+ v - I_i^- v \leq v(x) \text{ if } v(x) \geq 0, \text{ and} \\ &0 \geq I_i^+ v - I_i^- v \geq v(x) \text{ if } v(x) \leq 0, \end{aligned} \tag{4.25}$$

and therefore,

$$|I_i^+ v - I_i^- v| \leq |v(x)| \text{ for any } x \in \omega_i. \tag{4.26}$$

Using this inequality, we obtain

$$||I_H v||^s_{0,s,\omega_i} = \left\| \sum_{x^j \in \omega_i} (I_j^+ v - I_j^- v) \phi_j \right\|^s_{0,s,\omega_i}$$
$$\leq \int_{\omega_i} \left(\sum_{x^j \in \omega_i} |I_j^+ - I_j^-| \phi_j \right)^s = \int_{\omega_i} \left(\sum_{x^j \in \omega_i} |v(x)| \phi_j \right)^s = \int_{\omega_i} |v(x)|^s = ||v||^s_{0,s,\omega_i}.$$

Taking again into account the regularity of the mesh, we get

$$||I_H v||^s_{0,s,\Omega_0} \leq \sum_{x^i \in \Omega_0} ||I_H v||^s_{0,s,\omega_i} \leq \sum_{x^i \in \Omega_0} ||v||^s_{0,s,\omega_i} \leq C \sum_{\tau \in \mathcal{T}_H} ||v||^s_{0,s,\tau},$$

and therefore, the first equation in (4.22) holds. To prove the second equation in (4.22), first we write

$$|I_H v|^s_{1,s,\omega_i} = \left| \sum_{x^j \in \omega_i} (I_j^+ v - I_j^- v) \phi_j \right|^s_{1,s,\omega_i}$$
$$\leq C H^{d-s} \max_{x^k, x^l \in \omega_i, \omega_k \cap \omega_l \neq \emptyset} |(I_k^+ v - I_k^- v) - (I_l^+ v - I_l^- v)|^s.$$

Since $\omega_k \cap \omega_l \neq \emptyset$, taking into account the definition of $I_i^+ v$ and $I_i^- v$ in (4.18), we get that $I_k^+ v - I_k^- v$ and $I_l^+ v - I_l^- v$ cannot be both different from zero and have different signs. Therefore, if we write

$$|I_p^+ v - I_p^- v| - |I_q^+ v - I_q^- v| = \max_{x^k, x^l \in \omega_i, \omega_k \cap \omega_l \neq \emptyset} |(I_k^+ v - I_k^- v) - (I_l^+ v - I_l^- v)|,$$

using (4.26), we get

$$|I_H v|^s_{1,s,\omega_i} \leq C H^{d-s} (|I_p^+ v - I_p^- v| - |I_q^+ v - I_q^- v|)^s \leq C H^{d-s} (|v(x)| - |I_q^+ v - I_q^- v|)^s$$

for any $x \in \omega_p \cap \omega_q$. Since the mesh $\mathcal{T}_h$ is regular, we have $H^d \leq C|\omega_p \cap \omega_q|$, and integrating the above equation over $\omega_p \cap \omega_q$ we get

$$\begin{aligned} &|I_H v|^s_{1,s,\omega_i} \leq C H^{-s} \textstyle\int_{\omega_p \cap \omega_q} (|v(x)| - |I_q^+ v - I_q^- v|)^s \\ &= C H^{-s} \textstyle\int_{\omega_p \cap \omega_q} |v(x) - (I_q^+ v - I_q^- v)|^s \leq C H^{-s} \textstyle\int_{\omega_q} |v(x) - (I_q^+ v - I_q^- v)|^s. \end{aligned}$$

If there exists a point in ω_q at which v vanishes, then $I_q^+ v = I_q^- v = 0$, and, as in (4.23), we get

$$|I_H v|_{1,s,\omega_i} \leq C C_{d,s}(H,h) |v|_{1,s,\omega_q}.$$

Also, if $v > 0$ or $v < 0$ in ω_q, then there exists $x^q \in \omega_q$, node of $\mathcal{T}_h$, such that $v(x^q) = I_q^+ v - I_q^- v$, and we again get the above inequality applying Lemma 4.1. Finally, using again the fact that the mesh $\mathcal{T}_H$ is regular, we get the second equation in (4.22).

To prove that (4.21) and (4.22) hold on Ω, we see that $I_H v = 0$ on all the sets S_{x^i} introduced in (4.3). Therefore, (4.22) holds on all sets S_{x^i}. Also, since $v(x^i) = 0$, from Lemma 4.1, we get that (4.21) holds on S_{x^i}. Consequently, the above reasoning we made for Ω_0 can be done for Ω, too. From (4.25), (4.19), and (4.20), we get that for any $x \in \Omega$, we have

$$0 \leq I_H v(x) \leq v(x) \text{ if } v(x) \geq 0, \text{ and } 0 \geq I_H v(x) \geq v(x) \text{ if } v(x) \leq 0. \tag{4.27}$$

Therefore, we can find a $\theta(x) \in C^1(\Omega)$, $0 \leq \theta(x) \leq 1$, such that $\theta(x^i) = I_H v(x^i)/v(x^i)$ if $I_H v(x^i) \neq 0$, and $\theta(x^i) = 0$ if $I_H v(x^i) = 0$, at any node x^i of $\mathcal{T}_h$. Consequently, we can write $I_H v = L_h(\theta v + (1-\theta)0)$. Finally, if $0, v \in \mathcal{K}$, and $\mathcal{K}$ has Property 3.1, we get that $I_H v \in \mathcal{K}$. ∎

Now, we can prove the following proposition which shows that the constant C_0 in Assumption 2.1 is independent of the mesh and domain decomposition parameters if H/δ and H/h are constant. This result is similar to that given in [4] for the inequalities coming from minimization of the quadratic functionals. In the first part of the proof, the construction of v_i, $i = 1, \ldots, m$, is similar to that given for the one-level method. In the second part we define an appropriate v_0 using the previous lemma.

PROPOSITION 4.1. *Let $\Omega_1, \ldots, \Omega_m$ be the overlapping decomposition of the domain Ω defined in this section. Then Assumption* 2.1 *is verified for the piecewise linear finite element spaces $V = V_h$ and $V_0 = V_H^0$, $V_i = V_h^i$, and $i = 1, \ldots, m$, defined in* (3.3), (3.4), *and* (4.4), *respectively, and any convex set $K = K_h$ satisfying Property* 3.1. *The constant in* (2.3) *of Assumption* 2.1 *can be taken of the form*

$$C_0 = C(m+2)^{1-\frac{1}{p}} \left(1 + (m-1)\frac{H}{\delta}\right) C_{d,s}(H,h), \tag{4.28}$$

where C is independent of the mesh and domain decomposition parameters, and $C_{d,s}(H,h)$ is given in (4.6).

Proof. Let us consider $w \in K_h$, $w_0 \in V_H^0$, and $w_i \in V_h^i$ such that $w + \sum_{j=0}^{i} w_i \in K_h$, $i = 0, \ldots, m$, and let v be another element in K_h. In the following, we use unity partitions $(\theta_j^i)_{j=i,\ldots,m}$, of the domains $\cup_{j=i,m}^{m} \Omega_j$, $i = 1, \ldots, m$, having property (3.2).

Step 1. We assume that we have a $v_0 \in V_H^0$ satisfying

$$w + v_0,\ v + w_0 - v_0 \in K_h, \tag{4.29}$$

and we recursively construct $v_i \in V_h^i$, $i = 1, \ldots, m$, which satisfies (2.1) and (2.2) in Assumption 2.1. To this end, we define

$$v_1 = L_h\left(\theta_1^1(v - w - v_0) + (1 - \theta_1^1)w_1\right), \tag{4.30}$$

and, as in the previous section, we get

$$\begin{aligned} &v_1 \in V_h^1 \text{ and } w + w_0 + v_1 \in K_h,\\ &v - v_0 - v_1 + w_0 + w_1 \in K_h,\\ &v - w - v_0 - v_1 \in W_0^{1,s}\left(\bigcup_{j=2}^{m} \Omega_j\right) \text{ and}\\ &v - w - v_0 - v_1 = 0 \text{ in } \Omega - \overline{\cup_{j=2}^{m}\Omega_j}. \end{aligned}$$

Also, for $i = 2, \ldots, m-1$ we write

$$v_i = L_h\left(\theta_i^i\left(v - w - \sum_{j=0}^{i-1} v_j\right) + (1 - \theta_i^i)w_i\right), \tag{4.31}$$

and we prove

$$\begin{aligned} v_i \in V_h^i \text{ and } w + \sum_{j=0}^{i-1} w_j + v_i \in K_h,\\ v - \sum_{j=0}^{i} v_j + \sum_{j=0}^{i} w_j \in K_h,\\ v - w - \sum_{j=0}^{i} v_j \in W_0^{1,s}\left(\bigcup_{j=i+1}^{m} \Omega_j\right), \text{ and}\\ v - w - \sum_{j=0}^{i} v_j = 0 \text{ in } \Omega - \overline{\cup_{j=i+1}^{m}\Omega_j}, \end{aligned}$$

assuming that these equations hold for $i-1$. Finally, we take

$$v_m = v - w - \sum_{j=0}^{m-1} v_j \tag{4.32}$$

and we get that (2.1) and (2.2) in Assumption 2.1 hold.

Step 2. We define in this step a $v_0 \in V_H^0$ satisfying (4.29) and prove that condition (2.3) in Assumption 2.1 is satisfied with the constant C_0 given in (4.28). It is easy to see that (4.29) is equivalent with

$$v_0 - w_0 \in (K_h - (w + w_0)) \cap (v - K_h), \tag{4.33}$$

and also, since $v, w + w_0 \in K_h$, we get

$$v - w - w_0 \in (K_h - (w + w_0)) \cap (v - K_h)\,. \tag{4.34}$$

We write $\mathcal{K} = (K_h - (w + w_0)) \cap (v - K_h)$, and from the above equation and Lemma 4.2, we get that $I_H(v - w - w_0) \in \mathcal{K}$. From (4.21) and (4.22) we have

$$||v - w - w_0 - I_H(v - w - w_0)||_{0,s} \leq CHC_{d,s}(H,h)|v - w - w_0|_{1,s} \tag{4.35}$$

and

$$\begin{aligned} &||I_H(v - w - w_0)||_{0,s} \leq CC_{d,s}(H,h)||v - w - w_0||_{0,s} \\ &|I_H(v - w - w_0)|_{1,s} \leq CC_{d,s}(H,h)|v - w - w_0|_{1,s}, \end{aligned} \tag{4.36}$$

where $C_{d,s}(H,h)$ is defined in (4.6). Now we take

$$v_0 = w_0 + I_H(v - w - w_0), \tag{4.37}$$

and, from 4.34, the second part of Lemma 4.2, and (4.33), we get that it satisfies condition (4.29). To prove condition (2.3) in Assumption 2.1, we first notice that, starting from v_1 given in (4.30), by the recurrent application of (4.31), as in the proof of Proposition 3.1, we get v_i, $i = 1, \ldots, m$, of the form

$$v_i = L_h\left(\tau_0^i(v - w - v_0) + \sum_{j=1}^{i} \tau_j^i w_j\right),\ i = 1, \ldots, m, \tag{4.38}$$

where τ_j^i, $i = 1, \ldots, m$, $j = 0, \ldots, i$, satisfy (3.9). Using (3.10) and (3.11), we get

$$||L_h(\tau_j^i w_j)||_{1,s} \leq C||\tau_j^i w_j||_{1,s} \leq C\left(||w_j||_{1,s} + \frac{m-1}{\delta}||w_j||_{0,s}\right).$$

It follows from (4.1) that the diameters of the connected component of Ω_i are less than CH, and since $w_i \in V_h^i$, using the classical Friedrichs–Poincaré inequality, we get

$$||L_h(\tau_j^i w_j)||_{1,s} \leq C\left[1 + (m-1)\frac{H}{\delta}\right]|w_j|_{1,s},\ i = 1, \ldots, m,\ j = 1, \ldots, i. \tag{4.39}$$

On the other hand, taking into account (3.10), (3.11), (4.37), and (4.35), we get

$$\begin{aligned} &||L_h(\tau_0^i(v - w - v_0))||_{1,s} \leq C[|v - w - v_0|_{1,s} + \left(1 + \tfrac{m-1}{\delta}\right)||v - w - v_0||_{0,s}] \\ &= C[|v - w - v_0|_{1,s} + \left(1 + \tfrac{m-1}{\delta}\right)||v - w - w_0 - I_H(v - w - w_0)||_{0,s}] \\ &\leq C\left[|v - w - v_0|_{1,s} + (m-1)C_{d,s}(H,h)\tfrac{H}{\delta}|v - w - w_0|_{1,s}\right] \\ &\leq C(|v - w|_{1,s} + |v_0|_{1,s}) + C(m-1)C_{d,s}(H,h)\tfrac{H}{\delta}(|v - w|_{1,s} + |w_0|_{1,s}). \end{aligned}$$

Consequently, we have

$$\begin{aligned} &||L_h(\tau_0^i(v - w - v_0))||_{1,s} \leq C\left[1 + (m-1)\tfrac{H}{\delta}\right]C_{d,s}(H,h) \\ &\cdot(|v - w|_{1,s} + |w_0|_{1,s}) + C|v_0|_{1,s},\ i = 1, \ldots, m. \end{aligned} \tag{4.40}$$

Also, from (4.37) and (4.36), we get

$$|v_0|_{1,s} = |w_0 + I_H(v - w - w_0)|_{1,s} \le |w_0|_{1,s} + |I_H(v - w - w_0)|_{1,s}$$
$$\le |w_0|_{1,s} + CC_{d,s}(H,h)|v - w - w_0|_{1,s},$$

and therefore,

$$|v_0|_{1,s} \le CC_{d,s}(H,h)(|v - w|_{1,s} + |w_0|_{1,s}). \tag{4.41}$$

Now, from (4.40) and (4.41), we get

$$\begin{aligned} &||L_h(\tau_0^i(v - w - v_0))||_{1,s} \\ &\le C\left[1 + (m-1)\tfrac{H}{\delta}\right] C_{d,s}(H,h)(|v - w|_{1,s} + |w_0|_{1,s}),\ i = 1, \dots, m. \end{aligned} \tag{4.42}$$

Finally, from (4.38), (4.39), (4.41), and (4.42) we obtain that condition (2.3) in Assumption 2.1 holds with C_0 given in (4.28). ∎

Remark 4.2. As in Remark 3.1, we notice that, since the number m of the subdomains Ω_i is the number of colors of the overlapping domain decomposition $\{O_i\}_{1 \le i \le M}$, the error estimates in Theorem 2.1 depends only on C_0 given in (4.28). Therefore, if the overlapping size δ and the mesh sizes H and h are chosen such that H/h and H/δ are constant, then the convergence rate of the two-level multiplicative Schwarz method is independent of the mesh and domain decomposition parameters.

5. Multilevel multiplicative Schwarz method. We consider over the domain $\Omega \subset \mathbf{R}^d$ a family of regular meshes $\mathcal{T}_{h_j}$ of mesh sizes h_j, $j = 1, \dots, L$, such that $\mathcal{T}_{h_{j+1}}$ is a refinement of $\mathcal{T}_{h_j}$, $j = 1, \dots, L-1$. We write

$$\Omega_j = \bigcup_{\tau \in \mathcal{T}_{h_j}} \tau \tag{5.1}$$

and we assume that $\Omega = \Omega_L$. As in the previous section, we assume that, if a node of $\mathcal{T}_{h_j}$ lies on $\partial\Omega_j$, then it lies on $\partial\Omega_{j+1}$, too, that is, it lies on $\partial\Omega$. Also, for the nodes $x^j \in \partial\Omega$ of $\mathcal{T}_{h_j}$, $j = 1, \dots, L-1$, we consider the union of all $\tau \in \mathcal{T}_{h_j}$ having x^j as a vertex, ω_j, and define the set S_{x^j} as the union of ω_j with all $\tau \in \mathcal{T}_{h_{j+1}}$, $\tau \not\subset \Omega_j$, which are contained in the smallest sphere which is centered at x^j and contains ω_j. We assume that

$$\Omega_{j+1} \backslash \Omega_j \subset \bigcup_{x^j \text{ node of } \mathcal{T}_{h_j},\ x^j \in \partial\Omega} S_{x^j} \text{ for } j = 1, \dots, L-1. \tag{5.2}$$

Since the mesh $\mathcal{T}_{h_{j+1}}$ is a refinement of $\mathcal{T}_{h_j}$, we have $h_{j+1} \le h_j$, and assume that there exists a constant γ, independent of the number of meshes, L, such that

$$1 < \gamma \le \frac{h_j}{h_{j+1}}, \quad j = 1, \dots, L-1. \tag{5.3}$$

At each level $j = 1, \dots, L$, we consider an overlapping decomposition $\{O_j^i\}_{1 \le i \le M_j}$ of Ω_j, and assume that the mesh partition $\mathcal{T}_{h_j}$ of Ω_j supplies a mesh partition for each O_j^i, $1 \le i \le M_j$. Also, we assume that the overlapping size for the domain decomposition at the level $1 \le j \le L$ is δ_j, i.e.,

$$O_j^i \cap \partial\left(\bigcup_{l \ne i} O_j^l\right) \ne \emptyset \text{ and } \operatorname{dist}\left(\partial O_j^i \backslash \partial\Omega_j, O_j^i \cap \partial\left(\bigcup_{l \ne i} O_j^l\right)\right) \ge \delta_j \tag{5.4}$$

is satisfied. In addition, we suppose that there exists a constant C such that

$$\operatorname{diam}(O^i_{j+1}) \le Ch_j,\ j = 1, \dots, L-1,\ i = 1, \dots, M_j. \tag{5.5}$$

Now, at each level $j = 1, \dots, L$, we color the subdomains O^i_j, $i = 1, \dots, M_j$, and obtain the overlapping subdomains Ω^i_j, $i = 1, \dots, m_j$, as in the previous section. Finally, we assume that $m_1 = 1$, and write

$$m = \max_{j=1,\dots,L} m_j. \tag{5.6}$$

At each level $j = 1, \dots, L$, we introduce the linear finite element spaces,

$$V_{h_j} = \{v \in C^0(\bar{\Omega}_j) : v|_\tau \in P_1(\tau),\ \tau \in \mathcal{T}_{h_j},\ v = 0 \text{ on } \partial\Omega_j\}, \tag{5.7}$$

and, for $i = 1, \dots, m_j$, we write

$$V^i_{h_j} = \{v \in V_{h_j} : v = 0 \text{ in } \Omega_j \backslash \Omega^i_j\}. \tag{5.8}$$

The convex set will be a subset K_{h_L} of V_{h_L} having Property 3.1.

In order to prove that Assumption 2.1 holds for the convex set $K = K_{h_L}$ and the spaces $V = V_{h_L}$, $V^i_j = V^i_{h_j}$, $j = 1, \dots, L$, $i = 1, \dots, m_j$, and to find the constant C_0 in (2.3) as a function of the domain decomposition and mesh parameters, we need the following lemma. This result generalizes to more than two levels the second inequality (4.22) in Lemma 4.2. To this end, we introduce operators $I_{h_k} : V_{h_{k+1}} \to V_{h_k}$, $k = 1, \dots, L-1$, which are similar to the operator $I_H : V_h \to V_H$ defined in (4.20).

LEMMA 5.1. *For a given $1 \le j < L-1$, let $v_k,\ w_k \in V_{h_k}$, $k = j+1, \dots, L-1$, such that*

$$v_k = w_k + I_{h_k}(v_{k+1}). \tag{5.9}$$

Then,

$$\begin{aligned} |I_{h_j} v_{j+1}|_{1,s,\Omega_j} \le C(L-j)^{\frac{s-1}{s}} \Bigg\{ & \sum_{k=j+1}^{L-1} C_{d,s}(h_j, h_k)^s |w_k|^s_{1,s,\Omega_j} \\ & + C_{d,s}(h_j, h_L)^s |v_L|^s_{1,s,\Omega_j} \Bigg\}^{\frac{1}{s}}. \end{aligned} \tag{5.10}$$

Moreover, (5.10) *also holds if its seminorms over Ω_j are replaced with seminorms over Ω_k, for any $k = j+1, \dots, L$.*

Proof. Let ω_j be the support of the nodal basis function in V_{h_j} corresponding to the node x^j of $\mathcal{T}_{h_j}$. Then there exists two nodes of $\mathcal{T}_{h_j}$, $x^j_1, x^j_2 \in \omega_j$, such that

$$|I_{h_j} v_{j+1}|^s_{1,s,\omega_j} \le Ch_j^{d-s} |(I_{h_j} v_{j+1})(x^j_1) - (I_{h_j} v_{j+1})(x^j_2)|^s. \tag{5.11}$$

Starting from (5.11), we prove that, for each $k = j, \dots, L-1$, there exist two nodes of $\mathcal{T}_{h_{k+1}}$, $x^{k+1}_1 \in \omega^1_k$ and $x^{k+1}_2 \in \omega^2_k$, ω^1_k and ω^2_k being the supports of the nodal basis function in V_{h_k} corresponding to the nodes x^k_1 and x^k_2 of $\mathcal{T}_{h_k}$, respectively, such that

$$\begin{aligned} & |I_{h_j} v_{j+1}|^s_{1,s,\omega_j} \\ & \le Ch_j^{d-s} \left[\sum_{k=j+1}^{L-1} |w_k(x^k_1) - w_k(x^k_2)| + |v_L(x^L_1) - v_L(x^L_2)| \right]^s. \end{aligned} \tag{5.12}$$

First, we assume that, starting with x_1^j and x_2^j in (5.11), at each level $k = j, \dots, L-1$, the values of $(I_{h_k} v_{k+1})(x_1^k)$ and $(I_{h_k} v_{k+1})(x_2^k)$ are obtained as values of v_{k+1} at two nodes $x_1^{k+1} \in \omega_k^1$ and $x_2^{k+1} \in \omega_k^2$, respectively, that is, we have

$$(I_{h_k} v_{k+1})(x_1^k) = v_{k+1}(x_1^{k+1}) \text{ and } (I_{h_k} v_{k+1})(x_2^k) = v_{k+1}(x_2^{k+1}). \tag{5.13}$$

Therefore, starting from (5.11), using (5.9), for any $j+1 \le N \le L-1$, we get

$$\begin{aligned} &|I_{h_j} v_{j+1}|^s_{1,s,\omega_j} \le C h_j^{d-s} \\ &\cdot \left[\sum_{k=j+1}^{N} |w_k(x_1^k) - w_k(x_2^k)| + |(I_{h_N} v_{N+1})(x_1^N) - (I_{h_N} v_{N+1})(x_2^N)| \right]^s , \end{aligned} \tag{5.14}$$

and, consequently, we get (5.12). Now, we prove that there exist some nodes x_1^k and x_2^k of $\mathcal{T}_{h_k}$ such that (5.12) holds, even if (5.13) does not hold for all $k = j, \dots, L-1$. Let us assume that (5.13) holds for $k = j, \dots, N$, $j+1 \le N \le L-1$. Therefore we can get (5.14). From the definition of the operators I_i^+ and I_i^- in (4.18), it follows that if, for instance, $(I_{h_N} v_{N+1})(x_1^N) \ne v_{N+1}(x)$ for any node $x \in \omega_N^1$ of $\mathcal{T}_{h_{N+1}}$, then $(I_{h_N} v_{N+1})(x_1^N) = 0$ and v_{N+1} takes both positive and negative values at the nodes of $\mathcal{T}_{h_{N+1}}$ in ω_N^1. Consequently, if both $(I_{h_N} v_{N+1})(x_1^N) \ne v_{N+1}(x)$ for any node $x \in \omega_N^1$ of $\mathcal{T}_{h_{N+1}}$, and $(I_{h_N} v_{N+1})(x_2^N) \ne v_{N+1}(x)$ for any node $x \in \omega_N^2$ of $\mathcal{T}_{h_{N+1}}$, then $(I_{h_N} v_{N+1})(x_1^N) = (I_{h_N} v_{N+1})(x_2^N) = 0$, and we get that (5.12) holds for some arbitrary nodes of $\mathcal{T}_{h_k}$, $x_1^k \in \omega_{k-1}^1$, $x_2^k \in \omega_{k-1}^2$, $N+1 \le k \le L$. Also, if $(I_{h_N} v_{N+1})(x_1^N) \ne v_{N+1}(x)$ for any node $x \in \omega_N^1$ of $\mathcal{T}_{h_{N+1}}$, but there exists $x_2^{N+1} \in \omega_N^2$, node of $\mathcal{T}_{h_{N+1}}$, such that $(I_{h_N} v_{N+1})(x_2^N) = v_{N+1}(x_2^{N+1})$, then

$$|(I_{h_N} v_{N+1})(x_1^N) - (I_{h_N} v_{N+1})(x_2^N)| = |v_{N+1}(x_2^{N+1})| \le |v_{N+1}(x_1^{N+1}) - v_{N+1}(x_2^{N+1})|,$$

where $x_1^{N+1} \in \omega_N^1$ is an arbitrary node of $\mathcal{T}_{h_{N+1}}$ for which $v_{N+1}(x_1^{N+1})$ and $v_{N+1}(x_2^{N+1})$ have different signs. In this way we get that (5.14) holds for $N+1$, and can continue the same reasoning for $N+2 \le k \le L-1$.

If we write $\omega_{j-1}^1 = \omega_{j-1}^2 = \omega_j$, since, for $k = j, \dots, L$, the above nodes x_1^k and x_2^k of $\mathcal{T}_{h_k}$ belong to ω_{k-1}^1 and ω_{k-1}^2, respectively, and $\operatorname{diam}(\omega_{k-1}^1)$, $\operatorname{diam}(\omega_{k-1}^2) \le 2h_k$, then x_1^k and x_2^k, $k = j, \dots, L$, belong to the sphere centered at x^j and having the radius of $2h_j + h_{j+1} + h_{j+2} + \cdots + h_{L-1}$. Using (5.3), we get that they belong to the sphere centered at x^j with the radius of $\frac{2\gamma-1}{\gamma-1} h_j$. Consequently, if we write

$$\tilde{\omega}_j = \bigcup_{\tau \in \mathcal{T}_{h_j},\ \operatorname{dist}(\mathrm{x^j}, \tau) \le \frac{\gamma}{\gamma-1} \mathrm{h_j}} \tau, \tag{5.15}$$

then $x_1^k, x_2^k \in \tilde{\omega}_j$, $k = j, \dots, L$. For any $x \in \tilde{\omega}_j$, we get from (5.12),

$$\begin{aligned} &|I_{h_j} v_{j+1}|^s_{1,s,\omega_j} \le C h_j^{d-s} [2(L-j)]^{s-1} \\ &\left\{ \sum_{k=j+1}^{L-1} [|w_k(x_1^k) - w_k(x)|^s + |w_k(x_2^k) - w_k(x)|^s] \right. \\ &\left. + |v_L(x_1^L) - v_L(x)|^s + |v_L(x_2^L) - v_L(x)|^s \right\}, \end{aligned}$$

and integrating over $\tilde{\omega}_j$ we have,

$$(\tfrac{2\gamma-1}{\gamma-1}h_j)^d|I_{h_j}v_{j+1}|^s_{1,s,\omega_j} \le Ch_j^{d-s}[2(L-j)]^{s-1}$$
$$\left\{\sum_{k=j+1}^{L-1}[||w_k(x_1^k)-w_k||^s_{0,s,\tilde{\omega}_j}+||w_k(x_2^k)-w_k||^s_{0,s,\tilde{\omega}_j}]\right.$$
$$\left.+||v_L(x_1^L)-v_L||^s_{0,s,\tilde{\omega}_j}+||v_L(x_2^L)-v_L||^s_{0,s,\tilde{\omega}_j}\right\}.$$

From this inequality and (4.16), we get

$$|I_{h_j}v_{j+1}|^s_{1,s,\omega_j} \le C(L-j)^{s-1}\left(\tfrac{\gamma-1}{2\gamma-1}\right)^d$$
$$\left\{\sum_{k=j+1}^{L-1}C_{d,s}\left(2h_j\frac{2\gamma-1}{\gamma-1},h_k\right)^s|w_k|^s_{1,s,\tilde{\omega}_j}+C_{d,s}\left(2h_j\frac{2\gamma-1}{\gamma-1},h_L\right)^s|v_L|^s_{1,s,\tilde{\omega}_j}\right\},$$

and, taking into account the definition of $C_{d,s}$ in (4.6), we have

$$|I_{h_j}v_{j+1}|^s_{1,s,\omega_j} \le C(L-j)^{s-1}\left\{\sum_{k=j+1}^{L-1}C_{d,s}(h_j,h_k)^s|w_k|^s_{1,s,\tilde{\omega}_j}+C_{d,s}(h_j,h_L)^s|v_L|^s_{1,s,\tilde{\omega}_j}\right\}.$$

Finally, since the mesh $\mathcal{T}_{h_j}$ is regular and γ is independent of L and of the mesh parameters, then ω_j and $\tilde{\omega}_j$ contain a bounded number of simplexes in $\mathcal{T}_{h_j}$, which is also independent of L and of the mesh parameters. Consequently, we get (5.10). Since the nodes of $\mathcal{T}_{h_j}$ belonging to $\partial\Omega_j$ lie also on $\partial\Omega_{j+1}$, and $v_{j+1}=0$ on $\partial\Omega_{j+1}$, it follows that $I_{h_j}v_{j+1}=0$ on $\partial\Omega_j$. Consequently, they are extended with zero to Ω_k, $j+1\le k\le L$, and (5.10) holds for these domains, too. ∎

The following proposition shows that Assumption 2.1 holds for the multilevel method and writes the constant C_0 as a function of the domain decomposition and mesh parameters.

PROPOSITION 5.1. *Let, for each level $j=1,\dots,L$, $\Omega_j^1,\dots,\Omega_j^{m_j}$ be the overlapping decomposition of the domain Ω_j defined in this section with $\Omega_L=\Omega$ and $m_1=1$. Then Assumption* 2.1 *is verified for the piecewise linear finite element spaces, $V=V_{h_L}$ and $V_j^i=V_{h_j}^i$, $j=1,\dots,L$, $i=1,\dots,m_j$ defined in* (5.7) *and* (5.8)*, respectively, and any convex set $K=K_{h_L}\subset V_{h_L}$ with Property* 3.1. *The constant in* (2.3) *of Assumption* 2.1 *can be taken of the form*

$$C_0 = Cm^2(L+1)^{2-\frac{1}{p}-\frac{1}{s}}\sum_{j=1}^{L}\left[1+(m-1)\frac{h_{j-1}}{\delta_j}\right]C_{d,s}(h_{j-1},h_L) \tag{5.16}$$

in which we take $h_0=h_1$, C is independent of the mesh and domain decomposition parameters, and $C_{d,s}(H,h)$ is given in (4.6).

Proof. Let us consider $w\in K_{h_L}$, $w_j^i\in V_{h_j}^i$, $j=1,\dots,L$, $i=1,\dots,m_j$, such that $w+\sum_{j=1}^{k-1}\sum_{i=1}^{m_j}w_j^i+\sum_{i=1}^{l}w_k^i\in K_{h_L}$, $k=1,\dots,L$, $l=1,\dots,m_k$, and let v be another element in K_{h_L}. For $j=1,\dots,L$, we write

$$w_j^0=\sum_{i=1}^{m_j}w_j^i \quad\text{and}\quad w_j=\sum_{k=1}^{j}w_k^0=\sum_{k=1}^{j}\sum_{i=1}^{m_j}w_j^i.$$

Since $v, w + w_{L-2} \in K_{h_L}$, and also, $w + w_{L-2} + w^0_{L-1} \in K_{h_L}$ and $w + w_{L-2} + w^0_{L-1} + \sum_{i=1}^{l} w^i_L \in K_{h_L}$, $l = 1, \dots, m_L$, as in the proof of Proposition 4.1, we get that there exist $v^0_{L-1} \in V_{h_{L-1}}$ and $v^i_L \in V^i_{h_L}$, $i = 1, \dots, m_L$ such that

$$w + w_{L-2} + v^0_{L-1} \in K_{h_L}, \tag{5.17}$$

$$w + w_{L-2} + w^0_{L-1} + \sum_{i=1}^{l-1} w^i_L + v^l_L \in K_{h_L},\ l = 1, \dots, m_L, \tag{5.18}$$

$$v - w - w_{L-2} = v^0_{L-1} + \sum_{i=1}^{m_L} v^i_L, \tag{5.19}$$

and

$$\begin{aligned} &v^0_{L-1} = w^0_{L-1} + I_{h_{L-1}}(v - w - w_{L-2} - w^0_{L-1}), \\ &v^i_L = L_{h_L}(\tau^i_0 \left(v - w - w_{L-2} - v^0_{L-1}) + \sum_{l=1}^{i} \tau^i_l w^l_L \right),\ i = 1, \dots, m_L, \end{aligned} \tag{5.20}$$

where τ^i_j, $i = 1, \dots, m$, $j = 0, \dots, i$, satisfy (3.9). In this way, using (5.17), we get that $w + w_{L-3} + w^0_{L-2} + v^0_{L-1}, w + w_{L-3} \in K_{h_L}$, and also, $w + w_{L-3} + w^0_{L-2} \in K_{h_L}$ and $w + w_{L-3} + w^0_{L-2} + \sum_{i=1}^{l} w^i_{L-1} \in K_{h_L}$, $l = 1, \dots, m_{L-1}$. Consequently, there exist $v^0_{L-2} \in V_{h_{L-2}}$ and $v^i_{L-1} \in V^i_{h_{L-1}}$, $i = 1, \dots, m_{L-1}$ such that

$$w + w_{L-3} + v^0_{L-2} \in K_{h_L}, \tag{5.21}$$

$$w + w_{L-3} + w^0_{L-2} + \sum_{i=1}^{l-1} w^i_{L-1} + v^l_{L-1} \in K_{h_L},\ l = 1, \dots, m_{L-1}, \tag{5.22}$$

$$w^0_{L-2} + v^0_{L-1} = v^0_{L-2} + \sum_{i=1}^{m_{L-1}} v^i_{L-1}, \tag{5.23}$$

and

$$\begin{aligned} &v^0_{L-2} = w^0_{L-2} + I_{h_{L-2}}(v^0_{L-1}) \\ &v^i_{L-1} = L_{h_{L-1}} \left(\tau^i_0 (w^0_{L-2} + v^0_{L-1} - v^0_{L-2}) + \sum_{l=1}^{i} \tau^i_l w^l_{L-1} \right),\ i = 1, \dots, m_{L-1}. \end{aligned} \tag{5.24}$$

Starting with (5.21) we successively get for $j = 3, \dots, L-1$ that $w + w_{L-j-1} + w^0_{L-j} + v^0_{L-j+1}, w + w_{L-j-1} \in K_{h_L}$, and also, $w + w_{L-j-1} + w^0_{L-j} \in K_{h_L}$ and $w + w_{L-j-1} + w^0_{L-j} + \sum_{i=1}^{l} w^i_{L-j+1} \in K_{h_L}$, $l = 1, \dots, m_{L-j+1}$. Consequently, there exist $v^0_{L-j} \in V_{h_{L-j}}$ and $v^i_{L-j+1} \in V^i_{h_{L-j+1}}$, $i = 1, \dots, m_{L-j+1}$ such that

$$w + w_{L-j-1} + v^0_{L-j} \in K_{h_L}, \tag{5.25}$$

$$\begin{aligned} w + w_{L-j-1} + w^0_{L-j} + \sum_{i=1}^{l-1} w^i_{L-j+1} \\ + v^l_{L-j+1} \in K_{h_L},\ l = 1, \dots, m_{L-j+1}, \end{aligned} \tag{5.26}$$

$$w^0_{L-j} + v^0_{L-j+1} = v^0_{L-j} + \sum_{i=1}^{m_{L-j+1}} v^i_{L-j+1}, \tag{5.27}$$

and

$$
\begin{aligned}
&v^0_{L-j} = w^0_{L-j} + I_{h_{L-j}}(v^0_{L-j+1}) \\
&v^i_{L-j+1} = L_{h_{L-j+1}}\left(\tau^i_0(w^0_{L-j} + v^0_{L-j+1} - v^0_{L-j})\right. \\
&\left. + \sum_{l=1}^{i} \tau^i_l w^l_{L-j+1}\right),\ i = 1, \ldots, m_{L-j+1}.
\end{aligned} \tag{5.28}
$$

If we write $v^1_1 = v^0_1$, since $m_1 = 1$, then (5.18), (5.22), and (5.26) prove that (2.1) of Assumption 2.1 holds. Also, we get (2.2) of Assumption 2.1 from (5.19), (5.23), and (5.27). Now, if we write

$$
v^0_L = v - w - w_{L-1}, \tag{5.29}
$$

we get from (5.20), (5.24), and (5.28) that

$$
\begin{aligned}
&v^0_{j-1} = w^0_{j-1} + I_{h_{j-1}}(v^0_j), \\
&v^i_j = L_{h_j}\left(\tau^i_0(w^0_{j-1} + v^0_j - v^0_{j-1}) + \sum_{l=1}^{i} \tau^i_l w^l_j\right), \\
&\text{for } j = 2, \ldots, L,\ i = 1, \ldots, m_j.
\end{aligned} \tag{5.30}
$$

Similar to (4.39), we get that

$$
\begin{aligned}
&||L_{h_j}(\tau^i_l w^l_j)||_{1,s} \le C\left[1 + (m_j - 1)\tfrac{h_{j-1}}{\delta_j}\right]|w^l_j|_{1,s}, \\
&j = 2, \ldots, L,\ i = 1, \ldots, m_j,\ l = 1, \ldots, i.
\end{aligned} \tag{5.31}
$$

Replacing v^0_{j-1} given in the first equation of (5.30) into the second equation of (5.30), and using (4.21) and (4.22), we get

$$
\begin{aligned}
&||L_{h_j}(\tau^i_0(w^0_{j-1} + v^0_j - v^0_{j-1}))||_{1,s} = ||L_{h_j}(\tau^i_0(v^0_j - I_{h_{j-1}}v^0_j))||_{1,s} \\
&\le C\left[|v^0_j - I_{h_{j-1}}v^0_j|_{1,s} + \left(1 + \tfrac{m_{j-1}}{\delta_j}\right)||v^0_j - I_{h_{j-1}}v^0_j||_{0,s}\right] \\
&\le C\left\{[1 + C_{d,s}(h_{j-1}, h_j)]|v^0_j|_{1,s} + \left(1 + \tfrac{m_j - 1}{\delta_j}\right)h_{j-1}C_{d,s}(h_{j-1}, h_j)|v^0_j|_{1,s}\right\}.
\end{aligned}
$$

Therefore, we have

$$
\begin{aligned}
&||L_{h_j}(\tau^i_0(w^0_{j-1} + v^0_j - v^0_{j-1}))||_{1,s} \\
&\le C\left[1 + (m_j - 1)\tfrac{h_{j-1}}{\delta_j}\right]C_{d,s}(h_{j-1}, h_j)|v^0_j|_{1,s} \text{ for } j = 2, \ldots, L,\ i = 1, \ldots, m_j.
\end{aligned} \tag{5.32}
$$

From the second equation in (5.30), (5.31), and (5.32), for $j = 2, \ldots, L$ and $i = 1, \ldots, m_j$, we get

$$
\begin{aligned}
&||v^i_j||_{1,s} \le C[1 + (m_j - 1)\tfrac{h_{j-1}}{\delta_j}]C_{d,s}(h_{j-1}, h_j)|v^0_j|_{1,s} \\
&+ C\left[1 + (m_j - 1)\frac{h_{j-1}}{\delta_j}\right]\sum_{l=1}^{i}|w^l_j|_{1,s},
\end{aligned}
$$

and using (5.6), we have

$$
\begin{aligned}
&||v^i_j||_{1,s} \le C\left[1 + (m - 1)\tfrac{h_{j-1}}{\delta_j}\right]C_{d,s}(h_{j-1}, h_j)|v^0_j|_{1,s} \\
&+ C\left[1 + (m - 1)\frac{h_{j-1}}{\delta_j}\right]\sum_{l=1}^{m_j}|w^l_j|_{1,s} \text{ for } j = 2, \ldots, L.
\end{aligned} \tag{5.33}
$$

The first equation in (5.30) shows that the conditions of Lemma 5.1 are satisfied, and we get from (5.10) that for $j = 1, \dots, L-1$,

$$|v_j^0|_{1,s} \le C(L-j)^{\frac{s-1}{s}} \left[\sum_{k=j}^{L-1} C_{d,s}(h_j, h_k)^s |w_k^0|_{1,s}^s + C_{d,s}(h_j, h_L)^s |v_L^0|_{1,s}^s \right]^{\frac{1}{s}}.$$

Since $C_{d,s}(h_j, h_k) \le C_{d,s}(h_j, h_L)$, $j = 1, \dots L-1$, $j \le k \le L-1$, using (5.29), we get

$$|v_j^0|_{1,s} \le C(L-1)^{\frac{s-1}{s}} C_{d,s}(h_j, h_L) \left[\sum_{k=1}^{L-1} |w_k^0|_{1,s} + |v-w|_{1,s} \right] \quad \text{for } j = 1, \dots, L-1. \tag{5.34}$$

From (4.6), we have $C_{d,s}(h_{j-1}, h_j) C_{d,s}(h_j, h_L) \le C_{d,s}(h_{j-1}, h_L)$, and using it we get from (5.33) and (5.34),

$$||v_j^i||_{1,s} \le C(L-1)^{\frac{s-1}{s}} \left[1 + (m-1)^{\frac{h_{j-1}}{\delta_j}} \right] C_{d,s}(h_{j-1}, h_L) \left[\sum_{k=1}^{L} \sum_{l=1}^{m_k} |w_k^l|_{1,s} + |v-w|_{1,s} \right], \quad \text{for } j = 2, \dots, L.$$

Since $m_1 = 1$ and we have written $v_1^1 = v_1^0$ which vanishes on $\partial\Omega$, it follows from (5.34) that the above equation also holds for $j = 1$ with $h_0 = h_1$. From this equation we get

$$||v_j^i||_{1,s} \le C m^{\frac{p-1}{p}} (L+1)^{\frac{p-1}{p}} (L-1)^{\frac{s-1}{s}} \left[1 + (m-1)^{\frac{h_{j-1}}{\delta_j}} \right] C_{d,s}(h_{j-1}, h_L) \left[\sum_{k=1}^{L} \sum_{l=1}^{m_k} |w_k^l|_{1,s}^p + |v-w|_{1,s}^p \right]^{\frac{1}{p}}, \tag{5.35}$$

and (5.16) follows from it. □

5.1. Multigrid method. In the above multilevel method a mesh is the refinement of that on the previous level, but the domain decompositions are almost independent from one level to another. The multigrid method is obtained from the multilevel method by taking the subsets O_j^i of a particular form: we associate at each node x_j^i of $\mathcal{T}_{h_j}$, $j = 1, \dots, L$, $i = 1, \dots, M_j$, an O_j^i defined as the union of the simplexes in $\mathcal{T}_{h_j}$ having x_j^i as a vertex. Consequently, the subspaces $V_{h_j}^i$ will be direct sums of some one-dimensional spaces generated by the nodal basis functions associated with the nodes of $\mathcal{T}_{h_j}$. Evidently, all the previous assumptions on the domain decompositions are satisfied and we can take $\delta_j = h_j$. In the multigrid methods, the construction of a finer mesh from a coarse one, is made following the same procedure of division of the simplexes at each level. Therefore, we can replace (5.3) by

$$1 < \gamma \le \frac{h_j}{h_{j+1}} \le C\gamma, \quad j = 1, \dots, L-1, \tag{5.36}$$

where the constant C is independent of the number of meshes. Starting with the expression of the constant C_0 in (5.16), using (5.36), we have

$$\begin{aligned} & Cm^2(L+1)^{2-\frac{1}{p}-\frac{1}{s}} \sum_{j=1}^{L} \left[1+(m-1)\frac{h_{j-1}}{\delta_j}\right] C_{d,s}(h_{j-1},h_L) \\ & \leq Cm^2(L+1)^{2-\frac{1}{p}-\frac{1}{s}} L[1+(m-1)\gamma] C_{d,s}(h_1,h_L) \\ & \leq Cm^3 L^{3-\frac{1}{p}-\frac{1}{s}} \gamma C_{d,s}(h_1,h_L). \end{aligned}$$

If we write $h = h_1$ and denote by H the diameter of Ω, then the constant C_0 can be taken as

$$C_0 = CL^{3-\frac{1}{p}-\frac{1}{s}} \gamma C_{d,s}(H,h). \tag{5.37}$$

We point out that an iteration of Algorithm 2.1 using the one-dimensional spaces generated by the basis functions corresponding to the nodes of the L meshes represents half of a V-cycle multigrid iteration. Since a full V-cycle multigrid iteration uses these one-dimensional spaces more than once, in order to describe it we should repeat them in the list of the subspaces used by Algorithm 2.1. Consequently, for the multigrid method, only L in the expression of C_0 in (5.37) should be multiplicated by a constant. Therefore, C_0 given in (5.37) is valid for the multigrid method, too.

A MULTIGRID PRECONDITIONER FOR THE MIXED FORMULATION OF LINEAR PLANE ELASTICITY*

JOSEPH E. PASCIAK† AND YANQIU WANG‡

Abstract. In this paper, we develop a multigrid preconditioner for the discrete system of linear equations that results from the mixed formulation of the linear plane elasticity problem using the Arnold–Winther elements. This, in turn, can be reduced to the problem of finding a multigrid preconditioner for the form $(\cdot,\cdot)+(\mathbf{div}\,\cdot,\mathbf{div}\,\cdot)$ in the symmetric matrix space resulting from Arnold–Winther elements. Since the form is not uniformly elliptic, a Helmholtz-type decomposition is essential. The Arnold–Winther finite element space gives rise to nonnested multilevel spaces adding difficulty to the analysis. We prove that for the variable V-cycle multigrid preconditioner, the condition number of the preconditioned system is independent of the number of levels. The results of numerical experiments are also presented.

Key words. multigrid, mixed finite element, linear elasticity

1. Introduction.

Mixed finite element methods [7, 16] have been widely used in solving partial differential equations. Compared to the primal-based methods, mixed finite element methods have some well-known advantages. For example, the dual variable (in this case the stress), which is often the variable of primary interest, is computed directly as a fundamental unknown. Mixed methods also have some obvious disadvantages, such as the necessity of constructing stable pairs of finite element spaces and the fact that the resulting discrete system is indefinite. The construction of stable pairs of finite element spaces and the development of efficient iterative solvers for the resulting discrete system remain two of the most important issues in the applications of mixed finite element methods.

For decades, extensive research has been carried out to explore the mixed formulation of the plane elasticity problem. Most of this research was focused on developing stable pairs of mixed finite element spaces, and several different solutions have been proposed [5, 6, 26]. As stated in those papers, the crux of the difficulty is that the stress tensor in the Hellinger–Reissner principle has to be symmetric. Indeed, this symmetry condition is so hard to satisfy that the authors of [5, 26] resort to composite elements. Only recently did Arnold and Winther construct a stable pair of mixed finite elements [6] which did not use composite elements. The Arnold–Winther finite element spaces consist of piecewise polynomials over a triangular mesh tied together by degrees of freedom resulting in $\boldsymbol{H}(\mathbf{div})$ conforming symmetric approximation subspaces.

We mention some alternative ways to circumvent the difficulty of constructing stable pairs of finite elements. One way is to reformulate the saddle-point problem by using Lagrangian functionals so that it does not require symmetric matrices [1, 4].

Another way is to use the least-square formulation so that the classical discrete inf-sup condition is no longer needed [10, 17, 18]. Finally, other authors resort to the use of stabilizing techniques (see [22] and the references therein).

In this paper, we will focus on the lowest order Arnold–Winther finite element. The purpose is to develop and analyze a multigrid preconditioner for the resulting discrete system.

The discretization of the mixed formulation leads to a symmetric indefinite linear system. Generally speaking, there are three main approaches for solving large symmetric indefinite linear systems corresponding to mixed formulations. The first approach is to use Uzawa-type methods [9, 11, 20]. The second is the positive definite reformulation proposed by Bramble and Pasciak in [12] and [13]. The third is the preconditioned minimum residual method analyzed in [2, 27]. We adopt the idea of the preconditioned minimum residual method. An analysis similar to the one in [2] will show that the problem of constructing a preconditioner for the indefinite linear system derived from the mixed formulation of linear plane elasticity can be reduced to the problem of constructing a preconditioner for the $\boldsymbol{H}(\mathbf{div})$ problem on the Arnold–Winther finite element space on the symmetric matrix field.

In this paper, we construct and analyze a multigrid preconditioner for the $\boldsymbol{H}(\mathbf{div})$ problem. Multigrid methods provide efficient preconditioners for second order elliptic problems. A vast amount of research has been done in this area [15, 24, 29]. However, the classical techniques for the multigrid preconditioner do not work for the $\boldsymbol{H}(\mathbf{div})$ problem since the discrete operator which results from the $\boldsymbol{H}(\mathbf{div})$ problem is not uniformly elliptic. To deal with this difficulty, we follow the idea of using a Helmholtz-like decomposition [2, 3, 8, 21, 25] and decompose the Arnold–Winther finite element space into two orthogonal subspaces: the subspace of divergence-free functions and its orthogonal complement. Then, the analysis of our preconditioners can be done on these two subspaces separately. Our results show that for convex polygonal domains and the pure traction boundary problem, the condition number of the preconditioned system using the variable V-cycle multigrid preconditioner is independent of the number of levels.

The outline of the remainder of the paper is as follows. In section 2, we briefly introduce the mixed formulation of the elasticity problem, the Arnold–Winther mixed finite element for (2.3) and the technique for preconditioning a mixed system proposed in [2]. In section 3, the details of the multigrid preconditioner are explained, and the condition number of the preconditioned system is analyzed under certain assumptions on the smoother. In section 4, we construct a smoother and prove that it satisfies the assumptions stated in section 3. Finally, we give results of numerical experiments in section 5.

2. The mixed problem formulation, discretization, and preconditioning. In this section, we first state the mixed form of the linear elasticity problem. Next, we introduce the Arnold–Winther elements of lowest order. Finally, we briefly describe the idea of preconditioning the mixed system introduced in [2] which reduces the preconditioning problem to one on $\boldsymbol{H}_0(\mathbf{div}\,, \Omega, \mathbb{S}_2)$ (defined below).

2.1. Mixed elasticity formulation. Let Ω be a convex polygon in $\mathbb{R}^2$. We use the usual notation $H^s(\Omega)$, where s is a real number, to denote the Sobolev space defined on Ω [19]. For $s = 0$, the space is also denoted by $L^2(\Omega)$. Define $H_0^s(\Omega)$ to be the closure of $C_0^\infty(\Omega)$ under the $H^s(\Omega)$ norm.

Let $\mathbb{R}^2$ be the space of two-dimensional vector functions and $\mathbb{S}_2$ be the space of symmetric 2×2 matrix functions defined on Ω. Throughout the paper, we adopt

the convention that bold Latin characters in lower case denote vectors and bold Greek characters denote 2×2 symmetric matrices. Let $\boldsymbol{\tau} = (\tau_{ij})_{1\le i,j\le 2} \in \mathbb{S}_2$, $\boldsymbol{v} = (v_i)_{1\le i\le 2} \in \mathbb{R}^2$, and q be a scalar function. Define $\operatorname{div} \boldsymbol{v} = \frac{\partial v_1}{\partial x} + \frac{\partial v_2}{\partial y}$ and

$$\mathbf{div}\,\boldsymbol{\tau} = \begin{pmatrix} \frac{\partial \tau_{11}}{\partial x} + \frac{\partial \tau_{12}}{\partial y} \\ \frac{\partial \tau_{21}}{\partial x} + \frac{\partial \tau_{22}}{\partial y} \end{pmatrix}, \qquad \mathbf{airy}\, q = \begin{pmatrix} \frac{\partial^2 q}{\partial y^2} & -\frac{\partial^2 q}{\partial x \partial y} \\ -\frac{\partial^2 q}{\partial x \partial y} & \frac{\partial^2 q}{\partial x^2} \end{pmatrix}. \tag{2.1}$$

Denote the inner product between vectors and the inner product between matrices by

$$\boldsymbol{u} \cdot \boldsymbol{v} = u_1 v_1 + u_2 v_2, \quad \text{and} \quad \boldsymbol{\sigma} : \boldsymbol{\tau} = \sum_{i,j=1}^{2} \sigma_{ij} \tau_{ij}.$$

We generalize the definition of the Sobolev space to the cases of vector functions and symmetric matrix functions. Define the spaces

$$\boldsymbol{H}^s(\Omega, \mathbb{R}^2) = (H^s(\Omega))^2, \qquad \boldsymbol{H}^s(\Omega, \mathbb{S}_2) = (H^s(\Omega))^3$$

with norms

$$\|\boldsymbol{v}\|_{\boldsymbol{H}^s(\Omega,\mathbb{R}^2)} = (\|v_1\|^2_{H^s(\Omega)} + \|v_2\|^2_{H^s(\Omega)})^{1/2},$$
$$\|\boldsymbol{\tau}\|_{\boldsymbol{H}^s(\Omega,\mathbb{S}_2)} = (\|\tau_{11}\|^2_{H^s(\Omega)} + 2\|\tau_{12}\|^2_{H^s(\Omega)} + \|\tau_{22}\|^2_{H^s(\Omega)})^{1/2}.$$

We define $\boldsymbol{L}^2(\Omega, \mathbb{R}^2)$ and $\boldsymbol{L}^2(\Omega, \mathbb{S}_2)$ in the same fashion. For simplicity, denote $\|\cdot\|_{s,\Omega}$ to be the H^s-norm over scalar, vector, or symmetric matrix fields, depending on the type of the function. We also use the notation $(\cdot, \cdot)$ for the L^2 inner product over scalar, vector, or matrix fields defined on Ω.

Define

$$\boldsymbol{H}_0(\mathbf{div}\,, \Omega, \mathbb{S}_2) = \{\boldsymbol{\tau} \in \boldsymbol{L}^2(\Omega, \mathbb{S}_2) : \ \mathbf{div}\,\boldsymbol{\tau} \in \boldsymbol{L}^2(\Omega, \mathbb{R}^2) \text{ and } \boldsymbol{\tau}\boldsymbol{n}|_{\partial\Omega} = \mathbf{0}\},$$

where $\boldsymbol{n}$ is the outward normal vector on $\partial\Omega$. The norm on $\boldsymbol{H}_0(\mathbf{div}\,, \Omega, \mathbb{S}_2)$ is defined to be

$$\|\boldsymbol{\tau}\|^2_{\boldsymbol{H}(\mathbf{div}\,,\Omega,\mathbb{S}_2)} = \|\boldsymbol{\tau}\|^2_{0,\Omega} + \|\mathbf{div}\,\boldsymbol{\tau}\|^2_{0,\Omega}.$$

$\boldsymbol{H}_0(\mathbf{div}\,, \Omega, \mathbb{S}_2)$ is a Hilbert space with the inner product

$$\boldsymbol{\Lambda}(\boldsymbol{\sigma}, \boldsymbol{\tau}) = (\boldsymbol{\sigma}, \boldsymbol{\tau}) + (\mathbf{div}\,\boldsymbol{\sigma}, \mathbf{div}\,\boldsymbol{\tau}). \tag{2.2}$$

Next, we state the mixed formulation of the plane elasticity problem. We only consider the pure traction boundary problem [6, 16]: Find the stress $\boldsymbol{\sigma} \in \boldsymbol{H}_0(\mathbf{div}\,, \Omega, \mathbb{S}_2)$ and the displacement $\boldsymbol{u} \in \boldsymbol{L}^2(\Omega, \mathbb{R}^2)$ satisfying

$$\begin{cases} \int_\Omega \mathbb{A}\boldsymbol{\sigma} : \boldsymbol{\tau}\, d\boldsymbol{x} + \int_\Omega \mathbf{div}\,\boldsymbol{\tau} \cdot \boldsymbol{u}\, d\boldsymbol{x} = 0 & \text{for all } \boldsymbol{\tau} \in \boldsymbol{H}_0(\mathbf{div}\,, \Omega, \mathbb{S}_2), \\ \int_\Omega \mathbf{div}\,\boldsymbol{\sigma} \cdot \boldsymbol{v}\, d\boldsymbol{x} = \int_\Omega \boldsymbol{g} \cdot \boldsymbol{v}\, d\boldsymbol{x} & \text{for all } \boldsymbol{v} \in \boldsymbol{L}^2(\Omega, \mathbb{R}^2). \end{cases} \tag{2.3}$$

Here the fourth order compliance tensor $\mathbb{A}$ is bounded, symmetric, and uniformly positive definite the body force per unit volume $\boldsymbol{g}$ is in $\boldsymbol{L}^2(\Omega, \mathbb{R}^2)$. For (2.3) to be well posed, we need a compatibility condition on $\boldsymbol{g}$. Let

$$RM := span\left\{ \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \begin{pmatrix} -y \\ x \end{pmatrix} \right\}$$

be the space of infinitesimal rigid motions. By Korn's inequality, one can see that for any $\boldsymbol{g} \in \boldsymbol{L}^2(\Omega, \mathbb{R}^2)/RM$ (the orthogonal complement of RM in $\boldsymbol{L}^2(\Omega, \mathbb{R}^2)$), system (2.3) has a unique solution in $\boldsymbol{H}_0(\mathbf{div}\,, \Omega, \mathbb{S}_2) \times \boldsymbol{L}^2(\Omega, \mathbb{R}^2)/RM$ [16].

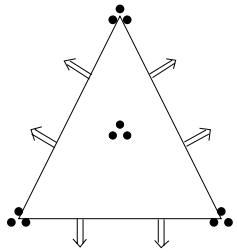

FIG. 2.1. *The Arnold–Winther finite element* $\boldsymbol{\Sigma}_T$.

2.2. Arnold–Winther elements. Let $\mathcal{T}$ be a quasi-uniform triangulation of Ω with characteristic mesh size h. On each triangle $T \in \mathcal{T}$ define

$$\begin{aligned}\boldsymbol{\Sigma}_T &= \{\text{symmetric matrices } \boldsymbol{\tau} \in (P_3(T))^3 \text{ such that } \mathbf{div}\,\boldsymbol{\tau} \in (P_1(T))^2\},\\ \boldsymbol{V}_T &= (P_1(T))^2,\end{aligned}$$

where $P_i(T)$ denotes the space consisting of polynomials of degree i or less. The degrees of freedom (dofs) for $\boldsymbol{\Sigma}_T$ are

- the nodal values of the three components of $\boldsymbol{\tau}(x)$ at each vertex of T (9 dofs);
- the moments of degree 0 and 1 of the two normal components of $\boldsymbol{\tau}$ on each edge of T (12 dofs);
- the moments of degree 0 of the three components of $\boldsymbol{\tau}$ on T (3 dofs).

The dofs of $\boldsymbol{V}_T$ are given as the zeroth and first order moments on T. Figure 2.1 illustrates the dofs for $\boldsymbol{\Sigma}_T$. The finite element spaces on the mesh $\mathcal{T}$ and domain Ω are defined as follows:

$$\begin{aligned}\boldsymbol{\Sigma}(\mathcal{T},\Omega) =&\{\boldsymbol{\tau} :\ \boldsymbol{\tau}|_T \in \boldsymbol{\Sigma}_T \text{ for each } T \in \mathcal{T},\ \boldsymbol{\tau} \text{ is continuous on the dofs}\\ &\qquad \text{on each vertex and each edge of } \mathcal{T} \text{ and } \boldsymbol{\tau}\boldsymbol{n}|_{\partial\Omega} = \mathbf{0}\},\\ \boldsymbol{V}(\mathcal{T},\Omega) =&\{\boldsymbol{v} \in \boldsymbol{L}_2(\Omega,\mathbb{R}^2) :\ \boldsymbol{v}|_T \in \boldsymbol{V}_T \text{ for each } T \in \mathcal{T}\}.\end{aligned}$$

The definition of $\boldsymbol{\Sigma}(\mathcal{T},\Omega)$ implies that $\boldsymbol{\Sigma}(\mathcal{T},\Omega) \subset \boldsymbol{H}_0(\mathbf{div},\Omega,\mathbb{S}_2)$ (see [6, 16]). Note that the boundary condition $\boldsymbol{\tau}\boldsymbol{n}|_{\partial\Omega} = \mathbf{0}$ implies two linear relations among the three components of $\boldsymbol{\tau}$ on boundary nodes. Hence on the corner vertices where two boundary edges meet, we will have $\boldsymbol{\tau} = \mathbf{0}$. This fact was noticed by Arnold and Winther in [6]. Another immediate observation is that by Green's formula,

$$\mathbf{div}\,\boldsymbol{\tau} \in RM^{\perp_{\boldsymbol{V}(\mathcal{T},\Omega)}} \qquad \text{for all } \boldsymbol{\tau} \in \boldsymbol{\Sigma}(\mathcal{T},\Omega).$$

The discrete elasticity problem can be written as follows: find $\boldsymbol{\sigma}_h \in \boldsymbol{\Sigma}(\mathcal{T},\Omega)$ and $\boldsymbol{u}_h \in \boldsymbol{V}(\mathcal{T},\Omega)$ such that

$$\begin{cases}(\mathbb{A}\boldsymbol{\sigma}_h,\boldsymbol{\tau}) + (\mathbf{div}\,\boldsymbol{\tau},\boldsymbol{u}_h) = 0 & \text{for all } \boldsymbol{\tau} \in \boldsymbol{\Sigma}(\mathcal{T},\Omega),\\ (\mathbf{div}\,\boldsymbol{\sigma}_h,\boldsymbol{v}) = (\boldsymbol{g},\boldsymbol{v}) & \text{for all } \boldsymbol{v} \in \boldsymbol{V}(\mathcal{T},\Omega).\end{cases} \tag{2.4}$$

Arnold and Winther have proved that the Arnold–Winther finite element spaces (without the essential boundary condition $\boldsymbol{\tau}\boldsymbol{n}|_{\partial\Omega} = \mathbf{0}$) satisfy the LBB condition [6]. In [28], it was proved that the Arnold–Winther finite element spaces $(\boldsymbol{\Sigma}(\mathcal{T},\Omega), \boldsymbol{V}(\mathcal{T},\Omega))$ (with the essential boundary condition $\boldsymbol{\tau}\boldsymbol{n}|_{\partial\Omega} = \mathbf{0}$) also satisfy the LBB condition.

Furthermore, the assumption on $\mathbb{A}$ implies that there exists a positive constant c such that

$$(\mathbb{A}\boldsymbol{\tau},\boldsymbol{\tau}) \geq c\|\boldsymbol{\tau}\|^2_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)} \quad \text{for all } \boldsymbol{\tau}\in \boldsymbol{H}_0(\mathbf{div},\Omega,\mathbb{S}_2) \text{ with } \mathbf{div}\,\boldsymbol{\tau}=\mathbf{0}. \tag{2.5}$$

Combining these results shows that problem (2.4) has a unique solution (for compatible $\boldsymbol{g}$) in $(\boldsymbol{\Sigma}(\mathcal{T},\Omega),\boldsymbol{V}(\mathcal{T},\Omega)/RM)$. Furthermore, if $(\boldsymbol{\sigma},\boldsymbol{u})$ is the solution of the weak problem (2.3) and $(\boldsymbol{\sigma}_h,\boldsymbol{u}_h)$ is the solution of the discrete problem (2.4), we have the following error estimates [6, 28]:

$$\begin{aligned} \|\boldsymbol{\sigma}-\boldsymbol{\sigma}_h\|_{0,\Omega} m &\leq ch^m\|\boldsymbol{\sigma}\|_{m,\Omega}, && 1\leq m\leq 3,\\ \|\mathbf{div}\,\boldsymbol{\sigma}-\mathbf{div}\,\boldsymbol{\sigma}_h\|_{0,\Omega}, &\leq ch^m\|\mathbf{div}\,\boldsymbol{\sigma}\|_{m,\Omega}, && 0\leq m\leq 2,\\ \|\boldsymbol{u}-\boldsymbol{u}_h\|_{\boldsymbol{L}^2(\Omega,\mathbb{R}^2)/RM}, &\leq ch^m\|\boldsymbol{u}\|_{m+1,\Omega}, && 1\leq m\leq 2, \end{aligned} \tag{2.6}$$

where c is a positive constant independent of h.

Next, we introduce the Argyris element, which plays an important role in later analysis. Let Q_T denote the Argyris element [19] defined on T. It is a quintic element and the dofs are

- the function value on each vertex (three dofs), the first derivatives at each vertex (six dofs), and the second derivatives at each vertex (nine dofs);
- the moments of degree 0 of the normal derivative on each edges of T (three dofs).

Define the space

$$\begin{aligned} \mathrm{Q}(\mathcal{T},\Omega) = \{q:\ & q|_T\in \mathrm{Q}_T \text{ for each } T\in\mathcal{T},\ q \text{ is continuous on the degrees of}\\ & \text{freedom on each vertex and each edge of } \mathcal{T} \text{ and } q|_{\partial\Omega}=0,\ \nabla q|_{\partial\Omega}=\mathbf{0}\}. \end{aligned}$$

Clearly $\mathrm{Q}(\mathcal{T},\Omega)\subset H^2_0(\Omega)$.

Similar to the De Rham sequence, it is elementary to see that the following exact sequence holds [6, 28]:

$$0 \xrightarrow{\subset} H^2_0(\Omega) \xrightarrow{\mathbf{airy}} \boldsymbol{H}_0(\mathbf{div},\Omega,\mathbb{S}_2) \xrightarrow{\mathbf{div}} \boldsymbol{L}^2(\Omega,\mathbb{R}^2)/RM \to 0.$$

Recall that operators in an exact sequence have the property that the range of the operator on the left equals the kernel of the operator on the right.

We can define an operator $\mathbf{div}^{-1}:\boldsymbol{L}^2(\Omega,\mathbb{R}^2)/RM\to \boldsymbol{H}_0(\mathbf{div},\Omega,\mathbb{S}_2)/Ker(\mathbf{div})$ as follows. For $\boldsymbol{v}\in\boldsymbol{L}^2(\Omega,\mathbb{R}^2)/RM$, let $\boldsymbol{\sigma}\in\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)$ and $\boldsymbol{u}\in\boldsymbol{L}^2(\Omega,\mathbb{R}^2)$ satisfy

$$\begin{cases} (\boldsymbol{\sigma},\boldsymbol{\tau})+(\mathbf{div}\,\boldsymbol{\tau},\boldsymbol{u})=0 & \text{for all } \boldsymbol{\tau}\in\boldsymbol{H}_0(\mathbf{div},\Omega,\mathbb{S}_2),\\ (\mathbf{div}\,\boldsymbol{\sigma},\boldsymbol{w})=(\boldsymbol{v},\boldsymbol{w}) & \text{for all } \boldsymbol{w}\in\boldsymbol{L}^2(\Omega,\mathbb{R}^2). \end{cases} \tag{2.7}$$

Since $\mathbf{div}$ maps $\boldsymbol{H}_0(\mathbf{div},\Omega,\mathbb{S}_2)$ onto $\boldsymbol{L}^2(\Omega,\mathbb{R}^2)/RM$, system (2.7) admits a unique solution in $(\boldsymbol{H}_0(\mathbf{div},\Omega,\mathbb{S}_2),\boldsymbol{L}^2(\Omega,\mathbb{R}^2)/RM)$ (see [16]). Then, set $\mathbf{div}^{-1}\boldsymbol{v}=\boldsymbol{\sigma}$. By definition, $\mathbf{div}^{-1}\boldsymbol{v}$ is orthogonal to any divergence free function in $\boldsymbol{H}_0(\mathbf{div},\Omega,\mathbb{S}_2)$ under both the $\boldsymbol{L}^2$ inner product and the $\boldsymbol{H}_0(\mathbf{div},\Omega,\mathbb{S}_2)$ inner product. Therefore, for all $\boldsymbol{\tau}\in\boldsymbol{H}_0(\mathbf{div},\Omega,\mathbb{S}_2)$, we have a unique orthogonal decomposition

$$\boldsymbol{\tau}=\mathbf{airy}\,q+\mathbf{div}^{-1}\boldsymbol{v},$$

where $q\in H^2_0(\Omega)$ and $\boldsymbol{v}=\mathbf{div}\,\boldsymbol{\tau}$. Furthermore, we have the regularity result (see [23]),

$$\mathbf{div}^{-1}\boldsymbol{v}\in\boldsymbol{H}^1(\Omega,\mathbb{S}_2) \quad\text{and}\quad \|\mathbf{div}^{-1}\boldsymbol{v}\|_{1,\Omega}\leq c\|\boldsymbol{v}\|_{0,\Omega}, \tag{2.8}$$

where c is a positive constant independent of $\boldsymbol{v}$.

Analogously, on the discrete level we have the following exact sequence:

$$0 \xrightarrow{\subset} \mathrm{Q}(\mathcal{T},\Omega) \xrightarrow{\mathbf{airy}} \boldsymbol{\Sigma}(\mathcal{T},\Omega) \xrightarrow{\mathbf{div}} \boldsymbol{V}(\mathcal{T},\Omega)/RM \to 0. \tag{2.9}$$

The exactness of this sequence for the Arnold–Winther finite element spaces follows from [6]. We define an operator $\mathbf{div}_{\mathcal{T}}^{-1} : \boldsymbol{L}^2(\Omega,\mathbb{R}^2)/RM \to \boldsymbol{\Sigma}(\mathcal{T},\Omega)/Ker(\mathbf{div})$ as follows. For $\boldsymbol{v} \in \boldsymbol{L}^2(\Omega,\mathbb{R}^2)/RM$, let $\boldsymbol{\sigma}_h \in \boldsymbol{\Sigma}(\mathcal{T},\Omega)$ and $\boldsymbol{u}_h \in \boldsymbol{V}(\mathcal{T},\Omega)$ satisfy

$$\begin{cases} (\boldsymbol{\sigma}_h,\boldsymbol{\tau}) + (\mathbf{div}\,\boldsymbol{\tau},\boldsymbol{u}_h) = 0 & \text{for all } \boldsymbol{\tau} \in \boldsymbol{\Sigma}(\mathcal{T},\Omega), \\ (\mathbf{div}\,\boldsymbol{\sigma}_h,\boldsymbol{w}) = (\boldsymbol{v},\boldsymbol{w}) & \text{for all } \boldsymbol{w} \in \boldsymbol{V}(\mathcal{T},\Omega). \end{cases} \tag{2.10}$$

Since the Arnold–Winther finite element spaces satisfy the LBB condition, the solution to (2.10) exists and is unique in $(\boldsymbol{\Sigma}(\mathcal{T},\Omega), \boldsymbol{V}(\mathcal{T},\Omega)/RM)$. Define $\mathbf{div}_{\mathcal{T}}^{-1}\boldsymbol{v} = \boldsymbol{\sigma}_h$. Then, for all $\boldsymbol{\tau} \in \boldsymbol{\Sigma}(\mathcal{T},\Omega)$, there exists a unique discrete orthogonal decomposition

$$\boldsymbol{\tau} = \mathbf{airy}\, q + \mathbf{div}_{\mathcal{T}}^{-1}\boldsymbol{v},$$

where $q \in \mathrm{Q}(\mathcal{T},\Omega)$ and $\boldsymbol{v} = \mathbf{div}\,\boldsymbol{\tau}$.

By the approximation property (2.6) of the Arnold–Winther element and the regularity result (2.8), for all $\boldsymbol{v} \in \boldsymbol{L}^2(\Omega,\mathbb{R}^2)/RM$,

$$\|\mathbf{div}^{-1}\boldsymbol{v} - \mathbf{div}_{\mathcal{T}}^{-1}\boldsymbol{v}\|_{0,\Omega} \le ch\|\mathbf{div}^{-1}\boldsymbol{v}\|_{1,\Omega} \le ch\|\boldsymbol{v}\|_{0,\Omega}, \tag{2.11}$$

where c is a positive constant independent of $\boldsymbol{v}$.

2.3. A block diagonal preconditioner for the mixed system. For simplicity, let $\boldsymbol{\Sigma} = \boldsymbol{\Sigma}(\mathcal{T},\Omega)$ and $\boldsymbol{V} = \boldsymbol{V}(\mathcal{T},\Omega)/RM$. Let $\|\cdot\|_{\boldsymbol{\Sigma}}$ and $\|\cdot\|_{\boldsymbol{V}}$ be the norms on $\boldsymbol{\Sigma}$ and $\boldsymbol{V}$, respectively, i.e., $\|\cdot\|_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)}$ and $\|\cdot\|_{\boldsymbol{L}^2(\Omega,\mathbb{R}^2)}$. Let $\boldsymbol{\Sigma}^*$ and $\boldsymbol{V}^*$ be the dual spaces of $\boldsymbol{\Sigma}$ and $\boldsymbol{V}$ with dual norms $\|\cdot\|_{\boldsymbol{\Sigma}^*}$ and $\|\cdot\|_{\boldsymbol{V}^*}$ and $<\cdot,\cdot>$ denote the duality pairing. Define the operators

$$\begin{cases} \mathcal{A} :\ \boldsymbol{\Sigma} \to \boldsymbol{\Sigma}^*, & <\mathcal{A}\boldsymbol{\sigma},\boldsymbol{\tau}> = (\mathbb{A}\boldsymbol{\sigma},\boldsymbol{\tau}) \quad \text{for all } \boldsymbol{\tau} \in \boldsymbol{\Sigma}, \\ \mathcal{B} :\ \boldsymbol{\Sigma} \to \boldsymbol{V}^*, & <\mathcal{B}\boldsymbol{\sigma},\boldsymbol{v}> = (\mathbf{div}\,\boldsymbol{\sigma},\boldsymbol{v}) \quad \text{for all } \boldsymbol{v} \in \boldsymbol{V}. \end{cases}$$

Let $\mathcal{B}^t :\ \boldsymbol{V} \to \boldsymbol{\Sigma}^*$ be the adjoint of $\mathcal{B}$. Equation (2.4) can be rewritten as

$$\mathcal{M}\begin{pmatrix}\boldsymbol{\sigma}\\ \boldsymbol{u}\end{pmatrix} = \begin{pmatrix}\mathcal{A} & \mathcal{B}^t\\ \mathcal{B} & 0\end{pmatrix}\begin{pmatrix}\boldsymbol{\sigma}\\ \boldsymbol{u}\end{pmatrix} = \begin{pmatrix}F\\ G\end{pmatrix}, \tag{2.12}$$

where $F \in \boldsymbol{\Sigma}^*$, $G \in \boldsymbol{V}^*$. The following lemma results from the LBB condition and (2.5). (See [16] for the proof.)

LEMMA 2.1. *The map $(F,G) \to (\boldsymbol{\sigma},\boldsymbol{u})$ defined by solving (2.12) with $F \in \boldsymbol{\Sigma}^*$ and $G \in \boldsymbol{V}^*$ is an isomorphism of $\boldsymbol{\Sigma}^* \times \boldsymbol{V}^*$ onto $\boldsymbol{\Sigma} \times \boldsymbol{V}$ and so*

$$c_0(\|F\|_{\boldsymbol{\Sigma}^*} + \|G\|_{\boldsymbol{V}^*}) \le \|\boldsymbol{\sigma}\|_{\boldsymbol{\Sigma}} + \|\boldsymbol{u}\|_{\boldsymbol{V}} \le c_1(\|F\|_{\boldsymbol{\Sigma}^*} + \|G\|_{\boldsymbol{V}^*}),$$

where c_0 and c_1 are positive and independent of h.

Our purpose is to find a preconditioner for the operator $\mathcal{M}$. By Lemma 2.1, we only need to find an operator $\mathcal{S} :\ \boldsymbol{\Sigma}^* \times \boldsymbol{V}^* \to \boldsymbol{\Sigma} \times \boldsymbol{V}$ such that $\|\mathcal{S}\|_{\mathcal{L}(\boldsymbol{\Sigma}^*\times\boldsymbol{V}^*,\boldsymbol{\Sigma}\times\boldsymbol{V})}$ and $\|\mathcal{S}^{-1}\|_{\mathcal{L}(\boldsymbol{\Sigma}\times\boldsymbol{V},\boldsymbol{\Sigma}^*\times\boldsymbol{V}^*)}$ are bounded uniformly in h (see [2] for details). Indeed, we can consider an operator in the form $\mathcal{S} = \begin{pmatrix}\mathcal{S}_1 & 0\\ 0 & \mathcal{S}_2\end{pmatrix}$, where $\mathcal{S}_1 :\ \boldsymbol{\Sigma}^* \to \boldsymbol{\Sigma}$ and $\mathcal{S}_2 :\ \boldsymbol{V}^* \to \boldsymbol{V}$

and their inverses are bounded uniformly in h. Consider the following problem: find $\boldsymbol{\sigma} \in \boldsymbol{\Sigma}$ such that

$$\boldsymbol{\Lambda}(\boldsymbol{\sigma}, \boldsymbol{\tau}) = F(\boldsymbol{\tau}) \qquad \text{for all } \ \boldsymbol{\tau} \in \boldsymbol{\Sigma}. \tag{2.13}$$

Clearly a good preconditioner for this problem will yield an ideal $\mathcal{S}_1$. Similarly, an ideal $\mathcal{S}_2$ will come from a good preconditioner for the following problem: find $\boldsymbol{u} \in \boldsymbol{V}$ such that

$$(\boldsymbol{u}, \boldsymbol{v}) = G(\boldsymbol{v}) \qquad \text{for all } \ \boldsymbol{v} \in \boldsymbol{V}. \tag{2.14}$$

The problem (2.14) is easy to solve efficiently. Indeed, we use the basis for $\boldsymbol{V}(\mathcal{T}, \Omega)$ in the implementation. (This, of course, provides a spanning set for $\boldsymbol{V}$.) First, we note that the functional G in original problem (2.12) is usually available as a functional $\widetilde{G}$ defined on $(\boldsymbol{V}(\mathcal{T}, \Omega))^*$ which vanishes on RM. This functional is naturally represented by its action on the basis functions for $\boldsymbol{V}(\mathcal{T}, \Omega)$ and provides the data for the first solve of (2.14). Subsequent solves of (2.14) involve this data plus the result of $\mathcal{B}$ applied to something in $\boldsymbol{\Sigma}$. Thus, at any step of the iteration, (2.14) will have to be solved with a known functional $\widetilde{G}$ on $(\boldsymbol{V}(\mathcal{T}, \Omega))^*$ which vanishes on RM. In this case, the solution of (2.14) coincides with the solution $\boldsymbol{u} \in \boldsymbol{V}(\mathcal{T}, \Omega)$ satisfying

$$(\boldsymbol{u}, \boldsymbol{v}) = \widetilde{G}(\boldsymbol{v}) \qquad \text{for all } \ \boldsymbol{v} \in \boldsymbol{V}(\mathcal{T}, \Omega). \tag{2.15}$$

The space $\boldsymbol{V}(\mathcal{T}, \Omega)$ consists of discontinuous linears on the triangles so the exact solution of (2.15) reduces to the inversion of a block diagonal matrix, with 3×3 diagonal blocks. Hence the problem of defining $\mathcal{S}$ reduces to the problem of constructing $\mathcal{S}_1$. In the remainder of this paper we will focus on constructing a multigrid preconditioner for problem (2.13).

3. The multigrid preconditioner. In this section, we construct and analyze a multigrid preconditioner for problem (2.13). To this end, let $\mathcal{T}_1$ be a unit-sized coarse triangulation of Ω. Subsequently finer triangulations are defined recursively. Given the kth level triangulation $\mathcal{T}_k$, define the $(k+1)$st level mesh $\mathcal{T}_{k+1}$ by breaking each triangle in $\mathcal{T}_k$ into four triangles by connecting the midpoints of the edges. Repeating this process gives a series of nested meshes $\mathcal{T}_1, \mathcal{T}_1, \ldots, \mathcal{T}_K$. Denote the characteristic mesh size of $\mathcal{T}_k$ as h_k. We clearly have $h_k = \frac{1}{2} h_{k-1} = O(2^{-k})$. For simplicity of notation, in the rest of this paper, we use $\lesssim$ to denote "less then or equal to" with a factor c independent of k or h_k.

Denote the finite element spaces on the kth level by

$$\mathrm{Q}_k = \mathrm{Q}(\mathcal{T}_k, \Omega), \qquad \boldsymbol{\Sigma}_k = \boldsymbol{\Sigma}(\mathcal{T}_k, \Omega), \qquad \boldsymbol{V}_k = \boldsymbol{V}(\mathcal{T}_k, \Omega)/RM.$$

Notice that we have $\mathrm{Q}_k \subset H_0^2(\Omega)$, $\boldsymbol{\Sigma}_k \subset \boldsymbol{H}_0(\mathbf{div}\,, \Omega, \mathbb{S}_2)$, and $\boldsymbol{V}_k \subset \boldsymbol{L}^2(\Omega, \mathbb{R}^2)$ for each k.

The bilinear form for the biharmonic problem will play an important role in the following analysis. It is defined on $H_0^2(\Omega)$ by

$$\begin{aligned} \mathrm{A}(q, p) &= \int_\Omega \left(\frac{\partial^2 q}{\partial x^2} \frac{\partial^2 p}{\partial x^2} + 2 \frac{\partial^2 q}{\partial x \partial y} \frac{\partial^2 p}{\partial x \partial y} + \frac{\partial^2 q}{\partial y^2} \frac{\partial^2 p}{\partial y^2} \right) d\boldsymbol{x} \\ &= (\mathbf{airy}\, q, \mathbf{airy}\, p). \end{aligned} \tag{3.1}$$

Define operators $\mathrm{A}_k : \mathrm{Q}_k \to \mathrm{Q}_k$ and $\boldsymbol{\Lambda}_k : \boldsymbol{\Sigma}_k \to \boldsymbol{\Sigma}_k$ by

$$\begin{aligned}(\mathrm{A}_k q, p) &= \mathrm{A}(q,p) \qquad \text{for all } q, p \in \mathrm{Q}_k,\\ (\boldsymbol{\Lambda}_k \boldsymbol{\sigma}, \boldsymbol{\tau}) &= \boldsymbol{\Lambda}(\boldsymbol{\sigma}, \boldsymbol{\tau}) \qquad \text{for all } \boldsymbol{\sigma}, \boldsymbol{\tau} \in \boldsymbol{\Sigma}_k,\end{aligned}$$

where the bilinear forms $\mathrm{A}(\cdot,\cdot)$ and $\boldsymbol{\Lambda}(\cdot,\cdot)$ were defined in (3.1) and (2.2), respectively.

The spaces $\{\mathrm{Q}_k\}$ and $\{\boldsymbol{\Sigma}_k\}$ are nonnested since, for example, a function $\boldsymbol{\sigma} \in \boldsymbol{\Sigma}_k$ is not necessarily continuous at the midpoints of the edges in the mesh $\mathcal{T}_k$ and a function $q \in \mathrm{Q}_k$ does not necessarily have continuous second order derivatives at the midpoints of the edges in the mesh $\mathcal{T}_k$. Hence we need to define interpolation operators $\mathcal{I}_k : \mathrm{Q}_{k-1} \to \mathrm{Q}_k$ and $\mathbf{I}_k : \boldsymbol{\Sigma}_{k-1} \to \boldsymbol{\Sigma}_k$. The easiest way to do this is by using the "local" nodal value interpolation on each triangle and then taking average on the discontinuous degrees of freedom at vertices.

Denote $\mathcal{N}_k$ to be the set of all nodes in the mesh $\mathcal{T}_k$. For any vertex $v \in \mathcal{N}_k$, let $S_{k-1}(v)$ be the set of all triangles in $\mathcal{T}_{k-1}$ which contain the vertex v and let $|S_{k-1}(v)|$ denote the number of triangles in $S_{k-1}(v)$. For $q \in \mathrm{Q}_{k-1}$ and $\boldsymbol{\tau} \in \boldsymbol{\Sigma}_{k-1}$, define the dofs for $\mathcal{I}_k q$ and $\mathbf{I}_k \boldsymbol{\tau}$ to be identical to those for q and $\boldsymbol{\tau}$ for all dofs excluding the second order derivatives at the vertices for $\mathcal{I}_k q$ and the nodal values at the vertices for $\mathbf{I}_k \boldsymbol{\tau}$. On the excluded dofs we use

$$\begin{aligned}\mathbf{airy}\,(\mathcal{I}_k q)(v) &= \frac{1}{|S_{k-1}(v)|} \sum_{T_v \in S_{k-1}(v)} \mathbf{airy}\, q(v)|_{T_v} \quad \text{for } v \in \mathcal{N}_k,\\ \mathbf{I}_k \boldsymbol{\tau}(v) &= \frac{1}{|S_{k-1}(v)|} \sum_{T_v \in S_{k-1}(v)} \boldsymbol{\tau}(v)|_{T_v} \qquad \text{for } v \in \mathcal{N}_k.\end{aligned}$$

Combining the above gives the definition of $\mathcal{I}_k q$ and $\mathbf{I}_k \boldsymbol{\tau}$ on all dofs. We then have

$$\begin{aligned}\mathcal{I}_k q &= q + \tilde{q} \qquad \text{for all } q \in \mathrm{Q}_{k-1},\\ \mathbf{I}_k \boldsymbol{\tau} &= \boldsymbol{\tau} + \tilde{\boldsymbol{\tau}} \qquad \text{for all } \boldsymbol{\tau} \in \boldsymbol{\Sigma}_{k-1},\end{aligned}$$

where $\tilde{q} \in H_0^2(\Omega)$ and $\tilde{\boldsymbol{\tau}} \in \boldsymbol{H}_0(\mathbf{div}, \Omega, \mathbb{S}_2)$ satisfy

$$\begin{aligned}\mathbf{airy}\,\tilde{q}(v)|_T &= \left(\frac{1}{|S_{k-1}(v)|} \sum_{T_v \in S_{k-1}(v)} \mathbf{airy}\, q(v)|_{T_v}\right) - \mathbf{airy}\, q(v)|_T,\\ \tilde{\boldsymbol{\tau}}(v)|_T &= \left(\frac{1}{|S_{k-1}(v)|} \sum_{T_v \in S_{k-1}(v)} \boldsymbol{\tau}(v)|_{T_v}\right) - \boldsymbol{\tau}(v)|_T\end{aligned} \tag{3.2}$$

at each vertex v of any triangle $T \in \mathcal{T}_k$ and vanish at all the other dofs. Define $\mathcal{P}_{k-1} : \mathrm{Q}_k \to \mathrm{Q}_{k-1}$ to be the A-adjoint of $\mathcal{I}_k$ and $\mathbf{P}_{k-1} : \boldsymbol{\Sigma}_k \to \boldsymbol{\Sigma}_{k-1}$ to be the $\boldsymbol{\Lambda}$-adjoint of $\mathbf{I}_k$.

LEMMA 3.1. *We have*

$$\boldsymbol{\Lambda}(\mathbf{I}_k \boldsymbol{\sigma}_{k-1}, \mathbf{I}_k \boldsymbol{\sigma}_{k-1}) \le \omega \boldsymbol{\Lambda}(\boldsymbol{\sigma}_{k-1}, \boldsymbol{\sigma}_{k-1}) \quad \textit{for all } \boldsymbol{\sigma}_{k-1} \in \boldsymbol{\Sigma}_{k-1},$$

where ω is independent of k. Consequently,

$$\boldsymbol{\Lambda}(\mathbf{P}_{k-1} \boldsymbol{\sigma}_k, \mathbf{P}_{k-1} \boldsymbol{\sigma}_k) \le \omega \boldsymbol{\Lambda}(\boldsymbol{\sigma}_k, \boldsymbol{\sigma}_k) \quad \textit{for all } \boldsymbol{\sigma}_k \in \boldsymbol{\Sigma}_k.$$

Proof. The proof follows from a standard scaling argument, the definition of $\mathbf{I}_k$, and the quasi-uniformity of the mesh. ∎

We have the following two lemmas concerning the interpolation operators $\mathcal{I}_k$ and $\mathbf{I}_k$ from [28].

LEMMA 3.2. *Let T be a triangle and v_i, $i = 1, 2, 3$, be its vertices. Let $\boldsymbol{\tau}_i$, $i = 1, 2, 3$, be given constant symmetric matrices. Define $q \in \mathrm{Q}_T$ and $\boldsymbol{\tau} \in \boldsymbol{\Sigma}_T$ such that*

$$\begin{aligned} \mathbf{airy}\, q(v_i) &= \boldsymbol{\tau}_i \qquad \text{for } i = 1, 2, 3, \\ \boldsymbol{\tau}(v_i) &= \boldsymbol{\tau}_i \qquad \text{for } i = 1, 2, 3, \end{aligned}$$

while vanishing on all the other dofs. Then $\mathbf{airy}\, q = \boldsymbol{\tau}$.

LEMMA 3.3. *The following commutative diagram of exact sequences holds:*

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{Q}_{k-1} & \xrightarrow{\mathbf{airy}} & \boldsymbol{\Sigma}_{k-1} & \xrightarrow{\mathbf{div}} & \boldsymbol{V}_{k-1}/RM & \to & 0 \\ & & \downarrow \mathcal{I}_k & & \downarrow \mathbf{I}_k & & \downarrow id & & \\ 0 & \longrightarrow & \mathrm{Q}_k & \xrightarrow{\mathbf{airy}} & \boldsymbol{\Sigma}_k & \xrightarrow{\mathbf{div}} & \boldsymbol{V}_k/RM & \to & 0. \end{array} \tag{3.3}$$

It is not our goal to study the general approximation properties of the interpolation operator $\mathbf{I}_k$. Instead, for the multigrid analysis, we require the specific results obtained in the following two lemmas.

LEMMA 3.4. *Let $\boldsymbol{\tau}_{k-1}$ be piecewise linear with respect to $\mathcal{T}_{k-1}$ on all components. Then,*

$$((\mathbf{I} - \mathbf{I}_k)\boldsymbol{\sigma}_{k-1}, \boldsymbol{\tau}_{k-1}) = 0 \quad \text{for all } \boldsymbol{\sigma}_{k-1} \in \boldsymbol{\Sigma}_{k-1}.$$

Proof. Let $T \in \mathcal{T}_{k-1}$ and v_i, $i = 1, 2, 3$, be the three midpoints of each edge of T. We note that $(\mathbf{I} - \mathbf{I}_k)\boldsymbol{\sigma}_{k-1}$ restricted to T is in $\boldsymbol{\Sigma}(\mathcal{T}_k, T)$ and has nonzero dofs only on the nodal values at v_i, $i = 1, 2, 3$. On each of the four finer triangles T_i, $i = 1, \ldots, 4$, making up T, we have

$$(\mathbf{I} - \mathbf{I}_k)\boldsymbol{\sigma}_{k-1} = \mathbf{airy}\, q_i$$

for q_i as defined in Lemma 3.2. By construction, these q_i share the same nodal values at v_j, $j = 1, 2, 3$, and thus the function q whose restriction is q_i on T_i is in $Q(\mathcal{T}_k, T) \subset C^1(T)$. Now, since $\boldsymbol{\sigma}_{k-1}$ has continuous normal components, we have

$$(\mathbf{I} - \mathbf{I}_k)\boldsymbol{\sigma}_{k-1}\, \boldsymbol{n}|_{\partial T} = \mathbf{airy}\, q\, \boldsymbol{n}|_{\partial T} = \mathbf{0},$$

i.e., $\frac{\partial^2 q}{\partial \boldsymbol{n} \partial \boldsymbol{s}} = \frac{\partial^2 q}{\partial \boldsymbol{s}^2} = 0$, where $\boldsymbol{n}$ is the outward normal vector and $\boldsymbol{s}$ is the normal tangential vector of ∂T. It follows that both q and ∇q vanish on ∂T and are continuous across ∂T_i. Thus, integration by parts gives that for any linear function f on T,

$$((\mathbf{I} - \mathbf{I}_k)\boldsymbol{\sigma}_{k-1}, f)_{L^2(T)} = (\mathbf{airy}\, q, f)_{L^2(T)} = 0.$$

This completes the proof of the lemma. ∎

LEMMA 3.5. *There exists a positive constant c such that for all $\boldsymbol{v}_{k-1} \in \boldsymbol{V}_{k-1}$,*

$$\|(\mathbf{I} - \mathbf{I}_k)\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_{k-1}\|_{0,\Omega} \le c h_k \|\boldsymbol{v}_{k-1}\|_{0,\Omega}.$$

Here $\mathbf{div}_k^{-1} = \mathbf{div}_{\mathcal{T}_k}^{-1}$ as defined by (2.10).

Proof. Notice that $(\mathbf{I} - \mathbf{I}_k)\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_{k-1}$ is divergence free by Lemma 3.2. Therefore

$$((\mathbf{I} - \mathbf{I}_k)\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_{k-1}, \mathbf{div}^{-1}\boldsymbol{v}_{k-1}) = 0.$$

According to Lemma 3.4, for any $\boldsymbol{\tau}_{k-1} \in \boldsymbol{\Sigma}_{k-1}$ which is continuous and piecewise linear with respect to $\mathcal{T}_{k-1}$,

$$((\mathbf{I}-\mathbf{I}_k)\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_{k-1}, \boldsymbol{\tau}_{k-1}) = 0.$$

Let $\boldsymbol{\tau}_{k-1}$ be the L^2 projection of $\mathbf{div}^{-1}\boldsymbol{v}_{k-1}$ into the space of continuous piecewise linear functions based on $\mathcal{T}_{k-1}$. Notice that $\mathbf{I}_k\boldsymbol{\tau}_{k-1} = \boldsymbol{\tau}_{k-1}$. By the regularity result (2.8) and the approximation result (2.11),

$$\begin{aligned}\|(\mathbf{I}-\mathbf{I}_k)\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_{k-1}\|_{0,\Omega}^2 &= ((\mathbf{I}-\mathbf{I}_k)\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_{k-1}, \mathbf{div}_{k-1}^{-1}\boldsymbol{v}_{k-1} - \mathbf{div}^{-1}\boldsymbol{v}_{k-1}) \\ &\quad - ((\mathbf{I}-\mathbf{I}_k)\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_{k-1}, \mathbf{I}_k(\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_{k-1} - \boldsymbol{\tau}_{k-1})) \\ &\lesssim \|(\mathbf{I}-\mathbf{I}_k)\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_{k-1}\|_{0,\Omega}(h_k\|\boldsymbol{v}_{k-1}\|_{0,\Omega} + \|\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_{k-1} - \boldsymbol{\tau}_{k-1}\|_{0,\Omega}).\end{aligned}$$

Thus,

$$\begin{aligned}\|(\mathbf{I}-\mathbf{I}_k)\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_{k-1}\|_{0,\Omega} &\lesssim h_k\|\boldsymbol{v}_{k-1}\|_{0,\Omega} + \|\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_{k-1} - \mathbf{div}^{-1}\boldsymbol{v}_{k-1}\|_{0,\Omega} \\ &\quad + \|\mathbf{div}^{-1}\boldsymbol{v}_{k-1} - \boldsymbol{\tau}_{k-1}\|_{0,\Omega} \\ &\lesssim h_k\|\boldsymbol{v}_{k-1}\|_{0,\Omega}.\end{aligned}$$

This completes the proof of the lemma. ∎

Now we state the variable V-cycle multigrid preconditioner. Let $\mathbf{R}_k : \boldsymbol{\Sigma}_k \to \boldsymbol{\Sigma}_k$ be a symmetric and positive definite linear operator which we call a smoother. A construction for $\mathbf{R}_k$ will be given in the next section. Let m_k, the number of smoothing steps on the kth level, satisfy

$$\beta_0 m_k \le m_{k-1} \le \beta_1 m_k, \qquad \text{where } 1 < \beta_0 \le \beta_1.$$

The choice of $\beta_0 = \beta_1 = 2$ is typical. Denote $\mathbf{I}_k^t : \boldsymbol{\Sigma}_k \to \boldsymbol{\Sigma}_{k-1}$ to be the $\boldsymbol{L}^2$-adjoint of $\mathbf{I}_k$, i.e.,

$$(\mathbf{I}_k^t\boldsymbol{\sigma}_k, \boldsymbol{\tau}_{k-1}) = (\boldsymbol{\sigma}_k, \mathbf{I}_k\boldsymbol{\tau}_{k-1}) \quad \text{for all } \boldsymbol{\tau}_{k-1} \in \boldsymbol{\Sigma}_{k-1}.$$

The variable V-cycle multigrid preconditioner $\mathbf{B}_k : \boldsymbol{\Sigma}_k \to \boldsymbol{\Sigma}_k$ is defined inductively as follows.

ALGORITHM 1. *Set* $\mathbf{B}_1 = \boldsymbol{\Lambda}_1^{-1}$. *Assuming that* $\mathbf{B}_{k-1} : \boldsymbol{\Sigma}_{k-1} \to \boldsymbol{\Sigma}_{k-1}$ *has been defined, define* $\mathbf{B}_k : \boldsymbol{\Sigma}_k \to \boldsymbol{\Sigma}_k$ *as follows. For* $\boldsymbol{g} \in \boldsymbol{\Sigma}_k$, *set* $\boldsymbol{\tau}^0 = \mathbf{0}$ *and define*

(1) $\boldsymbol{\tau}^l = \boldsymbol{\tau}^{l-1} + \mathbf{R}_k(\boldsymbol{g} - \boldsymbol{\Lambda}_k\boldsymbol{\tau}^{k-1})$ *for* $l = 1, \ldots, m_k$;
(2) $\boldsymbol{\sigma}^{m_k} = \boldsymbol{\tau}^{m_k} + \mathbf{I}_k\mathbf{B}_{k-1}\mathbf{I}_k^t(\boldsymbol{g} - \boldsymbol{\Lambda}_k\boldsymbol{\tau}^{m_k})$;
(3) $\boldsymbol{\sigma}^l = \boldsymbol{\sigma}^{l-1} + \mathbf{R}_k(\boldsymbol{g} - \boldsymbol{\Lambda}_k\boldsymbol{\sigma}^{l-1})$ *for* $l = m_k + 1, \ldots, 2m_k$;
Set $\mathbf{B}_k\boldsymbol{g} = \boldsymbol{\sigma}^{2m_k}$.

Remark 1. It appears that one needs to solve linear systems involving the mass matrix for the computation of $\mathbf{I}_k^t$ and $\boldsymbol{\Lambda}_k$ in the above algorithm. This Gram matrix inversion is avoided in the implementation because of the judicious choice of $\mathbf{R}_k$. For these and other implementation issues, see [15, 28].

The following theorem and its proof is a straightforward variation of Theorem 7.4 in [15].

THEOREM 3.6. *Assume that*

(M.1) *the spectrum of* $\mathbf{I} - \mathbf{R}_k\boldsymbol{\Lambda}_k$ *lies inside the interval* $[0, 1)$;
(M.2) *there exist a constant* $0 < \alpha \le 1$ *and a constant* C_p *independent of* k *such that for all* $\boldsymbol{\tau} \in \boldsymbol{\Sigma}_k$,

$$|\boldsymbol{\Lambda}((\mathbf{I} - \mathbf{I}_k\mathbf{P}_{k-1})\boldsymbol{\tau}, \boldsymbol{\tau})| \le C_p^{2\alpha}(\mathbf{R}_k\boldsymbol{\Lambda}_k\boldsymbol{\tau}, \boldsymbol{\Lambda}_k\boldsymbol{\tau})^{\alpha}\boldsymbol{\Lambda}(\boldsymbol{\tau}, \boldsymbol{\tau})^{1-\alpha}.$$

Then, the preconditioner $\mathbf{B}_k$ *is symmetric and positive definite. Furthermore,* $\mathbf{B}_k$ *satisfies*

$$\left(\frac{m_k^\alpha}{M+m_k^\alpha}\right)\mathbf{\Lambda}(\boldsymbol{\tau},\boldsymbol{\tau}) \le \mathbf{\Lambda}(\mathbf{B}_k\mathbf{\Lambda}_k\boldsymbol{\tau},\boldsymbol{\tau}) \le \left(\frac{M+m_k^\alpha}{m_k^\alpha}\right)\mathbf{\Lambda}(\boldsymbol{\tau},\boldsymbol{\tau}) \quad \textit{for all } \boldsymbol{\tau}\in\mathbf{\Sigma}_k,$$

where M *is a sufficiently large positive constant depending only on* C_p *and* α.

In the next section, we will construct an additive smoother and prove it satisfies assumptions (M.1) and (M.2).

4. An additive Schwarz smoother. Recall that $\mathcal{N}_k$ denotes the set of all nodes in the triangulation $\mathcal{T}_k$ (including the boundary nodes) and $S_k(v)$ denotes the set of triangles in $\mathcal{T}_k$ meeting at the vertex v for each $v\in\mathcal{N}_k$. The (interior of the) union of all triangles in $S_k(v)$ forms a subdomain which we denote $\Omega_{k,v}$. Clearly $\{\Omega_{k,v}\}_{v\in\mathcal{N}_k}$ is an overlapping decomposition of Ω such that each $x\in\Omega$ is in at most three subdomains in $\{\Omega_{k,v}\}_{v\in\mathcal{N}_k}$.

Let $\mathrm{Q}_{k,v}$ and $\mathbf{\Sigma}_{k,v}$ be the subspace of functions in Q_k and $\mathbf{\Sigma}_k$, respectively, which have support contained in $\overline{\Omega}_{k,v}$. It is easy to see that the span of $\{\mathrm{Q}_{k,v}\}$ (respectively, $\mathbf{\Sigma}_{k,v}$) is all of Q_k (respectively, $\mathbf{\Sigma}_k$). Let $\mathcal{P}_{k,v}:\mathrm{Q}_k\to\mathrm{Q}_{k,v}$ be the A-projection, $\mathbf{P}_{k,v}:\mathbf{\Sigma}_k\to\mathbf{\Sigma}_{k,v}$ be the $\mathbf{\Lambda}$-projection, and $\mathcal{I}_{k,v}^t:\mathrm{Q}_k\to\mathrm{Q}_{k,v}$, $\mathbf{I}_{k,v}^t:\mathbf{\Sigma}_k\to\mathbf{\Sigma}_{k,v}$ be the $\boldsymbol{L}^2$-projections. Define $\mathrm{A}_{k,v}:\mathrm{Q}_{k,v}\to\mathrm{Q}_{k,v}$ and $\mathbf{\Lambda}_{k,v}:\mathbf{\Sigma}_{k,v}\to\mathbf{\Sigma}_{k,v}$ by

$$\begin{aligned}(\mathrm{A}_{k,v}p,q) &= \mathrm{A}(p,q) \qquad &&\text{for all } p,q\in\mathrm{Q}_{k,v},\\ (\mathbf{\Lambda}_{k,v}\boldsymbol{\sigma},\boldsymbol{\tau}) &= \mathbf{\Lambda}(\boldsymbol{\sigma},\boldsymbol{\tau}) &&\text{for all } \boldsymbol{\sigma},\boldsymbol{\tau}\in\mathbf{\Sigma}_{k,v}.\end{aligned}$$

Clearly, we have $\mathrm{A}_{k,v}\mathcal{P}_{k,v}=\mathcal{I}_{k,v}^t\mathrm{A}_k$ and $\mathbf{\Lambda}_{k,v}\mathbf{P}_{k,v}=\mathbf{I}_{k,v}^t\mathbf{\Lambda}_k$. Define

$$\begin{aligned}\mathcal{R}_k &= \rho\sum_{v\in\mathcal{N}_k}\mathcal{P}_{k,v}\mathrm{A}_k^{-1}=\rho\sum_{v\in\mathcal{N}_k}\mathrm{A}_{k,v}^{-1}\mathcal{I}_{k,v}^t,\\ \mathbf{R}_k &= \rho\sum_{v\in\mathcal{N}_k}\mathbf{P}_{k,v}\mathbf{\Lambda}_k^{-1}=\rho\sum_{v\in\mathcal{N}_k}\mathbf{\Lambda}_{k,v}^{-1}\mathbf{I}_{k,v}^t,\end{aligned}\tag{4.1}$$

where $\rho>0$ is a scaling factor which will only depend on the finite overlapping constant, e.g., $\rho=1/3$. It is well known (see [30]) that since $\{\mathbf{\Sigma}_{k,v}\}$ spans $\mathbf{\Sigma}_k$, $\mathbf{R}_k$ is invertible and satisfies

$$(\mathbf{R}_k^{-1}\boldsymbol{\tau},\boldsymbol{\tau}) = \rho^{-1}\inf_{\substack{\boldsymbol{\tau}_v\in\mathbf{\Sigma}_{k,v}\\ \sum_v\boldsymbol{\tau}_v=\boldsymbol{\tau}}}\sum_{v\in\mathcal{N}_k}\mathbf{\Lambda}(\boldsymbol{\tau}_v,\boldsymbol{\tau}_v) \qquad \text{for all } \boldsymbol{\tau}\in\mathbf{\Sigma}_k.\tag{4.2}$$

Also, we note that $\mathcal{R}_k$ is defined purely for theoretical analysis and only $\mathbf{R}_k$ appears in the implementation. The implementation of $\mathbf{R}_k$ involves solving local problems on each $\Omega_{k,v}$.

Remark 2. The above smoother $\mathbf{R}_k$ is constructed by using an additive Schwarz scheme. A multiplicative version of the smoother can be constructed based on the same space decomposition.

In the remainder of this section, we prove that the smoother $\mathbf{R}_k$ satisfies assumptions (M.1) and (M.2). These results are gathered in the next two lemmas.

LEMMA 4.1. *For* $\rho\le 1/3$, *the smoother* $\mathbf{R}_k$ *satisfies assumption* (M.1).

Proof. The proof follows from the Cauchy–Schwarz inequality and the finite overlapping condition (see, e.g., [14]). ∎

LEMMA 4.2. *The smoother* $\mathbf{R}_k$ *satisfies assumption* (M.2).

Proof. As shown in section 2, there exists a decomposition $\boldsymbol{\sigma}_k = \mathbf{airy}\, q_k + \mathbf{div}_k^{-1}\boldsymbol{v}_k$ for $\boldsymbol{\sigma}_k \in \boldsymbol{\Sigma}_k$, where $q_k \in \mathrm{Q}_k$ and $\boldsymbol{v}_k = \mathbf{div}\,\boldsymbol{\sigma}_k \in \boldsymbol{V}_k/RM$. By Lemma 3.3,

$$(\mathbf{I} - \mathbf{I}_k\mathbf{P}_{k-1})\boldsymbol{\sigma}_k = \sum_{i=1}^{4} \boldsymbol{\sigma}_k^i,$$

where

$$\begin{aligned}
\boldsymbol{\sigma}_k^1 &= \mathbf{airy}\,(q_k - \mathcal{I}_k\mathcal{P}_{k-1}q_k),\\
\boldsymbol{\sigma}_k^2 &= \mathbf{I}_k(\mathbf{airy}\,\mathcal{P}_{k-1}q_k - \mathbf{P}_{k-1}\mathbf{airy}\,q_k),\\
\boldsymbol{\sigma}_k^3 &= \mathbf{div}_k^{-1}\boldsymbol{v}_k - \mathbf{I}_k\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_k,\\
\boldsymbol{\sigma}_k^4 &= \mathbf{I}_k(\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_k - \mathbf{P}_{k-1}\mathbf{div}_k^{-1}\boldsymbol{v}_k).
\end{aligned}$$

Notice that all $\boldsymbol{\sigma}_k^i$, $i = 1, 2, 3, 4$, are in $\boldsymbol{\Sigma}_k$ and $\boldsymbol{\sigma}_k^1$ is divergence free. Thus

$$\begin{aligned}
|\boldsymbol{\Lambda}((\mathbf{I} - \mathbf{I}_k\mathbf{P}_{k-1})\boldsymbol{\sigma}_k, \boldsymbol{\sigma}_k)| &= |\boldsymbol{\Lambda}(\boldsymbol{\sigma}_k^1 + \boldsymbol{\sigma}_k^2 + \boldsymbol{\sigma}_k^3 + \boldsymbol{\sigma}_k^4, \boldsymbol{\sigma}_k)|\\
&\lesssim |\boldsymbol{\Lambda}(\boldsymbol{\sigma}_k^1, \mathbf{airy}\, q_k)| + \sum_{i=2}^{4} (\mathbf{R}_k^{-1}\boldsymbol{\sigma}_k^i, \boldsymbol{\sigma}_k^i)^{1/2} (\mathbf{R}_k\boldsymbol{\Lambda}_k\boldsymbol{\sigma}_k, \boldsymbol{\Lambda}_k\boldsymbol{\sigma}_k)^{1/2}.
\end{aligned} \tag{4.3}$$

We will show that
(I) $|\boldsymbol{\Lambda}(\boldsymbol{\sigma}_k^1, \mathbf{airy}\, q_k)| \lesssim (\mathbf{R}_k\boldsymbol{\Lambda}_k\boldsymbol{\sigma}_k, \boldsymbol{\Lambda}_k\boldsymbol{\sigma}_k)^{1/4}\boldsymbol{\Lambda}(\boldsymbol{\sigma}_k, \boldsymbol{\sigma}_k)^{3/4}$;
(II) $(\mathbf{R}_k^{-1}\boldsymbol{\sigma}_k^i, \boldsymbol{\sigma}_k^i) \lesssim \boldsymbol{\Lambda}(\boldsymbol{\sigma}_k, \boldsymbol{\sigma}_k)$ for $i = 2, 3, 4$.
Then, since assumption (M.1) implies $(\mathbf{R}_k\boldsymbol{\Lambda}_k\boldsymbol{\sigma}_k, \boldsymbol{\Lambda}_k\boldsymbol{\sigma}_k) \le \boldsymbol{\Lambda}(\boldsymbol{\sigma}_k, \boldsymbol{\sigma}_k)$, assumption (M.2) with $\alpha = 1/4$ will follow from (4.3), (I), and (II).

To prove (I), first notice that for the biharmonic problem, we have (see [15])

$$\frac{1}{\tilde{\lambda}_k}\|\mathrm{A}_k q_k\|_{0,\Omega}^2 \lesssim (\mathcal{R}_k\mathrm{A}_k q_k, \mathrm{A}_k q_k) \quad \text{for all } q_k \in \mathrm{Q}_k,$$

where $\tilde{\lambda}_k = O(h_k^{-4})$ is the largest eigenvalue of the operator A_k.

Theorem 14.1 in [15] states that if Ω is a convex polygon, then

$$\mathrm{A}((\mathrm{I} - \mathcal{I}_k\mathcal{P}_{k-1})q_k, q_k) \lesssim (\mathrm{A}_k q_k, q_k)^{3/4} \left(\frac{\|\mathrm{A}_k q_k\|_{0,\Omega}^2}{\tilde{\lambda}_k}\right)^{1/4}.$$

Therefore,

$$\begin{aligned}
|\boldsymbol{\Lambda}(\boldsymbol{\sigma}_k^1, \mathbf{airy}\, q_k)| &= |\boldsymbol{\Lambda}(\mathbf{airy}\,(q_k - \mathcal{I}_k\mathcal{P}_{k-1}q_k), \mathbf{airy}\, q_k)|\\
&= |\mathrm{A}((\mathrm{I} - \mathcal{I}_k\mathcal{P}_{k-1})q_k, q_k)| \lesssim (\mathrm{A}_k q_k, q_k)^{3/4} \left(\frac{\|\mathrm{A}_k q_k\|_{0,\Omega}^2}{\tilde{\lambda}_k}\right)^{1/4}\\
&\lesssim \boldsymbol{\Lambda}(\boldsymbol{\sigma}_k, \boldsymbol{\sigma}_k)^{3/4} (\mathcal{R}_k\mathrm{A}_k q_k, \mathrm{A}_k q_k)^{1/4}.
\end{aligned}$$

Thus, to prove (I), we only need to show that

$$(\mathcal{R}_k\mathrm{A}_k q_k, \mathrm{A}_k q_k) \le (\mathbf{R}_k\boldsymbol{\Lambda}_k\boldsymbol{\sigma}_k, \boldsymbol{\Lambda}_k\boldsymbol{\sigma}_k). \tag{4.4}$$

Notice that by the definition of $\mathcal{R}_k$ and $\mathbf{R}_k$,

$$\begin{aligned}
(\mathcal{R}_k\mathrm{A}_k q_k, \mathrm{A}_k q_k) &= \rho \sum_{v \in \mathcal{N}_k} \mathrm{A}(\mathcal{P}_{k,v} q_k, \mathcal{P}_{k,v} q_k),\\
(\mathbf{R}_k\boldsymbol{\Lambda}_k\boldsymbol{\sigma}_k, \boldsymbol{\Lambda}_k\boldsymbol{\sigma}_k) &= \rho \sum_{v \in \mathcal{N}_k} \boldsymbol{\Lambda}(\mathbf{P}_{k,v}\boldsymbol{\sigma}_k, \mathbf{P}_{k,v}\boldsymbol{\sigma}_k).
\end{aligned}$$

Hence (4.4) will follow if for each $v \in \mathcal{N}_k$,

$$\mathrm{A}(\mathcal{P}_{k,v}q_k, \mathcal{P}_{k,v}q_k) = \mathbf{\Lambda}(\mathbf{airy}\,(\mathcal{P}_{k,v}q_k), \mathbf{airy}\,(\mathcal{P}_{k,v}q_k)) \le \mathbf{\Lambda}(\mathbf{P}_{k,v}\boldsymbol{\sigma}_k, \mathbf{P}_{k,v}\boldsymbol{\sigma}_k). \tag{4.5}$$

Notice that for any $p \in \mathrm{Q}_{k,v}$,

$$\begin{aligned}\mathbf{\Lambda}(\mathbf{P}_{k,v}\boldsymbol{\sigma}_k, \mathbf{airy}\,p) &= (\boldsymbol{\sigma}_k, \mathbf{airy}\,p) = (\mathbf{airy}\,q_k, \mathbf{airy}\,p)\\ &= (\mathbf{airy}\,(\mathcal{P}_{k,v}q_k), \mathbf{airy}\,p) = \mathbf{\Lambda}(\mathbf{airy}\,(\mathcal{P}_{k,v}q_k), \mathbf{airy}\,p).\end{aligned}$$

This implies that $\mathbf{airy}\,(\mathcal{P}_{k,v}q_k)$ is the $\mathbf{\Lambda}$-projection of $\mathbf{P}_{k,v}\boldsymbol{\sigma}_k$ into the subspace $\mathbf{airy}\,(\mathrm{Q}_{k,v})$ of $\mathbf{\Sigma}_{k,v}$. Therefore, (4.5) follows. This completes the proof of (I).

Next, we prove (II). For each $v \in \mathcal{N}_k$ let θ_v denote the piecewise continuous linear basis function associated with v. Clearly, $\sum_v \theta_v$ gives a partition of unity on Ω which satisfies

$$\begin{aligned}&(1)\ \theta_v|_T \in P_1(T) \text{ for any } T \in \mathcal{T}_k; \qquad (2)\ \mathrm{supp}(\theta_v) \subset \overline{\Omega}_{k,v};\\ &(3)\ |\theta_v|_{W^{j,\infty}(\Omega)} \lesssim h_k^{-j}, \quad j = 0, 1.\end{aligned}$$

Let Π_k denote the natural interpolation operator onto $\mathbf{\Sigma}_k$ associated with the dofs. Clearly Π_k is linear and preserves $\boldsymbol{\sigma}_k \in \mathbf{\Sigma}_k$. Notice that for each $\boldsymbol{\sigma}_k^i$, $\Pi_k(\theta_v\boldsymbol{\sigma}_k^i)$ is a well-defined function in $\mathbf{\Sigma}_{k,v}$ and $\boldsymbol{\sigma}_k^i = \sum_{v\in\mathcal{N}_k} \Pi_k(\theta_v\boldsymbol{\sigma}_k^i)$. Since the Arnold–Winther element is affine under the matrix Piola transformation [6], a simple scaling argument shows that

$$\|\Pi_k(\theta_v\boldsymbol{\tau})\|_{0,\Omega} \lesssim \|\theta_v\boldsymbol{\tau}\|_{0,\Omega}. \tag{4.6}$$

Also, it has been shown in [6] that $\mathbf{div}\,\Pi_k = \mathbf{P}_{\boldsymbol{V}_k}\mathbf{div}$, where $\mathbf{P}_{\boldsymbol{V}_k}$ is the $\boldsymbol{L}^2$ projection onto $\boldsymbol{V}_k$. Therefore

$$\|\mathbf{div}\,\Pi_k(\theta_v\boldsymbol{\tau})\|_{0,\Omega} = \|\mathbf{P}_{\boldsymbol{V}_k}\mathbf{div}\,(\theta_v\boldsymbol{\tau})\|_{0,\Omega} \le \|\mathbf{div}\,(\theta_v\boldsymbol{\tau})\|_{0,\Omega}.$$

By (4.2), (4.6), an inverse inequality, and the properties of θ_v, for $i = 2, 3, 4$,

$$\begin{aligned}(\mathbf{R}_k^{-1}\boldsymbol{\sigma}_k^i, \boldsymbol{\sigma}_k^i) &\le \rho^{-1}\sum_{v\in\mathcal{N}_k}(\|\Pi_k(\theta_v\boldsymbol{\sigma}_k^i)\|^2_{0,\Omega_{k,v}} + \|\mathbf{div}\,\Pi_k(\theta_v\boldsymbol{\sigma}_k^i)\|^2_{0,\Omega_{k,v}})\\ &\lesssim \sum_{v\in\mathcal{N}_k}(\|\theta_v\boldsymbol{\sigma}_k^i\|^2_{0,\Omega_{k,v}} + \|\mathbf{div}\,(\theta_v\boldsymbol{\sigma}_k^i)\|^2_{0,\Omega_{k,v}})\\ &\lesssim h_k^{-2}\|\boldsymbol{\sigma}_k^i\|^2_{0,\Omega} + \|\mathbf{div}\,\boldsymbol{\sigma}_k^i\|^2_{0,\Omega}.\end{aligned}$$

Hence the proof for (II) reduces to proving for $i = 2, 3, 4$ that

$$\begin{aligned}\|\boldsymbol{\sigma}_k^i\|_{0,\Omega} &\lesssim h_k\|\boldsymbol{\sigma}_k\|_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)},\\ \|\mathbf{div}\,\boldsymbol{\sigma}_k^i\|_{0,\Omega} &\lesssim \|\boldsymbol{\sigma}_k\|_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)}.\end{aligned} \tag{4.7}$$

For $\boldsymbol{\sigma}_k^2$ and any $\boldsymbol{\tau}_{k-1} = \mathbf{airy}\,p_{k-1} + \mathbf{div}_{k-1}^{-1}\boldsymbol{w}_{k-1} \in \mathbf{\Sigma}_{k-1}$,

$$\begin{aligned}&|\mathbf{\Lambda}(\mathbf{airy}\,\mathcal{P}_{k-1}q_k - \mathbf{P}_{k-1}\mathbf{airy}\,q_k, \boldsymbol{\tau}_{k-1})|\\ &\qquad = |(\mathbf{airy}\,\mathcal{P}_{k-1}q_k, \mathbf{airy}\,p_{k-1}) - (\mathbf{airy}\,q_k, \mathbf{I}_k\boldsymbol{\tau}_{k-1})|.\end{aligned}$$

Now

$$(\mathbf{airy}\,\mathcal{P}_{k-1}q_k, \mathbf{airy}\,p_{k-1}) = (\mathbf{airy}\,q_k, \mathbf{I}_k\mathbf{airy}\,p_{k-1})$$

so

$$\begin{aligned}|\boldsymbol{\Lambda}(\mathbf{airy}\,\mathcal{P}_{k-1}q_k - \mathbf{P}_{k-1}\mathbf{airy}\,q_k, \boldsymbol{\tau}_{k-1})| &= |(\mathbf{airy}\,q_k, \mathbf{I}_k\mathbf{div}_{k-1}^{-1}\boldsymbol{w}_{k-1})| \\ &\le |(\mathbf{airy}\,q_k, (\mathbf{I}_k - \mathbf{I})\mathbf{div}_{k-1}^{-1}\boldsymbol{w}_{k-1})| + |(\mathbf{airy}\,q_k, \mathbf{div}_{k-1}^{-1}\boldsymbol{w}_{k-1} - \mathbf{div}^{-1}\boldsymbol{w}_{k-1})| \\ &\lesssim h_k\|\boldsymbol{\sigma}_k\|_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)}\|\boldsymbol{\tau}_{k-1}\|_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)}.\end{aligned}$$

We used the Cauchy–Schwarz inequality, (2.11), and Lemma 3.5 for the last inequality above. Then, by setting $\boldsymbol{\tau}_{k-1} = \mathbf{airy}\,\mathcal{P}_{k-1}q_k - \mathbf{P}_{k-1}\mathbf{airy}\,q_k$ and using Lemma 3.1, we have

$$\begin{aligned}\|\boldsymbol{\sigma}_k^2\|_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)} &\lesssim \|\mathbf{airy}\,\mathcal{P}_{k-1}q_k - \mathbf{P}_{k-1}\mathbf{airy}\,q_k\|_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)} \\ &\lesssim h_k\|\boldsymbol{\sigma}_k\|_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)}.\end{aligned}$$

Therefore, $\boldsymbol{\sigma}_k^2$ satisfies (4.7).

Next, we consider $\boldsymbol{\sigma}_k^3$. Define $\mathbf{P}_{\boldsymbol{V}_{k-1}}$ to be the $\boldsymbol{L}^2$ projection onto $\boldsymbol{V}_{k-1}/RM$. Then

$$\|\mathbf{div}\,\boldsymbol{\sigma}_k^3\|_{0,\Omega} = \|\boldsymbol{v}_k - \mathbf{P}_{\boldsymbol{V}_{k-1}}\boldsymbol{v}_k\|_{0,\Omega} \le \|\boldsymbol{v}_k\|_{0,\Omega} \lesssim \|\boldsymbol{\sigma}_k\|_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)}$$

and by (2.11), Lemma 3.5, and the fact that $h_{k-1} = 2h_k$,

$$\begin{aligned}\|\boldsymbol{\sigma}_k^3\|_{0,\Omega} &\lesssim \|\mathbf{div}_k^{-1}\boldsymbol{v}_k - \mathbf{div}^{-1}\boldsymbol{v}_k\|_{0,\Omega} + \|\mathbf{div}^{-1}\boldsymbol{v}_k - \mathbf{div}_{k-1}^{-1}\boldsymbol{v}_k\|_{0,\Omega} \\ &\quad + \|(\mathbf{I} - \mathbf{I}_k)\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_k\|_{0,\Omega} \\ &\lesssim h_k\|\boldsymbol{v}_k\|_{0,\Omega} \lesssim h_k\|\boldsymbol{\sigma}_k\|_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)}.\end{aligned}$$

Hence $\boldsymbol{\sigma}_k^3$ satisfies (4.7).

For $\boldsymbol{\sigma}_k^4$, let $\boldsymbol{\tau}_{k-1} \in \boldsymbol{\Sigma}_{k-1}$ be arbitrary. Then

(4.8)
$$\begin{aligned}&|\boldsymbol{\Lambda}(\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_k - \mathbf{P}_{k-1}\mathbf{div}_k^{-1}\boldsymbol{v}_k, \boldsymbol{\tau}_{k-1})| = |\boldsymbol{\Lambda}(\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_k, \boldsymbol{\tau}_{k-1}) - \boldsymbol{\Lambda}(\mathbf{div}_k^{-1}\boldsymbol{v}_k, \mathbf{I}_k\boldsymbol{\tau}_{k-1})| \\ &\quad = |(\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_k, \boldsymbol{\tau}_{k-1}) - (\mathbf{div}_k^{-1}\boldsymbol{v}_k, \mathbf{I}_k\boldsymbol{\tau}_{k-1}) + (\mathbf{P}_{\boldsymbol{V}_{k-1}}\boldsymbol{v}_k - \boldsymbol{v}_k, \mathbf{div}\,\tau_{k-1})| \\ &\quad = |(\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_k, \boldsymbol{\tau}_{k-1}) - (\mathbf{div}_k^{-1}\boldsymbol{v}_k, \mathbf{I}_k\boldsymbol{\tau}_{k-1})|.\end{aligned}$$

Since $(\mathbf{div}^{-1}\boldsymbol{v}_k, (\mathbf{I} - \mathbf{I}_k)\boldsymbol{\tau}_{k-1})$ is zero, by (4.8), (2.11), and Lemma 3.1, we have

$$\begin{aligned}|\boldsymbol{\Lambda}(\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_k - \mathbf{P}_{k-1}\mathbf{div}_k^{-1}\boldsymbol{v}_k, \boldsymbol{\tau}_{k-1})| &= |(\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_k - \mathbf{div}^{-1}\boldsymbol{v}_k, \boldsymbol{\tau}_{k-1}) \\ &\quad + (\mathbf{div}^{-1}\boldsymbol{v}_k - \mathbf{div}_k^{-1}\boldsymbol{v}_k, \mathbf{I}_k\boldsymbol{\tau}_{k-1})| \\ &\lesssim h_k\|\boldsymbol{\sigma}_k\|_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)}\|\boldsymbol{\tau}_{k-1}\|_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)}.\end{aligned}$$

Setting $\boldsymbol{\tau}_{k-1} = \mathbf{div}_{k-1}^{-1}\boldsymbol{v}_k - \mathbf{P}_{k-1}\mathbf{div}_k^{-1}\boldsymbol{v}_k$ and using Lemma 3.1 gives

$$\begin{aligned}\|\boldsymbol{\sigma}_k^4\|_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)} &\lesssim \|\mathbf{div}_{k-1}^{-1}\boldsymbol{v}_k - \mathbf{P}_{k-1}\mathbf{div}_k^{-1}\boldsymbol{v}_k\|_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)} \\ &\lesssim h_k\|\boldsymbol{\sigma}_k\|_{\boldsymbol{H}(\mathbf{div},\Omega,\mathbb{S}_2)}.\end{aligned}$$

Therefore, $\boldsymbol{\sigma}_k^4$ satisfies (4.7).

Combining all the above shows that $\mathbf{R}_k$ satisfies assumption (M.2) with a constant C_p independent of k. ∎

5. Numerical results. We report some numerical results for the multigrid preconditioners for the $\boldsymbol{H}(\mathbf{div})$ problem (2.13). Let Ω be the unit square $(0,1)\times(0,1)$. We solve problem (2.13) by the preconditioned conjugate gradient method (PCG). The right-hand side is selected randomly.

Three different multigrid preconditioners are considered. For variable V-cycle preconditioners, we use $\beta_0 = \beta_1 = 2$ and one smoothing on the finest grid. First, we consider the variable V-cycle multigrid preconditioner with Richardson smoother (denoted by $\mathbf{B}_k^R$). Secondly, we experiment on the variable V-cycle multigrid preconditioner $\mathbf{B}_k$ with the additive Schwarz smoother built on the vertex-based subspaces, as defined in section 4. The scaling factor ρ in (4.1) is set to be $\frac{1}{3}$. Finally, we consider the variable V-cycle multigrid preconditioner $\mathbf{B}_k^m$ using the multiplicative Schwarz smoother as discussed in Remark 2. For all three preconditioners, we set the first level mesh by bisecting Ω using its negatively sloped diagonal.

Experiments show that $\mathbf{B}_k^R$ does not work well, as shown in Table 5.1. We report the condition number estimates for $\mathbf{B}_k\mathbf{\Lambda}_k$ in Table 5.1, together with the condition number estimates for $\mathbf{B}_k^m\mathbf{\Lambda}_k$. Both appear to be bounded independently of k. These results also indicate that $\mathbf{B}_k^m$ works better than $\mathbf{B}_k$, which is not surprising since multiplicative overlapping Schwarz methods have been observed to work better than additive overlapping Schwarz methods for many other applications.

Further experiments also suggest that the V-cycle multigrid preconditioner $\mathbf{B}_k^V$ with the additive Schwarz smoother as in $\mathbf{B}_k$ and one smoothing on each level is also optimal for this test problem (see Table 5.2). We are unable to explain this theoretically.

LOCALIZED POINTWISE A POSTERIORI ERROR ESTIMATES FOR GRADIENTS OF PIECEWISE LINEAR FINITE ELEMENT APPROXIMATIONS TO SECOND-ORDER QUASILINEAR ELLIPTIC PROBLEMS*

ALAN DEMLOW†

Abstract. Two types of pointwise a posteriori error estimates are presented for gradients of finite element approximations of second-order quasilinear elliptic Dirichlet boundary value problems over convex polyhedral domains Ω in space dimension $n \geq 2$. We first give a residual estimator which is equivalent to $\|\nabla(u-u_h)\|_{L_\infty(\Omega)}$ up to higher-order terms. The second type of residual estimator is designed to control $\nabla(u-u_h)$ locally over any subdomain of Ω. It is a novel a posteriori counterpart to the localized or weighted a priori estimates of [Sch98]. This estimator is shown to be equivalent (up to higher-order terms) to the error measured in a weighted global norm which depends on the subdomain of interest. All estimates are proved for general shape-regular meshes which may be highly graded and unstructured. The constants in the estimates depend on the unknown solution u in the nonlinear case, but in a fashion which places minimal restrictions on the regularity of u.

Key words. finite element methods, quasilinear elliptic problems, a posteriori error estimation, pointwise error analysis

1. Introduction and results.

1.1. Introduction. We consider finite element approximations to second-order quasilinear elliptic Dirichlet boundary value problems having the form

$$-\sum_{i=1}^{n} \frac{\partial}{\partial x_i} F_i(x,u,\nabla u) + F_0(x,u,\nabla u) = 0 \text{ in } \Omega, \qquad u = b \text{ on } \partial\Omega. \tag{1.1}$$

Here Ω is a convex polyhedral domain in $\mathbb{R}^n$, $n \geq 2$, and we assume that $u \in C^{1,\alpha}(\overline{\Omega})$ for some $0 < \alpha \leq 1$. The coefficients $F_i(x,z,p)$ are assumed to be elliptic (although not necessarily uniformly so) and to satisfy minimal smoothness requirements given in detail later. Problems ranging from uniformly elliptic equations to highly nonlinear, nonuniformly elliptic equations take the form (1.1). Examples which may be treated with the techniques presented here include uniformly elliptic linear problems, where $F_i(x,z,p) = \sum_{j=1}^n a_{ij}(x)p_j$, $1 \leq i \leq n$, and $F_0(x,z,p) = \vec{b}(x)\cdot p + c(x)z - f(x)$; the prescribed mean curvature equation, where $F_i(x,z,p) = p_i/\sqrt{1+|p|^2}$, $1 \leq i \leq n$, and $F_0(x,z,p) = -H(x)$; and mildly nonlinear equations, where $F_i(x,z,p) = \sum_{j=1}^n a_{ij}(x,z)p_j$, $1 \leq i \leq n$, and $F_0(x,z,p) = -f(x)$.

In this paper we provide two types of computationally efficient residual-based pointwise a posteriori error estimators for the gradient error $\nabla(u-u_h)$ in the piecewise linear finite element approximation u_h to u. We first give estimators which are

equivalent up to constants and logarithmic factors to $\|\nabla(u-u_h)\|_{L_\infty(\Omega)}$. While most a posteriori error estimates in the literature similarly control global norms of the error, the quantity of interest in many practical calculations is dependent only on the solution in some subset D of Ω. The goal in these cases is to refine the mesh enough globally to ensure that the solution in $\Omega \setminus D$ does not "pollute" the solution in D while not overrefining in $\Omega \setminus D$. To this end, we prove an a posteriori error estimate for $\|\nabla(u-u_h)\|_{L_\infty(D)}$ which is a novel a posteriori counterpart to the weighted or localized a priori pointwise estimates proved in [Sch98]. The resulting estimators, which we call localized estimators, bound $\|\nabla(u-u_h)\|_{L_\infty(D)}$ and are essentially equivalent to a certain weighted global norm of $\nabla(u-u_h)$. Both types of estimates are valid on general shape-regular meshes and under reasonable regularity assumptions on coefficients and the solution u. To our knowledge, these estimates are the first to provide pointwise error control for gradients in either global or local norms on highly graded, unstructured meshes.

The W^1_∞ estimates we give here are in several senses an extension of the framework for a posteriori analysis of nonlinear problems in integral norms which was proposed in [Ver94]. As in that work, our estimates provide a theoretical basis for a posteriori error estimation and adaptive mesh refinement but also suffer from several drawbacks. The first is that we can prove reliability of our estimators only under the uncomputable condition that $\|\nabla(u-u_h)\|_{L_\infty(\Omega)}$ is small enough. Second, a priori constants appear in our a posteriori upper bounds. Finally, the estimates presented here suffer from a "spectral gap" between the a posteriori upper and lower bounds when the maximum pointwise ratio of the largest and smallest eigenvalues of the coefficient matrix $[\frac{\partial}{\partial p_j} F_i(x,u,\nabla u)]$ is large. [FV03] proposes a method which essentially eliminates the first two of these problems in the context of a posteriori error estimation in the energy norm for equations of prescribed mean curvature. The third problem mentioned above, ill conditioning resulting from a spectral gap, seems to be an essential feature of residual-type estimators for linear as well as nonlinear problems; cf. [FV03] and [BV00].

In the present work we focus on presenting a basic theory for problems on polyhedral domains. Two important questions which we do not consider here are the case of smooth boundaries and the treatment of the constants arising in our estimates. The first of these questions is important for many nonlinear problems as even theoretical results are not always available on polygonal domains. However, the proper treatment of finite element approximations involving curved boundaries is somewhat technical even when considering a posteriori energy-norm bounds (cf. [DR98]), and we do not wish to clutter our presentation. Second, the constants in our a posteriori estimates depend on the unknown solution u in nonlinear problems and even in linear problems may depend on the coefficients in a fashion that will require a local weighting of the residuals. In [De05] we combine further theoretical results with computational experiments in order to investigate this problem.

1.2. Outline of results. Before outlining our results, we introduce some notation. First note that we shall restrict most of our presentation to a model problem having the form

$$\begin{aligned} -\sum_{i=1}^{n} \frac{\partial}{\partial x_i} F_i(x,\nabla u) &= f \text{ in } \Omega, \\ u &= 0 \text{ on } \partial\Omega, \end{aligned} \tag{1.2}$$

where Ω is convex and polygonal. Most of the examples mentioned in the previous

section are of the form (1.2). Extension to more general coefficients is fairly immediate under appropriate assumptions. In section 5 we sketch the necessary modifications and also provide a brief analysis of problems with nonhomogeneous Dirichlet boundary conditions.

Let $\mathcal{T}$ be a decomposition of Ω (now assumed to be polygonal) into shape-regular simplices. Let also $h_T = |T|^{1/n}$ for each element $T \in \mathcal{T}$, let $\underline{h} = \min_{T\in\mathcal{T}} h_T$, and let S_h be the continuous piecewise linear functions which are 0 on $\partial\Omega$. We emphasize that we place no restrictions on the mesh other than shape regularity, so that both highly graded and unstructured meshes are allowed throughout. A logarithmic factor which for technical reasons is different when $n = 2$ also appears in our estimates, and for convenience we define $\gamma(2) = 2$, $\gamma(n) = 1$ for $n > 2$, and $\ell_{\underline{h},n} = (\log(1/\underline{h}))^{\gamma(n)}$.

We next define a first-order maximum norm residual. Let S be a face shared by two elements T_1 and T_2, and let $\vec{n}$ be a unit normal on S (with arbitrary orientation). For $v_h \in S_h$, we then define

$$[v_h]_S(x) = \sum_{i=1}^{n} [F_i(x, \nabla v_h|_{T_1}) - F_i(x, \nabla v_h|_{T_2})]n_i$$

with $[v_h]_S(x) = 0$ when $S \subset \partial\Omega$. Dropping the subscript S as it will cause no confusion, we define the residual

$$\mathcal{E}_T = h_T \|f + \sum_{i=1}^{n} \frac{\partial}{\partial x_i} F_i(\cdot, \nabla u_h)\|_{L_\infty(T)} + \|[u_h]\|_{L_\infty(\partial T)}. \tag{1.3}$$

Our first result is the global estimate

$$\frac{1}{\tilde{C}_1} \max_{T\in\mathcal{T}} (\mathcal{E}_T - R_1(T)) \le \|\nabla(u - u_h)\|_{L_\infty(\Omega)} \le C_1 \ell_{\underline{h},n} \max_{T\in\mathcal{T}} \mathcal{E}_T + R_2(\Omega), \tag{1.4}$$

where R_i, $i \ge 1$, denotes a higher-order term which will be defined more precisely later and C_1 and $\tilde{C}_1$ depend on the coefficients F_i, $\|\nabla u\|_{L_\infty(\Omega)}$, and the Dini continuity of ∇u in the nonlinear case. Thus our estimators are equivalent to the actual error up to constants, logarithmic factors, and higher-order terms, that is, they are efficient and reliable. We do not attempt to provide asymptotically exact estimators. Besides having obvious application to control of global norms of gradient errors, our global estimates may also be combined with the results of [Noc95] and [DDP00] to establish a posteriori estimates for $\|u - u_h\|_{L_\infty(\Omega)}$ for nonlinear problems on convex polygonal and polyhedral domains in two and three space dimensions.

In order to provide local error control, we present novel localized estimators which are inspired by the localized or weighted a priori pointwise estimates proved in [Sch98]. These estimates are valid for smooth linear Neumann problems on globally quasi-uniform meshes of size h. Defining the weight $\sigma_{x_0}(y) = \frac{h}{|y-x_0|+h}$, it was shown that

$$|\nabla(u - u_h)(x_0)| \le \|\sigma_{x_0} \nabla(u - u_h)\|_{L_\infty(\Omega)} \le C \min_{\chi\in S_h} \|\sigma_{x_0} \nabla(u - \chi)\|_{L_\infty(\Omega)}.$$

In our a posteriori results, we wish to control $\nabla(u - u_h)$ over any subset D of Ω, so we define the piecewise constant weight

$$\sigma_D(T) = \frac{h_T}{dist(T, D) + h_T}.$$

We prove the localized a posteriori estimate

$$\begin{aligned}(1.5)\quad \tfrac{1}{C_1}\max_{T\in\mathcal{T}}\sigma_D(T)(\mathcal{E}_T - R_1(T)) &\le \|\sigma_D\nabla(u-u_h)\|_{L_\infty(\Omega)}\\ &\le C_2\ell_{\underline{h},n}\max_{T\in\mathcal{T}}(\sigma_D(T)\mathcal{E}_T + \mathcal{E}_T^2) + R_3(\Omega).\end{aligned}$$

Here C_2 depends on the coefficients F_i and $\|u\|_{W^2_\infty(\Omega)}$ in the nonlinear case, and the term $\mathcal{E}_T^2$ may be dropped in the linear case. Note that the right-hand side of (1.5) also bounds $\|\nabla(u-u_h)\|_{L_\infty(D)}$ since $\sigma_D \equiv 1$ on D. Beyond the evaluation of standard residuals, the only requirement for the practical implementation of the estimator $\max_{T\in\mathcal{T}}(\sigma_D(T)\mathcal{E}_T + \mathcal{E}_T^2)$ is the ability to efficiently compute the distance to the set D.

The constants C_1 and C_2 appearing in the estimates (1.4) and (1.5) depend on the unknown solution u in nonlinear situations, and these estimates are thus not strictly speaking a posteriori estimates. We do establish that C_1 depends only on weak regularity properties of u ($\|\nabla u\|_{L_\infty(\Omega)}$ and the Dini continuity of ∇u), and C_2 depends on moderate regularity properties of u ($\|u\|_{W^2_\infty(\Omega)}$). Although perhaps possible, tracing a more precise theoretical dependence of these constants on u would be difficult and, more important for practical purposes, unlikely to yield sharp results. In nonlinear problems especially, the estimators given here are therefore at most suitable for use as error indicators in adaptive mesh refinement.

We finally give a brief survey of relevant work related to pointwise a posteriori estimates and a posteriori estimates for nonlinear problems. In [Ver94], a general framework is given for a posteriori error estimation in canonical or energy norms for nonlinear problems. As mentioned in the introduction, our global estimates are maximum-norm analogues (in a rather more restricted situation) to the estimates presented in that work in that they yield reliable estimators only for u_h close enough to u, and the constants in the a posteriori estimates depend on the unknown solution u. The method of proof used here is partially inspired by that used in [Noc95] and [DDP00] to establish reliable and efficient a posteriori estimates for $\|u-u_h\|_{L_\infty(\Omega)}$ for linear problems on general shape regular grids on arbitrary polygonal domains in $\mathbb{R}^2$ and $\mathbb{R}^3$. A technique related to our localized estimates when D consists of a single point is the "dual weighted residual" method of [BR01], which involves solving a linear dual problem for each point for which one wishes to control the gradient error. Finally, in [HSWW01] and [SW04], localized a priori pointwise estimates are employed to provide sharply local and asymptotically exact pointwise control of the gradient via "gradient recovery" operators. These estimates have been shown to be valid only for smooth linear problems and on globally quasi-uniform meshes, however.

The outline of the paper is as follows. Section 2 contains further preliminaries and assumptions. In sections 3 and 4 we give precise results and proofs along with more detailed discussion of our global and localized a posteriori estimates, respectively. In section 5 we briefly discuss extensions to problems of the form (1.1).

2. Preliminaries. In this section we make a number of definitions and state some lemmas.

2.1. Finite element approximation and mesh. In addition to the notation and assumptions introduced in the previous section, we make the following definitions. By shape regular we mean that there exist positive constants r_1 and r_2 such that for each $T \in \mathcal{T}$, one may inscribe a sphere of radius $r_1 h_T$ in T and inscribe T in a sphere of radius $r_2 h_T$. Letting T_x be an arbitrary element containing the point x, we denote by $h(x)$ the quantity h_{T_x}. Additionally, we define the patches $P_T =$

$\cup_{\{T'\in\mathcal{T} \text{ such that } \bar{T}\cap\bar{T}'\neq\emptyset\}}\bar{T}'$, $P_T' = \cup_{\{T'\subset P_T\}}P_{T'}$, and $P_T'' = \cup_{\{T'\subset P_T'\}}P_{T'}$. Finally, we assume that there exists a finite element approximation $u_h \in S_h$ to u satisfying

$$\int_\Omega \sum_{i=1}^n F_i(x,\nabla u_h)\chi_{x_i}\,\mathrm{d}x = \int_\Omega f\chi\,\mathrm{d}x \;\forall\; \chi \in S_h. \tag{2.1}$$

The proof of our localized estimates requires a global growth condition on the mesh which is implied by shape regularity, a fact which we now formulate and prove.

PROPOSITION 2.1. *Assume the triangulation $\mathcal{T}$ is shape regular. Then there exists a constant $C_{\mathcal{T}}$ depending only on the shape regularity of $\mathcal{T}$ such that for the barycenter x_T of each element $T \in \mathcal{T}$, there holds for each point $y \in \Omega \setminus T$*

$$h(y) \le C_{\mathcal{T}}|x_T - y|. \tag{2.2}$$

Proof. First fix an element T with barycenter x_T. Shape regularity implies that there exists $0 < K_1$ such that

$$dist(x_T, \partial T) \ge K_1 h_T. \tag{2.3}$$

Next note that the elements contained in P_T are quasi-uniform, that is, there exist constants $K_3 \le 1 \le K_4$ such that for each $T' \subset P_T$,

$$K_3 h_T \le h_{T'} \le K_4 h_T.$$

We shall without loss of generality assume that $K_4 \ge K_1$. Finally, shape regularity implies that there exists $0 < K_2 \le 1$ such that for each point $y \in T$,

$$B_{K_2 h_T}(y) \subset P_T. \tag{2.4}$$

We now assert that (2.2) holds with $C_{\mathcal{T}} = \frac{K_4}{K_1K_2}$. Note from (2.3) that if $y \in P_T \setminus T$, then $|y - x_T| \ge dist(x_T, \partial T) \ge K_1 h_T$. Since $K_2 \le 1$, we thus have

$$h(y) \le K_4 h_T \le \frac{K_4}{K_1}|y - x_T| \le \frac{K_4}{K_1K_2}|y - x_T|.$$

Now assume that $y \notin P_T$, that is, $\bar{T} \cap \bar{T}_y = \emptyset$. In order to reach a contradiction, we assume that $h(y) > \frac{K_4}{K_1K_2}|y - x_T|$. Then since $\frac{K_4}{K_1} \ge 1$,

$$K_2 h(y) > \frac{K_4}{K_1}|x_T - y| \ge |x_T - y|,$$

that is, $x_T \in B_{K_2h(y)}(y)$. Thus by (2.4), $x_T \in B_{K_2h(y)}(y) \subset P_{T_y}$, that is, $\bar{T} \cup \bar{T}_y \neq \emptyset$. This is a contradiction, so our proposition is proved. ∎

We shall also employ the Scott–Zhang interpolation operator I_h defined in [SZ90] which preserves homogeneous boundary conditions and satisfies

$$\|v - I_h v\|_{L_1(T)} \le C h_T^{1+j} \|v\|_{W_1^{1+j}(P_T)},\; j = 1, 2, \tag{2.5}$$

and

$$\|v - I_h v\|_{W_1^1(T)} \le C h_T^{j} \|v\|_{W_1^{1+j}(P_T)},\; j = 0, 1. \tag{2.6}$$

Here and throughout, C is a constant which depends at most on Ω and the shape regularity of $\mathcal{T}$.

2.2. Auxiliary problems and assumptions on coefficients. We assume that the coefficients $F_i(x,p)$ are twice continuously differentiable in p and define $F_{ij}(x,p) = \frac{\partial}{\partial p_j}F_i(x,p)$ and $F_{ijk}(x,p) = \frac{\partial^2}{\partial p_j \partial p_k}F_i(x,p)$. We also require that $F_i(x,p)$, $1 \le i \le n$, have derivatives with respect to the x variable which are uniformly bounded with respect to both x and p. We note that the analysis of our global results requires only that $F_{ij}(x,p)$ be Dini-continuous with respect to the x variable, but $F_i(x,p)$ must possess bounded spatial derivatives over each element in order to guarantee that the residual (1.3) is computable. Finally, we assume the ellipticity condition

$$\sum_{i,j=1}^{n} F_{ij}(x,p)\xi_i\xi_j > 0 \quad \forall \quad x \in \overline{\Omega},\ \xi \in \mathbb{R}^n \setminus \{0\}, p \in \mathbb{R}^n. \tag{2.7}$$

Remark 2.2. The conditions placed on the coefficients F_i may be slightly relaxed at the expense of some complication in our presentation. First, for our global results it is necessary not that $F_{ijk}(x,p)$ exist but rather only that $F_{ij}(x,p)$ be Hölder continuous in p with Hölder exponent $0 < \alpha \le 1$. A perturbation term of the form $\|\nabla(u-u_h)\|^2_{L_\infty(\Omega)}$ arising in our global results would be replaced in this situation by $\|\nabla(u-u_h)\|^{1+\alpha}_{L_\infty(\Omega)}$. Second, the ellipticity condition (2.7) must only hold for $p \in \overline{range(\nabla u)}$ and not for all p in $\mathbb{R}^n$. This latter observation would, for example, allow analysis of the β-Laplacian, where $F_i(x,p) = p_i|p|^{\beta-2}$ and $1 < \beta < \infty$, if it could be established a priori that $|\nabla u| \ge C > 0$. For W^2_∞ solutions of the β-Laplacian with $\beta > 2$, Lemma 4.2 of [BL93] establishes such an inequality if $|f| \ge C > 0$. However, we are not aware of any regularity results in the literature which would guarantee such smooth solutions of this problem.

Two auxiliary linear problems are used in our analysis of quasilinear problems. Following for example [FR78], we define

$$a^h_{ij} = \int_0^1 F_{ij}(x, \nabla u_h + t\nabla(u-u_h))\ \mathrm{d}t, \quad i,j = 1,\dots,n,$$

and

$$a_{ij} = F_{ij}(x, \nabla u), \quad i,j = 1,\dots,n.$$

Correspondingly, we define bilinear forms

$$A_h(v,w) = \int_\Omega \sum_{i,j=1}^{n} a^h_{ij} v_{x_j} w_{x_i}\,\mathrm{d}x \tag{2.8}$$

and

$$A(v,w) = \int_\Omega \sum_{i,j=1}^{n} a_{ij} v_{x_j} w_{x_i}\,\mathrm{d}x.$$

From the ellipticity and smoothness of the coefficients F_i and the boundedness of ∇u, we can conclude that $[a_{ij}]$ is uniformly elliptic in Ω, that is,

$$\lambda|\xi|^2 \le \sum_{i,j=1}^{n} a_{ij}\xi_i\xi_j \le \Lambda|\xi|^2. \tag{2.9}$$

We emphasize that for nonlinear problems, λ and Λ in general depend on $\|\nabla u\|_{L_\infty(\Omega)}$.

The ellipticity of A_h, on the other hand, depends upon $\|\nabla u_h\|_{L_\infty(\Omega)}$, but A_h satisfies the error equation

$$A_h(u-u_h,\chi)=\int_\Omega \sum_{i=1}^n (F_i(x,\nabla u)-F_i(x,\nabla u_h))\chi_{x_i}\,\mathrm{d}x=0 \tag{2.10}$$

for $\chi\in S_h$, and in fact for general $v\in H_0^1(\Omega)$,

$$A_h(u-u_h,v)=\int_\Omega \sum_{i=1}^n (F_i(x,\nabla u)-F_i(x,\nabla u_h))v_{x_i}\,\mathrm{d}x. \tag{2.11}$$

We finally note that with S denoting the convex hull of $range(\nabla u)$ and $range(\nabla u_h)$,

$$\begin{aligned} |a_{ji}-a_{ji}^h| &= \Big|\int_0^1 F_{ji}(\nabla u)-F_{ji}(\nabla u_h+t\nabla(u-u_h))\,\mathrm{d}t\Big| \\ &\le \int_0^1 \sum_{k=1}^n \|F_{jik}\|_{L_\infty(S)}(1-t)|\nabla(u-u_h)|\,\mathrm{d}t \\ &\le C_F|\nabla(u-u_h)|. \end{aligned} \tag{2.12}$$

The essential estimate $\max_{1\le i,j,k\le n}\|F_{ijk}\|_{L_\infty(S)}\le C_F$ may be established here in one of two ways. It sometimes happens that F_{ijk} is bounded on $\Omega\times\mathbb{R}^n$, so that the bound is immediate and does not rely on ∇u and ∇u_h. If F_{ijk} is not globally bounded, then we must assume a priori that $\|\nabla u_h\|_{L_\infty(\Omega)}\le C$ or alternatively that $\|\nabla(u-u_h)\|_{L_\infty(\Omega)}\le C$. C_F can then be taken to be the bound for $\max_{1\le i,j,k\le n}|F_{ijk}(x,p)|$ on the compact set $\{x\in\overline{\Omega},\ |p|\le\|\nabla u\|_{L_\infty(\Omega)}+C\}$. Thus we shall assume that either $F_{ijk}(x,p)$ is globally bounded in both x and p for all $1\le i,j,k\le n$ or that $\|\nabla u_h\|_{L_\infty(\Omega)}\le C$.

2.3. Green's function estimates. We denote by $G(x,y)$ the Green's function satisfying $A(G(x,\cdot),v)=v(x)$ for sufficiently smooth $v\in H_0^1(\Omega)$. The following estimate for the first and mixed second derivatives of G is essential to our proofs.

LEMMA 2.3. *Assume that the coefficients a_{ij} are Dini-continuous and satisfy the uniform ellipticity condition* (2.9)*, and let Ω be smooth or convex. Assume that $|\alpha|\le 1$ and $|\beta|\le 1$. Then for $n\ge 3$*

$$|D_x^\alpha D_y^\beta G(x,y)|\le C_G|x-y|^{2-n-|\alpha|-|\beta|} \tag{2.13}$$

and for $n=2$

$$|D_x^\alpha D_y^\beta G(x,y)|\le C_G|x-y|^{2-n-|\alpha|-|\beta|}\log\frac{1}{|x-y|}. \tag{2.14}$$

Here C_G depends on Ω, the Dini-continuity of the coefficients a_{ij}, and λ and Λ.

The estimate (2.13) for space dimension $n\ge 3$ may be found in [GW82] assuming that $\partial\Omega$ satisfies a uniform exterior sphere condition. This condition is met by both convex and smooth domains. The proof given in [GW82] does not carry directly over to $n=2$ due to the logarithmic nature of the singularity, but one may use the same method to obtain the suboptimal estimate (2.14) so long as the estimate

$$|G(x,y)|\le C(\lambda,\Lambda,\Omega)\log\frac{1}{|x-y|}$$

is known. This estimate is contained in [DM95] under the weak restrictions of L_∞ and uniformly elliptic coefficients and Lipschitz boundary $\partial\Omega$. The suboptimal estimate (2.14) will only add an additional logarithmic factor to our results in the case $n=2$.

3. Global estimate. In this section we state, discuss, and prove reliability and efficiency results for global estimators for $\nabla(u-u_h)$.

3.1. Reliability of global estimators. First we state the following upper bound for $\|\nabla(u-u_h)\|_{L_\infty(\Omega)}$.

THEOREM 3.1. *In addition to the assumptions of section 2, assume that $u \in C^{1,\nu}(\overline{\Omega})$ for some $0<\nu\le 1$. Then for any $0<\alpha\le\nu$ and any $\beta\ge 1$,*

$$\begin{aligned}\|\nabla(u-u_h)\|_{L_\infty(\Omega)} \le{}& C_1\beta^{\gamma(n)}\ell_{\underline{h},n}\bigl(\max_{T\in\mathcal{T}}\mathcal{E}_T + C_F\|\nabla(u-u_h)\|^2_{L_\infty(\Omega)}\bigr)\\ &+ C\underline{h}^{\alpha\beta}|u|_{C^{1,\alpha}(\overline{\Omega})}.\end{aligned}\tag{3.1}$$

Here C_1 depends on C_G, the ellipticity coefficients λ and Λ, and the shape regularity of $\mathcal{T}$. In the nonlinear case, C_1 thus depends on $\|\nabla u\|_{L_\infty(\Omega)}$, the Dini-continuity of ∇u, and the coefficients F_i. In the linear case, C_1 does not depend on u and the term $\|\nabla(u-u_h)\|^2_{L_\infty(\Omega)}$ in (3.1) does not appear.

Remark 3.2. The term $\underline{h}^{\alpha\beta}|u|_{C^{1,\alpha}(\overline{\Omega})}$ may be omitted for $\underline{h}$ small enough if we make the nondegeneracy assumption $\underline{h}^{\epsilon}|u|_{C^{1,\alpha}(\overline{\Omega})}\le\|\nabla(u-u_h)\|_{L_\infty(\Omega)}$ for some $\epsilon>0$. We may then take $\beta=(\epsilon+1)/\alpha$ and $\underline{h}$ small enough to kick back the resulting term $C\underline{h}\|\nabla(u-u_h)\|_{L_\infty(\Omega)}$. In [De04] we give a more precise nondegeneracy assumption which relies on lower bounds for polynomial approximations. In particular, assume that there exists a single point $\tilde{x}\in\Omega$ and $\eta>0$ such that $|D^2u(\tilde{x})|\ge\tilde{C}>0$ and $\|u\|_{W^3_\infty(B_\eta(\tilde{x}))}\le\tilde{C}'$. The term $\underline{h}^{\alpha\beta}|u|_{C^{1,\alpha}(\overline{\Omega})}$ may then be removed at the expense of a weak preasymptotic a priori dependence in the logarithmic factor. We do not give the details here. This more precise nondegeneracy assumption leads to an estimate which for linear problems is reliable on coarse meshes, and in most practical situations we may thus omit this term.

In [Noc95] and [DDP00], the Hölder continuity of u (instead of ∇u) and an assumption similar to the condition $\underline{h}^{\epsilon}|u|_{C^{1,\alpha}(\overline{\Omega})}\le\|\nabla(u-u_h)\|_{L_\infty(\Omega)}$ above were used in the establishment of asymptotically reliable residual estimators for $\|u-u_h\|_{L_\infty(\Omega)}$ for linear problems on nonconvex polygonal domains. The technique we use in [De04] to remove the term $\underline{h}^{\alpha\beta}|u|_{C^{1,\alpha}(\overline{\Omega})}$ is essentially a more rigorous and careful version of the argument contained in these works. A different and more sophisticated argument was used in [NSV03] to remove such nondegeneracy assumptions completely and thus prove L_∞ estimates which have no a priori dependence in the upper bounds and which are valid on coarse meshes. This technique does not appear to be applicable in the current context of W^1_∞ estimates, however.

Remark 3.3. The estimate (3.1) includes a logarithmic factor, whereas typical a priori estimates for $\|\nabla(u-u_h)\|_{L_\infty(\Omega)}$ do not. It is possible to remove the logarithmic factor under the restriction that the mesh be quasi-uniform on balls of size $c\log(1/\underline{h})$ for any fixed $c>0$. Removing this computationally negligible factor would also lead to a stronger dependence of C_1 on u in the nonlinear case or on the coefficients a_{ij} in the linear case.

Next note that we may kick back the term $\|\nabla(u-u_h)\|^2_{L_\infty(\Omega)}$ in (3.1) if

$$C_1C_F\beta^{\gamma(n)}\ell_{\underline{h},n}\|\nabla(u-u_h)\|_{L_\infty(\Omega)}\le C^*<1.\tag{3.2}$$

See [FR78] for an asymptotic a priori estimate for $\|\nabla(u-u_h)\|_{L_\infty(\Omega)}$ on quasi-uniform meshes and under stricter regularity assumptions than we have made here. Using (3.2) and Remark 3.2 while noting that $\|u_h\|_{L_\infty(\Omega)}\le C$ if (3.2) holds, we may formulate an asymptotic reliability result which yields a computable estimator.

COROLLARY 3.4. *Assume that $\mathcal{T}$ is shape regular, $u \in C^{1,\nu}(\overline{\Omega})$, $\|\nabla(u-u_h)\|_{L_\infty(\Omega)}$ is small enough, $\underline{h} \leq C$, and that $\|\nabla(u-u_h)\|_{L_\infty(\Omega)} \geq C\underline{h}^{\epsilon}|u|_{C^{1,\nu}(\overline{\Omega})}$ for some $\epsilon > 0$. Then*

$$\|\nabla(u-u_h)\|_{L_\infty(\Omega)} \leq C_1 \left(\frac{\epsilon+1}{\nu}\right)^{\gamma(n)} \ell_{\underline{h},n} \max_{T\in\mathcal{T}} \mathcal{E}_T. \tag{3.3}$$

Here C_1 is as in Theorem 3.1.

As stated in the introduction, the condition that $\|\nabla(u-u_h)\|_{L_\infty(\Omega)}$ is small enough is an a priori and uncomputable condition. We refer again to [Ver94] for a posteriori estimates for nonlinear problems in integral norms which are reliable only for u_h close enough to u and which have reliability constants depending on the unknown solution u. For energy norms, an alternative approach to that of [Ver94] is to bound the error in a weighted problem-dependent norm depending on u_h. In some cases one may thus avoid the problem of unknown a priori constants replace the requirement that ∇u and ∇u_h be close enough with a computable condition whose fulfillment ensures reliability of the a posteriori upper bound; cf. [FV03] for such an example.

We finally note that our results may easily be combined with those of [Noc95] and [DDP00] to establish a bound for $\|u-u_h\|_{L_\infty(\Omega)}$ for quasilinear problems on convex polyhedral domains in two and three space dimensions.

COROLLARY 3.5. *Assume that the conditions of Theorem* 3.1 *are satisfied and that in addition the coeffcients F_i are nonlinear and $u \in W^2_\infty(\Omega)$. Then for any $\alpha > 0$ and $\beta > 0$,*

$$\begin{aligned}\|u-u_h\|_{L_\infty(\Omega)} \leq{}& \tilde{C}\beta^{\gamma(n)}\ell_{\underline{h}}[\max_{T\in\mathcal{T}} h_T\mathcal{E}_T + \max_{T\in\mathcal{T}} \mathcal{E}_T^2 \\ &+ \|\nabla(u-u_h)\|^4_{L_\infty(\Omega)}] + C[\underline{h}^{\alpha\beta}|u|_{C^\alpha(\overline{\Omega})} + \underline{h}^{2\alpha\beta}|u|_{C^{1,\alpha}(\overline{\Omega})}],\end{aligned} \tag{3.4}$$

where $\tilde{C}$ depends on $\|u\|_{W^2_\infty(\Omega)}$ and the coefficients F_i, and $\ell_{\underline{h}}$ is a generic logarithmic factor.

Dropping the higher-order terms in the second line yields an asymptotically reliable estimator for $\|u-u_h\|_{L_\infty(\Omega)}$.

3.2. Efficiency of global estimators. Before stating our efficiency result, we define P_h to be the L_2 projection onto the functions which are piecewise constant on $\mathcal{T}$ and let $\tilde{P}_h$ be the L_2 projection onto the set of functions which are piecewise constant on the edges of elements in $\mathcal{T}$.

THEOREM 3.6. *Assume that either F_{ij} is globally bounded for $1 \leq i,j \leq n$, or that $\|\nabla u_h\|_{L_\infty(\Omega)} \leq C$. Then for any element $T \in \mathcal{T}$,*

$$\begin{aligned}\mathcal{E}_T \leq{}& \tilde{C}_1\|\nabla(u-u_h)\|_{L_\infty(P_T)} + Ch_T\|\tilde{f}_h - P_h\tilde{f}_h\|_{L_\infty(P_T)} \\ &+ C\|[u_h] - \tilde{P}_h[u_h]\|_{L_\infty(\partial T)}.\end{aligned} \tag{3.5}$$

Here $\tilde{f}_h(x) = f(x) + \sum_{i=1}^n \frac{\partial}{\partial x_i} F_i(x,\nabla u_h)$ and $\tilde{C}_1 = C\|a^h_{ij}\|_{L_\infty(\Omega)}$ is bounded independent of u_h under the assumptions of this theorem.

Remark 3.7. If the coefficients $F_i(x,p)$ do not depend on x (as is the case for example for the prescribed mean curvature problem), then the higher-order term $h_T\|\tilde{f}_h - P_h\tilde{f}_h\|_{L_\infty(P_T)} + \|[u_h] - \tilde{P}_h[u_h]\|_{L_\infty(\partial T)}$ reduces to $\|f - P_h f\|_{L_\infty(P_T)}$.

3.3. Proof of reliability. In our proofs we shall use a discrete δ-function. Modifying the technique used in [Noc95], we fix a point x and define a function δ_x as follows. Let $x \in T \in \mathcal{T}$. We then fix a simplex $\tilde{T}$ such that $x \in \tilde{T} \subset T$ and $\tilde{T}$ is shape regular

with diameter $\rho = \underline{h}^\beta$ for $\beta \geq 1$, where β is as given in the statement of Theorem 3.1. We then let $\delta_x \in C_0^\infty(\tilde{T})$ be a nonnegative function such that $\int_{\tilde{T}} \delta_x \, \mathrm{d}y = 1$,

$$\|\delta_x\|_{W_p^k(\tilde{T})} \leq C\rho^{n(1-1/p)-k}, \tag{3.6}$$

and $dist(\mathrm{supp}(\delta_x), \partial\tilde{T}) \geq c\rho$ for some $c > 0$. Such a function δ_x is easy to define by scaling and translation to $\tilde{T}$ from a reference element.

Denote by ∂ a first-order directional differential operator, that is, $\partial = \nabla \cdot \vec{v}$ for some $\vec{v}$ with $|\vec{v}| = 1$. Let $x_0 \in T$ and ∂ be such that $\|\nabla(u - u_h)\|_{L_\infty(\Omega)} \leq C|\partial(u - u_h)(x_0)|$, and let $\overline{\partial u} = \frac{1}{|\tilde{T}|}\int_{\tilde{T}} \partial u \, \mathrm{d}x$. Noting that ∂u_h is constant on $\tilde{T}$ and that $\overline{\partial u} = \partial u(x_1)$ for some $x_1 \in \tilde{T}$, we compute

$$\begin{aligned}
\|\nabla(u - u_h)\|_{L_\infty(\Omega)} &\leq C|\partial(u - u_h)(x_0)| \\
&\leq C(|\partial u(x_0) - \partial u(x_1)| + |\overline{\partial u} - \partial u_h|) \\
&\leq C(\rho^\alpha |u|_{C^{1,\alpha}(\tilde{T})} + |(\overline{\partial u} - \partial u_h, \delta_{x_0})|) \\
&\leq C(\rho^\alpha |u|_{C^{1,\alpha}(\tilde{T})} + |(\overline{\partial u} - \partial u, \delta_{x_0})| + |(\partial(u - u_h), \delta_{x_0})|) \\
&\leq C(\rho^\alpha |u|_{C^{1,\alpha}(\tilde{T})} + \|\partial u(x_1) - \partial u\|_{L_\infty(\tilde{T})} + |(u - u_h, \partial\delta_{x_0})|) \\
&\leq C(\rho^\alpha |u|_{C^{1,\alpha}(\Omega)} + |(u - u_h, \partial\delta_{x_0})|) \\
&\leq C(\underline{h}^{\alpha\beta} |u|_{C^{1,\alpha}(\Omega)} + |(u - u_h, \partial\delta_{x_0})|).
\end{aligned} \tag{3.7}$$

We next introduce a discrete Green's function. With ∂ and x_0 as above, we define $g^{x_0} \in H_0^1(\Omega)$ as the unique function satisfying

$$A(v, g^{x_0}) = (\partial\delta_{x_0}, v) \tag{3.8}$$

for all $v \in H_0^1(\Omega)$. Since the bound given below does not depend upon x_0, we shall suppress the dependence of g and δ on x_0 for the rest of this section. The heart of our proof consists of proving the following bound for $\|g\|_{W_1^1(\Omega)}$.

LEMMA 3.8. *If the conditions of Theorem* 3.1 *are satisfied, then*

$$\|g\|_{W_1^1(\Omega)} \leq C_g \beta^{\gamma(n)} \ell_{\underline{h},n}, \tag{3.9}$$

where $C_g = C(C_G, \lambda, \Lambda)$.

In order to complete the proof of Theorem 3.1 given Lemma 3.8, we use (3.8), (2.10), and (2.11) to find that

$$\begin{aligned}
(u - u_h, \partial\delta) &= A(u - u_h, g) = (A - A_h)(u - u_h, g) + A_h(u - u_h, g) \\
&= (A - A_h)(u - u_h, g) + A_h(u - u_h, g - I_h g) \\
&\leq C_F \|\nabla(u - u_h)\|_{L_\infty(\Omega)}^2 \|g\|_{W_1^1(\Omega)} \\
&\quad + \left| \int_\Omega \sum_{i=1}^n (F_i(x, \nabla u) - F_i(x, \nabla u_h))(g - I_h g)_{x_i} \, \mathrm{d}x \right|.
\end{aligned} \tag{3.10}$$

Note that $A_h = A$ if (1.2) is a linear problem, so the term $\|\nabla(u - u_h)\|_{L_\infty(\Omega)}^2$ is dropped in this case as claimed. We use the easily-proven scaled trace inequality

$$\|v\|_{L_1(\partial T)} \leq C(h_T^{-1}\|v\|_{L_1(T)} + \|\nabla v\|_{L_1(T)})$$

and integrate the last term in (3.10) by parts elementwise to find

$$
\begin{aligned}
&\left|\int_\Omega \textstyle\sum_{i=1}^n (F_i(x,\nabla u)-F_i(x,\nabla u_h))(g-I_hg)_{x_i}\,\mathrm{d}x\right| \\
&\quad=\left|\sum_{T\in\mathcal{T}}\int_T\sum_{i=1}^n (F_i(x,\nabla u)-F_i(x,\nabla u_h))(g-I_hg)_{x_i}\,\mathrm{d}x\right| \\
&\quad=\left|\sum_{T\in\mathcal{T}}\int_T(-\sum_{i=1}^n\frac{\partial}{\partial x_i}(F_i(x,\nabla u)-F_i(x,\nabla u_h))(g-I_hg)\,\mathrm{d}x\right. \\
&\qquad\left.+\int_{\partial T}\sum_{i=1}^n (F_i(x,\nabla u)-F_i(x,\nabla u_h))n_i(g-I_hg)\,\mathrm{d}s\right| \qquad (3.11)\\
&\quad\le\sum_{T\in\mathcal{T}}\|f+\sum_{i=1}^n\frac{\partial}{\partial x_i}F_i(\cdot,\nabla u_h)\|_{L_\infty(T)}\|g-I_hg\|_{L_1(T)} \\
&\qquad+\|[u_h]\|_{L_\infty(\partial T)}\|g-I_hg\|_{L_1(\partial T)} \\
&\quad\le\sum_{T\in\mathcal{T}}\left\|f+\sum_{i=1}^n\frac{\partial}{\partial x_i}F_i(\cdot,\nabla u_h)\right\|_{L_\infty(T)}\|g-I_hg\|_{L_1(T)} \\
&\qquad+\|[u_h]\|_{L_\infty(\partial T)}(h_T^{-1}\|g-I_hg\|_{L_1(T)}+\|\nabla(g-I_hg)\|_{L_1(T)}).
\end{aligned}
$$

Finally, we apply the approximation results (2.5) and (2.6) and thus obtain

$$
\begin{aligned}
&\sum_{T\in\mathcal{T}}\left\|f+\textstyle\sum_{i=1}^n\frac{\partial}{\partial x_i}F_i(\nabla u_h)\|_{L_\infty(T)}\|g-I_hg\right\|_{L_1(T)} \\
&\qquad+\|[u_h]\|_{L_\infty(\partial T)}(h_T^{-1}\|g-I_hg\|_{L_1(T)}+\|\nabla(g-I_hg)\|_{L_1(T)}) \qquad (3.12)\\
&\quad\le\sum_{T\in\mathcal{T}}\mathcal{E}_T\|g\|_{W_1^1(P_T)} \\
&\quad\le C\|g\|_{W_1^1(\Omega)}\max_{T\in\mathcal{T}}\mathcal{E}_T.
\end{aligned}
$$

Combining (3.12), (3.11), (3.10), and (3.7) and finally applying (3.9) completes the proof of Theorem 3.1 assuming Lemma 3.8.

To begin the proof of Lemma 3.8, we first note the elementary inequality

$$
\|g\|_{H^1(\Omega)}\le\frac{C(\Omega)}{\lambda}\|\delta\|_{L_2(\Omega)}. \qquad (3.13)
$$

In order to prove (3.9) for $n\ge 3$, we then note that if $|x-x_0|>2\rho$, we may apply (2.13) and (3.6) to find that

$$
\begin{aligned}
|\nabla_x g(x)|&=\left|\int_{\mathrm{supp}(\delta)}\nabla_x G(x,y)\partial\delta(y)\,\mathrm{d}y\right| \\
&=\left|\int_{\mathrm{supp}(\delta)}\partial_y\nabla_x G(x,y)\delta\,\mathrm{d}y\right| \qquad (3.14)\\
&\le C_G|x_0-y|^{-n}\|\delta\|_{L_1(\Omega)}\le C_G|x_0-x|^{-n},
\end{aligned}
$$

and similarly,

$$|g(x)| \le C_G |x_0 - x|^{1-n}. \tag{3.15}$$

We then use (3.13), (3.6), (3.14), and (3.15) to compute

$$\begin{aligned}
\|g\|_{W_1^1(\Omega)} &\le C\rho^{n/2}\|g\|_{H^1(B_{3\rho(x_0)})} + \|g\|_{W_1^1(\Omega\setminus B_{3\rho}(x_0))} \\
&\le \rho^{n/2}\frac{C(\Omega)}{\lambda}\|\delta\|_{L_2(\Omega)} + C_G\int_{C\rho}^{\operatorname{diam}(\Omega)} r^{-n}r^{n-1}dr \\
&\le \frac{C(\Omega)}{\lambda}\rho^{n/2}\rho^{-n/2} + C_G\log(1/\rho) \\
&\le C\left(\frac{1}{\lambda} + C_G\right)\beta\log(1/\underline{h}).
\end{aligned}$$

If $n = 2$, we must apply (2.14) instead of (2.13). Since we always apply (2.14) with $|x - y| \ge C\rho$, this results in an extra factor of $\log(1/\rho)$ in our estimates. ∎

Proof of Corollary 3.5. Letting $\delta_{x_0} = \delta$ be as above, it is easy to compute that for some $x_0 \in \Omega$, $\|u - u_h\|_{L_\infty(\Omega)} \le C\underline{h}^{\alpha\beta}|u|_{C^\alpha(\overline{\Omega})} + |(u - u_h, \delta)|$. Let then $\overline{g} \in H_0^1(\Omega)$ satisfy $A(v, \overline{g}) = (v, \delta)$ for all $v \in H_0^1(\Omega)$. Then

$$\begin{aligned}
|(u - u_h, \delta)| &= |A(u - u_h, \overline{g})| \le |(A - A_h)(u - u_h, \overline{g})| + |A_h(u - u_h, \overline{g} - I_h\overline{g})| \\
&\le C(\|\nabla(u - u_h)\|_{L_\infty(\Omega)}^2 + \max_{T\in\mathcal{T}} h_T\mathcal{E}_T)\|\overline{g}\|_{W_1^2(\Omega)}.
\end{aligned} \tag{3.16}$$

Inserting the bounds established in Theorem 3.1 of [Noc95] ($n = 2$) and Corollary 2.3 of [DDP00] ($n = 3$) for $\|\overline{g}\|_{W_1^2(\Omega)}$ and also (3.1) into (3.16) yields (3.4). ∎

3.4. Proof of efficiency. We follow here the local argument given in [Ver89] and adapted to the maximum norm case in [Noc95] and [DDP00]. Recalling the definition of $\tilde{f}_h$ from Theorem 3.6, we note first that for any $v \in H_0^1(\Omega)$,

$$\sum_{T\in\mathcal{T}}\int_T \tilde{f}_h v\,\mathrm{d}x + \frac{1}{2}\int_{\partial T}[u_h]v\,\mathrm{d}s = A_h(u - u_h, v). \tag{3.17}$$

Now fix an element T and choose $v = b_T$, where b_T is the polynomial bubble function of degree $n + 1$ which is obtained by multiplying the barycentric coordinates and scaling so that b_T is 1 at the barycenter of T. By transforming from a reference element, we see that $\int_T b_T\,\mathrm{d}x = Ch_T^n$, $\|b_T\|_{L_1(T)} \le Ch_T^n$, and $\|\nabla b_T\|_{L_1(T)} \le Ch_T^{n-1}$. Since $b_T = 0$ on ∂T, we may thus compute from (3.17) that

$$\begin{aligned}
\tilde{C}_1 h_T^{n-1}\,&\|\nabla(u - u_h)\|_{L_\infty(T)} \ge |A_h(u - u_h, b_T)| \\
&= \left|\int_T \tilde{f}_h b_T\,\mathrm{d}x + \frac{1}{2}\int_{\partial T}[u_h]b_T\,\mathrm{d}s\right| = \left|\int_T \tilde{f}_h b_T\,\mathrm{d}x\right| \\
&= \left|\int_T (\tilde{f}_h - P_h\tilde{f}_h)b_T\,\mathrm{d}x + P_h\tilde{f}_h|_T\int_T b_T\,\mathrm{d}x\right| \\
&\ge Ch_T^n|P_h\tilde{f}_h|_T| - C\|\tilde{f}_h - P_h\tilde{f}_h\|_{L_\infty(T)} \\
&\ge Ch_T^n(|\|\tilde{f}_h\|_{L_\infty(T)} - \|\tilde{f}_h - P_h\tilde{f}_h\|_{L_\infty(T)}| - C\|\tilde{f}_h - P_h\tilde{f}_h\|_{L_\infty(T)}) \\
&\ge Ch_T^n(\|\tilde{f}_h\|_{L_\infty(T)} - C\|\tilde{f}_h - P_h\tilde{f}_h\|_{L_\infty(T)})
\end{aligned}$$

so that

$$h_T\|\tilde{f}_h\|_{L_\infty(T)} \le \tilde{C}_1\|\nabla(u - u_h)\|_{L_\infty(T)} + Ch_T\|\tilde{f}_h - P_h\tilde{f}_h\|_{L_\infty(T)}. \tag{3.18}$$

Next let $S = \overline{T} \cap \overline{T'}$ be a face of T not contained in $\partial\Omega$. We then define q_S to be the continuous piecewise polynomial of degree n which is 0 on $\partial(T \cup T')$ and 1 at the barycenter of S. Note that $\|q_S\|_{L_1(T\cup T')} \leq Ch_T^n$, $\|\nabla q_S\|_{L_1(T\cup T')} \leq Ch_T^{n-1}$, $\|q_S\|_{L_1(S)} \leq Ch_T^{n-1}$, and $\int_S q_S \mathrm{d}s = Ch_T^{n-1}$. Again computing using (3.17), we find that

$$\begin{aligned}\tilde{C}_1 h_T^{n-1}\|\nabla(u-u_h)\|_{L_\infty(T\cup T')} &\geq A_h(u-u_h, q_S)\\ &= \int_T \tilde{f}_h q_S \,\mathrm{d}x + \int_S ([u_h] - \tilde{P}_h[u_h])q_S \mathrm{d}s + \int_S \tilde{P}_h[u_h] q_S \mathrm{d}s\\ &\geq Ch_T^{n-1}\|[u_h]\|_{L_\infty(S)}\\ &\quad - C(h_T^n\|\tilde{f}_h\|_{L_\infty(T\cup T')} + h_T^{n-1}\|[u_h] - \tilde{P}_h[u_h]\|_{L_\infty(S)})\end{aligned}$$

and

$$\begin{aligned}\|[u_h]\|_{L_\infty(S)} &\leq \tilde{C}_1\|\nabla(u-u_h)\|_{L_\infty(P_T)}\\ &\quad + Ch_T\|\tilde{f}_h\|_{L_\infty(P_T)} + C\|[u_h] - \tilde{P}_h[u_h]\|_{L_\infty(S)}.\end{aligned} \tag{3.19}$$

Recalling that $\mathcal{E}_T = h_T\|\tilde{f}_h\|_{L_\infty(T)} + \|[u_h]\|_{L_\infty(\partial T)}$ and combining (3.18) with (3.19) completes the proof of (3.5). ∎

4. Localized estimates.

4.1. Reliability of localized estimators. We first give an a posteriori bound for $\|\sigma_D\nabla(u-u_h)\|_{L_\infty(\Omega)}$.

THEOREM 4.1. *Let $D \subset \Omega$. In addition to the assumptions of section 2, assume that $u \in C^{1,\nu}(\overline{\Omega})$ for some $0 < \nu \leq 1$ if the coefficients F_i are linear and $u \in W^2_\infty(\Omega)$ if the coefficients F_i are nonlinear. Then for any $0 < \alpha \leq \nu$ and any $\beta \geq 1$,*

$$\begin{aligned}\|\nabla(u-u_h)\|_{L_\infty(D)} &\leq \|\sigma_D\nabla(u-u_h)\|_{L_\infty(\Omega)}\\ &\leq \beta^{\gamma(n)}\ell_{\underline{h},n}[C_2 \max_{T\in\mathcal{T}}\sigma_D(T)\mathcal{E}_T + C_1C_F\|\nabla(u-u_h)\|^2_{L_\infty(\Omega)}]\\ &\quad + C\underline{h}^{\alpha\beta}\max_{T\in\mathcal{T}}\sigma_D(T)|u|_{C^{1,\alpha}(\overline{T})}.\end{aligned} \tag{4.1}$$

Here C_1 is as in Theorem 3.1 and C_2 depends on C_G, $\|a_{ij}\|_{W^1_\infty(\Omega)}$, λ, Λ, and the shape regularity of $\mathcal{T}$. In the nonlinear case, C_2 thus depends on $\|u\|_{W^2_\infty(\Omega)}$ and the coefficients F_i. In the linear case, C_2 does not depend on u and the term $\|\nabla(u-u_h)\|^2_{L_\infty(\Omega)}$ in (4.1) does not appear.

Note that the term $\|\nabla(u-u_h)\|^2_{L_\infty(\Omega)}$ in (4.1) is not generally of higher order, in contrast to the situation which arises when the global estimate (3.1) is applied. One may insert (3.3) into (4.1) in the nonlinear case to yield the following asymptotic reliability result.

COROLLARY 4.2. *Assume that $u \in W^2_\infty(\Omega)$, $\|\nabla(u-u_h)\|_{L_\infty(\Omega)}$ and $\underline{h}$ are small enough and $\|\sigma_D\nabla(u-u_h)\|_{L_\infty(\Omega)} \geq C\underline{h}^\epsilon \max_{T\in\mathcal{T}}\sigma_D(T)|u|_{C^{1,\nu}(\overline{T})}$ for some positive ν and ϵ. Then*

$$\begin{aligned}&\|\nabla(u-u_h)\|_{L_\infty(D)}\\ &\leq C_2\left(\frac{1+\epsilon}{\nu}\right)^{\gamma(n)}\ell_{\underline{h},n}\max_{T\in\mathcal{T}}\sigma_D(T)\mathcal{E}_T + C_1^3C_F\left(\frac{1+\epsilon}{\nu}\right)^{2\gamma(n)}\ell^3_{\underline{h},n}\max_{T\in\mathcal{T}}\mathcal{E}_T^2\\ &\leq C(C_1,C_2,\epsilon)\ell_{\underline{h}}\max_{T\in\mathcal{T}}(\sigma_D(T)\mathcal{E}_T + \mathcal{E}_T^2).\end{aligned} \tag{4.2}$$

Here C_1 and C_2 are as in Theorems 3.1 and 4.1, $\ell_{\underline{h}}$ is a generic logarithmic factor, and the term $\mathcal{E}_T^2$ may be dropped in the linear case.

As in the case of our global estimator, the constants C_1 and C_2 potentially make it difficult to apply (4.2) efficiently and accurately as an error estimator in the nonlinear case. Even if we only wish to apply (4.2) as an error indicator, it likely will be necessary in most situations to gain some knowledge of the relative sizes of C_1 and C_2 as the terms in (4.2) could be weighted improperly otherwise. As stated in the introduction, a purely theoretical determination of these constants appears difficult, and their investigation is the subject of ongoing work.

One application of (4.2) is the computation of a gradient at a single point $x_0 \in \Omega$ to within a given tolerance without requiring that ∇u_h approximate ∇u to the same tolerance globally (as would be the case if a global estimator were used). Here the localized estimate (4.2) is an alternative to the "dual weighted residual" approach of [BR01], which in this case essentially involves computing a finite element approximation to the discrete Green's function g^{x_0} and inserting this approximation (using appropriate methods such as difference quotients to approximate second derivatives) into the appropriate residual equation, which for linear problems is

$$|\partial(u-u_h)(x_0)| \le C \sum_{T\in\mathcal{T}} h_T \mathcal{E}_T |g^{x_0}|_{W_1^2(T)}.$$

Note that our localized analysis essentially involves bounding $|g^{x_0}|_{W_1^2(T)}$ a priori instead of a posteriori as in the dual residual method. Since more of the work is done ahead of time, so to speak, localized estimators may be applied more easily and over larger subdomains than dual estimators, but potentially at the expense of some sharpness and unknown constants as compared with the dual weighted residual method. The advantages of localized estimators are their lower computational cost (the local nature of the discrete Green's function is employed a priori instead of being computed a posteriori) and the fact that they can easily be applied over larger subdomains.

4.2. Efficiency of localized estimators. We shall show that our localized estimator is efficient (up to higher-order terms) in the linear case and in a certain sense also in the nonlinear case.

THEOREM 4.3. *Under the same conditions as are assumed in Theorem* 3.6,

$$\begin{aligned}\sigma_D(T)\mathcal{E}_T \le{}& \tilde{C}_1 \|\sigma_D \nabla(u-u_h)\|_{L_\infty(P_T)} + C\|h\sigma_D(\tilde{f}_h - P_h\tilde{f}_h)\|_{L_\infty(P_T)} \\ &+ C\|\sigma_D([u_h]-\tilde{P}[u_h])\|_{L_\infty(\partial T)}.\end{aligned} \tag{4.3}$$

Here $\tilde{C}_1 = \|a_{ij}^h\|_{L_\infty(\Omega)}$, *and* C *only depends on* $\mathcal{T}$.

Proof. To prove (4.3), we simply distribute the weight $\sigma_D(T)$ through (3.5) while noting that h and σ_D are always equivalent on adjacent elements (and in particular on P_T). ∎

Remark 4.4. In the linear case, (4.3) establishes immediately that up to higher-order terms,

$$\frac{1}{\tilde{C}_1} \max_{T\in\mathcal{T}} \sigma_D(T)\mathcal{E}_T \le \|\sigma_D\nabla(u-u_h)\|_{L_\infty(\Omega)} \le C_2 \beta^{\gamma(n)} \ell_{\underline{h},n} \max_{T\in\mathcal{T}} \sigma_D(T)\mathcal{E}_T.$$

In the nonlinear case, the perturbation term $\max_{T\in\mathcal{T}} \mathcal{E}_T^2$ "morally" should behave as $\|h_T\nabla(u-u_h)\|_{L_\infty(\Omega)}$, which is bounded by $\|\sigma_D\nabla(u-u_h)\|_{L_\infty(\Omega)}$. However, one would have to resort to a priori estimates to prove such a statement. Instead, we combine the global reliability and efficiency estimates (3.1) and (3.5) with the localized estimates (4.2) and (4.3) while consolidating constants and ignoring higher-order terms to yield

the estimate

$$\begin{aligned}\frac{1}{\overline{C}}\max_{T\in\mathcal{T}}(\sigma_D(T)\mathcal{E}_T+\mathcal{E}_T^2)&\le\|\sigma_D\nabla(u-u_h)\|_{L_\infty(\Omega)}+\|\nabla(u-u_h)\|^2_{L_\infty(\Omega)}\\&\le\overline{C}\ell_{\underline{h}}\max_{T\in\mathcal{T}}(\sigma_D(T)\mathcal{E}_T+\mathcal{E}_T^2).\end{aligned}$$

Thus the estimator $\max_{T\in\mathcal{T}}(\sigma_D(T)\mathcal{E}_T+\mathcal{E}_T^2)$ reliably and efficiently estimates the quantity $\|\sigma_D\nabla(u-u_h)\|_{L_\infty(\Omega)}+\|\nabla(u-u_h)\|^2_{L_\infty(\Omega)}$ instead of just the weighted norm $\|\sigma_D\nabla(u-u_h)\|_{L_\infty(\Omega)}$ as originally intended.

4.3. Proof of Theorem 4.1. First we assume that D is a single point $x_0\in\Omega$. We begin by picking a point $x_1\in\Omega$ and a first-order directional derivative ∂ such that $\|\sigma_{x_0}\nabla(u-u_h)\|_{L_\infty(\Omega)}\le C\sigma_{x_0}(x_1)|\partial(u-u_h)(x_1)|$. Here we have abused notation slightly by letting $\sigma_{x_0}(x_1)=\sigma_{x_0}(T_{x_1})$, where T_{x_1} is any element with $x_1\in\overline{T}_{x_1}$. Proceeding as in (3.7) while noting that $\|\sigma_{x_0}\|_{L_\infty(\Omega)}=1$, we obtain

$$\begin{aligned}\|\sigma_{x_0}\nabla(u-u_h)\|_{L_\infty(\Omega)}&\le C\sigma_{x_0}(x_1)|\partial(u-u_h)(x_1)|\\&\le C\sigma_{x_0}(x_1)(|(u-u_h,\partial\delta_{x_1})|+\underline{h}^{\alpha\beta}|u|_{C^{1,\alpha}(\overline{T_{x_1}})}).\end{aligned}\tag{4.4}$$

We now compute as in (3.10) and (3.11) that

$$\begin{aligned}|(u-u_h,\partial\delta_{x_1})|&\le|(A-A_h)(u-u_h,g^{x_1})|+|A_h(u-u_h,g^{x_1}-I_hg^{x_1})|\\&\le C_F\|\nabla(u-u_h)\|^2_{L_\infty(\Omega)}\|g^{x_1}\|_{W_1^1(\Omega)}\\&\quad+\sum_{T\in\mathcal{T}}\Bigg[\left\|f+\sum_{i=1}^n\frac{\partial}{\partial x_i}F_i(x,\nabla u_h)\right\|_{L_\infty(T)}\|g^{x_1}-I_hg^{x_1}\|_{L_1(T)}\\&\quad+\|[u_h]\|_{L_\infty(\partial T)}(h_T^{-1}\|g^{x_1}-I_hg^{x_1}\|_{L_1(T)}+\|\nabla(g^{x_1}-I_hg^{x_1})\|_{L_1(T)})\Bigg].\end{aligned}\tag{4.5}$$

Next we note that by shape regularity, the elements in P''_T are quasi-uniform. Also, the weight σ_{x_1} is equivalent to 1 on $P''_{T_{x_1}}$ and is always equivalent on adjacent elements. Using these facts, we then apply (2.2) along with (2.5) and (2.6) to obtain

$$\begin{aligned}&\sum_{T\in\mathcal{T}}\left\|f+\sum_{i=1}^n\frac{\partial}{\partial x_i}F_i(\cdot,\nabla u_h)\right\|_{L_\infty(T)}\|g^{x_1}-I_hg^{x_1}\|_{L_1(T)}\\&\quad+\|[u_h]\|_{L_\infty(\partial T)}(h_T^{-1}\|g^{x_1}-I_hg^{x_1}\|_{L_1(T)}+\|\nabla(g^{x_1}-I_hg^{x_1})\|_{L_1(T)})\\&\le\sum_{T\subset P''_{T_{x_1}}}\mathcal{E}_T\|g^{x_1}\|_{W_1^1(P_T)}\\&\quad+\sum_{T\cap P''_{T_{x_1}}=\emptyset}\frac{h_T}{\operatorname{dist}(x_1,T)+h_T}\mathcal{E}_T(\operatorname{dist}(x_1,T)+h_T)|g^{x_1}|_{W_1^2(P_T)}\\&\le C(\|g^{x_1}\|_{W_1^1(\Omega)}+\sum_{T\cap P'_{T_{x_1}}=\emptyset}(\operatorname{dist}(x_1,T)+h_T)|g^{x_1}|_{W_1^2(T)})\\&\quad\cdot\max_{T\in\mathcal{T}}\sigma_{x_1}(T)\mathcal{E}_T\\&\le C(\|g^{x_1}\|_{W_1^1(\Omega)}+\int_{\Omega\setminus P'_{T_{x_1}}}|x-x_1||D^2g^{x_1}|\,\mathrm{d}x)\max_{T\in\mathcal{T}}\sigma_{x_1}(T)\mathcal{E}_T.\end{aligned}\tag{4.6}$$

We next state the fundamental lemma in the proof of our localized estimate.

LEMMA 4.5. *If the conditions of Theorem* 4.1 *are satisfied, then for any* $x_1 \in \Omega$,

$$\int_\Omega |x - x_1||D^2 g^{x_1}(y)|\,\mathrm{d}x \le C_g' \beta^{\gamma(n)} \ell_{\underline{h},n}, \tag{4.7}$$

where C_g' *depends on* λ, Λ, $\|a_{ij}\|_{W^1_\infty(\Omega)}$, *and the constant* C_g *from Lemma* 3.8.

Assuming (4.7), we apply (3.9) and combine (4.4), (4.5), and (4.6) to find that

$$\begin{aligned}\|\sigma_{x_0}\nabla(u-u_h)\|_{L_\infty(\Omega)} \le \beta^{\gamma(n)}\ell_{\underline{h},n}[C_g' \max_{T\in\mathcal{T}} \sigma_{x_0}(T_{x_1})\sigma_{x_1}(T)\mathcal{E}_T \\ + C_F C_g \|\nabla(u-u_h)\|^2_{L_\infty(\Omega)}] + C\max_{T\in\mathcal{T}}\sigma_D(T)|u|_{C^{1,\alpha}(\overline{T})}.\end{aligned} \tag{4.8}$$

In order to complete our proof, we thus must show that for $T \in \mathcal{T}$,

$$\sigma_{x_0}(x_1)\sigma_{x_1}(T) \le \sigma_{x_0}(T). \tag{4.9}$$

We shall compute with the weight $\frac{h(x)}{|x_0-x|+h(x)}$, which is equivalent to but more convenient than $\sigma_{x_0}(x)$. Thus for any $T \in \mathcal{T}$ and $x_2 \in T$,

$$\begin{aligned}\sigma_{x_0}(x_1)\sigma_{x_1}(T) &\le C\frac{h(x_1)h(x_2)}{(|x_0-x_1|+h(x_1))(|x_1-x_2|+h(x_2))} \\ &= C\frac{h(x_2)}{|x_0-x_2|+h(x_2)}\frac{h(x_1)(|x_0-x_2|+h(x_2))}{(|x_0-x_1|+h(x_1))(|x_1-x_2|+h(x_2))} \\ &\le C\sigma_{x_0}(x_2)\frac{h(x_1)(|x_0-x_2|+h(x_2))}{(|x_0-x_1|+h(x_1))(|x_1-x_2|+h(x_2))}.\end{aligned} \tag{4.10}$$

Using the triangle inequality and noting from (2.2) that $h(x_1) \le C(|x_1-x_2|+h(x_2))$, we next compute that

$$\begin{aligned}&h(x_1)(|x_0-x_2|+h(x_2)) \\ &\quad\le h(x_1)(|x_0-x_1|+|x_1-x_2|+h(x_2)) \\ &\quad= h(x_1)|x_0-x_1| + h(x_1)(|x_1-x_2|+h(x_2)) \\ &\quad\le C(|x_1-x_2|+h(x_2))|x_0-x_1| + h(x_1)(|x_1-x_2|+h(x_2)).\end{aligned} \tag{4.11}$$

Noting that the expression above is bounded by C times the denominator of (4.10), we combine (4.10) and (4.11) to obtain (4.9). Inserting (4.9) into (4.8) completes the proof of (4.1) for $D = x_0$ assuming Lemma 4.5. Taking the maximum of (4.1) over $x_0 \in D$ while recalling (4.9) completes the proof of (4.1) for arbitrary $D \subset \Omega$.

In order to prove Lemma 4.5, we shall need the linear H^2_2 regularity result

$$\|g\|_{H^2_2(\Omega)} \le C_{reg}\|\partial\delta\|_{L_2(\Omega}, \tag{4.12}$$

where $C_{reg} = C(\lambda, \Lambda, \|a_{ij}\|_{W^1_\infty(\Omega)})$. This result is standard for smooth domains and may be found in [Gr85] for convex (including convex polyhedral) domains. Here and in what follows we suppress the dependence of g and δ on x_1.

We now decompose Ω into dyadic annuli. Let $\Omega_0 = B_{3\rho}(x_1)$, so that according to our definitions $\mathrm{dist}(supp(\delta), \partial\Omega_0) > C\rho$. We then define $d_j = 2^j 3\rho$, $j = 0, \dots, N$, $\tilde{\Omega}_j = \{x \in \mathbb{R}^n \text{ such that } d_{j-1} \le |x - x_1| \le d_j\}$, $\Omega_j = \tilde{\Omega}_j \cap \Omega$, and $\Omega_j' = \Omega_{j-1} \cup \Omega_j \cup \Omega_{j+1}$. Note that $\Omega = \bigcup_{j=0}^N \Omega_j$ with $N \le C\log(1/\rho)$. Finally, we let $\omega_j \in C_0^\infty(\tilde{\Omega}_{j-1} \cup \tilde{\Omega}_j \cup \tilde{\Omega}_{j+1})$ be a cutoff function which is 1 on $\tilde{\Omega}_j$ and which satisfies

$\|\omega_j\|_{W^k_\infty(\Omega)} \leq C d_j^{-k}$, $k = 0, 1, 2$. Then

$$\begin{aligned}\int_\Omega |x - x_1||D^2 g^{x_1}|\,\mathrm{d}x &\leq C d_1^{n/2+1}\|D^2 g\|_{L_2(\Omega_1')} + \sum_{i=2}^N d_j \|D^2 g\|_{L_1(\Omega_j)} \\ &\leq C_{reg}\rho^{n/2+1}\|\partial\delta\|_{L_2(\Omega)} + \sum_{i=2}^N d_j \|D^2(\omega_j g)\|_{L_1(\Omega)} \\ &\leq C_{reg} + \sum_{i=2}^N d_j \|D^2(\omega_j g)\|_{L_1(\Omega)}.\end{aligned} \tag{4.13}$$

Abusing notation slightly by letting A denote the matrix of coefficients $[a_{ij}]$, we compute that for $v \in H_0^1(\Omega)$ and $j > 1$,

$$\begin{aligned}A(v, \omega_j g) &= (v, -\operatorname{div}(A^*\nabla(\omega_j g))) \\ &= (v, -\operatorname{div}(A^*(g\nabla\omega_j + \omega_j \nabla g))) \\ &= (v, -g\operatorname{div}(A^*\nabla\omega_j) - A^*\nabla\omega_j \cdot \nabla g - A^*\nabla g \cdot \nabla\omega_j - \omega_j \operatorname{div}(A^*\nabla g)) \\ &= (v, -g\operatorname{div}(A^*\nabla\omega_j) - A^*\nabla\omega_j \cdot \nabla g - A^*\nabla g \cdot \nabla\omega_j - \omega_j\delta) \\ &= (v, -g\operatorname{div}(A^*\nabla\omega_j) - A^*\nabla\omega_j \cdot \nabla g - A^*\nabla g \cdot \nabla\omega_j)\end{aligned}$$

since ω_j and δ have disjoint support for $j > 1$. Then applying the regularity result (4.12) to $\omega_j g$, we find that

$$\|D^2(\omega_j g)\|_{L_2(\Omega)} \leq C_{reg}\|a_{ij}\|_{W^1_\infty(\Omega)} \left(\frac{1}{d_j^2}\|g\|_{L_2(\Omega_j')} + \frac{1}{d_j}\|\nabla g\|_{L_2(\Omega_j')}\right). \tag{4.14}$$

We then insert (4.14) into (4.13) while recalling (3.14) and (3.15) to find that for $n \geq 3$,

(4.15)

$$\begin{aligned}\int_\Omega |x - x_1|\,|D^2 g^{x_1}|\,\mathrm{d}x &\leq C(C_{reg} + \sum_{i=1}^N d_j^{n/2+1}\left(\frac{1}{d_j^2}\|g\|_{L_2(\Omega_j)} + \frac{1}{d_j}\|\nabla g\|_{L_2(\Omega_j)})\right) \\ &\leq C_{reg}\|a_{ij}\|_{W^1_\infty(\Omega)}\left(1 + \sum_{i=1}^N (d_j^{n-1}\|g\|_{L_\infty(\Omega_j)} + d_j^n\|\nabla g\|_{L_\infty(\Omega_j)})\right) \\ &\leq C_{reg}\|a_{ij}\|_{W^1_\infty(\Omega)} C_G\left(1 + \sum_{i=1}^N (d_j^{n-1}d_j^{1-n} + d_j^n d_j^{-n})\right) \\ &\leq C_{reg}\|a_{ij}\|_{W^1_\infty(\Omega)} C_G(1 + \log(1/\rho)) \\ &\leq C_{reg}\|a_{ij}\|_{W^1_\infty(\Omega)} C_G \beta \log(1/\underline{h}).\end{aligned}$$

When $n = 2$, an extra factor of $\log(1/\rho)$ enters the estimate (4.15) as before. Thus the proof of Lemma 4.5 is completed. □

5. Extension of results to the general quasilinear equation (1.1). In this section we outline the steps necessary to extend our results to operators of the form (1.1). We first consider the treatment of nonhomogeneous Dirichlet conditions in a model problem of the form (1.2), then we consider general operators of the form (1.1) with homogeneous boundary conditions.

5.1. Nonhomogeneous boundary conditions. We consider here the model problem (1.2), but now with the more general Dirichlet boundary condition $u = b$ on $\partial\Omega$ for some $b \in W^1_\infty(\Omega)$. We also assume that b_h is a piecewise linear finite element approximation to b and that u_h with $u_h - b_h \in S_h$ solves (2.1). The following is a corollary to Theorem 3.1 and Theorem 4.1.

COROLLARY 5.1. *Under the conditions of Theorem* 3.1*,*

$$\begin{aligned}\|\nabla(u-u_h)\|_{L_\infty(\Omega)} \le C_1\beta^{\gamma(n)}\ell_{\underline{h},n}[\max_{T\in\mathcal{T}}\mathcal{E}_T + C_F\|\nabla(u-u_h)\|^2_{L_\infty(\Omega)} \\ + \|\nabla(b-b_h)\|_{L_\infty(\Omega)}] + C\underline{h}^{\alpha\beta}|u|_{C^{1,\alpha}(\overline{\Omega})}.\end{aligned} \tag{5.1}$$

Under the conditions of Theorem 4.1*,*

$$\begin{aligned}&\|\nabla(u-u_h)\|_{L_\infty(D)} \\ &\quad\le \beta^{\gamma(n)}\ell_{\underline{h},n}[C_2\max_{T\in\mathcal{T}}\sigma_D(T)\mathcal{E}_T + C_1C_F\|\nabla(u-u_h)\|^2_{L_\infty(\Omega)}] \\ &\qquad + C_1\|(b-b_h)[dist(\cdot,D)+\underline{h}^\beta]^{-n}\|_{L_1(\partial\Omega)} \\ &\qquad + C\underline{h}^{\alpha\beta}\max_{T\in\mathcal{T}}\sigma_D(T)|u|_{C^{1,\alpha}(\overline{T})}.\end{aligned} \tag{5.2}$$

Sketch of Proof. We procede as in (3.7) through (3.10), then let $\vec{n}$ be the outward normal on $\partial\Omega$ and compute that for δ and g defined with respect to the point x_0,

$$(u-u_h,\partial\delta) = A(u-u_h,g) - \int_{\partial\Omega}(b-b_h)(A\nabla g\cdot\vec{n})\,\mathrm{d}\sigma. \tag{5.3}$$

To prove (5.1), we bound $A(u-u_h,g)$ precisely as before and compute

$$\begin{aligned}\left|\int_{\partial\Omega}(b-b_h)(A\nabla g\cdot\vec{n})\,\mathrm{d}\sigma\right| &= |(b-b_h,\partial\delta) - A(b-b_h,g)| \\ &\le |(\partial(b-b_h),\delta)| + \Lambda\|\nabla(b-b_h)\|_{L_\infty(\Omega)}\|\nabla g\|_{L_1(\Omega)}.\end{aligned} \tag{5.4}$$

and then apply (3.6) with $p=1$ and $k=1$ along with Lemma 3.8.

In order to prove (5.2), we let $x_0 \in D$ be such that $\|\nabla(u-u_h)\|_{L_\infty(D)} = |\nabla(u-u_h)(x_0)|$. Recall that δ_{x_0} may always be defined so that $dist(\mathrm{supp}(\delta),\partial\Omega) \ge c\rho$. A calculation similar to (3.14) then yields $|(A\nabla g\cdot\vec{n})(y)| \le C_1[|\rho+|x_0-y|]^{-n}$ for $y\in\partial\Omega$. Inserting this inequality into (5.3), recalling that $\rho = \underline{h}^\beta$, and bounding $A(u-u_h,g)$ as in (4.5) and following completes the proof. ∎

In [DR98] an a posteriori energy-norm bound is given which treats Dirichlet data in a fashion similar to (5.1). The term $\|(b-b_h)[dist(\cdot,D)+\underline{h}^\beta]^{-n}\|_{L_1(\partial\Omega)} \le Ch^{-1}\|b-b_h\|_{L_\infty(\partial\Omega)}$ in (5.2) is very similar to one appearing in the a priori estimates given in Theorem A.1 of [BTW03]. One may easily compute that

$$\|(b-b_h)[dist(\cdot,D)+\underline{h}^\beta]^{-n}\|_{L_1(\partial\Omega)} \le C\min(dist(D,\partial\Omega)^{-1},\underline{h}^{-\beta})\|b-b_h\|_{L_\infty(\partial\Omega)}. \tag{5.5}$$

If $D \subset\subset \Omega$ this term is thus of higher order, reflecting the localization of the error to D. If D abuts $\partial\Omega$, however, the term $\underline{h}^\beta$ leads to suboptimality if $\beta > 1$. (Note that this problem is not encountered in the a priori estimates of [BTW03] on quasi-uniform meshes, where $\underline{h}^\beta$ may be replaced by the mesh size h.) One may in this case instead estimate the error in approximating the Dirichlet data by $\|\nabla(b-b_h)\|_{L_\infty(\Omega)}$ as in (5.1), but this estimate does not reflect the more local nature of the error. Thus (5.2) could likely be improved, although it appears difficult to do so using the present techniques.

5.2. Theoretical comments on more general operators. We assume that u solves (1.1) with $u = 0$ on $\partial\Omega$. As before, we assume Ω to be convex and polygonal. We also assume that $u_h \in S_h$ satisfies

$$\int_\Omega \sum_{i=1}^n F_i(x, u_h, \nabla u_h) v_{h,x_i} + F_0(x, u_h, \nabla u_h) v_h \, \mathrm{d}x = 0, \ v_h \in S_h.$$

The essential linear auxiliary operators A and A_h defined in section 2.2 may be easily modified to aid in the analysis of problems of the form (1.1). Letting $F_{j0} = \frac{\partial}{\partial z} F_j(x, z, p)$ and $v_{x_0} = v$, we have for $i = 0, \ldots, n$ that

$$\begin{aligned} &F_i(x, u, \nabla u) - F_i(x, u_h, \nabla u_h) \\ &\quad = \sum_{j=0}^n \int_0^1 F_{ij}(x, u_h + t(u - u_h), \nabla u_h + t\nabla(u - u_h))(u - u_h)_{x_j} \, \mathrm{d}t. \end{aligned}$$

For $0 \le i, j \le n$, we then make the definitions

$$\begin{aligned} a_{ij}^h(x) &= \int_0^1 F_{ij}(x, u_h + t(u - u_h), \nabla(u_h + t\nabla(u - u_h)) \, \mathrm{d}t, \\ a_{ij}(x) &= F_{ij}(x, u, \nabla u), \\ A_h(v, w) &= \int_\Omega \sum_{i,j=0}^n a_{ij}^h(x) v_{x_j} w_{x_i} \, \mathrm{d}x, \\ A(v, w) &= \int_\Omega \sum_{i,j=0}^n a_{ij}(x) v_{x_j} w_{x_i} \, \mathrm{d}x. \end{aligned}$$

Note also that

$$|a_{ij}(x) - a_{ij}^h(x)| \le \sum_{k=0}^n \|F_{ijk}\|_{L_\infty} |(u - u_h)_{x_k}(x)|. \tag{5.6}$$

A and A_h as defined here differ from their previous incarnations mainly in that some lower-order terms are now included. (Note that summation indices now run from 0 to n instead of from 1 to n.) Finally, the residual $\mathcal{E}_T$ must be modified to reflect the presence of lower-order terms. Thus we now define

$$\mathcal{E}_T = h_T \left\| \sum_{i=1}^n \frac{\partial}{\partial x_i} F_i(\cdot, u_h, \nabla u_h) - F_0(\cdot, u_h, \nabla u_h) \right\|_{L_\infty(T)} + \|[u_h]\|_{L_\infty(\partial T)}.$$

The analytical assumptions of section 2 must be modified only slightly. We must still assume that the operator A is uniformly elliptic in Ω, a fact which may be established exactly as in seciton 2.2. Second, we must assume that A admits unique and sufficiently regular solutions for homogeneous Dirichlet problems. Note that establishing existence and uniqueness of solutions of such problems is potentially complicated by the presence of lower-order terms. In nonlinear problems, we must as before assume some regularity of u as well, although lower regularity may be required of u in the case of mildly nonlinear problems, as we show below. Next, the Green's function estimates of Lemma 2.3 must hold. [GW82] states such results only for divergence form operators with no lower-order terms, although the same techniques should apply when lower-order terms are present. Finally, the constant C_F arising in (2.12) must be bounded as before.

5.3. Example: A mildly nonlinear problem. Consider the mildly nonlinear problem

$$-\sum_{i,j=0}^{n}\frac{\partial}{\partial x_i}(\tilde{a}_{ij}(x,u)\frac{\partial u}{\partial x_j}) = f(x) \text{ in } \Omega, \qquad u = 0 \text{ on } \partial\Omega, \tag{5.7}$$

where we assume that the coefficients $F_i(x,u,\nabla u) = \sum_{j=1}^{n}\tilde{a}_{ij}(x,u)u_{x_j}$ satisfy the requirements outlined in the previous subsection. Note that the term $(A-A_h)(u-u_h,g)$ appearing in (3.10) and (4.5) of the proofs of Theorem 3.1 and Theorem 4.1 led there to a nonlinear perturbation error term of the form $\|\nabla(u-u_h)\|^2_{L_\infty(\Omega)}$. Since $F_i(x,u,\nabla u)$ now depends only linearly on ∇u, however, (5.6) yields

$$|a_{ij}-a^h_{ij}| \le C_F|u-u_h|$$

so that

$$|(A-A_h)(u-u_h,g)| \le C\|u-u_h\|_{L_\infty(\Omega)}\|\nabla(u-u_h)\|_{L_\infty(\Omega)}\|g\|_{W^1_1(\Omega)}.$$

Thus the nonlinear perturbation term is now of higher order than it generally is for approximations of u solving (1.1).

Using this observation, we may obtain estimates similar to, but often simpler than, those in Theorem 3.1, Corollary 3.5, and Theorem 4.1. We assume here that a nondegeneracy condition as outlined in Remark 3.2 is satisfied and that u possess sufficient regularity. First, analogous to Theorem 3.1 and Corollary 3.4, we find that if $\|u-u_h\|_{L_\infty(\Omega)}$ is small enough, then

$$\begin{aligned}&\|\nabla(u-u_h)\|_{L_\infty(\Omega)}\\ &\quad\le C_3\ell_{\underline{h},n}(\max_{T\in\mathcal{T}}\mathcal{E}_T + C_F\|u-u_h\|_{L_\infty(\Omega)}\|\nabla(u-u_h)\|_{L_\infty(\Omega)})\\ &\quad\le 2C_3\ell_{\underline{h},n}\max_{T\in\mathcal{T}}\mathcal{E}_T.\end{aligned}$$

Analogous to Corollary 3.5, we obtain for $\|\nabla(u-u_h)\|_{L_\infty(\Omega)}$ small enough that

$$\begin{aligned}\|u-u_h\|_{L_\infty(\Omega)} &\le C_4\ell_{\underline{h}}(\max_{T\in\mathcal{T}}h_T\mathcal{E}_T + C_F\|u-u_h\|_{L_\infty(\Omega)}\|\nabla(u-u_h)\|_{L_\infty(\Omega)})\\ &\le 2C_4\ell_{\underline{h}}\max_{T\in\mathcal{T}}h_T\mathcal{E}_T.\end{aligned} \tag{5.8}$$

Finally, we employ (5.8) and note that $h_T \le C\sigma_D(T)$ for $D\subset\Omega$ to find that for $\|\nabla(u-u_h)\|$ small enough,

$$\begin{aligned}&\|\sigma_D\nabla(u-u_h)\|_{L_\infty(\Omega)}\\ &\quad\le C_5\ell_{\underline{h},n}(\max_{T\in\mathcal{T}}\sigma_D(T)\mathcal{E}_T + C_F\|\nabla(u-u_h)\|_{L_\infty(\Omega)}\|u-u_h\|_{L_\infty(\Omega)})\\ &\quad\le C_5\ell_{\underline{h},n}(\max_{T\in\mathcal{T}}\sigma_D(T)\mathcal{E}_T + C_F\|\nabla(u-u_h)\|_{L_\infty(\Omega)}C_4\ell_{\underline{h}}\max_{T\in\mathcal{T}}h_T\mathcal{E}_T)\\ &\quad\le C_5\ell_{\underline{h},n}\max_{T\in\mathcal{T}}\sigma_D(T)\mathcal{E}_T(1 + C_F\|\nabla(u-u_h)\|_{L_\infty(\Omega)}C_4\ell_{\underline{h}})\\ &\quad\le 2C_5\ell_{\underline{h},n}\max_{T\in\mathcal{T}}\sigma_D(T)\mathcal{E}_T.\end{aligned} \tag{5.9}$$

Since the coefficients of the dual linear operator A now have essentially the same regularity as u instead of as ∇u, the constants C_3, C_4, and C_5 above depend more weakly on the regularity of u than do the corresponding constants in Theorem 3.1, Corollary 3.5, and Theorem 4.1. Indeed, C_3 depends on $\|u\|_{L_\infty(\Omega)}$ and the Dini-continuity of u as opposed to C_1 from Theorem 3.1, which depends on $\|\nabla u\|_{L_\infty(\Omega)}$

and the Dini-continuity of ∇u. C_4 and C_5 depend only on $\|u\|_{W^1_\infty(\Omega)}$ as opposed to $\tilde{C}$ and C_2 from Corollary 3.5 and Theorem 4.1, which both depend on $\|u\|_{W^2_\infty(\Omega)}$. We also note that (5.8) and (5.9) only require that $u \in C^{1,\nu}(\overline{\Omega})$ for some $\nu > 0$ in order to hold, whereas the corresponding estimates in Corollary 3.5 and Theorem 4.1 require $u \in W^2_\infty(\Omega)$.

Acknowledgments. The author would like to thank Gerhard Dziuk and two anonymous referees for their many helpful comments.

MAXIMUM PRINCIPLE AND CONVERGENCE ANALYSIS FOR THE MESHFREE POINT COLLOCATION METHOD*

DO WAN KIM† AND WING KAM LIU‡

Abstract. The discrete Laplacian operator is considered in the sense of the meshfree point collocation method which will be called the strong meshfree Laplacian operator. To define the strong meshfree Laplacian operator, we use the fast version of the generalized moving least square approximation, which can calculate the approximated derivatives of shape functions. Some types of the locally layered node distribution are defined in this paper, and two specific domains are constructed onto which we can distribute locally layered nodes. At such nodes, the discrete maximum principle can be shown to hold through the representation formula for the strong meshfree Laplacian operator. The discrete maximum principle, together with the reproducing property of the meshfree approximations, results in an a priori estimate for the strong meshfree Laplacian operator in the nodal solution space. Furthermore, the a priori estimate we have obtained guarantees the existence and the uniqueness of the numerical solution and plays a central role in achieving converged results for the Poisson problem with Dirichlet boundary conditions in the nodal solution space. The order of convergence of the nodal solutions can be raised up to $O(h^2)$ at the proposed type of nodes in specific domains. For generally shaped domains immersed in the previously mentioned domains, we can obtain the first order convergence result of $O(h)$.

1. Introduction.

In the field of numerical computations, meshfree methods have been developed for more than a decade. In order to solve many physical problems represented by partial differential equations, researchers and scientists have proposed meshfree approximations, examples of which include the element free Galerkin method [3], the moving least square reproducing kernel method [10, 17], the partition of unity finite element method [2], the reproducing kernel hierarchical partition of unity [11, 12, 13, 15], the reproducing kernel element method [14, 16, 18, 20], etc.

The above pioneering work has presented a common framework for meshfree methodologies and shown the potential of meshfree methods. In many cases, the work in meshfree fields has been based on the weak formulation of the model equation, but only a few papers supply the mathematical convergence for numerical solutions in the one-dimensional (1-D) case [2, 12].

In this paper, we focus on uniform convergence analysis for the numerical solution of the strong formulation using a meshfree approximation. Here we use the generalized moving least square approximation for efficient calculation of higher order

shape function derivatives, which stem from the reproducing kernel hierarchical partition of unity method by Li and Liu [11, 12], and from the fast moving least square reproducing kernel approximation method by D. W. Kim and Y. Kim [8, 9]. Such approximations are desired to convert the higher order differential operator into a discrete one by attacking the strong formulation and utilizing the point collocation method. The meshfree point collocation method (MPCM) follows the philosophy of the meshfree method in which no structured meshes are used.

In mathematical analyses of the Galerkin formulation using meshfree approximations, difficulties arise mainly in the treatment of Dirichlet boundary conditions. The construction of a test function space which belongs to the Sobolev space $H_0^1(\Omega)$ is a challenging issue in meshfree Galerkin formulations, particularly for higher dimensions. However, once one can overcome this difficulty, then the remaining part of the convergence analysis follows similarly from the mathematical theories of the finite element method. For the finite element method, uniform convergence has been shown by Ciarlet and Raviart [4] for second order elliptic models under some specially shaped meshes. To achieve first order uniform convergence, they used the discrete maximum principle and obtained an a priori estimate for the discrete solution of the Poisson-type problem. For local pointwise error estimates in finite element methods, one can see the important results for second order elliptic problems in [5] written by L. B. Wahlbin.

The meshfree point collocation methods, in contrast to the Galerkin formulation, have few mathematical results, as the theory of function spaces is not directly available. Thus, the objective of this paper is to build the underlying theories for the MPCM, particularly for the discrete Laplacian operator, and based on those theories to prove uniform convergence of the nodal solutions of the Poisson problem with Dirichlet boundary conditions. For the convergence estimate in the MPCM, the first step is to define the rigorous point collocation scheme—an important portion of the mathematical analysis. Next, we will show that the discrete Laplacian operator satisfies the discrete maximum principle for some classes of nodes, and then obtain an a priori estimate for the strong meshfree Laplacian operator on the nodal solution space, provided the discrete maximum principle holds.

As for the discrete maximum principle itself, many researchers are interested in cases in which it occurs and their applications [1, 4, 7, 19, 21, 22]. The discrete maximum principle for the discretized Laplacian operator in the finite difference method on evenly spaced grid points is well-known and is closely related to the mean-value property for the Laplace solutions. This means that the average value on the surrounding four points in a five-point stencil for the Laplacian operator is equal to the center value. Inspired by the difference scheme for the Laplacian operator in the finite difference method, we can obtain the representation formula at each node for the strong meshfree Laplacian operator which is followed by the discrete maximum principle.

As a result of the discrete maximum principle, an a priori estimate for the strong meshfree Laplacian is derived in the nodal solution space. The a priori estimate guarantees the existence and the uniqueness of the numerical solution governed by the point collocation scheme. We finally achieve convergence for the numerical solutions of the Poisson problem with Dirichlet boundary conditions. The convergence order can be up to second order on some specific domains, while we have first order convergence for general domains immersed in the specific domains.

We know that finite difference methods and finite element methods have discrete maximum principle for elliptic partial differential equations. However, for meshfree

strong form collocation methods, the authors are not aware of any previous theoretical results. This is an important aspect, and this is the first paper to the authors knowledge that deals with the theoretical foundation of the meshfree collocation method.

2. Generalized moving least square reproducing kernel approximation. To make this paper self-contained, we will describe how to obtain the meshfree approximation of the Laplacian operator. For a moment, we will make general statements on the moving least square reproducing kernel approximation as we can see similar content in the literature [8, 11, 12].

Let Ω be a bounded domain in $\mathbb{R}^n$ and also $\Lambda \equiv \{\mathbf{x}_I \in \overline{\Omega} \,|\, I = 1, \ldots, N\}$ where Λ is a set of distributed nodes in $\overline{\Omega}$. Throughout the paper, the multi-index notation and related definitions are employed as follows:

$$\alpha = (\alpha_1, \ldots, \alpha_n), \quad |\alpha| \equiv \sum_{i=1}^{n} \alpha_i, \quad \alpha! \equiv \alpha_1! \alpha_2! \cdots \alpha_n!, \tag{2.1}$$

$$\mathbf{x} = (x_1, \ldots, x_n) \in \mathbb{R}^n, \quad \mathbf{x}^\alpha \equiv x_1^{\alpha_1} \ldots x_n^{\alpha_n}, \quad D^\alpha_{\mathbf{x}} \equiv \partial^{\alpha_1}_{x_1} \ldots \partial^{\alpha_n}_{x_n}, \tag{2.2}$$

where α_k's are nonnegative integers and α is called the multi-index. We consider a vector of complete basis functions of order m in $\mathbb{R}^n$ such that

$$\mathbf{B}_m(\mathbf{x}) = (b_{\beta_1}(\mathbf{x}), b_{\beta_2}(\mathbf{x}), \ldots, b_{\beta_L}(\mathbf{x}))^T, \quad |\beta_k| \leq m, \tag{2.3}$$

where β_k's are all multi-indices in lexicographical order. Here we note that the number of β_k's is $L \equiv \frac{(m+n)!}{m!n!}$ and the complete basis of order m means that the $L \times L$ matrix $J_{\mathbf{B}_m}(\mathbf{0})$ is invertible if we define the Jacobian of $\mathbf{B}_m(\mathbf{x})$ at $\mathbf{0}$ as

$$J_{\mathbf{B}_m}(\mathbf{0}) \equiv \lim_{\mathbf{x} \to \mathbf{0}} \left(D^\alpha_{\mathbf{x}} \, b_\beta(\mathbf{x}) \right), \quad |\alpha|, |\beta| \leq L. \tag{2.4}$$

Let $B_r(\mathbf{z}) \equiv \{\mathbf{y} \,|\, \|\mathbf{y} - \mathbf{z}\| < r\}$ be the r-ball in $\mathbb{R}^n$ with center $\mathbf{z}$. We introduce the continuous nonnegative window function with its support on $\overline{B_1(\mathbf{0})}$ of the following type

$$W(\mathbf{x}) = (1 - \|\mathbf{x}\|^{\frac{1}{2}})^2 \quad \text{for} \quad \|\mathbf{x}\| < 1, \, \mathbf{x} \in \mathbb{R}^n \tag{2.5}$$

and the continuous positive dilation function

$$\rho(\mathbf{x}) > 0 \quad \text{on} \quad \overline{\Omega}. \tag{2.6}$$

For brevity, we will use $\rho_{\mathbf{x}}$ instead of $\rho(\mathbf{x})$.

Remark 1. The decreasing rate of the window function values apart from the origin is essential in proving the discrete maximum principle for the strong meshfree Laplacian operator introduced in a later section. The window function of the form (2.5) meets this decreasing rate. The support of the window function in this paper has the n-dimensional unit ball shape.

Remark 2. The dilation parameter used in most meshfree methods can be replaced with the dilation function defined on the whole domain $\overline{\Omega}$. The required regularity for the dilation function is only the continuity to be well defined when the center of window function moves to the evaluation point. The dilation function controls the support and its size of shape functions, and thus is directly available to the geometrically multiple scale problems [9].

The subsequent procedure to make the shape functions and the approximated derivative operators is addressed in detail in Appendix I. This includes the generalized

reproducing properties of meshfree shape functions and the proposal of a sufficient condition to regenerate the dilated basis functions. These are novel differences from the standard moving least square reproducing kernel approximation.

From this point forward, we restrict our attention to polynomial basis functions; that is, if there is no comment, then the basis functions will be maintained as complete polynomials up to order m

$$\mathbf{B}_m(\mathbf{x}) = (\mathbf{x}^{\beta_1}, \mathbf{x}^{\beta_2}, \ldots, \mathbf{x}^{\beta_L}), \quad |\beta_k| \le m \tag{2.7}$$

throughout the mathematical analysis.

For the subsequent analysis, we require the definition of the proper node distributions.

DEFINITION 1 (proper triple). *Let $(\Omega, \Lambda, \rho_{\mathbf{x}})$ be the triple of a domain, a set of distributed nodes on $\overline{\Omega}$, and a dilation function. The triple $(\Omega, \Lambda, \rho_{\mathbf{x}})$ is said to be proper if the moment matrix $M^{\rho_{\mathbf{x}}}(\mathbf{x}_I)$ is invertible for every interior node $\mathbf{x}_I \in \Lambda \cap \Omega$ under the dilation function $\rho_{\mathbf{x}}$.*

This definition is preventive of the degenerate distribution of nodes to approximate functions in the meshfree method.

3. Problem statement and the definition of the discrete problem. We will now consider the discretization of the Poisson problem as the popular model in the second order elliptic problem with Dirichlet boundary conditions and prepare the terminology for its convergence analysis. The Poisson equation uses the Laplacian operator, the principal operator in most physical models. Furthermore, the Laplacian is an interesting operator in itself, since it has the salient feature referred to as the maximum principle. Many mathematical theories have been developed based on this property. Among them, the regularity and the uniqueness of solutions of the Poisson equation is highly involved with the maximum principle. For the discrete case analogous to the continuous one, the discrete maximum principle has been reported not only for the Galerkin formulation [4] in the finite element method but also for the solution of some algebraic systems [7].

We consider the Poisson problem with Dirichlet data on the boundary of a domain Ω and propose the corresponding discrete problem using the point collocation approach based on the generalized meshfree approximation operators described in the previous section and Appendix I in detail. The model problem considered in this paper is governed by the following equations:

$$(\mathbf{CP}) \begin{cases} \Delta u = f, & \text{in } \Omega \\ u = g, & \text{on } \Gamma, \end{cases} \tag{3.1}$$

where $\Gamma \equiv \partial\Omega$ represents the boundary of the open bounded domain Ω. According to Theorem 6.13 in [6] for the general existence and regularity of a unique solution of (**CP**), if Ω is a bounded domain satisfying an exterior sphere condition at every boundary point and we have $f \in C^{s-2,\,\alpha}(\Omega)$ for $s = 3, 4$ and $g \in C(\partial\Omega)$, then the Dirichlet problem (**CP**) has a unique solution $u \in C^0(\overline{\Omega}) \cap C^{s,\,\alpha}(\Omega)$, where $C^0(\overline{\Omega})$ is the vector space to consist of all bounded and uniformly continuous functions on Ω and $C^{s,\alpha}(\Omega)$ represents the Hölder space of exponent $0 < \alpha \le 1$ equipped with the norm

$$\|v\|_{C^{s,\alpha}(\Omega)} \equiv \max_{0 \le |\beta| \le s} \sup_{\mathbf{x} \in \Omega} |D^\beta v(\mathbf{x})| + \max_{0 \le |\beta| \le s} \sup_{\mathbf{x},\mathbf{y} \in \Omega, \mathbf{x} \ne \mathbf{y}} \frac{|D^\beta v(\mathbf{x}) - D^\beta v(\mathbf{y})|}{|\mathbf{x} - \mathbf{y}|^\alpha}. \tag{3.2}$$

To discretize the problem (**CP**) in terms of meshfree point collocation method, we focus on the second order meshfree approximation ($m = 2$); that is, the complete polynomial basis functions up to second order are adopted to obtain all the shape functions (see Appendix I). It is taken to satisfy the minimum order of consistency for the discretization of second order partial differential equations since we approximate the Laplace operator in a pointwise manner. Higher order approximation could be better than the second order one in general but, since the focus in this paper is on analyzing the structure of the meshfree Laplace operator, the second order meshfree approximation must be the starting point. We also consider the 2-D space ($n = 2$) and hence the relevant multi-index $\beta_k\,(k = 1, \ldots, 6)$ appearing in the basis polynomials (2.7) which are fixed in lexicographical order as follows:

$$(0,0), \quad (1,0), \quad (0,1), \quad (2,0), \quad (1,1), \quad (0,2). \tag{3.3}$$

The analysis in this paper is expected to hold for the higher dimensions as well as for higher orders. It could depend on the construction of the local nodes and the adequate dilation function.

In order to define the discrete counterpart of the continuous problem (3.1), we assume Λ is a set of well distributed nodes on the domain Ω and its boundary, so that $(\Omega, \Lambda, \rho_{\mathbf{x}})$ becomes the proper triple. Let $C(\overline{\Omega})$ be the space of continuous functions up to the boundary of Ω, and V be the finite dimensional space of functions defined on Λ. We will call the function space V the nodal solution space if V is equipped with the following seminorm:

$$\|v\|_{\infty,A} \equiv \max_{\mathbf{x}_K \in A} |v_K| \quad \text{when} \quad v \in V, \tag{3.4}$$

where A is a nonempty subset of Λ. In the case when $A = \Lambda$, the seminorm becomes the norm on V.

If the restriction map $i : C(\overline{\Omega}) \to V$ to Λ is defined such that, for any $u \in C(\overline{\Omega})$,

$$i(u)(\mathbf{x}_I) \equiv u(\mathbf{x}_I) \quad \text{for any } \mathbf{x}_I \in \Lambda, \tag{3.5}$$

then the point collocation Laplacian operator Δ^ρ can be defined on V into itself such that if $v \in V$, then

$$(\Delta^\rho v)(\mathbf{x}_I) \equiv \sum_{\mathbf{x}_J \in \Lambda} v(\mathbf{x}_J)\, \psi_J^{\Delta}(\mathbf{x}_I) \quad \text{for any } \mathbf{x}_I \in \Lambda, \tag{3.6}$$

where the function $\psi_J^{\Delta}(\mathbf{x}_I)$ will be called the Laplacian shape function at $\mathbf{x}_I$ and is defined by

$$\psi_J^{\Delta}(\mathbf{x}_I) \equiv \psi_J^{[(2,0)]}(\mathbf{x}_I) + \psi_J^{[(0,2)]}(\mathbf{x}_I) \tag{3.7}$$

which is the sum of the $(2,0)$th and $(0,2)$th approximate derivatives whose definition comes from (7.3) in Appendix I. In fact, the operator Δ^ρ stems from the meshfree approximated Laplacian operators $D^{(2,0)}_{m,\rho_{\mathbf{x}}} + D^{(0,2)}_{m,\rho_{\mathbf{x}}} \sim \Delta$. Hereafter, we will often use the symbol u_J instead of $u(\mathbf{x}_J)$ if $u \in V$ and $\mathbf{x}_J \in \Lambda$.

Using these operators i and Δ^ρ, we define the meshfree point collocation discretization of Poisson problem (**CP**) as the following:

$$u_h \in V \,:\, \begin{cases} \Delta^\rho u_h = i(f), & \text{on } \Lambda^o \\ u_h = g, & \text{on } \Lambda^b \end{cases}, \tag{3.8}$$

where $\Lambda = \Lambda^o \cup \Lambda^b$ and Λ^o and Λ^b are sets of interior nodes and Dirichlet boundary nodes, respectively. Consequently, our discrete problem for (**CP**) results in finding the nodal solution $u_h \in V$ such that

$$(\mathbf{DP}) \begin{cases} u_h \in V_g \equiv \{v_J \in \mathbb{R} \,|\, v_K = g(\mathbf{x}_K) \text{ for all } \mathbf{x}_K \in \Lambda^b\} \subset V \\ \Delta^\rho u_h = i(f), \quad \text{on } \Lambda^o. \end{cases} \tag{3.9}$$

This final formulation will be called *the discrete Poisson problem* (**DP**) and the operator Δ^ρ will be called *the strong meshfree Laplacian operator*.

In order to attain the error estimate, we begin discussion of the discrete maximum principle for the strong meshfree Laplacian operator Δ^ρ.

4. Discrete maximum principle for the strong meshfree Laplacian operator $\boldsymbol{\Delta^\rho}$. Let $(\Omega, \Lambda, \rho_{\mathbf{x}})$ be the proper triple. For convenience sake, the r-neighbor nodes of $\mathbf{x}$ are assumed to be the following set:

$$\Lambda_r(\mathbf{x}) \equiv \{\mathbf{x}_K \in \Lambda \,|\, \mathbf{x}_K \in B_r(\mathbf{x})\}, \quad r > 0 \tag{4.1}$$

and the symbol A^* for a subset $A \subset \Lambda$ implies the set defined by

$$A^* \equiv \bigcup_{\mathbf{x}_J \in A} \Lambda_{\rho_{\mathbf{x}_J}}(\mathbf{x}_J). \tag{4.2}$$

If there is no confusion, we briefly write $\Lambda(\mathbf{x}_K)$ instead of $\Lambda_{\rho_{\mathbf{x}_K}}(\mathbf{x}_K)$ for any node $\mathbf{x}_K \in \Lambda$.

We now state the definition of the discrete maximum principle.

DEFINITION 2 (discrete maximum principle for the operator Δ^ρ). *Assume the proper triple $(\Omega, \Lambda, \rho_{\mathbf{x}})$ is given. We will say the strong meshfree Laplacian Δ^ρ satisfies the discrete maximum principle at a node $\mathbf{x}_I \in \Lambda$ if the condition $(\Delta^\rho v)(\mathbf{x}_I) \geq 0$ for $v \in V$ implies that either $v_I < \max_{\mathbf{x}_K \in \Lambda(\mathbf{x}_I) \setminus \{\mathbf{x}_I\}} v_K$ or $v_K = v_I$ for all $\mathbf{x}_K \in \Lambda(\mathbf{x}_I)$. We also will say the operator Δ^ρ satisfies the discrete maximum principle on a subset $A \subset \Lambda$ if it satisfies the discrete maximum principle at all nodes in A.*

In fact, the discrete maximum principle for the discrete Laplace operator is known to depend on the geometry of the mesh in the finite element method and the orthogonal grid in the finite difference method, respectively. For example, if all the angles of the triangles of the triangulation on a domain are less than or equal to $\frac{\pi}{2}$, then the discrete maximum principle is known to hold in the finite element method [4]. Hence it can also be expected that the relative attitude between nodes strongly affects this kind of phenomenon in the meshfree area. Therefore, we are interested in finding such node distributions from the meshfree point of view. On the other hand, to perform the convergence analysis on such nodes, we have to inspect closely the moment matrix and its inverse, since it is located in the core of Laplacian shape functions in (3.7).

The moment matrix for the given set Λ of nodes has the following form in the generalized moving least square reproducing kernel approximation [17] (see also (7.5) in Appendix I)

$$M^{\rho_{\mathbf{x}}}(\mathbf{x}) = \sum_{\mathbf{x}_I \in \Lambda} \mathbf{B}_m \left(\frac{\mathbf{x}_I - \mathbf{x}}{\rho_{\mathbf{x}}} \right) \mathbf{B}_m^T \left(\frac{\mathbf{x}_I - \mathbf{x}}{\rho_{\mathbf{x}}} \right) W \left(\frac{\mathbf{x}_I - \mathbf{x}}{\rho_{\mathbf{x}}} \right), \tag{4.3}$$

where $\mathbf{B}_m \left(\frac{\mathbf{y} - \mathbf{x}}{\rho_{\mathbf{x}}} \right)$ is the normalized basis polynomial up to order m at the center

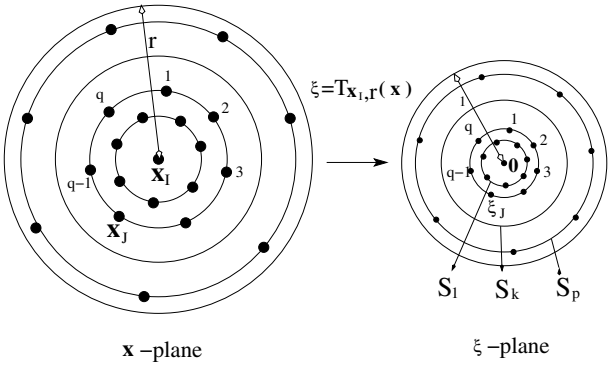

FIG. 4.1. *The locally (p,q)-layered nodes ($\mathbf{x}$-plane) and the normalizing ones (ξ-plane) by $T_{\mathbf{x}_I,r}(\mathbf{x})$. S_K's are the layers of the normalized nodes.*

point $\mathbf{x} \in B_{\rho_{\mathbf{x}}}(\mathbf{x})$ such that

$$\mathbf{B}_m\left(\frac{\mathbf{y}-\mathbf{x}}{\rho_{\mathbf{x}}}\right) = \left(\left(\frac{\mathbf{y}-\mathbf{x}}{\rho_{\mathbf{x}}}\right)^{\beta_1}, \left(\frac{\mathbf{y}-\mathbf{x}}{\rho_{\mathbf{x}}}\right)^{\beta_2}, \ldots, \left(\frac{\mathbf{y}-\mathbf{x}}{\rho_{\mathbf{x}}}\right)^{\beta_L}\right), \quad |\beta_k| \le m. \tag{4.4}$$

To calculate the moment matrix and its inverse concretely, we need to focus on some class of node distributions. In order to define some classes of nodes, we must first introduce the normalizing transformation $T_{\mathbf{x},r}(\mathbf{y}) : B_r(\mathbf{x}) \to B_1(\mathbf{0})$ such that, as shown in Figure 4.1,

$$\xi = T_{\mathbf{x},r}(\mathbf{y}) \equiv \frac{\mathbf{y}-\mathbf{x}}{r}. \tag{4.5}$$

DEFINITION 3 (layered node distribution). *Let $A_r(\mathbf{x}_I) \equiv \{\mathbf{x}_K \,|\, \mathbf{x}_K \in B_r(\mathbf{x}_I)\}$ be the finite subset of nodes within the distance r around $\mathbf{x}_I$. The set of nodes $A_r(\mathbf{x}_I)$ is said to be the locally (p,q)-layered at $\mathbf{x}_I$ if all the normalized nodes in $T_{\mathbf{x}_I,r}(A_r(\mathbf{x}_I))$ remain on the p-layer sets $S_1, \ldots, S_p$ in the increasing radial direction from the origin and the q nodes are distributed evenly on each layer. All the layer sets S_k's have the spherical shape only. Furthermore, we say that the node set Λ is possibly layered if, for any interior node $\mathbf{x}_I \in \Lambda$, $\Lambda(\mathbf{x}_I)$ is the locally (p,q)-layered at $\mathbf{x}_I$ for some $p,q > 0$.*

As a matter of fact, the possibly layered distribution of nodes is not a simple matter since the property of the locally (p,q)-layered at every neighboring node has to be achieved. Thus, we will propose two kinds of available distribution of nodes and show that they are the possibly layered. On such types of the possibly layered nodes, the discrete maximum principle for the strong meshfree Laplacian will be proven.

We begin with the calculation of the moment matrix that will play an essential role in proving the discrete maximum principle on some possibly layered nodes. If the subset of nodes $\Lambda(\mathbf{x}_I) \subset \Lambda$ is the locally (p,q)-layered at $\mathbf{x}_I$, then the moment matrix at $\mathbf{x}_I$ can be calculated from the following manner:

$$M^{\rho_{\mathbf{x}}}(\mathbf{x}_I) = W(\mathbf{0})\,\mathbf{B}_m(\mathbf{0})\mathbf{B}_m(\mathbf{0})^T + \sum_{K=1}^{p} \delta_K\,\mathbf{D}_K \left(\sum_{\xi_J \in S_K} \mathbf{B}_m(\zeta_J)\mathbf{B}_m(\zeta_J)^T\right) \mathbf{D}_K, \tag{4.6}$$

where S_K is the Kth layer set in the definition and for any nonzero $\xi_J \in S_K$ we use the symbols

$$\xi_J \equiv T_{\mathbf{x}_I}(\mathbf{x}_J), \quad \tau_K \equiv |\xi_1| = \cdots = |\xi_q| < 1, \quad \zeta_J \equiv \frac{\xi_J}{\tau_K}, \tag{4.7}$$

$$\delta_K \equiv W(\xi_1) = \cdots = W(\xi_q), \tag{4.8}$$

and $\mathbf{D}_K$ is the diagonal matrix such that

$$\mathbf{D}_K \equiv \mathrm{Diag}(\tau_K^{|\alpha_1|}, \tau_K^{|\alpha_2|}, \ldots, \tau_K^{|\alpha_L|}). \tag{4.9}$$

Since we have assumed $n = 2$, we have, without loss of generality, the ζ_J's distributed evenly on the layer S_K and represented by

$$\zeta_j = \left(\cos\left(\theta_K + j\,\frac{2\pi}{q}\right), \sin\left(\theta_K + j\,\frac{2\pi}{q}\right)\right), \quad j = 0, 1, \ldots, q-1, \tag{4.10}$$

where θ_K is the angle of the starting node ζ_1 on S_K. If the distribution of nodes around $\mathbf{x}_I$ is assumed to be the locally (p, q)-layered at $\mathbf{x}_I$, then, from the trigonometric identities in Appendix II, the term $\sum_{\xi_J \in S_K} \mathbf{B}(\zeta_J)\mathbf{B}(\zeta_J)^T$ in (4.6) has the following forms for the cases when $q = 4$ and $q \geq 5$:

- $\sum_{\xi_J \in S_K} \mathbf{B}(\zeta_J)\mathbf{B}(\zeta_J)^T$ when $q = 4$,

$$4\begin{bmatrix} 1 & 0 & 0 & \frac{1}{2} & 0 & \frac{1}{2} \\ 0 & \frac{1}{2} & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{2} & 0 & 0 & 0 \\ \frac{1}{2} & 0 & 0 & \frac{3}{8} + \frac{1}{8}\cos 4\theta_K & \frac{1}{8}\sin 4\theta_K & \frac{1}{8} - \frac{1}{8}\cos 4\theta_K \\ 0 & 0 & 0 & \frac{1}{8}\sin 4\theta_K & \frac{1}{8} - \frac{1}{8}\cos 4\theta_K & -\frac{1}{8}\sin 4\theta_K \\ \frac{1}{2} & 0 & 0 & \frac{1}{8} - \frac{1}{8}\cos 4\theta_K & -\frac{1}{8}\sin 4\theta_K & \frac{3}{8} + \frac{1}{8}\cos 4\theta_K \end{bmatrix}; \tag{4.11}$$

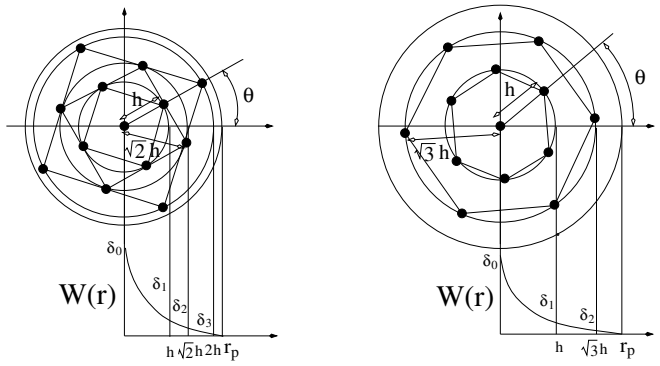
- $\sum_{\xi_J \in S_K} \mathbf{B}(\zeta_J)\mathbf{B}(\zeta_J)^T$ when $q \geq 5$

$$q\begin{bmatrix} 1 & 0 & 0 & \frac{1}{2} & 0 & \frac{1}{2} \\ 0 & \frac{1}{2} & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{2} & 0 & 0 & 0 \\ \frac{1}{2} & 0 & 0 & \frac{3}{8} & 0 & \frac{1}{8} \\ 0 & 0 & 0 & 0 & \frac{1}{8} & 0 \\ \frac{1}{2} & 0 & 0 & \frac{1}{8} & 0 & \frac{3}{8} \end{bmatrix}. \tag{4.12}$$

Here we note that, if the number of nodes on the layer S_K is greater than or equal to 5, then the moment matrix does not depend on θ_K. This means that the (p, q)-layered node distributions for $q \geq 5$ makes the rotation invariant moment matrix.

The strong meshfree Laplacian operator Δ^ρ at $\mathbf{x}_I$ on the (p, q)-layered node set $\Lambda(\mathbf{x}_I)$ can be calculated from the equivalent form:

$$\begin{aligned} \sum_{\mathbf{x}_J \in \Lambda(\mathbf{x}_I)} u_h(\mathbf{x}_J)\, \psi_J^{\Delta}(\mathbf{x}_I) &= \mathbf{d}_\Delta\, M^{\rho\star}(\mathbf{x}_I)^{-1}\, \mathbf{B}_m(\mathbf{0})\, W(\mathbf{0})\, u_h(\mathbf{0}) \\ &+ \mathbf{d}_\Delta\, M^{\rho\star}(\mathbf{x}_I)^{-1} \sum_{K=1}^{p} \delta_K\, \mathbf{D}_K \left[\mathbf{B}_m\left(\zeta_1^K\right)\ \mathbf{B}_m\left(\zeta_2^K\right)\ \cdots\ \mathbf{B}_m\left(\zeta_q^K\right)\right] \mathbf{u}_h^K, \end{aligned} \tag{4.13}$$



(I) Type I : Locally (p, 4)–layered nodes p = 2, 3 (II) Type II : Locally (p, 6)–layered nodes p = 1, 2

FIG. 4.2. *Two types of locally* (p, q)*-layered node distribution:* (I) *the set of Type* I *and,* (II) *the set of Type* II.

where $\mathbf{u}_h^K \equiv [u_h(\xi_1^K), \ldots, u_h(\xi_q^K)]^T$ is a column vector, the superscript of ξ_J^K means that ξ_J is on S_K, and when $m = 2$ the symbol $\mathbf{d}_\Delta$ designates the following row vector:

$$\mathbf{d}_\Delta \equiv \left[0,\ 0,\ 0,\ \frac{(2,0)!}{\rho_{\mathbf{x}_I}^{|(2,0)|}},\ 0,\ \frac{(0,2)!}{\rho_{\mathbf{x}_I}^{|(0,2)|}}\right]. \tag{4.14}$$

We now consider the two kinds of locally (p, q)-layered node distributions. The first one is composed of orthogonally positioned nodes and the other comes from a hexagonal structure.

In constructing specific types of nodes, we use the symbol δ_K as defined in (4.8) including $\delta_0 \equiv W(0) = 1$, or equivalently we have $\delta_K \equiv W(\tau_K)$ since our window function W in (2.5) depends only on the radial values. The terminology of the multi-index β_k defined in (3.3) is also utilized.

Let $h > 0$ and θ be the given angle.

4.1. Type I: The locally $(p, 4)$-layered nodes $(p = 2, 3)$. Let $A_{r_p}(\mathbf{0})$ be the set consisting of the following nodes as shown in Figure 4.2(I):

$$\{(0,0)\} \cup \bigcup_{K=1}^{p} \left\{ \left(t_K\, h\, \cos\left(\theta_K + i\,\frac{2\pi}{4}\right),\ t_K\, h\, \sin\left(\theta_K + i\,\frac{2\pi}{4}\right) \right) \,\middle|\, i = 0, 1, 2, 3 \right\}, \tag{4.15}$$

where $t_K = \sqrt{2}^{K-1}$, $\theta_K = \theta + (K-1)\frac{\pi}{4}$, and

$$r_p = h\,\frac{\sqrt{2}+2}{2},\ h\,\frac{2+\sqrt{5}}{2},\ \text{respectively when } p = 2, 3. \tag{4.16}$$

If A is a subset of nodes with $\mathbf{x}_I$ as its center node and it has the same property as $A_{r_p}(\mathbf{0})$ for $p = 2, 3$ under the normalizing transform (4.5), then it is said to be *the set of Type I at the node* $\mathbf{x}_I$. In this case, the values of τ_K's in (4.7) are calculated as the following:

$$\tau_K = \frac{h\, t_K}{r_p}, \quad 1 \le K \le p = 2, 3. \tag{4.17}$$

When $p = 3$, the determinant of the moment matrix in (4.6) at the center node can be calculated such as

$$|M^{r_p}(\mathbf{0})| = 2^6 \tau_1^{2\sum_{k=1}^{6}|\beta_k|}\, \delta_2\,(\delta_1 + 2\,\delta_2 + 4\,\delta_3)^2\,(\delta_1 + 16\,\delta_3)\,A_R \neq 0, \tag{4.18}$$

where the symbol A_R stands for the following positive value:

$$A_R = \delta_1 + 4\,\delta_2 + 16\,\delta_3 + 4\,\delta_1\delta_2 + 16\,\delta_2\delta_3 + 36\,\delta_1\delta_3. \tag{4.19}$$

When $p = 2$, we may simply set $\delta_3 = 0$.

On this kind of local node distribution, the strong meshfree Laplacian operator at the origin is calculated from the equation (4.13) as follows:

$$\psi^{\Delta}_{\mathbf{0}}(\mathbf{0}) = -\frac{4}{h^2}\,\frac{\delta_0\,(\delta_1 + 2\,\delta_2 + 4\,\delta_3)}{A_R}, \tag{4.20}$$

$$\psi^{\Delta}_{\xi_J \in S_1}(\mathbf{0}) = \frac{1}{h^2}\,\frac{\delta_1\,(1 - 4\,\delta_2 - 12\,\delta_3)}{A_R} \equiv \frac{1}{h^2}\,A_1, \tag{4.21}$$

$$\psi^{\Delta}_{\xi_J \in S_2}(\mathbf{0}) = \frac{1}{h^2}\,\frac{2\,\delta_2\,(1 + 2\,\delta_1 - 4\,\delta_3)}{A_R} \equiv \frac{1}{h^2}\,A_2, \tag{4.22}$$

$$\psi^{\Delta}_{\xi_J \in S_3}(\mathbf{0}) = \frac{1}{h^2}\,\frac{4\,\delta_3\,(1 + 3\,\delta_1 + 2\,\delta_2)}{A_R} \equiv \frac{1}{h^2}\,A_3, \tag{4.23}$$

where S_K $(K = 1, 2, 3)$ is the Kth layer and there are 4-nodes on each S_K. Therefore, from (4.20), (4.21), (4.22), and (4.23) and the fact that $A_1 + A_2 + A_3 = \frac{\delta_1 + 2\,\delta_2 + 4\,\delta_3}{A_R}$ since $\delta_0 \equiv W(\mathbf{0}) = 1$, we have, for any $v \in V$,

$$h^2 \sum_{\mathbf{x}_J \in A_r(\mathbf{0})} v(\mathbf{x}_J)\,\psi^{\Delta}_J(\mathbf{0}) = \sum_{k=1}^{3} A_k \left(-4\,v(\mathbf{0}) + \sum_{\xi_J \in S_k} v(\xi_J) \right). \tag{4.24}$$

If we set $\delta_3 = 0$ in the above formula, then we obtain the case when $p = 2$. With these types of nodes, the moment matrix depends on the rotation of nodes (θ) but the discrete Laplacian shape function $\psi^{\Delta}_J(\mathbf{0})$ is invariant under the rotation.

Summarizing the above discussion, we have the following lemma on the set of Type I at $\mathbf{x}_I$.

LEMMA 1. *Let $(\Omega, \Lambda, \rho_{\mathbf{x}})$ be a proper triple and $\Lambda(\mathbf{x}_I) \subset \Lambda$ be the set of Type I at the node $\mathbf{x}_I$. Then we have the following properties:*

1. *The following representation formula for the strong meshfree Laplacian operator holds:*

$$\sum_{\mathbf{x}_J \in \Lambda(\mathbf{x}_I)} v(\mathbf{x}_J)\,\psi^{\Delta}_J(\mathbf{x}_I) = \frac{1}{h^2} \sum_{K=1}^{p} A_K \left(-4\,v(\mathbf{x}_I) + \sum_{\xi_J \in S_K} v(\xi_J) \right) \tag{4.25}$$

for some coefficients A_K which depend on the window function.

2. *If the coefficients A_K are positive, then the following type of inverse inequality for the Laplacian shape functions holds:*

$$\sum_{\mathbf{x}_J \in \Lambda(\mathbf{x}_I)} \left|\, \psi^{\Delta}_J(\mathbf{x}_I) \,\right| \leq \frac{8}{h^2}. \tag{4.26}$$

Proof. The first property directly comes from (4.24). For the second property, if $A_K > 0$ for $K = 1, \ldots, p$ where $p = 2, 3$, then we have the following bound from (4.20), (4.21), (4.22), and (4.23):

$$\sum_{\mathbf{x}_J \in \Lambda(\mathbf{x}_I)} \left|\psi_J^{\Delta}(\mathbf{x}_I)\right| = -\psi_I^{\Delta}(\mathbf{x}_I) + \sum_{\mathbf{x}_J \in \Lambda(\mathbf{x}_I)\setminus\{\mathbf{x}_I\}} \psi_J^{\Delta}(\mathbf{x}_I) = \frac{8}{h^2} \sum_{K=1}^{p} A_K \le \frac{8}{h^2} \tag{4.27}$$

since $\psi_I^{\Delta}(\mathbf{x}_I)$ is the only nonpositive term among $\psi_J^{\Delta}(\mathbf{x}_I)$ for all J, $\mathbf{x}_J \in \Lambda(\mathbf{x}_I)$. ∎

4.2. Type II: The locally $(p, 6)$-layered nodes ($p = 1, 2$). Let $A_{r_p}(\mathbf{0})$ be the set consisting of the following nodes as shown in Figure 4.2(II):

$$\{(0,0)\} \cup \bigcup_{K=1}^{p} \left\{ \left(t_K\, h\, \cos\left(\theta_K + i\,\frac{2\pi}{6}\right),\ t_K\, h\, \sin\left(\theta_K + i\,\frac{2\pi}{6}\right) \right) \,\middle|\, i = 0, 1, 2, 3, 4, 5 \right\}, \tag{4.28}$$

where $t_K = \sqrt{3}^{K-1}$, $\theta_K = \theta + (K-1)\frac{\pi}{6}$, and

$$r_p = h\frac{\sqrt{3}^{p-1} + \sqrt{3}^{p}}{2}, \quad p = 1, 2. \tag{4.29}$$

If A is a subset of nodes with $\mathbf{x}_I$ as its center node and it has the same property as $A_{r_p}(\mathbf{0})$ for $p = 1, 2$ under the normalizing transform (4.5), then it is said to be *the set of Type II at the node* $\mathbf{x}_I$. Here, we can see that

$$\tau_K = \frac{h\, t_K}{r_p}, \quad 1 \le K \le p = 1, 2. \tag{4.30}$$

When $p = 2$, the determinant of the moment matrix in (4.6) at the center node in this case can be calculated as follows:

$$|M^{r_p}(\mathbf{0})| = 3^5 \tau_1^{\,2} \sum_{k=1}^{6} |\beta_k| \,(\delta_1 + 3\,\delta_2)^2 (\delta_1 + 9\,\delta_2)^2\, A_H \neq 0, \tag{4.31}$$

where the symbol A_H means the following positive value:

$$A_H = \delta_1 + 9\,\delta_2 + 24\,\delta_1\delta_2. \tag{4.32}$$

In the case when $p = 1$, we can set $\delta_2 = 0$.

On this kind of local node distribution, the strong meshfree Laplacian operator at the origin is derived from (4.13) as follows:

$$\psi_{\mathbf{0}}^{\Delta}(\mathbf{0}) = -\frac{4}{h^2}\,\frac{\delta_0\,(\delta_1 + 3\,\delta_2)}{A_H}, \tag{4.33}$$

$$\psi_{\xi_J \in S_1}^{\Delta}(\mathbf{0}) = \frac{1}{h^2}\,\frac{\frac{2}{3}\delta_1\,(1 - 12\,\delta_2)}{A_H} \equiv \frac{1}{h^2} A_1, \tag{4.34}$$

$$\psi_{\xi_J \in S_2}^{\Delta}(\mathbf{0}) = \frac{1}{h^2}\,\frac{2\delta_2\,(1 + 4\,\delta_1)}{A_H} \equiv \frac{1}{h^2} A_2, \tag{4.35}$$

where $S_K\,(K = 1, 2)$ is the Kth layer and there are 6-nodes in each S_K. Thus, from (4.33), (4.34), (4.35), and the identity $A_1 + A_2 = \frac{\frac{2}{3}(\delta_1 + 3\,\delta_2)}{A_H}$, we also obtain, for any $v \in V$,

$$h^2 \sum_{\mathbf{x}_J \in A_r(\mathbf{0})} v(\mathbf{x}_J)\, \psi_J^{\Delta}(\mathbf{0}) = \sum_{k=1}^{2} A_k \left(-6\, v(\mathbf{0}) + \sum_{\xi_J \in S_k} v(\xi_J) \right). \tag{4.36}$$

In the case when $p = 1$, we can only set $\delta_2 = 0$.

Summarizing the above discussion, on the set of Type II at $\mathbf{x}_I$, we have the following lemma similar to Lemma 1.

LEMMA 2. *Let $(\Omega, \Lambda, \rho_{\mathbf{x}})$ be a proper triple and $\Lambda(\mathbf{x}_I) \subset \Lambda$ be the set of Type II at the node $\mathbf{x}_I$. Then we have the following properties:*

1. *The following representation formula for the strong meshfree Laplacian operator holds:*

$$\sum_{\mathbf{x}_J \in \Lambda(\mathbf{x}_I)} v(\mathbf{x}_J)\, \psi_J^{\Delta}(\mathbf{x}_I) = \frac{1}{h^2} \sum_{K=1}^{p} A_K \left(-6\, v(\mathbf{x}_I) + \sum_{\xi_J \in S_K} v(\xi_J) \right) \tag{4.37}$$

for some coefficients A_K which depend on the window function.

2. *If the coefficients A_K are positive, then the following inverse inequality for the Laplacian shape functions holds:*

$$\sum_{\mathbf{x}_J \in \Lambda(\mathbf{x}_I)} \left| \psi_J^{\Delta}(\mathbf{x}_I) \right| \le \frac{8}{h^2}. \tag{4.38}$$

Proof. The proof is similar to that in Lemma 1, so we omit the proof. ∎

Remark 3. The set of Type I and Type II belong to the locally $(p, 4)$-layered and locally $(p, 6)$-layered class, respectively. The significant feature of the set of Type I and Type II nodes is the staggered distribution of nodes across layers. Particularly, in the case of Type I, it is essential for the invertibility of the moment matrix at the center node since the matrix (4.11) derived from the nodes in each layer is singular with kernel dimension 1. However, in the case of Type II, the nodes do not have to be staggered through layers since one can see the nonsingular matrix (4.12) is independent of the attitude of nodes in each layer. Hence, Type II is more natural than Type I in the meshfree approximation.

4.3. Two possibly layered node distributions on specific domains. We propose two kinds of evenly spaced nodes on some domains. The size, the rotation, and the translation of the domain we are to construct are not critical in the subsequent analysis (i.e., the subsequent analysis is independent of the similarity transfromation).

As shown in Figure 4.3(a), we first consider the open square domain Ω_R with 4 vertices at

$$(1, 1),\ (-1, 1),\ (-1, -1),\ (1, -1). \tag{4.39}$$

In this case, the nodes can be distributed on $\overline{\Omega_R}$ to be Type I (i.e., staggered locally $(p, 4)$-layered $(p = 2, 3)$) at each interior node. The set of such nodes on Ω_R is written by the symbol Λ_R.

As depicted in Figure 4.3(b), the hexagonal domain Ω_H with the six vertices located at

$$(1, 0),\ \left(\frac{1}{2}, \frac{\sqrt{3}}{2}\right),\ \left(-\frac{1}{2}, \frac{\sqrt{3}}{2}\right),\ (-1, 0),\ \left(-\frac{1}{2}, -\frac{\sqrt{3}}{2}\right),\ \left(\frac{1}{2}, -\frac{\sqrt{3}}{2}\right) \tag{4.40}$$

is taken as the second open domain. On the domain $\overline{\Omega_H}$, the nodes can be entirely distributed to be Type II (i.e., locally $(p, 6)$-layered $(p = 1, 2)$) at each interior node. Such a set of nodes is denoted by Λ_H.

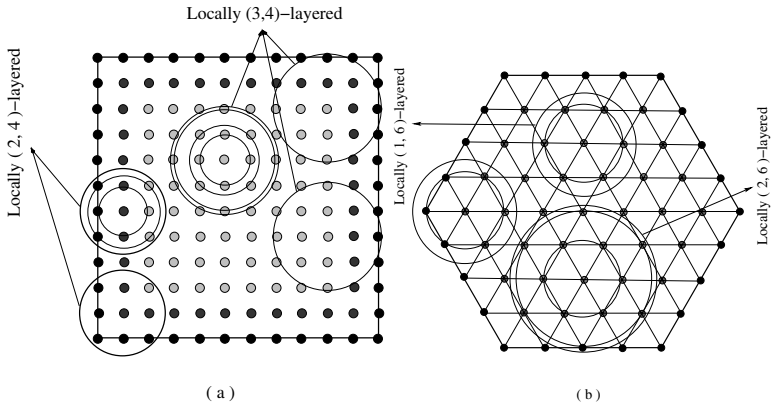


FIG. 4.3. *Possibly layered node distribution:* (*a*) Ω_R, *and* (*b*) Ω_H.

In both cases, the minimum node distance is set by $h \equiv \frac{2}{n}$ where n is regarded as the number of divisions. Now, we determine the dilation function $\rho_{\mathbf{x}}$ for each case. We only need the values of $\rho_{\mathbf{x}}$ at nodes. First of all, we notice that the value $\rho_{\mathbf{x}_I}$ at each node $\mathbf{x}_I$ on Λ_R (or Λ_H) depends on how we take the p number in the locally (p,q)-layered set $\Lambda(\mathbf{x}_I)$ at $\mathbf{x}_I$. As illustrated in Figure 4.3(a) and (b), we choose them in the following way:

$$\rho^R_{\mathbf{x}_I} = \begin{cases} h\,\frac{\sqrt{2}+2}{2}, & \mathbf{x}_I \notin \partial\Omega_R,\ \mathrm{dist}(\mathbf{x}_I, \partial\Omega_R) < \frac{3}{2}h \\ h\,((3-p)\frac{\sqrt{2}+2}{2} + (p-2)\frac{2+\sqrt{5}}{2}), & \mathbf{x}_I \notin \partial\Omega_R,\ \mathrm{dist}(\mathbf{x}_I, \partial\Omega_R) \geq \frac{3}{2}h \end{cases}, \tag{4.41}$$

$$\rho^H_{\mathbf{x}_I} = \begin{cases} h\,\frac{1+\sqrt{3}}{2}, & \mathbf{x}_I \notin \partial\Omega_H,\ \mathrm{dist}(\mathbf{x}_I, \partial\Omega_H) < \frac{3}{2}h \\ h\,((2-p)\frac{1+\sqrt{3}}{2} + (p-1)\frac{\sqrt{3}+3}{2}), & \mathbf{x}_I \notin \partial\Omega_H,\ \mathrm{dist}(\mathbf{x}_I, \partial\Omega_H) \geq \frac{3}{2}h \end{cases} \tag{4.42}$$

in which $\mathrm{dist}(\mathbf{x}_I, B) \equiv \min_{\mathbf{y}\in B} \|\mathbf{x}_I - \mathbf{y}\|$ represents the distance between $\mathbf{x}_I$ and the closed set B as usual and $p = 2, 3$ and $p = 1, 2$, respectively, in (4.41) and (4.42). The dilation function values on the interior nodes, taken by (4.41) and (4.42), make the node sets Λ_R and Λ_H be the possibly layered. Furthermore, every $\Lambda_{\rho_{\mathbf{x}_I}}(\mathbf{x}_I)$ for interior node $\mathbf{x}_I$ becomes the set of Type I or Type II at $\mathbf{x}_I$.

On the boundary nodes for both cases, the dilation function values can be assigned arbitrarily but they must be large enough to ensure the inverse of the moment matrices at the nodes themselves. Actually, the dilation function values on the boundary nodes do not affect the subsequent theorems for the convergence proof.

From the construction of two triples, namely, $(\Omega_R, \Lambda_R, \rho^R_{\mathbf{x}})$ and $(\Omega_H, \Lambda_H, \rho^H_{\mathbf{x}})$, we can see that both Λ_R and Λ_H are the possibly layered and hence the two triples become the proper triples attributed to (4.24) and (4.36). Although we could not say how many possibly layered node distributions exist, we find at least two types of the possibly layered set of nodes.

4.4. Discrete maximum principle on the set of Type I or Type II. For these locally (p,q)-layered nodes of Type I and Type II, we should pay attention to the discretized form (4.24) and (4.36). If the window function is suitably chosen so that all the coefficients A_k may be strictly positive, then we can prove the discrete maximum principle at the center node.

LEMMA 3. *Let* $(\Omega, \Lambda, \rho_{\mathbf{x}})$ *be the triple. If the local node set* $\Lambda(\mathbf{x}_I) \subset \Lambda$ *is of either Type I or Type II at* $\mathbf{x}_I$*, then the strong meshfree Laplacian operator* Δ^{ρ} *satisfies the*

discrete maximum principle at the center node $\mathbf{x}_I$.

Proof. Let $\mathbf{x}_I \in \Lambda$ be the center node of $\Lambda(\mathbf{x}_I)$ that is either Type I or Type II at $\mathbf{x}_I$. Then the set $\Lambda(\mathbf{x}_I)$ is obviously the locally (p,q)-layered where $p = 2, 3$ for $q = 4$ or $p = 1, 2$ for $q = 6$. The discrete Laplacian shape functions have been calculated in (4.24) and (4.36) for both cases. First, we will show that all the coefficients A_K of the representation formula in Lemmas 1 and 2 are strictly positive. In the case of Type I which is the $(p,4)$-layered, we claim that, when $p = 3$,

$$1 - 4\,\delta_2 - 12\,\delta_3 > 0, \quad 1 + 2\,\delta_1 - 4\,\delta_3 > 0, \quad 1 + 3\,\delta_1 + 2\,\delta_2 > 0 \tag{4.43}$$

and, when $p = 2$,

$$1 - 4\,\delta_2 > 0, \quad 1 + 2\,\delta_1 > 0. \tag{4.44}$$

If $\delta_2 < \frac{1}{16}$ and $\delta_3 < \frac{1}{36}$, then all the left terms in (4.43) stay positive. Indeed, when $p = 3$, from (4.17) we have $\delta_2 = W(\frac{2\sqrt{2}}{2+\sqrt{5}}) < \frac{1}{16}$ and $\delta_3 = W(\frac{4}{2+\sqrt{5}}) < \frac{1}{36}$. In the other case when $p = 2$, it is true from (4.17) that $\delta_2 = W(\frac{2\sqrt{2}}{2+\sqrt{2}}) < \frac{1}{16}$. Therefore, we are done with the proof for the case of the locally $(p,4)$-layered nodes $(p = 2, 3)$.

On the other hand, when $\Lambda(\mathbf{x}_I)$ is of Type II which is the locally $(p,6)$-layered, all the coefficients A_1 and A_2 of the representation formula in Lemma 2 are positive since we know from (4.30) that $\delta_2 = W(\frac{2\sqrt{3}}{3+\sqrt{3}}) < \frac{1}{16}$ when $p = 2$. For the case when $\Lambda(\mathbf{x}_I)$ is the locally $(1,6)$-layered at $\mathbf{x}_I$, we trivially have $A_1 > 0$.

Let $\Lambda(\mathbf{x}_I)$ be the set of Type I or Type II at $\mathbf{x}_I \in \Lambda$ as mentioned in this Lemma. To prove the discrete maximum principle, suppose $(\Delta^\rho v)(\mathbf{x}_I) \geq 0$ for some $v \in V$. Due to the window function of type (2.5), the coefficients A_i in Lemmas 1 or 2 are proved to be positive in the above. From the positivity of the coefficients of the representation formula in both Lemmas 1 and 2, it never happens under this assumption that the center nodal value v_I of v at $\mathbf{x}_I$ is strictly greater than all the other nodal values v_K at the node $\mathbf{x}_K \in \Lambda_{\rho_{\mathbf{x}_I}}(\mathbf{x}_I)$ and therefore we have

$$v_I \leq \max_{\mathbf{x}_K \in \Lambda(\mathbf{x}_I) \setminus \{\mathbf{x}_I\}} v_K. \tag{4.45}$$

If the equality holds, then the event $v_I > v_K$ for some $\mathbf{x}_K, K \neq I$ makes $(\Delta^\rho v)(\mathbf{x}_I) < 0$. Hence, all v_K's must be equal to v_I. Therefore, the operator Δ^ρ satisfies the discrete maximum principle at the node $\mathbf{x}_I$ and this completes the proof. ∎

4.5. A priori estimate for the strong meshfree Laplacian operator. For the set of nodes on which the discrete maximum principle holds, we can obtain the general results in the meshfree regime.

LEMMA 4. *Let* $(\Omega, \Lambda, \rho_{\mathbf{x}})$ *be a proper triple. Assume the operator* Δ^ρ *satisfies the discrete maximum principle on a finite subset* $A \subset \Lambda$. *Then we have the following inequality:*

$$\max_{\mathbf{x}_J \in A} v_J \leq \max_{\mathbf{x}_K \in A^* \setminus A} v_K \tag{4.46}$$

whenever $v \in V$ *and* $\Delta^\rho v \geq 0$ *on* A.

Proof. Let us assume $v \in V$ and $\Delta^\rho v \geq 0$ on A. Suppose the maximum of nodal values over A occurs at the node $\mathbf{x}_{K^*} \in A$; that is,

$$v_{K^*} = \max_{\mathbf{x}_J \in A} v_J. \tag{4.47}$$

Then only two cases are possible. The first case is when $\Lambda(\mathbf{x}_{K^*})\backslash A \neq \emptyset$. In this case, from the maximum principle we have nothing to prove. In the other case, we have $\Lambda(\mathbf{x}_{K^*}) \subset A$. For this case, all v_K's in $\Lambda(\mathbf{x}_{K^*})$ are the same as v_{K^*}. If we set $A_0 \equiv \Lambda(\mathbf{x}_{K^*})$, then we can construct the set $A_1 \equiv A_0^*$ strictly larger that A_0 (i.e., A_1 contains at least one node not in A_0). If $A_1\backslash A \neq \emptyset$, then this lemma is proved. If not, all coefficients v_K in A_1 must have the same value v_{K^*}. Continuing this process, we can construct $A_2 = A_1^*, A_3 = A_2^*, \ldots$. However, this process has to stop in a number of finite steps since the number of nodes in A is finite. Therefore, we have proven this lemma. ∎

THEOREM 1 (a priori estimate for the strong meshfree Laplacian operator). *Let $(\Omega, \Lambda, \rho_{\mathbf{x}})$ be a proper triple. Assume the strong meshfree Laplacian operator Δ^ρ satisfies the discrete maximum principle on a finite subset $A \subset \Lambda$. Then, we have the following a priori estimate*

$$\|v\|_{\infty,A} \leq C(A)\,\|\Delta^\rho v\|_{\infty,A} + \|v\|_{\infty,A^*\backslash A} \quad \textit{whenever} \quad v \in V, \tag{4.48}$$

where $C(A) = \min_{\mathbf{x}_*} \max_{\mathbf{x}_L \in A^*\backslash A} \frac{1}{4}\|\mathbf{x}_L - \mathbf{x}_*\|^2$.

Proof. Let $v \in V$ be assumed to be the nodal function on Λ. Then from the definition of the strong meshfree Laplacian Δ^ρ, we have

$$(\Delta^\rho v)(\mathbf{x}_K) = \sum_{\mathbf{x}_J \in \Lambda} v_J\, \psi_J^{\Delta}(\mathbf{x}_K), \quad \mathbf{x}_K \in A. \tag{4.49}$$

Obviously we see that

$$-\|\Delta^\rho v\|_{\infty,A} \leq (\Delta^\rho v)(\mathbf{x}_K) \leq \|\Delta^\rho v\|_{\infty,A} \quad \text{for any} \quad \mathbf{x}_K \in A. \tag{4.50}$$

Owing to the reproducing property for polynomials up to second order, we have, for any $\mathbf{x}_K \in A$,

$$\Delta^\rho \left(\|\Delta^\rho v\|_{\infty,A}\, i\left(\frac{1}{4}\|\mathbf{x} - \mathbf{x}_*\|^2\right)\right) = \sum_{\mathbf{x}_J \in \Lambda} \left(\|\Delta^\rho v\|_{\infty,A}\, \frac{1}{4}\|\mathbf{x}_J - \mathbf{x}_*\|^2 \right) \psi_J^{\Delta}(\mathbf{x}) \tag{4.51}$$

$$= \|\Delta^\rho v\|_{\infty,A}, \tag{4.52}$$

where $\mathbf{x}_*$ is an arbitrary point. The first equality (4.51) comes from the definition of the operator Δ^ρ on V. The last identity (4.52) enables us to derive the following inequalities due to (4.50). For any $\mathbf{x}_K \in A$,

$$\sum_{\mathbf{x}_J \in \Lambda} \left[v_J + \left(\|\Delta^\rho v\|_{\infty,A}\, \frac{1}{4}\|\mathbf{x}_J - \mathbf{x}_*\|^2 \right)\right] \psi_J^{\Delta}(\mathbf{x}_K) \geq 0, \tag{4.53}$$

$$\sum_{\mathbf{x}_J \in \Lambda} \left[-v_J + \left(\|\Delta^\rho v\|_{\infty,A}\, \frac{1}{4}\|\mathbf{x}_J - \mathbf{x}_*\|^2 \right)\right] \psi_J^{\Delta}(\mathbf{x}_K) \geq 0. \tag{4.54}$$

From the discrete maximum principle (4.46) in Lemma 4 and both inequalities (4.53) and (4.54), we can conclude that

$$v_K \leq \max_{\mathbf{x}_L \in A^*\backslash A} \left(v_L + \left(\|\Delta^\rho v\|_{\infty,A}\, \frac{1}{4}\|\mathbf{x}_L - \mathbf{x}_*\|^2 \right)\right), \tag{4.55}$$

$$-v_K \leq \max_{\mathbf{x}_L \in A^*\backslash A} \left(-v_L + \left(\|\Delta^\rho v\|_{\infty,A}\, \frac{1}{4}\|\mathbf{x}_L - \mathbf{x}_*\|^2 \right)\right) \tag{4.56}$$

for all $\mathbf{x}_K \in A$. Therefore, the following estimate holds:

$$|v_K| \le \max_{\mathbf{x}_L \in A^* \setminus A} |v_L| + \max_{\mathbf{x}_L \in A^* \setminus A} \left(\|\Delta^\rho v\|_{\infty, A} \frac{1}{4} \|\mathbf{x}_L - \mathbf{x}_*\|^2 \right). \tag{4.57}$$

This completes the proof. ∎

5. Error estimate for Poisson problem on specific domains Ω_R and Ω_H. From here, we will achieve the convergence of the numerical solutions using the meshfree point collocation approach (**DP**) in (3.1) for the Poisson equation with Dirichlet data on two specific domains—Ω_R and Ω_H. Through the convergence proof, we can also understand the basic phenomena on the strong meshfree Laplacian operator and can view the structure of the meshfree approximations.

For the numerical solution of the problem (**DP**), the meshfree point collocation scheme is proposed in the manner of (3.9). The existence and uniqueness of the numerical solutions of (**DP**) follows immediately from the a priori estimate in Theorem 1.

THEOREM 2 (existence and uniqueness). *Assume that* $(\Omega, \Lambda, \rho_{\mathbf{x}})$ *is either* $(\Omega_R, \Lambda_R, \rho_{\mathbf{x}}^R)$ *or* $(\Omega_H, \Lambda_H, \rho_{\mathbf{x}}^H)$. *Then there exists the unique solution of the problem* (**DP**) *on* V.

Proof. Let us introduce the linear mapping $\widehat{\Delta^\rho} : V \to V$ defined by

$$(\widehat{\Delta^\rho}\, v)(\mathbf{x}_K) \equiv \begin{cases} (\Delta^\rho v)(\mathbf{x}_K), & \mathbf{x}_K \in \Lambda^o \\ v_K, & \mathbf{x}_K \in \Lambda^b \end{cases} \quad \text{for all } v \in V, \tag{5.1}$$

where $\Lambda^o \equiv \Lambda \cap \Omega$ and $\Lambda^b \equiv \Lambda \setminus \Lambda^o$. Then our discrete problem (**DP**) is equivalent to the following:

$$\text{find } v \in V \text{ such that } \quad \widehat{\Delta^\rho}\, v = \begin{cases} i(f) & \text{on } \Lambda^o \\ g & \text{on } \Lambda^b \end{cases}. \tag{5.2}$$

Since Λ is the possibly layered, the discrete maximum principle holds on Λ^o. Applying the a priori estimate in Theorem 1 to the problem (5.2), we have

$$\|v\|_{\infty, \Lambda \cap \Omega} \le C \, \|i(f)\|_{\infty, \Lambda \cap \Omega} + \|g\|_{\infty, \Lambda \cap \partial\Omega}. \tag{5.3}$$

We claim that the linear mapping $\widehat{\Delta^\rho}$ is one-to-one and onto. It suffices to show that the mapping is one-to-one since solution space V has finite dimension.

Suppose $\widehat{\Delta^\rho}\, v = \mathbf{0}$. This means that f and g become zero on the right-hand side of (5.3). Consequently, we have $\|v\|_{\infty, \Lambda \cap \Omega} = 0$ and hence $v = 0$ on $\Lambda \cap \Omega$. This implies $v = 0$ on Λ since $g = 0$ on $\Lambda \cap \partial\Omega$. Therefore, the mapping $\widehat{\Delta^\rho}$ is injective. From the fact that $\operatorname{Im} \widehat{\Delta^\rho} = (\operatorname{Ker} \widehat{\Delta^\rho})^\perp = V$, we also are done with the surjective proof. ∎

Furthermore, the following error estimate of the unique nodal solution of the problem (**DP**) holds on two specific domains Ω_R and Ω_H under the regularity assumption of the continuous problem (**CP**).

THEOREM 3. *Let* $(\Omega, \Lambda, \rho_{\mathbf{x}})$ *be either the triple* $(\Omega_R, \Lambda_R, \rho_{\mathbf{x}}^R)$ *or* $(\Omega_H, \Lambda_H, \rho_{\mathbf{x}}^H)$. *Assume* $u \in C^0(\overline{\Omega}) \cap C^{s,\alpha}(\Omega)\, (s = 3, 4)$ *is the classical solution of Poisson problem* (**CP**) *with Dirichlet data and* $u_h \in V$ *is the nodal solution of the discrete Poisson problem* (**DP**) *on the node set* Λ *corresponding to* Ω. *If* $\Lambda \cap \Omega$ *is the interior nodes of* Λ, *then we have the following error estimate:*

$$\|i(u) - u_h\|_{\infty, \Lambda \cap \Omega} \le K \, h^{s-2} \, \|u\|_{C^{s,\alpha}(\Omega)} \tag{5.4}$$

for some constant $K > 0$ independent of h.

Proof. We note that the set of nodes $\Lambda \equiv \Lambda_R$ (or Λ_H) of the proper triple $(\Omega_R, \Lambda_R, \rho_{\mathbf{x}}^R)$ (or $(\Omega_H, \Lambda_H, \rho_{\mathbf{x}}^H)$) is obviously the possibly layered from the construction. Thus we can calculate the operator Δ^ρ at every interior node $\mathbf{x}_I \in \Lambda \cap \Omega$. Let $\Lambda^o \equiv \Lambda \cap \Omega$ be the interior nodes of Λ. If $u_h \in V$ is the nodal solution of (**DP**) and $u \in C^0(\overline{\Omega}) \cap C^{s,\alpha}(\Omega)\,(s = 3, 4)$ is the solution of (**CP**), then we can derive the error equation on Λ^o such that

$$(\Delta^\rho u_h)(\mathbf{x}_I) - \Delta u(\mathbf{x}_I) = 0 \quad \text{for all} \quad \mathbf{x}_I \in \Lambda^o. \tag{5.5}$$

From the error equation (5.5), we can obtain

$$\sum_{\mathbf{x}_J \in \Lambda} (u_J^h - u(\mathbf{x}_J))\, \psi_J^\Delta(\mathbf{x}_I) = \Delta u(\mathbf{x}_I) - \sum_{\mathbf{x}_J \in \Lambda} u(\mathbf{x}_J)\, \psi_J^\Delta(\mathbf{x}_I) \tag{5.6}$$

for all $\mathbf{x}_I \in \Lambda^o$. Since the domain Ω is convex, we can obtain the following Taylor expansions for $u(\mathbf{x})$ at $\mathbf{x}_I \in \Lambda^o$. For every $\mathbf{x}_J \in \Lambda(\mathbf{x}_I)$,

$$\begin{aligned} u(\mathbf{x}_J) = &\sum_{|\beta| \le s-1} \frac{1}{\beta!} (\mathbf{x}_J - \mathbf{x}_I)^\beta D^\beta u(\mathbf{x}_I) \\ &+ \sum_{|\beta| = s} \frac{1}{\beta!} \int_0^1 (1-\tau)^{s-1} D^\beta u(\mathbf{x}_I + \tau(\mathbf{x}_J - \mathbf{x}_I))\, d\tau (\mathbf{x}_J - \mathbf{x}_I)^\beta. \end{aligned} \tag{5.7}$$

Since $\Lambda(\mathbf{x}_I)$ is the locally (p, q)-layered $(q = 4, 6)$ at $\mathbf{x}_I \in \Lambda^o$, we can observe the symmetric node structure such that $-(\mathbf{x}_J - \mathbf{x}_I)$ and $\mathbf{x}_J - \mathbf{x}_I$ are on the same layer for all $\mathbf{x}_J \in \Lambda(\mathbf{x}_I)$. This implies that, when $|\beta| = 3$,

$$\sum_{\mathbf{x}_J \in \Lambda} (\mathbf{x}_J - \mathbf{x}_I)^\beta\, \psi_J^\Delta(\mathbf{x}_I) = 0. \tag{5.8}$$

Thus, inserting the expansions (5.7) into the right-hand side of (5.6), the following is obtained from the second order reproducing property and the symmetric factor (5.8):

$$\sum_{\mathbf{x}_J \in \Lambda} (u_J^h - u(\mathbf{x}_J))\, \psi_J^\Delta(\mathbf{x}_I) = \sum_{\mathbf{x}_J \in \Lambda} c_{IJ} \psi_J^\Delta(\mathbf{x}_I) \quad \text{for all} \quad \mathbf{x}_I \in \Lambda^o, \tag{5.9}$$

where the coefficients c_{IJ} are defined as

$$c_{IJ} = -\sum_{|\beta| = s} \frac{1}{\beta!} \int_0^1 (1-\tau)^{s-1} D^\beta u(\mathbf{x}_I + \tau(\mathbf{x}_J - \mathbf{x}_I))\, d\tau (\mathbf{x}_J - \mathbf{x}_I)^\beta. \tag{5.10}$$

Since the left-hand side of (5.9) is the image of the strong meshfree Laplacian operator Δ^ρ of $u^h - i(u) \in V$, the a priori estimate (4.48) due to the maximum principle on Λ^o leads to the following estimate

$$\max_{\mathbf{x}_J \in \Lambda^o} |u_J^h - u(\mathbf{x}_J)| \le C(\Lambda^o) \max_{\mathbf{x}_I \in \Lambda^o} \sum_{\mathbf{x}_J \in \Lambda(\mathbf{x}_I)} |c_{IJ}| \left|\psi_J^\Delta(\mathbf{x}_I)\right| + \max_{\mathbf{x}_J \in \Lambda^{o*} \backslash \Lambda^o} |u_J^h - u(\mathbf{x}_J)|. \tag{5.11}$$

In the case of the node distributions assumed, we know that $\Lambda^b = \Lambda^{o*} \backslash \Lambda^o$ and $u_J^h - u(\mathbf{x}_J) = 0$ on Λ^b because of the Dirichlet boundary conditions and hence the second

term on the right-hand side of the inequality (5.11) vanishes. For the estimate of the first term on the right-hand side of the inequality (5.11), we need the estimate of $|c_{IJ}|$ for all $\mathbf{x}_J \in \Lambda(\mathbf{x}_I)$ as follows. For each $\mathbf{x}_I \in \Lambda^o$,

$$|c_{IJ}| \le \left(\max_{|\beta|=s} \sup_{\mathbf{x}\in\Omega} |D^\beta u(x)|\right) \left(\max_{\mathbf{x}_J\in\Lambda(\mathbf{x}_I)} |\mathbf{x}_J - \mathbf{x}_I|\right)^s \frac{1}{s} \sum_{|\beta|=s} \frac{1}{\beta!} \tag{5.12}$$

$$\le K_s \, \|u\|_{C^{s,\,\alpha}} \, \|i(\rho)\|^s_{\infty,\Lambda(\mathbf{x}_I)}, \tag{5.13}$$

where $K_s = \frac{1}{s}\sum_{|\beta|=s} \frac{1}{\beta!}$ and ρ is the dilation function. Therefore, we have the following error bound

$$\max_{\mathbf{x}_J\in\Lambda^o} |u^h_J - u(\mathbf{x}_J)| \le K_s \, C(\Lambda^o) \, \|i(\rho)\|^s_{\infty,\Lambda^o} \, \|u\|_{C^{s,\,\alpha}} \max_{\mathbf{x}_I\in\Lambda^o} \sum_{\mathbf{x}_J\in\Lambda(\mathbf{x}_I)} \left|\psi^\Delta_J(\mathbf{x}_I)\right|. \tag{5.14}$$

On the other hand, the constant $C(\Lambda^o)$ is bounded by the diameter of the domain Ω, and the dilation function ρ in the assumed triple $(\Omega, \Lambda, \rho_{\mathbf{x}})$ satisfies

$$h < \|i(\rho)\|_{\infty,\Lambda^o} < C\, h \tag{5.15}$$

for some constant C independent of h. Furthermore, from Lemmas 1 and 2,

$$\sum_{\mathbf{x}_J\in\Lambda(\mathbf{x}_I)} \left|\psi^\Delta_J(\mathbf{x}_I)\right| \le \frac{8}{h^2}. \tag{5.16}$$

Consequently, we obtain the error estimate derived from (5.14):

$$\|i(u) - u_h\|_{\infty,\Lambda\cap\Omega} \le K\, h^{s-2} \, \|u\|_{C^{s,\alpha}(\Omega)} \tag{5.17}$$

for some $K > 0$ independent of h. □

Remark 4. As seen in the proof of Theorem 3, the convergence order of the numerical solution to the exact one can be proven only to be 2, although the regularity index s of the solution becomes greater than 4. The higher order of basis polynomials in the fast version of the generalized moving least square meshfree approximation is directly related to a lift in the convergence order (see [8]). Its proof seems to need the boundary error estimate for the numerical solution without the discrete maximum principle, while the interior error estimate is the same as ours.

The error ratio of about 4 in Table 5.1 implies the second order convergence even for the less-regularity case. The numerical result not only attests the validation of the error estimate but also shows the numerical scheme proposed could be more accurate than we anticipated. A numerical example is proposed to verify the theoretical convergence result. The solution $u(x, y)$ is assumed to be defined on both domains $(\Omega_R, \Lambda_R, \rho^R_{\mathbf{x}})$ and $(\Omega_H, \Lambda_H, \rho^H_{\mathbf{x}})$ as follows:

$$u(x, y) = e^{x+y-1} \left|x - \frac{1}{2}\right| \left(x - \frac{1}{2}\right)^2. \tag{5.18}$$

Applying the Laplacian operator to this solution, the corresponding force is given as follows:

$$f(x, y) = 2 \left|x - \frac{1}{2}\right| e^{x+y-1} \left(x^2 + 2x + \frac{7}{4}\right). \tag{5.19}$$

TABLE 5.1

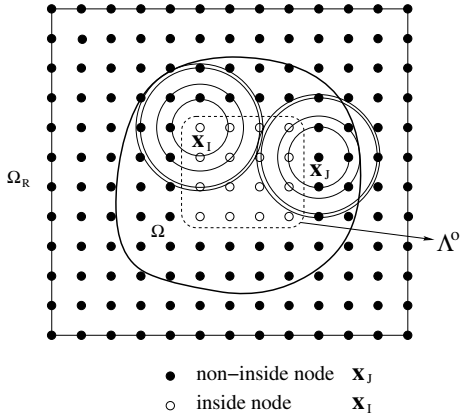

FIG. 5.1. *The immersed domain* Ω *in* Ω_R.

In this case, Dirichlet boundary condition on either $\partial\Omega_R$ or $\partial\Omega_H$ is presumed from the exact solution $u(x, y)$. The function u, in fact, belongs to $C^{2,1}$-class of functions on considered domains whose regularity is weaker than that stated in Theorem 3; nevertheless, the numerical example produces the second order convergence result as seen in Table 5.1.

6. Error estimate in the general domain immersed in Ω_R or Ω_H. We will try to analyze the convergence of our discrete problem (**DP**) with the boundary condition zero on a domain Ω which is immersed in the larger domain, for example, $\Omega \subset \hat{\Omega}_R$ (or $\Omega \subset \hat{\Omega}_H$) where $\hat{\Omega}_R$ (or $\hat{\Omega}_H$) is the image domain transformed from Ω_R (or Ω_H) by the similarity map. For brevity, we will rename it by Ω_R (or Ω_H).

Let $\Lambda \equiv \Lambda_R$ be the set of nodes in the triple $(\Omega_R, \Lambda_R, \rho^R_{\mathbf{x}})$. Assume that the nodal solution space V in this case is defined on Λ. As shown in Figure 5.1, we separate the set of nodes into two parts—the set Λ^o of inside nodes and the set Λ^b of non-inside nodes which are defined as the following:

$$\Lambda^o \equiv \{\mathbf{x}_J \in \Lambda \,|\, \Lambda(\mathbf{x}_J) \subset \Omega\}, \quad \Lambda^b \equiv \Lambda \setminus \Lambda^o. \tag{6.1}$$

The inside node $\mathbf{x}_I \in \Lambda$ implies that the $\rho_{\mathbf{x}_I}$-neighbor nodes are contained in the open set Ω while the nonside node is anything else. The following is the immersed meshfree

Poisson problem:

$$(\mathbf{IMP})\begin{cases} u_h \in V_0 \equiv \{v_J \in \mathbb{R} \,|\, v_K = 0 \text{ for all } \mathbf{x}_K \in \Lambda^b\} \subset V \\ \Delta^\rho u_h = i(f) \quad \text{on } \Lambda^o \end{cases}. \tag{6.2}$$

Let the solution u of the Poisson problem (**CP**) with zero Dirichlet data belong to $C^0(\overline{\Omega}) \cap C^{3,\alpha}(\Omega)$ and $u_h \in V_0$ be the nodal solution of the immersed meshfree Poisson problem (**IMP**). If we extend u to $\Omega_R \setminus \Omega$ by zero, then we conjecture that

$$\|i(u) - u_h\|_{\infty,\Lambda\cap\Omega} \le K\, h\, \|u\|_{C^{3,\alpha}(\Omega)}, \tag{6.3}$$

where the constant K is independent of h.

THEOREM 4 (existence and uniqueness). *Let* $(\Omega_R, \Lambda_R, \rho^R_{\mathbf{x}})$ *and* $(\Omega_H, \Lambda_H, \rho^H_{\mathbf{x}})$ *be the triples. Assume* Ω *is immersed in either* Ω_R *or* Ω_H*. Then there exists the unique solution of the problem* (**IMP**) *on* V*.*

The proof of the theorem is similar to that of Theorem 2 and thus it is omitted.

In order to prove the convergence result (6.3) for the immersed meshfree Poisson problem (**IMP**), let $(\Omega_R, \Lambda_R, \rho^R_{\mathbf{x}})$ be the triple defined in section 5. First, we have the following error:

$$\|i(u) - u_h\|_{\infty,\Lambda^{o*}\setminus\Lambda^o} = \|i(u)\|_{\infty,\Lambda^{o*}\setminus\Lambda^o} \tag{6.4}$$

since $\Lambda^{o*} \setminus \Lambda^o \subset \Omega$ and $u_h(\mathbf{x}_J) = 0$ on it. Through the similar procedure to the proof of Theorem 3 and from the fact that $\Lambda(\mathbf{x}_I) \subset \Omega$ for any $\mathbf{x}_I \in \Lambda^o$, we can obtain the following error equation:

$$\sum_{\mathbf{x}_J\in\Lambda} (u^h_J - u(\mathbf{x}_J))\, \psi^\Delta_J(\mathbf{x}_I) = \sum_{\mathbf{x}_J\in\Lambda} c_{IJ}\psi^\Delta_J(\mathbf{x}_I) \quad \text{for all} \quad \mathbf{x}_I \in \Lambda^o, \tag{6.5}$$

where the coefficients c_{IJ} are calculated as follows:

$$c_{IJ} = -\sum_{|\beta|=3} \frac{1}{\beta!} \int_0^1 (1-\tau)^2 D^\beta u(\mathbf{x}_I + \tau(\mathbf{x}_J - \mathbf{x}_I))\, d\tau (\mathbf{x}_J - \mathbf{x}_I)^\beta. \tag{6.6}$$

From a priori estimate in Theorem 1 due to the discrete maximum principle on Λ^o and from the identity (6.4), we obtain the following estimates:

$$\begin{aligned} \|i(u) - u_h\|_{\infty,\Lambda^o} &\le C(\Lambda^o) \max_{\mathbf{x}_I\in\Lambda^o} \left| \sum_{\mathbf{x}_J\in\Lambda} c_{IJ}\psi^\Delta_J(\mathbf{x}_I) \right| + \|i(u) - u_h\|_{\infty,\Lambda^{o*}\setminus\Lambda^o} \\ &\le K_1\, h\, \|u\|_{C^{3,\alpha}(\Omega)} + \|i(u)\|_{\infty,\Lambda^{o*}\setminus\Lambda^o} \end{aligned} \tag{6.7}$$

for some constant $K_1 > 0$ independent of h. On the other hand, let us pay attention to the fact that

$$\|i(u) - u_h\|_{\infty,\Lambda^b\cap\Omega} = \|i(u)\|_{\infty,\Lambda^b\cap\Omega}. \tag{6.8}$$

Then, from this fact and (6.7), the nodal error on the nodes in Ω is bounded by

$$\|i(u) - u_h\|_{\infty,\Lambda\cap\Omega} \le K_1\, h\, \|u\|_{C^{3,\alpha}(\Omega)} + \|i(u)\|_{\infty,\Lambda^b\cap\Omega} \tag{6.9}$$

since $\Lambda^{o*} \setminus \Lambda^o \subset \Lambda^b \cap \Omega$. Here, the second term on the right-hand side of (6.9) is bounded by

$$\|i(u)\|_{\infty,\Lambda^b\cap\Omega} \le \left(\max_{\mathbf{x}_K\in\Lambda^b\cap\Omega} \operatorname{dist}(\mathbf{x}_K,\partial\Omega)\right) \|u\|_{C^{1,\alpha}(\Omega)} \le K_2\, h\, \|u\|_{C^{3,\alpha}(\Omega)} \tag{6.10}$$

for some constant $K_2 > 0$ independent of h. Therefore, we have obtained the following theorem.

THEOREM 5. *Let $\Omega \subset \mathbb{R}^2$ be an open bounded domain which is immersed in either Ω_R or Ω_H. Assume that $u \in C^0(\overline{\Omega}) \cap C^{3,\alpha}(\Omega)$ is the solution of* (**CP**) *and $u_h \in V_0$ is the nodal solution of* (**IMP**). *Then we have the following error estimate:*

$$\|i(u) - u_h\|_{\infty,\Lambda\cap\Omega} \le K\, h\, \|u\|_{C^{3,\alpha}(\Omega)}, \tag{6.11}$$

where the node set Λ is either Λ_R or Λ_H and K is constant independent of h.

7. Conclusion. The generalized moving least square approximation is introduced, and based on this, we can define the strong meshfree Laplacian operator in the sense of a point collocation strategy. From the mathematical point of view, the discrete maximum principle for the strong meshfree Laplacian operator is presented for several types of layered node distributions. Using this principle, we perform convergence analysis for the nodal solutions of the Poisson problem with Dirichlet data on the boundary. As a result, second order convergence is achieved on the specific nodes in two typical domains, while the generally shaped domain immersed in these domains produces first order convergence of the nodal solution. An a priori estimate for the strong Laplacian operator in the meshfree regime is newly obtained via the discrete maximum principle and it is located in the core of the convergence proof together with the point collocation scheme proposed in this paper.

Appendix I: Generalized moving least square reproducing operators. For a given window function $W(\mathbf{x})$ and a dilation function $\rho_{\mathbf{x}}$, we find the vector $\mathbf{a}$ to minimize the following weighted square functional at $\bar{\mathbf{x}} \in \overline{\Omega}$:

$$J(\mathbf{a};\bar{\mathbf{x}},u) \equiv \sum_{\mathbf{x}_I\in\Lambda} |u(\mathbf{x}_I) - \mathbf{U}_m^{\rho_{\bar{\mathbf{x}}}}(\mathbf{x}_I;\bar{\mathbf{x}},\mathbf{a})|^2\, W\left(\frac{\mathbf{x}_I - \bar{\mathbf{x}}}{\rho_{\bar{\mathbf{x}}}}\right), \tag{7.1}$$

where $u(\mathbf{x})$ is a continuous function defined in $\overline{\Omega}$ and $\mathbf{U}_m^{\rho_{\bar{\mathbf{x}}}}(\mathbf{x};\bar{\mathbf{x}},\mathbf{a}) \equiv \mathbf{B}_m(\frac{\mathbf{x}-\bar{\mathbf{x}}}{\rho_{\bar{\mathbf{x}}}}) \cdot \mathbf{a}$. Then the minimizer $\mathbf{a}$ should be a function of $\bar{\mathbf{x}}$ and u, and we can make the following approximation operators for u by limiting process

$$D_{m,\rho_{\mathbf{x}}}^{\beta_k} u(\mathbf{x}) \equiv \lim_{\bar{\mathbf{x}}\to\mathbf{x}} D_{\mathbf{x}}^{\beta_k} \mathbf{U}_m^{\rho_{\bar{\mathbf{x}}}}(\mathbf{x};\bar{\mathbf{x}},\mathbf{a}(\bar{\mathbf{x}},u)), \quad |\beta_k| \le m. \tag{7.2}$$

As a matter of fact, the operators $D_{m,\rho_{\mathbf{x}}}^{\beta_k}$ are linear in $u(\mathbf{x})$. We call the operator $D_{m,\rho_{\mathbf{x}}}^{\beta}$ ($|\beta| \le m$) the βth meshfree approximated derivative operator equipped with $\rho_{\mathbf{x}}$.

Suppose $\{u_I(\mathbf{x}) \,|\, u_I(\mathbf{x}_J) = \delta_{IJ},\ \mathbf{x}_I, \mathbf{x}_J \in \Lambda\}$ is a set of continuous functions. We define the following functions:

$$\psi_I^{\rho_{\mathbf{x}},[\beta_k]}(\mathbf{x}) \equiv D_{m,\rho_{\mathbf{x}}}^{\beta_k} u_I(\mathbf{x}). \tag{7.3}$$

Then the functions $\psi_I^{\rho_{\mathbf{x}},[\beta_k]}(\mathbf{x})$ can be characterized as follows:

$$\begin{pmatrix} {\rho_{\mathbf{x}}}^{|\beta_1|}\,\psi_I^{\rho_{\mathbf{x}},[\beta_1]}(\mathbf{x}) \\ {\rho_{\mathbf{x}}}^{|\beta_2|}\,\psi_I^{\rho_{\mathbf{x}},[\beta_2]}(\mathbf{x}) \\ \vdots \\ {\rho_{\mathbf{x}}}^{|\beta_L|}\,\psi_I^{\rho_{\mathbf{x}},[\beta_L]}(\mathbf{x}) \end{pmatrix} = J_{\mathbf{B}_m}(\mathbf{0})\, M^{\rho_{\mathbf{x}}}(\mathbf{x})^{-1}\, \mathbf{B}_m\left(\frac{\mathbf{x}_I-\mathbf{x}}{\rho_{\mathbf{x}}}\right) W\left(\frac{\mathbf{x}_I-\mathbf{x}}{\rho_{\mathbf{x}}}\right), \tag{7.4}$$

where $M^{\rho_{\mathbf{x}}}(\mathbf{x})$ is called the moment matrix and is defined such that

$$M^{\rho_{\mathbf{x}}}(\mathbf{x}) \equiv \sum_{\mathbf{x}_I\in\Lambda} \mathbf{B}_m\left(\frac{\mathbf{x}_I-\mathbf{x}}{\rho_{\mathbf{x}}}\right)\mathbf{B}_m^T\left(\frac{\mathbf{x}_I-\mathbf{x}}{\rho_{\mathbf{x}}}\right) W\left(\frac{\mathbf{x}_I-\mathbf{x}}{\rho_{\mathbf{x}}}\right). \tag{7.5}$$

We call the function $\psi_I^{\rho_{\mathbf{x}},[\beta]}(\mathbf{x})$ *the βth shape function* associated with the window function W and the dilation function $\rho_{\mathbf{x}}$, or briefly call it *the βth shape function* if no confusion arises. As a consequence of (7.3), the operator $D^{\beta_k}_{m,\rho_{\mathbf{x}}}$ defined by (7.2) can be rewritten as follows:

$$D^{\beta}_{m,\rho_{\mathbf{x}}} u(\mathbf{x}) = \sum_{\mathbf{x}_J\in\Lambda} u(\mathbf{x}_J)\,\psi_J^{\rho_{\mathbf{x}},[\beta]}(\mathbf{x}), \quad |\beta|\le m. \tag{7.6}$$

We also call this operator the βth meshfree approximated derivative operator and the following properties of this operator can be justified.

THEOREM 6 (generalized mth order consistency). *We have the following identities:*

$$\sum_{\mathbf{x}_I\in\Lambda} b_\alpha\left(\frac{\mathbf{x}_I-\mathbf{x}}{\rho_{\mathbf{x}}}\right)\psi_I^{\rho_{\mathbf{x}},[\beta]}(\mathbf{x}) = \frac{1}{{\rho_{\mathbf{x}}}^{|\beta|}}\,\frac{\partial^\beta}{\partial\mathbf{x}^\beta} b_\alpha(\mathbf{0}). \tag{7.7}$$

Proof. To the matrix equation (7.4) for *the βth shape functions*, multiplying $\mathbf{B}_m\left(\mathbf{x}_I-\mathbf{x}/\rho_{\mathbf{x}}\right)$ to the right on both sides and summing it over the whole nodes $\mathbf{x}_I$, we obtain the matrix equation. If we rewrite it in element-wise manner, then we have the resultant (7.7). □

The above theorem does not promise the βth meshfree approximated derivative operator to reproduce automatically all of the derivatives for the basis functions. However, for some useful class of functions including the polynomial class up to order m, we can have the generalized reproducing property which will play an important role in the convergence of approximations. For the class of the given basis functions to have such a generalized reproducing property, it is sufficient to satisfy the following condition.

COROLLARY 1 (sufficient condition for the generalized reproducing property). *Under the constant dilation function such that $\rho_{\mathbf{x}}\equiv\rho$, we assume that the basis functions satisfy the following relationships:*

$$b_\beta\left(\frac{\mathbf{y}}{\rho}\right) = \sum_{|\gamma|\le m} c_{\gamma\,\beta}\left(\frac{\mathbf{x}}{\rho}\right) b_\gamma\left(\frac{\mathbf{y}-\mathbf{x}}{\rho}\right), \quad |\beta|\le m \tag{7.8}$$

and the coefficient matrix is calculated from the equation

$$\left[c_{\alpha\,\beta}\left(\frac{\mathbf{x}}{\rho}\right)\right] \equiv C\left(\frac{\mathbf{x}}{\rho}\right) = J_{\mathbf{B}_m}(0)^{-1}\, J_{\mathbf{B}_m}\left(\frac{\mathbf{x}}{\rho}\right), \tag{7.9}$$

where $J_{\mathbf{B}_m}\left(\frac{\mathbf{x}}{\rho}\right)$ *is the Jacobian matrix defined as*

$$J_{\mathbf{B}_m}\left(\frac{\mathbf{x}}{\rho}\right) \equiv \left[\left(D^{\alpha} b_{\beta}\right)\left(\frac{\mathbf{x}}{\rho}\right)\right]. \tag{7.10}$$

Then the basis functions scaled by ρ *are exactly reproduced by the meshfree approximated derivative operators, i.e.,*

$$D^{\beta}_{m,\rho_{\mathbf{x}}} b_{\beta}\left(\frac{\mathbf{x}}{\rho}\right) = D^{\beta}_{\mathbf{x}} b_{\beta}\left(\frac{\mathbf{x}}{\rho}\right), \quad |\beta| \leq m. \tag{7.11}$$

Proof. Assume that $b_{\alpha}(\mathbf{x})$'s for $|\alpha| \leq m$ are the basis functions satisfying both conditions of (7.8) and (7.9). If we directly enforce (7.7) on these basis functions, then we obtain the result of (7.11). ∎

Corollary 1 provides us the opportunity of taking the general basis functions which can be reproduced in a dilated form. It is worth noting that the reproducing property does not happen in general if we take an arbitrary set of basis functions. That is why we propose the sufficient condition to ensure the reproducing condition for the dilated basis functions. According to the sufficient condition of (7.8) and (7.9) for the reproducing of basis functions, the class of polynomial basis up to order m can be shown to satisfy the exact reproducing property. That is, all of the derivatives of the basis itself are reproducible even in the case when involving the dilation function.

Corollary 2. *If we take the polynomials up to order* m *as basis functions, then the* β*th meshfree approximated derivative operator* $D^{\beta}_{m,\rho_{\mathbf{x}}}$ *is exactly the same as the differential operator* D^{β} *on the polynomial space up to order* m*. That is,*

$$D^{\beta}_{m,\rho_{\mathbf{x}}} u(\mathbf{x}) = D^{\beta}_{\mathbf{x}} u(\mathbf{x}) \tag{7.12}$$

whenever $u(\mathbf{x})$ *is a polynomial of order up to* m*.*

Proof. We can replace all $\rho_{\mathbf{x}}$ in Theorem 6 and all ρ in Corollary 1 with the number 1 for the case of polynomial basis up to order m. This fact suffices to prove this lemma. ∎

This corollary can be understood by recognizing that the βth meshfree approximated derivative operator $D^{\beta}_{m,\rho_{\mathbf{x}}}$ behaves in the same way as the exact derivative operator $D^{\beta}_{\mathbf{x}}$ at least on the polynomial function space up to order m.

Appendix II: Trigonometric identities. Let θ be an angle fixed. Then we have the following trigonometric identities for any natural number $n \geq 4$:

(7.13)
$$\sum_{k=0}^{n-1} \cos\left(\theta + k\,\frac{2\pi}{n}\right) = \sum_{k=0}^{n-1} \sin\left(\theta + k\,\frac{2\pi}{n}\right) = \sum_{k=0}^{n-1} \cos\left(\theta + k\,\frac{2\pi}{n}\right) \sin\left(\theta + k\,\frac{2\pi}{n}\right) = 0,$$

(7.14)
$$\sum_{k=0}^{n-1} \cos^2\left(\theta + k\,\frac{2\pi}{n}\right) = \sum_{k=0}^{n-1} \sin^2\left(\theta + k\,\frac{2\pi}{n}\right) = \frac{n}{2},$$

(7.15)
$$\sum_{k=0}^{n-1} \cos^3\left(\theta + k\,\frac{2\pi}{n}\right) = \sum_{k=0}^{n-1} \sin^3\left(\theta + k\,\frac{2\pi}{n}\right) = 0,$$

(7.16)
$$\sum_{k=0}^{n-1} \cos^2\left(\theta + k\,\frac{2\pi}{n}\right) \sin\left(\theta + k\,\frac{2\pi}{n}\right) = \sum_{k=0}^{n-1} \cos\left(\theta + k\,\frac{2\pi}{n}\right) \sin^2\left(\theta + k\,\frac{2\pi}{n}\right) = 0,$$

(7.17)
$$\sum_{k=0}^{n-1} \cos^4\left(\theta + k\,\frac{2\pi}{n}\right) = \sum_{k=0}^{n-1} \sin^4\left(\theta + k\,\frac{2\pi}{n}\right) = \begin{cases} \frac{3}{8}n + \frac{1}{8}n\,\cos 4\theta, & n = 4 \\ \frac{3}{8}n, & n \neq 4 \end{cases},$$

(7.18)
$$\sum_{k=0}^{n-1} \cos^2\left(\theta + k\,\frac{2\pi}{n}\right) \sin^2\left(\theta + k\,\frac{2\pi}{n}\right) = \begin{cases} \frac{1}{8}n - \frac{1}{8}n\,\cos 4\theta, & n = 4 \\ \frac{1}{8}n, & n \neq 4 \end{cases},$$

(7.19)
$$\sum_{k=0}^{n-1} \cos^3\left(\theta + k\,\frac{2\pi}{n}\right) \sin\left(\theta + k\,\frac{2\pi}{n}\right) = \begin{cases} \frac{1}{8}n\,\sin 4\theta, & n = 4 \\ 0, & n \neq 4 \end{cases},$$

(7.20)
$$\sum_{k=0}^{n-1} \cos\left(\theta + k\,\frac{2\pi}{n}\right) \sin^3\left(\theta + k\,\frac{2\pi}{n}\right) = \begin{cases} -\frac{1}{8}n\,\sin 4\theta, & n = 4 \\ 0, & n \neq 4 \end{cases}.$$

Acknowledgments. We would like to give thanks particularly to Professor Shaofan Li for invaluable suggestions and David Farrel for correction of proofs, and we are also thankful to the referees for their valuable comments.

A LEAST-SQUARES FINITE ELEMENT METHOD FOR THE LINEAR BOLTZMANN EQUATION WITH ANISOTROPIC SCATTERING*

TRAVIS M. AUSTIN† AND THOMAS A. MANTEUFFEL‡

Abstract. Least-squares methods have been applied to a wide range of differential equations and have been established to be competitive with other existing discretization strategies [P. B. Bochev and M. D. Gunzburger, SIAM Rev., 40 (1998), pp. 789–837]. In this article, we consider a least-squares method for the linear Boltzmann equation with anisotropic scattering. A similar method has already been developed, and extensively examined, for the linear Boltzmann equation with isotropic scattering. The success of the least-squares method for isotropic scattering depends on scaling the linear Boltzmann equation so that minimization of the least-squares functional in a discrete space always yields accurate discrete solutions. A similar scaling of the linear Boltzmann equation is employed for anisotropic scattering. In the previous work for isotropic scattering, coercivity and continuity results were established for the scaled least-squares functional relative to a physically reasonable norm. In this paper, we extend the previous coercivity and continuity results so that they hold in this more general case of anisotropic scattering. Additionally, we extend the bounds for the discretization error for the thin regime and for the thick regime. For the thick regime, we establish optimal error estimates for the case of highly anisotropic scattering.

1. Introduction.

In this paper, we examine a least-squares method that is used to obtain discrete solutions to the single-group, steady-state linear Boltzmann equation with anisotropic scattering. The least-squares method for isotropic scattering was carefully analyzed for slab geometry in [12] and for xyz-geometry in [13]. Here, in the context of xyz-geometry, we extend the generality of the least-squares method by allowing for anisotropic scattering, whereby a particle has a preferential direction of scatter after collision.

For isotropic scattering, where particles have no preferential direction of scatter, it was proved in [12, 13] that the least-squares method yields discrete solutions that exhibit the correct asymptotic behavior in the diffusion limit. In this limit, the leading-order asymptotic solution of the Boltzmann equation converges to the solution of a diffusion equation. In [13], ellipticity of the least-squares functional was proved and the existence of optimal error estimates for a P_N angular discretization and a finite element spatial discretization was established. In [14], the authors enhanced the least-squares approach by adding a boundary functional to the least-squares functional, thus, weakly imposing the boundary conditions.

In [5], anisotropic scattering in the scaled least-squares approach was first considered in the context of multigroup transport. A scaling operator for the least-squares

approach with anisotropic scattering in the multigroup context was introduced. Additionally, convergence results for a multilevel solution algorithm for the multigroup version of anisotropic scattering were presented. However, ellipticity of the scaled least-squares functional or estimates of the least-squares error were not considered.

For the single group equation, we set a foundation for the scaled least-squares approach introduced in [5] by proving ellipticity of the least-squares functional. We employ a scaling operator that is a single-group form of the scaling operator used in [5]. The proof of ellipticity for the thick regime with large absorption is identical to the equivalent case for isotropic scattering. The remaining cases depend on new techniques that were not used in [14]. Moreover, the proofs for the thin regime and the thick regime with small absorption have as special cases the proofs for the isotropic scattering [14]. It is the opinion of the authors that the proofs presented here are simpler and clearer than the proofs of [14], albeit resulting in small coercivity bounds.

The ellipticity results imply that the least-squares variational problem is well posed in an appropriate norm with ellipticity constants that are independent of the problem parameters. This ellipticity allows us to use Céa's lemma in establishing error bounds. Thus, once we introduce the discretization scheme (drawn from [5, 13, 14]), we use Céa's lemma to illustrate optimal bounds on the discretization error in the context of anisotropic scattering for the thin and thick regimes. For the thin regime, the proof from [14] can be invoked. For the thick regime with mildly anisotropic scattering, we merely indicate that the results are of the same form as [14]. There will, however, be new results for the thick regime with highly anisotropic scattering. These results will depend on an asymptotic expansion from Larsen and Pomraning in [10].

Most of the research on numerical methods for the linear Boltzmann equation with anisotropic scattering has focused on devising a plan to speed up source iteration, which is the standard iterative solution method used to solve isotropic transport problems [11]. Research has not focused on tailoring the discretization schemes used for isotropic scattering problems to anisotropic scattering problems because, in general, the same discretization techniques may be used [2, 15, 16]. Here, we focus on the formulation and discretization using a least-squares approach. We will not address the issue of what is the appropriate method for solving the resulting system of equations. For now we refer the reader to [5]. Since the approach for anisotropic scattering first described in [5] has not been studied theoretically, we concentrate on placing the method on firm ground. To this end, we proceed in the following way.

In section 2, we present the necessary preliminaries. Previous results for isotropic scattering are described in section 3. The scattering operator is presented in section 4 along with ellipticity results. In section 5, we describe the spatial and angular discretization scheme and present error estimates. In the final section, we discuss future work and further extensions of the least-squares method.

2. Preliminaries. As discussed in [11], the single-group, steady-state linear Boltzmann equation with anisotropic scattering is given by

$$\begin{aligned} [\boldsymbol{\Omega}\cdot\nabla+\sigma_t\mathcal{I}-\sigma_s\mathcal{K}]\,\psi(\mathbf{x},\boldsymbol{\Omega}) &= q \quad \text{for } (\mathbf{x},\boldsymbol{\Omega})\in R\times S^2\,, \\ \psi(\mathbf{x},\boldsymbol{\Omega}) &= g \quad \text{for } \mathbf{x}\in\partial R \text{ with } \mathbf{n}\cdot\boldsymbol{\Omega}<0, \end{aligned} \tag{2.1}$$

where σ_t is the *total cross section*, σ_s is the *scattering cross section*, and ψ is the *angular flux* to be determined for all points $\mathbf{x}\in R\subset\Re^3$ and all possible travel directions $\boldsymbol{\Omega}=(\sin\theta\cos\varphi\,,\sin\theta\sin\varphi,\cos\theta)\in S^2$. Spatial domain R is assumed to be an open connected set with $diam(R)=1$ and to have a piecewise $C^{1,1}$ boundary denoted by $\Gamma:=\partial R$.

To define anisotropic scattering operator $\mathcal{K}$, we must recall the normalized spherical harmonics from [3], given by

$$Y_{\ell m}(\mathbf{\Omega}) := Y_{\ell m}(\theta,\varphi) = (-1)^m \sqrt{\frac{(2\ell+1)(\ell-m)!}{(\ell+m)!}}\, P_\ell^m(\cos\,\theta)\, e^{im\varphi}, \tag{2.2}$$

where $P_\ell^m(\cdot)$ corresponds to the (ℓm)th associated Legendre moment. Normalization

$$\mathrm{d}\mathbf{\Omega} = \frac{\sin(\theta)\,\mathrm{d}\theta\,\mathrm{d}\varphi}{4\pi}$$

allows us to expand the scattering operator $\mathcal{K}$ as

$$(\mathcal{K}v)(\mathbf{x},\mathbf{\Omega}) = \sum_{\ell=0}^{\infty} \sigma_\ell \sum_{m=-\ell}^{\ell} Y_{\ell m}(\mathbf{\Omega}) \int_{S^2} Y_{\ell m}^*(\mathbf{\Omega}')\; v(\mathbf{x},\mathbf{\Omega}')\; \mathrm{d}\mathbf{\Omega}', \tag{2.3}$$

where $\sigma_\ell \in [0,1]$ for all $l > 0$ (with $\sigma_0 \equiv 1$) and $Y_{\ell m}^*$ is the complex conjugate of $Y_{\ell m}$. This infinite sum is truncated, in practice, such that for some $N_S \geq 0$,

$$(\mathcal{K}v)(\mathbf{x},\mathbf{\Omega}) = \sum_{\ell=0}^{N_S} \sigma_\ell \sum_{m=-\ell}^{\ell} Y_{\ell m}(\mathbf{\Omega}) \int_{S^2} Y_{\ell m}^*(\mathbf{\Omega}')\; v(\mathbf{x},\mathbf{\Omega}')\; \mathrm{d}\mathbf{\Omega}'. \tag{2.4}$$

Note that N_S depends on the degree of anisotropy in the scattering, and that when $N_S = 0$ in (2.4), we have

$$(\mathcal{K}v)(\mathbf{x},\mathbf{\Omega}) = \int_{S^2} v(\mathbf{x},\mathbf{\Omega}')\; \mathrm{d}\mathbf{\Omega}', \tag{2.5}$$

resulting in the isotropic transport operator. For the remainder, we refer to the operator in (2.5) as $\mathcal{P}$. Note that for subset $\Xi \subset \mathbb{N} \equiv \{0,1,2,3,\dots\}$ we can define the more general operator

$$(\mathcal{P}_\Xi\, v)(\mathbf{x},\mathbf{\Omega}) := \sum_{\ell\in\Xi} \sum_{m=-\ell}^{\ell} Y_{\ell m}(\mathbf{\Omega}) \int_{S^2} Y_{\ell m}^*(\mathbf{\Omega}')\; v(\mathbf{x},\mathbf{\Omega}')\; \mathrm{d}\mathbf{\Omega}'. \tag{2.6}$$

Next, to distinguish between the isotropic and anisotropic transport operators, we introduce the notation $\mathcal{L}_I$ and $\mathcal{L}_A$ such that, for $v : R \times S^2 \to \Re$,

$$\mathcal{L}_I\, v := \mathbf{\Omega}\cdot\nabla\, v + \sigma_t\,(\mathcal{I}-\mathcal{P})\, v + \sigma_a\,\mathcal{P}\, v \tag{2.7}$$

and

$$\mathcal{L}_A\, v := \mathbf{\Omega}\cdot\nabla\, v + \sigma_t\,(\mathcal{I}-\mathcal{K})\, v + \sigma_a\,\mathcal{K}\, v, \tag{2.8}$$

where $\sigma_a := \sigma_t - \sigma_s$ represents the *absorption cross section*. Also, at times, the scattering term of the anisotropic transport operator will be represented by

$$\mathcal{S} = \sigma_t(\mathcal{I}-\mathcal{K}) + \sigma_a\,\mathcal{K}, \tag{2.9}$$

or by

$$\mathcal{S}v(\mathbf{x},\mathbf{\Omega}) = \sum_{\ell=0}^{\infty} \mu_\ell \sum_{m=-\ell}^{\ell} Y_{\ell m}(\mathbf{\Omega}) \int_{S^2} Y_{\ell m}^*(\mathbf{\Omega}')\; v(\mathbf{x},\mathbf{\Omega}')\; \mathrm{d}\mathbf{\Omega}', \tag{2.10}$$

where

$$\mu_\ell = \sigma_t(1-\sigma_\ell) + \sigma_a\sigma_\ell. \tag{2.11}$$

Next, let the standard L^2 inner product and norm be denoted by

$$\langle u, v\rangle := \int_{S^2}\int_R u\, v^*\, \mathrm{d}\mathbf{x}\, \mathrm{d}\mathbf{\Omega}' \qquad \text{and} \qquad \|u\| := \sqrt{\langle u, u\rangle},$$

where v^* again is the complex conjugate of v. Denote by $\mathrm{L}^2(S^2 \times R)$ the set of functions that are L^2-integrable on $S^2 \times R$. Any function in $\mathrm{L}^2(S^2 \times R)$ has a unique expression in terms of the spherical harmonics since the spherical harmonics are an orthonormal basis for $\mathrm{L}^2(S^2)$. Specifically, every $v \in \mathrm{L}^2(S^2 \times R)$ has the expansion

$$v(\mathbf{x}, \mathbf{\Omega}) = \sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell} \phi_{\ell m}(\mathbf{x}) Y_{\ell m}(\mathbf{\Omega}), \tag{2.12}$$

with moments $\phi_{\ell m}(\mathbf{x})$ given by

$$\phi_{\ell m}(\mathbf{x}) = \int_{S^2} Y^*_{\ell m}(\mathbf{\Omega}')v(\mathbf{x}, \mathbf{\Omega}')\, \mathrm{d}\mathbf{\Omega}'. \tag{2.13}$$

3. Previous results for isotropic scattering. In [13], a scaling operator of the form $\mathcal{R} := a(\mathcal{I} - \mathcal{P}) + b\mathcal{P}$ was defined, with a and b depending on σ_t and σ_a. The isotropic form of (2.1) was then restated as the minimization of the least-squares functional

$$G_0(\psi; q) := \left\| \mathcal{R}^{-1/2}(\mathcal{L}_I\, \psi - q) \right\|^2. \tag{3.1}$$

The main result presented in [13] showed coercivity and continuity of the bilinear form $\left\langle \mathcal{R}^{-1}\mathcal{L}_I\, u, \mathcal{L}_I\, v \right\rangle$ with respect to

$$\|v\|_V^2 := \left\langle \mathcal{R}^{-1}\mathbf{\Omega}\cdot\nabla v, \mathbf{\Omega}\cdot\nabla v\right\rangle + \left\langle \mathcal{R}v, v\right\rangle. \tag{3.2}$$

To be more precise, defining V as the space of functions bounded in the V-norm and V_0 as the subspace of V with homogeneous inflow boundary conditions, the authors established V-ellipticity, i.e., constants C_e and C_c, independent of σ_t and σ_a, such that

$$C_e\, \|v\|_V^2 \le \left\langle \mathcal{R}^{-1}\mathcal{L}_I v, \mathcal{L}_I v\right\rangle \le C_c\, \|v\|_V^2 \tag{3.3}$$

for any $v \in V_0$. In [14], they extended this work by adding a boundary functional to the V-norm and the least-squares functional, and again proved ellipticity.

To describe the work in [14], it is necessary to describe the boundary functional. For each $\mathbf{x} \in \Gamma$, define $\mathbf{n}(\mathbf{x})$ to be the outward unit normal, define

$$\Gamma_I(\mathbf{\Omega}) := \{\mathbf{x} \in \Gamma \ : \ \mathbf{n}\cdot\mathbf{\Omega} < 0\}, \tag{3.4}$$

and define $\Gamma_O(\mathbf{\Omega}) := \Gamma/\ \Gamma_I(\mathbf{\Omega})$ to be the set of inflow and outflow particle travel directions. By defining $D := R \times S^2$, we then denote the inflow and outflow boundary of D by

$$\partial D_I := \{(\mathbf{x}, \mathbf{\Omega}) \in D \ : \ \mathbf{x} \in \Gamma_I(\mathbf{\Omega})\} \tag{3.5}$$

and

$$\partial D_O := \{(\mathbf{x}, \mathbf{\Omega}) \in D \ : \ \mathbf{x} \in \Gamma_O(\mathbf{\Omega})\}. \tag{3.6}$$

Corresponding to the inflow and outflow boundary of D are

$$b_I(u,v) := \int_{\partial R} \int_{\mathbf{n}\cdot\mathbf{\Omega}<0} uv|\mathbf{n}\cdot\mathbf{\Omega}| \,\mathrm{d}\mathbf{\Omega}\,\mathrm{d}\sigma \tag{3.7}$$

and

$$b_O(u,v) := \int_{\partial R} \int_{\mathbf{n}\cdot\mathbf{\Omega}>0} uv|\mathbf{n}\cdot\mathbf{\Omega}| \,\mathrm{d}\mathbf{\Omega}\,\mathrm{d}\sigma. \tag{3.8}$$

Associated with $b_I(\cdot,\cdot)$ is the inflow norm

$$\|v\|^2_{B_I} := b_I(v,v) \tag{3.9}$$

and the corresponding Sobolev space

$$B_I := \overline{\left\{v \in C^\infty(\overline{\partial R_I}) : \|v\|^2_{B_I} < \infty\right\}}. \tag{3.10}$$

For $q \in \mathrm{L}^2$ and $g \in B_I$, the least-squares functional studied in [14] is given by

$$G_I(\psi; q, g) := G_0(\psi; q) \ + \ 2b_I(\psi - g, \psi - g). \tag{3.11}$$

The authors obtained ellipticity results for (3.11) with respect to

$$\|v\|^2_{V_1} := \|v\|^2_V + b_I(v,v) \tag{3.12}$$

and the space V_1 consisting of functions bounded in the V_1-norm. Since G_I offers a more robust approximation of boundary conditions than G_0, we work exclusively in this paper with a least-squares functional that is similar in form to (3.12).

4. New results for anisotropic scattering. The scaling operator for anisotropic scattering is given by

$$\mathcal{R} := \begin{cases} \mathcal{I} & \text{in Region I}, \\ \sigma_t(\mathcal{I} - \mathcal{K}) + \sigma_a\mathcal{K} & \text{in Region II}, \\ \sigma_t(\mathcal{I} - \mathcal{K}) + \frac{1}{\sigma_t}\mathcal{K} & \text{in Region III}, \end{cases} \tag{4.1}$$

where Regions I, II, and III are defined in Figure 4.1. Note that $\mathcal{R}$ is a continuous function in σ_t and σ_a for fixed $\mathcal{K}$ and can be alternatively expressed as

$$\mathcal{R}v := \sum_{\ell=0}^{\infty} \nu_\ell \sum_{m=-\ell}^{\ell} \phi_{\ell m}(\mathbf{x})\, Y_{\ell m}(\mathbf{\Omega}), \tag{4.2}$$

using $\phi_{\ell m}$ in (2.13) and

$$\nu_\ell := \begin{cases} 1 & \text{for Region I}, \\ \sigma_t\,(1 - \sigma_\ell) + \sigma_a\,\sigma_\ell & \text{for Region II}, \\ \sigma_t\,(1 - \sigma_\ell) + \frac{1}{\sigma_t}\,\sigma_\ell & \text{for Region III}. \end{cases} \tag{4.3}$$

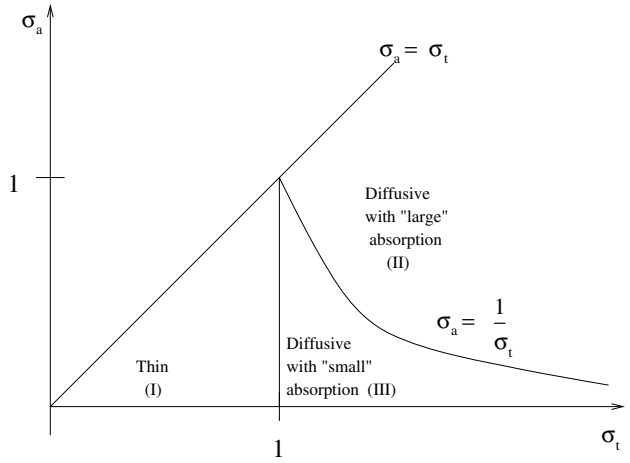

FIG. 4.1. *Division of parameters into Regions* I, II, *and* III.

In the remainder of this section, we develop V_1-ellipticity proofs for the case of anisotropic scattering using the scaling operator (4.1). Firstly, though, we note that the V_1-norm, defined by (3.12), does not change for anisotropic scattering once $\mathcal{R}$ is defined in terms of (4.1). Secondly, for $q \in \mathrm{L}^2$ and $g \in B_I$, we note that the solution of (2.1) can be expressed as

$$\psi = \arg\min_{v \in V_1} G_A(v;\, q, g), \tag{4.4}$$

where $G_A(v; q, g)$ is the anisotropic equivalent of $G_I(v; q, g)$. The corresponding variational form is: find $\psi \in V_1$ such that

$$a(\psi, v) := \left\langle \mathcal{R}^{-1}\mathcal{L}_A\,\psi, \mathcal{L}_A\,v \right\rangle + 2b_I(\psi, v) = \left\langle \mathcal{R}^{-1}q, \mathcal{L}_A\,v \right\rangle + 2b_I(g, v) \tag{4.5}$$

for every $v \in V_1$. Once we establish V_1-ellipticity results for $a(\psi, v)$, we will have established that (4.5) is well posed. This well posedness will imply that, for each pair $q \in \mathrm{L}^2$ and $g \in B_I$, there exists a unique $\psi \in V_1$ satisfying (2.1). Moreover, a standard stability result (cf. [4]) implies that we get the a priori estimate:

$$\|\psi\|_{V_1} \le C_e^{-1}\left(\left\|\mathcal{R}^{-1/2}q\right\| + b_I(g, g)^{1/2}\right), \tag{4.6}$$

where C_e is the coercivity bound.

4.1. Auxiliary lemmas. In this section, we present two lemmas. Most of the first lemma is a restatement of Lemma 3.1 from [14]. The second lemma is used in the thin and thick regime ellipticity proofs.

First, we define an operator that arises in Lemma 4.1, and the ellipticity proof for the thick regime with small absorption. To define the operator, we define $s = (\sigma_t - \frac{1}{\sigma_t})/(\sigma_t - \sigma_a)$ and split the moments into the two disjoint sets,

$$\Upsilon = \{\, \ell \in \mathbb{N} \;:\; \sigma_l > s\} = \{\ell \in \mathbb{N} \;:\; \mu_\ell < 1/\sigma_t\}, \tag{4.7}$$

$$\widehat{\Upsilon} = \{\, \ell \in \mathbb{N} \;:\; \sigma_l \le s\} = \{\ell \in \mathbb{N} \;:\; \mu_\ell \ge 1/\sigma_t\}. \tag{4.8}$$

We can then define the projection operator

$$\mathcal{P}_\Upsilon v(\mathbf{x}, \mathbf{\Omega}) := \sum_{\ell \in \Upsilon} \sum_{m=-\ell}^{\ell} \phi_{\ell m}(\mathbf{x}) Y_{\ell m}(\mathbf{\Omega}),$$

according to (2.6). A similar operator can be defined for $\widehat{\Upsilon}$. Furthermore, we introduce the operator $\mathcal{D}$ given by

$$\mathcal{D}\, v(\mathbf{x},\mathbf{\Omega}) := \mathcal{P}_\Upsilon v(\mathbf{x},\mathbf{\Omega}) + \sum_{\ell\in\widehat{\Upsilon}} \zeta_l \sum_{m=-\ell}^{\ell} \phi_{\ell m}(\mathbf{x}) Y_{\ell m}(\mathbf{\Omega}), \tag{4.9}$$

where $\zeta_\ell := (1-\sigma_\ell) + \frac{\sigma_a \sigma_\ell}{\sigma_t}$. Notice that $\mathcal{D}^s$ is a meaningful operator for any $s \in \Re$ and that $\|\mathcal{D}\| \leq 1$ since $\zeta_\ell \leq 1$. In the following, we use the notation, $\sum_\ell = \sum_\ell^\infty$.

LEMMA 4.1. *For $v \in V_1$, we have*

(i) $2\,\langle \mathbf{\Omega}\cdot\nabla v, v\rangle = b_O(v,v) - b_I(v,v) \geq -b_I(v,v)$;

(ii) *the Poincaré-Friedrichs inequality*

$$\|v\|^2 \leq 2\,\mathrm{diam}(R)^2\ \|\mathbf{\Omega}\cdot\nabla v\|^2 + 2\,\mathrm{diam}(R)\, b_I(v,v)\,; \tag{4.10}$$

(iii) *for* $\mathrm{diam}(R) = 1$ *and* $\sigma_t \geq 1$, *we have*

$$\|\mathcal{P}_\Upsilon\, v\|^2 \leq 2\left\|\mathcal{Q}^{-1/2}\,\mathbf{\Omega}\cdot\nabla v + \sigma_t\,\mathcal{P}_\Upsilon\,\mathbf{\Omega}\cdot\nabla v\right\|^2 + 2b_I(v,v)\,, \tag{4.11}$$

where $\mathcal{Q} := \mathcal{D}\,(\mathcal{I}-\mathcal{P}_\Upsilon)$ *and* $\mathcal{Q}^s := \mathcal{D}^s\,(\mathcal{I}-\mathcal{P}_\Upsilon)$ *for* $s \in \Re$.

Proof. The proofs of (i) and (ii) are found in Lemma 3.1 of [14], while (iii) is proved by assuming (ii), and noting that $\|\mathcal{P}_\Upsilon\, v\|^2 \leq \|v\|^2$ and

$$\|\mathbf{\Omega}\cdot\nabla\, v\|^2 \leq \left\|\mathcal{D}^{-1/2}\,(\mathcal{I}-\mathcal{P}_\Upsilon)\,\mathbf{\Omega}\cdot\nabla v + \sigma_t\,\mathcal{P}_\Upsilon\,\mathbf{\Omega}\cdot\nabla v\right\|^2. \qquad \square$$

LEMMA 4.2. *Given $\lambda_\ell > 0$ and $\omega_\ell > 0$, the minimum of*

$$I(d) := \sum_\ell (\lambda_\ell - d)^2 \omega_\ell \tag{4.12}$$

for $d \in [0,1]$ is achieved at

$$d_m = \frac{\sum_\ell \lambda_\ell \omega_\ell}{\sum_\ell \omega_\ell},$$

and furthermore,

$$I(d_m) = \sum_\ell \lambda_\ell^2 \omega_\ell - \frac{(\sum_\ell \lambda_\ell \omega_\ell)^2}{\sum_\ell \omega_\ell}.$$

Proof. The result is established by differentiating $I(d)$ with respect to d. $\square$

The thin regime and thick regime with small absorption ellipticity proofs that follow make use of the projection operator

$$\mathcal{P}_\ell v := \sum_{m=-\ell}^{\ell} \phi_{\ell m}(\mathbf{x}) Y_{\ell m}(\mathbf{\Omega}), \tag{4.13}$$

implying that (2.10) can be expressed as

$$\mathcal{S}v(\mathbf{x},\mathbf{\Omega}) = \sum_{\ell=0}^{\infty} \mu_\ell\, \mathcal{P}_\ell\, v(\mathbf{x},\mathbf{\Omega}). \tag{4.14}$$

Note the observation, $\sum_\ell \mathcal{P}_\ell = \mathcal{I}$, that we need in the following.

4.2. Thin regime ($0 \le \sigma_a \le \sigma_t \le 1$). For the thin regime, we have $\mathcal{R} = \mathcal{I}$ and

$$\|u\|_{V_1}^2 = \|\mathbf{\Omega} \cdot \nabla v\|^2 + \|v\|^2 + b_I(v,v).$$

THEOREM 4.3 (continuity and V_1-ellipticity for thin regime). *Assume that* $0 \le \sigma_a \le \sigma_t \le 1$. *Then, for all* $u, v \in V_1$, *we have*

$$\begin{aligned} |a(u,v)| = |\langle \mathcal{L}_A\, u, \mathcal{L}_A\, v\rangle + 2b_I(u,v)| &\le C_c\, \|u\|_{V_1}\, \|v\|_{V_1}, \\ a(v,v) = \langle \mathcal{L}_A\, v, \mathcal{L}_A\, v\rangle + 2b_I(v,v) &\ge C_e\, \|v\|_{V_1}^2, \end{aligned} \tag{4.15}$$

with $C_c \le 2$ *and* $C_e \ge 0.06574145$.

Proof. Using the Cauchy–Schwarz inequality, we obtain

$$\begin{aligned} |a(u,v)| &\le \|\mathcal{L}_A\, u\|\, \|\mathcal{L}_A\, v\| + 2b_I(u,u)^{\frac{1}{2}} b_I(v,v)^{\frac{1}{2}} \\ &\le \left(\|\mathcal{L}_A\, u\|^2 + 2b_I(u,u)\right)^{\frac{1}{2}} \left(\|\mathcal{L}_A\, v\|^2 + 2b_I(v,v)\right)^{\frac{1}{2}}. \end{aligned}$$

Given that $\sigma_t(1-\sigma_\ell) \le 1$ and $\sigma_a \sigma_\ell \le 1$, we have

$$\|\mathcal{L}_A\, u\|^2 \le 2\left(\|\mathbf{\Omega} \cdot \nabla u\|^2 + \|(\mathcal{I}-\mathcal{P})u\|^2 + \|\mathcal{P}u\|^2\right) = 2\left(\|\mathbf{\Omega} \cdot \nabla u\|^2 + \|u\|^2\right)$$

so that $\|\mathcal{L}_A\, u\|^2 + 2b_I(u,u) \le 2\, \|u\|_{V_1}^2$. This proves continuity of $a(\cdot,\cdot)$.

To prove ellipticity, we note that $0 \le \mu_\ell \le 1$ and refer the reader to (4.14). Using this definition of $\mathcal{S}$, we have

$$\begin{aligned} a(v,v) &= \langle \Omega \cdot \nabla v, \Omega \cdot \nabla v\rangle + 2\langle \Omega \cdot \nabla v, \mathcal{S}v\rangle + \langle \mathcal{S}v, \mathcal{S}v\rangle + 2\, b_I(v,v) \\ &= \langle \Omega \cdot \nabla v, \Omega \cdot \nabla v\rangle + 2\sum_\ell \mu_\ell \langle \Omega \cdot \nabla v, \mathcal{P}_\ell v\rangle + \sum_\ell \mu_\ell^2 \langle \mathcal{P}_\ell v, v\rangle + 2\, b_I(v,v). \end{aligned} \tag{4.16}$$

For any $d \in [0,1]$, adding the identity

$$2d\left[\langle \Omega \cdot \nabla v, v\rangle - \sum_\ell \langle \Omega \cdot \nabla v, \mathcal{P}_\ell v\rangle\right] = 0$$

to (4.16) and using Lemma 4.1(i) yields

$$\begin{aligned} a(v,v) \ge \langle \Omega \cdot \nabla v, \Omega \cdot \nabla v\rangle &+ 2\sum_\ell (\mu_\ell - d)\langle \Omega \cdot \nabla v, \mathcal{P}_\ell v\rangle \\ &+ \sum_\ell \mu_\ell^2 \langle \mathcal{P}_\ell v, v\rangle + (2-d)\, b_I(v,v). \end{aligned} \tag{4.17}$$

For convenience, we put $A_\ell = \|\mathcal{P}_\ell \mathbf{\Omega} \cdot \nabla v\|^2$, $A = \|\mathbf{\Omega} \cdot \nabla v\|^2$, $B_\ell = \|\mathcal{P}_\ell v\|^2$, and $B = \|v\|^2$. We also define $\gamma_\ell = A_\ell/A$ and $\delta_\ell = B_\ell/B$ and note that

$$\sum_\ell \delta_\ell = \sum_\ell \gamma_\ell = 1.$$

Thus we seek a proof of

$$a(v,v) \ge C\,(A + B + b_I(v,v))$$

for all $v \in V_1$. Applying the arithmetic-geometric inequality to the cross product term in (4.17) with $\eta > 0$ yields

$$\begin{aligned} a(v,v) &\geq \left(A - \eta \sum_\ell A_\ell \right) + \left(\sum_\ell \mu_\ell^2 B_\ell - \frac{1}{\eta} \sum_\ell (\mu_\ell - d)^2 B_\ell \right) + (2-d)\, b_I(v,v) \\ &= (1-\eta)\, A + \left(\sum_\ell \mu_\ell^2 \delta_\ell - \frac{1}{\eta} \sum_\ell (\mu_\ell - d)^2 \delta_\ell \right) B + (2-d)\, b_I(v,v) \end{aligned}$$

since $B_\ell = \delta_\ell B$. Making use of Lemma 4.2 we choose $d = \sum_\ell \mu_\ell \delta_\ell \leq \sum_\ell \delta_\ell = 1$, implying that

$$\begin{aligned} a(v,v) &\geq [1-\eta]\ A + \left[\sum_\ell \mu_\ell^2 \delta_\ell - \frac{1}{\eta} \left(\sum_\ell \mu_\ell^2 \delta_\ell - \left(\sum_\ell \mu_\ell \delta_\ell \right)^2 \right) \right] B + b_I(v,v) \\ &= [1-\eta]\, A + \left[\left(1 - \frac{1}{\eta} \right) \sum_\ell \mu_\ell^2 \delta_\ell + \frac{1}{\eta} \left(\sum_\ell \mu_\ell \delta_\ell \right)^2 \right] B + b_I(v,v). \end{aligned}$$

For convenience, define $\delta = \sum_\ell \mu_\ell^2 \delta_\ell \leq \sum_\ell \mu_\ell \delta_\ell \leq 1$ such that

$$\begin{aligned} a(v,v) &\geq [1-\eta]\, A + \left[\left(1 - \frac{1}{\eta} \right) \delta + \frac{1}{\eta} \delta^2 \right] B + b_I(v,v) \\ &= [1-\eta]\, A + \left[\delta - \frac{1}{\eta} \delta (1-\delta) \right] B + b_I(v,v). \end{aligned}$$

Using Lemma 4.1(ii) (assuming $\operatorname{diam}(R) = 1$) we get

$$a(v,v) \geq [1-\eta-\beta]\, A + \left[\delta - \frac{1}{\eta} \delta (1-\delta) + \frac{\beta}{2} \right] B + [1-\beta]\, b_I(v,v)$$

for any $\beta \geq 0$. Define

$$\begin{aligned} C_1 &= 1 - \eta - \beta, \\ C_2 &= \delta - \frac{1}{\eta} \delta (1-\delta) + \frac{\beta}{2}, \\ C_3 &= 1 - \beta. \end{aligned}$$

Next, set $\eta = \sqrt{\delta(1-\delta)}$ and choose β to make $C_1 = C_2$. This requires

$$1 - \sqrt{\delta(1-\delta)} - \beta = \delta - \sqrt{\delta(1-\delta)} + \frac{\beta}{2},$$

which implies

$$\beta = \frac{2}{3}(1-\delta) \geq 0.$$

Plugging back into C_1 yields

$$\begin{aligned} C_1 = C_2 &= 1 - \sqrt{\delta(1-\delta)} - \frac{2}{3}(1-\delta), \\ C_3 &= 1 - \frac{2}{3}(1-\delta) \geq \frac{1}{3}. \end{aligned}$$

Numerically we find that the minimum value of C_1 occurs at $\delta = \frac{1-\sqrt{16/52}}{2} \approx 0.2226499$ and yields $C_1 = C_2 \approx 0.06574145$. Comparing to the bound on C_3, we see that $C_e \geq 0.06574145$. ∎

4.3. Thick regime with "large" absorption ($1 \leq \boldsymbol{\sigma_t} < \infty$; $\frac{1}{\boldsymbol{\sigma_t}} \leq \boldsymbol{\sigma_a} \leq \boldsymbol{\sigma_t}$). For the thick regime with "large" absorption, the scaling is given by

$$\mathcal{R} = \sigma_t \left(\mathcal{I} - \mathcal{K}\right) + \sigma_a \mathcal{K}, \tag{4.18}$$

which implies that

$$\|v\|_V^2 := \left\langle \mathcal{R}^{-1} \boldsymbol{\Omega} \cdot \nabla v, \boldsymbol{\Omega} \cdot \nabla v \right\rangle + \langle \mathcal{R}\, v, v \rangle$$

and

$$\|v\|_{V_1}^2 = \|v\|_V^2 + b_I(v, v).$$

THEOREM 4.4 (continuity and V_1-ellipticity for the thick regime with "large" absorption). *Assume that* $1 \leq \sigma_t < \infty$ *and* $\frac{1}{\sigma_t} \leq \sigma_a \leq \sigma_t$. *Then, for all* $u, v \in V_1$, *we have*

$$\begin{aligned} |a(u,v)| &\leq 2 \, \|u\|_{V_1} \, \|v\|_{V_1}, \\ a(v,v) &\geq \|v\|_{V_1}^2 . \end{aligned} \tag{4.19}$$

Proof. See the proof establishing coercivity and continuity in thick regime with "large" absorption from [14]. Proof for coercivity is the same because, as in [14], scaling operator $\mathcal{R}$, in (4.18) is equal to scattering operator $\mathcal{S}$. ∎

4.4. Thick regime with "small" absorption ($1 \leq \boldsymbol{\sigma_t} \leq \infty$; $\boldsymbol{\sigma_a} \leq \frac{1}{\boldsymbol{\sigma_t}}$). For the thick regime with "small" absorption, we must define the scaling operator so that it does not become singular as $\sigma_a \to 0$. Hence, the scaling operator defined in (4.18) is recast as

$$\mathcal{R} = \sigma_t(\mathcal{I} - \mathcal{K}) + \frac{1}{\sigma_t}\mathcal{K}, \tag{4.20}$$

while the V-norm and the V_1-norm have the same dependence on $\mathcal{R}$.

One of the key ingredients of the following proof is the intermediate scaling operator defined below. Recall Υ and $\widehat{\Upsilon}$ defined by (4.7) and (4.8), and $\mathcal{Q}$ defined by (4.11). The intermediate scaling operator is

$$\mathcal{T} := \sigma_t \mathcal{Q} + \frac{1}{\sigma_t}\mathcal{P}_\Upsilon = \mathcal{S}(\mathcal{I} - \mathcal{P}_\Upsilon) + \frac{1}{\sigma_t}\mathcal{P}_\Upsilon.$$

Note that $\mathcal{Q} \leq \mathcal{I}$, and additionally, that $\sigma_a \mathcal{P}_\Upsilon \leq \mathcal{S}\mathcal{P}_\Upsilon \leq \frac{1}{\sigma_t}\mathcal{P}_\Upsilon$, which is equivalent to $\sigma_a \leq \mu_\ell \leq \frac{1}{\sigma_t}$ for $\ell \in \Upsilon$. The first inequality is true by definition of μ_ℓ, and the second is true by definition of Υ. We also introduce τ_ℓ according to

$$\tau_\ell := \begin{cases} \frac{1}{\sigma_t} & \text{for } \ell \in \Upsilon \\ \mu_\ell & \text{for } \ell \in \widehat{\Upsilon} \end{cases} \tag{4.21}$$

such that, from (4.13),

$$\mathcal{T} v(\mathbf{x}, \boldsymbol{\Omega}) = \sum_{\ell=0}^{\infty} \tau_\ell \mathcal{P}_\ell v(\mathbf{x}, \boldsymbol{\Omega}).$$

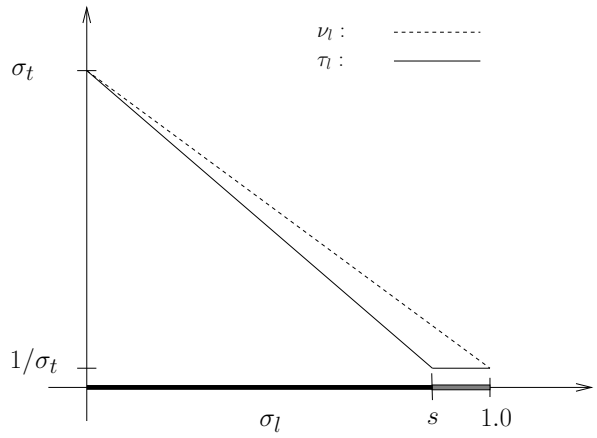

FIG. 4.2. *Graph of τ_ℓ and ν_ℓ, where the black region on $\sigma_\ell \in [0,1]$ denotes $\widehat{\Upsilon}$ and the grey region denotes Υ. From the graph we can see that the largest ratio occurs at the interface between $\widehat{\Upsilon}$ and Υ, which is where $\sigma_\ell = s$.*

For future reference, we note that

$$\mathcal{T}^{-1}\mathcal{S} = \mathcal{S}\mathcal{T}^{-1} = (\mathcal{I} - \mathcal{P}_\Upsilon) + \sigma_t \mathcal{S}\mathcal{P}_\Upsilon, \tag{4.22}$$

$$\mathcal{T}^{-1}\mathcal{S}^2 = \mathcal{S}^2\mathcal{T}^{-1} = \sigma_t \mathcal{Q} + \sigma_t \mathcal{S}^2\mathcal{P}_\Upsilon, \tag{4.23}$$

and $\mathcal{S}$ can be expressed as

$$\mathcal{S} = \mathcal{S}(\mathcal{I} - \mathcal{P}_\Upsilon) + \mathcal{S}\mathcal{P}_\Upsilon = \sigma_t \mathcal{Q} + \mathcal{S}\mathcal{P}_\Upsilon.$$

Note the inequality

$$\langle \mathcal{S}v, v\rangle \le \langle \mathcal{T}v, v\rangle \le \langle \mathcal{R}v, v\rangle \tag{4.24}$$

and the related inequality

$$\left\langle \mathcal{T}^{-1}v, v\right\rangle \ge \left\langle \mathcal{R}^{-1}v, v\right\rangle. \tag{4.25}$$

We also need the following lemma, which further relates $\mathcal{T}$ to $\mathcal{R}$.

LEMMA 4.5. *For $\sigma_t \ge 1$ and $\sigma_a \le 1/\sigma_t$, we have*

$$2\langle \mathcal{T}v, v\rangle \ge \langle \mathcal{R}v, v\rangle \qquad \text{and} \qquad \left\langle \mathcal{T}^{-1}v, v\right\rangle \le 2\left\langle \mathcal{R}^{-1}v, v\right\rangle.$$

Proof. To prove both results, we establish a bound relating τ_ℓ to ν_ℓ, where ν_ℓ is defined by (4.3). By observing the graph of τ_ℓ and ν_ℓ in Figure 4.2, we see that the ratio ν_ℓ/τ_ℓ is maximized at $s = (\sigma_t - \frac{1}{\sigma_t})/(\sigma_t - \sigma_a)$. Evaluating both ν_ℓ and τ_ℓ at s yields

$$\frac{\nu_\ell}{\tau_\ell} = \frac{\sigma_t(1-s) + s/\sigma_t}{1/\sigma_t} = \sigma_t^2(1-s) + s = \frac{2\sigma_t - \sigma_a\sigma_t^2 - 1/\sigma_t}{\sigma_t - \sigma_a}.$$

As $\sigma_a \to 0$, the value of s decreases to its minimum (dependent on σ_a) of $1 - 1/\sigma_t^2$. Since $\nu_\ell/\tau_\ell = \sigma_t^2(1-s) + s$, the maximum of the ratio is where s is at its minimum, i.e., where $\sigma_a = 0$. This implies

$$\frac{\nu_\ell}{\tau_\ell} \le 2 - 1/\sigma_t^2 \le 2.$$

Both results follow from this inequality. ∎

THEOREM 4.6 (continuity and V_1-ellipticity for thick regime with "small" absorption). *Assume that* $1 \leq \sigma_t < \infty$, $0 \leq \sigma_a \leq \frac{1}{\sigma_t}$. *Then, for all* $u, v \in V_1$, *we have*

$$|a(u,v)| = |\left\langle \mathcal{R}^{-1}\mathcal{L}_A\, u, \mathcal{L}_A\, v\right\rangle + 2b_I(u,v)| \leq C_c\ \|u\|_{V_1}\ \|v\|_{V_1}\,, \tag{4.26}$$

$$a(v,v) = \left\langle \mathcal{R}^{-1}\mathcal{L}_A\, v, \mathcal{L}_A\, v\right\rangle + 2b_I(v,v) \geq C_e\ \|v\|^2_{V_1}\,, \tag{4.27}$$

with $C_c \leq 2$ *and* $C_e \geq 0.01667$, *independent of* σ_t *and* σ_a.

Proof. The proof for continuity follows from the same reasoning as used in Theorem 4.4 since

$$|a(u,v)| \leq \left(\left\|\mathcal{R}^{-\frac{1}{2}}\mathcal{L}_A\, u\right\| + 2b_I(u,u)\right)^{\frac{1}{2}}\ \left(\left\|\mathcal{R}^{-\frac{1}{2}}\mathcal{L}_A\, v\right\| + 2b_I(v,v)\right)^{\frac{1}{2}}.$$

The observation that $\mu_\ell \leq \nu_\ell$ implies

$$\left\|\mathcal{R}^{-\frac{1}{2}}\mathcal{S}u\right\| \leq \left\|\mathcal{R}^{\frac{1}{2}}u\right\|.$$

One can easily show then that $\left\|\mathcal{R}^{-\frac{1}{2}}\mathcal{L}_A\, u\right\|^2 \leq 2\,\|u\|^2_V$.

To establish coercivity, we proceed as follows. We first define

$$\widetilde{a}(v,v) := \left\langle \mathcal{T}^{-1}\mathcal{L}_A v, \mathcal{L}_A v\right\rangle + 2\, b_I(v,v), \tag{4.28}$$

and through Lemma 4.5, we get

$$a(v,v) \geq \frac{1}{2}\,\widetilde{a}(v,v). \tag{4.29}$$

Assume for now that we have

$$\widetilde{a}(v,v) \geq \widetilde{C}_e\,\left(\left\|\mathcal{T}^{-1/2}\boldsymbol{\Omega}\cdot\nabla v\right\|^2 + \left\|\mathcal{T}^{1/2}v\right\|^2 + b_I(v,v)\right). \tag{4.30}$$

Using inequality (4.25) and Lemma 4.5, we can bound the first two terms on the right-hand side of (4.30) from below to get

$$\widetilde{a}(v,v) \geq \frac{\widetilde{C}_e}{2}\,\left(\left\|\mathcal{R}^{-1/2}\boldsymbol{\Omega}\cdot\nabla v\right\|^2 + \left\|\mathcal{R}^{1/2}v\right\|^2 + b_I(v,v)\right). \tag{4.31}$$

With (4.29) we get as an ellipticity constant in (4.27) the value of $\widetilde{C}_e/4$. Thus, we are only left to prove (4.30), and determine $\widetilde{C}_e$.

Noting (4.22) and (4.23) we write

$$\begin{aligned}
\widetilde{a}(v,v) &= \left\langle \mathcal{T}^{-1}\boldsymbol{\Omega}\cdot\nabla v, \boldsymbol{\Omega}\cdot\nabla v\right\rangle + \left\langle \mathcal{S}^2\mathcal{T}^{-1}v, v\right\rangle + 2\left\langle \mathcal{S}\mathcal{T}^{-1}\boldsymbol{\Omega}\cdot\nabla v, v\right\rangle + 2b_I(v,v)\\
&= \frac{1}{\sigma_t}\left\langle \mathcal{Q}^{-1}\boldsymbol{\Omega}\cdot\nabla v, \boldsymbol{\Omega}\cdot\nabla v\right\rangle + \sigma_t\left\langle \mathcal{P}_\Upsilon\boldsymbol{\Omega}\cdot\nabla v, \boldsymbol{\Omega}\cdot\nabla v\right\rangle + \sigma_t\left\langle \mathcal{Q}v, v\right\rangle\\
&\quad + \sigma_t\sum_{\ell\in\Upsilon}\mu_\ell^2\left\langle \mathcal{P}_\ell v, v\right\rangle + 2\left\langle \boldsymbol{\Omega}\cdot\nabla v, (\mathcal{I}-\mathcal{P}_\Upsilon)v\right\rangle + 2\sigma_t\sum_{\ell\in\Upsilon}\mu_\ell\left\langle \boldsymbol{\Omega}\cdot\nabla v, \mathcal{P}_\ell v\right\rangle\\
&\quad + 2b_I(v,v).
\end{aligned}$$

For any $d \in [0,1]$, adding the identity

$$2d\,\left[\langle\boldsymbol{\Omega}\cdot\nabla v, v\rangle - \langle\boldsymbol{\Omega}\cdot\nabla v, (\mathcal{I}-\mathcal{P}_\Upsilon)v\rangle - \langle\boldsymbol{\Omega}\cdot\nabla v, \mathcal{P}_\Upsilon v\rangle\right] = 0$$

to the last line above, and using the inequality from Lemma 4.1(ii), yields

$$\begin{aligned}\widetilde{a}(v,v) \geq \frac{1}{\sigma_t}\left\langle \mathcal{Q}^{-1}\boldsymbol{\Omega}\cdot\nabla v, \boldsymbol{\Omega}\cdot\nabla v\right\rangle + \sigma_t\left\langle \mathcal{P}_\Upsilon\boldsymbol{\Omega}\cdot\nabla v, \boldsymbol{\Omega}\cdot\nabla v\right\rangle + \sigma_t\left\langle \mathcal{Q}v, v\right\rangle \\ + \sigma_t\sum_{\ell\in\Upsilon}\mu_\ell^2\left\langle \mathcal{P}_\ell v, v\right\rangle - 2|1-d|\ |\langle \boldsymbol{\Omega}\cdot\nabla v, (\mathcal{I}-\mathcal{P}_\Upsilon)v\rangle| \\ -2\sum_{\ell\in\Upsilon}|\sigma_t\mu_\ell - d|\ |\langle \boldsymbol{\Omega}\cdot\nabla v, \mathcal{P}_\ell v\rangle| + (2-d)b_I(v,v).\end{aligned}$$

It is convenient to note that we may write

$$|\left\langle \boldsymbol{\Omega}\cdot\nabla v, (\mathcal{I}-\mathcal{P}_\Upsilon)v\right\rangle| \leq \left\|\frac{1}{\sqrt{\sigma_t}}Q^{-1/2}\boldsymbol{\Omega}\cdot\nabla v\right\|\ \left\|\sqrt{\sigma_t}Q^{1/2}v\right\|,$$

and for $\ell\in\Upsilon$,

$$|\left\langle \boldsymbol{\Omega}\cdot\nabla v, \mathcal{P}_\ell\, v\right\rangle| \leq \|\sqrt{\sigma_t}\,\mathcal{P}_\ell\,\boldsymbol{\Omega}\cdot\nabla v\|\ \left\|\frac{1}{\sqrt{\sigma_t}}\,\mathcal{P}_\ell\, v\right\|.$$

Let's now define

$$\delta_\ell := \frac{\left\|\frac{1}{\sqrt{\sigma_t}}\mathcal{P}_\ell v\right\|^2}{\left\|\sqrt{\sigma_t}\mathcal{Q}^{1/2}v + \frac{1}{\sqrt{\sigma_t}}\mathcal{P}_\Upsilon v\right\|^2} \quad\text{and}\quad \gamma_\ell := \frac{\left\|\sqrt{\sigma_t}\mathcal{P}_\ell\boldsymbol{\Omega}\cdot\nabla v\right\|^2}{\left\|\frac{1}{\sqrt{\sigma_t}}\mathcal{Q}^{-1/2}\boldsymbol{\Omega}\cdot\nabla v + \sqrt{\sigma_t}\mathcal{P}_\Upsilon\boldsymbol{\Omega}\cdot\nabla v\right\|^2}$$

for $\ell\in\Upsilon$. Additionally, let $\delta_0 = 1-\sum_{\ell\in\Upsilon}\delta_\ell$ and $\gamma_0 = 1-\sum_{\ell\in\Upsilon}\gamma_\ell$. For convenience, set

$$A = \left\|\mathcal{T}^{-1/2}\boldsymbol{\Omega}\cdot\nabla v\right\|^2 = \left\|\frac{1}{\sqrt{\sigma_t}}\mathcal{Q}^{-1/2}\boldsymbol{\Omega}\cdot\nabla v + \sqrt{\sigma_t}\mathcal{P}_\Upsilon\boldsymbol{\Omega}\cdot\nabla v\right\|^2$$

and

$$B = \left\|\mathcal{T}^{1/2}v\right\|^2 = \left\|\sqrt{\sigma_t}\mathcal{Q}^{1/2}v + \frac{1}{\sqrt{\sigma_t}}\mathcal{P}_\Upsilon v\right\|^2.$$

We can now use the arithmetic-geometric inequality to write, for any $\eta>0$,

$$\begin{aligned}\widetilde{a}(v,v) \geq \left\|\frac{1}{\sqrt{\sigma_t}}\mathcal{Q}^{-1/2}\boldsymbol{\Omega}\cdot\nabla v\right\|^2 + \sum_{\ell\in\Upsilon}\|\sqrt{\sigma_t}\mathcal{P}_\ell\boldsymbol{\Omega}\cdot\nabla v\|^2 + \left\|\sqrt{\sigma_t}\mathcal{Q}^{1/2}v\right\|^2 \\ + \sum_{\ell\in\Upsilon}(\sigma_t\mu_\ell)^2\left\|\frac{1}{\sqrt{\sigma_t}}\mathcal{P}_\ell v\right\|^2 - \eta\left\|\frac{1}{\sqrt{\sigma_t}}\mathcal{Q}^{-1/2}\boldsymbol{\Omega}\cdot\nabla v\right\|^2 \\ - \frac{(1-d)^2}{\eta}\left\|\sqrt{\sigma_t}\mathcal{Q}^{1/2}v\right\|^2 - \sum_{\ell\in\Upsilon}\eta\,\|\sqrt{\sigma_t}\mathcal{P}_\ell\boldsymbol{\Omega}\cdot\nabla v\|^2 \\ - \sum_{\ell\in\Upsilon}\frac{(\sigma_t\mu_\ell-d)^2}{\eta}\left\|\frac{1}{\sqrt{\sigma_t}}\mathcal{P}_\ell v\right\|^2 + (2-d)b_I(v,v)\end{aligned}$$

$$= \left[(1-\eta)\gamma_0 + \sum_{\ell\in\Upsilon}(1-\eta)\gamma_\ell\right]A + \left[\left(1-\frac{(1-d)^2}{\eta}\right)\delta_0 \tag{4.32}$$

$$+ \sum_{\ell\in\Upsilon}\left((\sigma_t\mu_\ell)^2 - \frac{(\sigma_t\mu_\ell-d)^2}{\eta}\right)\delta_\ell\right]B + (2-d)b_I(v,v). \tag{4.33}$$

We choose d to make the coefficient of B as large as possible. First we simplify this expression by temporarily setting $\mu_0 = 1/\sigma_t$ so that the coefficient on B can be expressed as

$$\sum_{\ell\in 0\cup\Upsilon} (\sigma_t\mu_\ell)^2\delta_\ell - \frac{1}{\eta}\sum_{\ell\in 0\cup\Upsilon} (\sigma_t\mu_\ell - d)^2\delta_\ell. \tag{4.34}$$

Then we see that d should be chosen to minimize the second sum, which by Lemma 4.2, yields

$$d = \sum_{\ell\in 0\cup\Upsilon} (\sigma_t\mu_\ell)\,\delta_\ell, \tag{4.35}$$

making use of the fact that $\sum_{\ell\in 0\cup\Upsilon}\delta_\ell = 1$. Note that $d\in[0,1]$ because $(\sigma_t\mu_\ell)\in[0,1]$.

Substituting d defined by (4.35) into (4.34) yields

$$\delta_0 + \sum_{\ell\in\Upsilon} (\sigma_t\mu_\ell)^2\delta_\ell - \frac{1}{\eta}\left(\left(\delta_0 + \sum_{\ell\in\Upsilon}(\sigma_t\mu_\ell)^2\,\delta_\ell\right) - \left(\delta_0 + \sum_{\ell\in\Upsilon}(\sigma_t\mu_\ell)\,\delta_\ell\right)^2\right). \tag{4.36}$$

For convenience, we rewrite (4.36) as

$$\Delta_0 - \frac{1}{\eta}\left(\Delta_0 - \Delta_1^2\right) = \Delta_0\left(1-\frac{1}{\eta}\right) + \frac{\Delta_1^2}{\eta},$$

where

$$\Delta_0 = \delta_0 + \sum_{\ell\in\Upsilon}(\sigma_t\mu_\ell)^2\delta_\ell \qquad \text{and} \qquad \Delta_1 = \delta_0 + \sum_{\ell\in\Upsilon}(\sigma_t\mu_\ell)\delta_\ell.$$

Note that Lemma 4.2 implies that $\Delta_0 \geq \Delta_1^2$. Also, $(\sigma_t\mu_\ell)^2 \leq (\sigma_t\mu_\ell) \leq 1$ for $\ell\in\Upsilon$ implies that $\Delta_0 \leq \Delta_1 \leq 1$. Hence, we get

$$\Delta_0 - \frac{1}{\eta}\left(\Delta_0 - \Delta_1^2\right) = \Delta_0\left(1-\frac{1}{\eta}\right) + \frac{\Delta_1^2}{\eta} \geq \Delta_0\left(1-\frac{1}{\eta}\right) + \frac{\Delta_0^2}{\eta}. \tag{4.37}$$

Lastly, notice that $\Delta_0 \geq \delta_0$.

Next, using (4.37) and the fact that $\gamma_0 = 1 - \sum_{\ell\in\Upsilon}\gamma_\ell$, we obtain from (4.32)–(4.33)

$$\begin{aligned}\widetilde{a}(v,v) &\geq [1-\eta]\,A + \left[\Delta_0\left(1-\frac{1}{\eta}\right) + \frac{\Delta_0^2}{\eta}\right]B + b_I(v,v)\\ &\geq [1-\eta]\,A + \left[\Delta_0 - \frac{\Delta_0(1-\Delta_0)}{\eta}\right]B + b_I(v,v).\end{aligned}$$

If we set $\delta = (1-\Delta_0) \leq (1-\delta_0)$, then using Lemma 4.1(iii), we can say

$$\begin{aligned}\frac{\beta\delta}{2}B \leq \frac{\beta(1-\delta_0)}{2}B &= \frac{\beta}{2}\left\|\frac{1}{\sqrt{\sigma_t}}\mathcal{P}_\Upsilon v\right\|^2\\ &\leq \beta\left\|\frac{1}{\sqrt{\sigma_t}}\mathcal{Q}^{-1/2}\mathbf{\Omega}\cdot\nabla v + \sqrt{\sigma_t}\mathcal{P}_\Upsilon\mathbf{\Omega}\cdot\nabla v\right\|^2 + \frac{\beta}{\sigma_t}b_I(v,v) = \beta A + \frac{\beta}{\sigma_t}b_I(v,v).\end{aligned}$$

This implies

$$\widetilde{a}(v,v) \geq [1-\eta-\beta]A + \left[(1-\delta) - \frac{\delta(1-\delta)}{\eta} + \frac{\beta\delta}{2}\right]B + \left[1-\frac{\beta}{\sigma_t}\right]b_I(v,v), \tag{4.38}$$

where $\beta\geq 0$ and $\eta\geq 0$ are to be determined.

Our choice of β is given by

$$\beta = \frac{2}{2+\delta}\left(\delta + \frac{\delta(1-\delta)}{\eta} - \eta\right), \tag{4.39}$$

which is found by setting $C_1 = C_2$, that is, setting

$$1 - \eta - \beta = (1-\delta) - \frac{\delta(1-\delta)}{\eta} + \frac{\beta\delta}{2}.$$

Plugging (4.39) into the coefficient on A generates the lower bound

$$C = 1 - \eta - \beta = \left(\frac{(2-\delta)}{(2+\delta)} - \frac{\delta}{2+\delta}\left(\eta + \frac{2(1-\delta)}{\eta}\right)\right). \tag{4.40}$$

This is maximized for $\eta = \sqrt{2(1-\delta)}$, which yields

$$C = \frac{(2-\delta) - 2\delta\sqrt{2(1-\delta)}}{2+\delta}. \tag{4.41}$$

Note that this is only valid when the corresponding $\beta \geq 0$, that is, (4.41) is valid only for $\delta \geq \delta_c$, where δ_c is the root of

$$\beta = \frac{2}{2+\delta}\left(\delta + \frac{\delta(1-\delta)}{\sqrt{2(1-\delta)}} - \sqrt{2(1-\delta)}\right) = \frac{2\delta - (2-\delta)\sqrt{2(1-\delta)}}{2+\delta} = 0.$$

This root is the only real root of the polynomial

$$\delta^3 - 3\delta^2 + 8\delta - 4 = 0.$$

Numerically we find that $\delta_c \approx 0.6117$, implying $C_c \approx 0.1188$. We also find numerically the minimum of C in (4.41) on $[\delta_c, 1]$ to be

$$C_m = \min_{\delta\in[\delta_c,1]} C \approx 0.06667, \tag{4.42}$$

which occurs at $\delta_m \approx 0.7836$.

Now, for $\delta \leq \delta_c$, we set $\beta = 0$ and choose η such that

$$1 - \eta = (1-\delta) - \frac{\delta(1-\delta)}{\eta},$$

resulting in

$$\eta = \frac{\delta + \sqrt{4\delta - 3\delta^2}}{2},$$

and, subsequently,

$$C = \frac{2 - \delta - \sqrt{4\delta - 3\delta^2}}{2}.$$

Clearly, C is a decreasing function of $\delta \in [0, \delta_c]$ implying it takes on its smallest value at δ_c. As mentioned previously $C \approx 0.1188$ for this value of δ.

We finally complete the proof with a bound on the coefficient of $b_I(v,v)$ in (4.38). The minimization of this term is only considered on $[\delta_c, 1]$ since $\beta = 0$ on $[0, \delta_c]$. Plotting β on $[\delta_c, 1]$ shows that β is an increasing function of δ on this interval implying $\beta \leq 2/3$. Thus, we have that $[1 - \beta/\sigma_t] \geq 1/3$. We finally conclude that

$$\widetilde{a}(v,v) \geq \widetilde{C}_e(A + B + b_I(v,v)),$$

where $\widetilde{C}_e = C_m \geq 0.06666$ coming from (4.42). Since $A \geq \left\|\mathcal{R}^{-1/2}\mathbf{\Omega}\cdot\nabla v\right\|^2$ and $2\,B \geq \left\|\mathcal{R}^{1/2}v\right\|^2$, we get

$$\widetilde{a}(v,v) \geq 0.03333\,\|v\|^2_{V_1},$$

implying that $C_e = 0.03333/2 = 0.01667$ from (4.31). ∎

5. Discretization and error bounds. Any finite dimensional subspace of V_1 may be used to construct an approximation to the solution of ψ. One approach, which is a subject of future research, is using a tessellation of the sphere to represent angular dependence and nonconforming finite elements to describe spatial variability. However, in this paper, we develop error bounds associated with a P_N approximation in angle and standard H^1 conforming finite elements in space. The angular approximation is represented by a truncated expansion of (2.12), which must be of greater order than the finite sum that represents the scattering kernel (i.e., $N \geq N_S$). A finite element approximation of the moments is defined on a triangulation $\mathcal{T}_h$ of R into hexahedrals or tetrahedrons.

Let $\mathbb{P}_k(\mathcal{T}_h)$ denote the space of piecewise polynomials of degree $\leq k$ on $\mathcal{T}_h$, let Π_h be the corresponding interpolation operator on $\mathbb{P}_k(\mathcal{T}_h)$, and let the truncation operator Π_N be defined by

$$\Pi_N\, v(\mathbf{x},\mathbf{\Omega}) := \sum_{\ell=0}^{N}\sum_{m=-\ell}^{\ell} \phi_{\ell m}(\mathbf{x}) Y_{\ell m}(\mathbf{\Omega}). \tag{5.1}$$

Then the discrete space V^h is defined by

$$V^h := \left\{ v_h \in V \;:\; v_h = \sum_{\ell=0}^{N}\sum_{m=-\ell}^{\ell} \phi^h_{\ell m}(\mathbf{x}), Y_{\ell m}(\mathbf{\Omega});\quad \phi^h_{\ell m}(\mathbf{x}) \in \mathbb{P}_k(\mathcal{T}_h) \right\}. \tag{5.2}$$

The definition of V^h yields the discrete problem: find $\psi^h \in V^h$ such that

$$a(\psi^h, v^h) = \left\langle \mathcal{R}^{-1}\, q, \mathcal{L}_A\, v^h \right\rangle + 2 b_I(g, v^h) \tag{5.3}$$

for all $v^h \in V^h$.

Bounds for the discretization error are obtained by following the procedure outlined in [14]. Thus, let the components of $\mathbf{\Omega} \in S^2$ and $\mathbf{x} \in R$ be denoted by $\mathbf{\Omega} = (\Omega_1, \Omega_2, \Omega_3)$, $\mathbf{x} = (x_1, x_2, x_3)$, respectively, and let β, γ be a multi-index such that $D^\beta_{\mathbf{x}} := \frac{\partial^{|\beta|}}{\partial^{\beta_1}_{x_1}\partial^{\beta_2}_{x_2}\partial^{\beta_3}_{x_3}}$, and $D^\gamma_{\mathbf{\Omega}} := \frac{\partial^{|\gamma|}}{\partial^{\gamma_1}_{\Omega_1}\partial^{\gamma_2}_{\Omega_2}\partial^{\gamma_3}_{\Omega_3}}$. Recall that the standard norms [1] of $H^k(R)\times H^l(S^2)$ and $H^k(\partial R)\times H^l(S^2)$ are given by

$$\|v\|^2_{k,l} := \sum_{|\beta|\leq k}\sum_{|\gamma|\leq l} \left\| D^\gamma_{\mathbf{\Omega}} D^\beta_{\mathbf{x}} v \right\|,$$

$$\|v\|^2_{k,l,\partial R} := \sum_{|\beta|\leq k}\sum_{|\gamma|\leq l} \int_{\partial R}\int_{S^2} |D^\beta_{\mathbf{x}} v|^2 \,\mathrm{d}\mathbf{\Omega}\,\mathrm{d}\sigma.$$

Note also the following bounds for the interpolation error (see [4]):

$$\begin{aligned} \|v - \Pi_h v\|_{p,0} &\leq Ch^{k+1-p} \|v\|_{k+1,0} \ \forall v \in H^{k+1}(R) \times H^l(S^2), \\ \|v - \Pi_h v\|_{p,0,\partial R} &\leq Ch^{k+1-p} \|v\|_{k+1,0,\partial R} \ \forall v \in H^{k+1}(\partial R) \times H^l(S^2) \end{aligned} \tag{5.4}$$

for $p \in 0, 1$. We also define

$$\mathcal{E}_h(v) := v - \Pi_h v \tag{5.5}$$

and

$$\mathcal{E}_N(v) := v - \Pi_N v \tag{5.6}$$

for all $v \in \mathrm{L}^2(S^2 \times R)$.

To bound the error of the truncated expansion (5.1), we recall that the spherical harmonics are eigenfunctions of the Laplacian operator on the unit sphere, which implies

$$\begin{aligned} \Delta_{\mathbf{\Omega}} Y_{\ell m}(\Omega) &= \left[\tfrac{1}{\sin\theta}\tfrac{\partial}{\partial\theta}\left(\sin\theta\tfrac{\partial}{\partial\theta}\right) + \tfrac{1}{\sin^2\theta}\tfrac{\partial^2}{\partial\varphi^2}\right] Y_{\ell m}(\mathbf{\Omega}) \\ &= -l(l+1) Y_{\ell m}(\mathbf{\Omega}) \end{aligned} \tag{5.7}$$

for $l \geq 0$ and $m = -l, \ldots, 0, \ldots, l$. Next, for the reader's convenience, we include Lemma 4.1 from [14], as it is used throughout the remaining proofs.

LEMMA 5.1. *For $N \geq 1$, $|\beta| \leq k+1$, and $v \in V \cap (H^{k+1}(R) \times H^2(S^2))$ with $v(\mathbf{x}, \mathbf{\Omega}) = \sum_{\ell=0}^{\infty} \sum_{m=-\ell}^{\ell} \phi_{\ell m}(\mathbf{x}) Y_{\ell m}(\mathbf{\Omega})$, we have the following:*

(i) $\|\mathbf{\Omega} \cdot \nabla v\| \leq \sqrt{3} \sum_{i=1}^{3} \left\| \frac{\partial v}{\partial x_i} \right\|$.

(ii) $\left\| D_{\mathbf{x}}^{\beta} \phi_{\ell m}(\mathbf{x}) \right\|^2 \leq \frac{1}{[l(l+1)]^2} \int_{S^2} |\Delta_{\mathbf{\Omega}} D_{\mathbf{x}}^{\beta} v(\mathbf{x}, \mathbf{\Omega})|^2 \, \mathrm{d}\mathbf{\Omega}$.

(iii) $\left\| D_{\mathbf{x}}^{\beta} \mathcal{E}_N(v) \right\| \leq \frac{2}{N+1} \left\| \Delta_{\mathbf{\Omega}} D_{\mathbf{x}}^{\beta} v \right\|$.

(iv) $b_I(v, v) \leq \|v\|_{0,0,\partial R}^2$.

(v) $\|\mathcal{E}_N(v)\|_{0,0,\partial R} \leq \frac{2}{N+1} \|\Delta_{\mathbf{\Omega}} v\|_{0,0,\partial R}$.

(vi) *If, in addition, v satisfies the asymptotic expansion* (5.9)*, then*

$$\|\Pi_N(\mathcal{E}_h(v))\|_{0,0,\partial R} \leq C \frac{1}{\sigma_t} h^k \|\Delta_{\mathbf{\Omega}} \phi_R\|_{k+1,\partial R}.$$

Proof. See the proof in [14]. ∎

In the following, we present theorems for the thin regime (without proof) and for the thick regime with highly anisotropic scattering.

THEOREM 5.2 (thin regime). *Suppose that $N > N_S \geq 1$, $0 \leq \sigma_a \leq \sigma_t \leq 1$ and that $\|\cdot\|_{V_1}$ is defined as in* (3.12)*. Let $\psi \in V_1 \cap (H^{k+1}(R) \times H^2(S^2))$ be the solution of* (4.5)*, and let ψ^h be the solution of* (5.3) *with V^h defined by* (5.2)*. Then we have*

$$\left\|\psi - \psi^h\right\|_{V_1} \leq \frac{C_1}{N+1} \left(\|\Delta_{\mathbf{\Omega}} \psi\|_{1,0} + \|\Delta_{\mathbf{\Omega}} \psi\|_{0,0,\partial R} \right) + C_2 h^k \left(\|\psi\|_{k+1,0} + \|\psi\|_{0,\partial R} \right)$$

with C_1 and C_2 independent of σ_t and σ_a.

Proof. See the proof of the isotropic case in [14]. ∎

The error bounds for the thick regime require considering the asymptotic limit defined by $\sigma_t \to \infty$. These bounds depend on the asymptotic form of ψ, which itself depends on assumptions regarding material parameters. For the case of isotropic

scattering, this limit has been extensively examined, where it is assumed that $\sigma_a = \zeta/\sigma_t$, where ζ is bounded independently of σ_t as $\sigma_t \to \infty$ (see [7, 6, 9, 8, 17]). In this limit, referred to as the diffusion limit, the solution to (2.1) with isotropic scattering can then be expressed as

$$\psi(\mathbf{x}, \mathbf{\Omega}) = \phi_D(\mathbf{x}) + \frac{1}{\sigma_t}\phi_R(\mathbf{x}, \mathbf{\Omega}),$$

with ϕ_R bounded independently of σ_t and the leading-order term ϕ_D satisfying a diffusion equation.

In [10], for anisotropic scattering Larsen and Pomraning presented two different asymptotic limits for $\sigma_t \to \infty$. These two different limits rely on different assumptions on the degree of anisotropy in the scattering. One is for the case of mildly anisotropic scattering, and the other is for highly anisotropic scattering. In the following, we only examine the case of highly anisotropic scattering because the case of mildly anisotropic scattering yields results identical to Theorem 4.3 of [14].

To define the asymptotic limit, we let ζ_l and ω_l be $O(1)$ constants. Then we define μ_ℓ in terms of these constants as

$$\mu_\ell = \begin{cases} \zeta_l, & 0 \le l \le N_S, \\ \frac{\sigma_t}{\omega_l + 1}, & l > N_S. \end{cases} \tag{5.8}$$

Note that with these assumptions, we get that $\sigma_a = O(1)$ and

$$\sigma_l = \begin{cases} \frac{\sigma_t - \zeta_l}{\sigma_t - \sigma_a}, & 0 \le l \le N_S, \\ \frac{\sigma_t \omega_l}{\sigma_s(\omega_l + 1)}, & l > N_S. \end{cases}$$

Under these assumptions, Larsen and Pomraning in [10] illustrated that ψ can be expressed as

$$\psi(\mathbf{x}, \mathbf{\Omega}) = \hat{\phi}_D(\mathbf{x}, \mathbf{\Omega}) + \frac{1}{\sigma_t}\hat{\phi}_R(\mathbf{x}, \mathbf{\Omega}), \tag{5.9}$$

where

$$\hat{\phi}_D(\mathbf{x}, \mathbf{\Omega}) := \sum_{\ell=0}^{N_S} \sum_{m=-\ell}^{\ell} \phi_{\ell m}(\mathbf{x}) Y_{\ell m}(\mathbf{\Omega})$$

satisfies the first-order P_{N_S} equations and $\hat{\phi}_R(\mathbf{x}, \mathbf{\Omega})$ can be bounded independently of σ_t.

Remark. The P_{N_S} equations are a set of $(N_S + 1)^2$ differential equations for $(N_S + 1)^2$ unknowns, which are obtained by substituting $\psi_{N_S} := \Pi_{N_S}\psi$ for ψ in (2.1) and setting the resulting equation orthogonal to all spherical harmonics up to order N_S. Furthermore, as was illustrated in [14], the least-squares formulation described here is nearly identical to a least-squares minimization of the P_{N_S+1} equations.

The two components, $\hat{\phi}_D$ and $\hat{\phi}_R$, of (5.9) are not orthogonal in $\mathrm{L}^2(S^2)$. But we can rewrite (5.9) such that this condition holds. Note that this condition is employed in the proof of Theorem 5.3. This new expression is

$$\psi(\mathbf{x}, \mathbf{\Omega}) = \phi_D(\mathbf{x}, \mathbf{\Omega}) + \frac{1}{\sigma_t}\phi_R(\mathbf{x}, \mathbf{\Omega}), \tag{5.10}$$

where $\mathcal{P}_\Sigma \phi_R = 0$ for $\Sigma = \{l \in \mathbb{N} \ : \ l \leq N_S\}$. Before proving Theorem 5.3, we introduce the notation $\|a\| \lesssim \|b\|$ meaning $\|a\| \leq C \|b\|$, where C denotes an arbitrary, parameter-independent, positive constant.

THEOREM 5.3. (diffusive regime with highly anisotropic scattering) *Suppose that $N > N_S \geq 1$, $1 \leq \sigma_t < \infty$ and that $\|\cdot\|_{V_1}$ is defined as in* (3.12). *Let $\psi \in V_1 \cap (H^{k+1}(R) \times H^2(S^2))$ be the solution of* (4.5), *and let ψ^h be the solution of* (5.3) *with V^h as defined in* (5.2) *using the scaling operator* (4.18). *Assuming that $\zeta_\ell \in (\zeta_m, \zeta_M)$ and $\omega_\ell \in (\omega_m, \omega_M)$ $\forall l$, where the minimum and maximum terms are $O(1)$ and independent of σ_t, and assuming that ψ satisfies the expansion* (5.10), *then*

$$\left\|\psi - \psi^h\right\|_{V_1} \quad \leq \quad \frac{C_1 D_1(\sigma_t, \phi_R)}{\sigma_t^{1/2}(N+1)} + C_2 D_2(\sigma_t, \phi_D, \phi_R)\, h^k$$

with C_1 and C_2 independent of σ_t and σ_a, and

$$D_1(\sigma_t, \phi_R) := \frac{1}{\sigma_t} \sum_{i=1}^{3} \left\| \Delta_{\mathbf{\Omega}} \frac{\partial \phi_R}{\partial x_i} \right\| + \|\Delta_{\mathbf{\Omega}} \phi_R\| + \frac{1}{\sigma_t^{1/2}} \|\Delta_{\mathbf{\Omega}}\, \phi_R\|_{0,0,\partial R}\,,$$

and

$$D_2(\sigma_t, \phi_D, \phi_R) := \|\phi_D\|_{k+1,0} + \|\Delta_{\mathbf{\Omega}} \phi_D\|_{k+1,0,\partial R} + \frac{1}{\sigma_t^{3/2}} \|\phi_R\|_{k+1,0} + \frac{1}{\sigma_t} \|\Delta_{\mathbf{\Omega}} \phi_R\|_{k+1,0,\partial R}\,.$$

Proof. Combining Céa's lemma with Theorem 4.4 yields

$$\|\psi - \psi_h\|_{V_1} \lesssim \left(\|\mathcal{E}_N(\psi)\|_{V_1} + \|\Pi_N(\psi - \Pi_h \psi)\|_{V_1} \right).$$

Using

$$\|v\|_{V_1} \leq \left(\|v\|_V^2 + \|v\|_{0,0,\partial R}^2 \right)^{1/2} \leq \|v\|_V + \|v\|_{0,0,\partial R}\,,$$

which is obtained from

$$b_I(v, v) \leq \int_{\partial R} \int_{S^2} |v|^2 = \|v\|_{0,0,\partial R}^2\,,$$

we have

(5.11)

$$\|\psi - \psi_h\|_{V_1} \lesssim \left(\|\mathcal{E}_N(\psi)\|_V + \|\mathcal{E}_N(\psi)\|_{0,0,\partial R} + \|\Pi_N(\mathcal{E}_h(\psi))\|_V + \|\Pi_N(\mathcal{E}_h(\psi))\|_{0,0,\partial R} \right).$$

Next, we note that $\sigma_t \mathcal{E}_N(\psi) = \mathcal{E}_N(\phi_R)$ because of the fact that ψ satisfies (5.10). $\Pi_{N_S}\left(\mathbf{\Omega} \cdot \nabla(\mathcal{E}_N(\phi_R))\right) = 0$ and $\Pi_{N_S}(\mathcal{E}_N(\phi_R)) = 0$ because of our our assumptions on N. Now, we bound the first term of (5.11) as

$$\begin{aligned}
\|\mathcal{E}_N(\psi)\|_V &= \frac{1}{\sigma_t} \|\mathcal{E}_N(\phi_R)\|_V \\
&\lesssim \frac{1}{\sigma_t^{3/2}} \|\mathcal{E}_{N_S}((\mathbf{\Omega} \cdot \nabla)\, \mathcal{E}_N(\phi_R))\| + \frac{1}{\sigma_t^{1/2}} \|\mathcal{E}_{N_S}(\mathcal{E}_N(\phi_R))\| \\
&\lesssim \frac{1}{\sigma_t^{1/2}} \left(\frac{1}{\sigma_t} \sum_{i=1}^{3} \left\| \frac{\partial}{\partial x_i} \mathcal{E}_N(\phi_R) \right\| + \|\mathcal{E}_N(\phi_R)\| \right) \\
&\lesssim \frac{1}{\sigma_t^{1/2}(N+1)} \left(\frac{1}{\sigma_t} \sum_{i=1}^{3} \left\| \Delta_{\mathbf{\Omega}} \frac{\partial \phi_R}{\partial x_i} \right\| + \|\Delta_{\mathbf{\Omega}} \phi_R\| \right),
\end{aligned}$$

where we used (i) and (iii) of Lemma 5.1 and the fact that $(\mathcal{I} - \Pi_{N_S})$ is an $\mathrm{L}^2(S^2)$ orthogonal projection. We bound the second term of (5.11) according to

$$\|\mathcal{E}_N(\psi)\|_{0,0,\partial R} = \frac{1}{\sigma_t} \|\mathcal{E}_N(\phi_R)\|_{0,0,\partial R} \leq \frac{2}{\sigma_t(N+1)} \|\Delta_{\mathbf{\Omega}}\phi_R\|_{0,0,\partial R},$$

given (v) of Lemma 5.1.

For the third term of (5.11), we first need to introduce $\mathcal{O}_{N_S} := \Pi_{N_S}(\mathbf{\Omega}\cdot\nabla)$. Since $\sigma_a > 1/\sigma_t$, we have

$$||\Pi_N(\mathcal{E}_h(\psi))||_V = ||\mathcal{E}_h(\phi_D)||_V + \frac{1}{\sigma_t} ||\Pi_N(\mathcal{E}_h(\phi_R))||_V .$$

We then say

$$\begin{aligned}
||\mathcal{E}_h(\phi_D)||_V &\lesssim \frac{1}{\sigma_t^{1/2}} ||\mathcal{E}_{N_S}((\mathbf{\Omega}\cdot\nabla)\,\mathcal{E}_h(\phi_D))|| + ||\mathcal{O}_{N_S}\mathcal{E}_h(\phi_D)|| + ||\mathcal{E}_h(\phi_D)|| \\
&\lesssim ||\mathbf{\Omega}\cdot\nabla(\mathcal{E}_h(\phi_D))|| + ||\mathcal{E}_h(\phi_D)|| \\
&\lesssim \sum_{i=1}^{3} \left|\left| \frac{\partial}{\partial x_i}\mathcal{E}_h(\phi_D) \right|\right| + ||\mathcal{E}_h(\phi_D)|| \\
&\lesssim h^k \left(\|\phi_D\|_{k+1,0} + h\,\|\phi_D\|_{k+1,0} \right) \\
&\lesssim h^k \|\phi_D\|_{k+1,0}
\end{aligned}$$

and

$$\begin{aligned}
||\Pi_N(\mathcal{E}_h(\phi_R))||_V &\lesssim \frac{1}{\sigma_t} ||\mathcal{O}_{N_S}\mathcal{P}_{N_S+1}(\mathcal{E}_h(\phi_R))|| + \frac{1}{\sigma_t^{3/2}} ||\mathcal{E}_{N_S}((\mathbf{\Omega}\cdot\nabla)\,\Pi_N\mathcal{E}_h(\phi_R))|| \\
&\quad + \frac{1}{\sigma_t^{1/2}} ||\Pi_N\mathcal{E}_h(\phi_R)|| \\
&\lesssim \frac{1}{\sigma_t} ||\mathbf{\Omega}\cdot\nabla(\mathcal{E}_h(\phi_R))|| + \frac{1}{\sigma_t^{1/2}} ||\Pi_N\mathcal{E}_h(\phi_R)|| \\
&\lesssim \sum_{i=1}^{3} \frac{1}{\sigma_t} \left|\left| \frac{\partial}{\partial x_i}\mathcal{E}_h(\phi_R) \right|\right| + \frac{1}{\sigma_t^{1/2}} ||\mathcal{E}_h(\phi_R)|| \\
&\lesssim \frac{h^k}{\sigma_t^{1/2}} \left(\frac{1}{\sigma_t^{1/2}} \|\phi_R\|_{k+1,0} + h\,\|\phi_R\|_{k+1,0} \right) \\
&\lesssim \frac{h^k}{\sigma_t^{1/2}} \|\phi_R\|_{k+1,0} .
\end{aligned}$$

Subsequently,

$$||\Pi_N(\mathcal{E}_h(\psi))||_V \lesssim h^k \left(\|\phi_D\|_{k+1,0} + \frac{1}{\sigma_t^{3/2}} \|\phi_R\|_{k+1,0} \right).$$

Last, we can bound the fourth term of (5.11) according to

$$\|\Pi_N(\mathcal{E}_h(\psi))\|_{0,0,\partial R} \lesssim h^k \|\Delta_{\mathbf{\Omega}}\psi\|_{k+1,0,\partial R} \lesssim \|\Delta_{\mathbf{\Omega}}\phi_D\|_{k+1,0,\partial R} + \frac{1}{\sigma_t} \|\Delta_{\mathbf{\Omega}}\phi_R\|_{k+1,0,\partial R},$$

where we have used (iv) of Lemma 5.1. ∎

6. Final remarks. In this paper, we have extended the least-squares method for the linear Boltzmann equation to the case of anisotropic scattering by establishing uniqueness and existence of the minimization problem (4.5). Furthermore, the ellipticity is with respect to a physically meaningful norm, and the ellipticity constants are independent of the problem parameters. Using the ellipticity constants, we have also established error bounds in all three parameter regimes.

Future work consists of examining the least-squares approach with respect to more complex discretization approaches. Besides spherical harmonics approximations, one can use tessellations of the sphere as a finite element representation of the angular dependency. One of the main advantages to this approach is that there is a reduced coupling among moments as compared to the spherical harmonics approach used here. For the spatial domain, we plan to investigate nonconforming finite elements so as to better approximate problems having discontinuous solutions. Lastly, since this work provides a partial foundation for [5], we hope to provide a complete foundation by extending the results introduced here to the case of multiple energy groups.

FOURIER SPECTRAL APPROXIMATION TO LONG-TIME BEHAVIOR OF DISSIPATIVE GENERALIZED KdV-BURGERS EQUATIONS*

SHUJUAN LÜ† AND QISHAO LU†

Abstract. In this paper, we consider a generalized KdV-Burgers equation with periodic initial value condition. Firstly, a fully discrete Galerkin–Fourier spectral approximation scheme, which is a linear one, is constructed. Next, the dynamical properties of the discrete system are analyzed for the autonomous case. The existence and the convergence of the global attractors of the discrete system are obtained by a priori estimates and the error estimates of the discrete solution. The stability of the discrete scheme is also proved. Finally, the long-time stability and the convergence of the discrete scheme are proved for the nonautonomous case. All results in this paper are obtained without any restriction on the time step size.

Key words. long-time stability, long-time convergence, global attractors, spectral methods, KdV-Burgers equation

1. Introduction and description of the method.

In the wake of the development in the study of infinite-dimensional dynamical systems, the long-time behavior of dissipative nonlinear partial differential equations has attracted more and more attention of scientists—for example, the existence and the estimate of dimension of global attractor, the inertial manifolds and the approximate inertial manifolds, the structure of global attractor, and so on (see [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]). However, these studies depended on the results of numerical experimentation to a great extent. For this reason, it is worth studying whether the numerical results are reliable and the calculation schemes are suitable. This work began in the late 1980s (see [11, 12, 13, 14, 15, 16, 17, 18, 19, 20]). Most of the existing classical Galerkin methods are nonlinear schemes, and the calculation is complex. The nonlinear Galerkin methods sometimes can be linear schemes, but the dimension of which is many times that of the classical Galerkin ones; consequently, the computation amount is very heavy. In addition, the stability and convergence of these discrete schemes were established under certain restrictions on the time step size.

In this paper, we construct a fully discrete classical Galerkin spectral scheme, which is a linear scheme. On the one hand, in comparison with the existing nonlinear Galerkin methods with linear schemes or classical Galerkin methods with nonlinear schemes, the computation amount of this scheme can be greatly reduced. On the other hand, without any restriction on the time step size, the results about the uniform stability and convergence of this discrete scheme are obtained.

To be more specific in this paper, we restrict ourselves to a class of damped generalized KdV-Burgers equations. More generally, similar schemes and analysis are applicable to other dissipative dynamical systems.

The damped KdV-Burgers equation is a kind of important nonlinear evolution equations. They are proposed in many physical problems; for example, see [21, 22]. For this reason, the research of them is of theoretical and practice significance. In [23, 24], the existence and the uniqueness for the global smooth solution of this kind of equation have been proved. In [25] the existence of chaotic phenomena for a KdV-Burgers equation has been found. In this paper, we consider the periodic initial value problem of the damped generalized KdV-Burgers equation

$$u_t - \alpha u_{xx} + \beta u_{xxx} + f(u)_x = g(u) + h, \quad x \in R, t > 0, \tag{1.1}$$

$$u(x + 2\pi, t) = u(x, t), \qquad x \in R, t \geq 0, \tag{1.2}$$

$$u(x, 0) = u_0(x), \qquad x \in R, \tag{1.3}$$

where $\alpha,\ \beta$ are real constants and $\alpha > 0,\ \beta \neq 0$; $f(u),\ g(u),\ h$ are real value functions.

In [6, 20] the existence of global attractors and the estimates of upper bounds of their Hausdorff and fractal dimensions were proved for problem (1.1)–(1.3). In [19, 20] the Fourier discrete schemes, which are nonlinear schemes, were constructed, and the existence and the convergence of approximate attractors were proved. In this paper, we first construct a fully discrete Fourier spectral approximation scheme, which is a linear one. Then the existence and the convergence of approximate attractors, as well as the stability of discrete scheme, are proved in the autonomous case. Furthermore, the long-time stability and the convergence of discrete scheme are obtained in the nonautonomous case.

Throughout this paper we use the following notation: $\Omega = [0, 2\pi]$; $(\cdot, \cdot)$ denotes the inner product of $L^2(\Omega)$, $\|\cdot\|_m$ the norm of Sobolev spaces $H^m(\Omega)$, and $\|\cdot\| = \|\cdot\|_0$, $\|\cdot\|_\infty = \|\cdot\|_{L^\infty(\Omega)}$.

For any given positive integer N, let $S_N = \mathrm{Span}\{\sin kx,\ \cos kx :\ |k| \leq N\}$, and denote by $P_N :\ L^2_p(\Omega) \to S_N$ the orthogonal projection operator (see [26]).

Let τ be the mesh size in the variable t, $t_k = k\tau$, $u^k = u(x, t_k)$, $\overline{\partial}_t u^k = \frac{1}{\tau}(u^k - u^{k-1})$. The Fourier spectral scheme for solving (1.1)–(1.3) is to find $u_N^k \in S_N$ such that

$$\begin{aligned} &(\overline{\partial}_t u_N^k - \alpha u_{Nxx}^k + \beta u_{Nxxx}^k,\ \varphi) + B(u_N^{k-1},\ u_N^k,\ \varphi) \\ &= (G(u_N^{k-1})u_N^k + h^k,\ \varphi) \quad \text{for all } \varphi \in S_N, \quad k = 1, 2, \ldots, \end{aligned} \tag{1.4}$$

$$u_N^0 = P_N u_0, \tag{1.5}$$

where

$$B(u_N^{k-1},\ u_N^k,\ \varphi) = (F(u_N^{k-1})u_{Nx}^k,\ \varphi) - (F(u_N^{k-1})u_N^k\ ,\ \varphi_x),$$

$$F(u) = \begin{cases} \dfrac{1}{u^2}\displaystyle\int_0^u sf'(s)ds & \text{for } u \neq 0, \\ \dfrac{1}{2}f'(0) & \text{for } u = 0, \end{cases}$$

$$G(u) = \begin{cases} \dfrac{g(u)}{u} & \text{for } u \neq 0, \\ g'(0) & \text{for } u = 0. \end{cases}$$

It is a linear iteration scheme, and then it needs only to solve a class of linear algebraic equations for every iteration.

The following lemmas are necessary for further discussion.

LEMMA 1.1 (see [26]). *If $u \in H_p^m(\Omega)$, then there exists a constant c independent of u, N such that*

$$\|u - P_N u\|_\mu \le cN^{\mu-m}\|D^m u\| \qquad \text{for all } 0 \le \mu \le m.$$

LEMMA 1.2 (Sobolev interpolation inequality [27]). *Suppose that $u \in L^q(\Omega)$, $D^m u \in L^r(\Omega)$, $\Omega \subset R^n$, $1 \le r \le \infty$, $0 \le j \le m$. Then there exists a constant $c = c(j, m, \Omega, p, q, r)$ independent of u such that*

$$\|D^j u\|_{L^p} \le c\|D^m u\|^a_{W^{m,r}(\Omega)}\|u\|^{1-a}_{L^q},$$

where

$$\frac{1}{p} = \frac{j}{n} + a\Big(\frac{1}{r} - \frac{m}{n}\Big) + (1-a)\frac{1}{q}, \quad \frac{j}{m} < a < 1.$$

LEMMA 1.3 (discrete Gronwall's inequality [17]). *Let y^k, g^k, h^k be three series satisfying*

$$\frac{y^{k+1} - y^k}{\tau} \le g^k y^k + h^k, \quad k = 0, 1, 2, \ldots.$$

Then we have

$$y^n \le y^0 \exp\left(\tau \sum_{k=0}^{n-1} g^k\right) + \tau \sum_{k=0}^{n-1} h^k \exp\left(\tau \sum_{i=k}^{n-1} g^i\right) \qquad \text{for all } n \ge 1.$$

LEMMA 1.4 (discrete uniform Gronwall's inequality [17]). *Let y^k, g^k, h^k be three series satisfying*

$$\frac{y^{k+1} - y^k}{\tau} \le g^k y^k + h^k \qquad \text{for all } k \ge k_0$$

and

$$\tau \sum_{k=k_1}^{n_0+k_1} g^k \le \alpha_1, \quad \tau \sum_{k=k_1}^{n_0+k_1} h^k \le \alpha_2, \quad \tau \sum_{k=k_1}^{n_0+k_1} y^k \le \alpha_3 \qquad \text{for all } k_1 \ge k_0$$

with $\tau n_0 = r$. Then

$$y^k \le \Big(\frac{\alpha_3}{r} + \alpha_2\Big)\mathrm{e}^{\alpha_1} \qquad \text{for all } k \ge\ n_0 + k_0.$$

An outline of this paper is as follows. We consider the autonomous case (i.e., $h = h(x)$) in sections 2 to 4. In section 2 the existence of discrete attractors $\mathcal{A}_N^\tau$ is obtained by the t-independent priori estimates of discrete solutions (Theorem 2.2). In section 3 the convergence of $\mathcal{A}_N^\tau$ is proved by the error estimates in $[0, +\infty)$ of the discrete solutions (Theorem 3.5). In section 4 we prove the stability of the discrete scheme (Theorem 4.1). Finally, we consider the nonautonomous case (i.e., $h = h(x, t)$) in section 5. The long-time stability and the convergence of discrete scheme are proved (Theorem 5.3 and Theorem 5.4).

2. Existence of approximation global attractors $\mathcal{A}_N^\tau$. In sections 2 to 4, we let $h = h(x)$ and $h(x+2\pi) = h(x)$. The main purpose of this section is to prove the existence of the global attractors $\mathcal{A}_N^\tau$ of problem (1.4)–(1.5). To the end, we need the following result (see [1]).

THEOREM 2.1. *Let H be a Banach space, $\{S(t), t \geq 0\}$ a set of continuous semigroup operations, i.e., $S(t) : H \to H$ satisfies*

$$S(t+\tau) = S(t) \cdot S(\tau) \quad \text{for all } t \geq 0,\ \tau \geq 0, \quad S(0) = I,$$

where I is the identity operator. We also assume that

(i) *there exists a bounded absorbing set $\mathcal{B}_0 \subset H$, i.e., for any given bounded set $\mathcal{B} \subset H$, there exists a constant $T(\mathcal{B})$ such that*

$$S(t)\mathcal{B} \subset \mathcal{B}_0 \qquad \text{for all } t \geq T(\mathcal{B});$$

(ii) *the operator $S(t)$ is uniformly compact for t enough large. By this we mean that for every bounded set $\mathcal{B}$ there exists a constant $t_0 = t_0(\mathcal{B})$ such that*

$$\bigcup_{t \geq t_0} S(t)\mathcal{B}$$

is relatively compact in H.

Then the semigroup of operators $\{S(t)\}_{t\geq}$ has a compact global attractor $\mathcal{A} \subset H$. By this we mean that

(a) $S(t)\mathcal{A} = \mathcal{A}$ for all $t \geq 0$;

(b) *for any given bounded set $\mathcal{B} \subset H$, $\lim_{t\to\infty} \operatorname{dist}(S(t)\mathcal{B}, \mathcal{A}) = 0$, where*

$$\operatorname{dist}(X, Y) = \sup_{x\in X} \inf_{y\in Y} \|x - y\|_H.$$

Now we give the main result in this section.

THEOREM 2.2. *If $f \in C^3$, $|f'(u)| \leq A|u|^2$, $g \in C^2$, $g(0) = 0$, $g'(u) \leq b < 0$, $|g(u)| \leq B|u|(|u|^4 + 1)$, $h(x) \in H_p^1(\Omega)$, and $u_0(x) \in H_p^2(\Omega)$, then the semigroup of operator $\{S_N^\tau(n)\}_{n\geq 0}$ generated by problem (1.4), (1.5) has a compact global attractor $\mathcal{A}_N^\tau \subset H_p^2(\Omega) \cap S_N$.*

To prove Theorem 2.2, the following results are necessary.

LEMMA 2.3. *If $f, g \in C^1$, $g(0) = 0$, $g'(s) \leq b < 0$; $h \in L^2(\Omega)$, $u_0 \in L_p^2(\Omega)$. Then for the solution u_N^n of problem (1.4), (1.5), we have the estimates*

$$\|u_N^n\|^2 \leq (1 - b\tau)^{-n}\|u_N^0\|^2 + \frac{\|h\|^2}{b^2} \leq \|u_0\|^2 + \frac{\|h\|^2}{b^2} \triangleq E_0^2 \quad \text{for all } n \geq 1,$$

$$\overline{\lim_{n\to\infty}} \|u_N^k\|^2 \leq \frac{\|h\|^2}{b^2} \triangleq (\rho_0')^2,$$

$$\tau^2 \sum_1^n \|\overline{\partial}_t u_N^k\|^2 \leq C_1(1 + t_n) \qquad \text{for all } n \geq 1,$$

where the constant $C_0 = C_0(\|u_o\|)$ is independent of N, n, and τ.

Proof. Set $\varphi = u_N^k$ in (1.4). Then we have

$$\frac{1}{2}\overline{\partial}_t\|u_N^k\|^2 + \frac{\tau}{2}\|\overline{\partial}_t u_N^k\|^2 + \alpha\|u_{Nx}^k\|^2 + B(u_N^{k-1}, u_N^k, u_N^k) = (G(u_N^{k-1})u_N^k, +h, u_N^k).$$

From the definition of $B(u,v,\varphi)$, $G(u)$ and ε- inequality, we obtain

$$\begin{aligned}
&B(u_N^{k-1},u_N^k,u_N^k)=0,\\
&(G(u_N^{k-1})u_N^k,u_N^k)=(g'(\theta u_N^{k-1})u_N^k,u_N^k)\le b\|u_N^k\|^2,\\
&(h,u_N^k)\le\|h\|\,\|u_N^k\|\le\frac{|b|}{2}\|u_N^k\|^2+\frac{1}{2|b|}\|h\|^2.
\end{aligned}$$

Therefore

$$\overline{\partial}_t\,\|u_N^k\|^2+\tau\,\|\overline{\partial}_t u_N^k\|^2+\alpha\,\|u_{Nx}^k\|^2-b\,\|u_N^k\|^2\le\frac{\|h\|^2}{|b|}. \tag{2.1}$$

Multiplying (2.1) by $(1-b\tau)^{k-1}$ and summing them for k from 1 to n, we have

$$\|u_N^n\|^2\le(1-b\tau)^{-n}\Big(\|u_N^0\|^2-\frac{\|h\|^2}{b^2}\Big)+\frac{\|h\|^2}{b^2}\le\|u_N^0\|^2+\frac{\|h\|^2}{b^2}\triangleq E_0^2,$$

which implies that

$$\overline{\lim_{n\to\infty}}\|u_N^k\|^2\le\frac{\|h\|^2}{b^2}\triangleq(\rho_0')^2.$$

Taking the sum of (2.1) for k from k_0+1 to n, we recover the proof of the lemma. ∎

COROLLARY 2.4. *For any given $\rho_0>\rho_0'$ and $R_0>0$, if $\|u_0\|\le R_0$, then*

$$\|u_N^n\|^2\le\rho_0^2\qquad\text{for all } n\ge n_0=\Big(\ln\frac{R_0^2}{\rho_0^2-(\rho_0')^2}\Big)\Big/\ln(1-b\tau).$$

LEMMA 2.5. *In addition to the conditions of Lemma 2.3, we suppose that $f\in C^2$, $|f'(u)|\le A|u|^2$; $|g(u)|\le B|u|(|u|^4+1)$; $u_0\in H_p^1(\Omega)$, $\|u_0\|\le R_0$. Then for the solution u_N^n of problem (1.4), (1.5), we have the estimates*

$$\begin{aligned}
\|u_{Nx}^k\|^2&\le\rho_1^2\qquad\text{for } n\ge n_0+N_0\triangleq n_1,\\
\|u_{Nx}^k\|^2&\le E_1^2\qquad\text{for } n\ge 1,\\
\tau^2\sum_{k=1}^{n}\|\overline{\partial}_t u_{Nx}^k\|^2&\le C_1(1+t_n)\qquad\text{for all } n\ge 1,
\end{aligned}$$

where n_0 is given by Corollary 2.4, N_0 an arbitrary positive integer, r an arbitrary positive number such that $N_0\tau=r$, the constant ρ_1 independent of N, n, τ, and $\|u_0\|_1$, $C_1=C_1(\|u_o\|_1)$, and $E_1=E_1(\|u_0\|_1)$ independent of N, n, and τ.

Proof. Let $\varphi=-u_{Nxx}^k$ in (1.4). Then we have

$$\begin{aligned}
&\frac{1}{2}\overline{\partial}_t\|u_{Nx}^k\|^2+\frac{\tau}{2}\|\overline{\partial}_t u_{Nx}^k\|^2+\alpha\|u_{Nxx}^k\|^2+B(u_N^{k-1},u_N^k,-u_{Nxx}^k)\\
&\qquad=(G(u_N^{k-1})u_N^k+h,-u_{Nxx}^k).
\end{aligned}\tag{2.2}$$

We now estimate the last two terms in the above equality. First, from the definition of $B(u,v,\varphi)$, we have

$$B(u_N^{k-1},u_N^k,-u_{Nxx}^k)=2(F(u_N^{k-1})u_{Nx}^k,-u_{Nxx}^k)+(F'(u_N^{k-1})u_{Nx}^{k-1}u_N^k,-u_{Nxx}^k),$$

where from the definition of $F(u)$, the mean theorem of integration, and the Sobolev interpolation inequality, we have for two terms in the above equality

$$\begin{aligned}
&2(F(u_N^{k-1})u_{Nx}^k, -u_{Nxx}^k)\\
=\ & 2\left(\frac{u_{Nx}^k}{(u_N^{k-1})^2}\int_0^{u_N^{k-1}} sf'(s)ds, -u_{Nxx}^k\right) = \ (f'(\theta u_N^{k-1})u_{Nx}^k, -u_{Nxx}^k)\\
\le\ & A\|u_N^{k-1}\|_\infty^2\,\|u_{Nx}^k\|\,\|u_{Nxx}^k\| \le c\|u_N^{k-1}\|\,\|u_N^{k-1}\|_1\,\|u_N^k\|^{\frac{1}{2}}\,\|u_{Nxx}^k\|^{\frac{3}{2}}\\
\le\ & \frac{\alpha}{8}\|u_{Nxx}^k\|^2 + c(\|u_N^{k-1}\|^4\,\|u_N^k\|^2\,\|u_{Nx}^{k-1}\|^4 + \|u_N^{k-1}\|^8\,\|u_N^k\|^2)
\end{aligned}$$

and

$$\begin{aligned}
&(F'(u_N^{k-1})u_{Nx}^{k-1}u_N^k, -u_{Nxx}^k)\\
=\ & \left(\left((u_N^{k-1})^2 f'(u_N^{k-1}) - 2\int_0^{u_N^{k-1}} sf'(s)ds\right)\frac{u_{Nx}^{k-1}u_N^k}{(u_N^{k-1})^3}, -u_{Nxx}^k\right)\\
=\ & \left(\left(\frac{f'(u_N^{k-1})}{u_N^{k-1}} - \frac{f'(\theta u_N^{k-1})}{u_N^{k-1}}\right)u_{Nx}^{k-1}u_N^k, -u_{Nxx}^k\right)\\
\le\ & 2A\|u_N^{k-1}\|_\infty\|u_N^k\|_\infty\|u_{Nx}^{k-1}\|\|u_{Nxx}^k\|\\
\le\ & \frac{\alpha}{8}\|u_{Nxx}^k\|^2 + c\|u_N^k\|^2(\|u_N^{k-1}\|^{\frac{4}{3}} + 1)(\|u_{Nx}^{k-1}\|^4 + \|u_N^{k-1}\|^4).
\end{aligned}$$

Therefore

$$B(u_N^{k-1}, u_N^k, -u_{Nxx}^k) \le \frac{\alpha}{4}\|u_{Nxx}^k\|^2 + c\|u_N^k\|^2(\|u_N^{k-1}\|^4 + 1)\,(\|u_{Nx}^{k-1}\|^4 + \|u_N^{k-1}\|^4).$$

Next, from the definition of $G(u)$ we have

$$\begin{aligned}
(G(u_N^{k-1})u_N^k, -u_{Nxx}^k) \le\ & \frac{5B}{4}(\|u_N^{k-1}\|_\infty^4 + 1)\|u_N^k\|\|u_{Nxx}^k\|\\
\le\ & \frac{\alpha}{8}\|u_{Nxx}^k\|^2 + c\|u_N^k\|^2(\|u_N^{k-1}\|^4\|u_{Nx}^{k-1}\|^4 + \|u_N^{k-1}\|^8 + 1).
\end{aligned}$$

In addition, we have

$$(h, -u_{Nxx}^k) \le \frac{\alpha}{8}\|u_{Nxx}^k\|^2 + \frac{4}{\alpha}\|h\|^2.$$

Hence (2.2) can be rewritten as

$$\begin{aligned}
&\overline{\partial}_t\|u_{Nx}^k\|^2 + \tau\|\overline{\partial}_t u_{Nx}^k\|^2 + \alpha\|u_{Nxx}^k\|^2\\
\le\ & c(\|u_N^{k-1}\|^4 + 1)\|u_N^k\|^2\,\|u_{Nx}^{k-1}\|^4 + c\big(\|u_N^k\|^2(\|u_N^{k-1}\|^8 + 1) + \|h\|^2\big).
\end{aligned} \tag{2.3}$$

By using (2.1), Lemma 2.3, and its corollary, we obtain for all $k_0 > n_0$

$$
\begin{aligned}
c\tau \sum_{k=k_0+1}^{k_0+N_0} (\|u_N^{k-1}\|^4+1)\|u_N^k\|^2\|u_{Nx}^{k-1}\|^2 \le\ & c\rho_0^2(1+\rho_0^4)\tau \sum_{k=k_0+1}^{k_0+N_0} \|u_{Nx}^{k-1}\|^2 \\
\le\ & c\rho_0^4(1+\rho_0^4)(1+r) \triangleq \alpha_1,
\end{aligned}
$$

$$
c\tau \sum_{k=k_0+1}^{k_0+N_0} \big(\|u_N^k\|^2(\|u_N^{k-1}\|^8+1)+\|h\|^2\big) \le c\big(\rho_0^2(\rho_0^8+1)+1\big)r \triangleq \alpha_2,
$$

$$
c\tau \sum_{k=k_0+1}^{k_0+N_0} \|u_{Nx}^k\|^2 \le c\Big(\rho_0^2+\frac{\|h\|^2}{|b|}N_0\tau\Big) \le c\rho_0^2(1+r) \triangleq \alpha_3.
$$

By applying the discrete uniform Gronwall's inequality to (2.3), we derive

$$
\|u_{Nx}^k\|^2 \le \Big(\frac{\alpha_3}{r}+\alpha_2\Big)\,\mathrm{e}^{\alpha_1} \triangleq \rho_1^2 \qquad \text{for all } n \ge n_1 = n_0+N_0.
$$

For $n \le n_1$, by applying the discrete Gronwall's inequality to (2.3), we have

$$
\begin{aligned}
\|u_{Nx}^k\|^2 \le\ & \Big(\|u_{0x}\|^2 + c\big(E_0^2(E_0^8+1)+\|h\|^2\big)t_n\Big)\exp\big(cE_0^2(E_0^4+1)(\|u_0\|^2+\rho_0^2 t_{n_1})\big) \\
\triangleq\ & (E_1')^2.
\end{aligned}
$$

Let $E_1^2 = \max\{(\rho_1')^2, (E_1')^2\}$. Then the second relation is obtained. Taking the sum of (2.3), we complete the proof of Lemma 2.5. □

COROLLARY 2.6. *Under the hypotheses of Lemma* 2.5*, we have*

$$
\begin{aligned}
&\|u_N^n\|_\infty \le c(\rho_0,\rho_1) \qquad \text{for all } n \ge n_1, \\
&\|u_N^n\|_\infty \le c(E_0,E_1) \qquad \text{for all } n \ge 1.
\end{aligned}
$$

LEMMA 2.7. *In addition to the conditions of Lemma* 2.5*, we suppose that* $f \in C^3$, $u_0 \in H_p^2(\Omega)$ *satisfying* $\|u_{0xx}\|^2 \le R_0^2$. *Then we have*

$$
\begin{aligned}
&\|u_{Nxx}^n\|^2 \le \rho_2^2 \qquad \text{for all } n \ge n_2 = n_1+N_0, \\
&\|u_{Nxx}^n\|^2 \le E_2^2 \qquad\quad \text{for all } n \ge 1, \\
&\tau^2 \sum_{k=1}^n \|\overline{\partial}_t u_{Nxx}^k\|^2 + \tau \sum_{k=1}^n \|u_{Nxxx}^k\|^2 \le c_2(1+t_n) \qquad \text{for all } n \ge 1,
\end{aligned}
$$

where n_1 *is given by Lemma* 2.5, N_0 *an arbitrary positive integer,* r *an arbitrary positive number such that* $N_0\tau = r$, *the constant* ρ_2 *independent of* N, n, τ, *and* $\|u_0\|_2$, $E_2 = E_2(\|u_0\|_2)$, *and* $C_2 = C_2(\|u_0\|_2)$ *independent of* N, n, *and* τ.

Proof. Let $\varphi = u_{Nx^4}^k$ in (1.4), and then we have

$$
\begin{aligned}
&\frac{1}{2}\overline{\partial}_t\|u_{Nxx}^k\|^2 + \frac{\tau}{2}\|\overline{\partial}_t u_{Nxx}^k\|^2 + \alpha\|u_{Nxxx}^k\|^2 + B(u_N^{k-1}, u_N^k, u_{Nx^4}^k) \\
=\ & (G(u_N^{K-1})u_N^k + h, u_{Nx^4}^k).
\end{aligned}
$$

When $\mathbf{k \geq n_1}$. From Lemma 2.3 to Corollary 2.6, we obtain

$$\begin{aligned}
B(u_N^{k-1}, u_N^k, u_{Nx^4}^k) =& \ (2F(u_N^{k-1})u_{Nx}^k + F'(u_N^{k-1})u_{Nx}^{k-1}u_N^k, u_{Nx^4}^k) \\
=& \ (2F(u_N^{k-1})u_{Nxx}^k + 3F'(u_N^{k-1})u_{Nx}^{k-1}u_{Nx}^k + F'(u_N^{k-1})u_{Nxx}^{k-1}u_N^k \\
& + F''(u_N^{k-1})(u_{Nx}^{k-1})^2 u_N^k, \ -u_{Nx^3}^k) \\
\leq& \ c(\rho_0,\rho_1)\|u_{Nxxx}^k\|^2(\|u_{Nxx}^k\| + \|u_{Nx}^{k-1}\|\|u_{Nx}^k\|_\infty + \|u_{Nxx}^k\| \\
& + \|u_N^k\|_\infty\|u_{Nx}^{k-1}\|_\infty\|u_{Nx}^{k-1}\|) \\
\leq& \ \frac{\alpha}{6}\|u_{Nxxx}^k\|^2 + c(\rho_0,\rho_1)(\|u_{Nx}^k\|^2 + \|u_N^k\|^2\|u_{Nx}^{k-1}\|^2) \\
& + c(\rho_0,\rho_1)(\|u_N^k\|\|u_{Nx}^k\| + \|u_N^k\|^2\|u_N^{k-1}\|^2)\|u_{Nxx}^{k-1}\|^2, \\
(G(u_N^{k-1})u_N^k, u_{Nx^4}^k) =& \ (G(u_N^{k-1})u_{Nx}^k, -u_{Nx^3}^k) + (G'(u_N^{k-1})u_{Nx}^{k-1}u_N^k, -u_{Nx^3}^k) \\
\leq& \ c(\rho_0,\rho_1)\|u_{Nxxx}^k\|(\|u_{Nx}^k\| + \|u_{Nx}^{k-1}\|) \\
\leq& \ \frac{\alpha}{6}\|u_{Nxxx}^k\|^2 + c(\rho_0,\rho_1)(\|u_{Nx}^k\|^2 + \|u_{Nx}^{k-1}\|^2),
\end{aligned}$$

and

$$(h, u_{Nx^4}^k) = (h_x, -u_{Nx^3}^k) \leq \frac{\alpha}{6}\|u_{Nxxx}^k\|^2 + c\|h_x\|^2.$$

Thus

$$\begin{aligned}
& \overline{\partial}_t\|u_{Nxx}^k\|^2 + \tau\|\overline{\partial}_t u_{Nxx}^k\|^2 + \alpha\|u_{Nxxx}^k\|^2 \\
\leq& \ c(\rho_0,\rho_1)(\|u_{Nx}^{k-1}\|^2 + \|u_{Nx}^k\|^2 + \|h_x\|^2).
\end{aligned} \tag{2.4}$$

By using Lemmas 2.3 and 2.5 and (2.3), we derive

$$\tau\sum_{k=k_0+1}^{k_0+N_0}\|u_{Nxx}\|^2 \leq \frac{1}{\alpha}\big(\rho_1^2 + rc(\rho_0,\rho_1)\big) \triangleq \alpha_3,$$

$$c(\rho_0,\rho_1)\tau\sum_{k=k_0+1}^{k_0+N_0}(\|u_{Nx}^k\|^2 + \|u_{Nx}^{k-1}\|^2 + \|h_x\|^2) \leq c(\rho_0,\rho_1)r \triangleq \alpha_2.$$

Then by applying discrete uniform Gronwall's inequality to (2.4), we have

$$\|u_{Nxx}^n\|^2 \leq \frac{\alpha_3}{r} + \alpha_2 \triangleq \rho_2^2 \quad \text{for all } n \geq n_2 = n_1 + N_0. \tag{2.5}$$

For $\mathbf{k \geq 1}$, as in the proof of the inequality (2.4), we have

$$\begin{aligned}
& \overline{\partial}_t\|u_{Nxx}^k\|^2 + \tau\|\overline{\partial}_t u_{Nxx}^k\|^2 + \alpha\|u_{Nxxx}^k\|^2 \\
\leq& \ c(E_0,E_1)(\|u_{Nx}^{k-1}\|^2 + \|u_{Nx}^k\|^2 + \|h_x\|^2).
\end{aligned} \tag{2.6}$$

Taking the sum of (2.6) for k from 1 to n, we obtain

$$\|u_{Nxx}^n\|^2 + \tau^2\|\overline{\partial}_t u_{Nxx}^n\|^2 + \alpha\tau\sum_{k=1}^n\|u_{Nxxx}^k\|^2 \leq C_2(t_n + 1) \quad \text{for all } n \geq 1. \tag{2.7}$$

Combining inequality (2.5) and (2.7), the proof of this lemma is complete. □

Proof of Theorem 2.2. Let $H = H_p^2(\Omega) \cap S_N$, $S_N^\tau(n)$ be a semigroup operator, i.e., the solution operator generated by problem (1.4), (1.5). On account of Theorem 2.1, we shall prove this theorem by checking the conditions (i) and (ii) in Theorem 2.1.

(i) By using the results of Lemmas 2.3–2.7, and assuming that $u_N^0 \in \mathcal{B} = \{u_N^0 \big|\ \|u_N^0\|_2 \le R_0\} \subset H_p^2(\Omega) \cap S_N$, we have

$$\|S_N^\tau(n)u_N^0\|_2 = \|u_N^n\|_2 \le (\rho_0^2 + \rho_1^2 + \rho_2^2)^{\frac{1}{2}} \qquad \text{for all } n \ge n_1(R).$$

Hence

$$\mathcal{B}_0 = \{u_N^n \in H_p^2(\Omega) \cap S_N :\ \|u_N^n\|_2 \le (\rho_0^2 + \rho_1^2 + \rho_2^2)^{\frac{1}{2}}\}$$

is a bounded absorbing set of the semigroup of operator $\{S_N^\tau(n)\}_{n\ge 0}$.

(ii) From Lemmas 2.3–2.7 and their corollaries, we have

$$\|S_N^\tau(n)u_N^0\|_2 \le (E_0^2 + E_1^2 + E_2^2)^{\frac{1}{2}} \qquad \text{for all } n \ge 0.$$

This means that $\{S_N^\tau(n)\}$ is uniformly bounded in $H_p^2(\Omega)\cap S_N$. Since a closed bounded set is a compact set in the finite dimensional space $H_p^2(\Omega) \cap S_N$, the operator $S_N^\tau(n)$ is uniformly compact for any $n \ge 0$.

On the other hand, it is easy to check the continuity of operator $S_N^\tau(n)$ from its boundedness. Thus the proof of the theorem is completed. □

3. Convergence of the global attractors $\mathcal{A}_N^\tau$. In this section, we study the convergence of attractors $\mathcal{A}_N^\tau$. To this end, we first give the following results.

Let $G_N :\ L_p^2(\Omega) \to S_N$ be the integral projection operator, i.e., for any given $u \in L^2(\Omega)$ we have

$$((G_N u)_x, v_x) + (G_N u, v) = (u, v) \quad \text{for all } \ v \in S_N. \tag{3.1}$$

Then for any $u,\ v \in L^2(\Omega)$, we have $(G_N u, v) = (u, G_N v)$.

LEMMA 3.1. *For the integral projection operator G_N, the following results hold:*

(A1) $\|G_N u\|_2 \sim \|P_N u\| \qquad$ for all $u \in L_p^2(\Omega)$;

(A2) $\|G_N u_x\| = \|(G_N u)_x\| \qquad$ for all $u \in H_p^1(\Omega)$,
$\|G_N u_{xx}\| = \|(G_N u_x)_x\| = \|(G_N u)_{xx}\|$ for all $u \in H_p^2(\Omega)$;

(A3) $\|G_N^2 u_{xx}\| = \|(G_N^2 u_x)_x\| = \|(G_N^2 u)_{xx}\|$ for all $u \in H_p^2(\Omega)$.

Proof. (A1). Setting $v = P_N u$ in (3.1) and applying the definition of P_N, it is obtained that

$$\|P_N u\| \le \|G_N u\| + \|(G_N u)_{xx}\|. \tag{3.2}$$

Setting $v = G_N u$ in (3.1), we have

$$\|G_N u\| \le \|P_N u\|. \tag{3.3}$$

Letting $v = (G_N u)_{xx}$ in (3.1), we find

$$\|(G_N u)_{xx}\| \le \|P_N u\|. \tag{3.4}$$

Combining (3.2), (3.3), and (3.4), the equality (A1) is obtained.

(A2). Using the definition of G_N repeatedly, the first equality of (A2) is obtained as follows:

$$\begin{aligned}\|G_N u_x\|^2 =& (G_N u_x, G_N u_x) = -(u, (G_N^2 u_x)x)\\ =& -((G_N u)_x, (G_N^2 u_x)_{xx}) - (G_N u, (G_N^2 u_x)_x)\\ =& ((G_N^2 u_x)_x, (G_N u)_{xx}) + (G_N^2 u_x, (G_N u)_x) = (G_N u_x, (G_N u)_x)\\ =& ((G_N(G_N u)_x, (G_N u)_{xx}) + (G_N(G_N u)_x, (G_N u)_x) = ((G_N u)_x, (G_N u)_x)\\ =& \|(G_N u)_x\|^2.\end{aligned}$$

By using the above equality and the definition of G_N repeatedly, the second equality of (A2) is recovered as follows:

$$\begin{aligned}\|G_N u_{xx}\|^2 &= ((G_N u_x)_x, (G_N u_x)_x) = (u_x, G_N u_x) - (G_N u_x, G_N u_x)\\ &= -(u, (G_N u_x)_x) - \|G_N u_x\|^2\\ &= ((G_N u)_{xx}, (G_N u_x)_x) + ((G_N u)_x, (G_N u_x)) - \|G_N u_x\|^2\\ &= -(u, (G_N u)_{xx}) - \|G_N u_x\|^2\\ &= \|(G_N u)_{xx}\|^2 + \|(G_N u)_x\|^2 - \|G_N u_x\|^2 = \|(G_N u)_{xx}\|^2.\end{aligned}$$

(A3). By using the definition of G_N and results of (A2), the equalities of (A3) are proved as follows:

$$\begin{aligned}\|G_N^2 u_{xx}\|^2 =& -((G_N^4 u_{xx})_x, u_x) = ((G_N u_x)_{xx}, (G_N^4 u_{xx})_x) + ((G_N u_x)_x, G_N^4 u_{xx})\\ =& ((G_N u_x)_x, G_N^3 u_{xx}) = -((G_N^3(G_N u_x)_x)_x, u_x)\\ =& -((G_N u_x)_x, (G_N^3(G_N u_x)_x)_{xx}) - (G_N u_X, (G_N^3(G_N u_x)_x)_x)\\ =& \|G_N(G_N u_x)_x\|^2 = \|(G_N^2 u_x)_x\|^2\end{aligned}$$

and

$$\begin{aligned}\|G_N^2 u_{xx}\|^2 &= -((G_N^4 u_{xx})_x, u_x) = (G_N^4 u_{xx}, u) - (G_N^3 u_{xx}, u)\\ &= -(u_x, (G_N^4 u)_x) + (u_x, (G_N^3 u)_x)\\ &= -(u, G_N^3 u) + (u, G_N^4 u) + (u, G_N^2 u) - (u, G_N^3 u)\\ &= -(G_N u, G_N^2 u) + (G_N^2 u, G_N^2 u) + (u, G_N^2 u) - (G_N u, G_N^2 u)\\ &= -((G_N^2 u)_x, (G_N^2 u)_x) + ((G_N u)_x, (G_N^2 u)_x)\\ &= ((G_N^2 u)_x, (G_N^2 u)_{xx}) - (G_N u, (G_N u, (G_N^2 u)_x)\\ &= -((G_N^2 u)_x, (G_N^2 u)_{xxx}) = \|(G_N^2 u)_{xx}\|^2. \qquad \square\end{aligned}$$

THEOREM 3.2 (see [20]). *If $f \in C^3$, $|f'(u)| \le A|u|^2$; $g \in C^1$, $g(0) = 0$, $g'(s) \le b < 0$; $h(x) \in H_p^1(\Omega)$; $u_0 \in H_p^2(\Omega)$, then there exists a unique global solution $u(x,t) \in L^\infty(R^+;\ H_p^2(\Omega))$ for the problem (1.1)–(1.3) such that*

$$\int_0^t (\|u\|_3^2 + \|u_t\|^2)\,\mathrm{d}t \le c(t+1) \qquad \text{for all } t \in R^+,$$

where the constant c is independent of t.

Furthermore, if $f \in C^3$, $g \in C^2$, then $u(x,t)$ satisfies

$$t\|u_{xxx}\|^2 \le c(t^2+1) \qquad \text{for all } t \in R^+,$$

and there exists a global attractor $\mathcal{A} \subset H_p^2(\Omega)$ of problem (1.1)–(1.3), i.e., there exist a set $\mathcal{A} \subset H_p^2(\Omega)$ such that

(a) $S(t)\mathcal{A} = \mathcal{A}$,

(b) $\operatorname{dist}(S(t)\mathcal{B},\ \mathcal{A}) \to 0$, *as* $t \to +\infty$.

THEOREM 3.3 (see [1]). *Suppose that*

(1) $\{H_\eta\}_{0<\eta\le\eta_0}$ *is a family of closed subspaces of Banach space* H *such that*

$$\bigcup_{0<\eta\le\eta_0} H_\eta$$

is dense in H.

(2) $S_\eta(t)$: $H_\eta \to H_\eta$ *and* $S(t)$: $H \to H$ *are two nonlinear semigroup operators,* $\mathcal{A}_\eta \subset H_\eta$ *and* $\mathcal{A} \subset H$ *are the global attractors of* $S_\eta(t)$ *and* $S(t)$, *respectively.*

(3) *For every compact interval* $I \subset (0, +\infty)$,

$$\delta_\eta(I) = \sup_{u_0\in H_\eta} \sup_{t\in I} \operatorname{dist}\left(S_\eta(t)u_0\,,\, S(t)u_0\right) \to 0 \quad as \quad \eta \to 0.$$

Then $\mathcal{A}_\eta$ *is convergent to* $\mathcal{A}$ *in the sense of the semidistance:*

$$\operatorname{dist}(\mathcal{A}_\eta, \mathcal{A}) \to 0 \quad \text{as} \quad \eta \to 0,$$

where

$$\operatorname{dist}(\mathcal{A}_\eta, \mathcal{A}) = \sup_{u\in\mathcal{A}_\eta} \inf_{v\in\mathcal{A}} \|u - v\|_H.$$

Finally, similar to Lemma 2.7, the following result can be proved easily.

LEMMA 3.4. *Under the hypotheses of Lemma* 2.7, *we have the estimates for the smooth solution* $u(x,t)$ *of problem* (1.1)–(1.3)

$$t\|u_t\|^2 + \int_0^t s\|u_{tx}\|^2 ds \le c(1+t^2),$$

$$t^2\|u_{tx}\|^2 + \int_0^t s^2\|u_{txx}\|^2 ds \le c(1+t^3),$$

$$t^3\|u_{txx}\|^2 + \int_0^t s^3(\|u_{tt}\|^2 + \|u_{txxx}\|^2) ds \le c(1+t^4),$$

$$t^4\|u_{tt}\|^2 + \int_0^t s^4\|u_{ttx}\|^2 ds \le c(1+t^5),$$

where the constant c *is independent of* t.

Now we give the main result of this section.

THEOREM 3.5. *Suppose that the conditions of Theorem* 2.2 *hold. Then*

$$\operatorname{dist}(\mathcal{A}_N^\tau, \mathcal{A}) \to 0 \qquad \text{as } \tau \to 0,\ N \to +\infty.$$

Proof. Let $\|u_0\|_2 \le R_0$. On account of Theorem 3.2, this theorem will be proved by taking the error estimates of the solution u_N^n of discrete problem (1.4), (1.5). Now we accomplish them through two steps.

Step 1. Take the error estimates of the solution v_N^n of the linear scheme as follows:

$$(\overline{\partial}_t v_N^k - \alpha v_{Nxx}^k + \beta v_{Nxxx}^k + \alpha v_N^k + f(u^k)_x, \varphi) = (g(u^k) + \alpha u^k + h, \varphi) \quad \text{for all } \varphi \in S_N,\ \ k = 1, 2, \cdots, \tag{3.5}$$

$$v_N^0 = P_N u_0. \tag{3.6}$$

Let $u^k - v_N^k = (u^k - P_N u^k) + (P_N u^k - v_N^k) = \rho^k + \theta^k$. Then θ^k satisfies

$$(\overline{\partial}_t \theta^k - \alpha\theta_{xx}^k + \beta\theta_{xxx}^k + \alpha\theta^k - (\overline{\partial}_t u^k - u_t^k),\ \ \varphi) = 0 \quad \text{for all } \varphi \in S_N, \tag{3.7}$$

$$\theta^0 = 0. \tag{3.8}$$

Letting $\varphi = \theta^k$ in (3.7), we have

$$\frac{1}{2}\overline{\partial}_t\|\theta^k\|^2 + \frac{\tau}{2}\|\overline{\partial}_t\theta^k\|^2 + \alpha\|\theta^k\|_1^2 = (\overline{\partial}_t\theta^k - u_t^k, \theta^k).$$

From the definition of G_N, we find

$$\begin{aligned}(\overline{\partial}_t u^k - u_t^k, \theta^k) &= ((G_N(\overline{\partial}_t u^k - u_t^k))_x, \theta_x^k) + (G_N(\overline{\partial}_t u^k - u_t^k), \theta^k)\\ &\le \frac{\alpha}{2}\|\theta^k\|_1^2 + \frac{1}{2\alpha}\|G_N(\overline{\partial}_t u^k - u_t^k)\|_1^2,\end{aligned}$$

where

$$\begin{aligned}\|G_N(\overline{\partial}_t u^k - u_t^k)\|_1^2 &= \frac{1}{\tau^2}\Big\|\int_{t_{k-1}}^{t_k}(s - t_{k-1})G_N u_{tt} ds\Big\|_1^2\\ &\le \frac{1}{\tau^2}\int_{t_{k-1}}^{t_k}\frac{(s-t_{k-1})^2}{s^2}\mathrm{d}s\int_{t_{k-1}}^{t_k} s^2\|G_N u_{tt}\|_1^2\mathrm{d}s\\ &\le \frac{\tau}{t_k^2}\int_{t_{k-1}}^{t_k} s^2\|G_N u_{tt}\|_1^2\mathrm{d}s.\end{aligned}$$

Thus

$$\overline{\partial}_t\|\theta^k\|^2 + \tau\|\overline{\partial}_t\theta^k\|^2 + \alpha\|\theta^k\|^2 \le \frac{1}{\alpha}\|G_N(\overline{\partial}_t u^k - u_t^k)\|_1^2 \le \frac{\tau}{\alpha t_k^2}\int_{t_{k-1}}^{t_k} s^2\|G_N u_{tt}\|_1^2\mathrm{d}s.$$

Multiplying the above inequality by t_k^2, taking the sum for k from 1 to n, and using $\|G_N u_{tt}\|_1 \le c\|u_t\|_2$, we have

$$\begin{aligned}&t_n^2\|\theta^n\|^2 + \alpha\tau\sum_{k=1}^n t_k^2\|\theta^k\|_1^2 + \tau^2\sum_{k=1}^n t_k^2\|\overline{\partial}_t\theta^k\|^2\\ \le\ & 3\tau\sum_{k=1}^n t_k\|\theta^k\|^2 + \frac{\tau^2}{\alpha}\sum_{k=1}^n\int_{t_{k-1}}^{t_k} s^2\|G_N u_{tt}\|_1^2\mathrm{d}s\\ \le\ & 3\tau\sum_{k=1}^n t_k\|\theta^k\|^2 + c\tau^2\int_0^{t_n} s^2\|u_t\|_2^2\mathrm{d}s\\ \le\ & 3\tau\sum_{k=1}^n t_k\|\theta^k\|^2 + c\tau^2(1 + t_n^3).\end{aligned} \tag{3.9}$$

Now we estimate $\tau\sum_{k=1}^n t_k\|\theta^k\|^2$ in the above inequality. Let $\varphi = G_N\theta^k$ in (3.7). Then it is obtained that

$$(\overline{\partial}_t\theta^k - \alpha\theta_{xx}^k + \beta\theta_{xxx}^k + \alpha\theta^k - (\overline{\partial}_t u^k - u_t^k), G_N\theta^k) = 0.$$

From the definition of G_N, we find

$$(\overline{\partial}_t\theta^k, G_N\theta^k) = (\overline{\partial}_t(G_N\theta^k)_x, (G_N\theta^k)_x) + (\overline{\partial}_t(G_N\theta^k), G_N\theta^k) = \frac{1}{2}\overline{\partial}_t\|G_N\theta^k\|_1^2,$$

$$(-\alpha\theta^k_{xx} + \alpha\theta^k, G_N\theta^k) = \alpha((G_N\theta^k)_x, \theta^k_x) + \alpha(G_N\theta^k, \theta^k) = \alpha(\theta^k,\ \theta^k) = \alpha\|\theta^k\|^2,$$

$$\begin{aligned}\beta(\theta^k_{xxx}, G_N\theta^k) &= -\beta(\theta^k,\ (G_N\theta^k)_{xxx})\\ &= -\beta((G_N\theta^k)_x,\ (G_N\theta^k)_{x^4}) - \beta(G_N\theta^k, (G_N\theta^k)_{xxx})\\ &= 0\end{aligned}$$

and

$$(\overline{\partial}_t u^k - u^k_t, G_N\theta^k) = (G_N(\overline{\partial}_t u^k - u^k_t), \theta^k) \le \frac{\alpha}{2}\|\theta^k\|^2 + \frac{2}{\alpha}\|G_N(\overline{\partial}_t u^k - u^k_t)\|^2.$$

Therefore

$$\overline{\partial}_t\|G_N\theta^k\|_1^2 + \alpha\|\theta^k\|^2 \le \frac{1}{\alpha}\|G_N(\overline{\partial}_t u^k - u^k_t)\|^2.$$

Multiplying this inequality by τt_k, summing them for k from 1 to n, and using $\|G_N u_{tt}\| \le c\|u_t\|_1$, we have

$$\begin{aligned}& t_n\|G_N\theta^k\|_1^2 + \alpha\tau\sum_{k=1}^n t_k\|\theta^k\|^2\\ \le\ & \frac{\tau^2}{\alpha}\sum_{k=1}^n t_k\|G_N(\overline{\partial}_t u^k - u^k_t)\|^2 + \tau\sum_{k=1}^n\|G_N\theta^k\|_1^2\\ \le\ & \frac{\tau}{\alpha}\int_0^{t_n} s\|G_N u_{tt}\|^2\mathrm{d}s + \tau\sum_{k=1}^n\|G_N\theta^k\|_1^2\\ \le\ & c\tau^2(1+t_n^2) + \tau\sum_{k=1}^n\|G_N\theta^k\|_1^2.\end{aligned} \tag{3.10}$$

To estimate $\tau\sum_{k=1}^n\|G_N\theta^k\|_1^2$ in the above relation, let $\varphi = G_N^2\theta^k$ in (3.7). Then we have

$$(\overline{\partial}_t\theta^k - \alpha\theta^k_{xx} + \beta\theta^k_{xxx} + \alpha\theta^k - (\overline{\partial}_t u^k - u^k_t), G_N^2\theta^k) = 0.$$

From the definition of G_N, we obtain

$$(\overline{\partial}_t\theta^k, G_N^2\theta^k) = \frac{1}{2}\overline{\partial}_t\|G_N\theta^k\|^2 + \frac{\tau}{2}\|G_N(\overline{\partial}_t\theta^k)\|^2,$$

$$(-\alpha\theta^k_{xx} + \alpha\theta^k, G_N^2\theta^k) = \alpha\|G_N\theta^k\|_1^2,$$

$$\beta(\theta^k_{xxx}, G_N^2\theta^k) = 0$$

and

$$\begin{aligned}(\overline{\partial}_t u^k - u^k_t, G_N^2\theta^k) =\ & ((G_N^2(\overline{\partial}_t u^k - u^k_t))_x, (G_N\theta^k)_x) + (G_N^2(\overline{\partial}_t u^k - u^k_t), G_N\theta^k)\\ \le\ & \frac{\alpha}{2}\|G_N\theta^k\|_1^2 + \frac{1}{2\alpha}\|G_N^2(\overline{\partial}_t u^k - u^k_t)\|_1^2.\end{aligned}$$

Therefore

$$\overline{\partial}_t\|G_N\theta^k\|^2 + \alpha\|G_N\theta^k\|_1^2 \le \frac{1}{\alpha}\|G_N^2(\overline{\partial}_t u^k - u^k_t)\|_1^2.$$

Taking the sum of the above relation for k from 1 to n, and applying $\|G_N^2 u_{tt}\|_1 \le c\|u_t\|$, it is derived that

$$\begin{aligned}\|G_N\theta^k\|^2 + \alpha\tau\sum_{k=1}^{n}\|G_N\theta^k\|_1^2 &\le \frac{\tau}{\alpha}\sum_{k=1}^{n}\|G_N^2(\overline{\partial}_t u^k - u_t^k)\|_1^2 \\ &\le \frac{\tau^2}{\alpha}\int_0^{t_n}\|G_N^2 u_{tt}\|_1^2 \mathrm{d}s \le c\tau^2(1+t_n).\end{aligned} \tag{3.11}$$

Combining (3.9)–(3.11), we have

$$\begin{aligned}&t_n^2\|\theta^n\|^2 + \tau^2\sum_{k=1}^{n}t_k^2\|\overline{\partial}_t\theta^k\|^2 + \alpha\tau\sum_{k=1}^{n}t_k^2\|\theta^k\|_1^2 + \alpha\tau\sum_{k=1}^{n}t_k\|\theta^k\|^2 \\ &\quad\le c\tau^2(1+t_n^3).\end{aligned} \tag{3.12}$$

Let $\varphi = -\theta_{xx}^k$ in (3.7), and then we have

$$\begin{aligned}\frac{1}{2}\overline{\partial}_t\|\theta_x^k\|^2 + \frac{\tau}{2}\|\overline{\partial}_t\theta_x^k\|^2 + \alpha\|\theta_{xx}^k\|^2 + \alpha\|\theta_x^k\|^2 &= (\overline{\partial}_t u^k - u_t^k, -\theta_{xx}) \\ &\le \frac{\alpha}{2}\|\theta_{xx}^k\|^2 + \frac{1}{2\alpha}\|\overline{\partial}_t u^k - u_t^k\|^2,\end{aligned}$$

namely,

$$\overline{\partial}_t\|\theta_x^k\|^2 + \tau\|\overline{\partial}_t\theta_x^k\|^2 + \alpha\|\theta_{xx}^k\|^2 + \alpha\|\theta_x^k\|^2 \le \frac{1}{\alpha}\|\overline{\partial}_t u^k - u_t^k\|^2.$$

Multiplying this by τt_k^3, taking the sum for k from 1 to n, and using (3.12), we have

$$\begin{aligned}&t_n^3\|\theta_x^n\|^2 + \tau^2\sum_{k=1}^{n}t_k^3\|\overline{\partial}_t\theta_x^k\|^2 + \alpha\tau\sum_{k=1}^{n}t_k^3(\|\theta_{xx}^k\|^2 + \|\theta_x^k\|^2) \\ \le\ & \frac{\tau}{\alpha}\sum_{k=1}^{n}t_k^3\|\overline{\partial}_t u^k - u_t^k\|^2 + 7\tau\sum_{k=1}^{n}t_k^2\|\theta_x^k\|^2 \\ \le\ & \frac{\tau}{\alpha}\left(\sum_{k=2}^{n}\frac{t_k^3}{\tau^2}\int_{t_{k-1}}^{t_k}\frac{(s-t_{k-1})^2}{s^3}\mathrm{d}s\int_{t_{k-1}}^{t_k}s^3\|u_{tt}\|^2\mathrm{d}s + \tau^3\|\overline{\partial}_t u^1 - u_t^1\|^2\right) \\ &\qquad + c\tau^2(1+t_n^3) \\ \le\ & \frac{2\tau^2}{\alpha}\int_{\tau}^{t_n}s^3\|u_{tt}\|^2\mathrm{d}s + \frac{2\tau^2}{\alpha}\Big\|\int_0^{\tau}u_t ds\Big\|^2 + \frac{2\tau^4}{\alpha}\|u_t^1\|^2 + c\tau^2(1+t_n^3) \\ \le\ & c\tau^2(1+t_n^4) + c\tau^3(1+\tau^2) + \frac{2\tau^2}{\alpha}\int_0^{\tau}\|u_t\|^2\mathrm{d}s \\ \le\ & c\tau^2(1+t_n^4).\end{aligned} \tag{3.13}$$

Multiplying (3.13) by $\dfrac{1}{\alpha\tau}$, we have

$$t_n^3\|\theta_{xx}^n\|^2 \le c\tau(1+t_n^4). \tag{3.14}$$

Step 2. Take the error estimates of solution u_N^n of problem (1.4), (1.5). Let $v_N^k - u_N^k = e^k$. Then e^k satisfies

$$\begin{aligned}&(\overline{\partial}_t e^k - \alpha e_{xx}^k + \beta e_{xxx}^k + f(u^k)_x, \varphi) - B(u_N^{k-1}, u_N^k, \varphi) \\ =\ & (\alpha\,\theta^k + g(u^k) - G(u_N^{k-1})u_N^k, \varphi) \quad \text{for all } \varphi \in S_N,\ \ k = 1, 2, \ldots,\end{aligned} \tag{3.15}$$

$$e^0 = 0. \tag{3.16}$$

Let $\varphi = e^k$ in (3.15), and then we have

$$\frac{1}{2}\overline{\partial}_t\|e^k\|^2+\frac{1}{2}\|\overline{\partial}_t e^k\|^2+\alpha\|e_x^k\|^2+B(u^k,u^k,e^k)-B(u_N^{k-1},u_N^k,e^k)$$
$$=(g(u^k)-G(u_N^{k-1})u_N^k,e^k)+\alpha(\theta^k,e^k).$$

We now estimate every term in the above equality. First,

$$\begin{aligned}&(g(u^k)-G(u_N^{k-1})u_N^k,e^k)\\ =\;&(g(u^k)-g(u_N^k)+G(u_N^k)u_N^k-G(u_N^{k-1})u_N^k,e^k),\end{aligned}$$

where

$$(g(u^k)-g(u_N^k),e^k)=(g'(\eta_1)(\rho^k+\theta^k+e^k),e^k)\le\frac{15b}{16}\|e^k\|^2+c(\|\rho^k\|^2+\|\theta^k\|^2)$$

and

$$(G(u_N^k)u_N^k-G(u_N^{k-1})u_N^k,e^k)\le\frac{|b|}{16}\|e^k\|^2+c\|\overline{\partial}_t u_N^k\|^2.$$

Thus

$$(g(u^k)-G(u_N^{k-1})u_N^k,e^k)\le\frac{7b}{8}\|e^k\|^2+c\,(\|\rho^k\|^2+\|\theta^k\|^2+\tau^2\|\overline{\partial}_t u_N^k\|^2).$$

Second,

$$\begin{aligned}&B(u^k,u^k,e^k)-B(u_N^{k-1},u_N^k,e^k)\\ =\;&(F(u^k)u_x^k-F(u_N^{k-1})u_{Nx}^k,e^k)-(F(u^k)u^k-F(u_N^{k-1})u_N^k,e_x^k),\end{aligned}$$

where

$$\begin{aligned}&(F(u^k)u_x^k-F(u_N^{k-1})u_{Nx}^k,e^k)\\ =\;&(F(u^k)(u_x^k-u_{Nx}^k),e^k)+(F(u^k)-F(u^{k-1}),u_{Nx}^k e^k)+(F(u^{k-1})-F(u_N^{k-1}),u_{Nx}^k e^k)\\ \triangleq\;&I_1+I_2+I_3,\\ &I_1=-(F(u^k)_x\,e^k+F(u^k)e_x^k,\,u^k-u_N^k)\le c\|u^k-u_N^k\|\,(\|e^k\|+\|e_x^k\|)\\ &\le c(\|e^k\|+\|e_x^k\|)\,(\|\rho^{k-1}\|+\|\theta^{k-1}\|+\|e^{k-1}\|+\tau\|\overline{\partial}_t u^k\|+\tau\|\overline{\partial}_t u_N^k\|)\\ &\le c\left(\|e^{k-1}\|^2+\|\rho^{k-1}\|^2+\|\theta^{k-1}\|^2+\tau\int_{t_{k-1}}^{t_k}\|u_t\|^2\mathrm{d}s+\tau^2\|\overline{\partial}_t u_N^k\|^2\right)\\ &\qquad+\Big(\frac{|b|}{16}\|e^k\|^2+\frac{\alpha}{16}\|e_x^k\|^2\Big),\\ &I_2=(F'(\eta)u_{Nx}^k(u^k-u^{k-1}),e^k)\le\frac{|b|}{16}\|e^k\|^2+c\tau\int_{t_{k-1}}^{t_k}\|u_t\|^2\,\mathrm{d}s,\\ &I_3=\;(F'(\eta)u_{Nx}^k(u^{k-1}-u_N^{k-1}),e^k)\\ &\le\;\frac{|b|}{16}\|e^k\|^2+c\big(\|\rho^{k-1}\|^2+\|e^{k-1}\|^2+\|\theta^{k-1}\|^2\big).\end{aligned}$$

Thus

$$\begin{aligned}(F(u^k)u_x^k-F(u_N^{k-1})u_{Nx}^k,e^k)\le\;&\frac{3|b|}{16}\|\mathrm{e}^k\|^2+\frac{\alpha}{16}\|\mathrm{e}_x^k\|^2\\ &+c\left(\|\mathrm{e}^{k-1}\|^2+\|\rho^{k-1}\|^2+\|\theta^{k-1}\|^2+\tau\int_{t_{k-1}}^{t_k}\|u_t\|^2\mathrm{d}s+\tau^2\|\overline{\partial}_t u_N^k\|^2\right).\end{aligned}$$

Similarly

$$\begin{aligned}
&(F(u^k)u^k - F(u_N^{k-1})u_N^k, e_x^k)\\
=\ &(u^k(F(u^k) - F(u^{k-1}) + (u^k(F(u^{k-1}) - F(u_N^{k-1})) + F(u^k)(u^k - u_N^k), e_x^k)\\
\le\ &\frac{\alpha}{16}\|e_x^k\|^2 + c\left(\|e^{k-1}\|^2 + \|\rho^{k-1}\|^2 + \|\theta^{k-1}\|^2 + \tau^2\|\overline{\partial}_t u_N^k\|^2 + \tau\int_{t_{k-1}}^{t_k}\|u_t\|^2\,\mathrm{d}s\right).
\end{aligned}$$

Thus

$$\begin{aligned}
B(u^k, u^k, e^k) - B(u_N^{k-1}, u_N^k, e^k) \le\ &\frac{\alpha}{8}\|e_x^k\|^2 + \frac{3|b|}{16}\|e^k\|^2\\
&+ c\left(\|e^{k-1}\|^2 + \|\rho^{k-1}\|^2 + \|\theta^{k-1}\|^2 + \tau^2\|\overline{\partial}_t u_N^k\|^2 + \tau\int_{t_{k-1}}^{t_k}\|u_t\|^2\,\mathrm{d}ds\right).
\end{aligned}$$

Finally

$$\alpha(\theta^k, e^k) \le \frac{|b|}{16}\|e^k\|^2 + c\|\theta^k\|^2.$$

Therefore

$$\begin{aligned}
\overline{\partial}_t\|e^k\|^2 + \alpha\|e_x^k\|^2 - b\|e^k\|^2 + \tau\|\overline{\partial}_t e^k\|^2 \le\ &c(\|e^{k-1}\|^2 + \|\rho^k\|^2 + \|\theta^k\|^2)\\
&+ c\left(\|\rho^{k-1}\|^2 + \|\theta^{k-1}\|^2 + \tau^2\|\overline{\partial}_t u_N^k\|^2 + \tau\int_{t_{k-1}}^{t_k}\|u_t\|^2\mathrm{d}s\right).
\end{aligned} \tag{3.17}$$

By applying the discrete Gronwall's inequality to (3.17), and using Lemma 1.1, Lemma 2.3, Theorem 3.2, (3.10), and (3.11), we have

$$\begin{aligned}
\|e^n\|^2 &\le\ c\,\mathrm{e}^{ct_n}\tau\sum_{k=1}^{n}\left(\|\rho^k\|^2 + \|\theta^k\|^2 + \tau^2\|\overline{\partial}_t u_N^k\|^2 + \tau\int_{t_{k-1}}^{t_n}\|u_t\|^2\mathrm{d}s\right)\\
&\le\ c(1 + t_n^2)\mathrm{e}^{ct_n}(N^{-4} + \tau).
\end{aligned} \tag{3.18}$$

Taking the sum of (3.17) for k from 1 to n and using (3.18) and (3.9)–(3.11), we have

$$\tau\sum_{k=1}^{n}\|e^k\|_1^2 + \tau^2\sum_{k=1}^{n}\|\overline{\partial}_t e^k\|^2 \le c(1 + t_n^3)\,\mathrm{e}^{ct_n}(N^{-4} + \tau). \tag{3.19}$$

Let $\varphi = -e_{xx}^k$ in (3.15), and then similarly as in (3.17) we have

$$\overline{\partial}_t\|e_x^k\|^2 + \alpha\|e_{xx}^k\|^2 \le\ c\big(\|\rho^k\|_1^2 + \|\theta^k\|_1^2 + \tau^2\|\overline{\partial}_t u_N^k\|_1^2 + \|e^k\|^2\big).$$

Multiplying the above relation by τt_k, summing them for k from 1 to n, and using Lemma 2.5, (3.18), (3.19), (3.9)–(3.11), we have

$$\begin{aligned}
&t_n\|e_x^k\|^2 + \alpha\tau\sum_{k=1}^{n}t_k\|e_{xx}^k\|^2\\
\le\ &\tau\sum_{k=1}^{n}\|e_x^k\|^2 + \tau\sum_{k=1}^{n}t_k(\|e^k\|^2 + \|\theta^k\|_1^2 + \|\rho^k\|_1^2 + \tau^2\|\overline{\partial}_t u_N^k\|_1^2)\\
\le\ &c(1 + t_n^4)\mathrm{e}^{ct_n}(N^{-2} + \tau).
\end{aligned} \tag{3.20}$$

Letting $\varphi = e_{x^4}$ in (3.15), we have

$$\begin{aligned}(3.21)\qquad &\frac{1}{2}\overline{\partial}_t\|e^k_{xx}\|^2+\frac{\tau}{2}\|\overline{\partial}_t e^k_{xx}\|^2+\alpha\|e^k_{xxx}\|^2+B(u^k,u^k,e^k_{x^4})-B(u^{k-1}_N,u^k_N,e^k_{x^4})\\ &\quad=(g(u^k)-G(u^{k-1}_N)u^k_N,e^k_{x^4})+\alpha(\theta^k,e^k_{x^4}).\end{aligned}$$

Now we estimate the last three terms in (3.21). First, from the definition of $B(u,v,\varphi)$, we have

$$\begin{aligned}&B(u^k,u^k,e^k_{x^4})-B(u^{k-1}_N,u^k_N,e^k_{x^4})\\ =\;&2\Big(F(u^k)u^k_{xx}-F(u^{k-1}_N)u^k_{Nxx},-e^k_{xxx}\Big)\\ &+3\Big(F'(u^k)(u^k_x)^2-F'(u^{k-1}_N)u^{k-1}_{Nx}u^k_{Nx},-e^k_{xxx}\Big)\\ &+\Big(F'(u^k)u^ku^k_{xx}-F'(u^{k-1}_N)u^k_Nu^{k-1}_{Nxx},-e^k_{xxx}\Big)\\ &+\Big(F''(u^k)u^k(u^k_x)^2-F''(u^{k-1}_N)u^k_N(u^{k-1}_{Nx})^2,-e^k_{xxx}\Big)\\ =\;&I_7+I_8+I_9+I_{10},\end{aligned}$$

where

$$\begin{aligned}I_7&\le\frac{\alpha}{16}\|e^k_{xxx}\|^2+c(\|\rho^k\|_2^2+\|\theta^k\|_2^2+\|e^k\|^2+\tau^2\|\overline{\partial}_t u^k_N\|^2),\\ I_8&\le\frac{\alpha}{16}\|e^k_{xxx}\|^2+c\Big(\|\rho^k\|_1^2+\|\theta^k_x\|^2+\|e^k\|^2+\tau^2\|\overline{\partial}_t u^k_N\|_1^2\Big),\\ I_9&\le\frac{\alpha}{16}\|e^k_{xxx}\|^2+c\big(\|\rho^k\|_2^2+\|\theta^k\|_2^2+\|e^k\|^2+\tau^2\|\overline{\partial}_t u^k_N\|_2^2\big)\end{aligned}$$

and

$$I_{10}\le\frac{\alpha}{16}\|e^k_{xxx}\|^2+\big(\|\rho^k\|_1^2+\|\theta^k\|_1^2+\|e^k\|^2+\tau^2\|\overline{\partial}_t u^k_N\|_1^2\big).$$

Thus

$$\begin{aligned}(3.22)\qquad &B(u^k,u^k,e^k_{x^4})-B(u^{k-1}_n,u^k_N,e^k_{x^4})\\ \le\;&\frac{\alpha}{4}\|e^k_{xxx}\|^2+c\big(\|\rho^k\|_2^2+\|\theta^k\|_2^2+\|e^k\|^2+\tau^2\|\overline{\partial}_t u^k_N\|_2^2\big).\end{aligned}$$

Second, by the definition of $G(u)$, we have

$$\begin{aligned}(3.23)\qquad &\Big(g(u^k)-G(u^{k-1}_N),e^k_{x^4}\Big)\\ =\;&\Big(g'(u^k)u^k_x-G'(u^{k-1}_N)u^{k-1}_{Nx}u^k_N-G(u^{k-1}_N)u^k_{Nx},-e^k_{xxx}\Big)\\ \le\;&\frac{1}{8}\|e^k_{xxx}\|^2+c\Big(\|\rho^k\|_1^2+\|\theta^k\|_1^2+\|e^k\|^2+\tau^2\|\overline{\partial}_t u^k_N\|_1^2\Big).\end{aligned}$$

Finally

$$(3.24)\qquad \alpha(\theta^k,e^k_{x^4})\le\frac{\alpha}{8}\|e^k_{xxx}\|^2+c\|\theta^k_x\|^2.$$

Combining (3.21)–(3.24), we have

$$(3.25)\qquad \overline{\partial}_t\|e^k_{xx}\|^2+\alpha\|e^k_{xxx}\|^2\le\;c(\|\rho^k\|_2^2+\|\theta^k\|_2^2+\|e^k\|^2+\tau^2\|\overline{\partial}_t u^k_N\|_1^2).$$

From Lemma 1.1, we have

$$\|\rho^k\|_2^2 \le cN^{-2}\|u_{xxx}^k\|^2.$$

From Theorem 3.2, we have

$$t_k\|u_{xxx}^k\|^2 \le c(1+t_k^2).$$

Hence multiplying (3.25) by τt_k^2, summing them and using (3.9)–(3.14), (3.19), and (3.20), we have

$$\begin{aligned} & t_n^2\|e_{xx}^n\|^2 + \alpha\tau\sum_{k=1}^n t_k^2\|e_{xxx}^k\|^2 \\ \le\ & c\tau\sum_{k=1}^n t_k^2(\|u_{xxx}^k\|^2N^{-2} + \|\theta^k\|_2^2 + \|e^k\|^2 + \tau^2\|\overline{\partial}_t u_N^k\|_1^2) + 2\tau\sum_{k=1}^n t_k\|e_{xx}^k\|^2 \\ \le\ & c(1+t_n^5)\mathrm{e}^{ct_n}(N^{-2}+\tau). \end{aligned}$$

By using the triangle inequality, we have

$$\begin{aligned} \|u^n - u_N^n\|_2^2 &\le 3(\|\rho^n\|_1^2 + \|\theta^n\|_2^2 + \|e^k\|_2^2) \\ &\le c\mathrm{e}^{ct_n}(1+t_n^{-3}+t_n^3)(N^{-2}+\tau) \qquad \text{for all } t\in(0,+\infty). \end{aligned}$$

Finally, applying Theorem 3.3, we complete the proof of this theorem. ∎

4. Stability of the discrete autonomous system. In this section, the stability of the discrete scheme (1.4), (1.5) is proved.

THEOREM 4.1. *Suppose that f, g, h satisfy the conditions of Lemma* 2.5. *Let $\{u_N^n\}$, $\{v_N^n\}$ be the two solutions of the discrete scheme* (1.4), (1.5) *with the initial values $\{u_N^0\}$, $\{v_N^0\}$, respectively, and the initial values satisfy $\|u_N^0\|_1 \le R_0$, $\|v_N^0\|_1 \le R_0$. Then we have*

$$\|u_N^n - v_N^n\|_1 \le c\mathrm{e}^{ct_n}\|u_N^0 - v_N^0\|_1 \qquad \text{for all } n\ge 1.$$

Furthermore, if f, g, h satisfy the conditions of Lemma 2.7, *and $\|u_N^0\|_2 \le R_0$, $\|v_N^0\|_2 \le R_0$, then we have*

$$\|u_N^n - v_N^n\|_2 \le c\mathrm{e}^{ct_n}\|u_N^0 - v_N^0\|_2 \qquad \text{for all } n\ge 1.$$

Proof. Let $w_N^k = u_N^k - v_N^k$, and then w_N^k satisfies

$$\begin{aligned} &(\overline{\partial}_t w_N^k - \alpha w_{Nxx}^k + \beta w_{Nxxx}^k, \varphi) + B(u_N^{k-1}, u_N^k, \varphi) - B(v_N^{k-1}, v_N^k, \varphi) \\ &\qquad = (G(u_N^{k-1})u_N^k - G(v_N^{k-1})v_N^k, \varphi), \qquad \text{for all } \varphi\in S_N, k=1,2,\ldots. \end{aligned} \tag{4.1}$$

First, we assume that the conditions of Lemma 2.5 are satisfied.

Letting $\varphi = w_N^k$ in (4.1), we have

$$\begin{aligned} \frac{1}{2}\overline{\partial}_t\|w_N^k\|^2 + \alpha\|w_{Nx}^k\|^2 \le &-\big(B(u_N^{k-1}, u_N^k, w_N^k) - B(v_N^{k-1}, v_N^k, w_N^k)\big) \\ &+(G(u_N^{k-1})u_N^k - G(v_N^{k-1})v_N^k, w_N^k). \end{aligned} \tag{4.2}$$

Now we estimate the last two terms. First, by applying the definition of $B(u,v,w)$ and $G(u)$, Sobolev interpolation inequality, Young's inequality, and the estimates in

section 2, we obtain

$$\begin{aligned}
&\big|B(u_N^{k-1},u_N^k,w_N^k)-B(v_N^{k-1},v_N^k,w_N^k)\big| = \big|B(u_N^{k-1},u_N^k,w_N^k)-B(v_N^{k-1},u_N^k,w_N^k)\big|\\
&= \big|\big(F(u_N^{k-1})-F(v_N^{k-1})\big)u_{Nx}^k,w_N^k)-((F(u_N^{k-1})-F(v_N^{k-1}))u_N^k,w_{Nx}^k\big)\big|\\
&\le \frac{|b|}{4}\|w_N^k\|^2+\frac{\alpha}{2}\|w_{Nx}^k\|^2+c\|v_N^k\|_1^2\,\|w_N^{k-1}\|^2
\end{aligned}$$

and

$$\begin{aligned}
&(G(u_N^{k-1})u_N^k-G(v_N^{k-1})v_N^k,w_N^k)\\
=\;&\big((G(u_N^{k-1})-G(v_N^{k-1})u_N^k,w_N^k)+(G(v_N^{k-1})w_N^k,w_N^k)\\
\le\;& c\|u_N^k\|_\infty\|w_N^k\|\,\|w_N^{k-1}\|+b\|w_N^k\|^2\le\frac{3b}{4}\|w_N^k\|^2+c\|u_N^k\|_1^2\|w_N^{k-1}\|^2.
\end{aligned}$$

Hence (4.2) can be rewritten as

$$\overline{\partial}_t\|w_N^k\|^2+\alpha\|w_{Nx}^k\|^2-b\|w_N^k\|^2\le c\|u_N^k\|_1^2\,\|w_N^{k-1}\|^2. \tag{4.3}$$

By applying the discrete Gronwall's inequality, we obtain

$$\|w_N^k\|^2\le\|w_N^0\|^2\mathrm{e}^{ct_n}=\mathrm{e}^{ct_n}\|u_N^0-v_N^0\|^2\qquad\text{for all } n\ge 1. \tag{4.4}$$

Taking the sum of (4.3) for k from 1 to n, we have

$$\|w_N^k\|^2+\tau\sum_{k=1}^n\|w_N^k\|_1^2\le(1+c\mathrm{e}^{ct_n})\|u_N^0-v_N^0\|^2. \tag{4.5}$$

Letting $\varphi=-w_{Nxx}^k$ in (4.1), we have

$$\begin{aligned}
&\frac{1}{2}\overline{\partial}_t\|w_{Nx}^k\|^2+\alpha\|w_{Nxx}^k\|^2+B(u_N^{k-1},u_N^k,-w_{Nxx}^k)-B(v_N^{k-1},v_N^k,-w_{Nxx}^k)\\
&\qquad\le(G(u_N^{k-1})u_N^k-G(v_N^{k-1})v_N^k,-w_{Nxx}^k).
\end{aligned} \tag{4.6}$$

Since

$$\begin{aligned}
&B(u_N^{k-1},u_N^k,-w_{Nxx}^k)-B(v_N^{k-1},v_N^k,-w_{Nxx}^k)\\
=\;&B(u_N^{k-1},w_N^k,-w_{Nxx}^k)+B(u_N^{k-1},v_N^k,-w_{Nxx}^k)-B(v_N^{k-1},v_N^k,-w_{Nxx}^k),
\end{aligned}$$

where

$$\begin{aligned}
B(u_N^{k-1},w_N^k,-w_{Nxx}^k)=\;&(2F(u_N^{k-1})w_{Nx}^k+F'(u_N^{k-1})u_{Nx}^{k-1}w_N^k,-w_{Nxx}^k)\\
\le\;&c\|w_{Nxx}^k\|(\|u_N^{k-1}\|_\infty\|w_{Nx}^k\|+\|u_{Nx}^{k-1}\|\,\|w_N^k\|_\infty)\\
\le\;&\frac{\alpha}{6}\|w_{Nxx}^k\|^2+c\|u_N^{k-1}\|_1^2\,\|w_N^k\|^2,\\
&B(u_N^{k-1},v_N^k,-w_{Nxx}^k)-B(v_N^{k-1},v_N^k,-w_{Nxx}^k)\\
=\;&2(F(u_N^{k-1})-F(v_N^{k-1}),-v_{Nx}^kw_{Nxx}^k)+(F'(u_N^{k-1})w_{Nx}^{k-1},-v_N^kw_{Nxx}^k)\\
&\qquad+(F'(u_N^{k-1})-F'(v_N^{k-1}),-v_{Nx}^{k-1}v_N^kw_{Nxx}^k)\\
\le\;&c\|w_{Nxx}^k\|\,(\|v_N^k\|_\infty\|w_{Nx}^{k-1}\|+(\|v_{Nx}^k\|+\|v_{Nx}^{k-1}\|)\,\|w_N^{k-1}\|_\infty)\\
\le\;&\frac{\alpha}{6}\|w_{Nxx}^k\|^2+c(\|v_N^k\|_1^2+\|v_N^{k-1}\|^2)\,\|w_N^{k-1}\|_1^2
\end{aligned}$$

and

$$\begin{aligned}
&(G(u_N^{k-1})u_N^k - G(v_N^{k-1})v_N^k, -w_{Nxx}^k)\\
=\ &(G(u_N^{k-1})w_N^k + (G(u_N^{k-1}) - G(v_N^{k-1})v_N^k, -w_{Nxx}^k)\\
\le\ &c\|w_{Nxx}^k\|\,(\|u_N^{k-1}\|_\infty\|w_N^k\| + \|v_N^k\|_\infty\|w_N^{k-1}\|)\\
\le\ &\frac{\alpha}{6}\|w_{Nxx}^k\|^2 + c(\|u_N^{k-1}\|_1^2 + \|v_N^k\|_1^2)\,(\|w_N^k\|^2 + \|w_N^{k-1}\|^2),
\end{aligned}$$

(4.6) can be rewritten as

$$\overline{\partial}_t\|w_{Nx}^k\|^2 + \alpha\|w_{Nxx}^k\|^2 \le\ c(\|w_N^k\|^2 + \|w_N^{k-1}\|_1^2). \tag{4.7}$$

Taking the sum of (4.7) for k from 1 to n, and applying (4.4) and (4.5), we have

$$\|w_{Nx}\|^2 + \alpha\tau\sum_{k=1}^{n}\|w_{Nxx}^k\|^2 \le \|w_{Nx}^0\|^2 + c\mathrm{e}^{ct_n}\|w_N^0\|^2. \tag{4.8}$$

Now we assume that the conditions of Lemma 2.7 are satisfied.
Letting $\varphi = w_{Nx^4}^k$ in (4.1), we have

$$\begin{aligned}
&\frac{1}{2}\overline{\partial}_t\|w_{Nxx}^k\|^2 + \alpha\|w_{Nxxx}^k\|^2 + B(u_N^{k-1}, u_N^k, w_{Nx^4}^k) - B(v_N^{k-1}, v_N^k, w_{Nx^4}^k)\\
&\qquad \le (G(u_N^{k-1})u_N^k - G(v_N^{k-1})v_N^k, w_{Nx^4}^k).
\end{aligned} \tag{4.9}$$

Since

$$\begin{aligned}
&B(u_N^{k-1}, u_N^k, w_{Nx^4}^k) - B(v_N^{k-1}, v_N^k, w_{Nx^4}^k)\\
=\ &B(u_N^{k-1}, w_N^k, w_{Nx^4}^k) + B(u_N^{k-1}, v_N^k, w_{Nx^4}^k) - B(v_N^{k-1}, v_N^k, w_{Nx^4}^k),
\end{aligned}$$

where

$$\begin{aligned}
&B(u_N^{k-1}, w_N^k, w_{Nx^4}^k)\\
=\ &(2F(u_N^{k-1})w_{Nx}^k + F'(u_N^{k-1})u_{Nx}^{k-1}w_N^k, w_{Nx^4}^k)\\
=\ &(2F(u_N^{k-1})w_{Nxx}^k + 3F'(u_N^{k-1})u_{Nx}^{k-1}w_{Nx}^k + F'(u_N^{k-1})u_{Nxx}^{k-1}w_N^k, -w_{Nxxx}^k)\\
&\quad + (F''(u_N^{k-1})(u_{Nx}^{k-1})^2w_N^k, -w_{Nxxx}^k)\\
\le\ &\|w_{Nxxx}^k\|\,(\|u_N^{k-1}\|\,\|w_{Nxx}^k\| + \|u_{Nx}^{k-1}\|_\infty\|w_{Nx}^k\|\\
&\qquad +\|u_{Nxx}^{k-1}\|\,\|u_{Nx}^{k-1}\|\,\|w_N^k\|_\infty + \|u_{Nx}^{k-1}\|_\infty\|w_N^k\|)\\
\le\ &\frac{\alpha}{8}\|w_{Nxxx}^k\|^2 + c\|u_N^{k-1}\|_2^2\,\|w_N^k\|^2;
\end{aligned}$$

similarly we have

$$B(u_N^{k-1}, v_N^k, w_{Nx^4}^k) - B(v_N^{k-1}, v_N^k, w_{Nx^4}^k) \le \frac{\alpha}{8}\|w_{Nxxx}^k\|^2 + c\|v_N^k\|^2\,\|w_N^{k-1}\|_2^2$$

and

$$\begin{aligned}
&(G(u_N^{k-1})u_N^k - G(v_N^{k-1})v_N^k, w_{Nx^4}^k)\\
\le\ &\frac{\alpha}{6}\|w_{Nxxx}^k\|^2 + c(\|u_N^{k-1}\|_2^2 + \|v_N^k\|_2^2)\,(\|w_N^k\|_1^2 + \|w_N^{k-1}\|_1^2),
\end{aligned}$$

hence

$$\overline{\partial}_t\|w_{Nxx}^k\|^2+\tau\|\overline{\partial}_t w_{Nxx}^k\|^2+\alpha\|w_{Nxxx}^k\|^2\le\ c(\|w_N^k\|^2+\|w_N^{k-1}\|_2^2). \tag{4.10}$$

Taking the sum of (4.10) for k from 1 to n, and using (4.4), (4.5), and (4.8), we have

$$\|w_{Nxx}^n\|^2\le\|w_{Nxx}^0\|^2+c\mathrm{e}^{ct_n}\|w_N^0\|_1^2 \qquad \text{for all } n\ge 1. \tag{4.11}$$

Combining (4.4), (4.8), and (4.11), we complete the proof of this theorem. □

5. Long-time stability and convergence of the discrete scheme. In this section, let $h=h(x,t)$. To prove the long-time stability and the convergence of discrete scheme (1.4), (1.5), the following results are necessary.

LEMMA 5.1. *Suppose that* $f\in C^m, g\in C^{m-1}$, $|f'(s)|\le A(|s|^2+1)$, $g(0)=0$, $g'(s)\le b<0$, $|g'(s)|\le B|s|(|s|^4+1)$; $h,h_t\in L^\infty(R^+;H_p^{m-2}(\Omega))\bigcap L^2(R^+;H_p^{m-3}(\Omega))$; $u_0\in H_p^m(\Omega)$ $(m\ge 5)$. *Then we have the solution* $u(x,t)\in L^\infty(R^+;H_p^m(\Omega))\cap L^2(R^+;H_p^{m+1}(\Omega))$ *of problem* (1.1)–(1.3), *and*

$$u_t\in L^\infty(R^+;H_p^{m-3}(\Omega))\cap L^2(R^+;H_p^{m-2}(\Omega));\quad u_{tt}\in L^2(R^+;H_p^{m-5}(\Omega)).$$

LEMMA 5.2. *Under the conditions of Lemma* 5.1, *we have the estimates for the solution* u_N^k *of discrete problem* (1.4), (1.5),

$$\|u_N^n\|_2^2+\tau^2\sum_{k=1}^n\|\overline{\partial}_t u_N^k\|_2^2+\tau\sum_{k=1}^n\|u_N^k\|_3^2\le c \qquad \text{for all } n\ge 1,$$

where the constant c *is independent of* N, τ, *and* n.

The proofs of Lemmas 5.1 and 5.2 are similar to those of Lemmas 2.3–2.7.

Now we give the main results in this section.

THEOREM 5.3. *Under the conditions of Lemma* 5.1, *we have the following error estimates for the solutions* u_N^k *of discrete scheme* (1.4), (1.5):

$$\|u^n-u_N^n\|_1^2\le c(N^{-2(m-1)}+\tau) \qquad \text{for all } n\ge 1,$$

where the constant $c=c(\|u_0\|_m)$ *is independent of* N, τ, *and* n.

Proof. Let $u^k-u_N^k=(u^k-P_Nu^k)+(P_Nu^k-u_N^k)\triangleq\eta^k+\xi^k$. Then ξ^k satisfies

$$\begin{aligned}&(\overline{\partial}_t\xi^k-\alpha\xi_{xx}^k+\beta\xi_{xxx}^k,\varphi)+B(u^k,u^k,\varphi)-B(u_N^{k-1},u_N^k,\varphi)\\ =\ &(g(u^k)-G(u_N^{k-1})u_N^k,\varphi)+(\overline{\partial}_t u^k-u_t^k,\varphi) \qquad \text{for all } \varphi\in S_N,\ n\ge 1,\end{aligned} \tag{5.1}$$

$$\xi^0=0. \tag{5.2}$$

Letting $\varphi=\xi^k$ in (5.1), we have

$$\begin{aligned}&\frac{1}{2}\overline{\partial}_t\|\xi^k\|^2+\frac{\tau}{2}\|\overline{\partial}_t\xi^k\|^2+\alpha\|\xi_x^k\|^2+B(u^k,u^k,\xi^k)-B(u_N^{k-1},u_N^k,\xi^k)\\ &\quad=(g(u^k)-G(u_N^{k-1})u_N^k,\xi^k)+(\overline{\partial}_t u^k-u_t^k,\xi^k).\end{aligned} \tag{5.3}$$

Now we estimate every term in the above equality. First,

$$(g(u^k)-G(u_N^{k-1})u_N^k,\xi^k)=(g(u^k)-g(u_N^k),\xi^k)+(g(u_N^k)-G(u_N^{k-1})u_N^k,\xi^k),$$

where from the definition of $G(u)$, we have

$$\begin{aligned}
&(g(u^k)-g(u_N^k),\xi^k)\\
&=(g'(0)(u^k-u_N^k)+g''(\theta_2)u_N^k(u^k-u_N^k)+\frac{1}{2}g''(\theta_1)(u^k-u_N^k)^2,\xi^k)\\
&\le b\|\xi^k\|^2+c\|\xi^k\|\|u^k-u_N^k\|(\|u^k\|_\infty+\|u_N^k\|_\infty)\\
&\le \frac{15|b|}{16}\|\xi^k\|^2+c(\|u^k\|_1^2+\|u_N^k\|_1^2)\left(\|\eta^{k-1}\|^2+\|\xi^{k-1}\|^2+\tau^2\|\overline{\partial}_t u_N^k\|^2+\tau\int_{t_{k-1}}^{t_k}\|u_t\|^2\,\mathrm{d}s\right)
\end{aligned}$$

and

$$(g(u_N^k)-G(u_N^{k-1})u_N^k,\xi^k)\le\frac{|b|}{8}\|\xi^k\|^2+c\tau^2\|\overline{\partial}_t u_N^k\|^2.$$

This implies

$$\begin{aligned}
&(g(u^k)-G(u_N^{k-1})u_N^k,\xi^k)\\
\le\ & c(\|u^k\|^2+\|u_N^k\|^2)\,(\|\xi^{k-1}\|^2+\|\eta^{k-1}\|^2)+\frac{7b}{8}\|\xi^k\|^2\\
&+c\Big(\tau^2\|\overline{\partial}_t u_N^k\|^2+\tau\int_{t_{k-1}}^{t_k}\|u_t\|^2\,\mathrm{d}s\Big).
\end{aligned}\tag{5.4}$$

Second,

$$\begin{aligned}
&B(u^k,u^k,\xi^k)-B(u_N^{k-1},u_N^k,\xi^k)\\
=\ &(F(u^k)u_x^k-F(u_N^{k-1})u_{Nx}^k,\xi^k)-((F(u^k)u^k-F(u_N^{k-1})u_N^k,\xi_x^k),
\end{aligned}$$

where from the definition of $F(u)$, we have

$$\begin{aligned}
&(F(u^k)u_x^k-F(u_N^{k-1})u_{Nx}^k,\xi^k)\\
=\ &(F(u^k)(u_x^k-u_{Nx}^k,\xi^k)+(u_{Nx}^k(F(u^k)-F(u_N^{k-1})),\xi^k)\\
=\ &(F(0)(u_x^k-u_{Nx}^k,\xi^k)+(F'(\theta u^k)u^k(u_x^k-u_{Nx}^k),\xi^k)+(u_{Nx}^k(F(u^k)-F(u_N^{k-1})),\xi^k)\\
\le\ & c\|\xi^k\|\big(\|u^k\|_\infty\|u_x^k-u_{Nx}^k\|+\|u_{Nx}^k\|_\infty(\|u^k-u^{k-1}\|+\|u_N^k-u_N^{k-1}\|)\big)\\
\le\ & c(\|u^k\|_1^2+\|u_N^k\|_2^2)(\|\xi^{k-1}\|^2+\|\eta^{k-1}\|^2+\|\eta_x^k\|^2)+\frac{|b|}{8}\|\xi^k\|^2+\frac{\alpha}{16}\|\xi_x^k\|^2\\
&+c\left(\tau\int_{t_{k-1}}^{t_k}\|u_t\|^2\,\mathrm{d}s+\tau^2\|\overline{\partial}_t u_N^k\|^2\right)
\end{aligned}$$

and

$$\begin{aligned}
((F(u^k)u^k-F(u_N^{k-1})u_N^k,\xi_x^k)\le\ &\frac{\alpha}{16}\|\xi_x^k\|^2+c(\|u^k\|_1^2+\|u_N^k\|_1^2)\|\xi^{k-1}\|^2\\
&+c(\|u^k\|_1^2+\|u_N^k\|_1^2)\Big(\|\eta^{k-1}\|^2+\tau^2\|\overline{\partial}_t u_N^k\|^2+\tau\int_{t_{k-1}}^{t_k}\|u_t\|^2\,\mathrm{d}s\Big).
\end{aligned}$$

Hence

$$\begin{aligned}
&B(u^k,u^k,\xi^k)-B(u_N^{k-1},u_N^k,\xi^k)\\
\le\ & c(\|u^k\|_1^2+\|u_N^k\|_2^2)(\|\xi^{k-1}\|^2+\|\eta^{k-1}\|^2+\|\eta^k\|_1^2)+\frac{\alpha}{8}\|\xi_x^k\|^2\\
&+\frac{|b|}{8}\|\xi^k\|^2+c\left(\tau^2\|\overline{\partial}_t u_N^k\|^2+\tau\int_{t_{k-1}}^{t_k}\|u_t\|^2\,\mathrm{d}s\right).
\end{aligned}\tag{5.5}$$

Finally

$$(\overline{\partial}_t u^k - u_t^k, \xi^k) \le \frac{|b|}{16}\|\xi^k\|^2 + c\tau \int_{t_{k-1}}^{t_k} \|u_{tt}\|^2 \,\mathrm{d}s. \tag{5.6}$$

Then combining (5.3) to (5.6), we obtain

$$\begin{aligned} &\overline{\partial}_t \|\xi^k\|^2 + \tau\|\overline{\partial}_t \xi^k\|^2 + \|\xi^k\|_1^2 \\ &\le\ c(\|u^k\|_1^2 + \|u_N^k\|_2^2)\,\|\xi^{k-1}\|^2 + c(\|u^k\|_1^2 + \|u_N^k\|_2^2)\,(\|\eta^{k-1}\|^2 + \|\eta^k\|_1^2) \\ &\qquad + c\left(\tau^2\|\overline{\partial}_t u_N^k\|^2 + \tau\int_{t_{k-1}}^{t_k} (\|u_{tt}\|^2 + \|u_t\|^2)\mathrm{d}s\right). \end{aligned} \tag{5.7}$$

By using the integrating formula by parts, it is easily proved that

$$\tau\sum_{k=0}^{\infty} \|u^k\|_1^2 \le \tau\int_0^{\infty} \|u_t\|_1^2 \,\mathrm{d}t + (1+\tau)\int_0^{\infty} \|u\|_1^2 \,\mathrm{d}t;$$

then by applying the discrete Gronwall's inequality to (5.7) and using Lemma 1.1 and Lemmas 5.1–5.2, we derive

$$\|\xi^n\|^2 \le c(N^{-2(m-1)} + \tau). \tag{5.8}$$

Taking the sum of (5.7) for k from 1 to n and using the above inequality, it is obtained that

$$\tau^2\sum_{k=1}^{n} \|\overline{\partial}_t \xi^k\|^2 + \tau\sum_{k=1}^{n} \|\xi^k\|_1^2 \le c(N^{-2(m-1)} + \tau).$$

Let $\varphi = \xi_{xx}^k$ in (5.1). Then similar to (5.7) we have

$$\begin{aligned} \overline{\partial}_t \|\xi_x^k\|^2 + \alpha\|\xi_{xx}^k\|^2 &\le c(\|u^k\|_1^2 + \|u_N^k\|_2^2)(\|\eta^k\|_1^2 + \|\eta^{k-1}\|^2) \\ &\quad + \left(\|\xi^k\|^2 + \tau^2\|\overline{\partial}_t u_N^k\|_1^2 + \tau\int_{t_{k-1}}^{t_k} \|u_{tt}\|^2 ds\right). \end{aligned}$$

Summing them for k from 1 to n, and using the previous estimates, we have

$$\|\xi_x^n\|^2 + \tau\sum_{k=1}^{n} \|\xi_{xx}^k\|^2 \le c(N^{-2(m-1)} + \tau). \tag{5.9}$$

Now combining (5.8) and (5.9) and using the triangle inequality, we complete the proof of the theorem. □

THEOREM 5.4. *Suppose that f, g satisfy the conditions of Theorem* 5.3*; h, $h_t \in L^2(R^+;\ H_p^1(\Omega))$; $\{u_N^n\}$ and $\{v_N^n\}$ are the two solutions of the discrete scheme* (1.4), (1.5) *with initial values $\{u_N^0\}$ and $\{v_N^0\}$, respectively; and the initial values satisfy $\|u_N^0\|_2 \le R_0$, $\|v_N^0\|_2 \le R_0$. Then we have*

$$\|u_N^n - v_N^n\|_2 \le c\|u_N^0 - v_N^0\|_2 \qquad \text{for all } n \ge 0,$$

where the constant c is independent of N, τ, and t_n.

Proof. The proof of this theorem is similar to that of Theorem 4.1. Let $u_N^k - v_N^k = w_N^k$. Then by applying Lemma 5.2 and the discrete Gronwall's inequality to (4.3), we have

$$\|w_N^n\|^2 \le \|w_N^0\|^2 \exp\left(c\tau \sum_{k=0}^{n} \|u_N^k\|_1^2\right) \le c\,\|w_N^0\|^2. \tag{5.10}$$

Taking the sum of (4.3) and using (5.10) and Lemma 5.2, we obtain

$$\tau^2 \sum_{k=1}^{n} \|\overline{\partial}_t w_N^k\|^2 + \alpha\tau \sum_{k=1}^{n} \|w_{Nx}^k\|^2 - b \sum_{k=1}^{n} \|w_N^k\|^2 \le c\|w_N^0\|^2. \tag{5.11}$$

Taking the sum of (4.7) and using (5.11), we have

$$\|w_{Nx}^n\|^2 + \tau^2 \sum_{k=1}^{n} \|\overline{\partial}_t w_{Nx}^k\|^2 + \alpha \sum_{k=1}^{n} \|w_{Nxx}^k\|^2 \le \|w_{Nx}^0\|^2 + c\|w_N^0\|^2. \tag{5.12}$$

Taking the sum of (4.10) and using (5.11), (5.12), we find

$$\|w_{Nxx}^n\|^2 \le \|w_{Nxx}^0\|^2 + c\|w_N^0\|_1^2. \tag{5.13}$$

Now combining (5.10), (5.12), and (5.13), we recover the results of this theorem. ∎

A MATRIX ANALYSIS OF OPERATOR-BASED UPSCALING FOR THE WAVE EQUATION*

OKSANA KOROSTYSHEVSKAYA† AND SUSAN E. MINKOFF†

Abstract. Scientists and engineers who wish to understand the earth's subsurface are faced with a daunting challenge. Features of interest range from the microscale (centimeters) to the macroscale (hundreds of kilometers). It is unlikely that computational power limitations will ever allow modeling of this level of detail. Numerical upscaling is one technique intended to reduce this computational burden. The operator-based algorithm (developed originally for elliptic flow problems) is modified for the acoustic wave equation. With the wave equation written as a first-order system in space, we solve for pressure and its gradient (acceleration). The upscaling technique relies on decomposing the solution space into coarse and fine components. Operator-based upscaling applied to the acoustic wave equation proceeds in two steps. Step one involves solving for fine-grid features internal to coarse blocks. This stage can be solved quickly via a well-chosen set of coarse-grid boundary conditions. Each coarse problem is solved independently of its neighbors. In step two we augment the coarse-scale problem via this internal subgrid information. Unfortunately, the complexity of the numerical upscaling algorithm has always obscured the physical meaning of the resulting solution. Via a detailed matrix analysis, the coarse-scale acceleration is shown to be the solution of the original constitutive equation with input density field corresponding to an averaged density along coarse block edges. The pressure equation corresponds to the standard acoustic wave equation at nodes internal to coarse blocks. However, along coarse cell boundaries, the upscaled solution solves a modified wave equation which includes a mixed second-derivative term.

1. Introduction.

Many problems in physics and engineering result in models involving multiple scales. Often, one is forced to solve partial differential equations with highly oscillatory coefficients over very large spatial domains. The size of the resulting discrete problems makes a direct numerical simulation extremely difficult. In reservoir simulation, for example, it is common to require tens of millions of grid blocks to capture the fluctuations in the permeability of the medium [10]. Upscaling (or multiscale) techniques provide a way to solve the problem on a coarser scale while still capturing some of the effects of the fine scale.

There are two main approaches to upscaling. The first idea involves averaging the input data and thereby forming effective (or upscaled) parameters. A new problem corresponding to this upscaled data is solved on a coarse grid [7], [10]. The second approach allows the problem to be solved on the coarse scale without explicitly forming effective coefficients. Instead, some kind of operator-based technique is used to incorporate the fine-grid information into a coarse solution [4], [14].

Averaging techniques [16], [10] and the methods based on homogenization [7], [8] are examples of the first approach. Averaging is one of the simplest methods for

calculating effective parameters. The general idea is to obtain an effective value on each coarse block as some kind of average (arithmetic, harmonic, or geometric) of the original input parameter field. The averaging methods have a limited range of application. They only give correct results for certain types of media [16].

The methods based on homogenization theory [7], [8], [1] use asymptotic analysis to replace the given problem by a macroscopic problem with simple effective coefficients. (In many cases the effective coefficients are constants.) Homogenization is based on two main hypotheses:

- the medium under study is periodic, and
- the period is small compared to the size of the domain.

In homogenization, the effective parameters are constructed analytically. This construction requires the solution of so-called cell problems—boundary value problems within a single period cell. The main drawback of such methods is that they are, typically, not applicable to realistic nonperiodic structures.

More recently, a number of methods of the second, operator-based, type have been introduced and developed. The multiscale finite element method for elliptic problems with rapidly oscillating coefficients developed by Hou and Wu is an example of this approach [14], [12]. The idea behind the multiscale finite element method is to construct special coarse-scale finite element basis functions which capture the small-scale information within each element. These basis functions are obtained by solving homogeneous elliptic equations in each element subject to specified boundary conditions. The effect of the small scale is then incorporated into the coarse solution through the global stiffness matrix. The main difficulty is that large errors may result from "resonance" between the grid scale and the scales of the continuous problem. An oversampling technique is used to overcome this limitation [9], [18], [13].

Another example of the operator-based approach to upscaling is the mortar method [15], [19]. This method is based on domain decomposition. The physical domain is decomposed into a series of blocks in which different numerical grids, physical models, and discretization techniques can be used. Mortar finite element spaces are then used to allow for nonmatching grids across the block interfaces and to impose physically meaningful interface continuity conditions. One of the advantages of the method is that one may vary the number of mortar degrees of freedom and thus achieve improvements in accuracy. The disadvantage of the mortar technique is that it can be expensive, especially when a large number of degrees of freedom are used in the interface problems.

The operator-based upscaling technique was introduced for elliptic equations by Arbogast, Minkoff, and Keenan in [4]. The method was further developed by Arbogast et al. in [3], [6], [5]. The idea of the method is to decompose the solution into two parts: a coarse grid representation and a subgrid component. The subgrids are the portions of the domain contained within each of the coarse-grid cells. The problem is solved in two steps. First, we solve for the fine-scale information internal to each coarse cell. Due to a simplifying assumption imposed on the boundaries of the coarse cells, these subgrid problems decouple and can be solved independently. The second step involves using the subgrid solutions to modify the coarse-scale operator. The resulting coarse-scale solution includes some of the fine-scale features of the problem under study. A significant advantage of this method is that we use data provided on the fine scale directly in our computations (no averaging). Further, we need not assume that the medium is periodic. Perhaps most importantly, however, the operator upscaling method does not assume a separation of scales (a fundamental underlying assumption of asymptotic techniques). Geologic materials contain heterogeneities on

a continuum of scales which for realistic problems negates the basic separation of scales hypothesis.

In the companion paper by Vdovina, Minkoff, and Korostyshevskaya [17] we adapt operator-based upscaling for use with the acoustic wave equation. We focus on the second-order in space and time acoustic wave equation which we write as a system of two first-order equations (in space). Thus we solve for both pressure and its derivative (acceleration). The practical details of both the serial and parallel implementations of the algorithm are described in that paper. Specifically we detail the numerical implementation of the system described in section 2.1 of this paper (the original upscaled system). The two-stage algorithm requires solving the subgrid equations (2.5–2.6) and the coarse equation (2.7) for each time step. In Vdovina et al. [17] we describe the relative costs of the serial and parallel implementations as well. Upscaling by definition implies that we are not solving the full fine-grid problem. Some simplifications must be made to speed up the computation. With this method our primary simplification is that we impose zero flux conditions between coarse blocks at the subgrid stage of the algorithm (when we solve for internal subwavelength scale information). This assumption means that the most costly part of the algorithm (the subgrid solve) is trivial to parallelize. Each coarse cell is solved independently of its neighbors. Thus we achieve near-optimal speedup for the parallel upscaling algorithm. Because acceleration is upscaled but pressure is defined only on the fine grid in our current implementation, we find that standard fine grid stability and dispersion results (CFL and number of gridpoints per wavelength) hold. (Extensions of the method for upscaling both pressure and acceleration are also discussed in [17].) Finally, three realistic numerical experiments are described in that paper. We compare the upscaled solution to a full finite difference solution of the wave equation for a periodic (checkerboard) velocity, a finely layered medium, and a stochastic velocity field describing a two-component mixture of materials taken from a von Karman distribution. These three velocity fields were chosen primarily for their geologic relevance. (They contain basic components one might encounter in subsurface regions such as the Gulf of Mexico or deep crust.) The upscaled solution qualitatively captures even the subwavelength-scale heterogeneity of the full solution.

Our focus in this work is on addressing the question of what the upscaled solution means. What physics does the solution model? Is our model still the acoustic wave equation or an attenuated version of the wave equation? We provide the first answers to these questions in this paper via a linear algebra analysis of the method. What this analysis highlights is that the numerical upscaling process solves a constitutive equation similar in form to the original equation. The constitutive equation relates acceleration to the gradient of pressure. For the coarse (upscaled) problem, however, the parameter field (density) reduces to an averaged density along coarse block edges. Similarly, when analyzing the pressure equation, we find the upscaled solution solves the original wave equation at nodes internal to the coarse blocks, but a modified equation at coarse block edges. Specifically, a cross-derivative (involving differentiation with respect to both x and y) enters the standard wave equation. This analysis not only simplifies the coding of the algorithm but illuminates the physical meaning of the upscaled solution. In this paper, we focus on the theory. (We do not include numerical experiments based on the system of equations which result from the analysis given in this paper.) However, the new formulation should simplify the simulations described in [17] considerably and is the subject of future work. The standard implementation of operator upscaling involves technicalities (such as the use of numerical Green's functions) that are no longer necessary as a result of this analysis.

It is important to point out that the equations which result from this analysis (specifically the conclusions of Theorems 1, 10, and 11) are to our knowledge entirely new. While other papers exist which discuss convergence of operator upscaling for elliptic problems in the context of finite elements, no other work (outside this paper and the related work by Vdovina et al. [17]) discusses operator upscaling for the wave equation. More importantly, the physics modeled by operator upscaling has not been illuminated (for any PDE) prior to this work.

In the remainder of the paper we describe the mathematics behind the upscaling algorithm. Then we begin the matrix analysis of the two-equation system. First we analyze the constitutive equation for coarse acceleration. The result is both a finite difference stencil and a continuous differential equation corresponding to the upscaled acceleration equation. Finally, we apply a similar analysis to the pressure equation. We define the finite difference stencils for pressure (which depend on the location of the pressure unknown within the coarse block) and corresponding continuous differential equations coming from the upscaling algorithm.

2. Upscaled acoustic wave equation.

2.1. Subgrid upscaling for the acoustic wave equation: Variational formulation. Let Ω be a two-dimensional domain with boundary Γ. We consider the acoustic wave equation in Ω written as a first-order system for acceleration $\vec{v}$ and pressure p:

$$\vec{v} = -\frac{1}{\rho}\nabla p, \tag{2.1}$$

$$\frac{1}{\rho c^2}\frac{\partial^2 p}{\partial t^2} = -\nabla \cdot \vec{v} + f. \tag{2.2}$$

Here c is the sound velocity, ρ is the density, and f is the source of acoustic energy. Both c and ρ are functions of spatial location only *and are assumed to be heterogeneous.* To simplify the presentation of the method, we will assume zero boundary conditions:

$$\vec{v} \cdot \vec{\nu} = 0 \quad \text{on} \quad \Gamma,$$

where $\vec{\nu}$ is the unit outward normal vector.

The subgrid upscaling technique is developed in the context of a mixed finite element method. Let

$$H_0(\text{div}, \Omega) = \{\vec{v} \in (L^2(\Omega))^2 : \nabla \cdot \vec{v} \in L^2(\Omega), \text{ and } \vec{v} \cdot \vec{\nu} = 0 \text{ on } \Gamma\}.$$

We rewrite (2.1)–(2.2) in weak form as follows: find $\vec{v} \in H_0(\text{div}; \Omega)$ and $p \in L^2(\Omega)$ such that

$$\langle \rho \vec{v}, \vec{u} \rangle = \langle p, \nabla \cdot \vec{u} \rangle \,, \tag{2.3}$$

$$\left\langle \frac{1}{\rho c^2}\frac{\partial^2 p}{\partial t^2}, w \right\rangle = -\langle \nabla \cdot \vec{v}, w \rangle + \langle f, w \rangle \tag{2.4}$$

for all $\vec{u} \in H_0(\text{div}; \Omega)$ and $w \in L^2(\Omega)$.

The idea of the upscaling method is that while the original problem is posed on a fine grid (specifically the input acceleration and density are measured fields on the fine grid), our goal is to solve the problem on a coarse mesh. We wish to capture some of the fine-scale information internal to each coarse cell and then to use this

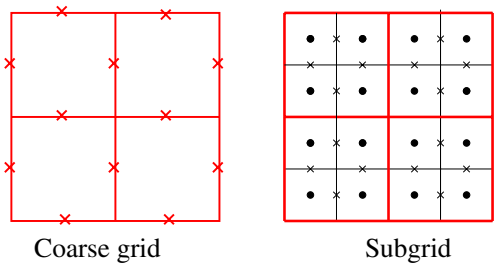

FIG. 2.1. *A 2×2 coarse grid with coarse acceleration unknowns and a corresponding 4×4 fine grid with subgrid unknowns. Pressures live at the centers of the cells. Acceleration lives on cell edges.*

information to determine the best solution possible on the coarse scale. We break the acceleration into two parts—the coarse representation (coarse-grid unknowns) and the subgrid part (fine-grid unknowns internal to each coarse-grid cell):

$$\vec{v} = \vec{v}^c + \delta\vec{v}.$$

In earlier work the pressure space was also decomposed. (See [4] for an example of this decomposition for the elliptic pressure equation.) Unfortunately, the basis functions for the pressure space are computationally clumsy. Since no additional work is required to keep the pressure on the fine grid, we have chosen to only decompose acceleration in this paper. Pressure can be projected onto the coarse grid as a post-processing step if so desired.

In the mixed finite element method, we use a rectangular two-scale mesh and approximate the pressure and the acceleration in finite element spaces W and V, respectively. We take the pressure space W to be the space of piecewise discontinuous constant functions on the fine grid with nodes at the centers of the cells. To define the acceleration space V for the upscaling method, we introduce two finite element spaces δV and V^c associated with the fine and coarse computational grids. Both of these spaces consist of piecewise linear vector functions of the form (a_1x+b_1, a_2y+b_2) living on the edges of the grid blocks (see Figure 2.1). We impose an important simplifying condition on the space δV, namely,

$$\delta\vec{u} \cdot \vec{\nu} = 0 \quad \text{on the boundary of each coarse element.}$$

This is the only simplifying assumption in the definition of our method. It allows us to decouple the subgrid problems coming from different coarse-grid cells. Note that this simplifying assumption only applies to the solution of the subgrid problems which were never intended to be solved exactly but merely approximated. Exact solution of the subgrid problems would lead us back to a full finite difference solution of the wave equation.

The upscaling process consists of two steps. First, we restrict to the subgrid test functions in (2.3)–(2.4) and use the above decomposition to obtain a series of subgrid problems, one for each coarse element E_c:

$$\langle \rho(\vec{v}^c + \delta\vec{v}), \delta\vec{u}\rangle = \langle p, \nabla \cdot \delta\vec{u}\rangle, \tag{2.5}$$

$$\left\langle \frac{1}{\rho c^2}\frac{\partial^2 p}{\partial t^2}, w \right\rangle = -\langle \nabla \cdot (\vec{v}^c + \delta\vec{v}), w\rangle + \langle f, w\rangle \tag{2.6}$$

for all $\delta\vec{u} \in \delta V$, $w \in W$. The values of $\vec{v}^c$ are unknown at this stage, so we find the solution to the subgrid problem as a function of the coarse unknowns. Note, that the pressure is completely determined by (2.5–2.6).

The second step of the upscaling process uses $\delta\vec{v}$ and p to determine $\vec{v}^c \in V^c$ through solution of the upscaled coarse equation ((2.3) with coarse-grid test functions):

$$\langle \rho(\vec{v}^c + \delta\vec{v}(\vec{v}^c)), \vec{u}^c \rangle = \langle p, \nabla \cdot \vec{u}^c \rangle \tag{2.7}$$

for all $\vec{u}^c \in V^c$.

The problem is solved sequentially in time. We use second-order finite differences to approximate the time derivative in (2.6). First, we find the pressure on the current time level using the velocities and pressure from the previous time levels. Then we solve (2.5) and (2.7) for the subgrid and coarse velocities. The process then repeats for the next time step.

2.2. A matrix analysis discussion of subgrid upscaling. One of the main purposes of this paper is to derive the explicit coarse-scale equation solved by the upscaling algorithm using the discrete form of the subgrid and coarse problems. The advantage of using the discrete formulation is that it allows us to obtain both finite difference and continuous differential equations for coarse acceleration. The finite difference equation yields an explicit stencil for pressure and coarse acceleration that could be implemented directly, thus giving an alternate, simpler way to code the algorithm over that which is detailed in section 2.1 of this paper and in [17]. This analysis shows that coarse acceleration is defined using the average of density values on the boundaries of coarse cells (in a sense defining an upscaled density). From the finite difference equation we can derive the continuous differential equation for the coarse problem which is similar to the original equation (2.1) with density replaced by the upscaled density. We see that the upscaled acceleration approximates the gradient of pressure on the *boundaries* of the coarse cells compensating for the simplifying zero boundary conditions used by the algorithm. In this section, we derive the matrix-vector form of the subgrid and coarse problems. In terms of linear algebra, we see that the subgrid problems can easily be solved for the subgrid acceleration in terms of the pressure and the coarse acceleration. Thus, we can eliminate the subgrid unknowns from the coarse problem to obtain a matrix equation for the coarse acceleration and pressure only. The analysis of the resulting system allows us to determine the differential equation solved by the upscaling algorithm and to understand the physical meaning of the coarse part of the solution.

Homogenization is an alternate technique for analyzing equations with parameters and unknowns that contain multiple scales. The operator upscaling analysis given in this paper is complete in itself and is distinct from a homogenization analysis. Future work may include comparison of operator-based upscaling results to those obtained from asymptotic series solutions. Arbogast and Boyd [2] examine the connection between the multiscale finite element method (a numerical technique based on homogenization) and operator upscaling in the context of elliptic problems. We do not discuss connections between methods here.

We begin by describing the finite element context in which the method is developed. In order to discretize the subgrid and the coarse problems, we use finite element approximations of the unknown functions. In this paper, we restrict our attention to the x component v_x of the acceleration vector, since the equations for v_y are similar.

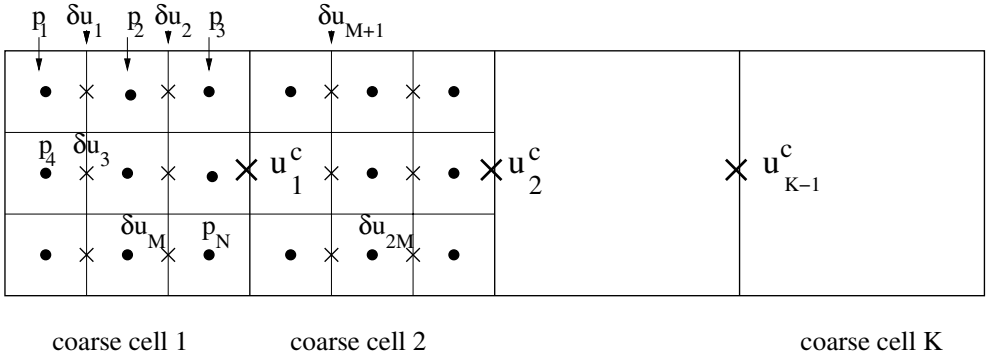

FIG. 2.2. *Subgrid and coarse unknowns. The grid consists of K total coarse cells.*

To simplify notation, consider a domain consisting of one row of coarse cells, each subdivided into a number of fine cells (Figure 2.2). If K is the number of coarse cells, we divide each coarse cell into n_x fine cells in the x direction and n_y fine cells in the y direction. Then the number of fine cells in one coarse block is $N = n_x n_y$, and the total number of fine cells is KN.

In the subgrid upscaling method we will describe here, both the coarse and fine components of the horizontal acceleration are approximated by the space of piecewise continuous linear functions in x and piecewise constants in y. Obviously, other choices of finite element spaces are also possible. However, this choice is the simplest. The coarse and subgrid basis functions $(u_x^c)_i$, $(\delta u_x)_i$ for the acceleration space have nodes at the midpoints of vertical edges of the coarse cells for the coarse acceleration and at the midpoints of vertical edges of the fine cells for the subgrid acceleration (Figure 2.2). At time t,

$$v_x^c(t,x,y) = \sum_{i=1}^{K-1} (\mathbf{v_x^c})_i(t)(u_x^c)_i(x,y), \tag{2.8}$$

$$\delta v_x(t,x,y) = \sum_{i=1}^{MK} (\delta \mathbf{v_x})_i(t)(\delta u_x)_i(x,y). \tag{2.9}$$

Here, $K-1$ is the number of the coarse acceleration unknowns, M is the number of the subgrid acceleration unknowns inside one coarse cell so that MK is the total number of the subgrid acceleration unknowns in the domain, and the coefficients $(\mathbf{v_x^c})_i$, $(\delta \mathbf{v_x})_i$ are to be determined. Since the subgrid acceleration lives on the vertical edges of the fine cells and there are no nodes on the boundaries of the coarse cells, we have that $M = N - n_y$.

The pressure p is approximated by piecewise constants defined on the fine grid. Thus, we have the expansion

$$p(t,x,y) = \sum_{i=1}^{NK} \mathbf{p}_i(t) w_i(x,y). \tag{2.10}$$

Here NK is the total number of pressure unknowns, and w_m is the basis function for pressure, which takes the value 1 on the mth subgrid cell and 0 everywhere else.

We will now derive the matrix forms of the subgrid and coarse problems and then use these equations to eliminate the subgrid unknowns from the coarse problem. To

obtain a linear system from subgrid equations (2.5)–(2.6), we use the finite element expansions given in (2.8)–(2.10):

(2.11)
$$\sum_{j=1}^{K-1}(\mathbf{v_x^c})_j\langle\rho(u_x^c)_j,(\delta u_x)_i\rangle+\sum_{j=1}^{MK}(\delta\mathbf{v_x})_j\langle\rho(\delta u_x)_j,(\delta u_x)_i\rangle=\sum_{j=1}^{NK}\mathbf{p}_j\left\langle w_j,\frac{\partial(\delta u_x)_i}{\partial x}\right\rangle,\quad i=1,2,\ldots,MK,$$

and

(2.12)
$$\sum_{j=1}^{NK}\frac{\partial^2\mathbf{p}_j}{\partial t^2}\left\langle\frac{1}{\rho c^2}w_j,w_i\right\rangle=-\sum_{j=1}^{K-1}(\mathbf{v_x^c})_j\left\langle\frac{\partial(u_x^c)_j}{\partial x},w_i\right\rangle-\sum_{j=1}^{MK}(\delta\mathbf{v_x})_j\left\langle\frac{\partial(\delta u_x)_j}{\partial x},w_i\right\rangle-(v_y\text{ terms})+\langle f,w_i\rangle,\quad i=1,2,\ldots,NK.$$

These equations can be written in matrix form by defining the following matrix entries:

$$a_{i,j}^{ff}=\langle\rho(\delta u_x)_j,(\delta u_x)_i\rangle,\quad a_{i,j}^{cf}=\langle\rho(u_x^c)_j,(\delta u_x)_i\rangle,\quad b_{i,j}^{f}=\left\langle w_j,\frac{\partial(\delta u_x)_i}{\partial x}\right\rangle,\tag{2.13}$$

$$w_{i,j}=\left\langle\frac{1}{\rho c^2}w_j,w_i\right\rangle,\qquad f_i=\langle f,w_i\rangle,\qquad b_{i,j}^{c}=\left\langle w_j,\frac{\partial(u_x^c)_i}{\partial x}\right\rangle.\tag{2.14}$$

Then the subgrid system reduces to the following linear system:

$$A^{cf}\mathbf{v_x^c}+A^{ff}\delta\mathbf{v_x}=B^f\mathbf{p},\tag{2.15}$$

$$W\frac{\partial^2\mathbf{p}}{\partial t^2}=-(B^c)^T\mathbf{v_x^c}-(B^f)^T\delta\mathbf{v_x}-(v_y\text{ terms})+F.\tag{2.16}$$

Similar steps lead to a discretization of the coarse problem (2.7). We obtain the matrix equation:

$$A^{cc}\mathbf{v_x^c}+(A^{cf})^T\delta\mathbf{v_x}=B^c\mathbf{p},\tag{2.17}$$

where the matrix A^{cc} has entries

$$a_{i,j}^{cc}=\langle\rho(u_x^c)_j,(u_x^c)_i\rangle.\tag{2.18}$$

We will now use the matrix form of the subgrid and coarse problems to eliminate the subgrid unknowns from the coarse equation. The subgrid equations are coupled to the coarse scale unknowns. In particular, (2.15) involves coarse acceleration unknowns $\mathbf{v_x^c}$, which are not known at the subgrid step of the algorithm. This equation can easily be solved for $\delta\mathbf{v_x}$ in terms of $\mathbf{v_x^c}$

$$\delta\mathbf{v_x}=-(A^{ff})^{-1}A^{cf}\mathbf{v_x^c}+(A^{ff})^{-1}B^f\mathbf{p}.\tag{2.19}$$

Substituting (2.19) into the coarse problem (2.17), we obtain the matrix equation for the coarse acceleration and pressure only,

$$(A^{cc}-(A^{cf})^T(A^{ff})^{-1}A^{cf})\mathbf{v_x^c}=(B^c-(A^{cf})^T(A^{ff})^{-1}B^f)\mathbf{p}\tag{2.20}$$

or

$$U\mathbf{v}_{\mathbf{x}}^{\mathbf{c}} = D\mathbf{p}. \tag{2.21}$$

Formula (2.21) gives us the matrix equation for the coarse acceleration and pressure. We will use (2.21) later to derive a difference and then differential equations for the coarse acceleration. Therefore, it is worthwhile to study the structure of the matrices U and D, and to explicitly define their entries. In Theorem 1, we show that the choice of bases for the finite element spaces results in matrices which are sparse and have special structure. Moreover, we obtain simple explicit formulas for the entries by computing them with special quadrature rules defined on the fine grid. The choice to use fine grid quadratures is based on the assumption that the parameter fields ρ and c vary on the fine scale. We do not want to introduce averaging errors by requiring these parameters to live on the coarse grid.

Let us begin with some notation that will be used throughout the rest of this paper. Let h_x and h_y be the lengths of a single fine cell in the x and y directions respectively, and H_x, H_y the lengths of a single coarse cell in these two directions. We denote by ρ_l and $(u_x^c)_j|_l$ the values of the density and coarse acceleration basis functions at the lth node of subgrid acceleration, and by ρ_l^j the values of the density on the boundary of the coarse cell corresponding to the jth coarse acceleration node.

THEOREM 1. *Consider the set of subgrid problems* (2.5)–(2.6) *and the coarse problem* (2.7). *The upscaling technique results in the linear system for the coarse acceleration and pressure of the form*

$$U\mathbf{v}_{\mathbf{x}}^{\mathbf{c}} = D\mathbf{p},$$

where U and D are given by (2.20)–(2.21). *U is of size $(K-1)\times(K-1)$ and D is of size $(K-1)\times NK$.*

Further, assume the density ρ and sound velocity c are smooth enough for the inner products in the matrix entries U and D to be computed using fine-grid midpoint and trapezoidal rules. Then the matrix U is diagonal and the matrix D is block upper bidiagonal with blocks of size $1\times N$. The entries of U are given by the sum of density values on the corresponding boundaries of the coarse cells

$$U_{i,i} = (h_x h_y)\sum_{l=1}^{n_y}\rho_l^i. \tag{2.22}$$

The blocks of D are given by

$$D_{i,i} = \frac{h_x h_y}{h_x}\left[0,\quad 0,\quad \ldots,\quad 1,\quad \ldots,\quad 0,\quad 0,\quad \ldots\quad 1\right], \tag{2.23}$$

$$D_{i,i+1} = \frac{h_x h_y}{h_x}\left[-1,\quad 0,\quad \ldots,\quad 0,\quad \ldots,\quad -1,\quad 0,\quad \ldots,\quad 0\right], \tag{2.24}$$

where the nonzero entries correspond to the pressure nodes located along the boundaries of the coarse cells.

Note. In this Theorem, we are using the trapezoidal rule on the fine grid in the x direction and the midpoint rule in the y direction to compute the integrals. When these rules are used, the quadrature node points coincide with the nodes of the subgrid basis functions. This fact simplifies the formulas for the matrix entries. Even more

importantly, both the midpoint rule and the trapezoidal rule are accurate enough that no additional error is incurred for our choice of interpolating polynomials.

The results of Theorem 1 will allow us to determine the explicit difference equation for coarse acceleration solved by the upscaling algorithm and to understand the physical meaning of the resulting problem solution.

Proof. First, let us discuss the coefficient matrix U of coarse acceleration. Recall that

$$U = A^{cc} - (A^{cf})^T (A^{ff})^{-1} A^{cf}. \tag{2.25}$$

In order to explicitly define the entries of U, we need to study the matrices A^{cc}, A^{cf}, and A^{ff}. The following lemmas describe the structure of these matrices.

LEMMA 2. *The matrix A^{cf} is a lower bidiagonal $K \times (K-1)$ block matrix with blocks of size $M \times 1$. If the entries of the matrix are evaluated by the trapezoidal rule in x and the midpoint rule in y on each fine cell, then*

$$a^{cf}_{l,j} = (h_x h_y) \rho_l (u^c_x)_j|_l. \tag{2.26}$$

Proof. The entries of the matrix A^{cf} are the inner products of the coarse and subgrid acceleration basis functions (2.13). Since the total number of subgrid acceleration basis functions is MK and the total number of coarse acceleration basis functions is $K-1$, the matrix A^{cf} is of size $MK \times (K-1)$.

Each coarse acceleration basis function is supported on two coarse cells and, therefore, has nonzero inner products with the subgrid functions from these coarse cells only. For example, the first coarse acceleration basis function is nonzero on the coarse cells 1 and 2 (Figure 2.2). Thus we can partition the matrix into blocks of size $M \times 1$ (where M is the number of subgrid acceleration nodes inside a single coarse cell). Each block A^{cf}_{ij} represents the interaction of the jth coarse basis function with the ith coarse cell. Then the matrix A^{cf} can be written as a $K \times (K-1)$ lower bidiagonal block matrix:

$$A^{cf} = \begin{bmatrix} A^{cf}_{1,1} & & & 0 \\ A^{cf}_{2,1} & A^{cf}_{2,2} & & \\ & \ddots & \ddots & \\ & & & A^{cf}_{K-1,K-1} \\ 0 & & & A^{cf}_{K,K-1} \end{bmatrix}. \tag{2.27}$$

We can evaluate the matrix entries by the trapezoidal rule in x and the midpoint rule in y on each fine cell, so that the quadrature nodal points coincide with the fine acceleration nodes (Figure 2.3). Applying these rules to each entry gives a product of the area of the cell $(h_x h_y)$ with the value of the integrand at the nodal points of the fine acceleration. Since any subgrid acceleration basis function is 1 at the corresponding node and 0 at all other nodes, we obtain

$$a^{cf}_{l,j} = \langle \rho (u^c_x)_j, (\delta u_x)_l \rangle = (h_x h_y) \rho_l (u^c_x)_j \big|_l. \qquad \square$$

LEMMA 3. *If the entries of the matrix A^{ff} are evaluated by the trapezoidal rule in x and the midpoint rule in y on each fine cell, then A^{ff} is an $MK \times MK$ diagonal matrix with entries*

$$a^{ff}_{ll} = (h_x h_y) \rho_l.$$

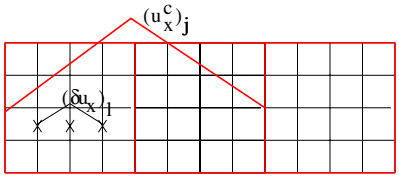

FIG. 2.3. *Coarse and subgrid acceleration basis functions* $(u_x^c)_j$ *and* $(\delta u_x)_l$. *The crosses represent the subgrid acceleration nodes which are used as quadrature nodal points.*

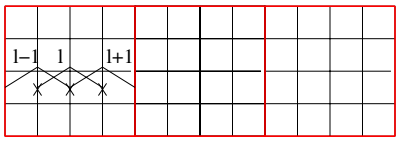

FIG. 2.4. *Subgrid acceleration basis functions* $(\delta u_x)_{l-1}$, $(\delta u_x)_l$, *and* $(\delta u_x)_{l+1}$. *The crosses represent the subgrid acceleration nodes which are used as quadrature nodal points.*

Note. A^{ff} is the coefficient matrix of subgrid unknowns in (2.15). The fact that we are able to reduce A^{ff} to a diagonal matrix makes the elimination of the subgrid unknowns cheap and easy.

Proof. The matrix A^{ff} is the coefficient matrix of subgrid unknowns in (2.15) and its entries are the inner products of subgrid acceleration basis functions (2.13). The total number of subgrid acceleration basis functions is MK, so the matrix A^{ff} has size $MK \times MK$. Each subgrid acceleration basis function interacts with itself and its neighbors to the left and to the right. As in Lemma 2, we use the trapezoidal rule in x and the midpoint rule in y on each fine cell to compute the entries. The quadrature nodal points coincide with the fine acceleration nodes (Figure 2.4). We obtain

$$a^{ff}_{l,l+1} = \langle \rho(\delta u_x)_l, (\delta u_x)_{l+1} \rangle = 0, \qquad a^{ff}_{l-1,l} = \langle \rho(\delta u_x)_{l-1}, (\delta u_x)_l \rangle = 0, \tag{2.28}$$

$$a^{ff}_{l,l} = \langle \rho(\delta u_x)_l, (\delta u_x)_l \rangle = (h_x h_y)\rho_l. \tag{2.29}$$

Here, we made use of the fact that any subgrid acceleration basis function is 1 at the corresponding node and 0 at all other nodes. We see that if the entries are computed as above, the matrix A^{ff} is diagonal. ∎

LEMMA 4. *The matrix* A^{cc} *is a* $(K-1)\times(K-1)$ *tridiagonal matrix. If the entries of* A^{cc} *are evaluated by the composite trapezoidal rule in the* x *direction and the midpoint rule in the* y *direction, then*

$$a^{cc}_{j,j+1} = (h_x h_y) \sum_{l=Mj+1}^{M(j+1)} \rho_l (u_x^c)_{j+1} (u_x^c)_j \big|_l,$$

$$a^{cc}_{j,j-1} = (h_x h_y) \sum_{l=M(j-1)+1}^{Mj} \rho_l (u_x^c)_{j-1} (u_x^c)_j \big|_l,$$

$$a^{cc}_{j,j} = (h_x h_y) \sum_{l=M(j-1)+1}^{M(j+1)} \rho_l (u_x^c)_j^2 \big|_l + (h_x h_y) \sum_{l=1}^{n_y} \rho_l^j.$$

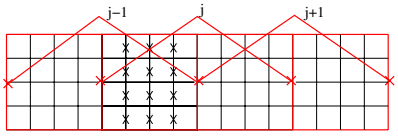

FIG. 2.5. *Coarse acceleration basis functions* $(u_x^c)_{j-1}$, $(u_x^c)_j$, *and* $(u_x^c)_{j+1}$. *The crosses represent the subgrid acceleration nodes* $l = M(j-1)+1, \dots Mj$, *which are used as quadrature nodal points in the computation of* $a^{cc}_{j,j-1}$.

Proof. The entries of the matrix A^{cc} are the inner products of coarse acceleration basis functions (2.18). The total number of the coarse acceleration nodes in the domain is $K-1$, therefore, the matrix has size $(K-1)\times(K-1)$.

Since each coarse acceleration basis function is supported on two coarse cells and interacts with both its neighbors (Figure 2.5), the matrix A^{cc} is tridiagonal. The entries can be computed by the composite trapezoidal rule in the x direction and composite midpoint rule in y on each coarse cell so that the quadrature nodal points coincide with the fine acceleration nodes. Fine grid quadrature is used because the parameter fields ρ and c live on the fine grid, and we do not want to average these parameters. We obtain

$$a^{cc}_{j,j-1} = \langle \rho(u_x^c)_{j-1}, (u_x^c)_j \rangle = (h_x h_y) \sum_{l=M(j-1)+1}^{Mj} \rho_l (u_x^c)_{j-1}\big|_l (u_x^c)_j\big|_l, \tag{2.30}$$

where M is the number of subgrid acceleration nodes inside one coarse cell, and the indices $M(j-1)+1,\dots,Mj$ represent the subgrid acceleration nodes inside coarse cell j (Figure 2.5). Notice that only the nodes internal to the coarse cell are involved in the computation, since either $(u_x^c)_j$ or $(u_x^c)_{j-1}$ is zero on its boundary. Similarly, for $\langle \rho(u_x^c)_{j+1}, (u_x^c)_j \rangle$ we have

$$a^{cc}_{j,j+1} = \langle \rho(u_x^c)_{j+1}, (u_x^c)_j \rangle = (h_x h_y) \sum_{l=Mj+1}^{M(j+1)} \rho_l (u_x^c)_{j+1}\big|_l (u_x^c)_j\big|_l, \tag{2.31}$$

where we sum over the subgrid acceleration nodes inside coarse cell $j+1$. The entry $\langle \rho(u_x^c)_j, (u_x^c)_j \rangle$ is the inner product of the coarse basis function with itself and, therefore, is supported on two coarse cells. We compute the diagonal entry using the composite trapezoidal rule in x and midpoint in y

$$a^{cc}_{j,j} = \langle \rho(u_x^c)_j, (u_x^c)_j \rangle = (h_x h_y) \sum_{l=M(j-1)+1}^{M(j+1)} \rho_l (u_x^c)_j^2\big|_l + (h_x h_y) \sum_{l=1}^{n_y} \rho_l^j. \tag{2.32}$$

The indices $M(j-1)+1,\dots,M(j+1)$ in the first term represent the subgrid acceleration nodes inside coarse cells j and $j+1$. The last term on the right corresponds to the boundary between the two cells at which the basis function $(u_x^c)_i$ has value 1, and ρ_l^j are the values of the density on this boundary. ∎

Proof of formula (2.22) *for* U. Let us now use the above results to study the matrix $U = A^{cc} - (A^{cf})^T (A^{ff})^{-1} A^{cf}$, the coefficient matrix of coarse acceleration in (2.21). Performing block matrix multiplications in $(A^{cf})^T (A^{ff})^{-1} A^{cf}$ and using Lemmas 2 and 3, we see that the product $(A^{cf})^T (A^{ff})^{-1} A^{cf}$ is a tridiagonal matrix.

Let us derive a formula for its upper diagonal entries. For convenience of notation, we present the derivation of the first upper diagonal entry $[(A^{cf})^T(A^{ff})^{-1}A^{cf}]_{1,2}$. The derivation of the rest of the entries is similar. We use the block notation for A^{cf} introduced in Lemma 2 and the fact that A^{ff} is diagonal (Lemma 3) to obtain

$$[(A^{cf})^T(A^{ff})^{-1}A^{cf}]_{1,2} = (A^{cf}_{2,1})^T \begin{bmatrix} (a^{ff}_{M+1,M+1})^{-1} & \dots & 0 \\ \vdots & & \\ 0 & \dots & (a^{ff}_{2M,2M})^{-1} \end{bmatrix} A^{cf}_{2,2}, \tag{2.33}$$

where the blocks $A^{cf}_{2,2}$ and $(A^{cf}_{2,1})^T$ have size $M \times 1$ and $1 \times M$, respectively. The block $A^{cf}_{2,1}$ represents the interaction of the first coarse acceleration basis function $(u^c_x)_1$ with the subgrid acceleration basis functions from the second coarse cell. The explicit formula (2.26) for the entries of A^{cf} gives that

$$(A^{cf}_{2,1})^T = (h_x h_y) \left[\rho_{M+1}(u^c_x)_1\big|_{M+1} \quad \dots \quad \rho_{2M}(u^c_x)_1\big|_{2M} \right], \tag{2.34}$$

where the indices $M+1, \dots, 2M$ are the subgrid acceleration nodes inside the second coarse cell (Figure 2.2). Similarly, the block $A^{cf}_{2,2}$ consists of the inner products of the second coarse acceleration basis function $(u^c_x)_2$ with the subgrid basis functions from the second coarse cell and is given by

$$A^{cf}_{2,2} = (h_x h_y) \begin{bmatrix} \rho_{M+1}(u^c_x)_2\big|_{M+1} \\ \vdots \\ \rho_{2M}(u^c_x)_2\big|_{2M} \end{bmatrix}. \tag{2.35}$$

The explicit formula (2.29) for the entries of A^{ff} and (2.34)–(2.35) result in

$$[(A^{cf})^T(A^{ff})^{-1}A^{cf}]_{1,2} = (h_x h_y) \sum_{l=M+1}^{2M} \rho_l (u^c_x)_2\big|_l (u^c_x)_1\big|_l. \tag{2.36}$$

We can obtain a general formula for the $(j, j+1)$-upper diagonal entry:

$$[(A^{cf})^T(A^{ff})^{-1}A^{cf}]_{j,j+1} = (h_x h_y) \sum_{l=Mj+1}^{M(j+1)} \rho_l (u^c_x)_{j+1}\big|_l (u^c_x)_j\big|_l. \tag{2.37}$$

Following the same manipulations, we derive the lower diagonal and diagonal entries

$$[(A^{cf})^T(A^{ff})^{-1}A^{cf}]_{j,j-1} = (h_x h_y) \sum_{l=M(j-1)+1}^{Mj} \rho_l (u^c_x)_{j-1}\big|_l (u^c_x)_j\big|_l, \tag{2.38}$$

$$[(A^{cf})^T(A^{ff})^{-1}A^{cf}]_{j,j} = (h_x h_y) \sum_{l=M(j-1)+1}^{M(j+1)} \rho_l (u^c_x)^2_j\big|_l. \tag{2.39}$$

Thus, summing the result for entries of A^{cc} from Lemma 4 ((2.30)–(2.32)) with results (2.37)–(2.39) gives us explicit formulas for the entries of U:

$$U_{j,j+1} = 0, \qquad U_{j,j-1} = 0, \qquad U_{j,j} = (h_x h_y) \sum_{l=1}^{n_y} \rho_l^j. \tag{2.40}$$

We see that the matrix U is diagonal and its entries depend only on those values of density which lie on the corresponding boundary of the coarse cell. ∎

Now let us turn our attention to the coefficient matrix of pressure, namely, D. This matrix is defined by

$$D = B^c - (A^{cf})^T (A^{ff})^{-1} B^f. \tag{2.41}$$

In order to write explicit formulas for the entries of D, we need to study the matrices A^{cf}, A^{ff}, B^f, and B^c. We have already discussed the matrices A^{cf} and A^{ff}. The following two lemmas describe the structure of the matrices B^c and B^f.

LEMMA 5. *The matrix B^f is a block diagonal $Kn_y \times Kn_y$ matrix with blocks of size $(n_x - 1) \times n_x$. The blocks of the matrix are given by*

$$T = -\frac{h_x h_y}{h_x} \begin{bmatrix} -1 & 1 & 0 & \dots & 0 & 0 \\ 0 & -1 & 1 & \dots & 0 & 0 \\ & \dots & \dots & & & \\ 0 & 0 & 0 & \dots & -1 & 1 \end{bmatrix}. \tag{2.42}$$

Proof. The entries of the matrix B^f are the inner products of the x derivative of subgrid acceleration basis functions with pressure basis functions, $b^f_{l,m} = \langle w_m, \frac{\partial(\delta u_x)_l}{\partial x} \rangle$. Since the total number of subgrid acceleration basis functions is $Kn_y(n_x - 1)$ and the total number of pressure basis functions is $Kn_y n_x$, the matrix B^f is of size $Kn_y(n_x - 1) \times Kn_y n_x$. The entries of the matrix can be evaluated easily since the subgrid acceleration basis function is piecewise linear in x and constant in y, so its derivative is easily computed

$$\frac{\partial(\delta u_x)_l}{\partial x} = \begin{cases} \dfrac{1}{h_x} & \text{left branch,} \\ -\dfrac{1}{h_x} & \text{right branch.} \end{cases} \tag{2.43}$$

Then $b^f_{l,m} = \pm(h_x h_y)\frac{1}{h_x}$ whenever the pressure basis function and the subgrid acceleration basis function have the same support. Since each subgrid acceleration basis function interacts with only two pressure nodes, one block of the matrix B^f has the form (2.42). Each block corresponds to the interactions of one row of the pressure and acceleration basis functions within a single coarse cell. Since one row of fine cells inside a single coarse cell has $n_x - 1$ subgrid acceleration nodes and n_x pressure nodes, each block T is of size $(n_x - 1) \times n_x$. Finally B^f can be written as the block diagonal matrix with blocks given by T. ∎

LEMMA 6. *The matrix B^c is an upper bidiagonal $(K - 1) \times K$ block matrix. The blocks are of size $1 \times N$ and are given by*

$$B^c_{l,l} = \frac{h_x h_y}{H_x} \begin{bmatrix} 1 & \dots & 1 \end{bmatrix}, \qquad B^c_{l,l+1} = -\frac{h_x h_y}{H_x} \begin{bmatrix} 1 & \dots & 1 \end{bmatrix}. \tag{2.44}$$

Proof. The entries of the matrix B^c are the inner products of the x derivative of coarse acceleration basis functions and pressure basis functions (2.14). The total number of the coarse acceleration nodes is $(K-1)$ and the total number of the pressure nodes is NK, so B^c has size $(K-1)\times NK$. Each coarse acceleration basis function is supported on two coarse cells and, therefore, has a nonzero inner product only with the pressure basis functions internal to those cells. If we introduce the blocks B^c_{ij} of size $1\times N$ which represent the interaction of the ith coarse basis function with the pressure basis functions from the jth coarse cell, then the matrix B^c can be written as a bidiagonal matrix:

$$B^c = \begin{bmatrix} B^c_{1,1} & B^c_{1,2} & & & 0 \\ & B^c_{2,2} & B^c_{2,3} & & \\ & & \ddots & \ddots & \\ 0 & & & B^c_{K-1,K-1} & B^c_{K-1,K} \end{bmatrix}. \tag{2.45}$$

The entries of B^c can be computed exactly. To evaluate $(b^c)_{l,m} = \langle w_m, \frac{\partial (u^c_x)_l}{\partial x}\rangle$, we use the fact that $(u^c_x)_l$ is a linear function in x and a constant in y. Thus, its derivative is easily computed and is given by

$$\frac{\partial (u^c_x)_l}{\partial x} = \begin{cases} \dfrac{1}{H_x} & l\text{th coarse cell,} \\ -\dfrac{1}{H_x} & (l+1)\text{th coarse cell.} \end{cases} \tag{2.46}$$

The pressure basis function w_m is 1 on the corresponding fine cell and 0 everywhere else. Therefore, we have

$$b^c_{l,m} = \left\langle w_m, \frac{\partial (u^c_x)_l}{\partial x} \right\rangle = \begin{cases} (h_x h_y)\dfrac{1}{H_x} & l\text{th coarse cell,} \\ -(h_x h_x)\dfrac{1}{H_x} & (l+1)\text{th coarse cell.} \end{cases} \tag{2.47}$$

Thus,

$$B^c_{l,l} = \frac{h_x h_y}{H_x}\begin{bmatrix} 1 & \dots & 1 \end{bmatrix}, \qquad B^c_{l,l+1} = -\frac{h_x h_y}{H_x}\begin{bmatrix} 1 & \dots & 1 \end{bmatrix}. \tag{2.48}$$ ∎

Proof of formula (2.23)–(2.24) *for* D. We can use Lemmas 2, 3, 5, and 6 to study the matrix D, which is given by formula (2.41). Performing block multiplication in $(A^{cf})^T(A^{ff})^{-1}B^f$, we see that the resulting matrix is an upper bidiagonal block matrix. Let us derive explicit formulas for the diagonal blocks first. The results obtained in Lemmas 2, 3, and 5 give that

$$\begin{aligned} &[(A^{cf})^T(A^{ff})^{-1}B^f]_{ii} \\ &\quad = \begin{bmatrix} (u^c_x)_i\big|_{(M(i-1)+1}, & (u^c_x)_i\big|_{M(i-1)+2}, & \dots & (u^c_x)_i\big|_{Mi} \end{bmatrix} \begin{bmatrix} T & & & 0 \\ & T & & \\ & & \ddots & \\ 0 & & & T \end{bmatrix}, \end{aligned} \tag{2.49}$$

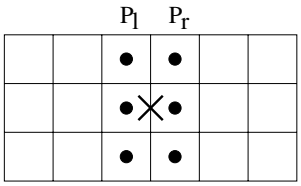

FIG. 2.6. *The nodes of coarse acceleration and pressure involved in the difference equation.*

where $(u_x^c)_i\big|_l$, $l = M(i-1)+1, M(i-1)+2, \ldots, Mi$, are the values of the coarse basis function at the nodal points of subgrid acceleration inside coarse cell i. Note that these values can be easily computed since the function $(u_x^c)_i$ is known (it is linear in x and constant in y, and it takes value 1 at the corresponding node and 0 at all other nodes).

After further matrix multiplications and application of Lemma 6, we see that D is block upper bidiagonal with the blocks given by (2.23)–(2.24). The nonzero entries correspond to those pressure nodes that are located along the boundary of the coarse cell i. □

2.3. Difference and differential equations for coarse acceleration. The results of Theorem 1 allow us to write the difference equation for the coarse acceleration explicitly as

$$(h_x h_y)\sum_{l=1}^{n_y}\rho_l^i(\mathbf{v_x^c})_i = -(h_x h_y)\left[\sum_{l=1}^{n_y}\frac{\mathbf{p}_{Ni+n_x(l-1)+1}}{h_x} - \sum_{l=1}^{n_y}\frac{\mathbf{p}_{N(i-1)+n_x l}}{h_x}\right]. \tag{2.50}$$

Notice that the two sums on the right-hand side of (2.50) are the sums of the pressure values to the right and to the left of the coarse cell boundary on which coarse acceleration $(\mathbf{v_x^c})_i$ is located (Figure 2.6). If we denote the average of pressure along the right and left boundary, respectively, by

$$\bar{\mathbf{p}}_r \equiv \frac{\sum_{l=1}^{n_y}\mathbf{p}_{Ni+n_x(l-1)+1}}{n_y}, \qquad \bar{\mathbf{p}}_l \equiv \frac{\sum_{l=1}^{n_y}\mathbf{p}_{N(i-1)+n_x l}}{n_y}, \tag{2.51}$$

then (2.50) reduces to

$$\bar{\rho}(\mathbf{v_x^c})_i = -\frac{\bar{\mathbf{p}}_r - \bar{\mathbf{p}}_l}{h_x}, \tag{2.52}$$

where $\bar{\rho}$ is the average of the density values on the boundary of the coarse cell, i.e.,

$$\bar{\rho} = \frac{\sum_{l=1}^{n_y}\rho_l^i}{n_y}.$$

Let us define a new function ρ^{ups}, which we will call upscaled density. This function is defined to be the original density values at node points interior to the coarse cells and is an average of density values $\bar{\rho}$ at node points along coarse block edges. In the following theorem, we derive the continuous differential equation for v_x^c and p.

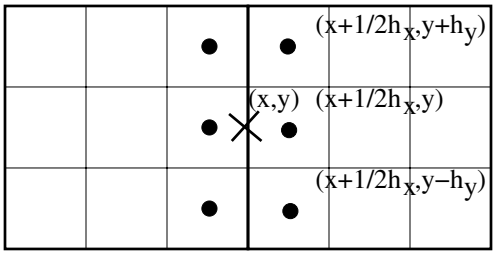

FIG. 2.7. *The coordinates of coarse acceleration and pressure involved in the difference equation in the case of* 3×3 *fine cells inside a single coarse cell.*

THEOREM 7. *Assume pressure* p *is at least four times continuously differentiable. Then the difference equation* (2.52) *is a discretization of the following differential equation*

$$\rho^{ups} v_x^c = -\frac{\partial p}{\partial x},$$

with order of approximation $O(h_x^2 + h_y^2)$.

Note. Theorem 7 gives a continuous differential equation for coarse acceleration which is essentially (2.1) from the original first-order system with density replaced by an upscaled density. We see that the upscaled acceleration approximates the gradient of pressure on the boundaries of coarse cells and, thus, compensates for the simplifying zero boundary conditions used in the algorithm.

Proof. Let acceleration node $(\mathbf{v_x^c})_\mathbf{i}$ be associated with the point (x, y). Replace $(\mathbf{v_x^c})_\mathbf{i}$, $\mathbf{p}_{Ni+n_x(l-1)+1}$, and $\mathbf{p}_{N(i-1)+n_x l}$ in the difference equation by the smooth functions v_x^c and p at the corresponding points and expand each pressure term in a Taylor series about the point (x, y). Notice that the pressure terms in $\bar{\mathbf{p}}_r$ are located at $(x + \frac{1}{2}h_x, y \pm jh_y)$, where jh_y is the distance between the corresponding pressure node and the acceleration node in the y direction. For example, in the case of 3×3 fine cells inside a single coarse cell, we see in Figure 2.7 that the terms in the sum $\bar{\mathbf{p}}_r$ are located at $(x + \frac{1}{2}h_x, y + h_y)$, $(x + \frac{1}{2}h_x, y)$, and $(x + \frac{1}{2}h_x, y - h_y)$. Thus, the subscript j takes on values $j = 0, 1$. Similarly, the pressure terms in $\bar{\mathbf{p}}_l$ are located at $(x - \frac{1}{2}h_x, y \pm jh_y)$. We expand each pressure term in (2.51) in a fourth-order Taylor series about (x, y). Since the pressure nodes are symmetric about the point (x, y), the linear and cubic terms in h_y cancel when computing the sums in (2.51), and we obtain for $\bar{\mathbf{p}}_r$ and $\bar{\mathbf{p}}_l$

(2.53)
$$\bar{\mathbf{p}}_r = \frac{\displaystyle\sum_{l=1}^{n_y} \left[p + \frac{\partial p}{\partial x}\left(\frac{1}{2}h_x\right) + \frac{1}{2}\left[\frac{\partial^2 p}{\partial x^2}\left(\frac{1}{2}h_x\right)^2 + \frac{\partial^2 p}{\partial y^2}(jh_y)^2\right]\right]}{n_y} + O(h_x^3) + O(h_x h_y^2)$$

and

(2.54)
$$\bar{\mathbf{p}}_l = \frac{\displaystyle\sum_{l=1}^{n_y} \left[p - \frac{\partial p}{\partial x}\left(\frac{1}{2}h_x\right) + \frac{1}{2}\left[\frac{\partial^2 p}{\partial x^2}\left(\frac{1}{2}h_x\right)^2 + \frac{\partial^2 p}{\partial y^2}(jh_y)^2\right]\right]}{n_y} + O(h_x^3) + O(h_x h_y^2),$$

where $p \equiv p(x, y)$. Substituting (2.53) and (2.54) into the difference equation (2.52) results in the following differential equation:

$$\rho^{ups} v_x^c = -\frac{\partial p}{\partial x}, \tag{2.55}$$

up to order $O(h_x^2 + h_y^2)$. We conclude that the upscaled acceleration approximates the x derivative of pressure on the boundary of the coarse cell with the upscaled density given by $\bar{\rho}$ at each nodal point. ∎

2.4. Matrix analysis of the pressure equation. In the next two sections, we will explain how coarse acceleration determines pressure in the time-dependent equation ((2.6) of the subgrid problem). The upscaling algorithm modifies the original wave equation on the boundaries of the coarse cells by using the coarse acceleration and the averaged density values on these boundaries. The equation which is solved includes an additional cross-derivative term not seen in the original wave equation. We follow the same basic outline as in sections 2.2–2.3. In other words, we start by analyzing the matrix form of (2.6) and then make use of results from the previous sections to derive the matrix equation for coarse acceleration and pressure. These results are then used to obtain a corresponding difference and finally differential equation for pressure resulting from the upscaling algorithm.

THEOREM 8. *Consider the set of subgrid problems* (2.5)–(2.6). *The elimination of the subgrid unknowns from the pressure equation* (2.6) *results in the following linear system for the coarse acceleration and pressure*

$$W \frac{\partial^2 \mathbf{p}}{\partial t^2} = -D^T \mathbf{v_x^c} - C\mathbf{p} - (v_y \text{ terms}) + F.$$

The matrix D and vector F are defined in Theorem 1 *by* (2.23), (2.24), *and* (2.14). *The matrix W is diagonal with entries having values of $\frac{1}{\rho c^2}$ at the corresponding pressure nodes. The matrix C is a block diagonal matrix. The blocks of C are of size $n_x \times n_x$ and are given by*

$$C_{i,i} = \frac{h_x h_y}{h_x^2} \begin{bmatrix} \rho_{I+1}^{-1} & -\rho_{I+1}^{-1} & & & 0 \\ -\rho_{I+1}^{-1} & \rho_{I+1}^{-1} + \rho_{I+2}^{-1} & -\rho_{I+2}^{-1} & & \\ \ddots & \ddots & \ddots & & \\ & & & & \\ & -\rho_{I+n_x-2}^{-1} & \rho_{I+n_x-2}^{-1} + \rho_{I+n_x-1}^{-1} & -\rho_{I+n_x-1}^{-1} & \\ 0 & & -\rho_{I+n_x-1}^{-1} & \rho_{I+n_x-1}^{-1} & \end{bmatrix}, \tag{2.56}$$

where $I = (i-1)(n_x - 1)$.

Proof. The idea of the proof is similar to that of Theorem 1. First, we use the matrix form of the subgrid problem (2.15)–(2.16) to eliminate the subgrid unknowns from the pressure equation (2.16). We obtain the time-dependent matrix equation for pressure and coarse acceleration only and derive explicit formulas for the matrix entries.

Recall that the matrix form of the subgrid problem is given by (2.15)–(2.16). We see that the first equation can be solved easily for $\delta \mathbf{v_x}$ in terms of $\mathbf{v_x^c}$. Thus, we can eliminate the subgrid unknowns from the time-dependent pressure equation. We

obtain

(2.57)
$$W\frac{\partial^2 \mathbf{p}}{\partial t^2} = -[(B^c)^T - (B^f)^T(A^{ff})^{-1}A^{cf}]\mathbf{v}_\mathbf{x}^\mathbf{c} - (B^f)^T(A^{ff})^{-1}B^f\mathbf{p} - (v_y \text{ terms}) + F,$$

or

$$W\frac{\partial^2 \mathbf{p}}{\partial t^2} = -D^T\mathbf{v}_\mathbf{x}^\mathbf{c} - C\mathbf{p} - (v_y \text{ terms}) + F. \tag{2.58}$$

In the rest of the proof of the theorem, we discuss the structure and entries of the matrices W, D^T, and C. In what follows, if i is the ith pressure node, then $\frac{1}{\rho c^2}\big|_i$ denotes the value of $\frac{1}{\rho c^2}$ at that node.

LEMMA 9. *The matrix W is a diagonal $NK \times NK$ matrix with nonzero entries given by*

$$w_{i,i} = (h_x h_y)\frac{1}{\rho c^2}\Big|_i. \tag{2.59}$$

Proof. The entries of the matrix W are the inner products of pressure basis functions with themselves, $\langle \frac{1}{\rho c^2} w_i, w_j \rangle$. Computing these entries using the midpoint rule and noting that each pressure basis function is supported on one fine cell only gives the desired result. ∎

Completion of the proof of Theorem 8. Let us now consider the matrix for coarse acceleration D^T. Notice that the matrix D was defined in Theorem 1 (2.23)–(2.24). Using those results, we see that D^T is a lower block bidiagonal matrix with blocks given by $D^T_{i,i+1}$ and $D^T_{i,i}$. The nonzero entries in D^T are associated with pressure unknowns located along the vertical boundaries of the coarse cells.

Let us now turn our attention to the coefficient matrix for pressure

$$C = (B^f)^T(A^{ff})^{-1}B^f.$$

The structure and the entries of A^{ff} and B^f were discussed in Lemmas 3 and 5. We have shown that A^{ff} is a diagonal matrix, and B^f is a block diagonal matrix with blocks of size $(n_x - 1) \times n_x$. Thus, C is also a block diagonal matrix with blocks of size $n_x \times n_x$.

We can derive explicit formulas for the entries of C. For simplicity of notation, let us discuss the derivation of the first block $C_{1,1}$. Using the explicit formulas for the entries of A^{ff} and the blocks of B^f in (2.29) and (2.42), we obtain

(2.60) $C_{1,1}$

$$= \frac{h_x h_y}{h_x^2}\begin{bmatrix} -1 & 0 & \dots & 0 \\ 1 & -1 & \dots & 0 \\ 0 & 1 & \dots & 0 \\ & \dots & \dots & \\ 0 & 0 & \dots & 1 \end{bmatrix}\begin{bmatrix} \rho_1^{-1} & & & 0 \\ & \ddots & & \\ 0 & & & \rho_{n_x-1}^{-1} \end{bmatrix}\begin{bmatrix} -1 & 1 & 0 & \dots & 0 & 0 \\ 0 & -1 & 1 & \dots & 0 & 0 \\ & & \dots & \dots & & \\ 0 & 0 & 0 & \dots & -1 & 1 \end{bmatrix}$$

$$= \frac{h_x h_y}{h_x^2}\begin{bmatrix} \rho_1^{-1} & -\rho_1^{-1} & 0 & \dots & 0 & 0 & 0 \\ -\rho_1^{-1} & \rho_1^{-1} + \rho_2^{-1} & -\rho_2^{-1} & \dots & 0 & 0 & 0 \\ & & & \dots & & & \\ 0 & 0 & 0 & \dots & -\rho_{n_x-2}^{-1} & \rho_{n_x-2}^{-1} + \rho_{n_x-1}^{-1} & -\rho_{n_x-1}^{-1} \\ 0 & 0 & 0 & \dots & 0 & -\rho_{n_x-1}^{-1} & \rho_{n_x-1}^{-1} \end{bmatrix}.$$

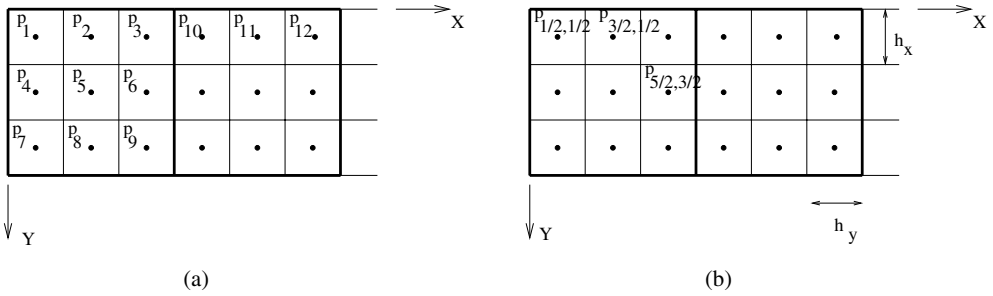

FIG. 2.8. *Pressure unknowns in the case of* 3×3 *fine cells inside a single coarse cell:* (a) *vector notation,* (b) *coordinate notation.*

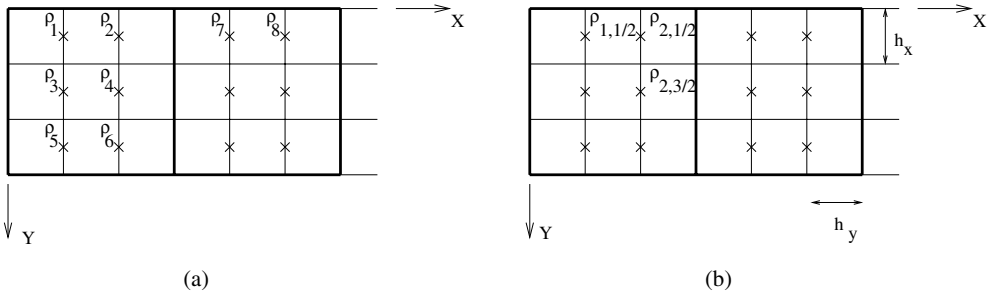

FIG. 2.9. *Density values at subgrid velocity nodes in the case of* 3×3 *fine cells inside a single coarse cell:* (a) *vector notation,* (b) *coordinate notation.*

Similarly, we can compute the rest of the blocks $C_{i,i}$ to get (2.56). Recall that blocks of C have size $n_x \times n_x$, so each block is associated with one row of pressure unknowns inside a single coarse cell. □

2.5. Difference and differential equations for pressure. To better understand the meaning of the matrix problem (2.58), we interpret it as a difference equation first and then as a continuous differential equation. In the following theorems, it is beneficial to change from vector notation (Figures 2.8(a) and 2.9(a)), used in the previous sections, to a spatial coordinate notation (Figures 2.8(b) and 2.9(b)). This notation change simplifies the discussion of the difference equation. In coordinate notation, $p_{i+1/2,j+1/2}$ will denote the value of pressure at the grid point $(x_{i+1/2} = (i + 1/2)h_x$, $y_{j+1/2} = (j + 1/2)h_y)$, and $\rho_{i,j+1/2}$ will be the value of density at the grid point $(x_i = ih_x,\ y_{j+1/2} = (j + 1/2)h_y)$, which is associated with the subgrid acceleration node (Figure 2.9). In the following theorems, we see that the matrix problem gives rise to different difference equations and hence different differential equations at different points in the spatial grid. The three pressure node locations we need to consider are (a) nodes internal to the coarse cell, (b) nodes along the right boundary of the coarse cell, and (c) nodes along the left boundary of the coarse cell (Figure 2.10).

In Theorem 10, we derive the difference and differential equations for the internal pressure nodes (Figure 2.10(a)). We then derive the difference and differential equations for the pressure nodes along the right boundary in Theorem 11. The result for pressure nodes along the left boundary of the coarse cells is similar.

THEOREM 10. *Let* $p_{i+1/2,j+1/2}$ *be a pressure unknown internal to a particular coarse cell (Figure* 2.10(a)*). Then the difference equation corresponding to matrix*

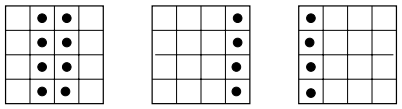

FIG. 2.10. *Three pressure node locations inside one coarse cell:* (a) *internal pressure nodes,* (b) *pressure nodes along the right boundary of the coarse cell,* (c) *pressure nodes along the left boundary of the coarse cell.*

problem (2.58) *has the following form:*

$$\begin{aligned}(2.61)\quad &\frac{1}{\rho c^2}\frac{\partial^2 p_{i+1/2,j+1/2}}{\partial t^2}\\ &= -\frac{1}{h_x^2}\Big(- p_{i+3/2,j+1/2}\rho^{-1}_{i+1,j+1/2} + p_{i+1/2,j+1/2}\left(\rho^{-1}_{i+1,j+1/2} + \rho^{-1}_{i,j+1/2}\right)\\ &\qquad\qquad - p_{i-1/2,j+1/2}\rho^{-1}_{i,j+1/2}\Big)\\ &\quad - \frac{1}{h_y^2}\Big(- p_{i+1/2,j+3/2}\rho^{-1}_{i+1/2,j+1} + p_{i+1/2,j+1/2}\left(\rho^{-1}_{i+1/2,j+1} + \rho^{-1}_{i+1/2,j}\right)\\ &\qquad\qquad - p_{i+1/2,j-1/2}\rho^{-1}_{i+1/2,j}\Big) + f_{i+1/2,j+1/2}.\end{aligned}$$

Further, assume pressure p *and density* ρ *are at least four times continuously differentiable. Then difference equation* (2.61) *is a discretization of the following continuous differential equation:*

$$(2.62)\qquad \frac{1}{\rho c^2}\frac{\partial^2 p}{\partial t^2} = \frac{\partial}{\partial x}\left(\rho^{-1}\frac{\partial p}{\partial x}\right) + \frac{\partial}{\partial y}\left(\rho^{-1}\frac{\partial p}{\partial y}\right) + f,$$

with order of approximation $O(h_x^2 + h_y^2)$.

Proof. Recall that the matrix equation for the pressure and coarse acceleration is given by (2.58). For simplicity, let us consider a particular case of 3×3 fine cells inside a single coarse cell (that is, $n_x = n_y = 3$), and we will focus initially on a particular pressure unknown, $p_{3/2,1/2}$, internal to the first coarse cell (Figure 2.8). Notice that in this case each coarse cell contains only three internal pressure unknowns. We chose $p_{3/2,1/2}$, since it is the only internal unknown in the first row of the first coarse cell. We first derive a difference equation for this unknown and then generalize the resulting formula. Since W is diagonal and its entries are given by (2.59) (Lemma 9), the product $W\frac{\partial^2 \mathbf{p}}{\partial t^2}$ yields

$$(2.63)\qquad (h_x h_y)\frac{1}{\rho c^2}\Big|_{3/2,1/2}\frac{\partial^2 p_{3/2,1/2}}{\partial t^2}.$$

As was shown in Theorem 8, the corresponding row of the matrix D^T contains zeroes. Therefore, the difference equation does not involve the coarse acceleration nodes. Let us now consider the term $C\mathbf{p}$. Since the unknown of interest is located in the first row of the first coarse cell, we need to consider the block $C_{1,1}$ (2.60). In the case where

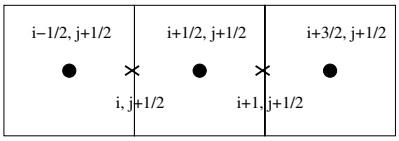

FIG. 2.11. *Finite-difference stencil for the internal pressure unknowns. Note that pressure nodes are denoted by circles and acceleration nodes by x's. Density lives at acceleration nodes, sound velocity at pressure nodes.*

$n_x = n_y = 3$, $C_{1,1}$ becomes

$$C_{1,1} = \frac{h_x h_y}{h_x^2} \begin{bmatrix} \rho_{1,1/2}^{-1} & -\rho_{1,1/2}^{-1} & 0 \\ -\rho_{1,1/2}^{-1} & \rho_{1,1/2}^{-1} + \rho_{2,1/2}^{-1} & -\rho_{2,1/2}^{-1} \\ 0 & -\rho_{2,1/2}^{-1} & \rho_{2,1/2}^{-1} \end{bmatrix}, \tag{2.64}$$

where we have used coordinate notation (Figure 2.9). The pressure unknown $p_{3/2,1/2}$ corresponds to the second entry in the vector $\mathbf{p}$. Thus, multiplying the second row of the matrix C by $\mathbf{p}$, we obtain a sum of three nonzero terms

$$\frac{h_x h_y}{h_x^2} \left(-p_{1/2,1/2} \rho_{1,1/2}^{-1} + p_{3/2,1/2} \left(\rho_{2,1/2}^{-1} + \rho_{1,1/2}^{-1} \right) - p_{5/2,1/2} \rho_{2,1/2}^{-1} \right). \tag{2.65}$$

Putting (2.63) and (2.65) together gives

$$\begin{aligned} \frac{1}{\rho c^2}\Big|_{3/2,1/2} \frac{\partial^2 p_{3/2,1/2}}{\partial t^2} = \frac{1}{h_x^2} \Big(& -p_{1/2,1/2} \rho_{1,1/2}^{-1} + p_{3/2,1/2} \left(\rho_{2,1/2}^{-1} + \rho_{1,1/2}^{-1} \right) - p_{5/2,1/2} \rho_{2,1/2}^{-1} \Big) \\ & - (v_y \text{ terms}) + f_{3/2,1/2}. \end{aligned} \tag{2.66}$$

The above formula can be generalized to the case of $n_x \times n_y$ fine cells inside a coarse cell. Since the structure of the matrices does not change, the same steps will lead us to the following difference equation for internal pressure unknowns (see Figure 2.11 for the x-derivative finite difference stencil):

$$\begin{aligned} & \frac{1}{\rho c^2} \frac{\partial^2 p_{i+1/2,j+1/2}}{\partial t^2} \\ & = -\frac{1}{h_x^2} \Big(- p_{i+3/2,j+1/2} \rho_{i+1,j+1/2}^{-1} + p_{i+1/2,j+1/2} \left(\rho_{i+1,j+1/2}^{-1} + \rho_{i,j+1/2}^{-1} \right) \\ & \qquad - p_{i-1/2,j+1/2} \rho_{i,j+1/2}^{-1} \Big) - (v_y \text{ terms}) + f_{i+1/2,j+1/2}. \end{aligned} \tag{2.67}$$

The difference expression for the v_y terms is similar.

Notice that the first term on the right-hand side of (2.67) is the standard second-order centered finite difference approximation of $\frac{\partial}{\partial x}(\rho^{-1} \frac{\partial p}{\partial x})$ [11]. Expanding the pressure and density terms in Taylor series around the point $(x_{i+1/2}, y_{j+1/2})$, we obtain from (2.67)

$$\frac{1}{\rho c^2} \frac{\partial^2 p}{\partial t^2} = \frac{\partial}{\partial x} \left(\rho^{-1} \frac{\partial p}{\partial x} \right) + \frac{\partial}{\partial y} \left(\rho^{-1} \frac{\partial p}{\partial y} \right) + f + O(h_x^2 + h_y^2). \tag{2.68}$$

This shows that the difference equation for the pressure unknowns internal to the coarse cell, which results from the upscaling algorithm, approximates the standard continuous acoustic wave equation up to order $O(h_x^2 + h_y^2)$. □

THEOREM 11. *Let $p_{i+1/2,j+1/2}$ be a pressure unknown located along the right boundary of a particular coarse cell (Figure* 2.10(b)*). Then the difference equation corresponding to* (2.58) *has the following form:*

(2.69)
$$\begin{aligned}
&\frac{1}{\rho c^2}\frac{\partial^2 p_{i+1/2,j+1/2}}{\partial t^2} \\
&= -\frac{1}{h_x}v_x^c - \frac{1}{h_x^2}\left(p_{i+1/2,j+1/2}\rho^{-1}_{i,j+1/2} - p_{i-1/2,j+1/2}\rho^{-1}_{i,j+1/2}\right) \\
&\quad -\frac{1}{h_y^2}\Big(- p_{i+1/2,j+3/2}\rho^{-1}_{i+1/2,j+1} + p_{i+1/2,j+1/2}\left(\rho^{-1}_{i+1/2,j+1} + \rho^{-1}_{i+1/2,j}\right) \\
&\qquad\qquad -p_{i+1/2,j-1/2}\rho^{-1}_{i+1/2,j}\Big) + f_{i+1/2,j+1/2},
\end{aligned}$$

where v_x^c is the value of the coarse acceleration on the given boundary.

Further, assume pressure p and density ρ are at least four times continuously differentiable. Then difference equation (2.69) *is a discretization of the following continuous differential equation with order of approximation $O(h_x + h_y)$:*

(2.70)
$$\frac{1}{\rho c^2}\frac{\partial^2 p}{\partial t^2} = \frac{\partial}{\partial x}\left((\rho^{ups})^{-1}\frac{\partial p}{\partial x}\right) + \left((\rho^{ups})^{-1}\frac{\partial^2 p}{\partial x \partial y}\right)K + \frac{\partial}{\partial y}\left((\rho^{ups})^{-1}\frac{\partial p}{\partial y}\right) + f,$$

where K is a constant which depends on the location of the pressure node within a single coarse cell.

Proof. The proof of the theorem is similar to that of Theorem 10. We first consider the case of 3×3 fine cells inside a single coarse cell and derive the difference equation for pressure unknown, $p_{5/2,1/2}$ located along the right boundary of the coarse cell (Figure 2.8(b)). The pressure unknown $p_{5/2,1/2}$ corresponds to the third entry in the vector $\mathbf{p}$ (Figure 2.8). Therefore, we need to look at the third rows of the matrices D^T and C. Only the first entry of the third row of D^T is nonzero (Theorems 1 and 8). The third row of the block $C_{1,1}$ in coordinate notation is given by (2.64). Thus, performing matrix-vector multiplications in matrix problem (2.58), we obtain

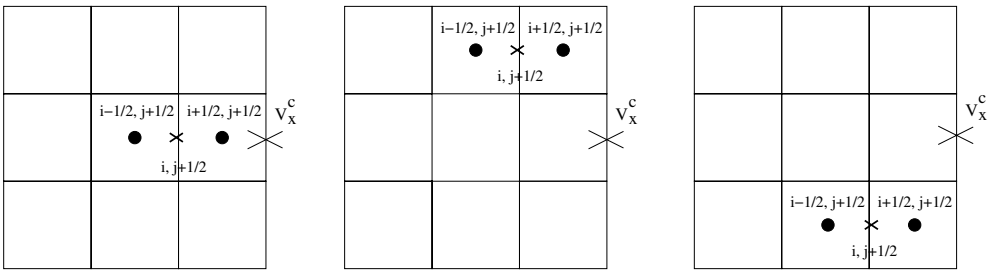

FIG. 2.12. *Locations of pressure nodes relative to coarse velocity for the case of 3×3 fine cells inside a single coarse cell. Note that pressure nodes are denoted by circles and subgrid and coarse acceleration nodes by x's and X's, respectively. Density lives at the same location as the subgrid acceleration nodes.*

the difference equation for $p_{5/2,1/2}$:

$$\frac{1}{\rho c^2}\frac{\partial^2 p_{5/2,1/2}}{\partial t^2} = -\frac{1}{h_x}v_x^c - \frac{1}{h_x^2}\left(p_{5/2,1/2}\rho_{2,1/2}^{-1} - p_{3/2,1/2}\rho_{2,1/2}^{-1}\right) - (v_y \text{ terms}) + f_{5/2,1/2}. \tag{2.71}$$

The above formula can be generalized to the case of $n_x \times n_y$ fine cells inside a coarse cell. We obtain the following difference equation for pressure unknowns along the boundary of the coarse cell (see Figure 2.12)

$$\frac{1}{\rho c^2}\frac{\partial^2 p_{i+1/2,j+1/2}}{\partial t^2} = -\frac{1}{h_x}v_x^c - \frac{1}{h_x^2}\left(p_{i+1/2,j+1/2}\rho_{i,j+1/2}^{-1} - p_{i-1/2,j+1/2}\rho_{i,j+1/2}^{-1}\right) - (v_y \text{ terms}) + f_{i+1/2,j+1/2}, \tag{2.72}$$

where v_x^c is the coarse acceleration unknown on the given boundary.

Let us now derive the differential equation. The idea is to use Taylor expansions around the point $(x_{i+1/2}, y_{j+1/2})$. First, consider the term v_x^c on the right-hand side of (2.72). We have shown in the previous sections that coarse acceleration is related to pressure through the difference equation

$$v_x^c = -\frac{1}{\bar\rho}\frac{\bar p_r - \bar p_l}{h_x}. \tag{2.73}$$

The terms $\bar p_r$, $\bar p_l$ are the averaged sums of pressure unknowns to the right and left of a particular boundary of the coarse cell, and $\bar\rho$ is the average of density values on the same boundary. We can write $\bar p_r$, $\bar p_l$, and $\bar\rho$ using coordinate notation as

$$\bar p_r = \frac{\sum_k p_{i+3/2,j+1/2+k}}{n_y}, \qquad \bar p_l = \frac{\sum_k p_{i+1/2,j+1/2+k}}{n_y}, \tag{2.74}$$

$$\bar\rho = \frac{\sum_k \rho_{i+1,j+1/2+k}}{n_y}, \tag{2.75}$$

where $p_{i+3/2,j+1/2+k} = p(h_x(i+3/2), h_y(j+1/2+k))$, $\rho_{i+1,j+1/2+k} = \rho(h_x(i+1), h_y(j+1/2+k))$, and kh_y represents the distance between the unknown and the point $(x_{i+1/2}, y_{j+1/2})$ in the y direction. The number of terms in each sum is equal to n_y, the number of fine cells inside a single coarse cell in the y direction. The values that k takes will depend on the number of fine cells inside a single coarse cell and the location of a particular pressure unknown in that cell. For example, Figure 2.13 shows that in the 3×3 case, if the pressure unknowns of interest are in bold, then k may take values -1, 0, 1 (Figure 2.13(a)); or the values 0, 1, 2 (Figure 2.13(b)); or 0, -1, -2 (Figure 2.13(c)). Expanding all the pressure unknowns in $\bar p_r$, $\bar p_l$ in a fourth-order Taylor series about the point $(x_{i+1/2}, y_{j+1/2})$ and using (2.73), we obtain for coarse acceleration

$$v_x^c = -\frac{1}{\bar\rho}\left[\frac{\partial p}{\partial x} + \frac{h_x}{2}\frac{\partial^2 p}{\partial x^2} + \frac{\sum_k k}{n_y}h_y\frac{\partial^2 p}{\partial x \partial y}\right] + O(h_x^2 + h_x h_y + h_y^2), \tag{2.76}$$

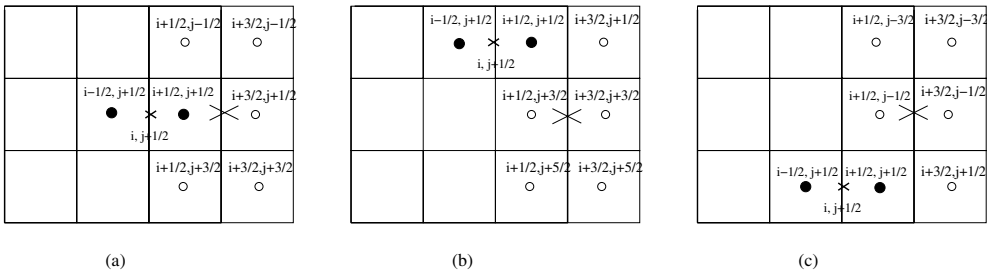

FIG. 2.13. *Examples of finite-difference stencils for different positions of pressure unknown* $p_{i+1/2,j+1/2}$ *in the case of* 3×3 *fine cells inside a single coarse cell. The open circles denote the pressure unknowns used in the calculation of* $\bar{p}_r$ *and* $\bar{p}_l$.

where $p \equiv p(x_{i+1/2}, y_{j+1/2})$. Expanding the rest of the terms on the right-hand side of (2.72) around the same point, we obtain

$$
\begin{aligned}
(2.77)\quad & -\frac{1}{h_x} v_x^c - \frac{1}{h_x^2}\left(p_{i+1/2,j+1/2}\rho^{-1}_{i,j+1/2} - p_{i-1/2,j+1/2}\rho^{-1}_{i,j+1/2}\right) \\
&\qquad = \frac{1}{\bar{\rho}}\left(\frac{1}{h_x}\frac{\partial p}{\partial x} + \frac{1}{2}\frac{\partial^2 p}{\partial x^2} + \frac{\sum\limits_k k}{n_y}\frac{h_y}{h_x}\frac{\partial^2 p}{\partial x \partial y}\right) \\
&\qquad\quad - \left(\frac{1}{h_x}\frac{\partial p}{\partial x} - \frac{1}{2}\frac{\partial^2 p}{\partial x^2}\right) \times \left(\rho^{-1} - \frac{h_x}{2}\frac{\partial \rho^{-1}}{\partial x}\right) + O(h_x + h_y),
\end{aligned}
$$

where $\rho \equiv \rho(x_{i+1/2}, y_{j+1/2})$. We can use the definition of the new function ρ^{ups} to say that

$$
(2.78)\qquad \frac{1}{\bar{\rho}} = \left(\rho^{ups}_{i+1,j+1/2}\right)^{-1}.
$$

Suppose the function ρ^{ups} can be constructed in such a way that it is smooth enough for Taylor series expansion. Expanding $(\rho^{ups}_{i+1,j+1/2})^{-1}$ around the point $(x_{i+1/2}, y_{j+1/2})$, we obtain from (2.77)

$$
\begin{aligned}
(2.79)\quad & -\frac{1}{h_x} v_x^c - \frac{1}{h_x^2}\left(p_{i+1/2,j+1/2}\rho^{-1}_{i,j+1/2} - p_{i-1/2,j+1/2}\rho^{-1}_{i,j+1/2}\right) \\
&\qquad = \frac{\partial p}{\partial x}\frac{\partial (\rho^{ups})^{-1}}{\partial x} + \frac{\partial^2 p}{\partial x^2}(\rho^{ups})^{-1} + \frac{\sum\limits_k k}{n_y}\frac{h_y}{h_x}\frac{\partial^2 p}{\partial x \partial y}(\rho^{ups})^{-1} + O(h_x + h_y).
\end{aligned}
$$

We use (2.79) in (2.72) to obtain the following differential equation

$$
(2.80)\qquad \frac{1}{\rho c^2}\frac{\partial^2 p}{\partial t^2} \;=\; \frac{\partial}{\partial x}\left((\rho^{ups})^{-1}\frac{\partial p}{\partial x}\right) + \left((\rho^{ups})^{-1}\frac{\partial^2 p}{\partial x \partial y}\right) K + (v_y \text{ terms}) + f,
$$

$$
\text{where } K = \frac{\sum\limits_k k}{n_y}\frac{h_y}{h_x}.
$$

Note. The constant K depends on the size of the fine mesh, the size of the coarse mesh, and the position of the pressure node under consideration. In particular, $K = 0$ when the pressure node has the same y coordinate as the coarse acceleration node. In this situation, k takes values $-1, 0, 1$, so that $\sum_k k = 0$ (see Figure 2.13(a)). ∎

3. Conclusions. To model subsurface phenomena ranging from the centimeter to the kilometer scale (micro- to macroscale), requires enormous amounts of computing power. Resolving all fine-scale features over large sections of the earth (at depths ranging from the near-surface down to the deep crust) is computationally prohibitive. Upscaling techniques allow us to perform these simulations on a coarser scale while capturing some of this fine-scale subwavelength information. There are a variety of upscaling methods. However, most of these techniques have been developed in the context of elliptic equations. We have adapted the operator-based upscaling technique, previously developed for elliptic flow, to the variable density, variable sound velocity acoustic wave equation. The upscaling method relies on decomposing the space of unknowns into coarse and subgrid subspaces. The problem is then naturally solved in two steps. First, we solve the subgrid problems for fine-scale information internal to each coarse cell. Then we use the subgrid solutions to augment the coarse-scale operator. A simplifying zero boundary condition imposed on each coarse cell decouples the subgrid problems from one coarse cell to the next. The fine-grid input parameters (density and sound velocity) are used throughout the computations. The algorithm does not explicitly average these input parameters. Further, separation of scales is not assumed with this technique. The numerical implementation of the upscaling algorithm for the wave equation is discussed in detail in Vdovina et al. [17]. Numerical experiments presented in that paper indicate that operator-based upscaling models wave propagation (even at the subwavelength scale) quite accurately relative to full finite difference solutions.

In this paper we convert the second-order acoustic wave equation into a system of two first-order equations (first-order in space) which involve solving for both pressure and its gradient (acceleration). The algorithm is based conceptually on the mixed finite element method. However, the pressure equation is solved via finite differences due to an equivalence between finite elements and finite differences. The first practical result from this analysis is that the system matrix for coarse acceleration is diagonal which greatly simplifies the implementation of the method.

Even more importantly, the analysis presented in this paper gives the first explanation of exactly which physical equations are solved by the upscaling algorithm. What we have shown is that the upscaling algorithm produces a coarse solution to the original constitutive equation for acceleration with the input density field redefined as an averaged density along coarse-block edges. This result indicates that the algorithm compensates for the simplifying zero boundary conditions on coarse block edges. Similarly, the upscaling algorithm leaves the wave equation for pressure untouched at nodes internal to coarse blocks. However, the pressure equation solved on coarse cell edges is modified to include a cross-derivative term for pressure (a second derivative involving both x and y) — a form of diffusion. This analysis allows us to simplify the algorithmic implementation of the method and to gain an understanding of what the solution produced by this technique models physically.

Acknowledgments. We thank Alan Levander and Bill Symes of Rice University for asking the extremely pertinent question, "What does the upscaled solution mean?" We further thank Bill Symes for suggesting that we look at the upscaling algorithm as a linear algebra problem. His insight led to the work described in this

paper. We thank Tetyana Vdovina of UMBC for her help with the derivation of the continuous differential equations for pressure from the difference equations. Finally, we are grateful to John Zweck of UMBC for reading an early draft of the manuscript. His suggestions greatly improved the overall structure of the paper.

ANALYSIS OF PROJECTION METHODS FOR RATIONAL FUNCTION APPROXIMATION TO THE MATRIX EXPONENTIAL*

L. LOPEZ† AND V. SIMONCINI‡

Abstract. Krylov subspace methods for approximating the action of the matrix exponential $\exp(A)$ on a vector v are analyzed with A Hermitian and negative semidefinite. Our approach is based on approximating the exponential with the commonly employed diagonal Padé and Chebyshev rational functions, which yield a system of equations with a polynomial coefficient matrix. We derive optimality properties and error bounds for the convergence of a Galerkin-type approximation and of a computationally feasible and extensively used alternative. As complementary results, we theoretically justify the use of a popular a posteriori error estimate, and we provide upper bounds for the components of the solution vector. Our theoretical and numerical results show that this methodology may provide an appropriate framework to devise new strategies such as more powerful acceleration schemes.

Key words. matrix, exponential, Krylov subspaces, rational functions, iterative methods

1. Introduction.

The problem of numerically approximating the action of the matrix exponential $\exp(A)$ on v for a given matrix A and vector v is of great importance in a wide range of applications. In fact, it is the core of many exponential integrators for solving systems of ordinary differential equations (see [26, 25]) or time-dependent partial differential equations [17, 19]. Over the years, several methods have been proposed for approximating the exponential of a matrix; we refer to [33] for a recent survey. For A of large dimension, Krylov subspace methods for approximating $\exp(A)v$ have been successfully used for a long time; see, e.g., [36, 39], the more recent publications [19, 25, 9], and references therein. In the past few years, important contributions have appeared that have significantly increased the theoretical understanding of this approach [48, 11, 12, 24, 41]. In this paper, we restrict our attention to the case of A Hermitian and negative semidefinite, as it is often the case in real applications, although the approach can be used even for non-Hermitian A. Given an $n \times n$ matrix A, the Krylov subspace $K_m(A, v) = \text{span}\{v, Av, \ldots, A^{m-1}v\}$ is characterized by the key relation

$$AV_m = V_{m+1}H_{m+1,m}, \qquad v = V_m e_1 \beta_0, \tag{1.1}$$

with $H_{m+1,m} \in \mathbb{R}^{(m+1)\times m}$ tridiagonal and $\beta_0 = \|v\|$, where $\|v\|$ is the 2-norm of v. Here and in the following, e_k denotes the kth vector of the canonical basis, whose dimension is clear from the context. In later sections, we use e_m^G and e_m^K to denote the *error* vectors for the analyzed methods. Relation (1.1), also known as the Lanczos recurrence, allows one to compute a matrix V_m whose orthonormal columns span $K_m(A, v)$, while $H_{m+1,m}$ contains the coefficients of the orthogonalization process. A

common approximation in $K_m(A, v)$ is

$$\exp(A)v \approx V_m \exp(H_m)e_1\beta_0; \tag{1.2}$$

here H_m is the (Hermitian) $m\times m$ principal part of $H_{m+1,m}$, i.e., $H_m = V_m^* A V_m$, where V_m^* is the transpose of V_m. This approximation was analyzed in [41], where it was also shown that the vector $V_m \exp(H_m)e_1\beta_0$ represents a polynomial approximation to $\exp(A)v$, in which the polynomial of degree $m-1$ interpolates the exponential function in the Hermite sense on the set of eigenvalues of H_m [41, Theorem 3.3]. Our analysis aims to explore this polynomial approach but from a different perspective.

The computation of $\exp(A)$, and of $\exp(H_m)$ cannot be carried out exactly, even assuming exact arithmetic [33]; we refer to [43] for a description of current software for computing the exponential of small matrices. In practice, $\exp(H_m)$ is often very accurately approximated by means of rational functions, such as Padé or Chebyshev functions; see, e.g., [1, 20, 21, 23, 19]. Therefore, given the rational function $\mathcal{R}_{\mu,\nu}(\lambda) := \Phi_\mu(\lambda)/\Psi_\nu(\lambda)$ for some specifically chosen polynomials Ψ_μ, Φ_ν of degree μ and ν, respectively, the approximate solution $V_m \exp(H_m)e_1\beta_0$ is replaced by the vector $V_m\mathcal{R}_{\mu,\nu}(H_m)e_1\beta_0$; see, e.g., the Matlab routine `expm` [32]. In the following we restrict our analysis to the case $\mu = \nu$, and thus we use $\mathcal{R}_\nu \equiv \mathcal{R}_{\nu,\nu}$; see section 3.

The aim of this paper is to increase our understanding of Krylov-subspace-based approximations to the exponential operator by exploiting rational functions and their approximation properties of the exponential. Rational functions may provide an appropriate framework to devise more powerful techniques, as well as to justify currently proposed approaches such as those in [6, 49]; see also section 6. In particular, we wish to set up the stage for the development of new acceleration strategies to computationally enhance the approximation process.

General results on approximation of matrix rational functions within Krylov subspaces are very limited; see, for instance, [51]. In practice, the theoretical as well as computational aspects associated with such approximation have not been completely addressed. We aim to contribute in filling this gap, as very general hypotheses on the rational functions are employed. Therefore, in this paper we first derive new error estimates for projection-type minimization methods used to approximate the action of matrix rational functions. Our results are very general and can be applied in contexts other than the approximation of the exponential. We then derive new insightful relations for the approximation of the exponential, with the commonly employed technique in (1.2).

We start with the preliminary consideration that the approximation

$$\exp(A)v \approx \mathcal{R}_\nu(A)v = (\Psi_\nu(A))^{-1}\Phi_\nu(A)v$$

entails solving the following system of equations:

$$\Psi_\nu(A)x = \Phi_\nu(A)v. \tag{1.3}$$

Note that as an alternative to solving (1.3), one could first approximately solve the system $\Psi_\nu(A)\hat{x} = v$ and then compute $x = \Phi_\nu(A)\hat{x}$. Since for $m > \nu$ it holds that $\Phi_\nu(A)v \in K_m(A, v)$, the approach (1.3) should be preferred in practice. Following [51], we analyze two procedures for solving (1.3). The first approach determines an approximation x_m by imposing a classical Galerkin condition on the residual. The second one, which we call the Krylov approximation,[1] is computationally more

[1] Also called Arnoldi or Lanczos approximation.

appealing and turns out to be equivalent to the standard procedure, namely,

$$x_m = V_m \mathcal{R}_\nu(H_m) e_1 \beta_0 \approx V_m \exp(H_m) e_1 \beta_0. \tag{1.4}$$

For the sake of simplicity, and without loss of generality, in the following we assume that $\|v\| = 1$ so that $\beta_0 = 1$. We analyze the optimality properties of the first method and show that the second method, although nonoptimal, provides an approximate solution that is significantly close to the optimal one. By using the partial fraction expansion of $\mathcal{R}_\nu$ we derive convergence bounds for both approaches that depend on the spectrum of A. In addition, we examine the role of the degree and the poles of both Padé and Chebyshev rational approximants in the convergence behavior as well as in the obtained error bounds.

Our convergence estimates predict linear, and not superlinear, convergence, and in this sense they are weaker than available error bounds; however, we also show that the superlinear behavior can be recovered by varying the degree ν. We stress here that our aim is not to derive better bounds than those in the literature. Instead, we wish to show that rational functions may represent a new numerical tool with no loss in convergence properties if the degree ν is taken into account.

Throughout the paper we assume exact precision arithmetic. We refer to [10] for a detailed analysis of the behavior of Krylov subspace approximations of matrix functions in finite precision computation.

In section 2 we review some basic facts on Krylov approximation of the exponential, while in section 3 we review several important properties of rational functions that will be used extensively in the paper. In section 4 we show an optimality property associated with the Galerkin method and provide bounds for the approximation error. In section 5 we analyze in detail the Krylov method. We first relate its approximate solution with that obtained with the optimal Galerkin approximation. Then, we derive new error estimates and compare them with those obtained for the Galerkin procedure. In section 6 we discuss some computational properties derived by using rational functions. In section 7 we analyze the Padé rational function approximation when the scaling and squaring procedure is employed to handle a matrix whose norm is significantly larger than one, while in section 8 we discuss the role of ν in the occurrence of superlinear convergence. Finally, section 9 discusses some related issues that our analysis brings to light.

2. Krylov subspace approximation to the matrix exponential. Krylov subspace approximations to the exponential have been analyzed in several papers; see, e.g., [41, 19]. However, the most significant error bounds were given in [48, 11] and later with a different approach in [24]. The authors of these papers were able to capture the so-called *superlinear* convergence of the approximation. As a reference, we recall here one of the results stated in [24] in our notation; see [48, 11] for qualitatively similar, although asymptotic bounds. We call these bounds *ideal* bounds, for reasons that will be clear in the following.

THEOREM 2.1 (see [24]). *Let A be a Hermitian negative semidefinite matrix with eigenvalues in the interval $[-4\rho, 0]$. Then the error in the Lanczos approximation of $\exp(A)v$ is bounded as follows:*

$$\|\exp(A)v - V_m \exp(H_m)e_1\| \le 10 e^{-m^2/(5\rho)}, \qquad \sqrt{4\rho} \le m \le 2\rho,$$
$$\|\exp(A)v - V_m \exp(H_m)e_1\| \le \frac{10}{\rho} e^{-\rho} \left(\frac{e\rho}{m}\right)^m, \qquad m \ge 2\rho.$$

Different bounds that also emphasize the superlinear character of the approximation have also been proposed in [47]; we found these latter bounds less sharp than those in [48, 11, 24], at least experimentally.

The Krylov approximation devised in (1.2) is not naturally equipped with a stopping criterion. Since the error norm $\| \exp(A)v - V_m \exp(H_m)e_1\beta_0\|$ cannot be computed explicitly as m increases, a criterion based on the quantity

$$h_{m+1,m}|e_m^* \exp(H_m)e_1\beta_0| \tag{2.1}$$

was proposed in [41, section 5.2]. This criterion works well in many cases, especially when $\|A\|$ is moderate, and qualitative arguments were discussed in [41] to justify its use; a higher order estimate can also be employed, which can be easily derived from (2.1) [41]. In general, an insightful interpretation of the quantity in (2.1) in not always immediate, usually due to the lack of a definition of residual, unlike in equation-based problems. An exception is the situation when the computation is related to the following initial value problem

$$\begin{cases} -Ax(t) + x'(t) = 0, \\ x(0) = v, \end{cases}$$

in which case it holds $h_{m+1,m}|e_m^* \exp(tH_m)e_1\beta_0| = \| - Ax_m(t) + x'_m(t)\|$, that is, the a posteriori estimate is indeed the residual associated with the approximate solution $x_m(t)$; see, e.g., [7, 10]. An alternative viewpoint was proposed in [26], where the authors introduced a new concept of residual norm by generalizing that of error norm in a functional setting. The new residual norm was shown to be equal to the estimate (2.1). With our derivation, we suggest a general role for the stopping criterion (2.1) in terms of residual associated with a matrix equation.

3. Rational function approximation. Rational functions are commonly used to accurately approximate analytic functions such as the exponential [1]. Here we review some characteristics of Chebyshev and Padé rational functions that are used in our analysis. However, several of the results in later sections apply to general rational functions and to the approximation of other smooth functions.

Let us assume that $\exp(\lambda)$ is approximated by the rational function $\mathcal{R}_\nu(\lambda)$. In this case, the quality of the approximation when using the Krylov subspace only affects part of the overall approximation. The bound

$$\begin{aligned} \| \exp(A)v - V_m \exp(H_m)e_1\| \le \| \exp(A)v - \mathcal{R}_\nu(A)v\| + \|\mathcal{R}_\nu(A)v - V_m\mathcal{R}_\nu(H_m)e_1\| \\ +\|\mathcal{R}_\nu(H_m)e_1 - \exp(H_m)e_1\| \end{aligned}$$

emphasizes that there are two components in the error estimate: the second term on the right is the "Krylov subspace error," and it can be monitored as the chosen approximation in $K_m(A, v)$ takes place, whereas the size of the second component, corresponding to the other two terms in the bound, depends on the accuracy of the rational function approximation employed.

The first component is related to the numerical solution of the system (1.3) in the Krylov subspace. The solution of algebraic systems having a matrix function as coefficient matrix by means of Krylov subspaces has been analyzed in detail by van der Vorst in [51]; see also the recent presentation in [50]. Two distinct methods are studied in [51] for special cases of Ψ_ν and for $\Phi_\nu = 1$. In the first approach, the problem is projected onto the smaller dimension space, whereas the second approach

is characterized by a sequential projection. In this paper we generalize these two methods to our framework and analyze their properties.

Several approaches have been considered for choosing the rational function approximation. In the context of one-step methods for initial value differential problems, a stable way to approximate $\exp(A)$ consists of employing diagonal Padé approximants $\mathcal{R}_\nu = \Phi_\nu/\Psi_\nu$, where Φ_ν, Ψ_ν are polynomials of degree ν; see, e.g., [26, 25] and references therein. These two polynomials satisfy $\Phi_\nu(\lambda) = \Psi_\nu(-\lambda)$ so that we can write

$$\Psi_\nu(\lambda) = \psi_\nu \cdot (\lambda - \xi_1) \cdots (\lambda - \xi_\nu), \qquad \Phi_\nu(\lambda) = \phi_\nu \cdot (\lambda + \xi_1) \cdots (\lambda + \xi_\nu). \tag{3.1}$$

Here ψ_ν and ϕ_ν are the leading term coefficients. The two polynomials are uniquely defined apart from a scaling factor. We shall assume in the following that this scaling factor is such that $\Psi_\nu(0) = \Phi_\nu(0) = 1$. The roots of Ψ_ν all have positive real part, so that those of Φ_ν have negative real part; in addition, they come in complex conjugate if their imaginary part is nonzero and their absolute value is larger than one, and increasing with ν. The leading coefficient ψ_ν satisfies

$$|\psi_\nu| = \frac{1}{|\xi_1 \cdot \cdots \cdot \xi_\nu|} \ll 1;$$

it is positive if ν is even, and negative if ν is odd. In addition, $|\Phi_\nu(\lambda)/\Psi_\nu(\lambda)| \le 1$ for $\lambda \le 0$ [52]. Finally, for any nonpositive real λ we have $\Psi_\nu(\lambda) > 0$. In our context, this property ensures that $\Psi_\nu(A)$ is Hermitian and positive definite for any Hermitian negative semidefinite matrix A, that is, $x^*\Psi_\nu(A)x > 0$ for any nonzero vector x.

In the context of parabolic partial differential equations, rational Chebyshev approximations have also been considered; see, e.g., [52, 19], which provide best rational approximations to $\exp(x)$ for $x \in (-\infty, 0]$ in the Chebyshev sense. If $\Phi_\nu(-\lambda)/\Psi_\nu(-\lambda)$ is the Chebyshev approximant for $\lambda \le 0$, then it is known that $\sup_{\lambda \le 0} |\exp(\lambda) - \Phi_\nu(-\lambda)/\Psi_\nu(-\lambda)| \approx 10^{-\nu}$; see [8, Table II]. In addition, since Ψ_ν has all strictly positive coefficients (cf. [8, Table III]), then $\Psi_\nu(x) > 0$ for $x \ge 0$, implying that $\Psi_\nu(-A)$ is positive definite for A Hermitian and negative semidefinite. The roots ξ_j of Ψ_ν appear with positive and negative real part, therefore $M_j = -A - \Re(\xi_j)I$ may be indefinite for some ξ_j, $j = 1, \ldots, \nu$. We note that the Chebyshev rational approximation uses $\Phi_\nu(-\lambda)/\Psi_\nu(-\lambda)$ with $\lambda \le 0$, whereas the Padé approximation employs $\Phi_\nu(\lambda)/\Psi_\nu(\lambda)$ with $\lambda \le 0$. In this paper we do not distinguish between the sign in the two cases, using $\Phi_\nu(\lambda)/\Psi_\nu(\lambda)$ with $\lambda \le 0$, while warning the reader that depending on the strategy used, the variable sign should be changed accordingly.

Padé approximants of degree up to $\nu = 14$ are commonly employed [23], and 10^{-14} is often considered a sufficiently good accuracy for the Chebyshev approximation. Unless otherwise specified, we thus restrict our experiments to the case $\nu \le 14$. For the sake of simplicity, we only consider equal degree approximants, whereas it is known that in the Padé approximation, $\Phi_{\nu-1}, \Psi_\nu$ also provide stable approximations in the context of stiff ordinary differential equations; see, e.g., [20]. In our analysis we use the fact that both the Padé and the Chebyshev approximants have simple poles, although the presence of multiple poles is addressed in section 7 in the context of the scaling and squaring method.

We also recall that the rational function $\mathcal{R}_\nu = \Phi_\nu/\Psi_\nu$ can be written by means of a partial fraction expansion as

$$\mathcal{R}_\nu(\lambda) = \tau_0 + \sum_{j=1}^{\nu} \frac{\tau_j}{(\lambda - \xi_j)}, \tag{3.2}$$

where $\xi_1, \dots, \xi_\nu$ are the distinct roots of Ψ_ν, $\tau_1, \dots, \tau_\nu$ are the coefficients (appearing in complex conjugates) of the expansion, and τ_0 is the remainder.

4. Convergence analysis of the Galerkin method. In this section we analyze the convergence properties of the Galerkin approximation. A Galerkin approach based on the Krylov subspace $K_m(A, v)$ approximates x in (1.3) as $x_m^G = V_m y_m^G$ by imposing that the residual $\Phi_\nu(A)v - \Psi_\nu(A)x_m^G$ be orthogonal to the Krylov subspace, namely, $V_m^*(\Phi_\nu(A)v - \Psi_\nu(A)x_m^G) = 0$. Therefore, y_m^G is computed as the solution to the system

$$V_m^* \Psi_\nu(A) V_m y = V_m^* \Phi_\nu(A) v. \tag{4.1}$$

The method is of interest from a theoretical point of view, because of its optimality properties. From a computational standpoint, the explicit computation of $V_m^*\Psi_\nu(A)V_m$ requires ν evaluations with A at each iteration, making the approach not appealing. The Krylov approximation thus represents a valuable competitive alternative, and we show that the convergence properties are indeed comparable.

We first show that the Galerkin approximate solution has a minimization property, ensuring that the error is nonincreasing with m in the considered norm; then we derive upper bounds for this error norm. All these results appear to be new.

PROPOSITION 4.1. *Let $x_\star = \mathcal{R}_\nu(A)v$ and let x_m^G be the Galerkin approximation to $x_\star$ in $K_m(A, v)$ and assume that $\Psi_\nu(A)$ is Hermitian and positive definite. Then*

$$\min_{x \in K_m(A,v)} \|x_\star - x\|_{\Psi_\nu(A)} = \|x_\star - x_m^G\|_{\Psi_\nu(A)}.$$

Proof. The result follows from imposing the Galerkin condition on the residual $\Psi_\nu(A)(x_\star - x_m)$; cf. [42, Proposition 5.2]. ∎

PROPOSITION 4.2. *Let $[\alpha, \beta]$ be the interval containing all eigenvalues of A and assume that the hypotheses of Proposition* 4.1 *hold. Then*

$$\begin{aligned}\min_{x \in K_m(A,v)} \|x_\star - x\|^2_{\Psi_\nu(A)} &= \min_{q \in \mathbb{P}_{m-1}} \|x_\star - q(A)v\|^2_{\Psi_\nu(A)} \\ &\le \min_{q \in \mathbb{P}_{m-1}} \max_{\lambda \in [\alpha,\beta]} \left|1 - \mathcal{R}_\nu(\lambda)^{-1} q(\lambda)\right|^2 \|v\|^2_{\Psi_\nu(A)}.\end{aligned}$$

Proof. Let $u_1, \dots, u_n$ be the unit norm eigenvectors of A associated with the eigenvalues $\lambda_1, \dots, \lambda_n$. Define $\chi_i := u_i^* x_\star$ and $s(\lambda) := 1 - q(\lambda)(\mathcal{R}_\nu(\lambda))^{-1}$. We have $x_\star - q(A)v = \left(I - q(A)(\mathcal{R}_\nu(A))^{-1}\right) x_\star = \sum_{i=1}^n u_i s(\lambda_i)\chi_i$ so that

$$\begin{aligned}\|x_\star - q(A)v\|^2_{\Psi_\nu(A)} &= \langle x_\star - q(A)v, \Psi_\nu(A)(x_\star - q(A)v)\rangle \\ &= \sum_{i=1}^n \Psi_\nu(\lambda_i)(s(\lambda_i))^2 \chi_i^2 \le \max_{\lambda \in [\alpha,\beta]} |s(\lambda)|^2 \|v\|^2_{\Psi_\nu(A)}.\end{aligned}$$ ∎

We next provide a bound for the polynomial min-max problem in Proposition 4.2; we use the following definitions. For each pole ξ_j, we set $M_j = A - \Re(\xi_j)I$, and we let α_j be the eigenvalue of M_j with largest absolute value and β_j be the eigenvalue of M_j with smallest absolute value. If $\Re(\xi_j) > 0$, then $\alpha_j < \beta_j < 0$. Moreover, we let

$$\rho_j = \gamma_j + \sqrt{\gamma_j^2 - 1} \quad \text{with} \quad \gamma_j = \frac{|\alpha_j - i\Im(\xi_j)| + |\beta_j - i\Im(\xi_j)|}{|\alpha_j - \beta_j|}. \tag{4.2}$$

The following bound holds.

THEOREM 4.3. *Assume that the spectrum of A is contained in the negative interval $[\alpha, \beta]$, and that Ψ_ν has distinct roots. Then, with the notation above,*

$$\min_{q\in\mathbb{P}_{m-1}} \max_{\lambda\in[\alpha,\beta]} \left|1 - (\mathcal{R}_\nu(\lambda))^{-1} q(\lambda)\right| \le 2 \sum_{j=1}^{\nu} \left(\max_{\lambda\in[\alpha,\beta]} \frac{|\tau_j|}{\mathcal{R}_\nu(\lambda)\,|\lambda - \xi_j|} \right) \frac{1}{\rho_j^m + 1/\rho_j^m}.$$

Proof. In the proof we omit the polynomial subscripts. We first rewrite the problem as

$$\min_{q\in\mathbb{P}_{m-1}} \max_{\lambda\in[\alpha,\beta]} \left|1 - (\mathcal{R}(\lambda))^{-1} q(\lambda)\right| = \min_{q\in\mathbb{P}_{m-1}} \max_{\lambda\in[\alpha,\beta]} \left| \frac{1}{\mathcal{R}(\lambda)} (\mathcal{R}(\lambda) - q(\lambda)) \right|. \tag{4.3}$$

Let q^* be the polynomial of degree at most $m-1$ that attains the minimum in (4.3). Using the partial fraction expansion in (3.2), for any $q \in \mathbb{P}_{m-1}$ we have

$$|\mathcal{R}(\lambda) - q^*(\lambda)| = \left| \tau_0 + \sum_{j=1}^{\nu} \frac{\tau_j}{\lambda - \xi_j} - q^*(\lambda) \right| \le \max_{\lambda\in[\alpha,\beta]} \left| \tau_0 + \sum_{j=1}^{\nu} \frac{\tau_j}{\lambda - \xi_j} - q(\lambda) \right|.$$

We choose $q \in \mathbb{P}_{m-1}$ defined as $q(\lambda) = \tau_0 + \sum_{j=1}^{\nu} \tau_j q^{(j)}(\lambda - \xi_j)$, with $\lambda \in [\alpha, \beta]$, while $q^{(j)} \in \mathbb{P}_{m-1}$, $j = 1, \ldots \nu$ are polynomials yet to be determined. We set $p^{(j)}(\lambda - \xi_j) = 1 - (\lambda - \xi_j) q^{(j)}(\lambda - \xi_j)$, with $p^{(j)} \in \mathbb{P}_m$ and $p^{(j)}(\xi_j) = 1$. Thus

$$\begin{aligned} \left| \tau_0 + \sum_{j=1}^{\nu} \frac{\tau_j}{\lambda - \xi_j} - q(\lambda) \right| &= \left| \sum_{j=1}^{\nu} \tau_j \left(\frac{1}{\lambda - \xi_j} - q^{(j)}(\lambda - \xi_j) \right) \right| \\ &= \left| \sum_{j=1}^{\nu} \tau_j \frac{1}{\lambda - \xi_j} p^{(j)}(\lambda - \xi_j) \right|. \end{aligned}$$

It was shown in [15, formula (38)] that the polynomial $p^{(j)}$ can be constructed so that $\max_{\zeta\in[\alpha-\xi_j,\beta-\xi_j]} |p^{(j)}(\zeta)| = 2/(\rho_j^m + 1/\rho_j^m)$. Hence, we can write

$$\begin{aligned} \min_{q\in\mathbb{P}_{m-1}} \max_{\lambda\in[\alpha,\beta]} \left| \frac{1}{\mathcal{R}(\lambda)} (\mathcal{R}(\lambda) - q(\lambda)) \right| &\le \max_{\lambda\in[\alpha,\beta]} \left| \sum_{j=1}^{\nu} \frac{\tau_j}{\mathcal{R}(\lambda)(\lambda - \xi_j)} p^{(j)}(\lambda - \xi_j) \right| \\ &\le \sum_{j=1}^{\nu} \left(\max_{\lambda\in[\alpha,\beta]} \frac{|\tau_j|}{\mathcal{R}(\lambda)\,|\lambda - \xi_j|} \right) \frac{2}{(\rho_j^m + 1/\rho_j^m)}. \end{aligned}$$

∎

The denominator in the bound always satisfies $|\lambda - \xi_j| \neq 0$ if $\Im(\xi_j) \neq 0$. For ν odd and real ξ_j, we have $\xi_j > 0$ for Padé so that $\lambda - \xi_j < 0$ for $\lambda \in [\alpha, \beta]$, while for Chebyshev, we have $\xi_j < 0$ and $-\lambda \in [\alpha, \beta]$ so that $\lambda - \xi_j > 0$. In both cases, $|\lambda - \xi_j| \neq 0$.

Remark 4.4. When $\beta = 0$, so that the eigenvalues of A are in $[\alpha, 0]$, then roughly $\rho_j \approx 2(1 + 2|\xi_j/\alpha|)$. Therefore, we obtain

$$\sum_{j=1}^{\nu} \left(\max_{\lambda\in[\alpha,\beta]} \frac{|\tau_j|}{\mathcal{R}_\nu(\lambda)\,|\lambda - \xi_j|} \right) \frac{2}{(\rho_j^m + 1/\rho_j^m)} \approx e^{-\alpha} \sum_{j=1}^{\nu} \max_{\lambda\in[\alpha,\beta]} \frac{|\tau_j|}{|\lambda - \xi_j|} \cdot \frac{2}{(2 + 4|\frac{\xi_j}{\alpha}|)^m},$$

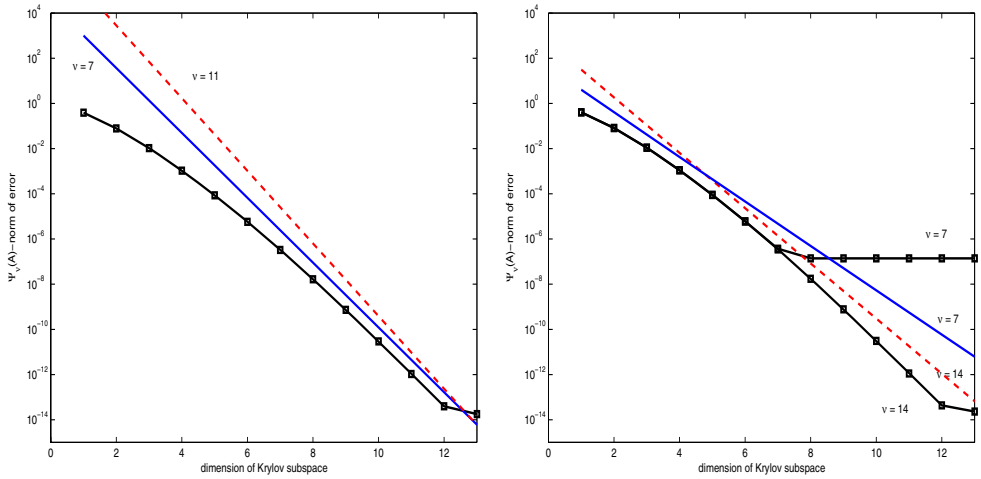

FIG. 4.1. *Example* 4.5*: Galerkin approximation. Left: Padé rational functions (black solid with squares) and upper bound for* $\nu = 7, 11$*. Right: Chebyshev rational functions (black solid with squares) and upper bounds for* $\nu = 7, 14$*.*

which shows the role of ξ_j as $|\alpha|$ gets large. See also section 8 for additional remarks on the role of the poles. ∎

To show the sharpness of the bound in Theorem 4.3, we next report a numerical experiment with both Padé and Chebyshev rational functions. Below and later in the paper, we show convergence curves for $\|\exp(A)v - x_m\|_*$, where $\|\cdot\|_*$ is the norm of interest. The bound $\|\exp(A)v - x_m\|_* \le \|\exp(A)v - \mathcal{R}_\nu(A)v\|_* + \|\mathcal{R}_\nu(A)v - x_m\|_*$ allows us to use estimates such as that in Theorem 4.3 to bound the second term in the right-hand side, whereas the first term depends on the accuracy of the rational function approximation. We will see that the error $\|\exp(A)v - x_m\|_*$ stagnates at the final accuracy level of $\|\exp(A)v - \mathcal{R}_\nu(A)v\|_*$.

Example 4.5. This is a contrived example but here and later in the text, it serves as a simple platform for describing the principal properties of the two rational approximations. We consider the 100×100 diagonal matrix A of the logarithm of equispaced values between 0.2 and 0.99. In Matlab notation, this can be defined as `A = diag(log(linspace(0.2,0.99,100)))`. The spectrum of A is contained in the interval $[-1.61, -0.0101]$. The vector v is chosen to be the vector of all ones, scaled so as to have unit norm. The Padé polynomials Ψ_ν, Φ_ν are computed for $\nu = 7$ and $\nu = 11$, and no prescaling of A is employed (see section 7). The approximate solution $x_m^G = V_m y_m^G$ is obtained at each step m by explicitly computing $V_m^* \Psi_\nu(A) V_m$ and $V_m^* \Phi_\nu(A) v$, and then solving (1.3).

In the left plot of Figure 4.1 we report the relative $\Psi_\nu(A)$-norm of the error, $\|\exp(A)v - x_m^G\|_{\Psi_\nu(A)}$ (solid black curve with squares), together with the upper bound in Theorem 4.3 corresponding to Padé rational functions with $\nu = 7, 11$. Note that the $\Psi_\nu(A)$-norm of the error is indistinguishable for the two values of ν. The right plot shows the same curves associated with Chebyshev rational functions with $\nu = 7, 14$. As predicted by the theory, the final level of accuracy is reached at about $10^{-\nu}$.

We remark that the bound is significantly accurate for the Padé approximation. The deterioration due to the high degree $\nu = 11$ is mostly noticed during the first phase of the convergence; but see also section 8. A very satisfactory bound is obtained for the Chebyshev approximation as well, especially for $\nu = 14$.

5. Layers of Galerkin approximations. The Krylov approximation in (1.4) requires the solution of the system $\Psi_\nu(H_m)y_m = \Phi_\nu(H_m)e_1$. This is interpreted in [51] as a sequential Galerkin projection onto the Krylov subspace $K_m(A, v)$ of the linear systems

$$(A - \xi_j I)w_m^{(j)} = w_m^{(j-1)}, \quad j = 1, \ldots, \nu,$$

with $w_m^{(0)} = V_m y_m^{(0)}$ and $y_m^{(0)} = \Phi_\nu(H_m)e_1$. The solution of each system in the Krylov subspace then corresponds to employing the full orthogonalization method (FOM) [42]. Indeed, writing $w_m^{(j)} = V_m y_m^{(j)}$ for $j = 1, \ldots, \nu$, we have

$$V_m^*(A - \xi_j I)V_m y_m^{(j)} = y_m^{(j-1)}, \quad j = 1, \ldots, \nu,$$

that is, $(H_m - \xi_j I)y_m^{(j)} = y_m^{(j-1)}$, $j = 1, \ldots, \nu$, so that, using (3.1),

$$\begin{aligned} y_m \equiv \frac{1}{\psi_\nu} y_m^{(\nu)} &= \frac{1}{\psi_\nu}(H_m - \xi_\nu I)^{-1} \cdots (H_m - \xi_1 I)^{-1}\Phi_\nu(H_m)e_1 \\ &\equiv (\Psi_\nu(H_m))^{-1}\Phi_\nu(H_m)e_1. \end{aligned}$$

In this section we try to increase our understanding of the Krylov approximation. The next result states an explicit relation between the Galerkin and Krylov solutions when the approximation subspace has dimension larger than ν. We show that the two matrices $V_m^*\Psi_\nu(A)V_m, \Psi_\nu(H_m)$ coincide except for the bottom $\nu - 1$ diagonal block. This result also allows us to conclude that the two solutions tend to coalesce as convergence takes place.

PROPOSITION 5.1. *For $m > \nu$, let $y_m^K = (\Psi_\nu(H_m))^{-1}\Phi_\nu(H_m)e_1$ and $y_m^G = (V_m^*\Psi_\nu(A)V_m)^{-1}V_m^*\Phi_\nu(A)v$ be the Krylov and Galerkin approximations to the vector $x_\star = (\Psi(A))^{-1}\Phi_\nu(A)v$, respectively. Then, there exists a $(\nu - 1) \times (\nu - 1)$ matrix S_ν, such that $V_m^*\Psi_\nu(A)V_m = \Psi_\nu(H_m) + S_{m,\nu}$, with $S_{m,\nu} = E_{m,\nu-1}S_\nu E_{m,\nu-1}^*$, and $E_{m,\nu-1}^* = [0, I_{\nu-1}] \in \mathbb{R}^{(\nu-1)\times m}$. As a consequence, $\Phi_\nu(A)v = V_m\Phi_\nu(H_m)e_1$, and*

$$y_m^K = y_m^G + (V_m^*\Psi_\nu(A)V_m)^{-1}E_{m,\nu-1}S_\nu E_{m,\nu-1}^* y_m^K$$

so that $\|y_m^G - y_m^K\| \le \|(V_m^*\Psi_\nu(A))^{-1}E_{m,\nu-1}S_\nu\| \, \|E_{m,\nu-1}^* y_m^K\|$.

Proof. We eliminate the polynomial subscripts in the proof. For any polynomial Ψ of degree at most ν, it can be explicitly shown that for $j \le m - \nu + 1$, $V_m^*\Psi(A)V_m e_j = \Psi(H_m)e_j$ and because of symmetry, it also holds $e_j^*V_m^*\Psi(A)V_m = e_j^*\Psi(H_m)$. Therefore, we can write $S_{m,\nu} = E_{m,\nu-1}S_\nu E_{m,\nu-1}^*$, $E_{m,\nu-1}^* = [0, I_{\nu-1}]$, for some $(\nu - 1) \times (\nu - 1)$ matrix S_ν, from which the first result follows.

The fact that the two vectors $\Phi(A)v$ and $V_m\Phi(H_m)e_1$ are equal is an immediate consequence of the matrix relation above. Using the definition of y_m^K, y_m^G, we have

$$\begin{aligned} (V_m^*\Psi(A)V_m - S_{m,\nu})y_m^K &= \Phi(H_m)e_1, \\ y_m^K - (V_m^*\Psi(A)V_m)^{-1}S_{m,\nu}y_m^K &= (V_m^*\Psi(A)V_m)^{-1}\Phi(H_m)e_1 \equiv y_m^G, \\ y_m^K - y_m^G &= (V_m^*\Psi(A)V_m)^{-1}S_{m,\nu}y_m^K, \end{aligned}$$

from which the relation and the final bound follow. ∎

Direct inspection shows that $\|S_\nu\| = O(h_{m+1,m}^2)$. In Table 5.1, we report some numerical results that highlight the relation between the two methods. Data in Example 4.5 with the Padé rational function of degree $\nu = 7$ are considered. The columns display the norm of the error for the Krylov method as the subspace dimension increases and the 2-norm and Ψ_ν-norm of the error for the Galerkin method. The two

approaches show very close, although not identical, approximation (cf. $\|x_m^K - x_m^G\|$). We also notice that the error between the two solutions decreases with m, the difference being one order of magnitude smaller than the approximation error.

Although the result of Proposition 5.1 sheds light on the similarities of the two methods for large m, the two approaches behave very similarly even for $m \le \nu$. The analysis for $m \le \nu$ is of great interest, since for $\|A\|$ not much greater than unit, high convergence rate can be observed for the two methods, and final accuracy is obtained for m possibly smaller than ν, as is the case in Example 4.5. In the following section we show that the error in the Krylov approximation can be bounded in a way similar to what we derived for the Galerkin approximation.

5.1. The Krylov approximation. The proof of Theorem 4.3 inspires an alternative way to justify the use of the Krylov approach in (1.4) to approximate the rational function $\mathcal{R}_\nu(A)v$. Using the partial fraction expansion in (3.2) we can write

$$x_\star = \mathcal{R}_\nu(A)v = \tau_0 v + \sum_{j=1}^{\nu} \tau_j (A - \xi_j I)^{-1} v. \tag{5.1}$$

Therefore, an approximation to $x_\star$ may be obtained by approximating the solution $d^{(j)}$ to each system $(A - \xi_j I)d = v$, $j = 1, \dots, \nu$; this type of approach has been explored, for instance, in [18, 5, 2, 4, 31]. Thanks to the shift invariance property of Krylov subspaces, i.e., $K_m(A, v) = K_m(A - \xi_j I, v)$ for any $\xi_j \in \mathbb{C}$, approximations to $d^{(j)}$ can be obtained in the same subspace $K_m(A, v)$ as $d_m^{(j)} = V_m y_m^{(j)}$ for some $y_m^{(j)}$ using the FOM method. More precisely, if $y_m^{(j)}$ is determined by imposing a Galerkin (orthogonality) condition on the residual $v - (A - \xi_j I)V_m y_m^{(j)}$, then we obtain $y_m^{(j)} = (H_m - \xi_j I)^{-1} e_1$. Therefore, substituting $y_m^{(j)}$ in the expansion yields

$$\begin{aligned} x_\star &= \tau_0 v + \sum_{j=1}^{\nu} \tau_j (A - \xi_j I)^{-1} v \approx \tau_0 v + \sum_{j=1}^{\nu} \tau_j V_m y_m^{(j)} \\ &= V_m \left(\tau_0 e_1 + \sum_{j=1}^{\nu} \tau_j (H_m - \xi_j I)^{-1} e_1 \right) = V_m \mathcal{R}_\nu(H_m) e_1. \end{aligned} \tag{5.2}$$

The last term is precisely the Krylov approximation (1.4).

Theorem 4.3 shows that the approximation obtained by a Galerkin projection minimizes the error in the $\Psi(A)$-norm over all approximations in the subspace $K_m(A, v)$, and thus we expect a larger error with the Krylov approximation. The derivation above shows that the Krylov approximation yields a Galerkin solution on each system with $(A - \xi_j I)$; however, since $(A - \xi_j I)$ is not Hermitian for ξ_j complex, the Galerkin solution does not yield an error minimizing process. Note, however, that if for some j, ξ_j is real (and positive), then the matrix $A - \xi_j I$ is negative definite. Therefore the Krylov approach does provide an error minimizing solution for that term in the expansion.

If one abandons the idea of using the Krylov approximation (5.2), the expansion in (5.1) suggests that one could use any available method for solving $(A - \xi_j I)d = v$ for each j. In particular, one could exploit the fact that $A - \xi_j I$ is normal and complex symmetric to devise an efficient minimum residual approach (cf. [28], [16, Theorem 3.4]) that would yield a termwise (with respect to the partial fraction expansion) optimal method for approximating $x_\star$. We refer to [35] for a discussion of a closely related approach from a polynomial point of view.

5.2. Residual and error in the Krylov approximation. We next provide a direct bound for the error of the Krylov approach in (5.2), defined as

$$e_m^K := \mathcal{R}_\nu(A)v - x_m^K = \sum_{j=1}^{\nu} \tau_j((A - \xi_j I)^{-1}v - V_m y_m^{(j)}). \tag{5.3}$$

We can also introduce the residual vector

$$r_m^K = \sum_{j=1}^{\nu} \tau_j(v - (A - \xi_j I)V_m y_m^{(j)}),$$

which is a linear combination of the ν residuals of the partial fraction expansion. It is remarkable that the error e_m^K and the residual r_m^K written in the expansion form are a fully algebraic representation of the error ϵ_m and of the generalized residual ρ_m defined using the Cauchy integral form in [26, section 6.3, p. 1566]; see also [22] where a similar connection is made. Denote with $r_m^{(j)}$ the residual of the jth term in the expansion. Since $r_m^{(i)} = v - (A - \xi_j I)V_m y_m^{(i)} = v - V_{m+1}H_{m+1,m}y_m^{(i)} = -v_{m+1}h_{m+1,m}e_m^* y_m^{(i)}$, we have

$$r_m^K = -v_{m+1}h_{m+1,m}\sum_{j=1}^{\nu} \tau_j e_m^* y_m^{(j)}, \qquad \text{with} \quad V_m^* r_m^K = 0, \tag{5.4}$$

and $e_m^K = -h_{m+1,m}\sum_{j=1}^{\nu}(A - \xi_j I)^{-1}v_{m+1}\tau_j e_m^* y_m^{(j)}$. Note that the Galerkin residual $r_m^G = \Phi_\nu(A)v - \Psi_\nu(A)x_m^G$ also satisfies $V_m^* r_m^G = 0$, however, r_m^G does not belong to the subspace generated by v_{m+1}.

The quantity $h_{m+1,m}|e_m^* y_m^K|$ is a well established a posteriori estimate of the error of the Krylov approximation [26, 41, 43]. As shown in (5.2), the Krylov approximation is given by $V_m y_m^K = \tau_0 V_m e_1 + V_m \sum_{j=1}^{\nu} \tau_j y_m^{(j)}$ so that $e_m^* y_m^K = \sum_{j=1}^{\nu} \tau_j e_m^* y_m^{(j)}$ for $m > 1$, and

$$h_{m+1,m}|e_m^* y_m^K| = \left| h_{m+1,m}\sum_{j=1}^{\nu} \tau_j e_m^* y_m^{(j)} \right| = \|r_m^K\|.$$

Hence, the a posteriori convergence estimate is precisely the norm of the residual r_m^K; see [7] for similar considerations.

We next bound the error of the Krylov approximation. We first need a lemma that bounds the error obtained when solving each system in the partial fraction expansion; see [29, formula (1.3)] for a qualitatively similar result.

LEMMA 5.2. *Let $M_j = A - \Re(\xi_j)I$, and let α_j, β_j be the largest and smallest eigenvalues of M_j in absolute value, respectively. Moreover, let $\widehat{\beta}_j = \beta_j$ if M_j is definite, which includes the case $\Im(\xi_j) = 0$, otherwise $\widehat{\beta}_j = 0$. Then, with the notation above, the error $e_m^{(j)} = (A - \xi_j I)^{-1}v - V_m(H_m - \xi_j I)^{-1}e_1$ satisfies*

$$\|e_m^{(j)}\| \le \widehat{\kappa}_j \|(A - \xi_j I)^{-1}v\| \frac{2}{\rho_j^m + 1/\rho_j^m},$$

where $\widehat{\kappa}_j = |\alpha_j - i\Im(\xi_j)|/|\widehat{\beta}_j - i\Im(\xi_j)|$ and ρ_j is the solution to the problem in (4.2).

Proof. The proof is inspired by that of [15, Theorem 4]. Let $d_\star = (A - \xi_j I)^{-1}v$, $d_m = V_m(H_m - \xi_j I)^{-1}e_1$, $e_m^{(j)} = d_\star - d_m$, $e_0^{(j)} = d_\star$, and $r_m = (A - \xi_j I)e_m^{(j)} = M_j e_m^{(j)} - i\Im(\xi_j)e_m^{(j)}$. In the following we will omit the superscript in the error, and we will use $\langle u, v\rangle = u^*v$. We have $\langle r_m, e_m\rangle = \langle M_j e_m, e_m\rangle - \langle i\Im(\xi_j)e_m, e_m\rangle$ so that

$$|\langle r_m, e_m\rangle|^2 = (\langle M_j e_m, e_m\rangle)^2 + \Im(\xi_j)^2(\langle e_m, e_m\rangle)^2 \ge (\widehat{\beta}_j^2 + \Im(\xi_j)^2)\|e_m\|^4.$$

We also have $\|r_m\|^2 = \|M_j e_m\|^2 + \Im(\xi_j)^2\|e_m\|^2 \le (\alpha_j^2 + \Im(\xi_j)^2)\|e_m\|^2$. Recalling that $r_m \perp K_m(M_j, v)$, for any $u \in K_m(M_j, v)$ we have

$$\begin{aligned} |\langle r_m, e_m\rangle|^2 &= |\langle r_m, d_\star - u\rangle|^2 \\ &\le \|r_m\|^2 \, \|d_\star - u\|^2 \le (\alpha_j^2 + \Im(\xi_j)^2)\|e_m\|^2 \, \|d_\star - u\|^2. \end{aligned}$$

Collecting all bounds, we obtain $(\widehat{\beta}_j^2 + \Im(\xi_j)^2)\|e_m\|^4 \le (\alpha_j^2 + \Im(\xi_j)^2)\|e_m\|^2 \, \|d_\star - u\|^2$, that is,

$$\|e_m\|^2 \le \frac{\alpha_j^2 + \Im(\xi_j)^2}{\widehat{\beta}_j^2 + \Im(\xi_j)^2} \, \|d_\star - u\|^2.$$

Since u is arbitrary, we take as u the solution to the problem

$$\min_{u \in K_m} \|d_\star - u\| = \min_{p \in \mathbb{P}_m, p(0)=1} \|p(A - \xi_j I)e_0\|.$$

Therefore, arguing as in the proof of Theorem 4.3, we have

$$\min_{p \in \mathbb{P}_m, p(0)=1} \|p(A - \xi_j I)e_0\| \le \|e_0\| \, \frac{2}{\rho_j^m + 1/\rho_j^m},$$

and the final result follows. ∎

In the lemma above, for ν odd, $M_j = A - \Re(\xi_j)I$ is negative definite for the real (positive) Padé pole, whereas in the case of the real (negative) Chebyshev pole, $M_j = -A - \Re(\xi_j)I$ is positive definite (we recall here the change of sign in the case of Chebyshev function). This ensures that the lemma holds for both Chebyshev and Padé rational functions. Moreover, for definite M_j, a sharper bound can be obtained; see Lemma 7.1.

THEOREM 5.3. *Assume the previous notation holds and that the poles ξ_j are distinct. Let $M_j = A - \Re(\xi_j)I$ and α_j, β_j be the largest and smallest eigenvalues of M_j in absolute value, respectively. Then, with the notation of Lemma* 5.2*,*

$$\|e_m^K\| \le 2\sum_{j=1}^{\nu} \left(|\tau_j|\widehat{\kappa}_j\|(A-\xi_j I)^{-1}v\|\right) \frac{1}{\rho_j^m + 1/\rho_j^m}.$$

Proof. Using the definition of e_m^K in (5.3) and its partial fraction representation, we have

$$\|e_m^K\| \le \sum_{j=1}^{\nu} |\tau_j|\|e_m^{(j)}\|, \qquad e_m^{(j)} = (M_j - i\Im(\xi_j)I)^{-1}v - V_m y_m^{(j)}. \tag{5.5}$$

From Lemma 5.2, it follows $\|e_m^{(j)}\| \le 2\widehat{\kappa}_j\|(A-\xi_j I)^{-1}v\|/(\rho_j^m + 1/\rho_j^m)$. Substituting in (5.5), the result follows. ∎

For $\widehat{\kappa}_j \approx 1$, we have

$$|\tau_j|\widehat{\kappa}_j\|(A-\xi_j I)^{-1}v\| \approx |\tau_j|\|(A-\xi_j I)^{-1}v\| \le \max_{\lambda\in[\alpha,\beta]} \frac{|\tau_j|}{|\lambda - \xi_j|},$$

where the last term is precisely the factor in the bound of the Galerkin approach; see Remark 4.4. The condition $\widehat{\kappa}_j \approx 1$ is met, for instance, when $[\alpha, \beta] \approx [-1, 0]$. Indeed, in this case, the poles in the partial fraction expansion are significantly larger in absolute value than the values in $[-1, 0]$ so that $\widehat{\kappa}_j = |(\alpha - \xi_j)/(\beta - \xi_j)| \approx |\xi_j|/|\xi_j| = 1$.

Roughly speaking, the result of Theorem 5.3 tells us that the convergence rate of the bound is driven by the convergence of the single systems $(A - \xi_j I)d = v$, $j = 1, \ldots, \nu$ with the FOM method. We also explicitly observe that the convergence rate of systems with matrix $A - \xi_j I$ is significantly different from that observed with A. This is due to the fact that the spectrum of $A - \xi_j I$ is in a complex line segment near ξ_j, sufficiently far away from the origin to ensure fast convergence. These observations should be compared to those in [24] and earlier literature, where the rate of convergence of iterative solvers for systems with A was observed to be an unsatisfactory tool for describing the convergence rate in the exponential approximation.

Finally, we have experimented with the bounds for the Krylov approximation as in Example 4.5, and numerical results almost identical to those of Figure 4.1 were obtained.

6. Some computational advantages of rational function approximation. The use of rational functions and their partial fraction expansion allows us to exploit and generalize known properties of Krylov subspace methods for the solution of algebraic linear systems. In particular, in this section we show that our formulation makes it easy to interpret recently proposed strategies.

As an immediate consequence of our formulation, in the following proposition we provide a bound for the components of the solution y_m^K. Analyzing the pattern of the solution components is of interest when using some recently developed preconditioning strategies [49]. In these promising techniques, the Krylov subspace with respect to the matrix $(I - \gamma A)^{-1}$ is generated for a conveniently chosen scalar γ. An approximation to $\exp(A)$ is then obtained in this rational space. Since $(I - \gamma A)^{-1}$ cannot be applied exactly, it is shown that the accuracy with which the inverse needs to be employed can be tied to the magnitude of the solution components in the generated Krylov subspace; we refer to [49, section 5] for a more comprehensive discussion.

PROPOSITION 6.1. *Assume the notation of the previous sections holds. Let* $x_m^K = V_m y_m^K$ *be the Krylov approximation to the exponential operator and assume that for* $k \le m$, *the matrix* $H_k - \xi_j I$ *is nonsingular for all poles* ξ_j, $j = 1, \dots, \nu$. *Then*

$$|e_k^* y_m^K| \le |e_k^* e_1 \tau_0| + \sum_{j=1}^{\nu} \frac{|\tau_j|}{\sigma_{\min}(H_m - \xi_j I)} \|r_{k-1}^{(j)}\|, \qquad k \le m,$$

where $\sigma_{\min}(H_m - \xi_j I)$ *is the smallest singular value of* $H_m - \xi_j I$, *and* $\|r_{k-1}^{(j)}\|$ *is the residual norm associated with the* j*th partial fraction expansion system in* $K_{k-1}(A, v)$.

Proof. Using the partial fraction expansion of $\mathcal{R}_\nu(H_m)$ we have

$$y_m^K = \tau_0 e_1 + \sum_{j=1}^{\nu} \tau_j (H_m - \xi_j I)^{-1} e_1 = \tau_0 e_1 + \sum_{j=1}^{\nu} \tau_j y_m^{(j)}, \tag{6.1}$$

from which

$$e_k^* y_m^K = e_k^* e_1 \tau_0 + \sum_{j=1}^{\nu} \tau_j e_k^* y_m^{(j)}. \tag{6.2}$$

It was shown in [46, Lemma 5.2] that if the matrix $H_k - \xi_j I$ is nonsingular for all $k = 1, \dots, m$ so that the residuals $r_{k-1}^{(j)}$ are well defined, then

$$|e_k^* y_m^{(j)}| \le |e_k^* e_1 \tau_0| + \frac{1}{\sigma_{\min}(H_m - \xi_j I)} \|r_{k-1}^{(j)}\|.$$

Substituting in (6.2), the result follows. ∎

The result of Proposition 6.1 shows that the components of y_m^K approximately decrease with the residuals of the shifted systems in the expansion. This fact can be exploited to rigorously show that the preconditioning technique proposed in [49] can be successfully implemented with an *inexact* application of $(I - \gamma A)^{-1}$ and a *relaxed* tolerance [40].

If convergence is not fast, a problem encountered with Krylov subspace approximation is that the maximum allowed approximation space dimension is limited by memory restrictions, and thus some form of restarting must be devised. We next show that our rational function framework provides a simple though effective way to describe a recently proposed restarting strategy. Once the vector $x_m^K = \tau_0 v + \sum_{j=1}^{\nu} V_m y_m^{(j)}$ is determined, a new approximation space can be obtained as $K_m(A, v_{m+1})$ with $v_{m+1} = V_{m+1} e_{m+1}$ and associated matrix $V_m^{(1)}$ so that the approximation can be updated as

$$x_m^K = \left(\tau_0 v + \sum_{j=1}^{\nu} V_m y_m^{(j)} \right) + \sum_{j=1}^{\nu} V_m^{(1)} (y_m^{(j)})^{(1)}, \tag{6.3}$$

with obvious notation for $(y_m^{(j)})^{(1)}$. We rewrite (6.3) as $x_m^K = \tau_0 v + \sum_{j=1}^{\nu} (V_m y_m^{(j)} + V_m^{(1)} (y_m^{(j)})^{(1)})$. Recalling that this approach approximates $\tau_0 v + \sum_{j=1}^{\nu} (A - \xi_j I)^{-1} v$, this relation shows that each term in the expansion formula is nothing but the approximate solution obtained by restarted FOM applied to each shifted system separately. This last statement can be verified by recalling that all system residuals $r_m^{(j)}$ are collinear

with v_{m+1} (cf. (5.4)) so that the method can be restarted with the same approximation space for all systems [45]. Further use of the properties of the restarted FOM method, see, e.g., [44], shows that this restarting procedure corresponds to Algorithm 2 in [14] when used with rational functions; see also [27] for more results on the derivation of the restarted approximation method.

Finally, appropriate Krylov subspace approaches and rational function approximations can be used to preserve geometric properties of the exponential of skew-symmetric matrices; this is the subject of current investigation [30].

7. The role of $\|A\|$ in the Padé approximation. In the previous sections we assumed that $\|A\|$ was not much greater than unit. For the case of Chebyshev rational functions, this is an unnecessary constraint, as good approximations to e^{-x} can be obtained for $x \in [0, +\infty)$; see, e.g., [8]. In the right plot of Figure 7.1 we report the convergence curve and its bound for the Krylov approximation using Chebyshev rational functions with $\nu = 14$ for the matrix in Example 7.3. In the plot, the ideal bound (2.1) is also reported.

Padé rational function approximation is effective for $\|A\|$ close to the origin. Otherwise, a procedure called scaling and squaring is commonly employed in conjunction with Padé functions that allows one to compute an approximation to the exponential of a conveniently scaled matrix; see, e.g., [21]. The procedure amounts to finding the smallest integer $s \geq 0$ such that $\|A\|_\infty/2^s$ is less than a prescribed value, a common value being $1/2$. Recent work by Higham has shown that this latter value can be significantly relaxed, depending on the rational function degree used in the approximation [23]. For the sake of simplicity, here we limit ourselves to the case $\|A\|_\infty 2^{-s} \leq \frac{1}{2}$. Setting $\widetilde{A} = A/2^s$, the scaling and squaring method produces the matrix $B = (\mathcal{R}_\nu(\widetilde{A}))^{-1}$ so that the sought after approximation is obtained as $\exp(A) \approx B^{2^s}$, where the operation is performed by repeated squaring of B. Within the Krylov approximation (1.2), scaling and squaring can be conveniently performed at each step m as $\exp(H_m)e_1 \approx (\mathcal{R}_\nu(H_m/2^s))^{2^s} e_1$, where s may vary with m [43].

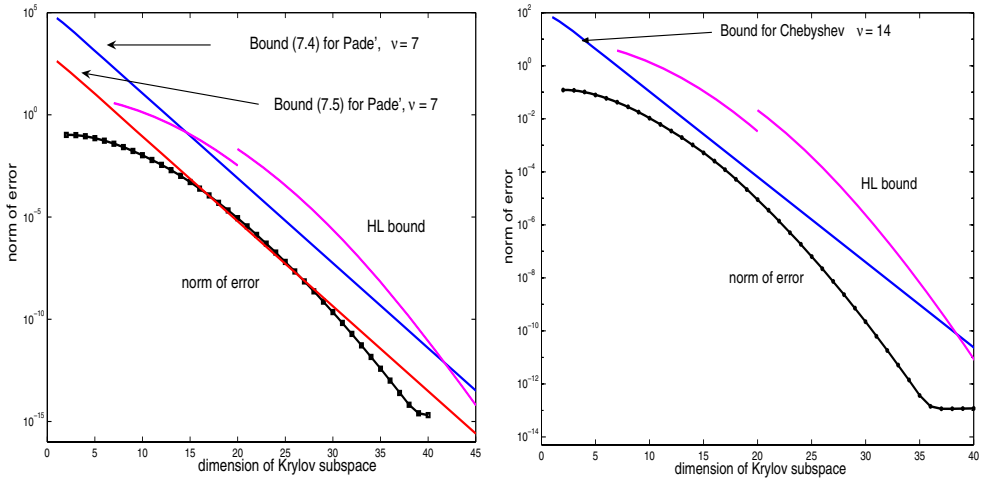

FIG. 7.1. *Example 7.3 with $\|A\| \gg 1$, Krylov approximation. Left. Padé rational function with scaling and squaring: convergence curve and upper bound for $\nu = 7$, and ideal bound. Right. Chebyshev rational function: convergence curve and upper bound for $\nu = 14$, and ideal bound.*

We next show that this corrected scheme can be included in our theoretical analysis. Let $s \geq 0$ be the smallest integer such that $\widetilde{A} := A/2^s$ satisfies $\|\widetilde{A}\| \leq 1/2$. The construction of the Krylov subspace $K_m(\widetilde{A}, v)$ corresponds to scaling H_m in (1.1) by the quantity 2^s, independent of m but dependent on $\|A\|$. Since $\|H_m\| \leq \|A\|$ for all $m \geq 0$, this approach is more conservative than the one that scales H_m by a different quantity at each iteration. We then approximate $\exp(A)v$ as

$$\exp(A)v \approx \left(\mathcal{R}_\nu(\widetilde{A})\right)^{2^s} v \approx V_m \left(\mathcal{R}_\nu(\widetilde{H}_m)\right)^{2^s} e_1 \equiv V_m y_m^K.$$

In the scaling and squaring method, the Padé approximant has poles of multiplicity 2^s so that the partial fraction expansion is given by

$$\mathcal{R}_\nu(\zeta)^{2^s} = \widetilde{\tau}_0 + \sum_{j=1}^{\nu} \sum_{\ell=1}^{2^s} \frac{\widetilde{\tau}_{j,\ell}}{(\zeta - \xi_j)^\ell}, \tag{7.1}$$

where $\xi_1, \ldots, \xi_\nu$ are the roots of Ψ_ν and

$$\widetilde{\tau}_{j,\ell} = \frac{1}{(\ell-1)!} \frac{d^{\ell-1}}{(d\zeta)^{\ell-1}} \frac{(\zeta - \xi_j)^{2^s} \Phi_\nu(\zeta)^{2^s}}{\Psi_\nu(\zeta)^{2^s}} \bigg|_{\zeta=\xi_j}.$$

Therefore, we can write

$$\left(\mathcal{R}_\nu(\widetilde{A})\right)^{2^s} v = \widetilde{\tau}_0 v + \sum_{j=1}^{\nu} \sum_{\ell=1}^{2^s} \widetilde{\tau}_{j,\ell} (\widetilde{A} - \xi_j I)^{-\ell} v.$$

Because of the multiple poles, the computation of $\widetilde{\tau}_{j,\ell}$ may be very ill conditioned, therefore, we do not advocate implementing this procedure. Instead, it provides a way to theoretically justify this computational strategy within our polynomial framework. Once again, setting $x_\star = \mathcal{R}_\nu(\widetilde{A})^{2^s} v$, we use the bound

$$\|\exp(A)v - V_m y_m^K\| \leq \|\exp(A)v - x_\star\| + \|x_\star - V_m y_m^K\|,$$

in which the magnitude of the first term depends on the accuracy of the rational approximation, whereas only the second term depends on the accuracy in the Krylov subspace. By approximating each inverse power in the Krylov subspace, we have

$$\begin{aligned} x_\star &= \widetilde{\tau}_0 v + \sum_{j=1}^{\nu} \sum_{\ell=1}^{2^s} \widetilde{\tau}_{j,\ell} (\widetilde{A} - \xi_j I)^{-\ell} v \\ &\approx \widetilde{\tau}_0 v + \sum_{j=1}^{\nu} \sum_{\ell=1}^{2^s} \widetilde{\tau}_{j,\ell} V_m (\widetilde{H}_m - \xi_j)^{-\ell} e_1 = V_m \left(\mathcal{R}_\nu(\widetilde{H}_m)\right)^{2^s} e_1. \end{aligned}$$

In spite of the presence of multiple poles, we next show that the error can be bounded similarly to what we did for the simple poles. In fact, the bound for the error in practice is not influenced by the presence of the scaling and squaring method.

We first derive a bound for the errors in the partial fraction expansion, which holds for symmetric and definite matrices.

LEMMA 7.1. *Let $M_j = A - \Re(\xi_j) I$ be a symmetric definite matrix, and let α_j, β_j be the largest and smallest eigenvalues of M_j in absolute value, respectively,*

so that $\kappa_j = \alpha_j/\beta_j > 0$ *is the condition number of* M_j. *Then, the error* $e_m^{(j)} = (A-\xi_j I)^{-1}v - V_m(H_m-\xi_j I)^{-1}e_1$ *satisfies*

$$\|e_m^{(j)}\| \le \kappa_j^{\frac{1}{2}}\eta_j\|(A-\xi_j I)^{-1}v\|\frac{2}{\rho_j^m + 1/\rho_j^m},$$

where $\eta_j = \left(1+\frac{\Im(\xi_j)^2(\kappa_j-1)^2}{4\kappa_j\Im(\xi_j)^2+\alpha_j^2(\kappa_j+1)^2}\right)^{\frac{1}{2}}$, *and* ρ_j *is the solution to the problem in* (4.2).

Proof. We assume that M_j is positive definite, otherwise we can work with $-M_j$. For each $j = 1,\dots,\nu$, $y_m^{(j)}$ is computed by imposing a Galerkin condition on the corresponding residual $v-(M_j - i\Im(\xi_j)I)V_m y_m^{(j)}$. It was shown in [15, Theorem 4] that if M_j is definite, then

$$\|e_m^{(j)}\|_{M_j} \le 2\frac{\eta_j}{\rho_j^m + \frac{1}{\rho_j^m}}\|e_0^{(j)}\|_{M_j}.$$

Then $\|e_m^{(j)}\| \le \|M_j^{-1/2}\|\|e_m^{(j)}\|_{M_j}$, $\|e_0^{(j)}\|_{M_j} \le \|M_j^{1/2}\|\|e_0^{(j)}\|$, where $\|M_j^{1/2}\|$ denotes the norm of $M_j^{1/2}$, induced by the vector 2-norm, and $\|e_0^{(j)}\| = \|(A-\xi_j I)^{-1}v\|$. ∎

The bound of Lemma 7.1 is analogous to that in Lemma 5.2 for $\widehat{\kappa}_j \approx 1$, which is the case when $\|A\| \le 1$. The new bound of Lemma 7.1 provides a sharper estimate for $\|A\| > 1$ and M_j definite; therefore it can be used with Padé rational functions.

THEOREM 7.2. *With the notation and definitions of Lemma* 7.1, *let* ξ_j, $j = 1,\dots,\nu$ *be the roots of* $\Psi_\nu(\lambda)$. *Assume that the eigenvalues of* A *are contained in* $[\alpha,\beta]$, *and that* $\frac{1}{2^s}\frac{|\lambda|}{|\xi_j|} \ll 1$ *for* $\lambda \in [\alpha,\beta]$. *Let* $x_\star = \left(\mathcal{R}_\nu(\widetilde{A})\right)^{2^s} v$ *and* $y_m^K = \left(\mathcal{R}_\nu(\widetilde{H}_m)\right)^{2^s} e_1$. *Finally, for* $j = 1,\dots,\nu$, *let*

$$\widehat{\tau}_j := \max_{\ell=1,\dots,2^s}\frac{|\widetilde{\tau}_{j,\ell}|}{|(-\xi_j)^{\ell-1}|}.$$

Then,

$$\|x_\star - V_m y_m^K\| \lesssim 2^{s+1}\sum_{j=1}^{\nu}|\widehat{\tau}_j|\kappa_j^{\frac{1}{2}}\frac{\eta_j}{\rho_j^m+\frac{1}{\rho_j^m}}\|(A-\xi_j I)^{-1}\|,$$

where $\lesssim$ *means that higher order terms are omitted.*

Note that the bound is in terms of A and not of its scaled counterpart $\widetilde{A}$.

Proof. Recalling (7.1), we have

$$\begin{aligned} R_{2^s}(\lambda) := \left(\mathcal{R}_\nu(\frac{\lambda}{2^s})\right)^{2^s} &= \widetilde{\tau}_0 + \sum_{j=1}^{\nu}\sum_{\ell=1}^{2^s}\frac{\widetilde{\tau}_{j,\ell}}{(\frac{\lambda}{2^s}-\xi_j)^\ell} \\ &= \widetilde{\tau}_0 + \sum_{j=1}^{\nu}\sum_{\ell=1}^{2^s}\frac{\widetilde{\tau}_{j,\ell}}{\xi_j^\ell(\frac{\lambda}{2^s\xi_j}-1)^\ell}. \end{aligned}$$

For $\frac{|\lambda|}{2^s|\xi_j|} \ll 1$, we have $(\frac{\lambda}{2^s\xi_j}-1)^\ell \approx (-1)^\ell(\frac{\ell}{2^s\xi_j}\lambda - 1)$ so that

$$R_{2^s}(\lambda) \approx \widetilde{\tau}_0 + \sum_{j=1}^{\nu}\sum_{\ell=1}^{2^s}\frac{\widetilde{\tau}_{j,\ell}}{(-\xi_j)^\ell(\frac{\ell\lambda}{2^s\xi_j}-1)} = \widetilde{\tau}_0 - \sum_{j=1}^{\nu}\sum_{\ell=1}^{2^s}\frac{\widetilde{\tau}_{j,\ell}}{(-\xi_j)^{\ell-1}(\frac{\ell}{2^s}\lambda-\xi_j)}.$$

Let $\omega_{j,\ell} := \widetilde{\tau}_{j,\ell}/(-\xi_j)^{\ell-1}$. Then,

$$\begin{aligned}\|x_\star - V_m y_m^K\| &= \|R_{2^s}(A)v - V_m R_{2^s}(H_m)e_1\| \\ &\approx \left\| \sum_{j=1}^{\nu}\sum_{\ell=1}^{2^s} \omega_{j,\ell} \left(\left(\frac{\ell}{2^s}A - \xi_j I\right)^{-1} v - V_m \left(\frac{\ell}{2^s}H_m - \xi_j I\right)^{-1} e_1 \right) \right\| \\ &\le \sum_{j=1}^{\nu}\sum_{\ell=1}^{2^s} |\omega_{j,\ell}| \|\epsilon_{j,\ell}\|,\end{aligned}$$

where $\epsilon_{j,\ell} = (\frac{\ell_j}{2^s}A - \xi_j I)^{-1}v - V_m(\frac{\ell_j}{2^s}H_m - \xi_j I)^{-1}e_1$. Note that the approximation above is ensured to hold for H_m because the eigenvalues of $H_m = V_m^T A V_m$ are also contained in $[\alpha, \beta]$ so that $\frac{|\theta|}{2^s|\xi_j|} \ll 1$ for any eigenvalue θ of H_m. Using Lemma 7.1 and appropriately modifying the notation, we have

$$\|\epsilon_{j,\ell}\| \le 2\left(\kappa\left(\frac{\ell}{2^s}A - \Re(\xi_j)I\right)\right)^{\frac{1}{2}} \frac{\eta_{j,\ell}}{\rho_{j,\ell}^m + \frac{1}{\rho_{j,\ell}^m}} \left\| \left(\frac{\ell}{2^s}A - \xi_j I\right)^{-1} v \right\|.$$

Since $\ell/2^s \le 1$ for $\ell \in \{1, \dots, 2^s\}$, we have $\|(\ell_j/2^s A - \xi_j I)^{-1}\| \le \|(A - \xi_j I)^{-1}\|$ and

$$\kappa\left(\frac{\ell_j}{2^s}A - \Re(\xi_j)I\right)\eta_{j,\ell}^2 \le \kappa(A - \Re(\xi_j)I))\eta_{j,2^s}^2 \equiv \kappa_j \eta_j^2; \tag{7.2}$$

see the appendix for a proof of this inequality. From the definition of $\rho_{j,\ell}$, it follows that

$$\begin{aligned}\frac{|\frac{\ell}{2^s}\alpha - \Re(\xi_j) - i\Im(\xi_j)| + |\frac{\ell}{2^s}\beta - \Re(\xi_j) - i\Im(\xi_j)|}{\frac{\ell}{2^s}|\alpha - \beta|} &= \frac{|\alpha - \frac{2^s}{\ell}\xi_j| + |\beta - \frac{2^s}{\ell}\xi_j|}{|\alpha - \beta|} \\ &\ge \frac{|\alpha - \xi_j| + |\beta - \xi_j|}{|\alpha - \beta|},\end{aligned}$$

from which it follows that $\rho_{j,\ell} \ge \rho_{j,2^s} > 1$, and because of monotonicity, we obtain

$$\frac{1}{\rho_{j,\ell}^m + \frac{1}{\rho_{j,\ell}^m}} \le \frac{1}{\rho_{j,2^s}^m + \frac{1}{\rho_{j,2^s}^m}}.$$

Since $\rho_{j,2^s}$ corresponds to the convergence with $(A - \xi_j I)$, we can set $\rho_{j,2^s} = \rho_j$. Collecting all bounds, we obtain

$$\|\epsilon_{j,\ell}\| \le 2\kappa_j^{\frac{1}{2}} \frac{\eta_j}{\rho_j^m + \frac{1}{\rho_j^m}} \|(A - \xi_j I)^{-1}\|.$$

Since $|\omega_{j,\ell}| \le |\widehat{\tau}_j|$, we finally have

$$\begin{aligned}\sum_{j=1}^{\nu}\sum_{\ell=1}^{2^s} |\omega_{j,\ell}|\|\epsilon_{j,\ell}\| &\le 2\sum_{j=1}^{\nu}\sum_{\ell=1}^{2^s} |\widehat{\tau}_j|\kappa_j^{\frac{1}{2}} \frac{\eta_j}{\rho_j^m + \frac{1}{\rho_j^m}} \|(A - \xi_j I)^{-1}\| \\ &\le 2 \cdot 2^s \sum_{j=1}^{\nu} |\widehat{\tau}_j|\kappa_j^{\frac{1}{2}} \frac{\eta_j}{\rho_j^m + \frac{1}{\rho_j^m}} \|(A - \xi_j I)^{-1}\|. \qquad \square\end{aligned}$$

A few remarks are in order. We first notice that the bound in Theorem 7.2 fully mimics the bound in Theorem 5.3. The only relevant difference is the presence of

the additional scaling factor 2^s. The two bounds also differ for the terms $\widehat{\tau}_j$. In our experiments, however, replacing $\widehat{\tau}_j$ with τ_j did not seem to affect the approximation.

Although the approximation $V_m y_m^K$ with Padé does require scaling and squaring, the convergence rate does not seem to depend on it. The proof suggests that one could use the following estimate:

$$\|x_\star - V_m y_m^K\| \approx \|\mathcal{R}_\nu(A)v - V_m \mathcal{R}_\nu(H_m)e_1\|, \tag{7.3}$$

where, however, for $\|A\| \gg 1$, neither $\mathcal{R}_\nu(A)v$ is a good approximation to $x_\star$, nor $V_m\mathcal{R}_\nu(H_m)e_1$ is a good approximation of $V_m y_m^K$.

Example 7.3. We consider the 1001×1001 diagonal matrix A in [24] with entries uniformly distributed in $[-40, 0]$ and the random vector v with uniformly distributed values in $[0, 1]$ (Matlab function `rand`) and unit norm. In Figure 7.1 we report the convergence of the error norm for the Krylov method, together with the ideal bound (2.1) from [24] (referred to as HL bound). In the plot, we also report the following estimate, derived from Theorem 7.2 by replacing $\widehat{\tau}_j$ with τ_j, the latter being the coefficients in the partial fraction expansion of $\mathcal{R}_\nu(\lambda)$,

$$\|x_\star - V_m y_m^K\| \lesssim 2^{s+1} \sum_{j=1}^{\nu} |\tau_j| \frac{\kappa_j}{\rho_j^m + \frac{1}{\rho_j^m}} \|(A - \xi_j I)^{-1}\|, \tag{7.4}$$

$$\|x_\star - V_m y_m^K\| \lesssim 2 \sum_{j=1}^{\nu} |\tau_j| \frac{\kappa_j}{\rho_j^m + \frac{1}{\rho_j^m}} \|(A - \xi_j I)^{-1}\|. \tag{7.5}$$

The new bound for the error norm does not significantly differ from those observed in previous sections, although in this case the actual Padé approximation is performed with scaling and squaring. In other words, convergence seems to be only driven by the spectral properties of the matrix, as stressed by the bound on the convergence rate that is based on polynomial estimates of the shifted spectrum of A.

8. Recovering superlinear convergence. Our bounds for both Galerkin and Krylov approximations with rational functions of degree ν predict *linear* convergence as the Krylov subspace dimension m increases. The superlinear convergence expressed, say, in the first bound of Theorem 2.1, can be recovered as a function of the degree of the rational function. To explain this approach, we first recall that the bounds in Theorem 2.1 were determined in two steps in [24, Theorem 2]. In the first step, the error is bounded by means of the Cauchy integral on a curve Γ, which is the boundary of a piecewise smooth bounded region containing the numerical range of A. The second step amounts to conveniently choosing Γ so as to appropriately bound the Cauchy integral. In particular, the selected curve is a parabola whose right-most point turns out to be equal to $\gamma = m^2/(4\rho)$ in the notation of Theorem 2.1 (cf. [24, pp. 1916-1917]). Therefore, the chosen curve moves away from the spectrum with m^2 as the Krylov subspace dimension m increases.

The partial fraction expansion of $\mathcal{R}_\nu$ may be viewed as a way to approximate the Cauchy integral representation of $\exp(\lambda)$ for a fixed integration curve passing through the expansion poles. It is known that in both cases of Padé and Chebyshev approximations $\mathcal{R}_\nu$, the values ξ_j increase as ν grows. Therefore, a larger degree ν corresponds to selecting a curve Γ that is farther away from the spectrum. In other words, we expect better approximation of the bounds with small ν at an early convergence stage, whereas larger ν are required to appropriately bound the convergence curve as the dimension of the Krylov subspace increases. For the Chebyshev approximation, superlinear convergence as ν increases may be observed in the right plot of

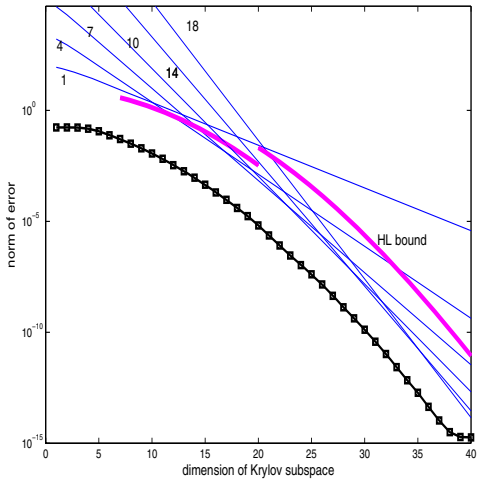

FIG. 8.1. *Example* 7.3*: Krylov approximation with Padé rational function; bound in* (7.4) *for* $\nu = 1, 4, 7, 10, 14, 18$. *The ideal bounds of Theorem 2.1 are also reported (labeled "HL bound").*

Figure 4.1, where the straight line for $\nu = 7$ better represents the early convergence stage, whereas the line for $\nu = 14$ sharply bounds the convergence curve for larger m.

In the case of Padé approximation, this behavior can be better formalized, yielding a relation between the approximation degree and the dimension of the Krylov subspace. Using [1, Theorem 5.7.3], we know that the poles of the Padé approximant $\mathcal{R}_\nu$ of degree ν are located in the complex annulus[2]

$$2 \cdot 0.27\nu \le |z| \le 2\nu + \frac{4}{3}.$$

Therefore, if we wish to employ poles on a curve that intersects the positive real semi-axis close to the "optimal value" $m^2/(4\rho)$, we require that ν satisfies $2 \cdot 0.27\nu \le \frac{m^2}{4\rho} \le 2\nu + \frac{4}{3}$, that is,

$$\frac{m^2}{8\rho} - \frac{2}{3} \le \nu \le \frac{1}{0.27}\frac{m^2}{8\rho}. \tag{8.1}$$

Hence, if the degree ν is chosen within the bounds above, we expect that the Padé rational function approximates the Cauchy integral on a quasi-optimal curve, with respect to m, in the sense of [24]. For instance, below are the values of ν satisfying the lower bound in (8.1) for $m \in \{1, \ldots, 40\}$ and $\rho = 10$.

m	4	8	12	16	20	24	28	32	36	40
ν	0	1	2	3	5	7	10	13	16	20

The fidelity of this correspondence can be fully appreciated in Figure 8.1 for the data in Example 7.3. Reported are the actual error curve (solid with squares), and the ideal bounds of Theorem 2.1. We also display the upper bounds in (7.4) for

[2]It is also possible to detect a parabolic region that is pole-free; see [1, Theorem 5.7.4]. This would more closely mimic the choice of the curve Γ in [24]. However, for the sake of simplicity we limit our presentation to this more intuitive case.

the Padé approximation with ρ_j associated with the poles for $\nu = 1, 4, 7, 10, 14, 18$. Remarkably, the envelope of the reported straight lines completely reproduces the true convergence history, while the single lines well represent the local convergence behavior at the corresponding subspace dimension m (e.g., the line for $\nu = 7$ well approximates the convergence slope around iteration $m = 24$).

Finally, we stress that all reported bounds, including the ideal bounds, only depend on the spectral interval of the given matrix, and not on the location of the eigenvalues within this interval. Particular eigenvalue distributions may cause severe overestimations of the true convergence behavior; see, e.g., [10, section 3.2].

9. Conclusions and outlook. We have proposed a new analysis of Krylov subspace methods for approximating the action of matrix rational functions with specific application to the matrix exponential operator. We have shown a minimization property of one of the methods, we have provided new upper bounds for the approximation error by using partial fraction expansion, and we have theoretically justified some computational strategies.

Our analysis may be generalized to cases in which the rational function employed to approximate the exponential is different from the widely used Padé or Chebyshev, as in [38, 3]. Among these generalizations, the case of polynomial approximation of the exponential is particularly appealing for its simplicity; see, e.g., [11]. We also refer to [14, 35] for examples of polynomial interpolation at points different from the eigenvalues of H_m. Without great differences, one could extend our results to the case of *restricted denominator* (RD) rational forms, which are rational functions $R_{j,k} = \frac{q_j(x)}{(1+\rho x)^k}$, where $\rho \in \mathbb{R}$ and q_j is a polynomial of degree not greater than j. Such RD-rational forms have been introduced in [37] and were recently used to approximate the exponential of a matrix in [34]. Our theoretical results may provide some insight into the selection of the parameters involved in the definition of the RD-rational form.

Some of our results may be naturally extended to the case of non-Hermitian A, although optimality results of the Galerkin method do not carry over. Finally, the techniques and the analysis used in this paper could be adapted to the numerical approximation of other analytic functions in the Krylov subspace, such as $A^{\frac{1}{2}}$; see [13, 53] and references therein.

Appendix. We prove inequality (7.2) in the proof of Theorem 7.2.

Proof. Let $\xi_j = \xi_R + i\xi_I$ and $\kappa_{j,\ell} = \kappa(\frac{\ell}{2^s}A - \xi_j I)$. We have

$$\kappa_{j,\ell}\eta_{j,\ell}^2 = \kappa_{j,\ell} + \kappa_{j,\ell}\frac{\xi_I^2(\kappa_{j,\ell}-1)^2}{4\kappa_{j,\ell}\xi_I^2 + \left(\frac{\ell}{2^s}\alpha - \xi_R\right)(\kappa_{j,\ell}+1)^2}.$$

Let $\chi = \ell/2^s$ and $\kappa_{j,\ell} = (\chi\alpha - \xi_R)/(\chi\beta - \xi_R) =: f(\chi)$. Since $\alpha < \beta < 0$ and $\xi_R > 0$, we have $f'(\chi) = \xi_R(-\alpha+\beta)/(\chi\beta - \xi_R)^2 > 0$, that is, f is a monotonically increasing function so that $\kappa_{j,\ell} = f(\chi) \le f(1) = \kappa_{j,2^s}$ for $\chi \in (0, 1]$. With analogous reasoning, we have that $\sqrt{f(\chi)} + 1/\sqrt{f(\chi)} \ge \sqrt{f(1)} + 1/\sqrt{f(1)}$ and that $(\chi\alpha - \xi_R) \ge (\alpha - \xi_R)$ for $\chi \in (0, 1]$. Therefore,

$$\begin{aligned}\kappa_{j,\ell}\eta_{j,\ell}^2 &= \kappa_{j,\ell} + \kappa_{j,\ell}\frac{\xi_I^2(\kappa_{j,\ell}-1)^2}{\kappa_{j,\ell}\left(4\xi_I^2 + \left(\frac{\ell}{2^s}\alpha - \xi_R\right)\left(\sqrt{\kappa_{j,\ell}} + \frac{1}{\sqrt{\kappa_{j,\ell}}}\right)^2\right)} \\ &\le \kappa_{j,2^s} + \frac{\xi_I^2(\kappa_{j,2^s}-1)^2}{4\xi_I^2 + (\alpha - \xi_R)\left(\sqrt{\kappa_{j,2^s}} + \frac{1}{\sqrt{\kappa_{j,2^s}}}\right)^2} = \kappa_j\eta_j^2. \qquad \square\end{aligned}$$

Acknowledgments. We thank Oliver Ernst for making some early notes of [14] available, and Leonid Knizhnerman, whose comments helped improve the presentation of this paper and also led to the development of section 8. We also acknowledge insightful conversations with Marlis Hochbruck.

TWO FINITE ELEMENT APPROXIMATIONS OF NAGHDI'S SHELL MODEL IN CARTESIAN COORDINATES*

ADEL BLOUZA†, FRÉDÉRIC HECHT‡, AND HERVÉ LE DRET‡

Abstract. We present a penalized version of Naghdi's model and a mixed formulation of the same model, in Cartesian coordinates for linearly elastic shells with little regularity, and finite element approximations thereof. Numerical tests are given that validate and illustrate our approach.

Key words. Naghdi's shell model, finite element approximation, penalty method, mixed formulation

1. Introduction. The purpose of this work is to approximate the solution of a formulation of Naghdi's shell model in Cartesian coordinates that is appropriate for linearly elastic shells that present curvature discontinuities. Our intent is to use finite elements of class C^0 and implement the approximation scheme as simply as possible using the general purpose, open source, two-dimensional finite element package FreeFem++ (http://www.freefem.org).

The formulation of Naghdi's model used here was introduced in Blouza [5] and Blouza and Le Dret [7]. This formulation is based on the idea of using a local basis-free formulation in which the unknowns are described in Cartesian coordinates instead of with covariant or contravariant components as is usually done in shell theory; see, for example, [4]. This formulation is able to accommodate shells with a $W^{2,\infty}$-midsurface, thus allowing for curvature discontinuities, as opposed to C^3 in the classical formalism, and makes for much simpler expressions. Although it was proven to be well-posed and to be the natural limit of the classical formulation when a sequence of regular midsurfaces converges to a $W^{2,\infty}$-midsurface in [7], the new formulation has not been used in a numerical setting to the best of our knowledge.

The literature on finite element approximation of two-dimensional shell models is huge. Let us just mention a few different approaches. Concerning conforming methods, the Ganev and Argyris triangles provide P_4 and P_5 interpolation with high order convergence in $O(h^4)$ when the solution is smooth enough. These elements were used, for example, to study the linear Koiter model for a C^3-shell in the classical covariant formulation; see [3]. This method was applied to approximate geometrically exact shell models in [10]. The Argyris element was also used in [15] for the numerical analysis of Koiter's model for shells with little regularity in the Cartesian formulation proposed in [6]. Let us also mention the three-dimensional shell element approach; see [11].

Still in the context of shells with little regularity, a nonconforming DKT element was used in [16] to approximate a Koiter model similar to the one introduced in [6].

This article is organized as follows. We first briefly recall the geometry of the midsurface and Naghdi shell formulation given in [5] and [7]. This formulation involves the infinitesimal rotation vector, a vector unknown that is tangent to the midsurface. Such tangency cannot be implemented in a conforming way in finite element spaces (a problem that does not occur in the classical covariant formulation).

Therefore, in section 3, we introduce a penalized version of Naghdi's model intended to approximate the above mentioned tangency. We prove the existence and uniqueness of the solution of the penalized model and establish its convergence to the solution of the original Naghdi problem when the penalization parameter tends to 0.

In section 4, we present a mixed formulation of Naghdi's model in which the tangency condition is enforced by a Lagrange multiplier. We prove that the inf-sup condition is satisfied and that the mixed problem is well-posed and solves the original Naghdi problem.

Section 5 is devoted to the finite element discretization of both formulations. The numerical analysis of the penalized version is rather standard. On the contrary, the discrete inf-sup condition for the mixed formulation does not follow from usual arguments, in the sense of those found in the discussion of approximations of the Stokes problem for instance.

Finally, we present a few numerical tests in section 6. The method was implemented in FreeFem++, a high level, free software package that manages mesh generation and adaption, matrix assembly, and linear system resolution automatically and generally uses as input the resolution domain, boundary conditions, and bilinear and linear forms. In addition to the resolution domain, boundary conditions, and applied loads, the only specific input required from the user by our code is the definition of the covariant vectors and of the partial derivatives of the normal vector. All the other geometrical and mechanical quantities, including the bilinear form, are code-generated. We present results for the standard hyperbolic paraboloid benchmark and for the planar-cylindrical $W^{2,\infty}$ shell considered in [15]. We also show results for a $W^{2,\infty}$ roof constructed on a basket-handle arch profile.

2. Notation. Greek indices and exponents take their values in the set $\{1, 2\}$ and Latin indices and exponents take their values in the set $\{1, 2, 3\}$. Unless otherwise specified, the summation convention for indices and exponents is assumed.

Let (e_1, e_2, e_3) be the canonical orthonormal basis of the Euclidean space $\mathbb{R}^3$. We note $u \cdot v$ the inner product of $\mathbb{R}^3$, $|u| = \sqrt{u \cdot u}$ the associated Euclidean norm and $u \wedge v$ the vector product of u and v.

Let ω be a domain of $\mathbb{R}^2$. We consider a shell whose midsurface is given by $S = \varphi(\bar{\omega})$, where $\varphi \in W^{2,\infty}(\omega; \mathbb{R}^3)$ is one-to-one mapping such that the two vectors

$$a_\alpha = \partial_\alpha \varphi$$

are linearly independent at each point $x \in \bar{\omega}$. We let

$$a_3 = \frac{a_1 \wedge a_2}{|a_1 \wedge a_2|}$$

be the unit normal vector on the midsurface at point $\varphi(x)$. The vectors a_i define the local covariant basis at point $\varphi(x)$. The contravariant basis a^i is defined by the relations $a_i \cdot a^j = \delta_i^j$, where δ_i^j is the Kronecker symbol. In particular $a_3(x) = a^3(x)$. Note that all these vectors are of class $W^{1,\infty}$. We let $a(x) = |a_1(x) \wedge a_2(x)|^2$ so that $\sqrt{a(x)}$ is the area element of the midsurface in the chart φ.

The first fundamental form of the surface is given in covariant components by

$$a_{\alpha\beta} = a_\alpha \cdot a_\beta.$$

Let $u \in H^1(\omega;\mathbb{R}^3)$ be a midsurface displacement and $r \in H^1(\omega;\mathbb{R}^3)$ a rotation of the normal vector (which is related to the actual infinitesimal rotation vector; see formula (15) below), i.e., H^1-regular mappings from ω into $\mathbb{R}^3$ such that r is tangent to the midsurface, given in covariant and Cartesian components by

$$u(x) = u_i(x)a^i(x) = u_i^c(x)e_i, \text{ where } u_i = u \cdot a_i \text{ and } u_i^c = u \cdot e_i,$$

and

$$r(x) = r_\alpha(x)a^\alpha(x) = r_i^c(x)e_i \text{ with the same meaning.}$$

Note that the tangency requirement is easily expressed in covariant coordinates, as it simply reads $r_3 = 0$, whereas it becomes

$$r_i^c(x)a_{3,i}^c(x) = 0 \text{ in } \omega \tag{1}$$

in Cartesian coordinates.

Let $a^{\alpha\beta\rho\sigma} \in L^\infty(\omega)$ be the elasticity tensor, which we assume to satisfy the usual symmetries and to be uniformly strictly positive. In the case of a homogeneous, isotropic material with Young modulus $E > 0$ and Poisson coefficient $0 \le \nu < 1/2$, we have

$$a^{\alpha\beta\rho\sigma} = \frac{E}{2(1+\nu)}(a^{\alpha\rho}a^{\beta\sigma} + a^{\alpha\sigma}a^{\beta\rho}) + \frac{E\nu}{1-\nu^2}a^{\alpha\beta}a^{\rho\sigma},$$

where $a^{\alpha\beta} = a^\alpha \cdot a^\beta$ are the contravariant components of the first fundamental form. In this context, the covariant components of the change of metric tensor read

$$\gamma_{\alpha\beta}(u) = \frac{1}{2}(\partial_\alpha u \cdot a_\beta + \partial_\beta u \cdot a_\alpha), \tag{2}$$

the covariant components of the change of transverse shear tensor read

$$\delta_{\alpha 3}(u,r) = \frac{1}{2}(\partial_\alpha u \cdot a_3 + r \cdot a_\alpha), \tag{3}$$

and the covariant components of the change of curvature tensor read

$$\chi_{\alpha\beta}(u,r) = \frac{1}{2}(\partial_\alpha u \cdot \partial_\beta a_3 + \partial_\beta u \cdot \partial_\alpha a_3 + \partial_\alpha r \cdot a_\beta + \partial_\beta r \cdot a_\alpha); \tag{4}$$

see [5] and [7]. Note that all these quantities make sense for shells with little regularity and are easily expressed with the Cartesian coordinates of the unknowns and geometrical data. For instance, we have

$$\partial_\alpha u \cdot a_\beta = \partial_\alpha u_i^c a_{\beta,i}^c \text{ and so on.}$$

We assume that the boundary $\partial\omega$ of the chart domain is divided into two parts: γ_0 of strictly positive one-dimensional measure on which the shell is clamped and a complementary part γ_1 on which the shell is subjected to applied tractions and moments.

Let us consider the function space, introduced in [5] and [7], which is appropriate in the context of shells with little regularity,

$$\mathcal{V} = \big\{(v,s) \in H^1(\omega;\mathbb{R}^3)^2;\ s\cdot a_3 = 0 \text{ in } \omega, v = s = 0 \text{ on } \gamma_0\big\}. \tag{5}$$

This space is endowed with the natural Hilbert norm

$$\|(v,s)\|_{\mathcal{V}} = \big(\|v\|^2_{H^1(\omega;\mathbb{R}^3)} + \|s\|^2_{H^1(\omega;\mathbb{R}^3)}\big)^{1/2}. \tag{6}$$

The boundary conditions considered are hard clamping conditions on part of the boundary. Soft clamping or simple support conditions correspond to $v = 0$ on γ_0. These conditions also work provided that $\varphi(\gamma_0)$ is not included in a straight line; see [7].

Let us now recall the problem formulation and the existence and uniqueness result in the space $\mathcal{V}$ for the linear Naghdi model for shells with little regularity.

THEOREM 2.1. *Let $f \in L^2(\omega;\mathbb{R}^3)$ be a given resultant force density, $N \in L^2(\gamma_1;\mathbb{R}^3)$ an applied traction density, $M \in L^2(\gamma_1,\mathbb{R}^3)$ an applied moment density such that $M\cdot a_3 = 0$ almost everywhere on γ_1, and $e > 0$ the thickness of the shell. Then there exists a unique solution to the following problem: find $(u,r) \in \mathcal{V}$ such that*

$$\forall (v,s) \in \mathcal{V},\ a\big((u,r);(v,s)\big) = L((v,s)), \tag{7}$$

where

$$\begin{aligned} a\big((u,r);(v,s)\big) = \int_\omega \Big\{ & e a^{\alpha\beta\rho\sigma}\left[\gamma_{\alpha\beta}(u)\gamma_{\rho\sigma}(v) + \frac{e^2}{12}\chi_{\alpha\beta}(u,r)\chi_{\rho\sigma}(v,s)\right] \\ & + e\frac{E}{1+\nu}a^{\alpha\beta}\delta_{\alpha 3}(u,r)\delta_{\beta 3}(v,s)\Big\}\sqrt{a}\,dx \end{aligned} \tag{8}$$

and

$$L((v,s)) = \int_\omega f\cdot v\sqrt{a}\,dx + \int_{\gamma_1}(N\cdot v + M\cdot s)\,d\gamma. \tag{9}$$

Proof. See [5] and [7]. □

Here and in the sequel, we make use of the following notational device: arguments in a bilinear form are separated by a semicolon, whereas members of a couple are separated by a comma. This will help keep track of who does what, since our bilinear forms often apply to couples.

3. A penalized version of Naghdi's model. The purpose of the present work is to approximate the solution of (7) with a finite element method and to proceed in the simplest possible way. (Note that we do not concern ourselves with locking in the present paper; in this respect see [2], [12].) As the solution is in H^1, C^0-Lagrange P_1 elements should be sufficient. However, we immediately encounter a problem since the tangency constraint $s\cdot a_3 = 0$ in ω clearly cannot be implemented in a conforming way for a general shell.

We thus introduce a penalized Naghdi problem in which the unknowns still are the displacement u and rotation r, elements of the space $H^1(\omega;\mathbb{R}^3)$ without any orthogonality constraint on r.

Let us introduce the relaxed function space

$$\mathcal{X} = \big\{(v,s) \in H^1(\omega;\mathbb{R}^3)^2; v = s = 0 \text{ on } \gamma_0\big\} \tag{10}$$

and equip it with the standard H^1 norm.

THEOREM 3.1. *Let $p \in \mathbb{R}$ such that $0 < p \leq 1$. Let $f \in L^2(\omega;\mathbb{R}^3)$, $N \in L^2(\gamma_1;\mathbb{R}^3)$, and $M \in L^2(\gamma_1,\mathbb{R}^3)$. Then there exists a unique solution to the following problem: find $(u_p, r_p) \in \mathcal{X}$ such that*

$$\forall (v,s) \in \mathcal{X}, \quad a\big((u_p,r_p);(v,s)\big) + \frac{1}{p} b(r_p \cdot a_3; s \cdot a_3) = L((v,s)), \tag{11}$$

where

$$b(\lambda;\mu) = \int_\omega \partial_\alpha \lambda \partial_\alpha \mu \, dx. \tag{12}$$

The proof is based on the following version of the infinitesimal rigid displacement lemma.

LEMMA 3.2. *Let $(u,r) \in H^1(\omega;\mathbb{R}^3)^2$ and assume that $\varphi \in W^{2,\infty}(\omega;\mathbb{R}^3)$.*

(i) *If $\gamma_{\alpha\beta}(u) = 0$, then there exists $\psi \in L^2(\omega;\mathbb{R}^3)$ such that $\partial_\alpha u = \psi \wedge a_\alpha$.*
(ii) *If $\delta_{\alpha 3}(u,r) = 0$, then $\partial_\alpha u \cdot a_3 = -r \cdot a_\alpha \in H^1(\omega)$.*
(iii) *If, in addition to* (i) *and* (ii), *$\chi_{\alpha\beta}(u,r) = 0$, then ψ is a constant vector in $\mathbb{R}^3$ and there exists $c \in \mathbb{R}^3$ such that*

$$u(x) = c + \psi \wedge \varphi(x), \tag{13}$$

and

$$r(x) = \psi \wedge a_3(x) + (r(x) \cdot a_3(x)) a_3(x). \tag{14}$$

Proof. The argument is exactly the same as in [7], except that we do not assume $r \cdot a_3 = 0$, hence the extra term in formula (14). ∎

Remarks. 1. Note that the infinitesimal rotation vector ψ is given by

$$\begin{aligned} \psi &= \varepsilon^{\alpha\beta}(\partial_\beta u \cdot a_3) a_\alpha + \varepsilon^{\alpha\beta}(\partial_\alpha u \cdot a_\beta) a_3 \\ &= \varepsilon^{\beta\alpha}(r \cdot a_\beta) a_\alpha + \varepsilon^{\alpha\beta}(\partial_\alpha u \cdot a_\beta) a_3, \end{aligned} \tag{15}$$

where $\varepsilon^{11} = \varepsilon^{22} = 0$ and $\varepsilon^{12} = -\varepsilon^{21} = 1/|a_1 \wedge a_2|$.

2. If $(v,s) \in \mathcal{X}$ are such that (13) and (14) are verified, then we have

$$u = 0 \text{ and } r = (r \cdot a_3) a_3 \text{ a.e. in } \omega,$$

due to the boundary conditions.

We now are in a position to prove the ellipticity of the penalized bilinear form.

LEMMA 3.3. *The bilinear form in* (11) *is $\mathcal{X}$-elliptic, uniformly with respect to p for $0 < p \leq 1$.*

Proof. The proof follows along lines similar to those found in [7] and we omit it for brevity. ∎

Proof of Theorem 3.1. Apply the Lax–Milgram lemma. ∎

Remark. It is important to note that the original bilinear form a is not $\mathcal{X}$-elliptic; indeed it does not even define a norm on the relaxed space. It is therefore necessary to add such terms as the extra terms $\|\partial_\alpha(s \cdot a_3)\|_{L^2}^2$ to recover ellipticity over the larger space. In the case of soft clamping, these extra terms are not sufficient, since $(0, a_3)$ still belongs to the kernel of the penalized bilinear form. In this case, one should add the full H^1 norm of $s \cdot a_3$, i.e., use a penalization term of the form $b(r \cdot a_3; s \cdot a_3) = \int_\omega \big[(r \cdot a_3)(s \cdot a_3) + \partial_\alpha(r \cdot a_3)\partial_\alpha(s \cdot a_3)\big] \, dx$.

It is now fairly classical that the penalization provides an approximation of the constrained problem.

THEOREM 3.4. *Let $U = (u, r)$ and $U_p = (u_p, r_p)$, respectively, be the unique solutions of problems* (7) *and* (11). *Then*

$$\|r_p \cdot a_3\|_{H^1(\omega)} \leq Cp \tag{16}$$

and

$$\|U_p - U\|_{\mathcal{X}} \leq Cp. \tag{17}$$

Proof. Let $\mathcal{L} = L^2(\omega; \mathbb{R}^2)$ and $\Psi \colon \mathcal{X} \to \mathcal{L}$ defined by $U \mapsto \nabla(r \cdot a_3)$. Now, we have $\mathcal{V} = \ker \Psi$ and $b(r \cdot a_3; r \cdot a_3) = (\Psi(U), \Psi(U))_{\mathcal{L}}$. It is known that if Ψ has closed range, then the following estimates hold true (see [9]):

$$\|\Psi(U_p)\|_{\mathcal{L}} \leq Cp \text{ and } \|U_p - U\|_{\mathcal{X}} \leq Cp.$$

The first estimate gives estimate (16) and the second estimate is just estimate (17).

Let us thus check that Ψ has closed range. Consider a sequence $U_n \in \mathcal{X}$ such that $\Psi(U_n) \to Z$ in $\mathcal{L}$. By the Poincaré inequality, it follows that $r_n \cdot a_3$ is bounded in $H^1(\omega)$ and we can extract a weakly convergent subsequence such that $r_n \cdot a_3 \rightharpoonup \zeta$ in $H^1(\omega)$. Moreover, since $r_n \cdot a_3 = 0$ on γ_0 in the sense of traces, it follows that $\zeta = 0$ on γ_0 as well. In addition, clearly $Z = \nabla\zeta$. We thus set $U = (0, \zeta a_3) \in \mathcal{X}$ and we see that $\Psi(U) = Z$. ∎

Remark. Since we are aiming for simplicity of implementation, we have made no attempt to make the penalization term intrinsic. In fact, it does depend on the chart, whereas the other terms do not. This could arguably be considered to be a poor choice, especially if a chart was used that gave much more weight to one part of the shell compared to the rest. An intrinsic choice that obviously works is

$$b'(r \cdot a_3; s \cdot a_3) = \int_\omega a^{\alpha\beta} \partial_\alpha (r \cdot a_3) \partial_\beta (s \cdot a_3) \sqrt{a}\, dx.$$

This penalization term has the same properties as our simple penalization term and does not suffer from the above mentioned drawback.

4. A mixed formulation of Naghdi's model. Another way of imposing a constraint in a variational problem is to use a mixed formulation. We follow this route in this section. Naturally, mixed formulations for Naghdi's model already exist of the displacement/stress type, but in the context of attempting to write nonlocking formulations; see, for instance, [2]. In the present article, we are not concerned with locking issues but only with imposing the tangency of the rotation vector in Cartesian coordinates. Hence the mixed formulation will be relatively simple. In particular, it involves the same bilinear forms as those used in the penalization approach. Let us set $\mathcal{M} = H^1_{\gamma_0}(\omega)$.

THEOREM 4.1. *For all $\rho \geq 0$, the variational problem of finding $(U, \lambda) \in \mathcal{X} \times \mathcal{M}$ such that*

$$\forall (V, \mu) \in \mathcal{X} \times \mathcal{M}, \begin{cases} a(U; V) + \rho b((r \cdot a_3); (s \cdot a_3)) + b((s \cdot a_3); \lambda) = L(V), \\ b((r \cdot a_3); \mu) = 0, \end{cases} \tag{18}$$

has a unique solution, which is such that $U \in \mathcal{V}$ is the solution of Naghdi's problem (7).

Proof. The bilinear form $a + \rho b$ is $\mathcal{V}$-elliptic (and even $\mathcal{X}$-elliptic for $\rho > 0$ by Lemma 3.3). In order to prove that problem (18) has a unique solution, we therefore

just need to prove that b satisfies the inf-sup condition; see [14], [9]. Let thus

$$\beta = \inf_{\mu\in\mathcal{M}} \sup_{V\in\mathcal{X}} \frac{b((s\cdot a_3);\mu)}{\|V\|_{\mathcal{X}}\|\mu\|_{\mathcal{M}}},$$

and we want to show that $\beta > 0$. Let $\mu \in \mathcal{M}\setminus\{0\}$ be arbitrary. Since μ vanishes on γ_0 and since $a_3 \in W^{1,\infty}(\omega;\mathbb{R}^3)$, we clearly have $V = (0,\mu a_3) \in \mathcal{X}$ and $\mu a_3 \cdot a_3 = \mu$. Therefore,

$$\sup_{V\in\mathcal{X}} \frac{b((s\cdot a_3);\mu)}{\|V\|_{\mathcal{X}}} \geq \frac{\|\nabla\mu\|^2_{L^2(\omega;\mathbb{R}^2)}}{\|a_3\otimes\nabla\mu + \mu\nabla a_3\|_{L^2(\omega;\mathbb{M}_{32})}}$$

so that

$$\beta \geq \inf_{\mu\in\mathcal{M}} \frac{\|\nabla\mu\|_{L^2(\omega;\mathbb{R}^2)}}{\|a_3\otimes\nabla\mu + \mu\nabla a_3\|_{L^2(\omega;\mathbb{M}_{32})}}.$$

It is quite clear that the left-hand side of the above inequality is strictly positive, since the denominator is basically a lower order perturbation of the numerator. Let us quickly show this by a contradiction argument. Assume thus that we are given a sequence $\mu_n \in \mathcal{M}$ such that

$$\|\nabla\mu_n\|_{L^2(\omega;\mathbb{R}^2)} \to 0 \text{ but } \|a_3\otimes\nabla\mu_n + \mu_n\nabla a_3\|_{L^2(\omega;\mathbb{M}_{32})} = 1.$$

Obviously, due to the boundary conditions and the Poincaré inequality, $\mu_n \to 0$ in $H^1(\omega)$, hence $a_3\otimes\nabla\mu_n \to 0$ in L^2 and $\mu_n\nabla a_3 \to 0$ in L^2 (recall that $a_3 \in W^{1,\infty}$), a contradiction. Hence the inf-sup condition holds true and the mixed formulation has one and only one solution.

Let us now check that this solution corresponds to the usual Naghdi problem. Taking $\mu = r\cdot a_3$ in the second equation, we see that $U \in \mathcal{V}$. Then, taking $V \in \mathcal{V}$ cancels all terms involving b in the first equation, hence the result. ∎

Remarks. 1. We can also replace b by any scalar multiple of itself, and in the case of soft clamping, we must replace it by the full H^1 scalar product between $s\cdot a_3$ and μ. The lack of intrinsic character can be cured in the same way as for the penalization.

2. The Lagrange multiplier λ that enforces the tangency constraint $r\cdot a_3 = 0$ does not have a specific mechanical meaning, since the bilinear forms are pretty arbitrary. Note that when nonzero, $r\cdot a_3$ is sometimes called the pinching component or pinching strain; see [11]. Indeed, it corresponds to a change in length of the deformed normal fiber in the three-dimensional Kirchhoff–Love displacement constructed from u and r. It is thus conceivable that a mechanical meaning could be ascribed to such a Lagrange multiplier, but we do not pursue this line of reasoning here.

3. We may choose $\rho = 0$ or $\rho > 0$. In the latter case, we are adding a penalization term in the spirit of augmented Lagrangian methods, which can be tuned for the best numerical results.

5. The discrete formulations.

5.1. Finite element discretization of the penalized problem. The penalized problem is a standard variational problem formulated in H^1. We thus propose to use a standard conforming finite element approximation.

Let thus T_h be a regular affine family of triangulations which covers the domain ω. The discrete space of admissible displacements and rotations is given by

$$\mathcal{X}_h = \{(v,s) \in C^0(\omega;\mathbb{R}^3)^2, (v,s)_{|K} \in P_1(K), v = s = 0 \text{ on } \gamma_0\}, \tag{19}$$

which is obviously contained in the continuous space $\mathcal{X}$.

The discrete problem thus reads as follows: find $(u_{p,h}, r_{p,h}) \in \mathcal{X}_h$ such that

$$\forall (v,s) \in \mathcal{X}_h,\ a\big((u_{p,h}, r_{p,h}); (v,s)\big) + \frac{1}{p} b(r_{p,h} \cdot a_3; s \cdot a_3) = L(v,s). \tag{20}$$

Naturally, this problem has a unique solution.

5.2. Convergence. By virtue of the classical properties of Galerkin approximation, we have the following convergence result.

THEOREM 5.1. *There exists a sequence $h_p \to 0$ such that*

$$\|(u,r) - (u_{p,h_p}, r_{p,h_p})\|_{\mathcal{X}} \longrightarrow 0 \quad \textit{when} \quad p \to 0. \tag{21}$$

Proof. For each p, we have $u_{p,h} \to u_p$ when $h \to 0$ because this is a Galerkin approximation of a classical variational problem. We then appeal to Theorem 3.4 to construct a converging diagonal sequence. ∎

If the solution is assumed to have some regularity, the second step of the approximation may of course be controlled via an error estimate.

PROPOSITION 5.2. *Assume that the solution $(u_p; r_p)$ of problem* (11) *belongs to $H^2(\omega, \mathbb{R}^3)^2$ for all p. Then there exists a constant C_p independent of h, such that*

$$\|(u_{p,h}, r_{p,h}) - (u_p, r_p)\|_{\mathcal{X}} \le C_p h \|(u_p, r_p)\|_{H^2}. \tag{22}$$

Proof. See [13], for example. ∎

Remarks. 1. Since we are mostly interested in shells with little regularity—otherwise classical formulations would apply—it is presumably not useful to look for higher order elements in the hope of improving the rate of convergence. Indeed, even without taking into account the penalization term, in the case of such a shell, the underlying system of PDEs has nonsmooth coefficients. It is therefore unclear whether elliptic regularity can be applied to yield even an H^2 regularity, let alone H^{k+1} regularity with $k \ge 1$. Note, however, that if the midsurface chart is smooth and we want to use our formulation nonetheless for simplicity as compared to the classical approach, then elliptic regularity will apply.

2. We could also combine estimates (17) and (22) to obtain a global error estimate for the whole penalization/discretization process. To achieve this goal, we would need to estimate the constant C_p in terms of p, which would probably include terms of the order of p^{-1} due to the continuity constant of the bilinear form a_p, and the term $\|(u_p, r_p)\|_{H^2}$. The latter term could be evaluated by using Nirenberg's translations method, but the technical aspects involved hardly seem worth the effort in this particular case, in view of the previous remark. In any case, it is reasonable to expect locking due to the penalization term.

5.3. Finite element discretization of the mixed problem. The mixed problem is also a standard variational problem formulated in H^1. In order to prove the convergence of conforming finite element approximations, we only need to establish the uniform discrete inf-sup condition. As is often the case, the uniform discrete inf-sup condition turns out to be harder to prove than its continuous counterpart and in our particular case, some of the arguments are rather nonstandard. Let us treat the P_1 case, with zero boundary condition for the multiplier, for simplicity. In this case, we have

$$\mathcal{M}_h = \{\mu_h \in C^0(\bar{\omega}), \mu_{h|K} \in P_1(K), \mu_h = 0 \text{ on } \partial\omega\}.$$

THEOREM 5.3. *For all $\rho \geq 0$, the variational problem of finding $(U_h, \lambda_h) \in \mathcal{X}_h \times \mathcal{M}_h$ such that*

(23)
$$\forall (V_h, \mu_h) \in \mathcal{X}_h \times \mathcal{M}_h, \ \begin{cases} a(U_h; V_h) + \rho b((r_h \cdot a_3); (s_h \cdot a_3)) + b((s_h \cdot a_3); \lambda_h) = L(V_h), \\ b((r_h \cdot a_3); \mu_h) = 0, \end{cases}$$

has a unique solution for h small enough. Moreover

$$\|U - U_h\|_{\mathcal{X}} + \|\lambda - \lambda_h\|_{\mathcal{M}} \to 0 \text{ when } h \to 0.$$

We first need a couple of geometrical results.

LEMMA 5.4. *Let φ be a $W^{2,\infty}$ chart. There exists a constant $C > 0$ such that for all x, y in ω,*

$$|a_3(x) \cdot (a_3(x) - a_3(y))| \leq C\|x - y\|^2. \tag{24}$$

Proof. We adapt an argument of [1, Lemma 3.5]. By our regularity hypothesis, the normal vector a_3 is Lipschitz on $\bar{\omega}$. Hence, for all $x_0 \in \bar{\omega}$, the function

$$Z(x) = (a_3(x) - a_3(x_0)) \cdot a_3(x_0)$$

is also Lipschitz. Therefore, by Rademacher's theorem it is almost everywhere differentiable and we have

$$\nabla Z(x) = \nabla a_3(x)^T a_3(x_0)$$

for almost all $x \in \omega$. Therefore, due to the identification between Lipschitz and $W^{1,\infty}$ functions in a Lipschitz domain (see [1] for a proof), there exists a constant C_ω depending only on ω such that

$$|Z(x)| = |Z(x) - Z(x_0)| \leq C_\omega \|\nabla a_3^T a_3(x_0)\|_{L^\infty(\bar{B}(x_0, \|x - x_0\|) \cap \omega; \mathbb{R}^2)} \|x - x_0\|.$$

Now, a_3 is a unit vector. Hence, at any point y of differentiability of a_3, $a_3(y)$ is orthogonal to the image of $\nabla a_3(y)$, that is to say, $\nabla a_3(y)^T a_3(y) = 0$. Consequently, we have that almost everywhere in $\bar{B}(x_0, \|x - x_0\|) \cap \omega$,

$$\nabla a_3(y)^T a_3(x_0) = \nabla a_3(y)^T a_3(x_0) - \nabla a_3(y)^T a_3(y)$$

so that

$$\begin{aligned} \|\nabla a_3(y)^T a_3(x_0)\| &\leq \|\nabla a_3(y)^T\| \|a_3(x_0) - a_3(y)\| \\ &\leq C_\omega \|\nabla a_3\|^2_{L^\infty(\omega; \mathbb{M}_{32})} \|y - x_0\| \end{aligned}$$

almost everywhere. Therefore,

$$\|\nabla a_3^T a_3(x_0)\|_{L^\infty(\bar{B}(x_0, \|x - x_0\|) \cap \omega; \mathbb{R}^2)} \leq C_\omega \|\nabla a_3\|^2_{L^\infty(\omega; \mathbb{M}_{32})} \|x - x_0\|,$$

hence the result with $C = C_\omega^2 \|\nabla a_3\|^3_{L^\infty(\omega; \mathbb{M}_{32})}$. ∎

Remark. Note that the above geometrical result holds true under the weaker, "minimal" regularity hypotheses advocated in [1] for a shell midsurface, namely, φ bilipschitz and such that a_3 is Lipschitz.

LEMMA 5.5. *Under the same hypotheses, there exists a constant $C > 0$ such that for all x and almost all y in ω,*

$$|a_3(x) \cdot \partial_\alpha a_3(y)| \leq C\|x - y\|. \tag{25}$$

Proof. Let y be a point of differentiability of a_3. We have

$$a_3(x) \cdot \partial_\alpha a_3(y) = (a_3(x) - a_3(y)) \cdot \partial_\alpha a_3(y)$$

so that

$$|a_3(x) \cdot \partial_\alpha a_3(y)| \leq C_\omega \|\nabla a_3\|^2_{L^\infty(\omega;\mathbb{M}_{32})}\|x - y\|$$

for all $x \in \omega$. ∎

We now turn to the inf-sup condition per se. Let Π_h denote either the vector-valued Lagrange interpolation operator from $C^0_0(\bar{\omega};\mathbb{R}^3)$ into $\mathcal{X}_h$ or the scalar-valued Lagrange interpolation operator from $C^0_0(\bar{\omega})$ into $\mathcal{M}_h$, depending on the context, and ψ^h_j the shape function associated with vertex S_j of the triangulation.

LEMMA 5.6. *For all $\mu_h \in \mathcal{M}_h$, we let $R_h(\mu_h) = \Pi_h(\mu_h a_3)$. There exists a constant $C > 0$ independent of h such that*

$$b(R_h(\mu_h) \cdot a_3; \mu_h) \geq C\|\mu_h\|^2_{\mathcal{M}}. \tag{26}$$

Proof. Note that while μ_h is scalar piecewise P_1, $\mu_h a_3$ is vector-valued and $R_h(\mu_h)$ is vector-valued piecewise P_1. Let us set

$$\delta_h = R_h(\mu_h) \cdot a_3 - \mu_h$$

so that

$$b(R_h(\mu_h) \cdot a_3; \mu_h) = \|\mu_h\|^2_{\mathcal{M}} + b(\delta_h; \mu_h)$$

with

$$|b(\delta_h; \mu_h)| \leq \|\mu_h\|_{\mathcal{M}}\|\delta_h\|_{\mathcal{M}}.$$

We thus just need to estimate δ_h in the norm of $\mathcal{M}$. By Lagrange interpolation, we have

$$\mu_h(x) = \sum_{S_j} \mu_h(S_j)\psi^h_j(x)$$

and

$$R_h(\mu_h)(x) = \sum_{S_j} \mu_h(S_j)\psi^h_j(x)a_3(S_j).$$

Therefore

$$R_h(\mu_h) \cdot a_3(x) = \sum_{S_j} \mu_h(S_j)[a_3(S_j) \cdot a_3(x)]\psi^h_j(x),$$

and

$$\delta_h(x) = \sum_{S_j} \mu_h(S_j)[(a_3(S_j) - a_3(x)) \cdot a_3(x)]\psi^h_j(x),$$

since $a_3(x)$ is a unit vector. Consequently, we arrive at the formula

$$\partial_\alpha \delta_h(x) = \sum_{S_j} \mu_h(S_j)[a_3(S_j)\cdot \partial_\alpha a_3(x)]\psi_j^h(x) + \sum_{S_j} \mu_h(S_j)[(a_3(S_j)-a_3(x))\cdot a_3(x)]\partial_\alpha \psi_j^h(x)$$

almost everywhere (namely inside the triangles). At every point of differentiability in ω, at most three terms in the sums are nonzero; therefore we can estimate

$$\|\partial_\alpha \delta_h\|_{L^\infty(\omega)} \le 3\|\mu_h\|_{L^\infty(\omega)} \max_j \max_{K_{k,j}} \left[|a_3(S_j)\cdot \partial_\alpha a_3(x)| + \frac{C}{h}|(a_3(S_j)-a_3(x))\cdot a_3(x)|\right],$$

where $K_{k,j}$ stand for all the triangles having S_j as vertex. Since all triangles have diameter bounded by a constant times h, we deduce with the help of Lemmas 5.4 and 5.5 that

$$\|\partial_\alpha \delta_h\|_{L^\infty(\omega)} \le Ch\|\mu_h\|_{L^\infty(\omega)},$$

where C does not depend on h nor on μ_h.

We now appeal to the classical discrete Sobolev estimate (see [8]) and deduce that

$$\|\nabla \delta_h\|_{L^2(\omega;\mathbb{R}^2)} \le C\|\nabla \delta_h\|_{L^\infty(\omega;\mathbb{R}^2)} \le Ch\|\mu_h\|_{L^\infty(\omega)} \le Ch(\ln h)^{1/2}\|\nabla \mu_h\|_{L^2(\omega;\mathbb{R}^2)}.$$

Taking h small enough so that $Ch(\ln h)^{1/2} \le \frac{1}{2}$, we obtain estimate (26). ∎
